6.7.10 Influence of Other Functions via Dynamic Settings

6.5.8.1 Description and *6.5.8.2 Application and Setting Notes (Advanced Stage)* describe the influence of other functions on dynamic settings.

6.8 Inrush-Current Detection

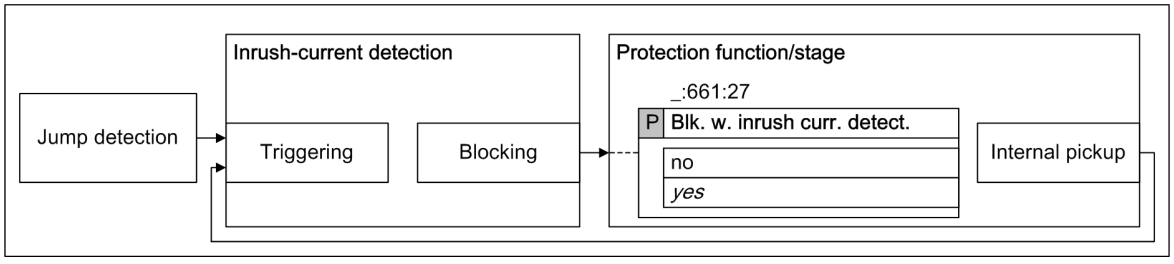
6.8.1 Overview of Functions

The function **Inrush-current detection**

- Recognizes an inrush process on transformers
- Generates a blocking signal for protection functions that protect the transformer (protected object) or for protection functions that are affected in undesirable ways when transformers are switched on
- Allows a sensitive setting of the protection functions

The following protection functions evaluate the blocking signal

- Overcurrent protection with a pickup value below the maximum inrush current
- Negative-sequence protection as sensitive backup protection for transformers



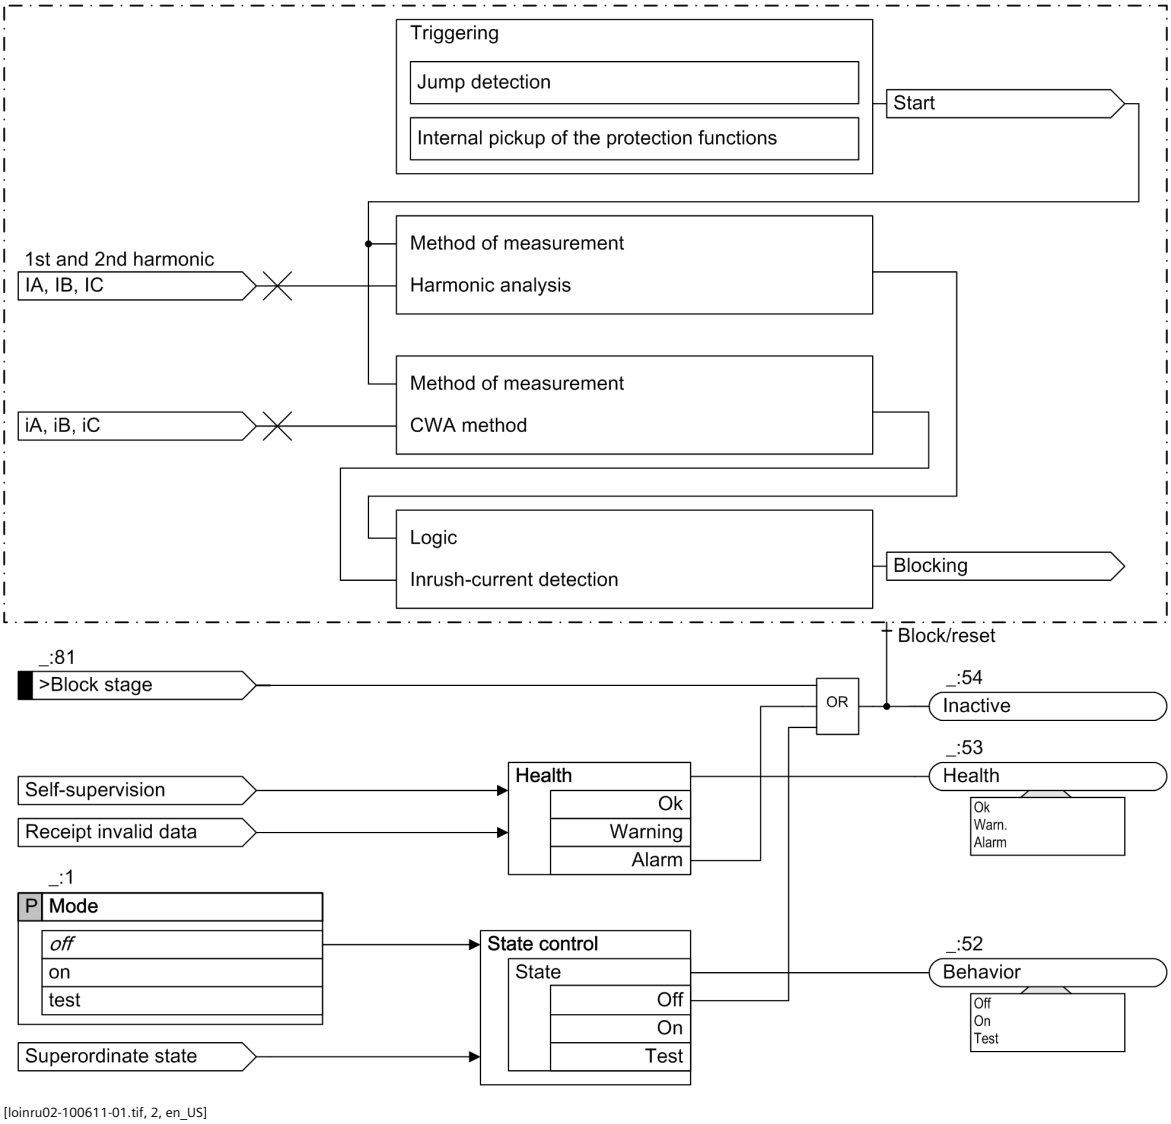
6.8.2 Structure of the Function

The function **Inrush current detection** is not an individual protection function. In the connection process of a transformer, it transmits a blocking signal to other protection functions. For this reason, the inrush-current detection must be in the same function group as the functions that are to be blocked.

The following figure shows the embedding of the function. The setting parameter **`Blk. w. inrush curr. detect.`** establishes the connection between inrush-current detection and the functions that are to be blocked. If the parameter is set to ***`yes`***, the connection is effective.

A jump detection or the threshold value exceeding of the functions to be blocked is used as trigger signal for synchronization of the internal measurement methods.

The jump detection reacts to changes in the current. The threshold value exceeding is recognized due to an internal pickup of the protection function that is to be blocked.



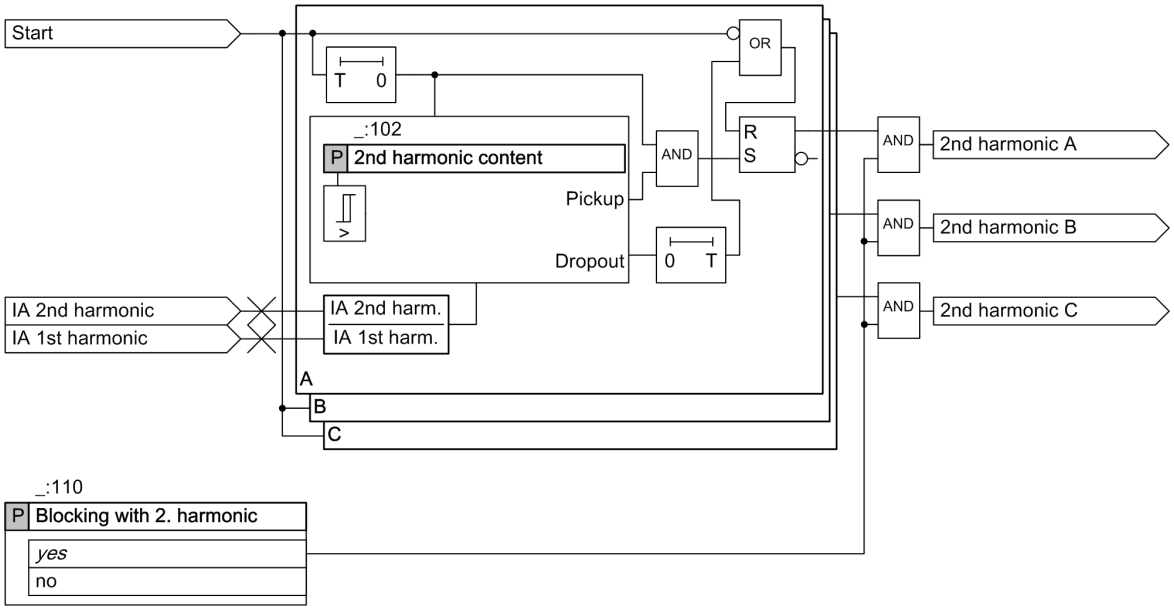
[dwirsh01-070611-01.tif, 1, en_US]

Figure 6-80 Structure/Embedding of the Function

6.8.3 Function Description

The function **Inrush-current detection** analyzes the trigger signal of the jump detection or the threshold-value violation of the function to be blocked in a start logic, and synchronizes the method of measurement. In order to securely record the inrush processes, the function uses the **Harmonic analysis** method of measurement and the **CWA method** (current wave shape analysis). Both methods work in parallel and link the results through a logical OR.

If you wish to work with only one process, deactivate the other method by way of the parameters **`Blocking with 2. harmonic`** or **`Blocking with CWA`** .



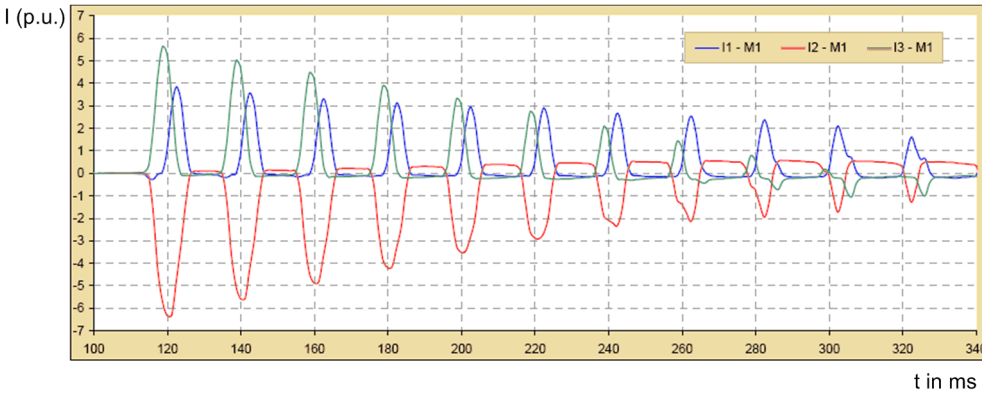
[loinru02-100611-01.tif, 2, en_US]

Figure 6-81 Basic Structure of the Inrush-Current Detection

Harmonic Analysis

For this method of measurement, the content of the 2nd harmonic and the fundamental component (1st harmonic) are determined for each of the phase currents I_A, I_B, and I_C and the quotient $I_{2nd\ harm} / I_{1st\ harm}$ is formed from this. If this quotient exceeds the set threshold value, a phase-selective signal is issued.

If 95 % of the set threshold value is exceeded, this leads to a pickup reset (dropout ratio = 0.95).

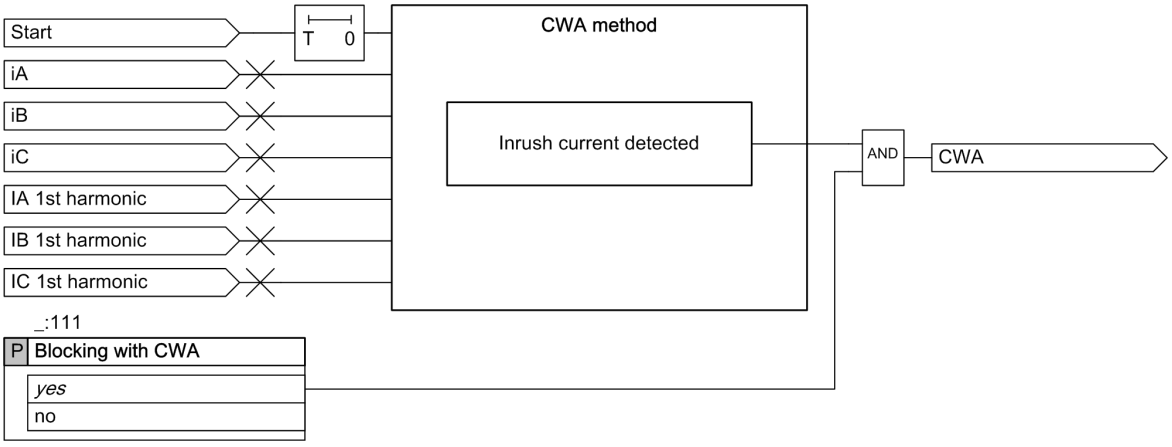


[loinru10-040912-01.tif, 1, en_US]

Figure 6-82 Logic of the Harmonic Analysis Function (T = 1 Period)

CWA Method (Current Wave Shape Analysis)

The CWA method executes a wave shape analysis of the phase currents IA, IB, and IC. If all 3 phase currents show flat areas at the same point in time, the inrush-current detection signal will be issued. This signal applies for all 3 phases simultaneously. The following figure shows a typical inrush-current characteristic, with the simultaneously occurring flat areas clearly recognizable.



[dwinru03-240211-01.tif, 1, en_US]

Figure 6-83 Inrush-Current Characteristic

The following figure shows the logic diagram of the CWA method.

From the present fundamental-component current (1st harmonic), the threshold value for identification of the flat areas is derived via an internal factor.

[loinru05-240211-01.tif, 1, en_US]

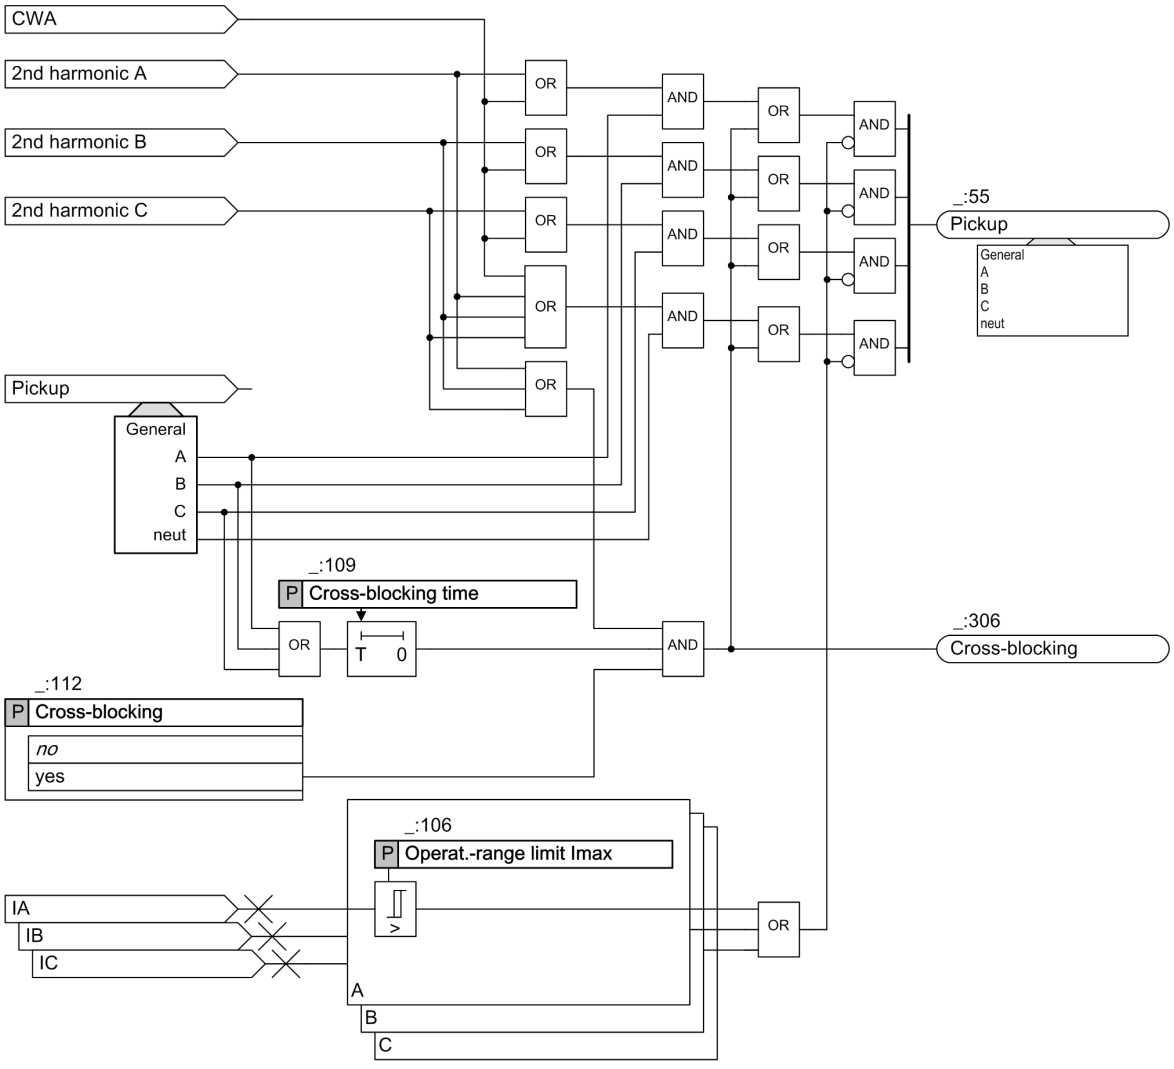


Figure 6-84 Logic of the CWA-Method Function (T = 1 Period)

Logic of the Inrush-Current Detection

The following logic diagram shows the link of the 2 methods of measurement **Harmonic Analysis** and **CWA method**.

The crossblock function influences the **Harmonic Analysis** process. If you have set the parameter **`Cross-blocking`** to ***`yes`***, you will receive in the event of threshold-value violation a blocking indication for all 3 phase currents and the measured or calculated zero-sequence current ($I_{2nd\ harm}$ / $I_{1st\ harm}$). The crossblock function works via a timer. Set parameters for the time depending on the expected duration factor via the parameter **`Cross-blocking time`**.

If the phase current exceeds the maximum permissible current **`Operat.-range limit Imax`**, the inrush-current detection will be blocked.

[loinru12-060912-01.tif, 1, en_US]

Figure 6-85 Logic Diagram of the Inrush-Current Detection

6.8.4 Application and Setting Notes

Parameter: Operat.-range limit Imax

- Recommended setting value **(_:106) Operat.-range limit Imax** = ***7.5 A***

  With the parameter **Operat.-range limit Imax** , you can specify at which current the inrush-current detection is blocked internally. The setting value must be above the maximum inrush current of the transformer. A practicable value is 7.5 times the transformer rated current.

Parameter: Blocking with CWA

- Recommended setting value = **(_:111) Blocking with CWA** = ***yes***

Parameter Value	Description
yes	**CWA process** activated.
no	**CWA process** deactivated.

Parameter: Blocking with 2. harmonic

- Recommended setting value **(_:110) Blocking with 2. harmonic** = ***yes***

Parameter Value	Description
yes	**Harmonic analysis** process activated.
no	**Harmonic analysis** process deactivated.

NOTE

Make sure that at least one process is activated. Siemens recommends retaining the advised setting values.

Parameter: 2nd harmonic content

- Recommended setting value **(_:102) 2nd harmonic content** = ***15 %***
  With the parameter **2nd harmonic content** , you can specify the pickup value of the harmonic analysis function. The setting value of 15 % is practicable for most transformers.

Parameter: Cross-blocking

- Recommended setting value **(_:112) Cross-blocking** = ***no***

Parameter Value	Description
no	Through the CWA process working in parallel in the inrush-current detection, the function is not activated as standard.
yes	If a subfunction of the inrush-current detection is identified in the course of the closure trials during commissioning, set the parameter **Cross-blocking** to ***yes*** .

Parameter: Cross-blocking time

- Default setting **(_:109) Cross-blocking time** = ***0.06 s***
  You define the duration of this blocking with the **Cross-blocking time** parameter. The default setting of ***0.06 s*** (about 3 periods) has proven practicable. Set the time as short as possible and check the value during the closure trials. The parameter **Cross-blocking time** is inactive at **Cross-blocking** = ***no*** .

Parameter: Start flt.rec

- Default setting **(_:114) Start flt.rec** = ***yes***
  With the **Start flt.rec** parameter, you determine whether a fault record should be started upon pickup of the inrush-current detection. The following settings are possible:

Parameter Value	Description
no	No fault recording starts with pickup.
yes	The fault recording starts with pickup. When the protection function is blocked by the inrush-current detection, a fault recording is started nevertheless.

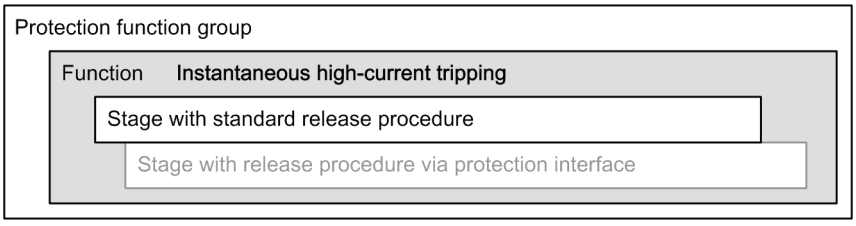
6.9 Instantaneous High-Current Tripping

6.9.1 Overview of Functions

The **Instantaneous high-current tripping** function has the following tasks:



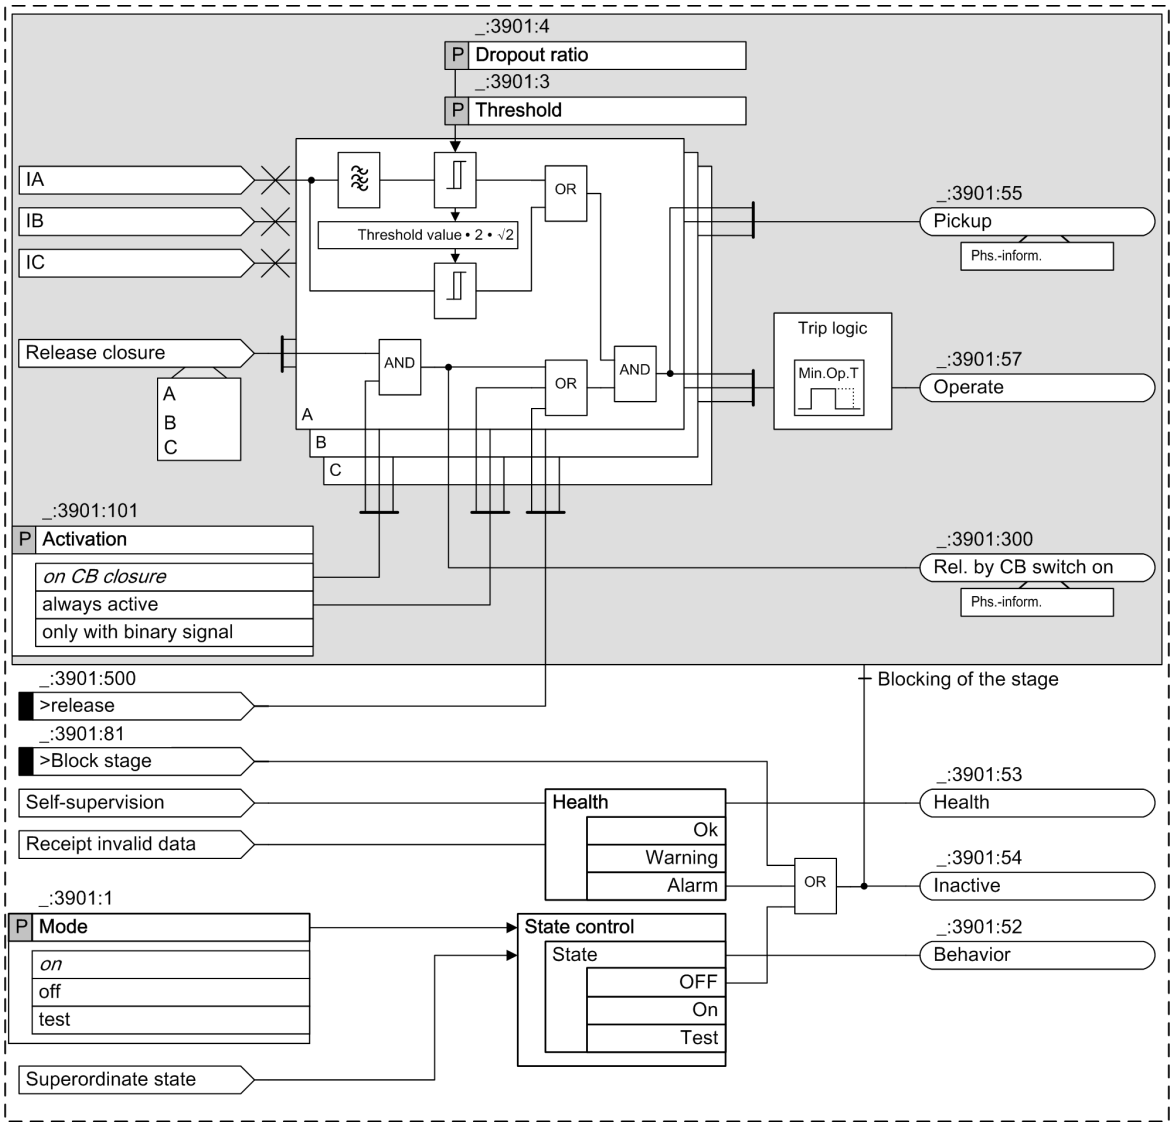
- Instantaneous tripping when switching onto an existing fault, for example, if a grounding switch is closed.
- Instantaneous disconnection of high currents above the highest overcurrent-protection stage.

6.9.2 Structure of the Function

The **Instantaneous high-current tripping** function offers 2 different increment types:

- Stage with standard release method
- Stage with release method via protection interface (only applicable if the device is equipped with a protection interface)

The function with the stage for the standard release procedure is factory-set.



[dwihcstr-230211-01.tif, 1, en_US]

Figure 6-86 Structure/Embedding of the Function

6.9.3 Standard Release Procedure

Logic

[lohlore3-160611-01.tif, 2, en_US]

Figure 6-87 Logic Diagram of Instantaneous High-Current Tripping with Standard Release Method

Activation

Using the **Activation** parameter, you set the conditions under which the stage is released.

- ***on CB closure***

With this procedure, the stage is released only if the circuit breaker is about to be closed (the CB is open) or if the circuit breaker is being closed or if the binary input signal *>release* is active. The way signals are generated *Rel. by CB switch on* is described in section *5.7.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions*.

- ***always active***

The stage is always released and is thus independent of closing of the circuit breaker switch and of the binary input signal *>release*.

- ***only with binary signal***

The stage is released only if the binary input signal *>release* is active.

Method of Measurement, Threshold Value

The stage works with 2 different methods of measurement.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically. A DC component is thus eliminated. The RMS value of the fundamental component is compared with the set threshold.
- Evaluation of the unfiltered measurand:
  If the current exceeds a preset threshold value by
  current ≥ 2·√2·threshold value
  this stage will use unfiltered measurands in addition. Thus, very short operate times are possible.

6.9.4 Application and Setting Notes

Parameter: Activation

- Default setting **(_:3901:101) Activation** = ***on CB closure***

Using the parameter **Activation**, you define the conditions under which the stage is released.

Parameter Value	Description
on CB closure	Select this setting to activate the stage only when the circuit breaker is closed.
always active	Select this setting to release the stage statically.
only with binary signal	Select this setting to release the stage via an external signal.

Parameter: Threshold

- Default setting **(_:3901:3) Threshold** = ***10.0 A*** for I_{rated} = 1 A or ***50.0 A*** for I_{rated} = 5 A

The stage works independently of the position of the remote circuit breakers. For this reason, set the **Threshold** so that the fault current flowing through does not trigger the stage. Thus, use this stage only if current grading over the protected object is possible, that is, for transformers, shunt reactors or long lines with low source impedance. In other cases, deactivate the stage.

EXAMPLE

Calculation example for current grading of a 110 kV overhead line measuring 150 mm²

s (length) = 100 km;

R_1/s = 0.21 Ω/km;

X_1/s = 0.43 Ω/km

Since the stage is non-directional, the calculation must consider the maximum short-circuit power at the start of the line or at the opposite end:

Ssc" = 3.5 GVA (subtransient, because the function can respond to the 1st peak value)

Current transformer: 600 A/5 A

The line impedance Z_L and the minimum source impedance Z_S are calculated on this basis:

Line impedance Z_L and Source impedance Z_S:

$$Z_1/s = \sqrt{0.21^2 + 0.43^2}\ \Omega/km = 0.479\ \Omega/km$$

$$Z_L = 0.479\ \Omega/km \cdot 100\ km = 47.9\ \Omega$$

$$Z_S = \frac{110\ kV^2}{3500\ MVA} = 3.46\ \Omega$$

[foglchzv-170309-01.tif, 1, en_US]

The maximum 3-phase short-circuit current I''_{sc} flowing through is (at a source voltage of 1.1 V_N):

$$I''_{sc} = \frac{1.1 \cdot V_{net}}{\sqrt{3} \cdot (Z_S + Z_L)} + \frac{1.1 \cdot 110\,kV}{\sqrt{3} \cdot (3.46\,\Omega + 47.9\,\Omega)} = 1360\,A$$

[foglchik-170309-01.tif, 1, en_US]

With a safety margin of 10 %, the following setting value results:

- **Threshold value** (primary) = 1.1 · 1360 A = 1496 A
- **Threshold value** (secondary) = $1.1 \cdot \frac{1360\,A}{600\,A} \cdot 5\,A = 12.5\,A$

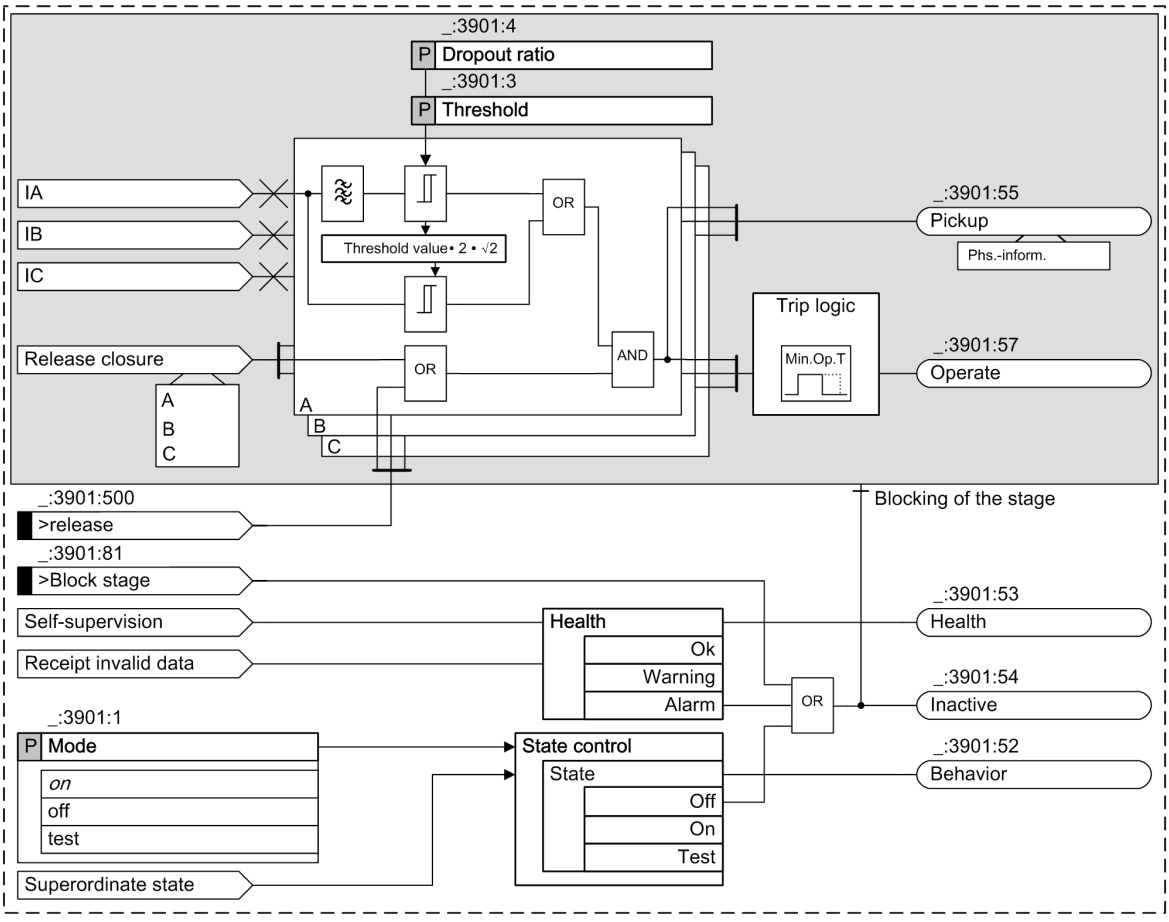
[foglnste-170309-01.tif, 1, en_US]

If short-circuit currents exceed 1496 A (primary) or 12.5 A (secondary), there is a short circuit on the line to be protected. It can be disconnected immediately.

NOTE

The calculation was performed with absolute values, which is accurate enough for overhead lines. A complex calculation is required only if the source impedance and the line impedance have extremely different angles.

Parameter: `Dropout ratio`



- Recommended setting value **`(_:3901:4) Dropout ratio`** = ***`0.90`***

The recommended setting value of ***`0.90`*** is sufficient for many applications. To obtain high-precision measurements, the **`Dropout ratio`** can be reduced. If you expect highly fluctuating measurands at the pickup threshold, you can increase the setting value of the parameter **`Dropout ratio`**. This avoids chattering of the tripping stage.

6.9.5 Release Procedure via Protection Interface

This stage can be applied only if the device is equipped with a protection interface.

Logic

[lohinre3-160611-01.tif, 1, en_US]

Figure 6-88 Logic Diagram of Instantaneous High-Current Tripping with Release Procedure via Protection Interface

Release

If one of the following conditions is fulfilled, the stage is released (the internal **Release** signal is present) (for further information, see chapter *5.8 Process Monitor*):

- No voltage has yet been applied to the protected object, which means that the remote circuit breakers are open, or
- Switching to the local circuit breaker is immanent.

These conditions are recognized internally if a circuit breaker is open or just closed

Furthermore, the stage can be activated externally via the **`>release`** binary input signal.

NOTE

To enable internal release of the stage, the devices at all ends of the protected object must be informed of the circuit-breaker position (the circuit-breaker auxiliary contacts must be connected to the devices; the respective binary input signals must be jumpered).

Method of Measurement, Threshold Value

The stage works with 2 different methods of measurement.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically. A DC component is thus eliminated. The RMS value of the fundamental component is compared with the set threshold.
- Evaluation of the unfiltered measurand:
  If the current exceeds a preset threshold value by
  current ≥ 2·√2·threshold value
  this stage will use unfiltered measurands in addition. Thus, very short operate times are possible.

6.9.6 Application and Setting Notes

Parameter: `Threshold`

- Default setting **`(_:3901:3) Threshold`** = ***`2.5 A`*** for I_{rated} = 1 A or ***`12.5 A`*** for I_{rated} = 5 A

Select the value high enough for the protection not to pick up on the RMS value of the inrush current that occurs when the local circuit breaker is closed. You do not have to consider short-circuit currents flowing through, because the stage is released only if the circuit breakers are opened at all remote ends of the protected object or the release was caused by the binary input *>release*.

Parameter: `Dropout ratio`

- Recommended setting value **`(_:3901:4) Dropout ratio`** = ***`0.90`***

The recommended setting value of ***`0.90`*** is sufficient for many applications. To obtain extremely accurate measurements, the dropout ratio can be reduced. If you expect highly fluctuating measurands at the pickup threshold, you can increase the dropout ratio. This avoids chattering of the tripping stage.

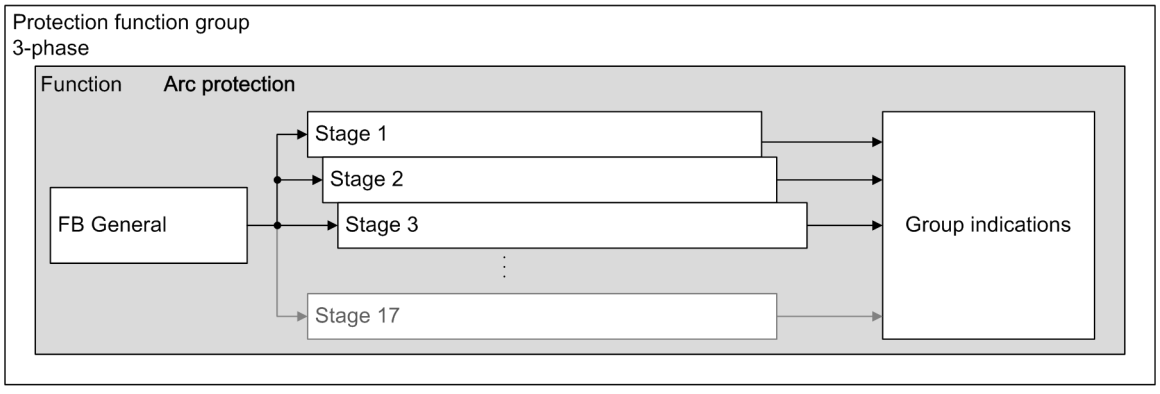
6.10 Arc Protection

6.10.1 Overview of Function

The function **Arc protection**:



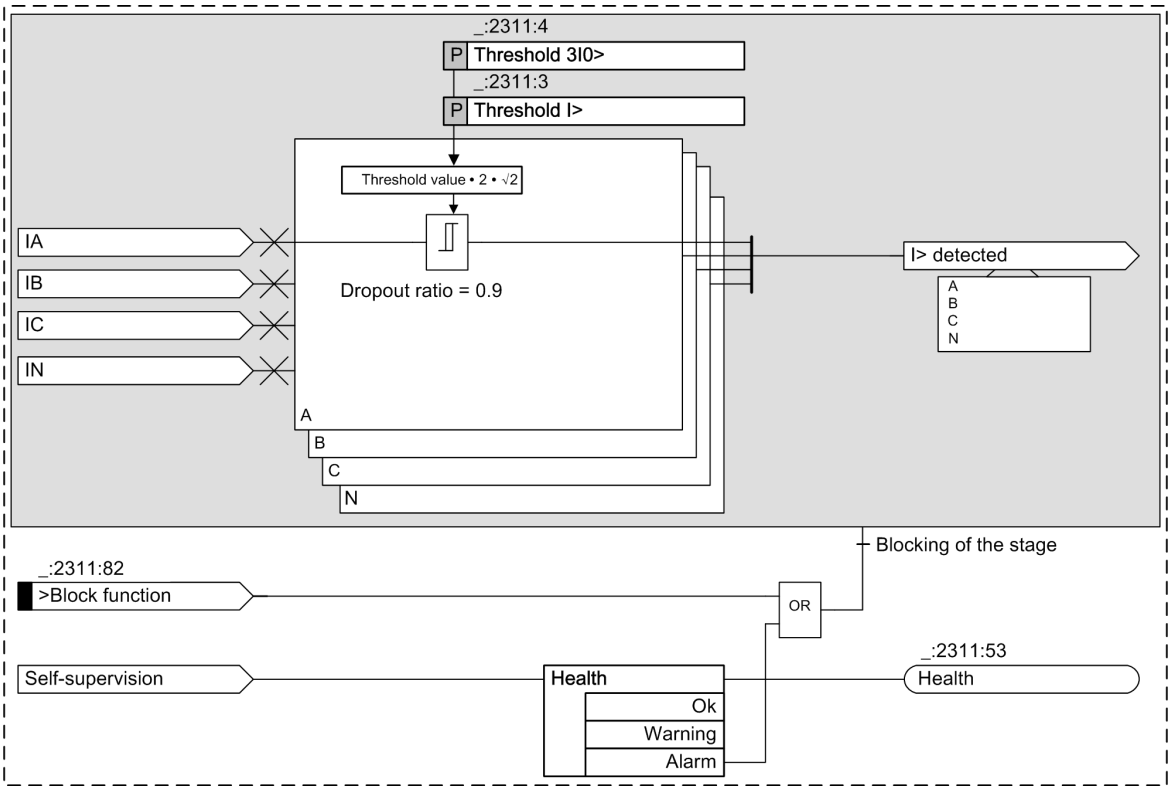
- Detects arcs in air-insulated switchgear parts without delay and in a fail-safe way
- Limits system damage through instantaneous high-speed tripping
- Protect systems from thermal overload
- Increases safety of personnel
- Trips in a 3-pole way
- Is suitable for use in all voltage levels

6.10.2 Structure of the Function

The **Arc protection** function can be added to function groups that provide current measured values.
The **Arc protection** function consists of the following blocks.

- General
- 3 stages
- Output logic 3-phase

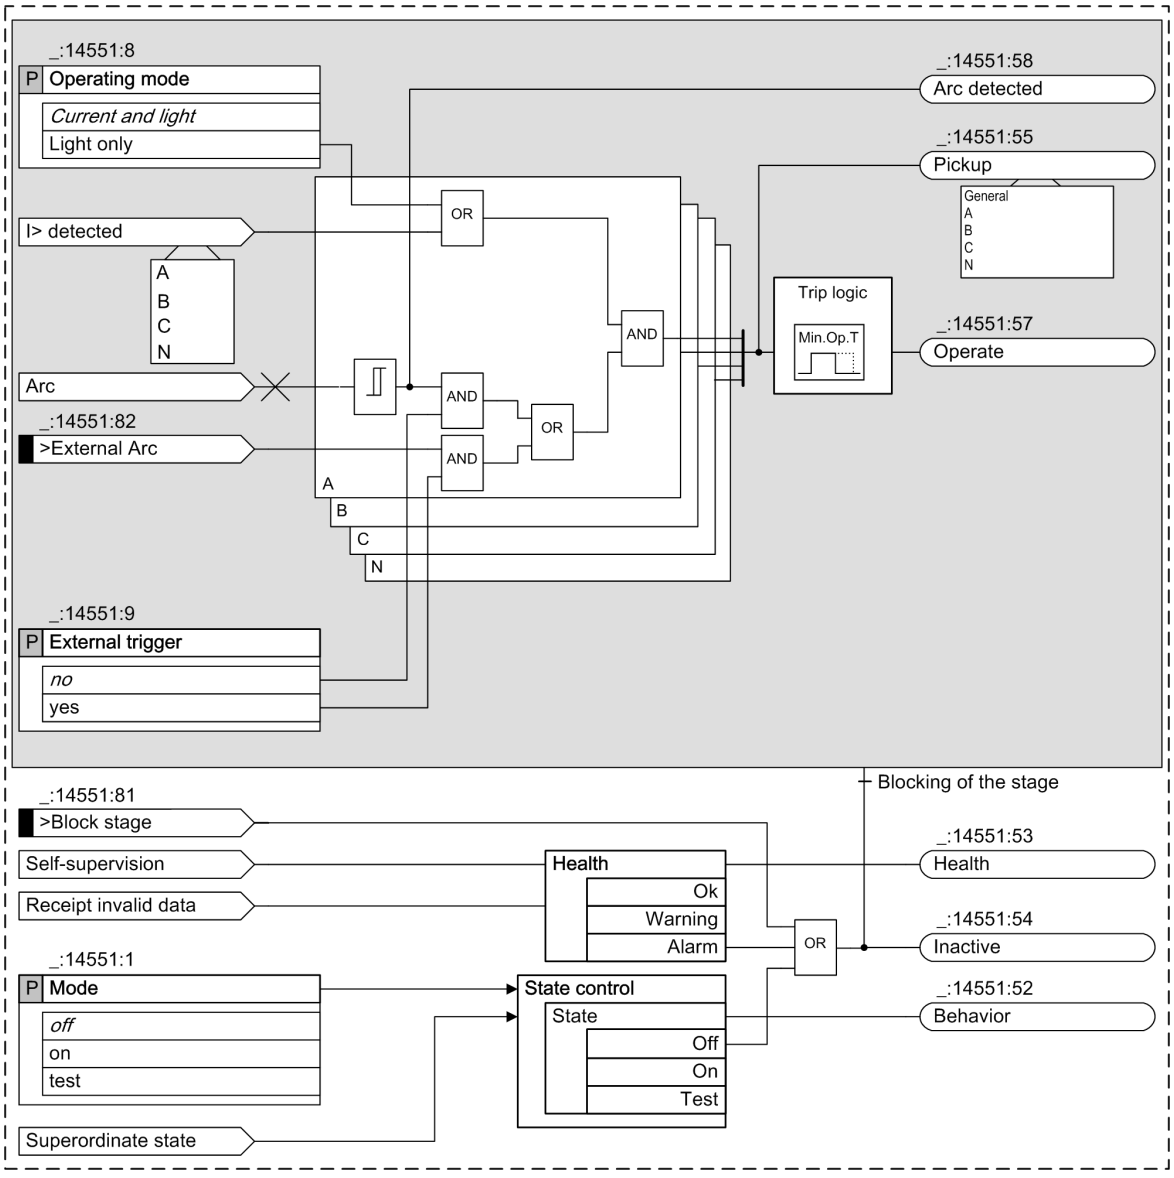
The **Arc protection** function is preconfigured with 3 stages. A maximum of 17 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.
The following figure shows the basic structure of the **Arc protection** function.



[dw_structure_arcprot, 2, en_US]

Figure 6-89 Structure/Embedding of the Arc Protection Function

6.10.3 Function Description



General Logic of the Function Block

[lo_fb0_arcprot, 1, en_US]

Figure 6-90 General Logic Diagram of the Function Block

Logic of the Stage

[lo_stage_arcprot, 1, en_US]

Figure 6-91 Logic Diagram of the Stage

The**Arc protection** function uses a locally connected optical arc sensor or an external trip initiation by other devices in order to detect arcs.

NOTE

Install the arc sensors inside the switchgear in such a way that they are not hidden behind other system components!

Shadowing of the arc sensors must be avoided!

NOTE

Once an optical sensor has detected an arc, you must replace the affected optical sensor!

Within the **Arc protection** function, you can use a fast current-flow criterion as an additional release criterion. The parameters for the current-flow criterion can be found in the **General** block. For each stage, you can select individually whether the current-flow criterion must be evaluated as well.

Method of Measurement, Current-Flow Criterion

The current-flow criterion works with 2 different methods of measurement.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically. A direct-current component is thus eliminated. The RMS value of the fundamental component is compared with the set threshold.
- Evaluation of the unfiltered measurand:
  If the current exceeds the threshold value set by the current amount $\geq 2 \cdot \sqrt{2} \cdot$ threshold value, the stage uses additional unfiltered measurands. Thus, very short operate times are possible.

NOTE

If using the current-flow criterion in addition to the light, prevent a potential overfunction caused by the suddenly occurring light signal.

If you use the current-flow criterion, arcs are typically detected in 4 ms!

Self Monitoring

The **Arc protection** function uses a self-monitoring circuit. This circuit monitors the optical arc sensors and the fiber-optic cables. The arc-protection module uses the fiber-optic cable to send a cyclic test signal (light) to the arc sensors. If the channel is operating properly, the test signal is sent back to the arc protection module. If the test signal is not returned to the arc protection module, the indication *channel # sensor failure* is generated.

If the self-monitoring function detects a fault, the indication *Health* is set to *Alarm* and the stage/function is blocked.

6.10.4 Application and Setting Notes – General Settings

Go to **General** under the function **Arc protection** and set the following parameters. The setting values apply to all stages.

Parameter: Threshold I>

- Default setting **(_:2311:3) Threshold I>** = *2.000 A*

Use the parameter **Threshold I>** to define the trigger threshold of the phase currents. The **Threshold I>** is relevant for the current-flow criterion of the **arc protection** function.

Set the **Threshold I>** of the function **Arc protection** in such a manner that the RMS value of the inrush current does not exceed the **Threshold I>** when activating the local circuit breaker.

For more information about how to calculate the setting value, refer to *6.3.4.2 Application and Setting Notes*

Parameter: Threshold 3I0>

- Default setting **(_:2311:4) Threshold 3I0>** = *1.000 A*

Use the parameter **Threshold 3I0>** to determine the tripping threshold for the zero-sequence current. The **Threshold 3I0>** is relevant for the current-flow criterion of the **Arc protection function**.

Set the **Threshold 3I0>** of the function **Arc protection** in such a manner that the RMS value of the inrush current does not exceed the **Threshold 3I0>** when activating the local circuit breaker.

For more information about how to calculate the setting value, refer to *6.5.4.2 Application and Setting Notes*

NOTE

If you set the parameter **CT connection** = ***3-phase, 2 primary CT*** for the **3-phase current measuring point**, the parameter **Threshold 3I0>** has no effect.

6.10.5 Application and Setting Notes for the Stage

Parameter: External trip initiation

- Default setting **(_:14551:9) External trip initiation** = ***no***

Use parameter **External trip initiation** to set whether an external input signal is used to trigger the stage.

Parameter Value	Description
no	The stage does not operate with an external input signal.
yes	The stage operates with an external input signal. If the stage operates with an external input signal, the binary input signal *>External Arc* must be routed in the DIGSI 5 information routing. In this setting option, the binary input signal *>External Arc* is only visible in the DIGSI 5 information routing **Note**: When working with external trip initiation, do not select a channel. If an additional channel is selected with this setting value, DIGSI 5 will signal an inconsistency.

Parameter: Operating mode

- Default setting **(_:14551:8) Operating mode** = ***Current and light***

Use the parameter **Operating mode** to define the basic functionality of the stage.

Parameter Value	Description
Current and light	The stage operates with the input variables current and light. The current-flow criterion ensures that the light signal originates from an arc. Siemens recommends using this setting.
Light only	This stage operates only with the input signal 'light' and is triggered even if current is not measured. This operating mode can cause a overfunction if light is detected suddenly. Use this setting value only if the effect caused by external light signals is impossible.

Parameter: Sensor

- Default setting **(_:14551:11) Sensor** = ***Point sensor***

Use the parameter **Sensor** to set which sensor type is connected to the device.

Parameter Value	Description
Point sensor	A point sensor is connected to the device.
Line sensor	A line sensor is connected to the device.
Custom	If you select this setting option, the parameter **Threshold Light** is visible. Siemens recommends the default setting values ***Point sensor*** or ***Line sensor***. This allows arcs to be detected reliably regardless of diffused light.

Parameter: Threshold Light

- Default setting **(_:14551:7) Threshold Light** = ***-20.00 dB***

Use the parameter **Threshold Light** to set the light sensitivity. If you set the **Threshold Light** to a smaller value, the sensitivity increases. If you set the **Threshold Light** to a higher value, the sensitivity decreases. If the sensors even pick up in case of a switching arc of the circuit breaker, set the **Threshold Light** parameter to a higher value.

Siemens recommends the default settings for point or line sensors.

Set the parameter **Threshold Light** manually only if you have special default settings for light sensitivity.

Parameter: Channel

- Default setting **(_:14551:10) Channel** = ***No channel is selected***

Use the parameter **Channel** to select which sensor channel the stage uses.

If the **Arc protection** function has several stages, a different channel must be selected for each stage.

For parameter **Channel**, the selection texts are identical to the name of the arc-protection module and its channels.

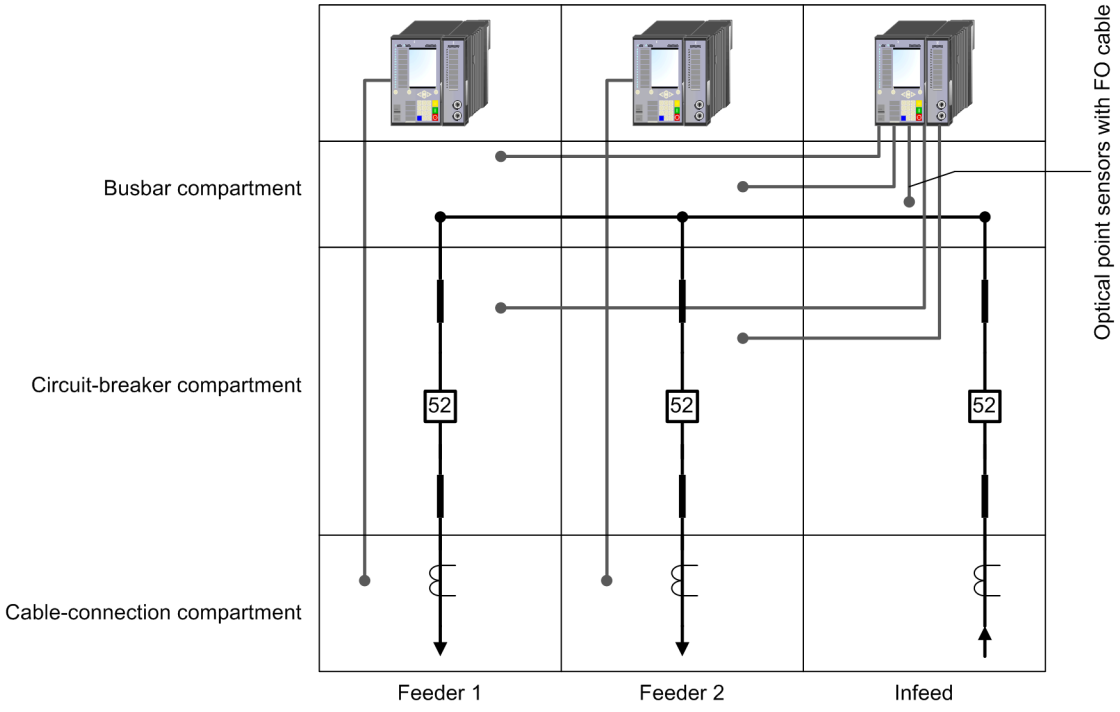
6.10.8 Application Example for Arc Protection with Point Sensors in Operating Mode: Light Only

6.10.8.1 Description



Overview

The example describes the **Arc protection** function in a medium-voltage switchgear with one infeed and 2 feeders. The **Arc protection** function operates with the **Operating mode** = ***Light only***.

The following items are considered in the example below:

- Positioning the optical point sensors in the switchgear
- Connecting the optical point sensors to the protection devices in the feeders and the infeed
- Number of necessary stages of the functions in the protection devices of the feeders and the infeed
- Setting notes about the selected parameters in the stages of the function

The following figure shows the arrangement and the connection of the optical point sensors:

[dw_arcprot-light-only, 2, en_US]

Figure 6-92 Layout and Connection of the Optical Point Sensors (Operating Mode = Light only)

For this example, the following is assumed:

- The circuit breaker of the infeed must be switched off. This ensures that the arcs in the busbar compartments of the infeed and the feeders or in the circuit-breaker compartment of the feeders are off.

  Install the optical point sensors in the busbar compartments (BB compartment) of the infeed and feeders. Install additional optical point sensors in the circuit-breaker compartment (CB compartment) of the feeders. Connect all optical point sensors to the protection device of the infeed.

- The optical point sensors in the cable-connection compartment of the feeders detect arcs in this compartment. Install one optical point sensor in the cable-connection compartment of the feeders and connect it to the protection device of the feeder. This allows for the selective clearing of arcs inside the cable-connection compartment.

  Due to the pressure waves that occur during the formation of an arc, partitions can deform and cause undesirable light influences in adjacent compartments. This can result in a non-selective tripping.

- If there is an arc in the circuit-breaker compartment and in the cable-connection compartment of the infeed, the superordinate protection device must switch off.

NOTE

If the **Arc protection** function operates in **`Operating mode`** = ***`Light only`***, the effects of external light can result in non-selective tripping.

NOTE

It must be considered that the number of arc protection modules connected to the device depends on the hardware configuration of the device.

When using modular devices, a maximum of 15 sensors can be connected. If using non-modular devices, a maximum of 6 sensors (3 sensors per module) can be connected.

6.10.8.2 Application and Setting Notes

General Notes

- Connect one optical point sensor from the cable-connection compartment in feeder 1 to the protection device in feeder 1. Arcs in the cable-connection compartment are cleared selectively by the circuit breaker in feeder 1.
- Connect one optical point sensor from the cable-connection compartment in feeder 2 to the protection device in feeder 2. Arcs in the cable-connection are cleared selectively by the circuit breaker in feeder 2.
- Connect optical point sensors from all busbar compartments and all circuit-breaker compartments of feeders 1 and 2 to the protection device in the infeed. Arcs in these compartments are detected and cleared by the device in the infeed.

Setting Notes for the Protection Device in Feeder 1

The **Arc protection** function operates with **one** stage.

Set the parameters of the stage as follows:

- Parameter: **Operating mode** = ***Light only***
- Parameter: **Sensor** = ***Point sensor***
- Parameter: **External trip initiation** = ***no***
- Parameter: **Channel** = ***Arc mod. 1 channel 1***

The parameters in block **General** are not relevant since the **Operating mode** = ***Light only***.

Setting Notes for the Protection Device in Feeder 2

The **Arc protection** function operates with **one** stage.

Set the parameters of the stage as follows:

- Parameter: **Operating mode** = ***Light only***
- Parameter: **Sensor** = ***Point sensor***
- Parameter: **External trip initiation** = ***no***
- Parameter: **Channel** = ***Arc mod. 1 channel 1***

The parameters in block **General** are not relevant since the **Operating mode** = ***Light only***.

Setting Notes for the Protection Device in the Infeed

The **Arc protection** function operates with **5** stages.

Set the parameters of the stages as follows:

- Parameter: **Operating mode** = ***Light only*** (applies to all stages)
- Parameter: **Sensor** = ***Point sensor*** (applies to all stages)
- Parameter: **External trip initiation** = ***no*** (applies to all stages)
- Parameter: **Channel** = ***Arc mod. 1 channel 1*** (Stage 1) → Busbar compartment supervision in feeder 1

  Parameter: **Channel** = ***Arc mod. 1 channel 2*** (Stage 2) → Circuit-breaker compartment supervision in feeder 1

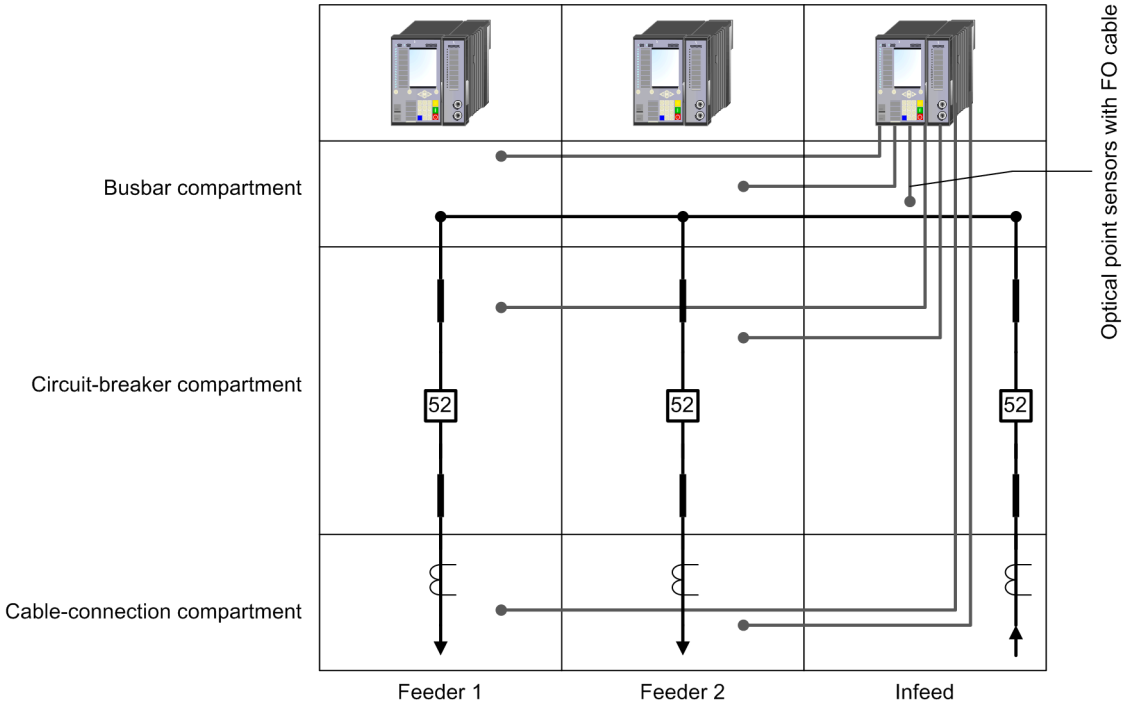
  Parameter: **Channel** = ***Arc mod. 1 channel 3*** (Stage 3) → Busbar compartment supervision in feeder 2

  Parameter: **Channel** = ***Arc mod. 2 channel 1*** (Stage 4) → Circuit-breaker compartment supervision in feeder 2

  Parameter: **Channel** = ***Arc mod. 2 channel 2*** (Stage 5) → Busbar compartment supervision in the infeed

The parameters in block **General** are not relevant since the **Operating mode** = ***Light only***.

6.10.9 Application Example for Arc Protection with Point Sensors in Operating Mode: Light and Current



6.10.9.1 Description

Overview

The example describes the **Arc protection** function in a medium-voltage switchgear with one infeed and 2 feeders. The **Arc protection** function operates with the **Operating mode** = ***Current and light***. In the example, all arcs are detected by the protection device in the infeed.

The following items are considered in the example:

- Positioning the optical point sensors in the switchgear
- Connecting the optical point sensors to the protection devices in the feeders and the infeed
- Number of necessary stages of the functions in the protection devices of the feeders and the infeed
- Setting notes about selected parameters in the stages of the function

[dw_light-and-current, 2, en_US]

Figure 6-93 Layout and Connection of the Optical Point Sensors (Operating Mode = Current and Light)

For this example, the following is assumed:

- The current-flow criterion offers additional security to prevent unwanted tripping caused by sudden light influences.

  Depending on the arc location in the cable-connection compartment of the feeder, it is not always possible to measure the current. If an arc is detected in the cable-connection compartment of the feeder, the current will therefore be evaluated in the infeed.
- Install the optical point sensors in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of the feeders as well as the busbar compartment of the infeed. Connect the optical point sensors to the protection device in the infeed.
- The protection device in the infeed clears all arcs in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of feeder 1 and 2. Furthermore, the protection device clears arcs in the busbar compartment of the infeed.

- If the optical point sensors in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of the feeders, or in the busbar compartment of the infeed detect an arc, the protection device in the infeed evaluates the current as well.
- If an arc occurs in the circuit-breaker compartment and in the cable-connection compartment of the infeed, the superordinate protection device must trip.

NOTE

If the **Arc protection** function operates with the **Operating mode** = ***Current and light***, the additional current-flow criterion prevents unwanted tripping caused by external light influences.

NOTE

This application example requires the connection of several optical point sensors to a single protection device. It must be considered that the number of arc-protection modules that are connected to the device depends on the hardware configuration of the device.

When using modular devices, a maximum of 15 sensors can be connected. If you use non-modular devices, a maximum of 6 sensors (3 sensors per module) can be connected.

6.10.9.2 Application and Setting Notes

General Notes

- Connect the optical point sensors from the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of feeders 1 and 2 to the protection device in the infeed. Arcs in the busbar compartment, the circuit-breaker compartment and the cable-connection compartment of feeders 1 and 2 are detected and cleared by the device in the infeed.
- Connect an optical point sensor from the busbar compartment in the infeed to the protection device in the infeed. Arcs in the busbar compartment of the infeed are cleared selectively by the circuit breaker in the infeed.

Setting Notes for the Protection Device in the Infeed

The **Arc protection** function operates with **7** stages.

Set the parameters of the stages as follows:

- Parameter: **Operating mode** = ***Current and light*** (applies to all stages)
- Parameter: **Sensor** = ***Point sensor*** (applies to all stages)
- Parameter: **External trip initiation** = ***no*** (applies to all stages)
- Parameter: **Channel** = ***Arc mod. 1 channel 1*** (Stage 1) → Busbar compartment supervision in feeder 1

  Parameter: **Channel** = ***Arc mod. 1 channel 2*** (Stage 2) → Circuit-breaker compartment supervision in feeder 1

  Parameter: **Channel** = ***Arc mod. 1 channel 3*** (Stage 3) → Cable-connection compartment supervision in feeder 1

  Parameter: **Channel** = ***Arc mod. 2 channel 1*** (Stage 4) → Busbar compartment supervision in feeder 2

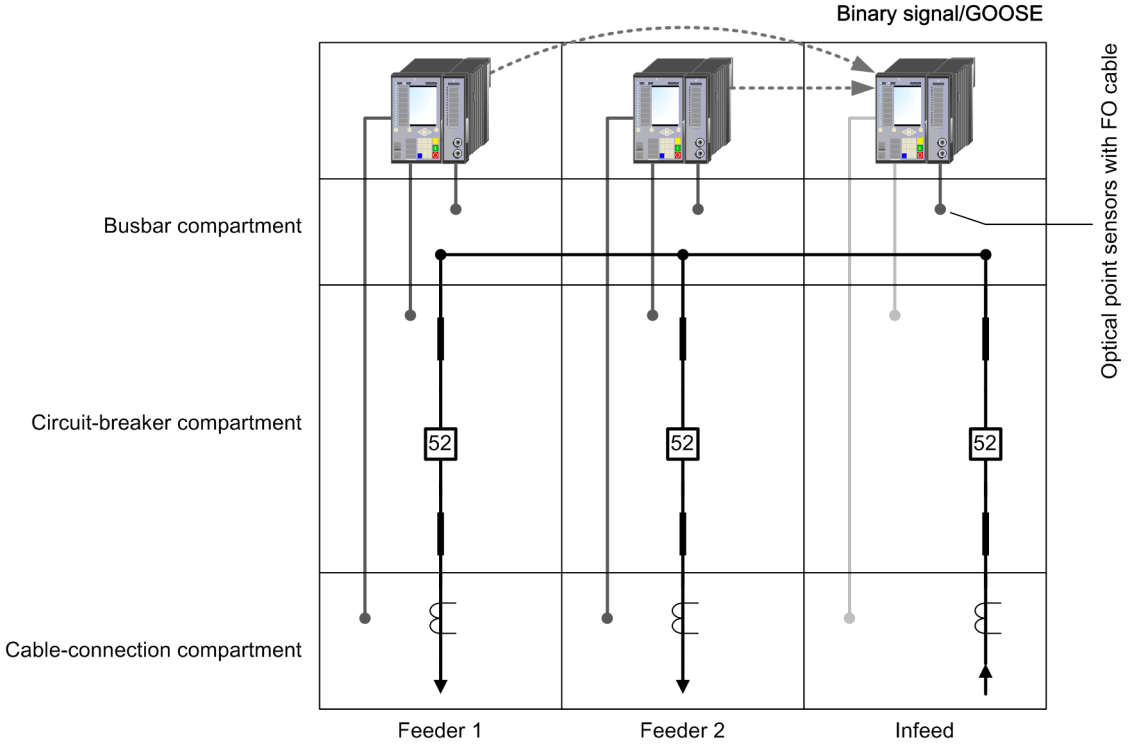
  Parameter: **Channel** = ***Arc mod. 2 channel 2*** (Stage 5) → Circuit-breaker compartment supervision in feeder 2

  Parameter: **Channel** = ***Arc mod. 2 channel 3*** (Stage 6) → Cable-connection compartment supervision in feeder 2

  Parameter: **Channel** = ***Arc mod. 3 channel 1*** (Stage 7) → Busbar compartment supervision in the infeed

You can find more information about the settings of the parameters **Threshold I>** and **Threshold 3I0>** in chapter *6.10.4 Application and Setting Notes – General Settings*.

6.10.10 Application Example for Arc Protection with Point Sensors via External Trip Initiation



6.10.10.1 Description

Overview

The example describes the **Arc protection** function in a medium-voltage switchgear with one infeed and 2 feeders. The stages of the **Arc protection** function are triggered by **`External trip initiation`**.

The following items are considered in the example below:

- Positioning the optical point sensors in the switchgear
- Connecting the optical point sensors to the protection devices in the feeders and the infeed
- Number of necessary stages of the functions in the protection devices of the feeders and the infeed
- Setting notes about the selected parameters in the stages of the function

[dw_arcprot-extern-input, 2, en_US]

Figure 6-94 Arc Protection with External Trip Initiation

For this example, the following is assumed:

- Install the optical point sensors in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of the feeder and the infeed. Connect the optical point sensors to the respective protection device in the feeder and infeed.
- If the optical point sensors detect an arc in the busbar compartment, the circuit-breaker compartment, or the cable-connection compartment of the feeders, the *`Arc detected`* indication is sent via binary inputs/outputs, a protection interface, or IEC 61850 GOOSE to the protection device in the infeed. Then, the protection device in the infeed evaluates the current as well. If the measured current exceeds the thresholds **`Threshold I>`** and/or **`Threshold 3I0>`**, the protection device in the infeed clears the malfunction.

  You can find detailed information in chapter *6.10.10.2 Application and Setting Notes*

- Alternatively, arcs in the cable-connection compartment of the feeders can be cleared selectively by the protection device of the affected feeder. To do this, the pickup indication from the infeed unit must be sent back to the appropriate protection device in the feeder.
- If an arc occurs in the circuit-breaker compartment and in the cable-connection compartment of the infeed, the superordinate protection device trips.

NOTE

If the **Arc protection** function operates via the **`External trip initiation`**, only 3 optical point sensors are required per feeder protection device in order to detect the arcs (only one arc-protection module).

The signals from the feeder protection devices are sent via binary inputs/outputs, a protection interface or IEC 61850 GOOSE to the protection device of the infeed and processed.

The number of GOOSE messages is not limited. Therefore, the number of feeders is not limited, and the protection of complex systems is feasible.

Siemens recommends using the **Arc protection** function with external trip initiation.

6.10.10.2 Application and Setting Notes

General Notes:

- Install the optical point sensors in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of the feeders and the infeed to the respective protection devices.
- Arcs in the busbar compartment, the circuit-breaker compartment, and the cable-connection compartment of the feeders must be cleared by the protection device in the infeed. To do this, the protection devices in the feeder device must send the indication *`Arc detected`* to the infeed device. Use the binary inputs/outputs, a protection interface, or IEC 61850 GOOSE.
- The protection device in the infeed evaluates the current. If the measured current exceeds the thresholds **`Threshold I>`** and/or **`Threshold 3I0>`**, the protection device in the infeed clears the malfunction.

  Connect the signals over 6 stages, using the external trip initiation or a CFC chart.

Setting Notes for the Protection Device in Feeder 1

The **Arc protection** function operates with **3** stages.

Set the parameters of the stages as follows:

- Parameter: **`Operating mode`** = ***`Light only`*** (applies to all stages)
- Parameter: **`Sensor`** = ***`Point sensor`*** (applies to all stages)
- Parameter: **`External trip initiation`** = ***`no`*** (applies to all stages)
- Parameter: **`Operate & flt.rec. blocked`** = ***`yes`*** (applies to all stages)
- Parameter: **`Channel`** = ***`Arc mod. 1 channel 1`*** (Stage 1) → Busbar compartment supervision in feeder 1

  Parameter: **`Channel`** = ***`Arc mod. 1 channel 2`*** (Stage 2) → Circuit-breaker compartment supervision in feeder 1

  Parameter: **`Channel`** = ***`Arc mod. 1 channel 3`*** (Stage 3) → Cable-connection compartment supervision in feeder 1

Setting Notes for the Protection Device in Feeder 2

The **Arc protection** function operates with **3** stages.

Set the parameters of the stages as follows:

- Parameter: **`Operating mode`** = ***`Light only`*** (applies to all stages)
- Parameter: **`Sensor`** = ***`Point sensor`*** (applies to all stages)

- Parameter: **External trip initiation** = ***no*** (applies to all stages)
- Parameter: **Operate & flt.rec. blocked** = ***yes*** (applies to all stages)
- Parameter: **Channel** = ***Arc mod. 1 channel 1*** (Stage 1) → Busbar compartment supervison in feeder 2

  Parameter: **Channel** = ***Arc mod. 1 channel 2*** (Stage 2) → Circuit-breaker compartment supervision in feeder 2

  Parameter: **Channel** = ***Arc mod. 1 channel 3*** (Stage 3) → Cable-connection compartment supervision in feeder 2

Setting Notes for the Protection Device in the Infeed

The **Arc protection** function operates with **9** stages.

Stage 1 (busbar compartment supervision):

- Parameter: **Operate & flt.rec. blocked** = ***no***

  If an arc is detected in the busbar compartment of the infeed and the thresholds **Threshold I>** or **Threshold 3I0>** are exceeded, an operate indication is generated immediately.
- Parameter: **Channel** = ***Arc mod. 1 channel 1***
- Parameter: **Operating mode** = ***Current and light***
- Parameter: **Sensor** = ***Point sensor***
- Parameter: **External trip initiation** = ***no***

Stage 2 (circuit-breaker compartment supervision):

- Parameter: **Operate & flt.rec. blocked** = ***yes***

  If an arc is detected in the circuit-breaker compartment of the infeed (light-gray point sensors in *Figure 6-94*), a pickup indication is generated immediately. The arc is cleared by a superordinate protection device.
- Parameter: **Channel** = ***Arc mod. 1 channel 2***
- Parameter: **Operating mode** = ***Current and light***
- Parameter: **Sensor** = ***Point sensor***
- Parameter: **External trip initiation** = ***no***

Stage 3 (cable-connection compartment supervision):

- Parameter: **Operate & flt.rec. blocked** = ***yes***

  If an arc is detected in the cable-connection compartment of the infeed (light-gray point sensors in *Figure 6-94*), a pickup indication is generated immediately. The arc is cleared by a superordinate protection device.

  Depending where the arc is generated in the cable-connection compartment of the infeed, it is not always possible to measure the current. If an arc is detected in the cable-connection compartment of the infeed, the current must be evaluated by the superordinate protection device.
- Parameter: **Channel** = ***Arc mod. 1 channel 3***
- Parameter: **Operating mode** = ***Light only***
- Parameter: **Sensor** = ***Point sensor***
- Parameter: **External trip initiation** = ***no***

Stage 4 to 9 (External trip initiation):

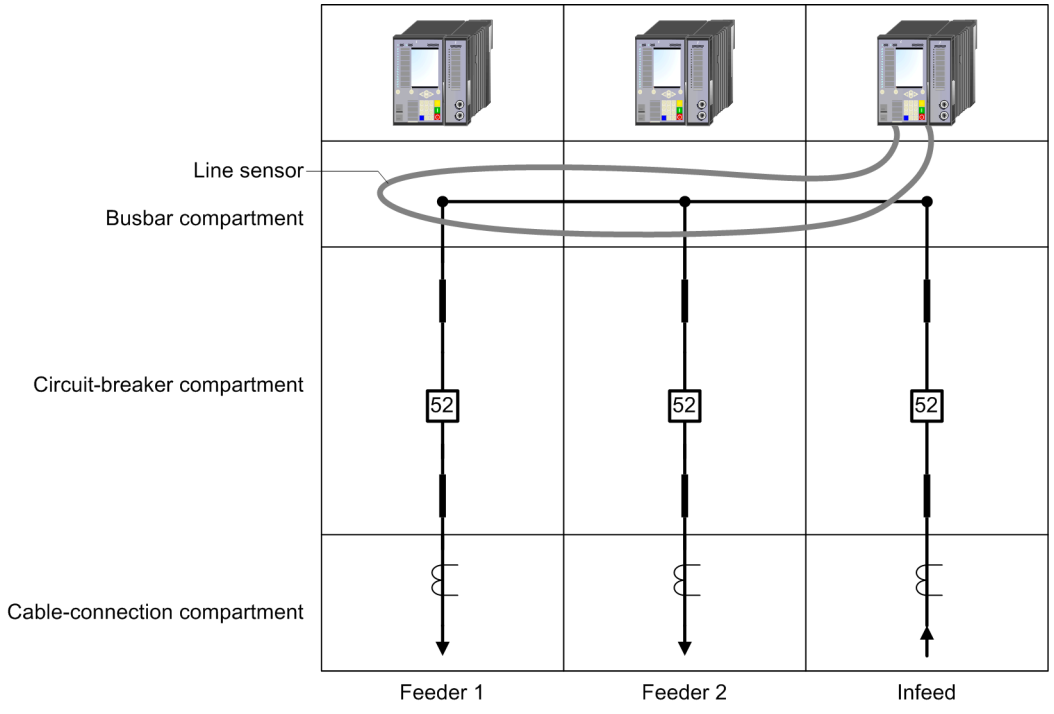
- Parameter: **Operate & flt.rec. blocked** = ***no***
- Parameter: **Operating mode** = ***Current and light***

- Parameter: **External trip initiation** = ***yes***

  If an arc is detected in the busbar compartment, the circuit-breaker compartment, or the cable-connection compartment of the feeder, the feeder device sends the indication *Arc detected* to the infeed device. Only if the indication in the infeed device *Arc detected* is connected with the signal *>External Arc*, an external trip initiation via these stages is effective.

  The protection device in the infeed evaluates the current. If the measured current exceeds the **Threshold I>** and/or **Threshold 3I0>** threshold values, the protection device in the infeed clears the arc.

6.10.11 Application Example for Arc Protection with a Line Sensor in Operating Mode: Light and Current



6.10.11.1 Description

Overview

The example describes the **Arc protection** function in a medium-voltage switchgear with 1 infeed and 2 feeders. The **Arc protection** function operates with the **Operating mode** = ***Current and light***. In the example, all arcs are detected by the protection device in the infeed.

The following items are considered in the example below:

- Optical line sensor placement in the switchgear
- Optical line sensor connection to the protection device in the infeed
- Number of necessary stages of the functions in the infeed protection device
- Setting notes about the selected parameters in the stages of the function

[dw_Liniensensor, 1, en_US]

Figure 6-95 Layout and Connection of the Optical Line Sensors (Operating Mode = Current and Light)

For this example, the following is assumed:

- The current-flow criterion offers additional protection to prevent unwanted tripping caused by the sudden effects of light.
- *Figure 6-95* shows how the optical line sensors should be routed. Start in the infeed busbar compartment and route the optical line sensor along the busbar and back again to the protection device in the infeed. Connect the optical line sensor to the protection device in the infeed.
- Depending on the routing options in the control cabinet, you can also route the optical line sensor through the circuit breaker and cable-connection compartments of the feeders.

  If this is not possible, you can detect arcs in these compartments using point sensors. For more detailed information, see chapters *6.10.8 Application Example for Arc Protection with Point Sensors in Operating Mode: Light Only* and *6.10.9 Application Example for Arc Protection with Point Sensors in Operating Mode: Light and Current*.
- If an arc occurs in the circuit-breaker compartment and in the cable-connection compartment of the infeed, the superordinate protection device will shut off.

NOTE

If the **Arc protection** function operates with the **Operating mode** = ***Current and light***, the additional current-flow criterion will prevent unwanted tripping caused by external light effects.

NOTE

Note that the number of arc protection modules that are connected to the device depend on the hardware configuration of the equipment.

When using modular equipment, a maximum of 15 sensors can be connected. If using non-modular equipment, a maximum of 6 sensors (3 sensors per module) can be connected.

Depending on the use case, you can combine point and line sensors.

6.10.11.2 Application and Setting Notes

Setting Notes for the Protection Device in the Infeed

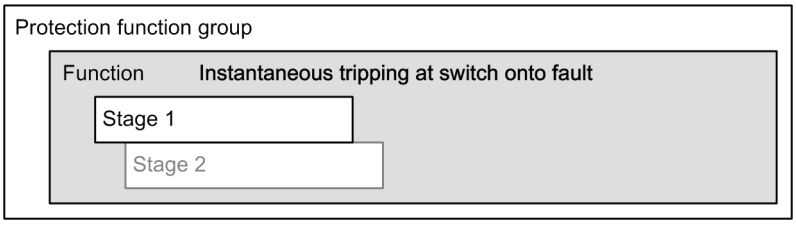
The **Arc protection** function operates with **1** stage.

Set the parameters of the stage as follows:

- Parameter: **Operating mode** = ***Current and light***
- Parameter: **Sensor** = ***Line sensor***
- Parameter: **External trip initiation** = ***no***
- Parameter: **Channel** = ***Arc mod. 1 channel 1*** (Stage 1) → Busbar compartment supervision (infeed, feeder 1, feeder 2)

You can find more information about the settings of the parameters **Threshold I>** and **Threshold 3I0>** in chapter *6.10.4 Application and Setting Notes – General Settings*.

6.11 Instantaneous Tripping at Switch onto Fault



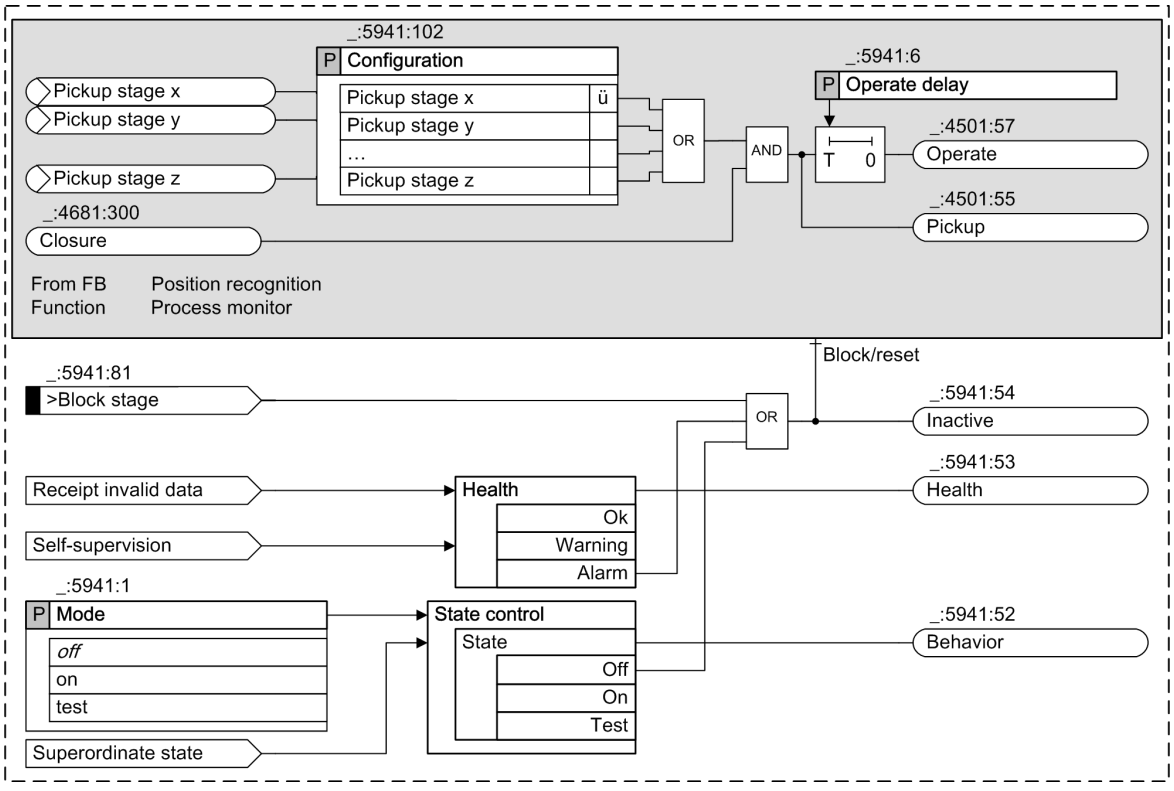
6.11.1 Overview of Functions

The **Instantaneous tripping at switch onto fault** function serves for immediate tripping when switching onto a fault.

The function does not have its own measurement and must be linked to another protection function with the pickup (measurement).

6.11.2 Structure of the Function

The function **Instantaneous tripping at switch onto fault** can be used in all protection function groups.The function is preconfigured with a stage. A maximum of 2 tripping stages can be operated simultaneously in the function. The stages have an identical structure.



[dwstrsto-030211-01.tif, 1, en_US]

Figure 6-96 Structure/Embedding of the Function

6.11.3 Stage Description

Logic of the Stage

[logisotf-170312-01.tif, 1, en_US]

Figure 6-97 Logic Diagram of the Stage Instantaneous Tripping at Switch onto Fault

Connection of the Stage

The stage is intended to initiate instantaneous tripping when switching onto a fault. To do this, the stage must be connected to one or more pickups from protection functions or protection stages, for example, to pickup of an overcurrent-protection stage . That is, the stage of the **Instantaneous tripping at switch onto fault** function does not have its own measuring function but requires the pickup of another protection function or protection stage to pick up.

The stage is active only if switching is pending or executed (for this, see section *6.3 Overcurrent Protection, Phases*).

NOTE

If the pickup of a protection stage takes place and tripping is blocked by the **Inrush-current detection** function, no pickup of the **Instantaneous tripping at switch onto fault** function takes place. In this case, there is no fault recording neither. Despite this, if a fault recording is necessary, you can activate it with the parameter **(_:114) Start flt.rec** of the **Inrush-current detection** function (see chapter *6.8 Inrush-Current Detection*).

6.11.4 Application and Setting Notes

Parameter: Configuration

- Default setting **(_:5941:102) Configuration** = ***no stage***

The **Configuration** parameter is used to define with which pickup of a protection function or protection stage the **Instantaneous tripping at switch onto fault** function responds.

Normally, the pickups of protection functions and stages with high fault current are selected:

- Distance Protection
- Overcurrent protection (phase and ground)
- Directional time-overcurrent protection (phase and ground)

A specific protection stage is generally used. This can be one of the protection stages provided for the protection application, which itself trips with a delay. An additional protection stage with settings optimized for this use case, for example, increased threshold value and blocking of self-tripping, can also be used.

Parameter: Operate delay

- Recommended setting value **(_:5941:6) Operate delay** = ***0.00 s***

When switching onto a fault, the tripping should usually be instantaneous. The tripping delay is therefore set to 0.

6.11.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting

6.12 Overcurrent Protection, 1-Phase

6.12.1 Function Overview

The **Overcurrent protection, 1-phase** function (ANSI 50N/51N):

- Detects and monitors the current measured in a transformer neutral point grounding
- Can operate as sensitive tank leakage protection
- Detects and monitors the circulating current between the neutral points of 2 capacitor banks
- Switches off high-current faults instantaneously

6.12.2 Structure of the Function

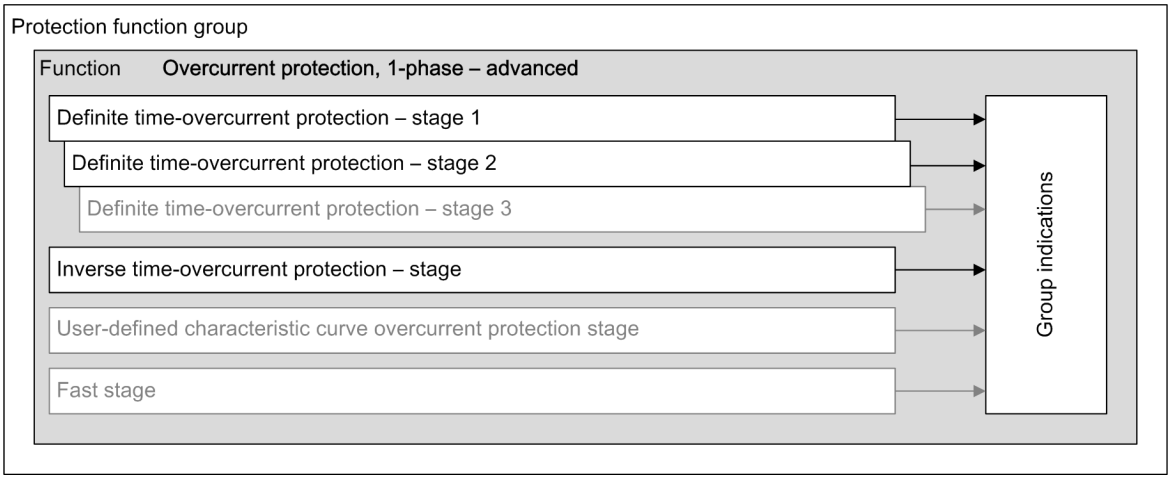
The **Overcurrent protection, 1-phase** function is used in protection function groups with 1-phase current measurement. 2 function types are offered:

- **Overcurrent protection, 1-phase – advanced** (50N/51N OC-1ph-A)
- **Overcurrent protection, 1-phase – basic** (50N/51N OC-1ph-B)

The function type Basic is provided for standard applications. The function type Advanced offers more functionality and is provided for more complex applications.

Both function types are pre-configured by the manufacturer with 2 **Definite time-overcurrent protection** stages and with 1 **Inverse time-overcurrent protection** stage.

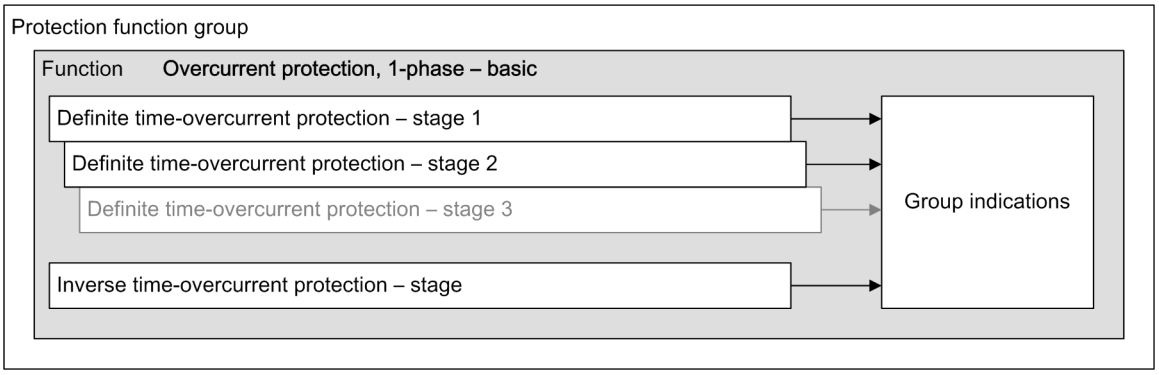
In the function type **Overcurrent protection, 1-phase – advanced** the following stages can be operated simultaneously:



- Maximum of 3 stages **Definite time-overcurrent protection** (UMZ)
- 1 stage **Inverse time-overcurrent protection** (AMZ)
- 1 stage **User-defined characteristic curve overcurrent protection**
- 1 **Fast stage**

In the function type **Time-Overcurrent protection, 1-phase – basic**, the following stages can operate simultaneously:

- Maximum of 3 stages **Definite time-overcurrent protection**
- 1 stage **Inverse time-overcurrent protection**



The non-preconfigured stages in *Figure 6-98* and *Figure 6-99* are shown in gray. Apart from the operate-delay characteristic curve, the **Definite time-overcurrent protection** stage, the **Inverse time-overcurrent protection** stage, and the **User-defined characteristic curve time-overcurrent protection** stage are structured identically.

The **Fast stage** uses a fast tripping algorithm. It is therefore suited in particular for sensitive ground-fault detection according to the high-impedance principle.

[dwocp1pa-280113-01.tif, 2, en_US]

Figure 6-98 Structure/Embedding the Function Overcurrent Protection, 1-Phase – Advanced

[dwocp1pb-310113-01.tif, 2, en_US]

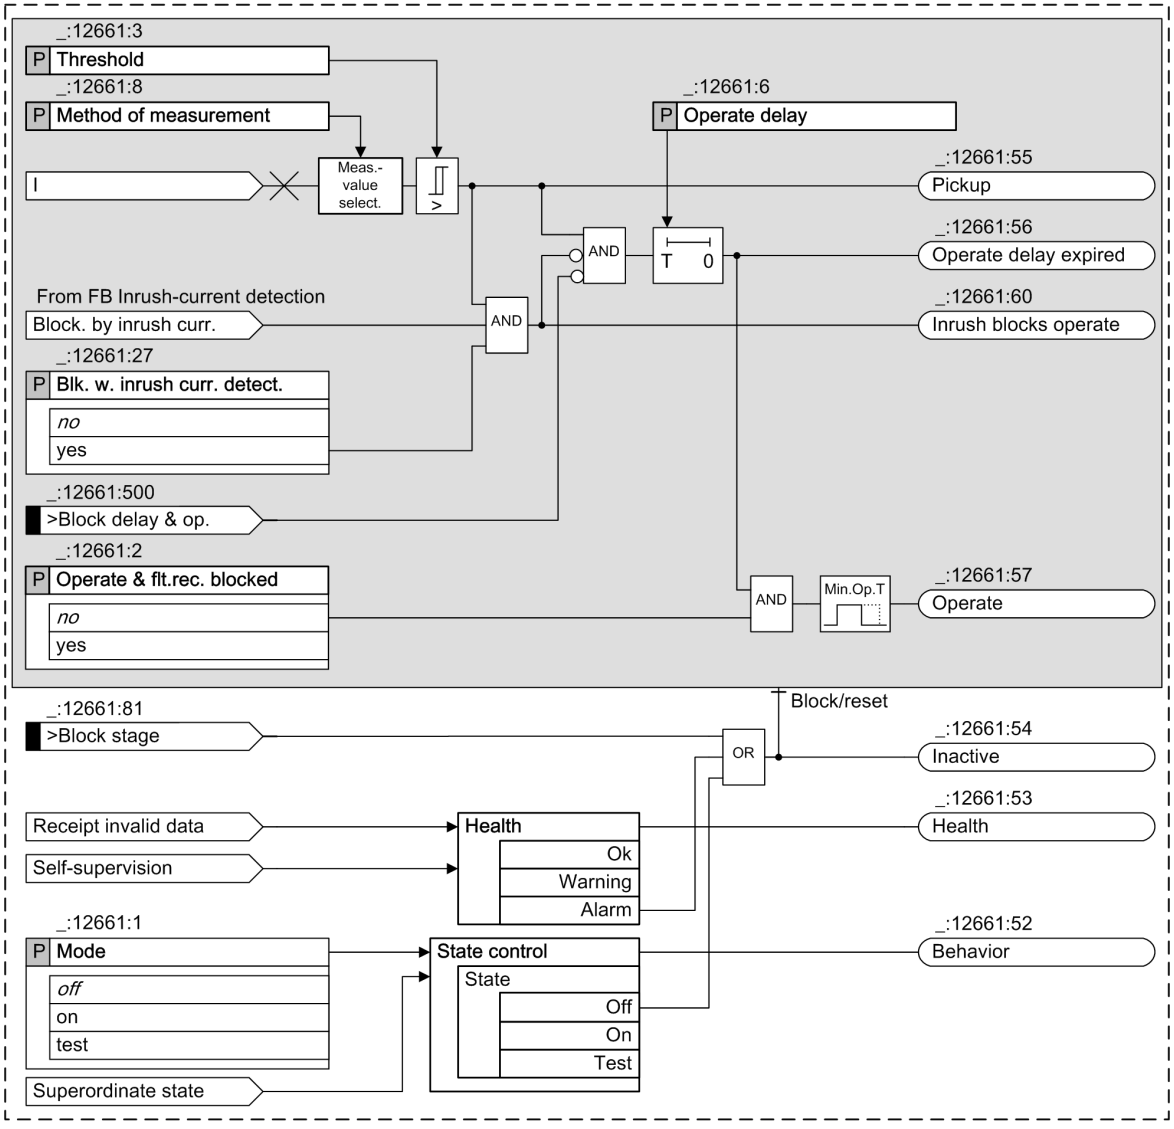


Figure 6-99 Structure/Embedding the Function Overcurrent Protection, 1-Phase – Basic

If the device is equipped with the **Inrush-current detection** function, you can stabilize the stages against issuing of the operate indication due to transformer inrush-currents.

6.12.3 Stage with Definite-Time Characteristic Curve

6.12.3.1 Description

Logic of a Stage

[loinvocp-270612-01.tif, 1, en_US]

Figure 6-100 Logic Diagram of the Definite Time-Overcurrent Protection, 1-Phase

Method of measurement

You use the **`Method of measurement`** parameter to define whether the stage uses the ***`fundamental comp.`*** or the calculated ***`RMS value`***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Blocking of the Stage

The picked up stage can reset completely via the binary input signal *>Block stage*.

Blocking of the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also tripping. A running time delay is reset. The pickup is reported and a fault is opened.

Blocking of Tripping via the Device-Internal Inrush-Current Detection Function

With the **Blk. w. inrush curr. detect.** parameter, you can block the operate indication of the stage for a threshold-value violation due to the inrush current. In case of a blocking, the stage picks up. The start of the time delay and the operate indication are blocked. The function signals this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started. When complete, the stage generates an operate indication. The blocking can only be set if the central function **Inrush-current detection** is effective.

Blocking of tripping with the **Inrush-current detection** function is possible only if the following conditions have been met:

- The central **Inrush-current detection** function has to be available in another protection function group with 3-phase current measurement.
- You have to connect the protection function group with 1-phase current measurement to the protection function group with 3-phase current measurement. You connect protection function groups in the DIGSI 5 Project Tree → Name of the device → **Function group connections**.

6.3.7.1 Description

6.12.3.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:12661:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Threshold, Operate delay

- Default setting **(_:12661:3) Threshold** = ***1.200 A*** (for the first stage)
- Default setting **(_:12661:6) Operate delay** = ***0.300 s*** (for the first stage)

Set the **Threshold** and **Operate delay** parameters for the specific application.

6.12.4 Stage with Inverse-Time Characteristic Curve

6.12.4.1 Description

Logic of the Stage

[lodefocp-270612-01.tif, 1, en_US]

Figure 6-101 Logic Diagram of the Inverse Time-Overcurrent Protection (1-Phase)

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve according to IEC and ANSI

When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The

dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

Method of Measurement

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the calculated ***RMS value***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Blocking of the Stage

The picked up stage can reset completely via the binary input signal *>Block stage*.

Blocking of the Time Delay

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also tripping. A running time delay is reset. The pickup is reported and a fault is opened.

Blocking of Tripping via the Device-Internal Inrush-Current Detection Function

With the **Blk. w. inrush curr. detect.** parameter, you can block the operate indication of the stage for a threshold-value violation due to the inrush current. In case of a blocking, the stage picks up. The start of the time delay and the operate indication are blocked. The function signals this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started. When complete, the stage generates an operate indication.

Blocking of tripping with the **Inrush-current detection** function is possible only if the following conditions have been met:

- The central **Inrush-current detection** function has to be available in another protection function group with 3-phase current measurement.
- You have to connect the protection function group with 1-phase current measurement to the protection function group with 3-phase current measurement. You connect protection function groups in the DIGSI 5 Project Tree → Name of the device → **Function group connections**.

6.12.4.2 Application and Setting Notes

Parameter: **Method of measurement**

- Recommended setting value **(_:12691:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: `Type of character. curve`

- Default setting **`(_:12691:108) Type of character. curve`** = ***`IEC normal inverse`***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **`Type of character. curve`** required for your specific application.

Parameter: `Threshold`

- Default setting **`(_:12691:3) Threshold`** = ***`1.20 A`***

Set the **`Threshold`** and **`Type of character. curve`** parameters for the specific application.

Note that a safety margin is set between pickup value and threshold value. The stage only picks up at approx. 10 % above the **`Threshold`**.

Parameter: `Time dial`

- Default setting **`(_:12691:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the parameter **`Time dial`** at ***`1`*** (default setting).

Parameter: `Reset`

- Default setting **`(_:12691:109) Reset`** = ***`disk emulation`***

You use the **`Reset`** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

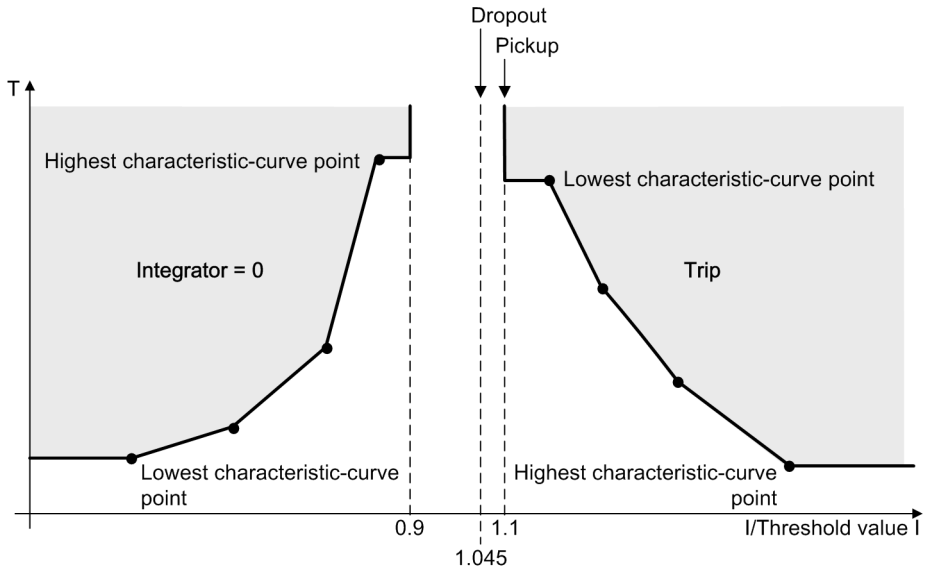
6.12.5 Stage with User-Defined Characteristic Curve

6.12.5.1 Description

The **User-defined characteristic curve time-overcurrent protection** stage is only available in the advanced function type.

This stage is structured the same way as the stage with the inverse-time characteristic curve. The only difference is that you can define the characteristic curve as desired.

User-Defined Characteristic Curve



With the user-defined characteristic curve, you can define the operate curve point by point using up to 30 value pairs of current and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.

Pickup and Dropout Behavior with the User-Defined Characteristic Curve

When the input variable exceeds the threshold value by 1.1 times, the characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

[dwocpken-140611-02.tif, 1, en_US]

Figure 6-102 Pickup Behavior and Dropout Behavior when Using a User-Defined Characteristic Curve

NOTE

Note that the currents that are lower than the current value of the smallest characteristic-curve point do not extend the operate time. The pickup characteristic runs in parallel to the current axis up to the smallest characteristic-curve point. Currents that are larger than the current value of the largest characteristic-curve point do not reduce the operate time. The pickup characteristic runs in parallel to the current axis from the largest characteristic-curve point.

6.12.5.2 Application and Setting Notes

This stage is structured the same way as the stage with the inverse-time characteristic curve. The only difference is that you can define the characteristic curve as desired. This chapter only provides application and setting notes for setting characteristic curves.

Parameter: `Current/time value pairs` (from the operate curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the **`Time dial`** parameter at ***`1`***.

Parameter: `Reset`

- Default setting **`Reset`** = ***`disk emulation`***

You use the **`Reset`** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	In the case of this setting, a dropout characteristic curve has to be set in addition to the operate curve. Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

Parameter: `Current/time value pairs` (of the dropout characteristic curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

6.12.6 Fast Stage

6.12.6.1 Description

Logic of a Stage

The fast stage is only available in function type Advanced.

[loocp1hs-280113-01.tif, 2, en_US]

Figure 6-103 Logic Diagram of the Fast Stage, 1-Phase

Method of Measurement, Pickup and Dropout Behavior of the Fast Stage

This stage evaluates the unfiltered measurands. Thus, very short response times are possible. When the absolute values of 2 consecutive sampled values of the last half period exceed the **Threshold**, the stage picks up. When all sampled values of the previous period are less than the dropout threshold, the stage drops out.

Blocking of the Stage

The picked up stage can reset completely via the binary input signal *>Block stage*.

6.12.6.2 Application and Setting Notes

Parameter: Threshold, Operate delay

- Default setting **(_:3) Threshold** = ***10.00 A***
- Default setting **(_:6) Operate delay** = ***0.00 s***

Set the **Threshold** and **Operate delay** parameters for the specific application.

Ensure that the sampled values are compared directly without an additional factor with the set threshold value.

Parameter: Dropout ratio

- Recommended setting value **(_:4) Dropout ratio** = ***0.90***

The recommended setting value of ***0.90*** is sufficient for many applications. To obtain high-precision measurements, the **Dropout ratio** can be reduced. If you expect highly fluctuating measurands at the pickup threshold, you can increase the **Dropout ratio** setting. This avoids chattering of the tripping stage.

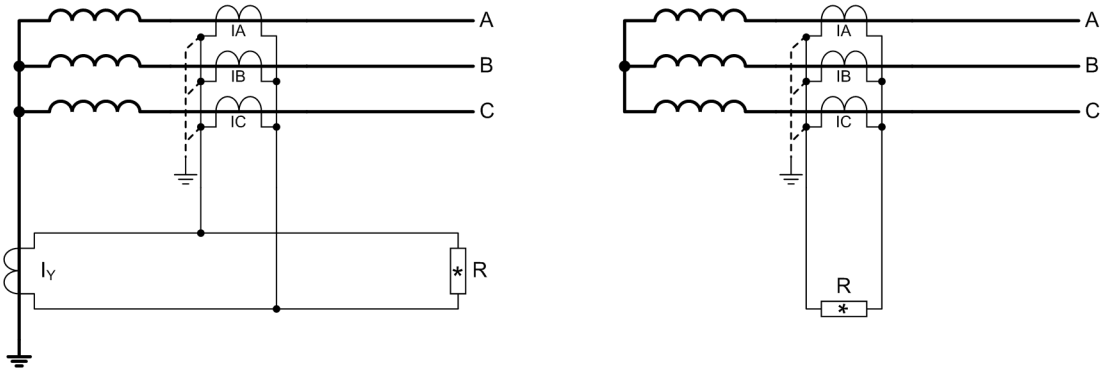
6.12.7 Application Example: High-Impedance Restricted Ground-Fault Protection



6.12.7.1 Description

With the high-impedance method, all current transformers operate in parallel at the limits of the protection range on a common, relatively high-impedance resistor R, the voltage of which is measured.

The current transformers must be of the same type of construction and have at least one core of their own for the High-impedance restricted ground-fault protection. Furthermore, they must have the same transfer ratio and approximately the same knee-point voltage.

The high-impedance principle is especially suited for ground-fault detection in grounded networks at transformers, generators, motors, and shunt reactors.

The left part of *Figure 6-104* shows an application example for a grounded transformer winding or a grounded motor/generator. The example at the right shows an ungrounded transformer winding or an ungrounded motor/generator. In this example, it is assumed that the network is grounded at a different point.

[dwhimpef-310113-01.tif, 2, en_US]

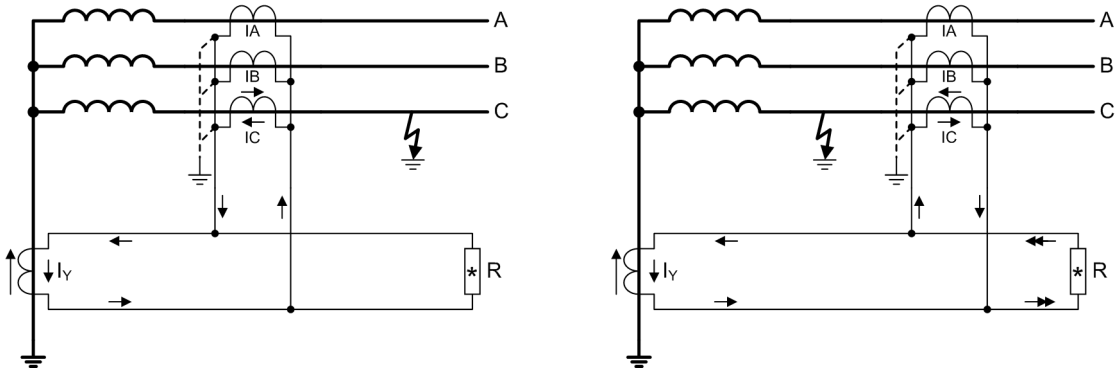


Figure 6-104 Restricted Ground-Fault Protection According to the High-Impedance Principle

Function of the High-Impedance Principle

The high-impedance principle is explained using the example of a grounded transformer winding.

In normal state, no residual currents flow, that is, in the transformer neutral point $I_Y = 0$ and in the phases $3I_0 = I_A + I_B + I_C = 0$.

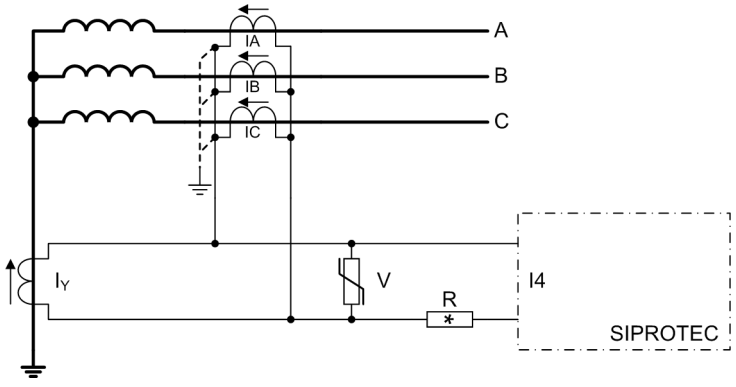
With an external ground fault (on the left in *Figure 6-105*), the short-circuit current of which is fed via a grounded neutral point, the same current flows in the transformer neutral point and in the phases. The respective secondary currents (with the same transfer ratio of all current transformers) draw each other off. They are connected in series. At the resistor R, only a little voltage arises, which results from the internal resistances of the transformers and those of the transformer connection lines. Even if a current transformer is briefly saturated, it becomes a low-impedance during the time of the saturation and forms a low-impedance shunt to the high-impedance resistor R. The high resistance of the resistor thus has a stabilizing effect (so-called resistor stabilization).

[dwprhimp-310113-01.tif, 2, en_US]

Figure 6-105 Principle of the Restricted Ground-Fault Protection According to the High-Impedance Principle

With a ground-fault in the protection range (on the right in *Figure 6-105*), a neutral-point current I_Y flows in any case. The magnitude of the residual current in the phase currents depends on the grounding conditions in the rest of the network. A secondary current corresponding to the entire short-circuit current attempts to flow via the resistor R. But since this resistor is high-impedance, a high voltage arises there which causes the saturation of the current transformers. The effective voltage at the resistor therefore corresponds approximately to the knee-point voltage of the current transformers.

The resistor R is thus dimensioned in such a way that even the smallest ground-fault current to be detected leads to a secondary voltage that corresponds to half of the knee-point voltage of the current transformers (see chapter 2.5.4).



Further information can be found at Sensitivity view for high-impedance ground-fault differential protection in chapter *6.12.7.2 Application and Setting Notes* .

High-Impedance Restricted Ground-Fault Protection with a SIPROTEC 5 Device

Use the I4 measuring input of the SIPROTEC 5 device for the high-impedance restricted ground-fault protection. This input for this application is to be executed as a sensitive measuring input. Since this is a current input, the current is detected by this resistor instead of the voltage at the resistor R.

Figure 6-106 shows the connection diagram. The protection device is connected in series with the resistor R and thus measures its current.

The varistor V limits the voltage in case of an internal fault. The varistor cuts the high instantaneous voltage peaks in the case of transformer saturation. Simultaneously, a smoothing of the voltage arises without any relevant reduction of the average value.

[dwanedif-310113-01.tif, 2, en_US]

Figure 6-106 Connection Diagram of the Restricted Ground-Fault Protection According to the High-Impedance Principle

As a protection against overvoltages, it is important that you connect the device directly at the grounded side of the current transformer. The high voltage at the resistor is thus kept away from the device.

In a similar manner, the high-impedance restricted ground-fault protection for generators, motors, and shunt reactors is used. With auto transformers, you must connect the upper-voltage side and low-voltage side current transformers and neutral-point transformer in parallel.

The method can be realized for each protected object. As busbar protection, the device, for example, is connected via the resistor to the parallel connection of the transformers of all feeders.

6.12.7.2 Application and Setting Notes

A prerequisite for the application of the high-impedance restricted ground-fault protection is that neutral-point current detection is possible on the station side (see example in (*Figure 6-106*). Furthermore, a sensitive input transformer must be available at device input I4. Set the pickup value for current at input I4 with the function **Overcurrent protection, 1-phase**.

Observe the interaction between current-transformer characteristic curve, external resistor R, and the voltage at R for the overall function of the high-impedance restricted ground-fault protection. Notes on this follow.

Current Transformer Data for High-Impedance Restricted Ground-Fault Protection

All affected current transformers must have the same ratio and approximately the same knee-point voltage. This is normally the case when the current transformers are of the same type and have the same rated data. You can calculate the knee-point voltage from the rated data as follows:

$$V_{KP} = \left(R_i + \frac{P_{rated}}{I_{rated}^2} \right) \cdot n \cdot I_{rated}$$

[foukniep-310113-01.tif, 1, en_US]

V_{KP}	Knee-point voltage
Ri	Internal resistance of the current transformer
P_{rated}	Rated power of the current transformer
I_{rated}	Secondary rated current of the current transformer
n	Rated overcurrent factor

Rated current, rated power, and overcurrent factor are found on the name plate of the transformer.

EXAMPLE

Current transformer with the following data on the name plate: 800/5; 5P10; 30 VA

You can read the following transformer data with this data:

I_{rated}	= 5 A (out of 800/**5**)
n	= 10 (out of 5P**10**)
P_{rated}	= **30** VA

The internal resistance is frequently to be found in the test report of the transformer. If it is not known, it can be approximately determined by a direct current measurement at the secondary winding.

EXAMPLE

Calculation of the knee-point voltage

Current transformer 800/5; 5P10; 30 VA with $R_i = 0.3\ \Omega$

$$V_{KP} = \left(R_i + \frac{P_{rated}}{I_{rated}^2} \right) \cdot n \cdot I_{rated} = \left(0.3\ \Omega + \frac{30\ VA}{(5\ A)^2} \right) \cdot 10 \cdot 5\ A = 75\ V$$

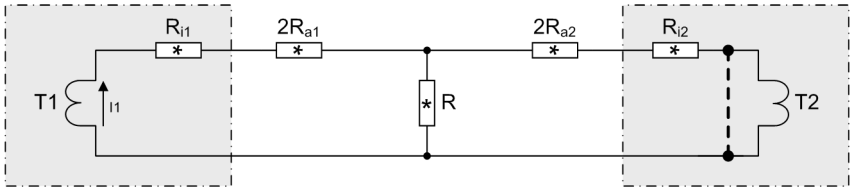
[foukp5aw-310113-01.tif, 1, en_US]

Current transformer 800/1; 5P10; 30 VA with $R_i = 5\ \Omega$

$$V_{KP} = \left(R_i + \frac{P_{rated}}{I_{rated}^2} \right) \cdot n \cdot I_{rated} = \left(5\,\Omega + \frac{30\ VA}{(1\,A)^2} \right) \cdot 10 \cdot 1\,A = 350\ V$$

[foukp1aw-310113-01.tif, 1, en_US]

Besides the current-transformer data, the resistance of the longest connection line between transformer and device must be known.



Stability Consideration for High-Impedance Restricted Ground-Fault Protection

The stability condition is based on the simplified assumption that one current transformer is completely saturated and the others transfer their partial currents proportionately in the case of an external fault. This is theoretically the worst case. A safety margin is automatically provided, since, in practice, even the saturated transformer still delivers some current.

Figure 6-107 shows an equivalent circuit of this simplification. CT1 and CT2 are assumed to be ideal transformers with their internal resistances R_{i1} and R_{i2}. R_a are the core resistances of the connection lines between transformer and resistance R; they are used doubled (forward line and return line). R_{a2} is the resistance of the longest connection line.

CT1 transmits the current I1. CT2 is assumed to be saturated. This is indicated by the dotted short-circuit line. The transformer thus represents a low-impedance shunt by its saturation.

A further prerequisite is $R >> (2R_{a2} + R_{i2})$.

[dwvebhdi-310113-01.tif, 2, en_US]

Figure 6-107 Simplified Connection Diagram of a Layout for High-Impedance Restricted Ground-Fault Protection

The voltage at R is, then,

$V_R = I_1 \cdot (2R_{a2} + R_{i2})$

A further assumption is that the pickup value of the SIPROTEC 5 device corresponds to half of the knee-point voltage of the current transformers. In the edge case,

$V_R = V_{KP}/2$

The stability limit I_{SL} results, which means the through-current up to which the arrangement remains stable:

$$I_{SL} = \frac{V_{KP}/2}{2 \cdot R_{a2} + R_{i2}}$$

[foistabl-310113-01.tif, 1, en_US]

EXAMPLE

For the 5 A transformer as above with V_{KP} = 75 V and R_i = 0.3 Ω

Longest connection line = 22 m with 4 mm² cross-section; that corresponds to R_a = 0.1 Ω

$$I_{SL} = \frac{V_{KP}/2}{2 \cdot R_{a2} + R_{i2}} = \frac{37.5\ V}{2 \cdot 0.1\,\Omega + 0.3\,\Omega} = 75\ A$$

[foisl5aw-310113-01.tif, 1, en_US]

In the example, the stability limit is 15 × rated current or 12 kA primary.

For the 1 A transformer as above with V_{KP} = 350 V and R_i = 5 Ω

Longest connection line = 107 m with 2.5 mm^2 cross-section; that corresponds to R_a = 0.75 Ω

$$I_{SL} = \frac{V_{KP}/2}{2 \cdot R_{a2} + R_{i2}} = \frac{175\ V}{2 \cdot 0.75\ \Omega + 5\ \Omega} = 27\ A$$

[foisl1aw-310113-01.tif, 1, en_US]

In the example, the stability limit is 27 × rated current or 21.6 kA primary.

Sensitivity Consideration for High-Impedance Restricted Ground-Fault Protection

The voltage present at the set of current transformers is supplied to the protection device via a series resistor R as proportional current for evaluation. For dimensioning of the resistor, the following must be taken into account:

The high-impedance restricted ground-fault protection should pick up at approximately half of the knee-point voltage of the current transformers. From this, you can calculate the resistor R.

Since the device measures the current through the resistor, the resistor and measuring input of the device must be connected in series. Since the resistor still should be high-impedance (aforementioned condition R >> $2R_{a2} + R_{i2}$), the inherent resistance of the measuring input can be neglected. The resistance results thus from the pickup current I_{pick} and half of the knee-point voltage:

$$R = \frac{V_{KP}/2}{I_{pick.}}$$

[foberecr-310113-01.tif, 1, en_US]

EXAMPLE

For the 5 A transformer as above

Desired pickup value I_{pick} = 0.1 A (corresponds to 16 A primary)

$$R = \frac{V_{KP}/2}{I_{pick.}} = \frac{75\ V/2}{0.1\ A} = 375\ \Omega$$

[fober5aw-310113-01.tif, 1, en_US]

For the 1 A transformer as above

Desired pickup value I_{pick} = 0.05 A (corresponds to 40 A primary)

$$R = \frac{V_{KP}/2}{I_{pick.}} = \frac{350\ V/2}{0.05\ A} = 3500\ \Omega$$

[fober1aw-310113-01.tif, 1, en_US]

The series resistor R must be designed for a minimum continuous load $P_{continuous}$.

$$P_{continuous} \geq \frac{(V_{KP}/2)^2}{R} = \frac{37.5^2}{375} = 3.75\ W \qquad \text{at the 5-A-transformer}$$

[fopdau5a-310113-01.tif, 1, en_US]

$$P_{continuous} \geq \frac{(V_{KP}/2)^2}{R} = \frac{175^2}{3500} = 8.75\ W \qquad \text{at the 1-A-transformer}$$

[fopdau1a-310113-01.tif, 1, en_US]

Further, the series resistor R must be designed for a fault current lasting approximately 0.5 s. This time is usually sufficient for fault clarification through backup protection.

The thermal stress of the series resistor depends on the voltage $V_{RMS,stab}$ that is present during an internal fault. It is calculated according to the following equations:

$$V_{RMS,rest} = 1.3 \cdot \sqrt[4]{V_{KP}^3 \cdot R \cdot I_{K,max,int}} = 1.3 \cdot \sqrt[4]{75^3 \cdot 375 \cdot 250} = 579.7\ V \qquad \text{at the 5-A-transformer}$$

[fousta5a-310113-01.tif, 1, en_US]

$$V_{RMS,rest} = 1.3 \cdot \sqrt[4]{V_{KP}^3 \cdot R \cdot I_{K,max,int}} = 1.3 \cdot \sqrt[4]{350^3 \cdot 3500 \cdot 50} = 2151.6\ V \qquad \text{at the 1-A-transformer}$$

[fousta1a-310113-01.tif, 1, en_US]

$I_{K,max,int}$ corresponds to the maximum fault current here in the case of an internal fault.

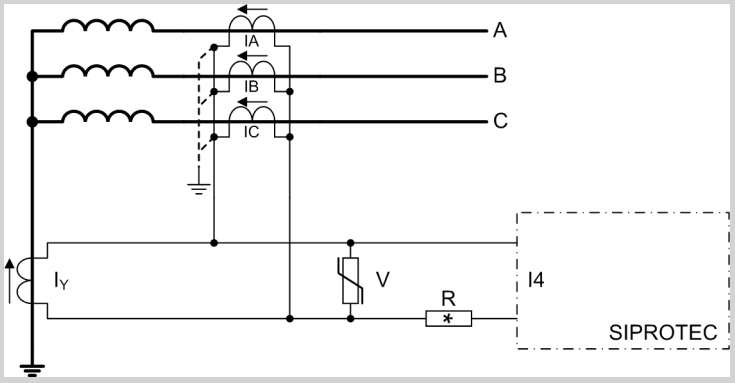
5-A current transformer 800/5 with 40 kA primary corresponds to $I_{K,max,int}$ = 250 A secondary.

1-A current transformer 800/1 with 40 kA primary corresponds to $I_{K,max,int}$ = 50 A secondary.

This results in a temporary load for the series resistor over 0.5 s of:

$$P_{0.5\,s} = \frac{V_{RMS,rest}^2}{R} = \frac{579.7^2}{375} = 896\ W \qquad \text{at the 5-A-transformer}$$

[fop05s5a-310113-01.tif, 1, en_US]



$$P_{0.5\,s} = \frac{V_{RMS,rest}^2}{R} = \frac{2151.6^2}{3500} = 1322.7\ W \qquad \text{at the 1-A-transformer}$$

[fop05s1a-310113-01.tif, 1, en_US]

Observe that with the selection of a higher pickup value I_{pick}, the resistor value must be lowered and therefore the dissipation rises sharply.

The varistor (see following figure) must be sized such that it remains high impedance up to the knee-point voltage, for example:

- Approx. 100 V with 5 A transformer
- Approx. 500 V with 1 A transformer

[dwanedif-310113-01.tif, 2, en_US]

Figure 6-108 Connection Diagram of the Restricted Ground-Fault Protection According to the High-Impedance Principle

Even with unfavorable wiring, the maximum occurring voltage peaks do not exceed 2 kV for safety reasons.

When for performance reasons, several varistors must be connected in parallel, give preference to types with flat characteristic curves, in order to avoid an unbalanced load. Siemens therefore recommends the following types by METROSIL:

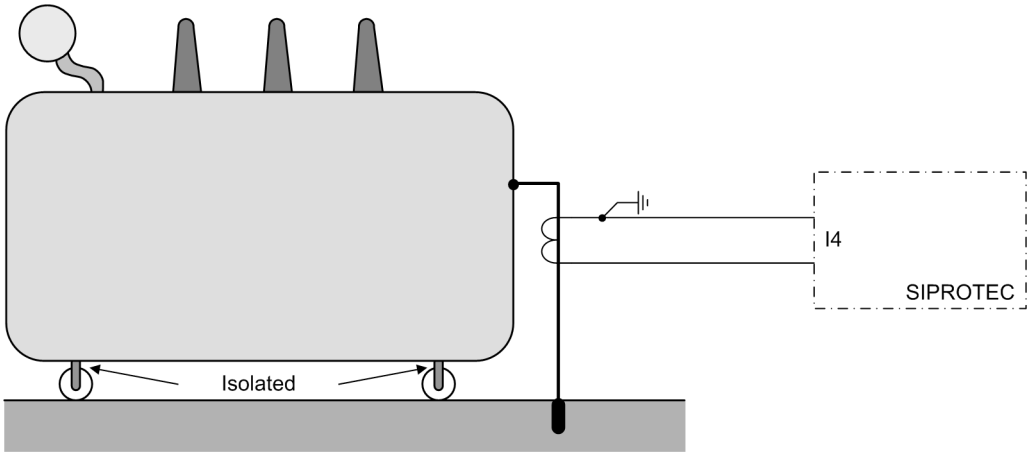
600A/S1/S256 (k = 450, β = 0.25)

600A/S1/S1088 (k = 900, β = 0.25)

In the example, set the pickup value of the first Definite time-overcurrent protection stage (setting **`Threshold`**) to 0.1 A for 5-A transformers or 0.05 A for 1-A transformers. No further protection stages are needed. Delete these or switch them off. Set the **`Operate delay`** setting to 0 s.

If several current transformers are connected in series, for example, with use as busbar protection with several feeders, the magnetization currents of the transformers switched in parallel can no longer be neglected. In

this case, add up the magnetization currents at half of the knee-point voltage (corresponds to the set **Threshold**). These magnetization currents reduce the current through the resistor R. Thus, the actual pickup value is correspondingly higher.



6.12.8 Application Example: Tank Leakage Protection

6.12.8.1 Description

Tank leakage protection records short-circuits to ground – including high-impedance ones – between a phase and the tank of a transformer. The tank is thus insulated, or at least grounded with high impedance. The tank must be connected with a line to ground. The current that flows through this line is fed to the protection device. If a short-circuit to ground occurs in a tank, a fault current (tank current) flows to substation ground via the ground connection.

The function **Overcurrent protection, 1-phase** detects the tank current. If the tank current exceeds the set **Threshold**, the function **Overcurrent protection, 1-phase** generates an operate indication. Depending on the set **Operate delay**, the transformer is tripped immediately or time-delayed on all sides.

For tank protection, a sensitive, 1-phase current measuring input is used.

[dwprkess-310113-01.tif, 2, en_US]

Figure 6-109 Tank-Control Principle

6.12.8.2 Application and Setting Notes

A prerequisite for the application of tank protection is the availability of a sensitive input transformer at device input I4.

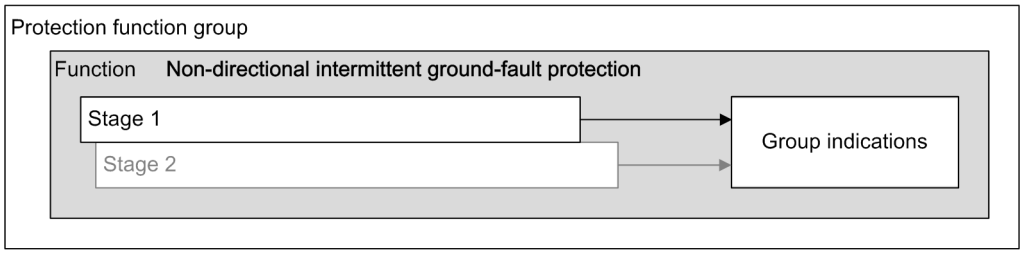
If you connect **Measuring point I 1-ph** with the function group **Voltage-current 1-phase**, the function **Overcurrent protection, 1-phase** works with the 1-phase current connected to input I4.

Use only the first definite time-overcurrent protection stage of function **Overcurrent protection, 1-phase**. The **Threshold** setting is used to set the pickup value. No further protection stages are needed. Delete these or switch them off. Set the **Operate delay** setting to 0 s.

6.13 Non-Directional Intermittent Ground-Fault Protection

6.13.1 Overview of Functions

A typical characteristic of intermittent ground faults is that they often extinguish automatically and strike again after some time. The fault duration can last between a few milliseconds and many seconds. Thus, such faults are not detected at all or not selectively by the ordinary overcurrent protection. If pulse durations are extremely short, not all protection devices in a short-circuit path can pick up. Thus, selective tripping is not ensured.



Due to the time delay of the overcurrent protection function, such faults are too short to initiate switching off the faulted cable. The short-circuit protection can clear such ground faults selectively only if the ground faults have become permanent.

But such intermittent ground faults already bear the risk of damaging the equipment thermally. This is why SIPROTEC 5 devices feature a protection function that is able to detect such intermittent ground faults and accumulates their duration. If the sum reaches a configurable value within a certain time, the limit of the thermal rating has been reached. If intermittent ground faults are distributed over a long period or if the ground fault disappears and does not restrike after some time, the equipment under load is expected to cool down. Tripping is not necessary in this case.

The **Non-directional intermittent ground-fault protection** function is used to protect against intermittent ground faults which occur, for example, in cables due to poor insulation or water ingress in cable joints.

6.13.2 Structure of the Function

The **Non-directional intermittent ground-fault protection** function can be used in protection function groups with current measurement. The function is preconfigured by the manufacturer with 1 stage, and a maximum of 2 stages can be operated simultaneously. The non-preconfigured stages are shown in gray in the following figure.

[DwIntGFP, 1, en_US]

Figure 6-110 Structure/Embedding of the Function

6.13.3 Stage Description

Logic

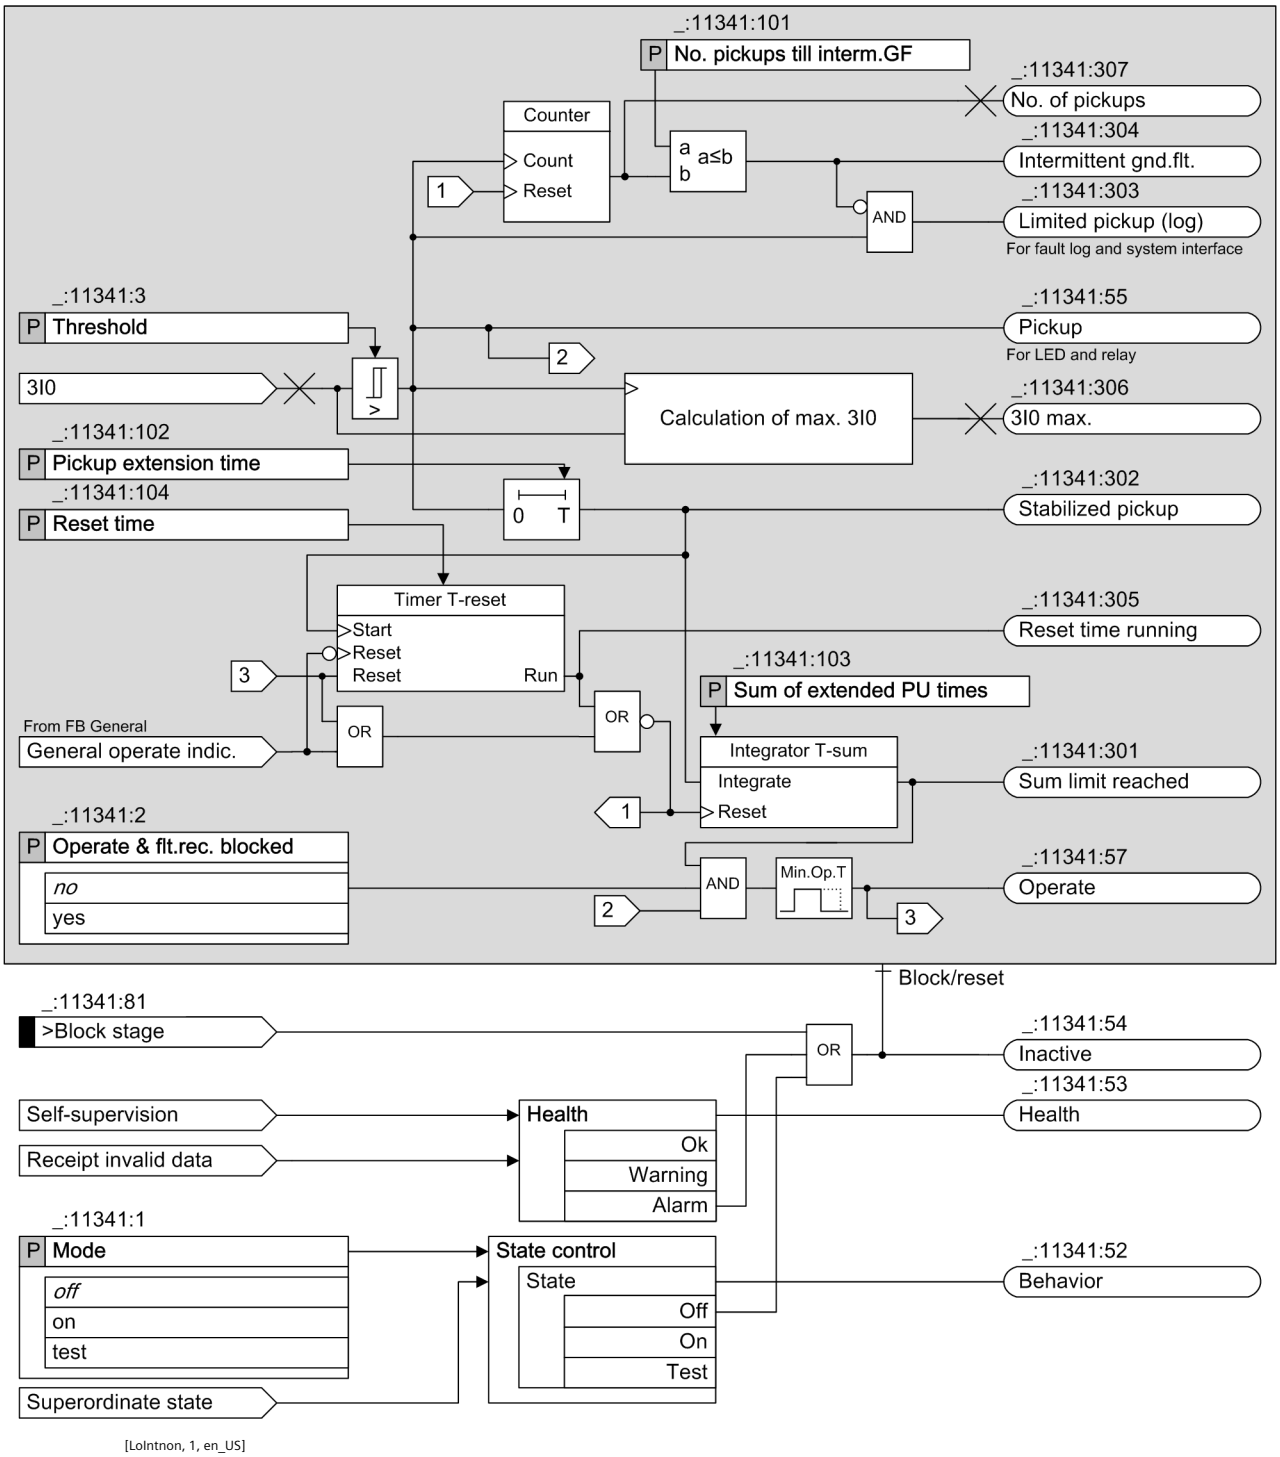


Figure 6-111 Logic of the Non-Directional Intermittent Ground-Fault Protection

Measured Value 3I0

The intermittent ground-fault current 3I0 can either be detected via the standard ground-current input I_N or via the sensitive ground-current input I_{NS}. It can also be calculated from the sum of the 3-phase currents. The measured value depends on the parameter **Connection type** of the measuring point I-3ph.

Table 6-9 Threshold Setting Range with Different Connection Types

Connection Type of the Measuring Point I-3ph	Ground Current	CT Terminal Type	Threshold Setting Range (Secondary at Irated = 1 A)
3-phase	Calculated	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
x + IN x + IN-separate	Measured	4 * Protection	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
	Measured and calculated when exceeding 1.6 A	3 * Protection, 1 * sensitive	0.001 A to 35.000 A

Method of Measurement

The stage calculates the RMS value of 3I0 since this value takes into account the higher-order harmonics components and the direct component (DC). Both components contribute to the thermal load.

Maximum 3I0 of the Fault

The stage records the maximum RMS value of 3I0 during the intermittent ground fault. The statistic value *3I0 max.* is a percentage value calculated through dividing the primary maximum RMS value by the rated current value of the protected object. With the coming operate signal, this value is logged via the information *3I0 max.*.

Pickup and Intermittent Ground-Fault Indication

When 3I0 exceeds the threshold value, the pickup signals *Pickup* and *Limited pickup (log)* are issued. The stage generates the *Stabilized pickup* signal by extending the *Pickup* for a defined time (parameter **Pickup extension time**).

The stage counts the *Pickup* signals. If the counted number reaches the configured **No. pickups till interm.GF**, the *Intermittent gnd.flt.* signal is issued. The signal *Limited pickup (log)* is not issued anymore after the issue of the *Intermittent gnd.flt.* signal.

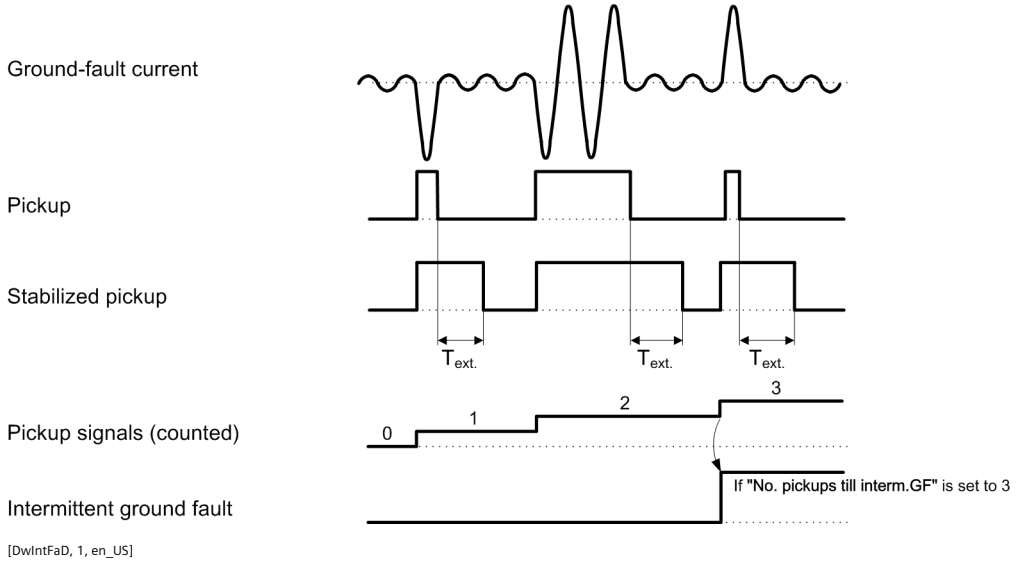

Figure 6-112 Fault Detection of the Intermittent Ground-Fault Protection

$T_{ext.}$ Defined time for extending the *Pickup* signal

Number of Pickups

The stage counts the number of *Pickup* signals during the intermittent ground fault. With the operate of the stage this number is logged via the information *No. of pickups*.

Accumulation of the Intermittent Ground-Fault Current and Issuing the Operate Signal

An intermittent ground fault can result in thermal stress on the protected equipment. The magnitude and the duration of the ground-fault current are decisive for the thermal stress. In order to calculate the thermal stress, the stage sums up the duration of the stabilized pickups with an integrator. If the integration value reaches the predefined **Sum of extended PU times**, the limit of the thermal load is reached. The stage issues the signal *Sum limit reached* and operates when the signal *Pickup* is active.

Reset Timer for the Definition of the Interval between Independent Ground Faults

If there is a large interval between independent ground faults or if ground fault extinguishes and does not restrike again within a larger time, the stressed equipment can cool down. In this case, an operation is not necessary. The interval between ground faults is monitored with the reset timer. If a ground fault occurs, the **Timer T-reset** with its setting **Reset time** is launched simultaneously with **Integrator T-sum**. Unlike the integrator, each new ground fault restarts the reset timer with its initial value. If **Timer T-reset** expires, that is, no new ground fault was detected during that period, all memories and the stage logics are reset. **Timer T-reset** thus determines the time during which the next ground fault must occur to be processed yet as intermittent ground fault in connection with the previous fault. A ground fault that occurs later is considered as a new fault event.

Reset Conditions

Under one of the following 2 conditions, **Timer T-reset** is reset.

- The Intermittent ground-fault protection stage operates.
- The general operate indication is going.

Under one of the following conditions, **Integrator T-sum** and **Counter** are reset and the whole stage is reset and returns to its idle state.

- **Timer T-reset** expires without an operate signal of this stage or another function was issued.
- The operate signal of the intermittent ground-fault protection stage is going.
- The general operate indication is going without the operate signal of the intermittent ground-fault protection stage issued.

Fault Log and Fault Recording

You can select between the ground-fault log without fault recording or the normal fault log with fault recording. If you set the parameter **Operate & flt.rec. blocked** to ***yes***, the operate of the stage and fault recording are blocked and the information automatically appears in the ground-fault log. Otherwise, the operate and fault recording are not blocked and the information appears in the normal fault log.

Start & Stop of Fault Recording, Fault Logging, and General Pickup

The *Stabilized pickup* signal initiates the fault recording, fault logging, and the general pickup of the function group. The fault recording starts according to the pre-trigger time before the *Stabilized pickup* signal rises.

With the reset condition of this stage, the fault recording, fault logging, and the general pickup of the function group are terminated.

Influence on Other Functions to Avoid a Burst of Signals

Intermittent ground faults may cause other functions, based on overcurrent measurement, to pick up, which may result in a burst of signals. In order to avoid an overflow of the fault log, a special mechanism is applied to the signals of these functions after detection of an intermittent ground fault (signal *Intermittent gnd.flt.*).

The special mechanism is applied for the following listed functions and other functions are not influenced:

- Overcurrent protection, phases
- Overcurrent protection, ground
- Directional overcurrent protection, phases
- Directional overcurrent protection, ground
- Overcurrent protection, 1-phase
- Negative-sequence protection with definite-time characteristic curve
- Directional negative-sequence protection with definite-time delay
- Directional overcurrent-protection stage with cos phi or sin phi measurement
- Directional overcurrent-protection stage with 3I0-phi (V,I) measurement
- Sensitive ground-current protection with 3I0

If a function picks up, normally its output signals are sent directly to the information targets, for example, the pickup signal is written to the fault log. To avoid overflow of logs due to intermittent ground faults, a special log buffer mechanism is used. If one of the preceding functions or stages picks up after an intermittent ground fault has been detected (signal *Intermittent gnd.flt.* has been issued), its output signals are processed as shown in the following 2 tables.

Table 6-10 Processing of the Signal Status Changes

Processing of Signal Status Changes	Description
Special buffering mechanism	The status changes of signals are written to a special buffer. This buffer can store a maximum of 2 status changes (the most recent ones) for each signal. With the pickup signal as example, if one of the preceding protection functions or stages picks up during an active *Intermittent gnd.flt.* signal, the pickup signal is not written in the fault log anymore unless one of the preceding functions operates. After the operation, the buffered signals are written to the information target with the original time stamp. This measure ensures that a pickup signal, although delayed, is always signaled in association with each operate command.
Discard	The signal status changes are discarded.
Pass through	The signal is forwarded to the information target without restriction. Special buffering does not apply for specific information targets as protection measure, for example, reverse interlocking, need these signals for proper operation.

Table 6-11 Information Target with Different Processing of Signal Status Changes

Information Target		Processing of Signal Status Changes
Processing of Signal Status Changes	Operational log Fault log Ground-fault log User-defined log	Special buffering mechanism
Communication interface	IEC 61850-8-1 Client/Server IEC 60870-5-103/104 DNP V3.0	Special buffering mechanism
Protection interface	PDI	Pass through
IEC 61850-8-1 GOOSE		Pass through
CFC		Pass through
LEDs		Pass through
Binary output		Pass through
Fault recorder		Pass through
Automatic reclosing function		Discard
Circuit-breaker failure protection		Discard
Group indications		Discard

6.13.4 Application and Setting Notes

No Start of the Automatic Reclosing Function

Automatic reclosing is not an effective measure against intermittent ground faults as the protection function only operates after repeated detection of a fault or after the integration value reaches the predefined **Sum of extended PU times**. Besides this, its basic design is to prevent thermal overload. For these reasons, the intermittent ground-fault protection function is not intended to start the automatic reclosing function.

Rooting of Pickup Signals

The signal *Pickup* is supposed to be routed to LED and relay. The signal *Limited pickup (log)* is only reported to the fault log and communication interface before the signal *Intermittent gnd.flt.* is issued. This scheme prevents a burst of messages.

NOTE

To avoid a burst of messages, do not route the signal *Pickup* to the operational log and fault log.

Parameter: 3I0 Threshold

- Default setting **(_:11341:3) Threshold** = ***1.00 A***

With the **Threshold** parameter, you set the threshold value of the ground current 3I0, measured as RMS value.

A rather sensitive setting is possible to respond also to short ground faults since the pickup time shortens as the ground-fault current increases.

Parameter: No. pickups till interm.GF

- Default setting **(_:11341:101) No. pickups till interm.GF** = ***3***

With the parameter **No. pickups till interm.GF**, you set the number of counted *Pickup* signals after which the ground fault is considered as intermittent.

Parameter: Pickup extension time

- Default setting **(_:11341:102) Pickup extension time** = ***0.10 s***

You can get a stabilized pickup signal with the **Pickup extension time** parameter. This stabilization is especially important for the coordination with existing static or electromechanical overcurrent protections.

Parameter: Sum of extended PU times

- Default setting **(_:11341:103) Sum of extended PU times** = ***20 s***

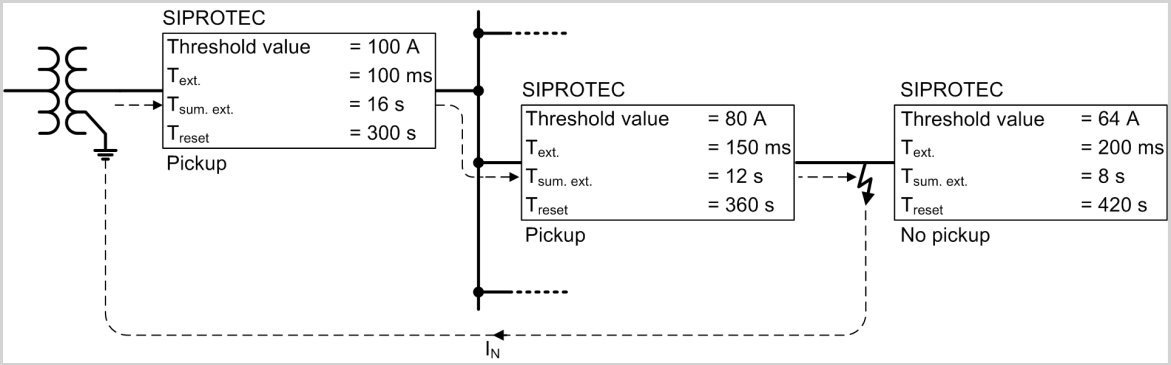
With the **Sum of extended PU times** parameter, you set the threshold value for the integrator. If the integration reaches **Sum of extended PU times**, the stage operates if the pickup state is present.

This **Sum of extended PU times** represents one of the 4 selectivity criteria (pickup threshold, pickup extension time, reset time, and integrator threshold value) for coordination of the relays on adjacent feeders. It is comparable to the time grading of the overcurrent protection. The protection in the radial system which is closest to the intermittent fault and picks up, has the shortest summation time **Sum of extended PU times**.

Parameter: Reset time

- Default setting **(_:11341:104) Reset time** = ***300 s***

With the parameter **Reset time**, you can define the maximum interval between 2 adjacent ground faults. If the interval is larger than the **Reset time**, the counter and integrator are reset.



The **Reset time** parameter must be much higher than the operate value of the **Sum of extended PU times**.

Parameter: Operate & flt.rec. blocked

- Default setting **(_:11341:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

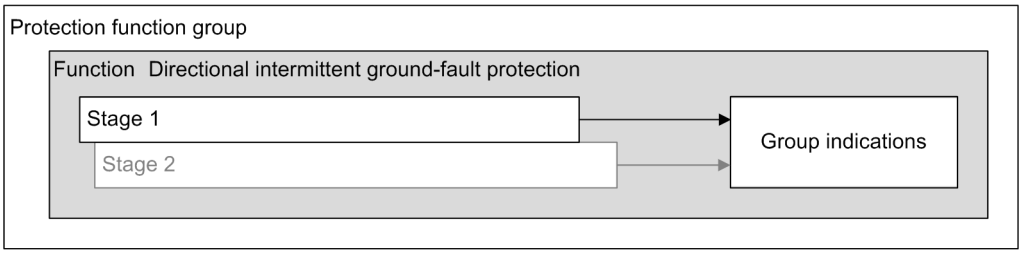
6.14 Directional Intermittent Ground-Fault Protection

6.14.1 Overview of Functions

The function **Directional intermittent ground-fault protection**:



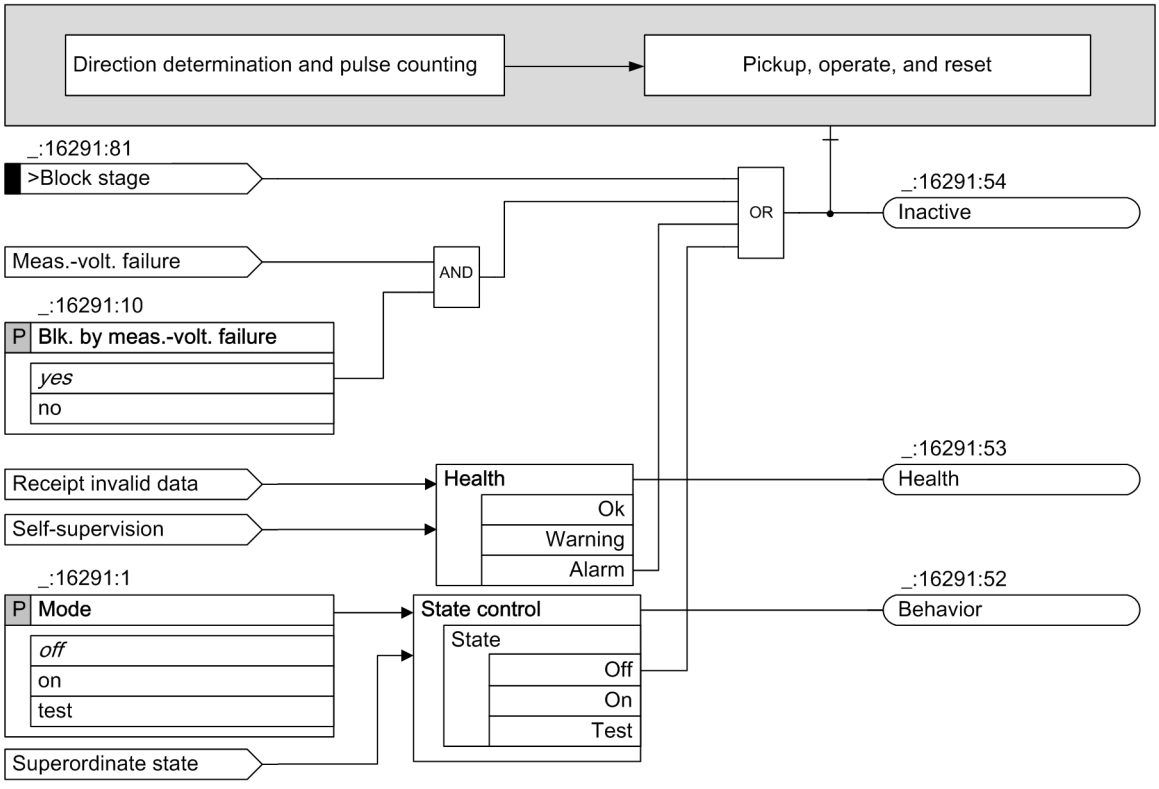
- Detects the intermittent ground faults in grounded, compensated, or isolated cable systems selectively
- Can be operated in 2 different modes:
  - Operate only by counting directional ground-current pulses
  - Operate by integration of the fault current in combination with a directional criterion by counting directional ground-current pulses

The intermittent ground faults in cable systems are frequently caused by weak insulation or water ingress in cable joints. The ground faults are characterized by the following properties:

- Intermittent ground faults show very short high ground-current pulses (up to several hundred amperes) with a duration of less than 1 ms.
- Intermittent ground faults are self-extinguishing and reignite within one half period up to several periods, depending on the power-system conditions and the fault type.
- Intermittent ground faults can persist over longer periods (several seconds to minutes) and develop to static ground faults.

6.14.2 Structure of the Function

The function **Directional intermittent ground-fault protection** can be used in protection function groups with current and voltage measurement. The function is preconfigured by the manufacturer with 1 stage, and a maximum of 2 stages can be operated simultaneously.



[DwStrDirIGFP_20140618, 1, en_US]

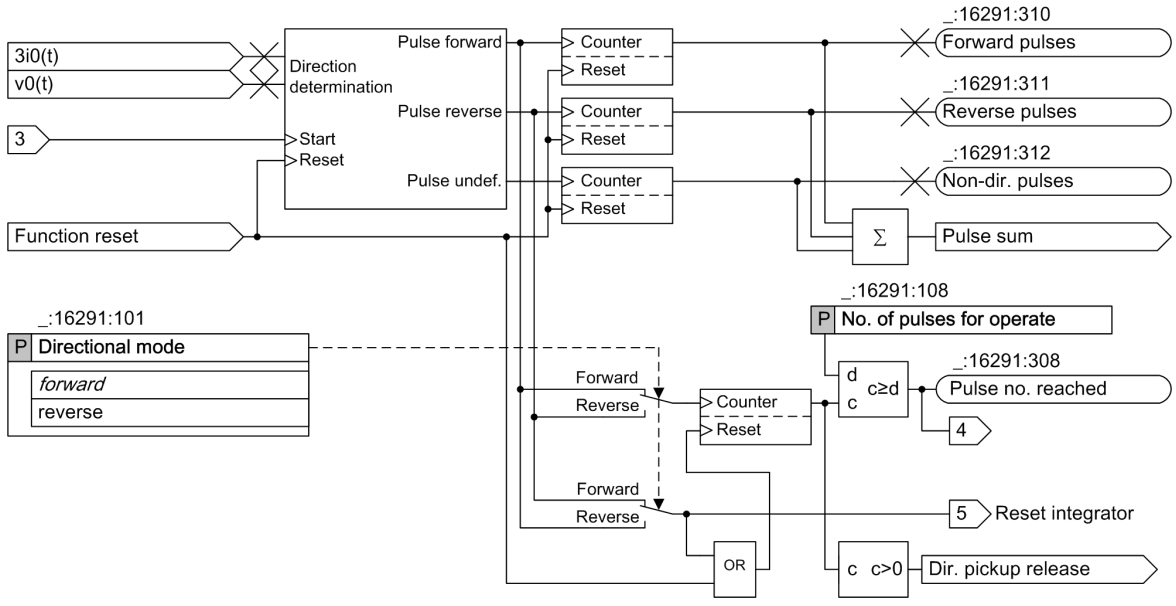
Figure 6-114 Structure/Embedding of the Function

6.14.3 Stage Description

Overview

[LoOverview, 1, en_US]

Figure 6-115 Logic of the Directional Intermittent Ground-Fault Protection



Blocking of the Stage with Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From an internal source upon pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **`Volt.-transf. c. b.`**, which links in the tripping of the voltage-transformer circuit breaker

The **`Blk. by meas.-volt. failure`** parameter can be set so that the measuring-voltage failure detection blocks the stage or does not block it.

Logic for Direction Determination and Pulse Counting

[LoIntdir1, 2, en_US]

Figure 6-116 Logic Diagram of Direction Determination and Pulse Counting

(1) The input signal 3 is from *Figure 6-117*.

Measurement Values for Direction Determination

The function **Directional intermittent ground-fault protection** uses the zero-sequence active energy to determine the direction of the ground-current pulse.

The zero-sequence active energy is calculated from v0(t) and 3i0(t). The zero-sequence voltage v0(t) can either be measured via the voltage input VN or can be calculated from the sum of 3 phase-to-ground voltages. The measured value depends on the parameter **Connection type** of the measuring point V-3ph.

The intermittent ground-fault current 3i0(t) can either be measured via the ground-current input IN or via the sensitive ground-current input INS. It can also be calculated from the sum of the 3 phase currents. The measured value and its setting range depend on the parameter **Connection type** of the measuring point I-3ph.

Table 6-12 Threshold Setting Range with Different Connection Types

Connection Type of the Measuring Point I-3ph	Ground Current	CT Terminal Type	Threshold Setting Range (Secondary at Irated = 1 A)
3-phase	Calculated	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
x + IN x + IN-separate	Measured	4 * Protection	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
	Measured and calculated when exceeding 1.6 A	3 * Protection, 1 * sensitive	0.001 A to 35.000 A

Direction Determination and Pulse Counting

When the RMS value of 3I0 exceeds the set threshold value (signal no. 3 in *Figure 6-116*), the direction determination process is started and is continuously carried out until the function resets. At first, the current pulse (current peak) detection takes place. If a current pulse is detected, the direction determination for this pulse is carried out.

The direction is determined by calculating the active zero-sequence energy of the current pulse. The active zero-sequence energy of the pulse is compared to internal threshold values resulting in the directional decision ***forward***, ***reverse***, or ***non-directional***. During the ongoing intermittent ground fault, the directional results for all current pulses are counted.

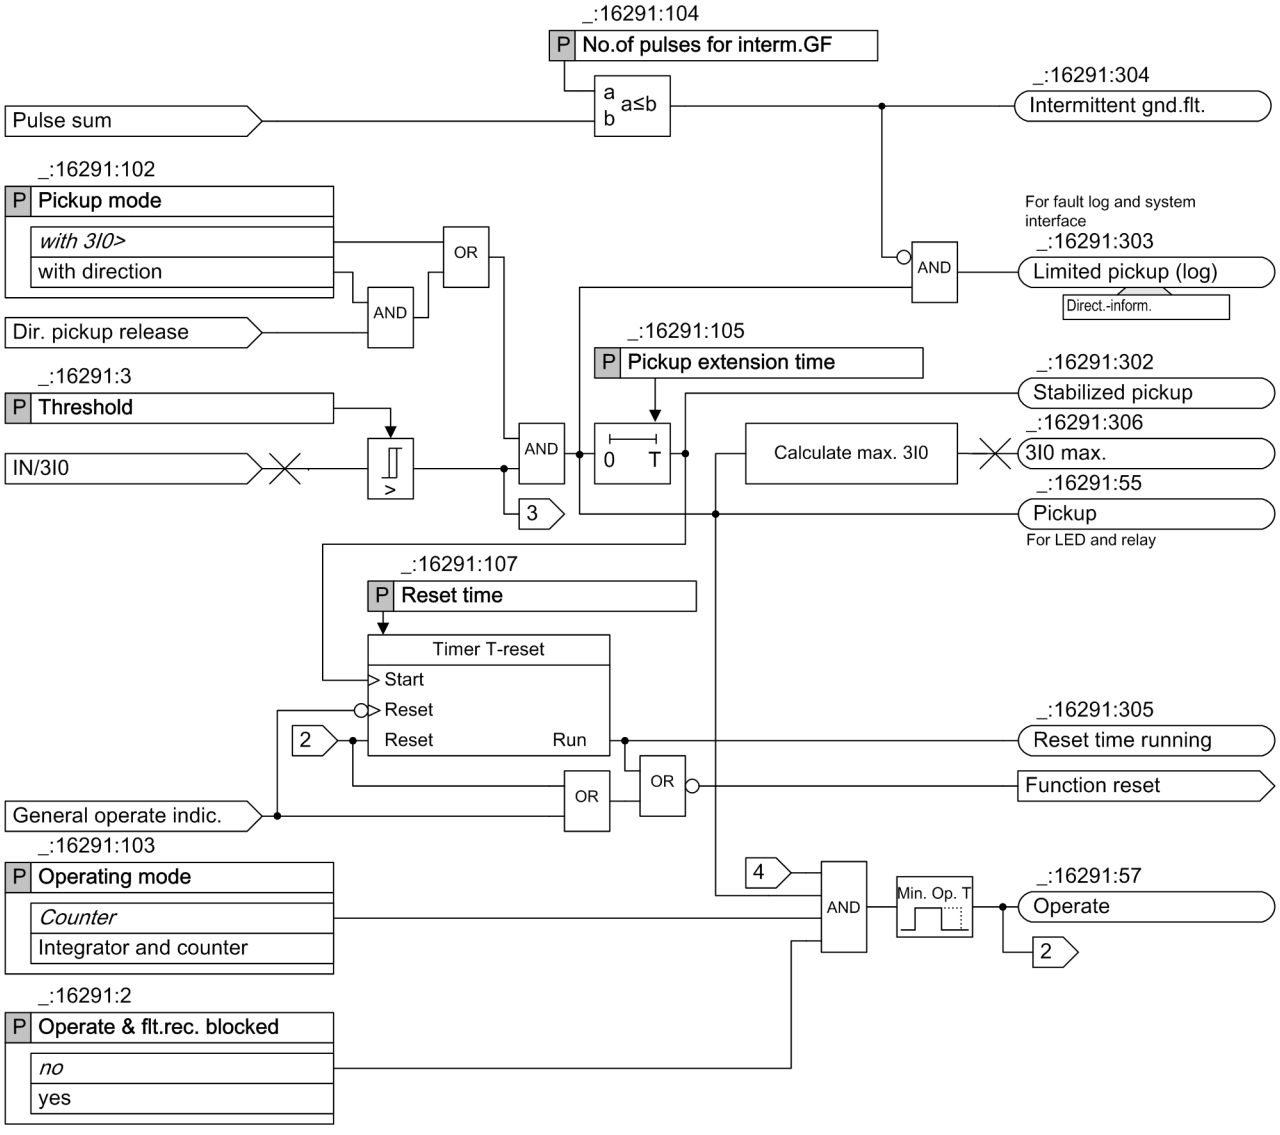
Directional Mode and Directional Pulse Counter Criterion

The parameter **Directional mode** defines whether the function operates in ***forward*** or in ***reverse*** direction. The pulses in the specified direction are counted. If the pulse counter reaches the threshold value set in the parameter **No. of pulses for operate**, the signal *Pulse no. reached* is issued. Depending on the operating mode (***Counter*** or ***Integrator and counter***) of the function, the signal can immediately cause the operate of the function (***Counter*** mode) or it is processed as directional release criteria (***Integrator and counter*** operating mode). Refer to the further description in the following sections.

The directional pulse counter is reset when a different direction than the set **Directional mode** is detected. An undefined direction result does not reset the counter.

Operating Mode

2 different functional operating modes are available: ***Counter*** and ***Integrator and counter***. You can select the different operating modes using the parameter **Operating mode**.



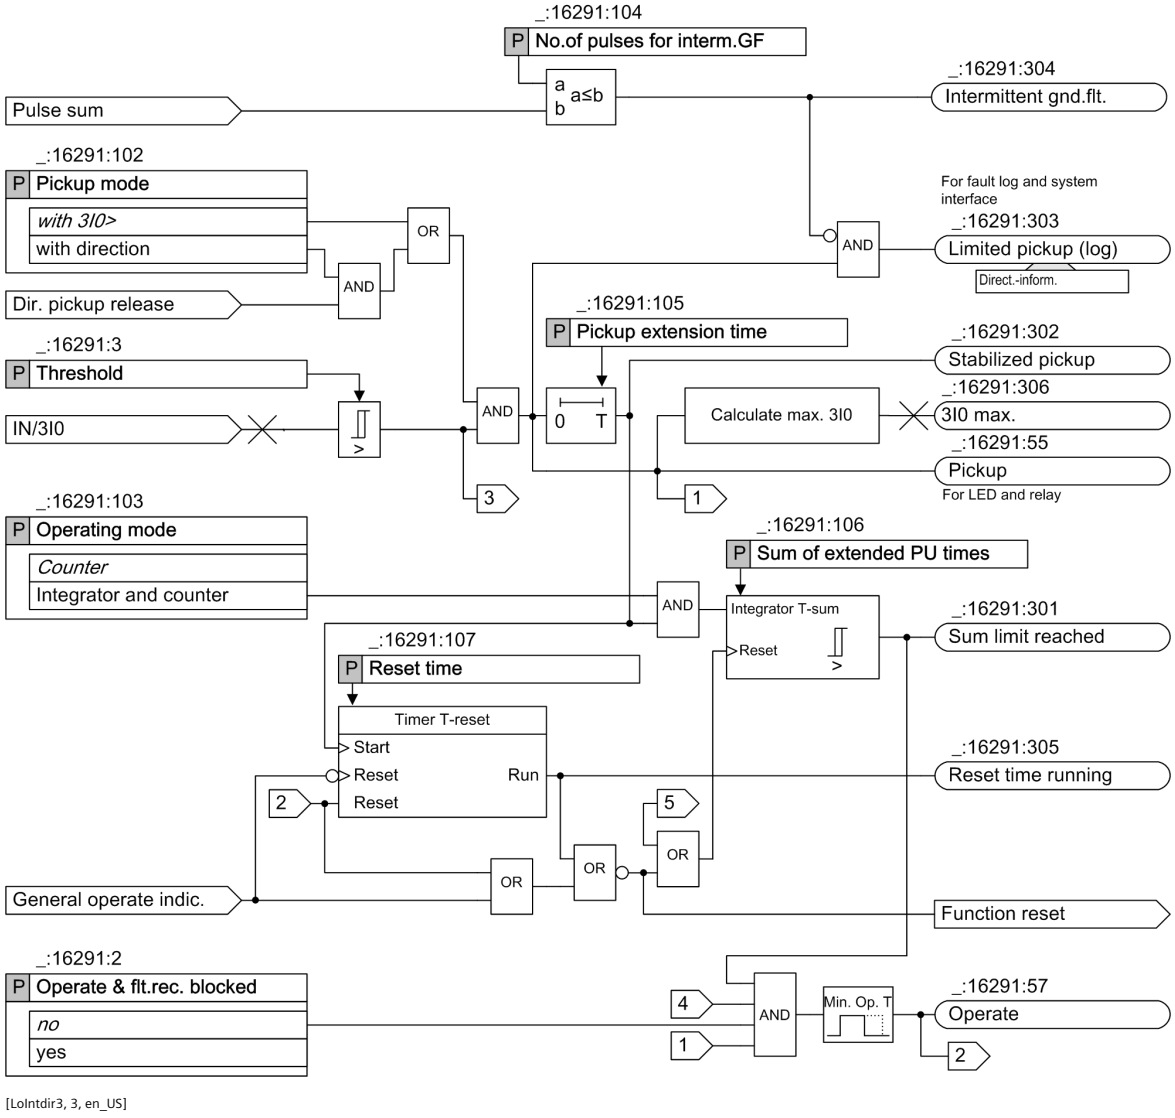
- Operating mode ***Counter***:

  Many ground-current pulses of intermittent ground faults can result in a damage of the protected object. In this mode, the criterion for operate is only the number of directional current pulses. This is similar to the SIPROTEC 4 implementation.

- Operating mode ***Integrator and counter***:

  An intermittent ground fault can result in thermal stress on the protected object. The magnitude and the duration of the ground-current pulses are decisive for the thermal stress. In order to calculate the thermal stress, the stage sums up the duration of the stabilized pickups with an integrator. If the integration value reaches the threshold value, one criterion for the operate is fulfilled. The 2nd criterion for the operate is the ground-fault direction. The ground-fault direction is determined by counting the directional ground-current pulses.

Pickup, Operate, and Reset logic for the Counter Mode



[LoIntdir2, 3, en_US]

Figure 6-117 Pickup, Operate, and Reset Logic in Operating Mode Counter

(1) The internal signal 4 is from *Figure 6-116*.

Pickup, Operate, and Reset logic for the Integrator and Counter Mode

[LoIntdir3, 3, en_US]

Figure 6-118 Pickup, Operate, and Reset Logic in Operating Mode Integrator and Counter

(1) The internal signal 4 and 5 are from *Figure 6-116*.

Measurement Value for Pickup and Integration

The stage calculates the RMS value of 3I0 since this value takes into account the higher-order harmonic components and the direct component (DC). Both components contribute to the thermal load.

Pickup, Limited Pickup, and Stabilized Pickup

Whenever 3I0 exceeds **Threshold**, the stage issues the signal *Pickup*. The signal is intended to be applied for LED and relay output.

Stabilized pickup is formed by prolonging the pickup indication by a settable time **Pickup extension time**. This stabilization is especially important for the coordination with the existing static or electromechanical overcurrent protection.

The *Limited pickup (log)* signal is intend to be applied for logging and communication interface. The *Limited pickup (log)* signal will be entered in the fault log and reported via the system interface unless the *Intermittent gnd.flt.* indication is given. This behavior prevents a burst of indications.

Intermittent Ground-Fault Indication

The stage counts the 3I0 pulses. If the sum of forward pulse counts, reverse counts, and directional undefined counts is equal to or greater than **No.of pulses for interm.GF**, the signal *Intermittent gnd.flt.* is issued.

If the signal *Intermittent gnd.flt.* is issued, the pickup indications of some protection functions will be restraint to avoid an indication burst during an intermittent ground fault.

Operate

The conditions for issuing the signal *Operate* depend on the operating mode.

Operating Mode	Conditions for Issuing the Operate Signal
Counter	• The current-pulse counter reached the **No. of pulses for operate**, which is signaled via the *Pulse no. reached* indication. • The pickup is active, which is signaled via the *Pickup* indication.
Integrator and counter	• The 3I0 current integration value reaches the predefined **Sum of extended PU times**, which is signaled via the *Sum limit reached* indication. • The current-pulse counter reached the **No. of pulses for operate**, which is signaled via the *Pulse no. reached* indication. • The pickup is active, which is signaled via the *Pickup* indication.

When an opposite current pulse against the setting **Directional mode** is detected, the **Integrator T-sum** and the **Counter** are reset.

Reset Time for the Definition of the Interval between Independent Ground Faults

If there is a large interval between independent ground faults or if the ground fault extinguishes and does not restrike again within a larger time, the stressed equipment can cool down. In this case, no operate is necessary. The interval between ground faults is monitored with the reset time. If a ground fault occurs, the **Timer T-reset** with the setting **Reset time** and the **Integrator T-sum** are launched simultaneously. Unlike the integrator, each new ground-current pulse restarts the reset time with its initial value. If the **Timer T-reset** expires, that is, no new ground fault was detected during that period, all memories and the stage logics are reset. The **Timer T-reset** thus determines the time during which the next ground fault must occur to be processed yet as intermittent ground fault in connection with the previous fault. A ground fault that occurs later is considered as a new ground-fault event.

Reset Conditions

Under one of the following 2 conditions, **Timer T-reset** is reset:

- The intermittent ground-fault protection stage operates.
- The general operate indication is going.

Under one of the following conditions, **Integrator T-sum** and **Counter** are reset and the whole stage is reset and returns to its idle state:

- The **Timer T-reset** expires without an operate signal of this stage or another function was issued.
- The operate signal of the intermittent ground-fault protection stage is going.
- The general operate indication is going without the operate signal of the intermittent ground-fault protection stage issued.

Maximum Value 3I0 of the Ground Fault

The stage records the maximum RMS value of 3I0 during the intermittent ground fault.The statistic value *3I0 max.* is a percentage value calculated through dividing the primary maximum RMS value by the rated current value of the protected object. If the function resets or operates, this value is logged via the signal *3I0 max.*.

Fault Log and Fault Recording

You can select between the ground-fault log without fault recording or the normal fault log with fault recording. If you set the parameter **Operate & flt.rec. blocked** to ***yes***, the operate of the stage and fault recording are blocked and the information automatically appears in the ground-fault log. Otherwise, the operate and fault recording are not blocked and the information appears in the normal fault log.

Start and Stop of Fault Recording, Fault Logging, and General Pickup

The *Stabilized pickup* signal initiates fault recording, fault logging, and the general pickup of the function group. The fault recording starts according to the pre-trigger time before the *Stabilized pickup* signal rises.

With the reset condition of this stage, the fault recording, fault logging, and the general pickup of the function group are terminated.

Influence on Other Functions to Avoid a Burst of Indications

In this case, the function uses the same mechanism as the **Non-directional intermittent ground-fault protection**. For more information, refer to chapter *Influence on Other Functions to Avoid a Burst of Signals, Page 538*.

6.14.4 Application and Setting Notes

No Start of the Automatic Reclosing Function

Automatic reclosing is not an effective measure against intermittent ground faults. For this reason, the **Directional intermittent ground-fault protection** function is not intended to start the Automatic reclosing function.

Routing of Pickup Signals

The signal *Pickup* is supposed to be routed to an LED and a relay. The signal *Limited pickup (log)* is only reported to the fault log and communication interface until the signal *Intermittent gnd.flt.* is issued. This scheme prevents a burst of indications.

NOTE

To avoid a burst of indications, do not route the signal *Pickup* to the operational log and to the fault log.

Parameter: Threshold

- Default setting **(_:16291:3) Threshold** = ***1.00 A***

With the parameter **Threshold**, you set the threshold value of the ground current 3I0, measured as RMS value.

A rather sensitive setting is possible to respond also to short ground faults since the pickup time shortens as the ground-fault current increases.

Parameter: Directional mode

- Default setting **(_:16291:101) Directional mode** = ***forward***

With the parameter **Directional mode**, you define if the function operates in *forward* or in *reverse* direction.

Parameter: Pickup mode

- Default setting **(_:16291:102) Pickup mode** = ***with 3I0>***

With the parameter **Pickup mode**, you define under which conditions pickup is detected and fault logging and recording start:

- When the parameter **Pickup mode** is set to ***with 3I0>***, the signal *Pickup* is released without considering the ground fault direction. The signal *Pickup* is issued once the IN/3I0 exceeds the threshold value.
- When the parameter **Pickup mode** is set to ***with direction***, the signal *Pickup* is issued when at least one pulse direction is the same as the direction specified by the set value of parameter **Directional mode**.

Parameter: Operating mode

- Default setting **(_:16291:103) Operating mode** = ***Counter***

With the parameter **Operating mode**, you define if the function operates in ***Counter*** or in ***Integrator and counter*** mode.

Operating Mode	Application and Setting Notes
Counter	The number of directional pulses is the determining operate criterion. This is a simple method which is similar to the implementation in the 7SJ SIPROTEC 4 devices. Siemens recommends using this method if no time grading or only simple time grading between protection devices (time grading of only 2 or 3 devices) is required. Time grading is then carried out by increasing the parameter value **No. of pulses for operate** towards the infeed.
Integrator and counter	The integrator and the counter are the determining operate criteria while the counter criterion is only used for the direction determination. The integrator works in the same way as for the non-directional intermittent ground fault function. This allows the same time-grading principles as for the non-directional intermittent ground fault function. Refer to this function for more description.

Parameter: No.of pulses for interm.GF

- Default setting **(_:16291:104) No.of pulses for interm.GF** = ***3***

With the parameter **No.of pulses for interm.GF**, you set the total number of pulse counts (***forward***, ***reverse*** and ***non-dir. pulses***) at which the ground fault is considered to be intermittent. Siemens recommends using the default setting.

Parameter: Pickup extension time

- Default setting **(_:16291:105) Pickup extension time** = ***0.10 s***

With the parameter **Pickup extension time**, you get a prolonged and thus stabilized pickup signal. This stabilization is especially important for the coordination with existing static or electromechanical overcurrent protections.

Parameter: No. of pulses for operate

- Default setting **(_:16291:108) No. of pulses for operate** = ***5***

The pulses in the specified direction from **Directional mode** are counted. If the pulse counter reaches the set value of the parameter **No. of pulses for operate**, the directional counter criterion is fulfilled.

The setting of parameter **No. of pulses for operate** depends on the **Operating mode**.

Operating Mode	Application and Setting Notes
Counter	The number of directional pulses is the determining operate criterion. Thus do not set the value for parameter **No. of pulses for operate** too small. Consider that a permanent intermittent ground fault will cause many current pulses. If no time-grading considerations are required, Siemens recommends using a value in the range of 10 to 20.
Integrator and counter	The integrator and the counter are the determining operate criteria while the counter criterion is only used for the direction determination. The value for parameter **No. of pulses for operate** to fulfill the directional criterion can be set to a rather small value in the range of 3 to 5.

Parameter: **Sum of extended PU times**

- Default setting **(_:16291:106) Sum of extended PU times** = ***20.00 s***

This parameter is only relevant in the operating mode ***Integrator and counter***.

With the parameter **Sum of extended PU times**, you set the threshold value for the integrator. If the integration reaches **Sum of extended PU times**, the stage operates if the *Pulse no. reached* signal and the pickup state is present.

The parameter **Sum of extended PU times** represents one of the 5 selectivity criteria (ground-fault direction, pickup threshold, pickup extension time, reset time, and integrator threshold value) for coordination of the relays on subordinate devices. It is comparable to the time grading of the overcurrent protection.

The **Sum of extended PU times** has the shortest summation time in the radial system for the device that is closest to the intermittent ground fault and that picks up.

Parameter: **Reset time**

- Default setting **(_:16291:107) Reset time** = ***300 s***

With the parameter **Reset time**, you can define the maximum interval between 2 adjacent ground faults. If the interval is larger than the **Reset time**, the counter and integrator are reset.

The **Reset time** parameter must be much higher than the operate value of the **Sum of extended PU times**.

Parameter: **Operate & flt.rec. blocked**

- Default setting **(_:16291:2) Operate & flt.rec. blocked** = ***no***

With the parameter **Operate & flt.rec. blocked**, you can block the operate indication, the fault recording, and the fault log. In this case, a ground-fault log is created instead of the fault log.

6.15 Sensitive Ground-Fault Detection

6.15.1 Overview of Functions

2 functions are available for ground-fault detection: A directional one that is used if, in addition to the zero-sequence current 3I0, the zero-sequence voltage V0 is also available, and a non-directional one that is used if only the zero-sequence current 3I0 is available.

The **Directional sensitive ground-fault detection** (ANSI 67Ns) serves:

- For directional detection of permanent ground faults in isolated or resonant-grounded systems
- For directional detection of fast extinguishing transient ground faults in isolated or resonant-grounded systems
- For determination of the faulty phase
- For detection of high-resistance ground faults in effectively (solidly) or low-resistance (semi-solidly) grounded systems

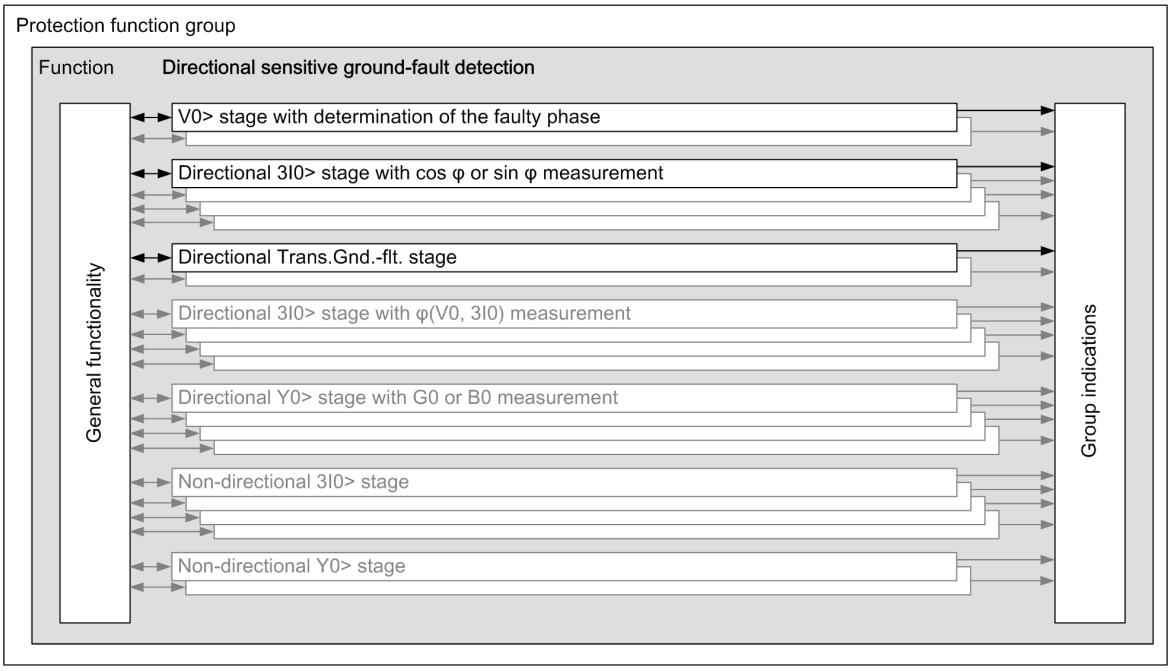
The **Non-directional sensitive ground-fault detection** (ANSI 51Ns) serves:

- For ground-fault detection in isolated or resonant-grounded systems
- For detection of high-resistance ground faults in effectively (solidly) or low-resistance (semi-solidly) grounded systems

6.15.2 Structure of the Function

Directional Sensitive Ground-Fault Detection

The **Directional sensitive ground-fault detection** function can be used in protection function groups that make current and voltage zero-sequence systems (3I0 and V0) available. The function is preconfigured at the factory with a **V0> stage**, a directional **3I0> stage with cos φ or sin φ measurement**, and a **transient ground-fault stage**.



The following stages can be operated simultaneously within the function:

- 2 **V0> stages** with determination of the faulty phase
- 4 directional **3I0> stages with cos φ or sin φ measurement**
- 2 directional **transient ground-fault stages**
- 4 directional **3I0> stages with φ(V0, 3I0) measurement**
- 4 directional **Y0> stages with G0 or B0 measurement** (admittance method)
- 4 non-directional **3I0> stages**
- 2 non-directional **Y0> stages**

The general functionality works across stages on the function level.

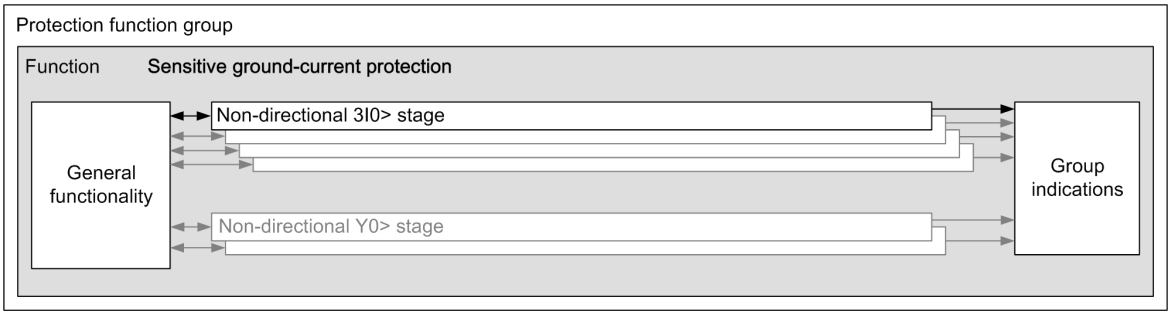
The group-indications output logic generates the following group indications of the entire function by the logical OR from the stage-selective indications:

- Pickup
- Operate indication

[DwStrGFP-250113-01, 4, en_US]

Figure 6-119 Structure/Embedding of the Directional Function in Protection Function Groups

Non-Directional Sensitive Ground-Fault Detection



The **Non-directional sensitive ground-fault detection** function can be used in protection function groups that only make the zero-sequence system (3I0) available. The function is preconfigured at the factory with a non-directional **3I0> stage**.

4 non-directional **3I0> stages** and 2 non-directional **Y0> stages** can be operated simultaneously in the function.

The general functionality works across stages on the function level.

The group-indications output logic generates the following group indications of the entire function by the logical OR from the stage-selective indications:

- Pickup
- Operate indication

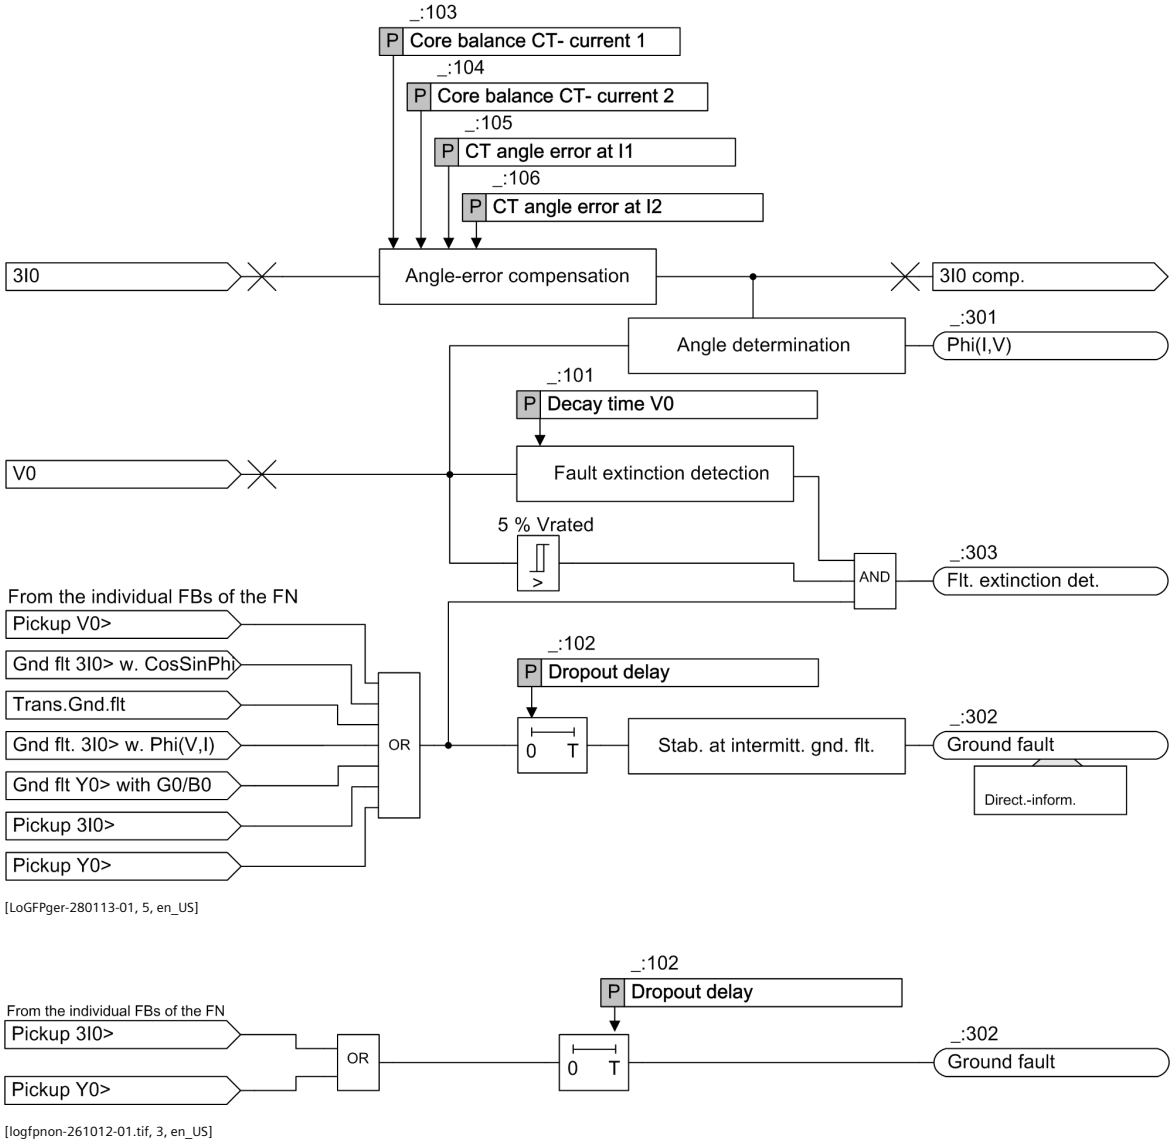
[DwSGFPu4-230113-01, 3, en_US]

Figure 6-120 Structure/Embedding of the Non-Directional Function in Protection Function Groups

6.15.3 General Functionality

6.15.3.1 Description

Logic



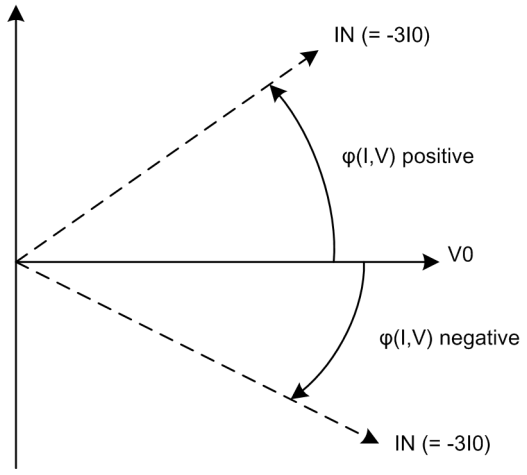


Figure 6-121 Logic Diagram of the Cross-Stage Functionality of the Non-Directional Function

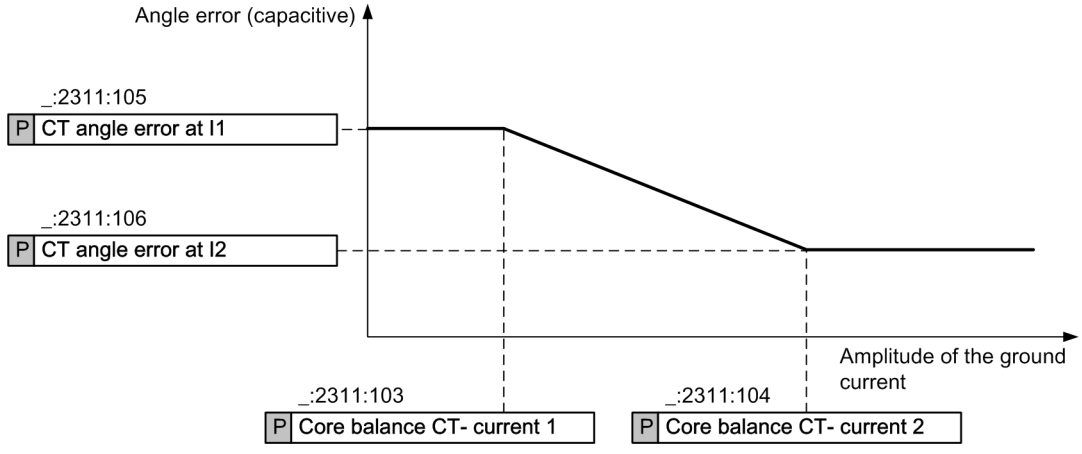
Operational Measured Value φ(I,V)

The function block calculates the angle between IN and V0 and makes the angle available as function measured value *Phi(I,V)* .

[DwPhINU0, 1, en_US]

Figure 6-122 Sign Definition for the Measured Value



Fault-Extinction Detection

The extinction of the fault is characterized by the fact that the zero-sequence voltage subsides. Depending on the system conditions and fault characteristics, this process can last several 100 ms. If a continuously falling zero-sequence voltage is detected during the set time **`Decay time V0`**, then the fault is considered extinguished. The signal ***`Flt. extinction det.`*** is issued.

Thus, the possibility exists, for example, to block the **3I0> stage with cos φ or sin φ measurement** directly after the fault extinction, in order to avoid an overfunction during the subsiding process with a very sensitive setting of the stage.

Angle-Error Compensation

The high reactive power factor in the arc-suppression-coil-ground system and the unavoidable air-gap of the core balance current transformer often make necessary a compensation of the angle error of the core balance current transformer. Using the characteristic shown in the following figure, the device approaches the angle error of the core balance current transformer with sufficient precision.

[dwerdwdl-110512-01.tif, 1, en_US]

Figure 6-123 Correction of the Transmission Characteristic Curve of a Core Balance Current Transformer

Ground-Fault Indication, Stabilization at Intermittent Ground Fault

The indication ***`(_:302) Ground fault`*** indicates the ground fault and manages the ground-fault log (see *Ground-Fault Log, Page 558*). The corresponding information of the stages used is accessed for the generation of this indication.

The indication *Ground fault* contains the direction information, independent of the parameterized working direction of a stage. The indication is thus suited for transfer to a station.

To avoid a flood of indications in case of an intermittent ground fault, a maximum of 30 status changes of this indication is logged per ground fault. An intermittent ground fault must be treated as a ground fault so that the stabilization can take action. This is ensured with the parameter **Dropout delay**, by the dropout of the indication *Ground fault* being delayed. If the next ignition of the ground fault takes place during the dropout delay, the indication does not dropout and the log remains open.

NOTE

The *Ground fault* indication in the general stage must be routed to the ground-fault log. If not, you can meet an overflow of the ground-fault log when an intermittent ground fault occurs.

Ground-Fault Log

Ground faults can be recorded in a designated buffer, the ground-fault log. As long as the **Operate & flt.rec. blocked** parameter is set to ***yes***, all indications routed into the ground-fault log are written in the ground-fault log.

The criterion for opening the ground-fault log is the raising of any indication which is routed to the ground-fault log, for example, the indication *Ground fault* . The criterion for closing is the clearing of all routed indications.

Related Topics

You can find general notes on the ground-fault login chapter **Indications** under *3.1.5.4 Ground-Fault Log* .

Value Indications

If the following value indications can be calculated, they are written into the log (ground-fault log or fault log) at the time of the 1st raising ground-fault indication and the 1st operate indication of any stage.

- 3I0 (value)
- 3I0 active component
- 3I0 reactive component
- V0
- φ (IN, V0)

6.15.3.2 Application and Setting Notes

Indication: Ground fault

To indicate the ground fault and its direction via the protocol, Siemens recommends using the indication *(_:302) Ground fault*. The indication contains the direction information, independent of the parameterized working direction of a stage. And this indication is also stabilized against a flood of indications in case of an intermittent ground fault.

Parameter: Decay time V0

- Recommended setting value **(_:101) Decay time V0** = ***0.10 s***

With the **Decay time V0** parameter, you specify the time slot for the detection of a fault extinction. If V0 continuously falls within this time, fault extinction is detected and the indication *Flt. extinction det.* is issued.

Siemens recommends using the default setting.

Parameter: Dropout delay

- Recommended setting value **(_:102) Dropout delay** = ***1.00 s***

To avoid chattering of the indication *Ground fault* during an intermittent ground fault and thus a frequent opening and closing of the ground-fault log, the dropout of the indication *Ground fault* (and thus the closing of the log) can be delayed by the **Dropout delay**.

Siemens recommends using the default setting.

Using the default setting ensures that no flood of indications arises in case of an intermittent ground fault for the indication *Ground fault*. The intermittent ground fault is then treated as a ground fault, and the stabilization of the indication *Ground fault* can thus take action.

Angle-Error Compensation of the Core Balance Current Transformer

- Default setting **(_:103) Core balance CT- current 1** = ***0.050 A***
- Default setting **(_:104) Core balance CT- current 2** = ***1.000 A***
- Default setting **(_:105) CT angle error at I1** = ***0.0°***
- Default setting **(_:106) CT angle error at I2** = ***0.0°***

The high reactive-power factor in the arc-suppression-coil-ground system and the unavoidable air gap of the core balance current transformer often make necessary a compensation of the angle error of the core balance current transformer. For the burden actually connected, the maximum angle error **CT angle error at I1** and the corresponding secondary current **Core balance CT- current 1** as well as a further operating point **CT angle error at I2**/**Core balance CT- current 2** are entered, from which point the angle error no longer changes appreciably.

In the isolated or grounded system, angle compensation is not necessary.

6.15.3.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting

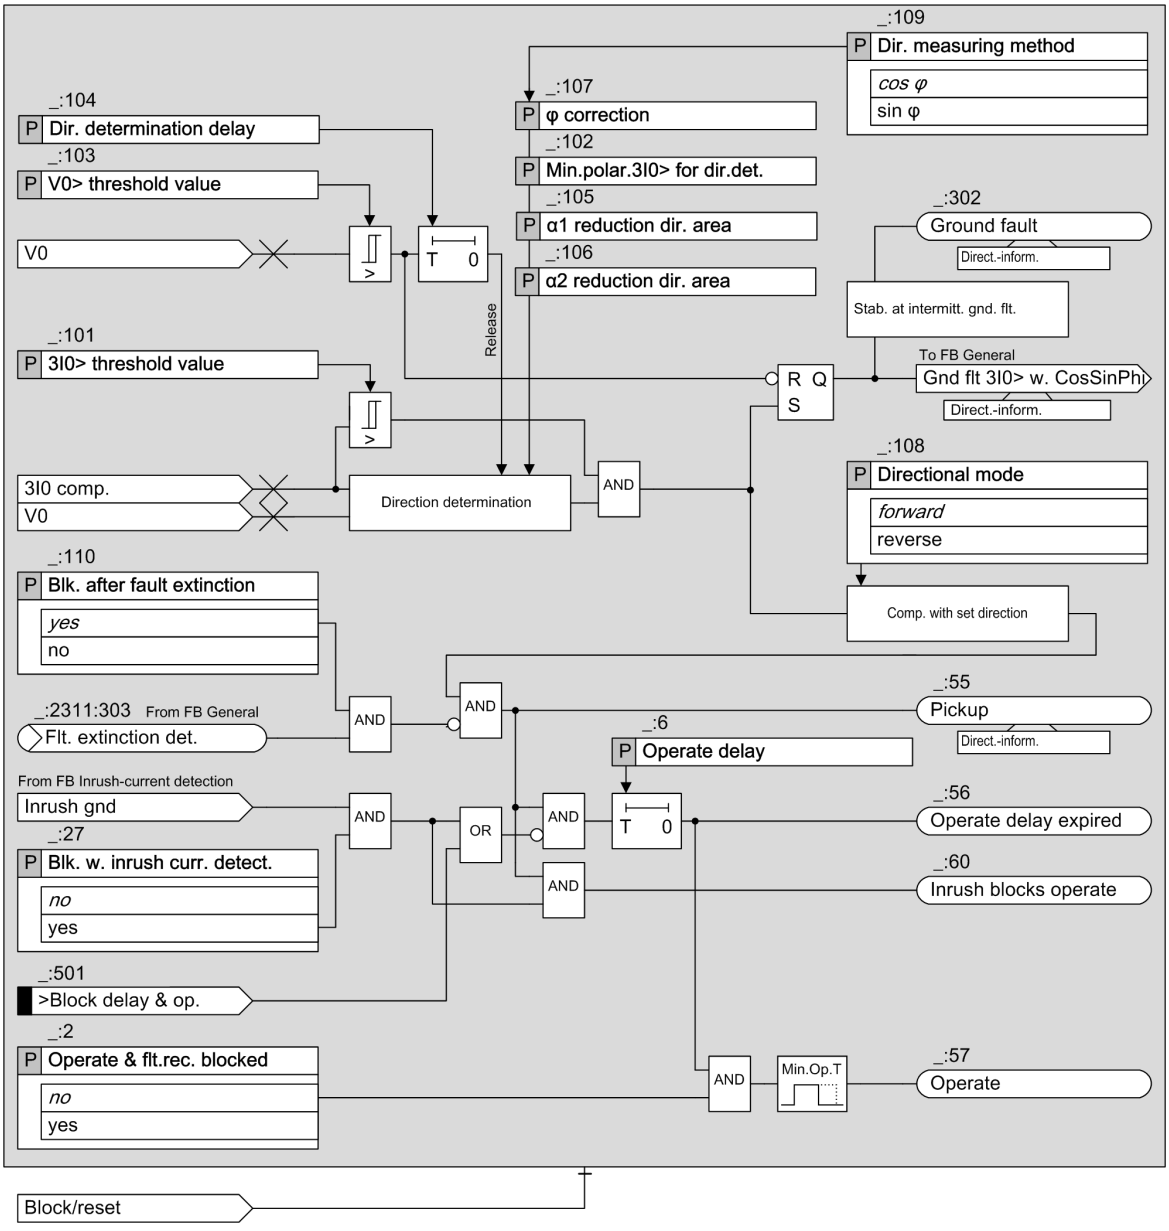
6.15.4 Directional 3I0 Stage with Cos φ or Sin φ Measurement



6.15.4.1 Description

Logic

[logfp3i0stufe-280314-01.vsd, 1, en_US]

Figure 6-124 Logic Diagram of the Stage Control

[logfp3i0f-280314-01, 3, en_US]

Figure 6-125 Logic Diagram of the Directional 3I0 Stage with Cos φ or Sin φ Measurement

Measured Value V0, Method of Measurement

The device measures the residual voltage at the broken-delta winding. The measured voltage is converted to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, Method of Measurement

The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

Depending on the setting of the parameter Connection type of the measuring point **I-3ph** as well as the current terminal block used, the following different linearity and settings ranges result in addition to the usual application:

Setting Value Connection Type of the Measuring Point I-3ph	3I0	Current Terminal Block	3I0 Threshold Value Settings Range (Secondary) [10]
3-phase + IN separate [11] 3-phase + IN	Measured	3 x protection, 1 x sensitive	0.001 A to 35.000 A
		4 x protection	0.030 A to 35.000 A
		4 x measurement	0.001 A to 1.600 A
3-phase	Calculates	4 x protection	0.030 A to 35.000 A
		3 x protection, 1 x sensitive	0.030 A to 35.000 A
		4 x measurement	0.001 A to 1.600 A

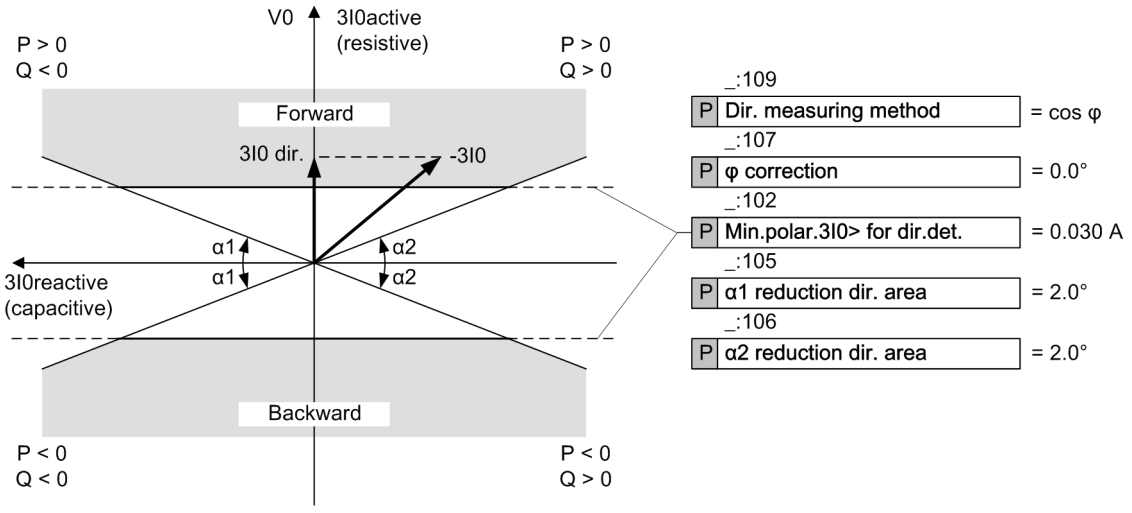
With the use of the function within a 1-phase function group and therefore at a 1-phase measuring point **I-1ph**, the following different linearity and settings ranges result:

Measuring Point I-1ph	3I0	Current Terminal Block	3I0 Threshold Value Settings Range (Secondary) [12]
	Measured	Sensitive	0.001 A to 1.600 A
		Protection	0.030 A to 35.000 A

The method of measurement processes the sampled current values and filters out the fundamental component numerically.

The methods of measurement are characterized by high accuracy and by insensitivity to harmonics, especially the 3rd and 5th harmonics frequently present in the ground-fault (leakage) current.

Ground-Fault Detection, Pickup



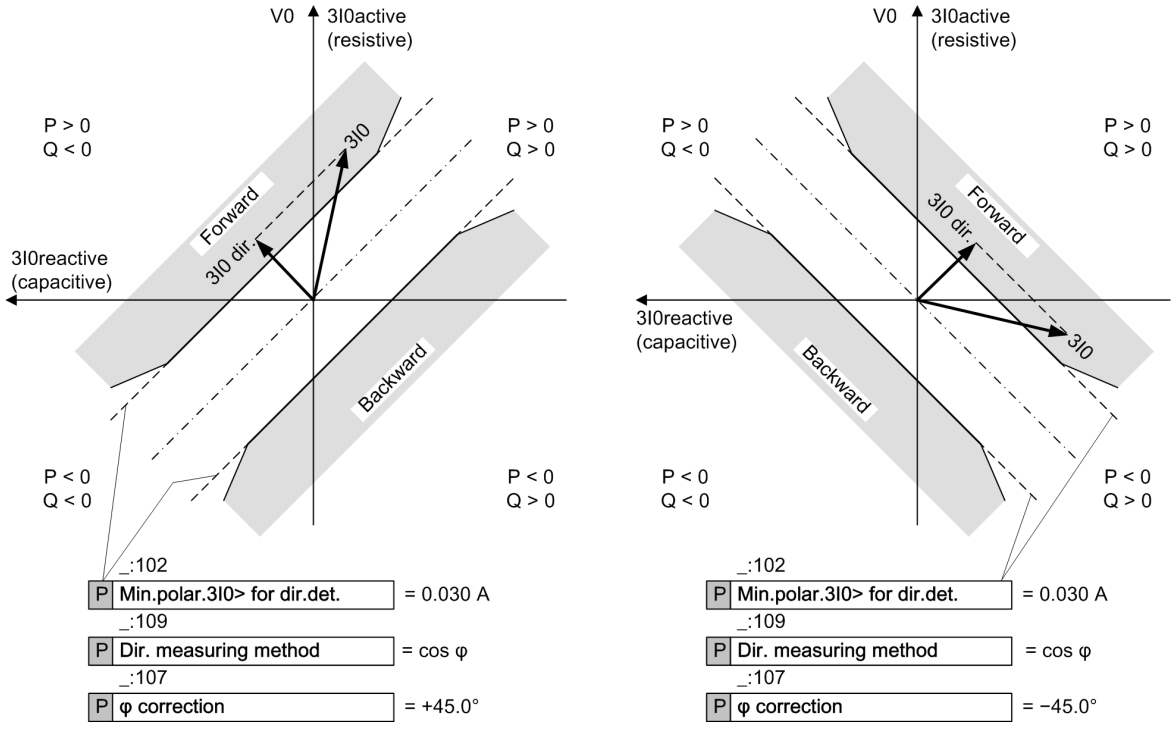
If the absolute value of the ground current 3I0 exceeds the threshold value **3I0> threshold value** and the absolute value of the zero-sequence voltage V0 exceeds the threshold value **V0> threshold value**, the stage recognizes the ground fault. The direction determination (see the next paragraph) is started when the V0 threshold value is exceeded. The direction result is indicated via the *Ground fault* signal (in the general function block). If the direction result equals the parameterized direction (parameter **Directional mode**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The result form the direction determination is only valid if the absolute value of the ground current 3I0 has also exceeded its threshold value.

The following figure shows an example of the direction determination in the complex phasor diagram for the cos-φ direction measurement method with a correction value of the direction straight lines from 0 (parameter **φ correction**). The example is suitable for the determination of the ground-fault direction in an arc-suppression-coil-ground system where the variable 3I0 · cos φ is decisive for the direction determination.

[10] These values apply for a secondary rated current of 1 A. The values need to be multiplied by 5 when the secondary rated current is 5 A.
[11] Usual application
[12] These values apply for a secondary rated current of 1 A. The values need to be multiplied by 5 when the secondary rated current is 5 A.



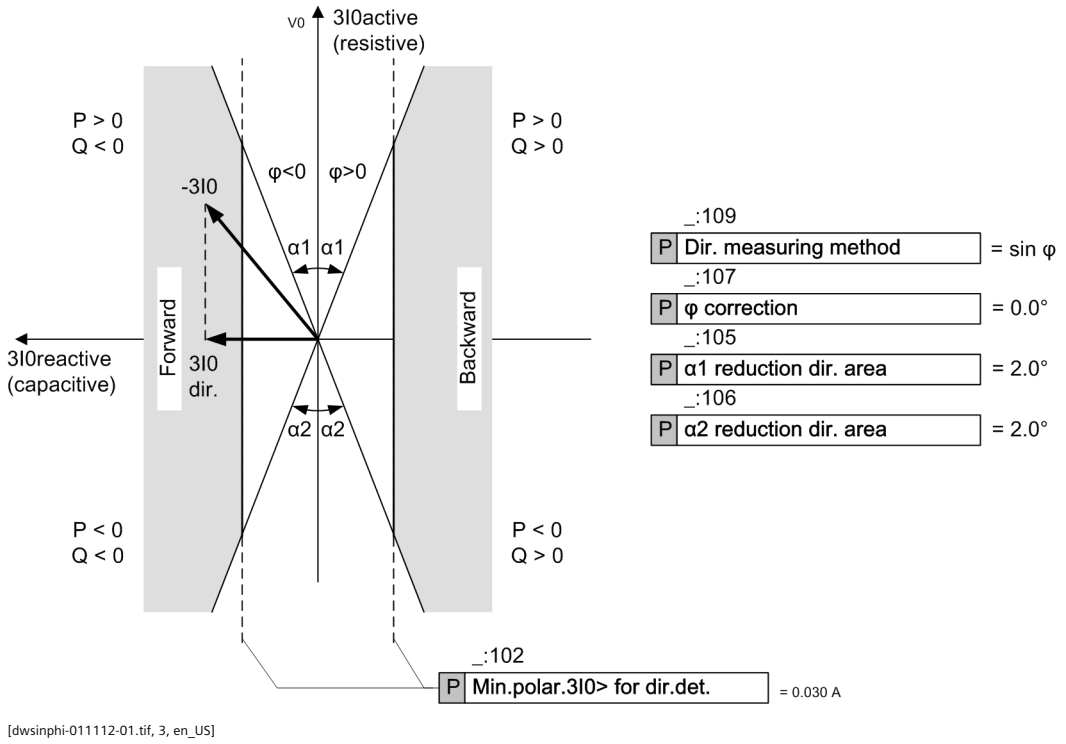
[dwcosphi-171012-01.tif, 2, en_US]

Figure 6-126 Direction-Characteristic Curve with Cos φ Measurement

The zero-sequence voltage V0 is basically the reference value for the real axis. The axis of symmetry of the direction-characteristic curve coincides with the 3I0react axis for this example. For the direction determination, basically the portion of the current vertical to the set direction-characteristic curve (= axis of symmetry) is decisive (3I0 dir.). In this example, this is the active portion 3I0active of the current 3I0. The current 3I0dir. (here = 3I0active) is calculated and compared with the setting value **`Min.polar.3I0> for dir.det.`**. If the current 3I0 dir. exceeds the positive setting value, the direction is forward. If the current 3I0 dir. exceeds the negative setting value, the direction is backward. In the range in between, the direction is undetermined.

With the **`α1 reduction dir. area`** and **`α2 reduction dir. area`** parameters, you can limit the forward and backward ranges as shown in the figure. With this, the direction determination is secured in case of high currents in the direction of the axis of symmetry.

The symmetry axis can be turned via a correction angle **`φ correction`** parameter) in a range of ±45. Through this, it is possible, for example, to attain the greatest sensitivity in grounded systems in the resistive-inductive range with a -45° turn. In the case of electric machines in busbar connection on the isolated system, the greatest sensitivity in the resistive-capacitive range can be attained with a rotation of +45°.



[dwphicor-171012-01.tif, 1, en_US]

Figure 6-127 Turning the Direction-Characteristic Curves with Cos φ Measurement with Angle Correction

If you set the **Dir. measuring method** parameter to ***sin φ*** and the **φ correction** parameter to ***0***, the symmetry axis of the direction-characteristic curve coincides with the 3I0active axis and the V0 axis. Since the portion of the current vertical to the direction-characteristic curve (= axis of symmetry) is decisive (3I0dir.), here, the current 3I0react is included in the direction determination. If the current 3I0dir. (here, =3I0react) exceeds the negative setting value **Min.polar.3I0> for dir.det.**, the direction is forward. If the current 3I0dir. exceeds the positive setting value, the direction is backward. In the range in between, the direction is undetermined.

This direction measurement thus is appropriate for the determination of ground-fault direction in isolated systems.

[dwsinphi-011112-01.tif, 3, en_US]

Figure 6-128 Direction-Characteristic Curve with Sin φ Measurement

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pick up of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Voltage transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that Measuring-voltage failure detection blocks the stage or does not block it.

Blocking the Pickup with Detection of the Fault Extinction

Using the evaluation of the instantaneous value developing of the zero-sequence voltage, the fault extinction can be recognized faster than via the dropout of the V0 fundamental-component value under the pickup value. The pickup of the stage is blocked with the fast detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. With the **Blk. after fault extinction** parameter, you enable or disable this accelerated detection of the fault extinction.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking the Operate Indication via the Device-Internal Inrush-Current Detection Function

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked by exceeding of the threshold values due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started.

6.15.4.2 Application and Setting Notes

Parameter: **Operate & flt.rec. blocked**

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: **Blk. by meas.-volt. failure**

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage transformer circuit breaker** is linked with the voltage transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: **Blk. w. inrush curr. detect.**

- Recommended setting value **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains unaffected by an enabling procedure.

Parameter: **Blk. after fault extinction**

- Recommended setting value **(_:110) Blk. after fault extinction** = ***yes***

If the **Blk. after fault extinction** parameter is set to ***yes***, the pickup is blocked after detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. Siemens recommends using the default setting.

Parameter: **Directional mode**

- Default setting **(_:108) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: `Dir. measuring method`, `φ correction`, `Min.polar.3I0> for dir.det.`, `3I0> threshold value`

- Default setting **`(_:109) Dir. measuring method`** = ***`cos φ`***
- Default setting **`(_:107) φ correction`** = ***`0.0°`***
- Default setting **`(_:102) Min.polar.3I0> for dir.det.`** = ***`0.030 A`***
- Default setting **`(_:101) 3I0> threshold value`** = ***`0.050 A`***

These parameters are used to define the direction characteristic of the stage. The direction characteristic to use is dependent on the neutral-point treatment of the system.

Note that, for the direction determination, basically only a portion of the current vertical to the set direction-characteristic curve (3I0dir.) is decisive, refer to *6.15.4.1 Description*. This portion of the current is compared to the threshold value **`Min.polar.3I0> for dir.det.`**. In contrast, the absolute value of the current 3I0 is compared with the **`3I0> threshold value`** parameter.

System Type/ Neutral-Point Treatment	Description
Grounded	In the arc-suppression-coil-ground system, the watt leakage current 3I0 · cos φ of the arc-suppression coil is decisive for the direction determination. To evaluate the watt leakage current, set the parameters as follows: • **`Dir. measuring method`** = ***`cos φ`*** • **`φ correction`** = ***`0.0°`*** The direction determination for a ground fault is made more difficult in that a much larger capacitive or inductive reactive current is superimposed on the small watt leakage current. Therefore, depending on the system configuration and the fault evaluation, the total ground current supplied to the device can vary considerably in its values regarding the magnitude and the phase angle. However, the device should only evaluate the active component of the ground-fault current. This requires extremely high accuracy, particularly regarding the phase-angle measurement of all the instrument transformers. Furthermore, the device must not be set to operate too sensitively. A reliable direction measurement can only be expected with connection to a core balance current transformer. For the setting of the **`Min.polar.3I0> for dir.det.`** parameter, the rule of thumb is: Set the pickup value only to half of the expected measuring current as only the watt leakage current can be put into use. The **`3I0> threshold value`** parameter can also be set to half of the expected measuring current, whereby here the entire zero-sequence current can be put to use.
Isolated	In the isolated system, the capacitive ground reactive current 3I0 · sin φ is decisive for the direction determination. To evaluate the capacitive ground reactive current, set the parameters as follows: • **`Dir. measuring method`** = ***`sin φ`*** • **`φ correction`** = ***`0.0°`*** In an isolated system, the capacitive ground-fault currents of the entire electrically connected system flow through the measuring point in case of a ground fault. The ground current of the faulty feeder is compensated in the measuring point. As the pickup value of the **`Min.polar.3I0> for dir.det.`** and **`3I0> threshold value`** parameters, select about half of this capacitive ground-fault current flowing via the measuring point.

System Type/ Neutral-Point Treatment	Description
Resistance-Grounded	In the resistance-grounded system, the ohmic-inductive ground-fault current is decisive for the direction determination. To evaluate this short-circuit current, set the parameters as follows: • **Dir. measuring method** = ***cos φ*** • **φ correction** = ***-45.0°*** Set the **Min.polar.3I0> for dir.det.** and **3I0> threshold value** parameters to a value below the minimum ground-fault current to be expected.

Parameter: α1 reduction dir. area, α2 reduction dir. area

- Recommended setting value **(_:105) α1 reduction dir. area** = ***2°***
- Recommended setting value **(_:106) α2 reduction dir. area** = ***2°***

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you specify the angle for the limitation of the direction range. Siemens recommends using the default setting of 2°.

In an arc-suppression-coil-ground system in feeders with a very large reactive current, it can be practical to set a somewhat larger angle α1 to avoid a false pickup based on transformer and algorithm tolerances.

Parameter: V0> threshold value

- Default setting **(_:103) V0> threshold value** = ***30.000 V***

The **V0> threshold value** parameter allows you to set the zero-sequence voltage sensitivity of the stage. Set the threshold value smaller than the minimum absolute value of the zero-sequence voltage V0 that must still be detected.

Parameter: Dir. determination delay

- Default setting **(_:104) Dir. determination delay** = ***0.00 s***

The start of the ground fault normally shows a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***2.0 s***

The parameterized time **Operate delay** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

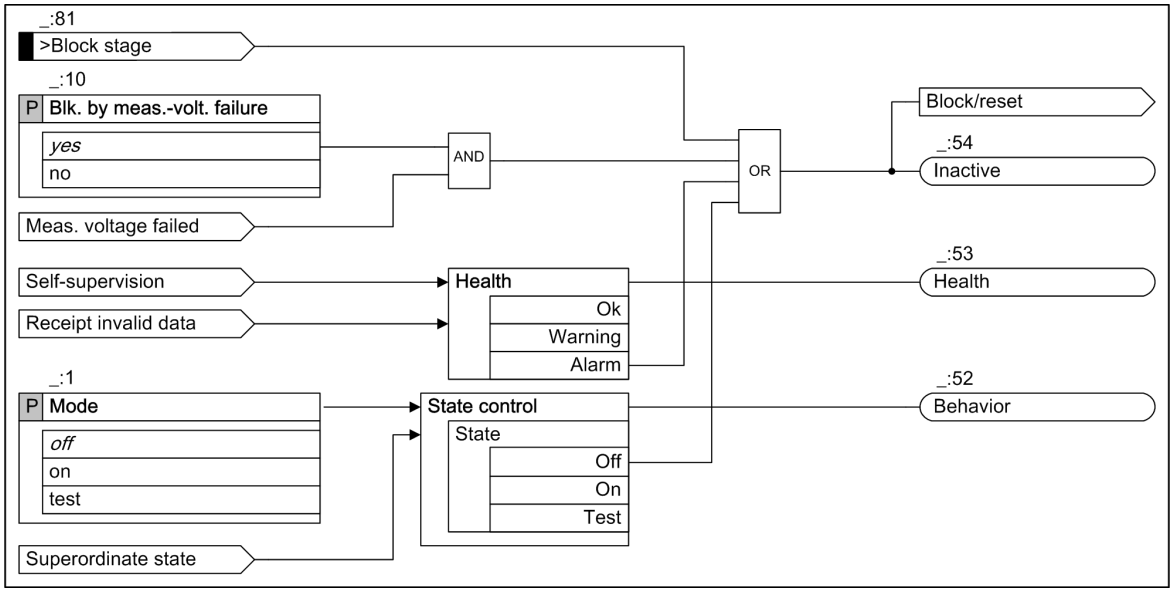
6.15.5 Directional Transient Ground-Fault Stage

6.15.5.1 Description



Overview

Ground faults occurring in arc-suppression-coil-ground systems quite often extinguish a short time after the ignition, mostly within a few milliseconds. Such transient occurrences are called transient ground faults. In order to detect the ground-fault direction, based on these transient occurrences, a special method of measurement is required that can also capture high frequencies. Conventional methods based on phasor calculations are not suitable. Even for ground faults lasting for a short time, usually, a high-frequency charging process occurs in healthy phases. The transient charging process is evaluated by the transient ground-fault method of measurement to determine the ground-fault direction. An integrating method of measurement ensures a high degree of sensitivity and a positive stability against parasitic signals in the zero-sequence system.

Since permanent ground faults also start with the transient charging process of flawless wires, those errors will be detected as well.

This process is most suitable for the use in closed loops or meshed systems. Operational, circulating zero-sequence currents are eliminated and therefore, cannot affect the directional result.

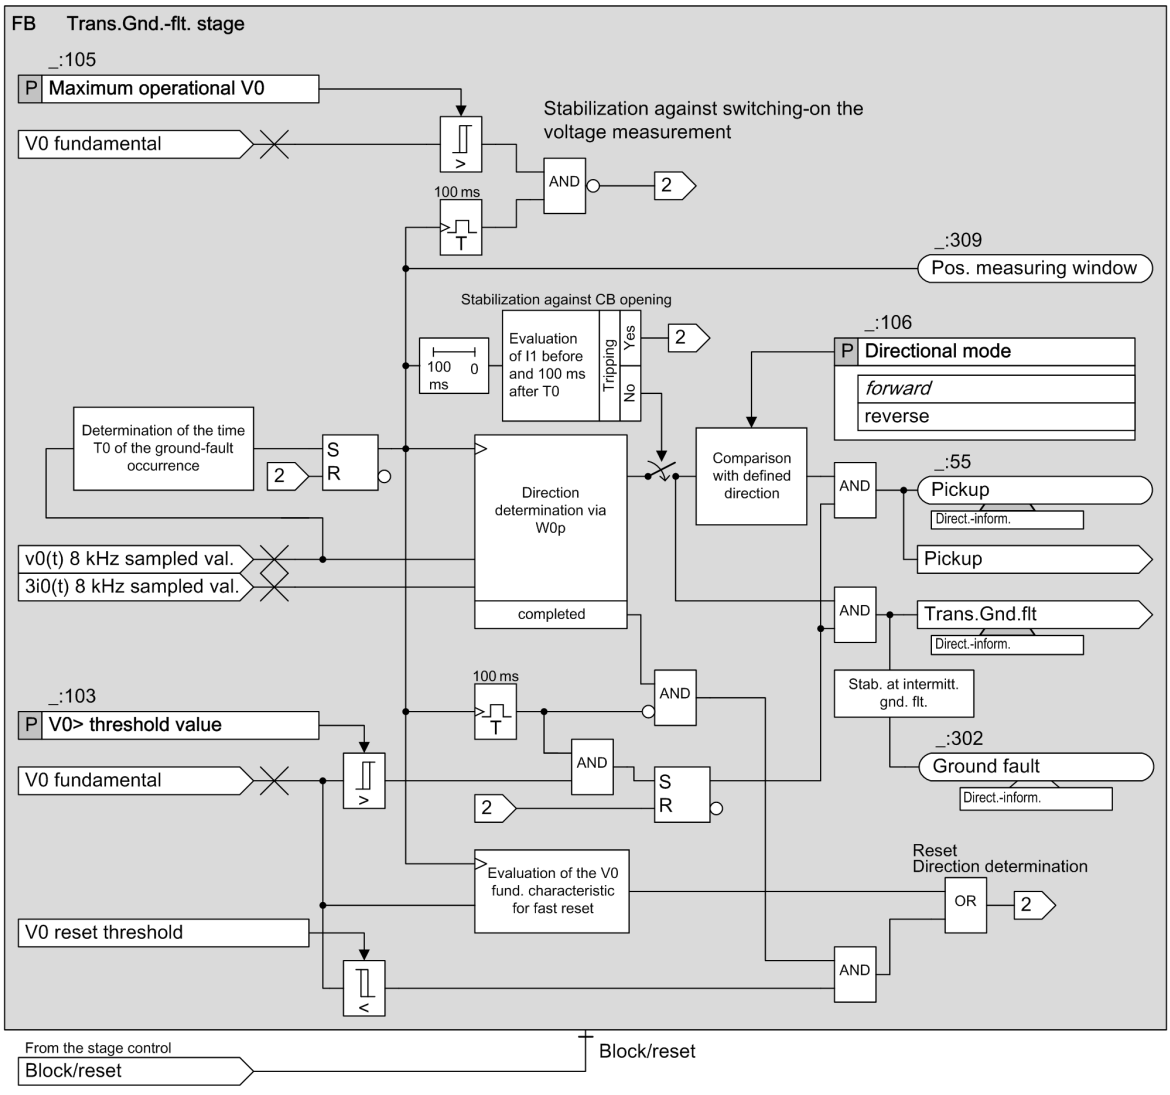
Stage-Control Logic

[lostuwis-240113-01.tif, 1, en_US]

Figure 6-129 Logic Diagram of the Stage Control

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage* . In the event of blocking, the picked up stage will be reset.



Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker.

The **`Blk. by meas.-volt. failure`** parameter can be set so that **measuring-voltage failure detection** blocks the stage or not.

Logic of the Transient Ground-Fault Functionality

[lowisfut-240113-01.tif, 6, en_US]

Figure 6-130 Logic Diagram of the Directional Transient Ground-Fault Stage

Measured Values, Method of Measurement

The zero-sequence values of zero-sequence voltage and zero-sequence current are measured directly or calculated from the phase variables. When measuring directly, the following is detected:

- Zero-sequence voltage on the broken-delta winding
- Zero-sequence current via Holmgreen connection or via core balance current transformer

The voltage measured on the broken-delta winding will be converted to zero-sequence voltage V_0.

The instantaneous values of the zero-sequence voltage V0(t) that are sampled at a high frequency (8 kHz) serve to determine the point in time of the ground fault occurrence T0.

The instantaneous values of the zero-sequence voltage V0(t) and the ground current 3I0(t), which are sampled at a high frequency (8 kHz), are the basis for direction determination.

The fundamental-component values of the zero-sequence voltage V0 serve to release the directional result and the pickup as well as a criterion for the stabilization against switching operations.

The positive-sequence system (if it exists as a measured value) serves as an additional criterion for the stabilization against switching operations.

The fundamental-component values V0 and 3I0 will be used in the optional trip logic.

Operational, meaning circulating zero-sequence currents, can occur in closed loops or meshed systems. This type of zero-sequence current is also present in case of a failure and can falsify the directional result. Therefore, an operational zero-sequence current is eliminated.

Determining the Time of the Ground-Fault Ignition

The algorithm uses the evaluation of the instantaneous values of the zero-sequence voltage to verify continuously if a ground fault occurred. This takes place regardless of whether the set threshold value for V0 is exceeded. If a ground fault occurred, the measuring window for determining the direction is positioned and the direction determination is performed. The position of the measuring window is logged via the indication *Pos. measuring window* (in FB **General**). The precise identification of the time T0 at which the ground fault occurred is decisive for the correct direction determination.

Determination of Direction, Method of Measurement

The active energy of the zero-sequence system is calculated for the direction determination. Once the ground fault occurrence has been detected, the active energy will be calculated across approximately 1 cycle frequency. If the active energy of the zero-sequence system is negative, a forward fault is present; otherwise it is a backward fault.

Direction Result Message, Pickup

Determining the time of the ground-fault ignition and the direction is always done with maximum sensitivity. With the parameter **V0> threshold value**, you define the sensitivity for the indication of the direction and the pickup of the stage.

If the fundamental-component value of the zero-sequence voltage V0 exceeds the associated threshold value (**V0> threshold value** parameter) within 100 ms after detecting the ground-fault ignition, the direction result will be reported. In this way, high-impedance ground faults are also reported in which the zero-sequence system values rise only slowly, and, for this reason, the occurrence of the ground fault is detected noticeably earlier than the exceedance of the parameterized threshold value.

The direction result will be reported to the function via the *(_:302) Ground fault* of the function block **General information**. This indication is reported irrespective of the parameterized direction of the function.

If the determined direction corresponds with the parameterized direction (parameter **Directional mode**), a pickup occurs.

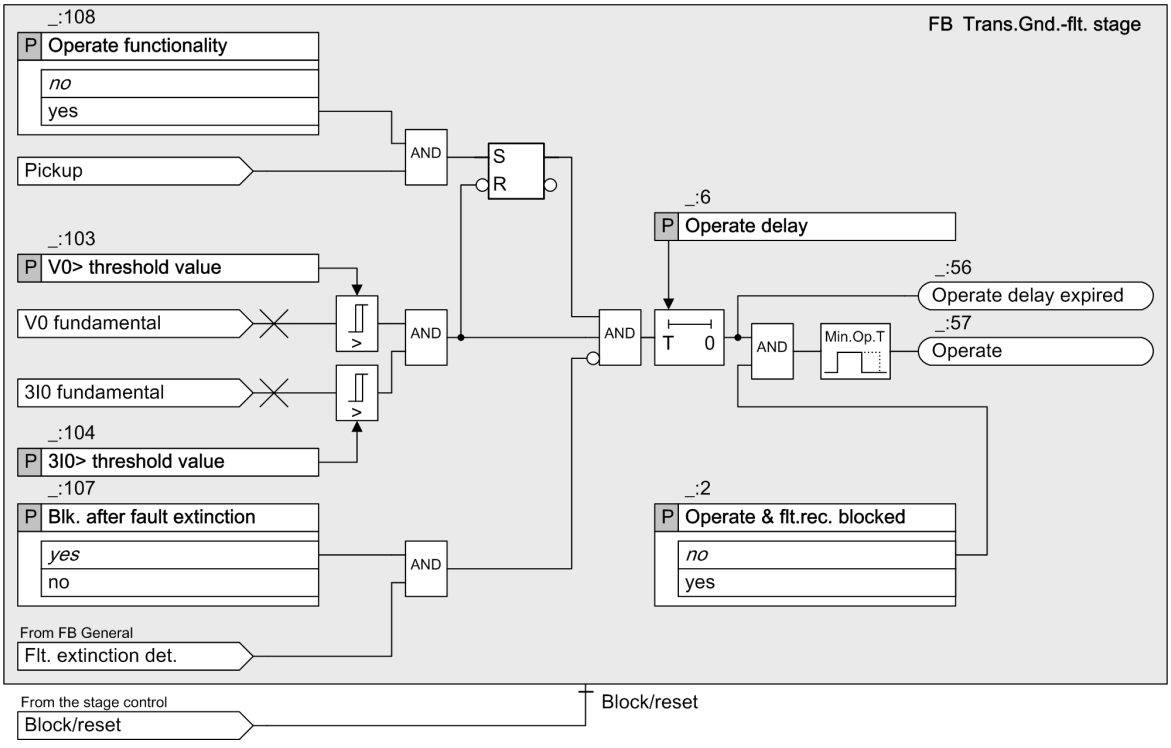
Reset of the Algorithm

To allow a new directional measurement, the algorithm needs to be reset. The normal reset takes place when the fundamental component of the zero-sequence voltage V0 drops below the V0 reset threshold. This reset threshold is a small device-internal V0 threshold. It is also depending on an operational V0 and is thus a dynamic threshold. The threshold value is 3.0 V secondary without dynamic influence.

Stabilization against Switching Operations

Switching operations in the system to be protected can cause transient signals in the zero-sequence system. The stage is stabilized against possible overfunction due to switching operations.

The following mechanisms are applied:



- For reporting the direction result, the fundamental-component value of the zero-sequence voltage must exceed the **V0> threshold value** in a time slot of 100 ms after the ground-fault extinction. This effectively suppresses wrong indications as a result of switching operations.
- The fundamental-component value of the zero-sequence voltage V0 is not influenced by switching operations and is thus a good criterion for distinguishing the ground fault from a switching procedure. The condition that the fundamental-component value must exceed the **V0> threshold value** for reporting the direction result effectively suppresses switching operations.

  For rare cases in which high zero-sequence voltages occur over longer time ranges after switching off the feeder or line, a criterion on the basis of the positive-sequence system current is also effective. This criterion compares the positive-sequence system current before and after the transient event and thus detects a disconnection. In case of disconnection, the direction result is not reported.

  Through stabilization mechanisms, the direction result is reported 100 ms after the ground-fault ignition. Thus a pickup occurs with a 100-ms delay.

  If the stage is used in a 1-phase function group, the additional criterion via the positive-sequence system current is not effective.
- The function detects transient occurrences in the zero-sequence voltage. In systems with operational zero-sequence voltages, if the measuring voltage is switched on, the function can internally be started. If the fundamental-component value of the zero-sequence voltage does not exceed the threshold of the **Maximum operational V0** parameter in a time slot of 100 ms after the function start, the function is reset internally.

Trip Logic

[loauswis-240113-01.tif, 2, en_US]

Figure 6-131 Trip Logic Diagram

In many applications, the transient ground-fault stage is used only to indicate the direction. In this case, the trip logic is not required and remains disabled. However, this stage can also be used to disable a permanent ground fault. For this, you enable the optional trip logic with the **Operate functionality** parameter. If the fundamental-component values V0 and 3I0 exceed the set threshold values, the operate delay (**Operate delay** parameter) starts with the pickup. In order to start the operate delay, the threshold values must be

exceeded during the time delay. The process of the operate delay will be indicated. If the **Operate & flt.rec. blocked** setting is set to ***no***, the pickup indication is sent.

Blocking the Pickup with Detection of the Fault Extinction

Using the evaluation of the instantaneous value cycle of the zero-sequence voltage, the fault extinction of the ground fault can be detected faster than via the dropout of the V0 fundamental-component value under the pickup value. The fast detection of the fault extinction (see function block **General information**) blocks the tripping time delay. When using the parameter **Blk. after fault extinction**, this accelerated blocking mechanism can be enabled or disabled.

6.15.5.2 Application and Setting Notes

Parameter: Operate functionality

- Default setting **(_:108) Operate functionality** = ***no***

If the transient ground-fault stage is used only to indicate the direction, this optional trip logic is not required and remains disabled. If the transient ground-fault stage is used to disable permanent faults as well, this optional trip logic is enabled. Pickup of the stage will initiate the tripping delay.

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage transformer circuit breaker** is linked with the voltage transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: Blk. after fault extinction

- Recommended setting value **(_:107) Blk. after fault extinction** = ***yes***

If the **Blk. after fault extinction** parameter is set to ***yes***, the tripping delay is reset after the detection of the fault extinction. Therefore, if the tripping delay is set for a short time, the possibility of an overfunction is avoided. The reason for an overfunction is a slower attenuation in the zero-sequence system following the fault extinction. Siemens recommends keeping this default setting if the stage is used for tripping. If you are using the stage only for reporting or for detecting intermittent faults, you have to disable the blocking.

Parameter: Directional mode

- Default setting **(_:106) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: V0> threshold value

- Default setting **(_:103) V0> threshold value** = ***15.000 V***

With the parameter **V0> threshold value**, you define the sensitivity for the indication of the direction and the pickup of the stage.

Note that the sensitivity of the direction determination itself is not thereby changed. The direction determination always works with maximum sensitivity.

Should high-resistive ground faults be reported as well, very sensitive settings are possible, for example, **V0> threshold value** = ***5 V*** secondary.

Parameter: Maximum operational V0

- Recommended setting value **(_:105) Maximum operational V0** = ***3.000 V***

The setting of the **Maximum operational V0** parameter is in conjunction with the stabilization against switching operations.

The setting is made with reference to the zero-sequence voltage V0 according to its definition.

Network Structure	Description
Radial system	In the primary system, no operational zero-sequence voltages are present. A measured zero-sequence voltage results from tolerances within the voltage measurement, for example, from the voltage transformers. Siemens recommends using the default value of 3.000 V.
Ring network, meshed network	Operational zero-sequence voltages can occur in such networks. The secondary operational zero-sequence voltages can be determined by reading the residual voltage $V_{N\,sec}$ or the zero-sequence voltage $V_{0\,sec}$ under the symmetrical components from the device or via DIGSI. In case you read the secondary residual voltage $V_{N\,sec}$, you convert it to $V_{0\,sec}$ with the **Matching ratio Vph / VN** parameter. You can find more information in chapter *6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph)* . If $V_{0\,sec}$ is greater than 2.5 V, the value of **Maximum operational V0** shall be increased to $V_{0\,sec} \cdot 1.2$. Example: $V_{N\,sec}$ = 5.000 V **Matching ratio Vph / VN** = $\sqrt{3}$ $V_{0\,sec}$ = 5.000 V $\cdot$ $\sqrt{3}$ / 3 = 2.887 V **Maximum operational V0** = 2.887 V $\cdot$ 1.2 = 3.464V In most cases, the operational zero-sequence voltages will be smaller than 2.500 V. Siemens recommends using the default value of 3.000 V.

Parameter: 3I0> threshold value

- Default setting **(_:104) 3I0> threshold value** = ***0.030 A***

The setting is significant only for optional trip logic for switching off permanent ground faults. Select the setting such that the static ground-fault current exceeds the threshold value.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***0.50 s***

The parameterized time **Operate delay** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

The setting of the **Operate delay** depends on the specific application. Ensure that the pickup is delayed by 100 ms with regard to the time of the ground-fault ignition.

6.15.6 Usage Information for Detection of Intermittent Ground Faults

The stage type **3I0> with cos φ or sin φ measurement** is suited for directional detection of intermittent ground faults. Many years of field experience and field tests have shown that the direction determination of this stage type reliably determines the direction of the current peaks. Between the current peaks, the direction is detected as *unknown*. To generate a tripping or an alarm, you can analyze the individual pickups of a stage (each directional pickup corresponds to a current peak) in a time-based way or count them via an additional user logic (CFC chart).

You can also ensure the result in the user logic via a 2nd directional stage that works in the backward direction, as well as a V0 stage.

You can operate a 3rd directional stage in parallel for detection of permanent ground faults.

In the following, certain settings are explained that are necessary for this application (detection of intermittent ground faults):

- Parameter: **(_:102) Dropout delay**

  The function must treat the intermittent process as one ground fault. For this, it is necessary that the indication *Ground fault* does not drop out between 2 consecutive current peaks. This is ensured via the **Dropout delay** parameter (FB **General**). A dropout delay of 1 s is a feasible value.

- Parameter: **(_:104) Dir. determination delay**

  You must set the delay of the direction determination to 0 s so that the direction of the current peaks can be determined.

- Parameter: **(_:105) α1 reduction dir. area** and **(_:106) α2 reduction dir. area**

  The current peaks show a clear ohmic component. With these parameters, you can limit the direction characteristic and ensure a reliable direction result.

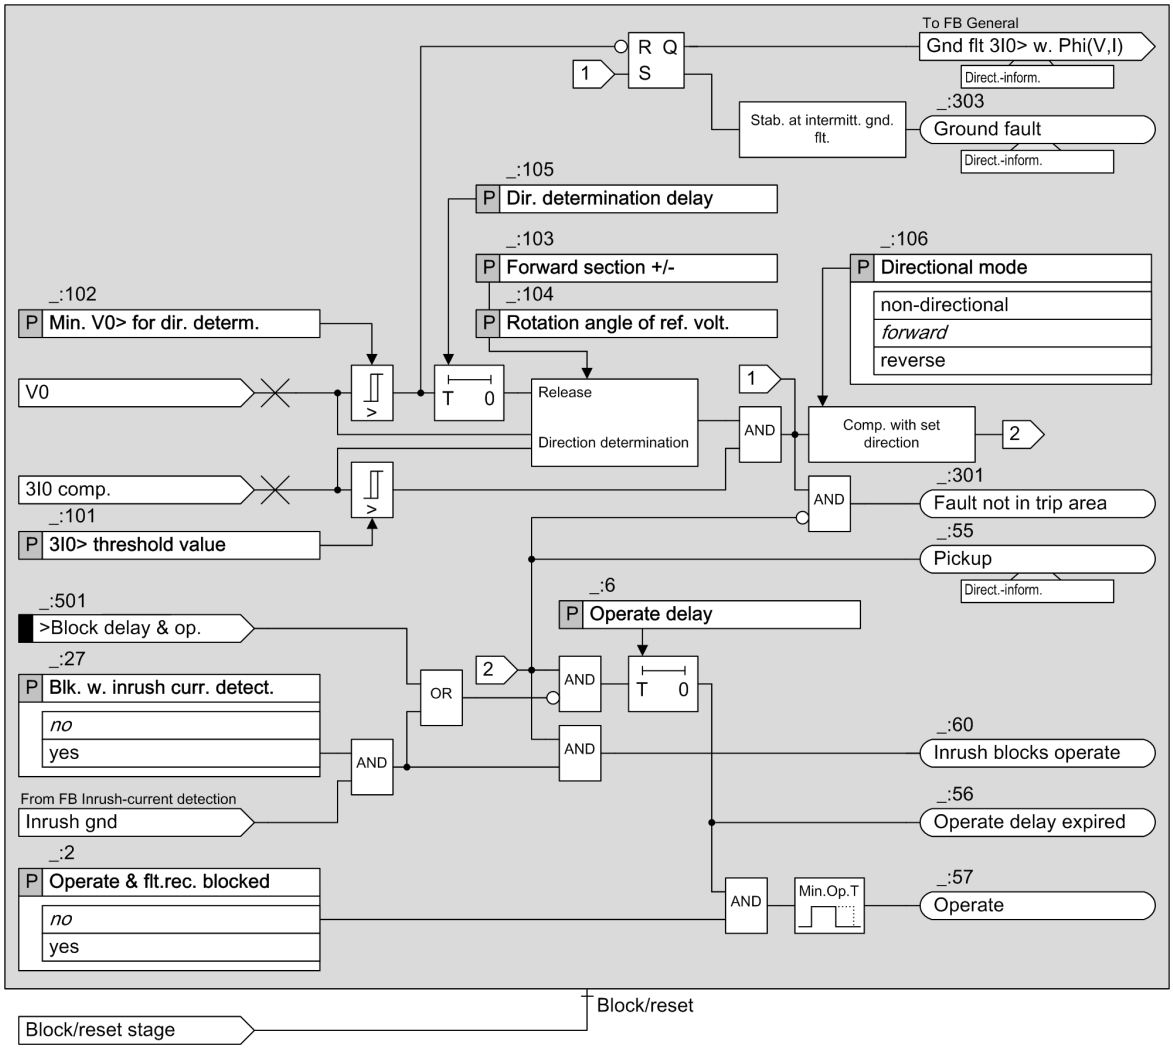
  Siemens recommends setting both parameters to 10°.

- Parameter: **(_:110) Blk. after fault extinction**

  To make possible a continuous and immediate detection of the current peaks, you must switch off the blocking after fault suppression.

No further parameters need particular consideration with regard to an intermittent ground fault. You can set these as for the detection of permanent ground faults.

6.15.7 Directional 3I0 Stage with φ(V0,3I0) Measurement



6.15.7.1 Description

Logic

[logfppvi-291112-02.vsd, 1, en_US]

Figure 6-132 Logic Diagram of the Stage Control

[logfppvi-291112-01.tif, 3, en_US]

Figure 6-133 Logic Diagram of the Directional 3I0 Stage with φ(V0,3I0) Measurement

Measured Value V0, Method of Measurement

The device measures the residual voltage at the broken-delta winding. The measured voltage is converted to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages VA, VB, and VC using the defining equation.

This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, Method of Measurement

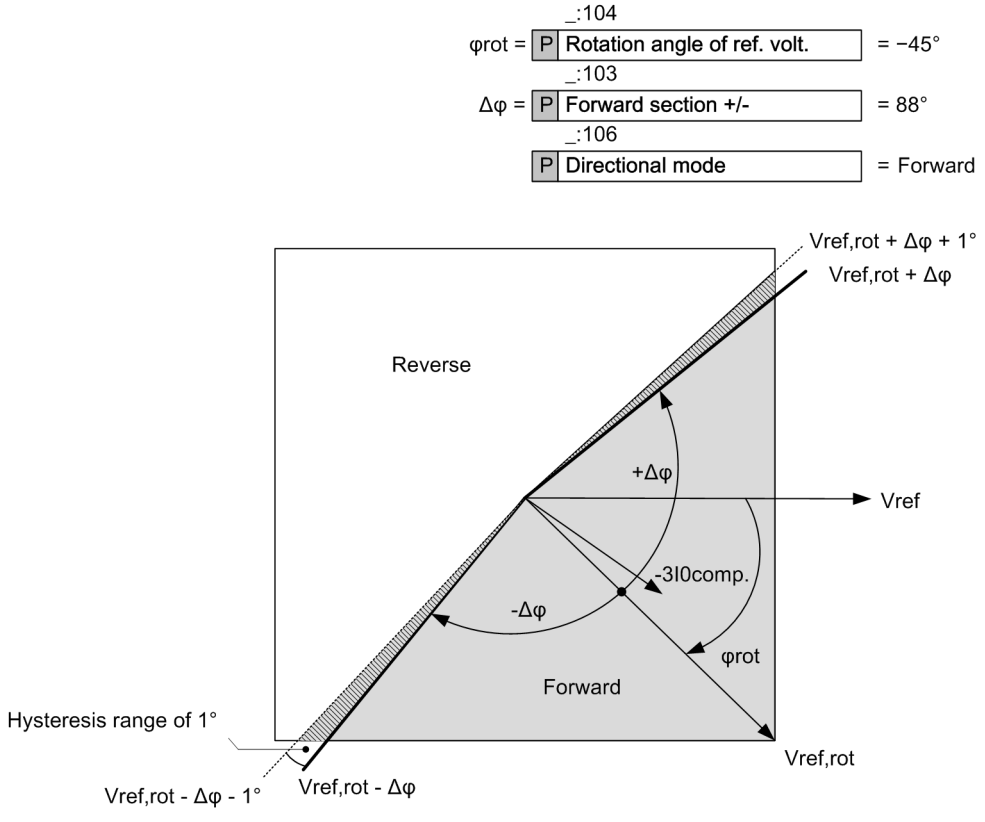
The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

The method of measurement processes the sampled current values and filters out the fundamental component numerically.

Depending upon the settings of the **`Connection type`** and **`Measuring point I-3ph`** parameters, as well as the current terminal blocks used, different linearity and setting ranges result, refer for this to chapter *6.15.4.1 Description* , Ground-Fault Detection, Pickup.

Ground-Fault Detection, Pickup

If the absolute value of the ground current 3I0 vector exceeds the threshold value **3I0> threshold value** and the absolute value of the zero-sequence voltage V0 vector exceeds the threshold value **Min. V0> for dir. determ.**, the stage detects the ground fault . The direction determination (see in the following paragraph) is started when the zero-sequence voltage exceeds the threshold. The result from the direction determination is only valid if the absolute value of the ground current 3I0 vector has also exceeded its threshold value. The direction result is indicated via the *Ground fault* signal (in the **General** function block).



As long as the direction result equals the parameterization direction (parameter **Directional mode**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands.

The direction is determined via the determination of the phase angle between the angle-error compensated ground current 3I0com. and the rotated zero-sequence voltage V0, indicated in the following as reference voltage $V_{ref,rot}$. To take different system conditions and applications into account, the reference voltage can be rotated through an adjustable angle (**Rotation angle of ref. volt.** parameter). This moves the vector of the rotated reference voltage close to the vector ground current -3I0com. Consequently, the result of direction determination is as reliable as possible.

The rotated reference voltage $V_{ref,rot}$ and the **Forward section +/-** parameter define the forward and reverse area. The forward area results as range ± Δφ around the rotated reference voltage $V_{ref,rot}$. The value ± Δφ is set with the **Forward section +/-** parameter. The remaining area besides the forward area is the reverse area. Between the forward and reverse area, a hysteresis is defined, refer to *Figure 6-134* .

[dwdirrot-011112-02.vsd, 1, en_US]

Figure 6-134 Directional Characteristic in Forward Mode

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>open* of the function block **Voltage transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that **measuring-voltage failure detection** blocks the stage or not.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking the Operate Indication via the Device-Internal Inrush-Current Detection Function

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked by exceeding of the threshold values due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started.

6.15.7.2 Application and Setting Notes

Parameter: **Operate & flt.rec. blocked**

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: **Blk. by meas.-volt. failure**

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>open* of the function block **Voltage transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: **Blk. w. inrush curr. detect.**

- Recommended setting value **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains unaffected by an enabling procedure.

Parameter: Directional mode

- Default setting **(_:106) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or reverse direction.

When the parameter **Directional mode** is set as ***non-directional***, the direction determination is not considered. The pickup condition depends only on the absolute values 3I0 and V0 and the respective thresholds.

Parameter: Rotation angle of ref. volt.,Forward section +/-

- Default setting **(_:104) Rotation angle of ref. volt.** = ***-45°***
- Default setting **(_:103) Forward section +/-** = ***88°***

With the **Rotation angle of ref. volt.** and **Forward section +/-** parameters, you set the direction characteristic, that is, the areas of forward and reverse. With this, you set the direction characteristic according to the system conditions and the neutral-point treatment.

Typical settings for the **Rotation angle of ref. volt.** parameter are:

- Arc-suppression-coil-ground system: 0°
- Isolated system: +45°
- Grounded system: -45°

The **Forward section +/-** parameter can normally be left at its default setting. A reduction of the forward area by a few degrees is practical, for example in an arc-suppression-coil-ground system with long cable feeders, that generate high capacitive fault currents.

Parameter: Min. V0> for dir. determ.

- Default setting **(_:102) Min. V0> for dir. determ.** = ***2.000 V***

With the **Min. V0> for dir. determ.** parameter, you determine the minimum voltage V0 necessary for the release of the direction determination that must be attained within the time delay **Dir. determination delay**.

Parameter: 3I0> threshold value

- Default setting **(_:101) 3I0> threshold value** = ***0.050 A***

The **3I0> threshold value** parameter allows you to set the ground-current sensitivity of the stage. Set the threshold value lower than the minimum absolute value of the ground-fault current 3I0 that must still be detected.

Parameter: Dir. determination delay

- Default setting **(_:105) Dir. determination delay** = ***0.10 s***

The start of the ground fault normally shows a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***0.50 s***

The parameterized time **Operate delay** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

6.15.8 Directional Y0 Stage with G0 or B0 Measurement

6.15.8.1 Description

[LoY0G0B0-300713-01, 4, en_US]

Figure 6-135 Logic Diagram of the Directional Y0 Stage with G0 or B0 Measurement

Measured Value V0, Method of Measurement

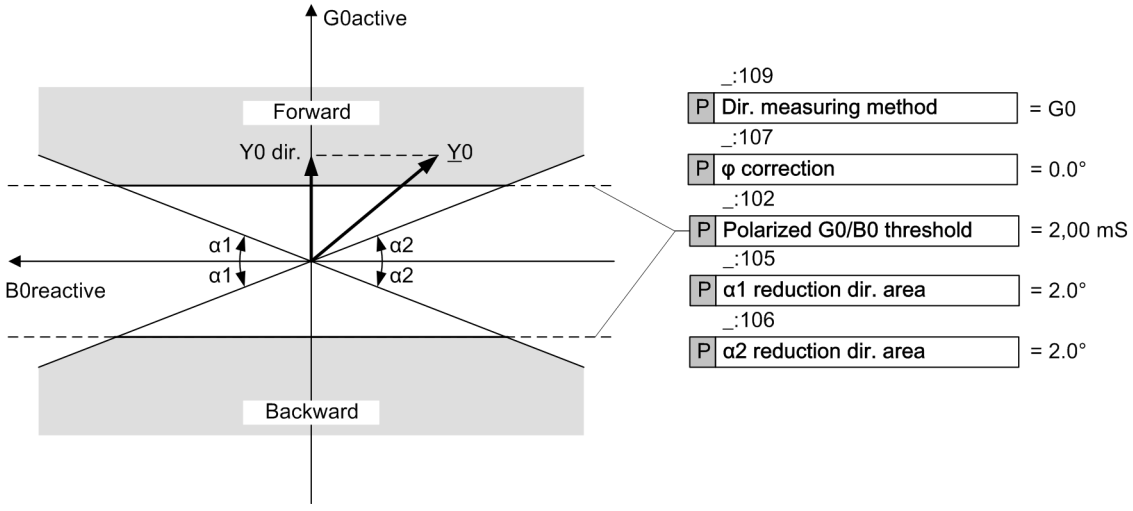
The device measures the residual voltage at the broken-delta winding. The measured voltage is converted to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages VA, VB, and VC using the definition equation.

This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, G0, B0, Method of Measurement

The function usually evaluates the ground current 3I0 sensitively measured via a core balance current transformer, this current being converted with the voltage V0 into the admittance Y0 = G0 + jB0. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 calculated from the phase currents. This results in a very large linearity and settings range.

The method of measurement processes the sampled current values and filters out the fundamental component numerically. The methods of measurement are characterized by high accuracy and by insensitivity to harmonics, especially the 3rd and 5th harmonics frequently present in the ground-fault (leakage) current.



Ground-Fault Detection, Pickup

If the absolute value of the ground current 3I0 exceeds the threshold value **`3I0> release thresh. value`** and the absolute value of the zero-sequence voltage V0 exceeds the threshold value **`V0> threshold value`**, the stage recognizes the ground fault. The calculation of G0 or B0 is started with exceeding the threshold values and then, the direction determination (see the following) is performed. The direction result is indicated via the *`Ground fault`* signal (in the **General** function block). If the direction result equals the parameterized direction (parameter **`Directional mode`**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **`Dir. determination delay`** parameter to achieve steady-state measurands. The result from the direction determination is only valid if the absolute value of the ground current 3I0 has also exceeded its release threshold value.

The following figure shows an example of the direction determination in the complex phasor diagram for the G0 direction measurement method with a correction value of the direction straight line from 0 (Parameter **`φ correction`**). The example is suitable for the determination of the ground-fault direction in an arc-suppression-coil-ground system where the value G0 is decisive for the direction determination.

[DwY0Dire-171012-01, 1, en_US]

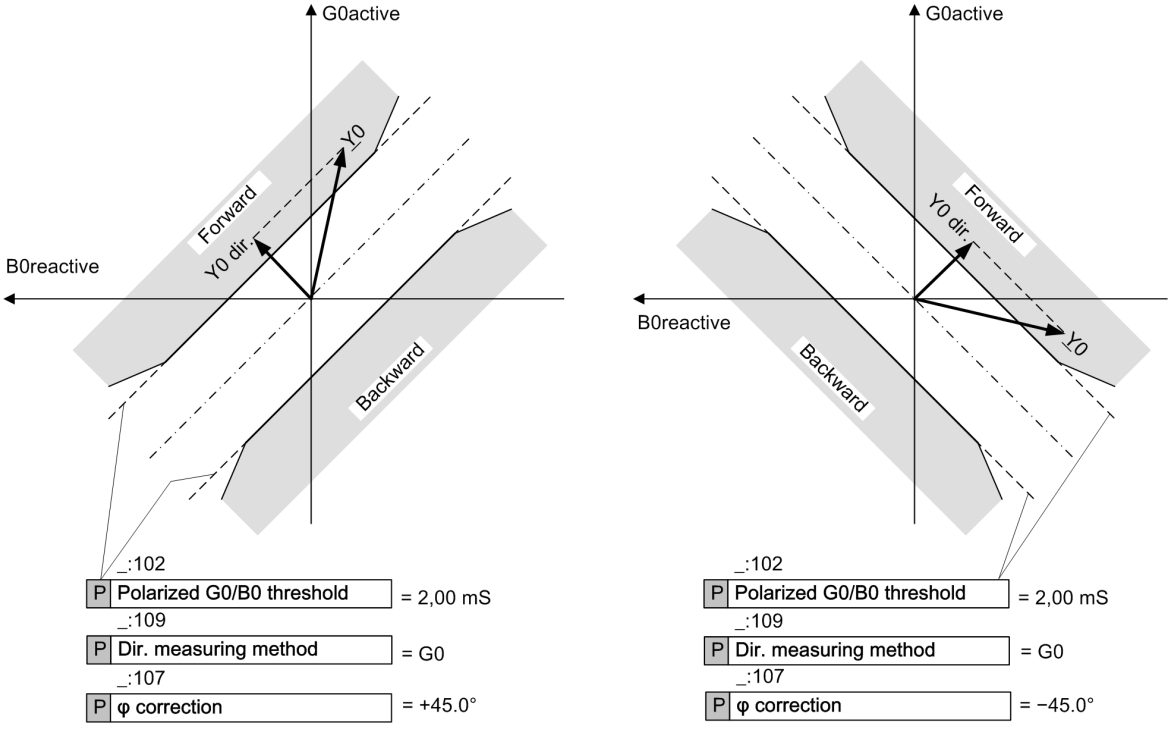


Figure 6-136 Direction-Characteristic Curve for the G0 Measurement

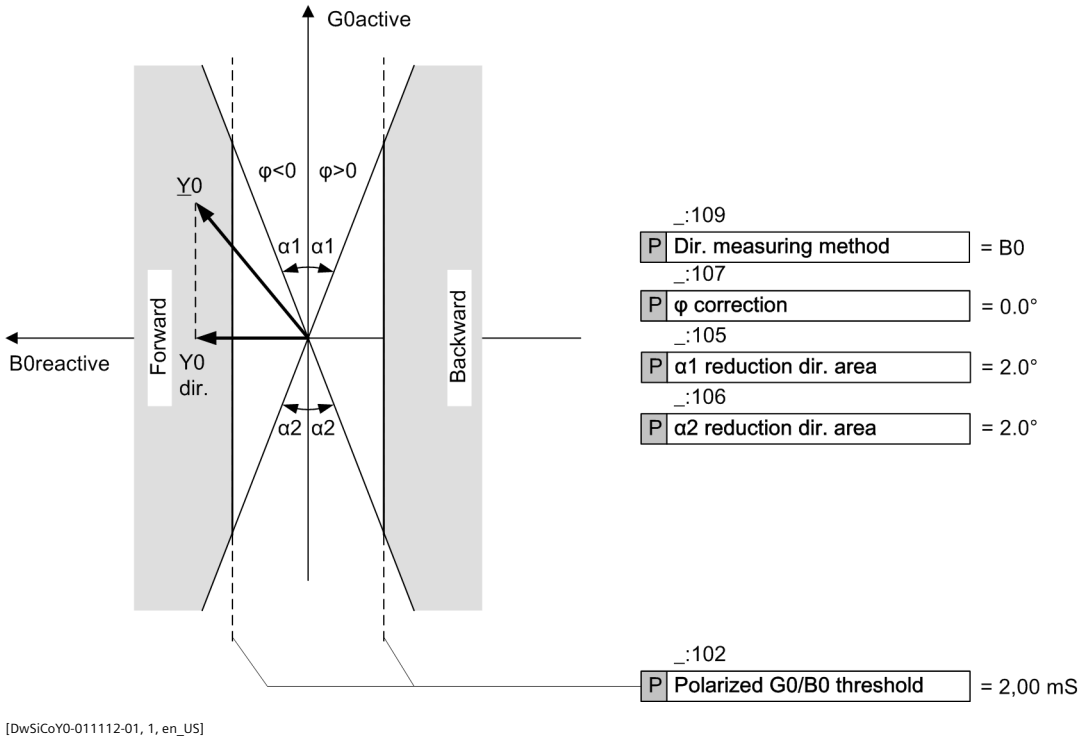
The zero-sequence voltage V0 is generally the reference value for the real axis and is identical to the G0 axis. The axis of symmetry of the direction-characteristic curve coincides with the B0 (reactive) axis for this example. For the direction determination, the component of the admittance perpendicular to the set direction-characteristic curve (= axis of symmetry) is decisive G0dir (=Y0dir). In this example, this is the active component **G0active** of the admittance Y0. The conductance G0dir. (here = G0active) is calculated and

compared with the setting value **Polarized G0/B0 threshold**. If the conductance G0dir. exceeds the positive setting value, the direction is forward. If the conductance G0dir. exceeds the negative setting value, the direction is backward. In the range in between, the direction is undetermined.

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you can limit the forward and backward ranges as shown in *Figure 6-137* . With this, the direction determination is secured in case of high currents in the direction of the axis of symmetry.

The symmetry axis can be turned via a correction angle (**φ correction** parameter) in a range of ±45. Through this, it is possible, for example, to attain the greatest sensitivity in grounded systems in the resistive-inductive range with a -45° turn. In the case of electric machines in busbar connection on the isolated system, the greatest sensitivity in the resistive-capacitive range can be attained with a turn of +45° (see following figure).



[DwY0meas-171012-01, 1, en_US]

Figure 6-137 Turning the Direction-Characteristic Curves with G0 Measurement with Angle Correction

If you set the **Dir. measuring method** parameter to B0 and the **φ correction** parameter to ***0***, the axis of symmetry of the direction-characteristic curve coincides with the G0 and V0 axes. Since the component of the admittance Y0 perpendicular to the direction-characteristic curve (= axis of symmetry) is decisive (B0dir. (=Y0dir.)), here, the susceptance B0 (reactive) is used in the direction determination. If the susceptance B0dir. (B0reactive) exceeds the negative setting value **Polarized G0/B0 threshold**, the direction is forward. If the susceptance B0dir. exceeds the positive setting value, the direction is backward. In the range in between, the direction is undetermined.

This direction measurement thus is appropriate for the determination of ground-fault direction in isolated systems.

[DwSiCoY0-011112-01, 1, en_US]

Figure 6-138 Direction-Characteristic Curve for the B0 Measurement

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>open* of the function block **Voltage transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that Measuring-voltage failure detection blocks the stage or does not block it.

Blocking the Pickup with Detection of the Fault Extinction

Using the evaluation of the instantaneous value developing of the zero-sequence voltage, the fault extinction can be recognized faster than via the dropout of the V0 fundamental-component value under the pickup value. The pickup of the stage is blocked with the fast detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. With the **Blk. after fault extinction** parameter, you enable or disable this accelerated detection of the fault extinction.

Blocking of the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking the Operate Indication via the Device-Internal Inrush-Current Detection Function

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked by exceeding of the threshold values due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started.

6.15.8.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage transformer circuit breaker** is linked with the voltage transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: Blk. w. inrush curr. detect.

- Recommended setting value **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains untouched by an enabling procedure.

Parameter: Blk. after fault extinction

- Recommended setting value **(_:110) Blk. after fault extinction** = ***yes***

If the **Blk. after fault extinction** parameter is set to ***yes***, the pickup is blocked after detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. Siemens recommends using the default setting.

Parameter: Directional mode

- Default setting **(_:108) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: **Dir. measuring method, φ correction, Polarized G0/B0 threshold, 3I0> release thresh. value**

- Default setting **(_:109) Dir. measuring method** = ***G0***
- Default setting **(_:107) φ correction** = ***0.0°***
- Default setting **(_:102) Polarized G0/B0 threshold** = ***2.00 mS***
- Default setting **(_:101) 3I0> release thresh. value** = ***0.002 A***

These parameters are used to define the direction characteristic of the stage. The direction characteristic to use is dependent on the neutral-point treatment of the system.

Note that, for the direction determination, basically only the component of the admittance perpendicular to the set direction-characteristic curve is decisive, see chapter *6.15.8.1 Description* . This admittance component is compared to the threshold value **Polarized G0/B0 threshold**. In contrast, the absolute value of the current 3I0 is compared with the **3I0> release thresh. value** parameter.

System Type/ Neutral-Point Treatment	Description
Grounded	In the arc-suppression-coil-ground system, the watt leakage current 3I0 · cos φ of the arc-suppression coil is decisive for the direction determination. To evaluate the watt leakage current, set the parameters as follows: • **Dir. measuring method** = *G0* • **φ correction** = *0.0°* The direction determination for a ground fault is made more difficult in that a much larger reactive current of capacitive or inductive character is superimposed on the small watt leakage current. Therefore, depending on the system configuration and the fault evaluation, the total ground current supplied to the device can vary considerably in its values regarding the magnitude and the phase angle. However, the device should only evaluate the active component of the ground-fault current. This requires extremely high accuracy, particularly regarding the phase-angle measurement of all the instrument transformers. Furthermore, the device must not be set to operate too sensitively. A reliable direction measurement can only be expected with connection to a core balance current transformer. For the setting of the **Polarized G0/B0 threshold** parameter, the following formula applies: $G0 > k_s \frac{I_{0active}}{\sqrt{3}V_{rated}} + \frac{I_{0min}}{V0>}$ where: k_s: Safety margin, k_s = 1.2 (cable networks), k_s = 2.0 (overhead lines) $I_{0active}$: Active component of the ground-fault current (watt leakage current) of the protected line V_{rated}: Secondary rated voltage in the healthy case I_{0min}: Min. ground current in the healthy case, 5 mA to 10 mA (core balance current transformer), 50 mA to 100 mA (Holmgreen transformer) V0>: Pickup threshold of the residual voltage $\approx 0.1\sqrt{3}V_{rated}$ If a parallel resistor Rp is used on the arc-suppression coil, the threshold value G0 must also be smaller than: $G0 \leq \frac{1}{k_s} \frac{I_{Rp}}{\sqrt{3}V_{rated}}$ where: k_s: Safety margin ≥ 1.5 I_{Rp}: Secondary rated current of the parallel resistor V_{rated}: Secondary rated voltage in the healthy case The **3I0> release thresh. value** parameter can be set to half of the expected measuring current and here, the entire zero-sequence current can be put to use.

