With the **Regulate with T2 at start** parameter, you can activate a shorter time than T1. This can be necessary for controlling a voltage recovery or after switching on a transformer. If voltage was not present beforehand, this setting controls with the shorter time T2 when starting the control action. You can switch this functionality on or off. If you always want to use the time T2 for control, you must set the *Block T1* controllable to ***On***.

For the three-winding transformer, the address of the parameter **Regulate with T2 at start** is _:15601:163 and it is _:16351:163 for the grid coupling transformer.

Parameter: Set point mode active

- Default setting **(_:14011:160) Set point mode active** = ***on***

With the **Set point mode active** = ***on*** parameter, you send a target voltage to the voltage controller via a communication network. The voltage controller uses the specified voltage value as the target voltage and the specified bandwidth instead of the parameterized bandwidth. If the voltage controller does not receive any valid voltage values or bandwidth, it uses the original target voltage or bandwidth respectively. You can enable or disable the parameter.

For the three-winding transformer, the address of the parameter **Set point mode active** is _:15601:171 and it is _:16351:171 for the grid coupling transformer.

7.9.4.4 Dynamic Voltage Control (DVC)

Parameter: DVC mode

- Default setting **(_:14011:177) DVC mode** = ***off***

With the parameter **DVC mode**, you can adapt the voltage target value of the voltage controller via a characteristic curve depending on the power direction. You can activate or deactivate the dynamic voltage control with the settings ***on*** (activate) or ***off*** (deactivate).

Parameter: Active power max

- Default setting **(_:14011:176) Active power max** = ***30 %***

With the parameter **Active power max**, you define the maximum value of the active power in percent.

Parameter: Active power min

- Default setting **(_:14011:175) Active power min** = ***-20 %***

With the parameter **Active power min**, you define the minimum value of the active power in percent.

Parameter: Target Voltage max

- Default setting **(_:14011:174) Target Voltage max** = ***114 V***

With the parameter **Target Voltage max**, you define the maximum value of the target voltage.

Parameter: Target Voltage min

- Default setting **(_:14011:173) Target Voltage min** = ***106 V***

With the parameter **Target Voltage min**, you define the minimum value of the target voltage.

Only Three-Winding Transformer:

Parameter: DVC mode

- Default setting **(_:15601:178) DVC mode** = ***off***

With the parameter **DVC mode**, you can adapt the voltage target value of the voltage controller via a characteristic curve depending on the power direction. You can activate or deactivate the dynamic voltage control with the settings ***on*** (activate) or ***off*** (deactivate).

Parameter: Active power max w1

- Default setting **(_:15601:185) Active power max w1** = ***30 %***

Parameter: Active power min w1

- Default setting **(_:15601:183) Active power min w1** = ***-20 %***

Parameter: Active power max w2

- Default setting **(_:15601:186) Active power max w2** = ***30 %***

Parameter: Active power min w2

- Default setting **(_:15601:184) Active power min w2** = ***-20 %***

Parameter: Target Voltage min w1

- Default setting **(_:15601:179) Target Voltage min w1** = ***106 V***

Parameter: Target Voltage max w1

- Default setting **(_:15601:181) Target Voltage max w1** = ***114 V***

Parameter: Target Voltage min w2

- Default setting **(_:15601:180) Target Voltage min w2** = ***106 V***

Parameter: Target Voltage max w2

- Default setting **(_:15601:182) Target Voltage max w2** = ***114 V***

Only Grid Coupling Transformer:

Parameter: DVC mode

- Default setting **(_:16351:178) DVC mode** = ***off***

With the parameter **DVC mode**, you can adapt the voltage target value of the voltage controller via a characteristic curve depending on the power direction. You can activate or deactivate the dynamic voltage control with the settings ***on*** (activate) or ***off*** (deactivate).

Parameter: Active power max w1

- Default setting **(_:16351:185) Active power max w1** = ***30 %***

Parameter: Active power min w1

- Default setting **(_:16351:183) Active power min w1** = ***-20 %***

Parameter: Active power max w2

- Default setting **(_:16351:186) Active power max w2** = ***30 %***

Parameter: Active power min w2

- Default setting **(_:16351:184) Active power min w2** = ***-20 %***

Parameter: Target Voltage min w1

- Default setting **(_:16351:179) Target Voltage min w1** = ***106 V***

Parameter: Target Voltage max w1

- Default setting **(_:16351:181) Target Voltage max w1** = ***114 V***

Parameter: Target Voltage min w2

- Default setting **(_:16351:180) Target Voltage min w2** = ***106 V***

Parameter: Target Voltage max w2

- Default setting **(_:16351:182) Target Voltage max w2** = ***114 V***

7.9.4.5 Line Compensation

Parameter: Line drop compensation

- Default setting **(_:14011:125) Line drop compensation** = ***off***

You can use the **Line drop compensation** parameter to select the correction procedure of the load-dependent line voltage drop. There are 2 procedures available for selection: ***LDC-Z*** and ***LDC-XandR***. The setting of the parameter **Set point mode active** is also taken into account here.

For setting the parameter **Line drop compensation** = ***LDC-Z***, consider the following parameter:

Parameter: Target voltage rising

- Default setting **(_:14011:126) Target voltage rising** = ***4.0 %***

With the **Target voltage rising** parameter, you set the voltage drop across the line. The value represents the voltage rising in % of the **Target voltage 1** that occurs at rated load. Only the magnitude of the current is considered. The set value is added to **Target voltage 1**.

Target voltage rising [%] = ΔV_{load} [%], if I_{load} = 100 %

$$\text{Target voltage rising}\,[\%] = \left(V_{SetComp}[\%] - V_{Set}[\%]\right) \cdot \frac{100\ \%}{I_{load}[\%]}$$

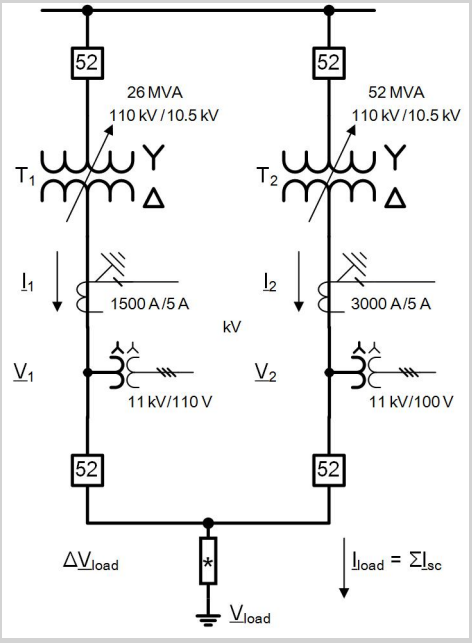
[foschlst-211013, 2, en_US]

where:

$V_{SetComp}$	Target voltage at the end of the line
V_{Set}	Target voltage
I_{load}	Load current in %

With the following equation, you can determine the percentage of the primary load current of the line from the rated current of the transformer k (k = 1, 2, ..., 8).

$$I_{load\,k}\ (\%) = \frac{I_{load}}{I_{rated\,k}} \cdot 100\ \%$$



[fo_ibs_load_cur_perc, 1, en_US]

where:

I_{load}	Primary load current
I_{rated}	Rated current of the transformer

Example

Application example of the LDC-Z line compensation for the voltage control of 2 transformers connected in parallel.

[dw_target_voltage_2exam, 2, en_US]

Figure 7-156 LDC-Z Line Compensation with 2 Parallel Transformers

In the example, a load current of I_{load} = 1430 A results in a voltage drop of V_{load} = 500 V.

Value	Transformer T_1	Transformer T_2
	$I_{load\ T1}\ (\%) = \frac{1430\ A}{1430\ A} 100\ \%$	$I_{load\ T2}\ (\%) = \frac{1430\ A}{2859\ A} 100\ \%$
I_{load}(%)	100 %	50 %
	$\Delta V_{load\ T1}\ (\%) = \frac{500\ V}{11\,000\ V} \cdot \frac{100\ \%}{100\ \%}$	$\Delta V_{load\ T2}\ (\%) = \frac{500\ V}{11\,000\ V} \cdot \frac{100\ \%}{50\ \%}$
Target voltage rising ΔV_{load}(%)	4.8 %	9.6 %

NOTE

Make sure that you configure the parameter **Max load current** on the voltage controller on the transformer T_1 to 200 %, as this summation load current is used for the line compensation.

Parameter: LDC is calculated

- Default setting **(_:14011:172) LDC is calculated** = ***on target voltage***

For the parameter **LDC is calculated**, you can select between the settings ***on target voltage*** and ***on measured voltage***. The voltage compensation is added to the target voltage with the setting ***on target voltage***, and to the measured voltage with the setting ***on measured voltage***.

Parameter: Max load current

- Default setting **(_:14011:127) Max load current** = ***100.0 %***

With the setting of the parameter **Max load current**, you can prevent the voltage at the transformer from becoming too high in the event of extraordinarily high load current. If the load current exceeds the set value, no additional load-current compensation is calculated.

For setting the parameter **Line drop compensation** = ***LDC-XandR***, consider the following parameters:

Parameter: R line

- Default setting **(_:14011:153) R line** = ***0.00 Ω***

With the **R line** parameter, you to set the ohmic resistance of the line.

Parameter: X line

- Default setting **(_:14011:154) X line** = ***0.00 Ω***

With the **X line** parameter, you set the reactance for the line to be protected.

In order to determine the voltage drop by the line, entering the parameters **R line** and **X line** is necessary for the procedure **Line drop compensation** = ***LDC-XandR***. If the primary values are known and you would like to set the secondary values, use the following formula for the calculation:

$$X_{sec} = \frac{Ratio_I}{Ratio_V} X_{prim}$$

[fo-I-V-Ratio-250214, 1, en_US]

As an example, calculate X_{sec} with the following parameters:

Current transformer ratio	: 1000 A/1 A
Voltage transformer ratio	: 380 kV/0.1 kV
X_{prim}	: 21 Ω

Therefore, the result for X_{sec} is:

$$X_{sec} = \frac{1000\,A/1\,A}{380\,kV/0.1\,kV} 21\,\Omega = 5.53\,\Omega$$

[fo-I-V-Ratio_Value-250214, 1, en_US]

If you are implementing a parallel control with the X and R compensation, then the X value is negative and considers the voltage rising from the busbar to the transformer.

Additional Parameters for the Three-Winding Transformer and for the Grid Coupling Transformer

Parameter: Line drop compensation

- Default setting **(_:125) Line drop compensation** = ***off***

For setting the parameter **Line drop compensation** = ***LDC-Z***, consider the following parameters:

Parameter: Target voltage rising w1

- Default setting **(_:126) Target voltage rising w1** = ***4.0%***

Parameter: Target voltage rising w2

- Default setting **(_:147) Target voltage rising w2** = ***4.0%***

Parameter: Max load current

- Default setting **(_:127) Max load current** = ***100.0 %***

For setting the parameter **Line drop compensation** = ***LDC-XandR***, consider the following parameters:

Parameter: R line w1

- Default setting **(_:153) R line w1** = ***0.0 Ω***

Parameter: R line w2

- Default setting **(_:155) R line w2** = ***0.0 Ω***

Parameter: X line w1

- Default setting **(_:154) X line w1** = ***0.0 Ω***

Parameter: X line w2

- Default setting **(_:156) X line w2** = ***0.0 Ω***

7.9.4.6 Limiting Values

Parameter: Lower tap-position limit

- Default setting **(_:14011:102) Lower tap-position limit** = ***1***

Parameter: Higher tap-position limit

- Default setting **(_:14011:103) Higher tap-position limit** = ***1***

With the parameters **Lower tap-position limit** and **Higher tap-position limit**, you can restrict the taps available in automatic operation. For example, using the parameter **Higher tap-position limit**, changes to higher taps to excessive ratios that would result in overvoltages in the event of a sudden loss of load are blocked.

Parameter: Vmin limiting

- Default setting **(_:14011:128) Vmin limiting** = ***on***

Parameter: Vmin threshold

- Default setting **(_:14011:129) Vmin threshold** = ***105.000 V***

Parameter: Vmin time delay

- Default setting **(_:14011:130) Vmin time delay** = ***10 s***

Parameter: Vmax limiting

- Default setting **(_:14011:131) Vmax limiting** = ***on***

Parameter: Vmax threshold

- Default setting **(_:14011:132) Vmax threshold** = ***115.000 V***

Parameter: Vmax time delay

- Default setting **(_:14011:133) Vmax time delay** = ***10 s***

The voltage limits are necessary only for special control situations. The overvoltage limit prevents a change to a higher tap by the voltage controller if the limiting value **Vmax threshold** is exceeded. The undervoltage limit prevents a change to a lower tap by the voltage controller if the voltage drops below the limiting value **Vmin threshold**.

Additional Parameters for the Three-Winding Transformer and for the Grid Coupling Transformer
Parameter: Vmin threshold w1 • Default setting **(_:129) Vmin threshold w1** = ***105.000 V***
Parameter: Vmin threshold w2 • Default setting **(_:148) Vmin threshold w2** = ***105.000 V***
Parameter: Vmax threshold w1 • Default setting **(_:132) Vmax threshold w1** = ***115.000 V***
Parameter: Vmax threshold w2 • Default setting **(_:149) Vmax threshold w2** = ***115.000 V***

7.9.4.7 Blockings

Parameter: Blocking behavior

- Default setting **(_:14011:134) Blocking behavior** = ***Auto-Manual***

If the corresponding voltage limits are exceeded in either direction, the blockings prevent a change to a lower or higher tap. On the one hand, this prevents excessive wear of the contacts of the tap changer and, on the other hand, it prevents a system incident. With the parameter **Blocking behavior**, you set whether these blockings are effective only in automatic operation or in both automatic and manual operation.

Parameter: V< Blocking

- Default setting **(_:14011:135) V< Blocking** = ***on***

Parameter: V< Threshold

- Default setting **(_:14011:136) V< Threshold** = ***90.000 V***

Parameter: V< Time delay

- Default setting **(_:14011:137) V< Time delay** = ***0 s***

Parameter: I> Blocking

- Default setting **(_:14011:138) I> Blocking** = ***on***

Parameter: I> Threshold

- Default setting **(_:14011:139) I> Threshold** = ***150 %***

Parameter: I> Time delay

- Default setting **(_:14011:140) I> Time delay** = ***0 s***

If the load current exceeds the threshold value **I> Threshold** for the time **I> Time delay**, the overcurrent blocking prevents changing to a higher or lower tap. Set the threshold value **I> Threshold** in % in relation to the rated current. To do this, set the parameter **I reference** for % values.

Parameter: I< Blocking

- Default setting **(_:14011:141) I< Blocking** = ***off***

Parameter: I< Threshold

- Default setting **(_:14011:142) I< Threshold** = ***10 %***

Parameter: I< Time delay

- Default setting **(_:14011:143) I< Time delay** = ***10 s***

If the load current drops below the threshold value **I< Threshold** for the time **I< Time delay**, the undercurrent blocking prevents changing to a higher or lower tap. Set the threshold value **I< Threshold** in % in relation to the rated current. To do this, set the parameter **I reference** for % values.

Additional Pararmeters for Three-Winding Transformers and for Grid Coupling Transformers
Parameter: V< Threshold w1
• Default setting **(_:136) V< Threshold w1** = ***90.000 V***
Parameter: V< Threshold w2
• Default setting **(_:150) V< Threshold w2** = ***90.000 V***

You can find the parameter and information lists in chapter *7.9.5 Settings*.

7.9.4.8 Parallel Control

Parameter: Parallel mode

- Default setting **(_:14011:161) Parallel mode** = ***No mode***

With the **Parallel mode** parameter, you can switch the voltage controller into one of the following modes:

No mode

Master

Follower

Circulat. react current

Parameter: Parallel-transfomer id

- Default setting **(_:14011:168) Parallel-transfomer id** = ***1***

The **Parallel-transfomer id** parameter indicates the ID of the transformer.

With this parameter, you identify individual transformers in a parallel group. Transformers belonging to the same parallel group must be uniquely identifiable based on the ID. The unique identification applies to all transformers which communicate via GOOSE.

Parameter: Parallel mode changeable

- Default setting **(_:14011:164) Parallel mode changeable** = ***by setting***

With the **Parallel mode changeable** parameter, you influence the parallel control ***by setting*** or via the setting ***controllable***.

Parameter: Force master changeable

- Default setting **(_:14011:165) Force master changeable** = ***by setting***

With the **Force master changeable** parameter, you determine ***by setting*** or via the setting ***controllable*** which device is the Master in the parallel operation. In a group of transformers working in parallel, only one device can be the Master. The presence of a Master is monitored.

Parameter: Maximal tap difference

- Default setting **(_:14011:166) Maximal tap difference** = ***2***

With the **Maximal tap difference** parameter, you set the maximum permissible difference of the tap-changer positions between the transformers of a group.

Parameter: Reactive I control factor

- Default setting **(_:14011:169) Reactive I control factor** = ***1.00***

The voltage deviation between the transformers is influenced with the parameter **Reactive I control factor**. This means that a deviation from one stage exceeds the bandwidth of the voltage controller. This allows the control deviation D_{CRC}, initiated by the circulating reactive current, to be adjusted individually for each parallel operation.

Parameter: VT supervision

- Default setting **(_:14011:146) VT supervision** = ***on***

With the **VT supervision** parameter, you switch the voltage supervision ***on*** or ***off***. The average voltage of all voltage controllers is compared with the measured voltage as a criterion and is blocked if it exceeds the setting value. Siemens recommends setting the **VT supervision** parameter to ***on*** to minimize the circulating reactive current.

NOTE

In the Master-Follower Method, you can use this parameter only if the follower is also measuring the voltage.

Parameter: VT supervision threshold

- Default setting **(_:14011:147) VT supervision threshold** = ***10.0 %***

With the **VT supervision threshold** parameter, you set the threshold value for the voltage supervision.

Parameter: VT supervision time delay

- Default setting **(_:14011:148) VT supervision time delay** = ***10 s***

With the **VT supervision time delay** parameter, you set the time for which exceeding the voltage supervision threshold does not lead to a blocking.

Parameter: Circul. current blocking

- Default setting **(_:14011:149) Circul. current blocking** = ***on***

With the **Circul. current blocking** parameter, you switch the supervision of the circulating reactive current off or on.

Parameter: Circul. current threshold

- Default setting **(_:14011:150) Circul. current threshold** = ***50 %***

With the **Circul. current threshold** parameter, you set the level of the circulating reactive current at which the supervision should pick up.

Parameter: Circul. current time delay

- Default setting **(_:14011:151) Circul. current time delay** = ***60 s***

With the **Circul. current time delay** parameter, you set the time for which exceeding the threshold value of the circulating reactive current supervision does not lead to a blocking.

7.9.5 Settings

Two-Winding Transformer and Parallel Control

Addr.	Parameter	C	Setting Options	Default Setting
Ref. for %-values				
_:2311:101	General:Rated current		0.20 A to 100000.00 A	1000.00 A
_:2311:102	General:Rated voltage		0.10 kV to 1200.00 kV	400.00 kV

7.10 Point-on-Wave Switching

The **Point-on-wave switching** function in SIPROTEC 5 is used to reduce increased electrodynamic and dielectric loads which are caused by non-optimal switching of circuit breakers in the network. In extreme cases, these loads reduce the reliability and life of the equipment installed in the network or lead to unnecessary opening operations by the protection device. To avoid effects such as overvoltages and inrush currents, this function can control the closing and opening instants of circuit breakers.

Table 7-34 Avoided Effects in Different Load Types

Load Type	Switching Operation	Avoided Effect
Inductive load:	Opening	Restriking, overvoltage
Transformer, reactance coil	Closing	Inrush current
Capacitive load:	Opening	Restriking, overvoltage
Capacitor bank, unloaded lines/cables, filter	Closing	Overvoltage, inrush current

The **Point-on-wave switching** function is always started via a control command, either from the device internal control or from an external control function. Protection functions generally directly trip the circuit breaker and have no interaction with the **Point-on-wave switching** function.

You can find more information about this function in the *Point-on-Wave Switching Function Manual*.

8 Supervision Functions

8.1	Overview	2040
8.2	Resource-Consumption Supervision	2041
8.3	Supervision of the Secondary System	2046
8.4	Supervision of the Device Hardware	2106
8.5	Supervision of Device Firmware	2111
8.6	Supervision of Hardware Configuration	2112
8.7	Supervision of Communication Connections	2113
8.8	Error Responses and Corrective Measures	2114
8.9	Group Indications	2123

8.1 Overview

SIPROTEC 5 devices are equipped with an extensive and integrated supervision concept. Continuous supervision:

- Ensures the availability of the technology used
- Avoids subfunction and overfunction of the device
- Protects persons and primary technical devices
- Offers effective assistance during commissioning and testing

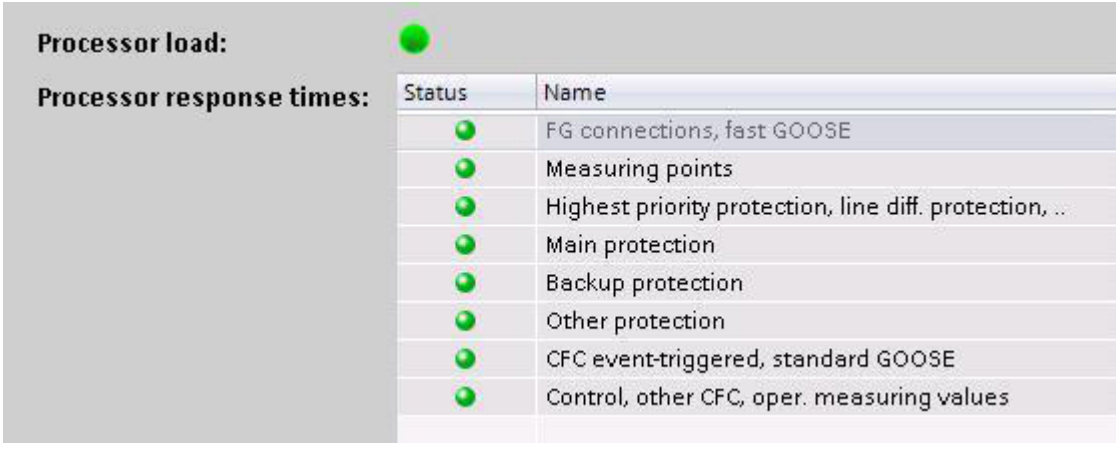
The following areas are monitored:

- Supervision the resource consumption of the application
- Supervision of the secondary system, including the external auxiliary power supply
- Supervision of device hardware
- Supervision of device firmware
- Supervision of hardware configuration
- Supervision of communication connections

When the supervision functions pick up, that will be displayed and also indicated. Error responses are defined for the device. The error responses are grouped in defect severities.

The supervision functions work selectively. When the supervision functions pick up - as far as possible - only the affected parts of the hardware and firmware are blocked. If this is not possible, the device goes out of operation into a secure state (fallback mode). In addition to safety, this warrants a high degree of availability.

8.2 Resource-Consumption Supervision



8.2.1 Load Model

SIPROTEC 5devices are freely configurable. A load model is integrated in DIGSI 5. The load model prevents you from overloading the device with an excessively large application.

The load model shows the device utilization and the response times for device functions. If it determines that an application created is likely to overload the device, DIGSI prevents the application from being loaded into the device.

In this rare case, you must then reduce the application in order to be able to load it into the device.

The load model can be found in the DIGSI 5 project tree under **Name of the device** → **Device information**. In the operating range, select the **Resource consumption** setting sheet. The following figure shows an example of the view of the load model in DIGSI 5:

[sc_lastmo_01, 1, en_US]

Figure 8-1 Visualization of the Load Model in DIGSI

A green total display for the processor response time indicates that the device is not overloaded by the present application. On the other hand, if you see a red exclamation mark, the planned application is overloading the device.

The list below the total display shows the individual functional areas. These areas combine functions with the same real-time requirements. A green display in front of an area (see *Figure 8-1*) indicates that the response times of the functions grouped in this area can be maintained. A red exclamation mark indicates that functions may have longer response times than specified in the Technical data for the device. In such a case, loading of the application into the device is blocked.

The following table provides an overview of the functional areas and the most important influencing quantities on device utilization:

Functional Area	Short Description	Change in Load
CFC event-triggered, fast	CFC charts that must be processed especially fast (for example, to invoke interlockings between protection functions)	Adding or removing CFC charts in the fast event-triggered process range • Create CFC chart • Delete CFC chart • Change the process range in the properties of the CFC chart Add to or remove from CFC charts in the fast event-triggered process area
Measuring points	Provision of measured values for protection, control, and measurement functions	Adding or removing • Measuring points (in the Measuring-points routing Editor) • Function groups that provide measured-value preprocessing for insertable functions (for example, Line function group and Circuit-breaker function group)
• FG connections • Fast GOOSE	• Interaction between individual function groups, for example, between the Line function group and the Circuit-breaker function group • Fast GOOSE communication	Adding or removing • Protection functions and their stages • Circuit-breaker function groups • Fast GOOSE connections
Protection Communication	Signal transmission via protection communication and differential protection communication	Adding or removing • Communication modules for the protection interface (in the DIGSI 5 Hardware and logs view) • Routings to the protection interface • Functions of theTransformer differential protection
Transformer Differential Protection	Transformer Differential Protection	Adding or removing differential protection functions
Main protection	Protection functions with high requirements for fast operate times	Adding or removing • Functions and zones of the distance protection; functions and tripping stages of the ground-fault protection • Power-swing blocking, functions and tripping stages of instantaneous high-current tripping
Backup protection	Protection functions with average requirements for fast operate times	Adding or removing • Functions and stages of overcurrent protection • Synchronization function
Other protection	Protection functions with low requirements for fast operate times	Adding or removing • Overload protection functions • Functions and stages of voltage protection • All functions not listed previously

Functional Area	Short Description	Change in Load
CFC event-triggered, standard GOOSE	CFC charts with a maximum processing time of 40 ms	Adding or removing CFC charts in the event-triggered process range • Create CFC chart • Delete CFC chart • Change the process range in the properties of the CFC chart Add to or remove from CFC charts in the event-triggered process area
• Control • Other CFC chart • Operational measured values	• Control and interlocking • CFC charts in the area of control, measured-value preprocessing, and event-controlled • Operational measured values	Adding or removing • Function blocks for control and interlocking • CFC charts in the control area • Switching devices (except circuit breakers), for example, Disconnector function groups • Operational measured values • CFC charts in the measured values area

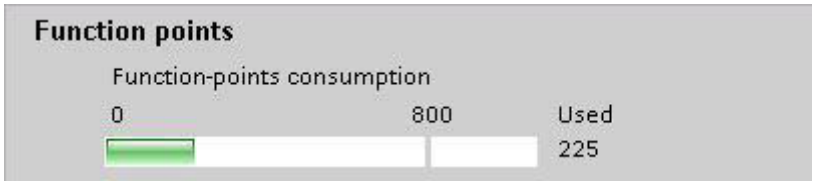
If the load model displays a warning, bear in mind the following general instructions:

The areas named in the table are listed in descending order of real-time requirements. If a warning appears to the effect that the guaranteed response times may be exceeded in an area, you can return to the permitted area by taking the following measures:

- Reduce the functional scope in the marked area (red exclamation mark)
- Reduce the functional scope in another area with higher real-time requirements

When you have reduced the application, check the display in resource consumption! If a function or stage has been switched off, it will continue to represent a load for the area. If you do not need the function or stage, delete it rather than switching it off.

Use the general **Circuit-breaker** function group only in the following cases:



- Interaction with a protection-function group is essential.
  That is to say, operate indications of protection functions cause the circuit breaker assigned to the **Circuit-breaker** function group to be switched off.
- You want to use functions such as the automatic reclosing function or circuit-breaker failure protection in the **Circuit-breaker** function group.

If a circuit breaker is only to be modeled for control purposes, use the **Circuit-breaker [state only]** function group.

8.2.2 Function Points

When you order a SIPROTEC 5 device, you are also ordering a function-points account for use of additional functions.

The following figure illustrates consumption of function points in the current application with respect to the existing function-points account.

[sc_fpunkt, 1, en_US]

Figure 8-2 Resource Overview: Function-Points Consumption

The remaining white bar shows the function points that have not yet been used up by your configuration. The number of function points available in a device depends on the device purchase order (position 20 of the product code). You can also order function points subsequently, and so increase the function-points account for the device.

NOTE

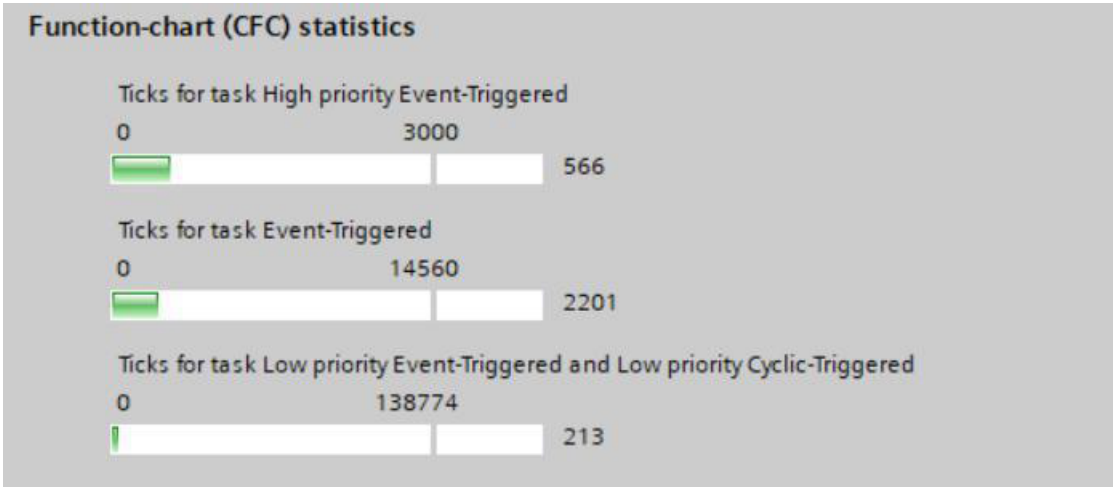
Find out the function-points requirement for the desired application before ordering the device. For this, you can use the device configurator. Alternatively, you order the device with 0 function points and create the license file with the required point credits ad hoc using the SIPROTEC function point manager (refer to *2.2 Application Templates/Adaptation of Functional Scope*).

8.2.3 CFC Resources

Task Levels of the CFC Function

A CFC chart, and thus the configured CFC function, runs in the SIPROTEC 5 device on exactly one of the 4 task levels. The individual task levels differ, on the one hand, in the priority of processing tasks and, on the other, in the cyclic or event-triggered processing of the CFC charts.

You can select between the following task levels:



Task Level	Description
High priority Event-triggered	Use the ***High priority Event-triggered*** task level for time-critical tasks, for example, if a signal should block a protection function within 2 ms to 3 ms. Functions on this task level are processed in an event-triggered way with the highest priority. Each change to a logical input signal is immediately processed. Processing can interrupt the execution of protection functions and functions on the ***Event-Triggered*** task level.
Event-triggered	Use the ***Event-triggered*** task level preferably for logic functions that need not be executed with highest priority. Each change to a logical input signal is immediately processed. Protection functions or functions on the ***High priority Event-triggered*** task level can disrupt processing. Functions on the ***Event-triggered*** task level are typically processed within a maximum of 5 ms in all devices. For busbar protection or line protection, the functions on the ***Event-triggered*** task level are processed within a maximum of 10 ms.
Low priority Cyclic-triggered	Use the ***Low priority Cyclic-triggered*** task level for processing measured values. Functions on this task level are processed cyclically every 500 ms.
Low priority Event-triggered	Use the ***Low priority Event-triggered*** task level preferably for logic functions that should be executed with lower priority than functions in the ***Event-triggered*** task level. If the available ticks of the ***Event-triggered*** task level shown in the following figure are sufficient for the required CFC functionality, you do not need to use the ***Low priority Event-triggered*** task level.

All CFC function blocks can be assigned to all the task levels. There are no device-specific function blocks. If enough ticks are available, all CFC charts can be created in the same task level. A tick is the measure of the performance requirement of CFC blocks.

The number of available ticks for each task is calculated depending on the created device configuration. This calculation is based on the previously described load model. In this process, it is recommended to create all selected functions and objects first followed by configuration of the CFC charts so that a realistic information about the remaining system capacitance for CFC charts is available. Significantly exceeding the typical response time is prevented by the load model by limiting the number of CFC function blocks in the corresponding task level via the number of ticks available.

The typical response times for CFC tasks are listed in the Technical Data.

The following figure shows an example of the CFC chart capacitances in DIGSI calculated by the load model. The ticks available for each task are shown here. The green bars represent the ticks used in the task levels. You reach this dialog with the following call: Device → Device information → Resource consumption.

[sc_cfc-statistic, 2, en_US]

Figure 8-3 CFC Statistics

NOTE

High priority Event-triggered CFC charts have the highest priority and are processed before all other tasks. At this level, a considerable smaller number of ticks are available than at all other tasks. It is recommended to configure only very-high-priority logic functions at this task and to configure the other logic functions in any other level.

NOTE

Empty CFC charts also consume system resources. Empty charts that are not required any more should be deleted.

8.3 Supervision of the Secondary System

8.3.1 Overview

The secondary circuits establish a connection to the power system from the point of view of the device. The measuring-input circuits (currents, voltages) as well as the command circuits to the circuit breakers are monitored for the correct function of the device. The connection to the station battery is ensured with the supervision of the external auxiliary voltage. The secondary system has the following supervision systems:

Measuring circuits (voltage):

- Measuring-voltage failure
- Voltage-transformer circuit breaker
- Voltage balance
- Voltage sum
- Voltage rotating field

Measuring circuits (current):

- Broken conductor of the current circuits
- Current balance
- Current sum
- Current rotating field
- Saturation detection

Trip Circuits

When the supervisions listed in the previous section pick up, corresponding warning indications are output. Some supervisions lead directly to the blocking of affected protection functions or to the marking of measuring points that have become invalid, so that affected protection functions can go into a secure state.

A detailed description of the supervision mechanisms and their error responses can be found in the respective function descriptions.

External Auxiliary Voltage

The supervision of the external auxiliary voltage is described in Error Responses and Corrective Measures starting with *8.8.1 Overview*.

8.3.2 Measuring-Voltage Failure

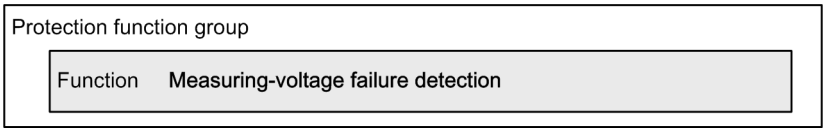
8.3.2.1 Overview of Functions

The **Measuring-voltage failure detection** function monitors the voltage transformer secondary circuits:

- Non-connected transformers
- Pickup of the voltage transformer circuit breaker (in the event of short circuits in the secondary circuit)
- Broken conductor in one or more measuring loops

All these events cause a voltage of 0 in the voltage transformer secondary circuits which can lead to failures of the protection functions.

Each of the following protection functions has the parameter **Blk. by meas.-volt. failure**. Using the setting value of the parameter, you can specify whether the protection functions react to a measuring-voltage failure or not (block/not block).



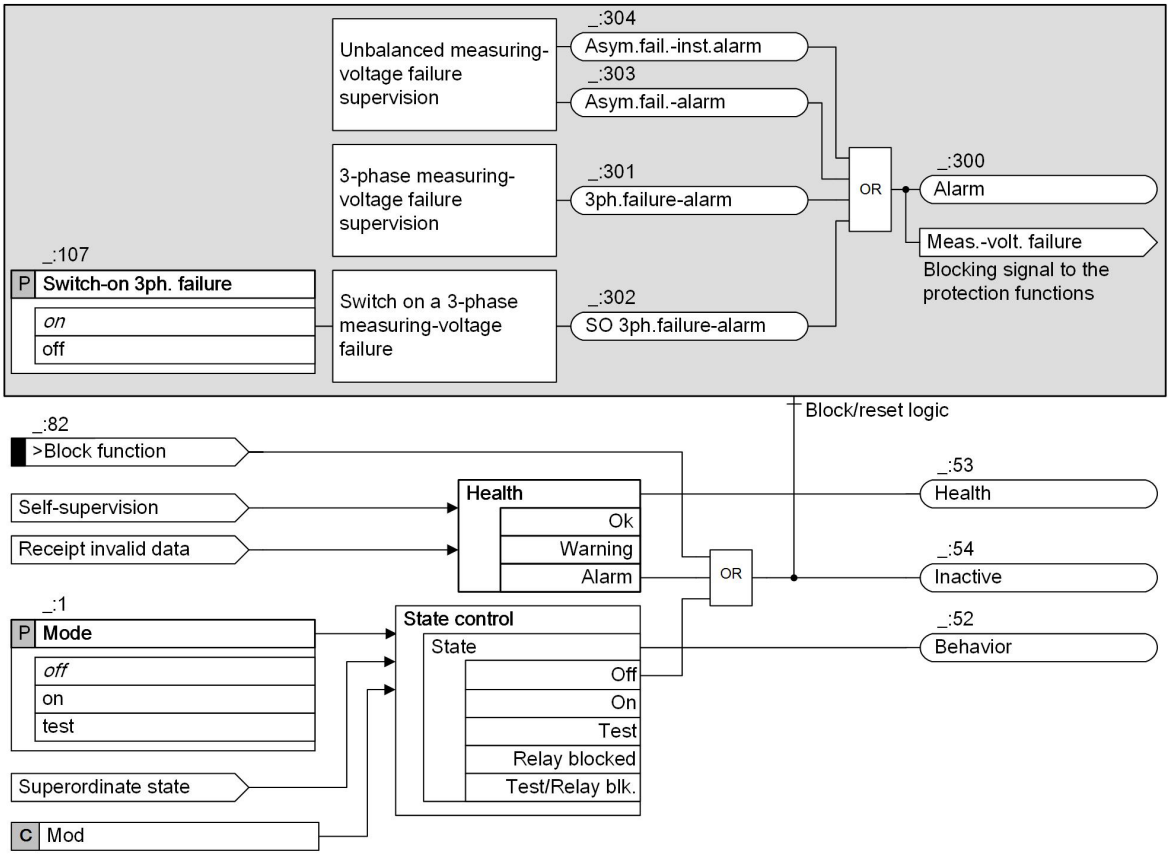
- Directional Overcurrent Protection, Phases
- Overvoltage Protection with Negative-Sequence Voltage
- Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage
- Undervoltage Protection with 3-Phase Voltage
- Overvoltage Protection with Positive-Sequence Voltage
- Voltage-Dependent Overcurrent Protection, Phases
- Overvoltage Protection with Negative-Sequence Voltage
- Overvoltage Protection with Positive-Sequence Voltage
- Undervoltage-Controlled Reactive-Power Protection

The following protection functions are automatically blocked in the case of a measuring-voltage failure:

- Distance protection
- Directional Negative-Sequence Protection
- Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems

8.3.2.2 Structure of the Function

The function is part of protection function groups which are connected with a 3-phase voltage and current measuring point.



[dw_strffm, 1, en_US]

Figure 8-4 Structure/Embedding of the Function

The function is broken down into 3 subfunctions (see *Figure 8-5*):

- Supervision for unbalanced measuring-voltage failure
- Supervision for 3-phase measuring-voltage failure
- Supervision for switching onto a 3-phase measuring-voltage failure

[lo_ffm-3p_zusamm, 3, en_US]

Figure 8-5 Breakdown of the Measuring-Voltage Failure Detection Function

Each subfunction creates its own monitoring indication. The function summarizes these indications via the group indication **Alarm**.

The response to the detection of a measuring-voltage failure is explained in the specific protection-function descriptions.

8.3.2.3 Unbalanced Measuring-Voltage Failure

Logic

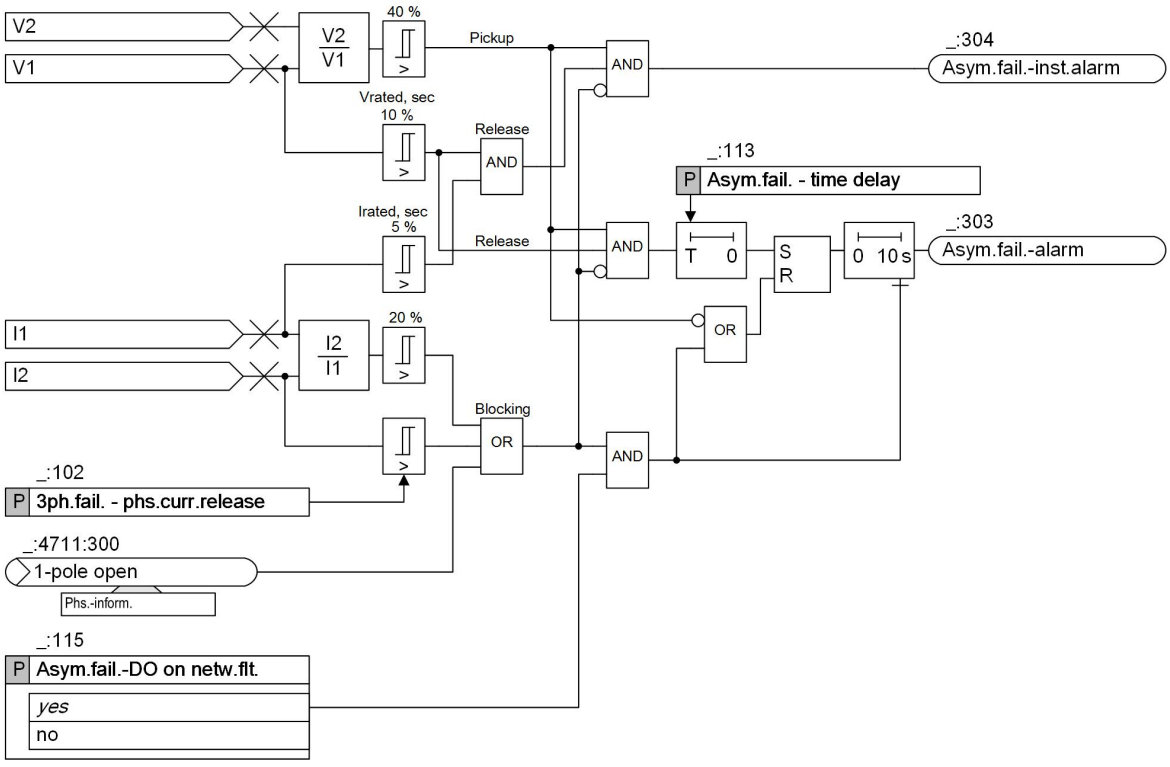


Figure 8-6 Logic Diagram Unbalanced Measuring-Voltage Failure Detection

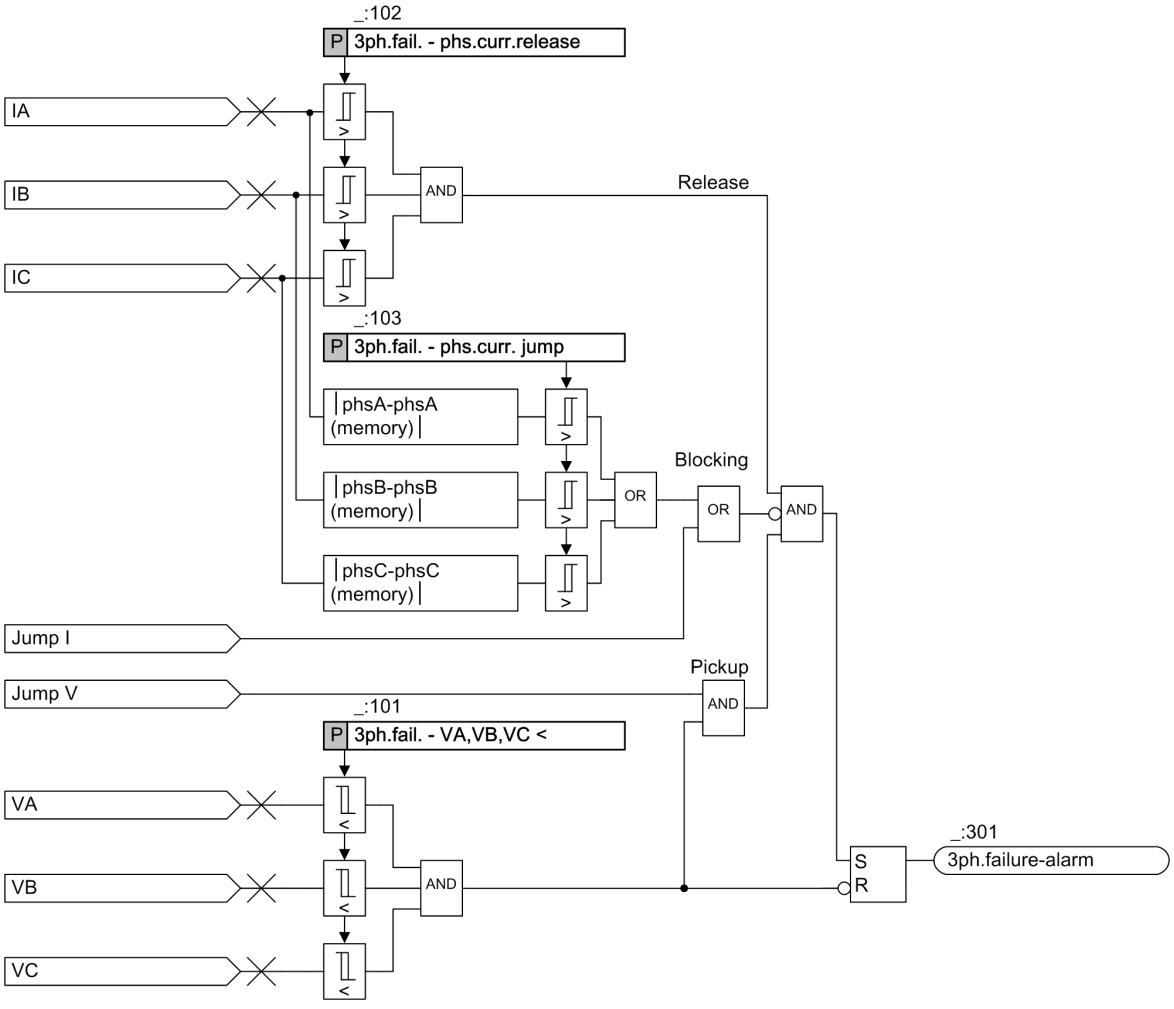
The criterion for detection of an unbalanced measuring-voltage failure is the voltage unbalance. This unbalance is determined based on the ratio between negative and positive-sequence voltage. If the threshold value is exceeded and the monitoring is released and not blocked, the monitoring picks up (see *Figure 8-6*). The indication *Asym.fail.-inst.alarm* is output.

The monitoring is released as soon as a certain minimum voltage is exceeded. This prevents a spurious response in the presence of low voltage measurands or a measurand of 0 (for example, circuit breaker open). Instantaneous monitoring also requires the presence of a minimum current. This prevents a spurious instantaneous pick up of the monitoring in the presence of a weak infeed (current < 10 % of rated current) combined with a power-system incident.

If the voltage unbalance is blocked by unbalanced faults in the primary system, the supervision is blocked. The device detects an unbalanced fault based on the ratio between negative-sequence and positive-sequence current.

Delay/Seal-In

In the presence of a weak infeed (current < 10 % of rated current), certain protection functions require more time for detection of a system incident. For this purpose, monitoring can be delayed using the parameter **Asym.fail. - time delay**.



If a system incident is detected during the time delay, the supervision drops off. This is because the function assumes that the unbalance - and consequently the pickup of the supervision - is due to the system incident.

After the time delay has elapsed, it definitely assumes a measuring-voltage failure. Monitoring seals in and the *Asym.fail.-alarm* indication is output. The dropout does not happen until the voltage unbalance has disappeared after a seal-in time of 10 s. In the presence of 3-pole close-in faults outside the protection zone, this seal-in time prevents the monitoring from dropping off too quickly and thus releasing the protection functions.

The sealing-in function can be deactivated using the **Asym.fail.-DO on netw.flt.** parameter. As soon as a system incident is detected, the monitoring drops off instantaneously.

8.3.2.4 3-Phase Measuring-Voltage Failure

Logic

[lo_symmet, 1, en_US]

Figure 8-7 Logic Diagram 3-Phase Measuring-Voltage Failure

Balanced Fault – VA, VB, VC <

A 3-phase measuring-voltage failure is detected if the following criteria are fulfilled simultaneously:

- All 3 phase-to-ground voltages drop below the threshold value **3ph.fail. - VA,VB,VC <**
- A jump of the voltage (signal **Jump V**)

If these criteria are fulfilled and the monitoring is released and not blocked, the **3ph.failure-alarm** indication is output. When the voltage returns (even as 1-phase), the monitoring drops out.

Release by Phase Current

When all phase currents exceed the threshold value **3ph.fail. - phs.curr.release** the monitoring is released.

If the device incorporates the distance-protection function, the device checks the input threshold value **3ph.fail. - phs.curr.release** against the minimum current setting of the distance protection for

plausibility. The threshold value **3ph.fail. - phs.curr.release** must be set to less than or equal to the release current of the distance protection.

For more information see *Distance protection* *6.15.2.1 Overview of Functions* .

Blocking in the Case of a System Incident

In the case of a 3-phase system incident, supervision must be blocked. The device detects a 3-phase system incident with a jump in the current. This change is detected via the internal signal **Jump I** or when the change in current of a phase current exceeds the threshold value **3ph.fail. - phs.curr. jump**. The change in current of phase currents is formed from the difference between the present current phasor and the current phasor of the previous period. This allows to take into account a jump of the current phase.

NOTE

If a voltage-transformer circuit breaker is installed in the secondary circuit of the voltage transformers, its position is communicated to the device via a binary input (see chapter *8.3.4.1 Overview of Functions*).

8.3.2.5 Switching onto a 3-Phase Measuring-Voltage Failure, Low Load

Logic

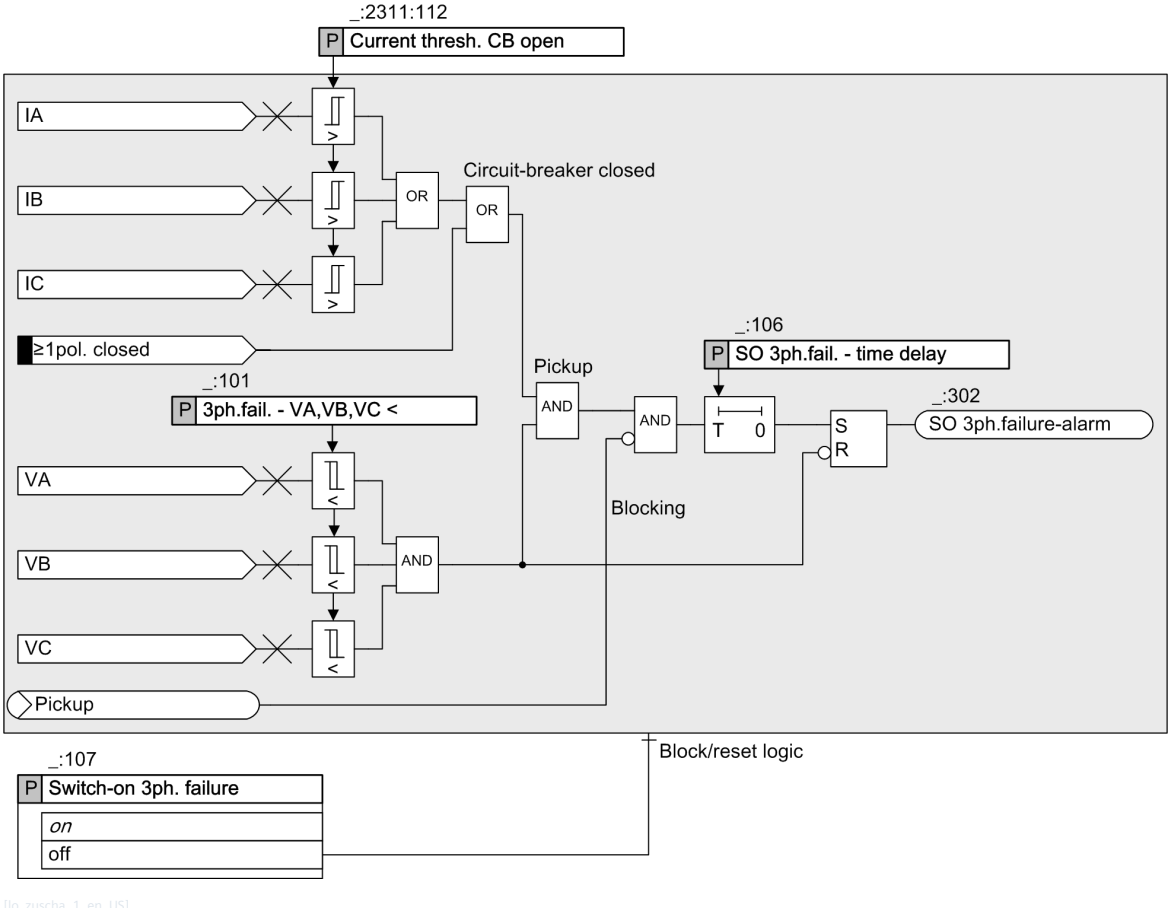


Figure 8-8 Logic Diagram Switching to 3-Phase Measuring-Voltage Failure

Switching onto a 3-phase measuring-voltage failure is detected if the following criteria are fulfilled simultaneously:

- All 3 phase-to-ground voltages have dropped below the threshold value **3ph.fail. - VA,VB,VC <**.
- The circuit breaker is detected to be in closed position. The detection takes place either via the phase currents or via the **≥1-pole closed** signal, which is generated via the circuit-breaker auxiliary contacts.
  For more detailed information, refer to *5.5.4.6 Circuit-Breaker Condition for the Protected Object*.

A voltage jump – such as in a 3-phase measuring-voltage failure with closed circuit breaker (refer to *8.3.2.4 3-Phase Measuring-Voltage Failure*) – does not occur in the case of switching to a 3-phase measuring-voltage failure. If the monitoring is not blocked, the time delay **SO 3ph.fail. - time delay** is started. After the time has elapsed, the indication **SO 3ph.failure-alarm** is displayed. A dropout of the monitoring is only possible by a recovery of the voltage.

The supervision is blocked as soon as a pickup of a protection function is detected within a protection function group and the time delay of the supervision has not yet elapsed.

This subfunction also covers the situation of a low load with 3-phase measuring-voltage failure and closed circuit breaker, because the circuit-breaker position is also determined from the circuit-breaker auxiliary contacts. The subfunction for detecting a 3-phase measuring-voltage failure (refer to *8.3.2.4 3-Phase Measuring-Voltage Failure*) is not released in this situation, for example, because the current flow is too low.

This subfunction can be switched on or off separately using the **Switch-on 3ph. failure** parameter.

8.3.2.6 Application and Setting Notes

Parameter: Asym.fail. - time delay

- Recommended setting value **(_:113) Asym.fail. - time delay** = ***10.00 s***

The **Asym.fail. - time delay** parameter allows you to set the time during which a system incident detected after the occurrence of the unbalance resets the monitoring. This setting is important in the case of weak infeed (current < 10 % of rated current) in order to give certain protection functions (such as distance protection) more time for detecting system incidents. As long as the time delay runs, it is assumed that the unbalance is due to a system incident.

As soon as the time has elapsed, the supervision assumes a measuring-voltage failure and seals in.

Siemens recommends using the default setting.

If you want the seal-in function to operate sooner or at once, you can reduce the time.

Parameter: Asym.fail.-DO on netw.flt.

- Recommended setting value **(_:115) Asym.fail.-DO on netw.flt.** = ***No***

Parameter Value	Description
no	After elapse of the time delay the supervision function seals in. Even if the system incident criterion is fulfilled, the protection functions concerned will remain blocked. This avoids an unselective tripping of the protection functions due to an absence of the measuring voltage in the case of an unbalanced system incident. This is the default setting.
yes	The seal-in function is switched off. The supervision drops out immediately when a system incident is detected. With this setting, the unbalanced measuring-voltage failure is only reported, and in the event of a double failure (measuring-voltage failure and system incident in parallel), unselective tripping is preferred.

Parameter: 3ph.fail. - VA,VB,VC <

- Recommended setting value **(_:101) 3ph.fail. - VA,VB,VC <** = ***5 V***

The **3ph.fail. - VA,VB,VC <** parameter allows you to set the pickup value of the monitoring.

Siemens recommends using the default setting.

If you expect major disturbances acting upon the voltage inputs, you can increase this value. Increasing the values makes the supervision more sensitive to 3-phase system incidents.

Parameter: 3ph.fail. - phs.curr.release

- Recommended setting value **(_:102) 3ph.fail. - phs.curr.release** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **3ph.fail. - phs.curr.release** parameter is used to define the phase current threshold above which the monitoring is released.

Siemens recommends using the default setting.

If the device incorporates the **Distance protection** function, this value must be set to less than or equal to the release current of the distance protection.

For more information, refer to chapter *Distance protection*, *6.15.2.1 Overview of Functions* .

Parameter: 3ph.fail. - phs.curr. jump

- Recommended setting value **(_:103) 3ph.fail. - phs.curr. jump** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **3ph.fail. - phs.curr. jump** parameter is used to set the differential current between the present current phasor and the stored phasor (from the previous period). If the value is exceeded, the function detects a system incident and blocks the monitoring.

Siemens recommends using the default setting.

Parameter: SO 3ph.fail. - time delay

- Recommended setting value **(_:106) SO 3ph.fail. - time delay** = ***3.00 s***

The **SO 3ph.fail. - time delay** parameter allows you to set the delay of the monitoring.

Siemens recommends using the default setting.

NOTE

Adapt the **SO 3ph.fail. - time delay** parameter to the inherent time of protection functions which are intended to block the monitoring function.

Note that with parameter values 0 s blocking of the monitoring function via a protection stimulation will not be possible any more.

Parameter: Operating mode

This parameter **(_:4711:101) Operating mode** and its settings are described in chapter *Process monitor*.

For more information, refer to the chapters starting at *5.5.4.1 Overview of Functions*.

Parameter: Switch-on 3ph. failure

- Recommended setting value **(_:107) Switch-on 3ph. failure** = ***on***

Parameter Value	Description
on	The subfunction **Switching to a 3-phase measuring-voltage failure** is active. In the case of low loads, the subfunction for detection of a 3-phase measuring-voltage failure is not released, for example, because the current flow is too low. In this situation, the subfunction **Switching to a 3-phase measuring-voltage failure** can perform the monitoring task. Siemens recommends switching that subfunction on.
off	With the setting ***off*** the subfunction **Switching to a 3-phase measuring-voltage failure** is not active.

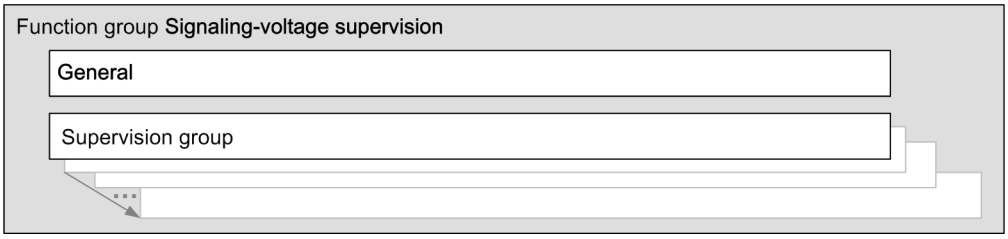
8.3.3 Signaling-Voltage Supervision



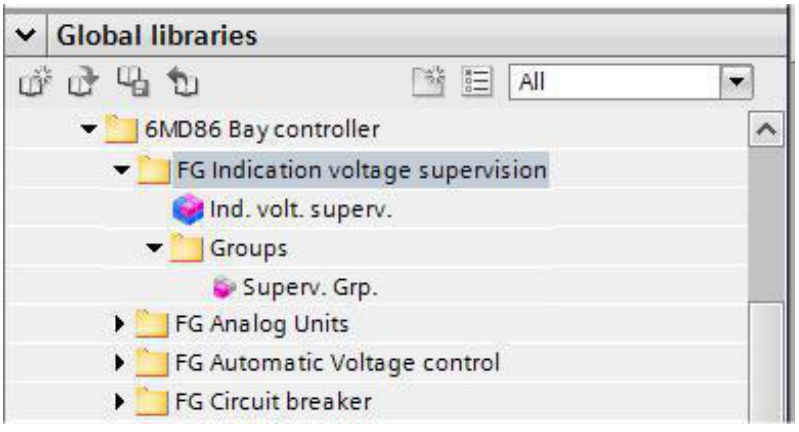
8.3.3.1 Overview of Functions

Signaling-voltage supervision is used to evaluate the validity of binary signals connected to the SIPROTEC device via binary inputs. For this purpose, one binary input is used to monitor the signaling voltage. If the signaling voltage fails, the associated binary signals are marked as invalid and a **Signaling-voltage malfunction** indication is issued.

Several signaling-voltage supervision groups can be created in one SIPROTEC device. Each of these groups monitors an adjustable area with binary inputs.

8.3.3.2 Structure of the Function

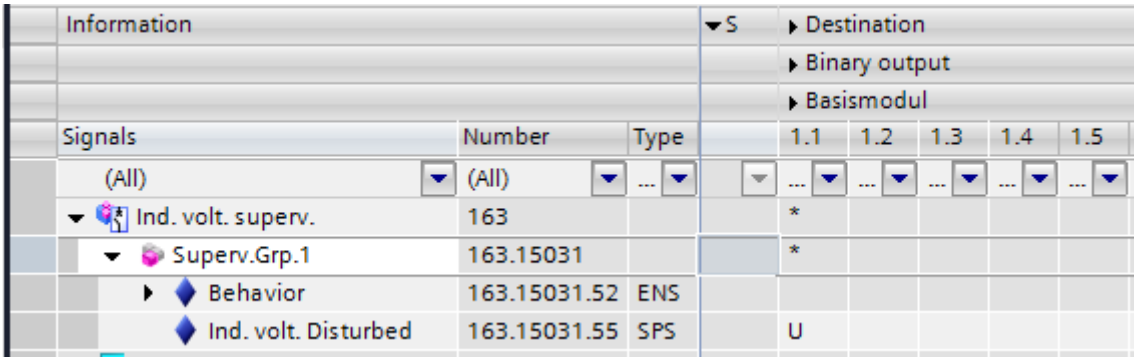
The **Signaling-voltage supervision** function group contains, besides the general functionality, one preinstantiated **Supervision group** stage. The **Supervision group** stage can be instantiated in DIGSI 5 multiple times.



[dw_ivsstr, 1, en_US]

Figure 8-9 Structure/Embedding of the Function Group

8.3.3.3 Function Description

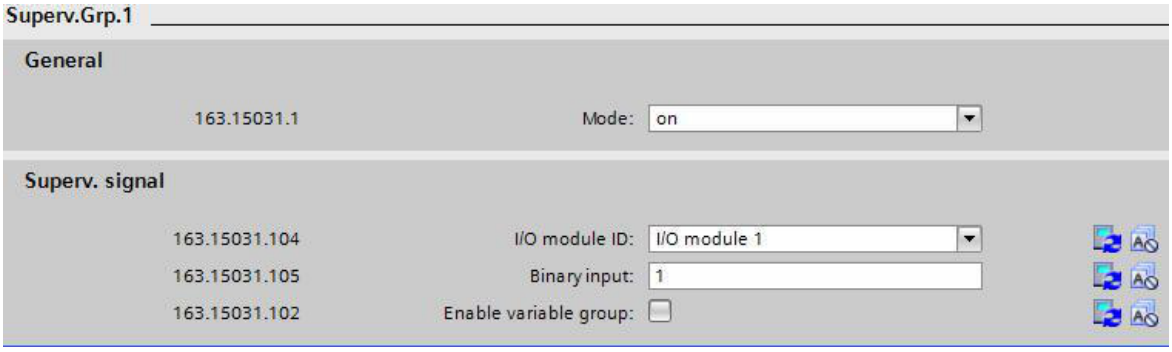


You can instantiate the **`Signaling-voltage supervision`** function group in the Global DIGSI 5 library. It contains 1 pre-instantiated **`Superv.Grp.`** function block (see the following figure). You can instantiate a maximum of 25 supervision groups.

[sc_ivslib, 1, en_US]

Figure 8-10 Entry in the Global Library

Following the instantiation of the function group in the DIGSI project tree, it appears in the information routing of DIGSI (see the following figure). The status indications of the supervision groups can be routed here, for example, to existing binary outputs and/or logs.

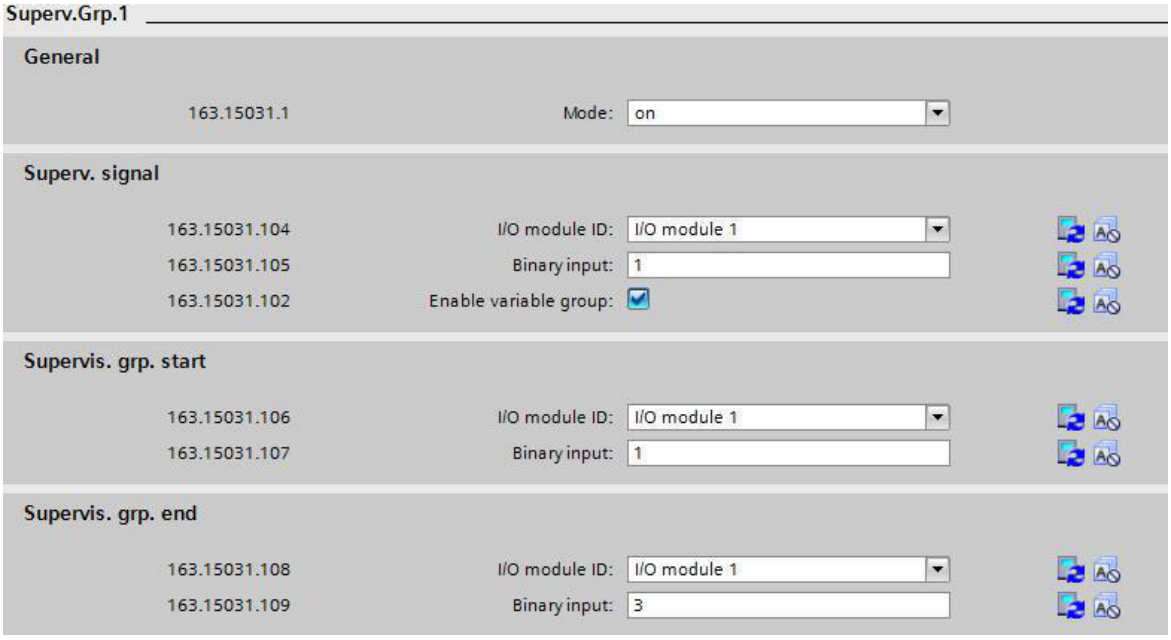


[sc_ivsrou, 1, en_US]

Figure 8-11 Information Routing

Set the binary input used for signaling-voltage supervision within one input/output module using the setting option (see the following figure). This binary input monitors the presence of the signaling voltage. If the signaling voltage fails, this sets the quality attribute for all other binary inputs of the parameterized input/output module to ***invalid***. The signal status of each of these binary inputs is frozen with its last valid value prior to the occurrence of the fault. The quality attribute of the binary inputs for other input/output modules are not taken into consideration by this.

If the signaling voltage again exceeds the binary threshold, the quality attribute of the binary inputs is reset to ***valid***.



[sc_ivsgrp, 2, en_US]

Figure 8-12 Parameterization Menu of the Supervision Group (I)

NOTE

Each status change of the monitored binary inputs is delayed by 3 ms.

You can also combine binary inputs across modules in one **Superv.Grp.** function block and define any binary input within this group for supervision of the signaling voltage. For this purpose, place a check mark at the parameter **(_:102) Enable variable group** when configuring the supervision group. This extends the parameterization menu by the sections **Supervis. grp. start** and **Supervis. grp. end** (see the following figure).

[sc_gruppe_de, 2, en_US]

Figure 8-13 Parameterization Menu of the Supervision Group (II)

There, for example, you are able to combine 1 to n different binary inputs into one supervision group. When doing so, the binary inputs on the input/output modules assignable to a supervision group must be related logically. With 3 input/output modules, for example, this allows only consecutive binary inputs to be grouped on the modules 1 and 2 or 2 and 3, but no binary inputs on modules 1 and 3. The binary inputs used for supervision can be located on any input/output module within the group defined in this manner.

If you have to monitor several binary inputs that, for example, work with different signaling voltages from different sources, then you can also instantiate and configure several **Superv.Grp.** function blocks within the **Signaling-voltage supervision** function group accordingly.

Within different supervision groups, only those consecutive binary inputs that are not already assigned to another supervision group can be grouped. The overlapping of binary inputs in different supervision groups is not permitted.

Error parameters are displayed to you by inconsistency indications in DIGSI.

Example

There are 4 input/output modules available.

Binary inputs of input/output modules 1 and 2 are already combined in supervision group 1. The 2 last binary inputs on module 2 are not included in the grouping.

In supervision group 2, only these 2 binary inputs of the input/output module 2 not used in supervision group 1 as well as further consecutive binary inputs of the input/output modules 3 and 4 can be combined.

8.3.3.4 Application and Setting Notes

Parameter (General): Mode

- Default setting **(_:1) Mode** = ***on***

With the **Mode** parameter, you specify whether you want to activate, deactivate, or test the supervision of the signaling voltage for the appropriate group. If you put the group into test mode, the *Sig. volt. disturbed* indication is given a test flag.

Parameter (Supervision Signal): I/O module ID

- Default setting **(_:104) I/O module ID** = ***I/O module 1***

Using the **I/O module ID** parameter, you specify the I/O module for which you want to activate supervision of the signaling voltage. Counting of the I/O modules starts in increasing order with the binary inputs of the base module. The binary inputs of the PS201 power-supply module permanently installed in the base module count as the 2nd I/O module followed by additional I/O modules (3 to n) on expansion boards of the device.

Parameter (Supervision Signal): Binary input

- Default setting **(_:105) Binary input** = ***1***

Using the **Binary input** parameter, you specify the binary input responsible for teh supervision of the signaling voltage for the parameterized I/O module. The quality attribute of all other binary inputs for this module are set to **valid** or **invalid** depending on the presence of the signaling voltage at the parameterized binary input.

Parameter (Supervision Signal): Enable variable group

- Default setting **(_:102) Enable variable group** = ***untrue***

You can activate the parameter **Enable variable group** by placing the checkmark. If you have not set the check mark (default setting), only these 2 parameters are available for the configuration of the supervision signal. If you have set the check mark, the parameter menu is extended by the areas **Start supervision group** and **End supervision group**. You can then use that to carry out the grouping of binary inputs for supervision groups explained in the function description.

Parameter (Start Supervision Group): I/O module ID

- Default setting **(_:106) I/O module ID** = ***I/O module 1***

Parameter **I/O module ID** is used to define the first I/O module that you want to assign to a supervision group. As the counting of the I/O module starts in ascending order with the binary inputs of the base module, this is the module with the lowest counter number that you can use for carrying out a grouping.

Parameter (Start Supervision Group): Binary input

- Default setting **(_:107) Binary input** = ***1***

Parameter **Binary input** is used to define the lowest binary input for the first I/O module (see **(_:106) I/O module ID**) that you want to assign to a supervision group.

Parameter (End Supervision Group): I/O module ID

- Default setting **(_:108) I/O module ID** = ***I/O module 1***

Parameter **I/O module ID** is used to define the last I/O module that you want to assign to a supervision group. As the counting of the I/O module starts in ascending order with the binary inputs of the base module, this is the module with the highest counter number that you can use for carrying out a grouping.

Parameter (End Supervision Group): Binary input

- Default setting **(_:109) Binary input** = ***1***

Parameter **Binary input** is used to define the highest binary input for the last I/O module (see **(_:108) I/O module ID**) that you want to assign to a supervision group.

8.3.4 Voltage-Transformer Circuit Breaker

8.3.4.1 Overview of Functions

The function **Voltage-transformer circuit breaker** detects the tripping of the voltage-transformer circuit breaker due to short circuits in the voltage-transformer secondary circuits.

The **Voltage-transformer circuit breaker** function works independently of **Measuring-voltage failure detection** and should be used – if possible – in parallel to it.

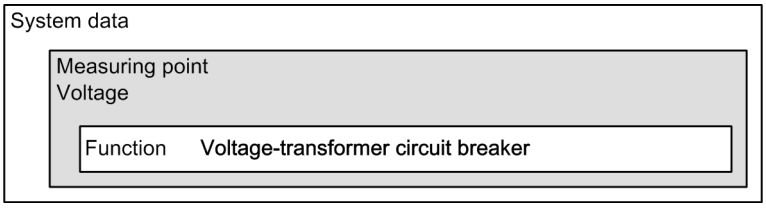
The tripping of the voltage-transformer circuit breaker impacts the quality of the recorded measured-value data (refer to *3.4 Processing Quality Attributes*).

The following protection functions are automatically blocked if the voltage-transformer circuit breaker trips:

- Distance protection
- Directional negative-sequence protection
- Ground-fault protection for high-resistive faults in grounded systems

For the following functions the reaction (block/not block) can be set within the function in cases of a tripping of the voltage-transformer circuit breaker:

- Directional overcurrent protection, phases
- Overvoltage protection with negative-sequence voltage



- Overvoltage protection with zero-sequence voltage/residual voltage
- Undervoltage protection with 3-phase voltage
- Undervoltage protection with positive-sequence voltage

NOTE

If the voltage signal is generated using the optional Merging unit function, the quality of the voltage signal is sent as ***invalid*** in the sampled value stream, depending on the status of the voltage-transformer circuit breaker. For more information about configuring the voltage-transformer circuit breaker function for devices with merging unit and process-bus client, refer to the *Process Bus manual*.

8.3.4.2 Structure of the Function

The *Figure 8-14* shows the position of the function in the device. Every voltage measuring point contains the **Voltage-transformer circuit breaker** function.

[dw_mcbstr, 1, en_US]

Figure 8-14 Structure/Embedding of the Function

8.3.4.3 Function Description

The tripping of the voltage-transformer circuit breaker is captured via the binary input signal **>Open**. With an active input signal the information about the measuring-voltage failure is relayed to the affected functions (see *8.3.4.1 Overview of Functions*). The response to the detection of a measuring-voltage failure is explained in the specific protection-function descriptions.

Response Time of the Voltage-Transformer Circuit Breaker

The response time of the voltage-transformer circuit breaker can be slower than the pickup time of the distance protection. This bears the risk of an overfunction. The response time is communicated to the device with the **Response time** parameter. For a timely detection of the tripping of the voltage-transformer circuit breaker, the pickup of the distance protection is delayed by that response time.

8.3.4.4 Application and Setting Notes

The function is always active and need not be switched on.

Input Signal: >Open

- Input signal: **(_:500) >Open**

The input signal **>Open** must be connected to the tripping of the voltage-transformer circuit breaker. As a rule, this occurs via the routing to a binary input.

Parameter: Response time of the voltage-transformer circuit breaker

- Recommended setting value **(_:101) Response time** = ***0 ms***

When the voltage-transformer circuit breaker drops out, the device must block the distance protection immediately to prevent an unwanted tripping of the distance protection due to the absence of the measuring voltage while the load current is flowing.

The blocking must be faster than the 1st stage of the distance protection. This requires an extremely short response time of the miniature circuit breaker (≤ 4 ms at 50 Hz, ≤ 3 ms at 60 Hz rated frequency). If the circuit-breaker auxiliary contact does not fulfill this requirement, you have to set the response time accordingly.

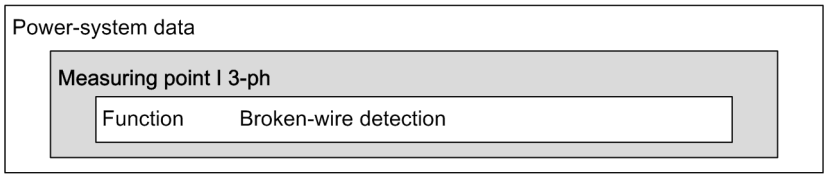
8.3.5 Broken-Wire Detection



8.3.5.1 Overview of Functions

The **Broken-wire detection** detects interruptions in the secondary circuit of the current transformers during steady-state operation. In addition to creating a hazard due to high voltages in the secondary circuit, such interruptions can mimic the presence of differential currents for the differential protection, as caused by short circuits in the protected object. To prevent overfunctions due to faulty current values, the affected protection functions are blocked, for example the Line differential protection and the Distance protection.

An interruption in the secondary circuit of the current transformer cannot always be distinguished from a broken conductor in the primary circuit. If the function **Line differential protection** is instantiated in the device, additional messages from the opposite end of the line improve the ability to differentiate between both cases.

8.3.5.2 Structure of the Function

The **Broken-wire detection** function is located in the power-system data of each 3-phase current measuring point.

[dw_bwsjsk_3_en_US]

Figure 8-15 Structure/Embedding of the Function

8.3.5.3 Function Description

Broken-Wire Detection

The function **Broken-wire detection** searches for current interruptions at all current measuring points. For this purpose, the instantaneous values of the currents are checked for their plausibility. In addition, further criteria must be met before a wire break can be detected and signaled with assurance.

Detection:

A wire break initially manifests itself as a sudden decrease of the current below the minimum threshold of 0.06 $I/I_{rated.}$ A plausibility test with the instantaneous values from the previous cycle confirms that the current has fallen below the minimum threshold. If the criteria for a wire break are satisfied, the affected phase is marked with **Broken wire suspected**. The following messages are generated: *(_:301) Phs A BW suspected*, *(_:302) Phs B BW suspected*, and/or *(_:303) Phs C BW suspected*, and *(_:307) Broken wire suspected*.

Resetting:

A broken-wire suspicion is reset by phase current flowing again, by a binary input signal, or by a controllable.

Broken-Wire Check

To prevent unwanted pickup of this monitoring function caused by special operating conditions, for example fault, maintenance, test, etc., the function checks various criteria.

If at least one of the following criteria is met, the broken-wire suspicion is reset including any associated protection blocking.

Local resetting criteria:

- At least one protection function has picked up.
- All circuit breakers assigned to the protection function group are open.
  For applications using a 1 1/2 circuit-breaker layout, both circuit breakers must be open.
- A wire break is detected on another phase of a local current measuring point.
- A voltage jump at a local voltage measuring point
- A current jump of the associated zero-sequence current
  This reset criterion applies only for **CT connection** = ***3-phase + IN-separate***.
- A current jump on the same phase of another local current measuring point
- The current in at least one phase is greater than 2.5 I_{rated}.

Additional reset criteria when using the function Line differential protection:

Criteria at the opposite end of the line can contradict a broken wire suspicion and cause resetting. The request to reset is transmitted via the protection interface.

Additional reset criteria:

- A wire break is detected on one phase of a current measuring point at the opposite end of the line.
- A wire break is detected on one phase of a voltage measuring point at the opposite end of the line.
- A jump is detected on one phase of a current measuring point at the opposite end of the line.
- The current in at least one phase at the opposite end of the line is greater than 2.5 I_{rated}.

Additional reset criteria in the FG Transformer side:

- A wire break is detected on one phase of the other transformer sides.
- A current jump is detected on one phase of the other transformer sides.
- A voltage jump is detected on one phase of the other transformer sides.
- The current in one phase of the measuring points of another transformer side is greater than 2.5 I_{rated}.
- At least one protection function has picked up.
- The neutral-point current is greater than 2.5 I_{rated}.

If a broken wire suspicion detected is not reset by a reset criterion, the wire break is assured. The messages *(_:304) Phase A broken wire*, *(_:305) Phase B broken wire*, and/or *(_:306) Phase C broken wire*, and *(_:308) Broken wire confirmed* are generated and maintained stable for a duration of at least 3 system periods.

Blocking the Protection

The decision to block the protection is performed phase-segregated for each 3-phase current measuring point of the device.

The parameter **(_:5581:101) Mode of blocking** controls the blocking behavior:

- ***not blocking***
  - Wire break is only signaled.
- ***blocking***
  - Each broken-wire suspicion causes the affected protection functions to be blocked.

8.3.5.4 Application and Setting Notes

Parameter: Mode

- Recommended setting value **(_:1) Mode** = ***off***

The parameter **Mode** is used to switch the **Broken-wire detection** to ***on*** or ***off*** or to activate the state ***test***.

Parameter: Mode of blocking

- Recommended setting value **(_:101) Mode of blocking** = ***blocking***

With the parameter **Mode of blocking**, you control the behavior when a broken-wire suspicion occurs, refer to *Blocking the Protection, Page 2063*. Siemens recommends using the default setting. The setting options are ***blocking*** and ***not blocking***.

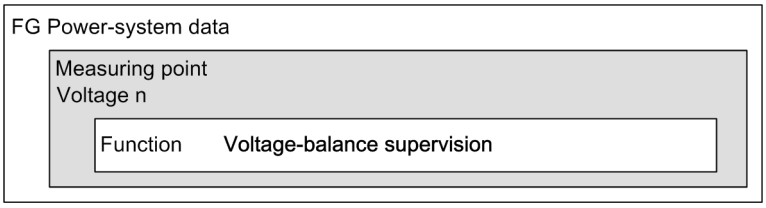
8.3.6 Voltage-Balance Supervision

8.3.6.1 Overview of Functions



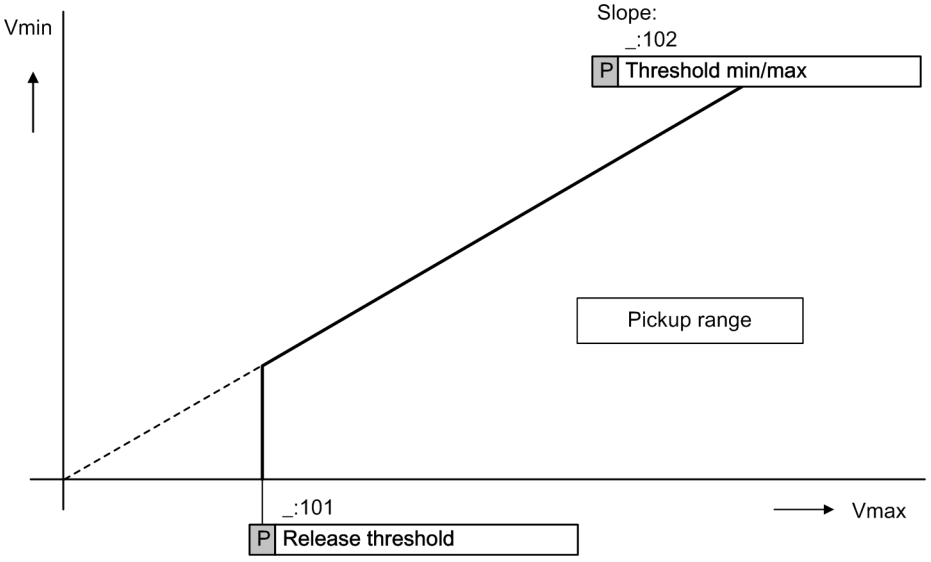
In healthy system operation, a certain balance between voltages can be assumed.
The **Voltage-balance supervision** function detects the following errors:

- Unbalance of phase-to-phase voltages in the secondary circuit
- Connection errors during commissioning or short circuits and interruptions in the secondary circuit

The voltage measurement is based on the RMS values of the fundamental component.

8.3.6.2 Structure of the Function

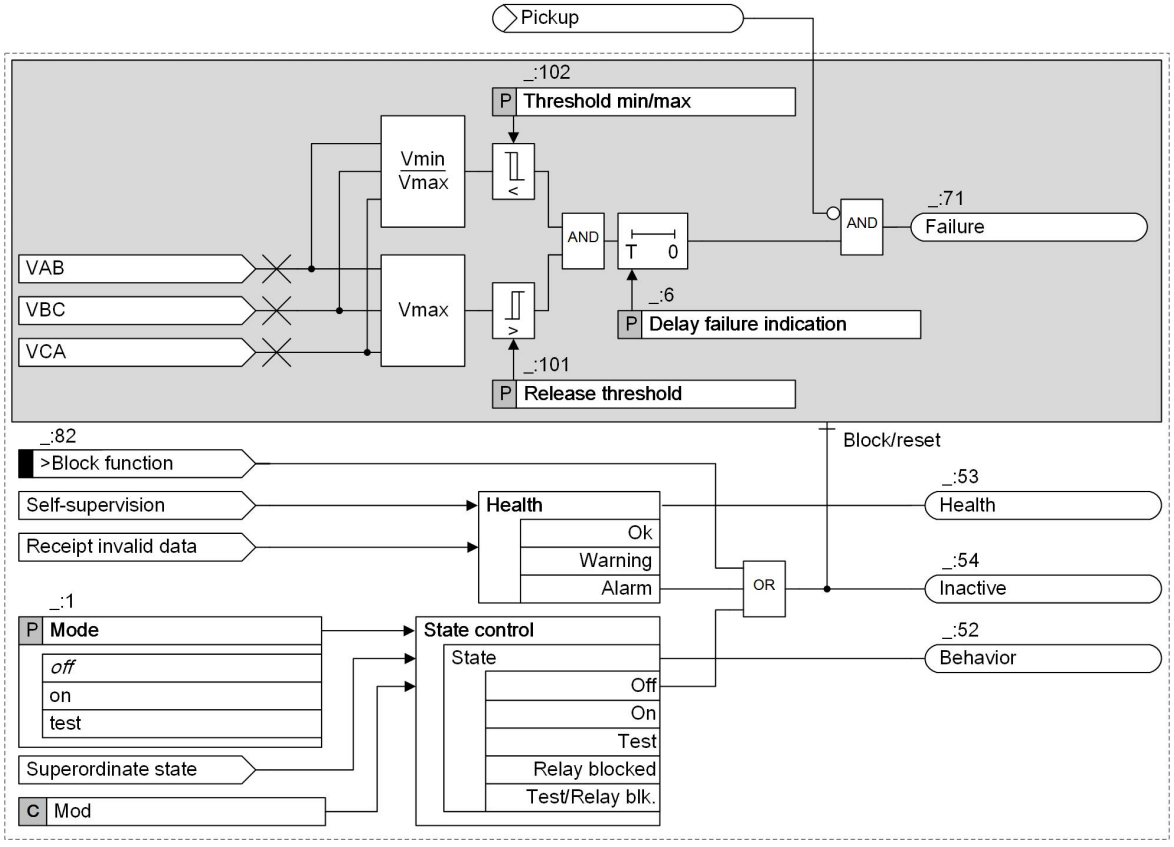
The **Voltage-balance supervision** function is located in the **Power-system data** of each 3-phase voltage measuring point.



[dw_strusy, 2, en_US]

Figure 8-16 Structure/Embedding of the Function

8.3.6.3 Function Description



The voltage balance is checked by a magnitude supervision function. This function relates the smallest phase-to-phase voltage to the largest phase-to-phase voltage. Unbalance is detected if
|Vmin| / |Vmax| < **`Threshold min/max`**, as long as Vmax > **`Release threshold`**

[lo_kenuns, 1, en_US]

Figure 8-17 Characteristic of the Voltage-Balance Supervision

Logic

[lo_sp_asym, 5, en_US]

Figure 8-18 Logic Diagram of the Voltage-Balance Supervision

The **Threshold min/max** parameter is the criterion by which a phase-to-phase voltage unbalance is measured. The device calculates the ratio between the minimum (V_{min}) and the maximum (V_{max}) phase-to-phase voltage.

Enter the lower limit of the maximum phase-to-phase voltage (V_{max}) with the parameter **Release threshold**. This specifies the lower limit of the operating range of this function.

Delay failure indication

If it falls below the balance factor **Threshold min/max** and at the same time the maximum phase-to-phase voltage exceeds the **Release threshold**, the delay of the failure indication (parameter: **Delay failure indication**) starts. If both conditions persist during this time, the indication **Failure** is generated.

Blocking the Function

The following blockings reset the picked up function completely:

- Externally or internally via the binary input signal *>Block function*
- A protection pickup
  The pickup signal of a protection function blocks the *Failure* indication.

8.3.6.4 Application and Setting Notes

Parameter: Threshold min/max

- Recommended setting value **(_:102) Threshold min/max** = *0.75*

The **Threshold min/max** parameter is used to set the ratio between the minimum (V_{min}) and the maximum (V_{max}) phase-to-phase voltage. Siemens recommends using the default setting.

Parameter: Release threshold

- Recommended setting value **(_:101) Release threshold** = ***50 V***

With the **Release threshold** parameter you set the lower limit of the maximum phase-to-phase voltage (V_{max}). Siemens recommends using the default setting.

Parameter: Delay failure indication

- Recommended setting value **(_:6) Delay failure indication** = ***5.00 s***

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

8.3.6.5 Settings

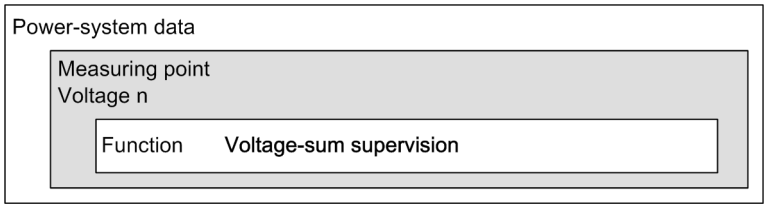
8.3.7 Voltage-Sum Supervision

8.3.7.1 Overview of Functions

In healthy system operation, the sum of all voltages at one measuring point must be approximately 0. The **Voltage-sum supervision** monitors the sum of all voltages of one measuring point in the secondary circuit. It detects connection errors during commissioning or short circuits and interruptions in the secondary circuit. For summation of the voltages, the 3 phase-to-ground voltages and the residual voltage (da-dn - voltage of an open-circuited delta winding) are required.

The voltage measurement is based on the RMS values of the fundamental component.



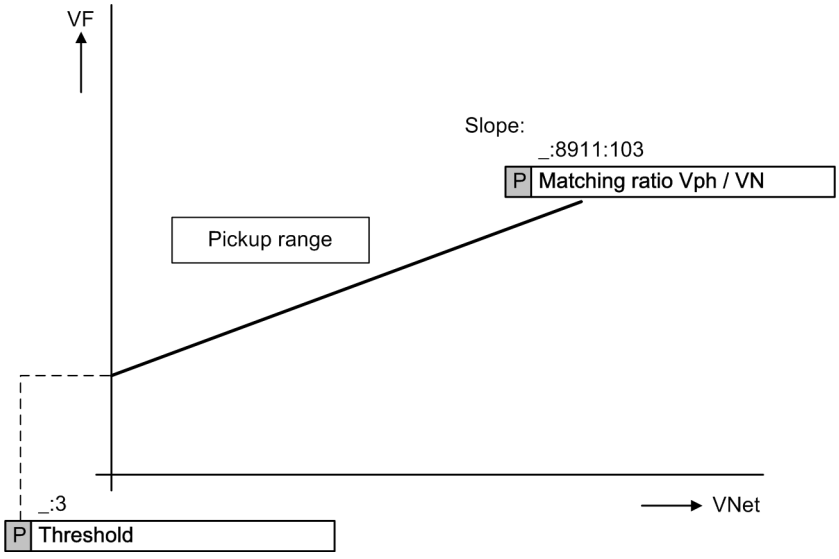
NOTE

For the **Voltage-sum supervision**, the externally generated residual voltage must be connected to the 4th voltage measuring input.

For the **Voltage-sum supervision** to work correctly, the **`Matching ratio Vph / VN`** parameter must be set accordingly.

8.3.7.2 Structure of the Function

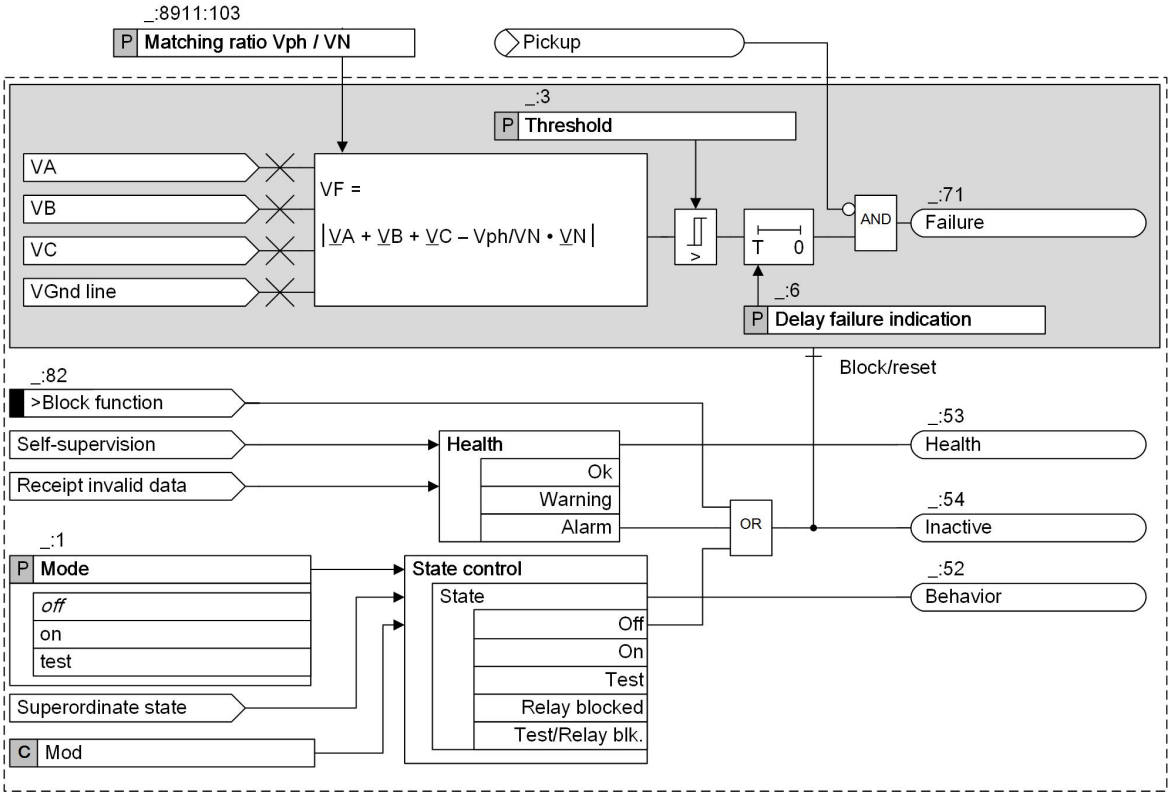
The **Voltage-sum supervision** function is located in the **Power-system data** function group of each 3-phase voltage measuring point.



[dw_strvss, 2, en_US]

Figure 8-19 Structure/Embedding of the Function

8.3.7.3 Function Description



The voltage sum is generated by addition of the voltage phasors. Errors in the voltage circuits are detected if VF = |$\underline{V}$A + $\underline{V}$B + $\underline{V}$C - Vph/VN • $\underline{V}$N| > **`Threshold`**, where Vph/VN forms the **`Matching ratio Vph / VN`** parameter.

[lo_kenvss-01.tif, 1, en_US]

Figure 8-20 Characteristic of the Voltage-Sum Supervision

Logic

[lo_volt-sum-supervision, 5, en_US]

Figure 8-21 Logic Diagram of the Voltage-Sum Supervision

The device measures the phase-to-ground voltage and the ground voltage of the lines to be protected. The sum of the 4 voltages must be 0.

Threshold

If the calculated fault voltage (V_F) exceeds the **Threshold** the parameter **Delay failure indication** triggers the indication **Failure**.

The device calculates the fault voltage (V_F) with the formula:

VF = |VA + VB + VC - Vph/UN • UN|, where Vph/VN forms the **Matching ratio Vph / VN** parameter.

The **Matching ratio Vph / VN** parameter takes into account the differing transformation ratios between the residual voltage input and the phase-voltage inputs.

You can find more information in this respect in chapter *8.3.7.1 Overview of Functions*).

Delay failure indication

When the threshold value for the delay of the failure indication (parameter: **Delay failure indication**) is exceeded, the indication **Failure** is generated.

Blocking the Function

The following blockings reset the picked up function completely:

- Externally or internally via the binary input signal *>Block function*
- A protection pickup
  The pickup signal of a protection function blocks the *Failure* indication.

8.3.7.4 Application and Setting Notes

Parameter: Threshold

- Recommended setting value **(_:3) Threshold** = ***25 V***

The **Threshold** parameter is used to set the voltage which the device uses to recognize the calculated fault voltage (V_F) as a failure of the voltage sums. Siemens recommends using the default setting.

Parameter: Delay failure indication

- Recommended setting value **(_:6) Delay failure indication** = ***5.00 s***

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

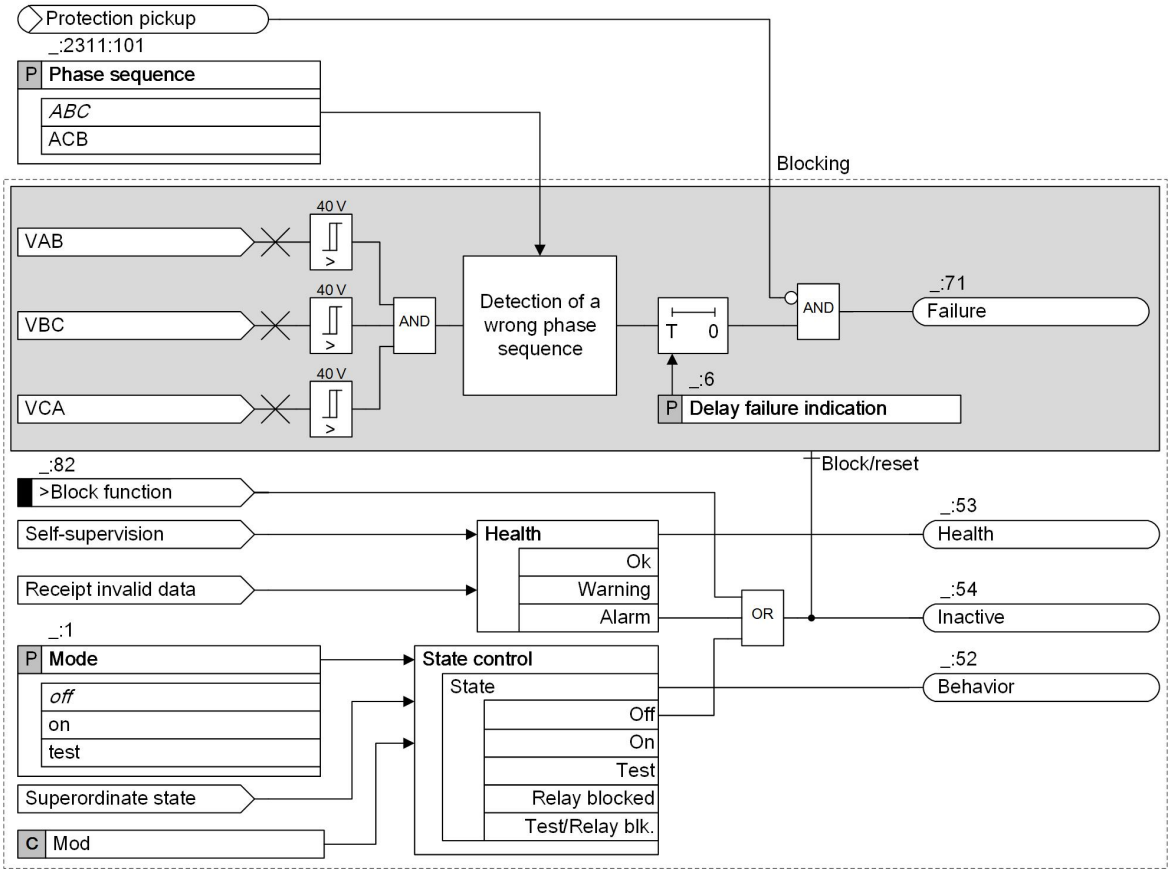
8.3.8 Voltage Phase-Rotation Supervision

8.3.8.1 Overview of Functions

The **Voltage phase-rotation supervision** function monitors the phase sequence of the secondary-circuit voltages by monitoring the sequence of the zero crossings (with same sign) of the voltages. This enables the device to detect connections that were inverted during commissioning. The criterion for the check is the setting of the **Phase sequence** parameter.

8.3.8.2 Structure of the Function

The **Voltage phase-rotation supervision** function is located in the **Power-system data** of each 3-phase voltage measuring point.



[dw_strvrs, 3, en_US]

Figure 8-22 Structure/Embedding of the Function

8.3.8.3 Function Description

Logic

[lo_volt-phs-rotation-supervision, 5, en_US]

Figure 8-23 Logic Diagram of the Voltage Phase-Rotation Supervision

The phase rotation is important for protection functions which process phase, loop, and directional information. You can set the phase sequence with the **Phase sequence** parameter in the function block **General** of the power-system data (see chapter *6.1 Power-System Data*).

To supervise the phase rotation, the device compares the measured phase sequence with the set phase sequence. For abnormal phase sequences, the indication *Failure* is generated.

The connection of the voltages to the device does not depend on the selected phase sequence. The connection diagrams are shown in chapter *A Appendix*.

Release Condition

The supervision of the voltage phase rotation is carried out when all measured phase-to-phase voltages are greater than 40 V.

Blocking of the Function

The following blockings reset the function completely:

- Via the binary input signal *>Block function* from an external or internal source
- Via a protection pickup
  The pickup signal from a protection function blocks the indication *Failure*.

Delay failure indication

When the device detects an inverted phase-rotation direction for the duration of the **Delay failure indication**, the indication *Failure* is generated.

8.3.8.4 Application and Setting Notes

Parameter: Delay failure indication

- Recommended setting value **(_:6) Delay failure indication** = *5.00 s*

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

8.3.9 Auxiliary Direct-Voltage Supervision

8.3.9.1 Overview of Functions

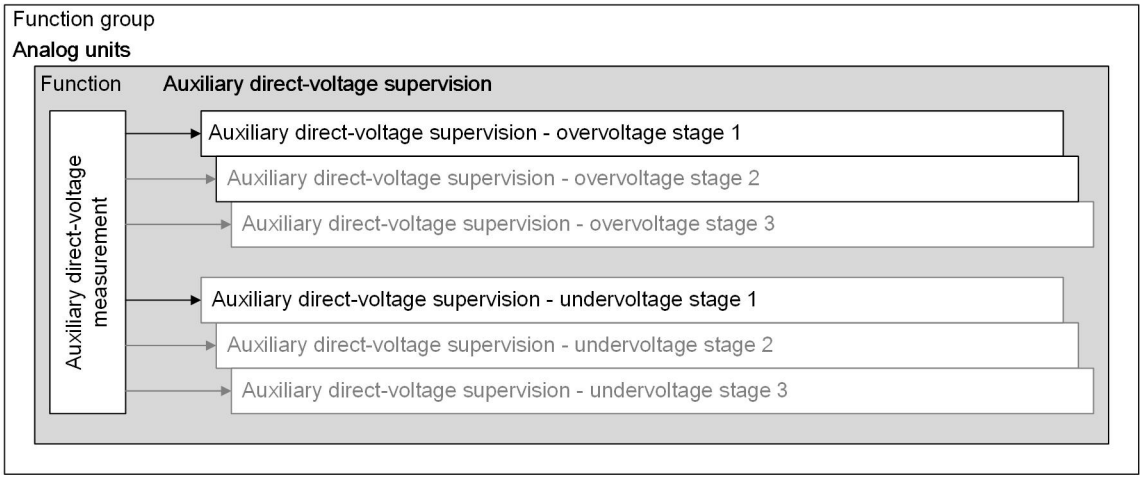
The function **Auxiliary direct-voltage supervision**:

- Measures the auxiliary direct-voltage of a substation battery system
- Provides sampled values for fault recording
- Monitors the battery direct-voltage by checking whether the measured voltage is greater or smaller than the specified threshold

The direct-voltage input is located on the plug-in module type ANAI-CE-2EL (1 input per module).

Once you have configured the plug-in module ANAI-CE-2EL, the function **Auxiliary direct-voltage supervision** is visible under the function group **Analog units**. You can find the function group **Analog units** in the **Settings** folder of the device in the DIGSI 5 project tree.

8.3.9.2 Structure of the Function



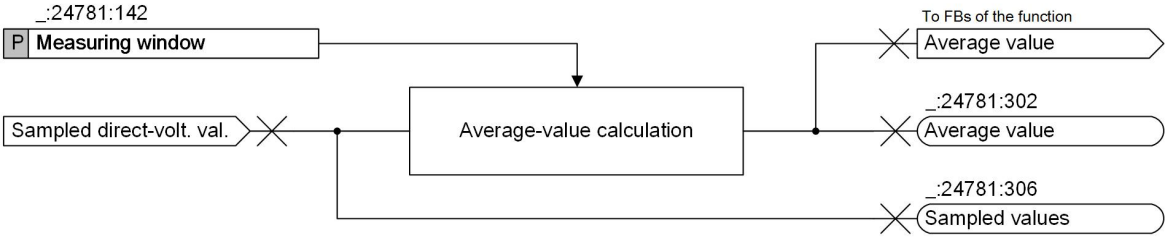
The function **Auxiliary direct-voltage supervision** can work only in the function group **Analog units**.

The function comes factory-set with 1 fixed function block **Auxiliary direct-voltage measurement**, 1 stage **Auxiliary direct-voltage supervision - overvoltage**, and 1 stage **Auxiliary direct-voltage supervision - undervoltage**.

The following stages can be operated simultaneously within the function:

- 3 stages **Auxiliary direct-voltage supervision - overvoltage**
- 3 stages **Auxiliary direct-voltage supervision - undervoltage**

Stages that are not preconfigured are shown in gray in the following figure. The stages are identical in structure.



[dw_DC supervision_Structure, 1, en_US]

Figure 8-24 Structure/Embedding of the Function

8.3.9.3 Auxiliary Direct-Voltage Measurement

Logic

[lo_DC voltage measurement, 1, en_US]

Figure 8-25 Logic Diagram of the Function Block Auxiliary Direct-Voltage Measurement

Calculation of Average Direct-Voltage Values

The FB **Auxiliary direct-voltage measurement** receives the sampled direct-voltage values from the interface of the plug-in module ANAI-CE-2EL and calculates an average value by a settable time interval (via the parameter **`Measuring window`**).

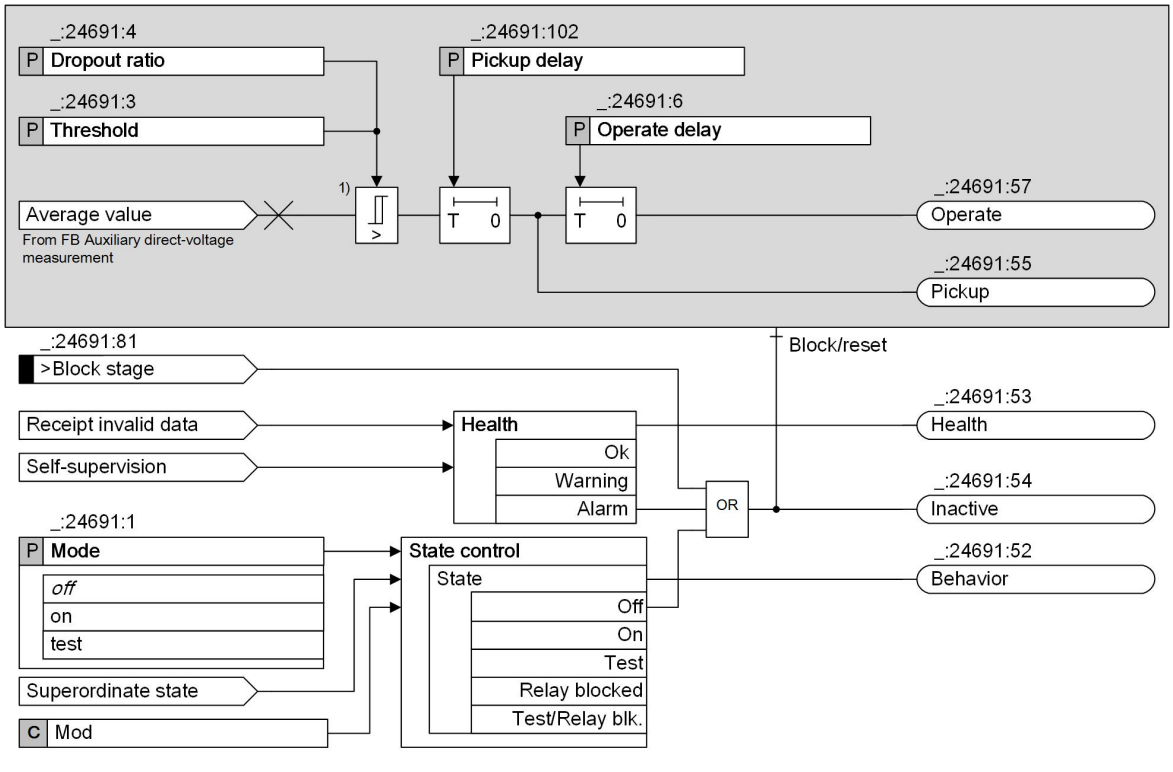
The calculation formula is:

$$V_{avg} = \frac{1}{m}\sum_{n=1}^{m} V_n$$

[fo_DC_volt_supervision, 1, en_US]

Where

V_{avg}	Average direct-voltage value
V_n	Sampled direct-voltage value in a measuring window
m	Number of sampled values in a measuring window



Functional Measured Value

Value	Description
Average value	Average value calculated from the sampled direct-voltage values

8.3.9.4 Stage Description

Logic

The logic of the stage **Auxiliary direct-voltage supervision - overvoltage** is the same as that of the stage **Auxiliary direct-voltage supervision - undervoltage**. The following figure shows the logic of the stage **Auxiliary direct-voltage supervision - overrvoltage** as an example.

[lo_DC supervision, 1, en_US]

Figure 8-26 Logic Diagram of the Stage Auxiliary Direct-Voltage Supervision - Overvoltage

(1) For the stage **Auxiliary direct-voltage supervision - undervoltage**, the symbol is:

Measurand

The stage obtains the average direct-voltage value from the FB **Auxiliary direct-voltage measurement**.

Pickup, Operate, Dropout

The stage compares the average direct-voltage value with the **Threshold**:

- **Overvoltage** stage
  If the average direct-voltage value exceeds the **Threshold**, the pickup delay (specified by the parameter **Pickup delay**) starts. If the value keeps exceeding the **Threshold** during the pickup delay, the pickup signal is issued.
- **Undervoltage** stage
  If the average direct-voltage value falls below the **Threshold**, the pickup delay (specified by the parameter **Pickup delay**) starts. If the value stays below the **Threshold** during the pickup delay, the pickup signal is issued.

Once the pickup signal is issued, the operate delay (specified by the parameter **Operate delay**) starts. After the expiration of the operate delay, the operate signal is issued.

With the parameter **Dropout ratio**, you can define the ratio of the dropout threshold to the **Threshold**.

NOTE

The pickup of the stages does not result in fault logging. The operate indications of the stages do not go into the trip logic of the device.

Blocking of the Stage

You can block the stage externally or internally via the binary input signal **>Block stage**. In the event of blocking, the picked up stage is reset.

8.3.9.5 Application and Setting Notes

Recording of Sampled Direct-Voltage Values

The recording of sampled direct-voltage values cannot be started via the pickup of stages. If you want to record the sampled direct-voltage values, you could use other starting methods. For more information about the methods, refer to *3.5 Fault Recording*.

Parameter: Measuring window

- Default setting **(_:24781:142) Measuring window** = ***20 ms***

With the parameter **Measuring window**, you set the measuring window that is used to determine the average value from the sampled values. If this parameter is set to ***20 ms***, the average value is calculated from the sampled values in the measuring window of 20 ms.

Extending the measuring window can improve the measurement accuracy but will increase the pickup time. If there are no specific requirements, Siemens recommends using the default setting of 20 ms.

Parameter: Threshold

- Default setting **(_:24691:3) Threshold** = ***264.0 V*** (for the **Overvoltage** stage)
- Default setting **(_:24721:3) Threshold** = ***176.0 V*** (for the **Undervoltage** stage)

Set the parameter **Threshold** for the specific application.

Parameter: Dropout ratio

- Default setting **(_:24691:4) Dropout ratio** = ***0.95*** (for the **Overvoltage** stage)
- Default setting **(_:24721:4) Dropout ratio** = ***1.05*** (for the **Undervoltage** stage)

For the **Overvoltage** stage, the recommended setting value of ***0.95*** is appropriate for most applications. To achieve high-precision measurements, the **Dropout ratio** can be reduced, for example, to ***0.98***.

For the **Undervoltage** stage, the recommended setting value of ***1.05*** is appropriate for most applications. To achieve high-precision measurements, the **Dropout ratio** can be reduced, for example, to ***1.02***.

Parameter: Pickup delay

- Default setting **(_:24691:102) Pickup delay** = ***0.00 s***

With the parameter **Pickup delay**, you define a time interval during which a pickup is not generated if the voltage exceeds the threshold (for the **Overvoltage** stage) or falls below the threshold (for the **Undervoltage** stage).

With the pickup delay, you can achieve that a short auxiliary-voltage disturbance will not be reported. If you want to detect all disturbances, use the default value of ***0.00 s***.

Parameter: Operate delay

- Default setting **(_:24691:6) Operate delay** = ***1.00 s***

The parameter **Operate delay** determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

NOTE

The pickup of the stages does not result in fault logging. The operate indications of the stages do not go into the trip logic of the device.

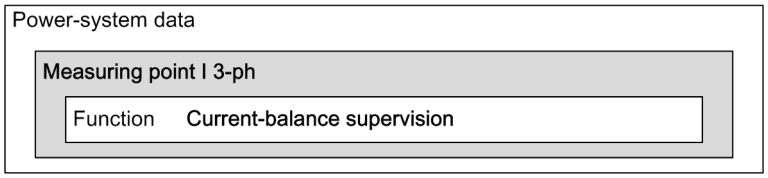
8.3.10 Current-Balance Supervision

8.3.10.1 Overview of Functions



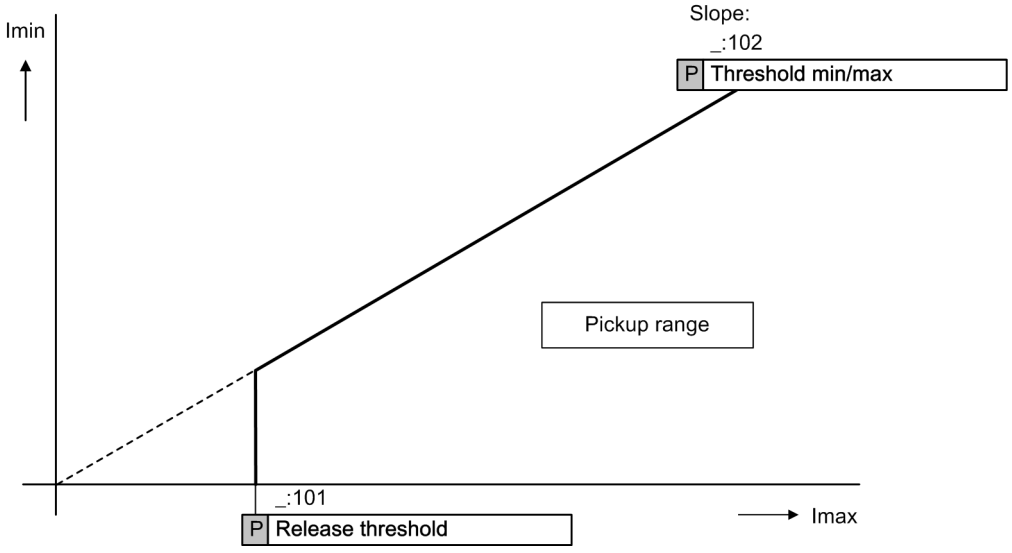
In healthy network operation, a certain balance between currents can be assumed.
The **Current-balance supervision** function detects the following errors:

- Unbalance of phase currents in the secondary circuit
- Connection errors during commissioning or short circuits and interruptions in the secondary circuit

The current measurement is based on the RMS values of the fundamental component.

8.3.10.2 Structure of the Function

The **Current-balance supervision** function is located in the **Power-system data** of each 3-phase current measuring point.

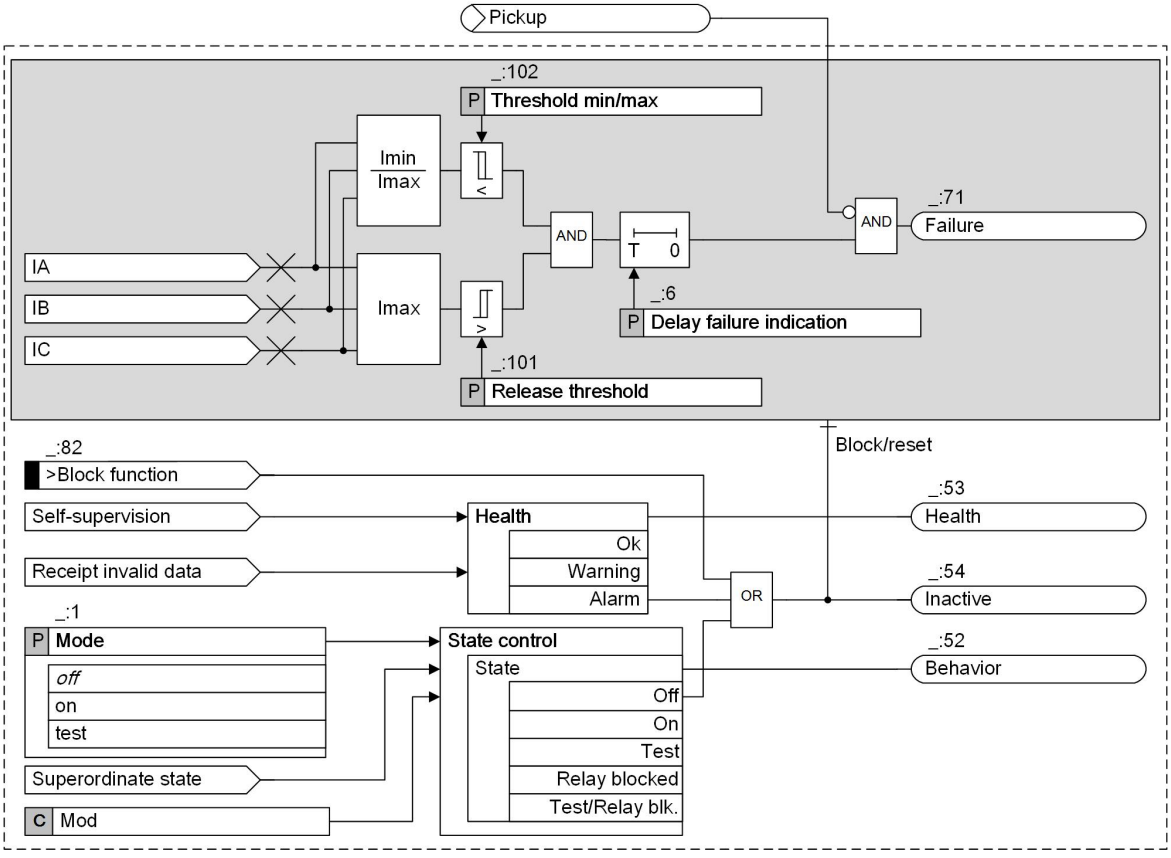


[dw_str_sym, 3, en_US]

Figure 8-27 Structure/Embedding of the Function

8.3.10.3 Function Description

The current balance is checked by a magnitude monitoring function. This function relates the smallest phase current to the largest phase current. Unbalance is detected if



|Imin| / |Imax| < **Threshold min/max**, as long as Imax > **Release threshold**.

[lo_symmke, 1, en_US]

Figure 8-28 Characteristic of the Current-Balance Supervision

Logic

[lo_cb_symm, 4, en_US]

Figure 8-29 Logic Diagram of the Current-Balance Supervision

The **Threshold min/max** parameter is the criterion by which unbalance in the phase currents is measured. The device calculates the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current.

Enter the lower limit of the maximum phase current (I_{max}) with the parameter **Release threshold**. This specifies the lower limit of the operating range of this function.

Delay failure indication

If it falls below the balance factor **Threshold min/max** at the same time as the maximum phase current exceeds the **Release threshold**, the operate delay of the failure indication (parameter **Delay failure indication**) starts. If both conditions persist during this time, the indication **Failure** is generated.

Blocking the Function

The following blockings completely reset the picked up function:

- Externally or internally via the binary input signal *>Block function*
- A protection pickup
  The pickup signal of a protection function blocks the indication *Failure*.

8.3.10.4 Application and Setting Notes

Parameter: Threshold min/max

- Recommended setting value **(_:102) Threshold min/max** = *0.5*

The **Threshold min/max** parameter is used to set the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current.

Parameter: Release threshold

- Recommended setting value **(_:101) Release threshold** = ***0.5 A*** for I_{rated} = 1 A or ***2.5 A*** for I_{rated} = 5 A

The **Release threshold** parameter is used to set the lower limit of the maximum phase current (I_{max}).

Parameter: Delay failure indication

- Recommended setting value **(_:6) Delay failure indication** = ***5.00 s***

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided.

8.3.10.5 Settings

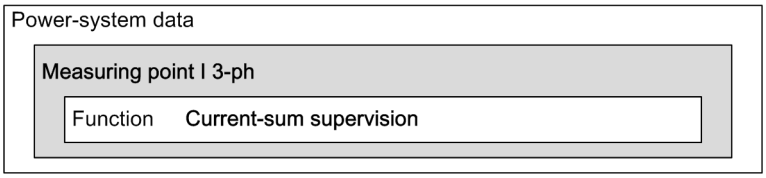
8.3.11 Current-Sum Supervision

8.3.11.1 Overview of Functions

In healthy system operation, the sum of all currents at one measuring point must be approximately 0. The **Current-sum supervision** function monitors the sum of all currents of one measuring point in the secondary circuit. It detects connection errors during commissioning or short circuits and interruptions in the secondary circuit.

For summation of the currents, the device requires the phase currents and the ground current of the current transformer neutral point or of a separate ground-current transformer at this measuring point. Select the following connection variant:



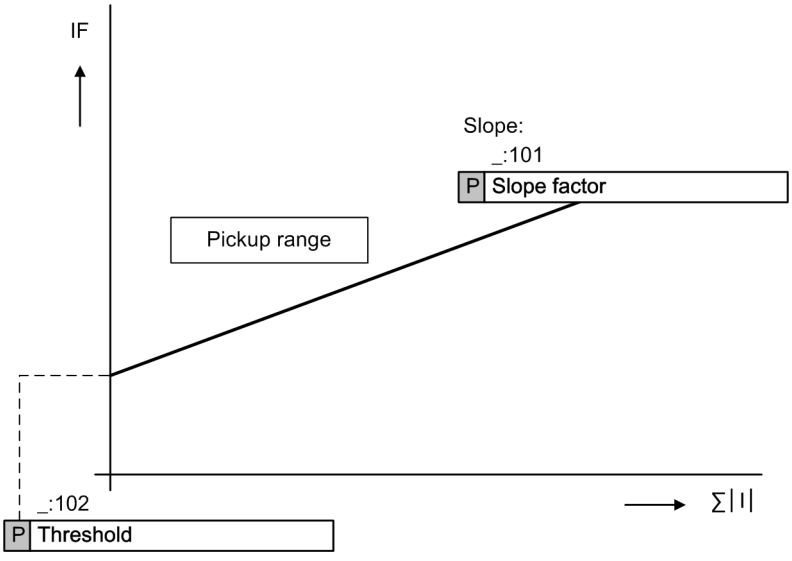
- Current-transformer connections connected to 3 current transformers and the neutral point (see *Figure A-10* in the *Attachment*)

NOTE

For current-sum supervision, the ground current of the line to be protected must be connected to the 4th current measurement input (I_N).

8.3.11.2 Structure of the Function

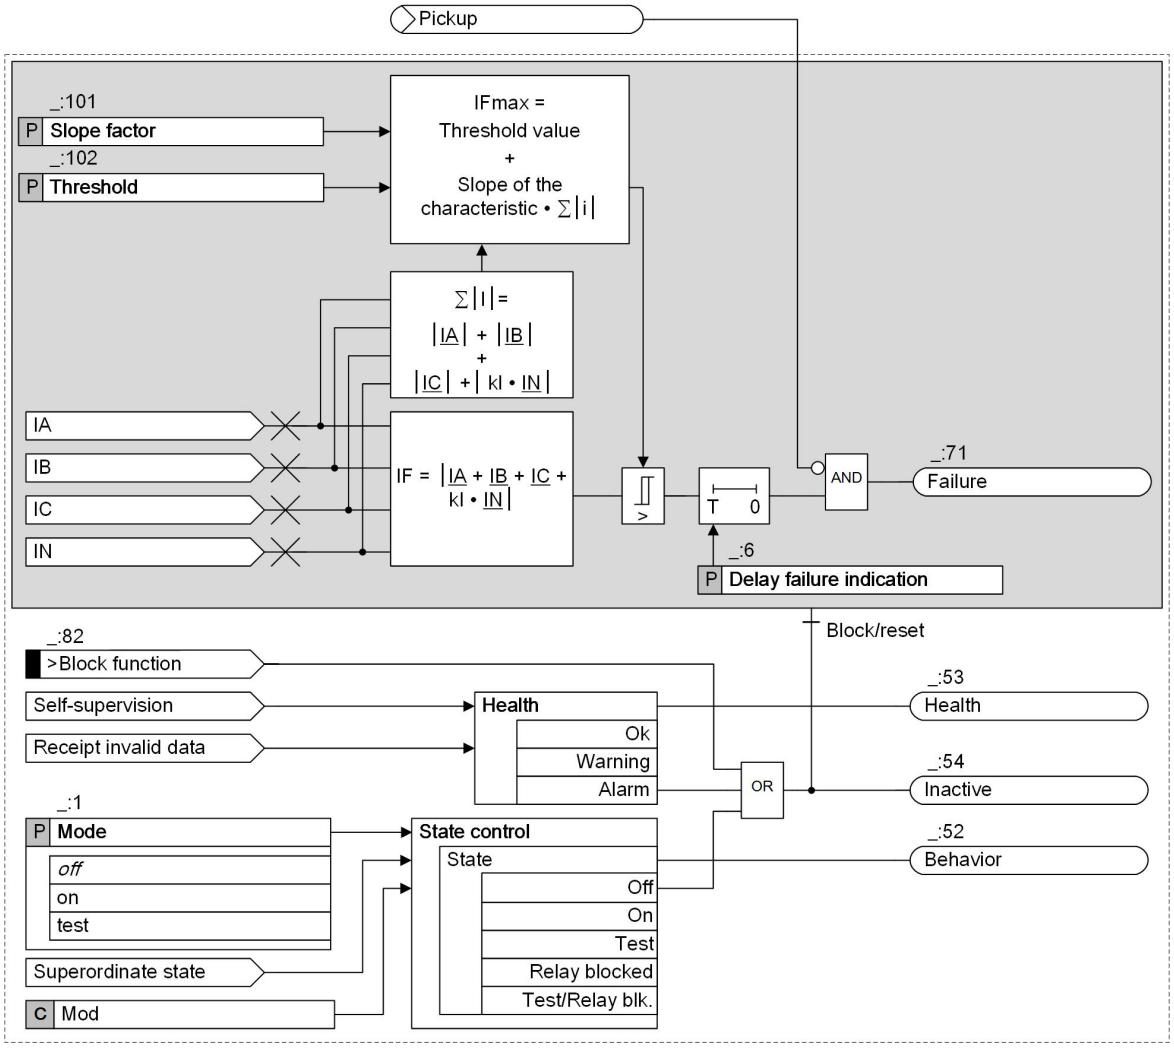
The **Current-sum supervision** function is located in the **Power-system data** of each 3-phase current measurement point.



[dw_str_css, 3, en_US]

Figure 8-30 Structure/Embedding of the Function

8.3.11.3 Function Description



The current sum is generated by addition of the current phasors. Errors in the current circuits are detected if IF = |IA + IB + IC + kI• IN| > **Threshold** + **Slope factor** •Σ | I |.

[lo_kensum, 1, en_US]

Figure 8-31 Characteristic of the Current-Sum Supervision

Logic

[lo_cs_summ, 4, en_US]

Figure 8-32 Logic Diagram of the Current-Sum Supervision

Slope of the Characteristic Curve

The **Slope factor** • Σ | I | part takes into account permissible current-proportional transformation errors of the transformer, which can occur in the case of high short-circuit currents.

The **Slope factor** and **Threshold** parameters are used to set the fault-current limit (I_{Fmax}) for the current-sum supervision. The device calculates this fault current limit with the formula:

I_{Fmax} = **Threshold** + **Slope factor** • Σ| I |

The device uses the current inputs (IA, IB, IC and IN) to calculate:

- The fault current IF = |IA + IB + IC + kI• IN|
- The maximum current Σ| I | = | IA| + |IB| +| IC| + |kI• IN|

with $\mathbf{k_I}$ taking into account a possible difference from the transformation ratio of a separated ground-current transformer (I_N), for example, cable type current transformer.

- Transformation ratio of zero-sequence current converter: $Ratio_N$
- Transformation ratio of phase-current converter: $Ratio_{ph}$

$$k_I = \frac{Ratio_N}{Ratio_{ph}}$$

[fo_glchki, 1, en_US]

Threshold

The **Threshold** parameter is the lower limit of the operating range of the **Current-sum supervision** function.

Delay failure indication

When the calculated fault current (I_F) exceeds the calculated fault current limit (I_{Fmax}), the delay of the failure indication (parameter: **Delay failure indication**) starts. If the threshold-value violation persists for that time, the **Failure** indication is generated.

Blocking the Function

The following blockings reset the picked up function completely:

- Externally or internally via the binary input signal *>Block function*
- A protection pickup
  The pickup signal of a protection function blocks the *Failure* indication.

8.3.11.4 Application and Setting Notes

Parameter: Slope factor

- Recommended setting value **(_:101) Slope factor** = ***0.1***

The **Slope factor** parameter is used to set the ratio between the minimum (I_{min}) and the maximum (I_{max}) phase current. This function calculates the RMS values.

Parameter: Threshold

- Recommended setting value **(_:102) Threshold** = ***0.1 A*** for I_{rated} = 1 A or ***0.5 A*** for I_{rated} = 5 A

The **Threshold** parameter is used to set the maximum phase current (I_{max}).

Parameter: Delay failure indication

- Recommended setting value **(_:6) Delay failure indication** = ***5.00 s***

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided.

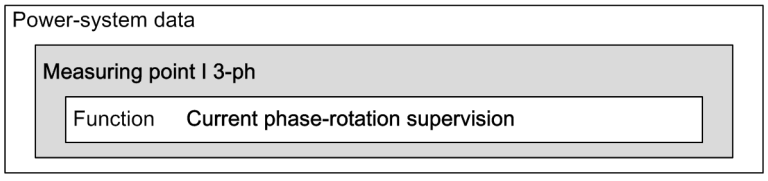
8.3.12 Current Phase-Rotation Supervision



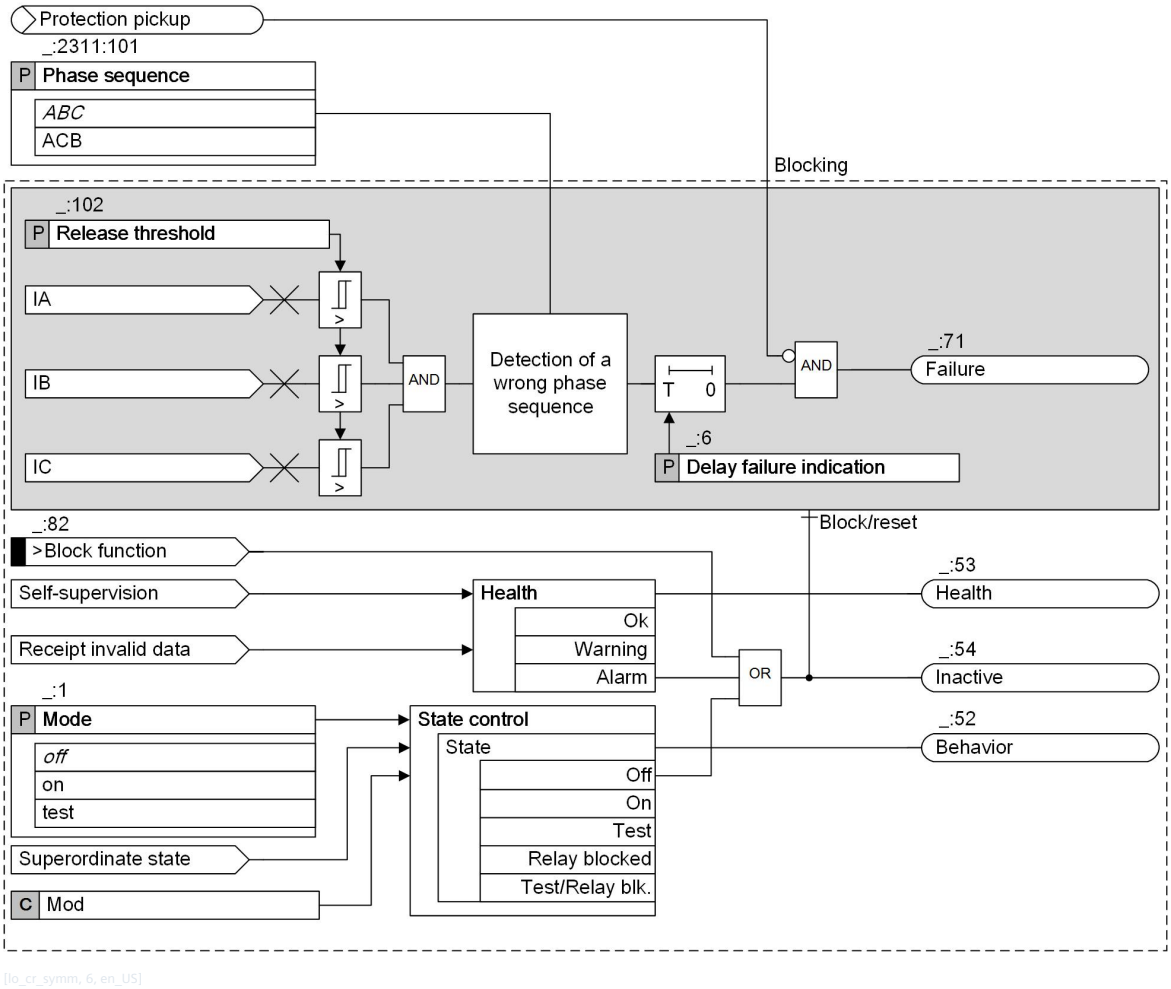
8.3.12.1 Overview of Functions

The **Current phase-rotation supervision** function monitors the phase sequence of the secondary-circuit currents by monitoring the sequence of the zero crossings (with same sign) of the currents. This enables the device to detect connections that were inverted during commissioning. The criterion for the check is the setting of the **`Phase sequence`** parameter.

The current measurement is based on the RMS values of the fundamental component.

8.3.12.2 Structure of the Function

The **Current phase-rotation supervision** function is located in the **Power-system data** of each 3-phase current measurement point.



[dw_str_crs, 4, en_US]

Figure 8-33 Structure/Embedding of the Function

8.3.12.3 Function Description

Logic

[lo_cr_symm, 6, en_US]

Figure 8-34 Logic Diagram of the Current Phase-Rotation Supervision

The phase rotation is important for protection functions which process phase, loop, and directional information. You can set the phase sequence with the **`Phase sequence`** parameter in the function block **General** of the power-system data (see *6.1 Power-System Data*).

To supervise the phase rotation, the device compares the measured phase sequence with the set phase sequence. For abnormal phase sequences, the indication *`Failure`* is generated.

The connection of the currents to the device does not depend on the selected phase sequence. For connection diagrams see *A Appendix*.

Release Condition

The supervision of the current phase rotation is carried out when all measured phase currents are greater than the value of the **`Release threshold`** parameter.

Blocking of the Function

The following blockings reset the function completely:

- Via the binary input signal *`>Block function`* from an external or internal source
- Via a protection pickup
  The pickup signal from a protection function blocks the indication *`Failure`*.

Delay failure indication

When the device detects an inverted phase sequence for the duration of the **Delay failure indication**, the indication *Failure* is generated.

8.3.12.4 Application and Setting Notes

Parameter: Release threshold

- Default setting **(_:102) Release threshold** = ***0.500 A*** for I_{rated} = 1 A or ***2.50 A*** for I_{rated} = 5 A

With the **Release threshold** parameter, you specify the lower limit of the phase current for phase-rotation supervision.

Parameter: Delay failure indication

- Default setting **(_:6) Delay failure indication** = ***5.00 s***

Set the **Delay failure indication** parameter so that overfunctions due to disturbing influences (such as switching operations) are avoided. Siemens recommends using the default setting.

8.3.13 Saturation Detection

8.3.13.1 Overview of Functions

The **Saturation detection** function evaluates the profile of the current signals and determines whether the current transformer is saturated.

Protection functions such as the **Line differential protection** require this information for their selective function.

8.3.13.2 Structure of the Function

[dwstr saett, 2, en_US]

Figure 8-35 Structure of the Function

The **Saturation detection** function is located in the **Power-system data** of each 3-phase current measuring point.

The **Saturat. det.** block is visible in the measuring point **Current 3-phase** only if the **I-DIFF fast 2** stage is instantiated in the **Line differential protection** function or if the **S-DIFF fast 2** stage is instantiated in the **Stub-differential protection** function.

8.3.13.3 Function Description

If current-transformer saturation occurs, this leads to an erroneous representation of the primary-current history. With this, typical signal distortions of the current-signal profile occur.

The **Saturation detection** function searches for these typical signal distortions in the current signals of the 3 phases. If the **Saturation detection** function detects the typical signal distortions, it transmits corresponding internal information to the protection functions. The protection functions evaluate this information and react if saturation is detected.

The **Saturation detection** does not operate until a configurable minimum current (parameter: **CT saturation threshold**) is exceeded.

8.3.13.4 Application and Setting Notes

Parameter: CT saturation threshold

- Default setting **(_:17731:101) CT saturation threshold** = ***8.0 A***

The **CT saturation threshold** parameter is in the **Saturat. det.** block and is only visible if the **I-DIFF fast 2** stage is instantiated in the **Line differential protection** function or if the **S-DIFF fast 2** stage is instantiated in the **Stub-differential protection** function.

With the **CT saturation threshold** parameter, you set the current threshold for the saturation detection. If the set value is exceeded, the saturation detection becomes active.

Calculate the setting value for the parameter **CT saturation threshold** according to the following formula:

$$I_{saturation\ >} = \frac{n'}{k_{CT}} \cdot I_{rated}$$

[fo_sup isaet, 1, en_US]

where:

k_{CT} Minimum current factor

n' Effective accuracy limiting factor

The effective accuracy limiting factor n´ is calculated as follows:

$$n' = n \cdot \frac{S_{rated} + S_i}{S' + S_i}$$

[fo_saet n, 1, en_US]

where:

n	Rated overcurrent factor
S_{rated}	Rated burden of the current transformers [VA]
S_i	Inherent burden of the current transformers [VA]
S'	Actually connected burden (protection device + secondary lines)

The minimum current factor k_{CT} establishes the relationship between the different classes of conventional primary current transformers and the expected minimum current that can result in saturation of the transformer.

Closed iron core transformers such as **X**, **P**, **PX**, **PS** and **TPS** are combined in the current-transformer class **TPX**. These transformers have a large amount of remanence and a large secondary time constant.

Conventional current transformers with an anti-remanence gap such as the **TPY** and the **PR** limit the maximum possible remanence to 10 %. The minimum expected current that can result in saturation of the transformer is greater for this current-transformer class.

Due to its linear characteristic curve, the current-transformer class of the linear transformers **TPZ** transforms the alternating-current component of the primary current very well. The direct-current component of the current is greatly reduced. Depending on the connected burden, saturation occurs just below the operational overcurrent.

The following table shows the minimum current factor k_{CT} for the different current-transformer classes:

Current-Transformer Class	TPX	TPY	TPZ
k_{CT}	5	3	1.5

8.3.13.5 Settings

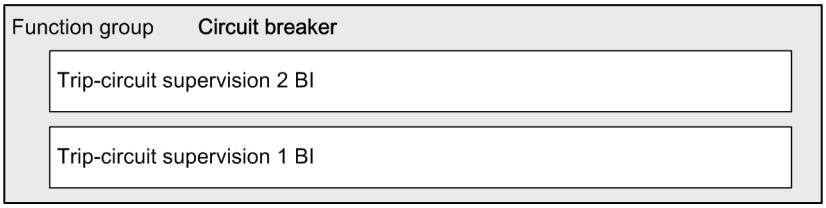
		1 A @ 50 Irated	1.200 A to 50.000 A	8.000 A
		5 A @ 50 Irated	6.00 A to 250.00 A	40.00 A

8.3.14 Trip-Circuit Supervision



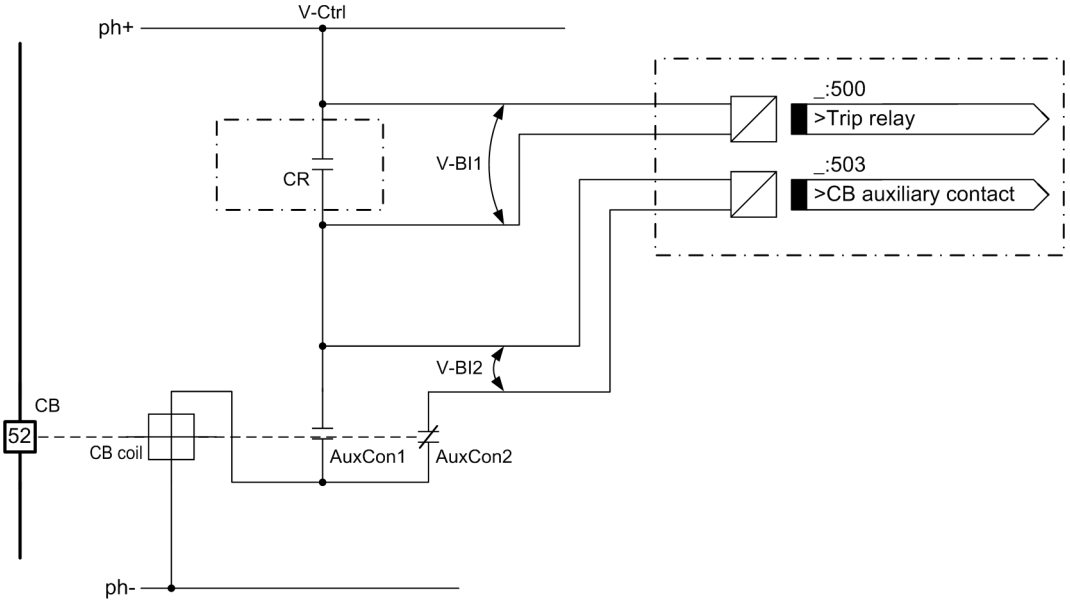
8.3.14.1 Overview of Functions

The **Trip-circuit supervision** function recognizes disruptions in the trip circuit. When 2 binary inputs are used, the function recognizes all disruptions in the trip circuit. If only 1 binary input is available, it will not recognize disruptions at the circuit breaker.

The control voltage for the circuit breaker must be greater than the sum of the minimum voltage drops at the binary inputs $V_{Ctrl} > 2\ V_{BImin}$. At least 19 V are required for each binary input. This makes the supervision usable only with a system-side control voltage of > 38 V.

8.3.14.2 Structure of the Function

The trip-circuit supervision is integrated into the **Circuit-breaker** function group. Depending on the number of available binary inputs, it works with 1 or 2 binary inputs.



[dw_tcsueb, 1, en_US]

Figure 8-36 Structure/Embedding of the Function

8.3.14.3 Trip-Circuit Supervision with 2 Binary Inputs

In order to recognize disruptions in the trip circuit for each switch position, you need 2 binary inputs. One input is connected parallel to the respective command relay of the protection, the other parallel to the circuit-breaker auxiliary contact.

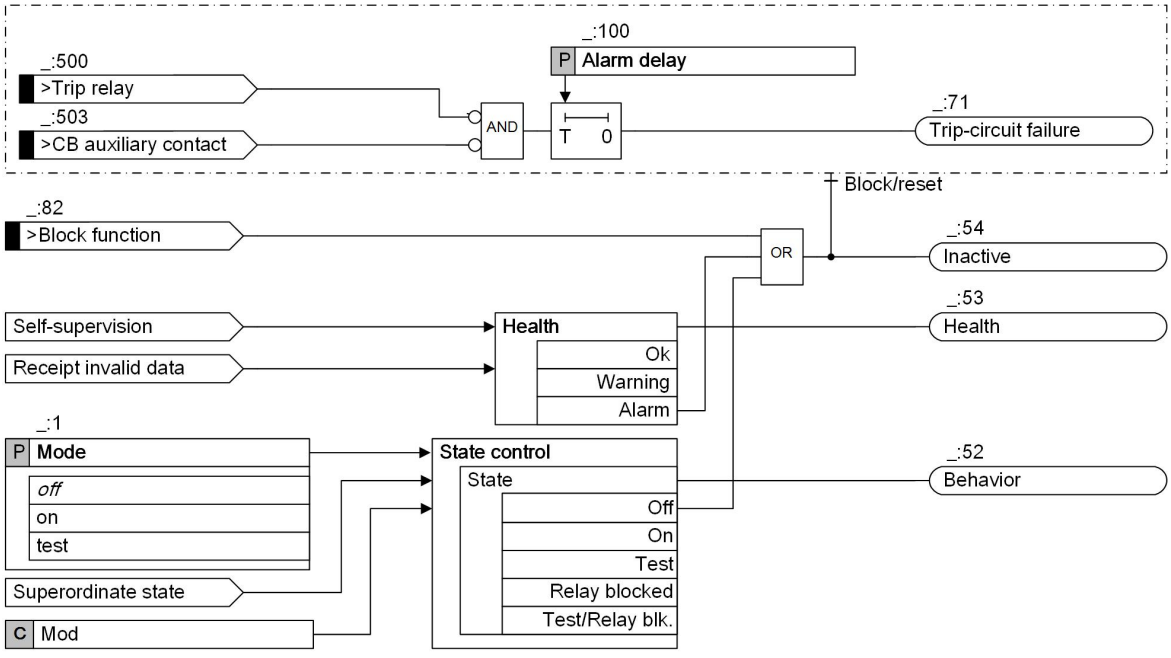
The following figure shows the principle of the trip-circuit supervision with 2 binary inputs.

[dw_tcs_2be, 3, en_US]

Figure 8-37 Principle of Trip-Circuit Supervision with 2 Binary Inputs

CR	Command relay
CB	Circuit breaker (open)
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (make contact)
AuxCon2	Circuit-breaker auxiliary contact (break contact)
V-Ctrl	Control voltage (tripping voltage)
V-BI1	Input voltage for binary input 1
V-BI2	Input voltage for binary input 2

Supervision with 2 binary inputs identifies disruptions in the trip circuit and the outage of the control voltage. It also monitors the reaction of the circuit breaker by way of the position of the circuit-breaker auxiliary contacts.



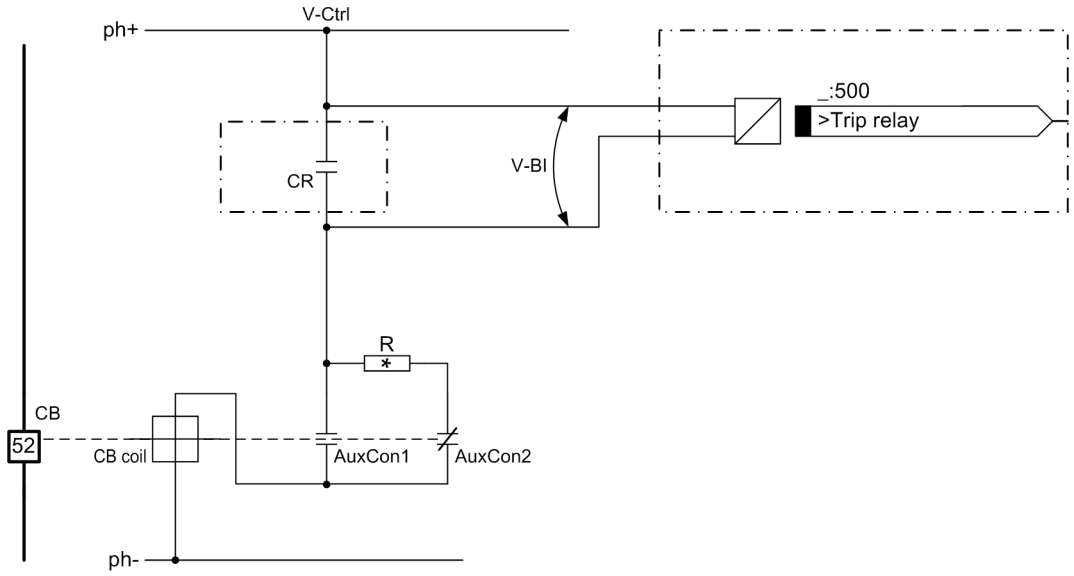
Depending on the switch position of the command relay and circuit breaker, the binary inputs are either activated (**H**) or not (**L**). If both binary inputs are not activated, there is a fault. The fault can be a disruption or a short circuit in the trip circuit, an outage of the battery voltage or a fault in the mechanics of the circuit breaker. With intact trip circuits, this state will occur only briefly while the command relay is closed and the circuit breaker has not yet been opened.

No.	Command Relay (CR)	CB	AuxCon1	AuxCon2	BI 1	BI 2	Dynamic State	Static State
1	Open	ON	Closed	Open	H	L	Normal operation with closed circuit breaker	
2	Open	OFF	Open	Closed	H	H	Normal operation with open circuit breaker	
3	Closed	ON	Closed	Open	L	L	Transmission or fault	Fault
4	Closed	OFF	Open	Closed	L	H	CR successfully activated the circuit breaker	

With the **`Alarm delay`** parameter, you can set the time delay. After fixing the fault in the trip circuit, the failure indication will automatically expire after the same time.

If the binary input signals *`>Trip relay`* or *`>CB auxiliary contact`* are not routed on the binary inputs of the device, then the *`Input sig. not routed`* indication is generated and the **Trip-circuit supervision** function is ineffective.

The following figure shows the logic diagram of the trip-circuit supervision with 2 binary inputs.



[lo_tcs_2be, 2, en_US]

Figure 8-38 Logic Diagram of Trip-Circuit Supervision with 2 Binary Inputs

8.3.14.4 Trip-Circuit Supervision with 1 Binary Input

When using 1 binary input, you will not identify any disruptions on the circuit breaker. The binary input is connected in parallel with the respective command relay of the protection device. The circuit-breaker auxiliary contact is bridged with a high-resistance equivalent resistance R.

The following figure shows the principle of the trip-circuit supervision with 1 binary input.

[dw_tcs_1be, 3, en_US]

Figure 8-39 Principle of Trip-Circuit Supervision with 1 Binary Input

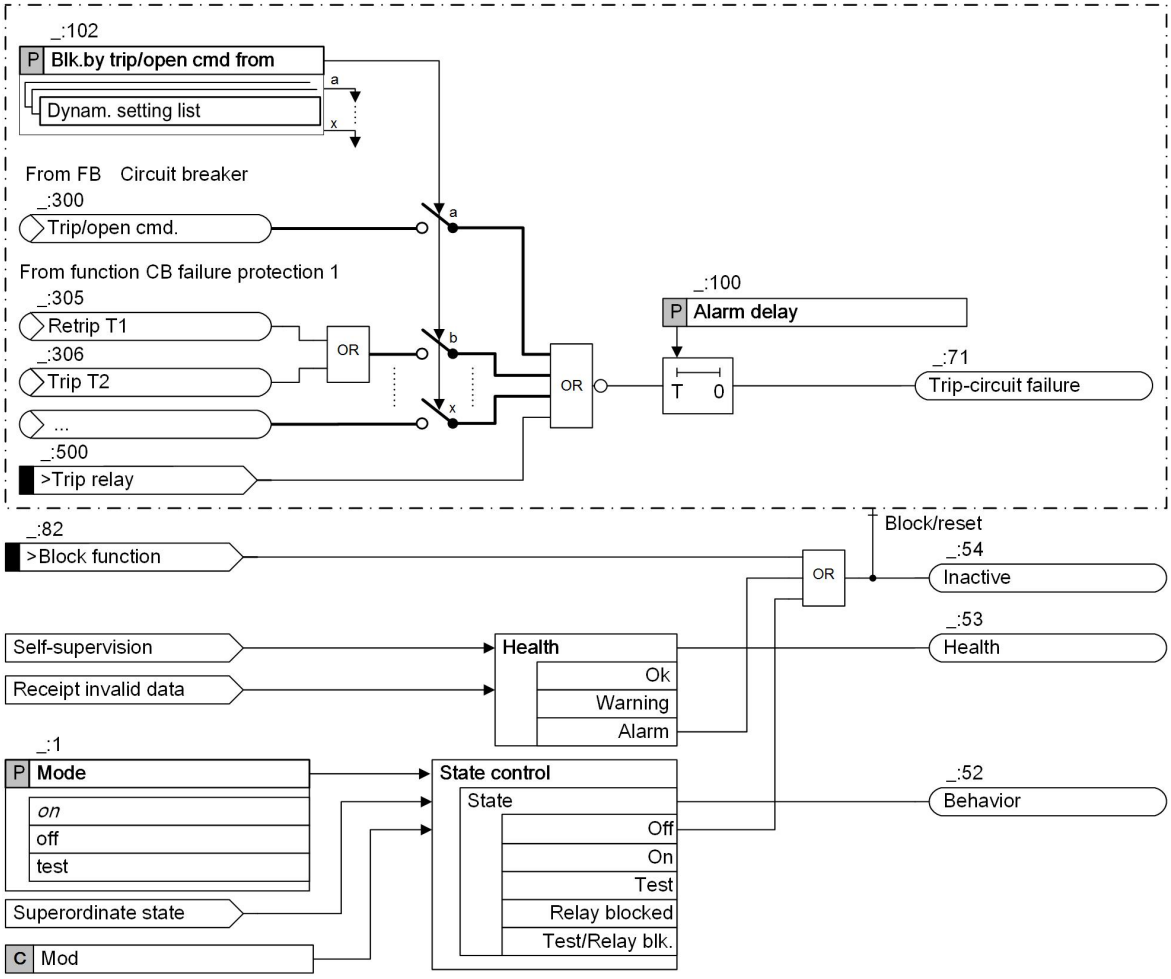
CR	Command relay
CB	Circuit breaker (open)
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (make contact)
AuxCon2	Circuit-breaker auxiliary contact (break contact)
V-Ctrl	Control voltage (tripping voltage)
V-BI	Input voltage for binary input
R	Equivalent resistance

The supervision with 1 binary input identifies disruptions in the trip circuit and the outage of the control voltage.

In normal operation, the binary input is activated with the command relay open and the trip circuit intact (**H**). The supervision circuit is closed with the equivalent resistance R or with the auxiliary contact AuxCon1 of the closed circuit breaker. The binary input is not activated while the command relay is closed (**L**). If the binary input is not activated for a prolonged time, there is a disruption in the trip circuit or the control voltage has failed.

No.	Command Relay	CB	AuxCon1	AuxCon2	BI	Dynamic State	Static State
1	Open	ON	Closed	Open	H	Normal operation with closed circuit breaker	
2	Open	OFF	Open	Closed	H	Normal operation with open circuit breaker	
3	Closed	ON	Closed	Open	L	Transmission or fault	Fault
4	Closed	OFF	Open	Closed	L	CR successfully activated the circuit breaker	

Use the parameter **`Blk.by trip/open cmd from`** to set the conditions under which the trip-circuit supervision is blocked. The following conditions can cause a blocking of the trip-circuit supervision function:



- The *`Trip/open cmd.`* of the circuit breaker is activated.
- One of the trip commands of the circuit-breaker failure protection is activated.

As long as the trip-circuit supervision function is blocked, the closed contact of the command relay does not cause a failure indication.

If the command contacts of other devices work in parallel on the trip circuit, the failure indication must be delayed. With the **`Alarm delay`** parameter, you can set the time delay. After fixing the fault in the trip circuit, the failure indication will automatically expire after the same time.

If the binary input signal *`>Trip relay`* is not routed to a binary input of the device (**information routing** in DIGSI 5), then the *`Input sig. not routed`* indication is generated and the **Trip-circuit supervision** function is not in effect.

The following figure shows the logic diagram of the trip-circuit supervision with 1 binary input.

[lo_tcs_1be, 2, en_US]

Figure 8-40 Logic Diagram of Trip-Circuit Supervision with 1 Binary Input

Equivalent Resistance R

The equivalent resistance R must be dimensioned such that the circuit-breaker coil is no longer activated when the circuit breaker is open. Simultaneously, the binary input must still be activated when the command relay is open.

In order to ensure the minimum voltage for activating the binary input, R_{max} results in:

$$R_{max} = \left(\frac{V_{Ctrl} - V_{BI\,min}}{I_{BI(High)}} \right) - R_{CBC}$$

[fo_r_max, 1, en_US]

So that the circuit-breaker coil does not remain activated, R_{min} results in:

$$R_{min} = R_{CBC} \cdot \left(\frac{V_{Ctrl} - V_{CBC(Low\ max)}}{V_{CBC(Low\ max)}} \right)$$

[fo_r_min, 1, en_US]

with:

V_{Ctrlst}	Control voltage for the trip circuit
$V_{BI\ min}$	Minimum activate voltage for BI
R_{CBC}	Ohm's resistance of the CB coil
$I_{BI(High)}$	Constant current with activated BI
$V_{CBC\ (Low\ max)}$	Maximum voltage at the CB coil that does not lead to a tripping

You can calculate the optimal value for the equivalent resistance R from the 2 values R_{min} and R_{max}:

$$R = \frac{R_{max} + R_{min}}{2}$$

[fo_r, 1, en_US]

The following applies for the power consumption of the equivalent resistance R:

$$P_R = I^2 \cdot R = \left(\frac{V_{Ctrl}}{R + R_{CBC}} \right)^2 \cdot R$$

[fo_pr, 1, en_US]

8.3.14.5 Application and Setting Notes

Parameter: Alarm delay

- Recommended setting value **(_:100) Alarm delay** = ***2 s*** (Trip-circuit supervision with 2 binary inputs)
- Recommended setting value **(_:100) Alarm delay** = ***300 s*** (Trip-circuit supervision with 1 binary input)

With the parameter **Alarm delay**, you can set the time for the delayed output of the indication *Trip-circuit failure*.

For **Trip-circuit supervision with 2 binary inputs**, you set the **Alarm delay** parameter so that the short-term transient states do not cause the function to activate.

For the **Trip-circuit supervision with 1 binary input,** you set the **Alarm delay** so that the longest duration of a trip command is bridged without fail. This ensures that the indication is emitted only if the trip circuit is actually interrupted.

Parameter: Blk.by trip/open cmd from

- Possible settings, application-dependent

The parameter works only with the trip-circuit supervision with 1 binary input.

Use the parameter **Blk.by trip/open cmd from** to set the conditions under which the trip-circuit supervision is blocked. The following conditions can cause a blocking of the trip-circuit supervision function:

- The *Trip/open cmd.* of the circuit breaker is activated.
- One of the trip commands of the circuit-breaker failure protection is activated.
- One of the trip commands of the circuit-breaker reignition protection is activated.

The circuit-breaker failure protection is set to protect a different trip circuit than the local circuit breaker. Using the configuration options of the **Blk.by trip/open cmd from** parameter, multiple trip-circuit supervision functions can be operated in parallel. For instance, a trip-circuit supervision function dedicated to a local

circuit breaker can also be operated parallel to a higher-level circuit breaker upon which the circuit-breaker failure protection acts.

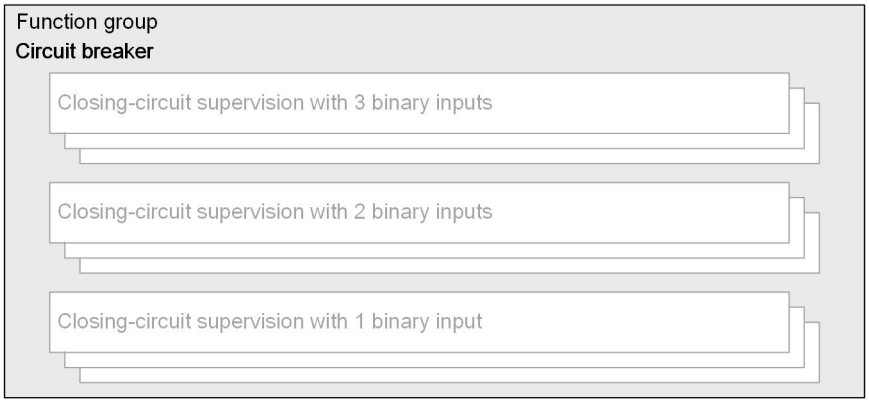
8.3.15 Closing-Circuit Supervision

8.3.15.1 Overview of Functions

The function **Closing-circuit supervision** detects disruptions in the closed circuit of the circuit breaker.



The control voltage for the closed circuit must be greater than the sum of the minimum voltage drops at the binary inputs, that is, $V_{Ctrl} > 2 \cdot V_{high}$ or $V_{Ctrl} > 3 \cdot V_{high}$ depending on the number of available binary inputs .

8.3.15.2 Structure of the Function

The function **Closing-circuit supervision** is integrated into the function group **Circuit breaker**. Depending on the available number of the binary inputs, the function works with 3 binary inputs, 2 binary inputs or 1 binary input.

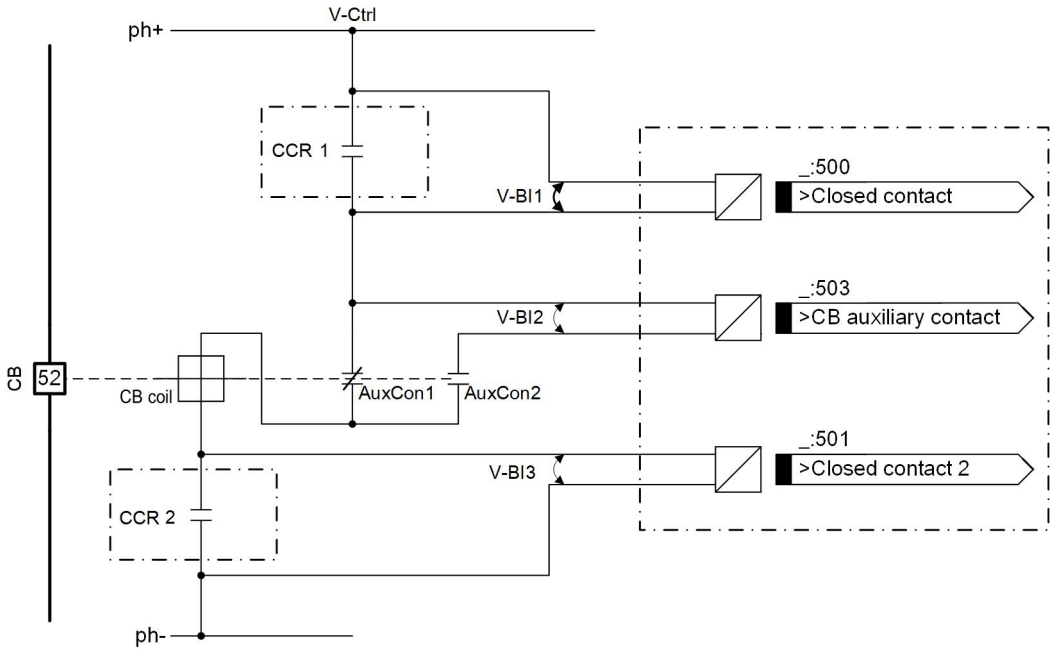
The following stages can be operated simultaneously in the function group **Circuit breaker**:

- Maximum of 3 stages **Closing-circuit supervision with 3 binary inputs**
- Maximum of 3 stages **Closing-circuit supervision with 2 binary inputs**
- Maximum of 3 stages **Closing-circuit supervision with 1 binary input**

[dw_CCS_structure_3BI, 1, en_US]

Figure 8-41 Structure/Embedding of the Function

8.3.15.3 Closing-Circuit Supervision with 3 Binary Inputs



Precondition

To use the function block **Closing-circuit supervision with 3 binary inputs**, set the control voltage larger than 3 times the voltage of the binary input ($V_{Ctrl} > 3 \cdot V_{high}$).

In the following descriptions, the minimum V_{high} of the binary input is 19 V.

Closing-Circuit Supervision with 3 Binary Inputs

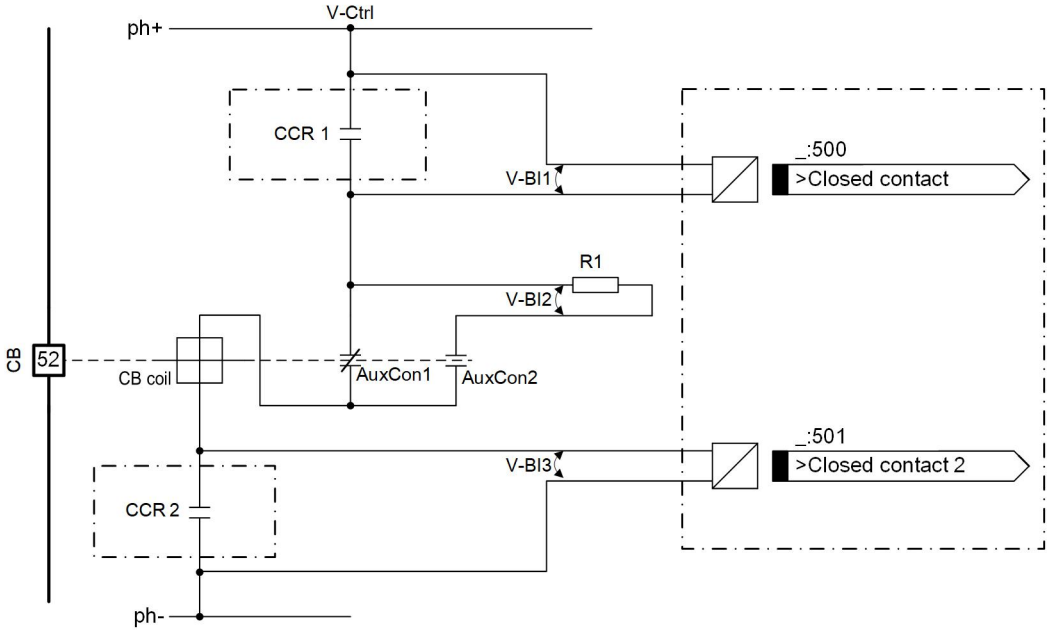
In order to recognize disruptions in the closed circuit for each switch position, you need 3 binary inputs. 2 inputs are connected parallel to the respective command relays of the protection, another is connected parallel to the circuit-breaker auxiliary contact.