System Type/ Neutral-Point Treatment	Description
Isolated	In the isolated system, the capacitive ground reactive current 3I0 · sin φ is decisive for the direction determination. To evaluate the capacitive ground reactive current, set the parameters as follows: • **Dir. measuring method** = ***B0*** • **φ correction** = ***0.0°*** In isolated systems, a ground fault allows the capacitive ground-fault currents of the entire electrically connected system, except for the ground current in the faulty cable itself, to flow through the measuring point as the latter flows directly away from the fault location (that is, not via the measuring point). The following formula can be used to determine the pickup value of the **Polarized G0/B0 threshold** parameter. $B0 \geq \frac{I_{0min}}{V0>}$ where: I_{0min}: Ground current in the healthy case V0>: Pickup threshold of the residual voltage $\approx 0.02\sqrt{3}V_{rated}$ In healthy operation, B0 ≤ 0. For the **3I0> release thresh. value** parameter, select around half of this capacitive ground-fault current flowing via the measuring point.
Resistance-Grounded	In the resistance-grounded system, the ohmic-inductive ground-fault current is decisive for the direction determination. To evaluate this short-circuit current, set the parameters as follows: • **Dir. measuring method** = ***G0*** • **φ correction**= ***-45.0°*** For the setting of the **Polarized G0/B0 threshold** parameter, the rule of thumb is: Set the pickup value according to the following formula where only the active ground-fault current can be put into use. $G0 > k_s \frac{I_{0active}}{\sqrt{3}V_{rated}} + \frac{I_{0min}}{V0>}$ where: k_s: Safety margin, k_s = 1.2 (cable networks), k_s = 2.0 (overhead lines) $I_{0active}$: Active component of the ground-fault current of the protected line V_{rated}: Secondary rated voltage in the healthy case I_{0min}: Min. ground current in the healthy case, 5 mA to 10 mA (core balance current transformer), 50 mA to 100 mA (Holmgreen transformer) V0>: Pickup threshold of the residual voltage $\approx 0.02\sqrt{3}V_{rated}$ The **3I0> release thresh. value** parameter must be set to a value below the minimum expected ground-fault current.

Parameter: **α1 reduction dir. area, α2 reduction dir. area**

- Recommended setting value **(_:105) α1 reduction dir. area** = ***2°***
- Recommended setting value **(_:106) α2 reduction dir. area** = ***2°***

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you specify the angle for the limitation of the direction range. Siemens recommends using the default setting of 2°.

In an arc-suppression-coil-ground system in feeders with a very large reactive current, it can be practical to set a somewhat larger angle α1 to avoid a false pickup based on transformer and algorithm tolerances.

Parameter: V0> threshold value

- Default setting **(_:103) V0> threshold value** = ***30.000 V***

The **V0> threshold value** parameter allows you to set the zero-sequence voltage sensitivity of the stage. The threshold value must be smaller than the minimum amount of the zero-sequence voltage V0 which must still be detected.

Parameter: Dir. determination delay

- Default setting **(_:104) Dir. determination delay** = ***0.10 s***

The start of the ground fault normally indicates a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed for this reason from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***2.0 s***

The parameterized time **Operate delay** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

6.15.9 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

6.15.9.1 Description

Logic

[logfpsv0-291112-01.tif, 3, en_US]

Figure 6-139 Logic Diagram of the Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

Measured Value, Method of Measurement

The device measures the residual voltage at the broken-delta winding. The measured voltage is converted to the zero-sequence voltage V_0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V_0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

Use the **Method of measurement** parameter to select the relevant method of measurement, depending on the application:

- Measurement of the fundamental component (standard filter):
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.
- Measurement of the RMS value (true RMS):
  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value.
- Measurement of the fundamental component over 2 cycle filters with triangular window:
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically. The extended filter length compared to the standard filter and the use of the triangular window results in a particularly strong attenuation of harmonics and transient faults. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see *12.18.6 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage*).

Pickup, Dropout

The stage compares the **Threshold** with the zero-sequence voltage V_0. The **Pickup delay** parameter allows you to delay the pickup of the stage depending on the residual voltage.
With the **Dropout ratio** parameter, you can define the ratio of the dropout value to the **Threshold**.

Determination of the Faulty Phase

With the **Detection of faulty phase** parameter, you can enable or disable the determination of the ground-fault phase. Determining is released when the stage picks up. If 2 phases exceed the threshold value **V> healthy ph-to-gnd volt.** and one phase falls below the threshold value **V< faulty ph-to-gnd volt.**, the last phase is determined to be faulty and is signaled as such.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal **>Block stage** from an external or internal source
- From inside on pickup of the **measuring-voltage failure detection** function. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal *>open* of the function block **Voltage transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or not.

6.15.9.2 Application and Setting Notes

Parameter: **Operate & flt.rec. blocked**

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: **Method of measurement**

- Recommended setting value **(_:8) Method of measurement** = ***fundamental comp.***

The **Method of measurement** parameter allows you to define whether the function works with the fundamental component or the calculated RMS value.

Parameter Value	Description
fundamental comp.	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks).
fund. comp. long filter	To implement particularly strong damping of harmonics and transient faults, select this method of measurement. At 2 periods, the length of the filter is longer than that of the standard filter. Note that in this case the pickup time of the stage increases slightly (see *12.18.6 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage*).

Parameter: `Pickup delay`

- Recommended setting value **`(_:107) Pickup delay`** = ***`0 ms`***

The **`Pickup delay`** parameter allows you to delay the analysis of the measurand (to generate the pickup) depending on the occurrence of the residual voltage. A pickup delay can be necessary if high transients are anticipated after fault inception due to high line and ground capacitances.
Siemens recommends using the default setting **`Pickup delay`** = ***`0 ms`***.

Parameter: `Threshold`

- Default setting **`(_:3) Threshold`** = ***`30 V`***

The threshold value of the function is set as the zero-sequence voltage V_0. The device calculates the zero-sequence voltage V_0 either from the residual voltage measured via the broken-delta winding or from the 3 phase-to-ground voltages.
The setting value depends on the system grounding:

- Since virtually the full residual voltage occurs during ground faults in isolated or arc-suppression-coil-grounded systems, the setting value is uncritical there. Siemens recommends setting the value between 20 V and 40 V. A higher sensitivity (= lower threshold value) can be necessary for high fault resistances.
- Siemens recommends setting a more sensitive (smaller) value in grounded systems. This value must be higher than the maximum residual voltage anticipated during operation caused by system unbalances.

EXAMPLE

For an isolated system

The residual voltage is measured via the broken-delta winding:

- If the ground fault is fully unbalanced, a residual voltage of 100 V is present at the device terminals.
- The threshold value should be set so that the stage picks up on 50 % of the full residual voltage.
- At full residual voltage, the zero-sequence voltage is 100 V/√3 = 57.7 V
  Setting value: 0,5 · 57.7 V = 28.9 V ≈ 30 V

Parameter: `Dropout ratio`

- Recommended setting value **`(_:4) Dropout ratio`** = ***`0.95`***

The recommended setting value of ***`0.95`*** is appropriate for most applications. To achieve high measurement precision, the dropout ratio can be reduced to 0.98, for example.

Parameter: `Operate delay`

- Default setting **`(_:6) Operate delay`** = ***`3.00 s`***

The **`Operate delay`** allows you to prevent transient residual voltages from initiating a trip. The setting depends on the specific application.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage transformer circuit breaker** is linked with the voltage transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: Detection of faulty phase

- Default setting **(_:109) Detection of faulty phase** = ***no***

The **Detection of faulty phase** parameter controls how the stage responds to determine which phase is affected by the ground fault.

Parameter Value	Description
no	The phase affected by the ground fault is not determined. Select the default setting if you do not want to use the stage to detect ground faults, for example for applications in grounded systems.
yes	After a pickup by the residual voltage, the device tries to determine which phase is affected by the ground fault. Select this setting for applications in isolated or arc-suppression-coil-grounded systems.

Parameter: V< faulty ph-to-gnd volt.

- Default setting **(_:104) V< faulty ph-to-gnd volt.** = ***30 V***

Set the threshold value for determining which phase is affected by the ground fault in the **V< faulty ph-to-gnd volt.** parameter. The setting value is a phase-to-ground quantity.

The set value must be smaller than the minimum phase-to-ground voltage occurring during operation. Siemens recommends using the default setting **V< faulty ph-to-gnd volt.** = ***30 V***.

Parameter: V> healthy ph-to-gnd volt.

- Default setting **(_:101) V> healthy ph-to-gnd volt.** = ***70 V***

Set the threshold value for the 2 healthy phases in the **V> healthy ph-to-gnd volt.** parameter. The setting value is a phase-to-ground measurand.

The set value must be above the maximum phase-to-ground voltage occurring during operation, but below the minimum phase-to-phase voltage present during operation. At V_{rated} = 100 V, the value has to be set to 70 V, for example. Siemens recommends using the default setting **V> healthy ph-to-gnd volt.** = ***70 V***.

Operation as Supervision Function

If you want the stage to have a reporting effect only, the generation of the operate indication and fault logging can be disabled via the **(_:2) Operate & flt.rec. blocked** parameter.

6.15.10 Non-Directional 3I0 Stage

6.15.10.1 Description

In the **Directional sensitive ground-fault detection** function, the **Non-directional 3I0 stage** also works on demand.

Logic

[logfpdyn-291112-01.tif, 1, en_US]

Figure 6-140 Logic Diagram of the Non-Directional 3I0 Stage

Measured Value 3I0

The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

Depending upon the settings of the **`Connection type`** and **Measuring point I-3ph** parameters, as well as the current terminal blocks used, different linearity and setting ranges result, refer for this to chapter *6.15.4.1 Description* , Ground-Fault Detection, Pickup.

Method of Measurement

You use the **`Method of measurement`** parameter to define whether the stage uses the ***`fundamental comp.`*** or the calculated ***`RMS value`***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.

- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking the Tripping via the Device-Internal Inrush-Current Detection Function

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked by exceeding of the threshold values due to an inrush current. In case of a blocking, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started.

6.15.10.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording and the fault log with the **Operate & flt.rec. blocked** parameter. In this case a ground-fault log is created instead of the fault log.

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the tripping is blocked during the detection of an inrush current.

Parameter: Method of measurement

- Recommended setting value **(_:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Threshold

- Default setting **(_:3) Threshold** = ***0.050 A***

The **Threshold** parameter allows you to set the threshold value of the ground current 3I0.

Parameter: `Pickup delay`

- Default setting **`(_:102) Pickup delay`** = ***`0.00 s`***

With the parameter **`Pickup delay`** you set whether pickup of the stage is to be delayed or not. If the transient cycle of the ground fault occurrence should not be evaluated, set a delay of 100 ms, for example.

Parameter: `Operate delay`

- Default setting **`(_:6) Operate delay`** = ***`0.30 s`***

The parameterized time **`Operate delay`** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

6.15.11 Non-Directional Y0 Stage

6.15.11.1 Description

In the **Directional sensitive ground-fault detection** function, the **Non-directional Y0 stage** also works on demand.

Logic

[logfpsy0-240614-01.vsd, 1, en_US]

Figure 6-141 Logic Diagram of the Non-Directional Y0 Stage

Measured Value 3I0, Y0

The function evaluates the sensitively measured ground current 3I0 via a core balance current transformer, this current being converted with the voltage V0 into the admittance Y0=I0/V0. Since the linearity range of the

sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

Depending on the settings of the **Connection type** and **Measuring point I-3ph** parameters, as well as the current terminal block used, different linearity and setting ranges result, refer for this to chapter *6.15.8.1 Description* .

Blocking the Stage via Binary Input Signal

Blocking of the stage is possible externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pick up of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>open* of the function block **Voltage transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

Blocking of the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Operate Indication via the Device-Internal Inrush-Current Detection Function

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked by exceeding of the threshold values due to an inrush current. In case of a blocking, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started.

6.15.11.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected. A measuring-voltage failure can only be detected if 1 of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.

Parameter Value	Description
no	The protection stage is not blocked.

Parameter: **Blk. w. inrush curr. detect.**

- Default setting **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the operate is blocked during the detection of an inrush current.

Parameter: **V0> threshold value**

- Default setting **(_:101) V0> threshold value** = ***5.000 V***

The **V0> threshold value** parameter allows you to set the zero-sequence voltage sensitivity of the stage. The threshold value must be smaller than the minimum amount of the zero-sequence voltage V0 which must still be detected.

Parameter: **Threshold Y0>**

- Default setting **(_:102) Threshold Y0>** = ***2.00 mS***

With the parameter **Threshold Y0>**, you set the threshold value of the ground admittance Y0. If the ground admittance for the setting value is unknown, you can assume the following relation:

$$Y0 > k_s \frac{I_{c,line}}{3V_{ph-gnd}} + \frac{3I_{0min}}{V0>}$$

[fo_SeGfY0-270614-01, 2, en_US]

k_s:	Factor, takes into account the ohmic components of the current (1.2 for overhead lines, 1.0-1.05 for cable systems)
$I_{c,line}$	Secondary capacitive ground-fault current for the protected line
V_{ph-gnd}	Secondary phase-to-ground voltage in the healthy case
$3I_{0min}$	Secondary ground current in the healthy case (resulting from transformer error), 5 mA to 10 mA (core balance current transformer), 50 mA to 100 mA (Holmgreen transformer)
V0>	Secondary pickup threshold of the residual voltage

Parameter: **Pickup delay**

- Default setting **(_:103) Pickup delay** = ***0.00 s***

With the parameter **Pickup delay**, you set whether pickup of the stage is to be delayed or not. If the transient cycle of the ground fault occurrence should not be evaluated, set a delay of 100 ms, for example.

Parameter: **Operate delay**

- Default setting **(_:6) Operate delay** = ***0.30 s***

The parameterized time **Operate delay** determines the minimum time within which the pickup conditions must be present. An operate indication is only issued when this time is exceeded.

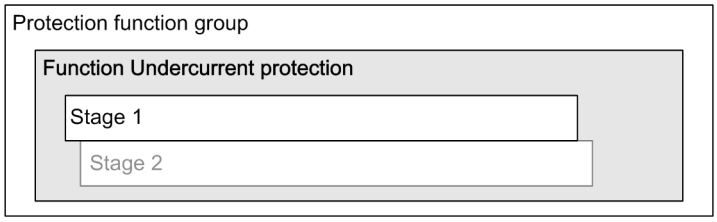
6.16 Undercurrent Protection

6.16.1 Overview of Functions



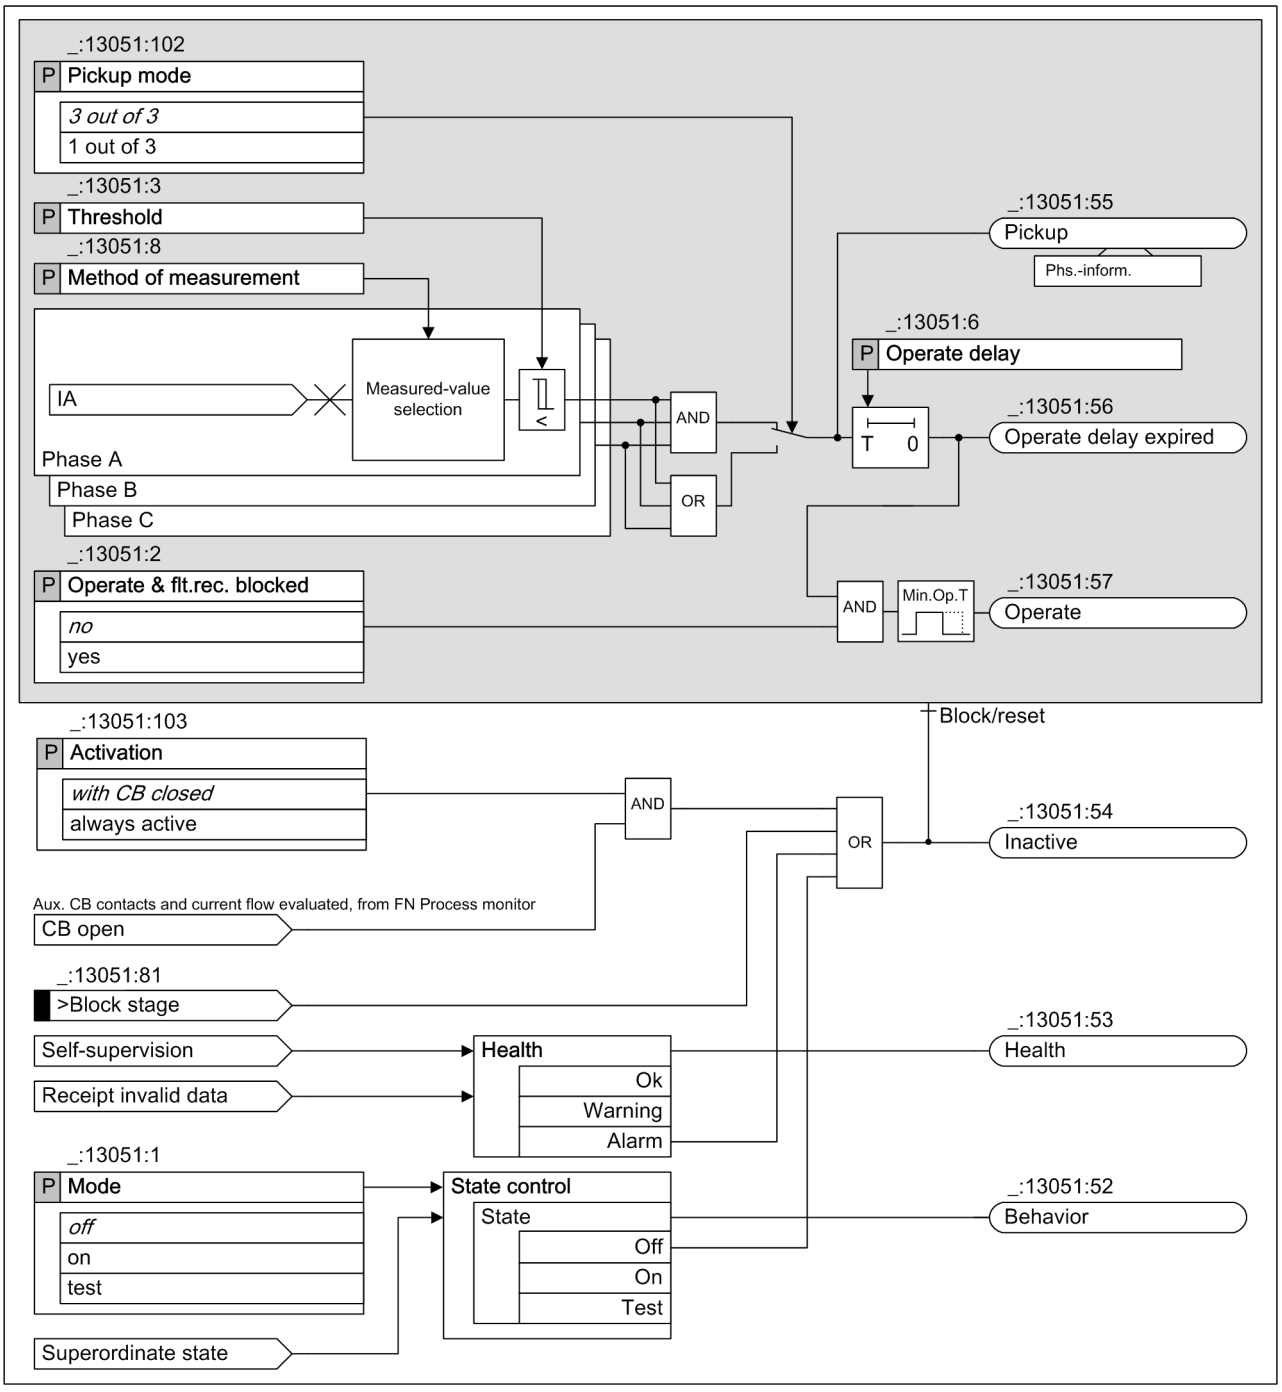
The **Undercurrent protection** function (ANSI 37):

- Detects the going current in a feeder after the opening of the infeed circuit breaker
- Detects the loss of loads
- Detects and protects pumps from running idle

6.16.2 Structure of the Function

The **Undercurrent protection** function is used in protection function groups with current measurement.

The **Undercurrent protection** function comes with 1 protection stage preconfigured at the factory. A maximum of 2 protection stages can be operated simultaneously in this function. The protection stages are structured identically.



[lostuundcu-150813, 2, en_US]

Figure 6-142 Structure/Embedding of the Function

6.16.3 Stage Description Undercurrent Protection

Logic of the Stage

[loundcur-200713-01.tif, 1, en_US]

Figure 6-143 Logic Diagram of the Undercurrent Protection

Method of Measurement

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

- Measurement of the fundamental comp.:
  This measurement method processes the sampled current values and numerically filters out the fundamental component.
- Measurement of the parameter value RMS value:
  This measurement method determines the current amplitude from the sampled values according to the definition equation of the RMS value. Harmonics are included in the analysis.

Pickup Mode

The **Pickup mode** parameter defines whether the protection stage picks up if all 3 measuring elements detect the undercurrent condition (***3 out of 3***) or if only 1 measuring element has to detect the undercurrent condition (***1 out of 3***).

Blocking the Stage

When blocked, the picked-up protection stage will drop out. Blocking the stage is possible externally or internally via the binary input signal *>Block stage*.

Activation and Blocking of the Stage Depending On the Circuit-Breaker Condition

With the parameter **Activation**, you define if the **Undercurrent protection** stage is always active or only active if the circuit breaker is indicating **closed**.

If the parameter **Activation** is set to ***with CB closed*** and the local circuit breaker is not **closed**, the function **Undercurrent protection** is blocked and no pickup is generated.

The circuit-breaker position is detected as **closed** if one of the following condition is met:

- The binary inputs are connected to the auxiliary contacts of the circuit breaker. The circuit-breaker switch position is detected as **closed** via the related binary inputs of the **Position** indication. This is also true under the condition that no phase current is flowing.
- The current-flow criterion indicates that the circuit breaker is **closed**. This is also true under the condition that the auxiliary contacts indicate the circuit breaker as **open**.

6.16.4 Application and Setting Notes

Parameter: Activation

- Default setting **(_:13051:103) Activation** = ***with CB closed***

Parameter Value	Description
with CB closed	The **Undercurrent protection** is active only when the circuit-breaker position is detected as **closed**. A precondition is, that the **Position** indication is routed to binary inputs to obtain the CB position information via the CB auxiliary contacts. If this is not the case, the function will always be inactive.
always active	The **Undercurrent protection** stage is always active independent of the position of the circuit breaker.

Parameter: Method of measurement

- Recommended setting value **(_:13051:8) Method of measurement** = ***fundamental comp.***

Use the **Method of measurement** parameter to define whether the tripping stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient current peaks. Siemens recommends using this method as default setting.

Parameter Value	Description
RMS value	Select this measurement method if you want the stage to take harmonics into account (for example, at capacitor banks).

Parameter: `Pickup mode`

- Default setting **`(_:13051:102) Pickup mode`** = ***`3 out of 3`***

Use the **`Pickup mode`** parameter to define whether the protection stage picks up if all 3 measuring elements detect the undercurrent condition (***`3 out of 3`***) or if only 1 measuring element has to detect the undercurrent condition (***`1 out of 3`***).

Parameter: `Threshold`

- Default setting **`(_:13051:3) Threshold`** = ***`0.050 A`***

Specify the **`Threshold`** (pickup threshold) for the specific application.

Parameter: `Operate delay`

- Default setting **`(_:13051:6) Operate delay`** = ***`0.05 s`***

Operate delay must be set according to the specific application. No general application notes can be given.

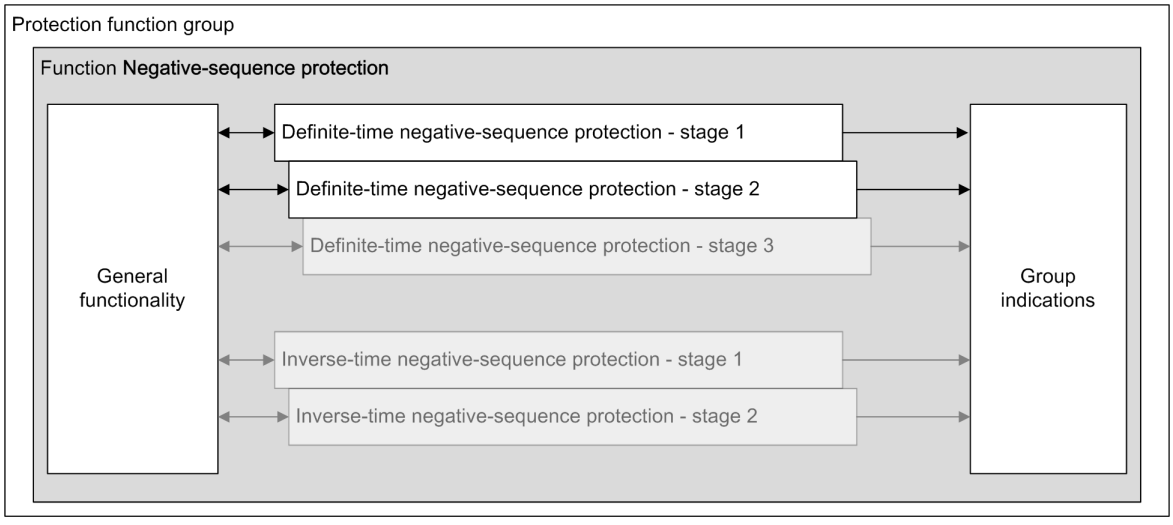
6.17 Negative-Sequence Protection

6.17.1 Overview of Functions

The function **Negative-sequence protection** (ANSI 46):

- Detects 1-phase or 2-phase short circuits in the electrical power system with clearly increased sensitivity compared to the classical overcurrent protection
- Protects electric machines during excessive unbalanced load
- Reports unbalanced load conditions in the electricity supply system
- Detects phase interruptions in the primary system
- Locates short circuits or inversions in the connections to the current transformers

6.17.2 Structure of the Function



The **Negative-sequence protection** function is used in protection function groups with current measurement.

The function is preconfigured by the manufacturer with 2 **Definite-time negative-sequence protection** stages.

In the function **Negative-sequence protection**, the following stages can be operated simultaneously:

- 3 stages **Definite-time negative-sequence protection**
- 2 stages **Inverse-time negative-sequence protection**

The stages have an identical structure. Stages that are not preconfigured are shown in gray in the following figure.

[dwnspstr-271112-01.tif, 3, en_US]

Figure 6-144 Structure/Embedding of the Function

If the device is equipped with the **Inrush-current detection** function, the stages can be stabilized against operate due to transformer-inrush currents.

6.17.3 General Functionality

6.17.3.1 Description

Logic

The following figure represents the logic of the general functionality which applies across all configured stages. It contains:

- Selection of the reference value
- Current-release criterion

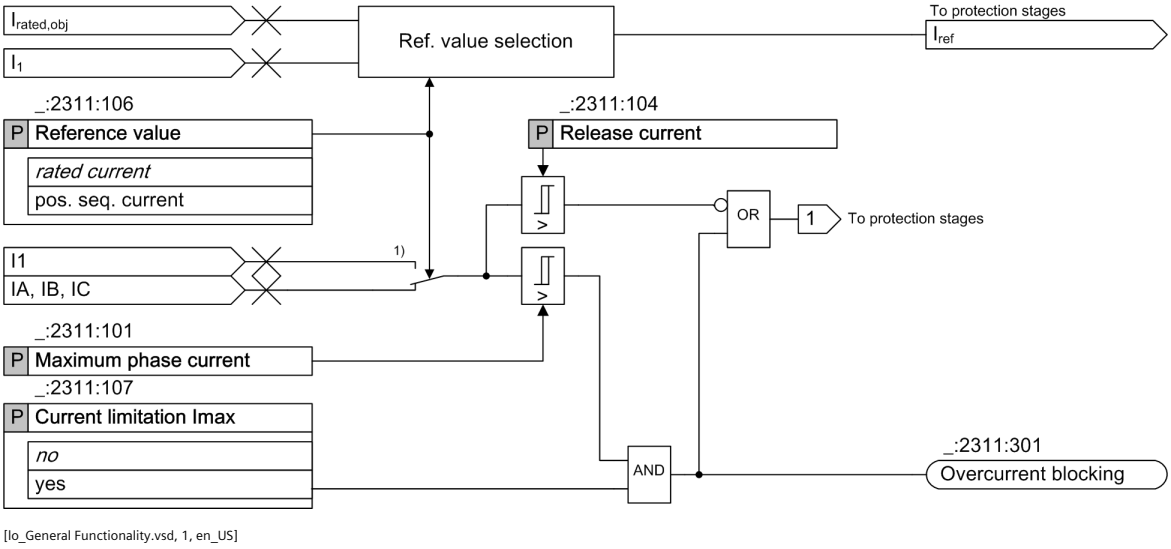


Figure 6-145 Logic Diagram of the General Functionality

(1) Switchover to I_1 with **(_:2311:106) Reference value** = ***pos. seq. current***

Reference Value

With the parameter **Reference value**, the negative-sequence current I_2 is normalized to the rated object current $I_{rated, obj}$ or to the positive-sequence current I_1. When I_2 is normalized to I_1, the sensitivity of the function for low short-circuit currents is increased.

Current Limitation and Maximum Phase Current

With the parameters **Current limitation Imax** and **Maximum phase current**, you restrict the operating range of the function. When the limiting is activated, pickup of the stages is blocked as soon as the maximum phase-current threshold value is exceeded. For more information, refer to the stage description.

Release Current

The threshold value of the **Release current** serves to release the negative-sequence protection.

6.17.3.2 Application and Setting Notes

Parameter: Reference value

- Default setting **(_:2311:106) Reference value** = ***rated current***

With the parameter **Reference value**, you define the normalization of the negative-sequence current I_2 to the rated object current $I_{rated, obj}$ ($I_2/I_{rated, obj}$) or to the positive-sequence current I_1 (I_2/I_1).

Parameter Value	Description
$I_2/I_{rated, obj}$	The negative-sequence current is referred to the rated current of the protected object. This is a preferred normalization for electrical machines, because the permissible limiting values are indicated exclusively referred to the machine rated current. You can also use this normalization for other applications.
I_2/I_1	The normalization of the negative-sequence system to the positive-sequence system yields a higher sensitivity. Use this normalization when detecting interruptions in the primary system.

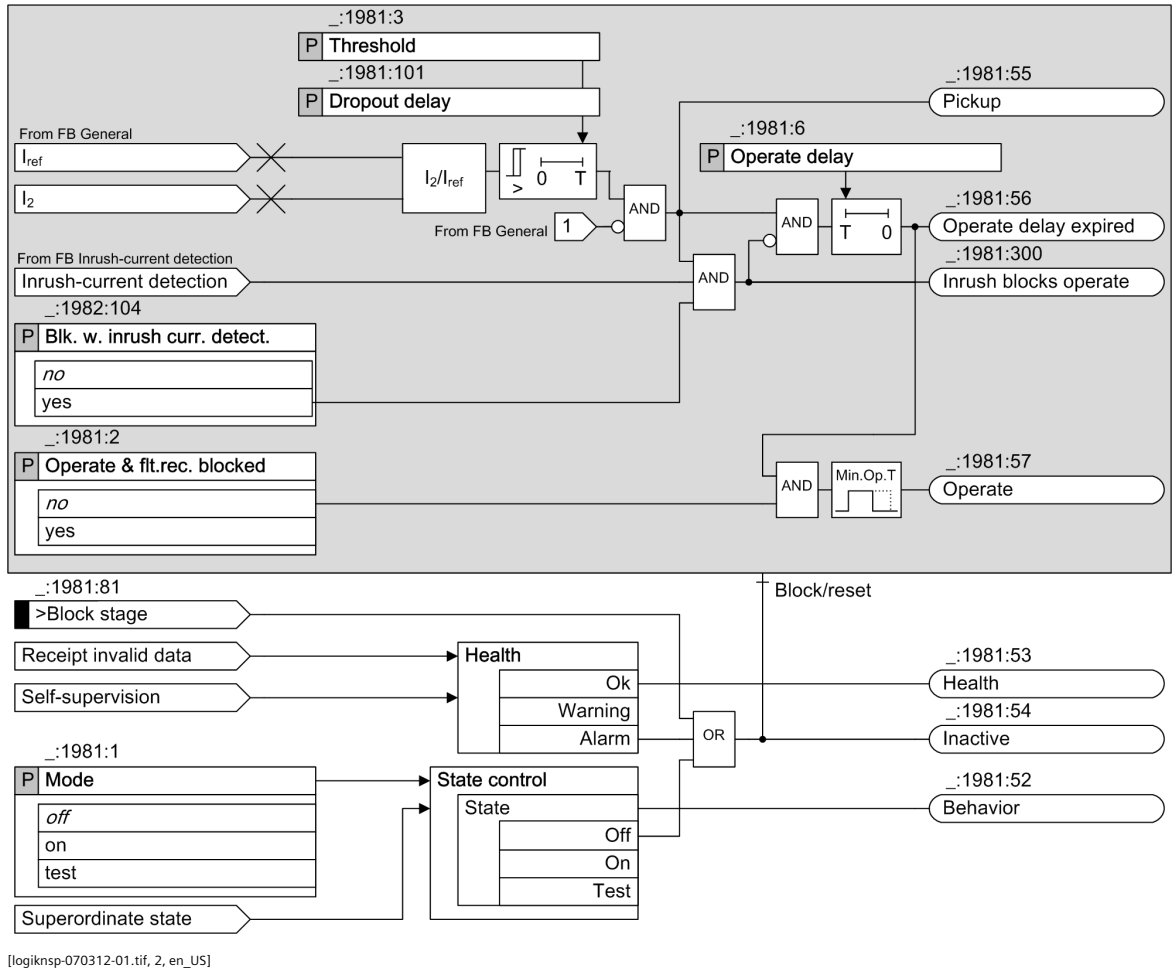
Set the parameter depending on the application.

Parameter: **Current limitation Imax, Maximum phase current**

- Default setting **(_:2311:107) Current limitation Imax** = ***no***
- Recommended setting value **(_:2311:101) Maximum phase current** = ***10.0 A at 1 A***

If the protection function needs a maximum current limitation, set the value of the **Current limitation Imax** parameter from ***no*** to ***yes***. With the parameter **Maximum phase current**, you set the upper limit of the phase current. CT saturation will cause negative-sequence current in the secondary system. To avoid over-function due to the CT saturation, a suitable phase-current limit value is 10 times of the rated protection-object current.

Parameter: **Release current**



- Recommended setting value **(_:2311:104) Release current** = ***0.05 A at 1 A***

For the safe calculation of negative-sequence currents, the current in at least one phase must be greater than 5 % of the secondary rated device current. For a 1-A device, the value of **Release current** is 0.05 A (0.25 A for a 5-A device).

6.17.4 Stage with Definite-Time Characteristic Curve

6.17.4.1 Stage Description

Logic of a Stage

[logiknsp-070312-01.tif, 2, en_US]

Figure 6-146 Logic Diagram of the Stage Negative-Sequence Protection with Definite-Time Characteristic Curve

Method of Measurement

The fundamental phasors are calculated from the 3-phase phase currents. Based on this, the negative-sequence system and the positive-sequence system are calculated. Following this, the negative-sequence current is normalized to the reference current. The selection of the reference current is made in the **FB General**.

Blocking of the Stage

When blocked, the picked-up protection stage will drop out.

Blocking the stage is possible externally or internally via the binary input signal **`>Block stage`**.

Blocking of Tripping via the Device-Internal Inrush-Current Detection Function

With the **`Blk. w. inrush curr. detect.`** parameter, you can define whether tripping of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking, the stage picks up. The start of the time delay and tripping are however blocked. The stage signals this by way of a

corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the tripping delay (time delay) is started. After that time, the stage operates.

6.17.4.2 Application and Setting Notes

Parameter: `Threshold`

- Recommended setting value **`(_:1981:3) Threshold`** = ***`10 %`***

The setting of the parameter **`Threshold`** depends on the respective application. A threshold value of 10 % is a practicable value for fault indications of electrical machines.

Parameter: `Operate delay`

- Recommended setting value **`(_:1981:6) Operate delay`** = ***`1500 ms`***

The setting of the **`Operate delay`** depends on the application. Observe the time grading in the power-system protection and do not set the time for monitoring too short. The default setting is practicable. For motors, the time depends on the permissible time period for the set unbalanced load.

Parameter: `Blk. w. inrush curr. detect.`

- Default setting **`(_:1981:104) Blk. w. inrush curr. detect.`** = ***`no`***

With the parameter **`Blk. w. inrush curr. detect.`**, the stage can be stabilized against tripping on transformer-inrush currents. If transformers are parts of the protection zones, set this parameter to **`yes`**.

6.17.5 Stage with Inverse-Time Characteristic Curve

6.17.5.1 Description

Logic of a Stage

[lo_NSP_Inverse, 1, en_US]

Figure 6-147 Logic Diagram of the Negative-Sequence Protection with Inverse-Time Characteristic Curve

Method of Measurement

The fundamental phasors are calculated from the 3-phase phase currents. Based on this, the negative-sequence system and the positive-sequence system are calculated. Following this, the negative-sequence current is normalized to the reference current. The selection of the reference current is made in the **FB General**.

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve according to IEC and ANSI

When the input variable exceeds the threshold value by a factor of 1.1, the stage picks up, and the inverse-time characteristic curve is processed. An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls below the pickup value by a factor of 0.95 (0.95 · 1.1 · threshold value), the dropout is started. The pickup is indicated as clearing. You can influence the dropout behavior via setting

parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

Blocking of the Stage

When blocked, the picked-up protection stage will drop out.

Blocking the stage is possible externally or internally via the binary input signal **>Block stage**.

Blocking of Tripping via the Device-Internal Inrush-Current Detection Function

With the **Blk. w. inrush curr. detect.** parameter, you can define whether tripping of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking, the stage picks up. The start of the time delay and tripping are however blocked. The stage signals this by way of a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the tripping delay (time delay) is started. After that time, the stage operates.

6.17.5.2 Application and Settings Notes

Parameter: Type of character. curve

- Default setting **(_:105) Type of character. curve** = ***IEC normal inverse***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **Type of character. curve** required for your specific application. For more information about the parameter **Type of character. curve**, refer to chapter *12.20.2 Stage with Inverse-Time Characteristic Curve*.

Parameter: Threshold

- Recommended setting value **(_:3) Threshold** = ***10.0 %***

The setting of the parameter **Threshold** depends on the respective application. A threshold value of 10 % is a practicable value for fault detection for different applications.

Parameter: Time dial

- Recommended setting value **(_:107) Time dial** = ***1.00***

With the parameter **Time dial**, you displace the characteristic curve in the time direction.

The set value for the parameter **Time dial** is derived from the time-grading schedule that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the **Time dial** parameter at 1.00 (default setting).

Parameter: Reset

- Default setting **(_:106) Reset** = ***disk emulation***

With the parameter **Reset**, you define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:104) Blk. w. inrush curr. detect.** = ***no***

With the parameter **Blk. w. inrush curr. detect.**, the stage can be stabilized against tripping on transformer-inrush currents. If transformers are parts of the protection zones, set this parameter to ***yes***.

6.17.5.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Inverse-T #				
_:1	Inverse-T #:Mode		• off • on • test	off

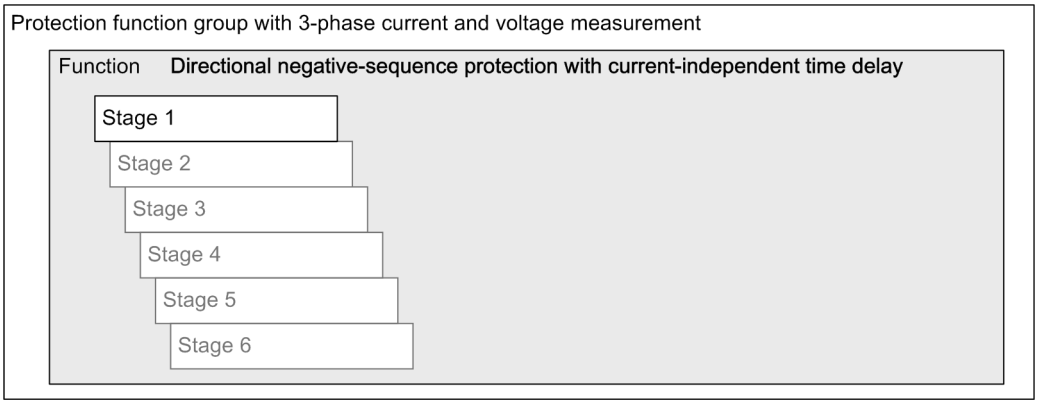
6.18 Directional Negative-Sequence Protection

6.18.1 Overview of Functions

The function **Directional negative-sequence protection with current-independent time delay** (ANSI 46) serves as the backup short-circuit protection for unbalanced faults.



With the negative-sequence system, various supervision and protection tasks can be realized, for example:

- Recording of 1 or 2-phase short circuits in the system with a higher sensitivity than in classic overcurrent protection. The pickup value can be set under the rated object current.
- Recording of phase conductor interruptions in the primary system and in the current-transformer secondary circuits
- Location of short circuits or reversals in the connections to the current transformers
- Indication of unbalanced states in the energy system
- Protection of electrical machines following unbalanced loads that are caused by unbalanced voltages or conductor interruptions (for example, through a defective fuse)

6.18.2 Structure of the Function

The **Directional negative-sequence protection with definite time delay** function can be used in protection function groups with 3-phase current and voltage measurement.

The function comes factory-set with 1 stage. A maximum of 6 tripping stages can be operated simultaneously in the function.

[dwnspdir-271112-01.tif, 1, en_US]

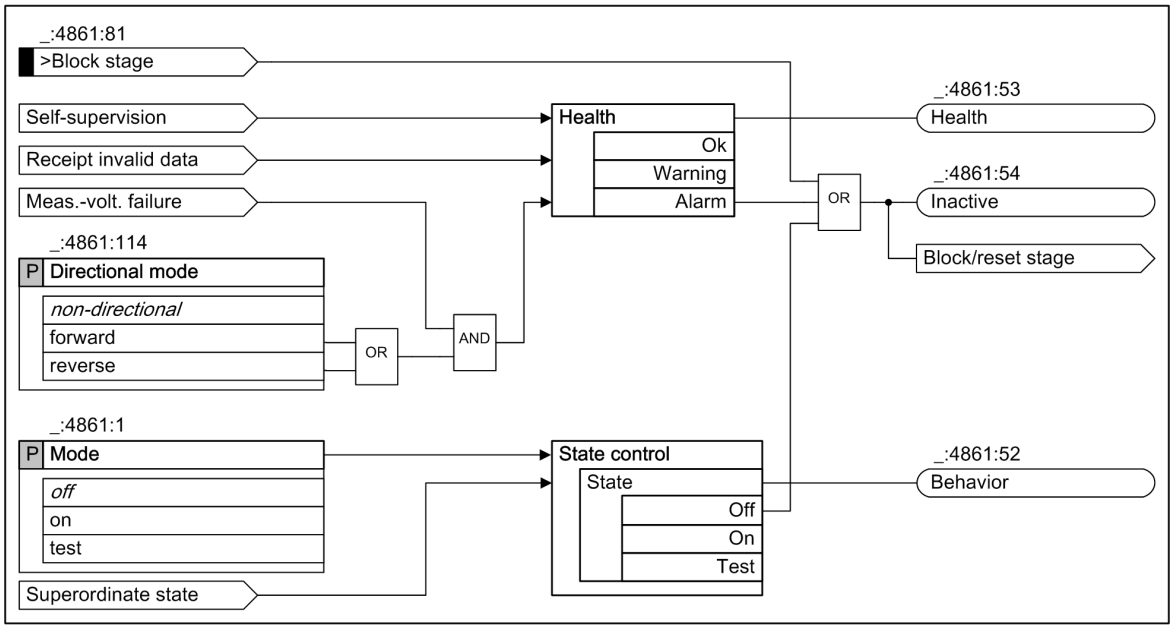


Figure 6-148 Structure/Embedding of the Function

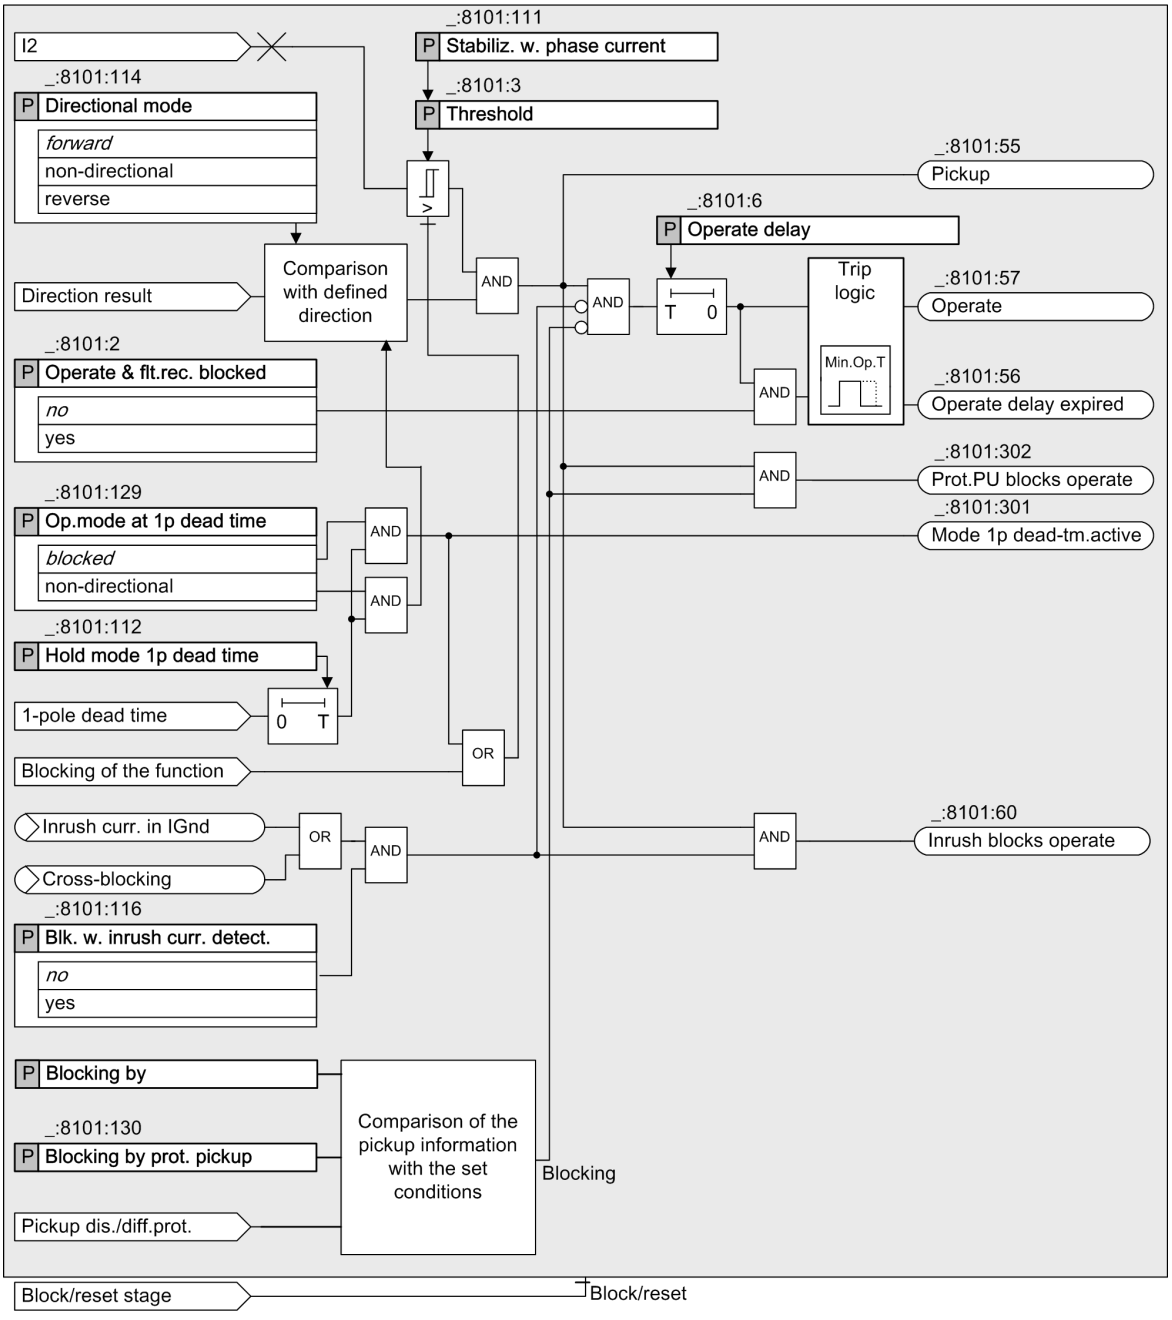
If the device is equipped with the **Inrush-current detection** function, the tripping stages can be stabilized against tripping due to transformer-inrush currents.

6.18.3 Function Description

Stage Control

The following figure shows a stage control. It is available separately for each stage.



[lostensp-070611-01.tif, 1, en_US]

Figure 6-149 Stage Control of the Directional Negative-Sequence System Protection

In addition to the generally valid stage control, the stage is blocked in the event of a measuring voltage failure, provided the stage is working directionally.

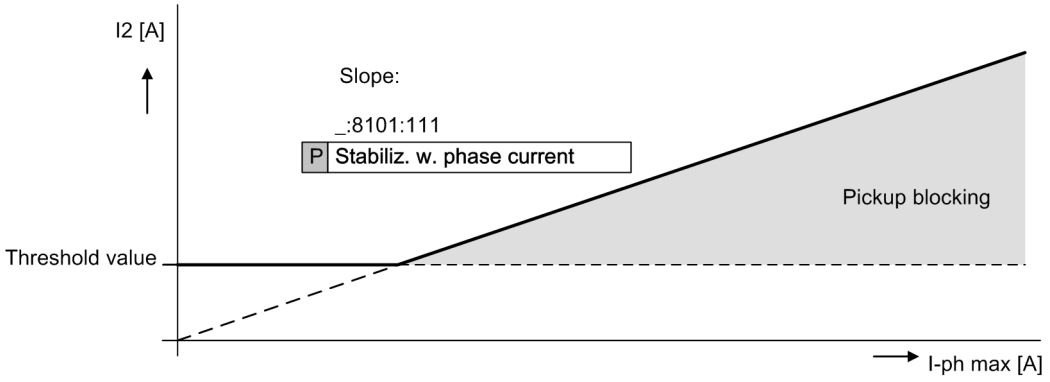
Logic of the Stage

[lonspdir-300112-01.tif, 1, en_US]

Figure 6-150 Logic Diagram of the Function Directional Negative-Sequence System Protection with Current-Independen Time Delay

Measurand

The negative-sequence current I2 is used as a measurand. From the 3-phase currents, the fundamental phasors are determined via a 1-cycle filter and, corresponding with the definition equation of the symmetrical components, the negative-sequence system is calculated from this.



Functioning

The stage picks up if the negative-sequence system current exceeds the set threshold value and the parameterized direction agrees with the measured direction. The pickup drops out if the negative-sequence system current falls below 95 % of the set threshold.

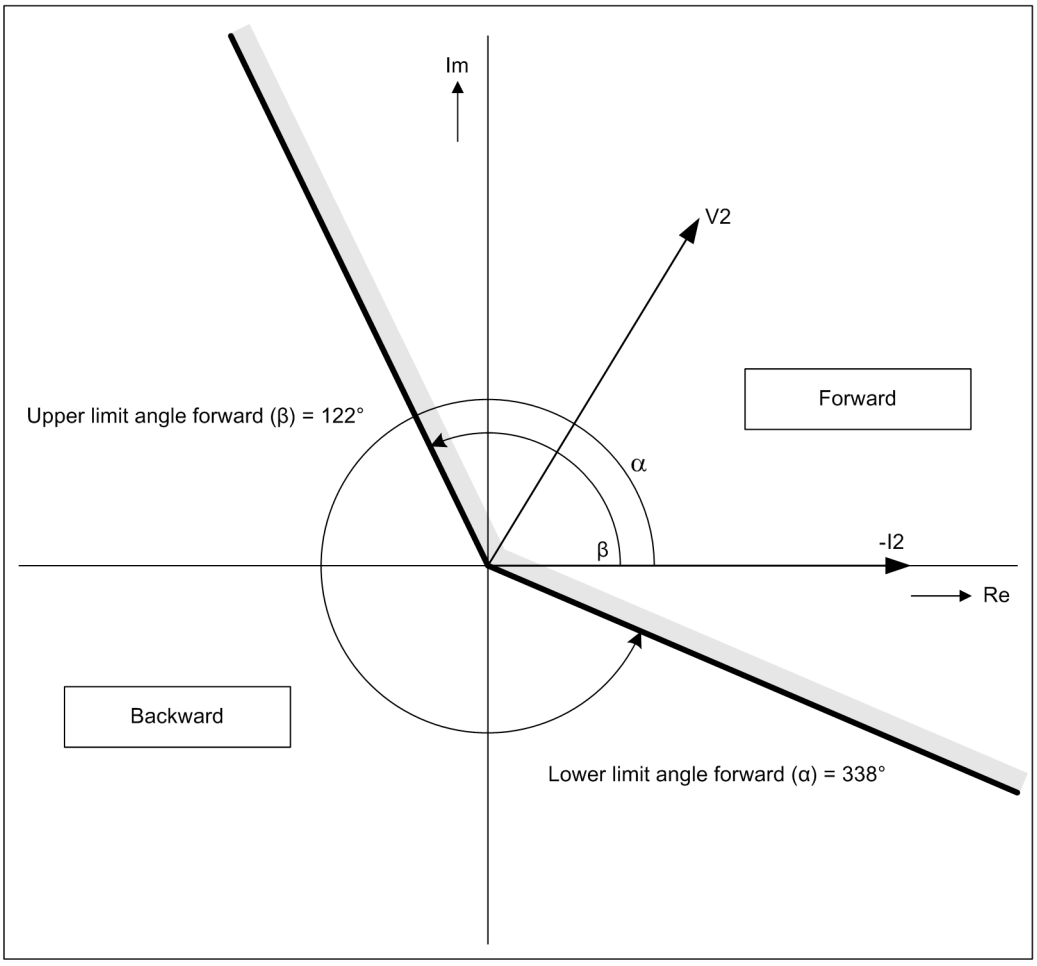
Stabilization with Phase Current

Unbalance in operation and unbalanced transformer ratios can lead to spurious pickups and incorrect tripping. In order to avoid this, the directional negative-sequence system stage is stabilized with the phase currents. The threshold value increases with rising phase currents (see next image).

You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

[dwstabil-300112-01.tif, 1, en_US]

Figure 6-151 Stabilization with Phase Currents

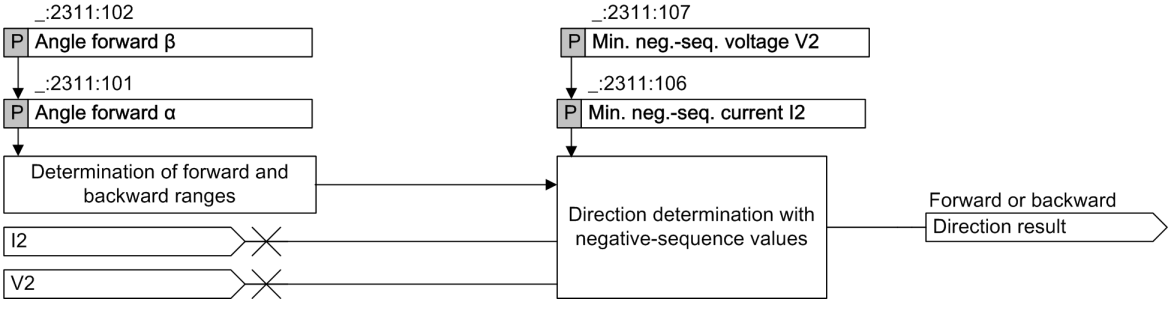


Direction Determination

The direction determination takes place with the negative-sequence system measurements I2 and V2.

The forward and reverse region is defined through the parameters **Angle forward α** and **Angle forward β** (see next figure). The reference for the 2 angles that must be set is the positive real axis. The angles are positively defined in a mathematical sense (counter-clockwise). The region between the limit angle α and the limit angle β - counted from the former in a positive direction - is the forward region. The remaining region is the reverse region.

For determining of the direction, the function places the measuring current I2 on the real axis. If the phasor of the negative-sequence system voltage V2 is located within the defined forward region, the function determines the direction as *forward*. In the other case, the function determines the direction as *reverse*.



The requirement for determining the direction is that the adjustable minimum variables have been exceeded for the negative-sequence system current and negative-sequence system voltage (parameters **Min. neg.-seq. current I2** and **Min. neg.-seq. voltage V2**).

[dwphasor-140212-01.tif, 1, en_US]

Figure 6-152 Phasor Diagram for Direction Determination with Negative-Sequence System Values

If the device determines a fault in the voltage-transformer secondary circuit (through the binary input *voltage transformer circuit-breaker dropout* or through **measuring-voltage failure detection**), direction determination will be disabled and every directionally set stage will be blocked. Non-directionally set stages become active again if there are faults in the voltage-transformer secondary circuit.

[lorichtu-070611-01.tif, 1, en_US]

Figure 6-153 Logic of Direction Determination

Directional Mode

You use the **`Directional mode`** parameter to define whether the stage works in a forward or reverse direction. Non-directional operation is also possible.

Blocking the Tripping by Pickup of the Main Protection Functions

The pickup and type of pickup for the main protection functions can block the tripping of the stage. You can perform this setting via 2 parameters:

- **Blocking by**

  This setting is used to select the zone or stage at which blocking is to occur in the event of pickup.

- **Blocking by prot. pickup**

  The pickup type at which the blocking is to occur is defined with this parameter. The blocking can occur at any pickup or only at 1-pole or only at multipole pickups.

  This parameter is also used to set that no blocking should occur when the main protection has picked up.

Blocking of Tripping via the Device-Internal Inrush-Current Detection Function

If the device is equipped with the additional **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer inrush currents.

With the **Blk. w. inrush curr. detect.** parameter, you can define whether tripping of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking, the stage picks up. The start of the time delay and tripping are however blocked. The stage signals this by way of a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the tripping delay (time delay) is started. After that time, the stage operates.

6.18.4 Application and Setting Notes for Direction Determination

Parameter: Limit Angle Region Forward

- Recommended setting value **(_:2311:101) Angle forward α** = ***338°***
- Recommended setting value **(_:2311:102) Angle forward β** = ***122°***

With the parameters **Angle forward α** and **Angle forward β**, you can change the location of the directional characteristic curve.

Siemens recommends using the defaults, because the function with these settings reliably determines the direction.

Parameter: Minimum Negative-Sequence System Variables V2 and I2

- Default setting **(_:2311:107) Min. neg.-seq. voltage V2** = ***0.7 V***
- Default setting **(_:2311:106) Min. neg.-seq. current I2** = ***0.05 A***

With the parameters **Min. neg.-seq. voltage V2** and **Min. neg.-seq. current I2**, you can specify the minimum negative-sequence system values for direction determination with V2 and I2. The set limiting values must not be exceeded by operational unbalances.

6.18.5 Application and Setting Notes for Stages

Parameter: Directional mode

- Default setting **(_:8101:114) Directional mode** = ***forward***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
non-directional	If the stage is to work in the forward and reverse direction (in the direction of the line and busbar), then select this setting. The stage will work with this setting even if no direction measurement is possible, for example due to insufficient polarization voltage (or none at all), or due to failure of the measuring voltage.

Parameter Value	Description
forward	Select these settings if the stage is only to work in a forward direction (in direction of the line).
reverse	Select this setting if the level is only to work in the reverse direction (in the direction of the busbar).

Parameter: Blk. w. inrush curr. detect.

If the device is equipped with the additional **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer inrush currents.

- Default setting **(_:8101:116) Blk. w. inrush curr. detect.** = ***no***

Parameter Value	Description
no	The transformer inrush current detection does not affect the stage. Select this setting in the following cases: 1) In cases where the device is not used on transformers. 2) In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer.
yes	When the transformer inrush current detection detects an inrush current that can lead to a tripping of the stage, the start of the time delay and tripping of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer.

Parameter: Blocking by the main Protection

- Recommended setting value **(_:8101:140) Blocking by** =

If you wish to give selective fault clarification through the main protection function precedence over tripping through the directional negative-sequence protection, you can define this via the 2 parameters **Blocking by** and **Blocking by prot. pickup**. The **Blocking by** parameter is used to select the zones or tripping stages of the main protection function(s), upon whose pickup the negative-sequence protection is to be blocked.

Parameter: Blocking by prot. pickup

- Default setting **(_:8101:130) Blocking by prot. pickup** = ***every pickup***

The **Blocking by prot. pickup** parameter can be used to define the type of pickup, which leads to the blocking.

Parameter Value	Description
every pickup	Blocking at every pickup
1-phase pickup	Blocking only at 1-pole pickup
multi-phase pickup	Blocking only at multipole pickup
no pickup	If the pickup of the main protection function should not lead to blocking of the negative-sequence protection, select this setting.

Parameter: Hold mode 1-p dead time

- Default setting **(_:8101:112) Hold mode 1p dead time** = ***0.040 s***

The **Hold mode 1p dead time** setting is used to define the time by which the device-internal signal for the 1-pole interruption is extended after the end of the 1-pole interruption.

At all line ends, there is no simultaneous switch-in after a 1-pole dead time. Thus, the parameterized operating mode for a 1-pole dead time must be retained for a certain time after the switch-in (end of the 1-pole dead time) until the other end or ends have securely switched in. The time to be set here corresponds to the maximum time between the switch-in of the 1st circuit breaker and the switch-in of the last circuit breaker at all ends of the feeder after a 1-pole dead time.

NOTE

The **Hold mode 1p dead time** setting is only available in devices with 1-/3-pole tripping. In devices with 3-pole tripping, this setting does not apply.

Parameter: Stabiliz. w. phase current

- Recommended setting value **(_:8101:111) Stabiliz. w. phase current** = ***10 %***

In order to avoid unwanted pickups and tripping, the negative-sequence system current stage is stabilized with the phase currents.

More information can be found in chapter *6.18.3 Function Description*.

The threshold value increases as the phase currents increase.

You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

Siemens recommends a default setting of 10 % under normal operations.

Parameter: Threshold

- Default setting **(_:8101:3) Threshold** = ***1.5 A***

Define the pickup value corresponding to the application. In doing so, for the time-graded stages, the setting for the superordinate and subordinate stages must be taken into account in the grading chart.

With a very sensitive setting, you must make sure that the negative-sequence system current does not lead to undesired response of the stage due to unbalance (for example non-twisted line).

Parameter: Operate delay

- Default setting **(_:8101:6) Operate delay** = ***0.30 s***

The tripping delay (time delay) to be set is derived from the time-grading schedule that has been prepared for the system.

When selecting the current and time setting, pay attention to whether the stage must work dependent on the direction.

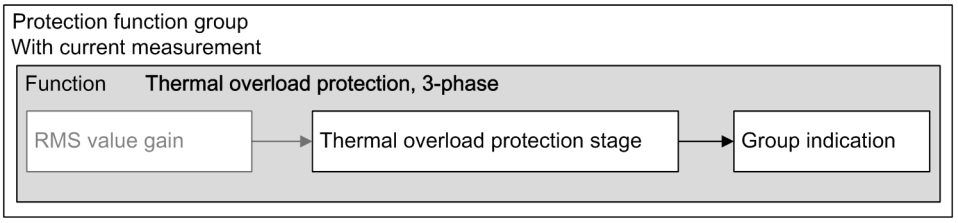
6.19 Thermal Overload Protection, 3-Phase

6.19.1 Overview of Functions

The **Thermal overload protection** function (ANSI 49) is used to:



- Protect the equipment (motors, generators, transformers, capacitors, overhead lines, and cables) against thermal overloads
- Monitor the thermal state of motors, generators, transformers, capacitors, overhead lines, and cables

6.19.2 Structure of the Function

The **Thermal overload protection, 3-phase** function is used in protection function groups with current measurement.

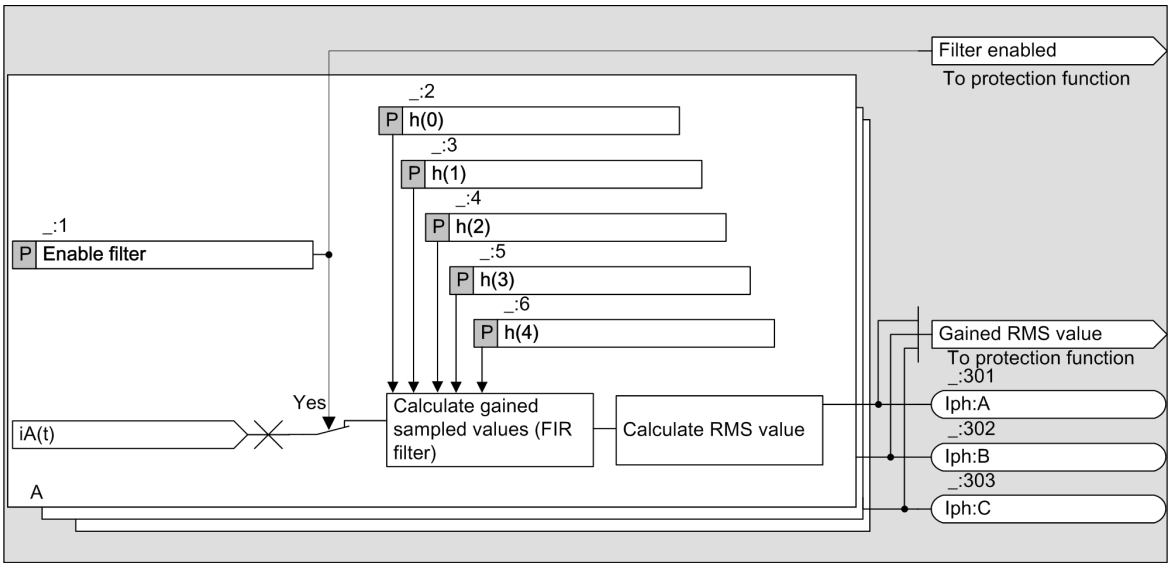
The function is preconfigured by the manufacturer with 1 **Thermal overload protection** stage.

The non-preconfigured function block **Filter** can optionally be applied to gain the RMS value used by the **Thermal overload protection** stage.

[dw_TOLP_with Filter stage, 1, en_US]

Figure 6-154 Structure/Embedding of the Function

6.19.3 Filter for RMS Value Gain



6.19.3.1 Description

The function block **Filter** can be used to adapt the RMS value for 2 means:

- To gain harmonics in a defined way. Higher harmonics can stress the protected object thermally more than lower harmonics. This is the case for reactors applied in AC filters. In addition, the amplitude attenuation of higher frequencies due to the anti-aliasing filter of the device is automatically compensated by the filter
- To only compensate the amplitude attenuation of higher frequencies by the device (due to the anti-aliasing filter)

The filter gain (amplitude response) is realized by a 9-order FIR filter.

Logic

[lo_TOLP_FilterStage, 1, en_US]

Figure 6-155 Logic Diagram of the Function Block Filter

The FIR filter gains the 8-kHz sampled values according to the set filter coefficients. Afterwards the RMS value is calculated. The symmetrical 9-order filter coefficients are set via the respective parameters **h(0)**, **h(1)**, **h(2)**, **h(3)** and **h(4)**.

NOTE

A FIR-filter configuration tool is provided as an auxiliary PC tool. With this PC tool, the coefficients h(0), h(1), h(2), h(3), h(4) of the FIR filter are generated according to the required gain factors (amplitude response). The tool can be obtained from the SIPROTEC download area. For more information about the tool, refer to the tool help function.

The gained RMS value is delivered to the protection stages only when the function block **Filter** is instantiated and the parameter **Enable filter** is set as ***yes*** . Otherwise, the normal RMS value is used.

Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
Iph:A	Filtered RMS measured value of current A	kA	A	Parameter **Rated current**
Iph:B	Filtered RMS measured value of current B	kA	A	Parameter **Rated current**
Iph:C	Filtered RMS measured value of current C	kA	A	Parameter **Rated current**

You can find the parameter **Rated current** in the **FB General** of function groups where the **Thermal overload protection** function is used.

If the parameter **Enable filter** is set to ***no***, the function values are shown as ---.

6.19.3.2 Application and Setting Notes

Parameter: Enable filter

- Default setting **(_:1) Enable filter** = ***no***.

With the parameter **Enable filter**, you set whether the **Filter** is enabled.

Parameter Value	Description
yes	If gained RMS values should be used in one of the protection stages, set parameter **Enable filter** = ***yes***.
no	If no gained RMS values are needed, set the parameter **Enable filter** = ***no***.

Parameter: **h(0),h(1),h(2),h(3),h(4)**

- Default setting **(_:2) h(0)** = ***0.000***
- Default setting **(_:3) h(1)** = ***0.000***
- Default setting **(_:4) h(2)** = ***0.000***
- Default setting **(_:5) h(3)** = ***0.000***
- Default setting **(_:6) h(4)** = ***1.000***

With the default value of the coefficients, the filter has no effect and no gain is applied.

If the filter shall be applied to adapt the RMS value calculation to a specific protection object such as a reactor, the reactor manufacturer has to provide the required amplitude response (gain factors) for the reactor. To determine the coefficients h(0) to h(4) for the FIR filter, you must enter the gain factors into the auxiliary PC tool which is available in the SIPROTEC download area. The 5 required coefficients are generated by the tool. They have to be entered manually as settings to configure the filter. The amplitude attenuation of higher frequencies due to the anti aliasing filter of the device is automatically taken into account and compensated by the filter.

To only compensate the attenuation of higher frequencies by the device, set the following coefficients in the filter.

Rated Frequency	Filter Coefficients for Only Compensating the Device Amplitude Attenuation
50 Hz	h(0) = -0.002 h(1) = -0.012 h(2) = 0.045 h(3) = -0.110 h(4) = 1.151
60 Hz	h(0) = -0.005 h(1) = -0.020 h(2) = 0.058 h(3) = -0.128 h(4) = 1.170

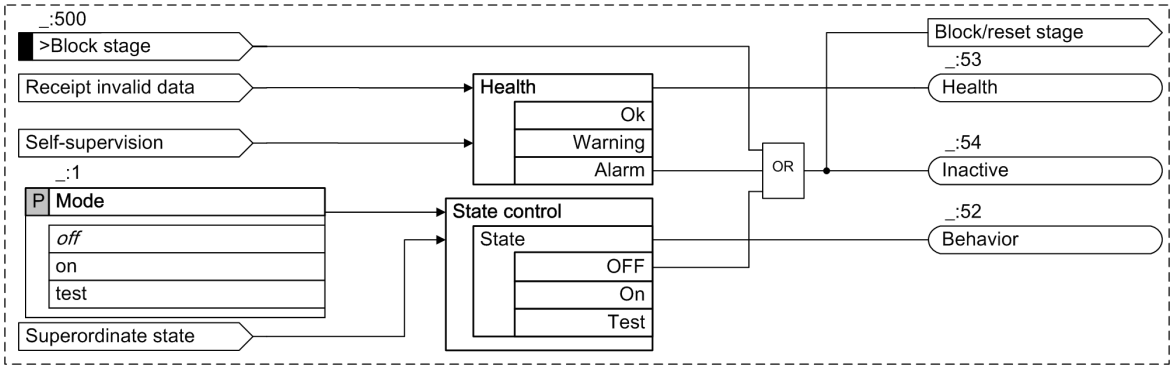
6.19.4 Stage with Thermal Overload Protection



6.19.4.1 Description

Logic

[lo_TOLP_withFilterstage, 1, en_US]

Figure 6-156 Logic Diagram of the Thermal Overload Protection Stage

[lo_Stage Control, 1, en_US]

Figure 6-157 Logic Diagram of the Stage Control

RMS-Value Selection

The protection function supports 2 kinds of RMS measurement:

- Normal RMS value
- Gained RMS value from the function block **Filter**

The gained RMS value is automatically used if the function block **Filter** is configured and the filter has been enabled.

NOTE

When the function block **Filter** is applied, only one current measuring point I-3ph is allowed to be connected to the 3-phase current interface of the function group.

Thermal Replica

The protection function calculates the overtemperature from the phase currents based on a thermal single-body model according to the thermal differential equation with

$$I_{p.u.}^2 = \tau_{th} \frac{d\theta}{dt} + \theta - \theta_{Amb}$$

[fo_diffgl-170914, 2, en_US]

With the following standardization:

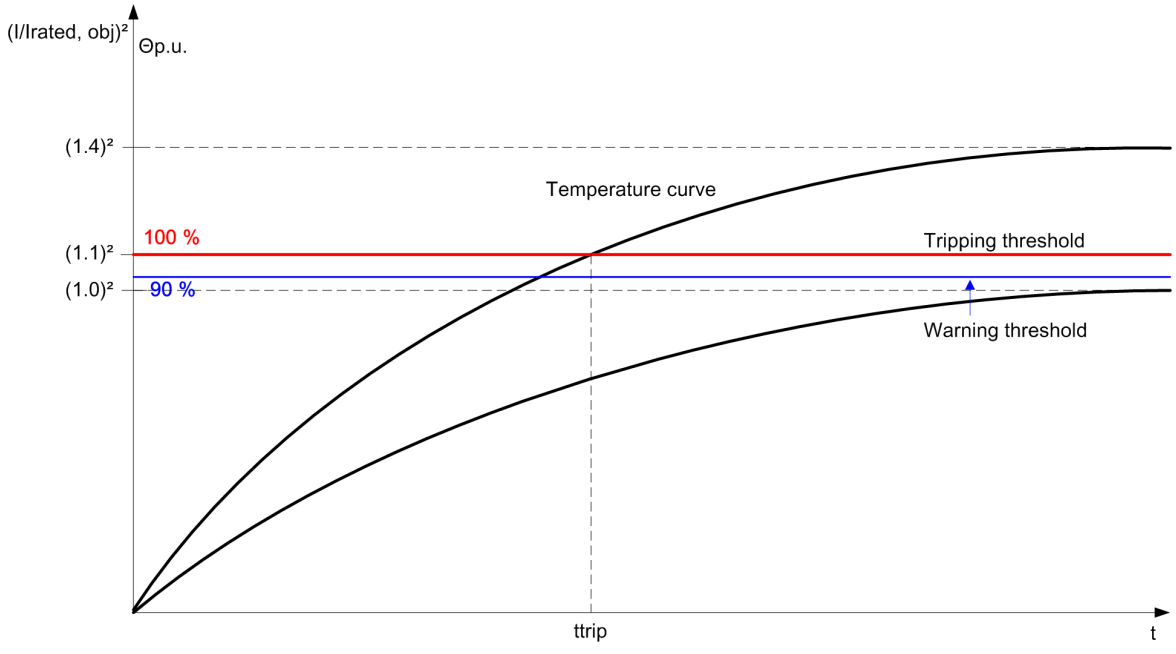
$$I_{p.u.} = \frac{I}{I_{max}} = \frac{I}{K \cdot I_{rated\ ,obj.}} \qquad \theta = \frac{\vartheta}{\vartheta_{max}} = \frac{\vartheta}{K^2 \cdot \Delta\vartheta_{rated\ ,obj.}}$$

$$\tau_{th} = R_{th} \cdot C_{th} \qquad \theta_{Amb} = \frac{\vartheta_{Amb} - 40\ °C}{\vartheta_{max}} = \frac{\vartheta_{Amb} - 40\ °C}{K^2 \cdot \Delta\vartheta_{Amb\ ,obj.}}$$

[fo_normie-170914, 2, en_US]

Θ	Current overtemperature, in relation to the final temperature at a maximum permissible phase current k $I_{rated, obj}$
Θ_{Amb}	Standardized ambient temperature, where ϑ_{Amb} describes the coupled ambient temperature. The coupled ambient temperature ϑ_{Amb} can be the measured ambient temperature or the ambient temperature preset using the **`Default temperature`** parameter.
$\Delta\vartheta_{rated\ obj}$	Overtemperature of the protected object set at rated current
τ_{th}	Thermal time constant (temperature rise/cooling) of the protected object

k	This factor indicates the maximum continuous permissible phase current. The factor refers to the rated current of the protected object ($k = I_{max}/I_{rated, obj}$)
$I_{rated, obj}$	Rated current of the protected object



At the same time, $I_{rated, obj}$ is the rated current of the assigned protected object side:

- In the case of transformers, the rated current of the winding to be protected, which the device calculates from the set rated apparent power and rated voltage, is decisive.
- The uncontrolled winding forms the basis in the case of transformers with voltage control
- In the case of generators, motors and reactors, the rated current, which the device calculates from the set rated apparent power and rated voltage, is decisive.
- In the case of lines, nodes and busbars, the rated current of the protected object is set directly

In a steady state, the solution to the thermal differential equation is an e-function whose asymptote represents the final overtemperature Θ_{end}. The time constant τ_{th} determines the rise. After reaching an initial adjustable overtemperature threshold Θ_{warn} (**Threshold thermal warn.**), a warning indication is given.

If the overtemperature limit Θ_{Off} (tripping overtemperature) is exceeded, an operate indication is immediately issued and the equipment disconnected from the power supply. This threshold is specified at 100 % and corresponds to the final temperature set at a flowing permissible continuous current (I_{max}).

Figure 6-158 shows the temperature rise at different overload currents and the supervision thresholds.

[dwtempve-030211-01.tif, 1, en_US]

Figure 6-158 Temperature History for Different Overload Currents (**K-factor** = ***1.1***)

The overtemperature is calculated separately for each phase. The current overtemperature can be obtained from the operational measured values. It is shown in percent. An indication of 100 % means that the thermal threshold has been reached. The maximum overtemperature of the phases is regarded as the tripping temperature. This means that the highest of the 3 phase currents is always assumed.

The analysis of the RMS values of the currents over a broad frequency band also includes the harmonic components. These harmonic components contribute to the temperature rise of the equipment.

If the flowing current falls below an adjustable minimum current **Imin cooling** , the **Cooling time constant** is activated.

Operate Curve

If the ambient temperature is not measured and set to 40°C, you can get the operate curve as following:

$$t = \tau_{th} \cdot \ln \frac{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - \left(\frac{I_{preload}}{k \cdot I_{rated,obj.}}\right)^2}{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - 1}$$

[foauslos-211010-01.tif, 1, en_US]

t	Operate time
τ_{th}	Time constant
I	Measured load current
$I_{preload}$	Preload current
k	Setting factor according to VDE 0435 part 3011 or IEC 60255-8 (K factor)
$I_{rated, obj}$	Rated current of the protected object

Ambient Temperature

This function can take the ambient temperature into consideration. The reference temperature of the thermal model is 40°C. If the ambient temperature drops below the reference temperature, the thermal limit increases. The equipment can be stressed more. If the ambient temperature is higher, the conditions change.

The **Default temperature** parameter can be used to fix or measure the ambient temperature. The **Minimal temperature** parameter limits the coupled ambient temperature. If the measured ambient temperature is lower than the minimum temperature, the minimum temperature is processed in the thermal model.

The ambient temperature refers to the overtemperature of the protected object, which sets itself at the rated current (parameter **Temperature rise at Irated**).

The measured ambient temperature is measured by an external RTD unit (RTD = Resistance Temperature Detector) and provided by the functions **RTD unit Ether.** or **RTD unit serial** of the function group **Analog transformer**. When using the **Temperature sensor** parameter, the respective temperature sensor can be selected.

If the temperature measurement is faulty, for example, due to an open circuit between the device and the RTD unit, the device reports this. In this case, the process continues with either the temperature measured last or the value set under the **Default temperature** parameter, depending on which value is the highest.

Current Influence

The thermal replica based on the single-body model applies with limitations to high overcurrent situations (short circuits, motor startup currents). To avoid an overfunction of the overload protection, the thermal replica must be influenced for overcurrents (exceeding **1** $_{threshold}$). You can select between 2 strategies for this:

- Freezing of the thermal memory
- Limitation of the input current for the thermal replica to the set current. The temperature rise is thereby **retarded** at high currents.

Warning Thresholds

The thermal warning threshold issues a warning indication before the tripping threshold (tripping temperature) is reached. In this way, for example, a load can be reduced in sufficient time and a disconnection avoided. At a normal **K-factor** of ***1.1*** , a thermal memory value of 83 % sets in at continuously flowing rated current.

Apart from the thermal warning threshold, the overload protection also has a current-warning threshold. This current-warning threshold can signal an overload current in sufficient time before the overtemperature value has reached the warning or tripping threshold.

Dropout of Tripping

Once the thermal memory has fallen below the setting value of the **Dropout threshold operate** , the trip command is cancelled upon tripping. In contrast, the current-warning threshold and the thermal warning threshold are reduced at a fixed dropout threshold (see Technical Data).

Behavior in the Event of Auxiliary-Voltage Failure

The behavior of the thermal replica can be controlled upon auxiliary-voltage failure via the setting parameter **Storage of thermal replica** . You can save the thermal state for a time of 500 min. Once the supply voltage returns, the thermal replica continues to function with the saved thermal state.

If the thermal replica is not saved, it will be reset to 0 upon failure of the auxiliary voltage.

Resetting the Thermal Map

You can reset the thermal memory via the binary input indication **>Reset thermal replica** . The thermal memory will then have a 0 value. A reparameterization will also lead to resetting the thermal memory.

Emergency Start

Depending on the operating conditions, tripping can be blocked or closure enabled despite the permissible thermal limits being exceeded. Upon activation of the binary input signal **>Emergency start** , tripping is blocked and closure enabled. This does not affect the state of the thermal memory. After the input **>Emergency start** disappears, the blocking remains in effect for the set **Emerg. start T overtravel** .

Blocking the Function

Blocking will cause a picked up function to be reset. The tripping function can be blocked externally or internally by the binary input signal **>Block stage** .

All indications then drop out and the thermal memory is set to the value 0.

Blocking Closure

The signal **Block close** can be used to prevent closure of the protected object at a high thermal load. The signal is set if the tripping overtemperature is exceeded, and cancelled if the temperature falls below the dropout threshold.

Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
(_:601:305) Time until trip	Expected time until tripping	s	s	s
(_:601:304) Time until close	Time until close release	s	s	s
(_:601:306) Overload phase A	Thermal measured values of the phases	%	%	Tripping temperature
(_:601:307) Overload phase B				
(_:601:308) Overload phase C				
(_:601:309) Overload maximum	Thermal measured value of the overload protection	%	%	Tripping temperature
(_:601:310) Equival. current phs A	Current measured value which serves as basis for the overload measured value	A	A	Rated operating current of the primary values

6.19.4.2 Application and Setting Notes

Parameter: `Threshold current warning`

- Recommended setting value **`(_:101) Threshold current warning`** = ***`1.1 A`*** at I_{rated} = 1 A

Set the threshold to the maximum permissible continuous current ($I_{max, perm}$). This results in the same setting value as for the **`K-factor`** .

Parameter: `Threshold thermal warn.`

- Recommended setting value **`(_:104) Threshold thermal warn.`** = ***`90 %`***

The default setting can be left at a **`K-factor`** , of ***`1.1`***, as the thermal memory results for 83 % at continuously flowing rated current. The calculation uses the rule of three: 100 % corresponds to (**`K-factor`**)^2 and x % corresponds to 1^2.

$$\frac{\Theta}{\Theta_{off}} = \frac{100\ \%}{k^2} = 83\ \%$$

[fowarnsc-100810-01.tif, 2, en_US]

At a **`K-factor`** of 1.05, the thermal memory for rated current is already 91 % filled. Increase the **`Threshold thermal warn.`** to 95 %.

Parameter: `Dropout threshold operate`

- Recommended setting value **`(_:105) Dropout threshold operate`** = ***`90 %`***

The **`Dropout threshold operate`** parameter is used to drop out pickup and tripping when the value drops below this threshold. A setting on the order of magnitude of the warning threshold is recommended. You can select a lower setting value for special applications, desired additional cooling or longer blocking of closing.
Note that the calculation of the operational measured value **`Time until close`** refers to this value.

Parameter: `Emerg. start T overtravel`

- Default setting **`(_:112) Emerg. start T overtravel`** = ***`6300 s`***

This functionality is not required for protection of lines and cables. If the logical binary indication is not routed, the **`Emerg. start T overtravel`** will be ineffective. The **`Emerg. start T overtravel`** presetting can therefore be retained.

Parameter: `K-factor`

- Recommended setting value **`(_:106) K-factor`** = ***`1.1`***

The **`K-factor`** parameter is used to describe the limiting value for the maximum permissible continuous load. The rated current $I_{rated, obj}$ of the protected object (for example, cable) is the basic current for overload sensing.
You can determine the **`K-factor`** on the basis of the thermally permissible continuous current $I_{max, perm.}$:

$$K\text{-factor} = \frac{I_{max,perm.}}{I_{rated,obj.}}$$

[fotolpkf-100810-01.tif, 2, en_US]

NOTE

The thermally permissible continuous current for the protected object is known from relevant tables or from the specifications of the manufacturer!

In the case of cables, the permissible continuous current depends on the cross-section, insulation material, design type, and the manner in which the cables have been laid. In the case of overhead lines, an overload of 10 % is permissible.

EXAMPLE

For the Permissible Continuous Current

Cross-linked polyethylene cables (N2XS2Y): 10 kV 150 mm² (Cu)

Current-carrying capacity (underground laying): $I_{max, perm}$ = 406 A

Selected **`K factor`** of 1.1

This yields a rated current of $I_{rated, obj}$= 369 A

Parameter: `Thermal time constant`

- Recommended setting value **`(_:110) Thermal time constant`** = ***`2777 s (46.29 min)`***

The **`Thermal time constant`** parameter is used to define the tripping characteristics of the stage. If no data on the **`Thermal time constant`** is available, you can determine this from the short-time current-rating capacity of the cable, for example, from the 1-s current. The 1-s current is the maximum current permissible for 1 s application time. The 1-s current can be found in the cable specifications. Calculate the **`Thermal time constant`** according to the following formula:

$$\tau[\text{min}] = \frac{1}{60}\left(\frac{\text{perm. 1–s–current}}{\text{perm. continuous current}}\right)^2$$

[fodauers-170309-07.tif, 2, en_US]

If the short-term current-rating capacity is specified for an application time other than 1 s, use the short-time current instead of the 1-s current. Multiply the result by the specified application time.

For a given short-term current-carrying capacity of 0.5 s, use the following formula:

$$\tau[\text{min}] = \frac{0.5}{60}\left(\frac{\text{perm. 0.5–s–current}}{\text{perm. continuous current}}\right)^2$$

[fodauers-170309-01.tif, 2, en_US]

EXAMPLE for a Cable

For a cable

Permissible continuous current: $I_{max, perm}$ = 406 A

Maximum short-circuit current for 1 s: I_{1s} = 21.4 kA

Therefore, for the **`Thermal time constant`**, it follows

$$\tau\ [\text{min}] = \frac{1}{60}\left(\frac{21400\ \text{A}}{406\ \text{A}}\right)^2 = \frac{1}{60}52.7^2 = 46.29\ \text{min}$$

[fokonsta-310510-01.tif, 2, en_US]

with 46.29 min = 2777 s

Parameter: `Cooling time constant`

- Recommended setting value **`(_:111) Cooling time constant`** = ***`2777 s`***

The **`Cooling time constant`** parameter is used to define the dropout behavior of the stage. Cables and overhead lines have the same time constant for both heating and cooling. Therefore, set the same value for the **`Cooling time constant`** as for the parameter **`Thermal time constant`**.

Parameter: `Imax thermal`

- Recommended setting value **`(_:107) Imax thermal`** = ***`2.5 A`*** at I_{rated} = 1 A

The **`Imax thermal`** parameter allows you to set the threshold current for the **`Behav. at I> Imax therm.`** parameter. The selected threshold current of 2.5 $I_{rated, obj}$ is a practicable value.

Parameter: `Imin cooling`

- Recommended setting value **`(_:108) Imin cooling`** = ***`0 A`***

If only the thermal time constant (parameter **`Thermal time constant`**) must provide protection, set the current parameter **`Imin cooling`** to 0 A.

Parameter: `Temperature rise at Irated`

- Default setting **`(_:109) Temperature rise at Irated`** = ***`70 K`***

As a value, set the overtemperature that is the result if the equipment is continuously operated with the rated current and at an ambient temperature of 40°C. Here, the rated current refers to the protected object. You can find the temperature value in the technical data of the equipment or measure it. If you use a temperature sensor when measuring at the rated current, deduct the actual ambient temperature or the coolant temperature from the measured value.

When selecting the setting value, you can also use the specified temperature class for orientation. Usually, you will find the overtemperature expressed in Kelvin (K), which can be accepted as is. If the absolute temperature is given, the ambient temperature must be deducted. As a rule, this is 40°C.

The overtemperature at maximum permissible current (***`ϑmax`***) and the **`Temperature rise at Irated`** (***`ϑrated,obj.`***) can be converted by using the following formula:

$$k^2 = \left(\frac{\Delta\vartheta_{max}}{\Delta\vartheta_{rated\ ,obj.}} \right)$$

[fo_ueb_for_Irated, 3, en_US]

EXAMPLE:

Temperature class **B** for continuous operation: permissible overtemperature = 80 K
From this, a temperature for I_{rated} of 120°C (80 K + 40°C) can be derived when using a temperature sensor for the measurement.
Temperature class **F** as thermal limiting value: permissible overtemperature = 105 K.
From this, a maximum temperature of 155°C (105 K + 40°C) derives.

From these values, the K factor can be derived:

$$k^2 = \frac{\Delta\vartheta_{max\ ,Obj.}}{\Delta\vartheta_{rated\ ,Obj.}} = \frac{105\ K}{80\ K} = 1.31 \qquad \rightarrow\ k = 1.146$$

[fo_bsp_kfaktor, 3, en_US]

If you select a setting value of 1.1 for the **`K-factor`**, your selection can be considered as conservative.

NOTE

For electrical machines, the limits can vary depending on the type of coolant.
Consult the machine manufacturer to agree on a setting value for the overtemperature.

Parameter: `Storage of thermal replica`

- Recommended setting value **`(_:113) Storage of thermal replica`** = ***`no`***

If a continuous auxiliary voltage for the bay units is ensured, the bay default setting can be retained.

Parameter: `Behav. at I> Imax therm.`

- Recommended setting value **`(_:114) Behav. at I> Imax therm.`** = ***`freeze therm. rep.`***

The **`Behav. at I> Imax therm.`** parameter is used to select the process by which the function reacts to short-circuit currents. To prevent premature tripping of the overload protection at low time constants, high preloading and high short-circuit currents, the thermal replica can be modified.
The default setting has been selected to be compatible with SIPROTEC 4 devices. If you wish to take further temperature rise into consideration, the ***`current limiting`*** procedure is recommended.

Parameter Value	Description
`freeze therm. rep.`	If input currents exceed the **`Imax thermal`** parameter, the thermal replica will be frozen for the time the parameter is exceeded. This parameter value is provided to enable compatibility with older products!
`current limiting`	The input currents are limited to the value set in the **`Imax thermal`** parameter. If the measured current exceeds the set current value, the limited current value is supplied to the thermal replica. An advisable current threshold is approx. 2 to 2.5 $I_{rated, obj}$.

Parameter: `Temperature sensor`

- Default value **`(_:44) Temperature sensor`** = ***`none`***

With the **`Temperature sensor`** parameter, you determine which temperature sensor to use to detect the ambient temperature.
A temperature sensor (RTD = Resistance Temperature Detector) is used to measure the ambient temperature of the protected object and feed it to the device via an RTD unit. The **Thermal overload protection** function receives the measured temperature value via the functions **RTD unit Ether.** or **RTD unit Serial** from the function group **Analog transformer**.

Parameter: `Default temperature`

- Recommended setting value **`(_:118) Default temperature`** = ***`40 °C`***

The **`Default temperature`** is set as ambient temperature under the following conditions:

- No temperature sensor for measuring the ambient temperature is connected.
- The temperature measurement is faulty and the last measured temperature value is less than the **`Default temperature`**.

Siemens recommends using the default setting.

Parameter: `Minimal temperature`

- Default setting **`(_:117) Minimal temperature`** = ***`-20 °C`***

If the measured ambient temperature drops below the set value, the set value is assumed as the ambient temperature. If the overload protection works with a prespecified outside temperature, and this temperature drops below the value set in the **`Minimal temperature`** parameter, the **`Minimal temperature`** is also used.

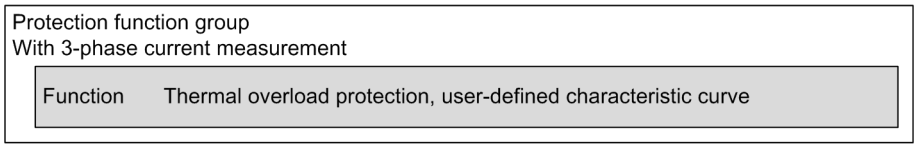
6.20 Thermal Overload Protection, User-Defined Characteristic Curve

6.20.1 Overview of Functions



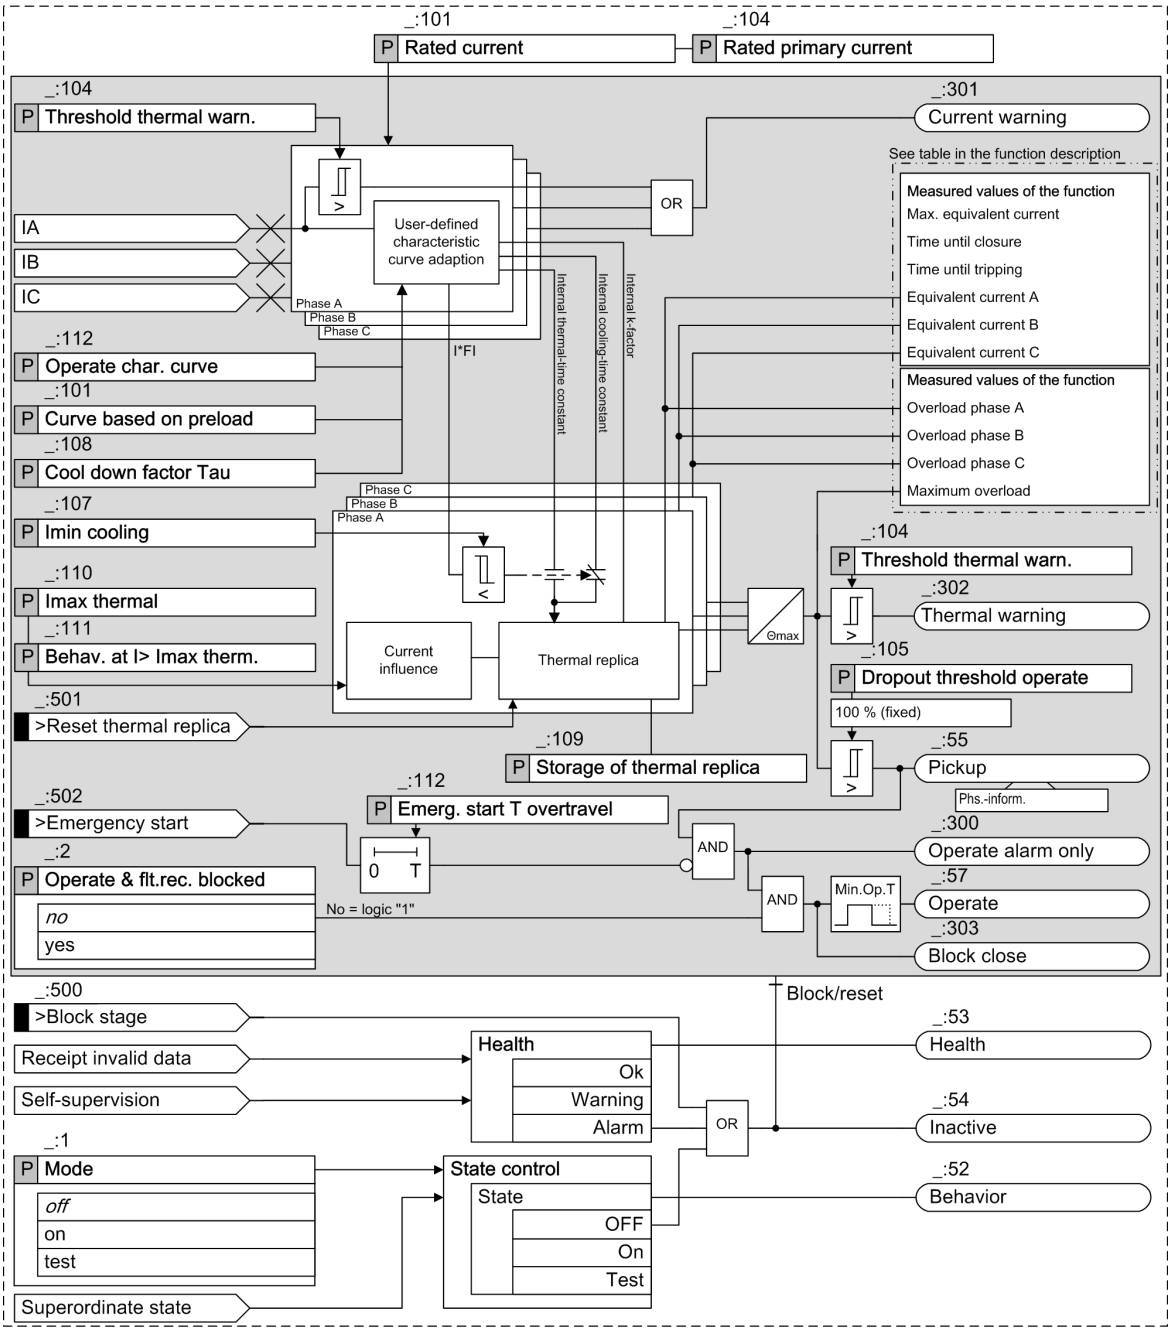
The **Thermal overload protection, user-defined characteristic curve** function (ANSI 49) is used to:

- Protect the equipment (motors, generators, and transformers) against thermal overloads
- Realize a manufacturer specific overload characteristic curve for specific equipment, for example, shunt reactors
- Monitor the thermal state of motors, generators, and transformers

6.20.2 Structure of the Function

The **Thermal overload protection, user-defined characteristic curve** function is used in protection function groups with 3-phase current measurement.

The **Thermal overload protection, user-defined characteristic curve** function is steplessly preconfigured.



[dw_TOLP_UserCurveStr, 1, en_US]

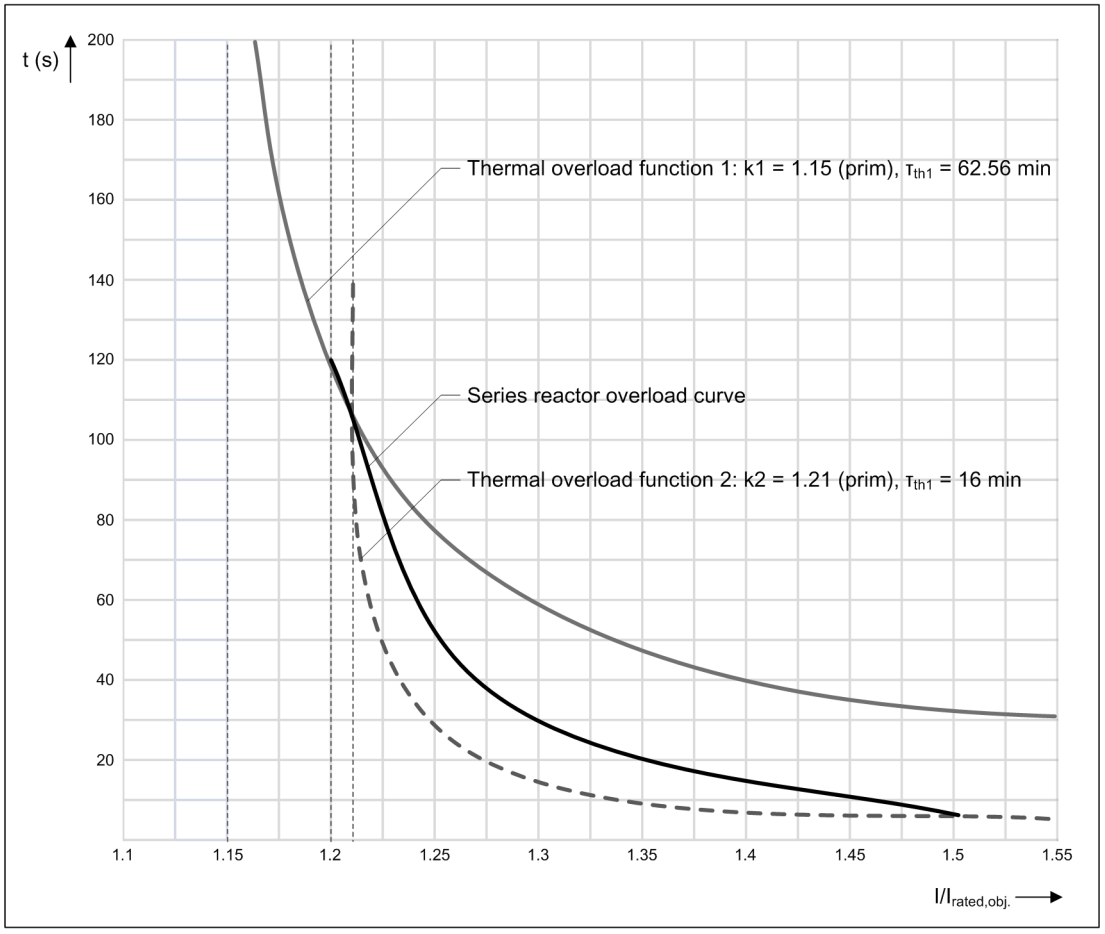
Figure 6-159 Structure/Embedding of the Function

6.20.3 Function Description

Logic

[lo_TOLP_UserCurve_stage, 1, en_US]

Figure 6-160 Logic Diagram of the Thermal Overload Protection, User-Defined Characteristic Curve Function



(1) The **(_:101) Rated current** parameter is from the protected object.

(2) The **(_:104) Rated primary current** parameter is from the used current transformer.

User-Defined Characteristic Curve

For specific equipment (for example, shunt reactors and transformers) or for special applications, the manufacturer specifies an overload characteristic curve. This curve cannot be described accurately with a single-

body model so that deviations can occur. The following figure shows an example of a predefined overload characteristic curve and 2 standard characteristic curves based on the single-body model.

[dw_TOLP_UserCurve_characteristic, 1, en_US]

Figure 6-161 User-Defined Characteristic Curve with Replica of Standard Characteristics

The calculation is identical to the realization of the standard **Thermal overload protection, 3-phase** function. You can find more information in the function description **Thermal overload protection, 3-phase** starting from chapter *6.19.1 Overview of Functions* .

The main deviations are as follows:

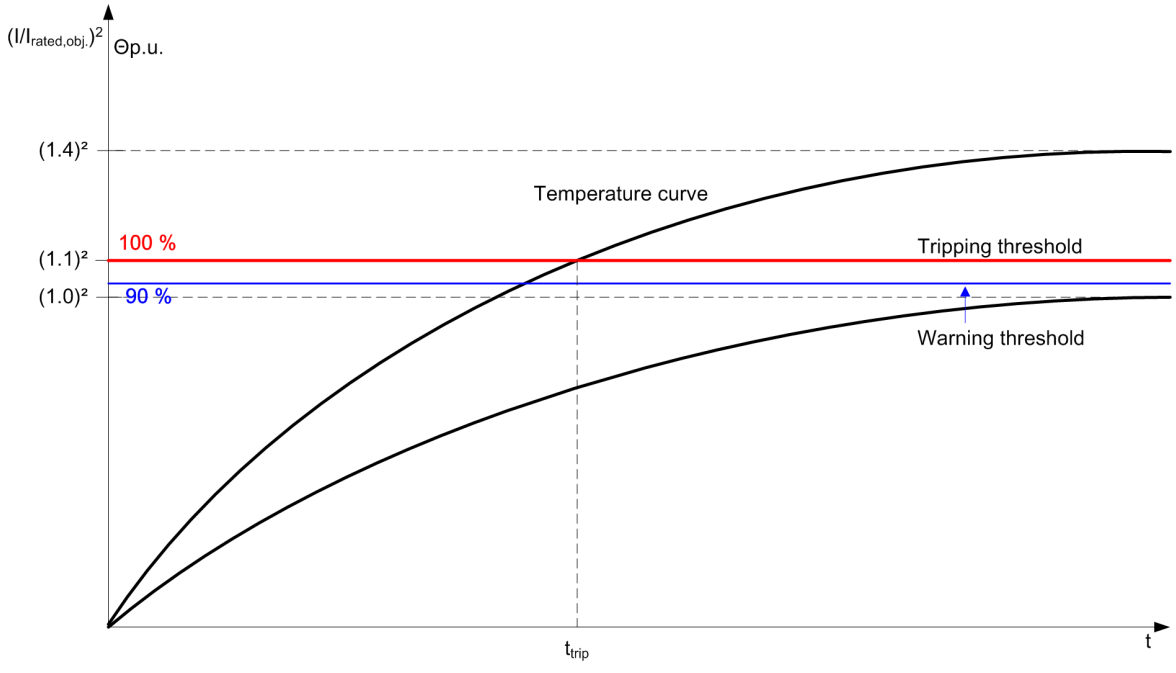
- The thermal characteristic is set with a flexible characteristic ($t_{trip} = f(I/I_{rated,obj})$).
  - The first point of the characteristic curve is important and is used to calculate the internal k-Factor.
  - The point at $I/I_{rated,obj} = 1.5$ is used to calculate the internal thermal time constant. If there is no point at $I/I_{rated,obj} = 1.5$, the point which is the closest to $I/I_{rated,obj} = 1.5$ from $I/I_{rated,obj} = 1.1$ is used to calculate the internal thermal time.
  - The points are set according to the maximum permissible load current.
- The **`Curve based on preload`** parameter describes for which thermal preload the user-defined characteristic curve is valid. Normally, such a curve is given for protected objects under rated load.
- The **`Cool-down factor Tau`** parameter is used for the determination of the cooling time constant. The set factor is multiplied with the internal calculated time constant.
- The thermal model is based on a constant ambient temperature of 40 °C. It cannot be corrected via the external measurement.

Thermal Replica

The protection function calculates the overtemperature from the phase currents on the basis of a thermal single-body model according to the thermal differential equation with

$$I_{p.u.}^2 = \tau_{th} \frac{d\theta}{dt} + \theta$$

[fo_TOLP_diffgl, 1, en_US]



With the following standardization:

$$I_{p.u.} = \frac{I}{I_{max}} = \frac{I}{K \cdot I_{rated\ ,obj.}} \qquad \theta = \frac{\vartheta}{\vartheta_{max}} = \frac{\vartheta}{K^2 \cdot \Delta\vartheta_{rated\ ,obj.}}$$

$$\tau_{th} = R_{th} \cdot C_{th}$$

[fo_TOLP_normie, 1, en_US]

Θ	Current overtemperature, in relation to the final temperature at a maximum permissible phase current k $I_{rated, obj}$
$\Delta\vartheta_{rated\ obj}$	Overtemperature of the protected object set at rated current
τ_{th}	Thermal time constant (temperature rise/cooling) of the protected object. The value is calculated internally.
K	This factor indicates the maximum continuous permissible phase current. The factor refers to the rated current of the protected object ($K = I_{max}/I_{rated, obj}$) and is calculated internally.
$I_{rated, obj}$	Rated current of the protected object

[dw_TOLP_Temperature, 1, en_US]

Figure 6-162 Temperature History for Different Overload Currents (**K-factor** = ***1.1***)

The overtemperature is calculated separately for each phase. The current overtemperature can be obtained from the operational measured values. It is shown in percent. An indication of 100 % means that the thermal threshold has been reached. The maximum overtemperature of the phases is regarded as the tripping temperature. This means that the highest of the 3 phase currents is always assumed.

The analysis of the RMS values of the currents over a broad frequency band also includes the harmonic components. These harmonic components contribute to the temperature rise of the equipment.

Current Influence

The thermal replica based on the single-body model applies only with limitations to high overcurrent situations (short circuits, motor startup currents). To avoid an overfunction of the overload protection, the thermal replica must be influenced in case of overcurrents (exceeding $I_{threshold}$). You can select between 2 strategies for this:

- Freezing of the thermal memory
- Limitation of the input current for the thermal replica to the set current. The temperature rise is thereby **retarded** at high currents.

Warning Thresholds

The thermal warning threshold issues a warning indication before the tripping threshold (tripping temperature) is reached. In this way, for example, a load can be reduced in sufficient time and a disconnection can be avoided. If the first setting value of the user-defined characteristic curve is set to 1.1 of the rated current, a thermal memory value of 83 % is set to the continuously flowing rated current.

Apart from the thermal warning threshold, the overload protection also has a current-warning threshold. This current-warning threshold can signal an overload current in sufficient time before the overtemperature value has reached the warning or tripping threshold.

Dropout of Tripping

Once the thermal memory has fallen below the setting value of the **Dropout threshold operate**, the trip command is cancelled upon tripping. In contrast, the current-warning threshold and the thermal warning threshold are reduced at a fixed dropout threshold (see Technical Data).

Behavior in the Event of Auxiliary-Voltage Failure

The behavior of the thermal replica can be controlled upon auxiliary-voltage failure via the setting parameter **Storage of thermal replica**. You can save the thermal state for a time of 500 min. Once the supply voltage returns, the thermal replica continues to function with the saved thermal state.

If the thermal replica is not saved, it will be reset to 0 upon failure of the auxiliary voltage.

Resetting the Thermal Memory

You can reset the thermal memory via the binary input indication **>Reset thermal replica**. The thermal memory will then have a 0 value.

Emergency Start

Depending on the operating conditions, tripping can be blocked or closure enabled despite the permissible thermal limits being exceeded. Upon activation of the binary input signal **>Emergency start**, tripping is blocked and closure enabled. This does not affect the state of the thermal memory. After the input **>Emergency start** disappears, the blocking remains in effect for the set **Emerg. start T overtravel**.

Blocking the Function

Blocking will cause a picked up function to be reset. The tripping function can be blocked externally or internally by the binary input signal **>Block stage**.

All indications then drop out and the thermal memory is not calculated.

Blocking Closure

The signal **Block close** can be used to prevent closure of the protected object at a high thermal load. The signal is set if the tripping overtemperature is exceeded, and cancelled if the temperature falls below the dropout threshold.

Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
(_:601:305) Time until trip	Expected time until tripping	s	s	s
(_:601:304) Time until close	Time until close release	s	s	s
(_:601:306) Overload phase A	Thermal measured values of the phases	%	%	Tripping temperature
(_:601:307) Overload phase B				
(_:601:308) Overload phase C				
(_:601:309) Overload maximum	Thermal measured value of the overload protection	%	%	Tripping temperature
(_:601:310) Equival. current phs A	Current measured value which serves as basis for the overload measured value	A	A	Rated operating current of the primary values
(_:601:311) Equival. current phs B				
(_:601:312) Equival. current phs C				
(_:601:313) Equival. current max.	Maximum current measured value which serves as basis for the overload measured value	A	A	Rated operating current of the primary values

6.20.4 Application and Setting Notes

Motors and generators as well as transformers are at risk from long-lasting overloads. You can adapt the given overload characteristic curve to the user-defined characteristic curve with the **Thermal overload protection, user-defined characteristic curve** function. You can find the predefined characteristic curve in the chapter *12.23 Thermal Overload Protection, User-Defined Characteristic Curve*.

When setting the parameters, consider the following:

- The settings for the used current transformer (primary values and secondary values) must be set correctly in the power system.
- The rated values for the protected object must be correct in the used function group.

Parameter: `Threshold current warning`

- Recommended setting value **`(_:101) Threshold current warning`** = ***`1.1 A`*** at I_{rated} = 1 A

Set the threshold to the maximum permissible continuous current ($I_{max, perm}$). This results in the same setting value as for the first value of the user-defined characteristic curve.

Parameter: `Threshold thermal warn.`

- Recommended setting value **`(_:104) Threshold thermal warn.`** = ***`90 %`***

If the first value of the user-defined characteristic curve is 1.1 of the rated current, the default setting can be left. The thermal memory results for 83 % at continuously flowing rated object current.

If the first value of the user-defined characteristic curve is 1.05 of the rated object current, the thermal memory for rated current is already 91 % filled. Increase the **`Threshold thermal warn.`** to 95 %.

Parameter: `Dropout threshold operate`

- Recommended setting value **`(_:105) Dropout threshold operate`** = ***`90 %`***

The **`Dropout threshold operate`** parameter is used to drop out pickup and tripping when the value drops below this threshold. A setting on the order of magnitude of the warning threshold is recommended. You can select a lower setting value for special applications, desired additional cooling or longer blocking of closing.

Note that the calculation of the operational measured value **`Time until close`** refers to this value.

Parameter: Emerg. start T overtravel

- Default setting **(_:112) Emerg. start T overtravel** = ***300 s***

The **Emerg. start T overtravel** parameter is used to set the time for which blocking of the tripping has to remain active after an outgoing binary input signal **>Emergency start**. With an outgoing input signal, the load on the protected object is removed. The emergency start T-overtravel must be set long enough to allow the thermal memory to fall below the dropout threshold after cooling. Select a time on the order of magnitude of the **Cooling time constant**. In the example, 5 min (300 s) have been assumed.

Parameter: Imax thermal

- Recommended setting value **(_:107) Imax thermal** = ***2.5 A*** at I_{rated} = 1 A

The **Imax thermal** parameter allows you to set the threshold current for the **Behav. at I> Imax therm.** parameter. If you calculate with relatively long start times for motors (longer than 25 s), the current limiting must be reduced to 2 $I/I_{rated, obj}$.

Parameter: Imin cooling

- Recommended setting value **(_:108) Imin cooling** = ***0.5 A*** at I_{rated} = 1 A

When defining the minimum current **Imin cooling**, you can use the no-load current for orientation. If no data is available, set 0.5 $I/I_{rated, obj}$. If the current falls below this value, the internal thermal time constant τ automatically switches to the internal cooling time constant with the **Cool-down factor Tau** parameter.

Parameter: Storage of thermal replica

- Recommended setting value **(_:113) Storage of thermal replica** = ***no***

If a continuous auxiliary voltage for the bay units is ensured, the default setting can be retained.

Parameter: Behav. at I> Imax therm.

- Recommended setting value **(_:114) Behav. at I> Imax therm.** = ***current limiting***

The **Behav. at I> Imax therm.** parameter is used to select the process by which the function reacts to short-circuit currents. To prevent premature tripping of the overload protection at low time constants, high preloading and high short-circuit currents, the thermal replica can be modified. As overcurrent due to a starting of the motor also leads to a certain heating of the stator winding, limiting the input current is recommended for machines.

Parameter Value	Description
current limiting	The input currents are limited to the value set in the **Imax thermal** parameter. If the measured current exceeds the set current value, the limited current value is supplied to the thermal replica. An advisable current threshold is approx. 2 to 2.5 $I_{rated, obj}$.
freeze therm. rep.	If input currents exceed the **Imax thermal** parameter, the thermal replica will be frozen for the time the parameter is exceeded.

Parameter: Curve based on preload

- Default value **(_:101) Curve based on preload** = ***100 %***

The **Curve based on preload** parameter is used for a certain load case. In most cases, it applies for an operation under rated conditions. For that, it is assumed that rated current is flowing permanently. This is referred to as warm condition. In this case, the default setting 100 % is applied.

Thus, the thermal behavior is also correct for different preloads.

For cases without preload or cold condition, set the parameter to 0 %.

Parameter: **Cool-down factor Tau**

- Default value **(_:108) Cool-down factor Tau** = ***7.0***

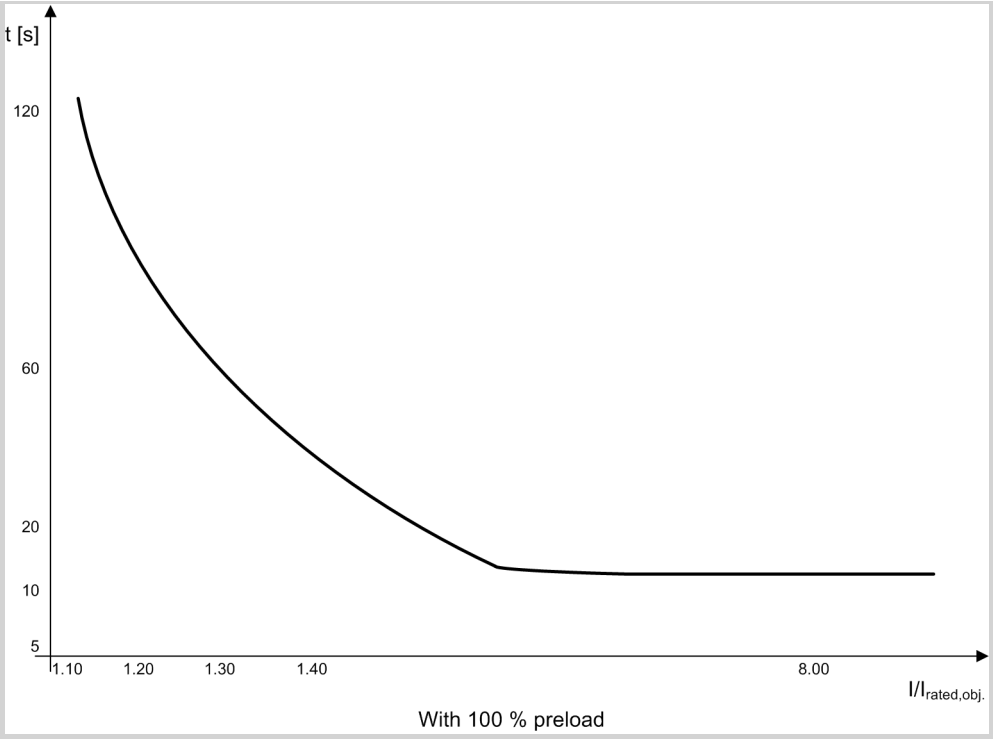
If the current becomes lower than the setting value of the **Imin cooling** parameter, you can set the **Cool-down factor Tau** parameter to calculate the internal cooling time constant.

Parameter: **Operate char. curve**

- Default value **Operate char. curve** = ***1.1 p.u., 600.00 s***

With the **Operate char. curve** parameter, you define the characteristic curve in a tabular form with ordered normalized current values and associated normalized time values.

When setting the parameter, consider the following:



- Set the current value as per-unit value with the rated current of the protected object as reference.
- Set the time value in seconds.
- Enter the values in continuous order.

EXAMPLE

With the following 12 points, you can get a user-defined characteristic curve as shown in the following figure.

Table 6-13 User-Defined Points

I / I_{obj}	t (s)
1.16	120.00
1.21	96.00
1.25	76.00
1.28	62.00
1.35	48.00
1.42	37.50
1.48	33.50
1.58	27.50
1.84	20.50
2.09	14.00
2.25	9.85
8.00	9.85

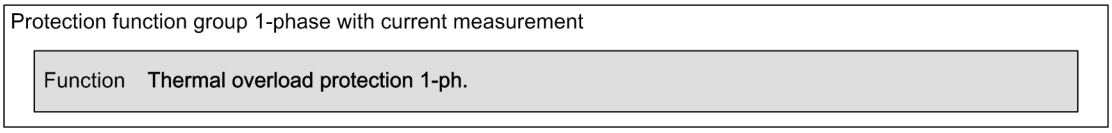
6.21 Thermal Overload Protection, 1-Phase

6.21.1 Overview of Functions



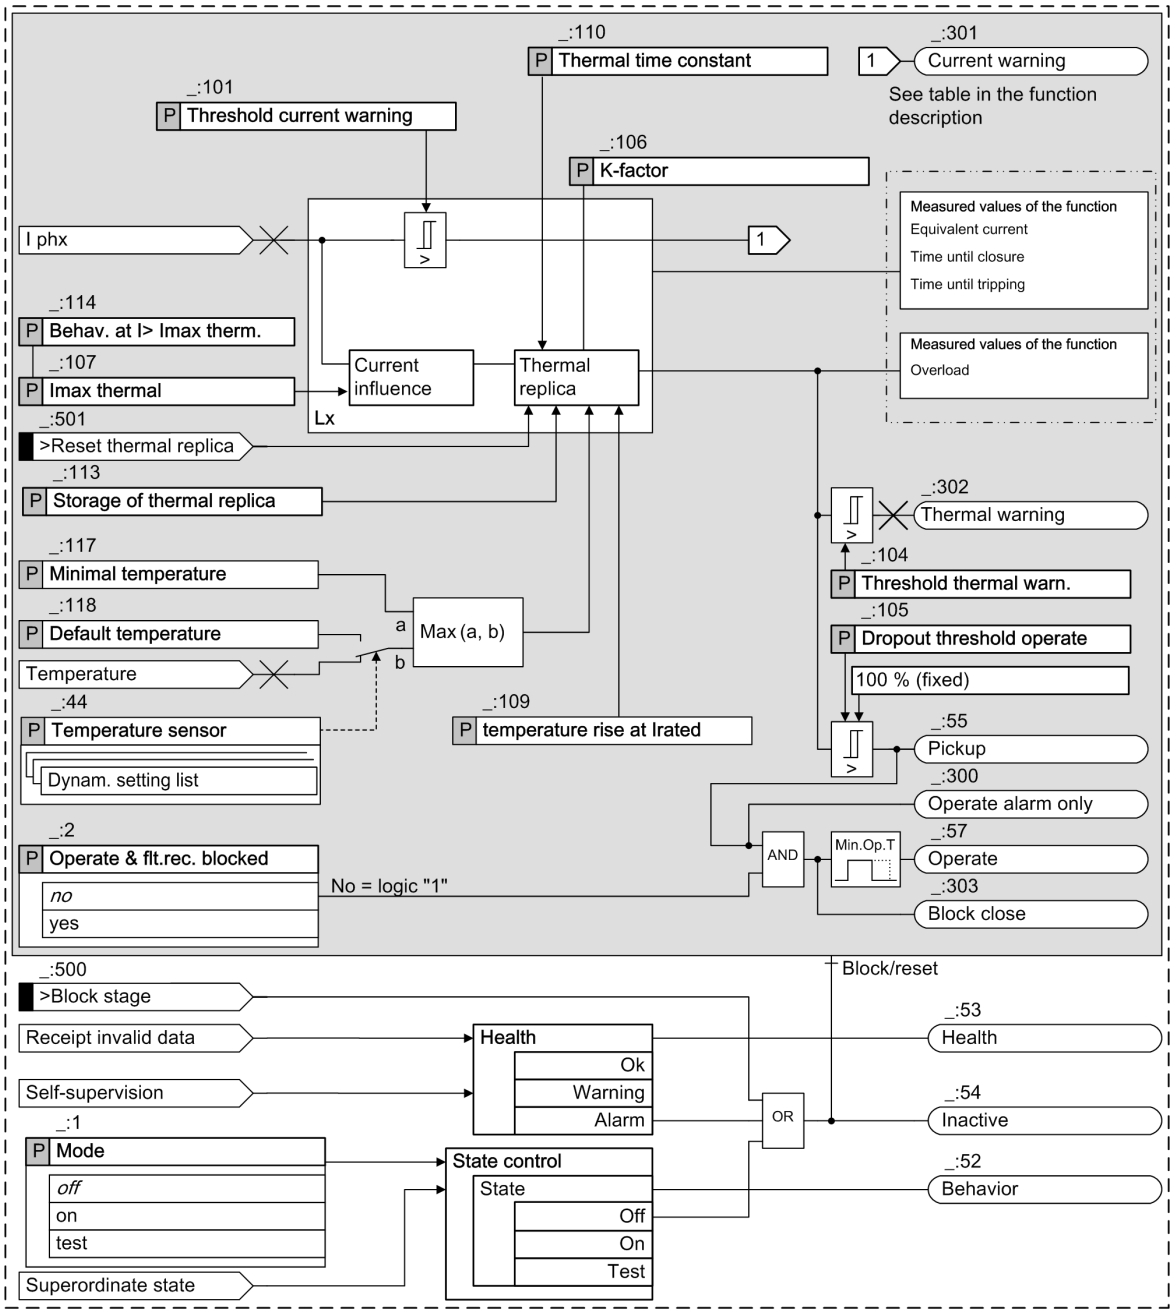
The **Thermal overload protection 1-phase** function (ANSI 49) is used to:

- Protect the equipment (reactors or resistors in the neutral point of a transformer) from thermal overload

6.21.2 Structure of the Function

The **Thermal overload protection 1-phase** function is used in 1-phase protection function groups with current measurement..

The **Thermal overload protection, 1-phase** function is steplessly preconfigured.



[dwtolp1p-270613-01.tif, 2, en_US]

Figure 6-164 Structure/Embedding of the Function

6.21.3 Function Description

Logic

[lotolp1p-250713-01.tif, 2, en_US]

Figure 6-165 Logic Diagram of the Thermal Overload Protection Function

Thermal Replica

The protection function calculates the overtemperature from the current flowing in the protected object (for example, reactor or resistance in the transformer neutral point) on the basis of a thermal single-body model according to the thermal differential equation with

$$I_{p.u.}^2 = \tau_{th} \frac{d\Theta}{dt} + \Theta - \Theta_V$$

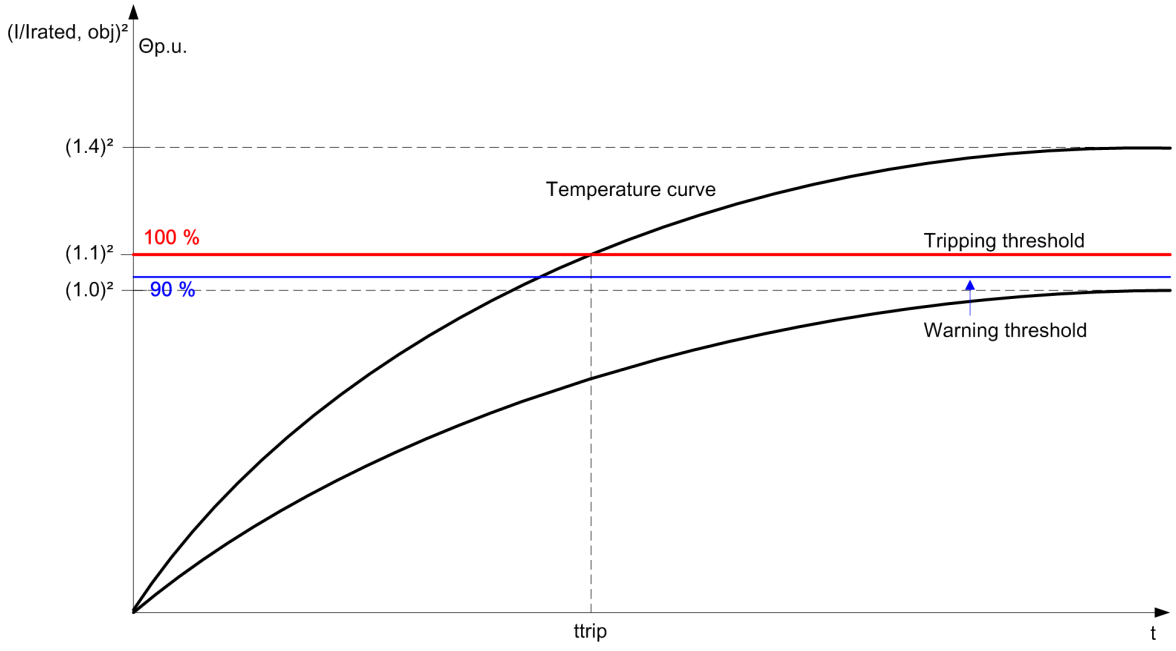
[fodiffgl-310510-01.tif, 2, en_US]

With the following standardization:

$$I_{p.u.} = \frac{I}{I_{max}} = \frac{I}{k \cdot I_{rated,obj.}} \qquad \Theta = \frac{\vartheta}{\vartheta_{max}} = \frac{\vartheta}{k^2 \cdot \Delta\vartheta_{rated,obj.}}$$

$$\tau_{th} = R_{th} \cdot C_{th} \qquad \Theta_V = \frac{\vartheta_{Amb} - 40\,°C}{\vartheta_{max}} = \frac{\vartheta_{Amb} - 40\,°C}{k^2 \cdot \Delta\vartheta_{rated,obj.}}$$

[fonormie-310510-01.tif, 2, en_US]



Θ	Current overtemperature, in relation to the final temperature at a maximum permissible current k $I_{rated, obj}$
Θ_V	Standardized ambient temperature, where ϑ_{Amb} describes the coupled ambient temperature. The coupled ambient temperature ϑ_{Amb} can be the measured ambient temperature or the ambient temperature preset using the **`Default temperature`** parameter.
$\Delta\vartheta_{rated\ obj}$	Overtemperature of the protected object set at rated current
τ_{th}	Thermal time constant (temperature rise/cooling) of the protected object
k	This factor indicates the maximum continuous permissible phase current. The factor refers to the rated current of the protected object ($k = I_{max}/I_{rated,\ obj}$)
$I_{rated.,\ obj}$	Rated current of the protected object

At the same time, $I_{rated,\ obj}$ is the rated current of the protected object.

In a steady state, the solution to the thermal differential equation is an e-function whose asymptote represents the final overtemperature Θ_{end}. The time constant τ_{th} determines the rise. After reaching an initial adjustable overtemperature threshold Θ_{warn} (**`Threshold thermal warn.`**), a warning indication is given.

If the overtemperature limit Θ_{Off} (tripping overtemperature) is exceeded, an operate indication is immediately issued and the equipment disconnected from the power supply. This threshold is specified at 100 % and corresponds to the final temperature set at a flowing permissible continuous current (I_{max}).

Figure 6-166 shows the temperature rise at different overload currents and the supervision thresholds.

[dwtempve-030211-01.tif, 1, en_US]

Figure 6-166 Temperature History for Different Overload Currents (**`K-factor`** = ***`1.1`***)

The current overtemperature can be obtained from the operational measured values. It is shown in percent. An indication of 100 % means that the thermal threshold has been reached.

The analysis of the RMS value of the current over a broad frequency band also includes the harmonic components. These harmonic components contribute to the temperature rise of the equipment.

Ambient Temperature

This function can take the ambient temperature into consideration The reference temperature of the thermal model is 40 °C. If the ambient temperature drops below the reference temperature, the thermal limit increases. The equipment can be stressed more. If the ambient temperature is higher, the conditions change.

The **Default temperature** parameter can be used to fix or measure the ambient temperature. The **Minimal temperature** parameter limits the coupled ambient temperature. If the measured ambient temperature is lower than the minimum temperature, the minimum temperature is processed in the thermal model.

The ambient temperature refers to the overtemperature of the protected object, which sets itself at the rated current (parameter **Temperature rise at Irated**).

The measured ambient temperature is recorded by an external RTD unit (RTD = Resistance Temperature Detector) and provided by the functions **RTD unit Ether.** or **RTD unit serial** of the function group **Analog units**. When using the **Temperature sensor** parameter, the respective temperature sensor can be selected.

If the temperature measurement is disrupted, for example, due to an open circuit between the device and the RTD unit, the device will report it. In this case, the process continues with either the temperature measured last or the value set under the **Default temperature** parameter, whichever value is the highest.

Current Influence

The thermal replica based on the single-body model applies with limitations to high overcurrent situations (short circuits). To avoid an overfunction of the overload protection, the thermal replica must be influenced for overcurrents (exceeding $\mathbf{I}_{\text{limit}}$). You can select between 2 strategies for this:

- Freezing of the thermal memory
- Limitation of the input current for the thermal replica to the set current. The temperature rise is thereby **retarded** at high currents.

Warning Thresholds

The thermal warning threshold issues a warning indication before the tripping threshold (tripping temperature) is reached. In this way, for example, a load can be reduced in sufficient time and a disconnection avoided. At a normal **K-factor** of ***1.1***, a thermal memory value of 83 % sets in at continuously flowing rated current.

Apart from the thermal warning threshold, the overload protection also has a current-warning threshold. This current-warning threshold can signal an overload current in sufficient time before the overtemperature value has reached the warning or tripping threshold.

Dropout of Tripping

Once the thermal memory has fallen below the setting value of the **Dropout threshold operate**, the trip command is cancelled upon tripping. In contrast, the current-warning threshold and the thermal warning threshold are reduced at a fixed dropout threshold (see technical data).

Behavior in the Event of Auxiliary-Voltage Failure

The behavior of the thermal replica can be controlled upon auxiliary-voltage failure via the **Storage of thermal replica** parameter. You can save the thermal state for a down time of 500 min. If the supply voltage returns, the thermal replica continues to function with the saved thermal state.

If the thermal replica is not saved, it will be reset to 0 upon failure of the auxiliary voltage.

Resetting the Thermal Map

You can reset the thermal memory via the binary input indication **>Reset thermal replica**. The thermal memory will then have a 0 value. A reparameterization will also lead to resetting the thermal memory.

Blocking the Function

Blocking will cause a picked up function to be reset. The function can be blocked externally or internally by the binary input signal **>Block stage**.

All indications then drop out and the thermal memory is set to the value 0.

Blocking Closure

The signal **Block close** can be used to prevent closure of the protected object at a high thermal load. The signal is set if the tripping overtemperature is exceeded, and cancelled if the temperature falls below the dropout threshold.

Functional Measured Values

Measured Value	Description
(_:310) Equival. current	Besides the thermal measured values in percent, the equivalent current is also issued as a thermal current-measured value (A or kA). The current equivalent is the primary current, which corresponds to the thermal measured value in percent, assuming steady-state conditions.
(_:304) Time until close	The **Time until close** is the expected time until it is possible for the protected object for reclosure. The calculation of this value is based on the assumption of constant currents. The thermal replica has then fallen below the setting value of the dropout threshold.
(_:305) Time until trip	The **Time until trip** is the expected time until tripping (100 % value exceeded) occurs. The calculation of this value is based on the assumption of constant currents.
(_:306) Overload	The value **Overload** indicates the current temperature of the protected object in percent. Tripping occurs if 100 % is exceeded.

6.21.4 Application and Setting Notes

Parameter: Threshold current warning

- Recommended setting value **(_:101) Threshold current warning** = ***1.1 A*** for I_{rated} = 1 A

Set the threshold to the maximum permissible continuous current ($I_{max, perm}$). This results in the same setting value as for **K-factor**.

Parameter: Threshold thermal warn.

- Recommended setting value **(_:104) Threshold thermal warn.** = ***90 %***

The default setting can be left at a **K-factor** of 1.1, because the thermal memory sets itself to 83 % at continuously flowing rated current. The calculation uses the rule of three: 100 % corresponds to (**K-factor**)^2 and x % corresponds to 1^2.

$$\frac{\Theta}{\Theta_{off}} = \frac{100\ \%}{k^2} = 83\ \%$$

[fowarnsc-100810-01.tif, 2, en_US]

At a **K-factor** of 1.05, the thermal memory for rated current is 91% filled. Increase the **Threshold thermal warn.** to 95%.

Parameter: Dropout threshold operate

- Recommended setting value **(_:105) Dropout threshold operate** = ***90 %***

The **Dropout threshold operate** parameter is used to cancel pickup and tripping when the value drops below this threshold. A setting on the order of magnitude of the warning threshold is recommended. You can select a lower setting value for special applications, desired additional cooling, or longer blocking of switching on.

The calculation of the operational measured value **Time until close** refers to this value.

Parameter: K-factor

- Recommended setting value **(_:106) K-factor** = ***1.1***

The **K-factor** parameter is used to describe the limiting value for the maximum permissible continuous load. The rated current $I_{rated, obj}$ of the protected object (for example, resistance) is the basic current for overload sensing.

You can determine **K-factor** on the basis of the thermally permissible continuous current $I_{max, perm.}$:

$$K\text{-factor} = \frac{I_{max,perm.}}{I_{rated,obj.}}$$

[fotoIpkf-100810-01.tif, 2, en_US]

NOTE

The thermally permissible continuous current for the protected object is known from relevant tables or from the specifications of the manufacturer!

Siemens recommends using the default value as it is a typical value for many applications.

Parameter: Thermal time constant

- Default value **(_:110) Thermal time constant** = ***900 s (15 min)***

The **Thermal time constant** parameter is used to define the operate curve of the stage. If no time constant is given, you can derive it from other values.

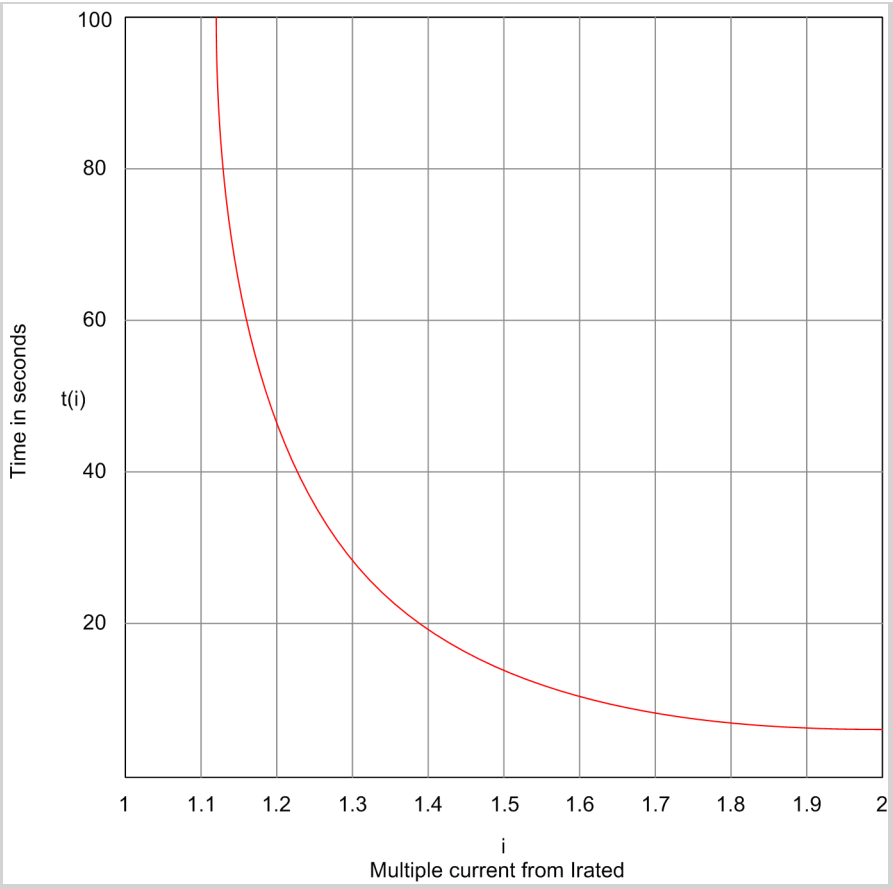
EXAMPLE

Protection of a current-limiting resistance

Rated current of the resistance: I_{rated} = 100 A

Values for the overload capability:

- 1.1 I_{rated} permanent (k-Factor = 1.1; k = 1.1)
- 1.5 I_{rated} for 20 s for charge by cold



The following time constant results from these assumed values:

$$\tau_{th} = t \times \left[\ln \frac{\left(\frac{I}{k \times I_{rated\ ,obj}}\right)^2}{\left(\frac{I}{k \times I_{rated\ ,obj}}\right)^2 - 1} \right]^{-1} = 20\ s \times \left[\ln \frac{\left(\frac{1.5}{1.1}\right)^2}{\left(\frac{1.5}{1.1}\right)^2 - 1} \right]^{-1} = 20\ s \times \left[\ln \frac{1.86}{0.86} \right]^{-1} \approx 26\ s$$

[fo_time_constance_11082015, 1, en_US]

For **Thermal time constant**, set 26 s.

The following time-dependent characteristic results from the data. In case of a current increase to 1.5 I_{rated}, the tripping occurs in 20 s.

[dwtime-dependent-110815-01.vsd, 1, en_US]

Parameter: Imax thermal

- Recommended setting value **(_:107) Imax thermal** = ***2.5 A*** for I_{rated} = 1 A

The **Imax thermal** parameter allows you to set the threshold current for the **Behav. at I> Imax therm.** parameter. The selected current threshold of 2.5 $I_{rated, obj}$ is a practicable value.

Parameter: Temperature rise at Irated

- Default setting **(_:109) Temperature rise at Irated** = ***70 K***

NOTE

For an application as a 1-phase overload protection, the ambient temperature measured via the temperature sensor is not taken into account. Therefore, the setting has no influence. You can keep the default setting. If you take into account the temperature, note the following descriptions.

Set the overtemperature as the value that is the result if the equipment is continuously operated with the rated current and at an ambient temperature of 40°C. Here, the rated current refers to the protected object. You can find the temperature value in the Technical data of the equipment or you can measure the value. If you use a temperature sensor when measuring at the rated current, deduct the actual ambient temperature or the coolant temperature from the measured value.

When selecting the setting value, you can also use the specified temperature class for orientation. Usually, you will find the overtemperature expressed in Kelvin (K), which can be accepted as is. If the absolute temperature is given, the ambient temperature must be deducted. As a rule, this is 40 °C.

The overtemperature at maximum permissible current (***ϑmax***) and the **Temperature rise at Irated** (***ϑrated,obj.***) can be converted by using the following formula:

$$k^2 = \left(\frac{\Delta\vartheta_{max}}{\Delta\vartheta_{rated\ ,obj.}} \right)$$

[fo_ueb_for_Irated, 3, en_US]

EXAMPLE:

Temperature class **B** for continuous operation: permissible overtemperature = 80 K
From this, a temperature for I_{rated} of 120 °C (80 K + 40 °C) can be derived when using a measuring element for the measurement.
Temperature class **F** as thermal limiting value: permissible overtemperature = 105 K.
From this, a maximum temperature of 155 °C (105 K + 40 °C) derives.
From these values, the magnitude of the K factor can also be derived.

$$k^2 = \frac{\Delta\vartheta_{max\ ,Obj.}}{\Delta\vartheta_{rated\ ,Obj.}} = \frac{105\ K}{80\ K} = 1.31 \qquad \rightarrow\ k = 1.146$$

[fo_bsp_kfaktor, 3, en_US]

If selecting a setting value of 1.1 for the **K-factor**, your selection can be considered as conservative.

Parameter: Storage of thermal replica

- Recommended setting value **(_:113) Storage of thermal replica** = ***no***

If a continuous auxiliary voltage of the bay units is ensured, the default setting can be retained.

Parameter: Behav. at I> Imax therm.

- Recommended setting value **(_:114) Behav. at I> Imax therm.** = ***current limiting***

The **Behav. at I> Imax therm.** parameter is used to select the process by which the function reacts to short-circuit currents. To prevent premature tripping of the overload protection at low time constants, high preloading and high short-circuit currents, the thermal replica can be modified.
The default setting has been selected compatible with SIPROTEC 4 devices. If you wish to take further temperature rise into consideration, the **current limiting** procedure is recommended.

Parameter Value	Description
current limiting	The input current is limited to the value set in the **Imax thermal** parameter. If the measured current exceeds the set current value, the limited current value is supplied to the thermal replica. An advisable current threshold is approx. 2 to 2.5 $I_{rated, obj}$.
freeze therm. rep.	If the input current exceeds the **Imax thermal** parameter, the thermal replica will be frozen for the time the parameter is exceeded. This parameter value is provided to enable compatibility with older products!

Parameter: Temperature sensor

- Default setting **(_:44) Temperature sensor** = ***none***

Use the **Temperature sensor** parameter to determine which temperature sensor to use to detect the ambient temperature.
A temperature sensor (RTD = Resistance Temperature Detector) is used to measure the ambient temperature of the protected object and to feed it to the device via an RTD unit. The function **Thermal overload protection** receives the measured temperature value via the function **RTD unit Ether.** or **RTD unit Serial** from the function group **Analog units**.

Parameter: Default temperature

- Recommended setting value **(_:118) Default temperature** = ***40 °C***

Under the following conditions, the **Default temperature** will be set as ambient temperature:

- A temperature sensor for measuring the ambient temperature is not connected.
- The temperature measurement is interrupted and the measured temperature value is less than the **Default temperature**.

Siemens recommends using the default setting.

Parameter: Minimal temperature

- Default setting **(_:117) Minimal temperature** = ***-20 °C***

If the measured ambient temperature drops below the preset value, the set value will be assumed as the ambient temperature. If the overload protection works with a prespecified outside temperature, and this temperature drops below the value set in the **Minimal temperature** parameter, the **Minimal temperature** can also be used.

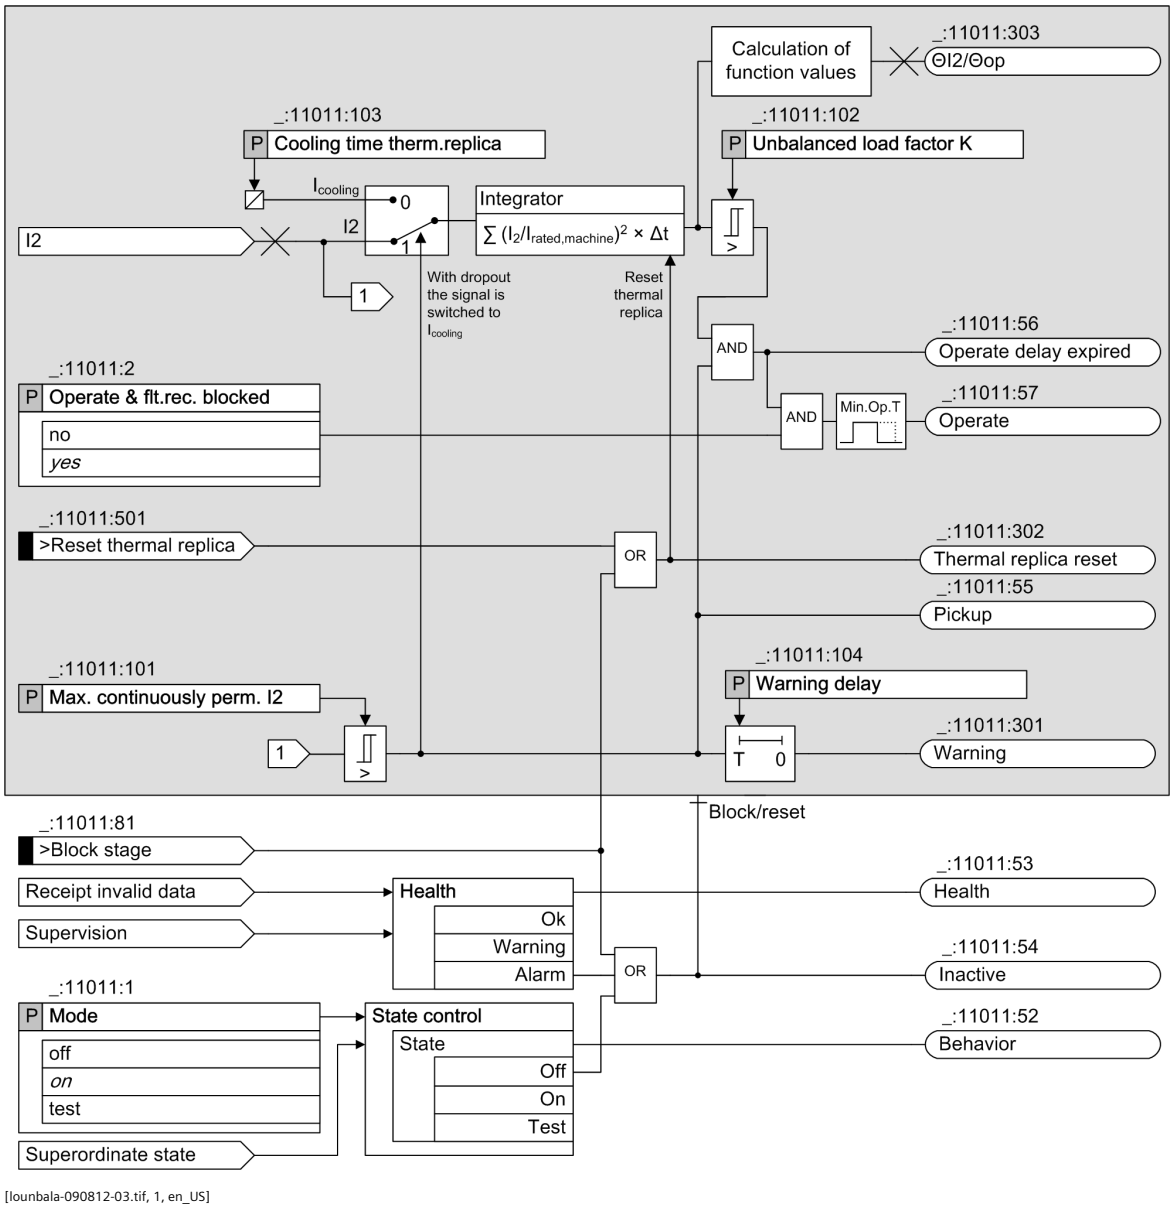
6.22 Unbalanced-Load Protection

6.22.1 Overview of Functions

The **Unbalanced-load protection** function detects unbalanced loads or line interruptions of electrical machines (generators and motors). Unbalanced loads create a counter-rotating magnetic field at double frequency in the rotor. The skin effect leads to local overheating on the surface of the rotor bars in the transition between the slot wedges and the winding bundles. Another effect of unbalanced loads is the overheating of the damper winding.

6.22.2 Structure of the Function

The **Unbalanced-load protection** function is used in the protection function group. The **Unbalanced-load protection** function is preconfigured with 1 stage. A maximum of 2 stages can operate simultaneously in the function.



[dwunbla-240913, 1, en_US]

Figure 6-167 Structure/Embedding of the Function

6.22.3 Function Description

Logic of the Stage

[lounbala-090812-03.tif, 1, en_US]

Figure 6-168 Logic Diagram of the Unbalanced-Load Protection Function

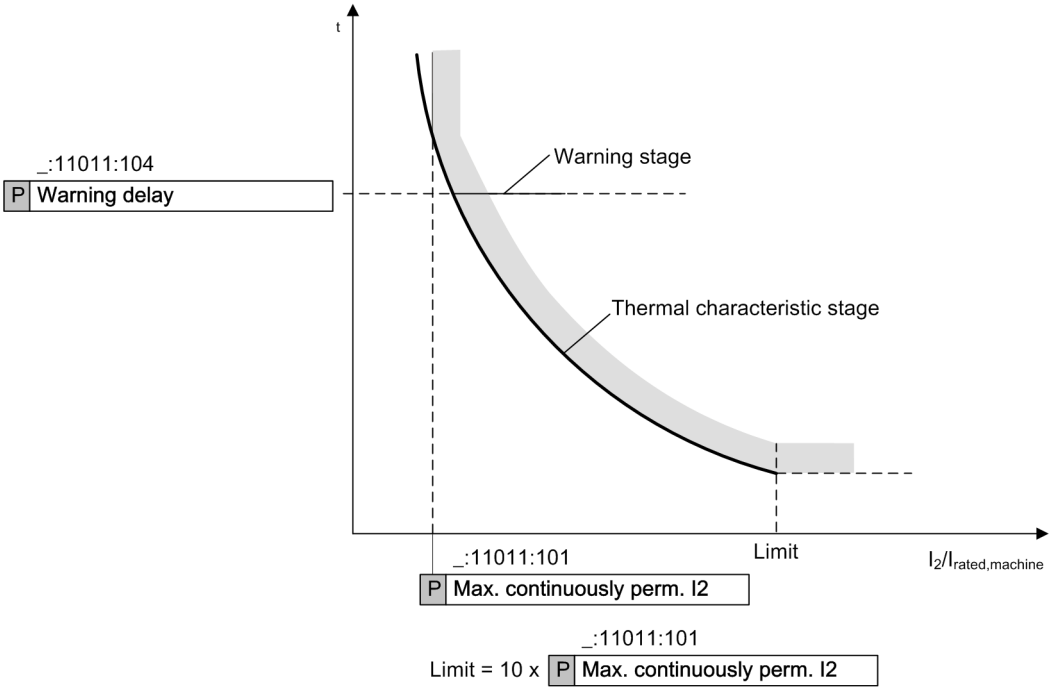
Method of Measurement

The stage uses the negative-sequence current I_2 as a measurand. The negative-sequence current is calculated from the measured 3-phase currents according to the defining equation of symmetrical components.

Warning Stage

If the negative-sequence current I_2 continuously exceeds the parameter **`Max. continuously perm. I2`**, the *`warning`* indication is given after expiry of a set time **`Warning delay`**.

Thermal Characteristic Stage



The machine manufacturers indicate the permissible unbalanced load using the following formula:

$$t_{I2\,Perm} = \frac{K}{\left(I_2 / I_{rated,machine}\right)^2}$$

[forbanl1-030812-02.tif, 1, en_US]

With:

t_{I2Perm}	Permissible time of the negative-sequence current
K	Unbalanced-load factor of the machine (parameter **Unbalanced load factor K**)
$I_2/I_{rated,machine}$	Actual unbalanced-load current as a per unit value(negative-sequence current/rated current of the machine)

[dwunbalo-230913, 2, en_US]

Figure 6-169 Operate Curve of the Unbalanced-Load Protection

The parameter **Unbalanced load factor K** depends on the machine. It also represents the time in seconds during which the machine can be loaded with a 100 % unbalanced load. This factor is typical in a range from 5 s to 40 s. The heating of the protected object starts to calculate as soon as the negative-sequence current I_2 exceeds the parameter **Max. continuously perm. I2**. The operate time is calculated from the flowing negative-sequence current I_2 with an integrating method of measurement depending on the thermal characteristic. As soon as the integrate result reaches the parameter **Unbalanced load factor K**, the thermal characteristic stage operates.

Limitation of Operate Curve

To avoid an overfunction of the thermal characteristic stage in the situation of unbalanced short circuits (for example, 2-phase short circuit), the input current I_2 is restricted to an upper limit. The limiting value is 10 times of **Max. continuously perm. I2**. If I_2 exceeds the limit, the operate time of the function is constant.

In addition, the thermal memory is limited to 200 % of **Unbalanced load factor K**. The limitation avoids a too long cooling after a delayed short-circuit tripping (for example, of external power-system faults).

Cooling Time Thermal Replica

The thermal replica starts to cool down as soon as the negative-sequence current I_2 is lower than **Max. continuously perm. I2**. The thermal replica decreases according to the parameter **Cooling time therm.replica**. The parameter **Cooling time therm.replica** is the time required by the thermal replica to cool down from 100 % to 0 %. If the parameter **Cooling time therm.replica** is set to 0, the thermal replica is reset immediately.

The parameter **Cooling time therm.replica** depends on the construction type of the machine, especially of the damper winding. Preloading is considered when unbalanced loading occurs again during the cooling time. The protection device thus operates in a shorter time.

Functional Measured Values

The following formula is used to calculate the functional measured value ΘI2/Θop:

$$\Theta I2/\Theta op = \frac{\sum_{0}^{t}\left(I_2/I_{rated,machine}\right)^2 \cdot \Delta t}{K} 100\ \%$$

[forunbl2-030812-02.tif, 1, en_US]

With

ΘI2/Θop	Functional measured value indicating the thermal replica of the unbalanced load
$\sum_{0}^{t}\left(I_2/I_{rated,\ machine}\right)^2 \cdot \Delta t$	Integrating method of measurement of the thermal replica of the negative-sequence system
K	Unbalanced-load factor of the machine (parameter **Unbalanced load factor K**)
$I_2/I_{rated,machine}$	Unbalanced-load as a per unit value (negative-sequence current/rated current of the machine)

If the functional measured value reaches 100 %, the operate of the function is initiated.

6.22.4 Application and Setting Notes

The function is used in the applications of machines. You can get the necessary settings from the technical data of the synchronous generators and motors. The setting example is applied for a generator application.

Parameter: Max. continuously perm. I2, Warning delay

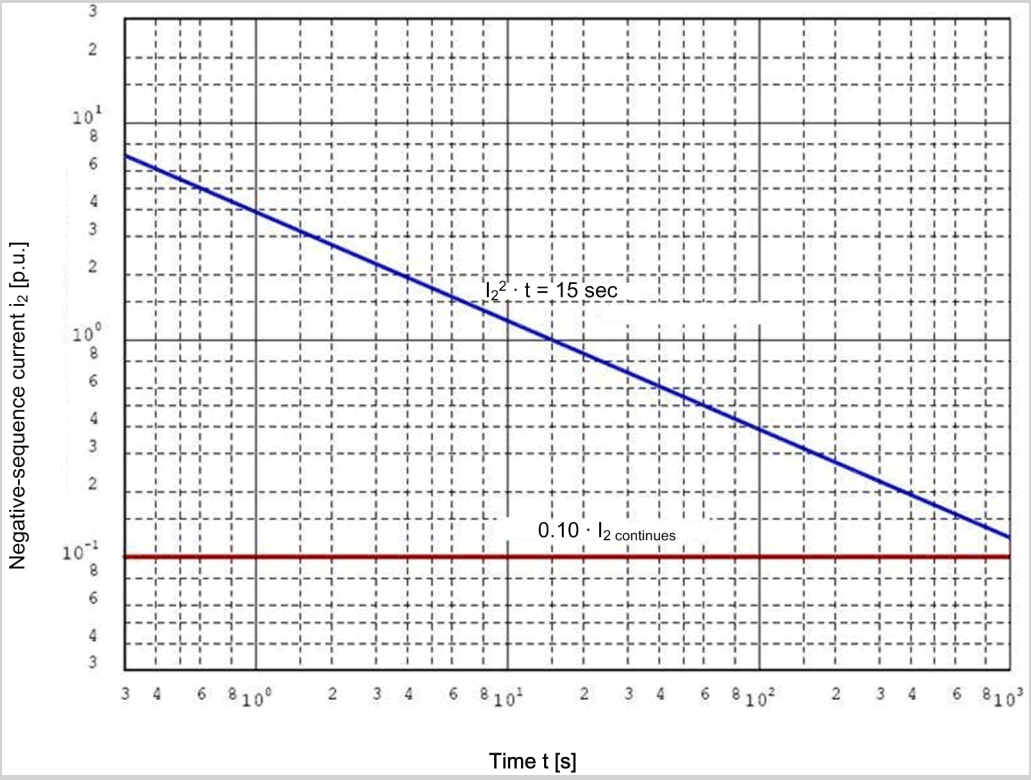
- Default setting **(_:11011:101) Max. continuously perm. I2** = ***10.0 %***
- Default setting **(_:11011:104) Warning delay** = ***15 s***

If the negative-sequence current I_2 exceeds **Max. continuously perm. I2** , the stage picks up and a warning indication is given after the set time delay **Warning delay** .

The parameter **Max. continuously perm. I2** is given in percentage of the rated current of the protected object.

The setting value of the parameter **Max. continuously perm. I2** depends on following parts:

- Design of the machine (salient pole or non-salient pole rotor synchronous machine)
- Cooling system (directly or indirectly cooled)
- Size of the machine



Depending on the standards IEEE C50.12 and IEC 60034-1, the parameter is given in the range between 5 % and 12 %. To set the parameter **Max. continuously perm. I2** , technical data of the machine is

required. The technical data of the machine is provided in the Technical Data Sheet of the machine manufacturer.

EXAMPLE

The following example shows the setting of the parameter **Max. continuously perm. I2** . The value 10 % is selected in the example.

To avoid issuing the *Warning* indication too fast, Siemens recommends a longer delay. Setting the parameter **Warning delay** in the range of 10 s to 20 s is practicable. 15 s is selected in the example.

[dwunbloc-030812, 1, en_US]

Figure 6-170 Example of an Unbalanced-Load Characteristic Specified by the Machine Manufacturer

Parameter: Unbalanced load factor K

- Default setting **(_:11011:102) Unbalanced load factor K** = ***15 s***

Unbalanced load factor K can be derived from the unbalanced-load characteristic according to *Figure 6-170* . You can read the time corresponding to **Unbalanced load factor K** at the point I_2 / $I_{rated,machine}$= 1. In the example, this is the p.u. value 10° which corresponds to a time of 15 s. As the example shows, the time is often written directly on the characteristic curve.

Parameter: Cooling time therm.replica

- Default setting **(_:11011:103) Cooling time therm.replica** = ***1500 s***

The parameter **Cooling time therm.replica** establishes the time required by the protected object to cool down the thermal replica to the initial value. If the machine manufacturer does not provide this information, the setting value of **Cooling time therm.replica** can be calculated from the setting values of **Unbalanced load factor K** and **Max. continuously perm. I2** by the formula in the following example.

EXAMPLE

$$\text{Cooling time therm. replica} = \frac{\text{Unbalanced load factor K}}{(\text{Max. continuously perm. I 2})^2}$$

[forbala2-290812-02.tif, 1, en_US]

Max. continuously perm. I_2	= 10.0 % (corresponds to 0.1)
Unbalanced load factor K	= 15 s
Cooling time therm. replica	= 1500 s

6.23 Overvoltage Protection with 3-Phase Voltage

6.23.1 Overview of Functions

The function **Overvoltage protection with 3-phase voltage** (ANSI 59) is used to:

- Monitor the permissible voltage range
- Protect equipment (for example, plant components, machines, etc.) against damages caused by overvoltage
- Decouple systems (for example, wind power supply)

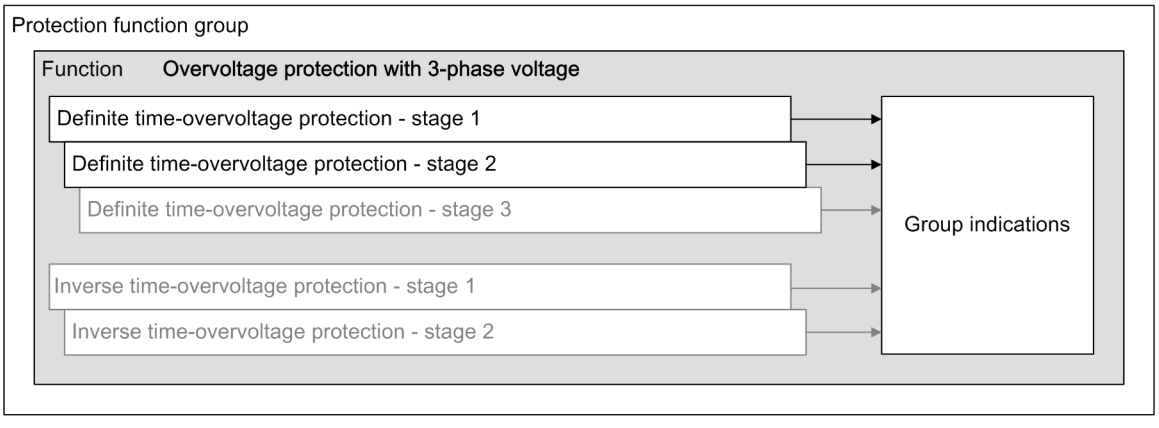
Abnormally high voltages in power systems are caused by voltage controller failure at the transformer or on long transmission lines under low-load conditions.

When using common-mode reactors in the protected power system, the device must shut down the line quickly if the reactors fail (for example, due to fault clearance). The insulation is endangered by the overvoltage condition.

Overvoltages at capacitor banks can be caused by resonances with line or transformer inductances.

In power plants increased voltage levels can be due to one of these factors:

- Incorrect operation when controlling the excitation system manually
- Failure of the automatic voltage controller
- After full load shedding of a generator
- Generators which are disconnected from the network or in island mode



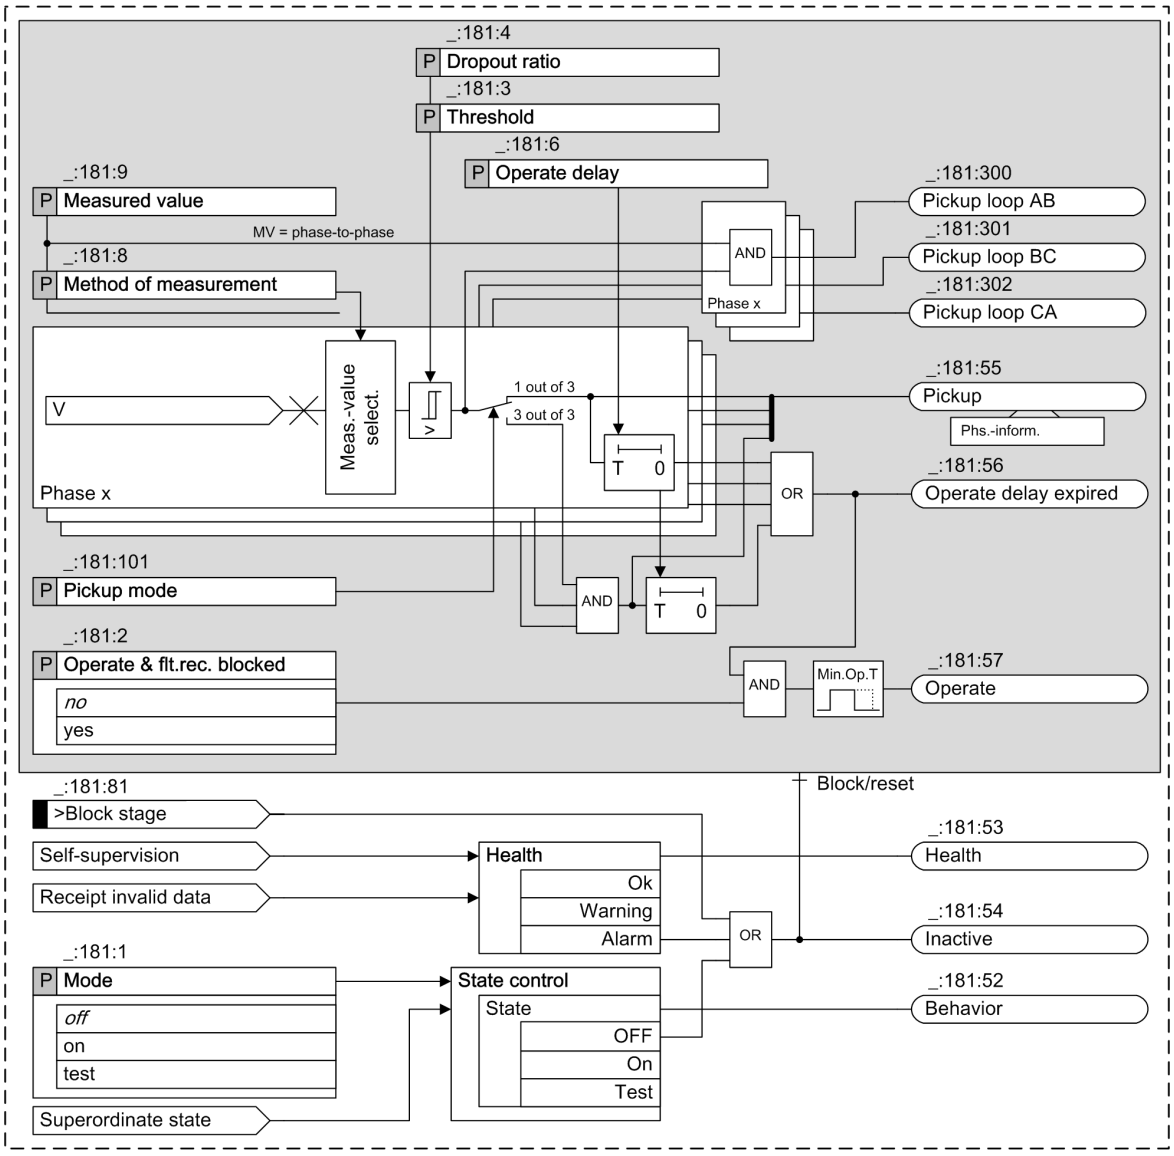
6.23.2 Structure of the Function

The **Overvoltage protection with 3-phase voltage** function is used in protection function groups with voltage measurement.

The **Overvoltage protection with 3-phase voltage** function is preconfigured by the manufacturer with 2 **Definite time-overvoltage protection** stages. In this function, the following stages can operate simultaneously:

- 3 stages **Definite time-overvoltage protection**
- 2 stages **Inverse time-overvoltage protection**

Stages that are not preconfigured are shown in gray in the following figure.



[dw3phovp-030211-01.tif, 3, en_US]

Figure 6-171 Structure/Embedding of the Function

6.23.3 Stage with Definite-Time Characteristic Curve

6.23.3.1 Description

Logic of the Stage

[lo3phasi-090611-01.tif, 3, en_US]

Figure 6-172 Logic Diagram of the Definite Time-Overvoltage Protection with 3-Phase Voltage

Method of Measurement

Use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the ***RMS value***.

- Measurement ***fundamental comp.***:
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.
- Measurement ***RMS value***:
  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Pickup Mode

The **Pickup mode** parameter defines whether the protection stage picks up if all 3 measuring elements detect the overvoltage condition (***3 out of 3***) or if only 1 measuring element detects the overvoltage condition (***1 out of 3***).

Measured Value

Use the **Measured value** parameter to define whether the tripping stage analyzes the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C.

If the measured value is set to phase-to-phase, the function reports those measuring elements that have picked up.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking is possible externally or internally via the binary input signal *>Block stage*.

6.23.3.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:181:8) Method of measurement** = ***fundamental comp.***

With the **Method of measurement** parameter, you define whether the stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends this method of measurement as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). Do not set the **threshold value** of the stage under 10 V for this method of measurement.

Parameter: Measured value

- Default setting **(_:181:9) Measured value** = ***phase-to-phase***

With the **Measured value** parameter, you define whether the stage monitors the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA} or the phase-to-ground voltages V_A, V_B, and V_C.

Parameter Value	Description
phase-to-phase	If you want to monitor the voltage range, keep ***phase-to-phase*** as the default setting. In this case, the function will not pick up on ground faults. Siemens recommends the measured value ***phase-to-phase*** as the default setting.
phase-to-ground	Select the ***phase-to-ground*** setting if you want to detect voltage unbalances and overvoltage conditions caused by ground faults.

Parameter: Threshold

- Default setting **(_:181:3) Threshold** = ***110 V***

Depending on the **Measured value** , the **Threshold** is set either as phase-to-phase quantity or as phase-to-ground quantity. The default setting assumes that the voltage range is monitored on long-distance transmission lines under low-load conditions.

Specify the **Threshold** (pickup threshold) for the specific application.

Parameter: Operate delay

- Default setting **(_:181:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:181:4) Dropout ratio** = ***0.95***

The recommended set value of ***0.95*** is appropriate for most applications. To achieve high measurement precision, the **Dropout ratio** can be reduced, to 0.98, for example.

Parameter: Pickup mode

- Recommended setting value **(_:181:101) Pickup mode** = ***1 out of 3***

With the **Pickup mode** parameter, you define whether the protection stage picks up if all 3 measuring elements detect the overvoltage condition (***3 out of 3***) or if only 1 measuring element detects the overvoltage condition (***1 out of 3***).

Parameter Value	Description
1 out of 3	Select the setting for protection applications or for monitoring the voltage range. Siemens recommends ***1 out of 3*** as the default setting. This reflects how the function behaved in previous generations (SIPROTEC 4, SIPROTEC 3).
3 out of 3	Select this setting when using the stage to disconnect from the power system (in the case of wind farms, for example).

Operation as Supervision Function

If you want the stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

EXAMPLE

Example for 2-stage overvoltage protection

The example describes the possible settings for a 2-stage overvoltage protection function. We will look at the settings of the parameters **Threshold** and **Operate delay**.

- 1. Stage:

  To detect stationary overvoltages, set the threshold value of the first overvoltage-protection element at least 10 % above the max. stationary phase-to-phase voltage anticipated during normal operation. When setting the parameter **Measured value** to phase-to-phase voltage and a secondary rated voltage of 100 V, the secondary setting value of the first overvoltage-protection element is calculated as follows:

Threshold value: 10 % above V_{rated}

$V_{threshold, sec} = 1.1\ V_{rated, sec} = 1.1 \times 100\ V = 110\ V$

This requires that the primary rated voltages of protected object and voltage transformer are identical. If they are different, you have to adjust the pickup value.

For the **Operate delay** set a value of 3 s.

- 2. Stage:

  The second overvoltage-protection stage is intended for high overvoltages with short duration. A high pickup value is selected here, for example, 1.5 times the rated voltage. A time delay setting of 0.1 s to 0.2 s is sufficient then.

Stage	Setting Values	
	Threshold value	Time delay
1	Time delay 1.1 V_{rated}	3 s

Stage	Setting Values	
2	1.5 V_{rated}	0.1 s to 0.2 s

6.23.4 Stage with Inverse-Time Characteristic Curve

6.23.4.1 Description

Logic of the Stage

[lo3phinv, 2, en_US]

Figure 6-173 Logic Diagram of the Inverse Time-Overvoltage Protection with 3-Phase Voltage

Method of Measurement

Use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the ***RMS value*** .

- Measurement ***fundamental comp.*** :

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

- Measurement ***RMS value*** :
  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Pickup Mode

With the **Pickup mode** parameter, you define whether the protection stage picks up if all 3 measuring elements detect the overvoltage condition (***3 out of 3***) or if only 1 measuring element detects the overvoltage condition (***1 out of 3***).

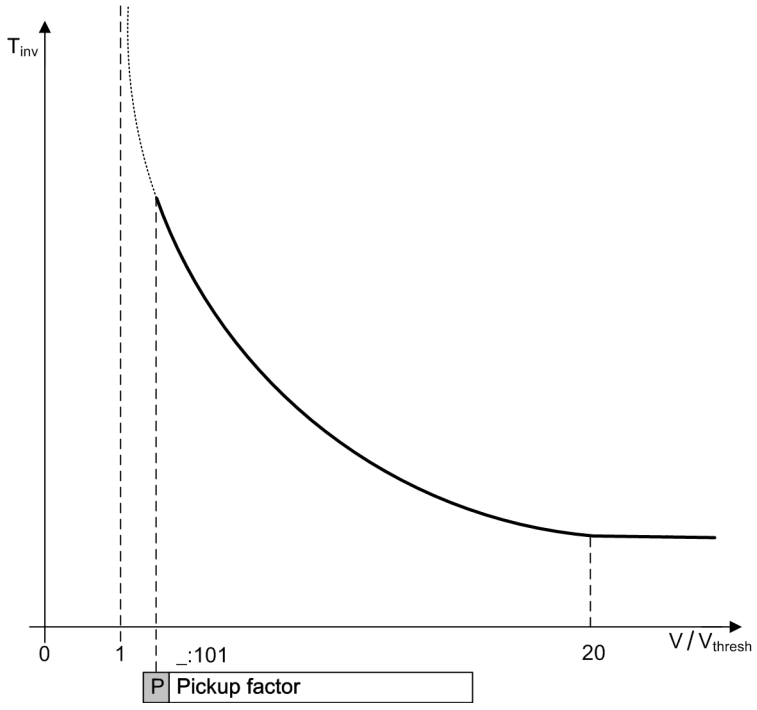
Measured Value

Use the **Measured value** parameter to define whether the stage analyzes the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C.

If the measured value is set to phase-to-phase, the function reports those measuring elements that have picked up.

Pickup and Operate Curve

When the input voltage exceeds the threshold value by a settable value **Pickup factor** , the stage picks up and the inverse-time characteristic curve is processed. Operate delay starts. The operate delay is the sum of inverse-time delay and additional time delay.



$$T_{op} = T_{inv} + T_{add}$$

Where

T_{op}	Operate delay
T_{inv}	Inverse-time delay
T_{add}	Additional time delay (parameter **Additional time delay**)

After pickup, the time value T_{inv} is calculated for every input voltage that exceeds the threshold. An integrator accumulates the value $1/T_{inv}$. Once the accumulated integral reaches the fixed value 1, the inverse-time delay expires. The additional time delay T_{add} starts. The stage operates after the additional time delay expires.

The inverse-time characteristic is shown in the following figure.

[dwovpinv, 2, en_US]

Figure 6-174 Operate Curve of Inverse-Time Characteristic

The inverse-time delay is calculated with the following formula:

$$T_{inv} = T_p \left(\frac{k}{\left(\frac{V}{V_{thresh}}\right)^{\alpha} - 1} + c \right) [s]$$

Where

T_{inv}	Inverse-time delay
T_p	Time multiplier (parameter **`Time dial`**)
V	Measured voltage
V_{thresh}	Threshold value (parameter **`Threshold`**)
k	Curve constant k (parameter **`Charact. constant k`**)
α	Curve constant α (parameter **`Charact. constant α`**)
c	Curve constant c (parameter **`Charact. constant c`**)

When V/V_{thresh} is equal to or greater than 20, the inverse-time delay does not decrease any further.

Dropout Behavior

When the voltage falls below the dropout threshold (0.95 × pickup factor × threshold value), the pickup signal is going and the dropout is started. You can define the dropout behavior via parameter **`Reset time`** . Instantaneous reset takes place by setting **`Reset time`** to 0 s. A delayed reset takes place by setting the desired delay time.

During the **`Reset time`** (> 0 s), the elapsed operate delay is frozen. If the pickup value is exceeded again within this period, the stage operates when the rest of operate delay expires.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking is possible externally or internally via the binary input signal *>Block stage* .

6.23.4.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:8) Method of measurement** = ***fundamental comp.***

With the **Method of measurement** parameter, you define whether the tripping stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends this method of measurement as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). Do not set the **threshold value** of the tripping stage under 10 V for this method of measurement.

Parameter: Measured value

- Default setting **(_:9) Measured value** = ***phase-to-phase***

With the **Measured value** parameter, you define whether the tripping stage monitors the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA} or the phase-to-ground voltages V_A, V_B, and V_C.

Parameter Value	Description
phase-to-phase	If you want to monitor the voltage range, keep ***phase-to-phase*** as the default setting. In this case, the function will not pick up on ground faults. Siemens recommends the measured value ***phase-to-phase*** as the default setting.
phase-to-ground	Select the ***phase-to-ground*** setting if you want to detect voltage unbalances and overvoltage conditions caused by ground faults.

Parameter: Threshold, Pickup factor

- Default setting **(_:3) Threshold** = ***110.000 V***
- Default setting **(_:101) Pickup factor** = ***1.10***

The stage picks up when the measured voltage value exceeds the pickup value **Threshold** × **Pickup factor**.

Depending on the **Measured value**, the **Threshold** is set either as phase-to-phase quantity or as phase-to-ground quantity.

With the **Pickup factor** parameter, you modify the pickup value. To avoid a long-time operate delay after pickup when the measured value is slightly over the threshold, Siemens recommends using the default setting.

Specify the **Threshold** (pickup threshold) and **Pickup factor** for the specific application.

Parameter: Pickup mode

- Recommended setting value **(_:182:101) Pickup mode** = ***1 out of 3***

With the **Pickup mode** parameter, you define whether the protection stage picks up if all 3 measuring elements detect the overvoltage condition (***3 out of 3***) or if only 1 measuring element detects the overvoltage condition (***1 out of 3***).

Parameter Value	Description
1 out of 3	Select the setting for protection applications or for monitoring the voltage range. Siemens recommends ***1 out of 3*** as the default setting. This reflects how the function behaved in previous generations (SIPROTEC 4, SIPROTEC 3).
3 out of 3	Select this setting when using the stage to disconnect from the power system (in the case of wind farms, for example).

Parameter: Charact. constant k, Charact. constant α, Charact. constant c

- Default setting **(_:102) Charact. constant k** = ***1.00***
- Default setting **(_:103) Charact. constant α** = ***1.000***
- Default setting **(_:104) Charact. constant c** = ***0.000***

With the parameters **Charact. constant k**, **Charact. constant α**, and **Charact. constant c**, you define the required inverse-time characteristic curve.

Parameter: Time dial

- Default setting **(_:105) Time dial** = ***1.00***

With the **Time dial** parameter, you displace the characteristic curve in the time direction.

As usually, there is no time grading for voltage protection and therefore no displacement of the characteristic curve, Siemens recommends leaving the **Time dial** parameter at ***1.00*** (default setting).

Parameter: Additional time delay

- Default setting **(_:106) Additional time delay** = ***0.00 s***

With the **Additional time delay** parameter, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, only the inverse-time delay is operative.

Parameter: Reset time

- Default setting **(_:107) Reset time** = ***0.00 s***

With the **Reset time** parameter, you define the reset time delay which is started when the voltage falls below the dropout threshold. Set the parameter **Reset time** to 0 s when instantaneous reset is desired.

Under network conditions of intermittent faults or faults which occur in rapid succession, Siemens recommends setting the **Reset time** to an appropriate value (> 0 s) to ensure the operation. Otherwise Siemens recommends to keep the default value to ensure a fast reset of the function.

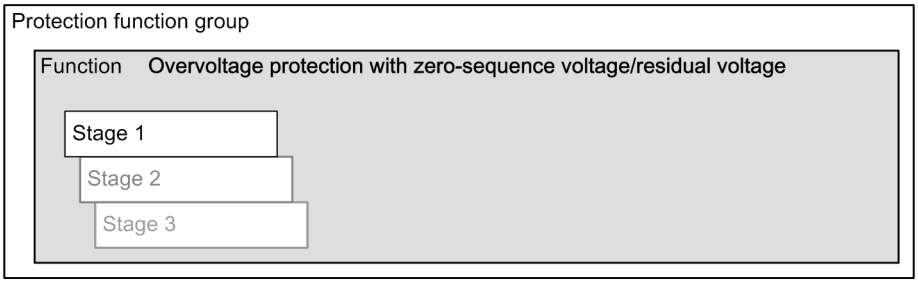
6.24 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage

6.24.1 Overview of Functions

The **Overvoltage protection with zero-sequence voltage/residual voltage** function (ANSI 59):



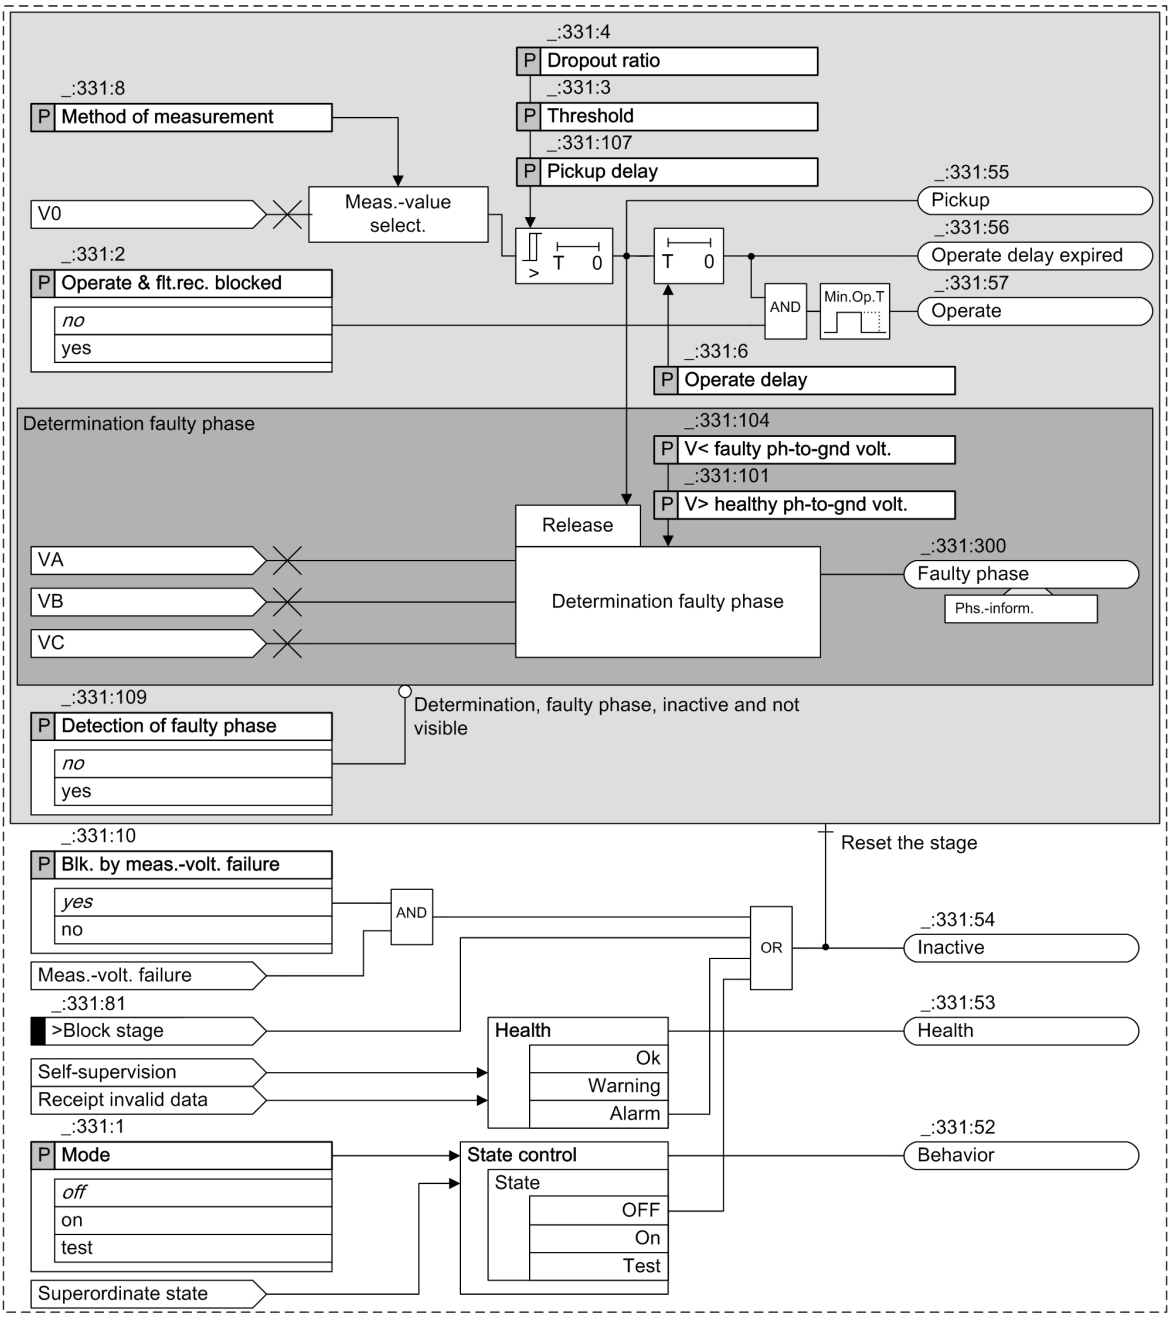
- Is used in isolated or arc-suppression-coil-grounded systems to detect ground faults
- determines the phase affected by the ground fault, if needed
- is used with electrical machines to detect ground faults in the stator winding.

6.24.2 Structure of the Function

The **Overvoltage protection with zero-sequence voltage/residual voltage** function is used in protection function groups, which are based on voltage measurement.

The **Overvoltage protection with zero-sequence voltage/residual voltage** function comes with 1 factory-set tripping stage. A maximum of 3 tripping stages can be operated simultaneously in the function.

The tripping stages have an identical structure.



[dwu0ovps-030211-01.tif, 1, en_US]

Figure 6-175 Structure/Embedding of the Function

6.24.3 Stage Description

Logic of a Stage

[loovpu03-090611-01.tif, 2, en_US]

Figure 6-176 Logic Diagram of an Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage Stage

Measured Value, Method of Measurement

The device measures the residual voltage at the broken-delta winding. The measured voltage is converted to the zero-sequence voltage V_0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V_0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

Use the **Method of measurement** parameter to select the relevant method of measurement, depending on the application.

- Measurement of the ***fundamental comp.*** (standard filter):

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

- Measurement of the ***RMS value*** parameter value (true RMS):

  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value.

- ***fund. comp. long filter*** (fundamental component over 2 cycle filters with triangular window):

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically. The extended filter length compared to the standard filter and the use of the triangular window results in a particularly strong attenuation of harmonics and transient faults. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see Technical Data).

Pickup, Dropout

The stage compares the **Threshold** with the zero-sequence voltage V_0. The **Pickup delay** parameter allows you to delay the pickup of the stage depending on the residual voltage.

With the **Dropout ratio** parameter you can define the ratio of the dropout value to the **Threshold**.

Determination of the Faulty Phase

You can use the **Detection of faulty phase** parameter to enable or disable the determining of the phase affected by the ground fault. Determining is released when the stage picks up. If 2 phases exceed the threshold value **V> healthy ph-to-gnd volt.** and 1 phase falls below the threshold value **V< faulty ph-to-gnd volt.**, the last phase is considered to be affected by the ground fault and is signaled as such.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal **>Block stage** from an external or internal source
- From inside on pick up of the **measuring-voltage failure detection** function (see chapter *9.3.2.1 Overview of Functions*). The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal **>Open** of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

6.24.4 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:331:8) Method of measurement** = ***fundamental comp.***

The **Method of measurement** parameter allows you to define whether the function works with the fundamental component or the calculated RMS value.

Parameter Value	Description
fundamental comp.	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.

Parameter Value	Description
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). Do not set the **threshold value** of the tripping stage under 10 V for this method of measurement.
fund. comp. long filter	To implement particularly strong damping of harmonics and transient disturbances, select this method of measurement. At 2 periods, the length of the filter is longer than that of the standard filter. Please note that in this case the pickup time of the tripping level increases slightly (see Technical Data).

Parameter: Pickup delay

- Recommended setting value **(_:331:107) Pickup delay** = ***0 ms***

The **Pickup delay** parameter allows you to delay the analysis of the measurand (to generate the pickup) depending on the occurrence of the residual voltage. A pickup delay can be necessary if high transients are anticipated after fault inception due to high line and ground capacitances.
Siemens recommends using the default setting **Pickup delay** = ***0 ms***.

Parameter: Threshold

- Default setting **(_:331:3) Threshold** = ***30 V***[13]

The threshold value of the function is set as the zero-sequence voltage V_0. The device calculates the zero-sequence voltage V_0 either from the residual voltage measured via the broken-delta winding or from the 3 phase-to-ground voltages.
The setting value depends on the system grounding:

- Since virtually the full residual voltage occurs during ground faults in isolated or arc-suppression-coil-grounded systems, the setting value is uncritical there. It should range between 20 V and 40 V. A higher sensitivity (= lower threshold value) can be necessary for high fault resistances.
- You should select a more sensitive (smaller) value in a grounded system. This value must be higher than the maximum residual voltage anticipated during operation caused by system unbalances.

EXAMPLE

For an isolated system
The residual voltage is measured via the broken-delta winding:

- If the ground fault is fully unbalanced, a residual voltage of 100 V is present at the device terminals.
- The threshold value should be set so that the stage picks up on 50 % of the full residual voltage.
- At full residual voltage, the zero-sequence voltage is 100 V/$\sqrt{3}$ = 57.7 V
  Setting value: 0.5 * 57.7 V = 28.9 V ≈ 30 V

Parameter: Dropout ratio

- Recommended setting value **(_:331:4) Dropout ratio** = ***0.95***

The recommended set value of ***0.95*** is appropriate for most applications. The dropout ratio can be reduced for example, to 0.98 to achieve a high measurement precision.

Parameter: Operate delay

- Default setting **(_:331:6) Operate delay** = ***3.00 s***

The **Operate delay** allows you to prevent transient residual voltages from initiating a trip. The setting depends on the specific application.

[13] The specific setting limits depend on the transformer data and transformer connections set.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:331:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following two conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see Chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: Detection of faulty phase

- Default setting **(_:331:109) Detection of faulty phase** = ***no***

The **Detection of faulty phase** parameter controls how the stage responds to determine which phase is affected by the ground fault.

Parameter Value	Description
no	The phase affected by the ground fault is not determined. Select the default setting if you do not want to use the stage to detect ground faults. For example, applications in grounded systems.
yes	After a pickup by the residual voltage the device tries to determine, which phase is affected by the ground fault. Select this setting for applications in isolated or arc-suppression-coil-grounded systems.

Parameter: V< faulty ph-to-gnd volt.

- Default setting **(_:331:104) V< faulty ph-to-gnd volt.** = ***30.000 V***[14]

Set the threshold value for determining which phase is affected by the ground fault in the **V< faulty ph-to-gnd volt.** parameter. The setting value is a phase-to-ground quantity.

The set value must be smaller than the minimum phase-to-ground voltage occurring during operation. Siemens recommends using the default setting **V< faulty ph-to-gnd volt.** = ***30.000 V***.

Parameter: V> healthy ph-to-gnd volt.

- Default setting **(_:331:101) V> healthy ph-to-gnd volt.** = ***75.000 V***[15]

Set the threshold value for the two healthy phases in the **V> healthy ph-to-gnd volt.** parameter. The setting value is a phase-to-ground quantity.

The set value must lie above the maximum phase-to-ground voltage occurring during operation, but below the minimum phase-to-phase voltage present during operation. At V_{rated} = 100 V, the value has to be set to 75 V, for example. Siemens recommends using the default setting **V> healthy ph-to-gnd volt.** = ***75.000 V***.

Operation as Supervision Function

If you want the stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

[14] The specific setting limits depend on the transformer data and transformer connections set.
[15] The specific setting limits depend on the transformer data and transformer connections set.

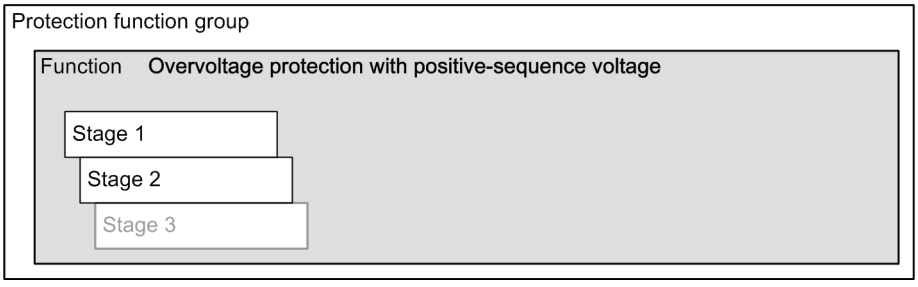
6.25 Overvoltage Protection with Positive-Sequence Voltage

6.25.1 Overview of Functions

The function **Overvoltage protection with positive-sequence voltage** (ANSI 59) is used to:



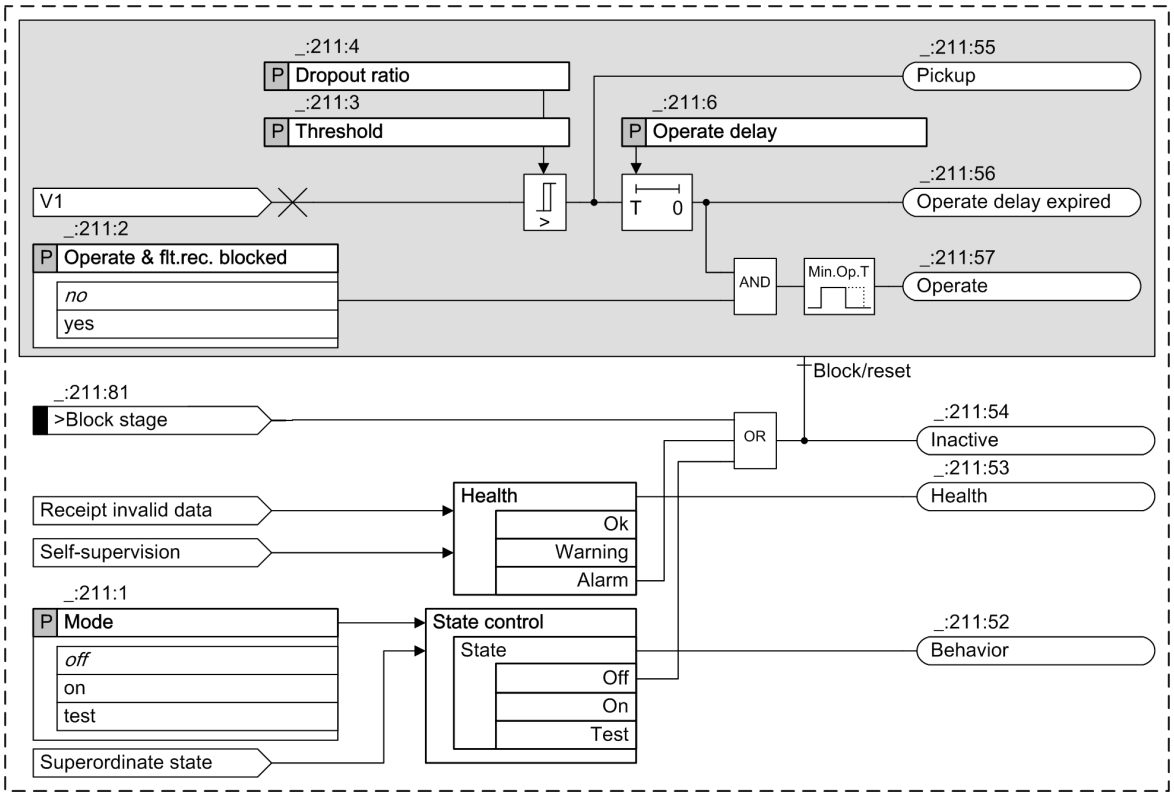
- Detect symmetric stationary overvoltages
- Supervise the voltage range if the positive-sequence voltage is the decisive quantity

Unbalanced overvoltages, for example, caused by ground faults and unbalanced faults, are not detected due to the evaluation of the positive-sequence voltage.

6.25.2 Structure of the Function

The **Overvoltage protection with positive-sequence voltage** function is used in protection function groups, which are based on voltage measurement.

The function **Overvoltage protection with positive-sequence voltage** comes with 2 factory-set stages. A maximum of 3 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.



[dwovpu1s-030211-01.tif, 1, en_US]

Figure 6-177 Structure/Embedding of the Function

6.25.3 Stage Description

Logic of a Stage

[logovpu1-090611-01.tif, 1, en_US]

Figure 6-178 Logic Diagram of a Stage: Overvoltage Protection with Positive-Sequence Voltage

Method of Measurement

The stage uses the positive-sequence voltage. The positive-sequence voltage is calculated from the measured phase-to-ground voltages according to the defining equation.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking is possible externally or internally via the binary input signal **>Block stage**.

6.25.4 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:211:3) Threshold** = ***65 V***

The Threshold is set according to the definition of the positive-sequence system.

Specify the Threshold (pickup threshold) for the specific application.

Parameter: Operate delay

- Default **(_:211:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:211:4) Dropout ratio** = ***0.95***

The default value of ***0.95*** is appropriate for most applications. To achieve high measurement precision, the **Dropout ratio** can be reduced, to 0.98, for example.

General Notes

If the overvoltage is high, the first stage can trip with a short time delay. If overvoltages are lower, the second stage can either only signal the threshold value violation (see Operation as monitoring function) or trip with a longer delay to allow the voltage controller to regulate the voltage back into the nominal range.

Operation as Supervision Function

If you want the tripping stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

6.26 Overvoltage Protection with Negative-Sequence Voltage

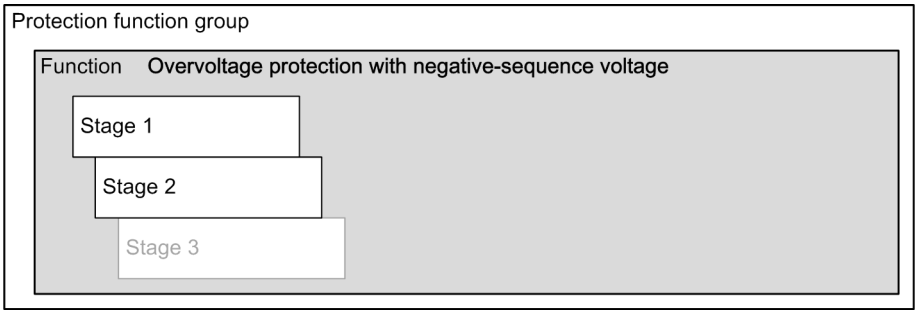
6.26.1 Overview of Functions

The function **Overvoltage protection with negative-sequence voltage** (ANSI 47) is used to:

- Monitor the power system and electric machines for voltage unbalances
- Establish a release criterion of overcurrent protection for unbalanced faults

Voltage unbalances can be caused by various factors:

- The most common cause is unbalanced load, caused by different consumers in the individual phases, for example.
- Voltage unbalance can also be caused by phase failure, for example due to a tripped 1-phase fuse, a broken conductor, etc.
- Other causes can include faults in the primary system, for example, at the transformer or in installations for reactive-power compensation.



6.26.2 Structure of the Function

The **Overvoltage protection with negative-sequence voltage** function is used in protection function groups, which are based on voltage measurement.

The **Overvoltage protection with negative-sequence voltage** function comes with 2 factory-set stages.

A maximum of 3 stages can be operated simultaneously in the function.

The stages have an identical structure.

[dwu2ovpsExt.vsd, 2, en_US]

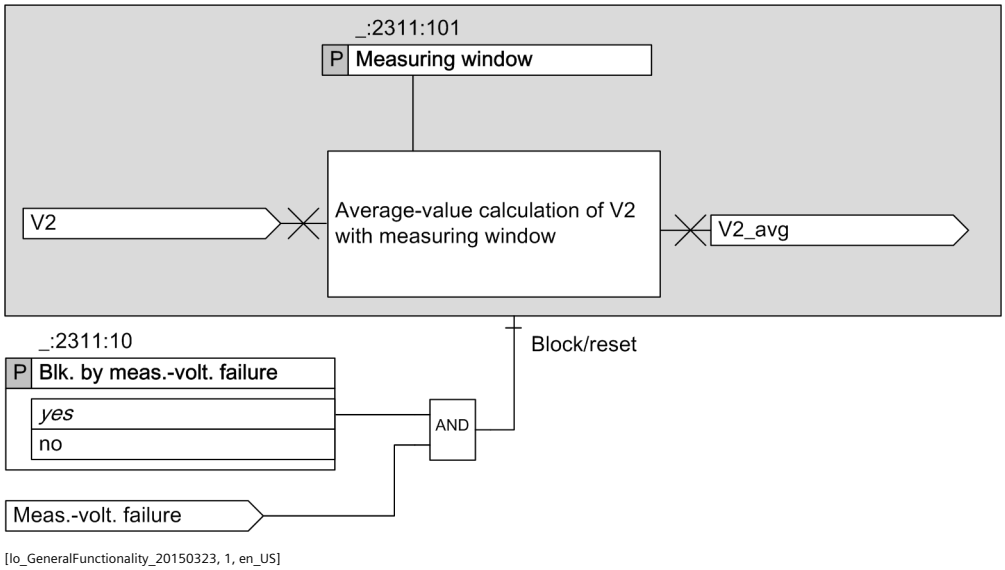


Figure 6-179 Structure/Embedding of the Function

6.26.3 General Functionality

6.26.3.1 Description

Logic

The following figure represents the logic of the average-value calculation of the negative-sequence voltage. The average value is forwarded to all subordinate stages.

[lo_GeneralFunctionality_20150323, 1, en_US]

Figure 6-180 Logic Diagram of the General Functionality

Measurand

The average value of negative-sequence voltage is determined by a settable time interval (parameter: **Measuring window**). With the parameter **Measuring window**, you can adapt this function to all power-system conditions.

You can set the parameter **Measuring window** with a large value to get a more accurate calculated result, which leads to a longer pickup time however.

Blocking the Function with Measuring-Voltage Failure Detection

In case of blocking, the picked up function is reset. The following blocking options is available for the function:

- From inside on pick up of the **Measuring-voltage failure detection** function (see section *9.3.2.1 Overview of Functions*).
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker.

The parameter **Blk. by meas.-volt. failure** can be set so that the measuring-voltage failure detection blocks the function or does not block it.

6.26.3.2 Application and Setting Notes

Parameter: Measuring window

- Default setting **(_:2311:101) Measuring window** = ***1 cycle***

  With the parameter **Measuring window**, you can optimize the measuring accuracy or the pickup time of this function.

  For sensitive settings of the parameter **Threshold**, for example, lower than 10 % of the rated voltage, Siemens recommends using a higher number of cycles. Siemens recommends ***10 cycles***, and in this case, the pickup time is increased.

  For further information, refer to chapter *12.32 Overvoltage Protection with Negative-Sequence Voltage* .

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:2311:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the function when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The protection function is blocked (= default setting). Siemens recommends using the default setting.
no	The protection function is not blocked.

6.26.4 Stage with Negative-Sequence Voltage

6.26.4.1 Description

Logic of a Stage

[lou23pol-090611-01.tif, 3, en_US]

Figure 6-181 Logic Diagram of the Stage: Overvoltage Protection with Negative-Sequence Voltage

Method of Measurement

The stage uses the average value of the negative-sequence voltage, which is calculated from the function block **General Functionality**. For more information, refer to chapter *6.26.3.1 Description*.

Blocking the Stage

In case of blocking, the picked up function is reset. The following blocking option is available for the function:

- From an external or internal source via the binary input signal *>Block stage*

6.26.4.2 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:271:3) Threshold** = *5.800 V*

The parameter **Threshold** is set according to the definition of the negative-sequence system.

Specify the **Threshold** (pickup threshold) for the specific application.

The secondary voltage of the voltage transformer can be used if the voltage transformer is adapted to the rated voltage. The value of the 10 % negative-sequence voltage at a 100 V rated secondary voltage is:

100 V / 1.73 * 0.1 = 5.77 V

Parameter: Dropout ratio

- Default setting **(_:271:4) Dropout ratio** = ***0.95***

The default setting of ***0.95*** is appropriate for most applications.

You can decrease the dropout ratio to avoid chattering of the stage if the threshold value is low. For example, for the stage with a 2 % setting, you can use a dropout ratio of 0.90.

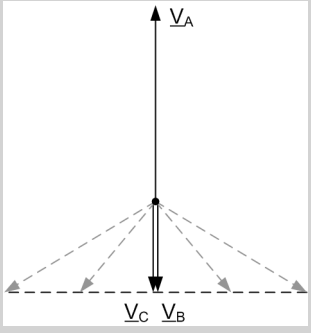
Parameter: Operate delay

- Default setting **(_:271:6) Operate delay** = ***3.00 s***

Specify the **Operate delay** for the specific application. 3.00 s is a practicable value.

For a higher threshold value, a shorter tripping delay is required.

Operation as Supervision Function



If you want the stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

Example 1:

Releasing an overcurrent protection stage for unbalanced faults

The following section describes how to set the function to release an **Overcurrent-protection** stage when unbalanced faults occur. Set the **Overcurrent-protection** stage only slightly higher than the load current, that is very sensitive. To prevent the **Overcurrent-protection** stage from picking up inadvertently, the **Overcurrent-protection** stage is released when the **Negative-sequence voltage** stage picks up. The **Overcurrent-protection** stage remains blocked as long as the **Negative-sequence voltage** stage has not picked up.

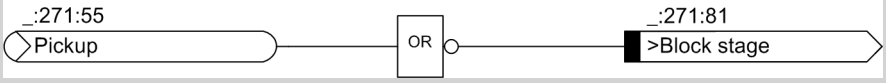
Figure 6-182 shows the voltage phasors during a 2-phase local fault between phases B and C. The phase-to-phase voltage V_{BC} is virtually 0.

[dwuazeig-020412-01.tif, 1, en_US]

Figure 6-182 Voltage Phasors during a 2-Phase Local Fault

A 2-phase local fault generates a relatively large negative-sequence voltage of up to 50 % referred to the phase-to-ground voltage. The portion of the negative-sequence decreases in case of a remote fault. The lower setting limit results from the possible unbalance at full load. If you assume for example 5 % negative-sequence voltage, the pickup value must be higher. A setting value of 10 % warrants sufficient stability during unbalanced operating states and sufficient sensitivity to release the **Overcurrent-protection** stage when a fault occurs.

For a secondary rated voltage of 100 V, set the following secondary threshold value:



$$V2_{sec} = \frac{V_{rated}}{\sqrt{3}} \times 10\,\% = \frac{100\ V}{\sqrt{3}} \times 0.1 \approx 5.8\ V$$

[fo_OVP_V2_Secondary Threshold, 1, en_US]

You can keep the default setting of 0.95 for the dropout ratio. This avoids chattering of the stage.

Set the **Negative-sequence voltage** stage so that it does not generate a fault when it picks up and does not initiate tripping. The **Overcurrent-protection** stage generates a fault indication. The pickup of the **Negative-sequence voltage** stage is used as the release criterion because the **Short-circuit** function must be released immediately when the **Negative-sequence voltage** stage has picked up. The time delay is thus not relevant and can be left at the default setting.

You implement the release of the **Overcurrent-protection** stage using a logic block chart. An inverter links the pickup of the **Negative-sequence voltage** stage with the **Overcurrent-protection** stage blocking.

[loinvert-020412-01.tif, 1, en_US]

Figure 6-183 Linking the Pickup of the Negative-Sequence Voltage Stage

Stage	Setting Values		
	Secondary Threshold Value	Time Delay	Dropout Ratio
1	5.800 V	3.00 s	0.95

The second stage is not needed. It is deleted or remains off.

Example 2:

A negative-sequence voltage in the auxiliary system of the power plant causes negative-sequence currents on motors. This leads to a thermal overload of the rotors. The following estimation can be used as a basis: 1 % negative-sequence voltage can lead to approximately 5 % or 6 % negative-sequence current.

A negative-sequence voltage can be caused by a broken conductor on the high-voltage side. If a negative-sequence voltage occurs, this can, for example, initiate a switching of the infeed in order to prevent a protection trip of an unbalanced-load protection of the motors.

Siemens recommends using multiple stages for a better grading, whereby a sensitive setting of the threshold permits an increased tripping delay.

For a reference, only 2 stages are discussed.

The first stage has a pickup threshold of 10 % with a time delay of 1.5 s. The second stage has a pickup threshold of 3 % with a time delay of 8 s, see *Table 6-14*. Further, it is assumed that the voltage transformer is well adapted to the rated voltage.

$$V2_{sec} = \frac{100\ V}{1.73} \times \frac{V2\ [\%]}{100\%}$$

[fo_OVP_V2_SecondaryThreshold2, 1, en_US]

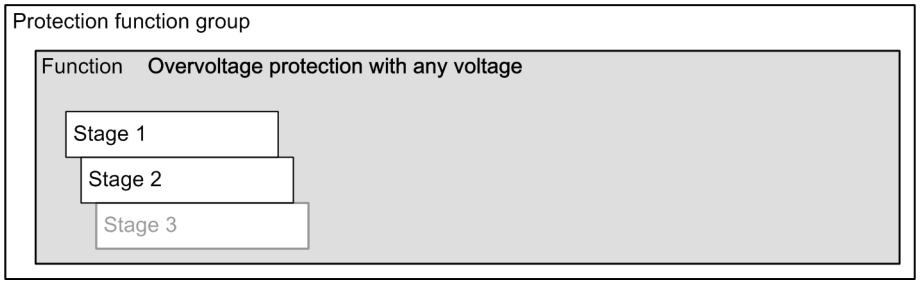
6.27 Overvoltage Protection with Any Voltage



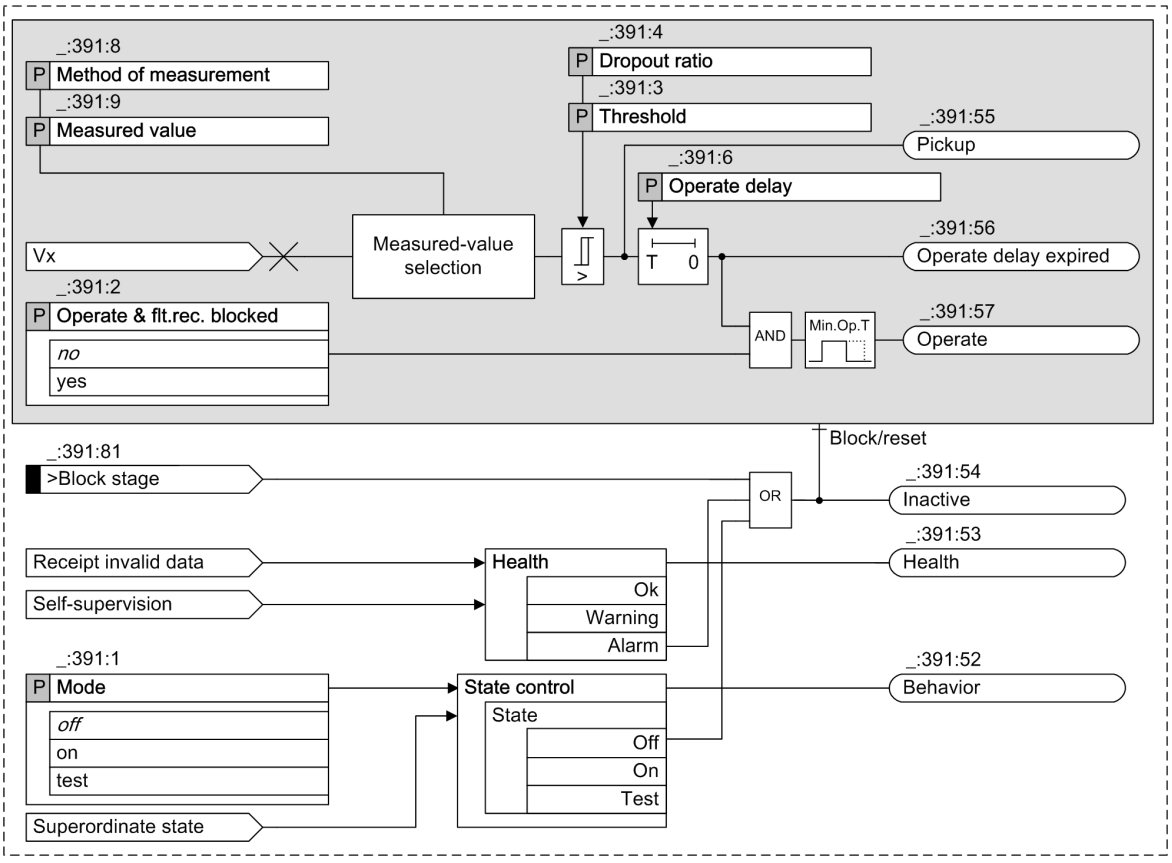
6.27.1 Overview of Functions

The function **Overvoltage protection with any voltage** (ANSI 59) detects any 1-phase overvoltages and is intended for special applications.

6.27.2 Structure of the Function

The **Overvoltage protection with any voltage** function is used in protection function groups, which are based on voltage measurement.

The function **Overvoltage protection with any voltage** comes with 2 factory-set stages. A maximum of 3 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.



[dwovpuxs-030211-01.tif, 1, en_US]

Figure 6-184 Structure/Embedding of the Function

6.27.3 Stage Description

Logic of a Stage

[louxovpr-211212-01.tif, 1, en_US]

Figure 6-185 Logic Diagram of a Stage: Overvoltage Protection with Any Voltage

NOTE

If the function **Overvoltage protection with any voltage** is used in a 1-phase function group, the parameter **`Measured value`** is not visible.

Method of Measurement

The **`Method of measurement`** parameter allows you to define whether the function works with the fundamental component or the calculated RMS value.

- Measurement of the ***`fundamental comp.`***:

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

- Measurement of the parameter value ***`RMS value`***:

  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Measured Value

The parameter **`Measured value`** allows you to select whether the stage uses a measured (directly connected) voltage or a calculated phase-to-phase voltage.

If the function **Overvoltage protection with any voltage** is used in a 1-phase function group, the parameter **`Measured value`** is not visible.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking is possible externally or internally via the binary input signal *>Block stage*.

6.27.4 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:391:8) Method of measurement** = ***fundamental comp.***

Use the **Method of measurement** parameter to define whether the tripping stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends this method of measurement as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks). Do not set the **threshold value** of the tripping stage under 10 V for this method of measurement.

Parameter: Measured value

- Default setting **(_:391:9) Measured value** = ***VA measured***

The **Measured value** parameter is used to specify which voltage is monitored by the stage.

The scope of setting options depends on the connection type for the voltage transformers and the routing of the measured values to the terminals of the voltage measuring point. You can find connection examples for voltage transformers in the Appendix.

The following setting options can be available:

- Measured phase-to-ground voltage V_A (***VA measured***)
- Measured phase-to-ground voltage V_B (***VB measured***)
- Measured phase-to-ground voltage V_C (***VC measured***)
- Measured phase-to-phase voltage V_{AB} (***VAB measured***)
- Measured phase-to-phase voltage V_{BC} (***VBC measured***)
- Measured phase-to-phase voltage V_{CA} (***VCA measured***)
- Calculated phase-to-phase voltage V_{AB} (***VAB calculated***)
- Calculated phase-to-phase voltage V_{BC} (***VBC calculated***)
- Calculated phase-to-phase voltage V_{CA} (***VCA calculated***)
- Calculated voltage V0 (***V0 calculated***)

The selection depends on the corresponding application.

NOTE

If the function **Overvoltage protection with any voltage** is used in a 1-phase function group, the parameter **Measured value** is not visible.

Parameter: Threshold

- Default setting **(_:391:3) Threshold** = ***110 V***

Specify the **Threshold** (pickup threshold) for the specific application.

Depending on the measured value, the **Threshold** is set either as **Measured voltage** or as **Phase-to-phase** quantity.

Parameter: Operate delay

- Default setting **(_:391:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:391:4) Dropout ratio** = ***0.95***

The recommended set value of ***0.95*** is appropriate for most applications. To achieve high measurement precision, the **Dropout ratio** can be reduced, to 0.98, for example.

Operation as Supervision Function

If you want the tripping stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

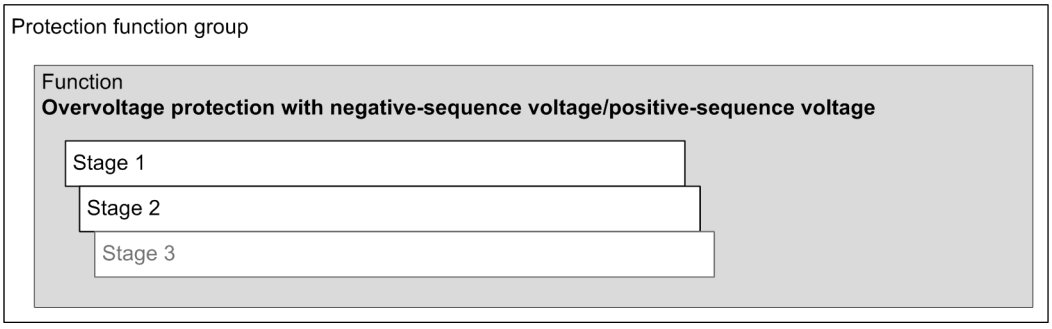
6.28 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage

6.28.1 Overview of Functions

The function **Overvoltage protection with negative-sequence voltage/positive-sequence voltage** is used to:

- Monitor the power system and electric machines for voltage unbalances
- Establish a release criterion of overcurrent protection for unbalanced faults



Voltage unbalances can be caused by various factors:

- The most common cause is unbalanced load, caused by different consumers in the individual phases, for example.
- Voltage unbalance can also be caused by phase failure, for example due to a tripped 1-phase fuse, a broken conductor, etc.
- Other causes can include faults in the primary system, for example, at the transformer or in installations for reactive-power compensation.

6.28.2 Structure of the Function

The **Overvoltage protection with negative-sequence voltage/positive-sequence voltage** function is used in protection function groups, which are based on voltage measurement.

The **Overvoltage protection with negative-sequence voltage/positive-sequence voltage** function comes with 2 factory-set stages. A maximum of 3 stages can be operated simultaneously in the function. The stages have an identical structure.

[Structure-V2/V1_20150521, 2, en_US]

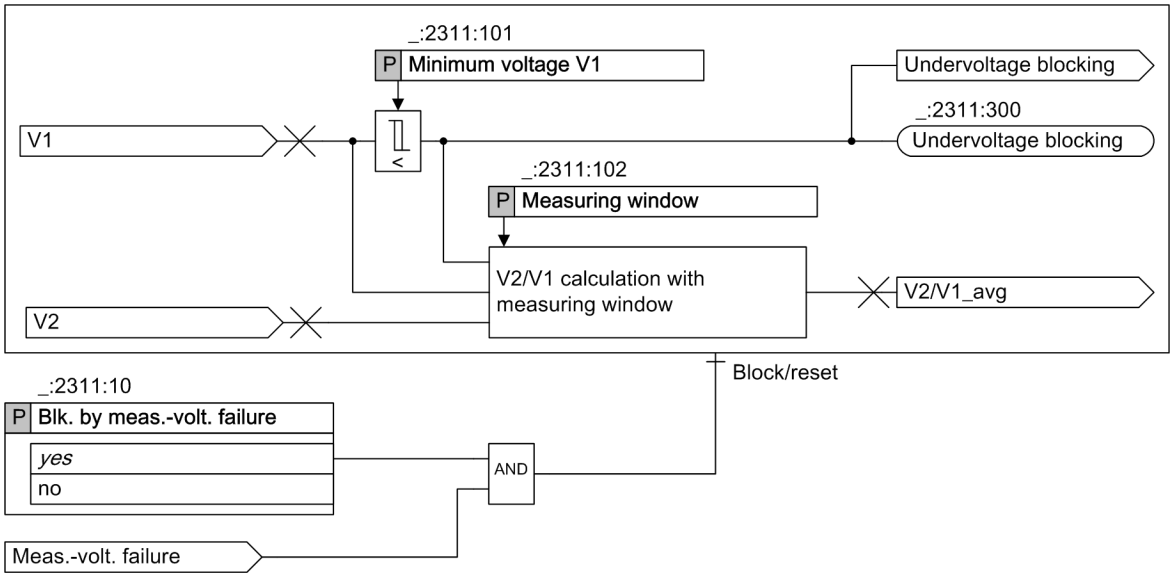


Figure 6-186 Structure/Embedding of the Function

6.28.3 General Functionality

6.28.3.1 Description

Logic

The following figure represents the logic of the average-value calculation of the ratio of negative-sequence voltage to positive-sequence voltage. The average value is forwarded to all subordinate stages.

[lo_V2toV1_FB General_20150326, 1, en_US]

Figure 6-187 Logic Diagram of the General Functionality

Measurand

The average value of the ratio of negative-sequence voltage to positive-sequence voltage is determined by a settable time interval (parameter: **Measuring window**). With the parameter **Measuring window**, you can adapt this function to all power-system conditions.

You can set the parameter **Measuring window** with a large value to get a more accurate calculated result, which leads to a longer pickup time however.

Blocking the Function with Measuring-Voltage Failure Detection

In case of blocking, the picked up function is reset. The following blocking options is available for the function:

- From inside on pick up of the **Measuring-voltage failure detection** function (see section *9.3.2.1 Overview of Functions*).
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker.

The parameter **Blk. by meas.-volt. failure** can be set so that the measuring-voltage failure detection blocks the function or does not block it.

6.28.3.2 Application and Setting Notes

Parameter: Measuring window

- Default setting **(_:2311:102) Measuring window** = ***1 cycle***

  With the parameter **Measuring window**, you can optimize the measuring accuracy or the pickup time of this function.

  For sensitive settings of the parameter **Threshold**, for example, lower than 10 % of the rated voltage, Siemens recommends using a higher number of cycles. Siemens recommends ***10 cycles***, and in this case, the pickup time is increased.

  For further information, refer to chapter *12.35 Overvoltage Protection with Negative-Sequence Voltage/ Positive-Sequence Voltage* .

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:2311:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the function when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The protection function is blocked (= default setting). Siemens recommends using the default setting.
no	The protection function is not blocked.

6.28.4 Stage with Negative-Sequence Voltage/Positive-Sequence Voltage

6.28.4.1 Description

Logic of a Stage

[lo_V2V1_PROV_20150326, 1, en_US]

Figure 6-188 Logic Diagram of the Stage: Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage

Method of Measurement

The stage uses the average value of the negative-sequence voltage/positive-sequence voltage, which is calculated from the function block **General Functionality**. For more information, refer to chapter *6.28.3.1 Description* .

Blocking the Stage

In case of blocking, the picked up function is reset. The following blocking option is available for the function:

- From an external or internal source via the binary input signal *>Block stage*

6.28.4.2 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:17071:3) Threshold** = *10.00 %*

The parameter **Threshold** is set in percentage according to the definition of the symmetrical compents. It is the ratio of the negative-sequence voltage to positive-sequence voltage.

Specify the **Threshold** (pickup threshold) for the specific application.

In the application with a lower threshold setting of about 2.00 %, there is a risk of an overfunction due to the measuring errors with small values as well as an influence via disturbances.

Parameter: Dropout ratio

- Default setting **(_:17071:4) Dropout ratio** = ***0.95***

The default setting of ***0.95*** is appropriate for most applications if a higher threshold is used.

You can decrease the dropout ratio to avoid chattering of the stage if the threshold value is low. For example, for the stage with a 2 % setting, you can use a dropout ratio of 0.90.

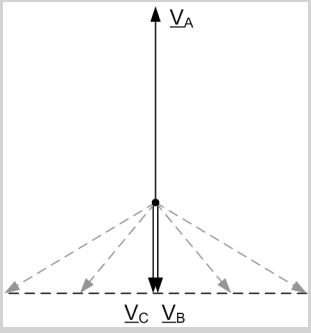
Parameter: Operate delay

- Default setting **(_:17071:6) Operate delay** = ***3.00 s***

Specify the **Operate delay** for the specific application. When using the sensitive setting of the threshold value that is described in this chapter, the function can be delayed by 3.00 s.

For a higher threshold value, a shorter tripping delay is required.

Operation as Supervision Function



If you want the stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

Example 1:

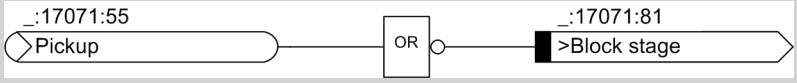
Releasing an overcurrent protection stage for unbalanced faults

The following section describes how to set the function to release an **Overcurrent-protection** stage when unbalanced faults occur. Set the **Overcurrent-protection** stage only slightly higher than the load current, that is very sensitive. To prevent the **Overcurrent-protection** stage from picking up inadvertently, the **Overcurrent-protection** stage is released when the **Negative-sequence voltage** stage picks up. The **Overcurrent-Protection** stage remains blocked as long as the **Negative-sequence voltage** stage has not picked up.

Figure 6-189 shows the voltage phasors during a 2-phase local fault between phases B and C. The phase-to-phase voltage V_{BC} is virtually 0.

[dwuazeig-020412-01.tif, 1, en_US]

Figure 6-189 Voltage Phasors during a 2-Phase Local Fault



A 2-phase local fault generates a relatively large negative-sequence voltage of up to 100 % referred to the positive-sequence voltage. The portion of the negative-sequence decreases in case of a remote fault. The lower setting limit results from the possible unbalance at full load. If you assume for example 5 % of the negative-sequence voltage to positive-sequence voltage, the pickup value must be higher. A setting value of 10 % warrants sufficient stability during unbalanced operating states and sufficient sensitivity to release the **Overcurrent-protection** stage when a fault occurs.

You can keep the default setting of 0.95 for the dropout ratio. This avoids chattering of the stage.

Set the **Negative-sequence voltage** stage so that it does not generate a fault when it picks up and does not initiate tripping. The **Overcurrent-protection** stage generates a fault indication. The pickup of the **Negative-sequence voltage** stage is used as the release criterion because the **Short-circuit** function must be released

immediately when the **Negative-sequence voltage** stage has picked up. The time delay is thus not relevant and can be left at the default setting.

You implement the release of the **Overcurrent-protection** stage using a logic block chart. An inverter links the pickup of the **Negative-sequence voltage** stage with the **Overcurrent-protection** stage blocking.

[lo_Pickup of V2_20150507, 1, en_US]

Figure 6-190 Linking the Pickup of the Negative-Sequence Voltage Stage

Stage	Setting Values		
	Percentage of the Negative-Sequence Voltage to Positive-Sequence Voltage	Time Delay	Dropout Ratio
1	10.00 %	3.00 s	0.95

The second stage is not needed. It is deleted or remains off.

Example 2:

A negative-sequence voltage in the auxiliary system of the power plant causes negative-sequence currents on motors. This leads to a thermal overload of the rotors. The following estimation can be used as a basis: 1 % negative-sequence voltage can lead to approximately 5 % or 6 % negative-sequence current.

A negative-sequence voltage can be caused by a broken conductor on the high-voltage side. If a negative-sequence voltage occurs, this can, for example, initiate a switching of the infeed in order to prevent a protection trip of an unbalanced-load protection of the motors.

Siemens recommends using multiple stages for a better grading, whereby a sensitive setting of the threshold permits an increased tripping delay.

For a reference, only 2 stages are discussed.

The first stage has a pickup threshold of 10 % with a time delay of 1.5 s. The second stage has a pickup threshold of 3 % with a time delay of 8 s, see *Table 6-15* .

6.29 Undervoltage Protection with 3-Phase Voltage

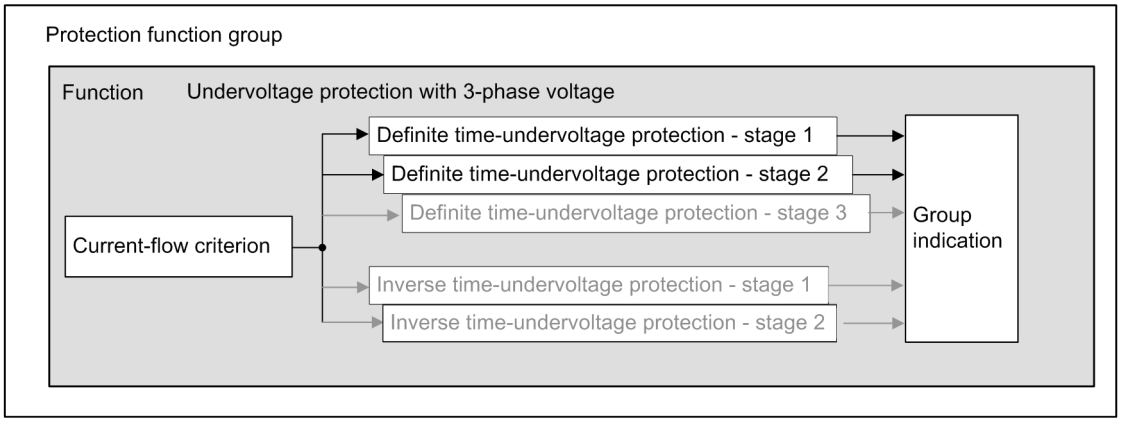
6.29.1 Overview of Functions

The function **Undervoltage protection with 3-phase voltage** (ANSI 27) is used to:

- Monitor the permissible voltage range
- Protect equipment (for example, plant components and machines) against damages caused by undervoltage
- Handle disconnection or load shedding tasks in a system

6.29.2 Structure of the Function

The **Undervoltage protection with 3-phase voltage** function is used in protection function groups with voltage measurement.



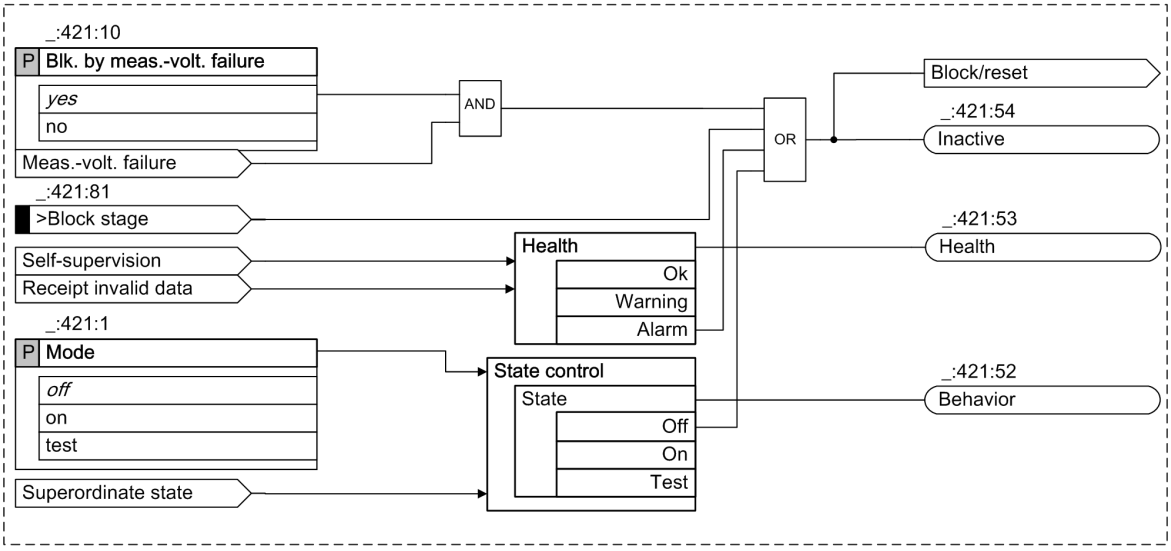
The **Undervoltage protection with 3-phase voltage** function is preconfigured by the manufacturer with 2 **Definite time-undervoltage protection** stages.

In the function **Undervoltage protection with 3-phase voltage**, the following stages can be operated simultaneously:

- 3 stages **Definite time-undervoltage protection**
- 2 stages **Inverse time-undervoltage protection**

Stages that are not preconfigured are shown in gray in the following figure.

The protection function is structured such that one current-flow criterion can act on all undervoltage protection stages (see *Figure 6-191*). If the protection function group used has no current measurement, you can only set the current-flow criterion as **fulfilled** via the corresponding binary input signal.



[dwstru3p-110211-01.tif, 3, en_US]

Figure 6-192 Logic Diagram of the Stage Control

[louvp3ph-140611-01.tif, 2, en_US]

Figure 6-193 Logic Diagram of the Function

Method of Measurement

With the **`Method of measurement`** parameter, you select the relevant method of measurement, depending on the application.

- Measurement fundamental component:

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

- Measurement RMS value:

  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Measured Value

With the **`Measured value`** parameter, you define whether the stage analyzes the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C.

If the measured value is set to phase-to-phase, the function reports those measuring elements that have picked up.

Pickup Mode

With the **Pickup mode** setting, you define whether the stage picks up when there is a lower threshold-value violation in one measuring element (***1 out of 3***) or when there is a lower threshold-value violation in all 3 measuring elements (***3 out of 3***).

Pickup Delay

The **Pickup delay** parameter is only available and of relevance if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***).

If the circuit breaker opens when the current-flow criterion is being used, the undervoltage detection and current-flow dropout functions conflict with one another. Depending on the threshold value settings for undervoltage detection and current-flow criterion, it is possible that the undervoltage is detected before the current-flow criterion has dropped out. In this case, the stage picks up briefly. Use the **Pickup delay** parameter to prevent the stage from briefly picking up in this way when the circuit breaker opens. This is achieved by delaying pickup by approximately 40 ms.

Current-Flow Criterion

The undervoltage protection stages work optionally with a current-flow criterion. The **Current-flow criterion** works across all tripping stages.

When the **Current-flow criterion** parameter is activated, the undervoltage protection stages only pick up if a settable minimum current (**Threshold I>**) is exceeded. A current below the minimum current blocks the stages.

The current-flow criterion can also be set to **fulfilled** with the binary input signal **>Current flow-criterion**. The function reports when the current-flow criterion is fulfilled.

Figure 6-193 illustrates the influence of the current-flow criterion.

NOTE

If the **(_:2311:104) Current-flow criterion** parameter is deactivated, the device picks up immediately if a missing measuring voltage is detected while the undervoltage protection is active. The parameter setting can be changed even when the device has picked up.

Blocking the Stage

In the event of blocking, the picked-up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal *>Block stage* from an external or internal source
- From inside on pick up of the **measuring-voltage failure detection** function (see section *9.3.2.1 Overview of Functions*). The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

6.29.3.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:421:8) Method of measurement** = ***fundamental comp.***

Use the **Method of measurement** parameter to define whether the stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends using this parameter value as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks). Do not set the **threshold value** of the stage under 10 V for this method of measurement.

Parameter: Measured value

- Recommended setting value **(_:421:9) Measured value** = ***phase-to-phase***

Use the **Measured value** parameter to define whether the stage monitors the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C. Parameter Value

Parameter Value	Description
phase-to-phase	If you want to detect voltage dips caused by multiphase short circuits, or generally monitor the voltage range, keep phase-to-phase as the default setting. The function will not pick up on ground faults. Siemens recommends the measured value ***phase-to-phase*** as the default setting.
phase-to-ground	Select the ***phase-to-ground*** setting if you want to detect voltage unbalances or overvoltage conditions caused by ground faults.

Parameter: Threshold

- Default setting **(_:421:3) Threshold** = ***80 V***

The **Threshold** is set in accordance with the **Measured value** as either a ***phase-to-phase*** or ***phase-to-ground*** variable.

Specify the **Threshold** (pickup threshold) for the specific application.

For the default setting, the lower limit of the voltage range to be monitored is assumed to be 80% of the rated voltage of the protected object.

EXAMPLE:

Rated voltage of the protected object: $V_{rated,\ obj.} = 10\ kV$

Voltage transformer:

$$Ratio_V = \frac{10\ kV/\sqrt{3}}{100\ V/\sqrt{3}}$$

Threshold value: 80 % of $V_{rated,\ obj.}$

The secondary setting value is calculated as follows:

$$V_{Threshold\ value,\ sec} = \frac{0.8 \cdot V_{rated,obj.}}{Ratio_V} = \frac{0.8 \cdot 10\ kV \cdot 100\ V}{10\ kV} = 80\ V$$

[foschwlw-190309-01.tif, 2, en_US]

Parameter: Pickup mode

- Recommended setting value **(_:421:101) Pickup mode** = ***1 out of 3***

With the **Pickup mode** parameter, you specify whether the stage picks up when there is a lower threshold-value violation in one measuring element (***1 out of 3***) or when there is a lower threshold-value violation in all 3 measuring elements (***3 out of 3***).

Parameter Value	Description
1 out of 3	Use this setting for protection applications or for monitoring the voltage range. Siemens recommends ***1 out of 3*** as the default setting. This reflects how the function behaved in previous generations (SIPROTEC 4, SIPROTEC 3).
3 out of 3	Select this setting when using the stage to disconnect from the power system (in the case of wind farms, for example).

Parameter: Pickup delay

- Default setting **(_:421:102) Pickup delay** = ***no***

The **Pickup delay** parameter is only available if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***). If the current-flow criterion is deactivated, no pickup delay is required.

With the parameter **Pickup delay** you set whether pickup of the stage is to be delayed by approximately 40 ms or not. The delay avoids possible brief pickup of the stage when the circuit breaker opens.

Parameter Value	Description
no	Use this setting if you definitely do not want stage pickup to be subject to a time delay in the event of a fault. This setting results in pickup and, where applicable, tripping being performed as quickly as possible. Note that switching procedures (opening of the CB) can result in brief pickup of the stage, depending on the threshold-value settings for undervoltage pickup and the current-flow criterion. To prevent unwanted tripping, you must set a minimum tripping delay of 50 ms.
yes	Use this setting when switching procedures (opening of the CB) are not permitted to result in stage pickup. Note that pickup is delayed by approximately 40 ms. This delay is added to the operate time.

Parameter: Operate delay

- Default **(_:421:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:421:4) Dropout ratio** = ***1.05***

The recommended set value of ***1.05*** is appropriate for most applications. To achieve high-precision measurements, the **Dropout ratio** can be reduced (to 1.02, for example).

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:421:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following two conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see Chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.

Parameter Value	Description
no	The protection stage is not blocked.

Parameter: Current-flow criterion

- Recommended setting value **(_:2311:104) Current-flow criterion** = ***on***

Depending on the system, the voltage transformers are arranged either on the supply side or the junction side. These 2 possible voltage transformer locations induce a different behavior of the function after tripping and opening of the circuit breaker:

- If they are located on the supply side, the voltage remains on
- If they are located on the junction side, the voltage is cleared.

Parameter Value	Description
on	If the voltage transformers are located on the junction side, you can use the current-flow criterion to make the pickup fall back when the current falls below a minimum value (parameter **Threshold I>**).
off	Since the voltage is switched off, the pickup of the undervoltage protection stage persists when the current-flow criterion is not used.

Parameter: Threshold I>

- Recommended setting value **(_:2311:101) Threshold I>** = ***0.05 A***

The **Threshold I>** parameter makes it possible to detect when the circuit-breaker is closed. Siemens recommends setting the **Threshold I>** parameter to 5% of the rated current. With a secondary rated transformer current of 1 A, the secondary setting value for **Threshold I>** would be 0.05 A.

If the sensitivity of the **Threshold I>** parameter is set too high, compensation processes in the secondary circuit of the current transformer will extend the dropout time when breaking extremely high currents. To speed up dropout, increase the default setting.

Operation as Supervision Function

If you want the stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

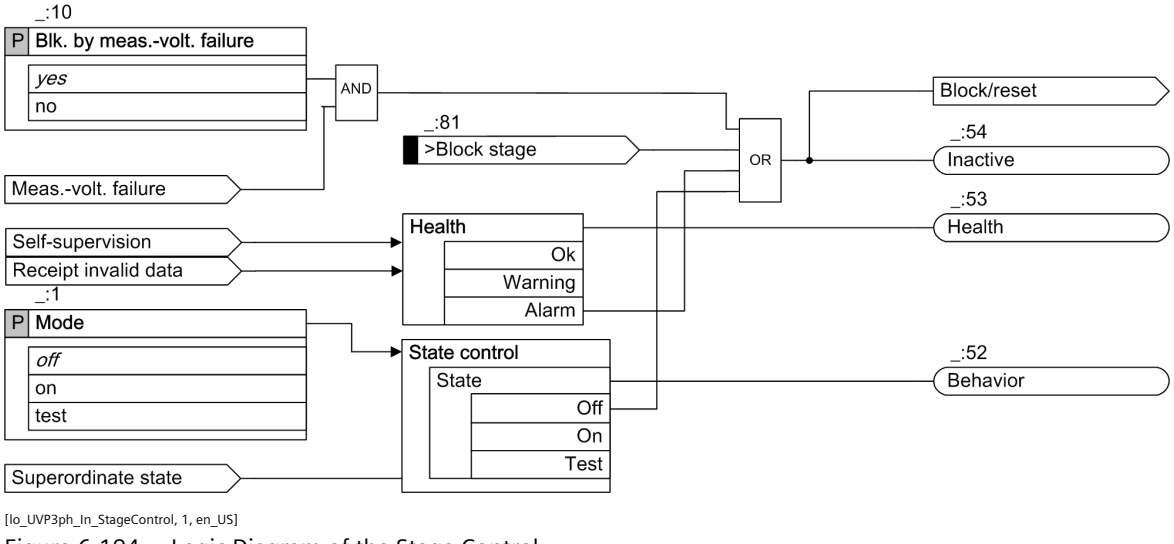
6.29.4 Stage with Inverse-Time Characteristic Curve

6.29.4.1 Description

Logic



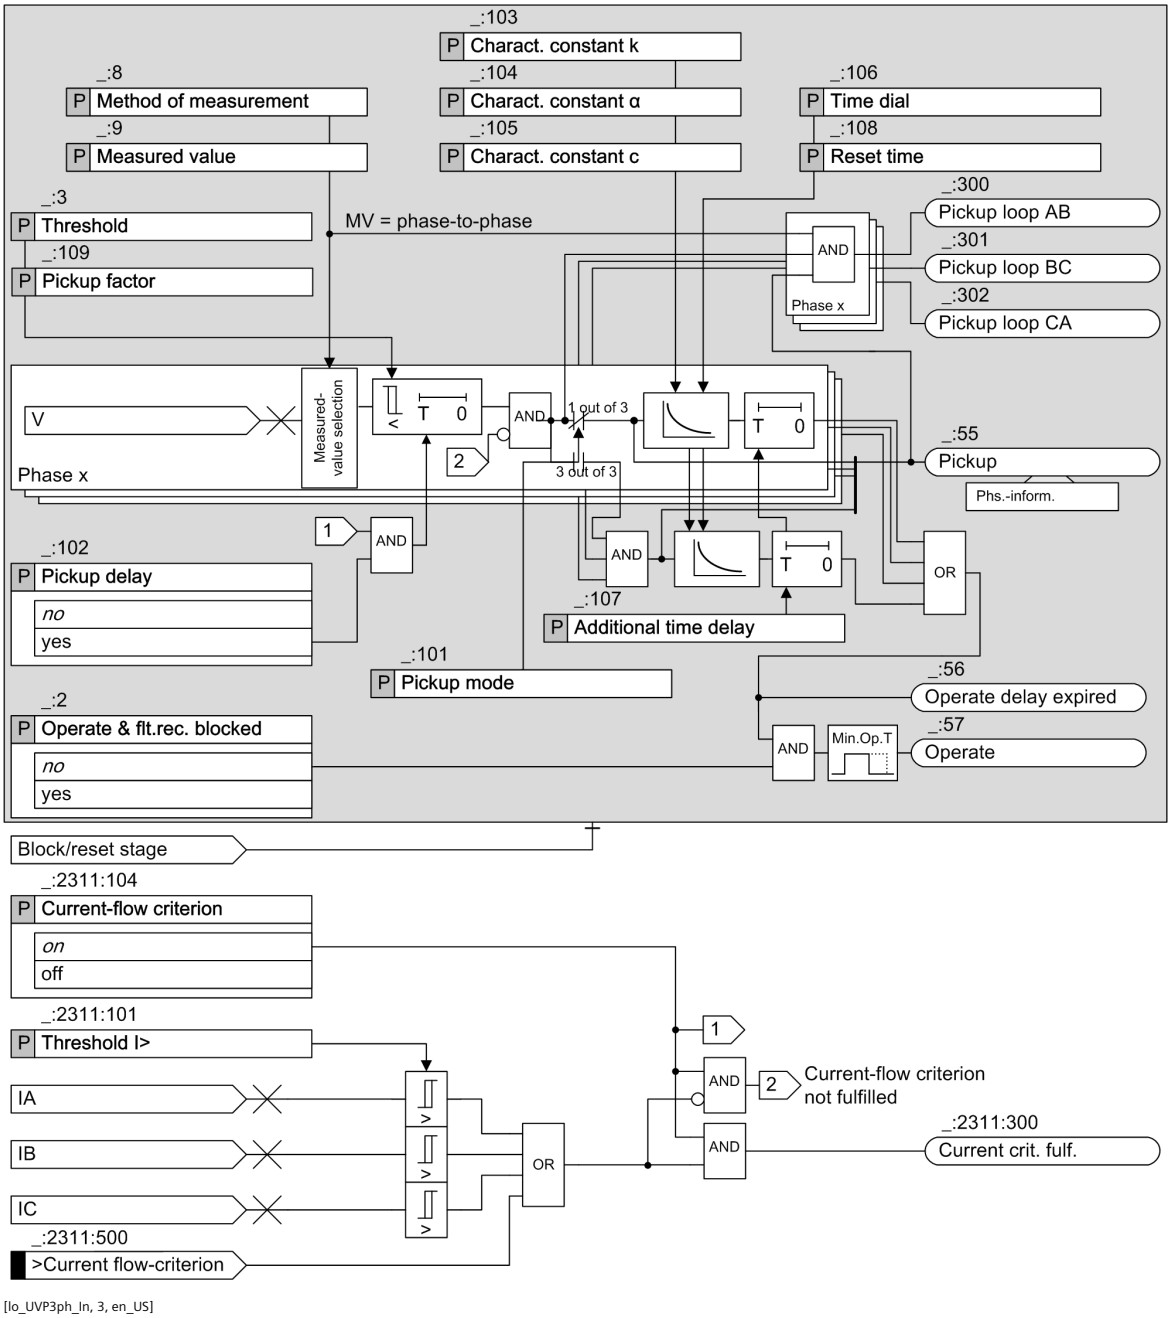


Figure 6-194 Logic Diagram of the Stage Control

[lo_UVP3ph_In, 3, en_US]

Figure 6-195 Logic Diagram of the Function

Method of Measurement

Use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the ***RMS value***.

- Measurement ***fundamental comp.***:

  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

- Measurement ***RMS value***:

  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Measured Value

Use the **Measured value** parameter to define whether the stage analyzes the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C.

If the measured value is set to phase-to-phase, the function reports those measuring elements that have picked up.

Pickup Mode

Use the **Pickup mode** parameter to define whether the stage picks up when there is a lower threshold-value violation in one measuring element (***1 out of 3***) or when there is a lower threshold-value violation in all 3 measuring elements (***3 out of 3***).

Pickup and Operate Curve

When the input voltage falls below the threshold value by a settable value **Pickup factor**, the stage picks up and the inverse-time characteristic curve is processed. The operate delay starts. The operate delay is the sum of inverse-time delay and additional time delay.

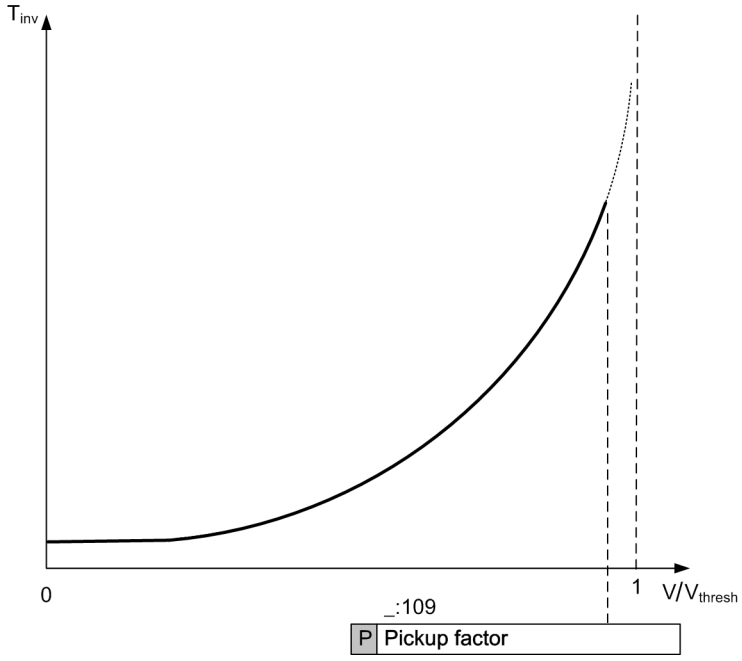
$T_{op}=T_{Inv}+T_{add}$

Where:

T_{op}	Operate delay
T_{Inv}	Inverse-time delay
T_{add}	Additional time delay (Parameter **Additional time delay**)

After pickup the time value T_{Inv} is calculated for every input voltage less than the dropout value. An integrator accumulates the value $1/T_{Inv}$. Once the accumulated integral reaches the fixed value 1, the inverse-time delay expires. The stage operates after the additional time delay.

The inverse-time delay is calculated with the following formula:



$$T_{Inv} = T_p \left(\frac{k}{1 - \left(\frac{V}{V_{Thresh}} \right)^{\alpha}} + c \right) [s]$$

[fo_UVP3ph_inverse, 2, en_US]

Where

T_{Inv}	Inverse-time delay
T_p	Time multiplier (Parameter **Time dial**)
V	Measured undervoltage
V_{Thresh}	Threshold value (Parameter **Threshold**)
k	Curve constant k (Parameter **Charact. constant k**)
α	Curve constant α (Parameter **Charact. constant α**)
c	Curve constant c (Parameter **Charact. constant c**)

The inverse-time characteristic is shown in the following figure:

[dwUVP3ph_inverse, 1, en_US]

Figure 6-196 Inverse-Time Characteristics for Undervoltage Protection

Pickup Delay

The **Pickup delay** parameter is only available and of relevance if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***).

If the circuit breaker opens when the current-flow criterion is being used, the undervoltage detection and current-flow dropout functions conflict with one another. Depending on the threshold value settings for undervoltage detection and current-flow criterion, it is possible that the undervoltage is detected before the current-flow criterion has dropped out. In this case, the stage picks up briefly. Use the **Pickup delay** parameter to prevent the stage from briefly picking up in this way when the circuit breaker opens. This is achieved by delaying pickup by approximately 40 ms.

Dropout Behavior

When the voltage exceeds the dropout value (1.05 x pickup factor x threshold value), the pickup signal is going and the dropout is started. You can define the dropout behavior via parameter **Reset time**. Instantaneous reset takes place by setting **Reset time** to 0 s. A delayed reset takes place by setting the desired delay time.

During the Reset time (> 0 s), the elapsed operate delay is frozen. If the stage picks up again within this period, the stage operates when the rest of operate delay expires.

Current-Flow Criterion

The undervoltage protection stages work optionally with a current-flow criterion. The **Current-flow criterion** works across all tripping stages.

When the **Current-flow criterion** parameter is activated, the undervoltage-protection stages only pick up if a settable minimum current (**Threshold I>**) is exceeded. A current below the minimum current blocks the stages.

The current-flow criterion can also be set to **fulfilled** with the binary input signal **>Current flow-criterion**. The function reports when the current-flow criterion is fulfilled.

Figure 6-193 illustrates the influence of the current-flow criterion.

NOTE

If the **(_:2311:104) Current-flow criterion** parameter is deactivated, the device picks up immediately if a missing measuring voltage is detected while the undervoltage protection is active. The parameter setting can be changed even when the device has picked up.

Blocking the Stage

In the event of blocking, the picked-up stage is reset. The following blocking options are available for the stage:

- Via the binary input signal *>Block stage* from an external or internal source
- From inside on pick up of the **Measuring-voltage failure detection** function (see chapter *9.3.2.1 Overview of Functions*) . The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

6.29.4.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:8) Method of measurement** = ***fundamental comp.***

Use the **Method of measurement** parameter to define whether the stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends using this parameter value as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks). Do not set the **threshold value** of the stage under 10 V for this method of measurement.

Parameter: Measured value

- Recommended setting value **(_:9) Measured value** = ***phase-to-phase***

Use the **Measured value** parameter to define whether the stage monitors the phase-to-phase voltages V_{AB}, V_{BC}, and V_{CA}, or the phase-to-ground voltages V_A, V_B, and V_C.

Parameter Value	Description
phase-to-phase	If you want to detect voltage dips caused by multiphase short circuits, or generally monitor the voltage range, keep phase-to-phase as the default setting. The function will not pick up on ground faults. Siemens recommends the measured value ***phase-to-phase*** as the default setting.
phase-to-ground	Select the ***phase-to-ground*** setting if you want to detect voltage unbalances or overvoltage conditions caused by ground faults.

Parameter: Threshold, Pickup factor

- Default setting **(_:3) Threshold** = ***80.000 V***
- Default setting **(_:109) Pickup factor** = ***0.90***

The stage picks up when the measured voltage value falls below the pickup value **Threshold** × **Pickup factor**.

Depending on the **Measured value**, the **Threshold** is set either as ***phase-to-phase*** quantity or as ***phase-to-ground*** quantity.

With the **Pickup factor**, you modify the pickup value. To avoid a long operate delay time after pickup, Siemens recommends using the default value of **Pickup factor** .

Specify the **Threshold** (pickup threshold) and **Pickup factor** for the specific application.

Parameter: Pickup mode

- Recommended setting value **(_:101) Pickup mode** = ***1 out of 3***

With the **Pickup mode** parameter, you specify whether the stage picks up when there is a lower threshold-value violation in one measuring element (***1 out of 3***) or when there is a lower threshold-value violation in all 3 measuring elements (***3 out of 3***).

Parameter Value	Description
1 out of 3	Use this setting for protection applications or for monitoring the voltage range. Siemens recommends ***1 out of 3*** as the default setting. This reflects how the function behaved in previous generations (SIPROTEC 4, SIPROTEC 3).
3 out of 3	Select this setting when using the stage to disconnect from the power system (in the case of wind farms, for example).

Parameter: Pickup delay

- Default setting **(_:102) Pickup delay** = ***no***

The **Pickup delay** parameter is only available if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***). If the current-flow criterion is deactivated, no pickup delay is required.

With the parameter **Pickup delay**, you set whether pickup of the stage is to be delayed by approximately 40 ms or not. The delay avoids possible brief pickup of the stage when the circuit breaker opens.

Parameter Value	Description
no	Use this setting if you definitely do not want stage pickup to be subject to a time delay in the event of a fault. This setting results in pickup and, where applicable, tripping being performed as quickly as possible. Note that switching procedures (opening of the CB) can result in brief pickup of the stage, depending on the threshold-value settings for under-voltage pickup and the current-flow criterion. To prevent unwanted tripping, you must set a minimum tripping delay of 50 ms.
yes	Use this setting when switching procedures (opening of the CB) are not permitted to result in stage pickup. Note that pickup is delayed by approximately 40 ms. This delay is added to the operate time.

Parameter: Charact. constant k, Charact. constant α, Charact. constant c

- Default setting **(_:103) Charact. constant k** = ***1.00***
- Default setting **(_:104) Charact. constant α** = ***1.000***
- Default setting **(_:105) Charact. constant c** = ***0.000***

With the **Charact. constant k**, **Charact. constant α**, and **Charact. constant c** parameters, you define the required inverse-time characteristic.

Parameter: `Time dial`

- Default setting **`(_:106) Time dial`** = ***`1.00`***

With the **`Time dial`** parameter, you displace the characteristic curve in the time direction.

As usually, there is no time grading for voltage protection and therefore no displacement of the characteristic curve, Siemens recommends leaving the **`Time dial`** parameter at ***`1.00`*** (default setting).

Parameter: `Reset time`

- Default setting **`(_:108) Reset time`** = ***`0.00 s`***

With the **`Reset time`** parameter, you define the reset time delay which is started when the voltage exceeds the dropout value. Set the parameter **`Reset time`** to 0 s when instantaneous reset is desired.

Under network conditions of intermittent faults or faults which occur in rapid succession, Siemens recommends setting the **`Reset time`** to an appropriate value > 0 s to ensure the operation. Otherwise, Siemens recommends to keep the default value to ensure a fast reset of the function.

Parameter: `Additional time delay`

- Default setting **`(_:107) Additional time delay`** = ***`0.00 s`***

With the parameter **`Additional time delay`**, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, only the inverse-time delay is operative.

Parameter: Blk. by meas.-volt. failure

- Default setting **`(_:10) Blk. by meas.-volt. failure`** = ***`yes`***

You use the **`Blk. by meas.-volt. failure`** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following two conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **`>Open`** of the function block **`VTCB`** is connected to the voltage-transformer circuit breaker (see chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
`yes`	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
`no`	The protection stage is not blocked.

Parameter: Current-flow criterion

- Recommended setting value **`(_:2311:104) Current-flow criterion`** = ***`on`***

Depending on the system, the voltage transformers are arranged either on the supply side or the junction side. These 2 possible voltage-transformer locations induce a different behavior of the function after tripping and opening of the circuit breaker:

- If they are located on the supply side, the voltage remains on.
- If they are located on the junction side, the voltage is cleared.

Parameter Value	Description
`on`	If the voltage transformers are located on the junction side, you can use the current-flow criterion to make the pickup fall back when the current falls below a minimum value (parameter **`Threshold I>`**).
`off`	Since the voltage is switched off, the pickup of the undervoltage protection stage persists when the current-flow criterion is not used.

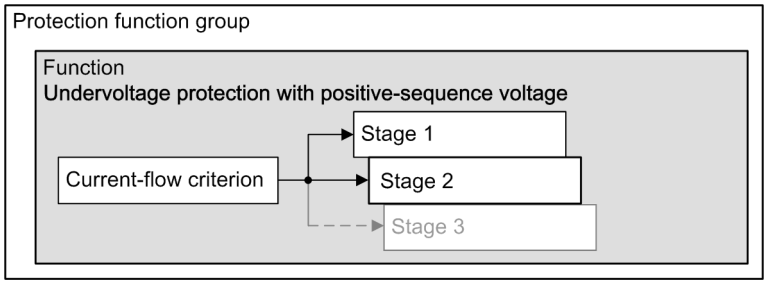
6.30 Undervoltage Protection with Positive-Sequence Voltage

6.30.1 Overview of Functions

The **Undervoltage protection with positive-sequence voltage** function (ANSI 27) is used to:

- Monitor the permissible voltage range
- Protect equipment (for example, plant components and machines) from damage caused by undervoltage
- Protect motors and generators from inadmissible operating states and a possible loss of stability in the event of voltage dips



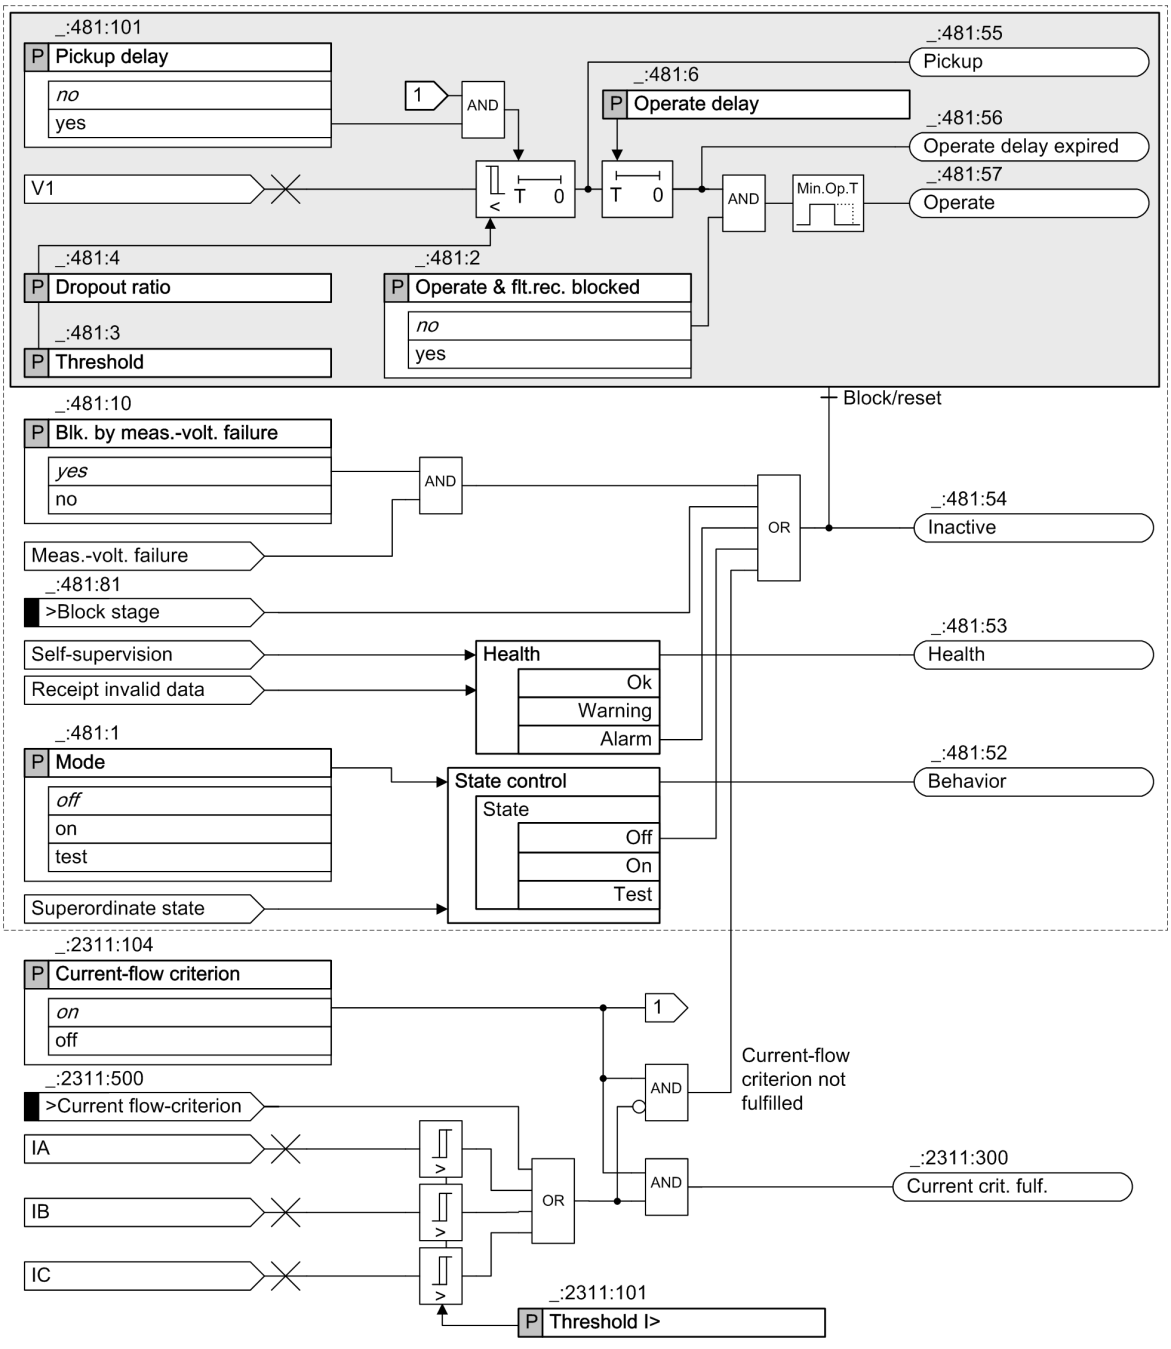
2-phase short circuits or ground faults lead to an unbalanced voltage collapse. In comparison to three 1-phase measuring systems, such events have no noticeable impact on the positive-sequence voltage. This makes this function particularly suitable for the assessment of stability problems.

6.30.2 Structure of the Function

The **Undervoltage protection with positive-sequence voltage** function is used in protection function groups, which are based on voltage measurement.

The **Undervoltage protection with positive-sequence voltage** function comes with 2 factory-set tripping stages. A maximum of 3 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.

The protection function is structured such that one current-flow criterion can act on all undervoltage protection stages (see *Figure 6-197*). If the protection function group used has no current measurement, you can only set the current- flow criterion as **fulfilled** via the corresponding binary input signal.



[dwstuvu1-110211-01.tif, 3, en_US]

Figure 6-197 Structure/Embedding of the Function

6.30.3 Stage Description

Logic of a Stage

[louv3pu1-021012-01.tif, 1, en_US]

Figure 6-198 Logic Diagram of a Stage: Undervoltage Protection with Positive-Sequence Voltage

Method of Measurement

The stage uses the positive-sequence voltage. The positive-sequence voltage is calculated from the measured phase-to-ground voltages according to the defining equation.

Pickup Delay

The **Pickup delay** parameter is only available and of relevance if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***).

If the circuit breaker opens when the current-flow criterion is being used, the undervoltage detection and current-flow dropout functions conflict with one another. Depending on the threshold value settings for undervoltage detection and current-flow criterion, it is possible that the undervoltage is detected before the current-flow criterion has dropped out. In this case, the tripping stage picks up briefly. Use the **Pickup delay** parameter to prevent the tripping stage from briefly picking up in this way when the circuit breaker opens. This is achieved by delaying pickup by approximately 40 ms.

Current-Flow Criterion

The undervoltage-protection stages work optionally with a current-flow criterion. The current-flow criterion works across all stages.

When the **Current-flow criterion** parameter is activated, the undervoltage protection stages only pick up if a settable minimum current (**Threshold I>**) is exceeded in at least one phase. A current below the minimum current blocks the tripping stages.

The current-flow criterion can also be set to **fulfilled** with the binary input signal **>Current flow-criterion**. The function reports when the current-flow criterion is fulfilled.

Figure 6-198 illustrates the influence of the current-flow criterion.

NOTE

If the **Current-flow criterion** parameter is deactivated, the device picks up immediately if a missing measuring voltage is detected while the undervoltage protection is active. The parameter setting can be changed even when the device has picked up.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal *>Block stage* from an external or internal source
- From inside on pickup of the **Measuring-voltage failure detection** function (see chapter *9.3.2.1 Overview of Functions*). The **Blk. by meas.-volt. failure** parameter can be set to either block or not block the tripping stage when the measuring-voltage failure detection picks up.
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

6.30.4 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:481:3) Threshold** = ***46 V***

Specify the **Threshold** (pickup threshold) for the specific application. For the default setting, it has been assumed that the lower voltage range, that is, 80 % of the rated voltage of the protected object, is to be monitored.

Parameter: Pickup delay

- Default setting **(_:481:101) Pickup delay** = ***no***

The **Pickup delay** parameter is only available if you are using the current-flow criterion of the function (parameter **Current-flow criterion** = ***on***). If the current-flow criterion is deactivated, no pickup delay is required.

With the parameter **Pickup delay** you set whether pickup of the stage is to be delayed by approximately 40 ms or not. The delay avoids possible brief pickup of the stage when the circuit breaker opens.

Parameter Value	Description
no	Use this setting if you definitely do not want tripping-stage pickup to be subject to a time delay in the event of a fault. This setting results in pickup and, where applicable, tripping being performed as quickly as possible. Note that switching procedures (opening of the CB) can result in brief pickup of the tripping stage, depending on the threshold-value settings for undervoltage pickup and the current-flow criterion. To prevent unwanted tripping, you must set a minimum tripping delay of 50 ms.
yes	Use this setting when switching procedures (opening of the CB) are not permitted to result in tripping-stage pickup. Note that pickup is delayed by approximately 40 ms. This delay is added to the operate time.

Parameter: Operate delay

- Default setting **(_:481:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:481:4) Dropout ratio** = ***1.05***

The recommended setting value of 1.05 is sufficient for many applications. To obtain extremely accurate indications, the **Dropout ratio** can be reduced.

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:481:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following two conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The protection stage is blocked (= default setting). Siemens recommends using the default setting.
no	The protection stage is not blocked.

Parameter: Current-flow criterion

- Recommended setting value **(_:2311:104) Current-flow criterion** = ***on***

Depending on the system, the voltage transformers can be located on the supply or the outgoing side. These 2 possible voltage transformer locations induce a different behavior of the function after tripping and opening of the circuit breaker:

- If they are located on the supply side, the voltage remains on
- If they are located on the output side, the voltage is switched off

Parameter Value	Description
on	The current-flow criterion allows to achieve, in the case of voltage transformers located on the output side, that the pickup drops out when the current drops below a minimum value (parameter Threshold value I>).

Parameter Value	Description
off	Since the voltage is switched off, the pickup of the undervoltage-protection stage persists when the current-flow criterion is not used.

Parameter: Threshold I>

- Recommended setting value **(_:2311:101) Threshold I>** = ***0.05 A***

The **Threshold I>** parameter makes it possible to detect when the circuit-breaker is closed. We recommend that you set the **Threshold I>** parameter to 5% of the rated current. With a secondary rated transformer current of 1 A, the secondary setting value for **Threshold I>** would be 0.05 A.

If the sensitivity of the **Threshold I>** parameter is set too high, compensation processes in the secondary circuit of the current transformer can extend the dropout time when breaking extremely high currents. To speed up dropout, increase the default setting.

Operation as Supervision Function

If you want the tripping stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

EXAMPLE of a 2-stage undervoltage protection

The undervoltage protection can be used for the protection of motors within the power plant's own power system. The example describes the possible settings for a two-stage undervoltage-protection function. We will look at the settings of the parameters **Threshold** and **Operate delay**.

1. Stage:

Set the **Threshold** to approx. 80 % of the rated voltage. In the case of voltage dips down to that value, the motors can still start up. Depending on the machine characteristic, the **Threshold** can also be set somewhat lower.

The following data apply:

Rated motor voltage:	$V_{rated,M} = 6\ kV$
Minimum startup voltage:	80 % of rated motor voltage
Voltage-transformer ratio:	$Ratio_V = \frac{6\ kV/\sqrt{3}}{100\ V/\sqrt{3}}$

When setting the threshold value, make sure that the positive-sequence voltage as defined is equal to the value of one phase-to-ground voltage. Taking into account the rated primary voltage of the motor, the primary setting value of the first stage is calculated as follows:

$$V_{prim} = 0.8 \cdot V_{rated,M} = 0.8 \cdot \frac{6\ kV}{\sqrt{3}} = 2.77\ kV$$

[fobglei1-190309-01.tif, 2, en_US]

When setting secondary values, you calculate the secondary setting value as follows, taking into account the voltage-transformer ratio:

$$V_{sec} = \frac{V_{prim}}{Ratio_V} = \frac{2.77\ kV}{6\ kV/\sqrt{3}} \cdot 100\ V/\sqrt{3} = 46.2\ V$$

[fobglei3-190309-01.tif, 2, en_US]

Set a value of 3 s for the **Operate delay**.

2. Stage:

Undervoltage cause excessive torques and current surges which place inadmissible strains on the motor. The voltage at which motors do no longer start up is in the range of (0.55 ... 0.70) $V_{rated,M}$. If no data are available, use the empirical value of approx. 70% of the rated voltage for setting the parameter **Threshold**. Set the **Operate delay** so that it slightly overlaps the tripping time of the overcurrent protection for the power-plant auxiliary power. Unless otherwise required by the motor manufacturer, set a **Operate delay** between 0.5 s and 3 s. The shorter time should be preferred.

Stage	Setting Values	
	Threshold value	Time delay
1	0.70 to 0.85 $V_{rated,M}$ (for example, 0.80 $V_{rated,M}$)	Approx. 3 to 5 s
2	0.55 to 0.70 $V_{rated,M}$ (for example, 0.70 $V_{rated,M}$)	0.5 s to 3 s

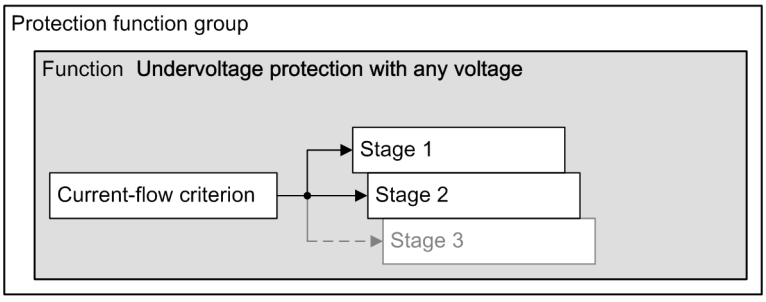
6.31 Undervoltage Protection with Any Voltage

6.31.1 Overview of Functions



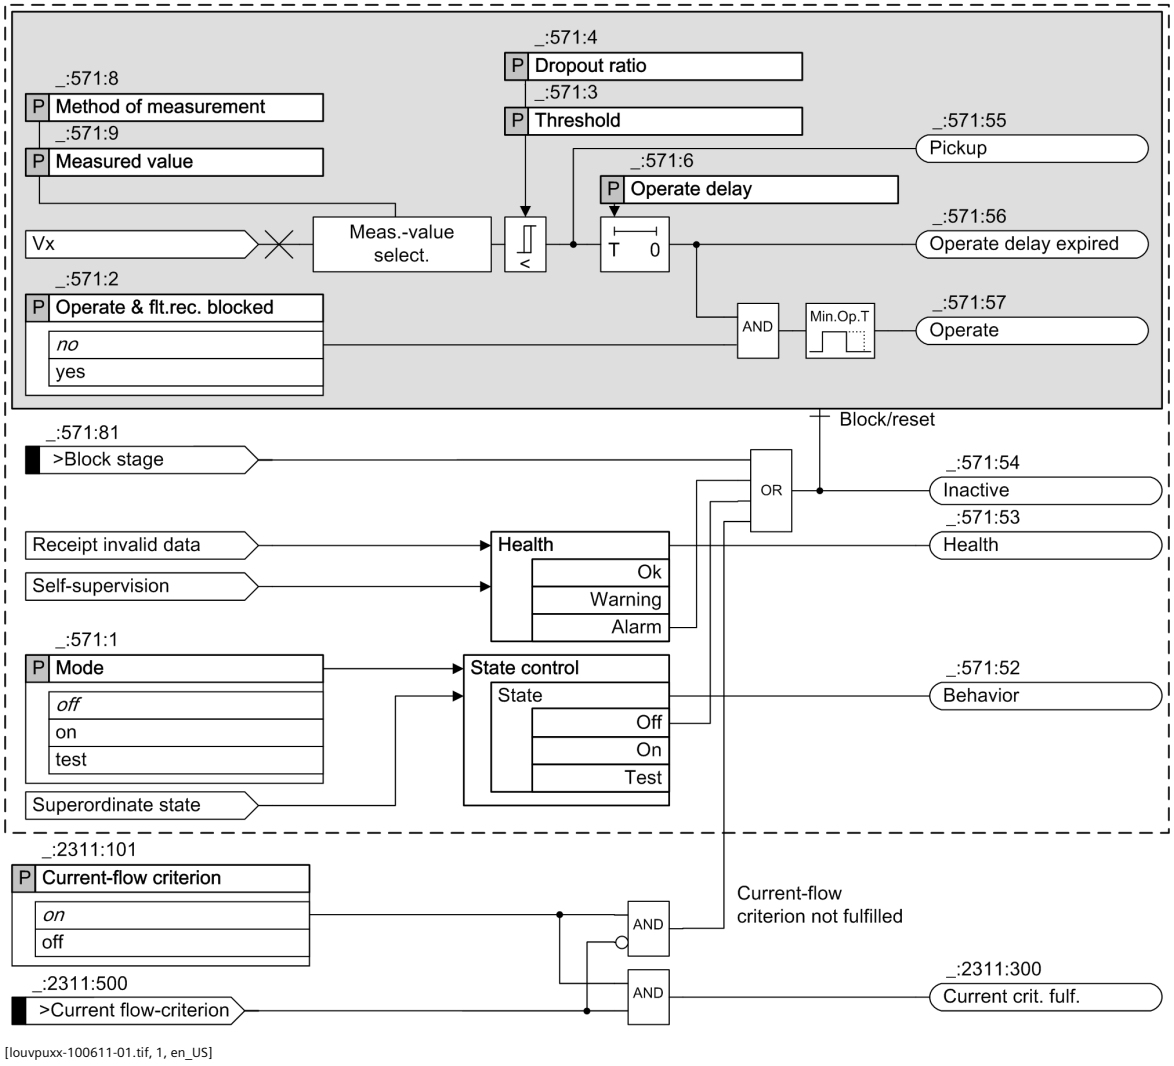
The function **Undervoltage protection with any voltage** (ANSI 27) detects any 1-phase undervoltage and is intended for special applications.

6.31.2 Structure of the Function

The **Undervoltage protection with any voltage** function is used in protection function groups, which are based on voltage measurement.

The function **Undervoltage protection with any voltage** comes with 2 factory-set stages. A maximum of 3 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.

The protection function is structured such that one current-flow criterion can act on all undervoltage protection stages (see *Figure 6-199*).



[dwstuvux-110211-01.tif, 1, en_US]

Figure 6-199 Structure/Embedding of the Function

6.31.3 Stage Description

Logic of a Stage

[louvpuxx-100611-01.tif, 1, en_US]

Figure 6-200 Logic Diagram of a Stage: Undervoltage Protection with Any Voltage

NOTE

If the function is used in 1-phase function groups, the parameter **`Measured value`** is not available.

Method of Measurement

The **`Method of measurement`** parameter allows you to define whether the function works with the fundamental component or the calculated RMS value.

- Measurement of the fundamental component:
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Measured Value

The parameter **Measured value** allows you to select whether the stage uses a measured (directly connected) voltage or a calculated phase-to-phase voltage.

If the function is used in 1-phase function groups, the parameter **Measured value** is not available.

Current-Flow Criterion

The undervoltage-protection stages work optionally with a current-flow criterion. The current-flow criterion works across all stages.

When the **Current-flow criterion** parameter is switched on, the undervoltage protection stages only pick up when the current-flow criterion has been set to **fulfilled** via the binary input signal **>Current flow-criterion**. The function reports when the current-flow criterion is fulfilled.

Figure 6-200 illustrates the influence of the current-flow criterion.

NOTE

If the **(_:2311:101) Current-flow criterion** parameter is deactivated, the device picks up immediately if a missing measuring voltage is detected while the undervoltage protection is active. The parameter setting can be changed even when the device has picked up.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking the stage is possible externally or internally via the binary input signal *>Block stage*.

6.31.4 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:571:8) Method of measurement** = ***fundamental comp.***

Use the **Method of measurement** parameter to define whether the tripping stage uses the fundamental component (standard method = default setting) or the calculated RMS value.

Parameter Value	Description
fundamental comp.	Select this method of measurement to suppress harmonics or transient voltage peaks. Siemens recommends using this parameter value as the default setting.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks). Do not set the **threshold value** of the tripping stage under 10 V for this method of measurement.

Parameter: Measured value

- Default setting **(_:571:9) Measured value** = ***VA measured***

The **Measured value** parameter is used to specify which voltage is monitored by the stage.

The scope of setting options depends on the connection type for the voltage transformers and the routing of the measured values to the terminals of the voltage measuring point. You can find connection examples for voltage transformers in the Appendix.

The following setting options can be available:

- Measured phase-to-ground voltage V_A (***VA measured***)
- Measured phase-to-ground voltage V_B (***VB measured***)
- Measured phase-to-ground voltage V_C ***VC measured***)
- Measured phase-to-phase voltage V_{AB} (***VAB measured***)

- Measured phase-to-phase voltage V_{BC} (***VBC measured***)
- Measured phase-to-phase voltage V_{CA} (***VCA measured***)
- Calculated phase-to-phase voltage V_{AB} (***VAB calculated***)
- Calculated phase-to-phase voltage V_{BC} (***VBC calculated***)
- Calculated phase-to-phase voltage V_{CA} (***VCA calculated***)
- Calculated voltage V0 (***V0 calculated***)

The selection depends on the corresponding application.

NOTE

If the function is used in 1-phase function groups, the parameter **Measured value** is not available.

Parameter: Threshold

- Default setting **(_:571:3) Threshold** = ***80 V***

Specify the **Threshold** (pickup threshold) for the specific application.

Depending on the **Measured value**, the **Threshold** is set either as **measured voltage** or as a **phase-to-phase** variable.

Parameter: Operate delay

- Default setting **(_:571:6) Operate delay** = ***3 s***

The **Operate delay** must be set for the specific application.

Parameter: Dropout ratio

- Recommended setting value **(_:571:4) Dropout ratio** = ***1.05***

The recommended set value of ***1.05*** is appropriate for most applications. To achieve high measurement precision, the **Dropout ratio** can be reduced to 1.02, for example.

Parameter: Current-flow criterion

- Recommended setting value **(_:2311:101) Current-flow criterion** = ***on***

Parameter Value	Description
on	Because of the application, it makes sense that the stage is only active (that is, not blocked) when a certain current flow is present (see note).
off	Current flow monitoring does not make sense for the application.

NOTE

Because of the flexible setting options of the voltage measurand, the function itself does not determine the current associated with the voltage. A suitable current-flow monitoring function must be created by the user with the Continuous Function Chart (CFC), and connected to the binary input signal **>Current flow-criterion**.

Operation as Supervision Function

If you want the tripping stage to have a reporting effect only, generation of the operate indication and fault logging can be disabled via the **Operate & flt.rec. blocked** parameter.

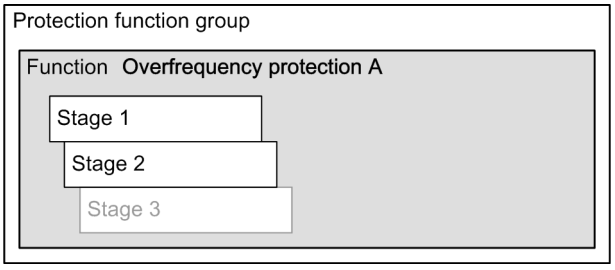
6.32 Overfrequency Protection

6.32.1 Overview of Functions

The **Overfrequency protection** function (ANSI 81O):

- Detect overfrequencies in electrical power systems or machines
- Monitor the frequency band and output failure indications
- Disconnect generating units when the power frequency is critical
- Provide additional turbine protection if the speed limiter fails

Frequency deviations are caused by an unbalance between the active power generated and consumed. Overfrequency is caused by load shedding (island network), power system disconnection or disturbances of the frequency controller. Overfrequency implies a risk of self excitation of machines which are connected to long lines without load.



Overfrequency protection is available in two functional configurations (selectable from the DIGSI functions library). The functional configurations differ in the frequency measurement method they use.

6.32.2 Structure of the Function

The **Overfrequency protection** function is used in protection function groups, which are based on voltage measurement.

The overfrequency protection function comes with 2 factory-set stages. A maximum of 3 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.

The parameters **`Dropout differential`** and **`Minimum voltage`** are set for all stages.

6.32.3 Overfrequency-Protection Stage

Logic of a Stage

[lostofqp-040411-01.tif, 1, en_US]

Figure 6-202 Logic Diagram of the Overfrequency-Protection Stage

Frequency-Measurement Method

Overfrequency protection is available in 2 functional configurations. These work with different frequency-measurement methods. You select the frequency-measurement method in dependence of the application.

- Angle-difference method (method A):

  The angle-difference method determines the phasor of the positive-sequence voltage in multiphase systems. In the case of 1-phase connection, it always processes the phasor of the connected voltage. Since the change of angle of the voltage phasor over a given time interval is proportional to the frequency change, the current frequency can be derived from it.

- Filtering method (method B):

  The filtering method processes the instantaneous voltage values and determines the current frequency using a suitable combination of filters. The frequency-protection function selects automatically the largest voltage as the measurand. In a multiphase connection, the phase-to-phase voltage is always the largest. If in a multiphase connection the selected voltage is no longer available, the function changes over automatically to the next maximum voltage. The function can even operate with just one voltage.

Both methods of measurement are characterized by a high measuring accuracy combined with a short pickup time. Disturbance values such as harmonics, high frequency disturbances, phase-angle jumps during switching operations and compensation processes due to power swings are effectively suppressed.

Functional Measured Value

The angle-difference method provides the following measured value:

Value	Description
f	Calculated frequency with the angle-difference method

Behavior on Leaving the Operating Range

The sampling frequency tracking makes an additional frequency-operating range possible. If the stage has picked up before leaving the frequency-operating range and the measuring voltage is higher than the set minimum voltage, the pickup is maintained. A dropout of the pickup is only possible by means of a blocking.

Blocking the Stage

Blocking will cause a tripping stage that has picked up to dropout. The following blocking options are available for the stage:

- Externally or internally via the logical binary input *>Block stage*
- Internally when the voltage drops below the **Minimum voltage**

6.32.4 Application and Setting Notes

Frequency-Measurement Method

The frequency measurement method is selected with the functional configuration from the DIGSI functions library. The letter at the end of the function name describes the method of measurement.

Redundant solutions can be implemented by combining 2 different methods of frequency measurement. You can implement a **2-out-of-2 decision** by connecting the operate indications of both functions in a CFC with a logical AND gate. This increases the reliability of protection.

Frequency-Measurement Method	Description
Angle difference method (method A)	Select this method of measurement if the frequency protection stage is used for the protection of machines.
Filtering method (method B)	Select this method of measurement if the frequency protection stage is used in an electrical power system.

Parameter: Threshold

- Recommended setting value **(_:31:3) Threshold** = ***50.20 Hz*** for f_{rated} = 50 Hz

The **Threshold** parameter is used to define the pickup threshold of the overfrequency protection stage in dependence of the application. 50.20 Hz is a typical warning threshold in 50-Hz systems.

Parameter: Operate delay

- Recommended setting value **(_:31:6) Operate delay** = ***10 s***

The **Operate delay** parameter is used to set the stage so that overfunctions due to disturbing influences (for example, switching operations) are avoided. Fairly high time delays are sufficient for warning indications.

Parameter: Minimum voltage

- Recommended setting value **(_:2311:101) Minimum voltage** = **37.5 V**

For the **Undervoltage blocking**, 65 % of the protected object's rated voltage is recommended.

When determining the setting value, please keep in mind the measurement method and the measuring connection that you have selected. If you work with the positive-sequence voltage, remember that the maximum voltage is equal to the phase-to-ground voltage. The default setting is referred to this value.

Parameter: Dropout differential

- Recommended setting value **(_:2311:109) Dropout differential** = ***20 mHz***

Due to the high-precision frequency measurement, the recommended setting value for the **Dropout differential** can remain at 20 mHz. If in your application you wish a subsequent dropout of the tripping stage, then increase the setting value of the dropout differential. For instance, if the pickup value (parameter **Threshold**) of the tripping stage is set to 50.20 Hz and the **Dropout differential** to 100 mHz, the stage will drop out at 50.10 Hz.

Application example of the overfrequency protection

Overfrequency protection can be used for monitoring the frequency range. If the frequency deviates from the rated frequency by for example, 0.2 Hz, a fault indication is generated. The trip command is delayed to avoid overfunction due to disturbing influences (for example, switching operations). A delay of a few seconds (for example, 10 s) is deemed to be a good value. You can leave the **Dropout differential** at the default value of ***20 mHz***. The following table shows a setting recommendation.

For this application, 1 stage of the overfrequency protection is used. The following table shows a setting suggestion.

Stage	Caused by	Setting Values		
		At f_{rated} = 50 Hz	At f_{rated} = 60 Hz	Delay
f1>	Warning	50.20 Hz	60.20 Hz	10.00
f2>	Not used (OFF)	-	-	-

NOTE

This table shows one example of a possible frequency protection setting. The setting values can differ depending on the application.

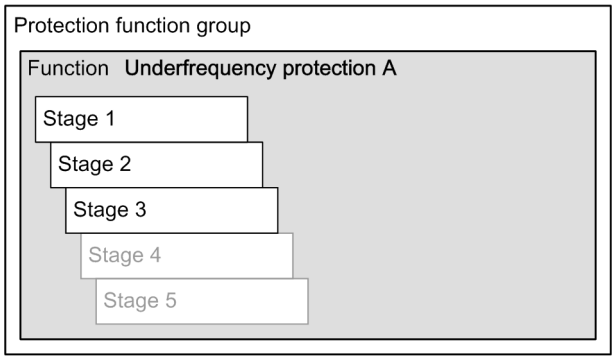
6.33 Underfrequency Protection

6.33.1 Overview of Functions

The **Underfrequency protection** function (ANSI 81U) is used to:

- Detect underfrequencies in electrical power systems or machines
- Monitor the frequency band and output failure indications
- Decouple power systems
- Load shedding to ensure power system stability and protect motors
- Disconnect generating units when the power system frequency is critical (for example, $f < 0.95\ f_{rated}$)

Frequency deviations are caused by an unbalance between the active power generated and consumed. Underfrequency is caused by an increase of the consumers' active power demand or by a decrease of the power generated. These conditions occur in the case of power system disconnection, generator failure, or disturbances of the power and frequency controller.



Underfrequency protection is available in 2 functional configurations (selectable from the DIGSI functions library). The functional configurations differ in the frequency measurement method they use.

6.33.2 Structure of the Function

The **Underfrequency protection** function is used in protection function groups, which are based on voltage measurement.

The **Underfrequency protection** function comes with 3 factory-set stages. A maximum of 5 tripping stages can be operated simultaneously in the function. The tripping stages have an identical structure.

The parameters **`Dropout differential`** and **`Minimum voltage`** are set for all stages.

6.33.3 Underfrequency-Protection Stage

Logic of a Stage

[lostufqp-040411-01.tif, 2, en_US]

Figure 6-204 Logic Diagram of the Underfrequency-Protection Stage

Frequency-Measurement Method

Underfrequency protection is available in 2 functional configurations. These work with different frequency-measurement methods. You select the frequency-measurement method in dependence of the application.

- Angle-difference method (method A):

  The angle-difference method determines the phasor of the positive-sequence voltage in multiphase systems. In the case of 1-phase connection, it always processes the phasor of the connected voltage. Since the change of angle of the voltage phasor over a given time interval is proportional to the frequency change, the current frequency can be derived from it.

- Filtering method (method B):

  The filtering method processes the instantaneous voltage values and determines the current frequency using a suitable combination of filters. The frequency-protection function selects automatically the largest voltage as the measurand. In a multiphase connection, the phase-to-phase voltage is always the largest. If in a multiphase connection the selected voltage is no longer available, the function changes over automatically to the next maximum voltage. The function can even operate with just one voltage.

Both methods of measurement are characterized by a high measuring accuracy combined with a short response time. Disturbance values such as harmonics, high frequency disturbances, phase-angle jumps during switching operations and compensation processes due to power swings are effectively suppressed.

Behavior on Leaving the Operating Range

The sampling frequency tracking makes an additional frequency-operating range possible. If the stage has picked up before leaving the frequency-operating range and the measuring voltage is higher than the set minimum voltage, the pickup is maintained. A dropout of the pickup is only possible by means of a blocking.

Blocking the Stage

Blocking will cause a tripping stage that has picked up to dropout. The following blocking options are available for the stage:

- Via the binary input signal *>Block stage* from an external or internal source
- Internally when the voltage drops below the **Minimum voltage**

6.33.4 Application and Setting Notes

Frequency-Measurement Method

The frequency measurement method is selected with the functional configuration from the DIGSI functions library. The letter at the end of the function name describes the method of measurement.

Redundant solutions can be implemented by combining 2 different methods of frequency measurement. You can implement a **2-out-of-2 decision** by connecting the operate indications of both functions in a CFC with a logical AND gate. This increases the reliability of protection.

Method of Measurement	Description
Angle difference method (method A)	Select this method of measurement if the frequency protection stage is used for the protection of machines.
Filtering method (method B)	Select this method of measurement if the frequency protection stage is used in an electrical power system.

Parameter: Threshold

- Recommended setting value **(_:61:3) Threshold** = ***49.80 Hz*** for f_{rated} = 50 Hz

The **Threshold** parameter is used to define the pickup threshold of the underfrequency protection stage in dependence of the application. 49.8 Hz is a typical warning threshold in 50-Hz systems.

Parameter: Operate delay

- Recommended setting value **(_:61:6) Operate delay** = ***10.00 s***

The **Operate delay** parameter is used to set the stage so that overfunctions due to disturbing influences (for example, switching operations) are avoided. Fairly high time delays are sufficient for warning indications.

Parameter: Minimum voltage

- Recommended setting value **(_:2311:101) Minimum voltage** = **37 500 V**

For the **Undervoltage blocking**, 65 % of the protected object's rated voltage is recommended.

When determining the setting value, please keep in mind the measurement method and the measuring connection that you have selected. If you work with the positive-sequence voltage, remember that the maximum voltage is equal to the phase-to-ground voltage. The default setting is referred to this value.

Parameter: Dropout differential

- Recommended setting value **(_:2311:109) Dropout differential** = ***20 mHz***

Due to the high-precision frequency measurement, the recommended setting value for the **Dropout differential** can remain at 20 mHz. If in your application you wish a subsequent dropout of the tripping stage, then increase the setting value of the dropout differential. For instance, if the pickup value (parameter **Threshold**) of the tripping stage is set to 49.8 Hz and the **Dropout differential** to 100 mHz, the stage will drop out at 49.9 Hz.

Application example of the underfrequency protection

Frequency protection can be used for load shedding. The UCTE has defined a 5-stage plan for the Western European power grid. The setting values of the stages are based on that plan (see table below).

Table 6-16 Stage Plan

Frequency	Activity
49.80 Hz	Alarm and activation of reserves following an established plan
49.00 Hz	Undelayed disconnection of 10 % to 15 % of the power system load
48.70 Hz	Undelayed disconnection of another 10 % to 15 % of the power system load
48.40 Hz	3rd load shedding stage. Another 15 % to 20 % of the power system load is disconnected.
47.50 Hz	Power plants are decoupled from the electrical power system

For this application, 3 stages of the underfrequency protection are used. 2 of these stages are used for load shedding. The following table shows a setting suggestion.

Stage	Caused by	Setting Values		
		At f_{rated} = 50 Hz	At f_{rated} = 60 Hz	Delay
f1<	Warning	49.80 Hz	59.80 Hz	10.00
f2<	1st load shedding	49.00 Hz	59.00 Hz	0.00
f3<	2nd load shedding	48.70 Hz	58.70 Hz	0.00

NOTE

This table shows one example of a possible frequency protection setting. The setting values can differ depending on the application.

6.33.5 Settings

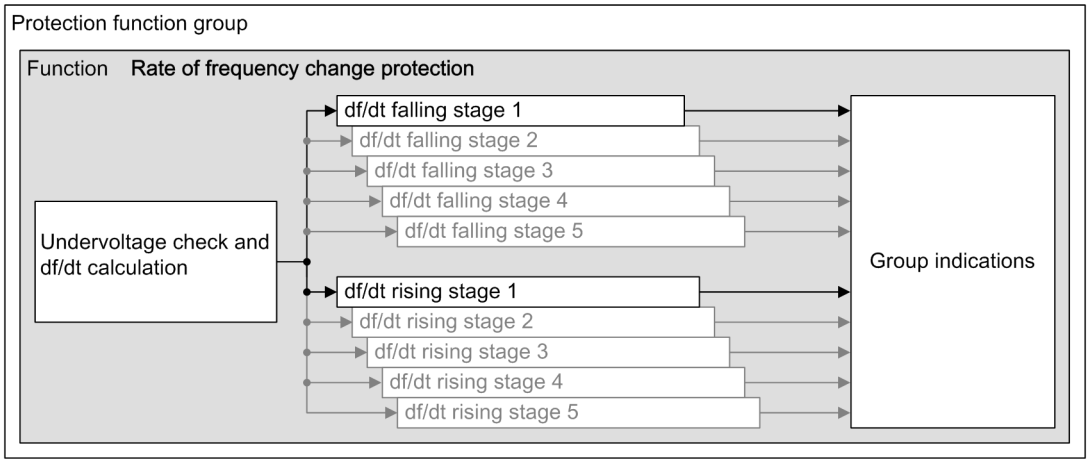
6.34 Rate of Frequency Change Protection

6.34.1 Overview of Functions

The function **Rate of frequency change protection** is used to:

- Detect a frequency change quickly
- Prevent the system from not secure states caused by unbalance between the generated and consumed active power
- Network decoupling
- Load shedding

6.34.2 Structure of the Function



The function **Rate of frequency change protection** can be used in protection function groups containing a 3-phase voltage measurement.

2 function block types are available:

- **df/dt rising**
- **df/dt falling**

The function **Rate of frequency change protection** is preconfigured by the manufacturer with 1 df/dt rising stage and 1 df/dt falling stage. A maximum of 5 df/dt rising stages and 5 df/dt falling stages can operate simultaneously within the function. Both of the function block types are similar in structure.

Undervoltage check and df/dt calculation are general functionalities and take place on the function level. All stages use these general functionalities.

[dwdfdt01-160113-01.tif, 1, en_US]

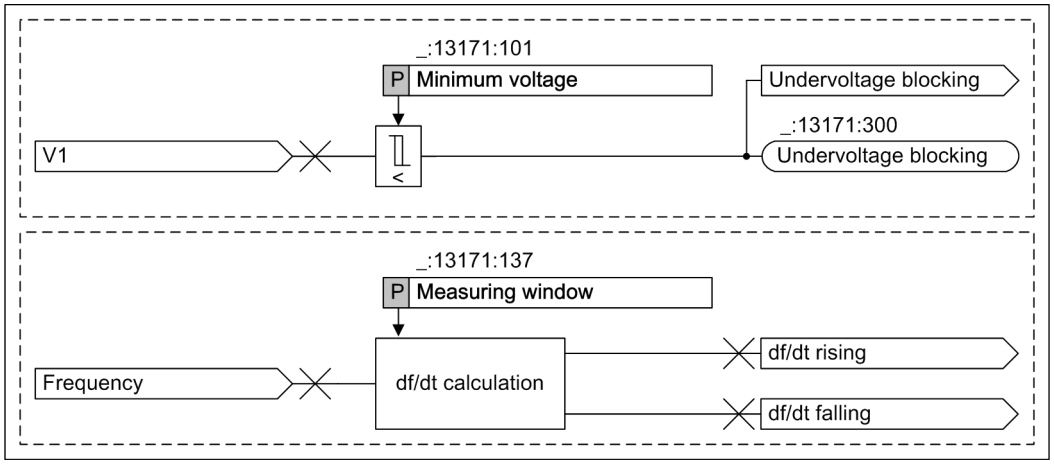


Figure 6-205 Structure/Embedding of the Function

6.34.3 General Functions (Undervoltage Test, df/dt Calculation)

6.34.3.1 Description

Logic

The following figure represents the logic of undervoltage check and df/dt calculation. It applies to all types of stages.

[lodfdtgf-160113-01.tif, 1, en_US]

Figure 6-206 Logic Diagram of General Functionality

Measurand

This function uses the frequency calculated via the angle difference algorithm.

For more information, refer to chapter *6.32.3 Overfrequency-Protection Stage* .

The frequency difference is calculated over a settable time interval (default setting: 5 periods).

The ratio between the frequency difference and the time difference reflects the frequency change which can be positive or negative.

A stabilization counter works to avoid overfunction. This counter is increased if the set threshold value is exceeded. If the value drops below the threshold value, the counter is reset immediately. The counter is set to 8 internally and is activated at each half system cycle.

Undervoltage Blocking

If the measuring voltage drops below the **`Minimum voltage`**, the **Rate of frequency change protection** is blocked because precise frequency values cannot be calculated anymore.

Functional Measured Value

Value	Description
df/dt	Calculated rate of frequency change

6.34.3.2 Application and Setting Notes

Parameter: `Minimum voltage`

- Recommended setting value **`(_:13171:101) Minimum voltage`** = ***`37.500 V`***

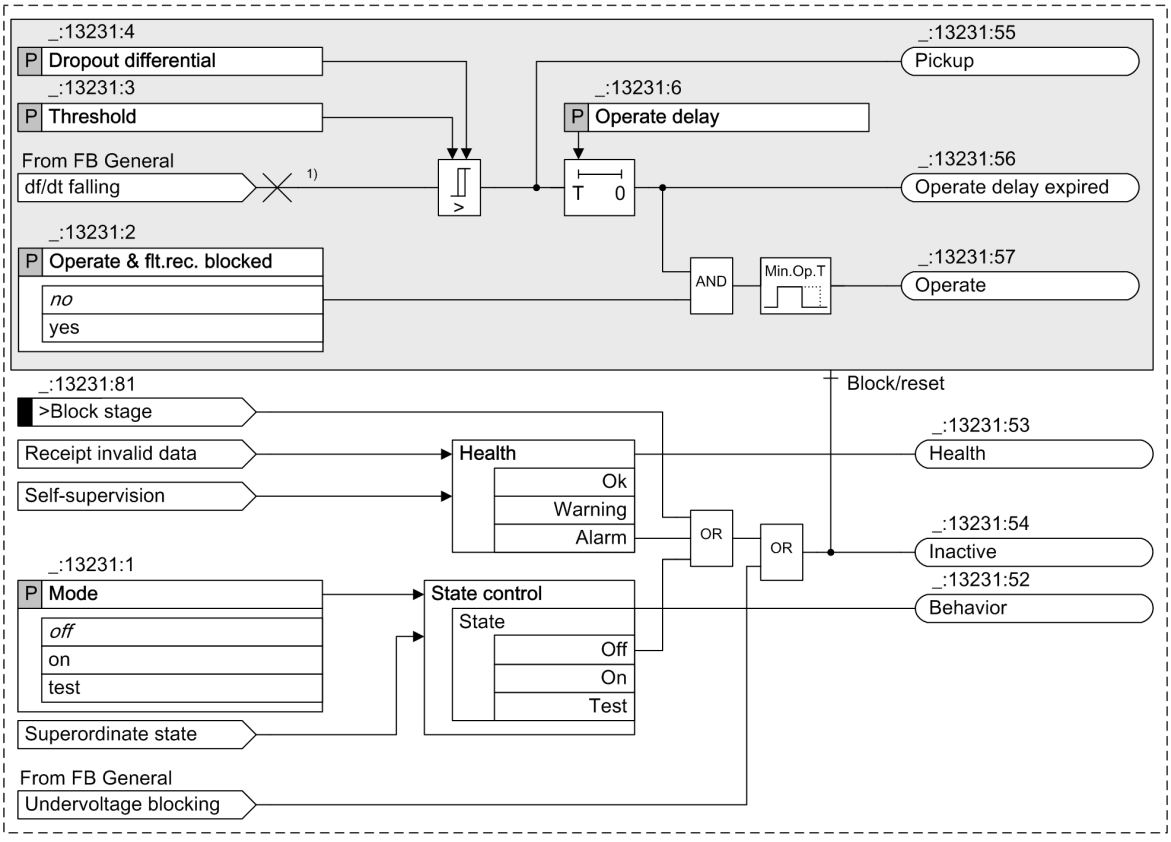
For the **Undervoltage blocking**, 65 % of the rated voltage of the protected object is recommended.

The method of measurement uses the phasor of the positive-sequence voltage. When determining the setting value, keep in mind that the absolute value of the sound positive-sequence voltage is equal to the absolute value of the phase-to-ground voltage. The default setting is referred to this value.

Parameter: `Measuring window`

- Default setting **`(_:13171:137) Measuring window`** = ***`5 periods`***

You can use the **`Measuring window`** parameter to optimize the measuring accuracy or the pickup time of the function. For information regarding pickup time and measuring accuracy, refer to the technical data.



The default setting provides maximum measuring accuracy. If you do not have specific requirements for a decreased pickup time, Siemens recommends using the default setting.

The default setting is a reasonable compromise between measuring accuracy and pickup time. For a non-sensitive setting (high threshold value), you can set the parameter **`Measuring window`** to a smaller value.

6.34.4 Stage Description

6.34.4.1 Description

Logic of the Stage

[lodfdtst-160113-01.tif, 1, en_US]

Figure 6-207 Logic Diagram of Rate of Frequency Change Protection

(1) For the stage type **df/dt rising**, the value **df/dt rising** is used.

Frequency Rising/Falling

The stage **df/dt falling** is used to detect frequency falling and the stage **df/dt rising** is used to detect frequency rising.

You set the threshold value as an absolute value. You define the frequency-change direction via the selected stage type.

Blocking of the Stage

The following blockings reset the picked up stage completely:

- Via the binary input signal *`>Block stage`*
- Via the undervoltage blocking when the voltage drops below the **`Minimum voltage`**

6.34.4.2 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:13231:3) Threshold** = ***3.0 Hz/s***

The pickup value depends on the application and is determined by power-system conditions. In most cases, a network analysis will be necessary. A sudden disconnection of loads leads to a surplus of active power. The frequency rises and causes a positive frequency change. On the other hand, a failure of generators leads to a deficit of active power. The frequency drops and results in a negative frequency change.

The following relations can be used as an example for estimation. They apply for the change rate at the beginning of a frequency change (approximate 1 s).

$$\frac{df}{dt} = -\frac{f_{rated}}{2H} \cdot \frac{\Delta P}{S_{rated}}$$

Where:

f_{rated}	Rated frequency
ΔP	Active power change $\Delta P = P_{Consumption} - P_{Generation}$
S_{rated}	Rated apparent power of the machines
H	Inertia constant

Typical data for H:

For hydro generators (salient-pole machines)	H = 1.5 s to 6 s
For turbine-driven generators (non-salient pole rotors)	H = 2 s to 10 s
For industrial turbine-driven generators	H = 3 s to 4 s

EXAMPLE

f_{rated} = 50 Hz

H = 3 s

Case 1: $\Delta P/S_{rated}$ = 0.12

Case 2: $\Delta P/S_{rated}$ = 0.48

Case 1: df/dt = -1 Hz/s

Case 2: df/dt = -4 Hz/s

Parameter: Operate delay

- Default setting **(_:13231:6) Operate delay** = ***1.00 s***

You can use the **Operate delay** parameter to avoid overfunction due to disturbing influences (for example, switching operations). If the protection function is supposed to respond quickly, set the **Operate delay** parameter to 0 s.

For monitoring small changes (< 1 Hz/s), a small time delay is useful to avoid overfunctioning.

Parameter: Dropout differential

- Recommended setting value **(_:13231:4) Dropout differential** = ***0.10 Hz/s***

You can use the **Dropout differential** parameter to define the dropout value. The recommended value is ***0.10 Hz/s***.

NOTE

In case of power-system incidents, especially in case of transmission incidents and influence of voltage-stabilizing measures via power-electronic components (reactive-power compensation through SVC), the magnitude and the phase angle of the voltage can change. Sensitive settings can lead to overfunction. Therefore, it is reasonable to block the **Rate of Frequency Change Protection** if other protection functions, for example, residual voltage or negative-sequence voltage, pick up. To do this, use the blocking input *>Block stage* and connect it via CFC.

6.34.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting

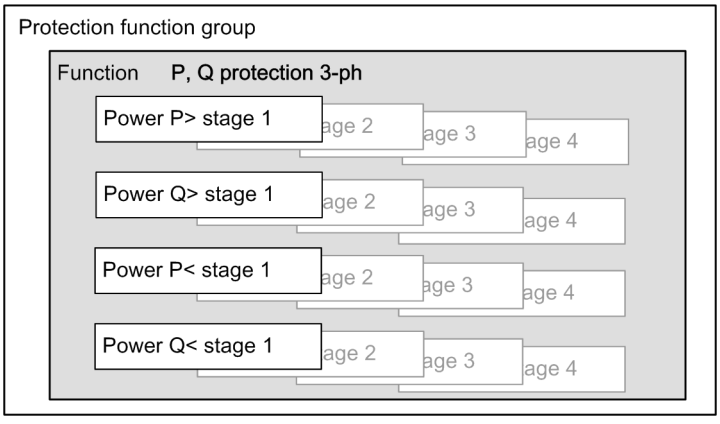
6.35 Power Protection (P,Q), 3-Phase

6.35.1 Overview of Functions

The **3-phase power protection (P, Q)** function (ANSI 32) is used to:

- Detect whether the active or reactive power rises above or drops below a set threshold
- Monitor agreed power limits and output warning indications
- Detect both active and reactive power feedback in the power systems or on electric machines
- Detect machines (motors, generators) running without load and output an indication to shut them down.
- Be integrated into any automation solution, for example, to monitor very specific power limits (further logical processing in CFC)



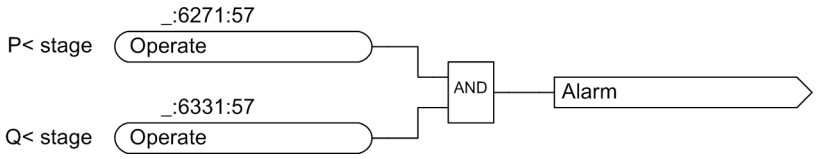
6.35.2 Structure of the Function

The **3-phase power protection (P, Q)** function can be integrated in function groups, which provide measured voltages and currents of the 3-phases for calculation of the power.

The **3-phase power protection (P,Q)** function comes with one factory-set stage each for the active and the reactive power. The following stages are preconfigured:

- Power P>
- Power Q>
- Power P<
- Power Q<

A maximum of 4 active power stages and 4 reactive power stages can be operated simultaneously in the function. The tripping stages have an identical structure.

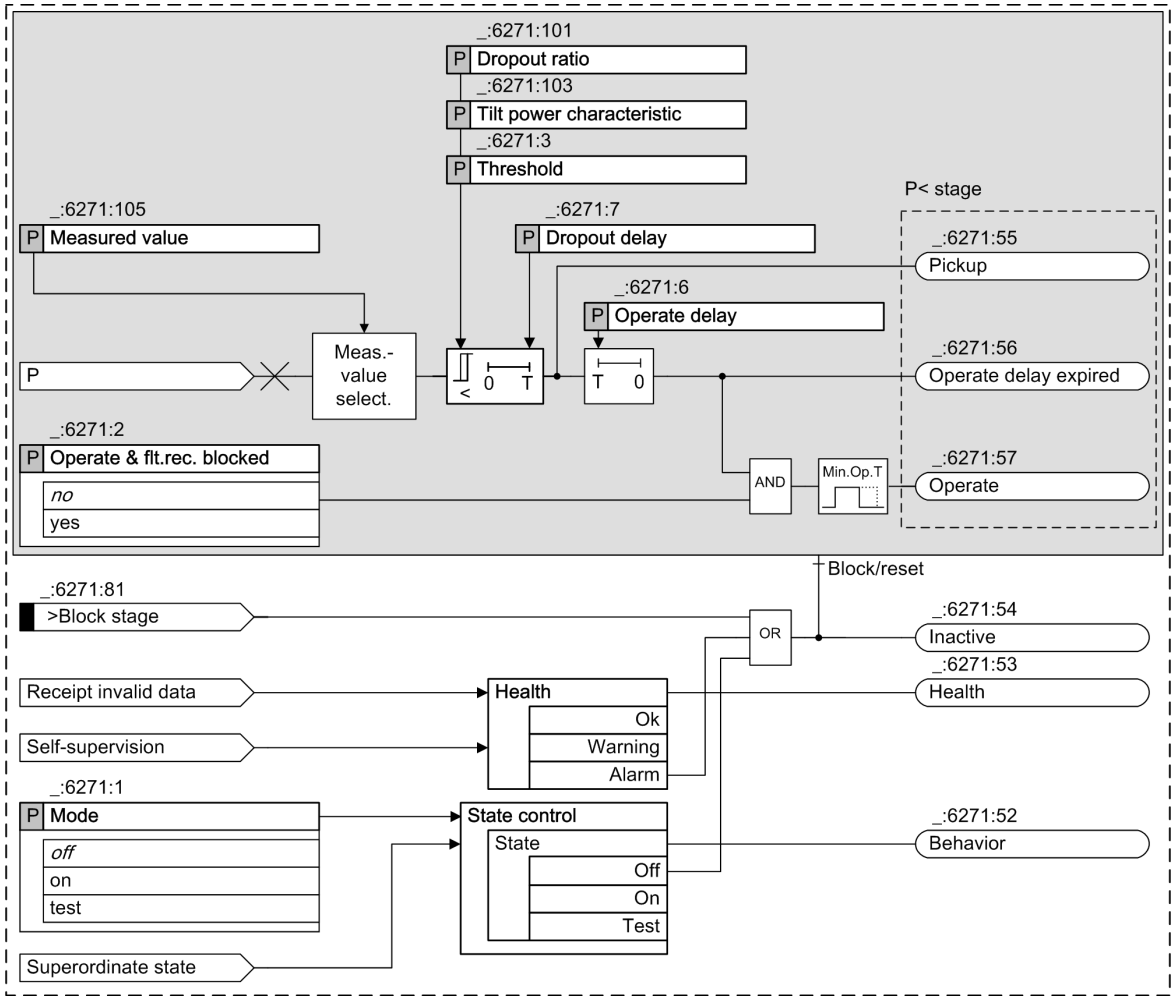


[dwstpq3p-110211-01.tif, 1, en_US]

Figure 6-208 Structure/Embedding of the Function

Logical Combination of Output Signals

The operate indications of the active and reactive power stage(s) can be logically combined in CFC. When an operate indication is present in both the active and the reactive power stage, an alarm indication is generated.



[loausmel-050411-01.tif, 1, en_US]

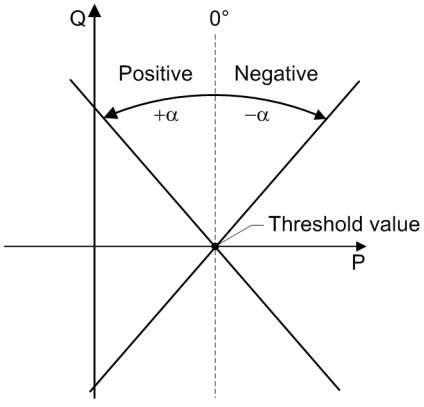
Figure 6-209 Logical Combination of Operate Indications in CFC

6.35.3 Active Power Stage

Logic of a Stage

[lop3phas-040411-01.tif, 1, en_US]

Figure 6-210 Logic Diagram of the Active Power Stage (Stage Type: Power P<)



Measured Value

The **Measured value** parameter is used to specify which measured power value is analyzed by the tripping stage. Possible settings are ***positive seq. power*** and the phase-selective powers ***power of phase A***, ***power of phase B*** or ***power of phase C***.

Pickup Characteristic

With the stage type you specify if the stage work as a **greater stage** (stage type: **Power P>**) or as a **smaller stage** (stage type: **Power P<**).

The **Threshold** parameter is used to define the pickup threshold of the stage. The **Tilt power characteristic** parameter is used to define the tilt of the pickup characteristic. The figure below shows the definition of the signs.

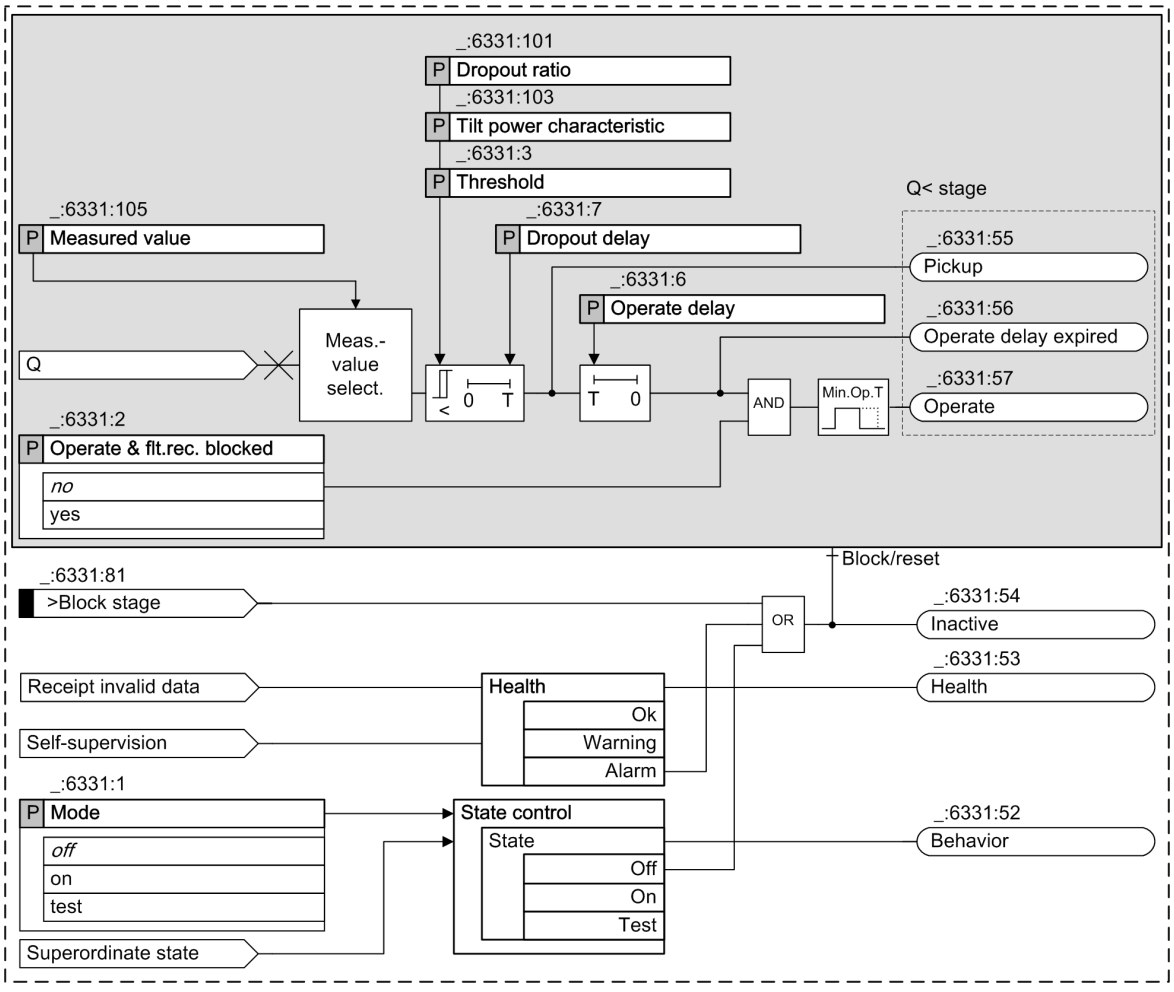
[dwdvzpgr-100611-01.tif, 1, en_US]

Figure 6-211 Tilt-Power Characteristic

Pickup

The stage compares the selected power value with the set **Threshold**. Depending on the stage type (**Power P>** or **Power P<**) being above or falling below the threshold value will lead to a pickup.

Dropout Delay



A delay can be set for the dropout when the measured value falls below the dropout threshold. The pickup is maintained for the specified time. The time delay of the tripping (parameter **Operate delay**) continues to run. Once the **Operate delay** has elapsed, the stage trips.

Blocking the Stage

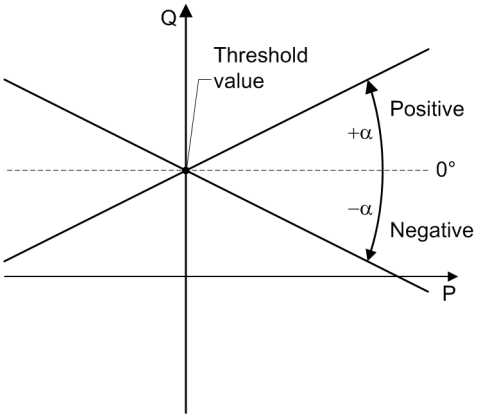
In the event of blocking, the picked up stage will be reset. Blocking the stage is possible externally or internally via the binary input signal *>Block stage*.

6.35.4 Reactive Power Stage

Logic of a Stage

[loq3phas-040411-01.tif, 1, en_US]

Figure 6-212 Logic Diagram of the Reactive Power Stage (Stage Type: Power Q<)



Measured Value

The **Measured value** parameter is used to specify which measured power value is processed by the tripping stage. Possible settings are ***positive seq. power*** and the phase-selective powers ***power of phase A***, ***power of phase B*** or ***power of phase C***.

Pickup Characteristic

With the stage type you specify if the stage work as a **greater stage** (stage type: **Power Q>**) or as a **smaller stage** (stage type: **Power Q<**).

The **Threshold** parameter is used to define the pickup threshold of the stage. The **Tilt power characteristic** parameter is used to define the tilt of the pickup characteristic. The figure below shows the definition of the signs.

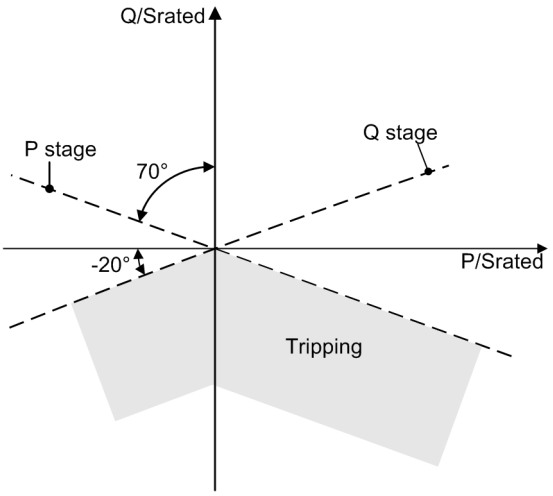
[dwdvzqgr-100611-01.tif, 1, en_US]

Figure 6-213 Tilt-Power Characteristic

Pickup

The stage compares the selected power value with the set **Threshold**. Depending on the stage type (**Power Q>** or **Power Q<**) being above or falling below the threshold value will lead to a pickup.

Dropout Delay



A delay can be set for the dropout when the measured value falls below the dropout threshold. The pickup is maintained for the specified time. The time delay of the tripping (parameter **Operate delay**) continues to run. Once the **Operate delay** has elapsed, the stage trips.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking the stage is possible externally or internally via the binary input signal *>Block stage*.

6.35.5 Application Example

The setting of the function will be explained using an active/reactive power range as an example. If the apparent power phasor is within the power range (in *Figure 6-214* tripping zone defined by characteristics), an alarm indication is generated. For this purpose, you have to make an AND operation of the stage indications of the active and reactive power stage in CFC. The function used is 3-phase power measurement. *Figure 6-214* shows the threshold values and the location of the characteristics in the PQ diagram.

[dwpqd7sa-110211-01.tif, 1, en_US]

Figure 6-214 Pickup Values and Characteristic Curves

6.35.6 Setting Notes for the Active Power Stage

Stage Type

In the following example, a drop of the active power below a threshold is to be monitored. In the **3-phase circuit breaker (P, Q)** function, work with the stage type **Power P<**.

Parameter: Measured value

- Recommended setting value **(_:6271:105) Measured value** = ***positive seq. power***

The **Measured value** parameter is used to specify which measured power value is evaluated. For 3-phase measurement, Siemens recommends to evaluate the positive-sequence system power.

Parameter: Threshold

- Recommended setting value **(_:6271:3) Threshold** = ***0 %***

The **Threshold** parameter is used to define the pickup threshold of the active power stage. In the example, the pickup characteristic runs across the point of origin of the coordinates. Set the parameter **Threshold** to ***0%***.

NOTE

If you use several settings groups, consider the following:

- The dropout value of a stage must have the same sign in all settings groups.
- Switching from a positive dropout value to a negative dropout value or vice versa is not allowed. As a result, DIGSI reports an inconsistency.
- If you want to change the sign of the dropout value of a stage in an additional settings group, instantiate a new stage and enable it. If the new stage should not be effective in another settings group, disable the stage there.

Parameter: Dropout ratio

- Recommended setting value **(_:6271:101) Dropout ratio** = ***1.05***

A hysteresis of 5 % is sufficient for most applications. The setting value for the **lower stage** is therefore 1.05.

Parameter: Tilt power characteristic

- Recommended setting value **(_:6271:103) Tilt power characteristic** = ***+70°***

The **Tilt power characteristic** parameter is used to incline the pickup characteristic. In the above example, an inclination is required. The setting value is ***+70°*** (for a definition of the sign, see *Figure 6-211*).

Parameter: Dropout delay

- Recommended setting value **(_:6271:7) Dropout delay** = ***20 ms***

The **Dropout delay** parameter maintains the pickup even if the measured value drops momentarily below the threshold value. A delay is required for very low pickup values to prevent a so-called chattering of the function. In the example, the setting value is 20 ms.

Parameter: Operate delay

- Recommended setting value **(_:6271:6) Operate delay** = ***100 ms***

The **Operate delay** must be set for the specific application. In the example, a setting value of 100 ms has been selected.

6.35.7 Setting Notes for the Reactive Power Stage

Stage Type

In the example, the reactive power is to be monitored if it falls below the threshold. In the **3-phase circuit breaker (P, Q)** function, work with the stage type **Power Q<**.

Parameter: Measured value

- Recommended setting value **(_:6331:105) Measured value** = ***positive seq. power***

The **Measured value** parameter is used to specify which measured power value is evaluated. For 3-phase measurement, Siemens recommends to evaluate the positive-sequence system power.

Parameter: Threshold

- Recommended setting value **(_:6331:3) Threshold** = ***0 %***

The **Threshold** parameter is used to define the pickup threshold of the reactive power stage. In the example, the pickup characteristic runs across the point of origin of the coordinates. Set the parameter **Threshold** to ***0%***.

NOTE

If you use several settings groups, consider the following:

- The dropout value of a stage must have the same sign in all settings groups.
- Switching from a positive dropout value to a negative dropout value or vice versa is not allowed. As a result, DIGSI reports an inconsistency.
- If you want to change the sign of the dropout value of a stage in an additional settings group, instantiate a new stage and enable it. If the new stage should not be effective in another settings group, disable the stage there.

Parameter: Dropout ratio

- Recommended setting value **(_:6331:101) Dropout ratio** = ***0.95***

A hysteresis of 5 % is sufficient for most applications. The setting value for the **lower stage** is therefore 0.95.

Parameter: Tilt power characteristic

- Recommended setting value **(_:6331:103) Tilt power characteristic** = ***+20°***

The **Tilt power characteristic** parameter is used to incline the pickup characteristic. In the example (see *Figure 6-214*), the power characteristic has a tilt of 20°. Set the **Tilt power characteristic** parameter to ***+20°*** (for a definition of the sign, see *Figure 6-213*).

Parameter: Dropout delay

- Recommended setting value **(_:6331:7) Dropout delay** = ***20 ms***

The **Dropout delay** parameter maintains the pickup even if the measured value drops momentarily below the threshold value. A delay is required for very low pickup values to prevent a so-called chattering of the function. In the example, the setting value is 20 ms.

Parameter: Operate delay

- Recommended setting value **(_:6331:6) Operate delay** = ***100 ms***

The **Operate delay** must be set for the specific application. In the example, a setting value of 100 ms has been selected.

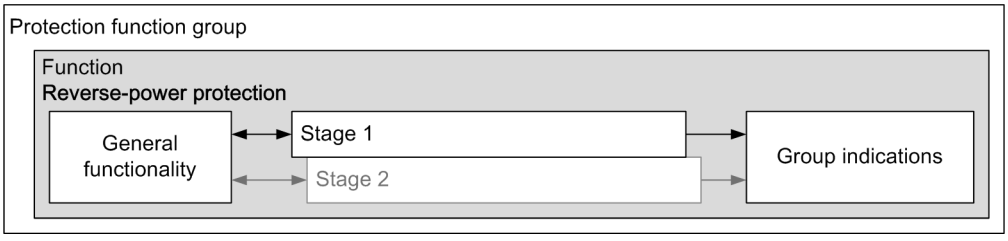
6.36 Reverse Power Protection

6.36.1 Overview of Functions

The **Reverse-power protection** function (ANSI 32R):



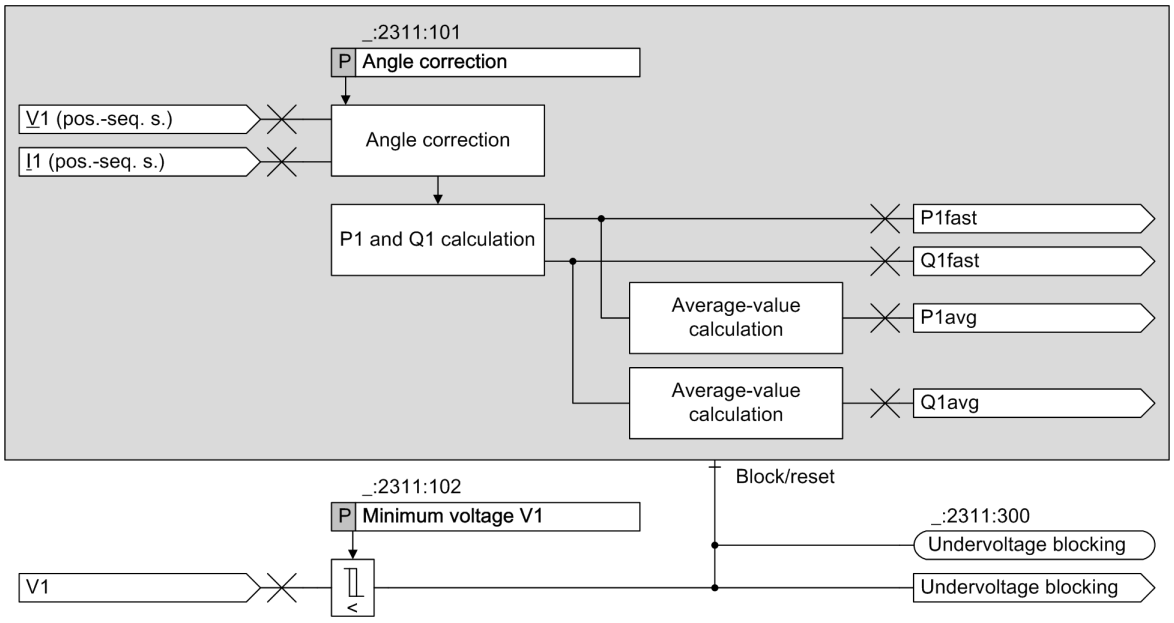
- Monitors the motor operation of generators and thus detects driving-power failure
- Prevents endangering the turbine (e.g. the turbine-blade damage due to overheating) by opening the circuit breaker of the system
- Protects a turbo-generator set

For the generator, there is a danger that the turbo-generator set accelerates and reaches overspeed in case of an incorrect residual-steam passage (quick-stop valves defective) after the circuit breaker has opened. Consequently, disconnecting the system (opening the circuit breaker of the system) shall only occur after reverse power (active-power consumption) has been detected.

6.36.2 Structure of the Function

The **Reverse-power protection** function comes factory-set with 1 stage. A maximum of 2 stages can be operated simultaneously within the function.

In all function groups, the function works with a 3-phase voltage and current interface.



[dwstruct-160410-01.tif, 2, en_US]

Figure 6-215 Structure/Embedding of the Function

6.36.3 General Functionality

6.36.3.1 Description

Logic of the Function

[lo_RPP_01, 1, en_US]

Figure 6-216 Logic Diagram of the Cross-Stage Functionality

Calculating the Reverse Power

The reverse-power protection calculates the active power from the symmetrical components of the fundamental components of the voltages and currents. It generates the average value of the active power over a fixed number of cycles. Since positive-sequence variables are used for evaluation, the reverse power is determined independently of unbalance in currents or voltages. The frequency-tracking sampled values are used for calculation. The determined reverse power corresponds to the load on the driving-power side. The calculated active-power value corresponds to the total active power.

Taking the phase-displacement angle of the voltage and current transformers into account, the function calculates the exact active power even with a high apparent power and a small cos φ. A constant correction angle φ_{corr} makes correction possible. The influence of the current-transformer angle error is predominant here.

Determine this constant correction angle when you commission the protection device in the plant and adjust it as specified in the table (see *Table 11-1*).

Power Calculation and Angle Correction

To satisfy the high measuring-accuracy requirements, the power measured value is additionally averaged over 16 cycles before it is supplied to the protection function. The active power is calculated from the symmetrical-component vectors of voltage V1 and current I1. The total power is evaluated as power. The complex apparent power results from the following relationship. The real component is the active power:

$\underline{S} = 3\underline{V}_1 \cdot \underline{I}_1^{\,*} = 3V_1 e^{j\varphi V} \cdot I_1 e^{-j\varphi I} = 3V_1 I_1 e^{j(\varphi V - \varphi I)}$

$P = 3V_1 I_1 \cos(\varphi_V - \varphi_I)$

The angle error between voltage transformer and current transformer has a strong influence on the measuring accuracy. With the parameter **(_:2311:101) Angle correction** , you can correct the angle error. The following 2 methods are possible here:

- Determine the angle error from the transformer test report data. Ask the transformer manufacturer for these values when you order the transformer.
- While the generator is connected to the power system, measure to determine the angle error (see chapter *11.14.2 Primary Test*).

The influence on the power-system voltage makes it very difficult to test high-power generators with a measurement while the generator is connected to the power system. In this case, you must determine the angle error from the transformer test report data (see chapter *6.36.3.2 Application and Setting Notes*). Alternatively, you can use instrument transformers with small angle errors. This is ensured with class 0.2 instrument transformers (voltage and current). The following equation describes the influence of the angle error:

$P = 3V_1\ I_1 \cos(\varphi_V + \varphi_{V,F} - (\varphi_I + \varphi_{I,F})) = 3V_1\ I_1 \cos(\varphi_U - \varphi_I + (\varphi_{V,F} - \varphi_{I,F}))$

The angle error to be corrected results as:

$\varphi_{Corr} = \varphi_{V,F} - \varphi_{I,F}$

To rotate in the correct direction, the correction angle is considered with inverted sign inside the unit.

Functional Measured Values

You can use the following functional measured values to check the behavior of the protection function and to support commissioning. The total power is represented as the measured value.

Measured Value	Description	
P1fast	Positive-sequence system active power calculated per cycle	Angle correction influences the measured value
Q1fast	Positive-sequence system reactive power calculated per cycle	Angle correction influences the measured value
P1avg	Positive-sequence system active power calculated from **P1fast** over 16 cycles	Input value for Reverse-power protection
Q1avg	Positive-sequence system reactive power calculated from **Q1fast** over 16 cycles	–

6.36.3.2 Application and Setting Notes

In the general functionality, you can adjust the parameter **(_:2311:101) Angle correction** . The parameter results from the angle error of the primary transformer. In SIPROTEC 5, the input transformers are calibrated so that the angle error is negligible. You can assume an error of < 0.1°. There is no difference between a protection input and an instrument-transformer input.

NOTE

If you use class 0.2 instrument transformers on the primary side to avoid the influence of the angle, you can connect a protection device with a protection current transformer without any problems.

Class 0.2 voltage transformers have a maximum admissible angle error of 10 min (0.17°). The angle error of a class 0.2 measuring current transformer at rated current is approximately 10 min, at 0.2 I_{rated} = 15 min, and at 0.05 I_{rated} = 30 min.

Parameter: Angle correction

- Default setting **(_:2311:101) Angle correction** = 0°

To determine the correction angle via measurement with the primary system, follow the instructions in chapter *11.14.2 Primary Test* .

You can use the method that is explained in the following section to derive the necessary correction angle from the transformer measuring reports.

Example

This example uses a class 0.2 voltage transformer with a rated burden of 45 VA. The following data was taken from the measuring report.

Table 6-17 For Phase A

V/Vn	$S_b = S_{br}$		$S_b = S_{br}/4$	
	ε_v [%]	δ_v [min]	ε_v [%]	δ_v [min]
0.8	-0.14	0.31	0.16	-0.34
1	-0.15	0.43	0.15	-0.24
1.2	-0.16	0.68	0.14	-0.06

The values resulting for the phases B and C are almost identical.

Furthermore, a termination with a rated burden (other measuring devices are still connected) is assumed so that an angle error of +0.43 min (rated-voltage value) is used as the calculation variable.

A current transformer of type 5PR is used here. This current transformer features a gap that limits the remanence to 10 %. However, this gap results in larger angle errors. The following tables show excerpts from the test reports.

Table 6-18 Phase A

I/I_n [%]	$Sb = S_{br}$ (cos β = 0.8)	
	ε_i [%]	δ_i [min]
100	0.314	46.40

Table 6-19 Phase B

I/I_n [%]	$Sb = S_{br}$ (cos β = 0.8)	
	ε_i [%]	δ_i [min]
100	0.247	35.10

Table 6-20 Phase C

I/I_n [%]	$Sb = S_{br}$ (cos β = 0.8)	
	ε_i [%]	δ_i [min]
100	0.702	41.10

Since the positive-sequence system power is evaluated in the device, take the sign into account when you add the angle errors per phase, and divide the result by 3.

The following value results in this example:

$$\delta_i[\text{min}] = \frac{1}{3}\left(\delta_{i,A} + \delta_{i,B} + \delta_{i,C}\right) = \frac{1}{3}(46.40 + 35.10 + 41.10) = 40.87 \text{ min}$$

The resulting correction angle is:

$$\varphi_{corr}[\text{min}] = \varphi_{V,F} - \varphi_{I,F} = 0.43 \text{ min} - 40.87 \text{ min} = -40.44 \text{ min}$$

$$\varphi_{corr}[^\circ] = \frac{\varphi_{corr[\text{min}]}}{60} \cdot 1^\circ = \frac{-40.44}{60} \cdot 1^\circ = -0.674^\circ$$

Set the parameter **(_:2311:101) Angle correction = *-0.67*°**.

Parameter: `Minimum voltage V1`

- Default setting **`(_:2311:102) Minimum voltage V1`** = 5.000 V

With the parameter **`Minimum voltage V1`** , you can limit the operating range of the reverse-power protection. If the positive-sequence voltage falls below the set value, the reverse-power protection is deactivated. If no other restrictions are known, Siemens recommends using the default setting.

6.36.4 Stage Description

6.36.4.1 Description

Logic of the Stage

[lo_RPP_02, 1, en_US]

Figure 6-217 Logic Diagram of the Reverse-Power Protection Stage

Trip Command

To bridge brief power consumption during synchronization or during power swings caused by system incidents, tripping (shutdown of the generator via reverse power) is delayed by a settable time (for example, 10 s).

A brief delay is enough when the quick-stop valve is closed. Couple the position of the quick-stop valve via the binary input signal **>Stop valve closed** . When quick stop is tripped, the short Operate delay thus becomes effective.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. Blocking of the stage is possible externally or internally via the binary input signal **>Block stage** .

6.36.4.2 Application and Setting Notes

If reverse power occurs in a power plant, the turbo-generator set must be disconnected from the electrical power system. Operating the turbine without the minimum steam flow (cooling effect) is dangerous. For a gas turbine cogeneration unit, the motor load can also be too great for the electrical power system.

Parameter: `Threshold`

- Recommended setting value **`(_:991:3) Threshold`** = ***`-1.00 %`***

The friction losses that have to be overcome mainly determine the active power consumed by a turbo-generator set. Depending on the plant, the consumed active power is of the following ranges:

Steam turbines	$P_{reverse}/S_{rated}$ = 1.00 % to 3.00 %
Diesel drives	$P_{reverse}/S_{rated}$ > 5.00 %
Gas turbines	$P_{reverse}/S_{rated}$ = up to 30.00 %

You can measure the reverse power of the turbo-generator set yourself in a primary test by using the protection function. Set the setting value **`P`** $_{reverse}$, for example, to 0.5 times the value of the measured reverse power. This power is shown additionally in the functional measured values in the **Reverse-power protection** function (**`P1avg`**). For large machines with very small reverse power, you must use the angle-error correction option of the current and voltage transformers.

NOTE

In the current-input selection, you can select protection current transformers or instrument transformers on the device side. Since the transformers are calibrated at the factory, there are hardly any differences between the transformers for the **Reverse-power protection** function. You can thus always select device inputs with a protection current transformer.

In contrast, a primary current transformer significantly influences the measuring accuracy via its angle error. The angle error of a class 0.2 instrument transformer is significantly smaller than the angle error of a class 5P protection current transformer. A separate function group is necessary for the connection to an instrument transformer. Use a **Voltage/current 3-phase** function group and load the **Reverse-power protection** function from the library.

Do not connect the **Reverse-power protection** function to a linear core-type transformer (for example, a TPZ type), as these transformers have a large angle error (for example, approx. 180 min).

6.36.4.3 Parameter

6.37 Overexcitation Protection

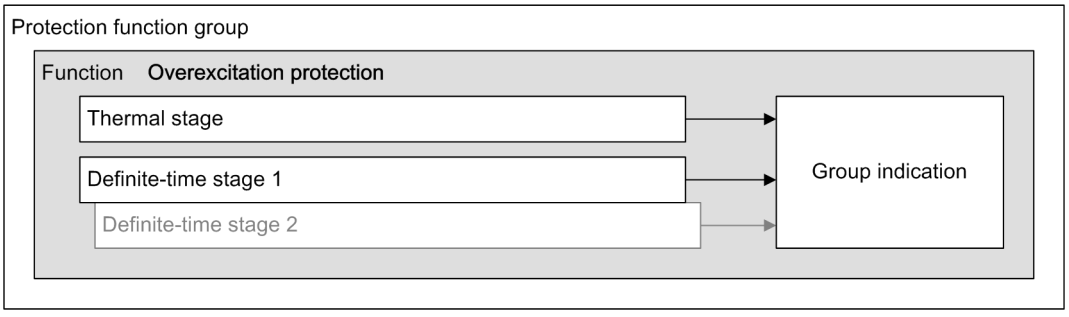
6.37.1 Overview of Functions

The **Overexcitation protection** (ANSI 24) is used for detecting high induction values in generators and transformers. It protects the equipment from excessive thermal loads.

The induction is recorded indirectly by analyzing the V/f ratio (also referred to as Volt per Hertz protection). Overvoltage leads to excessive magnetizing currents, while underfrequency leads to higher losses when resetting the magnetization.

If the power system is disconnected and the voltage and frequency control function in the remaining system does not react quickly or the power imbalance is excessive, there is a risk of overexcitation.

6.37.2 Structure of the Function



The **Overexcitation protection** function is used within protection function groups that have a 3-phase voltage input. The function comes with the following factory-set stages:

- Thermal stage adjustable with a user-defined characteristic curve
- Definite-time stage which can be delayed using a time component

Within this function, the following maximum number of stages can be operated simultaneously: one stage with a user-defined characteristic curve and 2 definite-time stages.

The group-indication output logic (see following figure) uses the logical OR function from the stage-selective indications to generate the following group indications of the entire **Overexcitation protection** function:

- Pickup
- Operate Indication

6.37.3 Stage with Dependent Characteristic Curve (Thermal Stage)

6.37.3.1 Function Description

Logic

[lothchuf-080513-01.tif, 1, en_US]

Figure 6-219 Logic of the Overexcitation Protection with Thermal Characteristic Curve

(1) Heating
(2) Cooling

V/f Method of Measurement

The input values of the protection function are the continuously measured voltage and the frequency. The phase-to-phase voltage is used to process the voltage. The angle difference method (see *6.32 Overfrequency Protection*) is used to determine the frequency. Both values form the V/f ratio. In order to arrive at an absolute value, standardized data is applied.

Thus, the ratio is derived from:

$$\frac{V/V_{rated,obj.}}{f/f_{rated}}$$

[foverufn-080523-01.tif, 1, en_US]

with

V	Measured voltage (maximum phase-to-phase voltage)
$V_{rated, obj.}$	Adjusted rated voltage of the protected object
f	Measured frequency
f_{rated}	Adjusted rated frequency

Based on the definition above, the protection function refers exclusively to primary values of the protected object. A deviation between the primary rated voltage of the voltage transformer and the protected object is corrected automatically.

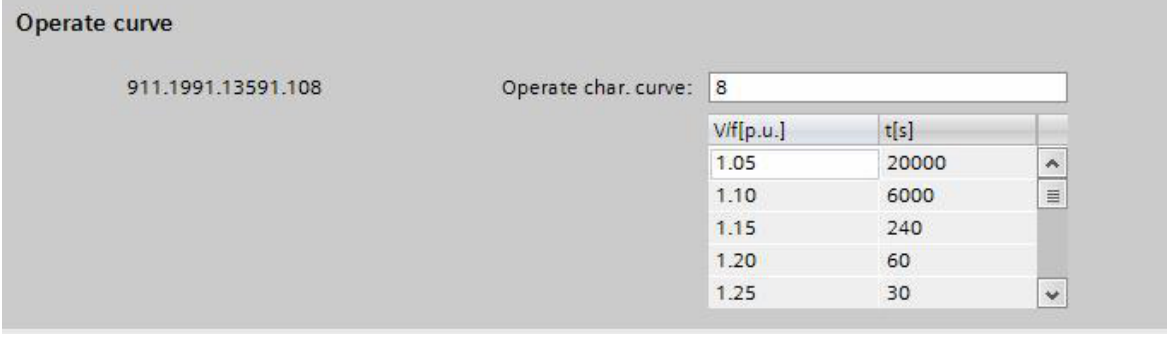
NOTE

This fact must be considered during a secondary test.

More information can be found in chapter *11.16 Functional Test for Overexcitation Protection* .

The function compares the calculated value of the measured V/f ratio with the threshold value and the user-defined thermal characteristic curve.

Depending on the characteristic curve, a **thermal** trip signal is triggered after a pre-determined duration.



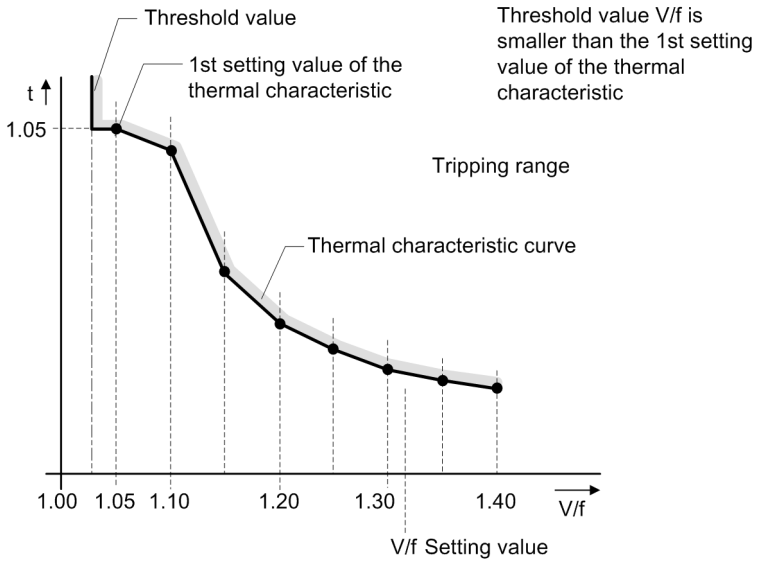
Characteristic Curve

You can freely configure the thermal characteristic curve with the user-defined values. This provides a flexible adjustment to the specified characteristics of the protected object. If the set threshold value (parameter **(_:13591:3) Threshold**) is exceeded, the evaluation of the characteristic curve is initiated. Exceeding the threshold value triggers an indication (*(_:13591:55) Pickup*). In addition, a definite-time stage may be used to generate a delayed indication output as (*(_:13591:301) warning*).

The pickup is used to start the integration process (weighted counting) of the thermal characteristic curve. If the time as a factor of V/f is reached, the pickup is triggered. Based on the replica of the thermal behavior, the trigger value is always 100 % (see *Thermal Behavior, Page 776*).

If the value drops below the pickup threshold, the trip command is rescinded and the **internal counter** of the parameterized cooling time (parameter **(_:13591:102) Cooling time therm.replica**) is reduced. The dropout threshold of the pickup threshold is fixed to 0.98 * **Threshold**.

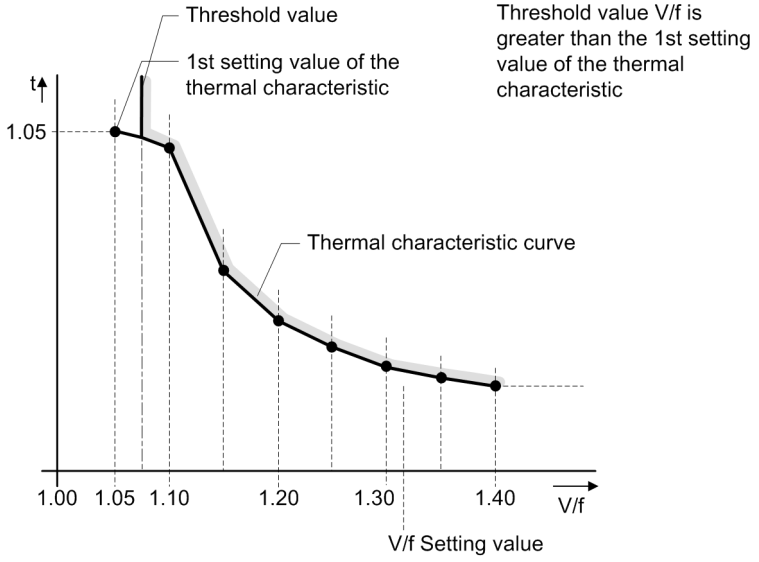
A maximum of 30 overexcitation value pairs V/f (referring to the rated values) and operate time t can be set. The default characteristic curve refers to a standard transformer.



[scaulskn-200214-01, 1, en_US]

Figure 6-220 Data Sheet for Adjustment of Thermal Characteristic Curve

The parameter **Threshold** (pickup threshold) affects the evaluation of the characteristic curve as follows:



If the **Threshold** is smaller than the first characteristic pair, the set time will be extended (see *Figure 6-221*).

[dwovexak-210313-01.tif, 1, en_US]

Figure 6-221 Tripping Zone of the Thermal Characteristic Curve (I)

If the **Threshold** is greater, then a cutoff occurs (see *Figure 6-222*).

[dwovexab-210313-01.tif, 1, en_US]

Figure 6-222 Tripping Zone of the Thermal Characteristic Curve (II)

Warning Threshold

If the **Threshold** is exceeded, the time delay (parameter **(_:13591:101) Warning delay**) is started. If the time delay has elapsed, the indication (*(_:13591:301) Warning*) will be displayed.

Thermal Behavior

The time derived from the characteristic curve and associated with the V/f value is set to 100 %. With each function call, the time will be increased according to the respective weighted invocation interval. If the 100 % value is exceeded, tripping is initiated. If the V/f value is changed, the associated time from the characteristic curve is added as a new 100 % value.

In order to prevent excessive cooling times, the thermal storage has been limited internally to 150 %. The *fill level* of the thermal storage will be provided as functional measured value.

Measured Value	Description
(_:13591:321) V/f th.	Thermal tripping of the overexcitation protection. If the value reaches 100 %, the tripping occurs.

Cooling Time

If the value drops below the threshold (**(_:13591:3) Threshold**), tripping of the thermal characteristic curve (dependent characteristic curve) is reverted. However, the parameterized cooling time (**Cooling time therm.replica**) reduces the thermal storage (counter content) to 0. This parameter is defined as time. It is required by the thermal replica in order to cool down from 100 % to 0 %.

Resetting the Thermal Map

The binary input indication *(_:13591:501) >Reset thermal replica* can be applied to reset the thermal replica. The thermal replica will then have a value of 0. A reparameterization will also lead to resetting the thermal replica.

Blocking the Stage

The function can be blocked externally or internally by the binary input signal *(_:13591:81) >Block stage*. Blocking will cause a picked up function to be reset.

6.37.3.2 Application and Setting Notes

Thermal overloads extended over a longer period will jeopardize electric equipment, for example, synchronous motors, generators, or transformers and may cause damage. When using the thermal, user-defined characteristic curve, the overexcitation protection lends itself perfectly for adjustment to the specified limits of the protection equipment.

The following provides the recommended settings:

NOTE

It must be noted that one requirement for the correct mode of operation of the function is based on the proper setting of the power-system data.

You can find more detailed information on this in chapter *6.1 Power-System Data* .

For additional setting recommendations, verity the following parameter in the power-system data:

- Adjusted rated frequency
- Adjusted rated voltage of the protected object
- Adjusted rated voltage of the voltage transformer of the applicable measuring point

Parameter: Threshold Value

- Default setting **(_:13591:3) Threshold** = *1.10*

  The **Threshold** parameter is used to describe the value for the permissible continuous overexcitation. The default value is a practical value used for transformers. The value may be less for generator applications. These values can be found in the manufacturer's information.

Parameter: Time Delayed Warning

- Default setting **(_:13591:101) Warning delay** = *10.00 s*

  When using the **Warning delay** parameter, the time can be determined by which the warning indication of the stage should be delayed after the pickup. This time delay depends on the specific application. This time must clearly exceed the reaction time of the regulators. 10 seconds is a feasible value.

Parameter: Cooling Time Therm. Replica

- Default setting **(_:13591:102) Cooling time therm.replica** = *3600 s*

The **Cooling time therm.replica** parameter is used to define the cooling characteristics of the thermal replica. If concrete specifications are not given, the default value can be maintained.

Parameter: V/f/time value pairs (operate curve)

With this parameter, the number of potting points along the thermal operate curve are defined. This is required for the calculation. The number of points defines the accuracy of the image of the specified characteristic curve. Adjust the value individually.

Set a V/f/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize. The default settings refer to a Siemens standard transformer.

NOTE

The value pairs must be entered in continuous order.

NOTE

Note that the V/f values that are lower than the V/f values of the smallest characteristic-curve point do not extend the operate time. Up to the smallest characteristic-curve point, the characteristic curves runs parallel to the V/f axis. V/f values that are larger than the V/f value of the largest characteristic-curve point do not reduce the operate time. From the largest characteristic-curve point, the pickup characteristic runs parallel to the V/f axis (see *Characteristic Curve, Page 775*).

6.37.4 Stage with Independent Characteristic Curve

6.37.4.1 Function Description

Logic

[lodtchuf-080513-01.tif, 1, en_US]

Figure 6-223 Logic of the Overexcitation Protection with Inpendent Characteristic Curve (Definite-Time Stage)

Method of Measurement

This stage evaluates also the V/f value that is identical to the input value of the thermal stage.

Measurement-relevant details can be found in chapter *6.37.3 Stage with Dependent Characteristic Curve (Thermal Stage)* .

How the Definite-Time Stage Works

The stage comprises a threshold and a time-delay stage. If the V/f value is greater than the set threshold value (**(_:13621:3) Threshold**), then the stage is tripped after an adjustable time delay has elapsed. You can set the time delay with the parameter **(_:13621:6) Operate delay**.

The dropout ratio for the **Threshold** is fixed to 98 %.

6.37.4.2 Application and Setting Notes

The definite-time stage can be applied when fast tripping is required in the presence of high V/f values. In this case, the stage acts superimposed on the thermal, dependent stage.

Parameter: Threshold Value

- Default setting **(_:13621:3) Threshold** = ***1.40***

  The **Threshold** parameter is used to describe the overexcitation value that causes the tripping function. The default value matches a feasible upper limit.

Parameter: `Tripping delay`

- Default setting **`(_:13621:6) Operate delay`** = ***`1.00 s`***

  The **`Operate delay`** parameter is used to determine the time by which the stage is delayed after the pickup. This time delay depends on the specific application. The default value is practical for the application described in the previous chapter.

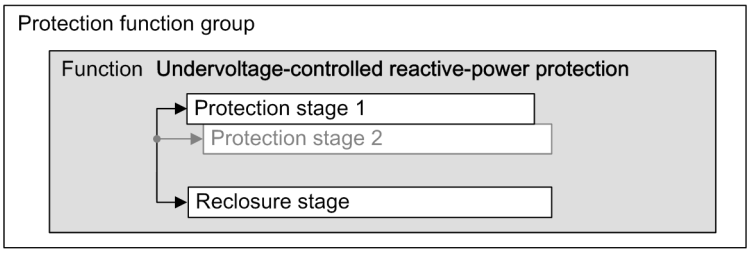
6.38 Undervoltage-Controlled Reactive-Power Protection



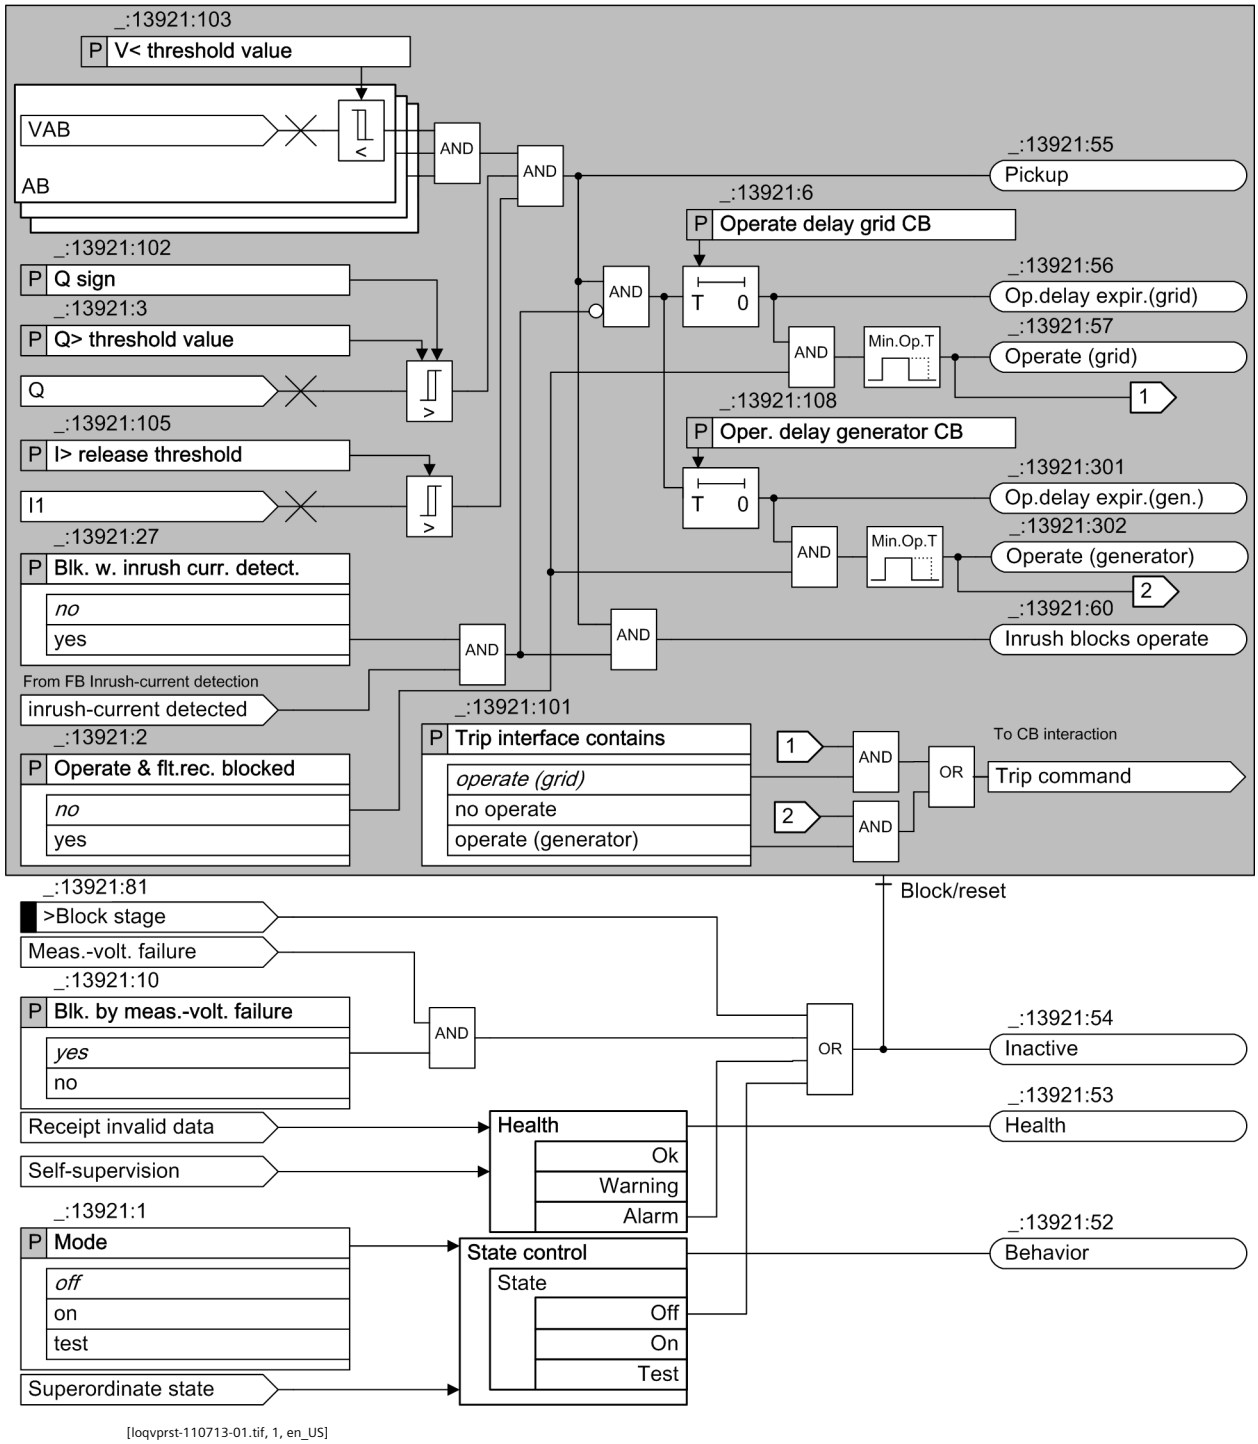
6.38.1 Overview of Functions

The **Undervoltage-controlled reactive-power protection** function (ANSI 27/Q):

- Detects critical power-system situations, mainly in case of regenerative generation
- Prevents a voltage collapse in power system by disconnecting the power-generation facility from the main power systems
- Ensures reconnection under stable power-system conditions

6.38.2 Structure of the Function

The **Undervoltage-controlled reactive-power protection** function can be used in protection function groups containing 3-phase voltage and current measurement. Depending on the device, it is preconfigured by the manufacturer with 1 **Protection stage** and 1 **Reclosure stage**. A maximum of 2 **Protection stages** and 1 **Reclosure stage** can operate simultaneously within the function.



[dwqvprot-110713-01.tif, 1, en_US]

Figure 6-224 Structure/Embedding of the Function

6.38.3 Description Protection Stage

6.38.3.1 Description

Logic of the Stage

[loqvprst-110713-01.tif, 1, en_US]

Figure 6-225 Logic Diagram of the Protection Stage of the Undervoltage-Controlled Reactive-Power Protection

Measurand

To detect critical power-system situations, the **Undervoltage-controlled reactive-power protection** function uses the fundamental values of the phase-to-phase voltages, the positive-sequence current, and the reactive power.

Q-Measurement Direction

The default directions of the positive reactive-power flow Q and the forward direction of the short-circuit protection are identical, in the direction of the protected object. Via parameter **`Q sign`**, the direction of the positive reactive-power flow Q can be changed by inverting the sign of the reactive power Q.

Pickup

The protection stage picks up under the following conditions:

- All 3 phase-to-phase voltages are below the parameterized threshold value.
- The positive-sequence current I_1 is above the parameterized threshold value.
- The power-generation facility requires more than the parameterized reactive power (Q is above the parameterized threshold value).

Trip Interface

The stage provides 2 operate signals, the *`Operate (generator)`* and the *`Operate (grid)`*. Depending on the parameter **`Trip interface contains`**, one or none of them will be forwarded to the trip interface of the circuit-breaker interaction.

Blocking of the Stage

The following blockings reset the picked up stage completely:

- Externally or internally via the binary input signal *`>Block stage`*
- Measuring-voltage failure
  For further information, refer to chapter *6.7.4.1 Description*.

Blocking of the Operate Delay and Operate Signal via the Device-Internal Inrush-Current Detection Function

The **`Blk. w. inrush curr. detect.`** parameter permits you to define whether the operate delay should be blocked by a threshod-value violation due to an inrush current.

For further information about device-internal **Inrush-current detection** function, refer to chapter *6.3.7.1 Description* .

6.38.3.2 Application and Setting Notes

Parameter: `Blk. by meas.-volt. failure`

- Recommended setting value **`(_:13921:10) Blk. by meas.-volt. failure`** = ***`yes`***

You use the **`Blk. by meas.-volt. failure`** parameter to control the response of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal **Measuring-voltage failure detection** function is configured and switched on.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
`yes`	The **Protection stage** is blocked when a measuring-voltage failure is detected. Siemens recommends using the default setting, as there is no assurance that the **Protection stage** will function correctly if the measuring voltage fails.

no	The **Protection stage** is not blocked when a measuring-voltage failure is detected.

Parameter: **Blk. w. inrush curr. detect.**

- Default setting **(_:13921:27) Blk. w. inrush curr. detect.** = ***no***

You use the **Blk. w. inrush curr. detect.** parameter to determine whether the operate delay and operate signal are blocked during the detection of an inrush current.

Parameter: **I> release threshold**

- Recommended setting value **(_:13921:105) I> release threshold** = ***0.100 A***

You use the **I> release threshold** parameter to define a precondition that the stage can pick up. The default setting is at 10 % of the rated current. Siemens recommends using the default setting.

Parameter: **V< threshold value**

- Recommended setting value **(_:13921:103) V< threshold value** = ***85.000 V***

You use the **V< threshold value** parameter to define one of the 2 pickup criteria. If all 3 phase-to-phase voltages drop below the parameterized undervoltage threshold value, the pickup criterion is fulfilled.

The setting should be set below the lower value of the permissible voltage range, according to the national transmission code. In Germany, the recommended undervoltage threshold is 85 % of the rated voltage. Therefore Siemens recommends using the default setting.

Parameter: **Q> threshold value**

- Default setting **(_:13921:3) Q> threshold value** = ***5 %***

You use the **Q> threshold value** parameter to define the second of the 2 pickup criteria. If the positive reactive power exceeds the parameterized **Q> threshold value**, the pickup criterion is fulfilled.

In the following example, the pickup takes place if Q exceeds 5 % of the power-supply system rated power.

EXAMPLE

The following example is given for settings in secondary values.

Rated voltage: $V_{rated,\ sec}$ = 100 V

Rated current: $I_{rated,\ sec}$ = 1 A

Threshold value: 5 % of the power-supply system rated power

You can calculate the setting value as follows:

$$Q>_{threshold} = 100\ V \cdot 1\ A \cdot \sqrt{3} \cdot 0.05 = 8.7\ VAr$$

[foqvprot-110713-01.tif, 1, en_US]

Parameter: **Operate delay**

- Default setting **(_:13921:6) Operate delay grid CB** = ***1.50 s***
- Default setting **(_:13921:108) Oper. delay generator CB** = ***0.50 s***

You can set the **Operate delay grid CB** for the circuit breaker at the power-supply system connection point, or set the **Oper. delay generator CB** for the circuit breaker of the facility, for example, the generator.

The time of the **Operate delay grid CB** should always be set longer than the time of the **Oper. delay generator CB**.

Parameter: `Trip interface contains`

- Default setting **`(_:13921:101) Trip interface contains`** = ***`operate (grid)`***

The stage provides 2 operate signals, the *`Operate (generator)`* and the *`Operate (grid)`*.
You use the **`Trip interface contains`** parameter to define whether one or none of them will be forwarded to the trip interface of the circuit-breaker interaction. The selected operate signal will trip the circuit breaker that has been connected to the protection function group.
The setting depends on the specific application.

Parameter: `Q sign`

- Default setting **`(_:13921:102) Q sign`** = ***`not reversed`***

The default directions of the positive reactive-power flow Q and the forward direction of the short-circuit protection are identical, in the direction of the main protected object (for example, a feeder). You use the **`Q sign`** parameter to reverse the sign and therefore the direction of the reactive-power flow Q. This reversal may be required for specific application, where the main protected object (for example, a line towards the main power systems) is in different direction to the power-generation facility.

Parameter Value	Description
`not reversed`	The protected object is in the same direction as the power-generation facility.
`reversed`	The protected object is not in the same direction as the power-generation facility.

6.38.4 Description Reclosure Stage

6.38.4.1 Description

Logic of the Stage

[loqvclst-110713-01.tif, 3, en_US]

Figure 6-226 Logic Diagram of Reclosure Stage in Undervoltage-Controlled Reactive-Power Protection

Measurand

The stage works with fundamental values of voltage and current.

Release for Reconnecting

The release for reconnecting the power-generation facility is given under the following conditions:

- All 3 phase-to-phase voltages are above the threshold value.
- The power frequency is within a specified range.
- The reclosure time delay, started by the operate of specific protection functions, has elapsed. The time delay is started by the first operate signal of the protection stages configured via the **Configuration** parameter. All protection stages of the voltage protection, the frequency protection, and the QV protection are available for configuration.

External Start of Reclosure Time Delay

Reclosure time delay can be started via the binary input signal *>V, f trip*, which can be connected to external voltage and frequency protection trip signals.

Blocking of the Stage

The stage can be blocked via the binary input signal *>Block stage*.

6.38.4.2 Application and Setting Notes

Parameter: Configuration

- Default setting **(_:13951:102) Configuration** = ***no stage***

You use the **Configuration** parameter to define which operate signal of specific protection functions starts the release time delay of the **Reclosure stage**:

- Overfrequency protection
- Underfrequency protection
- Overvoltage protection
- Undervoltage protection
- Protection stage of undervoltage-controlled reactive-power protection

When the protection stage of undervoltage-controlled reactive-power protection is selected, only the signal *Operate (generator)* can start the release time delay of this stage. The signal *Operate (grid)* cannot start the release time delay.
The configuration depends on the specific application.

Parameter: I> release threshold

- Recommended setting value **(_:13951:106) I> release threshold** = ***0.100 A***

You use the **I> release threshold** parameter to define a precondition that the stage can work.
The default setting is at 10 % of the rated current. Siemens recommends using the default setting.

Parameter: V> threshold value

- Recommended setting value **(_:13951:101) V> threshold value** = ***95.000 V***

You use the **V> threshold value** parameter to set one of the 2 release criteria. The setting should be set above the lower value of the allowed voltage range, according to the national transmission code. In Germany, the recommended overvoltage threshold is 95 % of the rated voltage. Therefore Siemens recommends using the default setting.

Parameter: Frequency range

- Recommended setting value **(_:13951:104) f difference positive** = ***0.05 Hz***
- Recommended setting value **(_:13951:105) f difference negative** = ***-2.50 Hz***

You use these 2 parameters to define the admitted frequency deviation from the rated frequency. **f difference positive** defines the upper frequency range limit. **f difference negative** defines the lower frequency range limit.

Siemens recommends using the default settings, which reflect common practice in Germany. Other national transmission codes may require a slightly different range.

Parameter: `Time delay`

- Default setting **`(_:13951:108) Time delay`** = ***`0.00 s`***

You use the **`Time delay`** parameter to specify the minimum time delay for releasing the reconnection of the power-generation facility after tripping by protection.

The setting depends on the specific application.

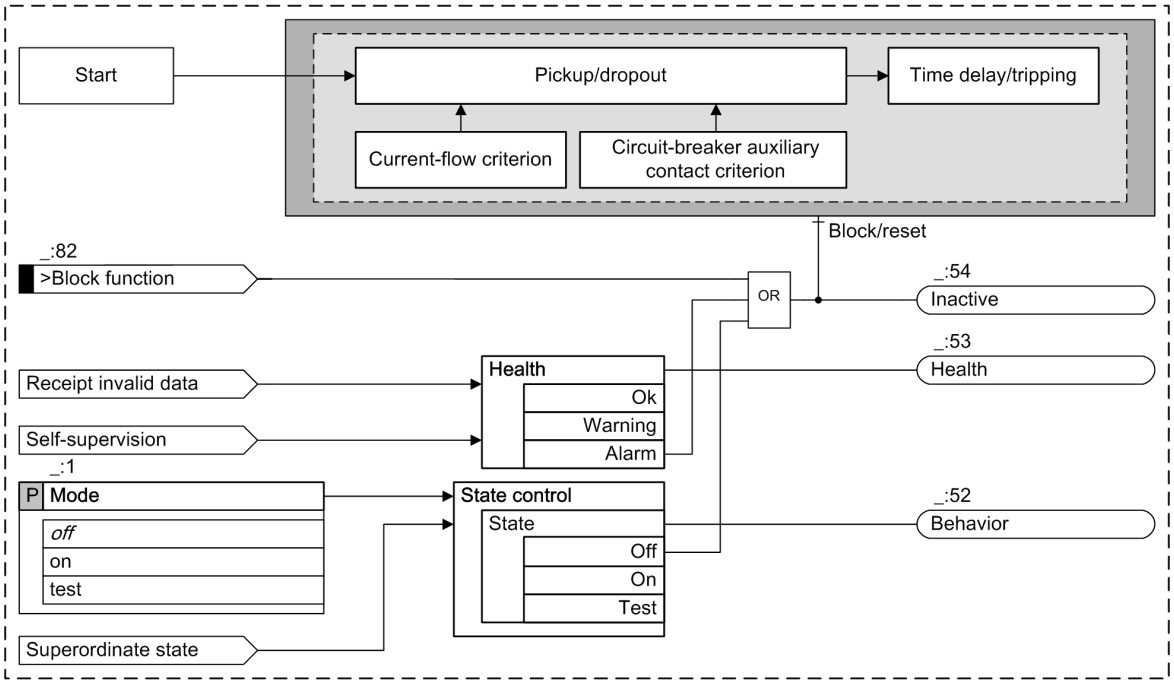
6.39 Circuit-Breaker Failure Protection

6.39.1 Overview of Functions

The **Circuit-breaker failure protection** function (ANSI 50BF) monitors the tripping of the associated circuit-breaker (CB) and generates a backup trip signal if the circuit-breaker fails.

6.39.2 Structure of the Function

The function **Circuit-breaker failure protection** (CBFP) can be used in the **Circuit-breaker** function group.



[dwstrbfp-260213-01.tif, 1, en_US]

Figure 6-227 Structure/Embedding of the Function

Figure 6-228 shows the functionalities and the function control of the function.

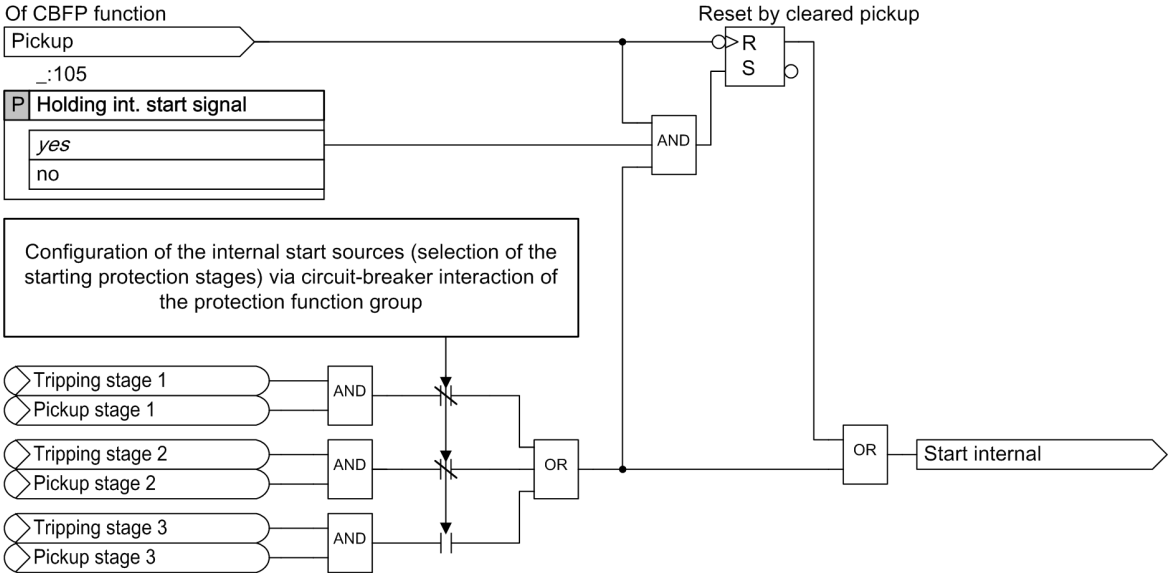
The start is initiated by the device-internal protection function or by an external protection. Along with the start, the current-flow criterion or the circuit-breaker auxiliary contact criterion is used to check whether the circuit breaker is closed. If the circuit breaker is closed, the function picks up and starts the time delay. During the time delay, the system checks continuously whether the circuit breaker has opened. If this is the case, the function drops out. If the circuit breaker is not opened, the function trips upon expiration of the time delay.

The following description elaborates on the detailed functionality of the individual function blocks.

[losvsbfp-090712-01.tif, 2, en_US]

Figure 6-228 Function Logic Overview

6.39.3 Function Description



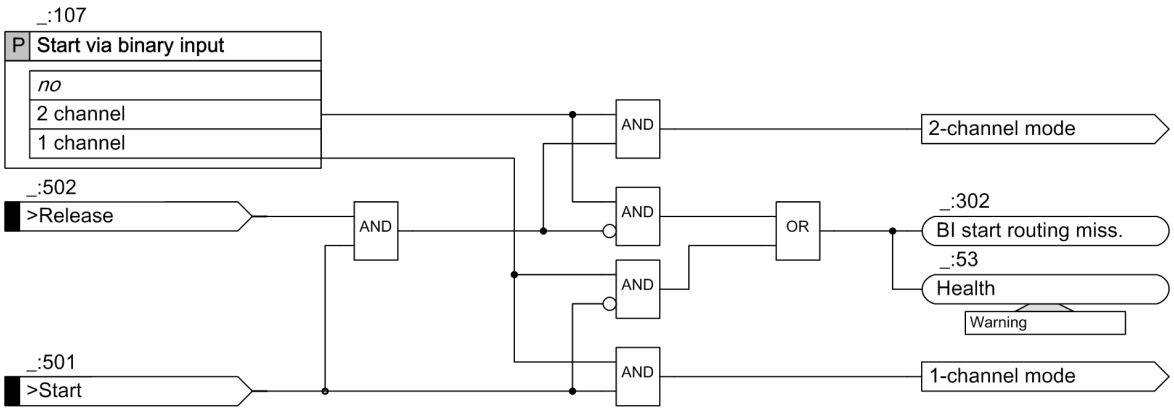
The Circuit-breaker failure protection function is started by device-internal protection functions and/or externally (via a binary input or an interface, such as GOOSE). *Figure 6-229* and *Figure 6-230* show the functionality.

Internal Start

By default, each device-internal protection stage, which has to control the local circuit breaker, starts the circuit-breaker failure protection. The function is started by the tripping of the protection stage. In the default setting, the starting signal **`Internal start`** (see *Figure 6-229*) is held when the pickup signal has a falling edge or the protection function has tripped. The Circuit-breaker failure protection function can in this case only dropout if the circuit breaker is detected to be open. This is detected using the current flow or circuit-breaker auxiliary contact criterion. If necessary, the Circuit-breaker failure protection function can also drop out when the pickup signal has a falling edge or the protection function trips (internal starting signal is not held).

Using routing, you can specify whether individual protection stages or protection functions are to be used as the starting source or whether starting happens only externally.

The internal starting sources are routed in the protection function groups via the **Circuit-breaker interaction** entry (for this, see *2.1 Function Embedding in the Device Figure 2-6*).



[loanwint-160611-01.tif, 1, en_US]

Figure 6-229 Internal Start of the Circuit-Breaker Failure Protection Function

External Start

The parameter **`Start via binary input`** is used to set whether the external start is initiated by a 1-channel or 2-channel signal. The required routing of the input signals is compared with the setting. If a routing is missing, an error message is generated. The Health signal changes to the state *`warning`*.

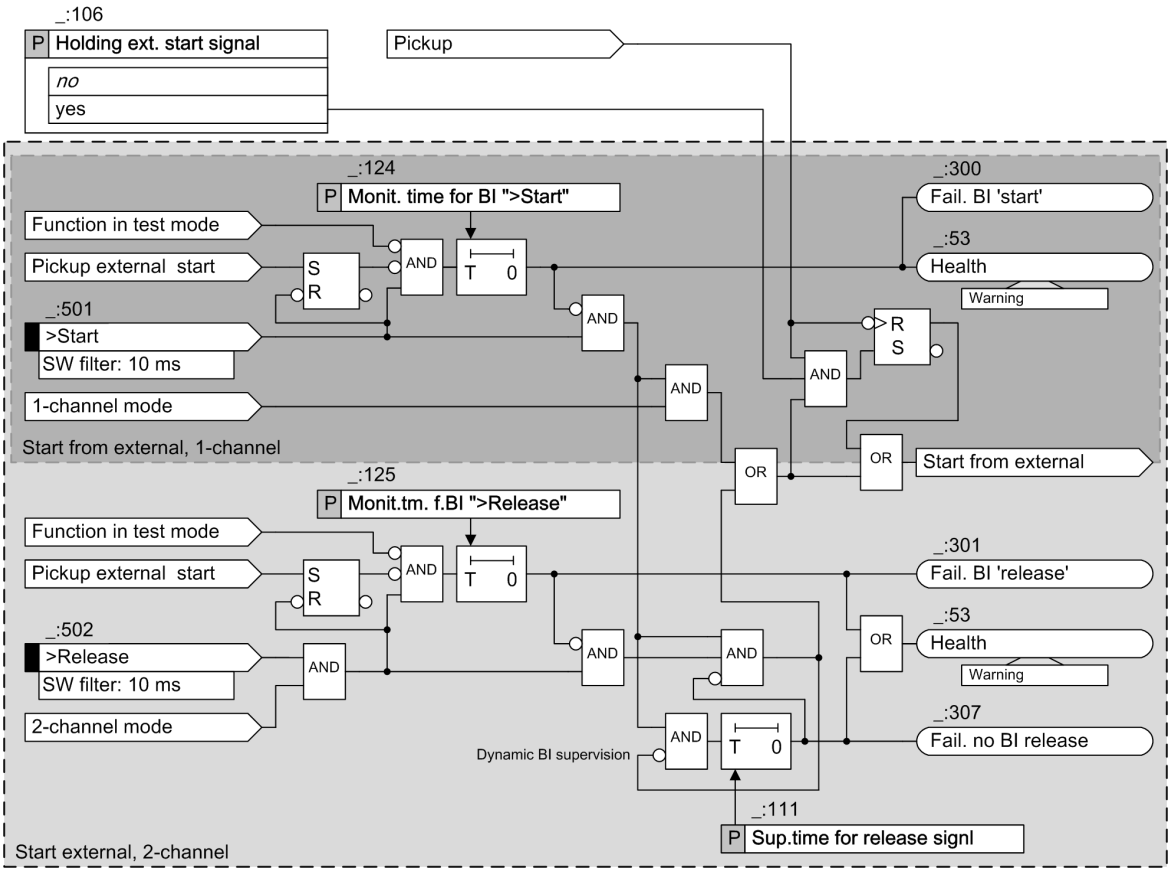
[loanwext-030211-01.tif, 1, en_US]

Figure 6-230 Configuration of the External Start of the Circuit-Breaker Failure Protection Function

In 1-channel operation, the start is initiated with the binary input signal **>Start** only.

In 2-channel operation, the binary input signal **>Release** must also be activated to initiate the start. In the default setting, the starting signal **External start** drops out immediately when the input signals have a falling edge (see *Figure 6-231*). If necessary, the starting signal can be held. In this case the start remains active when the binary input signals have a falling edge.

The input signals are monitored to avoid an unwanted pickup of the function.



If either of the signals **>Start** or **>Release** is active for more than the set time without the function picking up, an error in the binary input circuit is assumed. The corresponding signal is blocked to exclude an external pickup of the function. An indication to this effect is output, and the Health signal changes to the state *warning*. The blocking is reset as soon as the binary input signal drops out.

Supervision is disabled in the following cases:

- On pickup of the Circuit-breaker failure protection function (only in the case of an external start). This prevents an unwanted pickup of the supervision if the external protection that starts the Circuit-breaker failure protection function uses a lockout functionality. When the starting signal drops out, the supervision is active again.
- As long as the function or the device is in **test mode**. This allows to check the function without the supervision blocking the function.

If the **>Start** signal is active but no release signal is present after the settable supervision time expires, the pickup is blocked and an indication to this effect is output. The Health signal changes to the state Warning. The blocking is reset with the dropout of the starting signal.

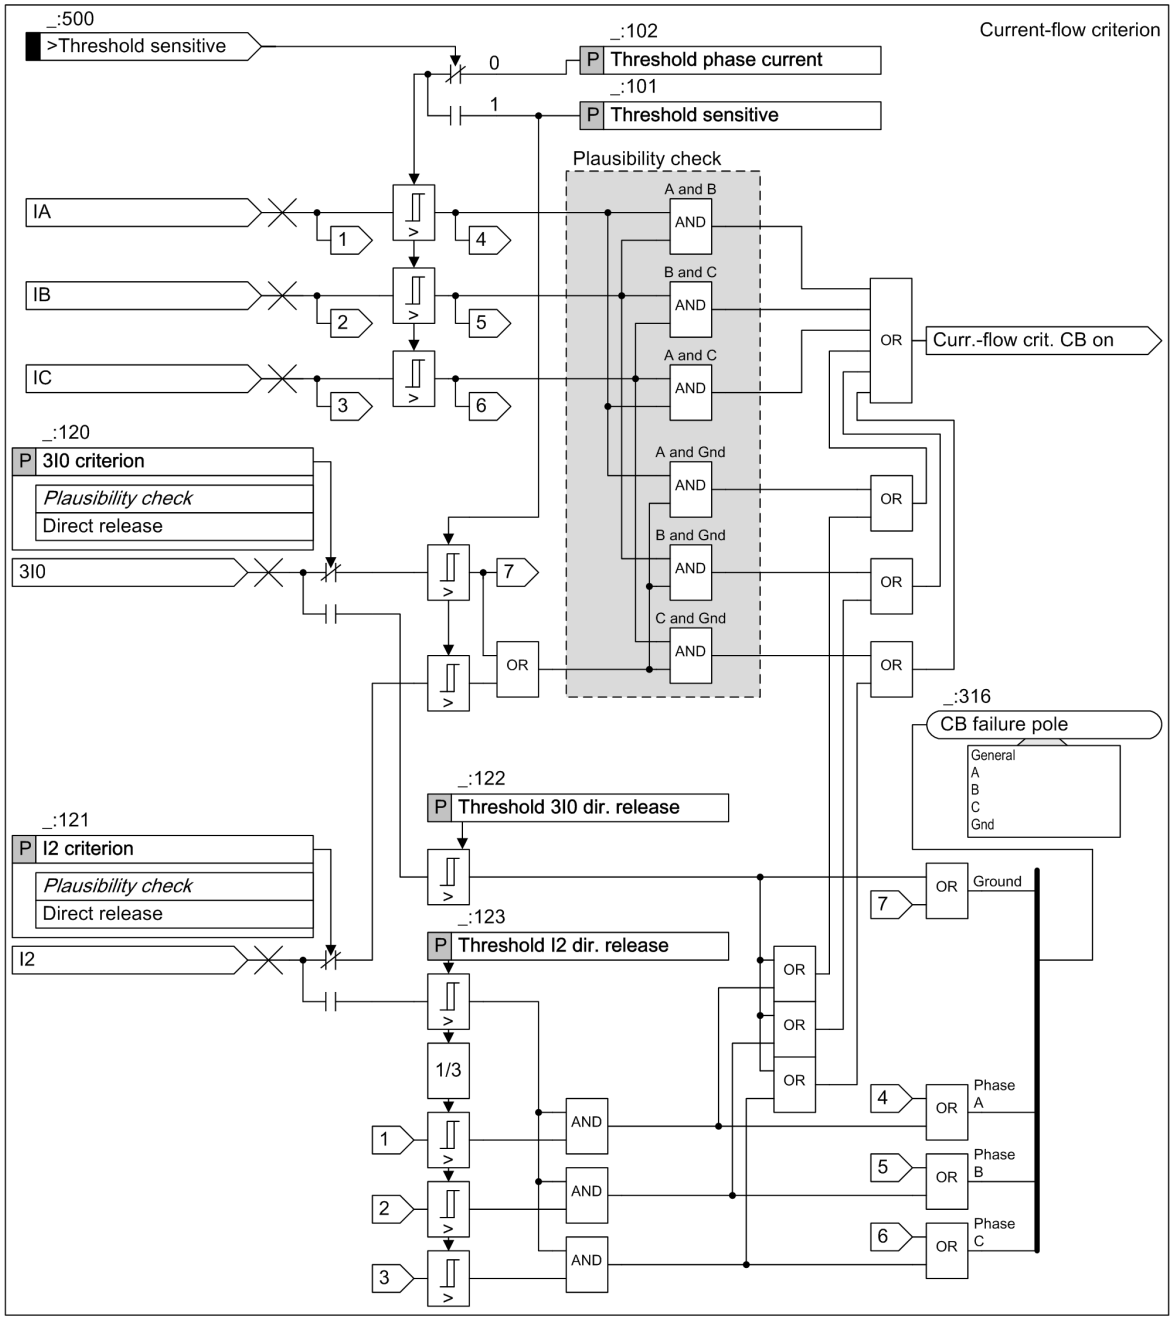
The binary input signals only take effect if the binary inputs are activated for at least 10 ms (SW filter, see *Figure 6-231*).

[logikext-070611-02.tif, 2, en_US]

Figure 6-231 External Start of the Circuit-Breaker Failure Protection Function, Logic

Current-Flow Criterion

The current-flow criterion is the primary criterion for determining the circuit-breaker position. A circuit-breaker pole is supposed to be closed, and the current-flow criterion fulfilled, as soon as one of the phase currents exceeds the phase-current threshold value, and at the same time a plausibility current exceeds the associated threshold value. The plausibility current can be either a 2nd phase current (to compare with the threshold value for phase currents) or the zero-sequence or negative-sequence current (to compare with the sensitive threshold value). The additional evaluation of the plausibility current increases the safety of the criterion.



In the case of ground faults, the sensitive threshold value can be dynamically applied to the phase currents as well. The current-flow criterion is fulfilled when the currents exceed the sensitive threshold value. The phase-current threshold value is then ineffective. The binary signal **>Threshold sensitive** is used for the switch-over.

If you set the **3I0 criterion** parameter to ***Direct release***, you prevent the plausibility check of the zero-sequence current. In this way, a pickup only by way of this current can be achieved. Using the **Threshold 3I0 dir. release** parameter, you set the threshold value to be exceeded.

If you set the **I2 criterion** parameter to ***Direct release***, you also switch off the plausibility check of the negative-sequence current. Using the **Threshold I2 dir. release** parameter, you set the threshold value to be exceeded.

If you set the **I2 criterion** parameter to ***Direct release***, a plausibility check is performed via the phase currents with 1/3 * **Threshold I2 dir. release**.

The measuring algorithm is optimized for fast dropout when the value drops below the threshold value.

[lostrom1-030211-01.tif, 3, en_US]

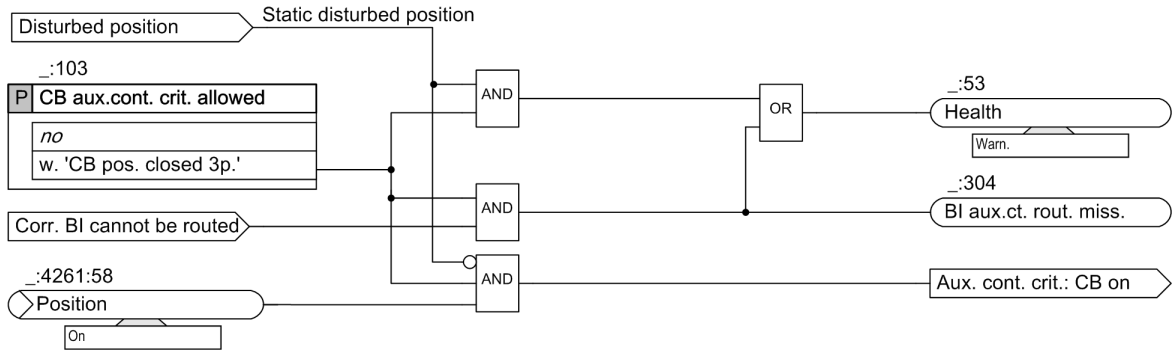


Figure 6-232 Current-Flow Criterion

Circuit-Breaker Auxiliary-Contact Criterion

Settings allow you to specify whether the circuit-breaker auxiliary contacts are permitted for determining the circuit-breaker position.

The double-point indication **`3-pole position`** (from the **Circuit-breaker** function block) is used to determine whether all 3 poles of the circuit breaker are closed. If the double-point indication is not routed, the output is an error message. Furthermore, the Health signal changes to the state *`warning`*.

The detection of a static disturbed position (not an intermediate position) has the effect that the circuit-breaker auxiliary-contact criterion is not used (the internal signal **`Aux.co.crit.: CB Clsd`** is disabled).

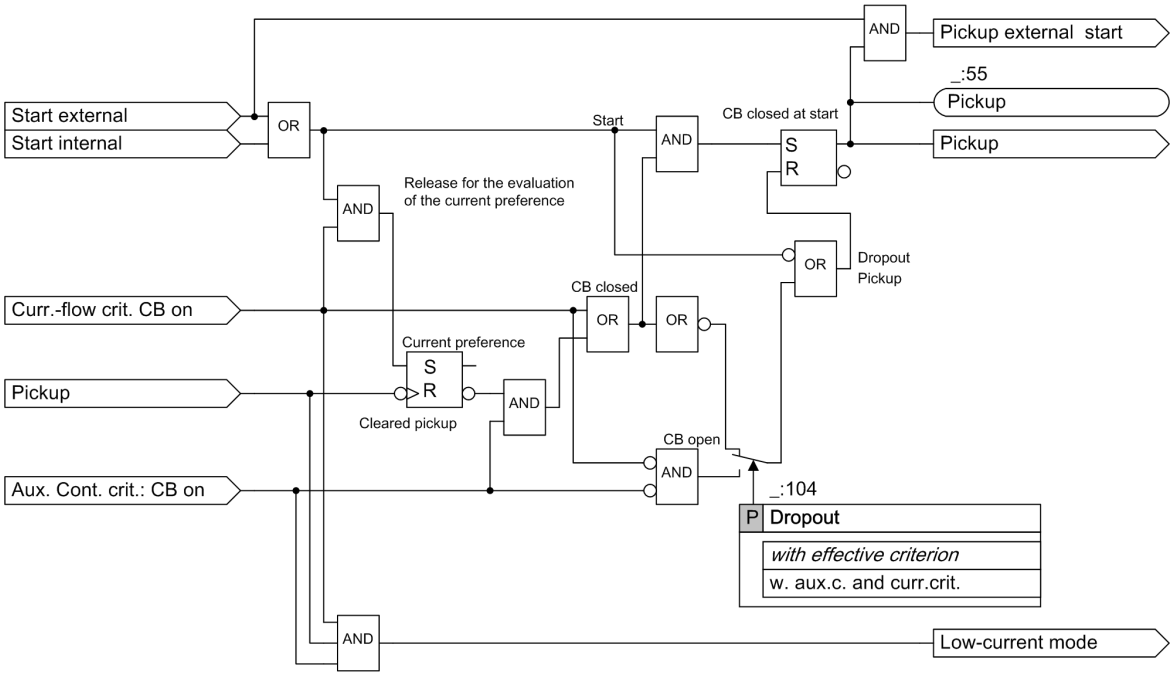
[lokriter-140611-01.tif, 1, en_US]

Figure 6-233 Circuit-Breaker Auxiliary-Contact Criterion

Pickup/Dropout

After the start, a check is performed whether the circuit breaker is closed. The current-flow criterion and the circuit-breaker auxiliary-contact criterion are available for this purpose.

Even if the circuit-breaker auxiliary-contact criterion is permitted, preference is given to the fulfilled current-flow criterion because the current-flow criterion is the most reliable criterion for detecting whether the circuit breaker is closed. This means that the circuit breaker is deemed to be closed if it is closed according to the current-flow criterion but at the same time open according to the circuit-breaker auxiliary-contact criterion.



If no current is flowing at the start time, the function can only pick up on the basis of the circuit-breaker auxiliary-contact criterion. For this purpose, the circuit-breaker auxiliary contacts must be permitted as criterion. When the current begins to flow after the start, the function switches over to the current-flow criterion.

If the circuit breaker is detected to be closed, the function picks up.

The pickup starts a time delay (see Delay/Tripping). While the delay is running, the system checks continuously whether the circuit breaker has opened. In the default setting, the opening of the circuit breaker is checked on the basis of the currently valid criterion, which is normally the current-flow criterion because it is preferred. If until expiration of the time delay, no current flow above the set threshold values has been detected, the circuit-breaker auxiliary-contact criterion becomes effective.

The function has also a setting in which dropout is only possible if both criteria in parallel detect the circuit breaker to be open (dropout with auxiliary contact and current-flow criterion).

In the default setting, the internal starting signal is held (see *Figure 6-229* and *Figure 6-231*). This means that dropout is controlled solely by the switch or the circuit-breaker auxiliary-contact criterion. If dropout is also to occur on the falling edge of the starting signal (that is, when the pickup signal has a falling edge or the protection function trips), holding of the start signal must be disabled.

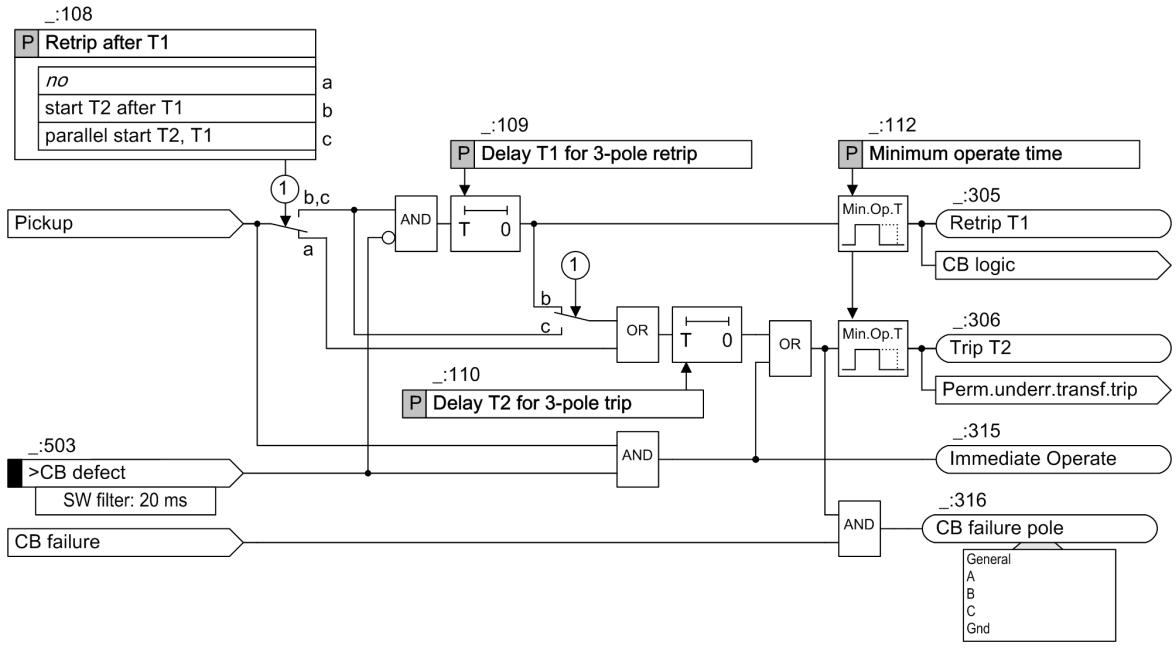
[loanreg1-030211-01.tif, 3, en_US]

Figure 6-234 Pickup/Dropout of the Circuit-Breaker Failure Protection Function

Delay/Tripping

In a first step, tripping at the local circuit breaker can be repeated. Tripping is repeated after expiration of the settable delay T1. If the local CB was not yet tripped, for example, in the event of an external start of the circuit-breaker failure protection, the trip logic of the circuit breaker itself is activated when the time delay T1 elapses.

Time delay T2 (backup tripping) can commence in parallel either with the start of time T1 or after expiration of time T1.



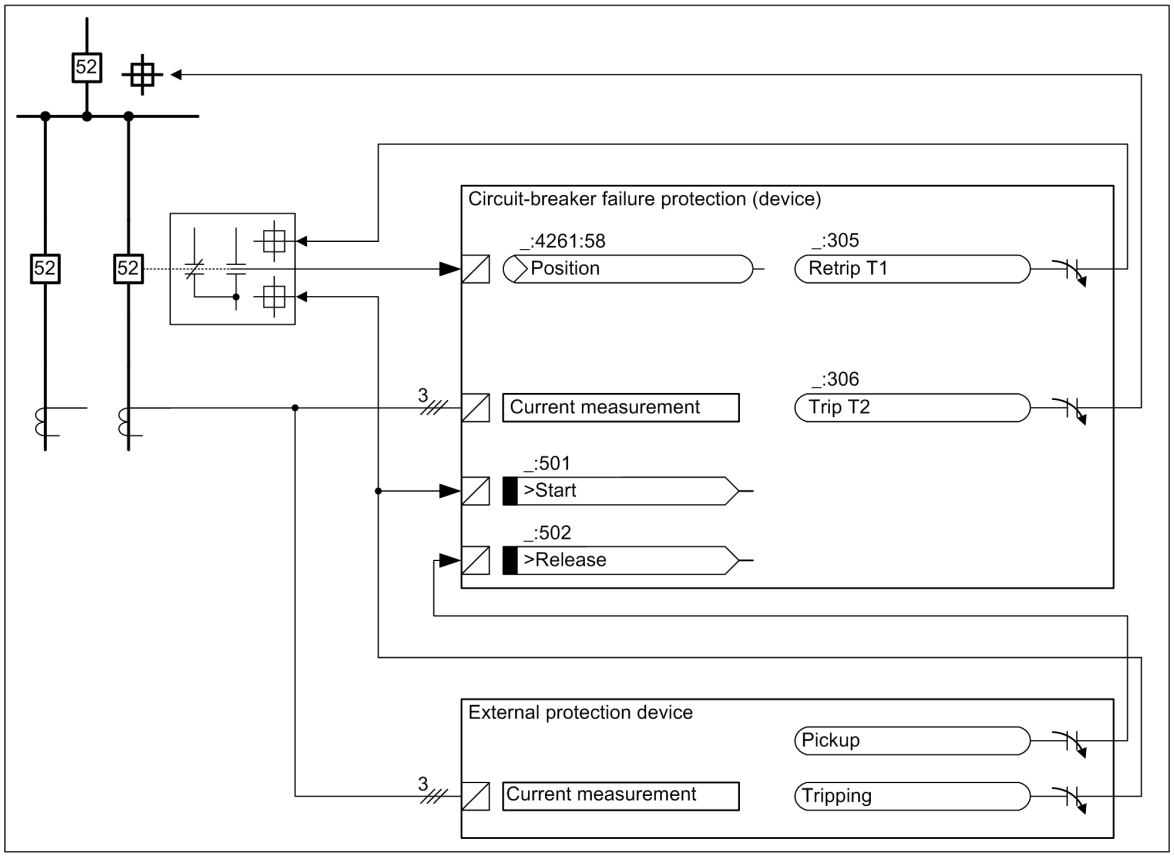
If time delay T2 expires without a dropout of the function, a circuit-breaker failure is assumed and the backup tripping signal **`Tripping T2`** is output. If there is a protection interface in the device, if needed a transfer-trip signal can be sent to the opposite end.

You can find detailed information in the chapter *3.5.3 Protection Interface and Protection Topology*.

If the **`>CB defect`** input signal is valid, any repetition of the trip signal is suppressed, and the backup tripping signal T2 is generated immediately (without delay). The binary input of the **`>CB defect`** input signal must be activated for at least 20 ms before the signal becomes valid.

With help of the *`CB failure pole`* indication, you can determine the phase currents that are above the threshold value at the tripping time T2.

The **`Minimum operate time`** parameter defines the minimum duration for tripping the function. In contrast to other protection functions, the parameter is set within its own function. As a result, the setting is independent of the identically named global parameter that is set in the **Device settings**.



[lo-bbp-verza-3ph.vsd, 4, en_US]

Figure 6-235 Delay/Tripping of the Circuit-Breaker Failure Protection Function

6.39.4 Application and Setting Notes

Figure 6-236 gives an overview of the functions involved in an external start of the CBFP function. In the case of an internal start, there is no external protection device and the protection functionality is located in the CBFP device.

[loextpol-021112-01.tif, 1, en_US]

Figure 6-236 Circuit-Breaker Failure Protection with External Start, Tripping Repetition and 3-Pole Tripping (T2)

Routing: Configuration of Internal Starting Sources (Internal Protection Function)

Configuration of the internal starting sources takes place in the protection function groups via the **Circuit-breaker interaction** entry (for this, see *2.1 Function Embedding in the Device*, *Figure 2-2*).

By default, the function can be started by any tripping of the internal protection functions, which control the local circuit breaker. Depending on the specific application, it can be necessary to exclude certain device-internal protection functions from starting the CBFP. For instance, busbar disconnection following a local circuit-breaker failure can be undesirable in the case of load-shedding applications or ground faults in isolated/resonant-grounded systems.

Where a start exclusively from external sources is required, all internal protection functions must be routed so that they are excluded as a starting source.

Parameter: Start via binary input

- Default setting **(_:107) Start via binary input** = ***no***

Parameter Value	Description
no	If no external start is intended, the parameter is set to ***no***.

Parameter Value	Description
2 channel	2-channel start is used if there is a risk that the circuit-breaker failure protection causes a tripping due to a faulty activation of the start binary input. This is the case in the following situations: a) The CBFP pickup value (threshold value) is set to less than the load current. b) There can be operating conditions under which the current flow is higher than the pickup value. To avoid a possible overfunction, Siemens recommends using the 2-channel start.
1 channel	The 1-channel start must be used where only one control circuit of a binary input is available for starting the CBFP.

Input Signals: >Start, >Release

The start and release input signals have a filtering time of ***10 ms*** as default setting. If a transient control signal to the binary inputs is to be expected due to the design of the external binary-input control circuits and due to environmental conditions, the filtering time can be extended. This delays the start of the CBFP function.

Input Signals	Description
>Start	The start input signal is linked with the tripping of the external protection device (see *Figure 6-236*).
>Release	The enabling input signal is normally linked with the pickup of the external protection device (see *Figure 6-236*). Another common configuration is the parallel wiring of the external trip initiation to both binary inputs (start and release).

Parameter: Supervision time release signal

- Default setting **(_:111) Sup.time for release signl** = ***0.06 s***

The setting depends on the external function which generates the release signal. If the pickup or tripping of the external protection is used as release signal, the default setting can be kept. If it is ensured that the release signal is always present before the starting signal, the time can be set to 0.

Parameter: Holding internal signal

- Recommended setting value **(_:105) Holding int. start signal** = ***yes***

Parameter Value	Description
yes	For an internal start, the starting signal is hold by default. The dropout of the CBFP depends exclusively on the determination of the CB position. This setting must be selected if it is not ensured that all 3 poles of the CB have opened when the pickup signal of the protection function has a falling edge. Siemens recommends using this method as the standard method.
no	Holding of the starting signal can be disabled if it is ensured by the application that the CB has reliably opened when the starting signal has a falling edge, or if the CBFP is explicitly required to dropout when the starting signal has a falling edge.

EXAMPLE

Holding internal starting signal (setting value: yes)

In the event of a 2-pole fault, only one contact of the CB opens. The fault current is thus reduced, and the starting phase short-circuit protection drops out.

Parameter: Holding ext. start signal

- Recommended setting value **(_:106) Holding ext. start signal** = ***no***

Parameter Value	Description
no	The CBFP drops out when the external starting signal has a falling edge. This setting prevents the CBFP from generating a tripping signal when an unwanted pulse is received at the binary input and the current flow is high enough. Siemens recommends using this method as the standard method.
yes	You can hold the starting signal if it is not ensured that the circuit breaker is open when the external starting signal has a falling edge.

EXAMPLE

Holding external starting signal (setting value: yes)

The function is started from the opposite end via an auxiliary device for command transmission. This device generates only a signal pulse.

NOTE

Siemens would like to point out that, with a hold signal, the CBFP generates a trip signal each time a starting pulse is received and the current flow is high enough. Remember this particularly in the case of an external start.

Parameter: Threshold phase current/Threshold sensitive

- Recommended setting value **(_:102) Threshold phase current** = ***approx. 0.50 $I_{sc,min}$***
- Recommended setting value **(_:101) Threshold sensitive** = ***approx. 0.50 $I_{sc,min}$***

In order to ensure that the disconnection of the fault is promptly detected and the function can drop out quickly, Siemens recommends setting both thresholds to half the minimum short-circuit current ($I_{sc, min}$).

If – depending on the neutral-point treatment and/or load conditions – ground faults lead to relatively low fault currents, a sensitive setting of the parameter **Threshold sensitive** must be selected according to the rule (0.5 $I_{sc,min}$). There can also be values which are noticeably below the rated or load current.

Input Signal: >Threshold sensitive

In order to ensure that the function picks up reliably in all switch positions of the power-supply system (examples: opposite end of line open, switching onto a ground fault), the setting of the parameter **Threshold sensitive** can be applied dynamically to all currents – including phase currents – in the presence of ground faults. For this purpose, the binary signal **>Threshold sensitive** must be activated. This can be done via a device-internal function for ground-fault detection (if provided in the device), for example, using **Overvoltage protection with zero-sequence voltage**. In this case, the pickup of the V0> function must be linked with the binary signal. Alternatively, the signal can be coupled from a separate device for sensitive ground-fault detection via a binary input.

Parameter: Circuit-breaker auxiliary-contact criterion allowed for protection

- Recommended setting value **(_:103) CB aux.cont. crit. allowed** = ***no***

Parameter Value	Description
no	If sufficient current flow is ensured under all conditions with the CB closed, Siemens recommends not to permit the auxiliary contacts as a further criterion for determining the CB position, because measurement based on the current flow is the most reliable criterion.

Parameter Value	Description
w. 'CB pos. closed 3p.'	The auxiliary contacts are permitted as a further criterion in applications (see the following examples) where the current is no reliable criterion for determining the circuit-breaker position.

Parameter: 3I0 criterion

- Recommended setting value (_:120) **3I0 criterion** = ***Plausibility check***

Parameter Value	Description
Plausibility check	The ground current serves only for the plausibility check of the phase currents. The threshold for the ground current uses the value set in the **Threshold sensitive** parameter.
Direct release	The current-flow criterion can be satisfied only by the ground current without the phase currents exceeding the set threshold value. The threshold for the ground current uses the value set in the **Threshold 3I0 dir. release** parameter in this case.

Parameter: I2 criterion

- Recommended setting value (_:121) **I2 criterion** = ***Plausibility check***

Parameter Value	Description
Plausibility check	The negative-sequence current serves only for the plausibility check of the phase currents. The threshold for the negative-sequence current uses the value set in the **Threshold sensitive** parameter.
Direct release	If one phase current exceeds 1/3 of the **Threshold I2 dir. release**, the current-flow criterion can be satisfied just by the negative-sequence current without the phase currents exceeding their set threshold value. The threshold for the negative-sequence current uses the value set in the **Threshold I2 dir. release** parameter in this case.

EXAMPLES

Applications which require you to permit the circuit-breaker auxiliary-contact criterion:

- Tripping of the high and low-voltage side CB on the transformer. If only one of the 2 CBs trips, there is no more current flow.
- Tripping of protection functions whose tripping decision is not based on current measurement, in combination with low-load situations.
- Injection of the tripping signal from Buchholz protection

Parameter: Dropout

- Recommended setting value **(_:104) Dropout** = ***with effective criterion***

The parameter **Dropout** is available if the circuit-breaker auxiliary-contact criterion is permitted (see parameter **CB aux.cont. crit. allowed**).

Parameter Value	Description
with effective criterion	Siemens recommends keeping the default setting, because it prefers the current as a reliable criterion for detection of an open CB and thus for dropout of the CBFP function.
w. aux.c. and curr.crit.	Select this setting for applications on transformers or generators (see the preceding examples) in which the current flow is such that the current is no longer a reliable criterion for detecting the opening of the CB.

Parameter: Retrip

- Default setting **(_:108) Retrip after T1** = ***no***

Parameter Value	Description
no	Where no redundant CB control is provided, a repetition of the trip signal to the local CB is not required.
start T2 after T1	Where a redundant CB control (2nd trip coil with 2 trip circuits) is provided, a repetition of the trip signal to the local CB makes sense. Siemens recommends the setting ***start T2 after T1*** because it provides a clear chronological separation of the processes for trip repeat and backup tripping. Remember here that the overall fault-clearance time in case of a failure of the local CB is the sum of T1 and T2.
parallel start T2, T1	As an alternative to the setting ***start T2 after T1***, the user can start T2 and T1 in parallel.

Parameter: Delay T1 for 3-pole retrip

- Default setting **(_:109) Delay T1 for 3-pole retrip** = ***0.05 s***

The parameter is visible only when retripping is set.

The setting depends on the user's philosophy.

The following settings make sense:

- If the minimum fault-clarification time has top priority, Siemens recommends setting the time to 0. This setting causes initiation of the retrip immediately upon the start. The drawback is that a defect of the 1st trip circuit is not detected.
- With a small time delay of, for instance, 50 ms, the defect of the 1st trip circuit can be detected based on the evaluation of the fault record.
- With a long time delay which reliably ensures the dropout of the CBFP with the CB open, the rising edge indication of the trip repeat **Retrip T1** is a sure signal for a fault in the 1st trip circuit. The following example shows how this time is determined.

EXAMPLE

Determining the T1 Time that Reliably Ensures the Dropout of the CBFP with the CB Open:

Time of binary device output (when tripping is caused by the device-internal protection)	5 ms
CB inherent time up to current interruption	2 periods (assumed rated frequency = 50 Hz)
Dropout time of CBFP function	1 period
Subtotal	65 ms
Security	Factor 2
Total (time T1)	130 ms

Parameter: Delay T2 for 3-Pole Trip

- Default setting **(_:110) Delay T2 for 3-pole trip** = ***0.13 s***

This setting has to ensure that after opening of the local CB the function drops out reliably and that backup tripping is avoided under all circumstances. The setting depends on the parameter **Retrip after T1**.

If T2 is started afterT1, there is no need to consider the time T1 for the setting of T2.

EXAMPLE

Determining the T2 Time that Reliably Ensures the Dropout of the CBFP with the CB Open:

Time of binary device output (when tripping is caused by the device-internal protection)	5 ms
CB inherent time up to current interruption	2 periods (assumed rated frequency = 50 Hz)
Dropout time of CBFP function	1 period
Subtotal	65 ms
Security	Factor 2
Total (time T2)	130 ms

If T1 and T2 are started in parallel, take into account the time T1 for the setting of T2.

EXAMPLE

Simultaneous start of T2 and T1

Time for a reliable dropout after the local CB has opened	130 ms
Setting of T1	50 ms
Total (= T2)	180 ms

Parameter: Minimum operate time

- Default setting **(_:112) Minimum operate time** = **-**

The **Minimum operate time** parameter is used to set the minimum duration for tripping the function.

CAUTION

Do not set a time that is too short.

If you set a time that is too short, there is a danger (dropout of the function without the current-flow criterion) that the device contacts will interrupt the control circuit. If this happens, the device contacts will burn out.

✧ Set a duration that is long enough to ensure that the circuit breaker reaches its final position **open** reliably after a control operation.

Input Signal: >CB defect

The input signal **>CB defect** has a default filtering time of 20 ms. This filtering time prevents the input signal from becoming effective in the case of a transient activation of the physical binary input, which can be caused by the pressure change when the CB opens.

This time can be set to 0 if such a transient pickup of the physical binary input can be excluded due to the CB design.

Output Signal: Retrip T1

If only one control circuit is available for the local CB, it is not mandatory to route the output signal because the signal also controls the CB trip logic.

If a 2nd control circuit is present, the output signal **Retrip T1** must be routed to the associated binary output.

Output Signal: Trip T2

In order to operate the adjacent circuit breakers, the backup tripping (indication **Trip T2**) must be routed to a binary output; andif necessary, to an interface (intertripping to opposite end).

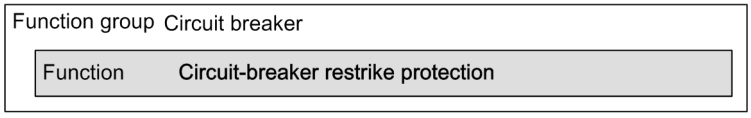
6.40 Circuit-Breaker Restrike Protection

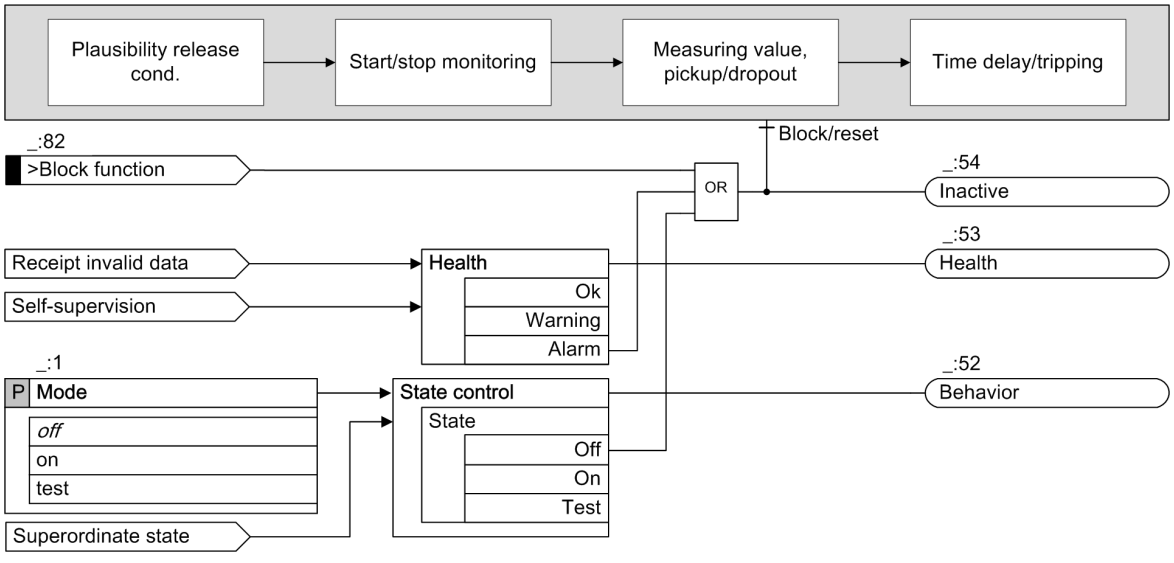


6.40.1 Overview of Function

The **Circuit-breaker restrike protection** function:

- Monitors the circuit breaker against restriking, for example, caused by an overvoltage over the circuit-breaker poles after switching off a capacitor bank
- Generates a backup operate signal in case of a circuit-breaker restriking

6.40.2 Structure of the Function



The **Circuit-breaker restrike protection** function is used in the **Circuit-breaker** function group. A maximum of 2 functions can operate simultaneously within the function group.

[lo_strrestrike_2014-03-05.vsd, 2, en_US]

Figure 6-237 Structure/Embedding of the Function

The function logic is grouped into the parts shown in *Figure 6-238*. In the following chapter, these logic parts are described in detail.

[lo_respro-210113-01.vsd, 1, en_US]

Figure 6-238 Logic Overview of the Function

6.40.3 Function Description

Plausibility Release

The function **Circuit-breaker restrike protection** issues a trip command to a superordinated circuit breaker, usually the infeed circuit breaker of a busbar. Overfunction of this protection can cause extreme problems for the whole application.

The logic of plausibility release strongly reduces the risk of a false start of the function by adding an extra release criteria for a function start.

Each criterion can be switched on or off individually.

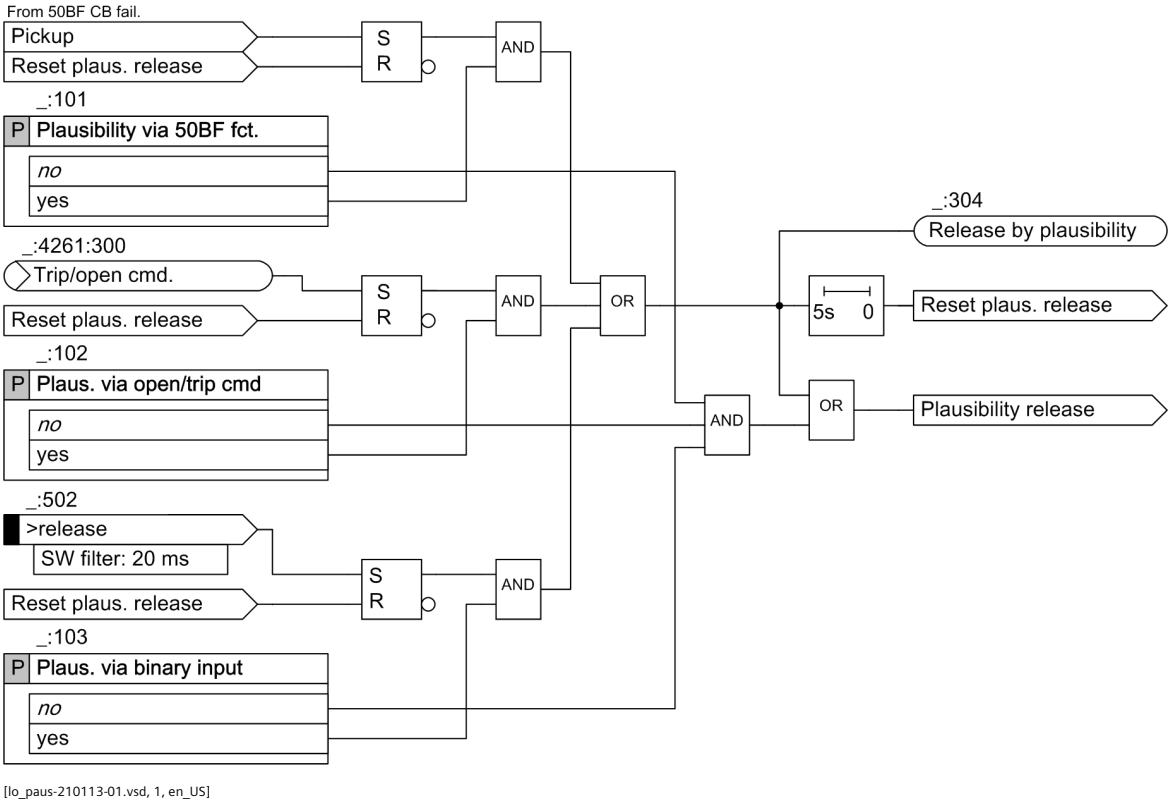


Figure 6-239 Logic Diagram for the Plausibility Release of the Circuit-Breaker Restrike Protection

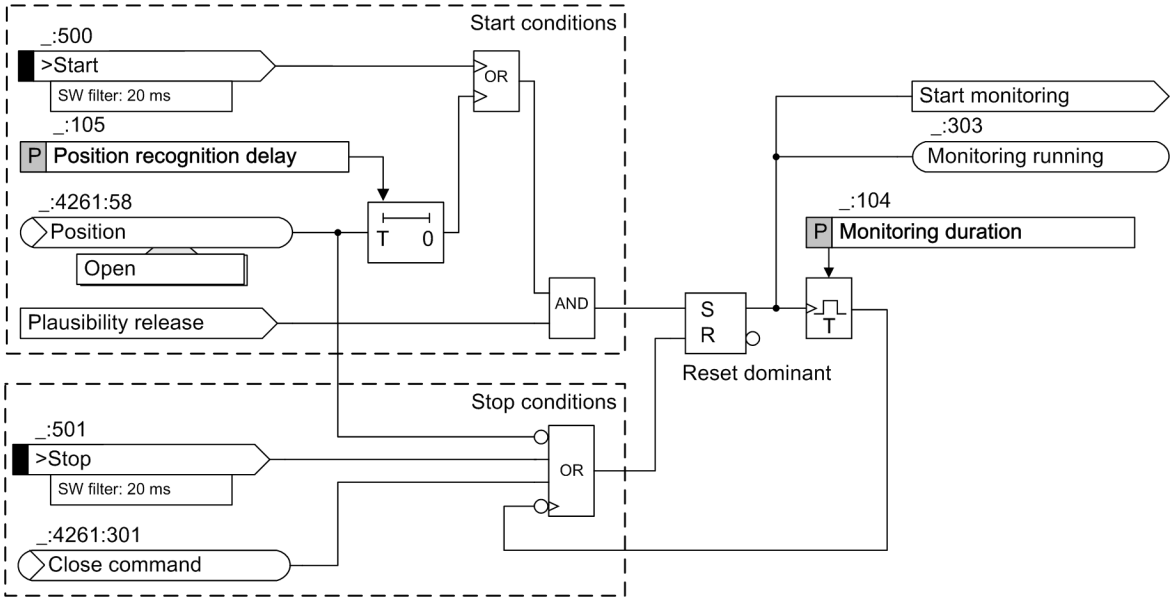
The plausibility-release logic checks the following conditions:

- When the parameter **Plausibility via 50BF fct.** is set to ***yes***, the pickup signal of the **Circuit-breaker failure protection** is monitored. The plausibility release is given if the **Circuit-breaker failure protection** has picked up.
- When the parameter **Plaus. via open/trip cmd** is set to ***yes***, the trip/open command is monitored. The plausibility release is given if the trip/open command has been generated.
- When the parameter **Plaus. via binary input** is set to ***yes***, the *>release* signal is monitored. The plausibility release is given if the *>release* signal has been received.



If one of the conditions is fulfilled, the plausibility release is given for 5 s. The 5-s timer ensures that the release criterion and start condition relate to the same circuit-breaker opening/tripping process.

If all the 3 plausibility settings are set to ***no***, the start/stop-monitoring logic considers the release as fulfilled.

For safety reasons, the input signal *>release* has a preset software filtering time of 20 ms.

Start/Stop Monitoring

Via the start/stop monitoring logic, the monitoring duration of the current signal regarding restriking is determined.

[lo_starstop-210113-01.vsd, 2, en_US]

Figure 6-240 Logic Diagram for Start/Stop Monitoring of the Circuit-Breaker Restrike Protection

The monitoring is started if one of the following conditions is met:

- The circuit-breaker position is detected as **open** via the circuit-breaker auxiliary contacts during the time set with the parameter **`Position recognition delay`**.

  The **`Position recognition delay`** time is used for safety means to ensure that the circuit breaker is definitely open when the monitoring starts. This parameter allows to adapt this start criterion to all kinds of auxiliary-contact configurations.

- The binary input signal *`>Start`* is activated.

For safety reasons, the input signal has a preset software filtering time of 20 ms.

In addition to the active start criterion, the plausibility release (refer to the *Plausibility Release, Page 808*) must be present to start the monitoring duration.

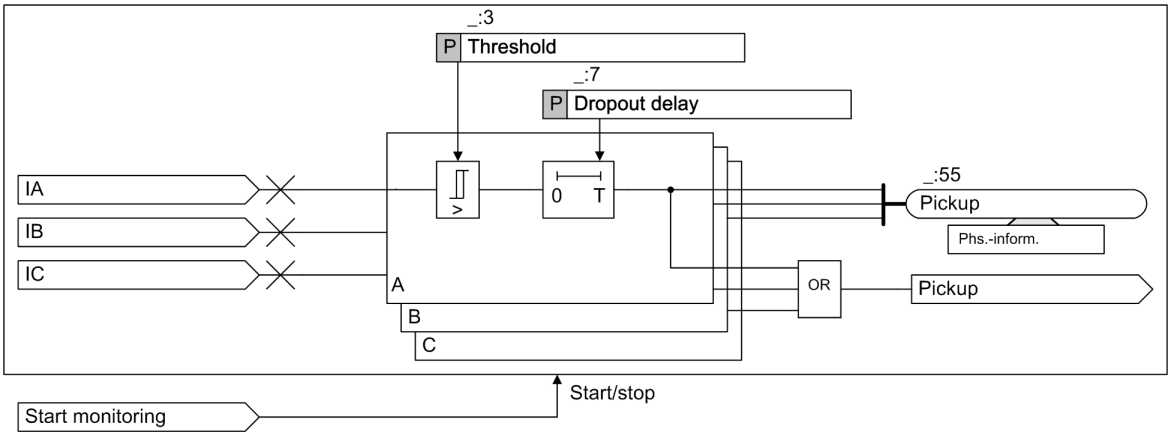
With the fulfilled start condition, the **`Monitoring duration`** timer is started. This timer defines how long the current signal is monitored regarding restriking. If the time expires, the monitoring is terminated.

The monitoring is also terminated immediately if one of the following conditions is met:

- The circuit-breaker position is detected no longer as **open**.
- A close command is given by the device.
- The binary input signal *`>Stop`* is activated.

  For safety reasons, the input signal has a preset software filtering time of 20 ms.

Measuring Value, Pickup/Dropout



During the **`Monitoring duration`**, the current signal is monitored phase-selectively regarding restriking.

As a measuring value, the fundamental component of the current is used.

- On one hand, current peaks are damped but still detected reliably by the fundamental-component value.
- On the other hand, a DC (Direct Current) component is suppressed. A DC component can occur after switching off the circuit breaker.

Thus, the fundamental-component value is a good choice for a reliable restrike detection.

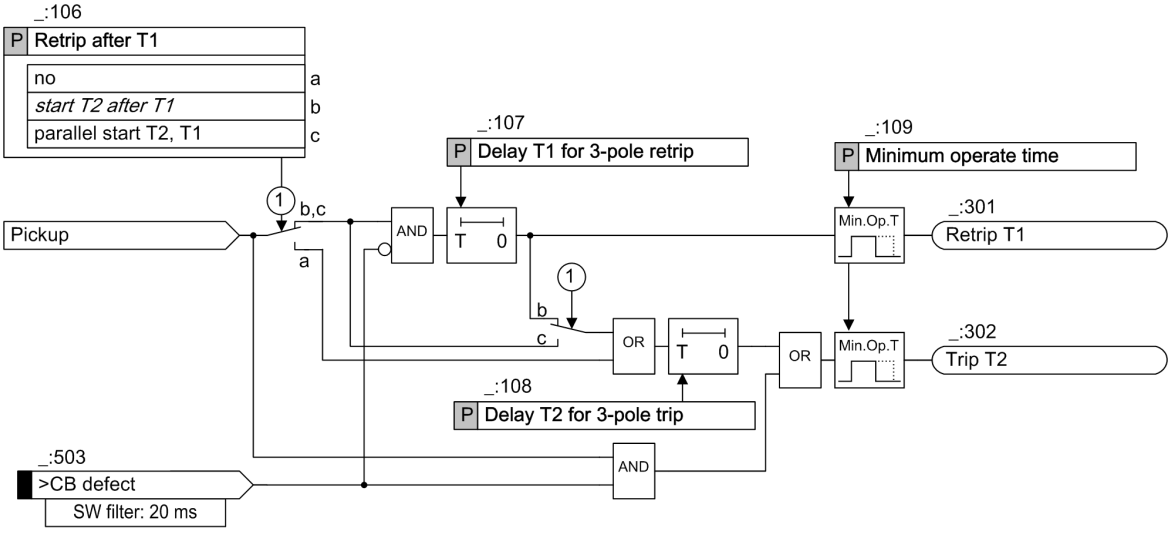
If any phase current exceeds the set current threshold value, the function picks up. The coming pickup indicates the first restrike current pulse. With the pickup, the operate delay timers are started, see also the following description *Delay/Tripping, Page 811*.

[lo_pickdrop-210113-01.vsd, 1, en_US]

Figure 6-241 Logic Diagram for Measuring Value, Pickup/Dropout of the Circuit-Breaker Restrike Protection

If restriking occurs, the current signal drops below the current threshold if the time between restrike pulses is long enough. In this case, the operate delay must not be reset. During the dropout delay, the pickup is extended to ensure that the operate delay timers are not reset. However, if the dropout delay time expires (no new current peak occurred), the function drops out and the operate delay timers are reset.

Delay/Tripping



In the first step, tripping of the local circuit breaker can be repeated. Tripping is repeated after expiration of the settable delay T1. The retrip on the local circuit breaker is as a safety mechanism as well. In the event of a wrong start and pickup, only the local circuit breaker is opened instead of the superordinated circuit breaker.

Time delay T2 (backup tripping) can start in parallel either with the start of time T1 or after expiration of time T1.

If time delay T2 expires, circuit-breaker restriking takes place and the backup-tripping signal *Trip T2* is generated.

If the *>CB defect* input signal is valid, any repetition of the trip signal is suppressed and the backup-tripping signal *Trip T2* is generated immediately (without delay). For safety reasons, a default software filter time of 20 ms is preset (configurable in DIGSI) for the binary input signal *>CB defect*.

The **Minimum operate time** parameter defines the minimum duration for the trip command of the function. In contrast to other protection functions, the parameter is set within its own function. As a result, the setting is independent of the identically named comprehensive parameter that is set in the **Device settings**.

[lo_deltrip-030211-01.vsd, 2, en_US]

Figure 6-242 Logic Diagram for Delay/Tripping of the Circuit-Breaker Restrike Protection

6.40.4 Application and Setting Notes

Parameter: Switch On or Off Additional Plausibility Release Criteria

- Default setting **(_:101) Plausibility via 50BF fct.** = *no*
- Default setting **(_:102) Plaus. via open/trip cmd** = *no*
- Default setting **(_:103) Plaus. via binary input** = *no*

When using the plausibility release, the start condition and the release condition instead of only the start condition must be present to start the current monitoring regarding restriking. Since the current threshold value is set below the operating current, a false start would directly cause tripping. Thus, the plausibility release strongly reduces the risk that a falsely given start criterion leads to a wrong tripping of the superordinated circuit breaker.

3 different release criteria are available. You can use one or more than one or none of them. The selection depends on the application.

NOTE

When using release criteria, it must be ensured that the criteria are given under all the conditions where the **Circuit-breaker restrike protection** shall be started. If you choose no release criteria, the release is permanently given.

- **Open/trip command by the device**

Use this criterion in case that all control or trip commands are given by the protection device.

NOTE

Opening the circuit breaker manually without using the device will not release the start of the **Circuit-breaker restrike protection**.

- **Pickup of the Circuit-breaker failure protection**

Use this criterion if the **Circuit-breaker restrike protection** should only be started in case that the **Circuit-breaker failure protection** was started (picked up) before.

NOTE

Opening the circuit breaker by control or manually will not trigger the circuit breaker failure protection. Consequently the **Circuit-breaker restrike protection** cannot be released either.

- **Binary input signal**

Use this option if neither of the above 2 release criteria fit the application and you want to define your own release criterion.

Input signals: *>Start, >release, >Stop*

Input Signals	Description
>Start	This input signal allows to start the monitoring, for example, via protocol commands from a master (by use of a CFC chart) or by other specific conditions.
>release	This input signal allows to define specific release conditions by use of a CFC chart. Also refer to *Parameter: Switch On or Off Additional Plausibility Release Criteria , Page 812*.
>Stop	This input signal allows to stop the monitoring, for example, via protocol commands from a master (by use of a CFC chart) or by other specific conditions.

The input signals *>Start* , *>release* , and *>Stop* have a filtering time of *20 ms* as default setting. If a transient spurious signal to the binary inputs is expected due to the design of the external binary-input control circuits and environmental conditions, the filtering time can be extended.

Parameter: Position recognition delay

- Default setting **(_:105) Position recognition delay** = *0.02 s*

With the parameter **Position recognition delay**, you define how long the circuit breaker must be detected as **open** (via the circuit-breaker auxiliary contacts) before the monitoring time is started. This definition is a safety feature to ensure that the monitoring is not started too early. For example, in case that due to a non-standard auxiliary-contacts configuration, the circuit-breaker is already detected as **open** while current flow is still present.

The setting depends on the circuit-breaker auxiliary-contacts configuration. If it can be ensured that the auxiliary contacts announce the circuit breaker as **open** after the current flow is interrupted, the time can be set to zero.

Parameter: Monitoring duration

- Default setting **(_:104) Monitoring duration** = *200.00 s*

With the parameter **Monitoring duration** , you define how long the current signal is monitored regarding restriking after the circuit breaker has been opened.

With ongoing discharging of the capacitor bank, the probability of restriking is decreasing. There is no need to set the monitoring time longer than the discharging time. Siemens recommends setting the monitoring time in the range of 0.5 * discharging time to 1 * discharging time.

Parameter: Threshold

- Default setting **(_:3) Threshold** = *0.250 A*

After opening of the circuit breaker, the phase currents are compared with the threshold value. If no restriking takes place, the current is zero. Consequently the threshold for detecting restriking can be set much smaller than the operating current. A typical value is 25 % of the operating current.

With a threshold below the operating current, a falsely-given start directly cause tripping. For minimizing this risk, Siemens recommends applying a release criterion additionally. Refer to *Parameter: Switch On or Off Additional Plausibility Release Criteria , Page 812*.

Parameter: Dropout delay

- Default setting **(_:7) Dropout delay** = *0.05 s*

The parameter **Dropout delay** ensures that a short dropping below the current threshold does not cause the operate delay timers to be reset.

Since restriking is normally a periodical effect, the dropout delay can be set to a rather small time. Siemens recommends applying the default value of 50 ms.

Input signal: *>CB defect*

The input signal *>CB defect* has a preset filtering time of 20 ms. This filtering time prevents the input signal from becoming effective in the case of a transient activation of the physical binary input, which can be caused by the pressure change when the circuit breaker opens.

This time can be set to 0 if such a transient response of the physical binary input can be excluded due to the circuit-breaker design.

Parameter: Retrip after T1

- Default setting **(_:106) Retrip after T1** = *start T2 after T1*

Parameter Value	Description
start T2 after T1	The retrip on the local circuit breaker is a safety mechanism to avoid false tripping of the superordinated circuit breaker. With generating a retrip, only the local circuit breaker is tripped in the event of a false start. Afterwards the **Circuit-breaker restrike protection** function drops out during the T2 delay time. Siemens recommends applying a retrip on the local circuit breaker. Siemens also recommends applying the parameter value ***start T2 after T1***. The parameter value provides a clear chronological separation of the processes for trip repeat and backup tripping. Remember that the overall fault-clearance time in case of circuit-breaker restriking is the sum of T1 and T2.
no	No retrip is given
parallel start T2, T1	As an alternative to the setting ***parallel start T2, T1*** the customer can start T2 and T1 in parallel.

Parameter: **Delay T1 for 3-pole retrip**

- Default setting (_:109) **Delay T1 for 3-pole retrip** = ***0.00 s***

The parameter is visible only when the parameter **Retrip after T1** is set to ***start T2 after T1*** or ***parallel start T2, T1*** .

The retrip on the local circuit breaker is as a safety mechanism to avoid false tripping of the superordinated circuit breaker. In the event of a false start, only the local circuit breaker is tripped by the retrip. Afterwards the **Circuit-breaker restrike protection function** will drop out during the T2 delay time.

Siemens recommends applying a retrip on the local circuit breaker. Since the retrip is a safety mechanism, it can be given without a delay time. Siemens recommends setting the delay time to 0 s.

Parameter: **Delay T2 for 3-pole trip**

- Default setting (_:110) **Delay T2 for 3-pole trip** = ***0.15 s***

This parameter defines the duration of restriking after the backup tripping is sent. The following should be considered:

- When using the retrip functionality, this delay time must ensure a safe function dropout after giving the retrip on the local circuit breaker.

Siemens recommends applying a delay time of 150 ms which is the default setting.

Parameter: **Minimum operate time**

- Default setting **(_:109) Minimum operate time** = ***0.15 s***

The **Minimum operate time** parameter is used to set the minimum duration for the trip command of the function.

CAUTION

Do not set a time that is too short.

If you set a time that is too short, there is a danger (dropout of the function without the current-flow criterion) that the device contacts interrupt the control circuit. If this happens, the device contacts burn out.

✧ Set a duration that is long enough to ensure that the circuit breaker reliably reaches its final position (**open**) after a control operation.

Output signal: *Retrip T1*

The output signal *Retrip T1* must be routed to a binary output.

If only one control circuit is available for the local circuit breaker, the output signal must be routed to the binary output to which the general circuit breaker trip command (command *Position*) is routed.

If a second control circuit is present, the *Retrip T1* output signal can be routed to the associated binary output.

Output signal: *Trip T2*

In order to trip the adjacent circuit breakers, the backup tripping (indication *Trip T2*) must be routed to a binary output and if necessary, to an interface (intertripping to the opposite end). Thus, the circuit breaker on the opposite end can be tripped without delay.

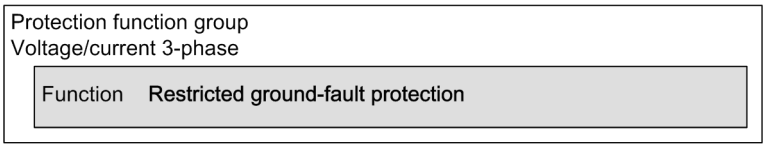
6.41 Restricted Ground-Fault Protection

6.41.1 Overview of Functions



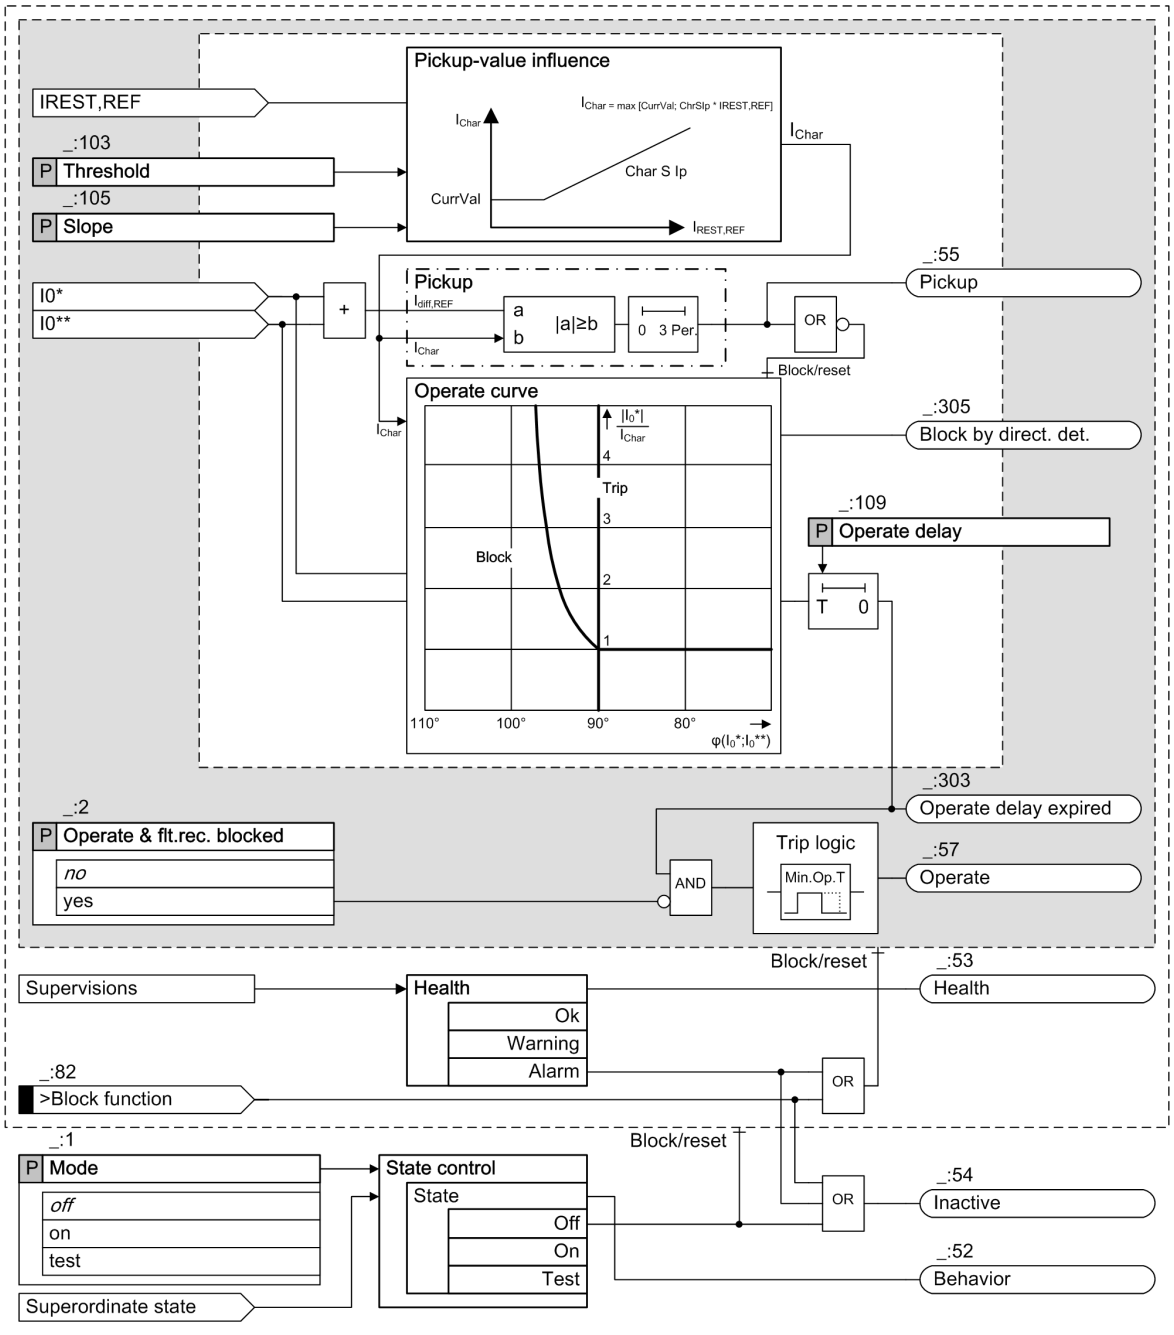
The **Restricted ground-fault protection** function (ANSI 87N):

- Detects ground faults in transformers, shunt reactors, neutral reactors or rotating machinery in which the neutral point is grounded.
- Has high sensitivity to ground faults near the neutral point.
- Is supplemental main protection to longitudinal differential protection.
- Protects grounding transformers in the protection range. It is required that a current transformer be used in the case of neutral point feed, that is, between neutral point and grounding conductor. The neutral point transformer and the phase current transformer define the protection range.
- Adapts itself to the highest-amperage side with auto transformers and thereby prevents overfunction in the event of external ground faults.

6.41.2 Structure of the Function

The **Restricted ground-fault protection** function is used in the **Transformer side** or **Auto transformer** protection function group. Furthermore, you can use the function in the stabilizing winding of the auto transformer or also in the **Standard UI** function. The function depends upon application in the corresponding application template preconfigured by the manufacturer or can be copied during the engineering into the corresponding function group.

The **Restricted ground-fault protection** function is stepless.

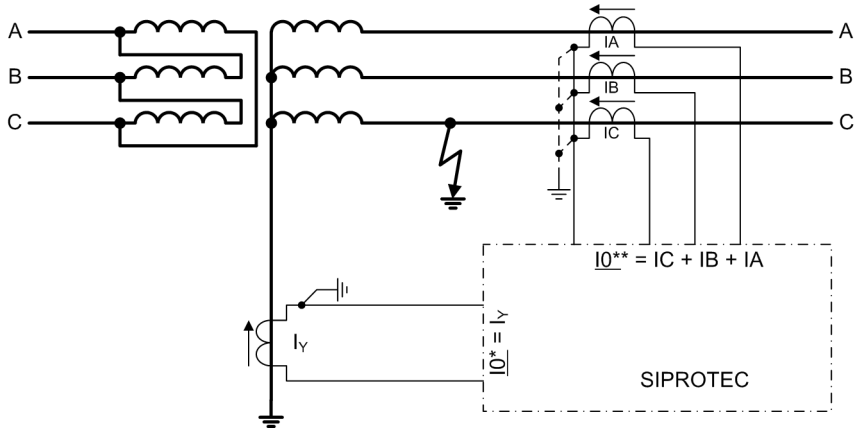


[dwstrupt-170712-01.tif, 2, en_US]

Figure 6-243 Structure/Embedding of the Function

6.41.3 Function Description

Logic of the Function



[loreffkt-170712-01.tif, 1, en_US]

Figure 6-244 Logic Diagram of the Restricted Ground-Fault Protection Function

The protection function processes the neutral-point current I_0* (exactly $3I_0$) and the calculated zero-sequence current I_0** (exactly $3I_0$) from the phase currents (see following figure). The protection range extends exclusively over the transformer winding, including current transformer. The amount-adapted (compensated) currents are described by the * icon. They are normalized to the rated object current of the respective side.

In case of an internal ground fault, the residual currents flow to the fault location. With an external ground fault, the fault current inverts itself in the phase current transformers. In this way, the direction of current flow serves as the decisive criterion for an internal fault.

[dwgrdpri-170712-01.tif, 1, en_US]

Figure 6-245 Basic Principle of the Function

In accordance with the logic diagram, *Figure 6-244* the protection function consists of 3 parts:

Effect of Pickup Value

The differential current and the restraint current are calculated from the residual currents. The reference arrows are defined as positive when pointing to the protected object (see *Figure 6-245*). Consider that the ground current in the fault record and in the DIGSI 5 Test Suite are displayed as positive if the current flows to ground from the protected object.

NOTE

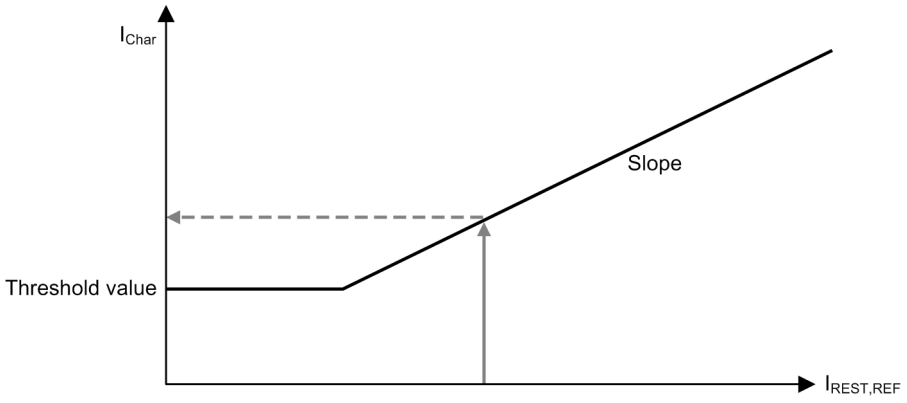
The following calculation applies to the configurations with a current transformer for the side. In a special case of several current transformers per side, the calculation of the restraint current must be performed in greater detail.

$\underline{I}_0^* = k_m \cdot 3\underline{I}_0'$

$\underline{I}_0^{**} = k_m \cdot 3\underline{I}_0'' \rightarrow 3\underline{I}_0'' = \underline{I}_A + \underline{I}_B + \underline{I}_C$

with $k_m = I_{N,transformer}/I_{N,side}$

$I_{Diff,REF} = |\underline{I}_0^* + \underline{I}_0^{**}|$



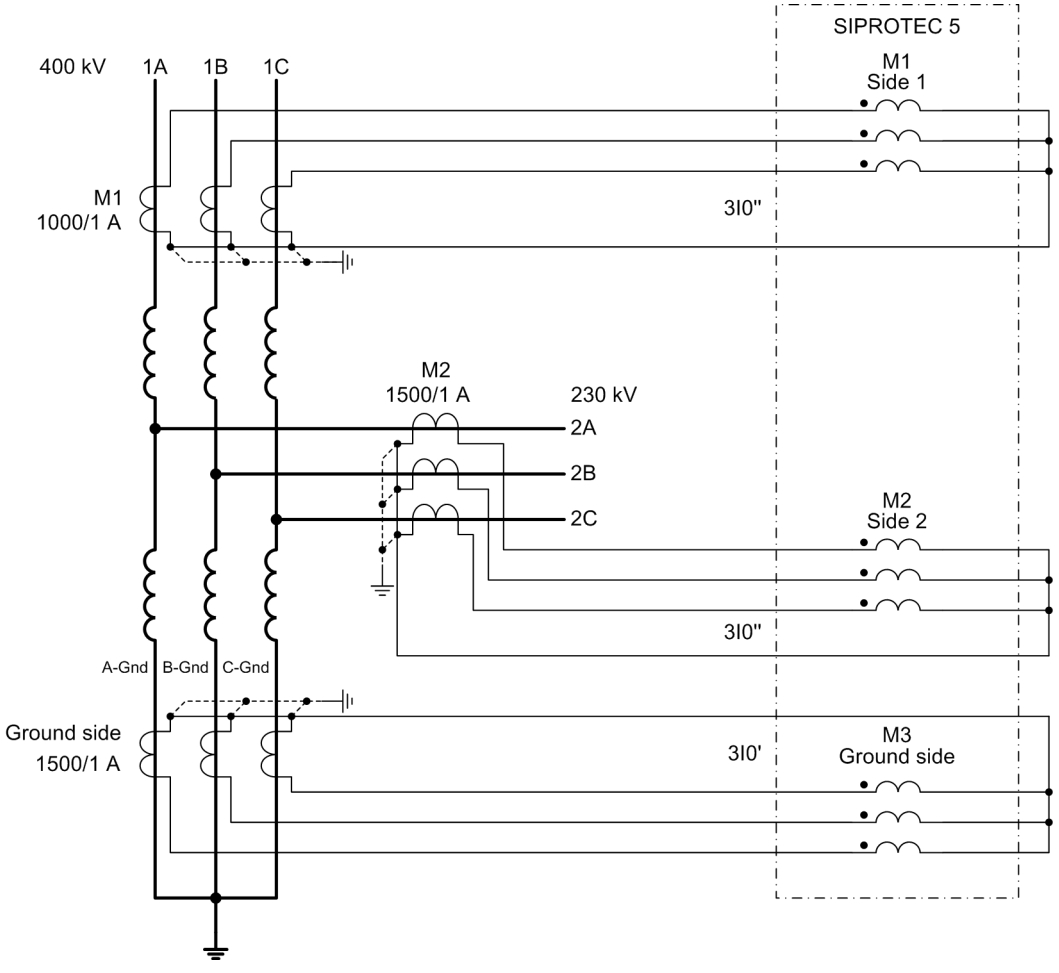
$I_{rest,REF} = |\underline{I}_0^*| + |\underline{I}_A| + |\underline{I}_B| + |\underline{I}_C|$

where:

$3\underline{I}_0'$	Measured zero-sequence current at neutral point
$3\underline{I}_0''$	Zero-sequence current calculated from the phase currents
k_m	Factor for amount adaptation (compensation)
$I_{rated,trans-former}$	Primary transformer rated current
$I_{rated,side}$	Primary rated current of the transformer side
$I_{Diff,REF}$	Differential current
$I_{Rest.,REF}$	Restraint current

Using the calculated restraint current, a current $I_{char.\ curve}$ which represents the pickup value for the tripping is determined from the characteristic curve (*Figure 6-246*). In this way, the protection function is stabilized in the event of external, multiphase ground faults, for example, a 2-pole ground fault. This means that the protection function becomes less sensitive.

If the **`Slope = 0`** is set here, the set **`Threshold`** of the operate curve is delivered independent of the restraint current.



[dwstabke-170712-01.tif, 1, en_US]

Figure 6-246 Stabilized Characteristic Curve

Processing a Ground Side for Auto Transformer

Instead of a 1-phase neutral point, with an auto transformer a 3-phase ground side can also be used.

[dwautraf-201112-01.tif, 1, en_US]

Figure 6-247 Connecting a Ground Side on the Auto Transformer

In this case the neutral-point current calculates as sum of the phase currents of the ground side:

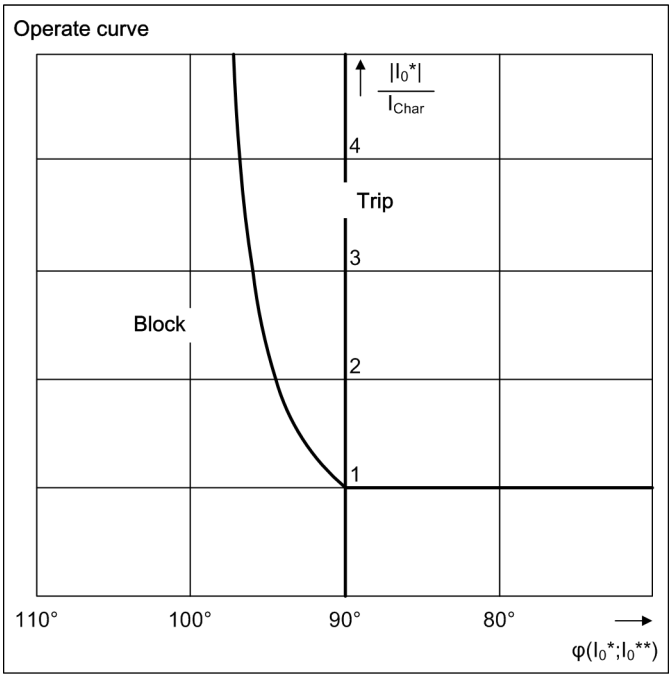
$I_0^* = k_m \cdot 3I_0' \rightarrow 3I_0' = I_{gnd,A} + I_{gnd,B} + I_{gnd,C}$

with $k_m = I_{N,transformer}/I_{N,side}$

The following applies for the restraint current:

The following applies for the restraint current: $I_{rest.,REF} = |I_{gnd,A}| + |I_{gnd,B}| + |I_{gnd,C}| + |I_A| + |I_B| + |I_C|$

NOTE



If both 1-phase neutral point and 3-phase ground side are connected, only the 1-phase neutral point is used by the restricted ground-fault protection. The 3-phase ground side is not considered.

Pickup

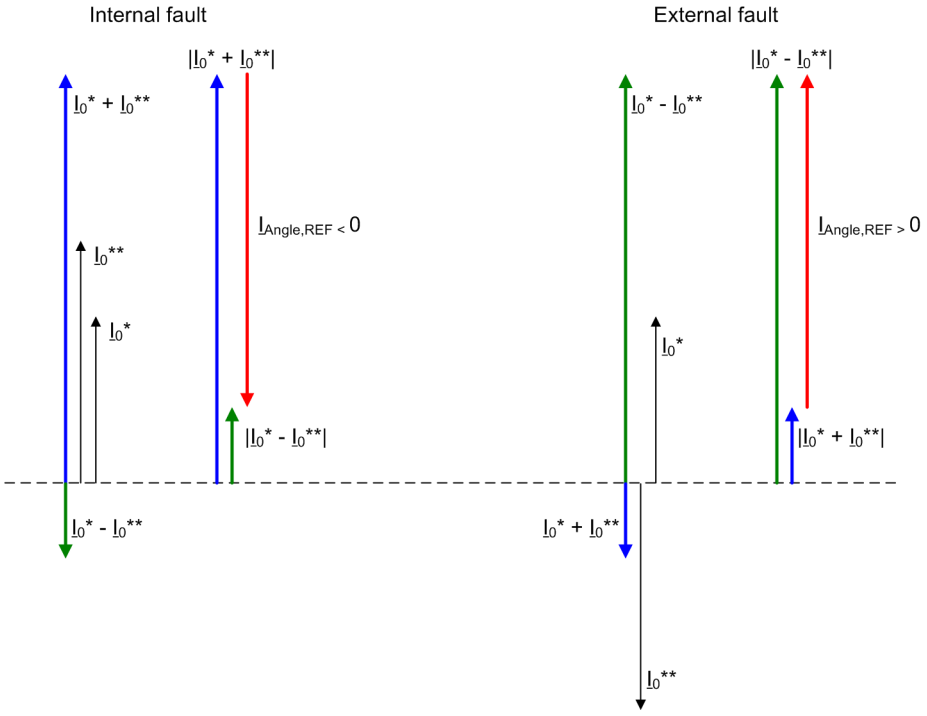
If the $I_{Diff,REF}$ calculated differential current exceeds the $I_{char.\ curve}$ calculated current (see *Figure 6-244*), pickup occurs and the internal processing is enabled. The pickup is indicated.

Operate Curve

The operate curve represented in the following figure consists of 2 parts. In the right part of the characteristic curve, you will find a case of an **internal ground fault**. Under ideal conditions, the angle between the two residual currents ($\angle(\underline{I}_0^*, \underline{I}_0^{**})$) equals 0. With current-transformer saturation, angle errors can result. The right part of the characteristic curve is valid for angles ≤ 90°. The tripping current is the current flowing at the neutral point ($\underline{I}_0^*$). It is compared to the set or increased threshold value.

[dwausken-170712-01.tif, 1, en_US]

Figure 6-248 Operate Curve Depending on the Phase Angle between $\underline{I}_0^*$ and $\underline{I}_0^{**}$ at $|\underline{I}_0^*| = |\underline{I}_0^{**}|$ (180° = External Fault)



In case of an **external ground fault** the zero-sequence current calculated from the phase currents reverses by 180°. The phase angle between the residual currents thus ($\angle(\underline{I}_0^*, \underline{I}_0^{**})$) equals 180°. They are located in the left part of the operate curve and recognize a clearly increased pickup value. Angle deviations of 180° are caused by transformer saturation in conjunction with external short-circuits.

The current $I_{angle,REF}$ for the **Angle Decision** is determined from the following subtraction and summation:

$I_{angle,REF} = |\underline{I}_0^* - \underline{I}_0^{**}| - |\underline{I}_0^* + \underline{I}_0^{**}|$

The resulting current $I_{angle,REF}$ results from the respective fault conditions, which are illustrated in the following figure. With an internal fault (angle = 0°) a current results that has a negative sign. If angle errors occur, the sign remains negative. The amount of the current decreases.

In an external short-circuit (180°), the current becomes positive. At a smaller angle (<180°) due to transformer saturation, the angle remains positive. The amount also decreases.

[dwwinken-011112-01.tif, 1, en_US]

Figure 6-249 Angle Decision in Internal and External Faults

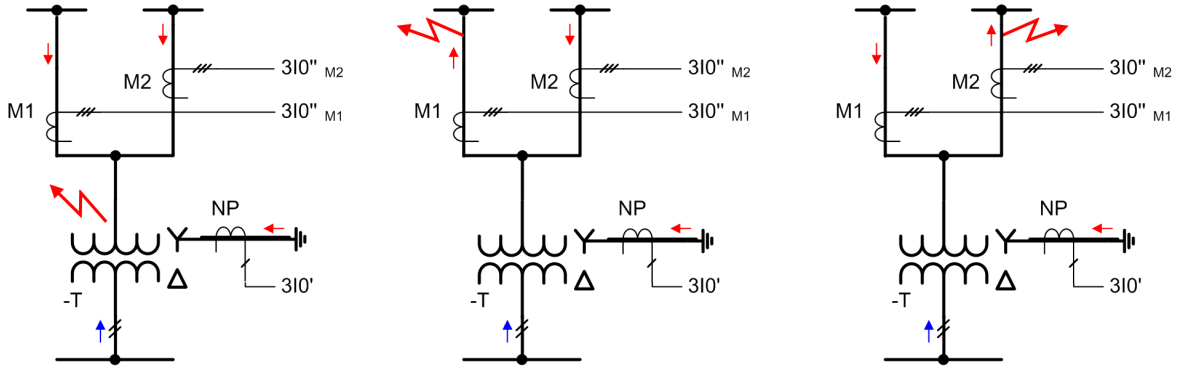
For tripping to occur, the neutral-point current I_0* must reach the value $I_{REF,off}$. The characteristic curve in the left part of the figure can be determined from the following relationship:

$I_{REF,off} = I_{char.\ curve} + k \cdot I_{angle,REF}$

where:

$I_{char.\ curve}$	Pickup value resulting from the pickup value increase
k	Factor (permanently set to 4.05657. With this value, the limit angle at $\|I_0^*\| = \|I_0^{**}\|$ is precisely 100°. No tripping is possible from this angle on.)

Processing of Several Measuring Points on One Side



If several measuring points are present on one side of a star winding, as with a 1 1/2 circuit-breaker application, the angle decision occurs separately for each measuring point. The maximum current $I_{angle,REF}$ is used to establish the tripping decision.

NOTE

With an external fault, the current $I_{angle,REF}$ is always > 0.

The following figure shows the behavior under different fault conditions.

Also observe that the restraint current ($I_{rest.,REF}$) always results from the sum of all currents (phase currents of the measuring points and the neutral-point current). For pickup, the differential current $I_{Diff,REF}$ is necessary. This differential current results from the geometric sum of all adapted residual currents. The residual currents of the measuring points on the outgoing side and of the neutral-point current are meant here.

[dwfehler-291112-01.tif, 1, en_US]

Figure 6-250 Behavior under Different Fault Conditions

Functional Measured Values

Measured Value	Description
(_:306) I REF,operate	Operate quantity of the restricted ground-fault protection from the angle criterion
(_:307) I Angle,REF	Stabilizing value (angle) of the restricted ground-fault protection from the angle criterion
(_:311) I REF,Trip operate	Operate quantity of the restricted ground-fault protection when OFF
(_:312) I angle,REF operate	Stabilizing value of the restricted ground-fault protection when OFF
(_:301) I diff.	Differential current
(_:302) I restr.	Restraint current

You will find the measured values for the **Restricted ground-fault protection** under the following device menu entries:

- Main menu → Measurements → function → Function values → 87N REF

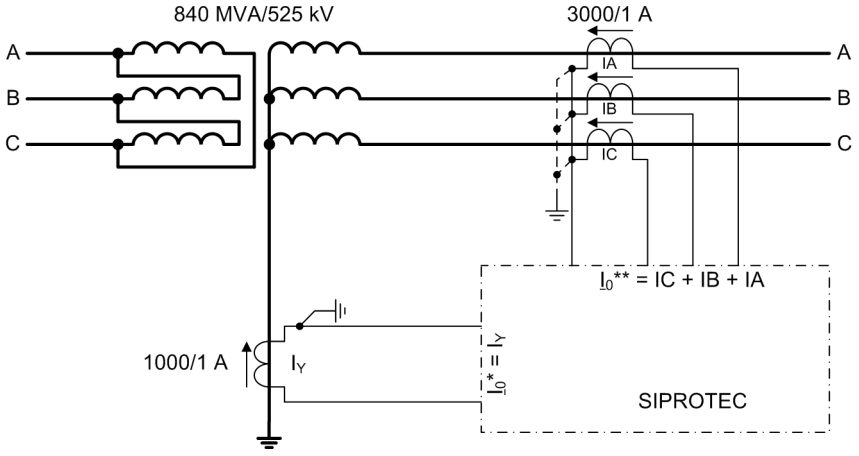
6.41.4 Application and Setting Notes

NOTE

The following conditions must be observed when setting the threshold values:

Threshold value ≥ max { *0.05 I/Irated,S* ; *0.05 I/Irated,S* * $I_{prim\ transf.\ max}$ / $I_{rated,\ protected\ object}$ }

Threshold value ≤ min { *2.00 I/Irated,S* ; *100.00 I/Irated,S* * $I_{prim\ transf.\ max}$ / $I_{rated,\ protected\ object}$ }



The value ***0.05 I/Irated,S*** is the minimum possible setting value and ***2.00 I/Irated,S*** the maximum possible. $I_{prim,transf.\ max}$ is the largest transformer current and $I_{rated,protected\ object}$ the protected object rated current. ***100.00 I/Irated,S*** is the upper measurement limit.

If otherwise it could happen that there is chattering of the pickup indication, the minimum threshold limit is lifted. The maximum limit on the other hand is corrected downward, if the exceeding current otherwise through the magnitude scaling must be so large, that it would already be outside of the measuring range of the transformer.

The adaptation of the setting limits is done automatically. In addition a setting is prevented outside of these limits.

In the following, typical applications are described for the restricted ground-fault protection.

Protection of a Solidly Grounded Star Winding (Y Side)

[dwanster-170712-01.tif, 1, en_US]

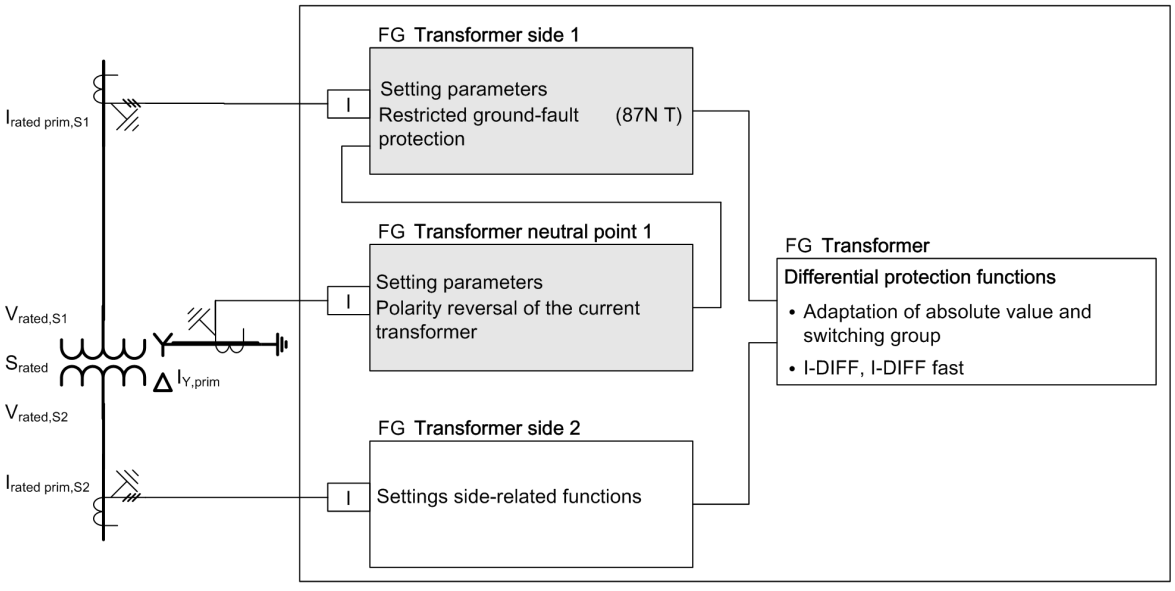


Figure 6-251 Application Star Side

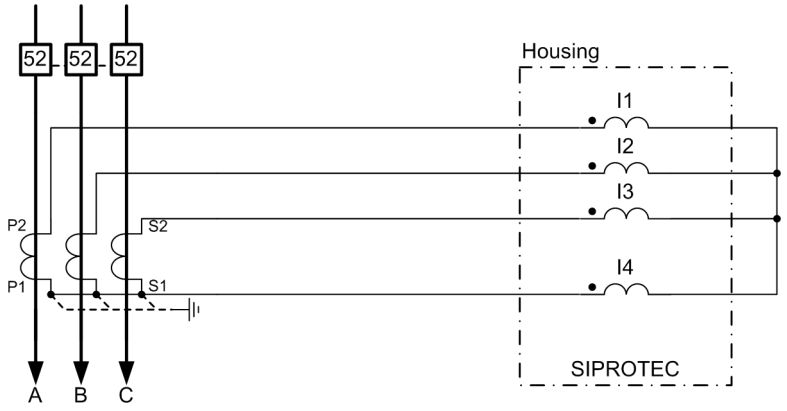
This application is a standard application. Here the phase currents of one side and the neutral-point current are processed. The function is located in the **Transformer Side** function group.

The following figure show the structural division of the function. The restricted ground-fault protection gets its measurands from the current transformers, which are connected to the **Transformer side** function group. The neutral-point current is guided via the **Transformer neutral point** function group to the **Transformer side** function group. To be compatible with SIPROTEC 4 (including reference arrow definition of the restricted ground-fault protection), in addition to the magnitude scaling of the neutral-point current, a rotation of the polarity (phase rotation by 180°) is also done in the **Transformer neutral point** function group.

NOTE

The fault record indicates the analog traces according to the connection. For this reason the neutral-point current is shown rotated by 180° in comparison to SIPROTEC 4.



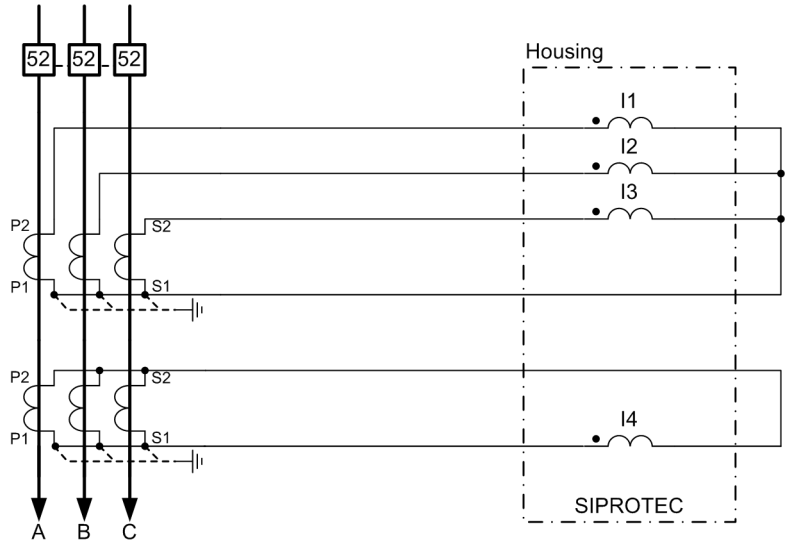
[dw2wtyde-201112-01.tif, 2, en_US]

Figure 6-252 Function Group Structure of the Restricted Ground-Fault Protection

Explanations on the Connection and Current-Direction Definition

Uniform reference arrows and transformer burdens are defined for the SIPROTEC 5 device series. These agreements also apply to the transformer protection devices. The special handling of the neutral-point current described previously is a result of this.

The current definition states that the sum of the currents flowing into the protected object is equal to 0 ($\underline{I}_A + \underline{I}_B + \underline{I}_C + \underline{I}_N = 0$ or $\underline{I}_A + \underline{I}_B + \underline{I}_C = -\underline{I}_N$). The protected object is located to the right or left of the transformer set. The following basic connections result from this.



Current transformer 3-phase: connection = **3-phase + IN**

[tileite2-070211-01.tif, 1, en_US]

Figure 6-253 Current Transformer Connection (1) According to Definition

or

Current transformer 3-phase: connection = **3-phase + IN-separate**

[tileite4-260313-01.tif, 1, en_US]

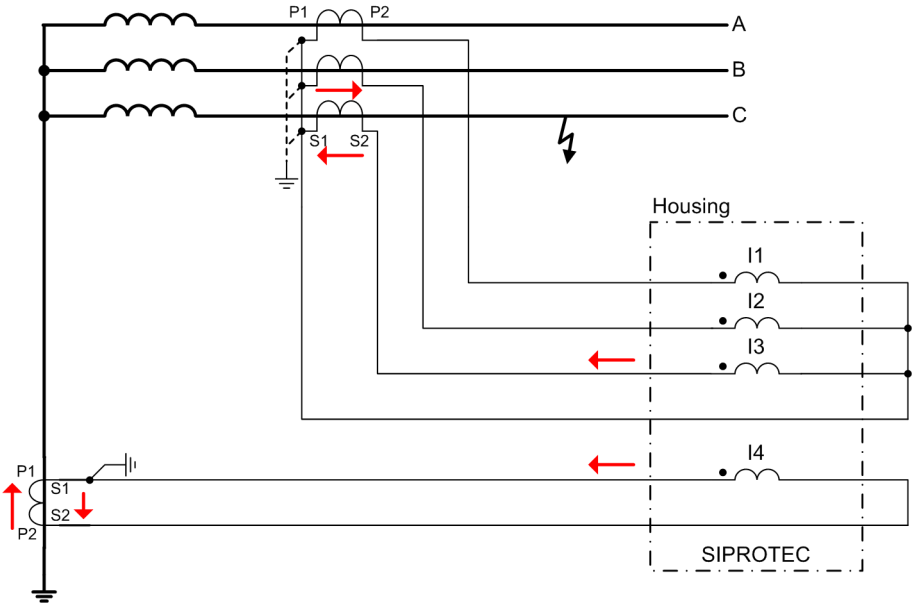


Figure 6-254 Current-Transformer Connection (2) According to Definition

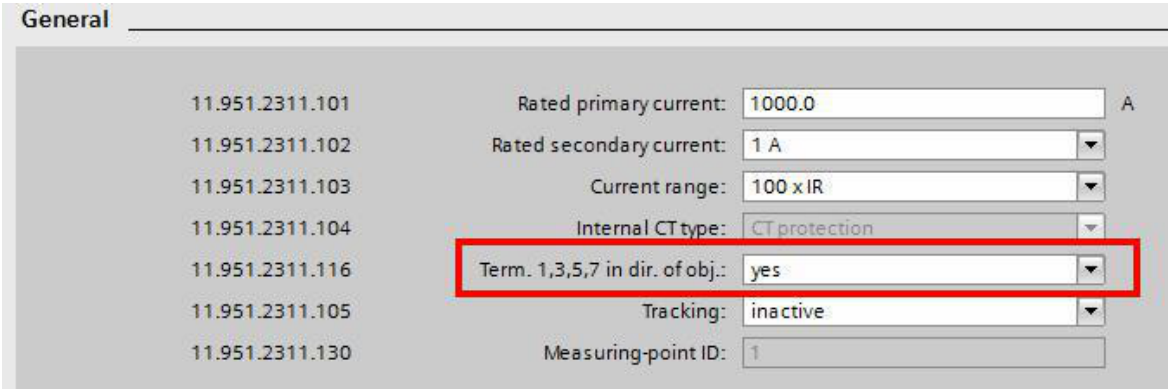
The following connection is defined for the transformer according to *Figure 6-255*. The current flow for an external ground fault is entered at the same time. It is recognized that the secondary currents each flow from the device. From this, a differential current ($I_{diff,REF} = |\underline{I}_Y + \underline{I}_A + \underline{I}_B + \underline{I}_C| = |-\underline{I}_4 - \underline{I}_3|$) results, according to the reference arrow definition for the restricted ground-fault protection (positive to the protected object) with an

external ground fault. To prevent that, the neutral-point current is rotated in the **Transformer neutral-point** function group. It follows that: $I_{Diff, REF} = |\underline{I}_4 - \underline{I}_3| = 0$.

NOTE

If the neutral-point current is included in the protection function (zero-sequence current correction), this rotation also has an effect for the differential protection.



Current transformer 3-phase: connection = **3-phase**

Current transformer 1-phase: connection = **IN**

[dwstwnas-281112-01.tif, 1, en_US]

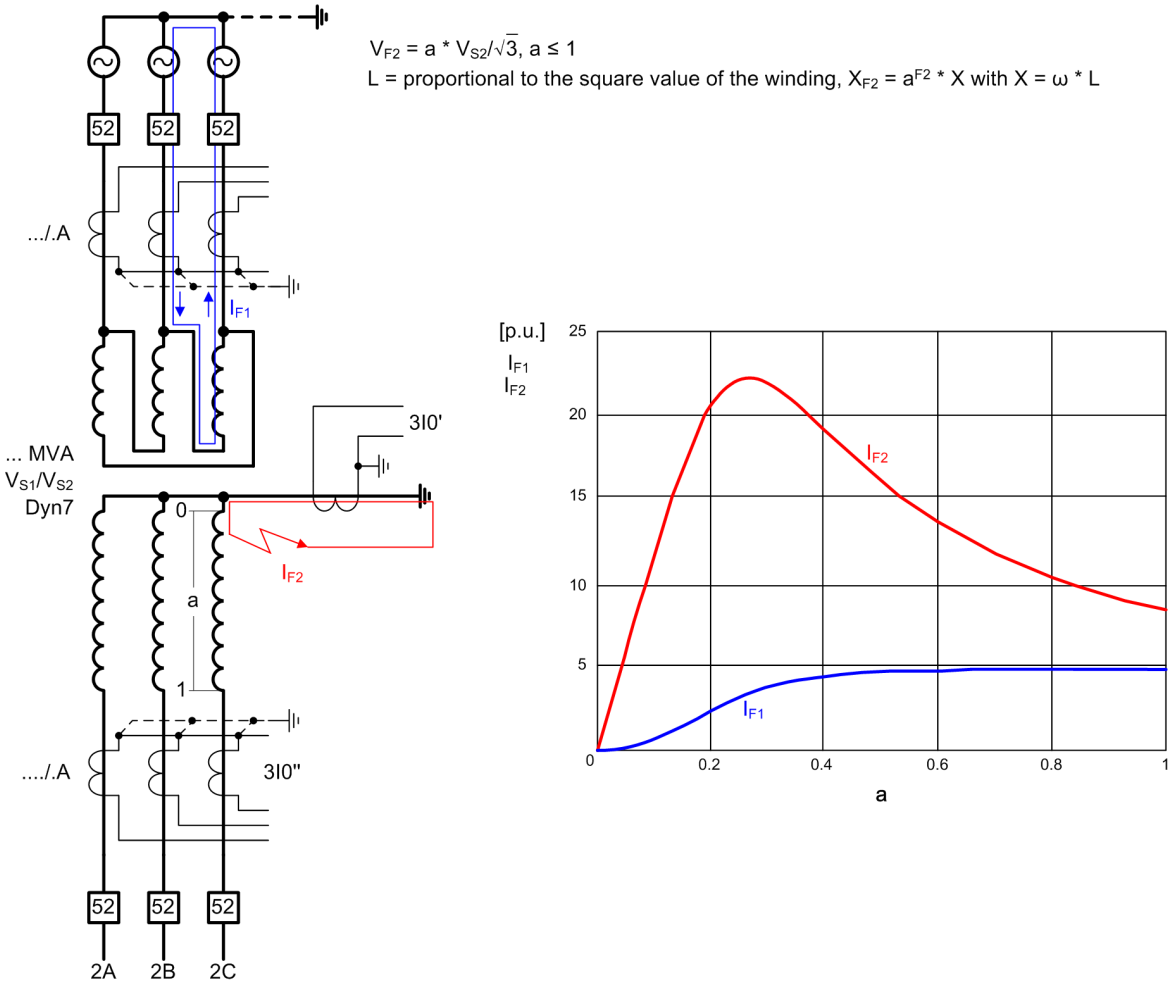
Figure 6-255 Current Transformer Connection on the Transformer

The setting of the 1-phase measuring point based on the definition is done as follows:

[scedsall-200214-01, 1, en_US]

Figure 6-256 DIGSI 5 Setting

The point in *Figure 6-255* describes the polarity of the current transformer. At the same time the current terminal is designed so that this side is fed out on an odd number terminal point. Since in the SIPROTEC 5 system each current transformer can be assigned a 1-phase measuring point, the odd number terminal points are named in the setting parameters. According to *Figure 6-255* the setting must be ***yes***.



- Default setting **(_:115) terminal 1,3,5,7 in dir.obj.** = ***yes***

The following view can be used to derive the threshold value. The transformer is supplied, for example, via the delta winding and a 1-pole ground fault occurs on the star side.

NOTE

For estimation of the short-circuit current, note that the inductance changes quadratically with the winding and the linearly with the voltage.

The right part in the following figure represents the fault current as a function of the fault location. The fault current curve $_{F1}$ shows that the longitudinal differential protection with faults near the neutral point has sensitivity problems due to the sinking current. On the other hand, the neutral-point current $_{F2}$ is sufficiently large. There is therefore no need to set the **Threshold** (current through the neutral point transformer) to sensitive.

[dwf1pole-170712-01.tif, 1, en_US]

Figure 6-257 Principal Fault Current Curves with a 1-Pole Ground Fault

- Recommended setting value **(_:103) Threshold** = ***0.2 I/Irated,S***

The previously mentioned condition must be maintained during the setting.

$$\text{Threshold value} \geq 0.05\ \text{I/Irated, S} \cdot \frac{I_{CT\,max,prim}}{I_{rated,side}}$$

[foschwe1-170712-01.tif, 1, en_US]

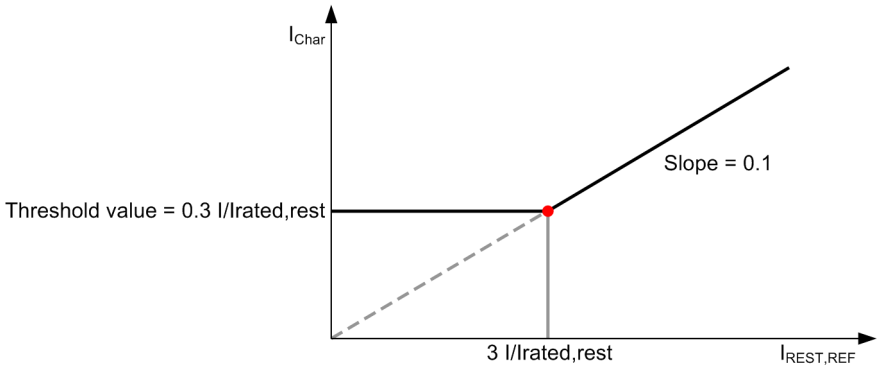
The following lower limiting value results from the data from *Figure 6-251*:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{3000\,\text{A}}{924\,\text{A}} = 0.162\ \text{I/Irated,S}$$

$$\text{with } I_{\text{object,side}} = \frac{S_{\text{rated}}}{\sqrt{3}\ V_{\text{rated}}} = \frac{840\,\text{MVA}}{\sqrt{3}\ 525\text{kV}} = 924\,\text{A}$$

[foschwe2-041012-01.tif, 1, en_US]

The recommended setting value of ***0.2 I/Irated,S*** lies above it.



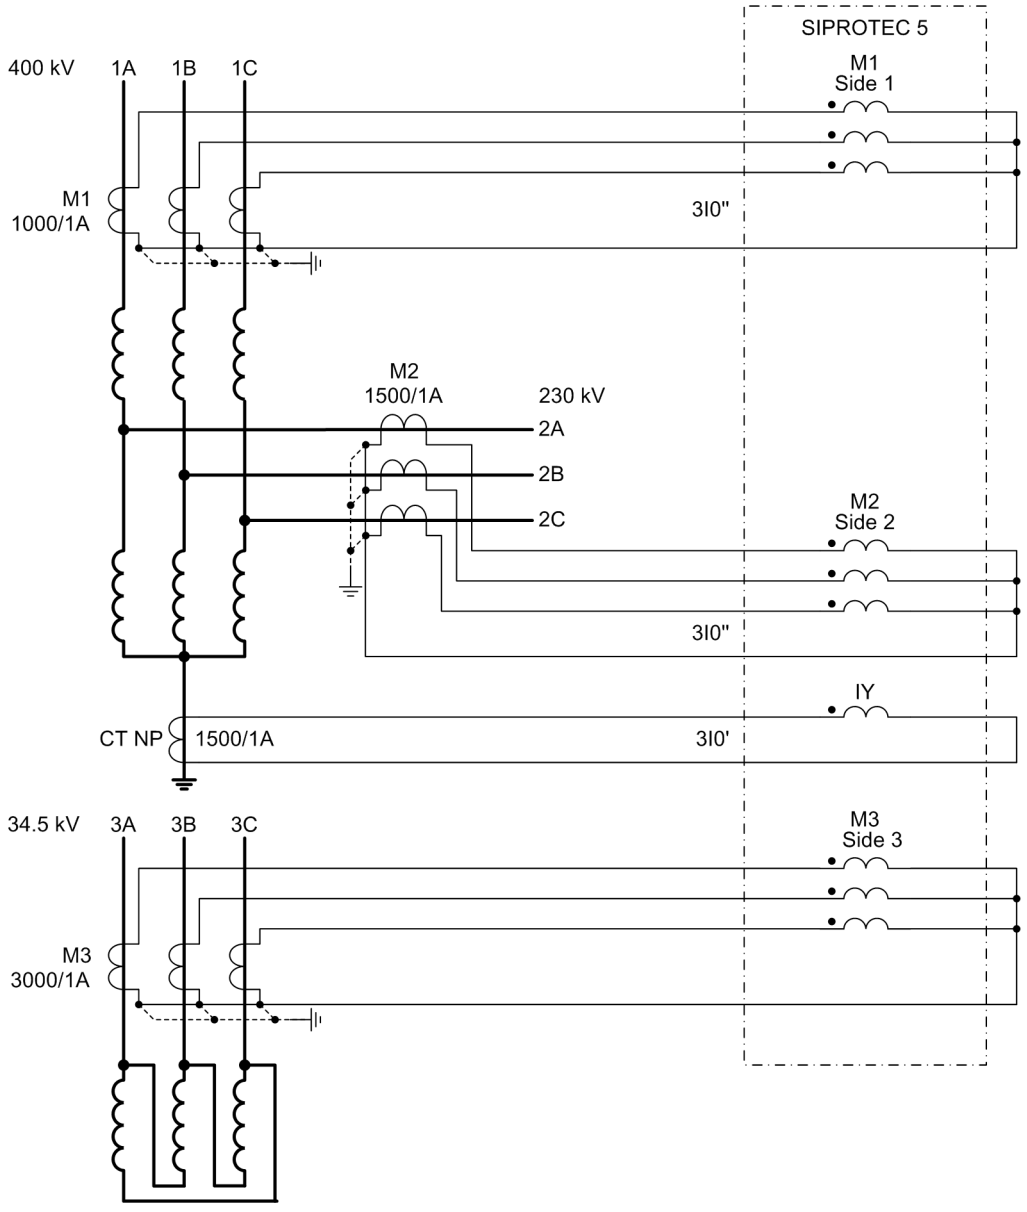
- Recommended setting value **(_:105) Slope** = ***0.07***

You can stabilize the protection function (less sensitive setting) with external multiphase short-circuits to ground with the parameter **Slope**. To determine the setting value, no pickup value increase can occur up to the rated current. After this, the gradient must be active. To derive the gradient, it is assumed that continuation of the straight line must go through the coordinate origin (see *Figure 6-258*). Determine the intersection from the threshold value and the restraint current at rated current. Calculate the gradient as follows:

$$I_{\text{rest,REF}} = \left|I_{:0}^{*}\right| + \left|I_{:A}\right| + \left|I_{:B}\right| + \left|I_{:C}\right| = 0 + 3\ \text{I/Irated, S} = 3\ \text{I/Irated, S}$$

$$\text{Slope} = \frac{\text{Threshold value}}{I_{\text{rest,REF}}} = \frac{0.2\ \text{I/Irated, S}}{3\ \text{I/Irated, S}} = 0.07$$

[fostbref-231012-01.tif, 1, en_US]



[dwsteiga-221012-01.tif, 1, en_US]

Figure 6-258 Derivation of the Setting Value for the Gradient

If you have several measuring points on an outgoing side (see *Figure 6-250*), Siemens recommends using the value **3 I/Irated,S** in the intersection calculation for the restraint current. In the load case, the maximum transformer rated current flows on one side.

If, however, several measuring points are on the supply side (for example, breaker-and-a-half layout), Siemens recommends including all phase currents in the intersection calculation, in order to avoid too strong of a stabilization. With 2 measuring points, a value of **6 I/Irated,S** results as intersection with the threshold value. The slope becomes flatter (**0.2 I/Irated,S/6 I/Irated,S = 0.03**).

Protection of an Auto Transformer

[dwsptran-170712-01.tif, 1, en_US]

Figure 6-259 Activation and Application Example of an Auto Transformer (500 MVA: 400 kV, 230 kV; 125 MVA: 34.5 kV)

Use the highest side rated current with the auto transformer for normalization. In the example (*Figure 6-259*), the measuring point is M2 (230 kV side). For this side, a rated current of 500 MVA/(√(3) · 230 kV) = 1255 A results. The primary transformer rated current is 1500 A. With this, you can estimate the minimum permissible pickup value.

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{I_{\text{CT max,prim}}}{I_{\text{object,side}}} = 0.05\ \text{I/Irated,S} \cdot \frac{1500\text{A}}{1255\text{A}} = 0.06\ \text{I/rated,S}$$

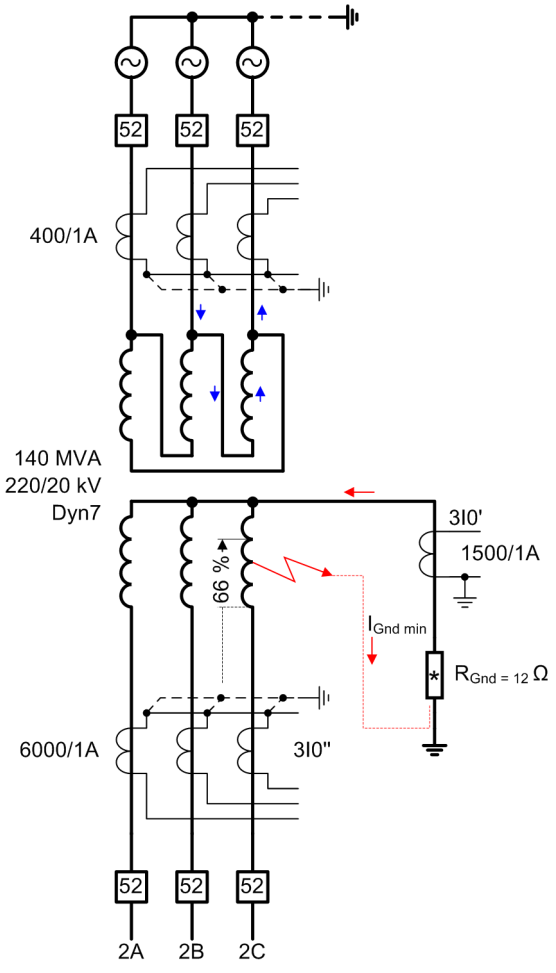
[foscwe01-170712-01.tif, 1, en_US]

Siemens recommends a setting value of **0.2 I/Irated,S**.

- Recommended setting value **(_:103) Threshold** = ***0.2 I/Irated,S***

To determine the **Slope**, the restraint current of both sides (400 kV and 230 kV) must be used. The rated current is used as starting value for the gradient. Since side 2 (230 kV) is the reference side for the normalization, the value of the 400 kV side must be adapted to this rated current. The adaptation factor results from the inverse ratio (230 kV/400 kV). The following restraint current goes into the calculation:

$$I_{rest,REF} = 3\ I/Irated,S2 + 3\frac{230\,kV}{400\,kV}\ I/Irated,S2 = 3\ I/Irated,S2 + 1.725\ I/Irated,S2 = 4.73\ I/Irated,S$$



$$Slope = \frac{Threshold\ value}{I_{rest,REF}} = \frac{0.2\ I/Irated,S}{4.73\ I/Irated,S} \approx 0.042$$

[fostbrst-231012-01.tif, 1, en_US]

Siemens recommends using the setting 0.07.

- Recommended setting value **(_:105) Slope** = ***0.07***

Protection of a Resistance-Grounded Star Winding (Y Side)

[dwrefspa-170712-01.tif, 1, en_US]

Figure 6-260 Application with Resistance-Grounded Neutral Point

To also capture faults in the resistance to ground, a current transformer must be installed at the neutral point of the protected object (see *Figure 6-260*). The pickup values can be derived from the data in the example. As side rated value, the following results:

140 MVA/(√3 · 20 kV) = 4042 A

The following threshold value results as lower limit:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{6000\,\text{A}}{4042\,\text{A}} = 0.07422\ \text{I/Irated,S}$$

$$\text{with } I_{\text{object,side}} = \frac{S_{\text{rated}}}{\sqrt{3} \cdot V_{\text{rated}}} = \frac{840\text{MVA}}{\sqrt{3} \cdot 525\text{kV}} = 924\,\text{A}$$

[foschwe3-170712-01.tif, 1, en_US]

So that the function is responsive, select a setting value of 0.08 I/Irated,S.

- Recommended setting value **(_:103) Threshold** = ***0.08 I/Irated,S***

As gradient, the following results:

$$\text{Slope} = \frac{\text{Threshold value}}{I_{\text{rest,REF}}} = \frac{0.08\ \text{I/Irated,S}}{3\ \text{I/Irated,S}} \approx 0.03$$

[fosteig1-170712-01.tif, 1, en_US]

- Recommended setting value **(_:105) Slope** = ***0.03***

Because of the grounding resistance R_E reduced protection range results. This can be estimated as follows: The grounding resistance is much larger than the winding reactance, thus the following maximum ground current results:

$I_{\text{Gnd max}}$ = 20 kV/(√3 · 12 Ω) = 962 A

You can determine the minimum tripping current from the setting value:

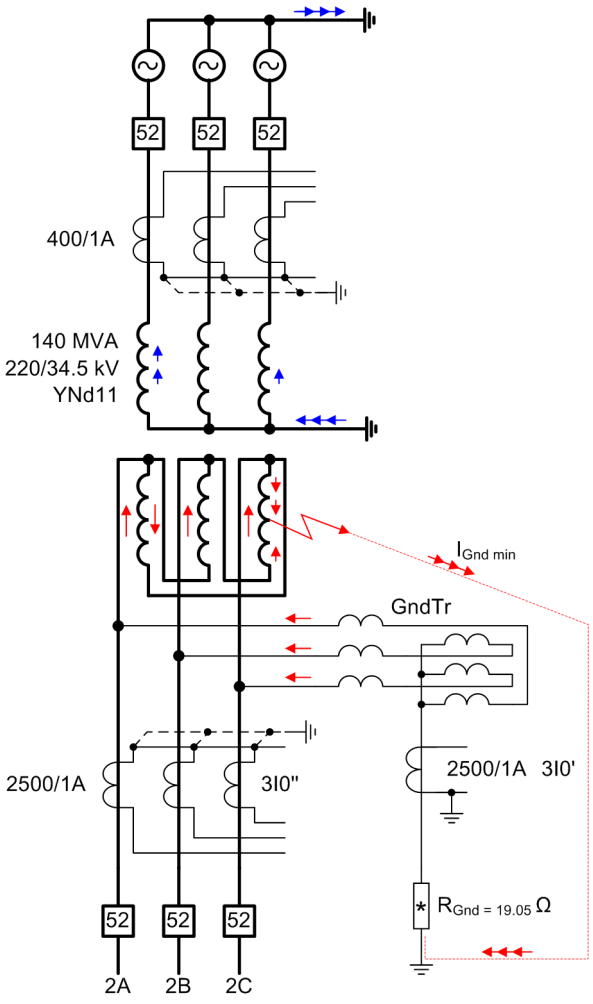
$I_{\text{Gnd min}}$ = side rated current * threshold value = 4042 A · 0.08 = 323 A

Thus, the following protection range results:

$$\text{Protection range} = 1 - \frac{I_{\text{gnd min}}}{I_{\text{gnd max}}} = 1 - \frac{323\,\text{A}}{962\,\text{A}} = 0.664$$

[foschwe4-170712-01.tif, 1, en_US]

The attainable protection range amounts to approx. 66.4 %. In order to capture ground faults near the neutral point, it is also recommended to connect a sensitive ground current protection to the neutral point transformer. You must coordinate its operate time with the line protection.



NOTE

Ensure that the protection range further limits itself with larger neutral-point resistances, or the restricted ground-fault protection can no longer be used.

Protection with Neutral Reactors on the Delta Side

To produce ground currents on the delta side of a transformer, neutral reactors (zigzag reactors) are used. A resistance for ground current limitation can also be present. In this case, the resistance is much greater than the reactor and delta reactance of the transformer. The following figure shows a typical implementation. The restricted ground-fault protection works between output-sided phase current transformers and the current transformer in the neutral point of the neutral reactor.

In the example, the fault current curve with the ground fault in a delta winding is also represented. The fault location in which the lowest fault current flows can also be seen. This current influences the protection setting set close.

[dwstrpkt-170712-01.tif, 1, en_US]

Figure 6-261 Application with Neutral Reactor

As side rated value, the following results:

140 MVA/($\sqrt{3}$ · 34.4 kV) = 2343 A

You can thus define the lower limit for the threshold value:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{2500\ \text{A}}{2343\ \text{A}} = 0.06\ \text{I/Irated,S}$$

[foschwe5-170712-01.tif, 1, en_US]

If the fault is in the middle of the winding, the minimum ground current will arise, as shown in *Figure 6-261*. The driving voltage is:

$V_{Gnd\ min} = V_{rated,S2}/(2\sqrt{3}) = 34.5\ kV/(2\sqrt{3}) = 9.96\ kV$

The following minimum ground current results:

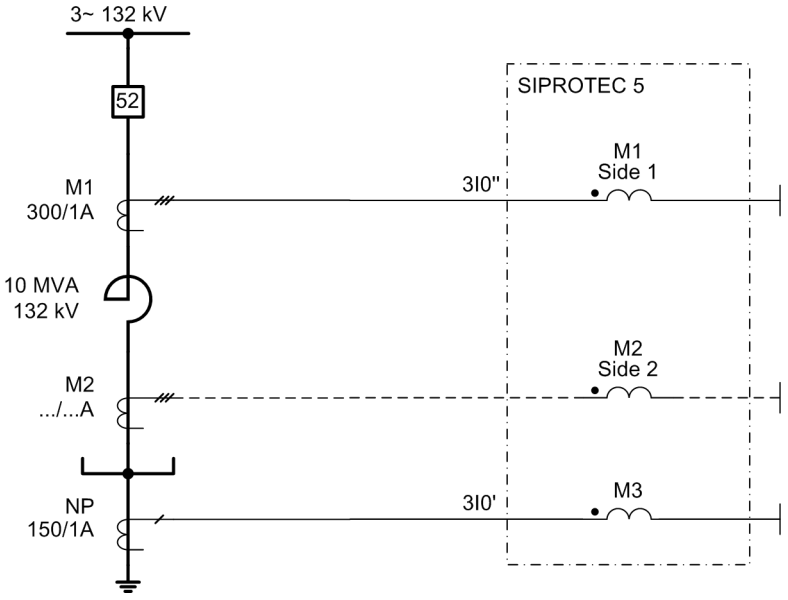
$I_{Gnd\ min} = V_{Gnd\ min}/R_{Gnd} = 9.96\ kV/19.05\ \Omega = 523\ A$

With reference to the side rated current, the relationship is:

$I_{Gnd\ min}/I_{rated,S} = 523\ A/2343\ A = 0.223$

With a safety margin of 2, 0.223/2 = 0.1115 results. Select this value as threshold value (rounded: 0.12 I/Irated,S).

- Recommended setting value **(_:103) Threshold** = ***0.12 I/Irated,S***



As gradient, the following results:

$$\text{Slope} = \frac{\text{Threshold value}}{I_{rest,REF}} = \frac{0.12\ I/I_{rated,S}}{3\ I/I_{rated,S}} \approx 0.04$$

[fosteig2-170712-01.tif, 1, en_US]

- Recommended setting value **(_:105) Slope** = ***0.04***

Protection of a Shunt Reactor

[dwanquer-170712-01.tif, 1, en_US]

Figure 6-262 Application with Neutral Reactor

As side rated value, the following results:

10 MVA/($\sqrt{3}$ · 132 kV) = 43.7 A

You can thus define the lower limit for the threshold value:

$$\text{Threshold value} \geq 0.05\ I/I_{rated,S} \cdot \frac{300\ A}{43.7\ A} = 0.343\ I/I_{rated,S}$$

[foschwe6-170712-01.tif, 1, en_US]

Select 0.35 I/Irated,S as threshold value.

- Recommended setting value **(_:103) Threshold** = ***0.35 I/Irated,S***

For the shunt reactor, there is no external fault that can lead to overfunction. Siemens recommends a minimum rise (0.05).

- Recommended setting value **(_:105) Slope** = ***0.05***

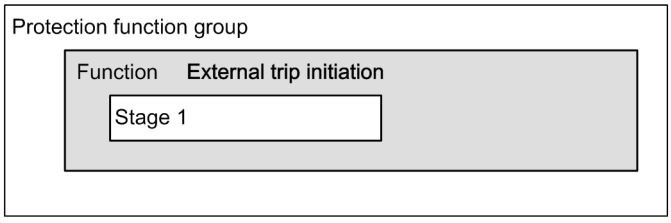
6.42 External Trip Initiation 3-Pole



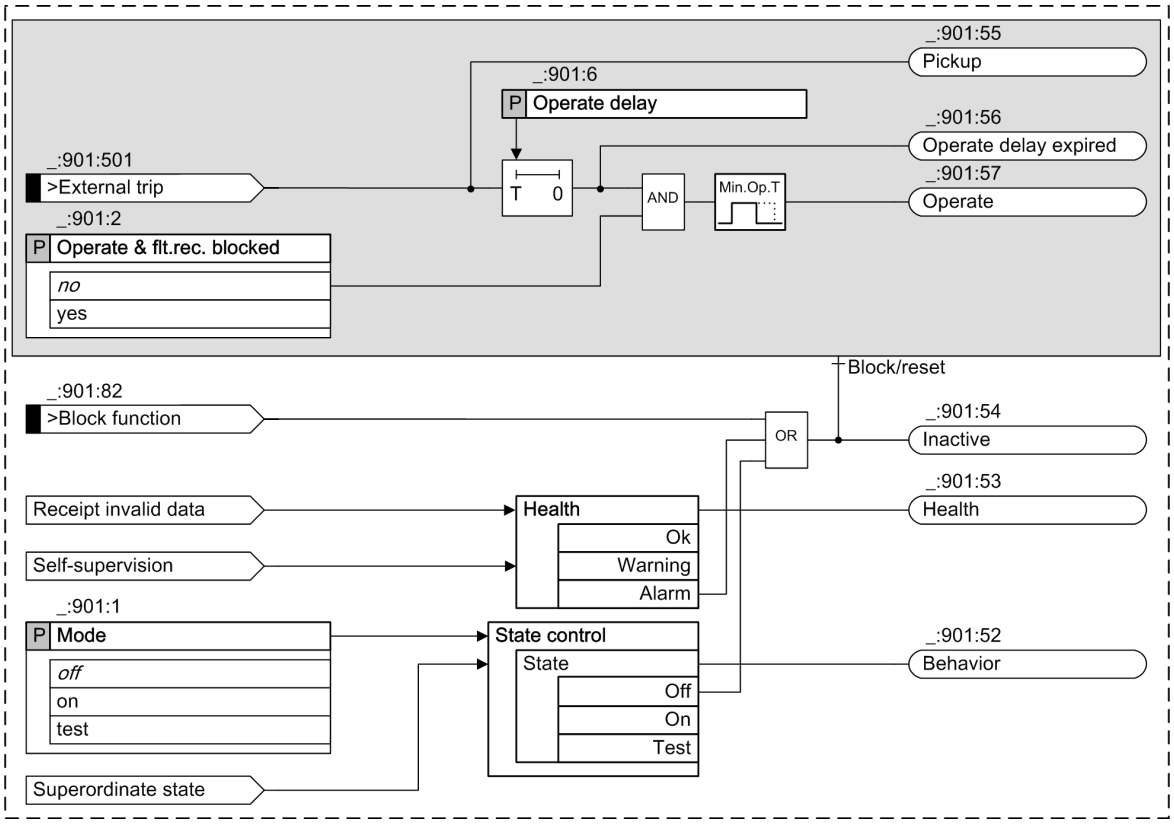
6.42.1 Overview of Functions

The **External trip initiation** function:

- Processes any signals from external protection or supervision devices
- Enables the integration of any signals from external protection equipment in the indication and tripping processing, for example from transient ground-fault relays or Buchholz protection
- Enables direct tripping of the circuit breaker in conjunction with busbar-protection applications
- Enables direct tripping of the circuit-breaker in the case of circuit-breaker failure at the other line end

6.42.2 Structure of the Function

The **External trip initiation** function contains one step. The **External trip initiation** function can be instantiated in DIGSI 5 multiple times.



[dwstrext-030211-01.tif, 1, en_US]

Figure 6-263 Structure/Embedding of the Function

6.42.3 Stage Description

Logic of the Stage

[lotrip3p-070611-01.tif, 1, en_US]

Figure 6-264 Logic Diagram for the External Trip-Initiation Stage

Binary Input Signal >External Trip

The binary input signal **>External trip** starts the **Pickup** and the **Operate delay**.

Blocking the Stage

The stage can be switched to ineffective via a number of signals. If the stage is in the pickup state at the time of blocking, it will be immediately reset. However, the operate indication remains stopped for the minimum operating time **(_:102) Minimum operate time**.

6.42.4 Application and Setting Notes

Parameter: Operate delay

- Recommended setting value **(_:901:6) Operate delay** = ***0.05 s***

The **Operate delay** parameter must be set for the specific application. After expiry of the **Operate delay** the time expiry and tripping are signaled. The duration of the initiation signal as well as the adjustable minimum command time determine the signal duration of the **Operate**.

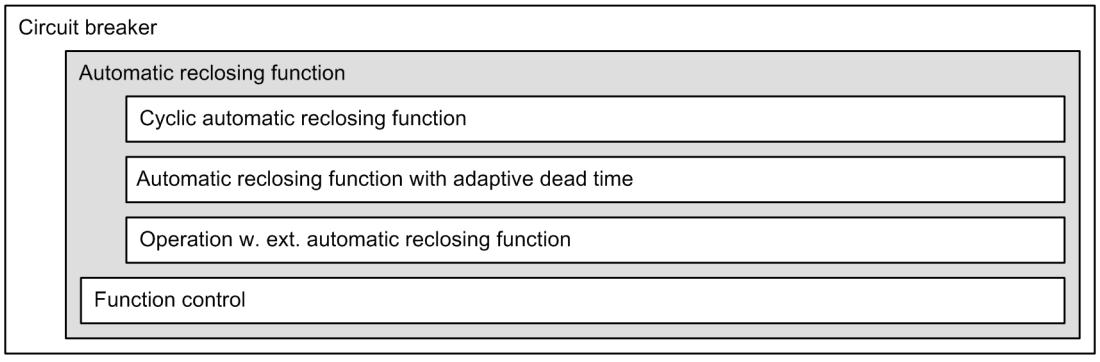
6.43 Automatic Reclosing Function

6.43.1 Overview of Functions

The Automatic reclosing function:

- Automatically closes overhead lines after arc short-circuits
- Is only permissible for overhead lines, because only the possibility of self-activated extinguishing of an arc short-circuit exists here
- Can be controlled by integrated protection functions and by external protection devices
- The automatic reclosing can occur through an external automatic reclosing function via binary inputs.

The automatic reclosing after switching off through a short-circuit protection is taken over by the automatic reclosing function (AREC). The following figure shows an example for the normal procedure with a two-time automatic reclosing where the second automatic reclosing attempt is successful.



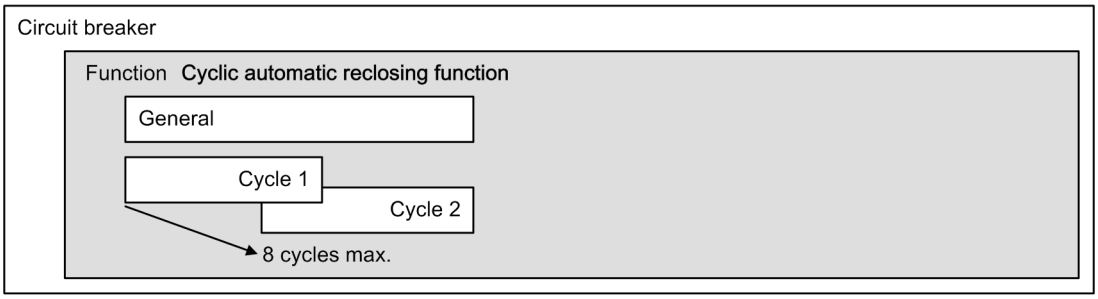
[dw2awewz-090210-01.tif, 1, en_US]

Figure 6-265 Process Diagram of a Two-Time Reclosing With Action Time (2nd Reclosing Successful)

The integrated Automatic reclosing function allows for up to 8 reclosing attempts. Each of the 8 disruption cycles can work with different parameters.

6.43.2 Structure of the Function

The automatic reclosing function is used in function groups for circuit breakers. In a function group for circuit breakers, one of the 3 types of functions illustrated in the following figures can be used. The Automatic reclosing function has a central function control.



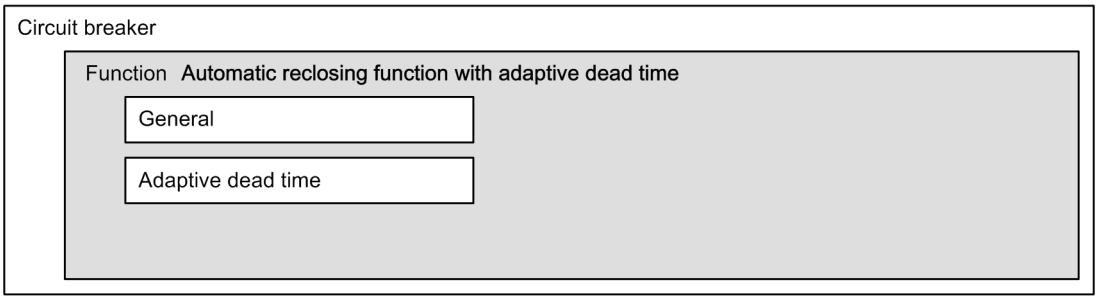
[dwfktawe-100611-01.tif, 1, en_US]

Figure 6-266 Structure/Embedding of the Function

Cyclic Automatic Reclosing Function

The Cyclic automatic reclosing function (*Figure 6-267*) allows for up to 8 reclosing attempts. Here each disruption cycle may work with different settings.

For the Cyclic automatic reclosing function, 1 cycle is preset. The preset cycle cannot be deleted. You can add and delete additional cycles from the function library in DIGSI 5.

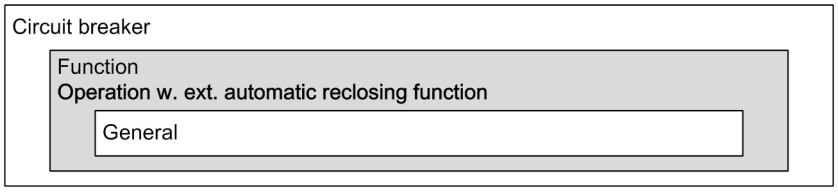


[dwzykawe-100611-01.tif, 1, en_US]

Figure 6-267 Structure/Embedding of the Cyclic Automatic Reclosing Function

Automatic Reclosing Function with Adaptive Dead Time

The Automatic reclosing function with adaptive dead time (ADT) works without fixed disruption cycles (*Figure 6-268*). The requirement for the usage of ADT is that voltage transformers on the line-side are connected or there is a possibility to transfer a close command to a remote line end. With the ADT, the Automatic reclosing function decides independently if and when an automatic reclosing is reasonable and permissible and when it is not. The criteria is the phase-to-ground voltage, which is switched through after reclosing from the opposite line end. The Automatic reclosing function with ADT occurs as soon as it is known that the line from the opposite end has been placed back under voltage.

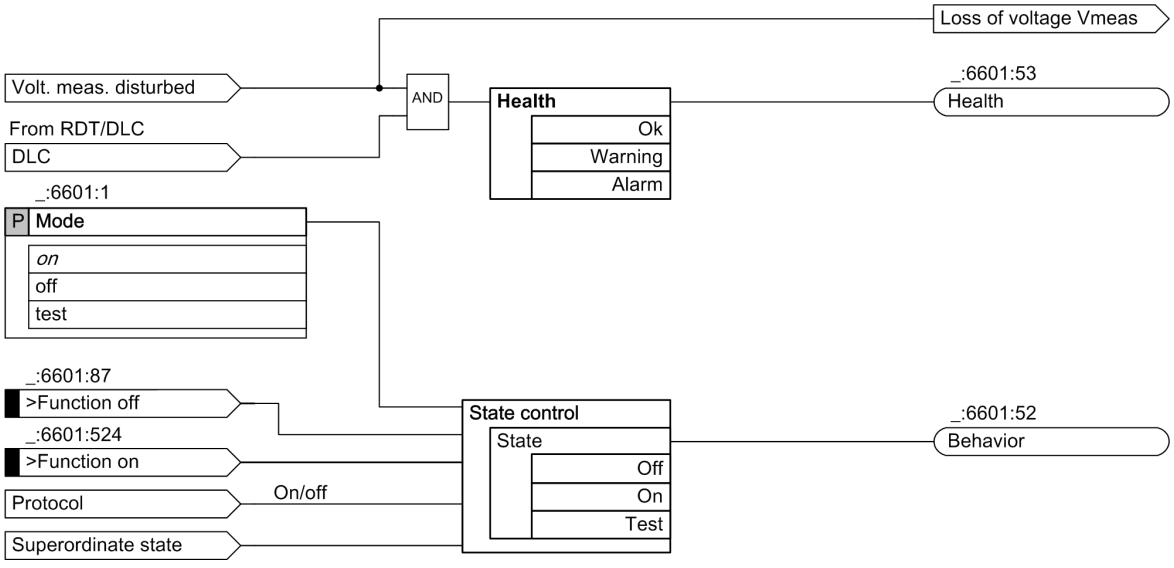


[dwaweasp-100611-01.tif, 1, en_US]

Figure 6-268 Structure/Embedding of the Automatic Reclosing Function With Adaptive Dead Time (ADT)

Operation with External Automatic Reclosing Function

The cooperation of an external reclosing device with the SIPROTEC protection device occurs through the function mode **Operation with external automatic reclosing function** (*Figure 6-269*). The function only provides binary inputs for the influence of the protection functions in the SIPROTEC protection device. The external automatic reclosing device delivers the close command. The SIPROTEC protection functions then provide for the trip commands.



[dwextawe-100611-01.tif, 1, en_US]

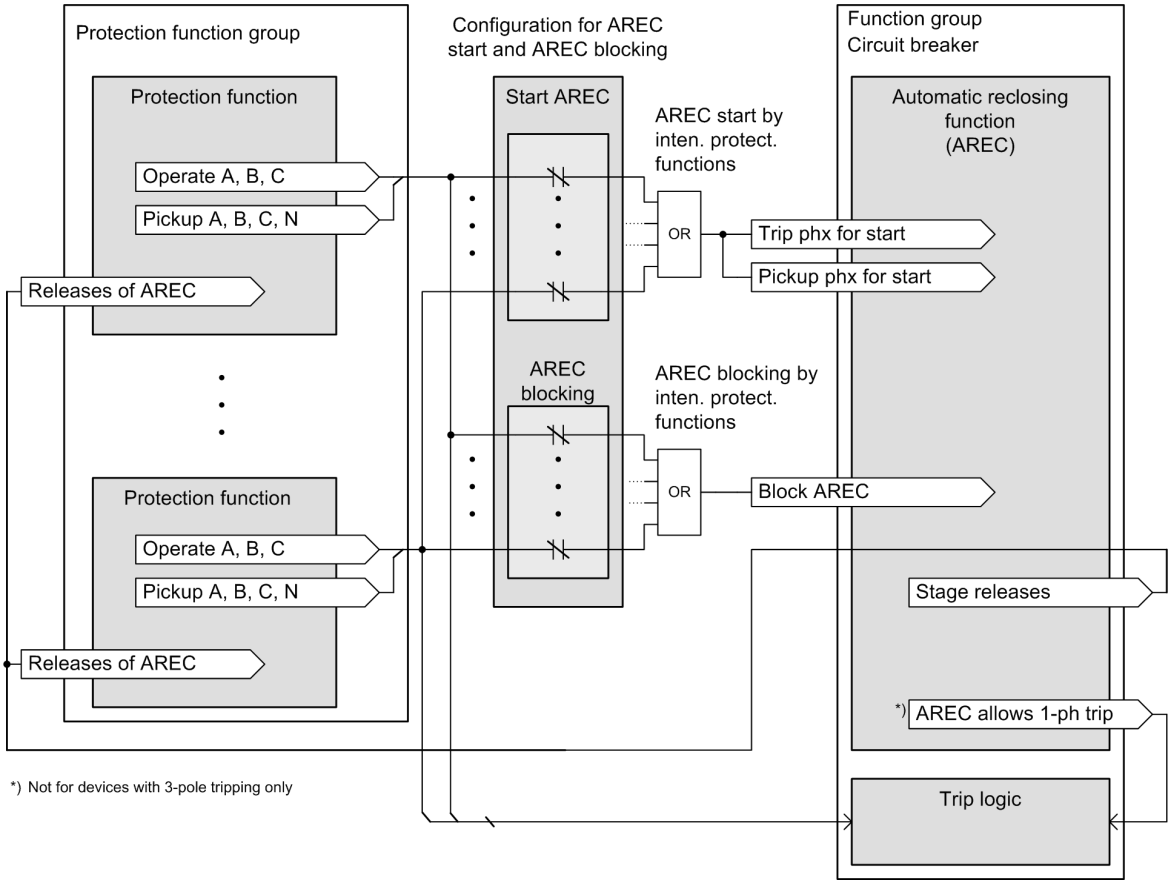
Figure 6-269 Structure/Embedding of the Operating Function With External Automatic Reclosing Function

Function Control

The automatic reclosing function contains a central function control, see the following figure. You can find detailed information on the function control in the section **Function/Stage Control**.

[loarcfkt-090211-01.tif, 1, en_US]

Figure 6-270 Function Control for the Automatic Reclosing Function

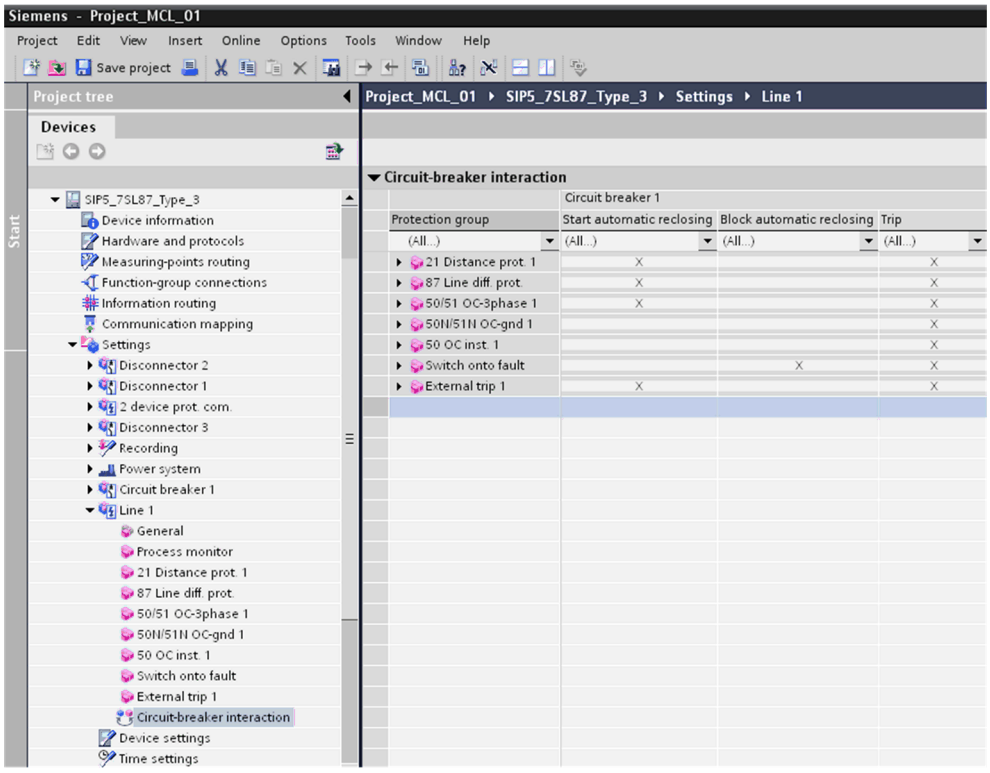


6.43.3 Cooperation of the Automatic Reclosing Function and Protection Functions

The Automatic reclosing function (AREC) can be influenced by the protection functions in the following way:

- The AREC is started through pickup indications and operate indications by the selected protection functions or protection stages. The start is independent of the set operating mode for the AREC.
- Individual protection functions or protection stages can be configured so that their operate indication blocks the AREC. If such a blocking exists, the AREC cannot be started. If the AREC is already started, the blocking will lead to the cancellation of the AREC.

The automatic reclosing device can thus have an influence on the effects of the protection functions. The following influence possibilities exist:



- The AREC provides signals that can be used by protection functions for the blocking or release of special stages or zones. An example is the release of overreaching zones with distance protection.

[loawesig-190912-01.tif, 1, en_US]

Figure 6-271 Signals between Protection Functions and Automatic Reclosing Functions

The configuration of the interaction between internal protection functions and automatic reclosing functions can be set separately for each protection function, see *Figure 6-271*. The configuration occurs in a matrix view in DIGSI, see the following figure..

[scdigsia-080311-01.tif, 1, en_US]

Figure 6-272 Configuration of the Protection Functions for Starting and Blocking the Automatic Reclosing Function in DIGSI 5

If a protection function or the stage of a protection function is connected with the AREC through the matrix, this means that the respective pickup and operate indications are forwarded to the AREC.

The links can be conducted separately

- For starting the automatic reclosing function and
- For the blocking of the automatic reclosing function

The Automatic reclosing function also has the corresponding binary inputs and binary outputs through which the external protection devices can be connected to the internal Automatic reclosing function.

6.43.4 Cyclic Automatic Reclosing Function

6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function

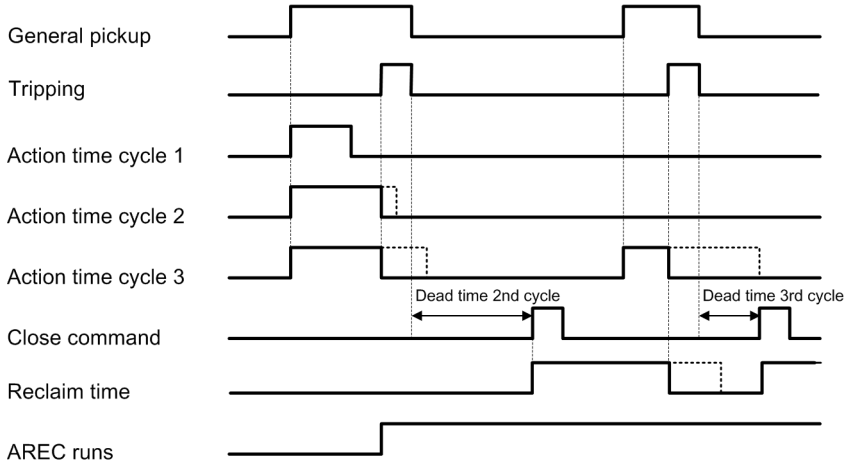
For the cyclic automatic reclosing function, there are 4 operating modes, from which one can be selected for the parameterization (parameter **(_:6601:101) 79 operating mode**).

The selection of the operating mode is dependent on the tripping behavior of the protection functions and the circuit breaker.

For applications with 3-pole tripping, all 4 operating modes are available.

- Operating mode 1: ***with op., with act. time***
- Operating mode 2: ***w.pickup, w. action time***
- Operating mode 3: ***with op., w/o act. time***
- Operating mode 4: ***w.pickup, w/o act. time***

Operating Mode 1: with op., with act. time



The operating mode ***with op., with act. time*** allows different automatic reclosing cycles depending on the tripping type and operate time of the protection function(s). With this operating mode, the automatic reclosing must be started with the operate indications. Additionally, the general pickup must also be considered.

With raising general pickup, the action times of the configured automatic reclosing cycles start. The general pickup is in this connection the group indication of all internal protection functions configured for starting the automatic reclosing and the external binary input for general pickup *>Gen. pickup for start*.

Through the time between the raising general pickup and clearing operate indication, the automatic reclosing cycle to be started will be determined. Here for multiple automatic reclosing cycles, the sequence of the expiring automatic reclosing cycles is not fixed, like the operating modes without action time.

The following example in *Figure 6-273* shows a tripping that comes after expiration of the action time of cycle 1, but still before the expiration of the action times from cycle 2 and cycle 3. Cycle 2 is now active.

Within the following reclaim time, there will be another pickup and tripping. Since cycle 2 is already complete, these and all lower cycles are no longer able to expire. The 2nd operate indication comes during the running action time of cycle 3. Thus, cycle 3 is now active.

[dwarce1d-190912-01.tif, 1, en_US]

Figure 6-273 Operating-Mode Signal Examples: With Tripping/With Action Time

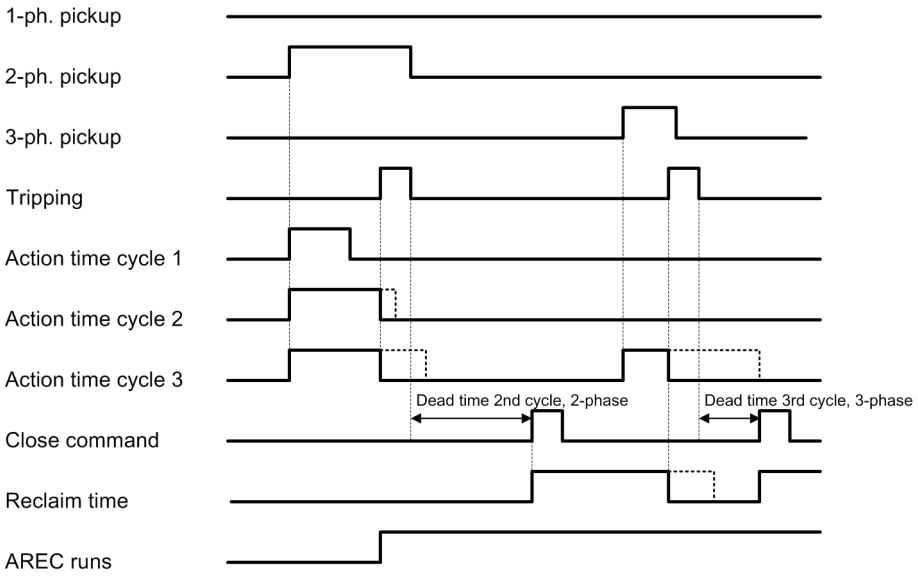
Through the action time, there is a direct influence on the dead time behavior of the automatic reclosing function. With faults with short operate times, other dead times can be realized than for removed faults with longer tripping time. With faults with short operate time, an automatic reclosing is executed, with removed faults this does not occur with longer operate time. The operating mode ***with op., with act. time*** allows for different automatic reclosing cycles depending on the operate time of the protection function(s).

Operating Mode 2: w.pickup, w. action time

The operating mode ***w.pickup, w. action time*** allows different automatic reclosing cycles depending on the operate time and type of fault. It is only suitable and applicable for applications with 3-pole tripping.

With this operating mode, the automatic reclosing must be started with the operate indications from the protection functions. Additionally, the pickup sample from the conductor pickups and the general pickup are considered:

- With 1-phase pickup, the automatic reclosing cycles set for 1-phase dead times are activated. 1-phase pickup includes both pickup samples **phase-to-ground** and **only grounding**.
- With 2-phase pickup, the automatic reclosing cycles set for 2-phase dead times are activated.
- With 3-phase pickup, the automatic reclosing cycles set for 3-phase dead times are activated.