[dw_closed-circuit supervision_3BIs, 2, en_US]

Figure 8-42 Principle of the Closing-Circuit Supervision with 3 Binary Inputs

CCR 1	Closed-command relay 1
CCR 2	Closed-command relay 2
CB	Circuit breaker (closed)
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (closed if the CB is closed)
AuxCon2	Circuit-breaker auxiliary contact (open if the CB is closed)
V-Ctrl	Control voltage (tripping voltage)
V-BI1	Input voltage for binary input 1
V-BI2	Input voltage for binary input 2
V-BI3	Input voltage for binary input 3

The stage **Closing-circuit supervision with 3 binary inputs** identifies disruptions in the closed circuit and the outage of the control voltage. It also monitors the reaction of the circuit breaker by way of the position of the circuit-breaker auxiliary contacts.



Depending on the switch position of the closed-command relay and the circuit breaker, the binary inputs are either activated (**H**) or deactivated (**L**). If both binary inputs are deactivated, a fault occurs. The fault can be a disruption or a short circuit in the closed circuit, a failure of the voltage of the binary inputs or a fault in the mechanics of the circuit breaker. With intact closed circuits, this state occurs only briefly while the command relay is closed and the circuit breaker is not opened.

Closed Command	CB	AuxCon1	AuxCon2	>Closed contact	>Closed contact 2	>CB auxiliary contact	State
No	Closed	Closed	Open	H	H	H	Normal operation with closed circuit breaker
No	Open	Open	Closed	H	H	L	Normal operation with open circuit breaker
Yes	Open	Open	Closed	L	L	L	Transient process
Yes	Closed	Closed	Open	L	L	H	Transient process
No	–	–	–	L	L	–	Fault

Closed Command	CB	AuxCon1	AuxCon2	>Closed contact	>Closed contact 2	>CB auxiliary contact	State
No	–	–	–	H	L	–	Fault
No	–	–	–	L	H	–	Fault

Closing-Circuit Supervision with 2 Binary Inputs and 1 Resistance

In *Figure 8-42*, when the circuit breaker is closed, the binary input *>CB auxiliary contact* is used to form the complete supervision circuit and limit the inductive current. Therefore, the function **Closing-circuit supervision** also works with 2 binary inputs and 1 resistance.

[dw_closed-circuit supervision_2BIs, 2, en_US]

Figure 8-43 Principle of the Closing-Circuit Supervision with 2 Binary Inputs and 1 Resistance

CCR 1	Closed-command relay 1
CCR 2	Closed-command relay 2
CB	Circuit breaker (closed)
CB coil	Circuit-breaker coil
AuxCon1	Circuit-breaker auxiliary contact (closed if the CB is closed)
AuxCon2	Circuit-breaker auxiliary contact (open if the CB is closed)
R	Equivalent resistance
V-Ctrl	Control voltage (tripping voltage)
V-BI1	Input voltage for binary input 1
V-BI2	Input voltage for binary input 2
V-BI3	Input voltage for binary input 3

Equivalent Resistance R

The equivalent resistance R must be dimensioned in such a way that the circuit-breaker coil is no longer activated when the circuit breaker is open. Simultaneously, the binary input must still be activated when the command relay is open.

In order to ensure the minimum voltage for activating the binary input, R_{max} results in:

$$R_{max} = \left(\frac{V_{Ctrl} - 2 \cdot V_{BImin}}{I_{BI(High)}}\right) - R_{CBC}$$

[fo_closed_circuit_supervision_1, 2, en_US]

If there is no closed command, the current flows via the binary inputs. Then the circuit current is limited to 2.5 mA at most. The closed circuit-breaker coil remains activated.
The following formula applies for the power consumption of the equivalent resistance R:

$$P_R = I^2 \times R$$

[fo_closed_circuit_supervision_2, 1, en_US]

In the following examples, you can find the calculation of R under different control voltages.

- **The control voltage is 110 V.**
  In the following example, if R_{CBC} is 90 Ω, R_{max} is calculated as follows:

  $$R_{max} = \left(\frac{V_{Ctrl} - 2 \cdot V_{BImin}}{I_{BI(High)}}\right) - R_{CBC} = \frac{110\ V - 2 \cdot 19\ V}{2.5\ mA} - 0.09\ k\Omega = 28.71\ k\Omega$$

  [fo_closed_circuit_supervision_RMax_110V, 2, en_US]

  Siemens recommends the resistance R of 18 kΩ, then the calculated maximum power is 0.11 W.

  $$P_R = I^2 \times R = \frac{2.5\ mA \cdot 2.5\ mA \cdot 18\ k\Omega}{1000} = 0.11\ W$$

  [fo_closed_circuit_supervision_PR_110V, 1, en_US]

  If the closed-command relay is open, the maximum voltage on the circuit-breaker coil and the minimum voltage on each binary input is calculated as follows:

  $$V_{CBCmax} = 1.5 \cdot 0.09\ k\Omega \cdot 2.5\ mA = 0.34\ V$$

  [fo_closed_circuit_supervision_Vmax_110V, 3, en_US]

  The circuit-breaker coil is not activated.

  $$V_{CBCmin} = \left[0.8 \cdot V_{CTR} - I_{BI(High)} \cdot (1.5 \cdot R_{CBC} + R)\right] \cdot 0.5 = \left[0.8 \cdot 110\ V - 2.5\ mA \cdot (1.5 \cdot 0.09\ k\Omega + 18\ k\Omega)\right] \cdot 0.5 = 21.33\ V$$

  [fo_closed_circuit_supervision_Vmin_110V, 3, en_US]

  The binary input is activated.

- **The control voltage is 220 V.**
  In the following example, if R_{CBC} is 36 Ω, R_{max} is calculated as follows:

$$R_{max} = \left(\frac{V_{Ctrl} - 2 \cdot V_{BImin}}{I_{BI(High)}}\right) - R_{CBC} = \frac{220\ V - 2 \cdot 19\ V}{2.5\ mA} - 0.36\ k\Omega = 72.44\ k\Omega$$

[fo_closed_circuit_supervision_RMax_220V, 2, en_US]

Siemens recommends the resistance R of 51 kΩ, then the calculated maximum power is 0.32 W.

$$P_R = I^2 \times R = \frac{2.5\ mA \cdot 2.5\ mA \cdot 51\ k\Omega}{1000} = 0.32\ W$$

[fo_closed_circuit_supervision_PR_220V, 1, en_US]

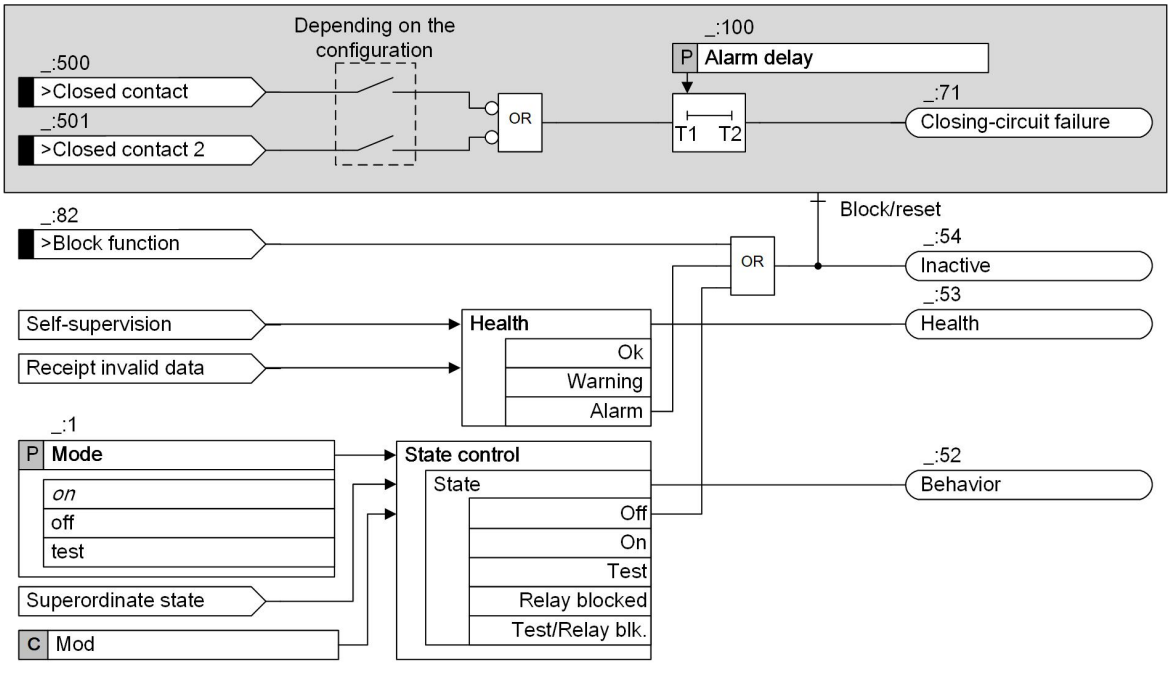
If the closed-command relay is open, the maximum voltage on the circuit-breaker coil and the minimum voltage on each binary input is calculated as follows:

$$V_{CBCmax} = 1.5 \cdot 0.36\ k\Omega \cdot 2.5\ mA = 1.35\ V$$

[fo_closed_circuit_supervision_Vmax_220V, 3, en_US]

The circuit-breaker coil is not activated.

$$V_{CBCmin} = \left[0.8 \cdot V_{CTR} - I_{BI(High)} \cdot (1.5 \cdot R_{CBC} + R)\right] \cdot 0.5 = [0.8 \cdot 220\ V - 2.5\ mA \cdot (1.5 \cdot 0.36\ k\Omega + 51\ k\Omega)] \cdot 0.5 = 23.58\ V$$



[fo_closed_circuit_supervision_Vmin_220V, 3, en_US]

The binary input is activated.

Logic

With the parameter **`Alarm delay`**, you can set the time delay. After fixing the faults in the closed circuit, the failure indication automatically expires after the **`Alarm delay`** time.

If the binary input signal *`>Closed contact`* or *`>Closed contact 2`* is not routed to the binary input of the device (**Information routing** in DIGSI 5), the function **Closing-circuit supervision** does not work.

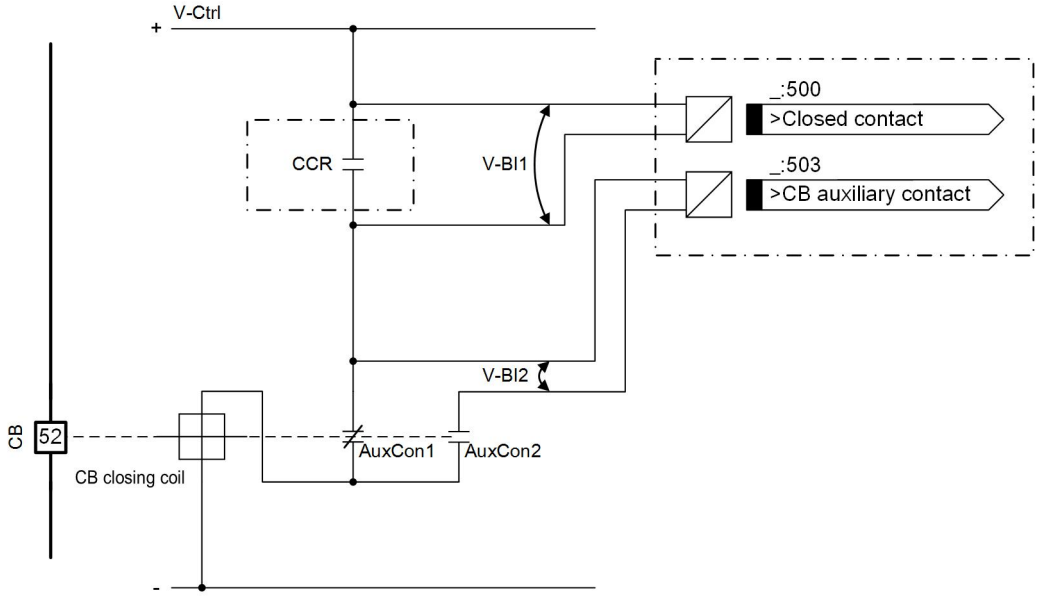
[lo_closed-circuit supervision_3BIs, 4, en_US]

Figure 8-44 Logic Diagram of the Stage Closing-Circuit Supervision with 3 Binary Inputs

The indication *Closing-circuit failure* is generated when the following 2 conditions are met:

- The binary input signal *>Closed contact* or *>Closed contact 2* is deactivated.
- The **Alarm delay** has elapsed.

The indication *Closing-circuit failure* disappears only when the following 2 conditions are met:



- The binary input signals *>Closed contact* and *>Closed contact 2* are activated.
- The **Alarm delay** has elapsed.

8.3.15.4 Closing-Circuit Supervision with 2 Binary Inputs

Principle

In order to detect disruptions in the closed circuit for each switch position, 2 binary inputs are necessary:

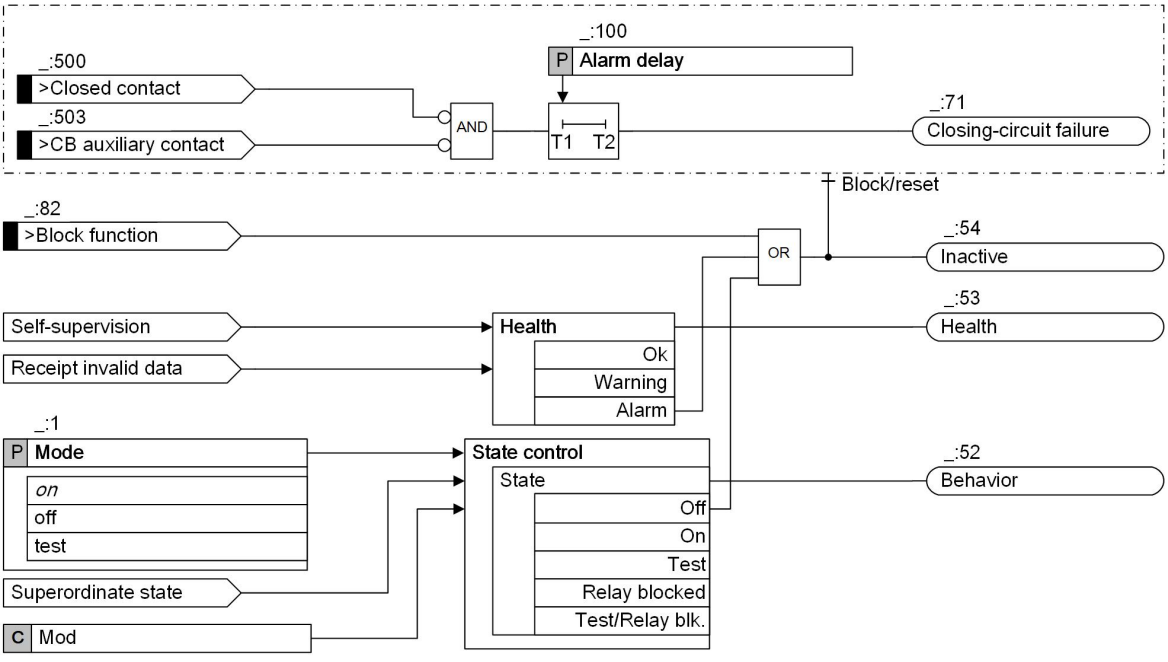
- One binary input is connected in parallel to the close-command relay.
- Another binary input is connected in series with the circuit-breaker auxiliary contact.

[dw_CCS_2BI, 1, en_US]

Figure 8-45 Principle of the Closing-Circuit Supervision with 2 Binary Inputs

CCR	Close-command relay
CB	Circuit breaker
CB closing coil	Circuit-breaker closing coil
AuxCon1	Circuit-breaker auxiliary contact 1 (open if the CB is closed)
AuxCon2	Circuit-breaker auxiliary contact 2 (closed if the CB is closed)
V-Ctrl	Control voltage for the closed circuit
V-BI1	Input voltage for binary input 1
V-BI2	Input voltage for binary input 2

The stage **Closing-circuit supervision with 2 binary inputs** detects disruptions in the closed circuit. It also monitors the reaction of the circuit breaker via the position of the circuit-breaker auxiliary contacts.



Depending on the switch position of the close-command relay and the circuit breaker, the binary inputs are either activated (H) or deactivated (L). If both binary inputs are deactivated, a fault occurs. The fault can be one of the following conditions:

- A disruption
- An outage of the battery voltage
- An adhesion present on the contact surface of the CCR

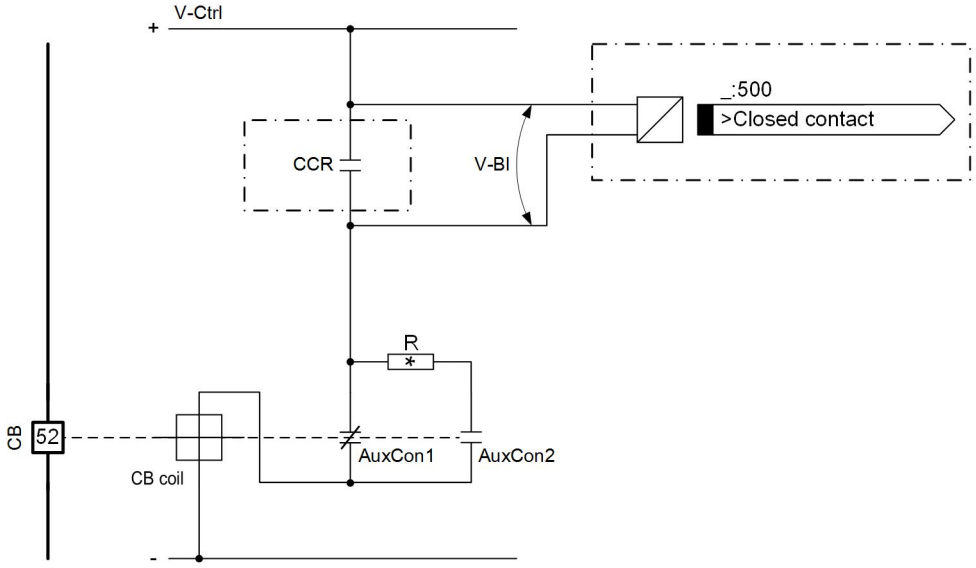
The following table shows all the states of the closed circuit:

CCR	CB	AuxCon1	AuxCon2	>Closed contact	>CB auxiliary contact	Dynamic State	Static State
Open	Open	Closed	Open	H	L	Normal operation with an open circuit breaker	
Open	Closed	Open	Closed	H	H	Normal operation with a closed circuit breaker	
Closed	Open	Closed	Open	L	L	Transient	Fault
Closed	Closed	Open	Closed	L	H	Transient, CCR is activated	

Logic

[lo_CCS_2BI, 3, en_US]

Figure 8-46 Logic Diagram of the Stage Closing-Circuit Supervision with 2 Binary Inputs



The indication *Closing-circuit failure* is generated when the following 2 conditions are met:

- The binary inputs **>Closed contact** and **>CB auxiliary contact** are both deactivated.
- The **Alarm delay** has elapsed.

8.3.15.5 Closing-Circuit Supervision with 1 Binary Input

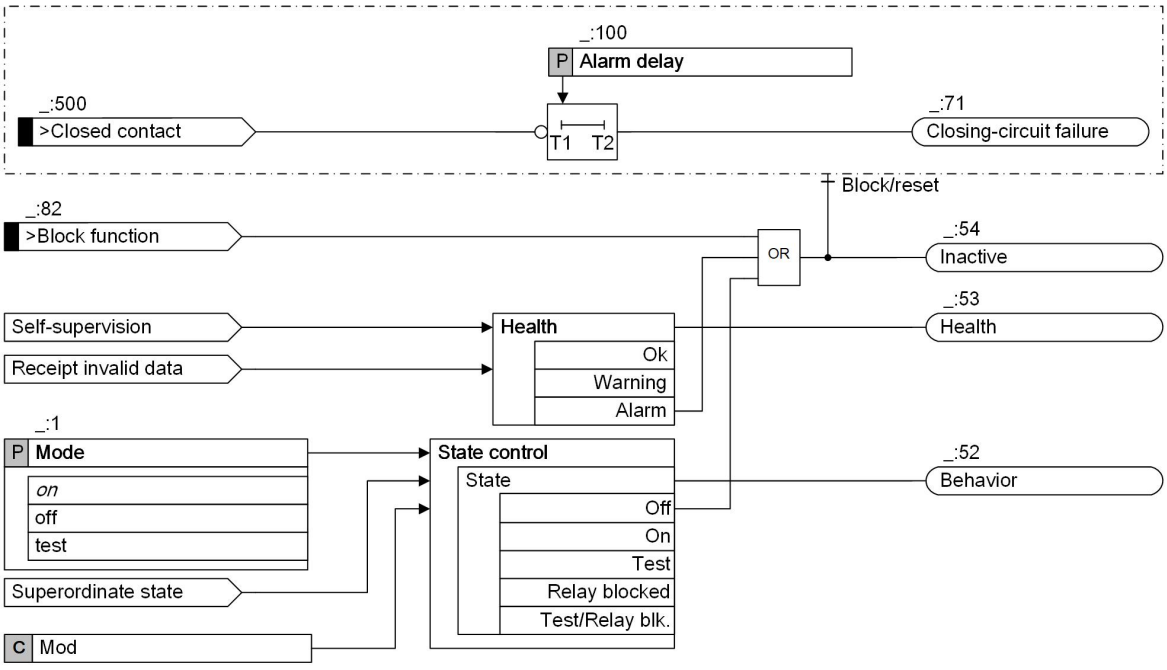
Principle

In the stage **Closing-circuit supervision with 1 binary input**, 1 binary input is used to detect the disruption in the closed circuit. The binary input is connected parallel to the close-command relay. The circuit-breaker auxiliary contact is bridged with an equivalent resistance R.

[dw_CCS_1BI, 1, en_US]

Figure 8-47 Principle of the Closing-Circuit Supervision with 1 Binary Input

CCR	Close-command relay
CB	Circuit breaker
CB closing coil	Circuit-breaker closing coil
AuxCon1	Circuit-breaker auxiliary contact 1 (open if the CB is closed)
AuxCon2	Circuit-breaker auxiliary contact 2 (closed if the CB is closed)
V-Ctrl	Control voltage for the closed circuit
V-BI	Input voltage for binary input
R	Equivalent resistance



Depending on the switch position of the close-command relay, the binary input is either activated (H) or deactivated (L). If the binary input is deactivated, a fault occurs. The fault can be one of the following conditions:

- A disruption
- An outage of the battery voltage
- An adhesion present on the contact surface of the CCR

The following table shows all the states of the closed circuit:

CCR	CB	AuxCon1	AuxCon2	>Closed contact	Dynamic State	Static State
Open	Open	Closed	Open	H	Normal operation with an open circuit breaker	
Open	Closed	Open	Closed	H	Normal operation with a closed circuit breaker	
Closed	Open	Closed	Open	L	Transient	Fault
Closed	Closed	Open	Closed	L	Transient, CCR is activated	

Logic

[lo_CCS_1BI, 3, en_US]

Figure 8-48 Logic Diagram of the Stage Closing-Circuit Supervision with 1 Binary Input

The indication *Closing-circuit failure* is generated when the following 2 conditions are met:

- The binary input **>Closed contact** is deactivated.
- The **Alarm delay** has elapsed.

Equivalent Resistance R

The equivalent resistance R must be dimensioned such that the circuit-breaker closing coil is no longer activated when the circuit breaker is open. Simultaneously, the binary input must still be activated when the command relay is open.

In order to ensure the minimum voltage for activating the binary input, R_{max} results in:

$$R_{max} = \left(\frac{V_{Ctrl} - V_{BImin}}{I_{BImax}}\right) - R_{CBC}$$

[fo_CCS_general_Rmax, 1, en_US]

Because the circuit-breaker closing coil does not remain activated, R_{min} results in:

$$R_{min} = R_{CBC} \cdot \left(\frac{V_{Ctrl} - V_{CBC(Lowmax)}}{V_{CBC(Lowmax)}}\right)$$

[fo_CCS_general_Rmin, 1, en_US]

You can calculate the optimal value for the equivalent resistance R from the 2 values R_{min} and R_{max}:

$$R = \frac{R_{max} + R_{min}}{2}$$

[fo_CCS_general_R, 1, en_US]

The following equation applies for the power consumption of the equivalent resistance R:

$$P_R = I^2 \cdot R = \left(\frac{V_{Ctrl}}{R_{CBC} + R}\right)^2 \cdot R$$

[fo_CCS_general_P, 1, en_US]

With:

V_{Ctrl}	Control voltage for the closed circuit
V_{BImin}	The minimum voltage to activate the binary input
I_{BImax}	The maximum current to activate the binary input
R_{CBC}	The resistance of the circuit-breaker closing coil
$V_{CBC(Lowmax)}$	The maximum voltage flow through the circuit-breaker closing coil, which does not result in the closing of the circuit breaker

8.3.15.6 Application and Setting Notes

Parameter: Alarm delay

- Default setting **(_:100) Alarm delay** = ***2.00 s*** (Closing-circuit supervision with 3 binary inputs)
- Default setting **(_:100) Alarm delay** = ***2.00 s*** (Closing-circuit supervision with 2 binary inputs)
- Default setting **(_:100) Alarm delay** = ***300.00 s*** (Closing-circuit supervision with 1 binary input)

With the parameter **Alarm delay**, you can set the time for the delayed output of the indication *Closing-circuit failure*.

For the stage **Closing-circuit supervision with 2 binary inputs** or **Closing-circuit supervision with 3 binary inputs**, set the parameter **Alarm delay** so that the short-term transient states do not cause the function to activate.

For the stage **Closing-circuit supervision with 1 binary input**, set the parameter **Alarm delay** so that the longest duration of a close command is bridged without fail. This setting ensures that the function is activated only when the closed circuit is disrupted.

8.4 Supervision of the Device Hardware

8.4.1 Overview

The correct state of the device hardware is a requirement for the correct functioning of the device. The failure or erroneous function of a hardware component leads to device malfunctions.
The following modules of the device hardware are monitored:

- Base module
- Expansion modules
- Plug-in modules on the interface locations

The error responses result, depending on type and degree of the error, as follows:
Hardware errors where the device remains in operation.
The error is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. Such errors are, for example:

- Failure communication module (module x)
- Measuring-transducer module failure (module x)
- USB interface
- Integrated Ethernet interface
- Real-time clock device
- A/D converter (fast current sum)
- Battery voltage
- Faulty or missing compensation values (magnitude/phase)

Failures which can partially be corrected by a restart of the device. The device goes briefly out of operation.
Such errors are, for example:

- Memory error (RAM) in the base module
- Defective module
- Module-connection error (PCB Link)
- Control circuit error binary output
- Outage of an internal auxiliary voltage

NOTE

If the error has not be rectified after 3 unsuccessful attempts, the system automatically recognizes it as a severe device malfunction. The device goes permanently out of operation into a secure state (fallback mode).

Fatal device errors with outage of central components: The device goes permanently out of operation into a secure state (fallback mode).
Such errors are, for example:

- Memory error (flash) in the base module
- CPU/Controller/FPGA error in the base module
- 3 unsuccessful restarts in a row

You can find the detailed description of the error responses in table form at the end of this chapter. You will find corresponding corrective measures there.

Device Operating Hours

The *Device operating hours* statistical value counts the operating hours of the physical device. The starting time and the time in Fallback mode are not considered.

You can neither reset nor change the statistical value.

8.4.2 Analog-Channel Supervision via Fast Current-Sum

8.4.2.1 Overview of Functions

The function **Supervision of the device-internal analog-digital converters** it performs the following tasks:

- Supervision of the correct functioning of the device-internal analog-digital converters, based on the sum of all currents of one measuring point in the secondary circuit.
- Detection of failures in the device-internal measuring circuits (for example, analog-digital converter)
- Blocking of protection and control functions that process the measured values from this current measuring point (for example, differential protection). This avoids an overfunction of the device.

The supervision principle is based on fast current-sum supervision with connection of the neutral-point current to the 4th current measuring input. In order to ensure that even the fast tripping stages of the protection functions can be blocked in time before a spurious pickup, the fast current measurement is based on instantaneous values.

For **Analog-digital converter supervision**, the neutral-point current of the line to be protected must be connected to the 4th current measuring input (I_N). The 4th current measuring input must be routed via the current-transformer neutral point (I_N neutral point) (see next figure).

Current transformer 3-phase: connection = 3-phase + IN

[ti_phase_2, 4, en_US]

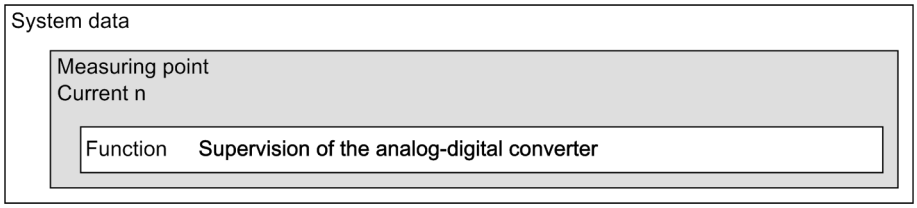

Figure 8-49 Connection to a 3-Phase Current Transformer and Measured Zero-Sequence Current (Current in Common Return Conductor)

NOTE

The analog channel supervision via fast current sum is only available when the 4th current input is a protection-class current transformer. In the DIGSI 5 project tree, under **Device** → **Measuring-point routing**, set the connection type ***3-phase + IN*** for the current measuring point. When using this function, check the correct connection of the neutral conductor/ground current by supplying an asymmetrical current. Otherwise, a 1-pole or 2-pole fault could result in an unwanted blocking of the protection.

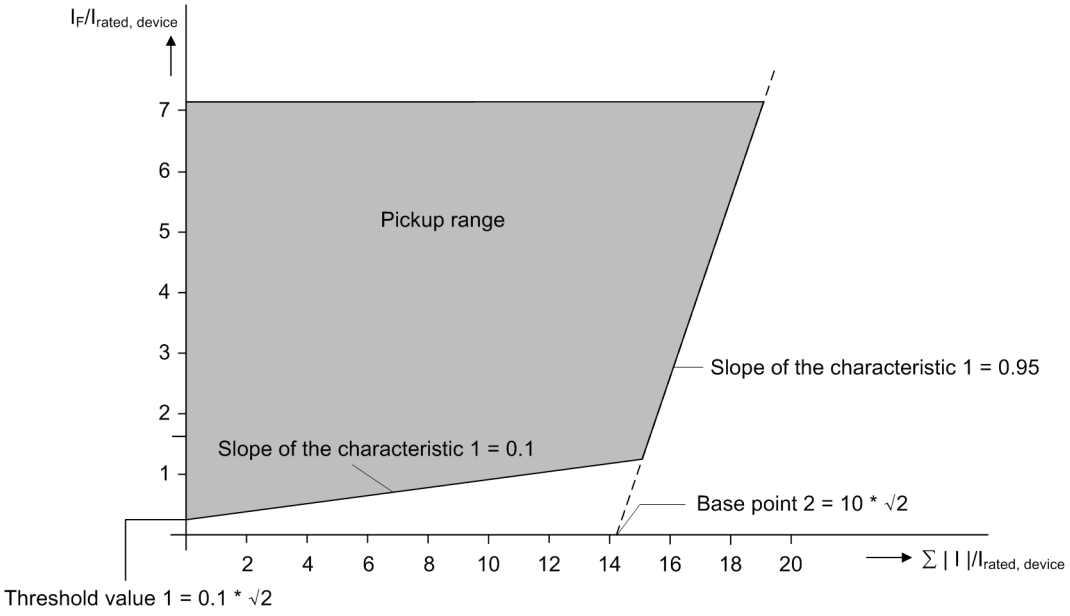
8.4.2.2 Structure of the Function

The **Supervision of the device-internal analog-digital converters** function is located in the **Power-system data** function group of each 3-phase current measuring point.

[dw_schstr, 1, en_US]

Figure 8-50 Structure/Embedding of the Function

8.4.2.3 Function Description

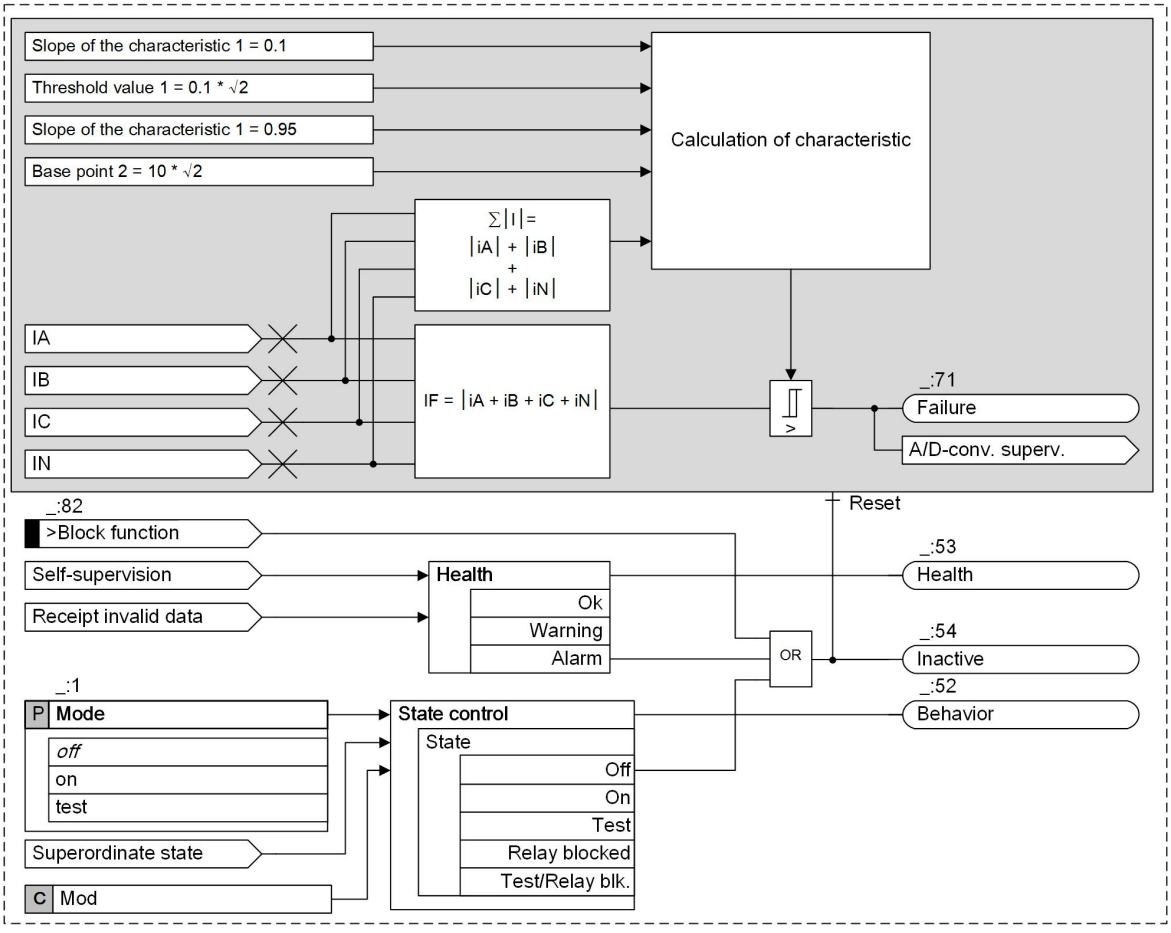


Errors in the current circuits are detected if

$I_F = |iA + iB + iC + iN| >$ **Threshold value** + **Slope of the characteristic 1** •Σ| i | and

$I_F >$ **Slope of the characteristic 2** • (Σ| i | - **Base point 2**)

The device uses the current inputs (iA, iB, iC, and iN) to calculate:



- Fault current $I_F = |iA + iB + iC + iN|$
- Maximum current Σ| i | = |iA|+|iB|+|iC|+ |iN|

[lo_kenisu, 2, en_US]

Figure 8-51 Characteristic Curve of the Supervision of the Device-Internal Analog-Digital Converters

Logic

[lo_sumsch, 4, en_US]

Figure 8-52 Logic Diagram of the Supervision of the Device-Internal Analog-Digital Converters

When the output signal **`A/D converter monit.`** is active, certain protection functions are blocked to avoid failures (see *12.84 Analog Channel Supervision via Fast Current Sum*).

NOTE

The parameters are set in the device and cannot be changed.

It is not necessary to change the parameters as a function of the application.

Threshold Value

The **threshold value** is the lower limit of the operating range of the **Supervision of the device-internal analog-digital converters** function.

The **threshold value** is permanently set to 10 % of the device rated current.

Slope of the Characteristic 1

The component **Slope of the characteristic 1** • Σ | i | accounts for permissible errors of the current input that can occur in the event of slight overcurrents.

The **Slope of the characteristic 1** is permanently set to 0.1.

Slope of the Characteristic 2

The component **Slope of the characteristic 2** accounts for permissible errors of the current input that can occur in the event of large overcurrents (high short-circuit currents).

The **Slope of the characteristic 2** is permanently set to 0.95. The base point of the **Slope of the characteristic 2** is permanently set to 10.

8.5 Supervision of Device Firmware

The device firmware determines essentially the functionality of the device.
The following supervisions ensure the stable function of the device:

- Supervisions of the data and version consistency
- Supervision of the undisturbed sequential activity of the device firmware
- Supervision of the available processor performance

When you start the device, load data via the interfaces and these supervisions of the device firmware will be in effect during the continuous operation. Depending on the type and severity of error, the following error responses will result:

Firmware failures where the device remains in operation.

The error is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. Such errors are, for example, errors in time synchronization (loss and errors).

Failures which can partially be corrected by a restart of the device. The device goes briefly out of operation.

Such errors are, for example:

- Device startup with faulty new parameter set. The old parameter set is still present.
- Overloading of the processor
- Program-sequence error

Fatal firmware error. The device goes permanently out of operation into a secure state (fallback mode).

Such errors are, for example:

- Device startup with faulty new parameter set. No usable parameter set is present.
- Device startup with version error
- CFC-runtime error
- 3 unsuccessful restarts in a row

You can find the detailed description, in table form, of the fault responses at the end of chapter *8.8 Error Responses and Corrective Measures*. You will find corresponding corrective measures there.

8.6 Supervision of Hardware Configuration

The modular hardware concept requires adherence to some rules within the product family and the modular system. Configuration errors show that the hardware configuration saved in the device does not agree with the hardware actually detected. Impermissible components and unallowed combinations must be detected just as missing configured components are.

Depending on the type and severity of error, the following error responses will result: The identified hardware configuration errors are assigned to the defect severities as follows:

Configuration errors for which the device remains in operation.

The failure is indicated. The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. Such errors are, for example, errors in the IE-converter configuration (normal/sensitive).

Fatal configuration error: The device goes permanently out of operation into a secure state (fallback mode).

Such errors are, for example:

- Missing hardware module (module x)
- Incorrect hardware module (module x)
- Incorrect hardware combination
- Incorrect plug-in module (module x)

You can find the detailed description of the error responses in table form at the end of this chapter. You will find corresponding corrective measures there. You can resolve configuration errors through another synchronization with DIGSI.

8.7 Supervision of Communication Connections

SIPROTEC 5 devices offer extensive communication options via fixed and optional interfaces. Beyond the hardware supervision , the transferred data must be monitored with respect to their consistency, failure, or outage.

Supervision

With the supervision of the communication connections, every communication port is monitored selectively.

- Failures are detected and indicated via the operational log. The device remains in operation!
- Additionally, each port is equipped with a separate communication log which displays details of the failures, for example the error rate.

Marking Fault Signals/Data

The signals/data affected by the failure are marked as **invalid**. In this way, the affected protection functions can go into a secure state. In the following, some examples are named:

- GOOSE signals can automatically be set to defined values in case of disturbed IEC 61850 communication.
- Disturbed protection interfaces set phasor values, analog measured values, and binary information to **invalid**, for example for the differential protection. Binary signal traces can be set to defined values in cases of failures.
- Disturbed time-synchronization signals can lead to an automatic change of the source of time synchronization.

You can correct communication failures by checking the external connections or by replacing the affected communication modules.

For further information on error responses, refer to to *8.8.4 Defect Severity 3*. Corresponding corrective measures are also be described there.

8.8 Error Responses and Corrective Measures

8.8.1 Overview

When device errors occur and the corresponding supervision functions pick up, this is displayed on the device and also indicated. Device errors can lead to corruption of data and signals. These data and signals are marked and tagged as **invalid**, so that affected functions automatically go into a secure state. If the supervision functions pick up, this will lead to defined error responses.

How Do Device Errors Make Themselves Noticeable

In case of a device error the supervision functions of the device pickup. The device responds according to the type and severity of the error. To report an error, supervision functions use outputs on the device and indications.

Run LED (green)	The external auxiliary voltage is present. The device is ready for operation.
Error LED (red)	The device is not ready for operation. The life contact is open.
Life contact	Signaling of device readiness following successful device startup.
Group-warning indication *Group warning*	The device remains in operation and signals an error via the prerouted LED and the log.
Log of the device	Indications of causes for defects and corrective measures

Determination of Causes for Defects and Corrective Measures

To determine the cause for defect and the corresponding corrective measure, proceed step by step.

Step 1: Pick up of supervisions leads to one of the following defect severities in all cases.

- **Defect severity 1:**
  Internal or external device error that is reported. The device remains in operation.
- **Defect severity 2:**
  Severe device failure, the device restarts (reset) to correct the cause for defect.
- **Defect severity 3:**
  Severe device failure, the device goes to a safe condition (fallback mode), as the correction of defects cannot be implemented by a restart. In fallback mode, the protection and automated functions are inactive. The device is out of operation.
- **Defect severity 4:**
  Severe device-external failure, the device switches the protection and automatic functions to inactive for safety, but remains in operation. Normally, the user can correct the fault by himself.

Step 2: For every defect severity, you will find detailed tables with information about causes for defects, error responses, and corrective measures in the following chapters.

Table 8-1 Error Responses

	Group-Warning Indication Group Warning	Indication in Operational Log	Indication in Device-Diagnosis Log	Indication of the Life Contact	All Protection and Automation Functions are inactive	Device restart (Reset)	Fallback Mode
Defect Severity 1	x	x	x	–	–	–	–
Defect Severity 2	–	–	x	x	During the starting time of the device	x	–
Defect Severity 3	–	–	x	x	x	–	x
Defect Severity 4	–	x	–	x	x	–	–

8.8.2 Defect Severity 1

Defect severity 1 faults allow the continued safe operation of the device. Defect severity 1 faults are indicated. The device remains in operation.

When the supervision functions pick up, corrupted data and signals are marked as **invalid**. In this way, the affected functions can go into a secure state. Whether functions are blocked is decided in the appropriate function itself. For more detailed information, refer to the function descriptions.

Life contact	Remains activated
Red error LED	Is not activated

Log

For every device fault, a corresponding supervision indication is generated. The device records these indications with a real-time stamp in the operational log. In this way they are available for further analyses. If supervisions in the communication interfaces area of the device pick up, there is a separate communication log available for each port. Extended diagnostic indications and measured values are available there. The device-diagnosis log contains expanded fault descriptions. There you also receive recommendations of corresponding corrective measures for each detected device error.

There is further information on handling the logs in *3.1 Indications*.

Group-Warning Indication Group Warning

As delivered, all monitoring indications of Defect Severity 1 are routed to the signal `(_:301)` **`Group warning`**. In this way, a device error can be indicated with only one indication. The majority of supervision indications are permanently connected to the **`Group warning`** (**Group warning** column = fixed). However, some supervision indications are routed flexibly to the **`Group warning`** via a logic block chart (**Group warning** column = CFC). If necessary, the routings via a CFC chart can be taken from the group indication again.

In delivery condition, the **`Group warning`** is routed to an LED.

The following logic diagram shows the correlation.

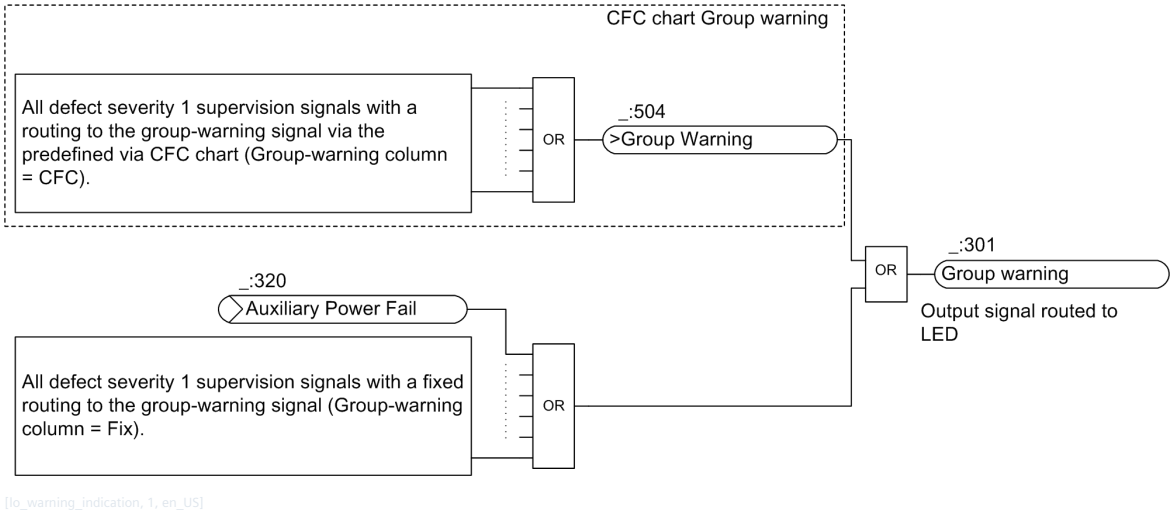


Figure 8-53 Forming the Warning Group Indication Group Warning

Overview of Errors

Indication	Type	Group Warning	Explanation
General:			
(_:53) **Health**	ENS	CFC	If the **Health** of an individual function block, for example a protection stage or an individual function, goes to the *Warning* or *Alarm* state, this state generates up to the general group indication **Health** (_:53) via the associated function group. Check from the operational log from which function or function block the error originates. In the associated function description, there is additional information as to why the Standby of the function or a function block can change.
(_:53) **Health** = ***Warning***	SPS		
(_:53) **Health** = ***Alarm***	SPS		

Indication		Type	Group Warning	Explanation
Device:				
	_:320 **Auxiliary Power Fail**	SPS	Fixed	Fault with the auxiliary power supply: Check the external power supply. This message does not appear if the device has a redundant PS204 power supply module, and is replaced by the messages described below for a device with PS204.
	(_:305) **Battery failure**	SPS		Battery fault: Replace the device battery. To avoid data loss, Siemens recommends replacing the device battery with the device supply voltage switched on. You can find more information on battery disposal in the hardware manual from version V07.80 (order number: C53000-G5040-C002-D).
	_:312 **Compensation error** x	ENS		Calibration error in module x: Contact the Customer Support Center. **Quality**: Measured values are marked with the quality attribute of *questionable* (measured value display with ≈).
	_:314 **Offset error** x	ENS		Offset error on module x: If this indication persists after the device start, contact the Customer Support Center. **Quality**: Measured values are marked with the quality attribute of *questionable* (measured value display with ≈).
	_:306 **Clock fail**	SPS		Internal time failure • Check the time settings first. • Then replace the device battery. • If the fault is not remedied, contact the Customer Support Center. **Quality**: The internal time is marked with the quality attribute of *Clock Failure*.
	(_:319) **Error memory**	SPS		Checksum (cyclic redundancy check) error in monitored memory areas of the device
	Measuring transducer error (x)	ENS		Hardware failure on the measuring-transducer module on plug-in module position E/F/M/N/P: Contact the Customer Support Center.

Indication	Type	Group Warning	Explanation
Device with redundant PS204 power supply module:			
_:330 **Power sup. Module fail.** x	INS	CFC	Internal device error on the power supply module at position x[63]: • The device remains in operation because it has a redundant power supply module, provided it is intact. • Exchange the defective power supply module so that redundancy is reestablished!
_:331 **Power sup. Module OK** x	INS		No internal device error in the power supply module at position x[63].
_:332 **Pow. sup. aux. pow. fail.** x	INS		Error in the external auxiliary power supply module at position x[63]: • The device remains in operation because it has a redundant power supply module, provided it is intact. • Check the auxiliary power supply module.
_:333 **Power sup.aux.pow.OK** x	INS		The external auxiliary power supply module at position x[63] is OK.
_:334 **Power sup. Module fail.** x	SPS	Fixed	At least one power supply module has an internal device error
_:335 **Pow. sup. aux. pow. fail.** x	SPS	Fixed	At least one power supply module does not have an adequate auxiliary power supply
Handling an alarm:			
(_:504) **>Group Warning**	SPS	Fixed	Input signal for user-defined generation of group warning
Time sync.:			
(_:305) **Time sync. error**	SPS	Fixed	Time synchronization error, the timing master is faulty: • Check the external time source first. • Check the external connections. • If the fault is not remedied, contact the Customer Support Center. **Quality**: The internal time is marked with the quality attribute of *Clock not synchronized*.
Power-system data:meas. point I-3ph:superv. Bal. I: (_:71) **Failure**	SPS	CFC	Current balance failure (see *8.3.10.1 Overview of Functions*)
Power-system data:meas. point I-3ph:superv. Phsseq.I: (_:71) **Failure**	SPS	CFC	Failure of the current phase-rotation supervision system (see *8.3.12.1 Overview of Functions*)
Power-system data:meas. point I-3ph:superv. Sum I (_:71) **Failure**	SPS	CFC	Failure of the current sum (see *8.3.11.1 Overview of Functions*)

[63] x refers to the PCB assembly slot (x =1,2,3,...)

Indication	Type	Group Warning	Explanation
Power-system data:meas. point I-3ph:superv.ADC sum.I: (_:71) **Failure**	SPS	CFC	Failure of the fast current sum (see *8.4.2.1 Overview of Functions*) The failure indication indicates a fault in the analog-digital converter at the power input. • Check the exterior wiring. • If the fault is not remedied, contact the Customer Support Center. **Quality**: The internally managed current measured values are marked with the *invalid* quality attribute. **Blocking**: The protection functions based on current measurement are blocked.
Power-system data:meas. point V-3ph: Volt.Trans.Cir.B: (_:500) **>Open**	SPS	CFC	Voltage-transformer circuit breaker is open. **Blocking**: Appropriate functions are either blocked definitely or the blocking can be set individually.
Power-system data:meas. point V-3ph: Superv. of Bal. V: (_:71) **Failure**	SPS	CFC	Failure of the voltage balance (see *8.3.6.1 Overview of Functions*)
Power-system data:meas. point V-3ph: Superv. Phsseq.V: (_:71) **Failure**	SPS	CFC	Failure of the voltage phase-rotation supervision (see *8.3.8.1 Overview of Functions*)
Power-system data:meas. point V-3ph: Superv. of Sum V: (_:71) **Failure**	SPS	CFC	Failure of the voltage sum (see *8.3.7.1 Overview of Functions*)
2 devices prot. comm.: Protection interface #:			Protection interface connection defective: • Check the connections and the external communication infrastructure. • If the fault is not remedied, contact the Customer Support Center. **Transferred Signals**: Faulty or not received telegrams are detected at the receive end and discarded. They do not result in failure of the applications. Configured binary signals are reset after a time that can be set.
(_:303) **Connection broken**	SPS	CFunctionC[64]	
(_:316) **Error rate / min exc.**	SPS		
(_:317) **Error rate / hour exc.**	SPS		
(_:318) **Time delay exceeded**	SPS		
(_:320) **Time delay jump**	SPS		
Motor: Mess.Volt.Fail detected: (_:300) **Failure**	SPS	CFC	Measuring-voltage failure detected: Check the exterior wiring. **Blocking**: Appropriate functions are either blocked definitely (for example, distance protection) or the blocking can be set individually.
Device: (_:343) SEU happened	SPS		SEU memory fault: Cosmic radiation can result in a Single Event Upset, which can be detected through bit flips (changes in the status of a bit) in the memory blocks. A reset to reinitialize the memory is initiated. You will find additional explanations on the physical background in a special SEU whitepaper.

8.8.3 Defect Severity 2

Faults of defect severity 2 are fatal device faults that lead to an immediate restart of the device (reset).

64 The indications are not pre-routed in the logic block chart. The indications must be added to by the user in the logic block chart!

This occurs when the device data is corrupted (for example, RAM memory), if a restart prevents restoration of data consistency. The device goes briefly out of operation, a failure is avoided.

Life contact	Is terminated during the restart
Red error LED	Is activated during the restart

NOTE

If the fault of defect severity 2 has not been removed after 3 unsuccessful restarts (reset), the fault is automatically assigned to defect severity 3. The device will automatically turn to the fallback mode.

Log

For every device error with a subsequent restart (reset), only the restart can be detected in the operational log. The actual supervision indication is entered in the device-diagnosis log at the point in time of the fault detection and before the restart. These indications are recorded with a real-time stamp and are thus available for later analyses. The device-diagnosis log contains expanded fault descriptions. There, you also receive recommendations of corresponding corrective measures for each detected device error.

For further information on handling the logs, refer to chapter *3*.

Overview of Errors

Number	Device-Diagnosis Log
826	Processor error on the base module: If the fault occurs numerous times, contact the Customer Support Center.
830	FPGA hardware error on the base module: Contact the Customer Support Center.
834	Memory error (short term): Reset initiated.
3823	Program run error: If the fault occurs numerous times, contact the Customer Support Center.
826	CPU overload: If the fault occurs numerous times, contact the Customer Support Center.
11160	SEU memory fault (short term): Reset initiated
Miscellaneous	Internal firmware error: If the fault occurs numerous times, contact the Customer Support Center.

8.8.4 Defect Severity 3

Faults of defect severity 3 are fatal device faults that lead to device immediately going into the fallback mode. The signal *(:301) Physical health* goes to the ***Alarm*** state. The ***Warning*** state is not supported for this signal.

Fatal device errors are errors that cannot be resolved by a restart of the device. In this case, contact the Customer Support Center. The device goes permanently out of operation, a failure is avoided. In the fallback mode, minimal operation of the device via the on-site operation panel and DIGSI is possible. In this way, for example, you can still read out information from the device-diagnosis log.

Life contact	Is terminated in the fallback mode
Red error LED	Is activated in the fallback mode

Log

For every device error that immediately leads to entry into the fallback mode, entries from supervision messages and the signal *(:301) Physical health* into the operational log are not possible. The actual supervision indication is entered in the device-diagnosis log at the point in time of the fault detection, that

is, before entry into the fallback mode. These indications are recorded with a real-time stamp and are thus available for later analyses. The device-diagnosis log contains expanded fault descriptions. There, you are offered recommendations of corresponding corrective measures for each detected device error.

You can find further information on handling the logs in chapter *3.1 Indications*.

Overview of Errors

Number	Device-Diagnosis Log
2822	Memory error (continuous) Contact the Customer Support Center.
4727, 5018-5028	Hardware failure at module 1-12: Contact the Customer Support Center.
4729	Device bus error (repeated): • Check the module configuration and the module connections. • Contact the Customer Support Center.
4733	Incorrect hardware configuration: Synchronize the hardware configuration of the device with DIGSI.
5037-5048	Wrong module 1-12 detected: Synchronize the hardware configuration of the device with DIGSI.
5031-5035	Identified wrong plug-in module on plug-in module position E/F/M/N/P: Synchronize the hardware configuration of the device with DIGSI.
	Wrong application configuration: Search for the cause in the operational log and load a valid configuration to the device.
3640, 4514	Data-structure error: Contact the Customer Support Center.
956	Firmware-version error: Contact the Customer Support Center.
2013, 2025	Signature error: Contact the Customer Support Center.
	CFC error: In DIGSI, check your CFC chart for the cause.
5050-5061	Binary-output error in module 1 - 12: Contact the Customer Support Center.
5088, 5089	A missing display configuration was established: Synchronize the hardware configuration of the device with DIGSI.

8.8.5 Defect Severity 4 (Group Alarm)

Errors of defect severity 4 are not device failures in the classical meaning. These errors do not affect the device hardware and are not detected or reported by internal device supervision functions. The condition of the defect severity 4 – the group alarm – is set user-specifically by the binary input signal *(_:503) >Group alarm*. If the binary input signal is reset, the device is no longer in the *Group alarm* condition and all functions return to the normal operating state.

If the group alarm is generated, the device reacts as follows:

- The group indication *(_:300) Group alarm* is generated and recorded in the operational log.
- The life contact is terminated.
- The red Error LED is activated.
- All protection and automation functions are blocked.

- The device remains in operation, does not carry out any restart (reset), and does not switch to the safe condition (Fallback mode).
- The signals managed internally are marked with the ***invalid*** quality attribute. Signals managed internally are, for example, measured values, binary input and output signals, GOOSE and CFC signals.

In the delivery condition, every device has the CFC chart **Process mode inactive**, that initiates the Group alarm (see chapter *8.9 Group Indications*).

Life contact	Is terminated in case of Group alarm
Red error LED	Is initiated in case of Group alarm

Log

The group indication *(_:300) Group alarm* is recorded in the operational log. Depending on the cause of the initiation, further information can be found in the operational log.
You can find further information on handling the logs in chapter *3*.

8.9 Group Indications

The following group indications are available:

- *(_:300) Group alarm*
- *(_:301) Group warning*
- *(_:302) Group indication*

You can find the signals in the DIGSI 5 project tree under **Name of the device** → **Information routing**. In the working area, you can find the signals under **Alarm handling** (see the following figure).

Information			Source		
			Binary input		
			Basismodul		
Signals	Number	Type	1.1	1.2	1.3
(All)	(All)	...	...	...	...
General	91				
Device	4171				
Alarm handling	5971				
>Group Alarm	5971.503	SPS			
>Group Warning	5971.504	SPS			
>Group Indication	5971.505	SPS			
Behavior	5971.52	ENS			
Health	5971.53	ENS			
Group alarm	5971.300	SPS			
Group warning	5971.301	SPS			
Group indication	5971.302	SPS			

[sc_grwarn, 1, en_US]

Figure 8-54 Group Monitoring Indication in the DIGSI 5 Information Routing Matrix

Group Indication Group Alarm

The indication *(_:300) Group alarm* is the group indication for defect severity 4 monitoring. This monitoring has a special purpose, as it is set user-specifically by a binary input signal and not by internal device supervision. Nevertheless, the response of the device is serious, such as blocking all protection and automatic functions (refer to *8.8.5 Defect Severity 4 (Group Alarm)*).

If the binary input signal *(_:503) >Group Alarm* is set, the group indication *(_:300) Group alarm* becomes active. If the binary input signal *(_:503) >Group Alarm* is reset, the signal *(_:300) Group alarm* is also reset and the device returns to the normal operating state.

In the delivery condition, every device has the CFC chart **Process mode inactive** that initiates the *>Group Alarm*. This CFC chart checks whether the device is still accidentally in the simulation or commissioning mode.

You can adapt the CFC chart as needed. You can find the CFC chart in the DIGSI 5 project tree under **Name of the device** → **Charts**.

Group Indication Group Warning

The indication *(_:301) Group warning* is the group indication for defect severity 1 monitoring. Some error messages of defect severity 1 are firmly linked to the signal *(_:301) Group warning*, others are connected flexibly in the device delivery condition via a CFC chart. This assignment is described in chapter *8.8.2 Defect Severity 1*.

In the delivery condition, every device has the CFC chart **Group warning**, that initiates the *Group warning*.

You can adapt the CFC chart as needed. You can find the CFC chart in the DIGSI 5 project tree under **Name of the device** → **Charts**.

The group-warning indication *(_:301) Group warning* is prerouted to an LED of the base module.

Group Indication

The *Group indication* is exclusively for user-specific purposes. There is no internal device supervision function that activates this indication. If the binary input signal *(_:505) >Group indication* is set, the indication *(_:302) Group indication* becomes active and is recorded in the operational log. This warning indication does not result in blocking a protection function. If the binary input signal is reset, the signal *(_:302) Group indication* drops out. Using a CFC chart, you can define when the binary input signal *(_:505) >Group indication* is to be set.

9 Measured Values, Energy Values, and Supervision of the Primary System

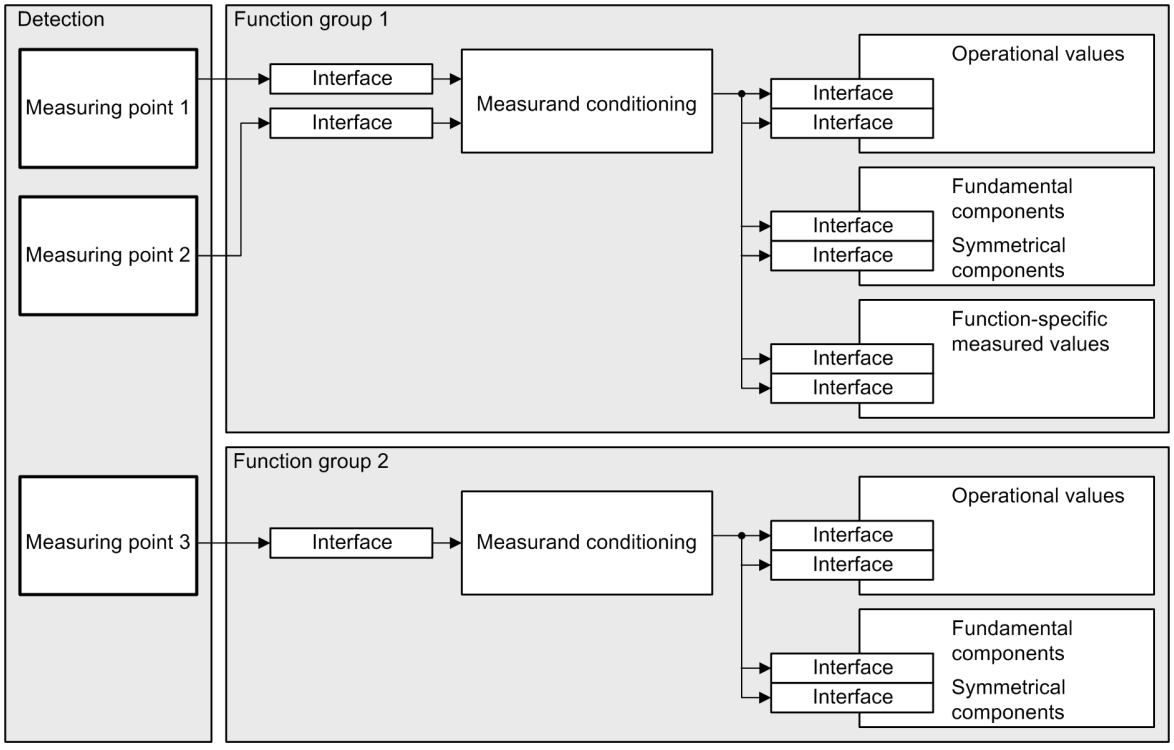
9.4	Fundamental and Symmetrical Components	2131
9.5	Phasor Measurement Unit (PMU)	2132
9.6	Average Values	2157
9.7	Minimum/Maximum Values	2160
9.8	Energy Values	2162
9.9	User-Defined Metered Values	2165
9.10	Statistical Values of the Primary System	2169
9.11	Measuring Transducers	2170
9.12	Circuit-Breaker Monitoring	2177
9.13	Disconnector-Switch Monitoring	2237



9.1 Overview of Functions

The measurands are recorded at the measuring points and forwarded to the function groups.

Within the function groups, further measurands are calculated from these measured values, which are required for the functions of this function group. This is how, for example, the electric power is calculated from the voltage and current measurands.

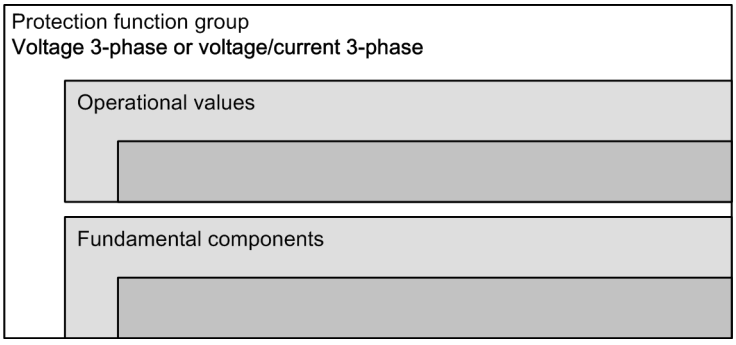
Measuring transducers are an exception as they already form various calculation parameters from the analog current and voltage inputs themselves.

You can find basic instructions for recording and editing process data in *2.1 Embedding of Functions in the Device*.

[dw_om_verf, 1, en_US]

Figure 9-1 Structure of Measured-Value Acquisition and Processing

For the display, the measured values of a SIPROTEC 5 device are summed up in the following groups:



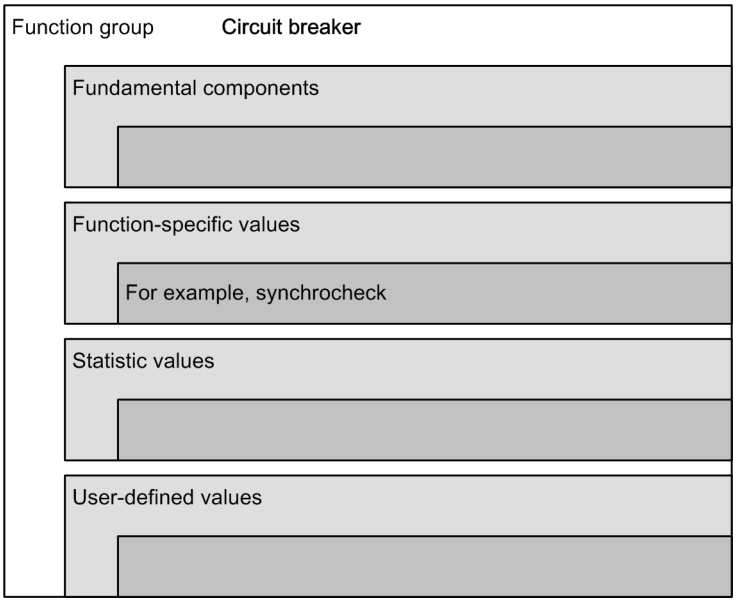
- Operational measured values
- Fundamental and symmetrical components
- Function-specific measured values
- Minimum values, maximum values, average values
- Energy metered values
- User-defined measured and metered values
- Statistical values

9.2 Structure of the Function

Depending on the interconnection of the function groups, these can contain different measured-value groups. 2 typical function groups are displayed below.

3-Phase Voltage and Voltage/Current 3-Phase Function Groups

In the simplest version, the **3-phase voltage** and **Voltage/current 3-phase** function groups obtain the measured values of the 3-phase voltage and current system and contain the following measured-value groups:



[dw_om_vstr, 1, en_US]

Figure 9-2 Structure of Measured Values in Function Groups

The **Operational measured values** and **Fundamental components** measured-value groups can be inserted from the DIGSI 5 library into the **3-phase voltage** and **Voltage/current 3-phase** function groups.
Details regarding the individual measured-value groups can be found in the tables in the following chapters.

Circuit-Breaker Function Group

The **Circuit-breaker** function group may contain the following measured values:

[dw_om_vls1, 1, en_US]

Inversion of Output-Related Measured and Statistical Values

The calculated, directional values in the operational measured values (power, power factor, energy and minimum, maximum, and average values based on these) are normally defined as positive in the direction of the protected object. This requires that the connection polarity for the used measuring points be correctly set

(see also parameter **(_:8881:116) Neutr.point in dir.of ref.obj** of the measuring point current, 3-phase). It is, however, possible, to set the "forward" direction for the protection functions and the positive direction for the powers, etc., differently, for example, such that the active power consumption (from the line to the busbar) is displayed positively. Then set the option ***reversed*** in the affected function groups at the parameter **P, Q sign**. With the setting ***not reversed*** (default setting), the positive direction for the powers etc. corresponds to the "forward" direction for the protection functions.

The affected values are given in detail in the chapters *9.3 Operational Measured Values* - *9.10 Statistical Values of the Primary System*.

9.3 Operational Measured Values

Operational measured values are assigned to different function groups.

The values can be displayed as primary and secondary values and as percentage values. They are updated every 180 ms.

The frequency is calculated using the filter algorithm, which is derived from the voltage or current. The voltage input has higher priority than the current input. If no voltage or current is present, the value contains the last valid frequency. **–** is displayed on the user interface.

The operational measured values are calculated according to the following definition equations:

RMS values

$$X = \sqrt{\frac{1}{T}\int_{t}^{t+T} x^2(t)\,dt}$$

Active power (per phase)

$$P_{phsx} = \frac{1}{T}\int_{t}^{t+T} v_{phsx}(t) \cdot i_{phsx}(t)\,dt$$

With x = 1 to 3

$v_{phsx}(t)$ – Instantaneous value of the phase voltage, that is, v_A, v_B, v_C

$i_{phsx}(t)$ – Instantaneous value of the phase current, that is, i_A, i_B, i_C

Active power (total)

$$P_{total} = \sum_{x=1}^{3} P_{phsx}$$

Apparent power (per phase)

$$S_{phsx} = V_{phsx} \cdot I_{phsx}$$

With V_{phsx} – RMS value of the phase-to-ground voltage (true RMS):

$$V_{phsx} = \frac{V}{\sqrt{3}}$$

With x = A to C

I_{phsx} – RMS value of the phase current (true RMS); with x = A to C

Apparent power (total)

$$S_{total} = \sum_{x=1}^{3} S_{phsx}$$

Reactive power (per phase)

$$Q_{phsx} = \sum_{n} V_n \cdot I_n \cdot \sin(\varphi_n)$$

With:

n – Harmonic order (up to n = 50)

φ_n – Angle difference between voltage and current of the nth harmonic

Reactive power (total)

$$Q_{total} = \sum_{x=1}^{3} Q_{phsx}$$

Power factor

$$\lambda = \frac{|P|}{S}$$

Active factor

$$\cos\varphi = \frac{P}{S}$$

NOTE

With the parameter **`P, Q sign`** in the function block **General** of the respective function group, the sign of the following measured values can be inverted (see chapter *5.5 Function-Group Type Line* in the subchapter *5.5.2 Structure of the Function Group*, section on the **Inversion of Output-Related Measured and Statistical Values**):

- Active power (total): P total
- Active power (phase-related): P_A, P_B, P_C
- Reactive power (total): Q total
- Reactive power (phase-related): Q_A, Q_B, and Q_C

9.4 Fundamental and Symmetrical Components

The fundamental components are calculated from the frequency-tracked instantaneous values through a Fourier filter (integration interval: one period). The results are phasor values that are described by way of the amount and phase angle.

In accordance with the transformation matrix, the symmetrical components are calculated from the voltage and current phasors. These are also phasor quantities.

Fundamental Components

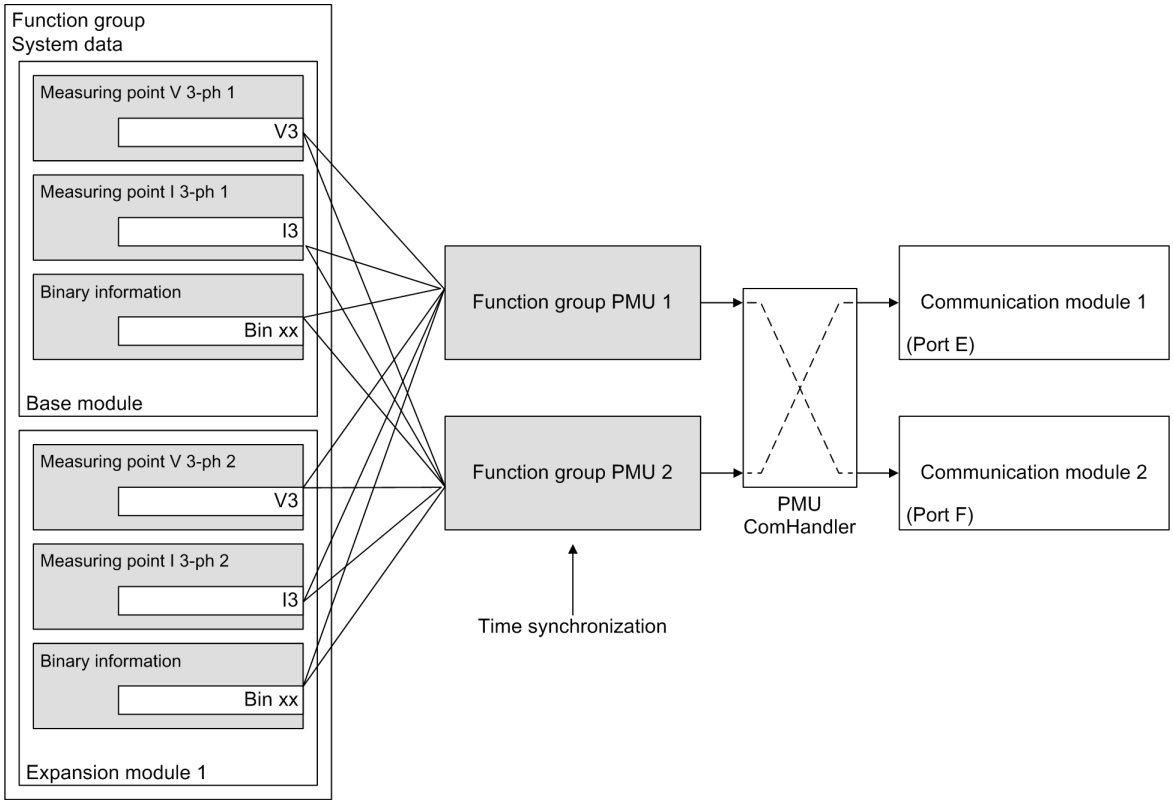
Table 9-1 Fundamental Components

Values		Primary	Secondary	Phase Angle	% Referenced to
$\underline{V}_A$, $\underline{V}_B$, $\underline{V}_C$	Phase-to-ground voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_N$	Measured neutral-point displacement voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_{12}$, $\underline{V}_{23}$, $\underline{V}_{31}$	Phase-to-phase voltage	kV	V	°	Rated operating voltage of the primary values
$\underline{I}_A$, $\underline{I}_B$, $\underline{I}_C$	Phase currents	A	A	°	Rated operating current of the primary values
$\underline{I}_N$	Neutral-point phase current	A	A	°	Rated operating current of the primary values

Symmetrical Components

Table 9-2 Symmetrical Components

Values		Primary	Secondary	Phase Angle	% Referenced to
$\underline{V}_0$	Zero-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_1$	Positive-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{V}_2$	Negative-sequence component of the voltage	kV	V	°	Rated operating voltage of primary values/√3
$\underline{I}_0$	Zero-sequence component of the current	A	A	°	Rated operating current of the primary values
$\underline{I}_1$	Positive-sequence component of the current	A	A	°	Rated operating current of the primary values
$\underline{I}_2$	Negative-sequence component of the current	A	A	°	Rated operating current of the primary values



9.5 Phasor Measurement Unit (PMU)

9.5.1 Overview of Functions

A Phasor Measurement Unit (PMU) measures the phasor values of current and voltage. These values get a high precision time stamp and together with the values of power frequency, power frequency change rate and optional binary data that are also time stamped are transmitted to a central analysis station. The standardized transmission protocol IEEEC 37.118 is used to do this.

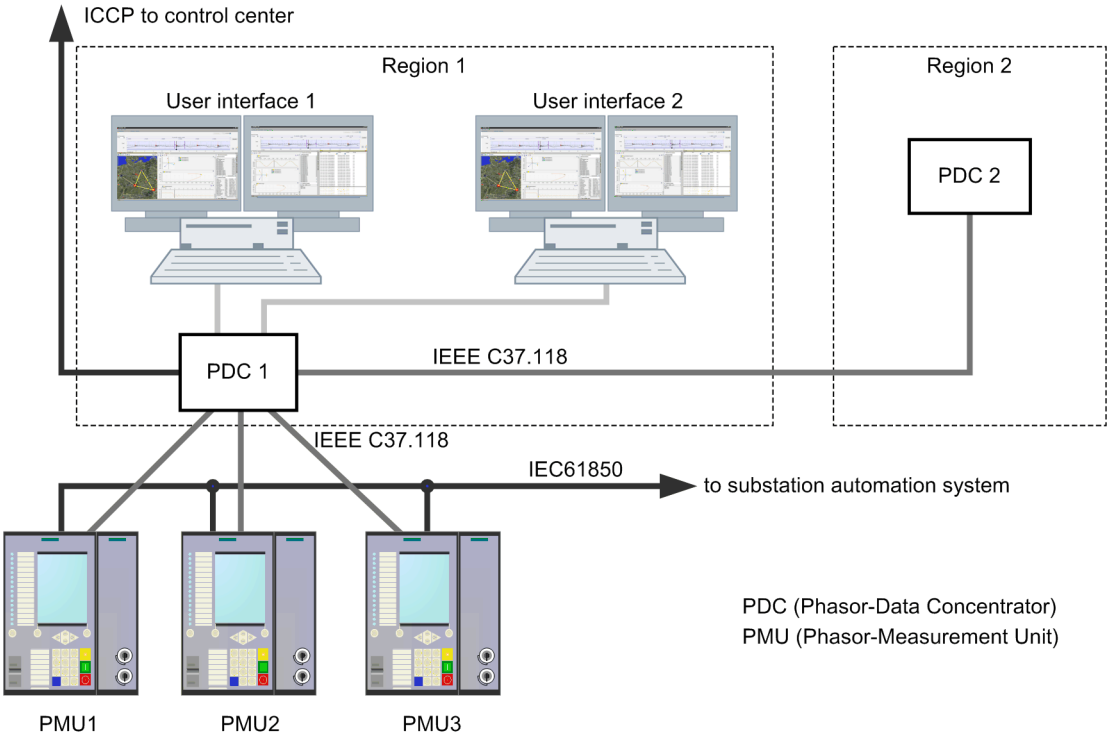
9.5.2 Structure of the Function Group

The **PMU** function group is activated by selecting the protocol *IEEE C37.118PMU* on an Ethernet module (electrical or optical). The PMU obtains the measured values from the measuring points and the precise time from time synchronization. The time-stamped synchrophasors for current and voltage are formed from this and transferred together with additional values via the communication module to a server (PDC, Phasor Data Concentrator).

[dw_strpmu, 2, en_US]

Figure 9-3 Structure/Embedding of the Function

9.5.3 Function Description



The synchrophasors, sent from the **PMU** in a continuous data stream to a PDC, are provided with time stamps and thus are comparable with the measured values of other PMUs. The power frequency, the power frequency change rate and optional binary information are also transmitted as time-stamped measured values. Therefore, you receive an overview of the transient processes in a distributed energy transfer system, for example network fluctuations and compensating processes.

The following table shows the differences between the PMU measured values and the remaining measured values of the device.

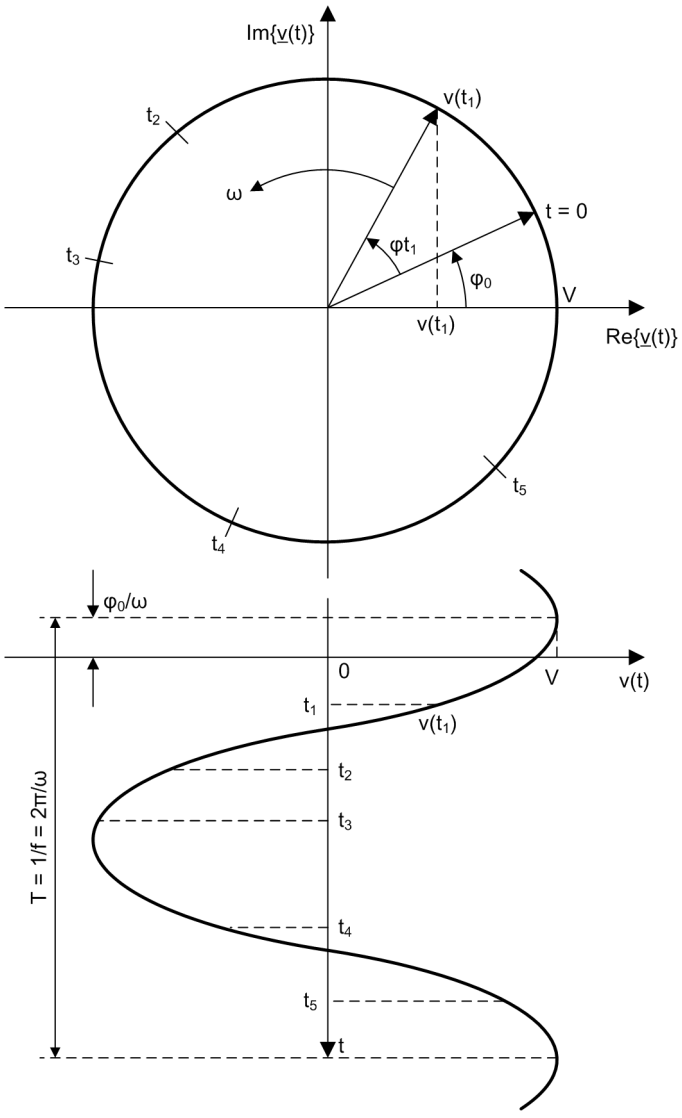
Table 9-3 Comparison of Synchrophasors and Conventional Measured Values

Synchrophasors of the PMU	Measured Values from the Measuring Points
Continuous updating (measured value of current) with, for example, 10 values per second (reporting rate)	Slow updating (typically every 5 seconds)
Every measured value has a time stamp	No time stamp for the measured values
Phasor values of current and voltage (amplitude and phase angle)	RMS values without phase angle

The following figure shows the structure of such a Wide Area Monitoring System. The data delivered from the PMUs on the PDC are transmitted via the Inter-Control Center Communications Protocol (ICCP) according to DIN EN 60870-6 to the network control center.

[dw_strwam, 1, en_US]

Figure 9-4 Structure of a Wide-Area Monitoring System with Phasor Measurement Units



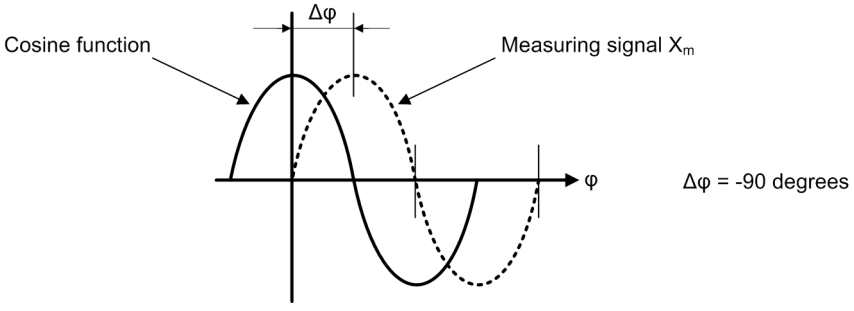
The phasor measurement units each have 2 communication interfaces: an Ethernet module for synchrophasor communication via IEEE C37.118 and another module for communication with the substation automation technology, for example, through the IEC 61850 protocol. If you use an ETH-BD-2FO communication module, you can activate IEEE C37.118 and IEC 61850-8-1 on the same module.

The central evaluation system, for example SIGUARD PDP Phasor Data Processor, receives the data, files, archives them and graphically displays them on a User Interface. In this system, a self-checking function may also be performed, for example, on undamped power swings. The further distribution of information to other PDCs or to a control center is done here.

To maintain the required maximum errors (TVE) required in the standard IEEE C37.118, the time tolerance relative to the UTC time reference (UTC = Universal Time Coordinated) may be maximum 10 µs. Therefore, the device must be directly synchronized with a GPS precise time signal for the correct function of the PMU.

Phasors

A phasor $u(t) = \underline{U}e^{j\omega t}$ can be displayed as a phasor that moves counterclockwise in the complex plane at the angular frequency ω. Therefore, the voltage function $u(t) = Re\{\underline{u}(t)\}$ is obtained as a projection of the phasor $\underline{u}(t)$ on the real axis.



[dw_geopdc, 1, en_US]

Figure 9-5 Geometric Representation of a Phasor

Reference Point for Determining the Angle

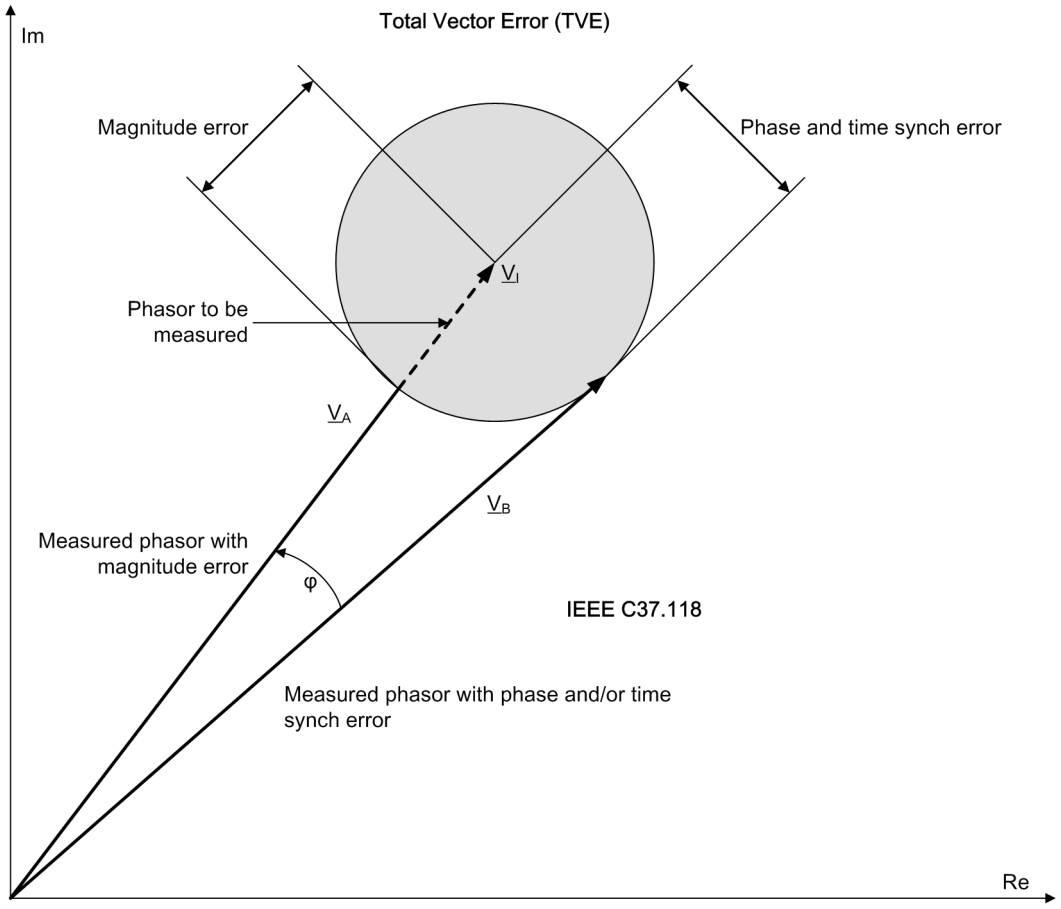
The phase angle of a measuring signal X_m is determined relative to a cosine function having a rated frequency, which is synchronized with the UTC time reference (see *Figure 9-6*).

[dw_utcphi, 1, en_US]

Figure 9-6 Determination of Phase Angle ρ of Measuring Signal X_m Relative to the Cosine Function

The number of phasors that are transmitted per second is configurable. The transmission rate is defined according to IEEE C37.118 as the reporting rate. The reporting rate defines the number of phasors that are transmitted per second. Extremely precise time synchronization is essential so that phasor measurement can be carried out to enable phasors from different sites to be compared via GPS.

Reporting Rate



You use the configurable reporting rate (parameter **(_:10621:102) Reporting rate**) to specify the number of telegrams that are generated and sent to the PDC per second. It is adjustable, depending on the rated frequency, and applies to all currents and voltages of the relevant **PMU** function group. If several **PMU** function groups are created on the device, these can work with different reporting rates.

Total Vector Error (TVE)

The TVE describes the error between the actual and the measured values of the input signal. The Synchrophasor Standard IEEE 37.118 defines upper limiting values of 120 % V_N and 200 % I_N, among other things. Up to these limiting values, the TVE of 1 % must not be exceeded for stationary signals. The standard defines the 2 performance classes, Class P and Class M, as ranges within which influencing variables are acceptable and the TVE of ≤1 % must be maintained. The SIPROTEC 5 devices support Class P and Class M, which specify the following influencing variables for a TVE of 1 %:

- Signal frequency (relative to f_N)
- Signal magnitude (relative to 100 % nominal magnitude) for voltage and current
- Phase angle (relative to 0°)
- Harmonic distortions (relative to < 0.2 % (THD) up to the 50th harmonic

The following figure graphically represents the total vector error. As well as the amplitude, the TVE also enters into the angle error.

[dw_klatve, 1, en_US]

Figure 9-7 Representation of the Total Vector Error

The TVE is defined as follows:

$$TVE = \sqrt{\frac{\left(X_{r(n)} - X_r\right)^2 + \left(X_{i(n)} - X_i\right)^2}{X_r^2 + X_i^2}}$$

[fo_utcphi_new, 1, en_US]

Where:

- $X_{r(n)}$ = Real part of measured signal
- $X_{i(n)}$ = Imaginary part of measured signal
- X_r = Real part, input signal
- X_i = Imaginary part, input signal

Variables that influence the TVE are:

- Amplitude errors
- Phase errors
- Synchronization accuracy (deviation from the UTC)

Synchronization accuracy is affected by a GPS timer and the precise correction of the time delay within the GPS receiver module, as well as by the optimal mounting arrangement of the GPS antenna.

9.5.4 Transmitted Data

The following data is transmitted from the PMU to the PDC:

- Current and voltage phasors
- Frequency
- Frequency rate of change
- Analog-channel data (active/reactive power)
- Binary information

The current and voltage channels transferred from a **PMU** function group are selected through the **Function group connections** editor in DIGSI 5. The frequency and frequency change rate are determined once per PMU. In this case, only the current and voltage channels selected via the **Function group connections** editor for this PMU are taken into consideration. You may route the binary information in the information routing matrix of DIGSI 5. You can instantiate the analog-channel data from the Global DIGSI 5 library in the **PMU** function group.

The channel used for specifying the frequency is selected dynamically during the device runtime. Each channel is checked for the presence of a signal in the following order:

1. 3-phase voltage measuring points
2nd 1-phase voltage measuring points
3rd 3-phase current measuring points
4th 1-phase current measuring points

The 1st measuring point found with a valid signal is used for specifying the frequency in the **PMU** function group.

In the case of 3-phase measuring points, the positive-sequence system can also be transmitted instead of or in addition to 3 individual sychrophasors. You can make the selection using the **(_:10621:103) Positive sequence** parameter, see *9.5.8 Application and Setting Notes*, *Parameter: Positive sequence, Page 2154*.

9.5.5 PMU Communication (IEEE C37.118)

PMU communication according to standard IEEE C37.118 is a client-server communication format in which the PDC (Phasor Data Concentrator) functions as both the client and the server.

Once the PDC has been successfully connected to the device PMU and the PMU configuration data has been queried, the PDC initiates transmission of the synchrophasor data by sending a close command to the PMU. If you use the method of spontaneous data transmission via UDP, data output starts immediately after the device boots without a close command to the PMU.

The values and names for the values are transmitted for the phasors, binary information, and analog channels. The names for the phasors and binary information are automatically generated by the respective PMU function groups. You must enter the analog-channel names yourself.

If necessary, you can edit the names for the phasors, binary information, and analog-channel data and assign your own designations for them. For more information, see chapter *9.5.6 Parameterizing the PMU with DIGSI*.

As an example, the names (generated) for measuring points or binary information may be as follows:

Table 9-4 Possible Measuring-Points Names

Name Displayed in the DIGSI Function Group Connections	Depending on the Connection Type, Name Transferred to the PDC (in case it cannot be assigned automatically)
Measuring point V-3ph 1[ID 1]	MP-V3ph VAB ID01 MP-V3ph VBC ID01 MP-V3ph VCA ID01 MP-V3ph VA ID01 MP-V3ph VB ID01 MP-V3ph VC ID01 MP-V3ph V1 ID01 MP-V3ph VN ID01
Measuring point I-3ph 1[ID 2]	MP-I3ph IA ID02 MP-I3ph IB ID02 MP-I3ph IC ID02 MP-I3ph I1 ID02 MP-I3ph IN ID02
Measuring point I-1ph 1[ID 3]	MP-I1ph ID03
Measuring point V-1ph 1[ID 4]	MP-V1ph ID04

Table 9-5 Possible Binary-Information Names

Path Displayed in DIGSI 5 (Can Be Edited)	Name Transferred to the PDC
PMU 1: Transf.bin.1: >BinaryInfo.6	BIN-01-INFO-6
PMU 1: Transf.bin.2: >BinaryInfo.8	BIN-02-INFO-8
PMU 1: Transf.bin.10: >BinaryInfo.3	BIN-10-INFO-3

Data is transmitted continuously from the PMU to the PDC at the configured reporting rate. The transmission is terminated by a corresponding trip command from the PDC or when the connection between the PDC and the PMU is interrupted.

Communication between the PMU and the PDC can be passed via TCP or UDP protocols.

The following ports are used for data transmission by default:

- TCP: Port 4712
- UDP: Port 4713

You can configure the ports anyway you wish in a range of 1 to 65535 using the **`TCP port`** and **`UDP port`** parameters.

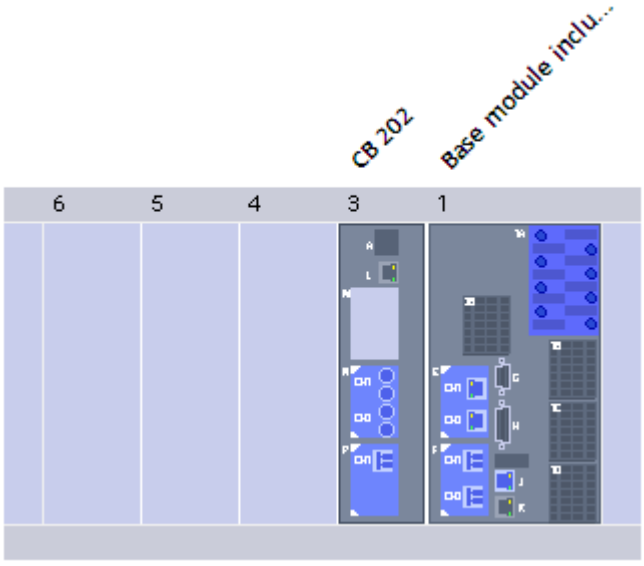
NOTE

When configuring the ports, do not set any ports already being used by other communication protocols. Configuring ports used elsewhere prevents communication with the PMU. In this case, data packets from the PDC cannot be received, and inquiries from the PMU cannot be transmitted.

If you are using the UDP protocol for communication between the PMU and the PDC, you can set either ***`command mode`*** or ***`asynchronous response mode`*** as the **`communication mode`**. In ***`asynchronous response mode`***, data can be transmitted continuously to preset PDC destination addresses in IEEE C37.118

format without a PDC having to request transmission of the synchrophasor data via a close command to the PMU.

Up to 4 different PDCs can be connected to one device PMU at the same time. The IP addresses of the maximum 4 PDCs are set in the **PMU** function group. If 4 device PMUs are configured, this enables support for up to 16 PDCs.



9.5.6 Parameterizing the PMU with DIGSI

You configure and parameterize the Phasor Measurement Unit with DIGSI. After a device has been added in a DIGSI project, one or more communication modules that support synchrophasors can be configured as PMUs. The device module supports a maximum of 2 communication modules that can be configured as PMUs. If more than 2 PMUs are needed, the device must be expanded with a CB202 plug-in module assembly (expansion module), which can accommodate 2 more communication modules.

The following communication modules support synchrophasors:

- ETH-BA-2EL (2 x Ethernet electric, RJ45)
- ETH-BB-2FO (2 x Ethernet optical, 2 km, LC duplex)
- ETH-BD-2FO (2 x Ethernet optical, 2 km, LC duplex)

These modules are then freely assignable to ports E, F, N, or P of the device, see *Figure 9-8*. You can view the selected port in the **`(_:10621:104) Port`**. This parameter is automatically managed by DIGSI and cannot be changed.

[sc_commod, 1, en_US]

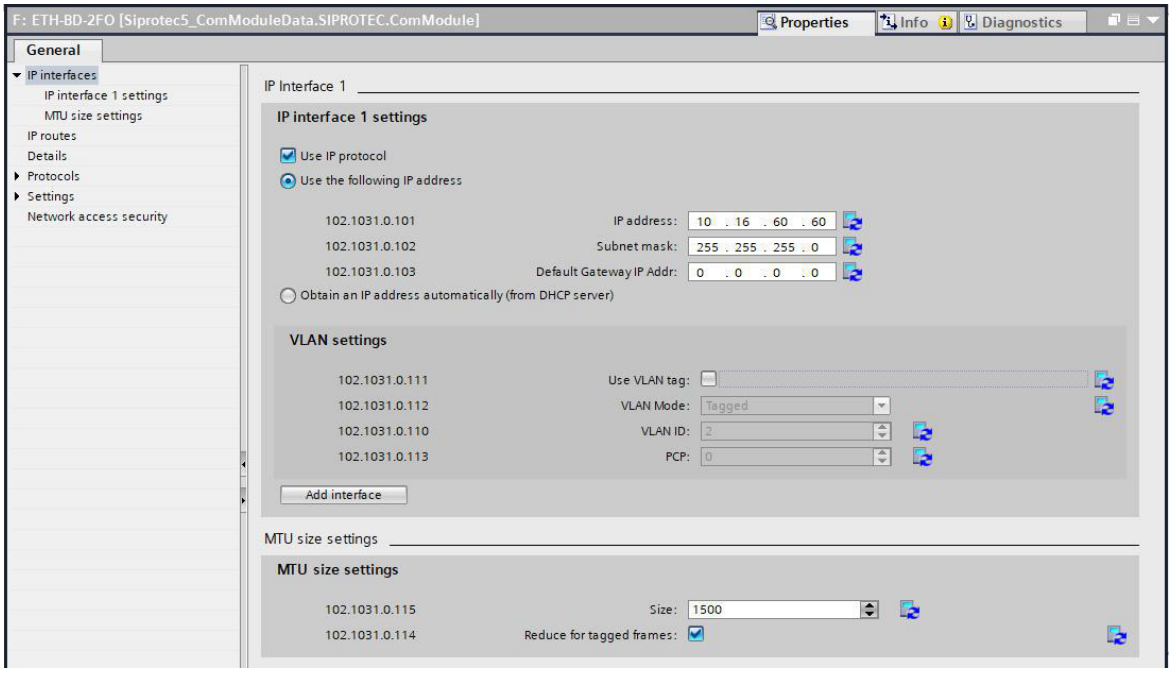


Figure 9-8 Placement of Communication Modules

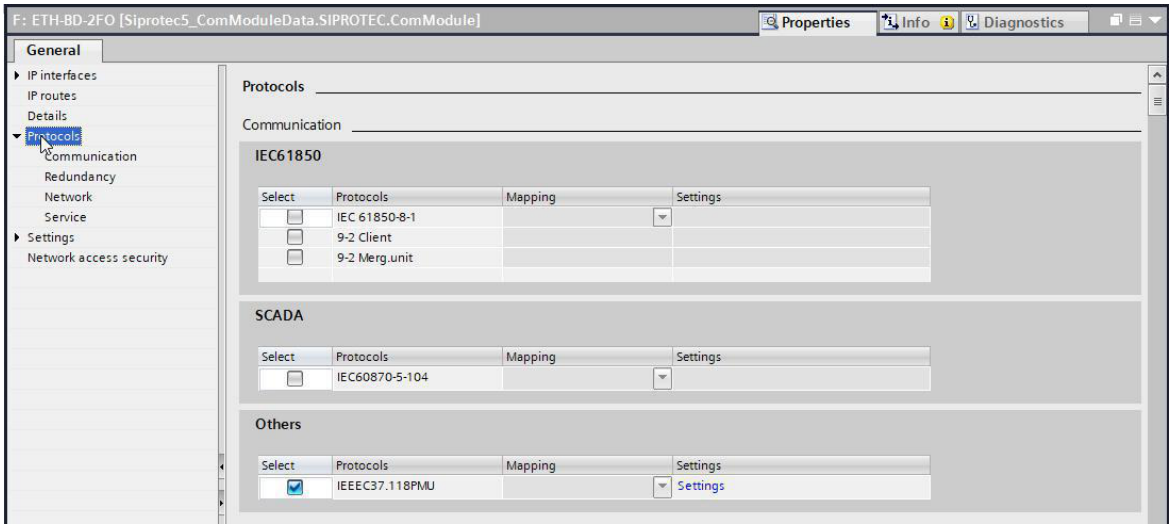
NOTE

Port M of the CB202 plug-in module assembly is used to accommodate measuring-transducer modules and cannot be used for the installation of communication modules.

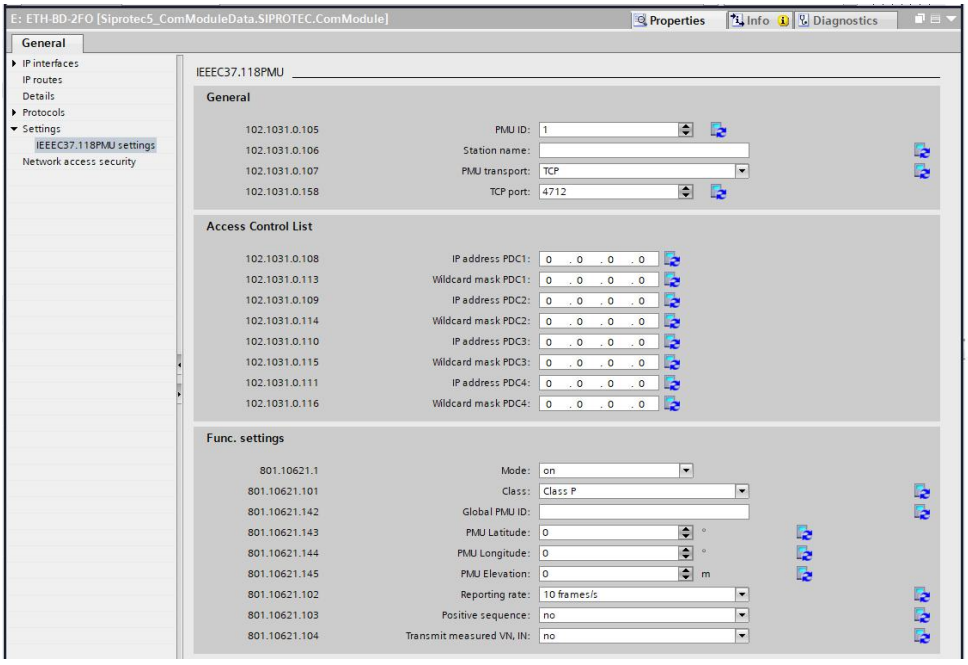
Addressing



You must configure the respective Ethernet address (IP address, subnet mask, etc.) for each communication module in DIGSI. This is done in the DIGSI **General settings** properties dialog of the communication module in item **Ethernet addresses** and so forms the IP address for the respective PMU.

[sc_ethern, 2, en_US]

Figure 9-9 Ethernet-Address Configuration



In the *Protocols – Communication* menu, select the synchrophasor protocol; see the following figure.

[sc_protoc, 2, en_US]

Figure 9-10 Protocol Selection

After you have selected the synchrophasor protocol for the communication module, a settings dialog for PMU-specific configuration opens in *Settings*; see the following figure.

[sc_wildcard, 3, en_US]

Figure 9-11 PMU-Specific Configuration

You configure the specific settings for the communication protocol in the top section of this settings dialog. In the bottom section, you specify the corresponding PMU-specific settings.

In order to permit a better configuration of larger wide-area supervision systems, changes have been implemented in the IEEE C37.118 communication configuration that permit a flexible IP configuration without the loss of safety aspects in the networks administered.

Configurable placeholders are allowed for every PDC/IP address with the ***TCP*** PMU transmission protocol in general and with ***UDP*** in the **Communication mode** ***Commanded operation***. These placeholders allow you to define a range of IP addresses where they are accepted within these accesses. The purpose of this is to permit each individual device or system access within the respective network without limits with regard to their hierarchy level. Therefore, with regard to security aspects, the limitation to individual IP addresses is eliminated. You are thus allowed to configure complete sections of IP addresses in each PMU and, as a result, very flexible when making changes to the configuration of the entire network, for example. The placeholder character must follow consecutively at the bit level, starting with the bit with the lowest value.

EXAMPLE of Placeholder Characters:

Example 1:

- binary 00000000.00000000.00000000.00101011 is not permitted
- binary 00000000.00000000.00000000.00111111 is permitted

Example 2:

- The PDC IP address is: 192.172.16.1
- Placeholder: 0.0.0.127

The device accepts requests within the IP address range of 192.172.16.1 to 192.172.16.127.

Example 3:

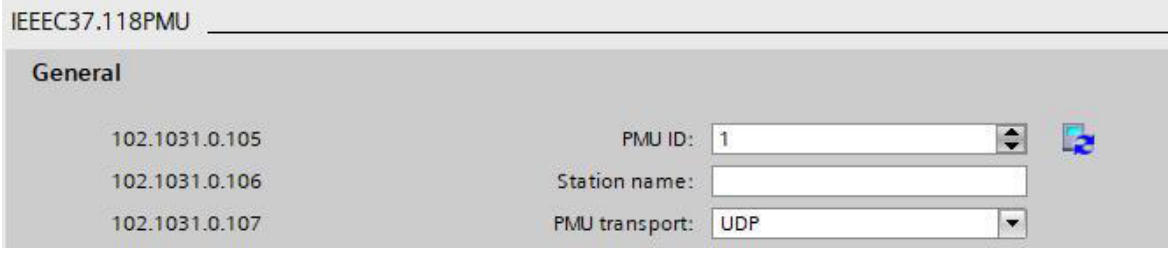
- The PDC IP address is: 192.172.16.100
- Placeholder: 0.0.0.3

The device accepts requests within the IP address range of 192.172.16.100 to 192.172.16.103.

If a PDC attempts to establish a connection to the device, the PDC IP addresses and corresponding placeholders are checked in the same order as they had been configured (IP address PDC1, IP address PDC2, IP address PDC3). Running through the list is stopped with the first match of the IP address, placeholder, and requested IP-address range and the connection is built-up. If there are no matches, the attempt to connect is rejected.

If you have configured the IP address 0.0.0.0 and the placeholder 255.255.255.255, every IP address received is accepted as valid. This could be of use in the course of commissioning measures.

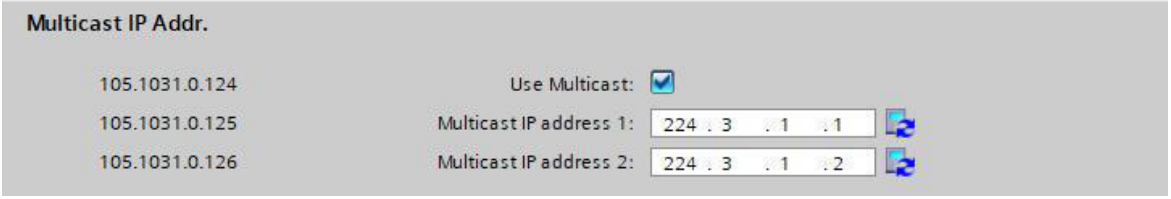
NOTE



You must have configured at least one IP address to establish a connection between the device and the PDC.

If you set ***UDP*** as the transmission protocol, you can transmit PMU data to groups of PDCs using IP multicast.

Using multicast, considerably more PDCs can be reached via one communication module than when every PDC connects in unicast mode. Usually, the address range from 224.0.0.0 to 239.255.255.255 is used.



NOTE

The router used must support the **IGMP** (Internet Group Management Protocol) V3 protocol.

[sc_PMU_multicast01, 1, en_US]

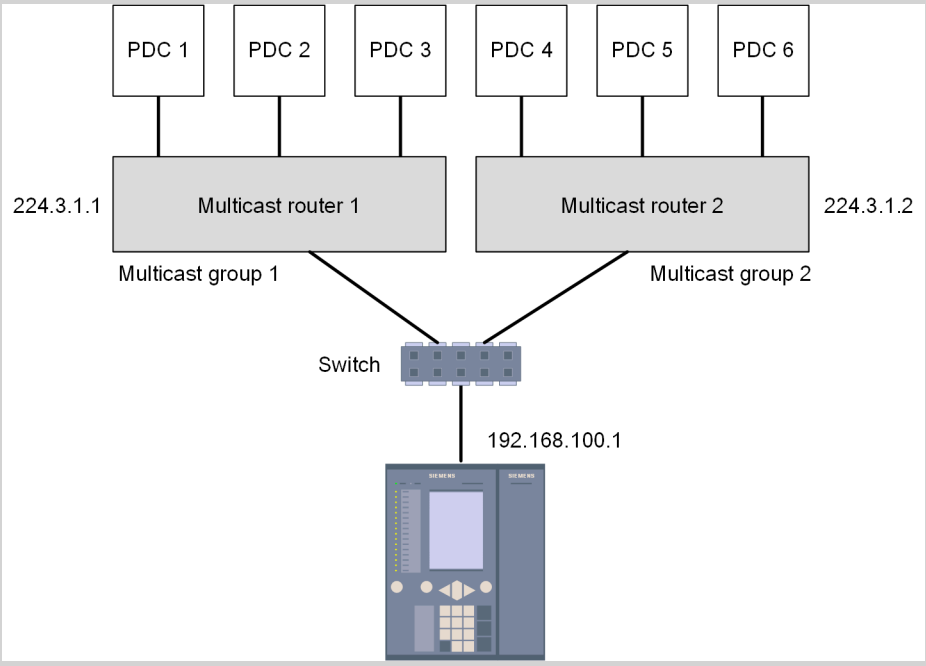
Make a checkmark at the ***Use multicast*** parameter. If ***Use multicast*** is checked, you can set up to 2 multicast IP addresses. If you do not put the checkmark in place, the settings for the multicast IP addresses are not displayed.

[sc_PMU_multicast03, 1, en_US]

NOTE

DIGSI does not check the validity of the set multicast IP address. A multicast IP address of 0.0.0.0 is ignored.

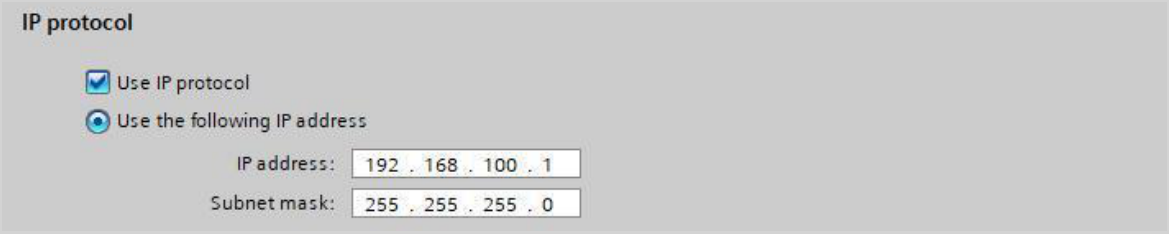
You can set the settings for the multicast IP addresses and the PDC IP addresses in the Access Control List. If ***Use multicast*** is active, all data packages of the PMU are transmitted to the parameterized multicast IP addresses, but not to the PDC IP addresses. Commands from PDCs in the Access Control List are processed as if operating without multicast. Responses are only transmitted by way of the multicast IP addresses. In the ***Command mode*** UDP communication mode, you need at least one additional PDC IP address in the Access Control List to start PMU data transmission (see *Figure 9-12*).



[sc_PMU_Multicast_Access, 1, en_US]

Figure 9-12 Access Control List

EXAMPLE



Multicast Operation

[dw_PMU_multicast_config_with_whitelist_PDC, 1, en_US]

Figure 9-13 PMU Multicast Configuration in Asynchronous Response Mode

Select the communication module in the **Hardware and protocols** menu in DIGSI. Set the IP address of the PMU (**192.168.100.1**) under **Properties → Ethernet addresses**.

[sc_IP_comm-mode_de, 1, en_US]

After you have selected the synchrophasor protocol for the communication module, a settings dialog for PMU-specific configuration opens in ***Settings***; see the following figure. Set the communication mode to ***Asynchronous response mode***.

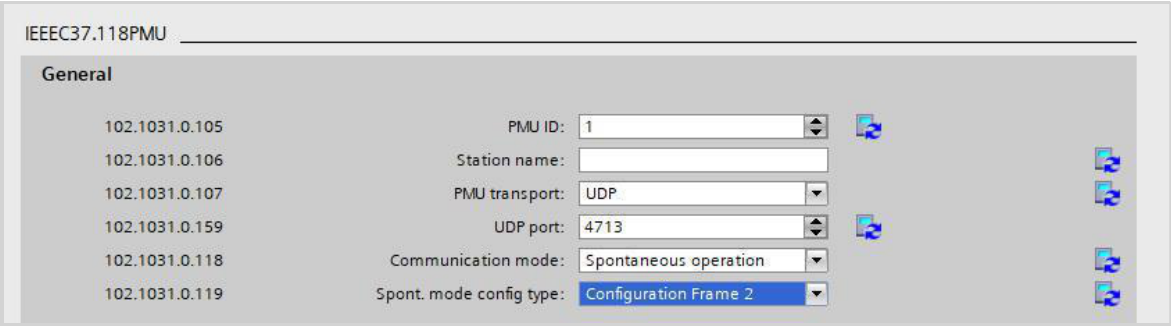


Figure 9-14 PMU Settings

In the following dialog, you set the IP addresses of the multicast routers:

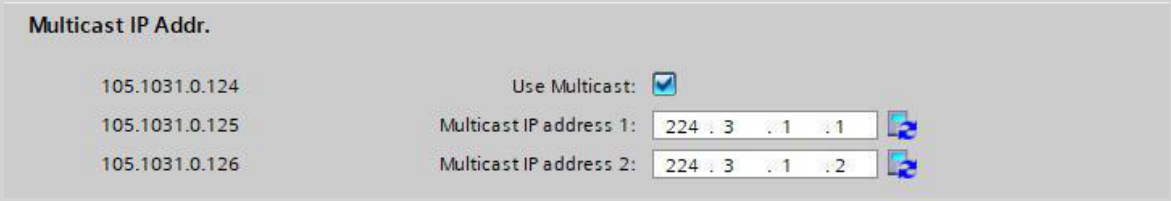

Figure 9-15 Additional Multicast IP Addresses During PMU Transport: UDP and Multicast

If you are using the **asynchronous data transmission method**, set the **`PMU transport`** parameter to ***`UDP`*** and the **`Communication mode`** parameter to ***`Spontaneous operation`***. The PMU data are then sent cyclically via UDP to every PDC/IP address permanently configured in DIGSI. You may not configure placeholders for PDC/IP address ranges in this communication mode.

Data output starts immediately after the device has booted. In this way, a starting signal from the PDC is not necessary to start data transmission.

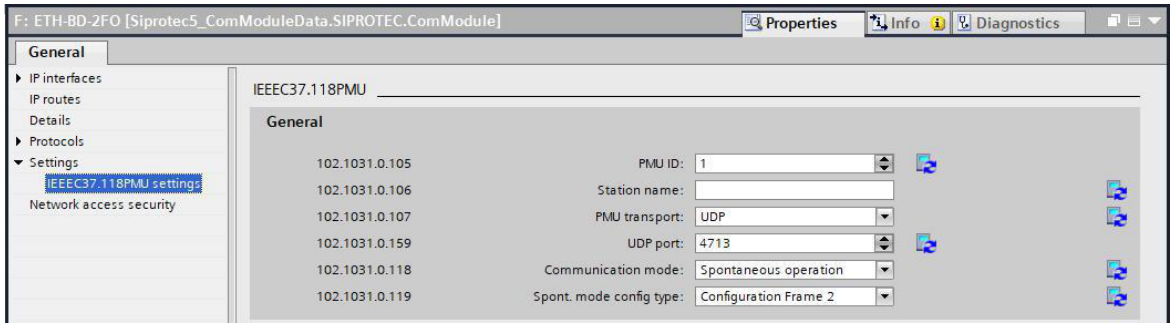

Figure 9-16 PMU Configuration for Spontaneous Transmission

The configuration dataset is transmitted 1x per minute. With the **`Spont. mode config type`** parameter, you select the type for the configuration data record. With the **`Reporting rate`** parameter, you configure the number of cyclic repetitions of the data packages. As UDP is a connectionless protocol, a preconfigured destination device with its PDC/IP address is not required to be physically present and/or connected. This allows uninterrupted provision of the data without bidirectional communication.

NOTE

If you have not configured valid PDC/IP addresses and still activate option for spontaneous data transmission, no cyclic data telegrams are sent.

NOTE

It is possible to configure IP addresses for various PDCs that are not present in the same subnetwork as the COM module. Such configurations are considered valid and can be loaded into the device. However, if the device transmits spontaneous data and configuration packages to these IP addresses, the PDC cannot be reached with the deviating subnetwork destination addresses.

NOTE

Commands or requests from an invalid PMU IP address are ignored.

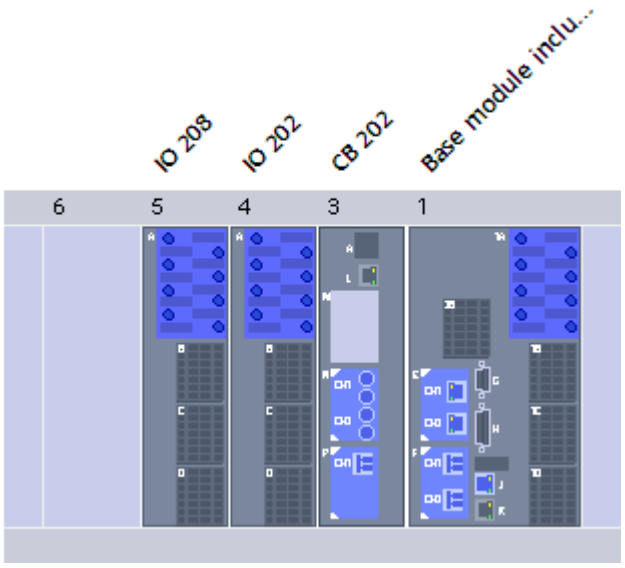
EXAMPLE

COM-Module Address Configuration

- IP address: **192**.168.100.1
- Subnet mask: **255**.255.255.0

PDC Address Configuration

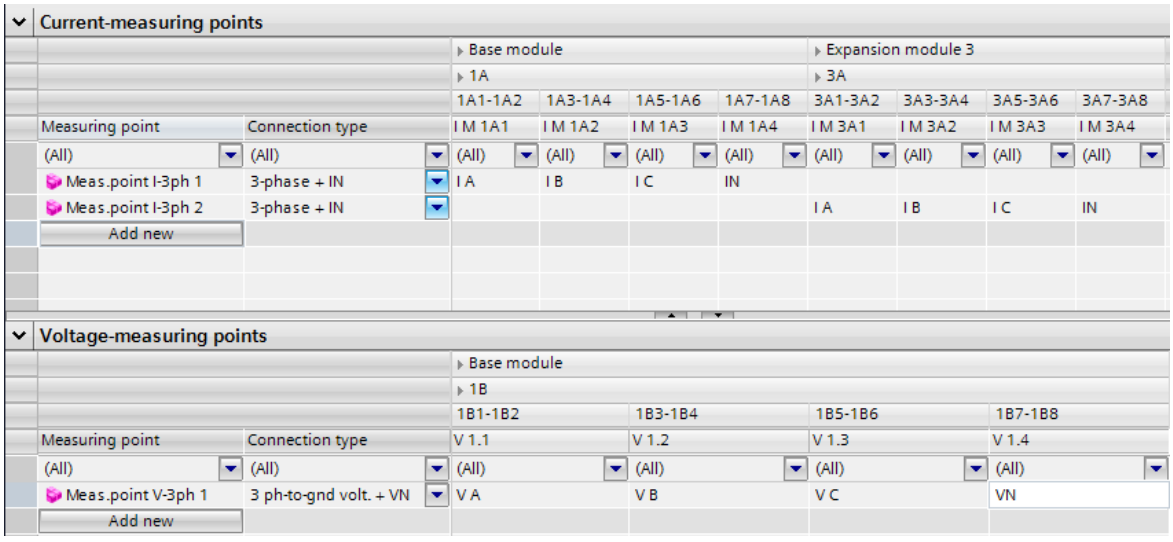
- IP address for PDC1: **192**.168.100.160
- IP address for PDC2: **86**.168.100.161



Only PDC1 receives the data because the IP address is in the same subnetwork as the COM module.

PDC2 cannot be reached because the subnetwork address (**86**.x) differs from the subnetwork address of the COM module (**192**.x). The PMU cannot transmit data to this address.

In addition to the PDCs IP addresses, the port can also be configured, which ensures the communication between the PMU and PDC. You can find the TCP or UDP port parameter in place for this purpose, depending on the configured transmission protocol. With the parameters, you can configure the port in a range of 1 to 65 535. The setting for these parameters is stored, even when the parameter is not visible due to the configuration of the transmission protocol. If, for example, TCP has been configured as a transmission protocol, the TCP port is not visible, but the setting has been stored in the background in DIGSI and is still available for use later on.



Measuring-Point Assignment

After adding measuring points to the device, you can assign these measuring points to each configured PMU. *Figure 9-17* shows an example of how the device configuration can be supplemented with 2 additional input/output modules. You connect the current and voltage inputs of these I/O modules to measuring points via the DIGSI routing matrix, see example in *Figure 9-18*.

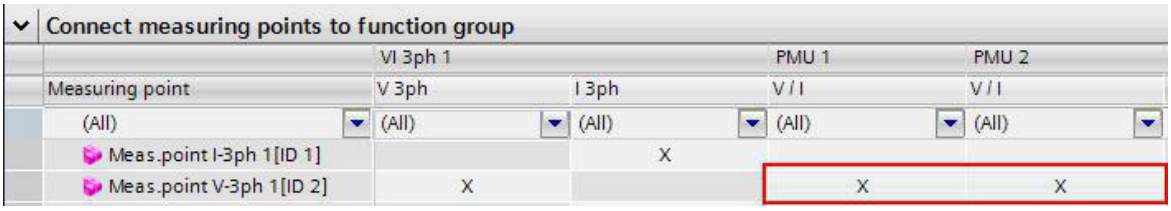
[sc_addios, 1, en_US]

Figure 9-17 Adding Additional Input/Output Modules

[sc_routin, 1, en_US]

Figure 9-18 Assignment of the Current and Voltage Inputs of the Added Input/Output Modules on Measuring Points

NOTE



Consider that the maximum amount of measuring points that can be routed is limited by the device.

The maximum numbers of measuring points that can be routed for one PMU are:

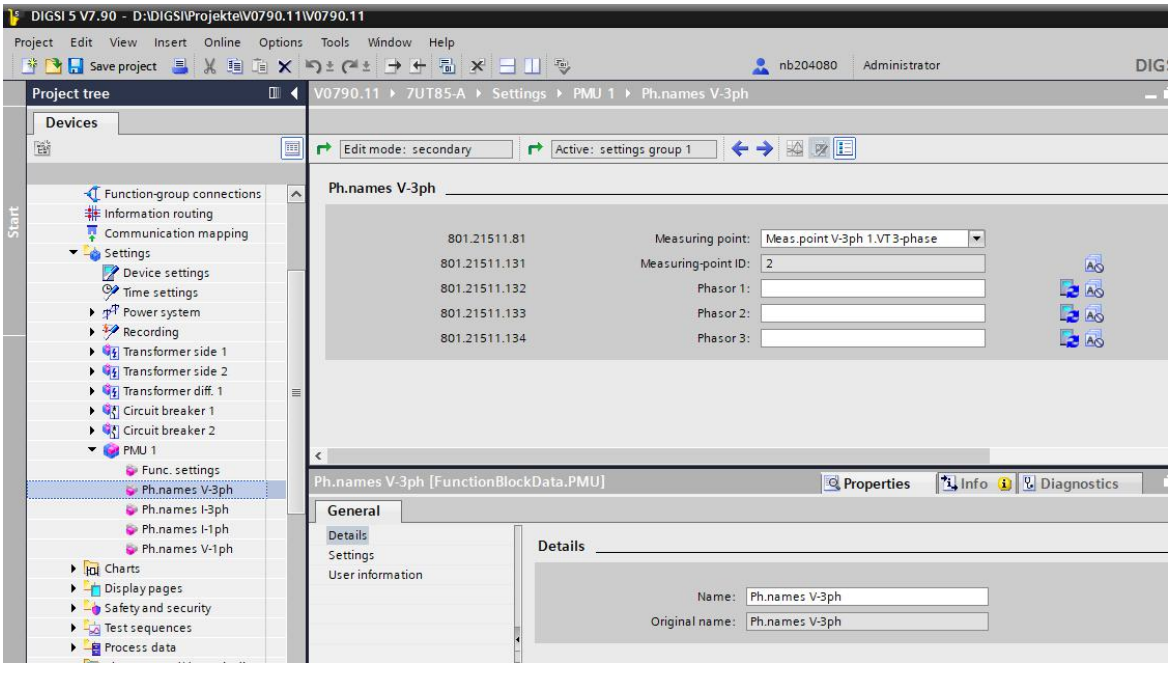
- 20 x 3-phase voltage measuring points
- 20 x 3-phase current measuring points
- 40 x 1-phase voltage measuring points
- 40 x 1-phase current measuring points

You can assign all supported measuring points to any PMU, see the following figure. Each PMU must be connected to at least one measuring point, and the total number of phasors (a 3-phase measuring point = 4

phasors) must not exceed 80 per PMU. The limitation of the load model must also be considered, depending on the device configuration.

[sc_fgconn, 1, en_US]

Figure 9-19 Connecting Measuring Points to the Configured PMU Function Groups



When these setting steps have been completed, the PMUs are fully configured. The **PMU** is a function group that functions independently of all the other function groups instantiated in the device.

Changing the Channel Names of Phasors

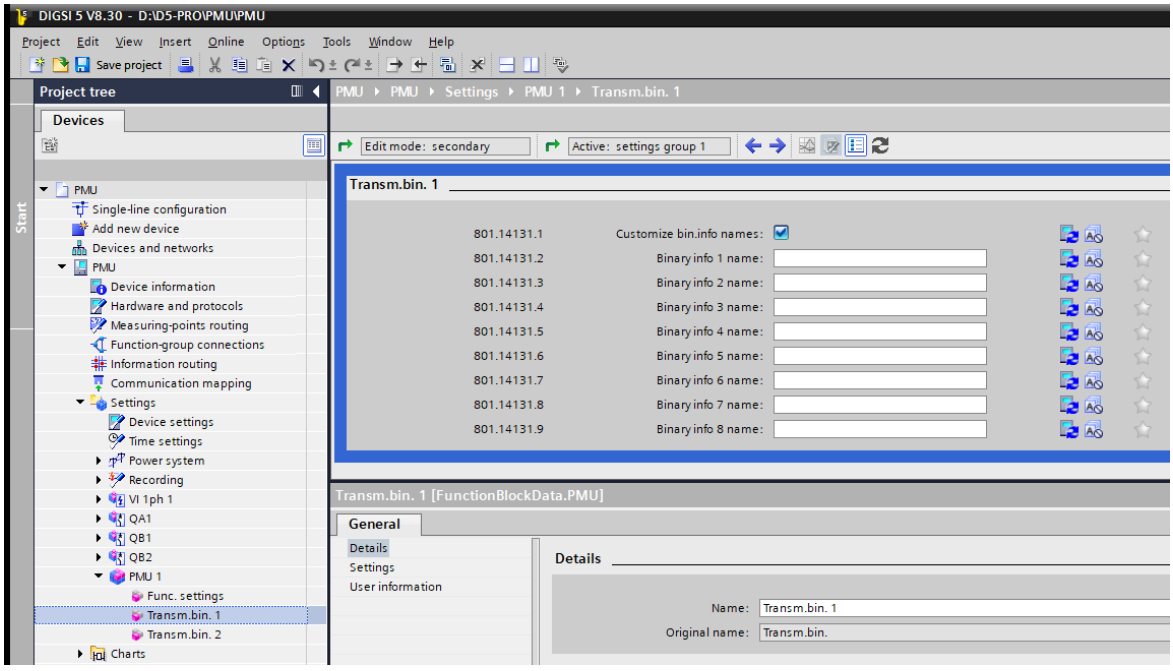
You can edit the names of the individual phasor channels for voltages and currents in DIGSI. Clearly structured channel designations support the testing and commissioning of PMU systems. Furthermore, only the names visible in the IEEE C37.118 interface can be changed. The function block designations themselves cannot.

The IEEE C37.118 defines the ASCII character set for changing the channel names. Due to the protocol, the designation length is limited to 255 ASCII characters per channel for CFG3, and to 16 ASCII characters per channel for CFG2.

In order to define your own channel names, firstly instantiate the required number of **Phasor names** function blocks in the **PMU** function group. Assignment to the corresponding measuring points is performed by the *Measuring point* selection. For this purpose, DIGSI shows all measuring points routed to the PMU in the function group connections (see following figure).

[sc_phasor_edit, 1, en_US]

Figure 9-20 Options for Editing the Names of the Individual Phasors



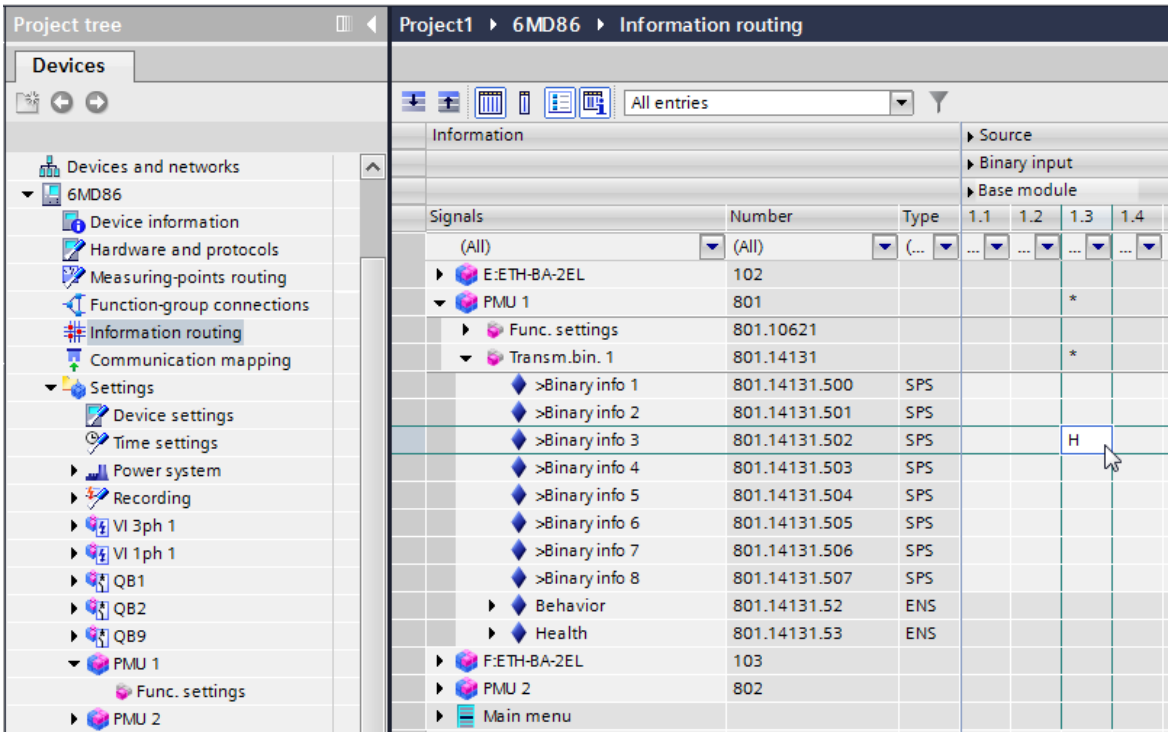
NOTE

You can only rename each individual phasor when you set the parameter **`Positive sequence`** to ***`no`*** or ***`additionally`*** in the function settings. Otherwise you will only be offered one single phasor for each 3-phase measuring point for renaming.

Changing the Channel Names of Binary Channels

You can edit the names of the binary channels in DIGSI. Clearly structured channel designations support the testing and commissioning of PMU systems. You can edit the names of the binary channels visible in the IEEE C37.118 interface in DIGSI. To do this, tick the **`My binary info names`** check box in the **Binary info transmission** function block (see *Figure 9-21*).

The IEEE C37.118 defines the ASCII character set for changing the channel names. Due to the protocol, the designation length is limited to 255 ASCII characters per channel for CFG3, and to 16 ASCII characters per channel for CFG2.



[sc_PMU_bin_info_edit, 1, en_US]

Figure 9-21 Options for Editing the Names of the Individual Binary Channels

Routing Binary Signals

You can connect binary inputs via DIGSI information routing to binary channels of the PMU. As an alternative, you can also route the binary inputs via a function chart (CFC). You will find, in the **Phasor Measurement Unit (PMU)** folder, the **Binary information transmission** function block in the DIGSI function library (see the following figure). You can instantiate this function block up to 10 times in one **PMU** function group. Each of these function blocks contains 8 options for routing binary channels.

[sc_pmu_bif, 1, en_US]

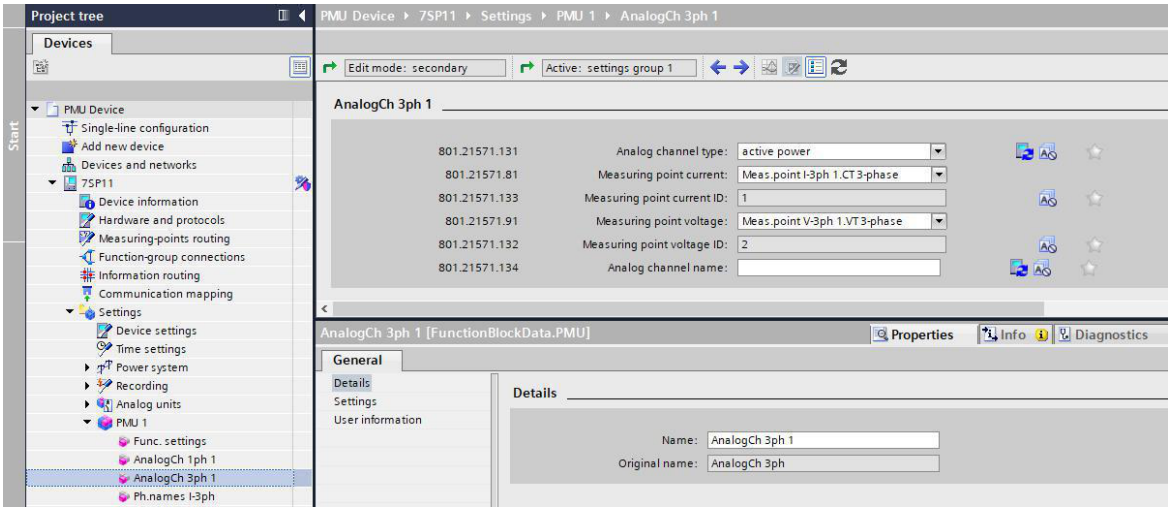


Figure 9-22 Information Routing in DIGSI 5

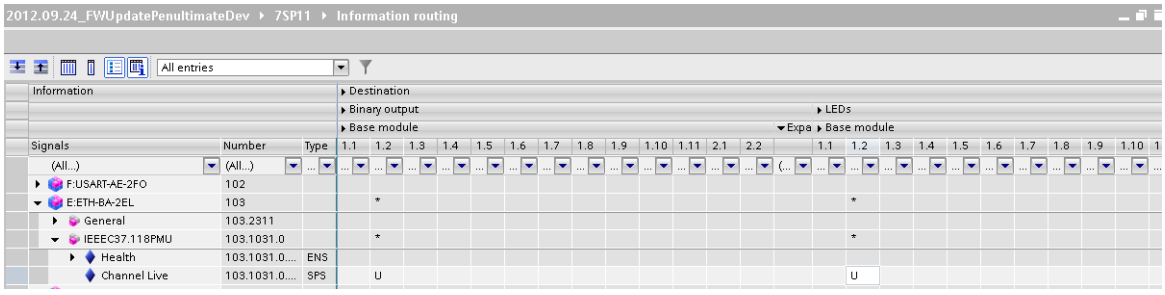
Routing Analog-Channel Data

In a **PMU** function group, you can instantiate the analog-channel data using the FBs **AnalogCh 1ph** or **AnalogCh 3ph**. In this case, a maximum of 30 instances per function-block type can be used.

With the parameters of the FBs **AnalogCh 1ph** or **AnalogCh 3ph**, you can assign the measuring points. You can only use the measuring points that have previously been assigned to the **PMU** function group.

You can also adjust whether the active or reactive power must be transmitted and assign a name to the analog channel. Due to the protocol, the designation length is limited to 255 ASCII characters for CFG3 and to 16 ASCII characters for CFG2.



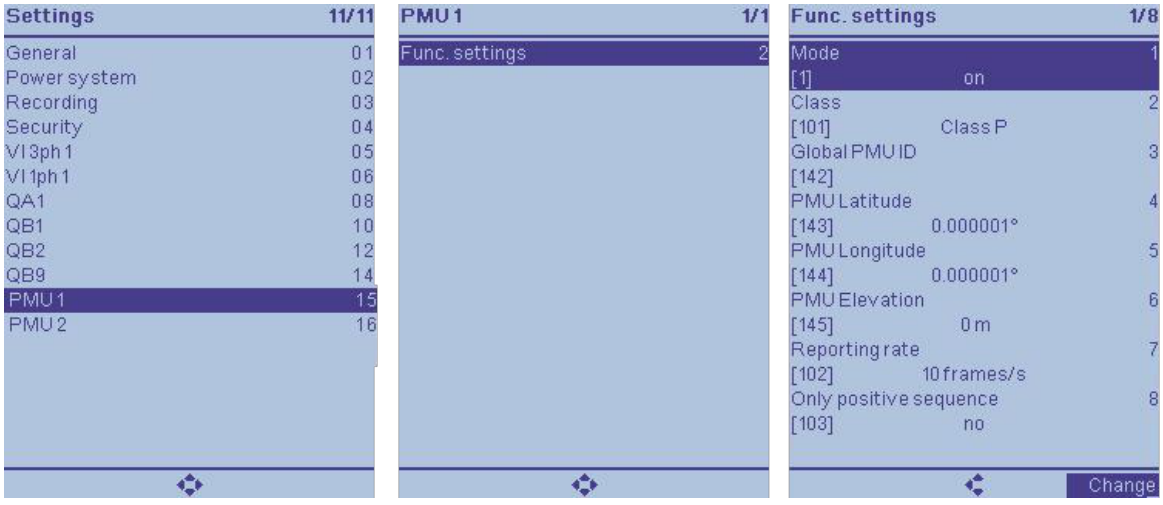
[sc_analog_channel, 1, en_US]

Figure 9-23 Routing Analog-Channel Data

Routing Indications

The routable indication *ChannelLive* of the PMU log

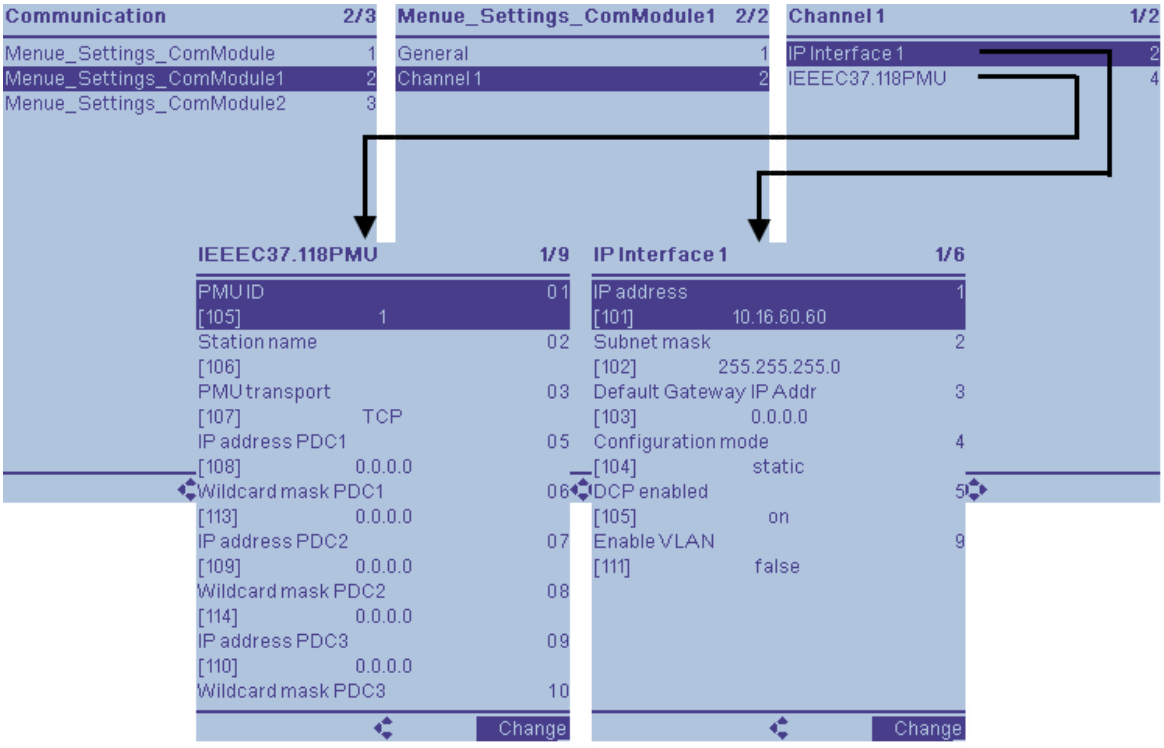
- raises when the PMU is connected to the PDC
- clears when the connection to the PDC is interrupted.



[sc_parami, 1, en_US]

Figure 9-24 Log Indication for Display of the PMU/PDC Connection

9.5.7 Parameterizing the PMU on the Device



You can also change the PMU settings directly on the device. To do this, select the desired PMU instance on the device display. By selecting menu item **Settings** you then access the editable setting values (see *Figure 9-25*). Note that the parameter **`Port`** cannot be changed, because this corresponds to the physical slot position of the communication module in question.

[sc_devpmu, 2, en_US]

Figure 9-25 Changing the PMU Setting Values via the Device Display

You can also change the communication settings in the same way. To do this, select the corresponding communication port in the **Communication** menu on the device display. From the **Channel 1** menu item, you can then access the detailed setting options for the IP or PMU communication settings (see *Figure 9-26*).

[sc_compmu, 2, en_US]

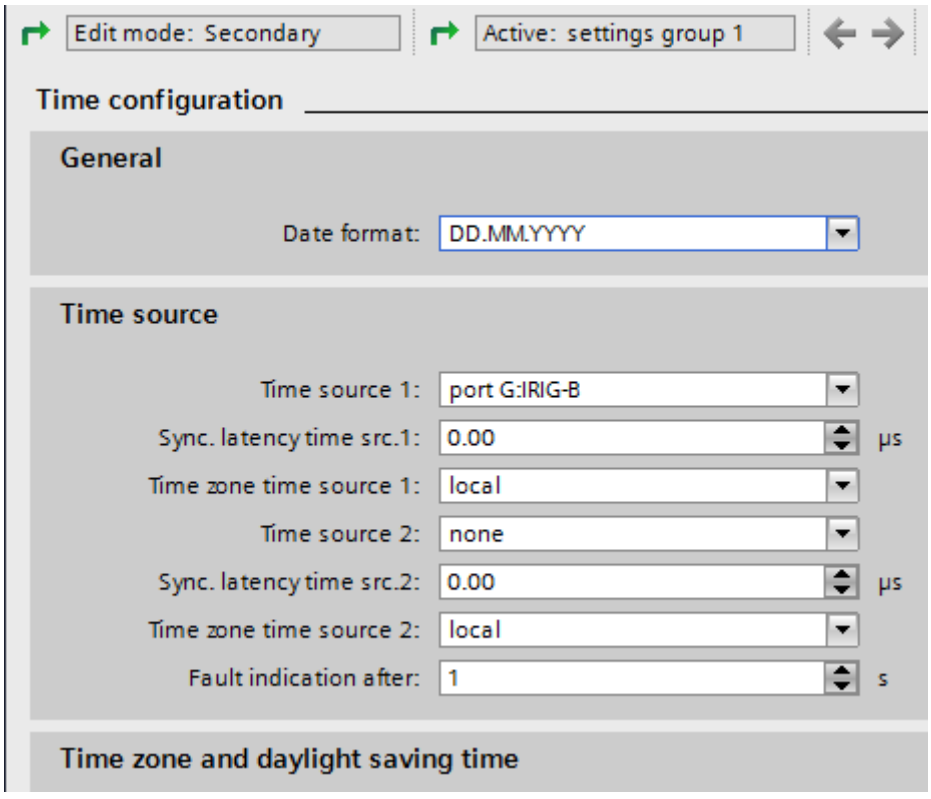


Figure 9-26 Changing the Communication Setting Values via the Device Display

9.5.8 Application and Setting Notes

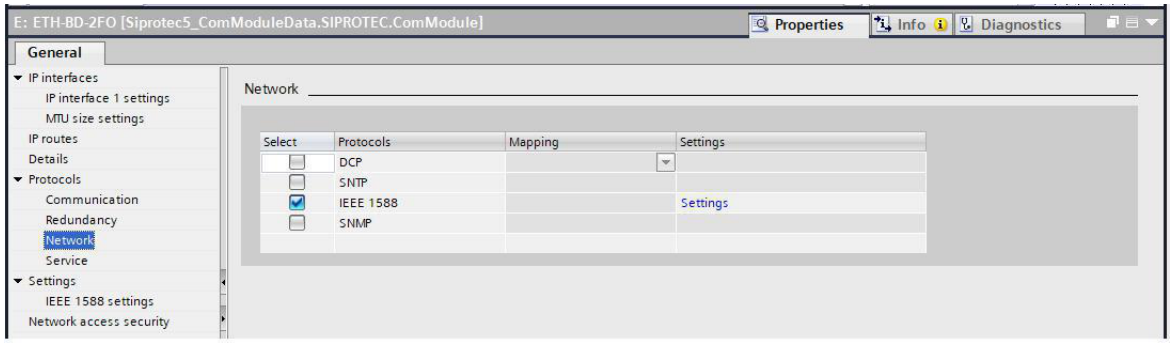
Time Synchronization

In order to ensure the time accuracy of the PMU, you must select **IRIG-B** as the protocol for the GPS clock (*Figure 9-27*) or, if an ETH-BD-2FO communication module is present, IEEE 1588 (*Figure 9-28*). With other settings, the **PMU function** function group indicates that it is not time synchronized.

Setting Time Synchronization – IRIG-B

[sc_setting time source, 1, en_US]

Figure 9-27 Setting Time Synchronization – IRIG-B

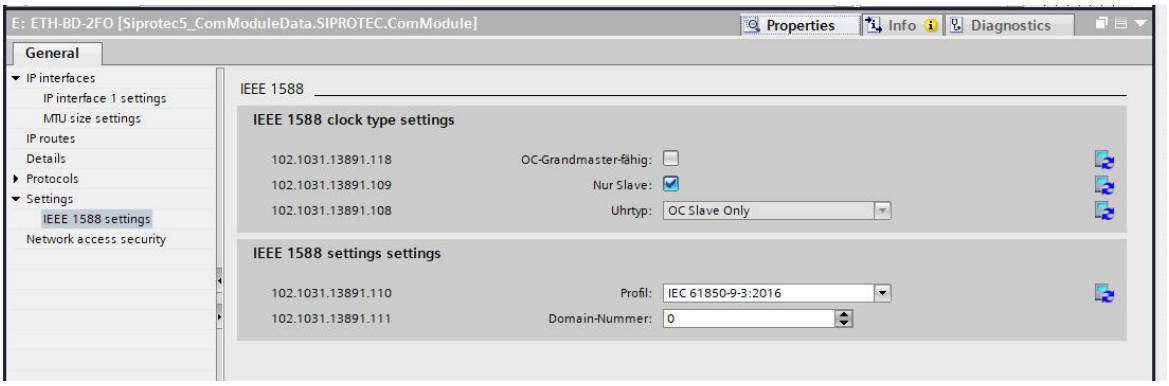


To detect a lack of synchronization quickly, also set the waiting time for the failure indication of the loss of time synchronization to the smallest possible value, thus to 1 s.

Setting Time Synchronization – IEEE 1588 (Precision Time Protocol (PTP))

Activate IEEE 1588 on the ETH-BD-2FO communication module.

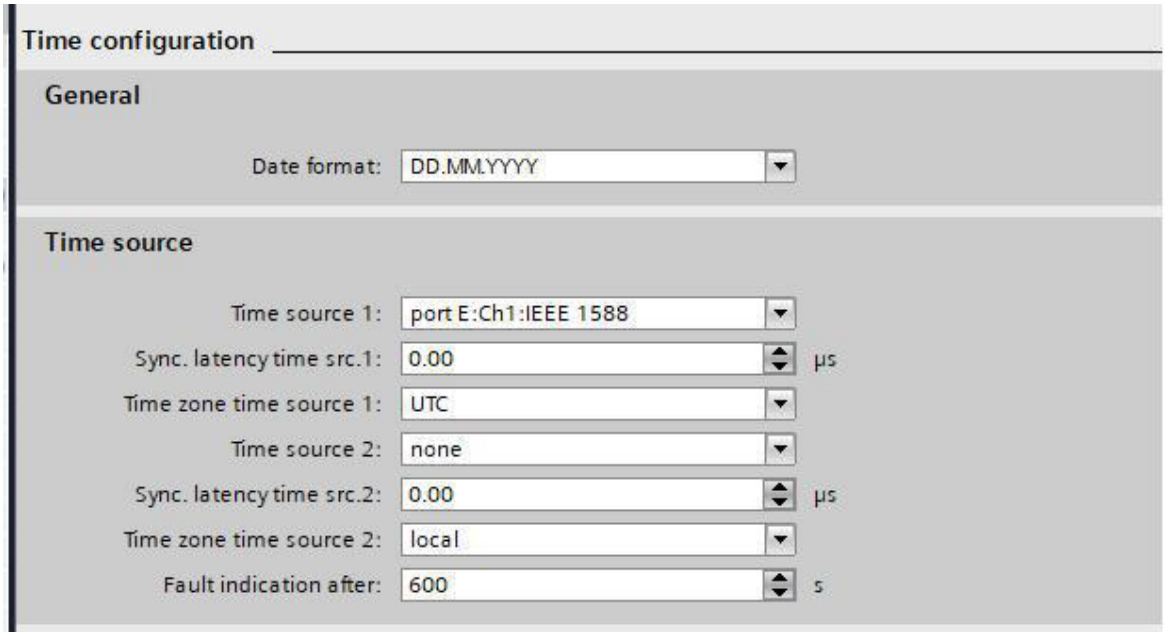
NOTE



For PMU applications, use the IEEE 1588 protocol on the communication modules ETH-BD-2FO, ETH-BA-2FO (revision 2), or ETH-BB-2FO (revision 2), because the IEEE 1588 protocol that can be activated on the other modules does not deliver the required accuracy.

[sc_activate_ieee_1588, 1, en_US]

Figure 9-28 IEEE 1588 Activation for the ETH-BD-2FO Module



Ensure that the domain number in the IEEE 1588 settings matches that of the switch used.

Select IEEE 1588 as the time source in the time configuration.

[sc_choose_of_time, 1, en_US]

Figure 9-30 Selection of Time Source

When selecting the switch used, make sure it supports the PTP standard IEEE 1588. Siemens recommends the RUGGEDCOM RSG2488.

Parameter: Mode

- Default setting **(_:10621:1) Mode** = ***on***

With the parameter **Mode**, you activate or deactivate the PMU, or you switch it to test mode. The possible setting values are ***on***, ***off*** and ***test***. In Test mode, the PMU data is marked as invalid.

Parameter: Reporting rate

- Default setting **(_:10621:102) Reporting rate** = ***10 frames/s***

With the parameter **Reporting rate**, you specify the number of telegrams that are compiled and sent to the PDC per second.

NOTE

Different setting values are shown or hidden, depending on the rated frequency set. You can set a reporting rate of 200 frames/s (50 Hz) or 240 frames/s (60 Hz) only when using an ETH-BD-2FO module.

Parameter: Positive sequence

- Default setting **(_:10621:103) Positive sequence** = ***no***

With the parameter **Positive sequence**, you can set whether the PMU transmits the positive-sequence system. The following setting values can be used:

Parameter Value	Meaning
no	The PMU only transmits the 3 individual synchrophasors for the 3-phase measuring points.
only	The PMU only transmits the positive-sequence system instead of the 3 individual synchrophasors for the 3-phase measuring points.
additionally	The PMU transmits the positive-sequence system in addition to the 3 individual synchrophasors for the 3-phase measuring points.

The setting you make here is then valid for all PMUs with 3-phase measuring points.

Parameter: Transmit measured VN, IN

- Default setting **(_:10621:104) Transmit measured VN, IN** = ***no***

This parameter is only visible if you route the **Measuring point V-3ph** or the **Measuring point I-3ph** with VN or IN to the **PMU** in DIGSI 5. The routing option is in the DIGSI 5 project tree in **Device Name** → **Function-group connections** in the **Measuring points** ↔ **Function group** settings sheet.

With this parameter, you define whether or not the **PMU** transmits VN and IN.

Parameter: Class

- Default setting **(_:10621:101) Class** = ***Class P***

With the parameter **Class**, you set which performance class is used for the calculation of the measured values. ***Class P*** is the standard case for PMUs. In this case, filters are used that provide a short response time and that are therefore suitable for recording dynamic processes. ***Class M*** is intended for applications that are unfavorably affected by alias effects and in which short response times are not relevant.

Parameter: Global PMU ID

- Default setting **(_:10621:142) Global PMU ID** = ***Freely editable text***

With the parameter **Global PMU ID**, you enter a global ID for the PMU, which can contain up to 16 characters.

Parameter: PMU Latitude

- Default setting **(_:10621:143) PMU Latitude** = ***0.00000000*** **°**

With the parameter **PMU Latitude**, you set the latitude to a value between -90,00000000 ° and +90,00000000 °.

Parameter: PMU Longitude

- Default setting **(_:10621:144) PMU Longitude** = ***0.00000000*** **°**

With the parameter **PMU Longitude**, you set the current longitude to a value between -180,00000000 ° and +180,00000000 °.

Parameter: PMU Elevation

- Default setting **(_:10621:145) PMU Elevation** = *0.00 m*

With the parameter **PMU Elevation**, you set the current height above sea level to a value between -50 000.00 m and +50 000.00 m.

Parameter: Port

This parameter cannot be set, because the **Port** results from the physical position where the corresponding communication module is inserted.

9.6 Average Values

9.6.1 Function Description of Average Values

Average values can be formed based on different measurands:

- Operational measured values
- Symmetrical components

Through the settings, you can set how and when the average values are formed. The settings describe:

- Time slot over which the average value is formed
  (Parameter: **Average calc. interval**)
- Update interval for the display of the average values
  (Parameter: **Average update interval**)
- Synchronization time for establishing the date of commencement updating information, for example, at the top of the hour (hh:00) or at one of the other times (hh:15, hh:30, hh:45).
  (Parameter: **Average synchroniz. time**)

Average values are formed through the following measurands:

- Operational measured values except for phase-related ratings
- Amounts of the symmetrical components

You reset the average value formation via the

- Binary input >Reset average value
- DIGSI
- The integrated operation panel

NOTE

With the **P, Q sign** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see Chapter *9.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

- Active power (total): P total
- Reactive power (total): Q total

9.6.2 Application and Setting Notes for Average Values

The average value formation functionality is not preconfigured with the devices in the function group. If you use the functionality, you must load it from the library into the respective function group.
The following settings listed for the calculation of the average values can be set with DIGSI and at the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Average calc. interval

- Default setting: **(_:104) Average calc. interval** = ***60 min***

Parameter Value	Description
1 min to 60 min	Time slot for averaging, for example 60 minutes

Parameter: Average update interval

- Default setting: **(_:105) Average update interval** = ***60 min***

Parameter Value	Description
1 min to 60 min	Update interval for displaying the average value, for example 60 minutes

Parameter: Average synchroniz. time

- Default setting: **(_:106) Average synchroniz. time** = ***hh:00***
  The parameter describes the synchronization time for average value formation.

Parameter Value	Description
hh:00	The parameter **Average update interval** will be effective on the full hour
hh:15	The parameter **Average update interval** will be effective 15 minutes after the full hour
hh:30	The parameter **Average update interval** will be effective 30 minutes after the full hour
hh:45	The parameter **Average update interval** will be effective 45 minutes after the full hour

NOTE

The average value calculation restarts after

- Changing one of the 3 settings for the average-value calculation
- Resetting the device (initial or normal reset)
- Changing the time
- Resetting the average values

The average values are reset immediately. The display changes to "---".

The following examples explain how to set parameters and to make a change.

Average calc. interval = **60 min**
Average update interval = **30 min**
Average synchroniz. time = ***hh:15***.

A new average value is formed every 30 min, at hh:15 (15 min after the top of the hour) and hh:45 (15 min before the top of the hour). All measured values obtained during the last 60 min are used for average value formation.
If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 12:15:00.
In this example, the **Average synchroniz. time** = ***hh:45*** acts as described above for = ***hh:15***.

Average calc. interval = **60 min**
Average update interval = **60 min**
Average synchroniz. time = ***hh:15***.

A new average value is formed every 60 min at hh:15 (15 min after the top of the hour). All measured values obtained during the last 60 min are used for average value formation.
If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 12:15:00.

Average calc. interval = **5 min**
Average update interval = **10 min**
Average synchroniz. time = ***hh:00***.

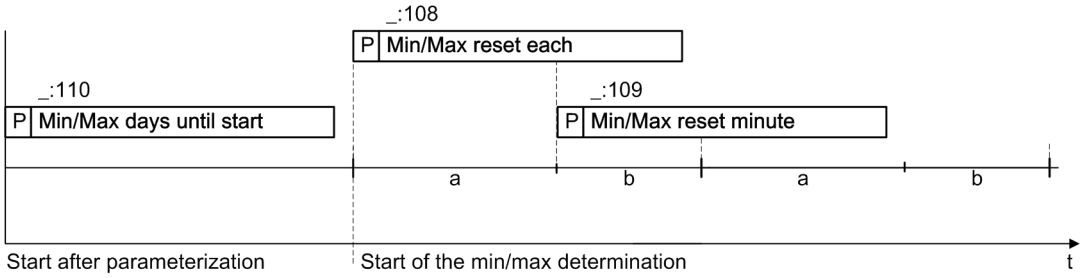
A new average value is formed every 10 min at hh:00, hh:10, hh:20, hh:30, hh:40, hh:50. All measured values obtained during the last 5 min are used to form the average value.

If these settings are changed to 11:03:25, for instance, the average values are first reset and "---" appears in the display. The 1st average value is then formed at 11:10:00.

9.7 Minimum/Maximum Values

9.7.1 Function Description of Minimum/Maximum Values

Minimum and maximum values can be formed based on different measured or calculated measurands:



- Operational measured values
- Symmetrical components
- Selected values

You can set which measurand will be used. The measurands for the minimum/maximum formation are loaded from DIGSI.

Calculation and resetting of the minimum and maximum values are controlled through settings. The settings describe the following points:

- Memories of the minimum/maximum values are reset to 0 cyclically or not at all.
  (Setting **`Min/Max cyclic reset`**)
- Point in time when the memories of the minimum/maximum values are reset to 0.
  (Setting **`Min/Max reset each`** and setting **`Min/Max reset minute`**)
- Point in time at which the cyclical reset procedure of the minimum/maximum values begins (after the parameterization)
  (Setting **`Min/Max days until start`**)

The following figure shows the effect of the settings.

[dw_min_max, 1, en_US]

Figure 9-31 Minimum and Maximum-Value Formation

Minimum and maximum values are time-stamped.

Minimum/maximum values are formed through:

- Operational measured values except for phase-related ratings
- Amounts of the symmetrical components
- Average values

The minimum and maximum values are reset on a regular basis or via the

- Binary input >Reset min/max
- DIGSI
- The integrated operation panel

NOTE

With the **P, Q sign** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see Chapter *9.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

- Minimum/maximum values of the active and reactive power:
  Min:Ptotal, Max:Ptotal, Min:Qtotal, Max:Qtotal
- Minimum/maximum values of the average values of the active and reactive power:
  AverageMin:Ptotal, AverageMax:Ptotal, AverageMin:Qtotal, AverageMax:Qtotal

9.7.2 Application and Setting Notes for Minimum/Maximum Values

The minimum/maximum values functionality is not preconfigured. If you want to use the functionality, you must load it from the library into the respective function group.

The following settings listed for the calculation of the minimum/maximum values can be set with DIGSI or at the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Min/Max cyclic reset

- Default setting: **(_:107) Min/Max cyclic reset** = ***yes***

Parameter Value	Description
Yes	Cyclical resetting of the minimum and maximum value memories is activated
No	Cyclical resetting of the minimum and maximum value memories is deactivated None of the following parameters are visible

Parameter: Min/Max reset each

- Default setting: **(_:108) Min/Max reset each** = ***1 day***

Parameter Value	Description
1 day to 365 days	Resetting of the minimum value and the maximum value, cyclically on all specified days, for example each day (1 day)

Parameter: Min/Max reset minute

- Default setting: **(_:109) Min/Max reset minute** = ***0 min***

Parameter Value	Description
0 min to 1439 min	Resetting the minimum value and the maximum value at the specified minute of the day, which is stated in the parameter **Min/Max Reset takes place every**, for example 0 min 0 min (= 00.00)

Parameter: Min/Max days until start

- Default setting: **(_:110) Min/Max days until start** = ***1 day***

Parameter Value	Description
1 day to 365 days	Indication of when the cyclical reset procedure of the minimum values and maximum values begins, for example in 1 day (after the parameterization)

9.8 Energy Values

9.8.1 Function Description of Energy Values

The device continually determines the values for the active and reactive energy from the power-measured values. It calculates the exported and imported electrical energy. The calculation (summation over time) begins immediately after the device startup. You can read the present energy values on the device display or through DIGSI, delete the energy value (set to 0), or set it to any initial value. After input, the energy-value calculation will continue with the new setting values.

Energy values can be transferred to a control center through an interface. The energy values are converted into energy metered values. Here the following applies:

$$\text{Energy metered value} = \frac{\text{Energy value}}{S_{N,obj.}} \cdot 60000 \frac{\text{Pulses}}{\text{h}}$$

[fo_omverg, 1, en_US]

Through the settings, you set how the metered values are processed. The setting parameters apply for all energy metered values of the device, and do not have a function-group specific effect. You determine the following points:

- Parameter **`Energy restore time`**

  Hour-related point in time; at this point in time, the device will provide a metered value at the communication interface for transmission. After this, it will be transferred in accordance with the selected log.

  Note: If the parameter is activated through a time setting, the parameter **`Energy restore interval`** will be deactivated automatically.

- Parameter **`Energy restore interval`**

  Adjustable period in minutes until the first and every further transfer of the metered value to the communication interface of the device. After this, it will be transferred in accordance with the selected log.

  Note: The transfer interval is used alternatively to the transfer time, and deactivates the set transfer time. The display of the device is always up to date.

  You will find these parameters in the device settings under **measured values**.

In addition, restoring can be triggered via a routable binary input (*>Restoring*). The rising edge of the binary input leads to restoring, that is, provision of the energy-metered value at the communication interface.

The metered-value memory and the energy values can be set to 0 via a binary input (*>Resetting*) if there is a rising edge.

Note: The binary inputs affect all energy/energy metered values simultaneously.

The following energy values are available:

Energy Values		Primary
Wp+	Active energy, output	kWh, MWh, GWh
Wp-	Active energy, input	kWh, MWh, GWh
Wq+	Reactive energy, output	kvarh, Mvarh, Gvarh
Wq-	Reactive energy, input	kvarh, Mvarh, Gvarh

In compliance with IEC 61850, when individually measured values are missing, the quality of the energy-metered values changes to the state **Questionable**.

This quality state is retained until a new meter content is specified for the energy value by:

- Confirmation of the current meter content via **Set**
- **Setting** a new counter status
- **Resetting** the counter status to 0

NOTE

With the **P, Q sign** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see chapter *9.2 Structure of the Function*, section on the Inversion of Output-Related Measured and Statistical Values):

- Active energy, output: Wp+
- Active energy, input: Wp-
- Reactive energy, output: Wq+
- Reactive energy, input: Wq-

9.8.2 Application and Setting Notes for Energy Values

The set parameters apply for all electricity meters of the device. You find the setting parameters in DIGSI in the project tree under **Settings > Device settings**.