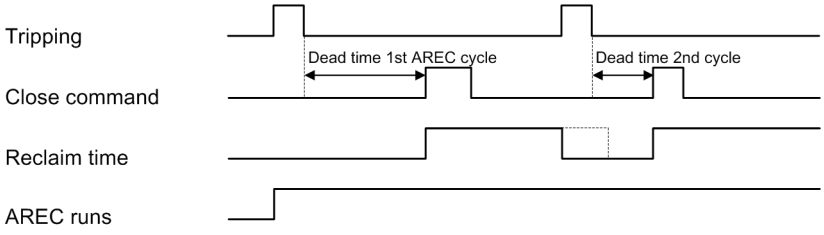
With each automatic reclosing cycle, it is checked to see if it is a 1-phase, 2-phase or 3-phase pickup.

With raising general pickup, the action times of the configured automatic reclosing cycles start. The general pickup is in this connection the group indication of all internal protection functions configured for starting the automatic reclosing and the external binary input for general pickup *>Gen. pickup for start*.

Through the time between the raising general pickup and raising trip command, the automatic reclosing cycle to be started will be determined. Here for multiple automatic reclosing cycles, the sequence of the expiring automatic reclosing cycles is not fixed, like the operating modes without action time.

The following example shows a tripping that comes after expiration of the action time of cycle 1, but still before the expiration of the action times from cycle 2 and cycle 3. Since it is a 2-phase pickup, cycle 2 is active with the dead-time setting for 2-phase faults.

After reclosing, there will be another, this time 3-phase, pickup and tripping within the following reclaim time. Since cycle 2 is already complete, these and all lower cycles are no longer able to expire. The trip command comes during the current action time of cycle 3. Thus, cycle 3 is active, with the dead time setting for 3-phase faults.



[dwarcbm2-190912-01.tif, 1, en_US]

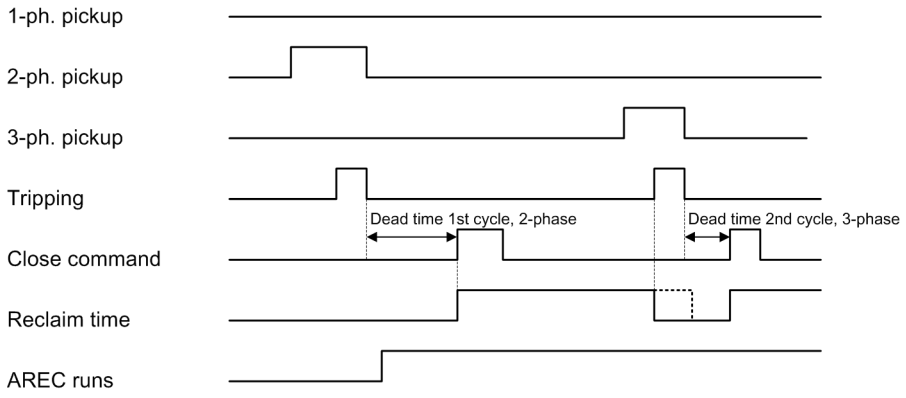
Figure 6-274 Operating-Mode Signal Examples: With Pickup/With Action Time

Operating Mode 3: with op., w/o act. time

With the operating mode ***with op., w/o act. time***, the respective dead time is started after each trip command. The pickups are not considered. If more than one automatic reclosing cycle is configured, the sequence of the expiring automatic reclosing cycles is identical with the cycle number (1, 2, and 3.).

[dwaweb3d-240810-01.tif, 1, en_US]

Figure 6-275 Operating-Mode Signal Examples: With Tripping/Without Action Time



Operating Mode 4: w.pickup, w/o act. time

With the operating mode ***w.pickup, w/o act. time***, the automatic reclosing must be started with the operate indications from the protection functions. It is only suitable and applicable for applications with 3-pole tripping.

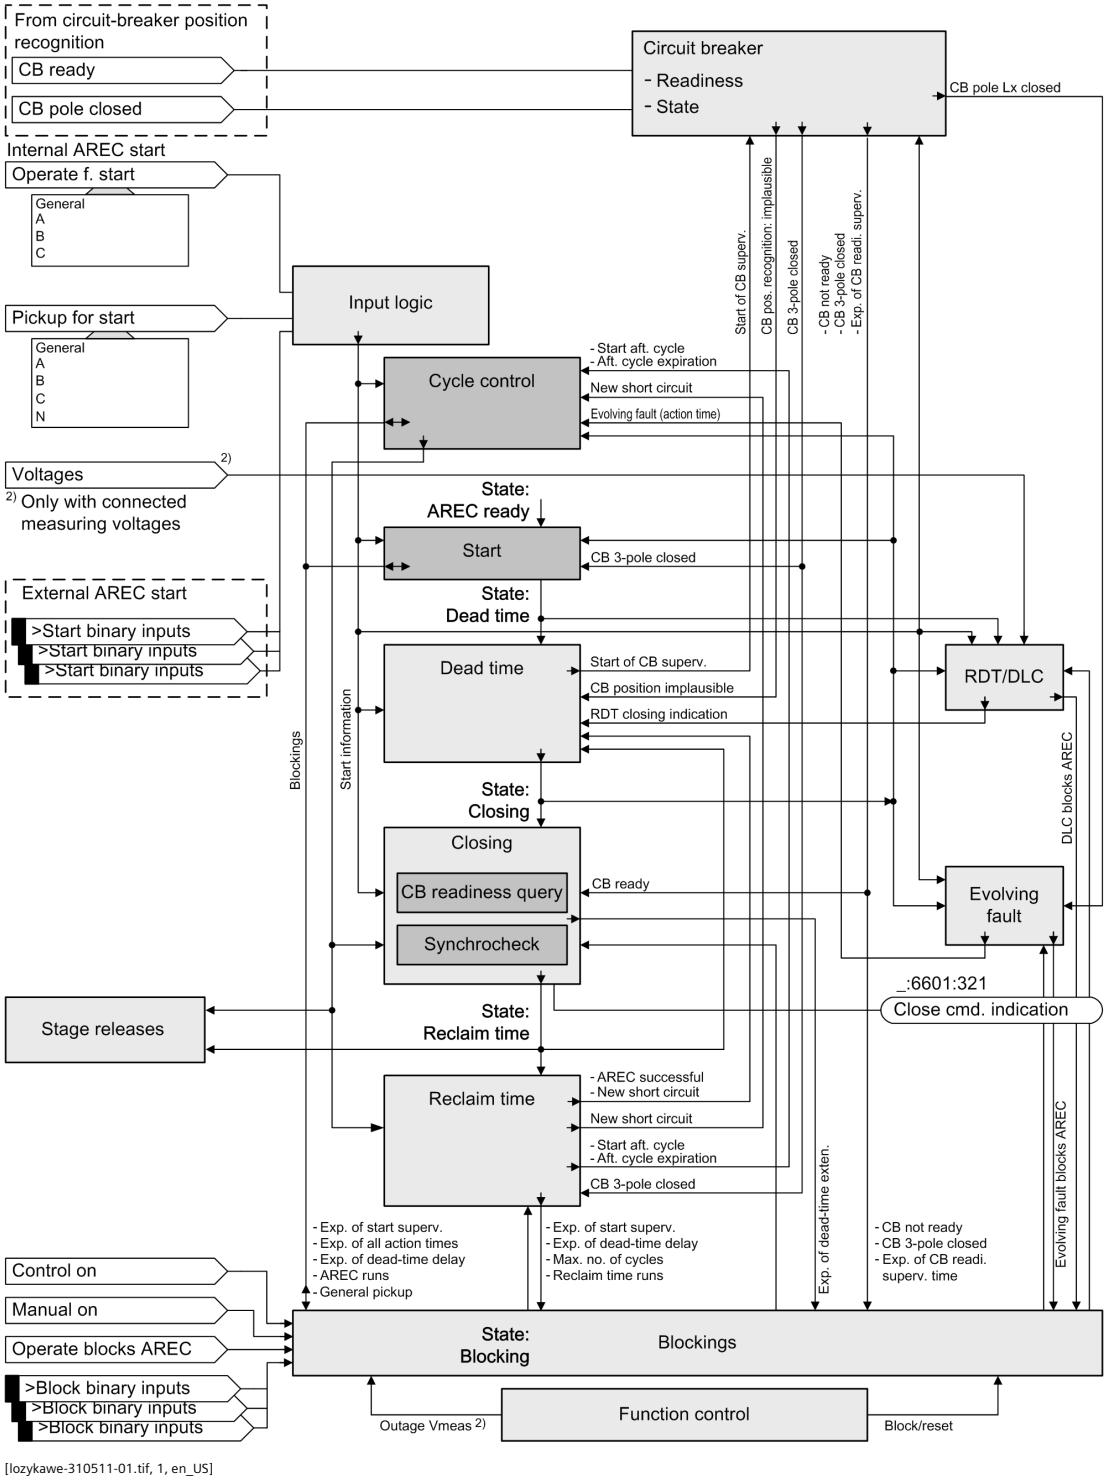
The start of the dead time occurs after each trip command. Additionally, the pickup sample from the conductor pickups is considered:

- With 1-phase pickup, the automatic reclosing cycles set for 1-phase dead times are activated. 1-phase pickup includes both pickup samples **phase-to-ground** and **only grounding**.
- With 2-phase pickup, the automatic reclosing cycles set for 2-phase dead times are activated.
- With 3-phase pickup, the automatic reclosing cycles set for 3-phase dead times are activated.

With each automatic reclosing cycle, it is checked to see if it is a 1-phase, 2-phase or 3-phase pickup. If more than one automatic reclosing cycle is configured, the sequence of the expiring automatic reclosing cycles is identical with the cycle number (1, 2, 3, etc.).

[dwarcbs4-170311-01.tif, 1, en_US]

Figure 6-276 Operating-Mode Signal Examples: With Pickup/Without Action Time



6.43.4.2 Structure of the Cyclic Automatic Reclosing Function

In *Figure 6-277*, the functional structure of the cyclic automatic reclosing function is illustrated as a block diagram. The figure displays the important signals, coming from outside of the cyclic automatic reclosing function, and the most important signals between the individual function blocks.

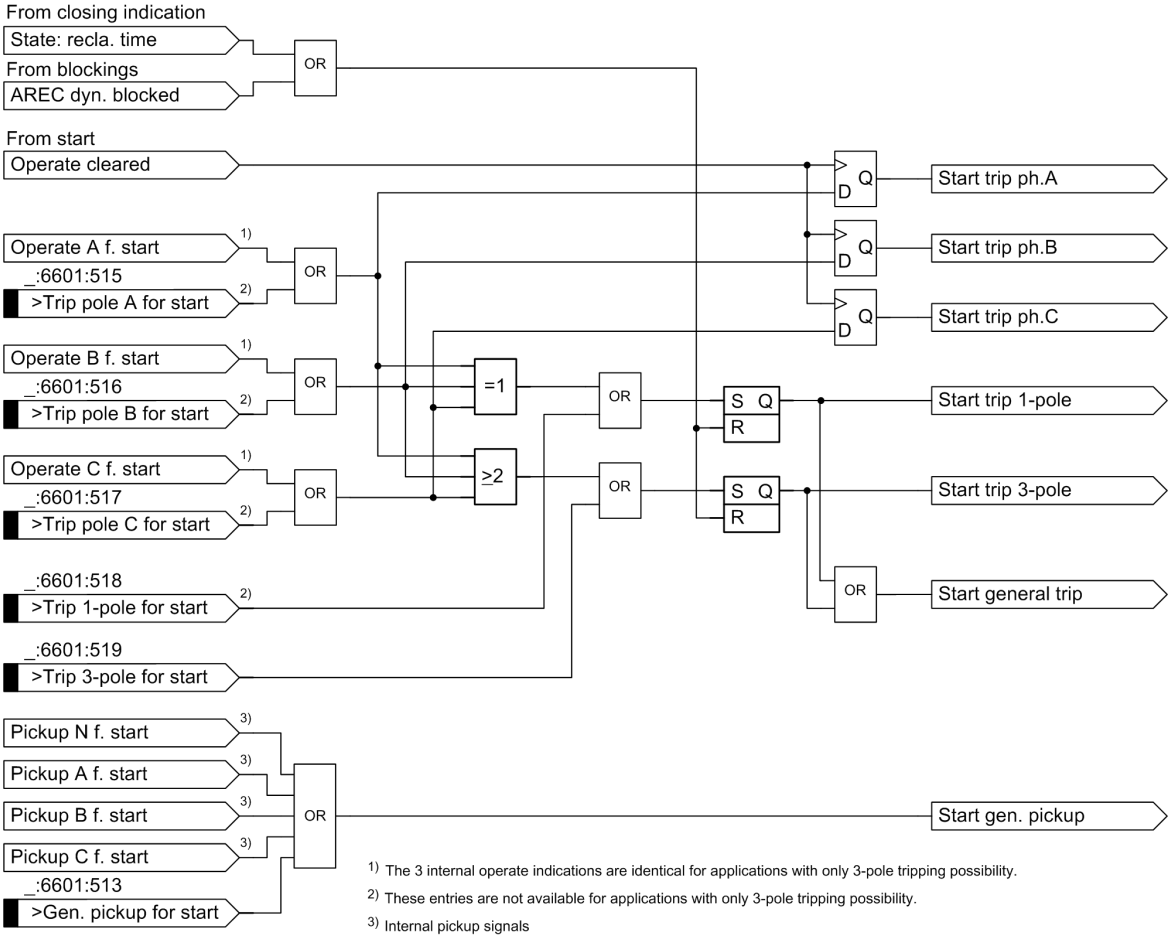
The automatic reclosing function works as a state machine. From the idle state **AREC ready**, the automatic reclosing function gets through the tripping or pickup indications of the protection functions to the **Dead time** state. After expiration of the dead time, the subsequent state is reached with the closing indication. The reclaim time is also started together with the closing indication. If the reclaim time can expire without further operate or pickup indications, the automatic reclosing is successful and the automatic reclosing function turns back to idle state.

If the automatic reclosing function is restarted during the current reclaim time, there will be either a dynamic blocking or other reclosing cycles will be executed. If other reclosing cycles are possible, there will be a dead time start and the described process starts again.

After the end of a dynamic blocking, the automatic reclosing function switches back to idle state or it goes into the state **Static Blocking** if the blocking condition is permanently present. In the following sections, the individual function blocks are described in detail.

[lozykawe-310511-01.tif, 1, en_US]

Figure 6-277 Cyclic Reclosing Function: Block Diagram of Automatic Reclosing



6.43.4.3 Input Logic for Operating Modes with Tripping

The operate indications are used as starting signals. For operating modes **with action time**, the start of the action time(s) occurs with the pickup messages. During all operating modes, the pickup indications are also required during the processing of faults and for supervision during the reclaim time.

Applications with 3-Pole Tripping

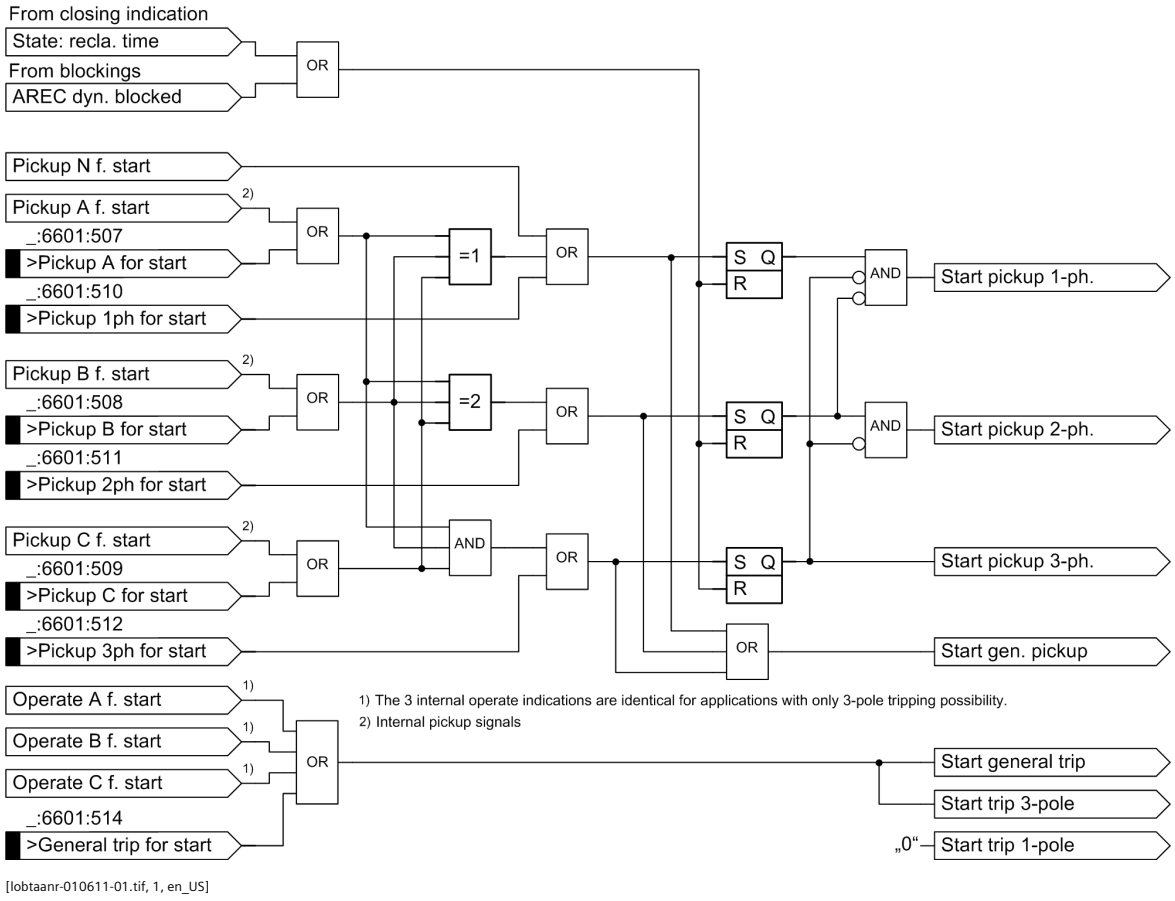
For applications with only 3-pole tripping options, the internal operate indications are always 3-pole. For external starts, there is a binary input, which signalizes a 3-pole tripping of the external protection device.

The outputs of the input logic signalize that the reclosing start has occurred through a 3-pole operate indication.

[lobtaaus-100611-01.tif, 2, en_US]

Figure 6-278 Input Logic for Operating Modes: With Tripping

6.43.4.4 Input Logic for Operating Modes with Pickup



The operate indications and the pickup indications are used as starting signals. The internal pickup indications are processed selective to the phase. Through binary inputs, the pickup information can also be coupled by external protection devices (*>Pickup A for start*, *>Pickup B for start* and *>Pickup C for start*). Optionally, the pickup information can be externally captured as a pickup sample, thus, as a 1-phase, 2-phase and 3-phase pickup.

The outputs of the input logic signalize if the automatic reclosing start occurs through a 1-phase, 2-phase, or 3-phase pickup:

- On **Start with 3-phase pickup**, it is recognized if all 3 phases were picked up in the period from the first raising pickup indication up to the last clearing outgoing pickup indication.
- On **Start with 2-phase pickup**, it is recognized if all 2 phases were picked up in the period from the first raising pickup indication up to the last clearing pickup indication and at no time 3 phases.
- On **Start with 1-phase pickup**, it is recognized if only 1 phase was picked up in the period from the first raising pickup indication up to the last clearing pickup indication.

For operating modes **with action time**, the start of the action time(s) occurs with the pickup indications. During operating modes **with pickup**, the pickup indications affect the selection of the dead times. During all operating modes, the pickup indications are also required during the processing of faults and for supervision during the reclaim time.

The automatic reclosing operating modes **with pickup** are only ideal for applications with 3-pole tripping. Therefore, the outputs of the input logic always signal 3-pole operate indications.

[lobtaanr-010611-01.tif, 1, en_US]

Figure 6-279 Input Logic for Operating Modes: With Pickup

6.43.4.5 Start

In the **Start** function block, the automatic reclosing function is switched from the idle state **AREC ready** to the state **Dead time**, see *Figure 6-280*. The length of the starting signals is controlled with a supervision time.

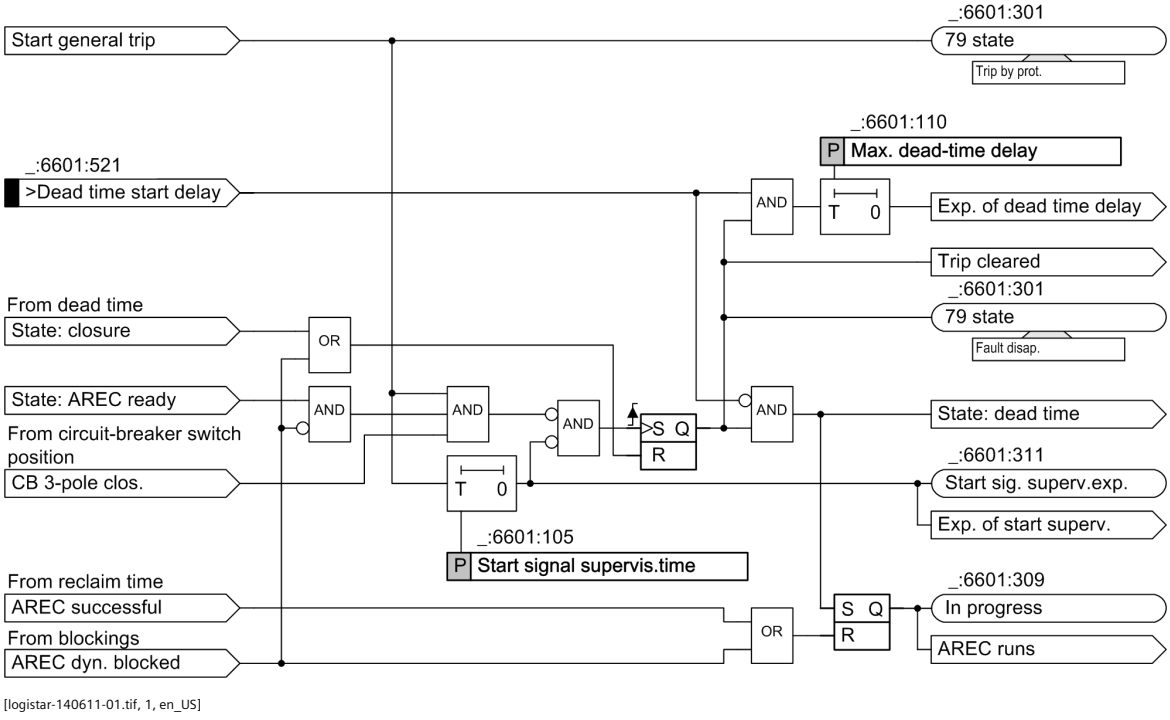
Start-Signal Supervision Time

The start-signal supervision stops the automatic reclosing if the short circuit is not switched off within the normal time; for example, in the case of a circuit-breaker failure.

With the first raising operate indication, the start-signal supervision time is initiated, parameter **`Start signal supervis.time`**. The time is stopped as soon as no operate indications are active or if the circuit breaker is recognized as being no longer 3-pole closed.

The automatic reclosing function is blocked if there is an expiration of the start-signal supervision time through a long operate indication. The blocking lasts until the operate indication stops, extended by a further 0.5 s.

Transition to the Dead-Time State



The transition of the automatic reclosing function to the **dead-time** state occurs for:

- Clearing operate indications if none of the signal inputs for operate indications are active
- or if the circuit breaker can no longer be recognized as 3-pole
- and the start-signal supervision time is not expired

Additionally, the following conditions must be fulfilled:

- The circuit breaker signalizes the readiness for automatic reclosing typically through a binary input. If the circuit breaker is not ready, the automatic reclosing function can be statically blocked. In this situation, the automatic closing function is not in idle state **automatic closing function ready**. The control of the circuit-breaker readiness is optional and can be turned off through settings, see also chapter *6.43.4.16 Circuit-Breaker Readiness* and *6.43.4.17 Blockings*.
- The circuit breaker must be closed before the 3-pole trip command. This condition is not considered if the circuit-breaker auxiliary contacts are not connected to the protection device.

You can delay the transition to the **dead time** state through the binary input *>Dead time start delay*. As long the corresponding binary signal is present, the dead time of the automatic reclosing function will not be started. The maximum duration of this binary signal is monitored through a time stage that can be set, parameter **Max. dead-time delay**. Upon expiration of this time stage, that is, if the binary signal is present longer than permitted, the automatic reclosing function will be blocked until the end of the binary signal, additionally extended by another 0.5 s. See also chapter *6.43.4.17 Blockings*.

[logistar-140611-01.tif, 1, en_US]

Figure 6-280 Logic for Function Block Start

6.43.4.6 Cycle Control with Operating Mode 1: With Tripping/With Action Time

The cycle control checks the readiness for each automatic reclosing cycle and controls the process of the action time(s). In *Figure 6-281*, the cycle control is illustrated.

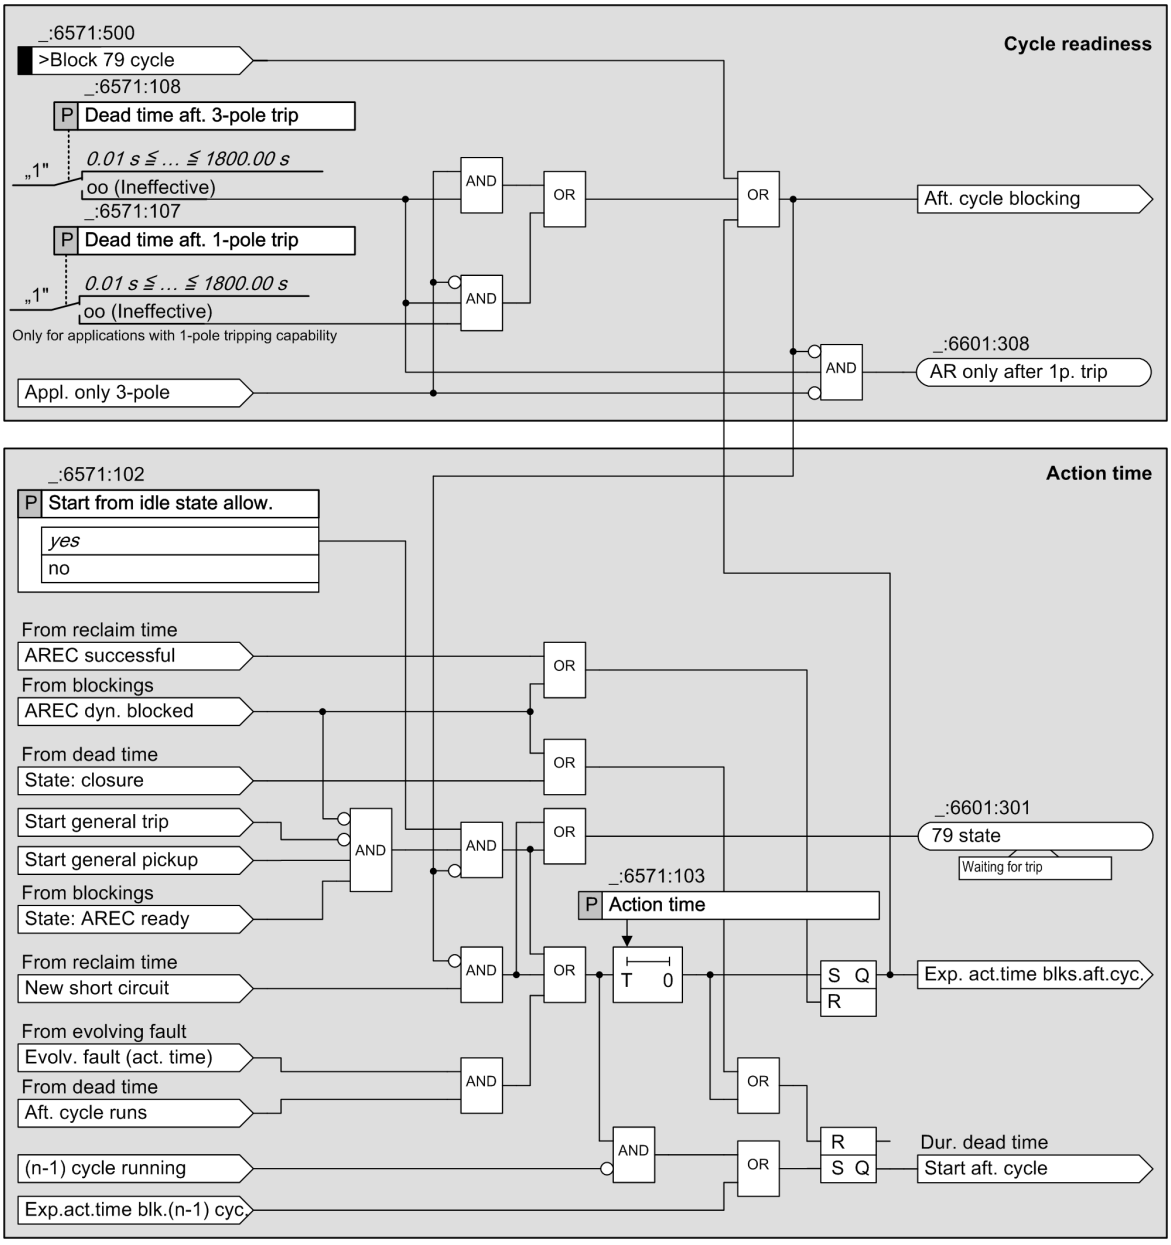
Cycle Availability

The cycle availability is influenced through the parameterization of the dead time and through a binary input. In this way, setting the parameter **Dead time aft. 3-pole trip** to ***invalid*** avoids an automatic reclosing after 3-pole tripping. Correspondingly, there is no automatic reclosing function if the **Dead time**

aft. 1-pole trip [16] is set to ***invalid***. If both dead times are set to ***invalid***, the respective automatic reclosing cycle will be completely blocked. With the binary input *>Block 79 cycle*, you can block the associated automatic reclosing cycle.

For applications with 1-pole tripping, the cycle control provides a signal, based on which the protection functions can recognize that the automatic reclosing function only occurs after 1-pole tripping (*AR only after 1p. trip*). The approval or switch over of special protection stages only occurs for types of fauts that lead to 1-pole tripping.

Action Time



If the automatic reclosing function is in the idle state **automatic reclosing function ready**, an incoming general pickup will affect the start of the action time. This applies for the reclosing function cycles that are released through the parameter **Start from idle state allow.** and not blocked.

During one of the started action times, the corresponding reclosing cycle is blocked and the reclosing cycle is assigned the next highest cycle number, whose action time is running and is not blocked.

With raising trip commands, the action times are stopped and reset. The process state of the action times existing at this moment determines the automatic reclosing cycle that should be started.

If all initiated action times expire without capturing a tripping, the automatic reclosing function does not take place. However, if a tripping function is initiated after expiry of the action time, the automatic closing function is blocked for 3 seconds. A new start of the reclosing function is only possible if the general pickup is no longer active.

[16] is not available for devices with only 3-pole tripping

[loauswir-140611-01.tif, 1, en_US]

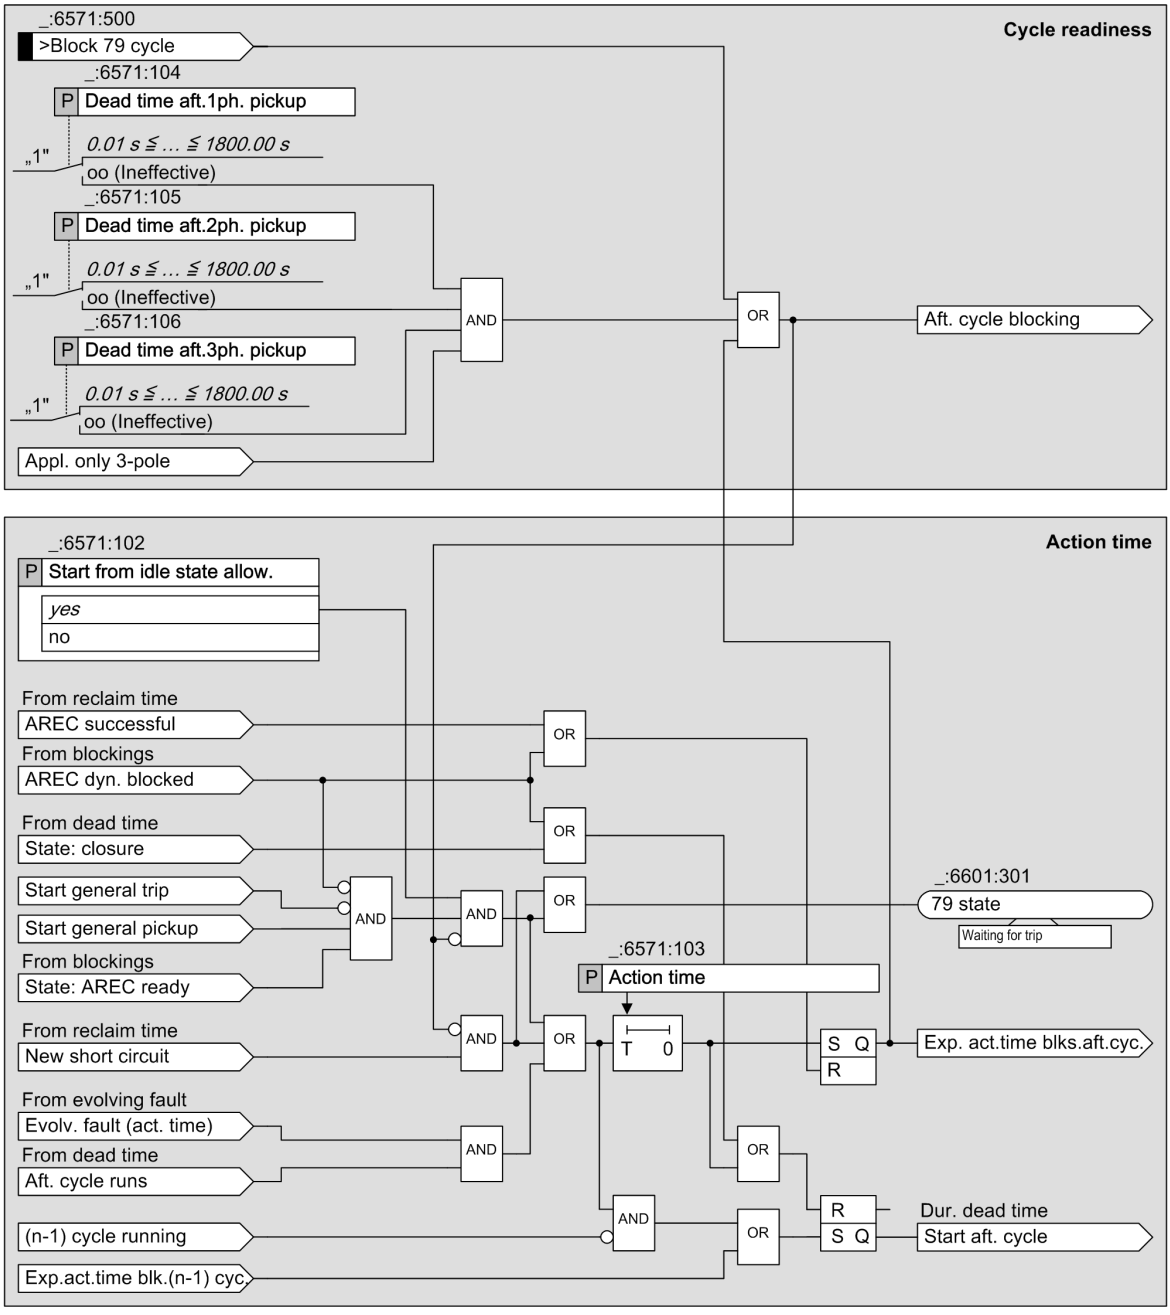
Figure 6-281 Cycle Control with Operating Mode: With Tripping/With Action Time

6.43.4.7 Cycle Control with Operating Mode 2: With Pickup/With Action Time

The cycle control checks the readiness for each automatic reclosing cycle and controls the process of the action time(s). In *Figure 6-282*, the cycle control is illustrated.

Cycle Availability

The cycle availability is influenced through the parameterization of the dead time and through a binary input. In this way, setting the parameter **Dead time aft.1ph. pickup** to ***invalid*** avoids an automatic reclosing after 3-pole tripping due to 1-phase short circuits. This also applies to **Dead time aft.2ph. pickup** and **Dead time aft.3ph. pickup**. If all 3 dead times are set to ***invalid***, the respective reclosing cycle will be completely blocked. With the binary input *>Block 79 cycle*, you can block the associated automatic reclosing cycle.



Action Time

If the automatic reclosing function is in the idle state **automatic reclosing function ready**, an incoming general pickup will affect the start of the action time. This applies for the reclosing function cycles that are released through the parameter **`Start from idle state allow.`** and not blocked.

During one of the started action times, the corresponding reclosing cycle is blocked and the reclosing cycle is assigned the next highest cycle number, whose action time is running and is not blocked.

With raising trip commands, the action times are stopped and reset. The process state of the action times existing at this moment determines the automatic reclosing cycle that should be started.

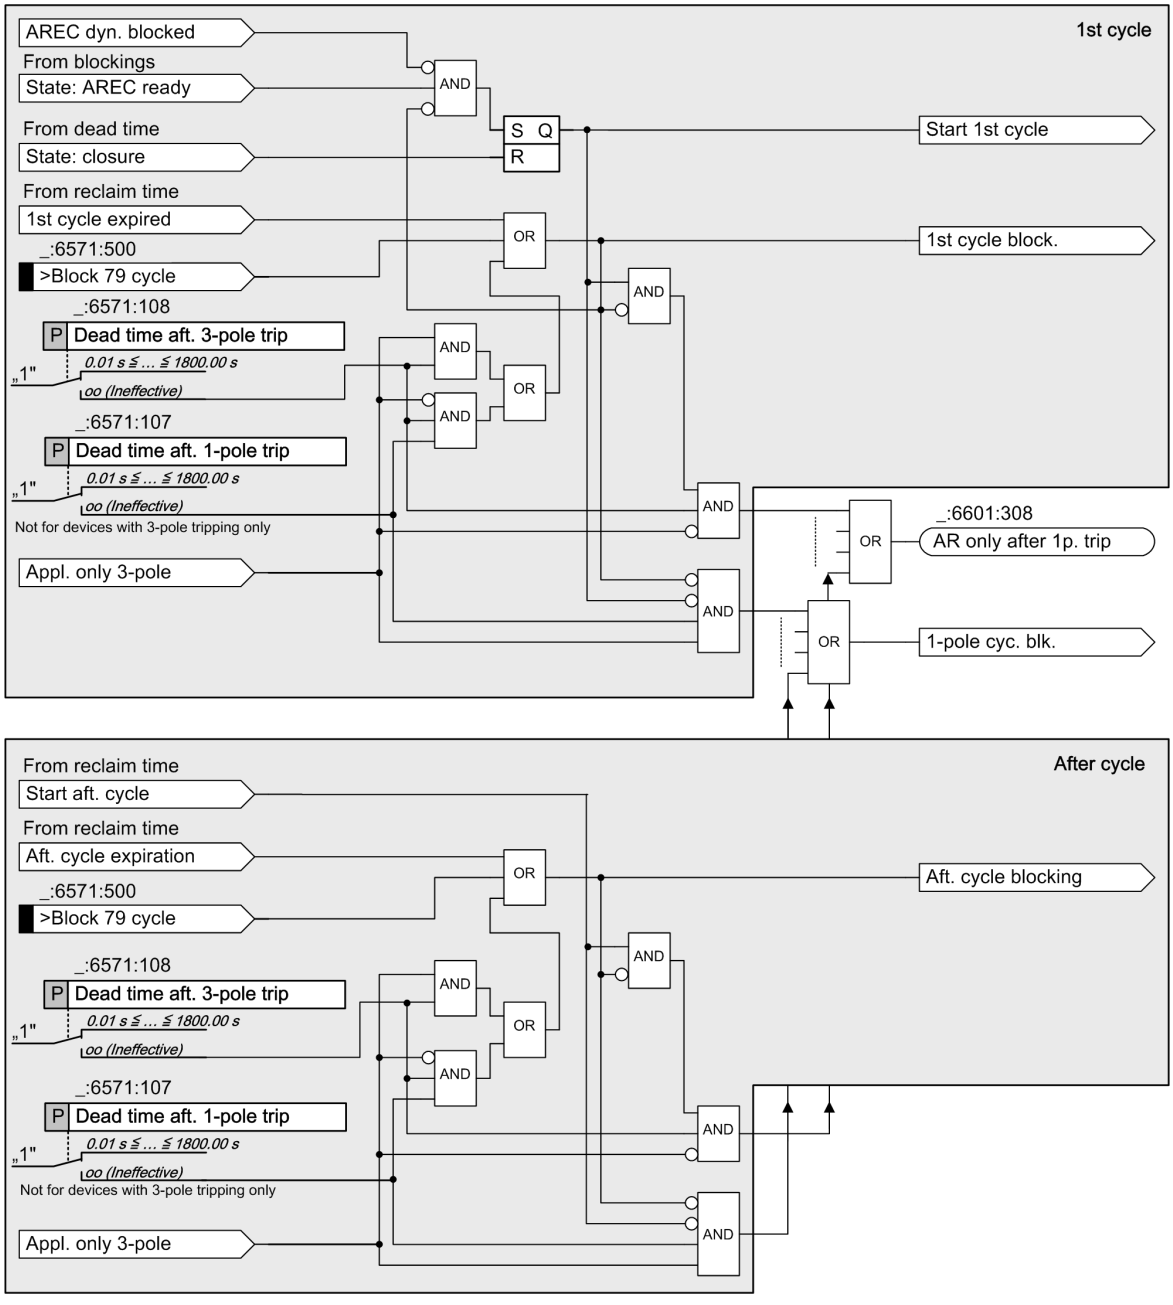
If all initiated action times expire without capturing a tripping, the automatic reclosing function does not take place. However, if a tripping function is initiated after expiry of the action time, the automatic closing function is blocked for 3 seconds. A new start of the reclosing function is only possible if the general pickup is no longer active.

[loanrwir-140611-01.tif, 1, en_US]

Figure 6-282 Cycle Control with Operating Mode: With Pickup/With Action Time

6.43.4.8 Cycle Control with Operating Mode 3: With Tripping/Without Action Time

The cycle control checks the availability for each automatic reclosing cycle. In *Figure 6-283*, the cycle control for the 1st automatic reclosing cycle and other reclosing cycles is illustrated. The further automatic reclosing cycles are generally described with the cycle number **n** and apply for all other configured automatic reclosing cycles.



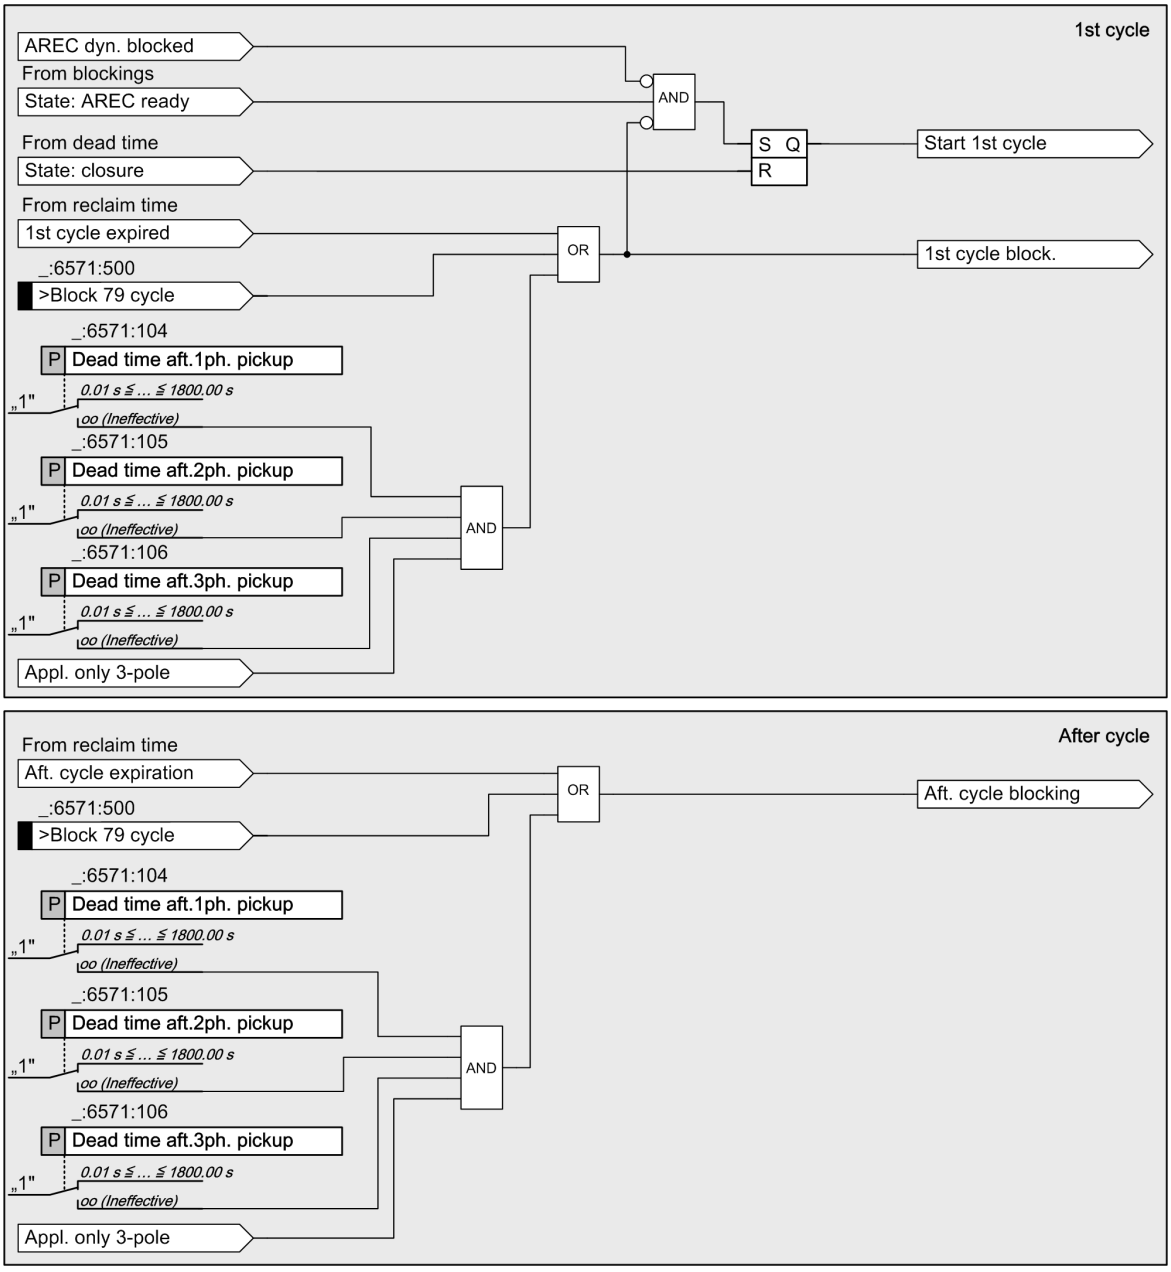
The cycle availability is influenced through the parameterization of the dead time and through a binary input.

In this way, setting the parameter **`Dead time aft. 3-pole trip`** to ***`invalid`*** avoids an automatic reclosing after 3-pole tripping. Correspondingly, there is no automatic reclosing function after 1-pole tripping if the **`Dead time aft. 1-pole trip`** [17] to ***`invalid`***. If both dead times are set to ***`invalid`***, the respec-

[17] is not available for devices with only 3-pole tripping

tive automatic reclosing cycle will be completely blocked. With the binary input *>Block 79 cycle*, you can block the associated automatic reclosing cycle.

For applications with 1-pole tripping, the cycle control provides a signal, based on which the protection functions can recognize that the automatic reclosing function only occurs after 1-pole tripping (*AR only after 1p. trip*). The approval or switch over of special protection stages only occurs for types of faults that lead to 1-pole tripping.



[loauowrk-210311-01.tif, 1, en_US]

Figure 6-283 Cycle Control with Operating Mode: With Tripping/Without Action Time

6.43.4.9 Cycle Control with Operating Mode 4: With Pickup/Without Action Time

The cycle control checks the availability for each automatic reclosing cycle. In *Figure 6-284*, the cycle control for the 1st automatic reclosing cycle and other reclosing cycles is illustrated. The further automatic reclosing cycles are generally described with the cycle number **n** and apply for all other configured automatic reclosing cycles.

The cycle availability is influenced through the parameterization of the dead time and through a binary input. In this way, setting the parameter **Dead time aft.1ph. pickup** to ***invalid*** avoids an automatic reclosing after 3-pole tripping due to 1-phase short circuits. This also applies to **Dead time aft.2ph. pickup** and **Dead time aft.3ph. pickup**. If all 3 dead times are set to ***invalid***, the respective reclosing cycle will be completely blocked. With the binary input *>Block 79 cycle*, you can block the associated automatic reclosing cycle.

[loanowrk-100611-01.tif, 1, en_US]

Figure 6-284 Cycle Control with Operating Mode: With Pickup/Without Action Time

6.43.4.10 Stage Release

The function block **Stage release** creates output indications for the release or switching over of special stages for protection functions (stage release in the 1st cycle or stage release in the n. cycle). Examples for this are the release of overreaching zones with distance protection and the dynamic adjustment of delays or threshold values with overcurrent protection.

Figure 6-285 shows the tripping stage release for the 1st automatic reclosing cycle. With available automatic reclosing functions, the tripping stage release typically occurs up to the expiration of the dead time. The cycle number in this state is on 1. However, if the automatic reclosing cycle is set only for 1-phase [18], the tripping stage release will be reset to the beginning of the 1-phase dead time. This is necessary, since every additional evolving fault that occurs within the dead time causes a 3-pole cut-off, and subsequently, the automatic reclosing function can no longer take place.

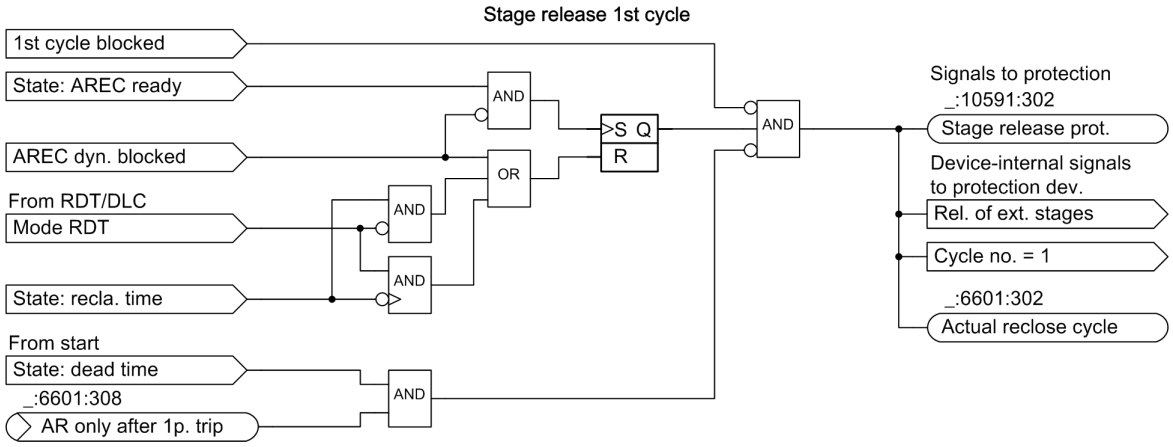


Figure 6-285 Stage Release for Protection Functions in the 1st Automatic Reclosing Cycle

The tripping stage release for higher automatic reclosing cycles is set to the beginning of the reclaim time for rising edge close commands. Simultaneously, the cycle number is increased. The reset condition is identical to the condition for the 1st automatic reclosing cycle. If the reduced dead time (RDT) mode is selected and no additional reduced dead time occurs, the release of the 2nd cycle will be maintained, since it can be assumed that the opposite end is open.

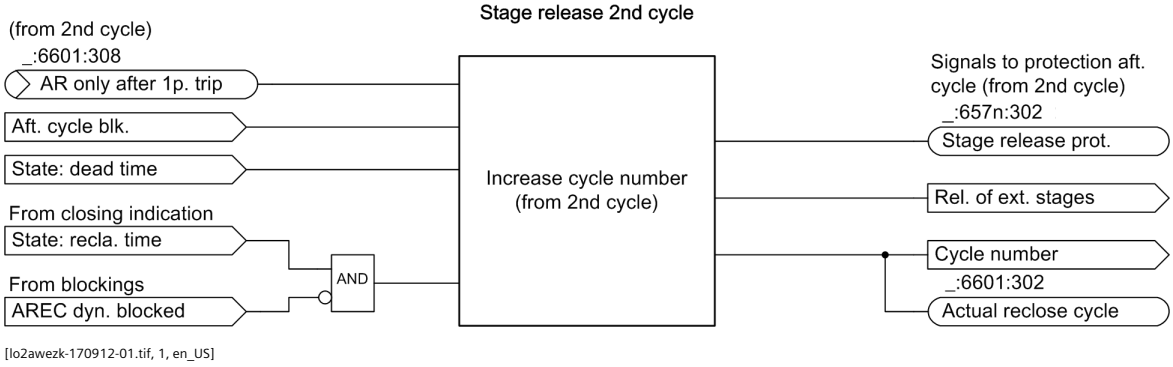

Figure 6-286 Stage Release for Protection Functions Starting With the 2nd Automatic Reclosing Cycle

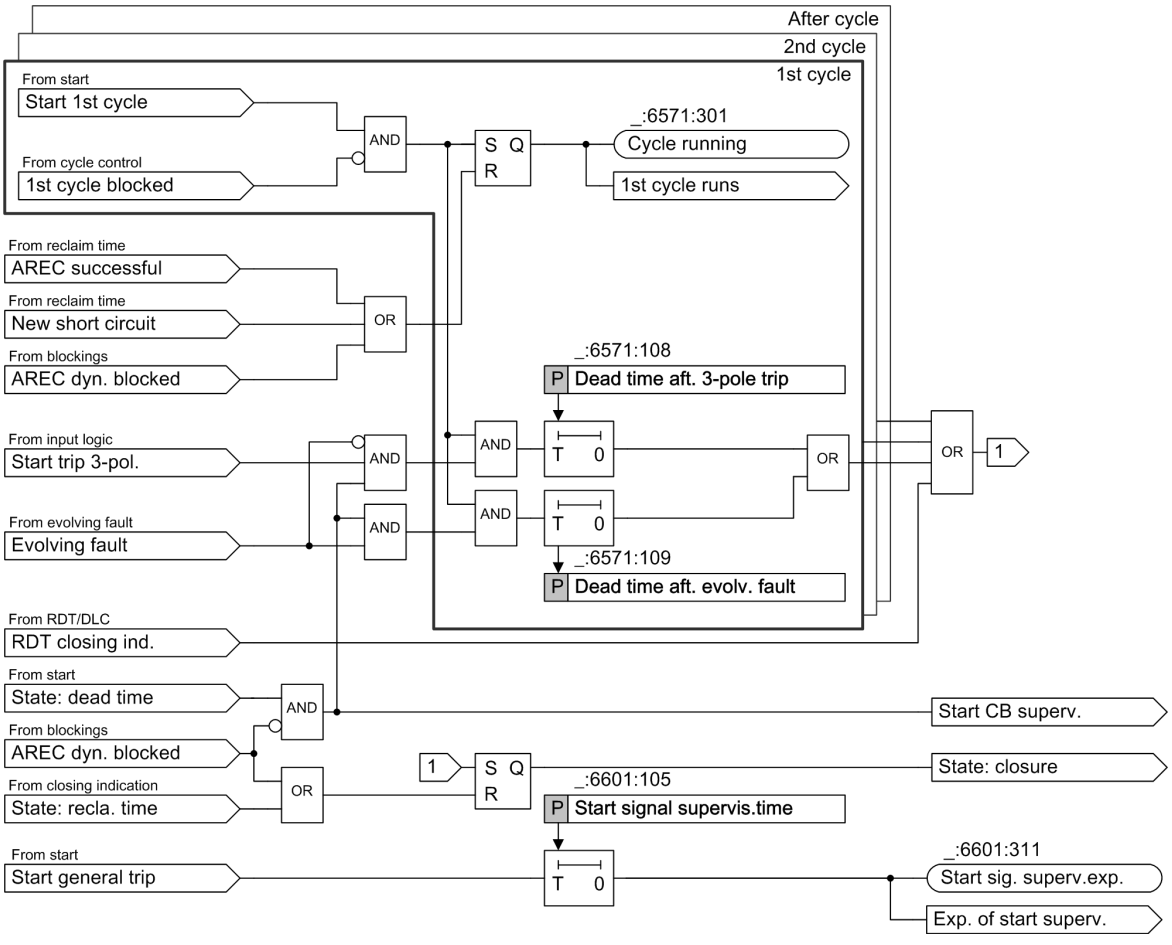
6.43.4.11 Dead Time for Operating Modes With Tripping



In the **Dead time** function block, that dead time which corresponds with the previous trip command is started. After expiration of the dead time, the automatic reclosing function changes to the status **Switch on**.
Figure 6-287 shows the dead time logic.
There are the following time stages that can be set differently:

- Dead time after 3-pole tripping
- Dead time after evolving fault

Setting the parameter **`Dead time aft. 3-pole trip`** to ∞ (= invalid) avoids an automatic reclosing after 3-pole tripping.

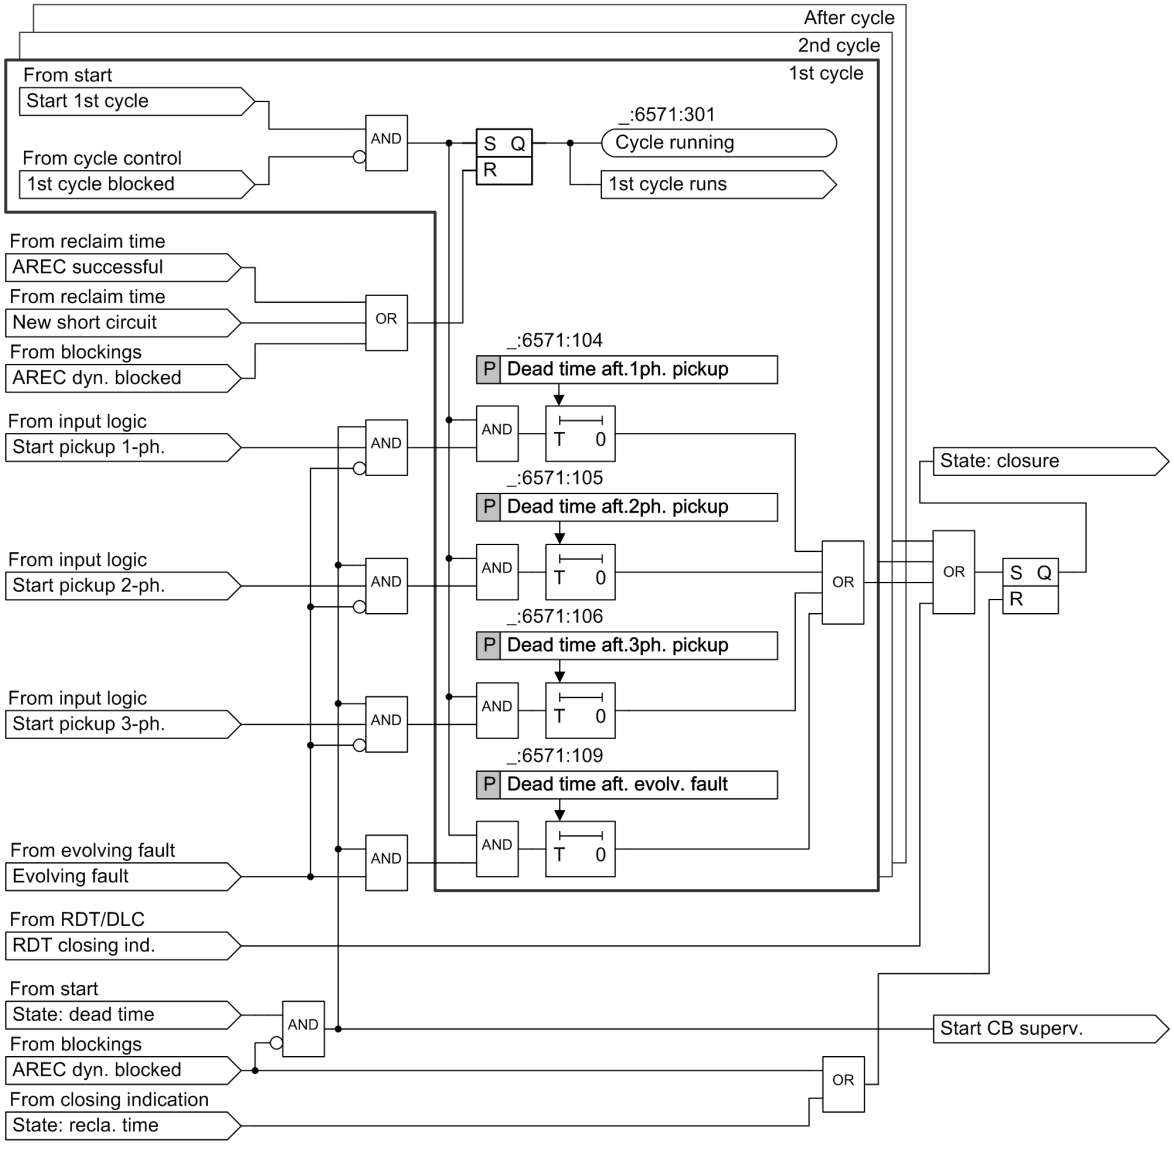
[18] not for devices with only 3-phase tripping

As soon as an evolving fault is recognized (see chapter *6.43.4.13 Evolving-Fault Detection During Dead Time*), switching to an automatic reclosing cycle for 3-pole interruption occurs. With the 3-pole cut-off of the evolving fault, a separate adjustable dead time for the evolving fault begins. The total dead time is composed of the part of the dead time that expired until the evolving fault was stopped for the first disruption plus the dead time for the evolving fault. With the setting of the parameter **`Dead time aft. evolv. fault`** to ∞ (= invalid), no other automatic reclosing cycle is executed after tripping by the evolving fault. The tripping through evolving faults is then finished.

[lopausjk-021212-01.tif, 1, en_US]

Figure 6-287 Cyclic Automatic Reclosing Function - Logic of the Dead Time for the Operating Modes: With Tripping

6.43.4.12 Dead Time for Operating Modes with Pickup



In the **dead time** function block, the dead time corresponding to the type of short circuit that led to the trip command is started. The automatic reclosing operating modes **with pickup** are only ideal for applications with 3-pole tripping. After expiration of the dead time, the automatic reclosing function changes to the status **Switch on**. *Figure 6-288* shows the dead time logic.

There are 4 time stages that can be set differently:

- Dead time after 1-phase short circuits
- Dead time after 2-phase short circuits
- Dead time after 3-phase short circuits
- Dead time for evolving faults

In this way, setting the parameter **`Dead time aft.1ph. pickup`** to ***`invalid`*** avoids an automatic reclosing after 3-pole tripping due to 1-phase short circuits. This also applies to **`Dead time aft.2ph. pickup`** and **`Dead time aft.3ph. pickup`** .

As soon as an evolving fault is recognized (see chapter *6.43.4.13 Evolving-Fault Detection During Dead Time*), a separate dead time for faults begins with the stopping of the fault. The total dead time is composed of the part of the dead time that expired until the evolving fault was stopped for the 1st disruption plus the dead time for the evolving fault. With the setting of the **Dead time aft. evolv. fault** to ***invalid***, no other automatic reclosing cycle is executed after tripping through the evolving fault. The tripping through evolving faults is then finished.

[lopauare-010611-01.tif, 1, en_US]

Figure 6-288 Cyclic Automatic Reclosing Function - Logic of the Dead Time for the Operating Modes: With Pickup

6.43.4.13 Evolving-Fault Detection During Dead Time

Evolving faults are short circuits, which occur after switching off a short circuit during dead time. This may be the case during 1-pole tripping and there is a short circuit in the non-switched conductors after this.

After 3-pole tripping there may also be evolving faults if the line is fed through a second (non-3-pole) opened circuit breaker, for example, for systems with a 1 1/2 circuit breaker layout.

The evolving-fault detection is divided into components:

- Detection of Evolving Faults
- Evolving-Faults Processing
- 3-pole circuit-breaker intertripping during evolving faults

The procedure during evolving faults is illustrated in *Figure 6-289*.

Detection of Evolving Faults

For the detection of an evolving fault, the following criteria can be selected through parameters:

- Parameter **Evolving-fault detection** = ***with trip***

  For this setting, **any tripping** during the dead time leads to evolving-fault detection. At **any tripping** it is decided if an internal protection function is tripped or if the tripping is signaled through a binary input. Thus, it does not matter if the tripping-protection function is configured for the start of the automatic reclosing function or not.

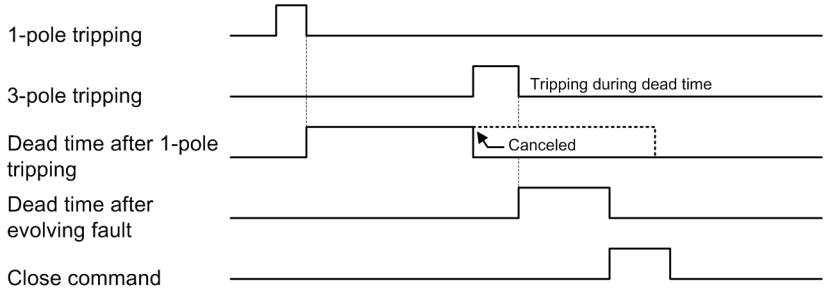
- Parameter **Evolving-fault detection** = ***with pickup***

  Evolving faults are detected if during the dead time a protection function configured for the automatic reclosing function start is picked up or if an external pickup is recognized through a binary input.

- Binary input *>Evolving fault start*

  The evolving-fault detection can also be introduced through a binary input without an internal protection pickup being available.

Reaction to Evolving Faults



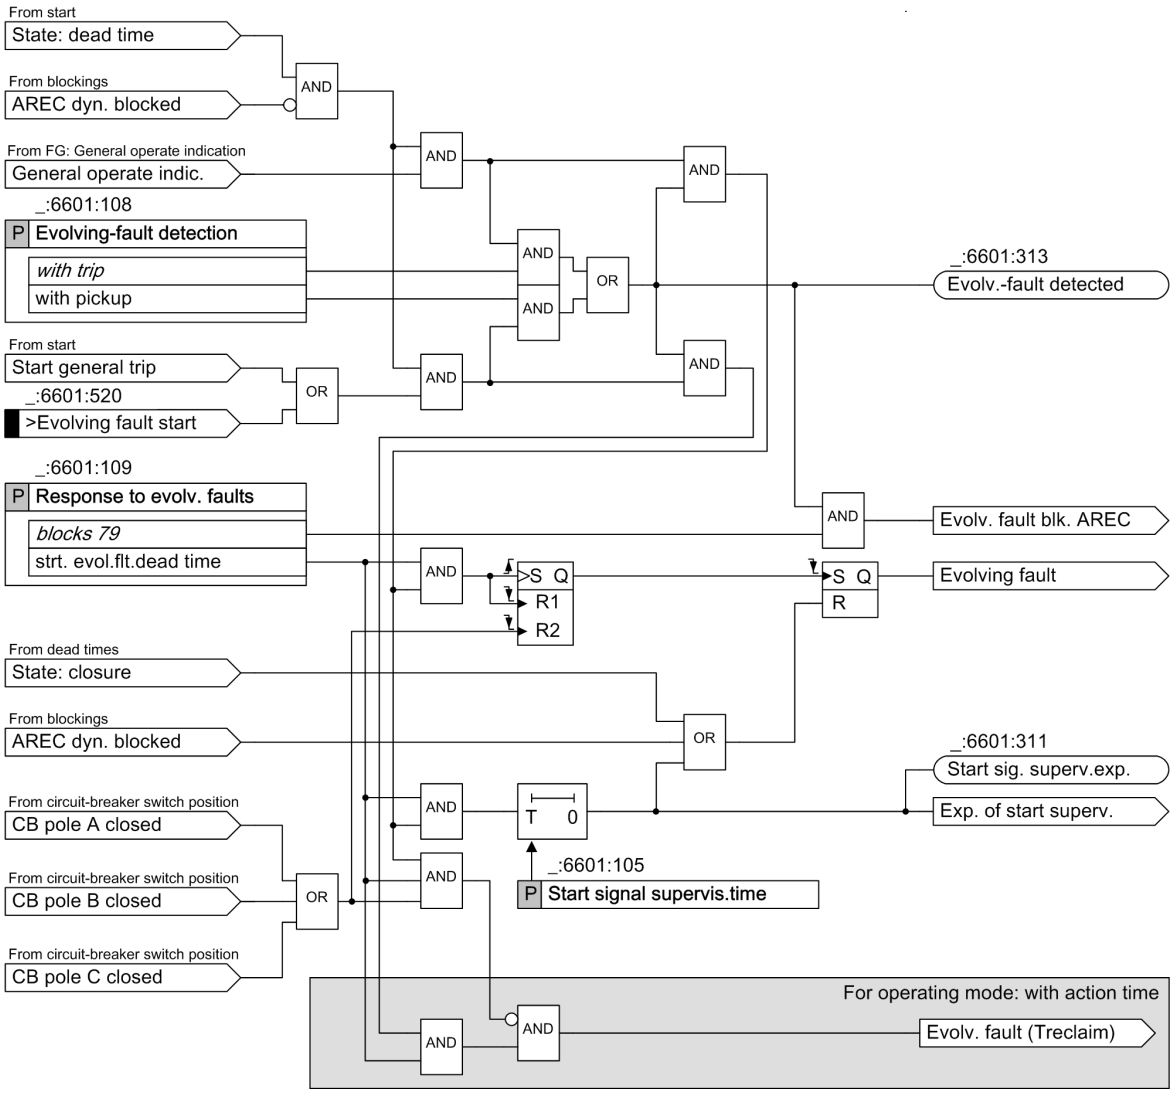
After a recognized evolving fault, the automatic reclosing function can be influenced in 2 ways.

- Parameter **Response to evolv. faults** = ***blocks 79***

  As soon as an evolving fault is recognized, the reclosing function will be blocked. There are no other reclosing attempts and the automatic reclosing function is blocked until the pickup and operate indications causing the evolving fault disappear.

- Parameter **Response to evolv. faults** = ***strt. evol.flt.dead time***

  As soon as an evolving fault is recognized, an automatic reclosing cycle for 3-pole interruption is switched to. The automatic reclosing function does not allow any 1-pole tripping until the fault is solved or there is a final switch off; thus, every following trip command will be 3-pole. When the evolving fault is fixed, the separate dead time for faults will start, see also chapter **Dead time**. The further process is as by 3-pole cycles.



[dwbspffe-100611-01.tif, 1, en_US]

Figure 6-289 Cyclic Automatic Reclosing Function - Example for an Evolving Fault

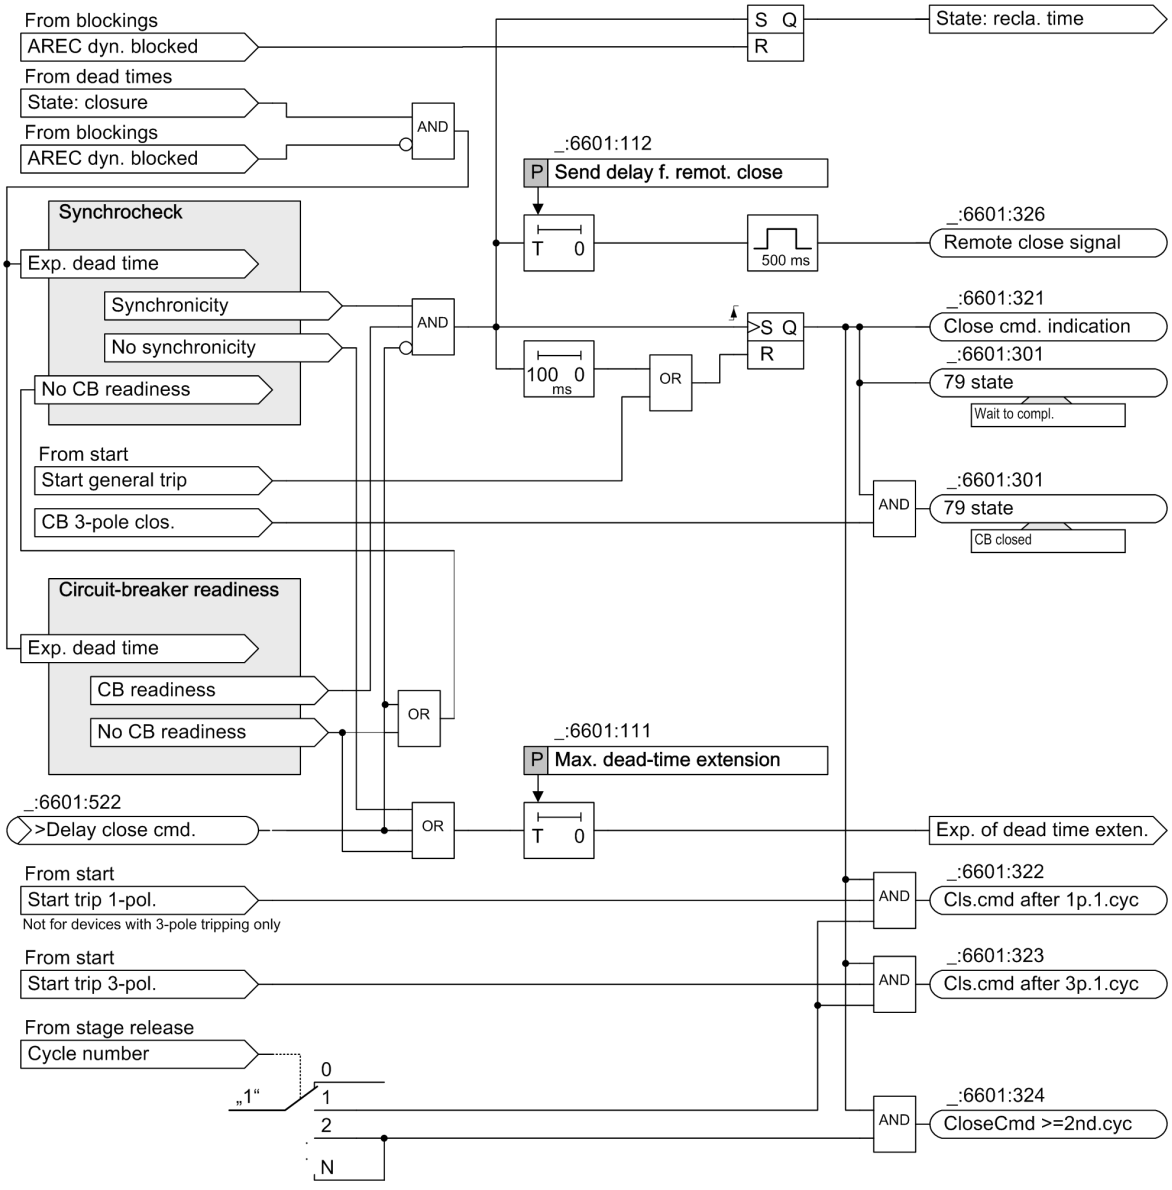
For tripping through evolving faults, the entire dead time consists of the part of the dead time expired until disconnecting the evolving fault for the 1-pole interruption plus the dead time for the fault together, see *Figure 6-290*.

The dead time for evolving faults is started with the return of the operate indication or with the opening of all 3 circuit-breaker poles, provided the circuit-breaker auxiliary contacts are connected.

[lofolsjk-021212-01.tif, 1, en_US]

Figure 6-290 Cyclic Automatic Reclosing Function - Logic of Evolving-Fault Detection

6.43.4.14 Closing Indication and Close Command



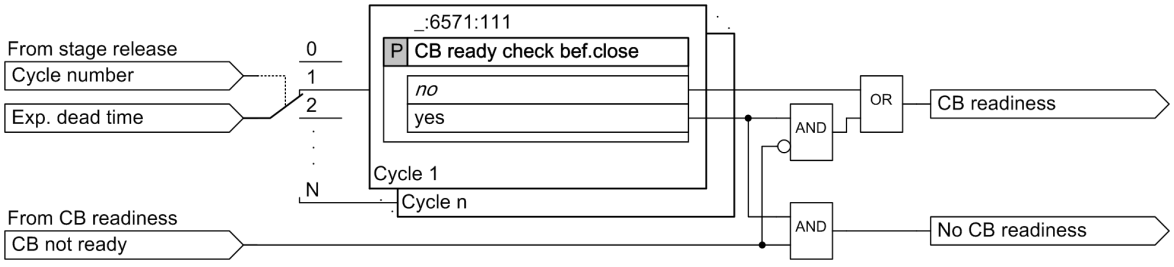
After the expiration of the dead time, the Automatic reclosing function will be in the **closing** state.

The **closing** state can depend on the following influences, see *Figure 6-291*:

- through a synchrocheck if the circuit breaker was opened during the 3-pole dead time
- Through the readiness of the circuit breaker signaled through the binary input
- Through a binary input for delaying the close command (*>Delay close cmd.*)

The *Close cmd. indication* is a requirement for the assignment of the actual close command to the circuit breaker.

The mentioned criteria must not be fulfilled directly after expiration of the dead time. If a dead-time prolongation is set, the mentioned criteria will be checked during the prolongation. With the release of the closing indication, the automatic reclosing function will switch to the **reclaim time** state.



[loeinsha-141111-01.tif, 1, en_US]

Figure 6-291 Cyclic Reclosing Function: Logic for the Closing Indication

Testing the Circuit-Breaker Readiness Directly before Closing

For each of the automatic reclosing cycles, you can set if a test of the circuit-breaker readiness should occur directly before closing (parameters **`CB ready check bef.close`**, *Figure 6-292*). Independent of this, a test of the circuit-breaker readiness before the start of the 1st automatic reclosing cycle can be set, see Chapter *6.43.4.5 Start* and chapter *6.43.4.16 Circuit-Breaker Readiness* .

[lolsvoei-130511-01.tif, 1, en_US]

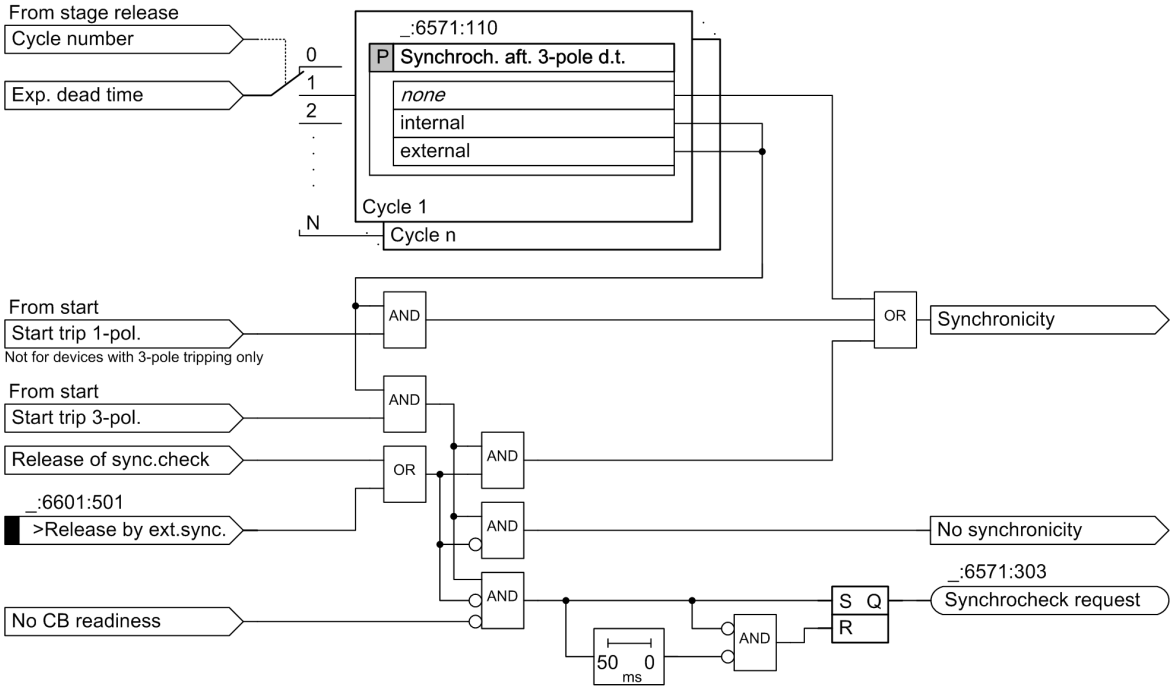


Figure 6-292 Cyclic Reclosing Function: Logic for the Query of the Circuit-Breaker Readiness Directly before Closing

Synchrocheck

For each of the configured automatic reclosing cycles, you can set if a synchrocheck should be executed and which functionality should be used here, see *Figure 6-293*. You may only use the internal synchrocheck if the device is connected to a voltage transformer.

Alternatively, you can also connect an external device with synchrocheck through a binary input.

The measuring request for the synchrocheck is placed if the optional test of the circuit-breaker readiness was positive. The measuring request for the synchrocheck exists until the synchrocheck assigns the allowance for the closure. If the allowance is not given within the set maximum dead time extension, the closure will be cancelled through the blocking of the automatic reclosing function. The minimum duration of the measuring request is 50 ms.

[losyncro-130511-01.tif, 1, en_US]

Figure 6-293 Cyclic Reclosing Function: Logic for the Inquiry of the Synchronism

Close Command

As soon as the test of the circuit-breaker readiness and the synchrocheck deliver a positive result, the closing indication will be created. It will be assigned for 100 ms. The actual close command is not created by the automatic reclosing function, but rather from the circuit-breaker function block outside of the automatic reclosing function. Here the set maximum duration of the close command is also considered.

In addition to the closing indication, additional indications will be created that describe the type of closure. These include:

- Close command after 3-pole tripping in the first cycle (*Cls.cmd after 3p.1.cyc*)
- Close command after 1-pole or 3-pole tripping starting with the second cycle (*CloseCmd >=2nd.cyc*)

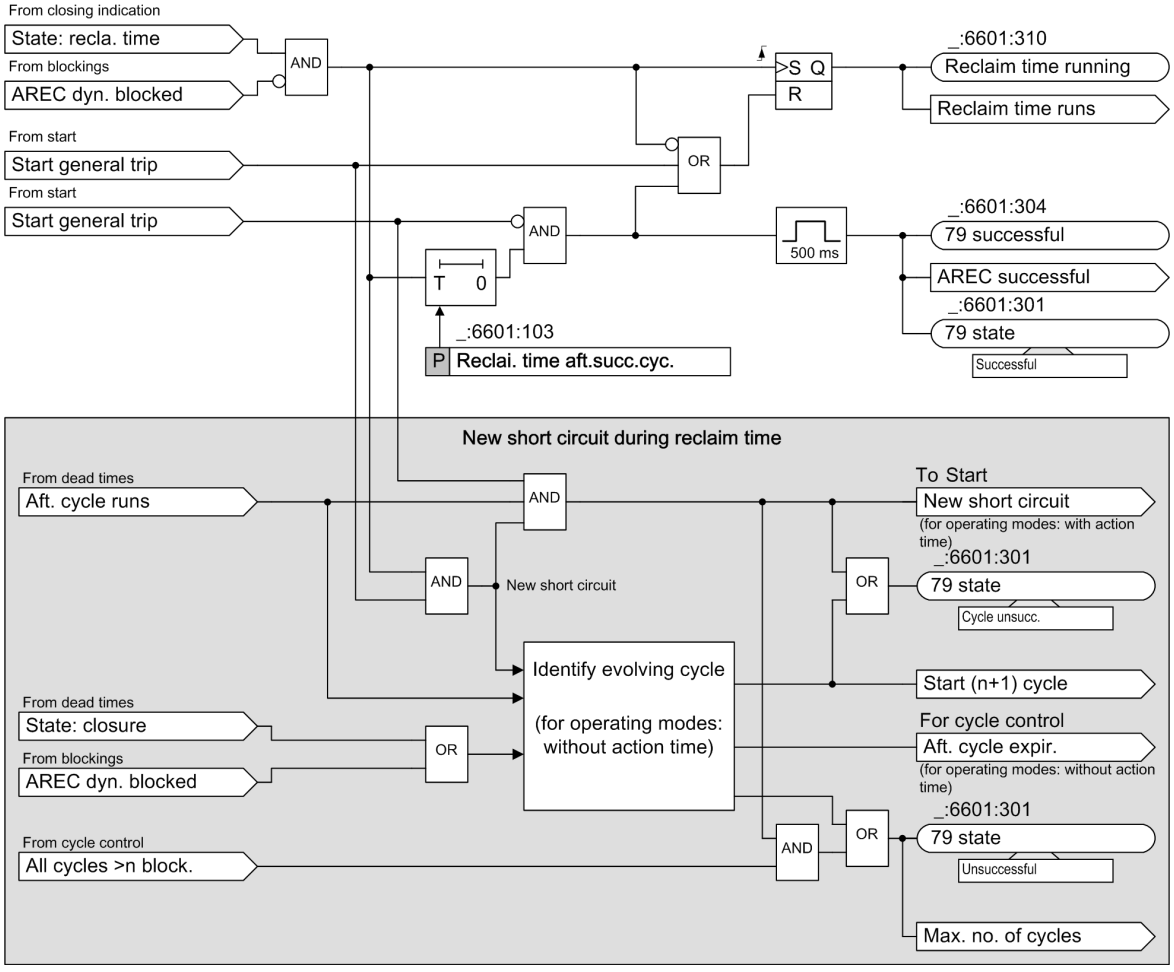
Creation of the Signal Remote close signal

The cyclic automatic reclosing function can create information *Remote close signal*. This information can be transferred to the protection device as a binary signal on the line that is to be protected on the opposite end. From the reclosing function, it can be processed in the operating mode **adaptive dead time (ASP)**. Furthermore, the binary signal may be arranged as data for transmission via an existing protection interface.

The information *Remote close signal* is created by the closing logic. It can be delayed by a set time over the local close indication. With this delay, you can make sure that information is only set if the automatic reclosing was successful and there was no further tripping. The pulse duration of the inter-close signal has a fixed length of 500 ms.

6.43.4.15 Reclaim Time

With the assignment of the close command, the automatic reclosing function goes into the **reclaim time** state. During this time, it is decided if the current reclosing cycle was successful or not.



- If during the reclaim time no further tripping occurs, the currently running automatic reclosing cycle, and thus the entire automatic reclosing, was successful.
- If during the reclaim time another tripping occurred, the currently running automatic reclosing cycle was not successful. If other automatic reclosing cycles are permitted, one of these cycles will be used to continue the process. If, in contrast, the currently executed cycle was the last permissible cycle, the automatic reclosing process will end and be reported as unsuccessful.

In both cases, the automatic reclosing function switches back to the idle state **automatic reclosing function ready**.

Short Circuits during Running Reclaim Time

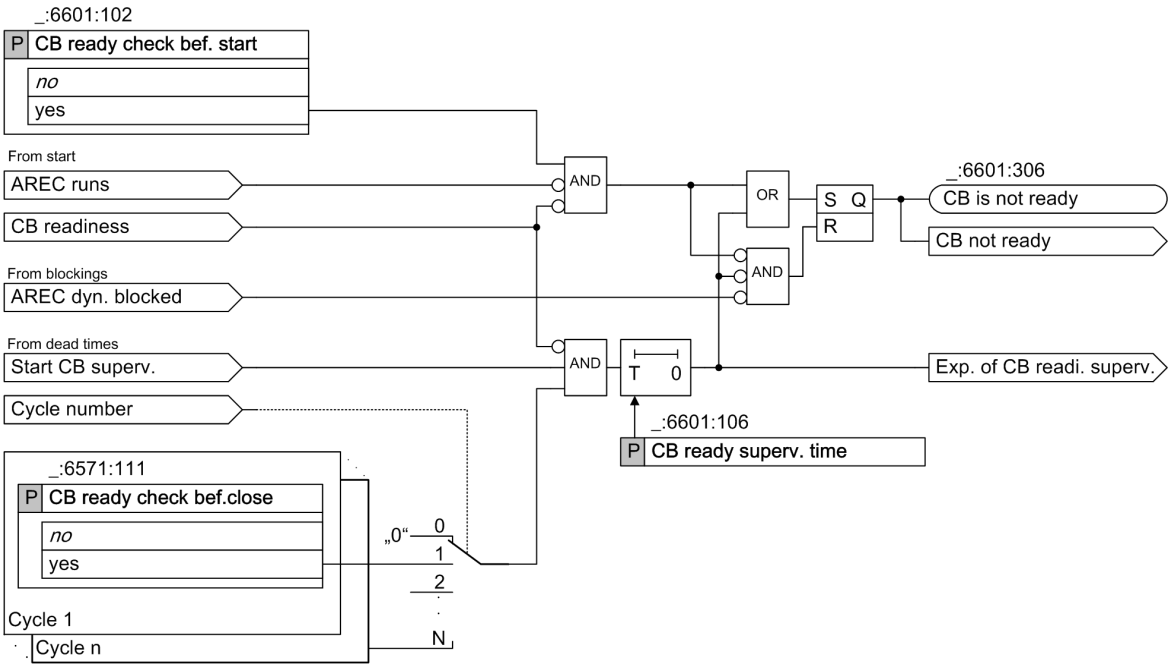
A trip command that occurs during a reclaim time leads to a cancellation of the reclaim time. If further automatic reclosing cycles are allowed, the regulation of the cycle depends on if the automatic reclosing function is executed in an operating mode **with action times** or **without action times**, see *Figure 6-294*.

- With operating modes **with action time**, the action times of all higher cycles are started with the beginning of the new general pickup if these are not blocked. The cycle with the lowest cycle number is selected, whose action time is not yet expired with the incoming trip indication. If no further cycles are possible or if the action times of all possible cycles are expired before the operate indication, there will be no further reclosing.
- With the operating modes **without action time**, the cycle following the current cycle will always be selected in the set cycle. If this is blocked, the cycle following this one will be selected, etc. If no higher cycles exist or if they are all blocked, there will be no further automatic reclosing.

[losperre-140611-01.tif, 1, en_US]

Figure 6-294 Cyclic Reclosing Function: Logic for the reclaim time

6.43.4.16 Circuit-Breaker Readiness



The automatic reclosing function requires the readiness of the circuit breaker for the following purposes, see *Figure 6-295*:

- Recognition of the circuit-breaker readiness from the beginning:

  In idle state of the automatic reclosing function, an unavailable circuit breaker leads to the blocking of the automatic reclosing function. This monitoring is optional and must be switched off through settings if the readiness signal is not available for the protection device.

- Analysis of the circuit-breaker readiness directly before the close command:

  For each of the configured automatic reclosing cycles, it can be set whether the circuit-breaker readiness is a requirement for the assignment of the close command. This monitoring is also optional.

[lolsbere-130511-01.tif, 1, en_US]

Figure 6-295 Cyclic Reclosing Function: Logic for the Circuit-Breaker Readiness

6.43.4.17 Blockings

The Automatic reclosing function differentiates between 2 types of blockings, see *Figure 6-296*:

- Static blocking
- Dynamic blocking

Static Blocking

The Automatic reclosing function is statically blocked if the function is switched on, but is not ready for reclosing and also cannot be started as long as this blocking is present. The dynamic blocking is signaled with the indication *Inactive*.

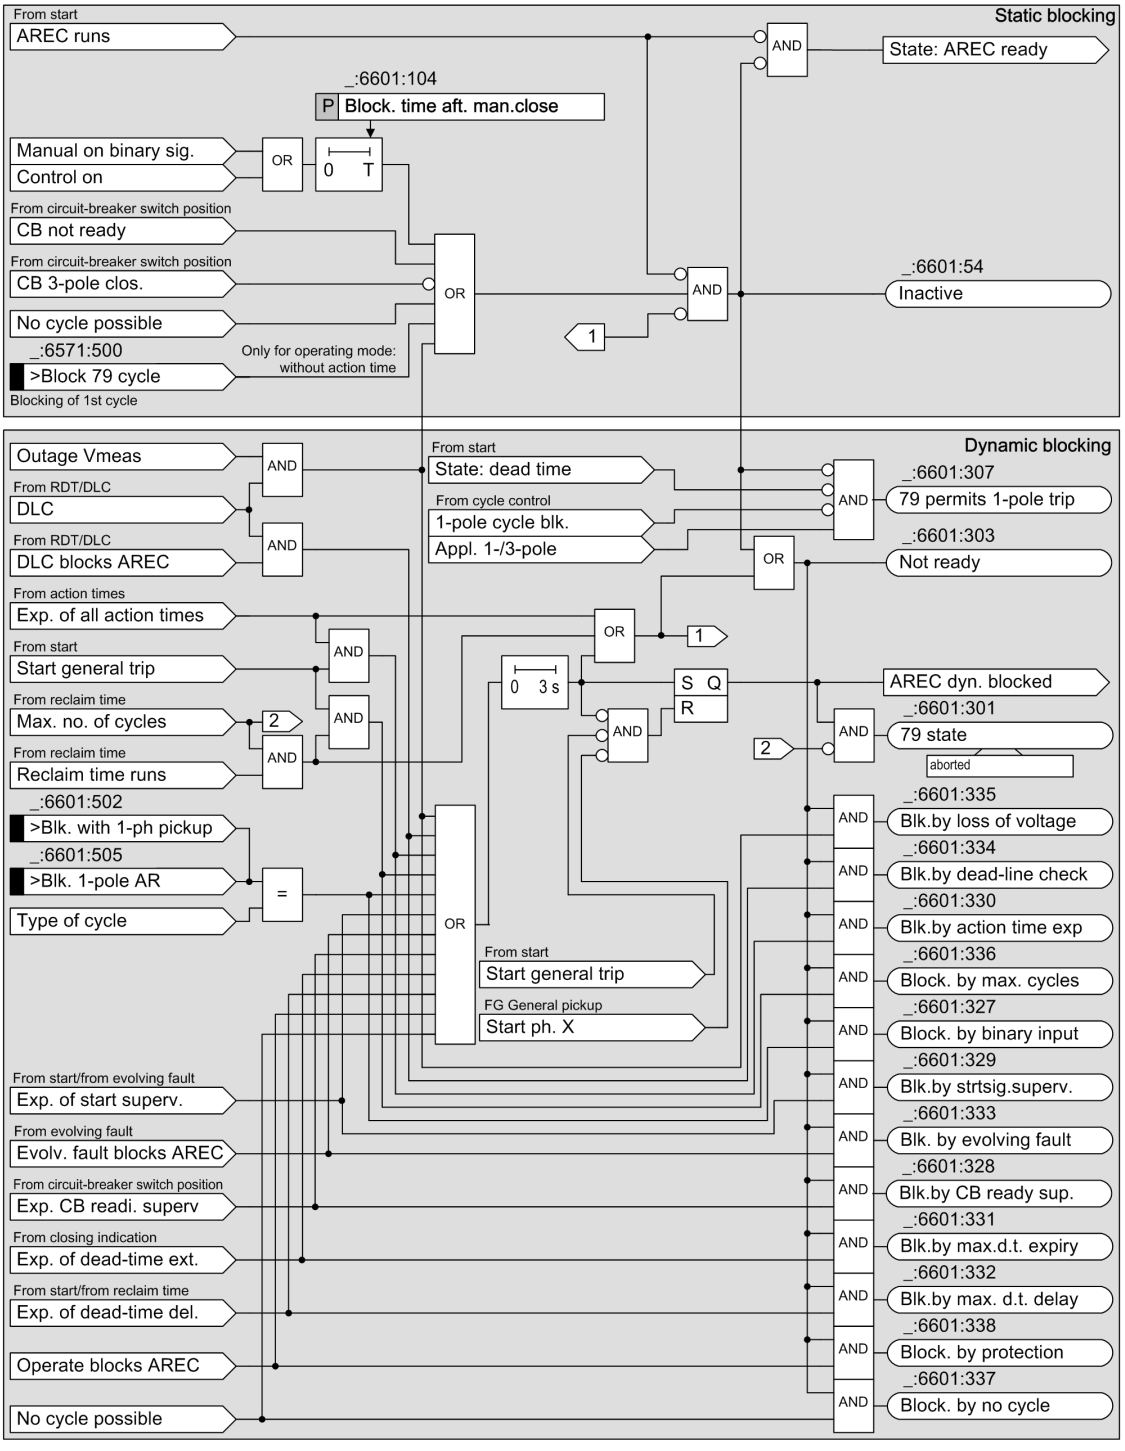
The following conditions lead to the static blocking:

Condition	Indication
Manual closing of the circuit breaker, recognition through binary input or internal device control. The blocking is temporary, the duration can be set with the parameter **Block. time aft. man.close**.	Inactive
Circuit breaker not available for automatic reclosing function, recognition through binary input. This cause can be switched on or off through the parameter **CB ready check bef.close**.	Inactive
Circuit breaker of non-closed 3-pole, recognition through binary input. This criteria is used if the circuit-breaker auxiliary contacts are connected.	Inactive

Condition	Indication
No reclosing cycle possible Recognition due to the following causes: • Automatic reclosing cycle is not set. • Automatic reclosing cycles are set, but all are blocked, for example, via binary input. • There is no internal device function and no binary input configured for starting the automatic reclosing function. • With operating modes **with tripping**: – both 1-pole and 3-pole cycles are blocked via binary inputs • With operating modes **with pickup**: – 1-phase, 2-phase and 3-phase automatic reclosing cycles, the blocking is done through binary inputs. • With operating modes **without action time**: – the first automatic reclosing cycle is blocked via binary input. • With the **dead-line check** functionality: – if the voltage measurement is not available or is disrupted.	Inactive

Dynamic Blocking

The automatic reclosing function is **blocked dynamically** if a blocking condition occurs while an automatic reclosing function is running. The dynamic blocking is signalized with the indication *Not ready*.



After the occurrence of a dynamic blocking, it is checked in intervals of 0.5 s to see if the blocking can be removed. If the blocking condition remains or if a different blocking condition occurs in the meantime, the blocking will remain. If, in contrast, the cause of the blocking disappears, the dynamic blocking will be removed if no general pickup or no tripping configured for the automatic reclosing function start is available.

A separate indication for logging exists for each individual blocking cause.

The following conditions lead to the dynamic blocking:

Condition	Indication
If no reclosing cycle fitting the fault type is released: • With operating modes **with tripping**: If a 1-pole or 3-pole operate indication occurs during the automatic reclosing function start input, however, the automatic reclosing function does not start in accordance with the parameterization for this type of tripping, the respective dead time will be set to ***invalid***. • With operating modes **with pickup**: If a 1-phase, 2-phase or 3-phase pickup indication occurs during the automatic reclosing function starting process, but the automatic reclosing function may not be started in accordance with the parameterization for this type of pickup.	*Not ready* Block. by no cycle
If a protection function causes the automatic reclosing function to be blocked in accordance with the configuration	*Not ready* Block. by protection
If the maximum set waiting time for the delay of the start of the dead time through the binary input *>Dead time start delay* expires without the binary input becoming inactive during this time lapse	*Not ready* Blk.by max. d.t. delay
If the synchrocheck is set and the synchronism conditions after the expiration of the maximum dead-time prolongation are not fulfilled before the assignment of the close command	*Not ready* *Blk.by max.d.t. expiry*

Condition	Indication
If the inquiry of the circuit-breaker readiness is switched on directly before the close command through the parameter and the maximum dead-time prolongation expires	*Not ready* *Blk.by CB ready sup.* *Blk.by max.d.t. expiry*
If the closing indication is delayed through the binary input *>Delay close cmd.* for so long until the maximum dead time extension is exceeded before the assignment of the close command	*Not ready* *Blk.by max.d.t. expiry*
If an evolving fault occurs and the parameter **Response to evolv. faults** is set to ***blocks 79***	*Not ready* *Blk. by evolving fault*
If the start-signal supervision time for the operate indication starting from the automatic reclosing function or the starting binary input expires. In this case, a circuit-breaker failure is assumed.	*Not ready* *Blk.by strtsig.superv.*
If after the start of the automatic reclosing function a dead time is already running and a blocking binary input is active, with the following binary inputs: *>Blk. 1-pole AR*, *>Blk. 3-pole AR*, *>Blk. with 1-ph pickup*, *>Blk. with 2-ph pickup*, >Blk. with 3-ph pickup	*Not ready* *Block. by binary input*
If the maximum number of automatic reclosing attempts is reached and there is a trip command within the reclaim time	*Not ready* *Block. by max. cycles*
With operating modes **with action time**: If the action times of all released automatic reclosing cycles expire without a trip command	*Not ready* *Blk.by action time exp*
For applications with voltage measurement and switched on functionalities with **dead-line check**: If during the dead time the required voltage criteria is not fulfilled	*Not ready* *Blk.by dead-line check*
For applications with voltage measurement and switched on functionalities with **dead-line check**: If during a running automatic reclosing cycle a failure of the measuring voltage is determined. After the completion of the automatic reclosing cycle, the dynamic blocking becomes static blocking if there is a continued failure of the measuring voltage.	*Not ready* *Blk.by loss of voltage*

Figure 6-296 Cyclic Reclosing Function: Blocking Logic in the Example for a 1-Pole Cycle (Static and Dynamic Blocking)

6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)

The additional functions **Dead-line check (DLC)** and **Reduced dead time (RDT)**, are only possible for applications with a voltage-transformer connection. Another requirement is that the voltage of the line being switched on can be correctly measured with an open circuit breaker. This is only possible if the voltage transformer is aligned on the line-side - seen from the circuit breaker.

Both additional functions DLC and RDT are mutually exclusive, because the DLC checks if the value falls below a voltage threshold, while the RDT checks if the value exceeds the voltage threshold.

The respectively selected additional function runs in the automatic reclosing state **dead time**.

Reduced Dead Time (RDT)

With the **Reduced dead time**, a close command can be assigned before the expiration of the set dead times if the line to switch on is recognized as fault-free through the measurement of the line voltage.

The voltage measurement occurs with the 3 phase-to-phase-voltages.

In systems with a grounded neutral point, the 3 phase-to-ground voltages are additionally observed.

In systems with compensated or with isolated neutral points, the largest 2 of the 3 phase-to-ground voltages are additionally considered. Through this, a RDT can also be executed with 1-phase ground connections.

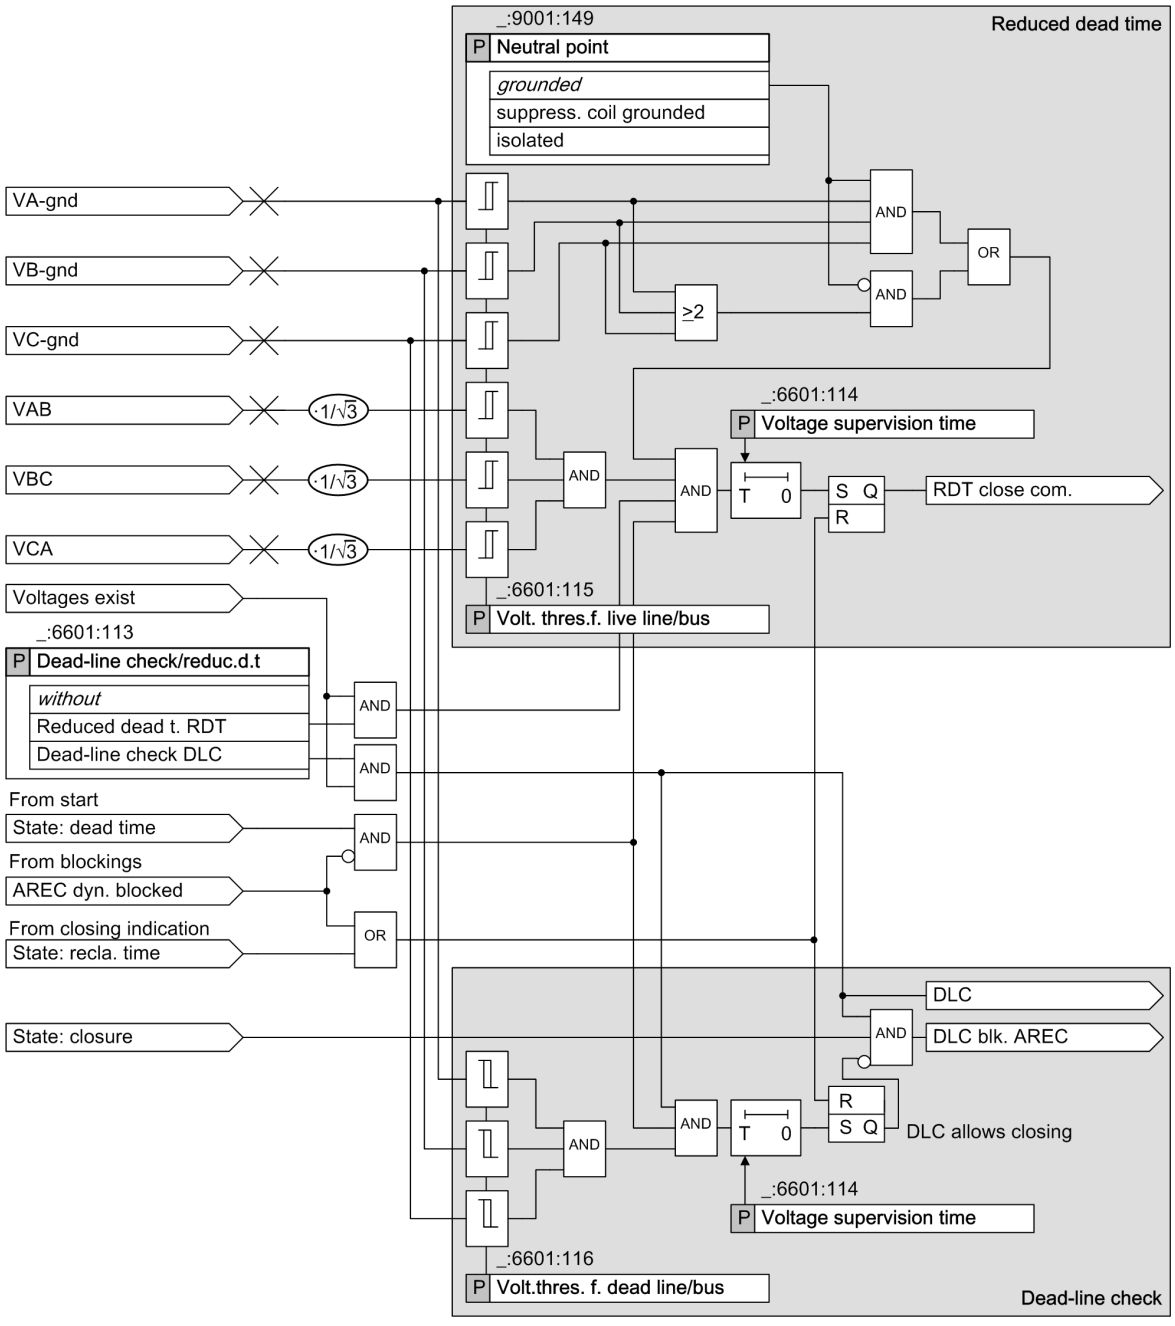
For the approval of the close command with RDT, the following conditions apply:

- The automatic reclosing function is in the state **dead time**.
- Each measured voltage is above the set threshold values **`Volt. thres.f. live line/bus`**
  The phase-to-phase voltages are divided by √3 prior to comparing the threshold value. Thus, the phase-to-ground voltage $U_N\sqrt{3}$ applies as the reference size for the parameterization.
- Exceeding the threshold is fulfilled for the set duration **`Voltage supervision time`**.

Dead-Line Check (DLC)

If after switching off a short-circuit the voltage on the switched off line does not disappear, the automatic reclosing function can be avoided with the **dead-line check (DLC)**.

The voltage measurement occurs with the 3 phase-to-ground voltages.



For the release of the close command with DLC, the following conditions apply:

- The automatic reclosing function is in the state **dead time**.
- All measured voltages for the set duration **`Voltage supervision time`** are below the set threshold **`Volt. thres.f. live line/bus`**.
- The set dead time is expired.

As soon as the voltages fall below the threshold value for the set duration, the allowance for automatic reclosing with DLC is assigned. This also applies if the values are not below the voltage threshold until the expiration of the set dead time. In this way, an automatic reclosing is executed if the automatic reclosing function is first switched to at the end of the protected line and thus, the line is exposed to voltage again.

The automatic reclosing function is blocked by the DLC under the following conditions:

- The automatic reclosing function is in the **Closure** state, the dead time has expired
- All measured voltages were not simultaneously below the set threshold values **`Volt.thres. f. dead line/bus`** for the set duration **`Voltage supervision time`** during the dead time.

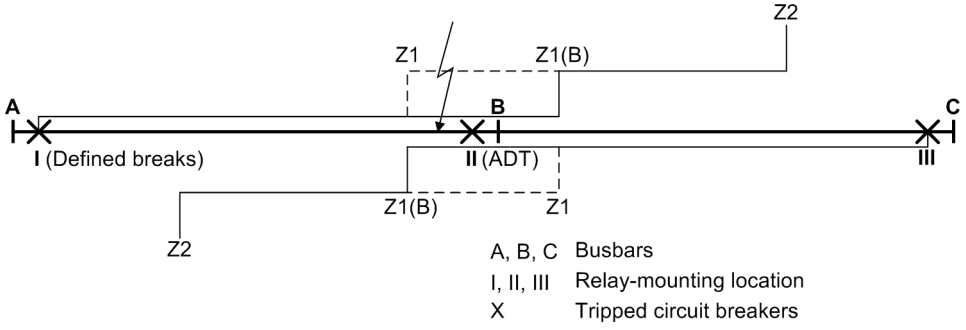
6.43.5 Automatic Reclosing Function with Adaptive Dead Time (ADT)

6.43.5.1 Description

Considering the cyclic automatic reclosing function, it is assumed that defined and similar dead times were set at both line ends and, if applicable, they are set for different types of faults and/or disruption cycles.

It is also possible to set the dead times only at one line end and to configure the adaptive dead time at the other end or ends. The requirements for this is that the voltage transformer aligned on the line side or a possibility to transfer a close command to a remote line end exists.

Figure 6-298 shows an example with a voltage measurement. It is assumed that device I works with defined dead times, while the adaptive dead time is configured in device II. It is important that the line is at least fed from the busbar A, so from the side with the defined dead times.



With the adaptive dead time, the automatic reclosing function at the line end II decides independently if and when a reclosing is reasonable and permissible and when it is not. The criteria is the voltage of the line at the end II, which is switched through after reclosing from end I. The reclosing at end II occurs, as soon as it exists, so that the line from end I is set back under voltage. Basically, all phase-to-phase and phase-to-ground voltages are monitored.

With an implied short-circuit, the lines at the positions I, II, and III in the example are switched off. Position I is switched on again after the dead time set there. At position III the reduced dead time (RDT) can be executed with the appropriate configuration (see chapter *6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)*) if an infeed is also available on busbar B.

If the short circuit has been cleared after successful reclosing, the line A-B from the busbar A will be set under voltage through the position I. Device II recognizes this voltage and switches on to warrant adequate voltage measurement time after a short delay The system incident is thus successfully cleared.

If the short circuit is not cleared after closure at position I, I will be switched to the fault again. At line end II, now no healthy voltage will appear. The device here recognizes this and does not close again.

With multiple reclosing, the process may repeat if the reclosing is unsuccessful until one of the reclosings is successful or a final closing occurs.

[dwarcasp-100611-01.tif, 1, en_US]

Figure 6-298 Example for Adaptive Dead Time (ADT)

As the example shows, the adaptive dead time brings along the following advantages:

- The circuit breaker at position II does not switch off again with a remaining fault and is protected through this.
- With a non-selective tripping through flashing over to position III, no more disruption cycles may exist here, because the short-circuit path through busbar B and the position II remains disrupted even with multiple reclosing.
- At position I, with multiple reclosing and even with a final tripping, an overlapping is allowed, because the line at position II remains open and thus, no actual overreaching can occur at position I.

The adaptive dead time also contains the reduced dead time (VWE), because the criteria are the same. A special setting of the reduced dead time (VWE) is unnecessary if the automatic reclosing function is used with adaptive dead time (ASP).

6.43.6 Cooperation with External Automatic Reclosing Function

6.43.6.1 Description

The operation of an external reclosing device with the SIPROTEC protection device occurs through the function mode **Operation with external automatic reclosing function**. In this function mode, the SIPROTEC protection functions create the trip command and the external reclosing device creates the close command.

The following figure shows the interaction of an external reclosing device with the functions of the SIPROTEC 5 device.

[loaweext-140212-01.tif, 1, en_US]

Figure 6-299 Connection of an External Automatic Reclosing Function

There are no setting parameters for operation with external automatic reclosing functions. The function provides exclusively the following described binary inputs. The external reclosing device can thus have an influence on the effects of the internal protection functions.

The following connection possibilities exist:

- From the external reclosing function, the signal *>Release stages* can be coupled so that the protection functions use special stages or zones for release. An example is the release of an overreaching zone with a distance protection or the non-delayed tripping of an overcurrent protection stage in the 1st reclosing cycle.
- For applications with 1-pole tripping, the external reclosing can provide the signal *>1-pole trip permitted*, based on which the protection functions can switch off the 1-pole circuit breaker.
- For applications with reclosing functions only with 1-pole faults and stage or zone releases through the reclosing function can the signal *>1-pole AR only* be connected. The protection functions use this information to allow the stage or zone release only affect 1-pole faults.

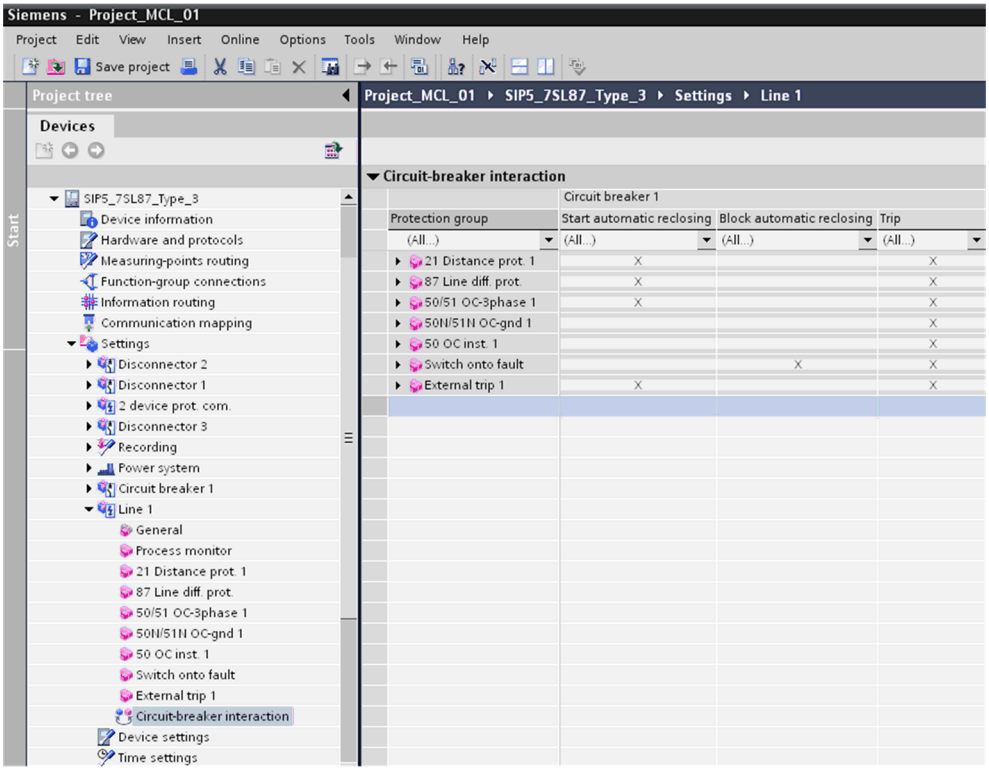
6.43.7 Application and Setting Notes for General Settings

For the automatic reclosing function, there are 3 functions available in the function library. In each circuit-breaker function group, a function from the automatic reclosing function can be used.



Configure one of the 3 following function specifications:

- Cyclic Automatic reclosing function
- Automatic reclosing function with adaptive dead time (ADT)
- Operation with External Automatic Reclosing Function

Starting the Automatic Reclosing Function

The configuration of the interaction between internal protection functions and the automatic reclosing function can be set separately for each protection function. The configuration occurs in a matrix view in DIGSI. The Automatic reclosing function also has the corresponding binary inputs and binary outputs through which the external protection devices can be connected to the internal Automatic reclosing function.

Configure the starting and blocking condition for the automatic reclosing function at the position shown in *Figure 6-300* in DIGSI (for example, a protection function group **Line** is shown here) or route the corresponding binary inputs.

[scdigsia-080311-01.tif, 1, en_US]

Figure 6-300 Configuration of the Protection Functions for Starting and Blocking the Automatic Reclosing Function in DIGSI

General Settings

If you use the **Cyclic automatic reclosing function** or **Automatic reclosing function with adaptive dead time** function, set the following settings under **General**.

There are no settings for the function **Operation with external automatic reclosing function**. The control occurs exclusively through binary inputs and binary outputs.

Parameter: 79 operating mode

- Default setting **(_:6601:101) 79 operating mode** = ***with op., with act. time***

You can use the **79 operating mode** parameter to determine which start criteria the automatic reclosing function works with.

Parameter Value	Description
with op., with act. time	The automatic reclosing function cycles are dependent on the operate time of the protection function(s). The start occurs with all protection function(s) or protection stages that are configured through the automatic reclosing function start matrix. Siemens generally recommends this setting for applications with 1/3-pole tripping and for applications with 3-pole tripping if a single dead time, independent of the type of connection working, is required in the automatic reclosing function cycle. Detailed information can be found in Chapter *6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function* , section **Operating mode 1**
w.pickup, w. action time	The automatic reclosing function cycles are dependent on the operate time of the protection function(s) and the type of fault. The start occurs with all protection function(s) or protection stages that are configured through the automatic reclosing function start matrix. For applications with 3-pole tripping and dead time dependent on the circuit type, Siemens recommends this setting. Detailed information can be found in the chapter *6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function* , section **Operating Mode 2**
with op., w/o act. time	Each operate indication starts the automatic reclosing function. The start occurs with all protection function(s) or protection stages that are configured through the automatic reclosing function start matrix. The automatic reclosing function start must be configured so that it only occurs from the protection stages/zones for which an automatic reclosing should occur after tripping. Detailed information can be found in the chapter *6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function* , section **Operating Mode 3**
w.pickup, w/o act. time	Each operate indication starts the automatic reclosing function. The automatic reclosing function cycles are dependent on the type of fault. The start occurs with all protection function(s) or protection stages that are configured through the automatic reclosing function start matrix. The automatic reclosing function start must be configured so that it only occurs from the protection stages/zones for which an automatic reclosing should occur after tripping. Detailed information can be found in the chapter *6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function* , section **Operating Mode 4**

Parameter: CB ready check bef. start

- Default setting **(_:6601:102) CB ready check bef. start** = ***no***

With the **CB ready check bef. start** parameter, you can determine if the readiness of the circuit breaker should be tested **before starting** the automatic reclosing function.

Additionally or alternatively, it is possible to check the readiness of the circuit breaker after the expiration of the dead time, directly before the assignment of the close command. There is another parameter described in the chapter *6.43.8 Application and Setting Notes for 1 Cycle of the Cyclic Automatic Reclosing Function* for this function.

Parameter Value	Description
yes	The automatic reclosing function checks the readiness of the circuit breaker for a switching cycle, consisting of a tripping-reclosing-switching. If the circuit breaker is ready - signaled through a binary input - the startup of the automatic reclosing function can occur. If the circuit breaker is not ready, the automatic reclosing function reports the static blocking. Siemens recommends using this setting. **Note:** The presetting of this parameter does not correspond with the recommended setting for operation. The automatic reclosing function would otherwise be blocked with a non-available circuit breaker-ready-signal. Please set the parameter as recommended.
no	The readiness of the circuit breaker is not checked before starting the automatic reclosing function. The test also does not occur if the readiness signal from the circuit breaker is connected to a binary input on the device.

Parameter: Reclai. time aft.succ.cyc.

- Default setting **(_:6601:103) Reclai. time aft.succ.cyc.** = ***3.00 s***

With the **Reclai. time aft.succ.cyc.** parameter, set the time used to decide if the currently running reclosing cycle was successful or not. Detailed information about the function of the reclaim time can be found in the chapter *6.43.4.15 Reclaim Time* .

The presetting for the reclaim time can be frequently maintained. In regions where thunderstorms and storms often occur, a shorter reclaim time makes sense in order to minimize the danger of the final disconnection due to sequential lightning strikes or cable spark over.

Select a long reclaim time if there is no possibility for circuit-breaker supervision with multiple automatic reclosing, for example, due to missing auxiliary contacts or lacking circuit-breaker-ready-information. In this case, the reclaim time must be longer than the recovery time of the circuit breaker.

Parameter: Block. time aft. man.close

- Default setting **(_:6601:104) Block. time aft. man.close** = ***1.00 s***

With the **Block. time aft. man.close** parameter, the time is determined for which the automatic reclosing should be blocked after a manual connection.

Set the time so that the circuit breaker can be safely switched on and off during connection to a short circuit without the automatic reclosing function being automatically closed.

Parameter: Start signal supervis.time

- Default setting **(_:6601:105) Start signal supervis.time** = ***0.25 s***

With the **Start signal supervis.time** parameter, set the maximum time after which a circuit breaker must be opened after a trip command. If the time expires, a failure of the circuit breaker is assumed and the automatic reclosing function is dynamically blocked.

Detailed information about the function of the start supervision time can be found in the chapter *6.43.4.5 Start* .

NOTE

With the use of an internal or external circuit-breaker failure protection at the same line branch, observe the following:

The start supervision time should be the same as the circuit-breaker failure protection time delay. With this, you can make sure that in the case of a circuit-breaker failure followed by the tripping of the busbar, no automatic reclosing will be executed.

(Note: An exception to this recommendation is described below.)

Parameter: CB ready superv. time

The setting of this parameter is only important if the cycle-specific parameter **CB ready check bef.close** is set to ***yes*** . Otherwise, this parameter has no effect.

- Default setting **(_:6601:106) CB ready superv. time** = ***3.00 s***

With the **CB ready superv. time** parameter, you can determine after which maximum time after the tripping the circuit breaker must be ready for the reclosing function.

Set the time somewhat longer than the regeneration time of the circuit breaker after an OFF-ON-OFF cycle.

Detailed information about the function can be found in Chapters *6.43.4.16 Circuit-Breaker Readiness* and *6.43.4.14 Closing Indication and Close Command* .

Parameter: Evolving-fault detection

This parameter is not important and cannot be set if you use the ADT function (automatic reclosing function with adaptive dead time).

- Default setting **(_:6601:108) Evolving-fault detection** = ***with trip***

With the **Evolving-fault detection** parameter, you can determine which criteria is used to recognize an evolving fault. The actual effect of the recognized evolving fault on the automatic reclosing function can be set with the parameter described below **Response to evolv. faults** .

Evolving faults are short circuits, which occur after switching off a short circuit during dead time.

You can find detailed information about evolving-fault detection in the chapter *6.43.4.13 Evolving-Fault Detection During Dead Time* .

Parameter Value	Description
with trip	Evolving faults are recognized if an operate indication occurs during the dead time. Thus, it does not matter if the tripping-protection function is configured for the start of the automatic reclosing function or not. The pickup of a protection function without an operate indication does not lead to evolving-fault detection.
with pickup	Evolving faults are detected if during the dead time a protection function configured for the automatic reclosing function start is picked up or if an external pickup is detected through a binary input.

For applications with 1-/3-pole tripping, Siemens recommends the setting ***with trip*** if the system is adequately interconnected.

If multiple individual lines in a row form a total transmission path, the setting ***with pickup*** may be better suitable. With this setting, you can prevent 2 lines following each other from switching to 1-pole in different conductors during evolving faults. The consequence of this fault would be the remainder of a single conductor in the dead time for the overall transmission path. This is particularly important if power plants are coupled through the overall transmission path.

Parameter: Response to evolv. faults

This parameter is not important and cannot be set if you use the ADT function (automatic reclosing function with adaptive dead time).

- Default setting **(_:6601:109) Response to evolv. faults** = ***blocks 79***

With the **Response to evolv. faults** parameter, you can determine how the automatic reclosing function reacts to recognized faults.

You can find detailed information about the automatic reclosing function for faults in the chapter *6.43.4.13 Evolving-Fault Detection During Dead Time* .

Parameter Value	Description
blocks 79	The automatic reclosing function is immediately blocked until the disconnection of the fault. For blockings through faults during the 1-pole dead times, you can force a 3-pole trip command through the automatic reclosing function if the you set the parameter **3-pole operate by 79** to ***yes*** .
strt. evol.flt.dead time	After the 3-pole trip command to clear up the fault, the automatic reclosing function starts a new 3-pole automatic reclosing function cycle with the set **Dead time aft. evolv. fault** .

Parameter: Max. dead-time delay

This parameter is not important and cannot be set if you use the ADT function (automatic reclosing function with adaptive dead time).

- Default setting **(_:6601:110) Max. dead-time delay** = ***0.5 s***

With the **Max. dead-time delay** parameter, you determine at which time the starting of the dead time may be delayed before the automatic reclosing function is dynamically blocked.

The delay of the start of the dead time is possible with the binary input **>Dead time start delay** .

You can find detailed information about the functionality in the chapter *6.43.4.5 Start* .

Parameter: Max. dead-time extension

- Default setting **(_:6601:111) Max. dead-time extension** = ***1.2 s***

With the **Max. dead-time extension** parameter, you determine the time by which the dead time may be extended before the automatic reclosing function is dynamically blocked.

With the setting ***oo (invalid)***, the extension is unlimited.

An extension of the dead time can be required under the following conditions:

- Waiting for the readiness of the circuit breaker
- Inquiry of a synchronous test
- Delay through binary input in order e.g. to give the leading automatic reclosing function priority in a system with 1 1/2 circuit breaker layout.

Remember that longer dead times after 3-pole disconnection are only permissible if no stability problems occur or if a synchronous test occurs before the reclosing.

You can find detailed information about the functionality in the chapter *6.43.4.14 Closing Indication and Close Command* .

Parameter: Voltage supervision time

This parameter is only important if you use the subfunctions RDT, DLC, or the ADT function. If you do not use any of these functions, the setting of this parameter is free to select.

- Default setting **(_:6601:114) Voltage supervision time** = ***0.1 s***

With the **Voltage supervision time** parameter, you can determine the measuring time that is available as a criteria for the voltage decision. It should be longer than all transient oscillations through switching operations.

For the subfunctions **Reduced dead time** and **Reclosing function with adaptive dead time**, this measuring time applies for the determination of the surpassing of a voltage threshold. For the subfunction **Dead-line check**, the surpassing of a voltage threshold is checked.

Siemens recommends the setting 0.10 s.

Detailed information about the functionality can be found in the following parameters and in the chapters *6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)* and *6.43.5.1 Description* .

Parameter: Volt. thres.f. live line/bus

This parameter is only important if you use the subfunction **RDT** or the function **ADT**. If you do not use any of these functions, the setting of this parameter is free to select.

- Default setting **(_:6601:115) Volt. thres.f. live line/bus** = ***48 V***

With the **Volt. thres.f. live line/bus** parameter, you can determine the limit voltage above which the line should be seen as fault-free. It must be lower than the smallest expected operating voltage. The phase-to-ground voltage applies as the reference value.

Detailed information about the functionality can be found in the following settings and in the chapters *6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)* and *6.43.5.1 Description* .

Parameter: Dead-line check/reduc.d.t

This parameter is not important and cannot be set if you use the ADT function (automatic reclosing function with adaptive dead time).

- Default setting **(_:6601:113) Dead-line check/reduc.d.t** = ***without***

With the **Dead-line check/reduc.d.t** parameter, you can determine if the automatic reclosing function should work with one of the additional functions ***Dead-line check DLC*** or ***Reduced dead t. RDT*** .

Parameter Value	Description
without	The automatic reclosing function occurs after the expiration of the parameterized dead times. DLC or RDT are not activated.
Reduced dead t. RDT	The automatic reclosing function works with a reduced dead time (RDT).
Dead-line check DLC	The automatic reclosing functions works with dead-line check. The closing indication is only assigned if the line was really de-energized during the dead time.

You can find detailed information about the functionality in the chapter *6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)* .

NOTE

Use RDT or DLC only if the voltages of the line can be correctly measured with an open circuit breaker. This is only possible if the voltage transformer is aligned on the line-side - seen from the circuit breaker.

Parameter: Volt.thres. f. dead line/bus

This parameter is only important if you use the Dead-line check subfunction. If you do not use any of this subfunction, the setting of this parameter is free to select.

- Default setting **(_:6601:116) Volt.thres. f. dead line/bus** = ***30 V***

With the **Volt.thres. f. dead line/bus** parameter, you can determine the limit voltage below which the line should be seen with certainty as idle or switched off. The threshold value is used by the Dead-line check subfunction (dead-line check). The reference size is the phase-to-ground voltage.

You can find detailed information about the functionality in the chapter *6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT)* .

Parameter: Send delay f. remot. close

With the **Send delay f. remot. close** parameter, you can determine after which time after the automatic reclosing function the information is sent to the remote closing.

- Default setting **(_:6601:112) Send delay f. remot. close** = ***oo (invalid)***

The transmission delay prevents the device operating in the adaptive dead time mode on the opposite side from closing unnecessarily if the local reclosing function remains unsuccessful. On the other hand, it must be remembered that the line is not available for transporting energy as long as the opposite end is also closed. Thus, the **Send delay f. remot. close** must be added to the dead time in order to determine the system stability.

You can find detailed information about this functionality in the chapter *6.43.4.14 Closing Indication and Close Command* .

6.43.8 Application and Setting Notes for 1 Cycle of the Cyclic Automatic Reclosing Function

For the function of the cyclic automatic reclosing function, 1 cycle is preset. The preset cycle cannot be deleted. You can add and delete more cycles from the function library in **DIGSI 5**.

Parameter: Start from idle state allow.

This parameter is only important and can be set if you use the automatic reclosing function in an operating mode ***with action time***.

- Default setting **(_:6571:102) Start from idle state allow.** = ***yes***

With the parameter **Start from idle state allow.** you can determine whether the action time of this automatic reclosing cycle is started, if the automatic reclosing function is in idle state during with incoming general pickup. Please set the parameter always to ***yes*** , if the automatic reclosing function is configured for only 1 cycle. If several cycles are configured, you can control the effectiveness of the automatic reclosing cycles with this parameter and various action times.

Detailed information about the functionality can be found in Chapters *6.43.4.6 Cycle Control with Operating Mode 1: With Tripping/With Action Time* und *6.43.4.7 Cycle Control with Operating Mode 2: With Pickup/With Action Time* .

Parameter: Action time

This parameter is only important and can be set if you use the automatic reclosing function in an operating mode ***with action time***.

- Default setting **(_:6571:103) Action time** = ***0.2 s***

With this parameter **Action time** you can determine, within which time frame the trip command must appear, in order to start the automatic reclosing function. If the trip command occurs only after the action time has expired, automatic reclosing does not occur within the active automatic reclosing cycle.

You can find detailed information about the functionality in

Chapters *6.43.4.6 Cycle Control with Operating Mode 1: With Tripping/With Action Time* and *6.43.4.7 Cycle Control with Operating Mode 2: With Pickup/With Action Time* .

Parameter: Dead time aft. 3-pole trip

This parameter is only important and can be set if you use the automatic reclosing function in an operating mode ***with tripping***.

- Default setting **(_:6571:108) Dead time aft. 3-pole trip** = ***0.5 s***

With this parameter **Dead time aft. 3-pole trip** , you can determine after which dead time the automatic reclosing function will be executed. After a 3-pole trip of the circuit breaker, the system stability is priority. Since the switched off line cannot develop synchronizing forces, only a short dead time is permitted in most cases. The usual duration is 0.3 s to 0.6 s. A longer period can be tolerated if a synchrocheck is carried out prior to reclosing. Longer 3-pole dead times are also possible in radial systems.

Parameter: Dead time aft.1ph. pickup, Dead time aft.2ph. pickup, Dead time aft.3ph. pickup

This parameter is only important and can be set if you use the automatic reclosing function in an operating mode ***with pickup***.

- Default setting **(_:6571:104) Dead time aft.1ph. pickup** = ***1.2 s***
- Default setting **(_:6571:105) Dead time aft.2ph. pickup** = ***1.2 s***
- Default setting **(_:6571:106) Dead time aft.3ph. pickup** = ***0.5 s***

With the 3 dead-time parameters, you can determine after which dead time the automatic reclosing function will be executed. Please set the times as desired for the respective type of short circuit.

- The parameter **Dead time aft.1ph. pickup** applies to dead times after 1-phase short circuits and the following protection tripping: A, B, C, or A-Gnd, B-Gnd, C-Gnd
- The parameter **Dead time aft.2ph. pickup** applies to dead times after 2-phase short circuits and the following protection tripping: A-B, B-C, C-A, or A-B-gnd, B-C-gnd, C-A-gnd
- The parameter **Dead time aft.3ph. pickup** applies to dead times after 3-phase short circuits and the following protection tripping: A-B-C or A-B-C-Gnd

NOTE

If you would like to avoid automatic reclosing during individual short-circuit types, please set the respective dead times to ***oo (invalid)***.

Example:

After 1-phase short-circuits, the automatic reclosing function should occur after 1.2 s. The automatic reclosing function should not occur for 2-phase and 3-phase short circuits.

For this application, the parameters should be set as follows:

- **Dead time aft.1ph. pickup** = ***1.2 s***
- **Dead time aft.2ph. pickup** = ***oo (invalid)***
- **Dead time aft.3ph. pickup** = ***oo (invalid)***

Parameter: Dead time aft. evolv. fault

These parameters are only significant if the parameter **(_:6601:109) Response to evolv. faults** is set to ***strt. evol.flt.dead time*** .

- Default setting **(_:6571:109) Dead time aft. evolv. fault** = ***1.2 s***

With the parameter **Dead time aft. evolv. fault** , you can determine after which dead time the automatic reclosing function should be executed, if based on an evolving fault during the current dead time, a 3-pole trip has occurred. For this 3-pole dead time, stability concerns for the system are also important. Often, this dead time as well as the parameter **(_:6571:108) Dead time aft. 3-pole trip** can be set.

Detailed information about the function during evolving faults during dead time are described in Chapter *6.43.4.13 Evolving-Fault Detection During Dead Time* .

Parameter: CB ready check bef.close

- Default setting **(_:6571:111) CB ready check bef.close** = ***no***

With the parameter **CB ready check bef.close** you can determine if after the expiration of the dead time (meaning, directly prior to assigning the close command) readiness of the circuit breaker should be queried.

Parameter Value	Description
no	With the setting ***no*** , the automatic reclosing function does not check again the readiness of the circuit breaker prior to assigning the close demand. Siemens recommends this setting, if it is sufficient to check the readiness of the circuit breaker for the entire switching cycle once before the start of a reclosing function, consisting of tripping-reclosing-tripping. The setting for checking the readiness of the circuit breaker prior to the start of the automatic reclosing function is done using the parameter **(_:6601:102) CB ready check bef. start** .

Parameter Value	Description
yes	With the setting ***yes*** , the dead time can be extended if after the expiration of the dead time the circuit breaker is not ready for the next ON-OFF cycle. The maximum delay of the dead time can be set with the parameter **(_:6601:111) Max. dead-time extension** . Siemens recommends this setting, if it can be assumed that the circuit breaker becomes available to switch on the reclosing function only after an additional waiting period.

Detailed information about the function can be found in Chapters *6.43.4.16 Circuit-Breaker Readiness* and *6.43.4.14 Closing Indication and Close Command* .

Parameter: Synchroch. aft. 3-pole d.t.

- Default setting **(_:6571:110) Synchroch. aft. 3-pole d.t.** = ***none***

With the parameter **Synchroch. aft. 3-pole d.t.** you can determine if a synchrocheck must be carried out for the configured automatic reclosing cycle.

If during a 3-pole interruption in the system stability problems may be a concern, the synchrocheck should be carried out. If only 1-pole reclosure cycles are possible or stability problems are not to be expected during the 3-pole dead time, for example, due to a highly intermeshed system or radial system, please select the parameter ***none*** .

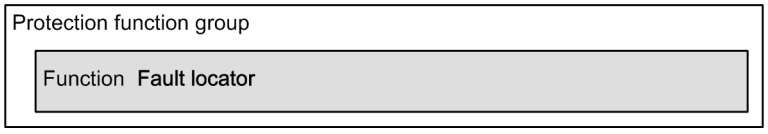
Parameter Value	Description
none	During the automatic reclosing cycle a synchrocheck is not executed.
internal	In the configured automatic reclosing cycle, a synchrocheck is executed after a 3-pole dead time prior to the close command of the circuit breaker. For the synchrocheck a synchrocheck stage of the internal synchronization function is used, which is contained in the same function group as the circuit breaker and the automatic reclosing function. The selection of the synchrocheck stage that is used in the automatic reclosing cycle occurs through the following described parameter **Internal synchrocheck**.
external	In the configured automatic reclosing cycle, a synchrocheck is executed after a 3-pole dead time prior to the close command of the circuit breaker. An external synchrocheck device initiates the synchrocheck. The external synchrocheck device is connected with the binary signals *Synchrocheck request* and *>Release by ext.sync.* . Detailed information about the function can be found in Chapter *6.43.4.14 Closing Indication and Close Command* under the section **Synchrocheck**.

Parameter: Internal Synchrocheck

These parameters are only significant if the previously described parameter **(_:6571:110) Synchroch. aft. 3-pole d.t.** is set to ***internal*** .

With the parameter **Internal Synchrocheck**, you can determine which function block of the synchronization function for the automatic reclosing function is used after a 3-pole dead time. This selection is only possible for function blocks of the synchronization function, and which are included in the same circuit-breaker function group as the automatic reclosing function. The setting options of the parameter will be generated dynamically, according to the actual parameterization.

6.44 Fault Locator



6.44.1 Overview of Functions

The **Fault locator** function serves for measuring the fault distance in the event of a short circuit.

Quick determination of fault location and the associated rapid troubleshooting increase the availability of the line for the power transmission in the electrical power system. Determining the fault location is based on the loop-impedance calculation of short-circuited measuring loops.

6.44.2 Structure of the Function

The **Fault locator** function can be used in protection function groups with 3-phase current and voltage measurement.

[dwstbafo-090812-01.tif, 1, en_US]

Figure 6-301 Structure/Embedding of the Function

The recording of phase currents and voltages is a prerequisite for calculation of fault locations. The **Fault locator** function contains all necessary control parameters.

The fault location is calculated based on the line parameter. The fault-location calculation starts ***with operate indication*** or ***for dropout*** of the short-circuit protection.

The following functions can start the fault locator:

- Overcurrent protection, phases or ground
- Directional overcurrent protection, phases or ground
- Instantaneous high-current tripping

NOTE

The **Fault locator** function does not work with all possible current and voltage transformer connection types. An error message is displayed in DIGSI 5 if the **Fault locator** function cannot work with the set connection types. In this case check the current and voltage transformer connection type. You will find the **`current transformer connection`** or **`voltage transformer connection`** settings in DIGSI 5 under **Power-system data** → **Measuring point I-3ph** or **Power-system data** → **Measuring point V-3ph**.

The **Fault locator** function only works with the following current and voltage transformer connection types (see parameter value).

Parameter	Parameter Value
`CT connection`	***`3-phase + IN-separate`***
	`3-phase + IN`
	`3-phase`
`VT connection`	***`3 ph-to-gnd volt. + VN`***
	`3 ph-to-gnd voltages`

6.44.3 Function Description

Starting Conditions

The fault location is an independent function with its own measurand memory and its own filter algorithms. To define the valid measuring loop and the most favorable time interval for the measured variable saving, only a start command is required by the short-circuit protection. The fault location can be started by tripping of the short-circuit protection or also at each pickup. If another protection device causes the disconnection of a short-circuit, a fault-location calculation is then also possible for each pickup. In the event of a fault outside the line to be protected, the fault-location indication cannot always be relevant, however, because the measurands can be falsified by the center infeed for example.

Determining the Fault Location

The recorded sampled values of the short-circuit voltage and voltage are frozen shortly after tripping of the protection. No error in the measured value has then occurred through the switch-off process, even in the case of very fast circuit-breakers. The measurands and the impedance calculations are automatically filtered and only indicate a steady-state measured value in the determined data window.

After disconnection of the short-circuit, the measured values are analyzed and the fault location calculated from the short-circuit loops. If no fault location can be calculated, the indication *FO invalid* is output.

Output of the Fault Location

The following results for the fault location are output:

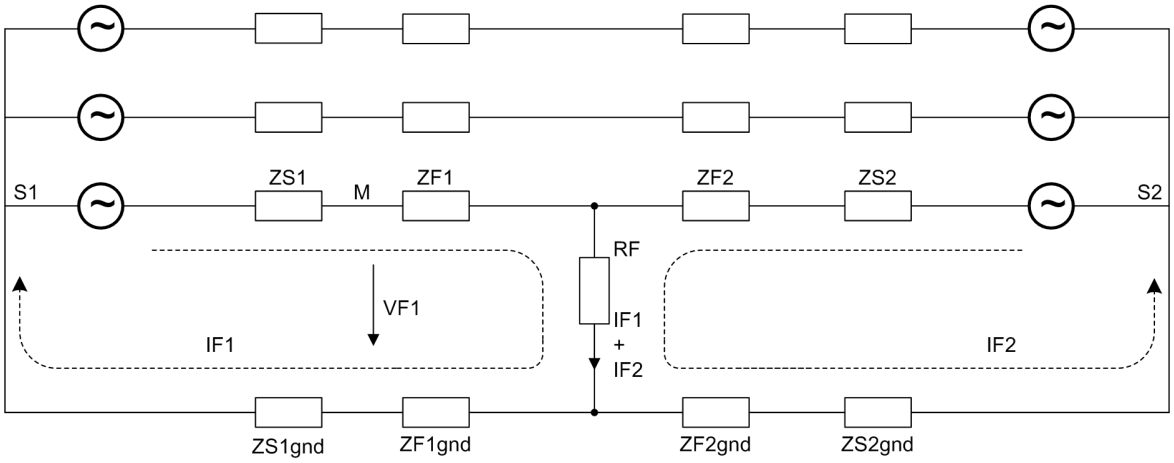
- Short-circuit loop determined from the fault reactance
- Fault reactance X in Ω primary
- Fault resistance R in Ω primary
- Fault impedance in polar coordinates (amount in Ω, angle in degrees)
- Fault distance ***d*** of the line proportional to the reactance in kilometers or miles, converted on the basis of the parameterized reactance per unit length of the line
- Fault distance ***d*** as a percentage of the line length, calculated on the basis of the parameterized reactance per unit length and the parameterized line length
- Selected fault loop for calculation of the fault location

NOTE

Specification of distance in kilometers, miles, or percent is relevant only for homogenous line sections. If the line comprises parts which exhibit different reactances per unit of length (for example, overhead-line-cable sections), you can then analyze the reactance determined from the fault location for separate calculation of the fault distance.

Measured-Value Correction for Parallel Lines

In the event of ground faults on double lines, the values determined for the impedance calculation are influenced by the coupling of the ground impedances of both line systems. Without special measures, this leads to measuring errors in the impedance-calculation result. The device is therefore equipped with parallel-line compensation. This parallel-line compensation takes into account the ground current of the parallel line in the line equation and consequently compensates the coupling influence, similar to determining of the distance in distance protection. The ground current of the parallel line must be connected to the device and configured for this. The parallel-line compensation applies only to faults on the line to be protected. Compensation is not possible for faults located externally including those on the parallel line.



You can activate and deactivate the parallel-line compensation with the **`Parallel-line compensat.`** parameter.

Measured-Value Correction at Load Current on Lines Fed on Both Sides

In the case of faults on lines fed on both sides and with load transport (see next figure), the fault voltage Y_{F1} is not only influenced by the source voltage E_1, but also by the source voltage E_2, if both voltage sources feed to the common fault resistance R_F. Without special measures, this leads to measuring errors in the impedance-calculation result, since the current component I_{F2} cannot record at the measuring point M. For long lines and lines subject to high loads, this measuring error can be considerable in the crucial X component of the fault impedance (for the distance calculation).

The fault location has a load compensation, which corrects this measuring error in 1-pole short-circuits. A correction is not possible for the R component of the fault impedance. However, the measuring error is not critical here, as only the X component is decisive for the fault distance.

The load compensation acts in 1-phase short circuits. In doing so, both the positive-sequence and zero-sequence system of the balanced components are analyzed for the correction. You can activate and deactivate the load compensation via the **`Load compensation`** parameter.

[dwfailur-190912-01.tif, 1, en_US]

Figure 6-302 Fault Currents and Voltages in a Line Fed on Both Sides

M	Measuring point
S1, S2	Source voltage (EMF)
IF1, IF2	Partial fault currents
IF1 + IF2	Total fault current
VF1	Fault voltage at the measuring point
RF	Common fault resistance
ZF1, ZF2	Fault impedances
ZF1gnd, ZF2gnd	Ground fault impedances
ZS1, ZS2	External impedances
ZS1gnd, ZS2gnd	Ground external impedances

6.44.4 Application and Setting Notes

The function requires the following key line data to calculate fault distance:

- Reactance per unit length of the line per kilometer or per mile
- Line length for the correct output of the fault distance as a percentage of the line length
- The residual compensation factors in setting format **`Kr`** and **`Kx`**

Parameter: Start

- Default setting **(_:101) Start** = ***with dropout***

The **Start** parameter is used to define the criterion for starting the fault location. The following functions can start the fault locator:

- Overcurrent protection, phases or ground
- Directional overcurrent protection, phases or ground
- Instantaneous high-current tripping

Parameter Value	Description
with dropout	The fault-location calculation starts with the dropout of one of the protection functions listed previously.
with operate indication	If one of the protection functions listed previously generates an operate indication, calculation of the fault location starts.

As an alternative, the fault locator can be started using external binary input.

Parameter: Load compensation

- Default setting **(_:103) Load compensation** = ***no***

The **Load compensation** parameter can be used to correct measuring errors for 1-pole short circuits on lines fed on both sides. This is the case for overhead lines without grounding cable or with unfavorable grounding conditions of the towers, if high transition resistances can occur in the event of 1-pole short circuits.

Parameter Value	Description
no	The load compensation is deactivated with this setting.
yes	The load compensation becomes effective with this setting.

Parameter: X per length unit

- Default setting **(_:113) X per length unit** = ***0.210 Ω/km***

With the **X per length unit** parameter you set the reactance per unit length for the line to be protected. You set the **X per length unit** parameter as a relative value in Ω/km or Ω/miles.

Parameter: Line length

- Default setting **(_:114) Line length** = ***60 km***

With the **Line length** parameter, you can set the length of the line to be protected as unit of length in km or miles.

Parameter: Line angle

- Default setting **(_:108) Line angle** = ***85.00°***

Calculate the setting value for the parameter **Line angle** from the line constants for the line to be protected as follows:

$$\tan\varphi = \frac{X_L}{R_L} \qquad \text{or} \qquad \varphi = \arctan\left(\frac{X_L}{R_L}\right)$$

[folwinkl-050509-01.tif, 1, en_US]

where:

R_L	Resistance of the line to be protected
X_L	Reactance of the line to be protected

EXAMPLE

110-kV overhead line, 150 mm² with the data

$R'_1 = 0.19\ \Omega/km$

$X'_1 = 0.42\ \Omega/km$

You calculate the setting value for the line angle as follows:

$$\tan\varphi = \frac{X_L}{R_L} = \frac{X'_1}{R'_1} = \frac{0.42\ \Omega/km}{0.19\ \Omega/km} = 2.21$$

$$\arctan(2.21) = 65.7°$$

[folwibsp-050912-01.tif, 1, en_US]

Parameter: Kr and Kx

- Default setting **(_:104) Kr** = ***1.00***
- Default setting **(_:105) Kx** = ***1.00***

The **Kr** and **Kx** parameters are used to set the residual compensation factors as scalar values. The **Kr** and **Kx** parameters are relevant for the **Fault locator** function.

Calculate the setting values for the parameters **Kr** and **Kx** from the line data as follows:

Resistance ratio

$$Kr = \frac{R_{gnd}}{R_L} = \frac{1}{3} \cdot \left(\frac{R_0}{R_1} - 1 \right)$$

Reactance ratio

$$Kx = \frac{X_{gnd}}{X_L} = \frac{1}{3} \cdot \left(\frac{X_0}{X_1} - 1 \right)$$

where:

R_0	Zero-sequence system resistance of the line
X_0	Zero-sequence system reactance of the line
R_1	Positive-sequence system resistance of the line
X_1	Positive-sequence system reactance of the line

This data can either be used for the entire line or as length-related values, since the quotients are length-independent. You can calculate the data both from the primary values and from the secondary values.

EXAMPLE

110-kV overhead line, 150 mm² with the data:

R_1/s	0.19 Ω/km positive-sequence system resistance
X_1/s	0.42 Ω/km positive-sequence system reactance
R_0/s	0.53 Ω/km zero-sequence system resistance
X_0/s	1.19 Ω/km zero-sequence system reactance
s	Line length

You receive the following setting values for the parameters **Kr** and **Kx** :

$$Kr = \frac{R_{gnd}}{R_L} = \frac{1}{3} \cdot \left(\frac{R_0}{R_1} - 1 \right) = \frac{1}{3} \cdot \left(\frac{0.53\ \Omega/km}{0.19\ \Omega/km} - 1 \right) = 0.60$$

$$Kx = \frac{X_{gnd}}{X_L} = \frac{1}{3} \cdot \left(\frac{X_0}{X_1} - 1 \right) = \frac{1}{3} \cdot \left(\frac{0.19\ \Omega/km}{0.42\ \Omega/km} - 1 \right) = 0.61$$

[forerlx1-050912-01.tif, 1, en_US]

Parameter: K0 and Angle (K0)

- Default setting **K0** = *1.000*
- Default setting **Angle (K0)** = *0.00°*

NOTE

The visibility of the **K0** and **Angle (K0)** parameters depends on the selected setting format of the residual compensation factors. The parameters **K0** and **Angle (K0)** only become visible after you have set the parameter **Set. format residu. comp.** = *K0* for the device. The **Set. format residu. comp.** parameter can be found in the DIGSI 5 project tree under **Name of the device** → **Parameter** → **Device settings**.

The **K0** and **Angle (K0)** parameters are used to set the complex residual compensation factor.

Make sure that the line angle is set correctly because the device needs the line angle for calculation of the compensation components from the K0 factor. The complex residual compensation factor is defined by the value and the angle. You can calculate the complex residual compensation factor from the line data as follows:

$$\underline{K}_0 = \left| \frac{\underline{Z}_{gnd}}{\underline{Z}_L} = \frac{1}{3} \cdot \left(\frac{\underline{Z}_0}{\underline{Z}_1} - 1 \right) \right|$$

[foforlk0-180912-01.tif, 1, en_US]

where:

$\underline{Z}_0$	(complex) zero-sequence impedance
$\underline{Z}_1$	(complex) positive-sequence impedance

This data can either be used for the entire line or as length-related values, since the quotients are length-independent. The data can be calculated both from the primary values and from the secondary values.

For overhead lines, you can use the values for the calculation because the angles of the zero-sequence system and the positive-sequence system differ only slightly. For cables, however, significant angular differences can occur, as the following example illustrates.

EXAMPLE

110-kV single-conductor liquid-filled cable 3 · 185 mm² Cu with the data:

$\underline{Z}_1/s$	$0.408 \cdot e^{j73°}$ Ω/km positive-sequence impedance
$\underline{Z}_0/s$	$0.632 \cdot e^{j18.4°}$ Ω/km zero-sequence impedance
s	Line length

The values for calculation of the residual compensation factor **K0** are:

$$\frac{\underline{Z}_0}{\underline{Z}_1} = \frac{0.632}{0.408} \cdot e^{j(18.4° - 73°)} = 1.55 \cdot e^{-j54.6°} = 1.55 \cdot (0.579 - j0.815)$$
$$= 0.898 - j1.263$$

[foforlk02-180912-01.tif, 1, en_US]

$$K_0 = \left| \frac{1}{3} \cdot \left(\frac{\underline{Z}_0}{\underline{Z}_1} - 1 \right) \right| = \left| \frac{1}{3} \cdot (0.898 - j1.263 - 1) \right| = \left| \frac{1}{3} \cdot (-0.102 - j1.263) \right|$$

[foforlk03-180912-01.tif, 1, en_US]

The setting value of the parameter **K0** is calculated from:

$$K_0 = \left| \frac{1}{3} \cdot \sqrt{(-0.102^2) + (-1.263^2)} \right| = 0.42$$

[fofork04-180912-01.tif, 1, en_US]

When determining the angle, take note of the quadrant of the result. The following table lists the quadrants and the angle range obtained from the operational signs of the real and imaginary parts of **K0** .

Real Part	Imaginary Part	tan Phi (K0)	Quadrant/Range		Calculation Method
+	+	+	I	0° to 90°	arc tan (|Im| / |Re|)
+	-	-	IV	-90° to 0°	–arc tan (|Im| / |Re|)
-	-	+	III	-90° to -180°	arc tan (|Im| / |Re|) –180°
-	+	-	II	+90° to +180°	–arc tan (|Im| / |Re|) +180°

In this example, the following setting value for the **Angle (K0)** parameter is obtained:

$$\varphi(k_0) = \arctan\left(\frac{1.263}{0.102}\right) - 180° = -94.6°$$

[fofork05-050509-01.tif, 1, en_US]

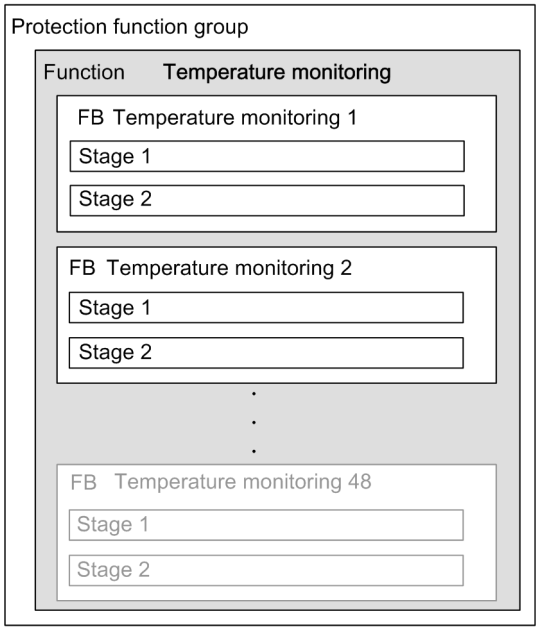
6.45 Temperature Supervision

6.45.1 Overview of Functions

The **Temperature supervision** function checks the thermal state of:

- Motors
- Generators
- Transformers



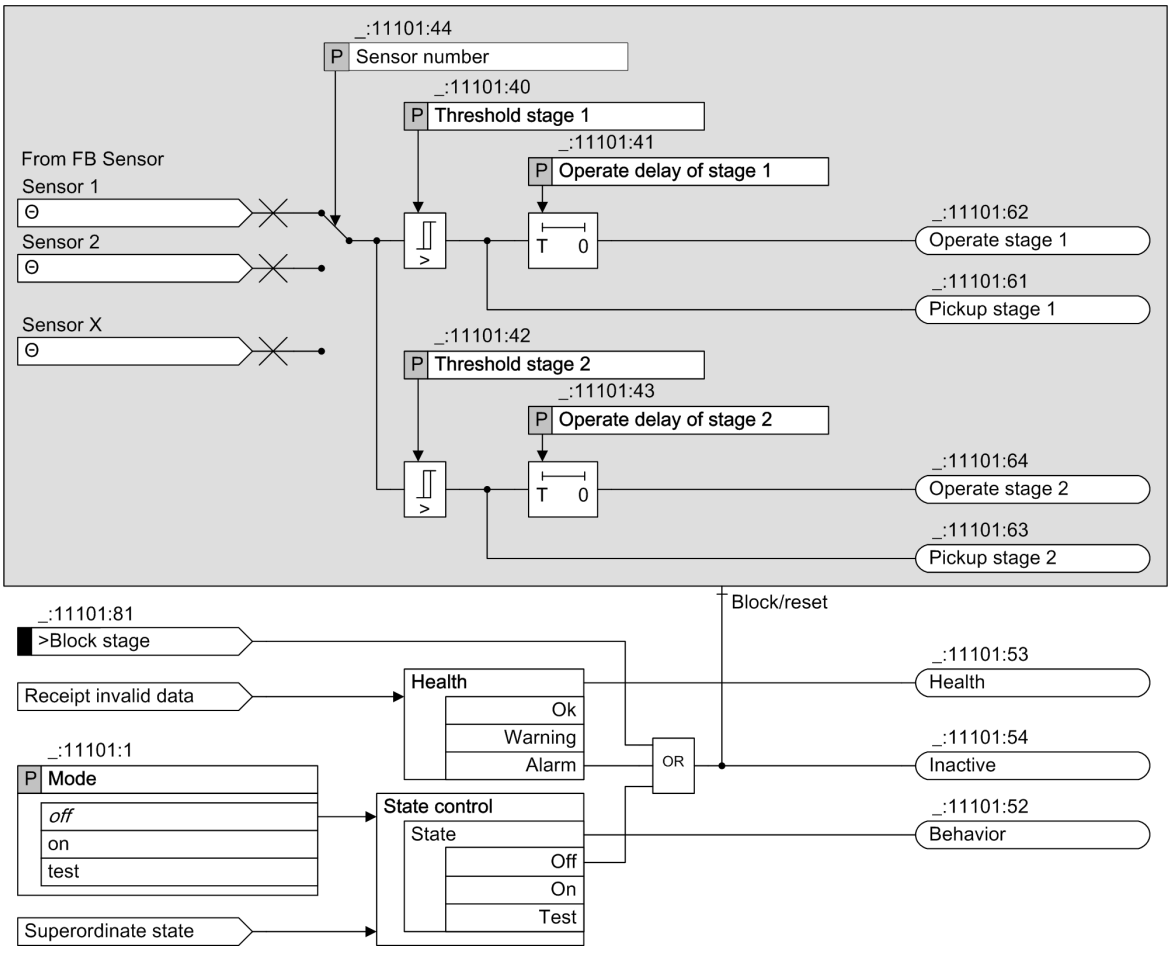
In rotating machines, it also checks bearing temperatures for a limit violation.

The temperatures are measured at various locations of the protected object using temperature sensors (RTD = Resistance Temperature Detector) and are sent to the device via one or more RTD units.

The **Temperature supervision** function receives its measured temperature values via the **RTD unit Ether.** or **Serial RTD unit** functions from the **Analog units** function group.

6.45.2 Structure of the Function

The Temperature supervision function can work in all protection function groups. A maximum of 48 temperature supervision locations can operate simultaneously in the **Temperature supervision function** function. Each temperature supervision location has 2 threshold stages.



[dwstrtmp-170712-01.tif, 1, en_US]

Figure 6-303 Structure/Embedding of the Function

6.45.3 Function Description

Logic

[lotmpsup-170712-01.tif, 1, en_US]

Figure 6-304 Logic Diagram for a Temperature Supervision Location

The **Temperature supervision location** function block (**Location** FB) receives a measured temperature value in °C or °F as an input variable delivered from the temperature sensor function blocks of the **Analog units** function group. The **Sensor number** parameter is used to select the temperature sensor.

2 threshold value decisions can be performed for each measuring point. If the measured temperature value is greater than or equal to the set threshold values, the stages generate a pickup indication independent of one another and, after a set tripping time delay, an operate indication.

The indications from the supervision locations remain available for further processing.

NOTE

The pickup of the stages does not result in fault logging. The operate indications of the stages do not go into the trip logic of the device.

6.45.4 Application and Setting Notes

If you use an external RTD unit, connect the RTD unit via an interface (Ethernet or serial) to the SIPROTEC 5 device. Observe the setting notes for configuration of the interfaces in chapter Analog Transformer Function Group Type under *5.6.7.3 Communication with an RTD Unit* .

Parameter: `Sensor location`

- Default setting **`(_:11101:46) Sensor location`** = ***`Other`***

You inform the device of the sensor installation location using the **`Sensor location`** parameter. ***`Oil`***, ***`Ambient`***, ***`Turn`***, ***`Bearing`*** and ***`Other`*** are available for selection. The selection is not evaluated in the device, it only serves an informational purpose in the medium in which the temperature measurement takes place.

Parameter: `Sensor number`

- Default setting **`(_:11101:44) sensor number`** = ***`no function block selected`***

With the **`sensor number`** parameter, you assign a specific sensor whose temperature is to be monitored to the **Location** function block. You perform the assignment in DIGSI using a list box that contains all connected RTD units and their sensors.

Parameter: `Threshold stage 1`

- Default setting **`(_:11101:40) Threshold stage 1`** = ***`100 °C`***

With the **`Threshold stage 1`** parameter you establish the temperature value whose exceedance causes a pickup of the 1st tripping stage.

Parameter: `Operate delay of stage 1`

- Default setting **`(_:11101:41) Operate delay of stage 1`** = ***`5 s`***

With the **`Operate delay of stage 1`** parameter you establish the time the operate indication of the 1st tripping stage should be delayed after the pickup. This time delay depends on the specific application. If you set the time delay to ∞ the operate indication is blocked.

Parameter: `Threshold stage 2`

- Default setting **`(_:11101:42) Threshold stage 2`** = ***`120 °C`***

With the **`Threshold stage 2`** parameter you establish the temperature value whose exceedance causes a pickup of the 2nd tripping stage.

Parameter: `Operate delay of stage 2`

- Default setting **`(_:11101:43) Operate delay of stage 2`** = ***`0 s`***

With the **`Operate delay of stage 2`** parameter you establish the time the operate indication of the 2nd tripping stage should be delayed after the pickup. This time delay depends on the specific application. If you set the time delay to ∞ the operate indication is blocked.

Temperature Unit

Temperature Unit To change the display and evaluation of measured temperature values from °C to °F, adapt the DIGSI user default settings accordingly (see *5.6.7.5 Temperature Sensor*).

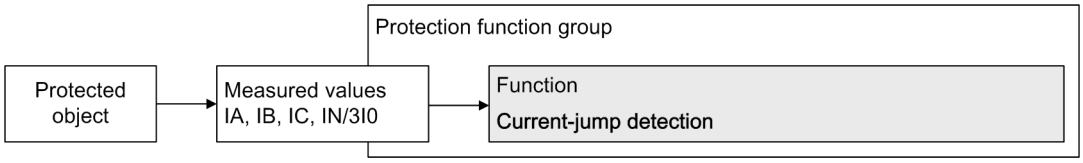
6.46 Current-Jump Detection

6.46.1 Overview of Functions



The **Current jump detection** function has the following tasks:

- Detection of jumps in the phase or zero-sequence current (ΔI)
- Generation of an indication when the measurands change by more than a configured threshold value from one system period to the next.

The function for detecting jumps in the phase or zero-sequence current is an additional function used for indication purposes or for further processing in user-specific CFC logics. Pick up of the function therefore neither opens a separate fault in the fault log nor generates an operate indication.

6.46.2 Structure of the Function

The **Current-jump detection** function is used in protection function groups based on current measurement. It can be instantiated multiple times.

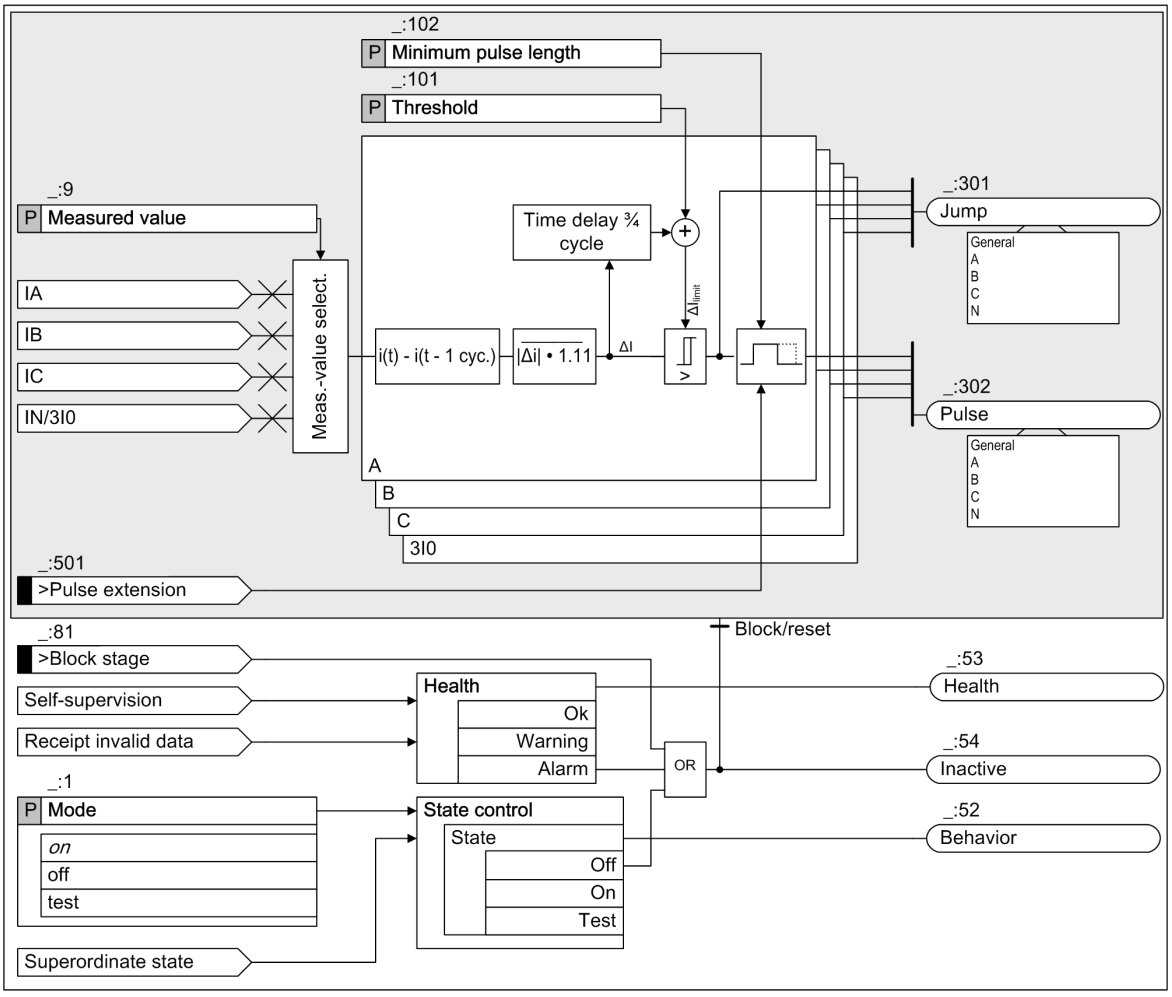
[dwstruki-111026-01.tif, 1, en_US]

Figure 6-305 Structure/Embedding of the Function

6.46.3 Function Description

Current-jump detection operates directly with the sampled values without numeric filtering. This provides very short response times to sudden changes in the current. The method used is not sensitive to slow changes of amplitude or frequency.

Using a configurable selection of measured values, you can select from 3 line currents or the residual current. Current-jump detection is phase-selective for the line current A, B and C.



The difference from the previous sampled value of the first system cycle is calculated for each sampled value. The rectified average is then determined for a ½ system cycle from this differential signal Δi(t). The rectified average for sinusoidal measurands is then converted to a RMS value ΔI by subsequent multiplication by 1.11. The resultant measurand ΔI is then compared with the threshold value.

If the parameter **(_:101) Threshold** is exceeded, the output indication *Jump* is generated. If you have selected the phase currents for measurement, the output indication data type used includes the separate phase information. If you have selected the residual current for measurement, the output indication data type used includes the NI information. If the current-jump detection responds (ΔI_{Limit}), the general information is generated in the output indication in all cases.

Dropout occurs with a dynamically increased threshold value (ΔI_{Limit}) in accordance with the logic in *Figure 6-306*. Dynamic increase of the dropout threshold value achieves optimally short dropout times.

The output indication *Pulse* is formed with the configurable timer **(_:102) Minimum pulse length**. As a consequence this output indication has a consistent minimum size. If you activate the binary input *>Pulse extension*, you can prolong the pulse duration even further. If the binary input *>Pulse extension* has been activated, the indication *Pulse* drops off when the configured time has elapsed and the falling edge of the binary input is detected.

Logic

[lojumpii-271011-01.tif, 1, en_US]

Figure 6-306 Current-Jump Detection Logic

6.46.4 Application and Setting Notes

Parameter: `Measured value`

- Default setting **`(_:9) Measured value`** = ***`phase currents`***

With the parameter **`Measured value`**, you set whether the line current(s) or the residual current is to be used for jump detection.

Parameter Value	Description
`phase currents`	The tripping stage evaluates the line currents IL1, IL2 and IL3 phase-selectively to detect a jump.
`zero-sequence current`	The tripping stage evaluates the residual current IN/3I0 to detect a jump.

Parameter: `Threshold`

- Default setting **`(_:101) Threshold`** = ***`0.10 A`*** for I_{rated} = 1A or ***`0.50 A`*** for I_{rated} = 5 A

With the parameter **`Threshold`**, you set the threshold value for the measurand which, when exceeded, generates the output indication *`Jump`*.

Parameter: `Minimum pulse length`

- Default setting **`(_:102) Minimum pulse length`** = ***`0.10 s`***

With the parameter **`Minimum pulse length`**, you specify a consistent minimum size for the output indication *`Pulse`*.

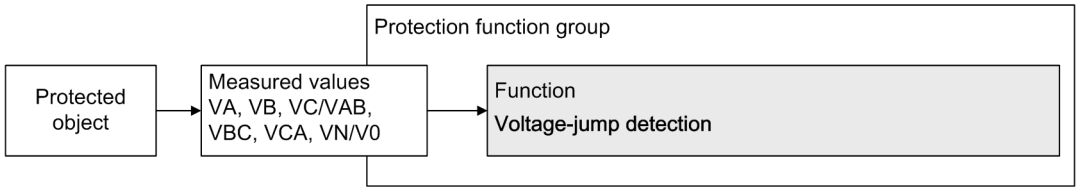
6.47 Voltage-Jump Detection

6.47.1 Overview of Functions



The **Voltage-jump detection** function has the following tasks:

- Recognition of jumps in the phase or zero-sequence voltage (ΔV)
- Generation of an indication when the measurands change by more than a configured threshold value from one system cycle to the next.

The function for detecting jumps in the phase or zero-sequence voltage is an additional function used for indication purposes or for further processing in user-specific CFC logics. Pick up of the function therefore neither opens a separate fault in the fault log nor generates an operate indication.

6.47.2 Structure of the Function

The **Voltage-jump detection** function is used in protection function groups based on voltage measurement. It can be instantiated multiple times.

[dwstruku-011211-01.tif, 1, en_US]

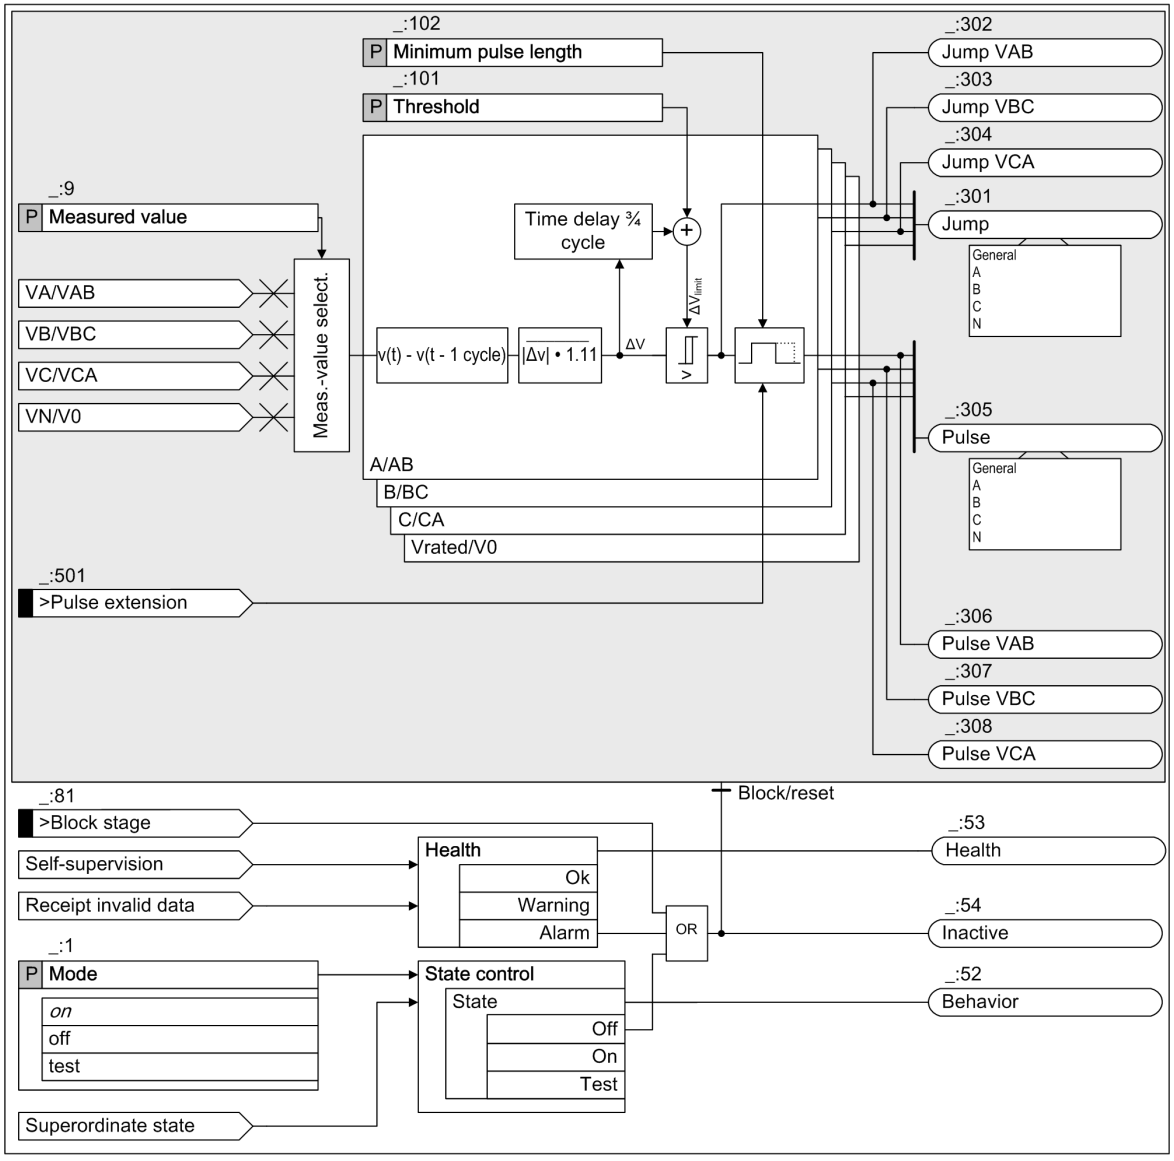
Figure 6-307 Structure/Embedding of the Function

6.47.3 Function Description

Voltage-jump detection operates directly with the sampled values without numeric filtering. This provides very short response times to sudden changes in the voltage. The method used is not sensitive to slow changes of amplitude or frequency.

By using a configurable selection of measured values, you can select from phase-to-ground voltages, phase-to-phase voltages or the zero-sequence voltage. Voltage-jump detection is phase-selective.

The difference from the previous sampled value of 1 system cycle is calculated for each sampled value. The rectified average is then determined for a ½ system cycle from this differential signal Δv(t). The rectified average for sinusoidal measurands is then converted to a RMS value ΔV by subsequent multiplication by 1.11. The resultant measurand ΔV is then compared with the threshold value.



If the parameter **(_:101) Threshold** is exceeded, the output indication *Jump* is generated. If the measured value is set to phase-to-phase, the sudden change in voltage is signaled selectively for the individual measuring elements that have picked up (*Jump VAB*, *Jump VBC* or *Jump VCA*). If you have selected the phase-to-phase or phase-to-ground voltages for measurement, the output indication data type used included the separate phase information. If you have selected the zero-sequence voltage for measurement, the output indication data type used includes the N information. If the voltage-jump detection responds (ΔV_{Limit}), the general information is generated in the output indication in all cases.

Dropout occurs with a dynamically increased threshold value ΔU_{Limit} in accordance with the information in *Figure 6-308*. Dynamic increase of the dropout threshold value achieves optimally short dropout times.

A timing element is added to the indication *Jump*. The element generates a pulse from this. The length of this pulse can be set using the parameter **(_:102) Minimum pulse length**. This gives the output indication *Pulse* a reliable minimum size. If you activate the binary input *>Pulse extension*, you can prolong the pulse duration even further. If the binary input *>Pulse extension* has been activated, the indication *Pulse* drops off when the configured time has elapsed and the falling edge of the binary input is detected. If

the measured value is set to phase-to-phase, the pulse duration is signaled selectively for the individual measuring elements that have picked up (*Pulse VAB*, *Pulse VBC* or *Pulse VCA*).

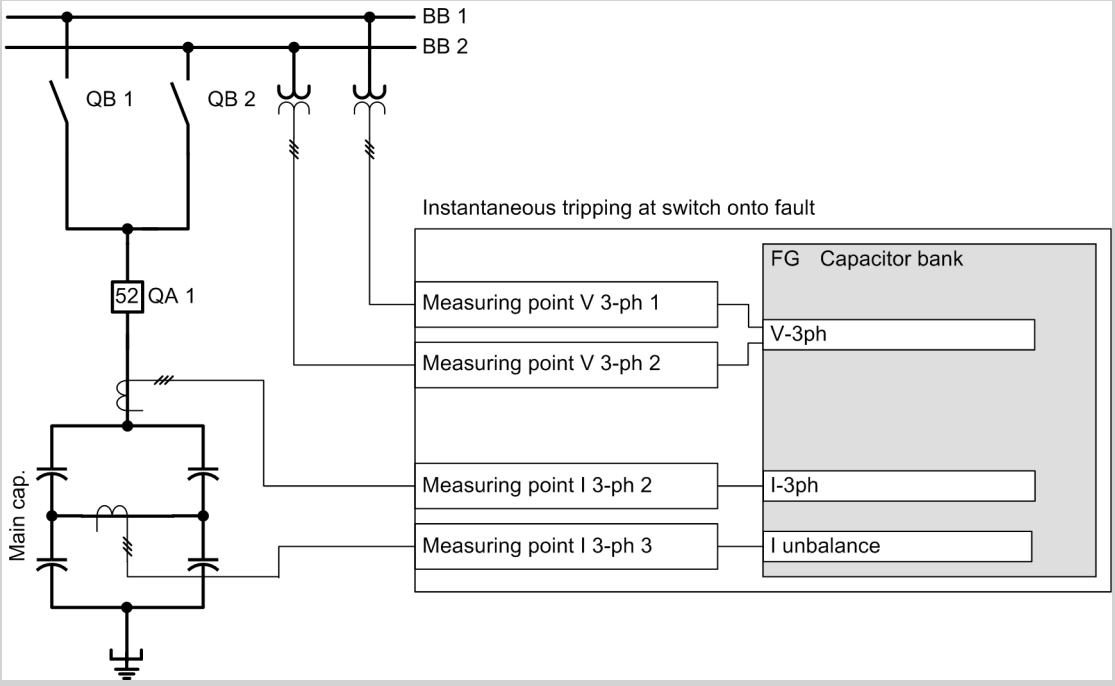
6.48 Voltage Measuring-Point Selection

6.48.1 Overview of Functions

The function block **Voltage measuring-point selection** can:

- Provide the ability to switchover the voltage measuring points to be applied, if various voltage measuring points are connected to the voltage interface of the function group
- Select the correct voltage based on the switch position of the plant

If more than one voltage measuring points are connected to the same voltage interface of the function group, use the **Voltage measuring-point selection** function block in the function group to select the correct voltage based on the switch position of the plant.



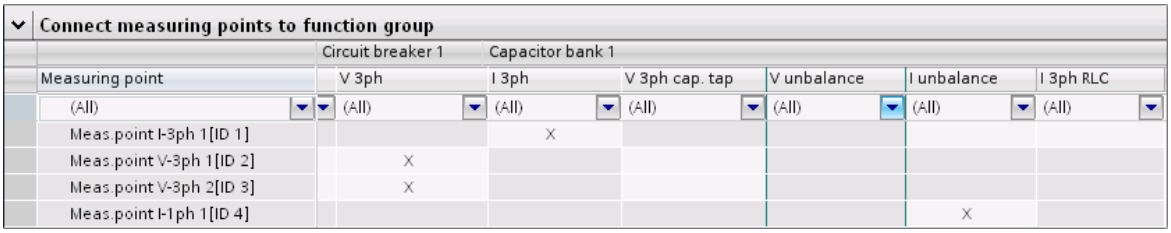
The **Voltage measuring-point selection** is a common functionality for the function groups of the protected objects.

6.48.2 Function Description

The **Voltage measuring-point selection** function block realizes the selection of voltage measuring points by a logic block chart. The logic block chart controls the input *>MP-ID selection* depending on the switch positions of disconnectors.

Example

Figure 6-309 shows an example of voltage measuring points selection for the function group **Capacitor bank** in a double busbar application.



[dwbusbardouble.vsd, 2, en_US]

Figure 6-309 Double Busbar with Capacitor Bank

Connecting Measuring Points to Capacitor Bank Function Group

Figure 6-310 shows the connection of the function group **Capacitor bank** with several measuring points in DIGSI. The ID of each measuring point appears in the bracket after the name.

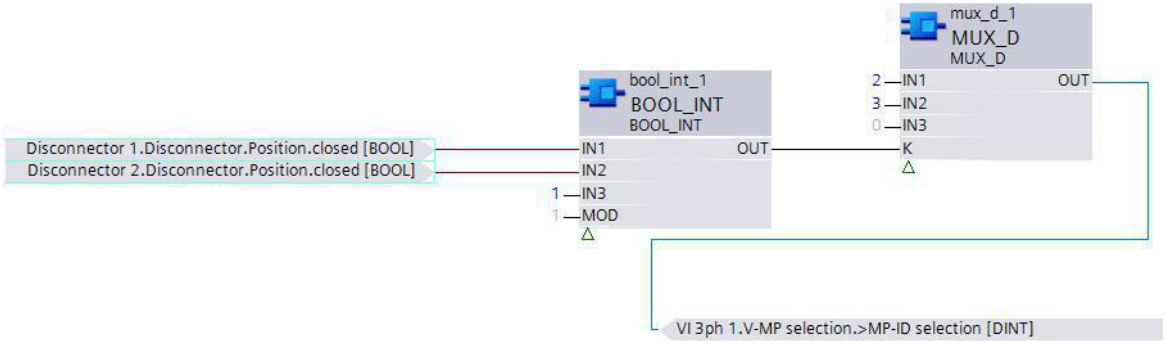
[scconnection, 1, en_US]

Figure 6-310 Connecting the Measuring Points with the Capacitor Bank Function Group

There are consistency checks that validate the connections of voltage measuring points to the function group:

- The connection type must be identical for all measuring points connected to the same interface of the function group.
- The rated voltage (primary and secondary) must be identical for all measuring points connected to the same interface.
- If more than 1 measuring point is connected to one voltage interface, a function block must be added to enable the selection of the voltage measuring points.

6.48.3 Application and Setting Notes



CFC Control

The voltage measuring point is selected by logic block chart on basis of the measuring point IDs. If more than one measuring point is connected to the interface of the function group, instantiate the function block **Voltage measuring-point selection** from the library in the corresponding function group.

In order to ensure the correct measuring-point connection for the function group, a logic block chart has to define the actual valid IDs for the input *>MP-ID selection* of the function block.

The following logic block chart implementation is based on the example given in *Figure 6-309*.

If the Disconnector 1 (QB1) is closed and no matter what the position the Disconnector 2 (QB2) is, the value 2 is the output of CFC block **mux_d_1** and transferred to the input *>MP-ID selection*. Then, the **Meas.point V-3ph** with ID 2 is selected as the reference voltage. Similarly, the **Meas.point V-3ph** with ID 3 is selected as the reference voltage if the Disconnector 1 (QB1) is not closed (open or in intermediate position) while Disconnector 2 (QB2) is closed.

[SclocfcVP, 1, --_--]

Figure 6-311 Logic Block Chart: Voltage Selection Using Measuring Point ID

However, the disconnectors might be both open or in a transient state. In this case, the input IN3 of the block **bool_int_1** becomes true, the value 0 is used as the ID for voltage selection input (*>MP-ID selection*). If ID 0 is selected, then all voltage values of the respective function-group interface are set to 0 V immediately. An alarm indication *Selection invalid* is issued and the indication *Health* is issued as ***OK***. In case you want to supply the function group with voltage values under the condition that both disconnectors are open or in transient state from one or the other busbar, you can alter the CFC chart respectively.

NOTE

An invalid measuring-point selection (ID < 0 or an ID of a unconnected measuring point) for input *>MP-ID selection* results in the following:

- The voltage measured values are displayed as **failure**.
- The validity of the voltage measured values is set to **invalid**.
- The indication *Health* is set to ***Alarm***.
- The indication *Selection invalid* becomes true.

7.7	Voltage Differential Protection for Capacitors	977
7.8	Differential Protection for Capacitor Banks	988
7.9	Detuning Supervision for Capacitor Banks	1012

7.1 Introduction

Capacitors and capacitor banks are used for various applications. Examples are:

- Reactive-power compensation for voltage stabilization
- Fast voltage- and reactive-power control
- Filter circuits for the elimination of certain frequencies

Capacitor banks for transmission systems are complex systems customized for the special application. The design depends much on the used switching technology (for example, mechanically or via thyristor). In detail hardly one capacitor bank resembles another. However, a capacitor bank consists always of the same components (C, R, L, and switches). A capacitor bank often consists of several subcomponents which are connected to the capacitor-bank busbar via the circuit breakers.

The modularity of hardware and protection functionality allows to tailor the protection device exactly to the needs of the capacitor bank or the subcomponent of the capacitor bank and to realize the complete protection of the whole capacitor bank or the capacitor- bank subcomponent with only one 7SJ8 device.

Capacitor banks require the use of extensive protection functionality. The protection consists of standard protection functions and specific capacitor protection functions. The following topics are described in the next chapters:

- Extensions on standard protection functions for optimal utilization in a capacitor bank
- Specific capacitor protection functions
- Application of standard protection functions for specific protection tasks within a capacitor bank

7.2 Overcurrent Protection for Capacitor Banks

7.2.1 Overview

You can use the following overcurrent protection function types in the **Capacitor Bank** function group:

- **Overcurrent protection, phases** with phase-segregated operate indications for short-circuit protection in the area between the busbar and the capacitor and for protecting against overload of a subbank.
- **Overcurrent protection, phases** for protection against overload of RLC filter circuit elements (**Overcurrent -3ph RLC**)
- **Overcurrent protection, ground** as protection or backup protection in the event of ground faults

Figure 5-15 in Chapter *5.4.2 Structure of the Function Group* shows

- The standard protection functions that you can use in the **Capacitor Bank** function group.
- The specific protection functions that are available for protecting a capacitor bank.
- The assignment of protection functions to the interfaces of the function group.

Figure 5-13 in Chapter *5.4.2 Structure of the Function Group* shows the assignment of the interfaces in the **Capacitor Bank** function group to the measuring points of the device with reference to an example.

NOTE

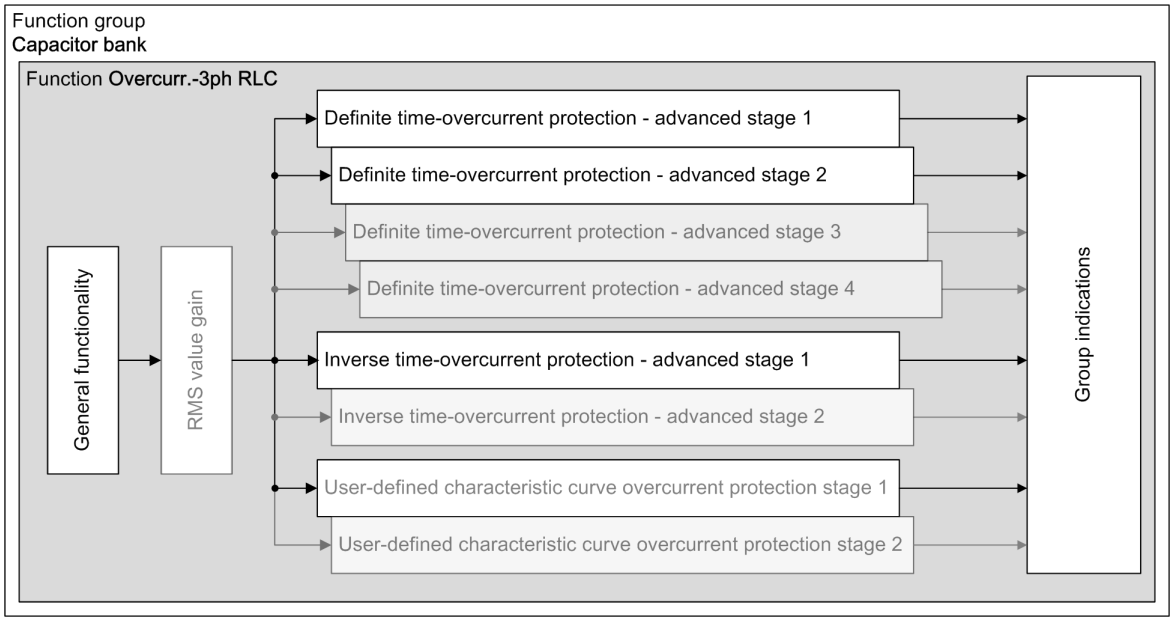
The structure of the function **Overcurrent protection, Phases for protecting RLC elements of a filter circuit** differs only slightly from the standard function **Overcurrent protection, Phases – Advanced**.

In this chapter, only the differences between this and the standard function are described.

For more information, please refer to the function description **Overcurrent protection, Phases** starting from Chapter *6.3.1 Overview of Functions* .

NOTE

Starting from V07.30, the function type **50/51 OC-3ph 1p** is no longer offered in the DIGSI 5 global library in the function group **Capacitor bank**. Instead you can use now the standard advanced overcurrent function **Overcurrent protection, phases – advanced** to apply phase-segregated operate indications.



7.2.2 Overcurrent Protection, Phases for Protection of RLC Filter-Circuit Elements

7.2.2.1 Structure of the Function

In the **Capacitor Bank** function group, the **Overcurrent protection, Phases for protecting RLC filter circuit elements** function (**Overcurr. -3ph RLC**) is based on the standard protection function **Overcurrent protection, Phases – Advanced**.

The **Overcurrent protection, Phases for protecting RLC filter circuit elements** function differs from the standard protection function as follows:

- Superordinate measuring point selection
- Setting the rated current of the protected object (for example, reactor or resistor) within the function
- Measured function values of connected phase currents

[dwocpRLC-190813-01.vsd, 2, en_US]

Figure 7-1 Structure/Embedding of the Overc. -3-Ph RLC Function

7.2.2.2 Description

A feature of the **Overcurrent -3ph RLC** function is the **selection of measuring points**. A capacitor bank can include multiple filter circuits. Each filter can include, for example, a 3-phase current measurement device, each of which is assigned a measuring point. In order to protect the filter circuits, multiple instances of the **Overcurrent -3ph RLC** function can be created. Each instance of the function is assigned to a measuring point via **Measuring point selection**.

The function is structured such that the **Measuring point selection** is superordinate to the advanced overcurrent-protection stages.

Measuring-Point Selection

With the **`MP selection`** parameter, you can select from a list of measuring points a measuring point that is connected to the **I 3ph RLC** interface in the **Capacitor Bank** function group. The **Overcurrent -3ph RLC** function processes the current that is connected to the measuring point.

For more information, refer to the description of the **Capacitor Bank** function group starting from chapter *5.4.1 Overview*.

Rated Current of the Protected Object

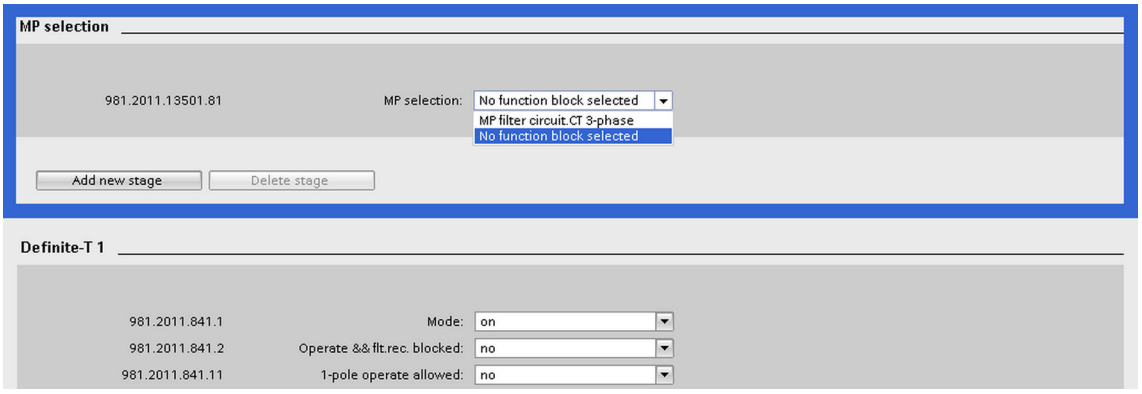
The rated current for the whole capacitor bank is set in the **Capacitor Bank** function group. However, the capacitor bank rated current does not apply for individual reactors or resistors used within a capacitor-bank installation. Such reactors or resistors require an individual rated current setting.

Functional Measured Values

The function provides the connected phase currents as measured function values for display, further processing or transmission to a station.

Values	Description	Primary	Secondary	% Referenced to
Iph:A Iph:B Iph:C	Phase current of measuring point	kA	A	% referenced to parameter **RLC rated current**

You can find the parameter **RLC Rated current** in the function block **General** of the **Overcurrent -3ph RLC** function.



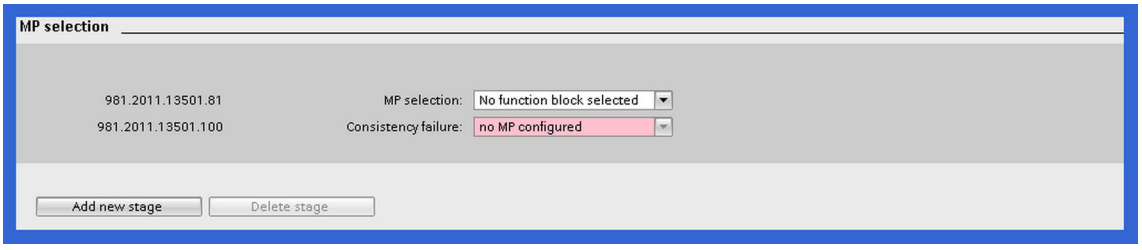
7.2.2.3 Application and Setting Notes

Parameter: MP selection

- Default setting **(_:13501) MP selection** = ***No meas. point config.***

With the **MP selection** parameter, you can select a measuring point that is connected to the **I 3ph RLC** interface in the **Capacitor Bank** function group.

The selection list displays the measuring points that are connected to the **I 3ph RLC** interface of the **Capacitor Bank** function group:



[scmpselection_ocp_rlc-150813, 2, en_US]

Figure 7-2 Example of Measuring-Point Selection

The **MP selection** parameter is set for all stages. The setting applies equally to all stages of the function.

In the default setting, a measuring point is not selected. You must select a measuring point. If you do not select a measuring point, an inconsistency is indicated via the read-only parameter **Consistency failure**:

[scinconsistency_ocp_rlc-150813, 2, en_US]

Figure 7-3 Function Inconsistency Indication

Parameter: RLC Rated Current

- Default setting **(_:2311:101) RLC rated current** = ***1000 A***

The parameter **RLC rated current** is used to set the primary rated current of the respective protected object which is usually a reactor or resistor branch within the capacitor bank installation. The **RLC rated current** specified here is the reference value for the percentage-measured values and setting values made in percentages.

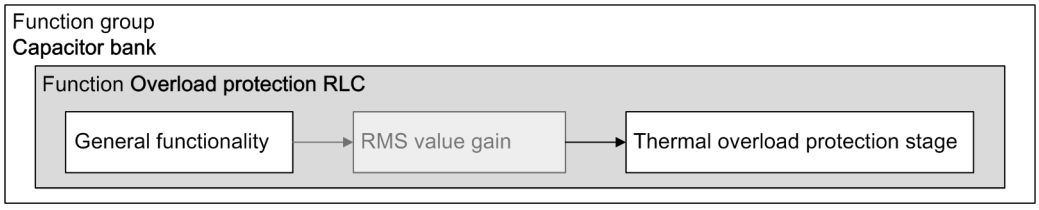
7.3 Thermal Overload Protection for Capacitor Banks

7.3.1 Overview of Functions

The function **Overload RLC** protects RLC filter circuit elements in a capacitor bank from thermal overload.

NOTE

The structure of the function **Overload RLC** differs only slightly from that of the standard **Thermal overload protection, 3-phase** function. In this chapter, only the differences between these and the standard function are described.



For more information, refer to the function description **Thermal overload protection, 3-phase** starting from chapter *6.19.1 Overview of Functions* .

7.3.2 Structure of the Function

The function **Overload protection RLC** is used in the **Capacitor bank** function group.

The **General functionality** differs from the standard **Thermal overload protection** function and consists of:

- Measuring-point selection
- Setting the rated current of the protected object (for example, reactor or resistor) within the function

[dwtolp_rlc-200813, 2, en_US]

Figure 7-4 Structure/Embedding of the Function

7.3.3 Description

A feature of the function **Overload RLC** is the **measuring-point selection**. A capacitor bank can include multiple filter circuits. Each filter can include, for example, a 3-phase current measurement device, each of which is assigned a measuring point. In order to protect all filter circuits, multiple instances of the function **Overload RLC** can be created. Each instance of the function is assigned to a measuring point via **measuring-point selection**.

The function is structured such that the **measuring-point selection** is superordinate to the **Thermal overload protection**.

Measuring-Point Selection

With the parameter **`MP selection`**, you can select from a list of measuring points a measuring point that is connected to the **I 3ph RLC** interface in the **Capacitor bank** function group. The function **Overload RLC** processes the current that is connected to the measuring point.

For more information, refer to the description of the **Capacitor bank** function group starting from Chapter *5.4.1 Overview* .

Rated Current of the Protected Object

The rated current for the whole capacitor bank is set in the **Capacitor Bank** function group. However, the capacitor bank rated current does not apply for individual reactors or resistors used within a capacitor bank installation. Such reactors or resistors require an individual rated current setting.

Function Values

Measured Values	Description	Primary	Secondary	% Referred to
(_:601:304) Time until close	Time until close	s	s	s
(_:601:305) Time until trip	Estimated time until trip	s	s	s
(_:601:306) Overload phase A	Thermal measured values of phases	%	%	Trip temperature
(_:601:307) Overload phase B				
(_:601:308) Overload phase C				
(_:601:309) Overload maximum	Thermal measured values of overload protection	%	%	Trip temperature
(_:601:310) Equival. current phs A	Current measured value as base for overload measured value	A	A	Parameter **RLC rated current**

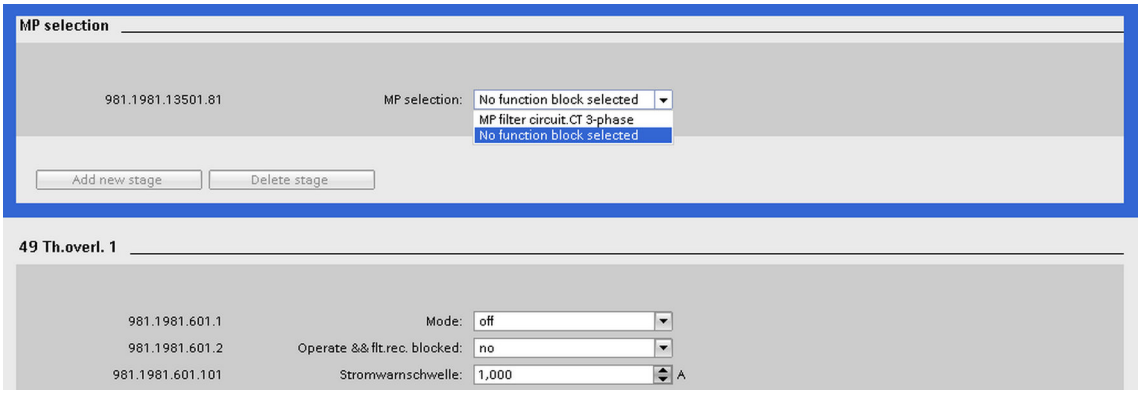
(_:601:312) Equival. current phs C				
(_:601:313) Equival. current max.	Maximum current measured value as base for overload value	A	A	Parameter **RLC rated current**



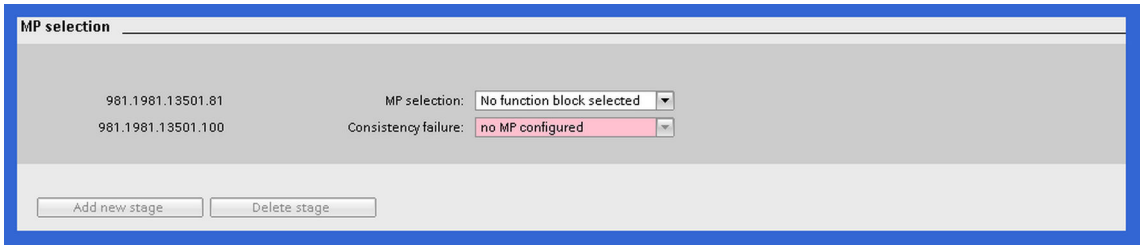
7.3.4 Application and Setting Notes

Parameter: MP selection

- Default setting **(_:13501) MP selection** = ***no MP configured***

With the **MP selection** parameter, you can select a measuring point that is connected to the **I 3ph RLC** interface in the **Capacitor bank** function group.

The selection list displays the measuring points that are connected to the **I 3ph RLC** interface of the **Capacitor bank** function group:



[scmpselection_tolp_rlc-150813, 2, en_US]

Figure 7-5 Example of Measuring-Point Selection

The **MP selection** parameter is set for all stages. The setting applies equally to all stages of the function.

In the default setting, a measuring point is not selected. You must select a measuring point. If you do not select a measuring point, an inconsistency is indicated via the read-only parameter **Consistency failure** :

[scinconsistency_tolp_rlc-150813, 2, en_US]

Figure 7-6 Function Inconsistency Indication

Parameter: RLC rated current

- Default setting **`RLC rated current`** = ***`1000 A`***

The parameter **`RLC rated current`** is used to set the primary rated current of the respective protected object which is usually a reactor or resistor branch within the capacitor bank installation. The setting is used as $I_{rated, obj}$ for the nominalization calculation within the thermal model.

7.3.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`General`

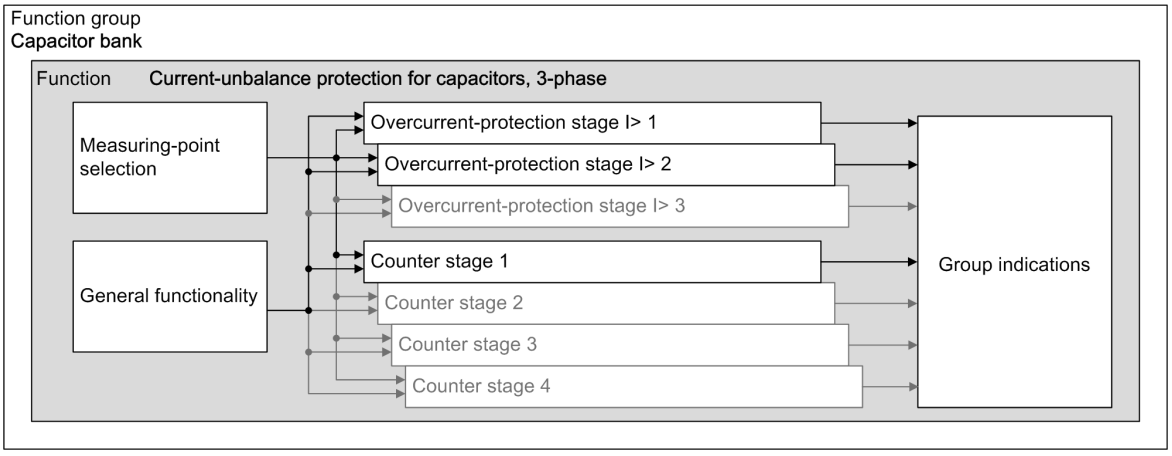
7.4 Current-Unbalance Protection for Capacitors, 3-Phase

7.4.1 Overview of Functions



The **Current-unbalance protection for capacitors, 3-phase** function (ANSI 60C):

- Protects in case of capacitor elements (C-elements) faults of a capacitor bank in H connection
- Provides very sensitive supervision of the unbalanced current between the 2-star points
- Allows counting of individual faulty C-elements

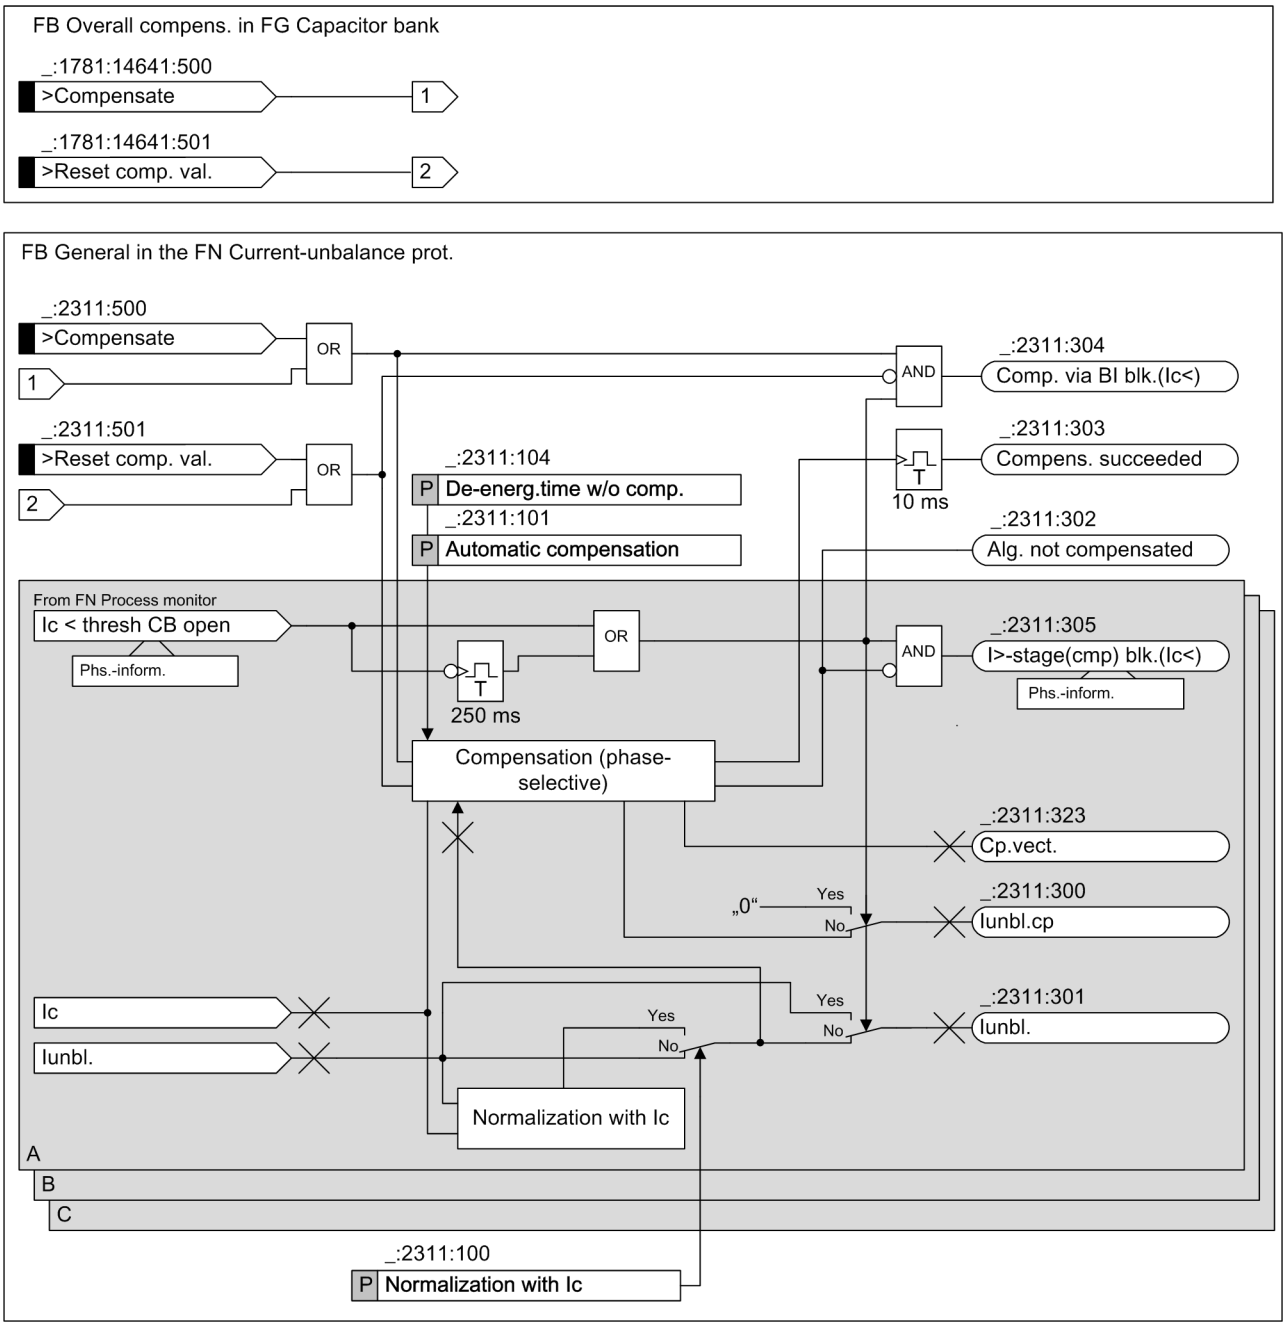
7.4.2 Structure of the Function

The **Current-unbalance protection for capacitors, 3-phase** function is used in the **Capacitor bank** function group. It is preconfigured at the factory with 2 overcurrent-protection stages **I>** and one stage of the type **Counter**. A maximum of 3 overcurrent-protection stages and 4 counter stages can be operated simultaneously in the function.

The function is designed so that the **General functionality** (including compensation) and the **Measuring-point selection** can work across the stages.

[dwocplunbalanced-300813, 4, en_US]

Figure 7-7 Structure/Embedding of the Function



7.4.3 General Functions and Measuring-Point Selection

7.4.3.1 Description

The General functionality is structured in the following functional parts:

- Compensation of the unbalance
- Normalization of the unbalanced current with the current I_c
- Counting faulty C-elements (the stage type **Counter** is used to monitor the counter status)

Logic for Compensation and Normalization

[lo_FBallg_iunbal-020913.tif, 3, en_US]

Figure 7-8 Cross-Stage Functionality

Measuring-Point Selection

With the **`MP selection`** parameter, you can select from a list of measuring points a measuring point that is connected to the **I Unbalanced** interface in the **Capacitor bank** function group. The **Current-unbalance protection for capacitors, 3-phase** function processes the current that is connected to the measuring point.

For more information, refer to the description of the **Capacitor bank** function group starting from chapter *5.4.1 Overview* .

Measurands, Method of Measurement

The function receives its measurands via the **I Unbalanced** interface of the **Capacitor bank** function group.

The compensated and non-compensated unbalanced currents are provided for the overcurrent-protection stage. Within the protection stage, one of the 2 values is selected in the protection stage via the parameter **Measured value**. Both values are available as functional measured values (see *Figure 7-8*).

Configure across the stages whether the unbalanced current must be normalized with the current I_c that flows into the capacitor bank. You can find more information in this chapter under *Normalization with I_c , Page 926* .

The method of measurement used processes the sampled unbalanced-current values and filters out the fundamental component numerically. The protection stages evaluate the fundamental component of the unbalanced current.

General Notes on the Compensation

An operational unbalanced current is added to an unbalanced current resulting from faulty capacitor elements. This corrupts the measuring result.

Operational unbalanced currents can result from the following causes:

- Manufacturing tolerances of the capacitor
- Aging of the capacitor
- Environmental influences, for example, temperature

The compensation eliminates operational unbalanced currents by calculation. For this purpose, the phasor of the operational unbalanced current $\underline{I}_{unbal.,op.}$ is stored at specific times. The stored phasor (compensation phasor), is subtracted from the actually measured unbalanced-current phasor:

$$\underline{I}_{unbal.,comp.} = \underline{I}_{unbal.} - \underline{I}_{unbal.,op.}$$

[fo_compensatied unbal., 1, en_US]

The following indications describe the status of the compensation:

Indication	Description
Alg. not compensated	The algorithm is not compensated. The compensated values are not available under the following conditions: • After initial startup of the device before any compensation is carried out • After activating the binary input *>Reset comp. val.* • After change of $I_{rated,obj}$ Protection stages that are working with compensated values are inactive.
Compens. succeeded	This indication is issued (as transient indication with a pulse duration of 10 ms) if the existing unbalance has been compensated manually or automatically. In case of automatic compensation, the signal is issued at each event-based situation where full compensation is carried out.
Comp. via BI blk.(Ic<)	If a manual compensation has been initiated and the current I_c (current flowing into the capacitor bank) at this time is less than the threshold **Current threshold CB open**, the manual compensation is not executed. This is signaled via the *Comp. via BI blk.(Ic<)* indication.

2 different methods are available for the compensation:

- Manual compensation via binary input signals
- Automatic compensation

Manual Compensation via Binary Input Signal

If the binary input signal *>Compensate* is activated, the manual compensation starts. This will fully compensate any unbalance that exists at this time. This means the value $\underline{I}_{unbal.,comp.}$ will then become 0. You can also use the manual compensation in parallel with the automatic compensation.

Automatic Compensation

When using the parameter **Automatic compensation** , this automatic compensation function can be enabled or disabled.

The automatic compensation consists of 2 different mechanisms:

- The event-based compensation of any existing unbalance.
  This compensation is performed in the following situations:
  - After energizing the capacitor bank or a phase of the bank (phase-selective compensation)
  - After counting a faulty C-element (phase-selective compensation)
  - After each startup of the device
  - After specific parameter changes:
    - Switching on the automatic compensation
    - Changing the rated current of the capacitor bank

  In order to avoid transient inrush-current effects, the compensation is delayed by 250 ms after energizing has been detected.
  Full compensation after bank energization can be avoided in case of only short de-energization by means of parameter **De-energ.time w/o comp.**. If the de-energized duration is less than the setting of parameter **De-energ.time w/o comp.**, the full compensation is not carried out after energizing a phase or the whole bank.
- Cyclic, slow and thus gradual compensation of an existing unbalance in small increments.
  This permits, for example, the automatic compensation of environmental influences.

Resetting the Compensation

The algorithm can be reset to the non-compensated status. Compensated values are not available in this case. Protection stages that work with compensated values are rendered inactive. The binary input signal *>Reset comp. val.* of the function or function group resets the compensation (see also *Figure 7-8*).

NOTE

When operating with manual compensation, changing the value of parameter **capacitor reference current** will reset the compensation values.

Normalization with I_c

The threshold for the unbalanced current is usually set by assuming the rated capacitor current $I_{c,rated}$. The current I_c flowing into the capacitor bank determines the amount of the unbalanced current. A lower I_c also means a lower unbalanced current. If $I_c < I_{c,rated}$, the protection becomes less sensitive. This influence can be compensated via the normalization. Normalization keeps the sensitivity of the protection function constant by normalizing the unbalance value with the current I_c. When using the parameter **Normalization with Ic** , normalization is enabled or disabled.

I_c Lower than Current Thresh.CB Open

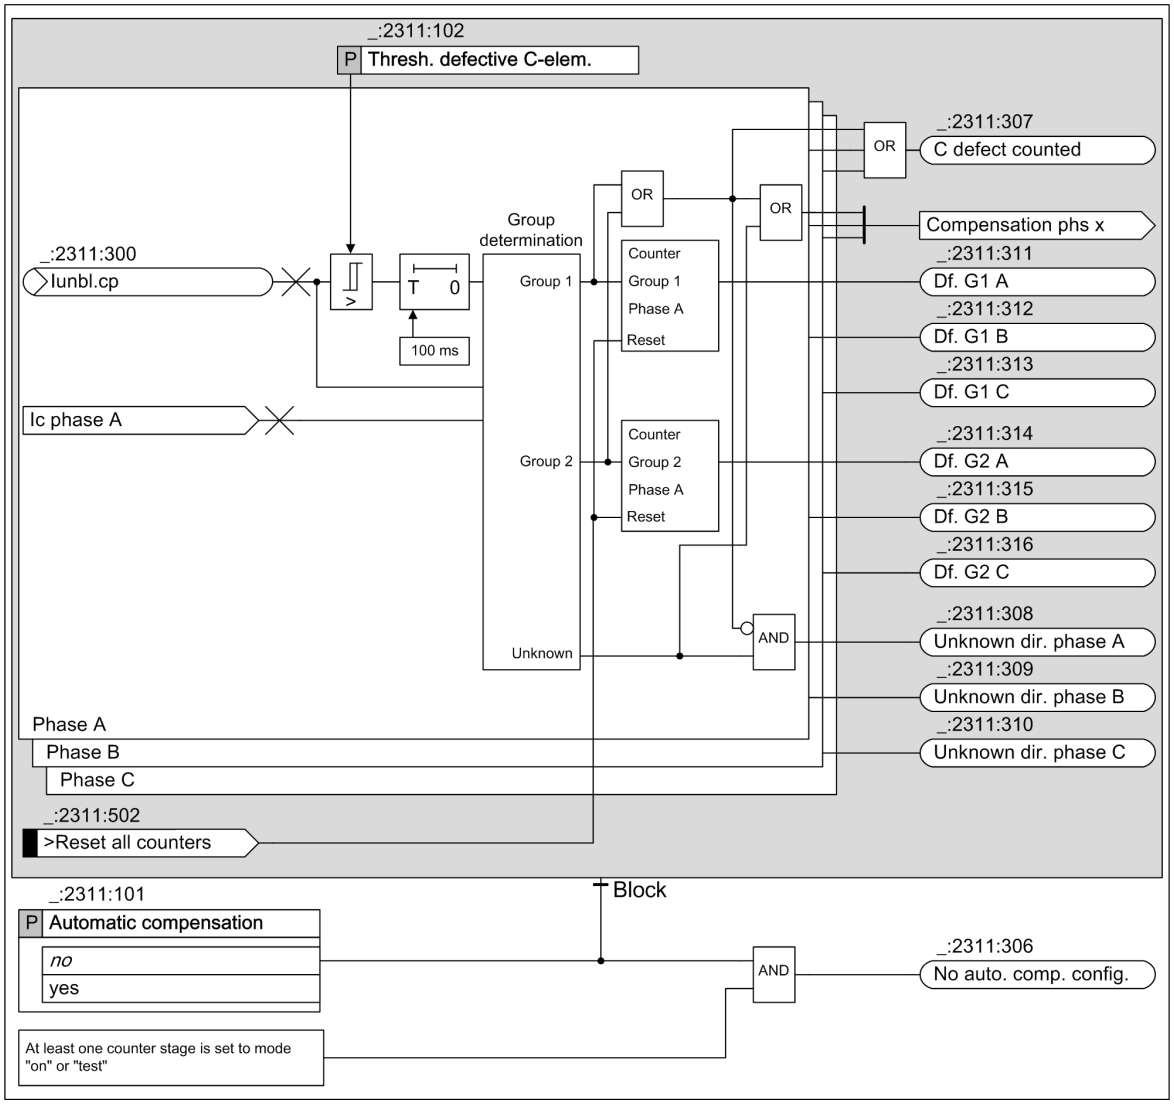
If the current I_c is lower than the threshold **Current Thresh.CB Open**, the compensated value can no longer be computed with sufficient accuracy. To avoid a malfunction, the compensated unbalanced value $I_{unbal.,comp.}$ is set to 0 A in a phase-segregated way (see *Figure 7-8*). This deactivates the affected phase measuring components of the protection stages that work with compensated values.

This condition will be indicated in a phase-segregated manner (indication *I>-stage(cmp) blk.(Ic<)*). In this case, normalization with current I_c will no longer work properly either. The normalization is canceled in a phase-segregated manner. This means that the non-normalized value is used in place of the normalized value (see *Figure 7-8*).

Charging/Energizing the Capacitor Bank or a Phase of the Bank

Charging of the bank takes place when the discharged bank is switched on to the network. Charging of a phase can occur in case of network faults. If a phase-to-ground voltage drops to 0 V due to a network fault, the respective phase is discharged and the return of the phase-to-ground (after the fault has been cleared) will charge the phase.

Charging the bank or a phase of the bank causes inrush currents in the respective phases. To avoid overfunction in case of sensitive threshold settings, the stages using compensated unbalanced values are blocked in a phase-selective way by setting $\underline{I}_{unbal.,comp.}$ to 0 A. These stages are:



- Counter stage
- I> stage, if set to operate with compensated unbalanced values

The blocking ($\underline{I}_{unbal.,comp.}$ set to 0 A) lasts for 250 ms after energizing detection. Afterwards, the calculated $\underline{I}_{unbal.,comp.}$ is processed again.

Energizing detection takes place in a phase-selective way by monitoring the phase current I_c flowing into the bank. If a phase current exceeds the threshold **`Current Thresh.CB Open`**, energizing in this phase is detected.

Logic for Counting Faulty C-Elements

This part of the General functionality is only important if counter stages are used.

[lo-cnt-EF-260314-01, 3, en_US]

Figure 7-9 Counting Faulty C-Elements

Activation/Blocking Counting

If at least one counter stage is enabled, the counter function is active. Furthermore, the counter function works only if the automatic compensation is enabled.

In order to prevent counting as a consequence of the charging process, the counter function is implicitly blocked for 250 ms by setting $I_{unbal.,comp.}$ to 0 A, after the capacitor energizing has been detected.

Measurands, Counting

The measurand is the phase-selective compensated unbalanced current $I_{unbal.,comp.}$. If a single C-element is faulty, an unbalance occurs in the H connection. This unbalance causes an unbalanced current; this means, a small current jump is generated in the unbalanced current. Set the parameter **`Thresh. defective C-elem.`**, so that the current jump can be detected (refer also to *7.4.3.2 Application and Setting Notes*). The unbalanced current that was caused by the fault must exceed the threshold for 100 ms before the affected group is determined and counting (incrementing the counter) takes place. There is one counter for each phase and group. After the counting, the existing unbalance is compensated; this means, the unbalance is reset to 0 A. If the faulty group cannot be determined, the unbalance is also compensated.

Resetting/Setting the Counters

You can reset or set the counters of group 1 and group 2 via:

- On-site operation panel directly on the device
- Online DIGSI connection to the device
- Binary input *>Reset all counters* (only reset of all counters)
- Communication connection with the control center

You can directly set or reset the counters via IEC 61850 by setting the counter values to the desired value. If you want to reset the counters via DNP3, IEC 60870-5-103, Modbus, or IEC 60870-5-104, an additional configuration with CFC is necessary. For more information, refer to chapter *7.4.3.2 Application and Setting Notes*.

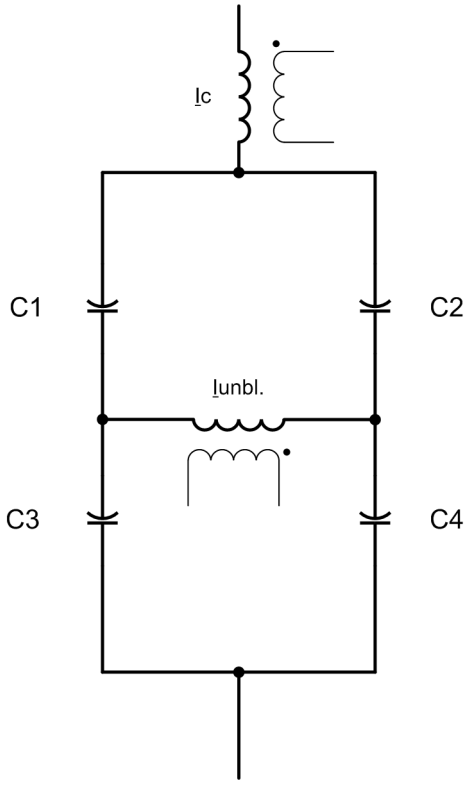
Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
(_:2311:300) Iunbl.cp	Compensated unbalanced current $\underline{I}_{unbal.,comp.}$	kA	A	Parameter **Rated primary current**
(_:2311:301) Iunbl.	Non-compensated unbalanced current $\underline{I}_{unbal.}$	kA	A	Parameter **Rated primary current**
(_:2311:323) Cp.vect.	Compensation vector $\underline{I}_{comp.,vect.}$	kA	A	Parameter **Rated primary current**

You can find the value of the parameter **Rated primary current** of the preceding table in the chapter *6.1.6 Settings* according to the specified parameter **MP selection**.

$\underline{I}_{comp.,vect.}$ is normalized with I_c. The normalization is carried out no matter if the parameter **Normalization with Ic** is set to ***yes*** or ***no***. $\underline{I}_{comp.,vect.}$ keeps its value unchanged until the next compensation occurs.

$$\underline{I}_{comp.,\,vect.} = \underline{I}_{unbal.\,op.}\frac{I_{c,rated}}{I_c}$$



[fo_compensation vector, 1, en_US]

Where:

$\underline{I}_{unbal.op.}$	Operational unbalanced current at the moment the compensation is carried out
$I_{c,rated}$	Rated current of the capacitor bank
I_c	Current of the capacitor bank at the moment the compensation is carried out

Definition of the Group and Fault Location with the Capacitor in H Connection

If the capacitor is designed in an H connection, the following definition is assumed:

[dwfehlerortinf_iunsy-020913, 1, en_US]

Figure 7-10 Definition of the Fault-Location Information

The black dot indicates the orientation of the current transformer. For the connection of the current transformer shown in the previous figure, the following definition applies:

- Group 1: C1 and C4
- Group 2: C2 and C3

In order to determine the fault location (group 1 or 2) correctly, use the parameter **Capacitor element type** (in FB **General** of the **Capacitor bank** function group) to tell the device whether the elements of the capacitor bank have internal fuses or not.

The angle reference of the unbalanced-current phasor to the reference current I_c is used to determine the direction of the unbalanced current and, thus, the affected group is determined. If the direction cannot be determined with confidence, an appropriate indication will be generated.

7.4.3.2 Application and Setting Notes

Parameter: MP selection

- Default setting **(_:13501:81) MP selection** = ***None***

With the **MP selection** parameter, you can select from a list the measuring point that is connected to the **I Unbalanced** interface of the **Capacitor bank** function group.

The setting applies equally to all stages of the function.

In the default setting, a measuring point is not selected. You must select a measuring point. If you do not select a measuring point, an inconsistency is indicated via the read-only parameter **Consistency failure**.

Parameter: Automatic compensation

- Default setting **(_:2311:101) Automatic compensation** = ***no***

The parameter applies equally to all stages of the function that work with compensated measurands.

If no counter stages are applied, Siemens recommends switching the automatic compensation off and using the manual compensation. You can find more information on this recommendation in chapter *7.4.4.2 Application and Setting Notes* (setting notes for the operate delay of the **I>** stage).

If the counter stages are applied, the automatic compensation must be switched on, otherwise the counting function will not work.

Parameter: `De-energ.time w/o comp.`

- Default setting **`(_:2311:104) De-energ.time w/o comp.`** = ***`2.00 s`***

In case of networks faults, the faulty phases are discharged. With the returning voltage after fault clearance, charging takes place. For such conditions, Siemens recommends that no automatic full compensation takes place in the affected phases. Otherwise, C-element defects occurring in this period (for example, because of discharging stress due to network-fault inception) will not be detected.

With the parameter **`De-energ.time w/o comp.`**, you define the duration of short de-energization after which no automatic compensation takes place. The parameter must be set to a value larger than the slowest fault-clearing time in your network plus a safety margin.

If the setting is set to 0 s, an automatic full compensation is carried out after each energizing detection.

Parameter: `Normalization with Ic`

- Default setting **`(_:2311:100) Normalization with Ic`** = ***`no`***

This parameter applies equally to all stages of the function.

Parameter Value	Description
`no`	Select this setting if you can safely assume that I_c will not change for operational reasons or if you do not desire normalization of the unbalanced current with I_c. Please consider that the protection sensitivity will decrease with decreasing I_c.
`yes`	Select this setting if you want to keep the sensitivity of the protection stages constant during changes of I_c.

Parameter: `Thresh. defective C-elem.`

- Default **`(_:2311:102) Thresh. defective C-elem.`** = ***`0.030 A`***

Set the parameter **`Thresh. defective C-elem.`** to ensure that the jump in the unbalanced current caused by the faulty C-element is detected. Information about occurring unbalanced current as a consequence of single faulty C-elements will be provided by the manufacturer of the capacitor bank. Siemens recommends to set the threshold value to approx. 75 % of the unbalanced current that occurs after the fault of the 1st C-element.

Example 1: Information about the Unbalanced Current Available from the Manufacturer of the Capacitor Bank

Table 7-1 Unbalanced Current, Depending on the Number of Faulty C-Elements

Number of Faulty C-Elements	Primary Unbalanced Current
0	0.00 A
1	0.71 A
2	1.47 A
3	2.29 A
...	...

Assumed current transformer ratio: 10 A/1 A

Primary unbalanced current if 1st C-element fails: 0.71 A

Secondary unbalanced current if 1st C-element fails: 0.071 A

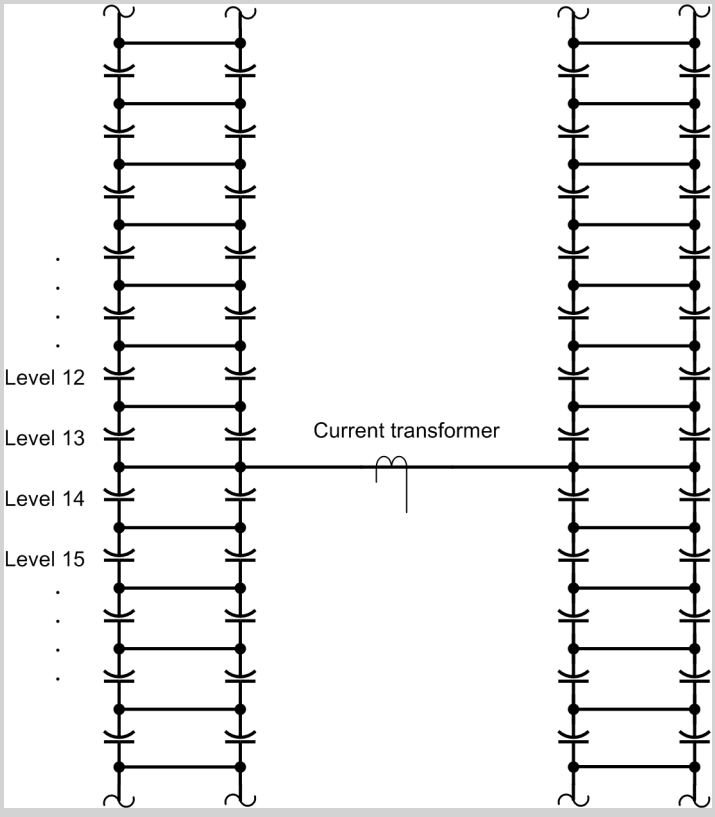
Secondary setting value: 0.75 · 0.071 A = 0.053 A

NOTE

Use sensitive device current inputs in order to apply secondary thresholds of < 30 mA.

If no information is provided by the manufacturer of the capacitor bank, the following example can be used as a basis in order to determine the value.

Example 2 (a to h): Unbalanced-Current Information Not Available from the Manufacturer of the Capacitor Bank, External Capacitor-Bank Structure with Cross-Linked Cans



The following consideration applies to one phase.

2a) External Structure of the Capacitor Bank

The external structure of the capacitor bank must be known or must be determined. This information can be requested from the manufacturer of the capacitor bank.

This example assumes the following external structure of the capacitor bank:

- 28 levels (cans) in series
- 4 cans per level
- H transformer between levels 13 and 14, counting from top to bottom
- 2 parallel cans are always cross-linked, refer to the following diagram

[dwexaufbcb-120314-01, 1, en_US]

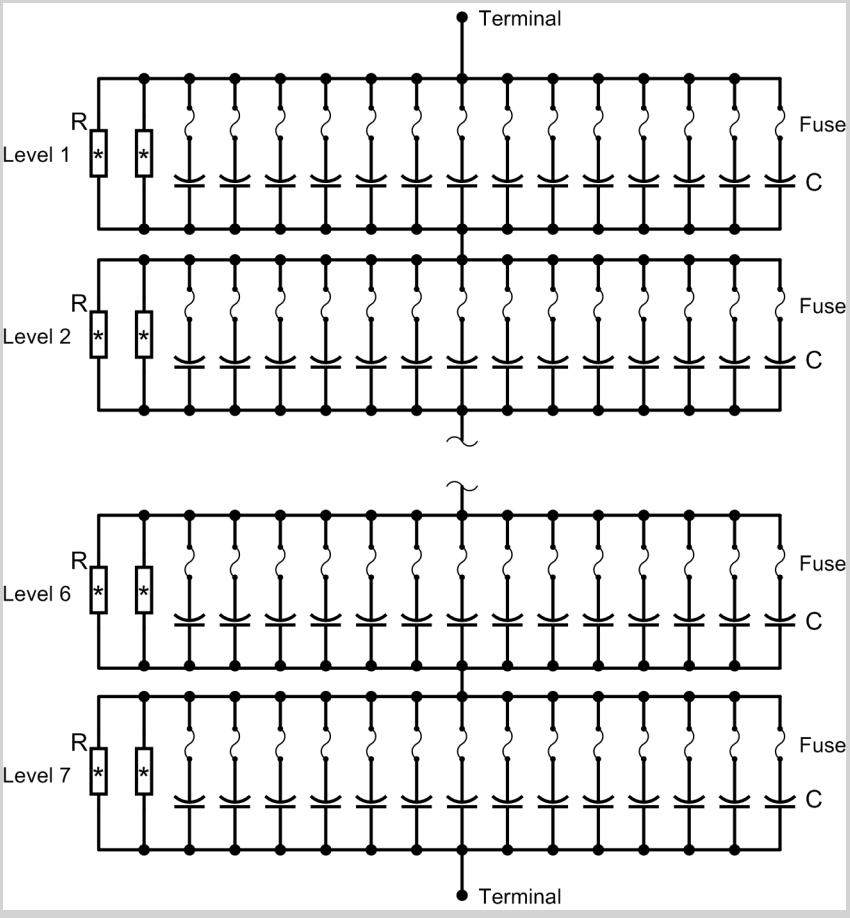


Figure 7-11 External Structure of the Capacitor Bank

2b) Internal Structure of a Can

The internal structure of a can must be known or must be determined. This information can be requested from the manufacturer of the capacitor bank.

This example assumes the following internal structure of the can:

- 14 parallel capacitances
- Internal fuses (one internal fuse per capacitance)
- 7 capacitance levels in series

[dwintauka-120314-01, 2, en_US]

Figure 7-12 Internal Structure of a Can

2c) Capacitance of a Can

The capacitance of a can must be known or must be determined. This information can be requested from the manufacturer of the capacitor bank.

- Capacitance per can: $C_K = 19.67\ \mu F$

2d) Current per Phase

The unbalanced current is derived under the assumption of a certain phase current.

In this example, the phase current is determined using the following assumptions and data:

- 1-phase rated capacitance of the capacitor bank: 2.81 µF
- Phase-to-ground voltage of the fundamental component of the capacitor bank: 249.1 kV
- Current per phase: $I_C = V_{Ph.\ fund.} \cdot \omega C = 249.1\ kV \cdot 2\pi \cdot 50\ Hz \cdot 2.81\ \mu F = 219.9\ A$

2e) Capacitance of a Can during an Element Fault

To do this, the capacitance of an individual C-element will be determined first:

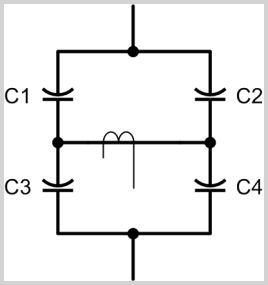
- Capacitance of a C-element:

$$C_E = \frac{C_K}{\text{No. C in parallel}} \cdot \text{No. C in series} = \frac{19.67\ \mu F}{14} \cdot 7 = 9.835\ \mu F$$

- Capacitance of a can during an element fault:

$$\frac{1}{C_{K,1EF}} = \frac{\text{No. C in series without a fault}}{\text{No. C in parallel} \cdot C_E} + \frac{1}{(\text{No. C in parallel} - 1) \cdot C_E}$$

$$\frac{1}{C_{K,1EF}} = \frac{6}{14 \cdot C_E} + \frac{1}{13 \cdot C_E} = \frac{1}{0.051397\ \mu F}$$



$C_{K,1EF} = 19.456\ \mu F$

2f) Capacitance in the Quarter of the H Connection during an Element Fault

Consider 2 special conditions:

- Cross-linking and therefore the parallel connection of 2 cans, refer to *Figure 7-11*
- Current transformer is not in the center of the levels

Therefore, the following calculation must be performed for the upper (C1) and lower quarter (C3).

[dw4tlkbnk-120314-01, 1, en_US]

Figure 7-13 Quarters of the Capacitor Bank

Based on the cross-linking of the cans, in case of an element fault, the capacitance of the parallel cans must be determined first:

- Capacitance of 2 parallel cans in case of an element fault:

  $C_{2K,1EF} = 19.456\ \mu F + 19.67\ \mu F = 39.126\ \mu F$

  Capacitance in the quarter of C1 in case of an element fault:

$$\frac{1}{C1_{1EF}} = \frac{\text{No. cans in series without a fault}}{2 \cdot C_K} + \frac{1}{C_{2K,1EF}}$$

$$\frac{1}{C1_{1EF}} = \frac{12}{2 \cdot 19.67\ \mu F} + \frac{1}{39.126\ \mu F} = \frac{1}{0.3306\ \mu F}$$

$C1_{1EF} = 3.0249\ \mu F$

- Capacitance in the quarter of C3 in case of an element fault:

$$\frac{1}{C3_{1EF}} = \frac{14}{2 \cdot 19.67\ \mu F} + \frac{1}{39.126\ \mu F} = \frac{1}{0.3814\ \mu F}$$

$C3_{1EF} = 2.6217\ \mu F$

2g) Capacitance in the Quarters of the H Connection without Element Fault

- Capacitance in the quarters of C1 and C3 without element fault:

$$C1 = \frac{2 \cdot C_K}{\text{No. cans in series}} = \frac{2 \cdot 19.67\ \mu F}{13} = 3.026\ \mu F$$

$$C3 = \frac{2 \cdot C_K}{\text{No. cans in series}} = \frac{2 \cdot 19.67\ \mu F}{15} = 2.623\ \mu F$$

2h) Unbalanced Current and Threshold-Value Setting in Case of a C-Element Fault

- Unbalanced current:

$$I_{unbl.} = I_C \left| \frac{C1}{(C1 + C2)} - \frac{C3}{(C3 + C4)} \right|$$

- Unbalanced current in case of an element fault in C1:

$$I_{unbl.} = 219.9\ A \left| \frac{3.0249\ \mu F}{(3.0249\ \mu F + 3.026\ \mu F)} - \frac{3.623\ \mu F}{(3.623\ \mu F + 3.623\ \mu F)} \right| = 20.0\ mA$$

- Unbalanced current in case of an element fault in C3:

$$I_{unbl.} = 219.9\ A \left| \frac{3.026\ \mu F}{(3.026\ \mu F + 3.026\ \mu F)} - \frac{3.6217\ \mu F}{(3.6217\ \mu F + 3.623\ \mu F)} \right| = 27.3\ mA$$

The lesser of both values is relevant for the setting of the threshold value. For instance, set the threshold to 75 % of this value:

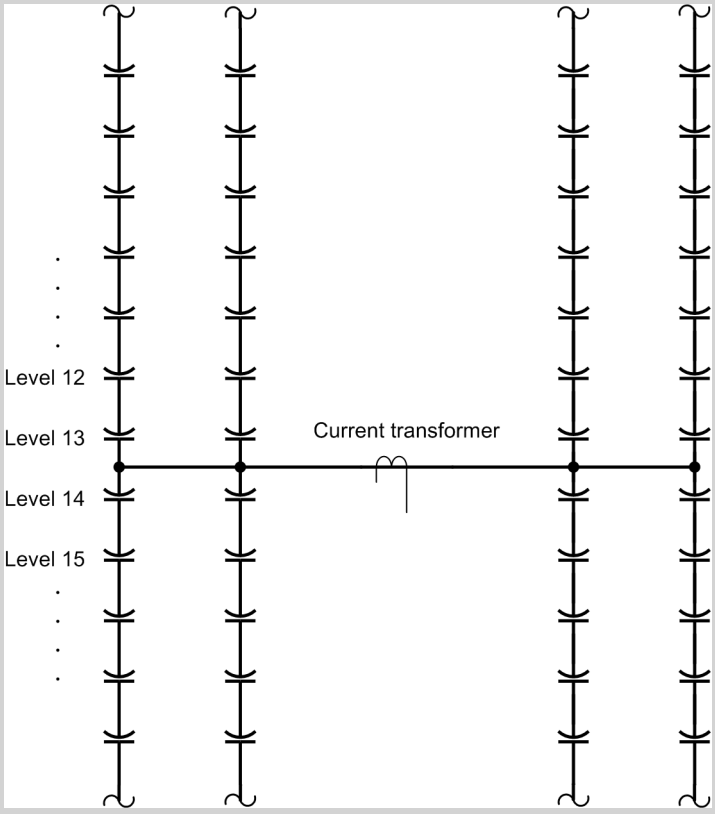
- Threshold value (primary): 0.75 · 20.0 mA = 15.0 mA

The threshold is a primary value. In order to detect this, a 1:1 transformer is required. Under this assumption, the secondary setting value is equal to the primary value.

NOTE

Use sensitive device current inputs in order to apply secondary thresholds of < 30 mA.

Example 3 (a to d): Unbalanced-Current Information Not Available from the Manufacturer of the Capacitor Bank, External Capacitor-Bank Structure without Cross-Linked Cans



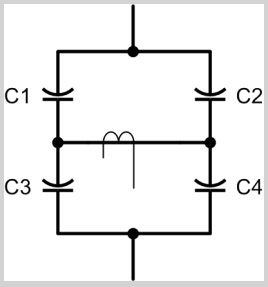
Example 3 is almost identical to example 2. The only difference is that the cans are not cross-linked. Here, only the calculation part is discussed that is a result of the different external structure. Information for additional calculations can be found in example 2.

3a) External Structure of the Capacitor Bank

The external structure of the capacitor bank must be known or must be determined. This information can be requested from the manufacturer of the capacitor bank.

This example assumes the following external structure of the capacitor bank:

- 28 levels (cans) in series
- 4 cans per level
- H transformer between levels 13 and 14, counting from top to bottom
- Parallel cans are not cross-linked, refer to the following diagram



[dwexafbocb-260314-01, 1, en_US]

Figure 7-14 External Structure of the Capacitor Bank

3b) Capacitance in the Quarter of the H Connection during an Element Fault

The current transformer is not located in the center of the levels; therefore, the following calculation for the upper (C1) and the lower quarter (C3) must be performed.

[dw4tlkbnk-120314-01, 1, en_US]

Figure 7-15 Quarters of the Capacitor Bank

- Capacitance in the quarter of C1 in case of an element fault ($C1_{1EF}$):

  Capacitance in the row without element fault:

  $$\frac{1}{C1_{Ro\,EF}} = \frac{\text{No. cans in series}}{C_K} = \frac{13}{19.67\ \mu F}$$

  $C1_{RoEF} = 1.5130\ \mu F$

- Capacitance in the row with element fault:

  $$\frac{1}{C1_{Rm\,EF}} = \frac{\text{No. cans in series without a fault}}{C_K} + \frac{1}{C_{k,1EF}} = \frac{12}{19.67\ \mu F} + \frac{1}{19.456\ \mu F}$$

  $C1_{RmEF} = 1.5118\ \mu F$

  $C1_{1EF} = C1_{RoEF} + C1_{RmEF} = 1.5130\ \mu F + 1.5118\ \mu F = 3.0248\ \mu F$

- Capacitance in the quarter of C3 in case of an element fault ($C3_{1EF}$):

  Capacitance in the row without element fault:

  $$\frac{1}{C3_{Ro\,EF}} = \frac{\text{No. cans in series}}{C_K} = \frac{15}{19.67\ \mu F}$$

  $C3_{RoEF} = 1.3113\ \mu F$

- Capacitance in the row with element fault:

  $$\frac{1}{C3_{Rm\,EF}} = \frac{\text{No. cans in series without a fault}}{C_K} + \frac{1}{C_{k,1EF}} = \frac{14}{19.67\ \mu F} + \frac{1}{19.456\ \mu F}$$

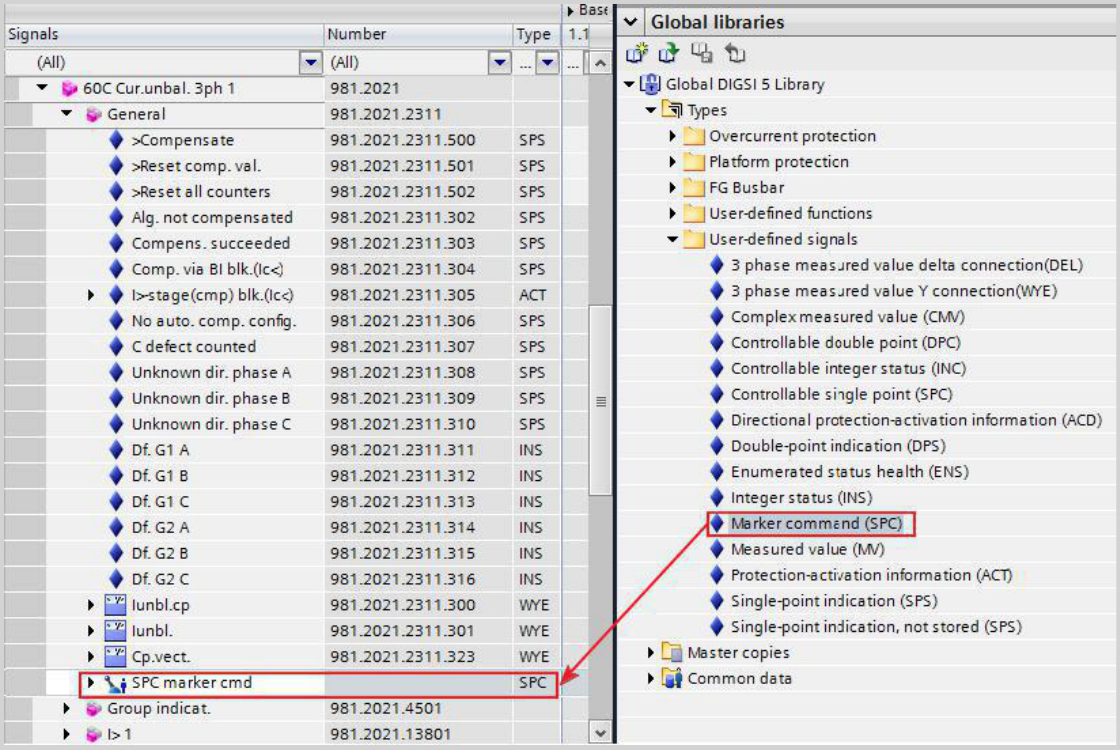
  $C3_{RmEF} = 1.3104\ \mu F$

  $C3_{1EF} = C3_{RoEF} + C3_{RmEF} = 1.3113\ \mu F + 1.3104\ \mu F = 2.6217\ \mu F$

3c) Capacitance in the Quarters of the H Connection without Element Fault

The values are identical to those values in the example *2g) Capacitance in the Quarters of the H Connection without Element Fault, Page 935* .

3d) Unbalanced Current and Threshold-Value Setting in Case of a C-Element Fault

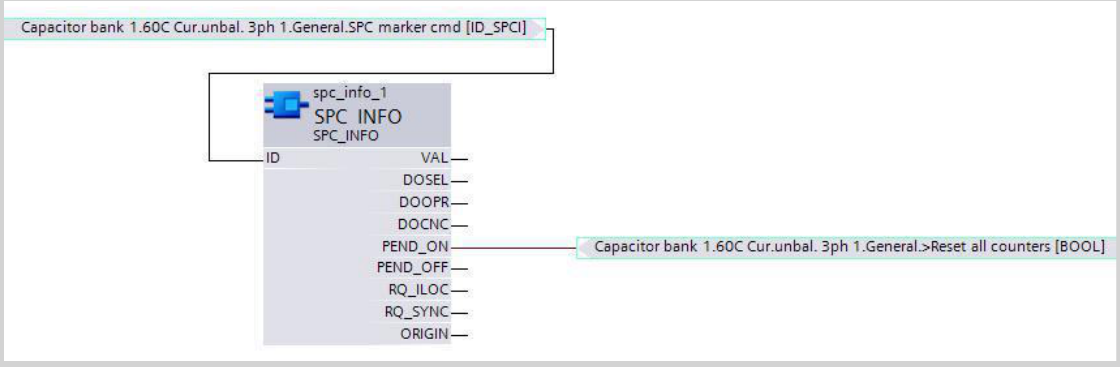


Use the values determined under 3b) for those formula listed in example *2h) Unbalanced Current and Threshold-Value Setting in Case of a C-Element Fault, Page 935* .

Resetting the Counters via Protocols IEC 60870-5-103, IEC 60870-5-104, DNP3, or Modbus

The following example shows how to use a function chart (CFC) to reset the counters with the protocols IEC 60870-5-103, IEC 60870-5-104, DNP3, or Modbus.

EXAMPLE



- Add a **Marker command (SPC)** signal to the information list.

[sc_add_SPC_signal, 1, en_US]

Figure 7-16 Adding Marker Command (SPC) Signal to Information List

- Set up the following CFC. Connect the SPC signal as input, and the signal *>Reset all counters* as output.

[sc_CFC_60C_3ph, 1, en_US]

Figure 7-17 Function Chart (CFC): Activating the Binary Input Signal

- Send a single-point control command from the control center to the SPC signal to activate the signal *>Reset all counters*. Then the counters are reset.

7.4.4 Overcurrent-Protection Stage I>

7.4.4.1 Description

Logic of a Stage

[lounbalstufe-020913, 1, en_US]

Figure 7-18 Logic Diagram of the Overcurrent-Protection Stage I>

Measurands

Within the protection stage, the compensated and the non-compensated unbalanced currents are available. Use the parameter **`Measured value`** to select one of the 2 values. Both values are displayed as measured values of the function at the function stage.

Pickup, Tripping Delay

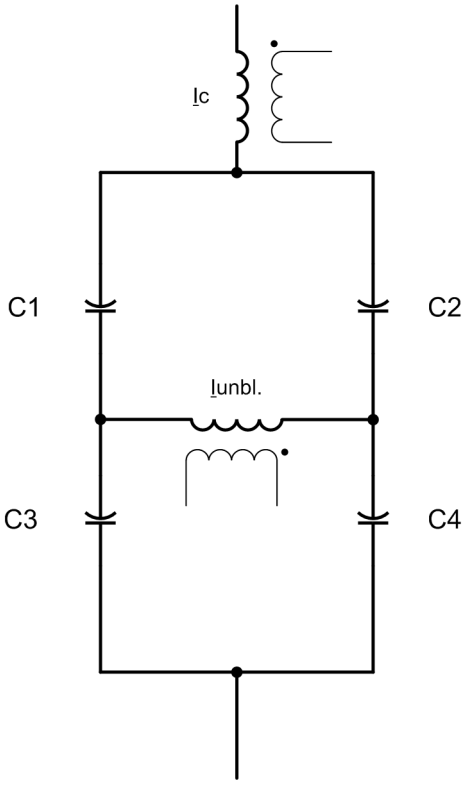
If the selected measurand in one of the phase measuring element exceeds the threshold, the stage picks up. The pickup starts a tripping time delay, and a fault-location information is issued. More information can be found in this chapter under *Fault-Location Information, Page 941* . If the threshold is exceeded during the entire tripping delay, a phase-selective operate indication is issued.

Please note that, when using the compensated measurands as well as the automatic compensation, the currently measured current unbalance (that resulted in the threshold being exceeded) is gradually compensated. This means that even in case of a constantly existing unbalance in the primary system, the compensated measurand becomes gradually lower and may therefore fall below the threshold again at some time. The timing depends on by how much the threshold is exceeded.

For this reason and under those conditions, long time delays must not be set, see also chapter *7.4.4.2 Application and Setting Notes* .

This effect does not occur if manual compensation or the non-compensated measurand is used.

Blocking While Charging



In order to prevent pickup as a consequence of the charging process, the **I>** stage is implicitly blocked in a phase-selective way for 250 ms by setting $I_{unbal.,comp.}$ to 0 A, after capacitor energizing has been detected.

Blocking only takes place if the stage operates with compensated unbalanced values.

Fault-Location Information

When picking up, the stage provides information about the faulty group of the capacitor bank. If the location can be safely determined, the corresponding indication *Fault position group 1* or *Fault position group 2* is issued.

Both indications also contain the information about the faulty phase. If the capacitor is implemented as an H connection, the following definition is assumed:

[dwfehlerortinf_iunsy-020913, 1, en_US]

Figure 7-19 Definition for the Fault-Location Information

The black dot indicates the orientation of the current transformer. For the connection of the current transformer shown in the previous figure, the following definition applies:

- Group 1: C1 and C4
- Group 2: C2 and C3

In order to determine the fault location (group 1 or 2) correctly, use the parameter **Capacitor element type** (in FB **General** of the **Capacitor bank** function group) to tell the device whether the elements of the capacitor bank have internal fuses or not.

Non-Compensated Status

If no compensated values are available and the stage has been set to use such values, the stage will be blocked. The readiness of the stage turns to *Warning*. This condition will be reported on the function stage (indication *Alg. not compensated*).

7.4.4.2 Application and Setting Notes

Parameter: Measured value

- Default setting **(_:13801:100) Measured value** = ***no***

With the parameter, you set the **Measured value**.

Parameter Value	Description
compensated	The stage uses compensated unbalanced values. This means an operational current unbalance will be eliminated. This allows you to significantly increase the sensitivity of the measurement. Note the following: If the current I_c is lower than the threshold **Current threshold CB open**, the affected phase measuring elements are rendered inactive by setting $I_{unbal.,comp.}$ to 0 A. This condition is held for 250 ms after energizing has been detected in order to avoid a pickup as a consequence of the charging process. Siemens recommends using compensated unbalanced values. In case that automatic compensation is applied, please consider the setting notes for the operate delay.
non-compensated	The stage works with non-compensated unbalanced values. This means the measurand may contain an existing operational current unbalance.

Parameter: Threshold

- Default setting **(_:13801:3) Threshold** = ***0.2 A***

Set the parameter **Threshold** for the specific application.

When using compensated unbalanced values, very sensitive settings are possible. When using non-compensated unbalanced values, the threshold must be higher than the maximum operational unbalanced current.

Parameter: Operate delay

- Default setting **(_:13801:6) Operate delay** = ***0.08 s*** (for the 1st stage)

Set the parameter **Operate delay** for the specific application.

NOTE

If the function has been set to automatic compensation and the stage works with compensated values, the maximum permitted operate delay is 80 ms. If the operate delay is set to longer than 80 ms, the automatic compensation might cause dropout of the picked-up stage. This risk does not exist when manual compensation or non-compensated values are used.

7.4.5 Counter Stage

7.4.5.1 Description

Logic of a Stage

[lo-cnt-stage-260314-01, 2, en_US]

Figure 7-20 Logic Diagram of the Counter Stage

Measurands/Input Values

The measurand/input values of the counter stage are the phase- and group-segregated counter contents that are determined in the **General** FB.

Pickup, Tripping Delay

Supervision of the counter contents is phase-segregated. If a counter reaches the preset threshold (parameter **Max. no. of def. elem. phs A** , **Max. no. of def. elem. phs B** , **Max. no. of def. elem. phs C**), the stage picks up. When using the parameter **Type of counting groups** , a selection is made whether the supervision function occurs group-segregated or with the sum value of both groups. The pickup starts the time delay. If the time delay has elapsed, the operate indication will be issued.

Automatic Compensation

If the automatic compensation function is enabled, the counter stage is working. If this is not the case, the readiness status of the stage changes to the state *warning.*

7.4.5.2 Application and Setting Notes

General Notes

- The setting notes for the current-threshold value for counting faulty C-elements are provided in chapter *7.4.3.2 Application and Setting Notes* as you must set this parameter across all stages.
- In order to react quickly to the simultaneous fault of many C-elements, always use an overcurrent-protection stage I> with a short tripping delay (< 100 ms) in addition to the counter stage. This is necessary as the counter function counts each current jump only once, regardless of its height.

Parameter: Type of counting groups

- Default setting **(_:13651:104) Type of counting groups** = ***segregated***

When using the parameter **Type of counting groups**, you specify whether the group-segregated counter status or the sum of both group counters are compared to the threshold.

Parameter: Maximum Number of Faulty Elements, Operate delay

- Default setting **(_:13651:101) Max. no. of def. elem. phs A** = *10*
- Default setting **(_:13651:102) Max. no. of def. elem. phs B** = *10*
- Default setting **(_:13651:103) Max. no. of def. elem. phs C** = *10*
- Default setting **(_:13651:6) Operate delay** = *0.00 s*

Set the parameters for the specific application.

It is possible to configure several stages for different tasks:

- Reporting only (with or without fault record)

  Use this stage to report 1 or 2 faulty C-elements. To do this, set the 3 parameters **Max. no. of def. elem. phs A**, **Max. no. of def. elem. phs B** and **Max. no. of def. elem. phs C** to a small value (1 or 2). The parameter **Operate delay** can be set to 0.

  If you would like to prevent the operate (tripping) and fault logging (fault log and fault record), set the parameter **Operate & flt.rec. blocked** to ***yes***.

  If you would like to prevent only the operate (tripping) and the fault logging must occur, remove this stage from the interface **Trip** to the circuit breaker (see also *5.4.2 Structure of the Function Group*, **Interfaces with Circuit-Breaker Function Group**).

- Indication with delayed operate

  Use this stage to report in case of some faulty C-elements and set a relatively long time delay of the operate, for example, 2 hours. During this time, the fault of the C-elements can be clarified. If it is possible to find a solution, the counter status can be reset manually. This way, the stage drops out. If a solution cannot be found within 2 hours, the stage trips and disconnects the capacitor bank.

- Immediate operate

  The stage is used to initiate the operate immediately after a larger number of C-elements became faulty.

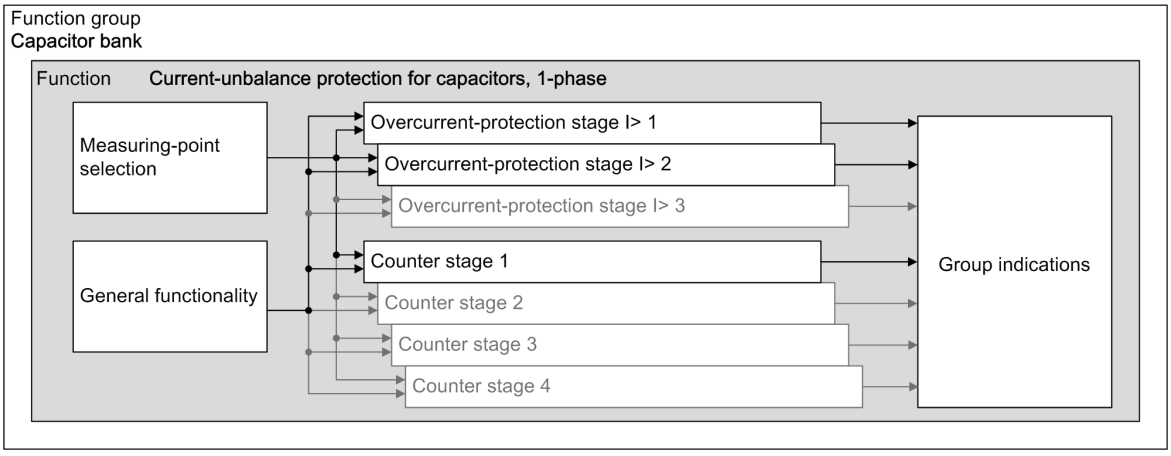
7.5 Current-Unbalance Protection for Capacitors, 1-Phase

7.5.1 Overview of Functions



The **Current-unbalance protection for capacitors, 1-phase** function (ANSI 60C):

- Protects in case of faults in capacitor elements (C-elements) of a double neutral point capacitor bank
- Provides very sensitive supervision of the unbalanced current between the 2 neutral points
- Allows counting individual faulty C-elements

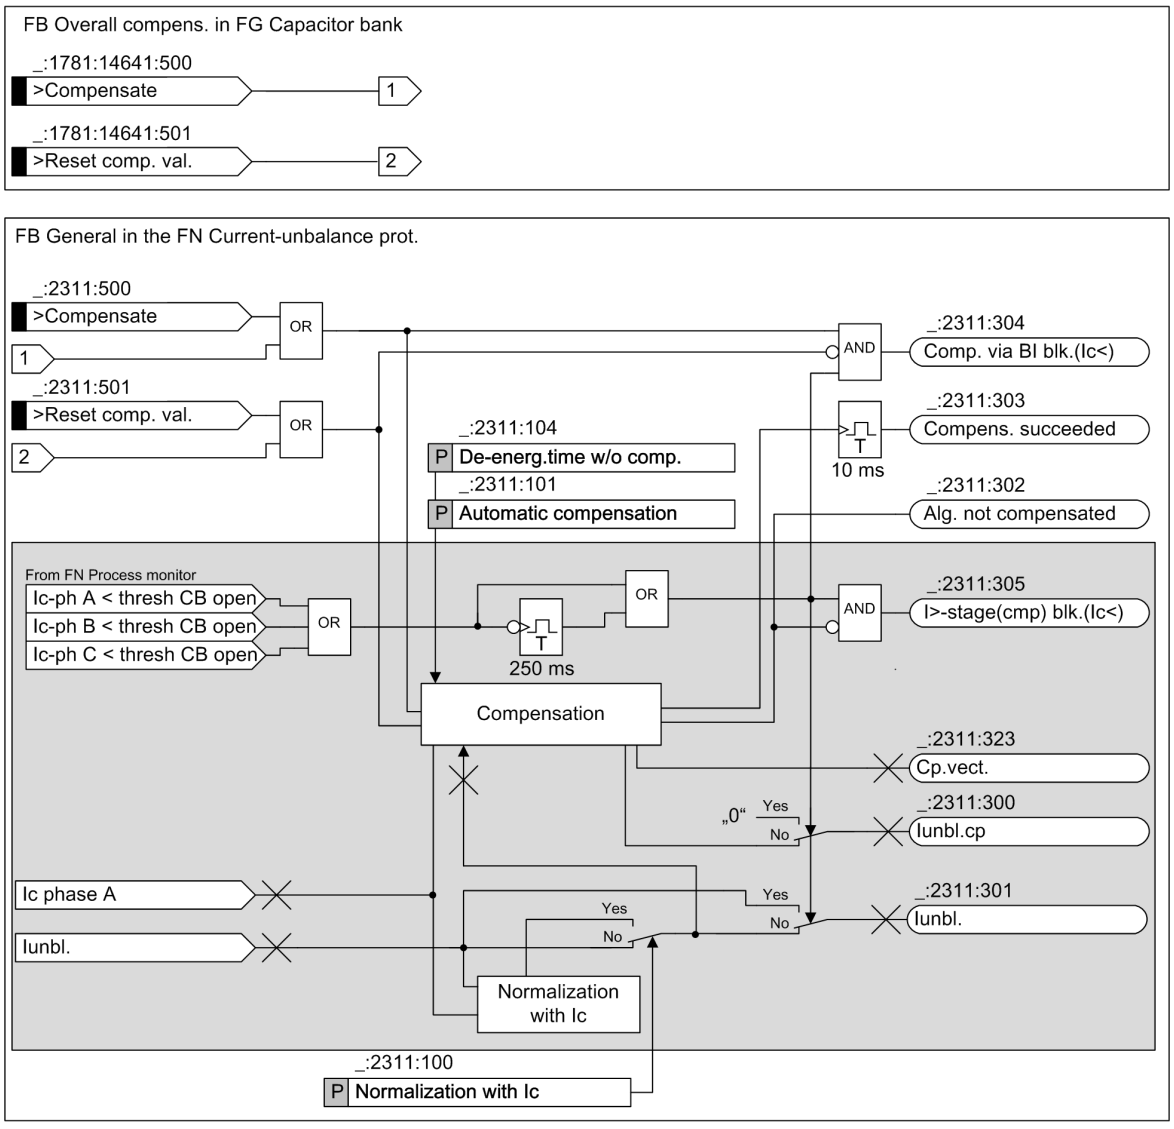
7.5.2 Structure of the Function

The **Current-unbalance protection for capacitors, 1-phase** function is used in the **Capacitor bank** function group. It is preconfigured at the factory with 2 overcurrent-protection stages **I>** and 1 stage of the type **Counter**. A maximum of 3 overcurrent-protection stages and 4 counter stages can be operated simultaneously in the function.