Parameter: Energy restore interval

- Default setting: **(_:111) Energy restore interval** = ***10 min***

Parameter Value	Description
0 min	Restoring deactivated
60 min	Cyclical restoring after the set time 1 minute to 60 minutes

Note: If the parameter is activated through a time setting, the parameter **Energy restore time** is not in effect and will be deactivated automatically.

Parameter: Energy restore time

- Default setting: **(_:112) Energy restore time** = ***none***

Parameter Value	Description
none	Deactivated
hh:00	Restoring on the full hour
hh:15	Restoring 15 minutes after the full hour
hh:30	Restoring 30 minutes after the full hour
hh:45	Restoring 45 minutes after the full hour

Note: If the parameter is activated through a time setting, the parameter **Energy restore interval** is not in effect and will be deactivated automatically.

Parameter: Energy restore

- Default setting: **(_:120) Energy restore** = ***latest value***

Parameter Value	Description
latest value	Restoring of the current energy value
delta value	Restoring the difference value between the current energy value and the energy value of the last restoring operation

Parameter: Energy restore by A.time

- Default setting: **(_:121) Energy restore by A.time** = ***false***

Parameter Value	Description
False	Restoring deactivated
True	The cyclic restoring after the set time of the parameter **(_:111) Energy restore interval**will also be synchronized with the system time. Example: **Energy restore interval** = 30 min; current system time: 12:10 o'clock First restore: 12:30 o'clock; next restore: 13:00 o'clock etc.

Note: When the parameter is activated, the following setting values are possible for the parameter **(_:111) Energy restore interval**: 1 min; 2 min; 3 min; 4 min; 5 min; 6 min; 10 min; 12 min; 15 min; 20 min; 30 min; 60 min.

Input Signals: >Restoring and >Resetting

Binary Inputs	Description
>Restoring	The restoring of the metered values is initiated via a binary input.
>Reset	The metered value memory is set to 0 through the binary input.

You route these logical signals in the DIGSI routing matrix. Open the function group, for example, Line, where you created the energy value. There, under the tab **Measured values** you will find the tab **Energy, 3-phase**. In this tab, you will find the logical signals in addition to the measured values.

9.9 User-Defined Metered Values

9.9.1 Function Description of Pulse-Metered Values

NOTE

You can define additional metered values through DIGSI for user-specific applications.

Use pulse meters; then you can define the respective metered values through DIGSI and set parameters for them analogously to the energy values. You can read out the metered values on the display of the device or via DIGSI.

Through settings, you can individually set how each pulse-metered value is processed:

- Parameter **Restore time**

  Hour-related point in time when the device will provide a metered value at the communication interface for transmission. After this, the transfer takes place in accordance with the selected protocol.

  Note: If the parameter is activated through a time setting, the parameter **Restore interval** will automatically be deactivated.

- Parameter **Restore interval**

  Adjustable period in minutes until the first and every further transfer of the metered value to the communication interface of the device. After this, it will be transferred in accordance with the selected log.

  Note: If the parameter is activated through a time setting, the parameter **Restore time** will automatically be deactivated.

In addition, restoring can be triggered via a routable binary input (**>Restore trigger**) or via a logical internal binary input. The rising edge of the binary input leads to restoring and thus to provision of the metered value at the communication interface.

The counter pulse of any external/internal pulse generator is connected to the device via a routable binary input (**>Pulse input**). If this does not deliver any plausible values, this can be signaled to the device via another routable binary input (**>External error**).

In compliance with IEC 61850, in the event of an external error, the quality of the pulse-metered value changes to the state **Questionable**. No more pulses are added as long as the external error persists. Once the external fault condition has been cleared, pulses are added again.

The quality of the pulse-metered value remains **Questionable** until a new meter content is specified for the pulse-metered value by:

- Confirmation of the current meter content via **Setting**
- **Setting** a new meter content
- **Resetting** the meter content to 0

- Parameter **Edge trigger**

  Through settings, you can select between counting only with a rising edge or with rising and falling edges on the pulse input.

The pulse counter can be reset to 0. You can perform this resetting via the rising edge of a routable binary input (**>Reset**) or via operation on the device.

To display the counting amount at the device display, use DIGSI to set the desired weighting of the counter pulses, the unit of the metered value and a multiplication factor for every pulse generator. You can also assign a user-specific name.

To do this, open the functional area **Pulse-metered value** in DIGSI information routing. (see *Figure 9-32*). Select the metered value and enter the settings under **Properties**.

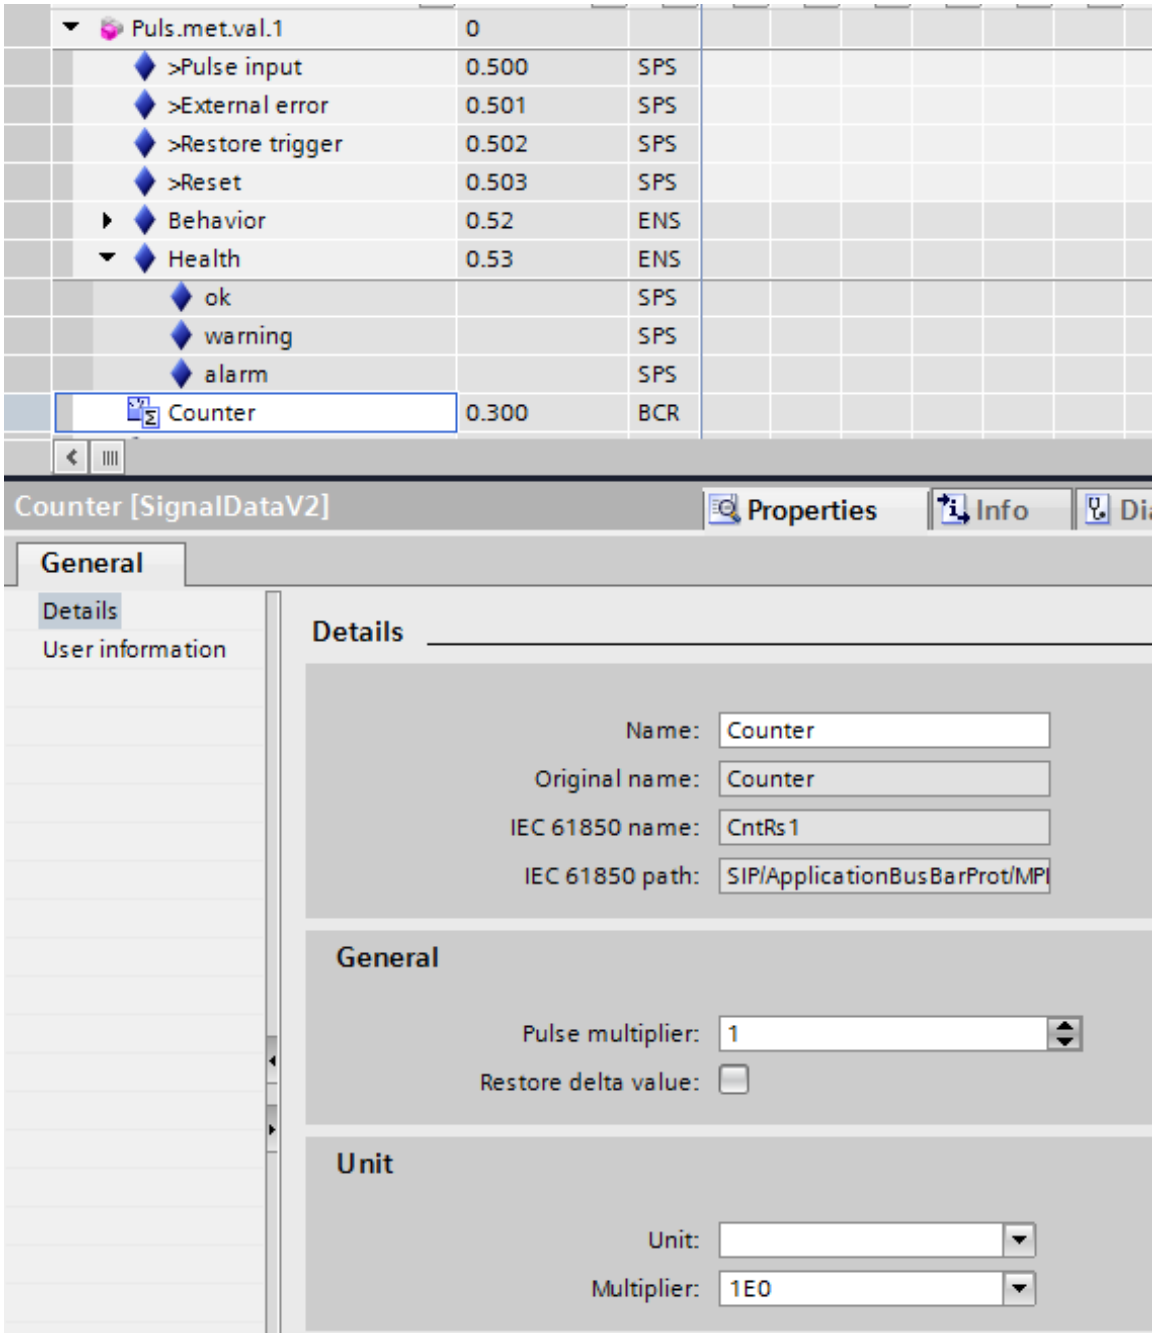


Figure 9-32 Setting with DIGSI, General Settings, Pulse-Metered Values

9.9.2 Application and Setting Notes for Pulse-Metered Values

The functionality **Pulse-metered values** is not preconfigured. If you want to use the functionality, you must load it from the library into the respective function group.

The parameters can be set individually for every pulse counter. You will find the setting parameters in DIGSI in the project tree under **Parameter > Function group**. The maximum repetition rate when detecting the pulse-metered values is 50 Hz.

For pulse-metered values, the following described settings and binary inputs are available.

Parameter: `Restore time`

- Default setting **`(_:101) Restore time`** = ***`none`***

Parameter Value	Description
none	Deactivated
`hh:00`	Transfer on the full hour
`hh:15`	Transfer 15 minutes after the full hour
`hh:30`	Transfer 30 minutes after the full hour
`hh:45`	Transfer 45 minutes after the full hour

Note: If the parameter is activated through a time setting, the parameter **`Restore interval`** is not in effect and will be deactivated automatically.

Parameter: `Restore interval`

- Default setting **`(_:102) Restore interval`** = ***`0 min`***

Parameter Value	Description
0 min	Deactivated
1 min to 60 min	Cyclical transfer after the set time 1 minute to 60 minutes

Note: If the parameter is activated through a time setting, the parameter **`Restore time`** is not in effect and will be deactivated automatically.

Parameter: `Edge trigger`

- Default setting **`(_:103) Edge trigger`** = ***`rising edge`***

Parameter Value	Description
`rising edge`	Counting with rising edge at the pulse input
`rising & falling edge`	Counting with rising and falling edge at the pulse input

Parameter: `Restore by absolute time`

- Default setting: **`(_:104) Restore by absolute time`**= ***`False`***

Parameter Value	Description
`False`	Deactivated
`True`	The cyclic restoring of setting **`Restore interval`** after the set time is also synchronized with the system time. Example: **`Restore interval`** = 30 min; current system time: 12:10 o'clock. First restoring operation: 12:30 o'clock; next restoring operation: 13:00 o'clock, etc.

Input Signals: >Pulse input, >External error, >Restore trigger, >Reset

Binary inputs	Description
`>Pulse input`	Input for the counting pulses of an external pulse generator
`>External error`	Indication that the counter pulses of the external pulse generator are faulty. The indication has an effect on the quality identifier of the pulse value.
`>Restore trigger`	The transfer of the metered values is initiated via a binary input.
`>Reset`	The rising edge at the binary input resets the pulse counter to 0.

The amount of energy indicated by a pulse generator is to be displayed as a measured value.
1 pulse corresponds to 100 Wh.
The pulse weighting, the SI unit, and the factor must be adjusted to one another.
Display value = Calculated metered value * Pulse weighting * Factor * SI unit.

If the check box **Restore delta value** is activated, the differential value is transferred at the restore time set via the communication interface. The difference value is formed by subtracting the counter content of the last restoring operation from the current counter content.

You route the logical signal ***>Pulse input*** to a binary input to which the pulse generator is connected.

Set the following values:

Name	Active Power Meter
Pulse weighting	100
Restore differential value	Activated
SI unit	Wh
Factor	1

The factor is used for adaptation to larger units (for instance, 1000 for kWh). It is adjustable in powers of ten (1, 10, 100, 1000, etc.). The following figure shows the signals that can be arranged in the DIGSI information matrix. Open the function group where you created the pulse-metered value, for example, Line 1. There, you will find the function area **Pulse-metered value**. Here you will also find the logical signals next to the metered value. Select the metered value and enter the settings under **Properties**.

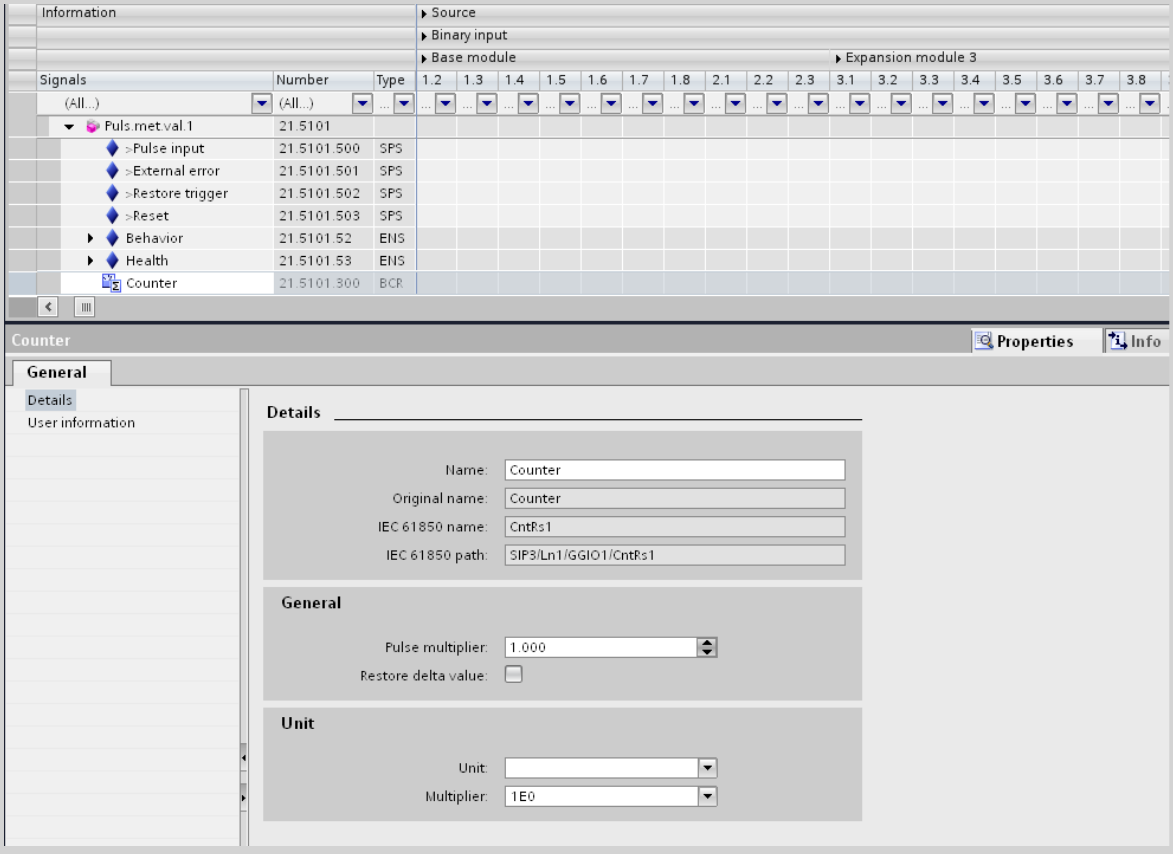

Figure 9-33 Setting with DIGSI

9.10 Statistical Values of the Primary System

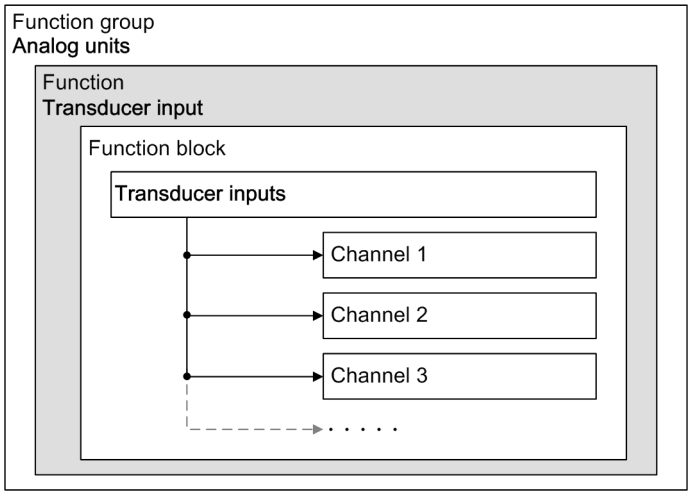
The device has statistical values for circuit breakers and disconnectors.

The following values are available for each circuit breaker:

- Total number of trippings of the circuit breaker initiated by the device
- Number of trippings of the circuit breaker initiated by the device, separately for each circuit breaker pole (if 1-pole tripping is possible)
- Total sum of primary breaking currents
- Sum of the primary breaking currents, separately for each breaker pole
- Hours with open circuit breaker
- Hours under load

The following values are available for each disconnector switch:

- Total number of switching operations of the disconnector switch initiated by the device
- Number of switching operations of the disconnector switch initiated by the device, separately for each switch pole (if 1-pole switching is possible)



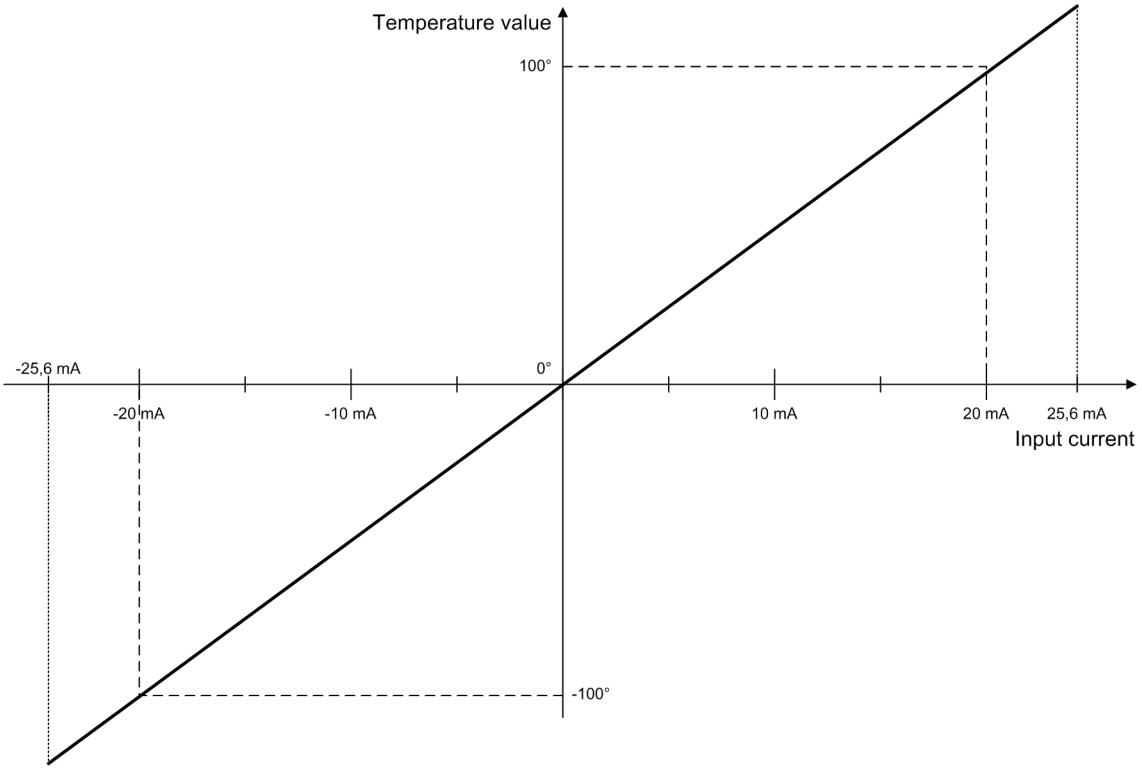
9.11 Measuring Transducers

9.11.1 Overview of Functions

Measuring transducers with an input rated at 20 mA can be used in the devices. 4 such inputs are available as module ANAI-CA-4EL, which can be plugged into a communication module slot (for instance, port E or F). Up to 4 such modules can be plugged in. Typically, slowly changing process variable such as temperature or gas pressure are recorded with such 20-mA measured values and reported to the substation automation technology.

9.11.2 Structure of the Function

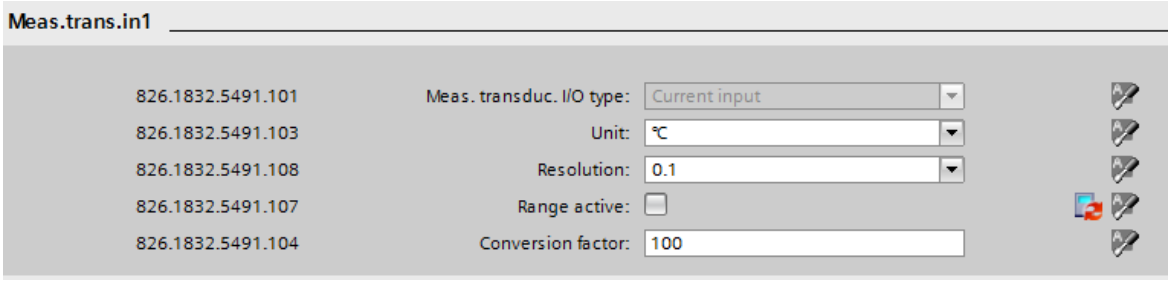
The measuring-transducer blocks are embedded in the **Analog units** function group and contain input and output channels that are configurable independently of each other.



[dw_strumu, 1, en_US]

Figure 9-34 Structure/Embedding of the Function

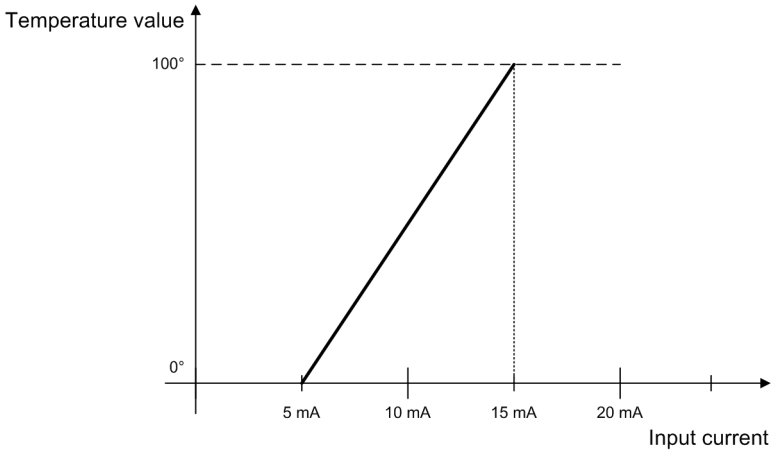
9.11.3 Function Description



The 20-mA inputs typically transmit a value which represents a physical quantity such as a temperature or a pressure. Therefore, the device must contain a characteristic curve that assigns the physical quantity to the 20-mA value. If the parameter **`Range active`** is not activated (no x in the check box), the function operates over the range -25.6 mA to +25.6 mA. The setting of the range for the scaled value goes from a usable range of -25.6 mA to +25.6 mA. The following figure shows an example.

[dw_klbsp_1, 3, en_US]

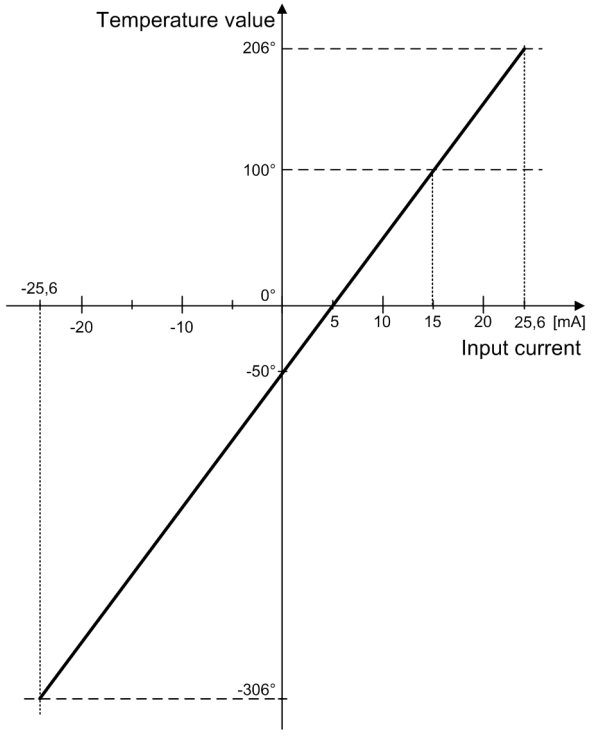
Figure 9-35 Characteristic Curve of a 20-mA Input (Example 1)



In this example, the measured value 0 mA means a temperature of 0 degrees Celsius and the measured value 20 mA means a temperature of 100 degrees Celsius. Thus, **Unit** = ***°C*** and **Conversion factor** = ***100*** are entered. The resolution (decimal place) of the temperature value can be selected; for one decimal place, select **Resolution** = ***0.1***.

[sc_transd, 1, en_US]

Figure 9-36 Parameter Settings for Example 1



If a value smaller than -25.6 mA or larger than +25.6 mA is applied to the measuring-transducer input, the measured value is marked as outside the range of values. If the parameter **Range active** is activated, the 2 additional parameters **Upper limit** and **Lower limit** appear. Both limiting values indicate the input currents in mA, for which the value set by the **Conversion factor** (**Upper limit**) and the value 0 (**Lower limit**) of the calculated measurand are valid (see following figure).

[dw_kl_example_2, 1, en_US]

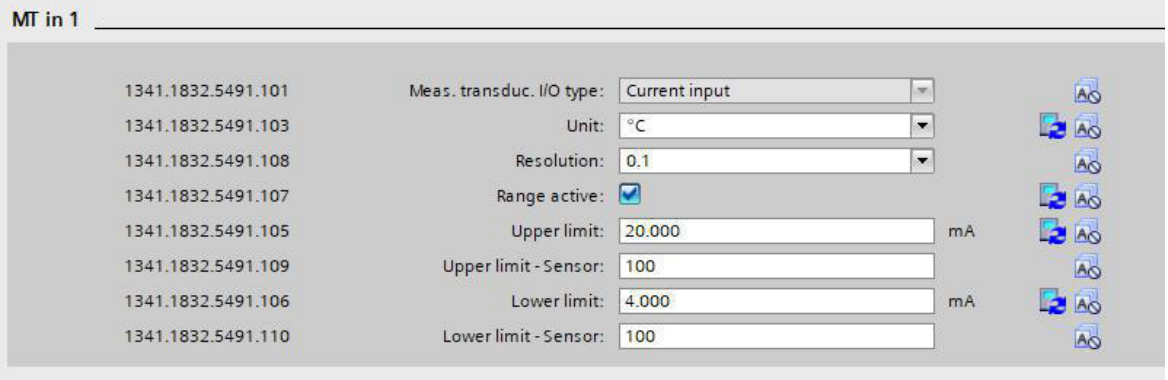


Figure 9-37 Characteristic Curve of a 20-mA Input (Example 2)

In this example, **Range active** is selected. The **Upper limit** is at 15 mA, the **Lower limit** is at 5 mA and the **Conversion factor** remains at 100. Overall, this results in a characteristic curve as shown in the following figure, taking into account all possible valid measured values from -25.6 mA to +25.6 mA. The parameter **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The parameter **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

[dw_klges_2, 3, en_US]

Figure 9-38 Total Characteristic Curve in Example 2

[sc_trans2, 2, en_US]

Figure 9-39 Parameter Setting for Example 2

Each measuring-transducer input provides the scaled measured value (these are the temperature values in the examples) and the original current measured value in mA in the information routing for further processing.

Table 9-6 Measuring-Transducer Measured Values

Measured Value		Display
TD scale MV (_:301)		
	Primary	Measured value converted to the sensor
	Secondary	–
	Percent	100 % ≙ parameter **(_:104) Conversion factor** (for **(_:107) Range active** = ***false***)
		100 % ≙ max. absolute value of the parameter **(_:109) Upper limit - Sensor** or of the parameter **(_:110) Lower limit - Sensor** (for **(_:107) Range active** = ***true***)
TD direct MV (_:302)		
	Primary	–
	Secondary	-20.000 mA to +20.000 mA or -10 V to +10 V
	Percent	100 % ≙ 20 mA or 10 V

The measuring-transducer values can be displayed in the display image and processed with CFC charts.

9.11.4 Application and Setting Notes

Parameter: Unit

- Recommended setting value **(_:103) Unit** = ***°C***

With the parameter **Unit**, you set the physical unit of measurement the measured values. The possible setting values are listed in the settings table.

Parameter: Conversion factor

With the parameter **(_:104) Conversion factor**, you set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:108) Resolution** = ***0.1***

With the parameter **Resolution**, you set the resolution of the scaled values.

Parameter: Range active

- Default setting **(_:107) Range active** = ***false***

If you do not activate the parameter **Range active** (no cross in the check box), the function operates over the range -25.6 mA to +25.6 mA. The setting of the range for the scaled value goes from a usable range of -25.6 mA to +25.6 mA.

If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**, **Upper limit - Sensor**, **Lower limit**, and **Lower limit - Sensor**appear.

Parameter: Upper limitLower limitUpper limit - Sensor and Lower limit - Sensor

- Default setting **(_:105) Upper limit** = ***20.000 mA***
- Default setting **(_:109) Upper limit - Sensor** = ***100***
- Default setting **(_:106) Lower limit** = ***4.000 mA***
- Default setting **(_:110) Lower limit - Sensor** = ***100***

If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The parameter **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The parameter **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

If you keep the preset limiting values, the following conditions are possible:

- If the input current is < 2.000 mA
  The function issues the indication ***Broken wire*** and the quality of the output value is invalid. The functions that use the output value as the measured value can be deactivated.
- If the input current is > 2.500 mA
  The indication ***Broken wire*** drops out.

9.12 Circuit-Breaker Monitoring

9.12.1 Overview of Functions

The **Circuit-breaker monitoring** function:

- Detects the abrasion of the circuit breakers phase-selectively
- Allows an adaptation of maintenance intervals for switching contacts of the circuit breakers according to the real abrasion
- Sends a warning signal when the abrasion of the circuit breaker reaches a certain degree
- Allows the supervision of the circuit-breaker make time
- Allows the supervision of the circuit-breaker break time

One of the main advantages of this function is the reduction of maintenance and service costs.

9.12.2 Structure of the Function

The function **Circuit-breaker monitoring** can be used in the function group **Circuit-breaker**.
The function offers 9 independent operating methods with different methods of measurement:

- **ΣI^x-method**
  Sum of the breaking-current potentials
- **2P-method**
  2 points method for calculating the remaining switching cycles
- **I^2t-method**
  Sum of all breaking-current square integrals
- **Make time**
  Monitoring of the circuit-breaker make time
- **Break time**
  Monitoring of the circuit-breaker break time
- **Pole scatter time open**
  Supervision of the difference in the switch-off times of the individual phases
- **Pole scatter time close**
  Supervision of the difference in the switch-on times of the individual phases
- **Mechanical switching time open**
  Supervision of the switching time open detected via the feedback contacts
- **Mechanical switching time close**
  Supervision of the switching time close detected via the feedback contacts
- **Operation counter**
  Supervision of the number of switching cycles performed

9.12.3 General Functionality

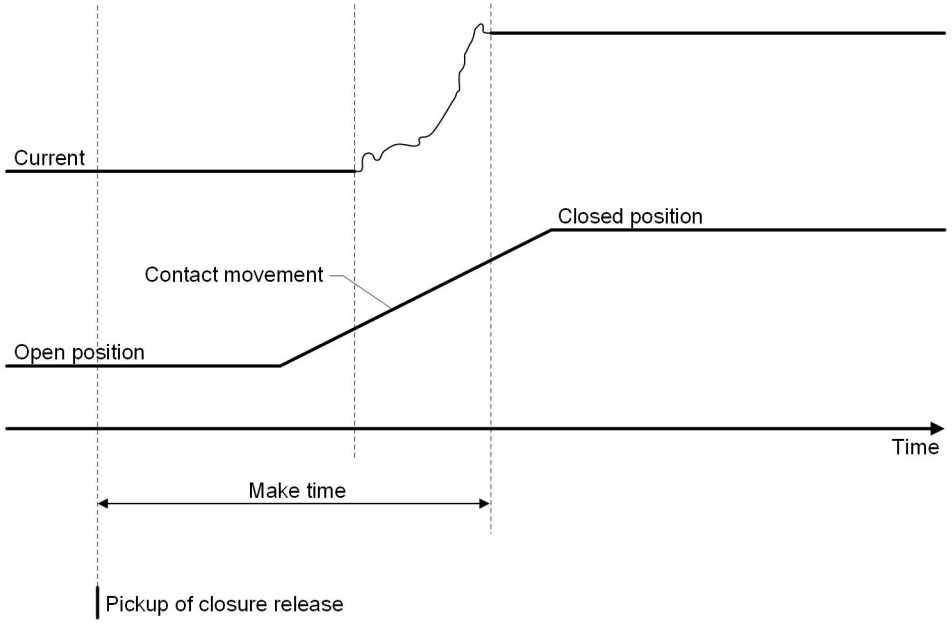
9.12.3.1 Description

Start Criterion for the Function Circuit-Breaker Monitoring

The methods **ΣI^x**, **2P** and **I²t** are started if one of the following criteria is met:

- The circuit breaker is opened via a command or a protection tripping.
- The binary input signal *>Start calc. for open* is initiated, for example, via an external signal.
- The signal for the closed position of the circuit breaker is going. This signal is built via the circuit-breaker auxiliary-contacts. Thus, a manual opening of the circuit breaker is detected.

The methods **Make time**, **Mechanical switching time close** are started if one of the following criteria is met:

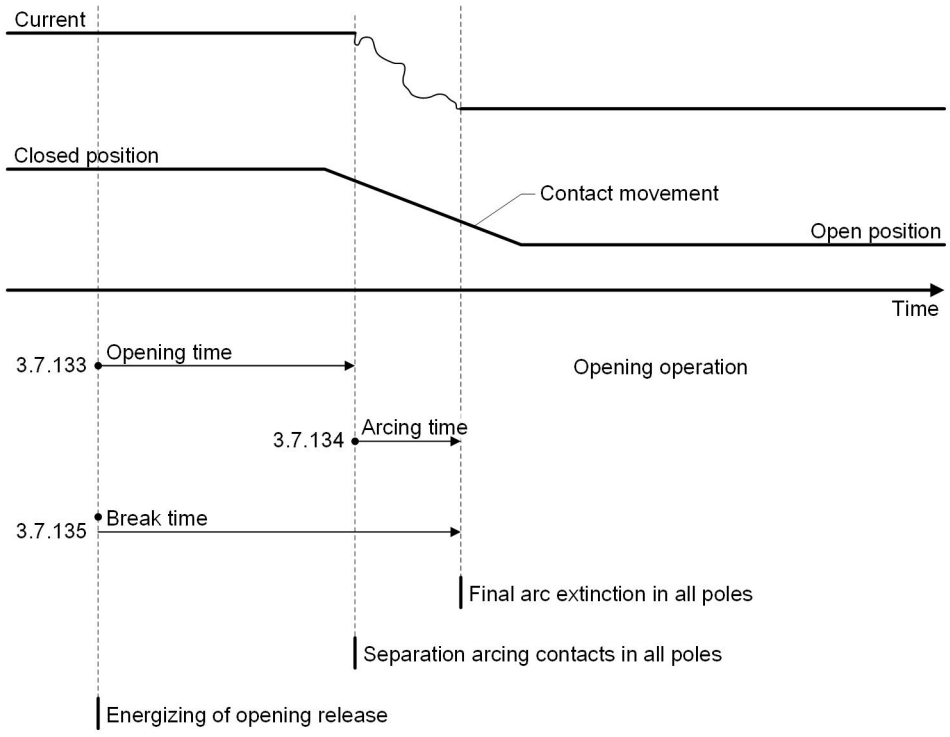


- The circuit breaker is closed via a command.
- The binary input signal *>Start calc. for close* is initiated, for example, via an external signal.

The methods **Break time**, **Mechanical switching time open** and **Pole scatter time open** are started if one of the following criteria is met:

- The circuit breaker is opened via a command.
- The circuit breaker is opened via a protection tripping.
- The binary input signal *>Start calc. for open* is initiated, for example, via an external signal.

Definition of the Times when Opening and Closing the Circuit Breaker



With the paramter **Make time**, you define the point in time when the circuit-breaker poles are closed and the current has reached a constant value.

[dw_maketime, 1, en_US]

Figure 9-40 Definition of Make Time

With the parameter **Opening time**, you define the point in time when the circuit-breaker poles begin to open. With the parameter **Break time**, you define the point in time when the circuit-breaker poles are separated and the arc is extinct. The following graphic shows the relation between these 2 points in time of the circuit breaker.

[dw_breaktime, 1, en_US]

Figure 9-41 Circuit-Breaker Times

9.12.3.2 Application and Setting Notes

Parameter: `Apply PhaseA config to all`

- Default setting **`(_:2311:1) Apply PhaseA config to all`** = ***`inactive`***

If the parameter **`Apply PhaseA config to all`** is activated, all settings of phase A are adopted for phases B and C.

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: `Opening time`

- Default setting **`(_:23971:101) Opening time`** = ***`65 ms`***

With the parameter **`Opening time`**, you define the interval between the activation of the shunt release for the circuit breaker and the moment, when the circuit-breaker poles open.

For information on the setting value, refer to the technical data of the used circuit breaker. For futher information, refer to *Figure 9-41*.

Parameter: `Break time`

- Default setting **`(_:23971:102) Break time`** = ***`80 ms`***

With the parameter **`Break time`**, you define the interval between the activation of the shunt release for the circuit breaker and the moment, when the arc extincts (and the circuit-breaker poles are open).

For information on the setting value, refer to the technical data of the used circuit breaker. For further information, refer to *Figure 9-41*.

Parameter: `Make time`

- Default setting **`(_:23971:103) Make time`** = ***`80 ms`***

With the parameter **`Make time`**, you define the typical time interval between the activation of the closing procedure for the circuit breaker and the point in time when the first current flows.

For information on the setting value, refer to the technical data of the used circuit breaker.

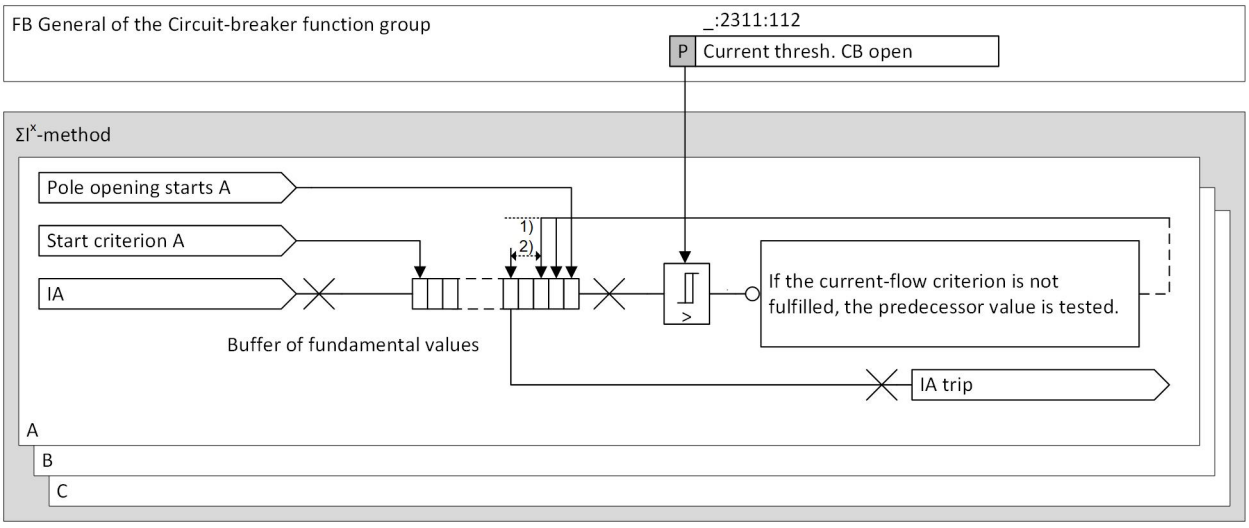
9.12.4 ΣIx Method

9.12.4.1 Description



[lo_Ix-calc, 1, en_US]

Figure 9-42 Logic of the ΣIx Method

Determination of the Tripping/Opening Current Value

RMS values of the fundamental components are stored for each phase in a buffer during the time between the start criterion and the pole-opening-starts criterion. With the coming pole-opening-starts criterion, the latest value in the buffer is searched for whose value is above the setting of parameter **`Current thresh. CB open`**. The one period prior value is used as tripping/opening current for further calculation.

If no value within the buffer is above the setting value, this circuit-breaker opening affects only the mechanical lifetime of the circuit breaker and is consequently not considered by this method.

[lo_cb_wixf, 3, en_US]

Figure 9-43 Logic of the Determination of the Tripping Current Value

(1) Current-flow criterion fulfilled
(2) 1 period prior value

Calculation of the Wear

If the **ΣIx-method** stage receives the logic release signal, the determined tripping current is used in the calculation of wear. The calculation results are then added to the existing statistic values of the ΣIx method as follows, with phase A as example.

$$\sum I_A^x = \frac{1}{I_{rated}^x} \sum_{q=1}^{m} I_{A\,trip,q}^x$$

[fo_CB-WI-xA, 1, en_US]

Mit:

x	Parameter exponent
q	No. of circuit-breaker switching cycle
$I_{A\,trip,\,q}^x$	Tripping/opening current of phase A to the power of x in the qth circuit-breaker operation
I_{rated}^x	Rated normal current to the power of x
$\sum I_A^x$	Statistic value of current phase A calculated with the ∑Ix method
m	Total number of switching cycles

The phase-selective ΣIx value is available as statistical value. You can reset or preset the statistics according to the specific application.
To simplify the interpretation of the sum of the tripping current powers, the values are set in relation to the exponentiated rated normal current I_{rated} of the circuit-breaker (see also setting notes).

Circuit-Breaker Maintenance Warning

If the summated ΣIx value of any phase is greater than the threshold, a phase-selective warning signal is generated.

9.12.4.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: Active

- Default setting **(_:23971:120) Active** = ***inactive***

With the parameter **Active**, you switch on the method.

Parameter: Exponent

- Default setting **(_:23971:121) Exponent** = ***2.0***

With the parameter **Exponent**, you specify the exponent for the ΣI^x method.

A typical value is the default setting of 2. However, due to practical experiences with individual circuit breakers, slightly different values may be requested.

Parameter: Threshold

- Default setting **(_:23971:122) Threshold** = ***10 000.00***

With the parameter **Threshold**, you define the threshold of the statistic value.

The relation of the tripping current powers to the exponentiated rated normal current I_{rated} allows the limiting value of the ΣI^x method to correspond to the maximum number of make-breaker operations. For a circuit breaker, whose contacts have not yet been worn, the maximum number of make-break operations can be entered directly as limiting value.

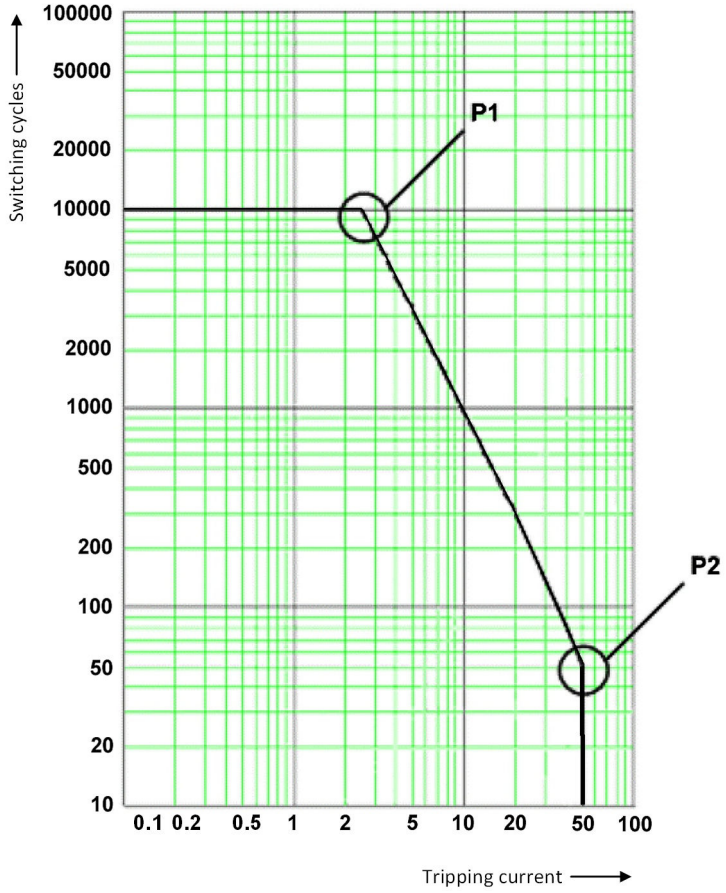
9.12.5 2P Method

9.12.5.1 Description

Logic of the Stage



[lo_2P-calc_1, en_US]

Figure 9-44 Logic 2P Method

Calculation of Remaining Switching Cycles

A double-logarithmic diagram provided by the circuit-breaker manufacturer illustrates the relationship of permitted switching cycles and the tripping/opening current, see the following figure. According to the example, this circuit breaker can operate approximately 1000 times at a tripping current of 10 kA.

2 points and their connecting line determine the relationship of switching cycles and tripping current. Point P1 is determined by the number of permitted switching cycles at rated normal current I_{rated}. Point P2 is determined by the maximum number of switching cycles at rated short-circuit breaking current I_{sc}. The 4 associated values can be configured with the parameters **`Rated normal current`**, **`Switching cycles at Ir`**, **`Rated short-circ.cur. Isc`**, and **`Switching cycles at Isc`**.

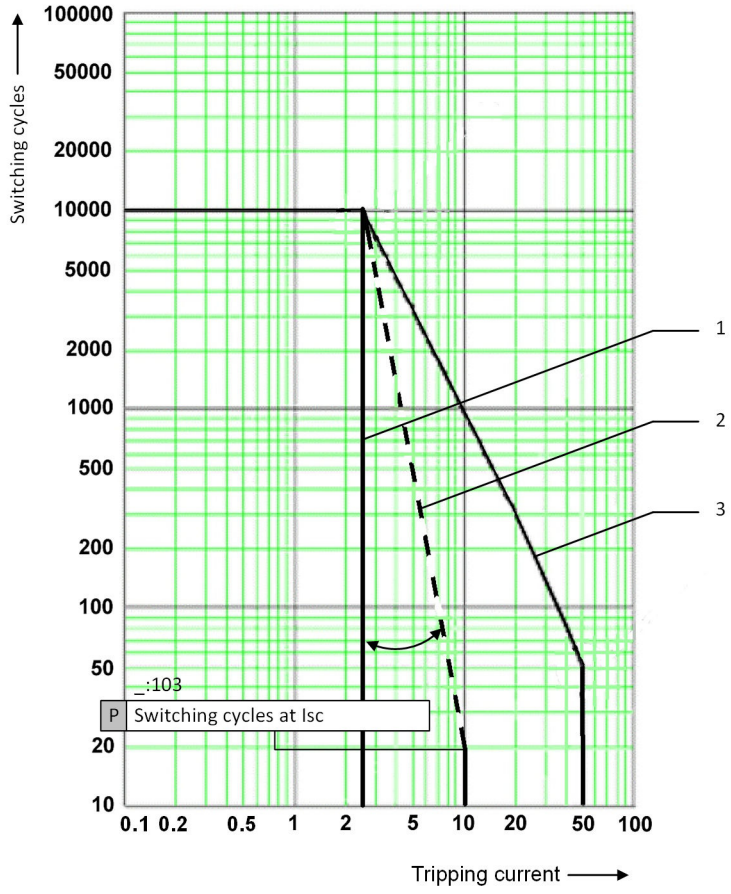
[dw_CB_WOpC, 2, en_US]

Figure 9-45 Diagram of Switching Cycles for the 2P Method

As shown in the preceding figure, a double-logarithmic diagram, the straight line between P1 and P2 can be expressed by the following exponential function:

$$n = b\left(\frac{I_{rated}}{I_{trip}}\right)^{m}$$

[fo_CB-W2-P1, 2, en_US]



Where:

I_{trip}	Tripping/opening current
I_{rated}	Rated normal current
m	Slope coefficient
b	Switching cycles at rated normal current
n	Number of switching cycles

The general line equation for the double-logarithmic representation can be derived from the exponential function and leads to the coefficients b and m.

NOTE

Since a slope coefficient of m < -4 is technically irrelevant, but could theoretically be the result of incorrect settings, the slope coefficient is limited to -4. If a coefficient is smaller than -4, the exponential function in the switching-cycles diagram is deactivated. The maximum number of switching cycles with I_{sc} is used instead as the calculation result for the current number of switching cycles, as the dashed line with m = -4.48 shows in following figure.

[dw_CB_WSlo, 2, en_US]

Figure 9-46 Value Limitation of Slope Coefficient

(1) Applied function from m < -4
(2) Parameterized function with m = -4.48
(3) Parameterized function with m = -1.77

If the **2P-method** stage receives the logic release signal, the current number of used up switching cycles (in relation to the number of switching cycles at rated normal current) is calculated based on the determined tripping current. This value is subtracted from the the remaining lifetime (switching cycles). The remaining lifetime is available as statistic value. For better understanding, refer to the example below.

You can reset or preset the statistical values according to the specific application. The reset operation changes the statistic values to 0, and not to their default values of 10 000.

The statistic value of the residual switching cycles is calculated according to the following formula:

$$2\text{p wear rest}_{i} = 2\text{p wear rest}_{i-1} - \frac{n_{rated}}{n_{trip}}$$

[fo_CB-2P-wear-rest_01, 2, en_US]

Where:

i	No. of latest circuit-breaker switching cycle
2p wear rest$_i$	Residual switching cycles with rated normal current, after the ith switching cycle
n_{rated}	Overall permissible switching cycles at rated normal current
n_{trip}	Overall permissible switching cycles at tripping current I_{trip}
n_{rated}/n_{trip}	Lost switching cycles referring to rated normal current

EXAMPLE

For calculating the residual switching cycles of a circuit breaker, the following is assumed:
P1 (2.5 kA, 10 000)
P2 (50.0 kA, 50)
The circuit breaker has made 100 opening operations with rated normal current, 2 tripping operations with rated short-circuit breaking current, and 3 tripping operations with 10 kA tripping current. Then, the residual switching cycles with rated normal current are:

$$\text{2p wear rest} = n_{rated} - \left(100\frac{n_{rated}}{n_{2.5\,kA}}\right) - \left(2\frac{n_{rated}}{n_{50\,kA}}\right) - \left(3\frac{n_{rated}}{n_{10\,kA}}\right)$$

$$= 10\,000 - \left(100\frac{10\,000}{10\,000}\right) - \left(2\frac{10\,000}{50}\right) - \left(3\frac{10\,000}{861}\right) = 9465$$

[fo_CB-2P-wear-rest_02, 2, en_US]

There are still 9465 possible break operations at rated normal current.

Cumulated Abrasion and Abrasion of the Last Switching Operation

In addition to the remaining switching cycles, the cumulated wear and the wear of the last switching operation is calculated. These are available as percentage values ***2P abrasion cumulated*** and ***2P abrasion last sw.op.***.

Circuit-Breaker Maintenance Warning and Alarm

If the adjustable threshold values are undershot, phase-selective warnings and alarms are generated.

9.12.5.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: `Active`

- Default setting **`(_:23971:110) Active`** = ***inactive***

With the parameter **`Active`**, you switch on the method.

Parameter: `Switching cycles at Ir`

- Default setting **`(_:23971:111) Switching cycles at Ir`** = ***10 000***

With the parameter **`Switching cycles at Ir`**, you define the number of permitted switching cycles at rated normal current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: Rated short-circ.cur. Isc

- Default setting **(_:23971:112) Rated short-circ.cur. Isc** = ***25 000 A***

With the parameter **Rated short-circ.cur. Isc**, you define the rated short-circuit breaking current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: Switching cycles at Isc

- Default setting **(_:23971:113) Switching cycles at Isc** = ***50***

With the parameter **Switching cycles at Isc**, you define the number of permitted switching cycles at rated short-circuit breaking current.
You can find the information on the setting value in the technical data of the used circuit breaker.

Parameter: Abrasion warn. threshold

- Default setting **(_:23971:114) Abrasion warn. threshold** = ***1000***

With the parameter **Abrasion warn. threshold**, you define the threshold value for the remaining switching cycles with rated operating current. If the statistical value is below the threshold value, a warning signal is generated.

Parameter: Abrasion alarm threshold

- Default setting **(_:23971:115) Abrasion alarm threshold** = ***500***

With the parameter **Abrasion alarm threshold**, you define the threshold value for the remaining switching cycles with rated operating current. If the statistical value is below the threshold value, an alarm signal is generated.

Example

Here is an example that shows you how to set the threshold parameters. Assuming a circuit breaker with the same technical data as provided in the example for residual switching cycles, 50 breaking operations with rated short-circuit breaking current are permitted.
A warning signal should be issued when the number of possible breaking operations with rated short-circuit breaking current is less than 3. For that condition, you set the threshold value based on the following calculation:

$$3 \cdot \frac{n_{rated}}{n_{50\,kA}} = 3 \cdot \frac{10000}{50} = 600$$

[fo_CB-W2-P4, 2, en_US]

9.12.6 I2t Method

9.12.6.1 Description

Logic of the Stage

[lo_I2t-calc_2, en_US]

Figure 9-47 Logic of the I²t Method

Calculation of the Wear

The I²t method evaluates the wear of a circuit breaker based the sampled measuring values of the phase currents during the arc time. The duration of the arc time is defined by the difference between the 2 settings of parameters **`Break time`** and **`Opening time`** (see also *Start Criterion for the Function Circuit-Breaker Monitoring, Page 2178*). The stage determines the ending point of the arc time by searching backward the zero-crossing point of the phase currents after it receives the logic release signal. Then, the squared fault currents during the arc time are integrated phase-selectively. The integrals are referred to the squared rated normal current of the circuit breaker as shown in the following formula, with phase A as example.

$$I^2t_{L1} \cdot \frac{1}{I^2_{rated}} = \int_{\text{Start arc time}}^{\text{End arc time}} i^2_{L1}(t)\,dt$$

[fo_CB-WI-2T, 2, en_US]

Where:

I_{rated}	Rated normal current
$i_A(t)$	Sampled measured current value of phase A

The calculated squared tripping current integrals are added to the existing statistic values.You can reset or preset the statistic value according to the specific application.

Circuit-Breaker Maintenance Warning

If the statistic value of any phase lies above the threshold, a phase-selective warning signal is generated.

9.12.6.2 Application and Setting Notes

Parameter: `Active`

- Default setting **`(_:23971:130) Active`** = ***`inactive`***

With the parameter **`Active`**, you switch on the method.

Parameter: `Threshold`

- Default setting **`(_:24033:131) Threshold`** = ***`10 000.00 I/Ir*s`***

With the parameter **`Threshold`**, you specify the maximum permitted integral of squared sampled measured values of the phase currents. The same applies to the threshold values of the other phases.

9.12.6.3 Settings

9.12.7 Make Time

9.12.7.1 Description

Logic of the Stage

[lo_LS-Überwachung_Einschaltzeit, 2, en_US]

Figure 9-48 Logic of the Make Time

Operating Mode

The stage for the monitoring of the circuit-breaker make time calculates phase-selectively the time between the circuit-breaker closing command and the point in time when the current exceeds the **`Oper.current threshold`**. If this threshold has not been exceeded after 2.5 times the value of the parameter **`Make time`**, the measurement is canceled and the output value *`Make time`* is set to 0 and marked with the quality invalid.

If one phase of the current has exceeded the parameter **Oper.current threshold** or the parameter **Current thresh. CB open** at the time of the circuit-breaker closing command, the measurement is canceled and the output value *Make time* is marked with the quality invalid.

You can define 2 independent thresholds for the monitoring of the measured make time. When these thresholds are exceeded or undershot, the corresponding outputs *Make-time warning* and *Make-time alarm* are activated for 100 ms. These can be routed in the log.

9.12.7.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: Active

- Default setting **(_:23971:140) Active** = ***inactive***

With the parameter **Active**, you switch on the method.

Parameter: Threshold for warning

- Default setting **(_:23971:141) Threshold for warning** = ***5 %***

With the parameter **Threshold for warning**, you define the percentage the measured value is allowed to exceed or undershot the parameter **Make time** at the output *Make time*, before the output *Make-time warning* is set. The output *Make-time warning* then drops out after 100 ms.

Parameter: Threshold for alarm

- Default setting **(_:23971:142) Threshold for alarm** = ***10 %***

With the parameter **Threshold for alarm**, you define the percentage the measured value is allowed to exceed or undershot the parameter **Make time** at the output *Make time*, before the output *Make-time alarm* is set. The output *Make-time alarm* then drops out after 100 ms.

Parameter: Oper.current threshold

- Default setting **(_:23971:143) Oper.current threshold** = ***0.100 A***

With the parameter **Oper.current threshold**, you define the current threshold. If the measured value exceeds this threshold, the measured value is detected as flowing operating current. As soon as an operating current flows, the end of the time interval *Make time* is detected.

Parameter: Delay correction time

- Default setting **(_:23971:144) Delay correction time** = ***0.000 s***

With the parameter **Delay correction time**, you define a correction value which will be subtracted from the *Make time* during calculation. This allows you to compensate delays caused by the system, for example, relay residual times, if necessary.

9.12.8 Break Time

9.12.8.1 Description

Logic of the Stage

[lo_LS-Überwachung_Ausschaltzeit, 1, en_US]

Figure 9-49 Logic of the Break Time

Operating Mode

The stage for the monitoring of the circuit-breaker break time calculates phase-selective the time between the circuit-breaker opening command and the point to which no load current flows. In the event of a restrike after the current was lost, the measurement of the break time is extended accordingly. If a current is still measured after 2.5 times of the value parameter **`Break time`**, the measurement is canceled and the output value ***`Break time`*** is set to 0 and marked with the quality invalid.

If no load current is measured at the time of the break time command, the measurement for the relevant phase is canceled and the output value ***`Break time`*** is marked with the quality invalid.

You can define 2 independent thresholds for the monitoring of the measured break time. When these thresholds are exceeded or undershot, the corresponding outputs *Break-time warning* and *Break-time alarm* are activated for 100 ms. These can be routed in the log.

9.12.8.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: Active

- Default setting **(_:23971:150) Active** = ***inactive***

With the parameter **Active**, you switch on the method.

Parameter: Threshold for warning

- Default setting **(_:23971:151) Threshold for warning** = ***5 %***

With the parameter **Threshold for warning**, you define the percentage the measured value is allowed to exceed or undershot the parameter **Break time** at the output *Break time*, before the output *Break-time warning* is set. The output *Break-time warning* then drops out after 100 ms.

Parameter: Threshold for alarm

- Default setting **(_:23971:152) Threshold for alarm** = ***10 %***

With the parameter **Threshold for alarm**, you define the percentage the measured value is allowed to exceed or undershot the parameter **Break time** at the output *Break time*, before the output *Break-time alarm* is set. The output *Break-time alarm* then drops out after 100 ms.

Parameter: Delay correction time

- Default setting **(_:23971:153) Delay correction time** = ***0.000 s***

With the parameter **Delay correction time**, you define a correction value which will be subtracted from the *Break time* during calculation. This allows you to compensate delays caused by the system, for example, relay residual times, if necessary.

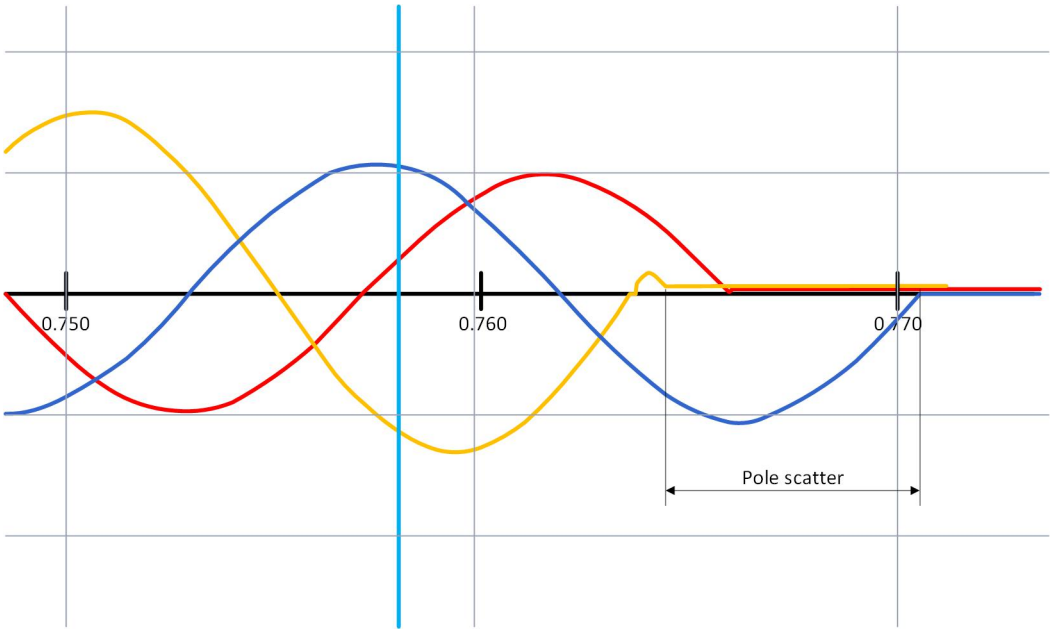
9.12.9 Pole Scatter Time Open

9.12.9.1 Description

Logic of the Stage



[lo_stage_pole-scatter_open, 1, en_US]

Figure 9-50 Logic of the Stage Pole Scatter Time Open

Operating Mode

The time between the extinction of the current of the first phase until the extinction of the last phase current when opening the circuit breaker is the pole scatter time. A greater time difference can lead to conclusions on the circuit-breaker abrasion.

[dw_charact_pole-scatter, 2, en_US]

Figure 9-51 Pole Scatter Time

The start criterion can be either the trip command of the circuit breaker or the input signal *>Start calc. for open*. You can set 2 independent threshold values for the supervision of the measured pole scatter time. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms.

9.12.9.2 Application and Setting Notes

Parameter: Threshold for warning

- Default setting **(_:26461:151) Threshold for warning** = ***5 ms***

With the parameter **Threshold for warning** , you define from which measured pole scatter time the output *ScatterTm open warn.* is set. The output *ScatterTm open warn.* drops out after 100 ms.

Parameter: Threshold for alarm

- Default setting **(_:26461:152) Threshold for alarm** = ***10 ms***

With the parameter **Threshold for alarm**, you define from which measured pole scatter time the output *ScatterTm open alarm* is set. The output *ScatterTm open alarm* drops out after 100 ms.

9.12.9.3 Settings

9.12.10 Pole scatter time close

9.12.10.1 Description

Logic of the Stage

[lo_stage_pole-scatter_close, 1, en_US]

Figure 9-52 Logic of the Stage Pole Scatter Time Close

Operating Mode

The time between reaching the operating current threshold of the first phase and reaching the operating current threshold of the last phase when closing the circuit breaker is the pole scatter time. A change of the time difference can lead to conclusions on the wear condition of the circuit breaker.

The start criterion can be either the close command of the circuit breaker or the input signal *>Start calc. for close*. You can set 2 independent threshold values for monitoring the measured pole scatter time. If a threshold value is exceeded, the corresponding output *Warning/alarm* is activated for 100 ms.

If the calculation is not finished after one second, it is canceled and the output signal *Pole scatter time close* is set to 0 and marked with the quality *invalid*.

9.12.10.2 Application and Setting Notes

Parameter: `Threshold for warning`

- Default setting **`(_:26461:181) Threshold for warning`** = ***5 ms***

With the parameter **`Threshold for warning`**, you define from which measured pole scatter time the output *ScatterTm close warn.* is set. The output *ScatterTm close warn.* drops out after 100 ms.

Parameter: `Threshold for alarm`

- Default setting **`(_:26461:182) Threshold for alarm`** = ***`10 ms`***

With the parameter **`Threshold for alarm`**, you define from which measured pole scatter time the output *`ScatterTm close alarm`* is set. The output *`ScatterTm close alarm`* drops out after 100 ms.

Parameter: `Oper.current threshold`

- Default setting **`(_:26461:183) Oper.current threshold`** = ***`0.1 A`***

With the parameter **`Oper.current threshold`**, you define from which measured current the poles of the circuit breaker are considered to be closed. The pole scattering time is determined from the time span between exceeding the threshold of the 1st phase and exceeding the threshold of the last phase.

9.12.10.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`Pole scatter time close`

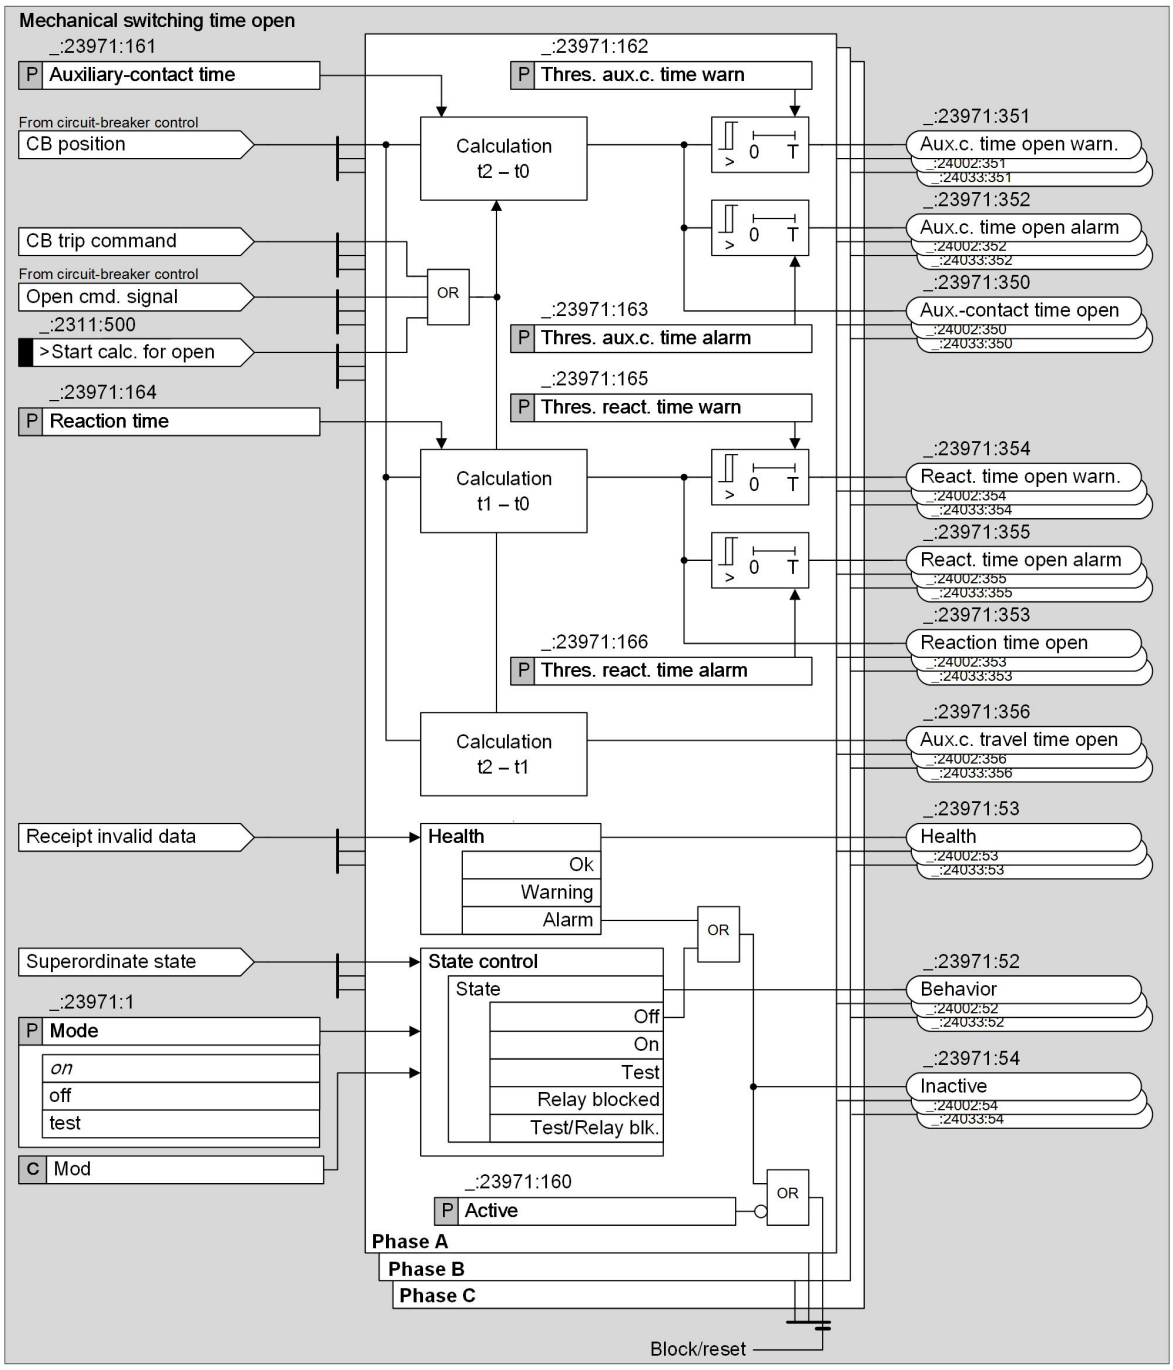
9.12.11 Mechanical Switching Time Open



9.12.11.1 Description

Logic of the Stage

[lo_mechanical_Break-time_3phs, 1, en_US]

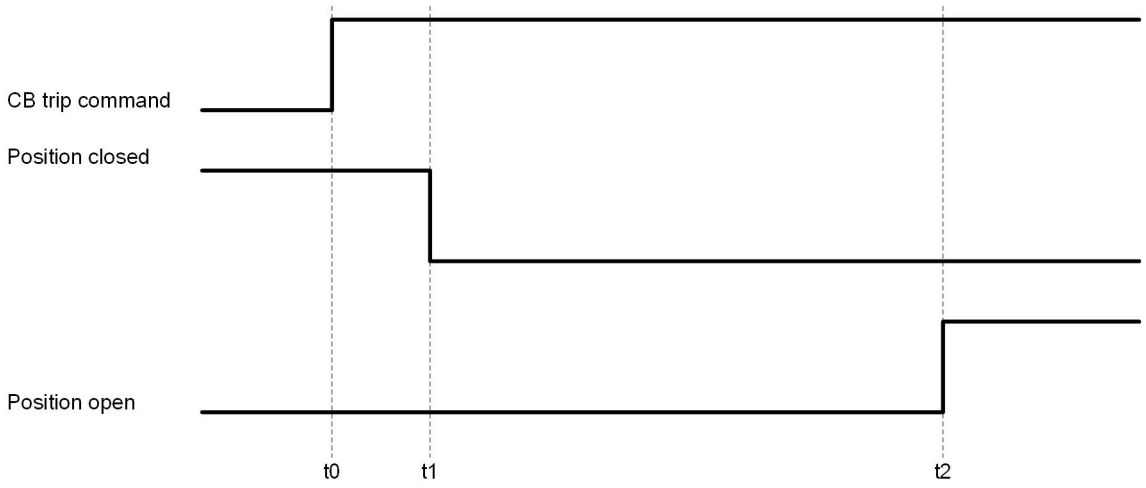


Figure 9-53 Logic of the Stage Mechanical Switching Time Open for Circuit Breakers 3-Pole

[lo_mechanical_Break-time_1phs, 1, en_US]

Figure 9-54 Logic of the Stage Mechanical Switching Time Open for Circuit Breakers 1-Pole

Operating Mode

[dw_charact_cb-breaktime, 1, en_US]

t2 - t0: Auxiliary-contact time opening
t1 - t0: Response time opening
t2 - t1: Auxiliary-contact moving time opening

The stage for supervision of the mechanical switching time opening of the circuit breaker measures the time between the starting criterion (t0) and the point in time when the position of the circuit breaker switches to **Intermediate position** (t1). The stage measures the time between the starting criterion (t0) and the point in time when the position of the circuit breaker switches to **Open** (t2). Additionally, it calculates the auxiliary-contact moving time from the intermediate position (t1) until reaching the position **Open** (t2).

The starting criterion can be either the opening command of the circuit breaker, trip from a protection function or the input signal *>Start calc. for open*.

You can set 2 independent threshold values for the supervision of the measured time t1-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. You can set 2 independent threshold values for the supervision of the measured time t2-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. For t2-t1, only the calculated time is to be indicated. There is no warning or alarm threshold.

If you use a 1-pole circuit breaker, the settings and indications are phase-selective. For 3-pole circuit breakers times cannot be determined phase selective. The settings are done in the section **3-phase**.

A precondition for the monitoring of the mechanical switching times is the routing of the open and closed circuit-breaker position in the function group **Circuit breaker**. If you route only one or no circuit-breaker feedbacks, the function **Mechanical switching time open** cannot work and indicates the status *Warning*.

9.12.11.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: `Auxiliary-contact time`

- Default setting **`(_:24002:161) Auxiliary-contact time`** = ***35 ms***

With the parameter **`Auxiliary-contact time`**, you define the time period from the circuit-breaker open command until the feedback contacts of the CB indicate **Open**.

Parameter: `Thres. aux.c. time warn`

- Default setting **`(_:24002:162) Thres. aux.c. time warn`** = ***5 ms***

With the parameter **Thres. aux.c. time warn**, you define by how many ms the auxiliary-contact time can be exceeded or undershot before the output ***Aux.c. time open warn.*** is set. The output ***Aux.c. time open warn.*** drops out after 100 ms.

Parameter: Thres. aux.c. time alarm

- Default setting **(_:24002:163) Thres. aux.c. time alarm** = ***10 ms***

With the parameter **Thres. aux.c. time alarm**, you define by how many ms the auxiliary-contact time can be exceeded or undershot before the output ***Aux.c. time open alarm*** is set. The output ***Aux.c. time open alarm*** drops out after 100 ms.

Parameter: Reaction time

- Default setting **(_:24002:164) Reaction time** = ***15 ms***

With the parameter **Reaction time**, you define the time between the circuit-breaker opening command and the indication **Intermediate position** by the feedback contacts of the CB.

Parameter: Thres. react. time warn

- Default setting **(_:24002:165) Thres. react. time warn** = ***3 ms***

With the parameter **Thres. react. time warn**, you define by how many ms the reaction time can be exceeded or undershot before the output ***React. time open warn.*** is set. The output ***React. time open warn.*** drops out after 100 ms.

Parameter: Thres. react. time alarm

- Default setting **(_:24002:166) Thres. react. time alarm** **(_:24033:166) Thres. react. time alarm** = ***5 ms***

With the parameter **Thres. react. time alarm**, you define by how many ms the reaction time can be exceeded or undershot before the output ***React. time open alarm*** is set. The ***React. time open alarm*** drops out after 100 ms.

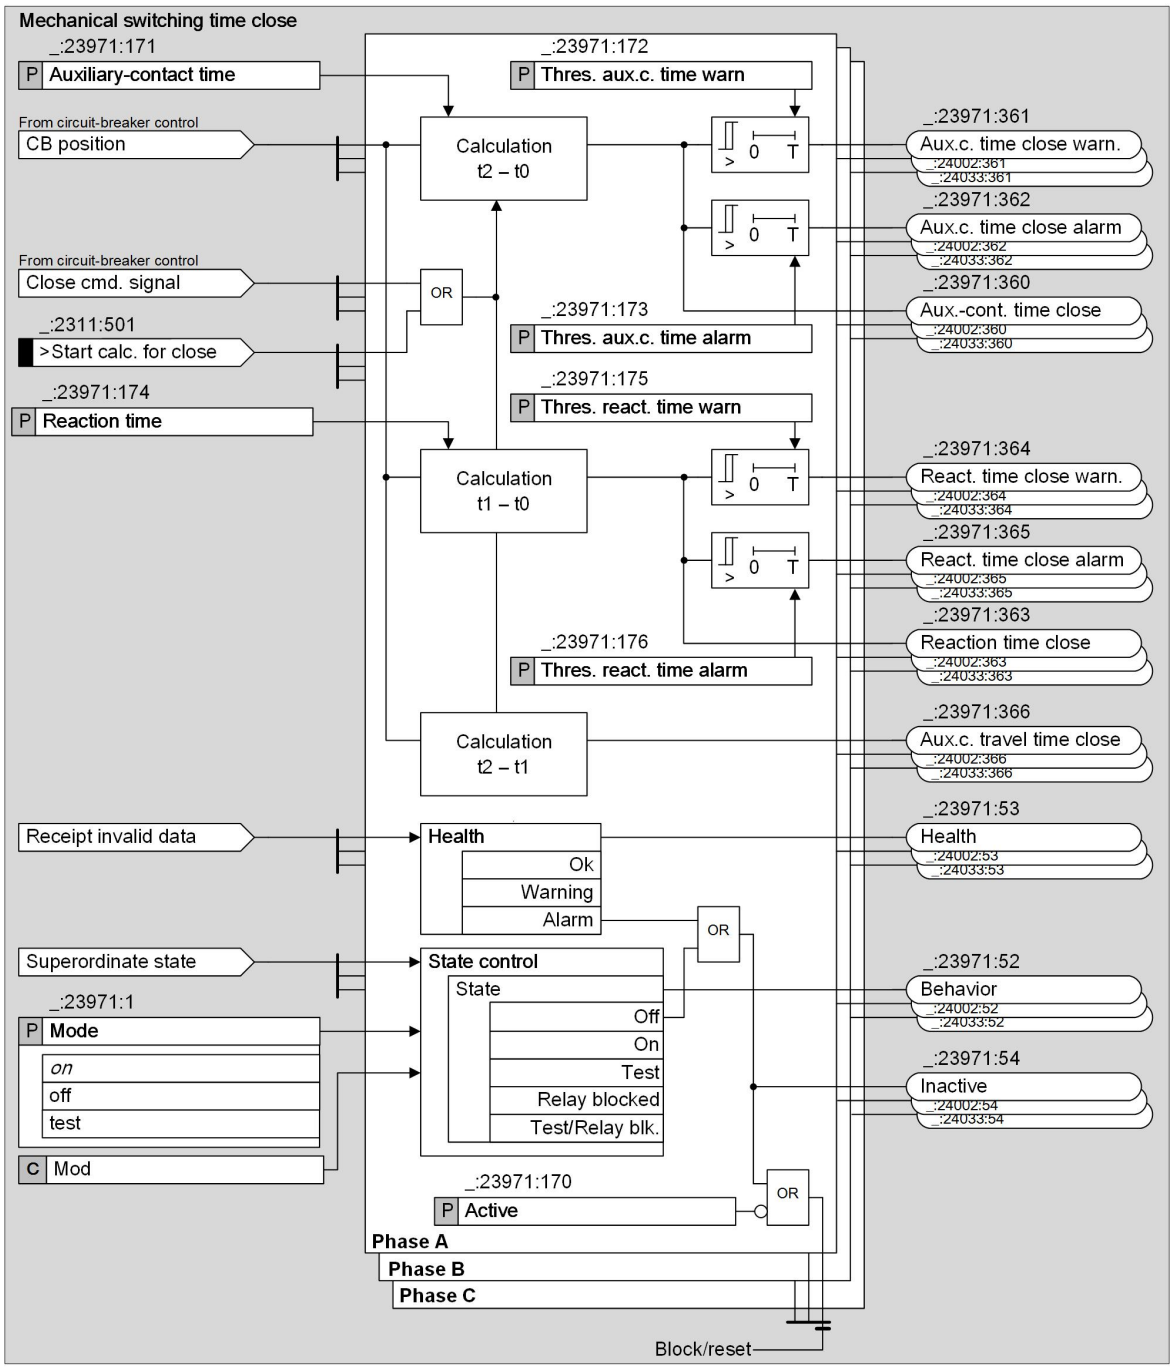
9.12.12 Mechanical Switching Time Close



9.12.12.1 Description

Logic of the Stage

[lo_mechanical_Make-time_3phs, 1, en_US]

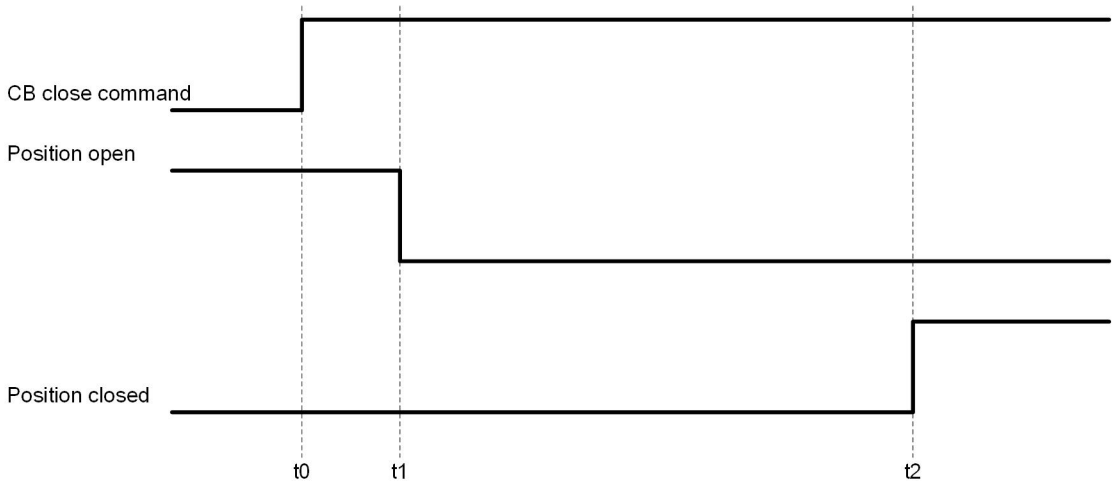


Figure 9-55 Logic of the Stage Mechanical Switching Time Close for Circuit Breakers 3-Pole

[lo_mechanical_Make-time_1phs, 1, en_US]

Figure 9-56 Logic of the Stage Mechanical Switching Time Close for Circuit Breakers 1-Pole

Operating Mode

[dw_charact_cb-maketime, 1, en_US]

t2 - t0: Auxiliary-contact time closing
t1 - t0: Response time closing
t2 - t1: Auxiliary-contact moving time closing

The stage for supervision of the mechanical switching time closing of the circuit breaker measures the time between the closing command of the circuit breaker (t0) and the point in time when the position of the circuit breaker switches to **Intermediate position** (t1). The stage measures the time between the close command of the circuit breaker (t0) and the point in time when the position of the circuit breaker switches to **Close** (t2). Additionally, it calculates the auxiliary-contact moving time from the intermediate position (t1) until reaching the position **Close** (t2).

The starting criterion can be either the closing command of the circuit breaker or the input signal *>Start calc. for close*.

You can set 2 independent threshold values for the supervision of the measured time t1-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. You can set 2 independent threshold values for the supervision of the measured time t2-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. For t2-t1, only the calculated time is to be indicated. There is no warning or alarm threshold.

If you use a 1-pole circuit breaker, the settings and indications are phase-selective. For 3-pole circuit breakers times cannot be determined phase selective. The settings are done in the section **3-phase**.

A precondition for the monitoring of the mechanical switching times is the routing of the open and closed circuit-breaker position in the function group **Circuit breaker**. If you route only one or no circuit-breaker feedbacks, the function **Mechanical switching time close** cannot work and indicates the status *Warning*.

9.12.12.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions apply similarly to the parameters of the remaining phases.

Parameter: `Auxiliary-contact time`

- Default setting **`(_:23971:171) Auxiliary-contact time`** = ***35 ms***

With the parameter **`Auxiliary-contact time`**, you define the time period from the circuit-breaker close command until the feedback contacts of the CB indicate **Closed**.

Parameter: **Thres. aux.c. time warn**

- Default setting **(_:23971:172) Thres. aux.c. time warn** = ***5 ms***

With the parameter **Thres. aux.c. time warn**, you define by how many ms the auxiliary-contact time can be exceeded or undershot before the output *Aux.c. time close warn.* is set. The output *Aux.c. time close warn.* drops out after 100 ms.

Parameter: **Thres. aux.c. time alarm**

- Default setting **(_:23971:173) Thres. aux.c. time alarm** = ***10 ms***

With the parameter **Thres. aux.c. time alarm**, you define by how many ms the auxiliary-contact time can be exceeded or undershot before the output *Aux.c. time close alarm* is set. The output *Aux.c. time close alarm* drops out after 100 ms.

Parameter: **Reaction time**

- Default setting **(_:23971:174) Reaction time** = ***15 ms***

With the parameter **Reaction time**, you define the time between the circuit-breaker closing command and the indication **Intermediate position** by the feedback contacts of the CB.

Parameter: **Thres. react. time warn**

- Default setting **(_:23971:175) Thres. react. time warn** = ***3 ms***

With the parameter **Thres. react. time warn**, you define by how many ms the reaction time can be exceeded or undershot before the output *React. time close warn.* is set. The output *React. time close warn.* drops out after 100 ms.

Parameter: **Thres. react. time alarm**

- Default setting **(_:23971:176) Thres. react. time alarm** = ***5 ms***

With the parameter **Thres. react. time alarm**, you define by how many ms the reaction time can be exceeded or undershot before the output *React. time close alarm* is set. The *React. time close alarm* drops out after 100 ms.

9.12.13 Operation counter

9.12.13.1 Description

The stage for the supervision of the switching cycles counts the number of switching cycles using the feedback contacts of the circuit breaker.

You can set 2 independent threshold values for the supervision. If a threshold value is exceeded, the corresponding output indication is issued. Use the circuit-breaker statistical values to set and reset the meter. You can also use the input signal *>Reset switch statist.* to reset the meter. You can find the input in the DIGSI 5 Information routing under the FG **Circuit breaker > Circuit break**.

9.12.13.2 Application and Setting Notes

NOTE

The following parameters apply to one phase. The descriptions also apply to the parameters of the other phases.

Parameter: `Threshold for warning`

- Default setting **`(_:26461:151) Threshold for warning`** = ***`9500`***

With the parameter **`Threshold for warning`**, you specify after how many switching cycles the output indication ***`Oper.-counter warning`*** is issued.

Parameter: `(_:26461:152) Threshold for alarm`

- Default setting **`Threshold for alarm`** = ***`10 000`***

With the parameter **`Threshold for alarm`**, you specify after how many switching cycles the output indication ***`Oper.-counter alarm`*** is issued.

9.12.13.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`Operation counter`				
_:26461:190	3-Phase:Active		• 0 • 1	false
_:26461:191	3-Phase:Threshold for warning		0 to 999 999 999	9500
_:26461:192	3-Phase:Threshold for alarm		0 to 999 999 999	10 000

9.13 Disconnector-Switch Monitoring

9.13.1 Overview of Functions

The function **Disconnector supervision**:

- Detects and reports temporal changes in the switching procedure of disconnectors

9.13.2 Structure of the Function

The function **Disconnector supervision** can be used in the function group **Disconnector**.
The function consists of 2 independent operating procedures:

- **Mechanical switching time open**
  Monitoring of the mechanical switching time for the opening operation, detected via the feedback contacts
- **Mechanical switching time close**
  Monitoring of the mechanical switching time for the closing operation, detected via the feedback contacts

9.13.3 General Functionality

9.13.3.1 Description

Start Criterion for the Function Disconnector Supervision

The operating procedure **Mechanical switching time close** is started if one of the following criteria is met:

- The disconnector is closed via a command.
- The binary input signal *>Start calc. for close* is initiated, for example, via an external signal.

The operating procedure **Mechanical switching time open** is started if one of the following criteria is met:

- The disconnector is opened via a command.
- The binary input signal *>Start calc. for open* is initiated, for example, via an external signal.

9.13.3.2 Application and Setting Notes

Parameter: Mode

- Default setting **(_:26671:1) Mode** = ***on***

With the parameter **Mode**, you can switch the disconnector supervision ***on***, ***off***, or in ***test*** mode.

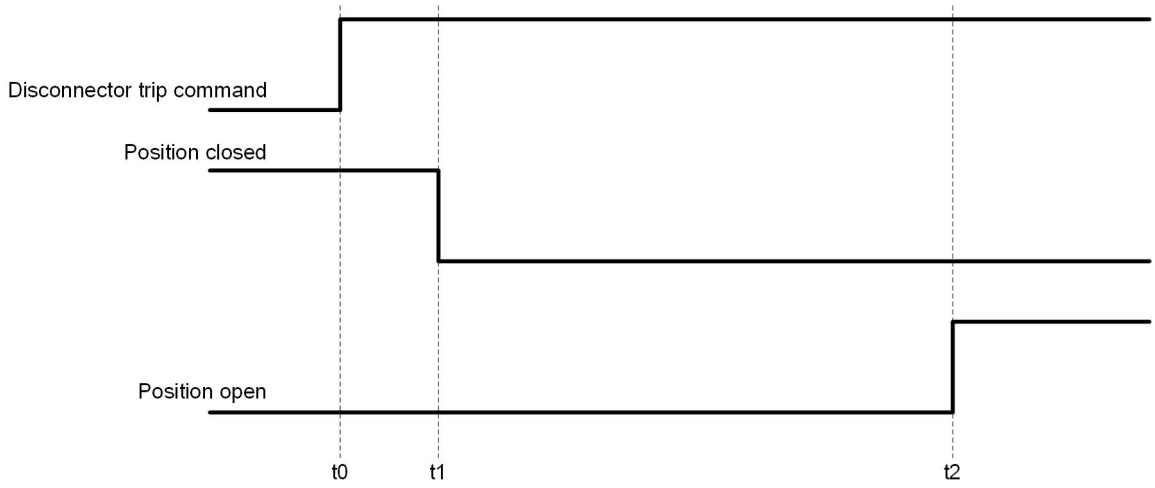
9.13.4 Mechanical Switching Time Open

9.13.4.1 Description



Logic of the Stage

[lo_mechanical_make-time_open, 1, en_US]

Figure 9-57 Logic of the Stage Mechanical Switching Time for Disconnector

Method of Operation

[dw_charact_dcs-maketime_op, 1, en_US]

1) t2 - t0: Auxiliary contact time open operation
2) t1 - t0: Reaction time open operation
3) t2 - t1: Auxiliary contact dead time open operation

The stage for monitoring the **mechanical switching time open** of the disconnector calculates the time between the start criterion (t0) and the time when the disconnector-switch position changes to the **intermediate position** (t1). The stage measures the time between the start criterion (t0) and the time when the disconnector-switch position changes to **open** (t2). Additionally, the stage calculates the time of the auxiliary contacts between the **intermediate position** (t1) until the **open** position is reached (t2).

The start criterion can be either the switching command **open** of the disconnector or the input signal *>Start calc. for open*.

You can define 2 independent threshold values for monitoring the measured time t1-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. You can define 2 independent threshold values for monitoring the measured time t2-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. For t2-t1, the calculated time must be displayed. There is no warning or alarm threshold.

For monitoring the mechanical switching times, you must route the open and closed disconnector-switch position in the function group **Disconnector**. If you route only one or no disconnector feedback, the function **Mechanical switching time open** cannot work and issues the state *Warning*.

9.13.4.2 Application and Setting Notes

Parameter: Auxiliary-contact time

- Default setting **(_:26671:161) Auxiliary-contact time** = *10 s*

With the parameter **Auxiliary-contact time**, you to define the duration between the disconnector trip command and the feedback contacts signaling the **open** position.

Parameter: Thres. aux.c. time warn

- Default setting **(_:26671:162) Thres. aux.c. time warn** = *12 s*

With the parameter **Thres. aux.c. time warn**, you define by how many seconds the auxiliary-contact time may be undercut or exceeded for the output *Aux.c. time open warn.* to be set. The output *Aux.c. time open warn.* drops out after 100 ms.

Parameter: Thres. aux.c. time alarm

- Default setting **(_:26671:163) Thres. aux.c. time alarm** = *14 s*

With the parameter **Thres. aux.c. time alarm**, you define by how many seconds the auxiliary-contact time may be undercut or exceeded for the output *Aux.c. time open alarm* to be set. The output *Aux.c. time open alarm* drops out after 100 ms.

Parameter: Reaction time

- Default setting **(_:26671:164) Reaction time** = *2 s*

With the parameter **Reaction time**, you define the duration between the disconnector trip command and the feedback contacts signaling the **intermediate position**.

Parameter: Thres. react. time warn

- Default setting **(_:26671:165) Thres. react. time warn** = *2.4 s*

With the parameter **Thres. react. time warn**, you define by how many seconds the reaction time may be undercut or exceeded for the output *React. time open warn.* to be set. The output *React. time open warn.* drops out after 100 ms.

Parameter: Thres. react. time alarm

- Default setting **(_:26671:166) Thres. react. time alarm** = *2.8 s*

With the parameter **Thres. react. time alarm**, you define by how many seconds the reaction time may be undercut or exceeded for the output *React. time open alarm* to be set. The output *React. time open alarm* drops out after 100 ms.

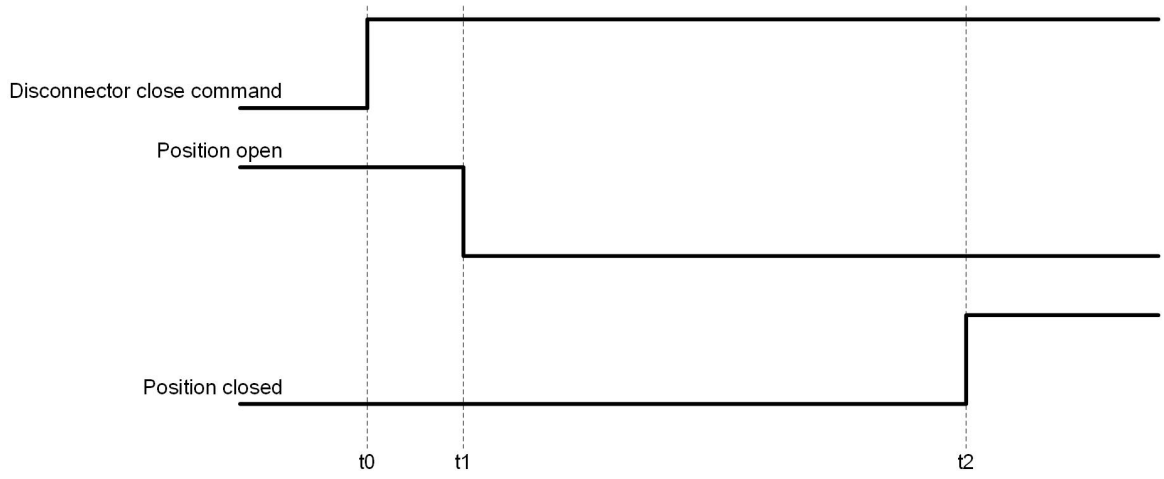
9.13.5 Mechanical Switching Time Close

9.13.5.1 Description



Logic of the Stage

[lo_mechanical_break-time_clo, 1, en_US]

Figure 9-58 Logic of the Stage Mechanical Switching Time Close for Disconnector

Method of Operation

[dw_charact_dcs-breaktime_clo, 1, en_US]

1) t2 - t0: Auxiliary contact time close operation
2) t1 - t0: Reaction time close operation
3) t2 - t1: Auxiliary contact dead time close operation

The stage for monitoring the **mechanical switching time close** of the disconnector measures the time between the disconnector close command (t0) and the time when the disconnector-switch position changes to the **intermediate position**. The stage measures the time between the disconnector close command (t0) and the time when the disconnector-switch position changes to **closed** (t2). Additionally, the stage calculates the time of the auxiliary contacts between the **intermediate position** (t1) until the **closed** position is reached (t2).

The start criterion can be either the disconnector close command or the input signal *>Start calc. for close*.

You can define 2 independent threshold values for monitoring the measured time t1-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. You can define 2 independent threshold values for monitoring the measured time t2-t0. If a threshold value is exceeded, the corresponding output *Warning/Alarm* is activated for 100 ms. For t2-t1, only the measured time must be reported. There is no warning or alarm threshold.

For monitoring the mechanical switching times, you must route the open and closed disconnector-switch position in the function group **Disconnector**. If you route only one or no disconnector feedback, the function **Mechanical switching time close** cannot work and issues the state *Warning*.

9.13.5.2 Application and Setting Notes

Parameter: Auxiliary-contact time

- Default setting **(_:26671:171) Auxiliary-contact time** = *10 s*

With the parameter **Auxiliary-contact time**, you define the duration between the disconnector close command and the feedback contacts signaling the **closed** position.

Parameter: Thres. aux.c. time warn

- Default setting **(_:26671:172) Thres. aux.c. time warn** = *12 s*

With the parameter **Thres. aux.c. time warn**, you define by how many seconds the auxiliary contact time may be undercut or exceeded for the output *Aux.c. time close warn.* to be set. The output *Aux.c. time close warn.* drops out after 100 ms.

Parameter: Thres. aux.c. time alarm

- Default setting **(_:26671:173) Thres. aux.c. time alarm** = ***14 s***

With the parameter **Thres. aux.c. time alarm**, you define by how many seconds the auxiliary contact time may be undercut or exceeded for the output *Aux.c. time close alarm* to be set. The output *Aux.c. time close alarm* drops out after 100 ms.

Parameter: Reaction time

- Default setting **(_:26671:174) Reaction time** = ***2 s***

With the parameter **Reaction time**, you define the duration between the disconnector close command and the feedback contacts signaling the **intermediate position**.

Parameter: Thres. react. time warn

- Default setting **(_:26671:175) Thres. react. time warn** = ***2.4 s***

With the parameter **Thres. react. time warn**, you define by how many seconds the reaction time may be undercut or exceeded for the output *React. time close warn.* to be set. The output *React. time close warn.* drops out after 100 ms.

Parameter: Thres. react. time alarm

- Default setting **(_:26671:176) Thres. react. time alarm** = ***2.8 s***

With the parameter **Thres. react. time alarm**, you define by how many seconds the reaction time may be undercut or exceeded for the output *React. time close alarm* to be set. The output *React. time close alarm* drops out after 100 ms.

10 Power Quality – Basic

10.1	Voltage Variation	2248
10.2	Voltage Unbalance	2264
10.3	THD and Harmonics	2277
10.4	Total Demand Distortion	2286

10.1 Voltage Variation

10.1.1 Overview of Functions

The function **Voltage variation** is used for measuring and monitoring short-duration variations of the voltage in distribution and industrial power systems. The power-quality events such as voltage dips, swells, and interruptions in 3-phase systems are detected.

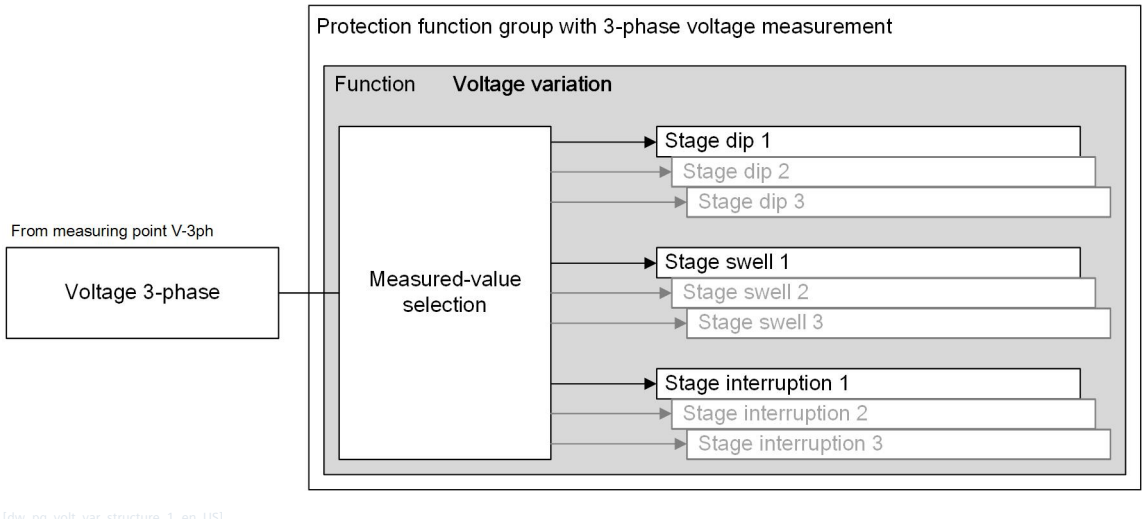
This measuring function provides the RMS value of the voltage for the minimum value in the event of a voltage dip, the lowest residual voltage in the event of an interruption or the highest swell, as well as the duration of the event.

All events can be logged in operational or user-defined logs. They can enable the fault recorder via binary warning indications, and write their values as tracks.

The values are recorded according to the standard for voltage quality IEC 61000-4-30 class S.

10.1.2 Structure of the Function

The function **Voltage variation** is used in protection function groups with 3-phase voltage measurement.



The function comes factory-set with the following stages:

- 1 stage **Dip**
- 1 stage **Swell**
- 1 stage **Interruption**

A maximum of 3 stages **Dip**, 3 stages **Swell**, and 3 stages **Interruption** can be operated simultaneously within the function.

Stages that are not preconfigured are shown in gray in the following figure. The stages are identical in structure.

The measured-value selection is a general functionality and has a uniform effect on the stages (see *Figure 10-1* and *10.1.3.1 Description*). This ensures that all stages of the function receive the same measured values.

{dw_pq_volt_var_structure, 1, en_US}

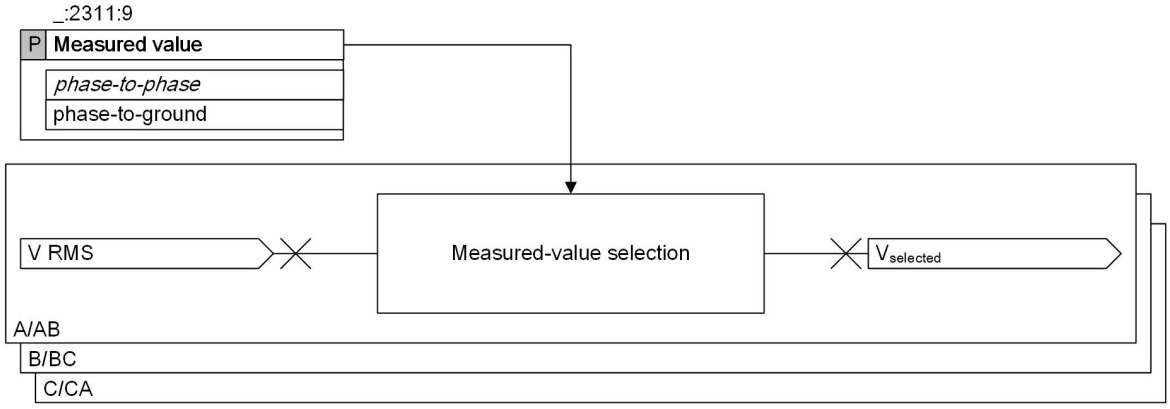


Figure 10-1 Structure/Embedding of the Function

10.1.3 General Functionality

10.1.3.1 Description

Measured-Value Selection

The function provides the option to select between the phase-to-phase and phase-to-ground voltage.

[lo_pq volt_var_general, 1, en_US]

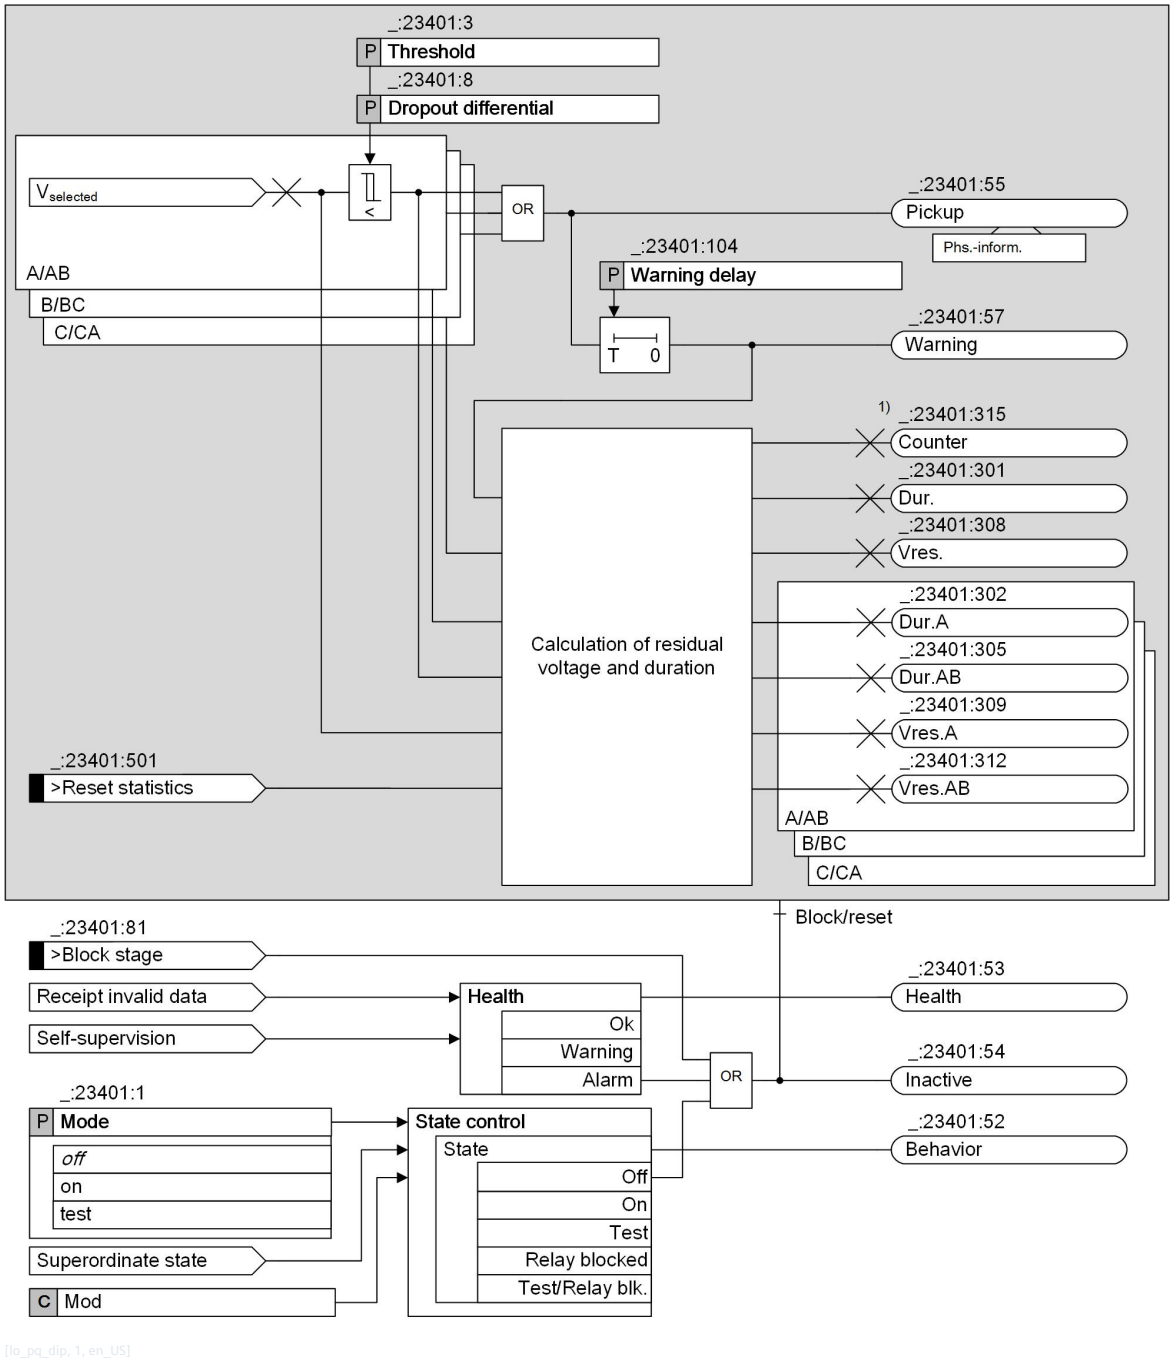
Figure 10-2 Logic Diagram of Measured-Value Selection

The 1-cycle RMS value of the voltage is used in the function.

The setting options of the parameter **Measured value** depend on the connection type of the 3-phase voltage measuring point.

Table 10-1 Setting Options of the Parameter **Measured value**

Connection Type	Setting Options of the Parameter **Measured value**
3 ph-to-gnd voltages 3 ph-to-gnd volt. + VN	• ***phase-to-ground*** • ***phase-to-phase***
3 ph-to-ph voltages 3 ph-to-ph volt. + VN 2 ph-to-ph voltages 2 ph-to-ph volt. + VN	• ***phase-to-phase*** The setting of the parameter is read-only.



10.1.4 Stage Dip

10.1.4.1 Description

The stage **Dip**:

- Detects a voltage dip in the power system and issues a warning signal for any phase
- Logs the dip duration and the minimum residual voltage for any phase when the voltage-dip event disappears
- Counts the number of voltage-dip events

Logic of the Stage

[lo_pq_dip, 1, en_US]

Figure 10-3 Logic Diagram of the Stage Dip

(1) Counter is a statistical value. It is not reset by the block or reset state of the stage. For more information, refer to *Counter Accumulation, Page 2253*.

Pickup and Warning

If the voltage falls below the threshold value, a signal *Pickup* is issued. After expiration of the time specified by the parameter **Warning delay**, a signal *Warning* is issued.

The phase information of the signal *Pickup* is issued according to the selected measured value:

- The ***phase-to-ground*** voltage is selected as the measured value:
  If a phase-to-ground voltage, for example, VA, falls below the threshold value, the phase information of phase A of the signal *Pickup* is issued.
- The ***phase-to-phase*** voltage is selected as the measured value:
  If a phase-to-phase voltage, for example, VAB, falls below the threshold value, the phase information of phase A and phase B of the signal *Pickup* is issued.

Value Indications

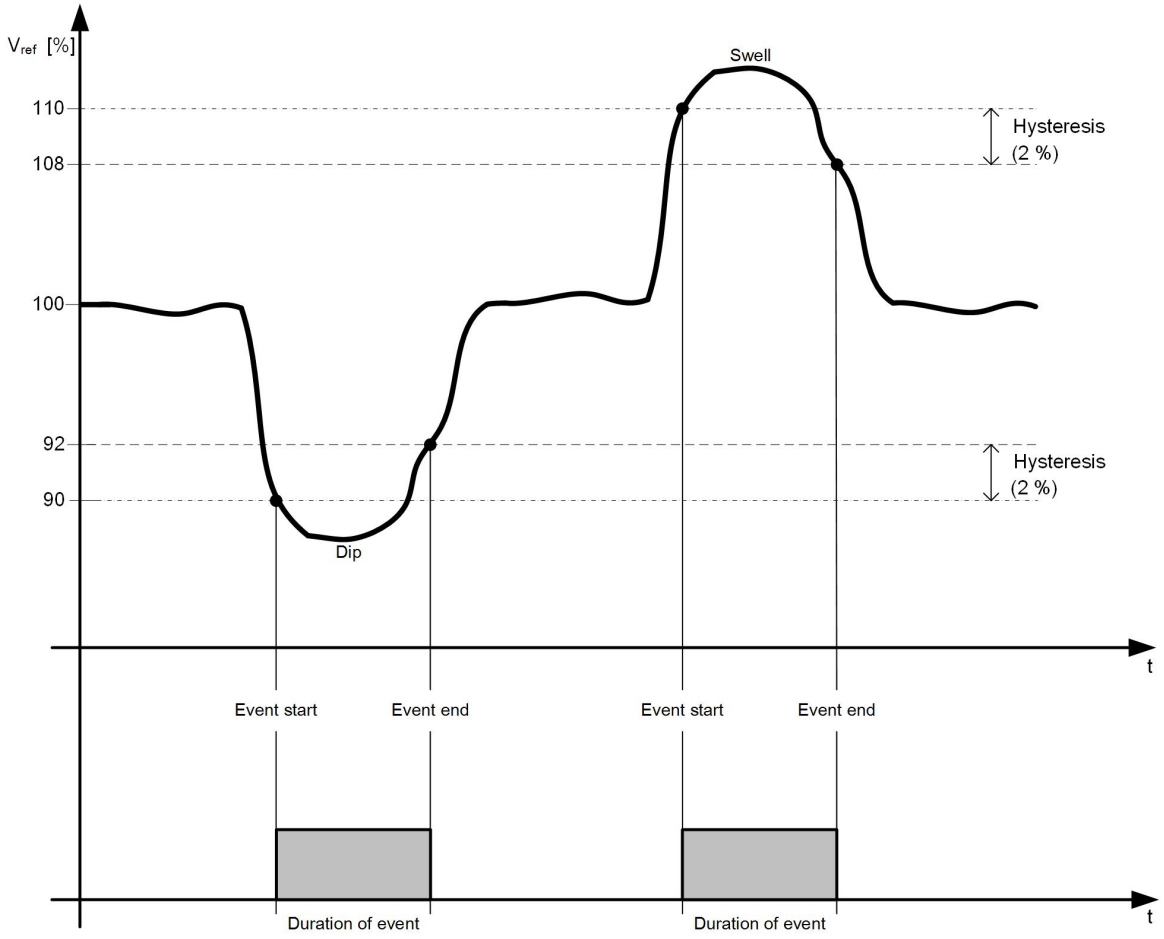
If the signal *Warning* is issued, it is regarded as a voltage-dip event. Once the voltage-dip event disappears (the signal *Warning* drops out), the following value indications are calculated:

- The durations and residual voltages of this event are calculated and can be logged in the operational or user-defined logs if routed.
- The counter of voltage-dip events is increased by 1.

If, after the pickup, the voltage dip disappears during the time delay, the signal *Warning* is not issued and the incident is regarded as a voltage chattering and not as a voltage-dip event. No duration or voltage is calculated and the counter is not increased.

Table 10-2 Value Indications of the Stage Dip

Value	Description	Calculation
Counter	Total number of voltage-dip events This is a statistical value stored in the NVRAM[65].	Refer to *Counter Accumulation, Page 2253*
Dur.	Calculated phase overall duration of a voltage-dip event	Refer to *Duration Calculation, Page 2251*
Dur.A Dur.B Dur.C	Durations of a voltage-dip event for the phases A, B, and C These values are only visible when the ***phase-to-ground*** voltage is selected.	
Dur.AB Dur.BC Dur.CA	Durations of a voltage-dip event for the phases AB, BC, and CA These values are only visible when the ***phase-to-phase*** voltage is selected.	
Vres.	Minimum residual voltage of all phases in a voltage-dip event among the phases A, B, and C or among the phases AB, BC, and CA	These values are percentage values related to the parameter **Rated voltage** (reference voltage) that is set in the function group. Refer to *Residual-Voltage Calculation, Page 2253*.
Vres.A Vres.B Vres.C	Minimum residual voltages in a voltage-dip event for the phases A, B, and C These values are only visible when the ***phase-to-ground*** voltage is selected.	
Vres.AB Vres.BC Vres.CA	Minimum residual voltages in a voltage-dip event for the phases AB, BC, and CA These values are only visible when the ***phase-to-phase*** voltage is selected.	



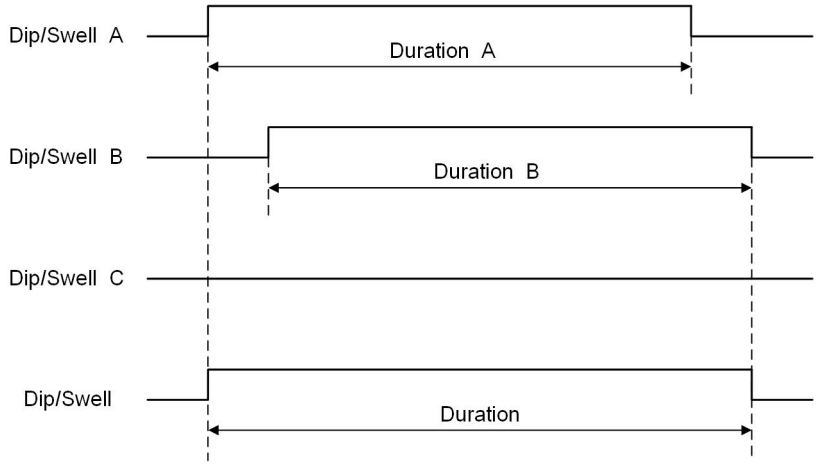
Duration Calculation

The duration of a voltage-dip or voltage-swell event is defined as the duration between the event start and event end, as shown in *Figure 10-4*.

65 NVRAM = Non-Volatile Random Access Memory; RAM, which does not lose the stored data, even when there is no power.

In the figure, it is assumed as follows:

- The dip threshold is 90 % (specified by the parameter **Threshold** of the stage **Dip**).
- The swell threshold is 110 % (specified by the parameter **Threshold** of the stage **Swell**).
- The hysteresis is 2 % (specified by the parameter **Dropout differential** of the respective stage).
- The warning delay is 0 s (specified by the parameter **Warning delay** of the respective stage).



[dw_pq_volt_var_event_duration, 1, en_US]

Figure 10-4 Duration of a Voltage-Dip or Voltage-Swell Event

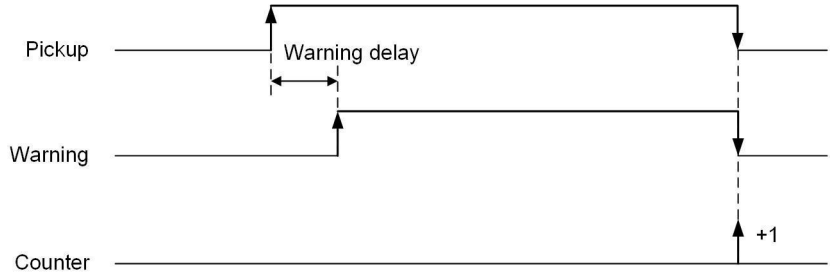
Where

Event start	The moment when the signal *Pickup* is issued
Event end	The moment when the signal *Pickup* drops out
V_{ref} [%]	The percentage value of the parameter **Rated voltage** (reference voltage) that is set in the function group

Only the durations of picked-up phases as well as the overall duration are calculated and logged. The following figure provides an example of phase-selective duration calculation with the ***phase-to-ground*** voltage selected as the measured value.

[dw_pq_volt_var_phs-selective_dur, 1, en_US]

Figure 10-5 Example of Phase-Selective and Overall Duration Calculation



In the preceding example, voltage dips or swells occur only in phases A and B. Therefore, durations of phases A and B and the overall duration are calculated and logged. No duration of phase C is calculated or logged.

Residual-Voltage Calculation

Only picked-up phases calculate the minimum values of the residual voltages. If the values are assigned to a log, they are also logged.

Counter Accumulation

The *Counter* value is increased by 1 when the voltage-variation event disappears, as shown in the following figure.

[dw_pq_counter_accum, 1, en_US]

Figure 10-6 Counter Accumulation

NOTE

The counter is accumulated also when the function is in test mode.

The *Counter* value is retained (not reset) in the following scenarios:

- The parameter **Mode** of the stage is set to *off*.
- The signal *>Block stage* is issued.
- Device restart
- Device power-off and power-on (with battery)

The *Counter* value can be reset based on the following possibilities:

- The signal *>Reset statistics* is issued (in condition that the stage is active).
- HMI reset (in condition that the stage is active)
- DIGSI online reset (in condition that the stage is active)
- Device reset (to factory settings)
- Via protocol (in condition that the stage is active)

Blocking of the Stage

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage is reset.

10.1.4.2 Application and Setting Notes

Evaluation Possibilities – Voltage Variation Function Provides Standard-Relevant Values und Information

The power-quality evaluating standard EN 50160 (grid code) refers to the measuring standard IEC 61000-4-30, with which this function aligns. If you use the default settings of this function, then the measured and logged values are fine for further user-based classifications on EN 50160 or other analysis possibilities of users. For more information, refer to the standard EN 50160.

Parameter: `Threshold`, `Dropout differential`

- Default setting **`(_:23401:3) Threshold`** = ***`90.0 %`***
- Default setting **`(_:23401:8) Dropout differential`** = ***`2.0 %`***

The parameters **`Threshold`** and **`Dropout differential`** are percentage values related to the parameter **`Rated voltage`** (reference voltage) that is set in the function group.

Set the parameters **`Threshold`** and **`Dropout differential`** for the specific application.

According to the standard IEC 61000-4-30, the dip threshold is typically in the range of 85 % to 90 % for troubleshooting or statistical applications, and the hysteresis (**`Dropout differential`**) is typically equal to 2 %.

Parameter: `Warning delay`

- Default setting **`(_:23401:104) Warning delay`** = ***`0.00 s`***

If you do not want to log a voltage-dip event that lasts shorter than a specific time duration, for example, 20 ms, you can set the parameter **`Warning delay`** to ***`0.02 s`***.

10.1.5 Stage Swell

10.1.5.1 Description

The stage **Swell**:

- Detects a voltage swell in the power system and issues a warning signal for any phase
- Logs the swell duration and the maximum swell voltage for any phase when the voltage-swell event disappears
- Counts the number of voltage-swell events

Logic of the Stage

[lo_pq_swell, 1, en_US]

Figure 10-7 Logic Diagram of the Stage Swell

(1) Counter is a statistical value. It is not reset by the block or reset state of the stage. For more information, refer to *Counter Accumulation, Page 2258*.

Pickup and Warning

If the voltage exceeds the threshold value, a signal *Pickup* is issued. After expiration of the time specified by the parameter **Warning delay**, a signal *Warning* is issued.

The phase information of the signal *Pickup* is issued according to the selected measured value:

- The ***phase-to-ground*** voltage is selected as the measured value:
  If a phase-to-ground voltage, for example, VA, exceeds the threshold value, the phase information of phase A of the signal *Pickup* is issued.
- The ***phase-to-phase*** voltage is selected as the measured value:
  If a phase-to-phase voltage, for example, VAB, exceeds the threshold value, the phase information of phase A and phase B of the signal *Pickup* is issued.

Value Indications

If the signal *Warning* is issued, it is regarded as a voltage-swell event. Once the voltage-swell event disappears (the signal *Warning* drops out), the following value indications are calculated:

- The durations and swell voltages of this event are calculated and can be logged in the operational or user-defined logs if routed.
- The counter of voltage-swell events is increased by 1.

If, after the pickup, the voltage swell disappears during the time delay, the signal *Warning* is not issued and the incident is regarded as a voltage chattering and not as a voltage-swell event. No duration or voltage is calculated and the counter is not increased.

Table 10-3 Value Indications of the Stage Swell

Value	Description	Calculation
Counter	Total number of voltage-swell events This is a statistical value stored in the NVRAM[66].	Similar to the counter accumulation of the stage **Dip**, refer to *Figure 10-6*
Dur.	Calculated phase overall duration of a voltage-swell event	Similar to the duration calculation of the stage **Dip**, refer to *Duration Calculation, Page 2251*
Dur.A Dur.B Dur.C	Durations of a voltage-swell event for the phases A, B, and C These values are only visible when the ***phase-to-ground*** voltage is selected.	
Dur.AB Dur.BC Dur.CA	Durations of a voltage-swell event for the phases AB, BC, and CA These values are only visible when the ***phase-to-phase*** voltage is selected.	
Vsw.	Maximum swell voltage of all phases in a voltage-swell event among the phases A, B, and C or among the phases AB, BC, and CA	These values are percentage values with relation to the parameter **Rated voltage** (reference voltage) that is set in the function group. Refer to *Swell-Voltage Calculation, Page 2258*.
Vsw.A Vsw.B Vsw.C	Maximum swell voltages in a voltage-swell event for the phases A, B, and C These values are only visible when the ***phase-to-ground*** voltage is selected.	
Vsw.AB Vsw.BC Vsw.CA	Maximum swell voltages in a voltage-swell event for the phases AB, BC, and CA These values are only visible when the ***phase-to-phase*** voltage is selected.	

Duration Calculation

For details, refer to *Duration Calculation, Page 2251*.

66 NVRAM = Non-Volatile Random Access Memory; RAM, which does not lose the stored data, even when there is no power.

Swell-Voltage Calculation

Only picked-up phases calculate the maximum values of the swells. If the values are assigned to a log, they are also logged.

Counter Accumulation

For details, refer to *Counter Accumulation, Page 2253*.

Blocking of the Stage

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage is reset.

10.1.5.2 Application and Setting Notes

Evaluation Possibilities – Voltage Variation Function Provides Standard-Relevant Values und Information

The power-quality evaluating standard EN 50160 (grid code) refers to the measuring standard IEC 61000-4-30, with which this function aligns. If you use the default settings of this function, then the measured and logged values are fine for further user-based classifications on EN 50160 or other analysis possibilities of users. For more information, refer to the standard EN 50160.

Parameter: **Threshold**, **Dropout differential**

- Default setting **(_:23491:3) Threshold** = *110.0 %*
- Default setting **(_:23491:8) Dropout differential** = *2.0 %*

The parameters **Threshold** and **Dropout differential** are percentage values related to the parameter **Rated voltage** (reference voltage) that is set in the function group.

Set the parameters **Threshold** and **Dropout differential** for the specific application.

According to the standard IEC 61000-4-30, the swell threshold is typically greater than 110 %, and the hysteresis (**Dropout differential**) is typically equal to 2 %.

Parameter: **Warning delay**

- Default setting **(_:23491:104) Warning delay** = *0.00 s*

If you do not want to log a voltage-swell event that lasts shorter than a specific time duration, for example, 20 ms, you can set the parameter **Warning delay** to *0.02 s*.

10.1.5.3 Settings

10.1.6 Stage Interruption

10.1.6.1 Description

The stage **Interruption**:

- Detects a voltage interruption in the power system and issues a warning signal
- Logs the interruption duration (not phase-selective) and the minimum residual voltage when the voltage-interruption event disappears
- Counts the number of voltage-interruption events

Logic of the Stage

[lo_pq_interrupt, 1, en_US]

Figure 10-8 Logic Diagram of the Stage Interruption

(1) Counter is a statistical value. It is not reset by the block or reset state of the stage. For more information, refer to *Counter Accumulation, Page 2262*.

Pickup and Warning

If all 3 voltage measured values fall below the threshold value, a signal *Pickup* is issued. After expiration of the time specified by the parameter **Warning delay**, a signal *Warning* is issued. The following measured-value types can be selected:

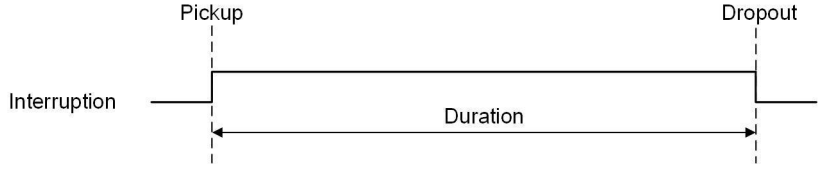
- The ***phase-to-ground*** voltage is selected as the measured value:
  If all the phase-to-ground voltages VA, VB, and VC fall below the threshold value, the signal *Pickup* is issued.

- The ***phase-to-phase*** voltage is selected as the measured value:
  If all the phase-to-phase voltages VAB, VBC, and VCA fall below the threshold value, the signal *Pickup* is issued.

Value Indications

If the signal *Warning* is issued, it is regarded as a voltage-interruption event. Once the voltage-interruption event disappears (the signal *Warning* drops out), the following value indications are calculated:

- The duration and residual voltages of this event are calculated and can be logged in the operational or user-defined logs if routed.
- The counter of voltage-interruption events is increased by 1.



If, after the pickup, the voltage interruption disappears during the time delay, the signal *Warning* is not issued and the incident is regarded as a voltage chattering and not as a voltage-interruption event. No duration or voltage is calculated and the counter is not increased.

Table 10-4 Value Indications of the Stage Interruption

Value	Description	Calculation
Counter	Total number of voltage-interruption events This is a statistical value stored in the NVRAM[67].	Similar to the counter accumulation of the stage **Dip**, refer to *Figure 10-6*
Dur.	Calculated phase overall duration of a voltage-interruption event	Refer to *Duration Calculation, Page 2261*
Vres.	Minimum residual voltage in a voltage-interruption event among the phases A, B, and C or among the phases AB, BC, and CA	These values are percentage values related to the parameter **Rated voltage** (reference voltage) that is set in the function group refer to *Residual-Voltage Calculation, Page 2261*.
Vres.A Vres.B Vres.C	Minimum residual voltages in a voltage-interruption event for the phases A, B, and C These values are only visible when the ***phase-to-ground*** voltage is selected.	
Vres.AB Vres.BC Vres.CA	Minimum residual voltages in a voltage-interruption event for the phases AB, BC, and CA These values are only visible when the ***phase-to-phase*** voltage is selected.	

Duration Calculation

The duration of a voltage-interruption event is defined as the duration between the event start and event end, which is similar to that of a voltage-dip or voltage-swell event. For more details, refer to *Figure 10-4*.

[dw_pq_volt_var_dur_interrupt, 1, en_US]

Figure 10-9 Duration Calculation of the Stage Interruption

Residual-Voltage Calculation

The minimum values of the residual voltages of all phases are calculated. If the values are assigned to a log, they are also logged.

67 NVRAM = Non-Volatile Random Access Memory; RAM, which does not lose the stored data, even when there is no power.

Counter Accumulation

For details, refer to *Counter Accumulation, Page 2253*.

Blocking of the Stage

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage is reset.

10.1.6.2 Application and Setting Notes

Evaluation Possibilities – Voltage Variation Function Provides Standard-Relevant Values und Information

The power-quality evaluating standard EN 50160 (grid code) refers to the measuring standard IEC 61000-4-30, with which this function aligns. If you use the default settings of this function, then the measured and logged values are fine for further user-based classifications on EN 50160 or other analysis possibilities of users. For more information, refer to the standard EN 50160.

Parameter: Threshold, Dropout differential

- Default setting **(_:23521:3) Threshold** = *5.0 %*
- Default setting **(_:23521:8) Dropout differential** = *2.0 %*

The parameters **Threshold** and **Dropout differential** are percentage values related to the parameter **Rated voltage** (reference voltage) that is set in the function group.

Set the parameters **Threshold** and **Dropout differential** for the specific application.

According to the standard IEC 61000-4-30, the interruption threshold can, for example, be set to 5 % or to 10 %, and the hysteresis (**Dropout differential**) is typically equal to 2 %.

Parameter: Warning delay

- Default setting **(_:23521:104) Warning delay** = *0.00 s*

If you do not want to log a voltage-interruption event that lasts shorter than a specific time duration, for example, 20 ms, you can set the parameter **Warning delay** to *0.02 s*.

10.2 Voltage Unbalance

10.2.1 Overview of Functions

In a 3-phase power system, the voltages are normally balanced, as well as the connected loads. In some cases, however, the balanced conditions can be disturbed due to various influences.
Voltage unbalances can be caused by various factors:

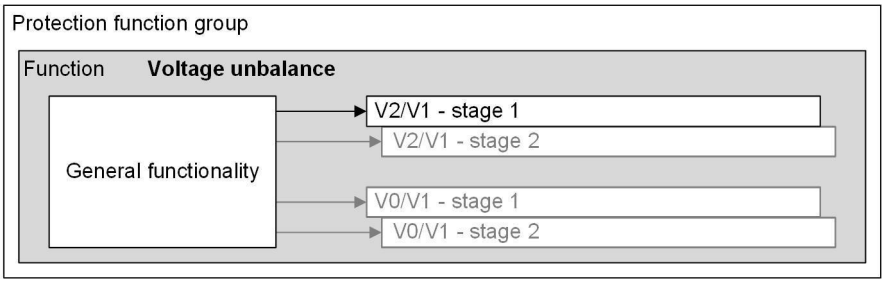
- Unbalanced load, for example, caused by different consumers in the individual phases
- Phase failure, for example, due to a tripped 1-phase fuse or a broken conductor
- Faults in the primary system, for example, at the transformer

The function **Voltage unbalance**:

- Detects the voltage-unbalance conditions in the distribution and industrial power systems.
- Monitors the voltage-unbalance conditions.

In the function **Voltage unbalance**, the following stage types are available:

- **V2/V1**: ratio of the negative-sequence voltage to the positive-sequence voltage
- **V0/V1**: ratio of the zero-sequence voltage to the positive-sequence voltage



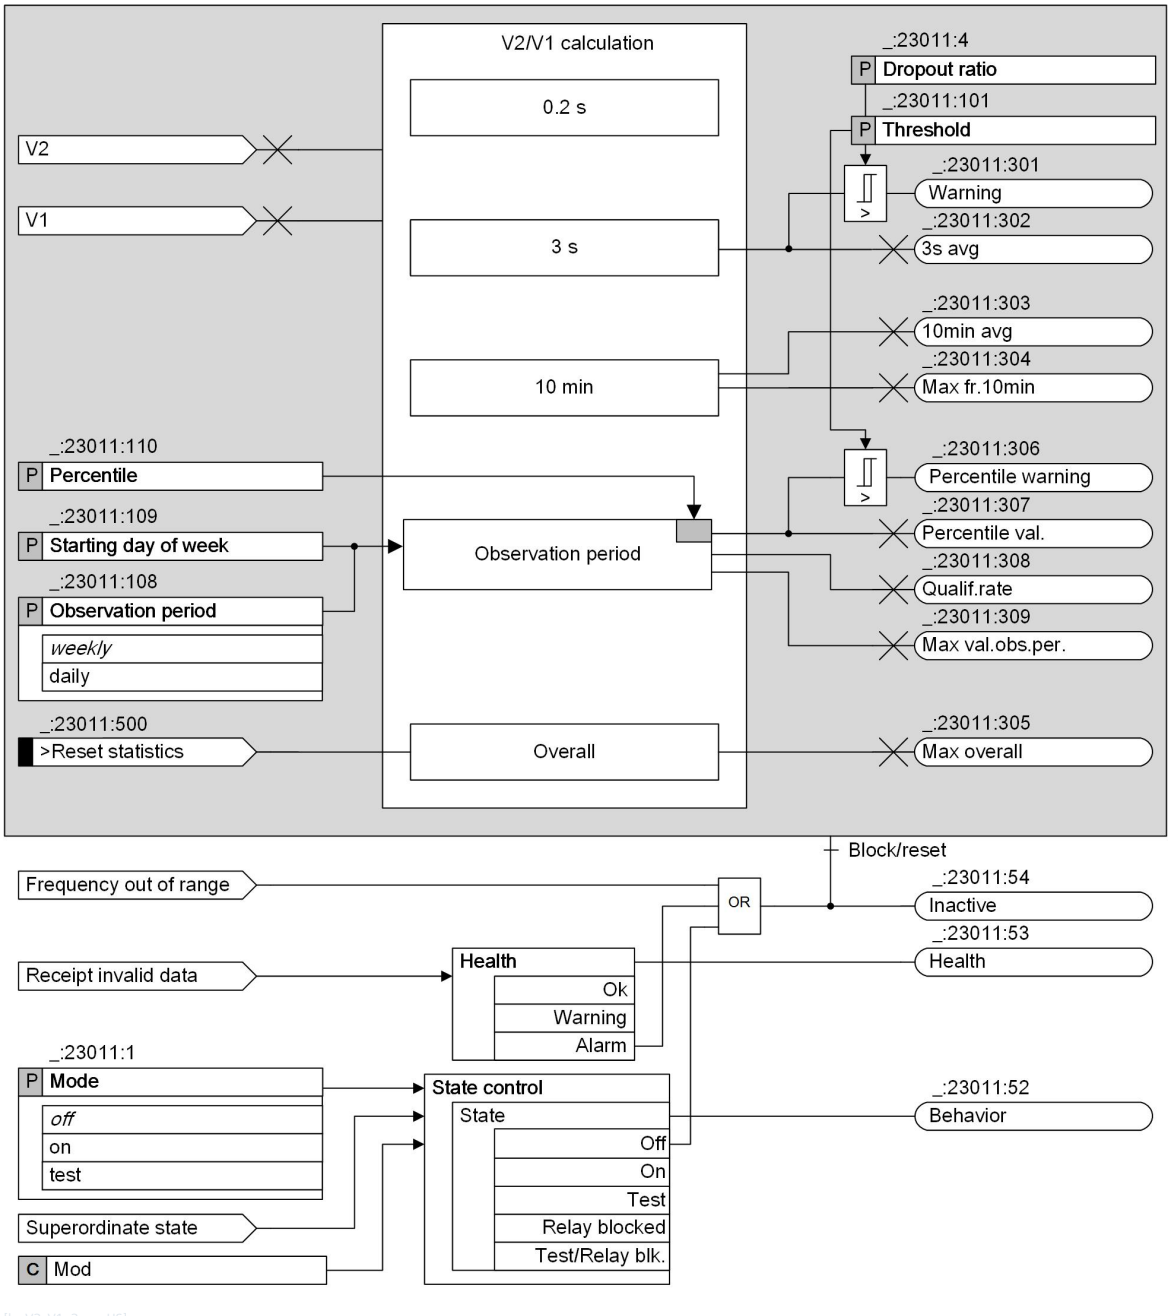
All the measured values are displayed under **Power quality basic** > **Voltage unbalance** of a specific function group in the HMI.
The specific function group in which the function **Voltage unbalance** is instantiated must be connected to the 3-phase voltage measuring point.
The values are recorded according to the standard for voltage quality IEC 61000-4-30 class S.

10.2.2 Structure of the Function

The function **Voltage unbalance** can be used in the protection function groups with 3-phase voltage measurement.
The function **Voltage unbalance** comes factory-set with a stage **V2/V1**.
The following stages can be operated simultaneously within the function:

- 2 stages **V2/V1**
- 2 stages **V0/V1**

The general functionality works across stages on the function level.
The stages are identical in structure. Stages that are not preconfigured are shown in gray in the following figure.



[dw_V_unbalance_structure, 1, en_US]

Figure 10-10 Structure/Embedding of the Function

10.2.3 Stage V2/V1

10.2.3.1 Description

Logic of the Stage

[lo_V2_V1_2, 2, en_US]

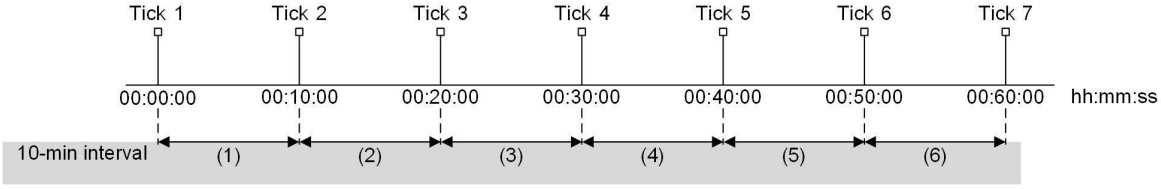


Figure 10-11 Logic Diagram of the Stage **V2/V1**

Measuring Intervals

Measuring Intervals	Description
0.2 s	10 cycles for the 50-Hz system or 12 cycles for the 60-Hz system This interval is the basic measuring interval for this stage. All further measured values are aggregated based on the 0.2-s values.
3 s	150 cycles for the 50-Hz system or 180 cycles for the 60-Hz system This interval is used for the calculation of the 3-s average value.
10 min	The calculation in the 10-min interval is based on the UTC 10-min tick. There is no gap and no overlap between 2 consecutive 10-min intervals. This interval is used for the calculation of the 10-min average value and the maximum 0.2-s value in 10 min.
Observation period	Settable interval of one week or one day
Overall	From the device startup or from the latest reset of statistical values until the current time The maximum value of V2/V1 in overall time is displayed as a statistical value.

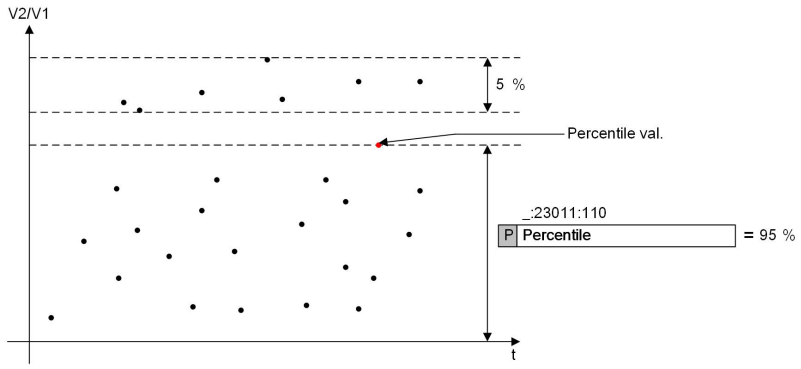
Aggregation by the UTC 10-Min Tick

The 10-min average values are aggregated by the UTC 10-min tick according to the standard IEC 61000-4-30. Each 10-min interval begins at a tick.

[dw_tick_interval, 1, en_US]

Figure 10-12 Ticks and 10-Min Intervals in an Hour

Warning of the Voltage Unbalance



If the 3-s average value exceeds the threshold value, a voltage-unbalance event occurs and the indication *warning* is generated.

If the 3-s average value is smaller than or equal to the result of the threshold value multiplied by the dropout ratio, the indication *warning* for the voltage unbalance disappears.

Observation

A settable observation period of *weekly* or *daily* is provided. In the observation period, the following measured values are observed to determine the voltage-unbalance conditions.

Table 10-5 Observed Values in the Observation Period

Value	Description
Percentile val.	To locate the value *Percentile val.*, you must set the parameter **Percentile**. The following figure shows an example of locating the percentile value: In the figure, all the 10-min average values of V2/V1 in the last observation period are displayed. The parameter **Percentile** is set to 95 %. Then, the value *Percentile val.* is determined as the value that 95 % of the 10-min average values in the last observation period are smaller than or equal to. 
Qualif.rate	Proportion of the 10-min average values that are smaller than the threshold value in the last observation period
Max val.obs.per.	Maximum 0.2-s value in the last observation period

During the observation period, if the value *Percentile val.* of the 10-min average values exceeds the threshold value, a voltage-unbalance event occurs and the indication *Percentile warning* is generated.

Functional Values

Value	Description
Max overall	Maximum 0.2-s value of V2/V1 from the device startup or from the latest reset of statistical values to the current time
3s avg	Average value of V2/V1 in the last 3-s interval, that is, 150 cycles or 180 cycles
10min avg	Average value of V2/V1 in the last 10-min interval
Max fr.10min	Maximum 0.2-s value of V2/V1 in the last 10-min interval
Percentile val.	The value *Percentile val.* is the value that, for example, 95 % (default setting of the parameter **Percentile**) of all 10-min average values in the last observation period are smaller than or equal to. For more information, refer to *Observation, Page 2266*.
Qualif.rate	Proportion of the 10-min average values that are smaller than the threshold value in the last observation period
Max val.obs.per.	Maximum 0.2-s value in the last observation period This value is refreshed at the end of each observation period.

Value Indications

If the indication *Percentile warning* is generated, routed value indications from the table *Table 10-6* can be entered in the log.

Table 10-6 Value Indications

Value	Description
Perc.value abnor.	**Percentile value abnormal** Percentile in case of a warning (percentile is above limiting value) and possible record It is the ame value as *Percentile val.* from the same observation interval.
Qual.rate abnor.	**Quality rate abnormal** Quality rate in case of a warning (percentile is above limiting value) and possible record It is the same value as *Qualif.rate* from the same observation interval.
Max val.obs.per.abnor.	**Maximum value observation period abnormal** Maximum value of the observation period in case of a warning (percentile is above limiting value) and possible record It is the same value as *Max val.obs.per.* from the same observation interval.

The value indications can be routed to the following logs:

- Operational log
- User-defined log 1
- User-defined log 2

Resetting the Statistical Value

The statistical value *Max overall* can be reset via the following methods:

- Via the binary input signal *>Reset statistics*
- Via the **Reset** button for the maximum value of statistic in the operation panel of the device
- Via communication protocols
- Via an online DIGSI connection to the device

Influences Caused by the Change of the Device Time

If the device time is changed, the calculated values in the 10-min intervals and in observation periods are influenced. There are 2 cases:

- After the change, the time is still in the time interval of the calculation.
  The calculation is not influenced and continues. The calculated value is refreshed at the end of the time interval.
- After the change, the time is out of the time interval of the calculation.
  The calculation is influenced and is terminated immediately. Meanwhile, the calculated value is refreshed and the calculation of the next time interval is started.

10.2.3.2 Application and Setting Notes

Evaluation Possibilities – the Stage V2/V1 of the function Voltage Unbalance Provides Standard-Relevant Values and Information

The power-quality evaluating standard EN 50160 (grid code) refers to the measuring standard IEC 61000-4-30, with which this function aligns. If you use the default settings of this function, then the measured and logged values are fine for further user-based evaluations on EN 50160 or other analysis possibilities of users. For more information, refer to the standard EN 50160.

Parameter: Minimum voltage V1

- Default setting **(_:2311:101) Minimum voltage V1** = ***5.000 V***

You can configure the parameter **Minimum voltage V1** in the function block **General**.

With the parameter **Minimum voltage V1**, you set the minimum value of the positive-sequence voltage V1. The calculation in the stage **V2/V1** or **V0/V1** starts only when V1 exceeds the set **Minimum voltage V1**.

Siemens recommends using the default setting.

Parameter: Threshold

- Default setting **(_:23011:101) Threshold** = ***2.00 %***

With the parameter **Threshold**, you set the threshold value to define the degree of voltage unbalance which is not considered as normal any more. If the average value of V2/V1 exceeds the threshold value, a voltage-unbalance event is detected and the indication *Warning* is generated.

According to the standard EN 50160 or IEC TS 62749, Siemens recommends using the default setting.

Parameter: Dropout ratio

- Default setting **(_:23011:4) Dropout ratio** = ***0.95***

With the parameter **Dropout ratio**, you set the dropout ratio for the voltage unbalance. If the average value of V2/V1 is smaller than or equal to the result of the threshold value multiplied by the dropout ratio, the indication *Warning* for the voltage unbalance disappears.

Siemens recommends using the default setting.

Parameter: Observation period

- Default setting **(_:23011:108) Observation period** = ***weekly***

With the parameter **Observation period**, you set the period for the observation.

Parameter Value	Description
weekly	The observation is executed and repeated weekly according to the start day specified by the parameter **Starting day of week**. After the device startup, the first observation starts immediately and ends at the time 00:00:00 of the first starting day. Then, the observation is repeated weekly.
daily	The observation is executed and repeated every day. After the device startup, the first observation starts immediately and ends at the time 00:00:00 of the next day. Then, the observation is repeated day by day.

Parameter: Starting day of week

- Default setting **(_:23011:109) Starting day of week** = ***Sunday***

This parameter is effective only when the parameter **Observation period** is set to ***weekly***.

With the parameter **Starting day of week**, you set the start day of the weekly observation. The start day can be set to any day of the week. For example, it is Tuesday today and the set start day is ***Sunday***, then, the first observation starts from Tuesday to Saturday, and the following observation is executed weekly starting from Sunday.

Parameter: Percentile

- Default setting **(_:23011:110) Percentile** = ***95 %***

With the parameter **Percentile**, you define the range of the 10-min average values that is used to locate the percentile value in the last observation period.

The default setting ***95 %*** is taken as an example. 95 % of the 10-min average values are smaller than or equal to the percentile value in the last observation period.

According to the standard EN 50160 or IEC TS 62749, Siemens recommends using the default setting.

10.2.3.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:2311:101	General:Minimum voltage V1		0.300 V to 60.000 V	5.000 V

10.2.4 Stage V0/V1

10.2.4.1 Description

Logic of the Stage

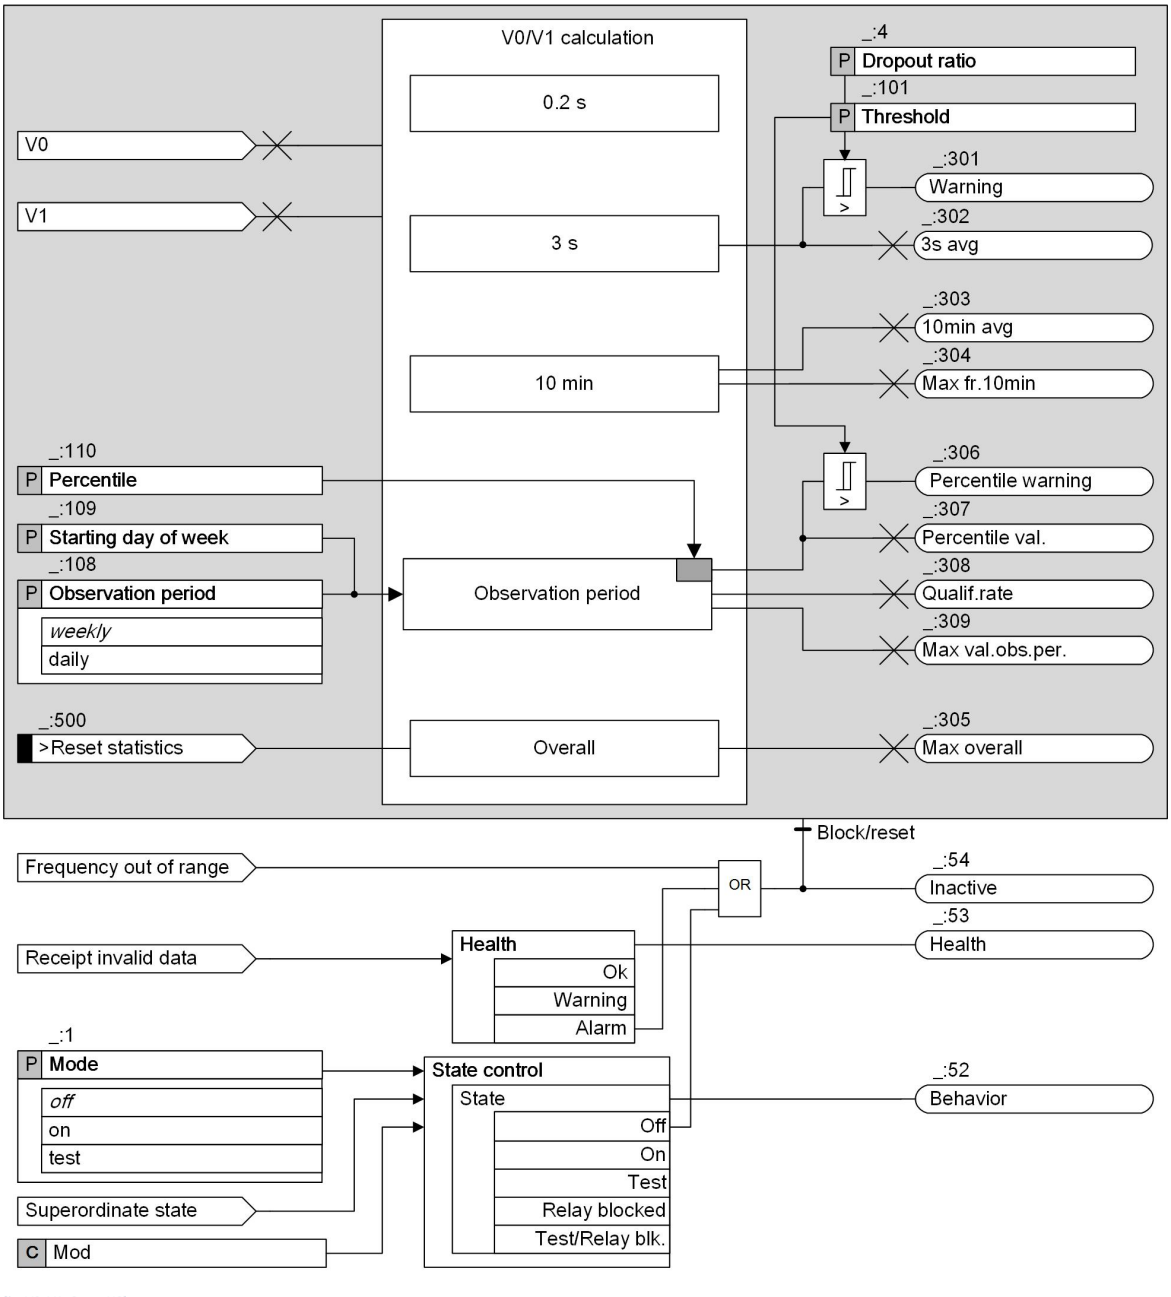

Figure 10-13 Logic Diagram of the Stage **V0/V1**

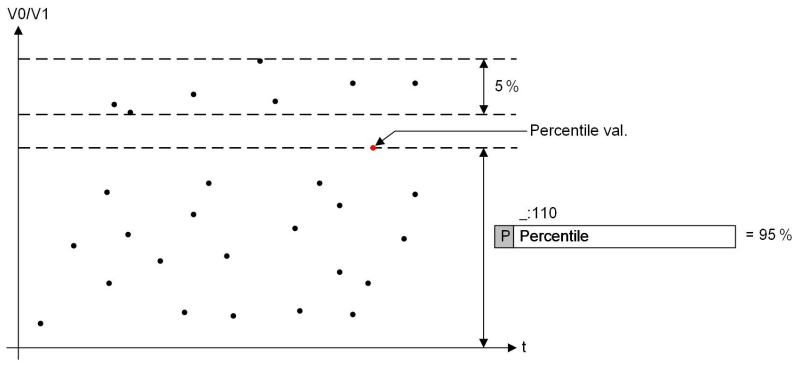
Measuring Intervals

Measuring Intervals	Description
0.2 s	10 cycles for the 50-Hz system or 12 cycles for the 60-Hz system This interval is the basic measuring interval for this stage. All further measured values are aggregated based on the 0.2-s values.
3 s	150 cycles for the 50-Hz system or 180 cycles for the 60-Hz system This interval is used for the calculation of the 3-s average value.
10 min	The calculation in the 10-min interval is based on the UTC 10-min tick. There is no gap and no overlap between 2 consecutive 10-min intervals. This interval is used for the calculation of the 10-min average value and the maximum 0.2-s value in 10 min.
Observation period	Settable interval of one week or one day
Overall	From the device startup or from the latest reset of statistical values to the current time The maximum value of V0/V1 in overall time is displayed as a statistical value.

Aggregation by the UTC 10-Min Tick

For details, refer to *Aggregation by the UTC 10-Min Tick, Page 2266*.



Warning of the Voltage Unbalance

For details, refer to *Warning of the Voltage Unbalance, Page 2266*.

Observation

A settable observation period of *weekly* or *daily* is provided. In the observation period, the following measured values are observed to determine the voltage-unbalance conditions.

Table 10-7 Observed Values in the Observation Period

Value	Description
Percentile val.	To locate the value *Percentile val.*, you must set the parameter **Percentile**. The following figure shows an example of locating the percentile value: In the figure, all the 10-min average values of V0/V1 in the last observation period are displayed. The parameter **Percentile** is set to 95 %. Then, the value *Percentile val.* is determined as the value that 95 % of the 10-min average values in the last observation period are smaller than or equal to. 
Qualif.rate	Proportion of the 10-min average values that are smaller than the threshold value in the last observation period
Max val.obs.per.	Maximum 0.2-s value in the last observation period

During the observation period, if the value *Percentile val.* of the 10-min average values exceeds the threshold value, a voltage-unbalance event occurs and the indication *Percentile warning* is generated.

Functional Values

Value	Description
Max overall	Maximum 0.2-s value of V0/V1 from the device startup or from the latest reset of statistical values to the current time
3s avg	Average value of V0/V1 in the last 3-s interval, that is, 150 cycles or 180 cycles
10min avg	Average value of V0/V1 in the last 10-min interval
Max fr.10min	Maximum 0.2-s value of V0/V1 in the last 10-min interval
Percentile val.	The value *Percentile val.* is the value that, for example, 95 % (default setting of the parameter **Percentile**) of all 10-min average values in the last observation period are smaller than or equal to. For more information, refer to *Observation, Page 2272*.
Qualif.rate	Proportion of the 10-min average values that are smaller than the threshold value in the last observation period
Max val.obs.per.	Maximum 0.2-s value in the last observation period This value is refreshed at the end of each observation period.

Value Indications

For details, refer to *Value Indications, Page 2267*.

Resetting the Statistical Value

For details, refer to *Resetting the Statistical Value, Page 2268*.

Influences Caused by the Change of the Device Time

For details, refer to *Influences Caused by the Change of the Device Time, Page 2268*.

Connection Type

In the stage **V0/V1**, the following connection types of the voltage transformer are available for the 3-phase voltage measuring point:

- *3 ph-to-gnd volt. + VN*
- *3 ph-to-gnd voltages*
- *3 ph-to-ph volt. + VN*
- *2 ph-to-ph volt. + VN*

The following connection types of the voltage transformer are not available for the 3-phase voltage measuring point. If one of the connection types is connected, DIGSI 5 reports an inconsistency:

- *3 ph-to-ph voltages*
- *2 ph-to-ph voltages*

10.2.4.2 Application and Setting Notes

Parameter: `Threshold`

- Default setting **`(_:101) Threshold`** = ***2.00 %***

With the parameter **`Threshold`**, you set the threshold value to define the degree of voltage unbalance which is not considered as normal any more. If the average value of V0/V1 exceeds the threshold value, a voltage-unbalance event is detected and the indication *Warning* is generated.
According to the standard EN 50160 or IEC TS 62749, Siemens recommends using the default setting.

Parameter: `Dropout ratio`

- Default setting **`(_:4) Dropout ratio`** = ***0.95***

With the parameter **`Dropout ratio`**, you set the dropout ratio for the voltage unbalance. If the average value of V0/V1 is smaller than or equal to the result of the threshold value multiplied by the dropout ratio, the indication *Warning* for the voltage unbalance disappears.
Siemens recommends using the default setting.

Parameter: `Observation period`

- Default setting **`(_:108) Observation period`** = ***weekly***

With the parameter **`Observation period`**, you set the period for the observation.

Parameter Value	Description
weekly	The observation is executed and repeated weekly according to the start day specified by the parameter **`Starting day of week`**. After the device startup, the first observation starts immediately and ends at the time 00:00:00 of the first starting day. Then, the observation is repeated weekly.
daily	The observation is executed and repeated every day. After the device startup, the first observation starts immediately and ends at the time 00:00:00 of the next day. Then, the observation is repeated day by day.

Parameter: `Starting day of week`

- Default setting **`(_:109) Starting day of week`** = ***Sunday***

This parameter is effective only when the parameter **Observation period** is set to ***weekly***.

With the parameter **Starting day of week**, you set the start day of the weekly observation. The start day can be set to any day of the week. For example, it is Tuesday today and the set start day is ***Sunday***, then, the first observation starts from Tuesday to Saturday, and the following observation is executed weekly starting from Sunday.

Parameter: Percentile

- Default setting **(_:110) Percentile** = ***95*** **%**

With the parameter **Percentile**, you define the range of the 10-min average values that is used to locate the percentile value in the last observation period.

The default setting ***95*** **%** is taken as an example. 95 % of the 10-min average values are smaller than or equal to the percentile value in the last observation period.

According to the standard EN 50160 or IEC TS 62749, Siemens recommends using the default setting.

10.3 THD and Harmonics

10.3.1 Overview of Functions

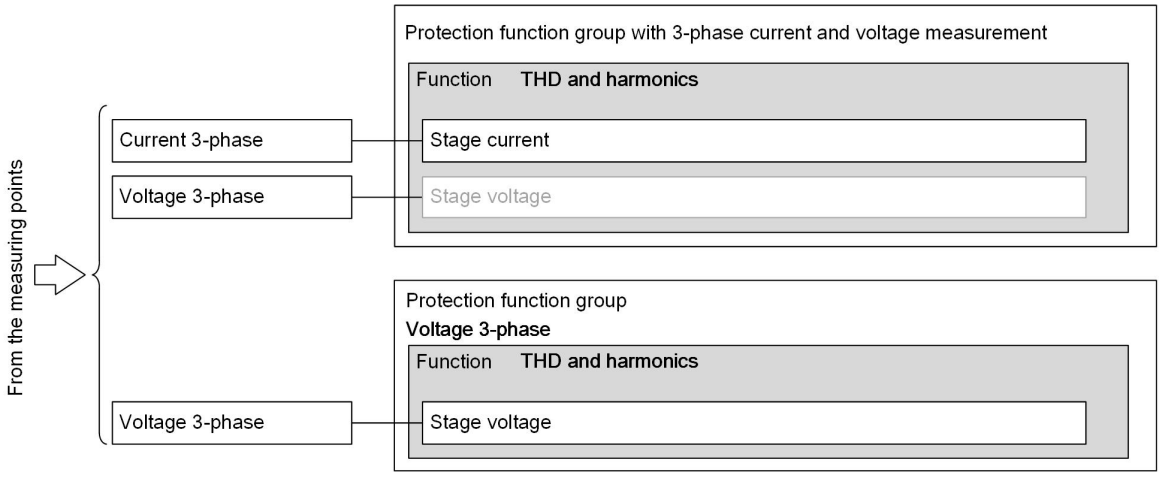
At the connection point to the public power system, the allowed total harmonic distortion (THD) is limited according to the power-quality related standards. The function **THD and harmonics** can be used to monitor the THD value.

The function **THD and harmonics** serves for the calculation of the following values:

- THD values of the 3-phase currents and 3-phase voltages
- Aggregated THD values of the 3-phase voltages
  If the aggregated THD value exceeds the threshold, a warning is generated.
- 2nd to 20th harmonics of the 3-phase currents and 3-phase voltages

The calculated THD values and harmonics are displayed under **Power quality basic** > **THD and harmonics** of a specific function group in the HMI or via the DIGSI Online-Editor. If routed, the calculated THD values and harmonics are available in the communication protocols and in the fault record. Abnormal values can be logged in the operational or user-defined log if routed.

10.3.2 Structure of the Function



The function **THD and harmonics** can be used in the protection function groups with 3-phase current and voltage measurements and in the protection function group with only 3-phase voltage measurement.

When being used in a function group with 3-phase current and voltage measurements, the function comes factory-set with 1 stage **Current**. The following stages can be operated simultaneously within the function:

- 1 stage **Current**
- 1 stage **Voltage**

When being used in a function group with only 3-phase voltage measurement, the function comes factory-set with 1 stage **Voltage**. Only 1 voltage stage can be operated within the function.

The 2 types of function groups are displayed in the following figure. The stage that is not preconfigured is shown in gray.

[dw_structure_THD harmonic, 3, en_US]

Figure 10-14 Structure/Embedding of the Function

10.3.3 Stage Current

10.3.3.1 Function Description

The stage **Current** calculates and displays the THD values and harmonics for the 3-phase currents.

Calculation of THD Values and Harmonics Values

The THD value of the current is a percentage value calculated as follows:

$$I_{THD} = \frac{\sqrt{\sum_{n=2}^{N} I_n^{\,2}}}{I_s} \cdot 100\ \%$$

[fo_THD value_I, 1, en_US]

Where

N	20 The function supports the THD calculation up to the 20th harmonic.
I_n	Harmonic value of order *n*
I_s	Fundamental-component value

The calculated harmonic values of the current are percentage values that take the fundamental-component value as reference:

$$I_{Harmonic_n} = \frac{I_n}{I_s} \cdot 100\ \%$$

[fo_harmonic ratio_I, 1, en_US]

Functional Measured Values

Table 10-8 Functional Measured Values of the stage **Current**

Value	Description
THD:A THD:B THD:C	THD values of the 3-phase currents for the phases A, B, and C These values are percentage values.
H2:A H2:B H2:C ... H20:A H20:B H20:C	Harmonic values from the 2nd to 20th harmonics of the 3-phase currents for the phases A, B, and C These values are percentage values.

Operating Range

The frequency operating range of the stage **Current** is 0.8 to 1.2 of the rated frequency:

- If the power frequency is in this range, the THD values and harmonics are calculated.
- If the power frequency is out of this range, the THD values and harmonics are shown as "---".

If the fundamental-component value is smaller than 1 % of the rated current, the THD values and harmonics are shown as "---".

10.3.4 Stage Voltage

10.3.4.1 Function Description

The stage **Voltage**:

- Calculates and displays the THD values and harmonics for the 3-phase voltages.
- Calculates and displays the aggregated THD values for the 3-phase voltages.
- Generates a warning signal if the aggregated THD value exceeds the threshold.

Logic of the Stage

[lo_voltage stage, 2, en_US]

Figure 10-15 Logic Diagram of the stage **Voltage**

Calculation of THD Values and Harmonic Values

The THD value of the voltage is a percentage value. The following table lists the formulas for the calculation of the raw value and the aggregated THD values.

Based on the raw value, the aggregated THD values of the phase-to-phase voltages and the phase-to-ground voltages are calculated.

Table 10-9 Calculation of THD Values

Value	Formula
Raw value	$V_{Raw} = \frac{\sqrt{\sum_{n=2}^{N} V_n^2}}{V_s} \cdot 100\ \%$ • N: 20 The function supports the THD calculation up to the 20th harmonic. • V_n: Harmonic value of order *n* • V_s: Fundamental-component value
THD Vph THD Vpp	$V_{THD} = \frac{1}{N} \sum_{n=0\ (t=0)}^{N\ (t=3\ s)} V_{Raw}\ (n)$ • N: Total number of the raw values over a 3-s interval
THD Vph max THD Vpp max	$V_{THD,\ max} = MAX\ \{V_{THD,\ 1}, V_{THD,\ 2}, V_{THD,\ 3} \ldots\}$
THD Vph agg THD Vpp agg	$V_{THD,\ agg} = \frac{1}{N} \sum_{n=0}^{N} V_{Raw}\ (n)$ • N: Total number of the raw values over the aggregation interval of 1 min or 10 min

The calculated harmonic values of the voltage are percentage values that take the fundamental-component values as reference.

Table 10-10 Calculation of Harmonic Values

Value	Formula
HPhV2 HPhV3 ... HPhV20	$V_{Harmonic_n} = \frac{V_n}{V_s} \cdot 100\ \%$ • V_n: Harmonic value of order *n* • V_s: Fundamental-component value
HPPV2 HPPV3 ... HPPV20	

Functional Values

For the stage **Voltage**, the functional values are divided into 2 submenus:

- Phase-to-ground voltage, as shown in *Table 10-11*.
- Phase-to-phase voltage, as shown in *Table 10-12*.

The functional values are all percentage values. They are calculated using the formulas in the section *Calculation of THD Values and Harmonic Values, Page 2280*.

Table 10-11 Functional Values for the Phase-to-Ground Voltage

Value	Description
THD Vph:A THD Vph:B THD Vph:C	Average THD values of the phase-to-ground voltages for the phases A, B, and C over a 3-s interval
THD Vph max	Maximum 3-s average THD value of the phase-to-ground voltage in the period from the device startup or from the latest reset of this maximum value to the current time
THD Vph agg:A THD Vph agg:B THD Vph agg:C	Average THD values of the phase-to-ground voltages for the phases A, B, and C over the aggregation interval of 1 min or 10 min
HPhV2:A HPhV2:B HPhV2:C ... HPhV20:A HPhV20:B HPhV20:C	Harmonic values from the 2nd to 20th harmonics of the phase-to-ground voltages for the phases A, B, and C

Table 10-12 Functional Values for the Phase-to-Phase Voltage

Value	Description
THD Vpp:AB THD Vpp:BC THD Vpp:CA	Average THD values of the phase-to-phase voltages for the phases AB, BC, and CA over a 3-s intervals
THD Vpp max	Maximum 3-s average THD value of the phase-to-phase voltage in the period from the device startup or from the latest reset of this maximum value to the current time
THD Vpp agg:AB THD Vpp agg:BC THD Vpp agg:CA	Average THD values of the phase-to-phase voltages for the phases AB, BC, and CA over the aggregation interval of 1 min or 10 min
HPPV2:AB HPPV2:BC HPPV2:CA ... HPPV20:AB HPPV20:BC HPPV20:CA	Harmonic values from the 2nd to 20th harmonics of the phase-to-phase voltages for the phases AB, BC, and CA

NOTE

Considering the device resources, do not route non-required harmonic measured values for transmission via communication protocols.

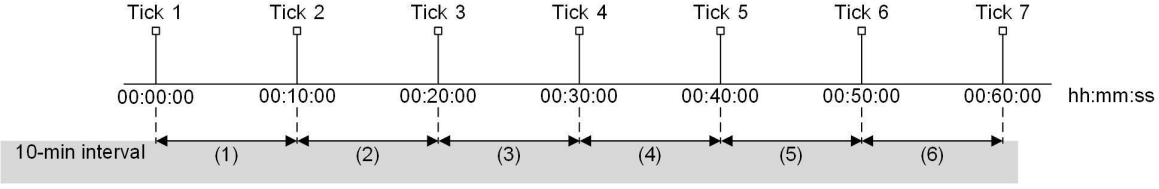
Resetting the Statistical Values

The statistical values *THD Vph max* and *THD Vpp max* can be reset via the following methods:

- Via the binary input signal *>Reset statistics*
- Via the **Reset** button for the maximum value of statistic in the operation panel of the device
- Via communication protocols
- Via an online DIGSI connection to the device

Monitoring of the Aggregation Values

If the aggregated THD value *THD Vph agg* or *THD Vpp agg* exceeds the threshold, a phase-selective indication *Warning* is generated. During the period when the indication *Warning* is active, the maximum aggregated THD value of the phase-to-phase voltages or the phase-to-ground voltages is logged as an abnormal value. The abnormal value can be routed to the following logs:



- Operational log
- User-defined log 1
- User-defined log 2

Table 10-13 Abnormal Values

Value	Description
THD Vph abnor.:A THD Vph abnor.:B THD Vph abnor.:C	Abnormal THD values (THD value is above limiting value) of the phase-to-ground voltages for the phases A, B, and C over the aggregation interval of 1 min or 10 min A record is possible.
THD Vpp abnor.:AB THD Vpp abnor.:BC THD Vpp abnor.:CA	Abnormal THD values of the phase-to-phase voltages for the phases AB, BC, and CA over the aggregation interval of 1 min or 10 min A record is possible.

Aggregation by the UTC 10-Min Tick

If the parameter **Aggregation interval** is set to ***10 min***, the THD values are aggregated by the UTC 10-min tick according to the standard IEC 61000-4-30. Each 10-min interval begins at a tick.

[dw_tick_interval, 1, en_US]

Figure 10-16 Ticks and 10-Min Intervals in an Hour

Influences Caused by the Change of the Device Time

If the device time is changed, the calculation of THD values is influenced. There are 2 cases:

- After the change, the time is still in the time interval of the calculation.
  The calculation is not influenced and continues. The calculated value is refreshed at the end of the time interval.
- After the change, the time is out of the time interval of the calculation.
  The calculation is influenced and is terminated immediately. Meanwhile, the calculated value is refreshed and the calculation of the next time interval is started.

Operating Range

The frequency operating range of the stage **Voltage** is 0.8 to 1.2 of the rated frequency:

- If the power frequency is in this range, the THD values and harmonics are calculated.
- If the power frequency is out of this range, the THD values and harmonics are not calculated and are shown as "---". Meanwhile, the function **THD and harmonics** becomes inactive.

If the fundamental-component value is smaller than 5 % of the rated voltage, the THD values and harmonics are shown as "---".

10.3.4.2 Application and Setting Notes

Parameter: `Aggregation interval`

- Default setting **`(_:101) Aggregation interval`** = ***`10 min`***

With the parameter **`Aggregation interval`**, you set the aggregation interval to 1 min or 10 min to determine the THD condition.
According to the standard IEC 61000-4-30, Siemens recommends using the default setting.

Parameter: `Threshold`

- Default setting **`(_:102) Threshold`** = ***`8.0 %`***

With the parameter **`Threshold`**, you set the threshold for the aggregated THD values. If the aggregated THD value exceeds the threshold, the indication *`Warning`* is generated. Meanwhile, the maximum aggregated THD value is logged as an abnormal value.
According to the standard IEC TS 62749, for the low-voltage or medium-voltage system, the THD value should be smaller than or equal to 8 %. Siemens recommends using the default setting.

10.3.4.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`Voltage`				
_:1	Voltage:Mode		• off • on • test	on
_:101	Voltage:Aggregation interval		• 1 min • 10 min	10 min

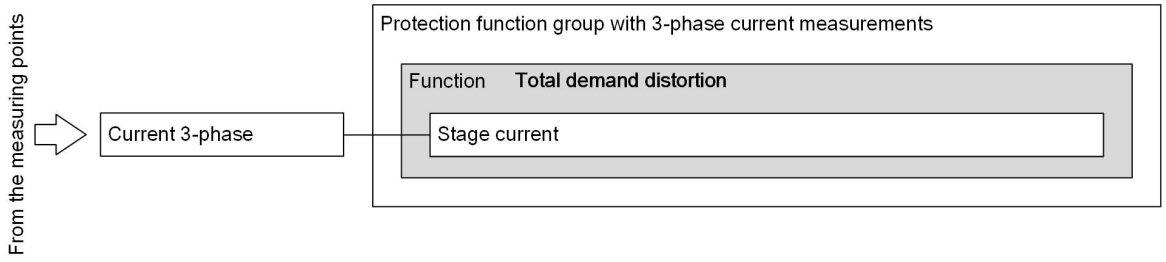
10.4 Total Demand Distortion

10.4.1 Overview of Functions

At the connection point to the public power system, the allowed total demand distortion (TDD) is limited according to the power-quality related standards. The function **Total demand distortion** can be used to monitor the TDD value.



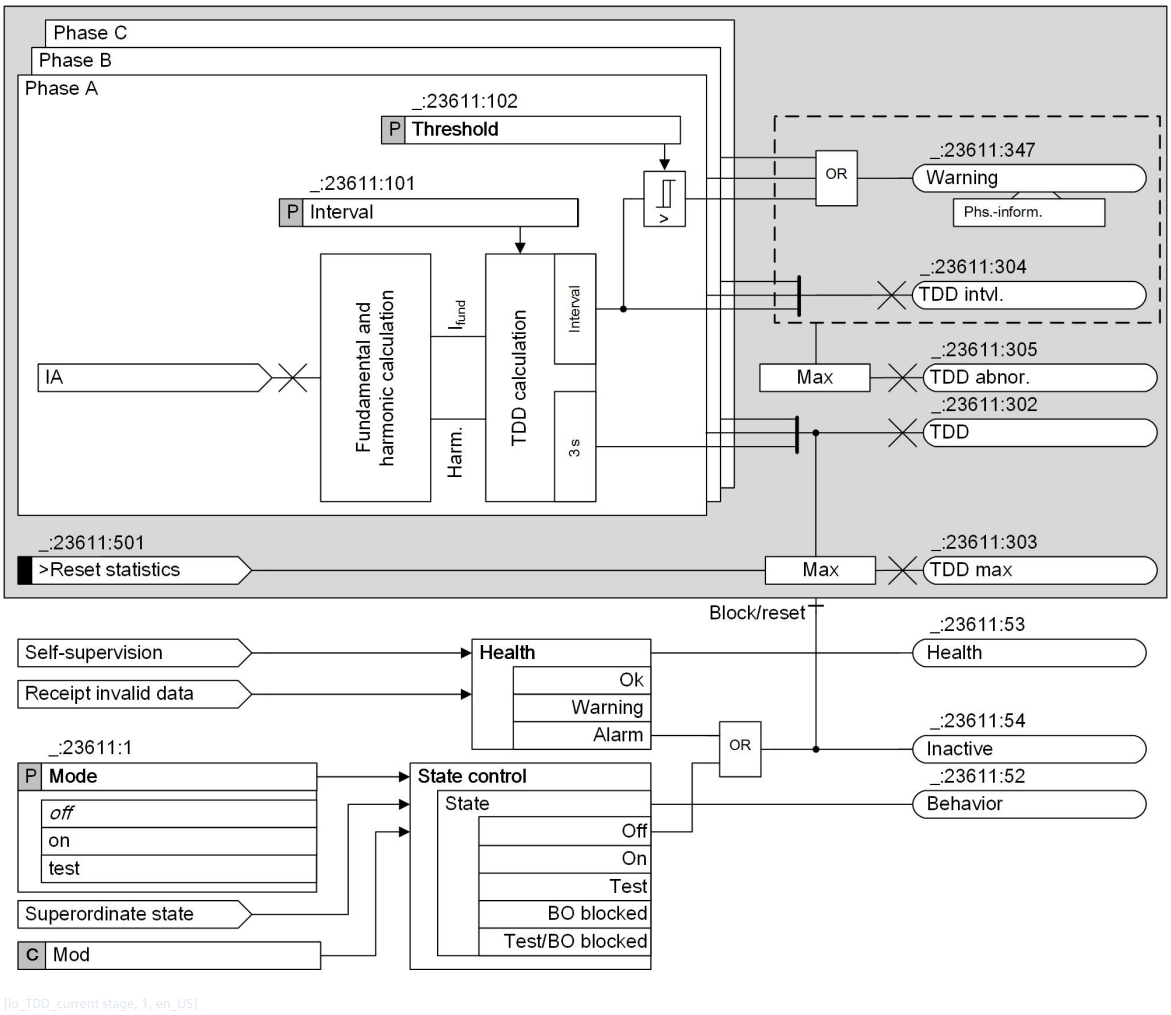
The function **Total demand distortion** serves for calculating the following values of the 3-phase currents:

- 3-s TDD value
- TDD value within an interval
  If the TDD value **`TDD intvl.`** exceeds the threshold value, a warning is generated.

The TDD values are displayed under **Power quality basic** > **TDD** of a specific function group in the HMI or via the DIGSI Online-Editor. If routed, the TDD values are available in the communication protocols and the fault records. Abnormal values can be logged in the operational log or user-defined logs.

10.4.2 Structure of the Function

The function **Total demand distortion** can be used in the protection function groups with 3-phase current measurements. When being used in such a function group, the function comes factory-set with 1 stage **Current**.



[dw_TDD_structure, 1, en_US]

Figure 10-17 Structure/Embedding of the Function

10.4.3 Stage Current

Logic of the Stage

[lo_TDD_current stage, 1, en_US]

Figure 10-18 Logic Diagram of the Stage Current

Calculation of TDD Values

Both the 3-s TDD value and the TDD value within an intervall are calculated as follows:

$$I_{TDD} = \frac{\sqrt{\sum_{k=2}^{N}[\text{mean}(I_k)]^2}}{I_{lmax}}$$

[fo_TDD_I, 1, en_US]

Where

N	20 The function supports the TDD calculation up to the 20th harmonic.
I_k	Harmonic value of order *k*
I_{lmax}	Maximum fundamental-component value of the demand load current over an interval
mean(I_k)	Arithmetic mean value of each order harmonic component over the whole interval

Functional Values

All functional values are given in percentage.

Table 10-14 Functional Values of the Stage Current

Value	Description
TDD:A TDD:B TDD:C	TDD values for phases A, B, and C over the 3-s intervals
TDD intvl.:A TDD intvl.:B TDD intvl.:C	TDD values for phases A, B, and C over the 15-min or 30-min interval
TDD max	Maximum TDD value in the period from the device startup or from the latest reset of this maximum value to the current time This value is the maximum value of the *TDD* which is calculated over the 3-s intervals.

Resetting the Statistical Values

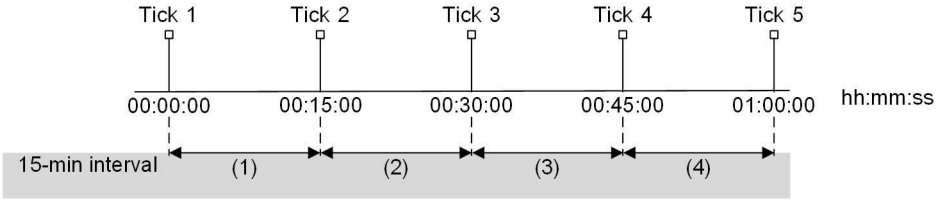
The statistical value *TDD max* can be reset with the following methods:

- Via the binary input signal *>Reset statistics*
- Via the **Reset** button for the maximum value of the statistic in the operation panel of the device
- Via communication protocols
- Via an online DIGSI connection to the device

Supervision of the TDD Value within an interval

The stage **Current** monitors the TDD value **TDD intvl.** within an interval and generates the phase-selective indication *Warning* if **TDD intvl.** exceeds the threshold.

When the indication *Warning* drops out, the maximum TDD value since the beginning of this indication which contains the maximum value of all phases, is entered as an abnormal value in the log (if the value is routed). You can route the abnormal value to the following logs:



- Operational log
- User-defined log 1
- User-defined log 2

Table 10-15 Abnormal Value

Value	Description
TDD abnor.:A TDD abnor.:B TDD abnor.:C	**TDD abnormal** Maximum TDD value **TDD intvl.** during the event as long as the indication *Warning* indication is active

Aggregation by the UTC 15-Min Tick

Based on the experience in THD values which are aggregated by the UTC 10-min tick according to the IEC 61000-4-30 standard, the parameter **Interval** in TDD is set to ***15 min*** by default. Each 15-min interval begins at a tick. The following figure shows the ticks and the 15-min intervals in an hour.

[dw_TDD_tick_interval, 1, en_US]

Figure 10-19 Ticks and 15-Min Intervals in an Hour

Influences Caused by the Change of the Device Time

If the device time is changed, the calculation of TDD values is influenced. There are 2 cases:

- After the change, the time is still in the time interval of the calculation.
  The calculation is not influenced and continues. The calculated value is refreshed at the end of the time interval.
- After the change, the time is out of the time interval of the calculation.
  The calculation is influenced and is terminated immediately. Meanwhile, the calculated value is refreshed and the calculation of the next time interval is started.

Operating Range

The frequency operating range of the stage **Current** is 0.8 to 1.2 of the rated frequency:

- If the power frequency is in this range, the TDD values are calculated.
- If the power frequency is out of this range, the TDD values are not calculated and are shown as `---`. Meanwhile, the function **Total demand distortion** becomes inactive.

If the fundamental-component value is smaller than 1 % of the rated current, TDD values and harmonics are set to `---`.

10.4.4 Application and Setting Notes

Parameter: _:23611:101 Interval

- Default setting **Interval** = ***15 min***

With the parameter **Interval**, you set the interval to 15 min or 30 min to determine the TDD condition.

Parameter: _:23611:102 Threshold

- Default setting **Threshold** = ***5.0 %***

With the parameter **Threshold**, you set the threshold for the TDD value. If the demand TDD values exceed the threshold value, the indication *Warning* is generated. Meanwhile, the maximum TDD value is taken as the abnormal value and is shown in the DIGSI 5 information lists.

Siemens recommends using the default setting.

10.4.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Stage				
_:23611:1	Stage:Mode		• off • on • test	off
_:23611:101	Stage:Interval		• 15 min • 30 min	15 min
_:23611:102	Stage:Threshold		1.0 % to 25.0 %	5.0 %

10.4.6 Information List

No.	Information	Data Class (Type)	Type
Stage			
_:23611:501	Stage:>Reset statistics	SPS	I
_:23611:51	Stage:Mode (controllable)	ENC	C
_:23611:54	Stage:Inactive	SPS	O
_:23611:52	Stage:Behavior	ENS	O
_:23611:53	Stage:Health	ENS	O
_:23611:347	Stage:Warning	ACT	O
_:23611:302	Stage:TDD	WYE	O
_:23611:303	Stage:TDD max	MV	O
_:23611:304	Stage:TDD intvl.	WYE	O
_:23611:305	Stage:TDD abnor.	WYE	O

11.22	Functional Test for the Phase-Rotation Reversal	2365
11.23	Primary and Secondary Testing of the Synchronization Function	2366

11.1 General Notes

Various tests have to be performed for commissioning to warrant the correct function of the device.

For tests using secondary test equipment, make sure that no other measurands are locked in and trip and close commands to the circuit breakers are interrupted, unless otherwise indicated.

Secondary tests can never replace primary tests because they cannot include connection faults. They can be used to check the setting values.

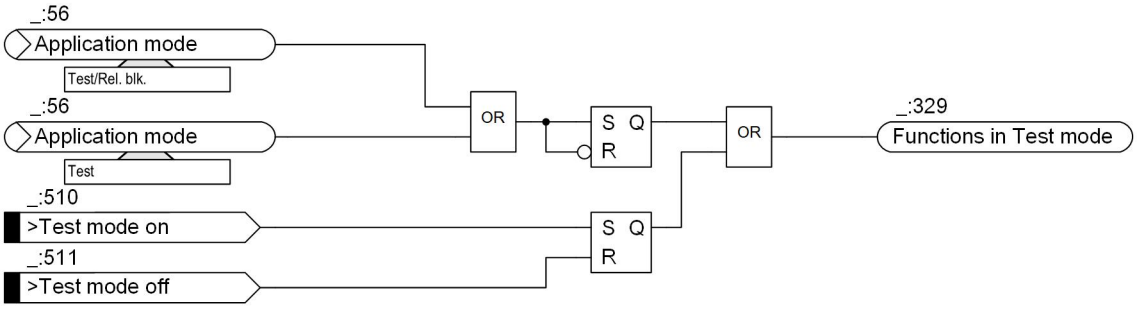
Primary tests may be done only by qualified personnel who are familiar with the commissioning of protection systems, with the operation of the system, and with safety regulations and provisions (switching, grounding, etc.).

Switching operations also have to be performed for the commissioning. The described tests require that these be capable of being performed safely. They were not conceived for operational checks.

11.2 Enabling/Disabling the Application/Test Mode for the Entire Device

Siemens recommends to enable the test mode for the entire device before you start testing protection functions.

You can enable or disable the test mode for the entire device as follows:

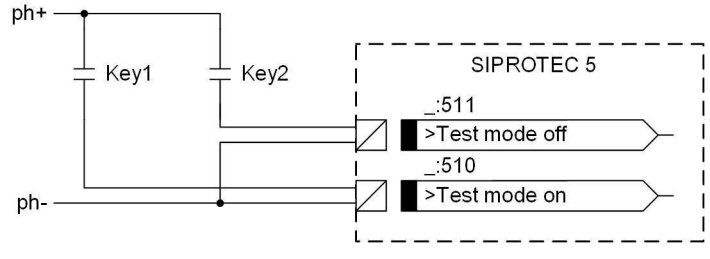


- Via the on-site operation panel under **Device functions > Operating states >** *Application mode* = ***Test*** or ***Test/Relay blk.***
- Via the binary inputs *(_:91:510) General:>Test mode on* and *(_:91:511) General:>Test mode off*

  You can find the binary inputs in the DIGSI information routing under **General**.
- Via communication (IEC 61850) with the controllable *(_:91:56) General:Application mode*

  You can find the controllable in the DIGSI information routing under **General**.

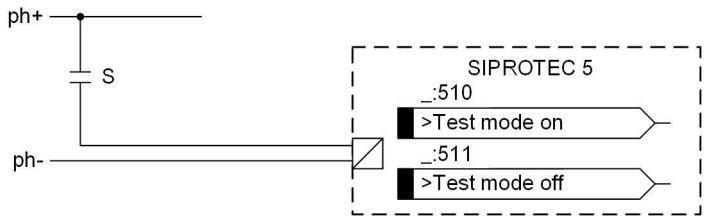
When the test mode for the entire device is enabled, the indication *(_:91:329) Functions in Test mode* is generated.



In the test mode of the device all device indications are marked with a test bit. This prevents the circuit breaker from switching unintentionally or protection functions from starting unintended actions. If you enable or disable the test mode for the entire device using the controllable *(_:91:56) General:Application mode*, the device stores the state of the controllable in a voltage-fail-safe memory.

[lo_application_mode_device, 1, en_US]

Figure 11-1 Logic Diagram: Enabling/Disabling the Test Mode for the Entire Device



The following figures show possible variants for enabling and disabling the test mode for the entire device using binary inputs. The following figure shows the use of push-buttons **Ta1** and **Ta2**:

[lo_application_mode_device_taster, 1, en_US]

The following figure shows the use of a switch **S**. Route the logical binary input *(_:91:510) General:>Test mode on* as **H** (high-active) and the logical binary input *(_:91:511) General:>Test mode off* as **L** (low-active) to a physical binary input.

[lo_application_mode_device_switch, 1, en_US]

Figure 11-3 External Wiring of Switches for Enabling/Disabling the Test Mode for the Entire Device

11.3 Checking System Integration

In addition to the protection setting and the correct routing of the signals, proper system integration is important. When checking the system integration, Siemens recommends the following procedure:

- ✧ The device must placed in the operating area at least 2 hours before you apply voltage for the first time. By allowing thermal equilibrium to be established, you avoid moisture and condensation on the device. Perform the connection checks on a completely installed device with the system switched off and grounded.

You will find connection examples of the current transformer circuits in the manual's appendix. Also observe the connector pin-outs (see Appendix *A.4 Standard Variant for 7UT82* , *A.5 Standard Variants for 7UT85*, *A.6 Standard Variants for 7UT86* and *A.7 Standard Variants for 7UT87*).

Proceed as follows in order to check the system connections:

DANGER

Hazardous voltages.

Noncompliance with the following measures can lead to death, serious physical injury or significant material damage.

- ✧ Only qualified individuals who are familiar with and follow the safety regulations and precautionary measures may perform checks.

CAUTION

Exercise caution when operating the device without a battery on a battery charging device.

Noncompliance with the following measure can cause impermissibly high voltages and, as a result, destruction of the device.

- ✧ Do not operate devices on a battery charging device without a battery connected (you will find limiting values in the Technical Data).

- ✧ Switch off the circuit breaker for the supply auxiliary voltage and the measuring voltage.

Measure all current and voltage transformer supply cables according to system and connection diagram:

- ✧ Check the connections of all sets of 3-phase current transformers to the device inputs. Are they connected correctly and do they match the configuration (measuring point assignment)?
- ✧ Check the connections of all sets of 1-phase current transformers to the device inputs. Are they connected correctly and do they match the configuration?
- ✧ Check whether the grounding of the current transformer is correct. Grounding in the direction of the protected object is preferred.
- ✧ Check whether the polarity of the current transformer connections is identical in each set of transformers.
- ✧ Check whether the phase allocation of all sets of 3-phase current transformers is correct.
- ✧ Check whether the polarity of all sets of 1-phase current transformers is correct (if used).
- ✧ Check whether the grounding of the voltage transformer is correct (if used).
- ✧ Check whether the polarity of the voltage transformer connections is identical and correct (if used).
- ✧ Check whether the phase allocation of the voltage transformer is correct (if used).
- ✧ If the test switch for the secondary test of the device is used, check its functions.

NOTE

Ensure that the current-transformer secondary lines are automatically short-circuited in the setting **Test**.

- ✧ Loop the ammeter into the supply line for auxiliary voltage and select a range from 2.5 A to 5 A.
- ✧ Switch on the circuit breaker for the supply auxiliary voltage.
- ✧ Check the voltage level and polarity on the device terminals or the connection modules.

The current consumption must correspond to the quiescent power consumption of the device. A short swing of the phasor is uncritical and displays the charging current inrush to the storage capacities.

- ✧ Switch off the circuit breaker for the supply auxiliary voltage.
- ✧ Remove the ammeter and restore the normal auxiliary voltage connection.
- ✧ Switch on the voltage-transformer circuit breaker (if used).
- ✧ Check the direction of the rotating field at the device terminals.
- ✧ Switch off the circuit breaker for the transformer voltage and supply auxiliary voltage.
- ✧ Check the trip lines to the circuit breakers.
- ✧ Check the control lines from and to other devices.
- ✧ Check the signaling wires.
- ✧ Switch on the circuit breaker for the transformer voltage and supply auxiliary voltage again.

11.4 Commissioning Notes Transformer Differential Protection

11.4.1 Secondary Tests

Secondary tests can never replace the primary tests described in the following *11.4.2 Primary Tests*, because they cannot include connection faults.
Secondary tests are used to check the following:

- Checking the setting values
- Proper response of the protection function
- Engineering (for example, routing the respective logic signals, display images with measured values, logics in CFC, and much more)

If you want to perform secondary tests, observe the following instructions.

NOTE

For tests with secondary test equipment, ensure that no other measurands are connected and the trip commands to the circuit breakers are open; otherwise, the circuit breaker could be activated.

Perform the tests with the current setting values for the device. If these values are not (yet) present, check with the default values.

NOTE

The measuring accuracy to be achieved depends on the electrical data of the used test sources. The accuracies stated in the Technical Data can be expected only if the reference conditions stipulated in VDE 0435/part 303 and IEC 60255 are ensured and precision instruments are used. The specified tolerances refer to the default data for the protected objects. If the rated current of the protected object in relation to the current transformer's rated current deviates considerably from the device's rated current, you must assume higher response tolerances.

For differential protection, you can check each side separately. This corresponds to the simulation of a fault supplied from one side. If a side has several measuring points, the measuring inputs not included in the test carry no current. The pickup value is tested by slowly increasing the test current.

NOTE

Tests of currents via quadruple device-rated current (or a maximum of 20 A) lead to an overload of the input circuits and may be performed only briefly. You can find more information in chapter *12.2 Transformer Differential Protection*. Interrupt testing to allow cool-down!

The set pickup values refer to symmetrical 3-phase current in the case of 3-phase protected objects.
If you are testing parameters set during operation, you must ensure that the setting value for the differential protection refers to the rated current of the protected object. The rated current is the primary current that results formally from:

$$I_{rated,obj} = \frac{S_{rated,obj}\,[MVA] \cdot 1000}{\sqrt{3} \cdot V_{rated,obj}\,[kV]}\,[A]$$

[fonennsl-170712-01.tif, 1, en_US]

$S_{rated,obj}$	Rated apparent power of the protected object
$V_{rated,obj}$	Rated voltage of the protected object or the winding being observed

For a winding with voltage control, the calculated voltage applies in accordance with *6.2.4 Application and Setting Notes*.

For transformers, the actual pickup values for 1-phase or 2-phase testing also depend on the vector group of the transformer. For 1-phase testing, the pickup values also depend on the treatment of the winding neutral point and the processing of the neutral point current.
To obtain the actual pickup value, multiply the setting value by a vector-group factor k_{SG} according to the following formula:

$$\frac{I_{\text{rated transf.}}}{I_{\text{rated transf. prim}}} k_{SG}$$

[foscgrfa-170712-01.tif, 1, en_US]

The following table shows this factor k_{SG} as a function of the vector group and the type of fault for 3-phase transformers.

Table 11-1 Correction Factor k_{SG} for the Vector Group (SG) and Fault Type

Fault Type	Reference Winding (High Voltage)	Even SG Number (0, 2, 4, 6, 8, 10)	Odd SG Number (1, 3, 5, 7, 9, 11)
3-phase	1	1	1
2-phase	1	1	$\sqrt{3}/2 \approx 0.866$
1-phase with I_0 elimination	3/2 = 1.5	3/2 = 1.5	$\sqrt{3} \approx 1.73$
1-phase without I_0 elimination	1	1	$3/(1+\sqrt{3}) \approx 1.1$

Example:

3-phase transformer	S_{rated} = 57 MVA
Vector group	Yd5
High voltage	V_{rated} = 110 kV
Current transformer	300 A/1 A
Undervoltage	V_{rated} = 25 kV
Current transformer	1500 A/1 A

The following applies to the upper-voltage winding:

$$I_{\text{rated transf.}} \frac{S_{\text{rated transf.}}\,[\text{MVA}] \cdot 1000}{\sqrt{3} \cdot V_{\text{rated winding}}\,[\text{kV}]}\,[\text{A}] = \frac{57\,[\text{MVA}] \cdot 1000}{\sqrt{3} \cdot 110\,[\text{kV}]}\,[\text{A}] = 299\ \text{A}$$

[foobersp-170712-01.tif, 1, en_US]

Here the rated current of the winding = rated current of current transformer. Thus, for a 3-phase or 2-phase test, the pickup value corresponds to the setting value **`threshold value`** of the device (k_{SG} = 1 for reference winding) with reference to the device rated current. For the threshold value the designation IDIFF> is used.
For a 1-phase test with residual current elimination, 1.5 times the value is to be expected as a pickup value.
The following applies to undervoltage:

$$I_{\text{rated transf.}} \frac{S_{\text{rated transf.}}\,[\text{MVA}] \cdot 1000}{\sqrt{3} \cdot V_{\text{rated winding}}\,[\text{kV}]}\,[\text{A}] = \frac{57\,[\text{MVA}] \cdot 1000}{\sqrt{3} \cdot 25\,[\text{kV}]}\,[\text{A}] = 1316\ \text{A}$$

[fountrsp-170712-01.tif, 1, en_US]

For the secondary test of this winding, the theoretical pickup value refers to device's rated value.

$$\frac{I_{\text{pickup}}}{I_{\text{rated device}}} = \frac{I_{\text{rated transf.}}}{I_{\text{rated transf., prim}}} \cdot k_{VG} \cdot \text{IDiff} >= \frac{1316\ \text{A}}{1500\ \text{A}} \cdot k_{VG} \cdot \text{IDiff} >= 0.877 \cdot k_{VG} \cdot \text{IDiff} >$$

[fothanwt-041016-01, 1, en_US]

Due to the odd vector-group numbers, the following pickup values apply (see *Table 11-1*):

3-phase $k_{SG} = 1$

$$\frac{I_{pickup}}{I_{rated\ device}} = 0.877 \cdot IDIFF>$$

[fo3phasw-170712-01.tif, 1, en_US]

2-phase $k_{SG} = \sqrt{3}/2$

$$\frac{I_{pickup}}{I_{rated\ device}} = 0.760 \cdot IDIFF>$$

[fo2phasw-170712-01.tif, 1, en_US]

1-phase $k_{SG} = \sqrt{3}$

$$\frac{I_{pickup}}{I_{rated\ device}} = 1.52 \cdot IDIFF>$$

[fo1phasw-170712-01.tif, 1, en_US]

11.4.2 Primary Tests

If secondary test equipment is connected to the device, remove it and switch the test switch to the operating position.

NOTE

Be aware that a trip results in case of incorrect connections.

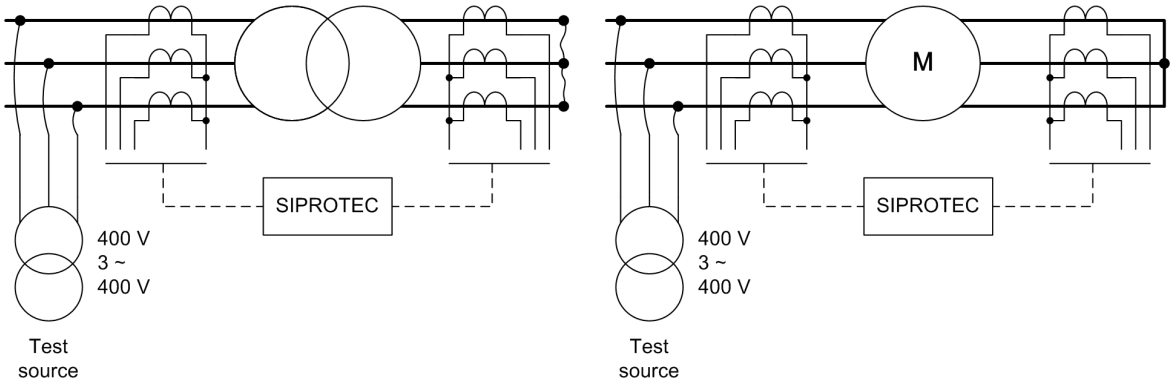
Preparation of Current Tests

So that the differential protection is effective as short-circuit protection for the first excitation of the protected object under a voltage load, perform the current tests in the case of initial commissioning before switching on the voltage for the first time. If the current tests are possible only when the protected object is switched on, for example, with network transformers when no test source for low voltage is available, then commission an external backup protection on the supply side first, for example, overcurrent protection. This backup protection works on the supply circuit breaker. The trip circuits of other protection equipment, for example, Buchholz protection, must also remain active

Repeat the current tests in the case of protected objects with more than 2 measuring points. All sides of the protected object must be included at least once in the current flow test. You do not have to check every possible current path. Siemens recommends beginning with measuring point 1 of the main protected object and testing it against each of the others. When a side has more than measuring point, you must include each at least once in the test. The remaining measuring points carry no current.

If other 3-phase protected objects are present, these are checked separately in accordance with their topology.

The test setup varies, depending on the use case.

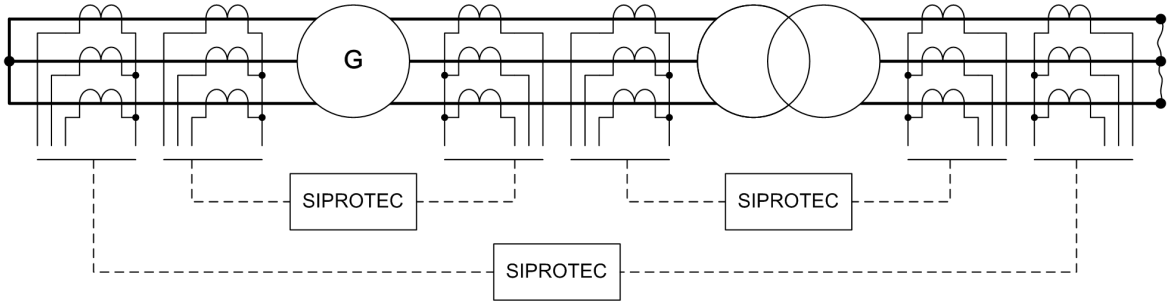


DANGER

Dead components hazardous due to capacitive coupling of other system parts!

Failure to comply with the safety notes, can result in death, severe injury, or considerable material damage.

✧ Primary tests may be performed only on dead and grounded system parts!



✧ Preferably, perform an undervoltage test on network transformers and asynchronous machines in which the protected object insulated from the line is supplied with current by a test source for low voltage. This symmetrical test source produces the test current via a loadable 2-pole cross connector externally incorporated to the protection range or via the motor neutral point. The test current source is connected in transformers on the upper-voltage side, the 2-pole cross connector on the low-voltage side.

[dwprfnsq-120202-01.tif, 1, en_US]

Figure 11-4 Test Setup With Low-Voltage Source – Example of Transformer and Motor

✧ For generator transformers and synchronous machines, perform the tests for short-circuits, with the machine itself serving as test current source. The test current is produced briefly by means of a loadable 2-pole cross connector incorporated externally to the protection range, with generator's rated current.

[dwprfgen-120202-01.tif, 1, en_US]

Figure 11-5 Test Setup in Power System with Generator as Voltage Source – Example

Performance of Current Tests

✧ Before you begin with the first current test, check the polarity setting for the measuring points and compare them to the actual current connections.

For the commissioning tests, a flowing current of at least 2 % of the device's rated current per phase is necessary.

NOTE

These tests cannot replace a visual check of the correct current transformer connections. Completed checks of the system connections are therefore a prerequisite.

The SIPROTEC 5 device makes operational measured values available. With these operational measured values, quick commissioning without external instrumentation is possible.

The following procedure is intended for 3-phase protected objects, namely, for measuring point 1 against measuring point 2. For transformers, it is assumed that side 1 is the upper-voltage side of the transformer. The remaining possible current circuits are tested analogously.

- ✧ Switch the test current on, or bring the generator to rated speed and excite it to test current. Acquisition of measured values in the SIPROTEC 5 device must not cause pick up. If a failure indication is present, you can see in the logs what causes come into question.

  – In the case of indications from balance supervisions, the primary system may actually be unbalanced. If this is a normal operating condition, then set the corresponding supervision function to be less sensitive.

  – The rotating field is clockwise (phase sequence: A, B, C). If the line has a phase sequence A, C, B, you must account for this when setting the power-system data. Incorrect direction of rotation is indicated. Check the phase assignment of the measurands and correct the affected measuring point after switching off. Then repeat the measurement.

Amount Measurement with Test Current Switched On:

Compare the currents displayed by the device under **Operational measured values** with those actually flowing.

This applies to all measuring points that belong to the tested current path. If deviations result which cannot be explained through measuring tolerances, there is a connection fault or an error in the test setup:

- ✧ Switch off the test source and the protected object. Ground the protected object or shut down the generator.
- ✧ Check the assignment of the measuring point currently being tested.
- ✧ Check the parameters for the compensation.
- ✧ Check and correct the connections and test setup.

  If a considerable ground current 3I0 occurs, the polarity of individual phases has been reversed at the corresponding measuring point:

  3I0 ≈ phase current → 1 or 2 phase currents are missing;

  3I0 ≈ double phase current → 1 or 2 phase currents are reversed;
- ✧ Repeat the measurement and check the amounts again.

Angle Measurement for Measuring Point 1 with Test Current Switched On

- ✧ Check the angles displayed by the device for measuring point 1 under **Measured values**. All angles refer to I_A.

  The following results must appear:

  $\varphi_A \approx 0°$

  $\varphi_B \approx 240°$

  $\varphi_C \approx 120°$

  If the angles are not correct, polarity faults are present in the connection of individual phase currents at the measuring point.
- ✧ Switch off the test source and the protected object. Ground the protected object or shut down the generator.
- ✧ Check and correct the connections and test setup.
- ✧ Repeat the measurement and check the angle.

Angle Measurement for Measuring Point 2 with Test Current Switched On

✧ Check the angles displayed by the device for measuring point 2 under **Measured values**. All angles refer to I_A.

Ensure that the currents into the protected object are always defined as positive. If the test current flows through, currents of the same phase at measuring point 2 are shifted by 180° with respect to measuring point 1.

The following results must appear:

$\varphi_A \approx 180°$

$\varphi_B \approx 60°$

$\varphi_C \approx 300°$

Measured via a transformer, depending on the vector group, approximately the results according to the following table.

If the angles are not correct, polarity faults are present in the connection of individual phase currents at the measuring point.

Table 11-2 Angle Display Depending on Protected Object (3-Phase)

Phase Angle	Protected Object											
	Generator/Motor/ short line	Transformer with vector-group numbers[68]										
		0	1	2	3	4	5	6	7	8	9	10	11
φ_{AM2}	180°	180°	150°	120°	90°	60°	30°	0°	330°	300°	270°	240°	210°
φ_{BM2}	60°	60°	30°	0°	330°	300°	270°	240°	210°	180°	150°	120°	90°
φ_{CM2}	300°	300°	270°	240°	210°	180°	150°	120°	90°	60°	30°	0°	330°

If the angles are not correct, there are polarity faults or a phase inversion in the connection of measuring point 2 or the other side to be tested at the tested measuring point.

- If deviations are present in individual phases, a polarity fault is present in the connection of these phase currents or an acyclic phase inversion is present.
- If all angles deviate by the same amount, there is a cyclic inversion of all 3 phases or an incorrect vector group in transformers. In the last case, check the vector-group adaptation. Also pay attention to the assignment of the measuring points to the sides and the assignment of the sides to the protected object.
- If all angles differ by 180°, the polarity of a set of current transformers for the second measuring point is not correct. You can fix this by testing and correcting the corresponding parameters of the substation configuration.

If you presume a connection fault:

✧ Switch off the test source and the protected object. Ground the protected object or shut down the generator.

✧ Check and correct the connections and test setup.

✧ Check the settings for the corresponding current transformer data.

✧ Repeat the measurement and check the angle.

Repeat all tests previously described until all measuring points for the main protected object are included in a test at least once.

Measuring Differential and Restraint Currents

To complete the symmetrical tests, check the differential and restraint current measurands. If the previous symmetrical measurements also reveal the connection fault, errors in the adaptation and in the vector-group assignment cannot be excluded.

[68] If the upper-voltage side is defined as side 1, the angles are valid. Otherwise, 360° minus the stated angle is valid.

The differential and restraint currents refer to the rated current of the protected object. Observe this when comparing the test currents. For more than 2 sides, the rated current of the protected object equals the highest rated current of all sides of the protected object.

✧ Read out the differential and restraint currents under **Measured values**.

– The differential currents **IDiffA:**, **IDiffB:**, **IDiffC:** must be low, at least one order of magnitude less than the test currents flowing through. Ideally, they are 0.

– The restraint currents **IStabA:**, **IStabB:**, **IStabC:** correspond to the test current flowing through.

– If differential currents occur on the order of magnitude of the restraint currents, there is a polarity reversal in the current transformer or current transformers on one side. Again check the polarity and correct it after short-circuiting all 6 current transformers. If you have made changes to current transformers, repeat the angle test.

– If substantial differential currents occur that are approximately the same in all phases, a faulty adaptation of the measurands is present. Faults in the vector-group adaptation in transformers are already discovered in the winding test. Check the settings of the device relevant for current adaptation. These are the data of the protected object:

✧ Finally, switch off the test source and the protected object or shut down the generator.

✧ If parameter settings have been changed for the tests, reset them to the values necessary for operation.

NOTE

Ensure that you perform the intended tests for each current path.

Zero-Sequence Current Test on the Protected Object

If the neutral point of a winding or side is grounded in the case of 3-phase protected objects, the following zero-sequence current tests are required. If several neutral points are grounded, you must perform the zero-sequence current tests for each of the grounded windings.

✧ If the neutral-point current is available and is conducted to the device via a 1-phase current input, the polarity of the ground current connection is essential for taking the neutral point current into account. This applies to the differential and restricted ground-fault protection.

✧ If no neutral point current is available, the zero-sequence current tests serve to verify the correct treatment of the zero-sequence currents in the differential protection.

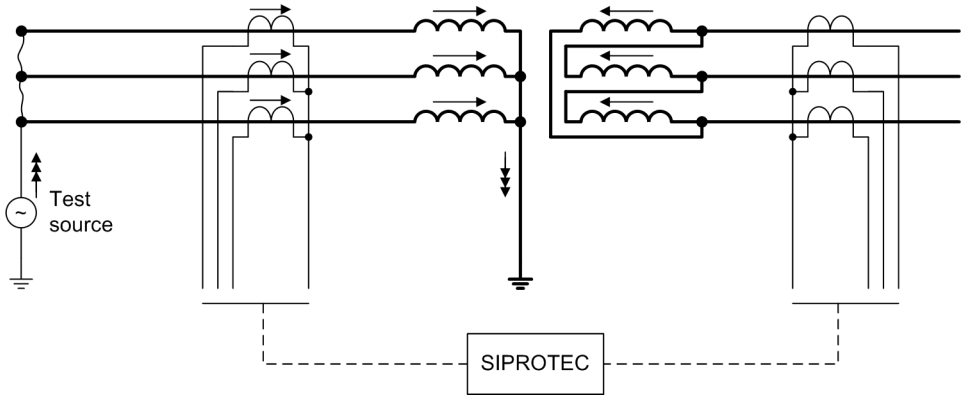
NOTE

Be aware that a trip results in case of incorrect connections.

Preparation of the Zero-Sequence Current Tests

✧ Perform the zero-sequence current measurements from the side or 3-phase measuring point for which the neutral point is grounded. For auto transformers, perform the measurement from the upper-voltage side. For transformers, a delta winding must be present (d-winding or stabilizing winding). The windings not included in the test remain open, since the delta winding creates the impedance of the zero-sequence current path by itself.

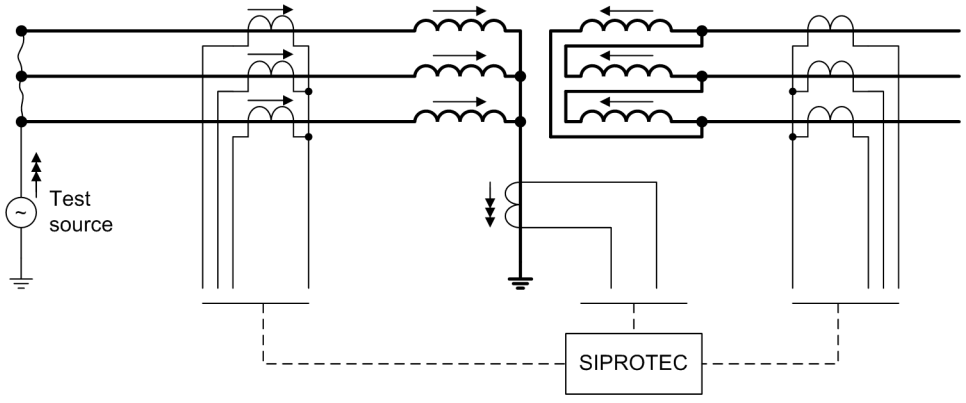
The test setup varies, depending on the use case. *Figure 11-6* to *Figure 11-12* schematically show an example of the test setup on a grounded star-delta transformer. The neutral-point current is included in the measurement. If the neutral point is not accessible, it is left out (compare *Figure 11-6* with *Figure 11-7*).



DANGER

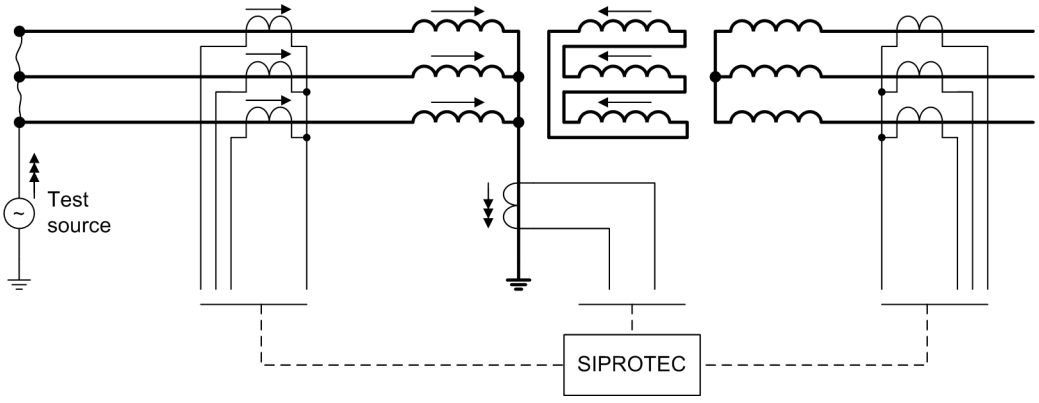
Dead components hazardous due to capacitive coupling of other system parts!

Failure to comply with the safety notes, can result in death, severe injury or considerable material damage.



✧ Primary tests may be performed only on dead and grounded system parts!

✧ Observe the following examples for measuring zero-sequence current.



[dwnsmsdt-120202-01.tif, 1, en_US]

Figure 11-12 Zero-Sequence Current Measurement on a Grounded Longitudinal Reactance (Reactor, Generator, Motor)

Performance of Zero-Sequence Current Tests

For the commissioning tests, a zero-sequence current at a level of at least 2 % of the device's rated current per phase is required, for example, the test current must be at least 6 %.

NOTE

The following tests cannot replace a visual check of the correct current transformer connections. The completed checks are a prerequisite.

- ✧ Switch on the test current.
- ✧ Perform the amount measurement with the test current switched on.
- ✧ Compare the currents displayed by the device under **Measured values** with those actually flowing:
- All phase currents of the tested measuring point correspond to approx. 1/3 of the test current.
- 3I0 of the tested measuring point corresponds to the test current.

- Phase currents and zero-sequence current on the untested measuring point are approx. 0 on transformers.
- The current of the 1-phase current input – to the extent included in the measurement – corresponds to the test current.

Deviations can only occur with the 1-phase measuring input (if measured), since connection faults in the phase currents were already recognized in the symmetric test.

In the case of deviations:

✧ Switch off the test source and the protected object. Ground the protected object or shut down the generator.

✧ Check the assignment of the additional measuring input currently being tested.

✧ Check the parameters for the compensation.

✧ Check and correct the connections and test setup.

✧ Repeat the measurement and check the amounts again.

Check Differential Protection

The tests described in the following encompass the current differential protection, not the restricted ground-fault protection. The tests represented in the previous figures must have the following results. Ensure that the test current corresponds to 3I0.

✧ Zero-sequence current elimination

In the function group **Transformer side**, the neutral point is set as (parameter: **`Neutral point`** = ***grounded***) grounded, and in the function group **Transformer**, there is the parameter **`Meas. gnd. current side 1`** = ***no***. The matrices are shown below.

$$\begin{pmatrix} I_{Diff,C} \\ I_{Diff,B} \\ I_{Diff,A} \end{pmatrix} = \left| \begin{pmatrix} I_{A,S1} \\ I_{B,S1} \\ I_{C,S1} \end{pmatrix} + \begin{pmatrix} I_{A,S2} \\ I_{B,S2} \\ I_{C,S2} \end{pmatrix} \right| = \left| \frac{1}{3} \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \right| = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

[fomatnse-170712-01.tif, 1, en_US]

$$\begin{pmatrix} I_{rest,A} \\ I_{rest,B} \\ I_{rest,C} \end{pmatrix} = \left| \begin{pmatrix} I_{A,max} \\ I_{B,max} \\ I_{C,max} \end{pmatrix} \right| = \left| \frac{1}{3} \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} \right| = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

[fomznel2-170712-01.tif, 1, en_US]

✧ Zero-sequence current correction

In the function group **Transformer side**, the neutral point is set as (parameter: **`Neutral point`** = ***grounded***) grounded, and in the function group **Transformer**, there is the parameter **`Meas. gnd. current side 1`** = ***yes***. The differential and restraint currents measured result from the one-sided test to 0. In the following, the matrices are represented. $\underline{I}_E$ is the measured zero-sequence current through the current transformer in the neutral point:

$$\begin{pmatrix} I_{Diff,A} \\ I_{Diff,B} \\ I_{Diff,C} \end{pmatrix} = \left| \begin{pmatrix} I_{A,S1} \\ I_{B,S1} \\ I_{C,S1} \end{pmatrix} + \begin{pmatrix} I_{A,S2} \\ I_{B,S2} \\ I_{C,S2} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} I_{Gnd} \\ I_{Gnd} \\ I_{Gnd} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} -3I_0 \\ -3I_0 \\ -3I_0 \end{pmatrix} \right| = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

[fomansko-170712-01.tif, 1, en_US]

$$\begin{pmatrix} I_{rest,A} \\ I_{rest,B} \\ I_{rest,C} \end{pmatrix} = \left| \begin{pmatrix} I_{A,max} \\ I_{B,max} \\ I_{C,max} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} I_{Gnd} \\ I_{Gnd} \\ I_{Gnd} \end{pmatrix} \right| = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

[fomansk2-170712-01.tif, 1, en_US]

If there is a polarity reversal on the current transformer at the neutral point, a value that corresponds to 2/3 of the test current (3I0) results for the differential and restraint current per phase. The following matrices illustrate the situation.

$$\begin{pmatrix} I_{Diff,A} \\ I_{Diff,B} \\ I_{Diff,C} \end{pmatrix} = \left| \begin{pmatrix} I_{A,S1} \\ I_{B,S1} \\ I_{C,S1} \end{pmatrix} + \begin{pmatrix} I_{A,S2} \\ I_{B,S2} \\ I_{C,S2} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} I_{Gnd} \\ I_{Gnd} \\ I_{Gnd} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} 3I_0 \\ 3I_0 \\ 3I_0 \end{pmatrix} \right| = 2 \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix}$$

[fomzvrpo-061112-01.tif, 1, en_US]

$$\begin{pmatrix} I_{rest,A} \\ I_{rest,B} \\ I_{rest,C} \end{pmatrix} = \left| \begin{pmatrix} I_{A,max} \\ I_{B,max} \\ I_{C,max} \end{pmatrix} \right| = \left| \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix} + \frac{1}{3} \begin{pmatrix} I_{Gnd} \\ I_{Gnd} \\ I_{Gnd} \end{pmatrix} \right| = 2 \begin{pmatrix} I_0 \\ I_0 \\ I_0 \end{pmatrix}$$

[fomzvrp2-061112-01.tif, 1, en_US]

11.5 Generator Differential Protection

11.5.1 Secondary Tests

Secondary tests can never replace the primary tests described in the following *11.5.2 Primary Tests*, because they cannot include connection faults. They are used to check the setting values, the proper reaction of the protection function, the engineering (for example, routing of the corresponding logical signals, display images with measured values, logics in the CFC, etc.) If you want to perform secondary tests, observe the following instructions.

NOTE

For tests with secondary test equipment, make sure that no other measurands are connected and the trip commands to the circuit breakers are interrupted; otherwise, the circuit breaker could be activated.

Perform the tests with the current setting values for the device. If these values are not (yet) available, check with the default values.

NOTE

The measuring accuracy to be achieved depends on the electrical data of the used test sources. The accuracies stated in the Technical Data can be expected only if the reference conditions stipulated in VDE 0435/part 303 and in IEC 60255 are ensured and if precision instruments are used. The specified tolerances refer to the default data for the protected objects. If the protected-object rated current that refers to the rated current of the current transformer deviates considerably from the device rated current, you must expect higher response tolerances.

For differential protection, you can check each side separately. This corresponds to the simulation of a fault supplied from one side. If a side has several measuring points, the measuring inputs not included in the test carry no current. The pickup value is tested by slowly increasing the test current.

NOTE

Tests of currents greater than 4 times the device-rated current (or a maximum of 20 A) lead to an overload of the input circuits and may be performed only briefly. You can find further information in the Technical Data. Interrupt testing to allow cool-down!

The set pickup values refer to the symmetrical 3-phase current in the case of 3-phase protected objects.

If you are testing parameters set during operation, you must note that the setting value for the differential protection refers to the rated current of the protected object. The rated current is the primary current that results formally from:

$$I_{rated,obj} = \frac{S_{rated,obj}\,[MVA] \cdot 1000}{\sqrt{3} \cdot V_{rated,obj}\,[kV]}\,[A]$$

[fonennsl-170712-01.tif, 1, en_US]

$S_{rated,Obj}$	Rated apparent power of the protected object
$V_{rated,Obj}$	Rated voltage of the protected object or the winding being observed

If you wish to check the characteristic curve, Siemens recommends using the standard testing programs of digital test equipment. For the manual checking of points on the characteristic curve, feed in a current **flowing through** which corresponds to a current value on the stabilization axis. Then change the phase angle of the test current on one side until the necessary differential current is reached. Check a value above and below the point on the characteristic curve which is to be tested with a tolerance of 5 %.

11.5.2 Primary Tests

Restricted primary testing is possible for generator protection applications. A wiring fault in the connection to the system could be a possible cause of the fault. With the system at a standstill, you can apply a test current of approx. 10 % to 20 % of the rated current directly to the current-transformer terminals and to the connected current transformer by means of a primary testing equipment. Simulate a load (current flowing through). The differential current must be 0 and the restraint current is the current which is fed in.

To prevent overfunction on initial switch-on, for example due to the incorrect installation of a transformer, Siemens recommends switching the differential protection to test mode. The protection function operates, but does not issue a trip command. Check the differential and the restraint current with the protection measured values in the fault log. The differential current must be 0 and the restraint current must correspond to the actually flowing generator current.

If the differential protection is functioning correctly, switch the protection function **ON**.

NOTE

If the differential protection is disabled (for example, function in test mode), an overcurrent protection must be active as short-circuit protection (without delay and set via the starting current).

11.6 Commissioning Notes Motor Differential Protection

11.6.1 Secondary Tests

Secondary tests can never replace the primary tests described in the following *11.6.2 Primary Tests*, because they cannot include connection faults. They are used to control the setting values, the proper reaction of the protection function, engineering (for example, routing of the appropriate logical signals, display images with measured values, logics in the CFC, etc.). If you want to perform secondary tests, observe the following instructions.

NOTE

For tests with secondary test equipment, ensure that no other measurands are connected and the trip commands to the circuit breakers are open, otherwise the circuit breakers could be activated.

Perform the tests with the current setting values for the device. If these values are not (yet) present, check with the default values.

NOTE

The measuring accuracy to be attained depends on the electrical data of the test sources. The accuracies stated in the Technical Data can be expected only if the reference conditions stipulated in VDE 0435/ part 303 and IEC 60255 are ensured and precision instruments are used. The stated tolerances refer to the default data for the protected objects. If the rated current of the protected object in relation to the rated current of the current transformer deviates considerably from the rated current of the device, you must assume higher response tolerances.

For differential protection, you can check each side separately. This corresponds to the simulation of a fault supplied from one side. If a side has several measuring points, the measuring inputs not included in the test carry no current. The pickup value is tested by increasing the test current slowly.

NOTE

Tests of currents exceeding quadruple device rated current (or a maximum of 20 A) lead to an overload of the input circuits and may be performed only briefly. You can find further information in the Technical Data. Interrupt testing to allow cool-down!

The set pickup values refer to symmetrical 3-phase current in the case of 3-phase protected objects.

If you are testing parameters set during operation, you must ensure that the setting value for the differential protection refers to the rated current of the protected object. The rated current is the primary current that results formally from:

$$I_{rated,obj} = \frac{S_{rated,obj}\,[MVA] \cdot 1000}{\sqrt{3} \cdot V_{rated,obj}\,[kV]}\,[A]$$

[fonennsl-170712-01.tif, 1, en_US]

$S_{rated,obj.}$	Rated apparent power of the protected object
$V_{rated,obj}$	Rated voltage of the protected object or the winding being observed

If you wish to check the characteristic curve, Siemens recommends the use of the standard testing programs of digital test equipment. For the manual checking of points on the characteristic curve, feed in a **through** current which corresponds to a current value on the stabilization axis. Then change the phase angle of the test current on one side, so that the necessary differential current is achieved. Check a value with a tolerance of 5 % above and below the point on the characteristic curve which is to be tested.

11.6.2 Primary Tests

Restricted primary testing is possible for motor protection applications. A wiring fault in the connection to the system could be a possible cause of the fault. With the system at a standstill, you can apply a test current of approx. 10 % to 20 % of the rated current directly to the transformer terminals and connected transformer by means of a primary testing device. Simulate a load (through current). The differential current must be zero and the restraint current is the current which is fed in.

To rule out overfunction on initial switch-on, for example, due to the incorrect installation of a transformer, Siemens recommends switching the differential protection to test mode. The protection function operates, but does not issue a trip command. With the protection measured values in the fault log, check the differential and the restraint current. The differential current must be 0 and the restraint current must correspond to the actual motor current.

If the differential protection is functioning correctly, switch the protection function **ON**.

NOTE

If the differential protection is disabled (for example, function in test mode), an overcurrent protection must be active as short-circuit protection (without delay and set via the starting current).

11.7 Functional Test Line Differential Protection

11.7.1 Test Options and Test Modes

The function **Line differential protection** also requires the measurands from remote devices and thus differs from most protection functions that only use local measurands.

The following test options are possible for testing the function **Line differential protection**:

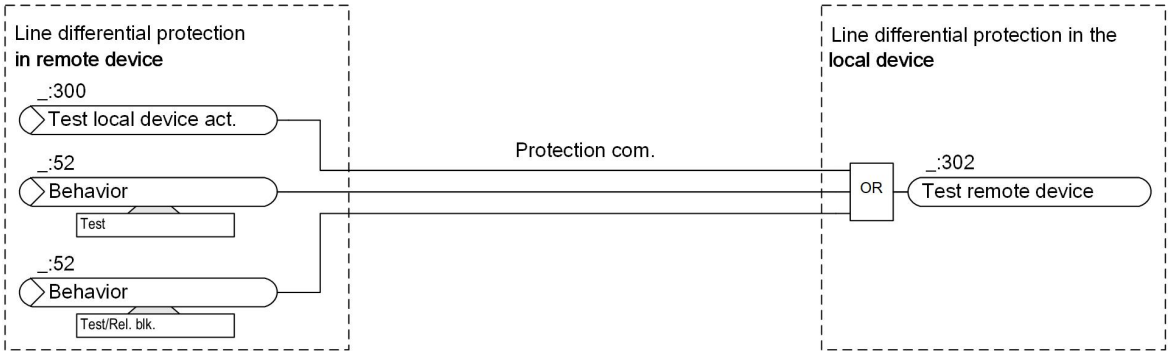
- Test with all line ends and with applied test currents, see *11.7.2 Functional Test in All Devices*
- Only test of the local line end with applied test currents, see *11.7.3 Functional Test in the Local Device*
- Inspection of the current operating point with all line ends with applied process variables, see *11.7.4 Checking the Operating Point*

SIPROTEC 5 supports the testing of functions using various test modes. The following test options are available for performing the 3 aforementioned test options:

- The device provides the test mode for the entire device, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device* and *3.11.2.1 Overview*.
- The function **Line differential protection** provides the special *Test local device* test mode.
- The function **Line differential protection** provides the special *Check op. point* test mode. This test mode replaces the previous *Test all devices*, see *Table 11-3*.

The following chapters describe the test procedure and the use of the different test modes.

If you switch the entire device or a protection function to test mode, all device protection functions or the protection function adopt the ***Test*** state. All indications are marked with a test bit. This prevents the circuit breaker from switching unintentionally or protection functions from starting unintended actions.



With the parameter **(_:151) Oper.bin.outp. under test**, you define whether the functions in ***Test*** state can activate relay outputs. If the parameter **(_:151) Oper.bin.outp. under test** and the test mode are activated for the entire device, all functions – including the relay outputs – are in ***Test*** state. If the parameter **(_:151) Oper.bin.outp. under test** is not active and the test mode is activated for the entire device, all functions – except the relay outputs – are in ***Test*** state. The relay outputs adopt the **Test/Relay blk.** state.

You can set the parameter **(_:151) Oper.bin.outp. under test** as follows:

- Via the operating dialog in DIGSI **> Settings > Device settings > Test support**:
  Place a check mark on parameter **(_:151) Oper.bin.outp. under test**.
- Via the on-site operation panel under **Settings > General > Test support > (_:151) Oper.bin.outp. under test**

For further information, refer to *Parameter: Oper.bin.outp. under test , Page 265*.

Depending on the selected procedure, the device supports testing of the function with different indications. If the function **Line differential protection** of a remote device is in ***Test*** or ***Test/Relay blk.*** state, or if the indication *(_:2311:300) Test local device act.* has been generated in a remote device, the local device generates the indication *(_:2311:302) Test remote device*.

[lo_generate-remote-device-test-message, 1, en_US]

Figure 11-13 Logic Diagram for Creation of the Indication *Test remote device*

If you use the function group **Advanced protection communication type 1 (line diff. protection)**, you will receive further helpful indications. The following indications are available in the information routing under **Prot. com (type 1).device comb.device n**:

- *(_:22711:328) Line diff. test*
  The indication shows for each device whether the function **Line differential protection** is in ***Test*** or in ***Test/Relay blk.*** state.
- *(_:22711:329) Local line diff. test*
  This indication shows for each device whether the function **Line differential protection** is in special *Test local device* test mode.

With version V9.40 and higher, the texts for the following binary inputs, controllables, and indications are changed as follows:

Table 11-3 Text Changes with Version V9.40 and Higher

Address	Text up to Version V9.3x	Text for Version V9.40 and Higher
_:2311:501	*>Test all devices on*	*>Check op. point on*
_:2311:502	*>Test all devices off*	*>Check op. point off*
_:2311:308	*Test all devices*	*Check op. point*
_:2311:301	*Test all devices activ*	*Check op. point active*
_:2311:304	*BI: Test all devices*	*BI: Check op. point*
_:2311:305	*Ctrl: Test all devices*	*Ctrl: Check op. point*

11.7.2 Functional Test in All Devices

11.7.2.1 General Information

For this test, the parameter **(_:2311:108) Action on Behavior = test** = ***Test loc. device man.*** must be set in each device of the device combination, see *Parameter: Action on Behavior = test, Page 732*.

If you want to test the function **Line differential protection** with all line ends, you must switch all devices of the device combination into test mode. See *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

If the test mode for the entire device is enabled in all devices of the device combination, the function **Line differential protection** to be tested is ***active*** again and is ready for the test.

These tests require action steps on all devices.

The indication *(_:2311:302) Test remote device* shows that the function **Line differential protection** in a remote device is already in ***Test*** or ***Test/Relay blk.*** state.

11.7.2.2 Procedure

Test Preparation and Implementation

Initial state:

- **I** and optionally **V** of the system are connected to the current and voltage inputs of the protection device.
- The function **Line differential protection** is ***active*** in all devices.

Proceed as follows:

✧ Switch on the test mode of the entire device in one device of the device combination, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.
→ The function **Line differential protection** is ***Inactive*** in all devices.

✧ Switch on the test mode of the entire device in all other devices of the device combination.
→ The function **Line differential protection** is ***active*** and in ***Test*** state in all devices.

✧ Disconnect the system transformers from the current and voltage inputs of the protection device and short-circuit the system current transformer.

✧ Start your tests and apply test currents and test voltages.

Procedure after Completion of the Tests

Initial state:

- The function **Line differential protection** is ***active*** and in ***Test*** state in all devices.

Proceed as follows:

✧ Complete your tests and remove the test currents and test voltages.

✧ Connect **I** and optionally **V** of the system to the current and voltage inputs of the protection device.

✧ Switch off the test mode of the entire device in one device of the device combination, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.
→ The function **Line differential protection** is ***Inactive*** in all devices.

✧ Switch off the test mode of the entire device in all other devices of the device combination.
→ The function **Line differential protection** is ***active*** in all devices.

11.7.3 Functional Test in the Local Device

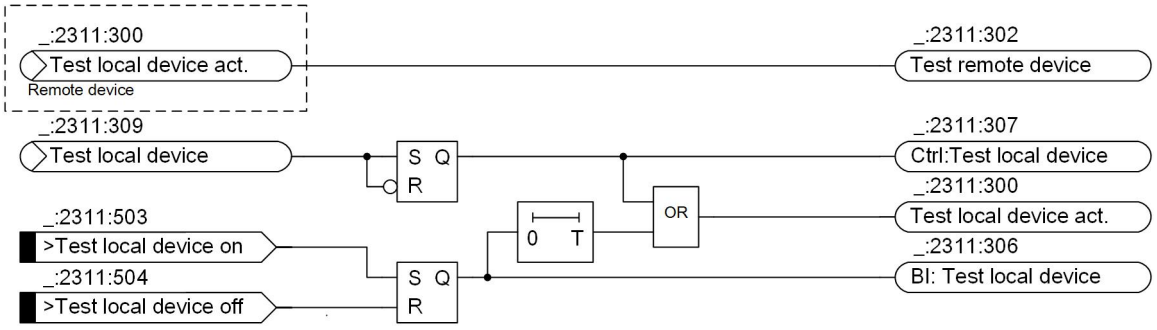
11.7.3.1 General Information

Use the special *Test local device* test mode to test the function **Line differential protection** in the local device with applied test currents. The local currents are interpreted as differential currents. The measured values of the remote devices are not used.

NOTE

This special test mode only makes sense when the entire device has been set into test mode. Otherwise, applied test currents also affect all other protection functions and can lead to unintentional pickup.

For further information, refer to *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.



You can test the function **Line differential protection** in the local device such that during the test the functions **Line differential protection** of the remote devices are either ***active*** or ***Inactive***.

Carry out all action steps on site on the device to be tested.

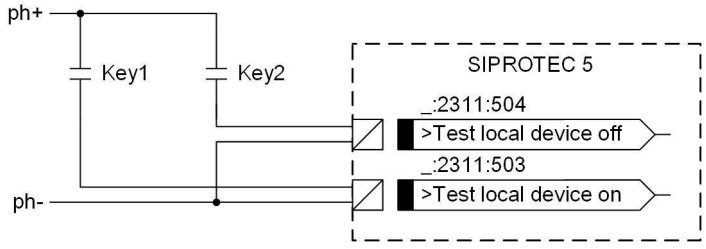
You can enable or disable the special *Test local device* test mode as follows:

- Via the operating dialog in DIGSI (online): **Online accesses > Interface > Device > Device information, Test and operation, Check local devices**
- Via the on-site operation panel under: **Main menu > Device functions > Line n > Line differential protection > Test local device**
- Via the communication by using the *(_:2311:309) Test local device* controllable
- Via the binary inputs *(_:2311:503) >Test local device on* and *(_:2311:504) >Test local device off*

The following figure shows the binary inputs, controllables, and indications linked to the *Test local device* test mode:

[lo Ldiff test device local, 2, en_US]

Figure 11-14 Logic Diagram for Enabling/Disabling the *Test local device* Test Mode

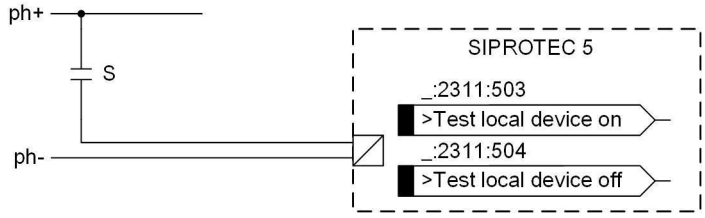


The indications *Ctrl:Test local device* or *BI: Test local device* indicate via which path the test mode test local device has been activated.

If you activate this special test mode in DIGSI, either via the communication interface or via on-site operation by the *Test local device* controllable, the device will issue the indication *Ctrl:Test local device*. The device stores the state of the *Test local device* controllable in a voltage-fail-safe memory.

If you enable or disable this special test mode via the binary inputs *>Test local device on* and *>Test local device off*, the device issues the indication *BI: Test local device*. If the *Test local device* test mode is enabled, the device generates the indication *Test local device act.*. The status indications of the instantiated **I-DIFF** stages indicate ***Test*** or ***Test/Relay blk.***.

The functions **Line differential protection** are not effective in the remote devices and report this state with the indications *Inactive* and *Test remote device*.



The following figures show possible variants of enabling/disabling the *test local device* test mode via binary inputs. The following figure shows the use of push-buttons **Ta1** and **Ta2**:

[lo_application_mode_device_taster_test-local-device, 1, en_US]

Figure 11-15 External Wiring of Push-Buttons for Enabling/Disabling the *Test local device* Test Mode

The following figure shows the use of a switch **S**. Route the logical binary input *>Test local device on* as **H** (high-active) and the logical binary input *>Test local device off* as **L** (low-active) to a physical binary input.

[lo_application_mode_device_ext-switch, 1, en_US]

Figure 11-16 External Wiring of Switches for Enabling/Disabling the *Test local device* Test Mode

11.7.3.2 Functional Test in Case of Non-Effective Line Differential Protection in the Remote Devices – Procedure 1

You can test the function **Line differential protection** in the local device while the line differential protection in the remote devices is ***Inactive***.

Test Preparation and Implementation

If the parameter **Action on Behavior = test** = ***Test loc. device man.***, Siemens recommends the following procedure for test preparation:

Initial state:

- **I** and optionally **V** of the system are connected to the current and voltage inputs of the protection device.
- The function **Line differential protection** is ***active*** in all devices.

Proceed as follows:

✧ Switch on the test mode for the entire device in the local device, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.
→ The function **Line differential protection** is ***Inactive*** in all devices.

✧ Disconnect the system transformers from the current and voltage inputs of the protection device and short-circuit the system current transformer.

✧ Switch on the *Test local device* test mode in the local device, see *11.7.3.1 General Information* .
→ The function **Line differential protection** is ***active*** and in ***Test*** state in the local device only.
→ The function **Line differential protection** is ***Inactive*** in the remote devices.

✧ Start your tests and apply test currents and test voltages.

Steps after Completion of the Tests

Initial state:

- The function **Line differential protection** is ***active*** and in ***Test*** state in the local device only.
- The function **Line differential protection** is ***Inactive*** in the remote devices.

Proceed as follows:

✧ Complete your tests and remove the test currents and test voltages.

✧ Switch off the *Test local device* test mode in the local device, see *11.7.3.1 General Information* .
→ The function **Line differential protection** is ***Inactive*** in all devices.

✧ Connect **I** and optionally **V** of the system to the current and voltage inputs of the protection device.

✧ Switch off the test mode of the entire device in the local device, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.
→ The function **Line differential protection** is ***active*** in all devices.

11.7.3.3 Functional Test in Case of Non-Effective Line Differential Protection in the Remote Devices – Procedure 2

You can test the function **Line differential protection** in the local device while the line differential protection in the remote devices is ***Inactive***.

Test Preparation and Implementation

Siemens recommends this procedure if you use a test switch to test the local function **Line differential protection**.

For further information, refer to *11.7.5 Use of Test Switches*.

If the parameter **Action on Behavior = test** = ***Test loc. device autom.***, Siemens recommends the following procedure for test preparation:

Initial state:

- **I** and optionally **V** of the system are connected to the current and voltage inputs of the protection device.
- The function **Line differential protection** is ***active*** in all devices.

Proceed as follows:

✧ Toggle the test switch.

→ The test switch disconnects the **I** and optionally the **V** of the system from the current and voltage inputs of the protection device.

→ The test switch enables the test mode for the entire device in the local device, see *11.7.3.1 General Information* .

If the parameter **Action on Behavior = test** = ***Test loc. device autom.***, the *Test local device* test mode is automatically enabled, see *Parameter: Action on Behavior = test, Page 732*

→ The function **Line differential protection** is ***active*** and in ***test*** state in the local device only.

→ The function **Line differential protection** is ***Inactive*** in the remote devices.

✧ Start your tests and apply test currents and test voltages.

Steps after Completion of the Tests

Initial state:

- The function **Line differential protection** is ***active*** and in ***Test*** state in the local device only.
- The function **Line differential protection** is ***Inactive*** in the remote devices.

Proceed as follows:

✧ Complete your tests and remove test currents and test voltages.

✧ Toggle the test switch.

→ The test switch disables the test mode for the entire device in the local device, see *11.7.3.1 General Information* .

→ The test switch connects the **I** and optionally the **V** of the system to the current and voltage inputs of the protection device.

Since the parameter **Action on Behavior = test** = ***Test loc. device autom.***, the *Test local device test mode is automatically disabled.*

→ The function **Line differential protection** is ***active*** in all devices.

11.7.3.4 Functional Test in Case of Effective Line Differential Protection in the Remote Devices – Procedure 1

You can test the function **Line differential protection** in the local device while the line differential protection in the remote devices remains ***active***. Log off the function **Line differential protection** of the local device to be tested from to the remote **line differential protection** functions, see *6.7.15 Logging Off the Local Line Differential Protection*. The current sum in the remote devices is then calculated without the logged out function.

For this operating mode, the feeder protected by the local line differential protection must be de-energized. This is because after logout, local currents must not influence the current sum of the remaining protected object, which might lead to unwanted tripping.

Test Preparation and Implementation

If the parameter **Action on Behavior = test** = ***Test loc. device man.***, Siemens recommends the following procedure for test preparation:

Initial state:

- **I** and optionally **V** of the system are connected to the current and voltage inputs of the protection device.
- The function **Line differential protection** is ***active*** in all devices.

Proceed as follows:

✧ Disconnect the feeder.

✧ Log off the function **Line differential protection** to be tested from the local device, see *6.7.15 Logging Off the Local Line Differential Protection*.

→ The function **Line differential protection** is ***active*** in the remote devices.

→ The function **Line differential protection** is ***Inactive*** in the local device.

✧ Switch on the test mode for the entire device in the local device, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

✧ Disconnect the system transformers from the current and voltage inputs of the protection device and short-circuit the system current transformer.

✧ Enable the *Test local device* test mode in the local device, see *11.7.3.1 General Information* .

→ The function **Line differential protection** is ***active*** and in ***Test*** state in the local device.

→ The function **Line differential protection** is ***active*** in the remote devices.

✧ Start your tests and apply test currents and test voltages.

Steps after Completion of the Tests

Initial state:

- The function **Line differential protection** is ***active*** and in ***Test*** state in the local device only.
- The function **Line differential protection** is ***Inactive*** in the remote devices.

Proceed as follows:

✧ Complete your tests and remove test currents and test voltages.

✧ Disable the *Test local device* test mode in the local device, see *11.7.3.1 General Information* .

→ The function **Line differential protection** is ***Inactive*** in the local device.

✧ Disable the test mode for the entire device in the local device, see *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

✧ Log on the tested function **Line differential protection** at the local device again, see *6.7.15 Logging Off the Local Line Differential Protection*.

→ The function **Line differential protection** is ***active*** in all devices.

✧ Reconnect the feeder.

11.7.3.5 Functional Test in Case of Effective Line Differential Protection in the Remote Devices – Procedure 2

You can test the function **Line differential protection** in the local device while the line differential protection in the remote devices remains ***active***. Log off the function **Line differential protection** of the local device to be tested from to the remote functions **Line differential protection**, see *6.7.15 Logging Off the Local Line Differential Protection*. The current sum in the remote devices is then calculated without the logged out function.

For this operating mode, the feeder protected by the local line differential protection must be de-energized. This is because after logout, local currents must not influence the current sum of the remaining protected object, which might lead to unwanted tripping.

Test Preparation and Implementation

Siemens recommends this procedure if you use a test switch to test the local function **Line differential protection**.

For further information, refer to *11.7.5 Use of Test Switches*.

If the parameter **(_:2311:108) Action on Behavior = test** = ***Test loc. device autom.***, Siemens recommends the following procedure for test preparation:

Initial state:

- **I** and optionally **V** of the system are connected to the current and voltage inputs of the protection device.
- The function **Line differential protection** is ***active*** in all devices.

Proceed as follows:

✧ Disconnect the feeder.

✧ Log off the function **Line differential protection** to be tested from the local device, see *6.7.15 Logging Off the Local Line Differential Protection*.

→ The function **Line differential protection** is ***active*** in the remote devices.

→ The function **Line differential protection** is ***Inactive*** in the local device.

✧ Toggle the test switch.

→ The test switch disconnects **I** and optionally **V** of the system from the current and voltage inputs of the protection device.

→ The test switch enables the test mode for the entire device in the local device, see *11.7.3.1 General Information* .

→ The setting value of the parameter **(_:2311:108) Action on Behavior = test** = ***Test loc. device autom.*** automatically enables the *Test local device* test mode.

✧ Start your tests and apply the test currents and test voltages.

Steps after Completion of the Tests

Initial state:

- The function **Line differential protection** is ***active*** and in ***Test*** state in the local device only.
- The function **Line differential protection** is ***active*** in the remote devices.

Proceed as follows:

✧ Complete your tests and remove the test currents and test voltages.

✧ Toggle the test switch.

→ The test switch disables the test mode for the entire device in the local device, see *11.7.3.1 General Information* .

→ The test switch connects **I** and optionally **V** of the system to the current and voltage inputs of the protection device.

→ The setting value of the parameter **(_:2311:108) Action on Behavior = test** = ***Test loc. device autom.*** automatically disables the *Test local device* test mode.

→ The function **Line differential protection** is ***Inactive*** in the local device.

✧ Log on the tested function **Line differential protection** at the local device again, see *6.7.15 Logging Off the Local Line Differential Protection*.

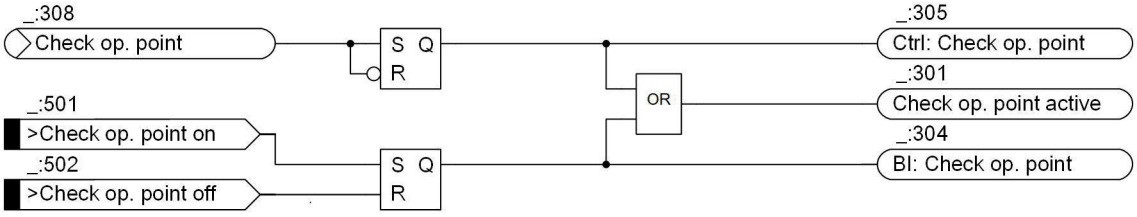
→ The function **Line differential protection** is ***active*** in all devices.

✧ Reconnect the feeder.

11.7.4 Checking the Operating Point

Use the special *Check op. point* test mode to check the differential current and the restraint current, for example, after setting changes prior to commissioning and with connected process variables (**V** and **I** of the system). In DIGSI 5, the current operating point in the differential protection characteristic curve can be checked, see *Figure 11-20*.

This test mode is not intended for testing with test currents and test voltages.



In this test mode, line differential protection works with all line ends, but does not generate any operate indications.

The special *Check op. point* test mode is only enabled/disabled at one device of the device combination. Meaning that you carry out all action steps on site on the device to be tested. The functions **Line differential protection** in the remote devices are automatically set to this test mode via the protection communication.

You can enable or disable the special *Check op. point* test mode as follows:

- Via the operating dialog in DIGSI (online): **Online access > Interface > Device > Device information, Test and operation, Check all devices**
- Via the on-site operation panel under: **Main menu > Device functions > Line n > Line differential protection > Check op. point**
- Via the communication by using the *(_:2311:308) Check op. point* controllable
- Via the binary inputs *(_:2311:501) >Check op. point on* and *(_:2311:502) >Check op. point off*

The following figure shows the binary inputs, controllables, and indications linked to the *Check op. point* test mode:

[lo_switch-on-off_special-test-mode_esting-work-point, 1, en_US]

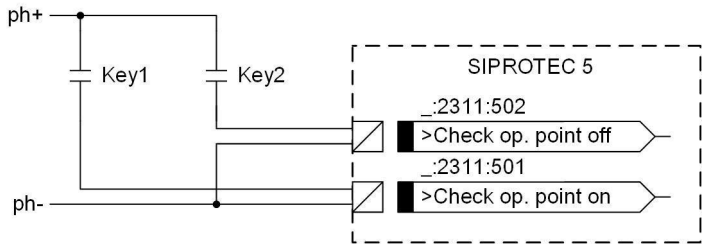


Figure 11-17 Logic Diagram for Enabling/Disabling the Special Check Op. Point Test Mode

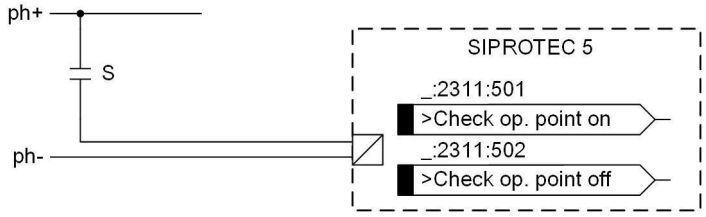
The indications *Ctrl: Check op. point* or *BI: Check op. point* indicate via which path the Check op. point test mode has been activated.

If you activate this special test mode in DIGSI, either via the communication interface or via on-site operation by the *Check op. point* controllable, the device issues the indication *Ctrl: Check op. point*. The device stores the state of the *Check op. point* controllable in a voltage-fail-safe memory.

If you enable or disable this special test mode via the binary inputs *>Check op. point on* and *>Check op. point off*, the device issues the indication *BI: Check op. point*. If the *Check op. point* test mode is enabled, the device generates the indication *Check op. point active*. During the test, the indications of the functioon **Line differential protection** are marked with a test bit in all devices. The status indications of the instantiated **I-DIFF** stages show ***Test*** or ***Test/Relay blk***..



The following figures show possible variants of enabling/disabling the *Check op. point* test mode via binary inputs. The following figure shows the use of push-buttons **Ta1** and **Ta2**:

[lo_application_mode_device_taster_work-point, 1, en_US]

Figure 11-18 External Wiring of Push-Buttons for Enabling/Disabling the *Check op. point* Test Mode

The following figure shows the use of a switch **S**. Route the logical binary input *>Check op. point on* as **H** (high-active) and the logical binary input *>Check op. point off* as **L** (low-active) to a physical binary input.

[lo_application_mode_device_ext-switch_work-point, 1, en_US]

Figure 11-19 External Wiring of Switches for Enabling/Disabling the *Check op. point* Test Mode

Test Preparation

Prior to starting the test, **V** and **I** of the system must be connected to the current and voltage inputs of the protection device and the function **Line differential protection** must be ***active*** in all devices.

✧ Switch on the special *Check op. point* test mode for the function **Line differential protection**.
→ The function **Line differential protection** is ***active*** and in ***Test*** state in all devices.

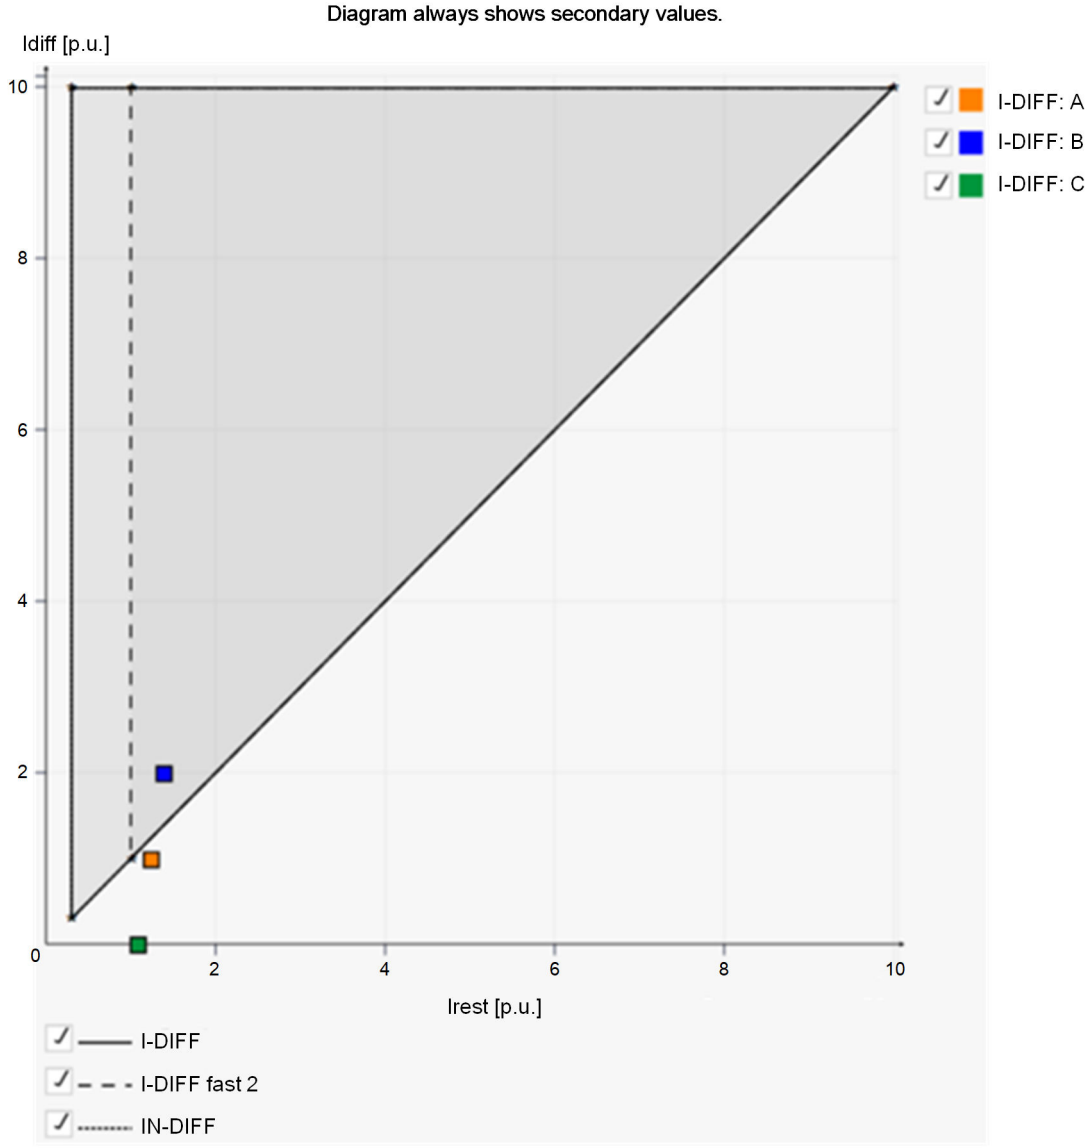
✧ Start with checking the operating point.

NOTE

If the local function **Line differential protection** is logged off, it is not possible for you to enable the special *Check op. point* test mode. The device rejects the activation.

Performing the Check

You can check the differential and restraint current directly on the device or with DIGSI 5.



- **Checking on the Device:**
  On the device, you can find the differential current and restraint current under **Operational measured values > Measurements > Line 1 > Functional neasured values > Line diff. protection**

- **Checking with DIGSI 5:**

  When using DIGSI 5 to check the differential and restraint current, first establish the connection with the device. You can find the operational measured values of the line differential protection under **Name of device > Measurements > Line 1**.

  In the working area, you can find the operational measured values of the function under **Functional measured values > Line diff. protection**.

  In DIGSI 5 the operating points (OP) derived from the differential and restraint current can also be checked in the graphic display of the differential protection characteristic curve. You can find the differential protection characteristic curve in DIGSI 5 in the project tree under **Online device (Name of device) > Test suite > Protection functions > Line 1 > Line diff. protection**. The following differential protection characteristic curve shows the operating points:

[dw_charac_line-diff-prot, 1, en_US]

Figure 11-20 Characteristic Curve of the Line Differential Protection

To ensure reliable functioning of line differential protection, the operating point must be located inside the working area and clearly below the tripping lines.

If the differential current monitoring function operates or the operating point lies within the tripping area, proceed as follows:

✧ Check the pickup value of the stage.

✧ Check the polarity of the current transformer.

✧ Verify that the differential current is generated by the primary system.

Possible causes of a differential current are:

- The charging current of the line
  The charging current is represented as a permanent differential current when voltage is applied to the line.
- Asynchronous communication networks
  Such asynchronicity can be created by coupling larger communication networks.
- Unbalances in the runtimes for the protection communication that have always existed but not been noticed.

Completion of the Tests

The function **Line differential protection** is ***active*** and in ***Test*** state in all devices.

✧ Complete the test.

✧ Switch off the special *Check op. point* test mode for the function **Line differential protection**.
→ The function **Line differential protection** is ***active*** in all devices.

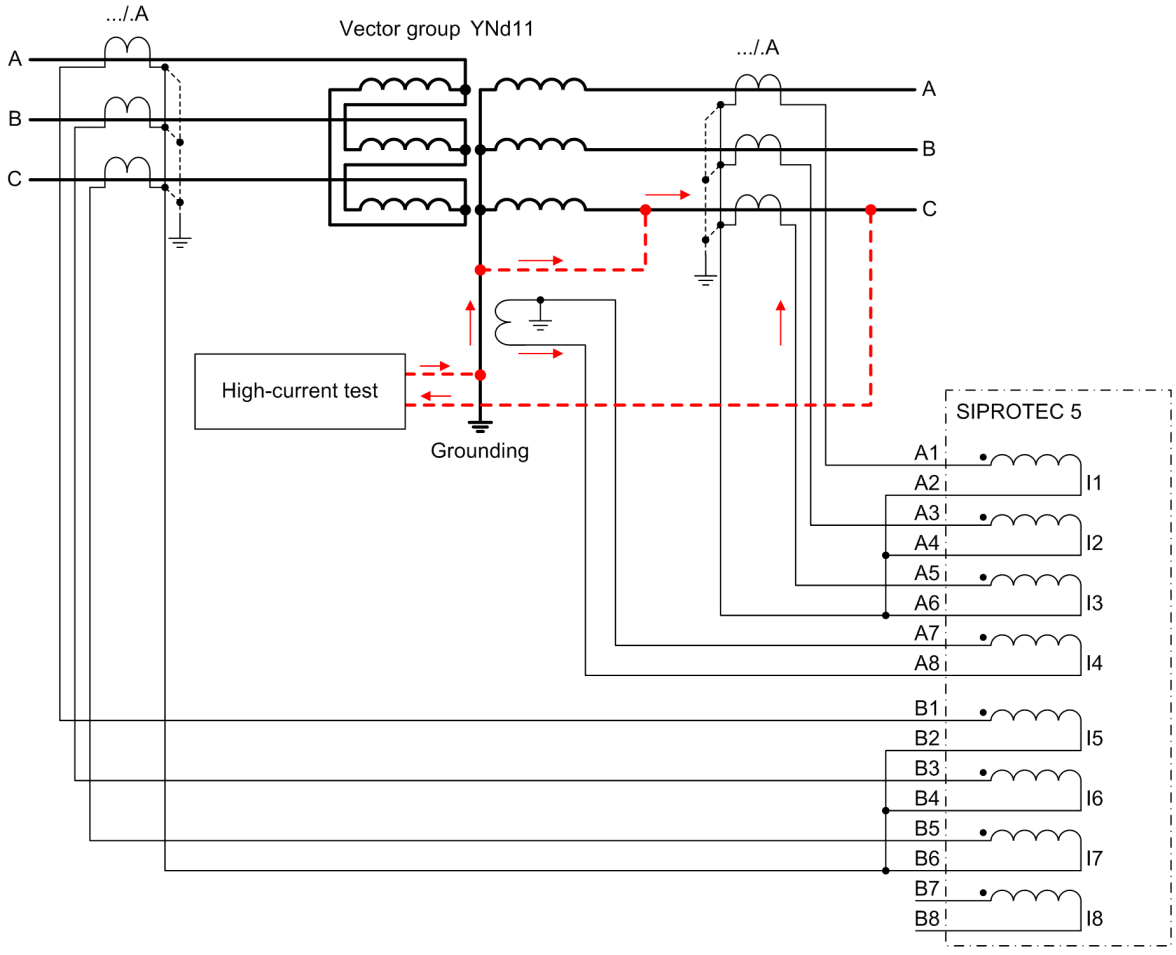
11.7.5 Use of Test Switches

When activated, a test switch has the following functions:

- Disconnects the current and voltage inputs of the protection device from the measurands **V** and **I** of the system and connects them to the outputs of a current and voltage generator for testing.
- Disconnects the protection device from the circuit breaker.
- Activates a test mode.

If you want to use a test switch for testing the entire line differential protection and for testing the function **Line differential protection** in the local device, Siemens recommends the following:

✧ Set the parameter **(_:2311:108) Action on Behavior = test** = ***Test loc. device man.***.



✧ Use the test switch to switch the test mode for the entire device on or off.

✧ You need to switch the special ***Test local device*** test mode on and off manually, see *11.7.3 Functional Test in the Local Device*.

11.8 Commissioning Notes for Restricted Ground-Fault Protection

In addition to the protection setting and the correct routing of the signals, proper system integration is important. When checking the system integration, Siemens recommends the following procedure:

- **Polarity test** of the current transformers and assurance that the positive definition (to the protected object) is maintained. With a 3-phase connection, the current-transformer neutral point points to the protected object. For the current transformer at the neutral point, it is important that the side of the current transformer that is connected to terminal A7 is in the direction of ground (see *Figure 11-21*).
- **Checking the pickup value** can be performed by feeding in a neutral-point current.
- **Checking stability with an external fault** is possible by feeding in a current, if no bushing-type transformers are present on the transformer. The *Figure 11-21* shows test proposal. A trip may not occur.

[dwhighct-170712-01.tif, 3, en_US]

Figure 11-21 Test with High-Current Test Equipment

If a generator step-up transformer is protected, the generator can be used as test source. During a shutdown, an external 1-phase short circuit is built in. After this, the generator is excited and a minimum current is supplied. This minimum current lies under the permissible negative-sequence current. Set the restricted ground-fault protection to the lower setting value. If the test current must be greater due to system conditions, the test takes place briefly (only a few seconds). Reestablish the original states after the test (primary plant, protection setting).

With smaller primary transformer rated currents, the test can take place by means of external supply (400 V method). Set the protection to the minimum threshold value.

11.9 Direction Test of the Phase Quantities (Current and Voltage Connection)

The proper connection of the current and voltage transformer is checked with load current over the line to be protected or the protected object . For this, the line or the protected object must be switched on. A load current of at least 0.1 I_{rated} has to flow over the line or the protected object ; it should be ohmic to ohmic inductive. The direction of the load current has to be known. In case of doubt, meshed and ring systems should be unraveled. The line or the protected object remains switched on the for the duration of the measurements.

The direction can be derived directly from the operational measured value. First make sure that the power measured values correspond to the power direction. Normally, it can be assumed that the forward direction (measuring direction) goes from the busbar toward the line or the protected object .

Using the power measured values at the device or DIGSI 5, make sure that it corresponds to the power direction:

- **P** is positive if the active power flows in the line or protected object.
- **P** is negative if the active power flows to the busbar or out of the protected object.
- **Q** is positive if the inductive reactive power flows in the line or protected object.
- **Q** is negative if the inductive reactive power flows to the busbar or out of the protected object.

If the power measured values have a different sign than expected, then the power flow is opposite the current-direction definition. This can be the case, for example, at the opposite end of the undervoltage side of a transformer . The current-transformer neutral point then points in the direction of the protected object (for example transformer).

If the values are not as expected, it may be due to a polarity reversal at the voltage connection.

As a final step, switch off the system.

11.10 Direction Test of Ground Quantities for Directional Ground-Fault Functions

11.10.1 Overview

If the CT and VT connections are in the way that the ground quantities (3I0 and V0) are calculated by the device from the phase quantities, then, no additional directional test is required. Testing according to *11.9 Direction Test of the Phase Quantities (Current and Voltage Connection)* is sufficient.

If the ground current IN or the ground voltage VN is directly measured via a device input (usually I4 or V4), the correct polarity of the ground current and the ground voltage path must be checked.

DANGER

Live system parts! Capacitive coupled voltages on dead parts!

Noncompliance with the following measures can lead to death, serious physical injury, or considerable material damage.

✧ Primary measures may be performed only on dead and grounded system parts.

11.10.2 Directional Testing for Solid or Resistive-Grounded Systems

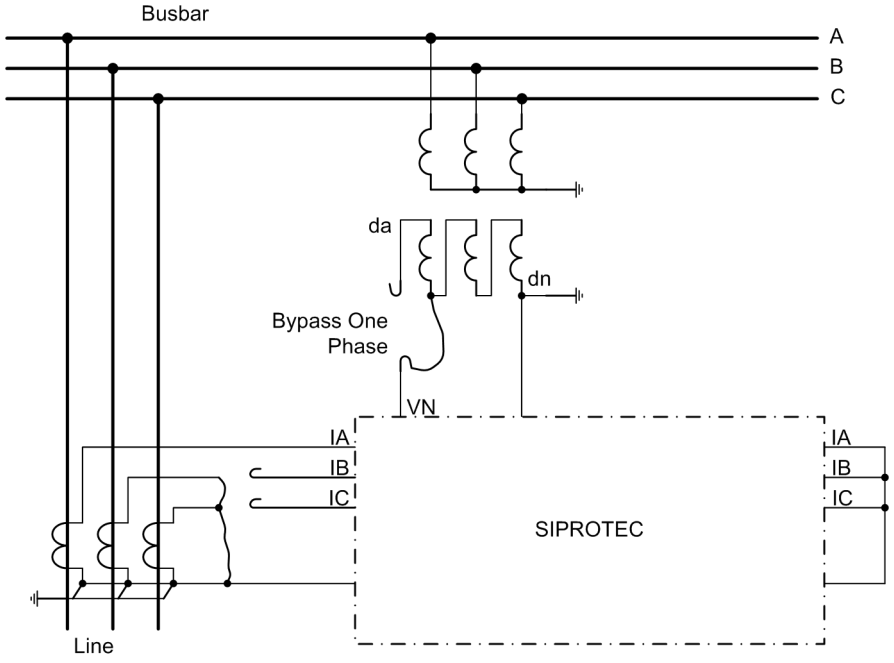
Primary Test

The primary test is used for the evaluation of the correct polarity of the transformer connections for the determination of the ground-fault direction.

To generate a zero-sequence voltage V0, the e-n winding of one phase in the voltage-transformer set (for example, phase A) is bypassed, see *Figure 11-22*. If no connection on the e–n windings of the voltage transformer is provided, the corresponding phase is disconnected on the secondary side, see *Figure 11-23*. Only the current of the transformer in the phase of which the voltage is missing is transferred via the current circuit. If the line carries resistive-inductive load, the protection is subject to the same conditions as existing during a ground fault in line direction.

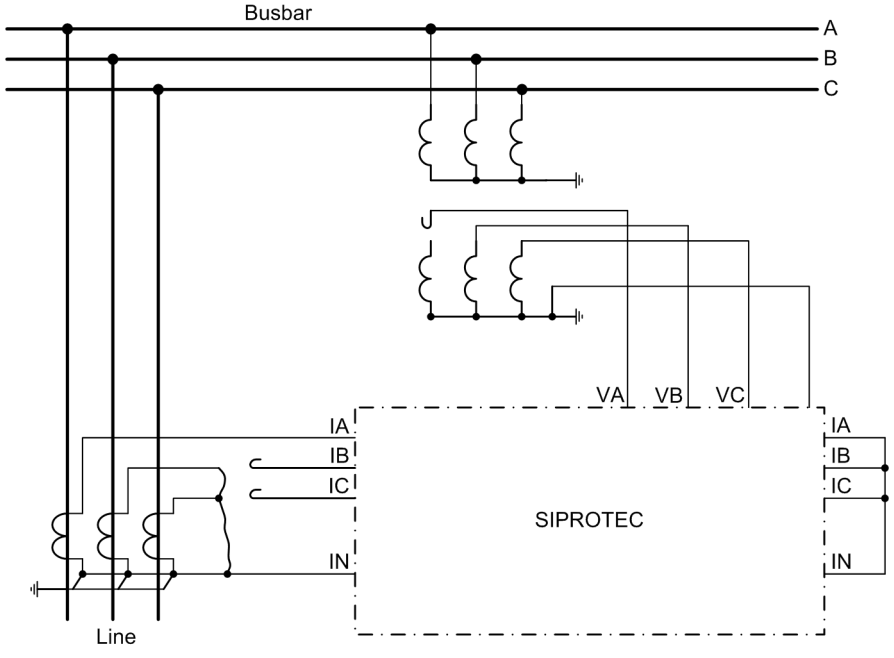
For directional testing, the **Directional ground-fault protection** function (67N) is configured and at least one stage is switched on. The pickup threshold of the stage must be below the load current of the line. If not, the binary input signal *(_:2311:501) >Test of direction* can be activated to lower the threshold temporarily for testing means without changing the respective parameter.

After switching the line on and off again, you can check the pickup signal of the directional protection stage in the fault log. A forward information must be logged. If no pickup information is logged at all, the 3I0 or U0 threshold is not exceeded.



If a wrong direction is logged, one of the following conditions may have occurred:

- The direction of the load flow is from the line towards the busbar.
- The ground-current connection is incorrect.
- The voltage connection is incorrect.

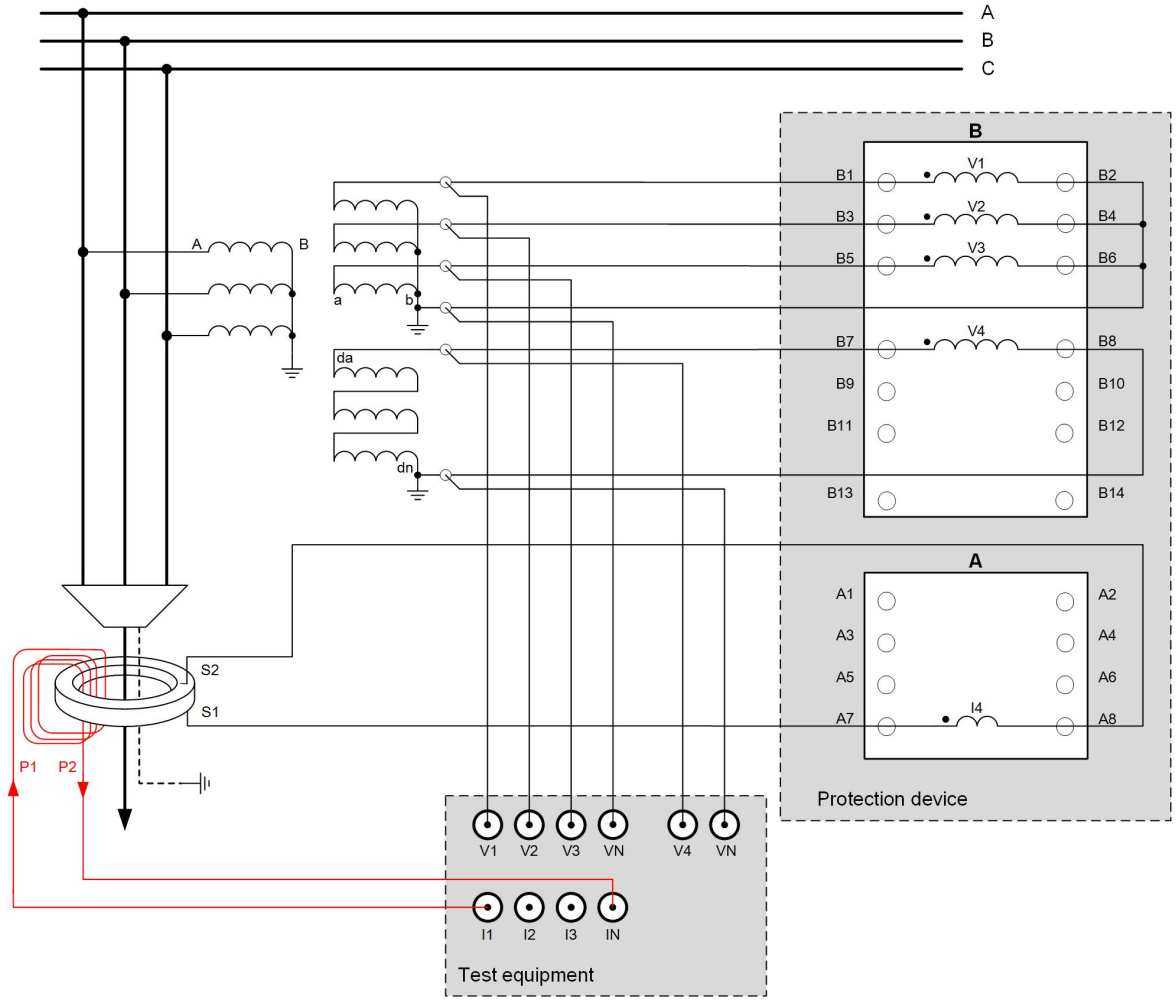


NOTE

Siemens recommends not to change parameter settings for the test. However, if parameters were changed for this test, they must be returned to their original state after completing the test!

[dw_conn_polarit1_diagram, 1, en_US]

Figure 11-22 Polarity Testing, Example with Current Transformers Configured in a Holmgreen-Connection and VTs with Broken-Delta Connection



[dw_conn_polarit2, 1, en_US]

Figure 11-23 Polarity Testing, Example with Current Transformers Configured in a Holmgreen-Connection and VTs with Star Connection

11.10.3 Directional Testing for Isolated or Resonant-Grounded Systems

Secondary Test with Core Balance Current Transformer

The secondary test is used for the evaluation of the correct ground-fault direction of the directional ground-fault protection functions. With this test, a core balance current transformer that is incorrectly connected can also be found.

[dw_secondary_test_SGFP, 2, en_US]

Figure 11-24 Connection with Primary Current Injection

In the preceding figure, the red pilot wire must be wired only for the testing purpose through the core balance current transformer.

- ✧ Make the connections of the test equipment according to *Figure 11-24*.
- ✧ Route the pilot wire through the core balance current transformer in the direction towards the protection object (towards the feeder).
- ✧ To achieve a higher measured ground current, route the pilot wire multiple times through the core balance current transformer.
- ✧ The equivalent primary test current is the test current of the test device multiplied by the number of pilot-wire windings.
- ✧ Inject the test quantities according to the following table. Select the quantities according to the networking grounding and direction to be tested.

Neutral Point	Isolated				Resonant-Grounded			
Direction	Forward		Reverse		Forward		Non-faulty	
V_A (V1)	0 V	0°	0 V	0°	0 V	0°	0 V	0°
V_B (V2)	100 V	-150°	100 V	-150°	100 V	-150°	100 V	-150°
V_C (V3)	100 V	+150°	100 V	+150°	100 V	+150°	100 V	+150°
$V_{da/dn}$ (V4)	100 V	+180°	100 V	+180°	100 V	+180°	100 V	+180°
I_A = 3I0 (I1[69]), see *Figure 11-24*	2 A	+90°	2 A	-90°	1 A	0°	2 A	-90°

✧ You can check the test result by the direction information from the log.

Primary Test

The primary test is used for the evaluation of the correct polarity of the transformer connections for the determination of the ground-fault direction.

For directional testing, the **Directional sensitive ground-fault detection** function (67Ns) is configured and a directional stage is switched on. For example, the directional 3I0> stage with cos φ or sin φ measurement.

The most reliable test is the one with a primary ground fault. Proceed as follows:

✧ Isolate the line and ground it on both sides; on the farthest line end it must remain open during the entire test.

✧ Place a **1-phase** ground fault bridge on the line. For overhead lines, this can be done at an arbitrary location, in any case behind the current transformer (as seen from the busbar of the feeder to be tested). For cables, the grounding is done on the farthest end (sealing end).

✧ Remove the protective grounding from the line.

✧ Switch on the circuit breaker on the line to be tested.

✧ Check direction indicator (LED if routed).

✧ Check the indication *(_:302) Ground fault* in the ground-fault log or fault log with regard to its direction. The indication *(_:302) Ground fault forward* must be logged as direction information.

If *backward* is determined as the direction, either with the current connections or the voltage connections, there is an inversion in the neutral path. For the display *unknown*, the ground current is probably too low.

✧ Switch the line off and ground it.

This completes the test.

69 Refers to I1 of the test equipment.

11.11 Commissioning Hints for Voltage Control

11.11.1 Secondary Tests

11.11.1.1 General

Secondary tests can never replace the primary tests described in the following (*11.11.2 Primary Tests*), because you cannot exclude connection faults.

Secondary tests are used for the following purposes:

- Checking the setting values
- Checking the correct reaction of the protection function, limits, indications, blocking, and voltage control functions
- Checking the engineering (for example, routing of the respective logic signals, display images with measured values and CFC logics)
- With parallel control check of the communication

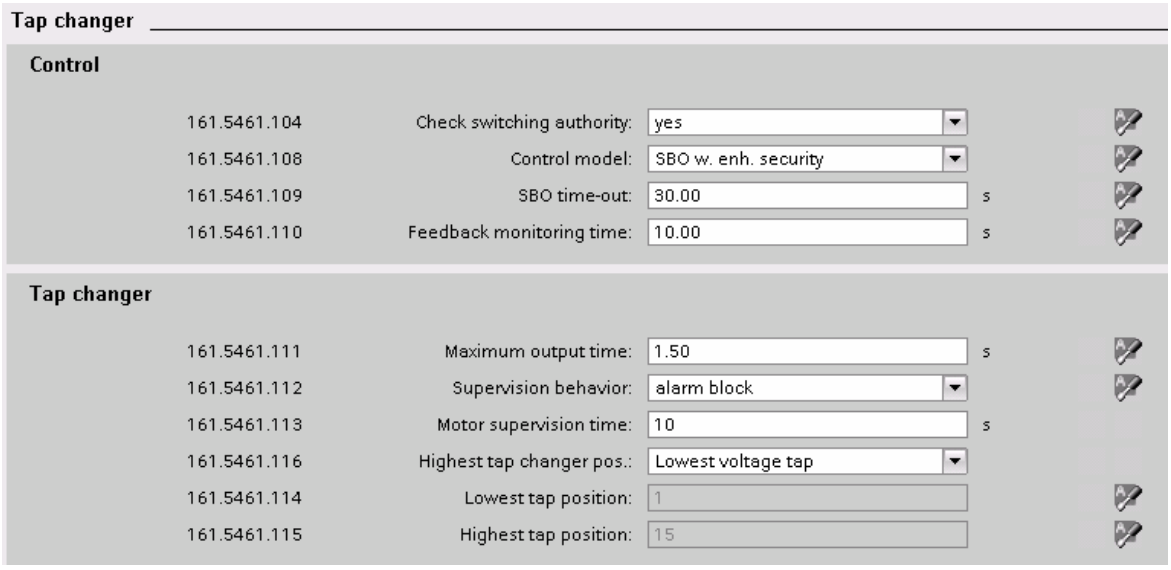
Note the following information during the secondary tests:

NOTE

For tests with secondary test equipment, make sure that no other measurands are connected and that the trip commands to the circuit breakers are interrupted. Otherwise, the circuit breaker may be activated.

If the tap-changer position is not updated manually during the secondary test, you must deactivate the tap-changer supervision. Otherwise, the voltage control is blocked after every switching procedure.

NOTE



Once you have completed the secondary test, you must activate the tap-changer supervision again.

11.11.1.2 Checking the Transformer Tap Position

General

For this test, the transformer must be de-energized, that is, circuit breakers and disconnectors are switched off/opened, protected against re-energizing and the maintenance grounding switch should be closed.

During the functional test of the on-load tap changer, the most important setting parameters for the tap-changer supervision such as **Motor supervision time**, **Highest tap changer pos.**, and **Maximum output time** must be checked and adjusted.

[scstuslt-100713-01.tif, 2, en_US]

Figure 11-25 Parameters of the Tap Changer

Tap-Position Display

You can route the current tap position as a position indication on a display page or into the operating indications. If no signal is present or the function is blocked, the device reports a position error. The display then indicates an invalid tap position with **---** (*Figure 11-26*). You can find information on which conditions lead to an invalid tap position in *7.8.1 Function Description* .

[sc_osop_valid_position, 1, en_US]

Figure 11-26 Invalid Tap-Changer Position in the Device Display

Parameterize BCD Code

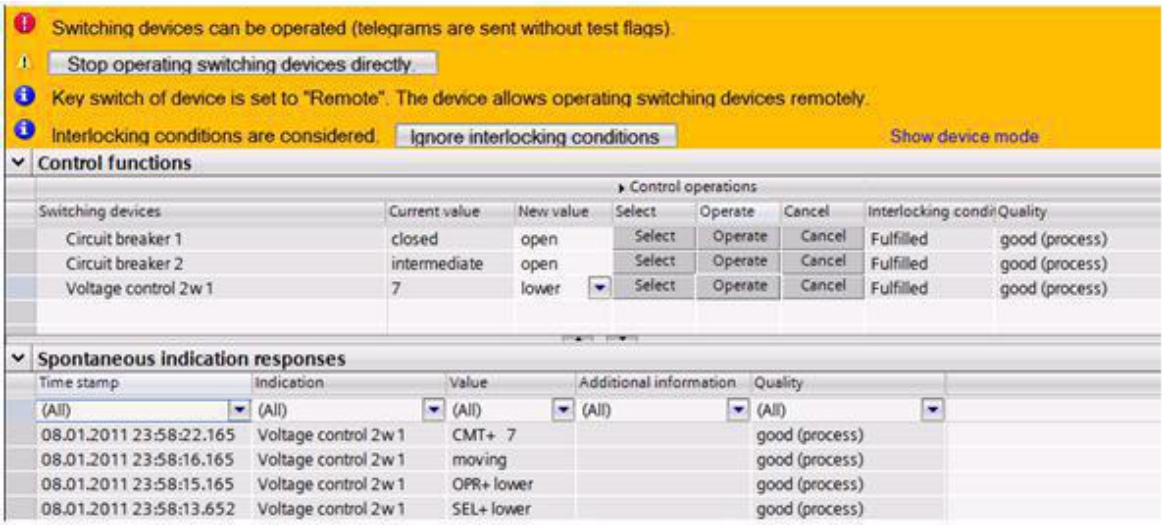
If the tap position of the tap changer is transmitted to the SIPROTEC 5 device via BCD code with prefix, then it is sufficient to assign the binary inputs with the corresponding functions according to the routing. Corresponding functions are for example:

- BCD1
- BCD2
- BCD4

- BCD8
- BCD10
- BCD20
- BCD40
- BCDminus
- Sliding contact

You can find a short introduction into parameter setting and routing of the binary inputs for the tap position in chapter *7.8.2 Application and Setting Notes*.

Besides the tap-position display via ***BCD with prefix***, the SIPROTEC 5 device offers the option to code the tap position as follows:



- Binary
- 1-of-n
- BCD
- Table
- Gray Code
- IEC 61850 GOOSE indication (Type BSC)

Optionally, you can also use an mA signal or a resistance-coded tap-position display. An ANAI module must be installed for the analog integration of the tap-position signal.

Checking the Tap Position

The active binary input is marked with a cross in the device menu under the entry **Binary IO**. Siemens recommends driving through all positions of the tap changer completely, if possible, thereby testing the correct tap-changer position indication once the parameterization of the tap position detection is finished and the tap-position display is activated.

You can carry out the tap-position check from the on-site operation panel or from the DIGSI Online-Editor. If you are using the DIGSI Online-Editor, set the switching authority of the device to ***Remote*** and the operating mode of the voltage controller to ***Manual***.

[sc_ibs_contr_func, 1, en_US]

Figure 11-27 DIGSI Online-Editor

Checking Sliding Contact

The device can monitor the runtime of the motor drive. This function is used to identify failures of the motor-drive mechanism during the switching procedure and to initiate actions (for example, blocking) if required. If you want to use the motor supervision time, you must route the motor run signal (most significant binary input) and set the motor runtime.

The maximum motor runtime can be calculated by measuring – during commissioning – how long the tap changer needs from the time point of the incremental command until completion of the tap changing. The tap changer needs approx. 7 s to 10 s for one tap-position change. Select the runtime to be 2 s to 3 s longer than the measured time. This takes into account a tolerance for the aging of the tap changer. If the tap changer has a run-through setting, select the motor lead time based on the run-through time of the switching tap (+ tolerance time).

If the tap-changer position is not manually updated during the secondary test, you must deactivate the tap-changer supervision. Otherwise, the voltage control is blocked after every switching procedure.

NOTE

Once you have completed the secondary test, you must activate the tap-changer supervision again.

11.11.1.3 Check of the Voltage-Control Function

The measured control deviation D results from the following formula:

$$D\ (\%) = \frac{V_{\text{act-prim}} - V_{\text{target-prim}}}{V_{\text{rated}}} \cdot 100\ \%$$

[fo_ibs_regelab, 1, en_US]

where:

$V_{\text{act-prim}}$	Actual voltage, primary
$V_{\text{target-prim}}$	**90V V.contr.2w** → **Target voltage** primary
V_{rated}	**90V V.contr.2w** → **General**:**Rated voltage**

With the **3-phase measuring point voltage** set to **VT connection** = ***3 ph-to-gnd volt. + VN***, the measured voltage primary $V_{\text{act-prim}}$ results from the ratio of the voltage transformer parameters **Rated secondary voltage** $V_{\text{CT-sec}}$ and **Rated primary voltage** $V_{\text{CT-prim}}$.

$$V_{\text{act-prim}} = V_{\text{act-sec}} \cdot \frac{\sqrt{3} \cdot V_{\text{CT-sec}}}{V_{\text{CT-prim}}}$$

[fo_ibs_prim_measur_volt, 1, en_US]

NOTE

The parameter **Measured value** has an effect on the secondary check, and therefore this checking example relates to the positive-sequence voltage.

This results in the secondary voltage $V_{\text{act-sec}}$ to be fed in depending on the control deviation D to be achieved with the connection type **VT connection** = ***3 ph-to-gnd volt. + VN / 3 ph-to-gnd voltages*** being:

$$V_{\text{act-sec}} = \left[\frac{D\ (\%) \cdot V_{\text{rated}}}{100\ \%} + V_{\text{target-prim}}\right] \cdot \frac{V_{\text{CT-sec}}}{\sqrt{3} \cdot V_{\text{CT-prim}}}$$

[fo_ibs_prim_measur_volt_2, 1, en_US]

This results in the secondary voltage $V_{\text{act-sec}}$ to be fed in depending on the control deviation D to be achieved with the connection type **VT connection** = ***3 ph-to-ph voltages*** being:

$$V_{act\text{-}sec} = \left[\frac{D\ (\%) \cdot V_{rated}}{100\ \%} + V_{target\text{-}prim}\right] \cdot \frac{V_{CT\text{-}sec}}{V_{CT\text{-}prim}}$$

[fo_ibs_prim_measur_volt_3, 1, en_US]

Table 11-4 Example Settings for the Power-System Data

Parameters	Value
Power-system data → **VT 3-phase:Rated primary voltage** $V_{CT\text{-}prim}$	15 kV
Power-system data → **VT 3-phase:Rated secondary voltage** $V_{CT\text{-}sec}$	110 kV
Voltage cont. 2W → **General:Rated voltage** V_{rated}	10.5 kV
Target voltage 1 V_{target}	11 kV

This results in the secondary voltage $V_{act\text{-}sec}$ with a phase-to-ground connection being:

$$V_{act\text{-}sec} = \left[\frac{D\ (\%) \cdot 10\ 500\ V}{100\ \%} + 11\ 000\ V\right] \cdot \frac{110\ V}{\sqrt{3} \cdot 15\ 000\ V}$$

[fo_ibs_prim_measur_volt_4, 1, en_US]

11.11.1.4 Further Tests

Control Deviation

- Check the control deviation D = 0 % at set point value infeed.
- Check the measured value of the control deviation D online in DIGSI or on the on-site operation panel of the device.

Secondary infeed values for the example:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec}$ = 46.6 V
Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec}$ = 46.6 V ·√3 = 80.7 V

Command Outputs

- Check the output of the **Lower adjusting command** after the parameterizable time **T1**.

With a set **bandwidth B** of 1 %, this results in the secondary pickup value:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec}$ > 47.1 V
Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec}$ > 47.1 V ·√3 = 81.5 V

- Check the output of the **Higher adjusting command** after the parameterizable time **T1**.

With a set **bandwidth B** of 1 %, this results in the secondary pickup value:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec}$ < 46.1 V
Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec}$ < 46.1 V ·√3 = 79.8 V

- Check the output of the **Lower adjusting command** after the parameterizable time **Fast step down T delay**.

For the set parameter **Fast step down limit** = ***6*** **%** the following secondary pickup values result:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec}$ > 49.3 V
Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec}$ > 49.3 V ·√3 = 85.3 V

- Check the output of the **Higher adjusting command** after the parameterizable time **Fast step up T delay**.

For the set parameter **Fast step up limit** = ***-6*** **%**, the following secondary pickup values result:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec}$ < 49.3 V

Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec} < 49.3\ V \cdot \sqrt{3} = 85.3\ V$

Blockings

- Check the undervoltage blocking **V< Blocking**.

For the set parameter **V< Blocking** = ***8 kV*** the following secondary pickup values result:
Voltage-transformer connection phase-to-ground: $V_{act\text{-}sec} < 58.7\ V$
Voltage-transformer connection phase-to-phase: $V_{act\text{-}sec} < 58.7\ V \cdot \sqrt{3} = 101.6\ V$

- Check the overcurrent blocking.

NOTE

The overcurrent blocking works with the maximum current of all phases, for this reason check the phases A, B, and C separately.

Example

Settings	Value
Power-system data → **CT 3-phase**:**Rated primary current** $I_{CT\text{-}prim}$	7500 A
Power-system data → **CT 3-phase**:**Rated secondary current** $I_{CT\text{-}sec}$	1 A
Voltage cont. 2W → **General**:**Rated current** I_{rated}	5500 A

$$I_{act\text{-}sec} = I_{rated} \cdot \frac{I> \text{Threshold}}{100\ \%} \cdot \frac{I_{CT\text{-}sec}}{I_{CT\text{-}prim}}$$

[fo_ibs_overcur_block, 1, en_US]

If you set the parameter **I> Threshold** to ***150 %***, this results in an infeed current secondary of $I_{act\text{-}sec} > 1.1\ A$ for this example.

Line Compensation

- Check the **Z Compensation**.

The parameter **Target voltage rising** represents the voltage drop across the line as a % under rated load. With a voltage drop primary of 504 V across the line at rated current, according to the setting notes in *7.9.4.5 Line Compensation*, this results in a setting value of 4.8 %.
The secondary current to be fed in at a load current for the 100 % load case results in:

$$I_{act\text{-}sec} = I_{rated} \cdot \frac{I_{CT\text{-}sec}}{I_{CT\text{-}prim}}$$

[fo_ibs_load_current, 1, en_US]

where:

$I_{CT\text{-}prim}$ Power-system data → **CT 3-phase**:**Rated primary current**
$I_{CT\text{-}sec}$ Power-system data → **CT 3-phase**:**Rated secondary current**
I_{rated} Voltage cont. 2W → **General**:**Rated current**

The secondary voltage to be fed in for the 100 % load case with a control deviation D [%] to be tested for the voltage-transformer connection phase-to-ground results in:

$$V_{act\text{-}sec} = \left(\frac{(\text{Target voltage rising}\ [\%] + D\ \%) \cdot V_{rated}}{100\ \%} + V_{target\text{-}prim} \right) \cdot \frac{V_{CT\text{-}sec}}{\sqrt{3} \cdot V_{CT\text{-}prim}}$$

[fo_ibs_sec_volt, 1, en_US]

For the voltage-transformer connection phase-to-phase, the reference must be multiplied with the factor √3. With a control deviation of D = 0 % to be tested and a setting value **Target voltage rising** of ***4.8 %*** in the example, this results in a secondary infeed voltage for the voltage-transformer connection phase-to-ground of:

$$V_{act\text{-}sec} = \left(\frac{4.8\ \% \cdot 10\,500\ V}{100\ \%} + 11\,000\ V\right) \cdot \frac{110\ V}{\sqrt{3} \cdot 15\,000\ V} = 48.7\ V$$

[fo_ibs_sec_volt_values, 1, en_US]

The infeed current for the 100 % load case is $I_{act\text{-}sec}$ = 0.733 A.

- Check the **X and R compensation**.

The control deviation results from the difference of the measured voltage $V_{act\text{-}prim}$ and a calculated compensated target voltage $V_{target\text{-}comp}$.

$$D = \frac{V_{act\text{-}prim} - V_{target\text{-}comp}}{V_{rated} \cdot 100\ \%}$$

[fo_ibs_target_comp, 1, en_US]

The calculated compensated target voltage is calculated from a numerically determined voltage V_{load} at the end of the line:

$V_{target\text{-}comp} = (V_{act\text{-}prim} - V_{load}) + V_{target}$

This numerically determined voltage V_{load} at the end of the line is determined form the parameters **X line**, **R line**, the flowing current $I_{act\text{-}prim}$ and the rotor angle φ.

The measured voltage at the voltage controller results from the dependency to the numerically determined voltage V_{load} and the flowing current $I_{act\text{-}prim}$ to:

$$V_{act\text{-}prim} = \sqrt{3} \cdot |\Delta V| + \sqrt{3 \cdot |\Delta V|^2 + V_{load}^2 - 3 \cdot I_{act\text{-}prim}^2 \cdot (X^2 + R^2)}$$

[fo_ibs_volt_prim_calcul, 1, en_US]

with $|\Delta V| = I_{act\text{-}prim} \cdot (\cos\varphi \cdot R + \sin\varphi \cdot X)$

If in the formula for V_{load} you insert the target voltage V_{set}, for the resulting control deviation this results in D = 0 %.

- Using the on-site operation panel or in DIGSI check whether the operational measured value ΔV has the value 0.

If you set the previous example values and for the parameter **R line** the value ***0.10 Ω*** and for the parameter **X line** the value ***0.15 Ω***, then this results in the following secondary infeed values at a rated load current of 5500 A and a cosφ = 0.707:

With a phase-to-ground connection

$$V_{act\text{-}sec} = V_{act\text{-}prim} \cdot \frac{V_{CT\text{-}sek}}{\sqrt{3} \cdot V_{CT\text{-}prim}} = 53.68\ V$$

[fo_ibs_input_values_LE, 1, en_US]

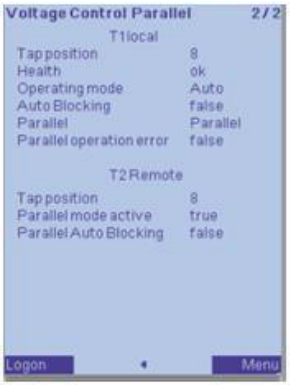
with $I_{act\text{-}sec}$ = 734 mA and φ_{load} = -45°

With a phase-to-phase connection

$$V_{act\text{-}sec} = V_{act\text{-}prim} \cdot \frac{V_{CT\text{-}sec}}{V_{CT\text{-}prim}} = 92.98\ V$$

[fo_ibs_input_values_LL, 1, en_US]

with $I_{act\text{-}sec}$ = 734 mA and φ_{load} = -75°



11.11.1.5 Voltage-Control Function for Parallel Transformers

Checking Settings of the Voltage Controller within a Group and of the GOOSE Communication

- For the functional test of **Voltage cont.2w**, route the indications *Health*, Local parallel mode, *Parallel-operation error*, and *Auto Blocking* to an LED.
- Check this routing.
- Route the GOOSE input indication *Cmd. with feedback* under **Voltage reg.2w** → **Parallel control** → **ParallelProxy** on one display page.

The tap positions received from the other voltage controllers are shown under:
Voltage reg.2w → **Parallel control** → **ParallelProxy**

- Switch all affected voltage controllers to parallel mode.

[sc_ibs_tap_changer_pos, 1, en_US]

Figure 11-28 Example of a User-Defined Display Page

If the indication *Parallel-operation error* is reported, the following causes are possible:

- Communication error
- Parallel-mode error – inconsistent setting **Parallel mode**
- Parameter **Parallel-transfomer id** inconsistent or identical on 2 voltage controllers
- Master error (number of Masters in the group ≠ 1), only with **Master-Follower method**
- Measured value invalid (for example with line compensation no current transformer assigned in the remote voltage controller)
- Mode error (inconsistent test mode of the voltage controllers)

You can find the reason for the indication in the operational log of the indication *Cause of par.op. error*.

NOTE

If the indication *Auto Blocking* and in **ParallelProxy**, the indication *Parallel Auto Blocking* are reported, the possible cause is that the remote voltage controller is blocked or the Follower-device with the **Master-Follower method** is in the ***Manual*** mode.

Checking Remote Measured Values

You can check the measured values received via GOOSE in the DIGSI Online Editor or on the on-site operation panel of the device under the following path:
Main menu → **Measurements** → **Voltage cont.2w** → **Function values** → **Parallel operat.** → **ParallelProxy**

Fundamental | **Function values** | Statistics | User-def. valu... | Power values

[sc_ibs_func_value, 1, en_US]

Figure 11-29 Functional Measured Values in DIGSI

Checking the Voltage-Control Function for Parallel Transformers

First you must check the tracking of the transformer taps in the operating mode ***Manual***. Proceed as follows:

- Switch the Master device to the operating mode ***Manual***.
- Switch the Follower devices to the operating mode ***Auto***.
- On the Master device, start a *Tap-position up command* for the tap changer.

The voltage controllers in Follower mode of the same group must also change to a higher tap once the new tap-changer position is reached.

- Check the tap position of the Follower devices on the device display of the on-site operation panel.
- Repeat the test with a *Tap-position down command*.

Checking the Voltage-Control Function of the Master-Follower Method

- Carry out the test items of the Voltage-controller function in *11.11.1.1 General* in the Master device.

NOTE

During this test note that the measured control voltage **Vact.m** is averaged from the measured voltages of all parallel voltage controllers and therefore the secondary voltage must be fed in with all voltage controllers.

Checking the Line Compensation

To check the **Z Compensation** (LDC-Z), proceed as follows:

The parameter **Target voltage rising** represents the voltage drop across the line as a % under rated load.

Since the rated load current in the Master and the Follower devices can be different, you must calculate the parameter **Target voltage rising** separately for each voltage controller.

- Next, based on the following reference, determine how high the percentage of the primary load current of the line is compared with the rated current of a transformer k (k = 1, 2, ..., 8).

$$I_{load\,k}\ (\%) = \frac{I_{load}}{I_{rated\,k}} \cdot 100\ \%$$

[fo_ibs_load_cur_perc, 1, en_US]

$$\Delta V_{load}\ (\%) = \frac{\Delta V_{prim}}{V_{target}} \cdot \frac{100\ \%}{I_{load}\ (\%)}$$

[fo_ibs_prim_load_voltage, 1, en_US]

The following calculation values result from the *Example, Page 2014*, which is shown in the setting notes in the chapter **Z Compensation**.

Parameters	Transformer T_1	Transformer T_2
Power-system data → **VT 3-phase:Rated primary voltage** $V_{CT\text{-}prim}$	11 kV	11 kV
Power-system data → **VT 3-phase:Rated secondary voltage** $V_{CT\text{-}sec}$	110 V	100 V
Power-system data → **CT 3-phase:Rated primary current** $I_{CT\text{-}prim}$	1500 A	3000 A
Power-system data → **CT 3-phase:Rated secondary current** $I_{CT\text{-}sec}$	1 A	5 A
Voltage cont. 2w → **General:Rated voltage** V_{rated}	10.5 kV	10.5 kV
Voltage cont. 2w → **General:Rated app. power transf.** S_{rated}	26 MVA	52 MVA
Voltage cont. 2w → **General:Rated current** I_{rated}	1430 A	2859 A
Target voltage V_{target}	11 kV	11 kV
Target voltage rising	4.8%	9.6%

- Based on the following table check the input currents and voltages for each voltage controller:

	Transformer T_1 Independent T_2 = off (I_2 = 0)	Transformer T_2 Independent T_1 = off (I_1 = 0)	Transformer T_1 Master Transformer T_2 Follower	
Input Values, Secondary				
I_{sec}	0.953 A	2.383 A	0.635 A	3.1833 A
Phase-to-ground V_{sec}	33.198 V	60.359 V	34.641 V	62.984 V
Phase-to-phase V_{sec}	57.501 V	104.54 V	60 V	109.1 V
Functional Measured Values				
V_{actual}	11.5 kV	11.5 kV	12.0 kV	12.0 kV
I_{load}	1430 A	1430 A	953 A	1910 A
$I_{load\sum}$	–	–	2860 A	2860 A
ΔV_{actual}	0 %	0 %	0 %	0 %
V_{target}	11.5 kV	11.5 kV	12.0 kV	12.0 kV

You can find more information in *7.9.4.5 Line Compensation*.

Checking the Voltage-Control Function with the Method of Minimizing the Circulating Reactive Current

The following secondary test is used to check the setting values. The current is fed into one voltage controller respectively and this current has a phase angle of -90° to the voltage.

- Also check the functional measured values for the circulating reactive current for the voltage controllers where no current is being fed in.

The following simplification results:
The current on one voltage controller is the total load current (I_{load}= I_k) and therefore the measured circulating reactive current has a dependency with the primary load current on a transformer:

$$I_{CRCk} = -1 \cdot \mathrm{Im}\left(I_{load\text{-}prim}\right)\left(1 - \frac{1}{X_k \cdot B_p}\right)$$

[fo_ibs_ccm_trafo, 1, en_US]

Where:

$B_p = \sum_{k=1}^{N} \frac{1}{X_k}$ Total susceptance value

X_k Transformer reactance on transformer k

The control deviation D_{CRCk} resulting from the circulating reactive current is determined in the voltage controller numerically according to the following formula:

$$D_{CRCk} = \text{Reactive I control factor}_k \cdot \frac{I_{CRCk} \cdot (X_k + \frac{1}{B_p - B_k}) \cdot \sqrt{3}}{V_{rated}} \cdot 100\ \%$$

[fo_regelabwdcc, 1, en_US]

The primary current to be fed in at a desired control deviation D_{CRCk} results:

$$\mathrm{Im}\left(I_{k\text{-}prim}\right) = -1 \cdot \frac{D_{CRCk} \cdot V_{rated}}{\text{Reactive I control factor}_k \cdot 100\ \% \cdot \sqrt{3} \cdot \left(1 - \frac{1}{X_k \cdot B_p}\right) \cdot \left(X_k + \frac{1}{B_p - \frac{1}{X_k}}\right)}$$

[fo_ibs_regelabwd_ccm, 1, en_US]

The current to be fed in is calculated from the following reference, with the phase angle to voltage being $\angle I_{actual\text{-}sec} = -90°$

$$I_{act\text{-}sec} = I_{k\text{-}prim} \cdot \frac{I_{CT\text{-}sec}}{I_{CT\text{-}prim}}$$

[fo_ibs_load_cur_prim, 1, en_US]

Example

Table 11-5 Example Values

Parameters	Transformer T_1	Transformer T_2
Power-system data → **VT 3-phase:Rated primary voltage** $V_{CT\text{-}prim}$	22 kV	11 kV
Power-system data → **VT 3-phase:Rated secondary voltage** $V_{CT\text{-}sec}$	110 V	100 V

Parameters	Transformer T_1	Transformer T_2
Power-system data → **CT 3-phase:Rated primary current** $I_{CT\text{-}prim}$	1500 A	3000 A
Power-system data → **CT 3-phase:Rated secondary current** $I_{CT\text{-}sec}$	1 A	5 A
Voltage cont. 2w → **General:Rated voltage** V_{rated}	10.5 kV	10.5 kV
Voltage cont. 2w → **General:Rated app. power transf.** S_{rated}	26 MVA	52 MVA
Voltage cont. 2w → **General:Rated current** I_{rated}	1430 A	2859 A
Target voltage V_{target}	11 kV	11 kV

For the transformer T_1 this results in the primary current at a desired control deviation of 1 % and the parameter **Reactive I control factor** = *1*:

$$\mathrm{Im}\left(I_{T1\text{-}prim}\right) = \frac{-1 \cdot 1\,\% \cdot 10\,500\ \mathrm{V}}{1 \cdot 100\,\% \cdot \sqrt{3} \cdot \left(1 - \frac{1}{0.42\ \Omega \cdot 6.38 \cdot \frac{1}{\Omega}}\right) \cdot \left(0.42\ \Omega + \frac{1}{6.38 \cdot \frac{1}{\Omega} - \frac{1}{0.42\ \Omega}}\right)}$$

[fo_ibs_regelabwd_ccm_values, 1, en_US]

- Check the function values in all voltage controllers according to the following table:

	Secondary Test Infeed Transformer T_1 for D = 1 %		Secondary Test Infeed Transformer T_2 for D = 1 %	
Input values, secondary	T_1	T_2	T_1	T_2
I_{sec}	0.09622 A -90° ph-gnd -150° ph-ph	0 A	0 A	0.4041 A -90° ph-gnd -150° ph-ph
Phase-to-ground V_{sec}	31.754 V	57.735 V	31.754 V	57.735 V
Phase-to-phase V_{sec}	55 V	100 V	55 V	100 V
Functional Measured Values				
V_{actual}	11.0 kV	11.0 kV	11.0 kV	11.0 kV
I_{load}	144 A	0 A	0 A	243 A
Phase angle	90°	–	–	0°
$I_{load\Sigma}$	144 A	144 A	243 A	243 A
I_{CRC}	90 A	-90 A	-91 A	91 A
ΔV_{act}	1 %	-1 %	-1 %	1 %
$\Delta V_{act\ u}$	0 %	0 %	0 %	0 %
$\Delta V_{act\ k}$	1 %	-1 %	-1 %	1 %

Checking the Pickup Value of the Circulating Reactive Current Blocking

If the value of the circulating reactive current exceeds the threshold value **Circul. current threshold** for a longer time than the set time delay **Circul. current time delay**, the indication *Circul. current blocking* is issued and the voltage control is blocked.

$$|I_{CRCk}| > \frac{\text{Circulating reactive current threshold}}{100\ \%} \cdot I_{rated}$$

[fo_ibs_ccm_cur_thresh, 1, en_US]

Therefore the secondary infeed current, where the phase angle to the voltage $\angle I_{act\text{-}sec} = -90°$, results in:

$$I_{k\,sec} > -1 \cdot \frac{\frac{\text{Circulating reactive current threshold}}{100\ \%} \cdot I_{rated\,k}}{\left(1 - \frac{1}{X_k \cdot B_p}\right)} \cdot \frac{I_{CT\text{-}sec}}{I_{CT\text{-}prim}}$$

[fo_ibs_ccm_cur_inp, 1, en_US]

The calculation from the values of *Table 11-5* for the transformer T_1 with a pickup value of 50 % results in:

$$I_{T1\text{-}sec} > -1 \cdot \frac{\frac{50\ \%}{100\ \%} \cdot 1430\ A}{\left(1 - \frac{1}{0.42\ \Omega \cdot 6.38\ \frac{1}{\Omega}}\right)} \cdot \frac{1\ A}{1500\ A}$$

[fo_ibs_ccm_cur_inp_value, 1, en_US]

With $I_{sec} > 0.76$ mA and $\angle_{act\text{-}sec} = -90°$

11.11.2 Primary Tests

If secondary test equipment is connected to the device, remove it or switch the test switch to the operating position.

- To be able to control the on-load tap changer manually, switch the voltage controller to the ***Manual*** operating mode.

NOTE

Be aware that a trip occurs in case of incorrect connections.

Checking the Polarity of the Voltage Transformer and Current Transformer

The correct connection of the current and voltage transformers is tested using the load current via the feeder to be controlled. For this, you must switch on the line or the protected object. A load current of at least 0.1 · I_{rated} must flow through the line or the protected object. The load current should be ohmic to ohmic inductive. The direction of the load current must be known. If there is a doubt, open meshed or ring systems.

The line or the protected object remains switched on for the duration of the measurements. You can derive the direction directly from the operational measured values.

- Make sure in DIGSI 5 or on the device with the following path that the power measured values correspond to the power direction:

  Main menu → **`Measured Values`** → **`Voltage cont.2w`** → **`Power values`**.

If active power flows in the line or the protected object, the power direction for **P** must be positive. If inductive reactive power flows in the line or the protected object, the power direction for **Q** must be positive. If the power measured values have a different sign than expected, then the power flow is opposite the current-direction definition. This can be the case, for example, at the opposite end of the low-voltage side of a transformer. The current-transformer neutral point then points in the direction of the protected object (for example, transformer). In this case, you must connect the **Measuring point I-3ph** in an inverted way to the function group **Voltage controller** in the function-group assignment (see chapter *Interface Between Function Group and Measuring Point, Page 59*).

Checking the Tap Direction and the Set Bandwidth

- Set the bandwidth according to the formula in chapter *7.9.4.3 Voltage Controller*.

The tap direction and the set bandwidth are checked with the following functional test.
With the correct tap direction, there will be a voltage increase when changing to a higher tap or a voltage reduction when changing to a lower tap.

- First switch the voltage controller to the ***Manual*** operating mode.
- Switch the tap changer to a higher or lower tap on the on-site operation panel or in the DIGSI Online-Editor until the voltage set point value is reached.
- Keep switching the tap changer higher until the bandwidth is exceeded.
  The difference in the control deviation I$\Delta V(n+1) - \Delta V(n)$I at a tap setting must be smaller than double the bandwidth.
- Switch the voltage controller to the ***Auto*** operating mode.
  After the parameterized time **T1**, the voltage controller should change to lower taps until the control deviation drops below the bandwidth.
- Switch the voltage controller back to the ***Manual*** operating mode.
  Keep switching the tap changer lower until the value drops below the bandwidth. The difference in the control deviation I$\Delta V(n-1) - \Delta V(n)$I at a tap setting must be smaller than double the bandwidth.
- Switch the voltage controller to the ***Auto*** operating mode.
  After the parameterized time **T1**, the voltage controller must change to higher taps until the control deviation drops below the bandwidth.

Checking the Circulating Reactive Current Sensitivity in Parallel Operation

The prerequisites for correct function of the parallel operation are the commissioning of the voltage controller in single operation and that the secondary tests have been completed.
For the functional test, the voltage controllers must be in the same parallel group according to the topology and the ***Manual*** mode as well as the **Method of minimizing the circulating reactive current** must be activated. In most cases, the default setting of the parameter **Reactive I control factor** is sufficient, since an optimal adjustment to the configuration takes place because of the entry of the parameter **General**:**Imp(Z): short circuit imp.** of the transformer.
If the control deviation is still larger than double the bandwidth due to the circulating reactive current at a tap-position difference of 1, alternating tap changing may take place. In this case, reduce the parameter **Reactive I control factor**.

NOTE

Carry out the following tests only at low load current.

- With all voltage controllers, approach ***one*** tap position which corresponds to the same no-load voltage to keep the circulating reactive current as low as possible and to reach the voltage set point value.
- Set one of the tap changers to a higher or lower tap. This results in a circulating reactive current.
  - If the difference of the circulating reactive current control deviation I$\Delta V_{actK}(n+1) - \Delta V_{actK}(n)$I is smaller than the set bandwidth, increase the parameter **Reactive I control factor**.
  - If the difference of the circulating reactive current control deviation I$\Delta V_{actK}(n+1) - \Delta V_{actK}(n)$I is larger than double the bandwidth, reduce the parameter **Reactive I control factor**.
- Repeat this test for all voltage controllers.

- With all voltage controllers, approach a *minimum* tap position where the same no-load voltages result everywhere, and repeat the following tests.
  - If the difference of the circulating reactive current control deviation $|\Delta V_{actK}(n+1) - \Delta V_{actK}(n)|$ is smaller than the set bandwidth, increase the parameter **Reactive I control factor**.
  - If the difference of the circulating reactive current control deviation $|\Delta V_{actK}(n+1) - \Delta V_{actK}(n)|$ is larger than double the bandwidth, reduce the parameter **Reactive I control factor**.
- Repeat this test for all voltage controllers.
- With all voltage controllers, approach a *maximum* tap position where the same no-load voltages result everywhere, and repeat the following tests.
  - If the difference of the circulating reactive current control deviation $|\Delta V_{actK}(n+1) - \Delta V_{actK}(n)|$ is smaller than the set bandwidth, increase the parameter **Reactive I control factor**.
  - If the difference of the circulating reactive current control deviation $|\Delta V_{actK}(n+1) - \Delta V_{actK}(n)|$ is larger than double the bandwidth, reduce the parameter **Reactive I control factor**.
- Repeat this test for all voltage controllers.

Since the transformer reactance can change slightly with the tap position, the points with *maximum* and *minimum* tap position mentioned in the preceding section are used to check the stable control.

Checking the Tap Direction and the Set Bandwidth in Parallel Operation with the Master-Follower Method

The following prerequisites apply for the following test:

- All transformers are switched on.
- All transformers feed to the same busbar.
- All voltage controllers are in parallel mode.
- The Master device is in the ***Manual*** operating mode.
- The Follower devices are in the ***Auto*** operating mode.

NOTE

Carry out these tests only at low load current.

The test sequence corresponds to the sequence under *Checking the Tap Direction and the Set Bandwidth, Page 2344*.

- In addition, test the manually updated tap position of the Follower devices.

If the current is measured on the involved voltage controllers, the line compensation or the circulating reactive current blocking is activated, you must check the currents.

NOTE

If a circulating reactive current forms despite the same tap position, there is an error in the tap-position assignment.

Performance of Current Tests

DANGER

Live system parts! Capacitive coupled voltages on dead parts!

Non-observance of the safety notes will result in death, severe injury, or considerable material damage.

✧ Primary measures may be performed only on dead and grounded system parts.

NOTE

These tests cannot replace a visual check of the correct current-transformer connections. Therefore, completed checks of the system connections are a prerequisite.

The SIPROTEC 5 device provides operational measured values. With these operational measured values, a fast commissioning without external instrumentation is possible.

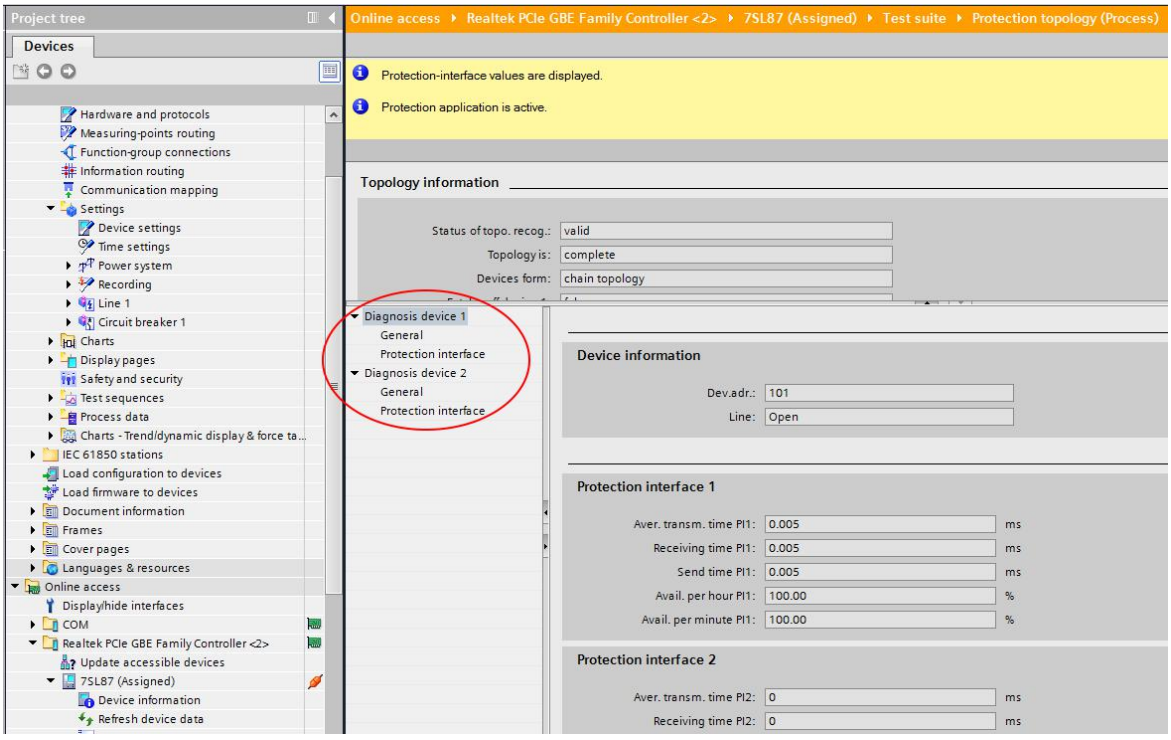
The following procedure is intended for 3-phase protected objects, that is, for measuring point 1 against measuring point 2. For transformers, it is assumed that side 1 is the upper-voltage side of the transformer. The other possible current circuits are tested in an analog way.

- Read out the differential and restraint currents under:
  Main menu → **`Measured values`**.
- Check the direction information of the *(_:302) Ground fault* indication in the fault log or in the ground-fault log. The direction information *forward* must be logged for the *(_:302) Ground fault* indication.
  If *backward* is determined as the direction, there is an inversion in the neutral path either for the current connections or for the voltage connections. If *unknown* is displayed, the ground current is probably too low.
- Switch off the line and ground it.

This completes the test.

11.12 Functional Test Protection Communication

11.12.1 Checking the Protection-Data Communication



Checking the Protection-Data Communication

If the devices are connected to one another via the protection interface and switched on, they contact each other automatically. If, for example, device 1 recognizes device 2, the successful connection is indicated (see next figure). Accordingly, each device signals to all devices that aProtection-data communication is available.

The following information is provided via the protection interfaces by the devices in the device combination:

- Address of the device in the device combination
- Circuit-breaker switch position (open/closed/undefined); only for protection interfaces of type 1
- Availability of the protection-interface communication within the last minute, as percentage
  Availability of the protection-interface communication within the last hour, as percentage
- Signal-transit time in the transmission and reception direction of the telegrams between the local device and the neighboring device

You can find this diagnostic data in DIGSI under the following menu structure:

[sc_protec, 1, en_US]

Figure 11-30 Diagnostic Data of the Protection-Interface Channels – Device Address

NOTE

To reset the measured values for the protection interface directly in the device, proceed as follows:
Device functions > x Device protection comm. > Protection interface y > Release measured values.

Proper communication of the devices among each other can be supervised during operation.

✧ Check the connections for each protection interface in DIGSI 5.

If a connection is successfully established, the **Status of topo recog.** field shows the indication *valid* in DIGSI 5 (see *Figure 11-30*).

If 2 devices are parameterized incorrectly, the **Status of topo recog.** field shows the indication *invalid* (see *Figure 11-30*).

In *Figure 11-31* there is no protection-data communication between device 1 and device 2, that is, the protection interfaces 1 and 2 of device 1 do not receive data. The transmission of protection data is interrupted and differential protection is ineffective. One reason for this can be a remote control with DIGSI via the protection interface. In this case, the protection connection is interrupted and the connection is used exclusively for DIGSI.

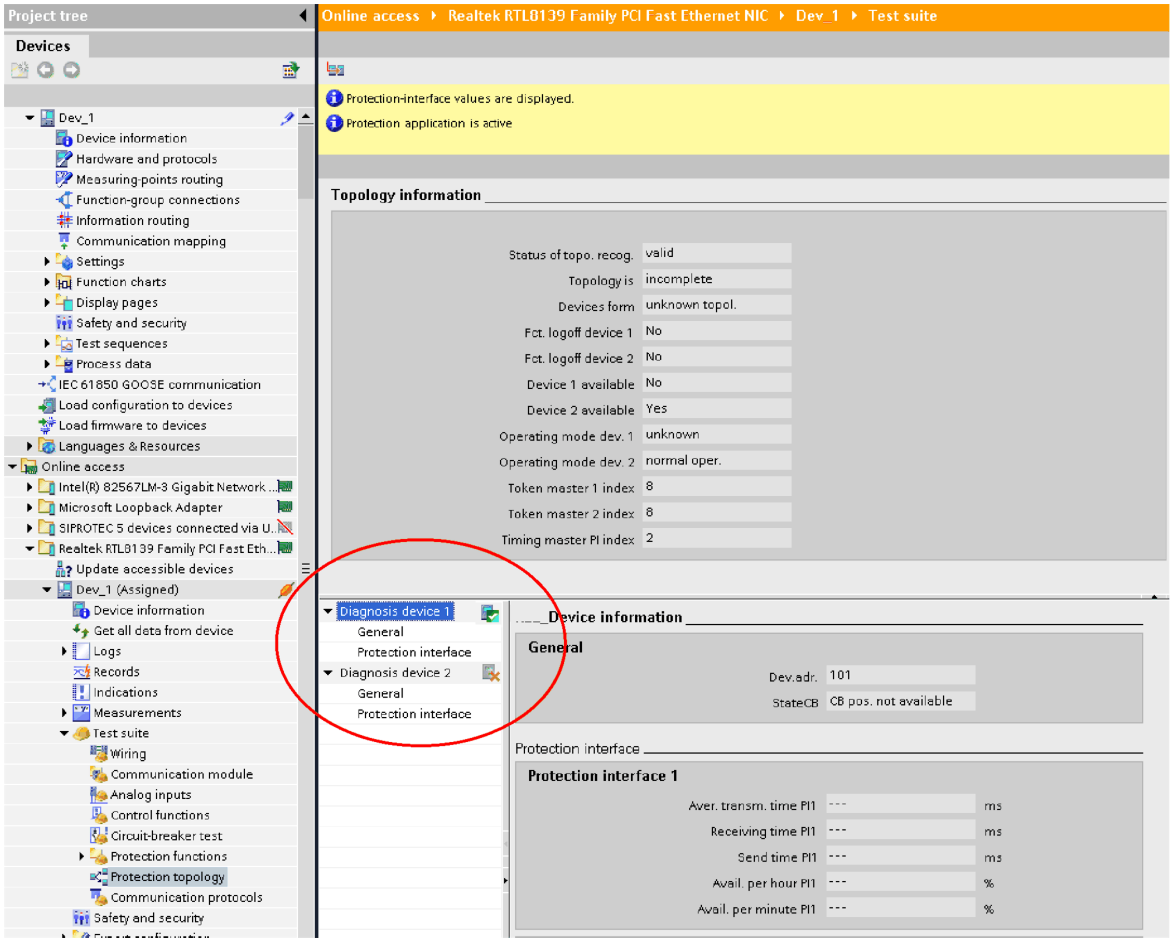


Figure 11-31 Protection-Data CommunicationDeactivated

11.12.2 Directional Test

In the case of protection interfaces of type 1 and type 2, the complex phasors of the voltage and current measuring point are exchanged between devices of one communication topology in order to be able to carry out a directional test during commissioning, for example. DIGSI 5 depicts this in the form of a phasor diagram. You can only route the measuring point to the protection interface. For 1 1/2 circuit-breaker layouts, a measuring point can therefore be transferred and checked optionally. You can also check and test the 2nd measuring point by rerouting. Furthermore, communication with DIGSI 5 can take place via the protection interface to other devices of the constellation. For this purpose, the protection-interface connection is interrupted and DIGSI 5 uses this connection for communication with the remote device.

✧ After completing the remote connection by DIGSI 5, the system switches back over to protection communication.

11.13 Functional Test for Overexcitation Protection

Secondary Test

NOTE

While performing the secondary test, ensure that the data of the protected object refer to the protection function.

This means that a mismatch between the voltage transformer and the protected object will be corrected automatically. For instance, when applying the secondary rated voltage and the rated frequency, this must not result in a V/f value of 1.

The mismatch of the voltage transformer must be taken into consideration when selecting the test voltage. Multiply the secondary test voltage with the following 'k' factor.

$$k = \frac{V_{rated,obj}}{V_{rated,transf.}}$$

[fo_kfakuf, 1, en_US]

Example

$V_{rated,obj}$ = 110 kV; $V_{rated,\ transf.}$ = 100 kV

It follows from the above that k = 1.1. For example, when verifying the nominal conditions if the secondary rated voltage is 100 V, a voltage of 1.1 * 100 V = 110 V must be supplied. The measured value of the function **Measured value V/f** must display 1.0000.

NOTE

When checking the dependent stage, ensure it is associated with a **thermal replica**. When repeating a test, always reset the replica, using the binary input indication **>Reset therm. replica** (_:13951:501).

Primary Test

The plausibility check between instantaneous overexcitation and the displayed operational measured value is used to verify the functionality of overexcitation.

Instantaneous overexcitation is a result of the following function:

$$\frac{V}{f} \cdot \frac{f_{rated}}{V_{rated}}$$

[fo_moweuf, 1, en_US]

where:

V	Instantaneous voltage
V_{rated}	Primary rated voltage of the protected object
f	Instantaneous frequency in f
f_{rated}	Rated frequency

11.14 Functional Test of Thermal Overload Protection

Secondary Test

For the secondary test for the overload protection, note that all setting parameters refer to primary variables of the protected object. The protection device extracts the current transformer ratio from the power-system data and internally performs the adjustments to device nominal variables. Take these characteristics into account for the test.

✧ Reset the thermal memory before you repeat the test. This is possible, for instance, via the binary input indication **>Reset thermal replica**. If the function is reparameterized or is switched off, the thermal replica will also be reset.

Test without Previous Load

✧ Test the operate time at 1.5 $I/I_{rated, obj.}$

In the example, the following power-system data are assumed:

$I_{rated, obj}$ = 483 A

$I_{rated, transf.prim}$ = 750 A

$I_{rated, transf.sec}$ = 1 A

The primary test current is 1.5 * 483 A = 724.5 A. This results in a secondary current of 724.5 A *1A/750A = 0.966 A. A secondary current of 0.966 A must therefore be supplied.

✧ Calculate the operate time with the following formula. Enter only primary variables here.

✧ Set $I_{previous\ load}$ = 0. The setting parameters reveal the **K-factor** (for example, 1.1) and the **Thermal time constant** (for example, 600 s or 10 min).

✧ Test from the cold state.

$$t = \tau_{th} \cdot \ln\left(\frac{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - \frac{1}{k^2}\left(\frac{I_{preload}}{I_{rated,obj.}}\right)^2}{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot \ln\left(\frac{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 0}{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\ s \cdot 0.772 = 463\ s$$

[fo_auslpr, 2, en_US]

✧ At a current of 0.966 A supplied on the secondary side, the protection function must trip after 463 s.

Test with Previous Load

✧ The object rated current ($I_{previous\ load} = I_{rated, obj}$) flows at a previous load of 1 (100 %).

✧ Supply 483 A *1 A/750 A = 0.644 A in this case.

After a finite time (greater than 5 τ_{th}), the stationary previous load sets in.

K-factor

✧ If you abruptly increase the supplied secondary current from 0.644 A to 0.966 A (1.5 $I/I_{rated, obj}$), the overload protection will trip in the following time.

$$t = \tau_{th} \cdot \ln\left(\frac{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - \frac{1}{k^2}\left(\frac{I_{preload}}{I_{rated,obj.}}\right)^2}{\frac{1}{k^2}\left(\frac{I}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot \ln\left(\frac{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - \frac{1}{1.1^2}\left(\frac{1.0 I_{rated,obj.}}{I_{rated,obj.}}\right)^2}{\frac{1}{1.1^2}\left(\frac{1.5 I_{rated,obj.}}{I_{rated,obj.}}\right)^2 - 1}\right) = 600\,s \cdot 0.184 = 110\,s$$

[fo_auslpr, 2, en_US]

NOTE

Owing to the relatively large time constants in practice, the tests are carried out with significantly reduced time constants. Reset the original setting value after completing the tests.

11.15 Functional Test Hotspot Calculation

11.15.1 Secondary Test

NOTE

For the secondary test of the **Hotspot calculation** function, note that all setting parameters refer to the primary variables of the protected object. The protection device considers the current transformer ratio from the power-system data and adapts the data to the device-rated variables. Take this behavior into account for the test.

- Reset the thermal memory before you repeat the test. This is possible, for instance, via the binary input indication *>Reset thermal replica*. If you change the settings of the function or switch it off, the thermal image is also reset.
- Check the calculated hotspot temperature at a load current of $1.5 \cdot I/I_{rated, Obj}$.

Once the oil or turn time constant has expired, the hotspot temperature comes from the measured oil temperature and the temperature difference between the hotspot and the top-oil temperature.

Example

If the measured oil temperature is a uniform 70 °C, a temperature differential results between the hotspot and the top-oil temperature of:

IEC 60076-7

$\Delta\Theta_{H,V}(t) = K^{Y}H_{gr}$

$Y = 1.6$

$H_{gr} = 22$

$K = 1.6$

IEEE C57.91 2011

$\Delta\Theta_{H,V}(t) = K^{2m}H_{gr}$

$m = 0.8$

$H_{gr} = 22$

$K = 1.5$

In steady state, the hotspot temperature settles to $\Theta_h(t) = 114$ °C.

NOTE

Owing to the relatively large time constants in practice, the tests are carried out with significantly reduced time constants. Reset the original setting value after completing the test.

11.16 Reverse-Power Protection

11.16.1 Secondary Test

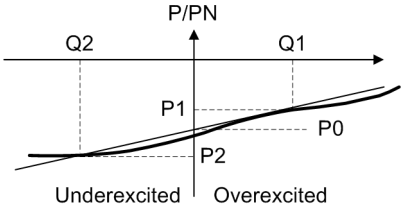
When performing the secondary test, note that the setting value for the reverse power refers to the machine variables. Due to the mismatching of the current transformer, you must check with reduced currents. You can deduce the reduction from the ratio $I_{rated,\ generator}$/ $I_{rated,\ CT}$. Check the reverse-power protection at rated voltage.

If the voltage transformer is not adjusted to the rated generator voltage, correct the secondary voltage, too. Use the following ratio:

$V_{rated,\ generator}/V_{rated,\ VT}$

11.16.2 Primary Test

For measurements on the protection current transformers and with sensitive setting of the reverse-power protection, Siemens recommends determining the reverse power and the angle-correction values. Regardless of the generator excitation, that is regardless of the reactive power Q, the reverse power P as a pure active power is constant. The resulting characteristic curve is a straight line that runs parallel to the Q axis. Due to possible angle errors of current transformers and voltage transformers, the protection device does not measure a constant active power. The current flowing at this time, which can be assumed as being proportional to the reactive power, has a substantial influence.



The deviations are determined with 3 measurements and the correcting quantity φ_{corr} is determined from the results.

To calculate the correction angle, enter the active power and reactive power measured with the device in the following table.

Use the functional measured values **`P1avg`** and **`Q1avg`** (type averaged).