The function is designed so that the **General functionality** (including adjustment) and the **Measuring-point selection** can work across the stages.

[dwocplunb1ph-020714, 3, en_US]

Figure 7-21 Structure/Embedding of the Function



7.5.3 General Functions and Measuring-Point Selection

7.5.3.1 Description

The General functionality is structured in the following functional parts:

- Compensation of the unbalance
- Normalization of the unbalanced current with the current I_c
- Counting faulty C-elements (the stage type **Counter** is used to monitor the counter status)

Logic for Compensation and Normalization

[lo_FBallgiunb1ph-070714-01, 3, en_US]

Figure 7-22 Cross-Stage Functionality

Measuring-Point Selection

With the **`MP selection`** parameter, you can select from a list of measuring points a 1-phase measuring point that is connected to the **I Unbalanced** interface in the **Capacitor bank** function group. The **Current-unbalance protection for capacitors, 1-phase** function processes the 1-phase current that is connected to the measuring point.

For more information, refer to the description of the **Capacitor bank** function group starting from chapter *5.4.1 Overview* .

Measurands, Method of Measurement

The function receives its measurands via the **I Unbalanced** interface of the **Capacitor bank** function group.

The compensated and non-compensated unbalanced currents are provided for the overcurrent-protection stage. Within the protection stage, one of the 2 values is selected in the protection stage via the parameter **`Measured value`**. Both values are available as functional measured values (see *Figure 7-22*).

Configure across the stages whether the unbalanced current must be normalized with the current I_c that flows into the capacitor bank. Phase A component of the current I_c flowing into the capacitor bank is used as the reference for the normalization. You can find more information in this chapter under *Normalization with I_c*, *Page 950* .

The method of measurement used processes the sampled unbalanced-current values and filters out the fundamental component numerically. The protection stages evaluate the fundamental component of the unbalanced current.

General Notes on the Compensation

An operational unbalanced current is added to an unbalanced current resulting from faulty capacitor elements. This corrupts the measuring result.

Operational unbalanced currents can result from the following causes:

- Manufacturing tolerances of the capacitor
- Aging of the capacitor
- Environmental influences, for example, temperature

The compensation eliminates operational unbalanced currents by calculation. For this purpose, the phasor of the operational unbalanced current $\underline{I}_{unbal.,op.}$ is stored at specific times. The stored phasor (compensation phasor), is subtracted from the actually measured unbalanced-current phasor:

$$\underline{I}_{unbal.,comp.} = \underline{I}_{unbal.} - \underline{I}_{unbal.,op.}$$

[fo_compensatied unbal., 1, en_US]

The following indications describe the status of the compensation:

Indication	Description
Alg. not compensated	The algorithm is not compensated. The compensated values are not available under the following conditions: • After initial startup of the device before any compensation is carried out • After activating the binary input *>Reset comp. val.* • After change of $I_{rated,obj}$ Protection stages that are working with compensated values are inactive.
Compens. succeeded	This indication is issued (as transient indication with a pulse duration of 10 ms) if the existing unbalance has been compensated manually or automatically. In case of automatic compensation, the signal is issued at each event-based situation where full compensation is carried out.
Comp. via BI blk.(Ic<)	If a manual compensation has been initiated and the current I_c (current flowing into the capacitor bank) at this time is less than the threshold **Current threshold CB open**, the manual compensation is not executed. This is signaled via the *Comp. via BI blk.(Ic<)* indication.

2 different methods are available for the compensation:

- Manual compensation via binary input signals
- Automatic compensation

Manual Compensation via Binary Input Signal

If the binary input signal *>Compensate* is activated, the manual compensation starts. This will fully compensate any unbalance that exists at this time. This means, the value $\underline{I}_{unbal.,comp.}$ will then become 0. You can also use the manual compensation in parallel with the automatic compensation.

Automatic Compensation

When using the parameter **Automatic compensation**, this automatic compensation function can be enabled or disabled.

The automatic compensation consists of 2 different mechanisms:

- Event-based compensation of any existing unbalance
  This compensation is performed in the following situations:
  - After energizing the capacitor bank or a phase of the bank
  - After counting a faulty C-element
  - After each startup of the device
  - After specific parameter changes:
    - Switching on the automatic compensation
    - Changing the rated current of the capacitor bank

  In order to avoid transient inrush-current effects, the compensation is delayed by 250 ms after energizing has been detected.
  Full compensation after bank energization can be avoided in case of only short de-energization by means of parameter **De-energ.time w/o comp.**. If the de-energized duration is less than the setting of parameter **De-energ.time w/o comp.**, the full compensation is not carried out after energizing a phase or the whole bank.
- Cyclic, slow and thus gradual compensation of an existing unbalance in small increments
  This permits, for example, the automatic compensation of environmental influences.

Resetting the Compensation

The algorithm can be reset to the non-compensated status. Compensated values are not available in this case. Protection stages that work with compensated values are rendered inactive. The binary input signal *>Reset comp. val.* of the function or function group resets the compensation (see also *Figure 7-22*).

Normalization with I_c

The threshold for the unbalanced current is usually set by assuming the rated capacitor current $I_{c,rated}$. The current I_c flowing into the capacitor bank determines the amount of the unbalanced current. A lower I_c also means a lower unbalanced current. If $I_c < I_{c,rated}$, the protection becomes less sensitive. This influence can be compensated via the normalization. Normalization keeps the sensitivity of the protection function constant by normalizing the unbalance value with the current I_c. Phase A component of the current I_c flowing into the capacitor bank is used as the reference for the normalization. When using the parameter **Normalization with Ic**, normalization is enabled or disabled.

I_c Lower than Current Thresh. CB Open

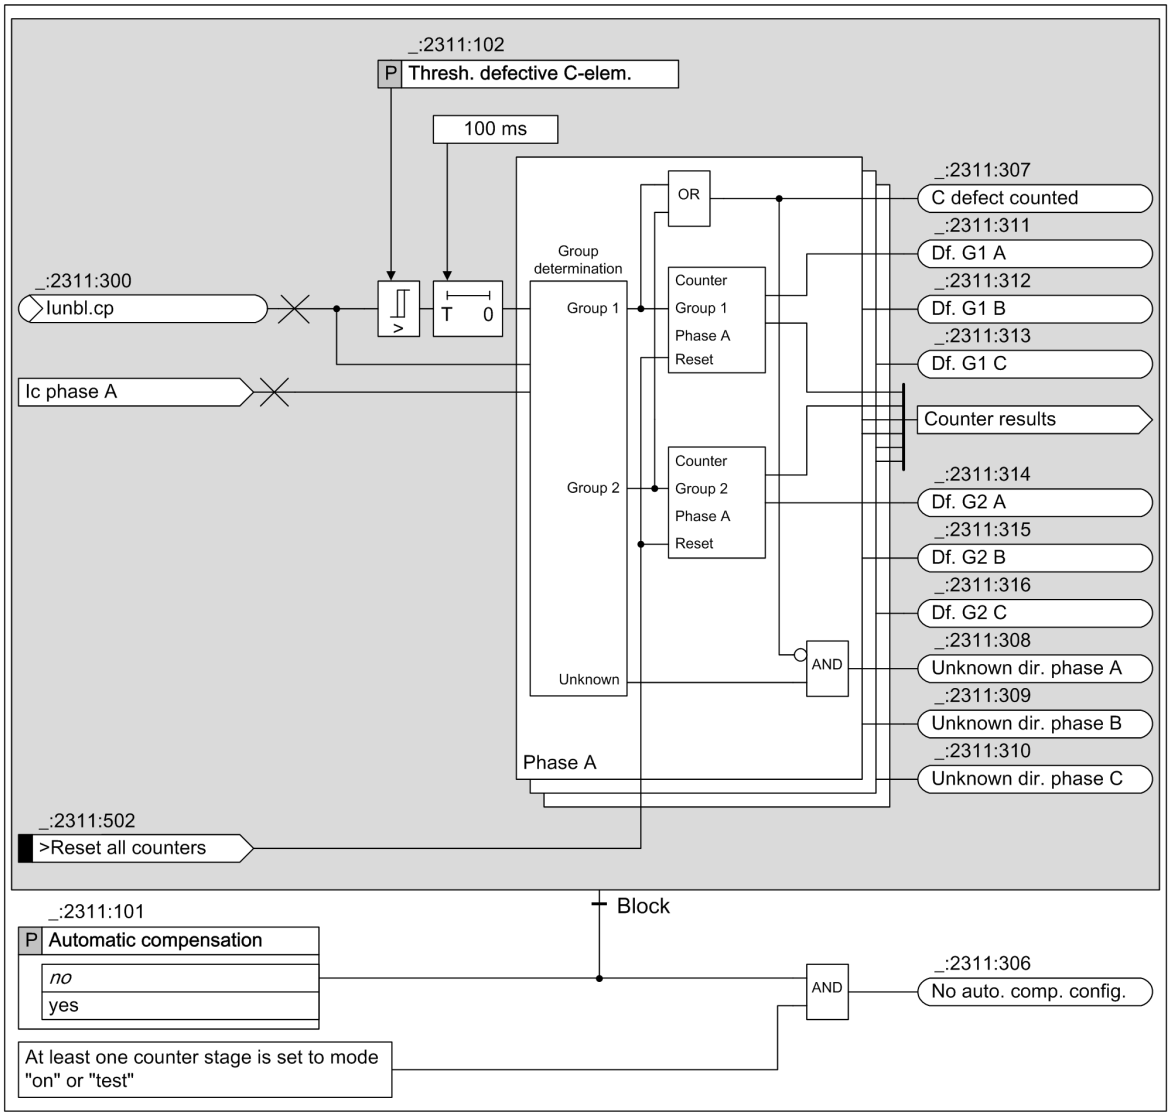
If any phase current of I_c is lower than the threshold **Current thresh. CB open**, the compensated value can no longer be computed with sufficient accuracy. To avoid a malfunction, the compensated unbalanced value $I_{unbal.,comp.}$ is set to 0 A (see *Figure 7-22*). This deactivates the protection stages that work with compensated values.
This condition will be indicated (indication *I>-stage(cmp) blk.(Ic<)*).
In this case, normalization with current I_c will no longer work properly either. Normalization is canceled. This means that the non-normalized value will be used instead of the normalized value (see *Figure 7-22*).

Charging/Energizing the Capacitor Bank or a Phase of the Bank

Charging of the bank takes place when the discharged bank is switched on to the network. Charging of a phase can occur in case of network faults. If a phase-to-ground voltage drops to 0 V due to a network fault, the respective phase is discharged and the return of the phase-to-ground voltage (after the fault has been cleared) will charge the phase.

Charging the bank causes inrush currents in the respective phases. To avoid overfunction in case of sensitive threshold settings, the stages using compensated unbalanced values are blocked by setting $I_{unbal.,comp.}$ to 0 A.

These stages are:



- Counter stage
- I> stage, if set to operate with compensated unbalanced values

The blocking ($I_{unbal.,comp.}$ set to 0 A) lasts for 250 ms after energizing detection. Afterwards, the calculated $I_{unbal.,comp.}$ is processed again.

Energizing detection takes place by monitoring the phases currents I_c flowing into the bank. If all three phase currents exceed the threshold **`Current Thresh.CB Open`**, energizing is detected.

Logic for Counting Faulty C-Elements

This part of the General functionality is only important if counter stages are used.

[locntEF1ph-070714-01, 3, en_US]

Figure 7-23 Counting Faulty C-Elements

Activation/Blocking Counting

If at least one counter stage is enabled, the counting function is active. Furthermore, the counting function works only if the automatic compensation is enabled.

In order to prevent counting as a consequence of the charging process, the counter function is implicitly blocked for 250 ms by setting $\underline{I}_{unbal.,comp.}$ to 0 A, after the capacitor energizing has been detected.

Measurands, Counting

The measurand is the 1-phase compensated unbalanced current $\underline{I}_{unbal.,comp.}$. If a single C-element is faulty, an unbalance occurs between the neutral points of the 2 capacitor banks. This unbalance causes an unbalanced current; this means, a small current jump occurs in the unbalanced current. Set the parameter **Thresh. defective C-elem.**, so that this current jump can be detected (see also *7.5.3.2 Application and Setting Notes*). The unbalanced current that was caused by the fault must exceed the threshold for 100 ms before the affected phase and the affected group are determined and counting (incrementing the counter) takes place. The angle reference of the unbalanced-current phasor to the reference current $I_{c,A}$ is used to determine the phase of the faulty C element. Thus, phase-segregated counting is possible. There is one counter for each phase and group. After the counting, the existing unbalance is compensated; this means, the unbalance is reset to 0 A. If the faulty group cannot be determined, the unbalance is also compensated.

Resetting/Setting the Counters

You can reset or set the counters of group 1 and group 2 via:

- On-site operation panel directly on the device
- Online DIGSI connection to the device
- Binary input *>Reset all counters* (only reset of all counters)
- Communication connection with the control center

You can directly set or reset the counters via IEC 61850 by setting the counter values to the desired value. If you want to reset the counters via DNP3, IEC 60870-5-103, Modbus, or IEC 60870-5-104, an additional configuration with CFC is necessary. For more information, refer to chapter *7.5.3.2 Application and Setting Notes*.

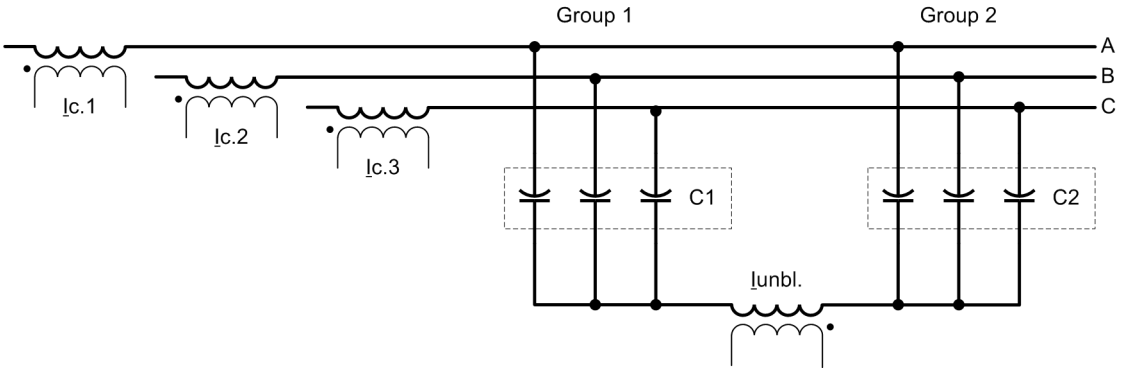
Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
(_:2311:300) Iunbl.cp	Compensated unbalanced current $\underline{I}_{unbal.,comp.}$	kA	A	Parameter **Rated primary current**
(_:2311:301) Iunbl.	Non-compensated unbalanced current $\underline{I}_{unbal.}$	kA	A	Parameter **Rated primary current**
(_:2311:323) Cp.vect.	Compensation vector $\underline{I}_{comp.,vect.}$	kA	A	Parameter **Rated primary current**

You can find the value of the parameter **Rated primary current** of the preceding table in the chapter *6.1.6 Settings* according to the specified parameter **MP selection**.

$\underline{I}_{comp.,vect.}$ is normalized with I_c. The normalization is carried out no matter if the parameter **Normalization with Ic** is set to ***yes*** or ***no***. $\underline{I}_{comp.,vect.}$ keeps its value unchanged until the next compensation occurs.

$$\underline{I}_{comp.,\,vect.} = \underline{I}_{unbal.\,op.}\frac{I_{c,rated}}{I_c}$$



[fo_compensation vector, 1, en_US]

Where:

$\underline{I}_{unbal.op.}$	Operational unbalanced current at the moment the compensation is carried out
$I_{c,rated}$	Rated current of the capacitor bank
I_c	Current of the capacitor bank at the moment the compensation is carried out

Definition of the Group and Fault Location in Case of a Capacitor Dual Switching

If the capacitor is designed with dual switching function, the following definition is assumed:

[dwfehlerortinf_iunsy1ph-070714-01, 1, en_US]

Figure 7-24 Definition of the Fault-Location Information

The black dot indicates the orientation of the current transformer. For the connection of the current transformer shown in the previous figure, the following definition applies:

- Group 1: C1
- Group 2: C2

In order to determine the fault location (group 1 or 2) correctly, use the parameter **Capacitor element type** (in FB **General** of the **Capacitor bank** function group) to tell the device whether the elements of the capacitor bank have internal fuses or not.

The angle reference of the unbalanced-current phasor to the reference current I_c is used to determine the direction of the unbalanced current and, thus, the affected group is determined. If the direction cannot be determined with confidence, an appropriate indication will be generated.

7.5.3.2 Application and Setting Notes

Parameter: MP selection

- Default setting **(_:13501:81) MP selection** = ***None***

With the **MP selection** parameter, you can select from a list the measuring point that is connected to the **I Unbalanced** interface of the **Capacitor bank** function group.

The setting applies equally to all stages of the function.

In the default setting, a measuring point is not selected. You must select a measuring point. If you do not select a measuring point, an inconsistency is indicated via the read-only parameter **Consistency failure**.

Parameter: Automatic compensation

- Default setting **(_:2311:101) Automatic compensation** = ***no***

The parameter applies equally to all stages of the function that work with compensated measurands.

If no counter stages are applied, Siemens recommends to switch the automatic compensation off and use the manual compensation. You can find more information on this recommendation in chapter *7.5.4.2 Application and Setting Notes* (setting notes for the operate delay of the **I>** stage).

If the counter stages are applied, the automatic compensation must be switched on, otherwise the counting function will not work.

Parameter: De-energ.time w/o comp.

- Default setting **(_:2311:104) De-energ.time w/o comp.** = ***2.00 s***

In case of networks faults, the faulty phases are discharged. With the returning voltage after fault clearance, charging takes place. For such conditions, Siemens recommends that no automatic full compensation takes place in the affected phases. Otherwise, C-element defects occurring in this period (for example, because of discharging stress due to network-fault inception) will not be detected.

With the parameter **De-energ.time w/o comp.**, you define the duration of short de-energization after which no automatic compensation takes place. The parameter must be set to a value larger than the slowest fault clearing time in your network plus a safety margin.

If the setting is set to 0 s, an automatic full compensation is carried out after each energizing detection.

Parameter: Normalization with Ic

- Default setting **(_:2311:100) Normalization with Ic** = ***no***

This parameter applies equally to all stages of the function.

Parameter Value	Description
no	Select this setting if you can safely assume that I_c will not change for operational reasons or if you do not desire normalization of the unbalanced current with I_c. Please consider that the protection sensitivity will decrease with decreasing I_c.
yes	Select this setting if you want to keep the sensitivity of the protection stages constant during changes of I_c.

Parameter: Thresh. defective C-elem.

- Default setting **(_:2311:102) Thresh. defective C-elem.** = ***0.030 A***

Set the parameter **Thresh. defective C-elem.** to ensure that the jump in the unbalanced current caused by the faulty C-element is detected. Information about occurring unbalanced current as a consequence of single faulty C-elements will be provided by the manufacturer of the capacitor bank. Siemens recommends to set the threshold value to approx. 75 % of the unbalanced current that occurs after the fault of the 1st C-element.

Example 1: Information about the Unbalanced Current Available from the Manufacturer of the Capacitor Bank

Table 7-2 Unbalanced Current, Depending on the Number of Faulty C-Elements

Number of Faulty C-Elements	Primary Unbalanced Current
0	0.00 A
1	0.71 A
2	1.47 A
3	2.29 A
...	...

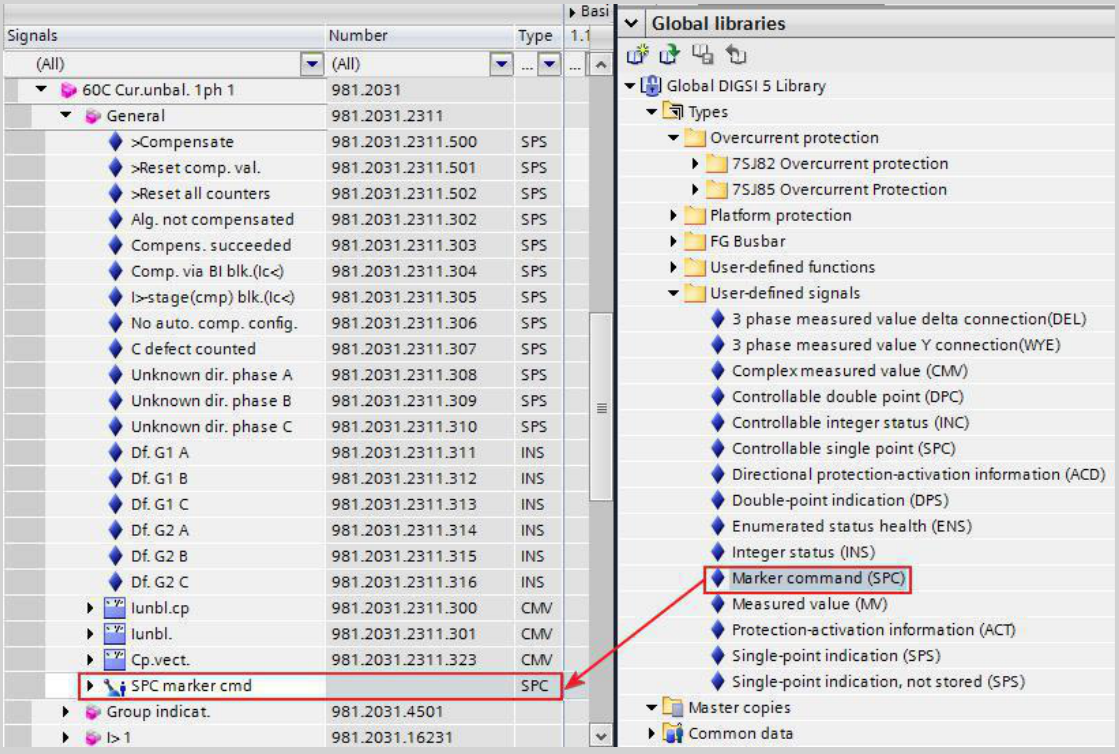
Assumed current transformer ratio: 10 A/1 A

Primary unbalanced current if 1st C-element fails: 0.71 A

Secondary unbalanced current if 1st C-element fails: 0.071 A

Secondary setting value: 0.75 · 0.071 A = 0.053 A

NOTE

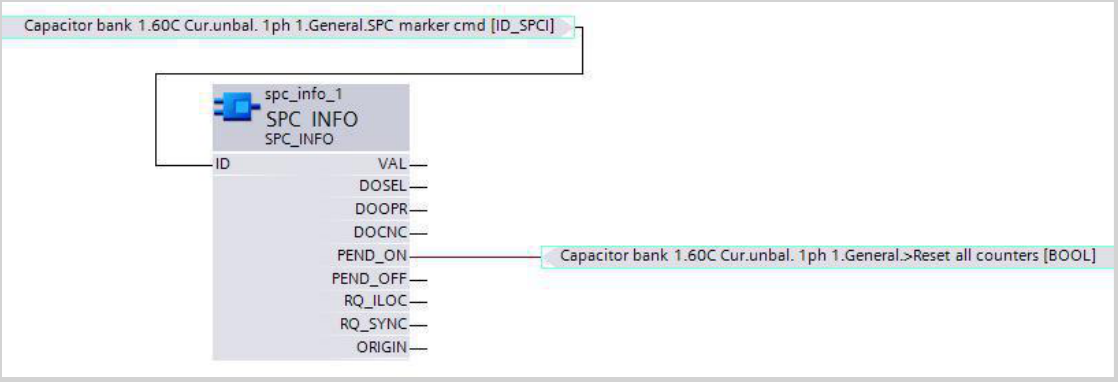


Use senstive device current inputs in order to apply secondary thresholds of < 30 mA.

Resetting the Counters via Protocols IEC 60870-5-103, IEC 60870-5-104, DNP3, or Modbus

The following example shows how to use a function chart (CFC) to reset the counters with the protocols IEC 60870-5-103, IEC 60870-5-104, DNP3, or Modbus.

EXAMPLE



- Add a **Marker command (SPC)** signal to the information list.

[sc_add_SPC_signal_1ph, 1, en_US]

Figure 7-25 Adding Marker Command (SPC) Signal to Information List

- Set up the following CFC. Connect the SPC signal as input, and the signal *>Reset all counters* as output.

[sc_CFC_60C_1ph, 1, en_US]

Figure 7-26 Function Chart (CFC): Activating the Binary Input Signal

- Send a single-point control command from the control center to the SPC signal to activate the signal *>Reset all counters*. Then the counters are reset.

7.5.4 Overcurrent-Protection Stage I>

7.5.4.1 Description

Logic of a Stage

[lounbalstu1ph-080714-01, 1, en_US]

Figure 7-27 Logic Diagram of the Overcurrent-Protection Stage I>

Measurands

Within the protection stage, the compensated and the non-compensated unbalanced currents are available. Use parameter **Measured value** to select one of the 2 values. Both values are displayed as measured values of the function at the function stage.

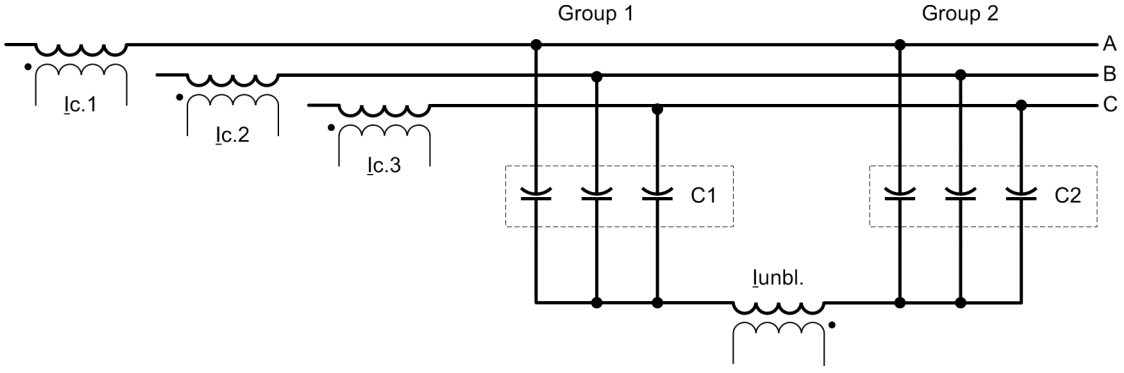
Pickup, Operate Delay

If the selected measurand exceeds the threshold, the stage picks up. The pickup starts the operate delay, and a fault-location information is issued. More information can be found in this chapter under *Fault-Location Information, Page 958* . If the threshold is exceeded during the entire operate delay, the operate indication is issued.

Please note that, when using the compensated measurands as well as the automatic compensation, the currently measured current unbalance (that resulted in the threshold being exceeded) is gradually compensated. This means that even in case of a constantly existing unbalance in the primary system, the compensated measurand becomes gradually lower and may therefore fall below the threshold again at some time. The timing depends on by how much the threshold is exceeded.

For this reason and under those conditions, long time delays must not be set, see also chapter *7.5.4.2 Application and Setting Notes* .

This effect does not occur if manual compensation or the non-compensated measurand is used.



Blocking While Charging

In order to prevent pickup as a consequence of the charging process, the **I>** stage is implicitly blocked for 250 ms by setting $I_{unbal.,comp.}$ to 0 A, after capacitor energizing has been detected. Blocking only takes place if the stage operates with compensated unbalanced values.

Fault-Location Information

When picking up, the stage provides information about the faulty group of the capacitor bank. If the location can be safely determined, the corresponding indication *Fault position group 1* or *Fault position group 2* is issued.

Both indications also contain the information about the faulty phase. If the capacitor is implemented with 2 neutral points, the following definition is assumed:

[dwfehlerortinf_iunsy1ph-070714-01, 1, en_US]

Figure 7-28 Definition for the Fault-Location Information

The black dot indicates the orientation of the current transformer. For the connection of the current transformer shown in the previous figure, the following definition applies:

- Group 1: C1
- Group 2: C2

In order to determine the fault location (group 1 or 2) correctly, use the parameter **Capacitor element type** (in FB **General** of the **Capacitor bank** function group) to tell the device whether the elements of the capacitor bank have internal fuses or not.

Non-Compensated Status

If no compensated values are available and the stage has been set to use such values, the stage will be blocked. The readiness of the stage turns to *Warning*. This condition will be reported on the function stage (indication *Alg. not compensated*).

7.5.4.2 Application and Setting Notes

Parameter: Measured value

- Default setting **(_:16231:100) Measured value** = ***compensated***

With this parameter you set the **Measured value** .

Parameter Value	Description
compensated	The stage uses compensated unbalanced values. This means an operational current unbalance will be eliminated. This allows you to increase significantly the sensitivity of the measurement. Note: If any phase current I_c is lower than the threshold **Current threshold CB open**, the stage is rendered inactive by setting $I_{unbal.,comp.}$ to 0 A. This condition is held for 250 ms after energizing has been detected in order to avoid a pickup as a consequence of the charging process. Siemens recommends using compensated unbalanced values. In case that automatic compensation is applied, consider the setting notes for the operate delay.
non-compensated	The stage works with non-compensated unbalanced values. This means the measurand may contain an existing operational current unbalance.

Parameter: Threshold

- Default setting **(_:16231:3) Threshold** = ***1.500 A***

Set the parameter **Threshold** for the specific application.

When using compensated unbalanced values, very sensitive settings are possible. When using non-compensated unbalanced values, the threshold must be higher than the maximum operational unbalanced current.

Parameter: Operate delay

- Default setting **(_:16231:6) Operate delay** = ***0.30 s*** (for the 1st stage)

Set the parameter **Operate delay** for the specific application.

NOTE

If the function has been set to automatic compensation and the stage works with compensated values, the maximum permitted operate delay is 80 ms. If the operate delay is set to longer than 80 ms the automatic compensation might cause dropout of the picked-up stage. This risk does not exist when manual compensation or non-compensated values are used.

7.5.5 Counter Stage

7.5.5.1 Description

Logic of a Stage

[lo-cnt-stage1ph-080714-01, 2, en_US]

Figure 7-29 Logic Diagram of the Counter Stage

Measurands/Input Values

The measurand/input values of the counter stage are phase-segregated and group-segregated counter contents that are determined in the **General** FB.

Pickup, Operate Delay

With the parameter **Type of counting phases**, a selection is made whether the supervision function occurs in a phase-segregated way or with the sum value of the phases. With the parameter **Type of counting groups**, a selection is made whether the supervision function occurs in a group-segregated way or with the sum value of both groups. If a counter reaches the set threshold, the stage picks up. The pickup starts the time delay. If the time delay has elapsed, the operate indication will be issued.

Automatic Compensation

If the automatic compensation function is enabled, the counter stage is working. If this is not the case, the readiness status of the stage changes to the state *warning*.

7.5.5.2 Application and Setting Notes

General Notes

- The setting notes for the current-threshold value for counting faulty C-elements are provided in chapter *7.5.3.2 Application and Setting Notes* as you must set this parameter across all stages.
- In order to react quickly to the simultaneous fault of many C-elements, always use an overcurrent-protection stage I> with a short operate delay (< 100 ms) in addition to the counter stage. This is necessary as the counter function counts each current jump only once, regardless of its height.

Parameter: Type of counting groups

- Default setting **(_:16261:101) Type of counting groups** = ***segregated***

With the parameter **Type of counting groups**, you specify whether the group-segregated counter status or the sum value of both group counters are compared to the threshold.

Parameter: Type of counting phases

- Default setting **(_:16261:102) Type of counting phases** = ***segregated***

With the parameter **Type of counting phases**, you specify whether the supervision function occurs in a phase-segregated way or with the sum value of the phases.

Parameter: Maximum Number of Faulty Elements, Operate delay

- Default setting **(_:16261:103) Max. no. of def. elem. phs A** = ***10***
- Default setting **(_:16261:104) Max. no. of def. elem. phs B** = ***10***
- Default setting **(_:16261:105) Max. no. of def. elem. phs C** = ***10***
- Default setting **(_:16261:106) Max. no. of def. elem.** = ***10***
- Default setting **(_:16261:6) Operate delay** = ***0.00 s***

Set the parameters for the specific application.

It is possible to configure several stages for different tasks:

- Reporting only (with or without fault record)

  Use this stage to report 1 or 2 faulty C-elements. To do this, set the parameters **Max. no. of def. elem. phs A**, **Max. no. of def. elem. phs B** , **Max. no. of def. elem. phs C** , or **Max. no. of def. elem.** to a small value (1 or 2). The parameter **Operate delay** can be set to 0.

  If you would like to prevent the operate (tripping) and fault logging (fault log and fault record), set the parameter **Operate & flt.rec. blocked** to ***yes***.

  If you would like to prevent only the operate (tripping) and the fault logging must occur, remove this stage from the interface **Trip** to the circuit breaker (see also *5.4.2 Structure of the Function Group* **Interfaces with Circuit-Breaker Function Group**).

- Indication with delayed operate

  Use this stage to report in case of some faulty C-elements and to set a relatively long time delay of the operate, for example, 2 hours. During this time, the fault of the C-elements can be clarified. If it is possible to find a solution, the counter status can be reset manually. This way, the stage drops out. If a solution cannot be found within 2 hours, the stage trips and disconnects the capacitor bank.

- Immediate operate

  The stage is used to initiate the operate immediately after a larger number of C-elements became faulty.

7.5.5.3 Settings

7.6 Peak Overvoltage Protection for Capacitors

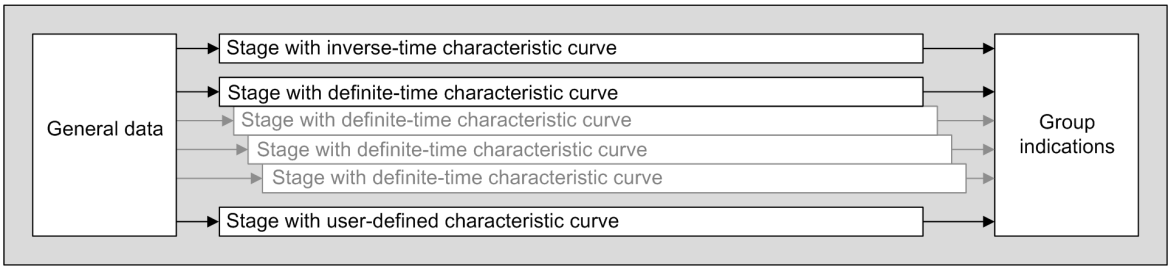
7.6.1 Overview of Functions

The **Peak overvoltage protection for capacitors (ANSI 59C)** function protects capacitors against:

- Peak overvoltages that stress the dielectric medium in the capacitor causing accelerated aging
- Peak overvoltages that in extreme cases can destroy the dielectric medium in the capacitor

7.6.2 Structure of the Function

The **Peak overvoltage protection for capacitors** function can be applied in the **Capacitor bank** function group.



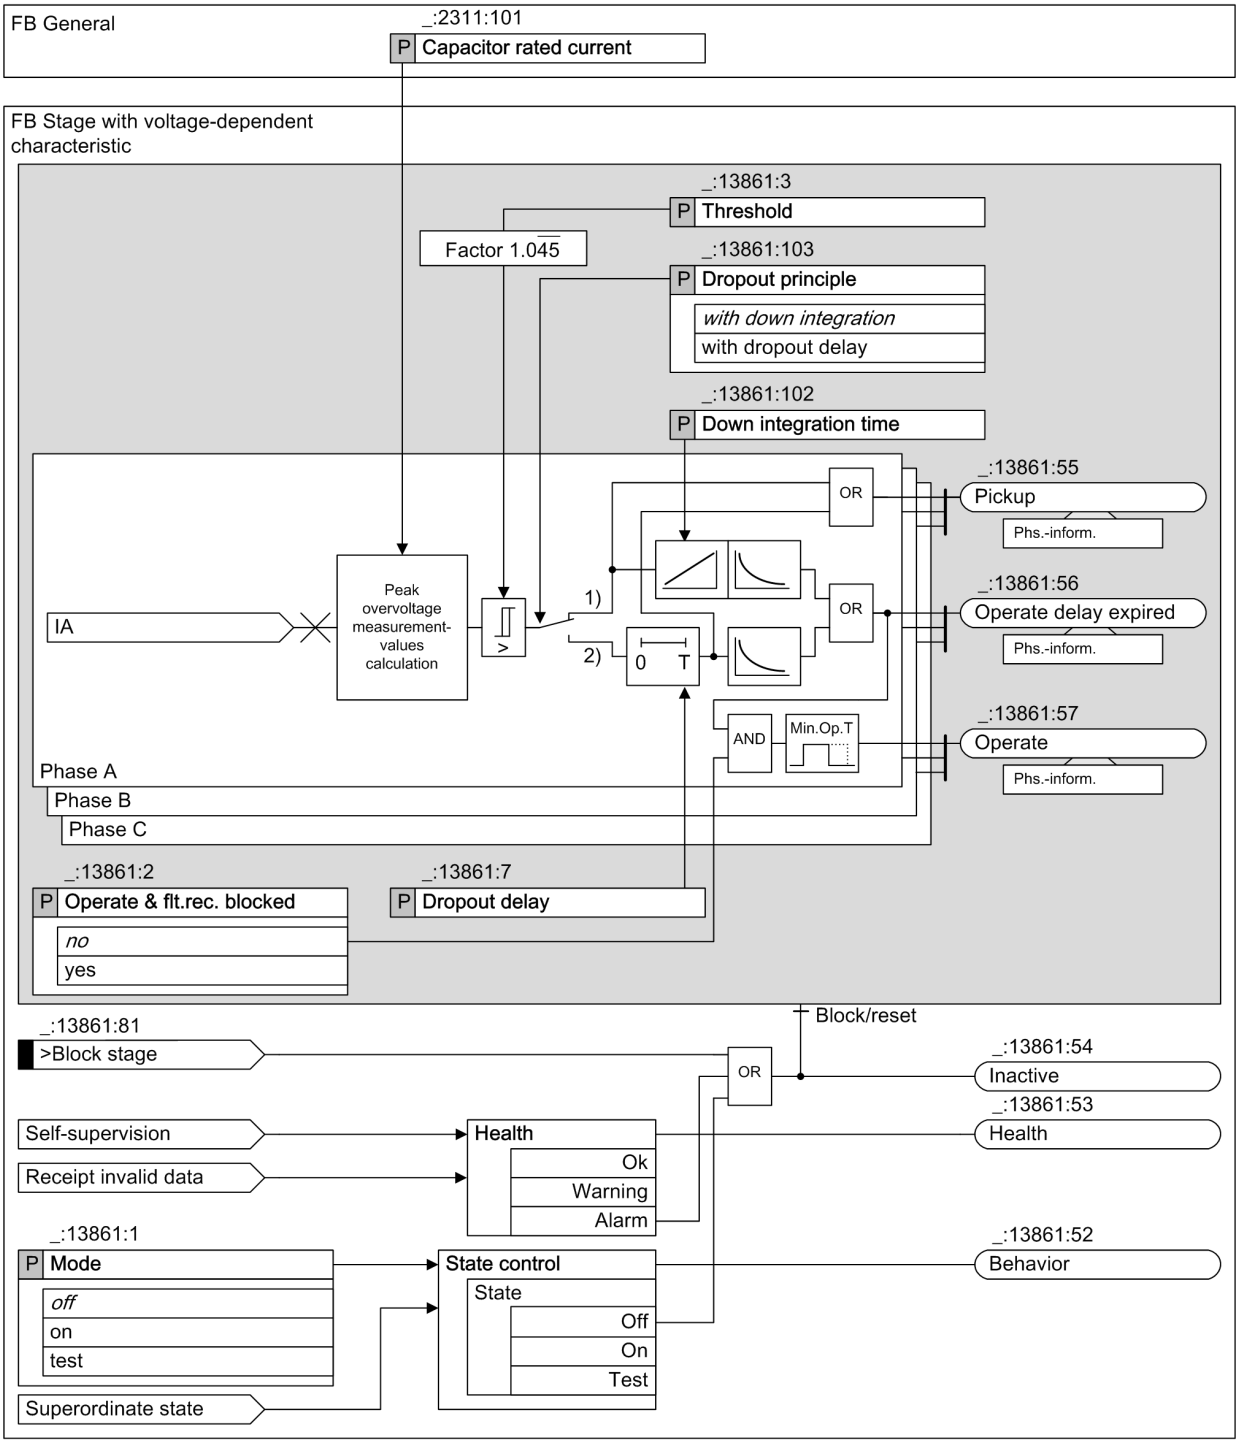
3 types of stages are available:

- Stage with inverse-time characteristic curve according to IEC and IEEE Standards
- Stage with definite-time characteristic curve
- Stage with user-defined characteristic curve

The function is preconfigured at the factory with a stage having an inverse-time characteristic curve and a stage having a definite-time characteristic curve.

Within the function, the following maximum number of stages can be operated simultaneously:

- 1 stage with an inverse-time characteristic curve
- 4 stages with a definite-time characteristic curve
- 1 stage with a user-defined characteristic curve



[dw_strpea-230813, 2, en_US]

Figure 7-30 Structure/Embedding of the Function

7.6.3 Stage with Inverse-Time Characteristic Curve

7.6.3.1 Description

Logic of the Stage

[lo_peainv-230813, 2, en_US]

Figure 7-31 Logic Diagram of the Stage with Inverse-Time Characteristic Curve

(1) With down integration time

(2) With dropout delay

Measurand, Method of Measurement

The function calculates the peak voltage in a phase-segregated way from the fundamental component and superimposed harmonics. Integration of the phase currents then yields the voltage. This approach captures the higher harmonics considerably better since they are transferred better by current transformers than by voltage transformers.

The peak voltage determined is then set with reference to the rated voltage of the capacitor. The resulting measurand is $\hat{U}/V_{C\text{-}rated}(t)$. The threshold value for the stage is thus set as a referenced quantity.

The phase-selective peak overvoltages $\hat{U}/V_{C\text{-}rated}(t)$ are available as measured values for display or further processing.

Pickup, Tripping and Dropout Behavior with the Inverse-Time Characteristic Curve

If the measurand $\hat{U}/V_{C\text{-}rated}(t)$ exceeds $1.0\overline{45}$ times the set threshold value (for example, $1.0\overline{45} \times 1.1 \approx 1.15$), pickup occurs and the inverse-time characteristic curve is then followed. For each input value that exceeds the pickup value ($1.0\overline{45}$ × threshold value), the time value T_{trip} is calculated. An integrator accumulates the value $1/T_{trip}$. When the accumulated integral reaches the fixed value of 1, the stage trips.

If the measurand falls below $1.0\overline{45}$ times the set threshold value (pickup value), processing of the characteristic (accumulation of the time values) stops. In the hysteresis region between the pickup value and dropout value (95 % of the pickup value, for example, 0.95 × 1.15 = 1.0925), the integral value remains unchanged. The stage, however, remains in the picked-up state.

Use the parameter **`Dropout principle`** to select the method for the dropout of the stage:

- Method **with down integration time**:

  If the measurand falls below the dropout threshold, the pickup drops out immediately. If the value drops below the pickup threshold, the internal integral value that depends on the selected **`Down integration time`** is slowly reduced. The **`Down integration time`** defines the duration in order to reduce the internal integral value linear from 100 % to 0 %. The internal integral value is limited to 100 % and is reached with the tripping function.

- Method **with dropout delay**:

  If the measurand falls below the dropout threshold, the pickup drops not out immediately. The pickup remains for the duration of the set **`Dropout principle`** . The integral value remains frozen during this time. If the pickup value is not exceeded again during this time, a dropout occurs and the integral value is reset to 0. If the pickup value is exceeded during this time again, the integrator continues with the integration of frozen values. The pickup remains active and the **`Dropout principle`** is reset.

Inverse-Time Characteristic Curve

The characteristic curve is defined by the Standards IEC 60871-1:2005 and IEEE Std 1036-2010, see *Figure 7-32* .

The points on the characteristic curve defined in the standards result from a threshold setting of 1.1. Threshold values differing from this value shift the characteristic as shown in *Figure 7-32* .

Straight-line segments are implemented between the defined points on semi-logarithmic coordinates.

[dw_pecinv-230813, 2, en_US]

Figure 7-32 Inverse-Time Characteristic Curve

Phase-Segregated Operate Indications

In contrast to what normally occurs in a 3-phase protection device, the function generates phase-segregated operate indications. These indications are needed for supervision applications.

Function Values

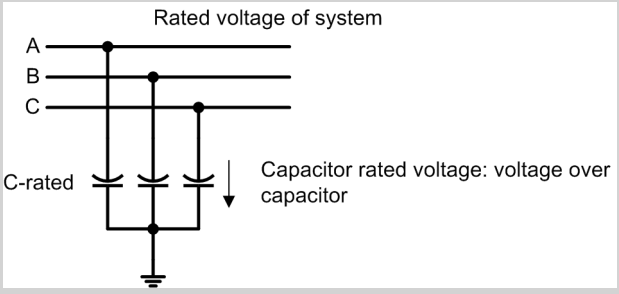
Values	Description	Primary	Secondary	% Referenced to
(_:2311:301) VpeakA	Peak voltage phase A	kV	V	Parameter **Capacitor reference volt.**/√3
(_:2311:302) VpeakB	Peak voltage phase B	kV	V	Parameter **Capacitor reference volt.**/√3
(_:2311:303) VpeakC	Peak voltage phase C	kV	V	Parameter **Capacitor reference volt.**/√3

You can find the parameter **Capacitor reference volt.** of the preceding table in the function block **General** of the function group **Capacitor bank**.

7.6.3.2 Application and Setting Notes

Parameter: Capacitor rated current

- Default setting **(_:2311:101) Capacitor rated current** = ***1000.0 A***



With the **Capacitor rated current** parameter, you set the primary rated current $I_{C\text{-rated}}$ of the capacitor or the capacitor bank.

Keep in mind that the rated current of the capacitor considers harmonics in addition to the fundamental component.

The rated current $I_{C\text{-rated}}$ is determined from the rated capacity and the rated voltage across the bank. Both values are listed in the Technical Data for the capacitor. Take note of the following:

- The rated voltage for the capacitor also takes harmonics into account. This is not the rated voltage of the system.
- The rated voltage to be used is the voltage applied across the capacitor; depending on the application, this can be a phase-to-phase or phase-to-ground voltage.

Example: Determining the Capacitor Rated Current for a Capacitor in a Star Connection

[dw_UC-Y-Schalt-110813, 1, en_US]

Figure 7-33 Capacitor in Star Connection

Rated voltage of the system	220 kV
Rated capacity per phase	5.233 µF
Capacitor rated voltage $V_{C\text{-rated}}$	192.30 kVrms
Rated frequency f	50 Hz

$I_{C\text{-rated}} = \omega C \times U_{C\text{-rated}} = 2\pi f \times C \times U_{C\text{-rated}} = 2\ \pi\ 50 \times 5.233\ 10^{-6} \times 192.3\ 10^{3}$ [Hz × F × U] = 316.1 [A]

Parameter: `Threshold`

- Default setting **`(_:13861:3) Threshold`** = ***`1.10`***

The peak voltage determined is then set with reference to the rated voltage of the capacitor. The threshold value is thus set as a referenced quantity.

The points on the characteristic curve defined in the Standards IEC 60871-1:2005 and IEEE Std 1036-2010 result from a threshold setting of ***`1.10`*** (see *Figure 7-32*). Threshold values differing from this shift the characteristic as shown in *Figure 7-32*.

Siemens recommends using the default setting.

Parameter: `Dropout principle`

- Default setting **`(_:13861:103) Dropout principle`** = ***`with down integration`***

Use the parameter **`Dropout principle`** to select the method for the dropout of the stage:

Parameter Value	Description
`with down integration`	If the measurand for the dropout threshold falls below the limit, the pickup drops out immediately. If the value drops below the pickup threshold, the internal integral value that depends on the selected down integration time is reduced from 100 % to 0 %
`with dropout delay`	If the measurand falls below the dropout threshold, the measurand remains active for the duration of the preset dropout delay. The integral value remains frozen during this time.

Parameter: **Down integration time**

- Default setting **(_:13861:102) Down integration time** = ***3.00 min***

Use the parameter **Down integration time** in order to determine the duration until the internal integration value is linearly reduced from 100 % to 0 %.

For example, if the integration value is 52 %, a duration of 52 % × down integration time is required until the integration value 0 % is reached. When using this parameter, the preloading of a capacitor can be considered and therefore released quicker.

If you are knowledgeable about recovery time of stressed capacitors, they can be considered with this parameter.

Parameter: **Dropout delay**

- Default setting **(_:13861:7) Dropout delay** = ***1.00 s***

The parameter **Dropout delay** can be used to prevent resetting of the integral value in the event that the measured value briefly falls below the dropout threshold.

7.6.4 Stage with Definite-Time Characteristic Curve

7.6.4.1 Description

Logic of the Stage

[lo_peadef-230813, 1, en_US]

Figure 7-34 Logic Diagram of the Stage with Definite-Time Characteristic Curve

Measurand, Method of Measurement

The function calculates the peak voltage in a phase-segregated way from the fundamental component and superimposed harmonics. Integration of the phase currents then yields the voltage. This approach captures

the higher harmonics considerably better since they are transferred better by current transformers than by voltage transformers.

The peak voltage determined is then set with reference to the rated voltage of the capacitor. The resulting measurand is $\hat{U}/V_{C\text{-rated}}(t)$. The threshold value for the stage is thus set as a referenced quantity.

The phase-segregated peak overvoltages $\hat{U}/V_{C\text{-rated}}(t)$ are available as measured values for display or further processing.

Pickup, Tripping and Dropout Behavior with the Definite-Time Characteristic Curve

If the measurand $\hat{U}/V_{C\text{-rated}}(t)$ exceeds the set threshold value, pickup occurs and the tripping delay starts. If the measurand remains above the dropout value (95 % of the threshold value) during the tripping delay, the stage trips.

Phase-Segregated Operate Indications

In contrast to what normally occurs in a 3-phase protection device, the function generates phase-segregated operate indications. These indications are needed for supervision applications.

Function Values

For the detailed information of the function values, refer to *Function Values, Page 968*.

7.6.4.2 Application and Setting Notes

Parameter: `Capacitor rated current`

- Default setting **`(_:2311:101) Capacitor rated current`** = ***`1000.0 A`***

You can find the setting notes for the parameter **`Capacitor rated current`** under *Parameter: **`Capacitor rated current`**, Page 968*.

Parameter: `Threshold`

- Default setting **`(_:13831:3) Threshold`** = ***`1.10`***

The peak voltage determined is then set with reference to the rated voltage of the capacitor. The **`Threshold`** is thus set as a referenced quantity.

The setting depends on the application of the stage. If this stage is intended to operate as a warning stage, a very sensitive setting of approx. ***`1.05`*** can be selected. If the stage is used for instantaneous tripping in addition to the stage with inverse-time characteristic curve, Siemens recommends a setting of ≥ ***`3.00`***.

Parameter: `Operate delay`

- Default setting **`(_:13831:6) Operate delay`** = ***`3.00 s`***

The setting depends on the application of the stage. If this stage is intended to operate as a warning stage, the time delay can be selected in a range of seconds. If the stage is used for instantaneous tripping in addition to the stage with inverse-time characteristic curve, the **`Operate delay`** can be set to ***`0.00 s`***.

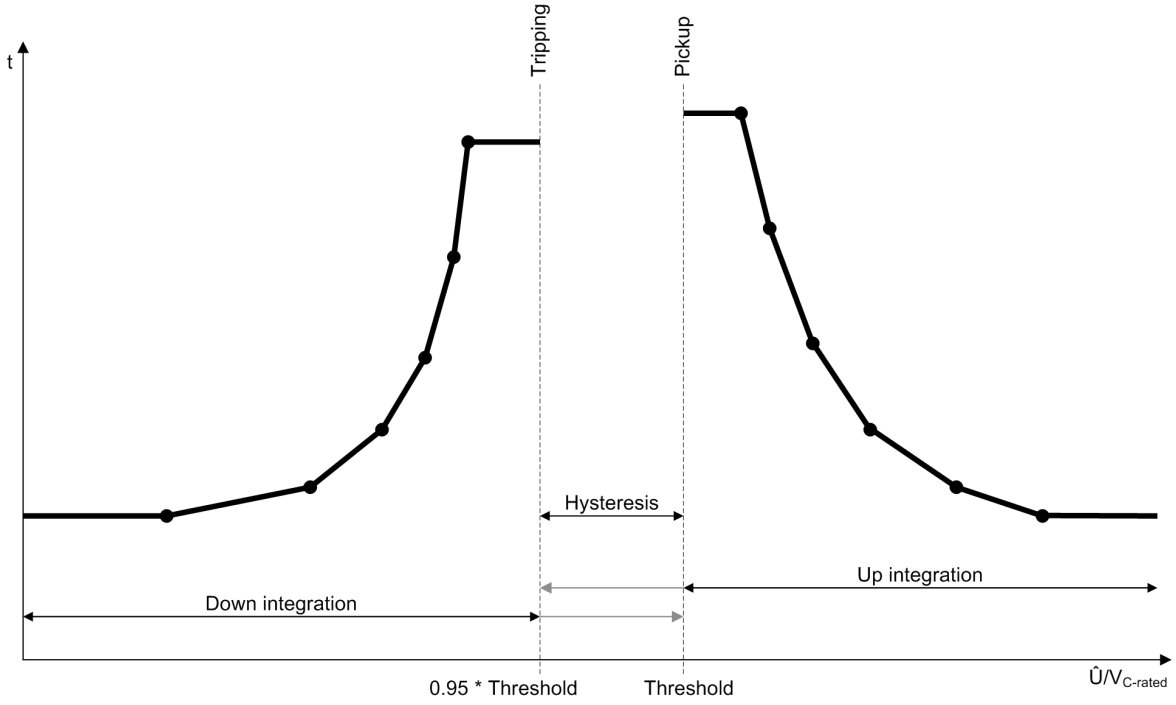
7.6.5 Stage with User-Defined Characteristic Curve

7.6.5.1 Description

This stage is structured the same way as the stage with a **voltage-dependent** characteristic (see chapter *7.6.3.1 Description*). The only difference is that you can define the characteristic curve as desired. This means that you can also define a dropout characteristic curve. This makes the **dropout delay** parameter superfluous and unneeded.



User-Defined Characteristic Curve

With the user-defined characteristic curve, you can define the operate curve point by point using up to 30 value pairs of voltage and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.

Pickup and Dropout Behavior with the User-Defined Characteristic Curve

If the measurand $\hat{U}/V_{C\text{-rated}}(t)$ exceeds the threshold value, the characteristic is followed. An integrating method of measurement summarizes the weighted time. The weighted time results from the characteristic curve. This means that the time associated with the present measured value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

If the measured value falls below 95 % of the set threshold value, the dropout is initiated. The pickup will be indicated as clearing. The weighted time results from the dropout characteristic curve. The integral value is reduced until it reaches 0.

[dw_pecuse-230813, 1, en_US]

Figure 7-35 Pickup Behavior and Dropout Behavior when Using a User-Defined Characteristic Curve

7.6.5.2 Application and Setting Notes

This stage is structured the same way as the stage with a **inverse-time** characteristic (see chapter *7.6.3.2 Application and Setting Notes*). The only difference is that you can define the characteristic curve as desired. This chapter provides only application and setting notes for setting characteristic curves.

Parameter: `Voltage/Time Value Pairs` (from the Operate Curve)

Use these settings to define the characteristic curve. Set a voltage/time value pair for each point on the characteristic curve. The setting depends on the characteristic curve you want to realize.

Set the voltage to a multiple of the threshold value. In order to obtain a simple relation, Siemens recommends setting the **`Threshold`** parameter to ***`1.00`***. You can change the threshold value setting afterwards if you want to shift the characteristic curve.

Set the time value in seconds. The characteristic curve is shifted via the **`Time dial`** parameter.

Set the number of value pairs to be used with DIGSI. You can define a maximum of 30 value pairs.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

Where no time grading of tripping and thus no shifting of the characteristic curve is required, leave the parameter **`Time dial`** at 1.

Parameter: `Voltage/Time Value Pairs` (from the Dropout Characteristic Curve)

Use these settings to define the characteristic curve. Set a voltage/time value pair for each point on the characteristic curve. The setting depends on the characteristic curve you want to realize.

Set the voltage to a multiple of the threshold value. Siemens recommends setting the **Threshold** parameter to ***1.00*** in order to obtain a simple relation. You can change the threshold value afterwards if you want to shift the characteristic curve.

Set the time value in seconds. The characteristic curve is shifted via the **Time dial** parameter.

Set the number of value pairs to be used with DIGSI. You can define a maximum of 30 value pairs.

NOTE

The value pairs must be entered in continuous order.

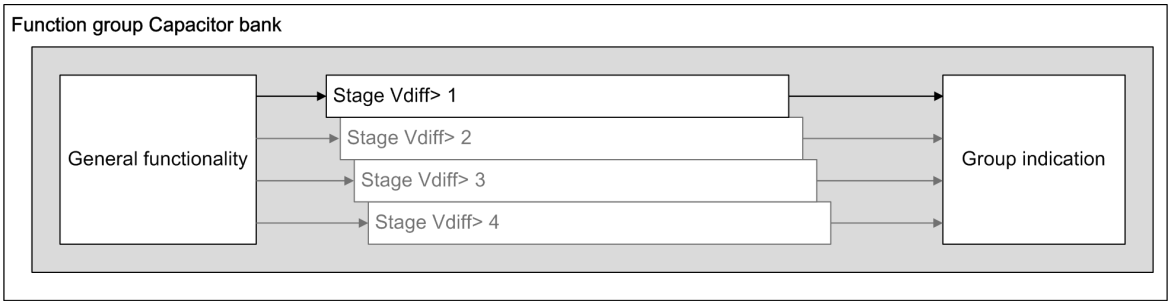
7.7 Voltage Differential Protection for Capacitors

7.7.1 Overview of the Functions

The function **Voltage-differential protection** (ANSI 87V) can be applied if the capacitor offers a voltage tap to measure the 3-phase voltage within the capacitor installation. The function:



- Calculates the differential voltage between bus and tap voltage by applying a matching factor
- Works as a capacitor unbalance function for protection of faults in capacitor elements (C elements)

7.7.2 Structure of the Function

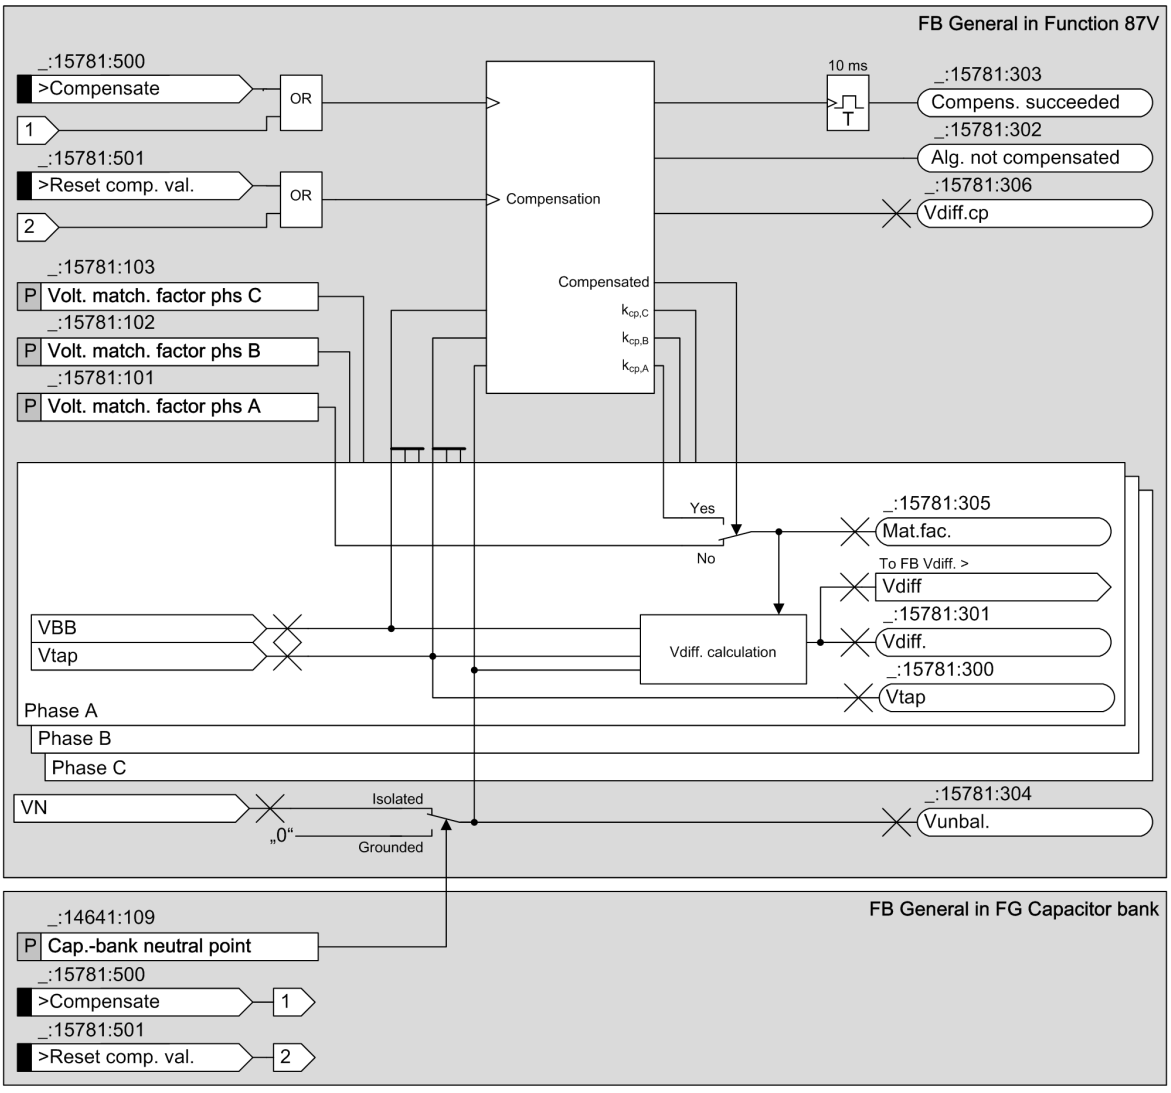
The function **Voltage-differential protection** is used in the function group **Capacitor bank**. The function is preconfigured at the factory with one protection stage **V_{diff} >**.

A maximum of 4 protection stages **V_{diff} >** can be operated simultaneously in the function.

The **General functionality** (including compensation) works across all stages.

[dw_strucVoldi-060213-01.vsd, 1, en_US]

Figure 7-36 Structure of the Function Voltage-Differential Protection



7.7.3 General Functionality

7.7.3.1 Description

The **General functionality** is structured in the following parts:

- Calculation of the differential voltage $V_{diff.}$
- Compensation of an operational differential voltage $V_{diff.}$

Logic for Calculation and Compensation

[Lo_voltdiffgeneral_20140714.vsd, 2, en_US]

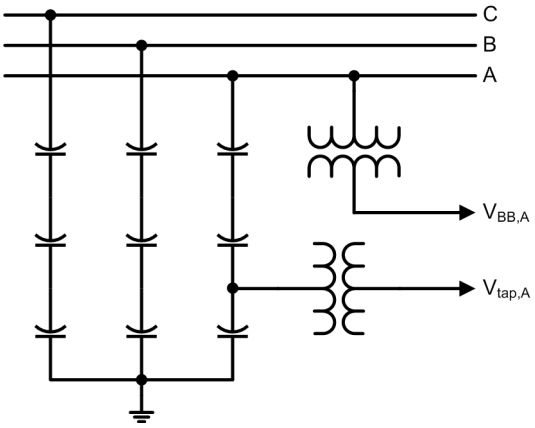
Figure 7-37 Logic Diagram of the General Functionality

Measurands, Method of Measurement

The function receives the 3-phase bus and tap voltage measurands (see also V_{BB} and V_{tap} in *Figure 7-37*) via the **3-phase voltage** and **3-phase voltage CB tap** interfaces of the function group **Capacitor bank**. For an isolated capacitor-bank system, the function receives the capacitor-bank neutral-point voltage V_N via the **Voltage unbalance** interface. The method of measurement used processes the sampled voltage values and filters out the fundamental component numerically.

The compensated or not compensated differential voltage is provided to the protection stage for evaluation.

Voltage Matching Factor



The phase-selective voltage matching factor k is used as a multiplier for the tap voltage to obtain an equivalent voltage value compared to the bus voltage. The voltage matching factor k is obtained either from the parameter **`Volt. match. factor phs A`**, **`Volt. match. factor phs B`**, and **`Volt. match. factor phs C`** or from the compensation functionality. If the compensation is carried out, the function calculates the voltage matching factor k through dividing the measured bus voltage by the measured tap voltage.

Calculation of the Differential Voltage

The calculation of the differential voltage depends on the capacitor-bank neutral-point grounding. With the parameter **`Cap. bank neutral point`**, you can set the grounding type.

2 capacitor-bank neutral-point grounding types are as follows:

- **Grounded capacitor-bank system**

[dw_voltage_measurement_grounded, 1, en_US]

Figure 7-38 Voltage Measurement for a Grounded Capacitor-Bank System

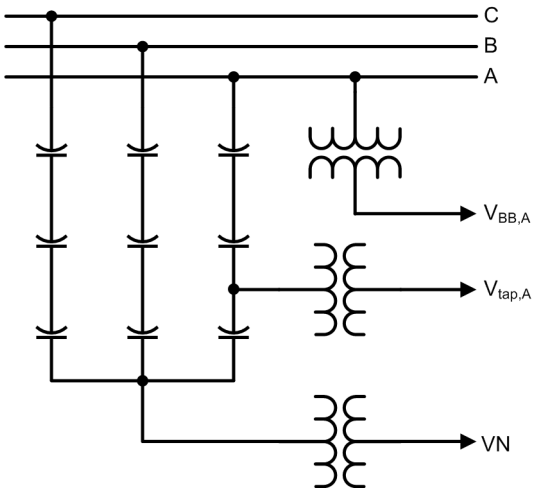
The following formula is used to calculate the differential voltage $V_{diff.}$ of phase A:

$$\underline{V}_{diff,A} = |\underline{V}_{BB,A} - \underline{k}_A \cdot \underline{V}_{tap,A}|$$

$V_{BB,A}$	Voltage from the busbar, phase A
$V_{tap,A}$	Voltage from the tap, phase A
k_A	Voltage matching factor, phase A

This calculation also applies to the calculation of the $V_{diff.}$ of phase B and phase C.

The voltage measuring-points are connected with the corresponding function-group interfaces.



Connect measuring points to function group

	Capacitor bank 1				
Measuring point	V 3ph	I 3ph	V 3ph cap. tap	I unbalance	I 3ph RLC
(All)	(All)	(All)	(All)	(All)	(All)
Meas.point I-3ph 1[ID 1]		X			
Meas.point V-3ph 1[ID 2]	X				
Meas.point V-3ph 2[ID 3]			X		

[Sc_grounded_ground, 1, en_US]

Figure 7-39 Connecting Measuring Points to the Function Group Capacitor Bank for the Grounded Capacitor-Bank System

- **Isolated capacitor-bank system**

[dw_voltage_measurement_isolated, 1, en_US]

Figure 7-40 Voltage Measurement for an Isolated Capacitor-Bank System

The following formula is used to calculate the differential voltage $V_{diff.}$ of phase A:

$$V_{diff,A} = |(\underline{V}_{BB,A} - \underline{V}_N) - \underline{k}_A \cdot (\underline{V}_{tap,A} - \underline{V}_N)|$$

$V_{BB,A}$	Bus voltage, phase A
$V_{tap,A}$	Tap voltage, phase A
k_A	Voltage matching factor, phase A
V_N	Neutral-point-to-ground voltage

This calculation also applies to the calculation of the $V_{diff.}$ of phase B and phase C.

The voltage V_N is obtained by connecting the measuring point **V-1ph** to the interface $\mathbf{V}_{\mathbf{unbalance}}$. **V-1ph** is used for measuring V_N.

Connect measuring points to function group

	Capacitor bank 1					
Measuring point	V 3ph	I 3ph	V 3ph cap. tap	V unbalance	I unbalance	I 3ph RLC

Meas.point V-1ph 1[ID 4]				X		

[Sc_isolate_ground, 1, en_US]

Figure 7-41 Connecting Measuring Points to the Function Group Capacitor Bank for the Isolated Capacitor-Bank System

Both the capacitor-bank tap voltage and the calculated differential voltage are displayed as measured values of the function.

General Notes on the Compensation

An operational differential voltage is added to a differential voltage resulting from faulty capacitor elements. This corrupts the measuring result.

The operational differential voltages can result from the following factors:

- Manufacturing tolerances of the capacitor
- Aging of the capacitor
- Environmental influences, for example, temperature

The compensation eliminates the operational differential voltage by adjusting the voltage matching factors. The adjusted phasors of the matching factor are calculated at the compensation moment, with the following formula (for phase A):

- **Grounded capacitor-bank system**
  $\underline{k}_{cp,A} = \underline{V}_{BB,A} / \underline{V}_{tap,A}$
- **Isolated capacitor-bank system**
  $\underline{k}_{cp,A} = (\underline{V}_{BB,A} - \underline{V}_{N}) / (\underline{V}_{tap,A} - \underline{V}_{N})$

With

$V_{BB,A}$	Bus voltage, phase A
$V_{tap,A}$	Tap voltage, phase A
$k_{cp,A}$	Calculated matching factor at the compensation moment, phase A
V_{N}	Neutral-point-to-ground voltage

The calculation also applies to the calculation of the voltage matching factors of phase B and phase C.
The phasors of the calculated voltage matching factors k_{cp} are stored and used for calculation of the differential voltage until the next compensation is applied or until the compensation is reset.
The phasors of the calculated voltage matching factors k_{cp} are displayed as functional measured values after the compensation is applied. In addition, the compensated differential voltage **Vdiff.cp** is available as functional measured value. **Vdiff.cp** is the differential voltage at the moment of the compensation compared to the uncompensated status. The compensated differential voltage **Vdiff.cp** is calculated with the following formula (for phase A):

- **Grounded capacitor-bank system**
  $V_{diff.cp,A} = | (\underline{V}_{BB,A} - \underline{V}_{N}) - k_{A} \cdot (\underline{V}_{tap,A} - \underline{V}_{N})|$
- **Isolated capacitor-bank system**
  $V_{diff.cp,A} = | \underline{V}_{BB,A} - k_{A} \cdot \underline{V}_{tap,A}|$

With

k_{A}	Parameter **Volt. match. factor phs A**
$V_{BB,A}$	Voltage from the busbar, phase A
$V_{tap,A}$	Voltage from the tap, phase A
V_{N}	Neutral-point-to-ground voltage

This calculation also applies to the calculation of the compensated differential voltage of phase B and phase C.

Manual Compensation via Binary Input Signal

Manual compensation via binary input signals is available.
The following indications describe the status of the compensation:

Indication	Description
Alg. not compensated	The algorithm is not compensated. Compensated values are not available.
Compens. succeeded	If the existing unbalance has been compensated manually, this indication is issued (as transient indication).

By activation of the binary input signal *>Compensate* , the manual compensation is started and the differential voltage that exists at that moment is compensated to 0. The value of $V_{diff.}$ becomes 0.

NOTE

If the measured bus voltage or tap voltage is too low, the manual compensation cannot be performed. No manual compensation is carried out under the following conditions:

- In the **grounded** system:
  $V_{BB} < 10\% * V_{BB,rated}$ or $V_{tap,sec} < 1\ V$
- In the **isolated** system:

$$\left| \underline{V}_{BB,prim} - \underline{V}_{N,prim} \right| < 10\% * V_{BB,rated,prim} \quad \text{or}$$

$$\left| \underline{V}_{tap,prim} - \underline{V}_{N,prim} \right| * \frac{V_{tap,rated,sec}}{V_{tap,rated,prim}} < 1\ V$$

[fo_isolated-system, 1, en_US]

Resetting the Compensation

If one of the following conditions is met, the function works in the not compensated status:

- Initial startup of the device before any compensation has been carried out
- Activation of the binary input *>Reset comp. val.*
- Change of the parameter **Capacitor-bank neutral point** in the function group **Capacitor bank** (refer to chapter *5.4.3 Application and Setting Notes*)

The not compensated status is indicated via the signal *Alg. not compensated*.

Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
(_:15781:300) Vtap	Tap voltage	kV	V	Parameter **Capacitor reference volt.**/√3
(_:15781:304) Vunbal.	Neutral-point voltage	kV	V	Parameter **Capacitor reference volt.**
(_:15781:301) Vdiff.	Differential voltage	kV	V	Parameter **Capacitor reference volt.**/√3
(_:15781:306) Vdiff.cp	The compensated differential voltage at the compensation moment	kV	V	Parameter **Capacitor reference volt.**/√3
(_:15781:101) Volt. match. factor phs A	Voltage matching factor of phase A	-	-	-
(_:15781:102) Volt. match. factor phs B	Voltage matching factor of phase B	-	-	-
(_:15781:103) Volt. match. factor phs C	Voltage matching factor of phase C	-	-	-

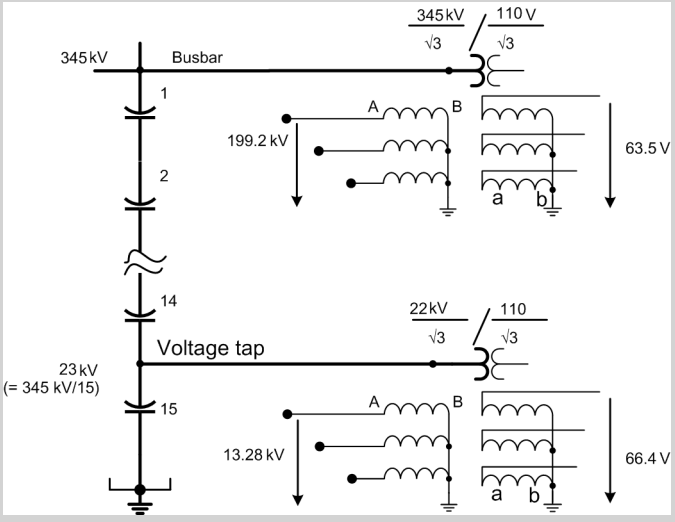
You can find the parameter **Capacitor reference volt.** in the function block **General** of the function group **Capacitor bank**.

NOTE

If the function works in the uncompensated status, the values of parameter **Volt. match. factor phs A**, **Volt. match. factor phs B** and **Volt. match. factor phs C** are displayed as functional measured values of the voltage matching factors. And the functional measured values of **Vdiff.cp** are shown as **---**.

7.7.3.2 Application and Setting Notes

Parameter: `Volt. match. factor phs A`, `Volt. match. factor phs B` and `Volt. match. factor phs C`



- Default setting **`(_:15781:101) Volt. match. factor phs A`** = ***2.0000***
- Default setting **`(_:15781:102) Volt. match. factor phs B`** = ***2.0000***
- Default setting **`(_:15781:103) Volt. match. factor phs C`** = ***2.0000***

The phase-selective parameters **`Volt. match. factor phs A`**, **`Volt. match. factor phs B`** and **`Volt. match. factor phs C`** are applied as multiplier for the primary tap voltage to calculate the differential voltage. It depends on the position of the tap-voltage measurement in the specific capacitor installation. The setting is defined as the ratio of the capacitor-bank reference voltage to the tap voltage.

EXAMPLE

The application consists of:

- Capacitor-bank busbar, with a rated voltage of 345 kV
- Capacitor bank, consisting of 15 can levels in series
- Capacitor-bank tap-voltage measurement between level 14 and 15

[lo_application example, 2, en_US]

Figure 7-42 Application Example for Setting the Voltage Matching Factor

Capacitor-bank bus voltage as phase-to-phase voltage (it equals to a phase-to-ground voltage of 199.2 kV)	345 kV
Capacitor-bank tap voltage as phase-to-phase voltage (it equals a phase-to-ground voltage of 13.28 kV)	23 kV
Voltage matching factors are set as: (including parameters **`Volt. match. factor phs A`**, **`Volt. match. factor phs B`**, and **`Volt. match. factor phs C`**)	345 kV/23 kV = 15

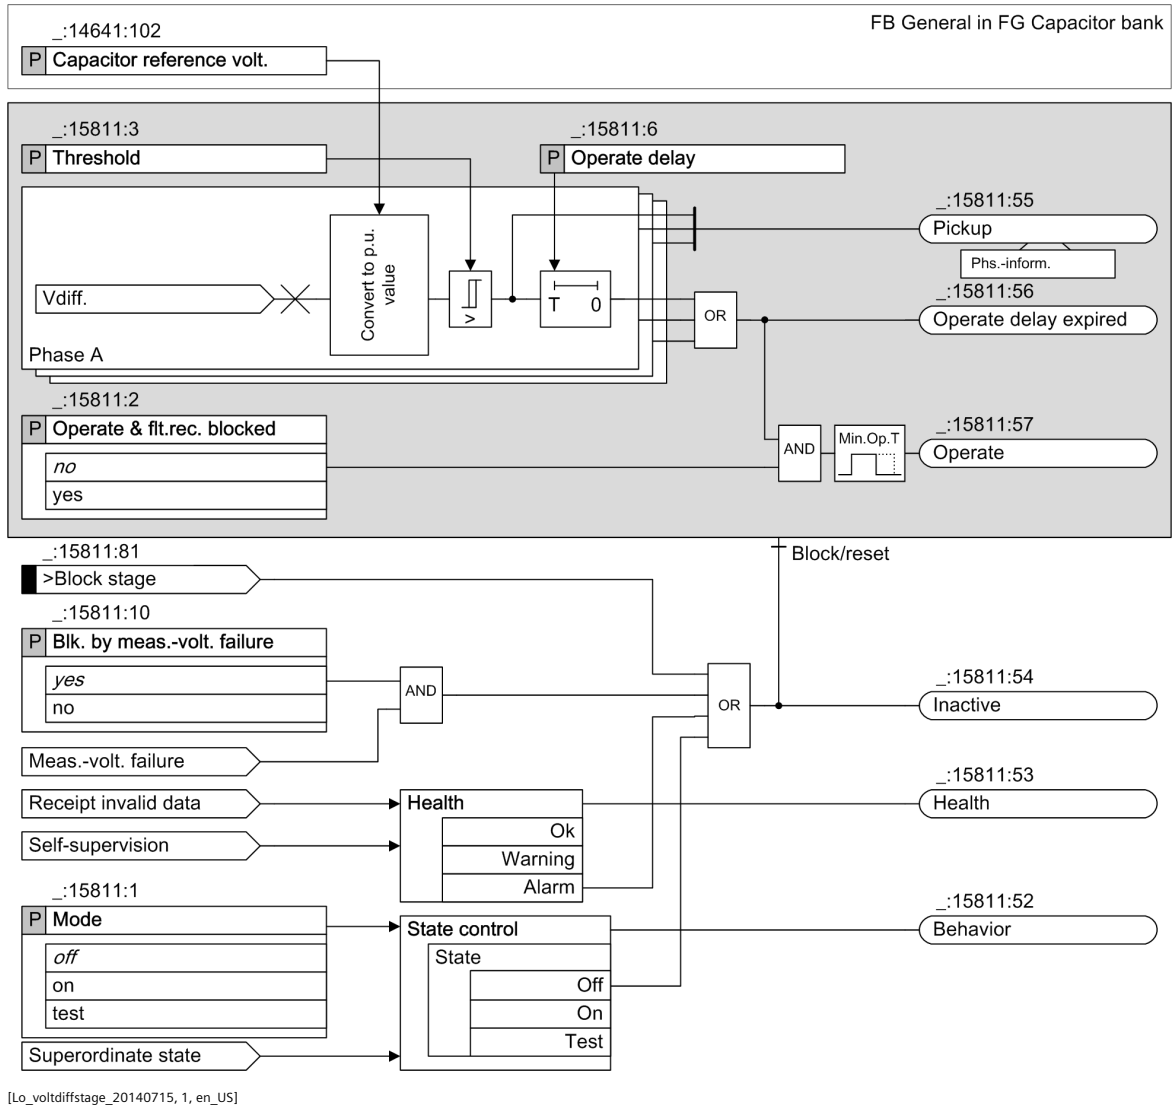
The voltage measuring points must be set as indicated in the figure:

Busbar transformer, rated primary voltage:	345 kV
Busbar transformer, rated secondary voltage:	110 V
Tap transformer, rated primary voltage:	22 kV
Tap transformer, rated secondary voltage:	110 V

Under normal operation, these settings result in a differential voltage of approximately 0 V and in the primary and secondary measured voltage values as indicated in the *7.7.3.2 Application and Setting Notes*.

NOTE

The sound secondary tap voltage must not be smaller than 1 V. Otherwise the function cannot work properly. Fulfill this condition by applying an appropriate voltage transformer for the tap voltage. Siemens recommends applying a tap voltage transformer which provides under normal operation a secondary voltage in the area of the rated secondary voltage.



EXAMPLE

In the **grounded** system:
Ratio of the capacitor-bank bus voltage to the tap voltage: matching factor k = 400 kV/400 V = 1000
Busbar transformer, rated primary voltage: 400 kV
Busbar transformer, rated secondary voltage: 100 V
To ensure an optimal tap-voltage measurement, the following transformer ratio is recommended:
Tap transformer, rated primary voltage: 400 V
Tap transformer, rated secondary voltage: 100 V

7.7.4 Description Protection Stage

7.7.4.1 Description

Logic of the Stage V_{diff}

[Lo_voltdiffstage_20140715, 1, en_US]

Figure 7-43 Logic of the Protection Stage V_{diff}

Measurand, Pickup and Operate

In the protection stage, the differential-voltage value is converted to a p.u. value in relation to the capacitor-bank reference voltage.

If the converted value exceeds the **`Threshold`** value, a *`Pickup`* indication is issued. If the threshold is exceeded continuously during the operate delay, an *`Operate`* signal is issued.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal *>Block stage* from an external or internal source.
- From inside on pickup of the function **Measuring-voltage failure detection** (see section *9.3.2.1 Overview of Functions*). The parameter **Blk. by meas.-volt. failure** can be set so that the measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker. The parameter **Blk. by meas.-volt. failure** can be set so that the measuring-voltage failure detection blocks the stage or does not block it.

7.7.4.2 Application and Setting Notes

Parameter: Threshold

- Default setting **(_:15811:3) Threshold** = ***0.200 p.u.***

The parameter **Threshold** is set as a p.u. value related to the parameter **Capacitor bank reference voltage** in the function group **Capacitor bank**.

The setting of the parameter **Threshold** depends on the differential voltage that occurs with the number of defective C elements for which a warning indication or a trip command shall be generated. Determine this differential voltage and set the **Threshold** slightly lower, for example, to 80 % of the value.

Parameter: Operate delay

- Default setting **(_:15811:6) Operate delay** = ***1.00 s***

Set the parameter **Operate delay** for the specific application.

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:15811:10) Blk. by meas.-volt. failure** = ***yes***

You can use the parameter **Blk. by meas.-volt. failure** to control the response of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal **Measuring-voltage failure detection** function is configured and switched on.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker. This binary input is available in the voltage transformers connected to the bus voltage and capacitor-bank tap voltage. The binary input is also available in the voltage transformer connected to the VN voltage in case of an isolated capacitor bank.

Parameter Value	Description
no	The stage Vdiff > is not blocked when a measuring-voltage failure is detected.
yes	The stage Vdiff > is blocked when a measuring-voltage failure is detected. Siemens recommends using the default setting, as correct operation of the stage cannot be guaranteed if a measuring-voltage failure occurs.

7.7.4.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting

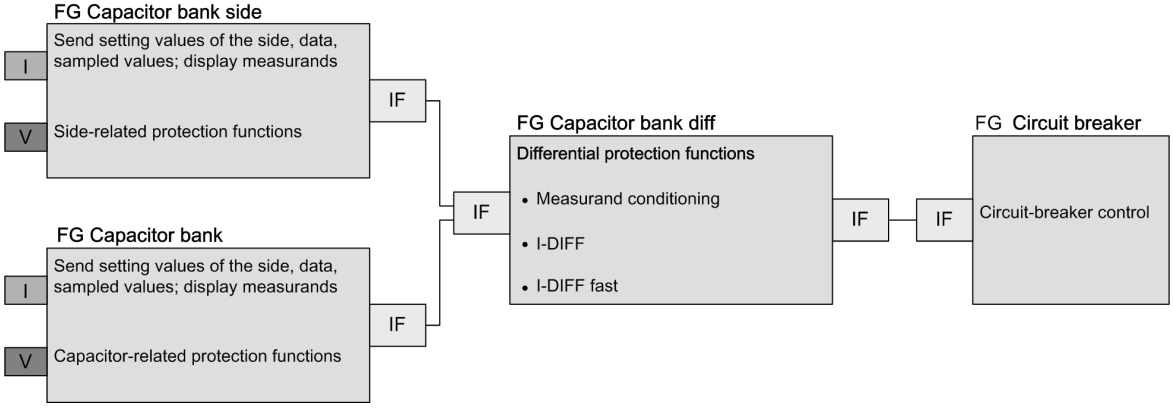
7.8 Differential Protection for Capacitor Banks

7.8.1 Function Overview

The function **Differential protection for capacitor banks** (ANSI 87C):

- Detects ground faults and multiphase short circuits at capacitor banks
- Detects ground faults during the operation of capacitors in systems with a grounded neutral point
- Uses the necessary stabilization procedures during energizing operations
- Trips safely and very fast in the case of internal high-current faults through an additional high-current stage

7.8.2 Structure of the Function



The **Differential capacitor bank protection** function is used in the **Capacitor Bank diff** protection function group. The function is preconfigured by the manufacturer in the corresponding application template depending on the application and can be copied during the engineering into the corresponding function group.

The **Differential capacitor bank protection** function consists of the stages IDiff and IDiff fast. The stages can be blocked, in addition you can switch the stages on and off.

The function group **Capacitor bank side** has the following characteristics:

- The side-related protection settings are performed
- The side-related calculations are performed
- All data (setting values, detected currents) are relayed to the **Capacitor bank Diff** function group

The side-related protection functions can run in the **Capacitor bank side** function group, for example overload protection, overcurrent protection, etc.

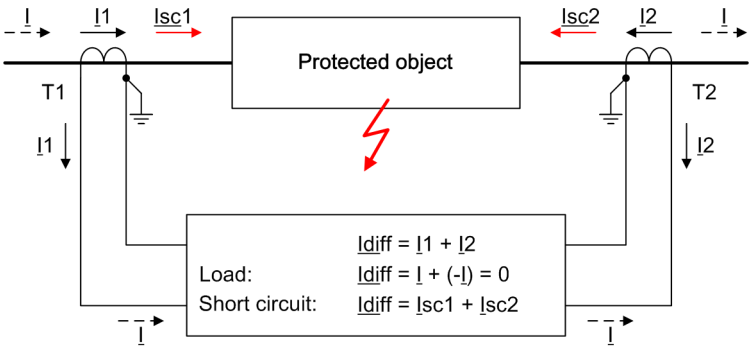

Figure 7-44 Structure/Embedding of the Function

7.8.3 Function Description

Basic Principle of Differential Protection

Differential protection is based on a comparison of currents (Kirchhoff current law). When comparing the current, use is made of the fact that a protected object uses the same current I in a non-faulty operating state on both sides (dotted in *Figure 7-45*). This current flows into the range being observed on one side and leaves it again on the other side. A current differential is a sure indication of a fault within the protected object. The calculation of the difference is determined through the current-direction definition. The current direction is

defined as positive to the protected object. The current difference results from the vector addition of the currents.

[dwprin2s-170712-01.tif, 1, en_US]

Figure 7-45 Basic Principle of Differential Protection Using the Example of 2 Sides

For safe operation, additional functions are required. The implementation of these additional functions is described in chapter *Differential Protection Function (Idiff), Page 993*.

Current Stabilization

If very large currents flow through the protection range in the case of external faults, with different transmission behavior of the transformers **W1** and **W2** (*Figure 7-45*), a corresponding differential current I_{diff} occurs. When this is larger than the corresponding pickup threshold, the device can issue a trip command, even though no fault is present in the protection range. Such a malfunction of the protection is avoided by the restraint current (I_{rest}) and is implemented in the form of a characteristic curve $I_{diff} = f(I_{rest})$.

The largest current of 2 or more measuring points of the protected object is used for stabilization.

The definition for 2 measuring points is:

A trip or differential current is

$I_{diff} = (\underline{I}_1 + \underline{I}_2)$

as well as a restraint current of

$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|)$

For more than 2 measuring points, this definition is expanded. This restraint method allows a reliable trip decision for more than 2 measuring points and different feeding behavior for internal short circuits.

$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2| ; \ldots |\underline{I}_n|)$

To clarify the effect, 3 important operating states are observed with ideal and adapted measurands.

- Through fault current in healthy operation or externally caused error:
  $\underline{I}_1$ flows into the protection range, $\underline{I}_2$ flows out of the protection range, that is, negative compared with the prefix definition, thus $\underline{I}_2 = -\underline{I}_1$;

  in addition $|\underline{I}_2| = |\underline{I}_1|$

  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 - \underline{I}_1| = 0$

  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$

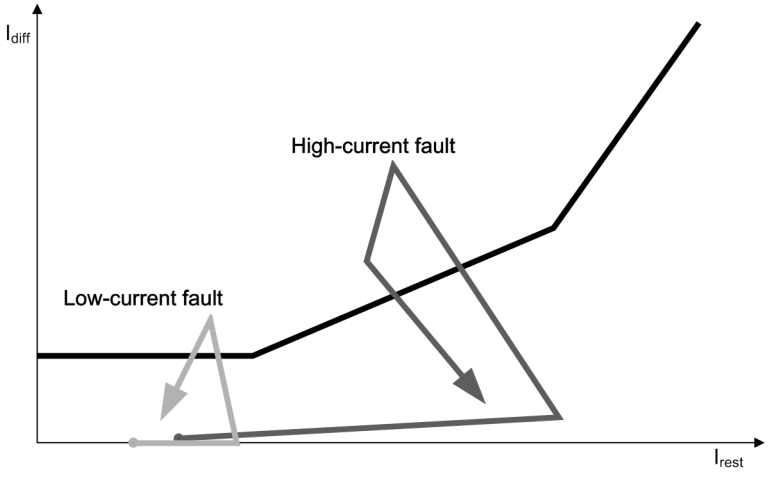
  No tripping quantity ($I_{diff} = 0$); the stabilization (I_{rest}) corresponds to the flowing current.

- Internal short circuit, feed from both sides with equal amount of currents, for example:
  Then $\underline{I}_2 = \underline{I}_1$; In addition $|\underline{I}_2| = |\underline{I}_1|$;

  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + \underline{I}_1| = 2 \cdot |\underline{I}_1|$

  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$

  The tripping quantity (I_{diff}) is twice as large as the short-circuit current and the restraining quantity (I_{rest}).



- Internal short circuit, feed only from one side:
  Then $\underline{I}_2 = 0$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + 0| = |\underline{I}_1|$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1|$
  The tripping quantity (I_{diff}) and the restraining quantity (I_{rest}) are of the same size and correspond to the short-circuit current.

Additional Stabilization with External Short Circuits

In case of an external short circuit, high short-circuit currents flowing through can lead to current-transformer saturation. This saturation can be more or less strongly pronounced at the measuring points, and in this way simulate a differential current. The differential current can lie in the tripping range of the characteristic curve for a certain time and lead to unwanted tripping without any particular measures. In accordance with *Figure 7-46*, there are 2 typical scenarios:

- High-current, external short circuit
  First, the current on both sides is transferred and leads to a large restraint current. After this, a transformer becomes saturated, resulting in a differential current I_{diff} that can exceed the operate curve. Simultaneously, the restraint current I_{rest} drops. Once the transformer is no longer saturated, the differential current decreases and falls below the characteristic curve.
- Low-current, external short circuit
  Current transformers can also become saturated through the large direct-current time constant (switching of transformers, motors), but small currents flowing through. This manifests itself as a phase-angle rotation of the current. Exceeding the characteristic curve in a non-stabilized area is possible.

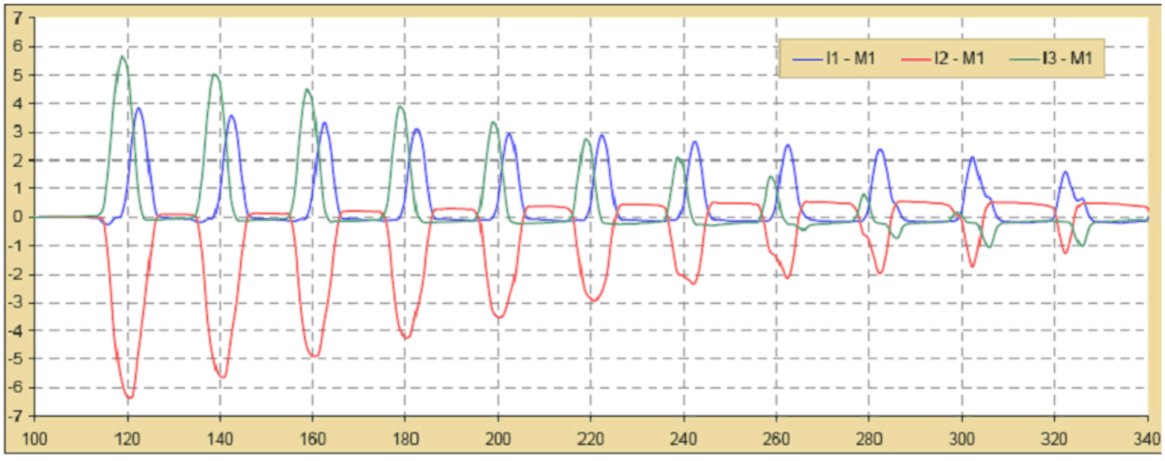
Intelligent saturation-detection methods capture this state and lead to a temporally limited blocking of the Differential protection function.

[dwislauf-170712-01.tif, 1, en_US]

Figure 7-46 Principle Current Course in External Short Circuit and Temporary Current-Transformer Saturation on One Side

Inrush-Current Detection

The inrush-current detection evaluates the calculated instantaneous values of the differential current. The inrush current develops with Sympathetic Inrush – connection of a parallel transformer or Recovery Inrush – inrush current subsequent to returning voltage after fault in the system considerably higher than in the side currents. An assignment to the corresponding blocking phases is possible only in the differential current due to the vector-group correction.

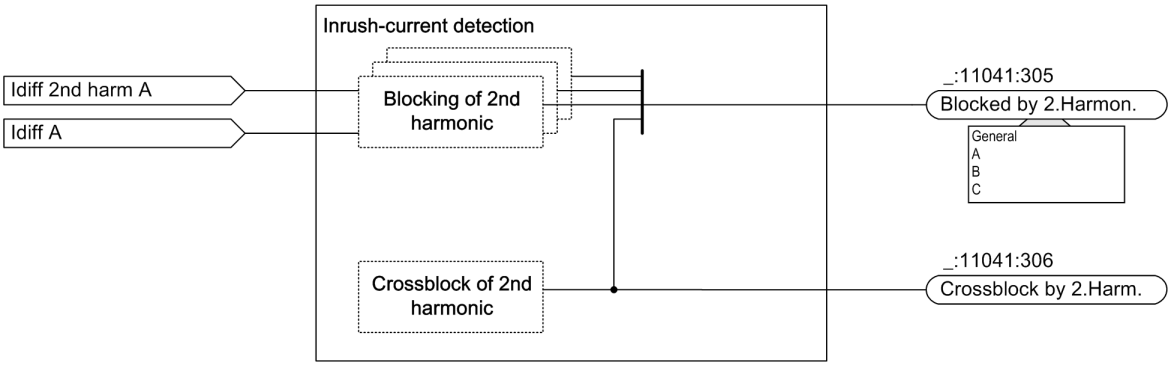


The inrush-current detection is activated when the pickup characteristic is exceeded. It is deactivated when it is blocked by an external fault.

For inrush-current detection, 2 methods working in parallel are used:

- **Share of the 2nd harmonic relative to the fundamental component in the differential current ($I_{2nd\ harm}/I_{1st\ harm}$)**

  As *Figure 7-47* also shows, the 2nd harmonic is clearly pronounced in the inrush current. If the share of the 2nd harmonic exceeds the set threshold value (parameter: **`2nd harmonic content`**), a phase-segregated blocking occurs. The harmonics develop differently in the different phases. If exceeding of the 2nd harmonic is detected in a phase, it may be necessary to block all phases simultaneously. This blocking must be limited with regard to time and is controlled by the parameter **`Crossblock. time 2nd har.`**. The correct positioning of the filter windows is controlled by the internal pickup.



If you want only one method to be active, the other method can be changed to inactive. For this, parameter **`Blocking with 2. harmonic`** = ***no*** is used.

Measurand Processing

Absolute-Value Correction

Since the current transformers cannot be adapted exactly to the rated currents of the protected object with regard to their primary rated data, a standardization to the nominal sizes of the protected object takes place. The conversion occurs every sampling time (thus, for instantaneous values). The differential protection function processes 20 sampled values per period. In addition, the sampled values tracked are used. A high degree of accuracy can be attained over the entire tracking range (from 10 Hz to 80 Hz).

The Idiff-fast stage works on non-frequency tracked values and thus, implements fast operate times with low frequencies.

The absolute value is adapted via the following formula:

$$i^*_{phsx} = k\, i_{phsx}$$

$$\text{with } k = \frac{I_{rated\,prim,Sx}}{I_{rated\,obj,Sx}} = \frac{I_{rated\,prim,Sx}}{\frac{S_{rated,ref}}{V_{rated,Sx}\sqrt{3}}}$$

[fobetr07-170712-01.tif, 1, en_US]

i_{phsx}*	Adapted instantaneous value per phase (x = A, B, C)
i_{phsx}	Instantaneous value per phase (x = A, B, C)
k	Correction value per measuring point
$I_{rated\ prim,Sx}$	Primary transformer rated current per measuring point
$I_{rated\ obj,Sx}$	Primary rated current of the protected object
$S_{rated,ref}$	Reference power (maximum rated apparent power of the protected object)
$V_{rated,Sx}$	Rated voltage of the respective side (measuring point) of the protected object

NOTE

For more than 2 capacitor bank sides (teed feeder), , the winding with the highest power is used as the reference winding. If several sides have the same highest amount of power, then the highest current side is selected as reference side. The absolute value of the neutral-point transformer is also adapted according to the previous formula. In this case, the absolute value should be adapted to the side with the greatest power.

Vector-Group Correction

The vector groups of the capacitor bank sides occur due to couplings that are different on each side. Therefore, the measured currents cannot be used directly for summation. The vector-group correction replicates the coupling of the capacitors and makes the measured currents comparable. The correction occurs such that each side is converted to vector group 0. Since you are in the 3-phase system, the conversion occurs via matrices which are stored for the respective vector-group type. The general description is given in the following formula. In the same calculation step, the absolute value is corrected:

$$\begin{bmatrix} i^*_A \\ i^*_B \\ i^*_C \end{bmatrix} = k * M_{SG} * \begin{bmatrix} i_A \\ i_B \\ i_C \end{bmatrix}$$

[foscha08-170712-01.tif, 1, en_US]

with

i_{phsx}*	Adapted instantaneous value per phase (x = A, B, C)
i_{phsx}	Instantaneous value per phase (x = A, B, C)
k	Absolute-value correction per measuring point
M_{SG}	Correction matrix

Differential Protection Function (Idiff)

A differential current per phase based on the instantaneous value variables is calculated from the processed currents (see section Measurand Processing). The direction of current flow is defined as to the **protected object as positive**. The fundamental component contribution to the differential current (I_{diff}) is calculated via a Fourier filter (filter length = 1 period (20 sampled values)).

The currents of that measuring point whose RMS value is the largest are used as restraint current. If, for example, the current collapses at a measuring point as a consequence of current-transformer saturation, the measuring point that has the largest current is automatically switched to at the point in time of the calculation.

NOTE

Differential protection does not work with sensitive ground-current transformers. Since sensitive transformers can go into saturation too quickly, false differential currents arise.

$$I_{diff,phsx} = \sum_{m=1}^{N} i^{*}_{phsx,Mm} \rightarrow I_{diff,phsx} = FIR(i_{diff,phsx})$$

$$I_{phsx,Mm} = \sqrt{\frac{1}{n}\sum_{k=1}^{n} i^{*2}_{phsx,Mm}(k)}$$

$$I_{rest,phsx} = \underset{m=1}{\overset{N}{MAX}}\, I_{phsx,Mm}$$

[fogrds16-170712-01.tif, 1, en_US]

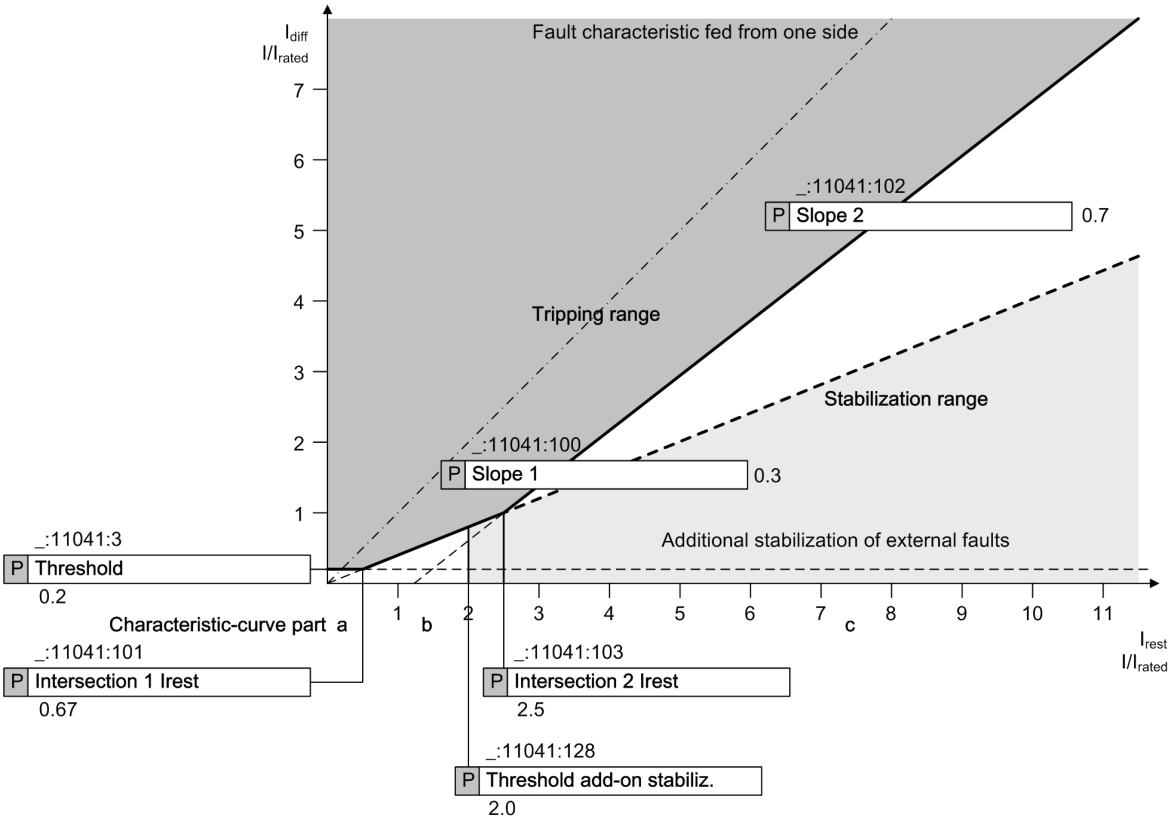
with

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points
n	Number of samples per period (n = 20)
FIR	Fourier filter
MAX	Maximum-value determination

Pickup Characteristic

Figure 7-50 shows the pickup characteristic of the differential protection. The characteristic curve branch **a** represents the sensitivity threshold of the differential protection (parameter **`Threshold`**) and considers constant fault currents like magnetizing currents.

The characteristic branch **b** (parameter **`Intersection 1 Irest`** and **`Slope 1`**) considers current-proportional faults under normal operating conditions.



These faults can occur for the following reasons:

- Transformation errors in the current transformer and the input transformer of the device
- Adaptation deviations

The characteristic curve branch **c** (parameter **`Intersection 2 Irest`** and **`Slope 2`**) protects the differential protection against overfunction in case of high-current external faults and transformer saturation. In this area, transformer saturation can arise due to high short-circuit currents, and because of this, a higher differential current results.

In order to avoid overfunction in the event of external faults with transformer saturation, a logic is implemented that uses the characteristic curve **Additional stabilization of external faults**. If the operating point is located in the additional stabilization area and exceeds the operate curve from there, then the logic becomes active and blocks the differential protection.

The additional stabilization range is derived from the **`Threshold add-on stabiliz.`** and **`Slope 1`** parameters.

[dwdifaus-030912-01.tif, 1, en_US]

Figure 7-50 Pickup Characteristic of the Differential Protection

If the differential current multiplied by the dropout ratio of 0.7 does not reach the pickup characteristic, the pickup drops out.

Detection of External Faults

To detect external faults with transformer saturation in a reliable way, the measurand curve is evaluated in the Diff.-Rest level by means of a detector. The detector has 2 essential tasks:

- **Blocking in the case of a definite high-current external fault**

  The differential current and the restraint current are monitored on a phase basis in the Diff/Restr level immediately after fault inception. To ensure the stability of the saturation detection for low saturation-free times of the primary current transformer, estimated values based on the difference quotients of the instantaneous values are used.

  If the estimated restraint current exceeds the **`Threshold add-on stabiliz.`** parameter and the expected value of the differential current of all phases is in the additional stabilization range (parameter **`Slope 1`**) (*Figure 7-50*) at the same time, the detector is active and the indication ***`Blocked by ext. fault phsx`*** appears. The tripping of the Differential protection function is blocked.

  If an external fault arises and is cleared by the protection responsible for it, the additional stabilization drops out. If the dropout ratio (0.7) of the RMS value of the restraint current does not reach the **`Threshold add-on stabiliz.`** parameter (*Figure 7-50*), the additional stabilization drops out. The indication ***`Blocked by ext. fault phsx`*** is reset.

  If the differential current exceeds **`Slope 1`** as a result of transformer saturation, that is, there is a pickup phsx, the blocking is limited in time (parameter: **`Time of add-on stabiliz.`**).

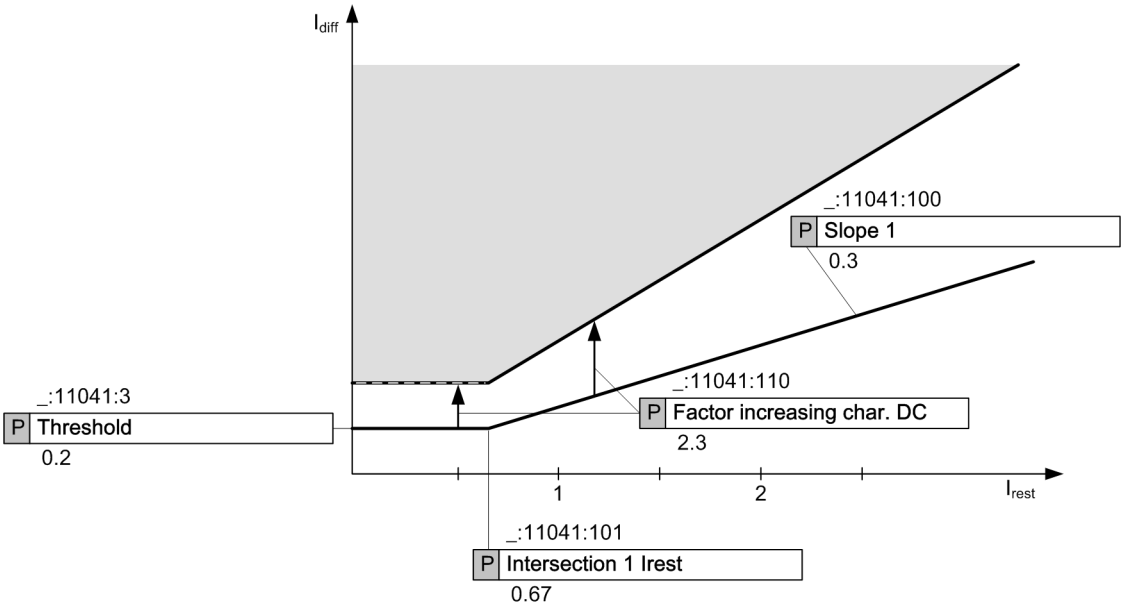
  Starting with the indication ***`Blocked by ext. fault phsx`***, the other phases can be blocked with it via the **`Cross-blk. time add-on st.`** parameter. If differential currents due to transformer saturation spread to the other phases through the vector-group correction or residual current elimination, this blocking is necessary.

- **Removal of the blocking with a change in fault location from external to internal**

  An internal fault can arise as a consequence of an external fault. This fault change must be recognized and the blocking must be removed. The critical case is a short-circuit with current-transformer saturation. The saturation detection examines here the instantaneous values of the differential current. With transformer saturation, the instantaneous values fall below an internal threshold in the saturation-free time. If this threshold is permanently exceeded and a pickup is present in the corresponding phase, an internal error is assumed. The other phases are also examined during the parameterization with cross block.

  The blocking of the tripping is removed and the indication *Blocked by ext. fault phsx* is reset.

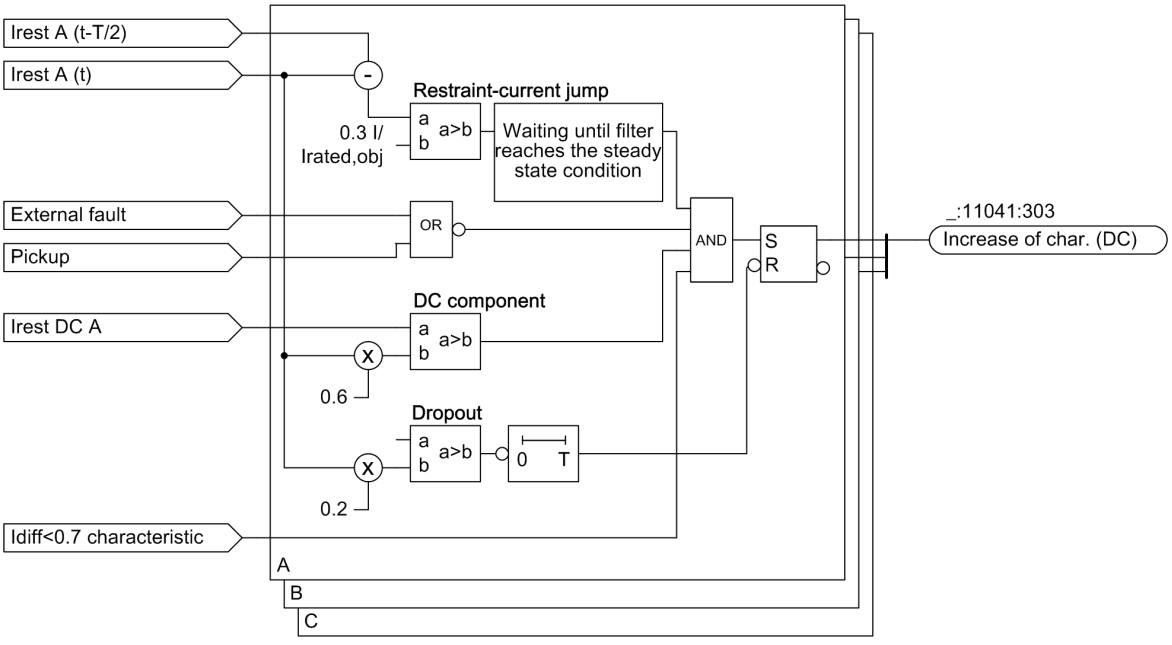
DC-Component Detection



Low-current external faults with large DC components can also lead to exceeding of the operate curve. The additional stabilization area is not attained, however.

To avoid an overfunction, the following steps are taken:

- The restraint current $I_{rest.;phsx}$ is monitored for a jump.
- If the jump occurs, the DC component is calculated, with a temporal delay (1 period), from the instantaneous value of the restraint current (current at the measuring point with the largest current) $i_{rest.,phsx} = i_{phsx,Mm}$. The result is $I_{rest.DC,phsx}$. This current is compared to the restraint current $I_{rest.,\ phsx}$ and is checked for exceeding of the internal threshold.
- The differential current $I_{diff,phsx}$ must lie below the dropout characteristic curve (characteristic curve · 0.7) in all 3 phases.
- If the first 3 points lead to positive results, then the operate curve is raised by the parameter **Factor increasing char.** with a default setting of ***2.3***. Here, only the threshold value and the gradient 1 are raised (see *Figure 7-51*). The indication *Increase of char. (DC)* is output. If the product of parameter **Factor increasing char.** and **Slope 1** exceeds **0.85**, the maximum increase of the raised **Slope 1** is limited to 0.85.
- As additional criterion, the pickup indication *Pickup* (internal fault is present) or the indication of the additional stabilization *Blocked by ext. fault phsx* (high-current external fault) is sampled. If one of the 2 conditions is present, the characteristic-curve increase is stopped. A retroactive pickup no longer resets the characteristic-curve increase. A pickup with DC-component detection occurs only if the raised operate curve is exceeded.



If the DC component $I_{rest.DC,phsx}$ falls below the internal dropout threshold, the dropout delay is determined as follows:

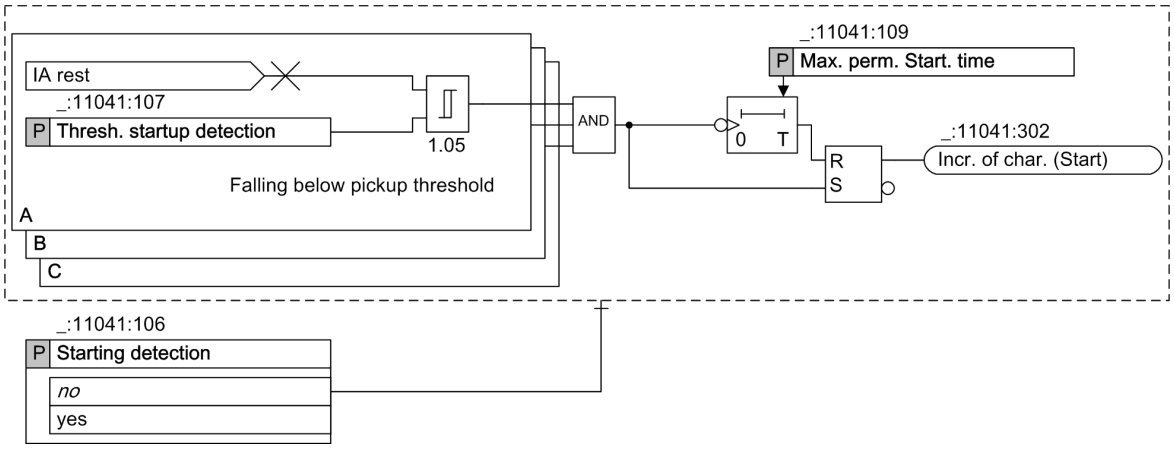
It is assumed that the de- and remagnetization of the transformer last equally long. The magnetization is at the highest at the point in time in which the internal dropout threshold is attained. The time is measured from the start of the DC-component detection until the internal dropout threshold is reached. Added to this time are 5 periods and from this, the dropout delay is derived. Following this, the characteristic-curve increase is reset to the original value. *Figure 7-52* shows the overall logic.

[dwdcerkn-201112-01.tif, 2, en_US]

Figure 7-51 Increasing the Characteristic Curve after DC Detection

[lodcerkn-170712-01.tif, 1, en_US]

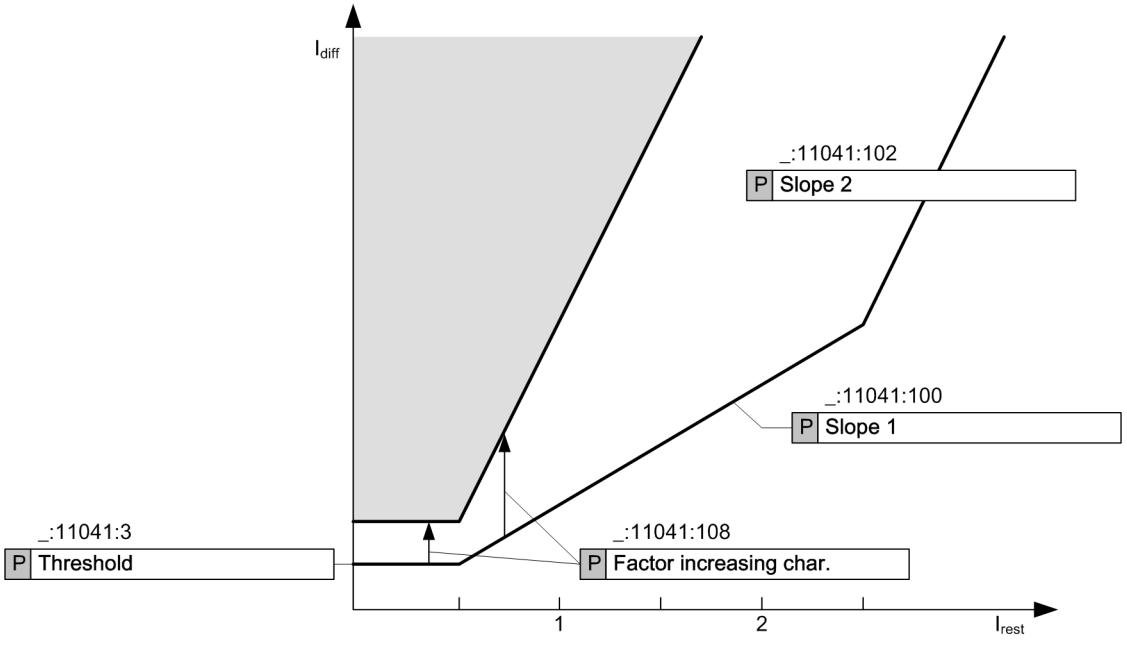
Figure 7-52 Logic DC Detection



Startup Detection

The pickup-value increase is particularly useful in the case of motors. In contrast to transformers, the inrush current with motors is a flowing current. Differential currents can arise, however, by the current transformers having different residual magnetization and being supplied with current at different operating points of their hysteresis. These differential currents are low in fact, but they can lead to overfunction with sensitive setting of the differential protection.

You can use the pickup-value increase at startup as an additional security against overfunction when switching in a previously currentless protected object. If the restraint current falls below a settable value **`Thresh. startup detection`** in all phases, the pickup-value increase is activated. The pickup value **`Threshold`**



and **Slope 1** are raised by the set value in accordance with parameter **Factor increasing char.** . As a rule here, **Slope 1** cannot exceed a value of 0.85.

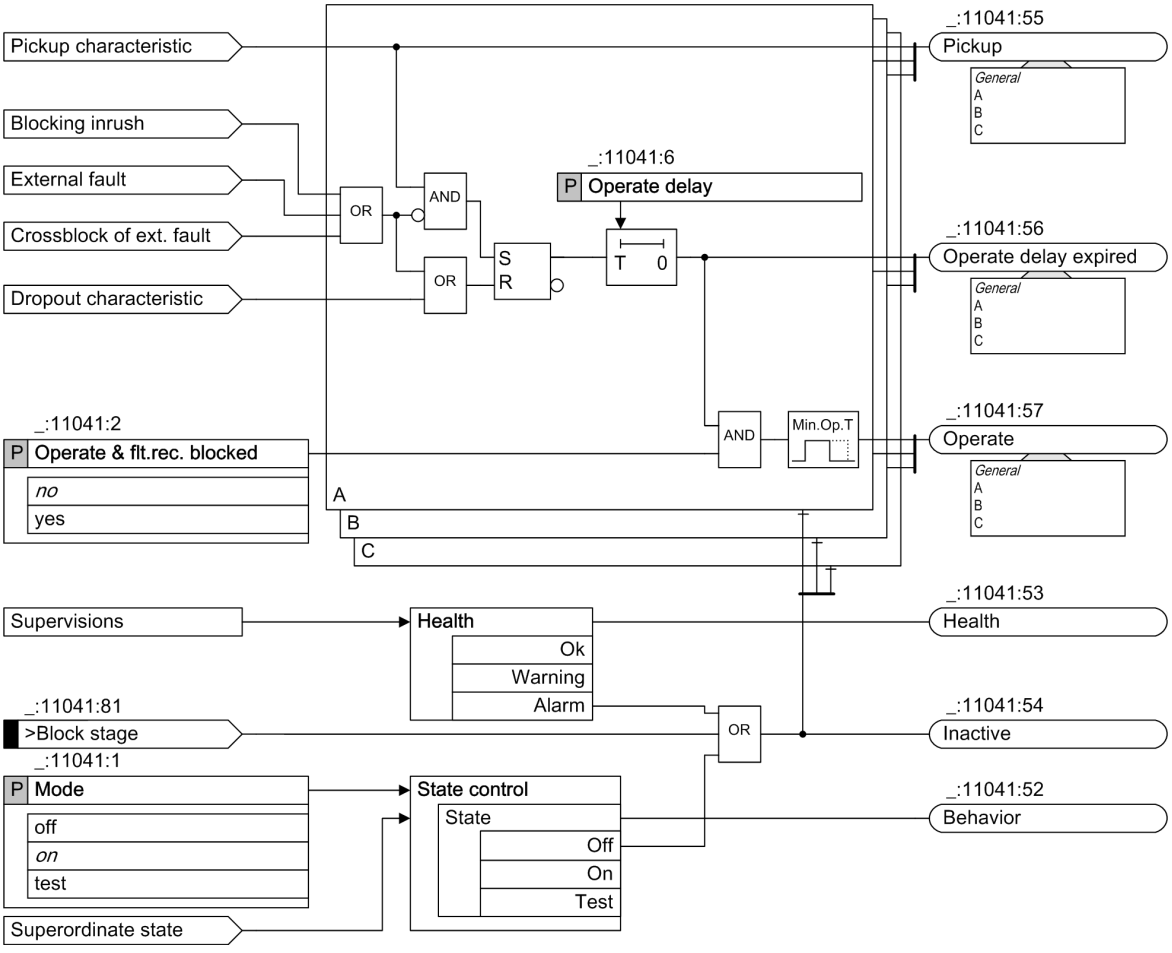
If the parameter **Thresh. startup detection** is exceeded, dropout occurs and a timing element (parameter **Max. perm. Start. time**) is started. Once this time has elapsed, the characteristics curve that was raised in all phases is reset to its original value. *Figure 7-53* shows the logic diagram of the pickup recognition and *Figure 7-54* the increased characteristic curve.

[loanlauf-170712-01.tif, 2, en_US]

Figure 7-53 Logic Pickup Recognition

[dwanlken-201112-01.tif, 1, en_US]

Figure 7-54 Characteristic-Curve Increase at Startup



Trip Logic of the Differential Function Idiff

Figure 7-55 shows the trip logic. If the characteristic curve is exceeded (see *Figure 7-50*), a pickup occurs. Redirection of the information for tripping can be blocked by the additional functions.

Blocking is possible through use of the following variables:

- Recognition of external faults that can simulate an internal fault through transformer saturation
- Recognition of the connection process (2nd harmonic)

In addition, in case of blocking due to an *external error*, a **Crossblock** mechanism comes into effect.

[loauscod-290414-01, 1, en_US]

Figure 7-55 Trip Logic of Idiff

Differential Protection Function (Idiff Fast)

As a supplement to the differential protection function (Idiff), the Idiff fast function is available. The main task consists in switching off high-current internal faults in the shortest amount of time. The method controls current-transformer saturation and is stable in the event of external transverse faults (integration in breaker-and-a-half arrangements).

Metrologically, 2 methods are combined:

- Instantaneous-value method
- Filter-based method

Instantaneous-Value Method

Through the instantaneous-values method, an immediate evaluation of the sampled values of the differential $i_{Diff}(t)$ and restraint current $i_{rest}(t)$ occurs. The absolute-value adapted and vector-group adapted currents (i*) are also the basis. The currents are defined positively to the node. The restraint current is the maximum current of all measuring points.

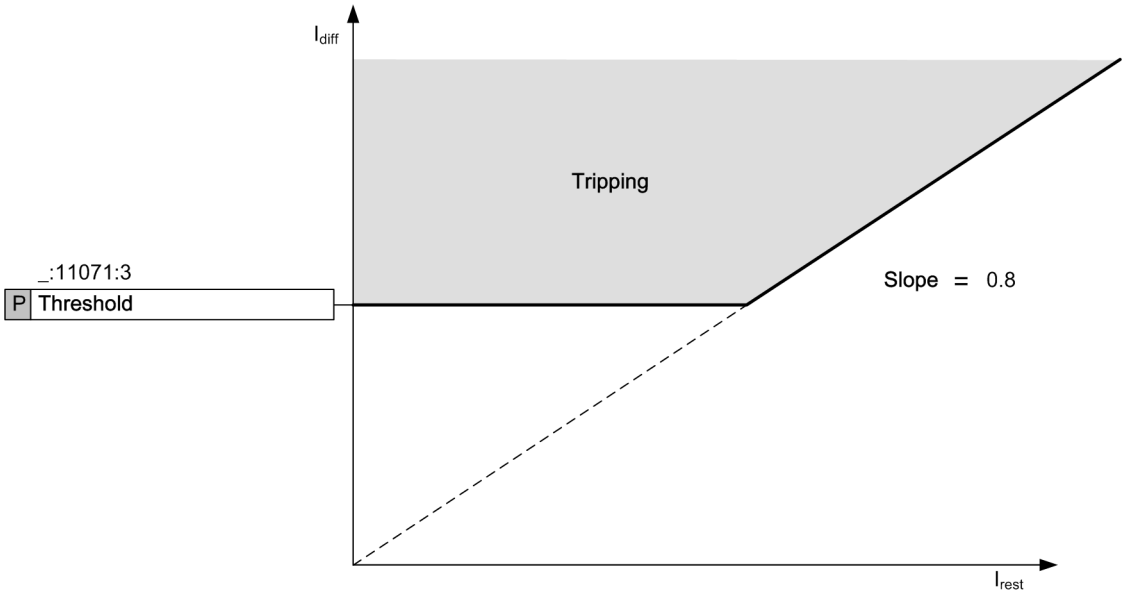
$$i_{diff,phsx}(t) = \left| \sum_{m=1}^{N} i^{*}_{phsx,Mm}(t) \right|$$

$$i_{rest,phsx}(t) = \frac{1}{2} \underset{m=1}{\overset{N}{MAX}} \left| i^{*}_{phsx,Mm}(t) \right|$$

[fomome27-170712-01.tif, 1, en_US]

with

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points

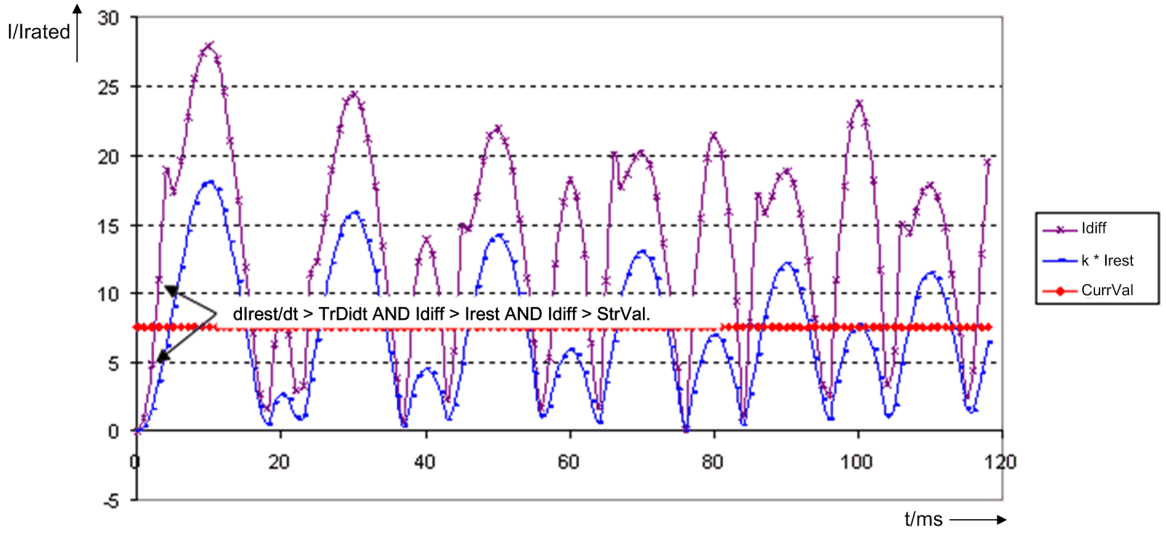


The evaluation of the restraint current is used to recognize saturated, high-current external faults.

Figure 7-56 shows the operate curve. The parameter **Threshold** is set here such that it lies over the maximum fault current flowing. The gradient of the characteristic curve is fixed at 0.8.

In the algorithm, the following conditions are processed:

- Condition 1: The increase of the restraint current $di_{rest}(t)/dt$ is determined continuously and compared with an internal threshold.
- Condition 2: After that, a comparison determines whether the differential current is larger than the restraint current (characteristic curve **Gradient** in *Figure 7-56*): $i_{diff}(t) > 0.8 \cdot i_{rest}(t)$.
- Condition 3: After that, a comparison determines whether the differential current exceeds the parameter **Threshold**.



When all conditions are met, tripping occurs immediately. If the 1st condition is recognized and not the 2nd condition, then the function is blocked for 300 ms.

[dwidfast-300114-01.tif, 1, en_US]

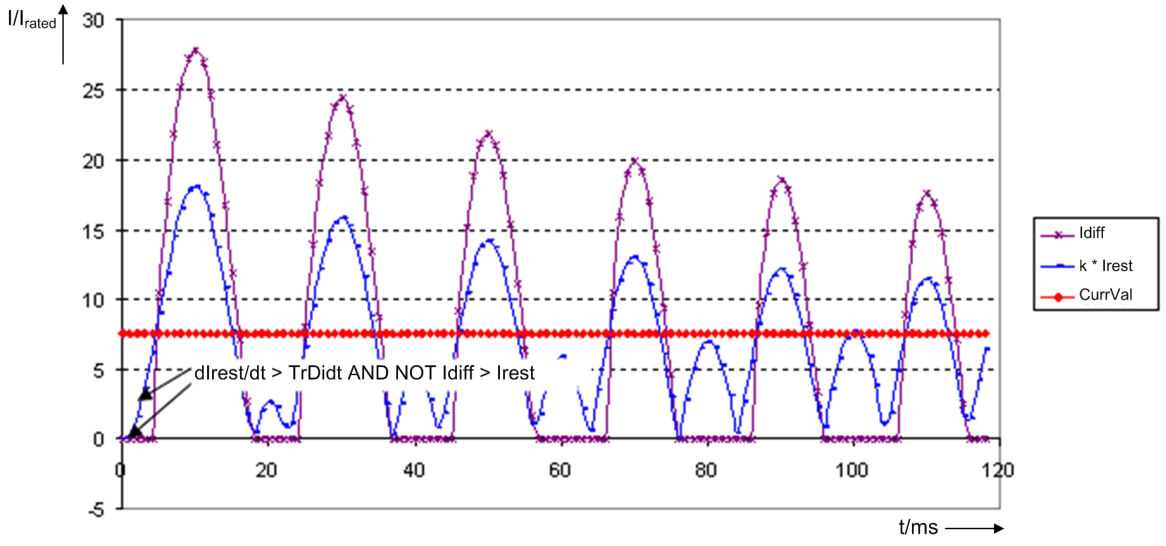


Figure 7-56 Characteristic Curve of Idiff fast

The 2 following figures show the behavior during an internal and an external fault. It is typical for the internal fault (*Figure 7-57*) that the differential current rises more quickly than the restraint current. After a few sampled values, the trip signal is issued. In case of an external fault, a differential current arises only after transformer saturation occurs. You can always assume, however, that the current is transferred a few milliseconds after occurrence of the fault. In accordance with *Figure 7-59*, the restraint current is larger than the differential current after occurrence of the fault, but condition 2 is not met and the function is therefore blocked.

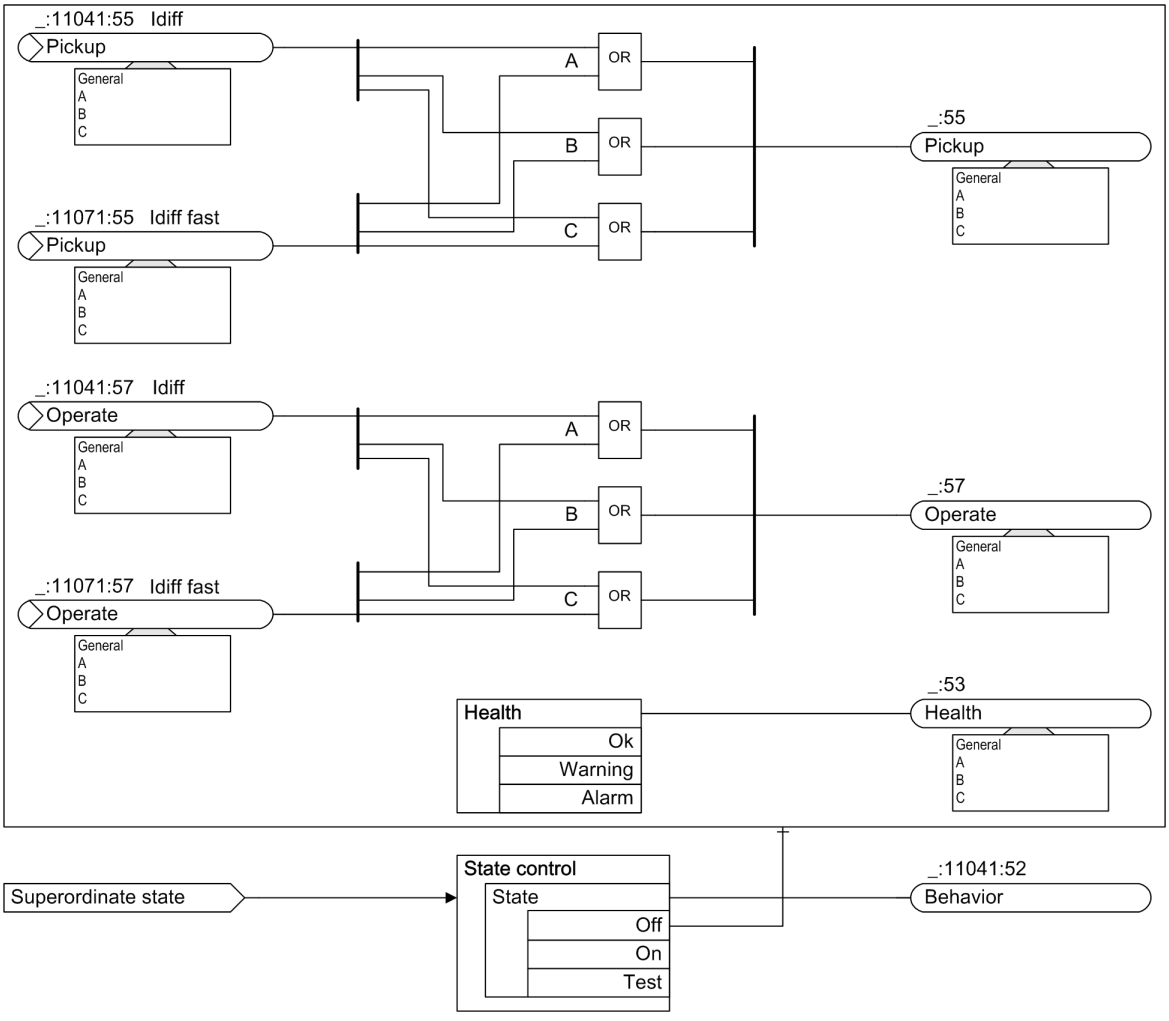
[dwextfel-170712-01.tif, 1, en_US]

Figure 7-58 Curve Plot for External Fault with Transformer Saturation (k= 0.65)

Fundamental-Component Method

Parallel to the instantaneous-value method, the fundamental-component method works with a temporal delay. Here, the same measured values are processed as with the Idiff method. The fundamental component of the differential current I_{diff} and the stabilization value (maximum current of a measuring point) $I_{rest.}$ are ordered in the operate curve according to *Figure 7-56* and the trip decision is made.

Figure 7-59 shows the overall logic.



[loidfast-151012-01.tif, 2, en_US]

Figure 7-59 Logic of the Differential Protection Function Idiff Fast

Trip Logic of the Differential Protection

A common trip signal is formed from both subfunctions Idiff and Idiff fast. *Figure 7-60* shows the respective logic.

[logesamt-170712-01.tif, 1, en_US]

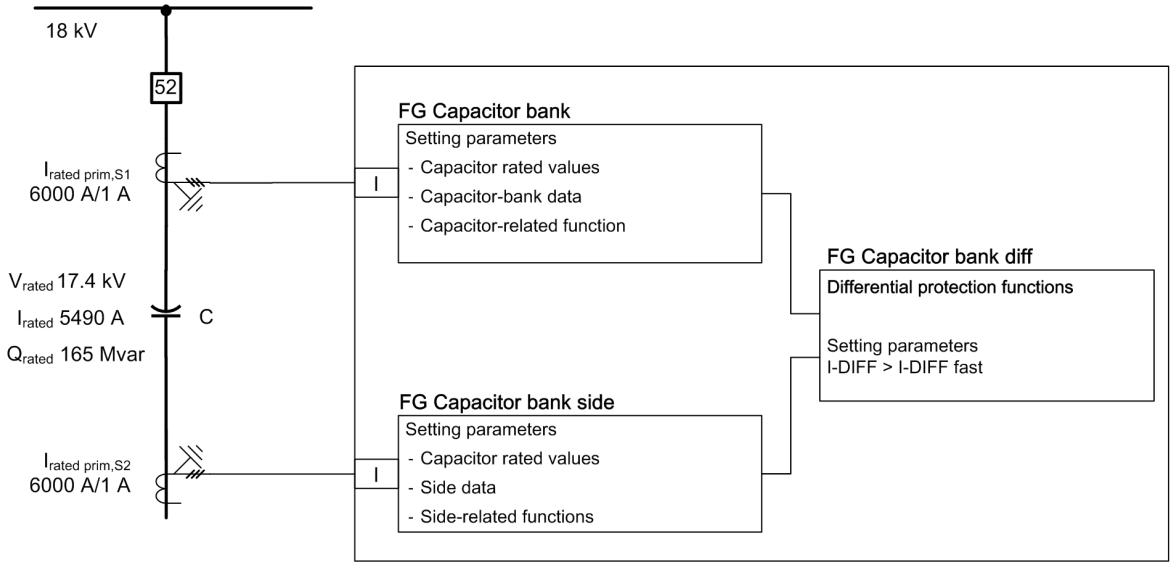


Figure 7-60 Overall Trip Logic

Fault Logging and Fault Recording

A fault is opened with every protection pickup. This means that a fault log and a fault recording are started. Saving of the fault record depends on the setting (see *3.4.3 Function Description*). Since pickup and tripping are the same in differential protection, the recording setting can be used with the pickup function. To enable fault recording even with external errors, along with the exceedance of the characteristic curve, a fault record is opened in case of a blocking by an external error or in case of a characteristic-curve increase through component recognition. This has the advantage that you can evaluate the transformer transfer method of the current transformers very well in case of a fault.

7.8.4 Application and Setting Notes

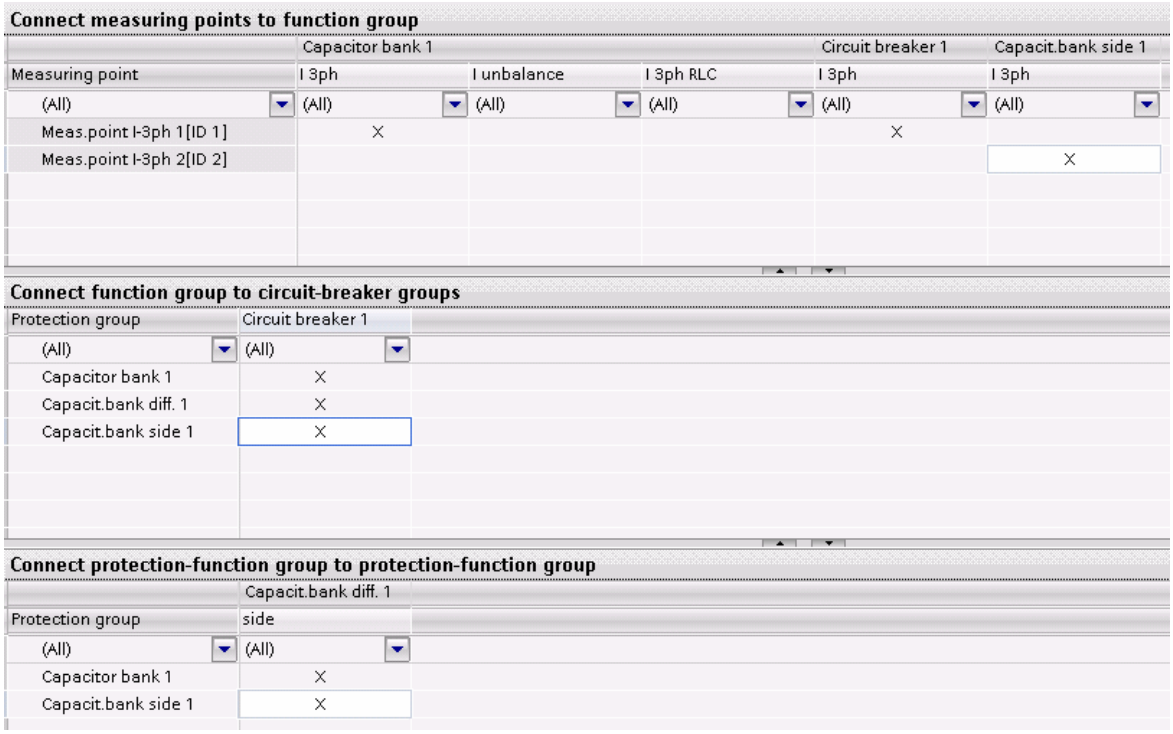

Figure 7-61 shows the application of a differential protection via a capacitor bank in a simplified way.

Figure 7-62 Internal Interconnection in DIGSI 5

Function Group Capacitor Bank

This chapter only refers to parameters that are important for the differential protection function application. You can find more information on further parameters in chapter *5.4.3 Application and Setting Notes* (**Capacitor bank** function group).

Parameter: `Capacitor reference curr.`

- Default setting **`(_:14641:101) Capacitor reference curr.`** = ***`1000 A`***

With the parameter **`Capacitor reference curr.`**, you set the reference current for the capacitor bank to be protected. The capacitor reference current set here is the reference value for the percentage measured values and for setting values in percent.

For the Differential protection, these values are used for absolute-value correction (rated current of the protected object).

Depending on the application, you can use the capacitor-bank rated current including the harmonics or the capacitor-bank fundamental-component current as a reference value.

Function Group Capacitor Bank Side

Proceed with the following settings in the **Capacitor bank side** function group:

Parameter: `Capacitor reference curr.`

- Default setting **`(_:1781:15571:101) Capacitor reference curr.`** = ***`1000 A`***

With the parameter **`Capacitor reference curr.`**, you set the reference current for the capacitor bank to be protected. The capacitor reference current set here is the reference value for the percentage measured values and for setting values in percent.

For the Differential protection, these values are used for absolute-value correction (rated current of the protected object).

If the capacitor bank is part of a delta connection, the value to be set here can differ from the capacitor reference current set in the **Capacitor bank** function group (by factor $\sqrt{3}$). Otherwise, set always the same values.

Depending on the application, you can use the capacitor-bank rated current including the harmonics or the capacitor-bank fundamental-component current as a reference value.

Parameter: `Capacitor reference volt.`

- Default setting **`(_:1781:15571:102) Capacitor reference volt.`** = ***`400.00 kV`***

With the parameter **`Capacitor reference volt.`**, you set the reference voltage of the capacitor bank to be protected. The reference voltage set here is the reference value for the percentage measured values and for setting values in percent.

Depending on the application, you can use the system rated voltage (busbar voltage) or the capacitor rated voltage as a reference value.

Parameter: `Neutral point`

- Default setting **`(_:1781:15571:149) Neutral point`** = ***`isolated`***

With the parameter **`Neutral point`**, you specify whether the neutral point in the protection range of the differential protection is ***`grounded`*** or ***`isolated`***. As this is not the case for the described application example, use the default setting ***`isolated`***.

You can find further information in the 7UT8 Device Manual in chapter 6.2.3 Function Description Neutral-Point Current Treatment .

NOTE

For the described application example, you do not need to change the parameters **`Winding configuration`** and **`Vector group numeral`**. If the capacitor bank is part of a delta connection, create the phase reference via the vector group.

You can find further information in the 7UT8 Device Manual in chapter 6.2.3 Function Description Vector-Group Correction .

Parameter: `Winding configuration`

- Default setting **`(_:1781:15571:104) Winding configuration`** = ***`Y (Wye)`***

With the parameter **Winding configuration**, you set ***D (Delta)*** for a delta connection. Another setting option is ***Y (Wye)*** for a star connection. The parameter **Winding configuration** is relevant for the differential protection function. You do not need to change this setting for the described application example.

Parameter: Vector group numeral

- Default setting **(_:1781:15571:100) Vector group numeral** = ***0***

This parameter is used to account for phase-angle rotation, which is expressed by a number.

Phase-angle rotation	0°	30°	60°	90°	120°	150°	180°	210°	240°	270°	300°	330°
Vector group numeral	0	1	2	3	4	5	6	7	8	9	10	11

In the function group, the following information is displayed additionally in the setting sheet:

- Side number
- Identification of the measuring points used
- Adaptation factor for the 3-phase measuring point (with reference to the side)

Each **Vector group numeral** from 0 to 11 can be set to the extent possible. Thus, for example, only even numbers are possible for the vector group Yy and Dd and only odd numbers are possible for Yd and Dy.

You do not need to change this setting for the described application example.

Function Group Capacitor Bank Diff

Proceed with the following settings in the **Capacitor bank Diff** function group for the IDiff function:

Parameter: Threshold (Setting of the Characteristic-Curve Parameters)

- Default setting **(_:11041:3) Threshold** = ***0.20 I/Irated,obj***

You set the pickup threshold for the differential current with this parameter. This is the total current flowing into the protection range during a short-circuit, regardless of how it is distributed on the sides of the protected object. The pickup value is relative to the rated current of the protected object. The default setting of ***0.20 I/Irated,obj*** is a practical value between sensitivity and possible disturbing influence.

Parameter: Intersection 1 Irest

- Default setting **(_:11041:101) Intersection 1 Irest** = ***0.67 I/Irated,obj***

The maximum current of the measuring point is used as restraint current. If you have to expect dynamic transmission errors of the current transformer even with small currents, half of the rated current is an appropriate setting value.

Parameter: Slope 1

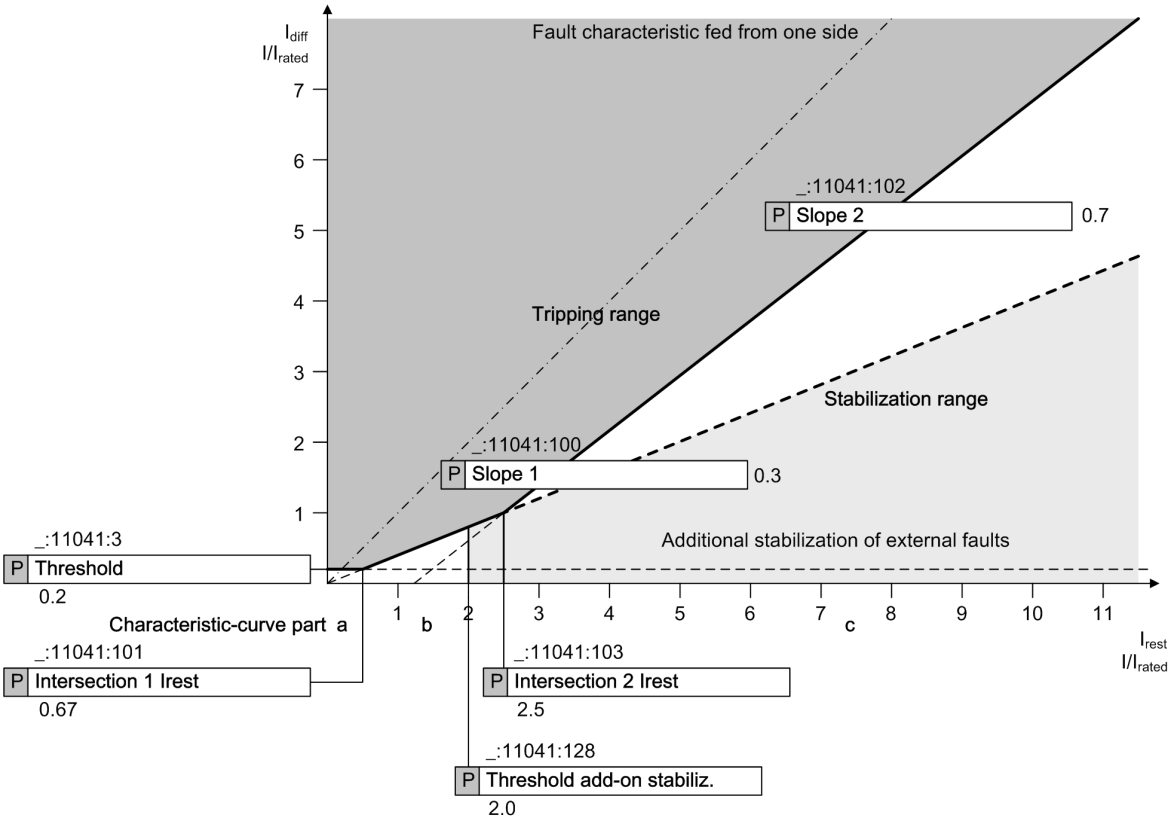
- Default setting **(_:11041:100) Slope 1** = ***0.30***

With the **Slope 1**, you avoid an overfunction of the differential protection with low-current external faults as a consequence of current-transformer transmission errors (stationary and dynamic faults). The default setting of ***0.30*** is sufficient for many applications.

Parameter: Intersection 2 Irest

- Default setting **(_:11041:103) Intersection 2 Irest** = ***2.50 I/Irated,obj***

NOTE



If you expect transmission problems for the current transformer in case of excessive current flows, set the **Slope 2** to a higher value.

The parameter **Intersection 2 Irest** determines from which restraint current the **Slope 2** begins. The default setting ***2.50 I/Irated,obj*** is a practical value.

Parameter: Slope 2

- Default setting **(_:11041:102) Slope 2** = ***0.70***

With the parameter **Slope 2**, an overfunction of the differential protection is avoided with high-current external faults as a consequence of current-transformer transmission errors (for example, due to saturation). A value greater than or equal to double the value of **Slope 1** is practical. As the default setting, ***0.70*** was selected.

[dwdifaus-030912-01.tif, 1, en_US]

Figure 7-63 Characteristic Curve with the Default Settings

Parameter: Starting detection

- Default setting **(_:11041:106) Starting detection** = ***yes***

To avoid an overfunction when switching on capacitor banks, you can set the parameter **Starting detection** = ***yes***. Siemens recommends the setting **Starting detection** = ***yes***.

Parameter: Thresh. startup detection

- Default setting **(_:11041:107) Thresh. startup detection** = ***0.1 I/Irated,Obj***

If the restraint current falls below this threshold value, the subsequently set characteristic-curve increase becomes effective with activated function. The default setting value of ***0.1 I/Irated,obj*** is recommended for the application.

Parameter: Factor increasing char.

- Default setting **(_:11041:108) Factor increasing char.** = ***2.0***

An increase to the value 2.0 has proven itself to be sufficient for many applications.

Parameter: Max. perm. Start. time

- Default setting **(_:11041:109) Max. perm. Start. time** = ***5.0 s***

The setting value must lie above the maximum inrush time of the connected capacitor bank. To guarantee tripping through the capacitor-bank protection (inrush/starting time supervision) and avoid overfunctions, select a somewhat longer time (factor 1.2 or higher).

Parameter: Factor increasing char. DC (DC-Component Recognition)

- Default setting **(_:11041:110) Factor increasing char. DC** = ***2.3***

The DC-component recognition is always active. As a result of the DC components, transmission problems can arise (for example, phase-angle rotations) in current transformers with small currents flowing. For this reason, the **Threshold** and the **Slope 1** are raised by the set factor. The default setting of 2.3 has proven itself with numerous applications.

Parameter: Blocking with 2. harmonic (Inrush-Current Detection)

- Default setting **(_:11041:115) Blocking with 2. harmonic** = ***no***

The inrush-current detection is not necessary for capacitor-bank applications.

Parameter: 2nd harmonic content

- Default setting **(_:11041:116) 2nd harmonic content** = ***15 %***

For many practical applications, the default setting value of ***15 %*** has proven useful. In exceptional cases, the setting value can be decreased with a small proportion of 2nd harmonic. Avoid a setting below 10 %, however. With an internal fault and current-transformer saturation, some proportion of 2nd harmonic also arises. A setting that is too sensitive leads to a blocking of the protection function.

Parameter: Crossblock. time 2nd har.

- Default setting **(_:11041:117) Crossblock. time 2nd har.** = ***0.00 s***

Since the inrush currents develop differently in the 3 phases, the pickup value, for example, is not attained in a phase, but the differential current exceeds the characteristic curve. Corrective action creates a mutual blocking. If a time unequal to 0 s is set, the crossblock function works. If an overfunction arises, the setting cannot be made until commissioning takes place. Do not set the duration for an excessive amount of time. Practical values showed a setting between 3 and 5 periods.

Recognition of External Faults

In *Figure 7-63* the range **Additional stabilization with external fault** is represented. The range is described by the parameters **Threshold add-on stabiliz.** and **Slope 1**. With an external short circuit, the differential currents can increase beyond this range and reach into the tripping area. With the following parameters, time-limited blocking can be performed.

Parameter: Threshold add-on stabiliz.

- Default setting **(_:11041:128) Threshold add-on stabiliz.** = ***2.00***

With the **Threshold add-on stabiliz.** parameter, you set the pickup value for the additional stabilization. Due to the selected method of measurement, a setting value of 2.00 is practical. The additional stabilization range is limited by the parameters **Threshold add-on stabiliz.** and **Slope 1**.

Parameter: Time of add-on stabiliz.

- Default setting **(_:11041:129) Time of add-on stabiliz.** = ***0.30 s***

You can use the operate time of the external feeder protection as an orientation for the setting value. Additionally, take into account the circuit-breaker opening time. Thus, the following calculation rule results:

$t_{Z\ rest.} \geq t_{off,ext\ protection} + t_{off,circuit\ breaker}$

The default value is a practical value. You must adapt the value according to the use case. The value 0 deactivates the recognition of external errors.

Parameter: `Cross-blk. time add-on st.`

- Default setting **`(_:11041:130) Cross-blk. time add-on st.`** = ***`0.30 s`***

The additional stabilization acts separately on each phase. However, it can be extended to block all phases. Siemens recommends the activation of the crossblock function by means of a corresponding setting of the time. The set time must be identical to the time that is set for the duration of the additional stabilization.

Protection Stage Idiff Fast

The task of this protection stage is the fast detection of high-current internal short circuits (see also *Differential Protection Function (Idiff Fast), Page 999*). For this reason, the protection stage must always be activated.

Parameter: `Threshold`

- Default setting **`(_:11071:3) Threshold`** = ***`7.5 I/Irated,obj`***

Siemens recommends setting the threshold value greater than or equal to the starting current.

7.8.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:11041:1	I-DIFF:Mode		• off • on • test	off

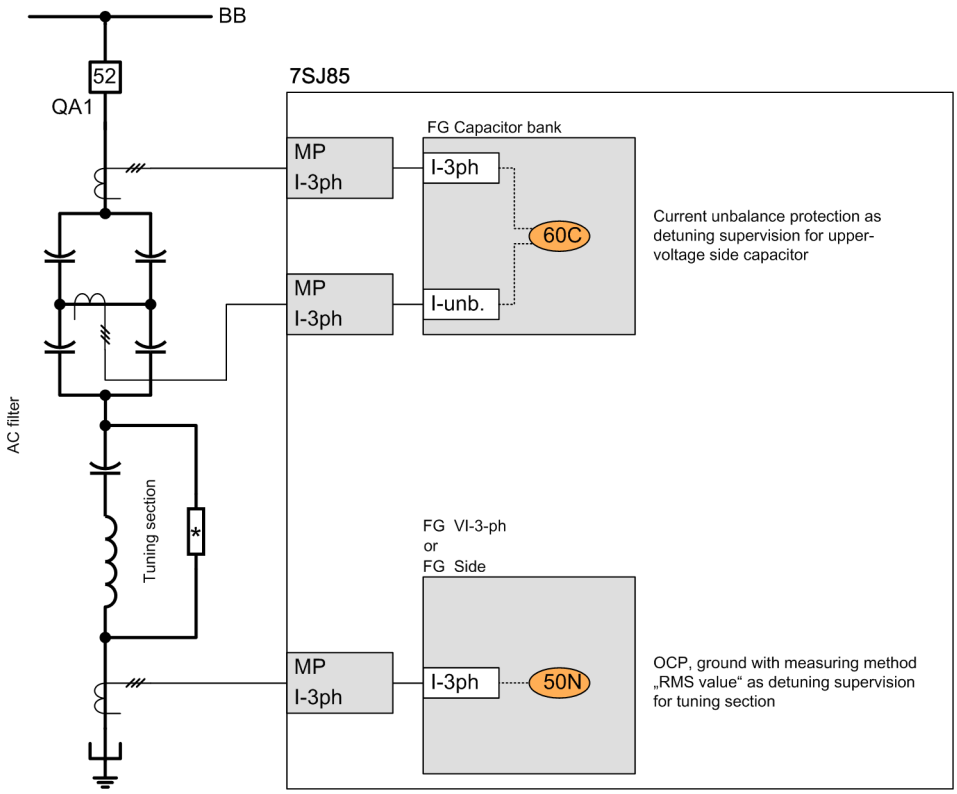
7.9 Detuning Supervision for Capacitor Banks

7.9.1 AC-Filter Detuning Supervision



Tuned AC filters serve to provide reactive power and to absorb specific frequencies from the busbar. They usually consist of the upper-voltage side capacitor (for providing reactive power) and the tuning section (for tuning to the frequencies to be absorbed). The tuning section consists of primary C, L and, if required, R elements, refer also to *Figure 7-64*.

Under normal operation, the RLC characteristics of the filter – the impedances – are identical per phase. A change in the impedance of one phase indicates that the filter characteristic of this phase has changed. This situation (a detuned filter) is not wanted and shall be detected.

The primary elements of the AC filter shall be subject of regular maintenance intervals where the compliance with the tolerances of the rated values specified in the design need to be checked. For the detection of detuning between the maintenance intervals, the protection device can be applied. Detuning supervision for the upper-voltage side voltage capacitor can be achieved by applying the phase-selective **Current unbalance** function (ANSI 60C), especially by using the counter function.

A criterion for the supervision of the primary elements of the tuning section is the ground or zero-sequence current (3I0) of the AC filter. The fundamental phase current of the AC filter is determined by the phase capacitance of the upper-voltage side capacitor. Consequently, a difference in the phase capacitances of the upper-voltage side capacitor will cause a fundamental ground current. Therefore it is not sufficient for the tuning-section supervision to evaluate only the fundamental ground current. Under normal operation and symmetrical network conditions, the fundamental ground current will be **0**. An unbalance in the phase impedances (detuning) will cause a ground current. A detuning of the tuning section will mainly cause harmonics in the ground current. Thus, the RMS value of the ground current needs to be evaluated. For a detuning supervision of the tuning section, the function OCP, ground (ANSI 50N) with the measuring method **RMS value** is applied. This allows detecting harmonics up to the 50th harmonic with high precision (refer also to Technical data).

When selecting the settings (pickup value, operate delay and function mode) for the function OCP, ground (ANSI 50N) the present network connecting conditions must be considered! Otherwise short-term power-system unbalances (for example, 1-pole fast auto reclosing) or statically present harmonics in the zero-sequence system may cause an overfunction. Since the primary elements of the AC filter are directly or inherently protected by other protection functions and due to the possible influence of the network conditions on the function OCP, ground (ANSI 50N), this function should be configured only as alarm function and not as tripping function.

[dw_AC-Filter_detuning-supervision, 1, en_US]

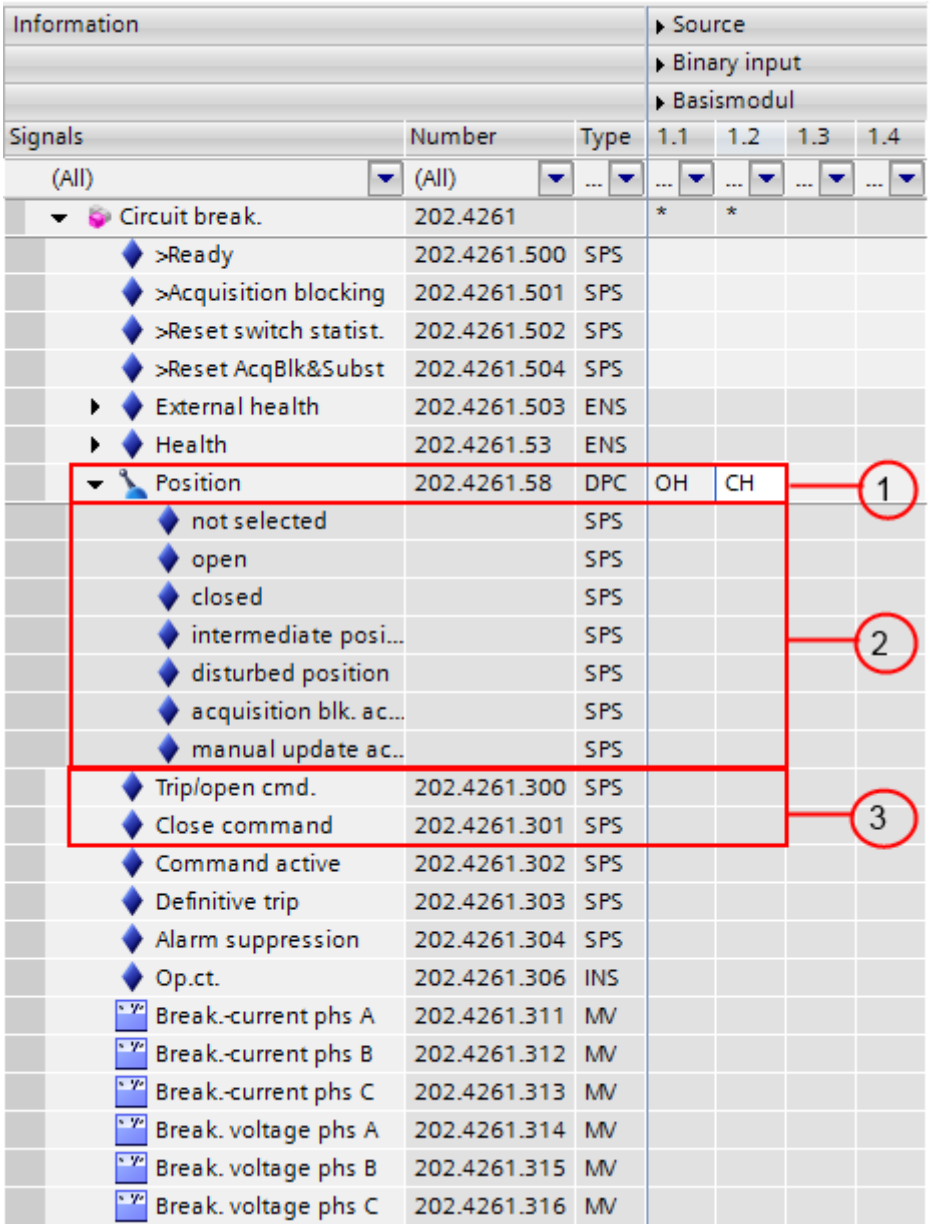
8 Control Functions

8.1	Introduction	1016
8.2	Switching Devices	1019
8.3	Control Functionality	1046
8.4	Synchronization Function	1070
8.5	Switching Sequences	1106
8.6	User-Defined Function Block [Control]	1113
8.7	CFC-Chart Settings	1115
8.8	Transformer Tap Changers	1117
8.9	Voltage Controller	1128



8.1 Introduction

8.1.1 Overview

The SIPROTEC 5 series of devices offers powerful command processing capability as well as additional functions that are needed when serving as bay controllers for the substation automation technology or when providing combi-protection. The object model for the devices is based on the IEC 61850 standard, making the SIPROTEC 5 series of devices ideally suited for use in systems employing the IEC 61850 communication protocol. In view of the function blocks necessary for the control functions, other logs are also used.

8.1.2 Concept of Controllables

The concept of so-called controllables is based on the data model described in IEC 61850. Controllables are objects that can be controlled, such as a switch with feedback. The model of a transformer tap changer , for example, contains controllables. The controllables are identifiable by their last letter **C** of the data type (for example, DPC = Double Point Controllable/Double Command with feedback or BSC = Binary-Controlled Step Position Indication / transformer tap command with feedback).

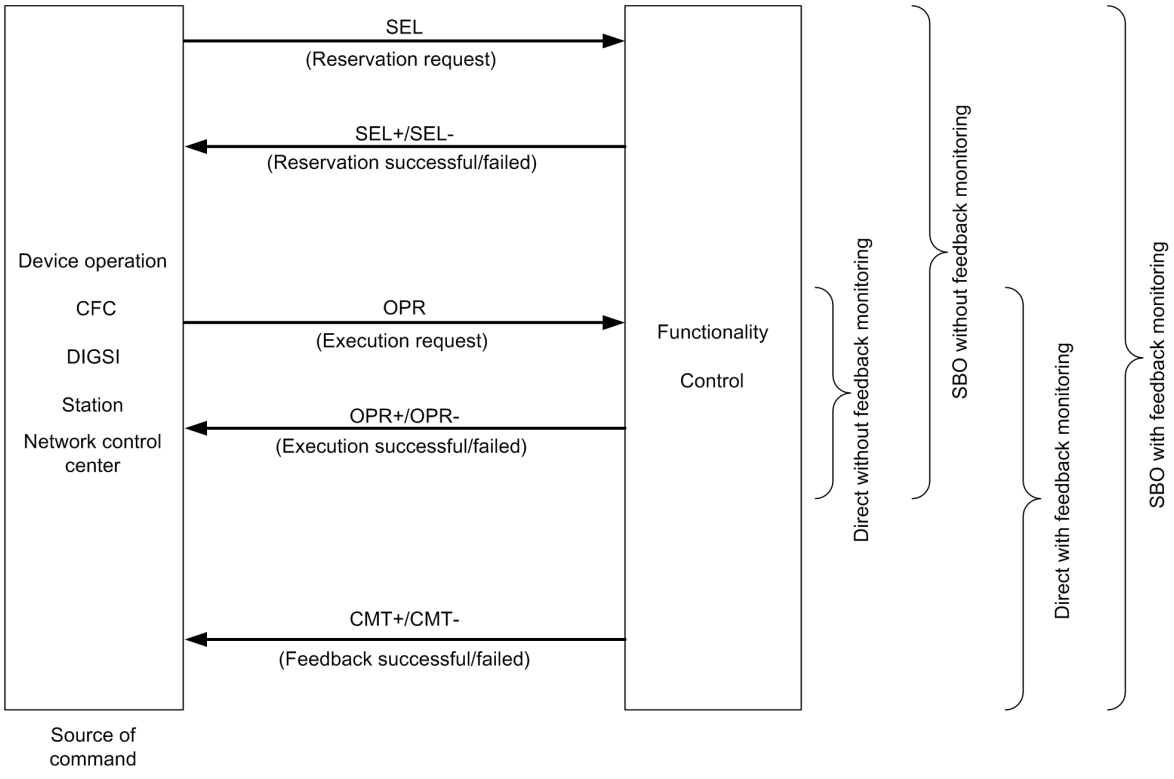
[sc_contrl, 1, en_US]

(1) Position (connect with binary inputs)

(2) Signalization of the current condition

(3) Command output (connect with relay)

The trip, opening and the close commands are connected to the relays. For the trip command, a choice between saved and unsaved output is possible. The position is connected with 2 binary inputs (double-point indication). In addition, signals are available that display the current state of the switch (**not selected**, **off**, **on**, **intermediate position**, **disturbed position**). These signals can be queried in CFC for example, in order to build interlocking conditions.



Control Models

You can set the operating mode of the controllables by selecting the control model.

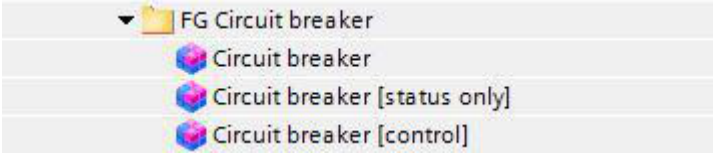
4 different control models are available:

- Direct without feedback monitoring (**`direct w. normal secur.`**)
- With reservation (SBO)[19] without feedback monitoring (**`SBO w. normal secur.`**)
- Direct with feedback monitoring (**`direct w. enh. security`**)
- With SBO with feedback monitoring (**`SBO w. enh. security`**)

The next figure shows the command sources, command types, and control models.

[dwsteuer-190912-01.tif, 1, en_US]

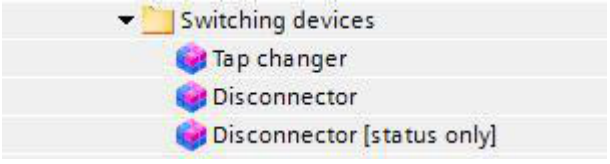
Figure 8-1 Command Sources, Command Types and Control Models



The figure shows the control models (right) with the respective control mechanisms (center). The standard control model for a switching command in an IEC 61850 compliant system is **SBO with feedback monitoring** (**`SBO w. enh. security`**). This control model is the default setting for newly created switching devices.

[19] SBO: Select Before Operate

8.2 Switching Devices



8.2.1 General Overview

The following switching devices can be found in the DIGSI 5 library in the **Circuit-breaker** and **Switching-devices** function groups (see the following images).

[sccbausw, 1, en_US]

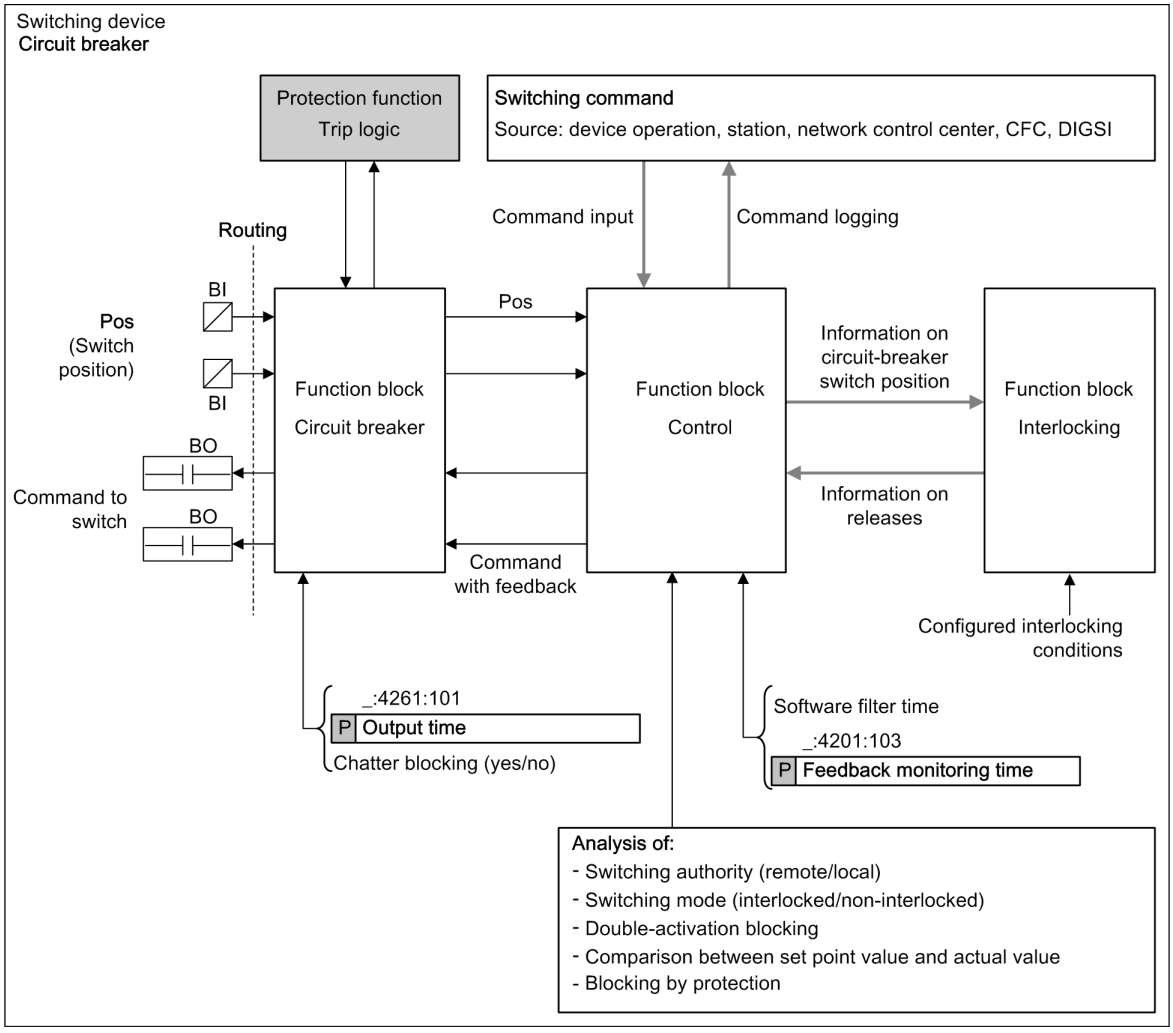
Figure 8-2 Selecting the Circuit-Breaker Switching Device Using the DIGSI Circuit-Breaker Function Group Menu

[scswausw, 1, en_US]

Figure 8-3 Selecting the Remaining Switching Devices Using the DIGSI Switching-Devices Menu

8.2.2 Switching Device Circuit Breaker

8.2.2.1 Structure of the Circuit-Breaker Switching Device



This chapter describes the control properties of the **Circuit breaker** switching device.

The **Circuit breaker** switching device contains the following function blocks that are needed for control:

- Function block **Circuit breaker**
- Function block **Control**
- Function block **Interlocking**

This corresponds to the logical nodes XCBR, CSWI, and CILO in IEC 61850.

In the case of protection devices or combined protection and control devices, additional functions can be contained in the **circuit breaker** switching device, for example, **synchrocheck**, the **automatic reclosing (AREC)**, the **trip logic** or **manual On function**. However, these are not relevant for the control function. The description of these functions is in the chapter Protection and Automatic Functions..

[dwbreake-220512-01.tif, 1, en_US]

Figure 8-4 Control Function Blocks of the Circuit-Breaker Switching Device

The circuit breaker in DIGSI 5 is linked with the binary inputs that acquire the switch position via information routing. The circuit breaker in DIGSI 5 is also linked with the binary outputs that issue the switching commands.

NOTE

When setting the parameters of a device, you will find 2 circuit-breaker types in the DIGSI 5 library:

- **3-pole circuit breaker** or **1-pole circuit breaker**, depending on the device type selected (3-pole or 1-pole tripping)
- **Circuit breaker (status only)**

Function Blocks of the Circuit Breaker

Table 8-1 Function Blocks of the Circuit-Breaker Function Group

Function Block	Description	Parameters	Function
Circuit breaker	The Circuit breaker function block in the SIPROTEC 5 device represents the physical switch.	**`Output time`**	The circuit breaker forms the switch position from the positions of the binary inputs and also outputs the command via the binary outputs.
Control	Command processing	**`Control model`** **`SBO time-out`** **`Feedback monitoring time`** **`Check switching authority`** **`Check if pos. is reached`** **`Check double activat. blk.`** **`Check blk. by protection`**	Command check, communication with the command source and with the function block **Circuit breaker**
Interlocking	Switchgear interlocking protection	Interlocking condition (deposited in CFC)	The **Interlocking** functionality generates the releases for switchgear interlocking protection.

The setting values of the parameter can be found in the chapter *8.2.2.2 Application and Setting Notes*.

Additional Setting Options of the Circuit-Breaker Switching Element

The setting options of the circuit breaker are assigned to the function blocks on the basis of their relevance. Additional setting options of the circuit breakers that cannot be directly assigned to one of the 3 function blocks are nevertheless available:

Table 8-2 Setting Options of the Controllable **`Command with Feedback`** in the **`Control`** Function Block of the Circuit Breaker.

Properties	Function	To Be Found in
`Software filtering time`	Software filtering time for position detection	Position of the **Control**(1) function block
`Retrigger filter` (yes/no)	Switching retriggering of the filtering time on/off by changing the position	Position of the **Control**(1) function block
`Message time before filtering` (yes/no)	Consideration of the hardware filtering time for position-detection time stamp	Position of the **Control**(1) function block
`Suppress intermediate position` (yes/no)	When activated, only the intermediate position is suppressed by the duration of the software filtering time.	Position of the **Control**(1) function block

Properties	Function	To Be Found in
Treatment of spontaneous position changes (Gen. software filt./Spont. software filt.)	If the ***General software filter*** setting is selected, the general settings for software filtering of spontaneous position changes and for position changes caused by a switching command apply. By selecting ***Spontaneous software filter***, a separate filtering is activated for spontaneous position changes.	Position of the **Control**(1) function block
Spontaneous software filtering time	Software filtering time for spontaneous position changes	Position of the **Control**(1) function block
Spontaneous retrigger filter (yes/no)	Switching on/off retriggering of the filtering time by spontaneous position change	Position of the **Control**(1) function block
Spontaneous indication timestamp before filtering (yes/no)	Consideration of the hardware filtering time for position-detection time stamp in case of a spontaneous change	Position of the **Control**(1) function block
Inhibit intermediate position for a spontaneous chng. (yes/no)	When activated, only the spontaneous change to the intermediate position is suppressed by the duration of the software filtering time.	Position of the **Control**(1) function block

Table 8-3 Setting Options of the Controllable **Position** in the Circuit Breaker Function Block (Chatter Blocking)

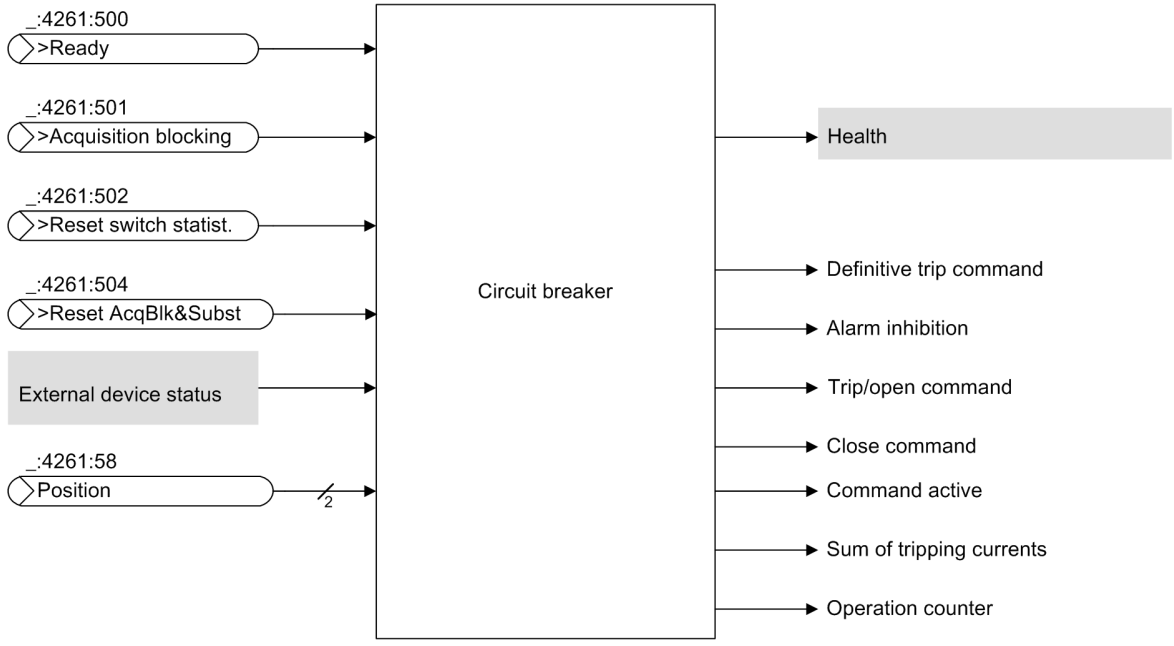
Properties	Function	To Be Found in
Chatter blocking (yes/no)	Switching chatter blocking on/off	Position of the **Circuit breaker** (1) function block

(1) First click **Position** and then click the **Details** button in the **Properties** window (below).

Table 8-4 Additional Settings in the Device Settings having Effects on the Circuit Breaker

Properties	Function	To Be Found in
Number of permissible status changes	Chatter-blocking setting value: Once for the entire device	Device settings (to be found under Settings)
Chatter test time		
Number of chatter tests		
Chatter idle time		
Chatter check time		

The inputs and outputs as well as the setting options of the **Circuit-breaker** and **Control** function blocks are described in the next section (see *8.2.2.3 Connection Variants of the Circuit Breaker*).



Interlocking

The **Interlocking** function block generates the releases for switchgear interlocking protection. The actual interlocking conditions are deposited in CFC. For more information on this, see chapter *8.3.1 Command Checks and Switchgear Interlocking Protection*.

8.2.2.2 Application and Setting Notes

Circuit Breaker

The Circuit breaker function block in the SIPROTEC 5 device represents the physical switch device. The task of the circuit breaker is to replicate the switch position from the status of the binary inputs.
The following figure shows the logical inputs and outputs of the **Circuit-breaker** function block.

[dwfuncls-140212-01.tif, 2, en_US]

Figure 8-5 Logical Inputs and Outputs of the Circuit-Breaker Function Blocks

Table 8-5 and *Table 8-6* list the inputs and outputs with a description of their function and type. For inputs, the effect of **Quality = invalid** on the value of the signal is described.

EXAMPLE

If the signal **>Ready** has the **Quality = invalid**, then the value is set to **cleared**. In problematic operating states, the circuit breaker should signal that it is not ready for an **Off-On-Off cycle**.

Table 8-5 Inputs of the Circuit-Breaker Function Block

Signal Name	Description	Type	Default Value if Signal Quality = invalid
>Ready	The signal **>Ready** indicates that the OFF-ON-OFF cycle is possible with the circuit breaker. This signal is used for the AREC standby status.	SPS	Going
>Acquisition blocking	The binary input activates acquisition blocking. You can also set this binary input with an external toggle switch.	SPS	Unchanged
>Reset AcqBlk&Subst	Acquisition blocking and the substitution of the circuit breaker are reset with this input. If the input is activated, setting the acquisition blocking and the substitution is blocked.	SPS	Unchanged
>Reset switch statist.	Among other things, the binary input sets the operation counter for the switch to the value 0.	SPS	Unchanged

Signal Name	Description	Type	Default Value if Signal Quality = invalid
External health	The binary input **External health** reflects the circuit-breaker status (EHealth). This input will be set by the CFC using the BUILD_ENS block. In turn, BUILD_ENS can query binary inputs that represent the conditions ***OK***, ***Warning***, ***Alarm*** (as a result of the function **Trip-circuit supervision**).	ENS	Unchanged
Position	The signal **Position** can be used to read the circuit-breaker position with double-point indication.	DPC	Unchanged

If the quality of the input signal assumes the status **Quality = invalid**, then the standby status (EHealth) of the **Circuit-breaker** function block is set to *Warning*.

Table 8-6 Outputs of the Circuit-Breaker Function Block

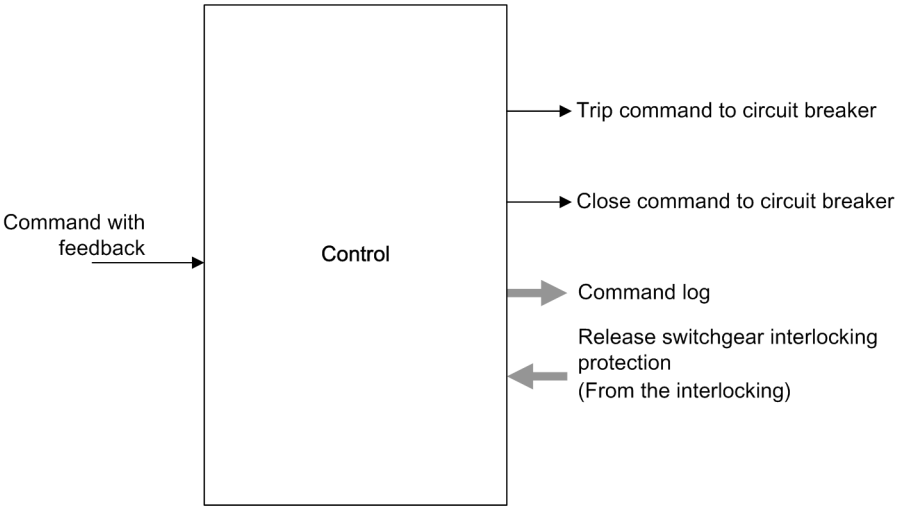
Signal Name	Description	Type
Definitive trip	Protection has finally been tripped.	SPS
Alarm suppression	The signaling contact for external alarm suppression is suppressed during the runtime of automatic reclosing (optional) as well as during the command output of switching commands.	SPS
Op.ct.	The information counts the number of switching cycles of the circuit breaker.	INS
Trip/open cmd.	This logic output is responsible for the command output **Off**.	SPS
Close command	This logic output is responsible for the command output **On**.	SPS
Command active	The binary output **Command active** is responsible for signaling a running command (relay active or selected switching device (SEL)).	SPS
CB open hours	The statistic value counts the hours the circuit breaker is open.	INS
Operating hours	The statistic value counts the hours where at least one phase current is greater than the **Current thresh. CB open** parameter.	INS

Control

It is the task of the controls to execute command checks and establish communication between the command source and the circuit breaker. Using the control settings, you specify how the commands are to be processed.

Through the function SBO (Select Before Operate, reservation[20]) reserves the switching device prior to the actual switching operation, thus it remains locked for additional commands. Feedback monitoring provides information about the initiator of the command while the command is in process, that means, informing whether or not the command was implemented successfully. These two options can be selected individually in the selection of the control model, so that 4 combinations in total are available (see the following table).

The control makes the following settings available (see next table).



Parameters	Default Setting	Possible Parameter Values
(_:4201:101) Control model	***SBO w. enh. security***[21]	***direct w. normal secur.*** ***SBO w. normal secur.*** ***direct w. enh. security*** ***SBO w. enh. security***
(_:4201:102) SBO time-out	***30.00 s***	0.01 s to 1800 s (Increment: 0.01 s)
(_:4201:103) Feedback monitoring time	***1.00 s***	0.01 s to 1800 s (Increment: 0.01 s)

[20] In the IEC 61850 standard, reservation is described as **Select before Operate (SBO)**.

[21] This default setting is the standard control model for a switching command in an IEC 61850-compliant system.

Parameters	Default Setting	Possible Parameter Values
(_:4201:104) Check switching authority	*yes*	*no* *yes* *advanced*
(_:4201:105) Check if pos. is reached	*yes*	*no* *yes*
(_:4201:106) Check double activat. blk.	*yes*	*no* *yes*
(_:4201:107) Check blk. by protection	*yes*	*no* *yes*

The following figure shows the logical inputs and outputs of the **Control** function block.

[dwsteue1-100611-01.tif, 1, en_US]

Figure 8-6 Logical Inputs and Outputs of the Control Function Block

Table 8-7 Control Function Block Input and Output

Signal Name	Description	Type	Value if Signal Quality=Invalid
Cmd. with feedback	With the **Cmd. with feedback** signal, the circuit-breaker position is accepted via the double-point indication of the **Circuit breaker** function block and the command is submitted.	Controllable (DPC) Unchanged	Unchanged

In the information routing of DIGSI 5, you may select a function key as a possible command source. In addition, it is displayed here if the command is activated by CFC. The logging is routed here.

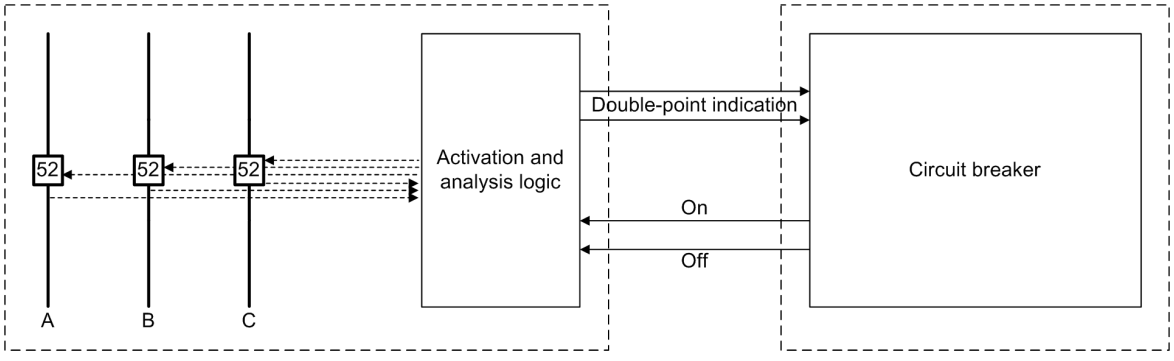
8.2.2.3 Connection Variants of the Circuit Breaker

For each switching device, you can establish the number of poles (for example, 1-pole, 1.5-pole or 2-pole) that are switched with or without feedback. This results in the necessary amount of information to be processed, thus establishing the command type.

Whether the circuit breaker is triggered 1-, 1.5-, or 2-phase, depends on the design of the auxiliary and control-voltage system. In most cases, the activation of the opening coil of the circuit breaker is 1-pole.

Table 8-8 Meaning of the Abbreviations of the Connection Variants

Abbreviation	Meaning of the Abbreviations of the Connection Variants
BO	Binary output

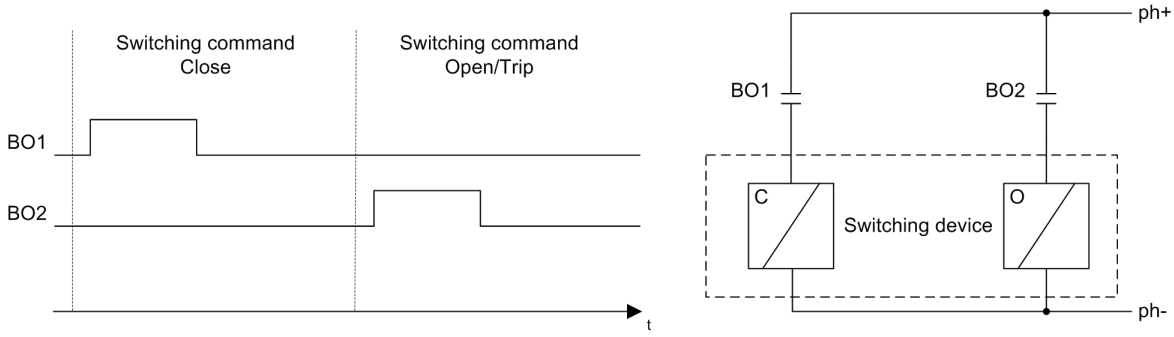


Abbreviation	Meaning of the Abbreviations of the Connection Variants
L+; L-	Control voltage
A	Trip command
Gnd	Close command

Table 8-9 Meaning of the Abbreviations in DIGSI

Abbreviation	Description of the Input in DIGSI
U	Unsaved trip command Click the right mouse button and enter **U**.
X	Close Command Click the right mouse button and enter **X** for the respective binary output.
OH	The switching-device feedback is in the position **OFF**, if there is voltage at the routed binary input (H). Click the right mouse button and enter **OH**.
OL	The switching-device feedback is in the position **OFF**, if there is no voltage at the routed binary input (L). Click the right mouse button and enter **OL**.
GH	The switching-device feedback is in the position **ON**, if there is voltage at the routed binary input (H). Click the right mouse button and enter **CH**.
CL	The switching-device feedback is in the position **ON**, if there is no voltage at the routed binary input (H). Click the right mouse button and enter **CL**.
TL	Trip command stored Click the right mouse button and enter **TL**.

Connection Variant: 3-Pole Circuit Breaker



This is the standard type for the control function. All 3 individual poles of the circuit breaker are triggered together by a double command.

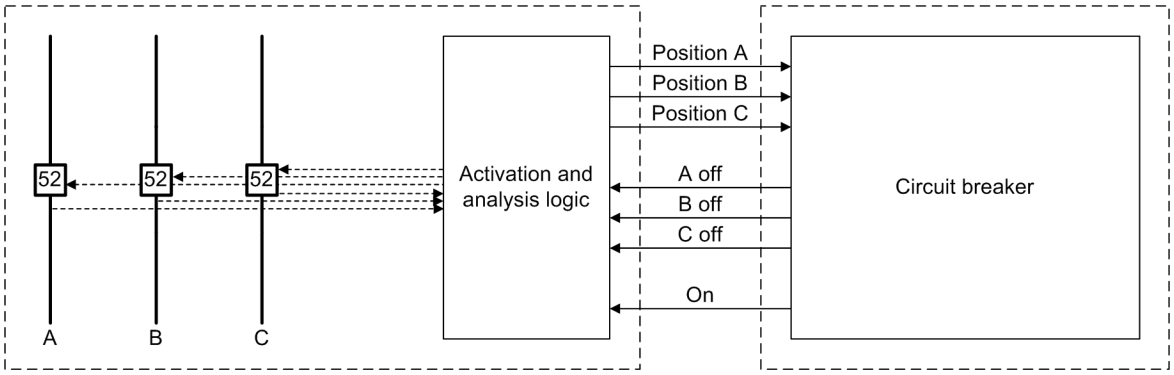
Figure 8-13 2-Pole Triggering, Routing in DIGSI

Connection Variant: 1-Pole Circuit Breaker

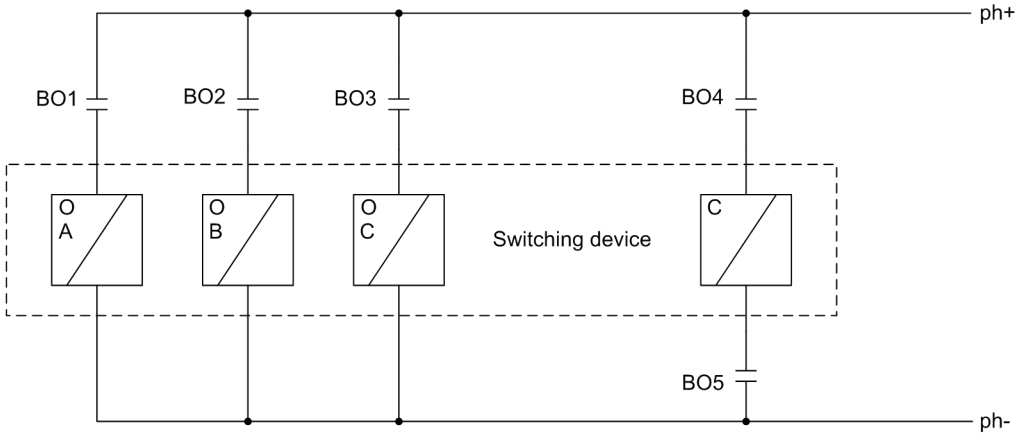


The 1-pole circuit breaker is used for separate activation and acquisition of the individual poles of a circuit breaker. It is intended for common use by 1-pole working protection and control functions.

NOTE

The wiring of the **Circuit-breaker** function group with binary inputs and binary outputs occurs once per device .

The control function in this type switches all 3 poles on or off simultaneously.



The protection functions can switch off 1-pole. The close command is always 3-pole. Optionally, only the open poles close.

[dw1polls-020211-01.tif, 1, en_US]

Figure 8-14 Circuit Breaker with 1-Pole Triggering

For the circuit breaker with 1-pole triggering, triggering takes place via one relay per phase for the trip command and via a 4th relay for the close command (see next figure).

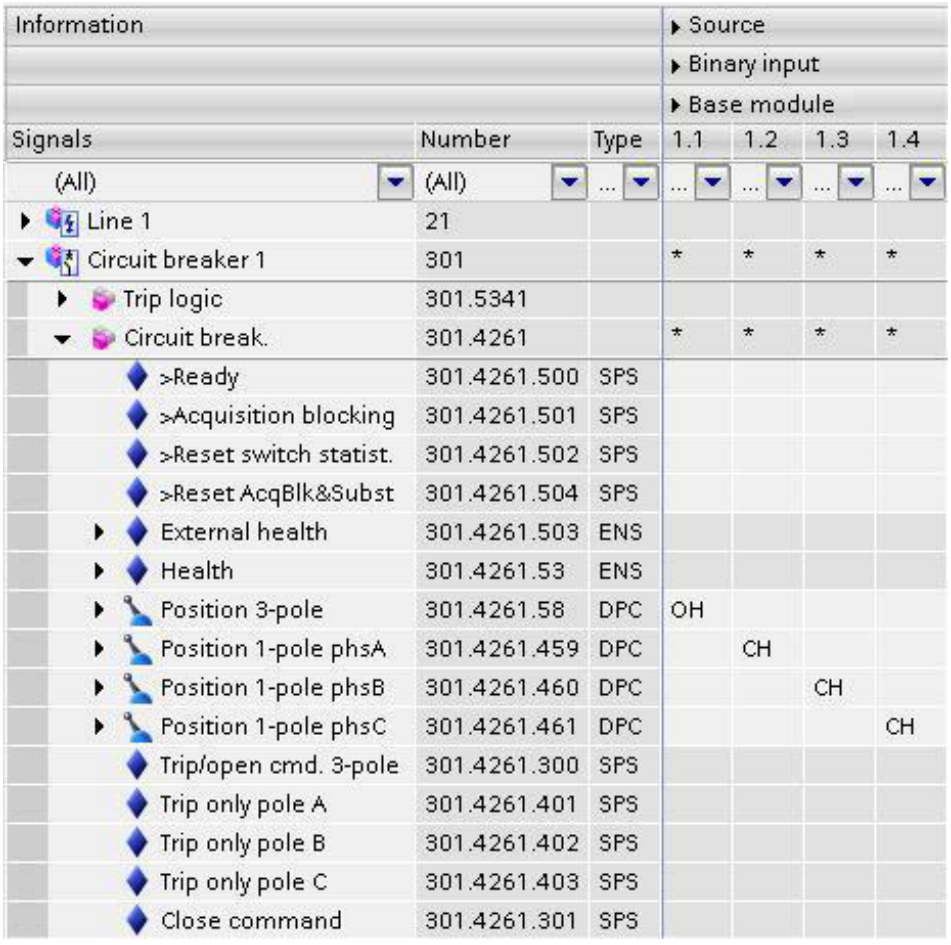
[scrang1pLS13pz, 1, en_US]

Figure 8-16 Routing in DIGSI

In the previous figure, the switch is connected 1-pole. The protection trip command is routed individually for the 3 phases (**`Trip only pole A`** to **`Trip only pole C`**). The protection trip command is routed for the 3 phases (**`Trip/open cmd. 3-pole`**). The control will always switch off the 3 poles of the switch. In addition, the 3 **U** (Unsaved) allocations of the activation and trip command are set to 3-pole. This routing is also used by protection functions that trip 3 poles. The close command is issued simultaneously for all 3 phases.



Example: Trip Command during Transition from 1-Pole to 3-Pole

During a transition from 1-pole to 3-pole tripping, **`Trip only pole A`** remains active. To inform, for example, an external AREC whether it is a 1-pole or 3-pole trip, you can use the indications *`Trip logic:Trip indication:1-pole`* and *`Trip logic:Trip indication:3-pole`*.

Acquisition of the Circuit-Breaker Position

The routing of the binary inputs for feedback of the switch position is done as shown in the previous figure (also see Chapter *5.7.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information*).

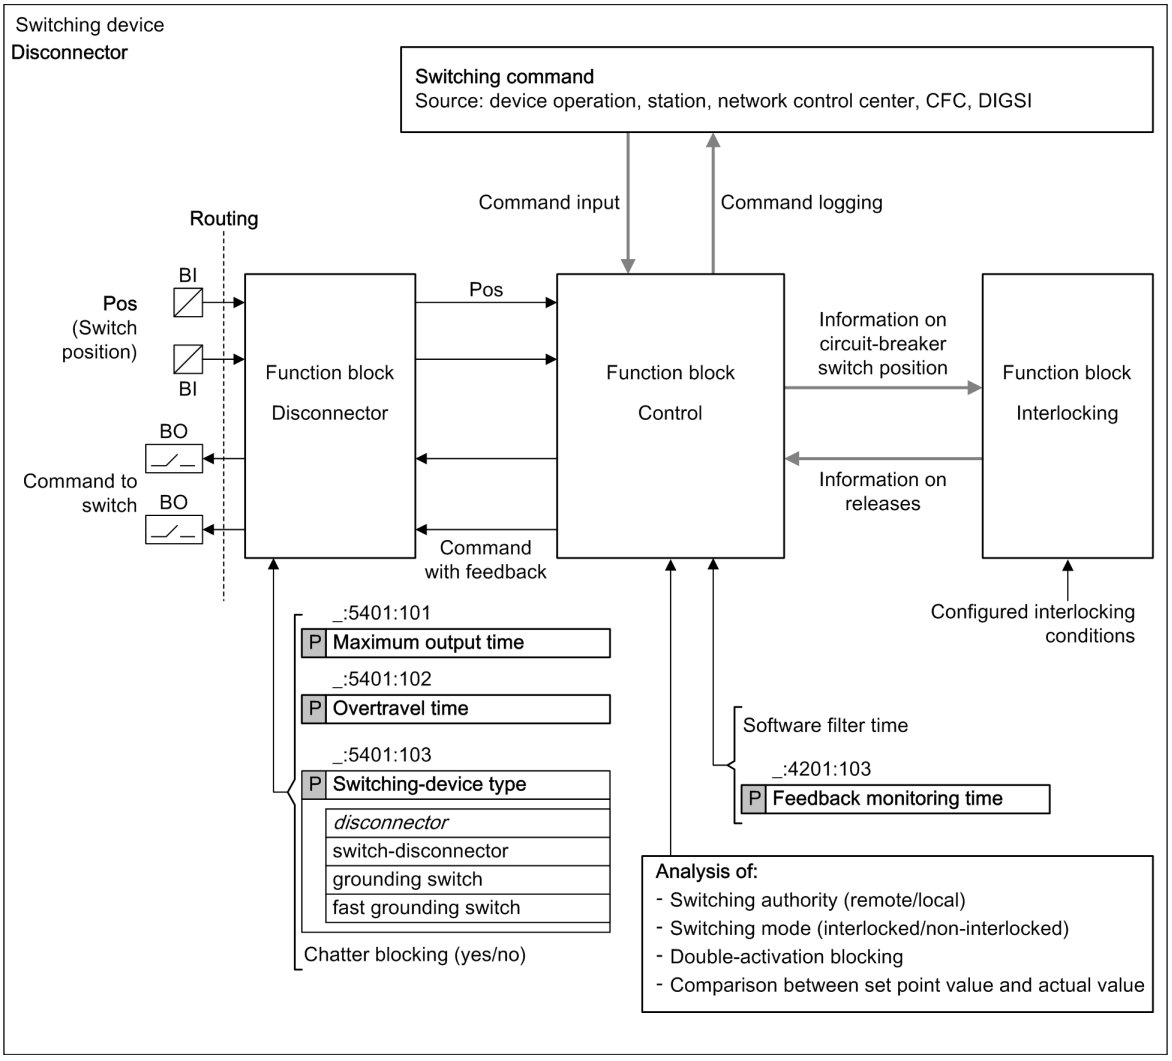
8.2.3 Disconnector Switching Device

8.2.3.1 Structure of the Disconnector Switching Device

Like the circuit breaker, the **Disconnector** switching device contains the following 3 function blocks:

- Function block **Disconnector**
- Function block **Control**
- Function block **Interlocking**



This corresponds to the logical nodes XSWI, CSWI und CILO in IEC 61850.

NOTE

In contrast to the **Circuit-breaker** switching device, the **Disconnector** switching device cannot contain any additional functions because protection functions or synchronization can have no effect on the disconnector.

The following figure shows the structure of the **Disconnector** switching element:

[dwdiscon-190612-01.tif, 1, en_US]

Figure 8-18 Control-Relevant Function Blocks of the Disconnector Switching Device

The **Disconnector** switching device behaves like the **Circuit-breaker** switching device. The only difference is the designation of the function block that the physical switch provides (disconnector instead of circuit breaker). Blocking by protection is not provided in the analysis of the **Control** function block.

The **Disconnector** switching device is available in the DIGSI 5 library in 2 different variants:

- **Disconnector with 3-pole connection**
  The device switches all 3 poles of the disconnector on or off simultaneously.
- **Disconnector without triggering (only status detection, no control)**
  This variant is rarely encountered. It is encountered with grounding switches that frequently cannot be controlled, but only provide their current position. In addition, the position of a disconnector in a neighboring bay can be acquired.

Function Blocks of the Disconnector

Table 8-10 Function Blocks of the Disconnector Function Group

Function Block	Description	Settings	Function
Discon-nector	The disconnector represents the physical switch in the SIPROTEC 5 device.	**Maximum output time** **Overtravel time** **Switching-device type**	The disconnector replicates the switch position from the status of the binary inputs and also transmits the command via the binary outputs.
Control	Command processing	**Control model** **SBO time-out** **Feedback monitoring time** **Check switching authority** **Check if pos. is reached** **Check double activat. blk.**	Command checks, communication with the command source and with the function block **disconnector**
Inter-locking	Switchgear interlocking protection	Interlocking condition (deposited in CFC)	The **Interlocking** functionality generates the releases for switchgear interlocking protection.

The setting values of the parameter can be found in the chapter *8.2.3.2 Application and Setting Notes*.

Additional Settings of Disconnector Switching Element

The settings of the disconnector are assigned to the function blocks on the basis of their relevance. Additional disconnector settings that cannot be directly assigned to one of the 3 function blocks and are identical to the circuit-breaker settings are available:

Table 8-11 Setting positions of the Controllable **Command with Feedback** in the **Control** Function Block of the Circuit Breaker

Properties	Function	To Be Found in
Software filtering time	Software filtering time for position detection	Position of the **Control**(1) function block
Retrigger filter (yes/no)	Switching retriggering of the filtering time on/off by changing the position	Position of the **Control**(1) function block
Message time before filtering (yes/no)	Consideration of the hardware filtering time for position-detection time stamp	Position of the **Control**(1) function block
Suppress intermediate position (yes/no)	When activated,only the intermediate position is suppressed by the duration of the software filtering time.	Position of the **Control**(1) function block

Properties	Function	To Be Found in
Spontaneous position changes filtered by (Gen. software filt./Spont. software filt.	If the ***General software filter*** setting is selected, the general settings for software filtering of spontaneous position changes and for position changes caused by a switching command apply. By selecting ***Spontaneous software filter***, a separate filtering is activated for spontaneous position changes.	Position of the **Control**(1) function block
Spontaneous software filter time	Software filtering time for spontaneous position changes	Position of the **Control**(1) function block
Spontaneous retrigger filter (yes/no)	Switching on/off retriggering of the filtering time by spontaneous position change	Position of the **Control**(1) function block
Spontaneous indication timestamp before filtering (yes/no)	Consideration of the hardware filtering time for position-detection time stamp in case of a spontaneous change	Position of the **Control**(1) function block
Spontaneous suppress intermediate position (yes/no)	When activated, only the spontaneous change to the intermediate position is suppressed by the duration of the software filtering time.	Position of the **Control**(1) function block

(1) First click **Position** and then the **Details** key in the **Properties** window (below).

Table 8-12 Setting Options of the Controllable **Position** in the Disconnector Function Block (Chatter Blocking)

Properties	Function	To Be Found in
Chatter blocking (yes/no)	Switching chatter blocking on/off	Position of the **Disconnector** (1) function block

(1) First click **Position** and then the **Details** key in the **Properties** window (below).

Table 8-13 Additional Settings in the Device Settings with effect on the Disconnector

Properties	Function	To Be Found in
Number of permissible state changes	Chatter-blocking setting value: Once for the entire device	Device settings (to be found under Settings)
Chatter test time		
Number of chatter tests		
Chatter dead time		
Chatter test time		

The inputs and outputs as well as the setting options of the **Disconnector switch** function block are described in the next chapter (see *8.2.3.3 Trigger Variants of the Disconnector*. The **Control** function block is described identically as the **Circuit-breaker** function block, with the exception that the command check blocking is available through protection only with the circuit breaker.

More information on this is can be found in chapter *8.2.2.2 Application and Setting Notes*

Interlocking

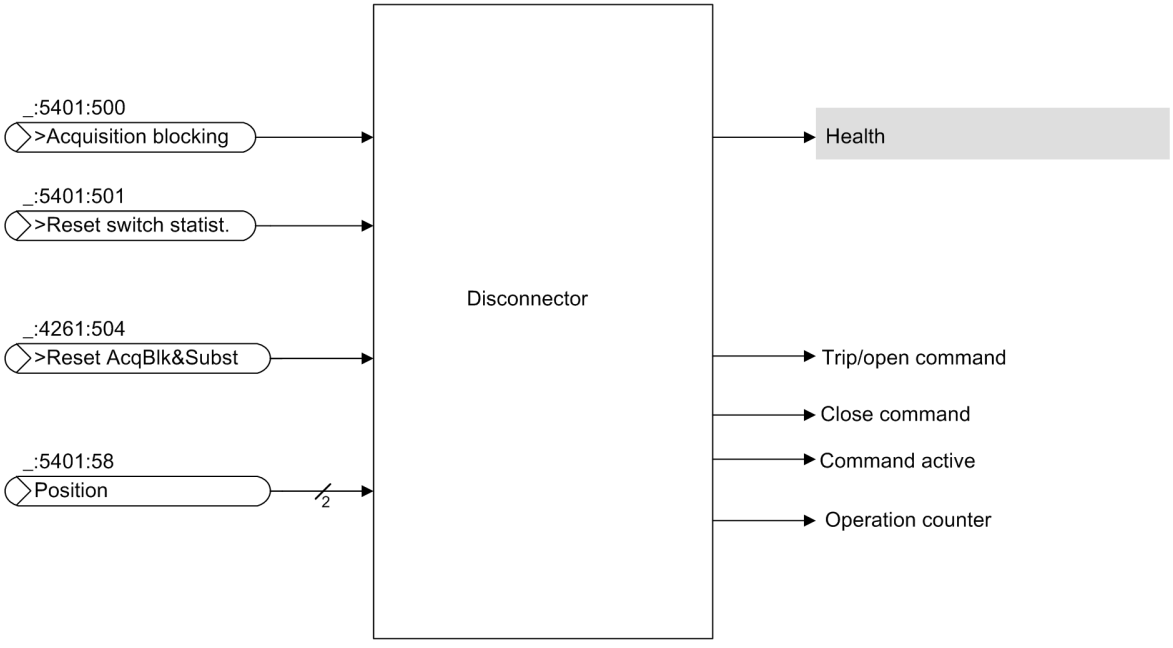
The **Interlocking** function block generates the releases for switchgear interlocking protection. The actual interlocking conditions are deposited in CFC. For more information on this, see section *8.3.1 Command Checks and Switchgear Interlocking Protection*.

8.2.3.2 Application and Setting Notes

Disconnector

The disconnector represents the physical switch in the SIPROTEC 5 device. The task of the disconnector is to replicate the switch position from the status of the binary inputs.

The **Disconnector** function block is linked automatically via the information matrix with the binary inputs that register the switch position and with the binary outputs that issue the switching commands.



The **Disconnector** function block makes the following settings available (see next table).

Settings	Default Setting	Possible Parameter Values
(_:5401:101) Maximum output time	***10.00 s***	0.01 s to 1800 s (Increment: 0.01 s)
(_:5401:102) Overtravel time	***0.00 s***	0 s to 60 s
(_:5401:103) Switching-device type	***disconnector***	***switch-disconnector*** ***disconnector*** ***grounding switch*** ***fast grounding switch***

NOTE

The parameter **Switching-device type** is effective only on the IEC 61850 interface. This parameter is used to set the disconnector type for communication via an IEC 61850 interface. It is a mandatory data object in the IEC 61850 standard.

The following figure shows the logical inputs and outputs of the **Disconnector** function block.

[dwoutinp-150212-01.tif, 2, en_US]

Figure 8-19 Logical Inputs and Outputs of the Disconnector Function Block

Table 8-14 and *Table 8-15* list the inputs and outputs with a description of their function and type. For inputs, the effect on **Quality = invalid** on the value of the signal is described.

Table 8-14 Inputs of the Disconnector Function Block

Signal Name	Description	Type	Value if Signal Quality=Invalid
>Acquisition blocking	The binary input activates acquisition blocking. You can also set this binary input with an external toggle switch.	SPS	Unchanged
>Reset AcqBlk&Subst	Acquisition blocking and the substitution of the circuit breaker are reset with this input. If the input is activated, setting of the acquisition blocking and of the substitution is blocked.	SPS	Unchanged
>Reset switch statist.	The binary input sets the operation counter for the switch to the value 0.	SPS	Unchanged
Position	The binary input **Position** can be used to read the disconnector position with double-point indication.	DPC	Unchanged

If the quality of the input signal assumes the status **Quality = invalid**, then the standby status (Health) of the **Disconnector** function block is set to *warning*.

Table 8-15 Outputs of the Disconnector Function Block

Signal Name	Description	Type
Open command	This binary output is responsible for the command output **Off**.	SPS
Close command	This binary output is responsible for the command output **On**.	SPS
Command active	The binary output **Command active** is a running command for the signalization (command active or selected switching device). During Command active either an On or Off command is active.	SPS
Op.ct.	The information counts the number of disconnector switching cycles.	INS

Control

It is the task of the controls to execute command checks and establish communication between the command source and the disconnector. Using the control settings, you specify how the commands are to be processed.

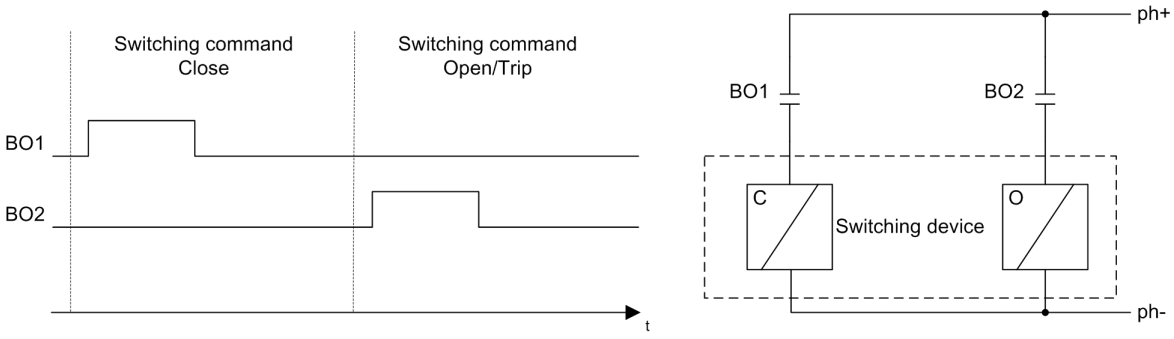
Through the function SBO (Select Before Operate, reservation[22]) selects the switching device prior to the actual switching function, thus it remains locked for additional commands. Feedback monitoring provides information about the initiator of the command while the command is in process, that means, informing whether or not the command was implemented successfully. These two options can be selected individually in the selection of the control model, so that 4 combinations in total are available (see the following table).

The control makes the following settings available (see next table).

Settings	Default Setting	Possible Parameter Values
(_:4201:101) Control model	***SBO w. enh. security***[23]	***direct w. normal secur.*** ***SBO w. normal secur.*** ***direct w. enh. security*** ***SBO w. enh. security***
(_:4201:102) SBO time-out	***30.00 s***	-
(_:4201:103) Feedback monitoring time	***10.00 s***	-

[22] in standard IEC 61850, Reservation is described as **Select before Operate (SBO)**.

[23] The default setting is the standard control model for a switching command in an IEC 61850-compliant system.



Settings	Default Setting	Possible Parameter Values
(_:4201:104) Check switching authority	*yes*	*no* *yes* *advanced*
(_:4201:105) Check if pos. is reached	*yes*	*no* *yes*
(_:4201:106) Check double activat. blk.	*yes*	*no* *yes*

8.2.3.3 Trigger Variants of the Disconnector

The activation types are identical to those for the circuit breaker. The meaning of abbreviations can be found in *8.2.2.3 Connection Variants of the Circuit Breaker* and *8.2.2.3 Connection Variants of the Circuit Breaker*.

Whether the disconnector is triggered for 1-, 1.5-, or 2-phases depends on the design of the auxiliary and control voltage system.

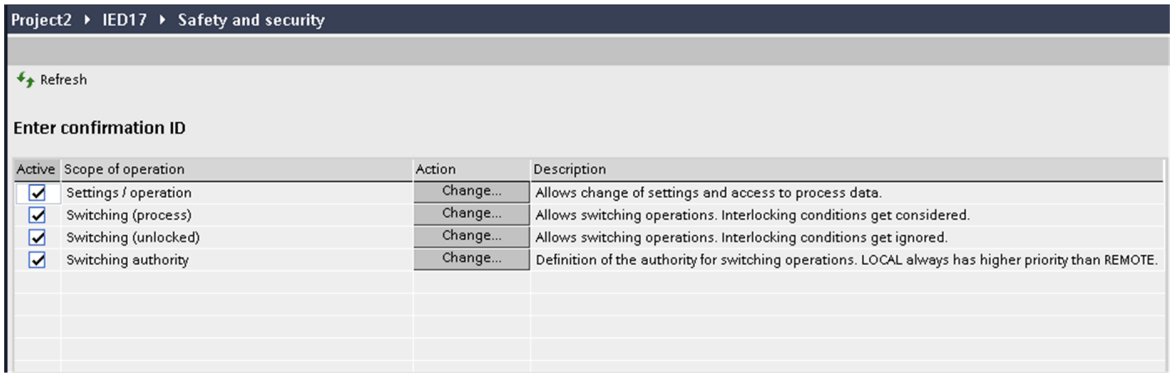
8.3 Control Functionality



8.3.1 Command Checks and Switchgear Interlocking Protection

Before switching commands can be issued by the SIPROTEC 5 device, several steps are used to check the command:

- Switching mode (interlocked/non-interlocked)
- Switching authority (local/DIGSI/station/remote)
- Switching direction (set=actual)
- Bay interlocking and substation interlocking
- 1-out-of-n check (double-activation blocking)
- Blocking by protection function

Confirmation IDs

SIPROTEC 5 devices offer the ability to safeguard various operations with **confirmation IDs**. The following **confirmation IDs** from the **Safety** menu apply to the control functions:

[scconfir-291110-01.tif, 1, en_US]

Figure 8-26 Confirmation IDs in DIGSI 5: Settings Menu

The following table identifies the meanings of the confirmation IDs:

Table 8-16 Relevant Confirmation IDs for Controls

Confirmation ID	Meaning	Description
Set/operate	Changing settings	The confirmation ID is requested before device parameters can be changed.
Control (process)	General release for control of switching devices	The confirmation ID is usually not needed for bay controllers. In the case of protection devices, this confirmation ID can be used to safeguard control of switching devices.
Control (non-interlocked)	Switching non-interlocked	Switching mode: Release for switching without querying the interlocking conditions (***S1 operation***). The fixed interlocking conditions (for example, **>Enable opening(fixed)** and **>Enable closing (fixed)**) are still queried if this is set in the parameters. The confirmation ID is queried only for devices without a key switch; otherwise it is replaced with the key switch position.

Confirmation ID	Meaning	Description
Switching Authority	Release for switching authority **Local**	The confirmation ID is queried only for devices without a key switch; otherwise it is replaced with the key switch position.

The confirmation IDs are preset with the following values:

- Set/operate 222222
- Control (process, interlocked) 333333
- Control (not-interlocked) 444444
- Switching authority local 666666

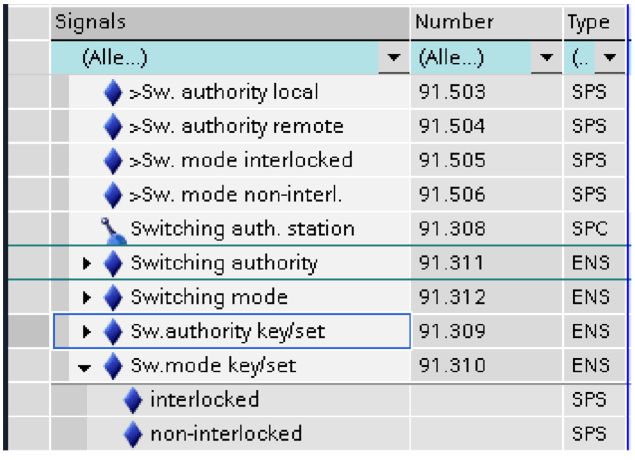
If you have configured a device with key switches, the confirmation IDs for non-interlocked switching and switching authority are not displayed or editable in DIGSI; the function is handled by the position of the key switch.

To increase security, change these codes with DIGSI.

Switching Mode (Interlocked/Non-Interlocked)

The switching mode determines whether or not the switchgear interlocking that has been configured in the CFC is checked before the command is output.

You can change the switching mode with the key switch **S1** (interlocking off/normal). For devices without a key switch, you can change the switching mode with a corresponding menu item on the display (after entering a confirmation ID). You can also set the switching mode for switching commands from the sources DIGSI, station or remote.



DANGER

If the switching mode = non-interlocked, the switchgear interlocking protection is shut off

Erroneous switching operations can lead to severe or fatal injuries.

✧ Ensure manually that all checks have been implemented.

In addition, you can set the switching mode directly with a binary input or CFC. Use the **General** function block (see next figure).

[scmoscha-260511-01.tif, 1, en_US]

Figure 8-27 Switching Mode in Function Block General

The following table shows the effects of changing the switching mode to use command checks.

Table 8-17 Relationship Between Switching Mode and Command Checks

Command Check	Switching Mode	
	Interlocked	Non-Interlocked
Switching authority	Checked	Checked
Switching direction (set=actual)	Checked	Checked
Fixed interlocking conditions	Checked	Checked
Interlocking conditions	Checked	Not checked
1-out-of-n check (double-activation blocking)	Checked	Not checked
Blocking by protection function	Checked	Not checked

Switching Authority

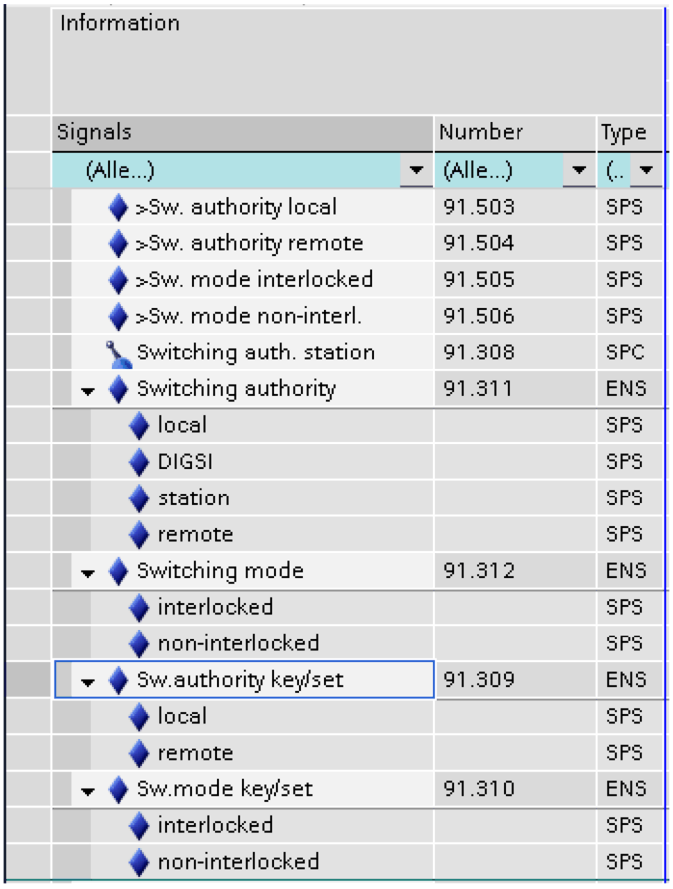
The switching authority determines which command source is allowed. The following command sources are possible:

- **Local**:

  A switching command from the local control (cause-of-error source **Location**) is possible only if the switching authority is set to **Local** and the device is capable of local operation. Setting the switching authority to **Local** is typically accomplished with key switch **S5** (Local/Remote). In this case, commands from all other sources are rejected. If the switching authority is set to **Local**, the setting cannot be changed **remotely**.

- **DIGSI**:

  A switching command from DIGSI (connected via USB or Ethernet, cause-of-error source **Maintenance**) is accepted only if the switching authority in the device is set to **Remote**. Once DIGSI has signed on the device for command output, no commands from other command sources or a different DIGSI PC will be executed.



- **Station**:

  This switching authority level can be activated via a parameter in the **General** function block. A switching command from the station level (cause-of-error source **Station** or **Automatic station**) is accepted if the switching authority is set to **Remote** and the controllable **Station switching authority** is set. This is accomplished by a command from the substation automation technology. Switching commands from the device or from outside the station (cause-of-error source **Local**, **Remote** or **Automatic remote**) are rejected.

  Full support of the this switching authority level is assured only when using the IEC 61850 protocol.

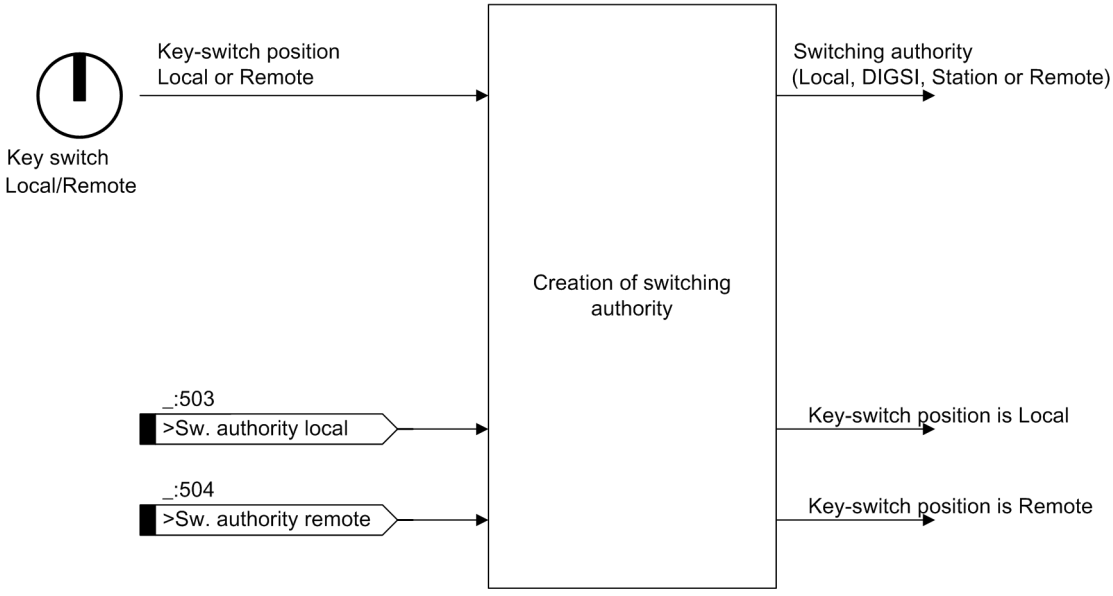
- **Remote**:

  This switching authority level stands from remote control directly from the network control center or (if the switching authority level **Station** is not activated) generally for **Remote** control. The cause-of-error source is **Automatic remote**. Commands from this level are accepted if the switching authority is set to **Remote** and the controllable **Station switching authority** is not set. Switching commands from the device or from the station (cause-of-error source **Local**, **Station** or **Automatic station**) are rejected.

[schoheit-260511-01.tif, 1, en_US]

Figure 8-28 Display of Switching Authority and Switching Mode in Information Routing (in Function Block General)

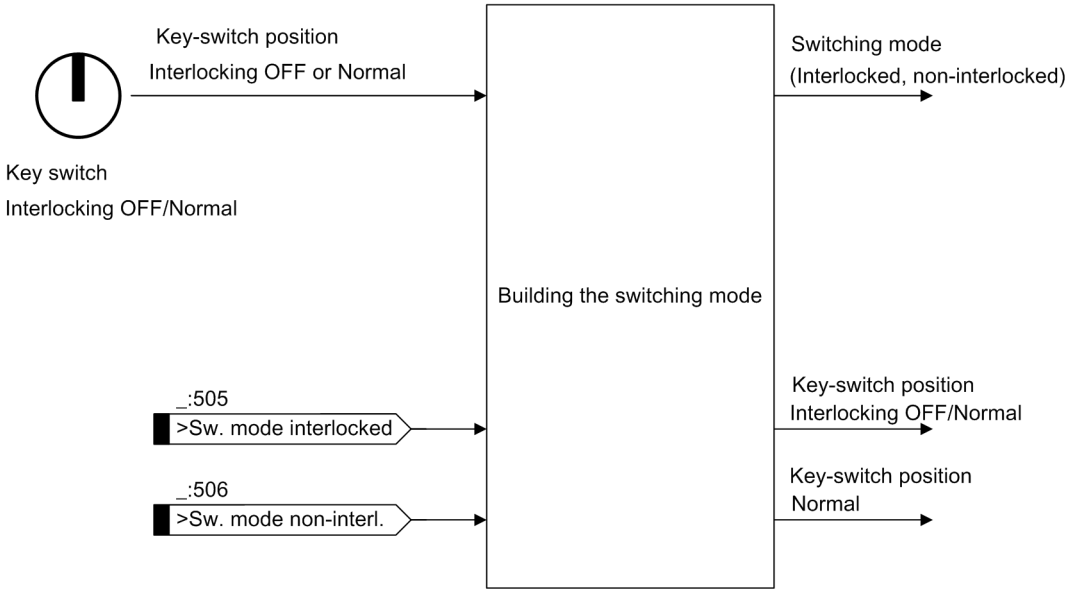
Sw. authority key/set and **Sw.mode key/set** indicate the current state of the key switch or parameter for switching authority or switching mode and provide this information for further processing in the CFC. In the CFC, for example, it is possible to set up an automatic routine to ensure that the switching authority is automatically set to ***Local*** when the key switch is set to ***not interlocked***.



The following table shows the dependency of the switching mode on the key-switch position and the switching authority. In the case of switching commands from **Remote**, the information on whether a locked or non-interlocked switching should take place is also sent. For this reason, the position of the key switch is irrelevant for the switching mode in these cases. The information in the table assumes that, in the case of **remote** switching commands or those from the **station**, the switching mode is *interlocked* in each case.

Table 8-18 Dependency of the Switching Mode on the Key Switch Position and Switching Authority

	Switching Authority		
Key switch for switching mode	**Local**	**Remote**	**Station**
Interlocked	Interlocked	Interlocked	Interlocked
Non-Interlocked	Non-Interlocked	Interlocked	Interlocked

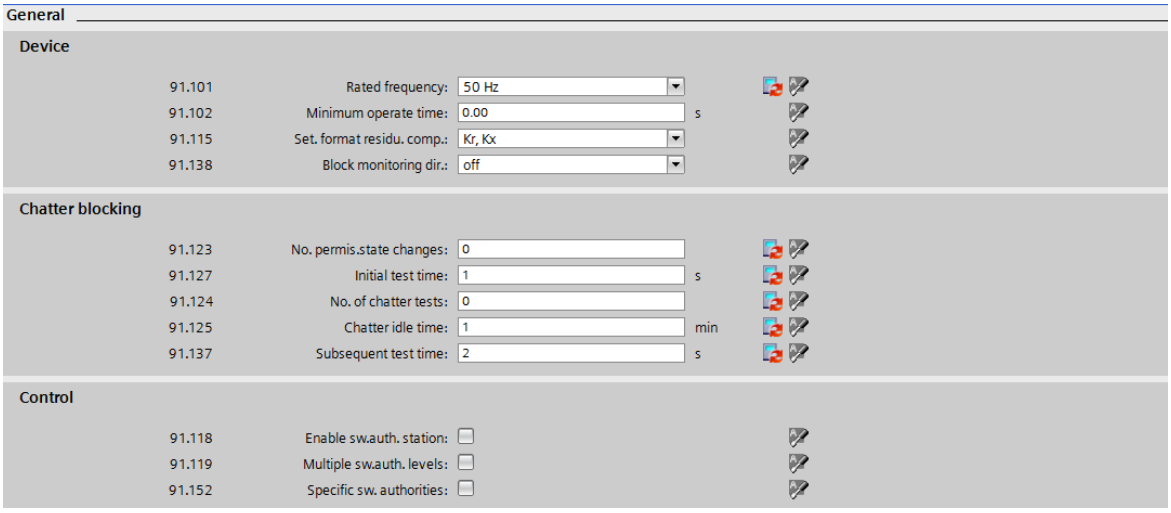


The signals shown in *Figure 8-28* in DIGSI 5 information routing have the following relationship:

- In terms of switching authority and switching mode, the respective key switch position serves as the input signal and the input signals in the matrix.
- The state of the switching authority and switching mode is indicated by corresponding output signals.
- The **Switching authority** and **Switching mode** functions link the input signals and in this way establish the output signals (see *Figure 8-29* and *Figure 8-30*).

[dwhoheit-260511-01.tif, 1, en_US]

Figure 8-29 Establishing Switching Authority



[dwmodsch-020513-01.tif, 1, en_US]

Figure 8-30 Establishing Switching Mode

In the case of both functions, the input signals overwrite the state of the key switch. This allows external inputs to also set the switching authority or switching mode, if desired (for instance, by querying an external key switch).

The following additional settings are available for the switching authority:

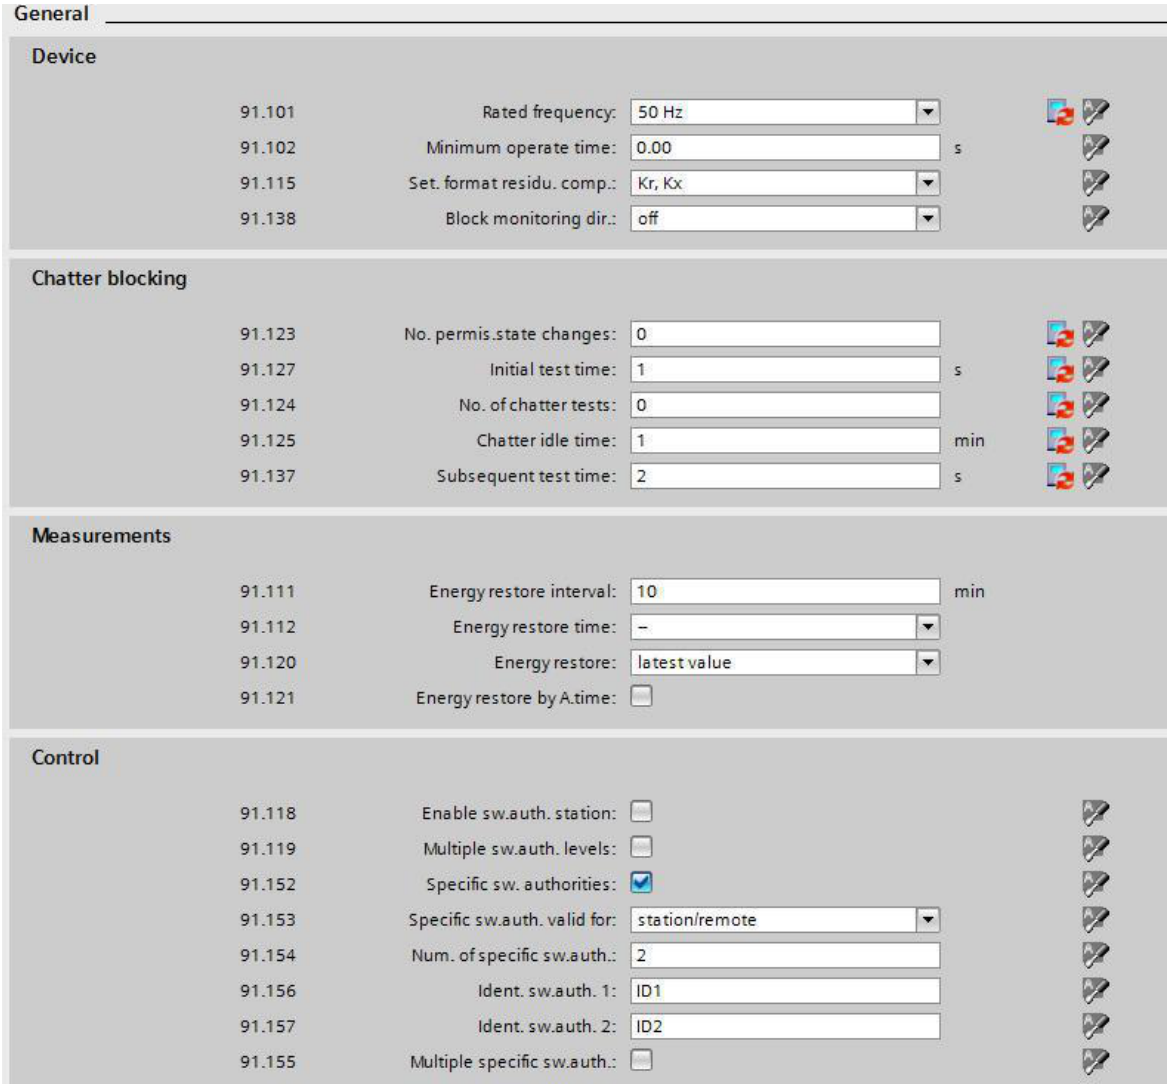
- **`Activation of Switching Authority Station`** (defined in IEC 61850 Edition 2):
  If you would like to use this switching authority, set the check mark **General/Control**.
- **`Multiple Switching Authority Levels`**:
  This option permits switching commands from several command sources in the device if the switching authority **Remote** is selected. Subsequently, a distinction between these command sources can also be made. You can find more details in the following table. Activate this option by setting the check mark **General/Control**.
- **`Specific sw. authorities`**:
  You can enable additional options for the switching authority check. You can find more information about these options in chapter *Specific Switching Authority, Page 1052*. By default, these are not used.

[scakthoh-161014, 1, en_US]

Figure 8-31 How to Activate the Station Switching Authority and to Enable Several Switching-Authority Levels

Table 8-19 Effect on Switching Authority when Several Switching-Authority Levels Are Enabled with/without Activation of the Station Switching Authority

Release Several Switching Authority Levels	Switching Authority in the Device	Status of DIGSI in the Device	Station Switching Authority Activated	State of the Station Switching Authority	Resulting Switching Authority
No	Local	-	-	-	Local
	Remote	Signed on	-	-	DIGSI
		Not signed on	No	-	Station and Remote
			Yes	Set	Station
				Not set	Remote
Yes	Local	-	-	-	Local
	Remote	Signed on	-	-	DIGSI
		Not signed on	No	-	Local and station and remote
			Yes	Set	Local and station
				Not set	Local and station and remote



The following table shows the result of the switching-authority check, based on the set switching authority and the cause of the command. This overview represents a simplified normal case (no multiple command sources when using Station and Remote).

Table 8-20 Result of a Switching-Authority Check

Cause Source	Switching Authority			
	Local	**DIGSI**	**Station**	**Remote**
Local	Release	Blocked	Blocked	Blocked
Station	Blocked	Blocked	Release	Blocked
Remote	Blocked	Blocked	Blocked	Release
Local automatic operation	Release	Release	Release	Release
Station automatic operation	Blocked	Blocked	Release	Blocked
Remote automatic operation	Blocked	Blocked	Blocked	Release
DIGSI	Blocked	Release	Blocked	Blocked

Specific Switching Authority

Special switching authorities can be configured as extension of the switching-authority check. This makes it possible to differentiate the **Remote** command sources at the bay level. Switching authorities can be routed to or revoked from different control centers that can, for example, belong to different companies. Thus, precisely one of these command sources can switch at a certain time. This function is based on extending the switching-authority check by verifying the identifier of the command source (field **Originator/orIdent** of switching command). In order to turn on the function, go to **General/Control** and set the check mark for the parameter **`Specific sw. authorities`**. More settings for the configuration of the identifiers and the behavior of the function as well as additional signals appear (see *Figure 8-33*). In order to permit an additional command source to switch, you must activate this specific switching authority. In order to do this, set the controllable **`Enable sw. auth. 1`** to **`Enable sw. auth. 5`**.

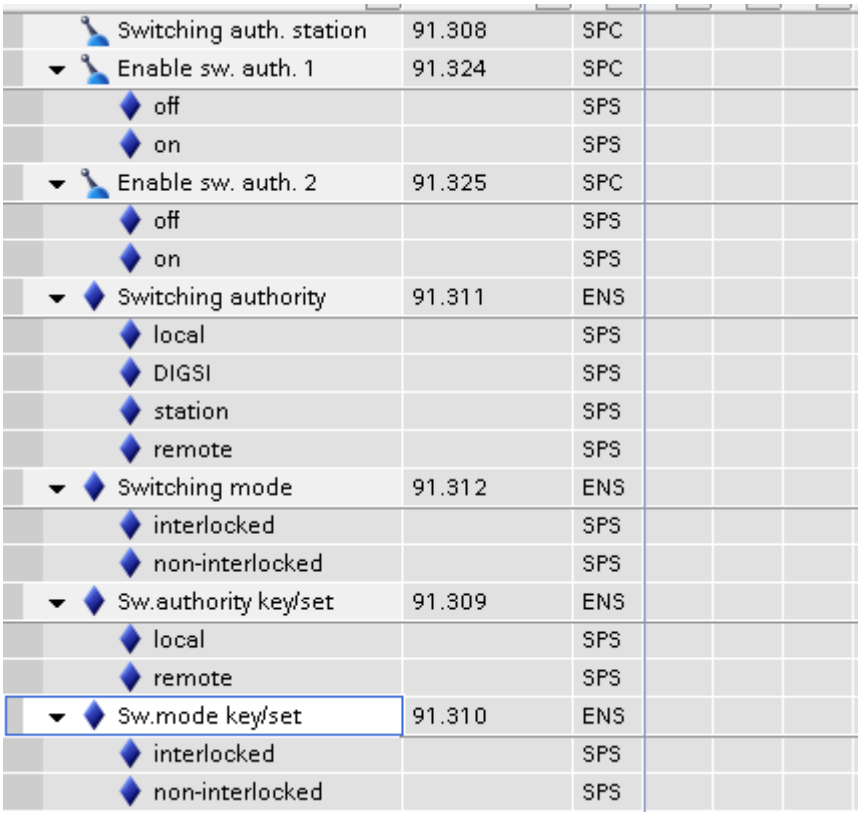
[sc_act additional options sw authority, 3, en_US]

Figure 8-32 Activating Additional Options of the Switching Authority

The additional parameters allow you to set the following options:

- **`Specific sw.auth. valid for`** (for ***`station/remote`***, only ***`remote`*** or only ***`station`***):
  With this parameter, you determine for which command source the extended switching-authority check is used.

Table 8-21 Result Derived from the Combination of the Parameter Value **`Specific sw.auth. valid for`** and the Level of the Command Source (Field **`Originator/orCat`** of the Switching Command)



Command Source	**`Specific sw.auth. valid for`**		
	`station`	***`station/remote`***	***`remote`***
Local, local automatic	No check	No check	No check
Station, station automatic	Check	Check	No check
Remote, remote automatic	No check	Check	Check
DIGSI	No check	No check	No check

- **Num. of specific sw.auth.**:
  With this parameter, you determine how many specific switching authorities are available. This determines the number of parameters **Identifier switching authority** as well as the controllable **Active. Sw. auth.**.
- **Identifier switching authority 1** to **Identifier switching authority 5**:
  The number of names that appear corresponds to the number set in the previous parameter. You can select the names as you wish, 1 to 64 characters are allowed. The command check verifies whether these titles correspond with those sent by the command source. This applies to the switching commands as well as to the activation of a specific switching authority. The requirement for this is the system interface IEC 61850. The field **Originator/orIdent** is used.
- **Multiple specific sw.auth.** ensures the simultaneous validity of the various command sources. The following table shows how to determine the resulting specific switching authority when activating the command sources of Remote or Station. If this parameter is activated, all parameterized command sources get permissible automatically (see last row in the table) and they cannot be deactivated via the controllable **Enable sw. auth. 1** to **Enable sw. auth. 5**. Otherwise, the enabled command source with the lowest number has always the highest priority and prevails against the other numbers.

Table 8-22 Determining Switching Authority if Multiple Command Sources Are Available

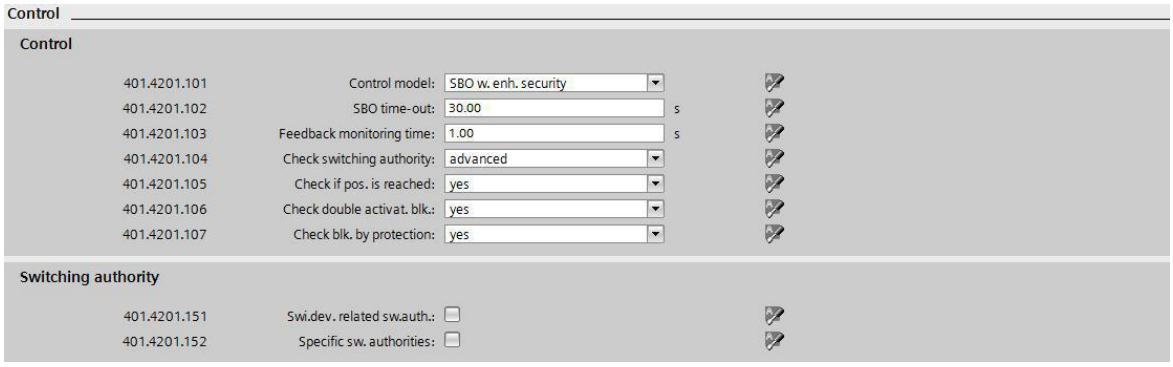
Multiple specific sw.auth.	Enable sw. auth. 1	Enable sw. auth. 2	Enable sw. auth. 3	Enable sw. auth. 4	Enable sw. auth. 5	Resulting Specific Switching Authority
No	on	*	*	*	*	Switch. auth. 1
No	off	on	*	*	*	Switch. auth. 2
No	off	off	on	*	*	Switch. auth. 3
No	off	off	off	on	*	Switch. auth. 4
No	off	off	off	off	on	Switch. auth. 5
No	off	off	off	off	off	None
Yes	on	on	on	on	on	All

The * symbol in the previous table refers to any value.

[sc_sw authority and mode in info routing, 1, en_US]

Figure 8-33 Display of Switching Authority and Switching Mode in the Information Routing (in Function Block General), Example of 2 Activated Remote Switching Authorities

Individual Switching Authority and Switching Mode for the Switching Devices

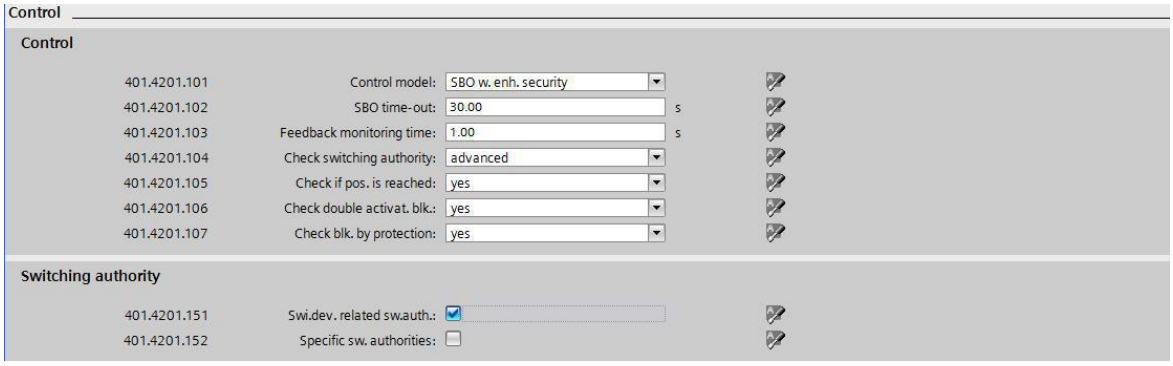


In a standard case, the functionalities switching authority, switching mode, and specific switching authority as described in the previous sections, are applicable to the entire bay unit and, therefore, are valid for all switching devices that are controlled by this bay unit. In addition, you can configure an individual switching authority and specific switching authority as well as individual switching modes for single switching devices. Therefore, individual switching devices can accept various switching authorities and switching modes simultaneously.

This is offered for the following function groups and function blocks:

- **Circuit-breaker** function group
- **Disconnector** function group
- **Transformer tap changer** function group
- **Switching sequence** function block

This allows to select individual settings for each switching device. This is useful if, for example, switching devices of different utilities are managed within a single bay.



In order to activate this option, go to the function block **Control** of a switching device and set the parameter **`Check switching authority`** to ***`advanced`***. An additional table containing initially 2 parameters is displayed.

[sc_add parameters sw authority sw device, 1, en_US]

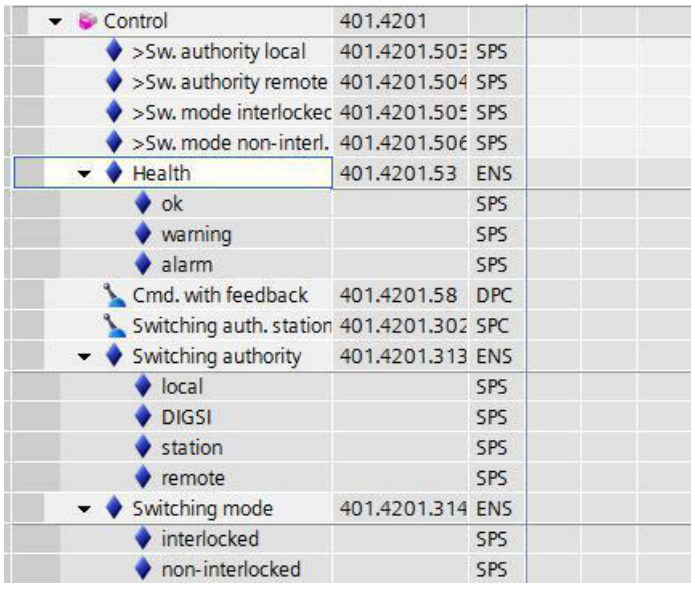


Figure 8-34 Additional Parameters for Switching Authorities in the Parameters of a Switching Device

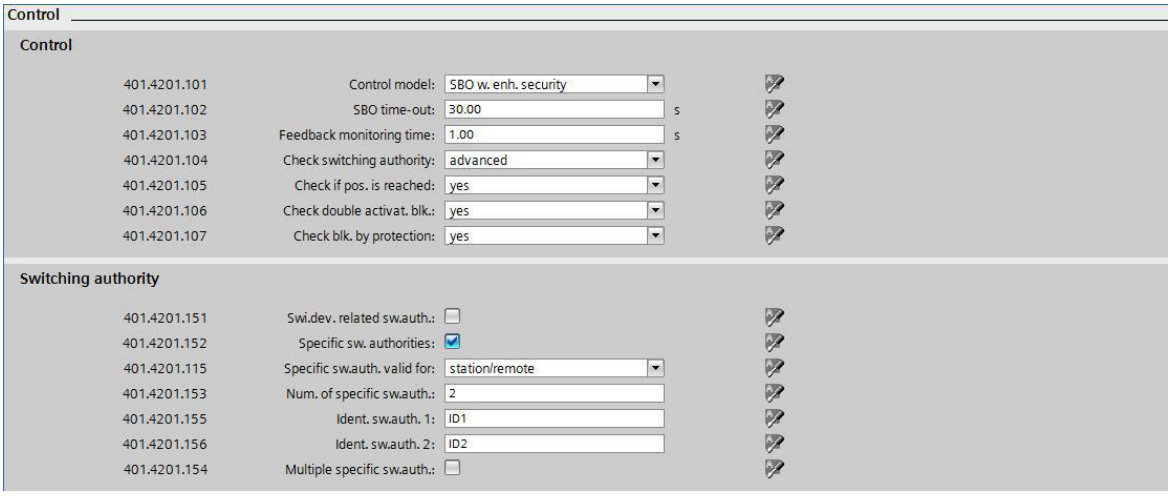
When activating the parameter **`Swi.dev. related sw.auth.`**, an individual switching authority as well as an individual switching mode for this switching device are configured. Additional signals are displayed in the **Control** function block of the corresponding switching device.

[sc_extended parameters sw authority sw device, 1, en_US]

Figure 8-35 Expanded Parameters for the Switching Authority in the Switching Device

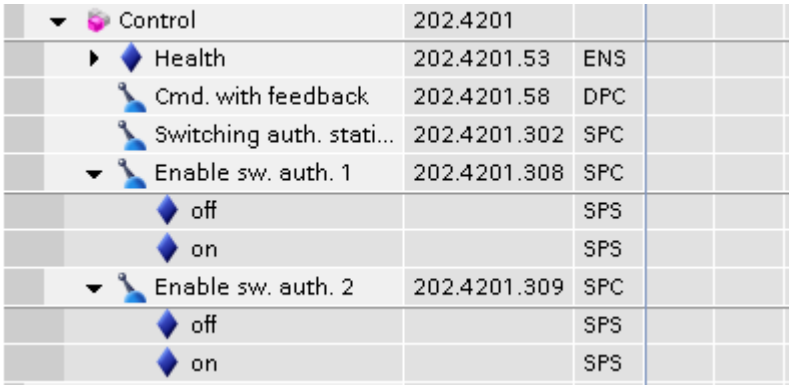


[sc_switching auth sw mode changeable, 1, en_US]

Figure 8-36 Individually Modifiable Switching Authority and Switching Mode for Switching Devices

The new input signals that are displayed allow you to set the individual switching authority and switching mode for the switching devices. For this switching device, these inputs overwrite the central switching

authority and the switching mode. The outputs *Switching authority* and *Switching mode* indicate the states only for this switching device.



When activating **Specific sw. authorities**, an individual specific switching authority for this switching device is configured. Additional parameters are displayed.

[sc_Parameters FB control all additional options, 1, en_US]

Figure 8-37 Parameters of the FB Control with all Additional Options

The functionality of the specific switching authority for the individual switching device and the significance of the additional parameters is identical to the operating mode of the central specific switching authority. Additional signals are displayed in the **Control** function block.

[sc_Specific sw authority changeable per sw device, 1, en_US]

Figure 8-38 Specific Switching Authority, Modifiable for each Switching Device

Switching Direction (Set = Actual)

With this check, you avoid switching a switching device into a state that has already been achieved. For instance, before a trip command is issued to a circuit breaker, its current position is determined. If this circuit breaker is already in the ***Off*** position, no command is issued. This is logged accordingly.

Switchgear Interlocking Protection

Switchgear interlocking protection means avoiding maloperation by checking the bay and substation interlocking and thus preventing equipment damage and personal injury. The interlocking conditions are always system-specific and for this reason are stored as CFC charts in the devices.

SIPROTEC 5 devices recognize 2 different types of interlocking conditions:

- Normal interlocking conditions:

  These can be revoked by changing the switching mode to **non-interlocked**.

- Non-revocable (fixed) interlocking conditions:
  These are still checked even if the switching mode is set to **non-interlocked**.
  Application: Replacing mechanical interlocking, for example, that prevent actuation of a medium-voltage switch.

Each of the two categories has 2 release signals (for the ***On*** and ***Off*** switching directions) that represent the result of the interlocking plan, so that interlocking is in effect during the command check (see the figure below). The default setting for all release signals is ***TRUE***, so that no switchgear interlocking checks take place if no CFC charts have been prepared.

[scverrie-260912-01.tif, 1, en_US]

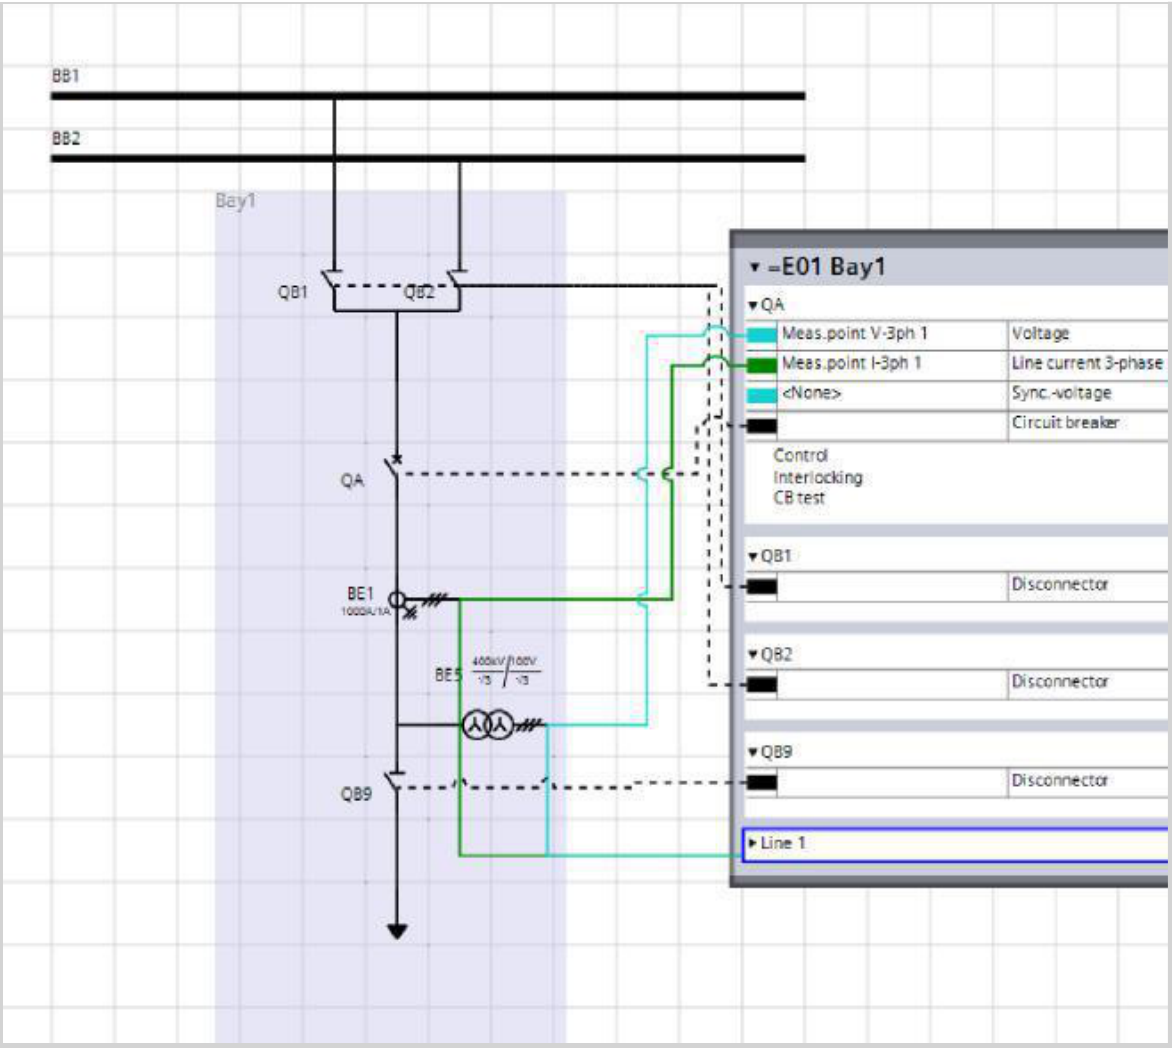

Figure 8-39 Interlocking Signals in Function Block Interlocking

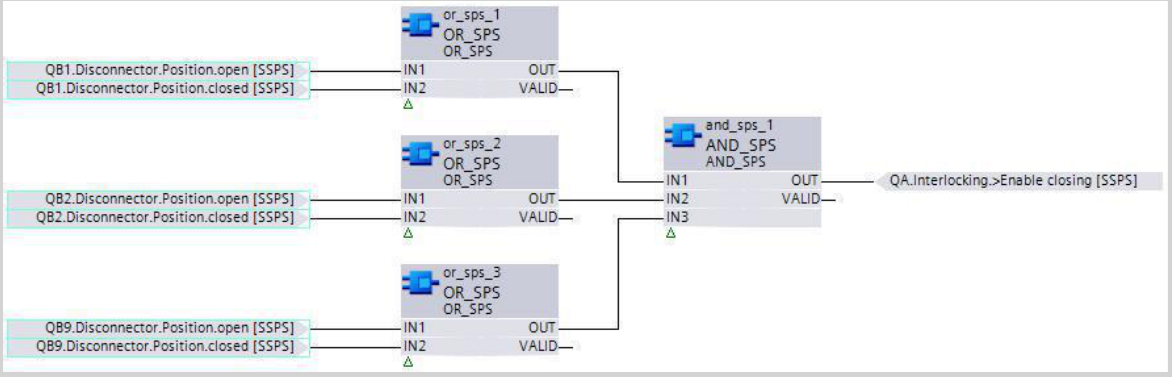
EXAMPLE

For interlocking

For the making direction of the circuit breaker QA in bay E01 (see the figure below), it is necessary to check whether the disconnectors QB1, QB2, and QB9 are in the defined position, that is, either **On** or ***Off***. Opening the circuit breaker QA should be possible at any time.



The interlocking equations are: QA_On = ((QB1 = On) or (QB1 = Off)) and ((QB2 = On) or (QB2 = Off)) and ((QB9 = On) or (QB9 = Off)). There is no condition for opening.

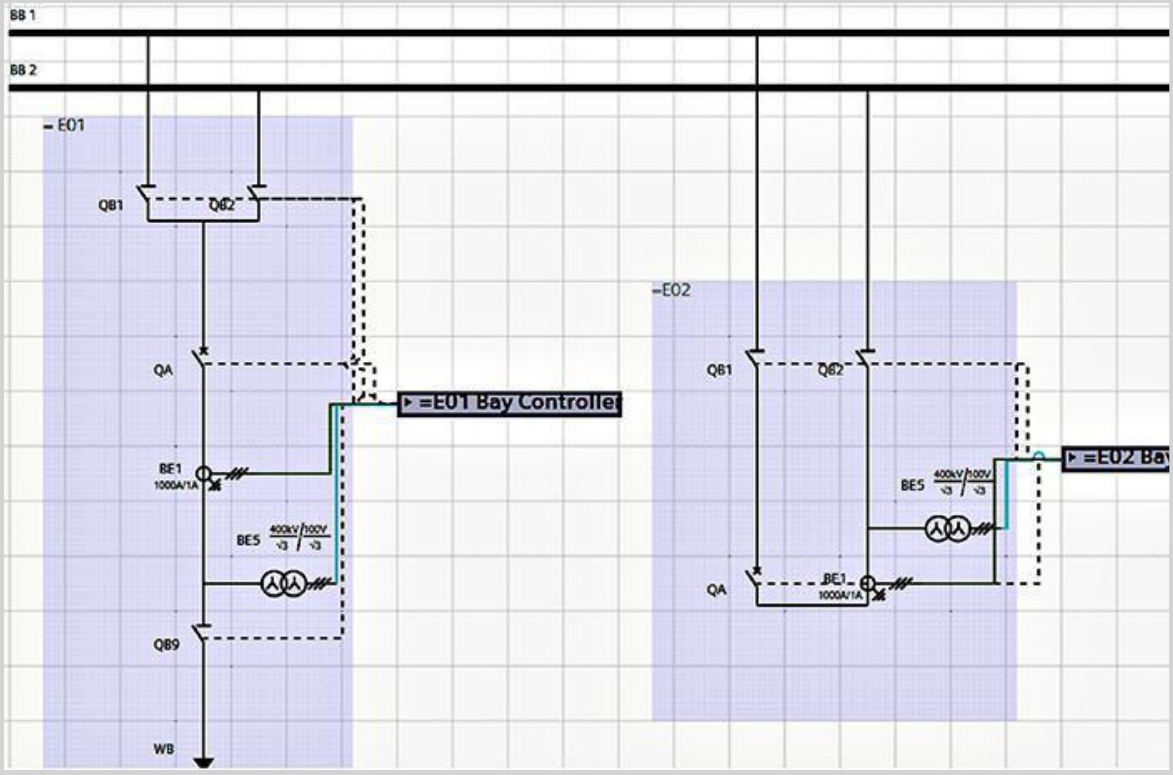
[ScAbgang-270410-deDE-01, 1, en_US]

Figure 8-40 Feeder Bay for a Double Busbar System

The CFC chart that is required to implement the interlocking equation is shown in the next figure.