Table 11-6 Value Table for Angle Correction

State	Reverse Power	Reactive Power
Reactive power near zero	P_0 =	Q_0 =
Overexcited	P_1 =	Q_1 =
Underexcited	P_2 =	Q_2 =

[dw_rpp_correction_angle, 2, en_US]

Figure 11-32 Determining the Correction Angle φ_{corr}

CAUTION

Be careful if you operate the turbine without a certain minimum steam flow (cooling effect).

Operating the turbine without a certain minimum steam flow (cooling effect) can overheat the turbine blades!

✧ The consumption of reverse power for a turbo-generator set is only allowed for a short time!

CAUTION

If the generator is underexcited, there is the risk of an out-of-step condition!

Non-observance of the following measures can result in minor personal injury or material damage.

✧ The following measures prevent the risk of an out-of-step condition.

✧ Regulate the driving power to 0 by closing the control valves. The generator draws its reverse power from the electrical power system.

✧ Change the excitation until the reactive power Q = 0. As a control measurement, read the active power P_0 and the reactive power Q_0 with the sign, and enter the values in *Table 11-6*.

✧ Increase the excitation slowly until reaching approx. 30 % of the rated apparent power of the generator (overexcited).
Read the reverse power P_1 with the sign (negative) and the reactive power Q_1 with the sign (positive) in the functional measured values and note these 2 values in the values table.

✧ Reduce the excitation slowly until reaching approx. 30 % of the rated apparent power of the generator (underexcited).
Read the reverse power P_2 with the sign (negative) and the reactive power Q_2 with the sign (negative) in the functional measured values and note these 2 values in the values table.

✧ Run the generator again at no-load excitation and select the desired operating state.

✧ With the measured value pairs (P_1, Q_1 and P_2, Q_2), calculate the correction angle ϕ_{corr} with the following formula:

$$\varphi_{corr} = \arctan \frac{P_1 - P_2}{Q_1 - Q_2}$$

[fo_RPP correction angle, 2, en_US]

NOTE

Insert the power values with the signs that you read previously!

✧ Enter this angle φ_{corr} with the same sign as the new correction angle (parameter ***(_:2311:101) Angle correction***):

Setting value ***(_:2311:101) Angle correction*** = φ_{corr}

✧ You can determine the pickup value of the reverse-power protection from the measured values P1 and P2.

Use the following formula: $P_{pickup} = (P_1+P_2)/4$

Set the value as pickup value: Parameter **(_:991:3) Threshold** = ***Ppickup***

Check of the Reverse-Power Protection

With a generator that is connected to the power system, the reverse power results from closing the control valves or from closing the quick stop.

✧ In both cases, check the consumed active power (reverse power). The valves could be leaking.

✧ Repeat the reverse-power measurement to confirm that the settings are correct.

- ✧ To check the efficiency of the reverse-power protection on the basis of the indications, use the parameter **(_:991:1) Mode** to switch the reverse-power protection to ***test*** .
  Proceed as follows:
- ✧ Start the generator and synchronize it with the power system.
- ✧ Close the control valves.
- ✧ From the functional measured value, take the reverse power that was measured by the protection device as the active power. Use 50 % of the functional measured value as setting value for the reverse-power protection.
- ✧ Increase the driving power up to normal operation.
- ✧ Check the quick-stop criterion.
  Proceed as follows:

NOTE

Make sure that the binary input **>Stop valve closed** is properly routed. The quick-stop criterion (the pressure-operated switch or the limit switch on the quick-stop valve) must control this binary input.

- ✧ Close the quick-stop valve.
- ✧ From the functional measured value **P1avg** , take the reverse power that was measured by the protection device as the active power.
- ✧ If – contrary to expectations – this value is smaller than the reverse power when the control valves are closed, take 50 % of this value as the setting value for the reverse-power protection.
- ✧ Shut down the machine by activating the reverse-power protection. Set the parameter **(_:991:1) Mode** to ***on*** .

11.17 Primary and Secondary Tests of the Circuit-Breaker Failure Protection

Integration of the Protection Function into the Station

The integration of the protection function into the station must be tested in the real-life application. Because of the multitude of possible applications and possible system configurations, the required tests cannot be described here in detail.

NOTE

Always keep the local conditions, the station plans, and protection plans in mind.

NOTE

Siemens recommends isolating the circuit breaker of the tested feeder at both ends before starting the tests. Line disconnector switches and busbar disconnector switches must be open so that the circuit breaker can be operated without risk.

General Precautions

CAUTION

Tests on the local circuit breaker of the feeder cause a trip command to the output to the adjacent (busbar) circuit breakers.

Noncompliance with the following measure can result in minor personal injury or material damage.

✧ In a first step, interrupt the trip commands to the adjacent (busbar) circuit breakers, for example, by disconnection of the corresponding control voltages.

For testing the circuit-breaker failure protection, it must be ensured that the protection (external protection device or device-internal protection functions) cannot operate the circuit breaker. The corresponding trip command must be interrupted.

Although the following list does not claim to be complete, it can also contain points, which have to be ignored in the current application.

Test Modes

The device and the function can be switched to test mode. These test modes support the test of the function in different ways:

Test Modes	Explanation
Device in test mode	This operating mode is relevant for the following tests: 1. Approach of current thresholds in the case of an external start: Supervision of the binary input signals in the case of an external start is disabled. This setting allows a static activation of the starting signals in order to approach the current threshold. 2. Check whether the issued trip commands actuate the corresponding circuit breakers, because the device contacts are also actuated in the device test mode.
CBFP function in test mode (device is NOT in test mode)	This operating mode is important for function tests in which the generated operate indications are NOT supposed to actuate the binary outputs.

NOTE

When the function or device is in test mode, all indications are given a test bit.

NOTE

In the mode **Device in test mode**, the operate indications generated by the function operate the binary outputs.

The function must also be tested in its normal, switched-on condition.

Consider the following in this case:

- ✧ The device contacts are actuated.
- ✧ Binary input signal supervision (in the case of an external start) is enabled and blocks the function.
- ✧ All indications generated are generated without test bit.

Circuit-Breaker Auxiliary Contacts

When circuit-breaker auxiliary contacts are connected to the device, they make an essential contribution to the reliability of the circuit-breaker failure protection, provided that their settings are set accordingly.

- ✧ Make sure that the correct assignment has been checked.

Internal Starting Conditions (Trip Command from Internal Protection Function)

The internal start can be tested by means of tripping a protection function, for example, the main protection function of the device.

- ✧ Check the settings for circuit-breaker failure protection. See also chapter *6.62.4 Application and Setting Notes*.
- ✧ For the circuit-breaker failure protection to be able to pick up, a phase current (see current-flow criterion) must be present. This can be generated by a device-internal test sequence (see description in the *Operating manual*). It can also be a secondary test current.
- ✧ Generate the trip for the protection function. This can be generated within the device by a test sequence (see description in the *Operating manual*) or by creating corresponding secondary test values.
- ✧ The trip command(s) and their time delay compared to the pickup, depending on the parameterization.

External Starting Conditions (Trip Command from External Protection Function)

If external protection devices are also able to start the circuit-breaker failure protection, the external starting conditions require checking.

- ✧ Check the settings for circuit-breaker failure protection.
  See also chapter *6.62.4 Application and Setting Notes*.
- ✧ For the circuit-breaker failure protection to be able to pick up, a phase current (see current-flow criterion) must be present. This can be generated by a device-internal test sequence (see description in the *Operating manual*). It can also be a secondary test current.
- ✧ Activate the binary input or inputs to which the start signal and possibly also the release signal for the CBFP function are routed. This can be done in 2 ways:
  – 1) Via internal test sequences
  – 2) By controlling the binary input or inputs via an auxiliary voltage
- ✧ Check the start input signal, and if available, check the enable input signal in the spontaneous or fault messages.
- ✧ Check the pickup indication in spontaneous or fault indications.
- ✧ The trip command(s) and their time delay compared to the pickup, depending on the parameterization.

Start by Trip Command from the External Protection

- ✧ Check the static and - in case of 2-channel operation - also the dynamic supervision of the binary input signals. For this purpose, induce pickup of the supervision and check the supervision indications and the ready signal in the event log buffer.

Start by Trip Command from the External Protection without Current Flow

- ✧ If start is possible without current flow: (see **Start by trip command from the external protection**).

Repetition of the Local Tripping (T1)

- ✧ Make sure that the trip repeat signal controls a 2nd circuit (2nd coil) for switching off the circuit breaker.

Backup Tripping in the Case of a Circuit-Breaker Failure (T2)

For tests in the station, it is important to check that the distribution of trip commands to the adjacent circuit breakers in the case of a circuit-breaker failure is correct. The adjacent circuit breakers are all circuit breakers, which must be tripped in order to ensure interruption of the short-circuit current if the feeder circuit-breaker fails. They are therefore the circuit breakers of all feeders which feed the busbar or busbar section to which the feeder with the fault is connected.

A general detailed test guide cannot be specified because the layout of the adjacent circuit breakers depends largely on the system topology.

- ✧ With multiple busbars, the trip distribution logic for the adjacent circuit breakers must be checked.

  The test has to check for every busbar section that, in case of a failure of the feeder circuit-breaker under observation, only those circuit breakers which are connected to the same busbar section are tripped.

Backup Tripping on Circuit-Breaker Failure (T2), Tripping of the Opposite End

If the trip command of the circuit-breaker failure protection must also trip the circuit breaker at the opposite end of the tested feeder, the communication channel for this remote trip has to be tested as well.

- ✧ It is practical to test the communication channel for the remote trip while transmitting other signals in accordance with *11.12.1 Checking the Protection-Data Communication*.

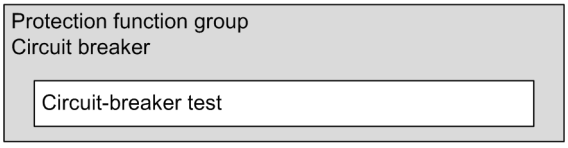
Termination

- ✧ All temporary measures taken for testing must be undone, such as special switch positions, interrupted trip commands, changes to setting values, or individually switched off protection functions.

11.18 Circuit-Breaker Test

The **Circuit-breaker test** function enables you to easily perform a complete test of the trip circuit, the closing circuit, and the circuit breaker. For this, the circuit-breaker test carries out an automatic opening and closing cycle or an only-open cycle of the circuit breaker during operation. You can also include a current-flow criterion in the test. The effect of the current-flow criterion is to ensure the circuit-breaker test is only carried out if the current flow across the circuit breaker is below the parametrizable threshold.

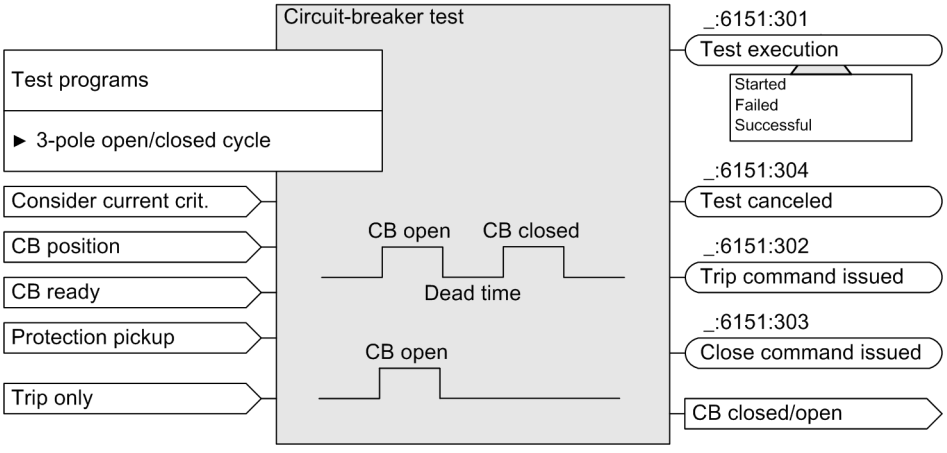
NOTE



If the circuit-breaker auxiliary contacts are not connected, a circuit breaker that has been opened can be permanently closed.

The following test program is available for you to carry out the circuit-breaker test.

No.	Test Program
1	3-phase open/closed cycle



Structure of the Function

The **Circuit-breaker test** function is used in protection function groups for circuit breakers.

[dw_cbch01, 1, en_US]

Figure 11-33 Embedding of the Function

[dw_zecbc3p2, 2, en_US]

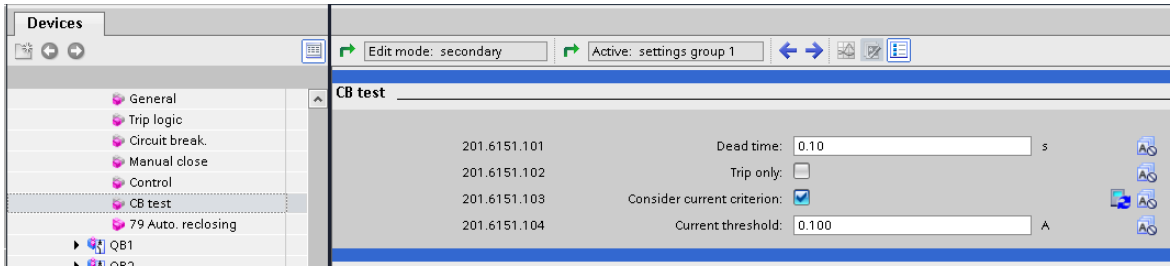


Figure 11-34 Structure of the Function

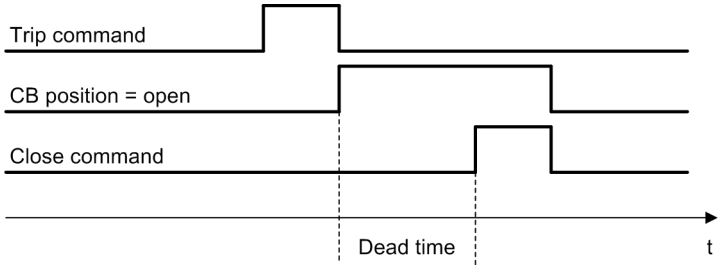
Test Procedure

The following conditions must be satisfied before the circuit-breaker test can start:

- ✧ If a circuit-breaker auxiliary contact signals the position of the breaker pole to the device via the binary inputs of the signal **`Position`**, the test cycle is not initiated unless the circuit breaker is closed.
- ✧ If the circuit-breaker auxiliary contact has not been routed, you must ensure that the circuit breaker is closed.
- ✧ The circuit breaker must be ready for an open-closed-open or only-open cycle (indication **`>Ready`**).

✧ A protection function must not have been picked up in the circuit-breaker protection function group responsible for the circuit breaker.



[sc_cbtest3p, 1, en_US]

Figure 11-35 Settings for the Circuit-Breaker Test

Figure 11-36 shows the progression over time of an open-close cycle. If you activated the **(_:6151:102) Trip only** option, the close command will not be executed and the dead time will not be taken into account.

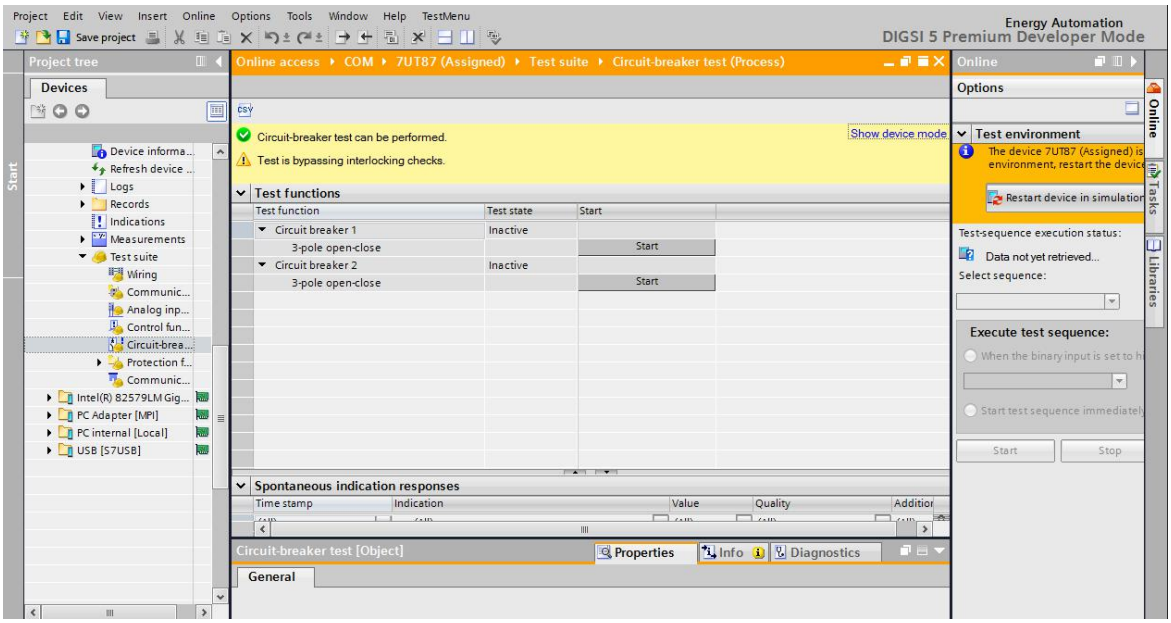
If a circuit-breaker auxiliary contact is connected, the function waits for the indication circuit breaker **Position** = ***open*** after the trip command is generated. When the indication **Position** = ***open*** is received, the close command is transmitted after a dead time (parameter **(_:6151:101) Dead time**) for an open-close cycle. If the feedback from the circuit-breaker positions is not received within the maximum transmission time (**Dead time** + 2 · **Output time** + 5 s), the circuit-breaker test is aborted and considered to be failed. The proper functioning of the circuit breaker is monitored via the feedback on the circuit-breaker positions.

[dw_cbch03, 1, en_US]

Figure 11-36 Progress over Time of a Circuit-Breaker Test Cycle

Use the **(_:6151:103) Consider current criterion** parameter to ensure the circuit-breaker test is only carried out when the current flowing through the circuit breaker does not exceed a specific current threshold (parameter **(_:6151:104) Current threshold**). Otherwise, the circuit-breaker test is not started.

✧ If the current-flowcriterion is deactivated, the current threshold is not evaluated. The circuit-breaker test is performed irrespective of the current-flow level through the circuit breaker.



NOTE

The circuit-breaker test does not perform a synchrocheck even if the synchrocheck has been configured in the protection-function groups for circuit breakers. This can cause stability problems in the system during a 3-pole interruption. Therefore, a 3-pole circuit-breaker test should be very short, or not performed at all under load.

You can start the test program as follows:

- Via the device-control panel
- Via DIGSI
- Via communication protocols
- Via control commands, which you can also connect in the CFC

The following figure illustrates operation of the circuit-breaker test in DIGSI.

[sc_cb_3pol, 1, en_US]

Figure 11-37 Circuit-Breaker Test in the Test Suite in DIGSI

- ✧ Select the function in the project tree on the left in the online access.
- ✧ Start the desired test program in the upper portion of the working area.
- ✧ The corresponding feedback is displayed in the bottom portion of the working area. Additional information about the behavior of other functions while the circuit-breaker test is being performed can be read in the operational log.

11.19 Functional Test of the Inrush-Current Detection

General

- ✧ For the test, make sure that the test current reflects the typical inrush current.
- ✧ Perform the test with transient signals. These can be recorded inrush currents or simulated currents from a transient system model.
- ✧ When using synthetic signals, observe the notes on the individual measuring principles.

Harmonic Analysis

- ✧ Superimpose on the fundamental-component current a test current of double frequency (2nd harmonic) and test the pickup behavior with this.
- ✧ Cause a threshold value excess (internal pickup) for one of the protection functions that you want to block.

  - or -

- ✧ Apply a test current with a load current as lead (current step).

The inrush current detection creates a blocking signal.

CWA Process

- ✧ Create a test current that has flat ranges of a minimum width of 3 ms simultaneously in all 3 phase currents.

The inrush current detection creates a blocking signal.

11.20 Functional Test of Transient Ground-Fault Protection

General

This function requires the correct polarity of the ground current IN and the neutral-point displacement voltage VN respectively the zero-sequence voltage V0.For the direction test of these quantities, refer to *11.17 Primary and Secondary Tests of the Circuit-Breaker Failure Protection*.

The function is based on the evaluation of the transient in the zero-sequence system after the ground-fault ignition.

For issuing the signal *(_:13021:302) Ground fault*, the following 2 conditions must be met:

- There is a transient in the ground quantities.
- The fundamental compoment of the zero-sequence voltage V0 exceeds the threshold **(_:13021:103) V0> threshold value**.

The following 2 methods are available for testing of the signal *(_:13021:302) Ground fault*:

- Replaying real transient ground-fault recordings to the device
- Using secondary test equipment which allows to simulate transients ground faults

However, the setting of parameter **(_:13021:103) V0> threshold value** cannot be tested precisely with the mentioned 2 methods, since this test requires a static V0. An easy way to test the setting is described in the following.

Secondary Test

This test must be carried out by injecting static secondary quantities. The test equipment needs to be configured in a way that it generates zero-sequence current 3I0 and zero-sequence voltage V0, which are injected to the SIPROTEC 5 device. By carrying out a shot, for example, a status change from zero-sequence values of 0 A and 0 V to the values not equal to zero, a transient is generated. The signal *(_:13021:302) Ground fault* is issued as long as the static zero-sequence voltage of the 2nd state is greater than the set threshold. As amplitude for the secondary 3I0, 100 mAis a suitable value. In this test, the directional result contained in the signal *(_:13021:302) Ground fault* is not defined and relevant, since the task is to test the setting of parameter **(_:13021:103) V0> threshold value** only.

For testing the threshold, shots must be carried out with a static V0 slightly below the threshold and slightly above the threshold, for example, to 98 % and 102 % of the threshold value or to a threshold value of -0.2 V and +0.2 V (the greater absolute deviation of the threshold value must be selected) .

Consider that the V0 threshold is defined according to the definition of the symmetrical components. A full neutral-point displacement voltage VN of 100 V causes V0 = 57.7 V.

Example

- **(_:13021:103) V0> threshold value** = 15 V
- 3 shots from 0 to V0 = 14.7 V and 3I0 = 100 mA
  No signal *(_:13021:302) Ground fault* is issued.
- 3 shots from 0 to V0 = 15.3 V and 3I0 = 100 mA
  Signal *(_:13021:302) Ground fault* is issued

If the test result is not as expected, check the injected static V0 voltage via the operational measurement of the device which contains the zero-sequence components.

11.21 Functional Test of the Trip-Circuit Supervision

General

- ✧ For the test, make sure that the switching threshold of the binary inputs is clearly below half the rated value of the control voltage.

2 Binary Inputs

- ✧ Make sure that the binary inputs used are isolated.

1 Binary Input

- ✧ Make sure that, in the circuit of the 2nd circuit-breaker auxiliary contact, an equivalent resistance R is connected.
- ✧ Observe the dimensioning notes under the section **Equivalent resistance R**.

11.22 Functional Test for the Phase-Rotation Reversal

- ✧ Check the phase sequence (direction of rotating field) at the device terminals. It must correspond to the setting of the **Phase sequence** parameter.
- ✧ The output indication *Phase sequence ABC* or *Phase sequence ACB* displays the determined phase sequence. This must correspond to the phase sequence that was set.
- ✧ You can also determine the phase sequence via the **Symmetrical components** measured values. If you obtain negative-sequence system variables (V_2, I_2) and no positive-sequence system variables (V_1, I_1) with symmetrical 3-phase infeed, the setting parameter **Phase sequence** does not correspond to the connection.

11.23 Primary and Secondary Testing of the Synchronization Function

Measuring the Circuit-Breaker Make Time

Under asynchronous system conditions, the circuit-breaker make time must be measured and set correctly. This achieves an exact parallel switching with a phase angle 0°. If switching occurs only in synchronous system conditions, this section can be skipped.

The make time can be determined via the following 2 methods:

- By reading from a fault record (recommended method)
- With external timer

1. A simple option for determining the make time involves reading the time between the close command and closure of the switch pole via the fault record. The time determined here is the real make time and not the operating time of the circuit breaker. You do not have to add any further time.

Siemens recommends the following procedure:

✧ Establish a condition in which the circuit breaker can be closed without hazard.

✧ If V2 is switched through, activate the operating mode **Close cmd. at V1< & V2>** for the synchronization stage[70] or by setting it to ***yes***.

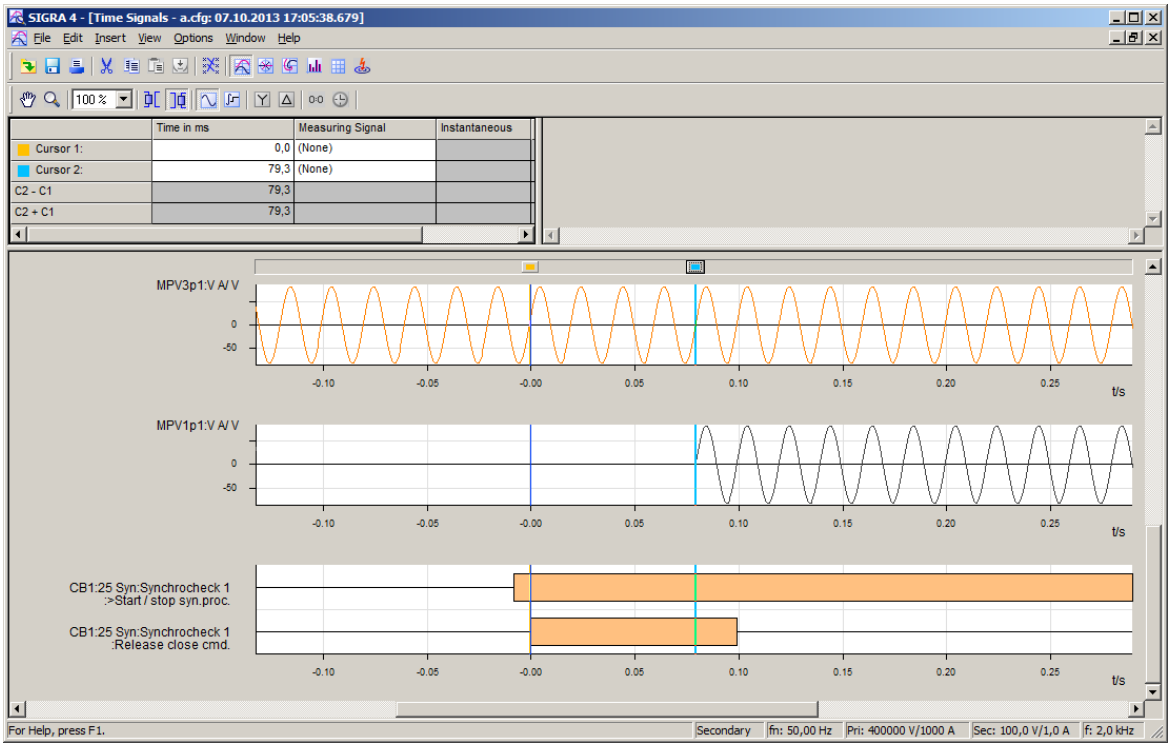
If V1 is switched through, activate the operating mode **Close cmd. at V1> & V2<**.

✧ Make sure that the fault recorder is turned on. Via a temporary CFC chart, link the signal **Release close cmd.** of the active synchronization stage to the binary input signal **>Manual start** (of the fault recorder). With the release of closure, a fault record of the parameterized duration is set up (the default setting of 500 ms is more than adequate for this).

✧ Starting the synchronization stage. The device activates immediately.

✧ Read the fault record and determine the make time via SIGRA (see *Figure 11-38*).

Use the 2 cursors and the time-measuring function for this. Position the first cursor on the raising close command. The occurrence of the 2nd voltage signals the closed power-switching poles. Place the 2nd cursor on the raising 2nd voltage.



✧ Set the determined time with the parameter **CB make time**.

Proceed in the same way for all other synchronization stages.

✧ Set the parameter **Close cmd. at V1< & V2>** or parameter **Close cmd. at V1< & V2<** back to its source value.

✧ Delete the CFC chart.

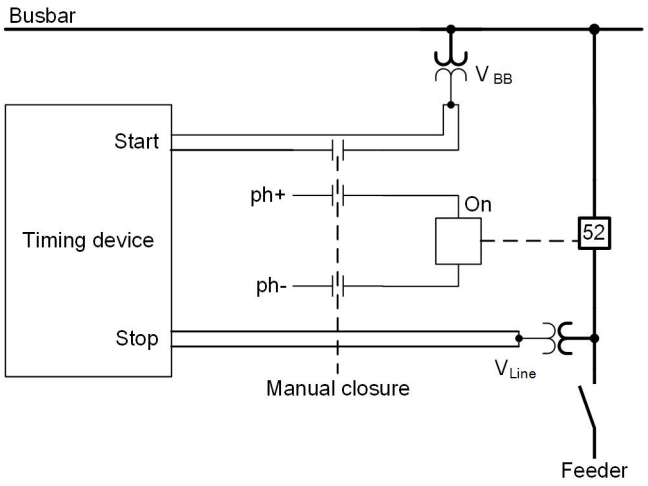
70 Synchronization stage represents the stage **Synchrocheck**, **Synchronous/Asynchronous (Sychr./Asycr.)**, or **Synchronous/asynchronous with balancing commands (Syn./Asy.bal.)**.

[sc_syn001-01, 2, en_US]

Figure 11-38 Measurement of the Circuit-Breaker Make Time

2. The configuration in *Figure 11-39* is suitable for measuring the circuit-breaker operating time with an external timer. Set the timer to the range 1 s or a tripping of 1 ms.

Connect the circuit breaker manually. The timer is started simultaneously by this. After the poles of the circuit breaker close, the voltage V_{Line} appears. The timer is then stopped.



If the timer is not stopped owing to an unfavorable closing moment, repeat the attempt.

Siemens recommends calculating the average value from several (3 to 5) successful switching attempts.

NOTE

Add the OOT (Output Operating Time) of the protected device to the measured time. The OOT exclusively depends in good approximation on the binary output used for the close command. You can find the OOTs for different binary outputs in *12 Technical Data*. Set the total time with the parameter **`CB make time`**. Proceed in the same way for all other synchronization stages used in the device.

Siemens recommends sending the close command via the hard-wired connection. If you use a GOOSE signal to send the close command, consider the time delay caused by the GOOSE communication while setting the parameter **`CB make time`**.

[dw_synae6-01, 2, en_US]

Figure 11-39 Measurement of the Circuit-Breaker Make Time

Checking the Measurement Chain

The measurement chain for the voltage measurement must be checked. As soon as one of the synchronization stages to be used is closed, all the necessary functional measured values are calculated. The synchronization stage, thus, does not have to be started for this check.

Proceed as follows when checking the measurement chain as a primary or secondary test:

a) As primary test

- ✧ Establish a synchronous state by closing the circuit breaker, if possible.
- ✧ Check the functional measured values within the synchronization function:
  – The delta values must be 0.
  – Check the voltages V1 and V2 for plausible values in comparison with the operational measured values for the voltage.
  – Check the frequencies f1 and f2 for plausible values in comparison with the operational measured value for the frequency.

b) As secondary test

- ✧ Establish a synchronous state by applying synchronous voltage values at both measuring points.
- ✧ Check the functional measured values within the synchronization function:
  – The delta values must be 0.
  – Check the voltages V1 and V2 for plausible values in comparison with the operational measured values for the voltage.
  – Check the frequencies f1 and f2 for plausible values in comparison with the operational measured value for the frequency.

Blind Switching Attempts when Used in Machines

Perform blind switching attempts when using the function in machines.

Prerequisite:

- ✧ You have checked the setting values again.
- ✧ The circuit breaker is switched off. The close command for the circuit breaker is interrupted (disconnecting the close command). The system voltage is switched through for the measurement.

a) Attempt with asynchronous systems:

- ✧ Via manual control, set the generator to a speed slightly below the permitted frequency difference according to the setting values **Max. frequency diff. f2>f1** and **Max. frequency diff. f2<f1**. The generator is excited to line voltage. You can read out the values in the operational measured values.
- ✧ Start the synchronization stage, for example, externally with binary input signal or via the integrated controller. You can use a synchronoscope to trigger the start at synchronism, that is, at **12 o'clock**. The duration until the close command then corresponds to a cycle with the duration 1/Δf. At a frequency difference of 0.1 Hz, the duration is thus 10 s.
- ✧ Insofar as permissible, perform this attempt several time for oversynchronous switching and subsynchronous switching.
- ✧ The switching performance can be checked with an external recorder or the integrated fault recording function. You have to start the fault recording explicitly.
- ✧ You can repeat the blind switching attempts at the limits of the permissible voltage difference.

b) Attempt with synchronous systems:

- ✧ Start the synchronization stage, for example, externally with binary input signal or via the integrated controller.
- ✧ Check the proper release for activation with the message log or via a fault record. You have to start the fault recording explicitly. All activation conditions have to be fulfilled within the time **Delay close command**.

  If you observe the change between synchronous and asynchronous operation, raise the changeover threshold **f-threshold ASYN<->SYN** slightly.

c) Attempt with synchrocheck:

- ✧ If you use this function in conjunction with the manual synchronization, check the proper release for closure.
- ✧ Synchronize the generator manually. Start the synchronization stage externally via a binary input. Check the proper release for closure with the indication log or via the fault record. You have to start the fault recording explicitly.

12.1 General Device Data

12.1.1 Analog Inputs

Current Inputs

All current, voltage, and power data are specified as RMS values.			
Rated frequency f_{rated}	50 Hz, 60 Hz		
Protection-class current transformers	Rated current I_{rated}	Measuring range of the modular devices	Measuring range of the non-modular devices
	5 A 1 A	0 A to 500 A 0 A to 100 A	0 A to 250 A 0 A to 50 A
Instrument transformers	5 A 1 A	0 A to 8 A 0 A to 1.6 A	0 A to 8 A 0 A to 1.6 A
Burden for rated current	Approx. 0.1 VA		
Thermal rating (protection and instrument transformers)	20 A continuously		
	25 A for 3 min		
	30 A for 2 min		
	150 A for 10 s		
	500 A for 1 s		
Dynamic load-carrying capacity	1250 A one half wave		

GIS Low-Power Current Input (via Module IO240)

All current, voltage, and power data are specified as RMS values.		
Rated frequency f_{rated}	50 Hz, 60 Hz	
GIS-LPCT input	Primary rated current I_{rated}	Measuring range
	Kr · GIS-LPCT secondary rated value Kr = Transformation ratio of the GIS-LPCT (DIGSI setting) Refer to the GIS manual for the GIS-LPCT secondary rated value.	K_{pcr} = 50 (protection channel) K_{pcr} = 1.6 (measuring channel)
Power consumption per current circuit at rated current	Max. 40 mVA Burden = 9.5 kΩ	
Thermal rating	Max. input voltage = 20 V	
Accuracy	Class 5TPE (protection channel) Class 0.2S (measuring channel)	

Optical Current Input (via Module IO245)

All current, voltage, and power data are specified as RMS values.			
Rated frequency f_{rated}	50 Hz, 60 Hz		
Rated current I_{rated}	Depending on the TOCT design		
Measuring range	Measuring channel	Protection channel	
	1.6 · I_{rated}	100 · I_{rated}	
Accuracy	Measuring channel	Protection channel	
	0.5, 0.2, 0.2S	< 10 kA	> 10 kA
		Comparable to measuring channel	5TPE

Voltage Input

All current, voltage, and power data are specified as RMS values.		
Rated frequency f_{rated}	50 Hz, 60 Hz	
Input and output modules	IO102, IO202, IO208, IO211, IO214	IO215
Measuring range	0 V to 200 V	0 V to 7.07 V
Burden	< 0.1 VA	< 0.01 VA
Thermal rating	230 V continuously	20 V continuously

GIS Low-Power Voltage Input (via Module IO240)

All current, voltage, and power data are specified as RMS values.		
Rated frequency f_{rated}	50 Hz, 60 Hz	
GIS-LPVT input	Primary rated voltage V_{rated}	Measuring range
	Kr · GIS-LPVT secondary rated value Kr = Transformation ratio of the GIS-LPVT (DIGSI setting) Refer to the GIS manual for the GIS-LPVT secondary rated value.	$K_{pcr} = 2$
Power consumption per current circuit at rated current	Max. 1 mVA Burden = 50 Ω	
Thermal rating	Max. input current = 4.4 mA	
Accuracy	Class 0.1	

RCVT Voltage Input (via Module IO240 or IO245)

All current, voltage, and power data are specified as RMS values.		
Rated frequency f_{rated}	50 Hz, 60 Hz	
RCVT input	Primary rated voltage V_{rated}	Measuring range
	100/√3 V L-N	$2 \cdot V_{rated}$
Burden	2 MΩ/50 pF	
Thermal rating	200 V L-N	
Accuracy	Class 0.1	

Measuring-Transducer Inputs (via Module ANAI-CA-4EL)

Insulation class	PELV (Protective Extra Low Voltage) (according to IEC 60255-27)
Connector type	8-pin terminal spring
Input channels	4 differential current inputs
Measuring range	DC -20 mA to +20 mA
Tolerance	0.5 % of the measuring range
Maximum measuring range	DC -25.6 mA to +25.6 mA
Input impedance	140 Ω
ADC type	16-Bit Delta-Sigma
Permissible potential difference between channels	DC 20 V
Galvanic separation from ground/ housing	AC 500 V, DC 700 V
Permissible overload	DC 100 mA continuously
Sampling rate	5 Hz

Fast Measuring Transducer Inputs, Voltage (via Module ANAI-CE-2EL, Channel 2, and IO218)

Insulation class	HLV (Hazardous Live Voltage) (in accordance with IEC 60255-27)
Input channels	1 DC voltage input, ANAI-CE-2EL, channel 2 (CH2) 3 DC voltage inputs, IO218
Measuring range	DC 0 V to + 300 V
Tolerance	0.2 % of measuring range
Input impedance	260 kΩ
Galvanic separation against ground/housing	DC 4.6 kV
Max. permissible voltage against ground on the measuring inputs	DC 300 V
Sampling rate	16 kHz

Inputs for Optical Sensors for Arc Protection (via Module ARC-CD-3FO)

Connector type	AVAGO AFBR-4526Z
Number of transceivers	3
Fiber type	Plastic Optical Fiber (POF) 1 mm
Receiver	
Maximum	-10 dBm ± 2 dBm
Minimum	-40 dBm ± 2 dBm
Spectrum	400 nm to 1100 nm
Attenuation	In the case of plastic optical fibers, you can expect a path attenuation of 0.2 dB/m. Additional attenuation comes from the plug and sensor head.
Optical budget[71]	Minimal 25 dB
Analog sampling rate	16 kHz
ADC type	10-bit successive approximation
Transmitter	
Type	LED
Wavelength	λ = 650 nm
Transmitter power	Minimum 0 dBm Maximum 2 dBm
Numerical aperture	0.5 [72]
Signal rate connection test	1 pulse per second
Pulse duration connection test	11 µs

Fast Measuring Transducer Inputs, Voltage/Current (via IO210, IO212)

NOTE

Current and voltage must not be connected at the same time to one measuring transducer input. Instead, only connect either current or voltage. For EMC reasons, do not connect a line to an unused input (current or voltage).

Use shielded cables.

71 All values in combination with sensors approved by Siemens.

72 Numerical aperture (NA = sin θ (launch angle))

Table 12-1 Fast Measuring Transducer Inputs, Voltage

Differential voltage input channels	IO210: 4[73] IO212: 8[74]
Measuring range	DC -10 V to +10 V
Fault	< 0.5 % of measuring range
Input impedance	48 kΩ
Max. permissible voltage with respect to ground on the measuring inputs	300 V
Permissible overload	DC 20 V continuously DC 60 V continuously (IO210 MU3 terminal point C9)

Table 12-2 Fast Measuring Transducer Inputs, Current

Differential current input channels	IO210: 4[75] IO212: 8[76]
Measuring range	DC -20 mA to +20 mA
Fault	< 0.5 % of measuring range
Input impedance, current	12 Ω
Permissible potential difference between channels	DC 3.5 kV
Galvanic separation with respect to ground/housing	DC 3.5 kV
Permissible current overload	DC 100 mA continuously

Table 12-3 Combined Data for Fast Measuring Transducer Voltage/Current Inputs

Conversion principle	Delta-sigma (16 bit)
Insulation test voltage between the channels	DC 3.5 kV
Insulation test voltage with respect to ground/housing	DC 3.5 kV
Measured value repetition	62.5 µs
Insulation class IO210	ELV (Extra Low Voltage) (as per IEC 60255-27)
Insulation class IO212	SELV (as per IEC 60255-27)

Table 12-4 Measuring Transducer Inputs, Current (via Module IO218)

Insulation class	PELV (Protective Extra Low Voltage) (acc. to IEC 60255-27)
Input channels	7 current inputs with common ground (MUx inputs and RTD not galvanically separated)
Measuring range	DC 0 mA to +20 mA
Tolerance	0.5 % of measuring range (MU1 to MU3) Typ. 1.0 % (max. 2.6 %) of measuring range (MU4 to MU7)
Maximum measuring range	DC 0 mA to +24.5 mA
Input impedance	12 Ω
ADC type	12-bit SAR

73 The IO210 has 4 fast measuring transducer inputs. They can be used either as a voltage or current input.
74 The IO212 has 8 fast measuring transducer inputs. They can be used either as a voltage or current input.
75 The IO210 has 4 fast measuring transducer inputs. They can be used either as a voltage or current input.
76 The IO212 has 8 fast measuring transducer inputs. They can be used either as a voltage or current input.

Permissible potential difference between channels	DC 20 V
Galvanic separation against ground/housing	AC 500 V, DC 700 V
Permissible overload	DC 100 mA continuously
Sampling rate	16 kHz (MU1 to MU3) 5 Hz (MU4 to MU7)

Temperature Inputs

Settings	Value	Note
Insulation class	PELV (Protective Extra Low Voltage) (acc. to IEC 60255-27)	With IO218: RTD and MUx inputs not galvanically separated.
Measurement mode	• Pt 100 Ω • Ni 100 Ω • Ni 120 Ω 3-wire connection, shielded cables	–
Temperature measuring range	-65 °C to +710 °C	For PT100
	-50 °C to +250 °C	For NI100
	-50 °C to +250 °C	For NI120

Temperature Inputs (via Module IO240)

Settings	Value
Sensor Type	PT100 (Class F 0.3 EN 60751) 4-wire shielded cable connection
Measurement range	-50 °C to +180 °C
Accuracy	±1 °C

Optical Temperature Input (via Module IO245)

Setting	Value
Sensor type	Optical GaAs (Gallium Arsenide) sensor Single cable with multi-mode fiber optic (OM1)
Measuring range	-50 °C to +150 °C
Accuracy	±2 °C

LPIT Digital Input (via Module IO240)

Shield Cover Input	
Sensor type	Dry contact input
Measurement type	Output voltage of 1 mA current injection @ max. DC 5 V

Insulation of LPIT Digital Input (via Module IO245)

Insulation (All Inputs)	
Configuration	The LPVT inputs are isolated from PE and the operator according to the requirements of IEC 61869-1 (AC 3 kV, 50 Hz, 1 min) and IEC 60255-27 for a rated voltage of 300 V despite the low-level signaling voltages. All channels are protected with differential-mode and common-mode voltage-limiting devices.
Test levels (type test)	AC 3250 V, 50 Hz, 1 min 6000 V 1.2/50 µs peak impulse

12.1.2 Supply Voltage

Integrated Power Supply			
For modular devices, the following modules contain a power supply: PS201 – Power supply of the base module and of the 1st device row PS203 – Power supply of the 2nd device row PS204 – Redundant power supply CB202 – Plug-in module assembly with integrated power supply, for example, to accommodate communication modules			
Permissible voltage ranges (PS201, PS203, PS204, CB202)	DC 19 V to DC 60 V	DC 48 V to DC 300 V AC 80 V to AC 265 V, 50 Hz/60 Hz	
Auxiliary rated voltage V_H (PS201, PS203, PS204, CB202)	DC 24 V/DC 48 V	DC 60 V/DC 110 V/DC 125 V/DC 220 V/ DC 250 V or AC 100 V/AC 115 V/AC 230 V, 50 Hz/60 Hz	
Permissible voltage ranges (PS101) Only for non-modular devices	DC 19 V to DC 60 V	DC 48 V to 150 V	DC 88 V to DC 300 V AC 80 V to AC 265 V, 50 Hz/60 Hz
Auxiliary rated voltage V_H (PS101) Only for non-modular devices	DC 24 V/DC 48 V	DC 60 V/DC 110 V/ DC 125 V	DC 110 V/ DC 125 V/ DC 220 V/DC 250 V or AC 100 V/AC 115 V/ AC 230 V, 50 Hz/60 Hz
Superimposed alternating voltage, peak-to-peak, IEC 60255-11, IEC 61000-4-17	≤ 15 % of the DC auxiliary rated voltage (applies only to direct voltage)		
Inrush current	≤ 18 A		
Recommended external protection	Miniature circuit breaker 6 A, characteristic C according to IEC 60898		
Internal fuse			
–	DC 24 V to DC 48 V	DC 60 V to DC 125 V	DC 24 V to DC 48 V AC 100 V to AC 230 V
PS101 Only for non-modular devices	4 A inert, AC 250 V, DC 150 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	2 A time-lag, AC 250 V, DC 300 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	
PS201, PS203, CB202 (to device version xA)	4 A inert, AC 250 V, DC 150 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	2 A time-lag, AC 250 V, DC 300 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	
PS201, PS203, PS204 (Device version xB and higher)	4 A inert, AC 250 V, DC 150 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	3.15 A time-lag, AC 250 V, DC 300 V, UL recognized SIBA type 179200 or Schurter type SPT 5x20	

Integrated Power Supply			
Power consumption (life relay active)			
–	DC	AC 230 V/50 Hz	AC 115 V/50 Hz
1/3 module, non-modular Without plug-in modules	7 W	16 VA, 7 W	12.5 VA, 7 W
1/3 base module, modular Without plug-in modules	13 W	55 VA, 13 W	40 VA, 13 W
1/6 expansion module	3 W	6 VA, 3 W	6 VA, 3 W
1/6 plug-in module assembly without plug-in modules (modules CB202)	3.5 W	14 VA, 3.5 W	7 VA, 3.5 W
Plug-in module for base module or plug-in module assembly (for example, communication module)	< 5 W	< 6 VA, < 5 W	< 6 VA, < 5 W
Stored-energy time for auxiliary voltage outage or short circuit, modular devices IEC 61000-4-11 IEC 61000-4-29		For V ≥ DC 24 V ≥ 50 ms For V ≥ DC 110 V ≥ 50 ms For V ≥ AC 115 V ≥ 50 ms	
Stored-energy time for auxiliary voltage outage or short circuit, non-modular devices IEC 61000-4-11 IEC 61000-4-29		For V ≥ DC 24 V ≥ 20 ms For V ≥ DC 60 V ≥ 50 ms For V ≥ AC 115 V ≥ 200 ms	

Power Supply for External Measuring Transducers (via Module IO218)

Insulation class	PELV (Protective Extra Low Voltage) (acc. to IEC 60255-27)
Output voltage	DC 24 V, common ground with MU inputs
Tolerance	10 %
Output current	Max. 210 mA, sustained short-circuit protection
Continuous power	Max. 5 W (at temperatures > 55 °C max. 2.5 W)

12.1.3 Binary Inputs

Standard Binary Input

Rated voltage range	DC 24 V to 250 V The binary inputs of SIPROTEC 5 are bipolar, with the exception of the binary inputs on the modules IO230, IO231, IO232, and IO233.	
Current consumption, picked up	Approx. DC 0.6 mA to 2.5 mA (independent of the control voltage)	
Max. power consumption	0.6 W	
Pickup time	Approx. 3 ms	
Dropout time[77]	Capacitive load (supply-line capacitance)	Dropout time
	< 5 nF	< 4 ms
	< 10 nF	< 6 ms
	< 50 nF	< 10 ms
	< 220 nF	< 35 ms

77 Pay attention to the specified dropout times for time-critical applications with active-low signals. If necessary, provide for active discharge of the binary input (for example, a resistor in parallel with the binary input or using a change-over contact).

Control voltage for all modules with binary inputs, except module IO233	Adapt the binary-input threshold to be set in the device to the control voltage.	
	Range 1 for 24 V, 48 V, and 60 V control voltage	V_{low} ≤ DC 10 V V_{high} ≥ DC 19 V
	Range 2 for 110 V and 125 V control voltage	V_{low} ≤ DC 44 V V_{high} ≥ DC 88 V
	Range 3 for 220 V and 250 V control voltage	V_{low} ≤ DC 88 V V_{high} ≥ DC 176 V
Control voltage for binary inputs of the IO233 module	Range for 125 V control voltage	V_{low} ≤ DC 85 V V_{high} ≥ DC 105 V
Maximum admissible voltage	DC 300 V	
The binary inputs contain interference suppression capacitors. To ensure EMC immunity, use the marked terminals shown in the terminal diagrams/connection diagrams to connect 2 or more binary inputs to the a common potential.		

Special Binary Input with Maximized Robustness against Electrical Disturbances and Failures (IO216)

Rated voltage range	DC 220 V The special binary inputs of the SIPROTEC 5 with maximized robustness against electrical disturbances and failures are bipolar and available only on the module IO216.	
Input impedance	50 kΩ to 60 kΩ	
Rejection pulse charge	> 200 µC	
Current consumption, excited	Approx. DC 1.2 mA to 2.0 mA (additionally to the current consumption of the input impedance)	
Power consumption, max.	1.5 W at DC 242 V	
Pickup time	Approx. 3 ms	
Dropout time[78]	Capacitive load (supply-line capacitance)	Dropout time
	< 5 nF	< 3 ms
	< 10 nF	< 4 ms
	< 50 nF	< 5 ms
	< 220 nF	< 10 ms
Control voltage for the module IO216	Range for 220 V control voltage	
	Threshold pickup	158 V to 170 V
	Threshold dropout	132 V to 154 V
Maximum permitted voltage	DC 300 V	
The binary inputs contain interference suppression capacitors. To ensure EMC immunity, use the terminals shown in the terminal diagrams/connection diagrams to connect the binary inputs to the common potential.		

12.1.4 Relay Outputs

Standard Relay (Type S)

Rated voltage (AC and DC)	250 V
Rated current (continuous) and total permissible current for contacts connected to common potential	5 A

78 For time-critical applications with low-active signals, consider the specified dropout times. If necessary, provide for active discharge of the binary input (for example, a resistor in parallel to the binary input or using a change-over contact).

Permissible current per contact (switching on and holding)	30 A for 1 s (make contact only)
Short-time current across closed contact	250 A for 30 ms
Breaking capacity	Max. 30 W (L/R = 40 ms) Max. 360 VA (power factor ≥ 0.35, 50 Hz to 60 Hz)
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	Make time: typical: 8 ms; maximum: 10 ms Break time: typical: 2 ms; maximum: 5 ms
Max. rated data of the output contacts in accordance with UL certification	DC 24 V, 5 A, general purpose DC 48 V, 0.8 A, general purpose DC 240 V, 0.1 A, general purpose AC 240 V, 5 A, general purpose AC 120 V, 1/6 hp AC 250 V, 1/2 hp B300 R300
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V
Safety/monitoring	2-channel activation

Fast Relay (Type F)

Rated voltage (AC and DC)	250 V
Rated current (continuous) and total permissible current for contacts connected to common potential	5 A
Permissible current per contact (switching on and holding)	30 A for 1 s (make contact only)
Short-time current across closed contact	250 A for 30 ms
Breaking capacity	Max. 30 W (L/R = 40 ms) Max. 360 VA (power factor ≥ 0.35, 50 Hz to 60 Hz)
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	Make time: typical: 4 ms; maximum: 5 ms Break time: typical: 2 ms; maximum: 5 ms
Max. rated data of the output contacts in accordance with UL certification	AC 120 V, 5 A, general purpose AC 250 V, 5 A, general purpose AC 250 V, 1/2 hp B300 R300
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V
Safety/monitoring	2-channel activation with cyclic testing (make contact only)

High-Speed Relay with Semiconductor Acceleration (Type HS)

Rated voltage	AC 200 V, DC 250 V
Rated current (continuous)	5 A (in accordance with UL approval) 10 A (not UL approved; AWG 14 / 2.5 mm^2copper conductors necessary)
Permissible current per contact (switching on and holding)	30 A for 1 s
Short-time current across closed contact	250 A for 30 ms
Breaking capacity	Max. 2500 W (L/R = 40 ms)

Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	Make time: typical: 0.2 ms; maximum: 0.2 ms Break time: typical: 9 ms; maximum: 9 ms
Max. rated data of the output contacts in accordance with UL certification	B150 Q300
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V
Safety/monitoring	2-channel activation

Power Relay (for Direct Control of Motor Switches)

Rated voltage (AC and DC)	250 V
Rated current (continuous) and total permissible current for contacts connected to common potential	5 A
Switching power for permanent and periodic operation In order to prevent any damage, the external protection circuit must switch off the motor in case the rotor is blocked.	250 V/4.0 A 220 V/4.5 A 110 V/5.0 A 60 V/5.0 A 48 V/5.0 A 24 V/5.0 A
Turn on switching power for 30 s, recovery time until switching on again is 15 minutes. For short-term switching operations, an impulse/pause ratio of 3 % must be considered. In order to prevent any damage, the external protection circuit must switch off the motor in case the rotor is blocked.	100 V/9.0 A 60 V/10.0 A 48 V/10.0 A 24 V/10.0 A
Permissible current per contact (switching on and holding)	30 A for 1 s
Short-time current across closed contact	250 A for 30 ms
Switching time OOT (**O**utput **O**perating **T**ime) Additional delay of the output medium used	≤ 16 ms
Max. rated data of the output contacts in accordance with UL certification	DC 300 V, 4.5 A – 30 s ON, 15 min OFF DC 250 V, 1 hp Motor – 30 s ON, 15 min OFF DC 110 V, 3/4 hp Motor – 30 s ON, 15 min OFF DC 60 V, 10 A, 1/2 hp Motor – 30 s ON, 15 min OFF DC 48 V, 10 A, 1/3 hp Motor – 30 s ON, 15 min OFF DC 24 V, 10 A, 1/6 hp Motor – 30 s ON, 15 min OFF
Interference suppression capacitors across the contacts	4.7 nF, ± 20 %, AC 250 V
Safety/monitoring	2-channel activation
The power relays operate in interlocked mode, that is, only one relay of each switching pair picks up at a time thereby avoiding a power-supply short circuit.	

12.1.5 Design Data

Masses

	Device Size Weight of the Modular Devices				
Type of construction	1/3	1/2	2/3	5/6	1/1
Flush-mounting device	4.4 kg	7.2 kg	9.9 kg	12.7 kg	15.5 kg

	Device Size Weight of the Modular Devices				
Surface-mounted device with integrated on-site operation panel	7.4 kg	11.7 kg	15.9 kg	20.2 kg	24.5 kg
Surface-mounted device with detached on-site operation panel	4.7 kg	7.8 kg	10.8 kg	13.9 kg	17.0 kg

Devices with IO240 weigh 0.9 kg more.

	Size	Weight
Detached on-site operation panel	1/3	1.9 kg
Detached on-site operation panel	1/6	1.1 kg

	Device Size Weight of the Non-Modular Devices 7xx81, 7xx82
Type of construction	1/3
Flush-mounting device	3.6 kg
Bracket for non-modular surface-mounting version	1.9 kg

Dimensions of the Base and Expansion Modules

Type of Construction		Max. Total Width x Max. Total Height x Max. Total Depth[79], Each Rounded up to the Next Full mm (in Inches)
Flush-mounting device	Base module	150 mm x 266 mm x 231 mm (5.91 x 10.47 x 9.09)
	Base module with IO240	150 mm x 266 mm x 277 mm (5.91 x 10.47 x 10.91)
	Base module with IO111	150 mm x 266 mm x 243 mm (5.91 x 10.47 x 9.57)
	Expansion module	75 mm x 266 mm x 231 mm (2.95 x 10.47 x 9.09)
	Expansion module with IO240, IO218	75 mm x 266 mm x 277 mm (2.95 x 10.47 x 10.91)
	Expansion module with IO111	75 mm x 266 mm x 243 mm (2.95 x 10.47 x 9.57)
Surface-mounted device with integrated on-site operation panel	Base module	150 mm x 315 mm x 341 mm (5.91 x 12.4 x 13.43)
	Expansion module	75 mm x 315 mm x 341 mm (2.95 x 12.4 x 13.43)

79 Including current terminal, excluding USB port cover

Type of Construction		Max. Total Width x Max. Total Height x Max. Total Depth[79], Each Rounded up to the Next Full mm (in Inches)
Surface-mounted device with detached on-site operation panel	Base module	150 mm x 315 mm x 231 mm (5.91 x 12.4 x 9.09)
	Base module with IO240	150 mm x 315 mm x 277 mm (5.91 x 12.4 x 10.91)
	Base module with IO111	150 mm x 315 mm x 243 mm (5.91 x 12.4 x 9.57)
	Expansion module	75 mm x 315 mm x 231 mm (2.95 x 12.4 x 9.09)
	Expansion module with IO240, IO218	75 mm x 315 mm x 277 mm (2.95 x 12.4 x 10.91)
	Expansion module with IO111	75 mm x 315 mm x 243 mm (2.95 x 12.4 x 9.57)

Dimensions of the Device Rows

Type of Construction	Max. Total Width x Max. Total Height x Max. Total Depth[80], Rounded to full mm (in Inches)				
Device width	1/3	1/2	2/3	5/6	1/1
Flush-mounting device	150 mm x 266 mm x 231 mm (5.91 x 10.47 x 9.09)	225 mm x 266 mm x 231 mm (8.86 x 10.47 x 9.09)	300 mm x 266 mm x 231 mm (11.81 x 10.47 x 9.09)	375 mm x 266 mm x 231 mm (14.76 x 10.47 x 9.09)	450 mm x 266 mm x 231 mm (17.72 x 10.47 x 9.09)

Surface-mounted device with detached on-site operation panel	150 mm x 315 mm x 231 mm (5.91 x 12.4 x 9.09)	225 mm x 315 mm x 231 mm (8.86 x 12.4 x 9.09)	300 mm x 315 mm x 231 mm (11.81 x 12.4 x 9.09)	375 mm x 315 mm x 231 mm (14.76 x 12.4 x 9.09)	450 mm x 315 mm x 231 mm (17.72 x 12.4 x 9.09)

79 Including current terminal, excluding USB port cover
80 Including current terminal, excluding USB port cover
81 Including connecting rail

Type of Construction	Max. Total Width x Max. Total Height x Max. Total Depth[80], Rounded to full mm (in Inches)				
Surface-mounted device with detached on-site operation panel with IO240, IO218	150 mm x 315 mm x 277 mm (5.91 x 12.4 x 10.91)	225 mm x 315 mm x 277 mm (8.86 x 12.4 x 10.91)	300 mm x 315 mm x 277 mm (11.81 x 12.4 x 10.91)	375 mm x 315 mm x 277 mm (14.76 x 12.4 x 10.91)	450 mm x 315 mm x 277 mm (17.72 x 12.4 x 10.91)
Surface-mounted device with detached on-site operation panel with IO111	150 mm x 315 mm x 243 mm (5.91 x 12.4 x 9.57)	225 mm x 315 mm x 243 mm (8.86 x 12.4 x 9.57)	300 mm x 315 mm x 243 mm (11.81 x 12.4 x 9.57)	375 mm x 315 mm x 243 mm (14.76 x 12.4 x 9.57)	450 mm x 315 mm x 243 mm (17.72 x 12.4 x 9.57)

Plug-In Module Dimensions

Type of Construction	Max. Width x Max. Height x Max. Depth (in Inches)
USART-Ax-xEL, ETH-Bx-xEL	61 mm x 45 mm x 121 mm (2.4 x 1.77 x 4.76)
USART-Ax-xFO, ETH-Bx-xFO (without protective cover)	61 mm x 45 mm x 133 mm (2.4 x 1.77 x 5.24)
ANAI-CA-4EL, ANAI-CE-2EL	61 mm x 45 mm x 120 mm (2.4 x 1.77 x 4.72)
ARC-CD-3FO	61 mm x 45 mm x 121 mm (2.4 x 1.77 x 4.76)

Minimum Bending Radii of the Connecting Cables Between the On-Site Operation Panel and the Base Module

Fiber-optic cable	R = 50 mm Pay attention to the length of the cable protection sleeve, which you must also include in calculations.
D-Sub cable	R = 50 mm (minimum bending radius)

Degree of Protection According to IEC 60529

For equipment in the surface-mounting housing	IP54[82] for front
For equipment in the flush-mounting housing	IP54[82] for front
For operator protection (back side)	IP2x for current terminal (installed) IP2x for voltage terminal (installed)
Degree of pollution, IEC 60255-27	2
Maximum operating altitude above sea level	2000 m (6561.68 ft)

UL Note

Type 1 if mounted into a door or front cover of an enclosure. When expanding the device with the 2nd device row, then they must be mounted completely inside an enclosure.

80 Including current terminal, excluding USB port cover

82 The supplied plug-in strips must be used for expansion modules with LEDs.

Tightening Torques for Terminal Screws

Type of Line	Current Terminal	Voltage Terminal with Spring-Loaded Terminals	Voltage Terminal with Screw Connection
Stranded wires with ring-type lug	2.7 Nm	No ring-type lug	No ring-type lug
Stranded wires with boot-lace ferrules or pin-type lugs	2.7 Nm	1.0 Nm	0.6 Nm
Solid conductor, bare (2 mm^2)	2.0 Nm	1.0 Nm	–
Blank stranded wire	Not permitted	1 Nm	0.6 Nm

NOTE

For current and voltage terminals, the maximum speed of the tool must not exceed 640 rpm.

NOTE

Use copper cables only.

Torques for Other Screw Types

Screw Type	Torque
M4 x 20	1.2 Nm
M4 x 8	1.2 Nm
M2.5 x 6	0.39 Nm
Countersunk screw, M2.5 x 6	0.39 Nm
Countersunk screw, M2.5 x 8	0.39 Nm
Collar screw, M4 x 20	0.7 Nm

12.2 Transformer Differential Protection

Setting Values

Operate curve			
Threshold value	$I/I_{rated,obj}$	0.05 to 2.00	Increments of 0.01
Slope 1		0.00 to 0.80	Increments of 0.01
Intersection 1 Irest	$I/I_{rated,obj}$	0.00 to 5.00	Increments of 0.01
Slope 2		0.25 to 0.95	Increments of 0.01
Intersection 2 Irest	$I/I_{rated,obj}$	1.00 to 20.00	Increments of 0.01
Startup detection			
Startup detection threshold value	$I/I_{rated,obj}$	0.1 to 2.0	Increments of 0.1
Characteristic curve increase factor		1.0 to 5.0	Increments of 0.1
Maximum starting time		0.1 s to 180.0 s	Increments of 0.1 s
DC-component detection			
Characteristic curve increase factor DC		1.0 to 5.0	Increments of 0.1
Inrush-current detection			
2nd harmonic content		10 % to 45 %	Increments of 1 %
Crossblk. time 2nd har.		0.00 s to 200.00 s or ∞	Increments of 0.01 s
Overexcitation blocking			
3rd harmonic content		10 % to 80 %	Increments of 1 %
Crossblk. time 3rd har.		0.00 s to 200.00 s or ∞	Increments of 0.01 s
5th harmonic content		10 % to 80 %	Increments of 1 %
Crossblk. time 5th har.		0.00 s to 200.00 s or ∞	Increments of 0.01 s
Idiff limit 3rd, 5th harm.	$I/I_{rated,obj}$	0.5 to 20.0	Increments of 0.1
Detection of external faults			
Add-on stabilization threshold value	$I/I_{rated,obj}$	1.00 to 20.00	Increments of 0.01
Add-on stabilization time		0.00 s to 5.00 s or ∞	Increments of 0.01 s
Crossblk. time additional stabilization		0.00 s to 2.00 s or ∞	Increments of 0.01 s
Operate curve		See *Figure 12-1*	

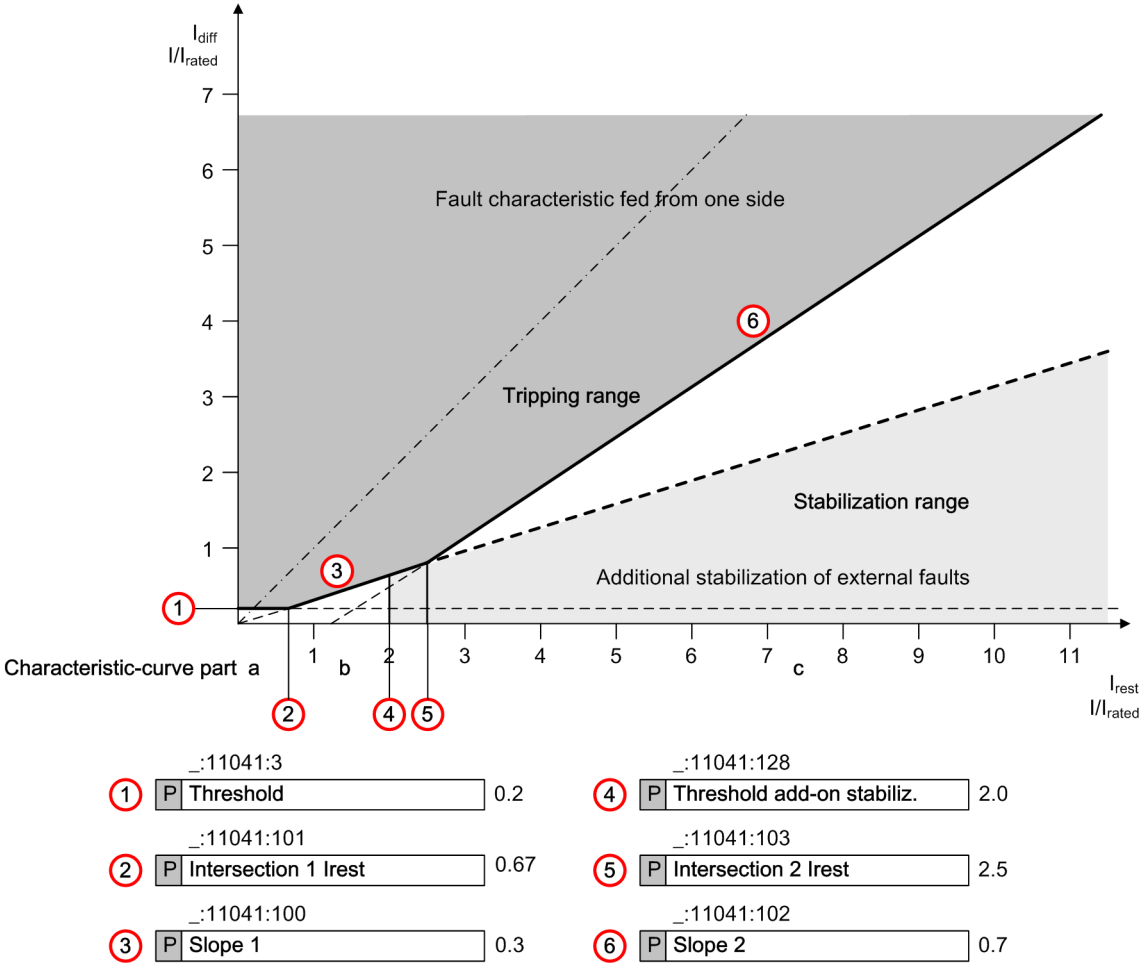
Functional Measured Values

Measured Value	Description
_:2311:300 A, B, C	Differential current
_:2311:301 A, B, C	Restraint current

I-DIFF Fast

Threshold value	$I/I_{rated,obj}$	0.5 to 35.0	Increments of 0.1
Tripping delay		0.00 s to 60.00 s	Increments of 0.01 s

I-DIFF Unrestrained



Threshold value	$I/I_{rated,obj}$	0.5 to 35.0	Increments of 0.1
Tripping delay		0.00 s to 60.00 s	Increments of 0.01 s

Response Tolerance

For preset characteristic curve parameters; for 2 sides with 1 measuring point each	
I-DIFF stage and characteristic curve	2 % of the setting value
I-DIFF fast stage	2 % of the setting value

Time Delays

I-DIFF stage	0.00 s to 60.00 s	Increments of 0.01 s
I-DIFF fast stage	0.00 s to 60.00 s	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms

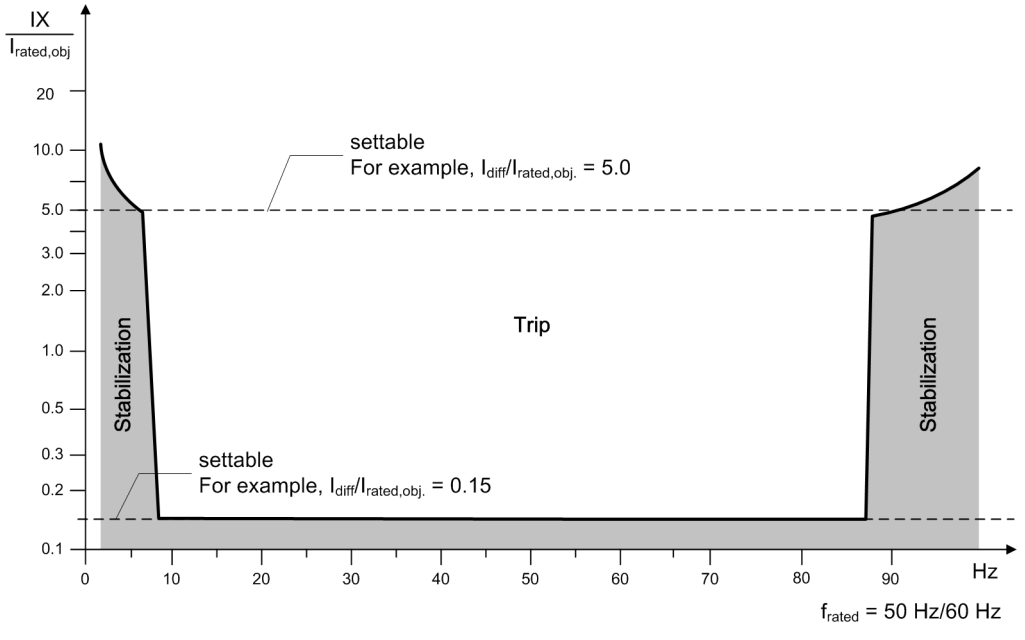
Figure 12-1 Operate Curve of the Differential Protection

Operate Times

Operate times for one-sided supply		
I-DIFF stage, min	50 Hz 60 Hz	23 ms + OOT[83] 20 ms + OOT
I-DIFF fast stage, min	50 Hz 60 Hz	8 ms + OOT 8 ms + OOT
I-DIFF unrestrained stage, min	50 Hz 60 Hz	8 ms + OOT 8 ms + OOT
Dropout time, approx.	50 Hz 60 Hz	29 ms 26 ms
Dropout ratio	Approx. 0.7	



Adaptation for Transformers

Vector-group adaptation	0 to 11 (x 30°)	Increments of 1
Neutral-point treatment	Grounded or not grounded (for each winding)	

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Frequency tracking	10 Hz to 90 Hz

[dw_trdffq, 2, en_US]

Figure 12-2 Frequency Influence when Using Transformer Differential Protection

83 Refer to protection functions, for example overcurrent protection

12.3 Restricted Ground-Fault Protection

Setting Values

Threshold value[84]	0.05 A to 2.00 A	Increments of 0.01 A
Gradient	0.00 to 0.95	Increments of 0.01
Operate curve	See figure	
Pickup tolerance (for preset characteristic curve parameters; for 2 sides with 1 measuring point each)	2 %	
Tripping delay	0.00 s to 60.00 s or ∞ (no tripping)	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	

Functional Measured Values

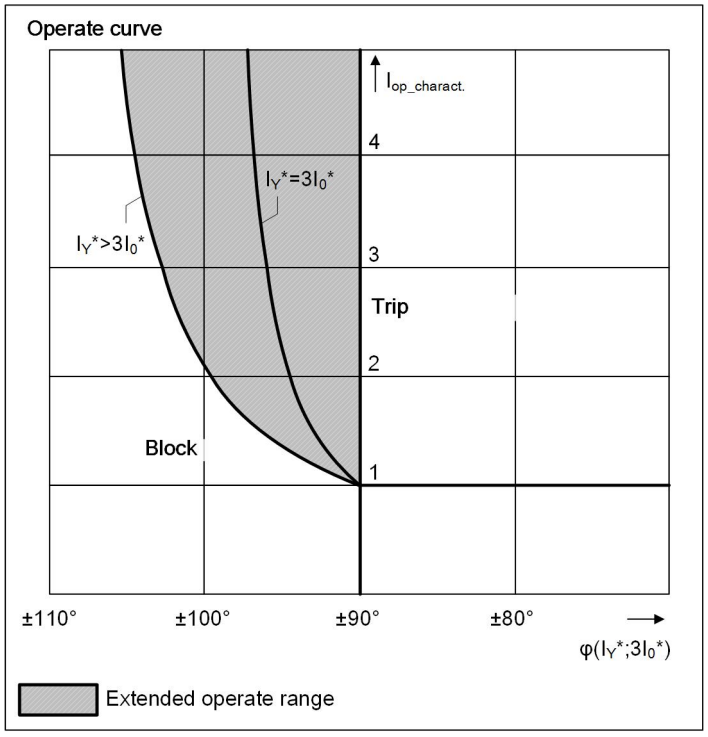
Measured Value	Description
(_:306) I REF,operate	Operate quantity of the restricted ground-fault protection from the angle criterion and can be displayed in the fault record
(_:307) I Angle,REF	Stabilizing value (angle) of the restricted ground-fault protection from the angle criterion and can be displayed in the fault record
(_:311) I REF,Trip operate	Operate quantity of the restricted ground-fault protection when OFF; will be issued in the log
(_:312) I angle,REF operate	Stabilizing value of the restricted ground-fault protection when OFF; will be issued in the log
(_:301) I diff.	Differential current; can be displayed in the fault record
(_:302) I restr.	Restraint current; can be displayed in the fault record

Dropout Ratio

Threshold value	0.7

Dropout

The greater dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria applies:



Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % applies for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformers	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)

Times

7UT82/7UT85/7UT86/7UT87		
Frequency	50 Hz	60 Hz
	Operate time	Operate time

84 The specified setting limit can be dynamically further limited, depending on the transformer adaptation factor, (for this refer to chapter *6.4.4 Application and Setting Notes*).

At 1.5 · setting value threshold value	33 ms + OOT	32 ms + OOT
At 2.5 · setting value threshold value	27 ms + OOT	26 ms + OOT
Dropout time approx.	30 ms	25 ms

Figure 12-7 Frequency Influence when Using Generator Differential Protection

12.6 Line Differential Protection

Tripping Thresholds Stage I-DIFF, Stage IN-DIFF, StageIN-DIFF unrest, Stage I2-DIFF

Threshold value	10.0 % to 2000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %
Threshold value upon switching	10.0 % to 2000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %

Tripping Thresholds, Stage I-DIFF fast 2

Threshold value	50.0 % to 10 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %
Threshold value upon switching	50.0 % to 10 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %

Tripping Thresholds, Stage I-DIFF fast

Threshold value	80.0 % to 10 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %
Threshold value upon switching	80.0 % to 10 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %

Trigger-Value Tolerances

When using up to 3 line ends	5 % of the setting value or 1 % of I_{rated} for each line end
When using up to 6 line ends	10 % of the setting value or 1 % of I_{rated} for each line end

Operating Times

The tripping times depend on the number of line ends, the communication speed, and the configured output contacts. The following data assume a transmission rate of at least 512 kbit/s.

Tripping times of the stages `I-DIFF`, `IN-DIFF`, `IN-DIFF unrest`, `I2-DIFF`		
When using 2 line ends	Minimum (50 Hz/60 Hz)	26 ms/23 ms + OOT[87]
	Typical (50 Hz/60 Hz)	28 ms/25 ms + OOT
When using 3 line ends	Minimum (50 Hz/60 Hz)	26 ms/23 ms + OOT
	Typical (50 Hz/60 Hz)	30 ms/27 ms + OOT
When using 6 line ends	Minimum (50 Hz/60 Hz)	31 ms/27 ms + OOT
	Typical (50 Hz/60 Hz)	37 ms/34 ms + OOT
Dropout times of the stages `I-DIFF`, `IN-DIFF`, `IN-DIFF unrest`, `I2-DIFF`		
For all line ends	Typical	34 ms to 49 ms + OOT

Tripping times of the stages `I-DIFF fast`/`I-DIFF fast 2`		
When using 2 line ends	Minimum	8 ms + OOT
	Typical	11 ms + OOT
When using 3 line ends	Minimum	8 ms + OOT
	Typical	11 ms + OOT
When using 6 line ends	Minimum	13 ms + OOT
	Typical	19 ms + OOT
Dropout times of the stages `I-DIFF fast`/`I-DIFF fast 2`		
For all line ends	Typical	34 ms to 49 ms + OOT

87 OOT (Output Operating Time): Additional time delay of the output medium used, for example, 1 ms with electronic relays.

Time Delays

Delay of the stage I-DIFF	0.00 s to 60.00 s	Increments of 0.01 s
Delay of the stages I-DIFF fast/I-DIFF fast 2	0.00 s	Not adjustable
Delay of 1-phase pickup in resonant-grounded/isolated systems	0.00 s to 0.50 s	Increments of 0.01 s
Delay of the stages **IN-DIFF**, **IN-DIFF unrest**, **I2-DIFF**	0.00 s to 60.00 s or ∞ (no tripping)	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	

Self-Stabilization (except IN-DIFF Unrest Stage)

Transformer Error for Each Line End of the Protected Object		
Error transmission ratio	1.00 to 10.00	Increments of 0.01
Transformer error A	0.5 % to 50.0 %	Increments of 0.1 %
Transformer error B	0.5 % to 50.0 %	Increments of 0.1 %
Other stabilizing values (adaptive self-stabilization)	Frequency deviations, runtime differences, harmonics, synchronism quality, jitter	

Adjustments for Transformers in the Protection Range

Vector group adjustment (V and I)	0 to 11	Increments of 1
Zero-sequence current elimination	Yes or no	

Adjustment of the Charging-Current Compensation

Additional rest. current Ic-rest./Ic-rated	1.0 to 4.0	Increments of 0.1
Total line length	0.1 km to 1000.0 km	Increments of 0.1 km

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	Operating range with rated accuracy
$0.8 \le f/f_{rated} \le 0.9$ $1.1 \le f/f_{rated} \le 1.2$	Normal operating range without rated accuracy
$0.0 \le f/f_{rated} \le 0.8$	Stable operation without rated accuracy

Measured Value of the I-DIFF Stage

In order to clarify failures, the **I-DIFF** stage provides the following measured values:

Measured Value	Description
(_:3451:300) I diff.	Differential current
(_:3451:301) I restr.	Restraint current (overall restraint)
(_:3451:307) I local	Value of local current phasor
(_:3451:308) I l.restr.	Local restraint current
(_:3451:309) I l.cTerr.	Partial component of the local restraint current that considers the transformer fault.

Measured Value	Description
(_:3451:310) I l.distor.	Subcomponent of the local restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabiliza-tion.
(_:3451:311) I sync.	Subcomponents of the overall restraint that are caused by faults during the time synchronization of the current phasor.

Measured Values of the Stage IN-DIFF

In order to clarify failures, the stage **IN-DIFF** provides the following measured values:

Measured Value	Description
(_:300) IN diff.	Ground differential current
(_:301) IN restr	Ground restraint current (overall restraint)
(_:307) IN local	Value of local ground-current phasor
(_:308) IN l.restr	Local ground restraint current
(_:309) IN l.CT	Partial component of the local ground restraint current that considers the transformer v.
(_:310) IN l.dist	Subcomponent of the local ground restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabilization.
(_:311) IN sync	Subcomponent of the overall restraint that is caused by faults during the time synchronization of the ground-current phasors.

Measured Values of the Stage IN-DIFF Unrest

In order to clarify failures, the stage **IN-DIFF Unrest** provides the following measured values:

Measured Value	Description
(_:300) IN diff.	Ground differential current
(_:301) IN threshold	Threshold value (pickup value)
(_:307) IN local	Value of local ground-current phasor

Measured Values of the Stage I2-DIFF

In order to clarify failures, the stage **I2-DIFF** provides the following measured values:

Measured Value	Description
(_:300) 3I2 diff.	Negative-sequence differential current
(_:301) 3I2 restr	Negative-sequence restraint current (overall restraint)
(_:307) 3I2 local	Value of local negative-sequence current phasor
(_:308) 3I2 l.rest	Local negative-sequence restraint current
(_:309) 3I2 l.CT	Partial component of the local negative-sequence restraint current that considers the transformer fault.
(_:310) 3I2 l.dist	Subcomponent of the local negative-sequence restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabilization.
(_:311) 3I2 sync	Subcomponents of the overall restraint that are caused by faults during the time synchronization of the current phasor.

12.7 Stub-Differential Protection

Tripping Thresholds of the S-DIFF Stage

Threshold value	10.0 % to 2 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %

Tripping Thresholds of the S-DIFF fast 2 Stage

Threshold value	80.0 % to 10 000.0 % of $I_{rated\ Operation}$	Increments of 0.1 %

Tolerances of the Tripping Thresholds

5 % of the setting value or 1 % of I_{rated}

Operating Times

The reported tripping times assume the issuance of commands via high-speed relays (type HS).

Tripping Times of the S-DIFF Stage	
Minimum (50 Hz/60 Hz)	26 ms/23 ms + OOT[88]
Typical (50 Hz/60 Hz)	28 ms/25 ms + OOT
Dropout Times of the S-DIFF Stage	
Typical	34 ms to 49 ms + OOT

Tripping Times of the Stages S-DIFF fast/S-DIFF fast 2	
Minimum	8 ms + OOT
Typical	11 ms + OOT
Dropout Times of the Stages S-DIFF fast/S-DIFF fast 2	
Typical	34 ms to 49 ms + OOT

Time Delays

Tripping delay of the S-DIFF stage	0.00 s to 60.00 s	Increments of 0.01 s
Tolerance	1 % of the setting value or 10 ms	

Self-Stabilization

Transformer Error for Each Line End of the Protected Object		
Error transmission	1.00 to 10.00	Increments of 0.01
Transformer error A	0.5 % to 50.0 %	Increments of 0.1 %
Transformer error B	0.5 % to 50.0 %	Increments of 0.1 %
Other stabilizing values (adaptive self-stabilization)	Frequency deviations, harmonic components	

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	Operating range with rated accuracy
$0.8 \le f/f_{rated} \le 0.9$ $1.1 \le f/f_{rated} \le 1.2$	Normal operating range without rated accuracy
$0.0 \le f/f_{rated} \le 0.8$	Stable operation without rated accuracy

88 OOT (Output Operating Time): Additional time delay of the output medium used, for example, 5 ms with fast relays

12.8 Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems

Setting Values for All Stage Types

Directional mode	Forwards, backwards, non-directional	
Method of Measurement	Fundamental component over 1 cycle filter (standard filter)	
	Fundamental component over 2 cycle filters	
Stabilization with conductor currents	0 % to 30 %	Increments of 1 %

Threshold value (pickup value)	For transformer type I-sensitive and $I_{N\text{-rated}}$ = 1 A	For $I_{ph\text{-rated}}$ = 1 A	0.003 A to 100.000 A	Increments of 0.001 A
		For $I_{ph\text{-rated}}$ = 5 A	0.003 A to 500.000 A	Increments of 0.001 A
	For transformer type I-sensitive and $I_{N\text{-rated}}$ = 5 A	For $I_{ph\text{-rated}}$ = 1 A	0.015 A to 100.000 A	Increments of 0.001 A
		For $I_{ph\text{-rated}}$ = 5 A	0.015 A to 500.000 A	Increments of 0.001 A
	For transformer type I-protection and $I_{N\text{-rated}}$ = 1 A		0.030 A to 100.000 A	Increments of 0.001 A
	For transformer type I-protection and $I_{N\text{-rated}}$ = 5 A		0.150 A to 500.000 A	Increments of 0.001 A

Settings Values for Stage Type 3I0 Definite Time-Overcurrent Protection

Time delay	0.000 s to 60.000 s	Increments of 0.001 s

Setting Values for Stage Type 3I0-IEC/ANSI

Type of characteristic curve	Characteristic curves according to IEC (see *Table 12-5*) and ANSI (see *Table 12-6*)	
Time multiplier	0.05 to 15.00	Increments of 0.01
Additional delay	0.000 s to 60.000 s	Increments of 0.001 s

Setting Values for Stage Type 3I0 Logarithmic Inverse

Characteristic curve: see *Figure 12-8*		
Threshold value multiplier	1.00 to 4.00	Increments of 0.01
Time multiplier	0.00 to 15.00	Increments of 0.01
Minimum time of the characteristic curve	0.000 s to 60.000 s	Increments of 0.001 s
Maximum time of the characteristic curve	0.000 s to 60.000 s	Increments of 0.001 s
Additional delay	0.000 s to 60.000 s	Increments of 0.001 s

Setting Values for Stage Type S0-Inverse

Characteristic curve: see *Figure 12-9*		
Threshold value multiplier	1.00 to 4.00	Increments of 0.01
S ref for Sr-characteristic	1.000 VA to 100.000 VA	Increments of 0.001 VA
k factor	0.000 s to 60.000 s	Increments of 0.001 s
Additional delay	0.000 s to 60.000 s	Increments of 0.001 s

Setting Values for Stage Type V0 Inverse

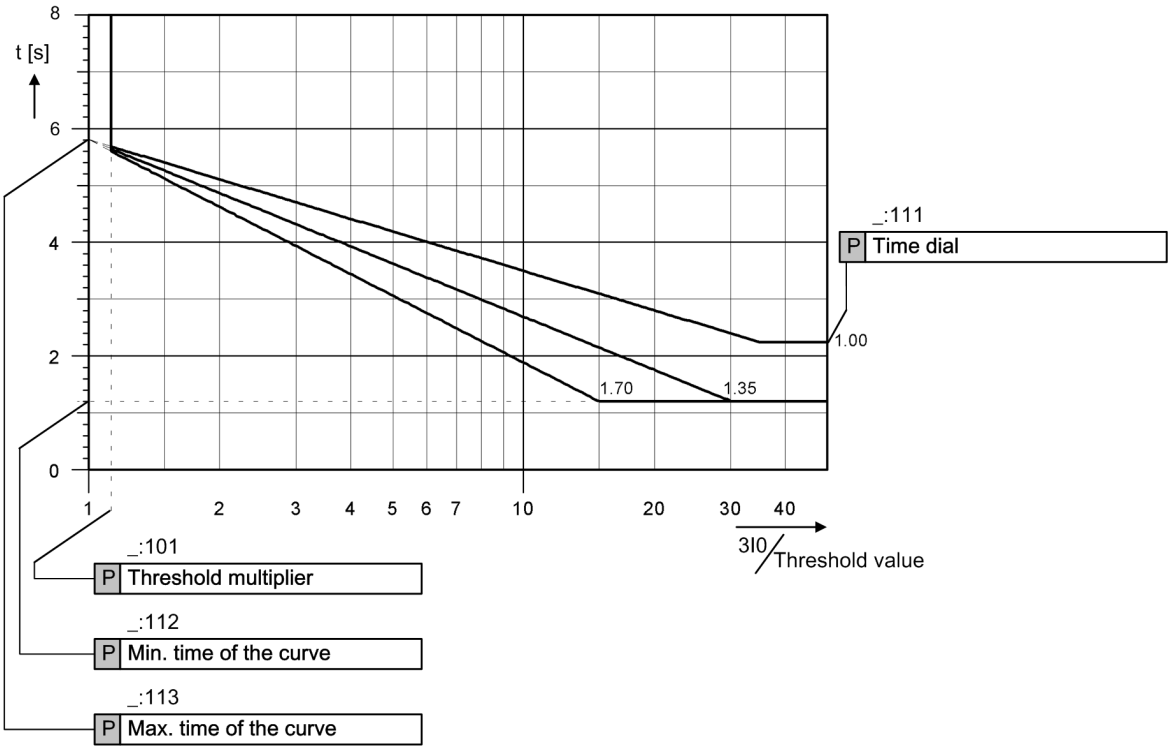
Characteristic curve: see *Figure 6-199*		
V0> threshold value	0.300 V to 340.00 V	Increments of 0.01
Min. zero-seq. volt. V0	0.000 V to 340.00 V	Increments of 0.001 VA
Time delay directional	0.00 s to 60.00 s	Increments of 0.01 s
Time delay non-direct.	0.00 s to 60.00 s	Increments of 0.01 s

Setting Values for Direction Determination

At angular measurement between measuring and reference values:			
Minimum zero voltage V0		0.150 V to 20.000 V	Increments of 0.001 V
Minimum transformer neutral point current IY	For I_{rated} = 1 A	0.030 A to 10.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 50.00 A	Increments of 0.01 A
Minimum negative-sequence system voltage V2		0.150 V to 20.000 V	Increments of 0.001 V
Minimum negative-sequence system current I2	For I_{rated} = 1 A	0.030 A to 10.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 50.00 A	Increments of 0.01 A
Upper limit angle forwards, β		0° to 360°	Increments of 1°
Lower limit angle forwards, α		0° to 360°	Increments of 1°
At angular measurement with zero power S0:			
Zero power for forwards direction		0.10 VA to 10.00 VA	Increments of 0.01 VA
Compensation angle		0° to 360°	Increments of 1°

Characteristic Curves

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms



You can select from the following tripping and dropout characteristic curves:

Table 12-5 Standard Characteristic Curves to IEC

Normal inverse: type A	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-10*
Very inverse: type B	
Extremely inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-11*
Long-term inverse	

Table 12-6 Standard Characteristic Curves to ANSI/IEEE

Extremely inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-13*
Long time inverse: type B	
Long-term inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-14*
Moderately inverse	
Very inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-15*
Extremely inverse	
Uniformly inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-16*

t = Maximum time of the characteristic curve – time multiplier • In (3I0/threshold value)

Figure 12-8 Operate Curves of the Independent Overcurrent Protection with Logarithmic Inverse Characteristic Curve

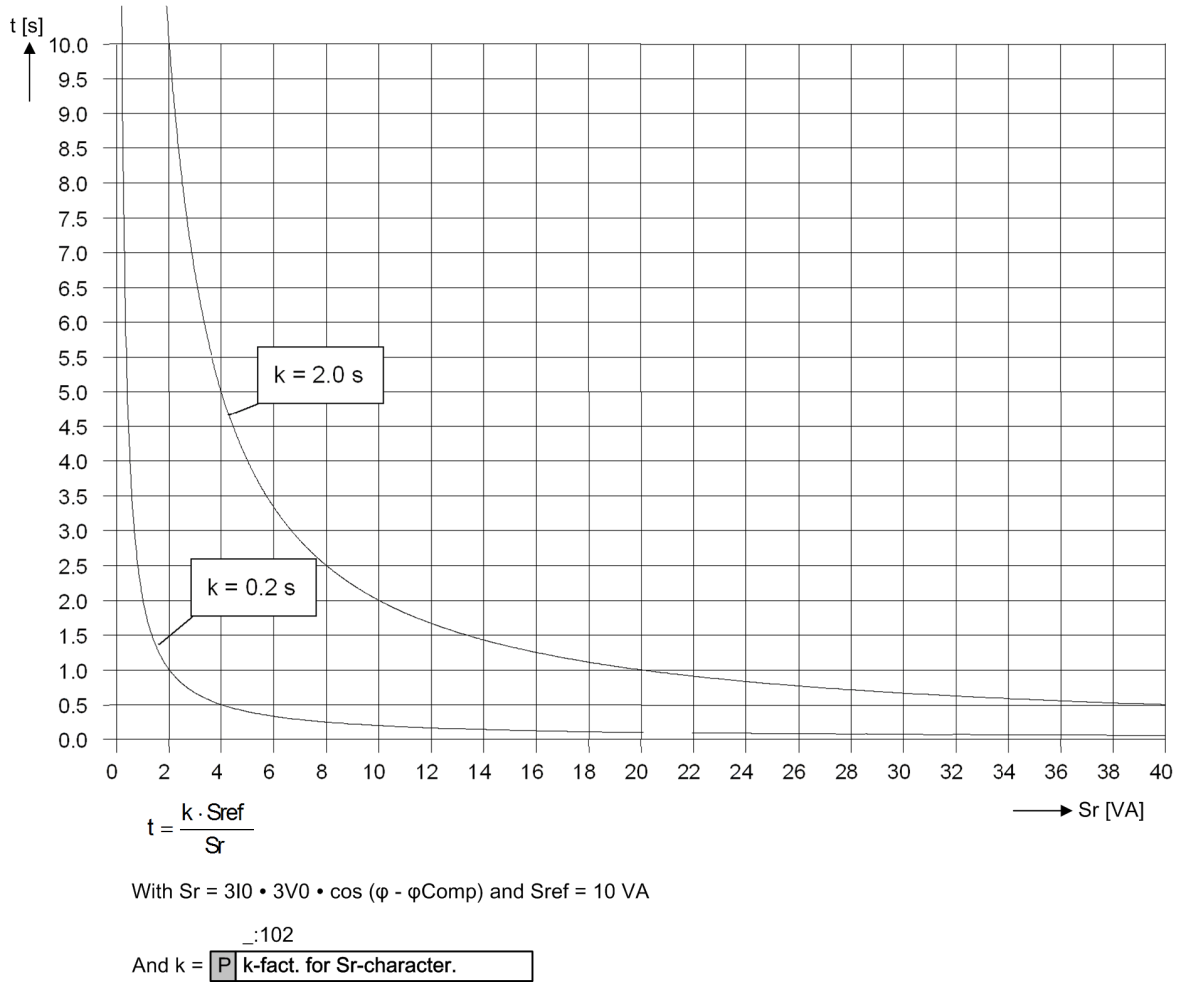

Figure 12-9 Operate Curve of the Zero Power Protection

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Values for Stage Type 3I0 Definite Time-Overcurrent Protection

Operate time with time delay = 0 ms	Fundamental component over 1 cycle filter (standard filter)	Approx. 25 ms + OOT[89] at 50 Hz Approx. 25 ms + OOT at 60 Hz
	Fundamental component over 2 cycle filters	Approx. 30 ms + OOT
Extension of the operate time during operation with transformer inrush-current detection		Approx. 10 ms
Dropout Time	Fundamental component over 1 cycle filter (standard time)	Approx. 20 ms + OOT
	Fundamental component over 2 cycle filters	Approx. 40 ms + OOT

Operating Range

f_{rated} ± 20%	Active
Outside of f_{rated} ± 20%	Not active

Tolerances

Threshold values:	
Response, release threshold value for zero-sequence current 3I0 with normal-sensitive ground-current transformer	1 % of the setting value or 1 % of the rated current
Response, release threshold value for zero-sequence current 3I0 with sensitive ground-current transformer	1 % of the setting value or 0.2 % of the rated current
Minimum zero voltage V0	1 % of the setting value or 0.1 V
Minimum transformer neutral point current IY	1% of the setting value or 1 % of the rated current
Minimum negative-sequence system voltage V2	1 % of the setting value or 0.1 V
Minimum negative-sequence system current I2	1 % of the setting value or 1 % of the rated current
Times:	
Independent time delays	1 % of the setting value or 10 ms
Current-dependent time delay, Characteristic curves to IEC, ANSI/IEEE and logarithmic inverse characteristic curve For ≤ 2 I/I_{3I0P} ≤ 20 and T_{3I0P} ≥ 1 s	5 % of the set point value ± 10 ms
Current-dependent time delay, Characteristic curve: logarithmic-inverse	3 % of the set point value ± 10 ms
S0-dependent time delay	3 % of the set point value ± 10 ms
V0-dependent time delay	3 % of the set point value ± 10 ms

Limit angle for direction determination via angular measurement between measuring and reference value	± 1,5°
Zero power for forwards direction	5% of the setting value ± 0.02 VA

Influencing Variables for the Thresholds

Transient excess pickup in method of measurement = fundamental component over 1 cycle filter (standard filter), for τ > 100 ms (with complete displacement)	< 5 %

89 OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.9 Teleprotection with Ground-Fault Protection

Permissive Overreach Transfer Trip

Adjustable process	Permissive overreach transfer trip, directional Unblock procedure, directional	
Transmission extension	0.00 s to 60.00 s	Increments of 0.01 s
Transmission delay	0.00 s to 60.00 s	Increments of 0.01 s
Trans. blk. pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Trans. blk. dropout delay	0.00 s to 60.00 s	Increments of 0.01 s
Delay	0.00 s to 60.00 s	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	
The times set are pure delay times.		

Permissive Overreach Transfer Trip via the Protection Interface

Trans. blk. dropout delay		
Adjustable method	Directional comparison	
Transmission extension	0.00 s to 60.00 s	Increments of 0.01 s
Release delay	0.000 s to 60.000 s	Increments of 0.001 s
Trans. blk. pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Trans. blk. dropout delay	0.00 s to 60.00 s	Increments of 0.01 s
Delay	0.00 s to 60.00 s	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	
The times set are pure delay times.		

12.10 Directional Intermittent Ground-Fault Protection

Setting Values

Threshold value 3I0>	For current transformer type **protection** and I_{rated} = 1 A		0.030 A to 35.000 A	Increments of 0.001 A
	For current transformer type **protection** and I_{rated} = 5 A		0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
No.of pulses for interm.GF			2 to 10	Increments of 1
Pickup extension time			0.00 s to 10.00 s	Increments of 0.01 s
Sum of extended PU times			0.00 s to 180.00 s	Increments of 0.01 s
Reset time			0.00 s to 600.00 s	Increments of 0.01 s
No. of pulses for operate			2 to 100	Increments of 1
Minimum operate delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Pickup time	Approx. 30 ms + OOT[90] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

90 OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

Tolerances

Currents	3I0 via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
	3I0 via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A)
Times	1 % of the setting value or ± 10 ms

12.11 Non-Directional Intermittent Ground-Fault Protection

Setting Values

Threshold value 3I0> interm.	For current transformer type **protection** and I_{rated} = 1 A		0.030 A to 35.000 A	Increments of 0.001 A
	For current transformer type **protection** and I_{rated} = 5 A		0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Number of pickups until intermittent ground fault			2 to 10	Increments of 1
Pickup extension time			0.00 s to 10.00 s	Increments of 0.01 s
Sum of extended pickup times			0.00 s to 180.00 s	Increments of 0.01 s
Reset time			0.00 s to 600.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[91] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

91 OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

Tolerances

Currents	-3I0 via protection-class current transformers: 1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
	-3I0 via sensitive current transformer: 1 % of setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A)
Times	1 % of the setting value or ± 10 ms

12.12 Sensitive Ground-Fault Detection

12.12.1 General

Setting Values

Decay time V0			0.03 s to 0.20 s	Increments of 0.01 s
Dropout delay			0.00 s to 60.00 s	Increments of 0.01 s
Core balance current transformer current 1 Core balance current transformer current 2	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Core balance current transformer angle correction F1 Core balance current transformer angle correction F2			0.0° to 5.0°	Increments of 0.1°

Times

Pickup times	Approx. 25 ms + OOT[92] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Dropout times	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances [93]
$f < 10\ Hz$ $f > 90\ Hz$	Active with less sensitivity [94]

Tolerances

Currents	-3I0 via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A)
	-3I0 via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Voltages	1 % of the setting value or 0.05 V

92 OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

93 Transient ground-fault stage is inactive

94 Transient ground-fault stage is inactive

Times	1 % of the setting value or ±10 ms
Direction-calculation angle error[95]	≤ 1° at 3I0 > 5 mA, V0 = 0.6 V ≤ 2° at 3I0 ≤ 5 mA, V0 = 0.6 V

12.12.2 Directional 3I0 Stage with cos φ or sin φ Measurement

Setting Values

Direction method of measurement			cos φ sin φ	–
Threshold value 3I0> Minimum directional 3I0> for direction determination	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Time delay of the direction determination			0.00 s to 60.00 s	Increments of 0.01 s
α1 constraint of the direction range α2 constraint of the direction range			1° to 15°	Increments of 1°
Angle correction φ			-45° to 45°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

95 Not applicable to *12.12.4 Directional 3I0 Stage with φ(V0,3I0) Measurement*

Times

Operate time with time delay = 0 ms	Approx. 38 ms + OOT[96] at 50 Hz Approx. 35 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

12.12.3 Directional Transient Ground-Fault Stage

Setting Values

3I0> threshold value 3I0> threshold for operate	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.000 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.00 A to 175.00 A	Increments of 0.01 A
	Sensitive current transformer for I_N	$I_{N\text{-}rated}$ = 1 A	0.000 A to 1.600 A	Increments of 0.001 A
		$I_{N\text{-}rated}$ = 5 A	0.000 A to 8.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Maximum operational V0			0.300 V to 200.000 V	Increments of 0.001 V
Dropout delay			0.00 s to 60.00 s	Increments of 0.01 s
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 115 ms + OOT[97] at 50 Hz Approx. 112 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT at 50 Hz Approx. 15 ms + OOT at 60 Hz

96 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

97 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.12.4 Directional 3I0 Stage with φ(V0,3I0) Measurement

Setting Values

Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Min. V0> for direction determination			0.300 V to 200.000 V	Increments of 0.001 V
Time delay of the direction determination			0.00 s to 60.00 s	Increments of 0.01 s
Rotation angle of the reference voltage			-180° to 180°	Increments of 1°
Forward range +/-			0° to 180°	Increments of 1°
Tripping delay			0.00 s to 100.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 23 ms + OOT[98] at 50 Hz Approx. 21 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 21 ms + OOT at 50 Hz Approx. 20 ms + OOT at 60 Hz

Tolerances

Direction-calculation angle error	≤ 1° at 3I0 ≥ 10 mA, V0 = 0.6 V ≤ 2° at 2 mA < 3I0 < 10 mA, V0 = 0.6 V ≤ 3° at 3I0 ≤ 2 mA, V0 = 0.6 V

98 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.12.5 Directional Y0 Stage with G0 or B0 Measurement (Admittance)

Setting Values

Direction method of measurement			B0 G0	–
Release Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Threshold value Y0>			0.10 mS to 100.00 mS	Increments of 0.01 mS
Time delay of direction determination			0.00 s to 60.00 s	Increments of 0.01 s
α1 constraint of direction range α2 constraint of direction range			1° to 15°	Increments of 1°
Angle correction φ			-45° to 45°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 39 ms + OOT[99] at 50 Hz Approx. 35 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

99 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Admittance	1 % of the setting value or 0.05 mS (I_{rated} = 1 A) or 0.25 mS (I_{rated} = 5 A)

12.12.6 Directional Stage with Phasor Measurement of a Harmonic

Setting Values

Min. 3I0> of the selected harmonic phasor	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Dropout ratio of the direction determination in terms of the zero-sequence harmonic current			0.10 to 0.95	Increments of 0.01
Threshold value V0>			0.300 V to 200.000 V	Increments of 0.001 V
Time delay of the direction determination			0.00 s to 60.00 s	Increments of 0.01 s
Extension of the direction result			0.00 s to 60.00 s	Increments of 0.01 s
Forward range +/-			0° to 90°	Increments of 1°
Tripping delay			0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 70 ms + OOT[100] at 50 Hz Approx. 60 ms + OOT at 60 Hz
Dropout time	Approx. 30 ms + OOT at 50 Hz Approx. 20 ms + OOT at 60 Hz

[100] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Zero-sequence harmonic current 3I0harm.	-3I0harm. via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A)
	-3I0harm. via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
V0 fundamental-component value	1 % of the setting value or 0.05 V
Direction-calculation angle error of the 3rd, 5th, or 7th harmonic phasor	≤ 1° at 3I0harm. > 5 mA ≤ 2° at 3I0harm. ≤ 5 mA

12.12.7 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

Setting Values

Threshold value[101]	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 100.00 s	Increments of 0.01 s
Pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01
V< faulty ph-gnd vltg.	0.300 V to 200.000 V	Increments of 0.001 V
V> healthy ph-gnd. vltg.	0.300 V to 200.000 V	Increments of 0.001 V

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	
Standard filter, true RMS value	Approx. 25 ms + OOT[102] at 50 Hz Approx. 22 ms + OOT at 60 Hz
2 cycle filters	Approx. 45 ms + OOT at 50 Hz Approx. 39 ms + OOT at 60 Hz
Dropout time	
Standard filter, true RMS value	Approx. 20 ms + OOT at 50 Hz Approx. 16.6 ms + OOT at 60 Hz
2 cycle filters	Approx. 31.06 ms + OOT at 50 Hz Approx. 27.06 ms + OOT at 60 Hz

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

101 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

102 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.12.8 Non-Directional 3I0 Stage

Setting Values

Method of Measurement			Fundamental component RMS value	
Threshold value 3I0>	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For transformer type I-sensitive and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For transformer type I-sensitive and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
Pickup delay			0.00 s to 60.00 s	Increments of 0.01 s
Tripping delay			0.00 s to 100.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[103] at 50 Hz Approx. 23 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

12.12.9 Non-Directional Y0 Stage

Setting Values

V0> threshold value	0.300 V to 200.000 V	Increments of 0.001 V
Threshold Y0>	0.10 mS to 100.00 mS	Increments of 0.01 mS

[103] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Pickup delay	0.00 s to 60.00 s	Increments of 0.01 s
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	Approx. 32 ms + OOT[104] at 50 Hz Approx. 29 ms + OOT at 60 Hz
Extension of operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 32 ms + OOT at 50 Hz Approx. 27 ms + OOT at 60 Hz

Current Operating Range

Minimum 3I0 threshold value for Y0 calculation	Protection-class current transformers	30 mA sec. (I_{rated} = 1 A)
		150 mA sec. (I_{rated} = 5 A)
	Sensitive current transformer	1 mA sec. (I_{rated} = 1 A)
		5 mA sec. (I_{rated} = 5 A)

Tolerances

Admittance	1 % of the setting value or 0.05 mS (I_{rated} = 1 A) or 0.25 mS (I_{rated} = 5 A)

12.12.10 Non-Directional 3I0 Harmonic Stage

Setting Values

3I0 harm. threshold	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
3I0 harm. dropout ratio			0.10 to 0.95	Increments of 0.01
Pickup extension time			0.00 s to 60.00 s	Increments of 0.01 s
Operate delay			0.00 s to 60.00 s	Increments of 0.01 s
Stabilization counter			1 to 10	Increments of 1

[104] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms and stabilization counter = 4	Approx. 70 ms + OOT[105] at 50 Hz Approx. 60 ms + OOT at 60 Hz
Dropout time	Approx. 40 ms + OOT at 50 Hz Approx. 30 ms + OOT at 60 Hz

Tolerances

Zero-sequence harmonic current 3I0harm.	-3I0harm. via sensitive current transformer: 1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A)
	-3I0harm. via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)

12.12.11 Pulse-Pattern Detection Stage

Setting Values

V0> threshold value			0.300 V to 200.000 V	Increments of 0.001 V
3I0> threshold value	Protection-class current transformers	For $I_{ph\text{-}rated}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	For $I_{ph\text{-}rated}$ = 1 A	0.001 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.001 A to 175.000 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	For $I_{ph\text{-}rated}$ = 1 A	0.005 A to 35.000 A	Increments of 0.001 A
		For $I_{ph\text{-}rated}$ = 5 A	0.005 A to 175.000 A	Increments of 0.001 A
3I0 delta pulse off-on			2 % to 50%	Increments of 1 %
Pulse-on duration Pulse-off duration			0.20 s to 10.00 s	Increments of 0.01 s

[105] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

No. of pulses for operate Monitoring time(in pulses)	2 to 100	Increments of 1
Max.tolera.pulse-on or off	0.02 s to 2.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undercurrent/undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Times

Operate delay = 0 ms	Approx. 2.5 s + 0.3 s + OOT[106] at 50 Hz and 60 Hz[107]
Dropout time	Approx. 32 ms + OOT at 50 Hz and 60 Hz

12.12.12 Intermittent Ground-Fault Blocking Stage

Setting Values

Threshold	For current transformer type **protection** and I_{rated} = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
	For current transformer type **protection** and I_{rated} = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 1 A	0.001 A to 1.600 A	Increments of 0.001 A
	For I_N transformer type **sensitive** and $I_{N\text{-}rated}$ = 5 A	0.005 A to 8.000 A	Increments of 0.001 A
No.of pulses for interm.GF		2 to 50	Increments of 1
Reset time		1.00 s to 600.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

106 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

107 After the first valid pulse is detected, the function picks up. For the typical settings 1.00 s of Pulse-on duration, 1.50 s of Pulse-off duration, and 0.15 s of Max.tolera.pulse-on or off, the inherent pickup time is approx. 1 s + 1.5 s + 2 · 0.15 s + OOT

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

Tolerances

Currents	3I0 via protection-class current transformers: 1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
	3I0 via sensitive current transformer: 1 % of the setting value or 0.2 mA (I_{rated} = 1 A) or 1 mA (I_{rated} = 5 A)
Times	1 % of the setting value or ± 10 ms

12.13 Distance Protection

Residual Compensation

Kr	-0.33 to 11.00	Increments of 0.01
Kx	-0.33 to 11.00	Increments of 0.01
K0	0.000 to 11.000	Increments of 0.001
Angle (K0)	-180.00° to +180.00°	Increments of 0.01°
	Configurable separately for each zone	

Parallel-Line Matching

KmR	0.00 to 8.00	Increments of 0.01
KmX	0.00 to 8.00	Increments of 0.01
Km0	0.000 to 8.000	Increments of 0.001
Angle (Km0)	-180.00° to +180.00°	Increments of 0.01

Phase Preference

For double ground faults in a grounded system	Block leading phase from ground Block lagging phase from ground Release all loops involved Release phase-to-ground loops involved Release phase-to-phase loops involved
For double ground faults in isolated or resonant-grounded system	C(A) acyclic A(C) acyclic B(A) acyclic A(B) acyclic C(B) acyclic B(C) acyclic C(A) cyclic A(C) cyclic All loops involved

Ground-Fault Detection

Threshold value 3I0>	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
Threshold value V0>		0.300 V to 200.000 V	Increments of 0.001 V
Measuring tolerances for sinusoidal measurands		± 5 %	

Pickup Method

Overcurrent pickup			
Iph>>	1 A @ 50 and 100 Irated	0.250 Ato 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	1.25 A to 175.00 A	Increments of 0.01 A
Dropout ratios		Approx. 0.95	
Measuring tolerances for sinusoidal measurands		± 5 %	

Voltage- and phase angle-dependent current pickup (V/I/ϕ) (optional)			
Characteristic		Cascaded with adjustable slopes	
Minimum phase current Iph>	1 A @ 50 and 100 Irated	0.100 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.50 A to 175.00 A	Increments of 0.01 A
Current in short circuit angle range Iϕ	1 A @ 50 and 100 Irated	0.100 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.50 A to 175.00 A	Increments of 0.01 A
Undervoltage phase-to-ground (individually separated according to Iph>, Iph>>, and Iϕ>)		0.500 V to 200.000 V	Increments of 0.001 V
Undervoltage phase-to-phase (individually separated according to Iph>, Iph>>, and Iϕ>)		1.000 V to 200.000 V	Increments of 0.001 V
Lower threshold angle ϕ>		30.0° to 60.0°	Increments of 0.1°
Upper threshold angle ϕ<		90.0° to 120.0°	Increments of 0.1°
Dropout ratios			
Iph>, Iϕ>		Approx. 0.95	
Phase-to-ground voltage Phase-to-phase voltage		Approx. 1.05	
Measuring tolerances for sinusoidal measurands			
Amounts of V, I		± 5 %	
Angle ϕ		± 3°	
Impedance pickup (optional)			
Minimum phase current Iph>	1 A @ 50 and 100 Irated	0.050 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.25 A to 175.00 A	Increments of 0.01 A
Under consideration of the respective direction, the limits of the zones that are set the furthest, are the most important ones.			
Dropout ratio		Approx. 1.05	

Distance Measurement

Characteristic		Quadrilateral, MHO, or circular characteristic curve	
Minimum phase current I>	1 A @ 50 and 100 Irated	0.050 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.25 A to 175.00 A	Increments of 0.01 A
φ_{Dist} = Angle of distance-protection characteristic		30.0° to 90.0°	Increments of 0.1°
Quadrilateral setting ranges:			
X reach = reach of reactance	For I_{rated} = 1 A	0.050 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.010 Ω to 120.000 Ω	
R (ph-ph) = Phase-to-phase resistance reserve	For I_{rated} = 1 A	0.050 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.010 Ω to 120.000 Ω	
R (ph-gnd) = Phase-to-ground resistance reserve	For I_{rated} = 1 A	0.050 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.010 Ω to 120.000 Ω	
α_{Pole} = Zone inclination		0° to 45°	Increments of 1°

Direction determination for polygon:			
For all fault types		With actual short-circuit, buffered or cross-polarized voltages	
Directional sensitivity		Dynamically unlimited, stationary about 1 V	
Every zone can be configured as forward, reverse, or non-directional.			
Setting ranges for MHO characteristic:			
Z_r impedance reach	For I_{rated} = 1 A	0.050 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.010 Ω to 120.00 Ω	
Polarization		With buffered or cross-polarized voltages	
Setting ranges for circular characteristic curve:			
Zr impedance reach	For I_{rated} = 1 A	0.100 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.020 Ω to 120.00 Ω	
Angle for R-reserve		10.0° to +90.0°	Increments of 0.1°
Every zone can be configured as forward or backward.			
Load cutout (for impedance pickup):			
R_{load} = Minimum load resistance	For I_{rated} = 1 A	0.050 Ω to 600.000 Ω	Increments of 0.001 Ω
	For I_{rated} = 5 A	0.010 Ω to 120.000 Ω	
φload = Maximum load angle		20.0° to 60.0°	Increments of 0.1°
Dropout ratios			
- Currents		Approx. 0.95	
- Impedances		Approx. 1.05	
Measured-value correction		For ground-current coupling in parallel lines	
Measuring tolerances for sinusoidal measurands		$\left\|\frac{\Delta X}{X}\right\| \le 5\%$ for $30^\circ \le \varphi_{sc} \le 90^\circ$	
		$\left\|\frac{\Delta R}{R}\right\| \le 5\%$ for $0^\circ \le \varphi_{sc} \le 60^\circ$	
		$\left\|\frac{\Delta Z}{Z}\right\| \le 5\%$ for $-30^\circ \le \varphi_{sc} - \varphi_{line} \le 30^\circ$	

Times

Shortest operate time	Approx. 9 ms + OOT[108] at 50 Hz Approx. 8 ms (60 Hz) + OOT	
Dropout time	Approx. 30 ms	
Incremental times	0.00 s to 60.00 s; ∞ for all zones	Increments of 0.01 s
Timer tolerance	1 % of the setting value or 10 ms	
The set times are pure time delays.		

Frequency Operating Range

0.9 f/f_{rated} to 1.1 f/f_{rated}	According to specified tolerances
0.8 $f/f_{rated} \le f < 0.9$ f/f_{rated} 1.1 $f/f_{rated} \le f \le 1.2$ f/f_{rated}	Slightly expanded tolerances
$f < 0.8$ f_{rated} $f > 1.2$ f_{rated}	Active

[108] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.14 Impedance Protection

Setting Values

Min. phase-current thresh	1 A @ 100 Irated	0.030 A to 100.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 500.00 A	Increments of 0.01 A
	1 A @ 50 Irated	0.030 A to 50.000 A	Increments of 0.001 A
	5 A @ 50 Irated	0.15 A to 250.00 A	Increments of 0.01 A
X reach (ph-g) = reach of reactance, phase-to-ground	For I_{rated} = 1 A	0.100 Ω to 600.000 Ω	Increments of 0.001 A
	For I_{rated} = 5 A	0.020 Ω to 120.000 Ω	Increments of 0.001 A
X reach (ph-ph) = reach of reactance, phase-to-phase	For I_{rated} = 1 A	0.100 Ω to 600.000 Ω	Increments of 0.001 A
	For I_{rated} = 5 A	0.020 Ω to 120.000 Ω	Increments of 0.001 A
R reach (ph-g) = reach of resistance, phase-to-ground	For I_{rated} = 1 A	0.100 Ω to 600.000 Ω	Increments of 0.001 A
	For I_{rated} = 5 A	0.020 Ω to 120.000 Ω	Increments of 0.001 A
R reach (ph-ph) = reach of resistance, phase-to-phase	For I_{rated} = 1 A	0.100 Ω to 600.000 Ω	Increments of 0.001 A
	For I_{rated} = 5 A	0.020 Ω to 120.000 Ω	Increments of 0.001 A

Dropout Ratios

Currents	About 0.95
Voltage	About 1.05
Impedances	About 1.05

Times

Operate time with time delay = 0 ms	Approx. 30 ms + OOT [109] at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Voltage	0.5 % of the setting value or 0.05 V
Impedances Measurement tolerances for sinusoidal values	$\left\|\frac{\Delta X}{X}\right\| \le 5\%$ for $30^\circ \le \varphi_{sc} \le 90^\circ$
	$\left\|\frac{\Delta R}{R}\right\| \le 5\%$ for $0^\circ \le \varphi_{sc} \le 60^\circ$

[109] OOT (Output Operating Time) additional delay of the used output medium, such as 5 ms with quick-acting relay

12.15 Power-Swing Blocking

General

Measuring principle	Cyclic supervision of impedance curves for monotony, continuity, and jump
Detectable power-swing frequency	0.1 Hz to 12 Hz for symmetrical operation, up to 7 Hz during 1-pole dead times and unbalanced faults
Power-swing blocking	Can be set separately for each distance-protection zone

Times

Power-swing detection time	≥ 2.5 power-system cycles
Dropout time	≥ 5.5 power-system cycles in case of unbalanced faults ≥ 5.5 power-system cycles in case of balanced faults Max. 5 s after leaving the pickup range of the distance protection

12.16 External Trip Initiation

Setting Values

Tripping delay	0.00 s to 60.00 s	Increments of 0.01 s

Times

Operate time with time delay = 0 ms - At initiation via binary input signal	Approx. 10 ms + OOT[110]

Tolerance

Sequence tolerance for time delays	1 % of the setting value or 10 ms

110 OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relay, see Chapter *12.1.4 Relay Outputs*

12.17 External Trip Initiation with Current-Flow Criterion

Setting Values

Tripping delay	0.00 s to 60.00 s	Increments of 0.01 s

Times

Operate time with time delay = 0 ms - At initiation via binary input signal	Approx. 10 ms + OOT[111].

Tolerance

Processing tolerance for time delays			1 % of the setting value or 10 ms
Threshold I>	Protection-class current transformers	At I_{rated} = 1 A	1 % of the setting value or 5 mA
		At I_{rated} = 5 A	1 % of the setting value or 25 mA
	Sensitive current transformer	At I_{rated} = 1 A	1 % of the setting value or 0.1 mA
		At I_{rated} = 5 A	1 % of the setting value or 0.5 mA

111 OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relay, see chapter *12.1.4 Relay Outputs*

12.18 Overcurrent Protection, Phases

12.18.1 Stage with Definite-Time Characteristic Curve

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

Setting Values for Protection Stage

Method of measurement		Fundamental component RMS value	–
Threshold value[112]	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Operate delay		0.00 s to 100.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s
Pickup delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT [113] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

112 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

113 OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value, no filter applied (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value with filter for the compensation of the amplitude attenuation due to the anti-aliasing filter (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	2 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value with filter for the gain of harmonics (including compensation of the amplitude attenuation[114] (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1.5 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A) [115]
Up to 50th harmonic, f_{rated} = 50 Hz	3% of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A) [116]
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A) [117]
Pickup delay	1 % of the setting value or 10 ms
Dropout delay	1 % of the setting value or 10 ms
Operate delay for the basic stage	1 % of the setting value or 10 ms

114 In case that the filter response exactly matches the user-defined gain factors

115 In case that the user-defined gain factor is set below 3. The tolerance increases, if the gain factor is larger.

116 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

117 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

Operate delay for the advanced stage	Operate delay mode = Running dur. DO-delay	1 % of the setting value or 10 ms
	Operate delay mode = Frozen dur. DO-delay	1 % of the reference value or 10 ms (Reference value = Setting value + Frozen time)

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.18.2 Stage with Inverse-Time Characteristic Curve

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

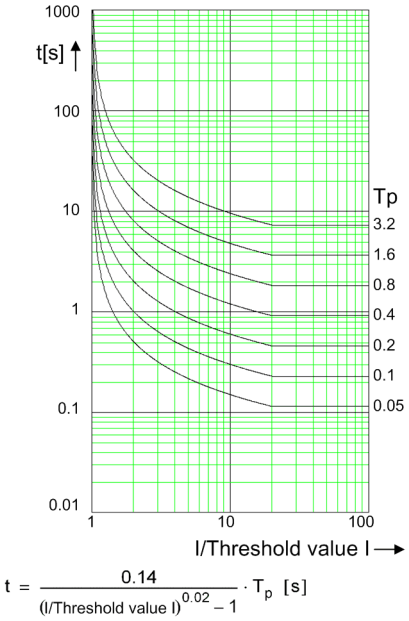
Setting Values for Protection Stage

Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.00 to 15.00	Increments of 0.01
Pickup delay		0.00 s to 60.00 s	Increments of 0.01 s
Minimum time of the curve		0.00 s to 1.00 s	Increments of 0.01 s
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)



Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Time delays	1 % of the setting value or 10 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.18.3 Stage with User-Defined Characteristic Curve

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

118 In case that the filter response exactly matches the user-defined gain factors

119 In case that the user-defined gain factor is set below 3. The tolerance increases, if the gain factor is larger.

120 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

Setting Values for Protection Stage

Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Absolute pickup value	1 A @ 50 and 100 Irated	0.000 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.00 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.000 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.000 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01
Number of value pairs for the operate curve		2 to 30	Increments of 1
X values of the operate curve		1.00 p.u. to 20.00 p.u.	Increments of 0.01 p.u.
Y values of the operate curve		0.00 s to 999.00 s	Increments of 0.01 s
Number of value pairs for the dropout characteristic curve		2 to 30	Increments of 1
X values of the dropout characteristic curve		0.05 p.u. to 0.95 p.u.	Increments of 0.01 p.u.
Y values of the dropout characteristic curve		0.00 s to 999.00 s	Increments of 0.01 s
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value or 95 % of the absolute pickup value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value, no filter applied (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value with filter for the compensation of the amplitude attenuation due to the anti-aliasing filter (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	2 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value with filter for the gain of harmonics (including compensation of the amplitude attenuation[121] (33 % harmonics, in relation to the fundamental component)	
Up to 30 harmonic	1.5 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A) [122]
Up to 50th harmonic, f_{rated} = 50 Hz	3% of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A) [123]
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A) [124]
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value +2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value +2 % current tolerance or 30 ms
Time delays	1 % of the setting value or 10 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

121 In case that the filter response exactly matches the user-defined gain factors

122 In case that the user-defined gain factor is set below 3. The tolerance increases, if the gain factor is larger.

123 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

124 In case that the user-defined gain factor is set below 7. The tolerance increases, if the gain factor is larger.

Operate Curves and Dropout-Time Characteristic Curves According to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

12.19 Overcurrent Protection, Ground

12.19.1 Stage with Definite-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[125]	1 A @ 50 and 100 Irated	0.010 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.05 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.002 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	5 mA sec. (I_{rated} = 1 A) or 25 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT[126] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

Operate Curves and Dropout-Time Characteristic Curves According to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

132 Insignificantly increased tolerances will occur during the calculation of 3I0, maximum factor of 2

133 Insignificantly increased tolerances will occur during the calculation of 3I0, maximum factor of 2

12.20 Overcurrent Protection, 1-Phase

12.20.1 Stage with Definite-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[134]	1 A @ 50 and 100 Irated	0.010 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.05 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.002 A to 8.000 A	Increments of 0.001 A
Dropout ratio (fixed)		0.95	–
Time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 15 ms + OOT[135] at 50 Hz Approx. 14 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT at 50 Hz Approx. 17 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

134 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

135 OOT (Output Operating Time): additional delay of the output medium used, see *12.1.4 Relay Outputs*

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A) valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A) valid for sensitive current transformers
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.20.2 Stage with Inverse-Time Characteristic Curve

Setting Values

Method of measurement		Fundamental component RMS value	–
Threshold value[136]	1 A @ 50 and 100 Irated	0.010 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.05 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.002 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

136 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Operate Curves and Dropout Characteristic Curves According to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value +2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value +2 % current tolerance or 30 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

Operate Curves and Dropout-Time Characteristic Curves according to IEC

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

12.21 Overcurrent Protection, 1-Phase (Fast Stage)

Setting Values

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio (fixed)		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 8 ms + OOT[137]
Dropout time	Approx. 25 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Pickup tolerance, current	5 % of the setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

[137] OOT (Output Operating Time): additional time delay of the output medium used, for example, 5 ms with fast relay

12.22 Voltage-Dependent Overcurrent Protection, Phases

Setting Values for All Stage Types

Method of measurement		Fundamental component RMS value	–
Overcurrent threshold value	For I_{rated} = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 175.00 A	Increments of 0.01 A
Time delay		0.10 s to 60.00 s	Increments of 0.01 s

Setting Values for Inverse-Time Overcurrent Protection Stages

Method of measurement	Fundamental component RMS value	–
Dropout ratio of undervoltage[138]	1.01 to 1.20	Increments of 0.01
Undervoltage threshold value[138]	0.300 V to 175.000 V	Increments of 0.001 V
Dropout	Disk emulation Instantaneous	–
Time multiplier	0.05 to 15.00	Increments of 0.01

Setting Values for Definite-Time Overcurrent Protection Stages

Seal-in voltage	0.300 V to 175.000 V	Increments of 0.001 V
Phase-to-phase voltage	0.300 V to 175.000 V	Increments of 0.001 V
Negative-sequence voltage V2	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Duration of V-seal-in time	0.10 s to 60.00 s	Increments of 0.01 s

Dropout for Inverse-Time Overcurrent Protection Stages

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout	
Current	95 % of 1.1 · threshold value
Voltage[138]	105 % of threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer [138]	150 mV sec.

Reset of the Integration Timer for Inverse-Time Overcurrent Protection Stages

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

[138] The value is for the inverse-time overcurrent voltage-released stage.

Dropout for Definite-Time Overcurrent Protection Stages

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent/overvoltage and of 105 % for undervoltage functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Operate Curves and Dropout Characteristic Curves According to IEC

Extension of the operate time during operation with inrush-current detection	Approx. 10 ms

The operate curves and dropout characteristic curves according to IEC can be found in the chapter *Technical Data* under *Inverse-Time Overcurrent Protection*.

Operate Curves and Dropout Characteristic Curves According to ANSI/IEEE

The operate curves and dropout characteristic curves according to IEC can be found in the chapter *Technical Data* under *Inverse-Time Overcurrent Protection*.

Times for Definite-Time Overcurrent Protection Stages

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[139] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)

[139] OOT (Output Operating Time): additional delay of the output medium used, see Chapter *12.1.4 Relay Outputs*

Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Voltage	0.5 % of the setting value or 0.05 V
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Time delays	1 % of the setting value or 10 ms

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for τ > 100 ms (with complete unbalance)	< 5 %

12.23 Directional Overcurrent Protection, Phases

12.23.1 Stage with Definite-Time Characteristic Curve

Setting Values

Rotation angle of the reference voltage		-180° to +180°	Increments of 1°
Directional mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value[140]	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio		0.90 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Direction Determination

Type	With healthy voltages With voltage memory 2 s
Forward range	$V_{ref,rot}$ ±88°
Dropout differential forward/reverse range	1°
Directional sensitivity	For 1 and 2-phase short circuits: unlimited For 3-phase short circuits: dynamically unlimited, stationary Approx. 13 V phase-to-phase

140 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 0.1 $I_{rated,sec}$.

Times

Operate time with time delay = 0 ms	Approx. 37 ms + OOT [141] at 50 Hz Approx. 31 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % harmonics, in relation to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Time delay	1 % of the setting value or 10 ms
Direction-determination angle error	1 °

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.23.2 Stage with Inverse-Time Characteristic Curve

Setting Values

Rotation angle of the reference voltage	-180° to +180°	Increments of 1°
Directional mode	Forward Backward	–
Method of measurement	Fundamental component RMS value	–

[141] OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

Threshold value[142]	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.00 to 15.00	Increments of 0.01
Minimum time of the curve		0.00 s to 1.00 s	Increments of 0.01 s
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Operate Curves and Dropout-Time Characteristic Curves according to IEC

Normal inverse: type A	See *Figure 12-10* in chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*
Very inverse: type B

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
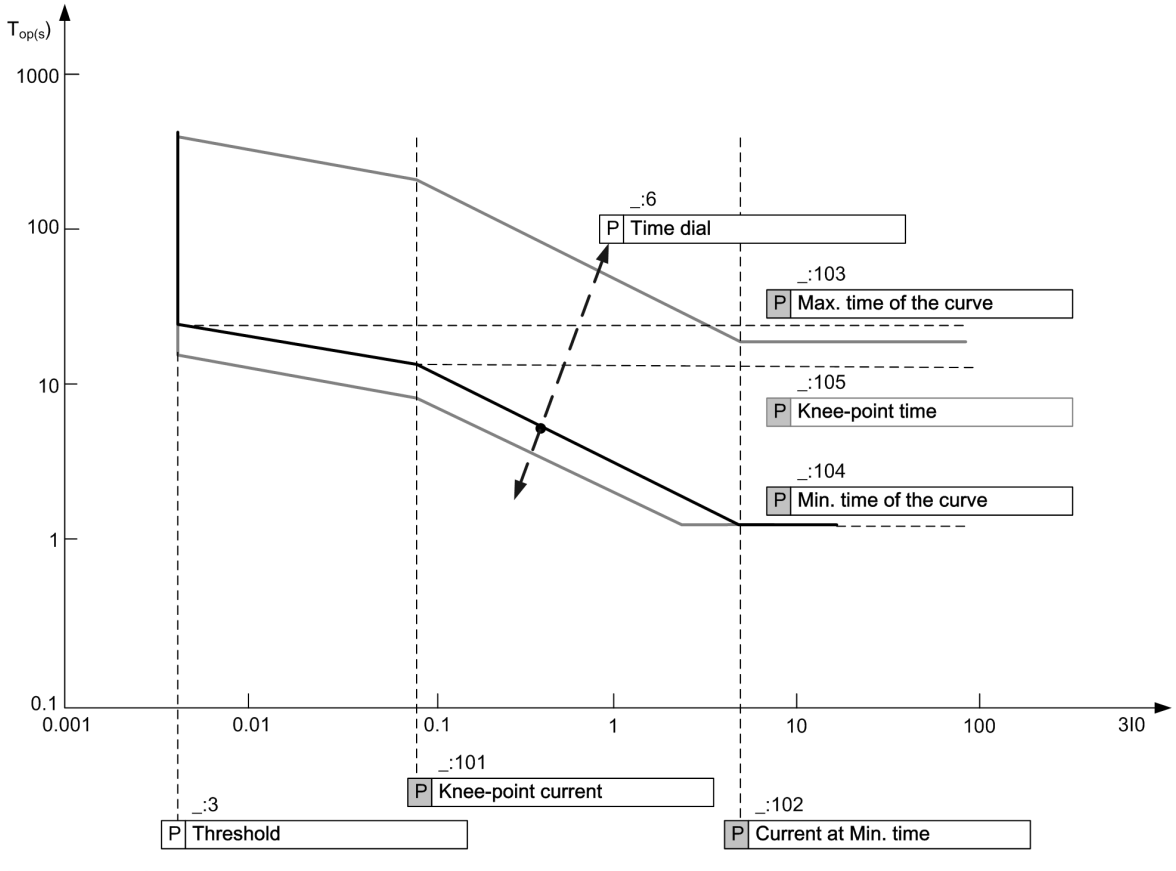
Inverse-time operate time to logarithmic inverse-time characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Inverse-time dropout time to logarithmic inverse-time characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %



12.24.4 Stage with Knee-Point Characteristic Curve

Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold value	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Characteristic curve: see *Figure 12-19*			
Minimum time of the characteristic curve		0.00 s to 30.00 s	Increments of 0.01 s
Knee-point time of the curve		0.00 s to 100.00 s	Increments of 0.01 s
Maximum time of the characteristic curve		0.00 s to 200.00 s	Increments of 0.01 s
Knee-point value		0.030 A to 40.000 A	Increments of 0.001 A
Current at minimum time of the curve		0.030 A to 40.000 A	Increments of 0.001 A
Time multiplier		0.05 to 1.50	Increments of 0.01

[dw_drloinkn_1, en_US]

Figure 12-19 Operate Curve of the Logarithmic Inverse Time with Knee-Point Characteristic (In the Example of **`Threshold = 0.004 A`**)

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Inverse-time operate time to logarithmic inverse time with knee-point characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Inverse-time dropout time to logarithmic inverse time with knee-point characteristic	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.24.5 Stage with User-Defined Characteristic Curve

Setting Values for the Function Direction Determination

Method for direction determination	Zero sequence Negative sequence	–
Minimum V0 or V2 threshold	0.150 V to 20.000 V	0.001 V
Rotation angle of the reference voltage	-180° to 180°	1°
Forward range	0° to 180°	1°

Setting Values

Direction mode		Forward Reverse	–
Method of measurement		Fundamental component RMS value	–
Threshold value	1 A @ 50 and 100 Irated	0.030 A to 40.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 200.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout		Disk emulation Instantaneous	–
Time multiplier		0.05 to 15.00	Increments of 0.01
X values of the operate curve		1.00 p. u. to 66.67 p. u.	Increments of 0.01 p. u.
Y values of the operate curve		0.00 s to 999.00 s	Increments of 0.01 s
Number of value pairs for the dropout characteristic curve		2 to 30	Increments of 1
X values of the dropout characteristic curve		0.05 p. u. to 0.95 p. u.	Increments of 0.01 p. u.
Y values of the dropout characteristic curve		0.00 s to 999.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Times

The maximum pickup time with operate delay = 0 ms	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
Extension of the operate time during operation with inrush-current detection	Approx. 10 ms
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

Tolerances

Currents, method of measurement = fundamental component	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % part of harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of the setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Direction-determination angle error	1°

Influencing Variables for Threshold Values

Transient excess pickup in method of measurement = fundamental component, for $\tau > 100$ ms (with complete unbalance)	< 5 %

12.25 Positive-Sequence Overcurrent Protection

12.25.1 Stage with Definite-Time Characteristic Curve

Setting Values for Protection Stage

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT [146] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Current	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

[146] OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

12.25.2 Stage with Inverse-Time Characteristic Curve

Setting Values for Protection Stage

Threshold	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Reset		instantaneous disk emulation	–
Time dial		0.00 to 15.00	Increments of 0.01

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	95 % of 1.1 · threshold value
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Operate and Dropout Characteristic Curves

You can select from the following operate and dropout characteristic curves:

Table 12-7 Standard Characteristic Curves according to IEC

Normal inverse: type A	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-10*
Very inverse: type B	
Extremely inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-11*
Long-time inverse: type B	

Table 12-8 Standard Characteristic Curves according to ANSI

Inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-13*
Short inverse	
Long inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-14*
Moderately inverse	
Very inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-15*
Extremely inverse	
Definite inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-16*

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT [147] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms
Dropout time	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Current	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Time delays	1 % of the setting value or 10 ms

147 OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

12.26 Negative-Sequence Protection

12.26.1 Stage with Definite-Time Characteristic Curve

Setting Values

Reference value for I_2 (I_{ref})		Rated object current $I_{rated, obj.}$ Positive-sequence current I_1	
Threshold		5.0 % to 999.9 % I_2/I_{ref}	Increments of 0.1
Dropout ratio		0.40 to 0.99	Increments of 0.01
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Release current (minimum current release)	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Maximum phase current (maximum current limiting)	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Dropout for the Threshold

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

- Dropout differential derived from the parameter **`Dropout ratio`**
- Dropout differential of 0.5 % of the object rated current

Dropout for the Release Current

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Pickup time	Approx. 40 ms + OOT[148] at 50 Hz
	Approx. 35 ms + OOT at 60 Hz
Dropout time	Approx. 35 ms + OOT

148 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Current Operating Range

Current range	At least one phase current ≥ setting value $I_{release}$
	All phase currents ≤ setting value $I_{ph, max}$

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Pickup value	
$I_2/I_{rated, obj}$	Approx. 1% of the setting value or 0.3% of the absolute value
I_2/I_1	Approx. 1 % of the setting value or 0.5 % of the absolute value ($I_1 > 50$ mA ($I_{rated} = 1$ A) or 250 mA ($I_{rated} = 5$ A))
Time delays	1 % of the setting value or 10 ms

12.26.2 Stage with Inverse-Time Characteristic Curve

Setting Values

Reference value for I_2 (I_{ref})		Rated object current $I_{rated,obj.}$ Positive-sequence current I_1	
Threshold		5.0 % to 999.9 % I_2/I_{ref}	Increments of 0.1
Reset		Disk emulation Instantaneous	
Time dial		0.05 to 15.00	Increments of 0.01
Release current (minimum current release)	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Maximum phase current (maximum current limiting)	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Dropout for the Threshold

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

- Dropout of 95 % of 1.1 · threshold value
- Dropout differential of 0.5 % of the object rated current

Reset of the Integration Timer

Instantaneous	With dropout
Disk emulation	Approx. < 0.90 · threshold value

Dropout for the Release Current

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Pickup time	Approx. 40 ms + OOT[149] at 50 Hz
	Approx. 35 ms + OOT at 60 Hz
Dropout time	Approx. 35 ms + OOT

Operate and Dropout Characteristic Curves

You can select from the following operate and dropout characteristic curves:

Table 12-9 Standard Characteristic Curves to IEC

Normal inverse: type A	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-10*
Very inverse: type B	
Extremely inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-11*
Long-time inverse: type B	

Table 12-10 Standard Characteristic Curves to ANSI

Inverse: type C	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-13*
Short inverse	
Long inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-14*
Moderately inverse	
Very inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-15*
Extremely inverse	
Definite inverse	See chapter *12.18.2 Stage with Inverse-Time Characteristic Curve*, *Figure 12-16*

Extension of the Operating Time

Extension of the operate time during operation with transformer inrush-current detection	Approx. 10 ms

[149] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Current Operating Range

Current range	At least one phase current ≥ setting value $I_{release}$
	All phase currents ≤ setting value $I_{ph, max}$

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Reference value = rated current	
Pickup value	Approx. 1 % of the setting value or 0.3 % of the absolute value
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the setting value or + 2 % of the current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the setting value or + 2 % of the current tolerance or 30 ms
Reference value = pos. seq. current	
Pickup value	Approx. 1 % of the setting value or 0.5 % of the absolute value (I1 > 50 mA (I_{rated} = 1 A) or 250 mA (I_{rated} = 5 A))
Operate time for 2 ≤ I/I threshold value ≤ 20	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms
Dropout time for I/I threshold value ≤ 0.90	5 % of the reference (calculated) value + 2 % current tolerance or 30 ms

12.27 Directional Negative-Sequence Protection with Definite-Time Delay

Setting Values

Directional mode	Forward, backward, non-directional	
Stabilization with phase currents	0 % to 30 %	Increments of 1 %

Threshold value (pickup value) at $I_{N\text{-rated}}$ = 1 A	0.030 A to 35.000 A	Increments of 0.001 A
Threshold value (pickup value) at $I_{N\text{-rated}}$ = 5 A	0.15 A to 175.00 A	Increments of 0.01 A

Extension time of the blocking after a 1-pole pause	0.00 s to 60.00 s	Increments of 0.01 s

Setting Values for Direction Determination

Minimum negative-sequence system voltage V2		0.150 V to 20.000 V	Increments of 0.001 V
Minimum negative-sequence system current I2	For I_{rated} = 1 A	0.030 A to 10.000 A	Increments of 0.001 A
	For I_{rated} = 5 A	0.15 A to 50.00 A	Increments of 0.01 A
Upper limit angle forward, β		0° to 360°	Increments of 1°
Lower limit angle forward, α		0° to 360°	Increments of 1°

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

- Dropout differential derived from the parameter **`Dropout ratio`**
- Dropout differential of 0.5 % of the object rated current

Times

Operate time with time delay = 0 ms	Approx. 40 ms + OOT[150] at 50 Hz Approx. 40 ms + OOT at 60 Hz
Dropout time	Approx. 39 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 80\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 80\ Hz$	Inactive

Tolerances

Threshold values:	
Negative-sequence voltage V2	1 % of the setting value or 0.05 V
Negative-sequence current I2	2 % of the setting value or 10 mA at I_{rated} = 1 A
	1 % of the setting value or 50 mA at I_{rated} = 5 A

[150] OOT (Output Operating Time) Additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Times:	
Independent time delays	1 % of the setting value or 10 ms

Limit angle in determining the direction	1°

12.28 Undercurrent Protection

Setting Values

Method of measurement		fundamental comp. RMS value	–
Threshold value I<	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Pickup delay		0.00 s to 60.00 s	Increments of 0.01 s
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Measurement repetition		0 to 10	Increments of 1

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with **`Measurement repetition`** = 0	Approx. 25 ms + OOT[151] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

151 OOT (Output Operating Time): additional delay of the output medium used, for example, 5 ms with fast relays, see chapter Relay Outputs

Tolerances

Currents, method of measurement = fundamental component	1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Currents, method of measurement = RMS value (33 % portion harmonic, referring to fundamental component)	
Up to 30th harmonic	1 % of setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 50 Hz	3 % of setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Up to 50th harmonic, f_{rated} = 60 Hz	4 % of setting value or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

12.29 Overexcitation Protection

Setting Values

Threshold value (Inverse-time characteristic curve pickup)		$\frac{V/V_{rated}}{f/f_{rated}}$	1.00 to 1.20	Increments of 0.01
Threshold value (Definite-time characteristic curve pickup)		$\frac{V/V_{rated}}{f/f_{rated}}$	1.00 to 1.40	Increments of 0.01
Time delay (warning delay and tripping delay)			0.00 s to 60.00 s	Increments of 0.01 s
Characteristic value pairs			2 to 30	
	Ranges of values	V/f	1.00 p.u. to 10.00 p.u.	Increments of 0.01 p.u.
		t	0 s to 100 000 s	Increments of 1 s
Cooling time therm. replica			0 s to 100 000 s	Increments of 1 s

Functional Measured Values

Measured Value	Description
(_:2311:322) V/f	Value calculated from voltage and frequency.
(_:13591) Therm.charact.	Thermal tripping of the overexcitation protection. If the value reaches 100 %, tripping occurs.

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Operating Times

Operate times/dropout times		
Operate time at frequency	50 Hz	60 Hz
Minimum	33 ms + OOT[1]	30 ms + OOT[152]
Dropout time	10 ms + OOT[1]	10 ms + OOT[1]

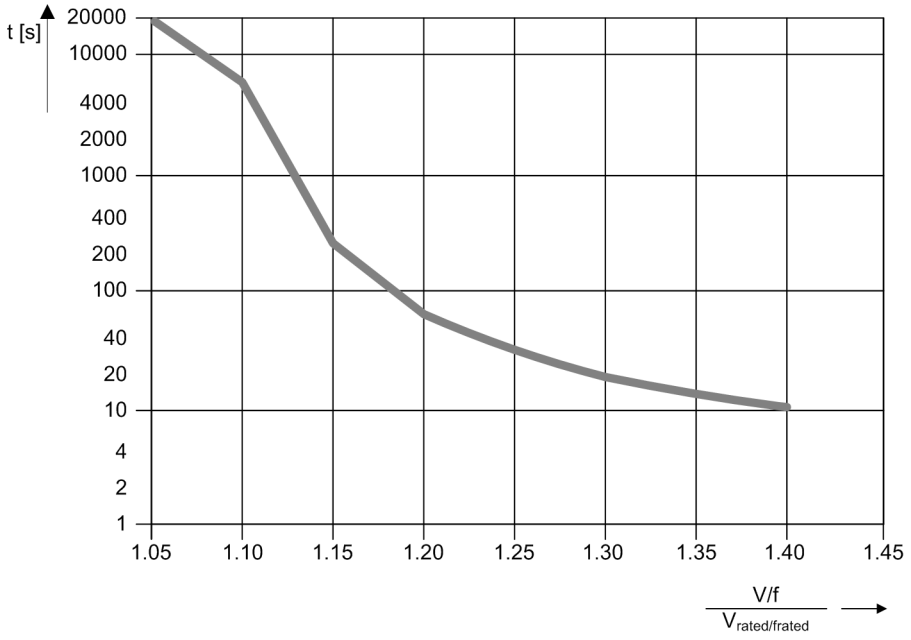
Dropout Ratios

Warning, tripping (independent stage)	Approx. 0.98

Operate Curve

Thermal replica	For default setting refer to the following characteristic curve *Figure 12-20*

Tolerances



V/f pickup	2 % of the setting value
Time delays	1 % of the setting value or 10 ms (min. 1.5 periods)
Thermal replica	5 % based on V/f ± 600 ms

[152] Refer to protection functions, for example overcurrent protection

Voltage measurement accuracy	0.5 % of the setting value or 0.5 V in the range fn ± 10 %
Frequency measurement accuracy	1.0 % of the setting value or 1.0 Hz in the frequency range 10 Hz to 90 Hz

Influencing Quantities

Auxiliary direct voltage in the 0.8 range	≤ 1 %
Time delays	≤ 0.5 %/10 K
Thermal replica	≤ 1 %
Harmonics	
up to 10 % of 3rd harmonics up to 10 % of 5th harmonics	≤ 1 % ≤ 1 %

[dw_rsasuf, 1, en_US]

Figure 12-20 Operate Curve from the Thermal Replica of the Overexcitation Protection (Default Setting)

12.30 Unbalanced-Load Protection

Setting Values

Maximum continuously perm. I2	3.0 % to 30.0 % $I2/I_{rated,machine}$	Increments of 0.1 %
Unbalanced load factor K	1.0 s to 100.0 s	Increments of 0.1 s
Warning delay	0.0 s to 60.0 s; ∞	Increments of 0.1 s
Cooling time thermal replica	0 s to 50 000 s	Increments of 1 s

Dropout

$I2_{perm} \cdot I_{rated.machine} \leq 10$ mA	Dropout value = $0.5 \cdot I2_{perm} \cdot I_{rated,machine}$
10 mA < $I2_{perm} \cdot I_{rated.machine} \leq 100$ mA	Dropout value = $I2_{perm} \cdot I_{rated,machine}$ - 5 mA
$I2_{perm} \cdot I_{rated.machine} > 100$ mA	Dropout value = $0.95 \cdot I2_{perm} \cdot I_{rated,machine}$

Operate Characteristics

Characteristic of the thermal replica	$t_{I2\,Perm} = \frac{K}{\left(I_2/I_{rated\,,machine}\right)^2}$	
Where:	t_{I2perm}	Permissible application time of the negative-sequence current
	K	Unbalanced load factor K
	$I2/I_{rated,machine}$	Unbalanced load (negative-sequence current/rated current of the machine)

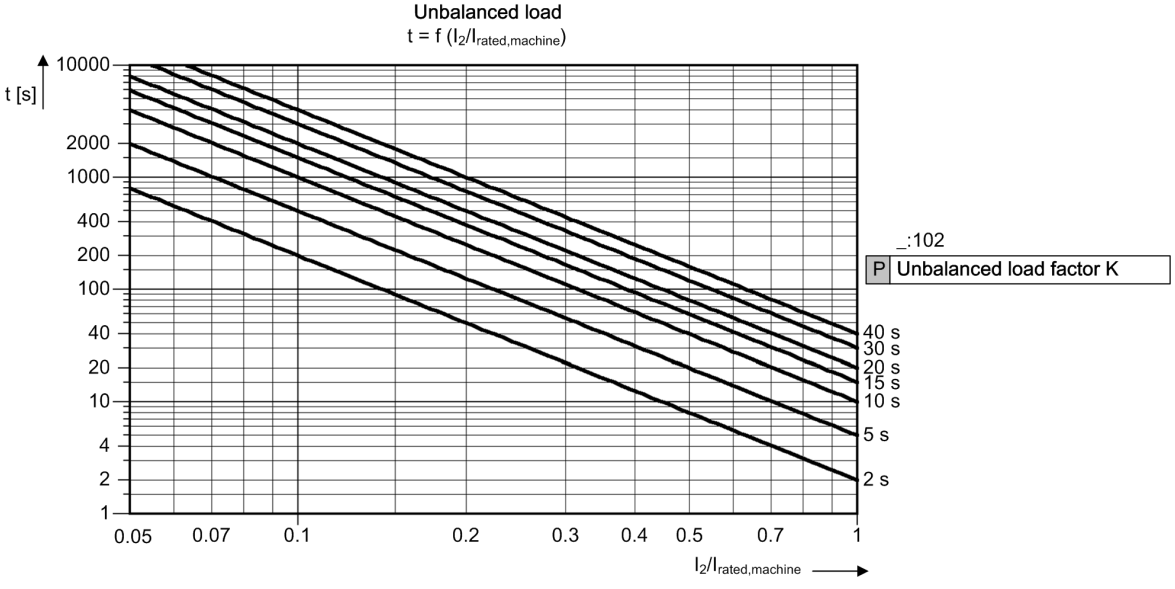


Figure 12-21 Thermal Characteristic for Unbalanced Load Protection

Times

Pickup time of the warning stage	Approx. 60 ms + OOT[153] at 50 Hz Approx. 50 ms + OOT at 60 Hz
Dropout time	Approx. 50 ms or better

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Negative-sequence current I_2	The value can be any of the following: • ≤ 1% of the setting value • 3 mA at I_{rated} = 1 A • 15 mA at I_{rated} = 5 A
Warning delay	1 % of the setting value or 10 ms
Time for $I2/I2_{perm} \leq 10$	< (5 % of the reference value + 2 % of the current tolerance) or 100 ms

Influencing Variables for the Thresholds

Harmonics	
– Up to 10 % 3rd harmonic	≤ 1 %
– Up to 10 % 5th harmonic	≤ 1 %

[153] OOT (Output Operating Time): additional delay of the output medium used, for example, 5 ms with fast relays

12.31 Instantaneous High-Current Tripping

Setting Values

Threshold value	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 50 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Dropout ratio	0.50 to 0.90	Increments of 0.01	

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time for current > 2 · √2· threshold value	Approx. 8 ms + OOT[154]

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Response tolerance, current	5 % of the setting value or 10 mA at I_{rated} = 1 A 5 % of the setting value or 50 mA at I_{rated} = 5 A
Time delays	1 % of the setting value or 10 ms

[154] OOT (Output Operating Time) Additional delay of the output medium used, see *12.1.4 Relay Outputs*

12.32 Overvoltage Protection with 3-Phase Voltage

Setting Values for the Function

Stabilization counter	0 to 10	Increments of 1

Setting Values for Stage Type Definite-Time Overvoltage Protection

Measured value	Phase-to-phase Phase-to-ground	
Method of measurement	Fundamental component RMS value	
Pickup mode	1 out of 3 3 out of 3	
Pickup value[155]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 300.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Setting Values for Stage Type Inverse-Time Overvoltage Protection

Measured value	Phase-to-phase Phase-to-ground	
Method of measurement	Fundamental component RMS value	
Pickup mode	1 out of 3 3 out of 3	
Pickup value	0.300 V to 340.000 V	Increments of 0.001 V
Pickup factor	1.00 to 1.20	Increments of 0.01
Characteristic constant k	0.00 to 300.00	Increments of 0.01
Characteristic constant α	0.010 to 5.000	Increments of 0.001
Characteristic constant c	0.000 to 5.000	Increments of 0.001
Time multiplier	0.05 to 15.00	Increments of 0.01
Additional time delay	0.00 s to 60.00 s	Increments of 0.01 s
Reset time	0.00 s to 60.00 s	Increments of 0.01 s

Operate Curve for Stage Type Inverse-Time Overvoltage Protection

$$T_{op} = T_{inv} + T_{add}$$

Where

T_{op} Operate delay

T_{inv} Inverse-time delay

T_{add} Additional time delay (parameter **`Additional time delay`**)

$$T_{inv} = T_p \left(\frac{k}{\left(\frac{V}{V_{thresh}}\right)^{\alpha} - 1} + c \right) [s]$$

[155] If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

Where

T_{inv}	Inverse-time delay
T_p	Time multiplier (parameter **Time dial**)
V	Measured voltage
V_{thresh}	Threshold value (parameter **Threshold**)
k	Curve constant k (parameter **Charact. constant k**)
α	Curve constant α (parameter **Charact. constant α**)
c	Curve constant c (parameter **Charact. constant c**)

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter Dropout ratio If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[156] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances for Stage Type Definite-Time Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

Tolerances for Stage Type Inverse-Time Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Operate time for 1.2 ≤ V/V threshold value ≤ 20	5 % of the setting value or 30 ms
Reset time delay	1 % of the setting value or 10 ms

[156] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.33 Overvoltage Protection with Positive-Sequence Voltage

Setting Values

Pickup value	0.300 V to 200.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[157] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

[157] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.34 Overvoltage Protection with Negative-Sequence Voltage

Setting Values for the Function

Measuring window	1 cycle to 10 cycles	Increments of 1 cycle

Setting Values

Pickup value of V2	0.300 V to 200.000 V	Increments of 0.001 V
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup times	55 ms to 210 ms + OOT [158] (depends on the measuring-window length) at 50 Hz 48 ms to 185 ms + OOT (depends on the measuring-window length) at 60 Hz
Dropout time	20 ms to 70 ms + OOT (depends on the measuring-window length)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Voltages	0.50 % of the setting value or 0.050 V
Time delays	1.00 % of the setting value or 10 ms

[158] OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

12.35 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage

Setting Values for the Function

Measuring window	1 cycle to 10 cycles	Increments of 1 cycle
Minimum voltage V1	0.300 V to 60.000 V	Increments of 0.001 V

Setting Values for Stage Types

Pickup value of V2/V1	0.50 % to 100.00 %	Increments of 0.01 %
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup times	55 ms to 210 ms + OOT[159] (depends on the measuring-window length) at 50 Hz 48 ms to 190 ms + OOT (depends on the measuring-window length) at 60 Hz
Dropout times	22 ms to 55 ms + OOT (depends on the measuring-window length) at 50 Hz 18 ms to 45 ms + OOT (depends on the measuring-window length) at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Voltages	0.50 % of the setting value or 0.050 V
Time delays	1.00 % of the setting value or 10 ms

[159] OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

12.36 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage

Setting Values for Stage Type Definite-Time Overvoltage Protection

Method of measurement	fundamental comp. fund. comp. long filter RMS value	
Blk. by meas.-volt. failure	no yes	
Detection of faulty phase	no yes	
Threshold[160]	0.300 V to 200.000 V	Increments of 0.001 V
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
Pickup delay	0.00 s to 320.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01
V< faulty ph-to-gnd volt.	0.300 V to 200.000 V	Increments of 0.001 V
V> healthy ph-to-gnd volt.	0.300 V to 200.000 V	Increments of 0.001 V

Setting Values for Stage Type Inverse-Time Overvoltage Protection

Method of measurement	fundamental comp. fund. comp. long filter RMS value	
Blk. by meas.-volt. failure	no yes	
Detection of faulty phase	no yes	
Threshold[160]	0.300 V to 200.000 V	Increments of 0.001 V
Pickup factor	1.00 to 1.20	Increments of 0.01
Charact. constant k	0.00 to 300.00	Increments of 0.01
Charact. constant α	0.010 to 5.000	Increments of 0.001
Charact. constant c	0.000 to 5.000	Increments of 0.001
Time dial	0.05 to 15.00	Increments of 0.01
Additional time delay	0.00 s to 60.00 s	Increments of 0.01 s
Reset time	0.00 s to 60.00 s	Increments of 0.01 s
V< faulty ph-to-gnd volt.	0.300 V to 200.000 V	Increments of 0.001 V
V> healthy ph-to-gnd volt.	0.300 V to 200.000 V	Increments of 0.001 V

Operate Curve for Stage Type Inverse-Time Overvoltage Protection

$$T_{op} = T_{inv} + T_{add}$$

Where

T_{op} Operate delay

T_{inv} Inverse-time delay

T_{add} Additional time delay (parameter **`Additional time delay`**)

[160] If you have selected the **Method of measurement** = **RMS value**, do not set the threshold value under 10 V.

$$T_{inv} = T_p \left(\frac{k}{\left(\frac{V}{V_{thresh}}\right)^{\alpha} - 1} + c \right) [s]$$

Where

T_{inv}	Inverse-time delay
T_p	Time multiplier (parameter **`Time dial`**)
V	Zero-sequence voltage
V_{thresh}	Threshold value (parameter **`Threshold`**)
k	Curve constant k (parameter **`Charact. constant k`**)
α	Curve constant α (parameter **`Charact. constant α`**)
c	Curve constant c (parameter **`Charact. constant c`**)

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms	
Standard filter, true RMS value, typical	Approx. 25 ms + OOT[161] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Standard filter, true RMS value, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
2 cycle filters, typical	Approx. 40 ms + OOT at 50 Hz Approx. 35 ms + OOT at 60 Hz
2 cycle filters, maximum	Approx. 45 ms + OOT at 50 Hz Approx. 40 ms + OOT at 60 Hz
Dropout time	
Standard filter, true RMS value, typical	Approx. 20 ms + OOT at 50 Hz Approx. 17 ms + OOT at 60 Hz
Standard filter, true RMS value, maximum	Approx. 25 ms + OOT at 50 Hz Approx. 20 ms + OOT at 60 Hz
2 cycle filters, typical	Approx. 30 ms + OOT at 50 Hz Approx. 25 ms + OOT at 60 Hz
2 cycle filters, maximum	Approx. 35 ms + OOT at 50 Hz Approx. 30 ms + OOT at 60 Hz

[161] OOT (Output Operating Time): additional delay of the output medium used, see *12.1.4 Relay Outputs*

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances for Stage Type Definite-Time Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

Tolerances for Stage Type Inverse-Time Overvoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Operate time for $1.2 \leq V/V$ threshold value ≤ 20	5 % of the setting value or 30 ms
Reset time delay	1 % of the setting value or 10 ms

12.37 Overvoltage Protection with Any Voltage

Setting Values

Measured value[162]	Measured phase-to-ground voltage V_A Measured phase-to-ground voltage V_B Measured phase-to-ground voltage V_C Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Calculated voltage V0	
Method of measurement	Fundamental component RMS value	
Pickup value[163]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.90 to 0.99	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[164] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

162 If the function **Overvoltage protection with any voltage** is used in a 1-phase function group, the measured-value parameter is not visible.

163 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

164 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

12.38 Undervoltage Protection with 3-Phase Voltage

Setting Values for the Function

Stabilization counter	0 to 10	Increments of 1

Setting Values for Stage Type Definite-Time Undervoltage Protection

Measured value		Phase-to-phase Phase-to-ground	
Method of measurement		Fundamental component RMS value	
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold value[165]		0.300 V to 175.000 V	Increments of 0.001 V
Time delay		0.00 s to 300.00 s	Increments of 0.01 s
Dropout ratio		1.01 to 1.20	Increments of 0.01

Setting Values for Stage Type Inverse-Time Undervoltage Protection

Measured value		Phase-to-phase Phase-to-ground	
Method of measurement		Fundamental component RMS value	
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold		0.300 V to 175.000 V	Increments of 0.001 V
Pickup factor		0.80 to 1.00	Increments of 0.01
Characteristic constant k		0.00 to 300.00	Increments of 0.01
Characteristic constant α		0.010 to 5.000	Increments of 0.001
Characteristic constant c		0.000 to 5.000	Increments of 0.001
Time multiplier		0.05 to 15.00	Increments of 0.01
Additional time delay		0.00 s to 60.00 s	Increments of 0.01 s
Reset time		0.00 s to 60.00 s	Increments of 0.01 s

Operate Curve

$T_{op}=T_{Inv}+T_{add}$

Where:

T_{op} Operate delay

[165] If you have selected the **Method of measurement** = **RMS value**, do not set the threshold value under 10 V.

T_{Inv} Inverse-time delay

T_{add} Additional time delay (parameter **Additional time delay**)

$$T_{Inv} = T_p \left(\frac{k}{1 - \left(\frac{V}{V_{Thresh}} \right)^{\alpha}} + c \right) [s]$$

[fo_uvp_3ph_inverse, 2, en_US]

Where

T_{Inv} Inverse-time delay

T_p Time multiplier (parameter **Time dial**)

V Measured undervoltage

V_{Thresh} Threshold value (parameter **Threshold**)

k Curve constant k (parameter **Charact. constant k**)

α Curve constant α (parameter **Charact. constant α**)

c Curve constant c (parameter **Charact. constant c**)

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter Dropout ratio If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[166] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10 \text{ Hz} \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90 \text{ Hz}$	Slightly expanded tolerances
$f < 10 \text{ Hz}$ $f > 90 \text{ Hz}$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

[166] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances for Stage Type Definite-Time Undervoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A), valid for instrument transformers
Time delays	1 % of the setting value or 10 ms

Tolerances for Stage Type Inverse-Time Undervoltage Protection

Voltages	0.5 % of the setting value or 0.05 V
Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A), valid for instrument transformers
Operate time for $0 < V/V_{Thresh} < 0.9$	5 % of the setting value or 30 ms
Reset time delay	1 % of the setting value or 10 ms

12.39 Undervoltage Protection with Positive-Sequence Voltage

Setting Values

Threshold value		0.300 V to 200.000 V	Increments of 0.001 V
Time delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio		1.01 to 1.20	Increments of 0.01
Current-flow criterion		On Off	
Threshold value I>	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[167] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

[167] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), valid for protection-class current transformers
	1 % of the setting value or 0.1 mA (I_{rated} = 1 A) or 0.5 mA (I_{rated} = 5 A), valid for instrument transformers
Time delays	1 % of the setting value or 10 ms

12.40 Undervoltage Protection with Any Voltage

Setting Values

Measured value	Measured phase-to-ground voltage V_A Measured phase-to-ground voltage V_B Measured phase-to-ground voltage V_C Measured phase-to-phase voltage V_{AB} Measured phase-to-phase voltage V_{BC} Measured phase-to-phase voltage V_{CA} Calculated phase-to-phase voltage V_{AB} Calculated phase-to-phase voltage V_{BC} Calculated phase-to-phase voltage V_{CA} Calculated voltage V0	
Method of measurement	Fundamental component RMS value	
Threshold value[168]	0.300 V to 340.000 V	Increments of 0.001 V
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	1.01 to 1.20	Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overvoltage and of 105 % for the undervoltage functionality.	
Minimum absolute dropout differential	150 mV sec.

Times

Operate time with time delay = 0 ms, typical	Approx. 25 ms + OOT[169] at 50 Hz Approx. 22 ms + OOT at 60 Hz
Operate time with time delay = 0 ms, maximum	Approx. 30 ms + OOT at 50 Hz Approx. 26 ms + OOT at 60 Hz
Dropout time, typical	Approx. 25 ms + OOT
Dropout time, maximum	Approx. 30 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive, maintained; Dropout of the pickup induced by blocking or by increasing the measurand beyond the dropout threshold

168 If you have selected the **method of measurement** = **RMS value**, do not set the threshold value under 10 V.

169 OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Tolerances

Voltages	0.5 % of the setting value or 0.05 V
Time delays	1 % of the setting value or 10 ms

12.41 Rate-of-Voltage-Change Protection

Setting Value for the Function

Measuring window	2 periods to 50 periods	Increments of 1 period

Setting Values for Stage Types

dV/second	0.500 V to 200.000 V	Increments of 0.001 V
Dropout delay	0.00 s to 60.00 s	Increments of 0.01 s
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The larger dropout differential (= **`| pickup value - dropout threshold |`**) of the following 2 criteria is used:	
Dropout differential derived from `Dropout ratio`	90 % for the **`dV/second`** parameter
Minimum absolute dropout differential	0.15 V per second

Times

Pickup time	• At 50 Hz: Pickup time = Measuring window + 120 ms + OOT[170] Max. 220 ms + OOT with the default measuring window of 5 periods • At 60 Hz: Pickup time = Measuring window + 100 ms + OOT Max. 183.3 ms + OOT with the default measuring window of 5 periods
Dropout time	• At 50 Hz: Dropout time = Measuring window + 120 ms + OOT Max. 220 ms + OOT with the default measuring window of 5 periods • At 60 Hz: Dropout time = Measuring window + 100 ms + OOT Max. 183.3 ms + OOT with the default measuring window of 5 periods

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

170 OOT (Output Operating Time): Additional delay of the output medium used, for example, 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

Tolerances

Threshold	1 % of the setting value or 0.05 V/s with a measuring window ≥ 5 periods For a measuring window < 5 periods, a slightly expanded tolerance results.
Time delays	1 % of the setting value or 10 ms

Functional Measured Value

Value	Description
dV/s	Calculated voltage change per second

12.42 Undervoltage-Controlled Reactive-Power Protection

Setting Values

Threshold value	Power Q	1.00 % to 200.00 %	Increments of 0.01 %
	Voltage of protection stage	3.000 to 175.000	Increments of 0.001 V
	Voltage of reclosure stage	3.000 V to 340.000 V	Increments of 0.001 V
Current I_1 release threshold value	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Release time delay of reclosure stage		0.00 s to 3600.00 s	Increments of 0.01 s

Dropout Ratio

Protection stage	
Reactive-power flow Q	Approx. 0.95
Voltage	Approx. 1.02
Release current	Approx. 0.95

Reclosure stage	
Voltage	Approx. 0.98
Release current	Approx. 0.95

Times

Pickup time	Approx. 55 ms + OOT[171] at 50 Hz Approx. 45 ms + OOT at 60 Hz
Dropout time	Approx. 55 ms + OOT at 50 Hz Approx. 45 ms + OOT at 60 Hz

Tolerances

Current I_1	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Voltage	0.5 % of the setting value or 0.05 V
Power Q	0.5 % S_{rated} ± 3 % of the setting value (S_{rated}: rated apparent power)
Time delays	1 % of the setting value or 10 ms
Reclosure time delay	1 % of the setting value or 10 ms

[171] OOT (Output Operating Time): additional delay of the output medium used, for example 5 ms with fast relays

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

12.43 Voltage-Comparison Supervision

Times

Alarm times	Approx. 3 ms to 12 ms + OOT [172]at 50 Hz Approx. 2.5 ms to 10 ms + OOT at 60 Hz
Dropout time	20 ms

Frequency Operating Range

10 Hz ≤ f ≤ 90 Hz	According to specified tolerances
f < 10 Hz	Inactive
f > 90 Hz	

Tolerances

Pickup threshold	
Voltage	0.5 % of the setting value or 0.05 V

[172] OOT (Output Operating Time): extra delay of the output medium used

12.44 Fault Locator

Setting Values

You can find the following settings in the line data of the **Line** protection function group: • Reactance per unit length of the line per kilometer or per mile • Line length for the correct output of the fault distance as a percentage of the line length • Residual compensation factors in the setting format Kr and Kx or K0 and angle (K0)	
Parallel-line compensation (optional)	For connection and disconnection
Consideration of the load current in the case of 1-phase ground faults	Correction of the X value, for connection and disconnection

Fault Distance

Output of the fault distance (line length)	In Ω primary In km, miles or in percent [173]

Tolerances

Measuring tolerances during sinusoidal measurands and error duration > 25 ms at 60 Hz or > 30 ms at 50 Hz	1.5 % from fault location at $V_K/V_{rated} \geq 0.01$ and one of the following scenarios: • Metal fault • Non-metal fault during single-side infeed without load

[173] The output of the fault distance in km, miles and percent presupposes a homogeneous line.

12.45 Fault Locator Plus

Setting Values

• Cb per length unit, C0 per length unit, and X per length unit of the line per kilometer or per mile • Line angle in ° • Line length for the correct output of the fault distance in km or miles and percent of the line length • The residual compensation factors in the setting format Kr and Kx or K0 and angle (K0)	
Parallel-line compensation (optional), only with instantiation of the function in the FG **line**	For connection or disconnection
Consideration of the load current in the case of 1-phase ground faults	Correction of the X value, for connection and disconnection

Output Values

Output of the fault distance (line length), for non-homogeneous lines with indication of the line section	In km, miles, or percent
Output of the fault resistance, fault contact resistance, and fault reactance	In Ω primary and secondary

Tolerances

Measuring tolerances during sinusoidal measurands and fault duration > 25 ms at 60 Hz or > 30 ms at 50 Hz	1.5 % from fault location[174] with $V_K/V_{rated} \geq 0.01$ and $I_F/I_{rated} \geq 0.1$

[174] Tolerance referenced to the total line length

12.46 Overfrequency Protection

Setting Values

Pickup values f>	Angle difference method	
	40.00 Hz to 90.00 Hz	Increments of 0.01 Hz
	Filtering method	
	40.00 Hz to 70.00 Hz	Increments of 0.01 Hz
Dropout differential	20 mHz to 2 000 mHz	Increments of 10 mHz
Time delay T	0.00 s to 600.00 s	Increments of 0.01 s
Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V

Times

Pickup times f>	Angle difference method	
	50 Hz 60 Hz	Approx. 70 ms + OOT[175] Approx. 60 ms + OOT
	Filtering method	
	50 Hz 60 Hz	Approx. 79 ms + OOT Approx. 65 ms + OOT
Dropout times f>	60 ms to 80 ms	

Dropout

The larger dropout differential (= **| pickup value – dropout threshold |**) of the following 2 criteria is used:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not present, a dropout ratio of 99.97 % applies to the overfrequency protection.	
Minimum absolute dropout differential	5 mHz

Operating Ranges

Voltage range	5 V to 230 V (phase-phase)	
Frequency range	Angle difference method	10 Hz to 90 Hz
	Filtering method	25 Hz to 80 Hz

Tolerances

Frequency f>	
f_{rated} - 0.20 Hz < f < f_{rated} + 0.20 Hz	± 5 mHz at V = V_{rated}
f_{rated} - 3.0 Hz < f < f_{rated} + 3.0 Hz	± 10 mHz at V = V_{rated}
Time delay T(f>)	1 % of the setting value or 10 ms
Minimum voltage	1 % of the setting value or 0.5 V

[175] OOT (Output Operating Time): Additional delay of the output medium used, for example, 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

12.47 Underfrequency Protection

Setting Values

Pickup values f<	30.00 Hz to 70.00 Hz	Increments of 0.01 Hz
Dropout differential	20 mHz to 2 000 mHz	Increments of 10 mHz
Time delay T	0.00 s to 600.00 s	Increments of 0.01 s
Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V

Times

Pickup times f<	Angle difference method	
	50 Hz 60 Hz	Approx. 70 ms + OOT[176] Approx. 60 ms + OOT
	Filtering method	
	50 Hz 60 Hz	Approx. 75 ms + OOT Approx. 64 ms + OOT
Dropout times f<	60 ms to 80 ms	

Dropout

The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not present, a dropout ratio of 100.03 % applies to the underfrequency protection.	
Minimum absolute dropout differential	5 mHz

Operating Ranges

Voltage range	5 V to 230 V (phase-phase)	
Frequency range	Angle difference method	10 Hz to 90 Hz
	Filtering method	25 Hz to 80 Hz

Tolerances

Frequency f<	
f_{rated} - 0.20 Hz < f < f_{rated} + 0.20 Hz	± 5 mHz at V = V_{rated}
f_{rated} - 3.0 Hz < f < f_{rated} + 3.0 Hz	± 10 mHz at V = V_{rated}
Time delay T(f<)	1 % of the setting value or 10 ms
Minimum voltage	1 % of the setting value or 0.5 V

176 OOT (Output Operating Time): Additional delay of the output medium used, for example, 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

12.48 Underfrequency Load Shedding

Setting Values for the Function

Minimum voltage	0.300 p.u. to 0.900 p.u.	Increments of 0.001 p.u.
Minimum current	0.020 p.u. to 0.200 p.u.	Increments of 0.001 p.u.
Power angle	-30° to 30°	Increments of 1°
Positive power direction	inv. to CT neu.pnt sett. acc. to CT neu.pnt sett.	
Threshold value for the df/dt-rising rate or df/dt-falling rate	0.1 Hz/s to 20.0 Hz/s	Increments of 0.1 Hz/s
df/dt measuring window	2 periods to 5 periods	Increments of 1 period
df/dt dropout differential	0.02 Hz/s to 0.99 Hz/s	Increments of 0.10 Hz/s
f < stabilization counter	1 to 20	Increments of 1

Setting Values for the Stage

Pickup threshold	40.00 Hz to 70.00 Hz	Increments of 0.01 Hz
Dropout differential	20 mHz to 2000 mHz	Increments of 10 mHz
Time delay	0.00 s to 60.00 s	Increments of 0.01 s

Times

Pickup times with stabilization counter = 6	Approx. 85 ms + OOT[177] at 50 Hz Approx. 80 ms + OOT at 60 Hz
Dropout time	Approx. 80 ms + OOT at 50 Hz Approx. 75 ms + OOT at 60 Hz

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout	
Frequency	0.01 Hz
df/dt-rising rate and df/dt-falling rate	0.1 Hz/s
Voltage V1	105 % of the threshold value
Current I1	105 % of the threshold value at φ ≤ 0 95.23 % of the threshold value at φ > 0
Power angle	1°
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Voltage transformer	150 mV sec.

Tolerances

Frequency f<	
f_{rated} - 0.20 Hz < f < f_{rated} + 0.20 Hz	± 5 mHz at V = V_{rated}

[177] OOT (Output Operating Time): additional time delay of the output medium used, for example, 5 ms with fast relay

f_{rated} - 3.0 Hz < f < f_{rated} + 3.0 Hz	± 10 mHz at V = V_{rated}
df/dt, measuring window > 3 periods	Approx. 3 % or 0.06 Hz/s
df/dt, measuring window ≤ 3 periods	Approx. 5 % or 0.06 Hz/s
Minimum voltage	0.5 % of the setting value or 0.05 V
Minimum current	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Power angle	1°
Time delays	1 % of the setting value or 10 ms

Frequency Operating Range

0.9 ≤ f/f_{rated} ≤ 1.1	According to specified tolerances
10 Hz ≤ f < 0.9 f_{rated} 1.1 f_{rated} < f ≤ 90 Hz	Slightly expanded tolerances
f < 10 Hz f > 90 Hz	Active

12.49 Rate of Frequency Change Protection

Setting Values for the Function

Minimum voltage	3.000 V to 175.000 V	Increments of 0.001 V
Measuring window	2 periods to 5 periods	Increments of 1 period

Setting Values for Stage Types

Threshold value	0.100 Hz/s to 20.000 Hz/s	Increments of 0.025 Hz/s
Dropout differential	0.02 Hz/s to 0.99 Hz/s	Increments of 0.01 Hz/s
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

Frequency	Parameterizable dropout differential
Minimum voltage	
The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria is used:	
Dropout differential derived from `Dropout ratio`	105 % for the **Minimum voltage** parameter
Minimum absolute dropout differential	150 mV secondary

Times

Pickup time	Approx. 160 ms + OOT[178] to 220 ms + OOT (depends on measuring window length) at 50 Hz Approx. 140 ms + OOT to 200 ms + OOT (depends on measuring window length) at 60 Hz
Dropout time	Approx. 160 ms + OOT to 220 ms + OOT (depends on measuring window length) at 50 Hz Approx. 140 ms + OOT to 200 ms + OOT (depends on measuring window length) at 60 Hz

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Threshold, measuring window > 3 periods	Approx. 3 % or 0.060 Hz/s
Threshold, measuring window ≤ 3 periods	Approx. 5 % or 0.060 Hz/s

178 OOT (Output Operating Time): Additional delay of the output medium used, for example, 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

Minimum voltage	1 % of the setting value or 0.5 V
Time delays	1 % of the setting value or 10 ms

Functional Measured Value

Value	Description
df/dt	Calculated rate of frequency change

12.50 Instantaneous Tripping at Switch onto Fault

Setting Values

Tripping delay	0.00 s to 60.00 s	Increments of 0.01 s

Tolerances

Times	< 1 % of the setting value or 10 ms

12.51 Thermal Overload Protection, 3-Phase – Advanced

Setting Value for the Function Block Filter

h(0)	-100.000 to 100.000	Increments of 0.001
h(1)	-100.000 to 100.000	Increments of 0.001
h(2)	-100.000 to 100.000	Increments of 0.001
h(3)	-100.000 to 100.000	Increments of 0.001
h(4)	-100.000 to 100.000	Increments of 0.001

Setting Values/Increments for the Protection Stage

Threshold current warning	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold thermal warn.		50 % to 100 %	Increments of 1 %
Dropout threshold operate		50 % to 99 %	Increments of 1 %
Emerg. start T overtravel		0 s to 15 000 s	Increments of 10 s
K-factor acc. to IEC 60225-149		0.10 to 4.00	Increments of 0.01
Thermal time constant		10 s to 60 000 s	Increments of 1 s
Cooling time constant		10 s to 60 000 s	Increments of 1 s
Imax thermal	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Imin cooling	1 A @ 50 and 100 Irated	0.000 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.00 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.000 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.000 A to 8.000 A	Increments of 0.001 A
Temperature rise at Irated		40 K to 200 K	Increments of 1 K
Default temperature		-55°C to 55°C	Increments of 1°C
Minimal temperature		-55°C to 40°C	Increments of 1°C

Dropout Ratios

Tripping threshold (fixed at 100 %)	Dropout if value drops below operate indication dropout threshold
Thermal warning threshold	About 0.99 of the setting value
Current warning threshold	About 0.95 of the setting value

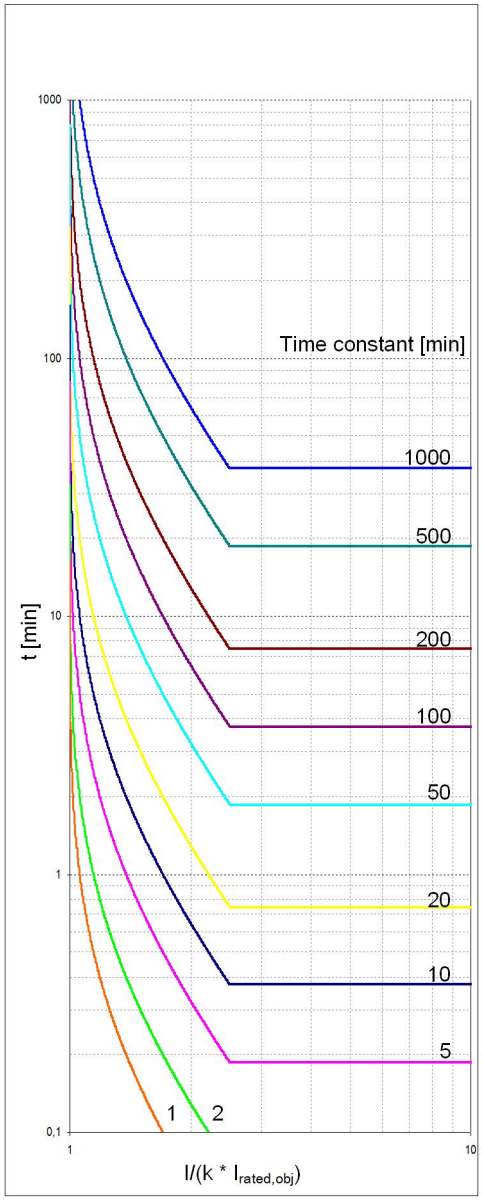
Frequency Range of the Input Signals

The function captures input signals up to the 50th harmonic.

Tolerances

No filter applied (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-149
	Up to 50th harmonic, f_{rated} = 50 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-149
	Up to 50th harmonic, f_{rated} = 60 Hz	5 % or 25 mA (I_{rated} = 1 A) or 125 mA (I_{rated} = 5 A), 5 % class acc. to IEC 60255-149
With the filter for compensation of the amplitude attenuation due to the anti-aliasing filter (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-149
	Up to 50th harmonic, f_{rated} = 50 Hz	3 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 3 % class acc. to IEC 60255-149
	Up to 50th harmonic, f_{rated} = 60 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-149
With the filter for gain of harmonics including compensation of the amplitude attenuation[179] (33 % harmonics, in relation to the fundamental component)		
With reference to $k \cdot I_{rated}$	Up to 30th harmonic	2 % or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), 2 % class acc. to IEC 60255-149[180]
	Up to 50th harmonic, f_{rated} = 50 Hz	4 % or 20 mA (I_{rated} = 1 A) or 100 mA (I_{rated} = 5 A), 4 % class acc. to IEC 60255-149[181]
	Up to 50th harmonic, f_{rated} = 60 Hz	5 % or 25 mA (I_{rated} = 1 A) or 125 mA (I_{rated} = 5 A), 5 % class acc. to IEC 60255-149[181]
With reference to the operate time	Up to 30th harmonic	3 % or 1 s for $I/(k \cdot I_{rated}) > 1.25$, 3 % class acc. to IEC 60255-149

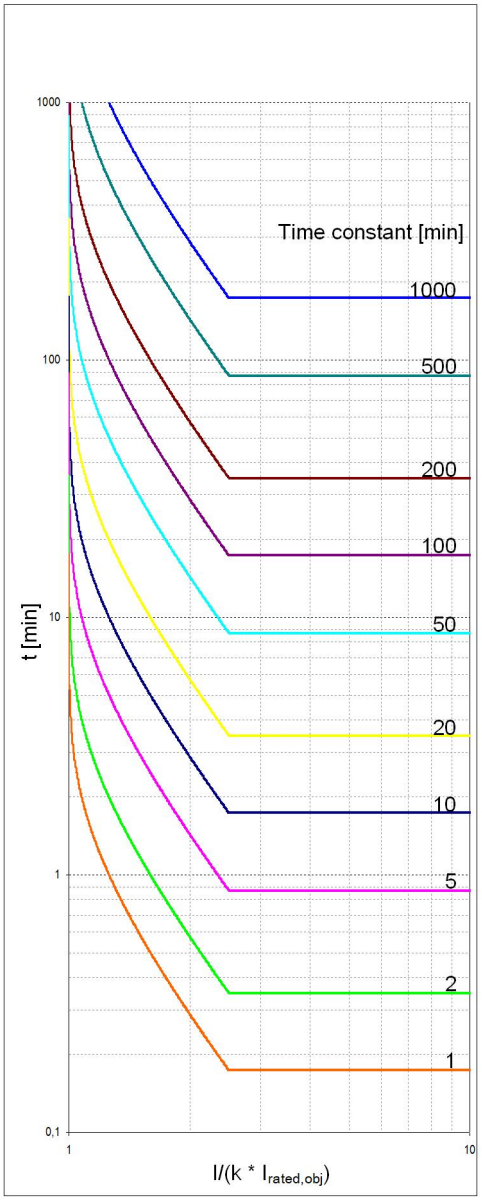
179 In case that the filter response exactly matches the user-defined gain factor.



180 In case that the user-defined gain factor is set below 3. The tolerance is increased if the gain factor is larger.

181 In case that the user-defined gain factor is set below 7. The tolerance is increased if the gain factor is larger.

Operate Curve



Operate curve	$t = \tau_{th} \cdot \ln \frac{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - \left(\frac{I_{preload}}{k \cdot I_{rated,obj.}}\right)^2}{\left(\frac{I}{k \cdot I_{rated,obj.}}\right)^2 - 1}$	
Where	t	Operate time
	τ_{th}	Time constant
	I	Current load current
	$I_{preload}$	Preload current
	k	Setting factor according to VDE 0435 part 3011 or IEC 60255-149 (K factor)
	$I_{rated, obj}$	Rated current of the protected object

Table 12-11 Operate Curve Overload Protection

With 80 % preload temperature ($\theta_{preload}$) and with $I_{max, therm} = 2.5 \cdot k \cdot I_{rated}$

$$t = \tau_{th} \cdot \ln \frac{\left(\frac{1}{k \cdot I_{rated,obj}}\right)^2 - \left(\frac{I_{preload}}{k \cdot I_{rated,obj}}\right)^2}{\left(\frac{1}{k \cdot I_{rated,obj}}\right)^2 - 1} \text{ [min]}$$

Without preload and with $I_{max, therm} = 2.5 \cdot k \cdot I_{rated}$

$$t = \tau_{th} \cdot \ln \frac{\left(\frac{1}{k \cdot I_{rated,obj}}\right)^2}{\left(\frac{1}{k \cdot I_{rated,obj}}\right)^2 - 1} \text{ [min]}$$

Frequency Operating Range

Unlimited

12.52 Thermal Overload Protection, User-Defined Characteristic Curve

Setting Values

Threshold current warning	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold thermal warn.		50 % to 100 %	Increments of 1 %
Dropout threshold operate		50 % to 99 %	Increments of 1 %
Emerg. start T overtravel		0 s to 15 000 s	Increments of 10 s

12.54 Function Group Analog Units

20-mA Inputs, Ethernet Interface 7XV5674-0KK00-1AA1

Max. number of connected 20-mA units	4
Max. number of channels per 20-mA unit	12

20-mA Unit Serial 7XV5674-0KK30-1AA1 (RS485) and 7XV5674-0KK40-1AA1 (Fiberglass)

Max. number of connected 20-mA units	4
Max. number of channels per 20-mA unit	12

RTD Unit (Ziehl TR1200) 7XV5662-6AD10

Max. number of connected RTD units	4
Max. number of sensors per RTD unit	12
Sensor type	Pt 100 to EN 60751; connection of Ni 100 and Ni 120 sensors possible. The measured values must be converted in the evaluation unit.

Temperature Measured Values

Unit of measurement for temperature	°C or °F, adjustable
Pt 100	-199 °C to 800 °C (-326 °F to 1472 °F)
Ni 100	-54 °C to 278 °C (-65 °F to 532 °F)
Ni 120	-52 °C to 263 °C (-62 °F to 505 °F)
Resolution	1 °C or 1 °F
Tolerance	±0.5 % of the measured value ±1 °C (±0.56 °F)

12.55 Temperature Supervision

Setting Values

Pickup value	-50 °C to 250 °C -58 °F to 482 °F	Increments of 1°C Increments of 1°F
Time delay	0 s to 60 s or ∞	Increments of 1 s

Dropout

Dropout differential	3 °C or 6 °F

Tolerances

Tripping delay	±1 % of the setting value or ±10 ms
Measured temperature value	±0.5 % of the setting value or ±1 °C or ±2 °F

12.56 Hotspot Calculation

Setting Values

Emerg. start T overtravel		0 s to 15 000 s	Increments of 1 s
HST Warning Threshold	°C	80 °C to 140 °C	Increments of 1 °C
	°F	176 °F to 284 °F	Increments of 1 °F
HST Alarm Threshold	°C	80 °C to 140 °C	Increments of 1 °C
	°F	176 °F to 284 °F	Increments of 1 °F
Aging Warning Threshold		0.125 to 128.000	Increments of 0.001
Aging Alarm Threshold		0.125 to 128.000	Increments of 0.001
Turn time constant		0 min to 30 min	Increments of 1 min

IEC 60076-7

y Turn exponent	1.6 to 2.0	Increments of 0.1
Temperature gradient	20 to 50	Increments of 1
Factor k21	1.0 to 5.0	Increments of 0.1
Factor k22	1.0 to 5.0	Increments of 0.1
Oil time constant	50 min to 500 min	Increments of 1 min

IEEE C57.91 2011

m Turn exponent	0.8 to 1.0	Increments of 0.1
Temperature gradient	20 to 50	Increments of 1

Functional Measured Values

Measured Value	Description
(_:13531:307) Tmp.A	Hotspot temperature for phase A in °C or °F (depending on the setting)
(_:13531:308) Tmp.B	Hotspot temperature for phase B in °C or °F (depending on the setting)
(_:13531:309) Tmp.C	Hotspot temperature for phase C in °C or °F (depending on the setting)
(_:13531:310) TmpMa	Hotspot temperature for the 3 phases in °C or °F (depending on the setting)
(_:13531:311) AgRate	Relative aging rate
(_:13531:305) RsWarn	Load margin until warning indication in percent
(_:13531:306) RsAlm	Load margin until alarm indication in percent

Frequency Operating Range

Frequency tracking	10 Hz to 90 Hz

Measured Temperatures

Temperature unit of the measurement	°C or °F
Resolution	1 °C or 1 °F
Tolerance	± 0.5 % of the measured value or ± 1 K

Dropout Ratio

Alarm threshold	Approx. 0.99 of the setting value
Warning threshold	Approx. 0.99 of the setting value

Power Factor

The accuracy of the power factor calculation is a function of the accuracy of the current measurement.

Operate Time

Synthesizing the hotspot temperature is a slow process. The measuring interval is 300 ms. The operate time is a function of the oil temperature and the load increase.

12.57 Circuit-Breaker Failure Protection

Starting Conditions

For circuit-breaker failure protection	3-pole tripping internal or external[182]

Setting Values

Phase-current threshold values	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Sensitive threshold value	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Supervision time of release signal		0.00 s to 1.00 s	Increments of 0.01 s
Time delays T1		0.000 s to 60.000 s	Increments of 0.001 s
Time delays T2		0.050 s to 60.000 s	Increments of 0.001 s
Supervision times of the binary inputs		0.05 s to 60.00 s	Increments of 0.01 s

Setting Values

Phase-current threshold values	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Sensitive threshold value	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Supervision time of release signal		0.00 s to 1.00 s	Increments of 0.01 s
Time delays T1		0.000 s to 60.000 s	Increments of 0.001 s
Time delays T2		0.050 s to 60.000 s	Increments of 0.001 s
Supervision times of the binary inputs		0.05 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup threshold – dropout threshold |**) of the following 2 criteria applies:

[182] Via binary inputs

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies to the current threshold values.	
Minimum absolute dropout differential	
Protection-class current transformers	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Circuit-Breaker Supervision

Position supervision via circuit-breaker auxiliary contacts	
For 3-pole CB tripping	One input each for make contact and break contact

NOTE

The circuit-breaker failure protection can also work without the circuit-breaker auxiliary contacts stated.

Auxiliary contacts are required for circuit-breaker failure protection in cases where the current flow is absent or too low for tripping (for example with a transformer or a Buchholz protection).

Times

Pickup time, in the case of an internal start Pickup time, in the case of an external start	< 1 ms < 5 ms
Typical dropout time	< 15 ms
Dropout time, via circuit-breaker auxiliary contact criterion[183]	< 5 ms

NOTE

Using the setting ***`Direct release`*** with the parameters **`3I0 criterion`** or **`I2 criterion`** can result in extended dropout times.

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Threshold values, dropout thresholds	2 % of the setting value or 1 % of the rated current
Times	1 % of the setting value or 10 ms

[183] The use of the transformer connection types **2ph, 2p. CT + IN-sep** result in slightly expanded tolerances

12.58 Circuit-Breaker Restrike Protection

Setting Values

Threshold value	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Monitoring duration		1.00 s to 600.00 s	Increments of 0.01 s
Position recognition delay		0.00 s to 60.00 s	Increments of 0.01 s
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s
Trip delay time		0.05 s to 60.00 s	Increments of 0.01 s
Retrip delay time		0.00 s to 60.00 s	Increments of 0.01 s
Minimum operate (trip) time		0.00 s to 60.00 s	Increments of 0.01 s

Dropout

The greater dropout differential (= **| pickup value – dropout value |**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for overcurrent and of 105 % for undercurrent functionality.	
Minimum absolute dropout differential	
Protection-class current transformer	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument current transformer	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Operate time with time delay = 0 ms	Approx. 25 ms + OOT at 50 Hz Approx. 22 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Threshold	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A)
Time delays	1 % of the setting value or 10 ms

12.59 Pole Discrepancy Protection

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active with reduced sensitivity

Tolerances

Pickup times with current check	≤ 40 ms
Pickup times without current check	≤ 20 ms
Time delays for the 1-pole discrepancy	1 % of the parameter **Delay for 1 pole open** or 10 ms
Time delays for the 2-pole discrepancy	1 % of the parameter **Delay for 2 poles open** or 10 ms

12.60 Arc Protection

Setting Values

Threshold I>	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold 3I0>>	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
External trip initiation		no current light	
Operating mode		light only current and light	
Sensor		point sensor line sensor custom	
Threshold light		-28.00 dB to 0.00 dB	Increments of 0.01
Channel		Possible settings, application-dependent	

Dropout

The larger dropout differential (= **`| pickup threshold – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 90 % applies to the current threshold values.	
Minimum absolute dropout differential	
Protection-class current transformers	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)

Times

Shortest operate time Operating mode = light only	Approx. 2.6 ms + OOT [184]
Shortest operate time Operating mode = Current and light	Approx. 4.0 ms + OOT at 50 Hz Approx. 3.8 ms + OOT at 60 Hz

184 OOT (Output Operating Time): Additional delay of the output medium used, for example, 5 ms with fast relay, see chapter *12.1.4 Relay Outputs*

12.61 Power-Plant Disconnection Protection

Setting Values

Threshold P1>		50.00 % to 100.00 %	Increments of 0.01 %
Threshold P1<		0.00 % to 60.00 %	Increments of 0.01 %
Threshold Vph-ph<		0.300 V to 175.000 V	Increments of 0.001 V
Threshold I>	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 50 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold dP1<		-100.00 % to -30.00 %	Increments of 0.01 %
Dropout delay		0.00 s to 60.00 s	Increments of 0.01 s
Operate delay		0.00 s to 60.00 s	Increments of 0.01 s
Operate curve		2 to 5	Increments of 1

Functional Measured Values

Functional measured values are available to you so that you can better evaluate the behavior of the function. You can collect these functional measured values in a fault record for example.

Measured Value	Description
P1(t)	Positive-sequence system active power, which is evaluated by the function. The measured value is calculated every 1/4 cycle.
dP1(t)	Continuous representation of the active-power change, starting from the trigger time. With this, you can evaluate the change of the active-power difference at the prefault instant (t_{prior}).
dP1(t)max	This measured value flows into the characteristic curve. It represents the maximum active power during the duration of the fault.

Times

Pickup times	
Characteristic curve = no	Approx. 28 ms + OOT[185] at 50 Hz Approx. 25 ms + OOT at 60 Hz
Characteristic curve = yes	Approx. 26 ms + OOT at 50 Hz Approx. 24 ms + OOT at 60 Hz
Dropout times	
Characteristic curve = no	Approx. 18 ms + OOT at 50 Hz Approx. 19 ms + OOT at 60 Hz
Characteristic curve = yes	Approx. 22 ms + OOT at 50 Hz Approx. 20 ms + OOT at 60 Hz

Tolerance

I>	1 % of the dropout value or 0.005 I_{rated}
P1>	0.5 % S_{rated} or ±3 % of the setting value when Q < 0.5 S_{rated}

185 OOT (Output Operating Time): additional delay of the output medium used

Vph-ph<	0.5 % of the dropout value or 0.05 V
dP1<	0.5 % S_{rated} or ±3 % of the setting value when Q < 0.5 S_{rated}
P1<	0.5 % S_{rated} or ±3 % of the setting value when Q < 0.5 S_{rated}

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

12.62 Inrush-Current Detection

Setting Values

Operat.-range limit Imax	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Content 2nd harmonic		10 % to 45 %	Increments of 1 %
Duration of the crossblock function		0.03 s to 200.00 s	Increments of 0.01 s

Times

Operating times	Approx. 29 ms

Pickup

Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	Setting value or at least
Protection-class current transformers	$I_{1st\ harm}$ = 10 mA sec. and $I_{2nd\ harm}$ = 10 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 50 mA sec. and $I_{2nd\ harm}$ = 50 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{1st\ harm}$ = 1 mA sec. and $I_{2nd\ harm}$ = 1 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 5 mA sec. and $I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 5 A)

Dropout

The greater dropout differential (= **`| pickup threshold – dropout threshold |`**) of the following criteria is used:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overcurrent protection and a dropout ratio of 105 % applies for the undercurrent protection.	
Minimum absolute dropout differential	
Protection-class current transformers	5 mA sec. (I_{rated} = 1 A) or 25 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	0.75
Protection-class current transformers	$I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 25 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{2nd\ harm}$ = 0.5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 2.5 mA sec. (I_{rated} = 5 A)

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Current measurement I_{max}	1 % of the setting value or 5 mA
Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	1 % of the setting value
Time delays	1 % of the setting value or 10 ms

12.63 2nd Harmonic Detection Ground

Setting Values

Measured value	IN measured 3I0 calculated	
2nd harmonic content	10 % to 45 %	Increments of 1 %

Times

Operating times	Approx. 29 ms

Pickup

Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	Setting value or at least
Protection-class current transformer	$I_{1st\ harm}$ = 10 mA sec. and $I_{2nd\ harm}$ = 10 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 50 mA sec. and $I_{2nd\ harm}$ = 50 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{1st\ harm}$ = 1 mA sec. and $I_{2nd\ harm}$ = 1 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 5 mA sec. and $I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 5 A)

Dropout

The greater dropout differential (= **`| pickup threshold – dropout threshold |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overcurrent protection and a dropout ratio of 105 % applies for the undercurrent protection.	
Minimum absolute dropout differential	
Protection-class current transformers	5 mA sec. (I_{rated} = 1 A) or 25 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Harmonics: $I_{2nd\ harm}/I_{1st\ harm}$	0.75 or
Protection-class current transformers	$I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 25 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{2nd\ harm}$ = 0.5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 2.5 mA sec. (I_{rated} = 5 A)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
$10\ Hz \le f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Harmonics: $I_{2nd\ harm}/I_{1st\ harm}$	1 % of the setting value for setting values $I_{2nd\ harm}/_{1st\ harm}$

12.64 2nd Harmonic Detection 1-Phase

Setting Values

Measured value	I	
2nd harmonic content	10 % to 45 %	Increments of 1 %

Times

Operating times	Approx. 29 ms

Pickup

Harmonic: $I_{2nd\ harm}/I_{1st\ harm}$	Setting value or at least
Protection-class current transformers	$I_{1st\ harm}$ = 10 mA sec. and $I_{2nd\ harm}$ = 10 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 50 mA sec. and $I_{2nd\ harm}$ = 50 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{1st\ harm}$ = 1 mA sec. and $I_{2nd\ harm}$ = 1 mA sec. (I_{rated} = 1 A) $I_{1st\ harm}$ = 5 mA sec. and $I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 5 A)

Dropout

The greater dropout differential (= **`| pickup threshold – dropout threshold |`**) of the following criteria applies:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies for the overcurrent protection and a dropout ratio of 105 % applies for the undercurrent protection.	
Minimum absolute dropout differential	
Protection-class current transformers	15 mA sec. (I_{rated} = 1 A) or 75 mA sec. (I_{rated} = 5 A)
Instrument transformers	0.5 mA sec. (I_{rated} = 1 A) or 2.5 mA sec. (I_{rated} = 5 A)
Harmonics: $I_{2nd\ harm}/I_{1st\ harm}$	0.75 or
Protection-class current transformers	$I_{2nd\ harm}$ = 5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 25 mA sec. (I_{rated} = 5 A)
Instrument transformers	$I_{2nd\ harm}$ = 0.5 mA sec. (I_{rated} = 1 A) or $I_{2nd\ harm}$ = 2.5 mA sec. (I_{rated} = 5 A)

Frequency Operating Range

$0.9 \le f/f_{rated} \le 1.1$	According to specified tolerances
10 Hz ≤ f < 0.9 f_{rated} 1.1 f_{rated} < f ≤ 90 Hz	Slightly expanded tolerances
f < 10 Hz f > 90 Hz	Inactive

Tolerances

Harmonics: $I_{2nd\ harm}/I_{1st\ harm}$	1 % of the setting value for setting values $I_{2nd\ harm}/I_{1st\ harm}$

12.65 Power Protection (P,Q), 3-Phase

Setting Values

Measured value	Positive sequence power Power of phase A Power of phase B Power of phase C	
Threshold	-200.0 % to -1.0 % 1.0 % to 200.0 %	Increments of 0.1
Tilt-power characteristic	-89.0° to +89.0°	Increments of 0.1°
Dropout delay time	0.00 s to 60.00 s	Increments of 0.01 s
Time delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	Upper stage: 0.90 to 0.99 Lower stage: 1.01 to 1.10	Increments of 0.01 Increments of 0.01

Dropout

The greater dropout differential (= **`| pickup value – dropout value |`**) of the following 2 criteria applies:

Dropout differential derived from the parameter `Dropout ratio`	
Minimum absolute dropout differential	0.5 % S_{rated}

Times

Pickup times	Approx. 55 ms + OOT[186] at 50 Hz Approx. 45 ms + OOT at 60 Hz
Dropout times	Approx. 55 ms + OOT at 50-Hz Approx. 45 ms + OOT at 60 Hz

Tolerances

Power	0.5 % S_{rated} or ±2 % of the setting value (S_{rated}: rated apparent power)
Time delays	1 % of the setting value or 10 ms

Variables That Influence Pickup Values

Auxiliary DC voltage in the range $0.8 \le V_{aux.}/V_{aux.,rated} \le 1.15$	≤ 1 %
Frequency in the range $0.95 \le f/f_{rated} \le 1.05$	≤ 1 %
Harmonics - Up to 10 % of 3rd harmonics - Up to 10 % of 5th harmonics	 ≤ 1 % ≤ 1 %

[186] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz < f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f$	Slightly expanded tolerances
$f \leq 10\ Hz$	Inactive

12.66 Reverse-Power Protection

Setting Values

Reverse power $P_{reverse}$ (p.u.)	-0.30 % to -30.00 %	Increments of 0.01 %
Angle correction	-10.00 ° to 10.00 °	Increments of 0.01 °
Minimum voltage V1	0.300 V to 60.000 V	Increments of 0.001 V
Tripping delay	0.00 s to 60.00 s	0.00 s to 60.00 s
Tripping delay with quick stop	0.00 s to 60.00 s	0.00 s to 60.00 s
Dropout delay	0.00 s to 60.00 s	Increments of 0.01 s
Dropout ratio	0.40 to 0.99	Increments of 0.01

Dropout

Reverse power $P_{reverse}$ (p.u.)	Parameterizable dropout differential

Times

Pickup times	Approx. 360 ms at f = 50 Hz Approx. 300 ms at f = 60 Hz
Dropout times	Approx. 360 ms at f = 50 Hz Approx. 300 ms at f = 60 Hz

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Reverse power	0.15 % S_{rated} or 5 % of the setting value when $Q < 0.5\ S_{rated}$
Time delays	1 % or 10 ms

12.67 Current-Jump Detection

Times

Pickup time	Approx. 10 ms + OOT[187] at 50 Hz Approx. 8 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Currents	3 % of setting value or 10 mA (I_{rated} = 1 A) or 50 mA (I_{rated} = 5 A), (f_{rated} ± 10 %) for amplitude changes of sinusoidal measurands
Pulse time	1 % of the setting value or 10 ms

[187] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.68 Voltage-Jump Detection

Times

Pickup time	Approx. 10 ms + OOT[188] at 50 Hz Approx. 8 ms + OOT at 60 Hz

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

Tolerances

Voltages	2 % of the setting value or 0.100 V for amplitude changes of sinusoidal measurands
Pulse time	1 % of the setting value or 10 ms

[188] OOT (Output Operating Time) additional delay of the output medium used, for example 5 ms with fast relays

12.69 Vector-Jump Protection

Setting Values

Threshold V1 min	0.300 V to 175.000 V	Increments of 0.001 V
Threshold V1 max	0.300 V to 175.000 V	Increments of 0.001 V
Threshold Δφ	2.0° to 30.0°	Increments of 0.1°
Operate delay	0.00 s to 60.00 s	Increments of 0.01 s
T Reset	0.00 s to 60.00 s	Increments of 0.01 s
T Block	0.00 s to 60.00 s	Increments of 0.01 s
I< Threshold	0.030 A to 35.000 A at 1 A 0.150 A to 175.000 A at 5 A	Increments of 0.001 A

Times

Pickup times	Approx. 80 ms + OOT[189] at 50 Hz Approx. 66.8 ms + OOT at 60 Hz
Dropout times	Approx. 80 ms + OOT at 50 Hz Approx. 66.8 ms + OOT at 60 Hz

Frequency Operating Range

f_{rated} - 3 Hz ≤ f or f_{rated} ≤ f_{rated} + 3 Hz	According to specified tolerances
f < f_{rated} - 3 Hz or f > f_{rated} + 3 Hz	Inactive

Tolerances

Angle jump	0.5° at V > 0.5 V_{rated}
Voltage blocking	1 % of the setting value or 0.500 V
Undercurrent release	For I_{rated} = 1 A: 1 % of the setting value or 10 mA For I_{rated} = 5 A: 1 % of the setting value or 50 mA
Time delay T	1 % or 10 ms

[189] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.70 Synchronization Function

Operating Modes

Synchrocheck
Switching synchronous systems
Switching asynchronous systems
De-energized switching
Direct closing command

Setting Values

Supervision/Delay times:		
Max.durat. sync.process	0.00 s to 3 600.00 s or ∞ (ineffective)	Increments of 0.01 s
Supervision time de-energized switching	0.00 s to 60.00 s	Increments of 0.01 s
Closure delay	0.00 s to 60.00 s	Increments of 0.01 s
Voltage threshold values:		
Upper voltage limit V_{max}	0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V
Lower voltage limit V_{min}	0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V
V<, for off-circuit conditions V>, for voltage present	0.300 V to 170.000 V (phase-to-phase) 0.300 V to 340.000 V (phase-to-phase)	Increments of 0.001 V Increments of 0.001 V
Differential values, changeover threshold values asynchronous/synchronous:		
Voltage differences V2 > V1; V2 < V1	0.000 V to 170.000 V	Increments of 0.001 V
Frequency difference f2 > f1; f2 < f1	0.000 Hz to 2.000 Hz (synchronous) 0.000 Hz to 4.000 Hz (asynchronous)	Increments of 0.001 Hz
Angle difference α2 > α1; α2 < α1	0° to 90°	Increments of 1°
Adjustments of the sides:		
Angle adjustment	-179.0° to 180.0°	Increments of 0.1°
Voltage adjustment	0.500 to 2.000	Increments of 0.001
Circuit breaker		
Make time of the circuit breaker	0.010 s to 0.600 s	Increments of 0.001 s

Dropout Ratio

Min./max. operating limit	1 % of the setting value
Voltage differential	10 % of the setting value or 0.5 V
De-energized/energized	5 % of the setting value
Frequency difference	3 mHz
Angle difference	0.1°

Measured Values of the Synchronization Function

Reference voltage V1 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage 10 % to 120 % of V_{rated} ≤ 1 % of the measured value or 0.5 % V_{rated}
Voltage to be synchronized V2 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage 10 % to 120 % of V_{rated} ≤ 1 % of the measured value or 0.5 % V_{rated}
Frequency of the voltage V1f1 • Range • Tolerance at rated frequency	f1 in Hz 25 Hz ≤ f ≤ 70 Hz 1 mHz
Frequency of the voltage V1f2 • Range • Tolerance at rated frequency	f2 in Hz 25 Hz ≤ f ≤ 70 Hz 1 mHz
Voltage difference V2-V1 • Range • Tolerance at rated frequency	In kV primary, in V secondary or in % V_{rated} Display always as phase-to-phase voltage in relation to side 1 10 % to 120 % of V_{rated} ≤ 1 % of the measured value or 0.5 % V_{rated}
Frequency difference f2-f1 • Range • Tolerance at rated frequency	In mHz f_{rated} ± 10 % 1 mHz
Angle difference λ2-λ1 • Range • Tolerance at rated frequency	In ° -180° to +180° 0.5°

Times

Measuring time, after switching on the variables	Approx. 80 ms

Operating Range

Voltage	20 V to 340 V
Frequency	f_{rated} - 4 Hz ≤ f_{rated} ≤ f_{rated} + 4 Hz

Tolerances

Tolerances of the voltage settings	2 % of the pickup value or 1 V
Voltage difference V2>V1; V2<V1	1 V
Frequency difference f2>f1; f2<f1	10 mHz
Angle difference α2>α1; α2<α1	1°
Tolerance of all time settings	10 ms
Max. phase displacement angle	5° for Δf ≤ 1 Hz 10° for Δf > 1 Hz

12.71 Voltage Controller

Setting Values

General Information		
I reference for % values[190]	0.20 A to 100000.00 A	Increments of 0.01 A
V reference for % values[191]	0.20 kV to 1200.00 kV	Increments of 0.01 kV
Rated app. power transf.[192]	0.20 MVA to 5000.00 MVA	Increments of 0.01 MVA
Volt. cont. 2W		
Target voltage 1	10.000 V to 340.000 V Tolerance: IδI ≤ 0.5 % of the setting value or 0.05 V	Increments of 0.001 V
Target voltage 2		
Target voltage 3		
Target voltage 4		
Volt. cont. 3W and GC		
Target voltage 1 w1	10.000 V to 340.000 V Tolerance: IδI ≤ 0.5 % of the setting value or 0.05 V	Increments of 0.001 V
Target voltage 2 w1		
Target voltage 3 w1		
Target voltage 4 w1		
Target voltage 1 w2		
Target voltage 2 w2		
Target voltage 3 w2		
Target voltage 4 w2		
Volt. cont. 2W, 3W, and GC		
Bandwidth	0.2 % to 10.0 %	Increments of 0.1 %
T1 delay	5 s to 600 s	Increments of 1 s
T1 Inverse Min	5 s to 100 s	Increments of 1 s
T2 delay	0 s to 100 s	Increments of 1 s
Fast step down limit	0.0 % to 50.0 %	Increments of 0.1 %
Fast step down T delay	0.0 s to 10.0 s	Increments of 0.1 s
Fast step up limit	-50.0 % to 0.0 %	Increments of 0.1 %
Fast step up T delay	0.0 s to 10.0 s	Increments of 0.1 s
Function monitoring	0 min to 120 min	Increments of 1 min
Line compensation LDC-Z		
Target voltage rising	0.0 % to 20.0 %	Increments of 0.1 %
Max load current	0.0 % to 500.0 %	Increments of 0.1 %
Line compensation LDC-XandR (two-winding transformer)		
R line	0.00 Ω to 30.00 Ω	Increments of 0.01 Ω
X line	-30.00 Ω to 30.00 Ω	Increments of 0.01 Ω
Line compensation LDC-XandR		
R line	0.0 Ω to 30.0 Ω	Increments of 0.1 Ω
X line	-30.0 Ω to 30.0 Ω	Increments of 0.1 Ω
Limiting values		
Vmin threshold	10.000 V to 340.000 V Tolerance: IδI ≤ 0.5 % of the setting value or 0.05 V	Increments of 0.001 V

190 Only visible in the voltage-control operation without parallel operation
191 Only visible in the voltage-control operation without parallel operation
192 Only visible in the voltage-control operation without parallel operation

Vmin time delay	0 s to 20 s Tolerance: IδI ≤ 1 % of the setting value or 10 ms	Increments of 1 s
Vmax threshold	10.000 V to 340.000 V Tolerance: IδI ≤ 0.5 % of the setting value or 0.05 V	Increments of 0.001 V
Vmax time delay	0 s to 20 s Tolerance: IδI ≤ 1 % of the setting value or 10 ms	Increments of 1 s
Blockings		
V< Threshold	10.000 V to 340.000 V Tolerance: IδI ≤ 0.5 % of the setting value or 0.05 V	Increments of 0.001 V
V< Time delay	0 s to 20 s Tolerance: IδI ≤ 1 % of the setting value or 10 ms	Increments of 1 s
I> Threshold	10 % to 500 %	Increments of 1 %
I> Time delay	0 s to 20 s Tolerance: IδI ≤ 1 % of the setting value or 10 ms	Increments of 1 s
I< Threshold	3 % to 100 %	Increments of 1 %
I< Time delay	0 s to 20 s Tolerance: IδI ≤ 1 % of the setting value or 10 ms	Increments of 1 s
Parallel control		
Parallel-transfomer id	0 to 8	Increments of 1
Maximal tap difference	1 to 9	Increments of 1
Reactive I control factor	0.01 to 100.00	Increments of 0.01
VT supervision threshold	0.5 % to 10.0 %	Increments of 0.1 %
VT supervision time delay	1 s to 600 s	Increments of 1 s
Circul. current threshold	10 % to 500 %	Increments of 1 %
Circul. current time delay	0 s to 1000 s	Increments of 1 s

Measured Values, Two-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
V act.	Current, measured positive-sequence voltage (referenced to phase-to-phase)	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	%	%	Voltage difference referenced to the rated voltage of the controlled winding
I load	Current measured load current (positive-sequence system)	A	A	Load current referenced to the rated value of the function
V max	Maximum positive-sequence voltage ever measured (referenced to phase-to-phase)	kV	V	Maximum voltage of the winding referenced to the rated voltage of the winding
V min	Minimum positive-sequence voltage ever measured (reference to phase-to-phase)	kV	V	Minimum voltage of the winding referenced to the rated voltage of the winding

Measured Value	Description	Primary	Secondary	% Referenced to
V target	Calculated target voltage with consideration of Z compensation	kV	V	Target voltage of the winding referenced to the rated voltage of the winding
PhAng	Phase angle of the currently measured load current	°	°	-
I load Σ	Sum of the currently measured load currents. Active when line compensation is activated.	A	A	Load current referenced to the rated current of the function
I circul.	Currently measured circulating reactive current	A	A	Circulating reactive current
Vact.m	Currently measured control voltage	kV	V	Current voltage of the control referenced to the rated voltage of the function
ΔV act V	Voltage difference	%	%	Voltage difference referenced to the rated voltage of the function
ΔV act C	Voltage difference	%	%	Voltage difference referenced to the rated voltage of the function

Measured Values for Parallel Control, Proxy

Measured Value	Description	Primary	Secondary	% Referenced to
V act.	Actual voltage of winding	kV	V	Target voltage of the primary system referenced to the rated voltage of the function
1/X trf.	Susceptance, internal value for GOOSE transmission	1/Ω		
I load	Load current	A	-	Load current referenced to the rated current of the function
PhAng	Phase angle of the load current relative to the voltage with a power factor of 1.0	°	°	Phase angle of the load current 100 % = 180°

Measured Values, Three-Winding Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	%	%	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1

Measured Value	Description	Primary	Secondary	% Referenced to
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to the rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to the rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

Measured Values Grid Coupling Transformer

Measured Value	Description	Primary	Secondary	% Referenced to
Vact.w1	Actual voltage of winding 1	kV	V	Target voltage of the primary system referenced to the rated voltage
Vact.w2	Actual voltage of winding 2	kV	V	Target voltage of the primary system referenced to the rated voltage
ΔV act.	Voltage difference between the target voltage and the actual voltage	%	%	Voltage difference referenced to the rated voltage of the controlled winding
I load w1	Load current of winding 1	A	A	Load current referenced to the rated current of winding 1
I load w2	Load current of winding 2	A	A	Load current referenced to the rated current of winding 2
Vmax 1	Maximum voltage of winding 1	kV	V	Maximum voltage of winding 1 referenced to the rated voltage of winding 1
Vmax 2	Maximum voltage of winding 2	kV	V	Maximum voltage of winding 2 referenced to the rated voltage of winding 2
Vmin 1	Minimum voltage of winding 1	kV	V	Minimum voltage of winding 1 referenced to rated voltage of winding 1
Vmin 2	Minimum voltage of winding 2	kV	V	Minimum voltage of winding 2 referenced to rated voltage of winding 2
V tar.w1	Target voltage of winding 1	kV	V	Target voltage of winding 1 referenced to the rated voltage of winding 1
V tar.w2	Target voltage of winding 2	kV	V	Target voltage of winding 2 referenced to the rated voltage of winding 2

Dropout Ratio

Threshold of the voltage limit	About 0.98 of the setting value
Threshold of the current limit	About 0.95 of the setting value

12.72 Current-Balance Supervision

Setting Values

Release threshold	1 A @ 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	1 A @ 50 Irated		
	5 A @ 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	5 A @ 50 Irated		
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Threshold min/max		0.10 to 0.95	Increments of 0.01
Delay failure indication		0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Overcurrent dropout ratio	Approx. 0.97
Undercurrent dropout ratio	Approx. 1.05

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.73 Voltage-Balance Supervision

Setting Values

Release threshold	0.300 V to 170.000 V	Increments of 0.001 V
Threshold min/max	0.58 to 0.95	Increments of 0.01
Delay failure indication	0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Overvoltage dropout ratio	Approx. 0.97
Undervoltage dropout ratio	Approx. 1.05

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.74 Current-Sum Supervision

Setting Values

Slope factor		0.00 to 0.95	Increments of 0.01
Threshold	1 A @ 50 and100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and100 Irated	0.15 A to 50.00 A	Increments 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Delay failure indication		0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Dropout ratio	Approx. 0.97

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.75 Voltage-Sum Supervision

Setting Values

Threshold	0.300 V to 170.000 V	Increments of 0.001 V
Delay failure indication	0.00 s to 100.00 s	Increments of 0.01 s

Dropout Ratio

Dropout ratio	Approx. 0.97

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.76 Current Phase-Rotation Supervision

Setting Values

Release threshold	1 A @ 50 and 100 Irated	0.030 A to 10.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 50.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Delay failure indication		0.00 s to 100.00 s	Increments of 0.01 s
Phase sequence		A B C A C B	

Dropout Ratio

Release-threshold dropout ratio	Approx. 0.97

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.77 Voltage Phase-Rotation Supervision

Setting Values

Tripping delay	0.00 s to 100.00 s	Increments of 0.01 s
Phase-rotation direction	A B C A C B	

Times

Tripping time	Approx. 500 ms
Dropout time	Approx. 500 ms

12.78 Auxiliary Direct-Voltage Supervision

Setting Value for the FB Auxiliary Direct-Voltage Measurement

Measuring window	10 ms, 20 ms, 40 ms, 60 ms, 80 ms, 100 ms

Setting Values for the Stages

Threshold	10.0 V to 295.0 V	Increments of 0.1 V
Dropout ratio for the **Overvoltage** stage	0.90 to 0.99	Increments of 0.01
Dropout ratio for the **Undervoltage** stage	1.01 to 1.10	Increments of 0.01
Pickup delay Operate delay	0.00 s to 60.00 s	Increments of 0.01 s

Dropout

Dropout differential is derived from the parameter **`Dropout ratio`**.

Times

Pickup time	(1 to 2) · **`Measuring window`** + OOT[193] Example for **`Measuring window`** of 20 ms: Pickup time = 20 ms to 40 ms + OOT
Dropout time	(1 to 2) · **`Measuring window`** + OOT Example for **`Measuring window`** of 20 ms: Dropout time = 20 ms to 40 ms + OOT

Tolerances

Direct voltage	0.2 % of the setting value or 50 mV
Operate delay	1 % of the setting value or 10 ms

[193] OOT (Output Operating Time): additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

12.79 Trip-Circuit Supervision

Setting Values

Number of monitored circuits per circuit-breaker function group	1 to 3	
Operating mode per circuit	With 1 binary input With 2 binary inputs	
Pickup and dropout time	About 1 s to 2 s	
Adjustable indication delay with 1 binary input	1.00 s to 600.00 s	Increments of 0.01 s
Adjustable indication delay with 2 binary inputs	1.00 s to 600.00 s	Increments of 0.01 s

12.80 Closing-Circuit Supervision

Setting Values (Closing-circuit supervision with 1 binary input or 2 binary inputs)

Operating mode per circuit	With 1 binary input With 2 binary inputs	
Adjustable indication delay with 1 binary input	1.00 s to 600.00 s	Increments of 0.01 s
Adjustable indication delay with 2 binary inputs	1.00 s to 30.00 s	Increments of 0.01 s

Setting Values (Closing-circuit supervision with 3 binary inputs)

Number of monitored circuits per circuit breaker function group	1 to 3	
Operating mode per circuit	With 2 binary inputs and 1 resistance With 3 binary inputs	
Pickup and dropout time	Approx. 1 s to 2 s	
Adjustable indication delay with 2 binary inputs and 1 resistance	1.00 s to 30.00 s	Increments of 0.01 s
Adjustable indication delay with 3 binary inputs	1.00 s to 30.00 s	Increments of 0.01 s

12.81 Protection Interface and Protection Topology

Setting Values

Mode	On Off	
Synchronization	External synchron. off Telegr. and ext. synch. Telegr. or ext. synch. External synch. only	
Blocking of the unbalanced runtimes	Yes No	
Maximum signal runtime threshold	0.1 ms to 30.0 ms	Increments of 0.1 ms
Maximum runtime difference	0.000 ms to 3.000 ms	Increments of 0.001 ms
Fault indication after	0.05 s to 2.00 s	Increments of 0.01 s
Transm. fail. alarm after	0.0 s to 6.0 s	Increments of 0.1 s
Max. error rate/h	0.000 % to 100.000 %	Increments of 0.001 %
Max. error rate/min	0.000 % to 100.000 %	Increments of 0.001 %

Transmission Rate

Direct connection:	
Transmission rate	2048 kbit/s
Connection via communication networks:	
Supported network interfaces	IP protection communication
	C37.94 at 64 kBit/s or 128 kBit/s or 512 kBit/s
	G703.1 at 64 kBit/s G703-T1 at 1.455 MBit/s G703-E1 at 2.048 MBit/s
	X.21 at 64 kBit/s or 128 kBit/s or 512 kBit/s
	Pilot wires at 128 kbit/s
Transmission rate	Transmission rate 64 kBit/s at G703.1 1.455 MBit/s at G703-T1 2.048 MBit/s at G703-E1
	512 kBit/s or 128 kBit/s or 64 kBit/s at X.21
	128 kBit/s for pilot wires

Transmission Times for Remote Data

Measured with a minimum of 512 kbit/s

Priority 1:		
Response time, total approx.		
For 2 ends	Minimum	3 ms + OOT[194]
	Typical	5 ms + OOT
For 3 ends	Minimum	5 ms + OOT
	Typical	9 ms + OOT
For 6 ends	Minimum	10 ms + OOT
	Typical	13 ms + OOT

194 OOT (Output Operating Time): Additional delay of the output medium used, for example, 1 ms with electronic relays

Dropout times, total approx.		
For 2 ends	Typical	15 ms + OOT
For 3 ends	Typical	15 ms + OOT
For 6 ends	Typical	21 ms + OOT

Priority 2		
Response time, total approx.		
For 2 ends	Minimum	4 ms + OOT
	Typical	11 ms + OOT
For 3 ends	Minimum	7 ms + OOT
	Typical	13 ms + OOT
For 6 ends	Minimum	12 ms + OOT
	Typical	18 ms + OOT
Dropout times, total approx.		
For 2 ends	Typical	19 ms + OOT
For 3 ends	Typical	20 ms + OOT
For 6 ends	Typical	27 ms + OOT

Priority 3[195]		
Response time, total approx.		
For 2 ends	Minimum	
	Typical	95 ms + OOT
For 3 ends	Minimum	
	Typical	145 ms + OOT
For 6 ends	Minimum	
	Typical	195 ms + OOT
Dropout times, total approx.		
For 2 ends	Typical	95 ms + OOT
For 3 ends	Typical	145 ms + OOT
For 6 ends	Typical	195 ms + OOT

195 Times cannot be determined because the signals are transmitted in fragments.

12.82 Date and Time Synchronization

Date format	DD.MM.YYYY (Europe)
	MM/DD/YYYY (USA)
	YYYY-MM-DD (China)
Time source 1, Time source 2	None IRIG B 002(003) IRIG B 006(007) IRIG B 005(004) with extension according to IEEE C37.118-2005 DCF77 PI (protection interface) [196] SNTP IEC 60870-5-103 DNP3 IEEE 1588 T104
Time zone 1, time zone 2	Local
	UTC
Fault indication after	0 s to 3600 s
Time zone and daylight saving time	Manually setting the time zones
Time zone offset with respect to GMT	-720 min to 840 min
Switching over to daylight saving time	Active
	Inactive
Beginning of daylight saving time	Input: day and time
End of daylight saving time	Input: day and time
Offset daylight saving time	0 min to 120 min [15 min. steps]

[196] if provided

12.83 Phasor Measurement Unit

Accuracy

IEEE Standard for Synchrophasor Measurements
IEEE Std C37.118.1a™-2014

Data Transfer

IEEE Standard for Synchrophasor Data transfer
IEEE Std C37.118.2™-2011

12.84 Analog Channel Supervision via Fast Current Sum

Times

Pickup times	Approx. 2 ms (faster than the fastest protection function)
Dropout time	Approx. 100 ms

Blockings

Blocked functions	All functions that process the measured values from this current measuring point (for example, differential protection).

12.85 Measuring-Voltage Failure Detection

Setting Values

3ph.fail. - VA,VB,VC <		0.300 V to 340.000 V	Increments of 0.001 V
3ph.fail. - phs.curr.release	1 A @ 50 and100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
3ph.fail. - phs.curr. jump	1 A @ 50 and100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.001 A
Asym.fail. - time delay		0.00 s to 30.00 s	Increments of 0.01 s
SO 3ph.fail. - time delay		0.00 s to 30.00 s	Increments of 0.01 s

Dropout

The larger dropout differential (= **`| pickup value – dropout threshold |`**) of the following 2 criteria is used:

Dropout differential derived from the parameter `Dropout ratio` If this parameter is not available, a dropout ratio of 95 % applies to the current threshold value and a dropout ratio of 105 % applies to the voltage threshold value.	
Minimum absolute dropout differential	150 mV sec.

Times

Pickup time	Approx. 10 ms + OOT[197] at 50 Hz Approx. 10 ms + OOT at 60 Hz
Dropout time	Approx. 20 ms + OOT

Times

Use in function group **Line**	
Pickup time	Approx. 10 ms + OOT[198] at 50 Hz Approx. 9 ms + OOT at 60 Hz

Use in other function group types	
Pickup time	Approx. 20 ms + OOT[199] at 50 Hz Approx. 18 ms + OOT at 60 Hz

197 OOT (Output Operating Time) Additional delay of the output medium used, see chapter *12.1.4 Relay Outputs*

198 OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

199 OOT (Output Operating Time) Additional delay of the output medium used, for example 5 ms with fast relays, see chapter *12.1.4 Relay Outputs*

Frequency Operating Range

$0.9 \leq f/f_{rated} \leq 1.1$	According to specified tolerances
$10\ Hz \leq f < 0.9\ f_{rated}$ $1.1\ f_{rated} < f \leq 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Active

Tolerances

Currents	1 % of the setting value or 5 mA (I_{rated} = 1 A) or 25 mA (I_{rated} = 5 A), (f_{rated} ± 10 %)
Voltages	0.5 % of the setting value or 0.5 V
Time delays	1 % of the setting value or 10 ms

12.86 Voltage-Transformer Circuit Breaker

Setting Values

Response time	0.000 s to 0.030 s	Increments of 0.001 s

12.87 Broken-Wire Detection

Setting Values

Mode of blocking	***blocking*** ***not blocking***

Frequency Operating Range

40 Hz < f_{rated} < 70 Hz	All functions processing the measured values of this current measuring point, for example, line differential protection, transformer differential protection, distance protection

Blockings

Blocked functions	All functions processing the measured values of this current measuring point, for example, line differential protection, transformer differential protection, distance protection

12.88 Operational Measured Values and Statistical Values

The following applies to the tolerances of the currents and voltages:

- The values apply both to the RMS values and the absolute value and phase angle of the fundamental components.
- These values were determined for pure sinusoidal signals – without harmonics.
- All measured values additionally have a tolerance of 1 DIGIT.

Voltages

V_A, V_B, V_C **Voltage range**	V secondary < 200 V
Secondary rated voltage Measuring range Frequency range	100 V to 125 V 0.1 V_{rated} to 2 V_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
V_{AB}, V_{BC}, V_{CA} **Voltage range**	V secondary < 200 V
Secondary rated voltage Measuring range Frequency range	100 V to 125 V 0.1 V_{rated} to 2 V_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
V_1, V_2, V_0 **Voltage range**	V secondary < 200 V
Secondary rated voltage Measuring range Frequency range	100 V to 125 V 0.1 V_{rated} to 2 V_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.25 % of the measured value in the above mentioned measuring range or 0.05 V
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.35 % of the measured value in the above mentioned measuring range or 0.05 V

Currents, Instrument Transformers

I_A, I_B, I_C, $3I_0$ **Current range**	A secondary < 1.6 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A 0.1 I_{rated} to 1.6 I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.15 % of the measured value in the above mentioned measuring range or 0.001 I_{rated}
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range or 0.002 I_{rated}
I_1, I_2, I_0 **Current range**	A secondary < 1.6 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A 0.1 I_{rated} to 1.6 I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range or 0.001 I_{rated}
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.35 % of the measured value in the above mentioned measuring range or 0.002 I_{rated}

Currents, Protection-Class Current Transformer

I_A, I_B, I_C, $3I_0$ **Current range**	A secondary < 100 I_{rated}
Rated currents Measuring range Frequency range	1 A, 5 A 0.1 I_{rated} to 5 I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.2 % of the measured value in the above mentioned measuring range or 0.001 I_{rated}
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.35 % f the measured value in the above mentioned measuring range or 0.002 I_{rated}
I_1, I_2, I_0 **Current range**	A secondary < 100 I_{rated}

Rated currents Measuring range Frequency range	1 A, 5 A 0.1 I_{rated} to 5 I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.25 % of the measured value in the above mentioned measuring range or 0.001 I_{rated}
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.4 % of the measured value in the above mentioned measuring range or 0.002 I_{rated}

Currents, Sensitive Ground-Current Transformer

$3I_0$ Current range	A secondary < 1.6 I_{rated}
Rated currents Measuring range Frequency range	1 A. 5 A 0.1 I_{rated} to 1.6 I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.15 % of the measured value in the above mentioned measuring range or 0.001 I_{rated}
Frequency range (expanded)	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range or 0.002 I_{rated}

Phase Angle

ΦV	°
Frequency range	47.5 Hz to 52.5 Hz at f_{rated} = 50 Hz 57.5 Hz to 62.5 Hz at f_{rated} = 60 Hz
Tolerance ΦV	0.2° at rated voltage
ΦI	°
Frequency range	47.5 Hz to 52.5 Hz at f_{rated} = 50 Hz 57.5 Hz to 62.5 Hz at f_{rated} = 60 Hz
Tolerance ΦI	0.2° at rated current

Power Values

Active power P	W secondary
Voltage range Current range Frequency range Power factor	0.8 V_{rated} to 1.2 V_{rated} 0.1 I_{rated} to 2 I_{rated} 45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz $\lvert\cos\varphi\rvert \geq 0.707$
Tolerance	0.5 % of S_{rated} in the above mentioned measuring range
Reactive power Q	var secondary

Voltage range Current range Frequency range Power factor	0.8 V_{rated} to 1.2 V_{rated} 0.1 I_{rated} to 2 I_{rated} 45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz |cosφ| ≤ 0.707
Tolerance	0.5 % of S_{rated} in the above mentioned measuring range
Apparent power S	VA secondary
Voltage range Current range Frequency range	0.8 V_{rated} to 1.2 V_{rated} 0.01 I_{rated} to 2 I_{rated} 45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.5 % of S_{rated} in the above mentioned measuring range

Power Factor

Voltage range	0.8 V_{rated} to 1.2 V_{rated}
Current range	0.1 I_{rated} to 2 I_{rated}
Frequency range	45 Hz to 55 Hz at f_{rated} = 50 Hz 55 Hz to 65 Hz at f_{rated} = 60 Hz
Tolerance	0.02 in the above mentioned measuring range

Frequency

Frequency f	Hz
Range	f_{rated} ± 0.20 Hz
Tolerance	± 2 mHz at V = V_{rated} or at I = I_{rated}
Range	f_{rated} ± 3.00 Hz
Tolerance	± 5 mHz at V = V_{rated} or at I = I_{rated}
Range	25 Hz to 80 Hz; operational measured values 10 Hz to 90 Hz; functional measured values, system frequency
Tolerance	± 10 mHz at V = V_{rated} or at I = I_{rated}

Statistical Values of the Device

Device operating hours	h
Range	0 h to 9999999 h
Tolerance	1 h

Statistical Values, Circuit Breaker

Op.cnt. (operation counter)	
Range	0 to 999999999
Tolerance	None
∑I Off (sum of the primary currents switched off)	A, kA, MA, GA, TA, PA primary
Range	0 to 9.2^{e+15}

Operating hours	h
Range	0 h to 9999999 h
Tolerance	1 h
Circuit breaker open hours	h
Range	0 h to 9999999 h
Tolerance	1 h

Statistical Values, Disconnector

Op.cnt. (operation counter)	
Range	0 to 999999999
Tolerance	None

12.89 Energy Values

Active energy W_p	kWh, MWh, GWh
Measuring range Voltage range Current range Frequency range	|cosφ| ≥ 0.01 (0.8 to 1.2) · V_{rated} (0.1 to 2) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	0.3 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 69 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	0.5 % of the measured value in the above mentioned measuring range

Reactive energy W_q	kvarh, Mvarh, Gvarh
Measuring range Voltage range Current range Frequency range	|cosφ| ≤ 0.984 (0.8 to 1.2) · V_{rated} (0.1 to 2) · I_{rated} 49 Hz to 51 Hz at f_{rated} = 50 Hz 59 Hz to 61 Hz at f_{rated} = 60 Hz
Tolerance	1.0 % of the measured value in the above mentioned measuring range
Frequency range (expanded)	40 Hz to 69 Hz at f_{rated} = 50 Hz 50 Hz to 70 Hz at f_{rated} = 60 Hz
Tolerance	1.5 % of the measured value in the above mentioned measuring range

Pulse metered values	
Maximum detection speed	50/s

12.90 Power Quality – Basic

12.90.1 Voltage Variation

The function **Voltage variation** complies with Class S according to IEC 61000-4-30.

Setting Values

Threshold of the **Dip** stage	10.0 % to 100.0 %	Increments of 0.1 %
Threshold of the **Swell** stage	100.0 % to 140.0 %	Increments of 0.1 %
Threshold of the **Interruption** stage	1.0 % to 20.0 %	Increments of 0.1 %
Dropout differential	1.0 % to 10.0 %	Increments of 0.1 %
Warning delay	0.00 s to 60.00 s	Increments of 0.01 s

Tolerances

Threshold value	1 % of the parameter **`Rated voltage`** that is set in the function group Class S according to IEC 61000-4-30
Warning delay	1 % of the setting value or 10 ms
Dip, swell, or interruption duration	2 network cycles Class S according to IEC 61000-4-30 (For the stage **Interruption**, Class S is met when the threshold value of the stage **Interruption** is set to be equal to or greater than 3 %.)
Residual or swell voltage	1 % of the parameter **`Rated voltage`** that is set in the function group Class S according to IEC 61000-4-30

Frequency Operating Range

$0.85\ f_{rated} \le f \le 1.15\ f_{rated}$	According to specified tolerances
$10\ Hz \le f < 0.85\ f_{rated}$ $1.15\ f_{rated} < f \le 90\ Hz$	Slightly expanded tolerances
$f < 10\ Hz$ $f > 90\ Hz$	Inactive

12.90.2 Voltage Unbalance

The function **Voltage Unbalance** complies with Class S according to IEC 61000-4-30.

Setting Value for the Function

Value	Setting Range	Increment
Minimum voltage V1	0.300 V to 60.000 V	0.001 V

Setting Values for the Stages

Value	Setting Range	Increment
Threshold	0.50 % to 10.00 %	0.01 %
Dropout ratio	0.90 to 0.99	0.01
Observation period	• daily • weekly	–

Value	Setting Range	Increment
Starting day of week	• Sunday • Monday • Tuesday • Wednesday • Thursday • Friday • Saturday	–
Percentile	80 % to 99 %	1 %

Tolerance

For all functional values in the measuring interval of 3 s or 10 min	
V2/V1, V0/V1	±0.15 % Class S according to IEC 61000-4-30

Dropout Ratio

Dropout ratio of warning	5 % of the setting value or 0.25

Frequency Operating Range

0.85 $f_{rated} \le f \le 1.15\ f_{rated}$	According to specified tolerances
10 Hz ≤ f < 0.85 f_{rated} 1.15 f_{rated} < f ≤ 90 Hz	Slightly expanded tolerances
f < 10 Hz f > 90 Hz	Inactive

12.90.3 THD and Harmonics

Setting Value for the Stage Voltage

Value	Setting Range	Increment
Threshold	1.0 % to 25.0 %	0.1
Aggregation interval	• 1 min • 10 min	–

Stage Current

Current range (Ia, Ib, Ic)	Sensitive transformer: 0.01 I_{rated} to 1.6 I_{rated} Protection transformer: 0.01 I_{rated} to 2 I_{rated}	
Tolerance THD value	$I_{fund.} \ge 0.1\ I_{rated}$	0.5 % in the measured range
	0.01 $I_{rated} \le I_{fund.} < 0.1\ I_{rated}$	2.0 % in the measured range
Tolerance harmonic value (2nd to 20th)	$I_{fund.} \ge 0.1\ I_{rated}$	0.5 % in the measured range
	0.01 $I_{rated} \le I_{fund.} < 0.1\ I_{rated}$	2.0 % in the measured range

Stage Voltage

Voltage range (Va, Vb, Vc)	0.1 V_{rated} to 2 V_{rated}
Tolerance THD value	0.5 % in the measured range
Tolerance harmonic value (2nd to 20th)	0.5 % in the measured range

Frequency Operating Range

$0.85\ f_{rated} \le f \le 1.15\ f_{rated}$	According to specified tolerances
$0.8\ f_{rated} \le f < 0.85\ f_{rated}$ $1.15\ f_{rated} < f \le 1.2\ f_{rated}$	Slightly expanded tolerances
$f < 0.8\ f_{rated}$ $f > 1.2\ f_{rated}$	Inactive

12.90.4 Total Demand Distortion

Setting Value for the Stage Voltage

Value	Setting Range	Increment
Threshold	1.0 % to 25.0 %	0.1
Interval	• 15 min • 30 min	–

Stage Current

Current range (Ia, Ib, Ic)	Sensitive transformer: 0.01 I_{rated} to 1.6 I_{rated} Protection transformer: 0.01 I_{rated} to 2 I_{rated}	
Tolerance of the TDD value	$I_{fund.} \ge 0.1\ I_{rated}$	0.5 % in the measured range
	$0.01\ I_{rated} \le I_{fund.} < 0.1\ I_{rated}$	2.0 % in the measured range

Frequency Operating Range

$0.85\ f_{rated} \le f \le 1.15\ f_{rated}$	According to specified tolerances
$0.8\ f_{rated} \le f < 0.85\ f_{rated}$ $1.15\ f_{rated} < f \le 1.2\ f_{rated}$	Slightly expanded tolerances
$f < 0.8\ f_{rated}$ $f > 1.2\ f_{rated}$	Inactive

12.91 Circuit-Breaker Monitoring

Setting Values

Threshold value	ΣI^x-method	0 to 10 000 000	Increments of 1
	2P-method	0 to 10 000 000	Increments of 1
	I^2t-method	0.00 I/Ir*s to 21 400 000.00 I/Ir*s	Increments of 0.01
	Make time	1 % to 100 %	Increments of 1 %
	Break time	1 % to 100 %	Increments of 1 %
	Pole scatter time open	1 ms to 100 ms	Increments of 1 ms
	Pole scatter time close	1 ms to 100 ms	Increments of 1 ms
	Mechanical switching time open	1 ms to 1000 ms	Increments of 1 ms
	Mechanical switching time close	1 ms to 1000 ms	Increments of 1 ms
CB opening time		1 ms to 500 ms	Increments of 1 ms
CB break time		1 ms to 600 ms	Increments of 1 ms
CB make time		1 ms to 600 ms	Increments of 1 ms
Exponent for ΣI^x method		1.0 to 3.0	Increments of 0.1
Switching cycles at I_r		100 to 10 000 000	Increments of 1
Rated short-circuit current I_{sc}		10 A to 100 000 A	Increments of 1 A
Switching cycles at I_{sc}		1 to 1000	Increments of 1
Operating current threshold	1 A @ 50 and 100 Irated	0.030 A to 35.000 A	Increments of 0.001 A
	5 A @ 50 and 100 Irated	0.15 A to 175.00 A	Increments of 0.01 A
	1 A @ 1.6 Irated	0.001 A to 1.600 A	Increments of 0.001 A
	5 A @ 1.6 Irated	0.005 A to 8.000 A	Increments of 0.01 A
Delay correction time		-50 ms to 50 ms	Increments of 1 ms
Auxiliary-contact time		1 ms to 1000 ms	Increments of 1 ms
Response time		1 ms to 1000 ms	Increments of 1 ms

Tolerances

Tolerance of the measured value Make time	± 2 ms
Tolerance of the measured value Break time	± 2 ms
Tolerance of the measured value Pole scatter time	± 2 ms
Tolerance of the measured value Aux.-contact time	± 2 ms
Tolerance of the measured value response time	± 2 ms

12.92 Disconnector Supervision

Setting Values

Threshold value	Mechanical switching time open	0.02 s to 1800.00 s	Increments of 0.01 s
	Mechanical switching time close	0.02 s to 1800.00 s	Increments of 0.01 s
Auxiliary contact time		0.02 s to 1800.00 s	Increments of 0.01 s
Reaction time		0.02 s to 1800.00 s	Increments of 0.01 s

Tolerances

Tolerance of the make-time measured value	±2 ms
Tolerance of the break-time measured value	±2 ms
Tolerance of the reaction-time measured value	±2 ms

12.93 CFC

Typical response times and maximum number of ticks of the CFC task levels:

Task Level	Time (in ms)	Ticks for CP100/CP150	Ticks CP300
High priority Event-triggered	<1	500	1000
Event-triggered	<10	12 367	12 023
Low priority Event-triggered	<10	117 564 in total	112 996 in total
Measurement	250		

The times describe the response time of a typical CFC chart at the respective task level. The maximum number of ticks applies to a typical load for the device based on the application template **3-winding trans. (Diff. Protection, CBFP, REF, DIS)**

The task level ***Measurement*** runs in cycles every 500 ms. All other task levels are event-triggered.

In order to estimate the tick consumption of a CFC chart, you can use the following formula:

$$T_{Chart} = 5 \cdot n_{Inp} + 5 \cdot n_{Outp} + T_{TLev} + \sum_i T_{int} + \sum_j T_{Block}$$

Where:

n_{Inp} Number of indications routed as input in the CFC chart

n_{Outp} Number of indications routed as output in the CFC chart

T_{TLev} 101 Ticks in the High priority Event-triggered level
104 Ticks in the Event-triggered level
54 Ticks in Measurement level
74 Ticks in the Low priority Event-triggered level

T_{int} Number of internal connections between 2 CFC blocks in one chart

T_{Block} Used ticks per CFC block (see *Table 12-13*)

A.1 Order Configurator and Order Options

Order Configurator

The order configurator assists you in the selection of SIPROTEC 5 products. The order configurator is a Web application that can be used with any browser. The order configurator can be used to configure complete devices or individual components, such as communication modules, expansion modules, or other accessories. At the end of the configuration process, the product code and a detailed presentation of the configuration result are provided. The product code unambiguously describes the selected product and also serves as an order number.

Ordering Options

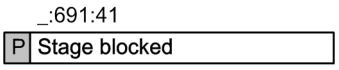
The following ordering options are possible for SIPROTEC 5 products:

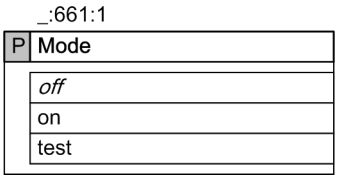
- Device
- Single part
- DIGSI 5
- Functional enhancement

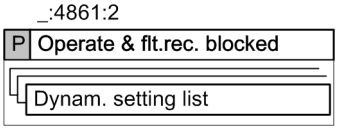
NOTE

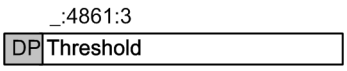
To order single parts in the order configurator, use the **Single part** link.

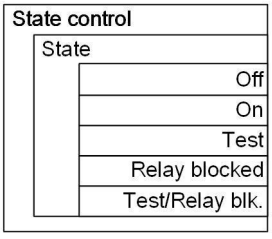
Individual parts are:

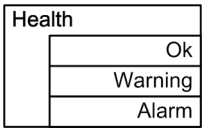


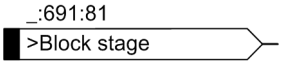


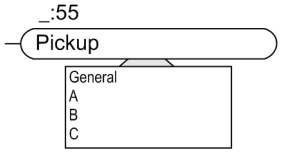


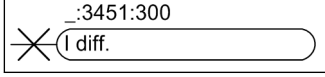




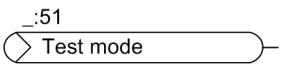


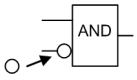


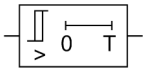


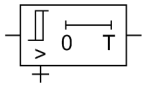


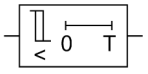
- Expansion module
- Plug-in module
- Sensors for arc protection
- Operation panel
- Terminal
- Accessories

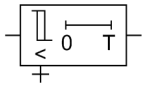


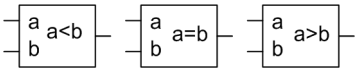


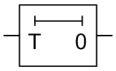


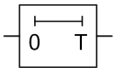


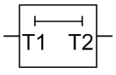




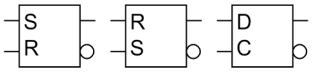


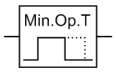






A.2 Typographic and Symbol Conventions



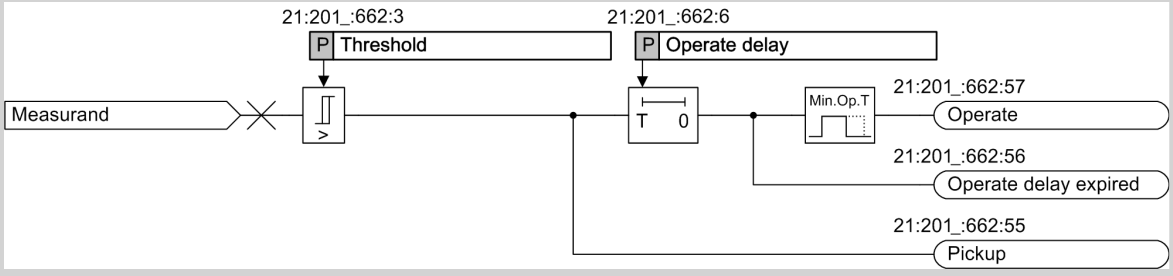


The following typefaces are used to characterize parameters in the text:

Mode	Parameter name
_:661:1	Parameter address _ stands for the address combination from function group:function 661, for example, stands for the address of the setting parameter
off	Parameter state

The following symbols are used in drawings:

Icon	Description
	Parameter
	Parameters with setting values The default setting is in the 1st position and is displayed in italics.
	Parameters with application-dependent setting values
	Dynamic settings
	State logic
	Health of a function, stage, or function block
	External binary input signal with indication number
	External output signal with indication number and additional information
	External output signal without indication number
	Measured output value



Icon	Description
	Binary input signal derived from an external output signal
	Internal input signal
	Internal output signal
	Analog input signal
	Reset/block a logic element
	AND gate
	OR gate
	XOR gate
	Negation
	Threshold stage exceeded
	Threshold stage exceeded with reset of input
	Threshold stage shortfall
	Threshold stage shortfall with reset of input
	Threshold stage exceeded with dropout delay
	Threshold stage exceeded with dropout delay and reset of input
	Threshold stage shortfall with dropout delay
	Threshold stage shortfall with dropout delay and reset of input
	Comparators
	Pickup delay
	Dropout delay
	Pickup and dropout delay

Icon	Description
	Trigger the pulse of duration T with a positive signal edge
	Trigger the pulse of duration T with a negative signal edge
	SR-flip-flop, RS-flip-flop, D-flip-flop
	Characteristic curve
	Minimum operate time
	Circuit breaker open
	Circuit breaker closed

A.3 Available Protection and Control Functions in the Transformer Differential Protection Function Groups

EXAMPLE

The structure of the text and reference number is shown in the protection-function group **Line** as an example of the parameter **`Threshold value`** and the indication **`Pickup`** of the 2nd definite-time overcurrent protection stage of the function **Overcurrent protection, phases** (see *Figure 2-9*). Only one function and one function group exist in the device. The representation of the stage is simplified.

[lo_stuumz_1_en_US]

Figure A-1 Stage of the Overcurrent Protection Function, Phases (without Representation of Stage Control)

The following table shows the texts and numbers of the hierarchy elements concerned:

	Name	Number of the Type	Instance Number
Protection function group	Line	2	1
Function	Overcurrent 3ph	20	1
Stage	Definite-time overcurrent protection	66	2
Settings	Threshold value	3	–
Indication	Pickup	55	–

The instance numbers arise as follows:

- Function group: Line **1**
  1 instance, because only one **Line** function group exists in the device
- Function: Overcurrent 3ph **1**
  1 instance, because only one **Overcurrent 3ph** function exists in the **Line** function group
- Stage: Definite-time overcurrent protection **2**
  2 instances, because 2 definite-time overcurrent protection stages exist in the **Overcurrent 3ph** function (here the 2nd instance as an example)

This results in the following texts and numbers (including the instance numbers):

Parameter:	**Number**
Line 1:Overcurrent 3-ph 1:Definite-time overcurrent protection 2:Threshold value	21:201:662:3
Indication:	**Number**
Line 1:Overcurrent 3-ph 1:Definite-time overcurrent protection 2:Pickup	21:201:662:55

The structure is simplified accordingly for parameters and indications with fewer hierarchy levels.

The following table gives you an overview of the protection and control functions which are available in the function groups of the devices 7UT82, 7UT85, 7UT86, and 7UT87.

Table A-1 Functions in the Function Groups

			Function Group FG																	
			90	91	92	93	94	95	96	97	86	87	81	83	82	59	58	16	2	20

A.8 Requirements for Current Transformers

The protection functions require current transformers that are dimensioned properly. This section describes the characteristics required for the dimensioning of the current transformer. The specified rules pertaining to dimensioning apply the definition of a protection current transformer from IEC 61869-2 (previously IEC 60044-1 and IEC 60044-6) as well as IEC TR 61869-100. Dimensioning according to ANSI C57.13 is also described.

Current Transformers

Parameter	Description
ALF	Accuracy limit factor
ALF'	Operational accuracy limit factor The operational accuracy limit factor is derived from the connected burden R_{bc}: $ALF' \approx ALF \cdot \frac{R_{ct} + R_b}{R_{ct} + R_{bc}}$
R_{ct}	Secondary winding resistance; corrected to 75 °C or another temperature as per the specification
R_b	Rated resistive burden
R_{bc}	Connected resistive operating burden
S_r	Rated power
K_{SSC}	Rated symmetrical short-circuit current factor $K_{SSC} = \frac{I_{psc}}{I_{pr}}$
I_{psc}	Rated primary short-circuit current
I_{pr}	Rated primary current
I_{sr}	Rated secondary current
K_{td}	Transient dimensioning factor
E_k	Rated knee-point EMF
V_{tc}	Current terminal voltage with 20-fold rated current and connected burden R_{bc} (ANSI C57.13)

Protected Object

Parameter	Description
$I_{SC\ Int}$	Maximum symmetrical short-circuit current in the event of an internal fault
$I_{SC\ Ext}$	Maximum symmetrical short-circuit current in the event of an external fault (a fault current flowing through)
I_{rTr}	Rated current of the transformer
v_{sc}	Short-circuit voltage of the transformer
I_{rG}	Rated current of the generator
$x''_{d\ Sat}$	Saturated direct-axis synchronous reactance of the generator
I_{rM}	Rated current of the motor
I_{AM}	Motor starting current
$I_{AM\ trans}$	Max. motor starting current (transient starting current after starting from a standstill)
K_{hr}	Additional dimensioning factor to consider high remanence values for current transformers with $K_R \geq 80\ \%$

You can find detailed descriptions in the following sections:

- Current transformer requirements for transformer differential protection,
  (*Requirements for Transformer Differential Protection to Dimension the Phase and Neutral-Point Current Transformers, Page 2616*)
- Current transformer requirements for generator differential protection,
  (*Requirements for the Generator Differential Protection to Dimension the Phase Current Transformers, Page 2621*)
- Current transformer requirements for motor differential protection,
  (*Requirements for Motor Differential Protection for Dimensioning the Phase Current Transformers , Page 2624*)
- Requirements for the core balance current transformer,
  (*Requirements for the Core Balance Current Transformer for Sensitive Ground-Fault Detection, Page 2627*)

Requirements for Transformer Differential Protection to Dimension the Phase and Neutral-Point Current Transformers

The requirements for current transformers are derived from observing the internal and external short circuit. The protection system must remain stable for the external short circuit and must trip safely for the internal short circuit due to potentially high short-circuit currents.

IEC Class	At Least	Internal Fault	External Fault
	Required ALF'		
5P, 10P[201] (up to 80 % remanence)	25	$\geq 0.5 \cdot \frac{I_{SC\,Int}}{I_{pr}}$	$\geq 2 \cdot \frac{I_{SC\,Ext}}{I_{pr}}$
5PR, 10PR[202]	12.5	$\geq 0.4 \cdot \frac{I_{SC\,Int}}{I_{pr}}$	$\geq 1.5 \cdot \frac{I_{SC\,Ext}}{I_{pr}}$
	Required product $K_{td} \cdot K_{SSC}$		
TPX (up to 80 % remanence)	25	$\geq 0.5 \cdot \frac{I_{SC\,Int}}{I_{pr}}$	$\geq 2 \cdot \frac{I_{SC\,Ext}}{I_{pr}}$
TPY, TPZ	12.5 (Burden: $R_b \geq R_{bc}$)	$\geq 0.4 \cdot \frac{I_{SC\,Int}}{I_{pr}}$	$\geq 1.5 \cdot \frac{I_{SC\,Ext}}{I_{pr}}$
	Required knee-point voltage E_k		
PX (up to 80 % remanence)	$20 \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 0.4 \cdot \frac{I_{SC\,Int}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 1.6 \cdot \frac{I_{SC\,Ext}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$
PXR	$10 \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 0.3 \cdot \frac{I_{SC\,Int}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 1.3 \cdot \frac{I_{SC\,Ext}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$

ANSI Class	At Least	Internal Fault	External Fault
	Required transformer terminal voltage V_{tc}		
C (I_{sr} = 5 A) (up to 80 % remanence)	$25 \cdot I_{sr} \cdot R_{bc}$	$\geq 0.5 \cdot \frac{I_{SC\,Int}}{I_{pr}} \cdot I_{sr} \cdot R_{bc}$	$\geq 2 \cdot \frac{I_{SC\,Ext}}{I_{pr}} \cdot I_{sr} \cdot R_{bc}$

Remanence may lead to a premature saturation, which is critical for the differential protection. For new plants, Siemens recommends anti-remanence cores in classes 5PR, PXR, and TPY. For expected high direct current components, Siemens recommends class TPZ, which avoids overfunctions if there are external faults.

201 Phase displacement (displacement angle) is not specified in IEC 61869-2. Class 10P is not recommended for differential protection for this reason.

202 Phase displacement (displacement angle) is not specified in IEC 61869-2: Class 10PR is not recommended for differential protection.

Avoid using different classes of current transformer at measuring points. This is particularly the case when combining current transformers of 5P class with current transformers of TPY or TPZ class. In contrast with class 5P current transformers, class TPY and TPZ current transformers heavily suppress a direct current component in the short-circuit current. Additional differential currents will occur when current transformer classes are mixed.

The request of at least ALF' = 25 for class P, PX, TPX, and C current transformers ensures stability if external low-current faults occur with high direct current components or high current transformer remanence at the default settings of the differential protection characteristic. If these current transformers only have a minimum ALF' of 20, Siemens recommends using a Diff> threshold value of 0.25 for the transformer differential protection characteristic and increasing **`Slope 1`** to 0.35. With a minimum ALF' of 15, Siemens recommends using an I-Diff> threshold value of at least 0.3 and adjusting **`Slope 1`** to 0.4.

NOTE

To avoid current transformer remanence, Siemens recommends the use of anti-remanence cores in classes 5PR, PXR, and TPY for differential protection systems. When using closed-iron transformers for low-impedance differential protection, ensure that the remanence factor[203] K_R, according to IEC 61869-2, is less than 80 %. Otherwise, Siemens recommends applying an additional dimensioning factor K_{hr}.

If you use current transformers with a remanence factor $K_R > 80$ % for differential protection, you need to take into account an additional dimensioning factor K_{hr} for the above equations resulting from the following table:

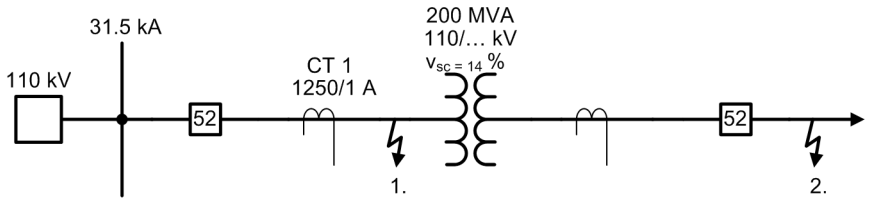
IEC class	Internal fault	External fault
PX	$E_k \geq 0.4 \cdot K_{hr} \cdot \frac{I_{SC,Int}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$E_k \geq 1.6 \cdot K_{hr} \cdot \frac{I_{SC,ext}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$
The 5P, 10P[204]	$ALF' \geq 0.5 \cdot K_{hr} \cdot \frac{I_{SC,Int}}{I_{pr}}$	$ALF' \geq 2 \cdot K_{hr} \cdot \frac{I_{SC,ext}}{I_{pr}}$

If current transformers of classes 5P, 10P, PX, and TPX have a remanence factor[203] $K_R > 80$ %, Siemens recommends a dimensioning factor $K_{hr} = 2$.

NOTE

When using distance or line differential protection functions in transformer differential protection, the current transformer requirements of the line protection must be taken into account. You can find these in the *Line protection manual* (C53000-G5040-C010).

NOTE



When using restricted ground-fault protection, the neutral point transformer can be designed lower by a factor of 0.5 to 1.0, depending on the required accuracy limit factor (ALF) of the phase current transformer. When using the zero-sequence current correction of the transformer differential protection, Siemens recommends designing the neutral point transformer according to the required accuracy limit factor (ALF) of the phase current transformer.

Example

The transformer for a power-plant unit that feeds into a 110-kV electrical power system is protected. Current transformer 1 (CT 1) is taken into account in the following plant as an example for current transformer design.

203 Remanence factor K_R = manufacturer specification or data from measuring logs

204 Phase displacement (displacement angle) is not specified in IEC 61869-2. Class 10P is not recommended for differential protection for this reason.

[dwwdlanf-301012-01.tif, 1, en_US]

Application of Current Transformers Class IEC 5P

For this example, it is checked whether an existing 5P15 10 VA current transformer meets the requirements.

Parameter	Value	Description
I_{pr}	1250 A	Rated primary current of the current transformer
I_{sr}	1 A	Rated secondary current of the current transformer
S_r	10 VA	Rated power
ALF	15	Accuracy limit factor
R_{ct}	5 Ω	Secondary winding resistance at 75 °C
l_{Cable}	50 m	Length of the secondary current transformer supply lines
A_{Cable}	4 mm²	Core cross section of the current transformer supply lines
ρ_{cu}	0.0213 Ω mm²/m	Specific copper cable resistivity at 75 °C (the value is 0.0179 Ω mm²/m at 20 °C)
S_{Device}	0.1 VA	Protection device burden at rated current

Calculation of the Connected Burden:

The burden R_{bc} connected to the terminals of the current transformer is derived from the double supply-line resistance (supply and return line) and the device burden as indicated below.

$$R_{Cable} = \frac{2 \cdot \rho_{Cu} \cdot l_{Cable}}{A_{Cable}} = \frac{2 \cdot 0.0213 \frac{\Omega \cdot mm^2}{m} \cdot 50}{4\ mm^2} = 0.5325\ \Omega$$

$$R_{Device} = \frac{S_{Device}}{I_{sr}^2} = \frac{0.1\ VA}{(1\ A)^2} = 0.1\ \Omega$$

$$R_b = \frac{S_r}{I_{sr}^2} = \frac{10\ VA}{(1\ A)^2} = 10\ \Omega$$

$$R_{bc} = R_{Cable} + R_{Device} = 0{,}5325\ \Omega + 0{,}1\ \Omega \approx 0{,}6325\ \Omega$$

$$ALF' \approx ALF \cdot \frac{R_{ct} + R_b}{R_{ct} + R_{bc}} = 15 \cdot \frac{5\ \Omega + 10\ \Omega}{5\ \Omega + 0{,}6325\ \Omega} \approx 39{,}9$$

Internal Short Circuit

Maximum short-circuit current: $I_{SC\ Int} = 31.5$ kA

Requirement:

$$ALF' \geq 0.5 \cdot \frac{I_{SC\ Int}}{I_{pr}} = 0.5 \cdot \frac{31.5\ kA}{1250\ A} = 12.6 \text{ at least } 25$$

External Short Circuit

Rated transformer current:

$$I_{rTr} = \frac{S_{rTr}}{\sqrt{3} \cdot V_{rTr}} = \frac{200\,\text{MVA}}{\sqrt{3} \cdot 110\,\text{kV}} = 1050\,\text{A}$$

$$I_{SC\,Ext} \approx \frac{I_{rTr}}{v_{SC}} \cdot 100\,\% = \frac{1050\,\text{A}}{14\,\%} \cdot 100\,\% = 7500\,\text{A}$$

Requirement:

$$ALF' \geq 2 \cdot \frac{I_{SC\,Ext}}{I_{pr}} = 2 \cdot \frac{7500\,\text{A}}{1250\,\text{A}} = 12 \text{ at least } 25$$

Comparison: ALF' current transformer > ALF' requirement
Result: 40 > 25
The current transformer meets the requirement.

Application of Current Transformers Class IEC 5PR

This current transformer should be replaced by a 5PR class current transformer.

Internal Short Circuit

Requirement:

$$ALF' \geq 0.4 \cdot \frac{I_{SC\,Int}}{I_{pr}} = 0.4 \cdot \frac{31.5\,\text{kA}}{1250\,\text{A}} = 10.1 \text{ at least } 12.5$$

External Short Circuit

Requirement:

$$ALF' \geq 1.5 \cdot \frac{I_{SC\,Ext}}{I_{pr}} = 1.5 \cdot \frac{7500\,\text{A}}{1250\,\text{A}} = 9 \text{ at least } 12.5$$

The 5PR15, 5 VA current transformer is selected in the example.
5 VA power was selected as current transformer internal burdens R_{ct} must be taken into account for a smaller rated power system. This makes them more flexible with the connected burden R_{bc} (longer current transformer supply lines are possible).

Application of Current Transformer Class IEC TPZ

The current transformers are specified by K_{SSC}, K_{td}, and R_b.

Internal Short Circuit

Symmetrical rated short-circuit current factor:

$$K_{SSC} = \frac{I_{psc}}{I_{pr}} = \frac{I_{sc\,Int}}{I_{pr}} = \frac{31.5\,\text{kA}}{1250\,\text{A}} = 25.2$$

Required product:

$$K_{td} \cdot K_{SSC} \geq 0.4 \cdot \frac{I_{SC\,Int}}{I_{pr}} = 0{,}4 \cdot \frac{31.5\,\text{k A}}{1250\,\text{A}} = 10.1 \text{ at least } 12.5$$

External Short Circuit

Symmetrical rated short-circuit current factor:

$$K_{SSC} = \frac{I_{psc}}{I_{pr}} = \frac{I_{sc\ Ext}}{I_{pr}} = \frac{7500\ A}{1250\ A} = 6$$

Required product:

$$K_{td} \cdot K_{SSC} \geq 1.5 \cdot \frac{I_{SC\ Ext}}{I_{pr}} = 1.5 \cdot \frac{7500\ A}{1250\ A} = 9 \text{ at least } 12.5$$

The required resistive dimensioning burden R_b of the current transformer must be greater than the connected resistive burden R_{bc} previously calculated. The burden connected in the example is $R_{bc} = 0.633\ \Omega$.

The resistive dimensioning burden is selected with $R_b = 1\ \Omega$.

NOTE

The K_{SSC} factor is determined by the maximum symmetrical short-circuit current. The minimum requirement in the example is $K_{SSC} = 25$ and $K_{td} = 0.4$. As the product is critical for the current transformer design, the standard permits K_{SSC} and K_{td} values can be freely selected, subject to certain limits (see DIN IEC TR 61869-100, *Section 11.5.3.3.5* and *Section 9.2*).
Specification $K_{SSC} = 12.5$ and $K_{td} = 1.0$ is permitted.

The current transformer is specified with $K_{SSC} = 15$, $K_{td} = 1$ and $R_b = 1\ \Omega$ in order to have a reserve. You must increase the burden to $R_b = 2.0\ \Omega$ for longer current transformer supply lines.

The current transformer is designated as follows: 1250 A/1 A, $R_b = 1\ \Omega$, cl. TPZ 15x1.

Application of Current Transformer Class IEC PX

The following values are incorporated into the calculation for the burdens in the example.

$R_{bc} = 0.633\ \Omega$

$R_{ct} = 4.5\ \Omega$

Internal Short circuit

Required knee-point voltage:

$$E_k \geq 0.4 \cdot \frac{I_{SC\ Int}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc}) = 0.4 \cdot \frac{31.5\ kA}{1250\ A} \cdot 1\ A \cdot (4.5\ \Omega + 0.633\ \Omega) = 51.85\ V$$

At least:

$$E_k \geq 20 \cdot I_{sr} \cdot (R_{ct} + R_{bc}) = 20 \cdot 1\ A \cdot (4.5\ \Omega + 0.633\ \Omega) = 102.7\ V$$

External Short circuit

Required knee-point voltage:

$$E_k \geq 1.6 \cdot \frac{I_{SC\ Ext}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc}) = 1.6 \cdot \frac{7500\ A}{1250\ A} \cdot 1\ A \cdot (4.5\ \Omega + 0.633\ \Omega) = 49.28\ V$$

The minimum requirement determines the knee-point voltage and must be ≥ 102.7 V.
The rated knee-point EMF is selected with $E_k = 150$ V.

Application of Current Transformer Class ANSI C

The rated secondary current of I_{sr} = 5 A causes the connected burden to change.

$$R_{Device} = \frac{S_{Device}}{I_{sr}^2} = \frac{0.1\ VA}{(5\ A)^2} = 0.004\ \Omega$$

$$R_{bc} = R_{Cable} + R_{Device} = 0.5325\ \Omega + 0.004\ \Omega \approx 0.537\ \Omega$$

Internal Short Circuit

The required transformer terminal voltage for the current transformer:

$$V_{tc} \geq 0.5 \cdot \frac{I_{SC\ Int}}{I_{pr}} \cdot I_{sr} \cdot R_{bc} = 0.5 \cdot \frac{31.5\ kA}{1250\ A} \cdot 5\ A \cdot 0.537\ \Omega = 33.83\ V$$

At least:

$$V_{tc} \geq 25 \cdot I_{sr} \cdot R_{bc} = 25 \cdot 5\ A \cdot 0.537\ \Omega = 67.1\ V$$

External Short Circuit

The required transformer terminal voltage for the current transformer:

$$V_{tc} \geq 2 \cdot \frac{I_{SC\ Ext}}{I_{pr}} \cdot I_{sr} \cdot R_{bc} = 2 \cdot \frac{7500\ A}{1250\ A} \cdot 5\ A \cdot 0.537\ \Omega = 32.22\ V$$

The class C current transformer must have a terminal voltage of ≥ 67.1 V. The C100 current transformer meets the conditions. The rated burden Z_b is 1 Ω.

The current transformer terminal voltage is:

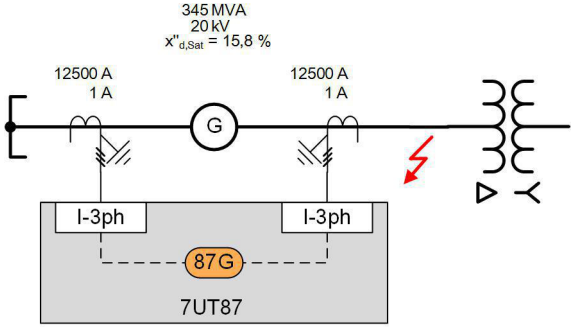
$$V_t = 20 \cdot I_{sr} \cdot Z_b = 20 \cdot 5\ A \cdot 1\ \Omega = 100\ V$$

Requirements for the Generator Differential Protection to Dimension the Phase Current Transformers

In comparison to transformer applications, the current transformer setup is sufficient for observing the external short circuit.

IEC Class	At Least	Requirement
	Required ALF'	
5P, 10P[205] (up to 80 % remanence)	30	$\geq 4 \cdot \frac{I_{SC\ Ext}}{I_{pr}}$
5PR, 10PR[206]	25	$\geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}}$
	Required product $K_{td} \cdot K_{SSC}$	
TPY, TPZ	25 (Burden $R_b \geq R_{bc}$)	$\geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}}$
	Required knee-point voltage E_k	
PX (up to 80 % remanence)	$25 \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$

205 Phase displacement (displacement angle) is not specified in IEC 61869-2. Class 10P is not recommended for differential protection.



206 Phase displacement (displacement angle) is not specified in IEC 61869-2. Class 10PR is not recommended for differential protection.

ANSI Class	At Least	Requirement
	Required transformer terminal voltage V_{tc}	
C (I_{sr} = 5 A) (up to 80 % remanence)	$25 \cdot I_{sr} \cdot R_{bc}$	$\geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}} \cdot I_{sr} \cdot R_{bc}$

Remanence may lead to a premature saturation which is critical for differential protection. For new plants, Siemens recommends anti-remanence cores in classes 5PR and TPY. For expected high direct current components, Siemens recommends class TPZ, which avoids overfunctions if there are external faults. Siemens recommends TPZ for larger generators (i.e > 500 MVA). Avoid using different classes of current transformer at the measuring points. This is the case when combining 5P class and TPY class systems, especially TPZ.
In contrast with class 5P current transformers, class TPY and TPZ current transformers heavily suppress a direct current component in the short-circuit current. Additional differential currents will occur when current transformer classes are mixed.

Example

The following example is used for checking the current transformer:

[dw_l gendiff exam-UT-200121, 1, en_US]

Application of Current Transformers Class IEC 5P

For this example, it is checked whether an existing 5P20 30 VA current transformer meets the requirements.

Parameter	Value	Description
I_{pr}	12500 A	Rated primary current of the current transformer
I_{sr}	1 A	Rated secondary current of the current transformer
S_r	30 VA	Rated power
ALF	20	Accuracy limit factor
R_{ct}	30 Ω	Secondary winding resistance at 75 °C
l_{Cable}	100 m	Length of the secondary current transformer supply lines
A_{Cable}	4 mm²	Core cross section of the current transformer supply lines
ρ_{cu}	0.0213 Ω mm²/m	Copper cable resistivity at 75 °C (the value is 0.0179 Ω mm²/m at 20 °C)
S_{Device}	0.1 VA	Protection device burden at rated current

Calculation of the Connected Burden:

The burden R_{bc} connected to the terminals of the current transformer is derived from the double supply-line resistance (supply and return line) and the device burden as indicated below.

$$R_{Cable} = \frac{2 \cdot \rho_{Cu} \cdot l_{Cable}}{A_{Cable}} = \frac{2 \cdot 0.0213 \frac{\Omega \cdot mm^2}{m} \cdot 100}{4\,mm^2} = 1.065\ \Omega$$

$$R_{Device} = \frac{S_{Device}}{I_{sr}^2} = \frac{0.1\ VA}{(1\ A)^2} = 0.1\ \Omega$$

$$R_b = \frac{S_r}{I_{sr}^2} = \frac{30\ VA}{(1\ A)^2} = 30\ \Omega$$

$$R_{bc} = R_{Cable} + R_{Device} = 1.065\ \Omega + 0.1\ \Omega \approx 1.165\ \Omega$$

$$ALF' \approx ALF \cdot \frac{R_{ct} + R_b}{R_{ct} + R_{bc}} = 20 \cdot \frac{30\ \Omega + 30\ \Omega}{30\ \Omega + 1{,}165\ \Omega} \approx 38{,}5$$

Generator rated current:

$$I_{rG} = \frac{S_{rG}}{\sqrt{3} \cdot V_{rG}} = \frac{345\ MVA}{\sqrt{3} \cdot 20\ kV} = 9959\ A$$

Maximum short-circuit current:

$$I_{SC\ Ext} \approx \frac{I_{rG}}{x''_{d,Sat}} \cdot 100\ \% = \frac{9959\ A}{15.8\ \%} \cdot 100\ \% \approx 63\,032\ A$$

Requirement:

$$ALF' \geq 4 \cdot \frac{I_{SC\ Ext}}{I_{pr}} = 4 \cdot \frac{63032\ A}{12500\ A} = 21.2\ \text{at least } 30$$

Comparison: ALF' current transformer > ALF' requirement
Result: 38.5 > 30
The current transformer meets the requirement.

Application of Current Transformers Class IEC 5PR

This current transformer should be replaced by a 5PR class current transformer.

Requirement:

$$ALF' \geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}} = 3 \cdot \frac{63032\ A}{12500\ A} = 15.13\ \text{at least } 25$$

The 5PR30, 5 VA current transformer is selected in the example.
5 VA power was selected as current transformer internal burdens R_{ct} must be taken into account for a smaller rated power system. This makes them more flexible with the connected burden R_{bc} (longer current transformer supply lines are possible).

Application of Current Transformers Class IEC TPZ

The current transformers are specified by K_{SSC}, K_{td}, and R_b.

Symmetrical rated short-circuit current factor:

$$K_{SSC} = \frac{I_{psc}}{I_{pr}} = \frac{I_{sc\ Ext}}{I_{pr}} = \frac{63\ 032\ A}{12\ 500\ A} = 5.04$$

Required product:

$$K_{td} \cdot K_{SSC} \geq 3 \cdot \frac{I_{SC\ Ext}}{I_{pr}} = 3 \cdot \frac{63032\ A}{12500\ A} = 15.13\ \text{at least}\ 25$$

The required resistive dimensioning burden R_b of the current transformer must be greater than the connected resistive burden R_{bc} previously calculated. The burden connected in the example is R_{bc} = 1.165 Ω.

The resistive rated burden is selected with t R_b = 2 Ω.

A current transformer with K_{SSC} = 10, K_{td} = 3 and R_b = 2 Ω meets the requirements. Increase the burden to R_b = 5 Ω for longer current transformer supply lines, if required.

The current transformer is designated as follows: 12500 A/1 A, R_b = 2 Ω, cl. TPZ 10x3.

Application of Current Transformers Class ANSI C

The rated secondary current of I_{sr} = 5 A causes the connected burden to change.

$$R_{Device} = \frac{S_{Device}}{I_{sr}^2} = \frac{0.1\ VA}{(5\ A)^2} = 0.004\ \Omega$$

$$R_{bc} = R_{Cable} + R_{Device} = 1.065\ \Omega + 0.004\ \Omega \approx 1.07\ \Omega$$

Required current transformer terminal voltage:

$$V_{tc} \geq 4 \cdot \frac{I_{SC\ Ext}}{I_{pr}} \cdot I_{sr} \cdot R_{bc} = 4 \cdot \frac{63\ 032\ A}{12\ 500\ A} \cdot 5\ A \cdot 1.07\ \Omega = 107.9\ V$$

At least:

$$V_{tc} \geq 30 \cdot I_{sr} \cdot R_{bc} = 30 \cdot 5\ A \cdot 1.07\ \Omega = 160.5\ V$$

The class C current transformer must have a terminal voltage of ≥ 160.5 V. The C200 current transformer meets the conditions. The rated burden Z_b is 2 Ω.

The terminal voltage is:

$$V_t = 20 \cdot I_{sr} \cdot Z_b = 20 \cdot 5\ A \cdot 2\ \Omega = 200\ V$$

Requirements for Motor Differential Protection for Dimensioning the Phase Current Transformers

In comparison to transformer and generator applications, the current transformer setup must observe the maximum starting current. This affects asynchronous motors during direct startup. The motors temporarily feed the current back into the electrical power system in the event of a short circuit. This fault current doesn't exceed the starting current.

IEC Class	At Least	Requirement
	Required ALF'	
5P, 10P[207] (up to 80 % remanence)	30	$\geq 4 \cdot \frac{I_{AM\ trans}}{I_{pr}}$
5PR, 10PR[208]	25	$\geq 3 \cdot \frac{I_{AM\ trans}}{I_{pr}}$

207 Phase displacement is not specified in IEC 61869-2. Class 10P is not recommended for differential protection.

208 Phase displacement is not specified in IEC 61869-2. Class 10PR is not recommended for differential protection.

	Required product $K_{td} \cdot K_{SSC}$	
TPY, TPZ	25 (Burden $R_b \geq R_{bc}$)	$\geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}}$
	Required knee-point voltage E_k	
PX (up to 80 % remanence)	$25 \cdot I_{sr} \cdot (R_{ct} + R_{bc})$	$\geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc})$

ANSI Class	At Least	Requirement
	Required transformer terminal voltage V_{tc}	
C (I_{sr} = 5 A) (up to 80 % remanence)	$25 \cdot I_{sr} \cdot R_{bc}$	$\geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}} \cdot I_{sr} \cdot R_{bc}$

Avoid using different classes of current transformer at the measuring points. This is the case when combining class 5P and class TPY, especially TPZ. In contrast with class 5P current transformers, class TPY and TPZ current transformers heavily suppress a direct current component in the short-circuit current. Additional differential currents will occur when current transformer classes are mixed.

EXAMPLE:

A motor is protected with a starting current in the event of rated voltage $I_{AM} = 5.6 \cdot I_{rM}$. The motor starts up in 4.5 s under rated conditions. You can find the remaining data in the figure below.

[dw_app-example_for_current-transf_connect-requirements_UT, 1, en_US]

$$I_{AM\,trans} \approx 2 \cdot I_{AM} = 2 \cdot 5.6 \cdot I_{rM} = 2 \cdot 5.6 \cdot 640\,A = 7168\,A$$

The current transformer data is specified below.

Application of Current Transformers Class IEC 5P

Requirement:

$$ALF' \geq 4 \cdot \frac{I_{AM\,trans}}{I_{pr}} = 4 \cdot \frac{7168\,A}{1000\,A} = 28.7 \text{ at least } 30$$

A 1000 A/1 A, 5P30 current transformer with S_r = 2.5 VA meets the requirements. The connected burden is required to be $R_{bc} < 2.5\ \Omega$. Increase the power to S_r = 5 VA for longer current transformer supply lines.

Application of Current Transformers Class IEC TPY

The current transformers are specified by K_{SSC}, K_{td}, and R_b.

Symmetrical rated short-circuit current factor:

$$K_{SSC} = \frac{I_{psc}}{I_{pr}} = \frac{I_{AM\,trans}}{I_{pr}} = \frac{7168\,A}{1000\,A} = 7.17$$

Required product:

$$K_{td} \cdot K_{SSC} \geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}} = 3 \cdot \frac{7168\,A}{1000\,A} = 21.5 \text{ at least } 25$$

The required resistive dimensioning burden R_b of the current transformer must be greater than the connected resistive burden R_{bc}. The connected burden that has been adopted is $R_{bc} < 2\ \Omega$.

The ohmic dimensioning burden is selected with $R_b = 2\ \Omega$.

A current transformer with $K_{SSC} = 10$, $K_{td} = 3$, and $R_b = 2\ \Omega$ meets the requirements. Increase the burden to $R_b = 5\ \Omega$ for longer current transformer supply lines.

The current transformer is designated as follows: 1000 A/1 A, $R_b = 2\ \Omega$, cl. TPY 10x3.

Application of Current Transformers Class IEC PX

The following values are incorporated into the calculation for the burden in the following example.

$R_{bc} = 1.5\ \Omega$

$R_{ct} = 4.5\ \Omega$

Required knee-point voltage:

$$E_k \geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}} \cdot I_{sr} \cdot (R_{ct} + R_{bc}) = 3 \cdot \frac{7168\,A}{1000\,A} \cdot 1\,A \cdot (4.5\,\Omega + 1.5\,\Omega) = 129\,V$$

At least:

$$E_k \geq 25 \cdot I_{sr} \cdot (R_{ct} + R_{bc}) = 25 \cdot 1\,A \cdot (4.5\,\Omega + 1.5\,\Omega) = 150\,V$$

The PX current transformer must have a knee-point voltage of ≥ 150 V.

The rated knee-point EMF is selected with $E_k = 150$ V. If the connected burdens change, you must adjust E_k, if required.

Application of Current Transformers Class ANSI C

The rated secondary current is I_{sr} for this class = 5 A. A 50 m/4 mm² supply line is adopted for the 2 current transformers. This results in the following for the connected burden:

$$R_{Cable} = \frac{2 \cdot \rho_{Cu} \cdot l_{Cable}}{A_{Cable}} = \frac{2 \cdot 0.0213 \frac{\Omega \cdot mm^2}{m} \cdot 50}{4\ mm^2} = 0.5325\,\Omega$$

$$R_{Device} = \frac{S_{Device}}{I_{sr}^2} = \frac{0.1\ VA}{(5\ A)^2} = 0.004\,\Omega$$

$$R_{bc} = R_{Cable} + R_{Device} = 0.5325\,\Omega + 0.004\,\Omega \approx 0.537\,\Omega$$

Required current transformer terminal voltage:

$$V_{tc} \geq 3 \cdot \frac{I_{AM\,trans}}{I_{pr}} \cdot I_{sr} \cdot R_{bc} = 3 \cdot \frac{7168\,A}{1000\,A} \cdot 5\,A \cdot 0.537\,\Omega = 57.7\,V$$

At least:

$$V_{tc} \geq 25 \cdot I_{sr} \cdot R_{bc} = 25 \cdot 5\,A \cdot 0.537\,\Omega = 67.1\,V$$

The class C current transformer must have a current transformer terminal voltage of ≥ 67.1 V. The C100 current transformer meets the conditions. The rated burden Z_b is 1 Ω.

The current transformer terminal voltage is:

$$V_t = 20 \cdot I_{sr} \cdot Z_b = 20 \cdot 5\ A \cdot 1\ \Omega = 100\ V$$

Requirements for the Core Balance Current Transformer for Sensitive Ground-Fault Detection

The requirements for the core balance current transformer are determined by the **sensitive ground-fault detection** function. A directional sensitive ground-fault protection system is used for selective sensitive ground-fault detection in the busbar connection for motors and generators. The protection function trips with a delay.

The electrical power systems are predominantly isolated. A grounding transformer with load equipment is available that feeds in a maximum active current of 10 A to enable the stator ground-fault protection system to be 80 % to 90 % effective. The cosφ method is used here. The capacitive current of the electrical power system is superimposed on the active current.

The following table shows the requirements and recommendations for the instrument transformer.

Parameter	Value	Note
I_{pr}	60 A	60 A is a recommended value for motor and generator protection applications.
I_{sr}	1 A	Preferred value
Class	1	This is the recommended class. If small currents need to be measured accurately, for example, up to 1 % I_{pr}, Siemens recommends the 0.5S class. Class 3 is sufficient for just measuring the ground current without being influenced by the angle accuracy. The measurement deviation for the transfer ratio of 3 % is defined in the range of (50 % to 120 %) I_{pr}.
S_r	1 VA	The accuracy specifications for the ratio error of measurement and the phase displacement in IEC 61869-2, *Section 5.6.201.3* refer to this rated power. The rated power is sufficient for a connected burden $R_{bc} < 1\ \Omega$. If there are larger burdens, you must increase the power, where the value of 15 VA may not be exceeded in accordance with IEC 61869-2, *Section 5.6.201.4*.
R_{bc}	< 1 Ω	The standard values of the accuracy classes apply for a burdening of 25 % to 100 % of the rated power. The connected burden must be R_{bc} in this range. In the event of deviations, you must adjust the rated power S_r. For small burdens, for example, during use in medium voltage cubicles, you must reduce the rated power to 0.5 VA.
FS	10	Required overcurrent limiting factor (FS 10). The number 10 expresses that the current is reduced to 10 · I_{pr} and **not** transmitted by the current transformer. The standard does not dictate what current the current transformer may be saturated from.

The recommended current transformer has the following specification: 60 A/1 A; 1 VA, cl.1 FS 10

NOTE

The neutral point on the transformer is partially grounded via a resistor in industry networks to minimize transient overvoltages in the event of a ground fault, and this leads to larger ground currents. Adjust the primary rated current I_{pr} of the core balance current transformer if required. The sensitive ground-current measurement function meets the requirements for selectivity, as a sufficient zero-sequence current flows in the faulty motor in the event of a ground fault.

.

Table A-2 Limiting Values for the Recommended Instrument Transformers in accordance with IEC 61869-2, Section 5.6.201.3

Class	**Ratio Error of Measurement (± %)**					**Phase Displacement (± Minutes)**				
	for current (% of rated current)					for current (% of rated current)				
	1	5	20	100	120	1	5	20	100	120
0.5S	1.5	0.75	0.5	0.5	0.5	90	45	30	30	30
1	–	3.0	1.5	1.0	1.0	–	180	90	60	60

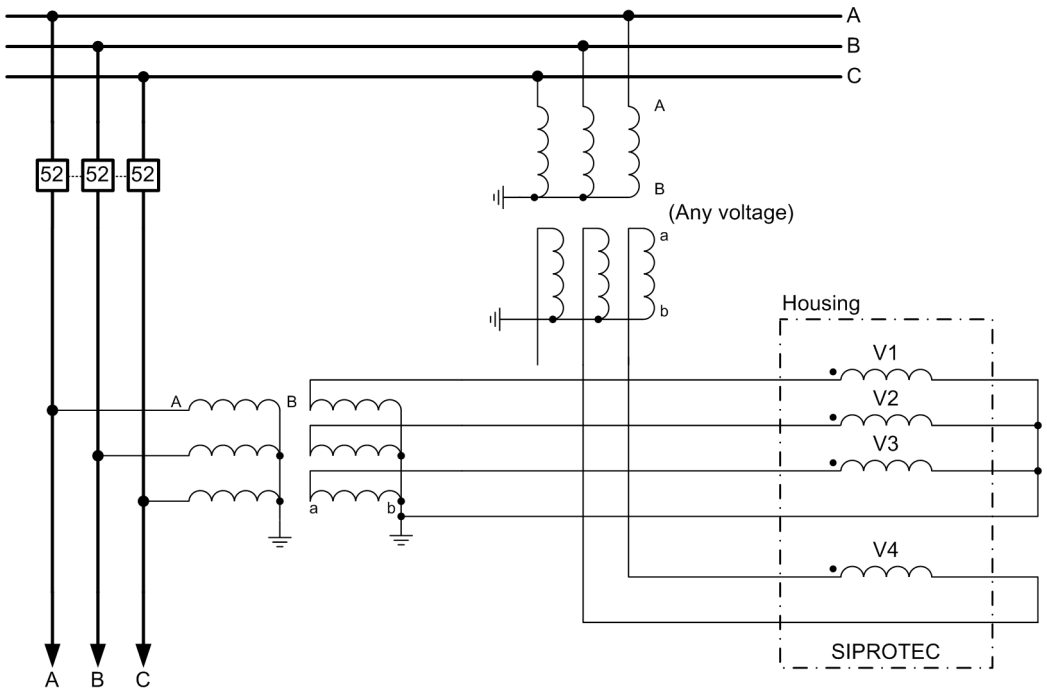
[tvvolta1-260313-01.tif, 1, en_US]

Figure A-21 Connection to 3 Star-Connected Voltage Transformers

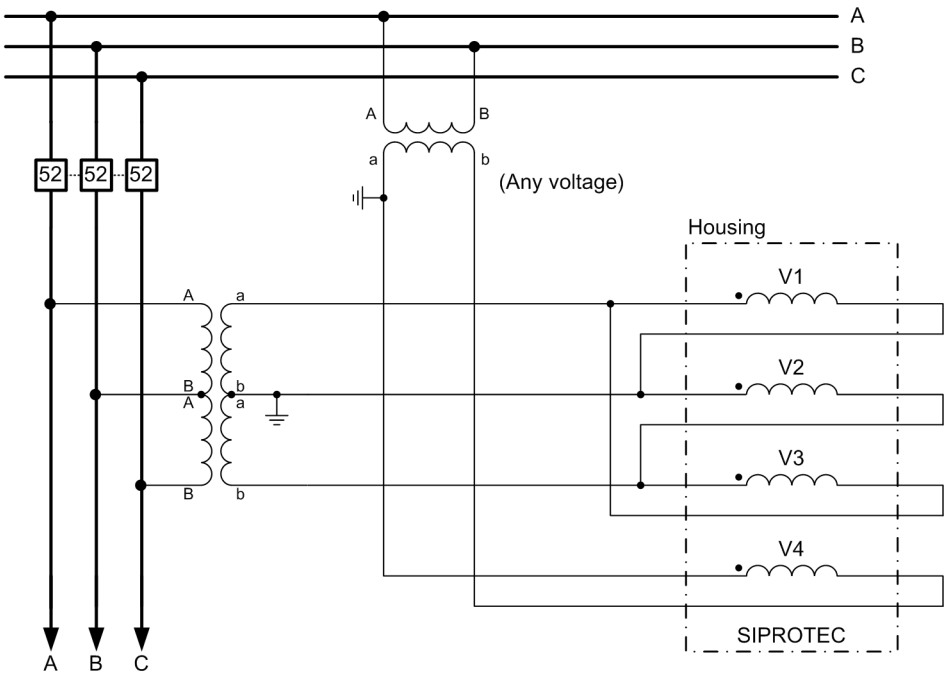


[tvvolta2-260313-01.tif, 1, en_US]

Figure A-22 Connection to 3 Star-Connected Voltage Transformers and to the Broken-Delta Winding

[tvvolta3-260313-01.tif, 1, en_US]

Figure A-23 Connection to 3 Star-Connected Voltage Transformers and to the Broken-Delta Winding of a Separate Voltage Transformer (for Example Busbar)



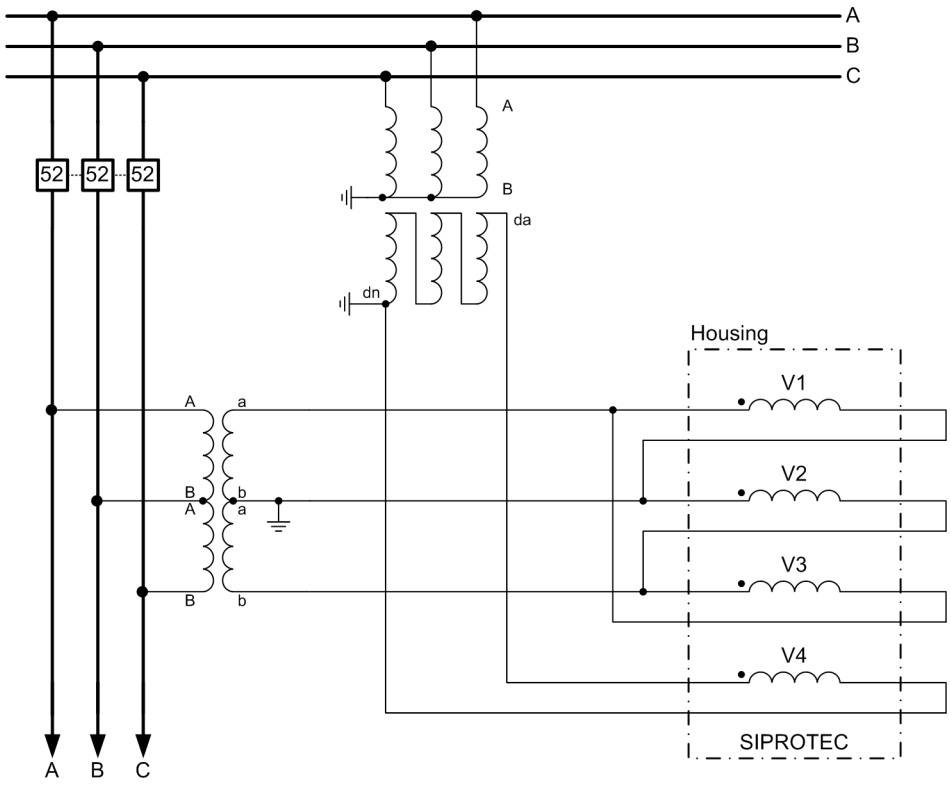
Voltage transformer 3-phase: connection = 3 ph-to-gnd voltages

Voltage transformer 1-phase: connection = VAB

[tvvolta4-260313-01.tif, 2, en_US]

Figure A-24 Connection to 3 Star-Connected Voltage Transformers and to the Phase-to-Phase Voltage of a Busbar Voltage Transformer (for Example for Synchrocheck Applications)

Voltage transformer 3-phase: connection = **3 ph-to-ph voltages**

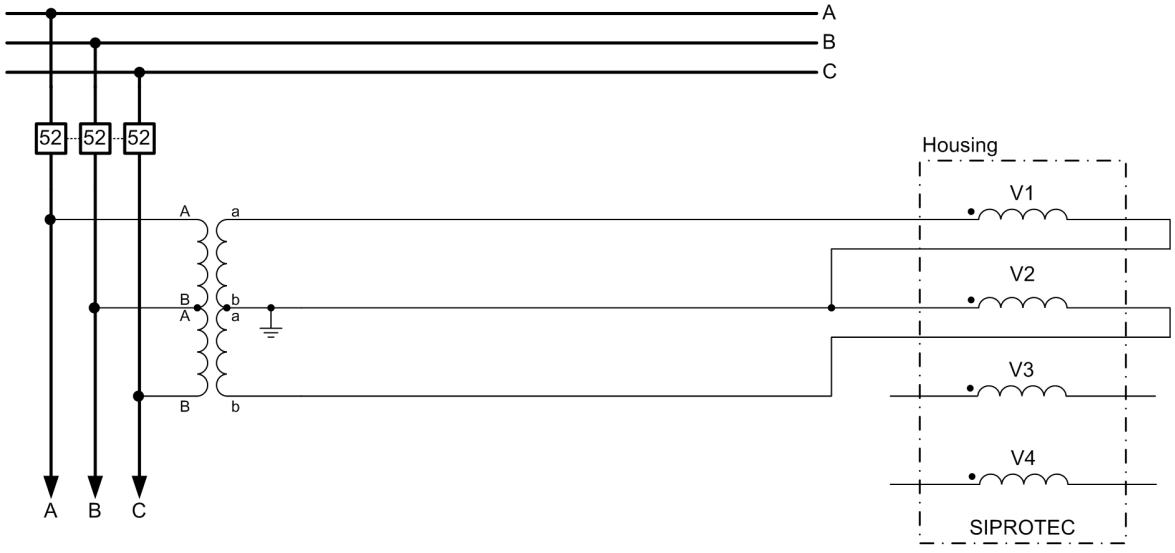


Voltage transformer 1-phase: connection = **VAB**

[tvvolta5-260313-01.tif, 1, en_US]

Figure A-25 Connection to V-Connected Voltage Transformer (Delta-Connected Device Input Transformer) and Connection to the Phase-to-Phase Voltage of a Busbar Voltage Transformer

NOTE



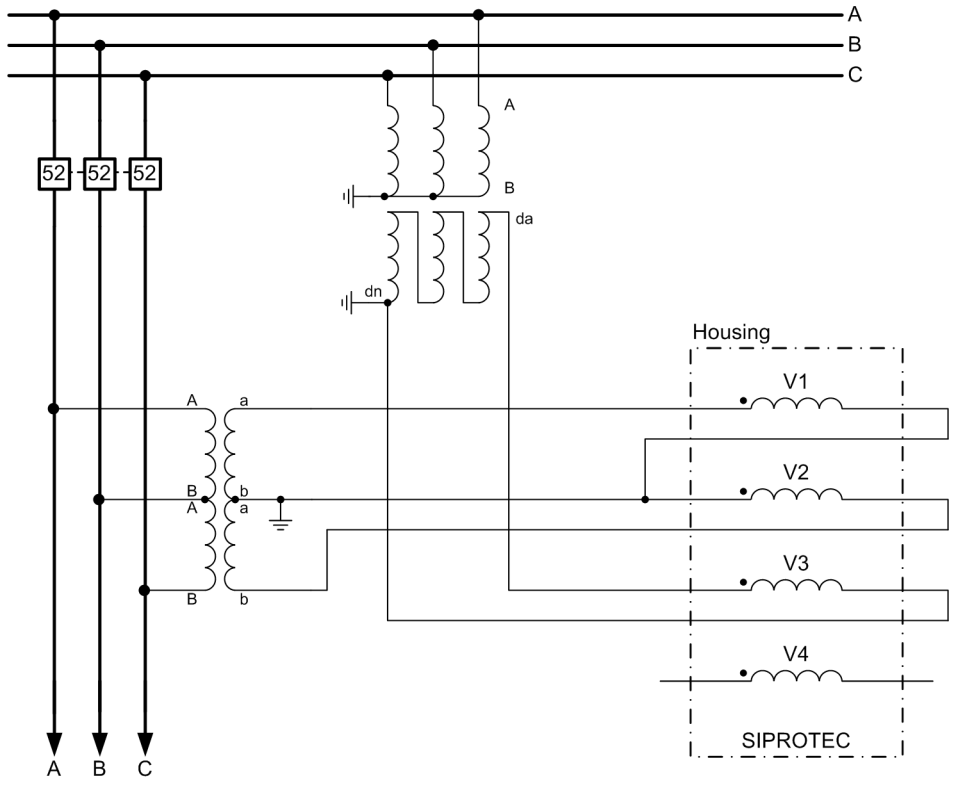
When using the connection type 3-phase-to-phase voltages, the zero-sequence voltage cannot be detected.

Voltage transformer 3-phase: connection = 3 ph-to-ph volt. + VN

[tvvolta6-260313-01.tif, 1, en_US]

Figure A-26 Connection to V-Connected Voltage Transformer (Delta-Connected Device Input Transformer) and Connection to the Broken-Delta Winding of a Busbar Voltage Transformer

Voltage transformer 3-phase: connection = 2 ph-to-ph voltages



Phase voltages = VAB, VBC

[tvvol2ll-260313-01.tif, 2, en_US]

Figure A-27 Connection to V-Connected Voltage Transformer (Measurement of 2 Phase-to-Phase Voltages)

NOTE

When using the connection type 2-phase-to-phase voltages, the zero-sequence voltage cannot be detected.

Voltage transformer 3-phase: connection = **2 ph-to-ph volt. + VN**

Phase voltages = VAB, VBC

[tvl2lluu-260313-01.tif, 2, en_US]

Figure A-28 Connection to V-Connected Voltage Transformer (Measurement of 2 Phase-to-Phase Voltages) and Connection to the Broken-Delta Winding of a Busbar Voltage Transformer

Glossary

ACD

IEC 61850 data type: Directional protection activation information

ACK

Data transfer acknowledgment

ACT

IEC 61850 data type: Protection-activation information

APC

Controllable analog set point information – information regarding a controllable analog value

ASDU

ASDU stands for **A**pplication **S**ervice **D**ata **U**nit. An ASDU can consist of one or more identical information objects. A sequence of the same information elements, for example measured values, is identified by the address of the information object. The address of the information object defines the associated address of the 1st information element of the sequence. A consecutive number identifies the subsequent information elements. The number builds on this address in integral increments (+1).

BAC

Binary controlled analog process value

Back-up battery

The back-up battery ensures that specified data areas, flags, timers, and counters are held as retentive.

Bay controller

Bay controllers are devices with control and supervision functions without protection functions.

BCR

IEC 61850 data type: **B**inary **C**ounter **R**eading

Best Master Clock Algorithm

A PTP network consists of communicating clocks. The best master clock algorithm (BMCA) is used to determine the device that indicates the most precise time. This device serves as a reference clock and is called the grandmaster. In case of changes to the network topology, the BMC algorithm is performed again for network segments which might be cut off from the grandmaster. If a participating device assumes the role of master and slave at the same time, it is also referred to as a boundary clock.

Big-endian

The terms big-endian and little-endian are used to describe the arrangement of the bytes when saving. In case of big-endian, the upper limiting value byte is saved at the lowest address. Little-endian saves the upper limiting value byte at the highest address.

Binary Controlled Analog Process Value

The data type BAC models a command with or without feedback. The BAC is used to control an arc-suppression coil, for example. The commands **Higher**, **Lower**, and **Stop** can be issued. The process delivers an analog value as feedback.

Binary Controlled Step Position

The data type BSC can, for example, be used to control a transformer tap changer. The commands **up**, **down** can be given.

Bit pattern indication

Bit pattern indication is a processing function with which items of digital process information applicable across several inputs can be detected together in parallel and further processed. The bit pattern length can be selected as 1, 2, 3, or 4 bytes.

BMCA

Best **M**aster **C**lock **A**lgorithm

Boundary clock

The PTP protocol recognizes different types of clock: An Ordinary Clock (OC), Boundary Clock (BC), and Transparent Clock (TC). The boundary clock transmits time information beyond a network limit. For example in a router which connects different switched networks. As a slave, the clock of the router receives time information and passes it on as a master.

BRCB

Buffered **R**eport **C**ontrol **B**lock

BSC

Binary Controlled Step Position

Buffered Report Control Block

Buffered Report Control Block (BRCB) is a form of report controlling. Internal events trigger the immediate sending of reports or saving of events for the transfer. Data values cannot therefore be lost on account of transport flow control conditions or connection interruptions. BRCB provides the functionality **SOE** (see sequence of events).

CB

Circuit breaker

CDC

Common **D**ata **C**lass

CFC

Continuous **F**unction **C**hart

Chatter blocking

A rapidly intermittent input (for example, due to a relay contact fault) is disconnected after a configurable supervision time and can thus not generate any further signal changes. The function prevents overloading of the system when a fault occurs.

CID

Configured **I**ED **D**escription

CIT

Conventional **I**nstrument **T**ransformer

CMV

Complex **m**easured **v**alue

Combination Device

Combination devices are bay units with protection functions and with feeder mimic diagram.

Common Data Class

Generic term for a data class according the IEC 61850 model.

Communication branch

A communication branch corresponds to the configuration of 1 to n participants that communicate via a common bus.

Configured IED Description

A Configured IED Description (CID) is a file for data exchange between the IED Configuration Tool and the IED itself.

Continuous Function Chart

The Continuous Function Chart (CFC) is a programming language. It is used for programmable logic controllers. The programming language Continuous Function Chart is not defined in the standard IEC 61131-3, but represents a common extension of IEC programming environments. CFC is a graphic programming language. Function blocks are linked to one another. This represents an essential difference from conventional programming languages, where sequences of commands are entered.

Control display

The control display becomes visible for devices with a large display after pressing the CTRL key. The diagram contains the switching devices to be controlled in the feeder, with status representation. The control display serves for the bushing of the switching operations. Defining this display is part of the project engineering.

Controllable Integer Status

The data type INC can be used to issue a command (to one or more relays, selectable in information routing) which is then monitored via a whole number as feedback.

Controller

The controller initiates the IO data communication.

COT

Cause **o**f **T**ransmission

CRC

Cyclic **r**edundancy **c**heck

DAN

Double **A**ttached **N**ode

DANP

Double **A**ttached **N**ode **P**RP

DataSet

Defines the current-transformer and/or voltage-transformer signals contained in a sampled value data stream

Data Type

The data type is a value set of a data object, together with the operations allowed on this value set. A data type contains a classification of a data element, such as the determination whether it consists of integers, letters, or suchlike.

Data unit

Information item with a joint transmission source. Abbreviation: DU – **D**ata **U**nit

Data window

The right section of the project window visualizes the content of the section selected in the navigation window. The data window contains for example, indications or measured values of the information lists or the function selection for parameterization of the device.

DCF

Device **C**onfiguration **F**ile

DCF77

The high-precision official time is determined in Germany by the Physikalisch-Technische Bundesanstalt PTB in Brunswick. The atomic clock unit of the PTB transmits this time via the long-wave time signal transmitter in Mainflingen near Frankfurt/Main. The emitted time signal can be received within a radius of approx. 1500 km from Frankfurt/Main.

DCP

Discovery and Basic **C**onfiguration **P**rotocol

DDD

DIGSI 5 **D**evice **D**river – SIPROTEC 5 device driver which must be loaded in DIGSI.

DEL

Phase-to-phase related measurements of a 3-phase system

Device 5 Export Format

DEX5

DEX5

Device 5 **Ex**port Format

You can archive the data from an individual SIPROTEC 5 device in DEX5 format.

DHCP

Dynamic **H**ost **C**onfiguration **P**rotocol

DIGDNP

DIGSI 5 protocol settings for DNP3

File extension for a file which is generated from DIGSI when the protocol configuration is exported from DIGSI 5.

DIGMOD

DIGSI 5 protocol settings for Modbus TCP

File extension for a file which is generated from DIGSI when the protocol configuration is exported from DIGSI 5.

DIGSI

Configuration software for SIPROTEC

DIGSI 5 Display Pages

You can archive individual or all display pages from a SIPROTEC 5 device in DSP5 format. You can also use this format to exchange display pages between SIPROTEC 5 devices. The DSP5 format is based on XML.

DIGSI 5 protocol settings for DNP3

If the protocol DNP3 is configured for a system interface, you can export the protocol settings in DIGDNP format. The DIGDNP format is specially designed to transfer interface data from DIGSI 5 into the substation automation system SICAM PAS.

DIGSI 5 protocol settings for IEC 60870-5-103

If the protocol IEC 60870-5-103 is configured for a system interface, you can export the protocol settings in DIGT103 format. The DIGT103 format is specially designed to transfer interface data from DIGSI 5 into the substation automation system SICAM PAS.

DIGSI 5 protocol settings for IEC 60870-5-104

If the protocol IEC 60870-5-104 is configured for a system interface, you can export the protocol settings in DIGT104 format. The DIGT104 format is specially designed to transfer interface data from DIGSI 5 into the substation automation system SICAM PAS.

DIGSI 5 protocol settings for Modbus TCP

If the protocol Modbus TCP is configured for a system interface, you can export the protocol settings in DIGMOD format. The DIGMOD format is specially designed to transfer interface data from DIGSI 5 into the substation automation system SICAM PAS.

DIGSI 5 Test Sequences

You can archive individual or all test sequences from a SIPROTEC 5 device in SEQ5 format. You can also use this format to exchange test sequences between SIPROTEC 5 devices. The SEQ5 format is based on XML.

DIGT103

DIGSI 5 protocol settings for IEC 60870-5-103

File extension for a file which is generated from DIGSI when the protocol configuration is exported from DIGSI 5.

DIGT104

DIGSI 5 protocol settings for IEC 60870-5-104

File extension for a file which is generated from DIGSI when the protocol configuration is exported from DIGSI 5.

Discovery and Basic Configuration Protocol

The DCP protocol is used to detect devices without an IP address and to assign addresses to these devices.

DNP3

DNP3 is a communication standard for telecontrol engineering. DNP3 is used as a general transmission protocol between control systems and substations, as well as between bay devices and the systems controls.

Double command

Double commands (DPC – **D**ouble **P**oint **C**ontrol) are process outputs which represent 4 process states at 2 outputs: 2 defined states (for example ON/OFF) and 2 undefined states (for example disturbed positions).

Double-point indication

A double-point indication (DPS – **D**ouble **P**oint **S**tatus) ia a process information that represents 4 process states at 2 inputs: 3 defined states (for example, On/Off and disturbed position) and 1 undefined state (00).

DPC

IEC 61850 data type: **D**ouble **P**oint **C**ontrol - double command

DPS

IEC 61850 data type: **D**ouble **P**oint **S**tatus - double-point indication

Drag and drop

Copying, moving, and linkin function, used in graphic user interfaces. Objects are selected with the mouse, held and moved from one data area to another.

DSP5

DIGSI 5 Display Pages

DU

Data **U**nit

Dynamic Host Configuration Protocol

In order to configure PCs automatically, centralized and uniformly in a TCP/IP network, a dynamic assignment of IP addresses is used. DHCP is utilized. The system administrator determines how the IP addresses are to be assigned and specifies the time lapse over which they are assigned. DHCP is defined in the Internet standards RFC 2131 (03/97) and RFC 2241 (11/97).

In the case of SIPROTEC 5, the device can also be assigned an IP address via DIGSI and DHCP.

Electrical CAD

Electrical CAD

You can import the topology information contained in an ELCAD file into a project and use it as the basis for a single-line configuration. The other information contained in the ELCAD file is not included in this process.

Electromagnetic compatibility

Electromagnetic compatibility (EMC) means that an item of electric equipment functions without error in a specified environment. The environment is not influenced in any impermissible way here.

ENC

Enumerated Status **C**ontrollable

ENS

Enumerated **S**tatus

ESD protection

The ESD protection is the entirety of all means and measures for the protection of electrostatic-sensitive devices.

Far End Fault Indication

Far End Fault Indication (FEFI) is a special setting of switches. It is always only possible to log a line interruption on the receive line. If a line interruption is detected, the link status of the line is changed. The status change leads to deletion of the MAC address assigned to the port in the switch. However, outage of the receive line from the aspect of the switch can only be detected in the receiver, that is, by the switch. The receiver then immediately blocks the transmit line and signals the connection failure to the other device. The FEFI setting in the switch triggers detection of the error on the receive line of the switch.

FC

Ferrule **C**onnector

FEFI

Far **E**nd **F**ault **I**ndication

FG

Function group

Fleeting indication

Fleeting indications are single-point indications present for a very short time, in which only the coming of the process signal is logged and further processed time-correctly.

Floating

Floating means that a free potential of the output voltage that is not connected to ground is generated. Therefore, no current flows through the body to ground in the event of touching.

Function group

Functions are brought together into function groups (FG). The assignment of functions to current and/or voltage transformers (assignment of functions to measuring points), the information exchange between the function groups via interfaces as well as the generation of group indications are important for this bringing together.

GaAs

Gallium arsenide

General Interrogation

The state of all process inputs, of the status, and of the fault image are scanned on system startup. This information is used to update the system-side process image. Likewise, the current process state can be interrogated after data loss with a general interrogation (GI).

General Station Description Mark-up Language

GSDML is an XML-based data description language for the creation of a GSD file.

Generic Object-Oriented Substation Event

GOOSE. Protocol of IEC 61850 for communication between bay units.

GI

General Interrogation

GIN

Generic Identification Number

Global Navigation Satellite System

A global navigation satellite system or GNSS is a system for determining position and for navigation on the ground and in the air. Position is determined by the receipt of signals from navigation satellites and pseudolites.

GNSS

Global **N**avigation **S**atellite **S**ystem

GOOSE

Generic **O**bject-**O**riented **S**ubstation **E**vent

Ground

The conductive ground whose electric potential can be set equal to 0 at every point. In the area of grounding conductors, the ground can have a potential diverging from 0. The term **reference ground** is also used for this situation.

Grounding

The grounding is the entirety of all means and measures for grounding.

GSDML

General **S**tation **D**escription **M**ark-up **L**anguage

Hierarchy level

Within a structure with higher-level and lower-level objects a hierarchy level is a level of equivalent objects.

High-Availability Seamless Redundancy Protocol

Like PRP (Parallel Redundancy Protocol), HSR (High-Availability Seamless Redundancy Protocol) is specified in IEC 62439-3. Both protocols offer redundancy without switching time.

The principal function can be found in the definition of PRP. With PRP, the same indication is sent via 2 separated networks. In contrast to this, in the case of HSR the indication is sent twice in the 2 directions of the ring. The recipient receives it correspondingly via 2 paths in the ring, takes the 1st indication and discards the 2nd indication (see PRP protocol).

Whereas NO indications are forwarded in the end device in the case of PRP, a switch function is installed in the HSR node. Thus, the HSR node forwards indications in the ring that are not directed at it.

In order to avoid circular indications in the ring, corresponding mechanisms are defined in the case of HSR.

SAN (Single Attached Node) end devices can only be connected with the aid of a RedBox in the case of HSR. PRP systems and HSR systems can be coupled redundantly with 2 RedBoxes.

HMI

Human-**M**achine **I**nterface (HMI)

HSR

High Availability **S**eamless **R**edundancy Protocol

HV bay description

The HV project description file contains details of bays which exist in a ModPara project. The actual bay information of each bay is stored in a HV field description file. Within the HV project description file, each bay receives an HV field description file through a reference to the file name.

HV project description

If the configuring and parameterization of PCUs and submodules is completed with ModPara, all the data will be exported. This data is distributed to several files. One file contains details about the fundamental project structure. This also includes, for example, information detailing which bays exist in this project. This file is called a HV project description file.

ICD

IED **C**apability **D**escription

IEC

International **E**lectrotechnical **C**ommission - International Electrotechnical Standardization Body

IEC 60870-5-103

International standard protocol for communication with IEDs (especially protection devices) Many protection devices, bay units, bay controllers, and measured-value acquisition devices use the IEC 60870-5-103 protocol to communicate with SICAM PAS.

IEC 60870-5-104

Standard international telecontrol protocol. Transmission protocol based on IEC 60870-5-101 for connecting the substation control level to the telecontrol center via TCP/IP protocols using a wide area network connection (WAN).

IEC 60870-5-104 is also used for communicating with IEDs.

IEC 61850

IEC 61850 is an international standard for continuous communication in switchgear. It defines the communication between devices in a switchgear and the corresponding system requirements. All automation functions of a switchgear and their engineering are supported this way. IEC 61850 can also be transferred to automation systems in other applications, for example for controlling and monitoring decentralized power generation.

IEC address

A unique IEC address must be assigned to each SIPROTEC device within an IEC bus. A total of 254 IEC addresses per IEC bus are available.

IEC communication branch

Within an IEC communication branch, the participants communicate on the basis of the protocol IEC 60870-5-103 via an IEC bus.

IED

Intelligent **E**lectronic **D**evice

IED stands for a physical part of a device (hardware, etc.)

IED Capability Description

Data exchange from the IED configuration software (DIGSI) to the system configurator. This file describes the performance properties of an IED.

IEEE

Institute of **E**lectrical and **E**lectronic **E**ngineers

IEEE 1588

Time-synchronization protocol according to the standard IEEE 1588-2008. Precision Clock Synchronization Protocol for Networked Measurement and Control Systems (IEEE 1588 v2) and the standard IEEE C37.238-2011: IEEE Standard Profile for Use of IEEE 1588 PTP protocol in Power System Applications (Power Profile).

IEEE 1588v2/PTP

PTP has many optional features and often offers more than one way of doing things. Meaning that it is not mandatory for PTP devices to work together. Provided that they are configured with a compatible set of selection options for IEEE 1588 options and settings. The solution for this is profiles. Profiles are rule sets with restrictions for PTP that are designed to be used to meet the requirements for specific applications or a set of similar applications. The IEEE 1588 standard itself only defines 1 profile, which is designated as the **Default profile**. 2 profiles are used in the power industry: IEC 61850-9-3 (Power Utility Profile) and C37.238-2017 (Power Profile).

IID

Instantiated **I**ED **D**escription

INC

Controllable Integer Status

Input data/input direction

Data is sent from the protocol slave to the protocol master.

INS

Integer **S**tatus

Instantiated IED Description

Files in IID format are ICD files adapted for the specific use case in the project. This format is mainly suitable for exchanging data between DIGSI 5 and an external system configurator or a substation automation system such as SICAM PAS. The ICD format uses SCL as the description language for this.

International Electrotechnical Commission

IEC

Internet Protocol

An Internet protocol (IP) enables the connection of participants which are positioned in different networks.

IO

Input-**O**utput

LAN

Local **A**rea **N**etwork

Link address

The link address indicates the address of a SIPROTEC device.

Link Layer Discovery Protocol

The Link Layer Discovery Protocol (LLDP) serves as the basis for topology detection and configuration determination.

List view

The right area of the project window displays the names and icons of the objects which are within a container selected in the tree view. As the visualization is in the form of a list, this area is also referred to as list view.

LLDP

Link **L**ayer **D**iscovery **P**rotocol

Local Area Network

A Local Area Network (LAN) is a regional, local PC network. The PCs are all equipped with a network interface card and work with one another via data exchange. The LAN requires an operating system on each PC and standardized data transport software. The operating systems can be different, as can the data transport software, but both must support a common transmission protocol (= TCP/IP protocols), so that all PCs can exchange data with one another.

LPIT

Low-**P**ower **I**nstrument **T**ransformer –

AKA **NCIT** – **N**on **C**onventional **I**nstrument **T**ransformer. Examples: Low-power current transformer, C dividers, R dividers, RC dividers, optical sensors

LPVT

Low-**P**ower **V**oltage **T**ransformer–

LSB

Least **S**ignificant **B**it

LSVS

Logical node **S**ampled **V**alue **S**ubscription supervision

MAC address

The MAC address (Media Access Control) is the hardware address of each individual network adaptor. It serves to identify the devices in the network unambiguously.

Management Information Base

A Management Information Base (MIB) is a database which continuously saves information and statistics concerning each device in a network. The performance of each device can be monitored with this information and statistics. In this way, it can also be ensured that all devices in the network function properly. MIBs are used with SNMP.

Manufacturing Message Specification

The standard Manufacturing Message Specification (MMS) serves for data exchange. The standard is used for the transmission protocols IEC 61850 and IEC 60870-6 TASE.2.

Master Clock

The **M**aster **C**lock (MC) contains a mechanical or electric mechanism and a contact device, which periodically transmits drive pulses to the slave clocks.

MC

Master **C**lock

Measured Value

This data type provides a measured value that can be used as a CFC result, for instance.

Merging Unit

The **M**erging **U**nit (MU) is used (also for IEC 61850 plant) for the field-signal bus interface. The publisher/server of the sampled measured values is designated as the merging unit.

Metered value

Metered values are a processing function, used to determine the total number of discrete similar events (counter pulses), for example, as integral over a time span. In the power utility field, electrical energy is often recorded as a metered value (energy import/delivery, energy transport).

MIB

Management **I**nformation **B**ase

Network Time Protocol

The **N**etwork **T**ime **P**rotocol is an international standard for time synchronization.

NTP

Network **T**ime **P**rotocol

Object

Each element of a project structure is designated as an object in DIGSI 5.

Object property

Each object has properties. These might be general properties that are common to several objects. Otherwise, an object can also have object-specific properties.

Offline

If there is no communication connection between a PC program (for example, configuration program) and a runtime application (for example, a PC application), the PC program is **offline**. The PC program executes in Offline mode.

Online

If there is a communication connection between a PC program (for example configuration program) and a runtime application (for example a PC application), the PC program is **online**. The PC program executes in Online mode.

Optical Switch Module

An Optical Switch Module (OSM) is a process for switching over switches in Ethernet networks that are ring-shaped in structure. OSM is a proprietary process from Siemens, which later became standard under the term MRP. OSM is integrated in the optical Ethernet module EN100-O. OSM is hardly used in IEC 61850 networks. RSTP is used there, this having become established as an international standard.

OSM

Optical **S**witch **M**odule

Output data/output direction

Data is sent from the protocol master to the protocol slave.

Parallel Redundancy Protocol

Parallel Redundancy Protocol (PRP) is a redundancy protocol for Ethernet networks that is specified in IEC 62439-3. Unlike conventional redundancy procedures, such as RSTP (Rapid Spanning Tree Protocol, IEEE 802.1D-2004), PRP offers uninterruptible switchover, which avoids any downtime in the event of a fault, and thus the highest availability.

PRP is based on the following approach: The redundancy procedure is generated in the end device itself. The principle is simple: The redundant end device has 2 Ethernet interfaces with the same address (DAN, Double Attached Node). Now the same indication is sent twice, in the case of PRP (**parallel**) over 2 separate networks, and unambiguously marks both with a sequence number. The receiver takes the information that it receives first, stores its ID based on the source address and the sequence number in a duplicate filter and thus recognizes the 2nd, redundant information. This redundant information is then discarded. If the 1st indication is missing, the 2nd indication with the same content comes via the other network. This redundancy avoids a switching procedure in the network and is thus interruption-free. The end device relays no indications to the other network. Since the process is realized in the Ethernet layer (same MAC address), it is transparent and usable for all Ethernet user data protocols (IEC 61850, DNP, other TCP/IP based protocols). In addition, it is possible to use one of the 2 networks for the transmission of non-redundant indications.

There are 2 versions of PRP: PRP-0 and its successor PRP-1. Siemens implements PRP-1.

Parameterization

Comprehensive term for all setting work on the device. You can set parameters for the protection functions with DIGSI 5 or sometimes also directly on the device.

Parameter set

The parameter set is the entirety of all parameters that can be set for a SIPROTEC device.

Participant address

A participant address comprises the name of the participant, the national code, the area index and the participant-specific phone number.

PB Client

Process-**B**us client. The sampled measured values subscriber is designated as a process-bus client.

PICS

Protocol **I**mplementation **C**onformance **S**tatement

Precision Time Protocol

The PTP protocol causes the time settings of several devices in a network to synchronize. PTP is defined in IEEE 1588. The focus of PTP is on higher accuracy and networks that are locally restricted. PTP can achieve an accuracy in the range of nanoseconds in a hardware variant, and in the range of a few milliseconds in a software variant.

PROFIBUS

PROcess **FI**eld **BUS**, German process and fieldbus standard (EN 50170). The standard specifies the functional, electrical, and mechanical characteristics for a bit-serial fieldbus.

PROFIBUS address

An unambiguous PROFIBUS address must be assigned to each SIPROTEC device within a PROFIBUS network. A total of 254 PROFIBUS addresses per PROFIBUS network are available.

Profile_ID

Together with an API, the Profile_ID unambiguously defines the access and behavior of an application.

PROFINET IO

PROFINET is the open Industrial Ethernet Standard of PROFIBUS for automation.

Programmable Logic

The programmable logic is a function in Siemens devices or station controllers, enabling user-specific functionality in the form of a program. This logic component can be programmed by various methods: CFC (Continuous Function Chart) is one of these. SFC (Sequential Function Chart) and ST (Structured Text) are others.

Programmable Logic Block

Building blocks are parts of the user program delimited by their function, structure, and intended use.

Programmable Logic Controller

Programmable logic controllers (PLC) are electronic controllers whose function is saved as a program in the control unit. The construction and wiring of the device do not therefore depend on the function of the control. The programmable logic controller has the structure of a computer; it consists of CPU with memory, input/output modules (for example, DI, AI, CO, CR), power supply (PS) and rack (with bus system). The peripherals and programming language are oriented towards the circumstances of the control engineering.

Project

Content-wise, a project is the image of a real energy supply system. Graphically, a project is represented as a number of objects which are integrated in a hierarchical structure. Physically, a project consists of a number of directories and files containing project data.

Project tree

The project tree contains a representation of the data structure. This data structure represents the content of the project and is created with a generic browser.

Protection communication

Protection communication includes all functionalities necessary for data exchange via the protection interface. Protection communication is created automatically during configuration of communication channels.

Protection device

A protection device detects erroneous states in distribution networks, taking into consideration various criteria, such as fault distance, fault direction, or fault duration, triggering a disconnection of the defective network section.

Protocol Implementation Conformance Statement

The performance properties of the system to be tested are summarized in the report on the conformity of implementation of a protocol (PICS = protocol implementation conformance statement).

PRP

Parallel **R**edundancy **P**rotocol

PTP

Precision-**T**ime **P**rotocol

Rapid Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP) is a standardized redundancy process with a short response time. In the Spanning Tree Protocol (STP protocol), structuring times in the multidigit second range apply in the case of a reorganization of the network structure. These times are reduced to several 100 milliseconds for RSTP.

Real Time

Real time

RedBox

Redundancy box

The RedBox is used to connect a device with only one interface redundantly to both PRP networks LAN A and LAN B. The RedBox is a DAN (Double Attached Node) and functions as a proxy server for the devices (VDANs) connected to it. The RedBox has its own IP address for configuration, administration, and monitoring.

Relay Information by OMICRON

You can use files in RIO format to exchange data between test systems from the company OMICRON and any other desired project-protection planning system. With DIGSI 5, you can export different settings from protection functions in RIO format, which the OMICRON test equipment 7VP15 can then continue to process. The relevant settings are described in the test equipment manual.

RIO

Data format **R**elay **I**nformation by **O**MICRON

RSTP

Rapid-**S**panning **T**ree **P**rotocol

Sampled Measured Value

IEC 61850 is a communication protocol for electrical substation automation systems. The abstract data models defined in IEC 61850 can be mapped with various protocols. At present, there are mappings in the standard for the following protocols:

MMS (Manufacturing Message Specification)

GOOSE (Generic Object Oriented Substation Event)

SMV (Sampled Measured Value)

Web services (coming soon)

These protocols can run with fast-switching Ethernet via TCP/IP networks or substation LANs to achieve the required response times for protection functions of under 4 ms.

Sampled value

Sampling is the registration of measured values for discrete, mostly equidistant periods of time. This can be used to extract a discrete time signal from a continuous time signal.

Sampling rate

In signal processing, sampling is reducing a continuous time signal (for example current and voltages) to a discrete time signal. A common example is converting soundwave (a continuous signal) into a sampling sequence (a discrete time signal).

SAN

Single **A**ttached **N**ode

An SAN is a non-redundant node in a PRP network. It is connected with a single port to a single network (LAN A or LAN B). It can only communicate in the connected network via nodes. Devices with only one connection can be connected to both networks, LAN A and LAN B, redundantly via a RedBox. In order to keep LAN A and LAN B symmetrical, Siemens recommends avoiding SANs and to connect the devices either via a RedBox or in a separate network without PRP support.

SBO

SEQ

Data type sequence

SEQ5

DIGSI 5 Test Sequences

Sequence of Events

Acronym: SOE. An ordered, time-stamped log of status changes at binary inputs (also referred to as state inputs). SOE is used to restore or analyze the behavior, or an electrical power system itself, over a certain period of time.

Service interface

Device interface for interfacing DIGSI 5 (for example, through a modem)

SFP

Small **F**orm-Factor **P**luggable

SICAM SAS

Substation **A**utomation **S**ystem – Modular substation automation system based on the SICAM SC substation controller and the HMI system SICAM WinCC.

SICAM WinCC

The operator control and monitoring system SICAM WinCC graphically displays the state of your network. SICAM WinCC visualizes alarms and indications, archives the network data, provides the option of intervening manually in the process and manages the system rights of the individual employees.

SIM

Simulation data format for single/multiple devices

Simple Network Management Protocol

The Simple Network Management Protocol (SNMP) is an Internet standard protocol and serves for the administration of nodes in an IP network.

Simple Network Time Protocol

The Simple Network Time Protocol (SNTP) is a protocol for the synchronization of clocks via the Internet. With SNTP, client computers can synchronize their clocks via the Internet with a time server.

Simulation data format for single/multiple devices

You can export simulation-related files of a SIPROTEC 5 device in SIM format. This new functionality in DIGSI 5 makes it possible to export the simulation data and to create a simulation of all devices in the DIGSI 5 project for testing and commissioning purposes. The simulation is achieved by importing the simulation file into a signal processing and automation system, which then simulates the device/devices using the process data like in a real-time system. This feature allows a device to be tested for various real-time conditions.

Single command

Single commands (SPC – **S**ingle **P**oint **C**ontrol) are process outputs which represent 2 process states (for instance on/off) at one output.

Single-line diagram

A single-line diagram (SLD) is a simplified electrical overview diagram of the switchgear. Instead of all 3 phases, only a single line is shown, hence the name single-line.

Single-Line Editor

The Single-Line Editor (SLE) contains the catalog with the topological elements of a single-line diagram. Using the single-line components, the customer can configure the topological part of the plant.

Single-point indication

Single-point indications (**SPS**) are a type of process information which represents 2 process states (for instance on/off) at one output.

SIPROTEC

The registered trademark SIPROTEC designates the product family of Siemens protection devices and fault recorders.

SIPROTEC 5 device

This object type represents a real SIPROTEC device with all the contained setting values and process data.

Slave device

A slave may only exchange data with a master after being prompted to do so by the master. SIPROTEC devices work as slaves. A master computer controls a slave computer. A master computer can also control a peripheral device.

ST

Structured **T**ext file

Structured Text file

You can import function charts (CFC) from DIGSI 4 in ST format. Before doing so, export your function charts from DIGSI 4.83 or higher.

Substation Configuration Description

A substation configuration description is an IEC 61850-compliant file for data exchange between the system configurator and the IED configurator. The substation configuration description contains information on the network structure of a substation. The substation configuration description contains for example, information on the assignment of the devices to the primary equipment, as well as on the station-internal communication.

Substation Configuration Description Language

Substation Configuration Description Language (SCL) is a description language standardized in IEC 61850 and based on XML. This description language allows all information relevant to an IEC 61850 substation to be documented consistently. This format is therefore suitable for exchanging IEC 61850-specific data between different applications, even if these come from different manufacturers. The described import checks are generally carried out for all SCL formats, not only for SCD imports.

SV Stream

Sampled **V**alue Stream

The SV stream is a set of current and voltage values that are transmitted in a fast and cyclical fashion. Information exchange is based on a publisher/subscriber mechanism. SV transmission is a continuous stream of layer-2 Ethernet telegrams in one direction. The content of an SV stream can be configured in anyway you wish in accordance with IEC 61869-9. IEC 61850-9-2 LE defines a fixed set of 4 voltage and 4 current values for each SV stream.

System Exchange Description

With files in SED format, you can exchange interface information between DIGSI 5 projects and thus between substations. To do this, the project extracts the data for the other projects from the file during import and writes its own data in the same file during export. The contents of an SED file are formulated in SCL.

System Specification Description

Files in SSD format contain the complete specification of a substation automation system including a single-line configuration of the substation. The assignment of logical nodes from IEC 61850 to primary equipment can also be described in SSD files. This allows device requirements to be defined in the SSD file so that the devices can be used in the substation. The contents of an SED file are formulated in SCL.

TAI

Temps **A**tomique **I**nternational - International atomic time

TC

Tap-position **c**ommand

TCP

Transmission **C**ontrol **P**rotocol

TEA-X

You can archive the data from individual SIPROTEC 5 devices or whole projects in TEA-X format. This format is also suitable for data exchange between different applications, such as DIGSI 5 and Engineering Base (EB). The TEA-X format is based on XML.

Time stamp

A time stamp is a value in a defined format. The time stamp assigns a point in time to an event, for example, in a log file. Time stamps ensure that events can be found again.

TOCT

Trench **O**ptical **C**urrent **T**ransformer – Optical current transformer manufactures by Trench

Topological view

The Topological View is oriented to the objects of a system (for example, switchgear) and their relationship to one another. The topological view describes the structured layout of the system in hierarchical form. The Topological View does not assign the objects to the devices.

Transmission Control Protocol

The Transmission Control Protocol (TCP) is a transmission protocol for transport services in the Internet. TCP is based on IP and ensures connection of the participants during the data transmission. TCP ensures the correctness of the data and the correct sequence of the data packets.

Transparent clock

The Precision Time Protocol (PTP) recognizes different types of clocks: a standard clock (referred to as Ordinary Clock, OC for short), a Boundary Clock (BC) and a Transparent Clock (TC). The transparent clock was integrated in the specification retrospectively in 2008 and serves to improve the transmission of time information within a network by receiving PTP messages and modifying (correcting) them before passing them on.

Tree view

The left area of the project window displays the names and icons of all containers of a project in the form of a folder tree structure. This area is called the tree view.

Tunneling

Technology for connecting two networks via a third network, whereby the through traffic is completely isolated from the traffic of the third network.

UDP

User **D**atagram **P**rotocol

Unbuffered Report Control Block

Unbuffered Report Control Block (URCB) is a form of report controlling. Internal events trigger the immediate sending of reports based on **best effort**. If no association exists or if the transport data flow is not fast enough, events can be lost.

URCB

Unbuffered **R**eport **C**ontrol **B**lock

USART

Universal **S**ynchronous/**A**synchronous **R**eceiver/**T**ransmitter

User Datagram Protocol

UDP is a protocol. The protocol is based on IP as TCP. In contrast to this, however, UDP works without a connection and does not have any safety mechanisms. The advantage of UDP in comparison to IP is the higher transmission rate.