[scverpla-270511-01.tif, 1, en_US]

Figure 8-41 Interlocking Chart for Bay Interlocking



Since the **Disconnector** function block provides the defined position ***On*** or ***Off***, the exclusive OR gate XOR is not necessary for interlocking. A simple OR suffices.

As can be seen in the CFC chart, the result of the check is connected to the **>Release on** signal in the **Interlocking** function block in the **Circuit breaker QA** function group (see *Figure 8-41*).

EXAMPLE

For system interlocking

This example considers the feeder = E01 from the previous example (bay interlocking) and additionally the coupler bay = E02 (see the figure below).

[ScAnlage-270410-deDE-01, 1, en_US]

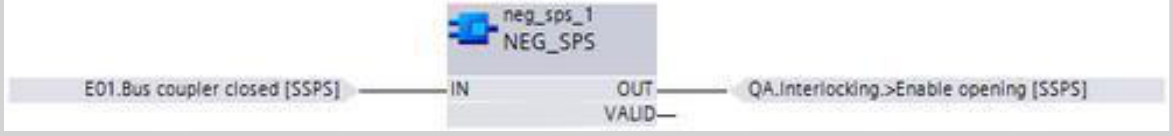


Figure 8-42 System with Feeder and Coupler Bays

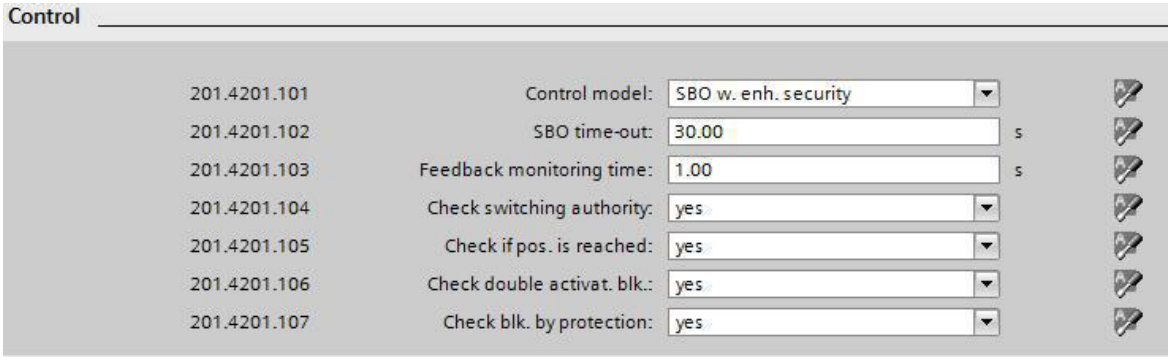
The circuit breaker QA in coupler bay = E02 will be considered next. As the multibay interlocking condition, you must provide the bus-coupler command block at the end:

If the 2 busbars in bay = E01 are connected, that is, if the 2 disconnectors QB1 and QB2 in bay =E01 are closed, the circuit breaker QA in bay = E02 is not allowed to be switched off. Accordingly, bay = E01 in the CFC of the device generates the indication *Bus coupler closed* from the positions of the switches QB1 and QB2 and, using IEC 61850-GOOSE, transmits it to bay = E02 in the device. You must then store the following interlocking condition in bay = E02:

QA_Off = NOT (= E01/Bus coupler closed)

In the CFC chart for the coupling device = E02, you must create the following CFC chart (see the figure below).



[scplanve-241013, 1, en_US]

Figure 8-43 Interlocking Chart for Substation Interlocking

1-Out-of-n Check (Double-Activation Blocking)

The double-activation blocking prevents 2 commands from being executed in the device simultaneously. You can set the device-internal check for each switching device as a parameter in the **Control** function block.

The default setting is ***Yes***, that is, double-activation blocking is active (see the figure below).

[scdoppel-260912-01.tif, 1, en_US]

Figure 8-44 Activating the Double-Activation Blocking

With SIPROTEC 5, it is also possible to achieve multibay double-activation blocking.

In this case, send the signal **`not selected`** to other devices for analysis using IEC 61850-GOOSE. This signal is available under **Position** in every **Circuit breaker** or **Disconnector** function block in the switching device function groups (see figure below).

Circuit breaker 1	201	
Trip logic	201.5341

[scnotselected-090315_de, 1, en_US]

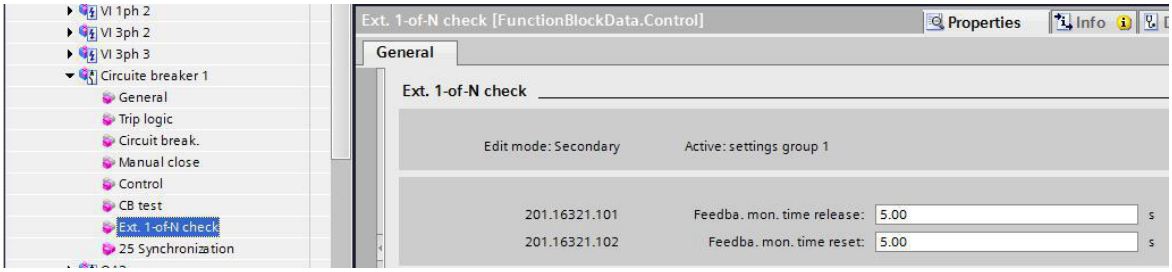

Figure 8-45 Signal *`Not selected`* in the Circuit-Breaker Function Block

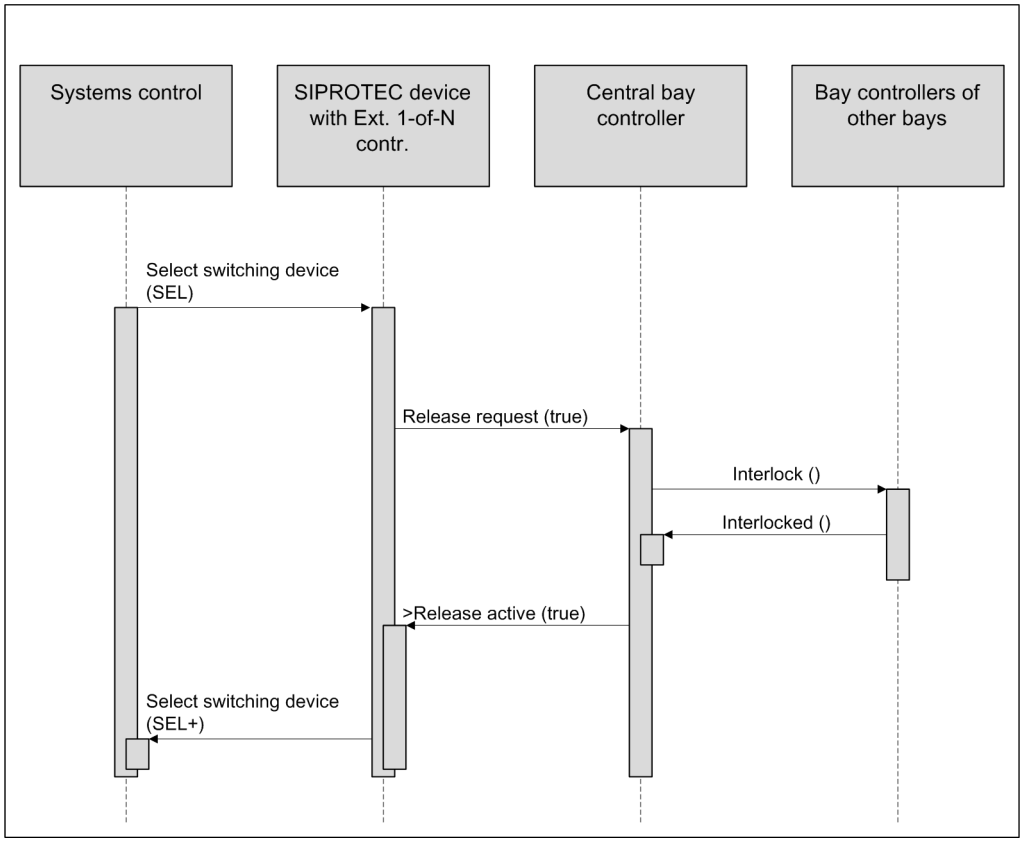
The signal is then queried in the CFC interlocking conditions for the associated switching devices and is used to generate the release signal (for example, **`>Release on`**).

External 1-of-N Check (Cross-Bay Double-Activation Blocking)

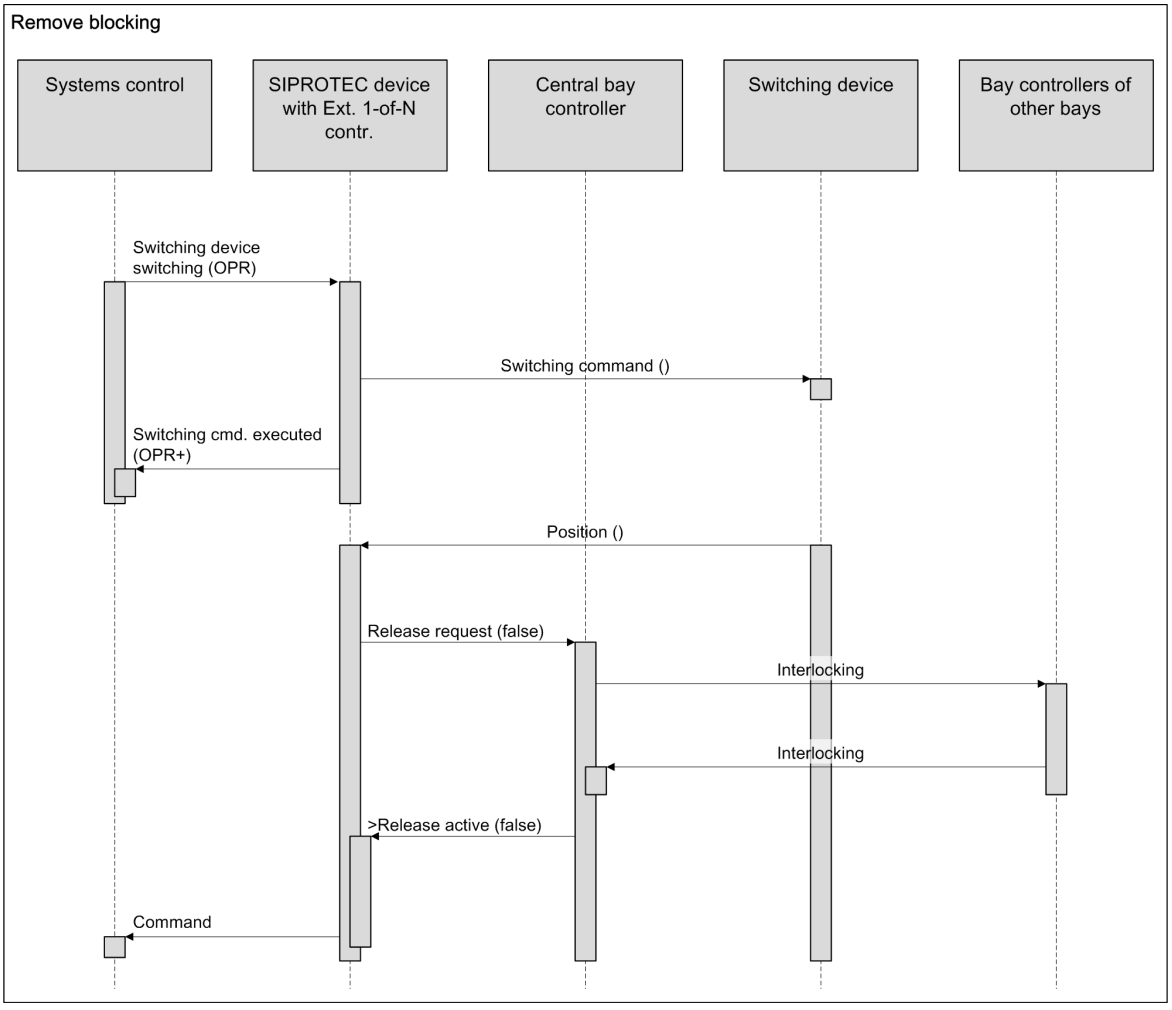
The function block **Ext. 1-of-N check** offers another option to implement a cross-bay 1-out-of-n check. You can select this function block in the FG **Circuit breaker** – **Control** in the DIGSI library. This function makes it possible to interlock other switching devices across all bays before the allocation of the switching device takes place in its own assigned bay or before the switching operation can be executed.



You can use the function block **Ext. 1-of-N check** in the **Circuit breaker** and **Disconnector** function groups. In order to use the function, a control model **with feedback monitoring** must be configured in the circuit-breaker control.

[sc_library properties info routing Ext 1-out-of-n control, 1, en_US]

Figure 8-46 Command Execution



If the external 1-of-N check is instantiated, the output ***Release request*** prompts a central bay controller before executing a switching command. This bay controller must permit the switching operation (see the following figure). If the allocated switching devices were locked in another bay, the release is issued. Only when the release was issued via the input ***>Release active*** the allocations (**`Control model`**: ***`SBO w. enh. security`***) or the switching command (**`Control model`**: ***`direct w. enh. security`***) are executed and confirmed. The central bay controller is parameterized to reject a 2nd switching request.

[dw_block-ext-setzen, 1, en_US]

Figure 8-47 Setting the Blocking

Once the switch position has been reached, interlocking of the switching devices is canceled via the output ***Release request***. The switching command is completed and acknowledged with CMT (see the following figure) only when interlocking termination has been acknowledged positively via the input ***>Release active***.

[dw_block-aufheben-1, 2, en_US]

Figure 8-48 Terminating the Blocking

User I/O Objects of the External 1-of-N Check Function Block

Name	I/O	Description	Range
Release request	O	This output remains active from the time of the switching prompt until the new position is reached.	true/false
>Release active	I	If this input is set, the switching device is released for switching operation. As long as this input is set, this switching device is blocked for additional switching operations.	true/false

Blocking by Protection Function

- Default setting **(_:107) Check blk. by protection** = ***yes***

In devices with protection and control functions, Siemens recommends that no switching commands can be issued while protection functions have picked up.

This applies to automatic reclosing as well. Switching commands must be prevented as long as automatic reclosing is active.

The default setting for blocking by the protection function is therefore ***yes***. If necessary, you can disable this blocking. You can find the settings on the same page as the double-activation blocking (see *Figure 8-44*).

NOTE

Remember, for instance, that pickup of the thermal overload protection can create a fault as well and thus prevent switching commands.

NOTE

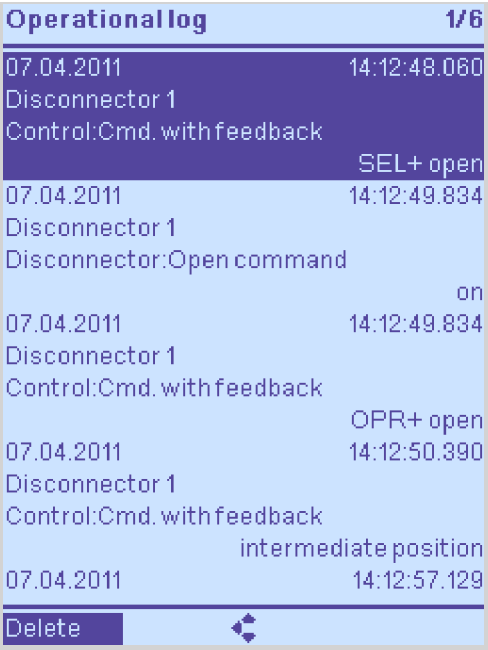
Note that the command check **Blocking by protection function** is only available for controlling circuit breakers, because in this case a unique relationship with protection functions and automatic reclosing has been configured. In disconnectors, this relationship is not always unique, precisely with regard to the 1 1/2 circuit-breaker layout, and it must be mapped for each system using CFC charts.

To carry out the command check **Blocking by protection function** for disconnectors, use the following indications (if present) in your interlocking conditions:

- Group indication: **`Pickup`** (Function group **Line**)
- Circuit-breaker failure protection: **`Pickup`** (**Circuit-breaker failure protection**)
- General: **`In progress`** (**Automatic reclosing function**)

8.3.2 Command Logging

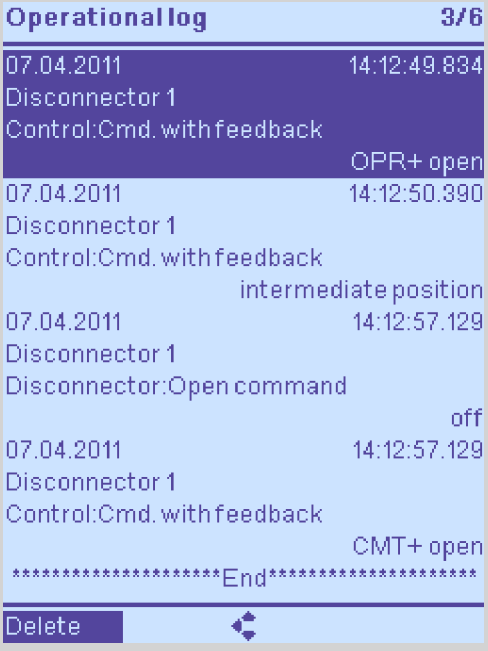
All commands in the sequence are logged. The command log contains:



- Date and time
- Name of the switching device (or function group)
- Reason for the transmission (SEL = Selected, OPR = Operate, CMT = Command execution end, SPN = Spontaneous)
- Status or switching direction

EXAMPLE

The following example illustrates control of a disconnector QB1 for various cases.



- Successful command output
- Interrupted command
- Command interrupted by switchgear interlocking
- Command ended due to missing feedback
- Spontaneous change of switch position without command output

Figure 8-49 to *Figure 8-55* indicates command logging for various scenarios of the standard control model SBO with feedback monitoring.

8.4 Synchronization Function

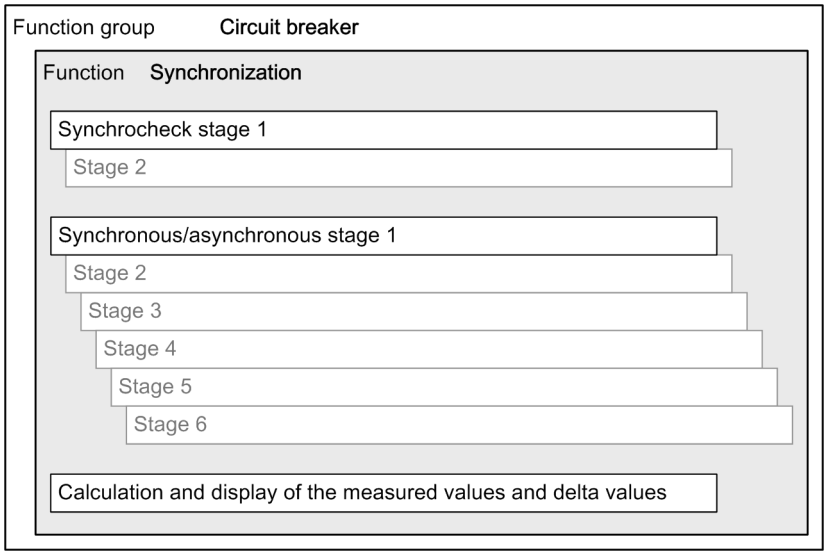
8.4.1 Overview of Functions

The **Synchronization function** (ANSI 25) checks whether the activation is permissible without a risk to the stability of the system when interconnecting 2 parts of an electrical power system. Typical applications are the synchronization of a line and a busbar or the synchronization of 2 busbars via a cross-coupling. A power transformer between the 2 measuring points can also be taken into consideration.

The following operating modes are covered:

- Synchrocheck
- Switching synchronous power systems
- Switching asynchronous power systems
- Switching to dead line line/busbar

8.4.2 Structure of the Function



The **Synchronization** function is used in the **Circuit-breaker** function group.

2 different types of stage can be used within the function:

- Synchrocheck stage
- Synchronous/asynchronous stage

Each of the stage types is preconfigured at the factory. You can operate maximum 2 stages of the synchrocheck stage type and maximum 6 stages of the synchronous/asynchronous type in parallel. In addition, the **Expanded delta-f options** stage type is available in the function library. It is not preconfigured.

As soon as the device is functional, the function measuring points are calculated and displayed.

[dwsynfn1-270213-01.tif, 1, en_US]

Figure 8-56 Structure/Embedding of the Function

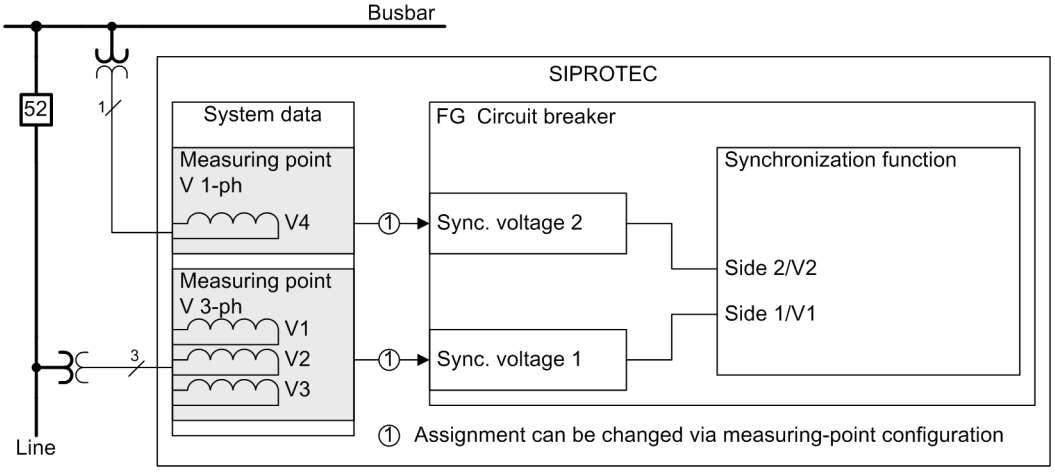
8.4.3 Connection and Definition

Connection

You can find examples for the synchronization of line and busbar in the following 2 figures. *Figure 8-59* shows an example for the synchronization of 2 busbars via bus coupler.

The synchronization function uses 2 voltages to check the connecting conditions: a voltage of the reference side 1 (V1) as well as a voltage to be used as a reference on side 2 (V2). The reference voltage of side 1 is designated in the synchronization function as V1[24]. This is always the voltage of the measuring point that is connected to the **Sync. voltage 1** interface of the Circuit-breaker function group. The voltage to be set as reference is designated with V2[1]. This is always the voltage of the measuring point that is connected to the **Sync. voltage 2** interface of the Circuit-breaker function group. The assignment of the measuring points to the interfaces of the circuit-breaker function group can be configured, see chapter *2.1 Function Embedding in the Device*.

The selection of the voltages used for the synchronization depends on the device connection to the primary system:

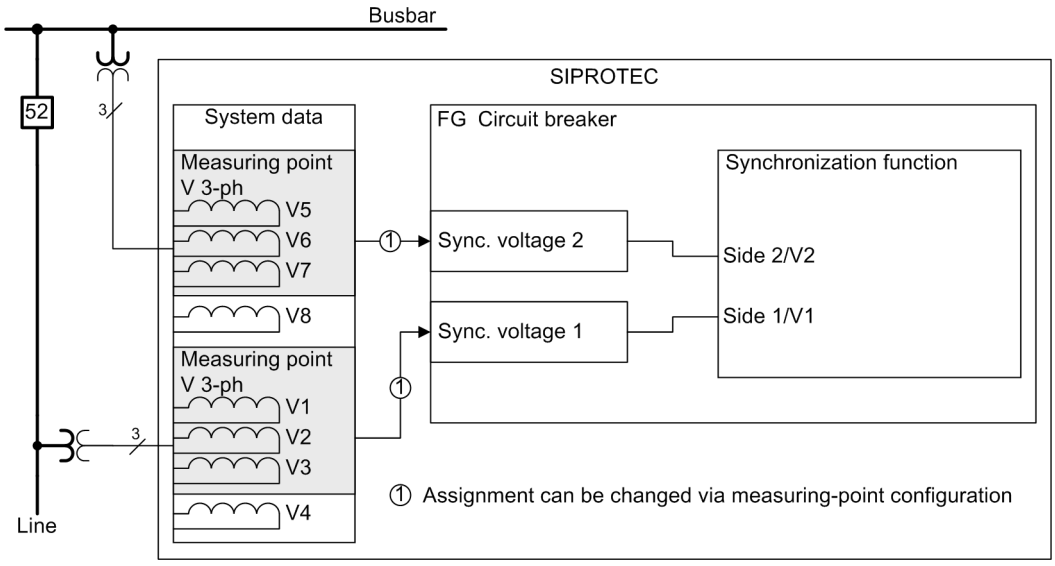


- Connection of the primary system via 4 voltage inputs and hence use of a 1-phase and a 3-phase measuring point (*Figure 8-57* and *Figure 8-59*):

  The voltage connected to the 1-phase measuring point is definitive here. If. for example, this is the phase-to-ground voltage V_A, the voltage V_A is also used by the other side of the 3-phase measuring point.

- Connection of the primary system via 6 voltage inputs and hence use of two 3-phase measuring points (*Figure 8-58*):

  The phase-to-phase voltage V_{AB} of both sides is always used for the test.



You can connect both the phase-to-ground voltages and the phase-to-phase voltages to the device. The possible interface connections are listed in the Appendix.

[dwsyns01-210912-01.tif, 1, en_US]

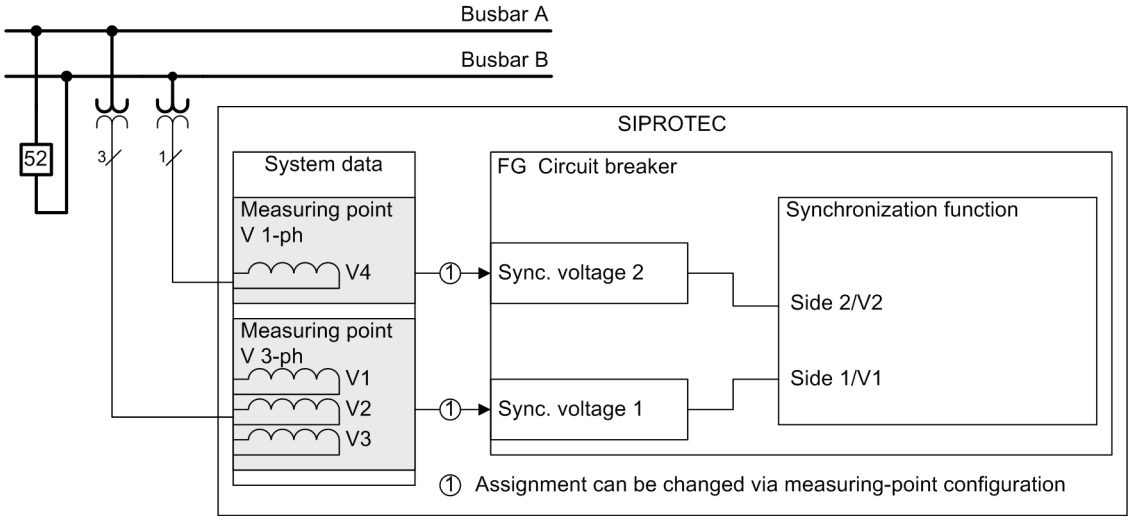


Figure 8-57 Synchronization of Line and Busbar, Connection via 4 Voltage Inputs

[24] Do not confuse the designations V1 and V2 with the numbering of the voltage inputs V1 to V4 (*Figure 8-57*) and V1 to V8 (*Figure 8-58*)

[dwsyns03-210912-01.tif, 1, en_US]

Figure 8-59 Synchronization of 2 Busbars via Cross-Coupling, Connection via 4 Voltage Inputs

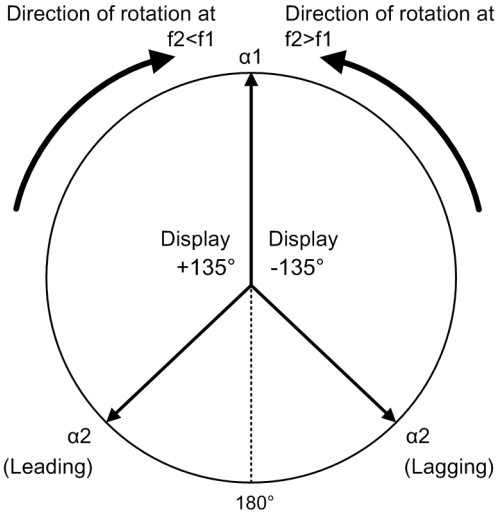
Definition of the Variables

The definition of the variables is important for understanding the following implementation. The reference side 1 indicates the function with 1. This yields the reference values voltageV1, frequencyf1, and phase angle α1. The side to be synchronized indicates the function with 2. The electrical variables of side 2 are then the voltageV2, frequencyf2, and phase angle α2.

When forming the differential variables, the function is oriented to the definition of the absolute measuring error (Δ x = measured value – real value). The reference value and hence the real value is side 1. This results in the following calculation specifications:

Differential voltage dV = V2 – V1

A positive sign means that the voltage V2 is greater than the voltage V1. In other cases, the sign is negative.



Differential frequency df = f2 – f1

A positive result means that according to the example from *Figure 8-57* the busbar frequency is greater than the line frequency.

Phase-angle difference dα = α2 – α1

The representation is limited to ±180°. A positive result means that α2 **leads** by a maximum of 180°. In the case of a negative value, α2 **lags** by a maximum of 180°. *Figure 8-60* shows the circumstances. The phase angle α1 was added to the zero axis as a reference system.

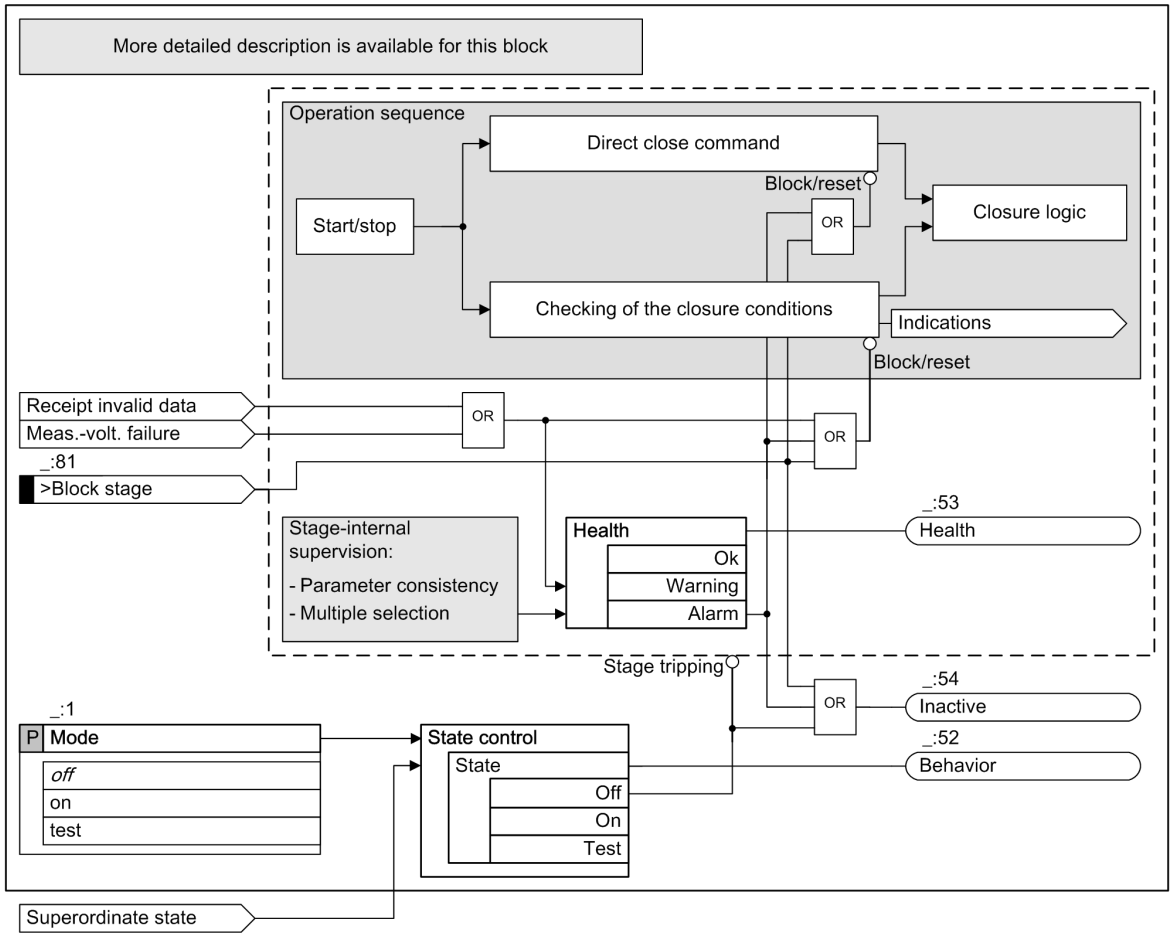
If asynchronous systems are present and the frequency f2 is greater than f1, the angle dα then changes from the negative value to 0 and then to the positive value. As shown in *Figure 8-60*, the direction of rotation is counterclockwise (mathematically positive). At f2 < f1, the direction of rotation is clockwise.

[dwsynp04-100611-01.tif, 1, en_US]

Figure 8-60 Phase-Angle Difference Representation dα

Only positive values are permissible for the setting parameters. Inequalities are used to characterize the setting parameters uniquely. The representation is explained with the example of differential voltage. 2 setting values are necessary to allow unbalanced settings.

The inequality V2 > V1 yields a positive value for dV. The associated parameter is **`Max. voltage diff. V2>V1`**. For the 2nd setting parameter **`Max. voltage diff. V2<V1`**, the inequality V2 < V1 applies. It corresponds to a negative dV.



The procedure is the same for the differential frequency and differential phase angle.

8.4.4 General Functionality

Overview of a Synchronization Stage (Sync Stage)

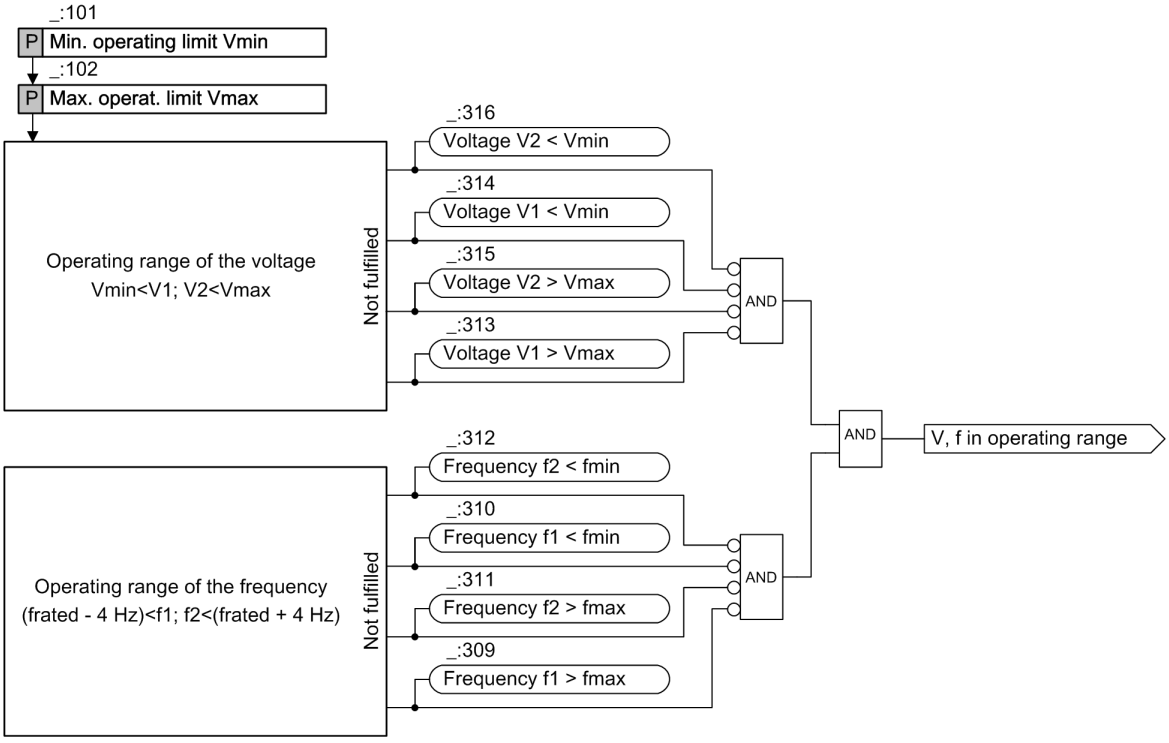
A synchronization stage can be integrated in the following blocks (see *Figure 8-61*):

- Stage control with mode, state control, standby and blocking (description in this chapter)
- Supervision (description in this chapter)
- Functional sequence for issuing the closing release (see chapter *8.4.6 Sequence of Functions*)

[losyn001-100611-01.tif, 1, en_US]

Figure 8-61 Overview of the Stage Logic

Stage Control



The normal stage control is used for a synchronization stage (see *Figure 8-61*).

Note the following special features:

- As soon as there is a synchronization function available in the device, the measured values are calculated and displayed. One stage must be activated for calculating all Delta settings. It is not necessary to start the stage for this purpose.
- If all synchronization stages are deactivated within the function, closure via the control will no longer be possible, as none of the stages can generate an closing release. If the synchronization function is deleted, the circuit breaker is no longer regarded as subject to compulsory synchronization. In this case, it is possible to activate via the control without synchronization.
- If more than one synchronization stage is switched on, then the **>Selection** signal must be active for exactly one stage, so that it can be activated via the controls.

You can block the entire synchronization stage via the binary signal **>Block stage**. A started process is completed and the entire stage reset after blocking. The stage must be restarted to initiate a new switching procedure. The blocking only affects the test process for the closing conditions. The measured values are still calculated and displayed.

Operating Range

[losyn002-160311-01.tif, 1, en_US]

Figure 8-62 Logic of the Operating Ranges

The operating range of the synchronization function is defined by the configurable voltage limits **Min. operating limit Vmin** and **Max. operat. limit Vmax** as well as by the specified frequency band f_{rated} ±4 Hz.

If one or both voltages are outside the permitted operating range when the measurement is started or a voltage leaves the range, this is displayed via corresponding indications **Frequency f1 > fmax**, **Frequency f1 < fmin**, **Voltage V1 > Vmax**, **Voltage V1 < Vmin** etc. The closing conditions are then not checked.

Supervision

The supervisions listed below are executed in a function-specific manner. If one of the monitors picks up, the Health goes to ***alarm***. The stage is indicated as **Inactive**. A closing release or direct close command is not possible in this case.

- For consistency of settings of specific parameters

  Definite threshold-value settings are checked after a parameter change. If there is an inconsistency, the error message **Setting error** is set.

- For multiple selection of the stage at the start time of the synchronization

  If there is a simultaneous selection of multiple closed synchronization stages at the start time, the error message **Multiple selection** is set.

Measuring-Voltage Failure

If a voltage-transformer fault (measuring-voltage failure) is recorded via the binary input signal **>Open** of one of the voltage-measuring points, then the closing commands of the synchronization stage are no longer tested. In other words, a release of the closure based on the measurement is no longer possible. The readiness of the stage turns to ***warning***. Direct close command is still possible.

The device-internal supervision function measuring-voltage failure detection (Fuse Failure Monitor) does not have any effect on the synchronization stage.

Function Measured Values

The function measured values for the Synchronization function are displayed in their own primary, secondary and percentage measured-value windows. Voltage measurements are always displayed as ph-ph voltages, even if the associated measuring point records phase-to-ground voltages. The function measured values are determined and displayed as soon as the device is functional. The difference values are calculated as soon as the stage is activated.

Table 8-24 Protection-Specific Values of the Synchronization

Values		Primary	Secon-dary	% Referenced to
V_1	Reference voltage V_1	kV	V	Rated operating voltage of the primary values
V_2	Voltage to be synchronized V_2	kV	V	Rated operating voltage of the primary values
f_1	Frequency of the voltage V_1	Hz	Hz	Rated frequency
f_2	Frequency of the voltage V_2	Hz	Hz	Rated frequency
dV	Voltage difference V_2-V_1	kV	V	–
df	Frequency difference f_2-f_1	Hz	Hz	–
dα	Angle difference α_2-α_1	°	–	–

Multiple Synchronization Points

The synchronization function can only be used within a Circuit-breaker function group. It always operates on the circuit breaker that is linked to the Circuit-breaker function group. The reference to the circuit breaker is therefore unique. If you wish to switch several circuit breakers (synchronization points) with the device, you must create several Circuit-breaker function groups.

Different Synchronization Conditions per Synchronization Point

Within the synchronization function, you can operate maximum 2 stages of the stage type **Synchrocheck** and maximum 6 stages of the type **Synchronous/asynchronous** in parallel. All setting parameters for a synchronization point are included in each synchronization stage.

If you have to synchronize with different synchronization conditions (parameter settings), several synchronization stages are used for a synchronization point/circuit breaker. In this case, you must define which of the synchronization stages is currently active via the binary signal **>Selection** (synchronization stage x). The closing conditions are checked if the respective stage is activated via the **>Selection** binary signal and the stage is activated.

The fault indication **Multiple selection** is issued upon simultaneous selection of different synchronization stages. If several synchronization stages are activated and the input signal **>Selection** (synchronization stage x) is missing at the starting time, a valid selection is awaited during the supervision time **Max.durat. sync.process**. If this does not come, the process is terminated.

Different Voltage-Transformer Ratios of Both Parts of the Electrical Power System

The settings of the rated parameters of the transformer for the measuring points automatically takes the different voltage-transformer transformation ratios of both parts of the electrical power system into account. The **Voltage adjustment** parameter is not needed for this purpose.

Synchronization via a Transformer

There are systems in which a power transformer is located between the voltage measuring points of the circuit breaker to be synchronized. The device automatically considers the different voltage stages by setting the transformer ratios (within the measuring points).

A phase displacement must be taken into account based on the transformer vector group, via the **Angle adjust. (transform.)** parameter.

The parameter is defined as -Δα = –(α2 – α1).

To calculate the Delta parameters, the voltage of side 2 is converted to the voltage of side 1 using to the settings of both parameters.

In the Application and Setting Notes, several examples are provided for using both parameters.

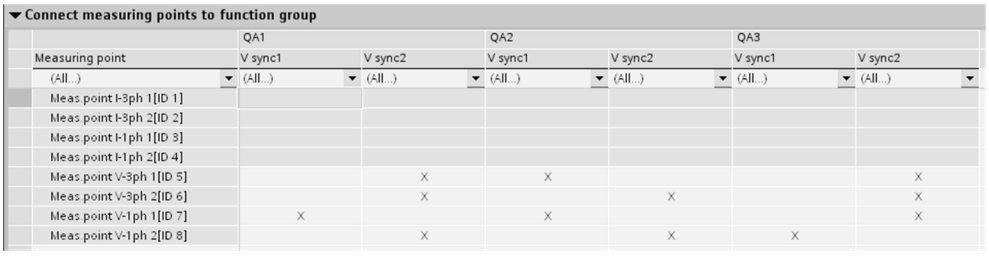
Different Connection Types on Both Sides

If both of the measuring points used by the synchronization functions record different voltages of the 3-phase system, the calculation of the phase displacement angle is automatically taken into consideration.

EXAMPLE:

The 1-phase measuring point connected with **Sync-voltage 1** records the phase-to-phase voltage V_{AB}. The 1-phase measuring point connected with **Sync-voltage 2** records V_A. In this case the phase angle between V_{AB} and V_A takes into consideration the delta variable Δα during calculation..

This automation guarantees that several voltage sources can be switched between during running operation, each of which records different voltages.



8.4.5 Dynamic Measuring-Point Switching

Dynamic measuring-point switching provides the capability to connect the voltages used in the Synchro-check function to various measuring points. In this way, for example, it is possible to use the correct voltage on the basis of the switch position on the switching devices. If more than 1 measuring point is connected to *V sync1* or *V sync2* , you must create the **`V sync select.`** function block in the **Circuit breakers** function group.

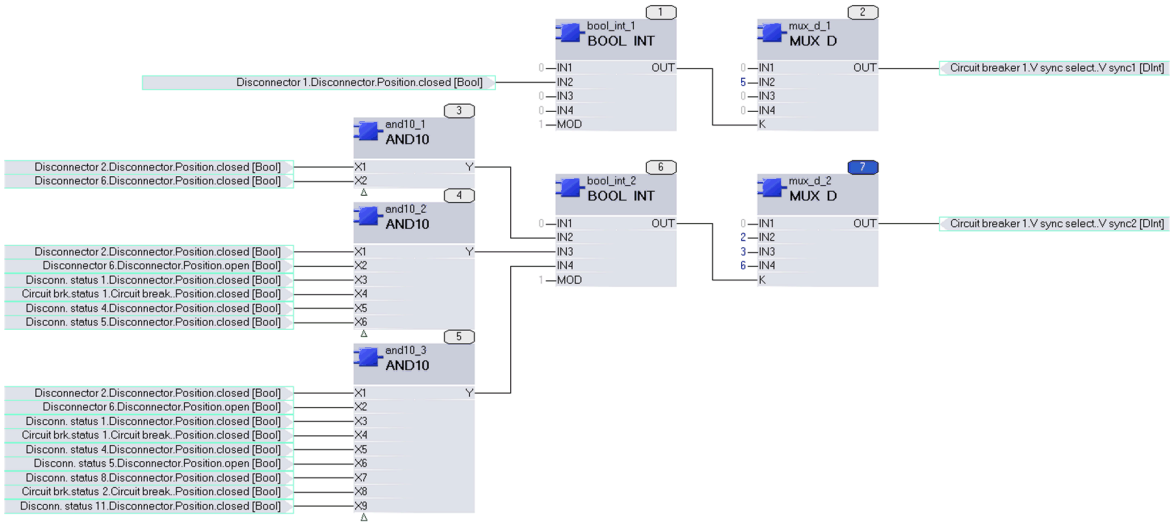
Selection of the desired voltage measuring points (*V sync1* and *V sync2*) for the **Circuit breakers** function group is controlled via Continuous Function Chart.

Connecting Measuring Points to Circuit-Breaker Function Group

The following figure shows the connection of the **Circuit-breaker** function group with several measuring points in DIGSI. The ID of each measuring point appears in parentheses after the name.

[scdynms2-211212-01.tif, 1, en_US]

Figure 8-63 Connecting the Measuring Points with the Circuit-Breaker Function Group



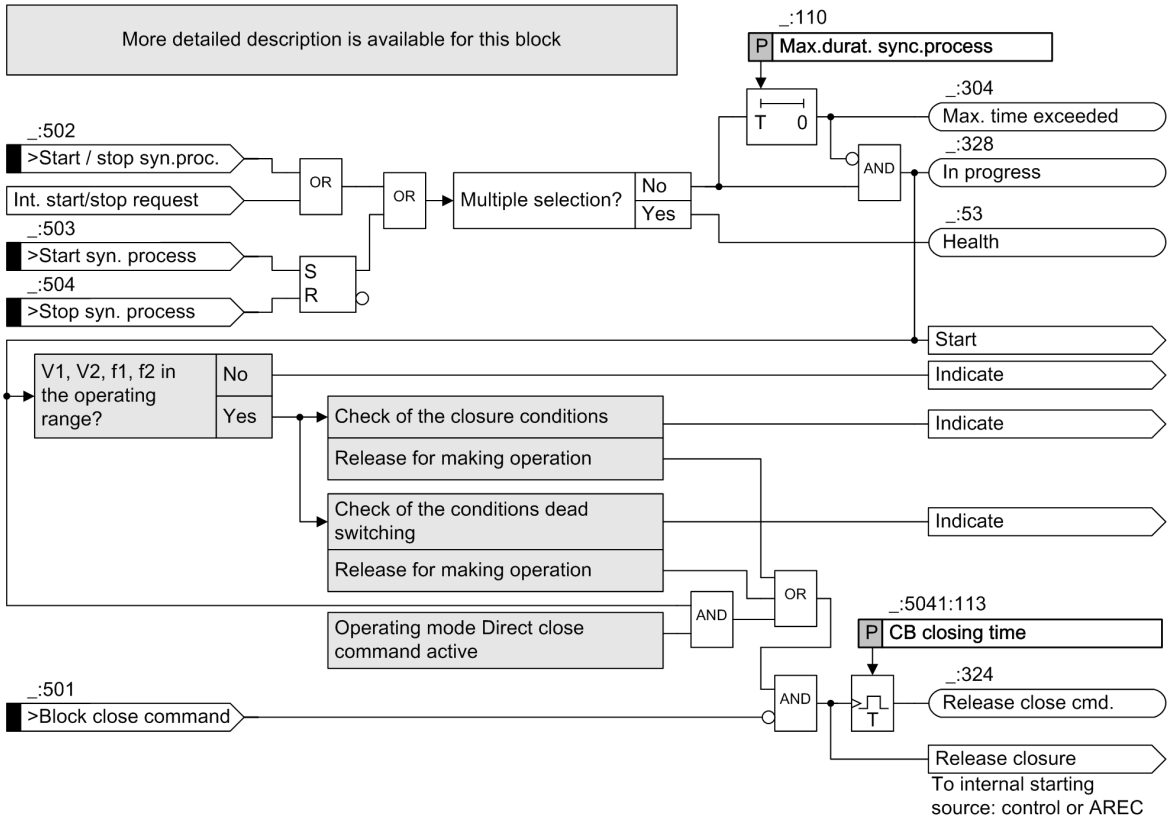
There are consistency checks that validate the connections of voltage measuring points to the function group:

- The connection type must be identical for all measuring points connected to the same interface.
- It is not permitted to route a measuring point to the function group using the option VN.
- The rated voltage (primary and secondary) must be identical for all measuring points connected to the same interface.
- If more than 1 measuring point is connected to 1 voltage interface, a function block must be expanded to enable selection of the synchronization voltage.

CFC Control

The voltages are selected by CFC logic on the basis of the measuring point IDs. If more than one measuring point is connected to interfaces V_{sync1} or V_{sync2} of the **Circuit-breaker** function group, the **`V sync select.`**

function block has to be removed from the library in the **Circuit-breaker** function group. A CFC logic (see following example) has to define IDs for the *V sync1* or *V sync2* inputs of this function block in order to ensure the correct measuring point connection for the Synchrocheck function.



[scdynmsx-160212-01.tif, 1, en_US]

Figure 8-64 CFC Logic: Voltage Selection Using Measuring Point ID

If no measuring point can be selected because of the switch or disconnector positions, the ID0 is used. If ID0 is selected, the indication *(_:2311:304) Blocked no V selected* is set. The synchrocheck is blocked. If you have activated the parameter **(_:5071:108) Direct close command** , unsynchronized switching is still possible.

8.4.6 Sequence of Functions

[losynf01-100611-01.tif, 1, en_US]

Figure 8-65 Sequence of Functions

Start

The synchronization stage must be started to check the closing conditions. The synchronization stage can be started device-internally by the controller and the reclosing, or externally, via binary input signals, for example by an external automatic reclosing (AREC), (see section *8.4.12 Interaction with Control, Automatic Reclosing (AREC), and External Triggering*).

At the start, the system checks whether there is a multiple selection by the synchronization stage (see section **Monitoring** in chapter *8.4.4 General Functionality*). If this is the case, the process is terminated. After a successful start, the indication **`In progress`** is cleared and the supervision time for the maximum duration of the synchronization process (parameter **`Max.durat. sync.process`** is started. The system also checks whether the voltages and frequencies are in the operating range (see section *8.4.4 General Functionality*). If this is not the case, the closing conditions are not checked.

Checking the Closing Conditions, Closure

After starting, the parameterized closing conditions are checked depending on the operating mode selected (see Chapter *8.4.8 Closing Conditions for the Synchronous/Asynchronous Stage Type* to *8.4.11 Direct Close Command*). Every condition fulfilled is explicitly indicated here. Conditions not fulfilled are also indicated. If all conditions are fulfilled, the synchronization stage sets the indication **`All sync. conditio. OK`**. The indication is active until all conditions are fulfilled. The further behavior for issuing the release for closing depends on the type of the stage (see Chapters *8.4.7 Closing Conditions for the Synchrocheck Stage Type* and *8.4.8 Closing Conditions for the Synchronous/Asynchronous Stage Type*). The release is signaled via the **`Release close cmd.`** indication. This indication is active for 100 ms. With an internal start, the controller or the AREC executes the actual closure, depending on the starting source.

Switching to Dead Line/Busbar

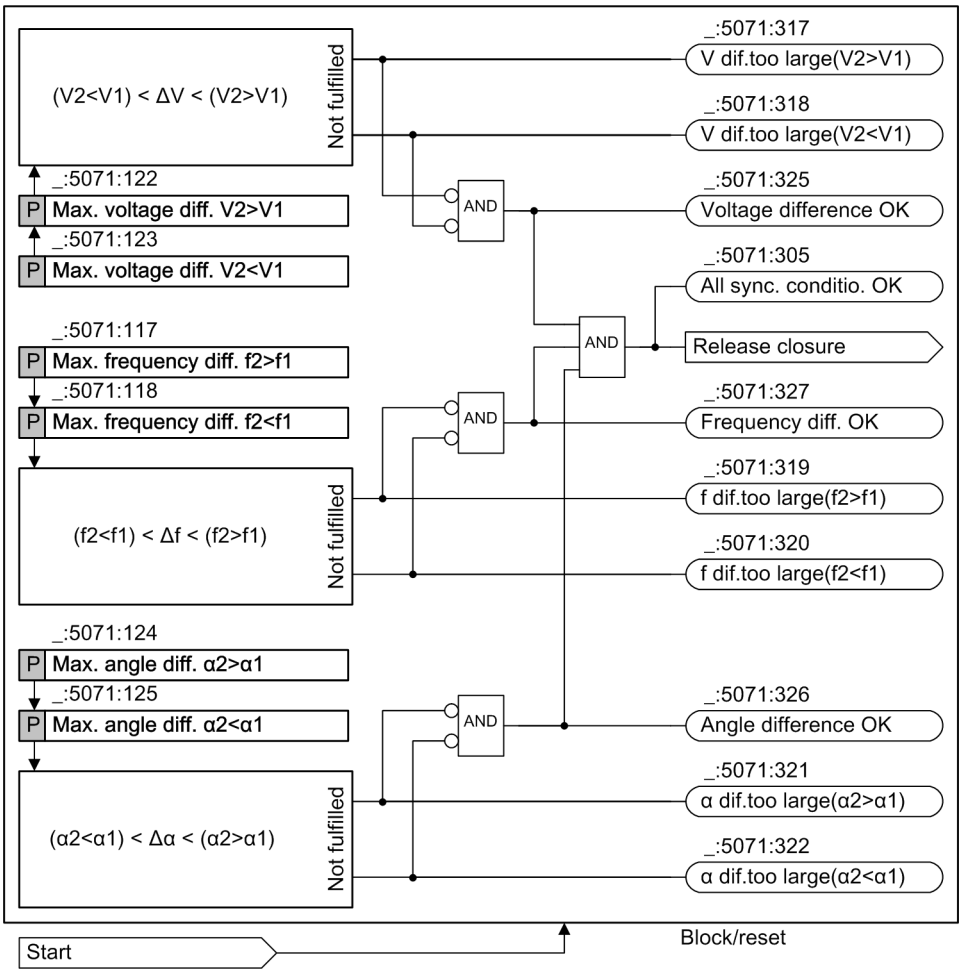
If operating modes for switching to dead parts of an electrical power system are configured, the associated conditions are also checked after the start (see chapter *8.4.10 Closing at De-Energized Line/Busbar*). The fulfilled conditions are signaled. An adjustable supervision time is started after the closure conditions are fulfilled (parameter **CB make time**). If the conditions remain valid until expiry of the time, the function gives the release for closure after expiry of the time.

Direct Closing Command

If the **Direct close command** operation is active, the function instantaneously initiates the release for closure after the successful start (see chapter *8.4.11 Direct Close Command*). A combination of direct close command with other release conditions is not advisable, as these conditions are bypassed by the direct close command.

End of the Process

If the function is started via the device-internal controller or AREC, these functions also terminate the synchronization process upon closure. The process is terminated via the corresponding binary signals in case of external starting.



If the supervision time (**Max.durat. sync.process** parameter) has expired, the process is also completed and the indication **Max. time exceeded** is issued. A renewed synchronization is only possible if the stage is restarted.

Blocking Closure

You can use the input signal *>Block close command* to block the release signal for the closure (signal **Release close cmd.**) as well as the closure itself. The measurement continues to operate during the blocking. If the blocking is revoked and the release conditions are still fulfilled, the release is given for closure.

8.4.7 Closing Conditions for the Synchrocheck Stage Type

Checking Closing Conditions

[losynche-160311-01.tif, 1, en_US]

Figure 8-66 Closing Conditions for the Synchrocheck Function

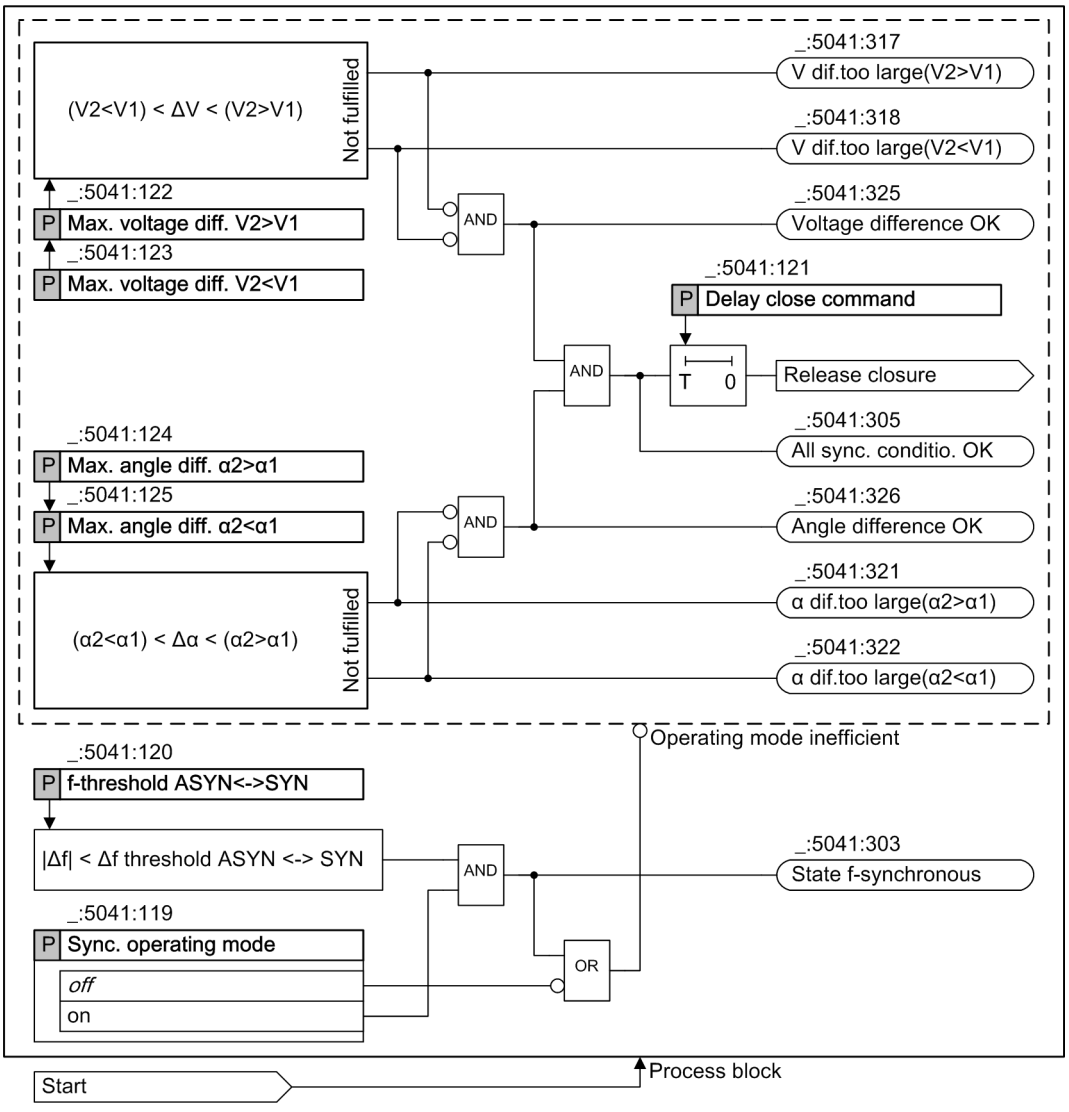
With this operating mode, the values ΔV, Δf, and Δα are checked before connecting the 2 parts of the electrical power system. The indication **`All sync. conditio. OK`** signals that the setting values (conditions) have been reached and that the release for closure has been given (see **Checking the Closing Conditions, Closure** in section *8.4.6 Sequence of Functions*).

Every fulfilled condition is signaled individually via the indications **`Voltage difference OK`**, **`Frequency diff. OK`**, and **`Angle difference OK`**.

If a condition is not fulfilled, detailed information on why the condition is not fulfilled is provided via indications. If the differential voltage is outside the setting limits, for example, the indication **`V dif.too large (V2<V1)`** is issued. The indication indirectly contains information that the voltage V2 has to be increased for a successful synchronization.

With the **Expanded delta-f options** stage type configured and an activated **`(_:140) Limit dfdiff/dt for sync. op`** parameter, the frequency difference rate of change is also checked. If the permissible frequency change rate (parameter **`(_:141) Max. value dfdiff/dt syn`**) is exceeded, the indication **`(_:329) d fdiff/dt too large`** is issued.

8.4.8 Closing Conditions for the Synchronous/Asynchronous Stage Type



A distinction according to synchronous and asynchronous systems can be made with this type of stage.

If galvanically coupled systems are switched in parallel, synchronous systems are present. A typical characteristic for synchronous systems is equality of frequency (Δf ≈ 0). If the frequency difference falls below the setting value of the **f-threshold ASYN<->SYN** parameter, synchronous systems are to be assumed. If the frequency difference exceeds the setting value of the **f-threshold ASYN<->SYN** parameter, asynchronous systems are to be assumed. This status occurs in galvanically isolated systems, for example.

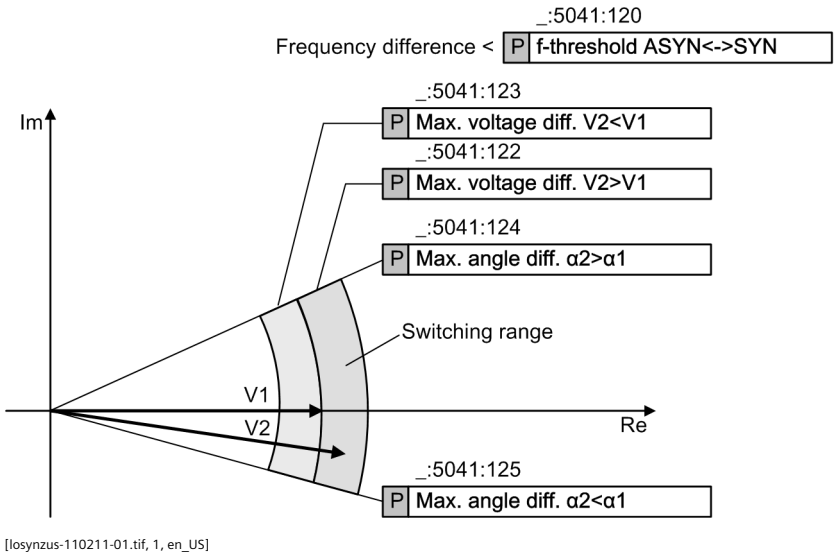
Both states have their own operating mode with its own closing conditions. Both operating modes can be switched on and off separately (parameter **Sync. operating mode** and **Async. operating mode**). The following combinations result from this:

Sync. operating mode	**Async. operating mode**	Functionality
on	***on***	If the frequency difference is below the threshold value set **f-threshold ASYN<->SYN**, the operating mode synchronous is active. In other cases, the operating mode asynchronous is active.
off	***on***	Regardless of the frequency difference and the threshold value **f-threshold ASYN<->SYN**, the operating mode is exclusively active asynchronously.
on	***off***	If the frequency difference is below the threshold value set **f-threshold ASYN<->SYN**, the operating mode synchronous is active. In other cases, the stage is inactive, i.e. a switching release cannot be issued.
off	***off***	Both operating modes are deactivated. No activation release can be be given via these operating modes either.

Checking the Closing Conditions in Synchronous Systems

[losynsyn-100611-01.tif, 1, en_US]

Figure 8-67 Closing Conditions when Switching Synchronous Systems

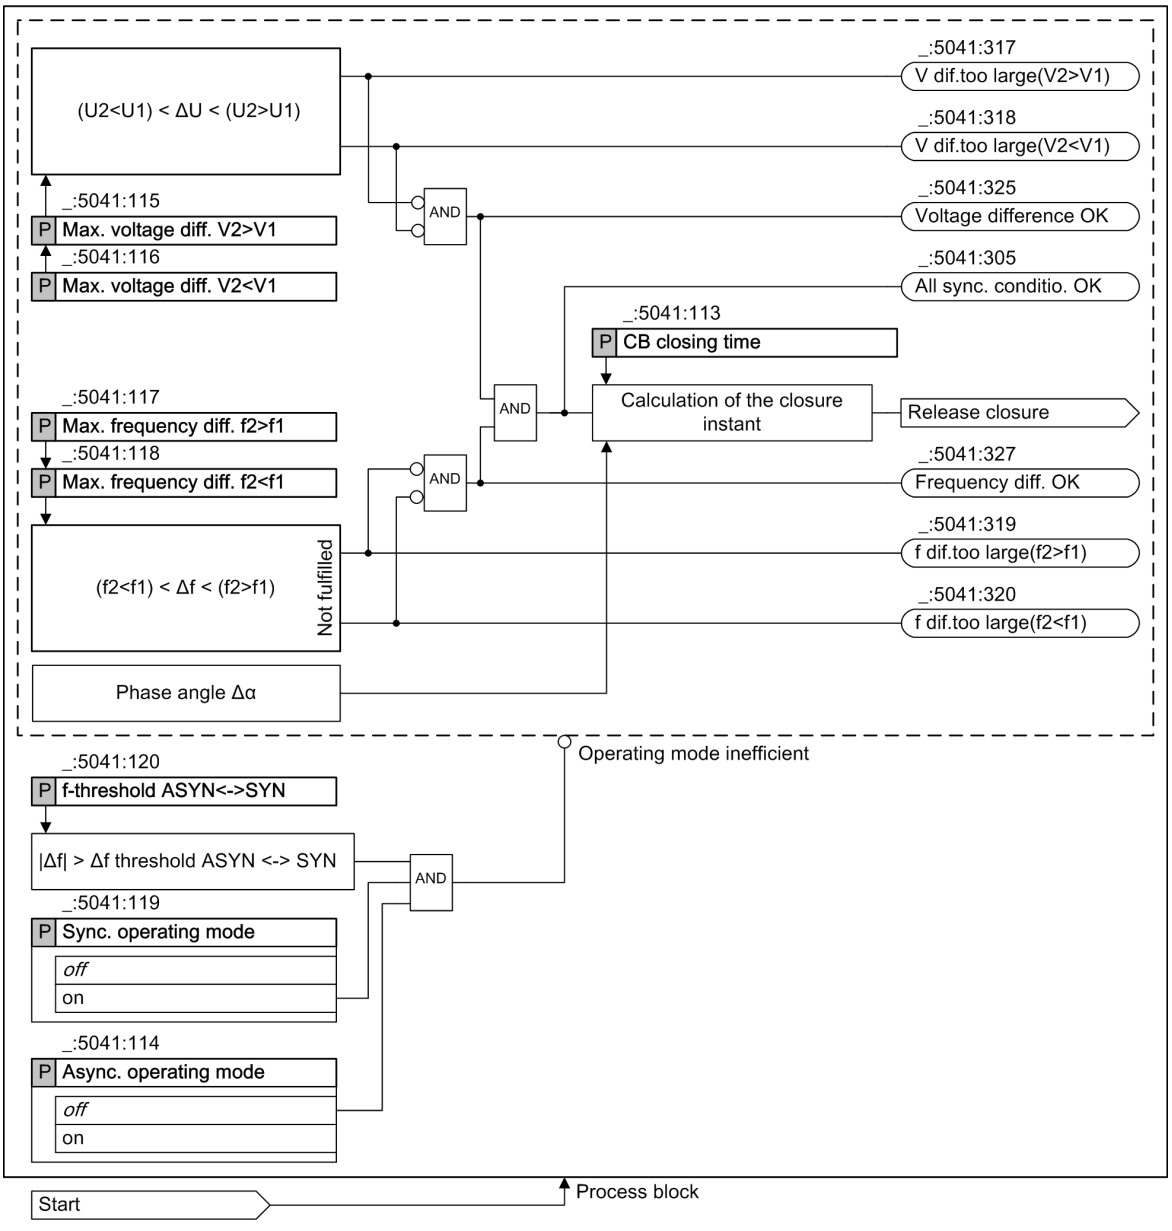


The frequency difference is very low in the synchronous systems operating mode. It is below the threshold value **f-threshold ASYN<->SYN**. The status is signaled via the **State f-synchronous** indication.

The parameters ΔV and Δα are checked for issuing an activation release (see *Figure 8-68*). The indication **All sync. conditio. OK** signals that both setting values (conditions) are reached. If the conditions remain fulfilled over the set time delay (parameter **Delay close command**), the release for closing is given (see also chapter *8.4.7 Closing Conditions for the Synchrocheck Stage Type*).

Every condition fulfilled is signaled individually via the indications **Voltage difference OK** and **Angle difference OK**.

If a condition is not fulfilled, detailed information on why the condition is not fulfilled is provided via indications. If the differential voltage is outside the setting limits, for example, the indication **V dif.too large(V2<V1)** is issued. The indication indirectly contains information that the voltage V2 has to be increased for a successful synchronization.

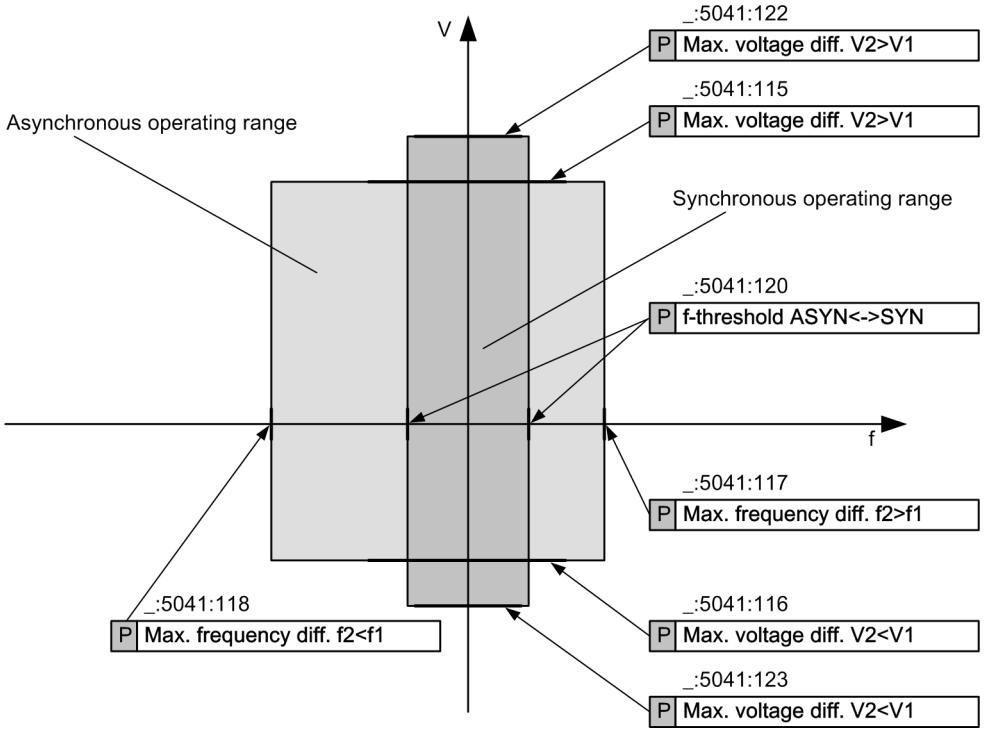


With the **Expanded delta-f options** stage type configured and an activated **(_:142) Limit dfdiff/dt for asyn. op** parameter, the frequency difference rate of change is also checked. If the permissible frequency change rate (parameter **(_:143) Max. value dfdiff/dt asyn**) is exceeded, the indication **(_:329) d fdiff/dt too large** is generated.

[losynzus-110211-01.tif, 1, en_US]

Figure 8-68 Connecting Under Synchronous System Conditions

Checking Closing Conditions in Asynchronous Systems



[losynasy-210912-01.tif, 1, en_US]

Figure 8-69 Closing Conditions when Switching Asynchronous Systems

In this operating mode, compliance with the voltage difference ΔV and frequency difference Δf conditions is checked. The function calculates the time point of the close command taking into account the angular difference Δα and the closing time of the circuit breaker. This is calculated so that the voltage phasors are equal at the moment of pole contact by the circuit breaker (ΔV ≈ 0, Δα ≈ 0).

Ranges in the Voltage-Frequency Diagram (V-f Diagram)

Figure 8-70 shows the setting parameters for synchronous and asynchronous conditions in the V-f diagram. The frequency range is very narrow owing to the functional principle in the case of synchronous systems.

[losynarb-080211-01.tif, 1, en_US]

Figure 8-70 Operating Range Under Synchronous and Asynchronous Conditions for Voltage (V) and Frequency (f)

8.4.9 Expanded Checks (df/dt and Smoothing of Oscillations)

When configuring the **Expanded delta-f options** function block, you can expand the synchronization checks to include the following aspects:

- Limitation of the frequency change rate

  With this option, you can define additional upper limits for the rate of permissible requency difference change. The release checks for both stage types take these additional upper limits into consideration. Both activation (parameters **(_:140) Limit dfdiff/dt for sync. op** and **(_:142) Limit dfdiff/dt for asyn. op**) and the upper limits (parameters **(_:141) Max. value dfdiff/dt syn** and **(_:143) Max. value dfdiff/dt asyn**) for the frequency change rate are adjustable selectively for synchronous and asynchronous conditions. Both stage types consider the frequency change rate when issuing the release for switching and indicate when the rate is exceeded.

  If you also activate the option to compensate for low-frequency oscillations (parameter **(_:150) Suppr. frequ. oscillations**), the frequency change rate is stabilized in the presence of such oscillations. Stabilization is in effect for asynchronous as well as synchronous operating modes.

- Compensation for low-frequency oscillations

  If you activate this option (parameter **(_:150) Suppr. frequ. oscillations**), low-frequency oscillations, for example, as a consequence of power swings in the range of 0.8 Hz to 1.6 Hz are detected and smoothed. This stabilizes the release checks in the presence of frequently changing violations of upper and lower limits for the specified frequency threshold values. The option affects the frequency check of the **Synchrocheck** stage types and the synchronous operating mode of the **Synchronous/Asynchronous** stage type. It does not affect the asynchronous operating mode.

  In the example of the following figure, the synchrocheck function would initiate energization, if the allowed frequency difference was set to 10 mHz without the parameter **Suppr. frequ. oscillations** as soon as the frequency f2 enters the 10-mHz band. If the parameter **Suppr. frequ. oscillations** is activated, energization is not initiated, since the average value of f2 is outside the band.

[dwsynfre-101013-01.vsd, 1, en_US]

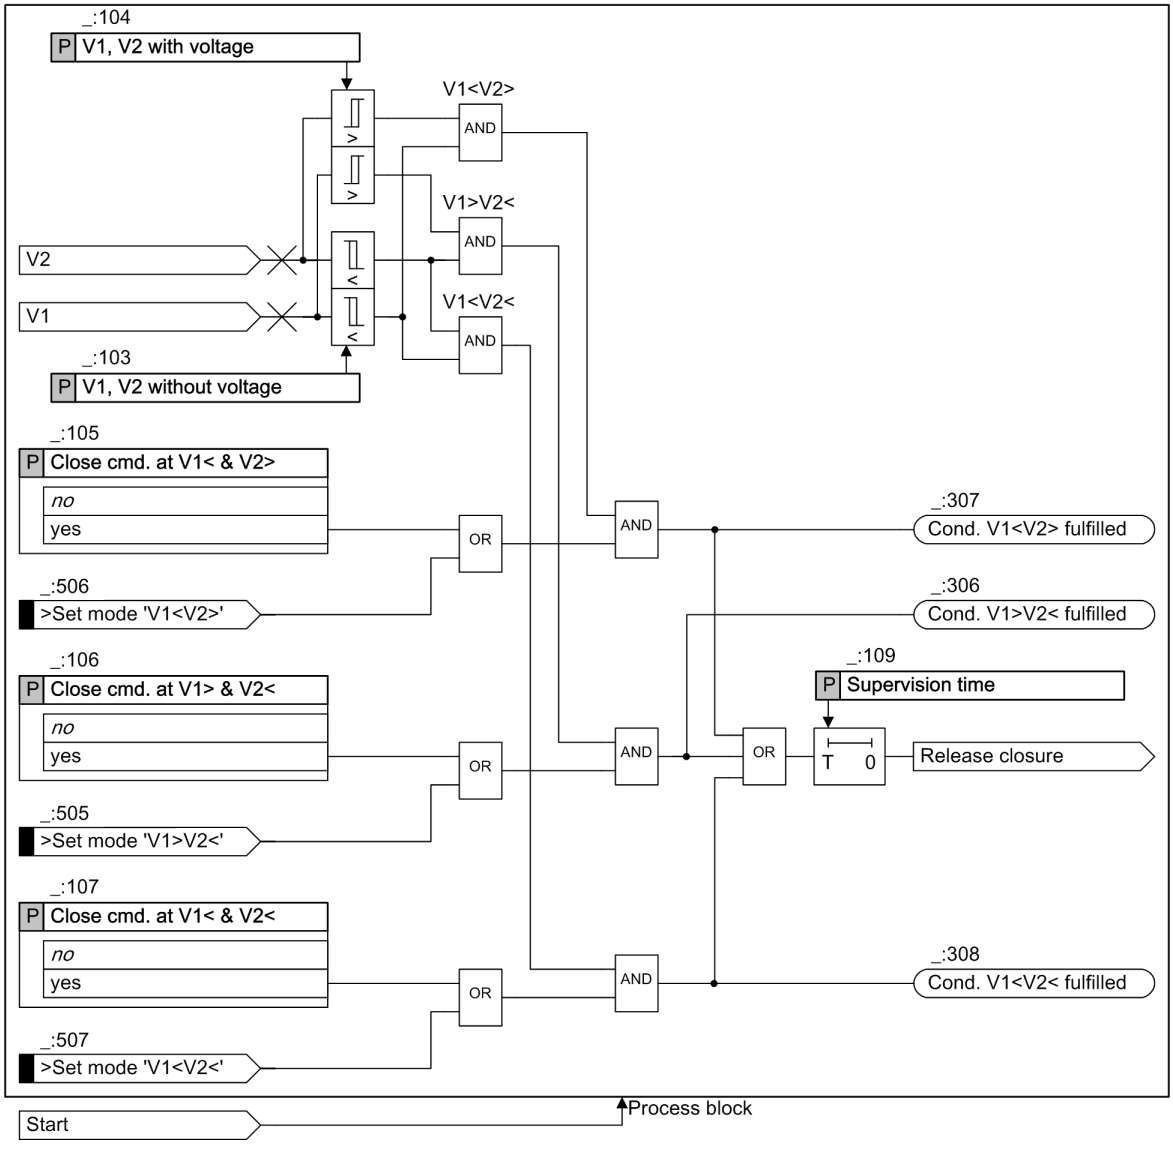
Figure 8-71 Example: Frequency Difference between the Constant Frequency f1 and the Sinusoidal Oscillating Frequency f2

With this option active, the range of function measured values is expanded by the smoothed frequency. Release of switching in synchronous networks occurs after one second at the earliest. This time is needed to smooth the frequency measured values.

The actual frequency can be larger or smaller than the smoothed value at any instant. The **Max. diff. "f threshold"** parameter makes it possible to limit the increase in instantaneous frequency value in relation to the respective frequency threshold value.

8.4.10 Closing at De-Energized Line/Busbar

If at least one of 2 parts of an electrical power system is de-energized, the parts of the electrical power system can be connected together via the following operating modes.



If the measured voltage is less than the threshold **V1, V2 without voltage**, the zero potential of the part of the electrical power system is detected. In this case, all phases are compared to the parameter **V1, V2 without voltage**. The energized side must be in the defined operating range with respect to voltage and frequency (see chapter *8.4.4 General Functionality*) and all phases must exceed the threshold **V1, V2 with voltage**.

The following additional closing conditions can be selected, which are then applied next to the closing conditions for the synchronism:

Settings	Description
Close cmd. at V1> & V2<	Closing release under the condition that the part V_1 of the power system is energized and the part of the electrical power system U_2 is de-energized.
Close cmd. at V1< & V2>	Closing release under the condition that the part V_1 of the power system is de-energized and the part of the electrical power system U_2 is energized.

Settings	Description
Close cmd. at V1< & V2<	Closing release provided mains adapters V_1 and V_2 are de-energized.

Each of these conditions can be made effective individually via parameters or binary input. You can also set parameters for combinations, for example a release for closure, if **Close cmd. at V1> & V2<** or **Close cmd. at V1< & V2>** has been fulfilled.

[losyn003-160311-01.tif, 1, en_US]

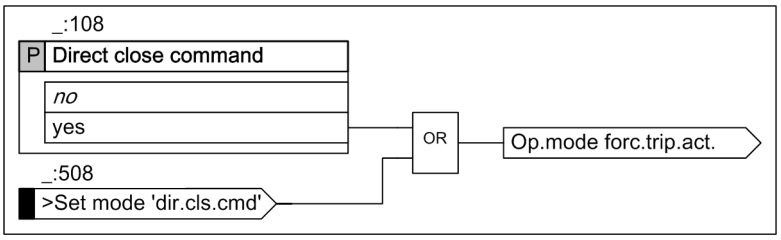


Figure 8-72 Release Conditions for Switching to De-Energized Line/Busbar

The indications **Cond. V1>V2< fulfilled**, **Cond. V1<V2> fulfilled** and **Cond. V1<V2< fulfilled** indicate that the relevant conditions are fulfilled.

You can use the **Supervision time** parameter to set a supervision time for which the closing conditions must at least be fulfilled with de-energized connection, before closing is allowed.

8.4.11 Direct Close Command

You can activate the operating mode direct close command statically via the **`Direct close command`** parameter or dynamically with the binary input signal **`>Op. mode 'dir.cls.cmd'`** (see *Figure 8-73*).

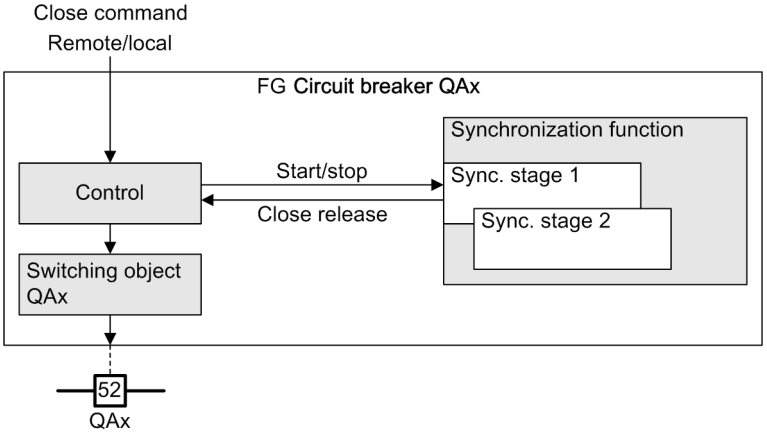
[losyndir-140611-01.tif, 1, en_US]

Figure 8-73 Activation of the Operating Mode Direct Close Command

The operating mode **Direct close command** function initiates a closure release without any testing upon start of the synchronization stage. The closure occurs immediately.

The combination **Direct close command** with other operating modes is not recommended, as the other operating data is bypassed.

If the synchronization function is defective (standby of the sync stage = alarm or warning), a direct close command is executed or not executed, depending on the type of fault (see also supervisions in chapter *8.4.4 General Functionality*).



8.4.12 Interaction with Control, Automatic Reclosing (AREC), and External Triggering

With Control

The control and synchronization function are always located in a function group **Circuit breaker**. The control and also the synchronization function always operate with the circuit breaker, which is linked to the function group **Circuit breaker**.

As soon as the synchronization function is in the function group **Circuit breaker**, the circuit breaker is subject to compulsory synchronization. If all synchronization stages are deactivated, the circuit breaker cannot be activated via the control, as no release can be generated for the closure. The circuit breaker is no longer subject to compulsory synchronization after deletion of the synchronization function. Closure without synchronization is then possible via the control.

If closure is to be synchronized via the control, the control automatically generates an internal signal which starts the synchronization function. The functional sequence is described in chapter *8.4.6 Sequence of Functions*. After fulfilling all closing conditions, the synchronization sends a release signal to the control, which closes the circuit breaker and then stops and synchronization function.

[losynaw1-310111-01.tif, 1, en_US]

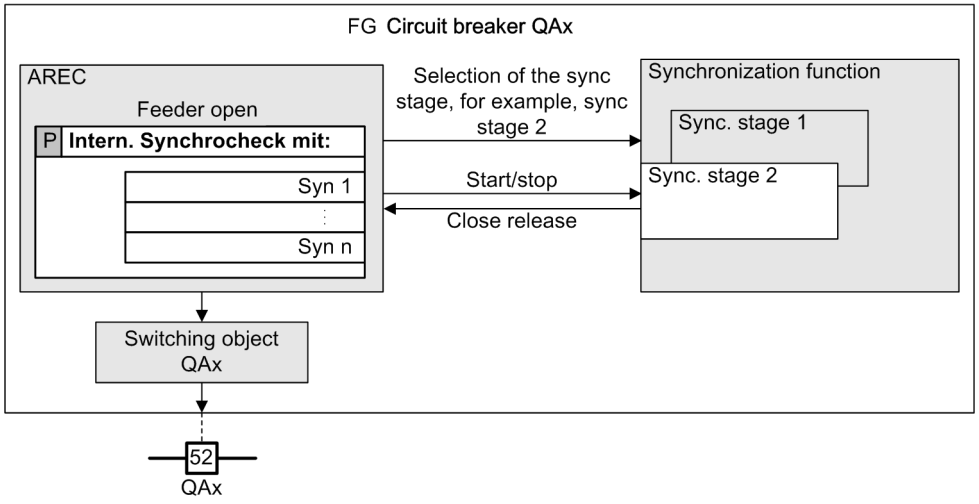


Figure 8-74 Interaction of the Control with the Synchronization Function

With Automatic Reclosing

The automatic reclosing mechanism (AREC) can also work with the synchronization function. Both functions are always located in a function group **Circuit breaker**. Consequently the AREC and synchronization function always work with the circuit.breaker that is linked to the function group **Circuit breaker**.

You must select a synchronization stage via settings within the AREC so that closure is synchronized by the AREC. The tests for the synchronization stage are used for the closure by the AREC. If no synchronization stage is selected, the AREC then activates without synchronization.

If closure is to be synchronized via the AREC, the AREC automatically generates an internal signal which starts the synchronization function. The functional sequence is described in chapter *8.4.6 Sequence of Functions*. After fulfilling all closing conditions, the synchronization sends a release signal to the AREC, which closes the circuit breaker and then stops and synchronization function.

[losynaw2-100611-01.tif, 1, en_US]

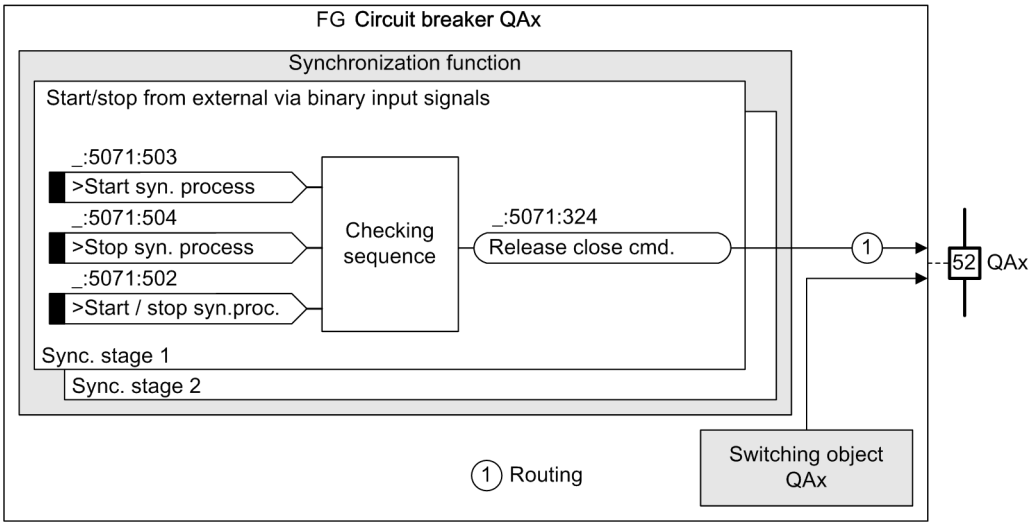

Figure 8-75 Connection of the AREC to the Synchronization Function

With External Control

You have the option of controlling the synchronization function externally via binary input signals. This can be done as follows:

- Edge-controlled
- Via the signals **>Start syn. process** and **>Stop syn. process**
- State-controlled, via the signal **>Start / stop syn.proc.** (see also chapter *8.4.6 Sequence of Functions*).

The start is followed by the functional sequence (see chapter *8.4.6 Sequence of Functions*). If the conditions are fulfilled, the output signal **Release close cmd.** is issued. The switched object QAx of the function group **Circuit breaker** is not closed. The output signal **Release close cmd.** must be explicitly assigned to the binary output in order to close the circuit breaker.

[losynaw3-160311-01.tif, 1, en_US]

Figure 8-76 Interaction of the Synchronization Function with External Control

8.4.13 Application and Setting Notes (General)

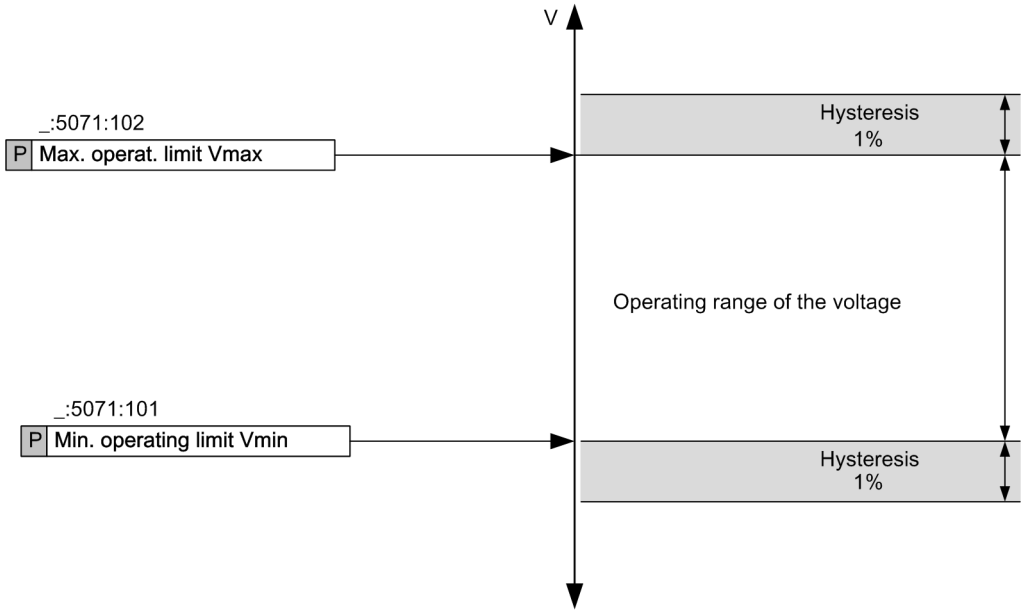
Stage-Type Selection

The following 2 types of stage are available:

Stage Type	Application
Synchrocheck stage	Select this type of stage to issue, for example, an additional release during an automatic reclosing or a manual reclosing for safety reasons. With this type, the variables ΔV, Δf and $\Delta\alpha$ are checked before connecting the 2 parts of the power system.
Synchronous/asynchronous stage	Select this type of stage if it is necessary to differentiate between synchronous and asynchronous systems, depending on the switch position. If galvanically coupled systems are switched in parallel, synchronous systems are present. A typical characteristic for synchronous systems is equality of frequency ($\Delta f \approx 0$). In this state, the conditions $\Delta\alpha$ and ΔV are checked. If the systems are galvanically isolated, asynchronous systems can be present. At the same time, compliance with the voltage difference ΔV and frequency difference Δf conditions is checked. The time of the direct close command is calculated taking into account the angle difference $\Delta\alpha$ and the closing time of the circuit breaker. The time of the direct close command is calculated so that the voltages are equal at the moment of pole contact of the circuit breaker ($\Delta V \approx 0$, $\Delta\alpha \approx 0$).

Configuration of the Voltages V1 (Reference Side) and V2

The voltages V1 and V2 are established via the connection of the measuring points to the interface of the function groups (refer to chapter *8.4.3 Connection and Definition*). The measuring point connected to the interface **Voltage** is the reference side 1 with the reference voltage V1. The measuring point connected to the interface **Sync. voltage** is the side 2 with V2. The definition of the Delta parameters that can be derived from this is also described in chapter *8.4.3 Connection and Definition* .



Parameter: **Min. operating limit Vmin ,Max. operat. limit Vmax**

- Recommended setting value **(_:5071:101) Min. operating limit Vmin** = ***90 V***
- Recommended setting value **(_:5071:102) Max. operat. limit Vmax** = ***110 V***

The values define the voltage operating range of the synchronization stage. A normal setting is approx. ±10 % of the rated voltage.

NOTE

All voltages connected according to the parameterized measuring-point connection type are subjected to the appropriate Vmin/Vmax test. Therefore, connected phase-to-ground voltages are multiplied by √3 as the threshold values with reference to the rated voltage (phase-to-phase voltage) must be set.

[lohyster-010415-01.vsd, 1, en_US]

If the Synchronization function is started within the hysteresis, no switching is performed as a result of the minimum and maximum operating limit (parameters **Min. operating limit Vmin** and **Max. operat. limit Vmax**). If the Synchronization function is started within the voltage operating range and the voltage exceeds the minimum or maximum operating limit during the synchronization process, selecting can occur in the area of the hysteresis.

Parameter: **Max.durat. sync.process**

- Default setting **(_:5071:110) Max.durat. sync.process** = ***30 s***

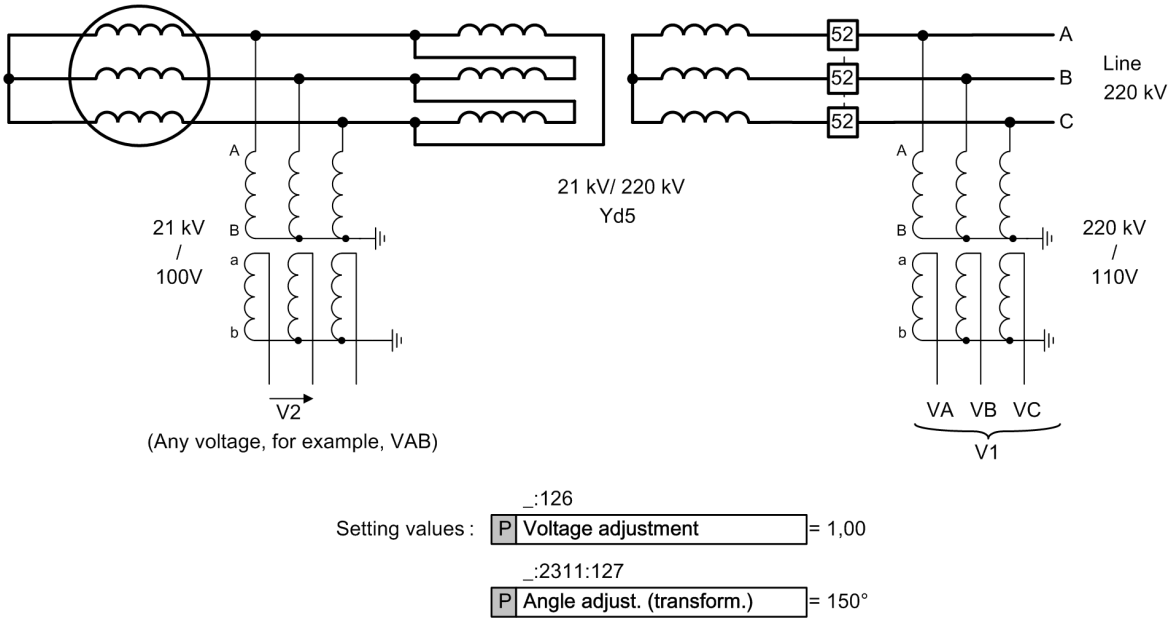
The parameterized conditions must be fulfilled within this time. If the conditions are not fulfilled, no further closing release takes place and the synchronization stage is stopped. If this time is set to ∞, the conditions are checked until they are fulfilled. This is also the default setting. Observe the operating conditions when defining the time limitation. This must be defined specifically for each system. If 0 or 0.01 s is set, then all conditions are checked once at the starting time point. Thereafter the process is stopped immediately.

Parameter: **Voltage adjustment**

- Default setting **(_:5071:126) Voltage adjustment** = ***1.00***

The parameter can be used for correction of amplitude errors, for example, due to indirect measurement (for example, tap changer).

To apply a transformer between measuring points, the **Voltage adjustment** parameter is not needed. The transformer ratios are set for the measuring points and the function will take them into account automatically.



Parameter: `Angle adjust. (transform.)`

- Default setting **`(_:2311:127) Angle adjust. (transform.)`** = *0* °

The parameter can be applied under the following conditions:

- 1. Phase-angle rotation by power transformer between the measuring points
- 2. Correction of phase-angle errors

1. Phase-angle rotation by power transformer between the measuring points:

[losynae1-160311-01.tif, 1, en_US]

Figure 8-77 Transformer Between the Measuring Points

If there is a power transformer between the voltage transformers of the circuit breaker to be synchronized, you then have to correct the phase-angle rotation for a vector group deviating from 0. *Figure 8-77* shows such an application. The **`Angle adjust. (transform.)`** parameter is used to save the phase-angle rotation.

The vector group of the transformer is defined by the upper voltage side to the lower voltage side. If the reference voltage transformer V1 is connected on the upper voltage side of the transformer (as in *Figure 8-77*), enter the phase-angle rotation directly according to the vector group. A vector-group figure of 5, for example, means an angular rotation of 5 · 30° = 150°. Set this value for the **`Angle adjust. (transform.)`** parameter.

If the voltage connection V1 is on the lower voltage side due to the system, you then have to apply the extension angle with 360°. A transformer with vector group 5 yields an angular adjustment of 360° – (5 · 30°) = 210°

2. Correction of phase-angle errors: You can correct a phase-angle error between the voltage transformers in increments. Ascertain a possible correction value during commissioning.

Parameter: CB make time

- Default setting **`(_:5041:113) CB make time`** = *0.06 s*

If you are to interconnect under asynchronous system conditions with the device as well, the closing time of the circuit breaker must be taken into account. The device uses this to calculate the time of the direct close command, so that the voltages are in phase at the moment of closure of the switch poles. Note that apart from the operating time of the switch, this also includes the pickup time of an auxiliary relay that may be upstream. You can determine the closing time using the protection device (see commissioning notes in chapter *11.12 Primary and Secondary Testing of the Synchronization Function*).

This parameter only occurs for the stage type **Synchronous/asynchronous**.

8.4.14 Application and Setting Notes (Synchrocheck)

Parameter: Maximum Differential Values of Voltage, Frequency and Angle

- Default setting **(_:5071:122) Max. voltage diff. V2>V1** = ***5.0 V***
- Default setting **(_:5071:123) Max. voltage diff. V2<V1** = ***5.0 V***
- Default setting **(_:5071:117) Max. frequency diff. f2>f1** = ***0.10 Hz***
- Default setting **(_:5071:118) Max. frequency diff. f2<f1** = ***0.10 Hz***
- Default setting **(_:5071:124) Max. angle diff. α2>α1** = ***10***°
- Default setting **(_:5071:125) Max. angle diff. α2<α1** = ***10***°

2 parameters are available for the differential values voltage, frequency, and angle. Unbalanced closing ranges can be set with this, if required.

The permissible differential values must ensure that no protection tripping or damage occurs in the system owing to compensation processes (circulating current) and power swings after interconnection of the parts of the power system. The settings must not be configured too closely on the other side so that necessary closures are not blocked.

Typical differential values are selected in the default setting. Depending on the system, the settings must be checked and adjusted, if necessary.

8.4.15 Application and Setting Notes (Synchronous/Asynchronous Closure)

Parameter: Synchronous operating mode, Asynchronous operating mode

- Default setting **(_:5041:119) Sync. operating mode** = ***off***
- Default setting **(_:5041:114) Async. operating mode** = ***off***

The operating modes of the stages can be activated or deactivated via the parameters. The operating modes are deactivated in the default setting for safety reasons.

The following combination options are possible:

Sync. operating mode	Async. operating mode	Description
on	***on***	If the frequency difference is below the threshold value set **f-threshold ASYN<->SYN**, the operating mode **synchronous** is active. In other cases, the operating mode **asynchronous** is active. If you wish to interconnect galvanically isolated systems, then select this operating mode.
off	***on***	Regardless of the frequency difference and the threshold value **f-threshold ASYN<->SYN**, the operating mode active is exclusively **asynchronous**. The closing time of the circuit breaker is this always taken into account for determining the connecting point. Select this operating mode if you wish to activate machines, for example generators or asynchronous motors. If the same frequency is present on the sides to be interconnected, then this operating mode is not possible. Since, in the case of dependency on the phase angle position (Δα), release of the closure may not be issued.

Sync. operating mode	Async. operating mode	Description
on	***off***	Use this operating mode for galvanically connected systems. Closure is only possible with synchronous systems (with low Δf).
off	***off***	Both operating modes are deactivated. No closing release can be therefore be given via this operating mode. This configuration is only advisable for special applications. Select this operating mode if you only wish to switch, for example de-energized parts of the power system.

Parameter for asynchronous operation: Max. voltage diff. of voltage and frequency

- Default setting **(_:5041:115) Max. voltage diff. V2>V1** = ***2.0 V***
- Default setting **(_:5041:116) Max. voltage diff. V2<V1** = ***2.0 V***
- Default setting **(_:5041:117) Max. frequency diff. f2>f1** = ***0.10 Hz***
- Default setting **(_:5041:118) Max. frequency diff. f2<f1** = ***0.10 Hz***

For information, see **Parameter for synchronous operation**

Parameter for synchronous operation: Maximum voltage diff. of voltage and angle

- Default setting **(_:5041:122) Max. voltage diff. V2>V1** = ***5.0 V***
- Default setting **(_:5041:123) Max. voltage diff. V2<V1** = ***5.0 V***
- Default setting **(_:5041:124) Max. angle diff. α2>α1**= ***10***°
- Default setting **(_:5041:125) Max. angle diff. α2<α1**= ***10***°

2 parameters are available for the differential values voltage, frequency, and angle. Unbalanced closing ranges can be set with this, if required.

The permissible differential values must ensure that no protection tripping or damage occurs in the system owing to compensation processes (circulating current) and power swings after interconnection of the parts of the power system. The settings must not be configured too closely on the other side so that necessary closures are not blocked.

Typical differential values are selected in the default setting. Depending on the system, the settings must be checked and adjusted, if necessary.

Parameter: Switchover between synchronous and asynchronous operation

- Recommended setting value **(_:5041:120) f-threshold ASYN<->SYN** = ***0.01 Hz***

This parameter is used to set the frequency difference for switching over between synchronous and asynchronous operation.

Siemens recommends using the default setting of ***0.01 Hz***.

8.4.16 Application and Setting Notes (De-Energized Switching/Direct Close Command)

If at least one of 2 parts of an electrical power system is de-energized, the parts of the electrical power system can be connected together via the following operating modes. The above potential release conditions are independent of one another and can also be combined.

NOTE

For reasons of safety, the releases have been deactivated in the default setting and are therefore at ***no***. Even if you wish to apply one of these operating modes, Siemens recommends leaving the setting at ***no*** for reasons of safety. Set the operating mode only dynamically via the assigned binary input signal (for example **>Operating mode 'U1>U2<'**) (see also *Figure 8-72*). This prevents one of these operating modes from being incorrectly activated statically thereby resulting in an incorrect switching.

Parameter: **Close cmd. at V1< & V2>**

- Recommended setting value **(_:5071:105) Close cmd. at V1< & V2>** = ***no***

Settings	Description
no	No release for closing is possible via this operating mode.
yes	If part V1 of the power system is de-energized and part V2 of the power system is energized, the release for closure is given upon starting the synchronization stage after the supervision time has passed. The setting depends on the operational requirements. Note the above information.

Parameter: **Close cmd. at V1> & V2<**

- Recommended setting value **(_:5071:106) Close cmd. at V1> & V2<** = ***no***

Settings	Description
no	No release for closing is possible via this operating mode.
yes	If part V1 of the power system is energized and part V2 of the power system is de-energized, the release for closure is given upon starting the synchronization stage after the supervision time has passed. The setting depends on the operational requirements. Note the above information.

Parameter: **Close cmd. at V1< & V2<**

- Recommended setting value **(_:5071:107) Close cmd. at V1< & V2<** = ***no***

Settings	Description
no	No release for closing is possible via this operating mode.
yes	If the parts V1 and V2 of the power system are de-energized, the release for closure is given upon starting the synchronization stage after the supervision time has passed. The setting depends on the operational requirements. Note the above information.

Parameter: **V1, V2 with voltage**

- Recommended setting value **(_:5071:104) V1, V2 with voltage** = ***80 V***

The setting value indicates the voltage above which a part of the power system (feeder or busbar) can be regarded as activated with certainty.

You must set the value below the minimum expected operational undervoltage. Siemens therefore recommends a setting value of approx. 80 % of the rated voltage. All voltages connected according to the parameterized measuring-point connection type are subjected to the appropriate Vmin/Vmax test.

Parameter: **V1, V2 without voltage**

- Recommended setting value **(_:5071:103) V1, V2 without voltage** = ***5 V***

The setting value indicates the voltage below which a part of the power system (feeder or busbar) can be regarded as deactivated with certainty.

Siemens recommends a setting value of approx. 5 % of the rated voltage for this. All voltages connected according to the parameterized measuring-point connection type are subjected to the appropriate Vmin/Vmax test.

Parameter: `Supervision time`

- Recommended setting value **`(_:5071:109) Supervision time`** = ***`0.1 s`***

The parameter defines a supervision time for which the above additional closing conditions have to be at least fulfilled at de-energized switching, before the release for closing is given. In order to include transient phenomena, Siemens recommends a value of ***`0.1 s`***.

Parameter: `Direct close command`

- Recommended setting value **`(_:5071:108) Direct close command`** = ***`no`***

In this operating mode, the function initiates a closing release without any testing upon start of the synchronization stage. The closure occurs immediately.

NOTE

For safety reasons, Siemens recommends leaving the setting at ***`no`***. If a direct close command is necessary, Siemens recommends only using this operating mode dynamically via the binary input signal **`>Op. mode 'dir.cls.cmd'`** (see also *Figure 8-74*). This prevents this operating mode from being incorrectly activated statically thereby resulting in an incorrect switching.

8.4.17 Settings

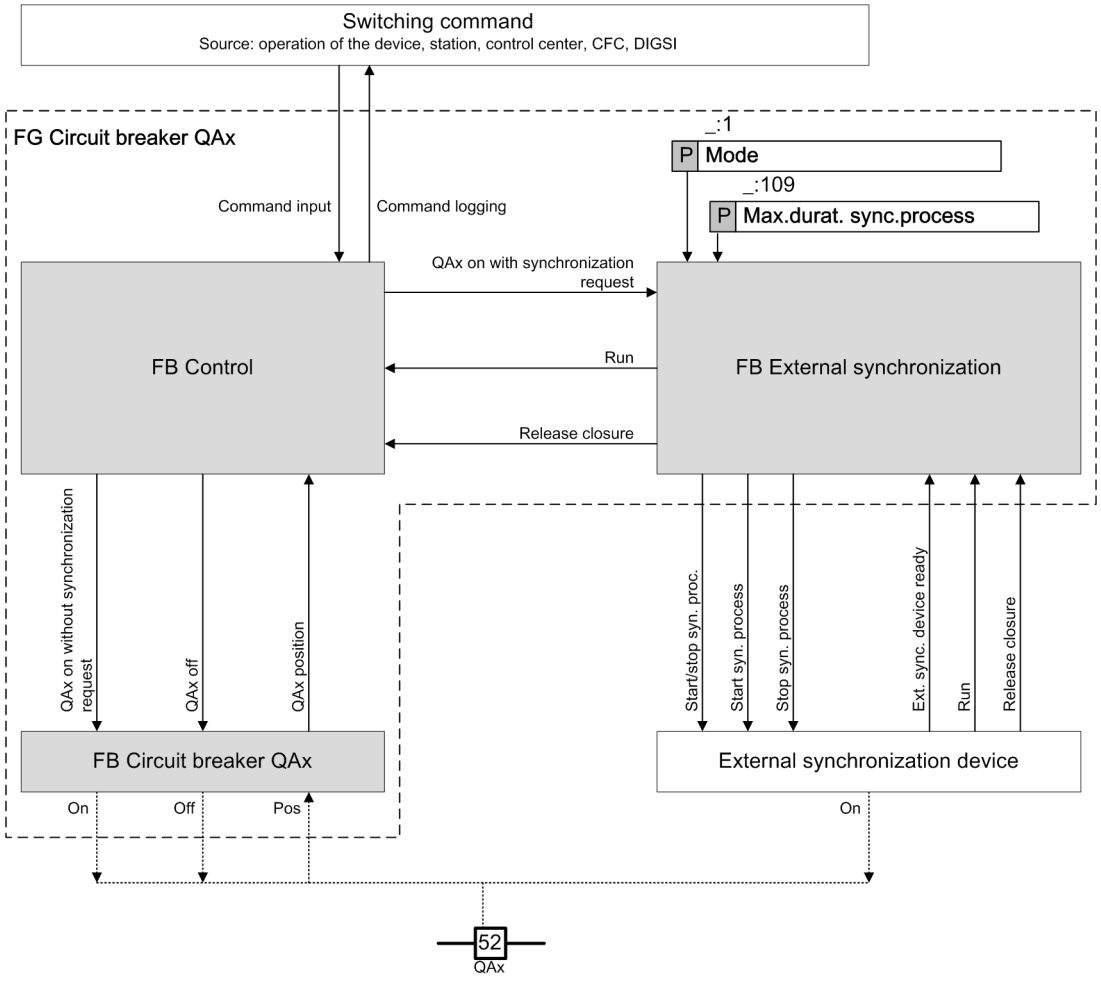
8.4.19 External Synchronization

The purpose of the **External synchronization** function is to control an external synchronization device.



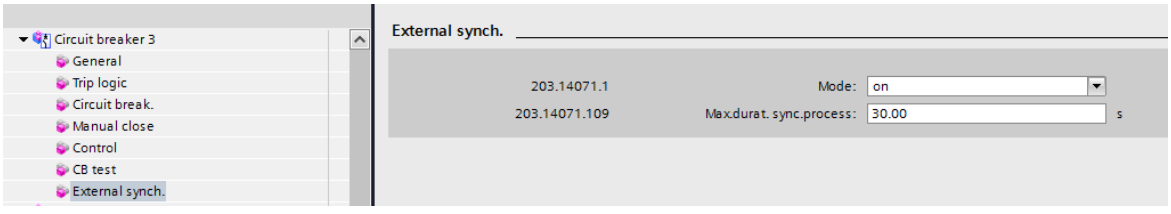
[dw_ctrl_ext_sync_device, 1, en_US]

Figure 8-78 Triggering an External Synchronization Device

The bay controller in bay x should switch the circuit breaker in bay x in synchrony. The synchronization check is carried out in the central paralleling device 7VE6. In addition to the paralleling device, another central bay controller ensures the switching of the correct measuring voltages and the routing of the CB close command from the 7VE6 to the correct circuit breaker in bay x. The bay controller x provides the information to the central bay controller via IEC61850-GOOSE.

The **External synchronization** is designed as a function block which can be used in the Circuit-breaker function group. The additional **External synchronization** function block integrates the external synchronization into command processing, so that the corresponding feedback can be forwarded to the command source.

If a circuit-breaker close command with a synchronization requirement is present, the external synchronization device is started. After successfully checking the synchronization conditions, the close command is issued from the external synchronization device to the circuit breaker. If a circuit-breaker close command without synchronization requirement is present, the circuit-breaker close command is issued directly from the **Circuit-breaker** function group to the circuit breaker. Also, each circuit-breaker trip command is issued directly to the circuit breaker.



[dwextsyn-01, 1, en_US]

Figure 8-79 Interaction between Control and External Synchronization

Parameterization with DIGSI

In the DIGSI library, the function is visible inside the **Circuit-breaker** function group as the **External synchronization** function block. You can instantiate the function block in the **Circuit-breaker** function group and the **Circuit-breaker (control)** function group. You can instantiate only 1 **External synchronization** function block within these function groups at a time.

[scextsyn, 1, 1, en_US]

Figure 8-80 Instantiating the **External Synchronization** Function Block in the **Circuit-Breaker** Function Group

It is not possible to jointly instantiate the **External synchronization** function block with the **25 synchronization** function in the same **Circuit-breaker** function group.

Notes for Optional Input Interconnections

You have the option of connecting the input signals *>Close cmd. released* and *>In progress* . If you omit these interconnections, observe the following instructions:

Input *>Close cmd. released* :

If you do not interconnect the input signal *>Close cmd. released* , the execution of a circuit-breaker close command with synchronization requirement is confirmed directly (execution successful: OPR+), as soon as the output signal *Start syn. process* is set. In this case, the **(_:109) Max.durat. sync.process** setting has no meaning. If you use a control model with feedback monitoring, consider that the feedback monitoring will start immediately when the *Start syn. process* signal is tripped. The **(_:4201:103) Feedback monitoring time** setting must therefore be set higher than the maximum synchronization time of the external synchronization device plus the circuit-breaker closing time. If *>Close cmd. released* is not routed, the output *Start/stop syn. proc.* is not set.

Input *>In progress* :

The interconnection of the input signal *>In progress* is intended to check whether the synchronization device has received the *Start syn. process* signal. If you do not interconnect this input signal and the external synchronization device rejects a start command, the negative acknowledgment of the circuit-breaker close command does not occur until the maximum synchronization time (parameter **(_:109) Max.durat. sync.process**) has expired.

8.4.20 Application and Setting Notes (External Synchronization)

Parameter: Mode

- Default setting **(_:1) Mode** = ***on***

With the **Mode** setting, you switch the external synchronization function on or off. If you set the **Mode** setting to ***off***, a circuit-breaker close command with synchronization requirement is rejected.

Parameter: Max.durat. sync.process

- Default setting **(_:109) Max.durat. sync.process** = ***30 s***

The **Max.durat. sync.process** setting defines the maximum synchronization time. The time starts when the **External synchronization** function block sends a close command to the external synchronization device. The command must be executed within this time. If the close command is not executed within this time, the **External synchronization** function block sends a command to cancel closing to the external synchronization device.

8.4.21 Settings

Addr.	Parameter	C	Setting Options	Default Setting
External synch.				
_:1	External synch.:Mode		• off • on • test	on
_:109	External synch.:Max.durat. sync.process		0.00 s to 3600.00 s	30.00 s

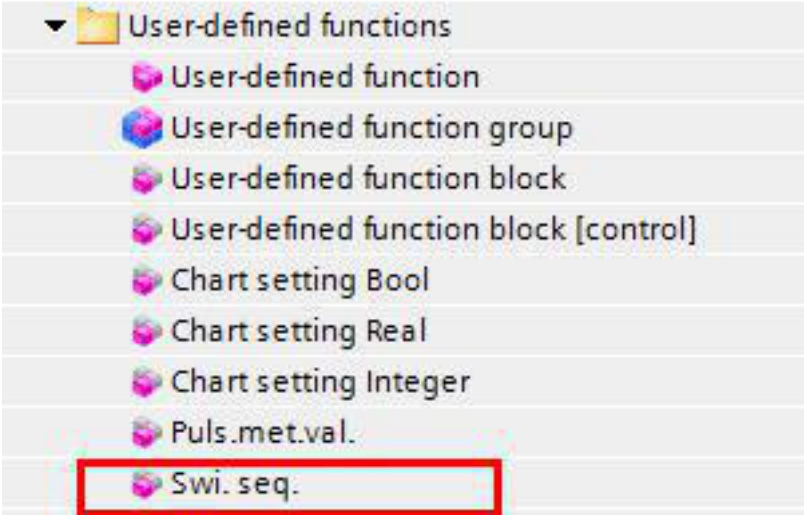
8.5 Switching Sequences



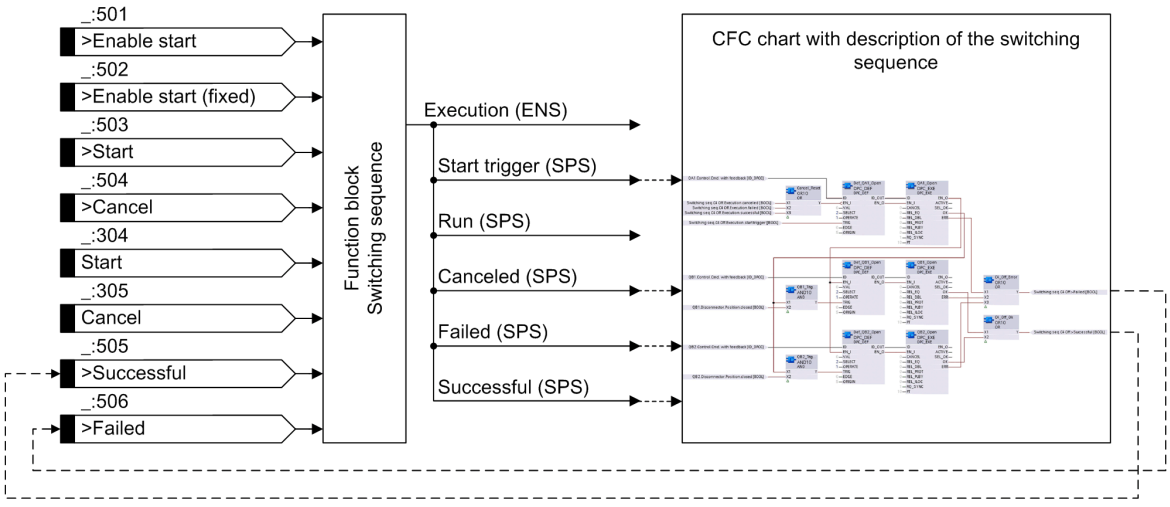
8.5.1 Overview of Functions

Switching sequences may be running inside the device that switch the switchgear automatically in a prespecified sequence.

A switching sequence consists of a special function block **Switching sequence** (Swi. seq.) from the DIGSI 5 Library and the project-specific list of the switching commands that are generated in the CFC.

8.5.2 Function Description

The function block **Switching sequence** is located in folder **User-defined functions** in the DIGSI 5 Library.



[scudeffb, 1, en_US]

Figure 8-81 Function block **Switching Sequence** in the Library

These function blocks can be used in the information matrix on the highest level (level of the function groups) or in a user-defined function group.

One **Switching sequence** function block is used per switching sequence. The function block is the interface for controlling and monitoring the condition of the CFC switching sequence. The task of the function block is to verify the relative conditions for control commands, for example, switching authority, interlocking conditions, etc. You can connect the signals of the function block with the CFC chart. They start and stop the switching sequence and provide data about the status of the switching sequence (see *Figure 8-82*). The CFC chart is used to activate the switching device that must be switched. The CFC blocks define, among other things, the switching devices that must be switched.

[dwswseq1-110913-01.vsd, 1, en_US]

Figure 8-82 **Switching Sequence** Function Block

Starting and Canceling a Switching Sequence

One of the following methods can be used to start a switching sequence:

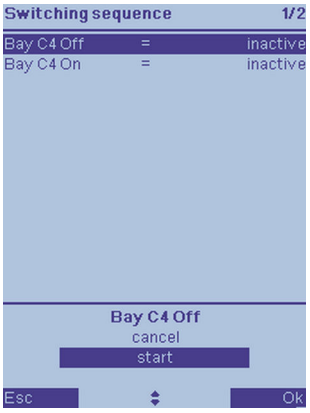
- On-site operation: menu or display page
- Input *>Start* during rising edge, for example, via binary input
- Controllable *Start* for the start via a communication protocol, for example, IEC 61850, T103, or DNP
- Input *>Start* via a function key
- Controllable *Start* via a function key

One of the following methods can be used to cancel a switching sequence:

- On-site operation: menu or display page
- Input *>Cancel* during rising edge, for example, via binary input
- Controllable *Cancel* for the cancelation via a communication protocol, for example, IEC 61850, T103, or DNP
- Input *>Cancel* via a function key
- Controllable *Cancel* via a function key

On-Site Operation

If at least one **Switching sequence** function block is used in the device, a new **Switching sequences** entry is shown in the first line of the **Control** menu. If this menu item is selected, an overview of all switching sequences and the current status will be displayed (see *Figure 8-83* , example with 2 switching sequences). You can start or cancel the switching sequences from this menu.



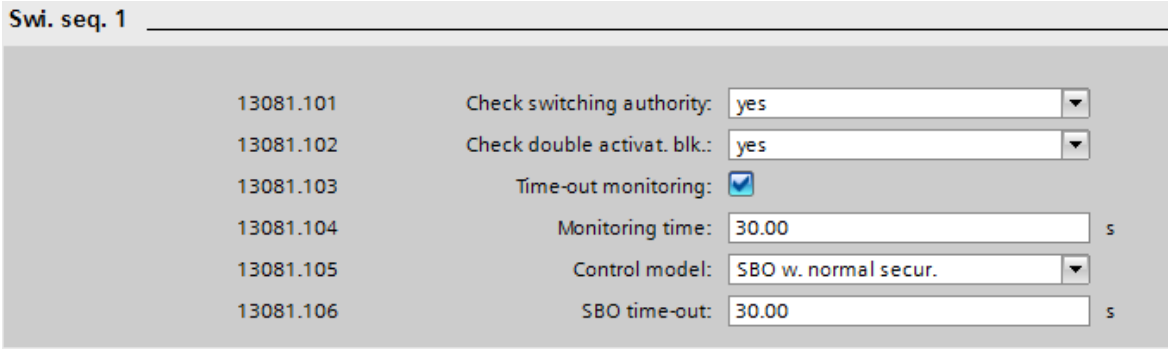


Figure 8-83
Overview of the Switching Sequences on the Device Display

8.5.3 Application and Setting Notes

This function block offers similar settings as the **Control** function block of a circuit breaker or disconnector (see chapter *8.2.1 General Overview*).

[scccs4pa-13112014_DE, 1, en_US]

Figure 8-84 Settings of the **Switching Sequence** Function Block

Parameter: **`Check switching authority`**

- Default setting **`(_:101) Check switching authority`** = ***`yes`***

With the **`Check switching authority`** parameter, you can determine whether the switching authority should be checked before the execution of the switching sequence.

Parameter: **`Check double activat. blk.`**

- Default setting **`(_:102) Check double activat. blk.`** = ***`yes`***

With the **`Check double activat. blk.`** parameter, you can determine whether the double activation of switching devices should be checked. The setting value ***`yes`*** indicates that a switching sequence will be started only if no switching commands for a circuit breaker and disconnector are activated, provided that double-activation blocking was activated for those switching devices.

Parameter: **`Time-out monitoring`**

With the **`Time-out monitoring`** parameter, you can determine whether the feedback from the process should be evaluated. The feedback is gathered via the inputs *`>Successful`* and *`>Failed`*.

Parameter: **`Monitoring time`**

- Default setting **`(_:104) Monitoring time`** = ***`30.00 s`***

With the **`Monitoring time`** parameter, you can determine the duration of the monitoring time.

Parameter: **`Control model`**

- Default setting **`(_:105) Control model`** = ***`SBO w. normal secur.`***

With the **`Control model`** parameter, you select between ***`direct w. normal secur.`*** or ***`SBO w. normal secur.`*** to start the switching sequence.

It is not possible to set a control model for cancelation of the switching sequence. The control model ***`direct w. normal secur.`*** is always used to cancel the function.

Information

The **Switching sequence** function block provides the following data:

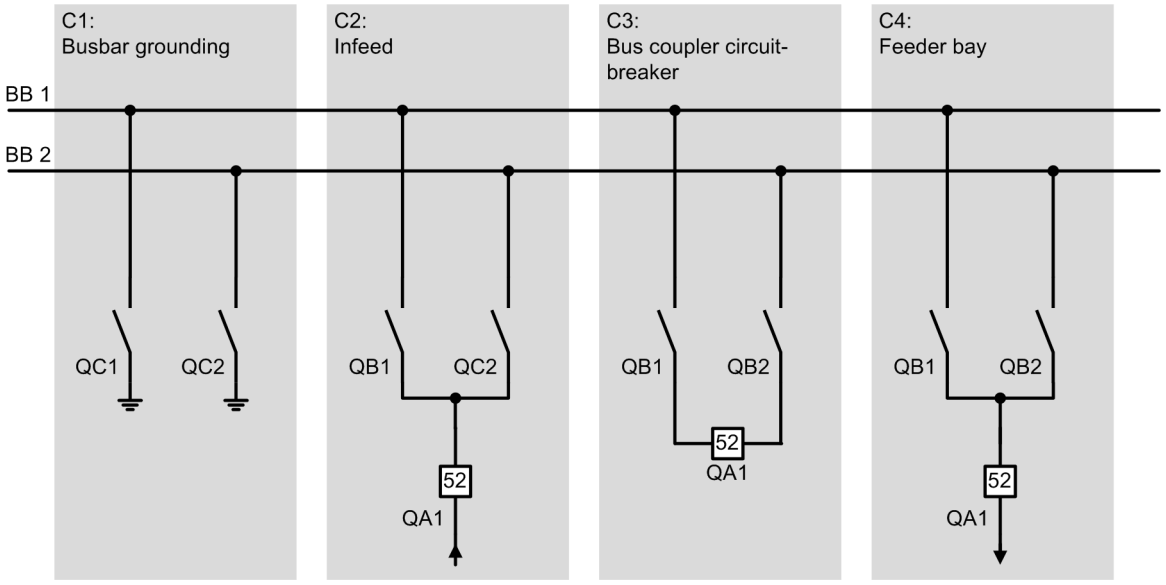
Swi. seq. 1	13081	
>Enable start	13081.501	SPS
>Enable start (fixed)	13081.502	SPS
>Start	13081.503	SPS
>Cancel	13081.504	SPS
>Successful	13081.505	SPS
>Failed	13081.506	SPS
Health	13081.53	ENS
Execution	13081.302	ENS
start trigger		SPS
running		SPS
canceled		SPS
failed		SPS
successful		SPS
Start	13081.304	SPC
Cancel	13081.305	SPC
Switching auth. station	13081.303	SPC

[scinfof1-13112014, 1, en_US]

Figure 8-85 Data Provided by the **Switching Sequence** Function Block

In the **Switching sequence** function block, the interlocking is analog to the **Interlocking** function block and it is possible to use it in the switching sequence:

- *`>Enable start`*: Connection to interlocking conditions (CFC) for the start of the entire switching sequence. Not in effect in the **non-interlocked** switching mode.
- *`>Enable start (fixed)`*: Non-revocable interlocking conditions for the start of the entire switching sequence. In effect regardless of the switching mode.

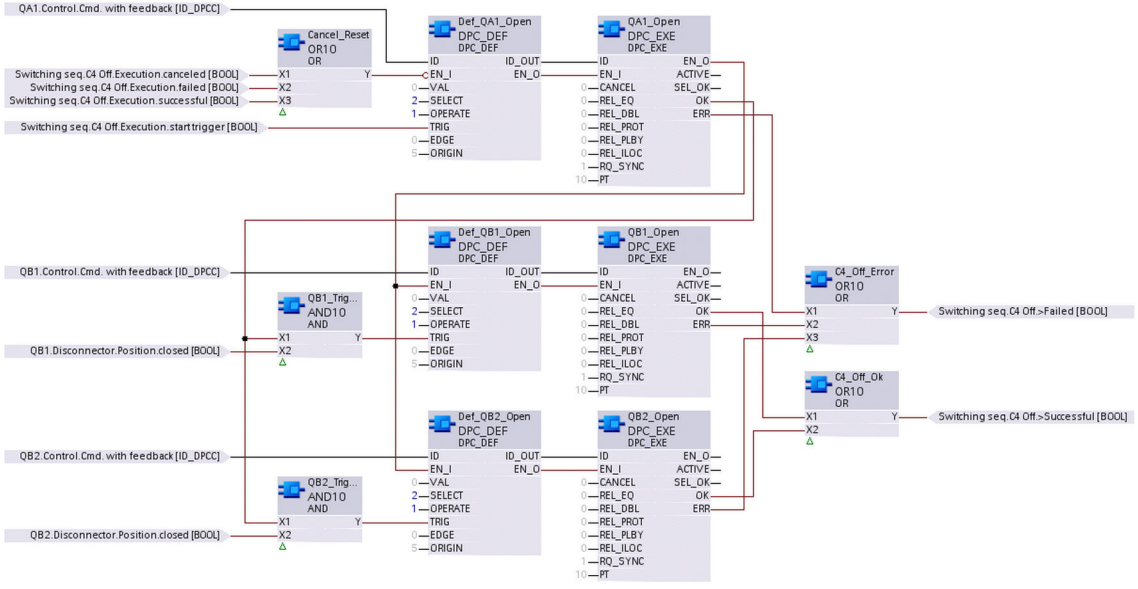


If the time-out monitoring is activated (parameter **`Time-out monitoring`**), the process feedback must take place via the inputs *`>Successful`* and *`>Failed`*. If the last switching command of the switching sequence was executed successfully, the input *`>Successful`* usually is set. To do this, connect the feedback of the last switching command from the CFC with this input of the function block during the device parameterization.

If a switching command fails, this feedback can be captured by the input *`>Failed`*. The active switching sequence will be ended immediately and does not have to wait for a time-out.

The indication *`Execution`* signals the current condition of the switching sequence. The events *`running`*, *`canceled`*, *`failed`*, and *`successful`* are generated only while the time-out monitoring is activated. The event *`Start Trigger`* is used to start the switching sequence in the CFC chart.

Example for a Switching Sequence with CFC



The following figure shows a single-line diagram for a substation with 4 bays: Busbar grounding, infeed, bus coupler, and feeder bay.

[dwbspunt-120913-01.vsd, 1, en_US]

Figure 8-86 Example of a Substation

The switching sequence **C4 Off** (*Figure 8-87*) should switch off feeder bay C4. The circuit breaker is opened; followed by opening of one of the 2 busbar disconnectors.

[Scssc4as-110913-01, 1, en_US]

Figure 8-87 CFC Switching Sequence **C4 Off**

Command Execution

As described in section *Starting and Canceling a Switching Sequence, Page 1107*, the display page or the **Control** menu can be used to start the switching sequence. The *Start Trigger* signal for indication *Execution* is used to recognize the start and initiates the switching sequence by pickup of **TRIG** in the DPC-DEF building block of circuit breaker QA1. Building blocks DPC-DEF and DPC-EXE are always used in pairs. The DEF building block controls the type and nature of the command

- **VAL** = Switching direction (0 = Off, 1 = On)
- **SELECT** = Select switching device (2 = Select with a value suitable for the preset control model ***SBO w. enh. security***)
- **OPERATE** = Switch switching device (1 = Switching device is switched on or off)

Using the connected DPC-EXE building block, the command checks can be deactivated (**REL_**...). In the application example, all inputs are set to 0 and therefore, all checks are activated.

After the open command of circuit breaker QA1 is acknowledged via the auxiliary contacts, the **OK** output of the CFC block DPC_EXE becomes active and triggers the next switching object. With the input **PT** the signal for the **OK** output is time-delayed (in the example by 10 ms) and creates a dead time between individual switching commands and the switching sequence. This dead time is important for the updating of the interlocking conditions.

If QB1 is closed, QB1 will be opened. If QB2 is closed, QB2 will be opened. In order to implement this logic, the **OK** output signal of QA1 is linked with the respective positions of circuit breakers QB1 and QB2 via the logical AND function. This signal serves as a trigger for the trip command of QB1 or QB2.

Because in this example the time-out monitoring is activated, the feedback about the successful or unsuccessful execution of the switching sequence must be parameterized. The **Switching sequence** function block provides the inputs *>Successful* and *>Failed*. In order to acknowledge the entire switching sequence positively, the OR operation of the **OK** outputs for the disconnectors QB1 and QB2 is sufficient. The feedback of all failed executions takes place via the OR operation of all **ERR** outputs of the switching devices. The benefit of such assessment is the fact that, in case of a failure, waiting for the time-out is not necessary, but the active switching sequence can be ended immediately.

In this example, the use of the **EN_I** input of building block DPC-DEF fulfills 2 tasks:

- Cancelation of the entire switching sequence
- Resetting of the outputs **OK** and **ERR** on building block DPC-EXE

By linking all **EN_I** inputs and **EN_O** outputs of building blocks DPC-DEF and DPC-EXE, the execution of the switching sequence can be controlled centrally since the value is transmitted between the building blocks. Only if input **EN_I** on the DPC-EXE is set to 1, a switching command is issued. If the input drops back to 0 while a command is being processed, this command will be canceled. With this behavior, cancelation of an entire switching sequence can be achieved. As recognition of a cancelation, the *canceled* signal of the indication *Execution* is used in the CFC chart and connected with the input **EN_I** of the first switching device, in this example, with the DPC-DEF building block of circuit breaker QA1.

Since the **OK** and **ERR** outputs of the DPC-EXE building block maintain their value until execution of the next command, it is necessary to reset the continuous output after each execution of the switching sequence for correct execution of the entire CFC switching sequence multiple times. In this case, the use of the **EN_I** input is also helpful. In the input drops back to 0, the **OK** and **ERR** outputs are also reset to 0. The triggers for ending the switching sequence are the events *failed* and *successful*. For this reason, in the above example, the signals *failed* and *successful* of the indication *Execution* were connected with **EN_I** of the DPC-DEF building block.

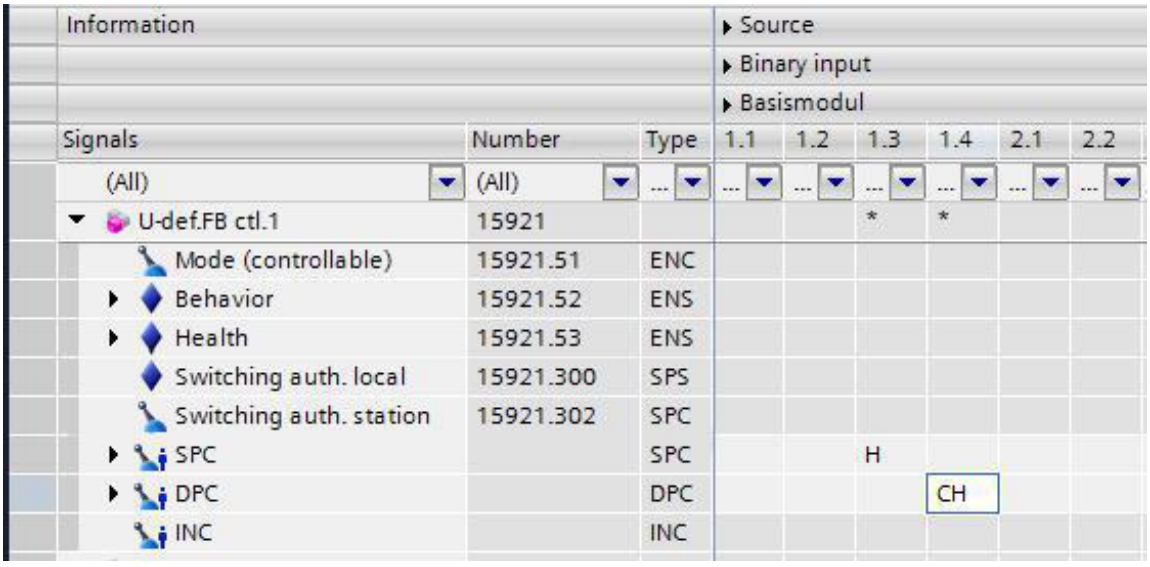
8.6 User-Defined Function Block [Control]

8.6.1 Overview of Functions



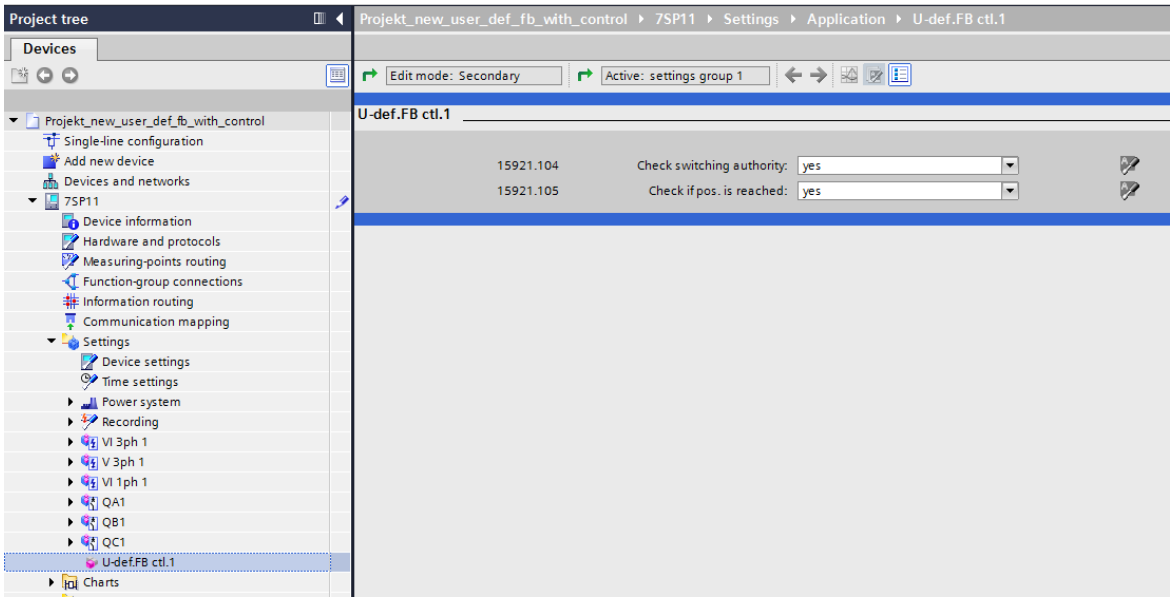
The **User-defined function block [control]** allows the switching-authority check of a control command and the check of whether the circuit breaker has reached the position for user-defined controllables.

8.6.2 Function Description

The **User-defined function block [control]** is located in the folder **User-defined functions** in the DIGSI 5 Library.

You can instantiate the user-defined function blocks on the top level (in parallel to other function groups) as well as within function groups and functions.

The task of the function block is to check the switching authority. For control commands, the function block checks whether the switching direction is the same as the current switch position. You can instantiate every user-defined signal (for example, SPS, DPC, INC) in the function block and route the corresponding indications (see following figure).



[scbenutz, 1, en_US]

Figure 8-88 Information Routing with Inserted User-Defined Function Block [Control]: Process Indications and Some Individual Indications

8.6.3 Application and Setting Notes

The function block contains the parameters **(_:104) Check switching authority** and **(_:105) Check if pos. is reached** as shown in the following figure. The parameter settings affect all controllables instantiated in the function block. Other signal types are not affected by these parameters and objects.

[user-def2, 1, en_US]

Figure 8-89 Parameterization Options of the User-Defined Function Block [Control]

Parameter: **`Check switching authority`**

- Default setting **`(_:104) Check switching authority`** = ***`yes`***

With the **`Check switching authority`** parameter, you determine whether the command source of switching commands must be checked (see chapter *8.3.1 Command Checks and Switchgear Interlocking Protection*).

Parameter: **`Check if pos. is reached`**

- Default setting **`(_:105) Check if pos. is reached`** = ***`yes`***

With the **`Check if pos. is reached`** parameter, you check at a switching command whether the switching direction equals the current position.

8.6.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`U-def.FB ctl.#`				
_:104	U-def.FB ctl.#:Check switching authority		• no • yes	yes
_:105	U-def.FB ctl.#:Check if pos. is reached		• no • yes	yes

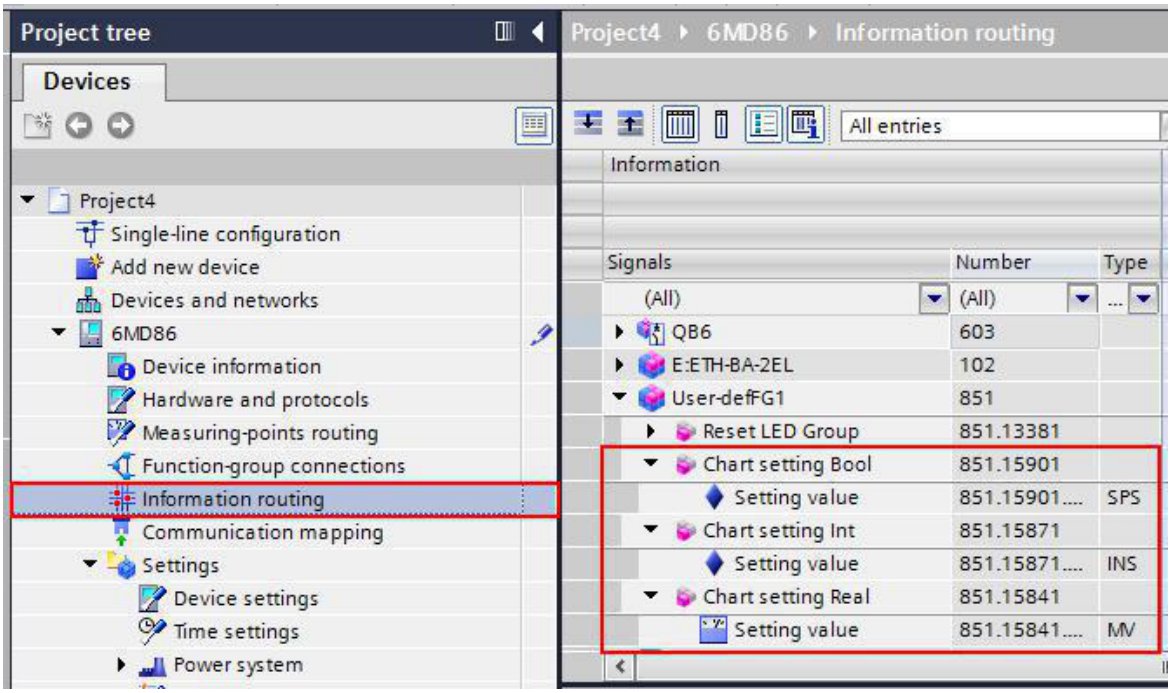
8.7 CFC-Chart Settings

8.7.1 Overview of Functions



If you want to process a parameter in a CFC chart and this parameter is to be changeable via DIGSI or HMI during runtime, you can use the function blocks **Chart setting Bool**, **Chart setting Integer**, and **Chart setting Real**. Instantiate the appropriate function block depending on the needed parameter value (logical, integer, or floating point).

8.7.2 Function Description

You can find the CFC-chart parameters **`Chart setting Bool`** , **`Chart setting Int`** , and **`Chart setting Real`** in the DIGSI library in the **User-defined functions** folder. Drag and drop the desired function block into a function group or a function. Set the appropriate parameter value of the function block in DIGSI using the parameter editor or via HMI under the **Settings** menu item. You can then use the parameter as an input signal in CFC charts.

NOTE

The user-defined function groups and the user-defined functions can be used to group the CFC-chart parameters. You can rename for the function block and change the parameter value in the DIGSI Information routing matrix to suit your specific application.

[sccfcparam, 1, en_US]

Figure 8-90 CFC-Chart Parameters within Information Routing

8.7.3 Application and Setting Notes

Parameter: `Chart setting Bool`

- Default setting **`Chart setting Bool`** = ***`False`***

You can use the parameter **Chart setting Bool** in a CFC chart as an input signal with a Boolean value. This input value can then be changed during the runtime of the CFC chart.

Parameter: Chart setting Int

- Default setting **Chart setting Int** = ***10***

You can use the parameter **Chart setting Int** in a CFC chart as an input signal with an integer value. This input value can then be changed during the runtime of the CFC chart.

Parameter: Chart setting Real

- Default setting **Chart setting Real** = ***100.000***

You can use the parameter **Chart setting Real** in a CFC chart as an input signal with a floating-point number. This input value can then be changed during the runtime of the CFC chart.

8.7.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Chart setting Bool				
_:105	Chart setting Bool:Value		• 0 • 1	false

Addr.	Parameter	C	Setting Options	Default Setting

8.8 Transformer Tap Changers

8.8.1 Function Description

With the device control function, you can change a transformer tap by moving it higher or lower and monitor the proper execution of the adjusting commands.

The function has built-in comprehensive options for measuring the tap changer position as well as supervision functions. The supervision functions are used to check the voltage and supply information about the tap position for adaptive matching of the transformer differential protection.

The following options are provided for control:

- Direct user commands via the device keypad or routed binary inputs
- User-defined conditions via the CFC

If the tap changer reaches the end positions, the control function issues the *(_:301) End higher pos.reached* or *(_:302) End lower pos.reached* indication.

The transformer tap controller is controlled by the function group **Tap changer**, which you can select from the DIGSI library (group **Switching devices**).

Tap changer 1	161		*	*	*	*
Tap changer	161.5461		*	*	*	*
>Acquisition blocking	161.5461.500	SPS

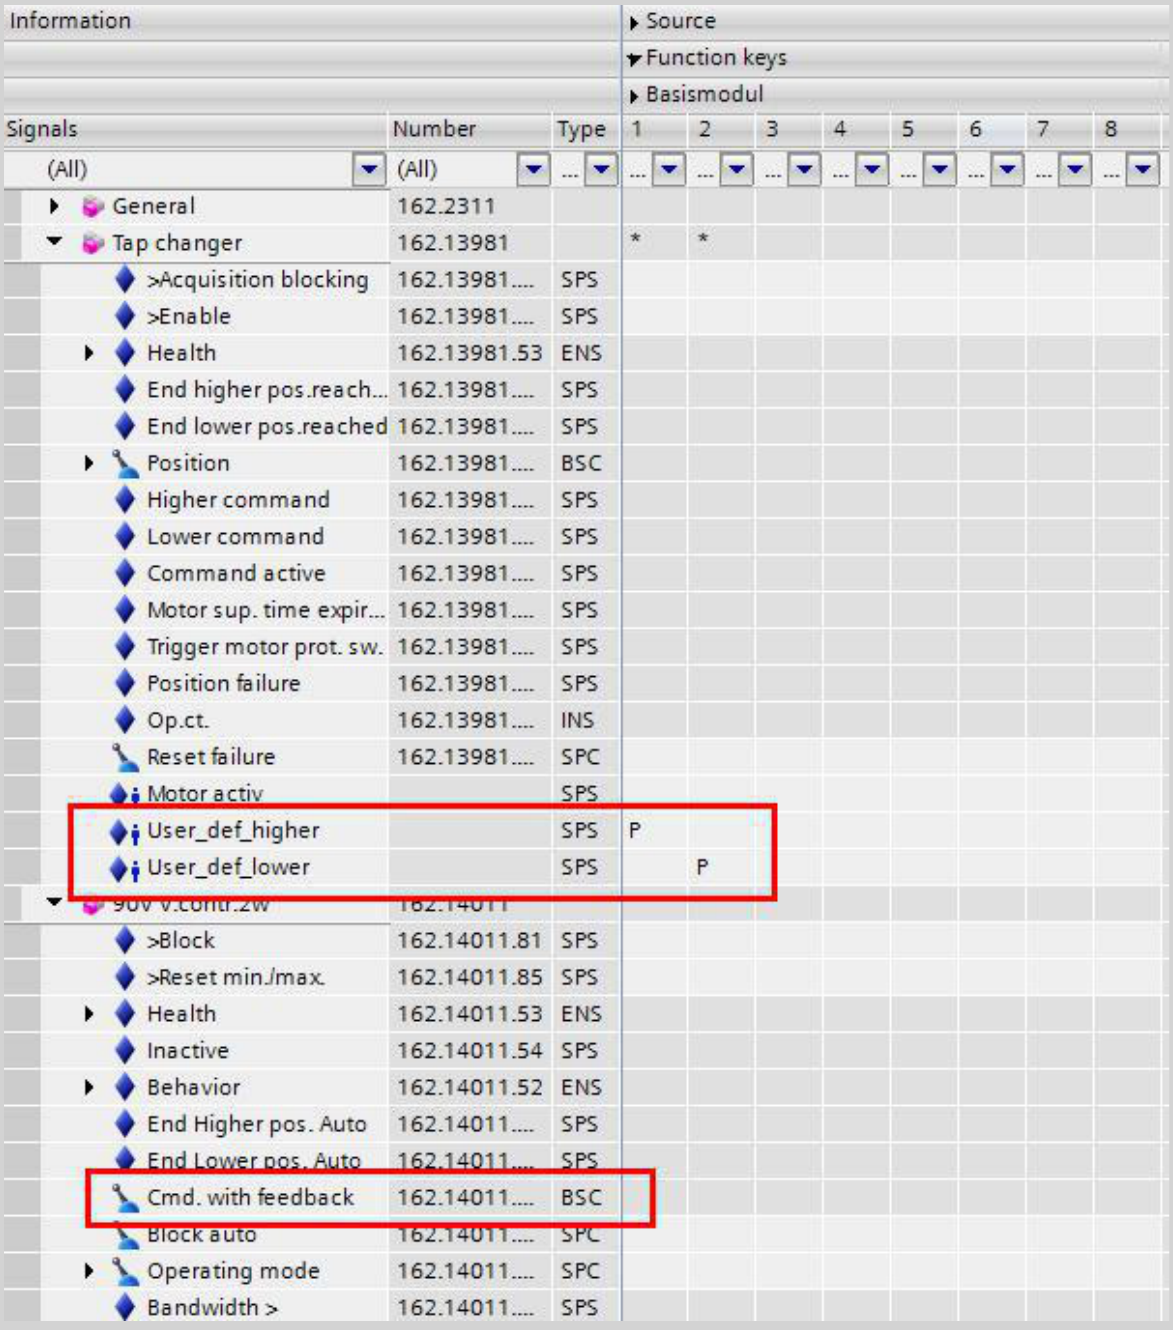
[sc_tssdig, 1, en_US]

Figure 8-91 Tap Changer Functionality in the DIGSI Information Matrix



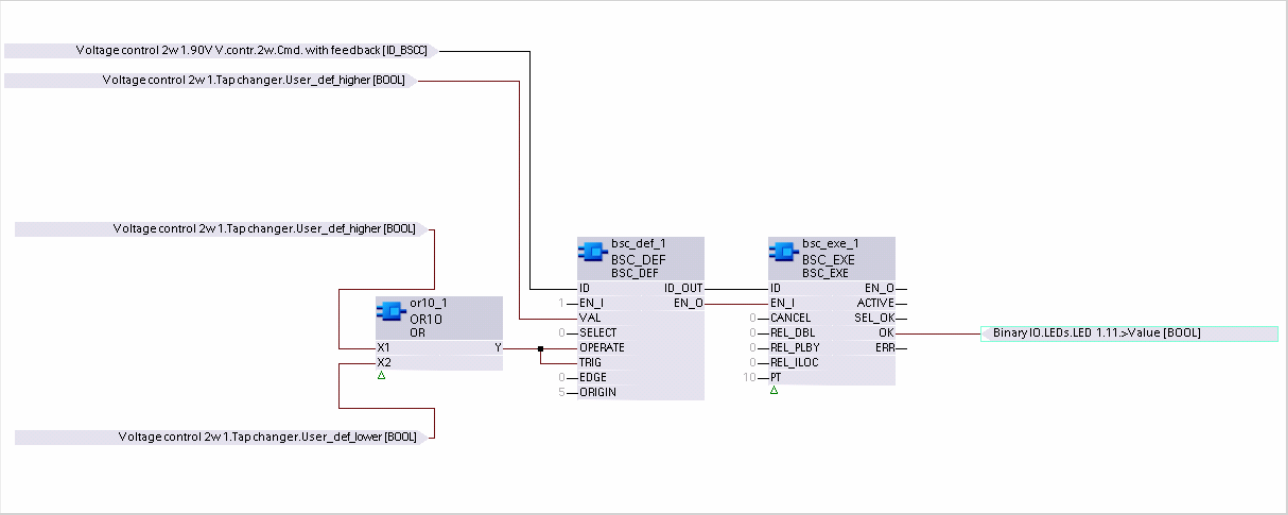
The central element is the Controllable **Position** of type BSC (Binary Controlled Step Position Information, based on IEC 61850). You connect this Controllable in the matrix to the desired number of binary inputs that indicate the current tap position.

You can find more information in chapter *8.8.2 Application and Setting Notes* .

The **Position** Controllable also contains settings. If you wish to change the settings, you must select the Controllable in the DIGSI information matrix and change the settings by way of the Properties dialog. The taps are controlled via the commands **Higher command** and **Lower command**, each of which must be connected to one binary output.

Example

The following 2 figures show a CFC chart as an example for transformer tap control with the routing of the function keys for stepping up or stepping down.



[schilocd-280316-01, 2, en_US]

Figure 8-92 Routing of the Function Keys and CFC Signals

To use the function keys, you create 2 user-defined single-point indications (SPS). These are used for the function keys (for example, <F1>, Higher function key and <F2>, Lower function key) and as the input signals for the appropriate CFC blocks. In addition, you must use the controllable **`Cmd. with feedback`** for the CFC chart.

You can select the control direction using the following values at the **Val** input of the BSC_DEF block.

- 1 means **step up**
- 0 means **step down**

[scbivctv-280715-01, 2, en_US]

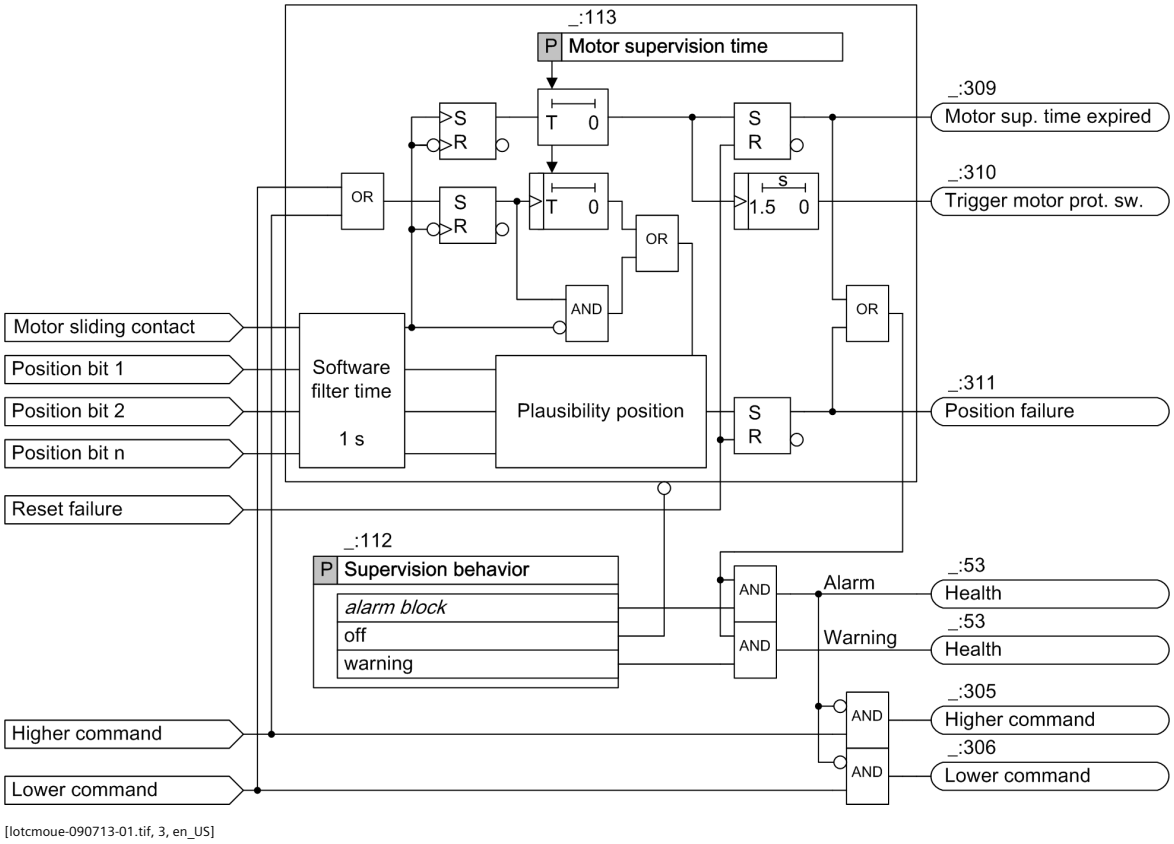
Figure 8-93 CFC Chart

Using this simple CFC chart, pressing the function keys to step up or down incrementally can be displayed.

Motor Supervision Time

The runtime of the motor drive can be monitored from the device. This function is used to identify failures of the motor drive during switching and to trip actions if necessary. To use the **Motor supervision time** , you must route the motor sliding contact (highest binary input) and set the proper motor runtime.

The motor sliding contact is active until the tap changer has reached the new position. This time is compared to the **Motor supervision time** . If the new tap position is not reached within the motor runtime, the *Motor sup. time expired* indication is set. The *Trigger motor prot. sw.* indication with which the motor can be switched off is output after 1.5 s.



Adjusting-Command Monitoring

The adjusting-command monitoring is used for checking the proper operation of the tap-changer mechanism. The **Tap changer** function calculates the next logical tap position as a result of the higher/lower command. The time of position detection is determined as a function of the availability of the motor sliding contact. After resetting the active motor sliding contact, the **Tap changer** function reads the new tap position value. If the value for the next tap position could not be received within the parameterized time **Motor supervision time** , the error message *Position failure* is issued.

The following position errors of the tap changer considered during this:

- Invalid tap position: The tap position is outside the predefined range of **minimum value** and **maximum value**
- Position command in the wrong direction (for example, if a higher tap was commanded and the tap changer responds with a lower position or vice versa)
- No operation of the tap changer (for example, if the tap-changer motor is defective or the position indication is not functioning)
- Illogical tap-change operation (for example, if no logical tap position following the previous position is indicated)

The value of 0 during an unexpected interruption of the auxiliary voltage represents a special case. An invalid tap-changer position without a corresponding adjusting command is signaled only as an invalid tap position in the **Position** controllable.

[lotcmoue-090713-01.tif, 3, en_US]

Figure 8-94 Position and Motor Supervision Logic

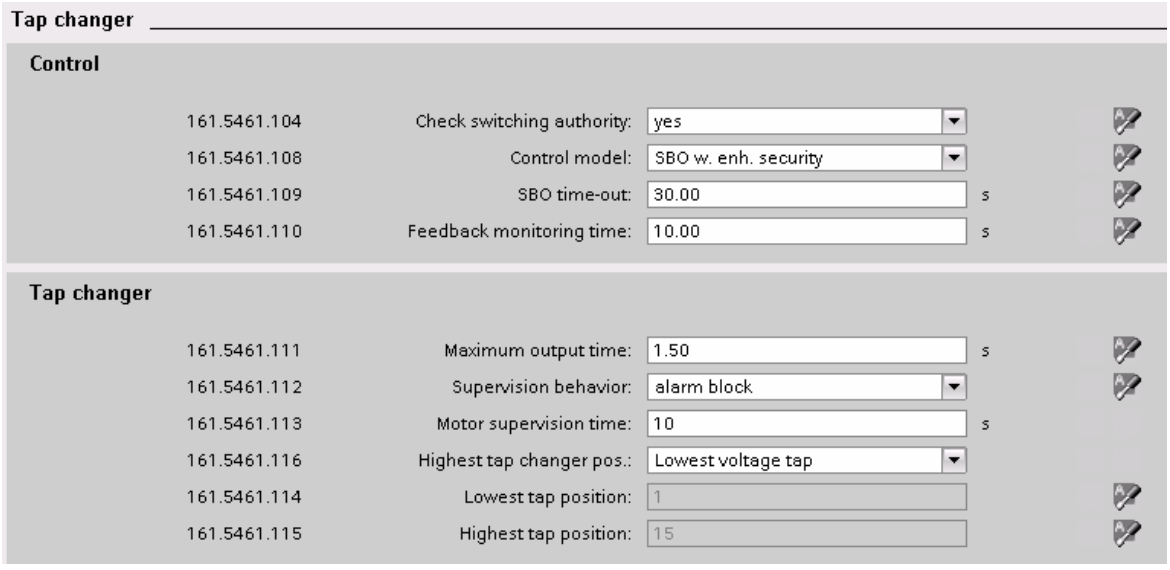
Supervision Behavior

Depending on the setting of the **Supervision behavior** parameter, the function reaches a health state of **Alarm** or **Warning**. You can set the **Supervision behavior** parameter to ***off*** , ***alarm block*** , or ***warning*** .

In the ***alarm block*** mode, the function is set to the health state **Alarm**. All tap-changer commands are blocked.

In the ***warning*** mode, the function is set to the health state **Warning**. Executing tap-changer commands is still possible.

You can reset the health state of ***alarm block*** or ***warning*** manually using the controllable **Reset errors** (Main menu → Device functions → Reset functions → Tap changer). As an alternative to this, you can also switch off the supervision function and then switch it on again.



Operating Meter

The device counts the number of successfully completed adjusting commands with the ***Op.Ct.*** switching cycle metered value. The meter and memory levels are protected against an auxiliary-voltage failure. The switching cycle metered value can be preconfigured to 0 or to any other starting value.

You can access the statistical values via the operation panel on the device (measured values/statistics), via DIGSI, or using various communication protocols.

8.8.2 Application and Setting Notes

Parameters of the Transformer Tap Changer Function Group

[scstuslt-100713-01.tif, 2, en_US]

Figure 8-95 Parameters of the Tap Changer

NOTE

If run positions, this means internal tap changer positions without voltage changes, are available, the following must be observed:

If these tap changer positions contain a suffix a and c or + and -, and additional switching pulses are not required, adjust the parameter for the feedback and motor supervision time to the actual motor runtime when passing through a run position. Siemens recommends parameterization with capturing the motor sliding contact.

Parameter: `Check switching authority`

- Default setting **`(_:104) Check switching authority`** = ***`yes`***

Parameter: `Control model`

- Default setting **`(_:108) Control model`** = ***`SBO w. enh. security`***

Use the **`Control model`** parameter to specify the control model according to IEC 61850-7-2. The following selection options are available:

- ***`direct w. normal secur.`***
- ***`SBO w. normal secur.`***
- ***`direct w. enh. security`***
- ***`SBO w. enh. security`***
- ***`status only`***

Parameter: `SBO time-out`

- Default setting **`(_:109) SBO time-out`** = ***`30 s`***

With this setting, you specify the time for detecting the time-out of the SBO command. The range of values extends from 0.01 s to 1800.00 s. This is the time that can elapse between command acceptance and command execution (command model as per IEC 61850-7-2).

Parameter: Feedback monitoring time

- Default setting **(_:110) Feedback monitoring time** = ***10 s***

Reaching a new tap position after the switching command is monitored. If a new tap position is not reached, you specify with this setting the time when the command is canceled. The range of values extends from 0.01 s to 1800.00 s.

Parameter: Maximum output time

- Default setting **(_:111) Maximum output time** = ***1.50 s***

This parameter specifies the maximum output time. The range of values extends from 0.01 s to 1800.00 s. For activating motors to change the tap position, a time of 1.50 s is practical.

Parameter: Supervision behavior

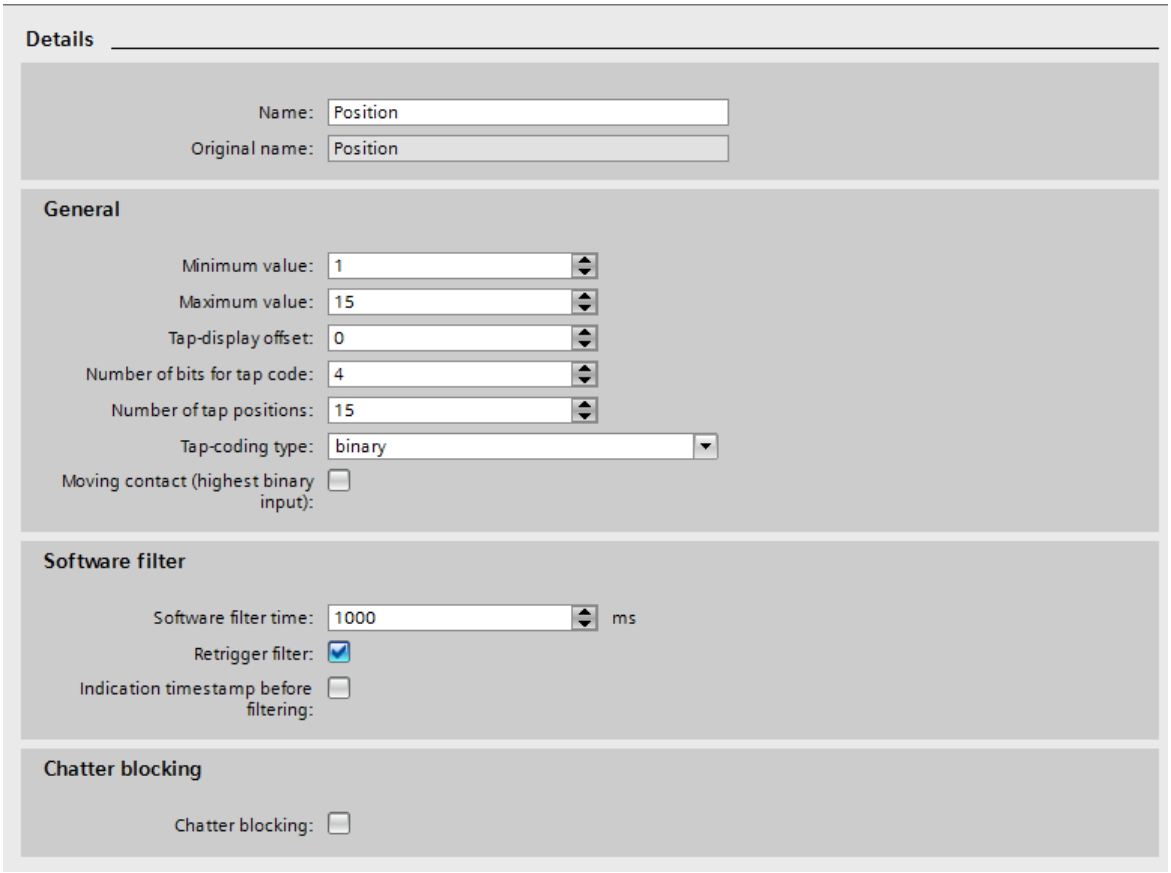
- Default setting **(_:112) Supervision behavior** = ***alarm block***

You can select whether the supervision is switched off (***off***) or if only a warning is indicated (***warning***). With the ***alarm block*** setting, an alarm indication is generated and the function is blocked.

Parameter: Motor supervision time

- Default setting **(_:113) Motor supervision time** = ***10 s***

After the motor supervision time has elapsed, the indication *Motor sup. time expired* is displayed. Additional information can be found in the margin title *Motor Supervision Time, Page 1119* . The range of values extends from 5 s to 100 s.



Parameter: Highest tap changer pos.

- Default setting **(_:116) Highest tap changer pos.** = ***Lowest voltage tap***

With the parameter **Highest tap changer pos.**, indicate whether the lowest or highest voltage is present at the highest tap changer position.

Additional Settings (Properties Dialog Position)

Additional settings are assigned to the controllable *Position*. To display and adjust the settings, select *Position* in the DIGSI information matrix and select the Properties dialog. To do this, click the **Properties** tab.

[scdeegts-170216-01, 1, en_US]

Figure 8-96 Properties Dialog

Parameter: `Minimum value`

- Default setting **`Minimum value`** = ***1***

Parameter: `Maximum value`

- Default setting **`Maximum value`** = ***15***

The **`Minimum value`** and **`Maximum value`** settings are initially calculated by DIGSI 5 based on the tap coding, the **`Number of tap positions`**, and the **`Tap-display offset`**. They represent the allowed control area of the position value. Positions outside this area are defined as invalid. This control area can be further restricted within the initially set physical range (see the **`Number of tap positions`** and the **`Tap-display offset`**).

Parameter: `Tap-display offset`

- Default setting **`Tap-display offset`** = ***0***

If you want to move the height of the displayed value in a positive or the negative direction with respect to the height of the actual value, enter the value for this in the **`Tap-display offset`** field.

Parameter: `Number of bits f. tap code`

- Default setting **`Number of bits f. tap code`** = ***4***

With the **`Number of bits f. tap code`** parameter, set the number of bits you need for coding the transformer taps. The number is dependent on the selected **Encoding** and on the **Moving contact**. For example, you need 3 bits for 7 binary-encoded transformer taps. The range of values extends from 2 to 32.

Parameter: `Number of tap positions`

- Default setting **`Number of tap positions`** = ***15***

With the **`Number of tap positions`** parameter, you set the number of transformer taps. The range of values extends from 2 to 127. The output of the tap position is limited from -63 to +63. If the number of taps is > 63, set the parameter **`Tap-display offset`** so that the tap position is within the range of -63 to +63.

Parameter: `Tap-coding type`

- Default setting **`Tap-coding type`** = ***binary***

In the **`Tap-coding type`** list box, select the interpretation type of the indication pending at the binary input.

You can select from the following options:

- ***binary***
- ***1-of-n***
- ***BCD***
- ***table***
- ***BCD signed***
- ***gray***

If you want to specify an individual **`Tap-coding type`**, select ***table***.

In the **`Representation of encoding`** section, select the numbering system in which your code table entries will take place, alternatively:

- ***Binary (2 characters)***
- ***Octal (8 characters)***
- ***Decimal (10 characters)***
- ***Hexadecimal (16 characters)***

The selected option is valid for all inputs in the **`Encoding`** column.

If you change the number system and there are already entries in this column these will be converted to the new number system. The selection area becomes visible as soon as you have selected the setting ***table*** in the list box **`Tap-coding type`**.

NOTE

If the binary inputs used for encoding are all inactive, this indicates an invalid tap position (regardless of the display offset). For an invalid tap position, the display shows the position **---** or **-64** with quality **invalid**; the exception is BCD with sign, see *Routing of the Binary Inputs (Tap Coding Type: BCD with Sign), Page 1125* .

Enter the encoding for the tap in the **Encoding** column in the **Code table**. Enter the value according to the numbering system previously selected. Select the desired number of taps and number of bits for tap coding. Taps with the same encoding and taps with 0 coding are not permitted.

Routing of the Binary Inputs (Tap Coding Type: Binary)

The following table shows the routing of 3 binary inputs (BI 1 to BI 3) with 4 transformer tap positions designated 3 to 6. BI4 is the moving contact. The encoding is in binary.

Table 8-25 Routing of the Binary Inputs (Tap Coding Type: Binary)

	Example					
	BI1	BI2	BI3	BI4	BI5	BI6
Tap changer	X	X	X	X		

	Example					
Meaning	Bit 1	Bit 2	Bit 3	Moving contact		
Tap = 1	1	0	0			

With 3 binary inputs, a maximum of 2^3 -1 = 7 tap positions can be mapped in binary code. If all routed binary inputs indicate 0, this is interpreted as a connection error and is reported by Position **---** or **-64** with quality **invalid**. The representation of transformer taps should start with the numerical value 3. The information properties must be configured as follows for the example:

Tap-coding type:	Binary
Number of tap positions:	4
Number of bits f. tap code:	4
Tap-display offset:	2
Moving contact (highest binary input):	Yes

The 3 binary inputs must be numbered sequentially, for example, BI 1, BI 2, BI 3 and BI 4 for the moving contact.

Routing of the Binary Inputs (Tap Coding Type: BCD with Sign)

The following table shows the routing of 3 binary inputs (BI 1 to BI 3) with 7 transformer tap positions designated -3 to 3. The encoding uses BCD with sign.

Table 8-26 Routing of the Binary Inputs (Tap Coding Type: BCD with Sign)

	Example					
	BI1	BI2	BI3	BI4	BI5	BI6
Tap changer	X	X	X			
Meaning	Bit 1	Bit 2	Sign			
Tap = 1	1	0	1			

Using 3 binary inputs, a maximum of 7 tap positions can be mapped with the tap coding type of BCD with sign. This yields the number of tap positions from -3 to 3. If all routed binary inputs indicate 0, this is recognized as tap 0. The 3 binary inputs must be numbered sequentially.

Tap-coding type:	BCD with sign
Number of tap positions :	7
Number of bits f. tap code:	3
Tap-display offset:	0
Moving contact (highest binary input):	No

Routing the Tap Position to Binary Outputs

For the output of the adjusting commands, route the information **step up** and **step down** on one relay each, see following figure.

Information			Source											Destination		
			Binary input									Function keys	CFC	Binary output		
			Base module									Base module		Base module

[sc_trass7, 1, en_US]

Figure 8-97 Routing the Tap Setting Commands

Parameter: `Moving contact (highest binary input)`

- Default setting **`Moving contact (highest binary input)`** = ***no***

If the tap position is not to be recognized as valid and accepted until the motor sliding contact signals that it has reached the taps, then activate the **`Moving contact (highest binary input)`** option. If this parameter is set, the new positions are shown and labeled with an *****.

Parameter: `Software filter time`

- Default setting **`Software filter time`** = ***1000 ms***

With this parameter, you specify the **`Software filter time`** for capturing the tap position. The range of values extends from 0 ms to 86400000 ms. Within this time, brief changes on the binary inputs are suppressed.

Parameter: `Retrigger filter`

- Default setting **`Retrigger filter`** = ***yes***

With this parameter, you switch retriggering of the filtering time by a position change on or off.

Parameter: `Indication timestamp before filtering`

- Default setting **`Indication timestamp before filtering`** = ***no***

With this parameter, you specify whether the hardware filtering time is accounted for in the time stamp of position capture.

Parameter: `Chatter blocking`

- Default setting **`Chatter blocking`** = ***no***

With this parameter, you switch **`Chatter blocking`** on or off.

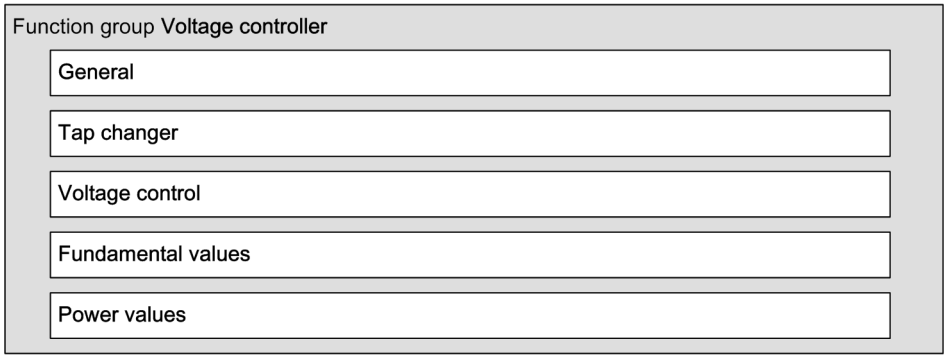
8.9 Voltage Controller

8.9.1 Overview of Functions

The transformer voltage controller functionality (ANSI 90V) is used to control power transformers (two-winding transformers, three-winding transformers, grid coupling transformers) and auto transformers using a motor-operated tap changer. The function provides automatic voltage control within a specified voltage range on the secondary side of the transformers or, as an alternative, at a remote load point (Z compensation or R/X compensation) in the network. In order to compensate for the voltage variations in the meshed system, use the ***LDC-Z*** procedure (Z compensation). For voltage drops on the line, use the ***LDC-XandR*** procedure (R/X compensation).

The control principle is based on the fact that a higher or lower command to the tap changer, as a function of the voltage change (ΔV) per tap, causes a voltage increase or decrease.



The voltage control operates on a tap-for-tap basis and compares the measured actual voltage (Vact) to the specified target voltage (Vtarget). If the voltage difference is greater than the set bandwidth (B), a higher or lower command is sent to the tap changer once the set time delay (T1) has elapsed. Specifying the time delay (T1) depends on the set controller response (inverse or linear), to avoid unnecessary adjusting commands during brief voltage deviations from the target value and for coordination with other automatic voltage controllers in the system.

The voltage controller function also monitors the currents on the upper-voltage side and the low-voltage side of the transformer to block the controller during impermissible operating states (overcurrent/undercurrent/undervoltage). The voltage controller function also has limiting values that, in special operating cases, suppress higher commands in the case of overvoltage and lower commands in the case of undervoltage.

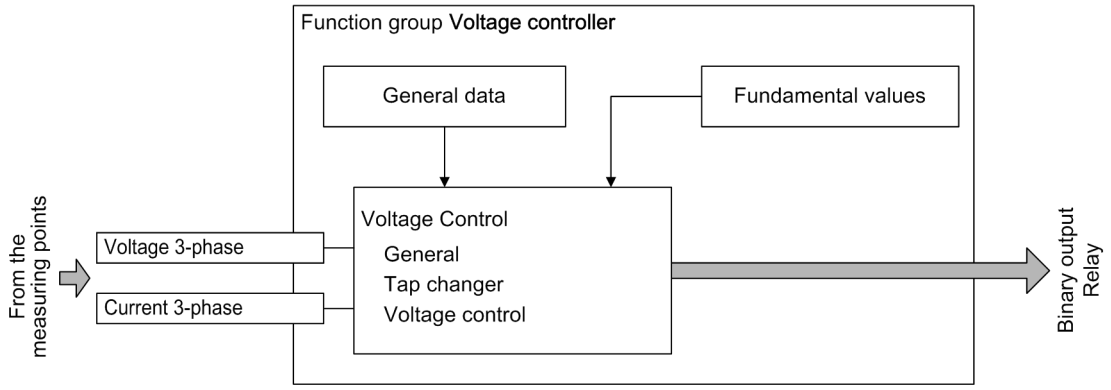
8.9.2 Structure of the Function

The **Two-winding transformer voltage controller**, **Three-winding transformer voltage controller**, and **Grid coupling transformer voltage controller** function groups consist of 5 function blocks. Depending on the application, the function groups are preconfigured in the relevant application template by the manufacturer or can be copied into the corresponding device project during engineering.

The following figure shows, for example, the functional scope of the **Two-winding transformer voltage controller** function group.

[dwvolctl-060913-01.vsd, 2, en_US]

Figure 8-98 Structure/Embedding of the Function Group



The functions **General** (GAPC), **Tap changer** (YLTC), and **Voltage controller** (ATCC) are logical node points in IEC 61850-8-1.

The tap changer (YLTC) is the interface between the voltage controller (ATCC) and the motor-operated tap changer of the transformer (OLTC). This means that the voltage controller (ATCC) sends higher and lower commands to the tap changer. This tap changer issues command pulses to the motor-operated tap changer of the transformer (OLTC). The tap changer (YLTC) measures the tap positions and monitors the action of the motor-operated tap changer (OLTC).

The function group has interfaces to the following measuring points:

- **Two-winding transformer**:
  - Voltage, 3-phase
  - Current, 3-phase (optional)
- **Three-winding transformer**:
  - 2 x voltage, 3-phase
  - 2 x current, 3-phase (optional)
- **Grid coupling transformer**:
  - 2 x 3-phase voltage
  - 2 x 3-phase current

Figure 8-99 shows these interfaces as a block structure.

[dwvocnti-060913-01.vsd, 2, en_US]

Figure 8-99 Structure of the Voltage Control Function Group

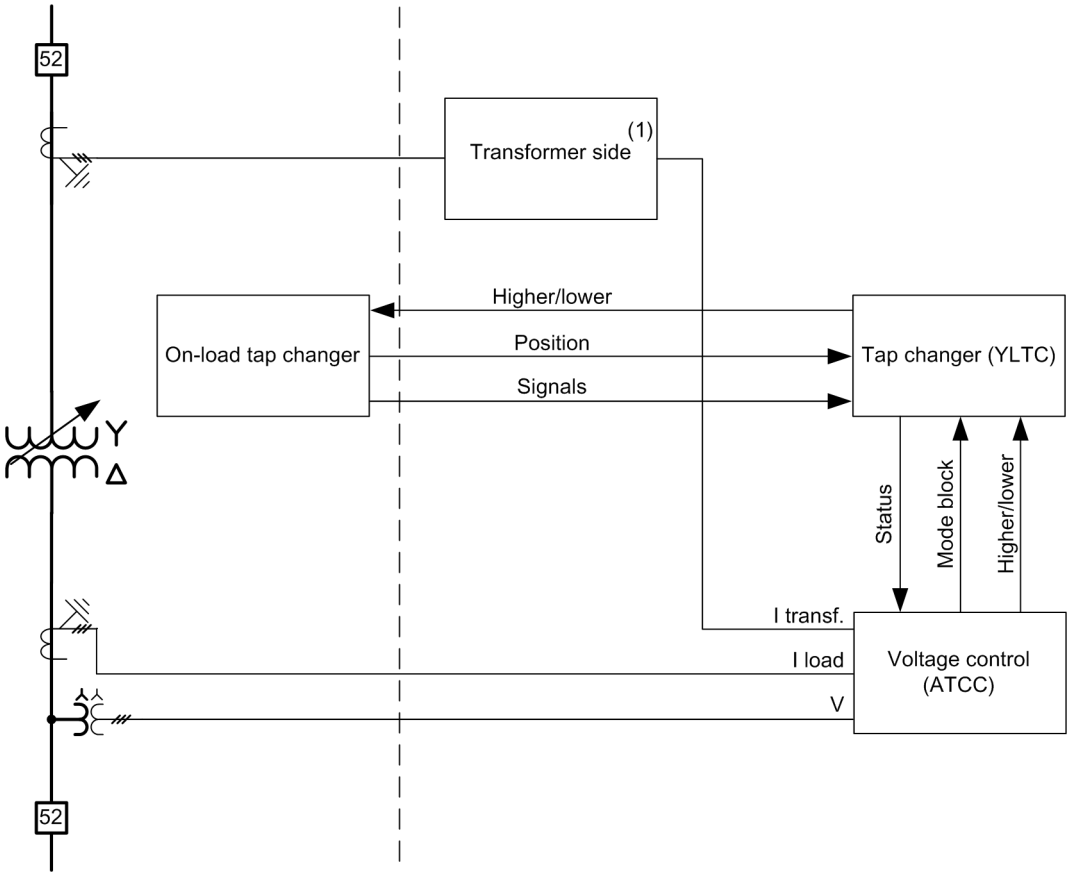
You can find the information and function measured values of the voltage controller in the DIGSI routing matrix.

8.9.3 Function Description

If the load is increased in an electricity-supply system, the voltage is reduced and vice versa. The power transformers are usually equipped with transformer tap changers (OLTC) so as to keep the power-system voltage at a constant level.

As a result, the transformer ratio is changed in predefined steps. Changing the transformer taps causes the voltage to change.

The Voltage control function is intended to control transformers with motor-operated transformer tap changers.

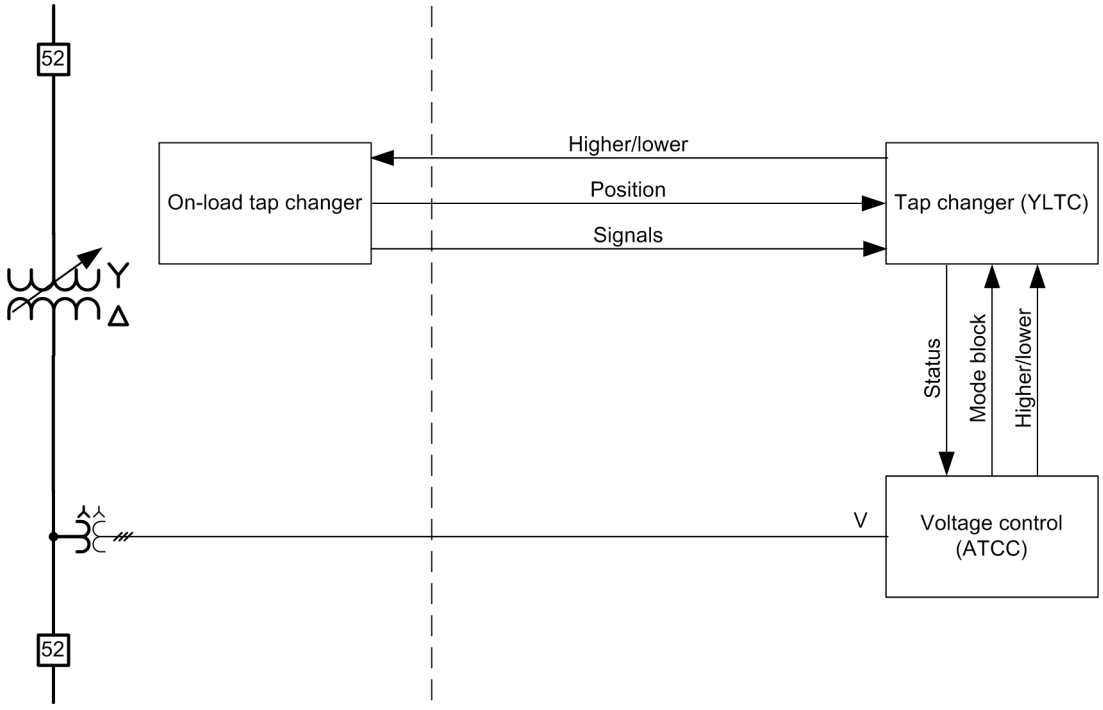


This function is designed to control the following:

- For two-winding transformers (2W): the voltage on the secondary circuit of the power transformer
- For three-winding transformers (3W): the voltage of the secondary winding 1 or winding 2
- For grid coupling transformers (GC): voltage of winding 1 or winding 2, selectively depending on the power direction

The control operation is based on a step-by-step principle. To move the tap changer one position higher or lower, a single control pulse is issued to the motor-drive mechanism of the tap changer. The length of the control pulse can be set over a large range so as to handle the very different types of tap-changer drives. The control pulse is issued if the measured voltage deviates from the set reference value by more than the preset voltage range for more than a given time period.

The voltage can be controlled at the voltage measuring point or at the load point in the electrical power system. In this case, the load-point voltage is calculated on the basis of the measured load current and the known impedance between the voltage measuring point and the load point.



The following figures show possible configurations of the voltage controller for two-winding transformers with and without current measurement.

[dwkonlst-060913.vsd, 1, en_US]

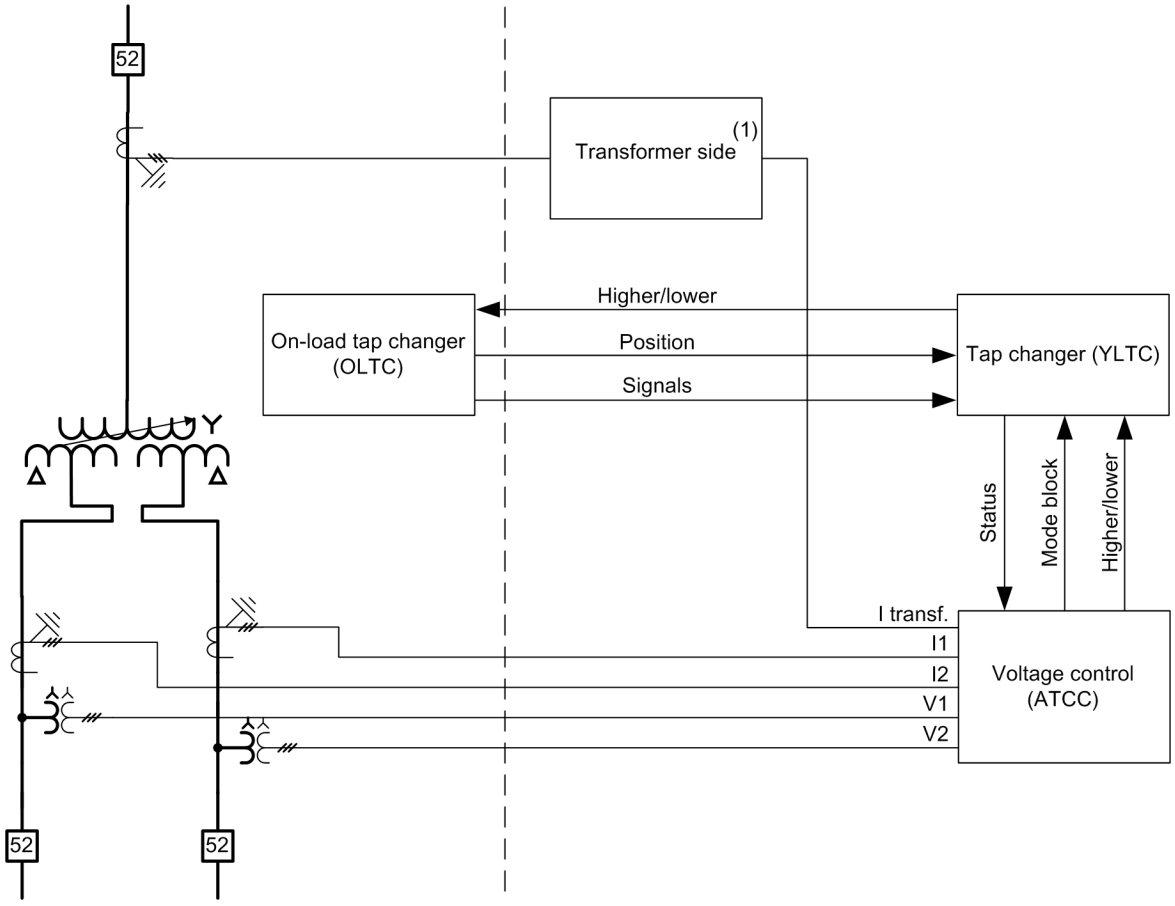
Figure 8-100 Voltage-Controller Constellation for Two-Winding Transformers with Current Measurement for Load Compensation at the End of the Line

(1) Only if a transformer side is present

[dwkonlsK-060913.vsd, 1, en_US]

Figure 8-101 Voltage-Controller Constellation for Two-Winding Transformers without Current Measurement

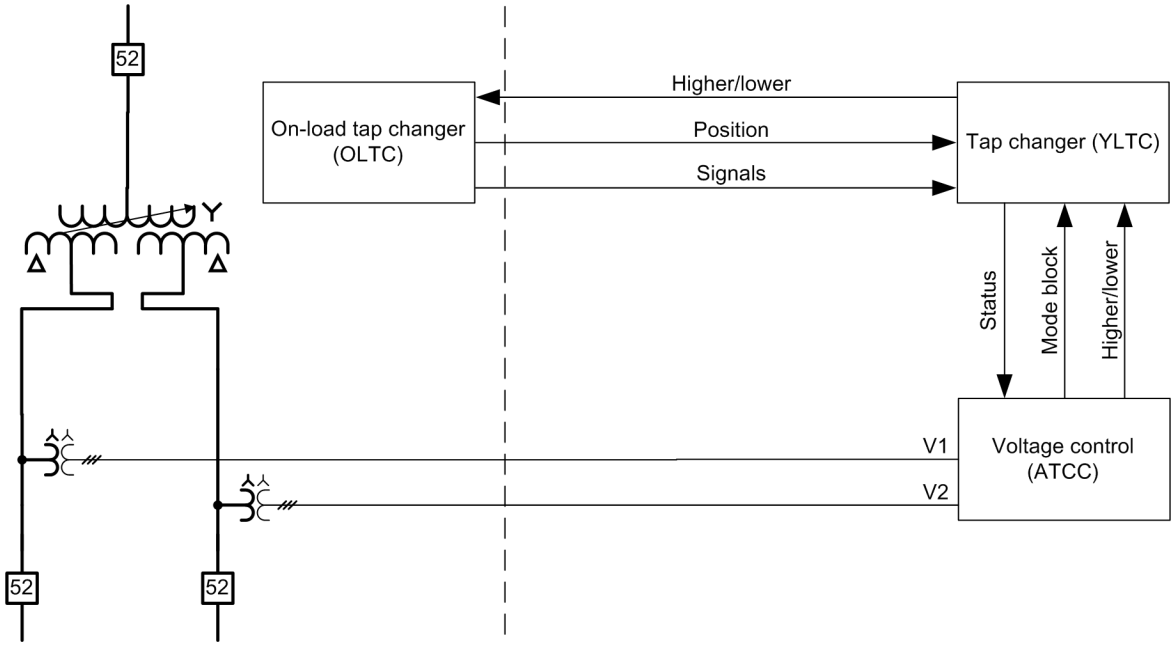
Three-Winding Transformers



Three-winding transformers are special power transformers that have 2 separate windings on the secondary circuit and typically supply 2 different busbars. The voltage levels on the secondary circuit of the power transformers can either be the same or different. In addition to designs with 2 tap changers on the secondary circuits, in most cases, three-winding transformers are equipped with only one tap changer or on-load tap changer on the primary side. It is therefore necessary to feed both voltages of the secondary windings to the voltage measuring inputs (V1, V2) and to specify one of them, depending on the busbar situation, to the voltage controller as the control variable.

The voltages of side 1 and 2 of the three-winding transformer are simultaneously monitored. In the process, the voltage to be monitored can be automatically selected via the load current of both sides or by using one parameter. This parameter is the settings group switching via binary input, protocol or function keys. The uncontrolled voltage can be monitored in parallel to ensure that it remains within the defined voltage limits.

If a current measuring point is assigned to a function group, the voltage to be controlled can be automatically selected dependent on the load.



For automatic load change, the voltage of the transformer side into which the larger load current flows is controlled. The respective uncontrolled voltage is monitored for undervoltage and overvoltage.

In contrast to overvoltage on the controlled side, for overvoltage on the uncontrolled side, the higher impulse is blocked and no fast step down to a lower tap occurs. In case of undervoltage on the uncontrolled side, the lower commands are blocked if this behavior is activated for undervoltage supervision.

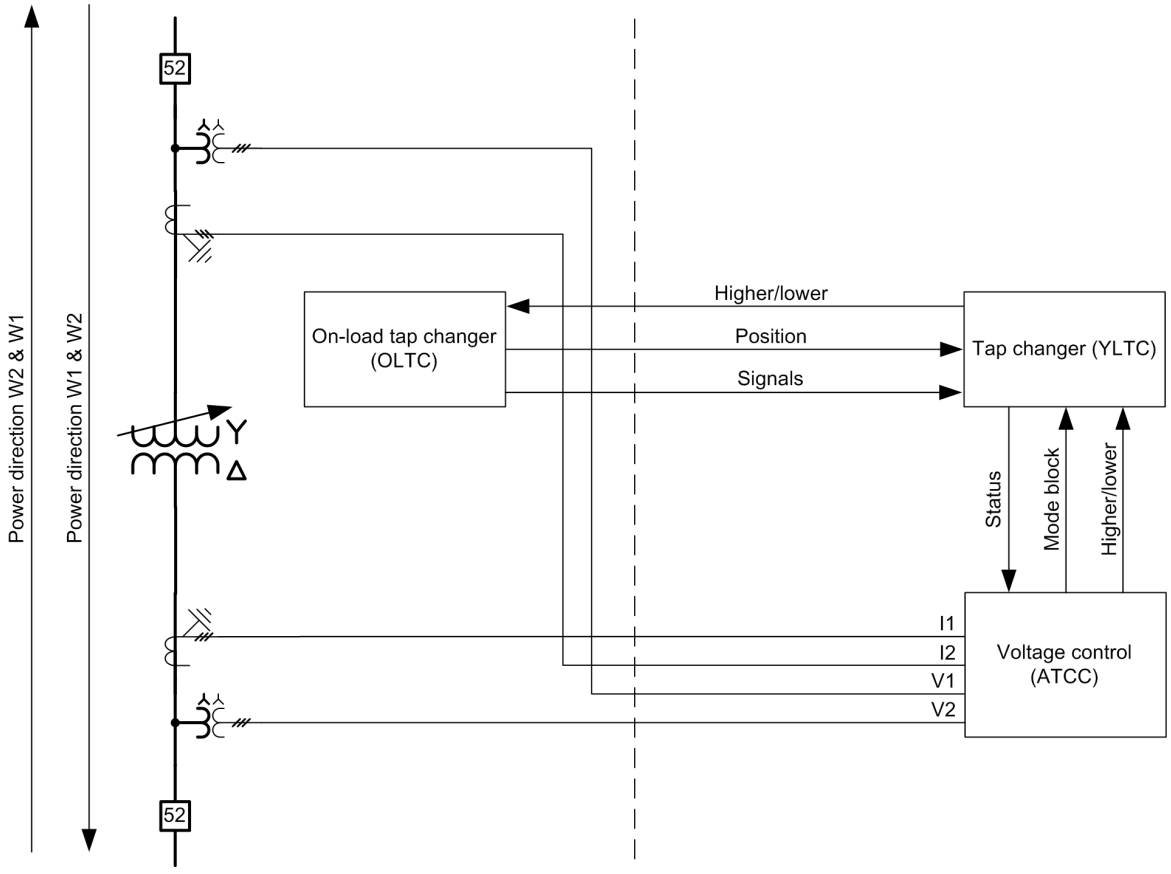
Figure 8-102 Voltage-Controller Constellation for Three-Winding Transformers with Current Measurement for Load Compensation at the End of the Line



[dw_V-constell-3wind-without-imeas-091014.vsd, 2, en_US]

Figure 8-103 Voltage-Controller Constellation for Three-Winding Transformers without Current Measurement

Grid Coupling Transformers

Grid coupling transformers are special power transformers that connect 2 electrical power systems to one another. The load-side voltage is controlled. The power flow can change during operation. That is why both voltages and currents, winding 1 and winding 2, voltage measuring inputs (V1, V2) and current measuring inputs (I1 and I2) must be fed. A voltage must be specified as a function of the load situation to the voltage controller as the control variable.

The voltages of the windings 1 and 2 of the grid coupling transformers are simultaneously monitored. In the process, you can select the voltage to be controlled using one parameter. This parameter can be changed using the settings group switching via the binary input, protocol, or function keys.

[dw_V-constell-2wind-coupl-transf.vsd, 1, en_US]

Figure 8-104 Voltage-Controller Constellation for Grid Coupling Transformers

On-Load Tap Changer

On-load tap changers are used to set the desired tap of a stepped winding of the transformer while under load. During switchover, the desired tap of the stepped winding is first selected by means of the tap selector. Next, the on-load tap changer switches over from the current-carrying tap to the selected tap. During this switchover, one tap of the stepped winding is briefly bridged by an ohmic resistor so that the load switchover takes place without power interruption. Physically, the tap changer is installed in the transformer tank or in a separate tank.

Tap Changer

The **Tap changer** function issues the adjusting commands to the on-load tap changer and receives the corresponding feedback. The function of the tap changer inside the voltage controller corresponds to that of the separate tap changer. The higher and lower tap commands are generated by the voltage controller. The **`Check switching authority`**, **`Control model`**, **`SBO time-out`** and **`Feedback monitoring time`** parameters are set only in the voltage controller.

You can find more information in chapter *8.9.4 Application and Setting Notes* .

Voltage Controller

The Voltage controller function controls the voltage within the bandwidth and within the set voltage limits. Using the **Mode** parameter, you can turn the voltage controller on or off or set it for test mode.

With the parameter **Number of target voltage**, you can specify up to 4 target voltages. You can only activate one of these target voltages at a time using function key, communication, or a binary input. With the **Set point mode active** parameter, you can specify a valid target voltage via a communication network.

If the voltage controller is switched off, adjusting commands cannot be given to the tap changer in automatic operation or in manual operation. The set on-site or remote switching authority is independent of this.

You can set the controller operating mode via the **Operating mode** parameter or the **Operating mode** command to automatic operation or manual operation. In automatic operation, the voltage is controlled automatically in accordance with the set parameters.

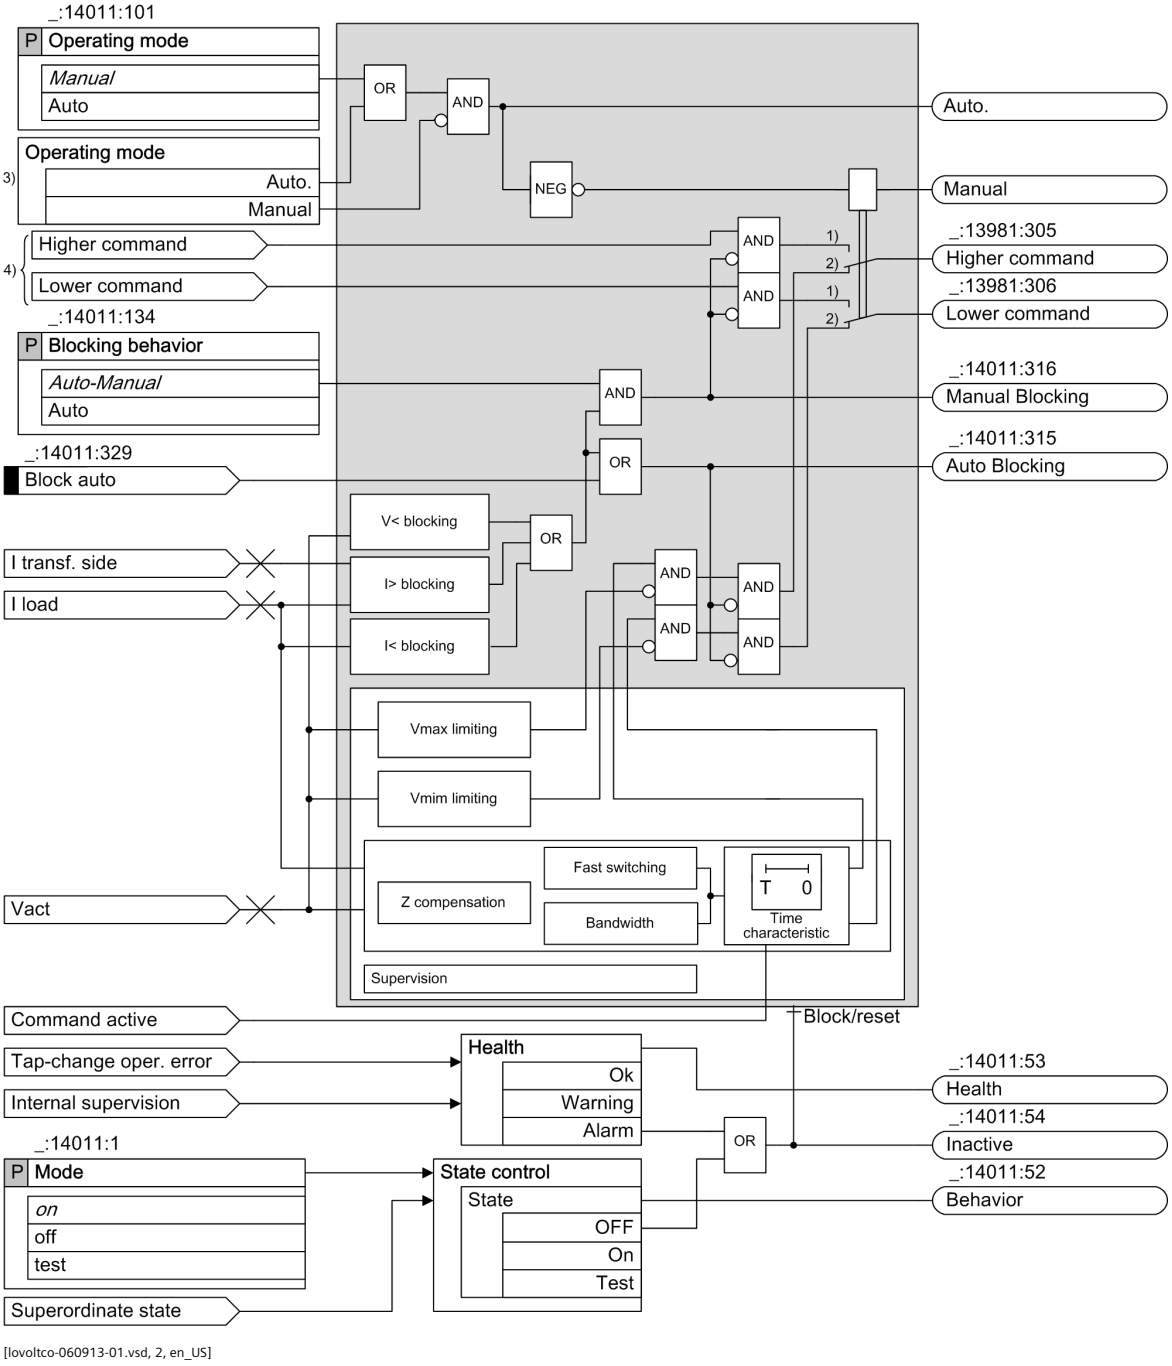
Three-Winding Transformer Voltage Controller

For the two-winding transformer voltage controller, the measurands that are used to manage the feedback control are permanently defined.

With the three-winding transformer voltage controller, these measurands can be specified using one parameter (parameter **Winding selection** = ***Winding 1*** or ***Winding 2***) or they can be automatically selected (**Winding selection** = ***WithMaxLoad***).

The winding is automatically selected by evaluating the load current in the windings. If the load current in one of the two windings is greater than the load current in the other winding by 5 % of the rated current for 10 s, then the winding voltage is controlled using the larger load current.

Grid Coupling Transformer Voltage Controller



For the two-winding transformer voltage controller, the measurands that are used to manage the feedback control are permanently defined.

With the grid coupling transformer voltage controller, these measurands can be selected using a parameter (parameter **Winding selection** = ***Winding 1*** or ***Winding 2***).

You can change the winding selection during operation using the settings group switching.

You can monitor the power-flow direction. If the difference in the power of ***Winding 1*** and ***Winding 2*** is greater than 10 % of the rated power on the control side, the *Power-flow superv.* indication appears and the function switches to the alarm state.

Logic of the Function

[lovoltco-060913-01.vsd, 2, en_US]

Figure 8-105 Higher-Level Logic of the Voltage Controller

(1) Manual operation
(2) Automatic operation
(3) Controllable
(4) Command

In accordance with the IEC 61850 standard, DOI LTCBlk (**Block automatic operation** command), automatic control can be blocked with a command.

The voltage controller measures the actual voltage (Vact) and compares it to the target voltage (Vtarget). If the difference between the measured voltage (control deviation D) is greater than the set bandwidth (B), a higher or lower command is sent to the tap changer once the set time delay (T1) has elapsed.

You can change the settings for control during operation with the settings group switching.

You can switchover the settings groups via the following alternatives:

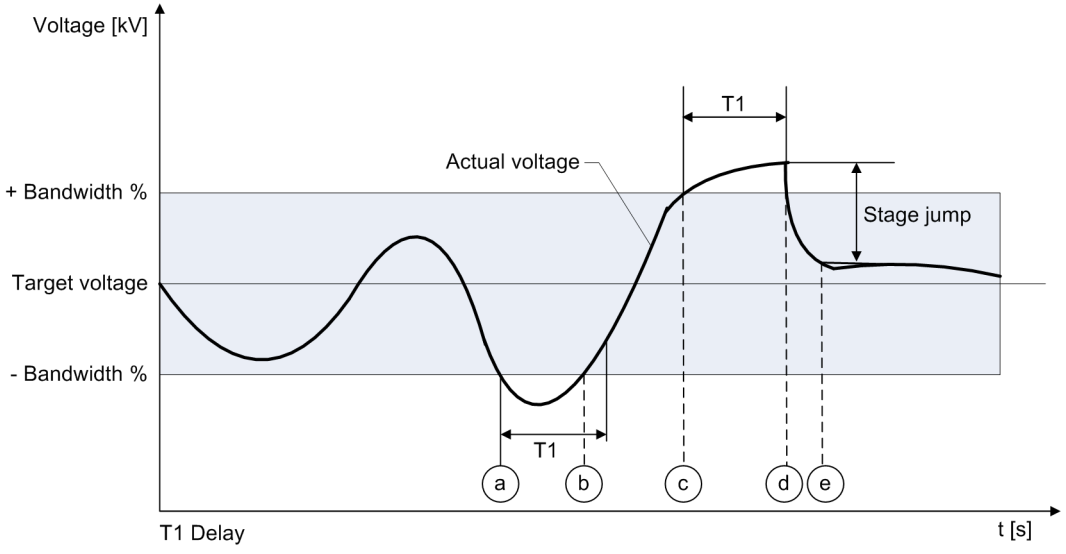
- Via the on-site operation panel directly on the device
- Via an online DIGSI connection to the device
- Via binary inputs
- Via a communication connection to a substation automation technology (IEC 60870-5-103, IEC 61850)

You can find more information in chapter *3.10.2 Settings-Group Switching* .

Control Deviation

The control deviation is calculated from the current actual voltage and the target voltage in relation to the rated voltage.

$$D = \frac{V_{act} - V_{target}}{V_{rated}} 100\ \%$$



[fokonisk-211013, 2, en_US]

D = Control deviation

Bandwidth

To minimize the number of switching operations by the tap changer, a permitted bandwidth is defined. If the actual voltage is within the bandwidth, no adjusting control commands are issued to the tap changer. If the actual voltage exceeds the defined bandwidth, an adjusting command is issued after the set time delay **`T1 delay`**. If the actual voltage returns to the voltage range of the bandwidth before **`T1 delay`** elapses, no adjusting control command is issued.

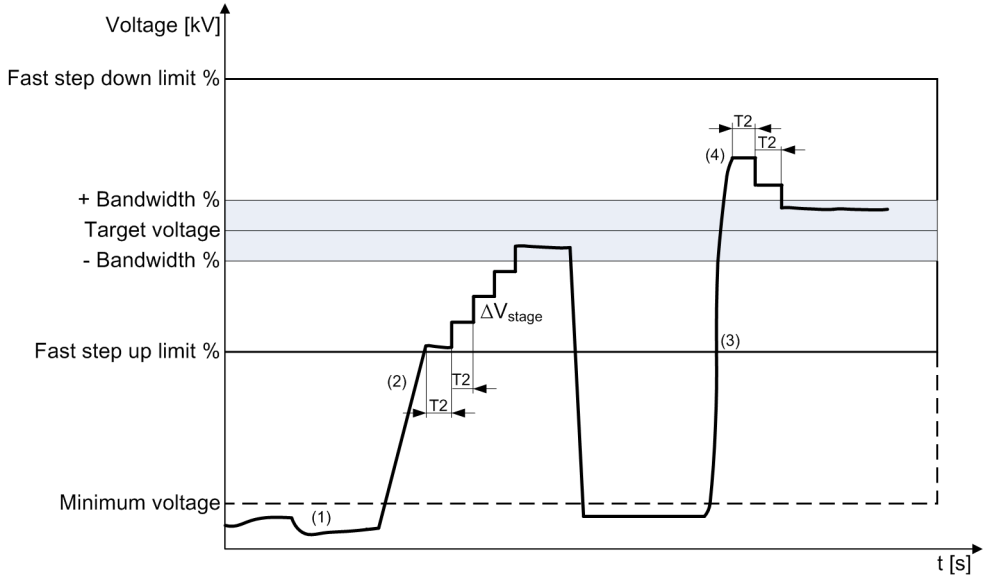
If the actual voltage returns to the voltage range of the bandwidth within the time delay T1, the running time delay T1 continues to count down, starting at the already elapsed time. If the actual voltage returns again to the set bandwidth while the time is counting down, the time delay T1 is started at the remaining time. In this way, the time delay is reduced in the event of frequent violations of the lower limit of the bandwidth.

[dwistspn-060913-01.vsd, 1, en_US]

Figure 8-106 Actual Voltage Curve during Control Deviation

(a) Actual voltage outside the bandwidth
(b) Actual voltage before T1 elapses within the bandwidth - no switching
(c) Actual voltage outside the bandwidth, T1 begins to elapse
(d) Actual voltage outside the bandwidth after T1, switching procedure initiated
(e) Switching procedure concluded, actual voltage within the bandwidth

Linear, Inverse Control Response



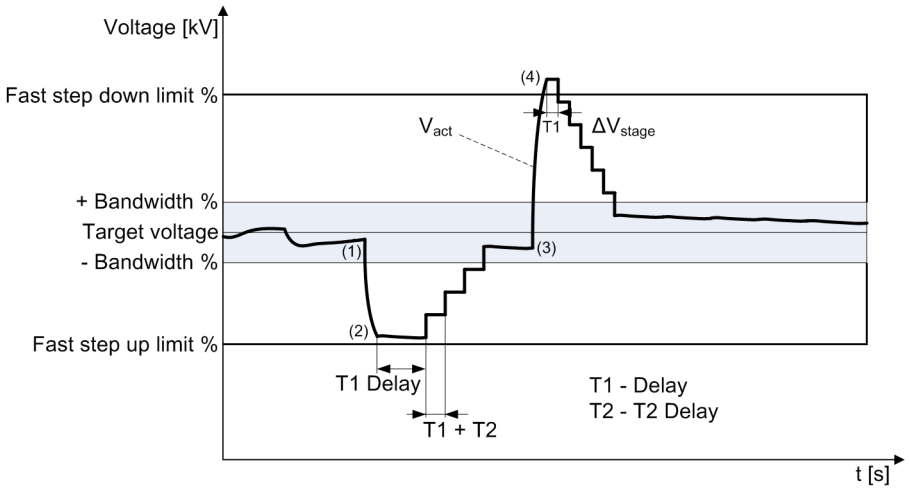
With **linear** control response, the controller reacts independently of the control deviation after the set time **`T1 delay`**. If more than one tap-position change is required to bring the actual voltage back within the bandwidth, the set time **`T2 delay`** takes effect.

With **inverse** control response, the time **`T1 delay`** depends on the magnitude of the control deviation. Small deviations are tolerated for longer than larger ones. If the time delay is very small in accordance with the set characteristic curve, the time **`T1 Inverse Min`** takes effect.

The set **inverse** characteristic curve is a function of the parameter **`T1 delay`**. The characteristic curves arising for different settings of the time **`T1 delay`** are shown in chapter *8.9.4 Application and Setting Notes* , margin title Parameter: **`T1 characteristic`**.

Control Response with Zero Potential or Voltage Recovery

If the actual voltage is not within the defined bandwidth after a voltage recovery, it can be necessary for the voltage controller to send the 1st adjusting command with the T2 time. For this purpose, the parameter **`Regulate with T2 at start`** must be switched on.



[dw_istgro-130215, 1, en_US]

Figure 8-107 Actual Voltage Curve during Control with T2

(1) Actual voltage below the minimum voltage
(2) After switching on, the change to a higher tap occurs with time T2
(3) After the voltage recovery, the actual voltage is above the bandwidth
(4) Actual voltage outside the bandwidth. A fast step down is made with the time T2 until the bandwidth is reached.

Control Response in the Event of Larger Voltage Deviations

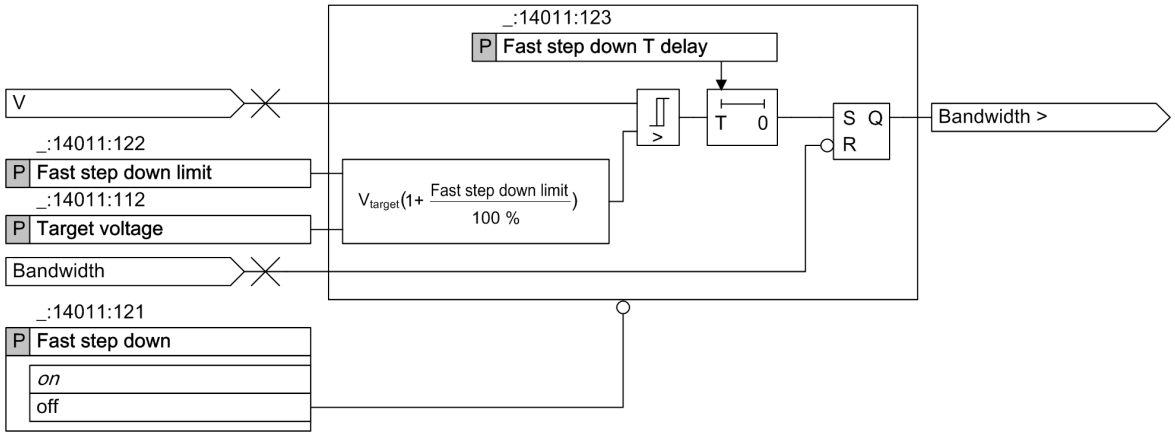
[dwistgro-060913-01.vsd, 2, en_US]

Figure 8-108 Actual Voltage Curve During Larger Control Deviations

(1) Actual voltage outside the bandwidth

(2) The change to a higher tap occurs after T1 and then T2

(3) Actual voltage inside the bandwidth



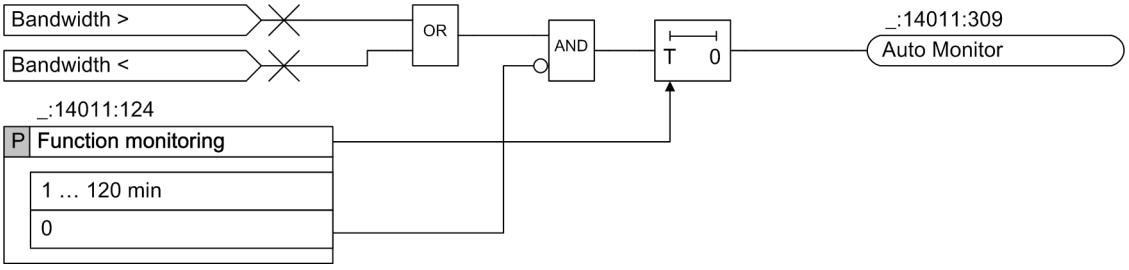
(4) Actual voltage outside the limit for a fast step down. A fast step down occurs until the bandwidth is reached.

Fast Step Up Mode and Fast Step Down Mode

The fast step down mode and the fast step up mode allow a fast reaction to abnormal voltage situations. *Figure 8-108* shows such a situation at point (4). A fast step down mode occurs until the bandwidth has been reached. The step time between 2 consecutive lower commands results from the following 2 conditions:

- The completion of a tap change command after the new valid position was detected
- The measurement time for capturing the new actual voltage

The activity of the fast step down mode and the fast step up mode is displayed with the indications *(_:14011:308) Fast Step Down active* and *(_:14011:307) Fast Step Up active*.



[losnlruk-090913-01.vsd, 2, en_US]

Figure 8-109 Logic of the Fast Step Down Mode

The fast step up mode operates in a similar fashion.

Function Supervision for Automatic Operation

If the actual voltage exceeds or falls below the set bandwidth for longer than the set time delay, this situation is shown by the indication *(_:14011:309) Auto Monitor*. If the actual voltage returns to the voltage range, the indication is reset. You can switch off the function monitor with a time delay = 0 min.

[lofktueb-090913-01.vsd, 1, en_US]

Figure 8-110 Logic of the Function Supervision for Automatic Operation

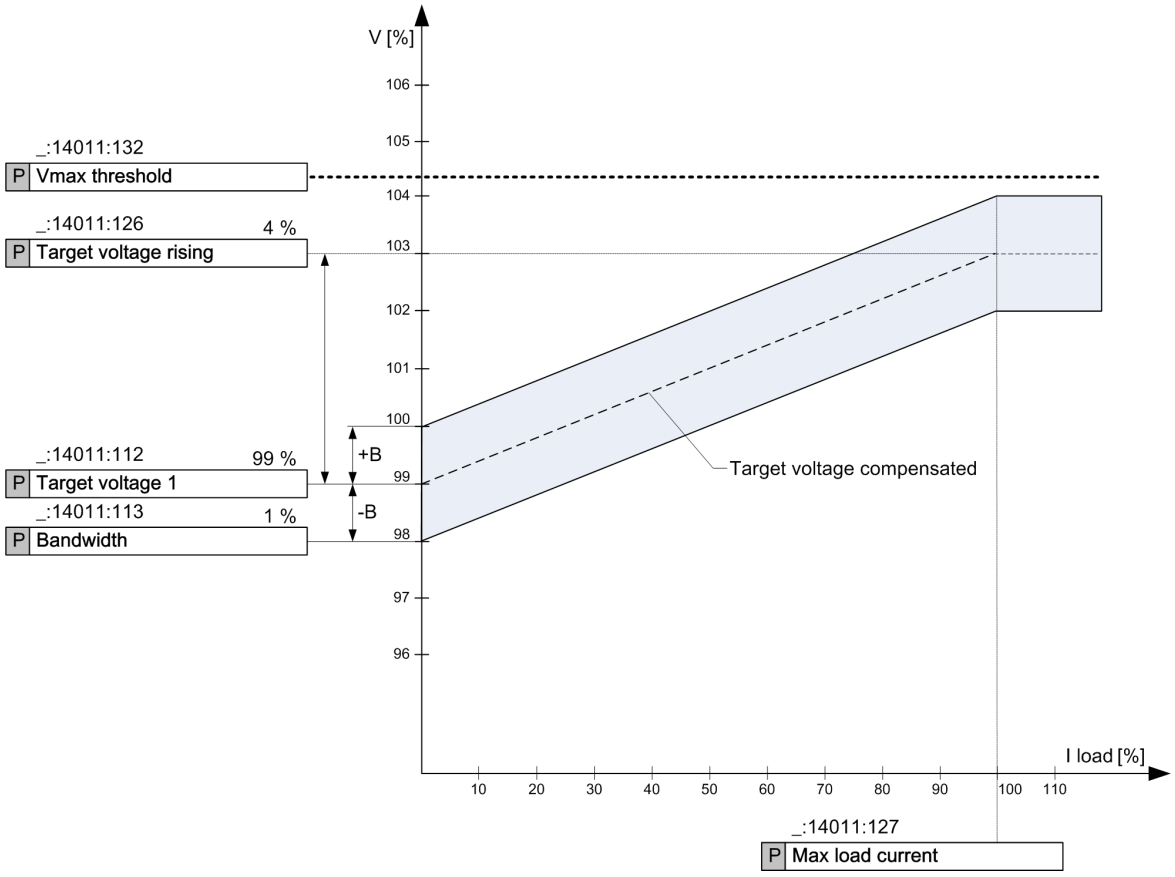
Phase Compensation

When using phase compensation, the voltage drop of a phase that is connected to a transformer can be included. In this case, 2 processes are available:

- Z compensation (LDC-Z)
- X and R compensation (LDC-XandR)

NOTE

The phase compensation is only active if power is flowing in the direction of the phase.



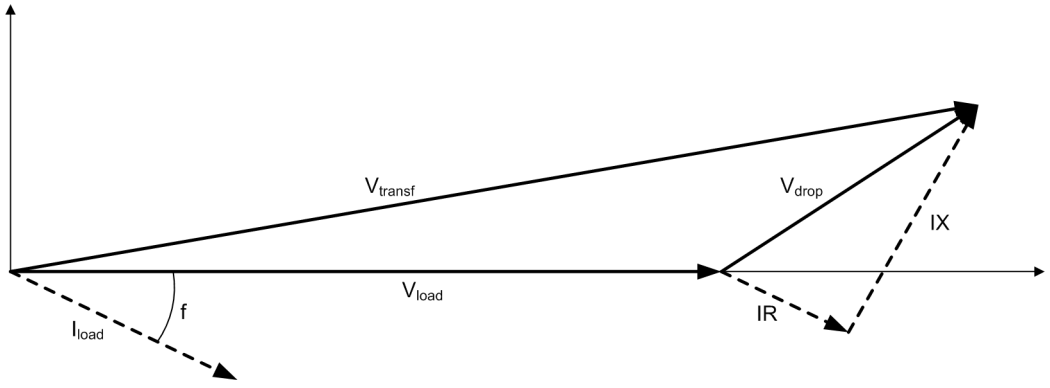
Z Compensation (LDC-Z)

Z compensation allows you to include the voltage drop of a line connected to the transformer. You can switch Z compensation on or off. If cosφ is roughly constant, you can use Z compensation. Setting the parameters requires the calculation of the voltage increase (**`Target voltage rising`**) taking into consideration the load current (**`Max load current`**).

The parameter **`Target voltage rising`** represents the voltage drop across the line as a % under rated load.

You can find more information and the calculation in chapter *8.9.4 Application and Setting Notes* .

In case of active Z compensation, you must limit the maximum permitted voltage increase in relation to the target voltage to avoid a voltage at the transformer that is too high. To do this, set the parameter **`Max load current`**. In addition, the parameter **`Vmax threshold`** is active. If the actual voltage exceeds this threshold value, no more higher tap change commands are issued.



[dwregchr-090913-01.vsd, 3, en_US]

Figure 8-111 Control Characteristic with Z Compensation

X and R Compensation (LDC-XandR)

When using the X and R compensation, you need the phase data. With this data, it is possible to precisely compensate the voltage drop of the transmission lines. The following figure shows the effect of this compensation type.

[dw-line-drop-kompensation-250214-01.vsd, 1, en_US]

Figure 8-112 Phasor Diagram of the X and R Compensation

You can also use the X and R compensation for the parallel control of transformers. If the X value is positive, the loss of voltage of the phase is compensated. If you are implementing parallel control with X and R compensation, then the X value is negative and considers the voltage increase from the busbar to the transformer.

V_{transf} Voltage on the transformer, voltage to be controlled

V_{load}	Voltage of load point (target voltage, $V_{load} = V_{transf} - V_{drop}$)
V_{drop}	Voltage drop of the phase
IR, IX	Voltage drop through R and X of the power line
I_{load}	Load current
φ	Load angle

If the X and R compensation is active, you must limit the maximum permitted voltage increase in relation to the target voltage to avoid a voltage at the transformer that is too high. To do this, set the parameter **Vmax threshold**. If the actual voltage exceeds this threshold value, no more higher tap change commands are issued.

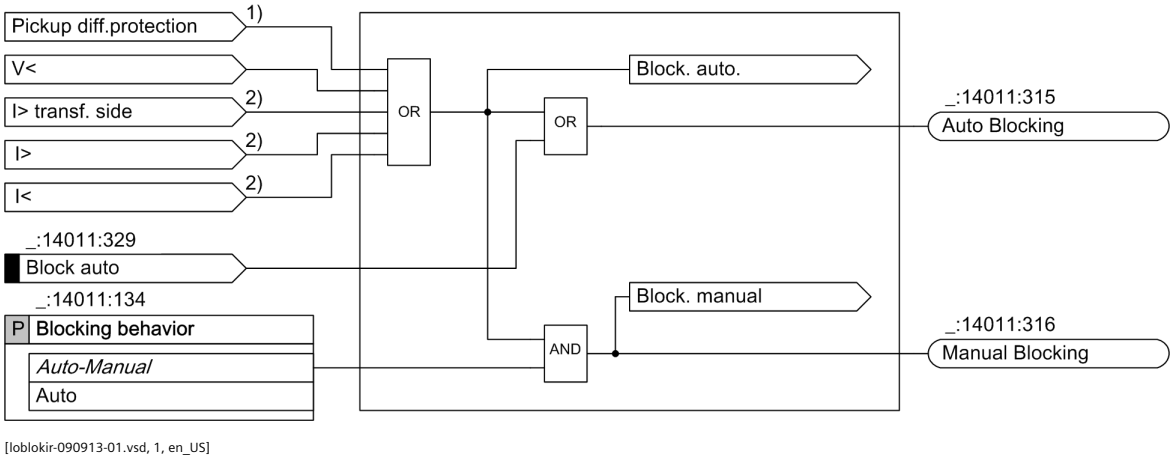
Limiting Values

The limiting values cause no higher or lower adjusting commands to be given to the tap changer in the event of an upper limit violation (**Vmax threshold**) or lower limit violation (**Vmin threshold**). In this way, changing taps under abnormal voltage conditions and changing taps in the incorrect direction (for example, in the event of wiring errors) is prevented.

The lower and upper tap changer limits are included in the limiting values. The parameters **Lower tap-position limit** and **Higher tap-position limit** cause an additional restriction of the control range.

Blockings

The blockings prevent tap positions under abnormal network conditions. The following blocking functions are available:



- Undervoltage
- Overcurrent, load current
- Undercurrent
- External blocking (binary input)
- Blocking command LTCBlock IEC 61850
- Blocking in the event of pickup of the transformer differential protection

Using the parameter **Blocking behavior**, you specify whether the blockings are to take effect only in automatic operation (***Auto***) or in both automatic and manual operation (***Auto-Manual***).

Overcurrent blocking prevents tap changes in the event of an overload. For the current blockings, the positive-sequence system of the load current and of the current on the upper-voltage side of transformers is calculated.

By assigning the tap changer to the transformer side, you also arrange the current of the upper-voltage side. Perform this assignment in the appropriate **Transformer side** . Here, you must use the tap changer of the voltage controller.

Undervoltage blocking prevents tap changes in the event of a network collapse. The output signals of the voltage controller are blocked and, depending on the operating mode, the indication *Auto Blocking* and/or *Manual Blocking* is issued.

[loblokir-090913-01.vsd, 1, en_US]

Figure 8-113 Logic Blockings

(1) If transformer differential protection is available

(2) If a current measurement is available

If the tap changer is assigned to the transformer side, is available, the current of the upper-voltage side is also monitored and the differential-protection pickup blocks the voltage controller automatically.

Additional Blockings for the Three-Winding Transformer Voltage Controller

The blockings described in the above sections also apply to the controlled winding of the three-winding transformer. In addition, the blockings for undervoltage, minimum voltage, and overcurrent are used for the measurands of the uncontrolled side.

Additional Blockings for the Grid-Coupling Transformer Voltage Controller

For voltage control in grid coupling transformers, the voltages and currents of both windings are always used for the blockings.

Functional Measured Values

You can read the current status of the measured values for the two-winding, three-winding, and grid-coupling transformers at any time. The following 3 tables show you the available measured values.

Measured Values, Two-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
V act.	Current, measured positive-sequence voltage (referenced to phase-to-phase)	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load	Current measured load current (positive-sequence system)	A	A	Load current referenced to the rated current of the winding
V max	Maximum positive-sequence voltage ever measured (referenced to phase-to-phase)	kV	V	Maximum voltage of the winding referenced to the rated voltage of the winding
V min	Minimum positive-sequence voltage ever measured (reference to phase-to-phase)	kV	V	Minimum voltage of the winding referenced to the rated voltage of the winding

Measured Value	Description	Primary	Secondary	% Referenced to
V target	Calculated target voltage with consideration of Z compensation	kV	V	Target voltage of the winding referenced to the rated voltage of the winding

The functional measured values V max and V min can be reset with the input indication *>Reset min./max.*.

For the **two-winding transformer**, you can find the measured values under the following menu items of the device:

- Main menu → Measurements → Voltage control 2w → 90V V.contr.2w
- Main menu → Measurements → Voltage control 2w → Statistics → 90V V.contr.2w

Measured Values, Three-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to the rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to the rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

The functional measured values Vmax 1, Vmax 2, Vmin 1 and Vmin 2 can be reset with the input indication *>Reset min./max.*.

For the **three-winding transformer**, you can find the measured values under the following menu items of the device:

- Main menu → Measurements → Voltage control 3w → 90V V.contr.3w
- Main menu → Measurements → Voltage control 3w → Statistics → 90V V.contr.3w

Measured Values Grid Coupling Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

The functional measured values Vmax 1, Vmax 2, Vmin 1 and Vmin 2 can be reset with the input indication *>Reset min./max.*.

For the **grid coupling transformer**, you can find the measured values under the following menu items of the device:

- Main menu → Measurements → Voltage control gc → 90V V.contr.gc
- Main menu → Measurements → Voltage control gc → Statistics → 90V V.contr.gc

Fundamental Values and Power Measured Values

The fundamental values and power measured values are always present in the **Two-winding transformer voltage controller**, **Three-winding transformer voltage controller**, and the **Grid coupling transformer voltage controller** function groups. Furthermore, you can find the fundamental values and power measured values for winding 1 and winding 2 in the **Three-winding transformer voltage controller** and in the **Grid coupling transformer voltage controller** function groups. These values cannot be deleted.

Table 8-27 and *Table 8-28* show the total scope in case a 3-phase voltage measuring point is also connected.

Table 8-27 Possible Fundamental Values for the Voltage Controller Function Group

Fundamental Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
V_A, V_B,V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3

Table 8-28 Possible Power Measured Values of the Voltage Controller Function Group

Power Measured Value		Primary	Secondary	% Referenced to
P_{total}	Active power (total power)	MW	W	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q_{total}	Reactive power (total power)	Mvar	var	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S_{total}	Apparent power (total power)	MVA	VA	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active power factor	(abs)	(abs)	100 % corresponds to cos φ = 1

8.9.4 Application and Setting Notes

Two-Winding Transformer: General

Parameter: Rated current

- Default setting **(_:2311:101) Rated current** = ***1000.00 A***

Parameter: Rated voltage

- Default setting **(_:2311:102) Rated voltage** = ***400.00 kV***

The measured values of the voltage controller can be displayed as primary values, secondary values, or in percent. With the **Rated current** and **Rated voltage** parameters, you set the reference value for the percentage values.

Three-Winding Transformer and Grid Coupling Transformer: General

Winding 1

Parameter: Rated current

- Default setting **(_:2311:101) Rated current** = ***1000.00 A***

Parameter: Rated voltage

- Default setting **(_:2311:103) Rated voltage** = ***400.00 kV***

Winding 2

Parameter: Rated current

- Default setting **(_:2311:102) Rated current** = ***1000.00 A***

Parameter: Rated voltage

- Default setting **(_:2311:104) Rated voltage** = ***400.00 kV***

The measured values of the voltage controller can be displayed as primary values, secondary values, or in percent. With the **Rated current** and **Rated voltage** parameters, you set the reference value for the percentage values.

Tap Changer

The parameters of the tap changer inside the voltage controller correspond to those of the tap changer in chapter *8.8.2 Application and Setting Notes* .

For the tap changer inside the voltage controller, the parameters for the control model are copies of those from the voltage controller. This concerns the parameters:

- Checking the switching authority
- Control model
- SBO[25] Time-out
- Feedback.monitor.time

Voltage Controller

Parameter: Mode

- Default setting **(_:14011:1) Mode** = ***on***

With the **Mode** parameter, you switch the voltage controller in ***on***, ***off***, or in ***test*** operation.

Parameter: Operating mode

- Default setting **(_:14011:101) Operating mode** = ***Manual***

With the **Operating mode** parameter, you specify whether the controller is operating in ***Auto*** mode or in ***Manual***.

Only Three-Winding Transformer:

Parameter: Winding selection

- Default setting **(_:15601:157) Winding selection** = ***Winding 1***

With the **Winding selection** parameter, you specify whether the controller controls the voltage of ***Winding 1*** or ***Winding 2***. With the ***WithMaxLoad*** setting, the voltage to be controlled is selected automatically as a function of the load current. You can switch to this method using the parameter **Winding selection** or the controllable *Automatic winding selection*.

If the controllable *Automatic winding selection* is set to **Off** or is not set, you can influence the winding to be controlled using the following 2 options:

- Via the **Winding selection** parameter
- Via the *Manual winding selection* controllable

The function value *Active winding* shows the winding selection.

Only Grid Coupling Transformer:

Parameter: Winding selection

- Default setting **(_:16351:161) Winding selection** = ***Winding 1***

With the **Winding selection** parameter, you specify whether the controller controls the voltage of ***Winding 1*** or ***Winding 2***.

You may select the winding to be controlled via the **Winding selection** parameter or the *Manual winding selection* controllable. The function value *Active winding* shows the winding selection.

[25] In the IEC 61850 standard, reservation is known as Select Before Operate (SBO).

Controlling

Parameter: Check switching authority

- Default setting **(_:107) Check switching authority** = ***yes***

With the **Check switching authority** parameter, you specify whether the switching authority (**On-site**, **Remote**) is checked during an adjusting command.

Parameter: Control model

- Default setting **(_:109) Control model** = ***SBO w. enh. security***

This parameter **Control model** specifies the control model according to IEC 61850-7-2 that corresponds to the behavior of the data (SBO – Select Before Operate).

You can select one of the following settings:

- ***direct w. normal secur.***
- ***SBO w. normal secur.***
- ***direct w. enh. security***
- ***SBO w. enh. security***

Parameter: SBO time-out

- Default setting **(_:110) SBO time-out** = ***30.00 s***

This parameter specifies the time for detecting the time-out of the SBO command. The range of values extends from 0.01 s to 1800.00 s. This is the time that can elapse between command acceptance and command execution (command model as per IEC 61850-7-2).

Parameter: Feedback monitoring time

- Default setting **(_:111) Feedback monitoring time** = ***10.00 s***

Reaching a new tap position after the adjusting command is monitored via the feedback-monitoring time. If a new tap position is not reached, the command is canceled after this time.

Parameter: Set point mode active

- Default setting **(_:14011:160) Set point mode active** = ***on***

With the parameter **Set point mode active** = ***on***, you can send a target voltage to the controller via a communication network. The controller uses the specified voltage value as target voltage. If the controller does not receive any valid voltage values, it uses the original target voltage. You can switch the parameter on or off.

For the three-winding transformer, the address of the **Set point mode active** parameter is _:15601:171 while the address is _:16351:171 for the grid coupling transformer.

Only Two-Winding Transformer:

Parameter: Number of target voltage

- Default setting **(_:14011:156) Number of target voltage** = ***1***

With this parameter, you specify the number of available **target voltages** (**1** to **4**). You can select a target voltage from the available ones using the function key, the communication, or a binary input.

NOTE

Keep in mind that the parameter **Number of target voltage** cannot be influenced by way of the settings group switching.

You can specify the **target voltages** (**1** to **4**) in primary, secondary, or in percent.

For the activation of the target voltages 1 to 4 via a binary input, you need a CFC chart.

Parameter: Target voltage 1

- Default setting **(_:14011:112) Target voltage 1** = ***110.000 V***

With the **Target voltage 1** parameter, you specify the voltage that the controller is supposed to reach.

Parameter: Target voltage 2

- Default setting **(_:14011:157) Target voltage 2** = ***110.000 V***

With the **Target voltage 2** parameter, you specify the 2nd voltage that the controller is supposed to reach.

Parameter: Target voltage 3

- Default setting **(_:14011:158) Target voltage 3** = ***110.000 V***

With the **Target voltage 3** parameter, you specify the 3rd voltage that the controller is supposed to reach.

Parameter: Target voltage 4

- Default setting **(_:14011:159) Target voltage 4** = ***110.000 V***

With the **Target voltage 4** parameter, you specify the 4th voltage that the controller is supposed to reach.

Only Three-Winding Transformer:

Parameter: Number of target voltage

- Default setting **(_:15601:164) Number of target voltage** = ***1***

With this parameter, you specify the number of available **target voltages** (**1 W1/2** to **4 W1/2**). You can select a target voltage from the available ones via the function key, the communication, or a binary input.

NOTE

Keep in mind that the parameter **Number of target voltage** cannot be influenced by way of the settings group switching.

You can specify the **target voltages** (**1 W1/2** to **4 W1/2**) in primary, secondary, or in percent.

For the activation of the target voltages 1 to 4 via a binary input, you need a CFC chart.

Parameter: Target voltage 1 w1

- Default setting **(_:15601:112) Target voltage 1 w1** = ***110.000 V***

Parameter: Target voltage 1 w2

- Default setting **(_:15601:146) Target voltage 1 w2** = ***110.000 V***

Parameter: Target voltage 2 w1

- Default setting **(_:15601:165) Target voltage 2 w1** = ***110.000 V***

Parameter: Target voltage 2 w2

- Default setting **(_:15601:168) Target voltage 2 w2** = ***110.000 V***

Parameter: Target voltage 3 w1

- Default setting **(_:15601:166) Target voltage 3 w1** = ***110.000 V***

Parameter: Target voltage 3 w2

- Default setting **(_:15601:169) Target voltage 3 w2** = ***110.000 V***

Parameter: Target voltage 4 w1

- Default setting **(_:15601:167) Target voltage 4 w1** = ***110.000 V***

Parameter: Target voltage 4 w2

- Default setting **(_:15601:170) Target voltage 4 w2** = ***110.000 V***

Only Grid Coupling Transformer:

Parameter: Number of target voltage

- Default setting **(_:16351:164) Number of target voltage** = ***1***

With this parameter, you specify the number of available **target voltages** (**1 W1/2** to **4 W1/2**). You can select a target voltage from the available ones via the function key, the communication, or a binary input.

NOTE

Keep in mind that the parameter **Number of target voltage** cannot be influenced by way of the settings group switching.

You can specify the **target voltages** (**1 W1/2** to **4 W1/2**) in primary, secondary, or in percent.

For the activation of the target voltages 1 to 4 via a binary input, you need a CFC chart.

Parameter: Target voltage 1 w1

- Default setting **(_:16351:112) Target voltage 1 w1** = ***110.000 V***

Parameter: Target voltage 1 w2

- Default setting **(_:16351:146) Target voltage 1 w2** = ***110.000 V***

Parameter: Target voltage 2 w1

- Default setting **(_:16351:165) Target voltage 2 w1** = ***110.000 V***

Parameter: Target voltage 2 w2

- Default setting **(_:16351:168) Target voltage 2 w2** = ***110.000 V***

Parameter: Target voltage 3 w1

- Default setting **(_:16351:166) Target voltage 3 w1** = ***110.000 V***

Parameter: Target voltage 3 w2

- Default setting **(_:16351:169) Target voltage 3 w2** = ***110.000 V***

Parameter: Target voltage 4 w1

- Default setting **(_:16351:167) Target voltage 4 w1** = ***110.000 V***

Parameter: Target voltage 4 w2

- Default setting **(_:16351:170) Target voltage 4 w2** = ***110.000 V***

Voltage Controller

Parameter: Bandwidth

- Default setting **(_:113) Bandwidth** = ***1.0%***

With the **Bandwidth** parameter, you specify the voltage range where no control action higher or lower is to occur about the **Target voltage 1**. If the actual voltage is outside the bandwidth referenced to the **Target voltage 1**, no correction takes place.

Calculation of the **Bandwidth**:

NOTE

When calculating the **Bandwidth** B, keep the maximum accepted voltage deviation in the electrical power system and the tap voltage of the tap changer on the secondary side of the transformer in mind.

Calculation of the minimum bandwidth:

$$B[\%] \geq 0{,}6 \cdot \left(\frac{V_{rated,sec}}{V_{Nprim}} - \frac{V_{rated,sec}}{V_{(N-1)prim}} \right) \cdot V_{rated,sec} \cdot 100\,\% \cdot \frac{V_{max,prim}}{V_{rated,prim}}$$

[fospnvrz-211013, 1, en_US]

$V_{rated,sec}$	Secondary rated voltage of the transformer
V_{Nprim}	Primary tap voltage of the transformer of tap N
$V_{(N-1)prim}$	Primary tap voltage of the transformer of tap N-1
$V_{max,prim}$	Maximum primary voltage of the transformer

Parameter: T1 characteristic

- Default setting **(_:114) T1 characteristic** = ***Linear***

Parameter: T1 delay

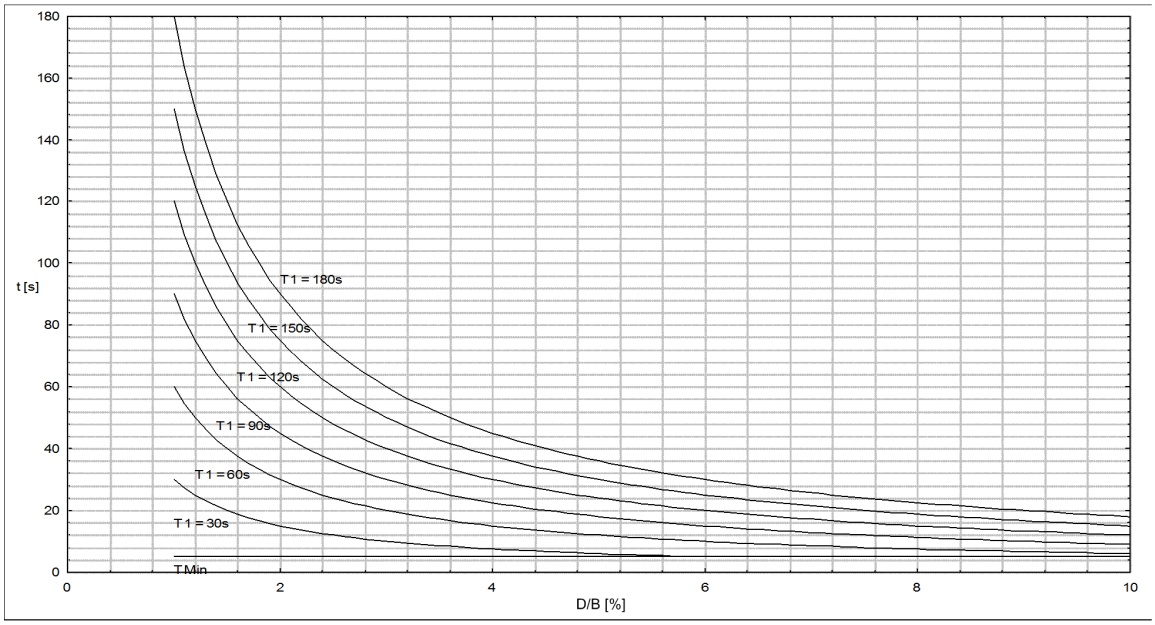
- Default setting **(_:115) T1 delay** = ***40 s***

You can adjust the control action so that the smallest number of adjusting commands possible is necessary. To do this, using **T1 characteristic**, you set the control response and, using **T1 delay**, you set a time delay.

In the ***Linear*** setting (linear control response), the control response is independent of the voltage deviation. A constant time delay applies here.

In the ***Inverse*** setting (inverse control response), the time delay is a function of the voltage deviation referenced to **Target voltage 1**. The greater the control deviation, the faster the control response. The control quality improves, but the switching frequency increases. The effective time delay results from:

$$t_{1_delay} = \frac{T_1 \cdot B}{|D|}$$



[fovrzzet-211013, 2, en_US]

T_1 – Parameter **T1 delay**

$$D = \frac{V_{act} - V_{target}}{V_{rated}} 100\ \%$$

[fokonisk-211013, 2, en_US]

D = Control deviation

[dwrglchr-160913-01.vsd, 2, en_US]

Figure 8-114 Inverse Control Characteristic

Parameter: T1 Inverse Min

- Default setting **(_:116) T1 Inverse Min** = ***5 s***

The **T1 Inverse Min** parameter is used to define the minimum time delay for the control action. This time applies only to the control response ***Inverse*** and the response cannot be shorter.

Parameter: T2 delay

- Default setting **(_:117) T2 delay** = ***5 s***

With the **T2 delay** parameter, you set the time the tap changer has to wait from one tap position to the next. During this time, several adjusting commands can be sent to the tap changer in one direction, which permits a correction of the actual voltage. The time delay T2 has an independent characteristic. The time T2 is generally set shorter than the time T1. If the time T2 is switched off by a setting equal to 0, the delay T1 is always active.

Parameter: Regulate with T2 at start

- Default setting **(_:14011:155) Regulate with T2 at start** = ***on***

With the **Regulate with T2 at start** parameter, you can activate a shorter time than T1. This can be necessary for controlling a voltage recovery or after switching on a transformer. If no voltage was available before, this setting controls with the shorter time T2 when starting the control action. You can switch this functionality on or off. If you always want to use the time T2 for control, you must set the *Block T1* controllable to ***On***.

For the three-winding transformer, the address of the **Regulate with T2 at start** parameter is _:15601:163 while the address is _:16351:163 for the grid coupling transformer.

Parameter: Fast step down

- Default setting **(_:121) Fast step down** = ***on***

Parameter: Fast step down limit

- Default setting **(_:122) Fast step down limit** = ***6.0 %***

Parameter: Fast step down T delay

- Default setting **(_:123) Fast step down T delay** = ***0.0 s***

With this parameter, you can specify the time delay of the fast step down mode. If the actual voltage is greater than the value of the limit for the fast step down mode (_:122), the fast step-down mode is activated. If the voltage limit is exceeded for only a brief period within the time delay, a fast step down mode is not activated.

Parameter: Fast step up

- Default setting **(_:118) Fast step up** = ***off***

Parameter: Fast step up limit

- Default setting **(_:119) Fast step up limit** = ***-6.0 %***

Parameter: Fast step up T delay

- Default setting **(_:120) Fast step up T delay** = ***2.0 s***

With this parameter, you can specify the time delay of the fast step up mode. If the actual voltage is less than the value of the limit for the fast step up mode (_:119), the fast step up mode is activated. If the value drops below the voltage limit for only a brief period within the time delay, a fast step up mode is not activated.

Parameter: Function monitoring

- Default setting **(_:124) Function monitoring** = ***15 min***

You can delay the pickup of the function monitor. With the setting **Function monitoring** = ***0 min***, the function monitor is switched off.

Voltage Controller Only Grid Coupling Transformer

Parameter: Power-flow supervision

- Default setting **(_:16351:162) Power-flow supervision** = ***on***

With the **Power-flow supervision** parameter, you can monitor the power flow. You can switch the parameter on or off.

Line Compensation for the Two-Winding Transformer

Parameter: Line drop compensation

- Default setting **(_:14011:125) Line drop compensation** = ***off***

You can use the **Line drop compensation** parameter to select the correction procedure of the load-dependent line voltage drop. There are 2 procedures available for selection: ***LDC-Z*** and ***LDC-XandR***.

Consider the following parameter for **Line drop compensation** = ***LDC-Z*** :

Parameter: Target voltage rising

- Default setting **(_:14011:126) Target voltage rising** = ***4.0 %***

With the **Target voltage rising** parameter, you set the voltage drop across the line. The value represents the voltage increase in % of the **Target voltage 1** that occurs at rated load. Only the magnitude of the current is considered. The set value is added to the **Target voltage 1**.

Target voltage rising [%] = ΔV_{load} [%] if I_{load} = 100 %

$$\text{Target voltage rising}[\%] = \left(V_{SetComp}[\%] - V_{Set}[\%]\right) \cdot \frac{100\ \%}{I_{load}[\%]}$$

[foschlst-211013, 1, en_US]

$V_{SetComp}$	Target voltage at the end of the line
V_{Set}	Target voltage
I_{load}	Load current in %

Parameter: Max load current

- Default setting **(_:14011:127) Max load current** = ***100.0 %***

With the setting of the parameter **Max load current**, you can prevent the voltage at the transformer from becoming too high in the event of extraordinarily high load current. If the load current exceeds the set value, no additional load-current compensation is calculated.

Consider the following parameter for **Line drop compensation** = ***LDC-XandR*** :

Parameter: R line

- Default setting **(_:14011:153) R line** = ***0.0 Ω***

With the **R line** parameter, you set the ohmic resistance of the power line.

Parameter: X line

- Default setting **(_:14011:154) X line** = ***0.0 Ω***

With the **X line** parameter, you set the reactance for the line to be protected.

In order to determine the voltage drop by the line, entering the parameter **R line** and **X line** is necessary for the procedure **Line drop compensation** = ***LDC-XandR***. If the primary values are known and you would like to set the secondary values, use the following formula for the calculation

$$X_{sec} = \frac{Ratio_I}{Ratio_V} X_{prim}$$

[fo-I-V-Ratio-250214, 1, en_US]

As an example, calculate X_{sec} with the following parameters:

Current transformer ratio	: 1000 A/1 A
Voltage transformer ratio	: 380 kV/0.1 kV
X_{prim}	: 21 Ω

Therefore, the result for X_{sec} is:

$$X_{sec} = \frac{1000\ A / 1\ A}{380\ kV / 0.1\ kV} 21\ \Omega = 5.53\ \Omega$$

[fo-I-V-Ratio_Value-250214, 1, en_US]

If you are implementing a parallel control with the X and R compensation, then the X value is negative and considers the voltage increase from the busbar to the transformer.

Line Compensation for the Three-Winding Transformers and Grid Coupling Transformers

Parameter: Line drop compensation

- Default setting **(_:125) Line drop compensation** = ***off***

Consider the following parameter for **Line drop compensation** = ***LDC-Z*** :

Parameter: Target voltage rising w1

- Default setting **(_:126) Target voltage rising w1** = ***4.0%***

Parameter: Target voltage rising w2

- Default setting **(_:147) Target voltage rising w2** = ***4.0%***

Parameter: Max load current

- Default setting **(_:127) Max load current** = ***100.0 %***

Consider the following parameter for **Line drop compensation** = ***LDC-XandR***:

Parameter: R line w1

- Default setting **(_:153) R line w1** = ***0.0 Ω***

Parameter: R line w2

- Default setting **(_:155) R line w2** = ***0.0 Ω***

Parameter: X line w1

- Default setting **(_:154) X line w1** = ***0.0 Ω***

Parameter: X line w2

- Default setting **(_:156) X line w2** = ***0.0 Ω***

Limiting Values for the Two-Winding Transformer

Parameter: Lower tap-position limit

- Default setting **(_:14011:102) Lower tap-position limit** = ***1***

Parameter: Higher tap-position limit

- Default setting **(_:14011:103) Higher tap-position limit** = ***1***

With the parameters **Lower tap-position limit** and **Higher tap-position limit**, you can restrict the taps available in automatic operation. For example, using the parameter **Higher tap-position limit**, changes to higher taps to excessive ratios that would result in overvoltages in the event of a sudden loss of load are blocked.

Parameter: Vmin limiting

- Default setting **(_:14011:128) Vmin limiting** = ***on***

Parameter: Vmin threshold

- Default setting **(_:14011:129) Vmin threshold** = ***105.000 V***

Parameter: Vmin time delay

- Default setting **(_:14011:130) Vmin time delay** = ***10 s***

Parameter: Vmax limiting

- Default setting **(_:14011:131) Vmax limiting** = ***on***

Parameter: Vmax threshold

- Default setting **(_:14011:132) Vmax threshold** = ***115.000 V***

Parameter: Vmax time delay

- Default setting **(_:14011:133) Vmax time delay** = ***10 s***

The voltage limits are necessary only for special control situations. The overvoltage limit prevents a change to a higher tap by the controller if the limiting value **Vmax threshold** is exceeded. The undervoltage limit prevents a change to a lower tap by the controller if the voltage drops below the limiting value **Vmin threshold**.

Limiting Values for Three-Winding Transformers and Grid Coupling Transformers

Parameter: Vmin threshold w1

- Default setting **(_:129) Vmin threshold w1** = ***105.000 V***

Parameter: Vmin threshold w2

- Default setting **(_:148) Vmin threshold w2** = ***105.000 V***

Parameter: Vmax threshold w1

- Default setting **(_:132) Vmax threshold w1** = ***115.000 V***

Parameter: Vmax threshold w2

- Default setting **(_:149) Vmax threshold w2** = ***115.000 V***

Blockings for the Two-Winding Transformers

Parameter: Blocking behavior

- Default setting **(_:14011:134) Blocking behavior** = ***Auto-Manual***

If the corresponding voltage limits are exceeded in either direction, the blockings prevent a change to a lower or higher tap. On the one hand, this prevents excessive wear of the contacts of the tap changer and, on the other hand, it prevents a system incident. With the parameter **Blocking behavior**, you set whether these blockings are effective only in automatic operation or in both automatic and manual operation.

Parameter: V< Blocking

- Default setting **(_:14011:135) V< Blocking** = ***on***

Parameter: V< Threshold

- Default setting **(_:14011:136) V< Threshold** = ***90.000 V***

Parameter: V< Time delay

- Default setting **(_:14011:137) V< Time delay** = ***0 s***

Parameter: I> Blocking

- Default setting **(_:14011:138) I> Blocking** = ***on***

Parameter: I> Threshold

- Default setting **(_:14011:139) I> Threshold** = ***150 %***

Parameter: I> Time delay

- Default setting **(_:14011:140) I> Time delay**= ***0 s***

If the load current exceeds the threshold value **I> Threshold** for the time **I> Time delay**, the overcurrent blocking prevents changing to a higher or lower tap. Set the threshold value **I> Threshold** in % in relation to the rated current. To do this, set the parameter **I reference** for % values.

Parameter: I< Blocking

- Default setting **(_:14011:141) I< Blocking** = ***off***

Parameter: I< Threshold

- Default setting **(_:14011:142) I< Threshold** = ***10 %***

Parameter: I< Time delay

- Default setting **(_:14011:143) I< Time delay** = ***10 s***

If the load current drops below the threshold value **I< Threshold** for the time **I< Time delay**, the undercurrent blocking prevents changing to a higher or lower tap. Set the threshold value **I< Threshold** in % in relation to the rated current. To do this, set the parameter **I reference** for % values.

Blockings for Three-Winding Transformers and Grid Coupling Transformers

Parameter: V< Threshold w1

- Default setting **(_:136) V< Threshold w1** = ***90.000 V***

Parameter: V< Threshold w2

- Default setting **(_:150) V< Threshold w2** = ***90.000 V***

8.9.5 Settings

Two-Winding Transformer

Addr.	Parameter	C	Setting Options	Default Setting
Ref. for %-values				
_:2311:101	General:Rated current		0.20 A to 100000.00 A	1000.00 A
_:2311:102	General:Rated voltage		0.20 kV to 1200.00 kV	400.00 kV
Tap changer				
_:13981:111	Tap changer:Maximum output time		0.02 s to 1800.00 s	1.50 s

9 Supervision Functions

9.1	Overview	1170
9.2	Resource-Consumption Supervision	1171
9.3	Supervision of the Secondary System	1176
9.4	Supervision of the Device Hardware	1213
9.5	Supervision of Device Firmware	1218
9.6	Supervision of Hardware Configuration	1219
9.7	Supervision of Communication Connections	1220
9.8	Error Responses and Corrective Measures	1221
9.9	Group Indications and Predefined CFC Charts	1228

9.1 Overview

SIPROTEC 5 devices are equipped with an extensive and integrated supervision concept. Continuous supervision:

- Ensures the availability of the technology used
- Avoids subfunction and overfunction of the device
- Protects persons and primary technical devices
- Offers effective assistance during commissioning and testing

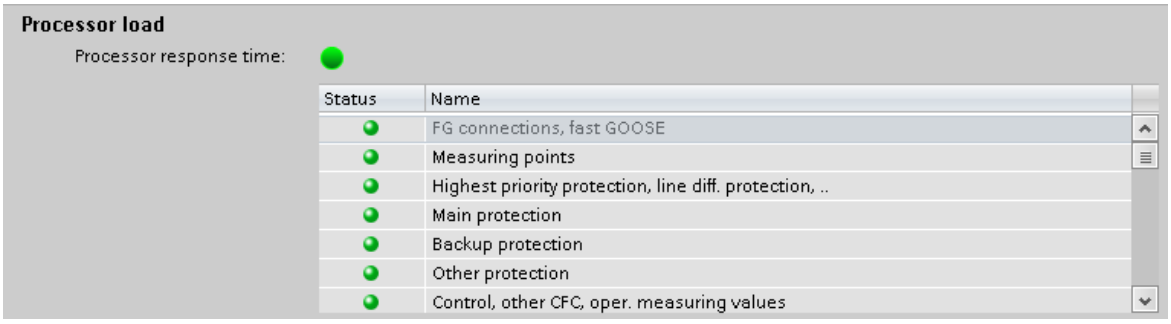
The following areas are monitored:

- Supervision the resource consumption of the application
- Supervision of the secondary system
- Supervision of device hardware
- Supervision of device firmware
- Supervision of hardware configuration
- Supervision of communication connections

When the supervision functions pick up, that will be displayed and also indicated. Error responses are defined for the device. The error responses are grouped in defect severities.

The supervision functions work selectively. When the supervision functions pick up - as far as possible - only the affected parts of the hardware and firmware are blocked. If this is not possible, the device goes out of operation into a secure state (fallback mode). In addition to safety, this warrants a high degree of availability.

9.2 Resource-Consumption Supervision



9.2.1 Load Model

SIPROTEC 5 devices are freely configurable. A load model is integrated in DIGSI 5. The load model prevents you from overloading the device with an excessively large application.

The load model shows the device utilization and the response times for device functions. If it determines that an application created is likely to overload the device, DIGSI prevents the application from being loaded into the device.

In this rare case, you must then reduce the application in order to be able to load it into the device.

The load model can be found in the DIGSI 5 project tree under **Name of the device → Device information**. In the operating range, select the **Resource consumption** setting sheet. The following figure shows an example of the view of the load model in DIGSI 5:

[sclasjsk-291112-01.tif, 1, en_US]

Figure 9-1 Visualization of the Load Model in DIGSI

A green total display for the processor response time indicates that the device is not overloaded by the present application. On the other hand, if you see a red exclamation mark, the planned application is overloading the device.

The list below the total display shows the individual functional areas. These areas combine functions with the same real-time requirements in groups. A green display in front of an area (see *Figure 9-1*) indicates that the response times of the functions grouped in this area can be maintained. A red exclamation point indicates that functions may have longer response times than are specified in the Technical data for the device. In such a case, loading of the application into the device is blocked.

The following table provides an overview of the functional areas and the most important influencing quantities on device utilization:

Functional Area	Brief Description	Change in Load
CFC event-triggered, fast	CFC charts that must be processed especially fast (for example, to invoke interlockings between protection functions)	Adding or removing CFC charts in the fast event-triggered process range • Create CFC chart • Delete CFC chart • Change the process range in the properties of the CFC chart Add to or remove from CFC charts in the fast event-triggered process area
Measuring points	Provision of measured values for protection, control, and measurement functions	Adding or removing • Measuring points (in the Measuring-points routing Editor) • Function groups that provide measured-value preprocessing for insertable functions (for example, Line function group and Circuit-breaker function group)

Functional Area	Brief Description	Change in Load
• FG connections • Fast GOOSE	• Interaction between individual function groups, for example, between the Line function group and the Circuit-breaker function group • Fast GOOSE communication	Adding or removing • Protection functions and their stages • Circuit-breaker function groups • Fast GOOSE connections
Protection Communication	Signal transmission via protection communication and differential protection communication	Adding or removing • Communication modules for the protection interface (in the DIGSI 5 Hardware and logs view) • Routings to the protection interface
Function Groups	Function Groups	Adding or removing function groups such as: • FG V/I 3-phase
Overcurrent protection	Overcurrent protection	Adding or removing • Overcurrent protection, phases • Overcurrent protection, ground
Measuring point supervising function, protection communication	• Measuring-point supervision functions • Scope of the data transmission via the protection communication	Adding or removing measuring points or individual supervising functions, such as • 3-phase current measuring point • 3-phase voltage measuring point • Measuring-voltage failure detection Add to or remove from transmission values via the protection communication • Single-point indications • Measured values
Other protection	Protection functions with low requirements for fast operate times	Adding or removing • Overload protection functions • Functions and stages of voltage protection • All functions not listed previously
CFC event-triggered, standard GOOSE	CFC charts with a maximum processing time of 40 ms	Adding or removing CFC charts in the event-triggered process range • Create CFC chart • Delete CFC chart • Change the process range in the properties of the CFC chart Add to or remove from CFC charts in the event-triggered process area
• Control • Other continuous function chart • Operational measured values	• Control and interlocking • CFC charts in the area of control, measured-value preprocessing, and event-controlled • Operational measured values	Adding or removing • Function blocks for control and interlocking • CFC charts in the control area • Switching devices (except circuit breakers), for example, disconnector function groups • Operational measured values • CFC charts in the measured values area

If the load model displays a warning, bear in mind the following general instructions:

The areas named in the table are listed in descending order of real time requirements. If a warning appears to the effect that the guaranteed response times may be exceeded in an area, you may be able to return to the permitted area by taking the following measures:

- Reduce the functional scope in the marked area (red exclamation mark)
- Reduce the functional scope in another area with higher real time requirements

When you have reduced the application, check the display in resource consumption! If a function or state has been switched off, it will continue to represent a load for the area. If you do not need the function or stage, delete it rather than switching it off.

Use the general **Circuit-breaker** function group only in the following cases:

- Interaction with a protection-function group is essential.

  That is, operate indications of protection functions cause the circuit breaker assigned to the **Circuit-breaker** function group to be switched off.
- You want to use functions such as the automatic reclosing function or circuit-breaker failure protection in the **Circuit-breaker** function group.

If a circuit breaker is only to be modeled for control purposes, use the **Circuit breaker [state only]** function group.

9.2.2 Function Points

When you order a SIPROTEC 5 device, you are also ordering a function-points account for use of additional functions.

The following figure illustrates consumption of function points in the current application with respect to the existing function-points account.

[scfpunkt-141210-01, 1, en_US]

Figure 9-2 Resource Overview: Function-Points Consumption

The remaining white bar shows the function points that have not yet been used up by your configuration. The number of function points available in a device depends on the device purchase order (position 20 of the product code). You can also order function points subsequently, and so increase the function-points account for the device.

NOTE

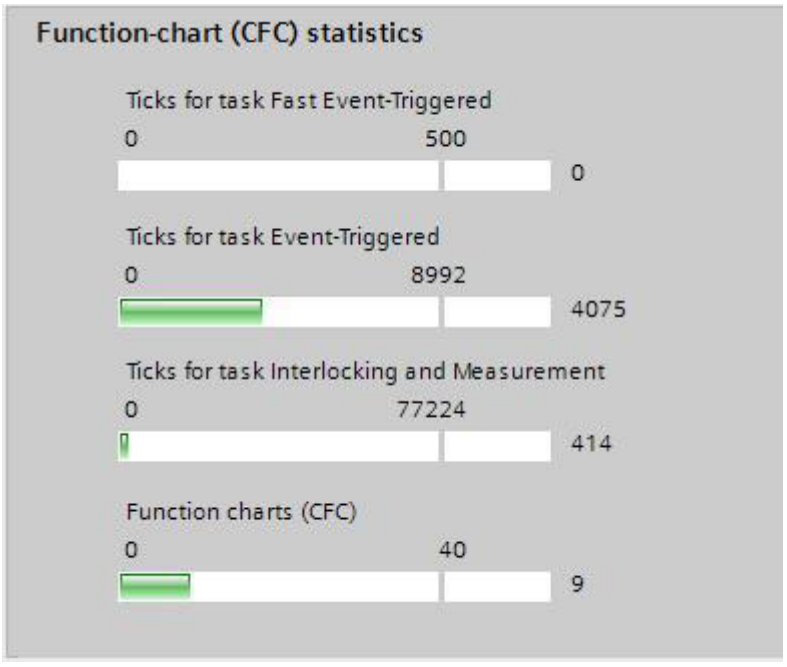
Find out the function-points requirement for the desired application before ordering the device. For this, you can use the device configurator.

9.2.3 CFC Resources

Task Levels of the CFC Function

A CFC chart, and thus the configured CFC function, runs in the SIPROTEC 5 device on exactly one of the 4 task levels. The individual task levels differ, on the one hand, in the priority of processing tasks and, on the other, in the cyclic or event-triggered processing of the CFC charts.

You can select between the following task levels:



Task Level	Description
Fast Event-Triggered	Use the ***Fast Event-Triggered*** task level for time-critical tasks, for example, if a signal should block a protection function within 2 ms to 3 ms. Functions on this task level are processed in an event-triggered way with the highest priority. Each change to a logical input signal is immediately processed. Processing can interrupt the execution of protection functions and functions on the ***Event-Triggered*** task level.
Event-Triggered	Use the ***Event-Triggered*** task level preferably for logic functions that need not be executed with highest priority. Each change to a logical input signal is immediately processed. Protection functions or functions on the ***Fast event-triggered*** task level can disrupt processing. Functions on the ***Event-Triggered*** task level are typically processed within a maximum of 5 ms in all devices. For busbar protection or line protection, the functions on the ***Event-Triggered*** task level are processed within a maximum of 10 ms.
Measurement	Use the ***Measurement*** task level for processing measured values. Functions on this task level are processed cyclically every 500 ms.
Interlocking	Use the ***Interlocking*** task level preferably for logic functions that should be executed with lower priority than functions in the ***Event-Triggered*** task level. If the available ticks of the ***Event-Triggered*** task level shown in the following figure are sufficient for the required CFC functionality, you do not need to use the ***Interlocking*** task level.

All CFC function blocks can be assigned to all the task levels. There are no device-specific function blocks. If enough ticks are available, all CFC charts can be created in the same task level. A tick is the measure of the performance requirement of CFC blocks.

The number of available ticks for each task is calculated depending on the created device configuration. This calculation is based on the previously described load model. In this process, it is recommended to create all selected functions and objects first followed by configuration of the CFC charts so that a realistic information about the remaining system capacitance for CFC charts is available. Significantly exceeding the typical response time is prevented by the load model by limiting the number of CFC function blocks in the corresponding task level via the number of ticks available.

The typical response times for CFC tasks are listed in the Technical Data.

The following figure shows an example of the CFC chart capacitances in DIGSI calculated by the load model. The ticks available for each task are shown here. The green bars represent the ticks used in the task levels. You reach this dialog with the following call: Device → Device information → Resource consumption.

[sc-cfc-statistic, 1, en_US]

Figure 9-3 CFC Statistics

NOTE

The fast-event-triggered CFC charts have the highest priority and are processed before all other tasks. At this level, a considerable smaller number of ticks are available than at all other tasks. It is recommended to configure only very-high-priority logic functions at this task and to configure the other logic functions in any other level.

NOTE

Empty CFC charts also consume system resources. Empty charts that are not required any more should be deleted.

9.3 Supervision of the Secondary System

9.3.1 Overview

The secondary circuits establish a connection to the power system from the point of view of the device. The measuring-input circuit (currents, voltages) as well as the command circuits to the circuit breakers are monitored for the correct function of the device. The connection to the station battery is ensured with the supervision of the external auxiliary voltage. The secondary system has the following supervision systems:

Measuring circuits (voltage):

- Measuring-Voltage Failure
- Voltage-Transformer Circuit Breaker
- Voltage balance
- Voltage sum
- Voltage rotating field

Measuring circuits (current):

- Broken conductor of the current circuits
- Current balance
- Current sum
- Current rotating field

Trip circuits

External auxiliary voltage

When these supervisions pick up, corresponding warning indications are output. Some supervisions lead directly to the blocking of affected protection functions or to the marking of measuring points that have become invalid, so that affected protection functions can go into a secure state.

A detailed description of the supervision mechanisms and their error responses can be found in the Function Description and as overall overview at the end of chapter 8.

9.3.2 Measuring-Voltage Failure

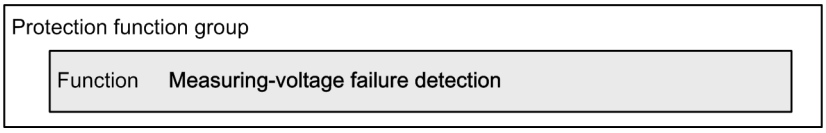
9.3.2.1 Overview of Functions

The **Measuring-voltage failure detection** function monitors the voltage transformer secondary circuits:

- Non-connected transformers
- Pickup of the voltage transformer circuit breaker (in the event of short circuits in the secondary circuit)
- Broken conductor in one or more measuring loops

All these events cause a voltage of 0 in the voltage transformer secondary circuits which can lead to failures of the protection functions.

For the following protection functions, the response (block/not block) to a measuring-voltage failure can be set within the function:



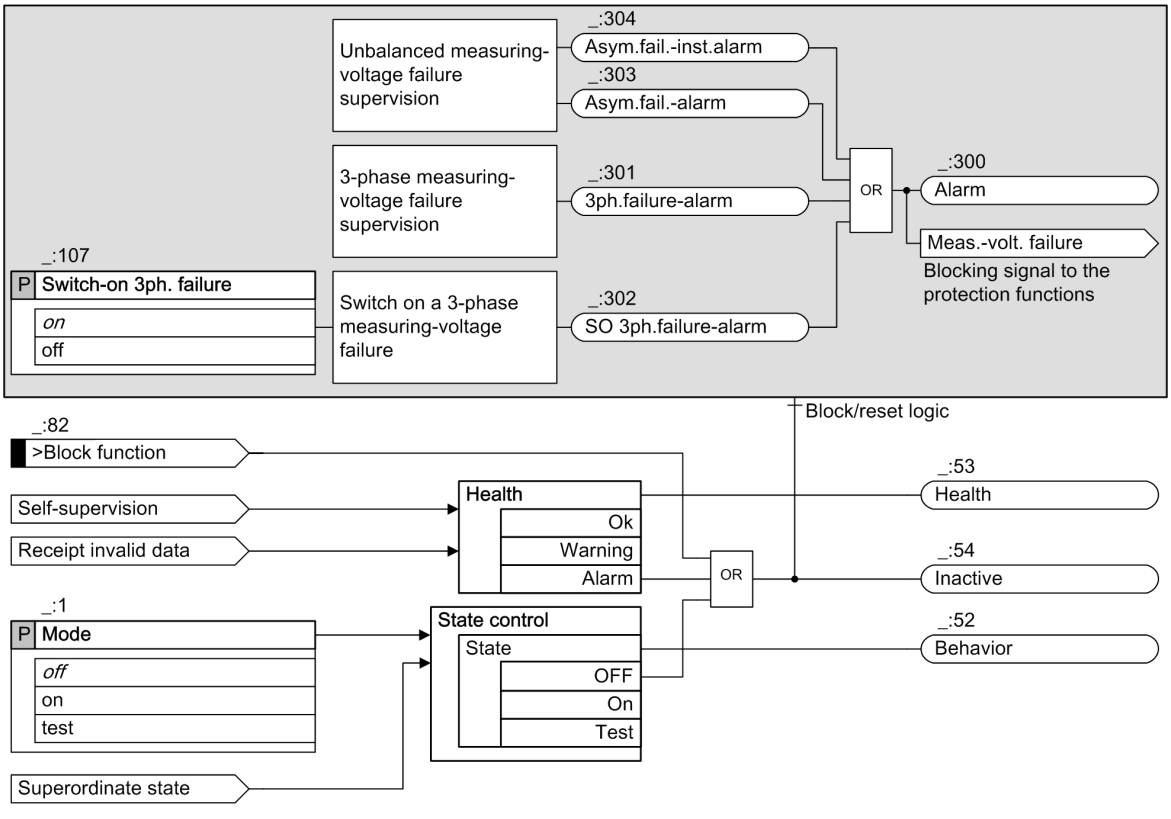
- Directional time-overcurrent protection, phases
- Overvoltage protection with negative-sequence voltage
- Overvoltage protection with zero-sequence voltage/residual voltage
- Undervoltage protection with 3-phase voltage
- Undervoltage protection with positive-sequence voltage

The following protection functions are automatically blocked in the case of a measuring-voltage failure:

- Distance protection
- Directional negative-sequence protection
- Ground-fault protection for high-resistance faults in grounded-neutral systems

9.3.2.2 Structure of the Function

The function is part of protection function groups which are connected with a 3-phase voltage and current measurement point.



[dwstrffm-210113-01.tif, 1, en_US]

Figure 9-4 Structure/Embedding of the Function

The function is broken down into 3 subfunctions (see *Figure 9-5*):

- Supervision for unbalanced measuring-voltage failure
- Supervision for 3-phase measuring-voltage failure
- Supervision for switching onto a 3-phase measuring-voltage failure

[lozusamm-100611-01.tif, 2, en_US]

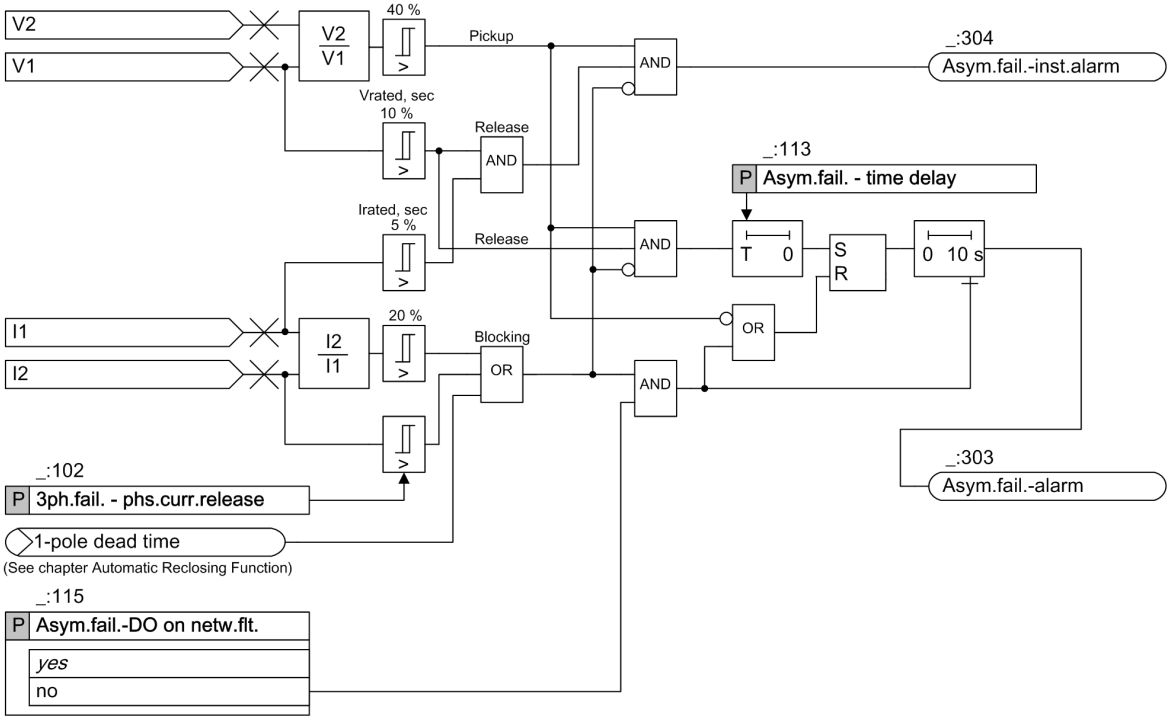


Figure 9-5 Breakdown of the Measuring-Voltage Failure Detection Function

Each subfunction creates its own monitoring indication. The function summarizes these indications via the group indication **`Alarm`**.

The response to the detection of a measuring-voltage failure is explained in the specific protection-function descriptions.

9.3.2.3 Unbalanced Measuring-Voltage Failure

Logic

[looppode-200812-05.tif, 2, en_US]

Figure 9-6 Logic Diagram Unbalanced Measuring-Voltage Failure Detection

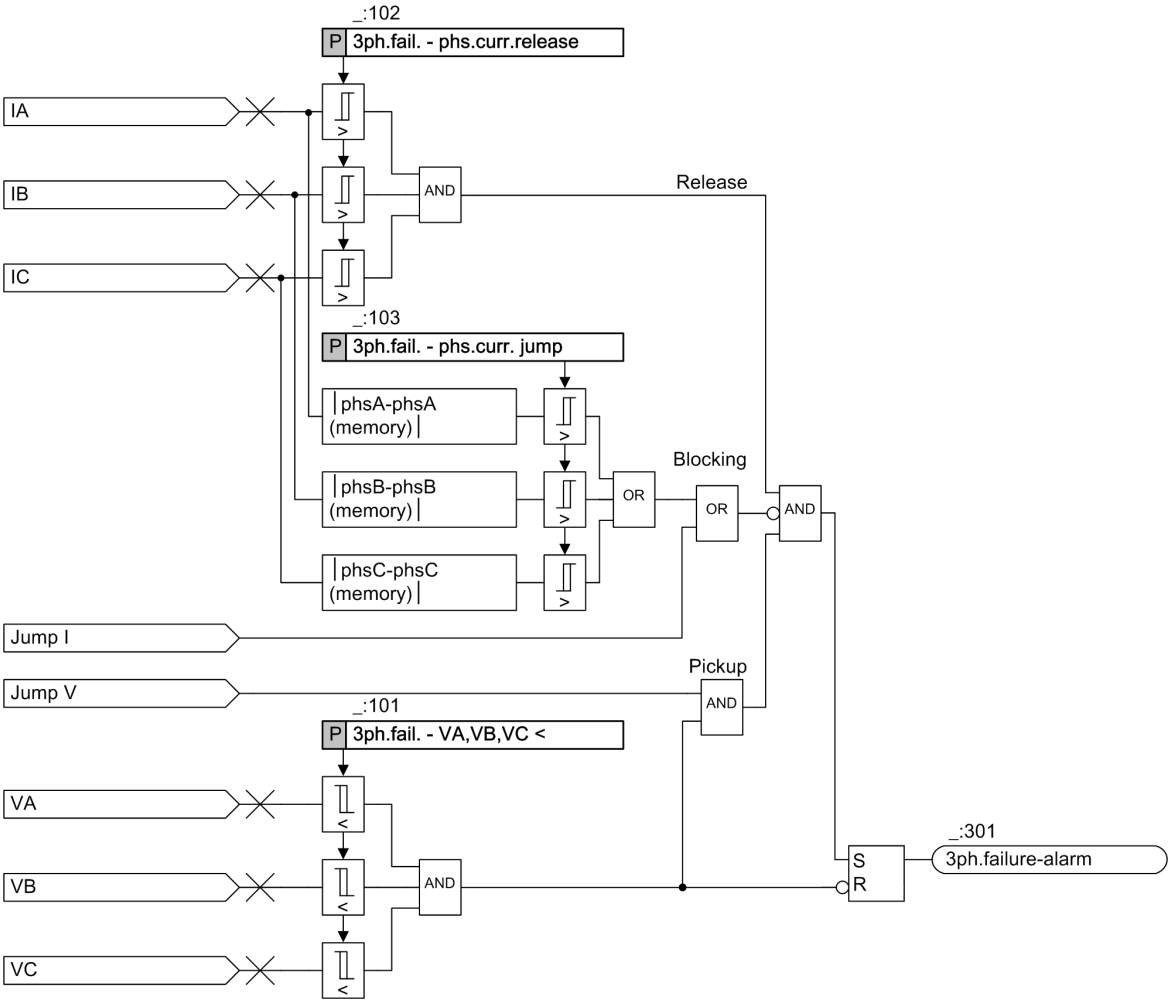
The criterion for detection of an unbalanced measuring-voltage failure is the voltage unbalance. This unbalance is determined based on the ratio between negative and positive-sequence voltage. If the threshold value is violated and the monitoring is released and not blocked, the monitoring picks up (see *Figure 9-6*). The indication *Asym.fail.-inst.alarm* is output.

The monitoring is released as soon as a certain minimum voltage is exceeded. This prevents a spurious response in the presence of low voltage measurands or a measurand of 0 (for example, circuit breaker open). Instantaneous monitoring also requires the presence of a minimum current. This prevents a spurious instantaneous pick up of the monitoring in the presence of a weak infeed (current < 10 % of rated current) combined with a power-system incident.

If the voltage unbalance is blocked by unbalanced faults in the primary system, the supervision is blocked. The device detects an unbalanced fault based on the ratio between negative-sequence and positive-sequence current. In the event of 1-pole automatic reclosing, the supervision is blocked.

Delay/Seal-In

In the presence of a weak infeed (current < 10 % of rated current), certain protection functions require more time for detection of a system incident. For this purpose, the monitoring can be delayed using the **Asym.fail. - time delay** parameter.



If a system incident is detected during the time delay, the supervision drops off. This is because the function assumes that the unbalance - and consequently the pickup of the supervision - is due to the system incident.

After the time delay has elapsed, it definitely assumes a measuring-voltage failure. The monitoring seals in and the *Asym.fail.-alarm* indication is output. The dropout does not happen until the voltage unbalance has disappeared after a seal-in time of 10 s. In the presence of 3-pole close-in faults outside the protection zone, this seal-in time prevents the monitoring from dropping off too quickly and thus releasing the protection functions.

The sealing-in function can be deactivated using the **Asym.fail.-DO on netw.flt.** parameter. As soon as a system incident is detected, the monitoring drops off instantaneously.

9.3.2.4 3-Phase Measuring-Voltage Failure

Logic

[losymmet-190912-01.tif, 1, en_US]

Figure 9-7 Logic Diagram 3-Phase Measuring-Voltage Failure

Balanced Fault – VA, VB, VC <

A 3-phase measuring-voltage failure is detected if the following criteria are fulfilled simultaneously:

- All 3 phase-to-ground voltages drop below the threshold value **3ph.fail. - VA,VB,VC <**
- A jump of the voltage (Signal **jump V**)

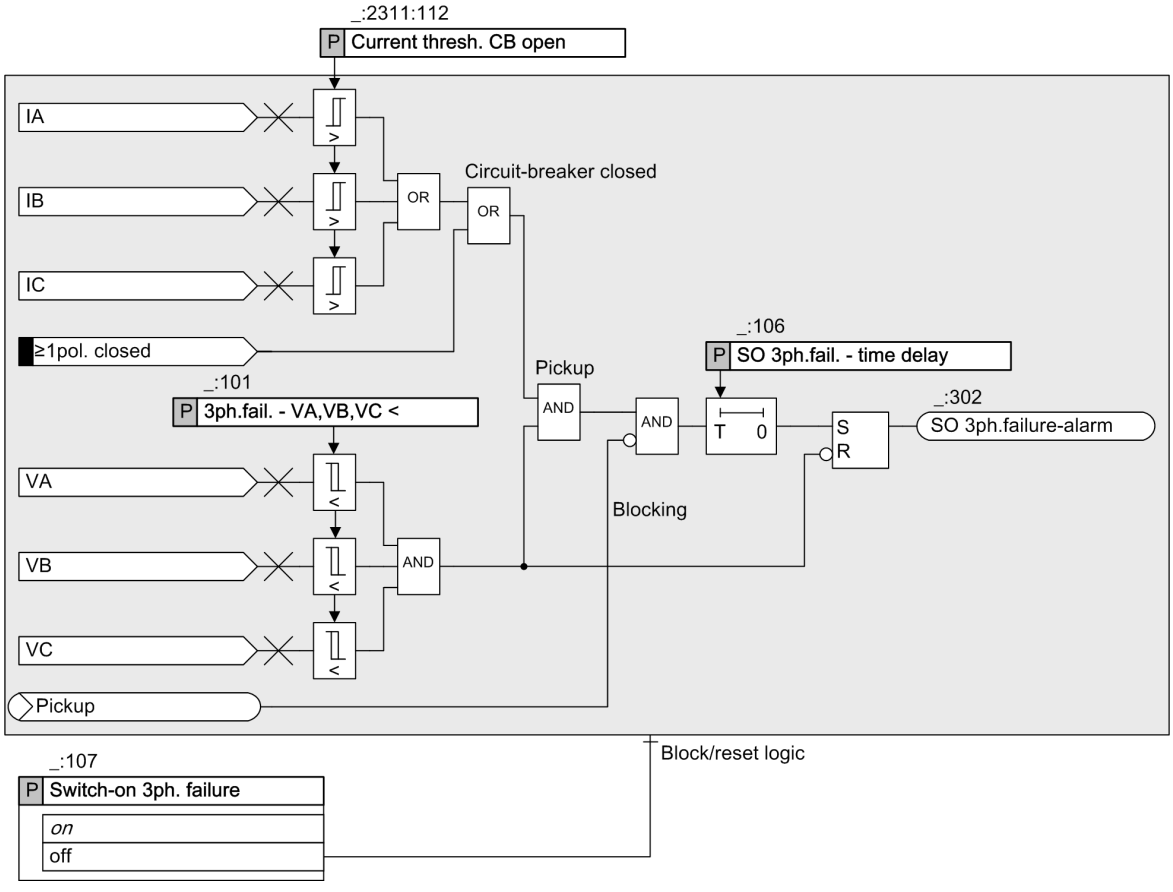
If these criteria are fulfilled and the monitoring is released and not blocked, the **3ph.failure-alarm** indication is output. When the voltage returns (even as 1-phase), the monitoring drops out.

Release by Phase Current

When all phase currents exceed the threshold value **3ph.fail. - phs.curr.release** the monitoring is released.

Blocking in the Case of a System Incident

In the case of a 3-phase system incident, supervision must be blocked. The device detects a 3-phase incident with a jump in the current. This change is detected via the internal signal **Jump I** or when the change in current of a phase current exceeds the threshold value **3ph.fail. - phs.curr. jump**. The change in



current of phase currents is formed from the difference between the present current phasor and the current phasor of the previous period. This allows to take into account a jump of the current phase.

NOTE

If a voltage transformer circuit-breaker is installed in the secondary circuit of the voltage transformers, its position is communicated to the device via a binary input (see chapter *9.3.4.1 Overview of Functions*).

9.3.2.5 Switching onto a 3-Phase Measuring-Voltage Failure, Low Load

Logic

[lozuscha-100611-01.tif, 1, en_US]

Figure 9-8 Logic Diagram Switching to 3-Phase Measuring-Voltage Failure

Switching onto a 3-phase measuring-voltage failure is detected if the following criteria are fulfilled simultaneously:

- All 3 phase-to-ground voltages have dropped below the threshold value **`3ph.fail. - VA,VB,VC <`**.
- The circuit breaker is detected to be in closed position. The detection takes place either via the phase currents or via the **`≥1-pole closed`** signal, which is generated via the circuit-breaker auxiliary contacts. You can find more detailed information in chapter *5.8.5 Circuit-Breaker Condition for the Protected Object*.

A voltage jump – such as in a 3-phase measuring-voltage failure with closed circuit breaker (see chapter*9.3.2.4 3-Phase Measuring-Voltage Failure*) – does not occur in the case of switching to a 3-phase measuring-voltage failure. If the monitoring is not blocked, the time delay **`SO 3ph.fail. - time delay`** is started. After the time has elapsed, the indication **`SO 3ph.failure-alarm`** is displayed. A dropout of the monitoring is only possible by a recovery of the voltage.

The supervision is blocked as soon as a pickup of a protection function is detected within a protection function group and the time delay of the supervision has not yet elapsed.

This subfunction also covers the situation of a low load with 3-phase measuring-voltage failure and closed circuit breaker, because the circuit-breaker condition is also determined from the circuit-breaker auxiliary contacts. The subfunction for detecting a 3-phase measuring-voltage failure (see chapter *9.3.2.4 3-Phase Measuring-Voltage Failure*) is not released in this situation, for example, because the current flow is too low.

This subfunction can be switched on or off separately using the **Switch-on 3ph. failure** parameter.

9.3.2.6 Application and Setting Notes

Parameter: Asym.fail. - time delay

- Recommended setting value **(_:113) Asym.fail. - time delay** = ***10.00 s***

The **Asym.fail. - time delay** parameter allows you to set the time during which a system incident detected after the occurrence of the unbalance resets the monitoring. This setting is important in the case of weak infeed (current < 10 % of rated current) in order to give certain protection functions (such as distance protection) more time for detecting system incidents. As long as the time delay runs, it is assumed that the unbalance is due to a system incident.

As soon as the time has elapsed, the supervision assumes a measuring-voltage failure and seals in.

Siemens recommends using the default setting.

If you want the seal-in function to operate sooner or at once, you can reduce the time.

Parameter: Asym.fail.-DO on netw.flt.

- Recommended setting value **(_:115) Asym.fail.-DO on netw.flt.** = ***No***

Parameter Value	Description
no	After elapse of the time delay the supervision function seals in. Even if the system incident criterion is fulfilled, the protection functions concerned will remain blocked. This avoids an unselective tripping of the protection functions due to an absence of the measuring voltage in the case of an unbalanced system incident. This is the default setting.
yes	The seal-in function is switched off. The supervision drops out immediately when a system incident is detected. With this setting, the unbalanced measuring-voltage failure is only reported, and in the event of a double failure (measuring-voltage failure and system incident in parallel), unselective tripping is preferred.

Parameter: 3ph.fail. - VA,VB,VC <

- Recommended setting value **(_:101) 3ph.fail. - VA,VB,VC <** = ***5 V***

The **3ph.fail. - VA,VB,VC <** parameter allows you to set the pickup value of the monitoring.

Siemens recommends using the default setting.

If you expect major disturbances acting upon the voltage inputs, you can increase this value. Increasing the values makes the supervision more sensitive to 3-phase system incidents.

Parameter: 3ph.fail. - phs.curr.release

- Recommended setting value **(_:102) 3ph.fail. - phs.curr.release** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **3ph.fail. - phs.curr.release** parameter is used to define the phase current threshold above which the monitoring is released.

Siemens recommends using the default setting.

Parameter: 3ph.fail. - phs.curr. jump

- Recommended setting value **(_:103) 3ph.fail. - phs.curr. jump** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **3ph.fail. - phs.curr. jump** parameter is used to set the differential current between the present current phasor and the stored phasor (from the previous period). If the value is exceeded, the function detects a system incident and blocks the monitoring.
Siemens recommends using the default setting.

Parameter: SO 3ph.fail. - time delay

- Recommended setting value **(_:106) SO 3ph.fail. - time delay** = ***3.00 s***

The **SO 3ph.fail. - time delay** parameter allows you to set the delay of the monitoring.
Siemens recommends using the default setting.

NOTE

Adapt the **SO 3ph.fail. - time delay** parameter to the inherent time of protection functions which are intended to block the monitoring function.
Note that with parameter values 0 s blocking of the monitoring function via a protection stimulation will not be possible any more.

Parameter: Switch-on 3ph. failure

- Recommended setting value **(_:107) Switch-on 3ph. failure** = ***on***

Parameter Value	Description
on	The subfunction **Switching to a 3-phase measuring-voltage failure** is active. In the case of low loads, the subfunction for detection of a 3-phase measuring-voltage failure is not released, for example, because the current flow is too low. In this situation, the subfunction **Switching to a 3-phase measuring-voltage failure** can perform the monitoring task. Siemens recommends to switch that subfunction on.
off	With the setting ***off*** the subfunction **Switching to a 3-phase measuring-voltage failure** is not active.

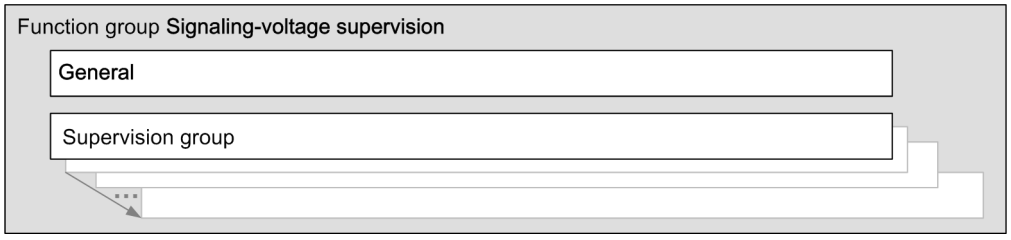
9.3.3 Signaling-Voltage Supervision



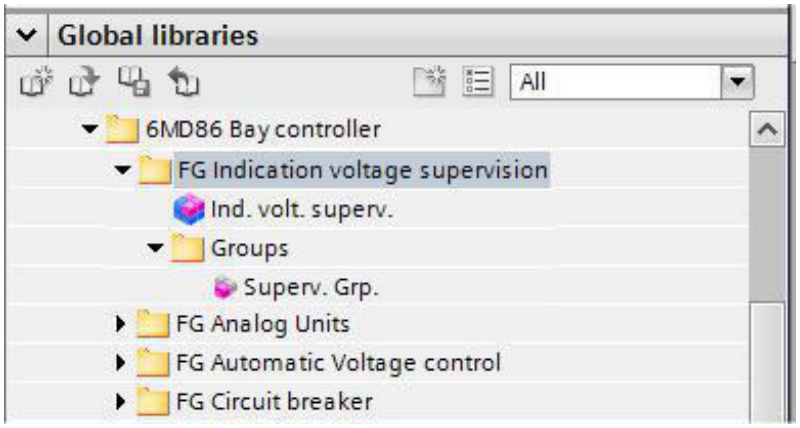
9.3.3.1 Overview of Functions

Signaling-voltage supervision is used to evaluate the validity of binary signals connected to the SIPROTEC device via binary inputs. For this purpose, one binary input is used to monitor the signaling voltage. If the signaling voltage fails, the associated binary signals are marked as invalid and a **Signaling-voltage malfunction** indication is issued.

Several signaling-voltage supervision groups can be created in one SIPROTEC device. Each of these groups monitors an adjustable area with binary inputs.

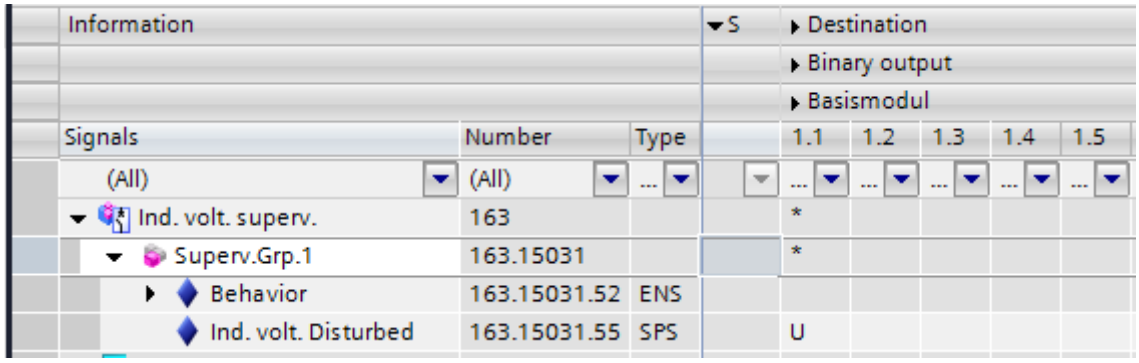
9.3.3.2 Structure of the Function

The **Signaling-voltage supervision** function group contains, besides the general functionality, one preinstantiated **Supervision group** stage. The **Supervision group** stage can be instantiated in DIGSI 5 multiple times.



[dwivsstr-060214-01.vsd, 1, en_US]

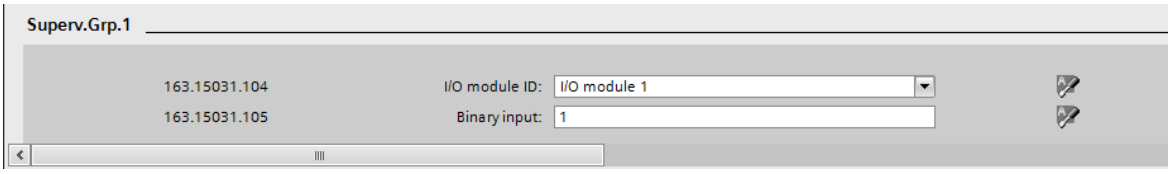
Figure 9-9 Structure/Embedding of the Function Group



9.3.3.3 Function Description

You can instantiate the **Signaling-voltage supervision** function group in DIGSI from the global library. It contains 1 pre-instantiated **Supervision group** function block (see the following figure). You can instantiate a maximum of 25 supervision groups.

[sc_ivslib, 1, en_US]

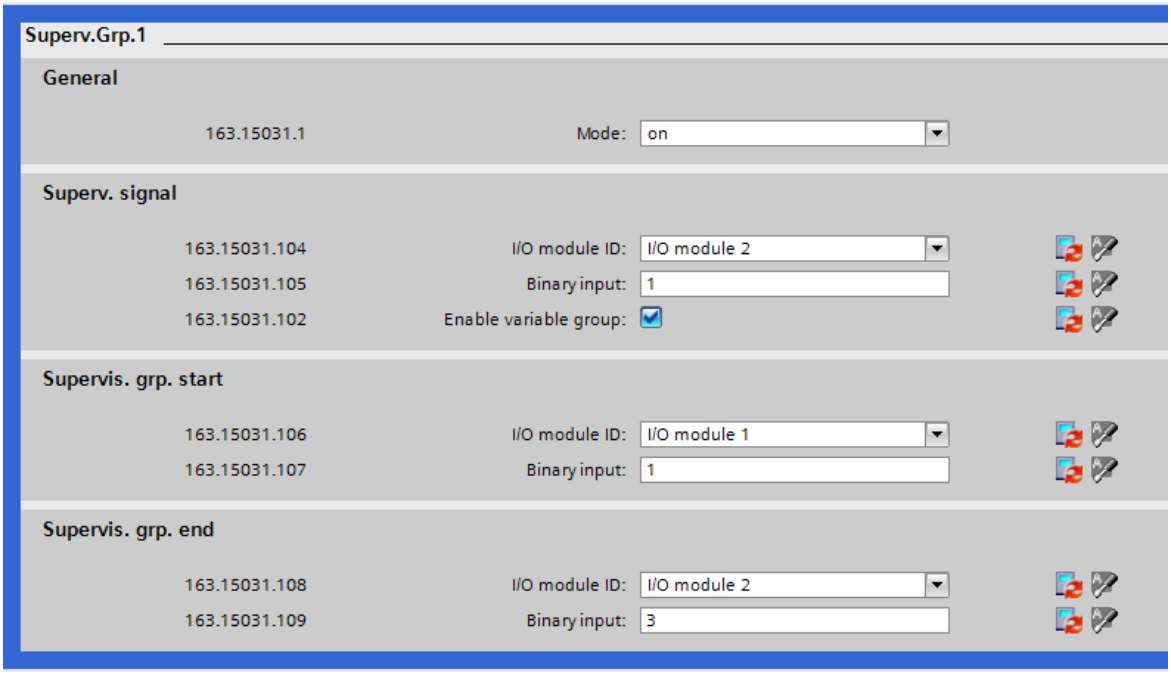


Following the instantiation of the function group in the DIGSI project tree, it appears in the information routing of DIGSI (see the following figure). The status indications of the supervision groups can be routed here, for example, to existing binary outputs and/or logs.

[sc_ivsrou, 1, en_US]

Set the binary input used for signaling-voltage supervision within one input/output module using the setting option (see the following figure). This binary input monitors the presence of the signaling voltage. If the signaling voltage fails, this sets the quality attribute for all other binary inputs of the parameterized input/output module to ***invalid***. The signal status of each of these binary inputs is frozen with its last valid value prior to the occurrence of the fault. The quality attribute of the binary inputs for other input/output modules are not taken into consideration by this.

If the signaling voltage again exceeds the binary threshold, the quality attribute of the binary inputs is reset to ***valid***.



[sc_ivsgrp, 1, en_US]

NOTE

Each status change of the monitored binary inputs is delayed by 3 ms.

You can also combine binary inputs across modules in one **Supervision group** function block, and define any binary input within this group for the supervision of the signaling voltage. For this purpose, place a check mark at the parameter **(_:102) Enable variable group** when configuring the supervision group. This extends the parameter menu by the sections **Start supervision group** and **End supervision group** (see the following figure).

[sc_gruppe_de, 1, en_US]

There, for example, you are able to combine 1 to n different binary inputs into one supervision group. When doing so, the binary inputs on the input/output modules assignable to a supervision group must be related logically. With 3 input/output modules, for example, this allows only consecutive binary inputs to be grouped on the modules 1+2 or 2+3, but no binary inputs on modules 1+3. The binary inputs used for supervision can be located on any input/output module within the group defined in this manner.

If you have to monitor several binary inputs that, for example, work with different signaling voltages from different sources, then you can also instantiate and configure several **Supervision group** function blocks within the **Signaling-voltage supervision** function group accordingly.

Within different supervision groups, only those consecutive binary inputs that are not already assigned to another supervision group can be grouped. The overlapping of binary inputs in different supervision groups is not permitted.

Example: There are 4 input/output modules. Binary inputs of input/output module 1+2 are already combined in supervision group 1. The 2 last binary inputs on module 2 are not included in the grouping. Thus, only these 2 binary inputs not used in the supervision group 1 of the input/output module 2 as well as, where applicable, further consecutive binary inputs of input/output modules 3+4 can be combined in supervision group 2.

Error parameters are displayed to you by inconsistency indications in DIGSI.

9.3.3.4 Application and Setting Notes

Parameter (General): Mode

- Default setting **(_:1) Mode** = ***on***

With the **Mode** parameter, you specify whether you want to activate, deactivate, or test the supervision of the signaling voltage for the appropriate group. If you put the group into test mode, the *Sig. volt. disturbed* indication is given a test flag. If the supervision input drops out in test mode, the assigned inputs retain their status without their quality attribute being set to **invalid**.

Parameter (Supervision Signal): I/O module ID

- Default setting **(_:104) I/O module ID** = ***I/O module 1***

Using the **I/O module ID** parameter, you specify the I/O module for which you want to activate signaling-voltage supervision. Counting of the I/O modules starts in increasing order with the binary inputs of the base module. The binary inputs of the PS201 power-supply module permanently installed in the base module count as the 2nd I/O module followed by additional I/O modules (3 to n) in the expansion boards of the device.

Parameter (Supervision Signal): Binary input

- Default setting **(_:105) Binary input** = ***1***

Using the **Binary input** parameter, you specify the binary input responsible for the supervision of the signaling voltage for the parameterized I/O module. The quality attribute of all other binary inputs for this module are set to **valid** or **invalid** depending on the presence of the signaling voltage at the parameterized binary input.

Parameter (Supervision Signal): Enable variable group

- Default setting **(_:102) Enable variable group** = ***untrue***

You can activate the parameter **Enable variable group** by placing the check mark. If you have not set the check mark (default setting), only these 2 parameters are available for the configuration of the supervision signal. If you have set the check mark, the parameter menu is extended by the areas **Start supervision group** and **End supervision group**. You can then use that to carry out the grouping of binary inputs for supervision groups explained in the function description.

Parameter (Start Supervision Group): I/O module ID

- Default setting **(_:106) I/O module ID** = ***I/O module 1***

Parameter **I/O module ID** is used to define the first I/O module that you want to assign to a supervision group. As the counting of the I/O module starts in ascending order with the binary inputs of the base module, this is the module with the lowest counter number that you can use for carrying out a grouping.

Parameter (Start Supervision Group): Binary input

- Default setting **(_:107) Binary input** = ***1***

Parameter **Binary input** is used to define the lowest binary input for the first I/O module (see **(_:106) I/O module ID**) that you want to assign to a supervision group.

Parameter (End Supervision Group): I/O module ID

- Default setting **(_:108) I/O module ID** = ***I/O module 1***

Parameter **I/O module ID** is used to define the last I/O module that you want to assign to a supervision group. As the counting of the I/O module starts in ascending order with the binary inputs of the base module, this is the module with the highest counter number that you can use for carrying out a grouping.

Parameter (End Supervision Group): `Binary input`

- Default setting **`(_:109) Binary input`** = ***1***

Parameter **`Binary input`** is used to define the highest binary input for the last I/O module (see **`(_:108) I/O module ID`**) that you want to assign to a supervision group.

9.3.4 Voltage-Transformer Circuit Breaker

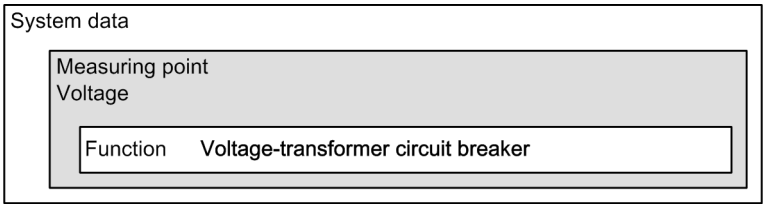
9.3.4.1 Overview of Functions

The **Voltage-transformer circuit breaker** function detects the tripping of the voltage-transformer circuit breaker due to short circuits in the voltage-transformer secondary circuits.

The **Voltage-transformer circuit breaker** function works independently of **Measuring-voltage failure detection** and should be used – if possible – in parallel to it.

The tripping of the voltage-transformer circuit breaker has an impact on the quality of the recorded measured-value data (see chapter *3.3 Processing Quality Attributes*).

The following protection function is automatically blocked in cases of the tripping of the voltage-transformer circuit breaker:



- Directional negative-sequence protection

For the following functions the reaction (block/not block) can be set within the function in cases of a tripping of the voltage-transformer circuit breaker:

- Directional time-overcurrent protection, phases
- Directional time-overcurrent protection, ground
- Directional sensitive ground-fault detection
- Overvoltage protection with negative-sequence voltage
- Overvoltage protection with zero-sequence voltage/residual voltage
- Undervoltage protection with 3-phase voltage
- Undervoltage protection with positive-sequence voltage

9.3.4.2 Structure of the Function

The *Figure 9-10* shows the position of the function in the device. Every voltage measuring point contains the **Voltage-transformer circuit breaker** function.

[dwmcbstr-040211-01.tif, 1, en_US]

Figure 9-10 Structure/Embedding of the Function

9.3.4.3 Function Description

The tripping of the voltage-transformer circuit breaker is captured via the binary input signal **>Open**. With an active input signal the information about the measuring-voltage failure is relayed to the affected functions (see *9.3.4.1 Overview of Functions*). The response to the detection of a measuring-voltage failure is explained in the specific protection-function descriptions.

Response Time of the Voltage-Transformer Circuit Breaker

The response time of the voltage-transformer circuit breaker can be slower than the pickup time of the distance protection. This bears the risk of an overfunction. The response time is communicated to the device with the **Response time** parameter. For a timely detection of the tripping of the voltage-transformer circuit breaker, the pickup of the distance protection is delayed by that response time.

9.3.4.4 Application and Setting Notes

The function is always active and need not be switched on.

Input Signal: >Open

- Input signal: **(_:500) >Open**

The input signal **>Open** must be connected to the tripping of the voltage-transformer circuit breaker. As a rule, this occurs via the routing to a binary input.

Parameter: Response time of the voltage-transformer circuit breaker

- Recommended setting value **(_:101) Response time** = ***0 ms***

When the voltage-transformer circuit breaker drops out, the device must block the distance protection immediately to prevent an unwanted tripping of the distance protection due to the absence of the measuring voltage while the load current is flowing.

The blocking must be faster than the 1st stage of the distance protection. This requires an extremely short response time of the miniature circuit breaker (≤ 4 ms at 50 Hz, ≤ 3 ms at 60 Hz rated frequency). If the circuit-breaker auxiliary contact does not fulfill this requirement, you have to set the response time accordingly.

9.3.4.5 Settings

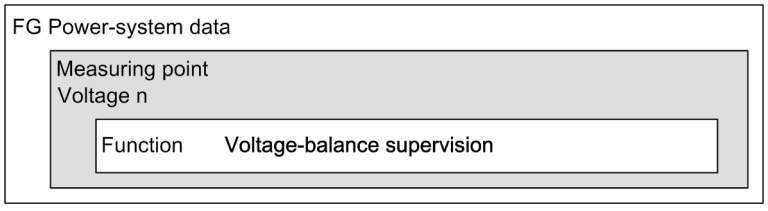
9.3.5 Voltage-Balance Supervision

9.3.5.1 Overview of Functions

In healthy system operation, a certain balance between voltages can be assumed.



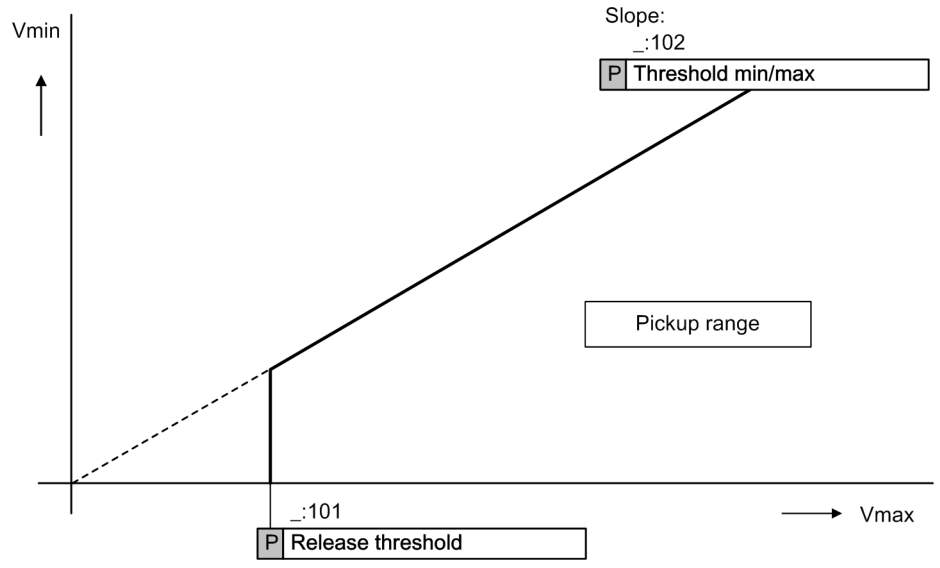
The **Voltage-balance supervision** function detects the following errors:

- Unbalance of phase-to-phase voltages in the secondary circuit
- Connection errors during commissioning or short circuits and interruptions in the secondary circuit

The voltage measurement is based on the RMS values of the fundamental component.

9.3.5.2 Structure of the Function

The **Voltage-balance supervision** function is located in the **Power-system data** of each 3-phase voltage measuring point.

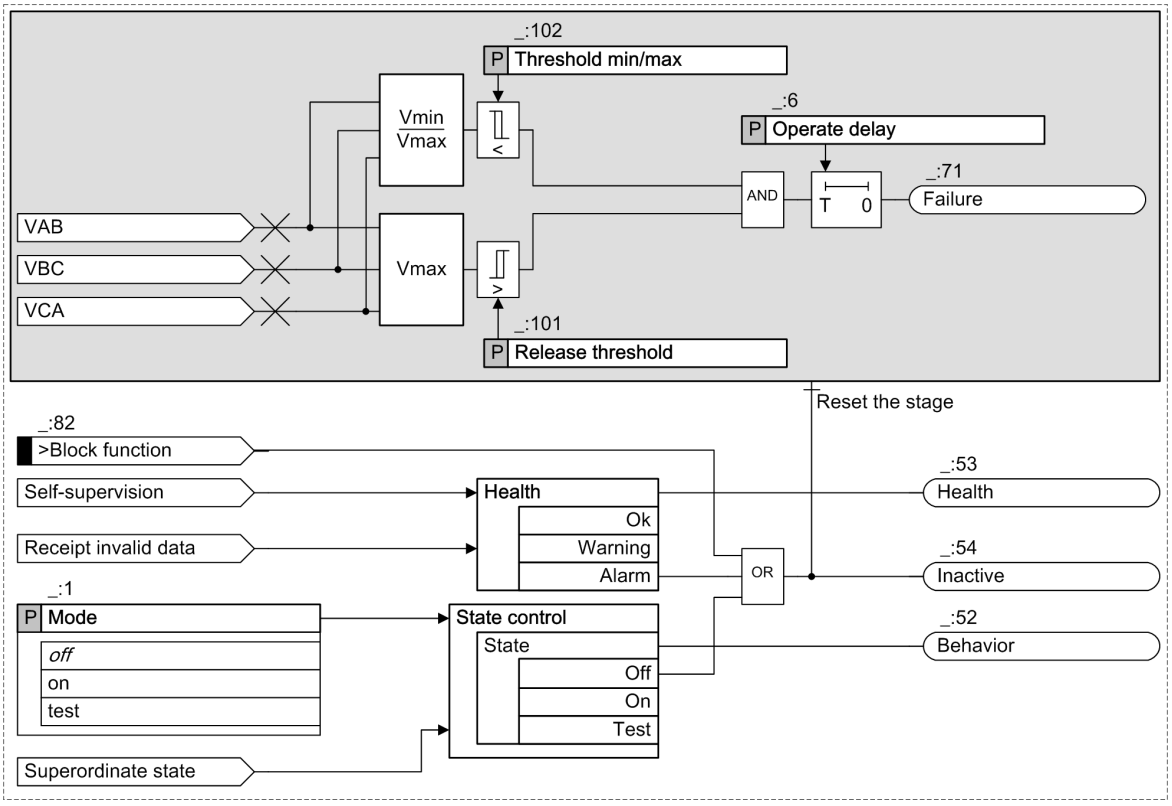


[dwstrusy-300913, 2, en_US]

Figure 9-11 Structure/Embedding of the Function

9.3.5.3 Function Description

The voltage balance is checked by a magnitude supervision function. This function relates the smallest phase-to-phase voltage to the largest phase phase-to-phase voltage. Unbalance is detected if



|Vmin| / |Vmax| < **`Threshold min/max`**, as long as Vmax > **`Release threshold`**.

[lokenuns-040211-01.tif, 1, en_US]

Figure 9-12 Characteristic of the Voltage-Balance Supervision

Logic

[lospasym-100611-01.tif, 2, en_US]

Figure 9-13 Logic Diagram of the Voltage-Balance Supervision

The **Threshold min/max** parameter is the criterion by which a phase-to-phase voltage unbalance is measured. The device calculates the ratio between the minimum (V_{min}) and the maximum (V_{max}) phase-to-phase voltage.

Enter the lower limit of the maximum phase-to-phase voltage (V_{max}) with the parameter **Release threshold**. This specifies the lower limit of the operating range of this function.

Operate delay

If it falls below the balance factor **Threshold min/max** and at the same time the maximum phase-to-phase voltage exceeds the **Release threshold**, the **Operate delay** begins. If both conditions persist during this time, the indication **Failure** is generated.

9.3.5.4 Application and Setting Notes

Parameter: Threshold min/max

- Recommended setting value **(_:102) Threshold min/max** = ***0.75***

The **Threshold min/max** parameter is used to set the ratio between the minimum (V_{min}) and the maximum (V_{max}) phase-to-phase voltage. Siemens recommends using the default setting.

Parameter: Release threshold

- Recommended setting value **(_:101) Release threshold** = ***50 V***

With the **Release threshold** parameter you set the lower limit of the maximum phase-to-phase voltage (V_{max}). Siemens recommends using the default setting.

Parameter: Operate delay

- Recommended setting value **(_:6) Operate delay** = ***5.00 s***

Set the **Operate delay** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

9.3.5.5 Settings

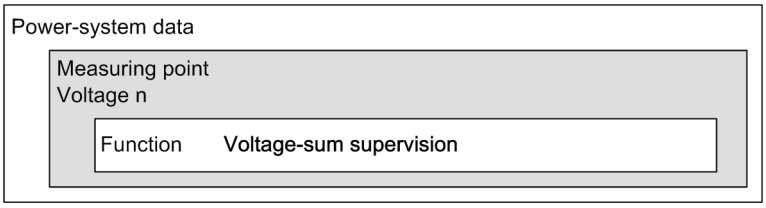
9.3.6 Voltage-Sum Supervision

9.3.6.1 Overview of Functions

In healthy system operation, the sum of all voltages at one measuring point must be approximately 0. The **Voltage-sum supervision** monitors the sum of all voltages of one measuring point in the secondary circuit. It detects connection errors during commissioning or short circuits and interruptions in the secondary circuit. For summation of the voltages, the 3 phase-to-ground voltages and the residual voltage (da-dn - voltage of an open-circuited delta winding) are required.

The voltage measurement is based on the RMS values of the fundamental component.



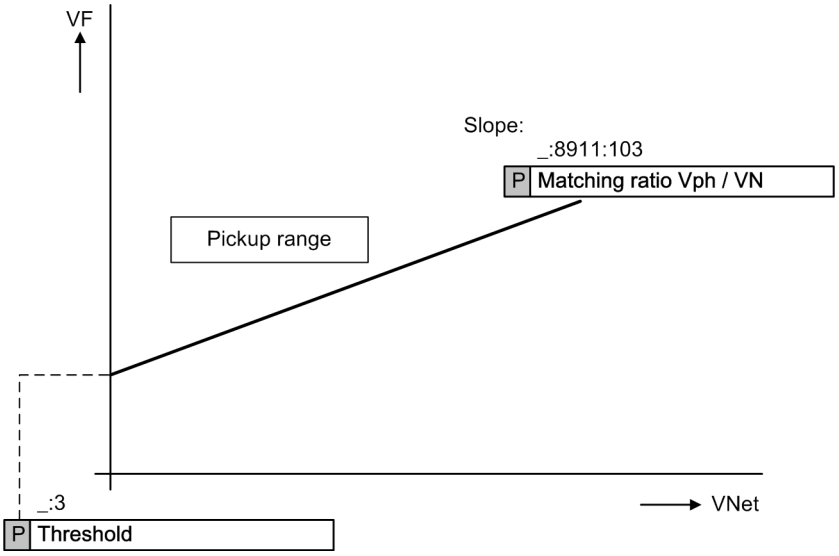
NOTE

For the **Voltage-sum supervision**, the externally generated residual voltage must be connected to the 4th voltage measuring input.

For the **Voltage-sum supervision** to work correctly, the **`Matching ratio Vph / VN`** parameter must be set accordingly.

9.3.6.2 Structure of the Function

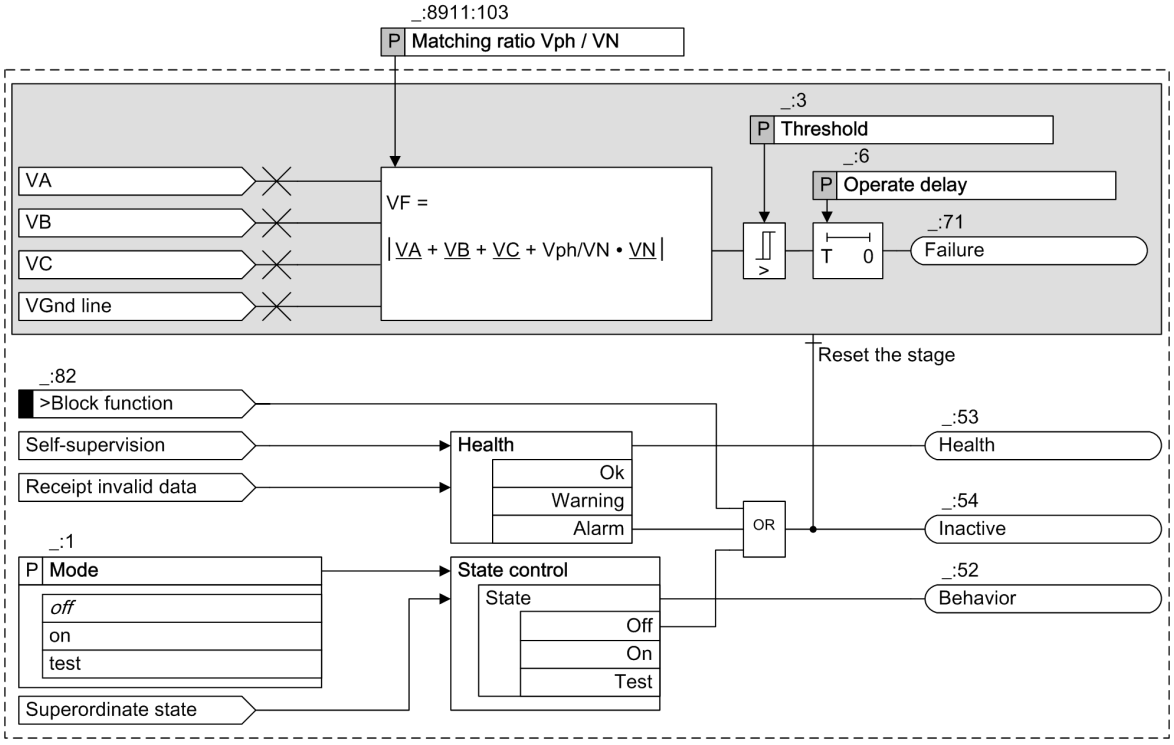
The **Voltage-sum supervision** function is located in the **Power-system data** function group of each 3-phase voltage measuring point.



[dwstrvss-100611-01.tif, 2, en_US]

Figure 9-14 Structure/Embedding of the Function

9.3.6.3 Function Description



The voltage sum is generated by addition of the voltage phasors. Errors in the voltage circuits are detected if VF = |VA+ VB + VC + Vph/VN • VN | > **`Threshold`**, where Vph/VN forms the **`Matching ratio Vph / VN`** parameter.

[lokenvss-100611-01.tif, 1, en_US]

Figure 9-15 Characteristic of the Voltage-Balance Supervision

Logic

[lovssumm-140611-01.tif, 1, en_US]

Figure 9-16 Logic Diagram of the Voltage-Sum Supervision

The device measures the phase-to-ground voltage and the ground voltage of the lines to be protected. The sum of the 4 voltages must be 0.

Threshold

If the calculated fault voltage (V_F) exceeds the **Threshold**, the parameter **Operate delay** triggers the indication **Failure**.

The device calculates the fault voltage (V_F) with the formula:

VF = |VA+ VB + VC + Vph/VN • VN |, where Vph/VN forms the **Matching ratio Vph / VN** parameter.

The **Matching ratio Vph / VN** parameter takes into account the differing transformation ratios between the residual voltage input and the phase-voltage inputs.

More information in this respect can be found in chapter *9.3.6.1 Overview of Functions*).

Operate delay

When the threshold value for the **Operate delay** is exceeded, the indication **Failure** is generated.

9.3.6.4 Application and Setting Notes

Parameter: Threshold

- Recommended setting value **(_:3) Threshold** = ***25 V***

The **Threshold** parameter is used to set the voltage which the device uses to recognize the calculated fault voltage (V_F) as a failure of the voltage sums. Siemens recommends using the default setting.

Parameter: Operate delay

- Recommended setting value **(_:6) Operate delay** = ***5.00 s***

Set the **Operate delay** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

9.3.6.5 Settings

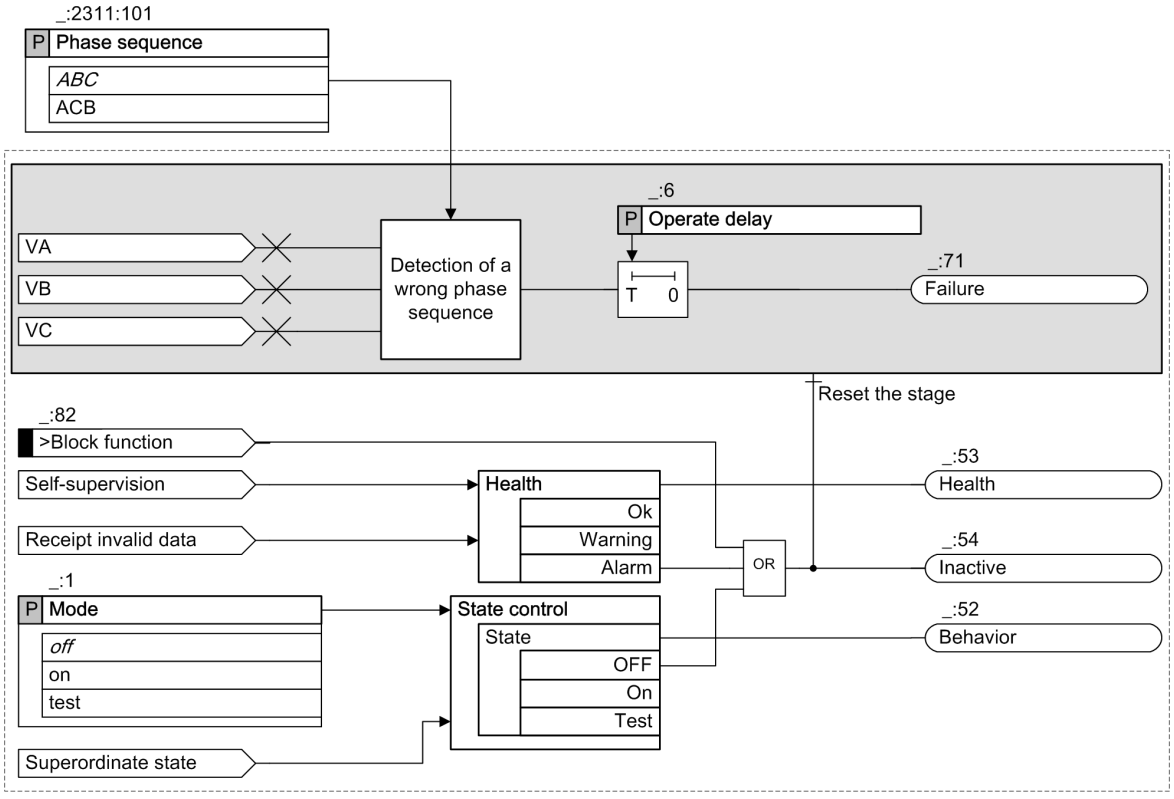
9.3.7 Voltage Phase-Rotation Supervision

9.3.7.1 Overview of Functions

The **Voltage phase-rotation supervision** function monitors the phase sequence of the secondary-circuit voltages by monitoring the sequence of the zero crossings (with same sign) of the voltages. This enables the device to detect connections that were inverted during commissioning. The criterion for the check is the setting of the **Phase sequence** parameter.

9.3.7.2 Structure of the Function

The **Voltage phase-rotation supervision** function is located in the **Power-system data** of each 3-phase voltage measuring point.



[dwstrvrs-060611-01.tif, 3, en_US]

9.3.7.3 Function Description

Logic

[lovrsymm-100611-01.tif, 2, en_US]

Figure 9-18 Logic Diagram for the Voltage Phase-Rotation Supervision

The device compares the measured phase sequence with the set phase-rotation direction.

You can find detailed information in the section **Power-system data**.

The phase rotation is important for protection functions which process phase, loop, and directional information. The connection of the currents to the device does not depend on the selected phase sequence.

The connection diagrams are shown in the section **Appendix**.

Operate delay

When the device detects an inverted phase-rotation direction for the duration of the **Operate delay**, the indication **Failure** is generated.

9.3.7.4 Application and Setting Notes

Parameter: Operate delay

- Recommended setting value **(_:6) Operate delay** = ***5,00 s***

Set the **Operate delay** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

9.3.8 Broken-Wire Detection

9.3.8.1 Overview of Functions

The purpose of the broken-wire detection is to detect interruptions in the secondary circuit of the current transformers during steady-state operation.

9.3.8.2 Structure of the Function

The **Broken-wire detection** function is located in the power-system data of each 3-phase current measuring point.

[dwbwsjsk-301112-01.tif, 2, en_US]

Figure 9-19 Structure/Embedding of the Function

The tasks of **Broken-wire detection** are:

- The instantaneous values of all current measuring points are checked on a phase-selective basis for implausible values.
- The affected phases are marked with wire-break suspected.
- Depending on the supervision mode, you can add a marker for blocking protection functions for the affected phases.
- After 10 ms of broken-wire check, the wire break is reliably signaled.

9.3.8.3 Function Description

Broken Wire Suspected

The **Broken-wire detection** function monitors the dynamic behavior of the currents of each phase and of all measuring points. For this purpose, the instantaneous values of the currents are checked for their plausibility. Each expected violation must be confirmed by additional criteria before a wire break can be detected and signaled with assurance.

The detection of the local broken wire suspected is performed on each 3-phase current measuring point of the device selectively for each phase.

Detection:

A wire break initially manifests itself as a sudden decrease of the current below the minimum threshold of 0.06 $I/I_{rated.}$ A plausibility test on one period of past instantaneous values confirms this condition. If the criteria for the local wire break are satisfied, the affected phase is marked with **Broken wire suspected**.

Resetting:

The broken wire suspected is reset by phase current flowing again or by a binary input signal. Binary resetting can be useful during laboratory tests among other applications.

Indication

If the broken-wire detection has not been reset within 10 ms, it will be indicated. The indication is held stable for the duration of at least 3 periods.

When using the fast measuring transducer inputs as 4 mA to 20 mA inputs, broken-wire detection is active. With a < 2 mA current, wire breaks are detected and the *wire break* indication is set. The measured values display remains unaffected.

9.3.8.4 Application and Setting Notes

Parameter: Mode

- Recommended setting value **(_:1) Mode** = ***off***

The **Mode** parameter is used to switch the broken-wire detection to ***on***, ***off*** and ***test***.

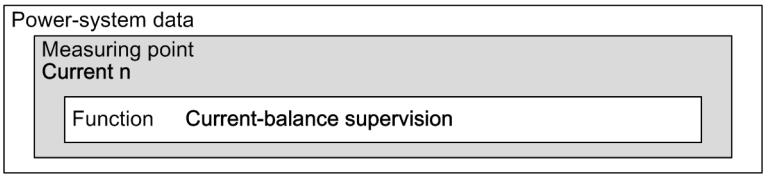
9.3.9 Current-Balance Supervision

9.3.9.1 Overview of Functions

In healthy network operation, a certain balance between currents can be assumed.



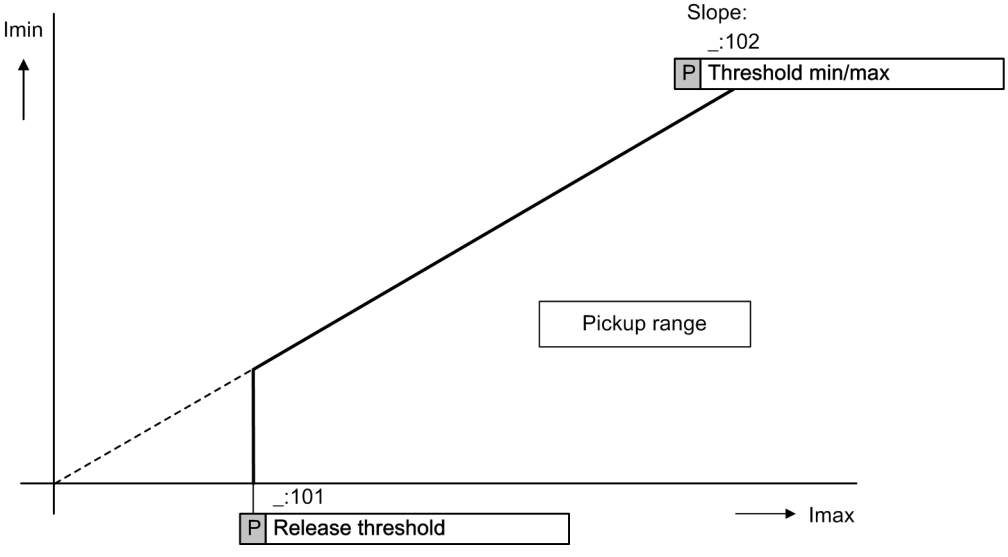
The **Current-balance supervision** function detects the following errors:

- Unbalance of phase currents in the secondary circuit
- Connection errors during commissioning or short circuits and interruptions in the secondary circuit

The current measurement is based on the RMS values of the fundamental component.

9.3.9.2 Structure of the Function

The **Current-balance supervision** function is located in the **Power-system data** of each 3-phase current measuring point.

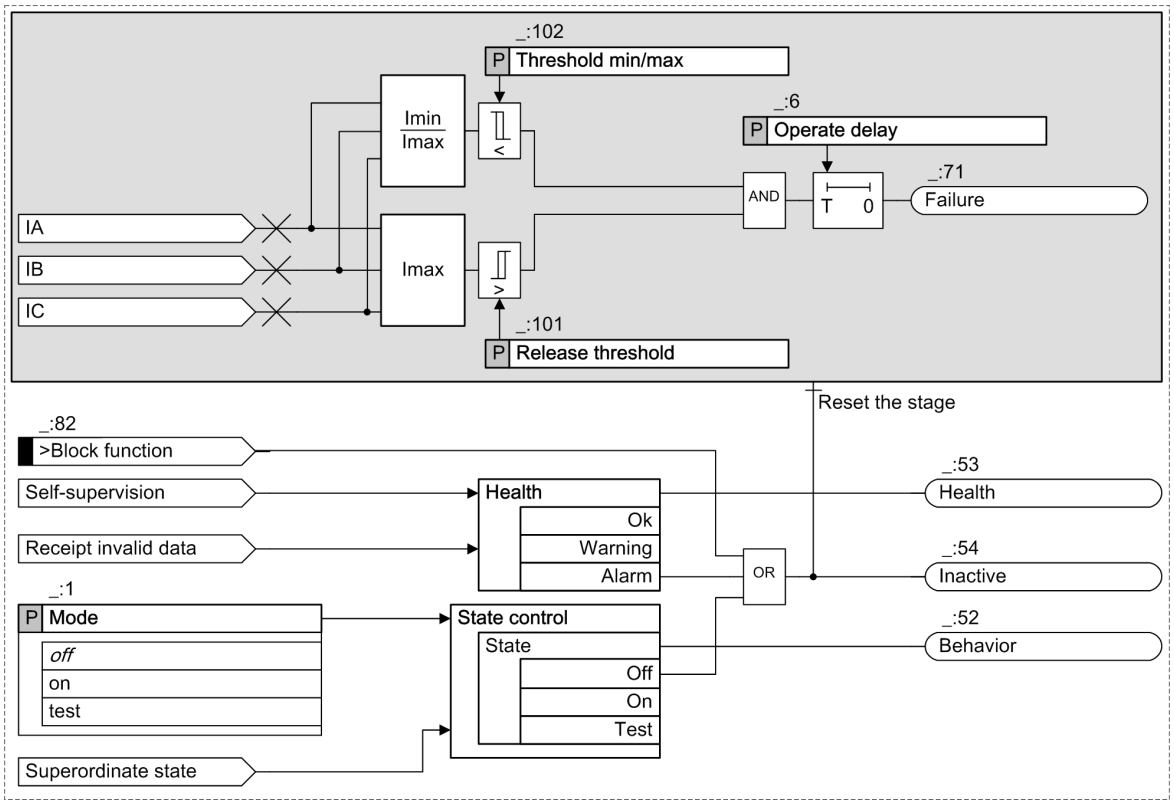


[dwstrsym-060611-01.tif, 2, en_US]

Figure 9-20 Structure/Embedding of the Function

9.3.9.3 Function Description

The current balance is checked by a magnitude monitoring function. This function relates the smallest phase current to the largest phase current. Unbalance is detected if



|Imin| / |Imax| < **Threshold min/max**, as long as Imax > **Release threshold** / IN.

[losymmke-040211-01.tif, 1, en_US]

Figure 9-21 Characteristic of the Current-Balance Supervision

Logic

[locbsymm-100611-01.tif, 1, en_US]

Figure 9-22 Logic Diagram of the Current-Balance Supervision

The **Threshold min/max** parameter is the criterion by which unbalance in the phase currents is measured. The device calculates the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current.

Enter the lower limit of the maximum phase current (I_{max}) with the parameter **Release threshold**. This specifies the lower limit of the operating range of this function.

Operate delay

If it falls below the balance factor **Threshold min/max** and at the same time the maximum phase current exceeds the **Release threshold**, the tripping delay begins. If both conditions persist during this time, the indication **Failure** is generated.

9.3.9.4 Application and Setting Notes

Parameter: Threshold min/max

- Recommended setting value **(_:102) Threshold min/max** = ***0.5***

The **Threshold min/max** parameter is used to set the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current.

Parameter: Release threshold

- Recommended setting value **(_:101) Release threshold** = ***0.5 A*** for I_{rated} = 1 A or ***2.5 A*** for I_{rated} = 5 A

The **Release threshold** parameter is used to set the lower limit of the maximum phase current (I_{max}).

Parameter: Operate delay

- Recommended setting value **(_:6) Operate delay** = ***5.00 s***

Set the **Operate delay** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided.

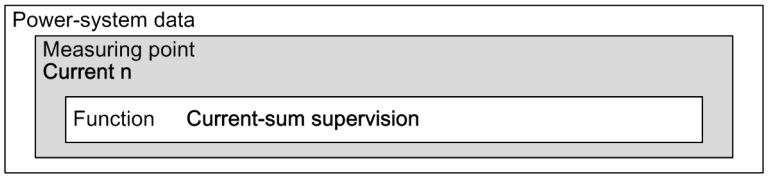
9.3.10 Current-Sum Supervision

9.3.10.1 Overview of Functions

In healthy system operation, the sum of all currents at one measuring point must be approximately 0. The **Current-sum supervision** monitors the sum of all currents of one measuring point in the secondary circuit. It detects connection errors during commissioning or short circuits and interruptions in the secondary circuit.

For summation of the currents, the device requires the phase currents and the ground current of the current transformer neutral point or of a separate ground-current transformer at this measuring point. The following connection variants are available:



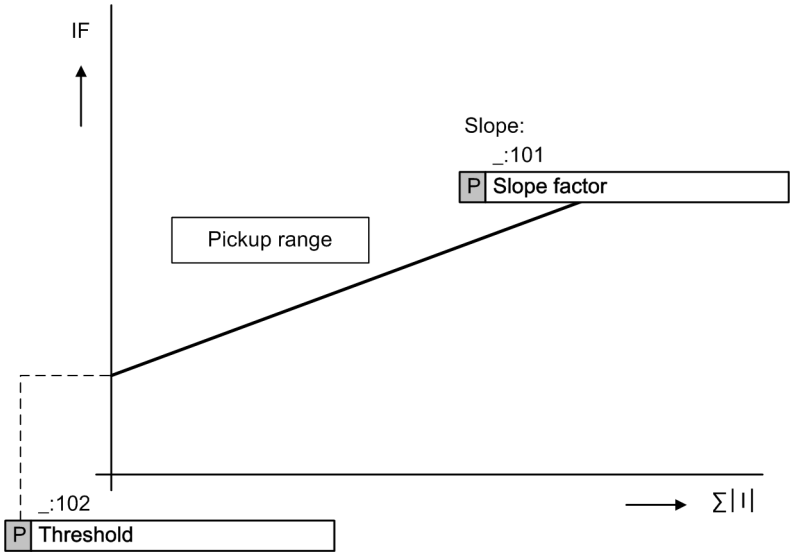
- Current-transformer connections connected to 3 current transformers and the neutral point (see *Figure A-12* in the Attachment)
- Ground current detected with 3 separate ground-current transformers (see *Figure A-14* in the Attachment)
- 3 current transformers and one summation current transformer connected (see *Figure A-13* in the Attachment)
- 2 current transformers and one summation current transformer connected (see *A.7 Connection Examples for Current Transformers* in the Attachment)

NOTE

For current-sum supervision, the ground current of the line to be protected must be connected to the 4th current measurement input (I_N).

9.3.10.2 Structure of the Function

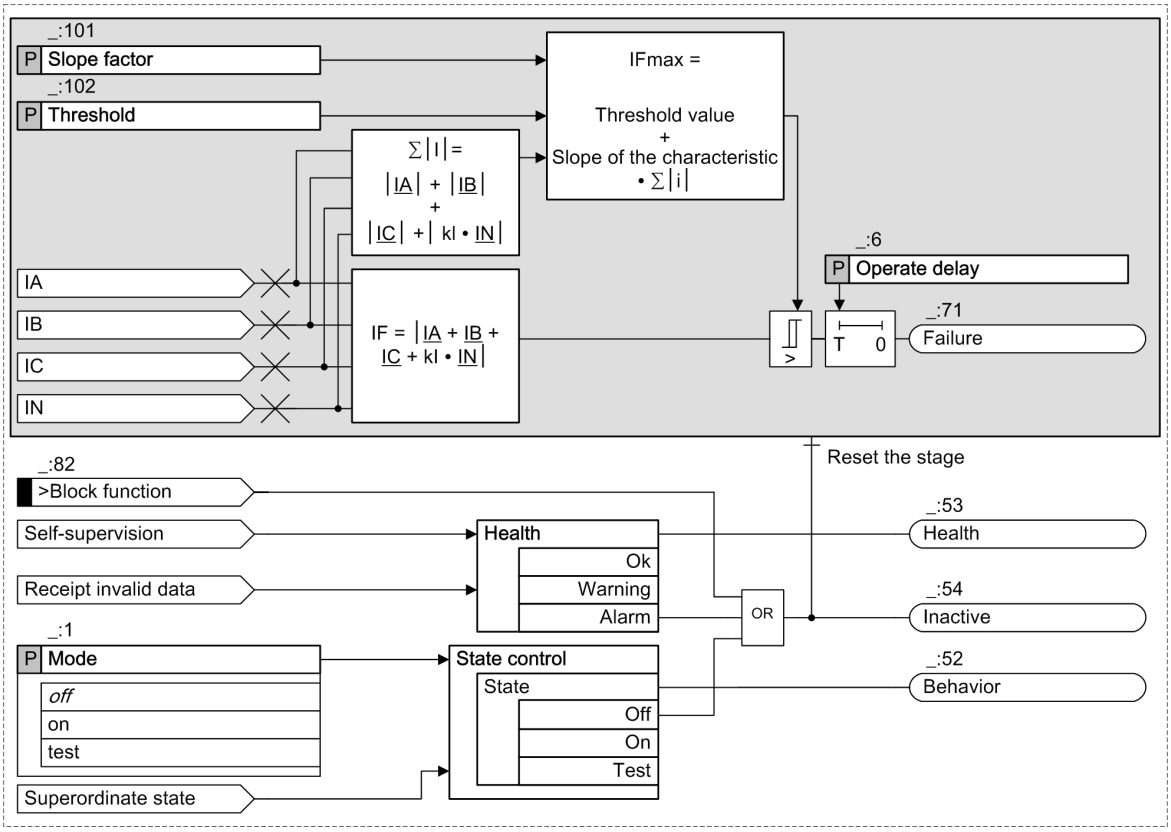
The **Current-sum supervision** function is located in the **Power-system data** of each 3-phase current measurement point.



[dwstrcss-300913, 2, en_US]

Figure 9-23 Structure/Embedding of the Function

9.3.10.3 Function Description



The current sum is generated by addition of the current phasors. Errors in the current circuits are detected if IF = |IA + IB + IC + kI• IN| > **Threshold** + **Slope factor** •Σ | I |.

[lokensum-300311-01.tif, 1, en_US]

Figure 9-24 Characteristic of the Current-Sum Supervision

Logic

[locssumm-140611-01.tif, 1, en_US]

Figure 9-25 Logic Diagram of the Current-Sum Supervision

Slope of the Characteristic Curve

The **Slope factor** • Σ | I | part takes into account permissible current-proportional transformation errors of the transformer, which can occur in the case of high short-circuit currents.

The **Slope factor** and **Threshold** parameters are used to set the fault-current limit (I_{Fmax}) for the current-sum supervision. The device calculates this fault current limit with the formula:

I_{Fmax} = **Threshold** + **Slope factor** • Σ| I |

The device uses the current inputs (IA, IB, IC and IN) to calculate:

- The fault current IF = |IA + IB + IC + kI• IN|
- The maximum current Σ| I | = | IA| + |IB| +| IC| + |kI• IN|

with $\mathbf{k_I}$ taking into account a possible difference from the transformation ratio of a separated ground-current transformer (I_N), for example, cable type current transformer.

- Transformation ratio of residual-current converter: $Ratio_N$
- Transformation ratio of phase-current converter: $Ratio_{ph}$

$$k_I = \frac{Ratio_N}{Ratio_{ph}}$$

[foglchki-040211-01.tif, 1, en_US]

Threshold

The **Threshold** parameter is the lower limit of the operating range of the **Current-sum supervision** function.

Operate delay

When the calculated fault current (I_F) exceeds the calculated fault current limit (I_{Fmax}), the **Operate delay** starts. If the threshold-value violation persists for that time, the **Failure** indication is generated.

9.3.10.4 Application and Setting Notes

Parameter: Slope factor

- Recommended setting value **(_:101) Slope factor** = ***0.1***

The **Slope factor** parameter is used to set the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current. This function calculates the RMS values.

Parameter: Threshold

- Recommended setting value **(_:102) Threshold** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **Threshold** parameter is used to set the maximum phase current (I_{max}).

Parameter: Operate delay

- Recommended setting value **(_:6) Operate delay** = ***5.00 s***

Set the **Operate delay** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided.

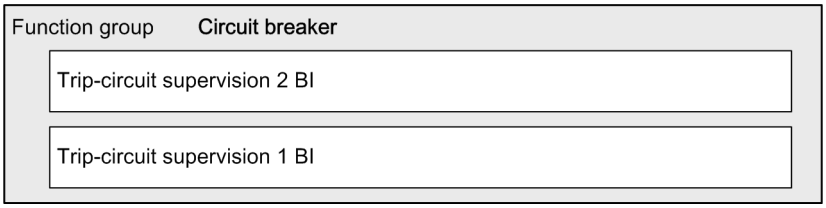
9.3.12 Trip-Circuit Supervision



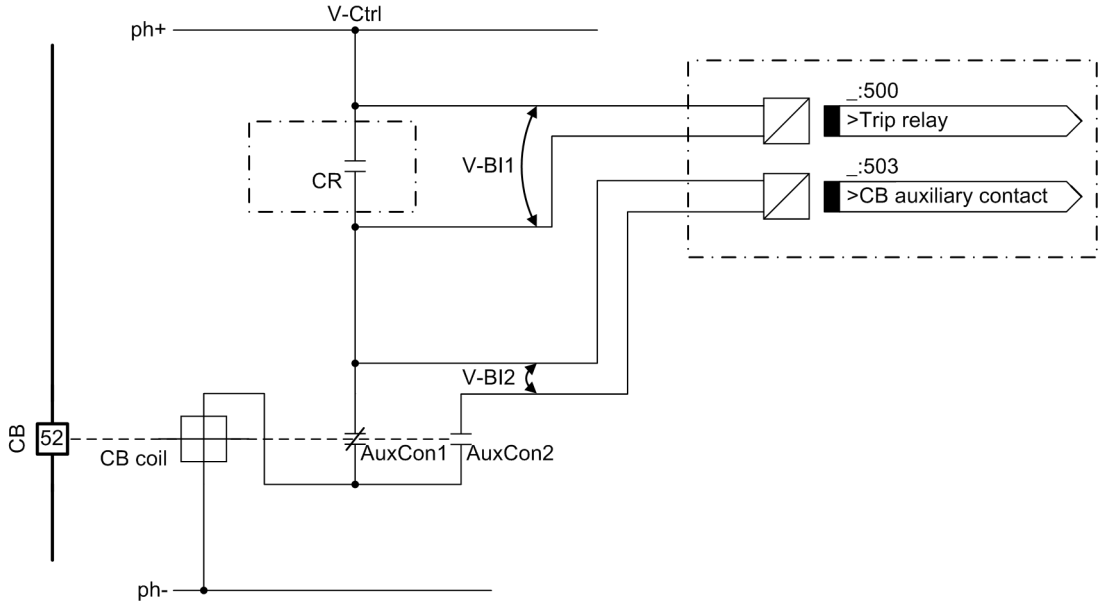
9.3.12.1 Overview of Functions

The **Trip-circuit supervision** function recognizes disruptions in the trip circuit. When 2 binary inputs are used, the function recognizes all disruptions in the trip circuit. If only 1 binary input is available, it will not recognize disruptions at the circuit-breaker.

The control voltage for the circuit breaker must be greater than the sum of the minimum voltage drops at the binary inputs $V_{Ctrl} > 2\ V_{BImin}$. At least 19 V are required for each binary input. This makes the supervision usable only with a system-side control voltage of > 38 V.

9.3.12.2 Structure of the Function

The trip-circuit supervision is integrated into the **Circuit-breaker** function group. Depending on the number of available binary inputs, it works with 1 or 2 binary inputs.



[dwtcsueb-010313-01.tif, 1, en_US]

Figure 9-28 Structure/Embedding of the Function

9.3.12.3 Trip-Circuit Supervision with 2 Binary Inputs

In order to recognize disruptions in the trip circuit for each switch position, you need 2 binary inputs. One input is connected parallel to the respective command relay of the protection, the other parallel to the circuit-breaker auxiliary contact.

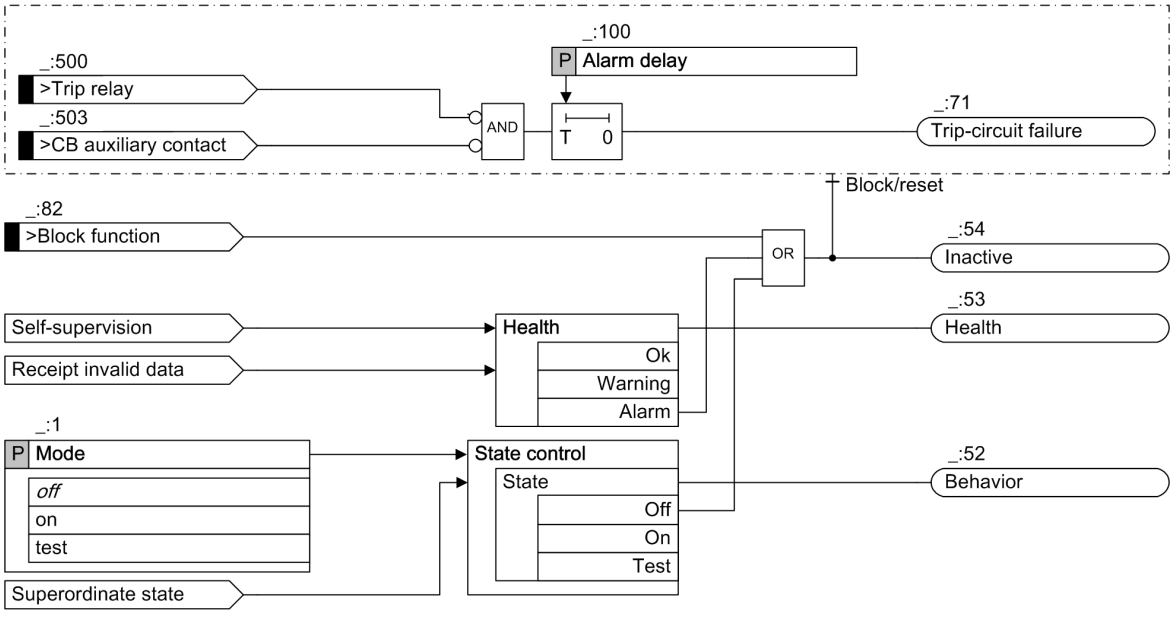
The following figure shows the principle of the trip-circuit supervision with 2 binary inputs.

[dwtcs2be-110611-01.tif, 2, en_US]

Figure 9-29 Principle of Trip-Circuit Supervision with 2 Binary Inputs

CR	Command relay
CB	Circuit breaker
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (NC)
AuxCon2	Circuit-breaker auxiliary contact (NO)
V-Ctrl	Control voltage (tripping voltage)
V-BI1	Input voltage for binary input 1
V-BI2	Input voltage for binary input 2

Supervision with 2 binary inputs identifies disruptions in the trip circuit and the outage of the control voltage. It also monitors the reaction of the circuit breaker by way of the position of the circuit-breaker auxiliary contacts.



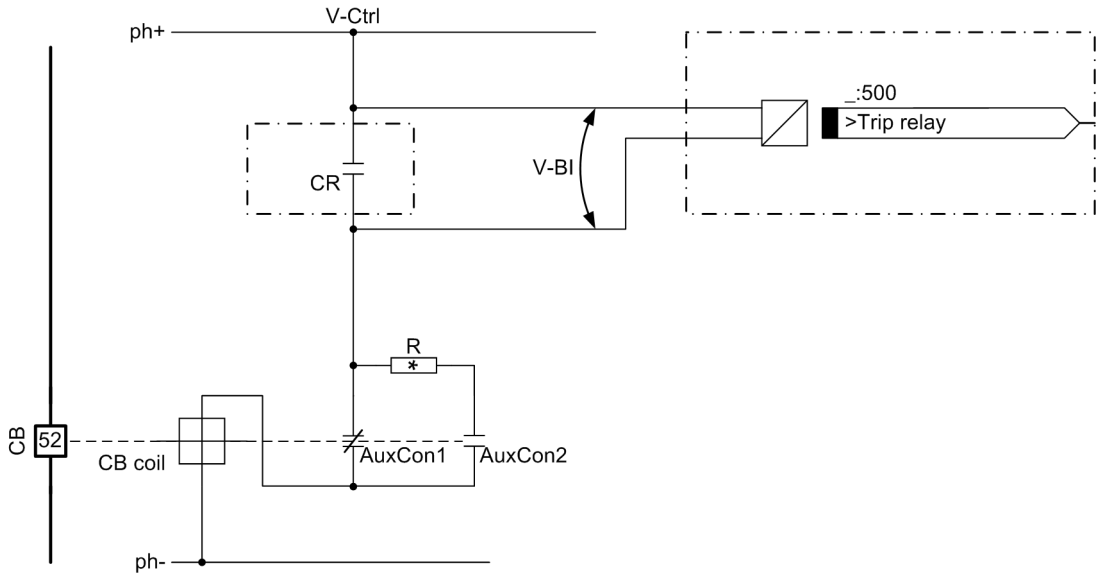
Depending on the switch position of the command relay and circuit breaker, the binary inputs are either activated (**H**) or not (**L**). If both binary inputs are not activated, there is a fault. The fault may be a interruption or a short circuit in the trip circuit, an outage of the battery voltage or a fault in the mechanics of the circuit breaker. With intact trip circuits, this state will occur only briefly while the command relay is closed and the circuit breaker has not yet been opened.

No.	Command Relay (CR)	CB	AuxCon1	AuxCon2	BI 1	BI 2	Dynamic State	Static State
1	Open	ON	Closed	Open	H	L	Normal operation with closed circuit breaker	
2	Open	OFF	Open	Closed	H	H	Normal operation with open circuit breaker	
3	Closed	ON	Closed	Open	L	L	Transmission or fault	Fault
4	Closed	OFF	Open	Closed	L	H	CR successfully activated the circuit breaker	

With the **`Alarm delay`** parameter, you can set the time delay. After fixing the fault in the trip circuit, the failure indication will automatically expire after the same time.

If the binary input signals *`>Trip relay`* or *`>CB auxiliary contact`* are not routed on the binary inputs of the device, then the *`Input sig. not routed`* indication is generated and the **Trip-circuit supervision** function is not in effect.

The following figure shows the logic diagram of the trip-circuit supervision with 2 binary inputs.



[lotcs2be-260912-01.tif, 1, en_US]

Figure 9-30 Logic Diagram of Trip-Circuit Supervision with 2 Binary Inputs

9.3.12.4 Trip-Circuit Supervision with 1 Binary Input

When using 1 binary input, you will not identify any disruptions on the circuit breaker. The binary input is connected in parallel with the respective command relay of the protection device. The circuit-breaker auxiliary contact is bridged with a high-resistance equivalent resistance R.

The following figure shows the principle of the trip-circuit supervision with 1 binary input.

[dwtcs1be-110611-01.tif, 2, en_US]

Figure 9-31 Principle of Trip-Circuit Supervision with 1 Binary Input

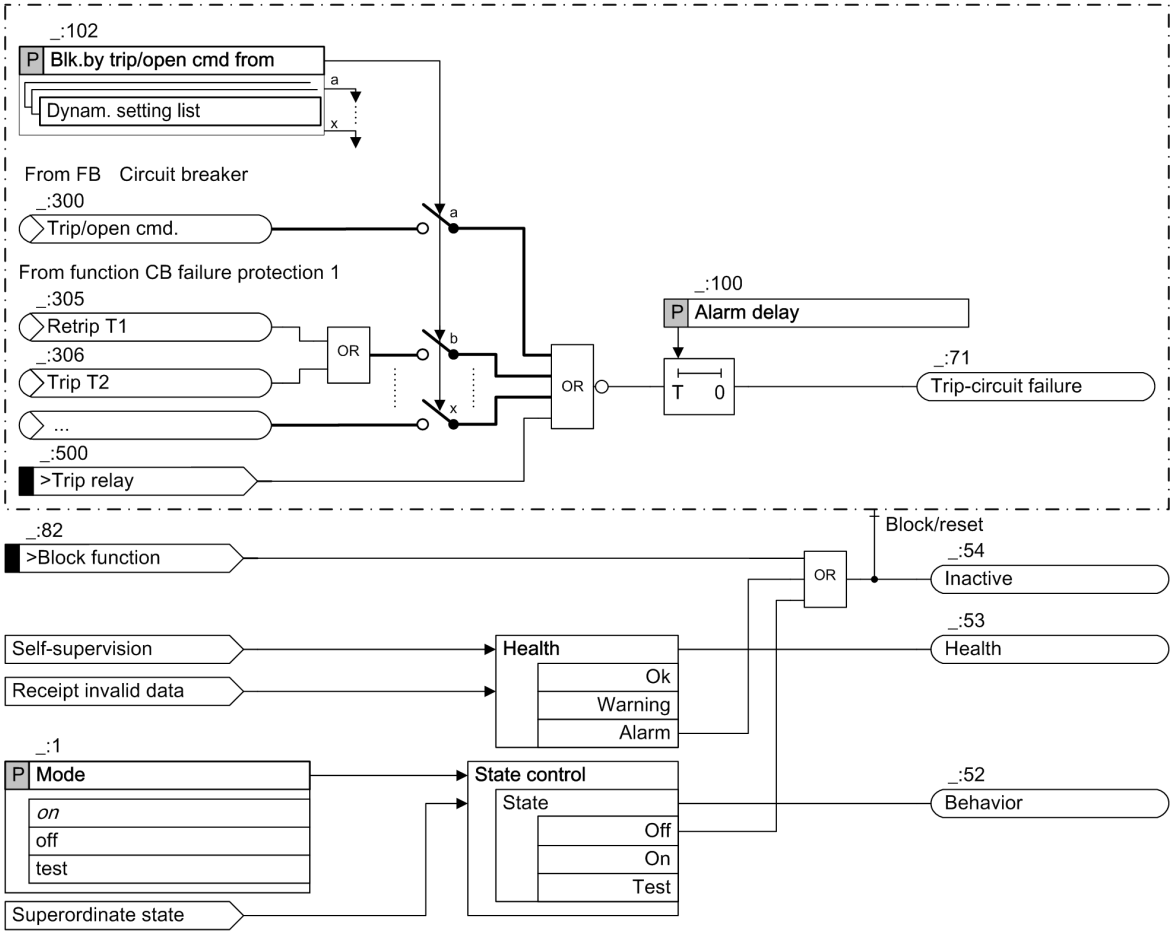
CR	Command relay
CB	Circuit breaker
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (NC)
AuxCon2	Circuit-breaker auxiliary contact (NO)
V-Ctrl	Control voltage (tripping voltage)
V-BI	Input voltage for binary input
R	Equivalent resistance

The supervision with 1 binary input identifies disruptions in the trip circuit and the failure of the control voltage.

In normal operation, the binary input is activated with the command relay open and the trip circuit intact (**H**). The supervision circuit is closed with the equivalent resistance R or with the auxiliary contact AuxCon1 of the closed circuit breaker. The binary input is not activated while the command relay is closed (**L**). If the binary input is not activated for a prolonged time, there is a disruption in the trip circuit or the control voltage has failed.

No.	Command Relay	CB	AuxCon1	AuxCon2	BI	Dynamic State	Static State
1	Open	ON	Closed	Open	H	Normal operation with closed circuit breaker	
2	Open	OFF	Open	Closed	H	Normal operation with open circuit breaker	
3	Closed	ON	Closed	Open	L	Transmission or fault	Fault
4	Closed	OFF	Open	Closed	L	CR successfully activated the circuit breaker	

Use the parameter **`Blk.by trip/open cmd from`** to set the conditions under which the trip-circuit supervision is blocked. The following conditions can cause a blocking of the trip-circuit supervision function:



- The *`Trip/open cmd.`* of the circuit breaker is activated.
- One of the trip commands of the circuit-breaker failure protection is activated.

As long as the trip-circuit supervision function is blocked, the closed contact of the command relay does not cause a failure indication.

If the command contacts of other devices work in parallel on the trip circuit, the failure indication must be delayed. With the **`Alarm delay`** parameter, you can set the time delay. After fixing the fault in the trip circuit, the failure indication will automatically expire after the same time.

If the binary input signal *`>Trip relay`* is not routed to a binary input of the device (**information routing** in DIGSI 5), then the *`Input sig. not routed`* indication is generated and **Trip-circuit supervision** is no longer in effect.

The following figure shows the logic diagram of the trip-circuit supervision with 1 binary input.

[lotcs1be-260912-01.tif, 1, en_US]

Figure 9-32 Logic Diagram of Trip-Circuit Supervision with 1 Binary Input

Equivalent Resistance R

The equivalent resistance R must be dimensioned such that the circuit-breaker coil is no longer activated when the circuit breaker is open. Simultaneously, the binary input must still be activated when the command relay is open.

In order to ensure the minimum voltage for activating the binary input, R_{max} results in:

$$R_{max} = \left(\frac{V_{Ctrl} - V_{BImin}}{I_{BI(High)}} \right) - R_{CBC}$$

[fofr1b02-090330-01.tif, 1, en_US]

So that the circuit-breaker coil does not remain activated, R_{min} results in:

$$R_{min} = R_{CBC} \cdot \left(\frac{V_{Ctrl} - V_{CBC(Lowmax)}}{V_{CBC(Low)}} \right)$$

[fofr1b03-090330-01.tif, 1, en_US]

You can calculate the optimal value for the equivalent resistance R from the 2 values R_{min} and R_{max}:

$$R = \frac{R_{max} + R_{min}}{2}$$

[fofr1b01-090330-01.tif, 1, en_US]

The following applies for the power consumption of the equivalent resistance R:

$$P_R = I^2 \cdot R = \left(\frac{V_{Ctrl}}{R + R_{CBC}} \right)^2 \cdot R$$

[fofr1b04-090330-01.tif, 1, en_US]

9.3.12.5 Application and Setting Notes

Parameter: Alarm delay

- Recommended setting value **(_:100) Alarm delay** = ***2 s*** (Trip-circuit supervision with 2 binary inputs)
- Recommended setting value **(_:100) Alarm delay** = ***300 s*** (Trip-circuit supervision with 1 binary input)

With the parameter **Alarm delay**, you can set the time for the delayed output of the indication *Trip-circuit failure*.

For **Trip-circuit supervision with 2 binary inputs**, you set the **Alarm delay** parameter so that the short-term transient states do not cause the function to activate.

For the **Trip-circuit supervision with 1 binary input,** you set the **Alarm delay** so that the longest duration of a trip command is bridged without fail. This ensures that the indication is emitted only if the trip circuit is actually interrupted.

Parameter: Blk.by trip/open cmd from

- Possible settings, application-dependent

The parameter works only with the trip-circuit supervision with 1 binary input.

Use the parameter **Blk.by trip/open cmd from** to set the conditions under which the trip-circuit supervision is blocked. The following conditions can cause a blocking of the trip-circuit supervision function:

- The *Trip/open cmd.* of the circuit breaker is activated.
- One of the trip commands of the circuit-breaker failure protection is activated.
- One of the trip commands of the circuit-breaker reignition protection is activated.

The circuit-breaker failure protection is set to protect a different trip circuit than the local circuit breaker. Using the configuration options of the **Blk.by trip/open cmd from** parameter, multiple trip-circuit supervision functions can be operated in parallel. For instance, a trip-circuit supervision function dedicated to a local circuit breaker can also be operated parallel to a higher-level circuit breaker upon which the circuit-breaker failure protection acts.

9.3.12.6 Settings

Addr.	Parameter	C	Setting Options	Default Setting
74TC sup.1BI #

9.4 Supervision of the Device Hardware

9.4.1 Overview

The correct state of the device hardware is a requirement for the correct functioning of the device. The failure or erroneous function of a hardware component leads to device malfunctions.

The following modules of the device hardware are monitored:

- Base module
- Expansion modules
- Plug-in modules on the interface locations

The fault responses result, depending on type and degree of the error, as follows:

Hardware errors where the device remains in operation.

The error is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can switch into a secure state. Such errors are, for example:

- Communication-module failure (module x)
- Measuring-transducer module failure (module x)
- USB interface
- Integrated Ethernet interface
- Real-time clock building block
- A/D converter (fast current sum)
- Battery voltage
- Faulty or missing compensation values (magnitude/phase)

Failures which can partially be corrected by a restart of the device. The device goes briefly out of operation.

Such errors are, for example:

- Memory error (RAM) in the base module
- Faulty module
- Module-connection error (PCB Link)
- Control circuit error binary output
- Outage of an internal auxiliary voltage

NOTE

If the error has not be rectified after 3 unsuccessful attempts, the system automatically recognizes it as a severe device malfunction. The device goes permanently out of operation into a secure state (fallback mode).

Fatal device errors with outage of central components: The device goes permanently out of operation into a secure state (fallback mode).

Such errors are, for example:

- Memory error (flash) in the base module
- CPU/Controller/FPGA error in the base module
- 3 unsuccessful restarts in a row

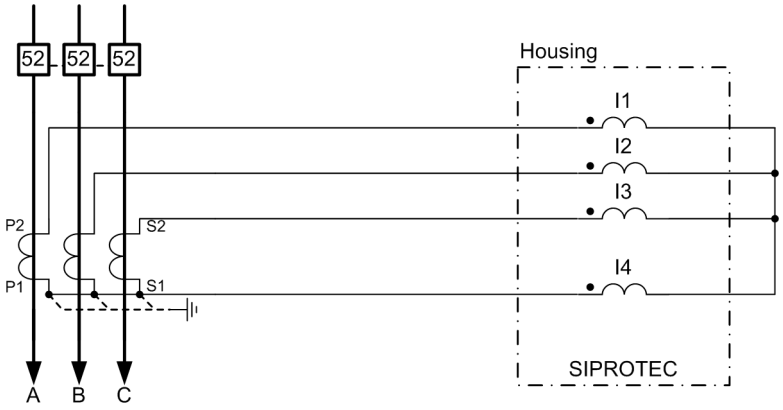
You can find the detailed description, in table form, of the fault responses at the end of chapter 8 . You will find corresponding corrective measures there.

Device Operating Hours

The *Device operating hours* statistical value counts the operating hours of the physical device. The starting time and the time in Fallback mode are not considered.

You can neither reset nor change the statistical value.

9.4.2 Analog-Channel Supervision via Fast Current-Sum



9.4.2.1 Overview of Functions

The function **Supervision of the device-internal analog-digital converters** it performs the following tasks:

- Supervision of the correct functioning of the device-internal analog-digital converters, based on the sum of all currents of one measuring point in the secondary circuit.
- Detection of failures in the device-internal measuring circuits (for example, analog-digital converter)
- Blocking of protection and control functions that process the measured values from this current measuring point (for example, differential protection). This avoids an overfunction of the device.

The supervision principle is based on fast current sum supervision with connection of the neutral-point current to the 4th current measurement input. In order to ensure that even the fast tripping stages of the protection functions can be blocked in time before a spurious pickup, the fast current measurement is based on instantaneous values.

For **Analog-digital converter supervision**, the neutral-point current of the line to be protected must be connected to the 4th current measuring input (I_N). The 4th current measuring input must be routed via the current-transformer neutral point (I_N neutral point) (see next figure).

Current transformer 3-phase: connection = **3-phase + IN**

[tileite2-070211-01.tif, 1, en_US]

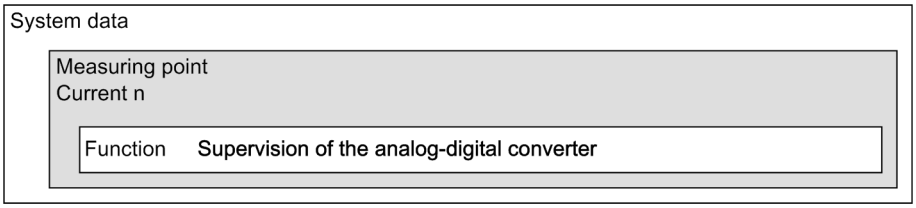


Figure 9-33 Connection to a 3-Phase Current Transformer and Measured Zero-Sequence Current (Current in Common Return Path)

NOTE

The analog channel supervision via fast current sum is only available when the 4th current input is a protection-class current transformer. In the DIGSI 5 project tree, under **Device** → **Measuring-point routing**, set the connection type ***3-phase + IN*** for the current measuring point.

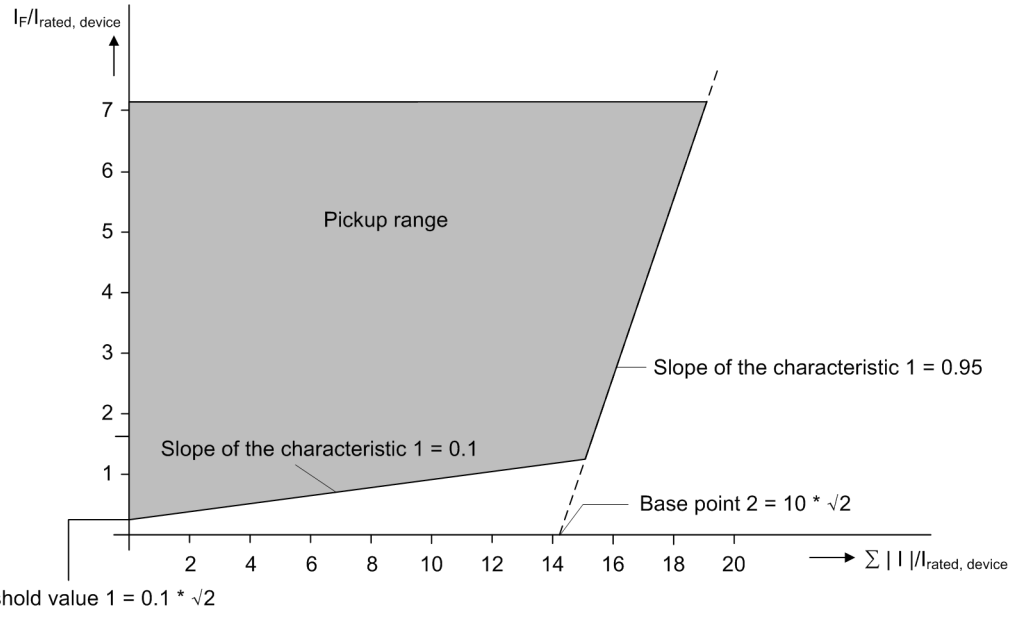
9.4.2.2 Structure of the Function

The **Supervision of the device-internal analog-digital converters** function is located in the **Power-system data** function group of each 3-phase current measuring point.

[dwschstr-040211-01.tif, 1, en_US]

Figure 9-34 Structure/Embedding of the Function

9.4.2.3 Function Description

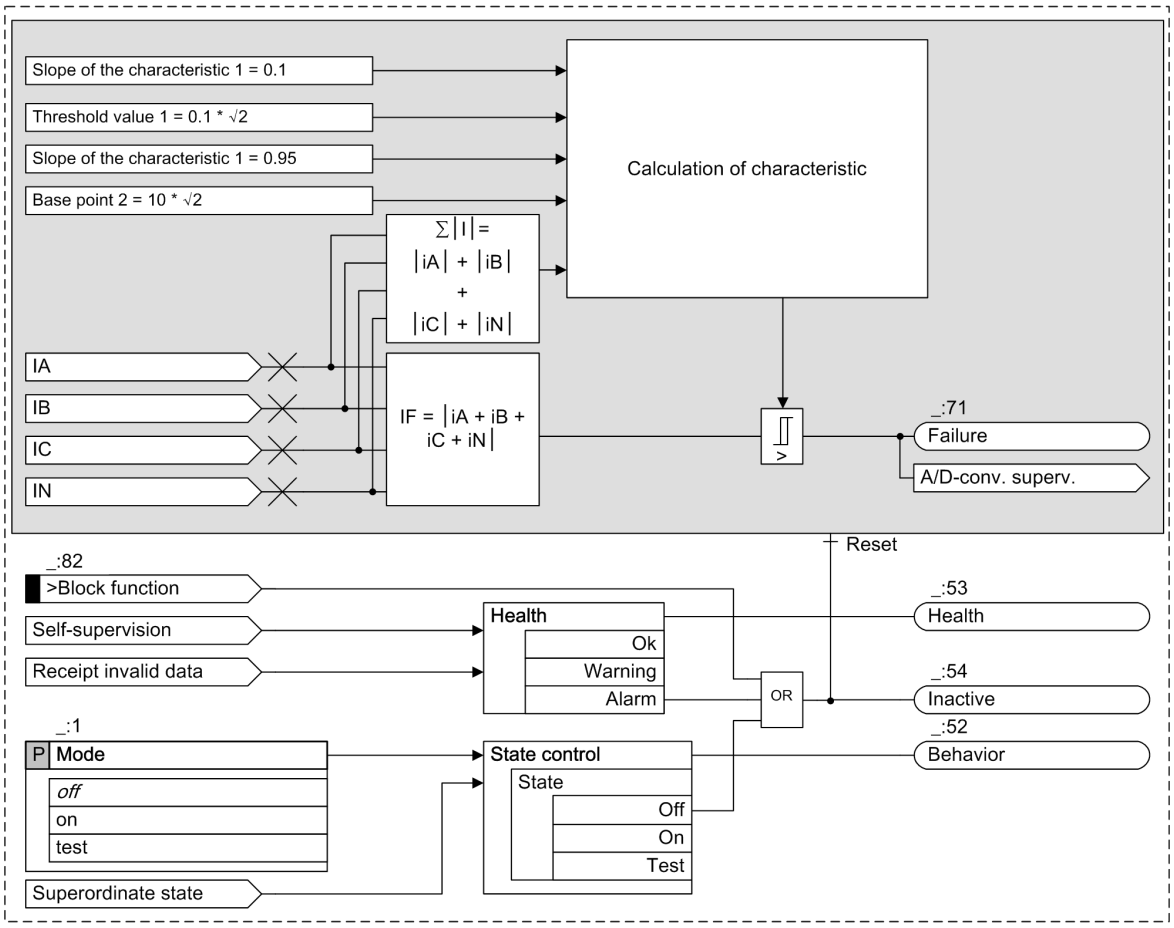


Errors in the current circuits are detected if

$I_F = |iA + iB + iC + iN| >$ **Threshold value** + **Slope of the characteristic 1** •Σ| i | and

$I_F >$ **Slope of the characteristic 2** • (Σ| i | - **Base point 2**)

With the current inputs (iA, iB, iC, and iN), the device calculates:



- The fault current $I_F = |iA + iB + iC + iN|$
- The maximum current Σ| i | = |iA|+|iB|+|iC| + |iN|

[lokenisu-240413-01.tif, 2, en_US]

Figure 9-35 Characteristic Curve of the Supervision of the Device-Internal Analog-Digital Converters

Logic

[losumsch-240413-01.tif, 3, en_US]

Figure 9-36 Logic Diagram of the Supervision of the Device-Internal Analog-Digital Converters

When the output signal **`A/D converter monit.`** is active, certain protection functions are blocked to avoid failures (see *12.64 Analog Channel Supervision via Fast Current Sum*).

NOTE

The parameters are fixed in the device and cannot be changed.

It is not necessary to change the parameters depending on the application.

Threshold Value

The **threshold value** is the lower limit of the operating range of the **Supervision of the device-internal analog-digital converters** function.

The **threshold value** is fixed to 10 % of the device rated current.

Slope of the Characteristic 1

The component **slope of characteristic 1** • Σ | i | takes into account permissible current-input errors, which can occur in the case of small overcurrents.

The **slope of characteristic 1** is fixed to 0.1.

Slope of the Characteristic 2

The component **slope of characteristic 2** takes into account permissible current-input errors, which can occur in the case of high overcurrents (high short-circuit currents).

The **slope of characteristic 2** is fixed to 0.95. The base point of the **slope of characteristic 2** is fixed to 10.

9.5 Supervision of Device Firmware

The device firmware determines essentially the functionality of the device.

The following supervisions ensure the stable function of the device:

- Supervisions of the data and version consistency
- Supervision of the undisturbed sequential activity of the device firmware
- Supervision of the available processor performance

When you start the device, load data via the interfaces and these supervisions of the device firmware will be in effect during the continuous operation. Depending on the type and severity of error, the following error responses will result:

Firmware failures where the device remains in operation.

The error is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. Such errors are, for example, errors in time synchronization (loss and errors).

Failures which can partially be corrected by a restart of the device. The device goes briefly out of operation.

Such errors are, for example:

- Device startup with faulty new parameter set. The old parameter set is still present.
- Overloading of the processor
- Program-sequence error

Fatal firmware error. The device goes permanently out of operation into a secure state (fallback mode).

Such errors are, for example:

- Device startup with faulty new parameter set. No usable parameter set is present.
- Device startup with version error
- CFC-runtime error
- 3 unsuccessful restarts in a row

You can find the detailed description, in table form, of the fault responsed at the end of chapter 8. You will find corresponding corrective measures there.

9.6 Supervision of Hardware Configuration

The modular hardware concept requires adherence to some rules within the product family and the modular system. Configuration errors show that the hardware configuration saved in the device does not agree with the hardware actually detected. Impermissible components and unallowed combinations must be detected just as missing configured components are.

Depending on the type and severity of error, the following error responses will result: The identified hardware configuration errors are assigned to the defect severities as follows:

Configuration errors where the device remains in operation.

The failure is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. Such errors are, for example, errors in IE converter configuration (loss and errors).

Fatal configuration error: The device goes permanently out of operation into a secure state (fallback mode).

Such errors are, for example:

- Missing hardware module (module x)
- Incorrect hardware module (module x)
- Incorrect hardware combination
- Incorrect plug-in module (module x)

You can find the detailed description, in table form, of the error reactions at the end of chapter 8 . You will find corresponding corrective measures there. You can resolve configuration errors through another synchronization with DIGSI.

9.7 Supervision of Communication Connections

SIPROTEC 5 devices offer extensive communication possibilities via fixed and optional interfaces. Beyond the hardware supervision of the communication plug-in modules the transferred data must be monitored with respect to their consistency, failure, or outage.

Supervision

With the supervision of the communication connections, every communication port is monitored selectively.

- Failures are detected and indicated via the operational log. The device remains in operation!
- Each port additionally is equipped with a separate communication log, with which details of the failures (for example, error rate) are displayed.

Marking Fault Signals/Data

The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. In the following, some examples are named:

- GOOSE signals can automatically be set to defined values in case of disturbed IEC 61850 communication.
- Disturbed protection interfaces set phasor values, both analog measured values and binary information to **invalid** (for example, for differential protection). Binary signal traces can be set to defined values in cases of failures.
- Disturbed time-synchronization signals can lead to an automatic change of the source of time synchronization.

Normally, you can correct communication failures by checking the external connections or by replacing the affected communication modules. In chapter *9.8.2 Defect Severity 1* to *9.8.4 Defect Severity 3*, you will find the detailed description, in tabular form, of the error responses. Corresponding corrective measures can also be found there.

9.8 Error Responses and Corrective Measures

9.8.1 Overview

When device errors occur and the corresponding supervision functions pick up, this is displayed on the device and also indicated. Device errors can lead to corruption of data and signals. These data and signals are marked and tagged as **invalid**, so that affected functions automatically go into a secure state. If the supervision functions pick up, this will lead to defined error responses.

How Do Device Errors Make Themselves Noticeable

In case of a device error the supervision functions of the device pickup. The device responds according to the type and severity of the error. To report an error, supervision functions use outputs on the device and indications.

Run LED (green)	The external auxiliary voltage is present. The device is ready for operation.
Error LED (red)	The device is not ready for operation. The life contact is open.
Life contact	Signaling of device readiness following successful device startup.
Group-warning indication *Group warning*	The device remains in operation and signals an error via the prerouted LED and the log.
Log of the device	Indications of causes for defects and corrective measures

Determination of Causes for Defects and Corrective Measures

To determine the cause for defect and the corresponding corrective measure, proceed step by step.

Step 1: Pick up of supervisions leads to one of the following defect severities in all cases.

- **Defect severity 1:**
  Internal or external device error that is reported. The device stays in operation.
- **Defect severity 2:**
  Severe device failure, the device restarts (reset) to correct the cause for defect.
- **Defect severity 3:**
  Severe device failure, the device goes to a safe condition (fallback mode), as the correction of defects by a restart is not possible. In fallback mode, the protection and automated functions are inactive. The device is out of operation.
- **Defect severity 4:**
  Severe device-external failure, the device switches the protection and automatic functions to inactive for safety, but stays in operation. Normally, the user can correct the fault by himself.

Step 2: For every defect severity, you will find detailed tables with information about causes for defects, error responses, and corrective measures in the following chapters.

	Error Responses						
	Group-Warning Indication Group Warning	Indication in the Operational Log	Indication in the Device-Diagnosis Log	Indication of the Life Contact	All Protection and Automation Functions Are Inactive	Device Restart (Reset)	Fallback Mode
Defect severity 1	x	x	x				
Defect severity 2			x	x	During the starting time of the device	x	
Defect severity 3			x	x	x		x
Defect severity 4		x		x	x		

9.8.2 Defect Severity 1

Defect severity 1 faults allow the continued safe operation of the device. Defect severity 1 faults are indicated. The device remains in operation.

When the supervision functions pick up, corrupted data and signals are marked as **invalid**. In this way, the affected functions can go into a secure state. Whether functions are blocked is decided in the appropriate function itself. For more detailed information, refer to the function descriptions.

Live status contact	Remains activated
Red error LED	Is not activated

Log

For every device fault, a corresponding supervision indication is generated. The device records these indications with a real-time stamp in the operational log. In this way they are available for further analyses. If supervisions in the communication interfaces area of the device pick up, there is a separate communication log available for each port. Extended diagnostic indications and measured values are available there. The device-diagnosis log contains expanded fault descriptions. There you also receive recommendations of corresponding corrective measures for each detected device error.

You can find further information on handling the logs in chapter 3.

Group-Warning Indication Group Warning

As delivered, all supervision indications of Defect Severity 1 are routed to the signal `(_:301)` **`Group warning`**. In this way, a device error can be indicated with only one indication. The majority of supervision indications are permanently connected to the **`Group warning`** indication (**Group warning** column = fixed). However, some supervision indications are routed flexibly to the **`Group warning`** via a CFC chart (**Group warning** column = CFC). If necessary, you can remove the routings via a CFC chart from the group indication.

In delivery condition, the **`Group warning`** is prerouted to an LED.

You can find further information on handling the logs in chapter 3.

Overview of Errors

Indication	Type	Group Warning	Explanation
General: (_:53) **Health**	ENS	CFC	If the **Health** of an individual function block, for example, a protection stage or an individual function, goes to the *warning* or *Alarm* state, this state is processed via the associated function group up to the general group indication **Health** (_:53). Check via the operational log from which function or function block the error originates. You can find additional information as to why the health of the function or a function block can change in the associated function description.
(_:53) **Health** = **Warning**	SPS		
(_:53) **Health** = **Alarm**	SPS		
Device: (_:320) **AuxVolt.fault**	SPS	Fixed	Fault with the auxiliary power supply: Check the external power supply.
Device: (_:305) **Battery fault**	SPS	Fixed	Battery fault: Replace the device battery.
Device: (_:312) **Compensation fault** x	ENS	Fixed	Calibration error in module x: Contact the Customer Support Center. **Quality**: Measured values are marked with the quality attribute of *questionable* (measured value display with ~).
Device: (_:314) **Offset error** x	ENS	Fixed	Offset error on module x: If this indication persists after the device start, contact the Customer Support Center. **Quality**: Measured values are marked with the quality attribute of *questionable* (measured value display with ~).
Device: (_:306) **Time failure**	SPS	Fixed	Internal time failure • Check the time settings first. • Then replace the device battery. • If the fault is not remedied, contact the Customer Support Center. **Quality**: The internal clock is marked with the quality attribute of *Clock Failure*.
Device: (_:319) **Memory fault**	SPS	Fixed	Checksum (CRC) error in monitored memory areas of the device
Device: Measuring-transducer error (x)	ENS	Fixed	Hardware error on measuring-transducer module in plug-in module position E/F/M/N/P: Contact the Customer Support Center.
Handling an alarm: (_:504) **>Group warning**	SPS	Fixed	Input signal for user-defined generation of the group warning
Time sync.: (_:305) **Time sync Fault**	SPS	Fixed	Time synchronization error, the timing master is faulty: • Check the external time source first. • Check the external connections. • If the fault is not remedied, contact the Customer Support Center. **Quality**: The internal clock is marked with the quality attribute of *Clock not synchronized*.

Indication	Type	Group Warning	Explanation
Power-system data:meas. point I-3ph:wire break: Wiring: (_:301) **Phase A possible wire break** (_:302) **Phase B possible wire break** (_:303) **Phase C possible wire break** (_:304) **Phase A wire break** (_:305) **Phase B wire break** (_:306) **Phase C wire break** (_:307) **Possible wire break** (_:308) **Confirmed wire break**	SPS SPS SPS SPS SPS SPS SPS SPS	 CFC CFC	Broken-wire detection indications (see chapter *9.3.8.1 Overview of Functions*) **Blocking**: Protection functions tending to over-function in the event of a wire break are blocked.

They do not result in failure of the applications. Configured binary signals are reset after a time that can be set.
VI-3ph: Mess.Volt.Fail detected: (_:300) **Failure**	SPS	CFC	Measuring-voltage failure detected: Check the exterior wiring. **Blocking**: Appropriate functions are either blocked definitely or you can set the blocking individually.

9.8.3 Defect Severity 2

Faults of defect severity 2 are fatal device faults that lead to an immediate restart of the device (reset).

This occurs when the device data is corrupted (for example, RAM memory), if a restart prevents restoration of data consistency. The device goes briefly out of operation, a failure is avoided.

Life contact	Is terminated during the restart
Red error LED	Is activated during the restart

NOTE

If the fault of defect severity 2 has not be been removed after 3 unsuccessful restarts (reset), the fault is automatically assigned to defect severity 3. The device will automatically turn to the fallback mode.

Log

For every device error with a subsequent restart (reset), only the restart can be detected in the operational log. The actual supervision indication is entered in the device-diagnosis log at the point in time of the fault detection and before the restart. These indications are recorded with a real-time stamp and are thus available for later analyses. The device-diagnosis log contains expanded fault descriptions. There you also receive recommendations of corresponding corrective measures for each detected device error.

You can find further information on handling the logs in chapter 3 .

Overview of Errors

Number	Device-Diagnosis Log
826	Processor error on the base module: If the fault occurs numerous times, contact the Customer Support Center.
830	FPGA hardware error on the base module: Contact the Customer Support Center.

[26] The indications are not prerouted in the CFC chart. The indications must be added to the CFC chart by the user!

Number	Device-Diagnosis Log
834	Memory error (short term): Reset initiated.
3823	Program run error: If the fault occurs numerous times, contact the Customer Support Center.
826	CPU overload: If the fault occurs numerous times, contact the Customer Support Center.
Miscellaneous	Internal firmware error: If the fault occurs numerous times, contact the Customer Support Center.

9.8.4 Defect Severity 3

Faults of defect severity 3 are fatal device faults that lead to device immediately going into the fallback mode. The signal *(_:301) Device status* goes to the ***Alarm*** state. The ***Warning*** state is not supported for this signal.

Fatal device errors are errors that cannot be resolved by a restart of the device. In this case, contact the Customer Support Center. The device goes permanently out of operation, a failure is avoided. In the fallback mode, minimal operation of the device via the on-site operation panel and DIGSI is possible. In this way, for example, you can still read out information from the device-diagnosis log.

Life contact	Is terminated in the fallback mode
Red error LED	Is activated in the fallback mode

Log

For every device error that immediately leads to entry into the fallback mode, entries from supervision messages and from the signal *(_:301) Device status* into the operational log are not possible. The actual supervision indication is entered in the device-diagnosis log at the point in time of the fault detection, that is, before entry into the fallback mode. These indications are recorded with a real-time stamp and are thus available for later analyses. The device-diagnosis log contains expanded fault descriptions. There, you are offered recommendations of corresponding corrective measures for each detected device error.

You can find further information on handling the logs in chapter 3 .

Overview of Errors

Number	Device-Diagnosis Log
2822	Memory error (continuous) Contact the Customer Support Center.
4727, 5018-5028	Hardware failure at module 1-12: Contact the Customer Support Center.
4729	Device bus error (repeated): • Check the module configuration and the module connections. • Contact the Customer Support Center.
4733	Incorrect hardware configuration: Synchronize the hardware configuration of the device with DIGSI.
5037-5048	Wrong module 1-12 detected: Synchronize the hardware configuration of the device with DIGSI.
5031-5035	Identified wrong plug-in module on plug-in module position E/F/M/N/P: Synchronize the hardware configuration of the device with DIGSI.
	Wrong application configuration: Search for the cause in the operational log and load a valid configuration to the device.
3640, 4514	Data-structure error: Contact the Customer Support Center.

Number	Device-Diagnosis Log
956	Firmware-version error: Contact the Customer Support Center.
2013, 2025	Signature error: Contact the Customer Support Center.
	CFC error: In DIGSI, check your CFC chart for the cause.
5050-5061	Binary-output error in module 1 - 12: Contact the Customer Support Center.
5088, 5089	A missing display configuration was established: Synchronize the hardware configuration of the device with DIGSI.

9.8.5 Defect Severity 4 (Group Alarm)

Errors of defect severity 4 are not device failures in the classical meaning. These errors do not affect the device hardware and are not detected or reported by internal device supervision functions. The condition of the defect severity 4 – the group alarm – is set user-specifically by the binary input signal *(_:503) >Group alarm*. If the binary input signal is reset, the device is no longer in the *Group alarm* condition and all functions return to the normal operating state.

If the group alarm is generated, the device reacts as follows:

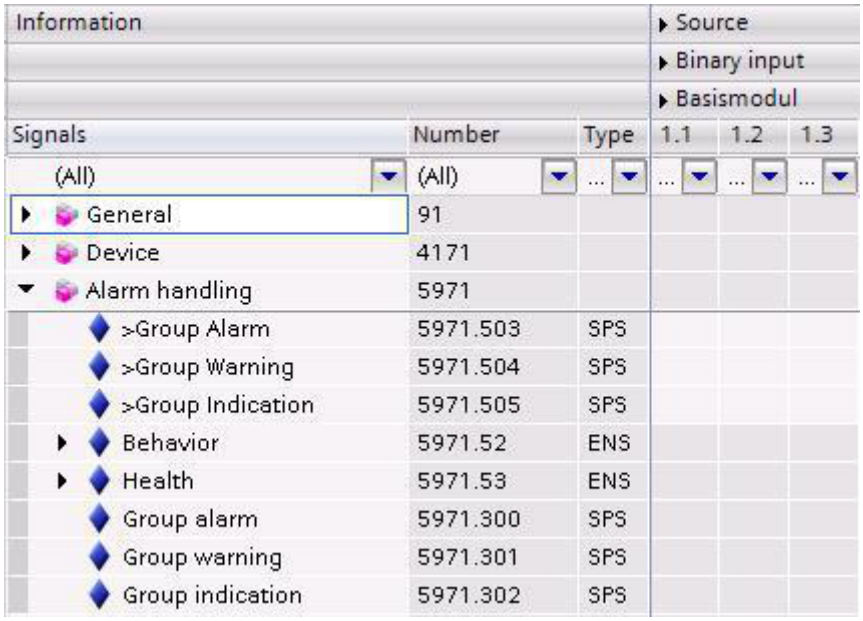
- The group indication *(_:300) Group alarm* is generated and recorded in the operational log.
- The life contact is terminated.
- The red Error LED is activated.
- All protection and automation functions are blocked.
- The device remains in operation, does not carry out any restart (reset), and does not switch to the safe condition (Fallback mode).
- The signals managed internally are marked with the ***invalid*** quality attribute. Signals managed internally are, for example, measured values, binary input and output signals, GOOSE and CFC signals.

In the delivery condition, every device has the CFC chart **Process mode inactive**, that initiates the Group alarm (see chapter *9.9 Group Indications and Predefined CFC Charts*).

Life contact	Is terminated in case of Group alarm
Red error LED	Is initiated in case of Group alarm

Log

The group indication *(_:300) Group alarm* is recorded in the operational log. Depending on the cause of the initiation, further information can be found in the operational log.



You can find further information on handling the logs in chapter 3 .

9.9 Group Indications and Predefined CFC Charts

The following group indications are available:

- *(_:300) Group alarm*
- *(_:301) Group warning*
- *(_:302) Group indication*

You can find the signals in the DIGSI 5 project tree under **Name of the device**) → **Information routing**. In the operating range, you can find the signals under **Alarm handling** (see the following figure).

[scgrwarn-010313-01, 1, en_US]

Figure 9-37 Group Monitoring Indication in the DIGSI 5 Information Routing Matrix

Group Indication Group Alarm

The indication *(_:300) Group alarm* is the group indication for defect-severity 4 monitoring. This monitoring has a special purpose, as it is set in a user-specific way by a binary input signal and not by internal device supervision. Nevertheless, the response of the device is serious, for example, the blocking of all protection and automatic functions (see chapter *9.8.5 Defect Severity 4 (Group Alarm)*).

If the binary input signal *(_:503) >Group Alarm* is set, the group indication *(_:300) Group alarm* is activated. If the binary input signal *(_:503) >Group Alarm* is reset, the signal *(_:300) Group alarm* is also reset and the device returns to the normal operating state.

In the delivery condition, every device has the CFC chart **Process mode inactive** that initiates the *>Group Alarm*. This CFC chart checks whether the device is still accidentally in the simulation or commissioning mode.

You can adapt the CFC chart as needed. You can find the CFC chart in the DIGSI 5 project tree under **Name of the device** → **Charts**.

Group Indication Group Warning

The indication *(_:301) Group warning* is the group indication for defect-severity 1 monitoring. Some error messages of defect severity 1 are firmly connected to the signal *(_:301) Group warning*, others are connected in a flexible way via a CFC chart in the device delivery condition. This allocation is described in chapter *9.8.2 Defect Severity 1* .

In the delivery condition, every device has the CFC chart **Group warning** that initiates the *Group warning*.

You can adapt the CFC chart as needed. You can find the CFC chart in the DIGSI 5 project tree under **Name of the device** → **Charts**.

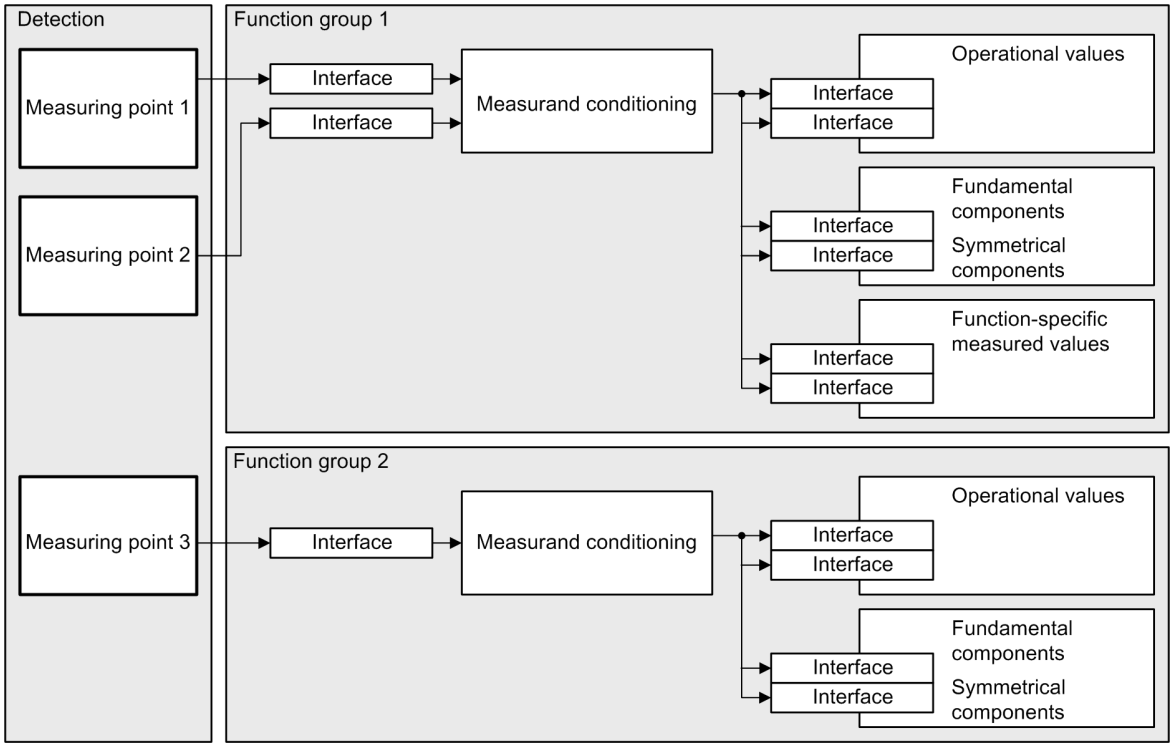
The group-warning indication *(_:301) Group warning* is prerouted to an LED of the base module.

Group Indication

The *Group indication* is used only for user-specific purposes. There is no internal device supervision function that activates this indication. If the binary input signal *(_:505) >Group Indication* is set, the indication *(_:302) Group indication* is activated and recorded in the operational log. In the delivery condition, there is no further response of the device. If the binary input signal is reset, the signal *(_:302) Group indication* drops out. You can define via a CFC chart when the binary input signal *(_:505) >Group Indication* is to be set.

10 Measured Values, Energy Values, and Supervision of the Primary System

10.1	Overview of Functions	1232
10.2	Structure of the Function	1233
10.3	Operational Measured Values	1235
10.4	Fundamental and Symmetrical Components	1237
10.5	Average Values	1238
10.6	Minimum/Maximum Values	1241
10.7	Energy Values	1243
10.8	User-Defined Metered Values	1246
10.9	Phasor Measurement Unit (PMU)	1250
10.10	Measuring Transducers	1269
10.11	Statistical Values of the Primary System	1275
10.12	Circuit-Breaker Wear Monitoring	1276



10.1 Overview of Functions

The measurands are recorded at the measuring points and forwarded to the function groups.

Within the function groups, further measurands are calculated from these measured values, which are required for the functions of this function group. This is how, for example, the electric power is calculated from the voltage and current measurands.

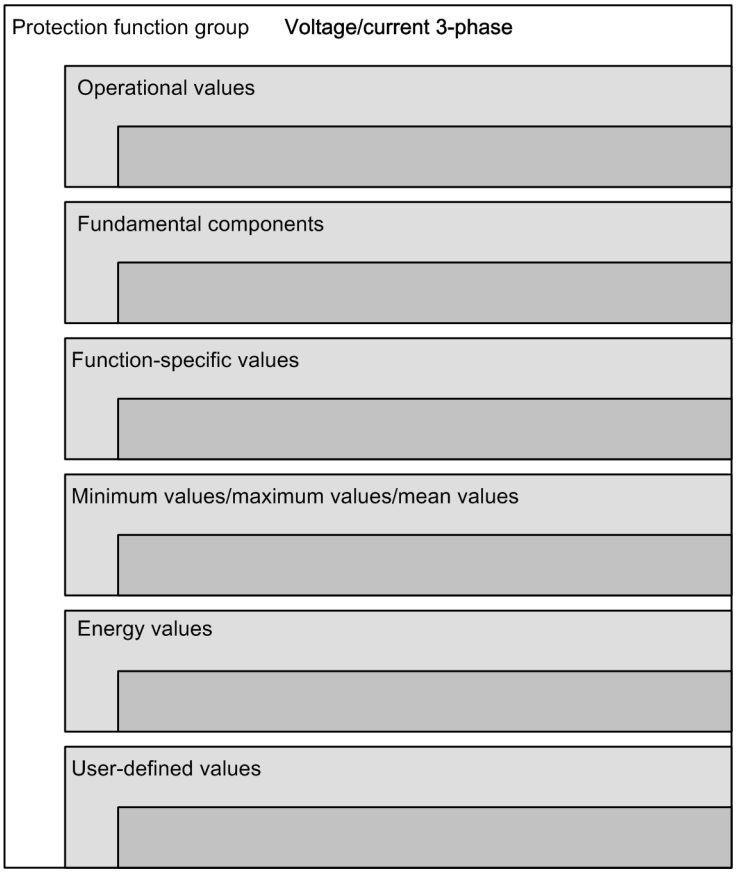
Measuring transducers are an exception as they already form various calculation parameters from the analog current and voltage inputs themselves.

Basic instructions for recording and editing process data can be found in the chapter *2.1 Function Embedding in the Device*.

[dwomverf-010212-01.tif, 1, en_US]

Figure 10-1 Structure of Measured-Value Acquisition and Processing

For the display, the measured values of a SIPROTEC 5 device are summed up in the following groups:



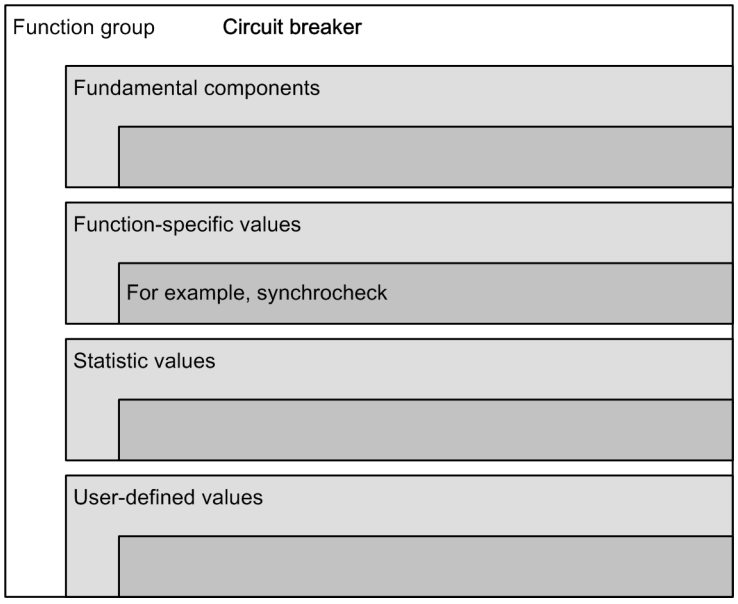
- Operational measured values
- Fundamental and symmetrical components
- Function-specific measured values
- Minimum values, maximum values, average values
- Energy metered values
- User-defined measured and metered values
- Statistic Values

10.2 Structure of the Function

Depending on the interconnection of the function groups, these can contain different measured-value groups. A typical function group is displayed below.

Voltage/Current 3-Phase Function Group Type

In the simplest version the **Voltage/Current 3-phase** function group obtains the measured values of the 3-phase voltage and current system and contains the following measured-value groups:



[dwstrciv-011012-01.tif, 1, en_US]

The **Minimum values/Maximum values/Average values** and **User-defined values** can be inserted from the library into the **Voltage/Current 3-phase** function group.

Details regarding the individual measured value groups can be found in the tables in the following chapters.

Circuit-Breaker Function Group

The **Circuit breaker** function group may contain the following measured values:

[dwomvls1-250211-01.tif, 1, en_US]

Inversion of Output-Related Measured and Statistical Values

The calculated, directional values in the operational measured values (power, power factor, energy and minimum, maximum, and average values based on these) are normally defined as positive in the direction of the protected object. This requires that the connection polarity for the measuring points used be correctly set (also compare **(_:8881:116) Neutr.point in dir.of ref.obj** parameter of the measuring point current, 3-phase). It is, however, possible, to set the "forward" direction for the protection functions and the positive direction for the powers, etc., differently, for example, such that the active power import (from the line to the busbar) is displayed positively. Then set the option **P, Q sign** in the affected function groups on the ***reversed*** parameter. With the parameter ***not reversed*** (default setting), the positive direction for the powers, etc., corresponds with the "forward" direction for the protection functions.

The affected values are given in detail in the Chapters *10.3 Operational Measured Values* - *10.11 Statistical Values of the Primary System* .

10.3 Operational Measured Values

Operational measured values are assigned to different function groups.
The values can be displayed as primary and secondary values and as percentage values.
The operational measured values are calculated according to the following definition equations:

RMS values

$$X = \sqrt{\frac{1}{T}\int_{t}^{t+T} x^2(t)dt}$$

Active power

$$P = \frac{1}{T}\int_{t}^{t+T} v(t)\,i(t)\,dt$$

Apparent power

$$S = \sqrt{3} * V * I$$

Reactive power

$$Q = \sum_{n} V_n \cdot I_n \cdot \sin(\varphi_n)$$

n Harmonic order

φ_n The angle difference between the voltage and current of the nth harmonic

Power factor

$$\lambda = \frac{|P|}{S}$$

Active power factor

$$\cos\varphi = \frac{P}{S}$$

Voltage/Current 3-Phase Function Group Type

The following table describes the operational measured values of the **3-phase voltage/current** function group.
All protection functions have access to the values.

Table 10-1 Operational Measured Values of the Voltage/Current 3-Phase Function Group

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary values
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary values
I_N	Neutral-point phase current	A	A	Rated operating current of the primary values
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of primary values/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary values
V_0	Calculated zero-sequence voltage	kV	V	Rated operating voltage of primary values/√3
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of primary values/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Active power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$

Measured Values		Primary	Secon-dary	% Referenced to
Cos φ	Active power factor	(abs)	(abs)	100 % corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Reactive power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$

NOTE

With the **`P, Q sign`** parameter in the function block **General** of the respective function group, the sign of the following measured values can be inverted:

- Active power (total): P total
- Active power (phase-related): P_A, P_B, P_C
- Reactive power (total): Q total
- Reactive power (phase-related): Q_A, Q_B and Q_C

10.4 Fundamental and Symmetrical Components

The fundamental components are calculated from the frequency-tracked instantaneous values through a Fourier filter (integration interval: one period). The results are phasor values that are described by way of the amount and phase angle.

In accordance with the transformation matrix, the symmetrical components are calculated from the voltage and current phasors. These are also phasor quantities.

Fundamental Components

Table 10-2 Fundamental Components

Values		Primary	Secondary	Phase Angle	% Referenced to
$\underline{V}_A$, $\underline{V}_B$, $\underline{V}_C$	Phase-to-ground voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_N$	Measured neutral-point displacement voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_{12}$, $\underline{V}_{23}$, $\underline{V}_{31}$	Phase-to-phase voltage	kV	V	°	Rated operating voltage of the primary values
$\underline{I}_A$, $\underline{I}_B$, $\underline{I}_C$	Phase currents	A	A	°	Rated operating current of the primary values
$\underline{I}_N$	Neutral-point phase current	A	A	°	Rated operating current of the primary values

Symmetrical Components

Table 10-3 Symmetrical Components

Values		Primary	Secondary	Phase Angle	% Referenced to
$\underline{V}_0$	Zero-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_1$	Positive-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_2$	Negative-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{I}_0$	Zero-sequence component of the current	A	A	°	Rated operating current of the primary values
$\underline{I}_1$	Positive-sequence component of the current	A	A	°	Rated operating current of the primary values
$\underline{I}_2$	Negative-sequence component of the current	A	A	°	Rated operating current of the primary values

10.5 Average Values

10.5.1 Function Description of Average Values

Average values can be formed based on different measurands:

- Operational measured values
- Symmetrical components

Through the settings, you can set how and when the average values are formed. The settings describe:

- Time slot over which the average value is formed
  (Parameter: **`Average calc. interval`**)
- Update interval for the display of the average values
  (Parameter: **`Average update interval`**)
- Synchronization time for establishing the date of commencement updating information, for example, at the top of the hour (hh:00) or at one of the other times (hh:15, hh:30, hh:45).
  (Parameter: **`Average synchroniz. time`**)

Average values are formed through the following measurands:

- Operational measured values except for phase-related ratings
- Amounts of the symmetrical components

You reset the average value formation via the

- Binary input >Reset average value
- DIGSI
- The integrated operation panel

NOTE

With the **`P, Q sign`** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see Chapter *10.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

- Active power (total): P total
- Reactive power (total): Q total

10.5.2 Application and Setting Notes for Average Values

The average value formation functionality is not preconfigured with the devices in the function group. If you use the functionality, you must load it from the library into the respective function group.

The following settings listed for the calculation of the average values can be set with DIGSI and at the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Average calc. interval

- Default setting: **`(_:104) Average calc. interval`** = ***`60 min`***

Parameter Value	Description
1 min to 60 min	Time slot for averaging, for example 60 minutes

Parameter: Average update interval

- Default setting: **`(_:105) Average update interval`** = ***`60 min`***

Parameter Value	Description
1 min to 60 min	Update interval for displaying the average value, for example 60 minutes

Parameter: Average synchroniz. time

- Default setting: **(_:106) Average synchroniz. time** = ***hh:00***
  The parameter describes the synchronization time for average value formation.

Parameter Value	Description
hh:00	The parameter **Average update interval** will be effective on the full hour
hh:15	The parameter **Average update interval** will be effective 15 minutes after the full hour
hh:30	The parameter **Average update interval** will be effective 30 minutes after the full hour
hh:45	The parameter **Average update interval** will be effective 45 minutes after the full hour

NOTE

The average value calculation restarts after

- Changing one of the 3 settings for the average-value calculation
- Resetting the device (initial or normal reset)
- Changing the time
- Resetting the average values

The average values are reset immediately. The display changes to "---".

The following examples explain how to set parameters and to make a change.

Average calc. interval = **60 min**
Average update interval = **30 min**
Average synchroniz. time = ***hh:15***.

A new average value is formed every 30 min, at hh:15 (15 min after the top of the hour) and hh:45 (15 min before the top of the hour). All measured values obtained during the last 60 min are used for average value formation.

If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 12:15:00.

In this example, the **Average synchroniz. time** = ***hh:45*** acts as described above for = ***hh:15***.

Average calc. interval = **60 min**
Average update interval = **60 min**
Average synchroniz. time = ***hh:15***.

A new average value is formed every 60 min at hh:15 (15 min after the top of the hour). All measured values obtained during the last 60 min are used for average value formation.

If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 12:15:00.

Average calc. interval = **5 min**
Average update interval = **10 min**
Average synchroniz. time = ***hh:00***.

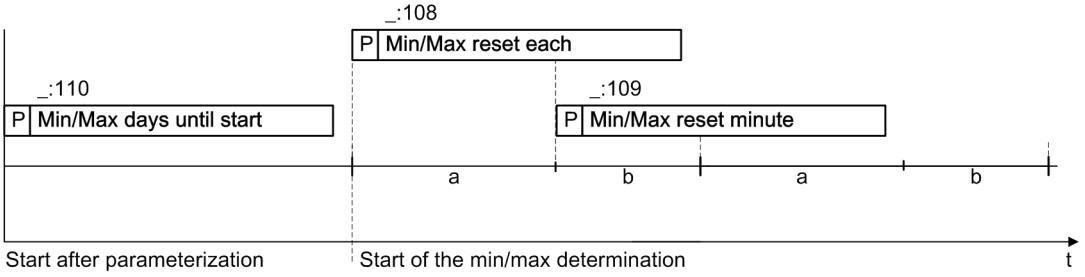
A new average value is formed every 10 min at hh:00, hh:10, hh:20, hh:30, hh:40, hh:50. All measured values obtained during the last 5 min are used to form the average value.

If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 11:10:00.

10.6 Minimum/Maximum Values

10.6.1 Function Description of Minimum/Maximum Values

Minimum and maximum values can be formed based on different measured or calculated measurands:



- Operational measured values
- Symmetrical components
- Selected values

You can set which measurand will be used. The measurands for the minimum/maximum formation are loaded from DIGSI.

Calculation and resetting of the minimum and maximum values are controlled through settings. The settings describe the following points:

- Memories of the minimum/maximum values are reset to 0 cyclically or not at all.
  (Setting **`Min/Max cyclic reset`**)
- Point in time when the memories of the minimum/maximum values are reset to 0.
  (Setting **`Min/Max reset each`** and setting **`Min/Max reset minute`**)
- Point in time at which the cyclical reset procedure of the minimum/maximum values begins (after the parameterization)
  (Setting **`Min/Max days until start`**)

The following figure shows the effect of the settings.

[dwminmax-100611-01.tif, 1, en_US]

Figure 10-2 Minimum and Maximum-Value Formation

Minimum and maximum values are time-stamped.

Minimum/maximum values are formed through:

- Operational measured values except for phase-related ratings
- Amounts of the symmetrical components
- Average values

The minimum and maximum values are reset on a regular basis or via the

- Binary input >Reset min/max
- DIGSI
- The integrated operation panel

NOTE

With the **P, Q sign** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see Chapter *10.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

- Minimum/maximum values of the active and reactive power:
  Min:Ptotal, Max:Ptotal, Min:Qtotal, Max:Qtotal
- Minimum/maximum values of the average values of the active and reactive power:
  AverageMin:Ptotal, AverageMax:Ptotal, AverageMin:Qtotal, AverageMax:Qtotal

10.6.2 Application and Setting Notes for Minimum/Maximum Values

The minimum/maximum values functionality is not preconfigured. If you want to use the functionality, you must load it from the library into the respective function group.

The following settings listed for the calculation of the minimum/maximum values can be set with DIGSI or at the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Min/Max cyclic reset

- Default setting: **(_:107) Min/Max cyclic reset** = ***yes***

Parameter Value	Description
Yes	Cyclical resetting of the minimum and maximum value memories is activated
No	Cyclical resetting of the minimum and maximum value memories is deactivated None of the following parameters are visible

Parameter: Min/Max reset each

- Default setting: **(_:108) Min/Max reset each** = ***1 day***

Parameter Value	Description
1 day to 365 days	Resetting of the minimum value and the maximum value, cyclically on all specified days, for example each day (1 day)

Parameter: Min/Max reset minute

- Default setting: **(_:109) Min/Max reset minute** = ***0 min***

Parameter Value	Description
0 min to 1439 min	Resetting the minimum value and the maximum value at the specified minute of the day, which is stated in the parameter **Min/Max Reset takes place every**, for example 0 min (= 00:00)

Parameter: Min/Max days until start

- Default setting: **(_:110) Min/Max days until start** = ***1 day***:

Parameter Value	Description
1 day to 365 days	Indication of when the cyclical reset procedure of the minimum values and maximum values begins, for example in 1 day (after the parameterization)

10.7 Energy Values

10.7.1 Function Description of Energy Values

The device continually determines the values for the active and reactive energy from the power-measured values. It calculates the exported and imported electrical energy. The calculation (summation over time) begins immediately after the device startup. You can read the present energy values on the device display or through DIGSI, delete the energy value (set to 0), or set it to any initial value. After input, the energy-value calculation will continue with the new setting values.

Energy values can be transferred to a control center through an interface. The energy values are converted into energy metered values. Here the following applies:

$$\text{Energy metered value} = \frac{\text{Energy value}}{S_{N,obj.}} \cdot 60000 \frac{\text{Pulses}}{\text{h}}$$

[foomverg-020311-01.tif, 1, en_US]

Through the settings, you set how the metered values are processed. The setting parameters apply for all energy metered values of the device, and do not have a function-group specific effect. You determine the following points:

- Parameter **`Energy restore time`**

  Hour-related point in time; at this point in time, the device will provide a metered value at the communication interface for transmission. After this, it will be transferred in accordance with the selected log.

  Note: If the parameter is activated through a time setting, the parameter **`Energy restore interval`** will automatically be deactivated.

- Parameter **`Energy restore interval`**

  Adjustable period in minutes until the first and every further transfer of the metered value to the communication interface of the device. After this, it will be transferred in accordance with the selected log.

  Note: The transfer interval is used alternatively to the transfer time, and deactivates the set transfer time. The display of the device is always up to date.

  You will find these parameters in the device settings under **measured values**.

In addition, restoring can be triggered via a routable binary input (*`>Restoring`*). The rising edge of the binary input leads to restoring, that is, provision of the energy-metered value at the communication interface.

The metered-value memory and the energy values can be set to 0 via a binary input (*`>Resetting`*) if there is a rising edge.

Note: The binary inputs affect all energy/energy metered values simultaneously.

The following energy values are available:

Energy Values		**Primary**
Wp+	Active energy, output	kWh, MWh, GWh
Wp-	Active energy, input	kWh, MWh, GWh
Wq+	Reactive energy, output	kvarh, Mvarh, Gvarh
Wq-	Reactive energy, input	kvarh, Mvarh, Gvarh

In compliance with IEC 61850, when individually measured values are missing, the quality of the energy-metered values changes to the state **Questionable**.

This quality state is retained until a new meter content is specified for the energy value by:

- Confirmation of the current meter content via **Set**
- **Setting** a new meter content
- **Resetting** the meter content to 0

NOTE

With the **P, Q sign** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see Chapter *10.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

- Active energy, output: Wp+
- Active energy, input: Wp-
- Reactive energy, output: Wq+
- Reactive energy, input: Wq-

10.7.2 Application and Setting Notes for Energy Values

The set parameters apply for all electricity meters of the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Energy restore interval

- Default setting: **(_:111) Energy restore interval** = ***10 min***

Parameter Value	Description
0 min	Restoring deactivated
60 min	Cyclical restoring after the set time 1 minute to 60 minutes

Note: If the parameter is activated through a time setting, the parameter **Energy restore time** is not in effect and will be deactivated automatically.

Parameter: Energy restore time

- Default setting: **(_:112) Energy restore time** = **--**

Parameter Value	Description
--	Deactivated
hh:00	Restoring on the full hour
hh:15	Restoring 15 minutes after the full hour
hh:30	Restoring 30 minutes after the full hour
hh:45	Restoring 45 minutes after the full hour

Note: If the parameter is activated through a time setting, the parameter **Energy restore interval** is not in effect and will be deactivated automatically.

Parameter: Energy restore

- Default setting: **(_:120) Energy restore** = ***latest value***

Parameter Value	Description
latest value	Restoring of the current energy value
delta value	Restoring the difference value between the current energy value and the energy value of the last restoring operation

Parameter: Energy restore by A.time

- Default setting: **(_:121) Energy restore by A.time** = ***Wrong***

Parameter Value	Description
Wrong	Restoring deactivated

Parameter Value	Description
True	The cyclic restoring after the set time of the parameter **(_:111) Energy restore interval** will be synchronized with the system time as well. Example: **Energy restore interval** = 30 min; current system time: 12:10 o'clock. First restore: 12:30 o'clock; next restore: 13:00 o'clock etc.

Note: If the parameter is activated, the following setting values are possible for the parameter **(_:111) Energy restore interval** : 1 min; 2 min; 3 min; 4 min; 5 min; 6 min; 10 min; 12 min; 15 min; 20 min; 30 min; 60 min.

Input Signals: >Restoring and >Resetting

Binary Inputs	Description
>Restoring	The restoring of the metered values is initiated via a binary input.
>Reset	The metered value memory is set to 0 through the binary input.

You route these logical signals in the DIGSI routing matrix. Open the function group, for example, Line, where you created the energy value. Under the tab **Measured values** you will find the tab **Energy, 3-phase**. In this tab, you will find the logical signals in addition to the measured values.

10.8 User-Defined Metered Values

10.8.1 Pulse-Metered Values Function Description

NOTE

You can define additional metered values through DIGSI for user-specific applications.

Use pulse meters; then you can define the respective metered values through DIGSI and set parameters for them analogously to the energy values. You can read out the metered values on the display of the device or via DIGSI.

Through settings, you can individually set how each pulse-metered value is processed:

- Parameter **`Restore time`**

  Hour-related point in time when the device will provide a metered value at the communication interface for transmission. After this, the transfer takes place in accordance with the selected protocol.

  Note: If the parameter is activated through a time setting, the parameter **`Restore interval`** will automatically be deactivated.

- Parameter **`Restore interval`**

  Adjustable period in minutes until the first and every further transfer of the metered value to the communication interface of the device. After this, it will be transferred in accordance with the selected log.

  Note: If the parameter is activated through a time setting, the parameter **`Restore time`** will automatically be deactivated.

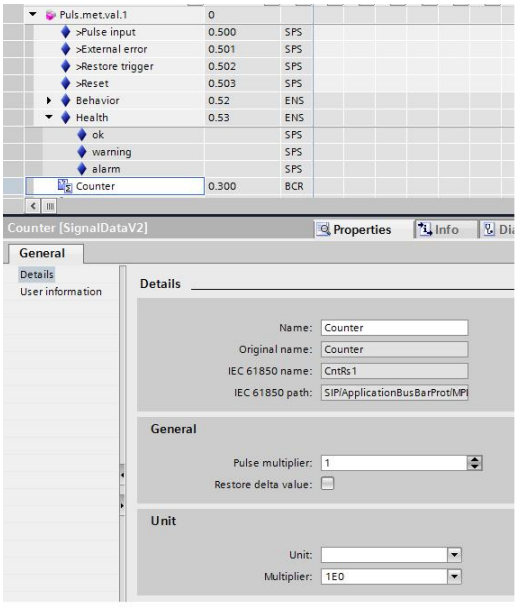
In addition, restoring can be triggered via a routable binary input (**`>Restore trigger`**) or via a logical internal binary input. The rising edge of the binary input leads to restoring and thus to provision of the metered value at the communication interface.

The counter pulse of any external/internal pulse generator is connected to the device via a routable binary input (**`>Pulse input`**). If this does not deliver any plausible values, this can be signaled to the device via another routable binary input (**`>External error`**).

In compliance with IEC 61850, in the event of an external error, the quality of the pulse-metered value changes to the state **Questionable**. No more pulses are added as long as the external error persists. Once the external fault condition has been cleared, pulses are added again.

The quality of the pulse-metered value remains **Questionable** until a new meter content is specified for the pulse-metered value by:

- Confirmation of the current meter content via **Setting**
- **Setting** a new meter content
- **Resetting** the meter content to 0



- Parameter **`Edge trigger`**

  Through settings, you can select between counting only with a rising edge or with rising and falling edges on the pulse input.

The pulse counter can be reset to 0. You can perform this resetting via the rising edge of a routable binary input (**`>Reset`**) or via operation on the device.

To display the counting amount at the device display, use DIGSI to set the desired weighting of the counter pulses, the unit of the metered value and a multiplication factor for every pulse generator. You can also assign a user-specific name.

To do this, open the functional area **Pulse-metered value** in DIGSI information routing. (see *Figure 10-3*). Select the metered value and enter the settings under **Properties**.

[scomvimp-010313-01.tif, 2, en_US]

Figure 10-3 Setting with DIGSI, General Settings, Pulse-Metered Values

10.8.2 Application and Setting Notes for Pulse-Metered Values

The functionality **Pulse-metered values** is not preconfigured. If you want to use the functionality, you must load it from the library into the respective function group.

The parameters can be set individually for every pulse counter. You will find the setting parameters in DIGSI in the project tree under **Parameter > Function group**

For pulse-metered values, the following described settings and binary inputs are available.

Parameter: `Restore time`

- Default setting: **`(_:101) Restore time`** = **`--`**

Parameter Value	Description
--	Deactivated
hh:00	Transfer on the full hour
hh:15	Transfer 15 minutes after the full hour Note:
hh:30	Transfer 30 minutes after the full hour Note:
hh:45	Transfer 45 minutes after the full hour Note:

Note: If the parameter is activated through a time setting, the parameter **`Restore interval`** is not in effect and will be deactivated automatically.

Parameter: `Restore interval`

- Default setting: **`(_:102) Restore interval`** = ***`0 min`***

Parameter Value	Description
0 min	Deactivated
1 min to 60 min	Cyclical transfer after the set time 1 minute to 60 minutes

Note: If the parameter is activated through a time setting, the parameter **Restore time** is not in effect and will be deactivated automatically.

Parameter: Edge trigger

- Default setting: **(_:103) Edge trigger** = ***rising edge***

Parameter Value	Description
rising edge	Counting with rising edge at the pulse input
rising & falling edge	Counting with rising and falling edge at the pulse input

Parameter: Restore by absolute time

- Default setting: **(_:104) Restore by absolute time**= ***False***

Parameter Value	Description
False	Deactivated
True	The cyclic restoring of setting **Restore interval** after the set time is also synchronized with the system time. Example: **Restore interval** = 30 min; current system time: 12:10 o'clock. First restoring operation: 12:30 o'clock; next restoring operation: 13:00 o'clock, etc.

Input Signals: >Pulse input, >External error, >Restore trigger, >Reset

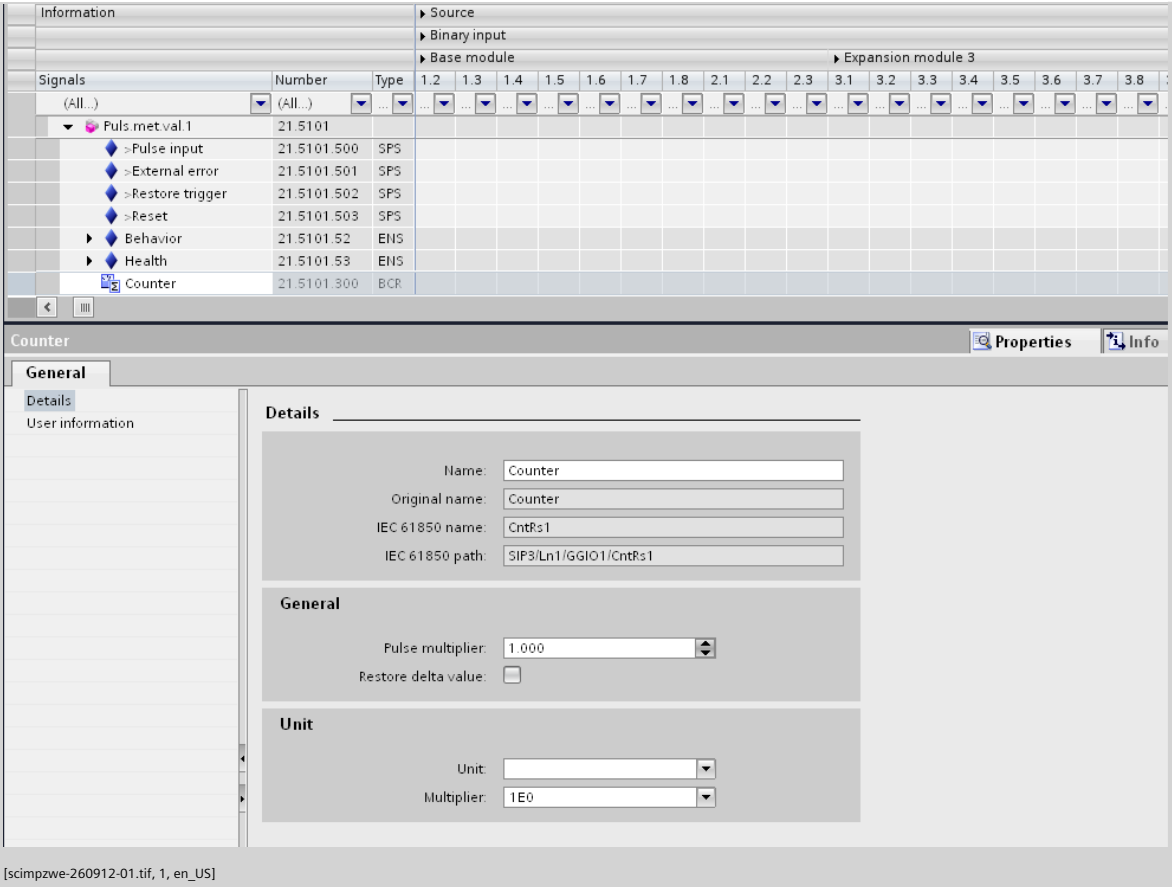
Binary inputs	Description
>Pulse input	Input for the counting pulses of an external pulse generator
>External error	Indication that the counter pulses of the external pulse generator are faulty. The indication has an effect on the quality identifier of the pulse value.
>Restore trigger	The transfer of the metered values is initiated via a binary input.
>Reset	The rising edge at the binary input resets the pulse counter to 0.

The amount of energy indicated by a pulse generator is to be displayed as a measured value.

1 pulse corresponds to 100 Wh.

The pulse weighting, the SI unit, and the factor must be adjusted to one another.

Display value = Calculated metered value * Pulse weighting * Factor * SI unit.



If the check box **Restore delta value** is activated, the differential value is transferred at the restore time set via the communication interface. The difference value is formed by subtracting the counter content of the last restoring operation from the current counter content.

You route the logical signal ***>Pulse input*** to a binary input to which the pulse generator is connected.

Set the following values:

Name	Active Power Meter
Pulse weighting	100
Restore differential value	Activated
SI unit	Wh
Factor	1

The factor is used for adaptation to larger units (for instance, 1000 for kWh). It is adjustable in powers of ten (1, 10, 100, 1000, etc.). The following figure shows the signals that can be arranged in the DIGSI information matrix. Open the function group where you created the pulse-metered value, for example, Line 1. There, you will find the function area **Pulse-metered value**. Here you will also find the logical signals next to the metered value. Select the metered value and enter the settings under **Properties**.

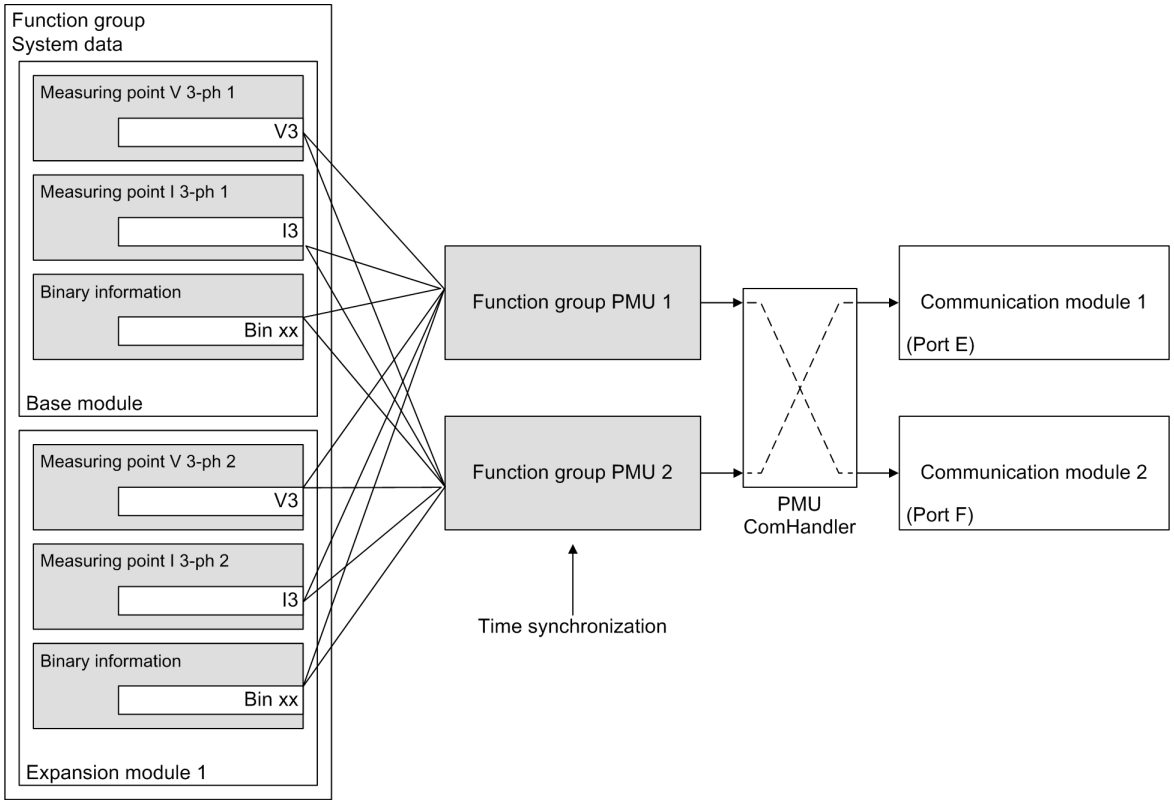
Figure 10-4 Setting with DIGSI



10.9 Phasor Measurement Unit (PMU)

10.9.1 Overview of Functions

A Phasor Measurement Unit (PMU) measures the phasor values of current and voltage. These values get a high precision time stamp and together with the values of power frequency, power frequency change rate and optional binary data that are also time stamped are transmitted to a central analysis station. The standardized transmission protocol IEEEC 37.118 is used to do this.

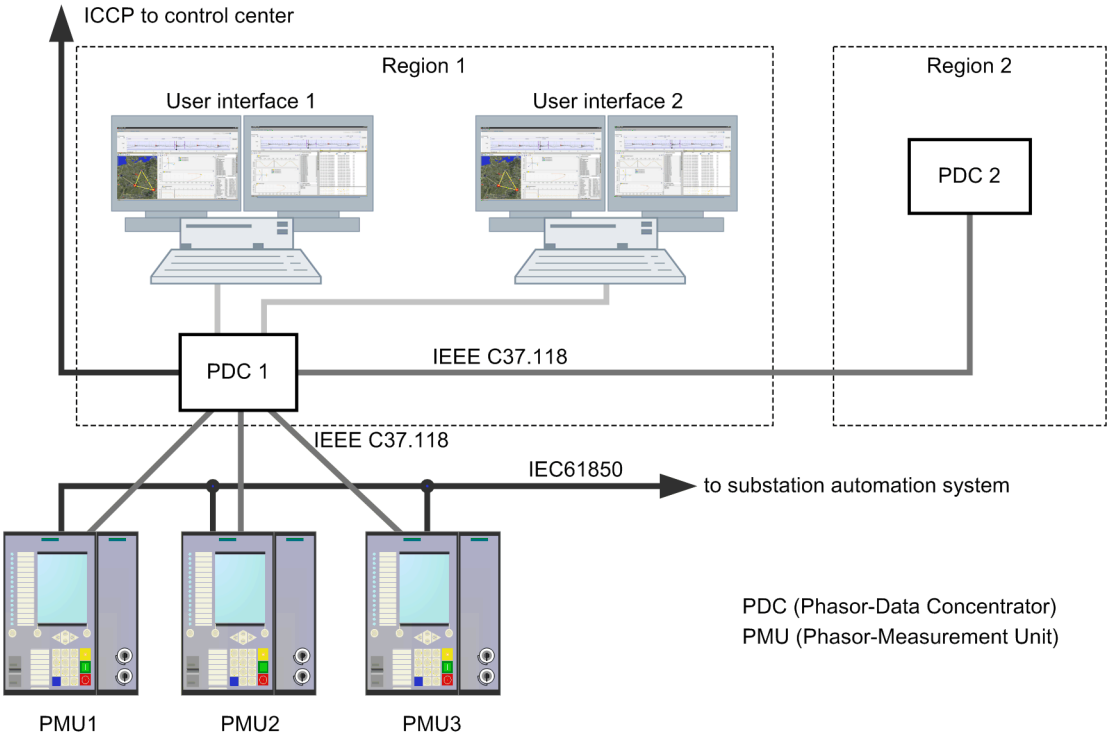
10.9.2 Structure of the Function Group

The **PMU** function group is activated by selecting the protocol *IEEE C37.118PMU* on an Ethernet module (electrical or optical). The PMU obtains the measured values from the measuring points and the precise time from time synchronization. The time-stamped synchrophasors for current and voltage are formed from this and transferred together with additional values via the communication module to a server (PDC, Phasor Data Concentrator).

[dwstrpmu-250613-01.tif, 2, en_US]

Figure 10-5 Structure/Embedding of the Function

10.9.3 Function Description



The synchrophasors, sent from the **PMU** in a continuous data stream to a PDC, are provided with time stamps and thus are comparable with the measured values of other PMUs. The power frequency, the power frequency change rate and optional binary information are also transmitted as time-stamped measured values. Therefore, you receive an overview of the transient processes in a distributed energy transfer system, for example network fluctuations and compensating processes.

The following table shows the differences between the PMU measured values and the remaining measured values of the device.

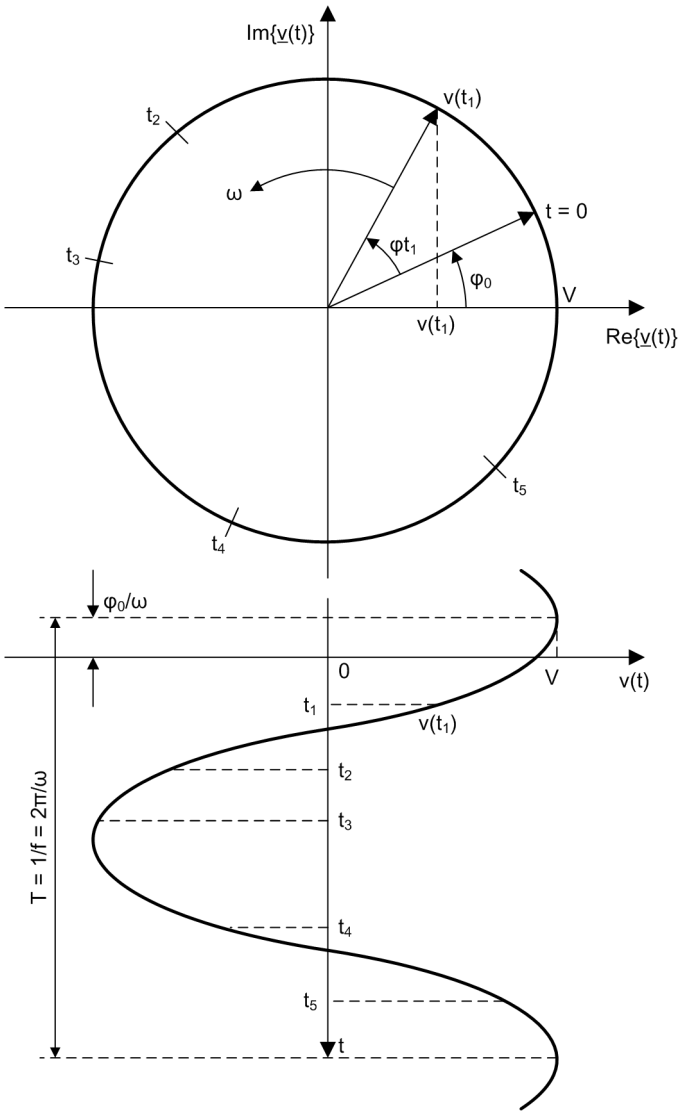
Table 10-4 Comparison of Synchrophasors and Conventional Measured Values

Synchrophasors of the PMU	Measured Values from the Measuring Points
Continuous updating (measured value of current) with, for example, 10 values per second (reporting rate)	Slow updating (typically every 5 seconds)
Every measured value has a time stamp	No time stamp for the measured values
Phasor values of current and voltage (amplitude and phase angle)	RMS values without phase angle

The following figure shows the structure of such a Wide Area Monitoring System. The data delivered from the PMUs on the PDC are transmitted via the Inter-Control Center Communications Protocol (ICCP) according to DIN EN 60870-6 to the network control center.

[dwstrwam-120124-01.tif, 1, en_US]

Figure 10-6 Structure of a Wide-Area Monitoring System with Phasor-Measurement Units



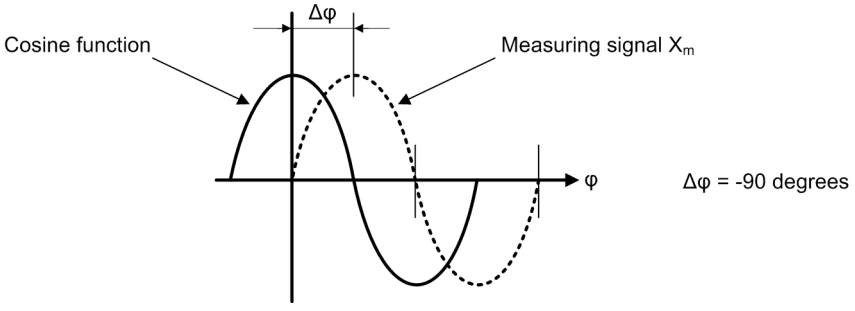
The phasor-measurement units each have 2 communication interfaces: an Ethernet module for synchrophasor communication via IEEE C37.118 and another module for communication with the substation automation technology, for example, through the IEC 61850 protocol.

The central evaluation system, e.g. SIGUARD PDP Phasor Data Processor, receives the data, files, archives them and graphically displays them on a User Interface. In this system, a self-checking function may also be performed, for example, on undamped power swings. The further distribution of information to other PDCs or to a control station is done here.

To maintain the required maximum errors (TVE) required in the standard IEEE C37.118, the time tolerance relative to the UTC time reference (UTC = Universal Time Coordinated) may be maximum 10 µs. Therefore, the device must be directly synchronized with a GPS precise time signal for the correct function of the PMU.

Phasors

A phasor $u(t) = \underline{U}e^{j\omega t}$ can be displayed as a phasor that moves counterclockwise in the complex plane at the angular frequency ω. Therefore, the voltage function $u(t) = Re\{\underline{u}(t)\}$ is obtained as a projection of the phasor $\underline{u}(t)$ on the real axis.



[dwgeopdc-061011-01.tif, 1, en_US]

Figure 10-7 Geometric Representation of a Phasor

Reference Point for Determining the Angle

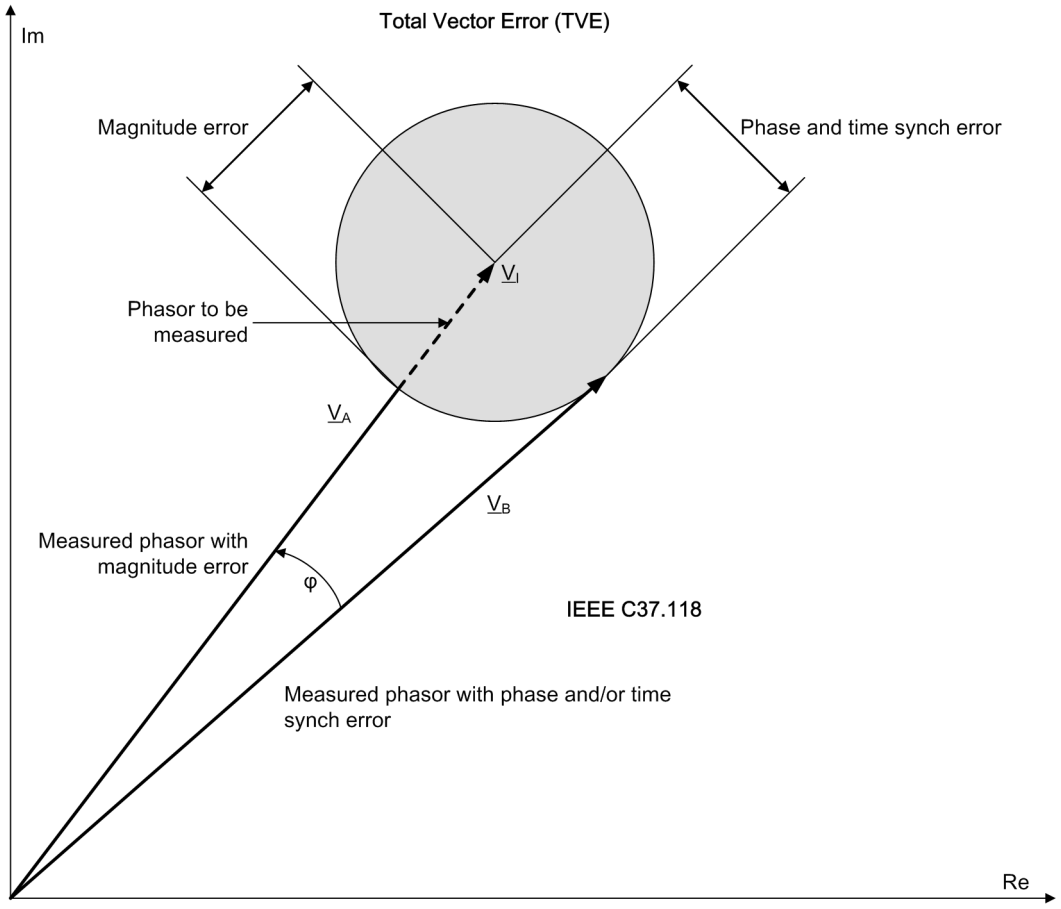
The phase angle of a measuring signal X_m is determined relative to a cosine function having a rated frequency, which is synchronized with the UTC time reference (see *Figure 10-8*).

[dwutcphi-260112-01.tif, 1, en_US]

Figure 10-8 Determination of Phase Angle ρ of Measuring Signal X_m Relative to the Cosine Function

The number of phasors that are transmitted per second is configurable. The transmission rate is defined according to IEEE C37.118 as the reporting rate. The reporting rate defines the number of phasors that are transmitted per second. Extremely precise time synchronization is essential so that phasor measurement can be carried out to enable phasors from different sites to be compared.

Reporting Rate



You use the configurable reporting rate (parameter **(_:10621:102) Reporting rate**) to specify the number of telegrams that are compiled and sent to the PDC per second. It is adjustable, depending on the rated frequency, and applies to all currents and voltages of the relevant **PMU** function group. If several **PMU** function groups are created on the device, these can work with different reporting rates.

Total Vector Error (TVE)

The TVE describes the error between the actual and the measured values of the input signal. The Synchrophasor Standard IEEE 37.118 defines upper limiting values of 120 % V_N and 200 % I_N, among other things. Up to these limiting values, the TVE of 1 % must not be exceeded for stationary signals. The standard defines the 2 performance classes, Class P and Class M, as ranges within which influencing variables are acceptable and the TVE of ≤1 % must be maintained. The SIPROTEC 5 devices support Class P and Class M, which specify the following influencing variables for a TVE of 1 %:

- Signal frequency (relative to f_N)
- Signal magnitude (relative to 100 % nominal magnitude) for voltage and current
- Phase angle (relative to 0°)
- Harmonic distortions (relative to < 0.2 % (THD) up to the 50th harmonic

The following figure graphically represents the total vector error. As well as the amplitude, the TVE also enters into the angle error.

[dwklatve-120124-01.tif, 1, en_US]

Figure 10-9 Representation of the Total Vector Error

The TVE is defined as follows:

$$TVE = \sqrt{\frac{(X_{r(n)} - X_r)^2 + (X_{i(n)} - X_i)^2}{X_r^2 + X_i^2}}$$

[fo_utcphi-111011-01.tif, 1, --_--]

where:

- $X_{r(n)}$ = Real part of measured signal
- $X_{i(n)}$ = Imaginary part of measured signal
- X_r = Real part of input signal
- X_i = Imaginary part of input signal

Variables that influence the TVE are:

- Amplitude errors
- Phase errors
- Synchronization accuracy (deviation from the UTC)

Synchronization accuracy is affected by a GPS timer and the precise correction of the time delay within the GPS receiver module, as well as by the optimal setup of the GPS antenna.

10.9.4 Transmitted Data

The following data is transmitted from the PMU to the PDC:

- Current and voltage phasors
- Frequency
- Frequency rate of change
- Binary information

The current and voltage channels transferred from a **PMU** function group are selected through the **Function group connections** editor in DIGSI 5. The frequency and frequency change rate are determined once per PMU. In this case, only the current and voltage channels selected via the **Function group connections** editor for this PMU are taken into consideration. You may route the binary information in the information routing matrix of DIGSI 5.

The channel used for specifying the frequency is selected dynamically during the device runtime. Each channel is checked for the presence of a signal in the following order:

1. 3-phase voltage measuring points
2. 1-phase voltage measuring points
3. 3-phase current measuring points
4. 1-phase current measuring points

The 1st measuring point found with a valid signal is used for specifying the frequency in the **PMU** function group.

In the case of 3-phase measuring points, the positive-sequence system can also be transmitted instead of 3 individual sychrophasors. This setting can be made via the parameter **(_:10621:103) Only positive sequence**.

10.9.5 PMU Communication (IEEE C37.118)

PMU communication according to standard IEEE C37.118 is a client-server communication format in which the PDC (Phasor Data Concentrator) functions as both the client and the server.

Once the PDC has been successfully connected to the device PMU and the PMU configuration data has been queried, the PDC initiates transmission of the synchrophasor data by sending a close command to the PMU. In addition to the phasors, the channel names of the routed measuring points and the binary information are transferred. Per default, these are automatically generated by the respective PMU function groups.

Where applicable, you can also edit the channel names of the measuring point and assign a designation of its own for this purpose. For more information, see chapter *10.9.6 Parameterizing the PMU with DIGSI*. The names for the binary information carried out are however, generally automatically generated by the respective PMU function group and cannot be edited.

As an example, the names (generated) for measuring points or binary information may be as follows:

Table 10-5 Possible Measuring-Point Names

Name Displayed in the DIGSI Function Group Connections	Depending on the Connection Type, Name Transferred to the PDC (in case it cannot be assigned automatically)
Measuring point U-3ph 1[ID 1]	MP-V3ph VAB ID01 MP-V3ph VBC ID01 MP-V3ph VCA ID01 MP-V3ph VA ID01 MP-V3ph VB ID01 MP-V3ph VC ID01 MP-V3ph V1 ID01

Name Displayed in the DIGSI Function Group Connections	Depending on the Connection Type, Name Transferred to the PDC (in case it cannot be assigned automatically)
Measuring point I-3ph 1[ID 2]	MP-I3ph IA ID02 MP-I3ph IB ID02 MP-I3ph IC ID02 MP-I3ph I1 ID02
Measuring point I-1ph 1[ID 3]	MP-I1ph ID03
Measuring point U-1ph 1[ID 4]	MP-V1ph ID03

Table 10-6 Possible Binary Information Names

Path Displayed in DIGSI 5 (Can Be Edited)	Name Transferred to the PDC (Cannot be Edited)
PMU 1: Transf.bin.1: >BinaryInfo.6	BIN-01-INFO-6
PMU 1: Transf.bin.2: >BinaryInfo.8	BIN-02-INFO-8
PMU 1: Transf.bin.10: >BinaryInfo.3	BIN-10-INFO-3

Data is transmitted continuously from the PMU to the PDC at the configured reporting rate. The transmission is terminated by a corresponding switch-off command from the PDC or when the connection between the PDC and the PMU is interrupted.

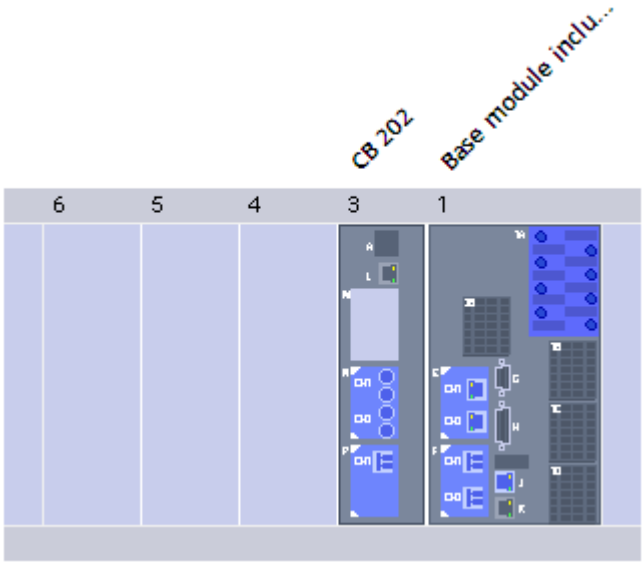
Communication between the PMU and the PDC can be passed via TCP or UDP protocols.

The following ports are used for data transmission:

- TCP: Port 4712
- UDP: Port 4713

The ports must be configured on the PDC.

Up to 3 different PDCs can be connected to one device PMU at the same time. The IP addresses of the maximum 3 PDCs are set in the **PMU** function group. If 4 device PMUs are configured, this enables support for up to 12 PDCs.



10.9.6 Parameterizing the PMU with DIGSI

You configure and parameterize the Phasor-Measurement Unit with DIGSI. After a device has been added in a DIGSI project, one or more communication modules that support synchrophasors can be configured as PMUs. The device module supports a maximum of 2 communication modules that can be configured as PMUs. If more than 2 PMUs are needed, the device must be expanded with a CB202 plug-in module assembly (expansion module), which can accommodate 2 more communication modules.

The following communication modules support synchrophasors:

- ETH-BA-2EL (2 x Ethernet electric, RJ45)
- ETH-BB-2FO (2 x Ethernet optical, 2 km, LC duplex)

These modules are then freely assignable to ports E, F, N or P of the device, see *Figure 10-10*. You can view the selected port in the **(_:10621:104) Port**. This parameter is automatically managed by DIGSI and cannot be changed.

[sccommod-140213-01.tif, 1, en_US]

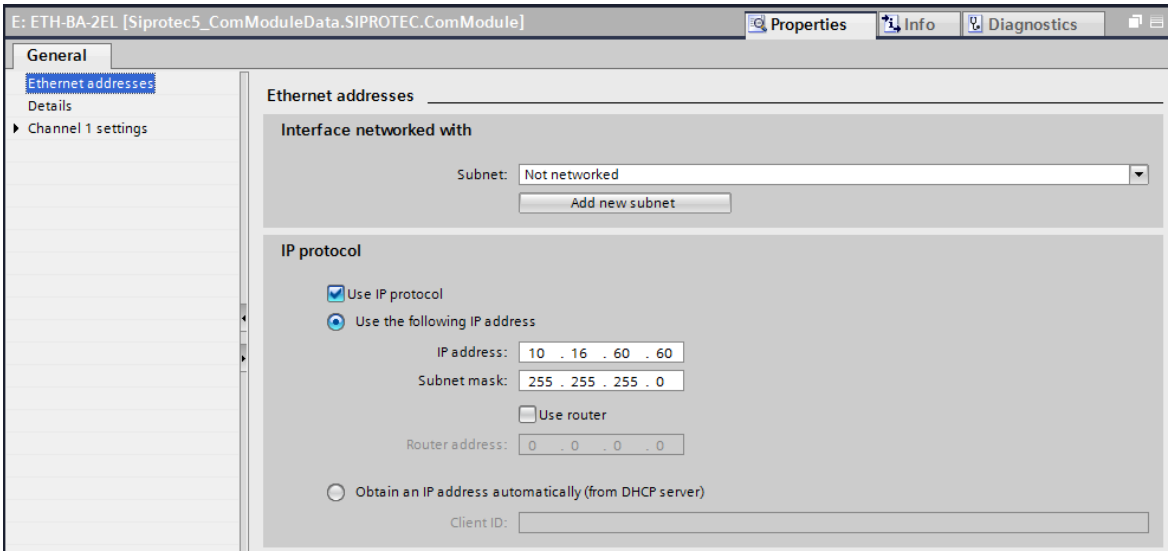


Figure 10-10 Placement of Communication Modules

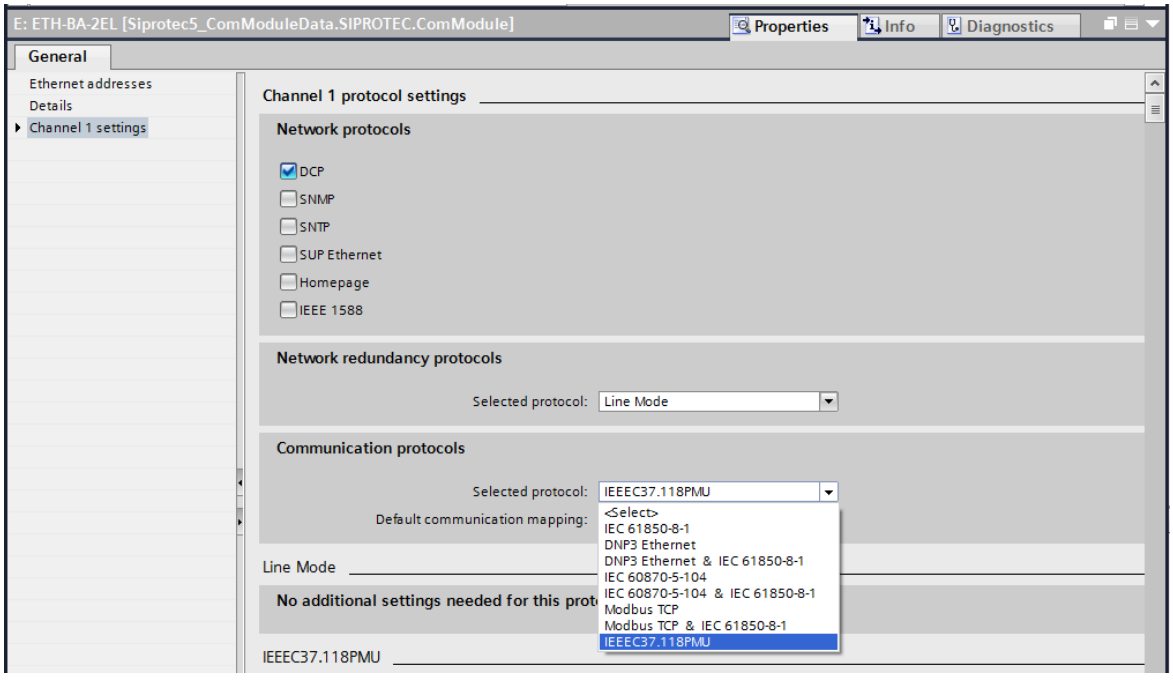
NOTE

Port M of the CB202 plug-in module assembly is used to accommodate measuring-transducer modules and cannot be used for the installation of communication modules.

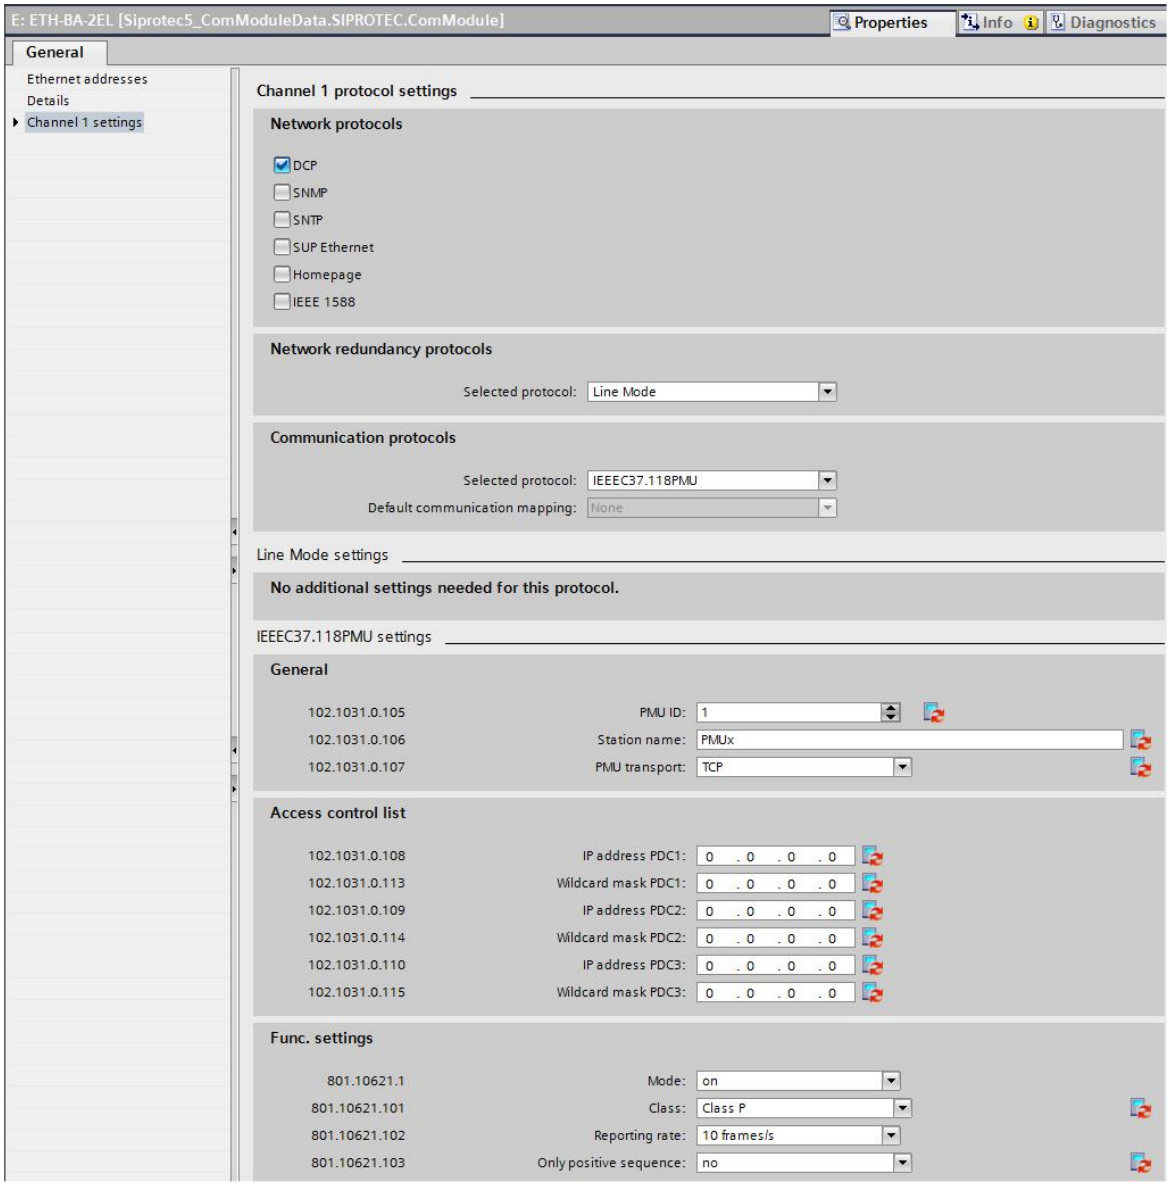
Addressing



You must configure the respective Ethernet address (IP address, subnet mask, etc.) for each communication module in DIGSI. This is done in the DIGSI **General settings** properties dialog of the communication module in item **Ethernet addresses** and so forms the IP address for the respective PMU.

[scethern-210415, 1, en_US]

Figure 10-11 Ethernet Address Configuration



In the DIGSI properties dialog for channel 1, select the synchrophasor protocol, see the following figure.

[scprotoc-210415, 1, en_US]

Figure 10-12 Protocol Selection

After you have selected the synchrophasor protocol for the communication module, an advanced settings dialog for PMU-specific configuration opens, see the following figure.

[scwildcard_de, 1, en_US]

Figure 10-13 PMU-Specific Configuration

You configure the specific settings for the communication protocol in the top section of this settings dialog. In the bottom section, you specify the corresponding PMU-specific settings.

In order to permit a better configuration of larger wide-area supervision systems, changes have been implemented in the IEEE C37.118 communication configuration that permit a flexible IP configuration without the loss of safety aspects in the systems administrated.

Configurable placeholders are permitted for each PDC IP address. These placeholders allow you to define a range of IP addresses where they are accepted within these accesses. The purpose of this is to permit each individual device or system access within the respective system without limits with regard to their hierarchy level. Therefore, with regard to security aspects, the limitation to individual IP addresses is eliminated. You are thus allowed to configure complete sections of IP addresses in each PMU and, as a result, very flexible when making changes to the configuration of the entire system, for example. The placeholder character must follow consecutively at the bit level, starting with the bit with the lowest value.

EXAMPLE of Placeholder Characters:

Example 1:

- binary 00000000.00000000.00000000.00101011 is not permitted
- binary 00000000.00000000.00000000.00111111 is permitted

Example 2:

- The PDC IP address is: 192.172.16.1
- Placeholder: 0.0.0.127

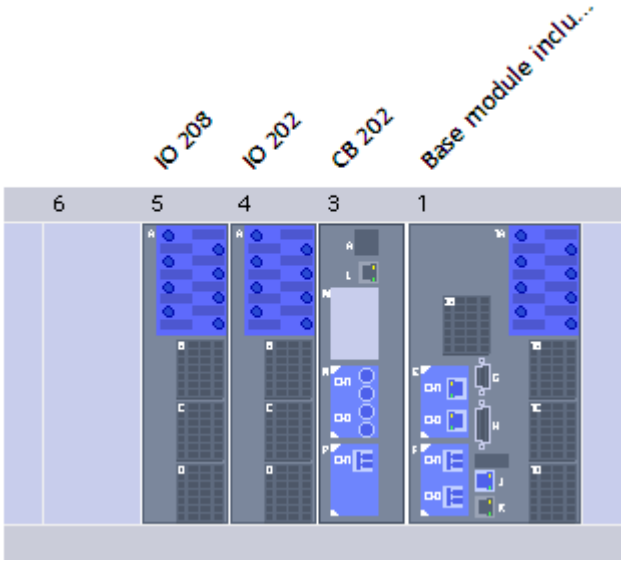
The device accepts requests within the IP address range of 192.172.16.1 to 192.172.16.127.

Example 3:

- The PDC IP address is: 192.172.16.100
- Placeholder: 0.0.0.3

The device accepts requests within the IP address range of 192.172.16.100 to 192.172.16.103.

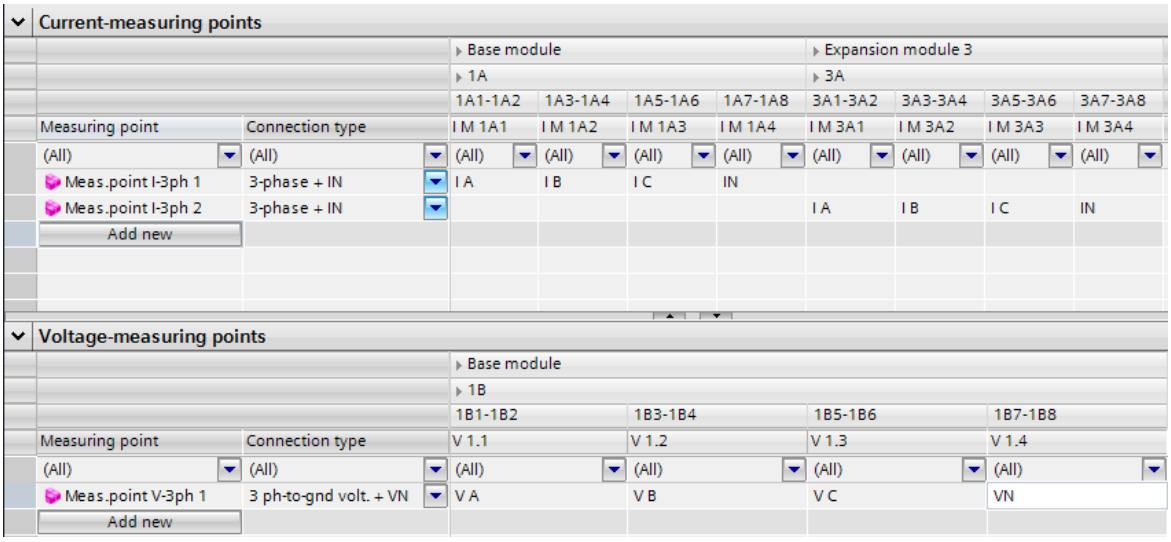
If a PDC attempts to establish a connection to the device, the PDC IP addresses and corresponding placeholders are checked in the same order as they had been configured (IP address PDC1, IP address PDC2, IP address PDC3). Running through the list is stopped with the first match of the IP address, placeholder and requested IP address range and the connection is built-up. If there are no matches, the attempt to connect is rejected.



If you have configured IP address 0.0.0.0 and the placeholder 255.255.255.255, every IP address received is accepted as valid. This could be of use in the course of commissioning measures.

NOTE

You must have configured at least 1 IP address in order to establish a connection between the device and PDC.

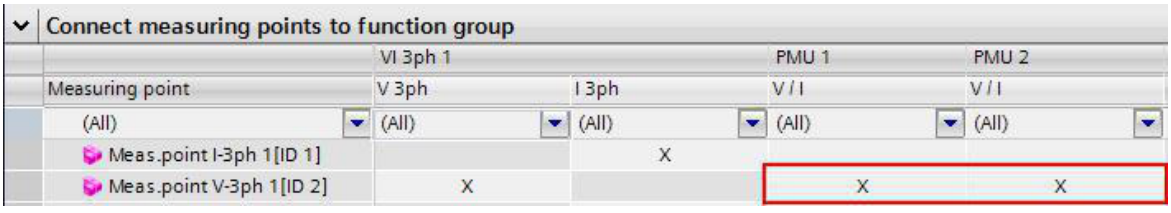


Measuring-Point Assignment

After adding measuring points to the device, you can assign these measuring points to each configured PMU. *Figure 10-14* shows as an example expansion of the device configuration by 2 additional input/output modules. You connect the current and voltage inputs of these I/O modules to measuring points via the DIGSI routing matrix, see example in *Figure 10-15*.

[scaddios-140213-01.tif, 1, en_US]

Figure 10-14 Adding Additional Input/Output Modules



[scroutin-210415, 1, en_US]

Figure 10-15 Assignment of the Current and Voltage Inputs of the Added Input/Output Modules on Measuring Points

The maximum numbers of measuring points that can be routed for one PMU are:

- 2 x 3-phase voltage measuring points
- 2 x 3-phase current measuring points
- 2 x 1-phase voltage measuring points
- 2 x 1-phase current measuring points

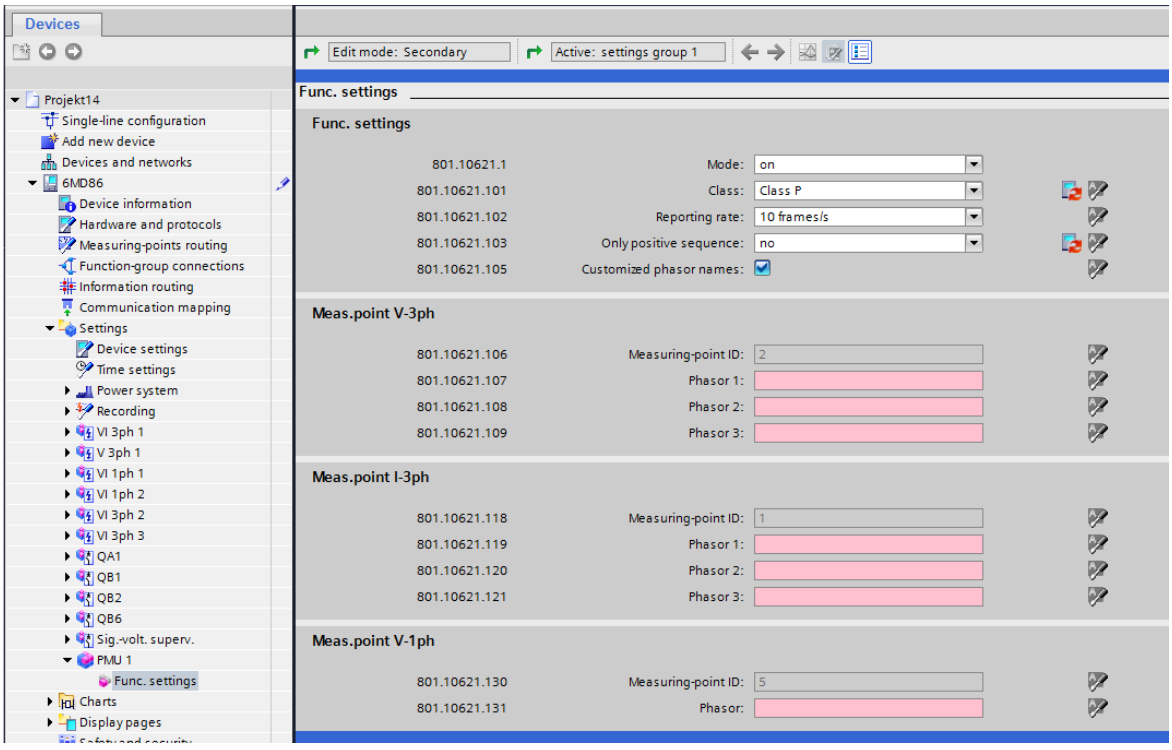
You can assign all supported measuring points to any PMU, see the following figure. However, each PMU must be connected to a 3-phase voltage measuring point.

[scfgconn-210415, 1, en_US]

Figure 10-16 Connecting Measuring Points to the Configured PMU Function Groups

When these setting steps have been completed, the PMUs are fully configured. The **PMU** is a function group that functions independently of all the other function groups instantiated in the device.

The device load, however, is dependent on:



- Number of PMUs
- Performance class (where Class M generates the greater load)
- Number of assigned channels
- Configured reporting rate of each PMU
- Number of binary signals to be transferred

Changing the Channel Names of Phasors

You can edit the names of the individual phasor channels for voltage and current in DIGSI. The clearly structured channel designations assist with when testing and commissioning PMU systems. Furthermore, only the names visible in the IEEE C37.118 interface can be changed. The function block designations themselves cannot.

The IEEE C37.118 defines the ASCII character set for changing the channel names in the scope of the SIPROTEC 5-PMU support. Due to the protocol, the designation length is limited to 16 ASCII characters per channel. However, when renaming, you have to assign at least 1 character. The renaming of binary channels is not supported in the current implementation.

You can start the renaming by setting the check mark at **Own phasor names** with the parameterization in the PMU function block **Functional settings**. Once you have activated this check mark, define a separate name for each phasor. For this purpose, DIGSI shows all routed measuring points on the PMU in the function group connections (see following figure).

[scPMUnam_de, 1, en_US]

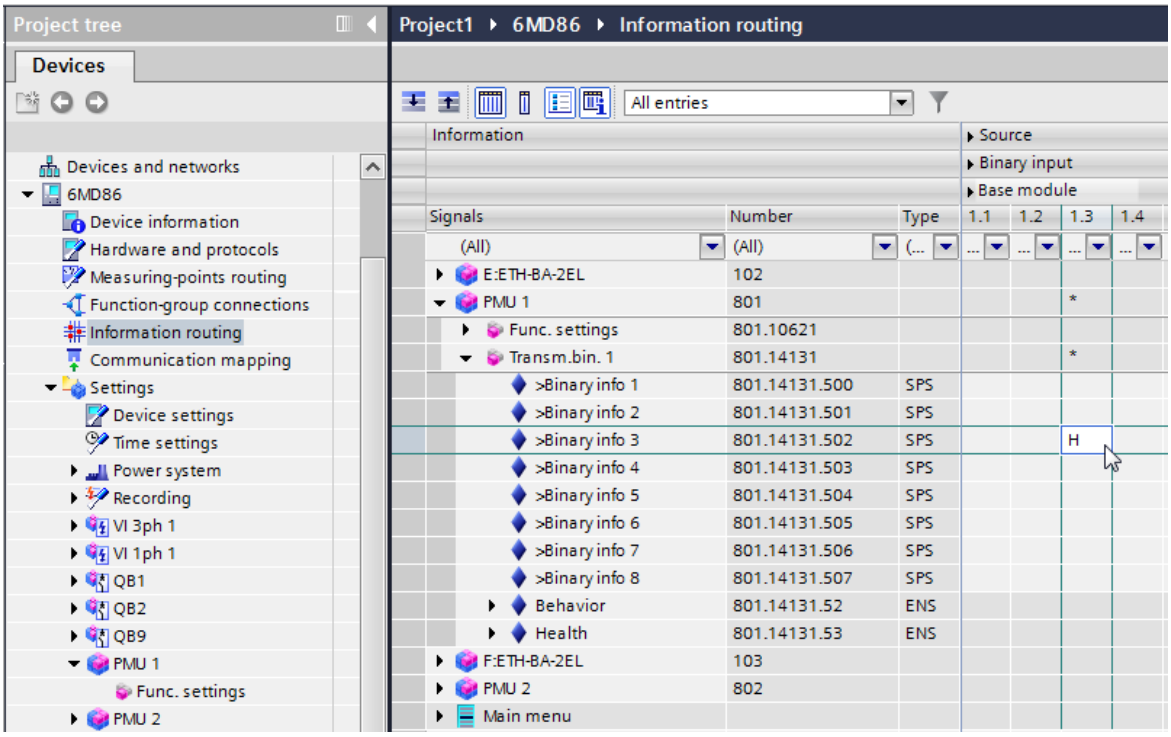


Figure 10-17 Options for Editing the Names of the Individual Phasors

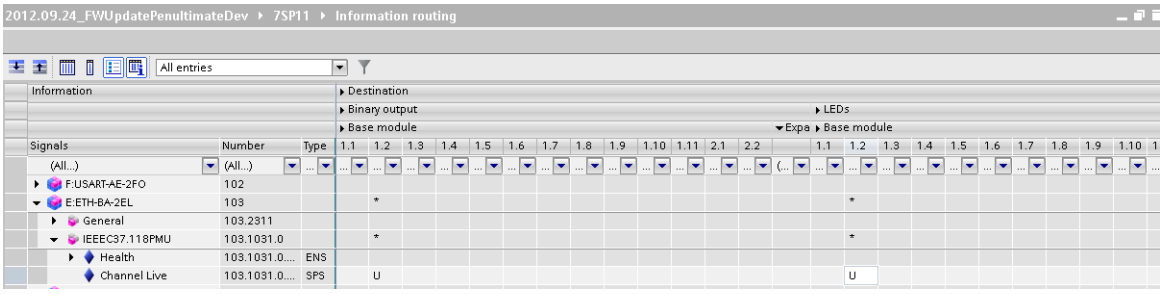
NOTE

You can only rename each individual phasor when you set the parameter **Positive-sequence system only** to ***No*** in the functional settings. Otherwise you will only be offered one single phasor for each 3-phase measuring point for renaming.

Routing Binary Signals

You can connect binary inputs or CFC information with binary channels of the PMU via DIGSI information routing. You will find, in the **Phasor Measurement Unit (PMU)** folder, the **Binary information transmission** function block in the DIGSI function library (see the following figure). You can instantiate this function block up to 10 times in one **PMU** function group. Each of these function blocks contains 8 options for routing binary channels.



[scpmubif-210415, 1, en_US]

Figure 10-18 Information Routing in DIGSI 5

Routing Indications

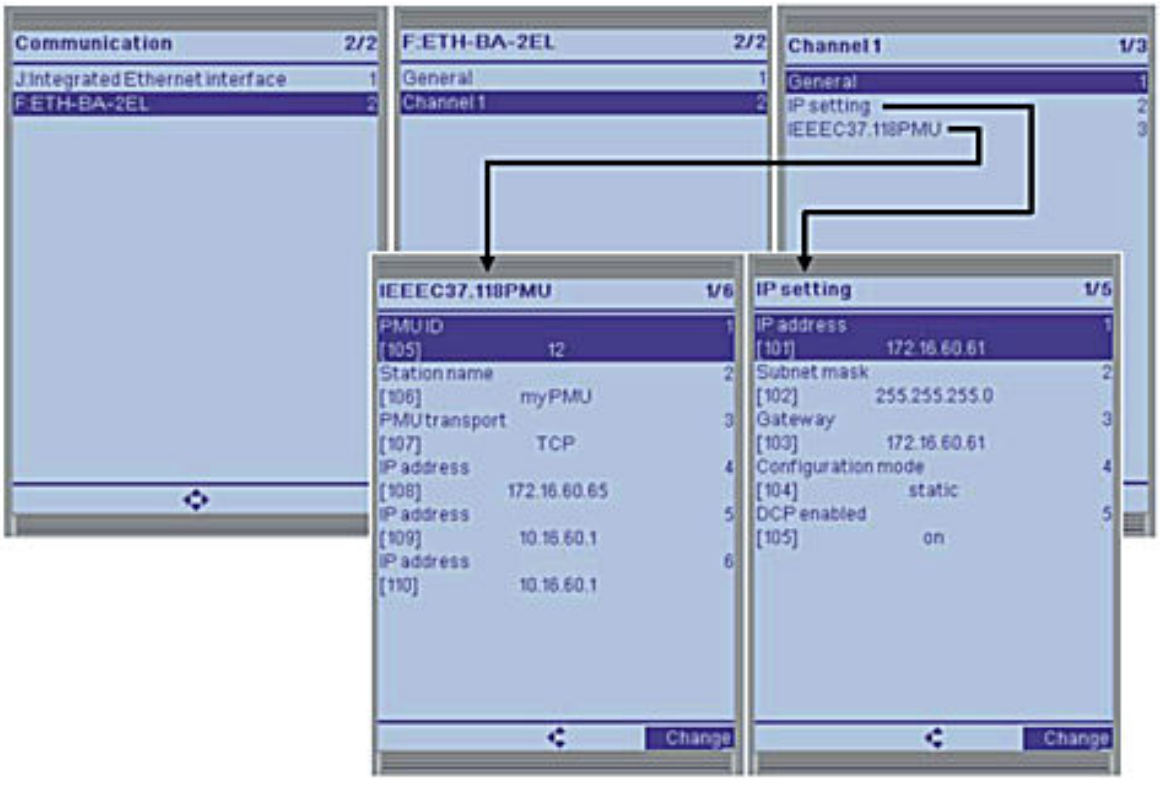
The routable indication *ChannelLive* of the PMU log

- raises when the PMU is connected to the PDC
- clears when the connection to the PDC is interrupted.

[scparami-260912-01.tif, 1, en_US]

Figure 10-19 Log Indication for Display of the PMU/PDC Connection

10.9.7 Parameterizing the PMU on the Device

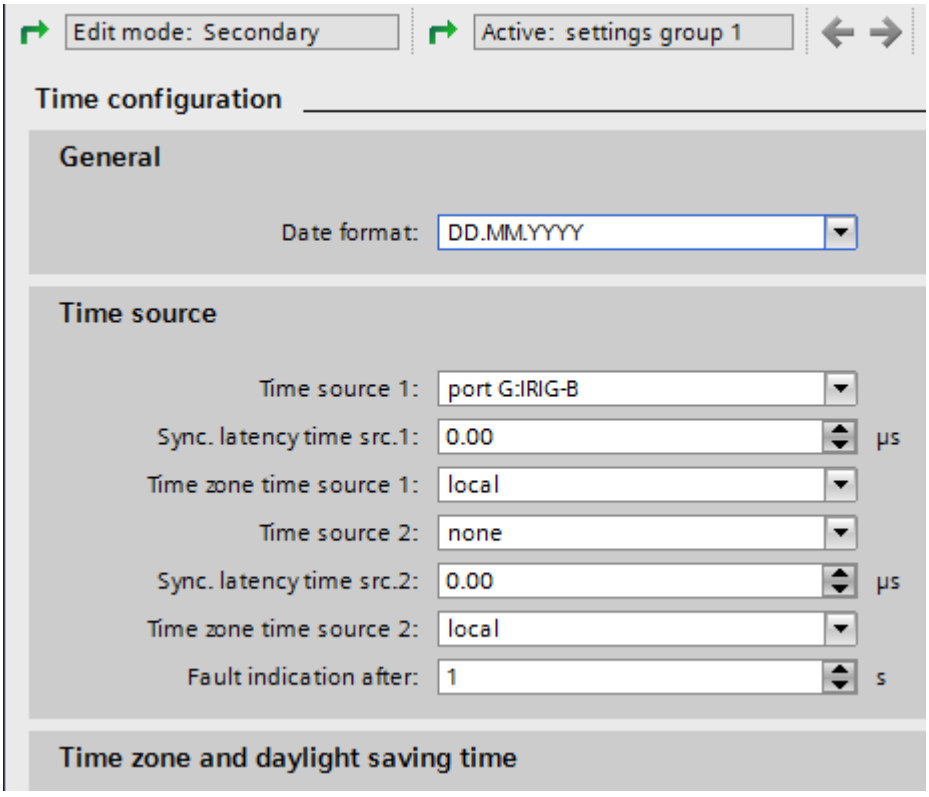


You can also change the PMU settings directly on the device. To do this, select the desired PMU instance on the device display. By selecting menu item **Settings** you then access the editable setting values (see *Figure 10-20*). Note that the parameter **Port** cannot be changed, because this corresponds to the physical slot position of the communication module in question.

[scdevpmu-210415, 1, en_US]

Figure 10-20 Changing the PMU Setting Values via the Device Display

You can also change the communication settings in the same way. To do this, select the corresponding communication port in the **Communication** menu on the device display. From the **Channel 1** menu item, you can then access the detailed setting options for the IP or PMU communication settings (see *Figure 10-21*).



[scdevcom-210415, 1, en_US]

Figure 10-21 Changing the Communication Setting Values Via the Device Display

10.9.8 Application and Setting Notes

Time Synchronization

In order to ensure the time accuracy of the PMU, you must select **IRIG-B** as protocol for the GPS clock, see the following figure. With other settings, the **PMU function** function group indicates that it is not time synchronized.

[sc_setting time source_2014-09-09, 1, en_US]

Figure 10-22 Setting Time Synchronization

To detect a lack of synchronization quickly, also set the waiting time for the failure indication of the loss of time synchronization to the smallest possible value, thus to 1 s.

Parameter: Mode

- Default setting **(_:10621:1) Mode** = ***on***

Activate and deactivate the PMU or switch to Test mode via the parameter **Mode**. The possible setting values are ***on***, ***off*** and ***test***. In Test mode, the PMU data is marked as invalid.

Parameter: Reporting rate

- Default setting **(_:10621:102) Reporting rate** = ***10 frames/s***

With the parameter **Reporting rate**, you specify the number of telegrams that are compiled and sent to the PDC per second.

NOTE

Different setting values are shown or hidden, depending on the rated frequency set.

Parameter: Only positive sequence

- Default setting **(_:10621:103) Only positive sequence** = ***no***

With the parameter **Only positive sequence**, you set whether the positive-sequence system is to be transmitted instead of 3 individual synchrophasors in the case of 3-phase measuring points. The setting you make here is then valid for all PMUs with 3-phase measuring points.

Parameter: Class

- Default setting **(_:10621:101) Class** = ***Class P***

With the setting **Class**, you set which performance class is used for the calculation of the measured values. ***Class P*** is the standard case for PMUs. In this case, filters are used that are suitable for a short response time and therefore are well suited for recording dynamic processes. ***Class M*** is conceived for applications that are unfavorably affected by alias effects and in which short response times are not relevant.

Parameter: Port

This parameter cannot be set because the **Port** results from the physical position where the corresponding communication module is inserted.

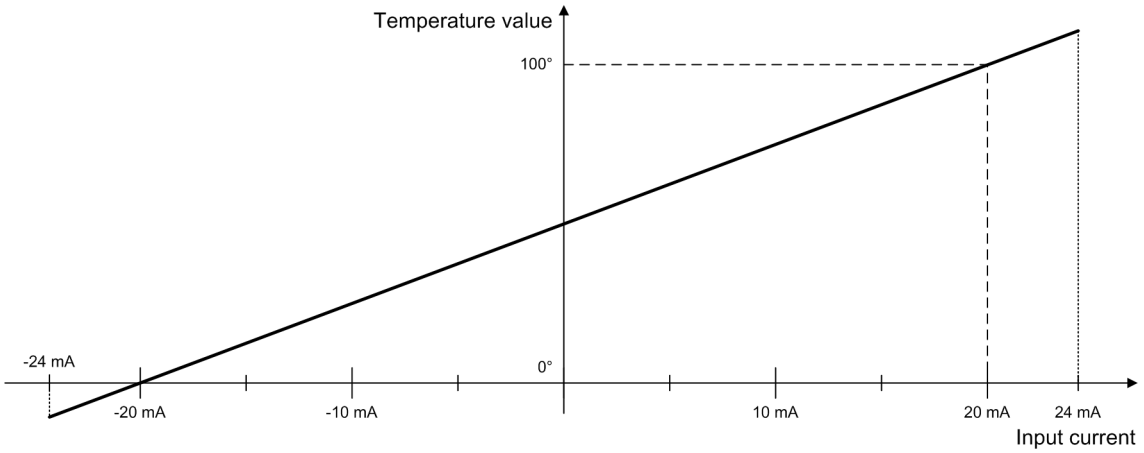
10.10 Measuring Transducers

10.10.1 Overview of Functions

Measuring transducers with an input rated at 20 mA can be used in the devices. 4 such inputs are available as module ANAI-CA-4EL, which can be plugged into a communication module slot (for instance, port E or F). Up to 4 such modules can be plugged in. Typically, slowly changing process variable such as temperature or gas pressure are recorded with such 20-mA measured values and reported to the substation automation technology.

10.10.2 Structure of the Function

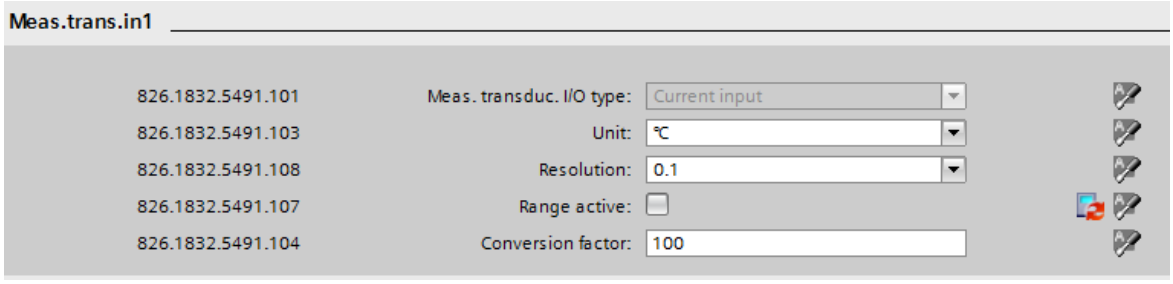
The measuring-transducer blocks are embedded in the **Analog units** function group and contain input and output channels that are configurable independently of each other.



[dwstrumu-050313-01.tif, 1, en_US]

Figure 10-23 Structure/Embedding of the Function

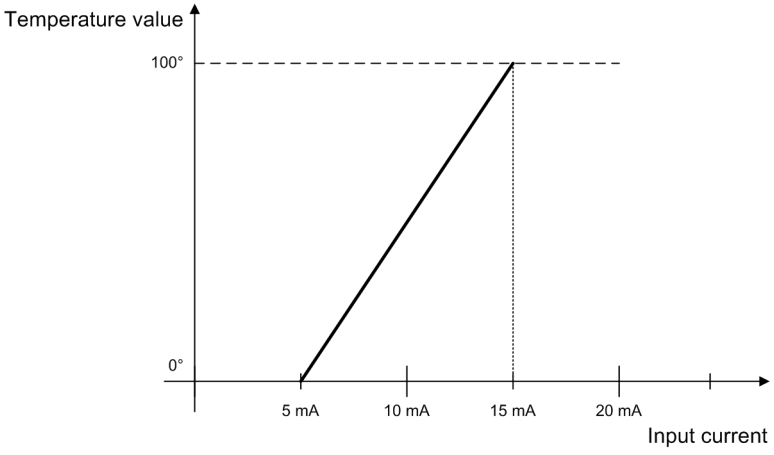
10.10.3 Function Description



The 20-mA inputs typically transmit a value which represents a physical quantity such as a temperature or a pressure. Therefore, the device must contain a characteristic curve that assigns the physical quantity to the 20-mA value. If the parameter **Range active** is not activated (no x in the check box), the function operates over the range -24 mA to +24 mA. The setting of the range for the scaled value goes from a usable range of -20 mA to +20 mA. The following figure shows an example.

[dwklbsp1-120124-01.tif, 1, en_US]

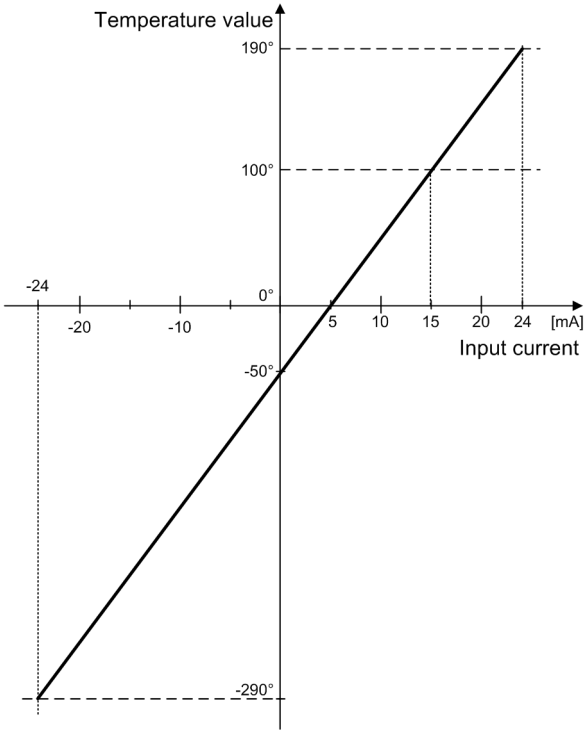
Figure 10-24 Characteristic Curve of a 20-mA Input (Example 1)



In this example, the measured value -20 mA means a temperature of 0 degrees Celsius and the measured value 20 mA a temperature of 100 degrees Celsius. Thus, **Unit** = ***°C*** and **Conversion factor** = ***100*** are entered. The resolution (decimal place) of the temperature value can be chosen; for a decimal place, select **Resolution** = ***0.1***.

[sctransd-210415, 1, en_US]

Figure 10-25 Settings for Example 1



If a value smaller than -24 mA or larger than +24 mA is applied to the measuring-transducer input, the measured value is marked as **invalid**. If the parameter **Range active** is activated, the 2 additional parameters **Upper limit** and **Lower limit** appear. Both limiting values indicate the input currents in mA, for which the value set by the **Conversion factor** (**Upper limit**) and the value 0 (**Lower limit**) of the calculated measurand are valid (see following figure).

[dwklbsp2-120124-01.tif, 1, en_US]

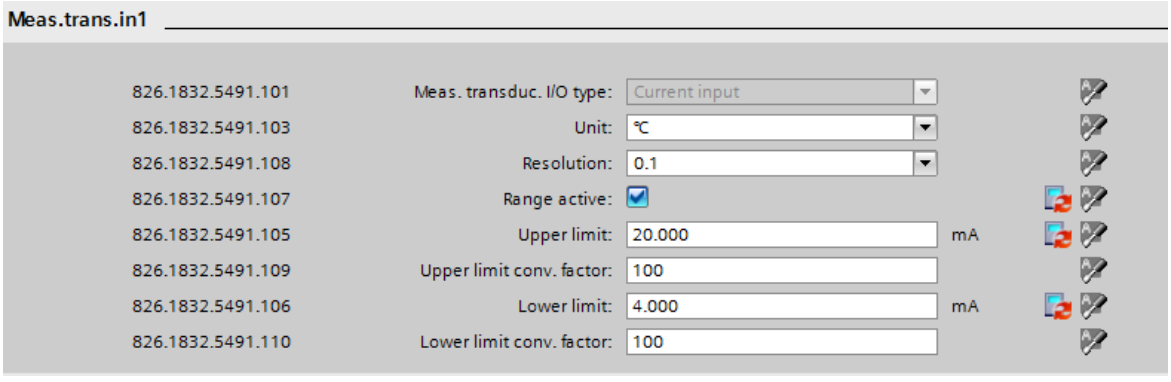


Figure 10-26 Characteristic Curve of a 20-mA Input (Example 2)

In this example, **Range active** is selected. The **Upper limit** is at 15 mA, the **Lower limit** is at 5 mA and the **Conversion factor** remains at 100. The total results in a characteristic curve as shown in the following figure, taking into account all possible valid measured values from -24 mA to +24 mA. The parameter **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The parameter **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

[dwklges2-120124-01.tif, 2, en_US]

Figure 10-27 Total Characteristic Curve in Example 2

[sctrans2-210415, 1, en_US]

Figure 10-28 Settings for Example 2

Each measuring transducer makes available the scaled measured value in the information matrix (these are the temperature values in the examples) and the original current measured value in mA for further processing. The measuring-transducer values can be displayed in the display image and processed with CFC charts.

10.10.4 Application and Setting Notes

Parameter: Unit

- Recommended setting value **(_:103) Unit** = ***°C***

You use the setting **Unit** to specify which physical unit of measurement the measured values represent. The possible setting values are listed in the settings table.

Parameter: Conversion factor

The **(_:104) Conversion factor** setting allows you to set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:108) Resolution** = ***0.1***

The **Resolution** setting is used to specify the measured value resolution.

Parameter: Range active

- Default setting **(_:107) Range active** = ***false***

If you do not activate the **Range active** setting (no x in the check box), the function operates over the range -24 mA to +24 mA. The setting of the range for the scaled value goes from a usable range of -20 mA to +20 mA.

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Upper limit - Sensor**, **Lower limit** and **Lower limit - Sensor** appear.

Parameter: Upper limit, Lower limit, Upper limit - Sensor and Lower limit - Sensor

- Default setting **(_:105) Upper limit** = ***20000 mA***
- Default setting **(_:109) Upper limit - Sensor** = ***100***
- Default setting **(_:106) Lower limit** = ***4000 mA***
- Default setting **(_:110) Lower limit - Sensor** = ***100***

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The setting **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The setting **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

10.11 Statistical Values of the Primary System

The device has statistical values for circuit breakers and disconnectors.

The following values are available for each circuit-breaker:

- Total number of trippings of the circuit-breaker initiated by the device.
- Number of trippings of the circuit breaker initiated by the device, separately for each circuit breaker pole (if 1-pole tripping is possible)
- Total sum of primary breaking currents
- Sum of the primary breaking currents, separately for each breaker pole
- Hours with open circuit breaker
- Hours under load

The following values are available for each disconnector switch:

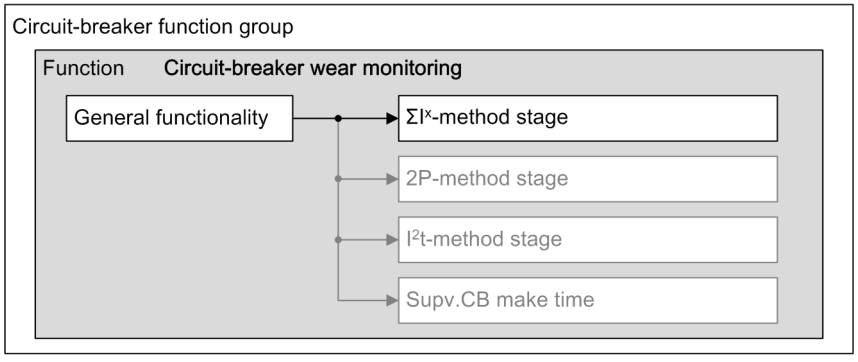
- Total number of switching operations of the disconnector switch initiated by the device
- Number of switching operations of the disconnector switch initiated by the device, separately for each switch pole (if 1-pole switching is possible)

10.12 Circuit-Breaker Wear Monitoring

10.12.1 Overview of Functions

The **Circuit-breaker wear monitoring** function:

- Records the wear of circuit breakers
- Allows maintenance intervals of the CB poles to be carried out when their actual degree of wear makes it necessary
- Sends a warning signal when the wear of a circuit breaker reaches a specified degree
- Allows the supervision of the circuit-breaker make time



Savings on maintenance and servicing costs is one of the main benefits this functionality offers.

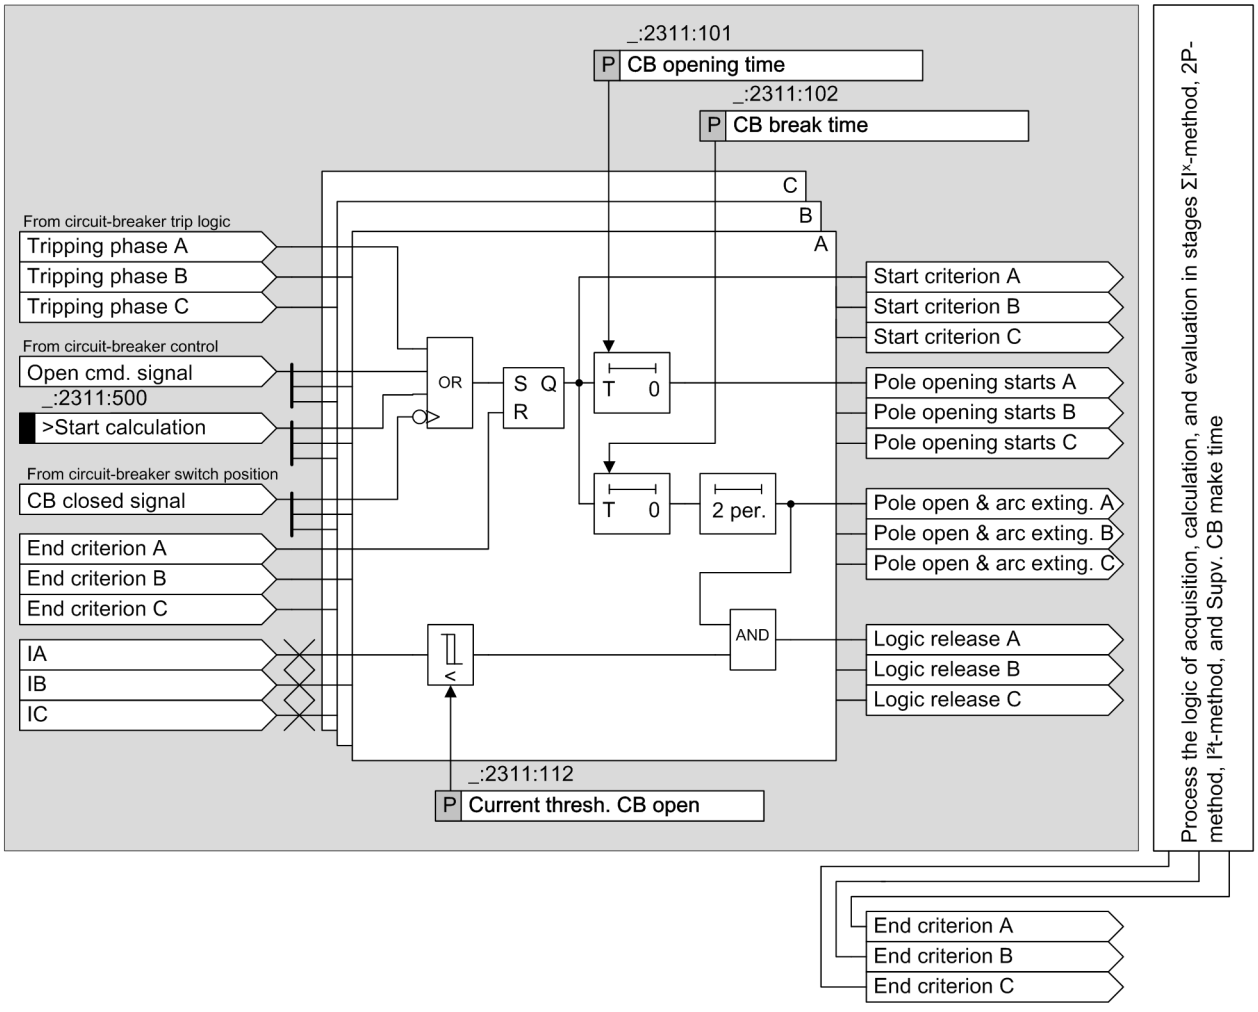
10.12.2 Structure of the Function

The **Circuit-breaker wear monitoring** function can be used in the **Circuit breaker** function group.
The function offers 4 independent operating stages with different measuring methods:

- **ΣI^x-method** stage
  Sum of tripping current powers
- **2P-method stage**
  2 points method for calculating the remaining switching cycles
- **I^2t-method stage**
  Sum of all squared fault-current integrals
- **Supv.CB make time stage**
  Supervision of the circuit-breaker make time

The function is preconfigured by the manufacturer with 1 **ΣI^x-method** stage. A maximum of 1 **ΣI^x-method** stage, 1 **2P-method** stage, 1 **I^2t-method** stage, and 1 **Supv.CB make time** stage can be operated simultaneously within this function.
The general functionality is available across stages and provides a uniform start criterion for the stages.

[DwCBWear, 2, en_US]
Figure 10-29 Structure/Embedding of the Function



10.12.3 General Functionality

10.12.3.1 Description

Logic

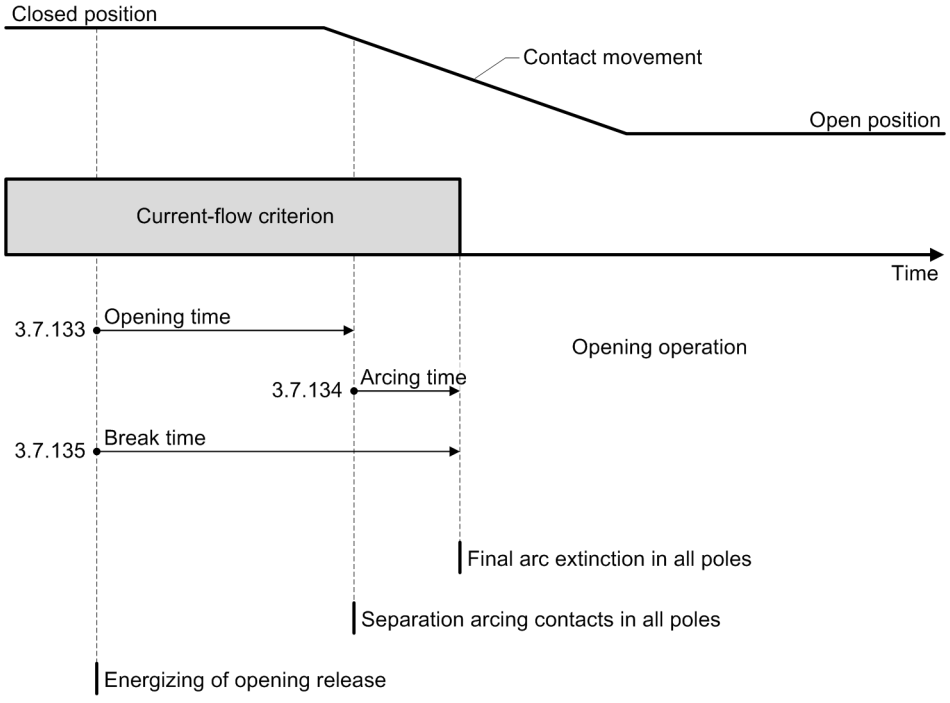
As the wear on the circuit breaker depends on the current amplitude and duration of the actual switching action, including arc deletion, determination of the start and end criteria is important. The following general functionality provides starting and further timing information to the different stages (methods).

The general functionality operates phase-selectively. The following figure shows the logic of the functionality across stages.

[LoCBWear, 3, en_US]

Figure 10-30 Logic Diagram of the Functionality Across Stages of the Circuit-Breaker Wear Monitoring Function

Start Criterion for the Circuit-Breaker Wear Monitoring Function



The **Circuit-breaker wear monitoring** function starts when any of the following criteria is fulfilled:

- Internal protection-function tripping signal from the function block **Trip logic** is received
- Open command signal from the internal **Control** function is received.
- Binary input signal *>Start calculation* is initiated, for example, from external.

- Closed position signal of circuit breaker is going
  This signal is derived form the circuit-breaker auxiliary contacts. In this way, opening the circuit-breaker manually is detected.

Logic Input Signals for Stages

As soon as the start criterion has been fulfilled, the timers of the parameterized opening time and break time are started. With the parameter **CB opening time**, the time when the circuit-breaker pole begins to open is defined. With the parameter **CB break time**, the time of the pole being open including the arc extinction is defined. The following figure shows the relationship between these circuit-breaker times.

[DwCBTime, 2, en_US]

Figure 10-31 Circuit-Breaker Times

In order to prevent an incorrect calculation in case of a circuit-breaker failure, the parameter **Current thresh. CB open** is used to verify whether the current actually returns to 0 after 2 additional cycles. Fundamental components are used for comparing the threshold values. When the current criterion fulfills the requirement of the phase-selective logic release, the calculation and evaluation of the respective methods are initiated.

End Criterion for the Circuit-Breaker Wear Monitoring Function

After calculation and evaluation have been completed, the end criterion of the circuit-breaker maintenance is fulfilled. The **Circuit-breaker wear monitoring** function is ready for a new initiation.

10.12.3.2 Application and Setting Notes

Parameter: CB opening time

- Default setting value **(_:2311:101) CB opening time** = ***0.065 s***

You use the **CB opening time** parameter to define the time span from energizing the shunt release of the circuit breaker until the start of opening of switching poles.

You can find the information on the setting value in the technical data of the used circuit breaker. Also refer to *Figure 10-31*.

Parameter: CB break time

- Default setting **(_:2311:102) CB break time** = ***0.080 s***

You use the **CB break time** parameter to define the time span from energizing the shunt release of the circuit breaker to the instant of arc extinction (and switching pole open).

You can find the information on the setting value in the technical data of the used circuit breaker. Also refer to *Figure 10-31*.

Parameter: CB make time

- Default setting **(_:2311:103) CB make time** = ***0.080 s***

With the parameter **CB make time**, you define the typical time interval between the activation of the closing procedure for the circuit breaker and the point in time when the first current flows.

You can find more information on the setting value in the technical data of the used circuit breaker.

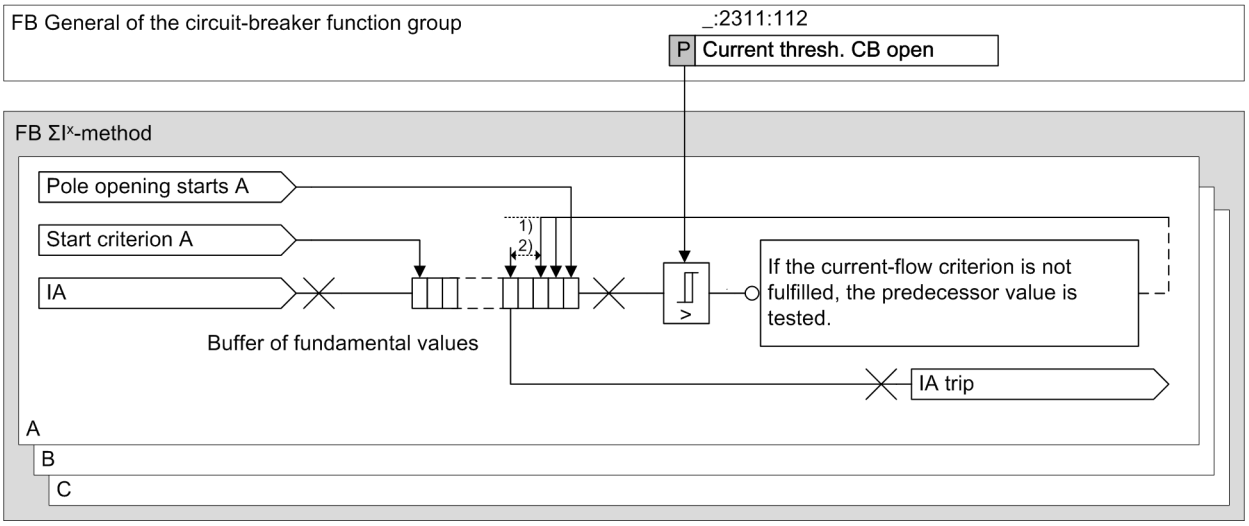
10.12.4 Stage Description ΣI* Method

10.12.4.1 Description

Logic of the Stage



[LoCBWIxS, 3, en_US]

Figure 10-32 Logic of the ΣIx-Method Stage

Determination of the Tripping/Opening Current Value

RMS values of the fundamental components are stored for each phase in a buffer during the time between the start criterion and the pole-opening-starts criterion. With the coming pole-opening-starts criterion, the latest value in the buffer is searched for whose value is above the setting of parameter **`Current thresh. CB open`**. The 20 ms prior value is used as tripping/opening current for further calculation.

If no value within the buffer is above the setting value, this circuit-breaker opening affects only the mechanical lifetime of the circuit breaker and is consequently not considered by this method.

[LoCBWIxF, 1, en_US]

Figure 10-33 Logic of the Determination of the Tripping Current Value

(1) Current-flow criterion fulfilled

(2) 20 ms prior value

Calculation of the Wear

If the **ΣIx-method** stage receives the logic release signal, the determined tripping current is used in the calculation of wear. The calculation results are then added to the existing statistic values of the ΣIx method as follows, with phase A as example.

$$\sum I_A^x = \frac{1}{I_{rated}^x} \sum_{q=1}^{m} I_{A\,trip,q}^x$$

[FoCBWIxA-301012-01.tif, 1, en_US]

Where:

x	Parameter exponent
q	No. of circuit-breaker switching cycle
$I_{A\,trip,q}^x$	Tripping/opening current of phase A to the power of x in the qth circuit-breaker operation
I_{rated}^x	Rated normal current to the power of x
$\sum I_A^x$	Statistic value of current phase A calculated with the ∑Ix method
m	Total number of switching cycles

The phase-selective ΣIx value is available as statistical value. You can reset or preset the statistics according to the specific application.

To simplify the interpretation of the sum of the tripping current powers, the values are set in relation to the exponentiated rated normal current I_{rated} of the circuit-breaker (see also Setting notes).

Circuit-Breaker Maintenance Warning

If the summated ΣIx value of any phase is greater than the threshold, a phase-selective warning signal is generated.

10.12.4.2 Application and Setting Notes

Parameter: `Exponent`

- Default setting **`(_:11371:101) Exponent`** = ***2.0***

You use the **`Exponent`** parameter to specify the exponent for the ΣI^x method.

A typical value is the default setting of 2. However, due to practical experiences with individual circuit breakers, slightly different values may be requested.

Parameter: `Threshold`

- Default setting **`(_:11371:102) Threshold`** = ***10 000.00***

You use the parameter **`Threshold`** to define the threshold of the statistic value.

The relation of the tripping current powers to the exponentiated rated normal current I_{rated} allows the limiting value of the ΣI^x method to correspond to the maximum number of make-break operations. For a circuit breaker, whose contacts have not yet been worn, the maximum number of make-break operations can be entered directly as limiting value.

10.12.5 Stage Description 2P Procedure

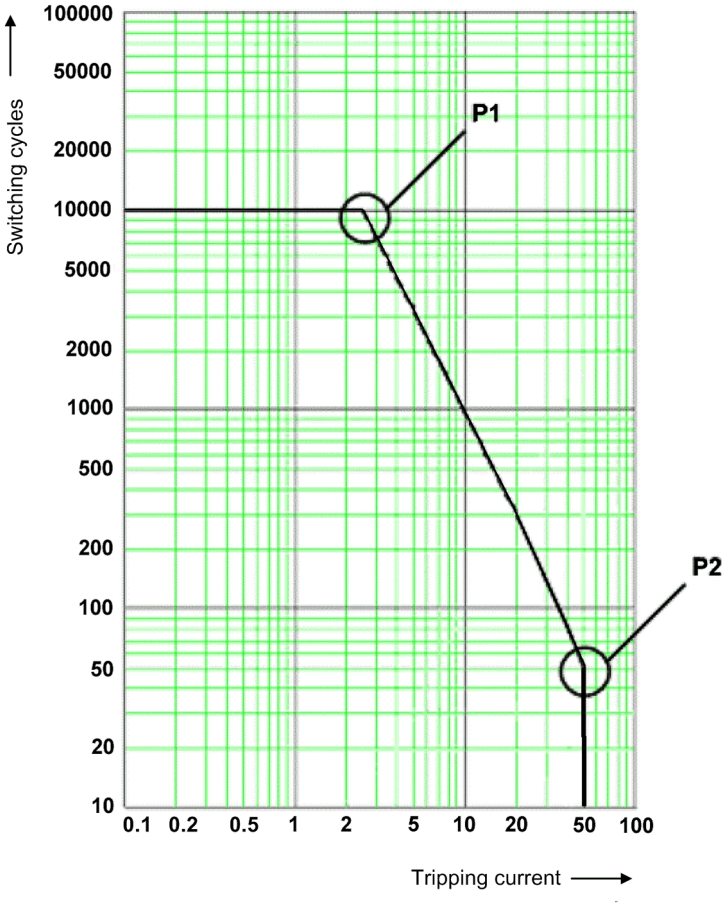
10.12.5.1 Description

Logic of the Stage

[LoCBW2PS, 2, en_US]

Figure 10-34 Logic of the 2P-Method Stage

Determination of the Tripping/Opening Current Value



For the description to determine the tripping/opening current value, refer to chapter *10.12.4.1 Description*.

Calculation of Remaining Switching Cycles

A double-logarithmic diagram provided by the circuit-breaker manufacturer illustrates the relationship of permitted switching cycles and the tripping/opening current, see the following figure. According to the example, this circuit breaker can operate approximately 1000 times at a tripping current of 10 kA.

2 points and their connecting line determine the relationship of switching cycles and tripping current. Point P1 is determined by the number of permitted switching cycles at rated normal current I_{rated}. Point P2 is deter-

mined by the maximum number of switching cycles at rated short-circuit breaking current I_{sc}. The 4 associated values can be configured with the parameters **`Rated normal current`**, **`Switching cycles at Ir`**, **`Rated short-circ.cur. Isc`**, and **`Switching cycles at Isc`**.

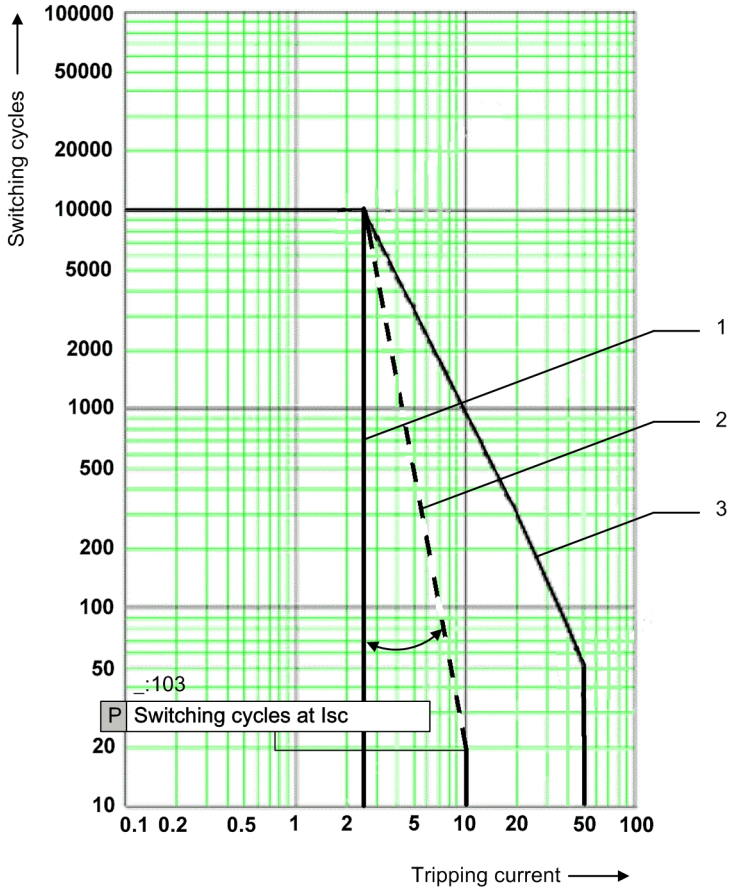
[DwCBWOpC, 1, en_US]

Figure 10-35 Diagram of Switching Cycles for the 2P Method

As shown in the preceding figure, a double-logarithmic diagram, the straight line between P1 and P2 can be expressed by the following exponential function:

$$n = b \cdot \left(\frac{I_{rated}}{I_{trip}} \right)^{m}$$

[FoCBW2P1-301012-01.tif, 1, en_US]



Where:

I_{trip}	Tripping/opening current
I_{rated}	Rated normal current
m	Slope coefficient
b	Switching cycles at rated normal current
n	Number of switching cycles

The general line equation for the double-logarithmic representation can be derived from the exponential function and leads to the coefficients b and m.

NOTE

Since a slope coefficient of m < -4 is technically irrelevant, but could theoretically be the result of incorrect settings, the slope coefficient is limited to -4. If a coefficient is smaller than -4, the exponential function in the switching-cycles diagram is deactivated. The maximum number of switching cycles with I_{sc} is used instead as the calculation result for the current number of switching cycles, as the dashed line with m = -4.48 shows in following figure.

[DwCBWSlo, 1, en_US]

Figure 10-36 Value Limitation of Slope Coefficient

(1) Applied function from m < -4

(2) Parameterized function with m = -4.48

(3) Parameterized function with m = -1.77

If the **2P-method** stage receives the logic release signal, the current number of used up switching cycles (in relation to the number of switching cycles at rated normal current) is calculated based on the determined tripping current. This value is subtracted from the the remaining lifetime (switching cycles). The remaining lifetime is available as statistic value. For better understanding, refer to the example below.

You can reset or preset the statistical values according to the specific application. The reset operation changes the statistic values to 0, and not to their default values of 10 000.

The statistic value of the residual switching cycles is calculated according to the following formula:

$$Endur_{\cdot i} = Endur_{\cdot i-1} - \frac{n_{rated}}{n_{trip}}$$

[FoCBW2P2-301012-01.tif, 1, en_US]

Where:

i	No. of latest circuit-breaker switching cycle
$Endur._i$	Residual switching cycles with rated normal current, after the ith switching cycle
n_{rated}	Overall permissible switching cycles at rated normal current
n_{trip}	Overall permissible switching cycles at tripping current I_{trip}
n_{rated}/n_{trip}	Lost switching cycles referring to rated normal current

EXAMPLE

For calculating the residual switching cycles of a circuit breaker, the following is assumed:
P1 (2.5 kA, 10 000)
P2 (50.0 kA, 50)
The circuit breaker has made 100 opening operations with rated normal current, 2 tripping operations with rated short-circuit breaking current, and 3 tripping operations with 10 kA tripping current. Then, the residual switching cycles with rated normal current are:

$$\text{Endurance} = n_{rated} - \left(100 \cdot \frac{n_{rated}}{n_{2.5kA}}\right) - \left(2 \cdot \frac{n_{rated}}{n_{50kA}}\right) - \left(3 \cdot \frac{n_{rated}}{n_{10kA}}\right)$$

$$= 10000 - \left(100 \cdot \frac{10000}{10000}\right) - \left(2 \cdot \frac{10000}{50}\right) - \left(3 \cdot \frac{10000}{861}\right) = 9465$$

[FoCBW2P3-301012-01.tif, 1, en_US]

There are still 9465 possible break operations at rated normal current.

Circuit-Breaker Maintenance Warning

If the residual switching cycles of any phase lie below the threshold, a phase-selective warning signal is generated.

10.12.5.2 Application and Setting Notes

Parameter: `Switching cycles at Ir`

- Default setting **`(_:101) Switching cycles at Ir`** = ***`10 000`***

You use the **`Switching cycles at Ir`** parameter to define the number of permitted switching cycles at rated normal current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: `Rated short-circ.cur. Isc`

- Default setting **`(_:102) Rated short-circ.cur. Isc`** = ***`25 000 A`***

You use the **`Rated short-circ.cur. Isc`** parameter to define the rated short-circuit breaking current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: `Switching cycles at Isc`

- Default setting **`(_:103) Switching cycles at Isc`** = ***`50`***

You use the **`Switching cycles at Isc`** parameter to define the number of permitted switching cycles at rated short-circuit breaking current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: `Threshold`

- Default setting **`(_:104) Threshold`** = ***1000***

You use the **`Threshold`** parameter to define the threshold of residual switching cycles with rated normal current. A warning signal is generated when the statistic is less than the **`Threshold`**.

Example

Here is an example that shows you how to set the **`Threshold`** parameter. Assuming a circuit breaker with the same technical data as provided in the example for residual switching cycles, 50 breaking operations with rated short-circuit breaking current are permitted.

A warning signal should be issued when the number of possible breaking operations with rated short-circuit breaking current is less than 3. For that condition, you set the **`Threshold`** value based on the following calculation:

$$3 \cdot \frac{n_{rated}}{n_{50kA}} = 3 \cdot \frac{10000}{50} = 600$$

[FoCBW2P4-301012-01.tif, 1, en_US]

10.12.6 Stage Description I²t Method

10.12.6.1 Description

Logic of the Stage

[LoCBWI2t, 1, en_US]

Figure 10-37 Logic of the I²t-Method Stage

Calculation of the Wear

The I²t method evaluates the wear of a circuit breaker based the sampled measuring values of the phase currents during the arc time. The duration of the arc time is defined by the difference between the 2 settings of parameters **`CB break time`** and **`CB opening time`** (see also *Figure 10-31*). The stage determines the ending point of the arc time by searching backward the zero-crossing point of the phase currents after it receives the logic release signal. Then, the squared fault currents during the arc time are integrated phase-

selectively. The integrals are referred to the squared rated normal current of the circuit breaker as shown in the following formula, with phase A as example.

$$I^2t_A = \frac{1}{I^2_{rated}} \int_{\text{Start arc time}}^{\text{End arc time}} i^2_A(t)\,dt$$

[FoCBWI2T-301012-01.tif, 1, en_US]

Where:

I_{rated}	Rated normal current
$i_A(t)$	Sampled measured current value of phase A

The calculated squared tripping current integrals are added to the existing statistic values.You can reset or preset the statistic value according to the specific application.

Circuit-Breaker Maintenance Warning

If the statistic value of any phase lies above the threshold, a phase-selective warning signal is generated.

10.12.6.2 Application and Setting Notes

Parameter: `Threshold`

- Default setting **`(_:101) Threshold`** = ***`10 000.00 I/Ir*s`***

You use the **`Threshold`** parameter to specify the maximum permitted integral of squared sampled measured values of the phase currents.

10.12.7 Stage Description Supervision CB Make Time

10.12.7.1 Description

Logic of the Stage

[Lo_sup-cb-make-time, 1, en_US]

Figure 10-38 Logic of the Supv.CB Make Time Stage

Operating Mode

The stage for the supervision of the circuit-breaker make time calculates the time between the circuit-breaker closing command and the point in time when the current from at least one phase exceeds the **Oper.current threshold**. If this threshold has not been exceeded after 2.5 times the value of the parameter **CB make time**, the measurement is canceled and the output value *Make time* is set to 0 and marked with the quality invalid.

If at least one phase of the current has exceeded the parameter **Oper.current threshold** or the parameter **Current thresh. CB open** at the time of the circuit-breaker closing command, the measurement is canceled and the output value *Make time* is marked with the quality invalid.

You can define 2 independent thresholds for the supervision of the measured make time. When these thresholds are exceeded, the corresponding outputs *Warning 1* and *Warning 2* are activated for 100 ms. These can be routed in the log.

10.12.7.2 Application and Setting Notes

Parameter: `Level of warning 1`

- Default setting **`(_:101) Level of warning 1`** = ***`5 %`***

With the parameter **`Level of warning 1`**, you define the percentage the measured value is allowed to exceed the parameter **`CB make time`** at the output *`Make time`*, before the output *`Warning 1`* is set. The output *`Warning 1`* then drops out after 100 ms.

Parameter: `Level of warning 2`

- Default setting **`(_:102) Level of warning 2`** = ***`10 %`***

With the parameter **`Level of warning 2`**, you define the percentage the measured value is allowed to exceed the parameter **`CB make time`** at the output *`Make time`*, before the output *`Warning 2`* is set. The output *`Warning 2`* then drops out after 100 ms.

Parameter: `Oper.current threshold`

- Default setting **`(_:103) Oper.current threshold`** = ***`0.100 A`***

With the parameter **`Oper.current threshold`**, you define the current threshold. If the measured value exceeds this threshold, the measured value is detected as flowing operating current. As soon as an operating current flows, the end of the time interval *`Make time`* is detected.

Parameter: `Delay correction time`

- Default setting **`(_:104) Delay correction time`** = ***`0.000 s`***

With the parameter **`Delay correction time`**, you define a correction value which will be subtracted from the *`Make time`* during calculation. This allows you to compensate delays caused by the system, for example, relay residual times, if necessary.

10.12.7.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`Supv.CB make time`

11.17	Functional Test Differential Protection for Capacitor Banks	1324

11.1 General Notes

Various tests have to be performed for commissioning to warrant the correct function of the device.

For tests using secondary test equipment, make sure that no other measurands are locked in and trip and close commands to the circuit breakers are interrupted, unless otherwise indicated.