UTC

Universal **T**ime **C**oordinated

Vendor ID

Manufacturer-specific part of the device labeling for PROFINET.

Virtual device

A virtual device (VD) comprises all communication objects, as well as their properties and states, which a communication user can utilize in the form of services. A VD can be a physical device, a module of a device or a software module.

Preface

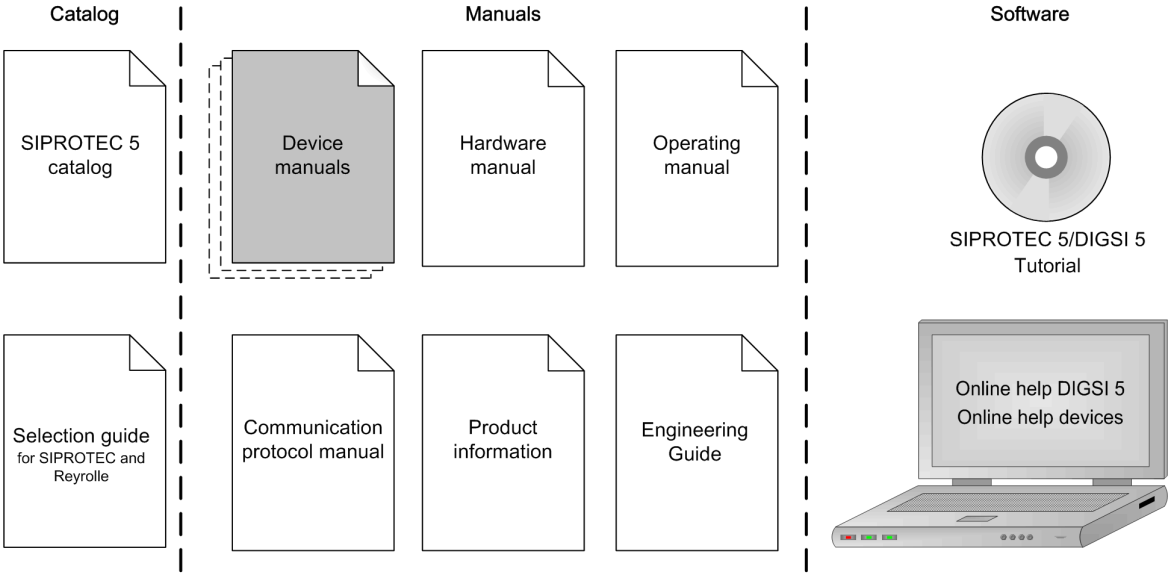
Purpose of the Manual

This manual describes the protection, automation, control, and supervision functions of the SIPROTEC 5 device functions for distance protection and line differential protection.



Target Audience

Protection system engineers, commissioning engineers, persons entrusted with the setting, testing and maintenance of automation, selective protection and control equipment, and operational crew in electrical installations and power plants.

Scope

This manual applies to the SIPROTEC 5 device family.

Further Documentation

[dwprefdm-221012-01.tif, 3, en_US]

- Device manuals

  Each Device manual describes the functions and applications of a specific SIPROTEC 5 device. The printed manual and the online help for the device have the same informational structure.

- Hardware manual

  The Hardware manual describes the hardware building blocks and device combinations of the SIPROTEC 5 device family.

- Operating manual

  The Operating manual describes the basic principles and procedures for operating and assembling the devices of the SIPROTEC 5 range.

- Communication protocol manual

  The Communication protocol manual contains a description of the protocols for communication within the SIPROTEC 5 device family and to higher-level network control centers.

- Product information

  The Product information includes general information about device installation, technical data, limiting values for input and output modules, and conditions when preparing for operation. This document is provided with each SIPROTEC 5 device.

- Engineering Guide

  The Engineering Guide describes the essential steps when engineering with DIGSI 5. In addition, the Engineering Guide shows you how to load a planned configuration to a SIPROTEC 5 device and update the functionality of the SIPROTEC 5 device.

- DIGSI 5 online help

  The DIGSI 5 online help contains a help package for DIGSI 5 and CFC.

  The help package for DIGSI 5 includes a description of the basic operation of software, the DIGSI principles and editors. The help package for CFC includes an introduction to CFC programming, basic examples of working with CFC, and a reference chapter with all the CFC blocks available for the SIPROTEC 5 range.

- SIPROTEC 5/DIGSI 5 Tutorial

  The tutorial on the DVD contains brief information about important product features, more detailed information about the individual technical areas, as well as operating sequences with tasks based on practical operation and a brief explanation.

- SIPROTEC 5 catalog

  The SIPROTEC 5 catalog describes the system features and the devices of SIPROTEC 5.

- Selection guide for SIPROTEC and Reyrolle

  The selection guide offers an overview of the device series of the Siemens protection devices, and a device selection table.

Indication of Conformity

CE

This product complies with the directive of the Council of the European Communities on harmonization of the laws of the Member States relating to electromagnetic compatibility (EMC Council Directive 2014/30/EU) and concerning electrical equipment for use within specified voltage limits (Low Voltage Directive 2014/35/EU).

This conformity has been proved by tests performed according to the Council Directive in accordance with the product standard EN 60255-26 (for EMC directive) and with the product standard EN 60255-27 (for Low Voltage Directive) by Siemens AG.

The device is designed and manufactured for application in an industrial environment.

The product conforms with the international standards of IEC 60255 and the German standard VDE 0435.

Other Standards

IEEE Std C 37.90

The technical data of the product is approved in accordance with UL.

For more information about the UL database, see *www.ul.com*

Select **Online Certifications Directory** and enter **E194016** as **UL File Number**.

Notes on Safety

This document is not a complete index of all safety measures required for operation of the equipment (module or device). However, it comprises important information that must be followed for personal safety, as well as to avoid material damage. Information is highlighted and illustrated as follows according to the degree of danger:

DANGER

DANGER means that death or severe injury **will** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid death or severe injuries.

WARNING

WARNING means that death or severe injury **may** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid death or severe injuries.

CAUTION

CAUTION means that medium-severe or slight injuries **can** occur if the specified measures are not taken.

✧ Comply with all instructions, in order to avoid moderate or minor injuries.

NOTICE

NOTICE means that property damage **can** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid property damage.

NOTE

Important information about the product, product handling or a certain section of the documentation which must be given particular attention.

Qualified Electrical Engineering Personnel

Only qualified electrical engineering personnel may commission and operate the equipment (module, device) described in this document. Qualified electrical engineering personnel in the sense of this manual are people who can demonstrate technical qualifications as electrical technicians. These persons may commission, isolate, ground and label devices, systems and circuits according to the standards of safety engineering.

Proper Use

The equipment (device, module) may be used only for such applications as set out in the catalogs and the technical description, and only in combination with third-party equipment recommended and approved by Siemens.

Problem-free and safe operation of the product depends on the following:

- Proper transport
- Proper storage, setup and installation
- Proper operation and maintenance

When electrical equipment is operated, hazardous voltages are inevitably present in certain parts. If proper action is not taken, death, severe injury or property damage can result:

- The equipment must be grounded at the grounding terminal before any connections are made.
- All circuit components connected to the power supply may be subject to dangerous voltage.
- Hazardous voltages may be present in equipment even after the supply voltage has been disconnected (capacitors can still be charged).
- Operation of equipment with exposed current-transformer circuits is prohibited. Before disconnecting the equipment, ensure that the current-transformer circuits are short-circuited.
- The limiting values stated in the document must not be exceeded. This must also be considered during testing and commissioning.

Open Source Software

The product contains, among other things, Open Source Software developed by third parties. The Open Source Software used in the product and the license agreements concerning this software can be found in the Readme_OSS. These Open Source Software files are protected by copyright. Your compliance with those license conditions will entitle you to use the Open Source Software as foreseen in the relevant license. In the event of conflicts between Siemens license conditions and the Open Source Software license conditions, the Open Source Software conditions shall prevail with respect to the Open Source Software portions of the software. The Open Source Software is licensed royalty-free. Insofar as the applicable Open Source Software License Conditions provide for it you can order the source code of the Open Source Software from your Siemens sales contact - against payment of the shipping and handling charges - for a period of at least 3 years since purchase of the Product. We are liable for the Product including the Open Source Software contained in it pursuant to the license conditions applicable to the Product. Any liability for the Open Source Software beyond the program flow intended for the Product is explicitly excluded. Furthermore any liability for defects resulting from modifications to the Open Source Software by you or third parties is excluded. We do not provide any technical support for the Product if it has been modified.

When using DIGSI 5 in online mode, you are provided with the option to go to the main menu **Show Open source information** and read and display the Readme_OSS file containing the original license text and copyright information.

To do this, the following steps are necessary:

- Switch to online mode.
- Select the device.
- Select **online** in the menu bar.
- Click **Show Open source information**.

NOTE

To read the Readme_OSS file, a PDF viewer must be installed on the computer.

In order to operate SIPROTEC 5 devices, a valid DIGSI 5 license is required.

3.8.1 Signal Filtering and Chatter Blocking for Input Signals ... 161
3.8.2 Acquisition Blocking and Manual Updating ... 165
3.8.3 Persistent Commands ... 168
3.9 General Notes for Setting the Threshold Value of Protection Functions ... 170
3.9.1 Overview ... 170
3.9.2 Modifying the Transformer Ratios in DIGSI 5 ... 170
3.9.3 Changing the Transformation Ratios of the Transformer on the Device ... 177
3.10 Device Settings ... 178
3.10.1 General Device Settings ... 178
3.10.1.1 Overview ... 178
3.10.1.2 Application and Setting Notes ... 179

3.10.1.3 Settings ... 180
3.10.1.4 Information List ... 180
3.10.2 Settings-Group Switching ... 180
3.10.2.1 Overview of Functions ... 180
3.10.2.2 Structure of the Function ... 181
3.10.2.3 Function Description ... 181
3.10.2.4 Application and Setting Notes ... 182
3.10.2.5 Settings ... 183
3.10.2.6 Information List ... 183

4 Applications ... 185

4.1 Overview ... 186
4.2 Application Templates and Functional Scope for the Devices 7SJ82/7SJ85 ... 187

5 Function-Group Types ... 193

5.1 Function-Group Type Voltage-Current 3-Phase ... 194
5.1.1 Overview ... 194
5.1.2 Structure of the Function Group ... 194
5.1.3 Application and Setting Notes ... 198
5.1.4 Write-Protected Settings ... 199
5.1.5 Settings ... 199
5.1.6 Information List ... 199
5.2 Function-Group Type Voltage-Current 1-Phase ... 201
5.2.1 Overview ... 201
5.2.2 Structure of the Function Group ... 201
5.2.3 Application and Setting Notes ... 203
5.2.4 Write-Protected Settings ... 203
5.2.5 Settings ... 204
5.2.6 Information List ... 204
5.3 Function-Group Type Voltage 3-Phase ... 205
5.3.1 Overview ... 205
5.3.2 Structure of the Function Group ... 205
5.3.3 Application and Setting Notes ... 206
5.3.4 Settings ... 207
5.3.5 Information List ... 207
5.4 Function-Group Type Capacitor Bank ... 208
5.4.1 Overview ... 208
5.4.2 Structure of the Function Group ... 209
5.4.3 Application and Setting Notes ... 217
5.4.4 Write-Protected Settings ... 218
5.4.5 Settings ... 219
5.4.6 Information List ... 219
5.5 Function-Group Type Capacitor Bank Differential Protection ... 220
5.5.1 Function-Group Types ... 220
5.5.2 Function-Group Type Capacitor Bank Diff ... 221
5.5.2.1 Overview ... 221
5.5.2.2 Structure of the Function Group ... 222
5.5.2.3 Information List ... 224

5.5.3 Function-Group Type Capacitor Bank Side ... 224
5.5.3.1 Overview ... 224
5.5.3.2 Structure of the Function Group ... 225
5.5.3.3 Application and Setting Notes ... 230
5.5.3.4 Write-Protected Settings ... 231
5.5.3.5 Settings ... 232
5.5.3.6 Information List ... 232
5.6 Function-Group Type Analog Units ... 233
5.6.1 Overview ... 233
5.6.2 Structure of the Function Group ... 234
5.6.3 20-mA Unit Ethernet ... 235
5.6.3.1 Overview ... 235
5.6.3.2 Structure of the Function ... 235
5.6.3.3 Communication with 20-mA Unit Ethernet ... 236
5.6.3.4 Application and Setting Notes ... 237
5.6.3.5 20-mA Channel ... 237
5.6.3.6 Application and Setting Notes ... 240
5.6.3.7 Settings ... 241
5.6.3.8 Information List ... 242
5.6.4 20-mA Unit Serial ... 242
5.6.4.1 Overview ... 242
5.6.4.2 Application and Setting Notes ... 242
5.6.4.3 Settings ... 244
5.6.4.4 Information List ... 245
5.6.5 Communication with 20-mA Unit ... 245
5.6.5.1 Integration of a Serial 20-mA Unit ... 245
5.6.5.2 Integration of a 20-mA Unit Ethernet ... 248
5.6.6 V/I-Measuring-Transducer Unit with Fast Inputs ... 250
5.6.6.1 Overview ... 250
5.6.6.2 Structure of the Function ... 251
5.6.6.3 Function Description ... 251
5.6.6.4 Application and Setting Notes ... 252
5.6.6.5 Settings ... 256
5.6.6.6 Information List ... 258
5.6.7 RTD Unit Ethernet ... 258
5.6.7.1 Overview ... 258
5.6.7.2 Structure of the Function ... 258
5.6.7.3 Communication with an RTD Unit ... 259
5.6.7.4 Application and Setting Notes ... 260
5.6.7.5 Temperature Sensor ... 261
5.6.7.6 Application and Setting Notes ... 261
5.6.7.7 Settings ... 262
5.6.7.8 Information List ... 262
5.6.8 RTD Unit, Serial ... 263
5.6.8.1 Overview ... 263
5.6.8.2 Application and Setting Notes ... 263
5.6.8.3 Settings ... 264
5.6.8.4 Information List ... 265
5.6.9 Communication with RTD Unit ... 266
5.6.9.1 Integration of a Serial RTD Unit (Ziehl TR1200) ... 266
5.6.9.2 Integration of an RTD-Unit Ethernet (TR1200 IP) ... 269
5.6.9.3 Temperature Simulation without Sensors ... 271
5.7 Function-Group Type Circuit Breaker ... 272
5.7.1 Overview ... 272
5.7.2 Structure of the Function Group ... 273

5.7.3 Application and Setting Notes ... 274
5.7.4 Settings ... 275
5.7.5 Information List ... 277
5.7.6 Trip Logic ... 278
5.7.6.1 Function Description ... 278
5.7.6.2 Application and Setting Notes ... 279
5.7.6.3 Settings ... 280
5.7.6.4 Information List ... 280
5.7.7 Circuit Breaker ... 280
5.7.7.1 Overview ... 280
5.7.7.2 Tripping, Opening, and Closing the Circuit Breaker ... 280
5.7.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information ... 282
5.7.7.4 Definitive Tripping, Circuit-Breaker Tripping Alarm Suppression ... 283
5.7.7.5 Tripping and Opening Information ... 284
5.7.7.6 Application and Setting Notes ... 285
5.7.7.7 Settings ... 287
5.7.7.8 Information List ... 287
5.7.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions ... 288
5.7.8.1 Overview ... 288
5.7.9 Detection Manual Closure (for AREC and Process Monitor) ... 288
5.7.9.1 Function Description ... 288
5.7.9.2 Application and Setting Notes ... 289
5.7.9.3 Settings ... 290
5.7.9.4 Information List ... 290
5.8 Process Monitor ... 291
5.8.1 Overview of Functions ... 291
5.8.2 Structure of the Function ... 291
5.8.3 Current-Flow Criterion ... 292
5.8.4 Application and Setting Notes (Current-Flow Criterion) ... 293
5.8.5 Circuit-Breaker Condition for the Protected Object ... 293
5.8.6 Closure Detection ... 294
5.8.7 Information List ... 294
5.8.8 Cold-Load Pickup Detection (Optional) ... 295
5.8.9 Application and Setting Notes (Cold-Load Pickup Detection) ... 296
5.8.10 Settings ... 297
5.8.11 Information List ... 297

6 Protection and Automation Functions ... 299

6.1 Power-System Data ... 301
6.1.1 Overview ... 301
6.1.2 Structure of the Power-System Data ... 301
6.1.3 Application and Setting Notes – General Settings ... 301
6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph) ... 302
6.1.5 Application and Setting Notes for Measuring Point Current 3-Phase (I-3ph) ... 305
6.1.6 Settings ... 308
6.1.7 Information List ... 314
6.2 Group Indications of Overcurrent Protection Functions ... 317
6.2.1 Description ... 317
6.3 Overcurrent Protection, Phases ... 318
6.3.1 Overview of Functions ... 318

6.3.2 Structure of the Function 318
6.3.3 Filter for RMS Value Gain 320
6.3.3.1 Description 320
6.3.3.2 Application and Setting Notes 321
6.3.3.3 Settings 322
6.3.3.4 Information List 322
6.3.4 Stage with Definite-Time Characteristic Curve 323
6.3.4.1 Description 323
6.3.4.2 Application and Setting Notes 327
6.3.4.3 Settings 330
6.3.4.4 Information List 333
6.3.5 Stage with Inverse-Time Characteristic Curve 334
6.3.5.1 Description 334
6.3.5.2 Application and Setting Notes 339
6.3.5.3 Settings 341
6.3.5.4 Information List 344
6.3.6 Stage with User-Defined Characteristic Curve 344
6.3.6.1 Description 344
6.3.6.2 Application and Setting Notes 345
6.3.6.3 Settings 346
6.3.6.4 Information List 349
6.3.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection 349
6.3.7.1 Description 349
6.3.7.2 Application and Setting Notes 350
6.3.8 Influence of Other Functions via Dynamic Settings 350
6.3.8.1 Description 350
6.3.8.2 Application and Setting Notes (Advanced Stage) 354
6.4 Voltage-Dependent Overcurrent Protection, Phases 355
6.4.1 Overview of Functions 355
6.4.2 Structure of the Function 355
6.4.3 Stage with Inverse Time-Overcurrent Protection, Voltage-Dependent 356
6.4.3.1 Description 356
6.4.3.2 Application and Setting Notes 358
6.4.3.3 Settings 360
6.4.3.4 Information List 360
6.4.4 Stage with Inverse Time-Overcurrent Protection, Voltage-Released 361
6.4.4.1 Description 361
6.4.4.2 Application and Setting Notes 362
6.4.4.3 Settings 363
6.4.4.4 Information List 363
6.4.5 Stage with Definite Time-Overcurrent Protection, Undervoltage Seal-In 364
6.4.5.1 Description 364
6.4.5.2 Application and Setting Notes 365
6.4.5.3 Settings 366
6.4.5.4 Information List 367
6.4.6 Stage with Definite Time-Overcurrent Protection, Voltage-Released Undervoltage Seal-In 368
6.4.6.1 Description 368
6.4.6.2 Application and Setting Notes 369
6.4.6.3 Settings 371
6.4.6.4 Information List 372
6.5 Overcurrent Protection, Ground 373
6.5.1 Overview of Functions 373
6.5.2 Structure of the Function 373

6.5.3 General Functionality ... 374
6.5.3.1 Description ... 374
6.5.3.2 Application and Setting Notes ... 375
6.5.3.3 Settings ... 376
6.5.4 Stage with Definite-Time Characteristic Curve ... 377
6.5.4.1 Description ... 377
6.5.4.2 Application and Setting Notes ... 379
6.5.4.3 Settings ... 381
6.5.4.4 Information List ... 383
6.5.5 Stage with Inverse-Time Characteristic Curve ... 384
6.5.5.1 Description ... 384
6.5.5.2 Application and Setting Notes ... 387
6.5.5.3 Settings ... 388
6.5.5.4 Information List ... 391
6.5.6 Stage with User-Defined Characteristic Curve ... 391
6.5.6.1 Description ... 391
6.5.6.2 Application and Setting Notes ... 392
6.5.6.3 Settings ... 393
6.5.6.4 Information List ... 395
6.5.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection ... 396
6.5.7.1 Description ... 396
6.5.7.2 Application and Setting Notes ... 396
6.5.8 Influence of Other Functions via Dynamic Settings ... 397
6.5.8.1 Description ... 397
6.5.8.2 Application and Setting Notes (Advanced Stage) ... 401
6.6 Directional Overcurrent Protection, Phases ... 402
6.6.1 Overview of Functions ... 402
6.6.2 Structure of the Function ... 402
6.6.3 Stage Control ... 404
6.6.3.1 Description ... 404
6.6.3.2 Application and Setting Notes ... 404
6.6.4 Stage with Definite-Time Characteristic Curve ... 405
6.6.4.1 Description ... 405
6.6.4.2 Application and Setting Notes ... 408
6.6.4.3 Settings ... 410
6.6.4.4 Information List ... 412
6.6.5 Stage with Inverse-Time Characteristic Curve ... 413
6.6.5.1 Description ... 413
6.6.5.2 Application and Setting Notes ... 416
6.6.5.3 Settings ... 418
6.6.5.4 Information List ... 421
6.6.6 Stage with User-Defined Characteristic Curve ... 422
6.6.6.1 Description ... 422
6.6.6.2 Application and Setting Notes ... 423
6.6.6.3 Settings ... 424
6.6.6.4 Information List ... 426
6.6.7 Direction Determination ... 426
6.6.7.1 Description ... 426
6.6.7.2 Application and Setting Notes ... 429
6.6.8 Influence of Other Functions via Dynamic Settings ... 430
6.6.9 Application Notes for Parallel Lines and Cable Runs with Infeed at Both Ends ... 430
6.6.10 Application Notes for Directional Comparison Protection ... 431
6.7 Directional Overcurrent Protection, Ground ... 434
6.7.1 Overview of Functions ... 434

6.7.2 Structure of the Function....434
6.7.3 General Functionality....436
6.7.3.1 Measured-Value Selection....436
6.7.3.2 Direction Determination....437
6.7.3.3 Application and Setting Notes....439
6.7.3.4 Settings....441
6.7.3.5 Information List....442
6.7.4 Stage Control....442
6.7.4.1 Description....442
6.7.4.2 Application and Setting Notes....442
6.7.5 Stage with Definite-Time Characteristic Curve....444
6.7.5.1 Description....444
6.7.5.2 Application and Setting Notes....447
6.7.5.3 Settings....449
6.7.5.4 Information List....452
6.7.6 Stage with Inverse-Time Characteristic Curve....453
6.7.6.1 Description....453
6.7.6.2 Application and Setting Notes....457
6.7.6.3 Settings....460
6.7.6.4 Information List....462
6.7.7 Stage with Inverse Time-Overcurrent Protection with Logarithmic-Inverse Characteristic Curve....464
6.7.7.1 Description....464
6.7.7.2 Application and Setting Notes....466
6.7.7.3 Settings....467
6.7.7.4 Information List....469
6.7.8 Stage Description Knee-Point Characteristic Curve....470
6.7.8.1 Description....470
6.7.8.2 Application and Setting Notes....471
6.7.8.3 Settings....472
6.7.8.4 Information List....473
6.7.9 Stage with User-Defined Characteristic Curve....474
6.7.9.1 Description....474
6.7.9.2 Application and Setting Notes....475
6.7.9.3 Settings....476
6.7.9.4 Information List....479
6.7.10 Influence of Other Functions via Dynamic Settings....479
6.8 Inrush-Current Detection....480
6.8.1 Overview of Functions....480
6.8.2 Structure of the Function....480
6.8.3 Function Description....480
6.8.4 Application and Setting Notes....484
6.8.5 Settings....485
6.8.6 Information List....486
6.9 Instantaneous High-Current Tripping....487
6.9.1 Overview of Functions....487
6.9.2 Structure of the Function....487
6.9.3 Standard Release Procedure....488
6.9.4 Application and Setting Notes....489
6.9.5 Release Procedure via Protection Interface....490
6.9.6 Application and Setting Notes....492
6.9.7 Settings....492

6.9.8 Information List ... 492
6.10 Arc Protection ... 494
6.10.1 Overview of Function ... 494
6.10.2 Structure of the Function ... 494
6.10.3 Function Description ... 495
6.10.4 Application and Setting Notes – General Settings ... 497
6.10.5 Application and Setting Notes for the Stage ... 498
6.10.6 Settings ... 499
6.10.7 Information List ... 500
6.10.8 Application Example for Arc Protection with Point Sensors in Operating Mode: Light Only ... 501
6.10.8.1 Description ... 501
6.10.8.2 Application and Setting Notes ... 503
6.10.9 Application Example for Arc Protection with Point Sensors in Operating Mode: Light and Current ... 504
6.10.9.1 Description ... 504
6.10.9.2 Application and Setting Notes ... 505
6.10.10 Application Example for Arc Protection with Point Sensors via External Trip Initiation ... 506
6.10.10.1 Description ... 506
6.10.10.2 Application and Setting Notes ... 507
6.10.11 Application Example for Arc Protection with a Line Sensor in Operating Mode: Light and Current ... 509
6.10.11.1 Description ... 509
6.10.11.2 Application and Setting Notes ... 510
6.11 Instantaneous Tripping at Switch onto Fault ... 511
6.11.1 Overview of Functions ... 511
6.11.2 Structure of the Function ... 511
6.11.3 Stage Description ... 512
6.11.4 Application and Setting Notes ... 512
6.11.5 Settings ... 513
6.11.6 Information List ... 513
6.12 Overcurrent Protection, 1-Phase ... 514
6.12.1 Function Overview ... 514
6.12.2 Structure of the Function ... 514
6.12.3 Stage with Definite-Time Characteristic Curve ... 516
6.12.3.1 Description ... 516
6.12.3.2 Application and Setting Notes ... 517
6.12.3.3 Settings ... 518
6.12.3.4 Information List ... 518
6.12.4 Stage with Inverse-Time Characteristic Curve ... 519
6.12.4.1 Description ... 519
6.12.4.2 Application and Setting Notes ... 520
6.12.4.3 Settings ... 521
6.12.4.4 Information List ... 522
6.12.5 Stage with User-Defined Characteristic Curve ... 522
6.12.5.1 Description ... 522
6.12.5.2 Application and Setting Notes ... 523
6.12.5.3 Settings ... 524
6.12.5.4 Information List ... 525
6.12.6 Fast Stage ... 525
6.12.6.1 Description ... 525

6.12.6.2 Application and Setting Notes ... 526
6.12.6.3 Settings ... 526
6.12.6.4 Information List ... 526
6.12.7 Application Example: High-Impedance Restricted Ground-Fault Protection ... 527
6.12.7.1 Description ... 527
6.12.7.2 Application and Setting Notes ... 529
6.12.8 Application Example: Tank Leakage Protection ... 533
6.12.8.1 Description ... 533
6.12.8.2 Application and Setting Notes ... 533
6.13 Non-Directional Intermittent Ground-Fault Protection ... 534
6.13.1 Overview of Functions ... 534
6.13.2 Structure of the Function ... 534
6.13.3 Stage Description ... 535
6.13.4 Application and Setting Notes ... 539
6.13.5 Settings ... 541
6.13.6 Information List ... 541
6.14 Directional Intermittent Ground-Fault Protection ... 543
6.14.1 Overview of Functions ... 543
6.14.2 Structure of the Function ... 543
6.14.3 Stage Description ... 544
6.14.4 Application and Setting Notes ... 550
6.14.5 Settings ... 552
6.14.6 Information List ... 553
6.15 Sensitive Ground-Fault Detection ... 554
6.15.1 Overview of Functions ... 554
6.15.2 Structure of the Function ... 554
6.15.3 General Functionality ... 556
6.15.3.1 Description ... 556
6.15.3.2 Application and Setting Notes ... 558
6.15.3.3 Settings ... 559
6.15.3.4 Information List ... 559
6.15.4 Directional 3I0 Stage with Cos φ or Sin φ Measurement ... 560
6.15.4.1 Description ... 560
6.15.4.2 Application and Setting Notes ... 566
6.15.4.3 Settings ... 568
6.15.4.4 Information List ... 569
6.15.5 Directional Transient Ground-Fault Stage ... 570
6.15.5.1 Description ... 570
6.15.5.2 Application and Setting Notes ... 574
6.15.5.3 Settings ... 576
6.15.5.4 Information List ... 576
6.15.6 Usage Information for Detection of Intermittent Ground Faults ... 576
6.15.7 Directional 3I0 Stage with φ(V0,3I0) Measurement ... 577
6.15.7.1 Description ... 577
6.15.7.2 Application and Setting Notes ... 580
6.15.7.3 Settings ... 582
6.15.7.4 Information List ... 582
6.15.8 Directional Y0 Stage with G0 or B0 Measurement ... 583
6.15.8.1 Description ... 583
6.15.8.2 Application and Setting Notes ... 587
6.15.8.3 Settings ... 591
6.15.8.4 Information List ... 592

6.15.9 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage 593
6.15.9.1 Description 593
6.15.9.2 Application and Setting Notes 594
6.15.9.3 Settings 597
6.15.9.4 Information List 597
6.15.10 Non-Directional 3I0 Stage 597
6.15.10.1 Description 597
6.15.10.2 Application and Setting Notes 599
6.15.10.3 Settings 600
6.15.10.4 Information List 600
6.15.11 Non-Directional Y0 Stage 601
6.15.11.1 Description 601
6.15.11.2 Application and Setting Notes 602
6.15.11.3 Settings 603
6.15.11.4 Information List 604
6.16 Undercurrent Protection 605
6.16.1 Overview of Functions 605
6.16.2 Structure of the Function 605
6.16.3 Stage Description Undercurrent Protection 606
6.16.4 Application and Setting Notes 607
6.16.5 Settings 608
6.16.6 Information List 608
6.17 Negative-Sequence Protection 610
6.17.1 Overview of Functions 610
6.17.2 Structure of the Function 610
6.17.3 General Functionality 611
6.17.3.1 Description 611
6.17.3.2 Application and Setting Notes 611
6.17.4 Stage with Definite-Time Characteristic Curve 613
6.17.4.1 Stage Description 613
6.17.4.2 Application and Setting Notes 614
6.17.4.3 Settings 614
6.17.4.4 Information List 615
6.17.5 Stage with Inverse-Time Characteristic Curve 616
6.17.5.1 Description 616
6.17.5.2 Application and Settings Notes 617
6.17.5.3 Settings 618
6.17.5.4 Information List 618
6.18 Directional Negative-Sequence Protection 619
6.18.1 Overview of Functions 619
6.18.2 Structure of the Function 619
6.18.3 Function Description 619
6.18.4 Application and Setting Notes for Direction Determination 624
6.18.5 Application and Setting Notes for Stages 624
6.18.6 Settings 626
6.18.7 Information List 627
6.19 Thermal Overload Protection, 3-Phase 628
6.19.1 Overview of Functions 628
6.19.2 Structure of the Function 628
6.19.3 Filter for RMS Value Gain 628
6.19.3.1 Description 628

6.19.3.2 Application and Setting Notes ... 629
6.19.3.3 Settings ... 630
6.19.3.4 Information List ... 631
6.19.4 Stage with Thermal Overload Protection ... 631
6.19.4.1 Description ... 631
6.19.4.2 Application and Setting Notes ... 636
6.19.4.3 Settings ... 639
6.19.4.4 Information List ... 640
6.20 Thermal Overload Protection, User-Defined Characteristic Curve ... 642
6.20.1 Overview of Functions ... 642
6.20.2 Structure of the Function ... 642
6.20.3 Function Description ... 643
6.20.4 Application and Setting Notes ... 647
6.20.5 Settings ... 650
6.20.6 Information List ... 651
6.21 Thermal Overload Protection, 1-Phase ... 653
6.21.1 Overview of Functions ... 653
6.21.2 Structure of the Function ... 653
6.21.3 Function Description ... 654
6.21.4 Application and Setting Notes ... 657
6.21.5 Settings ... 661
6.21.6 Information List ... 662
6.22 Unbalanced-Load Protection ... 663
6.22.1 Overview of Functions ... 663
6.22.2 Structure of the Function ... 663
6.22.3 Function Description ... 664
6.22.4 Application and Setting Notes ... 666
6.22.5 Settings ... 668
6.22.6 Information List ... 668
6.23 Overvoltage Protection with 3-Phase Voltage ... 669
6.23.1 Overview of Functions ... 669
6.23.2 Structure of the Function ... 669
6.23.3 Stage with Definite-Time Characteristic Curve ... 670
6.23.3.1 Description ... 670
6.23.3.2 Application and Setting Notes ... 671
6.23.3.3 Settings ... 673
6.23.3.4 Information List ... 673
6.23.4 Stage with Inverse-Time Characteristic Curve ... 675
6.23.4.1 Description ... 675
6.23.4.2 Application and Setting Notes ... 678
6.23.4.3 Settings ... 679
6.23.4.4 Information List ... 680
6.24 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage ... 681
6.24.1 Overview of Functions ... 681
6.24.2 Structure of the Function ... 681
6.24.3 Stage Description ... 682
6.24.4 Application and Setting Notes ... 683
6.24.5 Settings ... 686
6.24.6 Information List ... 686

6.25 Overvoltage Protection with Positive-Sequence Voltage 687
6.25.1 Overview of Functions 687
6.25.2 Structure of the Function 687
6.25.3 Stage Description 688
6.25.4 Application and Setting Notes 688
6.25.5 Settings 689
6.25.6 Information List 689
6.26 Overvoltage Protection with Negative-Sequence Voltage 691
6.26.1 Overview of Functions 691
6.26.2 Structure of the Function 691
6.26.3 General Functionality 691
6.26.3.1 Description 691
6.26.3.2 Application and Setting Notes 692
6.26.3.3 Settings 693
6.26.3.4 Information List 693
6.26.4 Stage with Negative-Sequence Voltage 694
6.26.4.1 Description 694
6.26.4.2 Application and Setting Notes 694
6.26.4.3 Settings 696
6.26.4.4 Information List 697
6.27 Overvoltage Protection with Any Voltage 698
6.27.1 Overview of Functions 698
6.27.2 Structure of the Function 698
6.27.3 Stage Description 699
6.27.4 Application and Setting Notes 700
6.27.5 Settings 701
6.27.6 Information List 702
6.28 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage 703
6.28.1 Overview of Functions 703
6.28.2 Structure of the Function 703
6.28.3 General Functionality 703
6.28.3.1 Description 703
6.28.3.2 Application and Setting Notes 704
6.28.3.3 Settings 705
6.28.3.4 Information List 705
6.28.4 Stage with Negative-Sequence Voltage/Positive-Sequence Voltage 706
6.28.4.1 Description 706
6.28.4.2 Application and Setting Notes 706
6.28.4.3 Settings 708
6.28.4.4 Information List 709
6.29 Undervoltage Protection with 3-Phase Voltage 710
6.29.1 Overview of Functions 710
6.29.2 Structure of the Function 710
6.29.3 Stage with Definite-Time Characteristic Curve 711
6.29.3.1 Description 711
6.29.3.2 Application and Setting Notes 713
6.29.3.3 Settings 716
6.29.3.4 Information List 717
6.29.4 Stage with Inverse-Time Characteristic Curve 718
6.29.4.1 Description 718
6.29.4.2 Application and Setting Notes 722

6.29.4.3 Settings ... 725
6.29.4.4 Information List ... 725
6.30 Undervoltage Protection with Positive-Sequence Voltage ... 726
6.30.1 Overview of Functions ... 726
6.30.2 Structure of the Function ... 726
6.30.3 Stage Description ... 727
6.30.4 Application and Setting Notes ... 728
6.30.5 Settings ... 731
6.30.6 Information List ... 732
6.31 Undervoltage Protection with Any Voltage ... 733
6.31.1 Overview of Functions ... 733
6.31.2 Structure of the Function ... 733
6.31.3 Stage Description ... 734
6.31.4 Application and Setting Notes ... 735
6.31.5 Settings ... 737
6.31.6 Information List ... 738
6.32 Overfrequency Protection ... 739
6.32.1 Overview of Functions ... 739
6.32.2 Structure of the Function ... 739
6.32.3 Overfrequency-Protection Stage ... 740
6.32.4 Application and Setting Notes ... 741
6.32.5 Settings ... 742
6.32.6 Information List ... 743
6.33 Underfrequency Protection ... 744
6.33.1 Overview of Functions ... 744
6.33.2 Structure of the Function ... 744
6.33.3 Underfrequency-Protection Stage ... 745
6.33.4 Application and Setting Notes ... 746
6.33.5 Settings ... 747
6.33.6 Information List ... 748
6.34 Rate of Frequency Change Protection ... 749
6.34.1 Overview of Functions ... 749
6.34.2 Structure of the Function ... 749
6.34.3 General Functions (Undervoltage Test, df/dt Calculation) ... 749
6.34.3.1 Description ... 749
6.34.3.2 Application and Setting Notes ... 750
6.34.4 Stage Description ... 751
6.34.4.1 Description ... 751
6.34.4.2 Application and Setting Notes ... 752
6.34.5 Settings ... 753
6.34.6 Information List ... 753
6.35 Power Protection (P,Q), 3-Phase ... 755
6.35.1 Overview of Functions ... 755
6.35.2 Structure of the Function ... 755
6.35.3 Active Power Stage ... 756
6.35.4 Reactive Power Stage ... 758
6.35.5 Application Example ... 759

6.35.6 Setting Notes for the Active Power Stage ... 760
6.35.7 Setting Notes for the Reactive Power Stage ... 761
6.35.8 Settings ... 762
6.35.9 Information List ... 763
6.36 Reverse Power Protection ... 765
6.36.1 Overview of Functions ... 765
6.36.2 Structure of the Function ... 765
6.36.3 General Functionality ... 766
6.36.3.1 Description ... 766
6.36.3.2 Application and Setting Notes ... 767
6.36.3.3 Parameter ... 769
6.36.3.4 Information List ... 769
6.36.4 Stage Description ... 770
6.36.4.1 Description ... 770
6.36.4.2 Application and Setting Notes ... 771
6.36.4.3 Parameter ... 771
6.36.4.4 Information List ... 772
6.37 Overexcitation Protection ... 773
6.37.1 Overview of Functions ... 773
6.37.2 Structure of the Function ... 773
6.37.3 Stage with Dependent Characteristic Curve (Thermal Stage) ... 774
6.37.3.1 Function Description ... 774
6.37.3.2 Application and Setting Notes ... 777
6.37.3.3 Settings ... 778
6.37.3.4 Information List ... 778
6.37.4 Stage with Independent Characteristic Curve ... 780
6.37.4.1 Function Description ... 780
6.37.4.2 Application and Setting Notes ... 780
6.37.4.3 Settings ... 781
6.37.4.4 Information List ... 781
6.38 Undervoltage-Controlled Reactive-Power Protection ... 783
6.38.1 Overview of Functions ... 783
6.38.2 Structure of the Function ... 783
6.38.3 Description Protection Stage ... 784
6.38.3.1 Description ... 784
6.38.3.2 Application and Setting Notes ... 785
6.38.3.3 Settings ... 787
6.38.3.4 Information List ... 788
6.38.4 Description Reclosure Stage ... 789
6.38.4.1 Description ... 789
6.38.4.2 Application and Setting Notes ... 790
6.38.4.3 Settings ... 791
6.38.4.4 Information List ... 791
6.39 Circuit-Breaker Failure Protection ... 792
6.39.1 Overview of Functions ... 792
6.39.2 Structure of the Function ... 792
6.39.3 Function Description ... 793
6.39.4 Application and Setting Notes ... 799
6.39.5 Settings ... 806
6.39.6 Information List ... 807

6.40 Circuit-Breaker Restrike Protection ... 808
6.40.1 Overview of Function ... 808
6.40.2 Structure of the Function ... 808
6.40.3 Function Description ... 808
6.40.4 Application and Setting Notes ... 812
6.40.5 Settings ... 815
6.40.6 Information List ... 816
6.41 Restricted Ground-Fault Protection ... 817
6.41.1 Overview of Functions ... 817
6.41.2 Structure of the Function ... 817
6.41.3 Function Description ... 818
6.41.4 Application and Setting Notes ... 823
6.41.5 Settings ... 833
6.41.6 Information List ... 834
6.42 External Trip Initiation 3-Pole ... 835
6.42.1 Overview of Functions ... 835
6.42.2 Structure of the Function ... 835
6.42.3 Stage Description ... 836
6.42.4 Application and Setting Notes ... 836
6.42.5 Settings ... 837
6.42.6 Information List ... 837
6.43 Automatic Reclosing Function ... 838
6.43.1 Overview of Functions ... 838
6.43.2 Structure of the Function ... 838
6.43.3 Cooperation of the Automatic Reclosing Function and Protection Functions ... 840
6.43.4 Cyclic Automatic Reclosing Function ... 842
6.43.4.1 Operating Modes for Cyclic Automatic Reclosing Function ... 842
6.43.4.2 Structure of the Cyclic Automatic Reclosing Function ... 845
6.43.4.3 Input Logic for Operating Modes with Tripping ... 846
6.43.4.4 Input Logic for Operating Modes with Pickup ... 847
6.43.4.5 Start ... 848
6.43.4.6 Cycle Control with Operating Mode 1: With Tripping/With Action Time ... 849
6.43.4.7 Cycle Control with Operating Mode 2: With Pickup/With Action Time ... 851
6.43.4.8 Cycle Control with Operating Mode 3: With Tripping/Without Action Time ... 853
6.43.4.9 Cycle Control with Operating Mode 4: With Pickup/Without Action Time ... 854
6.43.4.10 Stage Release ... 855
6.43.4.11 Dead Time for Operating Modes With Tripping ... 856
6.43.4.12 Dead Time for Operating Modes with Pickup ... 857
6.43.4.13 Evolving-Fault Detection During Dead Time ... 858
6.43.4.14 Closing Indication and Close Command ... 860
6.43.4.15 Reclaim Time ... 863
6.43.4.16 Circuit-Breaker Readiness ... 864
6.43.4.17 Blockings ... 865
6.43.4.18 Dead-Line Checking (DLC) and Reduced Dead Time (RDT) ... 868
6.43.4.19 Settings ... 870
6.43.4.20 Information List ... 872
6.43.5 Automatic Reclosing Function with Adaptive Dead Time (ADT) ... 874
6.43.5.1 Description ... 874
6.43.5.2 Settings ... 875
6.43.5.3 Information List ... 875

6.43.6 Cooperation with External Automatic Reclosing Function ... 877
6.43.6.1 Description ... 877
6.43.6.2 Information List ... 878
6.43.7 Application and Setting Notes for General Settings ... 879
6.43.8 Application and Setting Notes for 1 Cycle of the Cyclic Automatic Reclosing Function ... 885
6.44 Fault Locator ... 888
6.44.1 Overview of Functions ... 888
6.44.2 Structure of the Function ... 888
6.44.3 Function Description ... 889
6.44.4 Application and Setting Notes ... 890
6.44.5 Settings ... 894
6.44.6 Information List ... 894
6.45 Temperature Supervision ... 896
6.45.1 Overview of Functions ... 896
6.45.2 Structure of the Function ... 896
6.45.3 Function Description ... 897
6.45.4 Application and Setting Notes ... 897
6.45.5 Settings ... 898
6.45.6 Information List ... 903
6.46 Current-Jump Detection ... 906
6.46.1 Overview of Functions ... 906
6.46.2 Structure of the Function ... 906
6.46.3 Function Description ... 906
6.46.4 Application and Setting Notes ... 907
6.46.5 Settings ... 908
6.46.6 Information List ... 908
6.47 Voltage-Jump Detection ... 909
6.47.1 Overview of Functions ... 909
6.47.2 Structure of the Function ... 909
6.47.3 Function Description ... 909
6.47.4 Application and Setting Notes ... 910
6.47.5 Settings ... 911
6.47.6 Information List ... 911
6.48 Voltage Measuring-Point Selection ... 912
6.48.1 Overview of Functions ... 912
6.48.2 Function Description ... 912
6.48.3 Application and Setting Notes ... 913
6.48.4 Information List ... 914

7 Capacitor Bank Protection ... 915

7.1 Introduction ... 916
7.2 Overcurrent Protection for Capacitor Banks ... 917
7.2.1 Overview ... 917
7.2.2 Overcurrent Protection, Phases for Protection of RLC Filter-Circuit Elements ... 917
7.2.2.1 Structure of the Function ... 917
7.2.2.2 Description ... 918
7.2.2.3 Application and Setting Notes ... 919

7.3 Thermal Overload Protection for Capacitor Banks....920
7.3.1 Overview of Functions....920
7.3.2 Structure of the Function....920
7.3.3 Description....920
7.3.4 Application and Setting Notes....921
7.3.5 Settings....922
7.3.6 Information List....922
7.4 Current-Unbalance Protection for Capacitors, 3-Phase....923
7.4.1 Overview of Functions....923
7.4.2 Structure of the Function....923
7.4.3 General Functions and Measuring-Point Selection....923
7.4.3.1 Description....923
7.4.3.2 Application and Setting Notes....930
7.4.3.3 Settings....938
7.4.3.4 Information List....939
7.4.4 Overcurrent-Protection Stage I>....940
7.4.4.1 Description....940
7.4.4.2 Application and Setting Notes....942
7.4.4.3 Settings....943
7.4.4.4 Information List....943
7.4.5 Counter Stage....944
7.4.5.1 Description....944
7.4.5.2 Application and Setting Notes....945
7.4.5.3 Settings....946
7.4.5.4 Information List....946
7.5 Current-Unbalance Protection for Capacitors, 1-Phase....947
7.5.1 Overview of Functions....947
7.5.2 Structure of the Function....947
7.5.3 General Functions and Measuring-Point Selection....947
7.5.3.1 Description....947
7.5.3.2 Application and Setting Notes....953
7.5.3.3 Settings....955
7.5.3.4 Information List....956
7.5.4 Overcurrent-Protection Stage I>....957
7.5.4.1 Description....957
7.5.4.2 Application and Setting Notes....958
7.5.4.3 Settings....959
7.5.4.4 Information List....960
7.5.5 Counter Stage....961
7.5.5.1 Description....961
7.5.5.2 Application and Setting Notes....962
7.5.5.3 Settings....963
7.5.5.4 Information List....963
7.6 Peak Overvoltage Protection for Capacitors....965
7.6.1 Overview of Functions....965
7.6.2 Structure of the Function....965
7.6.3 Stage with Inverse-Time Characteristic Curve....966
7.6.3.1 Description....966
7.6.3.2 Application and Setting Notes....968
7.6.3.3 Settings....970
7.6.3.4 Information List....970

7.6.4 Stage with Definite-Time Characteristic Curve ... 972
7.6.4.1 Description ... 972
7.6.4.2 Application and Setting Notes ... 973
7.6.4.3 Settings ... 973
7.6.4.4 Information List ... 974
7.6.5 Stage with User-Defined Characteristic Curve ... 974
7.6.5.1 Description ... 974
7.6.5.2 Application and Setting Notes ... 975
7.6.5.3 Settings ... 976
7.6.5.4 Information List ... 976
7.7 Voltage Differential Protection for Capacitors ... 977
7.7.1 Overview of the Functions ... 977
7.7.2 Structure of the Function ... 977
7.7.3 General Functionality ... 977
7.7.3.1 Description ... 977
7.7.3.2 Application and Setting Notes ... 983
7.7.4 Description Protection Stage ... 985
7.7.4.1 Description ... 985
7.7.4.2 Application and Setting Notes ... 986
7.7.4.3 Settings ... 986
7.7.4.4 Information List ... 987
7.8 Differential Protection for Capacitor Banks ... 988
7.8.1 Function Overview ... 988
7.8.2 Structure of the Function ... 988
7.8.3 Function Description ... 988
7.8.4 Application and Setting Notes ... 1003
7.8.5 Settings ... 1009
7.8.6 Information List ... 1010
7.9 Detuning Supervision for Capacitor Banks ... 1012
7.9.1 AC-Filter Detuning Supervision ... 1012

8 Control Functions ... 1015

8.1 Introduction ... 1016
8.1.1 Overview ... 1016
8.1.2 Concept of Controllables ... 1016
8.2 Switching Devices ... 1019
8.2.1 General Overview ... 1019
8.2.2 Switching Device Circuit Breaker ... 1019
8.2.2.1 Structure of the Circuit-Breaker Switching Device ... 1019
8.2.2.2 Application and Setting Notes ... 1023
8.2.2.3 Connection Variants of the Circuit Breaker ... 1025
8.2.2.4 Settings ... 1033
8.2.2.5 Information List ... 1035
8.2.3 Disconnector Switching Device ... 1036
8.2.3.1 Structure of the Disconnector Switching Device ... 1036
8.2.3.2 Application and Setting Notes ... 1040
8.2.3.3 Trigger Variants of the Disconnector ... 1042
8.2.3.4 Settings ... 1044
8.2.3.5 Information List ... 1045
8.3 Control Functionality ... 1046
8.3.1 Command Checks and Switchgear Interlocking Protection ... 1046
8.3.2 Command Logging ... 1064

8.3.3 Settings....1068
8.3.4 Information List....1069
8.4 Synchronization Function....1070
8.4.1 Overview of Functions....1070
8.4.2 Structure of the Function....1070
8.4.3 Connection and Definition....1070
8.4.4 General Functionality....1073
8.4.5 Dynamic Measuring-Point Switching....1077
8.4.6 Sequence of Functions....1079
8.4.7 Closing Conditions for the Synchrocheck Stage Type....1081
8.4.8 Closing Conditions for the Synchronous/Asynchronous Stage Type....1082
8.4.9 Expanded Checks (df/dt and Smoothing of Oscillations)....1086
8.4.10 Closing at De-Energized Line/Busbar....1087
8.4.11 Direct Close Command....1089
8.4.12 Interaction with Control, Automatic Reclosing (AREC), and External Triggering....1089
8.4.13 Application and Setting Notes (General)....1091
8.4.14 Application and Setting Notes (Synchrocheck)....1094
8.4.15 Application and Setting Notes (Synchronous/Asynchronous Closure)....1094
8.4.16 Application and Setting Notes (De-Energized Switching/Direct Close Command)....1095
8.4.17 Settings....1097
8.4.18 Information List....1099
8.4.19 External Synchronization....1101
8.4.20 Application and Setting Notes (External Synchronization)....1104
8.4.21 Settings....1104
8.4.22 Information List....1105
8.5 Switching Sequences....1106
8.5.1 Overview of Functions....1106
8.5.2 Function Description....1106
8.5.3 Application and Setting Notes....1108
8.5.4 Settings....1111
8.5.5 Information List....1112
8.6 User-Defined Function Block [Control]....1113
8.6.1 Overview of Functions....1113
8.6.2 Function Description....1113
8.6.3 Application and Setting Notes....1113
8.6.4 Settings....1114
8.6.5 Information List....1114
8.7 CFC-Chart Settings....1115
8.7.1 Overview of Functions....1115
8.7.2 Function Description....1115
8.7.3 Application and Setting Notes....1115
8.7.4 Settings....1116
8.7.5 Information List....1116
8.8 Transformer Tap Changers....1117
8.8.1 Function Description....1117
8.8.2 Application and Setting Notes....1121

8.8.3 Settings....1126
8.8.4 Information List....1127
8.9 Voltage Controller....1128
8.9.1 Overview of Functions....1128
8.9.2 Structure of the Function....1128
8.9.3 Function Description....1129
8.9.4 Application and Setting Notes....1145
8.9.5 Settings....1155
8.9.6 Information List....1163

9 Supervision Functions....1169

9.1 Overview....1170
9.2 Resource-Consumption Supervision....1171
9.2.1 Load Model....1171

1 Introduction

1.1	General	38
1.2	Properties of SIPROTEC 5	40

1.1 General

The digital multifunctional protection and bay controllers of the SIPROTEC 5 device series are equipped with a powerful microprocessor. As a result, all tasks, from acquiring measurands to entering commands in the circuit breaker, are processed digitally.

Analog Inputs

The measuring inputs transform the currents and voltages sent by the instrument transformers and adapt them to the internal processing level of the device. A SIPROTEC 5 device has a current transformer and, depending on the device type, a voltage transformer. The current inputs are therefore intended for the detection of phase currents and ground current. The ground current can be detected sensitively using a core balance current transformer. In addition, phase currents can be detected very sensitively for a particularly precise measurement. The voltage inputs detect the measuring voltage of device functions requiring current and voltage measured values.

The analog values are digitized in the internal microcomputer for data processing.

Microcomputer System

All device functions are processed in the microcomputer system.

This includes, for example:

- Filtering and preparation of the measurands
- Constant monitoring of the measurands
- Monitoring of the pickup conditions for the individual protection functions
- Querying of limiting values and time-outs
- Controlling of signals for the logic functions
- Decision about the trip and close commands
- Storage of indications, fault data, and fault values for fault analysis
- Administration of the operating system and its functions, such as data storage, real-time clock, communication, interfaces, etc.
- External distribution of information

Binary Inputs and Outputs

Using the binary inputs and outputs, the device receives information from the system or from other devices (such as locking commands). The most important outputs include the commands to the switching devices and the indications for remote signaling of important events and states.

Front Elements

For devices with an integrated or offset operation panel, LEDs and an LC display on the front provide information on the device function and report events, states, and measured values. In conjunction with the LC display, the integrated keypad enables on-site operation of the device. All device information such as setting parameters, operating and fault indications or measured values can be displayed, and setting parameters changed. In addition, system equipment can be controlled via the user interface of the device.

Serial Interfaces

The serial interface in the front cover enables communication with a personal computer when using the DIGSI operating program. As a result, the operation of all device functions is possible. Additional interfaces on the back are used to realize various communication protocols.

Power Supply

The individual functional units of the device are powered by an internal power supply. Brief interruptions in the supply voltage, which can occur during short circuits in the system auxiliary voltage supply are generally bridged by capacitor storage (see also the Technical Data).

1.2 Properties of SIPROTEC 5

The SIPROTEC 5 devices at the bay level are compact and can be installed directly in medium and high-voltage switchgear. They are characterized by comprehensive integration of protection and control functions.

General Properties

- Powerful multiprocessor
- Fully digital measured-value processing and control, from sampling and digitizing of measurands to closing and tripping decisions for the circuit breaker
- Complete galvanic and interference-free isolation of the internal processing switches from the system measuring, control, and supply circuits through instrument transformers, binary input and output modules, and DC and AC voltage converters
- Easy operation using an integrated operator and display panel, or using a connected personal computer with user interface
- Continuous display of measured and metered values at the front
- Storage of min/max measured values (slave pointer function) and storage of long-term average values
- Storage of fault indications for system incidents (faults in system) with real-time assignment and instantaneous values for fault recording
- Continuous monitoring of the measurands as well as the device hardware and software
- Communication with central control and storage devices possible via the device interface
- Battery-buffered, synchronizable clock

Modular Concept

The SIPROTEC 5 modular concept ensures the consistency and integrity of all functionalities across the entire device series. Significant features here include:

- Modular system design in hardware, software, and communication
- Functional integration of various applications, such as protection, control, and fault recorder
- The same expansion and communication modules for all devices in the family
- Innovative terminal technology with easy assembly and interchangeability and the highest possible degree of safety
- The same functions can be configured individually across the entire family of devices
- Ability to upgrade with innovations possible at all times through libraries
- Open, scalable architecture for IT integration and new functions
- Multi-layered security mechanisms in all links of the security chain
- Self-monitoring routines for reliable localization and indication of device faults
- Automatic logging of access attempts and safety-critical operations on the devices and systems

Redundant Communication

SIPROTEC 5 devices maintain complete communication redundancy:

- Multiple redundant communication interfaces
- Redundant and independent protocols to control centers possible (such as IEC 60870-5-103 and IEC 61850, either single or redundant)
- Redundant time synchronization (such as IRIG-B, SNTP, or IEEE 1588)

2 Basic Structure of the Function

2.1	Function Embedding in the Device	42
2.2	Adjustment of Application Templates/Functional Scope	49
2.3	Function Control	51
2.4	Text Structure and Reference Number for Settings and Indications	55
2.5	Information Lists	57

2.1 Function Embedding in the Device

General

SIPROTEC 5 devices offer great flexibility in the handling of functions. Functions can be individually loaded into the device. Additionally, it is possible to copy functions within a device or between devices. The necessary integration of functions in the device is illustrated by the following example.

NOTE

The availability of certain settings and setting options depends on the device type and the functions available on the device!

EXAMPLE

A 1 1/2 circuit-breaker layout of the 7SA86 distance protection device serves as an example. The following protection functions are required for implementation (simplified and reduced):

- Distance protection (21)
- Overcurrent protection, phases (51)
- Circuit-breaker failure protection (50BF), for circuit breakers 1 and 2
- Basic functionality (handling of tripping, etc.)

Several predefined function packages that are tailored to specific applications exist for each device family. A predefined functional scope is called an **application template**. The existing application templates are offered for selection automatically when you create a new device in DIGSI 5.

EXAMPLE

When creating the device in DIGSI 5, you must select the appropriate application template. In the example, select the application template **DIS overhead line, grounded systems, 1 1/2 circuit-breaker layout**. This application template covers the required functional scope. Selecting this application template determines the preconfigured functional scope. This can be changed as necessary (see chapter *2.2 Adjustment of Application Templates/Functional Scope*).

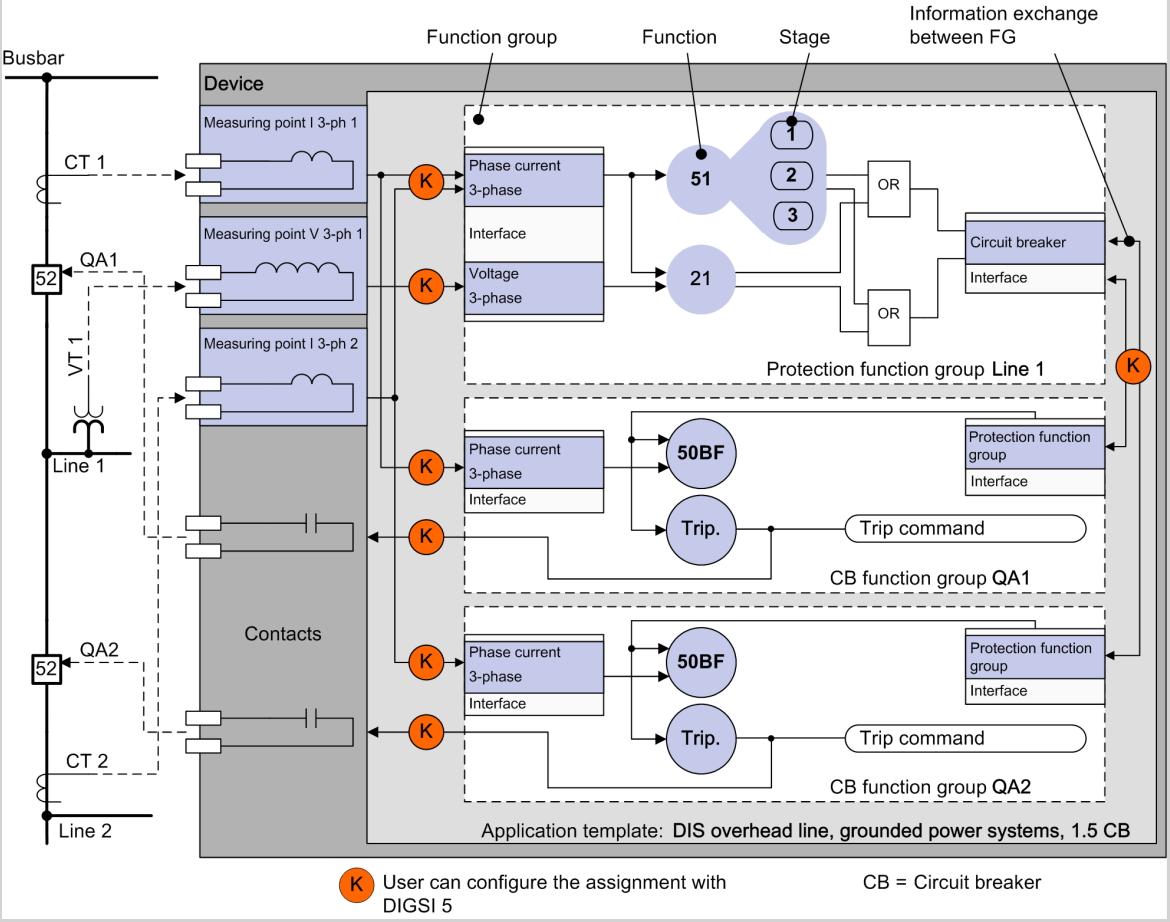
Function Groups (FG)

Functions are arranged in function groups. This simplifies handling of functions (adding and copying). The function groups are assigned to primary objects, such as a line, transformer, or circuit breaker.

The function groups bundle functions with regard to the following basic tasks:

- Assignment of functions to current and/or voltage transformers (assignment of functions to the measuring points and thus to the protected object)
- Exchange of information between function groups

When a function is copied into a function group, it automatically works with the measuring points assigned to the function group. Their output signals are also automatically included in the configured interfaces of the function group.



The number and type of function groups differ in the respective application templates, depending on the type of the device and application. You can add, copy, or even delete function groups for a specific application. You can also adapt the functional scope within a function group according to the use case. You can find detailed information on this in the DIGSI 5 Online help.

EXAMPLE

The selected application template **DIS overhead line, grounded systems, 1 1/2 circuit-breaker layout** comprises 3 function groups:

- Protection function group **Line 1**
- Circuit-breaker function group **QA 1**
- Circuit-breaker function group **QA 2**

The following figure shows the embedding of functions via function groups.

[dweifkfg-021012-01.tif, 1, en_US]

Figure 2-1 Embedding the Functions via Function Groups

Depending on the type of device, there are different types of function groups:

- Protection function groups
- Circuit-breaker function groups

Protection function groups bundle functions that are assigned to one protected object – for example, to the linethe transformer. Depending on the device type and nature of the protected object, there are different types of protection function groups (line, voltage/current 3-phase, transformer, motor, generator, etc.).

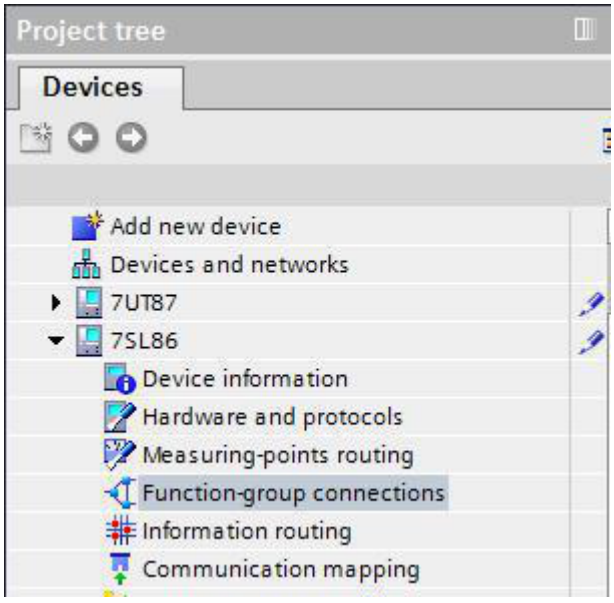
Circuit-breaker function groups bundle functions assigned to the local switches – for example, circuit breakers and disconnectors (such as processing of tripping, circuit-breaker failure protection, automatic reclosing).

The number and type of function groups differ in the respective application templates, depending on the type of the device and application. You can add, copy, or even delete function groups for a specific application. You can also adapt the functional scope within a function group according to the use case. Detailed information on this can be found in the DIGSI 5 Online help.

Interface Between Function Group and Measuring Point

The function groups receive the measurands of the current and voltage transformers from measuring points. For this, the function groups are connected to one or more measuring points.

The number of measuring points and the assignment of function groups to the measuring points are preset by the selected application template in accordance with the specific application. Therefore, this specifies which measuring point(s) and the corresponding measurands have to be used by which function within the function group.

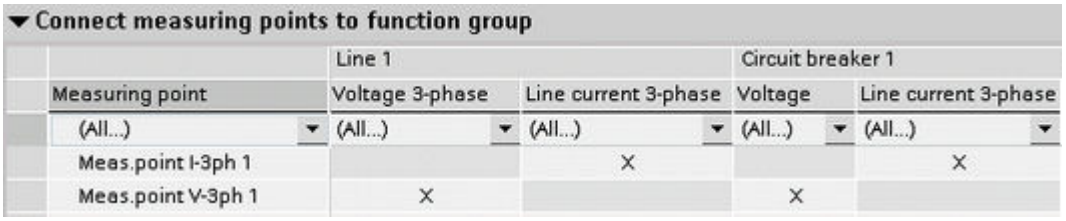


EXAMPLE

The measuring points are assigned to the function groups in the application template in *Figure 2-1* as follows:

- The protection function group **Line** is assigned to the measuring points **I-3ph 1**, **I-3ph 2** and **V-3ph 1**. The function group therefore receives the measured values from current transformers 1 and 2 and from voltage transformer 1. The currents of measuring points **I-3ph 1** and **I-3ph 2** are added geometrically for feeder-related processing.
- The circuit-breaker function group **QA1** is assigned to the measuring point **I-3ph 1** and receives the measured values from current transformer 1.
- The circuit-breaker function group **QA2** is assigned to the measuring point **I-3ph 2** and receives the measured values from current transformer 2.

The user can change the assignment as needed, that is, function groups can be assigned to any available measuring points of the device.



To check or change the assignment of measuring points to the function groups, double-click **Function-group connections** in the DIGSI 5 project tree.

[scfgverb-190214-01, 1, en_US]

Figure 2-2 Project Tree in DIGSI 5 (Detail)

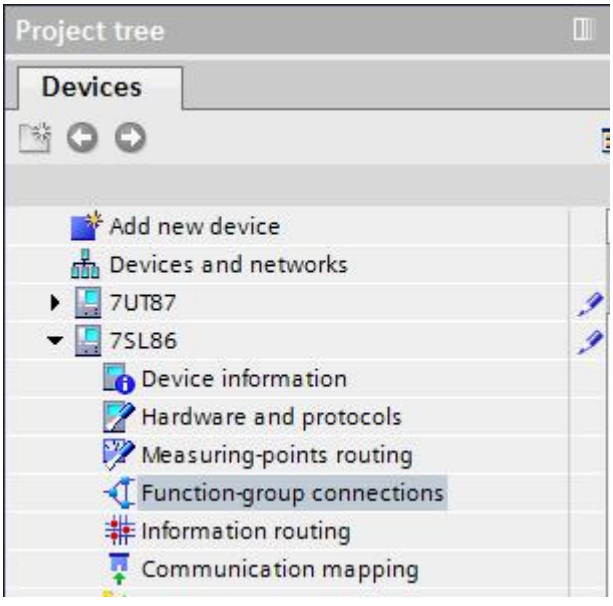
The window for routing of the measuring points opens in the working area (see the following Figure, does not correspond to the example).

[scmscofg-180311-01.tif, 1, en_US]

Figure 2-3 Connecting Measuring Points and Function Groups

Interface Between Protection and Circuit-Breaker Function Groups

The protection function group(s) is/are connected to one or several circuit-breaker function groups. This connection generally determines:

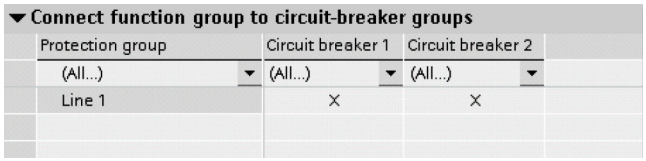


- Which circuit breaker(s) is/are started by the protection functions of the protection FG.
- Starting the **Circuit-breaker failure protection** function (if available in the Circuit-breaker function group) through the protection functions of the connected protection function group
- Starting the **Automatic reclosing** function (AREC, if available in the Circuit-breaker function group) through the protection functions of the connected Protection function group

Besides the general assignment of the protection function group(s) to the circuit-breaker function groups, you can also configure the interface for specific functionalities in detail. Further information on this is included later in the section. *Figure 2-6* shows how to reach the detail configuration. *Figure 2-7* shows the possible assignments in detail.

These definitions are also set appropriately for the specific application by the selected application template.

The user can change this linkage as needed, that is, protection function groups can be freely assigned to any Circuit-breaker function groups.

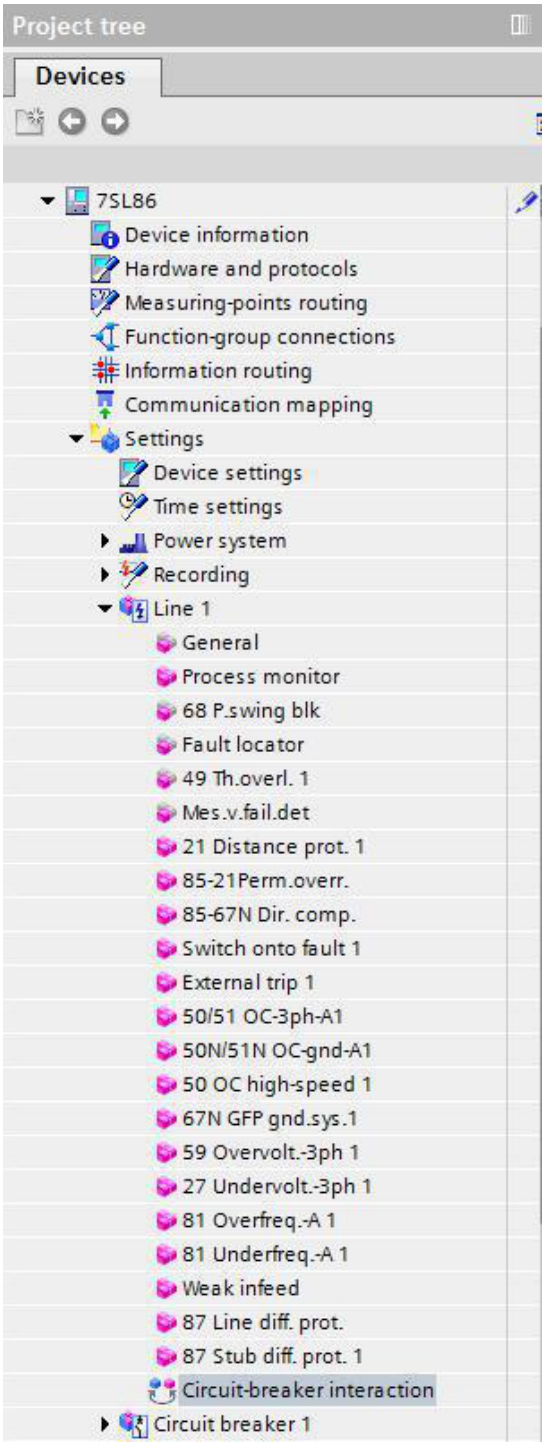


To check or change the allocation of the protection function groups to the circuit-breaker function groups, double-click **Function group connections** in the DIGSI 5 project tree → **Name of device** (see following figure).

[scfgverb-190214-01, 1, en_US]

Figure 2-4 Project Tree in DIGSI 5 (Detail)

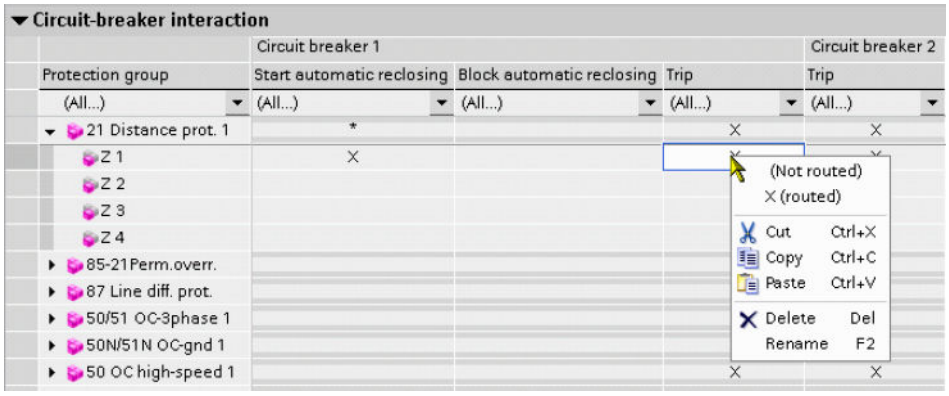
The window for general routing of the function groups opens in the working area (see following figure).



[scfgcols-220211-01.tif, 1, en_US]

Figure 2-5 Connection of Protection Function Group with Circuit-Breaker Function Group

Besides the general assignment of the protection function group(s) to the circuit-breaker function groups, you can also configure the interface for specific functionalities in detail. Proceed as follows:



- Open the SIPROTEC 5 device folder in the DIGSI 5 project tree.
- Open the function settings folder in the DIGSI 5 project tree.
- Open the respective protection function group in the DIGSI 5 project tree, for example, **Line 1** (see the following figure)

[sclsinta-190214-01, 1, en_US]

Figure 2-6 Project Tree in DIGSI 5 (Detail)

- Double-click Circuit-breaker interaction (see *Figure 2-6*)
- The window for detailed configuration of the interface between the protection function group and the circuit-breaker function group(s) opens in the working area.
- In this view, configure the interface via the context menu (right mouse button), see *Figure 2-7*.

[scdetail-220211-01.tif, 1, en_US]

Figure 2-7 Detail Configuration of the Interface Between the Protection Function Group and the Circuit-Breaker Function Group(s)

In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the automatic reclosing function
- Which protection functions block the automatic reclosing function
- Which protection functions start the Circuit-breaker failure protection function

Functions (FN), Tripping Stages/Function Blocks (FB)

As already illustrated in *Figure 2-1*, functions are assigned to the protected objects or other primary objects via function groups.

Functions can be further subdivided. For example, protection functions often consist of multiple protection stages (for example, the Overcurrent-protection function). Other functions can contain one or more function blocks.

Each stage, each function block, and each function (without stages/function blocks) can be individually switched into specific operating modes (for example, switch on/off). This is termed function control and is explained in chapter *2.3 Function Control*.

To adjust the functionality to the specific application, functions, tripping stages, and function blocks can be added, copied, and deleted (see chapter *2.2 Adjustment of Application Templates/Functional Scope*).

2.2 Adjustment of Application Templates/Functional Scope

Application Template

The application template defines the preconfigured functional scope of the device for a specific use case. A certain number of application templates is predefined for each device type. DIGSI 5 automatically offers the application templates for selection when a new device is installed. The available application templates with the respective functional scope are described in more detail in *4 Applications*.

The selection of the application template first predefines which function groups and functions are present in the device (see also *Figure 2-1* in chapter *2.1 Function Embedding in the Device*).

You can adjust the functional scope to your specific application.

Adjusting the Functional Scope

Adjust the functional scope based on the selected application template. You can add, copy or delete functions, tripping stages, function blocks, or complete function groups.

In the DIGSI 5 project tree, this can be done via the following Editors:

- Single-line configuration
- Information routing
- Function settings

Siemens recommends the **Single-line configuration** Editor to adjust the functional scope.

Complete missing functionalities from the Global DIGSI 5 Library. Then, the default settings of the added functionality are active. You can copy within a device and between devices as well. Settings and routings are also copied when you copy functionalities.

NOTE

If you delete a parameterized function group, function, or level from the device, all settings and routings will be lost. The function group, function, or tripping stage can be added again, but then the default settings are active.

In most cases, the adjustment of the functional scope consists of adding and deleting functions, tripping stages, and function blocks. As previously described, the functions, tripping stages, and function blocks automatically connect themselves to the measuring points assigned to the function group.

In few cases, it may be necessary to add a protection or circuit-breaker function group. These newly added function groups do not contain (protection) functions. You must individually load the (protection) functions for your specific application. You must also connect the protection or circuit-breaker function group to one or more measuring points (see chapter *2.1 Function Embedding in the Device*). You must connect newly added protection function groups to a circuit-breaker function group (see chapter *2.1 Function Embedding in the Device*).

Functions, tripping stages, function blocks, and function groups can be added up to a certain maximum number. The maximum number can be found in the respective function and function-group descriptions.

Function Points

Function points (FP) are assigned to specific functions, but not to other functions. Further information can be found in the description of application templates, in the chapter *4 Applications*.

The device is supplied with the acquired function-point credit. Functions with function points can be loaded into the device only within the available function-point credit. The functional scope cannot be loaded into the device if the required number of points of the functional scope is higher than the function-point credit. You must either delete functions or upgrade the function-point credit of the device.

No function points are required to add additional stages in functions.

Extending the Function-Point Credit

You can reorder function points if the function-point credit for the device is not enough.

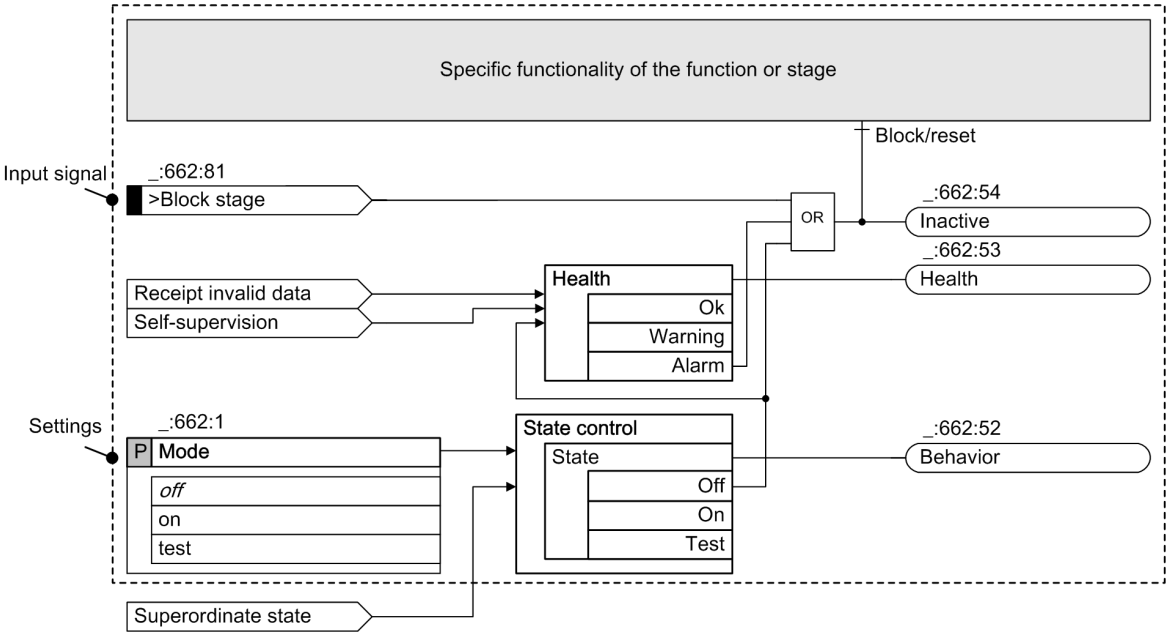
Proceed as follows:

- Determine the function point requirement of certain functions, for example, with DIGSI 5 or the SIPROTEC 5 Configurator.
- Order the additional function points from your local distributor or at *http://www.energy.siemens.com*.
- Siemens will provide you with a signed license file for your device, either via e-mail or for downloading.
- Use DIGSI 5 to load the signed license file into your device. The procedure is described in the Online Help of DIGSI 5.

2.3 Function Control

Function control is used for:

- Functions that do not contain stages or function blocks
- Stages within functions
- Function blocks within functions



NOTE

Simplifying **Functions** and **Function control** will be discussed in the following. The description also applies to tripping stage control and function block control.

Functions can be switched to different operating modes. You use the parameter **Mode** to define whether you want a function to run (***On***) or not (***Off***). In addition, you can temporarily block a function or switch it into test mode for the purpose of commissioning (parameter **Mode** = ***Test***).

The function shows the current status – such as an *Alarm* – via the *Health* signal.

The following explains the different operating modes and mechanisms and how you set the functions into these modes. The function control is shown in *Figure 2-8*. It is standardized for all functions. Therefore, this control is not discussed further in the individual function descriptions.

[losteurg-040411-01.tif, 1, en_US]

Figure 2-8 General Control of a Function

State Control

You can control the state of a function via the parameter **Mode** and the input **Superordinate state**.

You set the specified operating state of the function via the parameter **Mode**. The function mode can be set to ***On***, ***Off***, and ***Test***. The operating principle is described in *Table 2-2*. You can set the parameter **Mode** via:

- DIGSI 5
- On-site operation at the device
- Certain systems control protocols (IEC 61850, IEC 60870-5-103)

The possibility to adjust the **superordinate state** is limited. For test purposes, the complete device can set into test mode.

The state of the function resulting from the parameter **Mode** and the superordinate state is shown in the following table.

Table 2-1 Resulting State of the Function (from Linkage of Parameter Mode and Superordinate State)

Inputs		**Function State**
Mode Parameter (of the function)	**Superordinate State**	
Off	(any)	Off
(any)	Off	Off
On	On	On
On	Test	Test
Test	On	Test
Test	Test	Test

The following table shows the possible function states:

Table 2-2 Possible Function States

Function State	**Explanation**
On	The function is activated and operating as defined. The prerequisite is that the health of the function is ***OK***.
Off	The function is turned off. It does not create any information. The health of a disabled function always has the value ***OK***.

<table>
<tr><th>Function State</th><th colspan="2">Explanation</th></tr>
<tr><td>Test</td><td colspan="2">The function is set to test mode. This state supports the commissioning. All outgoing information from the function (indications and, if present, measured values) is provided with a test bit. This test bit significantly influences the further processing of the information, depending on the target.
For instance, among other things, it is possible to implement the functionality Blocking of the command relay known from SIPROTEC 4.</td></tr>
<tr><td></td><td>Target of the Information</td><td>Processing</td></tr>
<tr><td></td><td>Log</td><td>The indications are provided with the identification Test in the log.</td></tr>
<tr><td></td><td>Contact</td><td>An indication routed to contact is not triggering the contact.</td></tr>
<tr><td></td><td>Light-emitting diode (LED)</td><td>An indication routed to the LED triggers the LED (normal processing)</td></tr>
<tr><td></td><td>CFC</td><td>Here, the behavior depends on the state of the CFC chart.
• CFC chart itself is not in test state:
The CFC chart is not triggered by a status change of information with a set test bit. The initial state of the information (state before test bit was set) is not processed during execution of the CFC chart.
• CFC chart itself is in test state:
The CFC chart continues to process the information (indication or measured value) normally. The CFC outgoing information is provided with a test bit. The definitions in this table apply to its continued processing.
A CFC chart can be set to the test state only by switching the entire device to test mode.</td></tr>
<tr><td></td><td>Protocol</td><td>Indication and measured value are transmitted with set test bit, provided that the protocol supports this functionality.
If an object is transmitted as a GOOSE message, the test bit is set spontaneously and the GOOSE message is transmitted immediately. The receiver of the GOOSE message is automatically notified of transmitter test mode.
If an object is transmitted via the protection interface, the test bit is not transmitted. The Test state must also be transmitted as information for this state to be taken into account in the application on the receiver end. You must route the Test signal in the DIGSI 5 project tree → Device → Communication routing.
The test mode of the differential protection will be dealt with separately in the application.</td></tr>
</table>

Health

Health signals if a selected function can perform its designated functionality. If so, the health is *OK*. In case the functionality is only possible in a limited way or not at all, due to state or problems within the device, the health will signal *Warning* (limited functionality) or *Alarm* (no functionality).

Internal self-supervision can cause the functions to assume the health *Alarm* (see chapter *9 Supervision Functions*). If a function assumes the health state *Alarm*, it is no longer active (indication *not active* is generated).

Only a few functions can signal the health state *Warning*. The health state *Warning* results from function-specific supervision and - where it occurs - it is explained in the function description. If a function assumes the *Warning* status, it will remain active, that is, the function can continue to work in a conditional manner and trip in the case of a protection function.

Not Active

The indication *Not active* signals that a function is currently not working. The indication *Not active* is active in the following cases:

- Function is switched off
- The function is in the health state *Alarm*
- Function is blocked by an input signal (see *Figure 2-8*)

Blocking of the Operate Indication, No Fault Recording at Pickup

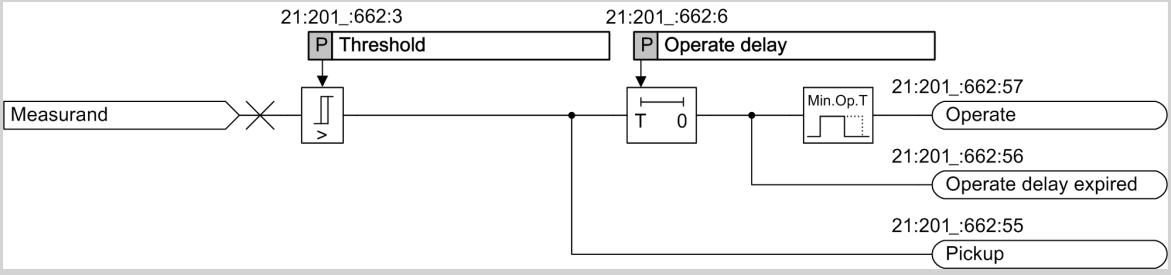
You use the parameter **Blk. Op. Ind. & Fault Rec.** to define whether a function works as a protection or supervision function. Further, you use this to determine the type and scope of the logging (see following table)

Parameter Value	Description
No	The function works as a protection function. It generates an operate indication and starts fault recording with pickup. During fault recording, a fault is created and logged as a fault record in the fault log.
Yes	The function works as a supervision function. The logic runs normally, but without creating the operate indication. The time-out indication is still generated and can be processed further if necessary. No fault recording starts with pickup.

2.4 Text Structure and Reference Number for Settings and Indications

Each parameter and each indication has a unique reference number within every SIPROTEC 5 device. The reference number gives you a clear reference, for example, between an indication entry in the buffer of the device and the corresponding description in the manual. You can find the reference numbers in this document, for example, in the application and setting notes, in the logic diagrams, and in the parameter and information lists.

In order to form explicit texts and reference numbers, each function group, function, function block/stage, and indication or parameter has a text and a number. This means that structured overall texts and numbers are created.



The structure of the texts and the reference numbers follow the hierarchy already shown in *Figure 2-1* :

- Function group:Function:Stage/Function Block:Indication
- Function group:Function:Stage/Function Block:Parameter

The colon serves as a structure element to separate the hierarchy levels. Depending on the functionality, not all hierarchy levels are always available. Function Group and Stage/Function block are optional. Since the function groups, functions as well as tripping stages/function blocks of the same type can be created multiple times, a so-called instance number is added to these elements.

EXAMPLE

The structure of the text and reference number is shown in the protection-function group **Line** as an example of the parameter **`Threshold value`** and the indication **`Pickup`** of the 2nd definite time-overcurrent protection stage of the function **Overcurrent protection, phases** (see *Figure 2-9*). Only one function and one function group exist in the device. The representation of the stage is simplified.

[lostuumz-180311-01.tif, 1, en_US]

Figure 2-9 Stage of the Overcurrent Protection Function, Phases (without Representation of Stage Control)

The following table shows the texts and numbers of the hierarchy elements concerned:

	Name	Number of the Type	Instance Number
Protection function group	Line	2	1
Function	Overcurrent 3ph	20	1
Stage	Definite time-overcurrent protection	66	2
Settings	Threshold value	3	–
Indication	Pickup	55	–

Die Instanznummern ergeben sich wie folgt:

- Function group: Line **1**
  1 instance, because only one **Line** function group exists in the device
- Function: Overcurrent 3ph **1**
  1 instance, because only one **Overcurrent 3ph** function exists in the **Line** function group

- Stage: Definite time-overcurrent protection **2**

  2 instances, because 2 definite time-overcurrent protection stages exist in the **Overcurrent 3ph** function (here the 2nd instance as an example)

This results in the following texts and numbers (including the instance numbers):

Parameter:	**Number**
Line 1:Overcurrent 3-ph 1:Definite time-overcurrent protection 2:Threshold value	21:201:662:3
Indication:	**Number**
Line 1:Overcurrent 3-ph 1:Definite time-overcurrent protection 2:Pickup	21:201:662:55

The structure is simplified accordingly for parameters and indications with fewer hierarchy levels.

2.5 Information Lists

For the function groups, functions, and function blocks, settings and miscellaneous signals are defined that are shown in the settings and information lists.

The information lists summarize the signals. The data type of the information may differ. Possible data types are ENS, ACD, ACT, SPS and MV, etc.

A type is assigned to the individual data types. The following table shows the possible types:

Type	Meaning
I	**I**nput – input signal
O	**O**utput – output signal
C	**C**ontrollable – control signal

EXAMPLE:

The following table shows the types for some data types as examples:

Data Type	Type
ENS	O
ACD	O
ACT	O
SPS	I or O
SPC	C
MV	O

3 System Functions

3.1	Indications	60
3.2	Measured-Value Acquisition	87
3.3	Processing Quality Attributes	89
3.4	Fault Recording	101
3.5	Protection Communication	107
3.6	Date and Time Synchronization	148
3.7	User-Defined Objects	156
3.8	Other Functions	161
3.9	General Notes for Setting the Threshold Value of Protection Functions	170
3.10	Device Settings	178

3.1 Indications

3.1.1 General

During operation, indications deliver information about operational states. These include:

- Measured data
- Power-system data
- Device supervisions
- Device functions
- Function procedures during testing and commissioning of the device

In addition, indications give an overview of important fault events after a failure in the system. All indications are furnished with a time stamp at the time of their occurrence.

Indications are saved in logs inside the device and are available for later analyses. The following number of indications are saved at least in the respective buffer (depending on the scope of the indications):

- Ground-fault log 100 indications
- Fault log 1000 indications
- User-defined log 200 indications
- Operational log 2000 indications

If the maximum capacity of the user-defined log or of the operational is exhausted, the oldest entries disappear before the newest entries. If the maximum capacity of the fault log or of the ground-fault log is reached, the number of the last fault is issued via the signal **Fault log is full**. During a supply-voltage failure, recorded data are securely held by means of battery buffering or storage in the flash memory. You can read and analyze the log from the device with DIGSI 5. The device display and navigation using keys allow you to read and analyze the logs on site.

Indications can be output spontaneously via the communication interfaces of the device and through external demand via general interrogation. In DIGSI 5 indications can be tracked spontaneously in online operation in a special indication window. Indications can be made accessible to higher-level control systems through mapping on various communication protocols.

NOTE

All indications are assigned to certain device functions. The text of each indication contains the corresponding function designation. You will find explanations of the meaning of indications in the corresponding device functions. However, you can also define indications yourself and group them into your own function blocks. These can be set by binary inputs or CFC logic.

Reading Indications

To read the indications of your SIPROTEC 5 device you can use the on-site operation panel of the device or a PC on which you have installed DIGSI 5. The subsequent section describes the general procedure.

3.1.2 Reading Indications on the On-Site Operation Panel

Procedure

The menus of the logs begin with a header and 2 numbers at the top right corner of the display. The number after the slash signifies the number of indications that are available. The number before the slash indicates how many indications have just been selected or shown. The end of the indication list is closed with the entry ***END***.

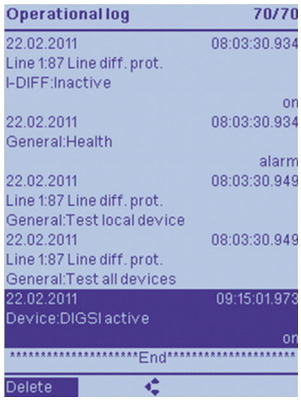


Figure 3-1
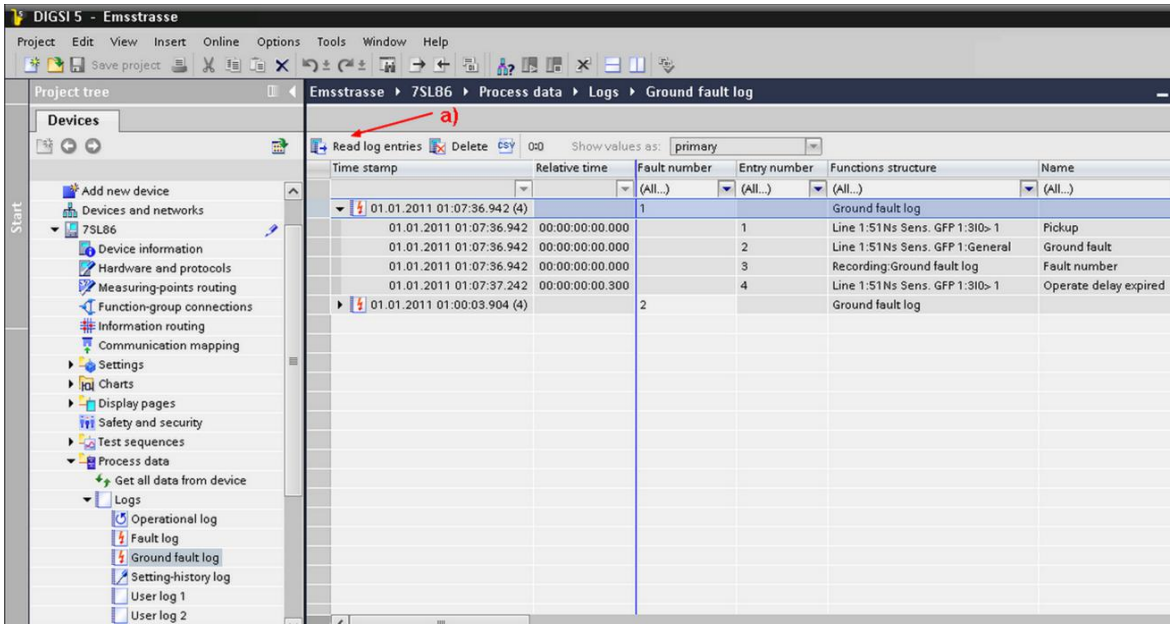
On-Site Display of an Indication List (Example: Operational Indications)

Menu Path	Log
Main menu → Indications →	Operational log Fault log Ground-fault log Setting changes User indications 1 User indications 2
Main menu → Test & Diagnosis → Indications →	Security indications Device diagnosis Communication indications

- ✧ To reach the desired log from the main menu, use the navigation keys of the on-site operation panel.
- ✧ Navigate inside the log using the navigation keys (top/bottom). You will find the most current indication at the top of the list. The selected indication is shown with a dark background.
- ✧ Which indications can be shown in the selected log depends on the assignments in the DIGSI 5 information routing matrix or is pre-defined. You will find information about this in chapter *3.1.5.1 General*.
- ✧ Every indication contains date, time and its state as additional information.
- ✧ In some logs you are given the option of deleting the entire indication list by softkey in the footer of the display. To know more about this, read chapter *3.1.6 Saving and Deleting the Logs*.

NOTE

No password entry is necessary to read indications from the device.



3.1.3 Reading Indications from the PC with DIGSI 5

Procedure

Menu Path (Project)	Log
Project → Device → Process data → Log →	Operational log Fault log Ground-fault log Setting changes User indications 1 User indications 2

Menu Path (Project)	Log
Project → Device → Device information → Log →	Security indication Device diagnosis Communication indications

- ✧ To read the indications with DIGSI 5 your PC must be connected via the **USB user interface** of the on-site operation panel or via an **Ethernet interface** of the device. A direct connection to your PC can be established via the Ethernet interfaces. It is also possible to access all connected SIPROTEC 5 devices via a data network from your DIGSI 5 PC.
- ✧ To reach the desired logs of the SIPROTEC 5 device, use the project-tree window. If you have not set up the device within a project, you can also attain this via **Online access**.
- ✧ After selecting the desired log, you are shown the last state of the log loaded from the device. To update, it is necessary to synchronize with the log in the device.
- ✧ To execute a synchronization with the logs, click the respective button in the headline of the log (see example of ground-fault log in *Figure 3-2* a)).

[scgrflmd-191012-01, 1, en_US]

Figure 3-2 DIGSI 5 Display of an Indication List (Example of Ground-Fault Log)

- ✧ You will find additional information about the deletion and saving of logs in chapter *3.1.6 Saving and Deleting the Logs*.
- ✧ To determine a relative time for all other indications, you can reference the display of log entries, if needed, to the real time of a certain entry. The real-time stamps of events remain unaffected.
- ✧ For this purpose click the respective button in the headline of the log (see example of ground-fault log in *Figure 3-2* a)).

Setting Relative Time Reference

- ✧ Which indications in the selected log can be displayed depends on the assignments in the DIGSI 5 information routing matrix or is predefined. You will find information about this in chapter *3.1.5.1 General*.

3.1.4 Displaying Indications

Displayed indications in DIGSI 5 and on the on-site operation panel are supplemented with the following information:

Table 3-1 Overview of Additional Information

Indications in	DIGSI 5 Information	Device Display Information
Log for operational indications and log for user-defined indications	Time stamp (date and time), Relative time, Increasing entry number, Value, Indication number, Quality, Cause	Time stamp (date and time), Value
log for fault indications	Time stamp (date and time), Relative time, Error number, Increasing entry number, Value, Indication number, Quality, Cause	Time stamp (date and time), Error number, Value
Log for ground-fault indications	Time stamp (date and time), Relative time, Error number, Increasing entry number, Value, Indication number, Quality, Cause	Time stamp (date and time), Error number, Value
Spontaneous indication window (DIGSI 5)	Time stamp (date and time), Error number, Increasing entry number, Value, Indication number, Quality, Cause	Time stamp (date and time), Error number, Value

DIGSI 5: Quality Indication Column

Quality	Meaning
Good	Indication is valid
Invalid	Indication is invalid

DIGSI 5: Additional Information Indication Column

The entries in the column for additional information are in the format Cause/Originator/Additional Cause:

- Cause → What was the cause?
- Originator → Who was the originator?
- Additional cause → Supplementary notes

Cause	Meaning
Data change	Value change in an indication
Data update	Update of notification value
General interrogation	General interrogation

Cause	Meaning
Cyclic	Cyclical general inquiry
Quality change	Change of the notification quality

Initiator	Meaning
Bay	Control local
Substation	Control via the substation
Remote control	Control via the network control center
Field (auto)	Control local via automatic function
Station (auto)	Control via the station via automatic function
Distance (auto)	Control via the network control center via automatic function
Maintenance	Maintenance
Process	Device operation (normal)

Additional Cause	Meaning
Switching authority test failed	Switching authority check failed
Selection failed	Selection failed
invalid position	invalid position
Position attained	Position attained
Settings change running	Settings change running
Final position attained	Final position attained
Impermissible mode	Impermissible mode
Blocking through process	Blocking by the process
Interlocked	Interlocked
Synchrocheck failed	Synchrocheck failed
Command already running	Command already running
Not ready	Not ready
1 out of N control failed	1 out of N control failed
Command cancellation	Command cancellation
Monitoring time expired	Monitoring time expired
Cancellation due to trip command	Cancellation due to trip command
Object not selected	Object not selected
No access right.	No access right
Final position exceeded	Final position exceeded
Target value not attained	Target value not attained
Loss of connection	Loss of connection
Unknown	Unknown
Blocking through command	Blocking through command
Object already selected	Object already selected
Inconsistent parameter(s)	Inconsistent parameter(s)
Blocked by foreign access	Blocked by foreign access
Select time-out	Select time-out
CB not open	Circuit breaker not open
Communication is interrupted	Communication is interrupted
Topology not stable	Topology not stable
FLO in process	Fault locator in processing
Trigger command active	Trigger command active
Close command active	Close command active

Additional Cause	Meaning
Blocked through protection	Blocked through protection
Fault occurred	Fault occurred
CB not closed	Circuit breaker not closed
CB not ready	Circuit breaker not ready
CB not open	Circuit breaker not open
Close command active	Close command active
CB check running	Circuit breaker check running

3.1.5 Logs

3.1.5.1 General

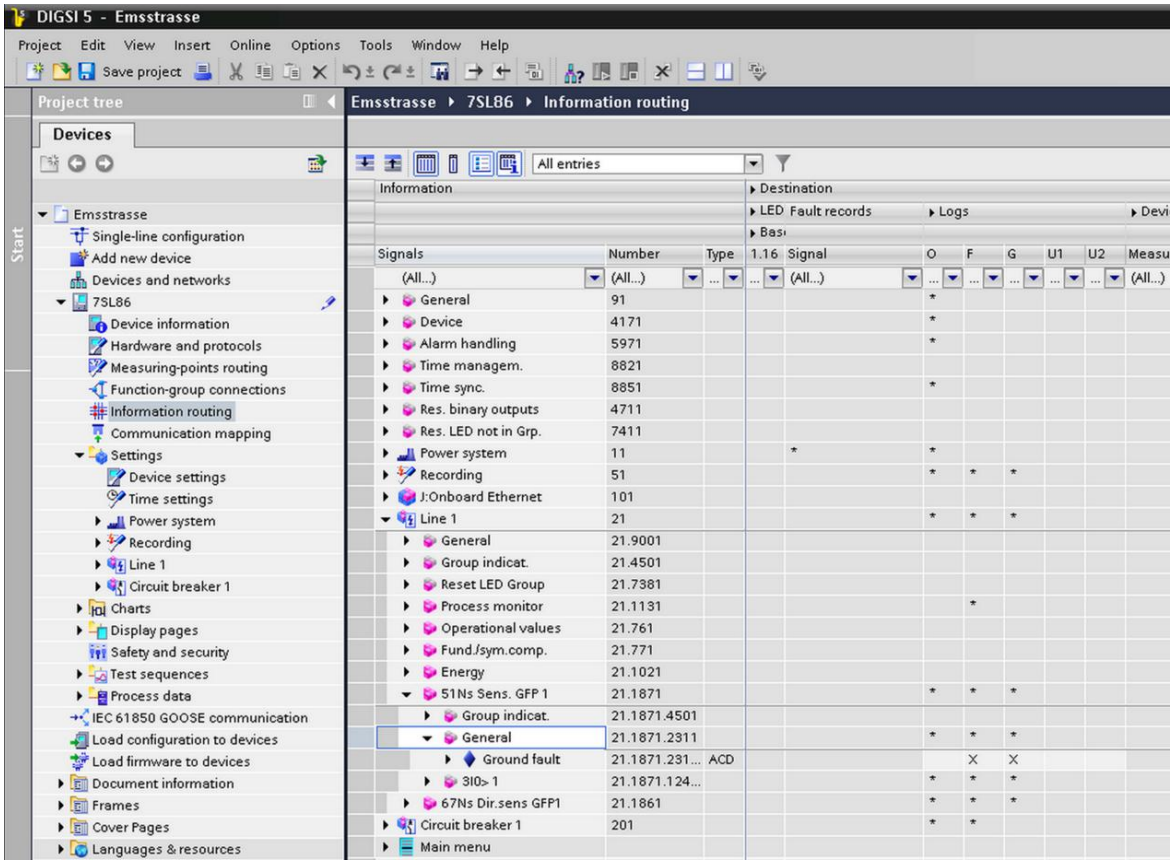
Indications are saved in logs inside the device and are available for later analyses. Different logs allow categorization of indication logging based on operating states (for example, operational and fault logs) and based on fields of application.

Table 3-2 Log Overview

Log	Logging
Operational log	Operational indications
Fault log	Fault indications
Ground-fault log	Ground-fault indications
Setting-history log	Setting changes
User-defined log	User-defined indication scope
Security log	Access with safety relevance
Device-diagnosis log	Error of the device (software, hardware) and the connection circuits
Communication log	Status of communication interfaces
Motor-startup log	Information on the motor startup

Managing Logs

Logs have a ring structure and are automatically managed. If the maximum capacity of a log is exhausted, the oldest entries disappear before the newest entries. If the maximum capacity of the fault or ground-fault log is reached, the number of the last fault is generated via the signal **Fault log is full**. You can route this signal in the information routing. If indications in the information routing of DIGSI 5 are routed to a log, then they are also saved. During a supply-voltage failure, recorded data are securely held by means of battery buffering or storage in the flash memory. You can read and analyze the log from the device with DIGSI 5. The device display and the navigation allow you to read and evaluate the logs on site using keys.



Configurability of Logs

The indication capacity to be recorded in configurable logs (for example, ground-fault log) is laid down in columns of the information routing (matrix) of DIGSI 5 specifically defined for this purpose.

Procedure

- To reach the information routing of your SIPROTEC 5 device, use the project-tree window. Access is only through the project:
  Project → Device → **Information routing**
- Select the associated routing column in the matrix from:
  Target → Log → **Column ground-fault log**

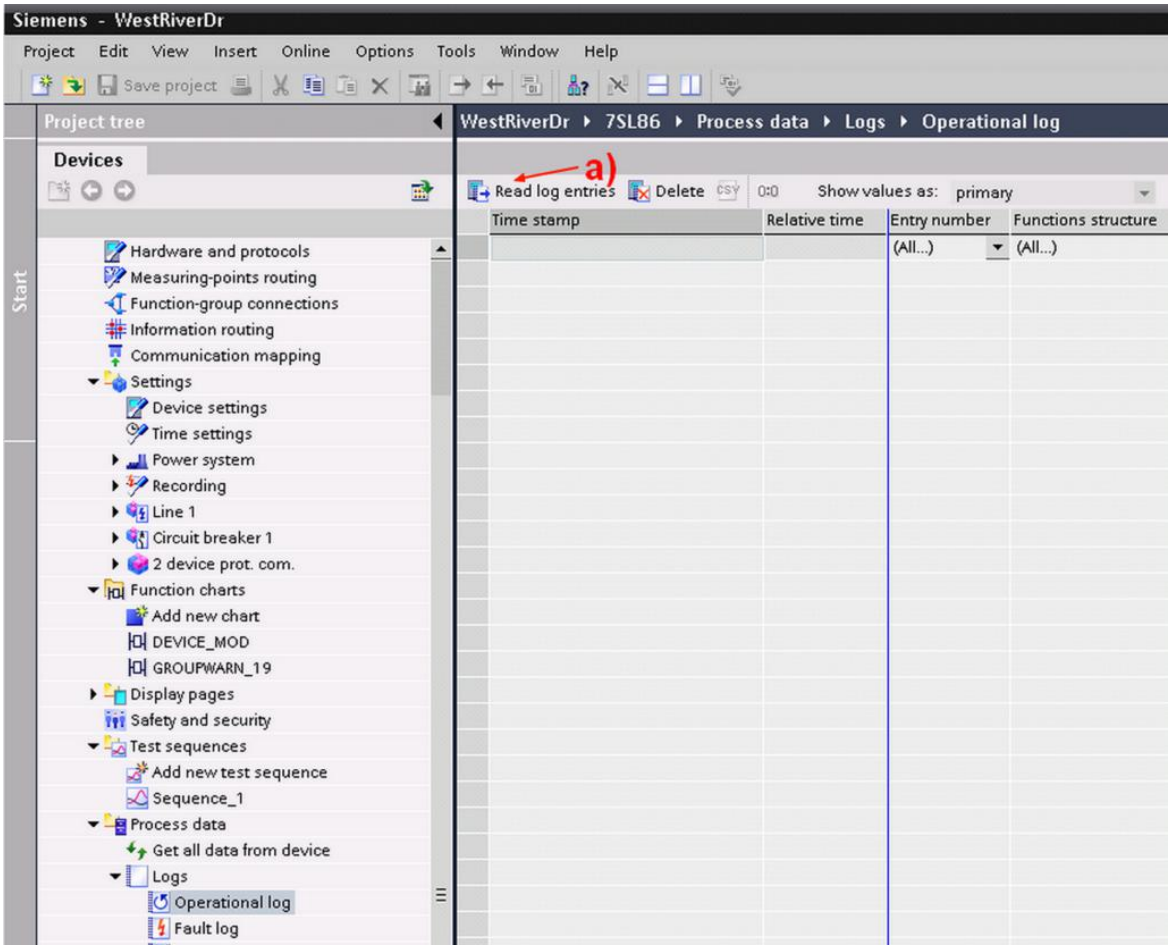
- The routing of the selected indication is done via right click. Select one of the options in the list box shown:
  - Routed (X)
  - Unrouted

[scinfpuf-191012-01, 1, en_US]

Figure 3-3 Indication Configuration in DIGSI 5 (Example: Ground-Fault Log)

For non-configurable logs (for example, setting-history logs) scope and type of logged indications are described separately (see following chapter about logs).

3.1.5.2 Operational Log



Operational indications are information that the device generates during operation. This includes information about:

- State of device functions
- Measured data
- Power-system data

Exceeding or dropping below limiting values is output as an operational indication. Short circuits in the network are indicated as an operational indication **Fault** with sequential fault number. For detailed information about the recording of system incidents, please refer to the description of the fault log (chapter *3.1.5.3 Fault Log*). Up to 2000 indications can be stored in the log.

Reading from the PC with DIGSI 5

- To reach the operational log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **Operational log**
- The status of the operational log last loaded from the device is shown to you. To update (synchronization with the device) click the button **Read log entries** in the headline of the indication list (*Figure 3-4* a)).

[scbetrmd-030211-01, 1, en_US]

Figure 3-4 Reading the Operational Log with DIGSI 5

Reading on the Device Through the On-Site Operation Panel

- To reach the operational log via the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **Operational log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

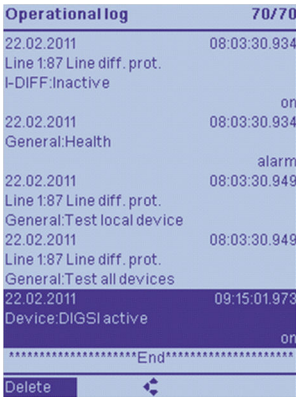


Figure 3-5
On-Site Display of an Indication List (Example: Operational Indications)

Deletability

The operational log of your SIPROTEC 5 device can be deleted. This is done usually after testing or commissioning the device. To know more about this, read chapter *3.1.6 Saving and Deleting the Logs* .

Configurability

The indication scope of the operational log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → **Operational log** column

Selected application templates and functions from the library bring with them a predefined set of operational indications which you can adjust individually at any time.

3.1.5.3 Fault Log

Fault indications are events which arise during a fault. They are logged in the fault log with real-time stamp and relative-time stamp (reference point: fault occurrence) . Faults are numbered consecutively in rising order. With fault recording engaged, a corresponding fault record with the same number exists for every fault logged in the fault log. A maximum of 128 fault logs can be stored. A maximum of 1000 indications can be recorded in each fault log.

Fault Definition

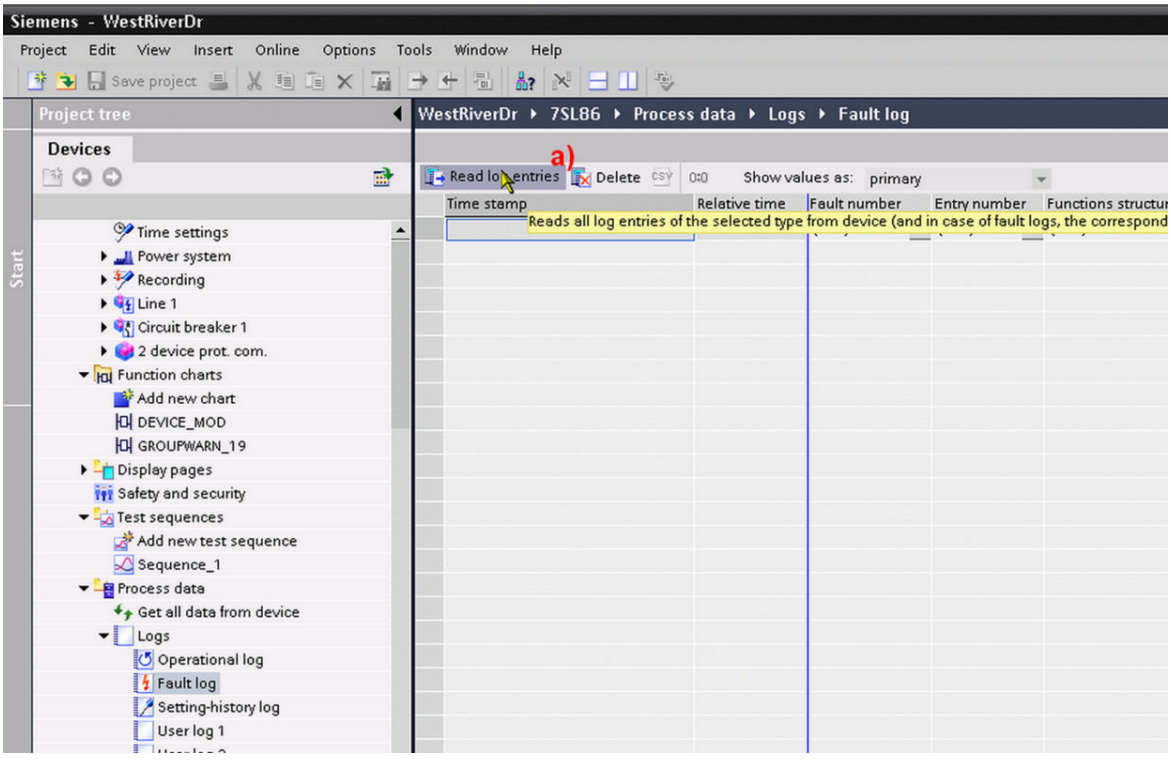
In general, a fault is started by the raising pickup of a protection function and ends with the cleared pickup after the trip command.

When using an automatic reclosing function, the complete reclosing cycle (successful or unsuccessful) is preferably integrated into the fault. If evolving faults appear within reclosing cycles, the entire clearing process is logged under one fault number even in multiple pickup cycles. Without automatic reclosing function every pickup is also recorded as its own fault.

User-defined configuration of a fault is also possible.

NOTE

The definition of the fault is done through settings of the fault recording (see Device manual). Events are logged in the fault log even when fault recording is switched off.



Apart from the recording of fault indications in the fault log, spontaneous display of fault indications of the last fault on the device display is also done. You will find details about this in chapter *3.1.8 Spontaneous Fault Display on the On-Site Operation Panel*.

Reading from the PC with DIGSI 5

- To reach the fault log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **Fault logs**

The status of the fault log last loaded from the device is shown to you.

- To update (synchronization with the device) click the button **Read log entries** in the headline of the indication list.

[scstflmd-030211-01, 1, en_US]

Figure 3-6 Reading the Fault Log with DIGSI 5

Deletability

The fault log of your SIPROTEC 5 device can be deleted. Read about it in chapter *3.1.6 Saving and Deleting the Logs*.

Reading on the Device through the On-Site Operation Panel

- To reach the fault log from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **Fault logs**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

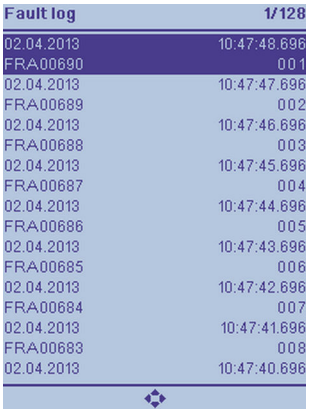


Figure 3-7
Reading the Fault Log on the On-Site Operation Panel of the Device

Configurability

The indication scope of the fault log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → **Fault log** column

Selected application templates and functions from the library already bring a predefined set of operational indications with them which you can adjust individually at any time.

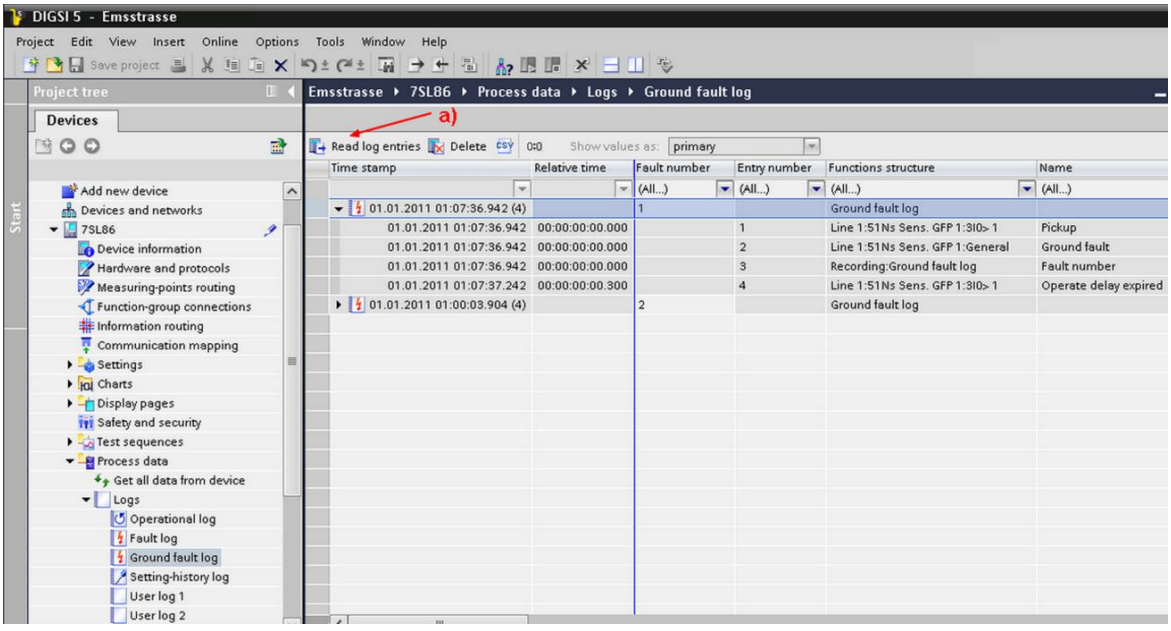
The operational measured values and the measured values of the fundamental components and symmetrical components (see Equipment Manual) are calculated every 9 cycles (at 50 Hz, this is every 180 ms). However, this can mean that the data are not synchronized with the sampled values of the analog channels. The recording of these measured values can be used to analyze the slowly changing processes.

3.1.5.4 Ground-Fault Log

Ground-fault indications are events which arise during a ground fault. They are logged in the ground-fault log with real-time stamp and relative-time stamp (reference point: ground-fault occurrence) . Ground faults are numbered consecutively in rising order. A maximum of 10 ground-fault logs are stored and for each ground-fault log, it is guaranteed that at least 100 indications are recorded.

The following functions can start the logging of a ground fault with the raising ground-fault indication:

- **Directional sensitive ground-fault protection for deleted and isolated systems** (67Ns)
- **Sensitive ground current protection with I0** (50Ns/51Ns)
- **Intermittent ground-fault protection**



The logging ends with the going ground-fault indication.

Reading from the PC with DIGSI 5

- To reach the ground-fault log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process data → Logs → **Ground-fault log**

The status of the device-diagnosis log last loaded from the ground-fault log is shown to you.

- To update (synchronization with the device) click the button **Read log entries** in the headline of the indication list (*Figure 3-8* a)).

[scgrflmd-191012-01, 1, en_US]

Figure 3-8 Reading the Ground-Fault Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the ground-fault log from the main menu, use the navigation keys of the on-site operation panel.

  Main Menu → Indications → **Ground-fault indication**

- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

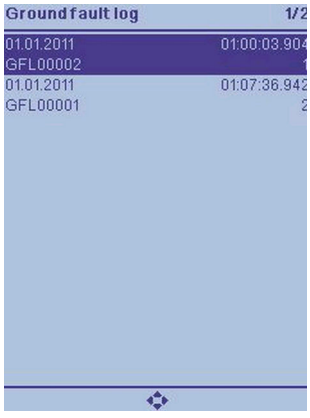


Figure 3-9
Reading the Ground-Fault Log on the On-Site Operation Panel of the Device

Deletability

The ground-fault log of your SIPROTEC 5 device can be deleted. Read about it in chapter *3.1.6 Saving and Deleting the Logs*.

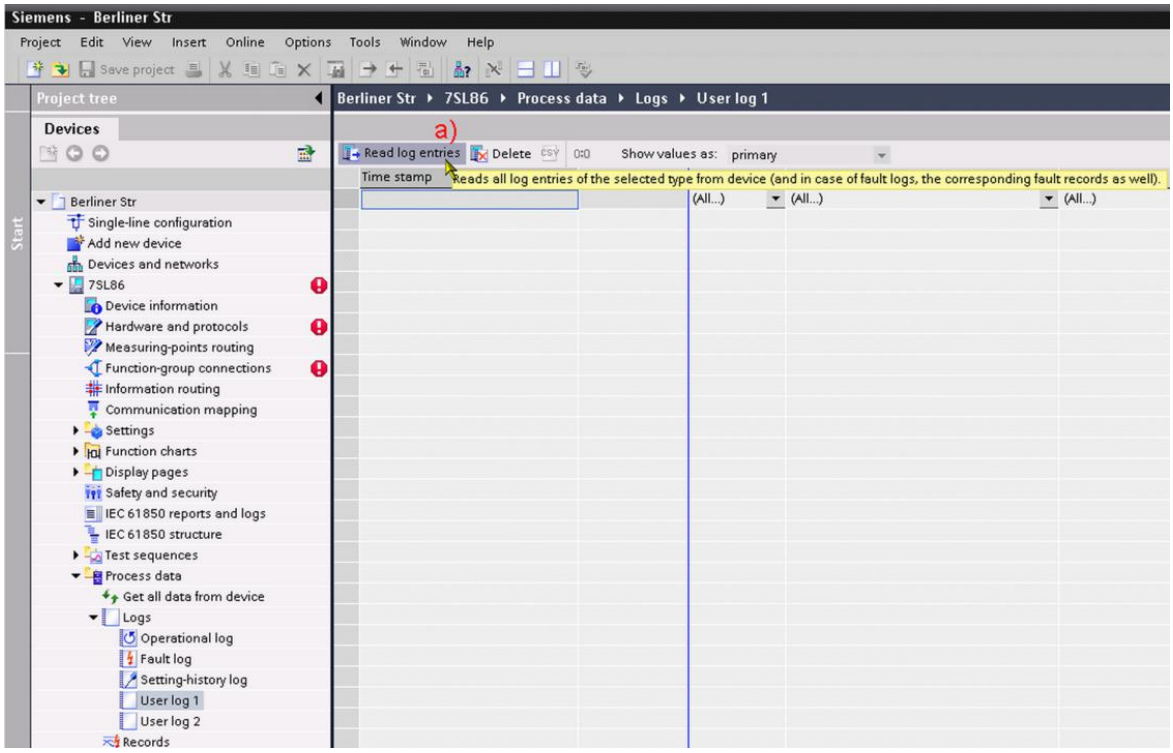
Configurability

The indication scope of the ground-fault log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → Column **Ground-fault log**

Selected application templates and functions from the library already bring a predefined set of operational indications with them which you can adjust individually at any time.

3.1.5.5 User Log



With the user-defined log (up to 2), you have the possibility of individual indication logging parallel to the operational log. This is helpful, for example, in special monitoring tasks but also in the classification into different areas of responsibility of the logs. Up to 200 indications can be stored in the user-defined log.

Reading from the PC with DIGSI 5

- To reach the user-defined log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **User log 1/2**

The status of the user-defined log last loaded from the device is shown to you.

- To update (synchronization with the device) click the button **Read log entries** in the headline of the indication list (*Figure 3-10* a)).

[scanwnmd-030211-01, 1, en_US]

Figure 3-10 Reading the User-Defined Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach user-specific logs from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **User-defined log 1/2**

You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

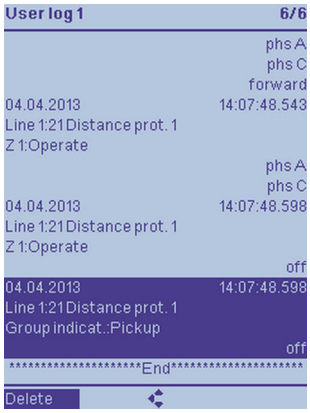


Figure 3-11
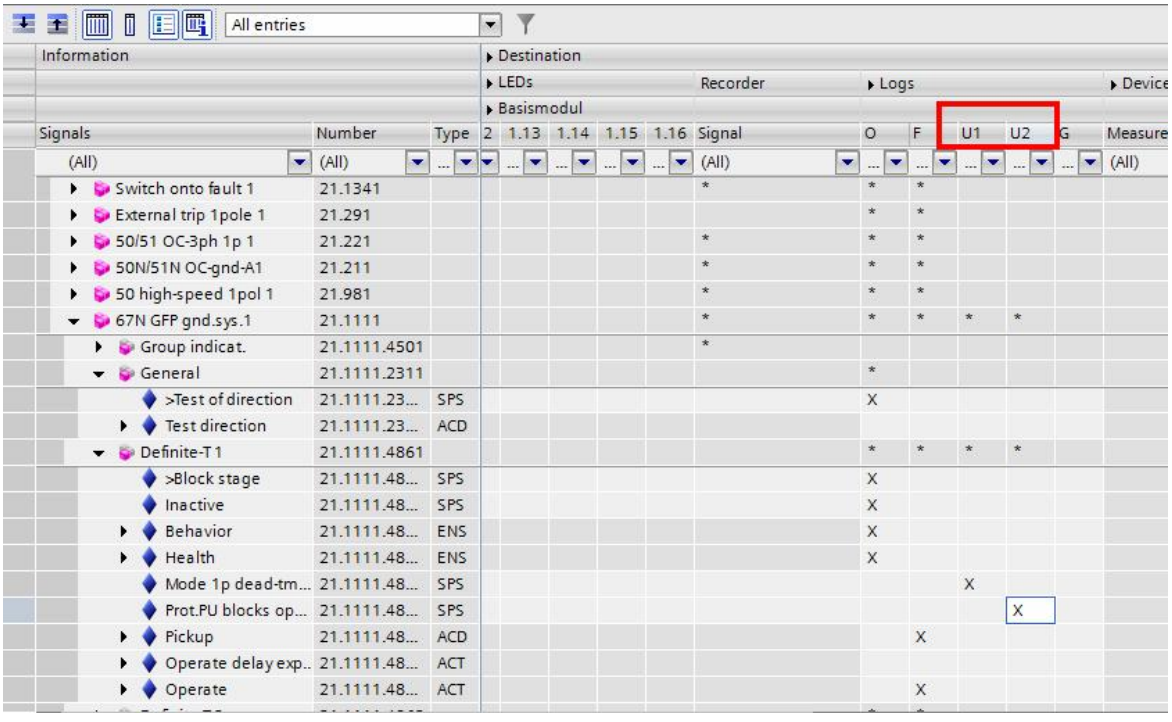
Reading the User-Defined Log on the On-Site Operation Panel of the Device



Deletability

The user-defined log of your SIPROTEC 5 device can be deleted. Read about it in chapter *3.1.6 Saving and Deleting the Logs*.

Configuration of a User-Defined Log

The indication capacity of a created user-defined log can be configured freely in the associated column of the information routing (matrix) of DIGSI 5:

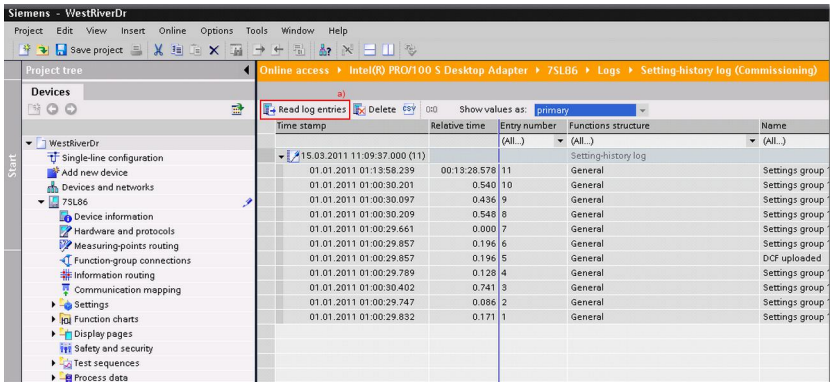
Target → Log → U1 or U2

[scdiu1u2-280415-01, 1, en_US]

Figure 3-12 Indication Configuration in DIGSI 5 (Example: User-Defined Log U1/2)

3.1.5.6 Setting-History Log

All individual setting changes and the downloaded files of entire parameter sets are recorded in the log for setting changes. This enables you to determine setting changes made are associated with events logged (for



example, faults). On the other hand, it is possible to prove with fault analyses, for example, that the current status of all settings truly corresponds to their status at the time of the fault. Up to 200 indications can be stored in the setting-history log.

Reading from the PC with DIGSI 5

- To reach the log for setting changes of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **Setting changes**

The status of the setting-history log last loaded from the device is shown to you.

- To update (synchronization with the device), click the **Read log entries** button in the headline of the indication list (*Figure 3-13*).

[scparamd-030211-01, 1, en_US]

Figure 3-13 Reading the Setting-History Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the setting-history log from the main menu, use the navigation keys of the on-site operation panel.
  Menu → Indications → **Setting changes**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

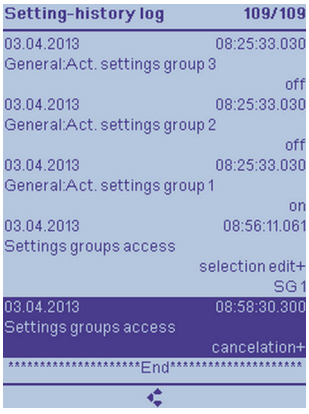


Figure 3-14
Reading the Setting-History Log on the On-Site Operation Panel of the Device

Indication Categories in the Setting-History Log

For this log, there is selected information that is stored in case of successful as well as unsuccessful setting changes. The following list gives you an overview of this information.

Table 3-3 Overview of Indication Types

Displayed Information	Explanation
Selection editing+	Selection of settings group to be edited
Reject+	Rejection of all changes successful
PG activation+	PG activation via command successful
PG activation-	PG activation via command failed
set+	Parameter value was changed
Acceptance+	Acceptance of change successful
Acceptance-	Acceptance of change failed
DCF loaded	DCF loaded into device
SG 1	Settings group 1
SG 2	Settings group 2
SG 3	Settings group 3
SG 4	Settings group 4
SG 5	Settings group 5
SG 6	Settings group 6
SG 7	Settings group 7
SG 8	Settings group 8

Example of Logging in Setting-History Log

For this log, there is selected information that is stored in case of successful as well as unsuccessful setting changes. The following list gives you an overview of this information.

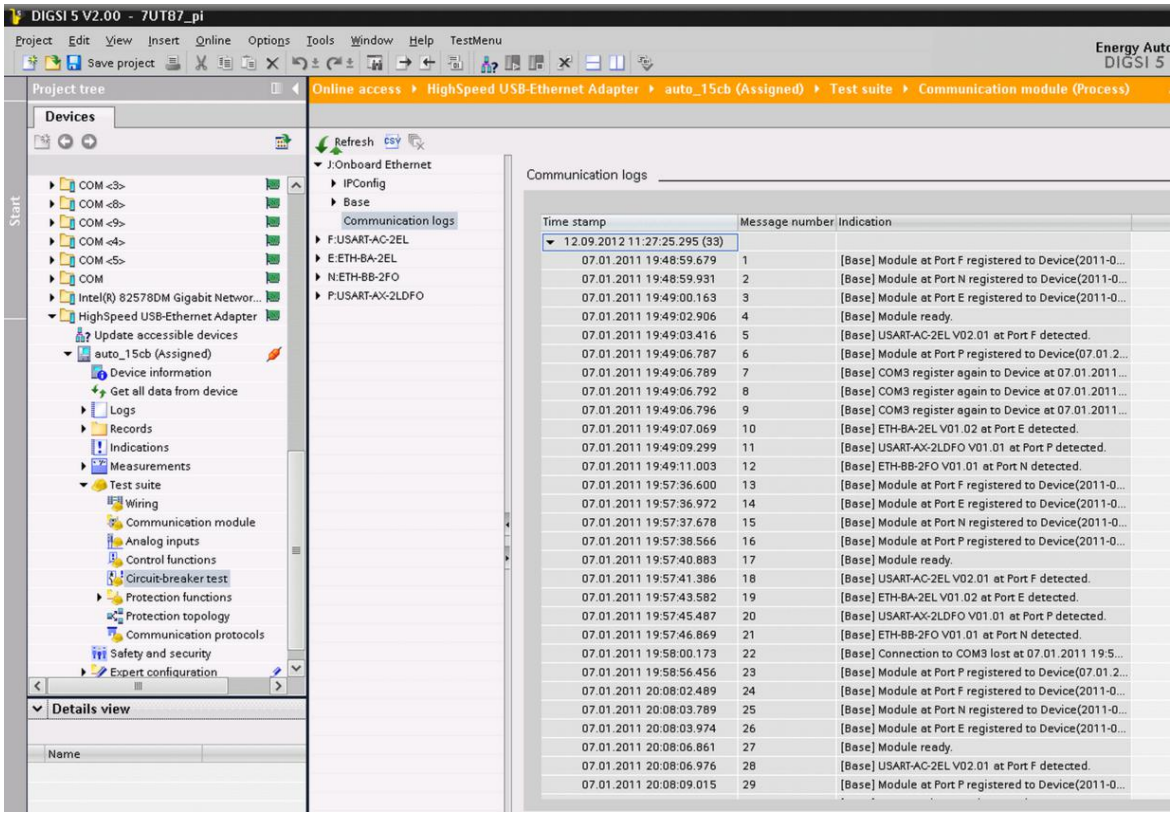
From top downward:

- In the example at the left, a device has started with the active settings group 1.
- Then the settings group 1 is selected for changes.
- The individual parameter for phase-rotation reversal was changed.
- The changes were successfully accepted.

NOTE

- The logged indications are preconfigured and cannot be changed!
- This log, which is organized as a ring buffer. cannot be deleted by the user!
- If you want to archive security-relevant information without loss of information, you must regularly read this log.
- You cannot route additional indication objects to the setting-history log.

3.1.5.7 Communication Log



The logging of the respective status such as ensuing faults, test and diagnosis operation, and communication capacity utilizations is done for all hardware-based configured communication interfaces. Up to 500 indications can be stored in the communication log. Logging occurs separately for each communication port of the configured communication modules.

Reading from the PC with DIGSI 5

- Use the project-tree window to reach the communication logs of your SIPROTEC 5 device.
  Online access → USB → Project → Test suite → Communication module
- Then select:
  J:Onboard Ethernet → **Communication log**

The status of the communication log last loaded from the device is shown to you under the Time stamp item.

- To update (synchronization with the device) click the button **Update** in the headline of the indication list.

[sccompuf-140912-01, 1, en_US]

Figure 3-15 Reading the Communication Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the communication log from the main menu, use the navigation keys on the on-site operation panel.
  Main Menu → Test & Diagnosis → Indications → **Communication log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

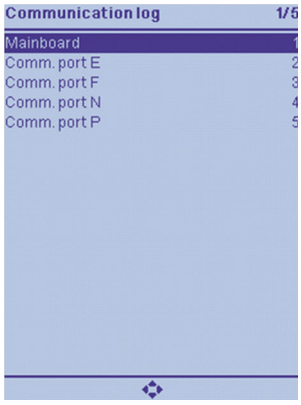


Figure 3-16
Reading the Communication Log on the On-Site Operation Panel of the Device

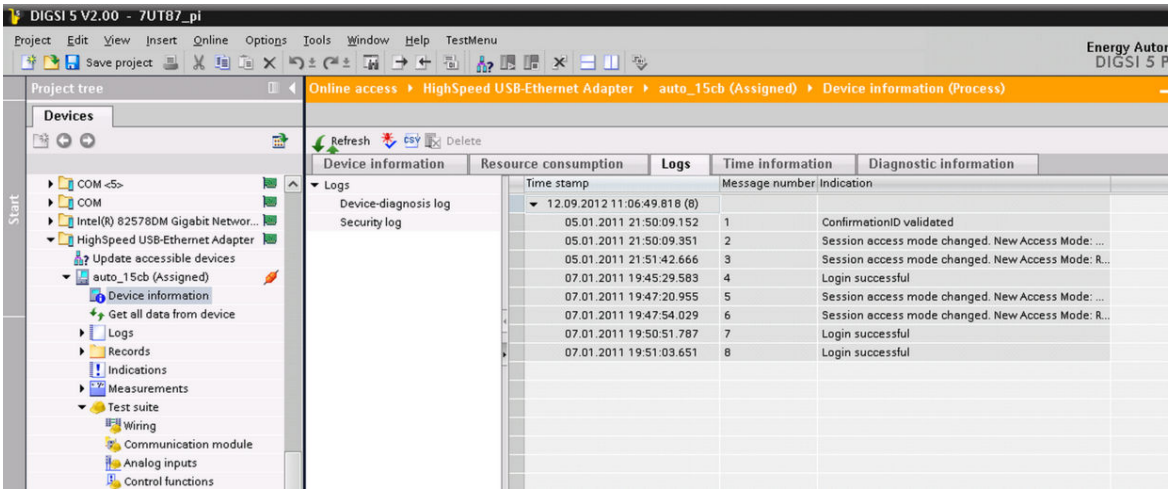
Deletability

The communication logs of your SIPROTEC 5 device can be deleted. Read details about this in chapter *3.1.6 Saving and Deleting the Logs*.

Configurability

The communication logs are not freely configurable. The entries are preconfigured.

3.1.5.8 Security Log



Access to areas of the device with restricted access right is recorded in the security log. Unsuccessful and unauthorized access attempts are also recorded. Up to 500 indications can be stored in the security log.

Reading from the PC with DIGSI 5

- To reach the security log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Device Information → Log → **Security log**

The status of the security log last loaded from the device is shown to you.

- To update (synchronization with the device) click the button **Update** in the headline of the indication list.

[scsecmld-140912-01, 1, en_US]

Figure 3-17 Reading the Communication Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the security log from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Test & Diagnosis → Indications → **Security log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

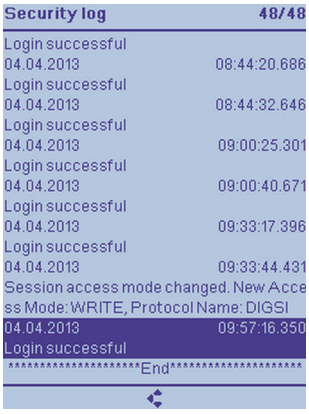


Figure 3-18
Reading the Security Log on the On-Site Operation Panel of the Device

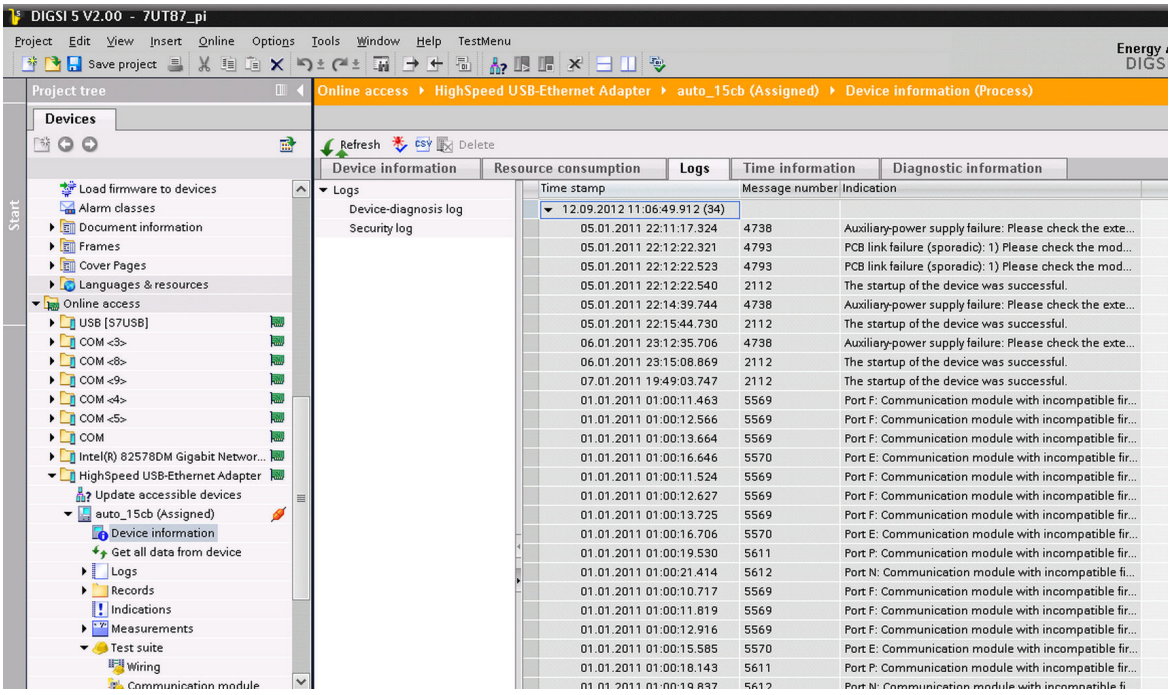
NOTE

- The logged indications are preconfigured and cannot be changed!
- This log, which is organized as a ring buffer. cannot be deleted by the user!
- If you want to archive security-relevant information without loss of information, you must regularly read this log.

3.1.5.9 Device-Diagnosis Log

The logging and the display of concrete instructions are done in the device-diagnosis log during

- Required maintenance (for example, battery supervision)
- Identified hardware defects
- Compatibility problems



Up to 500 indications can be stored in the device-diagnosis log. In normal operation of the device, it is sufficient for diagnostic purposes to follow the entries of the operational log. This specific significance is assumed by the device-diagnosis log when the device is no longer ready for operation due to hardware defect or compatibility problems and the fallback system is active.

Reading from the PC with DIGSI 5 in Normal Operation

- To reach the device-diagnosis log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Device Information → Log → **Device-diagnosis log**

The status of the device-diagnosis log last loaded from the device is shown to you.

- To update (synchronization with the device) click the button **Update** in the headline of the indication list.

[scdevdia-140912-01, 1, en_US]

Figure 3-19 Reading the Device-Diagnosis Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel in Normal Operation

- To reach the diagnosis log from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Test & Diagnosis → Indications → **Device diagnosis**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

Figure 3-20
Reading the Device-Diagnosis Log on the On-Site Operation Panel of the Device

NOTE

- The device-diagnosis log cannot be deleted!
- The logged indications are preconfigured and cannot be changed!

3.1.6 Saving and Deleting the Logs

Deleting the logs of the device in the operating state is unnecessary. If storage capacity is no longer sufficient for new indications, the oldest indications are automatically overwritten with new incoming events. In order for the memory to contain information about the new faults in the future, for example, after an inspection of the system, a deletion of the log makes sense. Resetting the logs is done separately for the various logs.

NOTE

Before you delete the content of a log on your SIPROTEC 5 device, save the log with DIGSI 5 on the hard disk drive of your PC.

NOTE

Not all logs of your SIPROTEC 5 device can be deleted. These limitations apply especially to logs with relevance for security and after-sales (security log, device-diagnosis log, setting-history log).

NOTE

Upon deletion of the fault log, the associated fault records are also deleted. In addition, the meters for fault number and fault-record number are reset to 0. In contrast, if you delete fault records, the content of the fault log, including the allocated fault numbers, remains.

NOTE

If the device executes an initial start, for example, after an update of the device software, the following logs are automatically deleted:

- Operational log
- Fault log
- Ground-fault log
- Setting-history log
- User log
- Motor-startup log

Back up the deletable logs using DIGSI 5.

NOTE

If a ground fault is currently active, the ground-fault log cannot be deleted.

Deleting Logs on the On-Site Operation Panel

- To reach the selected log from the main menu, use the navigation keys of the on-site operation panel (example operational log):
  Main Menu → Indications → **Operational log**

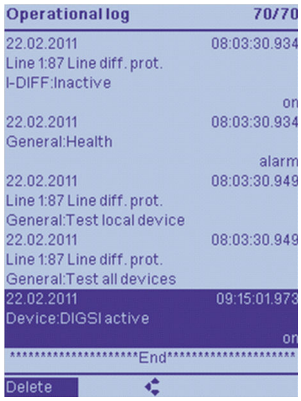


Figure 3-21
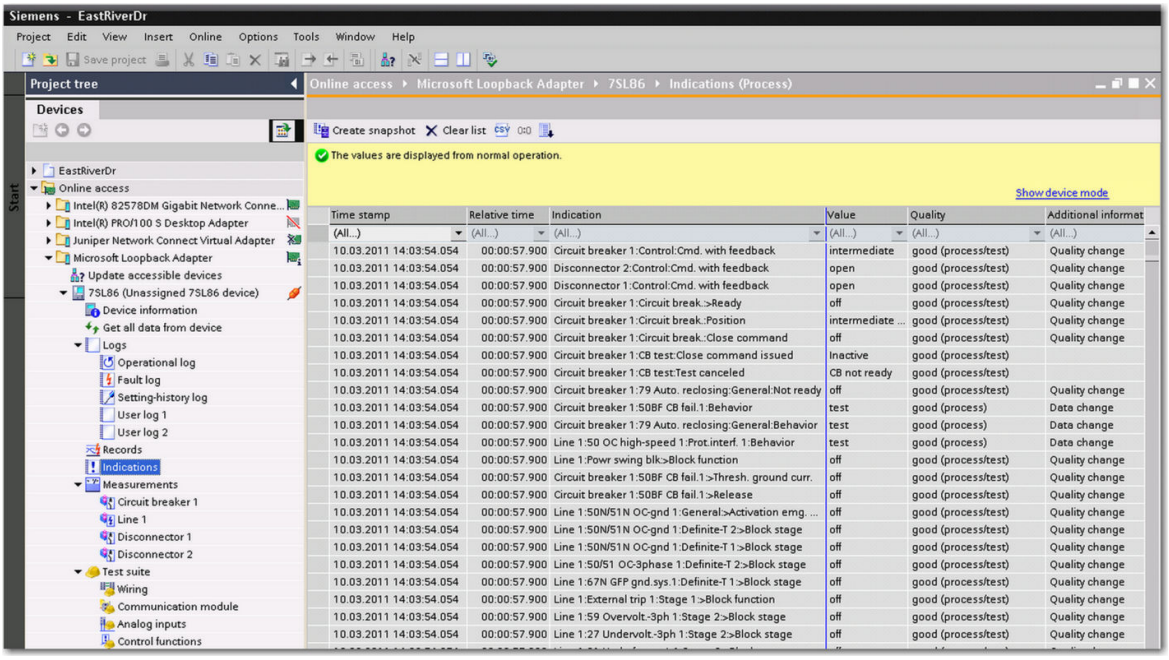
Deleting the Operational Log on the On-Site Operation Panel

- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.
- The option to delete the entire log is offered to you in the footer of the display at the bottom left. Use the softkeys below under the display to activate the command prompts. Confirm the request to **Delete**.
- After being prompted, enter the password and confirm with **Enter**.
- After being prompted, confirm the **Deletion of all entries** with **Ok**.

Deleting Logs from the PC with DIGSI 5



- To reach the selected log of your SIPROTEC 5 device, use the project-tree window (for example, operational log).
  Project → Device → Process data → Logs → **Operational log**

3.1.7 Spontaneous Indication Display in DIGSI 5

With DIGSI 5 you have the possibility of displaying all currently transmitted indications of the selected device in a special indication window.

Procedure

- Call up the spontaneous indications of your selected device in the navigation window under Online access.
- Click **Indications** in the path:
  Online access → Interface → Device → **Indications**
- The raising indications appear immediately without you having to wait for a cyclical update or initiate the manual update.

[scspnmld-230211-01, 1, en_US]

Figure 3-22 Displaying Spontaneous Device Indications in DIGSI 5

3.1.8 Spontaneous Fault Display on the On-Site Operation Panel

After a fault, the most important data of the last fault can be displayed automatically on the device display without further operational measures. In SIPROTEC 5 devices, protected objects and even circuit breakers can be freely created and configured depending on the application (even several instances). In DIGSI 5, several spontaneous fault displays can be configured, depending on the application, with each individual one being assigned a particular circuit breaker. These displays remain stored in the device until they are manually confirmed or reset by LED reset.

Configuration of a Spontaneous Fault Display with DIGSI 5

- To reach the **Fault-display configuration** of your SIPROTEC 5 device, use the project-tree window. Project → Device → Display pages → **Fault-display configuration**
- In the main window, all configured circuit breakers are displayed. A list of a maximum of 6 configurable display lines is offered for each circuit breaker. The activation of a spontaneous fault display occurs for each circuit breaker by selection via checkmark in the column **Display**.
- With the parameter **`(_:139) Fault-display`** (under Device → Parameter → Device settings) you determine whether spontaneous fault displays should be displayed for each pickup or only pickups with the off command.

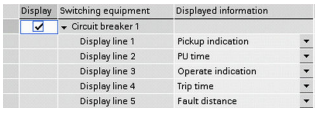


Figure 3-23 Configuration of the Spontaneous Fault Display on the Device

For every display line the following display options can be selected:

Table 3-4 Overview of Display Options

Displayed Information	Explanation
Pickup indication	Display of the first function stage picked up in a fault, as needed with additional information (phases, ground, direction).
PU time	Display of the entire pickup duration of the fault.
Operate indication	Display of the first function stage triggered in a fault, as needed with additional information (phases).
Trip time	Display of the operate time related to the beginning of the fault (pickup start).
Fault distance	Display of the measured fault-location distance.

Acknowledgement of the Spontaneous Fault Display on the Device

After faults, the last occurred fault is always displayed to you. In cases where more than one circuit breaker is configured, several stored fault displays can be present after faults, with the latest being displayed. These displays remain stored in the device until they are manually acknowledged or reset by LED reset.

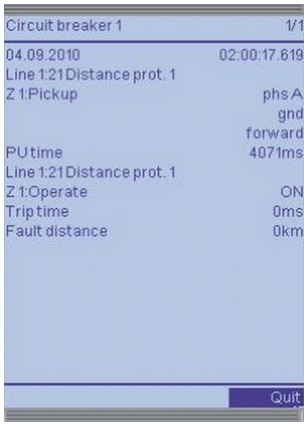

Figure 3-24
Spontaneous Fault Display on the Device

Method 1: Manual acknowledgement

- Press the softkey button **Quit** in the base bar of the display. The display is irretrievably closed. Repeat this step until no spontaneous fault display appears anymore.
- After completion of all confirmations the last display view is showed before the faults.

Method 2: Acknowledgement via LED reset

- An LED reset (device) causes the reset of all stored LEDs and binary output contacts of the device and also to the confirmation of all fault displays stored in the display.

You can find more details on the topic of LED reset in chapter *3.1.9 Stored Indications in the SIPROTEC 5 Device*.

3.1.9 Stored Indications in the SIPROTEC 5 Device

In your SIPROTEC 5 device, you can also configure indications as **stored**. This type of configuration can be used for LEDs as well as for output contacts. The configured output (LED or contact) is activated until it is acknowledged. Acknowledgment occurs via:

- On-site operation panel
- DIGSI 5

- Binary input
- Protocol of substation automation technology

Configuration of Stored Indications with DIGSI 5

- In the **Information Routing** of each device set up in DIGSI 5, you can route binary signals, among others, to LEDs and output contacts. For this, go to the project tree.
  Project → Device → **Information routing**
- Right-click the routing field of your binary indication in the desired LED or binary output column in the routing range of the targets.

You are offered the following options:

Table 3-5 Overview of Routing Options

Routing Options		LEDs	BOs	BIs	Description
H	(active)			X	The signal is routed as active with voltage.
L	(active)			X	The signal is routed as active without voltage.
V	(unlatched)	X	X		The signal is routed as unlatched. Activation and reset of the output (LED, BA) occurs automatically via the binary-signal value.
L	(latched)	X	X		The binary signal is latched when the output (LED) is activated. To reset, a targeted confirmation must occur.
NT	(stored only with tripping)	X			Fault indications are stored when the output (LED) is activated. If the fault is ended via a trip command from the device, the stored state is maintained. In case of dropout of the pickup without trip command from the device (for example, external fault), the state displayed before the fault is restored. **Note**: Observe here the parameter **(_:91:139) Fault-display** with the setting options ***with trip*** or ***with pickup***. For this routing option, select the setting ***with trip***.
TL	(stored only with tripping)		X		Routing option TL (tripping stored) is only possible for the switching object circuit breaker. The output is saved with protection tripping. The contact remains activated until acknowledged. Control commands are not affected. A control command is pending above the parameterized command period until feedback has been successfully received. **Note**: You can realize the functionality of the **Lockout** (ANSI 86) by storing the output relay with the routing option TL.

Acknowledgment of Stored Indications on the On-Site Operation Panel

Acknowledgment via **LED Reset**

Operating the button first causes the activation of all LEDs (LED test) when pressed, and when released the resetting of all stored indications. Stored LEDs, output contacts and spontaneous fault displays are reset.

Acknowledgment via the operating menu

Use the navigation buttons of the on-site operation panel, in order to reach the reset functions from the main menu.

- Select: Main menu → Device functions → **Reset functions**
  You are offered different reset options.
- Open the corresponding submenu.

Figure 3-25 Reset Functions on the On-Site Operation Panel

- Use **Res. binary outputs** to reset stored output contacts.
- Actuate the softkey **Start** in the base bar.
- As needed, enter the confirmation ID when requested and then confirm with the softkey **Enter**.
- Use **Reset LEDs not in FG** to reset stored LEDs that are not assigned to a special function group.
- Actuate the softkey **Start** in the base bar.
- As needed, enter the confirmation ID when requested and then confirm with the softkey **Enter**.

Depending on device configuration, the protection function group(s) are displayed to you as submenus for which separately corresponding, stored LEDs can be reset.

- Go to the submenu of the selected function group (example **Line 1**).
- Use **Reset LEDs** to reset stored LEDs in the selected function group.
- Actuate the softkey **Start** in the base bar.
- As needed, enter the confirmation ID when requested and then confirm with the softkey **Enter**.

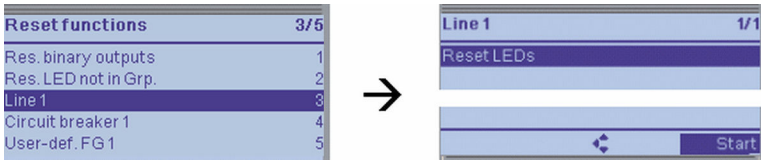

Figure 3-26 Reset Functions on the On-Site Operation Panel (for Example, Line FG)

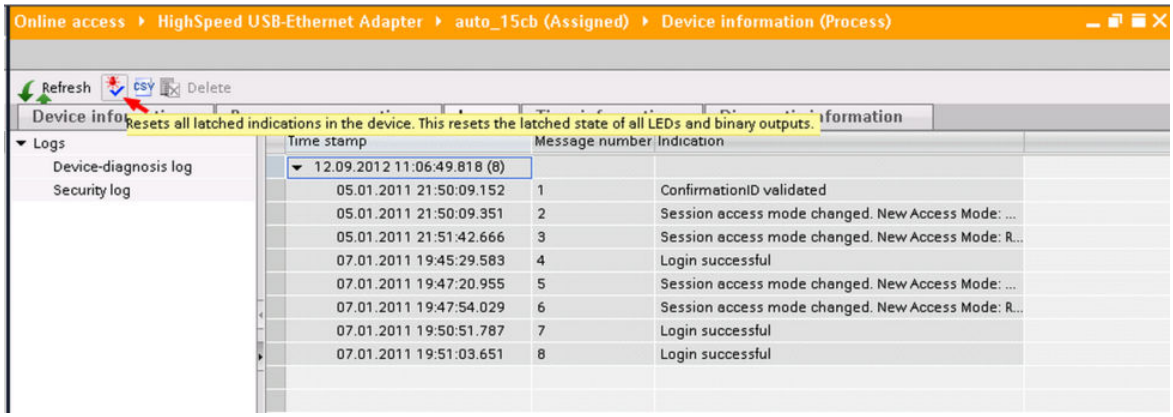
Acknowledgment of Stored Indications via Binary Inputs



Acknowledgment via entry **>LED Reset**

Acknowledgment via binary input **>LED-Reset** brings about the activation of all LEDs (LED test) and, in case of dropout of signal, the resetting of all stored indications. Stored LEDs, output contacts and spontaneous fault displays are reset.

Acknowledgment of Stored Indications with DIGSI 5

You can acknowledge stored indications via DIGSI 5 in online mode. For this, go to the project tree.

- Select Online access → Interface → Device → **Device information**

[scquiled-140912-01, 1, en_US]

Figure 3-27 LED Reset via DIGSI 5

- Click the LED reset button.
- Enter the confirmation ID.
- Confirm the process with OK.

Stored LEDs, output contacts and spontaneous fault displays are reset on the assigned device.

Acknowledgment of Stored Indications via Log

Initiation of acknowledgment of stored indications can also occur through communication via a connected substation automation technology. This can occur in conformance to standards (IEC 61850, IEC 60870-5-103) or via configuration (mapping) of the LED reset input signal for any protocol. Stored LEDs, output contacts, and spontaneous fault displays are reset.

NOTE

The acknowledgment of **stored** indications then leads to the resetting of configured LEDs and output contacts, as long as these active unstored indications are not present in parallel. That is, indications configured as **unstored** are not affected by the acknowledgment process.

3.1.10 Resetting Stored Indications of the Function Group

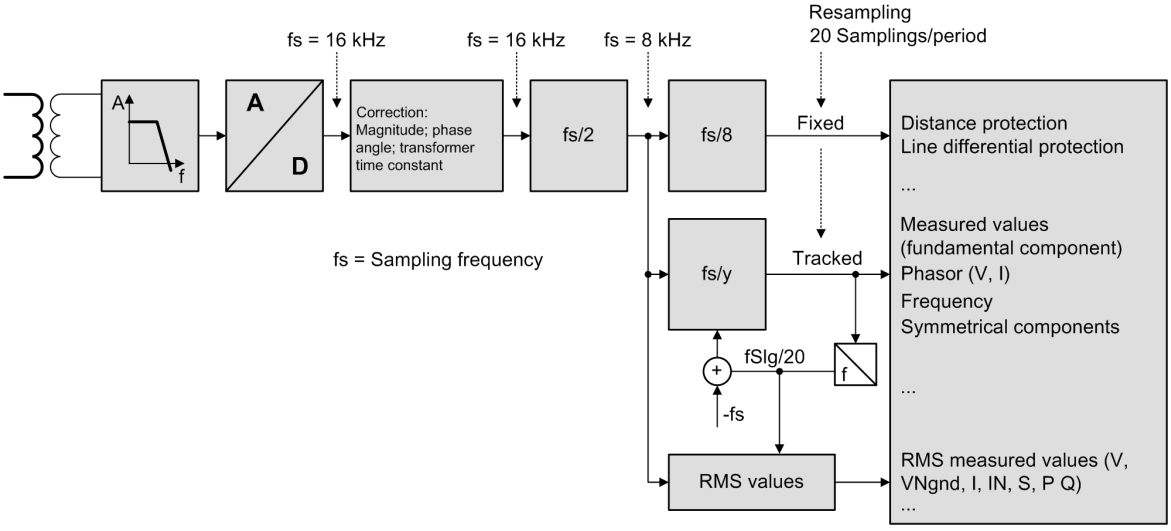
You can configure indications of individual functions as "stored" in a function group. This type of configuration can be used for LEDs as well as for output contacts. The configured output (LED or contact) is activated until it is acknowledged.

The protection and the circuit-breaker function groups contain the block **Reset LED FG**. The block **Reset LED FG** is visible only in the Information routing under the corresponding function group in DIGSI 5. You use the binary input signal *>Reset LED* to reset the stored LEDs in the respective function group. The configured outputs (contacts) are not reset.

3.1.11 Test Mode and Influence of Indications on Substation Automation Technology

If the test mode of the device or of individual functions is switched on, the SIPROTEC 5 device marks indications sent to substation automation technology station control system with an additional test bit. This test bit makes it possible to determine that an indication was set during a test. Necessary reactions in normal operation on the basis of an indication can thus be suppressed.

3.2 Measured-Value Acquisition



Basic Principle

SIPROTEC 5 devices are equipped with a powerful measured-value acquisition function. In addition to a high sampling frequency, they have a high measurand resolution. This ensures a high degree of measuring accuracy across a wide dynamic range. The 24-bit sigma/delta analog-digital converter represents the core of measured-value acquisition. In addition, the oversampling function supports the high measurand resolution. Depending on the requirements of the individual method of measurement, the sampling frequency is reduced (**Downsampling**).

In digital systems, deviations from the rated frequency lead to additional errors. In order to avoid this, 2 algorithm-dependent processes are used in all SIPROTEC 5 devices:

- Sampling-frequency tracking:
  The analog input channels are scanned for valid signals in cycles. The current power frequency is determined and the required sampling frequency is defined by using a **resampling algorithm**. The tracking is effective in the frequency range between 10 Hz and 80 Hz.
- Fixed sampling frequency – correction of the filter coefficients:
  This method operates in a limited frequency range (f_{rated} +/- 5 Hz). The power frequency is determined and, depending on the degree of the frequency deviation, the filter coefficients are corrected.

The following figure shows the basics of dealing with sampled values (SAV) in the measured-value acquisition chain. *Figure 3-28* shows to whom the various sampling frequencies are made available. In order to limit the bandwidth of the input signals, a low-pass filter (anti-aliasing filter to maintain the sampling theorem) is installed downstream. After sampling, the current input channels are adjusted. This means the magnitude, phase, as well as the transformer time constant are corrected. The compensation is designed to ensure that the current transformer terminal blocks can be exchanged randomly between the devices.

[dwmeserf-250211-01.tif, 1, en_US]

Figure 3-28 Measured-Value Acquisition Chain

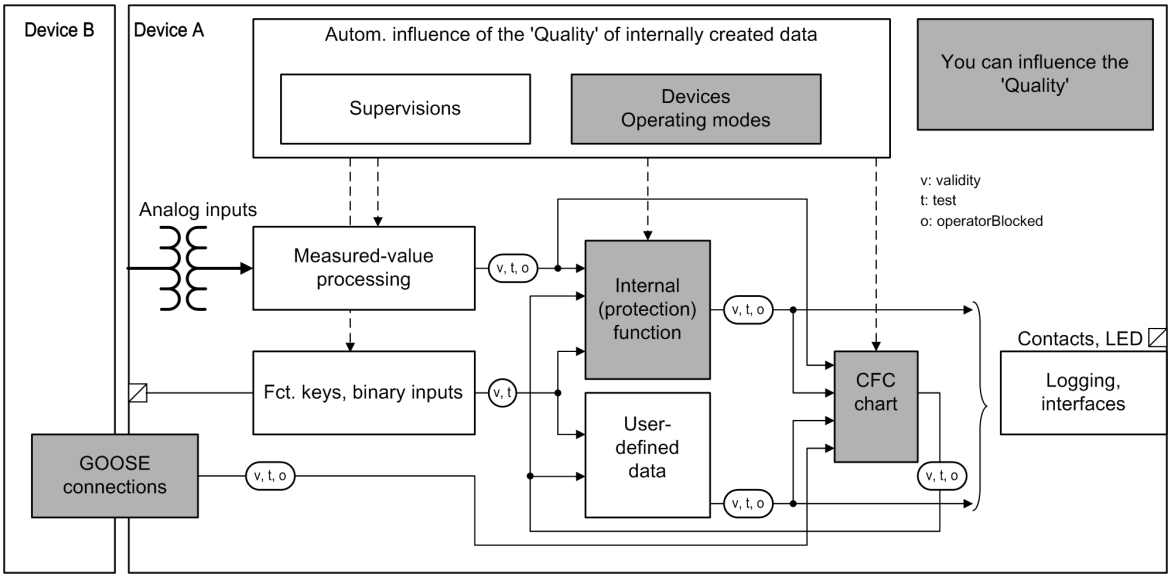
The internal sampling frequency of the SIPROTEC 5 devices is fixed at 16 kHz (sampling rate: 320 samplings per 50-Hz cycle). All current and voltage inputs are sampled. If the magnitude, phase, and transformer time constant are corrected, the sampling frequency is reduced to 8 kHz (160 samplings per 50-Hz cycle). This is the basic sampling frequency to which various processes, such as fault recording, RMS measured values, refer. For the RMS measurement, the measured-value window is adjusted on the basis of the power frequency. For numerous measurement and protection applications , 20 samplings per cycle are sufficient (if f_{rated} = 50 Hz: sampling every 1 ms, at f_{rated} = 60 Hz: sampling every 0.833 ms). This sampling rate is an adequate compromise between accuracy and the parallel processing of the functions (multi-functionality).

The 20 samplings per cycle will be made available to the algorithms processed in the function groups, in 2 variants:

- Fixed (not resampled)
- Resampled (frequency range from 10 Hz to 80 Hz)

Depending on the algorithms (see function descriptions), the respective data flow is considered. A higher sampling frequency is used for selected methods of measurement. Detailed information can be found in the corresponding function description.

NOTE



The measuring points for current and voltage are in the **Power-system data** (starting in chapter *6.1 Power-System Data*). Each measuring point has its own parameters.

3.3 Processing Quality Attributes

3.3.1 Overview

The IEC 61850 standard defines certain quality attributes for data objects (DO), the so-called Quality. The SIPROTEC 5 system automatically processes some of these quality attributes. In order to handle different applications, you can influence certain quality attributes and also the values of the data objects on the basis of these quality attributes. This is how you can ensure the necessary functionality.

The following figure describes roughly the general data flow within a SIPROTEC 5 device. The following figure also shows at which points the quality can be influenced. The building blocks presented in the figure are described in more detail in the following.

[loquali1-090212-02.tif, 2, en_US]

Figure 3-29 Data Flow within a SIPROTEC 5 Device

Supported Quality Attributes

The following quality attributes are automatically processed within the SIPROTEC 5 system.

- **Validity** using the values *good* or *invalid*

  The **Validity** quality attribute shows if an object transferred via a GOOSE message is received (valid, invalid) or not received (invalid). The *invalid* state can be suppressed in the receiver device by also setting a substitute value for the object that is not received (see *Figure 3-30*). The substitute value is forwarded to the functions.

  If the device receives one of these values, it is replaced by the *invalid* value and thus processed further as *invalid*.

  If one of the detailed quality attributes (detailQual) has the value *TRUE*, then **Validity** is set to the *invalid* value, unless this was already done at the transmitter end.

- **Test** using the values *TRUE*, *FALSE*

  The **Test** quality attribute indicates to the receiver device that the object received via a GOOSE message was created under test conditions and not operating conditions.