Secondary tests can never replace primary tests because they cannot include connection faults. They provide a theoretical check of the setting values only.

Primary tests may be done only by qualified personnel who are familiar with the commissioning of protection systems, with the operation of the system, and with safety regulations and provisions (switching, grounding, etc.).

Switching operations also have to be performed for the commissioning. The described tests require that these be capable of being performed safely. They were not conceived for operational checks.

11.2 Direction Test of the Phase Quantities (Current and Voltage Connection)

The proper connection of the current and voltage transformer is checked with load current over the line to be protected. For this, the line must be switched on. A load current of at least 0.1 I_{rated} has to flow over the line; it should be ohmic to ohmic inductive. The direction of the load current has to be known. In case of doubt, meshed and ring systems should be unraveled. The line remains switched on the for the duration of the measurements.

The direction can be derived directly from the operational measured value. First make sure that the power measured values correspond to the power direction. Normally, it can be assumed that the forward direction (measuring direction) goes from the busbar toward the line.

Using the power measured values at the device or DIGSI 5, make sure that it corresponds to the power direction:

- **P** is positive if the active power flows in the line or protected object.
- **P** is negative if the active power flows to the busbar or out of the protected object.
- **Q** is positive if the inductive reactive power flows in the line or protected object.
- **Q** is negative if the inductive reactive power flows to the busbar or out of the protected object.

If the power measured values have a different sign than expected, then the power flow is opposite the current-direction definition. This can be the case, for example, at the opposite end of the line . The current-transformer neutral point then points in the direction of the protected object (for example line).

If the values are not as expected, it may be due to a polarity reversal at the voltage connection.

As a final step, switch off the system.

11.3 Direction Test of Ground Quantities for Directional Ground-Fault Functions

11.3.1 Overview

If the CT and VT connections are in the way that the ground quantities (3I0 and V0) are calculated by the device from the phase quantities, then, no additional directional test is required. Testing according to *11.2 Direction Test of the Phase Quantities (Current and Voltage Connection)* is sufficient.

If the ground current IN or the ground voltage VN is directly measured via a device input (usually I4 or V4), the correct polarity of the ground current and the ground voltage path must be checked.

DANGER

Live system parts! Capacitive coupled voltages on dead parts!

Noncompliance with the following measures can lead to death, serious physical injury, or considerable material damage.

✧ Primary measures may be performed only on dead and grounded system parts.

11.3.2 Directional Testing for Solid or Resistive-Grounded Systems

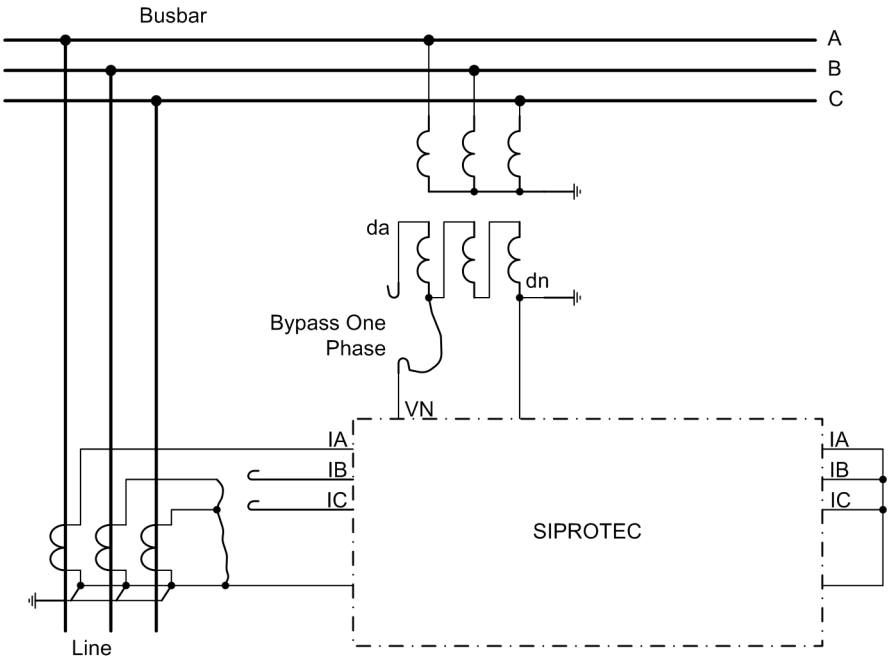
Primary Test

The primary test is used for the evaluation of the correct polarity of the transformer connections for the determination of the ground-fault direction.

To generate a zero-sequence voltage V0, the e-n winding of one phase in the voltage-transformer set (for example, phase A) is bypassed, see *Figure 11-1*. If no connection on the e–n windings of the voltage transformer is provided, the corresponding phase is disconnected on the secondary side, see *Figure 11-2* . Only the current of the transformer in the phase of which the voltage is missing is transferred via the current circuit. If the line carries resistive-inductive load, the protection is subject to the same conditions as existing during a ground fault in line direction.

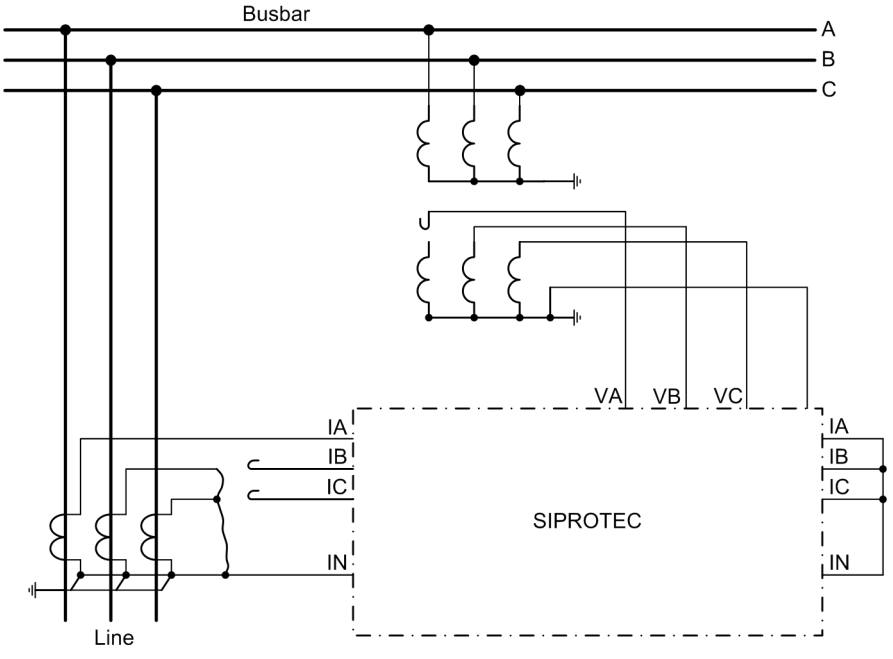
For directional testing, the **Directional ground-fault protection** function (67N) is configured and at least one stage is switched on. The pickup threshold of the stage must be below the load current of the line. If not, the binary input signal *(_:2311:501) >Test of direction* can be activated to lower the threshold temporarily for testing means without changing the respective parameter.

After switching the line on and off again, you can check the pickup signal of the directional protection stage in the fault log. A forward information must be logged. If no pickup information is logged at all, the 3I0 or U0 threshold is not exceeded.



If a wrong direction is logged, one of the following conditions may have occurred:

- The direction of the load flow is from the line towards the busbar.
- The ground-current connection is incorrect.
- The voltage connection is incorrect.



NOTE

Siemens recommends not to change parameter settings for the test. However, if parameters were changed for this test, they must be returned to their original state after completing the test!

[ConnPolarit1_diagram, 1, en_US]

Figure 11-1 Polarity Testing, Example with Current Transformers Configured in a Holmgreen-Connection and VTs with Broken-Delta Connection

[ConnPolarit2_201507, 1, en_US]

Figure 11-2 Polarity Testing, Example with Current Transformers Configured in a Holmgreen-Connection and VTs with Star Connection

11.3.3 Directional Testing for Isolated or Resonant-Grounded Systems

Primary Test

The primary test is used for the evaluation of the correct polarity of the transformer connections for the determination of the ground-fault direction.

For directional testing, the **Directional sensitive ground-fault detection** function (67Ns) is configured and a directional stage is switched on. For example, the directional 3I0> stage with cos φ or sin φ measurement.

The most reliable test is the one with a primary ground fault. Proceed as follows:

- ✧ Isolate the line and ground it on both sides; on the farthest line end it must remain open during the entire test.
- ✧ Place a **1-phase** ground fault bridge on the line. For overhead lines, this can be done at an arbitrary location, in any case behind the current transformer (as seen from the busbar of the feeder to be tested). For cables, the grounding is done on the farthest end (sealing end).
- ✧ Remove the protective grounding from the line.
- ✧ Switch on the circuit breaker on the line to be tested.
- ✧ Check direction indicator (LED if routed).
- ✧ Check the indication *(_:302) Ground fault* in the ground-fault log or fault log with regard to its direction. The indication *(_:302) Ground fault forward* must be logged as direction information.

  If *backward* is determined as the direction, either with the current connections or the voltage connections, there is an inversion in the neutral path. For the display *unknown*, the ground current is probably too low.
- ✧ Switch the line off and ground it.

This completes the test.

11.4 Functional Test of Thermal Overload Protection

Secondary Test

For the secondary test for the overload protection, note that all setting parameters refer to primary variables of the protected object. The protection device extracts the current transformer ratio from the power-system data and internally performs the adjustments to device nominal variables. Take these characteristics into account for the test.

✧ Reset the thermal memory before you repeat the test. This is possible, for instance, via the binary input indication **>Reset thermal replica**. If the function is reparameterized or is switched off, the thermal replica will also be reset.

Test without Previous Load

✧ Test the operate time at 1.5 $I/I_{rated,\ obj.}$

In the example, the following power-system data are assumed:

$I_{rated,\ obj}$ = 483 A

$I_{rated,\ transf.prim}$ = 750 A

$I_{rated,\ transf.sec}$ = 1 A

The primary test current is 1.5 * 483 A = 724.5 A. This results in a secondary current of 724.5 A *1A/750A = 0.966 A. A secondary current of 0.966 A must therefore be supplied.

✧ Calculate the operate time with the following formula. Enter only primary variables here.

✧ Set $I_{previous\ load}$ = 0. The setting parameters reveal the **K-factor** (for example, 1.1) and the **Thermal time constant** (for example, 600 s or 10 min).

✧ Test from the cold state.

$$t = \tau_{th} \cdot \ln\left(\frac{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - \frac{1}{k^2}\left(\frac{I_{preload}}{I_{rated,obj.}}\right)^2}{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot \ln\left(\frac{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 0}{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\ s \cdot 0.772 = 463\ s$$

[foauslpr-190309-01.tif, 2, en_US]

✧ At a current of 0.966 A supplied on the secondary side, the protection function must trip after 463 s.

Test with Previous Load

✧ The object rated current ($I_{previous\ load} = I_{rated,\ obj}$) flows at a previous load of 1 (100 %).

✧ Supply 483 A *1 A/750 A = 0.644 A in this case.

After a finite time (greater than 5 τ_{th}), the stationary previous load sets in.

K-factor

✧ If you abruptly increase the supplied secondary current from 0.644 A to 0.966 A (1.5 $I/I_{rated,\ obj}$), the overload protection will trip in the following time.

$$t = \tau_{th} \cdot \ln\left(\frac{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - \frac{1}{k^2}\left(\frac{I_{preload}}{I_{rated,obj.}}\right)^2}{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot \ln\left(\frac{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - \frac{1}{1,1^2}\left(\frac{1.0 I_{rated,obj.}}{I_{rated,obj.}}\right)^2}{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot 0.184 = 110\,s$$

[foauslpr-190309-02.tif, 2, en_US]

✧

NOTE

Owing to the relatively large time constants in practice, the tests are carried out with significantly reduced time constants. Reset the original setting value after completing the tests.

11.5 Primary and Secondary Tests of the Circuit-Breaker Failure Protection

Integration of the Protection Function into the Station

The integration of the protection function into the station must be tested in the real-life application. Because of the multitude of possible applications and possible system configurations, the required tests cannot be described here in detail.

NOTE

Always keep the local conditions, the station plans, and protection plans in mind.

NOTE

Siemens recommends isolating the circuit breaker of the tested feeder at both ends before starting the tests. Line disconnector switches and busbar disconnector switches must be open so that the circuit breaker can be operated without risk.

General Precautions

CAUTION

Tests on the local circuit-breaker of the feeder cause a trip command to the output to the adjacent (busbar) circuit breakers.

Noncompliance with the following measure can result in minor personal injury or physical damage.

✧ In a first step, interrupt the trip commands to the adjacent (busbar) circuit breakers, for example, by disconnection of the corresponding control voltages.

For testing the circuit-breaker failure protection, it must be ensured that the protection (external protection device or device-internal protection functions) cannot operate the circuit breaker. The corresponding trip command must be interrupted.

Although the following list does not claim to be complete, it can also contain points, which have to be ignored in the current application.

Test Modes

The device and the function can be switched to test mode. These test modes support the test of the function in different ways:

Test Modes	Explanation
Device in test mode	This operating mode is relevant for the following tests: 1. Approach of current thresholds in the case of an external start: Supervision of the binary input signals in the case of an external start is disabled. This setting allows a static activation of the starting signals in order to approach the current threshold. 2. Check whether the issued trip commands actuate the corresponding circuit breakers, because the device contacts are also actuated in the device test mode.
CBFP function in test mode (device is NOT in test mode)	This operating mode is important for function tests in which the generated operate indications are NOT supposed to actuate the binary outputs.

NOTE

When the function or device is in test mode, all indications are given a test bit.

NOTE

In the mode **Device in test mode**, the operate indications generated by the function operate the binary outputs.

The function must also be tested in its normal, switched-on condition.

Consider the following in this case:

- ✧ The device contacts are actuated.
- ✧ Binary input signal supervision (in the case of an external start) is enabled and blocks the function.
- ✧ All indications generated are generated without test bit.

Circuit-Breaker Auxiliary Contacts

When circuit-breaker auxiliary contacts are connected to the device, they make an essential contribution to the reliability of the circuit-breaker failure protection, provided that their settings are set accordingly.

- ✧ Make sure that the correct assignment has been checked.

Internal Starting Conditions (Trip Command from Internal Protection Function)

The internal start can be tested by means of tripping a protection function, for example, the main protection function of the device.

- ✧ Check the settings for circuit-breaker failure protection. See also chapter *6.39.4 Application and Setting Notes* .
- ✧ For the circuit-breaker failure protection to be able to pick up, a phase current (see current-flow criterion) must be present. This can be generated by a device-internal test sequence (see description in the Operating manual). It can also be a secondary test current.
- ✧ Generate the trip for the protection function. This can be generated within the device by a test sequence (see description in the Operating manual) or by creating corresponding secondary test values.
- ✧ The trip command(s) and their time delay compared to the pickup, depending on the parameterization.

External Starting Conditions (Trip Command from External Protection Function)

If external protection devices are also able to start the circuit-breaker failure protection, the external starting conditions require checking.

- ✧ Check the settings for circuit-breaker failure protection.
  See also chapter *6.39.4 Application and Setting Notes* .
- ✧ For the circuit-breaker failure protection to be able to pick up, a phase current (see current-flow criterion) must be present. This can be generated by a device-internal test sequence (see description in the Operating manual). It can also be a secondary test current.
- ✧ Activate the binary input or inputs to which the start signal and possibly also the release signal for the CBFP function are routed. This can be done in 2 ways:
  – 1) Via internal test sequences
  – 2) By controlling the binary input or inputs via an auxiliary voltage
- ✧ Check the start input signal, and if available, check the enable input signal in the spontaneous or fault messages.
- ✧ Check the pickup indication in spontaneous or fault indications.
- ✧ The trip command(s) and their time delay compared to the pickup, depending on the parameterization.

Start by Trip Command from the External Protection

- ✧ Check the static and - in case of 2-channel operation - also the dynamic supervision of the binary input signals. For this purpose, induce pickup of the supervision and check the supervision indications and the ready signal in the event log buffer.

Start by Trip Command from the External Protection without Current Flow

- ✧ If start is possible without current flow: (see **Start by trip command from the external protection**).

Repetition of the Local Tripping (T1)

- ✧ Make sure that the trip repeat signal controls a 2nd circuit (2nd coil) for switching off the circuit-breaker.

Backup Tripping in the Case of a Circuit-Breaker Failure (T2)

For tests in the station, it is important to check that the distribution of trip commands to the adjacent circuit breakers in the case of a circuit-breaker failure is correct. The adjacent circuit breakers are all circuit breakers, which must be tripped in order to ensure interruption of the short-circuit current if the feeder circuit-breaker fails. They are therefore the circuit breakers of all feeders which feed the busbar or busbar section to which the feeder with the fault is connected.

A general detailed test guide cannot be specified because the layout of the adjacent circuit-breakers depends largely on the system topology.

- ✧ With multiple busbars, the trip distribution logic for the adjacent circuit breakers must be checked.

  The test has to check for every busbar section that, in case of a failure of the feeder circuit-breaker under observation, only those circuit-breakers which are connected to the same busbar section are tripped.

Backup Tripping on Circuit-Breaker Failure (T2), Tripping of the Opposite End

If the trip command of the circuit-breaker failure protection must also trip the circuit-breaker at the opposite end of the tested feeder, the communication channel for this remote trip has to be tested as well.

- ✧ It is practical to test the communication channel for the remote trip while transmitting other signals in accordance with *11.15.1 Checking the Protection-Data Communication* .

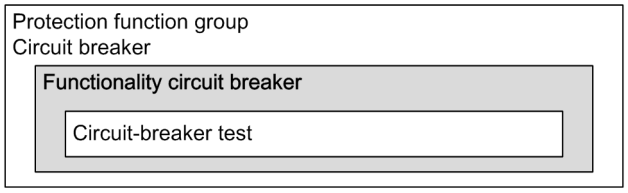
Termination

- ✧ All temporary measures taken for testing must be undone, such as special switch positions, interrupted trip commands, changes to setting values, or individually switched off protection functions.

11.6 Circuit-Breaker Test

The **Circuit-breaker test** function enables you to easily perform a complete test of the trip circuit, the closing circuit, and the circuit breaker. For this, the circuit-breaker test carries out an automatic opening and closing cycle of the circuit breaker during operation.

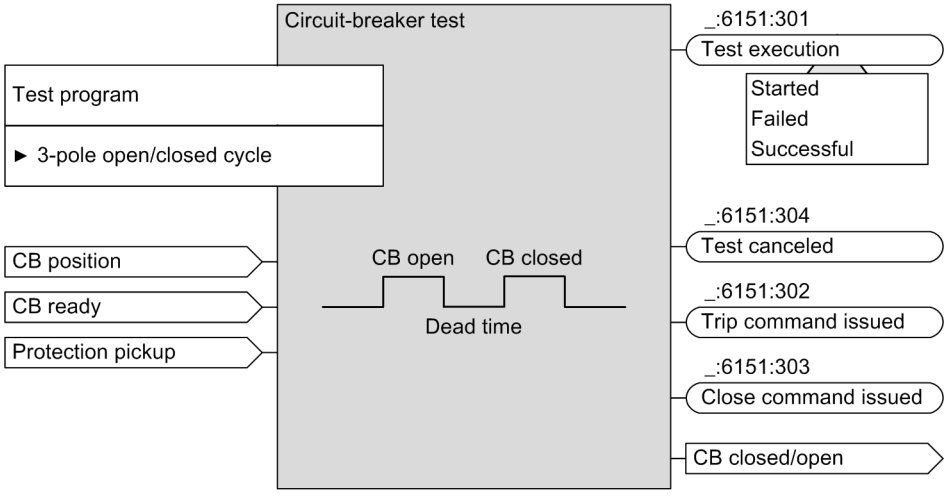
NOTE



If the auxiliary contacts are not connected, a circuit breaker that has been opened may be permanently closed.

The following test program is available for you to carry out the circuit-breaker test.

No.	Test Program
1	3-phase open/closed cycle



Structure of the Function

The **Circuit-breaker test** function is used in protection function groups for circuit breakers.

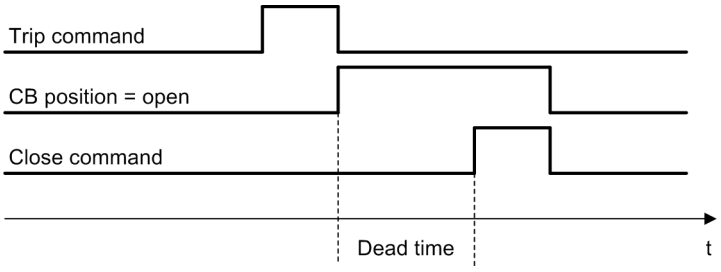
[dwcbch01-300913, 1, en_US]

Figure 11-3 Embedding of the Function

[dwcbc3p2-300913, 1, en_US]

Figure 11-4 Structure of the Function

Test Procedure



The following conditions must be satisfied before the circuit-breaker test can start:

- If a circuit-breaker auxiliary contact signals the position of the breaker pole to the device via the **Position** binary input, the test cycle is not initiated unless the circuit breaker is closed. If the circuit-breaker auxiliary contact has not been routed, you must ensure that the circuit breaker is closed.
- The circuit breaker must be ready for an open-closed-open cycle (indication **>Ready**).
- A protection function must not have been picked up in the circuit-breaker protection function group responsible for the circuit breaker.

Figure 11-5 shows the progression over time of an open-close test cycle.

If a circuit-breaker auxiliary contact is connected, the function waits for the indication circuit breaker **Position** = ***open*** after the trip command is generated. When the indication **Position** = ***open*** is received, the close command is transmitted after a dead time (parameter **(_:6151:101) Dead time**). If the feedback from the circuit-breaker positions is not received within the maximum transmission time (**Dead time**+ 2 · **Output time** + 5 s), the circuit-breaker test is aborted and considered to be failed. The proper functioning of the circuit breaker is monitored via the feedback on the circuit-breaker positions.

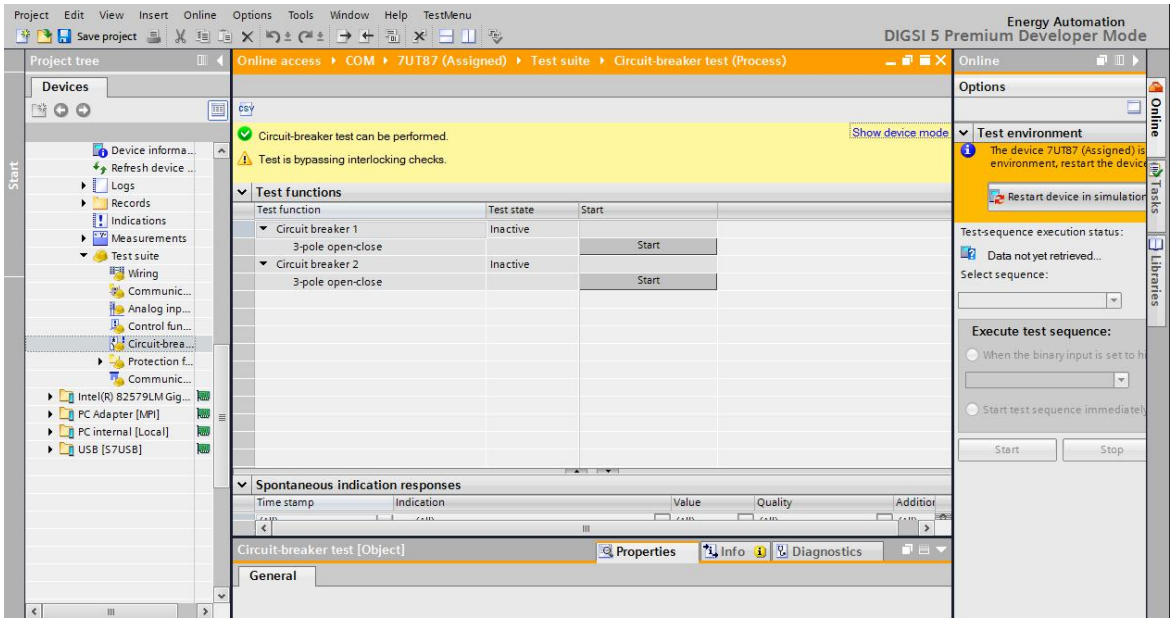
If the circuit-breaker auxiliary contact is not connected, the trip command is generated for the parameterized output time (parameter **(_:4261:101) output time**)). After the dead time (parameter **(_:6151:101) Dead time**) has elapsed, the close command follows, also for the duration of the parameterized time (**Output time**). In this case, you must ensure that the circuit breaker is closed.

[dwcbch03-300913, 1, en_US]

Figure 11-5 Progress over Time of a Circuit-Breaker Test Cycle

The **Circuit-breaker test** function is used in protection function groups for circuit breakers. If the actual **Circuit-breaker** functionality has been configured and wired further configuration is not necessary.

✧ You define the time between the trip command and the close command with the **(_:6151:101) Dead time** parameter.



NOTE

The circuit-breaker test does not perform a synchrocheck even if the synchrocheck has been configured in the protection-function groups for circuit breakers. This may cause stability problems in the system during a 3-pole interruption. Therefore, a 3-pole circuit-breaker test should be very short, or not performed at all under load.

You can start the test program as follows:

- Via the device-control panel
- Via DIGSI
- Via control commands, which you can also connect in the CFC

The following figure illustrates operation of the circuit-breaker test in DIGSI.

[sccb_3pol, 1, en_US]

Figure 11-6 Circuit-Breaker Test in the Test Suite in DIGSI

- ✧ Select the function in the project tree on the left in the online access.
- ✧ Start the desired test program in the upper portion of the middle window.
- ✧ The corresponding feedback is displayed in the bottom portion of the middle window. Additional information about the behavior of other functions while the circuit-breaker test is being performed can be read in the operational log.

11.7 Functional Test of the Inrush-Current Detection

General

- ✧ For the test, make sure that the test current reflects the typical inrush current.
- ✧ Perform the test with transient signals. These can be recorded inrush currents or simulated currents from a transient system model.
- ✧ When using synthetic signals, observe the notes on the individual measuring principles.

Harmonic Analysis

- ✧ Superimpose on the fundamental-component current a test current of double frequency (2nd harmonic) and test the pickup behavior with this.
- ✧ Cause a threshold value excess (internal pickup) for one of the protection functions that you want to block.

  - or -

- ✧ Apply a test current with a load current as lead (current step).

The inrush current detection creates a blocking signal.

CWA Process

- ✧ Create a test current that has flat ranges of a minimum width of 3 ms simultaneously in all 3 phase currents.

The inrush current detection creates a blocking signal.

11.8 Functional Test of Transient Ground-Fault Protection

General

This function requires the correct polarity of the ground current IN and the neutral-point displacement voltage VN respectively the zero-sequence voltage V0. For the direction test of these quantities, refer to chapter *11.3 Direction Test of Ground Quantities for Directional Ground-Fault Functions*.

The function is based on the evaluation of the transient in the zero-sequence system after the ground-fault ignition.

For issuing the signal *(_:302) Ground fault*, the following 2 conditions must be met:

- There is a transient in the ground quantities.
- The fundamental compoment of the zero-sequence voltage V0 exceeds the threshold **(_:103) V0> threshold value**.

The following 2 methods are available for testing of the signal *(_:302) Ground fault* :

- Replaying real transient ground-fault recordings to the device
- Using secondary test equipment which allows to simulate transients ground faults

However, the setting of parameter **(_:103) V0> threshold value** cannot be tested precisely with the mentioned 2 methods, since this test requires a static V0. An easy way to test the setting is described in the following.

Secondary Test

This test must be carried out by injecting static secondary quantities. The test equipment needs to be configured in a way that it generates zero-sequence current 3I0 and zero-sequence voltage V0, which are injected to the SIPROTEC 5 device. By carrying out a shot, for example, a status change from zero-sequence values of 0 A and 0 V to the values not equal to zero, a transient is generated. The signal *(_:302) Ground fault* is issued as long as the static zero-sequence voltage of the 2nd state is greater than the set threshold. As amplitude for the secondary 3I0, 100 mA is a suitable value. In this test, the directional result contained in the signal *(_:302) Ground fault* is not defined and relevant, since the task is to test the setting of parameter **(_:103) V0> threshold value** only.

For testing the threshold, shots must be carried out with a static V0 slightly below the threshold and slightly above the threshold, for example, to 98 % and 102 % of the threshold value or to a threshold value of -0.2 V and +0.2 V (the greater absolute deviation of the threshold value must be selected) .

Consider that the V0 threshold is defined according to the definition of the symmetrical components. A full neutral-point displacement voltage VN of 100 V causes V0 = 57.7 V.

Example

- **(_:103) V0> threshold value** = 15 V
- 3 shots from 0 to V0 = 14.7 V and 3I0 = 100 mA
  No signal *(_:302) Ground fault* is issued.
- 3 shots from 0 to V0 = 15.3 V and 3I0 = 100 mA
  Signal *(_:302) Ground fault* is issued

If the test result is not as expected, check the injected static V0 voltage via the operational measurement of the device which contains the zero-sequence components.

11.9 Functional Test of the Trip-Circuit Supervision

General

- ✧ For the test, make sure that the switching threshold of the binary inputs is clearly below half the rated value of the control voltage.

2 Binary Inputs

- ✧ Make sure that the binary inputs used are isolated.

1 Binary Input

- ✧ Make sure that, in the circuit of the 2nd circuit-breaker auxiliary contact, an equivalent resistance R is connected.
- ✧ Observe the dimensioning notes under the section **Equivalent resistance R**.

11.10 Functional Test for the Phase-Rotation Reversal

- ✧ Check the phase sequence (direction of rotating field) at the device terminals. It must correspond to the setting of the **Phase sequence** parameter.
- ✧ The output indication *Phase sequence ABC* or *Phase sequence ACB* displays the determined phase sequence. This must correspond to the phase sequence that was set.
- ✧ You can also determine the phase sequence via the **Symmetrical components** measured values. If you obtain negative-sequence system variables (V_2, I_2) and no positive-sequence system variables (V_1, I_1) with symmetrical 3-phase infeed, the setting parameter **Phase sequence** does not correspond to the connection.

11.11 Functional Test for Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage

Checking the Stator Ground-Fault Protection with the Machine

You have to check whether the protection function and the protection ranges are functioning correctly. The following tests are intended for the unit connection.

You can check the protection range by performing a test with a ground fault at the generator terminals. The ground fault test in the power system enables you to verify the noise suppression of the load resistor.

Checking the Protection Range with a Machine Ground Fault

DANGER

Touching live parts or reaching into rotating machines will result in death or serious injury.

✧ Perform primary measures only when the machine is at standstill and the system components are de-energized and grounded.

✧ Insert a 1-phase-to-ground jumper into the terminal circuit of the machine.

✧ Set the **Mode** parameter in the protection stage to ***test***. This prevents the trip command from being generated for the stage.

✧ Start the machine and excite it slowly up to approx. 20 % of the rated machine voltage.

✧ From the operational measured values, check the plausibility of the zero-sequence voltage V_0 and the input voltage at the connected input.

✧ Determine the protection range from the pickup voltage.
The following applies for the protection range S:

$$S = \frac{\frac{V_{NG}}{\sqrt{3}} - V_{0,\text{pickup value}}}{\frac{V_{NG}}{\sqrt{3}}} \cdot 100\ \%$$

[foschzbe-130309-01.tif, 2, en_US]

Example: Measurement with secondary voltages

V_{NG} Generator voltage transformed to the transformer secondary side = 100 V

$V_{0,\text{ pickup value}}$: Measured zero-sequence voltage at pickup = 5.68 V

S: Resulting protection range = 90 %

✧ Check the messages in the message buffer. If the **Detection of faulty phase** parameter is set to ***yes***, check the display of the phase affected by the fault.

✧ Shut the machine down and remove the ground fault bridge.

✧ Set the **Mode** protection stage parameter to ***on***.

Checking Disturbance-Voltage Suppression in the Load Resistor with a System Ground Fault

DANGER

Touching live parts or reaching into rotating machines will result in death or serious injury.

✧ Perform primary measures only when the machine is at standstill and the system components are de-energized and grounded.

✧ With the primary system de-energized and grounded, insert a 1-pole ground fault bridge on the high-voltage side of the unit transformer.

CAUTION

Material can be damaged during the test if there is a neutral-point grounding at the transformer and simultaneously a grounding on the high-voltage side.

✧ Neutral grounding at the transformer must be interrupted during the test.

✧ Start the machine and excite it slowly up to 30 % of the rated machine voltage.

✧ Read the zero-sequence voltage $V_{0,\ measured\ value}$ from the operational measured values.

✧ Extrapolate the zero-sequence voltage to 100 % of the machine voltage ($V_{0,\ fault}$).

✧ Calculate the safety margin by dividing the calculated fault value by the set threshold value.

If the result is less than 0.5, the safety margin is sufficient. If the fault voltage is lower, you can increase the sensitivity of the protection function.

EXAMPLE:

$V_{0,\ meas.}$ = 0.75 V

$V_{threshold\ value}$ = 5.68 V

$V_{0,\ fault}$ = 0.75 V * 100 % / 30 % = 2.5 V

Safety margin = 2.5 V / 5.68 V = 0.44

The calculated safety margin of 0.44 is sufficient because it is below 0.5.

✧ Shut the machine down and de-excite it. Remove the ground-fault bridge.

✧ Restore neutral-point grounding if you require grounded operation of the neutral on the high-voltage side of the unit transformer.

When using the function for startup ground-fault protection on a busbar connection, carry out the same check as for the unit connection, but only the part **Test during machine ground fault**.

11.12 Primary and Secondary Testing of the Synchronization Function

Measuring the Circuit-Breaker Closing Time

Under asynchronous system conditions, the circuit-breaker closing time must be measured and set correctly. This achieves an exact parallel switching with a phase angle 0°. If switching occurs only in synchronous system conditions, this section can be skipped.

The closing time can be determined via the following 2 methods:

- 1. By reading from a fault record (recommended method)
- 2. With external timer

1. A simple option for determining the closing time involves reading out the time between the close command and closure of the switch pole via the fault record. The time determined here is the real closing time and not the operating time of the circuit beaker. You do not have to add any further time.

Siemens recommends the following procedure:

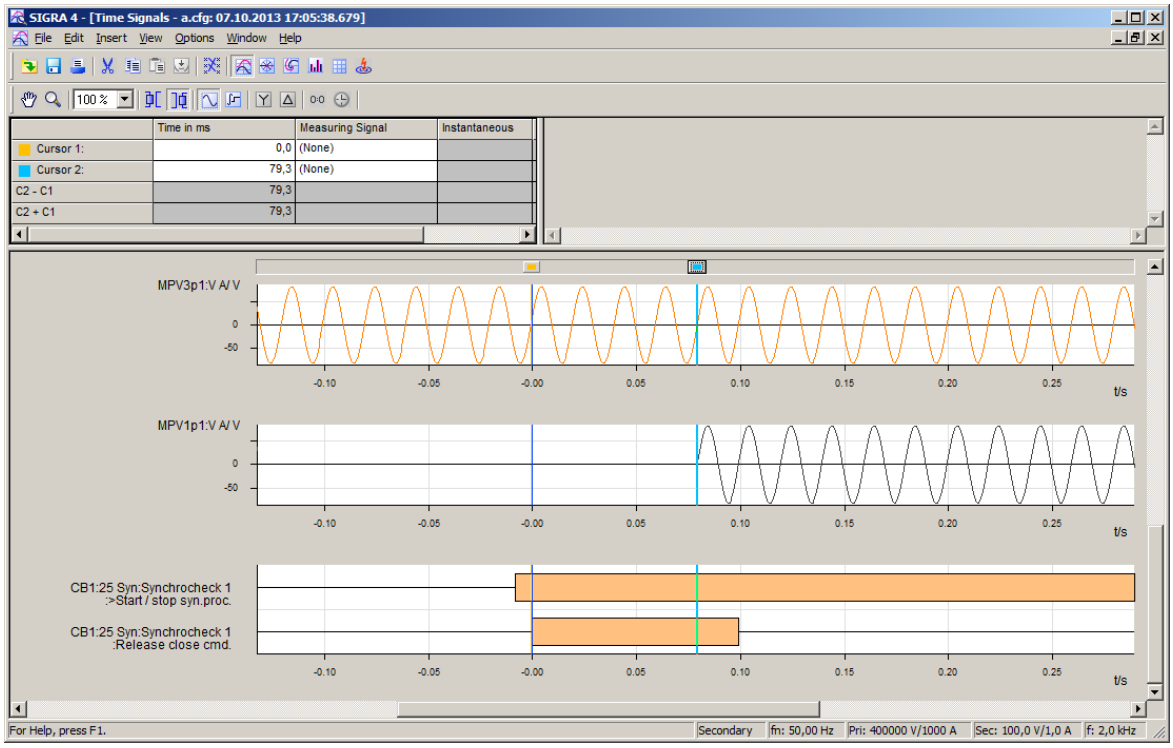
✧ Establish a condition in which the circuit breaker can be closed without hazard.

✧ If V2 switching through, activate the operating mode **Close cmd. at V1< & V2>** for the synchronization stage by setting to ***yes***.

If V1 is switched through, activate the operating mode **Close cmd. at V1> & V2<**.

✧ Make sure that the fault recorder is turned on. Via a temporary CFC chart, link the signal **Release close cmd.** of the active synchronization stage to the binary input signal **>Manual start** (of the fault recorder). With the release of closure, a fault record of the parameterized duration is set up (the default setting of 500 ms is more than adequate for this).

✧ Starting the synchronization stage. The device activates immediately.



✧ Read the fault record and determine the closing time via SIGRA (see *Figure 11-7*).

Use the 2 cursors and the time-measuring function for this. Position the first cursor on the raising close command. The occurrence of the second voltage signals the closed power-switching poles. Place the second cursor on the raising second voltage.

✧ Set the determined time with the **CB make time** parameter. Round off to the next lower adjustable value. Proceed in the same way for all other sync stages.

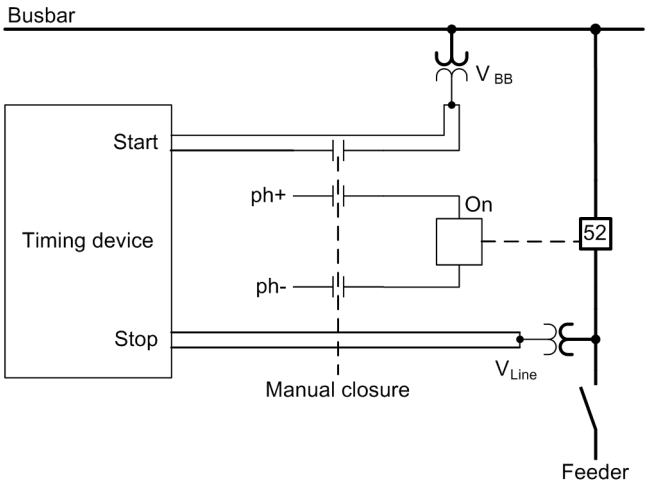
✧ Set the parameter **Close cmd. at V1< & V2>** or parameter **Close cmd. at V1< & V2<** back to its original value.

✧ Delete the CFC chart.

[scsyn001-170510-01.tif, 1, en_US]

Figure 11-7 Measurement of the Circuit-Breaker Closing Time

2. The arrangement in *Figure 11-8* is suitable for measuring the circuit-breaker operating time with external timer. Set the timer to the range 1 s or a tripping of 1 ms.



Connect the circuit breaker manually. The timer is started simultaneously by this. After the poles of the circuit breaker close, the voltage V_{Line} appears. The timer is then stopped.

If the timer is not stopped owing to an unfavorable closing moment, repeat the attempt.

Siemens recommends calculating the average value from several (3 to 5) successful switching attempts.

NOTE

Add the command output time of the protected device to measured time. This exclusively depends in good approximation on the binary output used for the close command. You can find the switching times for the different binary outputs in the Technical data. Set the total time with the parameter **`CB make time`**. Round off to the next lower adjustable value. Proceed in the same way for all other synchronization stages used.

[dwsynae6-080211-01.tif, 1, en_US]

Figure 11-8 Measurement of the Circuit-Breaker Closing Time

Checking the Measurement Chain

The measurement chain for the voltage measurement must be checked. As soon as one of the synchronization stages to be used is closed, all the necessary functional measured values are calculated. The synchronization stage, thus, does not have to be started for this check.

Proceed as follows when checking the measurement chain as a primary or secondary test:

a) As primary test

✧ Establish a synchronous state by closing the circuit breaker, if possible.

✧ Check the functional measured values within the synchronization function:

– The delta values must be 0.

– Check the voltages V1 and V2 for plausible values in comparison with the operational measured values for the voltage.

– Check the frequencies f1 and f2 for plausible values in comparison with the operational measured value for the frequency.

b) As secondary test

✧ Establish a synchronous state by applying synchronous voltage values at both measuring points.

✧ Check the functional measured values within the synchronization function:

– The delta values must be 0.

– Check the voltages V1 and V2 for plausible values in comparison with the operational measured values for the voltage.

– Check the frequencies f1 and f2 for plausible values in comparison with the operational measured value for the frequency.

Blind Switching Attempts when Used in Machines

Perform blind switching attempts when using the function in machines.

Requirement:

✧ You have checked the setting values again.

✧ The circuit breaker is switched off. The close command for the circuit breaker is interrupted (disconnecting the close command). The system voltage is switched through for the measurement.

a) Attempt with asynchronous systems:

✧ Via manual control set the generator to a speed slightly below the permitted frequency difference according to the setting values **`Max. frequency diff. f2>f1`** and **`Max. frequency diff. f2<f1`**. The generator is excited to line voltage. You can read out the values in the operational measured values.

- ✧ Start the synchronization stage, for example, externally with binary input signal or via the integrated controller. You can use a synchroscope to trigger the start at synchronism, that is, at **12 hours**. The duration until the close command then corresponds to a cycle with the duration 1/Δf. At a frequency difference of 0.1 Hz, the duration is thus 10 s.
- ✧ Insofar as permissible, perform this attempt several time for oversynchronous switching and subsynchronous switching.
- ✧ The switching performance can be checked with an external recorder or the integrated fault recording function. You have to start the fault recording explicitly.
- ✧ You can repeat the blind switching attempts at the limits of the permissible voltage difference.

b) Attempt with synchronous systems:

- ✧ Start the synchronization stage, for example, externally with binary input signal or via the integrated controller.
- ✧ Check the proper release for activation with the message log or via a fault record. You have to start the fault recording explicitly. All activation conditions have to be fulfilled within the time **`Delay close command`**.

  If you observe the change between synchronous and asynchronous operation, raise the changeover threshold **`f-threshold ASYN<->SYN`** slightly.

c) Attempt with synchrocheck:

- ✧ If you use this function in conjunction with the manual synchronization, check the proper release for closure.
- ✧ Synchronize the generator manually. Start the synchronization stage externally via a binary input. Check the proper release for closure with the indicatiion log or via the fault record. You have to start the fault recording explicitly.

11.13 Testing the Negative-Sequence Current

When testing, keep in mind that the measured values are standardized. In the setting $I_2/I_{rated, obj.}$, they are standardized to the rated current of the protected object. The conversion to secondary transformer values is accomplished in the device.

EXAMPLE:

The threshold value is set to 10 % of the protected object.

Transformer: 100 A/1 A

Rated current of the protected object: 80 A

Action Steps

✧ At a setting of 10 %, the primary negative-sequence current is 80 A • 10 %/100 % = 8 A.

For a current transformer ratio of 100, test with a secondary current of 0.08 A.

✧ With a transformer of 100 A/5 A, the test current is higher by the factor 5. Test with 0.4 A. The pickup value is at 1.1 • 0.4 A = 0.44 A.

✧ If deviations occur during the testing, you must check whether the power-system data were entered correctly.

NOTE

Keep in mind that the function works starting from the set minimum current.

11.14 Reverse Power Protection

11.14.1 Secondary Test

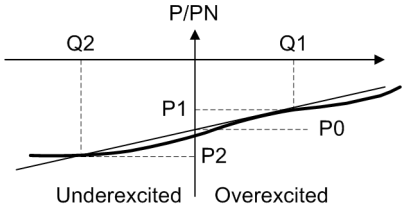
When performing the secondary test, note that the setting value for the reverse power refers to the machine variables. Due to the mismatching of the current transformer, you must check with reduced currents. You can deduce the reduction from the ratio $I_{rated, generator}$/ $I_{rated, CT}$. Check the reverse-power protection at rated voltage.

If the voltage transformer is not adjusted to the rated generator voltage, correct the secondary voltage, too. Use the following ratio:

$V_{rated, generator}/V_{rated, VT}$

11.14.2 Primary Test

For measurements on the protection current transformers and with sensitive setting of the reverse-power protection, Siemens recommends determining the reverse power and the angle-correction values. Regardless of the generator excitation, that is regardless of the reactive power Q, the reverse power P as a pure active power is constant. The resulting characteristic curve is a straight line that runs parallel to the Q axis. Due to possible angle errors of current transformers and voltage transformers, the protection device does not measure a constant active power. The current flowing at this time, which can be assumed as being proportional to the reactive power, has a substantial influence.



The deviations are determined with 3 measurements and the correcting quantity φ_{corr} is determined from the results.

To calculate the correction angle, enter the active power and reactive power measured with the device in the following table.

Use the functional measured values **`P1avg`** and **`Q1avg`** (type averaged).

Table 11-1 Value Table for Angle Correction

State	Reverse Power	Reactive Power
Reactive power near zero	P_0 =	Q_0 =
Overexcited	P_1 =	Q_1 =
Underexcited	P_2 =	Q_2 =

[dw_RPP_02, 1, en_US]

Figure 11-9 Determining the Correction Angle φ_{corr}

CAUTION

Be careful if you operate the turbine without a certain minimum steam flow (cooling effect).

Operating the turbine without a certain minimum steam flow (cooling effect) can overheat the turbine blades!

✧ The consumption of reverse power for a turbo-generator set is only allowed for a short time!

CAUTION

If the generator is underexcited, there is the risk of an out-of-step condition!

Non-observance of the following measures can result in minor personal injury or material damage.

✧ The following measures prevent the risk of an out-of-step condition.

✧ Regulate the driving power to 0 by closing the control valves. The generator draws its reverse power from the electrical power system.

✧ Change the excitation until the reactive power Q = 0. As a control measurement, read the active power P_0 and the reactive power Q_0 with the sign, and enter the values in *Table 11-1* .

✧ Increase the excitation slowly until reaching approx. 30 % of the rated apparent power of the generator (overexcited).
Read the reverse power P_1 with the sign (negative) and the reactive power Q_1 with the sign (positive) in the functional measured values and note these 2 values in the values table.

✧ Reduce the excitation slowly until reaching approx. 30 % of the rated apparent power of the generator (underexcited).
Read the reverse power P_2 with the sign (negative) and the reactive power Q_2 with the sign (negative) in the functional measured values and note these 2 values in the values table.

✧ Run the generator again at no-load excitation and select the desired operating state.

✧ With the measured value pairs (P_1, Q_1 and P_2, Q_2), calculate the correction angle φ_{corr} with the following formula:

$$\varphi_{corr} = \arctan \frac{P_1 - P_2}{Q_1 - Q_2}$$

[fo_RPP_01, 1, en_US]

NOTE

Insert the power values with the signs that you read previously!

✧ Enter this angle φ_{corr} with the same sign as the new correction angle (parameter ***(_:2311:101) Angle correction***):

Setting value ***(_:2311:101) Angle correction*** = φ_{corr}

✧ You can determine the pickup value of the reverse-power protection from the measured values P1 and P2.

Use the following formula: $P_{pickup} = (P_1+P_2)/4$

Set the value as pickup value: Parameter **(_:991:3) Threshold** = ***Ppickup***

Check of the Reverse-Power Protection

With a generator that is connected to the power system, the reverse power results from closing the control valves or from closing the quick stop.

✧ In both cases, check the consumed active power (reverse power). The valves could be leaking.

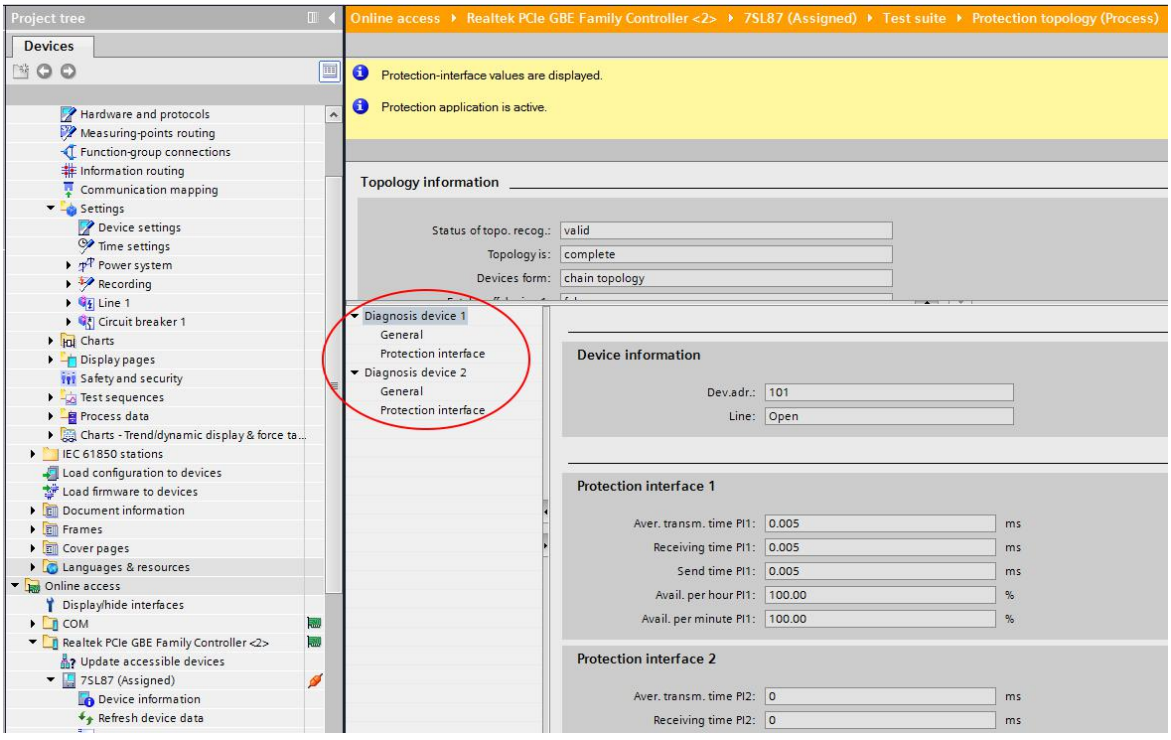
✧ Repeat the reverse-power measurement to confirm that the settings are correct.

✧ To check the efficiency of the reverse-power protection on the basis of the indications, use the parameter **(_:991:1) Mode** to switch the reverse-power protection to ***test*** .
Proceed as follows:

- ✧ Start the generator and synchronize it with the power system.
- ✧ Close the control valves.
- ✧ From the functional measured value, take the reverse power that was measured by the protection device as the active power. Use 50 % of the functional measured value as setting value for the reverse-power protection.
- ✧ Increase the driving power up to normal operation.
- ✧ Check the quick-stop criterion.
  Proceed as follows:

NOTE

Make sure that the binary input **>Stop valve closed** is properly routed. The quick-stop criterion (the pressure-operated switch or the limit switch on the quick-stop valve) must control this binary input.



- ✧ Close the quick-stop valve.
- ✧ From the functional measured value **P1avg** , take the reverse power that was measured by the protection device as the active power.
- ✧ If – contrary to expectations – this value is smaller than the reverse power when the control valves are closed, take 50 % of this value as the setting value for the reverse-power protection.
- ✧ Shut down the machine by activating the reverse-power protection. Set the parameter **(_:991:1) Mode** to ***on*** .

11.15 Functional Test Protection Communication

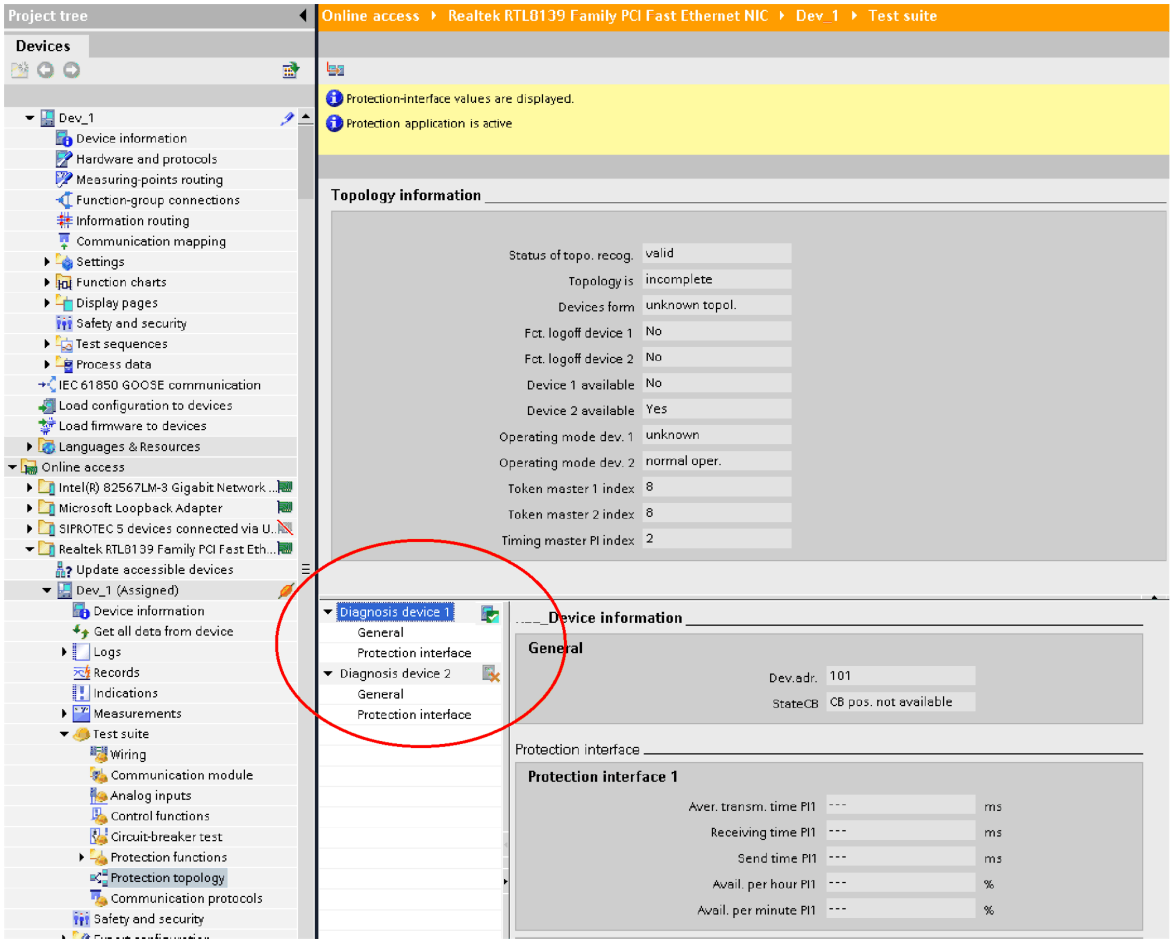
11.15.1 Checking the Protection-Data Communication

Checking the Protection-Data Communication

If the devices are connected to one another via the protection interface and switched on, they contact each other automatically. If, for example, device 1 recognizes device 2, the successful connection is indicated (see next figure). Accordingly, each device signals to all devices that aProtection-data communication is available.

[scprotec, 1, en_US]

Figure 11-10 Connection Establishment in DIGSI 5



Proper communication of the devices among each other can be supervised during operation.

✧ Check the connections for each protection interface in DIGSI 5.

If a connection is successfully established, the field **Status of topo recog.** shows the indication *valid* in DIGSI 5 (see *Figure 11-10*).

If 2 devices are parameterized incorrectly, the **Status of topo recog.** field shows the indication *invalid* (see *Figure 11-10*).

In *Figure 11-11* there is no protection-data communication between device 1 and device 2, that is, the protection interfaces 1 and 2 of device 1 do not receive data. The transmission of protection data is interrupted and differential protection is ineffective. One reason for this can be a remote control with DIGSI via the protection interface. In this case, the protection connection is interrupted and the connection is used exclusively for DIGSI.

[scprotco-061210-01.tif, 1, en_US]

Figure 11-11 Protection-Data CommunicationDeactivated

11.15.2 Directional Test

In the case of protection interfaces of type 1 and type 2, the complex phasors of the voltage and current measuring point are exchanged between devices of one communication topology in order to be able to carry out a directional test during commissioning, for example. DIGSI 5 depicts this in the form of a phasor diagram. You can only route the measuring point to the protection interface. For 1 1/2 circuit-breaker layouts, a measuring point can therefore be transferred and checked optionally. You can also check and test the 2nd measuring point by rerouting. Furthermore, communication with DIGSI 5 can take place via the protection interface to other devices of the constellation. For this purpose, the protection-interface connection is interrupted and DIGSI 5 uses this connection for communication with the remote device.

✧ After completing the remote connection by DIGSI 5, the system switches back over to protection communication.

11.16 Functional Test for Overexcitation Protection

Secondary Test

NOTE

While performing the secondary test, ensure that the data of the protected object refer to the protection function.

This means that a mismatch between the voltage transformer and the protected object will be corrected automatically. For instance, when applying the secondary rated voltage and the rated frequency, this must not result in a V/f value of 1.

The mismatch of the voltage transformer must be taken into consideration when selecting the test voltage. Multiply the secondary test voltage with the following 'k' factor.

$$k = \frac{V_{rated,obj}}{V_{rated,transf.}}$$

[fokfakuf-070513-01.tif, 1, en_US]

Example

$V_{rated,obj}$ = 110 kV; $V_{rated,\ transf.}$ = 100 kV

It follows from the above that k = 1.1. For example, when verifying the nominal conditions if the secondary rated voltage is 100 V, a voltage of 1.1 * 100 V = 110 V must be supplied. The measured value of the function **Measured value V/f** must display 1.0000.

NOTE

When checking the dependent stage, ensure it is associated with a **thermal replica**. When repeating a test, always reset the replica, using the binary input indication **>Reset therm. replica** (_:13951:501).

Primary Test

The plausibility check between instantaneous overexcitation and the displayed operational measured value is used to verify the functionality of overexcitation.

Instantaneous overexcitation is a result of the following function:

$$\frac{V}{f} \cdot \frac{f_{rated}}{V_{rated}}$$

[fomoweuf-070513-01.tif, 1, en_US]

where:

V	Instantaneous voltage
V_{rated}	Primary rated voltage of the protected object
f	Instantaneous frequency in f
f_{rated}	Rated frequency

11.17 Functional Test Differential Protection for Capacitor Banks

11.17.1 Secondary Tests

Secondary tests can never replace the primary tests described in the following chapter *11.17.2 Primary Tests*, because they cannot include connection faults.

Secondary tests are used to check the following:

- Checking the setting values
- Proper reaction of the protection function
- Engineering (for example, routing the respective logic signals, display images with measured values, logics in CFC, and much more)

If you want to perform secondary tests, observe the following instructions.

NOTE

For tests with secondary test equipment, ensure that no other measurands are connected and the trip commands to the circuit breakers are interrupted, otherwise, the circuit breakers could be activated.

Perform the tests with the current setting values for the device. If these values are not (yet) present, check with the default values.

NOTE

The measuring accuracy to be attained depends on the electrical data of the test sources. The accuracies stated in the Technical Data can be expected only if the reference conditions stipulated in VDE 0435/ part 303 and IEC 60255 are ensured and precision instruments are used. The stated tolerances refer to the default data for the protected objects. If the rated current of the protected object in relation to the rated current of the current transformer deviates considerably from the rated current of the device, you must assume higher response tolerances.

For differential protection, you can check each side separately. This corresponds to the simulation of a fault supplied from one side. If a side has several measuring points, the measuring inputs not included in the test carry no current. The pickup value is tested by increasing the test current slowly.

NOTE

Tests of currents via quadruple device-rated current (or a maximum of 20 A) lead to an overload of the input circuits and may be performed only briefly. You can find more information in chapter *12.28 Differential Protection for Capacitor Banks*. Interrupt testing to allow cool-down!

The set pickup values refer to symmetrical 3-phase current in the case of 3-phase protected objects.

If you are testing parameters set during operation, you must ensure that the setting value for the differential protection refers to the rated current of the protected object.

If you wish to check the characteristic curve, Siemens recommends using the standard testing programs of digital test equipment. For the manual checking of points on the characteristic curve, feed in a **through-flowing** current which corresponds to a current value on the stabilization axis. Then change the phase angle of the test current on one side, so that the necessary differential current is achieved. Check a value with a tolerance of 5 % above and below the point on the characteristic curve which is to be tested.

For capacitor banks, the actual pickup values for 2-phase testing also depend on the vector group of the capacitor bank.

To obtain the actual pickup value, multiply the setting value by a vector-group factor k_{SG} according to the following formula:

$$\frac{I_{\text{rated transf.}}}{I_{\text{rated transf. prim}}} k_{SG}$$

[foscgrfa-170712-01.tif, 1, en_US]

The following table shows this factor k_{SG} in dependence of the vector group and the fault type.

Table 11-2 Correction Factor k_{SG} for the Vector Group (SG) and Fault Type

Fault Type	Reference Winding (High Voltage)	Even SG Number (0, 2, 4, 6, 8, 10)	Odd SG Number (1, 3, 5, 7, 9, 11)
3-phase	1	1	1
2-phase	1	1	$\sqrt{3}/2 \approx 0.866$
1-phase with I_0 elimination	3/2 = 1.5	3/2 = 1.5	$\sqrt{3} \approx 1.73$
1-phase without I_0 elimination	1	1	$3/(1+\sqrt{3}) \approx 1.1$

11.17.2 Primary Tests

Restricted primary testing is possible for capacitor-bank applications. A wiring fault in the connection to the system could be a possible cause of the fault. With the system at a standstill, you can apply a test current of approx. 10 % to 20 % of the rated current directly to the transformer terminals and connected transformer with a primary testing device. Simulate a load (through-flowing current). The differential current must be 0 and the restraint current is the current which is fed in.

To rule out overfunction on initial switch-on, for example, due to the incorrect installation of a transformer, Siemens recommends switching the differential protection to test mode. The protection function operates, but does not issue a trip command. With the protection measurement values in the fault log, check the differential and the restraint current. The differential current must be 0 and the restraint current must correspond to the actual capacitor current.

If the differential protection is functioning correctly, switch the protection function **ON**.

NOTE

If the differential protection is disabled (for example, function in test mode), an overcurrent protection must be active as short-circuit protection (without delay and set via the starting current).

12.1 General Device Data

12.1.1 Analog Inputs

Current Inputs

All current, voltage, and power data are specified as RMS values.			
Rated frequency f_{rated}	50 Hz, 60 Hz		
Protection-class current transformers	Rated current I_{rated}	Measuring range of the modular devices	Measuring range of the non-modular devices
	5 A 1 A	0 A to 500 A 0 A to 100 A	0 A to 250 A 0 A to 50 A
Instrument transformers	5 A 1 A	0 A to 8 A 0 A to 1.6 A	0 A to 8 A 0 A to 1.6 A
Power consumption per current circuit at rated current	Approx. 0.1 VA		
Thermal rating (protection and instrument transformers)	500 A for 1 s		
	150 A for 10 s		
	20 A continuously		
	25 A for 3 min		
	30 A for 2 min		
Dynamic load-carrying capacity	1250 A one half wave		

Voltage Input

All current, voltage, and power data are specified as RMS values.		
Rated frequency f_{rated}	50 Hz, 60 Hz	
Input and output modules	IO202/IO208/IO211/IO214	IO215
Measuring range	0 V to 200 V	0 V to 7.07 V
Input impedance	< 0.1 VA	< 0.01 VA
Thermal rating	230 V continuously	20 V continuously

Measuring-Transducer Inputs (via Module ANAI-CA-4EL)

Connector type	8-pin multiple contact strip
Differential current input channels	4
Measuring range	DC -24 mA to +24 mA
Fault	< 0.5 % of measuring range
Input impedance	140 Ω
Conversion principle	Delta-sigma (16 bit)
Permissible potential difference between channels	DC 20 V
Galvanic separation from ground/ housing	DC 700 V
Permissible overload	DC 100 mA continuously
Measurement repetition	200 ms

Measuring-Transducer Inputs (via Module ARC-CD-3FO)

Connector type	AVAGO AFBR-4526Z
Number of transceivers	3

Fiber type	Polymer Optical Fiber (POF) 1 mm
Receiver	
Maximum	-10 dBm ± 2 dBm
Minimum	-40 dBm ± 2 dBm
Spectrum	400 nm to 1100 nm
Attenuation	In the case of plastic optical fibers, you can expect a path attenuation of 0.2 dB/m Additional attenuation comes from the plug and sensor head.
Optical budget [1]	Minimal 25 dB
Analog sampling rate	16 kHz
ADC type	10-bit successive approximation
Transmitter	
Type	LED
Wavelength	λ = 650 nm
Transmit power	Minimum 0 dBm Maximum 2 dBm
Numerical aperture	0.5 [2]
Signal rate connection test	1 pulse per second
Pulse duration connection test	11 µs
Comment: [1] All values in combination with sensors approved by Siemens. [2] Numerical aperture (NA = sin θ (launch angle))	

High-Speed Measuring-Transducer Inputs, Voltage/Current (via IO210, IO212)

NOTE

Current and voltage may not be connected to a measuring-transducer input at the same time; only either current or voltage may be connected. Due to EMC, no line may be connected to an input that is not used (current or voltage).

Use shielded cables.

Table 12-1 High-Speed Measuring-Transducer Inputs, Voltage

Differential voltage input channels	8[27]
Measuring range	DC -10 V to +10 V
Fault	< 0.5 % of the measuring range
Input impedance	48 kΩ
Conversion principle	Delta-sigma (16 bit)
Permissible potential difference between channels	DC 3.5 kV
Galvanic separation from ground/ housing	DC 3.5 kV
Permissible overload	DC 20 V continuously DC 60 V continuously (IO210 MT3 terminal point C9)
Measurement repetition	62.5 µs

Table 12-2 High-Speed Measuring-Transducer Inputs, Current

Differential current input channels	8[28]

[27] The IO212 has 8 high-speed measuring-transducer inputs. They can be used either as a voltage or as a current input.
[28] The IO212 has 8 high-speed measuring-transducer inputs. They can be used either as a voltage or as a current input.

Measuring range	DC -20 mA to +20 mA
Fault	< 0.5 % of the measuring range
Input impedance, current	12 Ω
Conversion principle	Delta-sigma (16 bit)
Permissible potential difference between channels	DC 3.5 kV
Galvanic separation from ground/ housing	DC 3.5 kV
Permissible current overload	DC 100 mA continuously
Measurement repetition	62.5 µs

12.1.2 Supply Voltage

Integrated Power Supply			
For modular devices, the following printed circuit-board assemblies have a power supply: PS201 – Power supply of the base module and of the 1st device row PS203 – Voltage supply of 2nd device row CB202 – Plug in module assembly with integrated power supply, for example, to accommodate communication modules			
Permissible voltage ranges (PS201, PS203, CB202)	DC 19 V to DC 60 V	DC 48 V to DC 300 V AC 80 V to AC 265 V, 50 Hz/60 Hz	
Auxiliary rated voltage V_H (PS201, PS203, CB202)	DC 24 V/DC 48 V	DC 60 V/DC 110 V/DC 125 V/DC 220 V/ DC 250 V or AC 100 V/AC 115 V/AC 230 V, 50 Hz/60 Hz	
Permissible voltage ranges (PS101)	DC 19 V to DC 60 V	DC 48 V to 150 V	DC 88 V to DC 300 V AC 80 V to AC 265 V, 50 Hz/60 Hz
Auxiliary rated voltage V_H (PS101)	DC 24 V/DC 48 V	DC 60 V/DC 110 V/ DC 125 V	DC 110 V/ DC 125 V/ DC 220 V/DC 250 V or AC 100 V/AC 115 V/ AC 230 V, 50 Hz/60 Hz
Superimposed alternating voltage, peak-to-peak, IEC 60255-11		≤ 15% of the DC auxiliary rated voltage (applies only to direct voltage)	
Inrush current		≤ 18 A	
Recommended external protection		Miniature circuit breaker 6 A, characteristic C according to IEC 60898	
Internal fuse			
–	DC 24 V to DC 48 V	DC 60 V to DC 125 V	DC 24 V to DC 48 V AC 100 V to AC 230 V
PS101	4 A intert, AC 250 V, DC 150 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	2 A time-lag, AC 250 V, DC 300 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	
PS201, PS203, CB202	2 A time-lag, AC 250 V, DC 300 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20		
Power consumption (life relay active)			
–	DC	AC 230 V/50 Hz	AC 115 V/50 Hz

Integrated Power Supply			
1/3 base module, non-modular Without plug-in modules	7.0 W	16 VA	12.5 VA
1/3 base module, modular Without plug-in modules	13 W	33 VA	24 VA
1/6 expansion module	3 W	6 VA	6 VA
1/6 plug-in module assembly without plug-in modules (modules CB202)	3.5 W	14 VA	7 VA
Plug-in module for base module or plug-in module assembly (for example, communication module)	< 5 W	< 6 VA	< 6 VA
Stored-energy time for auxiliary voltage outage or short circuit, modular devices		For V ≥ DC 24 V ≥ 50 ms For V ≥ DC 110 V ≥ 50 ms For V ≥ AC 115 V ≥ 50 ms	
Stored-energy time for auxiliary voltage outage or short circuit, non-modular devices		For V ≥ DC 24 V ≥ 20 ms For V ≥ DC 60 V/DC 110 V ≥ 50 ms For V ≥ AC 115 V ≥ 200 ms	

12.1.3 Binary Inputs

Rated voltage range	DC 24 V to 250 V The binary inputs of SIPROTEC 5 are bipolar with the exception of the binary inputs on the IO230 and on the IO231.	
Current consumption, excited	Approx. DC 0.6 mA to 1.8 mA (independent of the operating voltage)	
Power consumption, max.	0.6 VA	
Pickup time	Approx. 3 ms	
Dropout time	Approx. 4 ms	
Switching thresholds	Adjustable with DIGSI 5	
	Range 1 for 24 V, 48 V, and 60 V Operating voltage	V_{low} ≤ DC 10 V V_{high} ≥ DC 19 V
	Range 2 for 110 V and 125 V Operating voltage	V_{low} ≤ DC 44 V V_{high} ≥ DC 88 V
	Range 3 for 220 V and 250 V Operating voltage	V_{low} ≤ DC 88 V V_{high} ≥ DC 176 V
Maximum permitted voltage	DC 300 V	
The binary inputs contain interference suppression capacitors. In order to ensure EMC, use the terminals shown in the terminal diagrams/connection diagrams to connect the binary inputs to the common potential.		

12.1.4 Relay Outputs

Standard Relay (Type S)

Switching capacity	On: 1000 W/VA Off: 30 VA; 40 W ohmic; 30 W/VA at L/R ≤ 40 ms
AC and DC contact voltage	250 V

Permissible current per contact (continuous)	5 A
Permissible current per contact (switching on and holding)	30 A for 1 s (make contact)
Short-time current across closed contact	250 A for 30 ms
Total permissible current for contacts connected to common potential	5 A
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	≤ 10 ms, typically 8 ms
Max. rated data of the output contacts in accordance with UL certification	DC 24 V, 8 A, General Purpose DC 48 V, 0.8 A, General Purpose DC 240 V, 0.1 A, General Purpose AC 240 V, 5 A, General Purpose AC 120 V, 1/3 hp AC 250 V, 1/2 hp B300 R300
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V

Fast Relay (Type F)

Switching capacity	On: 1000 W/VA Off: 30 VA; 40 W ohmic; 30 W/VA at L/R ≤ 40 ms
AC and DC contact voltage	250 V
Permissible current per contact (continuous)	5 A
Permissible current per contact (switching on and holding)	30 A for 1 s (make contact)
Short-time current across closed contact	250 A for 30 ms
Total permissible current for contacts connected to common potential	5 A
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	Closing time, typical: 4 ms Opening time, typical: 2 ms ≤ 5 ms
Rated data of the output contacts in accordance with UL certification	AC 120 V, 8.5 A, General Purpose AC 277 V, 6 A, General Purpose AC 277 V, 0.7 hp AC 347 V, 4.5 A, General Purpose B300 R300
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V
Supervision	2-channel activation with cyclic testing (only for make contact)

High-Speed Relay with Semiconductor Acceleration (Type HS)

Switching capacity	On/Off: 1000 W/VA
Contact voltage	AC 200 V, DC 250 V
Permissible current per contact (continuous)	5 A

Permissible current per contact (switching on and holding)	30 A for 1 s (make contact)
Short-time current across closed contact	250 A for 30 ms
Total permissible current for contacts connected to common potential	5 A
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	Closing time, typical: 0.2 ms Opening time, typical: 6 ms Maximum: ≤ 9 ms
Rated data of the output contacts in accordance with UL certification	B150 Q300

Power Relay (for Direct Control of Motor Switches)

Switching capacity for permanent and periodic operation		
250 V/4.0 A 220 V/4.5 A 110 V/5.0 A 60 V/5.0 A 48 V/5.0 A 24 V/5.0 A	1000 W 1000 W 550 W 300 W 240 W 120 W	In order to prevent any damage, the external protection circuit must switch off the motor in case the rotor is blocked.
Turn on switching power for 30 s, recovery time until switching on again is 15 minutes. For short-term switching operations, an impulse/pause ratio of 3 % must be considered.		
100 V/9.0 A 60 V/10.0 A 48 V/10.0 A 24 V/10.0 A	1000 W 600 W 480 W 240 W	Continuous and inching operation is not permitted. In order to prevent any damage, the external protection circuit must switch off the motor in case the rotor is blocked.
AC and DC contact voltage		250 V
Permissible continuous current per contact		5 A
Permissible current per contact (switching on and holding)		30 A for 1 s
Short-time current across closed contact		250 A for 30 ms
Total permissible current for contacts connected to common potential		5 A
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used		≤ 16 ms
Rated data of the output contacts in accordance with UL certification		DC 300 V, 10 A, Resistive DC 250 V, 1 hp motor - 30 s ON, 15 min OFF DC 110 V, 3/4 hp motor - 30 s ON, 15 min OFF DC 60 V, 1/2 hp motor - 30 s ON, 15 min OFF DC 48 V, 1/3 hp motor - 30 s ON, 15 min OFF DC 24 V, 1/6 hp motor - 30 s ON, 15 min OFF
Interference suppression capacitors across the contacts		4.7 nF, ± 20 %, AC 250 V
The power relays operate in interlocked mode, that is, only one relay of each switching pair picks up at a time thereby avoiding a power-supply short circuit.		

12.1.5 Design Data

Masses

	Device Size Weight of the Modular Devices				
Type of construction	1/3	1/2	2/3	5/6	1/1
Flush-mounting device	4.8 kg	8.1 kg	11.4 kg	14.7 kg	18.0 kg
Surface-mounted device with integrated on-site operation panel	7.8 kg	12.6 kg	17.4 kg	22.2 kg	27.0 kg
Surface-mounted device with detached on-site operation panel	5.1 kg	8.7 kg	12.3 kg	15.9 kg	19.5 kg

	Size	Weight
Detached on-site operation panel	1/3	1.9 kg
Detached on-site operation panel	1/6	1.1 kg

	Device Size Weight of the Non-Modular Devices 7xx82
Type of construction	1/3
Flush-mounting device	3.7 kg
Bracket for non-modular surface-mounting variant	1.9 kg

Dimensions of the Basic and 1/3 Modules

Type of Construction (Maximum Dimensions)	Width over all x Height over all x Depth [29](in Inches)
Flush-mounting device	150 mm x 268 mm x 229 mm (5.91 x 10.55 x 9.02)
Surface-mounted device with integrated on-site operation panel	150 mm x 314 mm x 337 mm (5.91 x 12.36 x 13.27)
Surface-mounted device with detached on-site operation panel	150 mm x 314 mm x 230 mm (5.91 x 12.36 x 9.06)

Dimensions of Device Rows

Type of Construction (Maximum Dimensions)	Width over all x Height over all x Depth [30](in Inches)				
Type of construction	1/3	1/2	2/3	5/6	1/1
Flush-mounting device	150 mm x 268 mm x 229 mm (5.91 x 10.55 x 9.02)	225 mm x 268 mm x 229 mm (8.86 x 10.55 x 9.02)	300 mm x 268 mm x 229 mm(11.81 x 10.55 x 9.02)	375 mm x 268 mm x 229 mm (14.76 x 10.55 x 9.02)	450 mm x 268 mm x 229 mm (17.72 x 10.55 x 9.02)
Surface-mounted device with integrated on-site operation panel	150 mm x 314 mm x 337 mm (5.91 x 12.36 x 13.27)	225 mm x 314 mm x 337 mm (8.86 x 12.36 x 13.27)	300 mm x 314 mm x 337 mm (11.81 x 12.36 x 13.27)	375 mm x 314 mm x 337 mm (14.76 x 12.36 x 13.27)	450 mm x 314 mm x 337 mm (17.72 x 12.36 x 13.27)

[29] Width and depth rounded to whole numbers in mm
[30] Width and depth rounded to whole numbers in mm

Type of Construction (Maximum Dimensions)	Width over all x Height over all x Depth [30](in Inches)				
Surface-mounted device with detached on-site operation panel	150 mm x 314 mm x 230 mm (5.91 x 12.36 x 9.06)	225 mm x 314 mm x 230 mm (8.86 x 12.36 x 9.06)	300 mm x 314 mm x 230 mm (11.81 x 12.36 x 9.06)	375 mm x 314 mm x 230 mm (14.76 x 12.36 x 9.06)	450 mm x 314 mm x 230 mm (17.72 x 12.36 x 9.06)

Expansion Module Dimensions

Type of Construction (Maximum Dimensions)	Width x Height x Depth [31] (in Inches)
Flush-mounting device	75 mm x 268 mm x 229 mm (2.95 x 10.55 x 9.02)
Surface-mounted device with integrated on-site operation panel	75 mm x 314 mm x 337 mm (2.95 x 12.36 x 13.27)
Surface-mounted device with detached on-site operation panel	75 mm x 314 mm x 230 mm (2.95 x 12.36 x 9.06)

Plug-In Module Dimensions

Type of Construction (Maximum Dimensions)	Width x Height x Depth (in Inches)
USART-Ax-xEL, ETH-Bx-xEL	61 mm x 45 mm x 120.5 mm (2.4 x 1.77 x 4.74)
USART-Ax-xFO, ETH-Bx-xFO (without protection cover)	61 mm x 45 mm x 132.5 mm (2.4 x 1.77 x 5.22)
ANAI-CA-4EL	61 mm x 45 mm x 119.5 mm (2.4 x 1.77 x 4.7)
ARC-CD-3FO	61 mm x 45 mm x 120.5 mm (2.4 x 1.77 x 4.74)

Minimum Bending Radii of the Connecting Cables Between the On-Site Operation Panel and the Base Module

Fiber-optic cable	R = 50 mm Pay attention to the length of the cable protection sleeve, which you must also include in calculations.
D-Sub cable	R = 50 mm (minimum bending radius)

Degree of Protection to IEC 60529

For equipment in the surface-mounting housing	IP50
For equipment in the flush-mounting housing	Front IP51 Back side of the modular devices IP50 Back side of the non-modular devices IP40
For operator protection	IP2x for current terminal (installed removed) IP1x for voltage terminal (removed/without cover) IP2x for voltage terminal (removed/with cover) IP2x for voltage terminal (installed)
Degree of pollution, IEC 60255-27	2
Maximum altitude above sea level	2000 m (6561.68 ft)

[30] Width and depth rounded to whole numbers in mm
[31] Width and depth rounded to whole numbers in mm

UL Note

Type 1 if mounted into a door or front cover of an enclosure. When expanding the device with the 2nd device row, then they must be mounted completely inside an enclosure.

Tightening Torques for Terminal Screws

Type of Line	Current Terminal	Voltage Terminal with Spring-Loaded Terminals	Voltage Terminal with Screw Connection
Litz wire with ring-type lug	2.7 Nm	No ring-type lug	No ring-type lug
Stranded wires with boot-lace ferrules or pin-type lugs	2.7 Nm	1.0 Nm	0.6 Nm
Solid conductor, bare (2 mm^2)	2.0 Nm	1.0 Nm	–

NOTE

Use copper cables only.

Torques for Other Screw Types

Screw Type	Torque
M4 x 20	1.2 Nm
M4 x 8	1.2 Nm
M2.5 x 6	0.39 Nm
Countersunk screw, M2.5 x 6	0.39 Nm
Countersunk screw, M2.5 x 8	0.39 Nm
Collar screw, M4 x 20	0.7 Nm

12.2 Protection Interface and Protection Topology

Setting Values

Mode	On Off	
PPS Synchronization	Telegr. and PPS Telegr. or PPS PPS synchronization off	
Blocking of the unbalanced runtimes	Yes No	
Maximum signal runtime threshold	0.1 ms to 30.0 ms	Increments of 0.1 ms
Maximum runtime difference	0.000 ms to 3.000 ms	Increments of 0.001 ms
Failure indication after	0.05 s to 2.00 s	Increments of 0.01 s
Failure indication after	0.0 s to 6.0 s	Increments of 0.1 s
Max. error rate/h	0.000 % to 100.000 %	Increments of 0.001 %
Max. error rate/min	0.000 % to 100.000 %	Increments of 0.001 %
PPS failure indication after	0.5 s to 60.0 s	Increments of 0.1 s

Transmission Rate

Direct connection:	
Transmission rate	2048 kbit/s
Connection via communication networks:	
Supported network interfaces	G703.1 with 64 kBit/s G703-T1 with 1.455 MBit/s G703-E1 with 2.048 MBit/s
	X.21 with 64 kBit/s or 128 kBit/s or 512 kBit/s
	Pilot wires with 128 kbit/s
Transmission rate	64 kBit/s at G703.1 1.455 MBit/s at G703-T1 2.048 MBit/s at G703-E1
	512 kBit/s or 128 kBit/s or 64 kBit/s at X.21
	128 kBit/s for pilot wires

Transmission Times

Priority 1		
Response time, total approx.		
For 2 ends	Minimum	8 ms
	Typical	10 ms
For 3 ends	Minimum	10 ms
	Typical	14 ms
For 6 ends	Minimum	15 ms
	Typical	18 ms
Dropout times, total approx.		
For 2 ends	Typical	20 ms
For 3 ends	Typical	20 ms
For 6 ends	Typical	26 ms

Priority 2		
Response time, total approx.		
For 2 ends	Minimum	9 ms
	Typical	16 ms
For 3 ends	Minimum	12 ms
	Typical	18 ms
For 6 ends	Minimum	17 ms
	Typical	23 ms
Dropout times, total approx.		
For 2 ends	Typical	24 ms
For 3 ends	Typical	25 ms
For 6 ends	Typical	32 ms

Priority 3[32]		
Response time, total approx.		
For 2 ends	Minimum	
	Typical	100 ms
For 3 ends	Minimum	
	Typical	150 ms
For 6 ends	Minimum	
	Typical	200 ms
Dropout times, total approx.		
For 2 ends	Typical	100 ms
For 3 ends	Typical	150 ms
For 6 ends	Typical	200 ms

[32] Times cannot be determined because the signals are transmitted in fragments.

12.3 Date and Time Synchronization

Date format	DD.MM.YYYY (Europe)
	MM/DD/YYYY (USA)
	YYYY-MM-DD (China)
Time source 1, time source 2	None
	IRIG-B 002(003) IRIG-B 006(007) IRIG-B 005(004) with extension according to IEEE C37.118-2005
	DCF77
	PI (protection interface)[33]
	SNTP
	IEC 60870-5-103
	DNP3
	IEEE 1588
Time zone 1, time zone 2	Local
	UTC
Failure indication after	0 s to 3600 s
Time zone and daylight saving time	Transfer of PC settings
	Manually setting the time zones
Time zone offset with respect to GMT	-720 min to 840 min
Switching over to daylight saving time	Active
	Inactive
Beginning of daylight saving time	Input: day and time
End of daylight saving time	Input: day and time
Offset daylight saving time	-120 to 120 [steps of 15]

[33] If provided

12.4 Analog-Units Function Group

20-mA Unit Ether. 7XV5674-0KK00-1AA1

Max. number of connected 20-mA units	4
Max. number of channels per 20-mA unit	12

20-mA Unit Serial 7XV5674-0KK30-1AA1 (RS485) and 7XV5674-0KK40-1AA1 (fiberglass)

Max. number of connected 20-mA units	4
Max. number of channels per 20-mA unit	12

RTD Unit (Ziehl TR1200) 7XV5662-6AD10

Max. number of connected RTD units	4
Max. number of sensors per RTD unit	12
Sensor type	Pt 100 as per EN 60751

RTD Unit (Ziehl TR1200 IP) 7XV5662-8AD10

Max. number of connected RTD units	4
Max. number of sensors per RTD unit	12
Sensor type	Pt 100 as per EN 60751; connection of Ni 100 and Ni 120 sensors possible. The measured values must be converted in the evaluation unit.

Temperature Measured Values

Unit of measurement for temperature	°C or °F, can be adjusted
Pt 100	-199 °C to 800 °C (-326 °F to 1472 °F)
Resolution	1 °C or 1 °F
Tolerance	±0.5 % of the measured value ±1 K

12.5 Overcurrent Protection, Phases

12.5.1 Stage with Definite-Time Characteristic Curve

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

Setting Values for Protection Stage

Method of measurement		Fundamental component RMS value	–
Threshold value[34]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s
Pickup delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT [35] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

[34] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

[35] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value, no filter applied (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value with filter for the compensation of the amplitude attenuation due to the anti-aliasing filter (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	2 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value with filter for the gain of harmonics (including compensation of the amplitude attenuation[36] (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1.5 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), (f_{rated} ± 10 %) [37]
Up to 50th harmonic, f_{rated} = 50 Hz	3% of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %) [38]
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %) [39]
Time delays	1 % of the setting value or 10 ms

[36] In case that the filter response exactly matches the user-defined gain factors
[37] In case that the user-defined gain factor is set below 3. The tolerance increases, if the gain factor is larger.

[39] 3 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.5.2 Stage with Inverse-Time Characteristic Curve

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

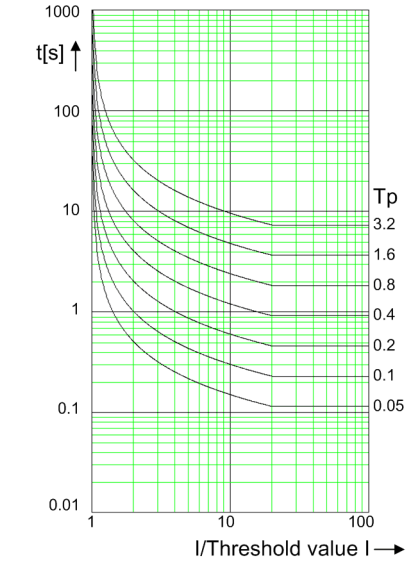
Setting Values for Protection Stage

Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.00 to 15.00	Increments of 0.01
Pickup delay		0.00 s to 60.00 s	Increments of 0.01 s
Minimum time of the curve		0.00 s to 1.00 s	Increments of 0.01 s
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)



Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

12.6 Voltage-Dependent Overcurrent Protection, Phases

Setting Values for All Stage Types

Method of measurement		Fundamental component RMS value	–
Overcurrent threshold value	For I_{rated} = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
Time delay		0.10 s to 60.00 s	Increments of 0.01 s

Setting Values for Inverse Time-Overcurrent Stages

Method of measurement	Fundamental component RMS value	–
Dropout ratio of undervoltage[48]	1.01 to 1.20	Increments of 0.01
Undervoltage threshold value[48]	0.300 V to 175.000 V	Increments of 0.001 V
Dropout	Disk emulation Instantaneous	–
Time multiplier	0.05 to 15.00	Increments of 0.01

Setting Values for Definite Time-Overcurrent Stages

Seal-in voltage	0.300 V to 175.000 V	Increments of 0.001 V
Phase-to-phase voltage	0.300 V to 175.000 V	Increments of 0.001 V
Negative-sequence voltage V2	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Duration of V-seal-in time	0.10 s to 60.00 s	Increments of 0.01 s

Dropout for Inverse Time-Overcurrent Stages

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	
Current	95 % of 1.1 · threshold value
Voltage[48]	105 % of threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer [48]	150 mV sec.

Reset of the Integration Timer for Inverse Time-Overcurrent Stages

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

[48] The value is for the inverse time-overcurrent voltage-released stage.

Dropout for Definite Time-Overcurrent Stages

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Operate Curves and Dropout-Time Characteristic Curves According to IEC

Extension of the operate time during operation with inrush-current detection	Approx. 10 ms

The operate curves and dropout-time characteristic curves according to IEC can be found in the chapter Technical Data under Inverse-Time Overcurrent Protection.

Operate Curves and Dropout-Time Characteristic Curves According to ANSI/IEEE

The operate curves and dropout-time characteristic curves according to IEC can be found in the chapter Technical Data under Inverse-Time Overcurrent Protection.

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % part of harmonic in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Voltage	0.5 % of the setting value or 0.05 V
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.7 Overcurrent Protection, Ground

12.7.1 Stage with Definite-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[49]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[50] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

[49] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

[50] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Tolerances

3I0 measured via I4[51], method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
3I0 measured via I4[52], method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Time delays	1 % of the setting value or 10 ms

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.7.2 Stage with Inverse-Time Characteristic Curve

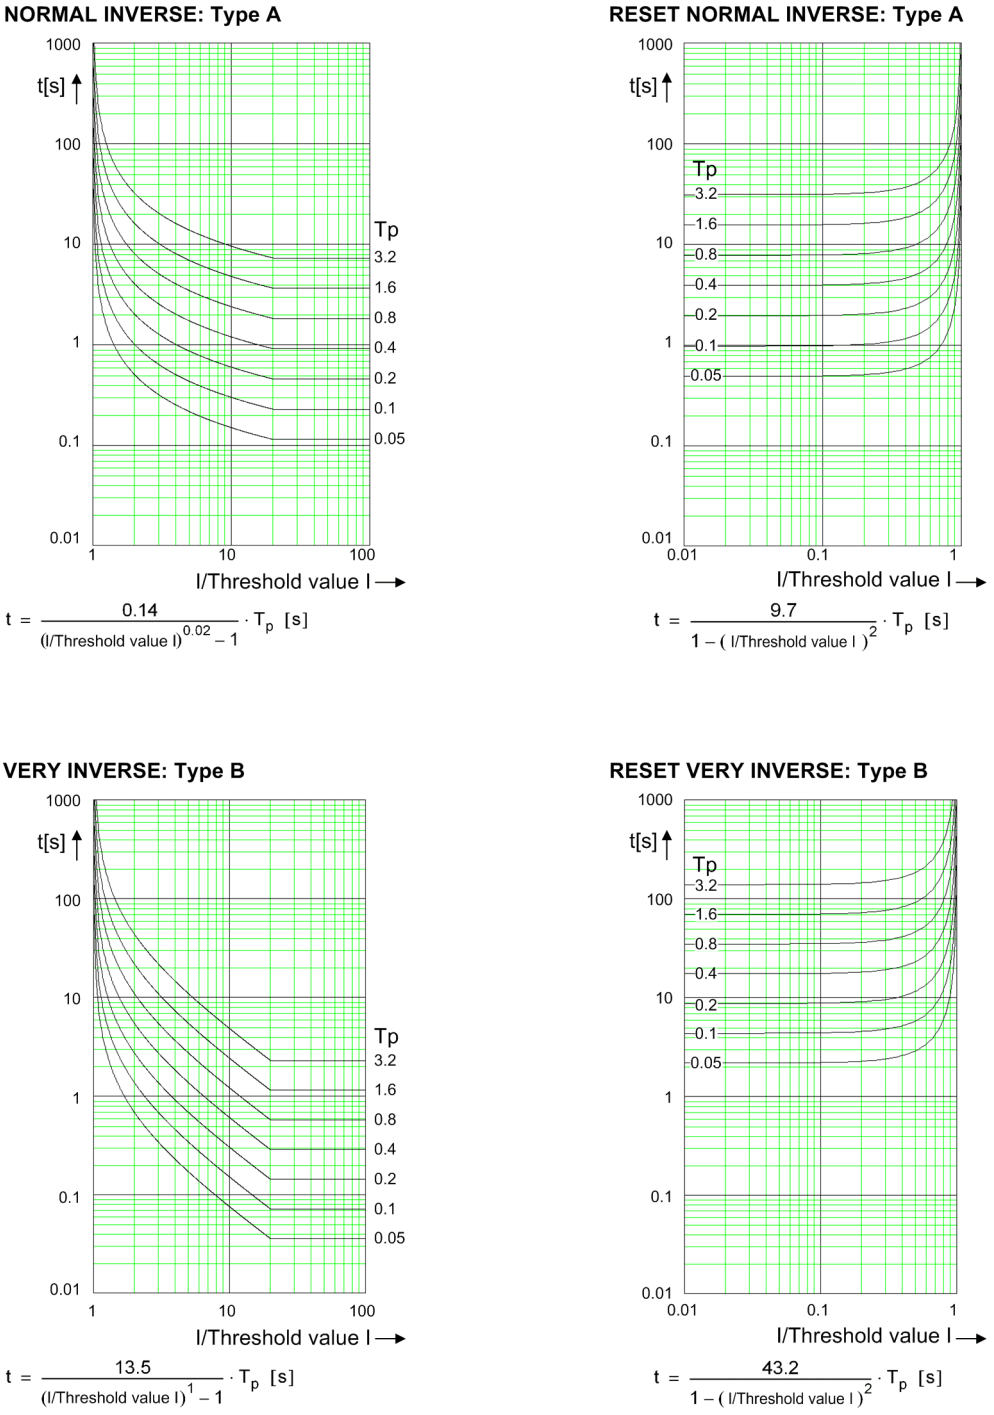
Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[53]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.00 to 15.00	Increments of 0.01
Minimum time of the curve		0.00 s to 1.00 s	Increments of 0.01 s
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)



[51] Slightly expanded tolerances will occur during the calculation of 3I0, maximum factor of 2
[52] Slightly expanded tolerances will occur during the calculation of 3I0, maximum factor of 2
[53] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Operate Curves and Dropout-Time Characteristic Curves According to IEC

[57] Insignificantly increased tolerances will occur during the calculation of 3I0, maximum factor of 2

12.8 Directional Overcurrent Protection, Phases

12.8.1 Stage with Definite-Time Characteristic Curve

Setting Values

Rotation angle of the reference voltage		-180° to +180°	Increments of 1°
Directional mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value[58]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Direction Determination

Type	With externally generated voltages With voltage memory 2 s
Forward range	$V_{ref,rot}$ ±88°
Dropout differential forward/reverse range	1°
Directional sensitivity	Unlimited for 1 and 2-phase short circuits Dynamically unlimited, stationary for 3-phase short circuits Approx. 13 V phase-to-phase

Times

Operate time with time delay = 0 ms	Approx. 37 ms + OOT [59] at 50 Hz Approx. 22 ms + OOT at 60 Hz

[58] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

[59] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)

12.9.1 Stage with Definite-Time Characteristic Curve

Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances

10 Hz ≤ f < 0.9 f_{rated} 1.1 f_{rated} < f ≤ 80 Hz	Slightly expanded tolerances
f < 10 Hz f > 80 Hz	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Time delays	1 % of the setting value or 10 ms
Direction-determination angle error	1°

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.9.2 Stage with Inverse-Time Characteristic Curve

Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Type of characteristic curve		Characteristic curves according to IEC and ANSI	
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.00 to 15.00	Increments of 0.01

Minimum time of the curve	0.00 s to 1.00 s	Increments of 0.01 s
Additional time delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Operate Curves and Dropout-Time Characteristic Curves according to IEC

Normal inverse: type A	Refer to the respective figure of the technical data for the non-dir-OC-ground function *12.7.2 Stage with Inverse-Time Characteristic Curve*
Very inverse: type B	
Extremely inverse: type C	
Long-time inverse: type B	

Operate Curves and Dropout-Time Characteristic Curves according to ANSI/IEEE

Inverse: type C	Refer to the respective figure of the technical data for the non-dir-OC-ground function *12.7.2 Stage with Inverse-Time Characteristic Curve*
Short inverse	
Long inverse	
Moderately inverse	
Very inverse	
Extremely inverse	
Definite inverse	

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active with reduced sensitivity

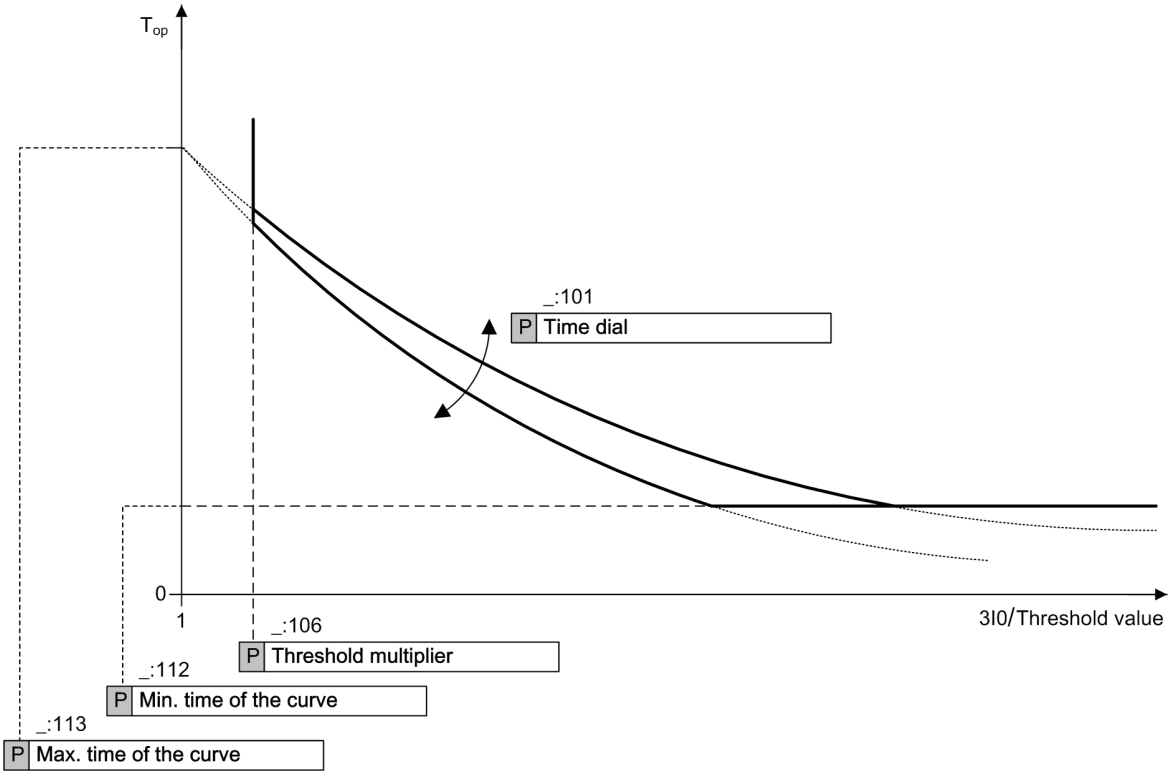
Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.9.3 Stage with Inverse Time-Overcurrent Protection with Logarithmic-Inverse Characteristic Curve



Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Characteristic curve: see *Figure 12-13*

Figure 12-14 Operate Curve of the Logarithmic Inverse Time with Knee-Point Characteristic (In the Example of **`Threshold = 0.004 A`**)

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Inverse-time operate time to logarithmic inverse time with knee-point characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Inverse-time dropout time to logarithmic inverse time with knee-point characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.9.5 Stage with User-Defined Characteristic Curve

Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01
X values of the operate curve		1.00 p. u. to 66.67 p. u.	Increments of 0.01 p. u.
Y values of the operate curve		0.00 s to 999.00 s	Increments of 0.01 s
Number of value pairs for the dropout characteristic curve		2 to 30	Increments of 1
X values of the dropout characteristic curve		0.05 p. u. to 0.95 p. u.	Increments of 0.01 p. u.
Y values of the dropout characteristic curve		0.00 s to 999.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.10 Inrush-Current Detection

Setting Values

Operat.-range limit Imax	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Component of 2nd harmonic		10 % to 45 %	Increments of 1 %
Duration of the crossblock function		0.03 s to 200.00 s	Increments of 0.01 s

Times

Pickup times	Approx. 29 ms

Dropout Ratios

Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	0.95

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Current measurement I_{max}	1 % of the setting value or 5 mA
Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	1 % of the setting value for settings of $I_{2nd\ harm}/_{1st\ harm}$
Time delays	1 % of the setting value or 10 ms

12.11 Arc Protection

Setting Values

Threshold I>	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold 3I0>>	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
External trip initiation		yes no	
Operating mode		Light only Current and light	
Sensor		Point sensor Line sensor Custom	
Threshold Light		-28.00 dB to 0.00 dB	Increments of 0.01
Channel		Possible settings, application-dependent	

Dropout

The larger dropout differential (= **`| pickup threshold – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the `Dropout ratio` parameter If this parameter is not available, a dropout ratio of 95 % applies to the overcurrent protection and a dropout ratio of 105 % applies to the undercurrent protection.	
Minimum absolute dropout differential	
Protection-class current transformers	15 mA sec. (I_{rated}= 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated}= 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Shortest operate time Operating mode = light only	Approx. 2.6 ms + OOT[64]
Shortest operate time Operating mode = Current and light	Approx. 4.0 ms + OOT at 50 Hz Approx. 3.8 ms + OOT at 60 Hz

[64] OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with a fast relay, see Chapter *12.1.4 Relay Outputs*

12.12 Instantaneous High-Current Tripping

Setting Values

Threshold value	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 50 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.50 to 0.90	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time for current > 2·√2·threshold value	Approx. 8 ms + OOT[65]

Tolerances

Response tolerance, current	5 % of setting value or 10 mA at I_{rated} = 1 A 5 % of setting value or 50 mA at I_{rated} = 5 A
Time delays	1 % of the setting value or 10 ms

[65] OOT (Output Operating Time) Additional delay of the output medium used, see Chap. *12.1.4 Relay Outputs*

12.13 Instantaneous Tripping at Switch onto Fault

Setting Values

Tripping delay	0.00 s to 60.00 s	Increments of 0.01 s

Tolerances

Times	< 1 % of the setting value or 10 ms

12.14 Overcurrent Protection, 1-Phase

12.14.1 Stage with Definite-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[66]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio (fixed)		0.95	–
Time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 15 ms + OOT[67] at 50 Hz Approx. 14 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT at 50 Hz Approx. 17 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

[66] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

[67] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Time delays	1 % of the setting value or 10 ms

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.14.2 Stage with Inverse-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[68]	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout

[68] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

Disk emulation	Approx. < 0.90 · threshold value

Operate Curves and Dropout-Time Characteristic Curves According to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

The tripping characteristic curves and dropout characteristic curves according to IEC can be found in the Technical Data chapter under Inverse Time-Overcurrent Protection.

Operate Curves and Dropout-Time Characteristic Curves According to ANSI/IEEE

The tripping characteristic curves and dropout characteristic curves according to ANSI/IEEE can be found in the Technical Data chapter under Inverse Time-Overcurrent Protection.

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value +2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value +2 % current tolerance or 30 ms

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.14.3 Stage with User-Defined Characteristic Curve

Setting Values

Method of measurement	Fundamental component RMS value	–

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01
Number of value pairs for the operate curve		2 to 30	Increments of 1
X values of the operate curve		1.00 p.u. to 66.67 p. u.	Increments of 0.01 p.u.
Y values of the operate curve		0.00 s to 999.00 s	Increments of 0.01 s
Number of value pairs for the dropout characteristic curve		2 to 30	Increments of 1
X values of the dropout characteristic curve		0.05 p.u. to 0.95 p. u.	Increments of 0.01 p.u.
Y values of the dropout characteristic curve		0.00 s to 999.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Frequency Operating Range

$0.9 \leq f/f_{rated} < 1.1$	According to specified tolerances
10 Hz $\leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80$ Hz	Slightly expanded tolerances
f < 10 Hz f > 80 Hz	Active with less sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)

Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value +2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value +2 % current tolerance or 30 ms

Influencing Variables for Thresholds

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

Operate Curves and Dropout-Time Characteristic Curves According to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

12.15 Overcurrent Protection, 1-Phase (Fast Stage)

Setting Values

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio (fixed)		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 8 ms + OOT[69]
Dropout time	Approx. 25 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Pickup tolerance, current	5 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

[69] OOT (Output Operating Time) additional time delay of the output medium used, for example, 5 ms with fast relay

12.16 Non-Directional Intermittent Ground-Fault Protection

Setting Values

Threshold value 3I0> interm.	For current transformer type **protection** and I_{rated} = 1 A		0.030 A to 35.000 A	Increments of 0.001 A
	For current transformer type **protection** and I_{rated} = 5 A		0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Number of pickups until intermittent ground fault			2 to 10	Increments of 1
Pickup extension time			0.00 s to 10.00 s	Increments of 0.01 s
Sum of extended pickup times			0.00 s to 100.00 s	Increments of 0.01 s
Reset time			1.00 s to 600.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[70] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active with less sensitivity

[70] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

Tolerances

Currents	-3I0 via protection-class current transformers: 1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
	-3I0 via sensitive current transformer: 1 % of setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A)
Times	1 % of the setting value or ± 10 ms

12.17 Directional Intermittent Ground-Fault Protection

Setting Values

Threshold value 3I0>	For current transformer type **protection** and I_{rated} = 1 A		0.030 A to 35.000 A	Increments of 0.001 A
	For current transformer type **protection** and I_{rated} = 5 A		0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Number of pulses until intermittent ground fault			2 to 10	Increments of 1
Pickup extension time			0.00 s to 10.00 s	Increments of 0.01 s
Sum of extended pickup times			0.00 s to 100.00 s	Increments of 0.01 s
Reset time			1.00 s to 600.00 s	Increments of 0.01 s
Number of pulses for operate			2 to 100	Increments of 1

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Pickup time	Approx. 30 ms + OOT[71] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active with less sensitivity

[71] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

Tolerances

Currents	3I0 via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
	3I0 via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A)
Times	1 % of the setting value or ± 10 ms

12.18 Sensitive Ground-Fault Detection

12.18.1 General

Setting Values

Decay time V0			0.06 s to 0.20 s	Increments of 0.01 s
Dropout delay			0.00 s to 60.00 s	Increments of 0.01 s
Core balance current transformer current 1 Core balance current transformer current 2	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Core balance current transformer angle correction F1 Core balance current transformer angle correction F2			0.0° to 5.0°	Increments of 0.1°

Times

Pickup times	Approx. 25 ms + OOT[72] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout times	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances [73]
$f < 10\ Hz$ $f > 80\ Hz$	Active with less sensitivity [74]

Tolerances

Currents	-3I0 via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A, f_{rated} ± 10 %)
	-3I0 via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A, f_{rated} ± 10 %)
Voltages	1 % of the setting value or 0.05 V
Times	1 % of the setting value or ±10 ms

[72] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays
[73] Transient ground-fault stage is inactive
[74] Transient ground-fault stage is inactive

Direction-calculation angle error[75]	≤ 1° at 3I0 > 5 mA, V0 = 0.6 V ≤ 2° at 3I0 ≤ 5 mA, V0 = 0.6 V

12.18.2 Directional 3I0 Stage with Cos φ or Sin φ Measurement

Setting Values

Direction method of measurement			cos φ sin φ	–
Threshold value 3I0> Minimum directional 3I0> for direction determination	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Time delay of the direction determination			0.00 s to 60.00 s	Increments of 0.01 s
α1 constraint of the direction range α2 constraint of the direction range			1° to 15°	Increments of 1°
Angle correction φ			-45° to 45°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[76] at 50 Hz Approx. 29 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

[75] Not applicable to *12.18.4 Directional 3I0 Stage with φ(V0,3I0) Measurement*
[76] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

12.18.3 Directional Transient Ground-Fault Stage

Setting Values

Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 1.600 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 8.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 1.600 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 8.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Maximum operational V0			0.300 V to 340.000 V	Increments of 0.001 V
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 115 ms + OOT[77] at 50 Hz Approx. 112 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT at 50 Hz Approx. 15 ms + OOT at 60 Hz

[77] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.18.4 Directional 3I0 Stage with φ(V0,3I0) Measurement

Setting Values

Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Min. V0> for direction determination			0.300 V to 200.000 V	Increments of 0.001 V
Time delay of the direction determination			0.00 s to 60.00 s	Increments of 0.01 s
Rotation angle of the reference voltage			-180° to 180°	Increments of 1°
Forward range +/-			0° to 180°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 23 ms + OOT[78] at 50 Hz Approx. 21 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 21 ms + OOT at 50 Hz Approx. 20 ms + OOT at 60 Hz

Tolerances

Direction-calculation angle error	≤ 1° at 3I0 ≥ 10 mA, V0 = 0.6 V ≤ 2° at 2 mA < 3I0 < 10 mA, V0 = 0.6 V ≤ 3° at 3I0 ≤ 2 mA, V0 = 0.6 V

[78] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.18.5 Directional Y0 Stage with G0 or B0 Measurement (Admittance)

Setting Values

Direction method of measurement			B0 G0	–
Release Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Threshold value Y0>			0.10 mS to 100.00 mS	Increments of 0.01 mS
Time delay of direction determination			0.00 s to 60.00 s	Increments of 0.01 s
α1 constraint of direction range α2 constraint of direction range			1° to 15°	Increments of 1°
Angle correction φ			-45° to 45°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[79] at 50 Hz Approx. 29 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

[79] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Admittance	1 % of the setting value or 0.05 mS (I_{rated} = 1.6 A) or 0.25 mS (I_{rated} = 8 A), (f_{rated} = ± 10 %)

12.18.6 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

Setting Values

Threshold value[80]	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01
V< faulty ph-gnd vltg.	0.300 V to 200.000 V	Increments of 0.001 V
V> healthy ph-gnd. vltg.	0.300 V to 200.000 V	Increments of 0.001 V

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	
Standard filter, true RMS	Approx. 25 ms + OOT[81] at 50 Hz Approx. 22 ms + OOT at 60 Hz
2 cycle filters	Approx. 45 ms + OOT at 50 Hz Approx. 39 ms + OOT at 60 Hz
Dropout time	
Standard filter, true RMS	Approx. 20 ms + OOT at 50 Hz Approx. 16.6 ms + OOT at 60 Hz
2 cycle filters	Approx. 31.06 ms + OOT at 50 Hz Approx. 27.06 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

[80] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.
[81] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

12.18.7 Non-Directional 3I0 Stage

Setting Values

Method of Measurement			Fundamental component RMS value	
Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For transformer type I-sensitive and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For transformer type I-sensitive and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Pickup delay			0.00 s to 60.00 s	Increments of 0.01 s
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[82] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

12.18.8 Non-Directional Y0 Stage

Setting Values

V0> threshold value	0.300 V to 200.000 V	Increments of 0.001 V
Threshold Y0>	0.10 mS to 100.00 mS	Increments of 0.01 mS

[82] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[83] at 50 Hz Approx. 29 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

Tolerances

Admittance	1 % of the setting value or 0.05 mS (I_{rated} = 1.6 A) or 0.25 mS (I_{rated} = 8 A), (f_{rated} = ± 10 %)

[83] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.19 Undercurrent Protection

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value I<	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time	Approx. 25 ms + OOT[84] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Currents, method of measurement = fundamental component	1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents, method of measurement = RMS value (33 % portion harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)

[84] OOT (Output Operating Time) additional delay of the output medium used, for example, 5 ms with fast relays, see Chapter Relay Outputs

Up to 50th harmonic, f_{rated} = 50 Hz	3 % of setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Time delays	1 % of the setting value or 10 ms

12.20 Negative-Sequence Protection

12.20.1 Stage with Definite-Time Characteristic Curve

Setting Values

Reference value for I_2 (I_{ref})		Rated object current $I_{rated, obj.}$ Positive-sequence current I_1	
Pickup value		5.0 % to 999.9 % I_2/I_{ref}	Increments of 0.1
Dropout ratio		0.40 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Release current (minimum current release)	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Maximum phase current (maximum current limiting)	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

- Dropout differential derived from the parameter **Dropout ratio**
- Dropout differential of 3 % of the object rated current

Times

Pickup time	Approx. 40 ms + OOT[85] at 50 Hz
	Approx. 35 ms + OOT at 60 Hz
Dropout time	Approx. 35 ms + OOT

Current Operating Range

Current range	At least one phase current ≥ setting value $I_{release}$
	All phase currents ≤ setting value $I_{ph, max}$

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

[85] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Pickup value	
$I_2/I_{rated, obj}$	Approx. 2 % of the setting value or 0.8 % of the absolute value
I_2/I_1	Approx. 2 % of the setting value or 4 % of the absolute value (I_1 > 50 mA (I_{rated} = 1 A) or 250 mA (I_{rated} = 5 A))
Time delays	1 % of the setting value or 10 ms

12.20.2 Stage with Inverse-Time Characteristic Curve

Setting Values

Reference value for I_2 (I_{ref})		Rated object current $I_{rated,obj.}$ Positive-sequence current I_1	
Pickup value		5.0 % to 999.9 % I_2/I_{ref}	Increments of 0.1
Dropout		Disk emulation Instantaneous	
Time multiplier		0.05 to 15.00	Increments of 0.01
Release current (minimum current release)	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Maximum phase current (maximum current limiting)	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

- Dropout differential derived from the parameter **Dropout ratio**
- Dropout differential of 3 % of the object rated current

Times

Pickup time	Approx. 40 ms + OOT[86] at 50 Hz
	Approx. 35 ms + OOT at 60 Hz
Dropout time	Approx. 35 ms + OOT

Dropout Ratio

Disk emulation	Approx. 0.90 · threshold value
Instantaneous	Approx. 1.05 · threshold value Approx. 0.95 · pickup value

[86] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Operate and Dropout Characteristic Curves

You can select from the following operate and dropout characteristic curves:

Table 12-3 Standard Characteristic Curves to IEC

Normal inverse: type A	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-1*
Very inverse: type B	
Extremely inverse: type C	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-2*
Long-time inverse: type B	

Table 12-4 Standard Characteristic Curves to ANSI

Inverse: type C	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-3*
Short inverse	
Long inverse	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-4*
Moderately inverse	
Very inverse	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-5*
Extremely inverse	
Definite inverse	See chapter *12.5.2 Stage with Inverse-Time Characteristic Curve* , *Figure 12-6*

Extension of the Operating Time

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

Current Operating Range

Current range	At least one phase current ≥ setting value $I_{release}$
	All phase currents ≤ setting value $I_{ph, max}$

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10 \text{ Hz} \le 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80 \text{ Hz}$	Slightly expanded tolerances
$f < 10 \text{ Hz}$ $f > 80 \text{ Hz}$	Inactive

Tolerances

Reference value = rated current	
Pickup value	Approx. 2 % of the setting value or 0.8 % of the absolute value
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the setting value or + 2 % of the current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the setting value or + 2 % of the current tolerance or 30 ms
Reference value = pos. seq. current	
Pickup value	Approx. 2 % of the setting value or 4 % of the absolute value (I1 > 50 mA (I_{rated} = 1 A) or 250 mA (I_{rated} = 5 A))

Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms

12.21 Directional Negative-Sequence Protection with Definite-Time Delay

Setting Values

Directional mode	Forward, backward, non-directional	
Stabilization with phase currents	0 % to 30 %	Increments of 1 %

Threshold value (pickup value) at $I_{N\text{-rated}}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
Threshold value (pickup value) at $I_{N\text{-rated}}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A

Extension time of the blocking after a 1-pole pause	0.00 s to 60.00 s	Increments of 0.01 s

Setting Values for Direction Determination

Minimum negative-sequence system voltage V2		0.150 V to 20.000 V	Increments of 0.001 V
Minimum negative-sequence system current I2	For I_{rated} = 1 A	0.030 A to 10.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 50.00 A	Increments of 0.01 A
Upper limit angle forward, β		0° to 360°	Increments of 1°
Lower limit angle forward, α		0° to 360°	Increments of 1°

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

- Dropout differential derived from the parameter **`Dropout ratio`**
- Dropout differential of 3 % of the object rated current

Times

Operate time with time delay = 0 ms	Approx. 40 ms + OOT[87] at 50 Hz Approx. 40 ms + OOT at 60 Hz
Dropout time	Approx. 39 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Threshold values:	
Negative-sequence voltage V2	1 % of the setting value or 0.5 V
Negative-sequence current I2	2 % of the setting value or 10 mA at I_{rated} = 1 A
	1 % of the setting value or 5 mA at I_{rated} = 5 A
Times:	
Independent time delays	1 % of the setting value or 10 ms

[87] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Limit angle in determining the direction	5°

12.22 Thermal Overload Protection, 3-Phase

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

Setting Values/Increments for the Protection Stage

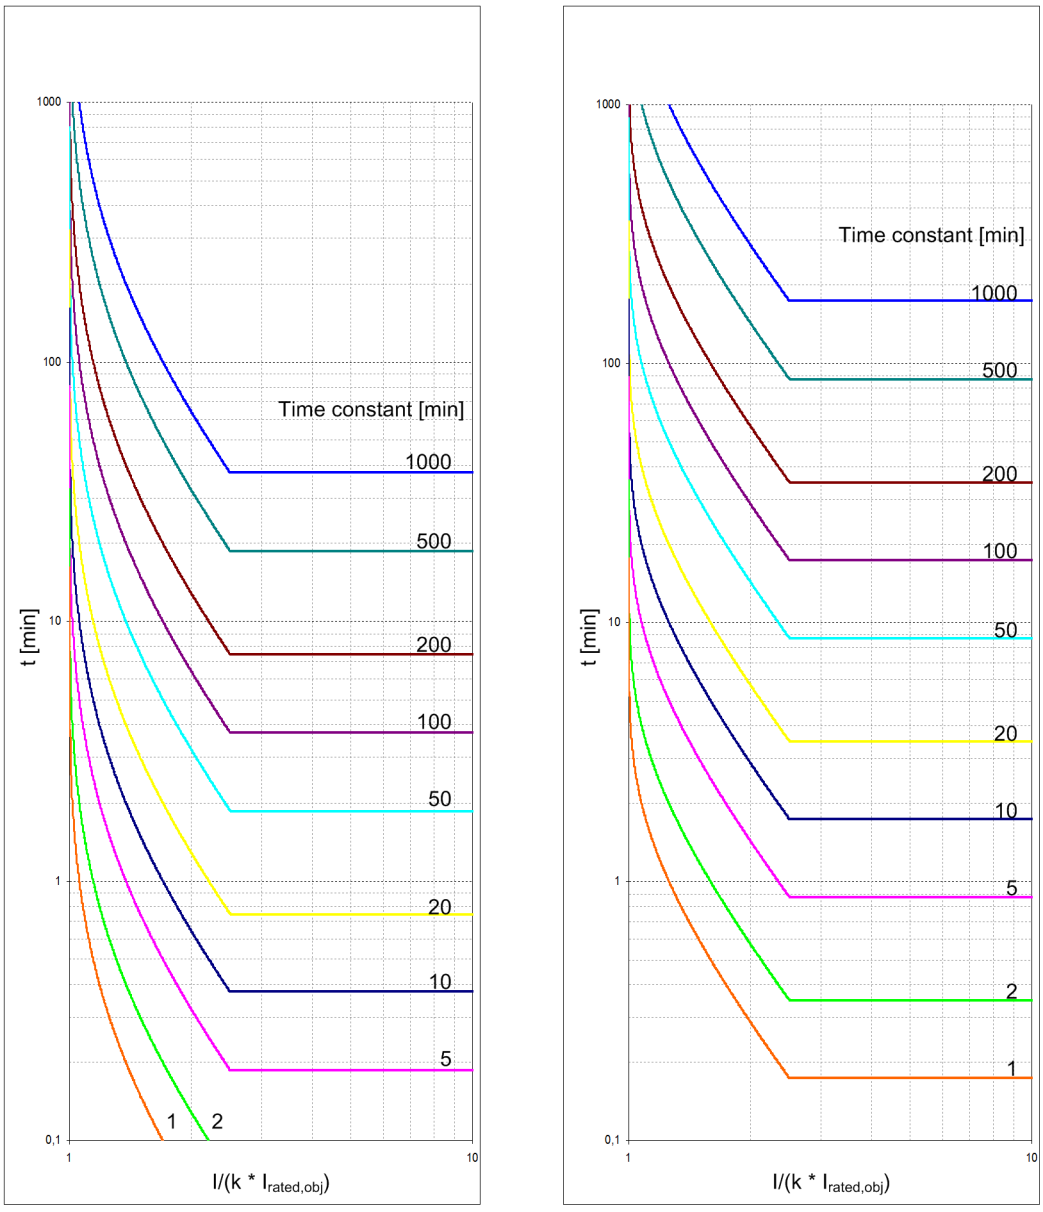
Threshold current warning	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold thermal warn.		50 % to 100 %	Increments of 1 %
Dropout threshold operate		50 % to 99 %	Increments of 1 %
Emerg. start T overtravel		0 s to 15 000 s	Increments of 10 s
K-factor acc. to IEC 60225-8		0.10 to 4.00	Increments of 0.01
Thermal time constant		10 s to 60 000 s	Increments of 1 s
Cooling time constant		10 s to 60 000 s	Increments of 1 s
Imax thermal	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Imin cooling	1 A @ 50 and 100 Irated	0.000 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.00 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.000 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.000 A to 8.000 A	Increments of 0.001 A
Temperature rise at Irated		40 K to 200 K	Increments of 1 K
Default temperature		-55°C to 55°C	Increments of 1°C
Minimal temperature		-55°C to 40°C	Increments of 1°C

Dropout Ratios

Tripping threshold (fixed at 100 %)	Dropout if value drops below operate indication dropout threshold
Thermal warning threshold	About 0.99 of the setting value
Current warning threshold	About 0.95 of the setting value

Frequency Range of the Input Signals

The function captures input signals up to the 50th harmonic.



Tolerances

No filter applied (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-8
	Up to 50th harmonic, f_{rated} = 50 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-8
	Up to 50th harmonic, f_{rated} = 60 Hz	5 % or 25 mA (I_{rated} = 1 A) or 125 mA (I_{rated} = 5 A), 5 % class acc. to IEC 60255-8
With the filter for compensation of the amplitude attenuation due to the anti-aliasing filter (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-8
	Up to 50th harmonic, f_{rated} = 50 Hz	3 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 3 % class acc. to IEC 60255-8
	Up to 50th harmonic, f_{rated} = 60 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-8
With the filter for gain of harmonics including compensation of the amplitude attenuation[88] (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-8[89]
	Up to 50th harmonic, f_{rated} = 50 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-8[90]
	Up to 50th harmonic, f_{rated} = 60 Hz	5 % or 25 mA (I_{rated} = 1 A) or 125 mA (I_{rated} = 5 A), 5 % class acc. to IEC 60255-8[90]
With reference to the operate time	Up to 30th harmonic	3 % or 1 s for $I/(k \cdot I_{rated}) > 1.25$, 3 % class acc. to IEC 60255-8

Operate Curve

Operate curve	$t = \tau_{th} \cdot \ln \frac{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - \left(\frac{I_{preload}}{k \cdot I_{rated,obj.}}\right)^2}{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - 1}$	
Where	t	Operate time
	τ_{th}	Time constant
	I	Current load current
	$I_{preload}$	Preload current
	k	Setting factor according to VDE 0435 part 3011 or IEC 60255-8 (K factor)
	$I_{rated, obj}$	Rated current of the protected object

[88] In case that the filter response exactly matches the user-defined gain factor.
[89] In case that the user-defined gain factor is set below 3. The tolerance is increased if the gain factor is larger.
[90] In case that the user-defined gain factor is set below 7. The tolerance is increased if the gain factor is larger.

With 80 % preload and with $I_{max, therm} = 2.5 * k * I_{rated}$

$$t = \tau_{th} \cdot \ln \frac{\left(\frac{I}{k \cdot I_{rated,obj}}\right)^2 - \left(\frac{I_{preload}}{k \cdot I_{rated,obj}}\right)^2}{\left(\frac{I}{k \cdot I_{rated,obj}}\right)^2 - 1} \quad [min]$$

Without preload and with $I_{max, therm} = 2.5*k*I_{rated}$

$$t = \tau_{th} \cdot \ln \frac{\left(\frac{I}{k \cdot I_{rated,obj}}\right)^2}{\left(\frac{I}{k \cdot I_{rated,obj}}\right)^2 - 1} \quad [min]$$

12.23 Thermal Overload Protection, User-Defined Characteristic Curve

Setting Values

Threshold current warning	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold thermal warn.		50 % to 100 %	Increments of 1 %
Dropout threshold operate		50 % to 99 %	Increments of 1 %
Emerg. start T overtravel		0 s to 15 000 s	Increments of 10 s
Imax thermal	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Imin cooling	1 A @ 50 and 100 Irated	0.000 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.00 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.000 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.000 A to 8.000 A	Increments of 0.001 A
Curve based on preload		1 % to 100 %	Increments of 1 %
Number of value pairs for the operate curve		2 to 30	Increments of 1
X values of the operate curve		1.10 p.u. to 20.00 p. u.	Increments of 0.0 p.u.
Y values of the operate curve		1.00 s to 20 000.00 s	Increments of 0.01 s

Dropout Ratios

Tripping threshold (fixed at 100 %)	Dropout if value drops below operate indication dropout threshold
Thermal warning threshold	About 0.99 of the setting value
Current warning threshold	About 0.95 of the setting value

Frequency Range of the Input Signals

The function captures input signals up to the 50th harmonic.

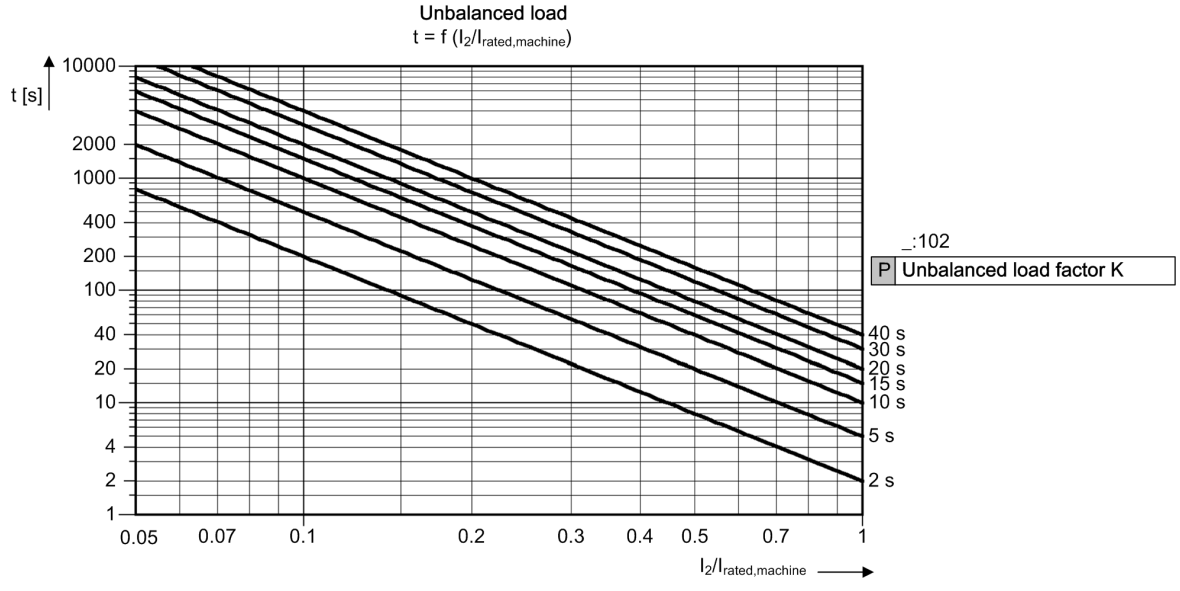
Tolerances

With reference to $k \cdot I_{rated}$	For I_{rated} = 1 A	2 % or 10 mA, class 2 % acc. to IEC 60255-8
	For I_{rated} = 5 A	2 % or 50 mA, class 2 % acc. to IEC 60255-8
With reference to operate time		3 % or 1 s, class 3 % acc. to IEC 60255-8 for $I/(k \cdot I_{rated}) > 1.25$

12.24 Unbalanced-Load Protection

Setting Values

Maximum continuously perm. I2	3.0 % to 30.0 % I2/ $I_{rated,machine}$	Increments of 0.1 %
Unbalanced load factor K	1.0 s to 100.0 s	Increments of 0.1 s
Warning delay	0.0 s to 60.0 s; ∞	Increments of 0.1 s
Cooling time thermal replica	0 s to 50 000 s	Increments of 1 s



Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

- Dropout differential derived from a dropout ratio of 95 %
- Dropout differential of 3 % of the object rated current

Operate Characteristics

Characteristic of the thermal replica	$t_{I2\,Perm} = \frac{K}{(I_2/I_{rated,machine})^2}$	
Where:	t_{I2Perm}	Permissible application time of the negative-sequence current
	K	Unbalanced load factor K
	$I_2/I_{rated,machine}$	Unbalanced load (negative-sequence current/rated current of the machine)

[dwunbaop-300913, 1, en_US]

Figure 12-16 Thermal Characteristic for Unbalanced Load Protection

Times

Pickup time of the warning stage	Approx. 60 ms + OOT[91] at 50 Hz Approx. 50 ms + OOT at 60 Hz

[91] OOT (Output Operating Time) additional delay of the output medium used, for example, 5 ms with fast relays

Dropout time	Approx. 50 ms or better

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Negative-sequence current I_2	Approx. 3 % of setting value or 0.030 A at I_{rated} = 1 A Approx. 3 % of setting value or 0.150 A at I_{rated} = 5 A
Warning delay	1 % of the setting value or 10 ms
Time for $2 \leq I_2/I_{2Perm} \leq 20$	5 % of reference (calculated) value or 100 ms ± (1 % current tolerance or 10 mA) at I_{rated} = 1 A 5 % of reference (calculated) value or 100 ms ± (1 % current tolerance or 50 mA) at I_{rated} = 5 A

Influencing Variables for the Thresholds

Harmonics	
– Up to 10 % 3rd harmonic	≤ 1 %
– Up to 10 % 5th harmonic	≤ 1 %

12.25 Current-Unbalance Protection for Capacitors, 3-Phase

Setting Values for the Function

Automatic compensation		Yes No	
Time between switch off and switch on		0.00 s to 60.00 s	Increments of 0.01 s
Normalization with Ic		Yes No	
Threshold of defective C-element	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Setting Values (Overcurrent-Protection Stage I>)

Measured value		compensated non-compensated	
$I_{unbal.}$	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
$I_{unbal.}$	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s

Setting Values (Counter Stage)

Type of counting groups	segregated sum	
Max. no. of def. elem. phs A	1 to 1000	Increments of 1
Max. no. of def. elem. phs B	1 to 1000	Increments of 1
Max. no. of def. elem. phs C	1 to 1000	Increments of 1
Operate delay	0.00 s to 10000.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[92] at 50 Hz Approx. 29 ms + OOT at 60 Hz

[92] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Currents I_c, $I_{unbal.}$ Protection-class current transformers	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Currents $I_{unbal.}$ Sensitive current transformer	1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A), (f_{rated} ± 10 %)
Time delays	1 % of the setting value or 10 ms

12.26 Current-Unbalance Protection for Capacitors, 1-Phase

Setting Values for the Function

Automatic compensation		Yes No	
Time between switch off and switch on		0.00 s to 60.00 s	Increments of 0.01 s
Normalization with Ic		Yes No	
Threshold of defective C-element	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Setting Values (Overcurrent-Protection Stage I>)

Current threshold $I_{unbal.}$	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.150 A to 175.000 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.005 A
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Measured value			compensated non-compensated

Setting Values (Counter Stage)

Type of counting groups		segregated sum
Type of counting phases		segregated sum
Max. no. of def. elem. phs A	1 to 1000	Increments of 1
Max. no. of def. elem. phs B	1 to 1000	Increments of 1
Max. no. of def. elem. phs C	1 to 1000	Increments of 1
Max. no. of def. elem.	1 to 1000	Increments of 1
Operate delay	0.00 s to 10000.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[93] at 50 Hz Approx. 29 ms + OOT at 60 Hz
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Currents I_c, $I_{unbal.}$ Protection-class current transformers	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10%)
Currents $I_{unbal.}$ Sensitive current transformer	1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A), (f_{rated} ± 10%)
Time delays	1 % of the setting value or 10 ms

[93] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.27 Voltage-Differential Protection for Capacitor Banks

Setting Values (General Functionality)

Voltage matching factor k	0.5000 to 2000.0000	Increments of 0.0001

Setting Values (Protection Stage V_{diff}>)

Threshold	0.005 p.u. to 1.000 p.u.[94]	Increments of 0.001 p.u.
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

Dropout ratio for sec. threshold > 3 V	95 %
Dropout differential for sec. threshold 0.3 V to 3 V	150 mV
Dropout ratio for sec. threshold 0.2 V to 0.3 V	50 %

Times

Operate time with time delay = 0 ms	Approx. 30 ms + OOT (Output Operating Time) at 50 Hz Approx. 27 ms + OOT (Output Operating Time) at 60 Hz
Dropout time	Approx. 20 ms + OOT (Output Operating Time) at 50 Hz Approx. 18 ms + OOT (Output Operating Time) at 60 Hz

Tolerances

Threshold ≥ 0.2 V	1 % of the setting value or 0.05 V (compensated)
Time delays	1 % of the setting value or 10 ms

Operating Range of the Secondary Differential Voltage

Operating Range of the secondary differential voltage	≥ 0.1 V (compensated)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
10 Hz ≤ f < 0.9 f_{rated} 1.1 f_{rated} < f ≤ 80 Hz	Slightly expanded tolerances
f < 10 Hz f > 80 Hz	Active

[94] Minimum secondary setting threshold = 0.2 V

12.28 Differential Protection for Capacitor Banks

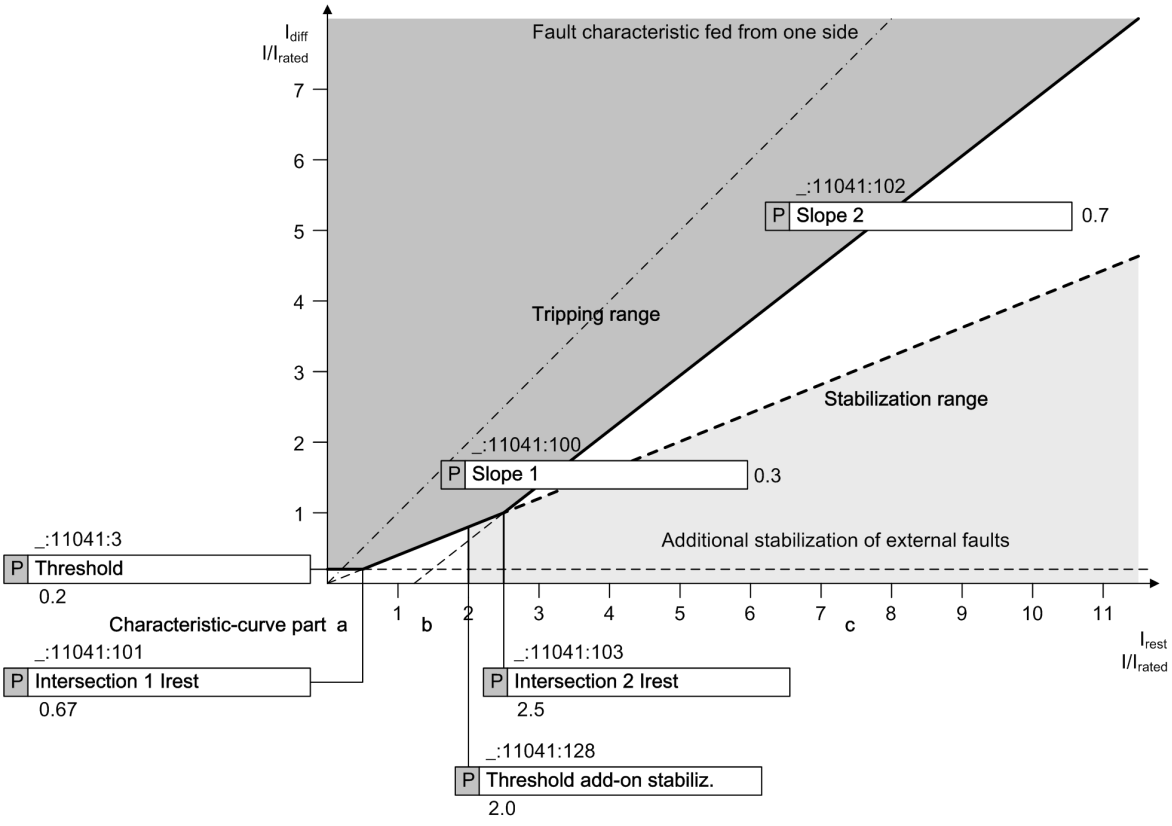
Setting Values

Operate Curve			
Threshold value	$I/I_{ratedObj}$	0.05 to 2.00	Increments of 0.01
Gradient 1		0.00 to 0.80	Increments of 0.01
Intersection 1 Irest	$I/I_{ratedObj}$	0.00 to 5.00	Increments of 0.01
Gradient 2		0.25 to 0.95	Increments of 0.01
Intersection 2 Irest	$I/I_{ratedObj}$	1.00 to 20.00	Increments of 0.01
Startup Recognition			
Startup threshold value	$I/I_{ratedObj}$	0.1 to 2.0	Increments of 0.1
Characteristic-curve increase factor		1.0 to 5.0	Increments of 0.1
Maximum starting time		0.1 s to 180.0 s	Increments of 0.1 s
DC-Component Recognition			
Characteristic-curve increase factor DC		1.0 to 5.0	Increments of 0.1
Inrush-current detection			
Content 2nd harmonic		10 % to 45 %	Increments of 1 %
Duration of crossblk. 2. har.		0.00 s to 200.00 s or ∞	Increments of 0.01 s
Recognition of External Faults			
Additional stabilization threshold value	$I/I_{ratedObj}$	1.00 to 20.00	Increments of 0.01
Additional stabilization duration		0.00 s to 5.00 s or ∞	Increments of 0.01 s
Operate curve		See *Figure 12-17*	

Idiff Fast

Threshold value	$I/I_{ratedObj}$	0.5 to 35.0	Increments of 0.1
Tripping delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout Ratio



Idiff stage	Approx. 0.7
Idiff fast stage	Approx. 0.8

Response Tolerance

For preset characteristic-curve parameters; for 2 sides with one measuring point each	
Idiff stage and characteristic curve	2 % of the setting value
Idiff fast stage	2 % of the setting value

Time Delays

Idiff stage	0.00 s to 60.00 s	Increments of 0.01 s
Idiff fast stage	0.00 s to 60.00 s	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	

[dwdifaus-030912-01.tif, 1, en_US]

Figure 12-17 Operate Curve of the Differential Protection

Operating Times

Operate times for infeed on one side		
Idiff stage, min	50 Hz 60 Hz	23 ms + OOT[95] 20 ms + OOT[1)]
Idiff fast stage, min	50 Hz 60 Hz	8 ms + OOT[1)] 8 ms + OOT[1)]
Dropout time, approx.	50 Hz 60 Hz	29 ms 26 ms

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

[95] Refer to protection functions, for example, Overcurrent protection

12.29 Overvoltage Protection with 3-Phase Voltage

Setting Values for Stage Type Definite Time-Overvoltage Protection

Measured value	Phase-to-phase Phase-to-ground	
Method of measurement	Fundamental component RMS value	
Pickup mode	1 out of 3 3 out of 3	
Pickup value[96]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 300.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Setting Values for Stage Type Inverse Time-Overvoltage Protection

Measured value	Phase-to-phase Phase-to-ground	
Method of measurement	Fundamental component RMS value	
Pickup mode	1 out of 3 3 out of 3	
Pickup value	0.300 V to 340.000 V	Increments of 0.001 V
Pickup factor	1.00 to 1.20	Increments of 0.01
Characteristic constant k	0.00 to 300.00	Increments of 0.01
Characteristic constant α	0.010 to 5.000	Increments of 0.001
Characteristic constant c	0.000 to 5.000	Increments of 0.001
Time multiplier	0.05 to 15.00	Increments of 0.01
Additional time delay	0.00 s to 60.00 s	Increments of 0.01 s
Reset time	0.00 s to 60.00 s	Increments of 0.01 s

Operate Curve for Stage Type Inverse Time-Overvoltage Protection

$$T_{op} = T_{inv} + T_{add}$$

Where

T_{op} Operate delay

T_{inv} Inverse-time delay

T_{add} Additional time delay (parameter **`Additional time delay`**)

$$T_{inv} = T_p \left(\frac{k}{\left(\frac{V}{V_{thresh}}\right)^{\alpha} - 1} + c \right) [s]$$

Where

T_{inv} Inverse-time delay

T_p Time multiplier (parameter **`Time dial`**)

V Measured voltage

[96] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

V_{thresh}	Threshold value (parameter **Threshold**)
k	Curve constant k (parameter **Charact. constant k**)
α	Curve constant α (parameter **Charact. constant α**)
c	Curve constant c (parameter **Charact. constant c**)

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter Dropout ratio If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[97] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances for Stage Type Definite Time-Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

Tolerances for Stage Type Inverse Time-Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Operate time for $1.2 \leq$ V/V threshold value ≤ 20	5 % of the setting value or 30 ms
Reset time delay	1 % of the setting value or 10 ms

[97] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.30 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage

Setting Values

Method of Measurement	RMS value Fundamental component Fundamental component over 2 cycle filters	
Block. on measuring-voltage outage	Yes No	
Determ. ph. aff. by grd. flt.	Yes No	
Threshold value[98]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Pickup delay	0.00 s to 320.00 s	Increments of 0.01 s
Dropout Ratio	0.90 to 0.99	Increments of 0.01
V< faulty ph-gnd vltg.	0.300 V to 200.000 V	Increments of 0.001 V
V> healthy ph-gnd. vltg.	0.300 V to 200.000 V	Increments of 0.001 V

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	
Standard filter, true RMS	Approx. 25 ms + OOT[99] at 50 Hz Approx. 22 ms + OOT at 60 Hz
2 cycle filters	Approx. 45 ms + OOT at 50 Hz Approx. 39 ms + OOT at 60 Hz
Dropout Time	
Standard filter, true RMS	Approx. 20 ms + OOT at 50 Hz Approx. 16.6 ms + OOT at 60 Hz
2 cycle filters	Approx. 31.06 ms + OOT at 50 Hz Approx. 27.06 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances

[98] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.
[99] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

f < 10 Hz f > 80 Hz	Active

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

12.31 Overvoltage Protection with Positive-Sequence Voltage

Setting Values

Pickup value	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[100] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

[100] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

12.32 Overvoltage Protection with Negative-Sequence Voltage

Setting Values for the Function

Measuring window	1 cycle to 10 cycles	Increments of 1 cycle

Setting Values

Pickup value of V2	0.300 V to 200.000 V	Increments of 0.001 V
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup times	55 ms to 210 ms + OOT [101] (depends on the measuring-window length) at 50 Hz 48 ms to 185 ms + OOT (depends on the measuring-window length) at 60 Hz
Dropout time	20 ms to 70 ms + OOT (depends on the measuring-window length)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Voltages	0.50 % of the setting value or 0.050 V
Time delays	1.00 % of the setting value or 10 ms

[101] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.33 Overvoltage Protection with Any Voltage

Setting Values

Measured value[102]	Measured phase-to-ground voltage V_A Measured phase-to-ground voltage V_B Measured phase-to-ground voltage V_C Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Calculated voltage V0	
Method of measurement	Fundamental component RMS value	
Pickup value[103]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[104] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

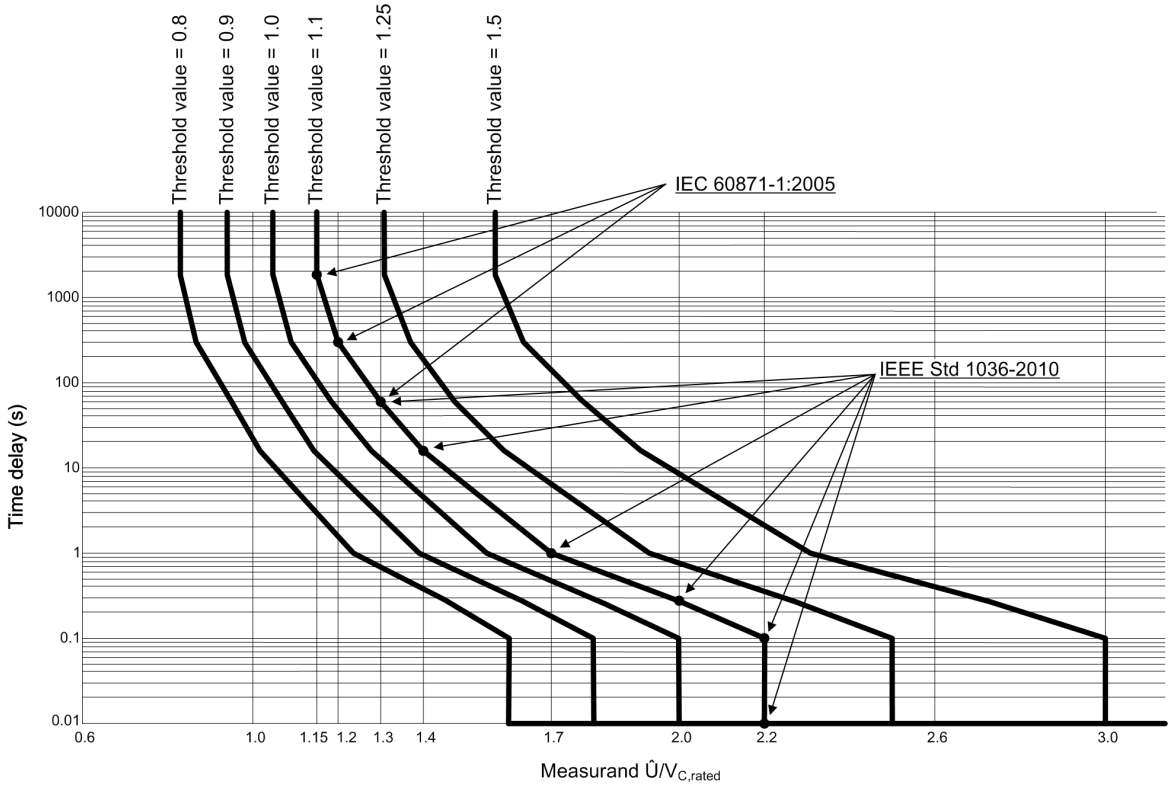
Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Voltages	0.5 % of the setting value or 0.05 V

[102] If the function **Overvoltage protection with any voltage** is used in a 1-phase function group, the measured-value parameter is not visible.
[103] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.
[104] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*



Time delays	1 % of the setting value or 10 ms

12.34 Peak Overvoltage Protection for Capacitors

Setting Values

Threshold value		
Inverse-time stage	0.80 to 3.00 p.u.	Increments of 0.01
Definite-time stage	0.80 to 10.00 p.u.	Increments of 0.01
User-defined characteristic curve	0.80 to 3.00 p.u.	Increments of 0.01
Tripping delay	0.01 s to 3600.00 s	Increments of 0.01 s
Dropout delay	0.00 s to 3600.00 s	Increments of 1.00 s
Down integration time	1 min to 1500 min	Increments of 1 min
Time multiplier	0.05 to 15.00	Increments of 0.01
Number of value pairs for the operate curve	30	Increments of 1
X values of the operate curve	1.00 p.u. to 4.00 p.u.	Increments of 0.01 p.u.
Y values of the operate curve	0.00 s to 9999.99 s	Increments of 0.01 s
Number of value pairs for the dropout characteristic curve	30	Increments of 1
X values of the dropout characteristic curve	0.01 p.u. to 0.95 p.u.	Increments of 0.01 p.u.
Y values of the dropout characteristic curve	0.00 s to 9999.99 s	Increments of 0.01 s

Inverse-Time Characteristic Curve (IEC/IEEE)

[dw_pecinv-230813, 2, en_US]

Figure 12-18 Inverse-Time Characteristic Curve

The points on the characteristic curve defined in the standards result from a threshold setting of 1.1. These single points are connected via semi-logarithmic line segments.

Table 12-5 Peak Overvoltage Inverse-Time Characteristic (for Threshold Setting 1.1)

Measurand $\hat{U}/V_{c,rated}$	**Time Delay**	**Curve Point According to**
<1.15	∞ (no pickup)	Siemens definition
1.15	1800.00 s	IEC 60871-1:2005
1.2	300.00 s	IEC 60871-1:2005
1.3	60.00 s	IEC 60871-1:2005, IEEE Std 1036-2010
1.4	15.00 s	IEEE Std 1036-2010
1.7	1.00 s	IEEE Std 1036-2010
2	0.25 s	IEEE Std 1036-2010
2.2	0.1 s	IEEE Std 1036-2010
>2.2	0.01 s	IEEE Std 1036-2010

Times

Pickup time	Approx. 35 ms + OOT at 50 Hz[1] Approx. 25 ms + OOT at 60 Hz[1]
Dropout Time	Depending on settings
[1] OOT (Output Operating Time) additional delay of the output medium used, for example, 5 ms with fast relays	

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Peak overvoltage (33 % harmonics, with reference to fundamental component)	
Up to 30th harmonic Up to 50th harmonic, f_{rated} = 50 Hz Up to 50th harmonic, f_{rated} = 60 Hz	1 % of the setting value or 0.005 p.u. (f_{rated} ± 10%) 3 % of the setting value or 0.02 p.u. (f_{rated} ± 10%) 4 % of the setting value or 0.02 p.u. (f_{rated} ± 10%)
Time delays	
Measured value of inverse-time stage	5 % of the setting value +1 % of the measured value or 30 ms
Measured value of definite-time stage	1 % of the setting value or 10 ms
Down integration time	5 % of the setting value or 30 ms

12.35 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage

Setting Values for the Function

Measuring window	1 cycle to 10 cycles	Increments of 1 cycle
Minimum voltage V1	0.300 V to 60.000 V	Increments of 0.001 V

Setting Values for Stage Types

Pickup value of V2/V1	0.50 % to 100.00 %	Increments of 0.01 %
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup times	55 ms to 210 ms + OOT[105] (depends on the measuring-window length) at 50 Hz 48 ms to 190 ms + OOT (depends on the measuring-window length) at 60 Hz
Dropout times	22 ms to 55 ms + OOT (depends on the measuring-window length) at 50 Hz 18 ms to 45 ms + OOT (depends on the measuring-window length) at 60 Hz

Frequency Operating Range

0.9 f/f_{rated} to 1.1 f/f_{rated}	According to specified tolerances
10 Hz to 0.9 f/f_{rated} 1.1 f/f_{rated} to 80 Hz	Slightly expanded tolerances
$f < 10$ Hz $f > 80$ Hz	Inactive

Tolerances

Voltages	0.50 % of the setting value or 0.050 V
Time delays	1.00 % of the setting value or 10 ms

[105] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.36 Undervoltage Protection with 3-Phase Voltage

Setting Values for Stage Type Definite Time-Undervoltage Protection

Measured value		Phase-to-phase Phase-to-ground	
Method of measurement		Fundamental component RMS value	
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Pickup value[106]		0.300 V to 175.000 V	Increments of 0.001 V
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio		1.01 to 1.20	Increments of 0.01

Setting Values for Stage Type Inverse Time-Undervoltage Protection

Measured value		Phase-to-phase Phase-to-ground	
Method of measurement		Fundamental component RMS value	
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold		0.300 V to 175.000 V	Increments of 0.001 V
Pickup factor		0.80 to 1.00	Increments of 0.01
Characteristic constant k		0.00 to 300.00	Increments of 0.01
Characteristic constant α		0.010 to 5.000	Increments of 0.001
Characteristic constant c		0.000 to 5.000	Increments of 0.001
Time multiplier		0.05 to 15.00	Increments of 0.01
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s
Reset time		0.00 s to 60.00 s	Increments of 0.01 s

Operate Curve

$T_{op}=T_{Inv}+T_{add}$

Where:

T_{op} Operate delay

T_{Inv} Inverse-time delay

T_{add} Additional time delay (parameter **`Additional time delay`**)

[106] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

$$T_{Inv} = T_p \left(\frac{k}{1 - \left(\frac{V}{V_{Thresh}} \right)^{\alpha}} + c \right) [s]$$

[fo_UVP3ph_inverse, 2, en_US]

Where

T_{Inv}	Inverse-time delay
T_p	Time multiplier (parameter **Time dial**)
V	Measured undervoltage
V_{Thresh}	Threshold value (parameter **Threshold**)
k	Curve constant k (parameter **Charact. constant k**)
α	Curve constant α (parameter **Charact. constant α**)
c	Curve constant c (parameter **Charact. constant c**)

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter Dropout ratio If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup time	Approx. 25 ms + OOT[107] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10 \text{ Hz} \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80 \text{ Hz}$	Slightly expanded tolerances
$f < 10 \text{ Hz}$ $f > 80 \text{ Hz}$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

Tolerances for Stage Type Definite Time-Undervoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A, f_{rated} ± 10 %), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A, f_{rated} ± 10 %), valid for instrument transformers
Time delays	1 % of the setting value or 10 ms

[107] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Tolerances for Stage Type Inverse Time-Undervoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A, f_{rated} ± 10 %), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A, f_{rated} ± 10 %), valid for instrument transformers
Operate time for $0 < V/V_{Thresh} < 0.9$	5 % of the setting value or 30 ms
Reset time delay	1 % of the setting value or 10 ms

12.37 Undervoltage Protection with Positive-Sequence Voltage

Setting Values

Measured value		Phase-to-phase Phase-to-ground	
Method of measurement		Fundamental component RMS value	
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Pickup value		0.300 V to 175.000 V	Increments of 0.001 V
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio		1.01 to 1.20	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time	Approx. 25 ms + OOT [108] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

Tolerances

Voltages	0.5 % of the setting value or 0.05 V

[108] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A, f_{rated} ± 10 %), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1.6 A) or 0.5 mA (I_{rated} = 8 A, f_{rated} ± 10 %), valid for instrument transformers
Time delays	1 % of the setting value or 10 ms

12.38 Undervoltage Protection with Any Voltage

Setting Values

Measured value	Measured phase-to-ground voltage V_A Measured phase-to-ground voltage V_B Measured phase-to-ground voltage V_C Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Calculated phase-to-phase voltage V_{AB} Calculated phase-to-phase voltage V_{BC} Calculated phase-to-phase voltage V_{CA} Calculated voltage V0	
Method of measurement	Fundamental component RMS value	
Pickup value[109]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	1.01 to 1.20	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[110] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

[109] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.
[110] OOT (Output Operating Time) additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.39 Overfrequency Protection

Setting Values

Pickup values f>	40.00 Hz to 70.00 Hz	Increments of 0.01 Hz
Dropout differential	20 mHz to 2 000 mHz	Increments of 10 mHz
Time delay T	0.00 s to 600.00 s	Increments of 0.01 s
Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V

Times

Pickup times f>	Angle difference method	
	50 Hz	Approx. 70 ms + OOT[111]
	60 Hz	Approx. 60 ms + OOT
	Filtering method	
	50 Hz	Approx. 75 ms + OOT
	60 Hz	Approx. 75 ms + OOT
Dropout times f>	60 ms to 80 ms	

Dropout

The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the `Dropout ratio` parameter If this parameter is not available, a dropout ratio of 95 % applies to the overvoltage protection and a dropout ratio of 105 % applies to the undervoltage protection.	
Minimum absolute dropout differential	150 mV sec.

Operating Ranges

Voltage range	5 V to 230 V (phase-phase)	
Frequency range	Angle difference method	10 Hz to 80 Hz
	Filtering method	25 Hz to 80 Hz

Tolerances

Frequency f>	
f_{rated} - 0.20 Hz < f < f_{rated} + 0.20 Hz	± 5 mHz at V = V_{rated}
f_{rated} - 3.0 Hz < f < f_{rated} + 3.0 Hz	± 10 mHz at V = V_{rated}
Time delay T(f>)	1 % of the setting value or 10 ms
Minimum voltage	1 % of the setting value or 0.5 V

[111] OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relay, see chapter *12.1.4 Relay Outputs*

12.40 Underfrequency Protection

Setting Values

Pickup values f<	40.00 Hz to 70.00 Hz	Increments of 0.01 Hz
Dropout differential	20 mHz to 2 000 mHz	Increments of 10 mHz
Time delay T	0.00 s to 600.00 s	Increments of 0.01 s
Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V

Times

Pickup times f<	Angle difference method	
	50 Hz 60 Hz	Approx. 70 ms + OOT[112] Approx. 60 ms + OOT
	Filtering method	
	50 Hz 60 Hz	Approx. 75 ms + OOT Approx. 75 ms + OOT
Dropout times f<	60 ms to 80 ms	

Dropout

The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following two criteria is used:

Dropout differential derived from the `Dropout ratio` parameter If this parameter is not available, a dropout ratio of 95 % applies to the overvoltage protection and a dropout ratio of 105 % applies to the undervoltage protection.	
Minimum absolute dropout differential	150 mV sec.

Operating Ranges

Voltage range	5 V to 230 V (phase-phase)	
Frequency range	Angle difference method	10 Hz to 80 Hz
	Filtering method	25 Hz to 80 Hz

Tolerances

Frequency f<	
f_{rated} - 0.20 Hz < f < f_{rated} + 0.20 Hz	± 5 mHz at V = V_{rated}
f_{rated} - 3.0 Hz < f < f_{rated} + 3.0 Hz	± 10 mHz at V = V_{rated}
Time delay T(f<)	1 % of the setting value or 10 ms
Minimum voltage	1 % of the setting value or 0.5 V

[112] OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relay, see chapter *12.1.4 Relay Outputs*

12.41 Rate of Frequency Change Protection

Setting Values for the Function

Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V
Measuring window	2 periods to 5 periods	Increments of 1 period

Setting Values for Stage Types

Threshold	0.1 Hz/s to 20.0 Hz/s	Increments of 0.1 Hz/s
Dropout differential	0.02 Hz/s to 0.99 Hz/s	Increments of 0.01 Hz/s
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup time	Approx.165 ms to 225 ms (depends on measuring window length)
Dropout time	Approx.165 ms to 225 ms (depends on measuring window length)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Threshold, measuring window > 3 periods	Approx. 3 % or 0.06 Hz/s
Threshold, measuring window ≤ 3 periods	Approx. 5 % or 0.06 Hz/s
Minimum voltage	1 % of the setting value or 0.5 V
Time delays	1 % of the setting value or 10 ms

Functional Measured Value

Value	Description
df/dt	Calculated rate of frequency change

12.42 3-Phase Power Protection (P,Q)

Setting Values

Measured value	Positive sequence power Power of phase A Power of phase B Power of phase C	
Threshold value	-200.0 % to +200.0 %	Increments of 0.1
Tilt-power characteristic	-89.0° to +89.0°	Increments of 0.1°
Dropout delay time	0.00 s to 60.00 s	Increments of 0.01 s
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	Upper stage: 0.90 to 0.99 Lower stage: 1.01 to 1.10	Increments of 0.01 Increments of 0.01

Times

Pickup times	Approx. 55 ms + OOT[113] at 50 Hz Approx. 45 ms + OOT at 60 Hz
Dropout times	Approx. 55 ms + OOT at 50-Hz Approx. 45 ms + OOT at 60 Hz

Tolerances

Power	0.5 % S_{rated} ± 3 % of setting value (S_{rated}: rated apparent power)
Time delays	1 % of the setting value or 10 ms

Variables That Influence Pickup Values

Auxiliary DC voltage in the range $0.8 \leq V_{Aux}/V_{AuxRated} \leq 1.15$	≤ 1 %
Frequency in the range $0.95 \leq f/f_{rated} \leq 1.05$	≤ 1 %
Harmonics - Up to 10 % of 3rd harmonics - Up to 10 % of 5th harmonics	 ≤ 1 % ≤ 1 %

[113] OOT (Output Operating Time) additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

12.43 Reverse-Power Protection

Setting Values

Reverse power $P_{reverse}$ (p.u.)	-0.30 % to -30.00 %	Increments of 0.01 %
Angle correction	-10.00 ° to 10.00 °	Increments of 0.01 °
Minimum voltage V1	0.300 V to 60.000 V	Increments of 0.001 V
Tripping delay	0.00 s to 60.00 s	0.00 s to 60.00 s
Tripping delay with quick stop	0.00 s to 60.00 s	0.00 s to 60.00 s
Dropout delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.40 to 0.99	Increments of 0.01

Times

Pickup times	Approx. 360 ms at f = 50 Hz Approx. 300 ms at f = 60 Hz
Dropout times	Approx. 360 ms at f = 50 Hz Approx. 300 ms at f = 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Reverse power	0.15 % S_{rated} or 5 % of the setting value when $Q < 0.5\ S_{rated}$
Time delays	1 % or 10 ms

12.44 Overexcitation Protection

Setting Values

Threshold value (characteristic curve dependent on pickup)		$\frac{U/U_{nenn}}{f/f_{nenn}}$	1.00 to 1.20	Increments of 0.01
Threshold value (characteristic curve independent on pickup)		$\frac{U/U_{nenn}}{f/f_{nenn}}$	1.00 to 1.40	Increments of 0.01
Time delay (warning delay and tripping delay)			0.00 s to 60.00 s	Increments of 0.01 s
Characteristic value pairs			2 to 30	
	Value ranges	V/f	1.00 p.u. to 10.00 p.u.	Increments of 0.01 p.u.
		t	0 s to 100 000 s	Increments of 1 s
Cooling time therm. replica			0 s to 100 000 s	Increments of 1 s

Functional Measured Values

Measured Value	Description
(_:2311:322) V/f	Value calculated from voltage and frequency.
(_:13591) Therm.charact.	Thermal tripping of the overexcitation protection. If the value reaches 100 %, tripping occurs.

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Operating Times

Operate times/dropout times		
Operate time at frequency	50 Hz	60 Hz
Minimum	33 ms + OOT[1]	30 ms + OOT[1][14]
Dropout time	10 ms + OOT[1]	10 ms + OOT[1]

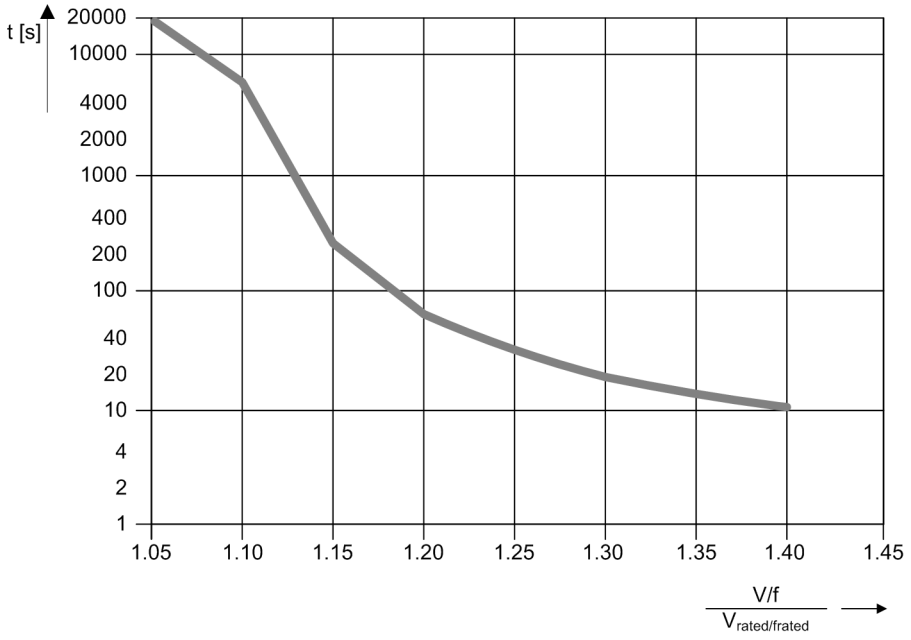
Dropout Ratios

Warning, tripping (independent stage)	Approx. 0.98

Operate Curve

Thermal replica	For default setting refer to the following characteristic curve *Figure 12-19*

Tolerances



V/f pickup	2 % of the setting value
Time delays	1 % of the setting value or 10 ms (min. 1.5 periods)
Thermal replica	5 % based on V/f ± 600 ms

[114] Refer to protection functions, for example overcurrent protection

Voltage measurement accuracy	0.5 % of the setting value or 0.5 V in the range fn ± 10 %
Frequency measurement accuracy	1.0 % of the setting value or 1.0 Hz in the frequency range 10 Hz to 80 Hz

Influencing Quantities

Auxiliary direct voltage in the 0.8 range	≤ 1 %
Time delays	≤ 0.5 %/10 K
Thermal replica	≤ 1 %
Harmonics	
Up to 10 % of 3rd harmonic Up to 10 % of 5th harmonic	≤ 1 % ≤ 1 %

[dwrsasuf-070513-01.tif, 1, en_US]

Figure 12-19 Operate Curve from the Thermal Replica of the Overexcitation Protection (Default Setting)

12.45 Undervoltage-Controlled Reactive-Power Protection

Setting Values

Threshold value	Power Q	1.00 % to 200.00 %	Increments of 0.01 %
	Voltage of protection stage	3.000 to 175.000	Increments of 0.001 V
	Voltage of reclosure stage	3.000 V to 340.000 V	Increments of 0.001 V
Current I_1 release threshold	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Release time delay of reclosure stage		0.00 s to 3600.00 s	Increments of 0.01 s

Dropout Ratio

Protection stage	
Reactive-power flow Q	Approx. 0.95
Voltage	Approx. 1.05
Release current	Approx. 0.95

Reclosure stage	
Voltage	Approx. 0.95
Release current	Approx. 0.95

Times

Pickup time	Approx. 55 ms + OOT[115] at 50 Hz Approx. 45 ms + OOT at 60 Hz
Dropout time	Approx. 55 ms + OOT at 50 Hz Approx. 45 ms + OOT at 60 Hz

Tolerances

Current I_1	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Voltage	0.5 % of the setting value or 0.05 V
Power Q	0.5 % S_{rated} ± 3 % of the setting value (S_{rated}: rated apparent power)
Time delays	1 % of the setting value or 10 ms
Reclosure time delay	1 % of the setting value or 10 ms

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances

[115] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

f < 10 Hz f > 80 Hz	Active

12.46 Circuit-Breaker Failure Protection

Starting Conditions

For circuit-breaker failure protection	3-pole tripping internal or external[116]

Setting Values

Phase-current threshold values	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Sensitive threshold value	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Supervision time of release signal		0.06 s to 1.00 s	Increments of 0.01 s
Time delays		0.05 s to 60.00 s	Increments of 0.001 s
Supervision time of binary inputs		0.05 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Circuit-Breaker Supervision

Position supervision via circuit-breaker auxiliary contacts	
For 3-pole CB tripping	1 input each for make contact and break contact

NOTE

The circuit-breaker failure protection can also work without the circuit-breaker auxiliary contacts stated.

Auxiliary contacts are required for circuit-breaker failure protection in cases where the current flow is absent or too low for tripping (for example with a transformer or a Buchholz protection).

[116] Via binary inputs

Times

Pickup time, in the case of an internal start Pickup time, in the case of an external start	< 1 ms < 5 ms
Typical dropout time	< 15 ms
Dropout time via circuit-breaker auxiliary-contact criterion	< 5 ms

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Threshold values, dropout thresholds	2 % of the setting value or 1 % of the rated current
Times	1 % of the setting value or 10 ms

12.47 Circuit-Breaker Restrike Protection

Setting Values

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Monitoring duration		1.00 s to 600.00 s	Increments of 0.01 s
Position recognition delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s
Trip delay time		0.05 s to 60.00 s	Increments of 0.01 s
Retrip delay time		0.00 s to 60.00 s	Increments of 0.01 s
Minimum operate (trip) time		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Active

Tolerances

Threshold	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

12.48 Restricted Ground-Fault Protection

Setting Values

Threshold value[117]	0.05 A to 2.00 A	Increments of 0.01 A
Gradient	0.00 to 0.95	Increments of 0.01
Operate curve	See figure	
Pickup tolerance (for preset characteristic curve parameters; for 2 sides with 1 measuring point each)	2 %	
Tripping delay	0.00 s to 60.00 s or ∞ (no tripping)	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	

Functional Measured Values

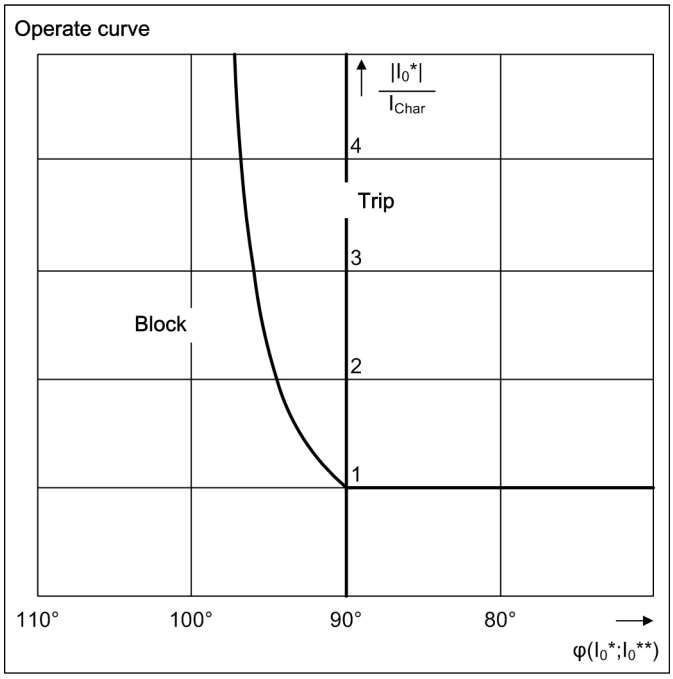
Measured Value	Description
(_:306) I REF,operate	Operate quantity of the restricted ground-fault protection from the angle criterion
(_:307) I Angle,REF	Stabilizing value (angle) of the restricted ground-fault protection from the angle criterion
(_:311) I REF,Trip operate	Operate quantity of the restricted ground-fault protection when OFF
(_:312) I angle,REF operate	Stabilizing value of the restricted ground-fault protection when OFF
(_:301) I diff.	Differential current
(_:302) I restr.	Restraint current

Dropout Ratio

Threshold value	0.7

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:



Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

7UT82/7UT85/7UT86/7UT87		
Frequency	50 Hz	60 Hz
	Operate time	Operate time

[117] The specified setting limit can be dynamically further limited, depending on the transformer adaptation factor, (for this refer to Chapter *6.41.4 Application and Setting Notes*).

At 1.5 · setting value threshold value	33 ms + OOT	32 ms + OOT
At 2.5 · setting value threshold value	27 ms + OOT	26 ms + OOT
Dropout time approx.	80 ms	67 ms

[dwausken-170712-01.tif, 1, en_US]

Figure 12-20 Restricted Ground-Fault Protection Operate Curve depending on the Phase Angle between II_0* and II_0** at $|II_0*| = |II_0**|$ (180° = External fault)

12.49 External Trip Initiation

Setting Values

Tripping delay	0.00 s to 60.00 s	Increments of 0.01 s

Times

Operate time with time delay = 0 ms - At initiation via binary input signal	Approx. 10 ms + OOT [118].

Tolerance

Sequence tolerance for delay times	1 % of the setting value or 10 ms

[118] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

12.50 Automatic Reclosing

Function specifications	Cyclic automatic reclosing function Automatic reclosing function with adaptive dead time (ADT) Operation with External Automatic Reclosing Function	
Number of reclosings	Max. 8, per individual settings	
Type (depending on the order variation)	1-pole, 3-pole, or 1-/3-pole	
Operating mode of the automatic reclosing function	With trip command, without action time With trip command, with action time With pickup, without action time With pickup, with action time	
Reclaim time after reclosing	0.50 s to 300.00 s	Increments of 0.01 s
Blocking time after dynamic blocking	0.5 s	-
Blocking time after manual closure	0.00 s to 300.00 s	Increments of 0.01 s
Start supervision time	0.01 s to 300.00 s	Increments of 0.01 s
Circuit-breaker supervision time	0.01 s to 300.00 s	Increments of 0.01 s
Evolving-fault detection	With trip command with Pickup	
Reaction to evolving faults	Blocks automatic reclosing function Start, evolving fault, dead time	
Action times (separated for all cycles)	0.00 s to 300.00 s or oo (ineffective)	Increments of 0.01 s
Dead times after trip command (separated for all types and all cycles)	0.00 s to 1 800.00 s or oo (ineffective)	Increments of 0.01 s
Dead time after evolving-fault detection (separated for all cycles)	0.00 s to 1 800.00 s	Increments of 0.01 s
Synchrocheck after 3-pole dead time	None Internal External	
Transmission delay, inter close command	0.00 s to 300.00 s or oo (ineffective)	Increments of 0.01 s
Dead-line check/reduced dead time	Without Reduced dead time (VWE) Dead line checking	
Voltage supervision warning time	0.10 s to 30.00 s	Increments of 0.01 s
Limiting value for fault-free line	0.3 V to 340.0 V	Increments of 0.1 V
Limiting value for zero potential	0.3 V to 340.0 V	Increments of 0.1 V

12.51 Fault Locator

Setting Values

Reactance per unit length of the line per kilometer or per mile Line length for the correct output of the fault distance as a percentage of the line length The residual compensation factors in the setting format Kr and Kx or K0 and angle (K0)	
Consideration of the load current for 1-pole ground faults	Correction of the X value, for connection and disconnection

Fault Distance

Output of the fault distance (line length)	In Ω primary and secondary In km, miles or in percent. [119]

Tolerances

Measuring tolerances during sinusoidal measurands and error duration > 25 ms at 60 Hz or > 30 ms at 50 Hz	1.5 % from fault location at $V_K/V_{rated} \geq 0.01$ and one of the following scenarios: • Metal fault • Non-metallic fault for one-side infeed without load

[119] The output of the fault distance in km, miles and percent presupposes a homogenous line.

12.52 Temperature Supervision

Setting Values

Pickup value	-50 °C to 250 °C -58 °F to 482 °F	Increments of 1°C Increments of 1°F
Time delay	0 s to 60 s or ∞	Increments of 1 s

Dropout Conditions

Dropout differential	3 °C or 6 °F

Tolerances

Tripping delay	±1 % of the setting value or ±10 ms
Measured temperature value	±0.5 % of the setting value or ±1 °C or ±2 °F

12.53 Current-Jump Detection

Times

Pickup time	Approx. 10 ms + OOT[120] at 50 Hz Approx. 8 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Currents	3 % of setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), ($f_{rated} \pm 10$ %) for amplitude changes of sinusoidal measurands
Pulse time	1 % of the setting value or 10 ms

[120] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.54 Voltage-Jump Detection

Times

Pickup time	Approx. 10 ms + OOT[121] at 50 Hz Approx. 8 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Voltages	2 % of the setting value or 0.100 V for amplitude changes of sinusoidal measurands
Pulse time	1 % of the setting value or 10 ms

[121] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.55 Synchronization Function

Operating Modes

Synchrocheck
Switching synchronous systems
Switching asynchronous systems
De-energized switching
Direct closing command

Setting Values

Supervision/Delay times:		
Max. Duration of synchronization process	0.00 s to 3 600.00 s or ∞ (ineffective)	Increments of 0.01 s
Supervision time de-energized switching	0.00 s to 60.00 s	Increments of 0.01 s
Closure delay	0.00 s to 60.00 s	Increments of 0.01 s
Voltage threshold values:		
Upper voltage limit V_{max}	0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V
Lower voltage limit V_{min}	0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V
V<, for off-circuit conditions V>, for voltage present	0.300 V to 170.000 V (phase-to-phase) 0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V Increments of 0.001 V
Differential values, changeover thresholds asynchronous/synchronous:		
Voltage differences V2 > V1; V2 < V1	0.000 V to 170.000 V	Increments of 0.001 V
Frequency difference f2 > f1; f2 < f1	0.000 Hz to 2.000 Hz (synchronous) 0.000 Hz to 4.000 Hz (asynchronous)	Increments of 0.001 Hz
Angular difference α2 > α1; α2 < α1	0° to 90°	Increments of 1°
Δf threshold ASYN <-> SYN	0.010 Hz to 0.200 Hz	Increments of 0.001 Hz
Adjustments of the sides:		
Angle adjustment	0.0° to 360.0°	Increments of 0.1°
Voltage adjustment	0.500 to 2.000	Increments of 0.001
Circuit breaker		
Closing time of the circuit breaker	0.01 s to 0.60 s	Increments of 0.01 s

Dropout Ratio

Min./max. operating limit	1 % of the setting value
Voltage differential	10 % of the setting value or 0.5 V
De-energized/energized	5 % of the setting value
Frequency difference	3 mHz
Angular difference	0.1°

Measured Values of the Synchronization Function

Reference voltage V1 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage 10 % to 120 % of V_{rated} ≤ 1% of the measured value or 0.5% V_{rated}
Voltage to be synchronized V2 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage 10 % to 120 % of V_{rated} ≤ 1% of the measured value or 0.5% V_{rated}
Frequency of the voltage V1f1 • Range • Tolerance at rated frequency	f1 in Hz 25 Hz ≤ f ≤ 70 Hz 1 mHz
Frequency of the voltage V1f2 • Range • Tolerance at rated frequency	f2 in Hz 25 Hz ≤ f ≤ 70 Hz 1 mHz
Voltage difference V2-V1 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage in relation to side 1 10 % to 120 % of V_{rated} ≤ 1% of the measured value or 0.5% V_{rated}
Frequency difference f2-f1 • Range • Tolerance at rated frequency	In mHz f_{rated} ± 10 % 1 mHz
Angular difference λ2-λ1 • Range • Tolerance at rated frequency	In ° -180° to +180° 0.5°

Times

Measuring time, after switching on the variables	Approx. 80 ms

Operating Range

Voltage	20 V to 340 V
Frequency	f_{rated} -4 Hz ≤ f_{rated} ≤ f_{rated} +4 Hz

Tolerances

Tolerances of the voltage settings	2 % of the pickup value or 1 V
Voltage difference V2>V1; V2<V1	1 V
Frequency difference f2>f1; f2<f1	10 mHz
Angular difference α2>α1; α2<α1	1°
Tolerance of all time settings	10 ms
Max. phase displacement angle	5° for Δf ≤ 1 Hz 10° for Δf > 1 Hz

12.56 Voltage Controller

Setting Values

General Information		
I reference for % values	0.20 A to 100 000.00 A	Increments of 0.01 A
V reference for % values	0.20 kV to 1 200.00 kV	Increments of 0.01 kV
Volt. cont. 2W		
Target voltage 1	40.00 kV to 1 360.00 kV	Increments of 0.01 kV
Target voltage 2		
Target voltage 3		
Target voltage 4		
Volt. cont. 3W and GC		
Target voltage 1 w1	40.00 kV to 1 360.00 kV	Increments of 0.01 kV
Target voltage 2 w1		
Target voltage 3 w1		
Target voltage 4 w1		
Target voltage 1 w2		
Target voltage 2 w2		
Target voltage 3 w2		
Target voltage 4 w2		
Volt. cont. 2W, 3W, and GC		
Bandwidth	0.2 % to 10.0 %	Increments of 0.1 %
T1 delay	5 s to 600 s	Increments of 1 s
T1 Inverse Min	5 s to 100 s	Increments of 1 s
T2 delay	0 s to 100 s	Increments of 1 s
Fast step down limit	0.0 % to 50.0 %	Increments of 0.1 %
Fast step down T delay	0.0 s to 10.0 s	Increments of 0.1 s
Fast step up limit	-50.0 % to 0.0 %	Increments of -0.1 %
Fast step up T delay	0.0 s to 10.0 s	Increments of 0.1 s
Function monitoring	1 min to 120 min	Increments of 1 min
Line compensation LDC-Z		
Target voltage rising	0.0 % to 20.0 %	Increments of 0.1 %
Max load current	0.0 % to 500.0 %	Increments of 0.1 %
Line compensation LDC-X and R		
R line	0.0 Ω to 30.0 Ω	Increments of 0.1 Ω
X line	-30.0 Ω to 30.0 Ω	Increments of 0.1 Ω
Limiting values		
Vmin threshold	40.00 kV to 1 360.00 kV	Increments of 0.01 kV
Vmin time delay	0 s to 20 s	Increments of 1 s
Vmax threshold	40.00 kV to 1 360.00 kV	Increments of 0.01 kV
Vmax time delay	0 s to 20 s	Increments of 1 s
Blockings		
V< Threshold	40.00 kV to 1 360.00 kV	Increments of 0.01 kV
V< Time delay	0 s to 20 s	Increments of 1 s
I> Threshold	10 % to 500 %	Increments of 1 %
I> Time delay	0 s to 20 s	Increments of 1 s
I< Threshold	3 % to 100 %	Increments of 1 %

I< Time delay	0 s to 20 s	Increments of 1 s

Measured Values, Two-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
V act.	Current, measured positive-sequence voltage (referenced to phase-to-phase)	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load	Current measured load current (positive-sequence system)	A	A	Load current referenced to the rated current of the winding
V max	Maximum positive-sequence voltage ever measured (referenced to phase-to-phase)	kV	V	Maximum voltage of the winding referenced to the rated voltage of the winding
V min	Minimum positive-sequence voltage ever measured (reference to phase-to-phase)	kV	V	Minimum voltage of the winding referenced to the rated voltage of the winding
V target	Calculated target voltage with consideration of Z compensation	kV	V	Target voltage of the winding referenced to the rated voltage of the winding

Measured Values, Three-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to the rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to the rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1

Measured Value	Description	Primary	Secondary	% Referenced to
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

Measured Values Grid Coupling Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	kV	V	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

Dropout Ratio

Threshold of the voltage limit	About 0.99 of the setting value
Threshold of the current limit	About 0.99 of the setting value

12.57 Current-Balance Supervision

Setting Values

Release threshold	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold value min/max		0.10 to 0.95	Increments of 0.01
Tripping delay		0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Overcurrent dropout ratio	About 0.97
Undercurrent dropout ratio	About 1.05

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.58 Voltage-Balance Supervision

Setting Values

Release threshold value	0,300 V to 170,000 V	Increments of 0.001 V
Threshold value min/max	0.58 to 0.95	Increments of 0.01
Tripping delay	0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Overvoltage dropout ratio	Approx. 0.97
Undervoltage dropout ratio	Approx. 1.05

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.59 Current-Sum Supervision

Setting Values

Slope of the characteristic curve		0.00 to 0.95	Increments of 0.01
Threshold	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Tripping delay		0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Dropout ratio	About 0.97

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.60 Voltage-Sum Supervision

Setting Values

Threshold value	0.300 V to 170.000 V	Increments of 0.001 V
Tripping delay	0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Dropout ratio	Approx. 0.97

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.61 Current Phase-Rotation Supervision

Setting Values

Tripping delay	0.00 s to 100.00 s	Increments of 0.01 s
Phase-rotation direction	A B C A C B	

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.62 Voltage Phase-Rotation Reversal

Setting Values

Tripping delay	0.00 s to 100.00 s	Increments of 0.01 s
Phase-rotation direction	A B C A C B	

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.63 Trip-Circuit Supervision

Setting Values

Number of monitored circuits per circuit-breaker function group	1 to 3	
Operating mode per circuit	With 1 binary input With 2 binary inputs	
Pickup and dropout time	About 1 s to 2 s	
Adjustable indication delay with 1 binary input	1.00 s to 600.00 s	Increments of 0.01 s
Adjustable indication delay with 2 binary inputs	1.00 s to 600.00 s	Increments of 0.01 s

12.64 Analog Channel Supervision via Fast Current Sum

Times

Pickup times	Approx. 2 ms (faster than the fastest protection function)
Dropout time	Approx. 100 ms

Blockings

Blocked functions	All functions that process the measured values from this current measuring point (for example, differential protection).

12.65 Measuring-Voltage Failure Detection

Setting Values

3ph.fail. - VA,VB,VC <		0.300 V to 340 000 V	Increments of 0.001 V
3ph.fail. - phs.curr.release	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
3ph.fail. - phs.curr. jump	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Asym.fail. - time delay		0.00 s to 30.00 s	Increments of 0.01 s
SO 3ph.fail. - time delay		0.00 s to 30.00 s	Increments of 0.01 s

Dropout

The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the `Dropout ratio` parameter If this parameter is not available, a dropout ratio of 95 % applies to the overvoltage protection and a dropout ratio of 105 % applies to the undervoltage protection.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup time	Approx. 10 ms + OOT[122] at 50 Hz Approx. 10 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Times

Use in function group **Line**	
Pickup time	Approx. 10 ms + OOT[123] at 50 Hz Approx. 9 ms + OOT at 60 Hz

Use in other function group types	
Pickup time	Approx. 20 ms + OOT[124] at 50 Hz Approx. 18 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances

[122] OOT (Output Operating Time) Additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*
[123] OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*
[124] OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

f < 10 Hz f > 80 Hz	Active

Tolerances

Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10%)
Voltages	0.5 % of the setting value or 0.5 V
Time delays	1 % of the setting value or 10 ms

12.66 Voltage-Transformer Circuit Breaker

Setting Values

Response time	0.000 s to 0.030 s	Increments of 0.001 s

12.67 Operational Measured Values and Statistical Values

The following applies to the tolerances of currents and voltages:

- The values apply both to the RMS values and the absolute value and phase angle of the fundamental components.
- The values were determined for pure sinusoidal signals – without harmonics.

Voltages

V_A, V_B, V_C Voltage range	V secondary < 200 V secondary
Secondary rated voltage Measuring range Frequency range	100 V to 125 V AC (0.8 to 2) · V_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
V_{AB}, V_{BC}, V_{CA} Voltage range	V secondary < 200 V
Secondary rated voltage Measuring range Frequency range	100 V to 125 V AC (0.8 to 2) · V_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range

Currents, Instrument Transformers

I_A, I_B, I_C, $3I_0$ Current range	A secondary < 1.6 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A (0.1 to 1.6) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.15 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range

Currents, Protection-Class Current Transformer

I_A, I_B, I_C, $3I_0$ Current range	A secondary < 100 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A 0.1 to 25 A 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range

Currents, Protection-Class Current Transformer

I_A, I_B, I_C, $3I_0$ Current range	A secondary < 50 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A 0.1 to 25 A 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.15 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.6 % of the measured value in the above mentioned measuring range

Currents, Sensitive Ground-Current Transformer

$3I_0$ Current range	A secondary < 1.6 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A (0.1 to 1.6) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.15 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 60 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range

Phase Angle

ΦV	°
Frequency range	47.5 Hz to 52.5 Hz at f_{rated} = 50 Hz 57.5 Hz to 62.5 Hz at f_{rated} = 60 Hz

Tolerance ΦV	0.2 ° at rated voltage
ΦI	°
Frequency range	47.5 Hz to 52.5 Hz at f_{rated} = 50 Hz 57.5 Hz to 62.5 Hz at f_{rated} = 60 Hz
Tolerance ΦI	0.2 ° at rated current

Power Values

Active power P	W secondary
Measuring range Voltage range Current range Frequency range	|cosφ| ≥ 0.01 (0.8 to 1.2) · V_{rated} (0.1 to 2) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 69 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.5 % of the measured value in the above mentioned measuring range
Reactive power Q	var secondary
Measuring range Voltage range Current range Frequency range	|cosφ| ≥ 0.984 (0.8 to 1.2) · V_{rated} (0.1 to 2) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	1.0 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 69 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	1.5 % of the measured value in the above mentioned measuring range
Apparent power S	VA
Measuring range Voltage range Current range Frequency range	(0.01 to 2) · S_{rated} (0.8 to 1.2) · V_{rated} (0.01 to 2) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 69 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.5 % of the measured value in the above mentioned measuring range

Frequency

Frequency f	Hz

Range	f_{rated} - 0.20 Hz < f_{rated} + 0.20 Hz
Tolerance	± 5 mHz in the V_{rated} range
Range	f_{rated} - 3.00 Hz < f_{rated} + 3.00 Hz
Tolerance	± 10 mHz in the V_{rated} range
Frequency range (expanded)	25 Hz to 80 Hz; operational measured values 10 Hz to 80 Hz; functional measured values, system frequency
Tolerance	20 mHz in the range f_{rated} ± 10 % for rated values

Statistical Values of the Device

Device operating hours	h
Range	0 to 9 999 999 h
Tolerance	1 h

Statistical Values of the Circuit Breaker

Op.cnt. (operation counter)	
Range	0 to 999 999 999
Tolerance	None
∑**I Off** (sum of the primary currents switched off)	A, kA, MA, GA, TA, PA primary
Range	0 to 9.2 e+15
Operating hours	h
Range	0 to 9 999 999 h
Tolerance	1 h
Circuit breaker open hours	h

Tolerance	1 h

Statistical Values of the Disconnector

Op.cnt. (operation counter)	
Range	0 to 999 999 999
Tolerance	None

12.68 Energy Values

Setting Values

Active energy W_p Reactive energy W_q	kWh, MWh, GWh kvarh, Mvarh, Gvarh
Range	≤ 2% for $I > 0.1\ I_{rated}$, $V > 0.1\ V_{rated}$ $\lvert\cos\varphi\rvert \geq 0.707$
Tolerance at rated frequency	1 %

12.69 Phasor Measurement Unit

Accuracy

As per IEEE Std C37.118.1a-2013

Synchrophasor Standard

IEEE Std C37.118.1-2011

12.70 Circuit-Breaker Wear Monitoring

Setting Values

Threshold value	ΣI^x-method stage	0 to 10 000 000	Increments of 1
	2P-method stage	0 to 10 000 000	Increments of 1
	I^2t-method stage	0.00 I/Ir*s to 21 400 000.00 I/Ir*s	Increments of 0.01
CB opening time		0.001 s to 0.500 s	Increments of 0.001 s
CB break time		0.001 s to 0.600 s	Increments of 0.001 s
CB make time		0.001 s to 0.600 s	Increments of 0.001 s
Exponent for the ΣI^x method		1.0 to 3.0	Increments of 0.1
Switching cycles at I_{rated}		100 to 1 000 000	Increments of 1
Rated short-circuit breaking current I_{sc}		10 to 100 000	Increments of 1
Switching cycles at I_{sc}		1 to 1000	Increments of 1
Level of warning 1		1 % to 100 %	Increments of 1 %
Level of warning 2		1 % to 100 %	Increments of 1 %
Operating current threshold	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Delay correction time		-0.050 s to 0.050 s	Increments of 0.001 s

Tolerances

Tolerance of the measured value make time	± 2 ms

12.71 CFC

Typical response times and maximum number of ticks of the CFC task levels:

Task Level	Time (in ms)	Ticks for Non-Modular Devices with CP100	Ticks for Modular Devices with CP200	Ticks for Modular Devices with CP300
Fast Event-Triggered	<1	500	500	1000
Event-Triggered	<10	12 367	12757	14702
Interlocking	<10	117 564 in total	121 537 in total	141 398 in total
Measurement	250			

The times describe the response time of a typical CFC chart at the respective task level. The maximum number of ticks applies to a typical load for the device based on the application template **Directional time-overcurrent protection, grounded electrical power system**. The maximum number can be lower in case of extensive protection applications.

The task level ***Measurement*** runs in cycles every 500 ms. All other task levels are event-triggered.

In order to estimate the tick consumption of a CFC chart, you can use the following formula:

$$T_{chart} = 5 \cdot n_{Inp} + 5 \cdot n_{Outp} + T_{TLev} + \sum_i T_{int} + \sum_j T_{Block}$$

where:

n_{Inp} Number of indications routed as input in the CFC chart

n_{Outp} Number of indications routed as output in the CFC chart

T_{TLev} 101 Ticks in Fast Event-Triggered Level
104 Ticks in Event-Triggered Level
54 Ticks in Measurement Level
74 Ticks in Interlocking Level

T_{int} Number of internal connections between 2 CFC blocks in one chart

T_{Block} Used ticks per CFC block (see Technical Data)

Table 12-6 Ticks of the Individual CFC Blocks

Element	Ticks
ABS_D	2.3
ABS_R	1.5

A.1 Order Configurator and Order Options

Order Configurator

The order configurator assists you in the selection of SIPROTEC 5 products. The order configurator is a Web application that can be used with any browser. The order configurator can be used to configure complete devices or individual components, such as communication modules, expansion modules, or other accessories. At the end of the configuration process, the product code and a detailed presentation of the configuration result are provided. The product code unambiguously describes the selected product and also serves as an order number.

Ordering Options

The following ordering options are possible for SIPROTEC 5 products:

- Device
- Single part
- DIGSI 5
- Functional enhancement

NOTE

To order single parts in the order configurator, use the **Single part** link.

Individual parts are:

- Replacement base module
- Expansion module
- Plug-in module
- Sensors for arc protection
- Operation panel
- Terminal
- Accessories

A.2 Ordering Accessories

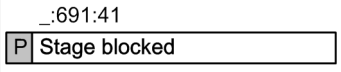
NOTE

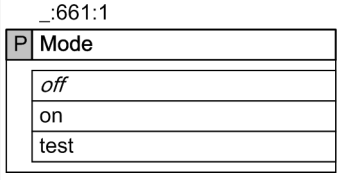
To order terminals, terminal accessories, and mechanical accessories in the order configurator, use the **Single part** link.

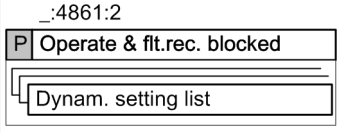
Table A-1 Accessories

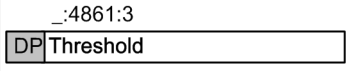
Group	Accessories
Terminal	Voltage terminal, terminal block, 14-pole
Terminal	Voltage input (power supply) Terminal block, 2-pole[125]
Terminal	Type A current terminal, 4 x protection (for modular devices)
Terminal	Type A current terminal, 3 x protection and 1 x measurement (for modular devices)
Terminal	Type A current terminal, 4 x measurement (for modular devices)
Terminal	Type B current terminal, 4 x protection (for non-modular devices)
Terminal	Type B current terminal, 3 x protection and 1 x measurement (for non-modular devices)
Terminal	2-pole cross connector for current terminal
Terminal	Terminal pair component IO110[125]
Terminal	Terminal kit only for IO230/231[125]
Terminal	2-pole cross connector for voltage terminal
Terminal	Cover for current terminal block
Terminal	Cover for voltage terminal block
Accessories	Cable, integrated operation panel 0.43 m
Accessories	Cable, detached operation panel 2.50 m
Accessories	Cable, detached operation panel 5.00 m
Accessories	Cable set COM link cable
Accessories	Cover plate for plug-in modules
Accessories	Set of angle brackets
Accessories	Labeling strips for LEDs/keypad
Accessories	Set of parts for mounting bracket 1/2
Accessories	Set of parts for mounting bracket 2/3
Accessories	Set of parts for mounting bracket 5/6
Accessories	Set of parts for mounting bracket 1/1
Accessories	Screw cover 1/3, type C11
Accessories	Screw cover 1/3, type C22
Accessories	Screw cover 1/6, type C21
Accessories	Bus termination plate
Accessories	Assembly frame for panel surface mounting for non-modular 7xx82 devices
Accessories	SDHC memory card for 7KE85

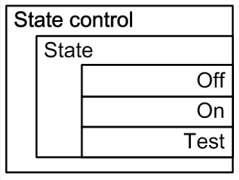
[125] Recommended tightening torque for fixing the terminal at the rear side: 0.3 Nm

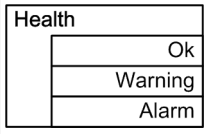


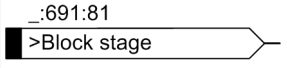


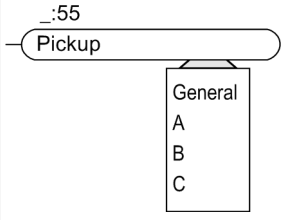


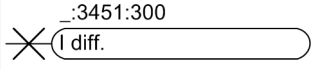




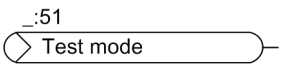


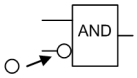


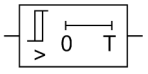


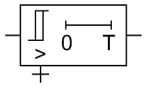


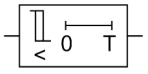
Group	Accessories
Accessories	Battery holder
Accessories	Connecting cable for 2nd row
Accessories	Arc push-buttons
Sensors for arc protection	Point sensor with line length of 3 m
Sensors for arc protection	Point sensor with line length of 4 m
Sensors for arc protection	Point sensor with line length of 5 m
Sensors for arc protection	Point sensor with line length of 10 m
Sensors for arc protection	Point sensor with line length of 15 m
Sensors for arc protection	Point sensor with line length of 20 m
Sensors for arc protection	Point sensor with line length of 35 m
Sensors for arc protection	Line sensor with line length of 5 m
Sensors for arc protection	Line sensor with line length of 10 m
Sensors for arc protection	Line sensor with line length of 20 m
Sensors for arc protection	Line sensor with line length of 30 m
Sensors for arc protection	Line sensor with line length of 40 m
Sensors for arc protection	Supply line for line sensors, length: 3 m
Sensors for arc protection	Supply line for line sensors, length: 5 m
Sensors for arc protection	Supply line for line sensors, length: 10 m

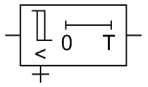


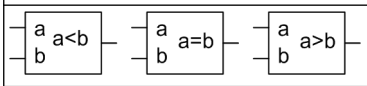


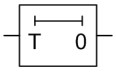


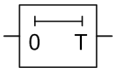


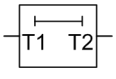




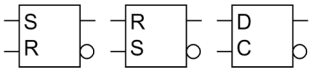


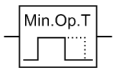






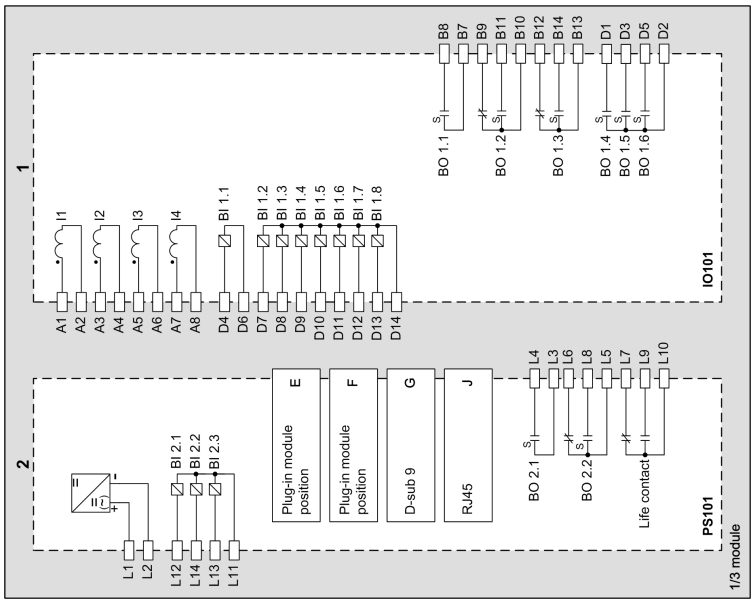
A.3 Typographic and Symbol Conventions





The following typefaces are used to characterize parameters in the text:

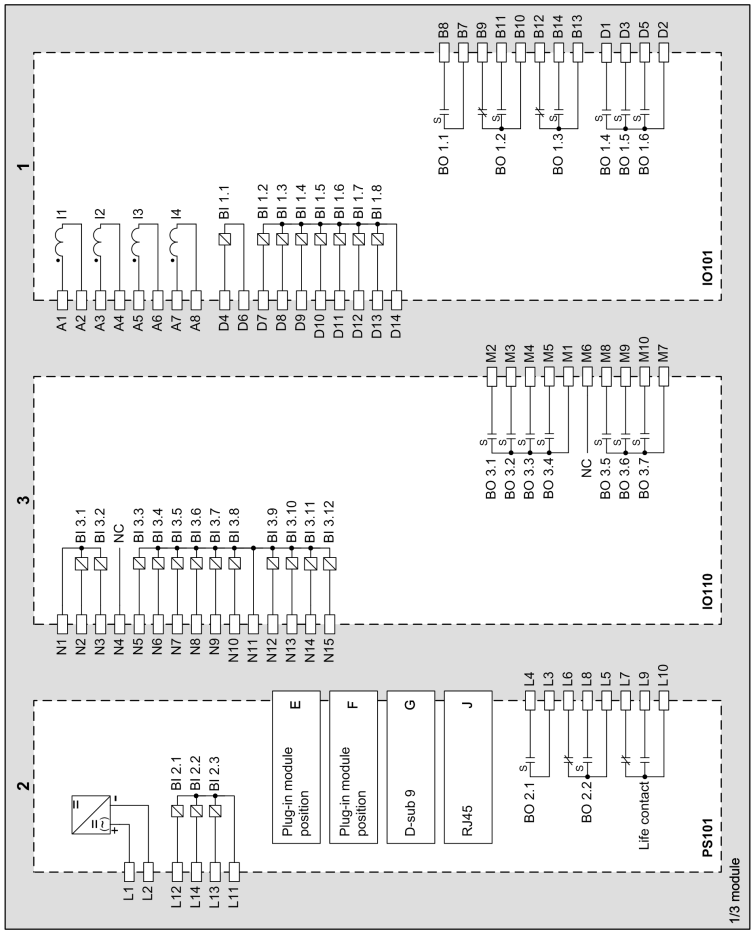
Mode	Parameter name
_:661:1	Parameter address _ stands for the address combination from function group:function 661, for example, stands for the address of the setting parameter
from	Parameter state



The following symbols are used in drawings:

Icon	Description
	Parameter
	Parameters with setting values The default setting is in the 1st position and displayed in italics
	Parameters with application-dependent setting values
	Dynamic settings:
	State logic
	Health of a function, stage, or function block
	External binary input signal with indication number
	External output signal with indication number and additional information
	External output signal without indication number
	Measured output value

Icon	Description
	Binary input signal derived from an external output signal
	Internal input signal
	Internal output signal
	Analog input signal
	Reset/Block a logic element
	AND gate
	OR gate
	XOR gate
	Negation
	Threshold stage exceeded
	Threshold stage exceeded with reset of input
	Threshold stage shortfall
	Threshold stage shortfall with reset of input
	Threshold stage exceeded with dropout delay
	Threshold stage exceeded with dropout delay and reset of input
	Threshold stage shortfall with Dropout delay
	Threshold stage shortfall with dropout delay and reset of input
	Comparators
	Pickup delay
	Dropout delay
	Pickup and dropout delay



Icon	Description
	Trigger the pulse of duration T with a positive signal edge
	Trigger the pulse of duration T with a negative signal edge
	SR-Flip-Flop, RS-Flip-Flop, D-Flip-Flop
	Characteristic curve
	Minimum operate time

A.6 Current Transformer Requirements

The requirements for phase current transformers are usually determined by the overcurrent protection, particularly by the high-current element settings. Besides, there is a minimum requirement based on experience.

The recommendations are given according to the standard IEC 60044-1.

The standards IEC 60044-6, BS 3938 and ANSI/IEEE C 57.13 are referred to for converting the requirement into the knee-point voltage and other transformer classes.

Accuracy Limiting Factors

Table A-2 Effective and Rated Accuracy Limiting Factor

Required minimum effective accuracy limiting factor	$K_{ALF'} = \frac{I \gg_{PU}}{I_{rated,\ prim}}$ but at least 20	
	with	
	$K_{ALF'}$	Minimum effective accuracy limiting factor
	$I>>_{PU}$	Primary pickup value of the high-current element
	$I_{rated,prim}$	Primary rated transformer current
Resulting rated accuracy limiting factor	$K_{ALF} = \frac{R_{BC} + R_{Ct}}{R_{BN} + R_{Ct}} \cdot K_{ALF'}$	
	with	
	K_{ALF}	Rated accuracy limiting factor
	R_{BC}	Connected burden (device and cables)
	R_{BN}	Rated burden
	R_{Ct}	Internal burden

Table A-3 Calculation Example According to IEC 60044–1

$I_{rated,sec}$ = 1 A $K_{ALF'}$ = 20 R_{BC} = 0.6 Ω (device and cables) R_{Ct} = 3 Ω R_{BN} = 5 Ω (5 VA)	$K_{ALF} = \frac{0.6 + 3}{5 + 3} \cdot 20 = 9$ K_{ALF} set to 10, so that: 5P10, 5 VA
with $I_{rated,sec}$ = Secondary rated transformer current	

Class Conversion

Table A-4 Conversion into Other Classes

British Standard BS 3938	$V_k = \frac{(R_{Ct} + R_{BN}) \cdot I_{rated,sec}}{1.3} \cdot K_{ALF}$
ANSI/IEEE C 57.13, class C	$V_{st\ max} = 20 \cdot I_{rated,sec} \cdot R_{BN} \cdot \frac{K_{ALF}}{20}$ $I_{rated,sec}$ = 5 A (typical value)

IEC 60044-6 (transient response), class TPS Classes TPX, TPY, TPZ	$V_{al} = K \cdot k_{SSC} \cdot (R_{Ct} + R_{BN}) \cdot I_{rated,sec}$ K≈ 1 $K_{SSC} \approx K_{ALF}$ You can find a calculation example in the above section Accuracy Limiting Factors with: $K_{SSC} \approx K_{ALF}$ T_P depending on power system and specified closing sequence	
	with	
	V_k	Knee-point voltage
	R_{Ct}	Internal burden
	R_{BN}	Rated burden
	$I_{rated,sec}$	Secondary rated transformer current
	K_{ALF}	Rated accuracy limiting factor
	$V_{s.t.max}$	Secondary terminal voltage at 20 $I_{rated,prim}$
	V_{al}	Secondary magnetization limit voltage
	K	Dimensioning factor
	K_{SSC}	Factor symmetric rated fault current
	T_P	Primary time constant

Cable Core Balance Current Transformer

The requirements to the cable core balance current transformer are determined by the function **Sensitive ground-fault detection**.
The recommendations are given according to the standards IEC 60044-1 and IEC 61869-2.

Table A-5 Requirements to the cable core balance current transformer according to IEC 60044-1 and IEC 61869-2

Transformation ratio, typical It may be necessary to select a different transformation ratio to suit the specific power system and thus the corresponding amount of the maximum ground fault current.	60 / 1
Accuracy limiting factor	FS = 10
Power	1 to 4 times the connected burden (device input plus infeeds)
Notes concerning the power: The burden of the sensitive ground-current input is very low (0.05 VA or 0.1 VA). Thus, an underburden of more than factor 4 is probable. In this case, clarify the suitability of the class accuracy concerning an important underburden with the transformer manufacturer. If necessary, request the accuracy for the range from 0 VA to the rated burden. This specification is then outside the standard, but in practice, it is possible in most cases. (Relevant standard: IEC 61869-2, Chapter 5.6.201.4 Extended burden range. There, the range 1 VA to rated burden is specified for rated burdens smaller than 15 VA.)	

Table A-6 Minimum Required Class Accuracy Depending on Neutral Grounding and Function Operating Principle

Neutral Point	**Isolated**	**Resonant-Grounded**	**High-Resistance Grounded**
Function directional	Class 1	Class 1	Class 1

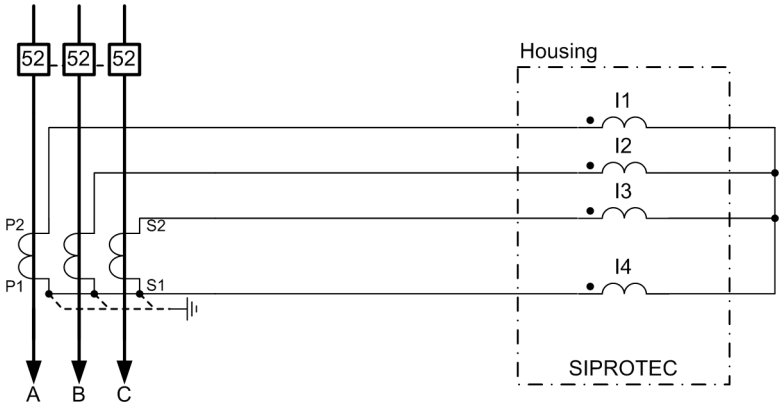
Function non-directional	Class 3	Class 1	Class 3

NOTE

The class accuracy according to IEC 61869-2 below 5% I_{rated} (< 50 mA secondary) is not defined in general.

For very sensitive directional measurements, Siemens recommends the classes 0.5S or 0.1S that define the class accuracy via an extended current range (up to 1% I_{rated}) (see chapter 5.6.201.5, IEC 61869-2).

Another possibility is to correct the phase-angle error of the transformer on the device, if this error is known (see function description **Sensitive ground-fault detection**.



A.7 Connection Examples for Current Transformers

Current transformer 3-phase: connection = **3-phase**

Glossary

ACD

IEC 61850 data type: Directional protection activation information

ACK

Data transfer acknowledgment

ACT

IEC 61850 data type: Protection activation information

APC

Controllable analog set point information

ASDU

ASDU stands for Application Service Data Unit. An ASDU can consist of one or more identical information objects. A sequence of the same information elements, for example measured values, is identified by the address of the information object. The address of the information object defines the associated address of the first information element of the sequence. A consecutive number identifies the subsequent information elements. The number builds on this address in integral increments (+1).

BAC

Binary Controlled Analog Process Value

Back-up battery

The back-up battery ensures that specified data areas, flags, times and counters are kept retentive.

Bay Controller

Bay controllers are devices with control and monitoring functions without protection functions.

BCR

IEC 61850 data type: Binary counter reading

Best master clock algorithm

A PTP network contains communicating clocks. With the best master clock algorithm (BMC), the device indicating the most precise time is determined. This device is used as a reference clock and is designated as grandmaster. If the network topology is changed, the BMC algorithm is executed again on network segments that are possibly disconnected from the grandmaster. If a participating device is a master and a slave, it is called a boundary clock.

Big-endian

Big-endian and little-endian describe the order in which a sequence of bytes is stored. In big-endian systems, the most significant byte is stored at the lowest storage address. In little-endian systems, the most significant byte is stored at the highest storage address.

Binary Controlled Analog Process Value

The data type BAC represents a command with or without feedback. The BAC is used for example for the control of an arc suppression coil. The commands **Higher**, **Lower**, and **Stop** are possible. The feedback from the process is an analog value.

Binary Controlled Step Position

The data type BSC can, for example, be used to control a transformer tap changer. The commands **up**, **down** can be given.

Bit pattern indication

A bit pattern indication is a processing function, with the help of which adjacent numerical process information can be logged coherently and processed further in parallel via multiple inputs. The bit pattern indication can be selected as 1, 2, 3 or 4 bytes.

BMC

See best master clock algorithm

Boundary Clock

The Precision Time Protocol knows different types of clocks: an ordinary clock (abbreviation: OC), a boundary clock (BC), and a transparent clock (TC). The boundary clock transports time information over a network limit, for example, in a router connecting different switched networks: As a slave, the clock of the router receives the time information and transmits this further on as a master.

BRCB

Buffered Report Control Block

BSC

Binary Controlled Step Position

Buffered Report Control Block

Buffered Report Control Block (BRCB) is a form of report controlling. Internal events trigger the immediate sending of reports or saving of events for the transfer. Data values cannot therefore be lost on account of transport flow control conditions or connection interruptions. BRCB provides the functionality **SOE** (See Sequence of Events).

CB

Circuit breaker

CDC

Common Data Class

CFC

Continuous Function Chart

Chatter Blocking

A rapidly intermittent input (for example, owing to a relay contact fault) is disconnected after a parameterizable monitoring time and therefore cannot generate any more signal changes. The function prevents the system from overloading in the event of an error.

CID

Configured IED Description

CMV

Complex measured value

Combination Device

Combination devices are bay units with protection functions and with feeder mimic diagram.

Common Data Class

Generic term for a data class according to the IEC 61850 model.

Communication branch

A communication branch corresponds to the configuration of 1 to n participants communicating via a joint bus.

Configured IED Description

A Configured IED Description (CID) is a file for data exchange between the IED Configuration Tool and the IED itself.

Container

If an object contains other objects, this is referred to as a container. The object **Folder** for example is such a container.

Continuous Function Chart

The Continuous Function Chart (CFC) is a programming language. It is used for programmable logic controllers. The programming language Continuous Function Chart is not defined in the standard IEC 61131-3, but represents a current extension of IEC programming environments. CFC is a graphic programming language. Function blocks are linked to one another. This represents an essential difference from conventional programming languages, where sequences of commands are entered.

Control display

The control display becomes visible for devices with a large display after pressing the Control key. The diagram contains the switching devices to be controlled in the feeder. The control display serves for implementing switching operations. Specification of this diagram forms part of configuring.

Controllable Integer Status

The data type INC can be used to issue a command (to one or more relays, selectable under information routing) that is monitored via a whole number as feedback.

Controller

The controller initiates the IO data communication.

CRC

Cyclic redundancy check

Data type

The data type is a value set of a data object, together with the operations allowed on this value set. A data type contains a classification of a data element, such as the determination whether it consists of integers, letters, or similar.

Data unit

Information item with a joint transmission source. Abbreviation: DU = Data Unit

Data window

The right area of the project window visualizes the content of the area selected in the navigation window. The data window contains for example, indications or measured values of the information lists or the function selection for parameterization of the device.

DCF

Device Configuration File: Device parameterization

DCF77

The precise official time is determined in Germany by the Physikalisch-Technische Bundesanstalt PTB in Brunswick. The atomic clock unit of the PTB transmits this time via the long-wave time signal transmitter in Mainflingen near Frankfurt/Main. The emitted time signal can be received within a radius of approx. 1500 km from Frankfurt/Main.

DCP

Discovery and Basic Configuration Protocol

DDD

SIPROTEC 5 device driver (DIGSI 5 Device Driver)

DEL

Phase-to-phase related measurements of a 3-phase system

Device 5 Export Format

DEX5

Device Container

In the component view, all SIPROTEC devices are subordinate to an object of the device container type. This object is also a special object from the DIGSI-5 Manager. However, as there is no component view in the DIGSI 5 Manager, this object only becomes visible in conjunction with STEP 7.

DEX5

Device 5 Export Format

You can archive the data from an individual SIPROTEC 5 device in DEX5 format.

DHCP

Dynamic Host Configuration Protocol

DIGDNP

DIGSI 5 protocol settings for DNP3

File extension for a file generated by DIGSI for exporting the protocol configuration from DIGSI 5.

DIGMOD

DIGSI 5 protocol settings for Modbus TCP

File extension for a file generated by DIGSI for exporting the protocol configuration from DIGSI 5.

DIGSI 5 Display Pages

You can archive individual or all display pages of a SIPROTEC 5 device in DSP5 format. You can also use this format to exchange display pages between SIPROTEC 5 devices. The DSP5 format is based on XML.

DIGSI 5 protocol settings for DNP3

If the DNP3 protocol is configured for a system interface, you can export the protocol settings in DIGDNP format. The DIGDNP format is specially designed to transmit interface data from DIGSI 5 into the SICAM PAS substation automation system.

DIGSI 5 protocol settings for IEC 60870-5-103

If the IEC 60870-5-103 protocol is configured for a system interface, you can export the protocol settings in DIGT103 format. The DIGT103 format is specially designed to transmit interface data from DIGSI 5 into the SICAM PAS substation automation system.

DIGSI 5 protocol settings for IEC 60870-5-104

If the IEC 60870-5-104 protocol is configured for a system interface, you can export the protocol settings in DIGT104 format. The DIGT104 format is specially designed to transmit interface data from DIGSI 5 into the SICAM PAS substation automation system.

DIGSI 5 protocol settings for Modbus TCP

If the Modbus TCP protocol is configured for a system interface, you can export the protocol settings in DIGMOD format. The DIGMOD format is specially designed to transmit interface data from DIGSI 5 into the SICAM PAS substation automation system.

DIGSI 5 Test Sequences

You can archive individual or all test sequences of a SIPROTEC 5 device in SEQ5 format. You can also use this format to exchange test sequences between SIPROTEC 5 devices. The SEQ5 format is based on XML.

DIGSI

Configuration software for SIPROTEC

DIGT103

DIGSI 5 protocol settings for IEC 60870-5-103

File extension for a file generated by DIGSI for exporting the protocol configuration from DIGSI 5.

DIGT104

DIGSI 5 protocol settings for IEC 60870-5-104

File extension for a file generated by DIGSI for exporting the protocol configuration from DIGSI 5.

Discovery and Basic Configuration Protocol

The DCP protocol is used to detect devices without IP addresses and to assign addresses to these devices.

DNP3

DNP3 is a communications standard for telecontrol engineering. DNP3 is used as a general transmission protocol between control systems and substations and between bay devices and the systems control.

Double Command

Double commands (DPC – Double Point Control) are process outputs which visualize 4 process states at 2 outputs: 2 defined states (for example, On/Off) and 2 undefined states (for example, disturbed positions).

Double-point indication

Double-point indications (DPS – Double point status) are process indications which visualize 4 process states at 2 inputs: 3 defined states (for example, On/Off and disturbed position) and 1 undefined state (00).

DPC

IEC 61850 data type: Double Point Control

DPS

IEC 61850 data type: Double-point status

Drag and drop

Copying, moving, and linking function, used in graphic user interfaces. The mouse is used to highlight and hold objects and then move them from one data area to another.

DSP5

DIGSI 5 Display Pages

DU

Data unit

Dynamic Host Configuration Protocol

In order to configure PCs automatically, centralized and uniformly in a TCP/IP network, a dynamic assignment of IP addresses is used. DHCP is used. The system administrator determines how the IP addresses are to be assigned and specifies the time lapse over which they are assigned. DHCP is defined in the Internet standards RFC 2131 (03/97) and RFC 2241 (11/97).

For SIPROTEC 5, a device can also be assigned an IP address via DIGSI via DHCP.

ELCAD

Electrical CAD

Electrical CAD

You can import the topology information contained in an ELCAD file into a project and use it as the basis for a single-line configuration. The other information contained in the ELCAD file is not included in this process.

Electromagnetic Compatibility

Electromagnetic compatibility (EMC) means that an item of electrical equipment functions without error in a specified environment. The environment is not influenced in any impermissible way here.

ENC

Enumerated Status Controllable

ENS

Enumerated Status

ESD Protection

The ESD protection is the entirety of all means and measures for the protection of electrostatic-sensitive devices.

Far End Fault Indication

Far End Fault Indication (FEFI) is a special setting of switches. It is always only possible to log a line interruption on the receive line. If a line interruption is detected, the link status of the line is changed. The status change leads to deletion of the MAC address assigned to the port in the switch. However, outage of the receive line from the aspect of the switch can only be detected in the receiver, that is, by the switch. The receiver then immediately blocks the transmit line and signals the connection failure to the other device. The FEFI setting in the switch triggers detection of the error on the receive line of the switch.

FEFI

Far End Fault Indication

FG

Function group

Fleeting indication

Fleeting indications are single-point indications present for a very short time, in which only the coming of the process signal is logged and further processed time-correctly.

Floating

Floating means that a free potential not connected to ground is generated. Therefore no current flows through the body to ground in the event of touching.

Folder

This object type helps when structuring a project hierarchically.

Function group

Functions are brought together into function groups (FG). The assignment of functions to current and/or voltage transformers (assignment of functions to measuring points), the information exchange between the function groups via interfaces as well as the generation of group indications are important for this bringing together.

General interrogation

The state of all process inputs, of the status, and of the error image are scanned on system startup. This information is used to update the system-side process image. Likewise, the current process state can be interrogated after data loss with a general interrogation (GA).

General Station Description Mark-up Language

GSDML is an XML-based description language for creating a GSD file.

Generic Object-Oriented Substation Event

GOOSE. Protocol of IEC 61850 for communication between bay units.

GI

General interrogation

GIN

Generic Identification Number

GOOSE

Generic Object-Oriented Substation Event

Ground

The conductive ground whose electric potential can be set equal to 0 at every point. In the area of grounding conductors, the ground can have a potential diverging from 0. The term **reference ground** is also used for this situation.

Grounding

The grounding is the entirety of all means and measuring for grounding.

GSDML

General Station Description Mark-up Language

Hierarchy Level

In a structure with superordinate and subordinate objects, a hierarchy level is a level of equal-ranking objects.

High Availability Seamless Redundancy Protocol

Like PRP (Parallel Redundancy Protocol), HSR (High Availability Seamless Redundancy Protocol) is specified in IEC 62439-3. Both protocols offer redundancy without switching time.

The principal function can be found in the definition of PRP. With PRP, the same indication is sent via 2 separated networks. In contrast to this, in the case of HSR the indication is sent twice in the 2 directions of the ring. The recipient receives it correspondingly via 2 paths in the ring, takes the 1st message and discards the 2nd (see PRP).

Whereas NO indications are forwarded in the end device in the case of PRP, a switch function is installed in the HSR node. Thus, the HSR node forwards indication in the ring that are not directed at it.

In order to avoid circular messages in the ring, corresponding mechanisms are defined in the case of HSR.

SAN (Single Attached Node) end devices can only be connected with the aid of a REDBOX in the case of HSR. PRP systems and HSR systems can be coupled redundantly with 2 REDBOXES.

HMI

Human-Machine Interface

HSR

High Availability Seamless Redundancy Protocol

HV bay description

The HV project description file contains data concerning which bays are present within a ModPara project. The actual bay information is saved for each bay in an HV bay description file. Within the HV project description file, each bay receives an HV bay description file through a reference to the file name.

HV Project Description

If the configuring and parameterization of PCUs and submodules is completed with ModPara, all the data will be exported. The data is distributed to several files during this process. A file contains data on the basic project structure. This typically includes information on which bays are present within this project. This file is designated as an HV project description file.

ICD

IED Capability Description

IEC

International Electrotechnical Commission

IEC 60870-5-103

International standard protocol for communication with IEDs (especially protective equipment). Many protective relays, bay devices, bay controllers and measurement acquisition devices use the IEC 60870-5-103 protocol to communicate with the SICAM system.

IEC 60870-5-104

Internationally standardized telecontrol protocol. Transmission protocol based on IEC 60870-5-101 for the connection of the substation control level to the telecontrol center using TCP/IP via a Wide Area Network (WAN) connection.

IEC 60870-5-104 is also used for the communication with IEDs.

IEC 61850

IEC 61850 is an international standard for consistent communication in substations. This standard defines the communication amongst devices in substations and the related system requirements. All substation automation functions as well as engineering functions are supported. IEC 61850 can also be transferred to automation systems in other applications, for example, for the control and monitoring of distributed power generation.

IEC address

A unique IEC address must be assigned to each SIPROTEC device within an IEC bus. A total of 254 IEC addresses per IEC bus are available.

IEC communication branch

Within an IEC communication branch, the participants communicate on the basis of the protocol IEC 60870-5-103 via an IEC bus.

IED Capability Description

Data exchange from the IED configuration software (DIGSI) to the system configurator. This file describes the performance properties of an IED.

IEEE 1588

Time-synchronization protocol according to IEEE Std 1588-2008: Precision Clock Synchronization Protocol for Networked Measurement and Control Systems (IEEE 1588 v2) and IEEE Std C37.238-2011: IEEE Standard Profile for Use of IEEE 1588 Precision Time Protocol in Power System Applications (Power Profile).

IID

Instantiated IED Description

INC

Controllable Integer Status

Initialization string

An initialization string consists of a series of modem-specific commands. If the modem is initialized, these commands are transferred to the modem. The commands can force definite settings for the modem, for example.

Input Data/Input Direction

Data is sent from the protocol slave to the protocol master.

INS

Integer Status

Instantiated IED Description

Files in IID format are ICD files adapted for the concrete application in the project. This format is mainly suitable for exchanging data between DIGSI 5 and an external system configurator or also a substation automation system such as SICAM PAS. The ICD format uses SCL as the description language for this purpose.

International Electrotechnical Commission

IEC

Internet protocol

An Internet protocol (IP) enables the connection of participants which are positioned in different networks.

IO

Input-Output

IO Provider Status

The provider (sender) of an IO data element uses this to signal the status (good/bad with error location).

IOPS

IO Provider Status

IP

Internet protocol

IPv4

Internet protocol version 4

ISC

Integer Step Controlled Position Information

LAN

Local Area Network

Link Address

The link address indicates the address of a SIPROTEC device.

Link Layer Discovery Protocol

The Link Layer Discovery Protocol supplies the basis for topology detection and for determination of the configuration.

List view

The right area of the project window displays the names and symbols of the objects which are within a container selected in the tree view. As the visualization is in the form of a list, this area is also referred to as list view.

LLDP

Link Layer Discovery Protocol

Local Area Network

A Local Area Network (LAN) is a regional, local PC network. The PCs are all equipped with a network interface card and work with one another via data exchange. The LAN requires an operating system on each PC and standardized data transport software. The operating systems can be different, as can the data transport software, but both must support a common transmission protocol (= TCP/IP protocols), so that all PCs can exchange data with one another.

LSB

Least Significant Bit

MAC address

The MAC address (Media Access Control) is the hardware address of each single system adaptor. With the MAC address, the device can be identified unambiguously in the system.

Management Information Base

A Management Information Base (MIB) is a database which saves information and statistics concerning each device in a network continuously. The performance of each device can be monitored with this information and statistics. In this way, it can also be ensured that all devices in the network function properly. MIBs are used with SNMP.

Manufacturing Message Specification

The standard Manufacturing Message Specification (MMS) serves for data exchange. The standard is used for the transmission protocols IEC 61850 and IEC 60870-6 TASE.2.

Measured Value

This data type provides a measured value that can be used as a CFC result, for instance.

Metered value

Metered values are a processing function, used to determine the total number of discrete similar events (counting pulses), for example, as integral over a time span. In the power supply utility field, electrical energy is often recorded as a metered value (energy import/delivery, energy transport).

MIB

Management Information Base

MICS

Model Implementation Conformance Statement

MMS

Manufacturing Message Specification

Modbus

The Modbus protocol is a communication protocol. It is based on a Master/Slave or Client/Server architecture.

Model Implementation Conformance Statement

Model Implementation Conformance Statement (see MICS)

The Model Implementation Conformance Statement describes in detail the standard data object models that are supported by the system or by the device.

Modem

Modem profiles for a modem connection are saved in this object type.

Modem Connection

This object type contains information on the two partners of a modem connection, local modem and remote modem.

Modem Profile

A modem profile comprises the name of the profile, a modem driver and optionally several initialization commands as well as a participant address. You can create multiple modem profiles for a physical modem. For this, link different initialization commands or participant addresses with a modem driver and its properties, and save these under various names.

Module

Self-contained unit at the device level. This can be a real module or a functional unit of the device.

MSB

Most Significant Bit

MV

Data type Measured Value

NACK

Negative acknowledgment

Navigation Window

Left area of the project window, which visualizes the names and symbols of all containers of a project in the form of a hierarchical tree structure.

Object

Each element of a project structure is designated as an object in DIGSI 5.

Object Property

Each object has properties. These can on the one hand be general properties that are common to several objects. Otherwise, an object can also have object-specific properties.

Offline

If there is no communication connection between a PC program (for example, configuration program) and a runtime application (for example, a PC application), the PC program is **offline**. The PC program executes in Offline mode.

Online

If there is a communication connection between a PC program (for example, configuration program) and a runtime application (for example, a PC application), the PC program is **online**. The PC program executes in Online mode.

Optical Switch Module

An Optical Switch Module (OSM) is a process for switching over switches in Ethernet networks that are ring-shaped in structure. OSM is a proprietary process from Siemens, which later became standard under the term MRP. OSM is integrated in the optical Ethernet module EN100-O. OSM is hardly used in IEC 61850 networks. RSTP is used there, this having become established as an international standard.

OSM

Optical Switch Module

Output data/Output direction

Data is sent from the protocol master to the protocol slave.

Parallel Redundancy Protocol

Parallel Redundancy Protocol (PRP) is a redundancy protocol for Ethernet networks that is specified in IEC 62439-3. Unlike conventional redundancy procedures, such as RSTP (Rapid Spanning Tree Protocol, IEEE 802.1D-2004), PRP offers uninterruptible switching, which avoids any down time in the event of a fault, and thus the highest availability.

PRP is based on the following approach: The redundancy procedure is generated in the end device itself. The principle is simple: The redundant end device has 2 Ethernet interfaces with the same address (DAN, Double Attached Node). Now, the same indication is sent twice, in the case of PRP (**parallel**) to 2 separate networks, and uniquely marks both with a sequence number. The recipient takes the information that it receives first, stores its ID based on the source address and the sequence number in a duplicate filter and thus recognizes the 2nd, redundant information. This redundant information is then discarded. If the 1st indication is missing, the 2nd indication with the same content comes via the other network. This redundancy avoids a switching procedure in the network and is thus interruption-free. The end device forwards no messages to the other network. Since the process is realized in the Ethernet layer (same MAC address), it is transparent and usable for all Ethernet payload protocols (IEC 61850, DNP, other TCP/IP based protocols). In addition, it is possible to use one of the 2 networks for the transmission of non-redundant messages.

There are 2 versions of PRP: PRP-0 and its successor PRP-1. Siemens implements PRP-1.

Parameterization

Comprehensive term for all setting work on the device. You can parameterize the protection functions with DIGSI 5 or sometimes also directly on the device.

Parameter set

The parameter set is the entirety of all parameters that can be set for a SIPROTEC device.

Participant address

A participant address consists of the name of the participant, the international dialing code, the local dialing code and the participant-specific telephone number.

PICS

Protocol Implementation Conformance Statement

PLC

See Programmable Logic Controller

PLC

Programmable Logic Controller

PROFIBUS

PROcess Feld BUS, German Process and Fieldbus standard (EN 50170). The standard specifies the functional, electrical and mechanical characteristics for a bit-serial fieldbus.

PROFIBUS Address

A unique PROFIBUS address must be assigned to each SIPROTEC device within a PROFIBUS network. A total of 254 PROFIBUS addresses per PROFIBUS network are available.

Profile_ID

A Profile_ID in combination with an API uniquely identifies the access and the behavior of an application.

PROFINET IO

PROFINET is an open Industrial Ethernet Standard from PROFIBUS for the automation.

Programmable Logic

The programmable logic is a function in Siemens devices or station controllers, enabling user-specific functionality in the form of a program. This logic component can be programmed by various methods: CFC (= Continuous Function Chart) is one of these. SFC (Sequential Function Chart) and ST (Structured Text) are others.

Programmable Logic Controller

Programmable logic controllers (PLC) are electronic controllers whose function is saved as a program in the control unit. The construction and wiring of the device do not therefore depend on the function of the control. The programmable logic controller has the structure of a computer; it consists of CPU with memory, installation/extension groups (for example, DI, AI, CO, CR), power supply (PS) and rack (with bus system). The peripherals and programming language are oriented towards the circumstances of the control system.

Programmable Logic Module

Modules are parts of the user program delimited by their function, structure and intended use.

Project

In terms of content, a project is the replication of a real energy supply system. In graphic terms, a project is represented as a number of objects which are incorporated in a hierarchical structure. Physically, a project consists of a series of directories and files containing project data.

Project tree

The Project tree is used to display a data structure. This data structure represents the content of the project and is created by a Generic Browser.

Protection communication

Protection communication includes all functionalities necessary for data exchange via the protection interface. Protection communication is created automatically during configuration of communication channels.

Protection Device

A protection device detects erroneous states in distribution networks, taking into account various criteria, such as error distance, error direction or fault direction, triggering a disconnection of the defective network section.

Protocol Implementation Conformance Statement

The performance properties of the system to be tested are summarized in the report on the conformity of implementation of a protocol (PICS = Protocol Implementation Conformance Statement).

PRP

Parallel Redundancy Protocol

Rapid Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP) is a standardized redundancy process with a short response time. In the Spanning Tree Protocol (STP protocol), structuring times in the multidigit second range apply in the case of a reorganization of the network structure. These times are reduced to several 100 milliseconds for RSTP.

Real Time

Real time

RedBox

Reduncancy box

The RedBox is used for the redundant connection of devices with only one interface to both the LAN A and the LAN B PRP network. The RedBox is a DAN (Double Attached Node) and operates as a proxy for the devices connected to it (VDANs). The RedBox has its own IP address in order to be able to configure, manage, and monitor it.

Relay Information by OMICRON

Files in RIO format can be used to exchange data between test systems from the OMICRON company and any other project-protection planning system. With DIGSI 5, you can export different settings from protection functions in RIO format, which the OMICRON test equipment 7VP15 can then continue to process. The relevant settings are described in the Test equipment manual.

RIO

Data format Relay Information by OMICRON

RSTP

Rapid Spanning Tree Protocol

SAN

Single Attached Node

A SAN is a non-redundant node in the PRP network. It is only connected with one port to one network (LAN A or LAN B). It can only communicate with nodes in the connected network. Via a RedBox, devices with only one connection can be redundantly connected to the 2 LAN A and LAN B networks. In order to obtain symmetrical LAN A and LAN B networks, Siemens recommends avoiding SANs and to connect the devices either via a RedBox or in a separate network without PRP support.

SBO

Select before operate

SC

See Single Command

SCD

See Substation Configuration Description

SCL

Substation Configuration Description Language

SED

System Exchange Description

SEQ

Data type Sequence

SEQ5

DIGSI 5 Test Sequences

Sequence of Events

Acronym: SOE. An ordered, time-stamped log of status changes at binary inputs (also referred to as state inputs). SOE is used to restore or analyze the performance, or an electrical power system itself, over a certain period of time.

Service Interface

Device interface for interfacing DIGSI 5 (for example, through a modem)

SICAM SAS

Substation Automation System – Modularly structured station control system, based on the substation controller SICAM SC and the SICAM WinCC operator control and monitoring system..

SICAM WinCC

The operator control and monitoring system SICAM WinCC graphically displays the state of your network. SICAM WinCC visualizes alarms and messages, archives the network data, provides the option of intervening manually in the process and manages the system rights of the individual employees.

SIM

Simulation data format for single/multiple devices

Simple Network Management Protocol

The Simple Network Management Protocol (SNMP) is an Internet standard protocol and serves for the administration of nodes in an IP network.

Simple Network Time Protocol

The Simple Network Time Protocol (SNTP) is a protocol for the synchronization of clocks via the Internet. With SNTP, client computers can synchronize their clocks via the Internet with a time server.

Simulation data format for single/multiple devices

You can export the simulation-related files of a SIPROTEC 5 device in the SIM format. This new functionality in DIGSI 5 provides the ability to export the simulation data and simulate all the devices in the DIGSI 5 project for test and commissioning needs. The simulation is achieved by importing the simulation file into a signal processing and automation system which will then simulate the device/devices with the process data as in a real-time system. This feature also ensures the testing of a device for various real-time system conditions.

Single Command

Single commands (SPC - Single Point Control) are process outputs which visualize 2 process states (for example, On/Off) at an output.

Single-line diagram

A single-line diagram (SLD) is a simplified electric overview of the switchgear. Only 1 phase is shown instead of all 3 phases of a line. Therefore, the diagram is called single-line.

Single-Line Editor

A Single-Line Editor contains a catalog of topological components to create a single-line diagram. The customer may use the single-line elements to configure the topological view of his substation.

Single-point indication

Single-point indications (SPS – Single point status) are process indications which visualize 2 process states (for example, On/Off) at an input.

SIPROTEC 5 device

This object type represents a real SIPROTEC device with all the contained setting values and process data.

SIPROTEC

The registered trademark SIPROTEC designates the product family of protection devices and fault recorders.

Slave device

A slave may only exchange data with a master after its has been requested to do so by this master. SIPROTEC devices work as slaves. A master computer controls a slave computer. A master computer can also control a peripheral device.

IEC 61850 data type: Single Point Control

SPS

IEC 61850 data type: Single point status

SSD

System Specification Description

ST

Structured Text file

Station Description

A station description is an IEC 61850-compliant file for data exchange between the system configurator and the IED configurator. The station description contains information on the network structure of a substation. The station description contains for example, information on the assignment of the devices to the primary equipment, as well as on the station-internal communication.

Structured Text file

You can import function charts (CFC) from DIGSI 4 in ST format. First, however, export your function charts from DIGSI 4.83 or higher.

Substation Configuration Description Language

A description language standardized in IEC 61850, SCL is based on XML. This description language allows all information relevant to an IEC 61850 substation to be documented consistently. This format is therefore suitable for exchanging IEC 61850-specific data between different applications, even if these come from different manufacturers. The described import checks are basically done for all SCL formats, not only for SCD imports.

System Exchange Description

Files in SED format can be used to exchange interface information between DIGSI 5 projects and thus between substations. To do this, the project extracts the data for the other projects from the file during import and writes its own data in the same file during export. The contents of an SED file are formulated in SCL.

System Specification Description

Files in SSD format contain the complete specification of a station automation system, including a single-line configuration of the station. The assignment of logical nodes from IEC 61850 to primary equipment can also be described in SSD files. This allows device requirements to be defined in the SSD file so that the devices can be used in the substation. The contents of an SED file are formulated in SCL.

TAI

Temps Atomique International - International Atomic Time

TC

Tap-position command – see Transformer Tap Position Command

TCP

Transmission Control Protocol

TEA-X

You can archive the data from individual SIPROTEC 5 devices or whole project in TEA-X format. This format is also suitable for data exchange between different applications, such as DIGSI 5 and Engineering Base (EB). The TEA-X format is based on XML.

Telephone book

Participant addresses for the modem connection are saved in this object type.

Time stamp

A time stamp is a value in a defined format. The time stamp assigns a time point to an event, for example, in a log file. Time stamps ensure that events can be found again.

Topological view

The Topological View is oriented to the objects of a system (for example, switch gear) and their relation to one another. The Topological View describes the structured layout of the system in hierarchical form. The Topological View does not assign the objects to the devices.

Transmission Control Protocol

The Transmission Control Protocol (TCP) is a transmission protocol for transport services in the Internet. TCP is based on IP and ensures connection of the participants during the data transmission. TCP ensures the correctness of the data and the correct sequence of the data packages.

Transparent Clock

The Precision Time Protocol knows different types of clocks: an ordinary clock (abbreviation: OC), a boundary clock (BC), and a transparent clock (TC). The transparent clock was added to the specification in 2008 and

improves the time-information transmission within a network by receiving PTP messages and transmitting them after modification (correction).

Tree view

The left area of the project window visualizes the names and symbols of all containers of a project in the form of a hierarchical tree structure. This area is referred to as a tree view.

Tunneling

Technology for connecting two networks via a third network, whereby the through traffic is completely isolated from the traffic of the third network.

UDP

User Datagram Protocol

Unbuffered Report Control Block

Unbuffered Report Control Block (URCB) is a form of report controlling. Internal events trigger the immediate sending of reports based on **best effort**. If no association exists or if the transport data flow is not fast enough, events can be lost.

URCB

Unbuffered Report Control Block

USART

Universal Synchronous/Asynchronous Receiver/Transmitter

User Datagram Protocol (UDP)

UDP is a protocol. The protocol is based on IP as TCP. In contrast to this, however, UDP works without a connection and does not have any safety mechanisms. The advantage of UDP in comparison to IP is the higher transmission rate.

UTC

Universal Time Coordinated

Vendor ID

Manufacturer-specific part of the device identification for PROFINET.

Virtual Device

A VD (virtual device) comprises all communication objects, as well as their properties and states, which a communication user can utilize in the form of services. A VD can be a physical device, a module of a device or a software module.

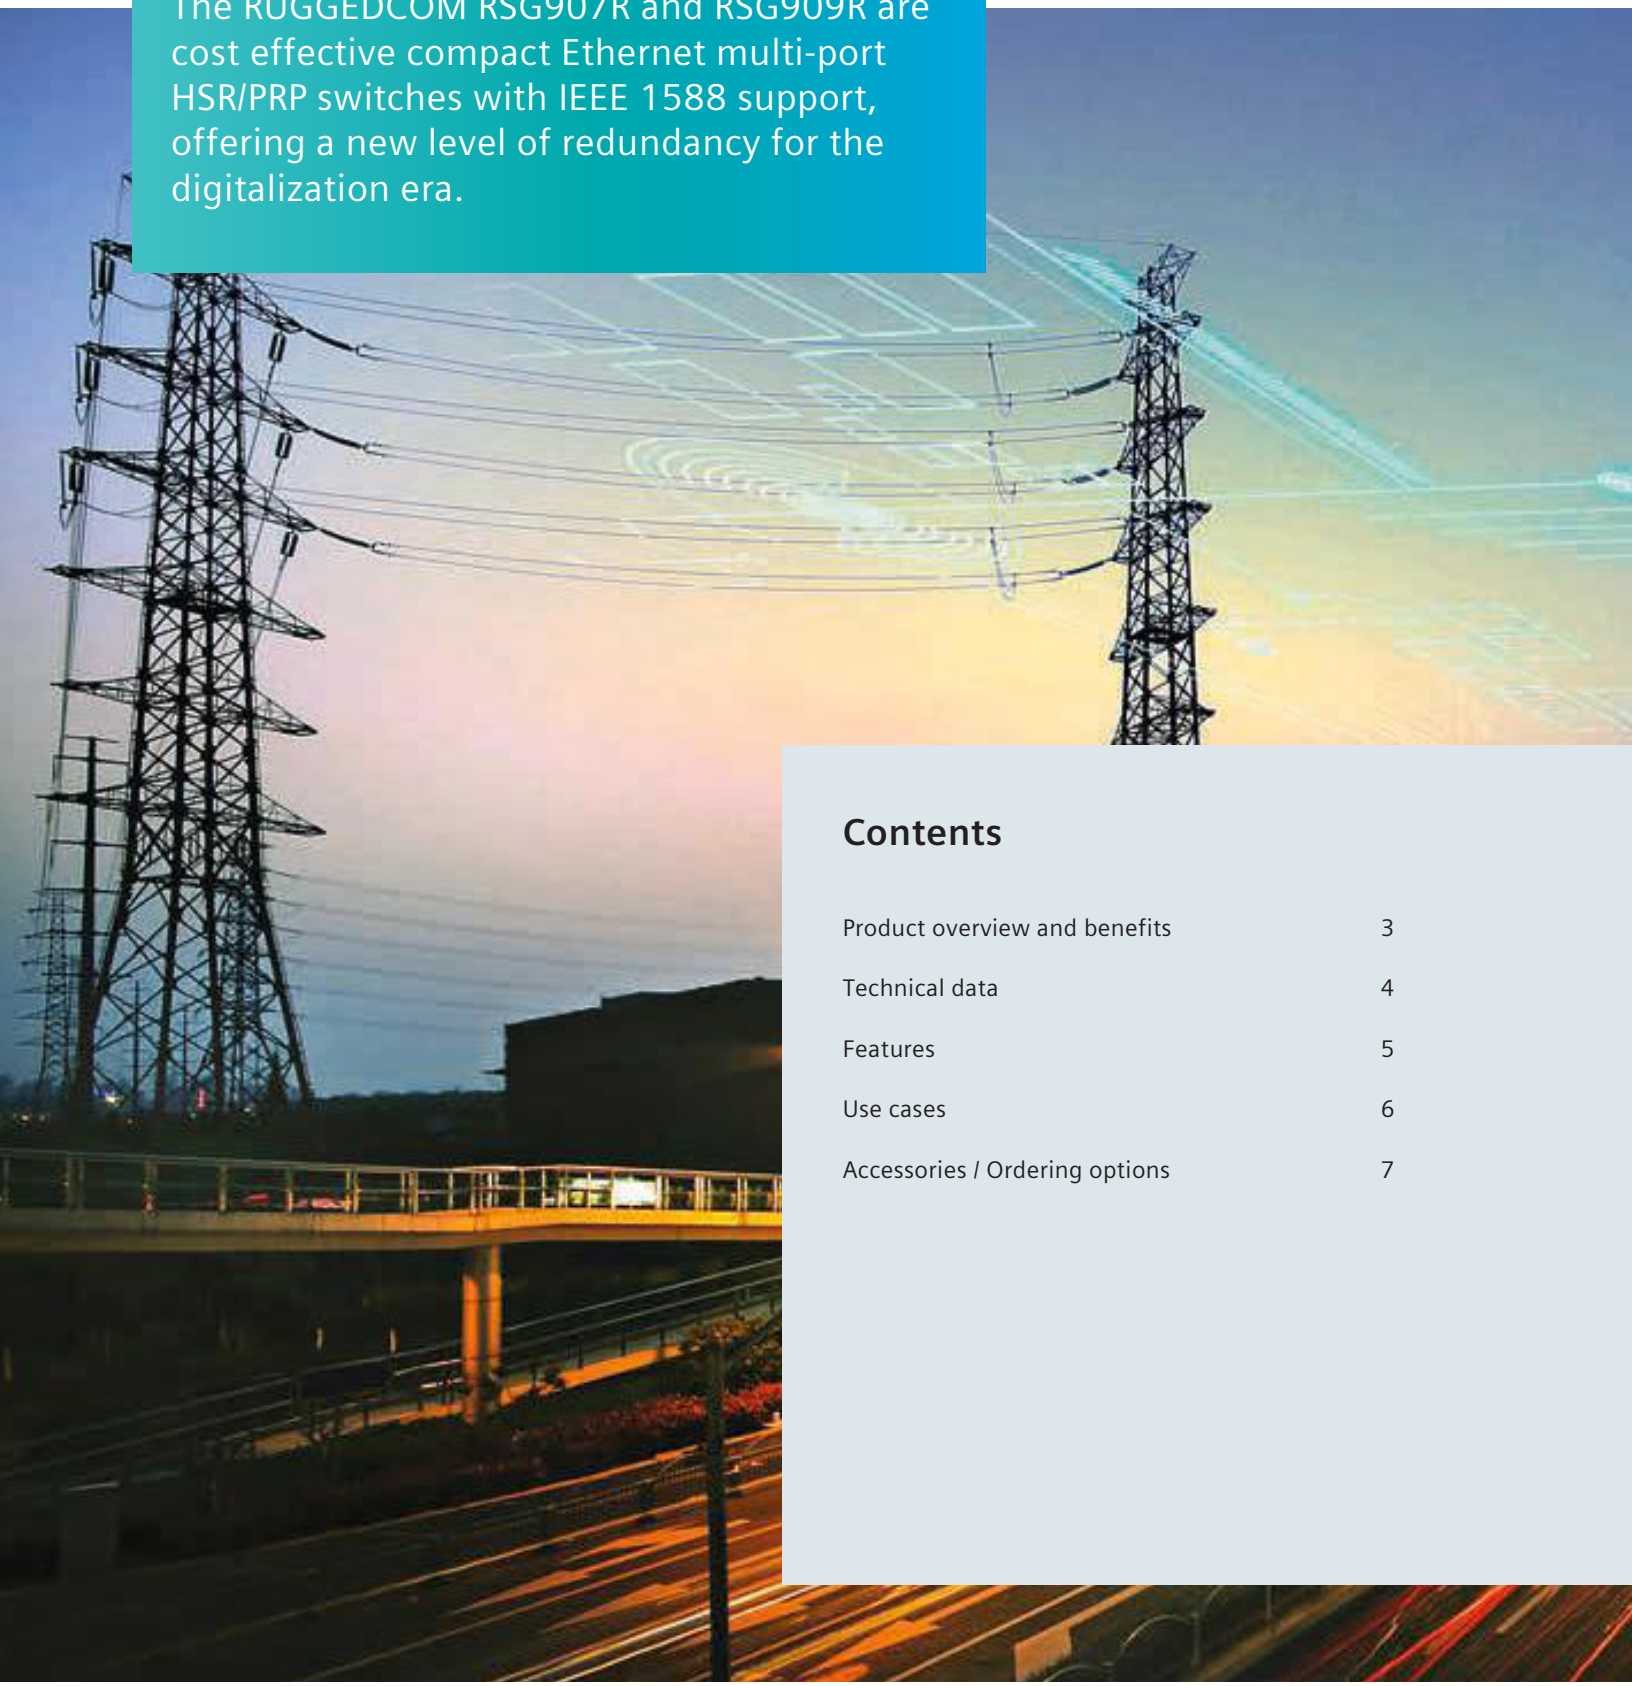
Rugged Communication

RUGGEDCOM RSG907R & RSG909R



Compact multi-port IEEE 1588 switches with HSR and PRP support

Brochure

Edition 02/2018

usa.siemens.com/ruggedcom

The RUGGEDCOM RSG907R and RSG909R are cost effective compact Ethernet multi-port HSR/PRP switches with IEEE 1588 support, offering a new level of redundancy for the digitalization era.

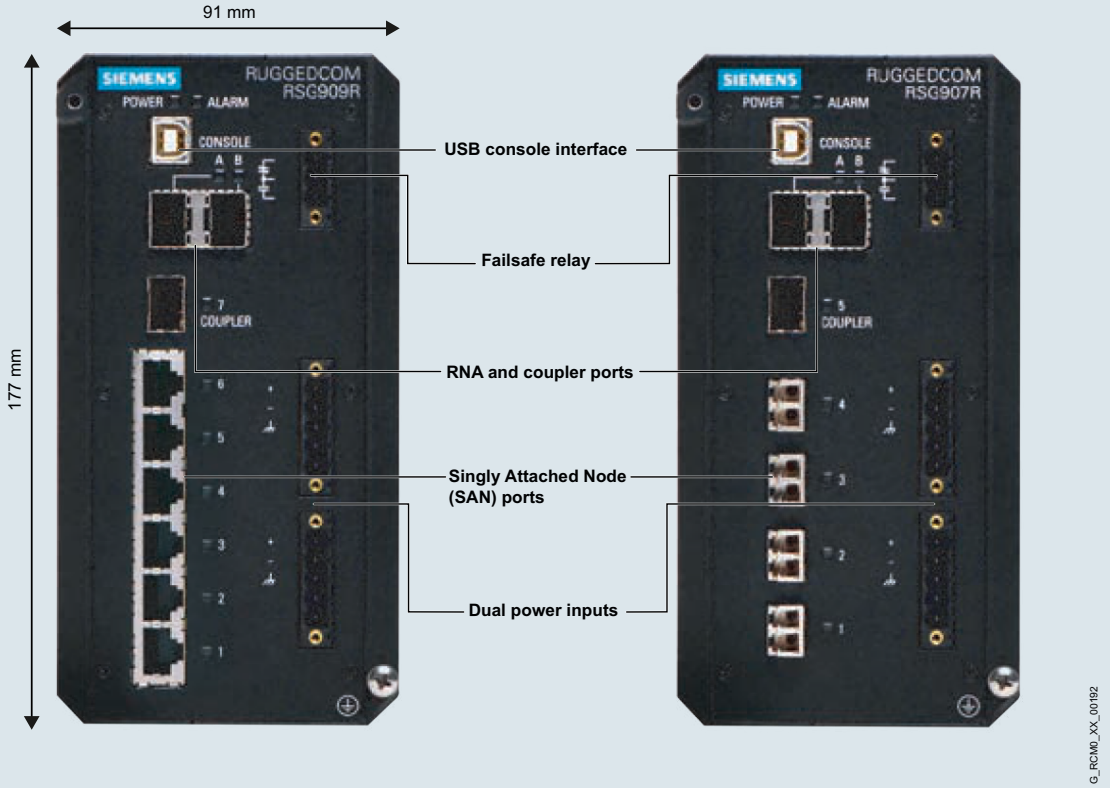
Product overview and benefits

The RUGGEDCOM RSG907R and RSG909R, two full Gigabit switches in a compact design, offering both HSR and PRP functionality to mitigate the risk of communication disruptions and downtime.
These rugged Gigabit switches are designed to operate in harsh environments with widely varying climatic and environmental conditions. Tested and certified to withstand extreme temperature, vibration and shock, the RUGGEDCOM RSG907R and RSG909R offer exceptional reliability for industrial applications such as electric utility substations, transportation systems and oil&gas.

The RUGGEDCOM RSG907R and RSG909R are ideal for applications that require high bandwidths and accommodate future network expansions. Three Redundant Network Access SFP ports providing ultimate flexibility in media and distance, with support for Gigabit bandwidth. The RSG907R connects up to 4 IEDs via 100BASE-FX fiber optics and RSG909R connects up to 6 IEDs via copper Ethernet on the Singly Attached Node ports.

Both products offer various network design options and cost savings through increased redundancy, reduced downtimes and high reliability.

HSR / PRP with Gigabit/s interfaces
Avoid revenue loss by mitigating the risk of communication disruptions and downtime with a redundant fault tolerant network supporting high bandwidth.



SFP RNA ports
SFP ports can be modified at any time allowing deployment flexibility for varying customer needs.

Power redundancy
Maintain continuous safe and reliable operations even during power failures, diminishing the risk of revenue and data loss.

Full fiber solution
Reduce failure rates due to increased immunity from electromagnetic phenomena.

IEEE 1588
The RSG907R and RSG909R enable the creation of a future proof network with support for IEEE 1588 time synchronisation.

Technical data

Technical data	RUGGEDCOM RSG907R	RUGGEDCOM RSG909R
Ethernet interfaces		
Ports	4 x 100BASE-FX + 3 x 1000 BASE-X (SFP)	6 x 10/100/1000BASE-T + 3 x 1000 BASE-X (SFP)
RNA uplinks (A / B) & coupler port	3 x 1 Gbit/s SFP ports	
Supported specifications	IEEE 1588	
Power supply characteristics		
Supported input voltage ranges	24/48 VDC (12 – 60 VDC) HI (85 – 264 VAC / 88 – 300 VDC)	
Mechanical specifications		
Dimensions (w x h x d) in mm	91 mm x 177 mm x 173 mm	
Weight	2.9 kg	
Mounting	DIN rail and panel mount	
Ambient conditions		
Operating temperature	-40° C to +85° C	
IP rating	IP40	
Other features		
IEEE 1588	Transparent Clock	

Features

Software
The RUGGEDCOM RSG907R and RSG909R both run on Rugged Operating System (ROS®) and deliver high performance switching.

ROS® supports the standard network technologies, such as Rapid Spanning Tree Protocol (RSTP), Multiple Spanning Tree Protocol (MSTP), Remote Monitoring (RMON), Simple Network Management Protocol (SNMP) and others, including proprietary protocol enhancements such as Siemens eRSTP (enhanced Rapid Spanning Tree Protocol) and Fast Root Failover (FRF).

Software features
- Quality of service (802.1p) for traffic prioritization
- NTP time synchronization (client and server)
- Smart power management for PoE interfaces
- Port rate and Broadcast Storm Limiting
- Port configuration, status, statistics, mirroring
- Simple Management interface through WebUI and console interface
- Single file configuration ensures easy installation and configuration control

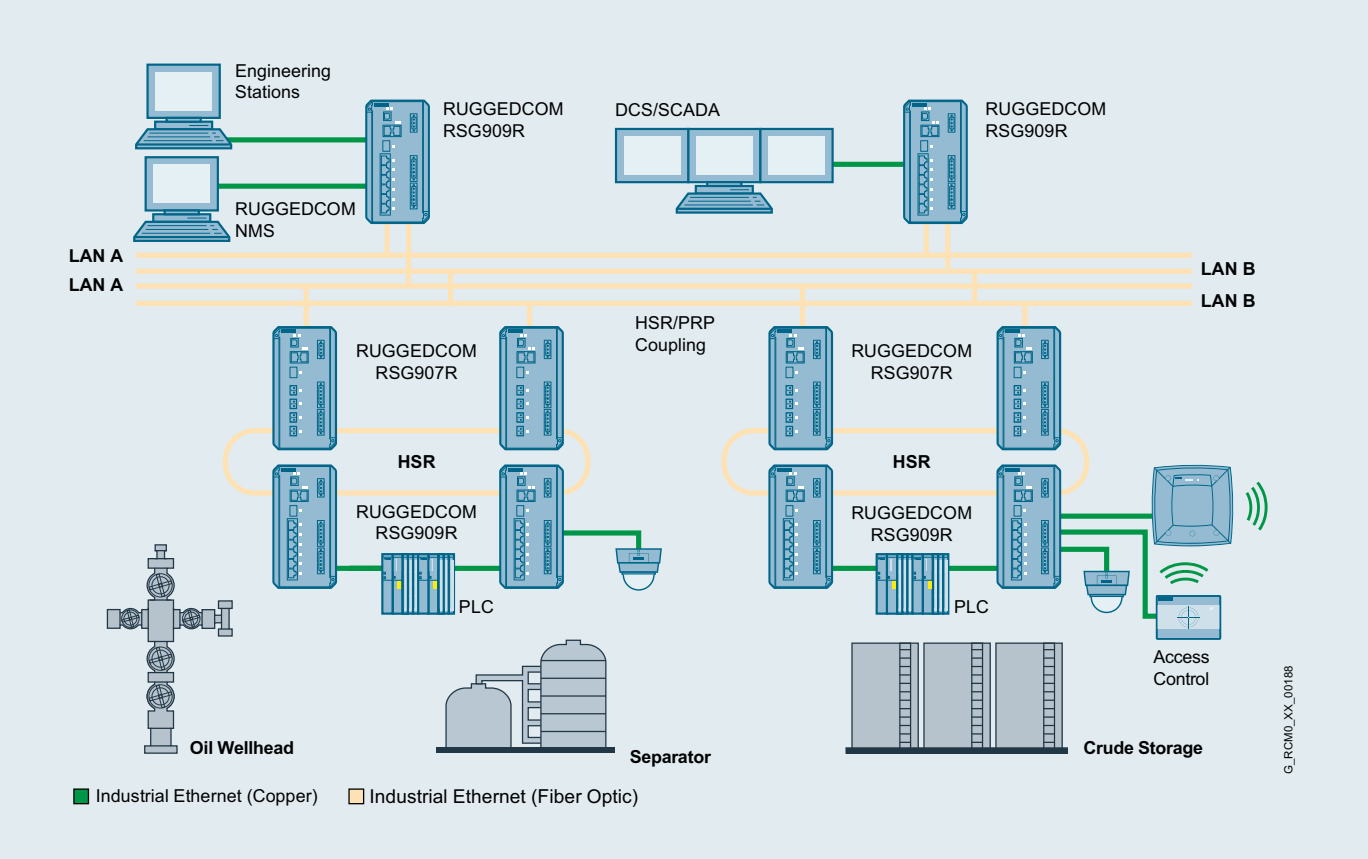
HSR/PRP redundancy
The RUGGEDCOM RSG907R and RSG909R are multi-port Ethernet switches combined with an HSR/PRP redundancy box (RedBox) in a convenient compact design. IEEE 1588 function support enables the RUGGEDCOM RSG909R and the RSG907R to combine precision timing and network communication data on one network, reducing maintenance costs:
- Multi-port redundancy box allows for interconnection of up to 6 non-PRP or non-HSR end devices
- PRP/HSR coupling functionality to cover all types of redundant network topologies

Cyber security
Cyber security is an important issue in many industries where advanced automation and communications networks play a crucial role in mission critical applications and where high reliability is of paramount importance. Key RUGGEDCOM RSG907R and RSG909R features that address security issues at the local area network level include:

- Passwords – support for multiple access levels with separate credentials for each level
- SSH / SSL – extends capability of password protection to add encryption of passwords and data as they cross the network
- Enable / disable ports – capability to disable ports so unauthorized devices can't connect to unused ports
- SNMPv3 – encrypted authentication and access security
- HTTPS – for secure access to the web interface
- 802.1x – to ensure only permitted devices can connect to the device
- MAC address authentication – control access to devices that do not support RADIUS

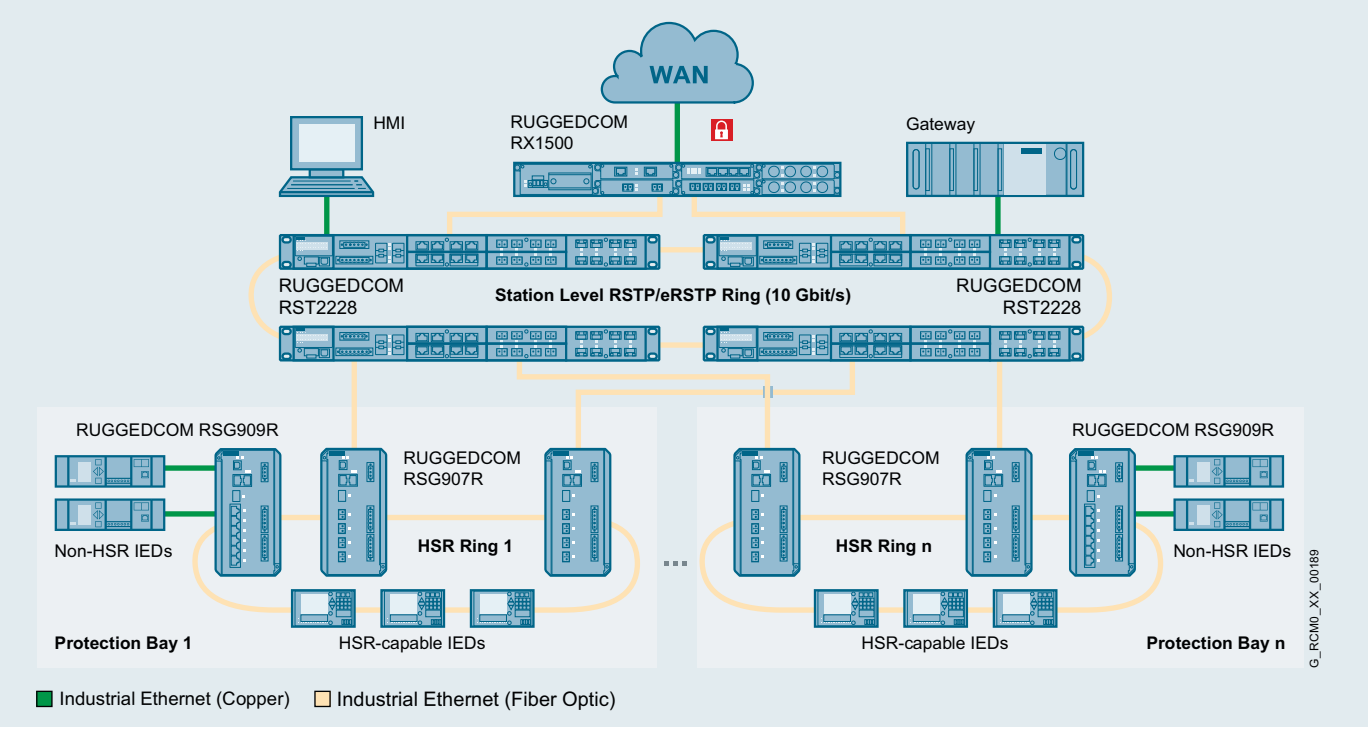
Hardware
The RUGGEDCOM RSG907R and RSG909R have been specifically designed and certified for substation and distribution automation applications within electric power industry.

Power Supply
- Integrated power supply with redundant inputs
- Universal high voltage range: 88 – 300 VDC or 85 – 264 VAC
- Universal low voltage power supply range: 12 – 60 VDC



Configuration interface
The RUGGEDCOM RSG907R and RSG909R are equipped with a USB interface which enables easy in-field configuration and upgrading.

Harsh environments
As with all RUGGEDCOM products, Highly Accelerated Life Testing (HALT) has been used in the early stages of product development to detect any design or performance issues.



- Temperature: -40° C to +85° C (fanless)
- Safety: CSA/UL 60950
- Vibration: IEC 60255-21-1, Class 2
- Shock: IEC 60255-21-2, Class 2
- Humidity: IEC 60068-2-30, up to 95% relative humidity

Certifications
- IEC 61000-6-2 (industrial environments)
- IEC 61850-3 (electric substations)
- IEEE 1613 (electric substations)

Use cases

Multi-port Redundancy Box (Redbox) allowing for interconnection of up to 6 non-PRP or non-HSR end devices.

RSG907R/RSG909R switches terminating each HSR ring can be directly connected to RSTP network via their coupling ports.

For that reason, we reserve the right to modify, at any time, the technology and product specifications contained herein.

Security information

Siemens provides products and solutions with industrial security functions that support the secure operation of plants, systems, machines and networks.

In order to protect plants, systems, machines and networks against cyber threats, it is necessary to implement – and continuously maintain – a holistic, state-of-the-art industrial security concept. Siemens' products and solutions only form one element of such a concept.

Customer is responsible to prevent unauthorized access to its plants, systems, machines and networks. Systems, machines and components should only be connected to the enterprise network or the internet if and to the extent necessary and with appropriate security measures (e.g. use of firewalls and network segmentation) in place.

Additionally, Siemens' guidance on appropriate security measures should be taken into account. For more information about industrial security, please visit:
siemens.com/industrialsecurity

Siemens' products and solutions undergo continuous development to make them more secure. Siemens strongly recommends to apply product updates as soon as available and to always use the latest product versions. Use of product versions that are no longer supported, and failure to apply latest updates may increase customer's exposure to cyber threats.

To stay informed about product updates, subscribe to the Siemens Industrial Security RSS Feed under:
siemens.com/industrialsecurity

The information provided in this brochure contains descriptions or characteristics of performance which in case of actual use do not always apply as described or which may change as a result of further development of the products. An obligation to provide the respective characteristics shall only exist if expressly agreed in the terms of contract. Availability and technical specifications are subject to change without notice. All product designations may be trademarks or product names of Siemens AG or supplier companies whose use by third parties for their own purposes could violate the rights of the owners.