- **OperatorBlocked** using the values *TRUE*, *FALSE*

  The **OperatorBlocked** quality attribute indicates whether an object transferred via GOOSE message originates from a device that is in a *functional logoff* state. When the sending device is switched off, the object is no longer being received and assumes the *invalid* state. However, since the **OperatorBlocked** quality was previously identified on the receiver device, the object can be treated differently at the receiving end (see chapter *3.3.2 Quality Processing/Affected by the User for Received GOOSE Values*). At the receiving end, the object may be treated like a dropped signal.

- **Source** using the values *process*, *substituted*

  The **Source** quality attribute indicates whether the object was updated in the sending device.

  You can find more detailed information in chapter *3.8.2 Acquisition Blocking and Manual Updating*.

Influencing Quality by the Operating Modes

In addition to the normal operation, the device also supports further operating modes that influence quality:

- **Test mode of the device**

  You can switch the entire device to test mode. In this case, all data objects generated in the device (state values and measured values) receive the quality attribute **Test** = *TRUE*.

  The CFC charts are also in test mode and all output data receive the quality attribute **Test** = *TRUE*.

- **Test mode for individual functions, stages, or function blocks**

  You can switch individual functions, stages, or function blocks into test mode. In this case, all data objects generated by the function, stage, or function block (state values and measured values) receive the quality attribute **Test** = *True*.

- **Functional logoff of the device**

  If you take the device out of operation and want to isolate it from the supply voltage, you can functionally log off the device ahead of time. Once you functionally log off the device, all data objects generated in the device (state values and measured values) receive the quality attribute **OperatorBlocked** = *TRUE*. This also applies to the output from CFC charts.

  If objects are transferred via a GOOSE message, the receiver devices can assess the quality. The receiver device detects a functional logoff of the transmitting device. After shutting down the sending device, the receiver device identifies that the sending device has been logged off operationally and did not fail. Now the receiving objects can automatically be set to defined states (see chapter *3.3.2 Quality Processing/Affected by the User for Received GOOSE Values*).

- **Switching off individual functions, stages, or function blocks**

  You can switch off individual functions, stages, or function blocks. In this case, all data objects generated by the function, stage, or function block (state values and measured values) receive the quality attribute **Validity** = *invalid*.

Influencing the Quality through Hardware Supervision

Supervision functions monitor the device hardware (see chapter *9.4 Supervision of the Device Hardware*). If the supervision functions identify failures in the data acquisition of the device, all recorded data will receive the quality attribute **Validity** = *invalid*.

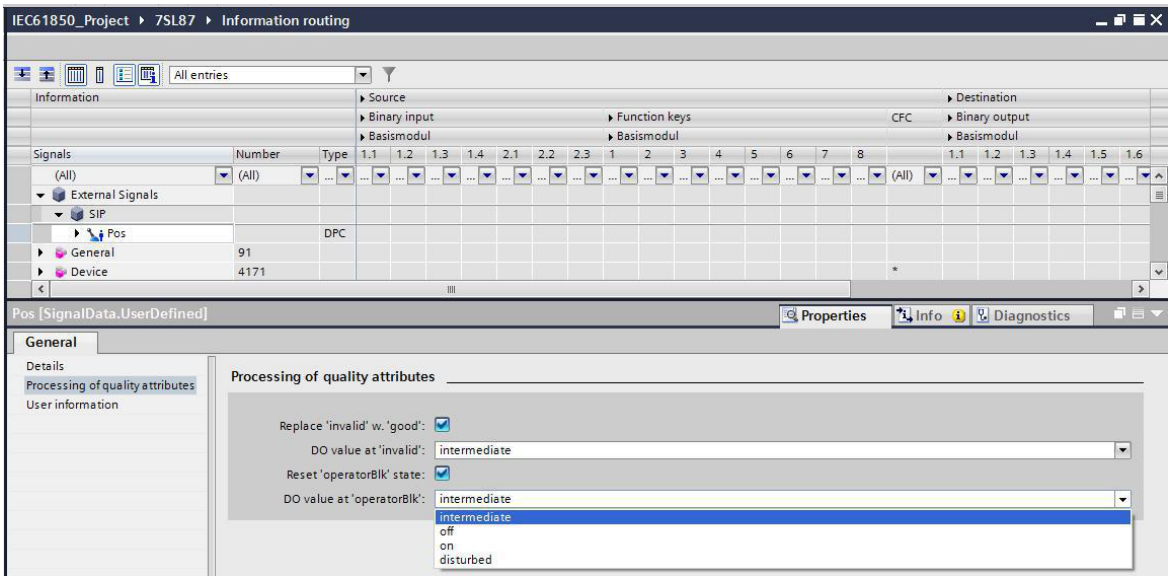
Influencing the Quality through Voltage-Transformer Circuit Breakers

If tripping of the voltage-transformer circuit breaker is detected (see chapter *9.3.4 Voltage-Transformer Circuit Breaker*), all recorded data will receive the quality attribute **Validity** = *invalid*.

Influencing the Quality by the User

You can influence the processing of data and their quality differently. In DIGSI 5, this is possible at the following 3 locations:

- In the **Information routing** editor for external signals of GOOSE connections
- In the CFC chart
- In the **Information routing** editor for binary input signals of device-internal functions



The following chapters describe in more detail the options regarding this influence as well as the automatic quality processing.

If a GOOSE connection is the data source of a binary input signal of a device-internal function, you can influence processing of the quality at 2 locations: at the GOOSE connection and at the input signal of the function. This is based on the following: A GOOSE date can be distributed within the receiving device to several functions. The GOOSE connection setting (influence) affects all functions. However, if different functions require customized settings, these are then set directly at the binary input signal of the function.

3.3.2 Quality Processing/Affected by the User for Received GOOSE Values

In the **Information Routing** editor, you can influence the data value and quality of all data types. The following figure shows the possible influence using the example of an DPC data type.

- In the DIGSI 5 project tree, double-click **Information Routing**.
- Select the desired signal in the **External Signals** group.
- Open the **Properties** window and select the **Processing Quality Attributes** sheet.

[sc_GOOSE values, 1, en_US]

Figure 3-30 Influence Option When Linking an DPC Type Data Object

The setting options work for the device receiving the data.

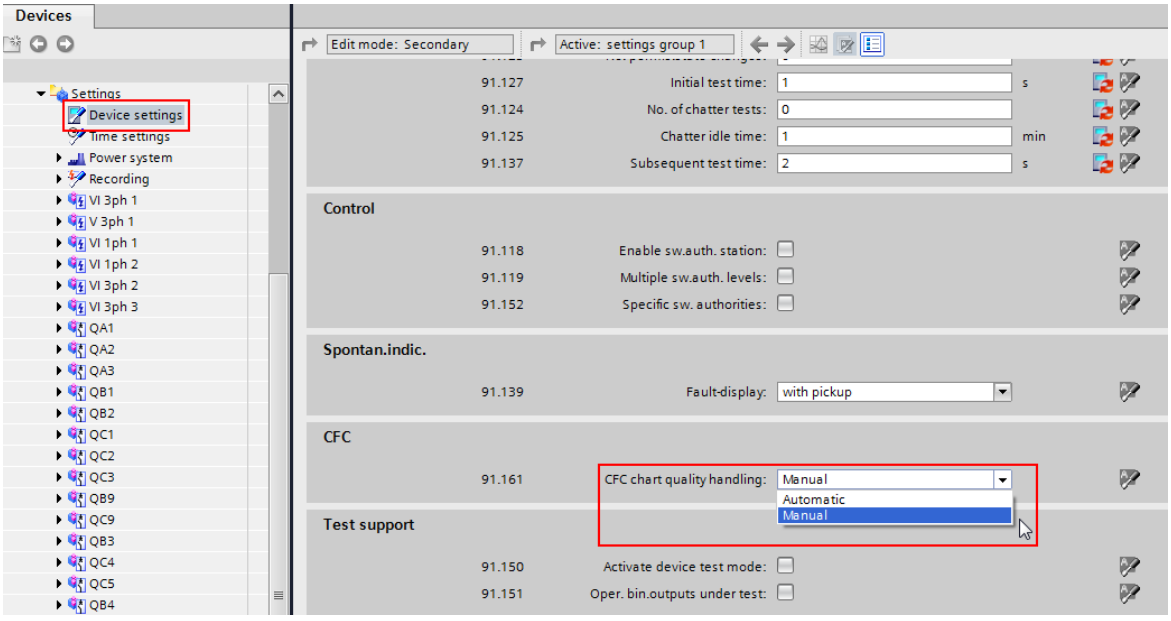
Quality Attribute: Validity	
The validity values *reserved* and *questionable* are replaced at the receiving end by the *invalid* value.	
• Check box is not set. • Check box is set and receipt of **Validity** = *good*	The validity attribute and data value are forwarded without change.
Check box is set and receipt of **Validity** = *invalid* is set (also applies to values *reserved* and *questionable*).	• The validity attribute is set to *good* and processed further using this value. • The data value is set to the defined substitute value and processed further using this substitute value.

Quality Attribute: OperatorBlocked (opBlk)	
• Check box is not set. • Check box is set and received **OperatorBlocked** = *FALSE*	The OperatorBlocked attribute and data value are forwarded without change.

Quality Attribute: OperatorBlocked (opBlk)	
Check box is set and received **OperatorBlocked** = *TRUE*	• The OperatorBlocked attribute is set to *FALSE* and processed further using this value. • The data value is set to the defined substitute value and processed further using this substitute value.

Interaction of the Quality Attribute Validity and OperatorBlocked	
OperatorBlocked check box is set and receipt of **OperatorBlocked** = *TRUE*	Regardless of whether the validity check box is set or not, and regardless of the current validity, the validity attribute is set to *good* and the substitute value of the OperatorBlocked data object is set. That is, the OperatorBlocked settings overwrite the Validity settings.
OperatorBlocked check box is not set and receipt of **OperatorBlocked** = *TRUE*	The OperatorBlocked attribute remains set and is forwarded. If the Validity check box is set and the receipt of validity = *invalid* is set, the respective data object substitute value is used. For continued signal processing and influence, it must be taken into account that in this configuration the data object substitute value for validity = *invalid* is set, but the quality attribute OperatorBlocked is not yet set.

Data Substitute Values



Depending on the data type, different data substitute values must be used.

Data Type	Possible Data Substitute Values	
ACD, ACT	general, phsA, phsB, pshC, neut	0 (False), 1 (True)
only ACD	dirGen	0, 1, 2, 3 (Unknown, Forward, Backward, Both)
	dirPhsA, dirPhsB, dirPhsC, dirNeut	0, 1, 2 (Forward, Backward, Both)
BAC, APC	mxVal	$1.401298 \cdot 10^{-45}$ to $7.922 \cdot 10^{28}$
	stSeld	0 (False), 1 (True)
	ctlNum	1 to 255
BCR	actVal, frVal, frTm	0 to 1 073 741 824
CMV	mag, ang	$1.401298 \cdot 10^{-45}$ to $7.922 \cdot 10^{28}$
DPC, DPS	stVal	0, 1, 2, 3 (intermediate-state, off, on, bad-state)
ENUM types (for example, ENS, EN, ENC)	SPS output	0 (False), 1 (True)
	INS output	The qualities of the object of the sending device are taken on.
INC	stVal	0 to 1 073 741 824
	stSeld	0 (False), 1 (True)
ING	setVal	0 to 1 073 741 824
INS	stVal	0 to 1 073 741 824
ISC, BSC	vWTpos	-64 to 64
	vWTInd	0 (False), 1 (True)
SEC	cnt	0 to 1 073 741 824
SPC, SPS	stVal	0 (False), 1 (True)
SPG	setVal	0 (False), 1 (True)

Data Type	Possible Data Substitute Values	
MV	mag	$1.401298 \cdot 10^{-45}$ to $7.922 \cdot 10^{28}$

3.3.3 Quality Processing/Affected by the User in CFC Charts

In DIGSI 5, you can control the quality processing of CFC charts. In the project tree, you can find the **CFC** block (see the following figure) under **Device name** → **Settings** → **Device settings** in the editor:

[sc quali cfc, 1, en_US]

Figure 3-31 Influencing CFC Quality Handling in DIGSI 5

With the **`CFC chart quality handling`** parameter, you control whether you want to influence the quality of CFC charts in a ***`Manual`*** or ***`Automatic`*** (default setting) manner.

If you select ***`Manual`***, the quality attribute of the CFC chart is always valid regardless of the quality of individual signals (**Validity** = ***good***)!

Only the **Test** quality attribute of the CFC chart is processed. If the device is in test mode or the input TEST of the CHART_STATE CFC block is set, the quality attribute of the CFC chart is set to ***`Test`***.

If you select ***`Automatic`***, the quality processing of the CFC charts is influenced as follows:

In the case of CFC charts, a distinction has to be made between the general quality processing and certain CFC blocks that are specifically designed for quality processing.

General Processing

Most of the CFC blocks do not have an explicit quality processing. For these blocks, the following general mechanisms shall apply.

Quality Attribute: Validity
If one *invalid* signal is received in the case of CFC input data, then **all** CFC output data will also be set to *invalid* if they originate from building blocks without explicit quality processing. In other words, the quality is not processed sequentially from building block to building block but the output data are set globally. This does not apply to CFC output data that originate from building blocks with explicit quality processing (see next section).

Quality Attribute: Test	
CFC chart is in **normal** state.	CFC input data with the **Test** = *TRUE* attribute are ignored. When the CFC chart is executed, then the data value that was used before the **Test** = *TRUE* attribute is used. The quality of this **old** value is also processed. This means that on the output side, the attribute **Test** = *FALSE*.
CFC chart is in **Test**[1)] state.	If the CFC chart is executed, then the attribute **Test** = *TRUE* is set for all data leaving the CFC chart. This does not depend on whether the data are formed via CFC blocks with or without quality processing.

[1)]A CFC chart can be switched to the test state by switching the entire device to test mode or the input TEST of the CFC block CHART_STATE is set.

Quality Attribute: OperatorBlocked	
CFC chart is in **normal** state.	In CFC charts for incoming data, the **OperatorBlocked** attribute is ignored.
CFC chart is in **functionally logged off**[1)] state .	In CFC charts for incoming data, the **OperatorBlocked** attribute is ignored. All CFC output data are labeled as functionally logged off.

[1)] This state only occurs if the device is functionally logged off. In this case, the quality attributes of all CFC outputs are labeled as **functionally logged off**.

Quality Processing Building Blocks (Condition Processing)

The first 3 blocks (x_SPS) process the quality automatically according to the stated logic. The other blocks are used to isolate the quality from a data object and add them back after separate logical processing.

<table>
<tr><th>Building Blocks</th><th>Description</th></tr>
<tr><td rowspan="20">OR_SPS
AND_SPS
NEG_SPS</td><td colspan="3">The blocks also process the supported quality attributes according to their logic. The following tables describe the logic using input values in connection with the quality attribute Validity. The input values are 0 or 1, the quality attribute Validity can have the value good (=g) or invalid (=i).
x = placeholder for the input value and quality attribute Validity</td></tr>
<tr><td colspan="3">OR_SPS</td></tr>
<tr><td>A (Value, Attribute)</td><td>B (Value, Attribute)</td><td>Q (Value, Attribute)</td></tr>
<tr><td>0, i</td><td>0, x</td><td>0, i</td></tr>
<tr><td>0, g</td><td>0, g</td><td>0, g</td></tr>

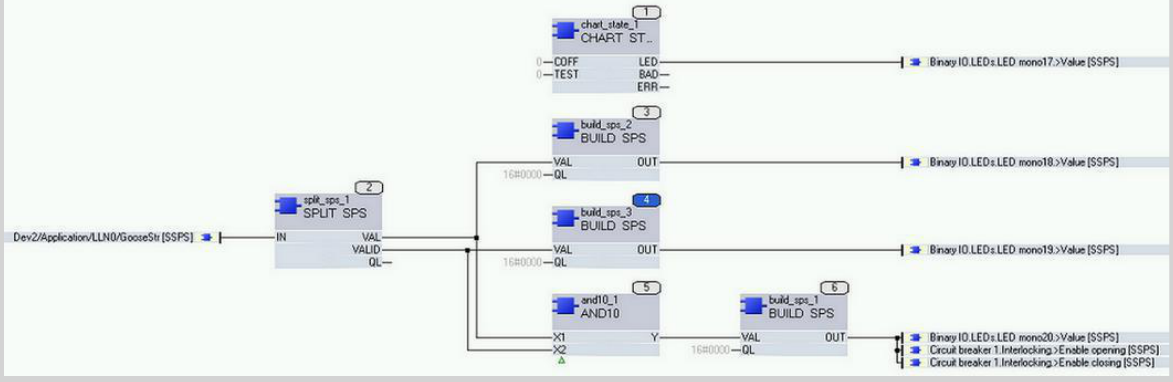
<tr><td>A (Value, Attribute)</td><td>Q (Value, Attribute)</td><td></td></tr>
<tr><td>0, i</td><td>1, i</td><td></td></tr>
<tr><td>0, g</td><td>1, g</td><td></td></tr>
<tr><td>1, i</td><td>0, i</td><td></td></tr>
<tr><td>1, g</td><td>0, g</td><td></td></tr>
<tr><td>SPLIT_SPS
SPLIT_DPS
SPLI_XMV</td><td colspan="3">The blocks isolate the data value and quality of a data object.
The requirement is that the quality is available from the input end. This is the case if the block is interconnected with CFC input data, or is connected downstream with a quality processing building block (x_SPS). In other cases, the CFC editor does not allow a connection.</td></tr>
<tr><td>SPLIT_Q</td><td colspan="3">The block performs binary separation of the quality into good, bad (= invalid), test, off and OperatorBlocked.
These 5 attributes can then be processed individually in a binary operation. The block must be connected downstream to a SPLIT_(DO) block.</td></tr>
<tr><td>BUILD_Q</td><td colspan="3">The building block enters a binary value for good and bad (= invalid) in each quality structure. Thus, with this building block the quality attributes good and bad (=invalid) can be set explicitly, for example, as the result of a monitoring logic.
All other quality attributes are set to the default state, for instance, Test = FALSE. If, for example, the entire CFC chart is in the test state (see Quality Attribute: Test Under General Processing), this default status can again be overwritten on the CFC output side.
The building block is normally connected downstream to a BUILD_(DO) building block.</td></tr>
</table>

Building Blocks	Description
BUILD_ACD **BUILD_ACT** **BUILD_BSC** **BUILD_DPS** **BUILD_ENS** **BUILD_SPS** **BUILD_XMV**	These blocks merge data value and quality. The block output is generally used as a CFC output. Generally, the BUILD_Q block is connected upstream from these building blocks.

CFC charts have a standard behavior in the processing of signals. If an input signal of the CFC chart has the quality *invalid*, all output signals of the CFC chart also get the quality *invalid*. This standard behavior is not desirable in some applications. If you use the building blocks for quality processing, the quality attributes of the input signals in the CFC chart are processed.



EXAMPLE: Switchgear Interlocking via GOOSE

The following conditions apply to the example:

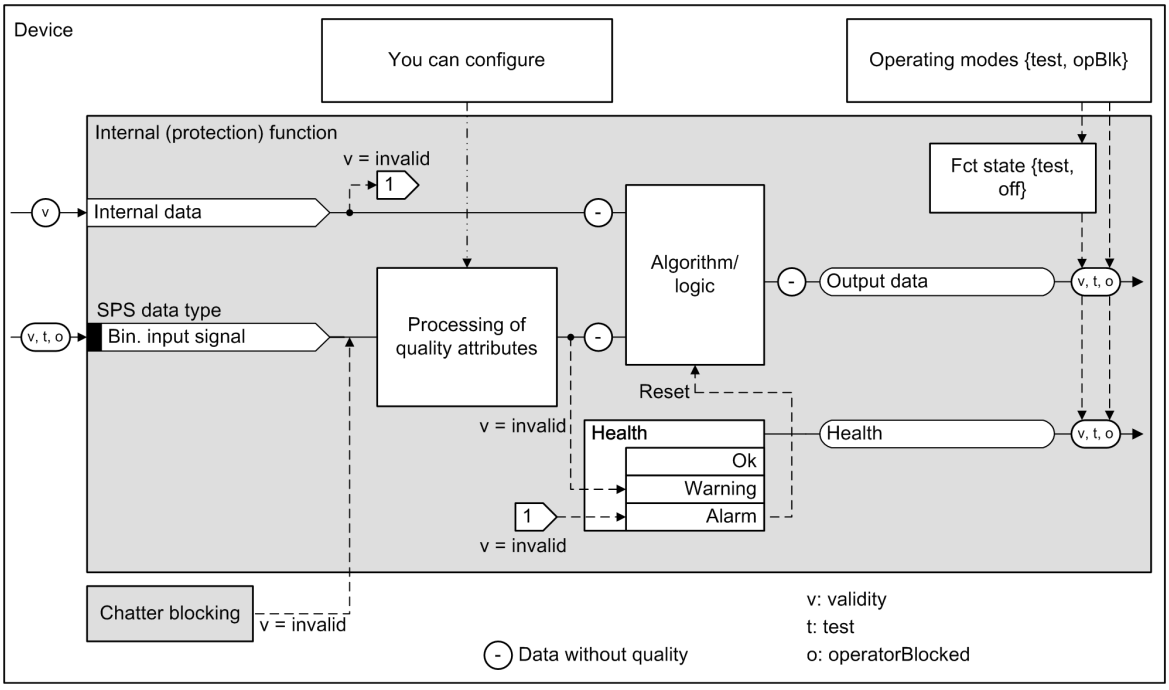
- The interlocking condition for switchgear interlocking protection is stored in the device as a CFC chart.
- The removed device sends the release signal for the interlocking condition via a GOOSE telegram.

If the communication connection has been interrupted, the release signal (**GOOSEStr**) incoming via the GOOSE telegram gets the quality *invalid*. If the CFC chart obtains an invalid input signal, there are the following possibilities: The last signal valid before the communication interruption is used (quality = *good*) or a substitute data value with the quality *good* is used (True, False).

To do this, you have to create a separate CFC chart in addition to the interlocking plan of the switchgear interlocking. Use the building blocks for quality processing in a separate CFC chart. With the SPLIT_SPS building block, split the input signal (data type = SPS) into data value and quality information. You can then continue to process these signals separately in the CFC chart. Use the quality information as an input signal for a BUILD_SPS building block and assign the quality *good* to the signal. You obtain an SPS signal as a result, with the quality *good*. You can use this to process release messages correctly. You can process the release messages with the quality *good* in the CFC chart of the actual interlocking. Therefore, the release signal for a switch illustrated in the interlocking logic is available as a valid result with the quality *good*. The following figure shows an example of the CFC chart with the building blocks for quality processing:

[sccfcran-220415-01, 1, en_US]

Figure 3-32 CFC Chart with Building Blocks for Quality Processing (Switchgear Interlocking via GOOSE)



If you do not want to convert the invalid release signal to a valid signal, as described, during the communication interruption, you can also assign a defined data value to the release signal. Proceed as follows: With the SPLIT_SPS building block, split the input signal (data type = SPS) into data value and quality information. Link the VALID output of the SPLIT_SPS building block with the data value of the input signal (AND gate). This way, you can set the value to a non-risk state with the valid input signals. In the example, the output of the CFC chart is set to the value *FALSE* when the input signal is invalid.

3.3.4 Quality Processing/Affected by the User in Internal Device Functions

Figure 3-33 provides an overview for processing the quality of data objects within a device-internal function.
A function can receive internal data or input data that is routable by the user (binary input signal or double commands). The respective quality attributes supported are evaluated by the function on the input side. The attributes are not passed through the specific algorithm/the specific logic of the function. The output data are supplied with a quality that is specified by the function state and device-operating mode.

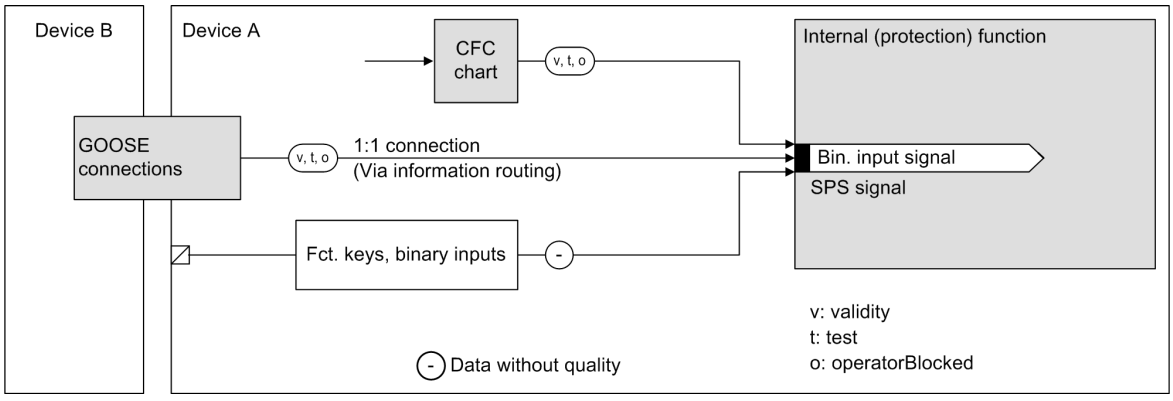
NOTE

Take into account that pickup of chatter blocking (see chapter *3.8.1 Signal Filtering and Chatter Blocking for Input Signals*) sets the corresponding **Validity** attribute to *invalid*.

[loquali3-100611-01.tif, 2, en_US]

Figure 3-33 Overview for Processing Quality within an Internal Function

Internal Input Data



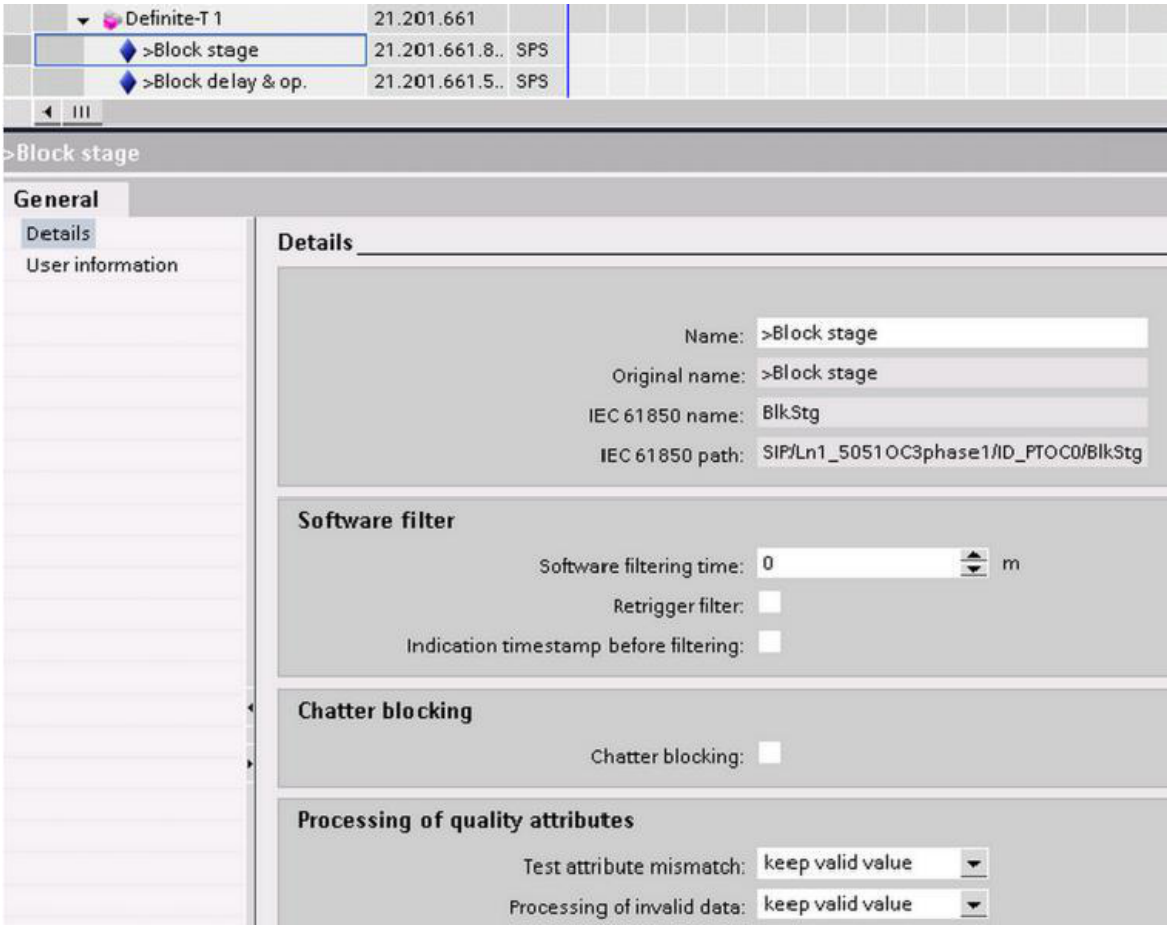
The quality processing is automatic for internal input data.

Supported Quality Attributes	Description
Validity	• At the receiving end, internal values can only be *invalid* or *good*. • If *invalid*, the function health is set to **Alarm** and the function is reset. Causes for invalid internal data are, for example: • The frequency operating range of the device was left. • The device is not calibrated. • The A/D converter monitoring identified an error.

Routable Binary Input Signals (SPS Data Type)

Figure 3-34 shows the possible sources for connecting a binary input signal. Depending on the source, different quality attributes can be set:

- CFC chart: See description in chapter *3.3.3 Quality Processing/Affected by the User in CFC Charts*
- GOOSE connection: See description in chapter *3.3.2 Quality Processing/Affected by the User for Received GOOSE Values*
- Device hardware: No quality attributes are set and supported.



[loquali2-230212-01.tif, 2, en_US]

Figure 3-34 Sources for Connecting a Binary Input Signal

For this signal type (SPS), you can influence the processing of the quality, see overview in *Figure 3-33* .

The following figure shows the possible influence on a binary input signal of a protection stage.

- In the DIGSI 5 project tree, double-click **Information routing**.
- In the operating range, select the desired binary input signal.
- In the **Properties** window, select the **Details** entry. There, you will find the item **Processing quality attributes**.

[sceinflu de, 1, en_US]

Figure 3-35 Influence Options for a Binary Input Signal (SPS Input Signal)

Quality Attribute: Validity	
The **Validity** attribute can have the values *good* or *invalid (reserved* and *questionable* were already replaced at the input end of the device by the value *invalid*).	
The input signal source is *invalid*.	The current data value of the source signal is ignored. You can select between the following options: • Further process last valid data value of the source signal (this is the default setting with only a few exceptions) • Set the binary value to be processed further to **0**. • Set the binary value to be processed further to **1**. This configuration option is necessary to satisfy different applications. The function health switches to Warning.
The input signal source is *good*.	The source signal data value is processed further.

Quality Attribute: Test	
• The input signal source and processed function are in test state. • The input signal source is not in test state and the function to be processed is in test state.	The source signal data value is processed further.

Quality Attribute: Test	
The input signal source is in a test state and the function to be processed is in normal state.	The data value of the source signal is ignored. You can select between the following options: • Further processing of the last valid source signal data value, before the source switches to the test state (that is the default setting) • The binary value to be processed further is set to **0**. • The binary value to be processed further is set to **1**. This configuration option is necessary to satisfy different applications.

Quality Attribute OperatorBlocked
The quality cannot be influenced at this position and does not lead to a response within the logic

Output Data

The quality is not processed through the actual algorithm/logic of the function. The following table displays the conditions required to set the quality of output signals of a function.

Cause	D0 Value	Quality Attribute	
		After **internal** (to the SIPROTEC 5 system, for example, in the direction of a CFC chart)	To the IEC 61850 interface, in buffer
Functional state = **Test** (thus, result of device operating mode = **Test** or function mode = **Test**)	Unchanged	**Test** = *TRUE*	**Test** = *TRUE*
Functional state = **Off** (thus, result of device operating mode = **Off**)	Function-specific, corresponding to the definition for switched off	**Validity** = *good*	**Validity** = *invalid*
Function health = **Alarm** (for example, result of invalid receive data)	Function-specific, corresponding to the definition for reset	**Validity** = *good*	**Validity** = *invalid*
Device operating mode = **functionally logged off**	Unchanged	**Validity** = *good* **OperatorBlocked** = *TRUE*	**Validity** = *good* **detailQual** = *oldData* **OperatorBlocked** = *TRUE*

3.4 Fault Recording

3.4.1 Overview of Functions

All SIPROTEC 5 devices have a fault memory in which fault recordings are kept securely. Fault recording documents operations within the power system and the way in which protection devices respond to them. You can read out fault recordings from the device and analyze them afterwards using evaluation tools such as SIGRA.

A fault record contains the following information:

- Sample values of the analog input channels
- Measured values calculated internally
- Any binary signals (for example, pickup signals and trip signals of protection functions)

You can individually configure the signals to be recorded. Furthermore, you can define the starting condition, the record duration, and the saving criterion of a recording. Fault records saved in the device are also available after a loss of auxiliary voltage.

3.4.2 Structure of the Function

The **Fault recorder** function is a central device function. Both the recording criterion and the measured-value and binary channels to be recorded are functionally preconfigured through the application templates. You are able to individually adapt the configuration in DIGSI 5. The fault recording and the fault log are subject to the same control. This ensures that real time, relative time, and numbering of the fault data are synchronized.

This means that all fault recordings function on the same real-time and relative-time basis.

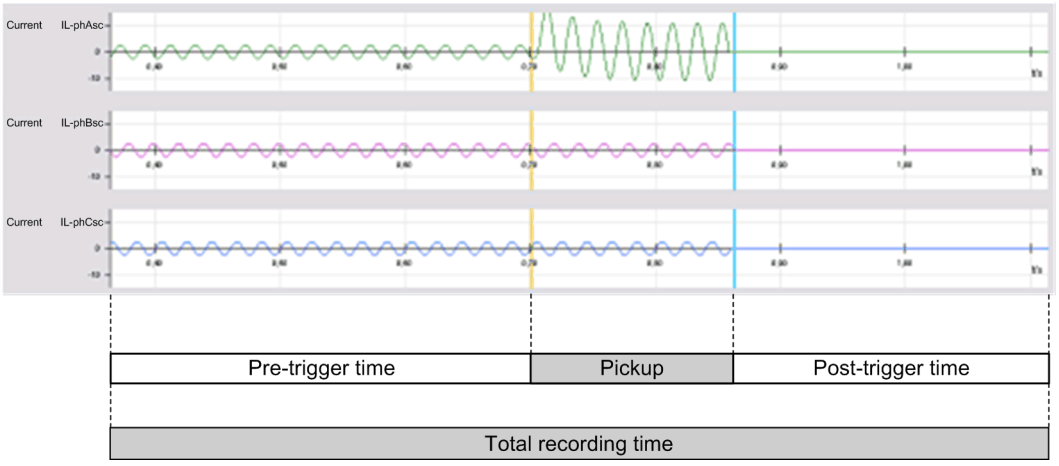
The data read out via the DIGSI-PC are saved in COMTRADE format. Fault recording data can be transferred to the substation automation technology by request in accordance with the standards via existing communication connections (such as IEC 61850, IEC 60870-5-103). The central device analyzes the data using appropriate programs.

3.4.3 Function Description

The **Fault recorder** function records the sampled values, specific to each device, of all analog inputs, the internally calculated measured values and the binary signals. The configuration, which is predefined for each device via an application template, can be adapted individually.

NOTE

You can find detailed information about selecting and deleting fault records in the Operating Manual (C53000-G5000-C003).



The fault memory of the device is automatically updated with every recording. When the fault memory is filled completely, the oldest records are overwritten automatically. Thus, the most recent recordings are always stored safely. The maximum number of recordings is 128.

Sampling Frequency

The analog measuring channels are sampled at a different sampling rate for fault recording. The **`Sampling frequency`** parameter is used to set the desired sampling frequency. Possible setting values are 1 kHz, 2 kHz, 4 kHz, and 8 kHz. This setting value applies only to fault recording and does not affect protection functions or calculated measured values.

Record Duration

The overall duration of a single fault recording comprises the total duration of the configurable recording criterion, the **`Pre-trigger time`** and the **`Post-trigger time`**. You can set the parameters for these components individually.

[dwsigrar-070813-01, 1, en_US]

Figure 3-36 Example of a Fault Recording

With the **Fault recording** parameter, you specify the start criterion of the recording.

You can set the following values:

- ***with pickup***:
  The fault recording records the complete fault until dropout. The resulting pickup signals of all function groups are taken into account.
- ***with pickup & AR cyc.***:
  In connection with an active automatic reclosing function (internal/external), the fault recordings record the fault including the short and long interruptions (automatic reclosing cycles).
- ***user-defined***:
  With this setting value, you can individually specify the recording criterion for the fault recording in DIGSI 5. Function-specific recording criteria can be realized in this way.

If a recording criterion reoccurs during the pickup time and post-trigger time, the recording which is currently active is extended to include a new post-trigger time.

For a sampling frequency of 8 kHz and 24 analog channels to be recorded, the duration of one individual fault recording can be up to 20 s.

The maximum record duration can be limited by the **Maximum record time** parameter.

In addition to starting the fault recording via the pickup, the following alternatives are possible:

- Externally via binary input signal *>External start* (for example, from an external protection device without fault recording by an object transferred via a GOOSE message)
- By way of a configurable input signal *>Manual start*, you can start fault records with a configurable length (parameter **Manual record time**).
- With DIGSI 5, you can start test fault records with a fixed length of 1 s.
- With a command from a central device via an existing communication connection (IEC 61850, IEC 60870-5-103)

NOTE

If a pickup signal is present continuously, the fault recording is closed after the **Maximum record time** expires and the fault record cannot be restarted!

Saving the Recording

Not every fault recording that is started actually needs to be saved. With the **Storage** parameter, you specify whether or not you want to save the fault recording that has started. You can also save only fault data for

which the pickup of a protection function also caused a tripping. With this setting, faults beyond the self-protection range will not lead to replacing fault recordings that have already been saved.

Configuration of Signals to Be Recorded

All analog inputs of the device that have been configured (currents and voltages) are recorded as sampled channels. Function-specific binary signals (for example, pickup and trip signals) and measured value channels can be configured individually for recording in the DIGSI information-routing matrix. For this purpose, a separate **Content** column is available.

The operational measured values and the measured values of the fundamental components and symmetrical components (see the Device Manual, chapters *10.3 Operational Measured Values* and *10.4 Fundamental and Symmetrical Components*) are calculated every 9 cycles (at 50 Hz, this is every 180 ms). However, this can mean that the data are not synchronized with the sampled values of the analog channels. The recording of these measured values can be used to analyze the slowly changing processes.

Numbering and Time Stamping

All fault recordings saved are automatically numbered in ascending order and assigned a real-time stamp for the start time. The fault recording logs the fault with a relative time. The reference-time point is the start of the recording. Every fault record has a corresponding fault log with the same number. This ensures that the fault recording can be uniquely assigned to the event log.

Fault Memory

The device manages its available fault memory dynamically, so that the maximum recording capacity is always available. When exceeding the limits of the fault memory, the oldest recordings are automatically overwritten. This means that the most recent records are always available. The sampling rate, type, and number of measured value trends to be recorded are the crucial variables when it comes to restricting the length and number of records possible. Parallel to the sampled tracks, up to 50 tracks with function-specific measured values and up to 100 binary tracks can be recorded. The following table provides an overview of the maximum storage capacities, in seconds, for different connection variations of the protection devices.

Table 3-6 Maximum Length of all Stored Records

Connection Examples	Sampling 1 kHz	Sampling 2 kHz	Sampling 4 kHz	Sampling 8 kHz
Feeder: 4I, 6 measured values, 20 binary tracks	1365 s	819 s	455 s	241 s
Feeder: 4I, 4V, 20 binary tracks	1125 s	566 s	284 s	142 s
Feeder: 4I, 4V, 6 measured values, 20 binary tracks	890 s	500 s	266 s	137 s
Feeder 1.5 CB: 8I, 8V, 6 measured values, 20 binary tracks	525 s	281 s	145 s	74 s

Input and Output Signals

The **Fault recorder** function provides several input signals that allow the precise starting , deleting of records. The output signals provide information about the function status.

In the following table, you can find input signals of the **Fault recorder** function:

Name	Type	Description
Control: Start recording	SPC	Start recording via the function key
Control: Reset memory	SPC	Delete all recording via the function key. The error numbers are reset.
Control: Delete memory	SPC	Delete all recording via the function key. The error numbers remain as is.

Name	Type	Description
Control: >External start	SPS	Start recording by an external binary signal, for example, by the trip command of an external protection device without separate recording. The set pre and post-trigger time are taken into account.
Control: >Manual start	SPS	Start a recording of fixed duration (parameter **Manual record time**) by way of an external binary signal, for example, manually via the function key or by an external binary signal.

In the following table, you can find output signals of the **Fault recorder** function:

Name	Type	Description
General: Mode	ENC	Status feedback of the fault recording according to chapter *2.3 Function Control*
General: State	ENS	
General: Standby	ENS	
Control: Error number	INS	The indication of the current error number allows a unique allocation of entries in the message buffers for the recorded fault records.
Control: Recording started	SPS	Fault recording running

3.4.4 Application and Setting Notes

Parameter: Fault recording

- Recommended setting value **(_:2761:130) Fault recording** = ***with pickup***

With the **Fault recording** parameter, you define the time interval at which faults are recorded. The total record duration is defined as the duration of the fault plus the total of the parameters **Pre-trigger time**, **Post-trigger time** and is limited by the maximum record duration.

Parameter Value	Description
with pickup	The fault recording time is determined by the total number of all protection pickups. The resulting pickup signals of all function groups are taken into account. Note: When the post-trigger time has expired, the indications of an automatic reclosing function are not recorded. Evolving faults after expiry of the post-trigger time can result in the opening of a new fault with its own recording.
with pickup & AR cyc.	The fault recording time is determined by the total number of all protection pickups including short and long interruptions (automatic reclosing cycles). It includes the resulting pickup signals of all function groups and the runtimes of initiated automatic reclosing cycles for all active automatic reclosing functions.
user-defined	The fault recording time is defined user-specific. Note: You must specify all signals for individual definition of the fault recording time in the DIGSI 5 information-routing matrix. In the information routing matrix in the **Fault record** column, the fault recording has for this purpose a separate column **Trigger**. The record duration is calculated from the logical OR operation of all initiated, configured signals.

Parameter: Storage

- Recommended setting value **(_:2761:131) Storage** = ***always***

With the **Storage** parameter, you define the storage criterion for a fault recording that has already started.

Parameter Value	Description
always	Each fault recording that has been started is saved.
with trip	If at least one protection function issues an operate indication during the record time, any fault recording that has been started will be saved.

Parameter: Maximum record time

- Default setting **(_:2761:111) Maximum record time** = ***5.00 s***

With the **Maximum record time** parameter, you configure the maximum record duration for an individual fault recording. When the time configured expires, an ongoing fault recording is canceled. This parameter merely limits the duration of the fault recording. It does not affect the logging of faults in the fault log.

Parameter: Pre-trigger time

- Recommended setting value **(_:2761:112) Pre-trigger time** = ***0.50 s***

With the **Pre-trigger time** parameter, you configure the pre-trigger time for an individual fault recording. The set pre-trigger time is prepended to the actual recording criterion for the fault recording.

Parameter: Post-trigger time

- Recommended setting value **(_:2761:113) Post-trigger time** = ***0.50 s***

With the **Post-trigger time** parameter, you configure the post-trigger time for an individual fault recording. The post-trigger time that has been configured is added to the actual recording criterion for the fault recording after the dropout.

Parameter: Sampling frequency

- Recommended setting value **(_:2761:140) Sampling frequency** = ***8 kHz***

With the **Sampling frequency** parameter, you define the sampling frequency of the fault recording. Possible setting values are 8 kHz, 4 kHz, 2 kHz, and 1 kHz.

Parameter: Manual record time

- Recommended setting value **(_:2761:116) Manual record time** = ***0.50 s***

With the parameter **Manual record time**, you set the duration of a recording if the fault record is activated dynamically (edge-triggered) via a separately configured input signal *>Manual start*.

In this case, pre-trigger and post-trigger times do not take effect.

3.4.5 Settings

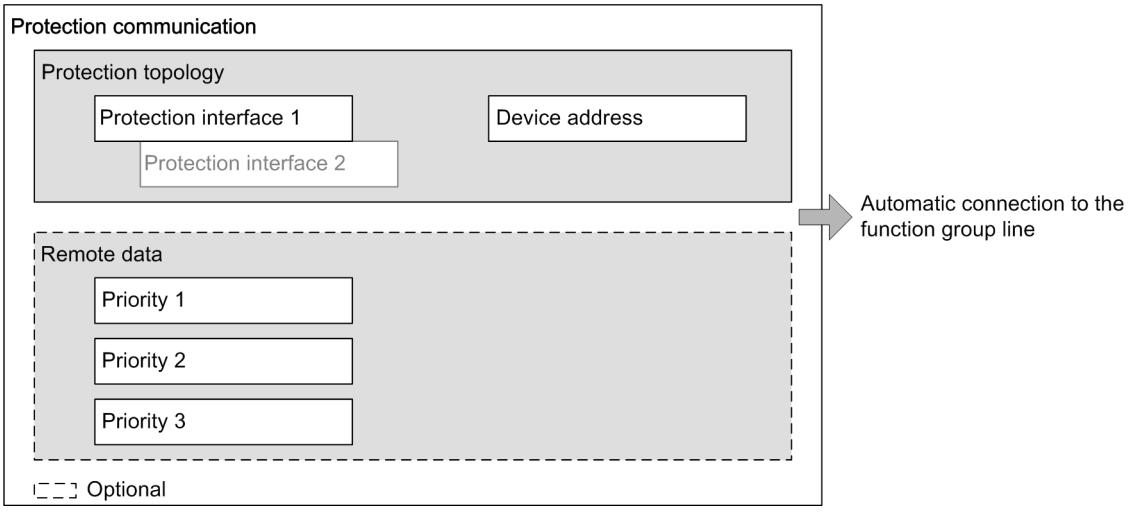
3.5 Protection Communication

3.5.1 Overview

Protection communication includes all functionalities required to exchange data via the protection interface (PI). It manages one or a maximum of 2 protection interfaces. The **Protection communication** is generated with the configuration of the channels as a protocol.



You can find detailed information in the section **Protection interface** in chapter *3.5.3.1 Overview of Functions*.

3.5.2 Protection-Communication Structure

The following **Protection communication** functions are visible:

- Topology recognition
- Remote data

The following figure shows the structure of **Protection communication**:

[dwstrufg-171012-01.tif, 1, en_US]

Figure 3-37 Protection-Data Communication Structure

Interface to VI 3-Phase Function Group

Binary signals, measured values, and other data are automatically exchanged between the **Protection-data communication** and the **VI 3-phase** protection function group.

Interface to Motor Function Group

Binary signals, measured values, and other data are automatically exchanged between the **Protection-data communication** and the **Motor** protection function group.

Remote Data

The **Remote data** functionality is applied if you route a specific signal or a measured value to the protection interfaces. The protection interface then attends to the transmitting and receiving of such signals. The maximum amount of remote data is defined by the available bandwidth.

3.5.3 Protection Interface and Protection Topology

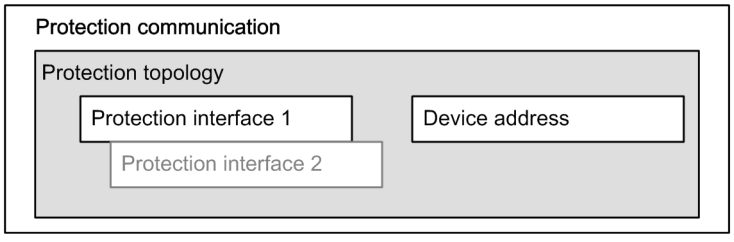
3.5.3.1 Overview of Functions

The **Protection topology and protection interface**function enables data exchange between the devices via synchronous serial point-to-point connections from 64 Kbits/s to 2 Mbits/s. These connections can be established directly via optical fibers or via other communication media, for example, via dedicated lines or via communication networks.

A protection topology consists of 2 to 6 devices which communicate via protection interfaces. It can be set up either as a redundant ring or as a chain structure. Within a topology, the protection interfaces can have a different bandwidth. Depending on the bandwidth, a certain amount of binary information and measured values can be transmitted bi-directionally between the devices. The connection with the lowest bandwidth defines this amount (of binary information and measured values).

The following information that is significant for the function of the protection interface is also transferred. You cannot change this information:

- Topology data and values are exchanged for monitoring and testing the connection.
  The results are displayed on the device or with DIGSI 5.
- Protection data, for example, differential protection data or teleprotection scheme binary data, are transferred for distance protection and ground-fault protection.
- The devices can be synchronized in time via the connection, whereby a device of the protection topology assumes the role of the timing master.



The connection is continuously monitored for data faults and outage, and the time delay of the data is measured.

The protection interfaces are typically used for differential protection and with the teleprotection scheme for distance protection and ground-fault protection. In SIPROTEC 5, you can configure protection interfaces in all devices and then use them for further protection applications. At the same time, any binary information and measured values can be transferred between the devices.

3.5.3.2 Structure of the Function

The protection interfaces of a device are located in the Protection communication function group. A device has 1 or 2 specifically parameterizable protection interfaces.

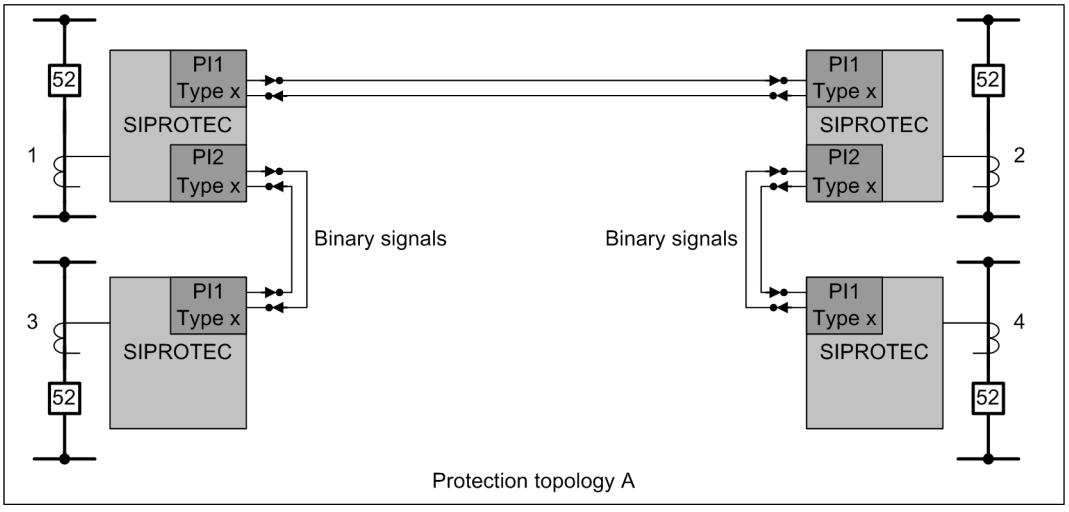
The **protection topology** is used for administration of that topology data relevant to the respective interfaces and containing data from other devices in the protection topology.

[dwstruct-030211-01.tif, 1, en_US]

Figure 3-38 Structure of the Protection Interface in a Device

The protection communication runs physically via a serial optical communication module. This module can have 1 or 2 channels. The protection communication can take place via various modules. This depends on the type of interface and the application. DIGSI 5 is used to configure 1 or 2 channels of a serial optical module as a protection interface. This enables communication with the values set at the **protection interface** via this channel.

3.5.3.3 Function Description



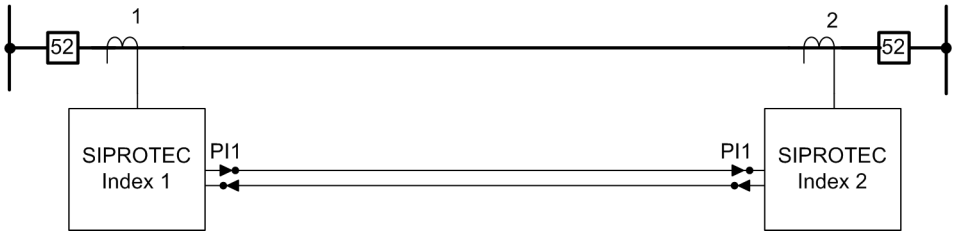
Topology and Type of Protection Communication

The protection interfaces (PI) establish a direct point-to-point connection between devices via different communication media. Data can be transferred within the switchgear or between switchgears.

Devices connected to one another with protection communication form a protection topology. Refer to *Figure 3-39*.

The protection communication in a device can be either type 1 or type 2. In the case of devices with differential protection function (7SD and 7SL), a protection communication of type 1 is automatically created. Type 2 is created for other devices, and is used for other data transmission. A device can contain only the same types of protection communication. Type 1 and type 2 protection communication do not work together in pairs via a protection function.

Types	Description
Type 1 Application using differential protection	With type 1, the differential protection function is the primary application. This application requires the greatest portion of the bandwidth, so that with type 1 the number of signals additionally available is lower. This becomes noticeable with a 64-kbps protection connection via a G703.1 or X21 interface. If a multiple-end differential-protection application is realized, all protection communications must be of type 1. A maximum of 6 line ends is possible. If the **Differential protection** und **Teleprotection scheme** functions are to operate in parallel in the device, the bit rate must not be less than 512 kbps!
Type 2 Application without using differential protection	Type 2 has a significantly higher amount of information that can be transferred as the differential-protection application is not used here. The transmission of protection data and other data, for example, measured values, is predominant here. Using type 2 protection communication, a maximum of 6 devices can be connected to one another and different device types (for example, 6MD, 7VK, 7SA, and 7SJ) can exchange data.



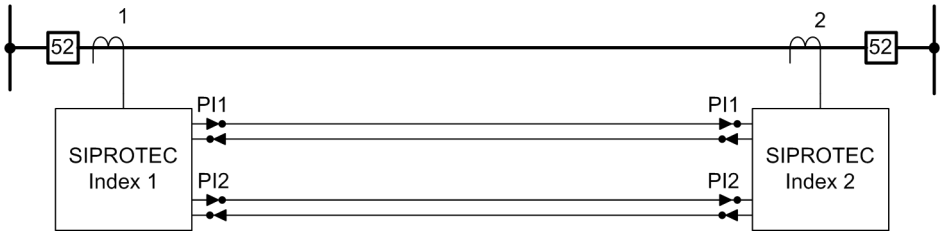
[dwintert-030211-02.tif, 1, en_US]

Figure 3-39 Data Exchange between 4 Devices with Protection Communications of Type 1 or Type 2 in a Protection Topology

2-Device Topology: Simple or Redundant Transfer

In the case of a simple 2-device topology, one protection communication per device is required (see next figure).

The most frequent application is the point-to-point exchange of data between 2 devices (the protection communication is of type 2), as performed by protection transmission devices.



[dwinterf-030211-01.tif, 1, en_US]

Figure 3-40 Data Exchange for 2 Devices, Each Having Protection Communication

NOTE

The index describes the consecutive numbering of the devices in a protection topology (see parameter **`Local device is device`**).

A maximum of 2 protection communications can be integrated in one device (see next figure). If 2 protection communications of the same type are connected to one another, this results in 100 % redundancy regarding the transmission route. The devices then search for the communication connection with the highest bandwidth (for example, optical fiber). If this connection fails, the system switches over automatically to the 2nd connection until the 1st connection is available again. As the connection with lower bandwidth defines the maximum amount of transferable information, the same information is exchanged via both connections. Both protection communications in the device are then of type 1.

[dwintera-030211-02.tif, 1, en_US]

Figure 3-41 Data Exchange for 2 Devices, Each Having 2 Protection Communications/Redundant Transmission Route

Protection-Interface Information Transfer

With the protection-interface information transfer, customer-specific indications and measured values can be communicated via the protection interface with settable update cycles (priorities).

There are 3 different priorities when transferring protection-interface information:

- **Priority 1**: Use **Priority 1** for the transmission of fast protection signals that are transferred and updated at a maximum of every 20 ms in a telegram.
- **Priority 2**: Use **Priority 2** for the transmission of fast single-point or double-point indications that are transferred and updated at a maximum of every 40 ms.
- **Priority 3**: Use **Priority 3** for all indications, measured, and metered values that are transferred and updated a maximum of every 100 ms.

The number of customer-specific signals, indications, and measured values conform with the remaining bandwidth. The remaining bandwidth is lower than with all other protection functions (type 2) when using a differential protection (type 1). Customer-specific measured values consume more bandwidth than single-point indications.

Communication Media

The communication takes place via direct fiber-optic connections, via communication networks or via 2-wire copper conductors. Siemens recommends a direct fiber-optic connection, as this offers the highest transmission rate of 2 Mbps and is immune to failures in the communication route while offering the shortest trans-

mission time. This also enables the transmission of a large amount of additional information on differential protection routes and the remote control of devices at the remote end with DIGSI 5.

The distance to be bridged and the transmission paths available determine the settings of the protection interface. External communication converters are used for the connection to communication networks via G703.1-, X21-, or G703.6 interfaces. The connection to 2-wire copper cores also takes place via a communication converter. The C37.94 interface, for example, with 2 Mbps, offers a direct fiber-optic connection to a multiplexer with the corresponding interface.

Table 3-7 to *Table 3-8* show examples of communication connections.

In the case of a direct connection, the transmission distance depends on the fiber type of the optical fiber. This distance can also be extended via external repeaters.

The modules in the device can be replaced from outside, so that adaptation to a transmission route is possible. In the case of the 820-nm double module USART-AE-2FO with 2 channels, 2 protection interfaces can be operated on one module.

The modules can be located at slots E and F in the base device, and at slots N and P in the plug-in module assembly with integrated power supply.

When using communication converters, the connection from the device to the communication converter by a module is established via optical fibers.

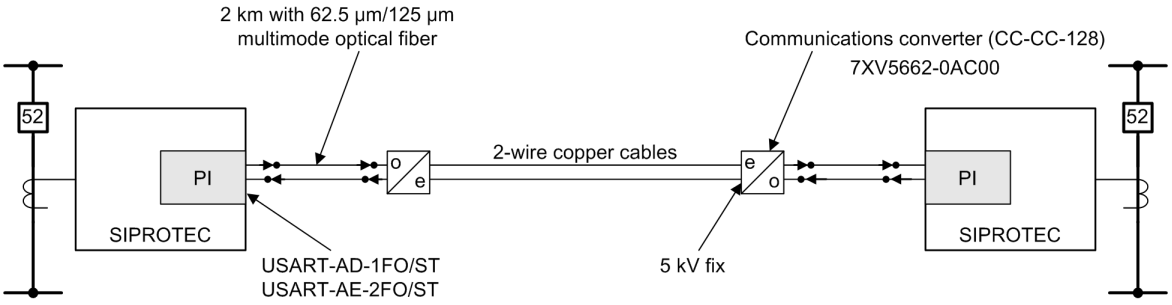
Figure 3-46 Connection via Communication Network with a G703.1 Interface

The connection to the multiplexer is established via a communication converter with a G703.1 interface (64 kbps) or X21 interface (64 kbps to 512 kbps). You can set the bit rate for the KU-XG-512 (for X21), KU-XG-256 (for X21), KU-XG-128 (for X21), and KU-XG-64 (for X21 or G703.1) with the parameter **Connection via**.

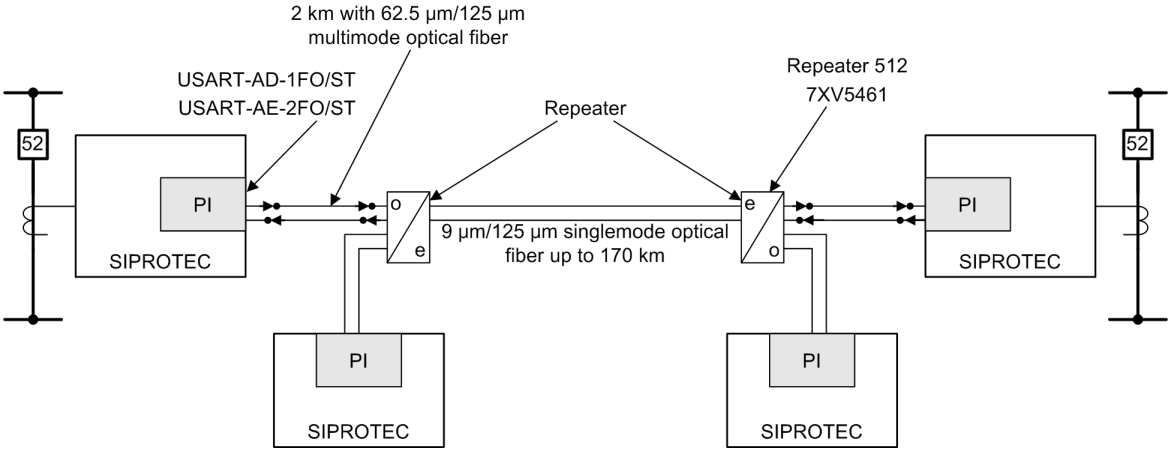
You can find more detailed information in *Table 3-9*.



[dwmultim-070611-06.tif, 1, en_US]

Figure 3-47 Connection via Communication Network with a G703.6 Interface

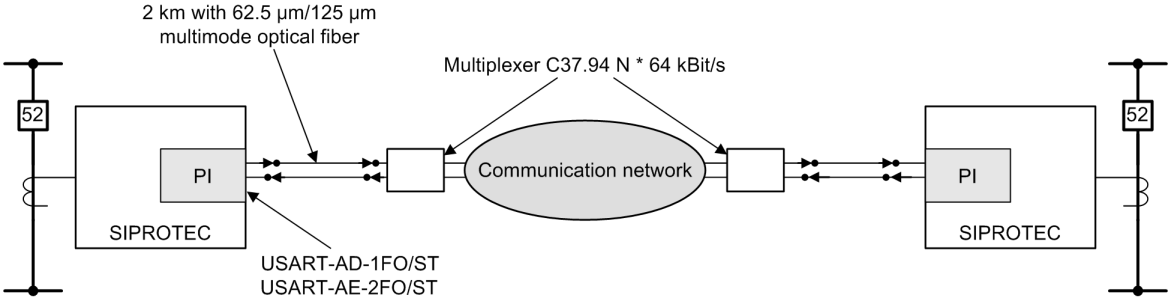
The connection to the multiplexer is established with 512 kbps via a communication converter with a G703.6 interface (E1 with 2 Mbps or T1 with 1.44 Mbps). The communication converter offers a 2nd interface for connecting an additional protection interface.



Make the setting for the bit rate with KU-2M-512 with 512 kbps in accordance with *Table 3-9* with the parameter **Connection via**.

[dwmulti7-070611-01.tif, 1, en_US]

Figure 3-48 Connection via 2-Wire Copper Cables



The connection to a communication converter with an integrated 5-kV isolation voltage is established with 128 kbps (KU-KU-128 setting in accordance with *Table 3-9*). A 20 kV isolation of the 2-wire connection is possible via an external 7XR9516 isolating transformer.

[dwrepeat-070611-10.tif, 1, en_US]

Figure 3-49 Direct Fiber-Optic Connection via an External Repeater

The repeater offers an interface for connecting an additional protection interface. The connection to a repeater is established with 512 kbps (repeater 512 setting in accordance with *Table 3-9*).

[dwmutip8-070611-01.tif, 1, en_US]

Figure 3-50 Direct Optical Connection to a Multiplexer with a C37.94 N * 64 kbps Interface (Time Slot N = 1; 2 or 8)

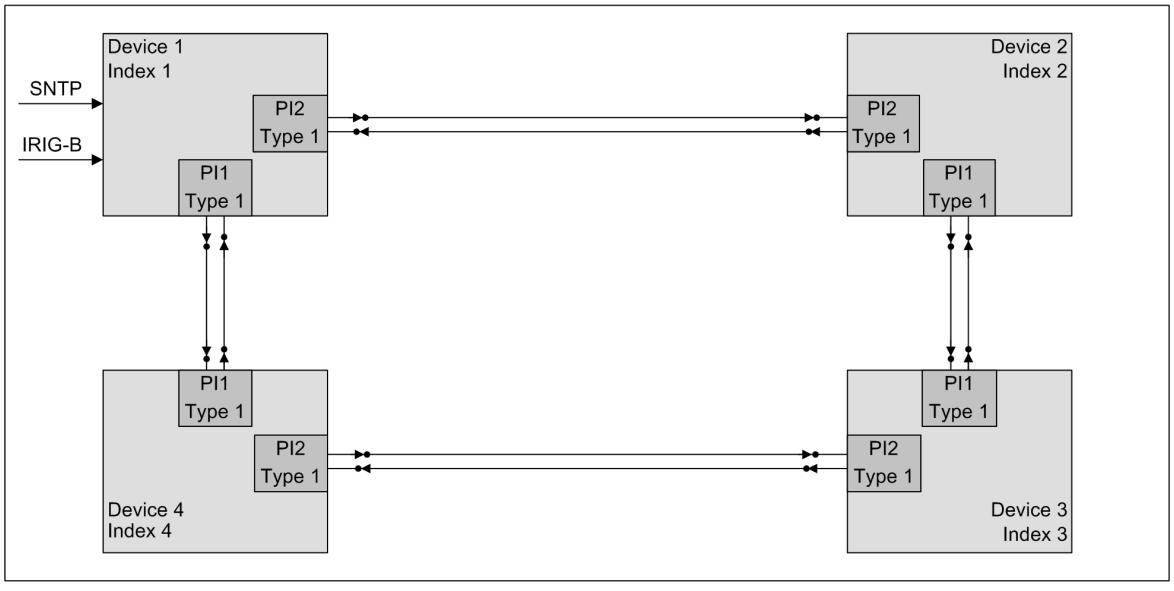
NOTE

The redundancy of different communication connections (for the ring topology) requires rigorous separation of all devices involved in the communication. Therefore, avoid different communication routes via the same multiplexer board, as no more substitute paths are possible if the board fails.

Supervision of the Communication

The communication is continuously monitored by the devices.

If a number of defective data telegrams, or no data telegrams at all, are received, this is regarded as a **failure** in the communication as soon as a failure time of 100 ms (default setting can be changed) is exceeded. A list of the measured values is shown in a window in DIGSI 5 (defective telegrams per minute/hour; transmitted and received telegrams per minute/hour, percentage fault rate per minute/hour). A corresponding failure indication is always available. If no alternative communication route exists (as in the ring topology), the protection function operating with the protection interface is not operating and the remote signals are not updated on the receiver side.



If the communication is interrupted for longer than an adjustable time **Data-connection failure**, this is regarded as a communication failure. A corresponding failure indication is always available.

Time Synchronization via the Protection Interface

All devices of a topology can be time-synchronized with one another. Synchronization is carried out with millisecond accuracy. The synchronization works independently of the protection function and is exclusively for simultaneous time keeping in the devices of a protection topology.

The device you set in the parameter **`Address of device 1`** is the device with index 1. This device functions as the timing master in a protection topology. If the timing master is logged off and switched off, the device with the next highest device index takes on the function of the timing master. The timing master synchronizes the clocks of the other devices of this topology via the protection interfaces. The time of the timing master is typically synchronized via a substation automation protocol (for example, Ethernet or SNTP) or via IRIG-B. For this, these time sources must be set as the 1st time source and optionally as the 2nd time source in the timing master. If available, the system switches over to the 2nd source upon outage of the 1st source in the timing master. This time is communicated with millisecond accuracy to the other devices of the topology.

Set the protection interface as the 1st time source in the other devices of the topology. In this way, all events in the devices of the protection topology are recorded with the same time and are time-synchronized even across different substations. This simplifies fault analysis and the fault records are recorded with the same time in all devices.

[dwtimesy-130212-01.tif, 1, en_US]

Figure 3-51 Time Synchronization in a Protection Topology

Figure 3-51 shows how device 1 with index 1 is synchronized with the devices 2, 3, and 4 via the protection interface. Device 1 is synchronized externally from 2 sources (IRIG-B and SNTP via Ethernet).

Time Synchronization of the Line Differential Protection Measured Values with Millisecond Accuracy

The measured values of the line differential protection for the various line ends are synchronized with each other with microsecond accuracy via the mechanisms of the protection interface. The protection interface displays this state with the RAISING indication *Protection interface synchronized*.

If communications problems occur, it is possible that the measured values may not be properly synchronized. In this case, the protection interface generates the CLEARED indication *Protection interface synchronized*. The line differential protection is blocked. This state can be corrected only by manual intervention.

NOTE

You can reset the synchronization of the protection interface directly in the device. Proceed as follows: **Device functions > x Device protection comm. > Protection interface y > Reset synchron**.

Synchronization via GPS Second Pulse

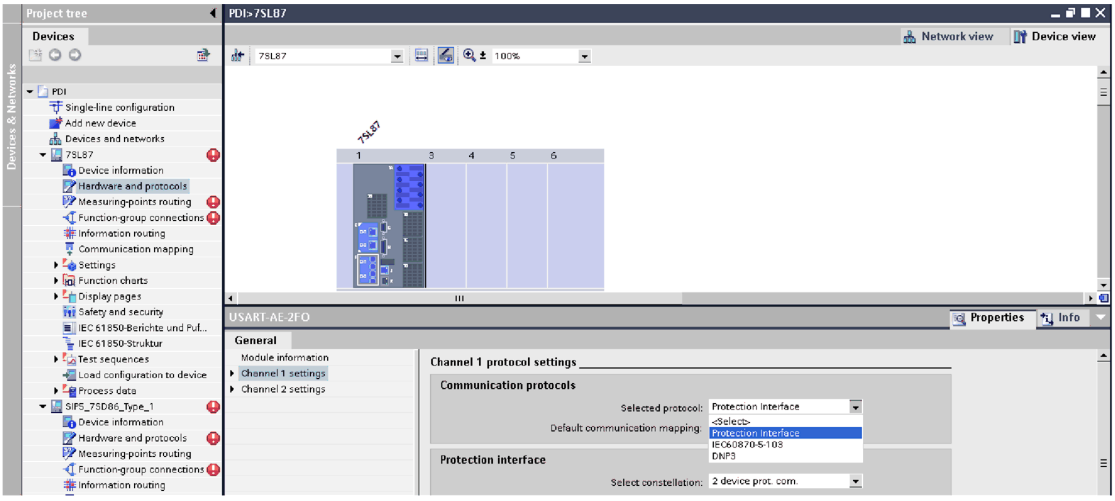
Millisecond-accurate synchronization of the devices (1*10E-06 s), connected via protection interfaces, can take place via a high-precision GPS second pulse at the time-synchronous port G for special differential protection applications or synchrophasor measuring devices. As a result, the transmission time of the communication route can be measured and displayed separately in the forward and reverse directions. This ensures that the maximum responsivity can be obtained during differential protection, even if transmission times are unbalanced in the communication networks. Different transmission times are insignificant for the transmission of protection data with a protection communication of type 2.

Log Off the Device

A device can be logged off for protection-function tests, system inspections, or disconnection of a feeder for operational reasons. The device that is logged off no longer participates in the distributed functionality and is therefore no longer a component of the topology. The protection functions are still in operation for the other end or ends.

The following conditions are necessary for a successful logoff of the device from the point of view of protection communication:

- The protection topology is not in a transient state and is stable in operation without switchovers.
- The local device is one of the 2 token masters if there is a chain topology. The token masters are the devices at the ends of the chain.
- The circuit breaker must be open and current must not be flowing.

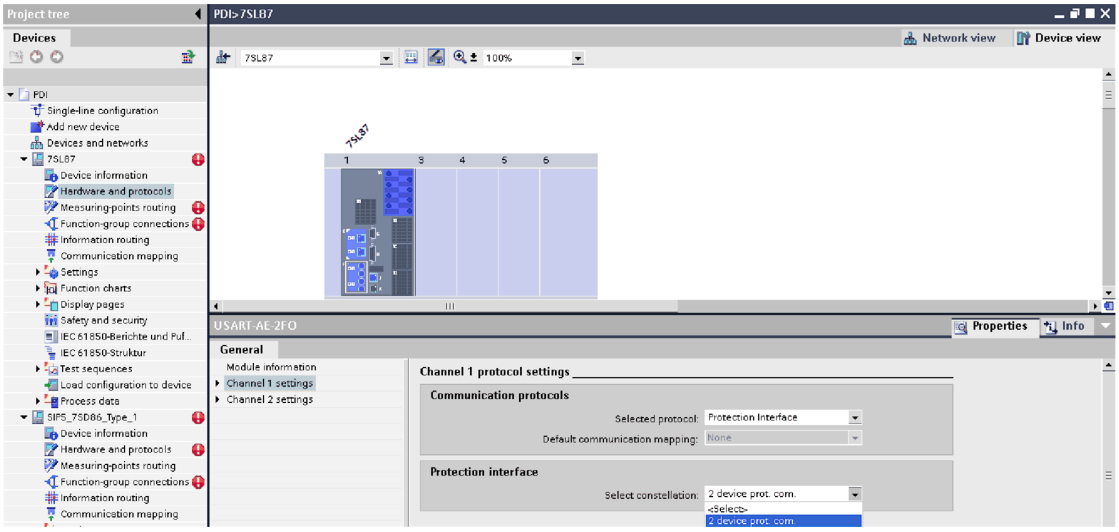


NOTE

If one of these conditions is not fulfilled, the device cannot be logged off.

3.5.3.4 Initialization and Configuration of the Protection Interface in DIGSI 5

If the device is provided with modules, proceed as follows:



- Select the desired communication module in the rear view of the device.
- Use the **Communication protocols** text box to select the protection interface. A text box entitled **Protection interface** will then appear.

[scconfcp-241110-01.tif, 1, en_US]

Figure 3-52 Selection of the Communication Protocol

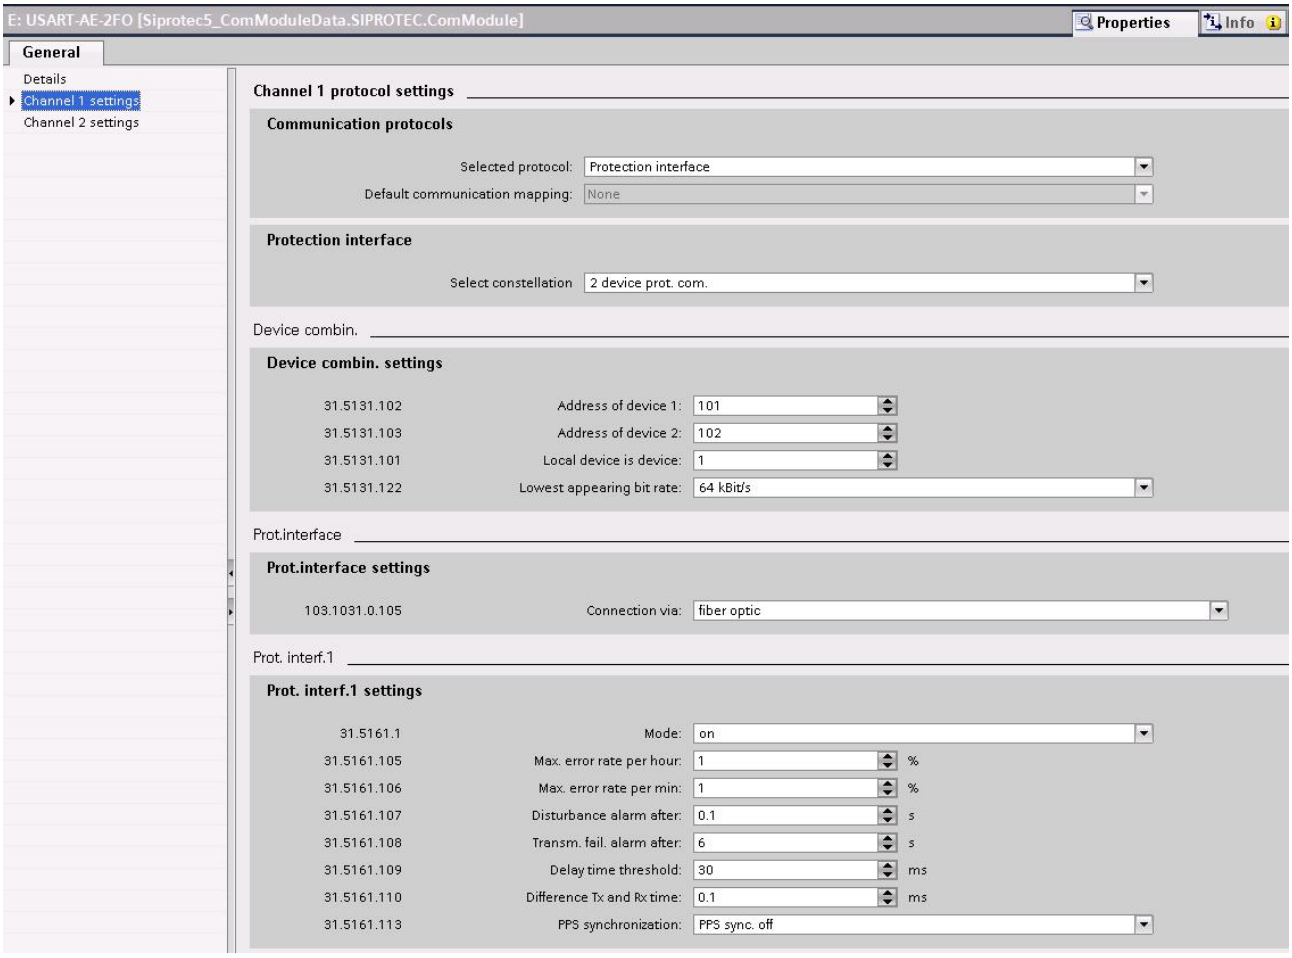
- Then select the **Select constellation** text box to select the number of devices (see next figure).

[scconfws-241110-01.tif, 1, en_US]

Figure 3-53 Selecting the Constellation

NOTE

You have the option of changing the number of devices (for example **2 protection communication devices**) depending on the product code any way you like via the **Select constellation** text box.



If you change the number of devices via the **Select constellation** text box, all activated constellation settings are lost.

If the module slot is not yet provided with modules, proceed as follows:

- Select the desired communication module in the rear view of the device.
- Select the module from the catalog and drag it to a channel. Thus is the channel configured with a module. DIGSI 5 indicates whether the module can be used for protection communication under **Device Information**.
- Use the **Communication protocols** text box to select the protection interface. A text box entitled **Protection interface** will then appear (see *Figure 3-52*).
- Then use the **Select constellation** text box to select the number of devices (for example **2 devices protection com.**) (see *Figure 3-53*).

3.5.3.5 Device-Combination Settings

Make the device-combination settings and the settings for protection communication (see next figure).

[scconfig-181013-01, 1, en_US]

Figure 3-54 Protection Interface Initialization and Configuration

Changes in a channel are always visible on the other channel as well. All further parameters can be set separately for individual channels.

Setting Device-Combination Settings

- Default setting **(_:5131:102) Address of device 1** = ***101***
- Default setting **(_:5131:103) Address of device 2** = ***102***
- Default setting **(_:5131:104) Address of device 3** = ***103***

- Default setting **(_:5131:105) Address of device 4** = ***104***
- Default setting **(_:5131:106) Address of device 5** = ***105***
- Default setting **(_:5131:107) Address of device 6** = ***106***

The parameters **Address of device 1** to **Address of device 6** can be used to give an address to each device. Set a unique and unambiguous address for each device.

- Default setting **(_:5131:101) Local device is device** = ***1***

With the **Local device is device** parameter, you set the index (number) of your device in the topology. A maximum of 6 devices can be present in one topology.

APPLICATION EXAMPLE

You have a topology with 2 devices.

For example, in DIGSI 5, select the parameter setting **Address of device 1** with the parameter value ***101*** for device 1 and the parameter setting **Address of device 2** with the parameter value ***102*** for device 2.

Then, use the **Local device is device** parameter to set the index of the local device.

The addresses must be configured identically for all devices involved in the constellation. A functional protection communication requires that you also assign the same index in all devices of a constellation for a device with a unique address.

- Default setting **(_:5131:122) Lowest appearing bit rate** = ***64 kBit/s***

The **Lowest appearing bit rate** parameter is used to set the smallest occurring bit rate in the device group. Set the smallest value in each device with a three-end constellation with 2 fiber-optic connections (2 MBit/s) and a 64-kBit/s connection with the lowest value (64 kBit/s). This value determines the maximum signals and measured values within a constellation.

Apart from the default value, you can also set the following bit rates:

- ***128 kBit/s***
- ***512 kBit/s***
- ***2048 kBit/s***

NOTE

If you use fiber-optic cables for the connection between the devices, set the value to ***2048 kBit/s*** .

3.5.3.6 Selecting the Connection

- Default setting **(_:105) Connection via** = ***fiber optic***

The **Connection via** parameter is used to set the bit rate required for the protection interface. Different discrete values can be entered depending on the means of communication (see following table).

Table 3-9 Means of Communication

Means of Communication	See	Setting Value	Bit Rate
Fiber-optic direct connection	*Figure 3-42* to *Figure 3-45*	***fiber optic***	2 MBit/s
CC-XG-512 communication converter	*Figure 3-46*	***CCXG 512 kBit/s***	512 kBit/s
CC-XG-128 communication converter	*Figure 3-46*	***CCXG 128 kBit/s***	128 kBit/s
CC-XG-64 communication converter	*Figure 3-46*	***CCXG 64 kBit/s***	64 kBit/s

Means of Communication	See	Setting Value	Bit Rate
Repeater 512 communication converter	*Figure 3-49*	***repeater 512 kBit/s***	512 kBit/s
CC-CC-128 Communication converter	*Figure 3-48*	***CCPW 128 kBit/s***	128 kBit/s
CC-2M-512 Communication converter	*Figure 3-47*	***CC2M 512 kBit/s***	512 kBit/s
Multiplexer with C37.94 interface	*Figure 3-50*	***C37.94 1 * 64 kBit/s*** ***C37.94 2 * 64 kBit/s*** ***C37.94 8 * 64 kBit/s***	64 kBit/s 128 kBit/s 512 kBit/s
Other (freely adjustable bit rates for a direct connection for special applications)		***64 kBit/s*** ***128 kBit/s*** ***512 kBit/s*** ***2048 kBit/s***	64 kBit/s 128 kBit/s 512 kBit/s 2048 kBit/s

NOTE

Keep in mind that the **Teleprotection schemes** require a minimum bandwidth for communication via a protection interface.

If the **Line differential protection** function is available in the device, the bit rate must not be less than 512 kBit/s!

The minimum bit rate of 512 kBit/s is important for the **Teleprotection with distance protection** and **Teleprotection with ground-fault protection** functions.

3.5.3.7 Setting Notes for the Protection Interface

Parameter: Max. Error Rate/h

- Default setting **(_:5161:105) Max. error rate per hour** = ***1.0 %***

The **Max. error rate per hour** parameter allows you to receive an error message on the number of faults per hour. An indication is then generated.

Parameter: Max. Error Rate/min

- Default setting **(_:5161:106) Max. error rate per min** = ***1.0 %***

The **Max. error rate per min** parameter allows you to receive an error message on the number of faults per minute. An indication is then generated.

Parameter: Disturbance Alarm After

- Default setting **(_:5161:107) Disturbance alarm after** = ***100 ms***

The **Disturbance alarm after** parameter determines the time delay after which defective or missing telegrams are signaled as faulty.

Parameter: Transm. Fail. Alarm After

- Default setting **(_:5161:108) Transm. fail. alarm after** = ***6.0 s***

The **Transm. fail. alarm after** parameter is used to set the time after which a failure of the communication is signaled.

NOTE

If the setting values of the parameters **Disturbance alarm after** and **Transm. fail. alarm after** are exceeded, then an indication is generated.

Parameter: Delay time threshold

- Default setting **(_:5161:109) Delay time threshold** = ***30.0 ms***

For the **Delay time threshold**, the default setting is selected such that it is not exceeded by normal communication networks. If this time delay is exceeded during operation (for example, upon switchover to another transmission route), the indication **Time delay exceeded** is issued.

Parameter: Difference Tx and Rx time

- Default setting **(_:5161:110) Difference Tx and Rx time** = ***0.1 ms***

The **Difference Tx and Rx time** parameter can be used to set a maximum time-delay difference between the send and receive paths.

Set this value to ***0*** for a direct fiber-optic connection. A higher value is necessary for transmission via communication networks. Reference value: ***0.1 ms*** (recommended setting value).

NOTE

Only if the **Line differential protection** function is instantiated, the **Difference Tx and Rx time** parameter is displayed.

NOTE

If the user employs a multiplexer with a C37.94 interface as a communication medium, Siemens recommends a setting value of ***0.25 ms*** to ***0.6 ms***.

Parameter: PPS Synchronization

- Default setting **(_:5161:113) PPS synchronization**=***PPS sync. off***

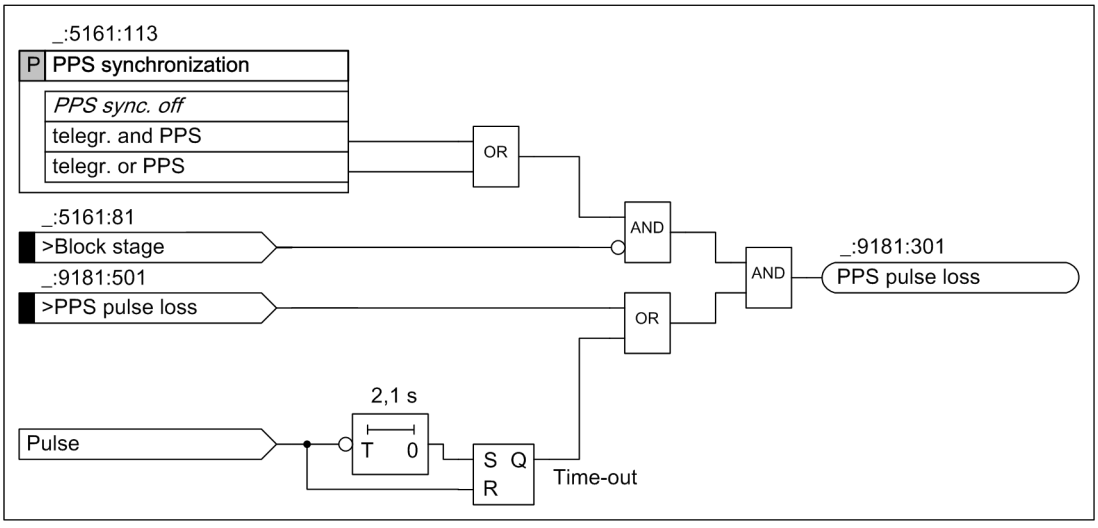
If the SIPROTEC device operates with PPS synchronization (PPS: pulse per second), use the **PPS synchronization** parameter to define how the protection is activated after restoration of the communication connection (basic state or after transmission fault).

Refer to *Figure 3-55*.

NOTE

The PPS measurement is used to consider the time delay in the send and receive directions. If PPS fails due to a reception fault or due to a short-term unfavorable satellite position, synchronization via conventional communication media remains active.

The **PPS synchronization** parameter offers 3 different setting options:



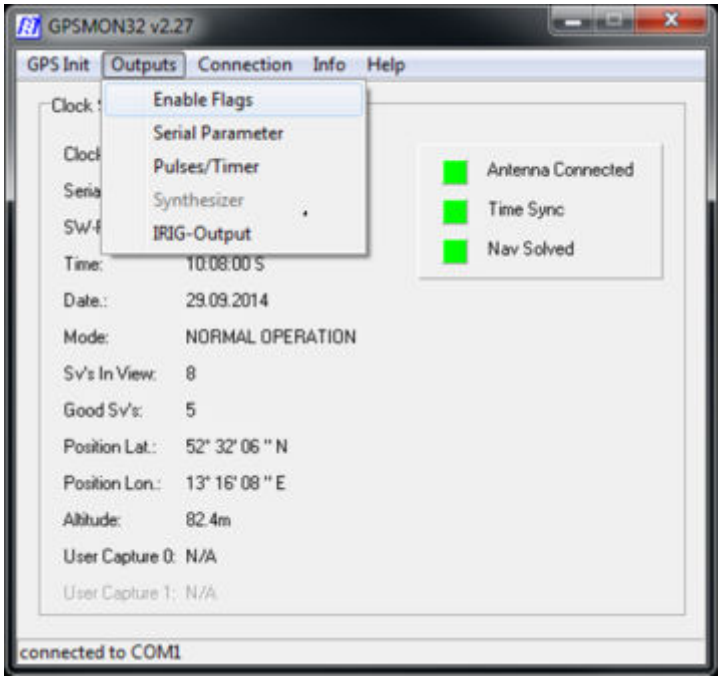
Parameter Value	Description
telegr. and PPS	With this setting, the differential protection is only enabled upon renewed establishment of the connection, if the communication section is synchronized via PPS or if symmetrical time delays are signaled by an external operation (binary input). This results in synchronization with the telegram measurement supported by the PPS measurement.
telegr. or PPS	In this setting, the differential protection is enabled immediately upon renewed establishment of connection (data telegrams are received). The conventional method is used up to synchronization. This results in synchronization with the telegram measurement supported by the PPS measurement.

Parameter Value	Description
PPS sync. off	This setting means that no synchronization is performed via PPS at the protection interface. This is typically the case if no time-delay differences are expected. The synchronization only takes place with the telegram measurement.

NOTE

The synchronization mode can be set separately for both protection interfaces.

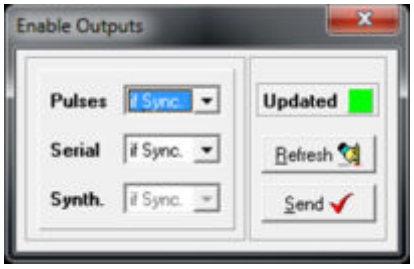
If no further PPS pulse is received within 2.1 s, the time-out supervision responds. If no new 2nd pulse occurs after the expiry of the supervision time, the indication **PPS pulse loss** is issued.



[loppssyn-100113-01.tif, 1, en_US]

Figure 3-55 Setting the PPS Synchronization

The binary input **>PPS pulse loss** can be used to signal an externally detected failure in the PPS signal (for example, error message from the receiver). Setting this binary input also leads to the indication **PPS pulse loss**.



If you are using a second pulse from a GPS receiver, you must ensure that a loss of reception or reception disturbances do not generate a second pulse. The GPS receivers recommended by Siemens are set by default so that a loss of reception or reception disturbances do not generate a second pulse. In the event of problems, check the setting value for the second pulse.

Siemens recommends the **Meinberg 164** GPS receiver. Check the default setting for the second pulse using the **GPSMON32** program. The program is available in the SIPROTEC *download area*. You can find the setting value under **Outputs** →**Enable Flags**. The second pulse must be set to the value ***if Sync.***

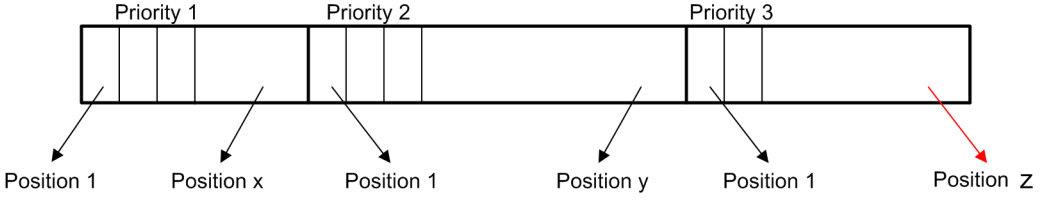

Figure 3-57 Checking the Setting Value for the 2nd Pulse Using the GPSMON32 Program, Step 2

3.5.3.8 Routing Information in DIGSI 5

Protection communications of the same type form a topology.

For more information on this, see chapter *3.5.3.3 Function Description* .

A data bar is exchanged between the devices of a topology connected via protection communication. This can be written into or read from by the devices. This can be used for exchanging various signals between the devices. In this case, each signal demands a certain number of data fields.

[dwdatenl-100113-01.tif, 1, en_US]

Figure 3-58 Data Bar Exchanged Between Devices

The data bar is divided into 3 priorities, which also have different transmission rates and data volumes.

The following basic principle applies for all messages: Only pure data contents are transmitted. The quality (for example, *valid*) is not automatically transmitted as well. If you want to transmit the quality as well (for

example, for further processing of GOOSE messages), the quality must be transmitted separately (for example, by using CFC). If a signal that has a test flag is transmitted (because its function is in test mode, for example), all signals are provided with a test flag on the receiving side. If the connection is broken, all received signals are flagged with the quality *Invalid*. If desired, the value can also be set to a secure state after a selectable dropout time, or the last value received can be retained (**Hold** setting). This can be configured separately for each received signal (see *Table 3-13*).

NOTE

For **ACT** type signals, only the phase information is transmitted.

Indications that are transferred data fields of priority 1 are sent with every telegram. They are preferably used for the transmission of rapid signals, for example, release for circuit-breaker intertripping. A strictly deterministic, rapid transmission is required there.

Signals of priority 2 are transmitted with at least every 2nd telegram. For bit rates >256 kBit/s, there are no differences between priority 1 and priority 2.

Priority 3 information is transmitted at least every 100 ms. This priority is used for transmission of measured and metered values. Complex values must be routed separately as the real and the imaginary part for transmission. Measured-value thresholds that lead to an updating of a measured value are set centrally as a property of the measured value. These measured-value thresholds apply with the corresponding reporting, for example, also for the transfer via IEC 61850 to a substation automation technology.

Indications which are written to a data area x under a priority on the data bar must be routed to an indication of the same type in the device reading this information. Otherwise, they are processed incorrectly on the receiving side. The data bar is organized in terms of bits. For information on the bit requirement of each signal type, refer to *Table 3-12* .

Table 3-10 and *Table 3-11* show the number of data areas in the data bar in relation to the available baud rate.

NOTE

The **Lowest appearing bit rate** parameter, which has to be set in each device for the protection interfaces of a topology, defines the number of data areas as well as the topology type.

If, for example, in a three-end constellation with a type 2 chain topology two devices are connected via direct optical fibers and 2 devices via the 64-kBit/s weakest line, the 64-kBit/s section is the limiting factor for the entire constellation.

Table 3-10 Available Bits - Minimum Constellation Baud Rate 64/128 kBit/s

	Priority 1	Priority 2	Priority 3
Type 1	8 Bits	24 Bits	128 Bits
Type 2	32 Bits	64 Bits	256 Bits

Table 3-11 Available Bits - Minimum Constellation Baud Rate 512/2048 kBit/s

	Priority 1	Priority 2	Priority 3
Type 1	48 Bits	128 Bits	384 Bits
Type 2	96 Bits	200 Bits	1024 Bits

Table 3-12 Requirement in Bits

Signal Type	Size in Bits
SP (single-point indication)	1 Bit
DP (double-point indication)	2 Bits
IN (metered values)	32 Bits

Signal Type	Size in Bits
MW (measured values)[5]	32 Bits
ACT	4 Bits

Table 3-13 Possible Dropout Values

Signal Type	Dropout Values
SP (single-point indication)	Outgoing, Incoming, Hold
DP (double-point indication)	On, Off, Intermediate Position, Disturbed Position, Hold
IN (metered values)	0, Hold
MW (measured values)	0, Hold
ACT	Hold

NOTE

If the protection link fails, these values can be set on the receiver side.

EXAMPLE

2 devices are connected via a 64-kBits channel. This is a type 1 topology. 8 bits are freely available for priority 1. Now, for example, 4 SPS and 2 DPS can be routed:

4 x 1 Bit + 2 x 2 Bits = 8 Bits

NOTE

Measured values are transmitted as primary values.

EXAMPLE

For the rated current display in the receiving device

When I_{rated} = 1000 A in the transmitting device and I_{Load} = 200 A, the number 200 is displayed in the receiving device.

Remote Data Transmission: Routing of the Indications and Measured Values to the Protection Interface

The transmission is organized in the form of a data bar which is continuously exchanged between the devices.

For this, see *Figure 3-58* .

A device indication or measured value is allocated to a definite data area of the bar.

Figure 3-59 to *Figure 3-62* show the routing for a communication topology of protection interface type 1.

To transmit signals to other devices, these signals must be routed in the communication matrix under **Transmit**. Binary inputs 1 and 2 are single-point indications (SPS) and are routed to position 1 and position 2 of the transmission with the highest priority (priority 1). For 64 kBit/s, for example, only 8 of these data areas are available for type 1; they are exchanged between the transmission routes with each telegram. Signals 3 and 4 are double-point indications (DPS), for example, a switch position that is transmitted by a device 1. A double-point indication occupies 2 positions on the data bar. In addition, a measured and metered value are communicated via priority 3.

As a measured or metered value uses 32 bits, value 2 starts at position 33. DIGSI 5 indicates the next available position.

[5] The complex vectors of a measuring point are pre-routed

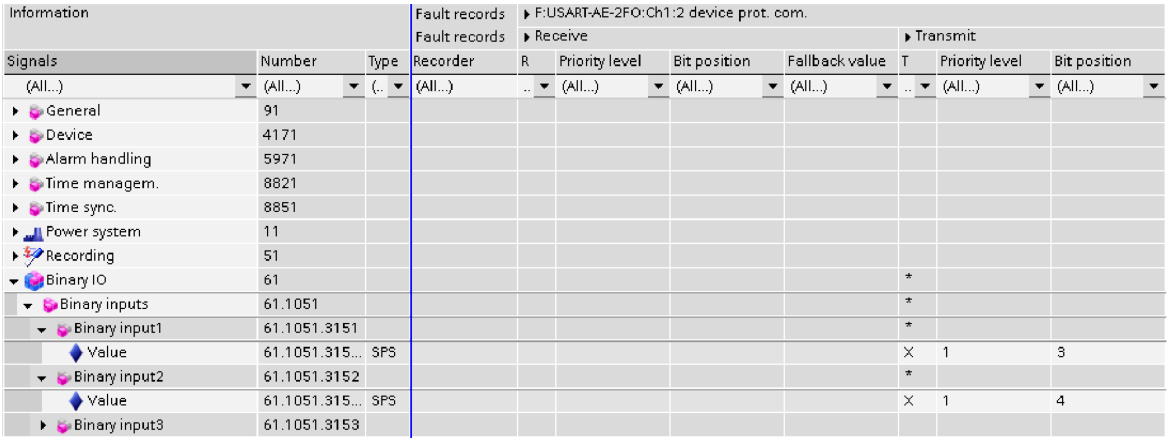
Figure 3-61 Routing of Metered Values to the Protection Interface in Device 1



This device also receives information (in the matrix under **Receive**). This must have been routed as a target for other devices (see next figure). The binary outputs 1 and 2 in device 1 receive their information via the protection interface. This is priority 1 information, which has been routed in another device to position 3 and 4 of the data bar. The secure state is defined in the **Fallback value** column. If the data connection fails, the single-point indication is reset to ***coming*** or **going** or its value is retained (***hold***). For data of the various priorities, you can also set a dropout time after which the resetting (see *Figure 3-61*) to the fallback value occurs, in order to retain the original state for a short time in the event of brief interruptions. These 3 dropout times apply for all data of one transmission priority and are set as parameters.

[scspsemp-021210-01.tif, 1, en_US]

Figure 3-62 Routing of Single-Point Indications (Receive) to the Protection Interface in Device 1

The following figure shows the routing in the 2nd device. Binary inputs 1 and 2 are routed with priority 1 to positions 3 and 4 there. In device 1, positions 1 and 2 are already occupied (see *Figure 3-59*). If you also route the signals to positions 1 and 2, the signals of the devices are then connected to the corresponding position with a logical **OR** operation. If measured and metered values are routed in the same data areas, this results in implausible values for the receivers that read the data. As a user, you are therefore responsible for the correct routing.

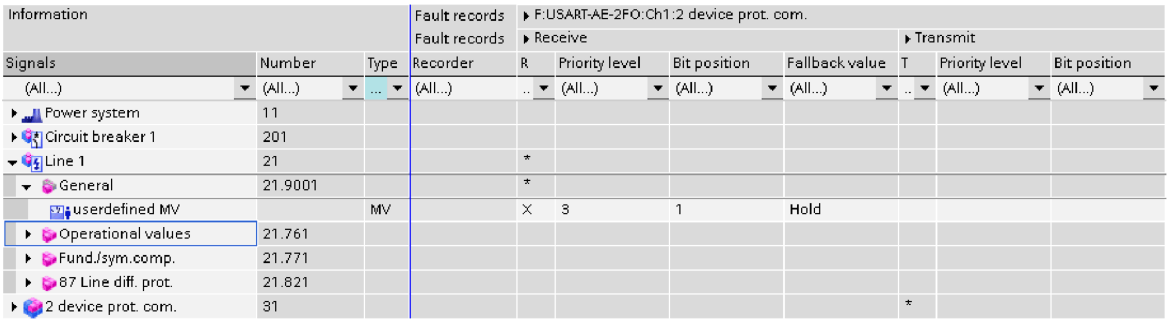
Figure 3-63 Routing of Single-Point Indications to be Sent to the Protection Interface in Device 2

The binary outputs 1 and 2 (**Receive**) in the 2nd device are connected to priority 1 signals 1 and 2 from the 1st device. This takes place via the data areas at positions 1 and 2 of the data bar, which transfer the state of the indications. Other devices can also read this information and link it to their internal signals. Here, too, the secure state, which is assumed when the protection connection is interrupted, is entered. This state depends on the information. In the case of single-point indications, the state is 0 or 1. In the case of double-point indications, the bit combinations 00, 01, 10, or 11 are possible, in order to directly signal a disturbed position upon failure of the data connection, for example.



Hold is used to retain the state.

3.5.3.9 Diagnostic Measured Values of the Protection Interface

The following diagnostic data is provided via the protection interfaces by the devices in the constellation:

- Address of the device in the constellation
- Circuit-breaker switch position (open/closed/undefined) (only for protection interfaces of type 1)
- Availability of protection-interface communication within the last minute, as percentage
  Availability of protection-interface communication within the last hour, as percentage
- Time delay in the send and receive direction of the telegrams between local and neighboring device

You can find this diagnostic data in DIGSI under the following menu structure (see *Figure 3-67*):

[sc_diagnose_wskanäle_geräteadresse, 2, en_US]

Figure 3-67 Protection-Interface Channel Diagnostic Data – Device Address

NOTE

You can use the following procedure to reset the measured values for the protection interface directly in the device:

Device functions > x Device protection comm. > Protection interface y > Reset measured values.

Output Signals of the Protection Interface

Each individual protection interface provides the following indications for commissioning and diagnosing communication:

Indication	Description
(_:5161:301) Status of lay. 1 and 2	The output signal gives you information about the state of communication layers 1 and 2 (1: Physical Layer, 2: Data Link Layer). The following indications values are possible: • *Initialized*: The protection interface is not connected and is in the Initial state. • *Protection interface connected*: The protection interface is connected to the protection interface of a device. • *Protection interface disturbance*: The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:107) Disturbance alarm after**. • *Protection interface failure*: The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:108) Transm. fail. alarm after**. • *not present*: The protection interface has not been assigned to a communication channel.

Indication	Description
(_:5161:302) Status of lay. 3 and 4	The output signal gives you information about the state of communication layers 3 and 4 (3: Network Layer, 4: Transport Layer). The following indications values are possible: • *no error*: The protection interface is operating correctly. • *Software version incompatible*: The firmware versions of the connected devices are incompatible. Update the firmware. • *System mirroring*: The protection interface is receiving its own data. Check the wiring. • *Dev. add. incorrect*: The device address of the partner device is incorrect. Check the settings for parameters **Address of device 1** to **address of device n** (_:5131:102 and following). • *Constell. incorrect*: The constellation settings of the devices are different. Check that the setting for the parameter **Select constellation** is identical in all devices. • *Const. param. incorrect*: Check that the same setting has been made for parameter **(_:5131:122) Lowest appearing bit rate** in all devices. • *Diff. Param. Error*: The line differential protection settings for the connected devices are incompatible. Check whether both devices are set to operate with or without line differential protection. The rated value of the line (parameter **(_:9001:101) Rated current** and **(_:9001:102) Rated voltage**) must have the identical setting at both ends of the line. If a transformer is installed in the line, both parameters must be set such that the rated apparent power is the same at both ends of the line (parameter **(_:9001:103) Rated apparent power**).

In order to clarify faults, each individual protection interface provides the following binary signals:

Binary Output Signal	Description
(_:5161:303) Connection broken	Signal *Connection broken* indicates that during a parameterized time (parameter **(_:5161:107) Disturbance alarm after**) faulty or missing telegrams were continuously received. If the 'Connection interrupted' indication occurs, the affected protection interface link will be terminated. This can cause the blocking of an active differential protection or a ring topology can change to a chain topology.
(_:5161:316) Error rate / min exc.	Signal *Error rate / min exc.* indicates that the set maximum error rate per minute (Parameter **(_:5161:106) Max. error rate per min**) has been exceeded.
(_:5161:317) Error rate / hour exc.	Signal *Error rate / hour exc.* indicates that the set maximum error rate per hour (Parameter **(_:5161:105) Max. error rate per hour**) has been exceeded.
(_:5161:318) Time delay exceeded	Signal *Time delay exceeded* indicates that the threshold value for the set signal-transit time (Parameter **(_:5161:109) Delay time threshold**) has been exceeded.
(_:5161:319) Time delay different	Signal *Time delay different* indicates that the threshold value for asymmetrical transit times has been exceeded. The setting value results from the setting value of the parameter **(_:5161:110) Difference Tx and Rx time**.
(_:5161:320) Time delay jump	Signal *Time delay jump* indicates that the data transit times changed abruptly. This is caused by switching the communication path in the communication network.

Binary Output Signal	Description
(_:5161:321) PI synchronized	Signal *PI synchronized* indicates that the protection-interface connection is synchronized with the opposite end.
(_:5161:340) Telegram lost	Signal *Telegram lost* indicates that an expected telegram has failed to arrive or a faulty telegram has been received. If you would like to allocate the communication failures or faults to other events, move the signal *Telegram lost* temporarily into the operational log. Such events can be switching operations in the primary system or operations on the components of the communication network. **Note:** If the signal is constantly routed, the operational log can overflow. Siemens recommends routing the signal only for clarification of faults.

Measured Values of the Protection Interface

The protection interface provides the following measured value to diagnose the protection interface communication:

Measured Value	Description
(_:5161:308) Tx tel/h	Telegrams sent during the last hour
(_:5161:309) Rx tel/h	Telegrams received during the last hour
(_:5161:310) Tx tel/min	Telegrams sent during the last minute
(_:5161:311) Rx tel/min	Telegrams received during the last minute
(_:5161:312) Tx err/h	Transmission failure rate during the last hour
(_:5161:313) Rx err/h	Reception failure rate during the last hour
(_:5161:314) Tx err/min	Transmission failure rate during the last minute
(_:5161:315) Rx err/min	Reception failure rate during the last minute
(_:5161:325) Aver.Δt	Mean signal-transit time (average value of the transit time in transmission and reception direction divided by 2, without GPS synchronization)
(_:5161:326) Rec. Δt	Signal-transit time in reception direction (with GPS synchronization)
(_:5161:327) Sen. Δt	Signal-transit time in transmission direction (with GPS synchronization)
(_:5161:334) Miss.tel/min	Number of telegram failures within the last minute
(_:5161:335) Miss.tel/h	Number of telegram failures within the last hour
(_:5161:336) Miss.tel/d	Number of telegram failures within the last day
(_:5161:337) Miss.tel/w	Number of telegram failures within the last week
(_:5161:338) M. loss/d	Longest lasting telegram failure within the last day
(_:5161:339) M. loss/w	Longest lasting telegram failures within the last week

NOTE

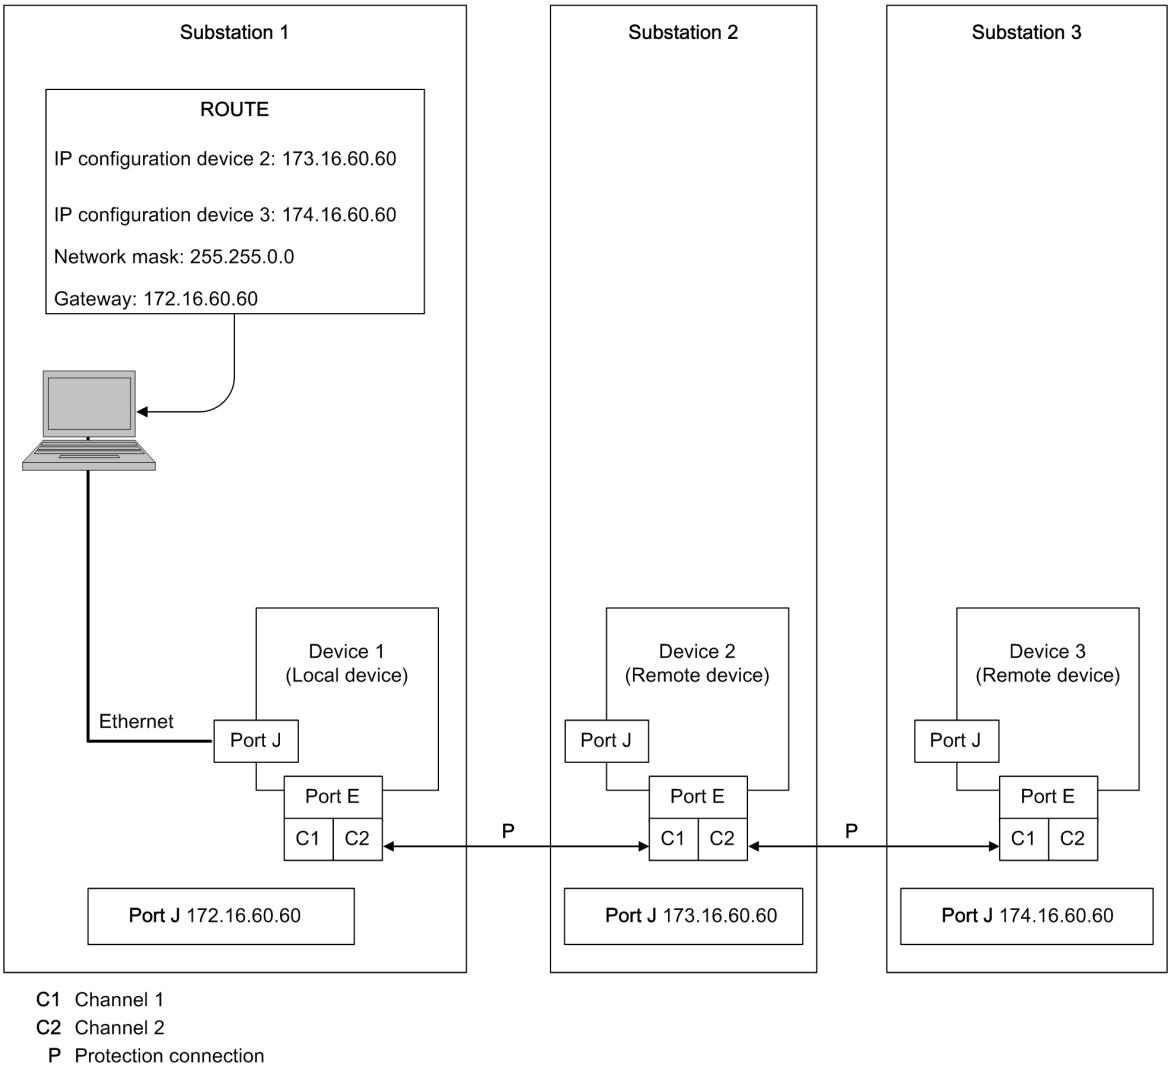
You can reset the measured values of the protection interface directly in the device. Proceed as follows: **Device functions > x Device protection comm. > Protection interface y > Reset measured values**.

3.5.3.10 Tunneling with DIGSI 5 via Protection Interface

Configuration of the Subnetworks

You can use a PC to access other devices within the constellation via the protection links. DIGSI 5 communication then operates exclusively via the connections and the protection-data communication is turned off. In this way, you operate the remote devices from the local device via DIGSI 5.

Remote control with DIGSI 5 is only possible if you are online with the local device and connected there with the integrated Ethernet interface RJ45



NOTE

All remote devices need an IP configuration for port J (integrated Ethernet interface) in all cases. The IP addresses of slots J of a protection topology must be in different subnetworks.

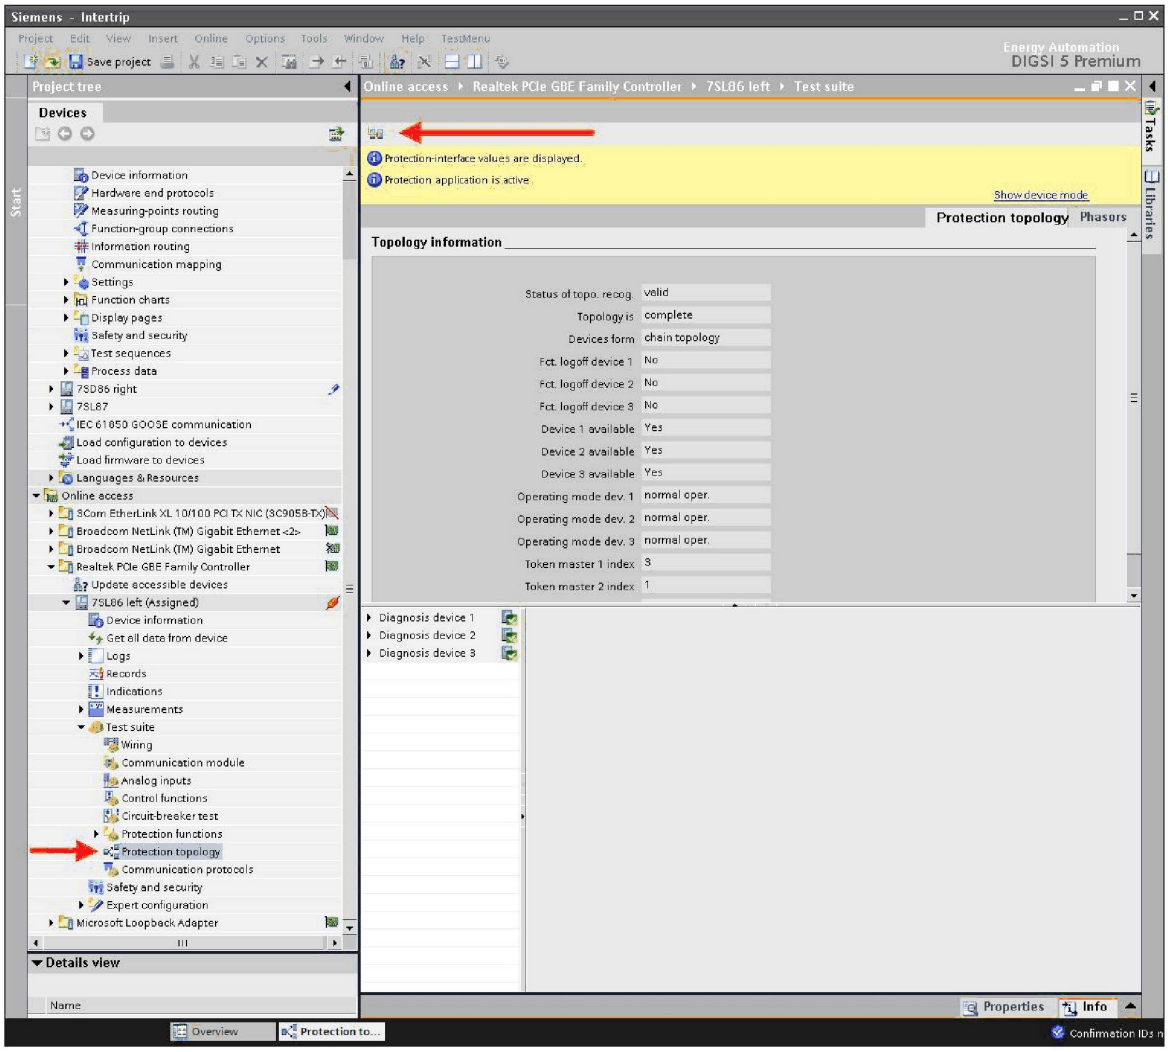
NOTE

If reparameterization requires a restart of the remote device, then the corresponding route is not available until after approx. 2 min. following a complete restart.

The following figure shows a configuration with 3 devices as an example.

[dwremote-030211-01.tif, 1, en_US]

Figure 3-68 Sample Configuration of a Remote Control with 3 Devices



Tunneling with DIGSI 5 via Protection Interface: Procedure

If you want to perform tunneling (remote control)[6] via DIGSI 5, proceed as follows:

- You make a connection between DIGSI 5 and the device through the Ethernet RJ45.
- Open the device concerned in **Online access**.
- Go to **Test suite**/**Protection topology**.
- Open **Protection topology**. In the next window, press the button at top left (see arrow in the following figure). The dialog for deactivating the protection communication then opens.

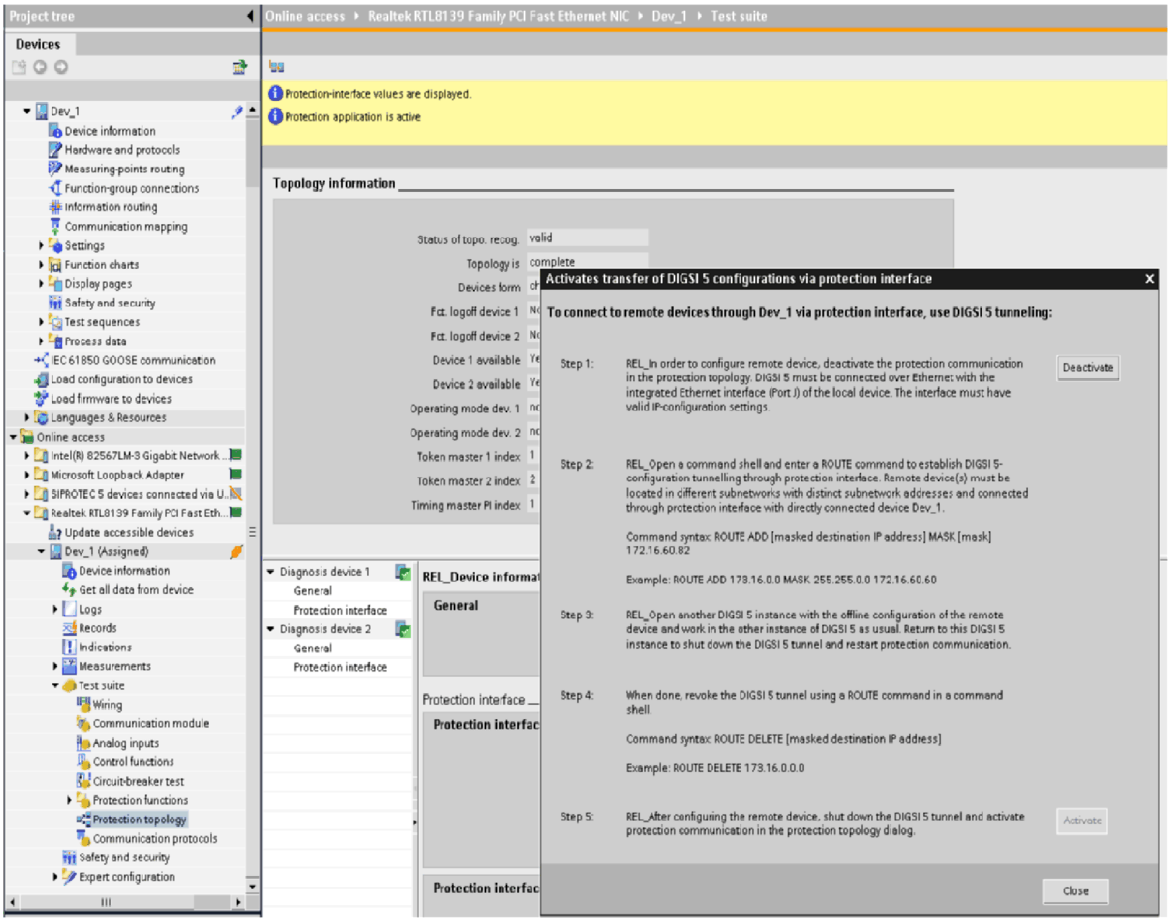
  If you confirm the query, protection communication is interrupted and the communication channels are used exclusively for DIGSI 5. Note that the protection functions that use protection data communications (e.g. differential protection) are deactivated and no remote data can be updated in the constellation. Then, the remote signals fall back to the secure state the user has defined earlier.

[6] This function is not yet implemented and will first be activated with a later firmware version.

[sctunnel-200213-01.tif, 1, en_US]

Figure 3-69 Tunneling with DIGSI 5

NOTE

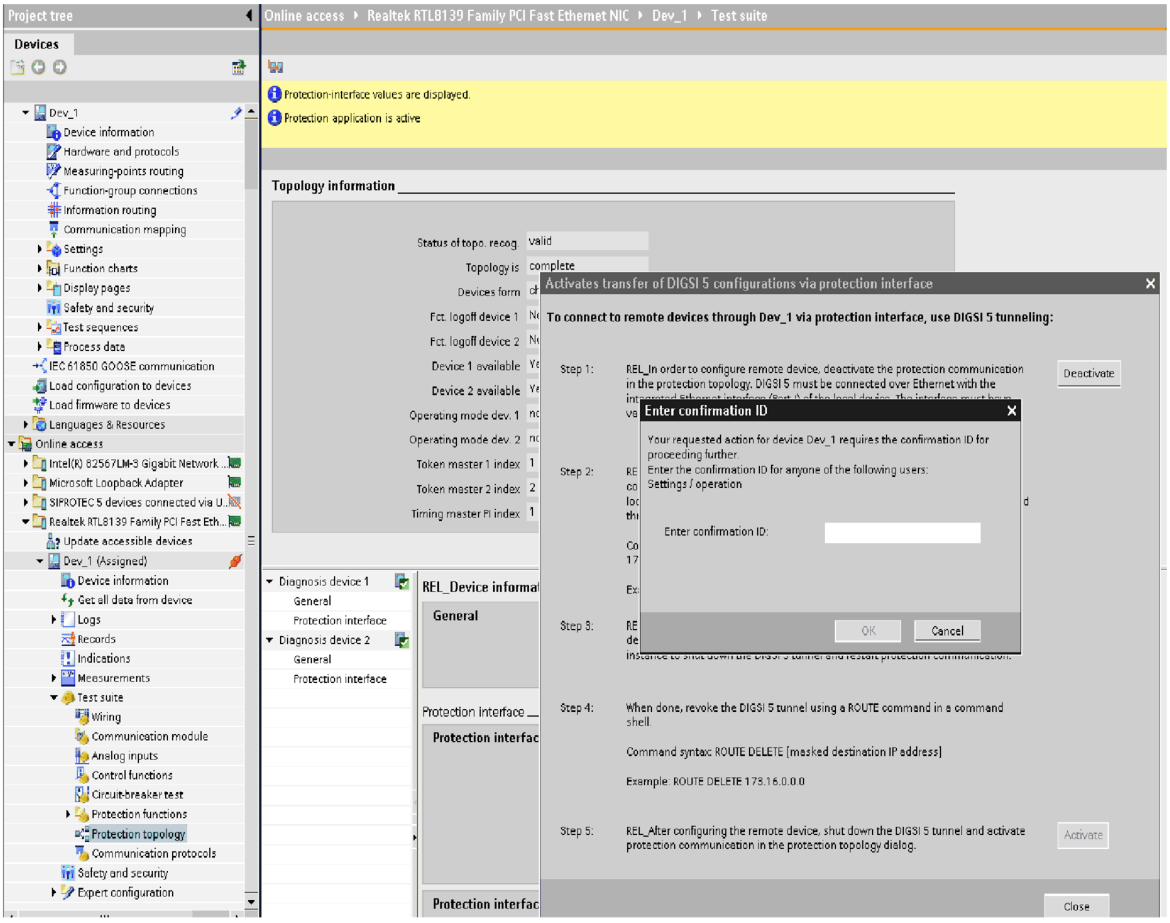


The protection communication remains interrupted until either the user reactivates it manually, or a maximum deactivation duration of 12 hours has been exceeded. After this, the connection reactivates itself. This ensures that the protection communication and protection function working with it are reactivated.

NOTE

Ensure that DIGSI 5 is connected via Ethernet to RJ45 of the local device. The local device must be configured with valid IP addresses.

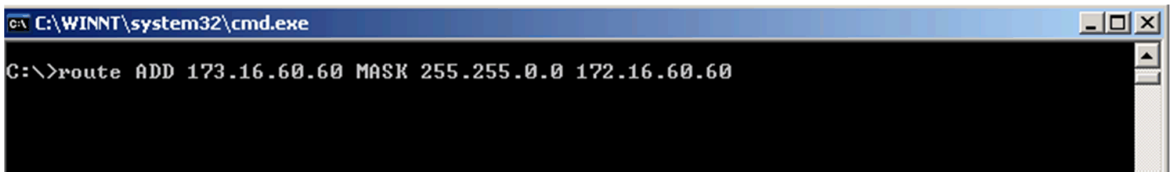
Figure 3-70 to *Figure 3-71* show the steps for the deactivation of protection communication.



In the next step, a window appears in DIGSI 5 containing the instructions for deactivating the protection data communication (see next figure).

[scdeadig-061210-01.tif, 1, en_US]

Figure 3-70 Steps for the Deactivation of Protection Communication



In order to be able to deactivate the protection-data communication, you must enter your confirmation ID if a security query is activated (see next figure). The default confirmation ID is **222222**.

[scdecode-061210-01.tif, 1, en_US]

Figure 3-71 Entering the Confirmation ID for the Deactivation of Protection Communication

- Under **Start ---> Run in Windows**, open an input window by entering **CMD**.
  Use the DOS box to enter a command line to set a route (see next figure). This is the prerequisite that DIGSI 5 can be routed further via the protection interface.

[scdosbox-310311-01.tif, 1, en_US]

Figure 3-72 Setting of the Route in the DOS Box

NOTE

To set the route, you must have administrator rights for the DIGSI PC.

- The following routing command is necessary to connect from device 1 to device 2 in the example shown (see *Figure 3-68*):
  - Route add 173.16.60.60 Mask 255.255.0.0 172.16.60.60
  - Route <Command> Destination (= Device 2) Mask (Routing Device) Local Device

  Remote devices must be available in different subnetworks and provided with unique IP addresses. For this, RJ45 of the relevant devices must already be configured so that these devices can now be accessed remotely.
- Now, select your DIGSI 5 project for substation 2 and connect this to the device. Although you are physically connected to the local device, this device now establishes a connection with the remote device. You can now fully operate the remote device with DIGSI 5.

  After completing the process, the protection communication must be reactivated. For this, end the connection with the remote device in DIGSI 5 at the local device for the protection interface.

  If this communication is not terminated properly, the protection-data communication then switches on again automatically after about 12 hours.
- Delete the route again by entering the following in the DOS box:
  - Route Delete 173.16.60.60
- If you wish to access device 3 via the protection interface, proceed in the same way. In this case, the DIGSI 5 communication is routed to device 3 via device 2 and you are connected from device 1 to device 3.
- To establish a connection with device 3, the following route is necessary:
  - Route add 174.16.60.60 Mask 255.255.0.0 172.16.60.60

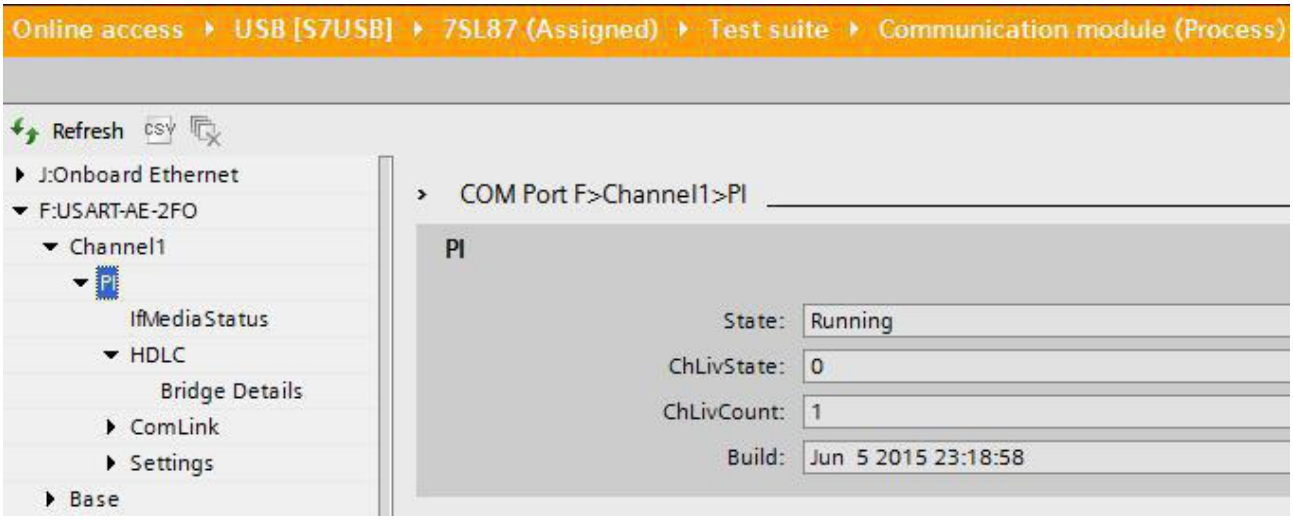
NOTE

If there is no connection between the local device and DIGSI 5 for longer than an hour, the connection automatically resets to protection communication.

3.5.3.11 Diagnostic Data for the Protection Interface

Diagnostic Data of the Channel in DIGSI 5

Different diagnostic data can be read with DIGSI 5.



For this, connect with the device via DIGSI 5 and query the device information. Diagnostic data for a module whose channel is configured with the protection interface can be received by selecting the module slots (for example, F) and the corresponding channel (1 or 2). The following figures show the extensive diagnostic data for the protection interface. It is particularly helpful if data failures occur or other irregularities in a communication connection (for example, transmission time fluctuations).

NOTE

The diagnostic data can also be read via the device control on the display of the device. The overview of DIGSI 5 does not offer this option, however.

The following table describes the displays.

[scdiapin-140912-01, 1, en_US]

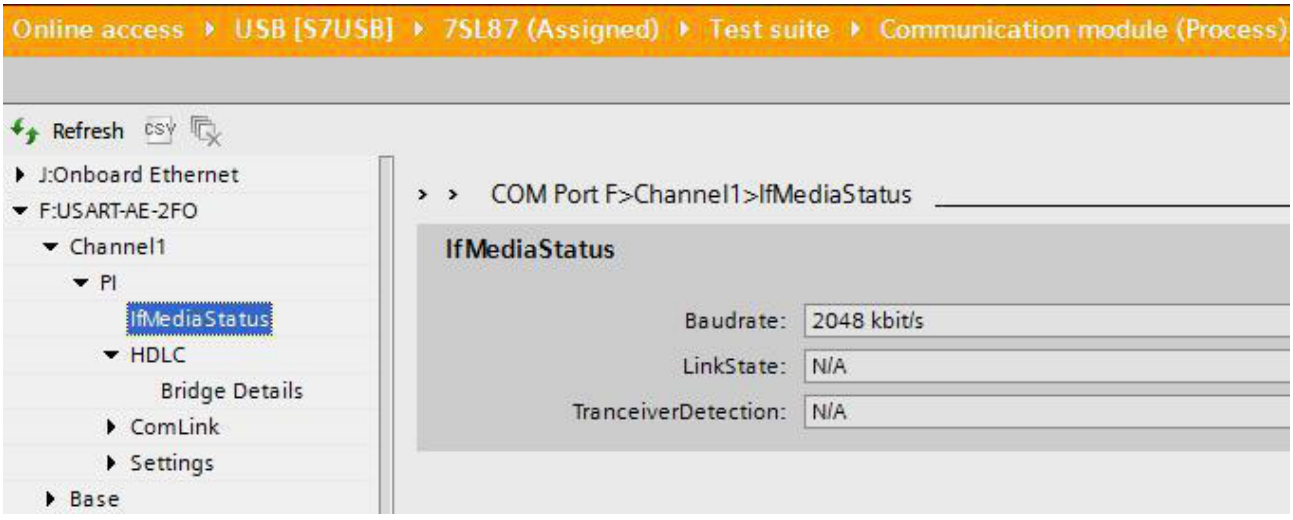


Figure 3-73 Diagnostic Data of a Channel Configured with the Protection Interface

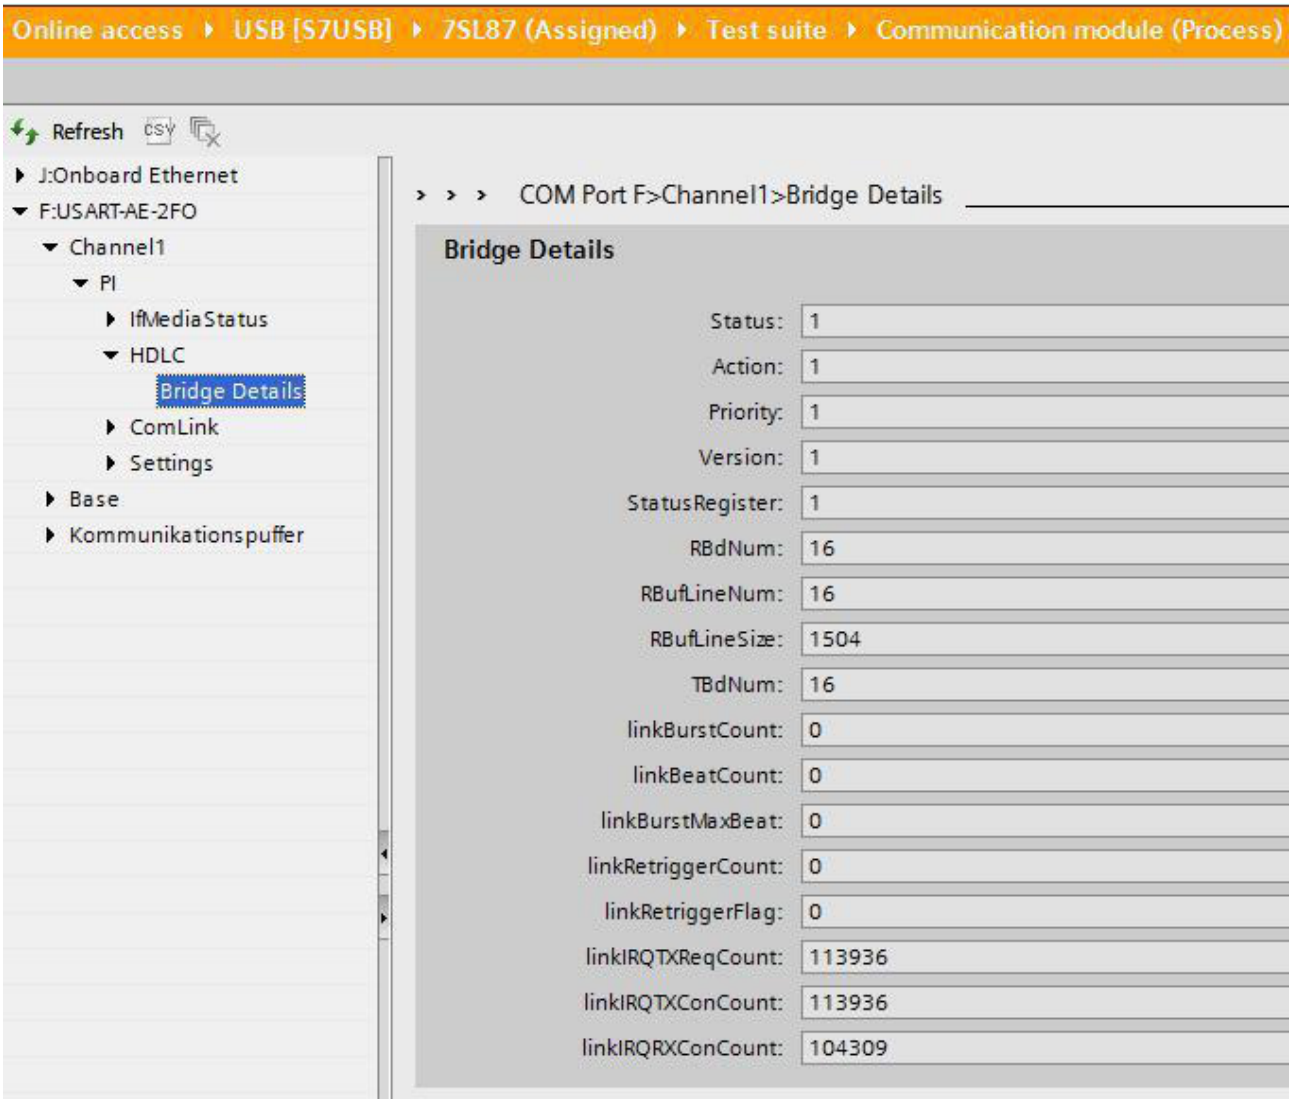
Table 3-14 Description of the Diagnostic Data under Protection Interface

Channel Type	Name	Values	Description - Diagnostic Information for Log PI
Protection interfaces - log	Status	Initial, Running, Error	Runtime status of the log
Protection interfaces - log	Build	Date/time	Date and time of the log version

Diagnostic Data of the Protection-Interface Log in DIGSI 5

The following figures and tables describe the displays of the protection-interface log.



[scdiamed-140912-01, 1, en_US]

Figure 3-74 Diagnostic Data of the Protection-Interface Log - Media Status

Table 3-15 Description of Diagnostic Data under Media Status

Protection Interfaces - Log Type	Name	Values	Description - Media Status Interface (in Direction of Outside Interface)

3.6 Date and Time Synchronization

3.6.1 Overview of Functions

Timely recording of process data requires precise time synchronization of the devices. The integrated date/time synchronization allows the exact chronological assignment of events to an internally managed device time that is used to time stamp events in logs, which are then transmitted to a substation automation technology or transferred via the protection interface. A clock module internal to the device and having battery backup is synchronized cyclically with the current device time so that the right device time is available and used even in case of auxiliary-voltage failure. At the same time, this permits hardware-supported monitoring of the device time.

3.6.2 Structure of the Function

The integrated date/time synchronization is a supervisory device function. Setting parameters and indications can be found in the following menus for the DIGSI and the device:

Set date and time:

- DIGSI: Online access -> Interface -> Device -> Device Information -> **Time Information**
- Device: Main menu → Device functions → **Date & Time**

Parameter:

- DIGSI: Project -> Device -> Parameter -> **Time Settings**

Indications:

- DIGSI: Project -> Device -> Information routing ->**Time keeping** or **Time Sync.**

3.6.3 Function Description

Every SIPROTEC 5 device maintains an internal device time with date. The date and time can also be set on the device via the on-site operation panel or via DIGSI 5. Within a system, or even beyond, it is usually necessary to record the time of process data accurately and to have exact time synchronization of all devices. For SIPROTEC 5 devices, the sources of time and synchronization options can be configured.

Configurable Synchronization Options:

- **None** (default setting)
  The device functions without any external time synchronization. The internal time synchronization continues to work with the help of the back-up battery even when the auxiliary voltage is shut down temporarily. The time can be adjusted manually.
- **Telegram**
  The time is synchronized via a telegram with an appropriately configured communication interface in accordance with the IEC 60870-5-103 or DNP3 protocol.
- **Connection to a radio clock**
  The time synchronization takes place with the set time telegram from an external IRIG-B or DCF77 receiver via the time synchronization interface of the device.
- **Ethernet**
  The time synchronization is done via Ethernet-based SNTP protocol (Simple Network Time Protocol), for example with IEC 61850 stations or via IEEE 1588. If you enable both services during configuration of Ethernet interfaces, these protocols are available as an option for the time synchronization.
- **Protection interface**
  The time synchronization takes place via the protection interfaces configured for your SIPROTEC 5 device. Here, the timing master takes over the time management.

Configurable Time Sources:

- 2 time sources can be taken into consideration with the SIPROTEC 5 devices. For each time source, the synchronization type may be selected based on the options provided.
- **Time source 1** takes precedence over **Time source 2**, that is, **Time source 2** will be effective for the synchronization of the device time only if **Time source 1** fails. If only one time source is available and it fails, then only the internal clock continues unsynchronized. The status of the time sources is indicated.
- For every time source it is possible to define via the **Time zone time source 1** parameter (or **Time zone time source 2**) if this source transmits its time by UTC (universal time) or if the settings correspond to the local time zone of the device.

NOTE

Make sure that the settings for the time sources coincide with the actual hardware configuration of your SIPROTEC 5 device. In any event, incorrect settings cause the status indications of time sources to pick up.

Configurable Date Format

Regardless of a feed time-synchronization source, a uniform format is maintained internally within the device. The following options are available for the customary local representation of the date format:

- Day.Month.Year: 24.12.2009
- Month/Day/Year: 12/24/2009
- Year-Month-Day: 2009-12-24

Taking Local Time Zones into Account

The internal device time is maintained in universal time (UTC). To display time stamps in DIGSI and on the device display, you can define the local time zone of the device (parameter Offset time zone for GMT), including the applicable daylight saving times (start, end, and offset of daylight saving time) using parameters. This allows the display of the local time.

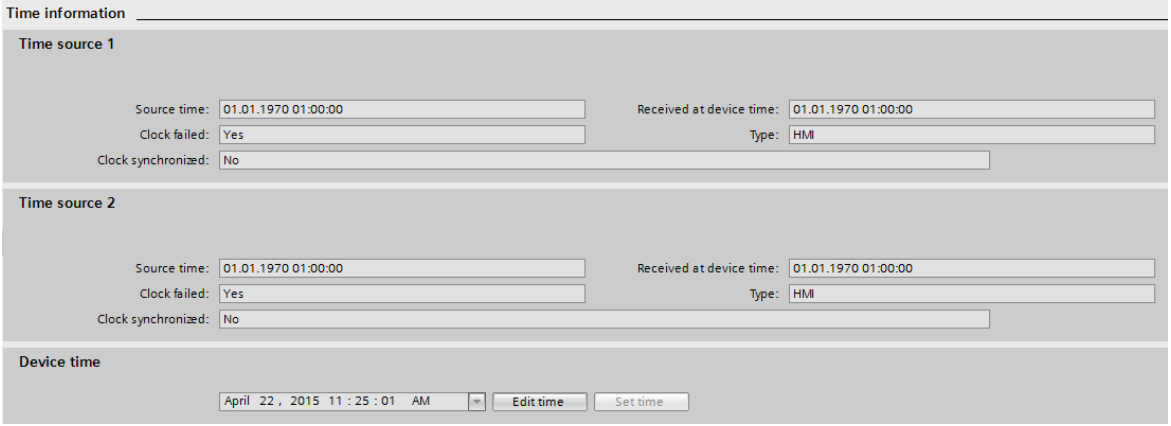
NOTE

- For time sources that transmit the status of the switch to daylight saving time, this will be taken into account automatically when creating the internal device time in the UTC format. The differential time of the daylight saving time set in the device (parameter Offset daylight saving time) is taken into consideration. However, in contrast, the settings of the start of daylight saving time and end of the daylight saving times are ignored when converting into the device internal UTC format.
- For active time sources, it is not possible to set the time via the device display or DIGSI 5. An exception is setting the calendar year for active time protocol IRIG-B.

Status, Supervision, and Indications of Time Management

Your SIPROTEC 5 device generates status and monitoring indications that provide important information regarding the correct configuration of the time source and the status of the internal time management during start-up and device operation.

Internal time synchronization is monitored cyclically. Important synchronization processes, the status of the time sources and errors detected are reported. A device time that has become invalid will be marked accordingly so that affected functions can go to a safe state.



Indication	Description
Device: *Clock fail*	This indication signals a high difference between the internally managed time and the time of the clock module that is not permissible. The triggering of the indication can point to a defect in the clock module or to an unacceptable high drift of the system quartz crystal. The time maintained internally is marked as invalid.
Time management: *Daylight saving time*	This indication signals whether daylight saving time has been enabled.
Time management: *Clock set manually*	This indication signals that the device time has been set manually via the on-site operation panel or via DIGSI 5.
Time synchronization: *Status time source 1* *Status time source 2*	These 2 indications signal whether the active time sources are recognized as valid and active from the device point of view. When the indications get triggered, it can also be an indication that an incorrect configuration of the port or channel numbers was done at the on-site operation panel.
Time synchronization: *Time sync. error*	This indication signals after the parameterized time **Fault indication after** that synchronization using an external time source has failed.
Time synchronization: *High accuracy*	This indication signals that the device is synchronized with an accuracy better than 1 µs. The indication is only of significance when the PMU function is used.

NOTE

In case of a missing or discharged battery, the device starts without active external time synchronization with the device time 2011-01-01 00:00:00 (UTC).

For the device, DIGSI 5 provides a compact overview of the status of the time synchronization of your SIPROTEC 5 device in online mode. All displays are updated continuously. You can access the overview in the project-tree window via Online access.

DIGSI: Online access -> Interface -> Device -> Device Information -> **Time Information**

[sctimedg-220415, 1, en_US]

Figure 3-77 Time Information in DIGSI

For every time source, you see the following:

- Last received time (with date)
- Receipt time of the last received time telegram

- Configured type of timer
- Indication of timer outage or failure
- Whether the device time is currently synchronized from the time source

The lower section displays the device time, which is continuously updated. If the internal device time and the infeed time source were synchronous at the time of telegram receipt, both displayed times are identical.

NOTE

All times displayed (also the time source) take into consideration the local time settings (zone and daylight saving time of the device) in the form of a numerical offset for UTC (universal time).

3.6.4 Application and Setting Notes

Parameter: Date Format

- Default setting **Date format** = ***YYYY-MM-DD***

With the **Date format** parameter, you define the local customary format of the date display.

Parameter Value	Description
YYYY-MM-DD	Day.Month.Year: Typical European display Example: 24.12.2010
YYYY-MM-DD	Month/Day/Year: Typical US representation Example: 12/24/2010
YYYY-MM-DD	Year-Month-Day: Typical Chinese display Example: 2010-12-24

Parameter: Time zone time source 1,Time zone time source 2

- Default setting **Time zone time source 1** = ***local***, **Time zone time source 2** = ***local***

With the **Time zone time source 1** and **Time zone time source 2** parameters, you define the handling of time zones of the external timer.

Parameter Value	Description
local	Local time zone and daylight saving time are considered as time zone offsets to GMT.
UTC	Time format according to UTC (universal time)

Parameter: Time source 1,Time source 2

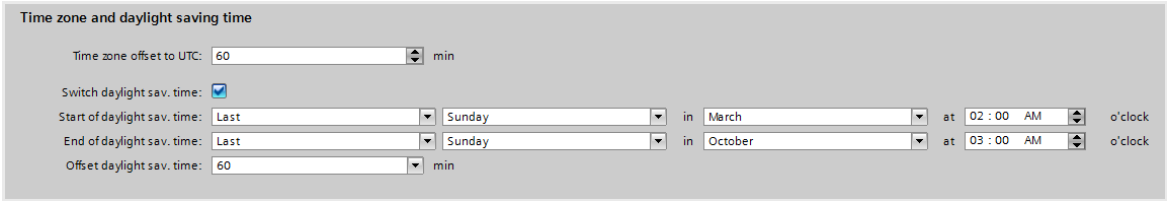
- Default setting **Time source 1** = ***none***, **Time source 2** = ***none***

With the **Time source 1** and **Time source 2** parameters, you can configure an external timer. The prerequisite is to have the corresponding hardware configuration of the communication interfaces of your SIPROTEC 5 device. This is listed as a prefix when making a selection in DIGSI 5.

Parameter Value	Description
none	The time source is not configured.

Parameter Value	Description
IRIG-B	Time synchronization by an external GPS receiver: SIPROTEC 5 devices support several protocol variants of the IRIG-B standards: • **IRIG-B 002(003)** The control function bits of the signal are not occupied. The missing year is formed from the current device time. In this case, it is possible to set the year via the online access in DIGSI 5. • **IRIG-B 006(007)** The bits for the calendar year are not equal to 00. The calendar year is set automatically by the time protocol. • **IRIG-B 005(004) with extension according to IEEE C37.118-2005** If, in the time signal, other control function bits are occupied in addition to the calendar year, then the device takes the additional information into consideration for leap seconds, daylight saving time, time offset (zone, daylight saving time) and time accuracy. **Time zone time source 1** or **Time zone time source 2**: The value of this setting is not evaluated by the device, since this protocol either transmits or in the case of local time, specifies the appropriate offset to UTC in each set time telegram.
DCF77	Time synchronization by an external DCF 77 receiver **Time zone time source 1** or **Time zone time source 2** = ***local*** Please note: There are also clocks that generate a DCF 77 signal representing UTC. In this case, UTC must be set.
PI	The time synchronization takes place via the protection interfaces configured for your SIPROTEC 5 device. Here, the timing master takes over the time management. Signal-transit times of the protection interface communication are calculated automatically. **Time zone time source 1** or **Time zone time source 2** = ***UTC*** A slave that receives a time or a SIPROTEC 5 master, receives its system time kept in UTC.
SNTP	The time synchronization is done via the Ethernet service SNTP (SNTP server or via IEC 61850). SIPROTEC 5 devices support both Edition1 and Edition2 in accordance with IEC 61850-7-2. In Edition2, the logical attributes LeapSecondsKnown, ClockFailure, ClockNotSynchronized, and the value TimeAccuracy are maintained in each time stamp. For Edition1, these signals contain default settings. Thus, the inter-operability for substation automation technology is ensured for both editions! The SNTP service must be enabled during configuration of Ethernet interfaces so that it is available as an option for the time synchronization. **Time zone time source 1** or **Time zone time source 2** = ***UTC***
IEC 60870-5-103	The time is synchronized via telegram with an appropriately configured communication interface in accordance with the IEC 60870-5-103 protocol. **Time zone time source 1** or **Time zone time source 2** = ***local*** However, there are also T103 systems that send the UTC.

Parameter Value	Description
DNP3	The time is synchronized via telegram with the appropriately configured communication interface in accordance with the DNP3 protocol. Two characteristics are supported in the process: • **Time synchronization via UTC** • **Time synchronization with local time** The daylight saving time status is not transmitted. The device assumes that the DNP3 master follows the same rules for the start and end of the daylight saving time as those that were set for the device. **Time zone time source 1** or **Time zone time source 2** = ***UTC*** is the current implementation ***local*** concerns older implementations.
IEEE 1588	Time is synchronized via an IEEE 1588 timing master. In this case, SIPROTEC 5 devices operate as slave-only clocks. IEEE 1588 v2 is supported with P2P and Ethernet Transport. The IEEE 1588 service must be enabled during configuration of Ethernet interfaces so that it is available as an option for the time synchronization. **Time zone time source 1** or **Time zone time source 2** = ***UTC***.



Parameter: Fault indication after

- Default setting **Fault indication after** = ***600 s***

With the **Fault indication after** parameter you set the time delay after which the unsuccessful attempts of time synchronization with external time sources configured are indicated.

Parameter: Time Zone and Daylight Saving Time

This parameter block contains all the settings for the local time zone and daylight saving time of your SIPROTEC 5 device. In addition to the individual parameters, configure the basic settings by preselecting via the radio buttons or check box.

[sctimezo-210415, 1, en_US]

Figure 3-78 Settings for Time Zone and Daylight Saving Time in DIGSI

Selection Button	Description
Manual settings (local time zone and daylight saving time regulation)	This setting must be selected if you want to select the local time zone and daylight saving time zone regulations of your SIPROTEC 5 device regardless of the PC settings. Input: **Offset time zone for GMT** [min] Selection: **Switchover to daylight saving time** [yes/no] via check box  • Input: **Start of daylight saving time** [Day and time] • Input: **End of daylight saving time** [Day and time] • Input: **Offset daylight saving time** [min] • Default settings as in the picture above

3.7 User-Defined Objects

3.7.1 Overview

Within a **User-defined function group**, you can use the **User-defined function block** and the **User-defined function block [Control]** to group user-defined objects that you find in the DIGSI 5 library under **User-defined functions**.

With user-defined function groups and user-defined functions, a grouping of user-defined objects, for example, user-defined function blocks, can be performed. 2 user-defined function blocks are available (see following figure).

[scudef_lib, 1, en_US]

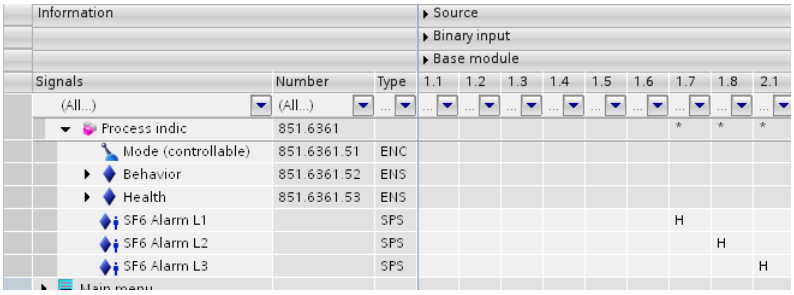

Figure 3-79 User-Defined Objects in the DIGSI 5 Library

You can insert single-point indications, pickup and operate indications (ACD, ACT), single or double commands, commands with a controllable whole number as well as measured values in the **User-defined function block** (see following figure). You can assign a superordinate name to the grouping (for example, **Process indications**, for a group of single-point indications that are read in via binary inputs). This function can be deactivated via the mode. Readiness is also evaluated and represented.

The user-defined function can be instantiated both at the highest level (in parallel to other function groups) and within the function groups and functions.

A **User-defined function block [control]** is also available. In addition to the mentioned option of a general **User-defined function block**, this block offers additional tests for user-defined control signals, for example, SPC or DP.

You can find more information in chapter *8.6.1 Overview of Functions*.

[scbenutz-260912-01.tif, 1, en_US]

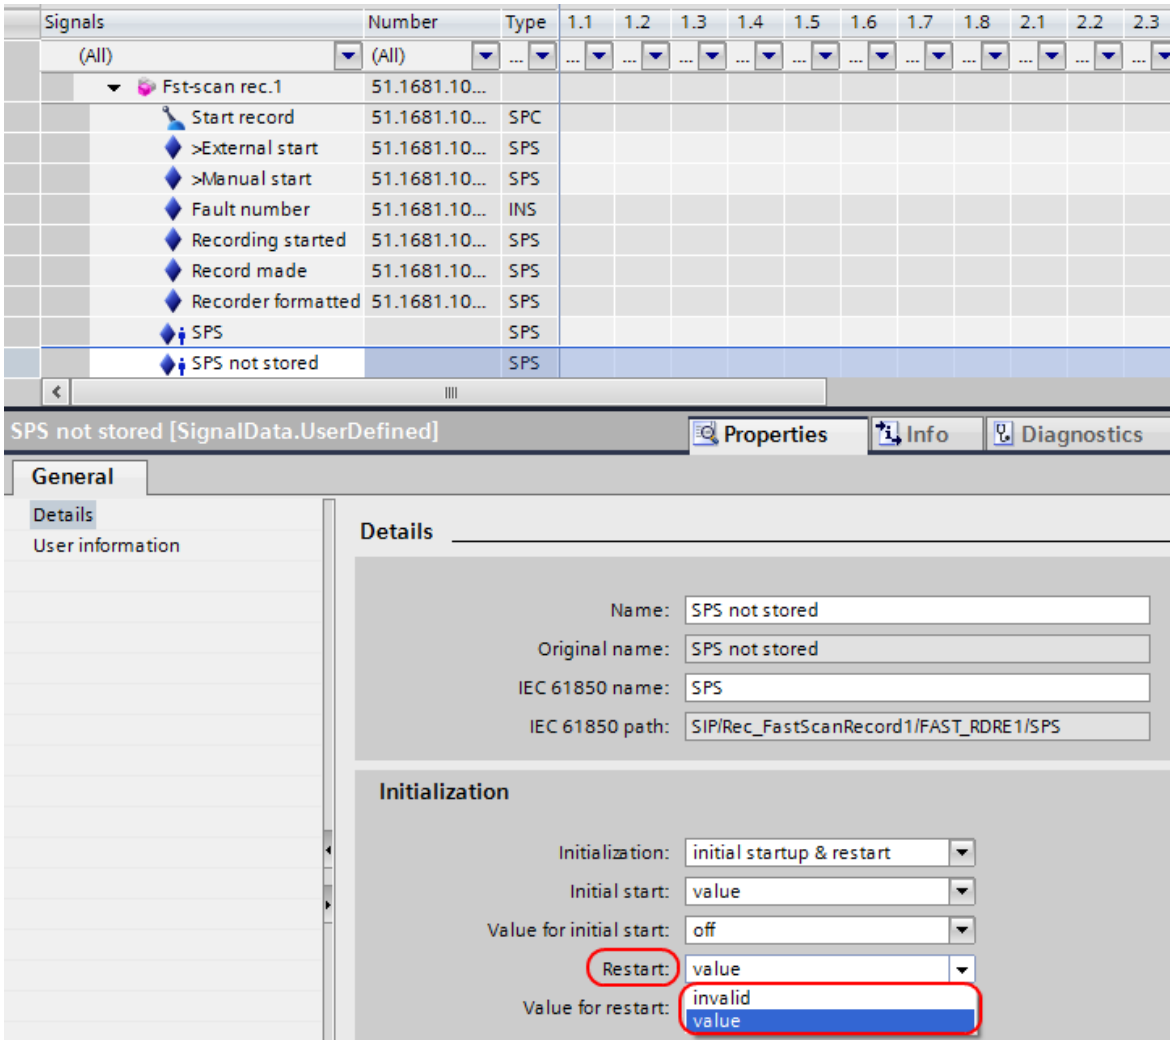
Figure 3-80 Information Routing Through Use of Added User-Defined Function Block: Process Indications and Single-Point Indications

3.7.2 Basic Data Types

The following data types are available for user-defined objects in the DIGSI 5 library under the heading **User-defined signals**.

Single-Point Indication (Type SPS: Single-Point Status)

The status of a binary input can be registered in the form of a single-point indication or forwarded as the binary result from a CFC chart.



EXAMPLE

Acquisition using binary input, further processing in a CFC and/or signaling using an LED.

Single-Point Indication (Type SPS unsaved: Single-Point Status Unsaved)

In contrast to **SPS** single-point indications, the state of the **SPS unsaved** indication is not maintained after the device restarts.

For this purpose, go to **Properties > Details > Initialization > Restart** and set the ***Value***.

[scspsfas-140613-01.tif, 1, en_US]

Figure 3-81 Single-Point Indication SPS Unsaved (Example: 7KE85 Fault Recorder)

Double-Point Indication (Type DPS: Double-Point Status)

When using a double-point indication, the status of 2 binary inputs can be captured simultaneously and mapped in an indication with 4 possible conditions (***ON***, ***Intermediate position***, ***OFF***, ***Disturbed position***).

EXAMPLE

Acquisition of a disconnector or circuit-breaker switch position.

Marker Command (Type SPC, Single-Point Controllable)

This data type can be used as a command without feedback for simple signaling or as an internal variable (marker).

State of a Whole Number (Type INS)

The data type **INS** is used to create a whole number that represents a CFC result.

EXAMPLE

The output of the CFC block **ADD_D** can, for example, be connected with the data type **INS**. The result can be shown on the display of the device.

State of an Enumeration Value (Type ENS)

The data type **ENS** is used to create an enumerated value that represents a CFC result.

Controllable Single-Point Indication (SPC, Single-Point Controllable)

This can be used to issue a command (to one or several relays, selectable under information routing) that is monitored via a single feedback.

Command with Double-Point Feedback (DPC, Double Point Controllable)

This can be used to issue a command (to one or several relays, selectable under information routing) that is monitored via double-point indication as feedback.

Command with a Whole Number (INC, Controllable Integer Status)

This can be used to issue a command (to one or more relays, selectable under information routing) that is monitored via a whole number as feedback.

Complex Measured Values (CMV)

This data type provides a complex measured value that can be used as a CFC result, for example.

Measured Values (MV)

This data type provides a measured value that can be used as a CFC result, for instance.

NOTE

Additional data types can be found under other headings in the DIGSI 5 library as well as in the corresponding function blocks. This applies to the following data types:

- Pulse-metered values (see **User-defined functions** in the DIGSI 5 library)
- Transformer taps
- Metered values

Phase-to-Ground Measured Values (WYE)

This data type represents the phase-to-ground measured values of a 3-phase system.

Phase-to-Phase Measured Values (DEL, Delta)

This data type represents the phase-to-phase measured values of a 3-phase system.

Protection Activation Information (ACT)

This object type is used by the protection functions for **Tripping**. It is available in the library for receiving protection information via the protection interface, which could also indicate **Tripping**.

Protection Activation Information with Direction (ACD)

This object type is used by the protection functions for **Pickup**. It is available in the library for receiving protection information via the protection interface, which could also indicate **Pickup**. In addition, both ACD and ACT can be generated and processed by CFC charts.

3.7.3 Pulse- and Energy- Metered Values , Transformer Taps

Pulse-Metered Values

Pulse-metered values are available as data types **BCR** (Binary Counter Reading) in the DIGSI library under **User-defined Functions**.

The functionality and the settings of the pulse-metered values can be found in chapter *10.8.1 Pulse-Metered Values Function Description* .

Transformer Taps

Transformer taps are contained in the **Transformer tap changers** switching element. When the **Transformer tap changer** switching element is created in the device, the transformer tap position is available as a data object of type **BSC** (binary controlled tap changer with tap-position information).

You can find detailed information in *8.8.1 Function Description* .

Energy-Metered Values

Energy-metered values no longer need to be created by the user separately. They are available as active and reactive power in each **Line** function group for reference and output direction. The calculation is based on the current and voltage transformers associated with the protected object.

You can find more detailed information in chapter *10.7.1 Function Description of Energy Values* .

3.7.4 Additional Data Types

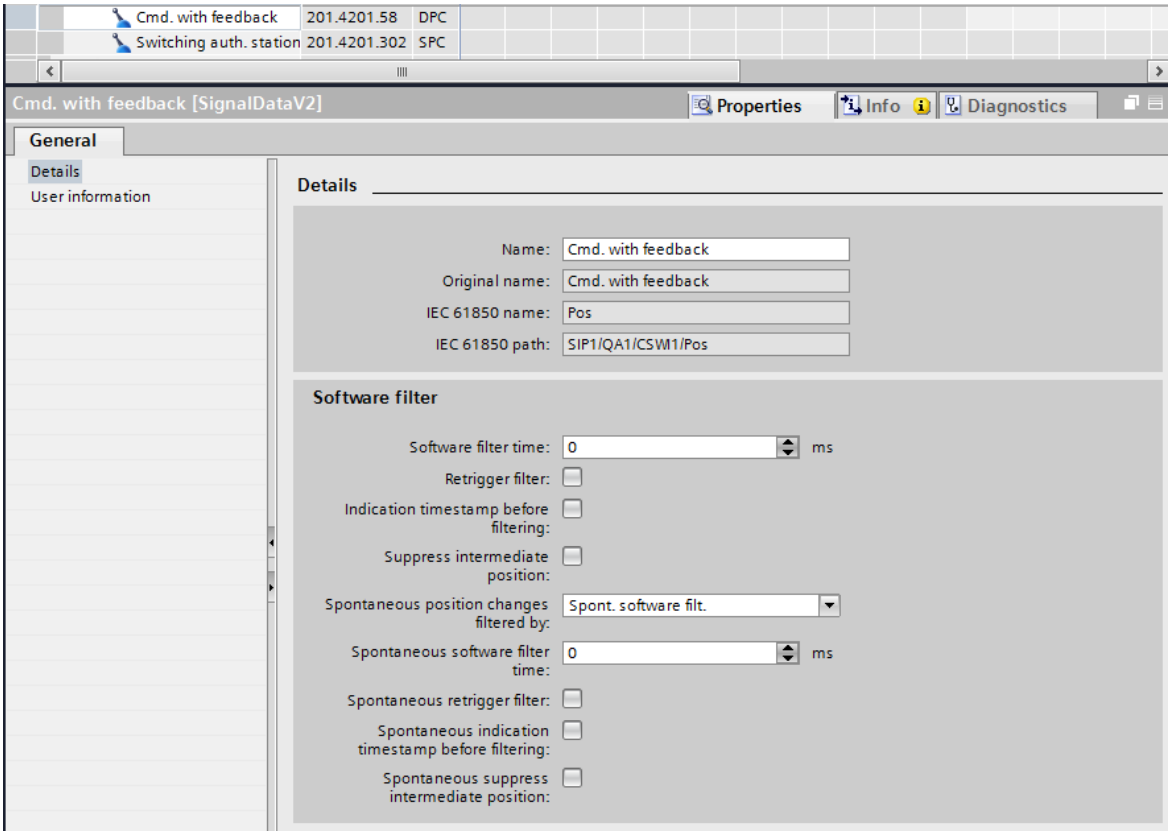
The following data types are also used in the system but are not available for general use as user-defined signals in the library:

- **ENC** (Enumerated Setting Controllable)
  The data type **ENC** models a command with which the user can set predefined values.
- **SEQ** (Sequence)
- **BSC** (Binary Controlled Step Position)
  The data type **BSC** can, for example, be used to control a transformer tap changer. The commands **up**, **down** can be given.

NOTE

Transformer taps are included in the **Transformer tap changer** switching element. If this switching element is created in the device, the transformer tap position is available as a data object of type **BSC** (binary controlled tap changer with tap-position information).

3.8 Other Functions



3.8.1 Signal Filtering and Chatter Blocking for Input Signals

Input signals can be filtered to suppress brief changes at the binary input. Chatter blocking can be used to prevent continuously changing indications from clogging the event list. After an adjustable number of changes, the indication is blocked for a certain period.

The settings for indication filtering can be found at the individual signals. The next figure shows the settings using the example of a controllable (circuit-breaker switch position).

NOTE

For the circuit breaker or the disconnector, the settings of the software filter for spontaneous position changes are available only in the **Control/Command with feedback** function block. These settings are not available in the **Circuit breaker** or **Disconnector** function blocks since these function blocks contain the actual unfiltered position of the switch in the bay.

[sclposi-260116, 1, en_US]

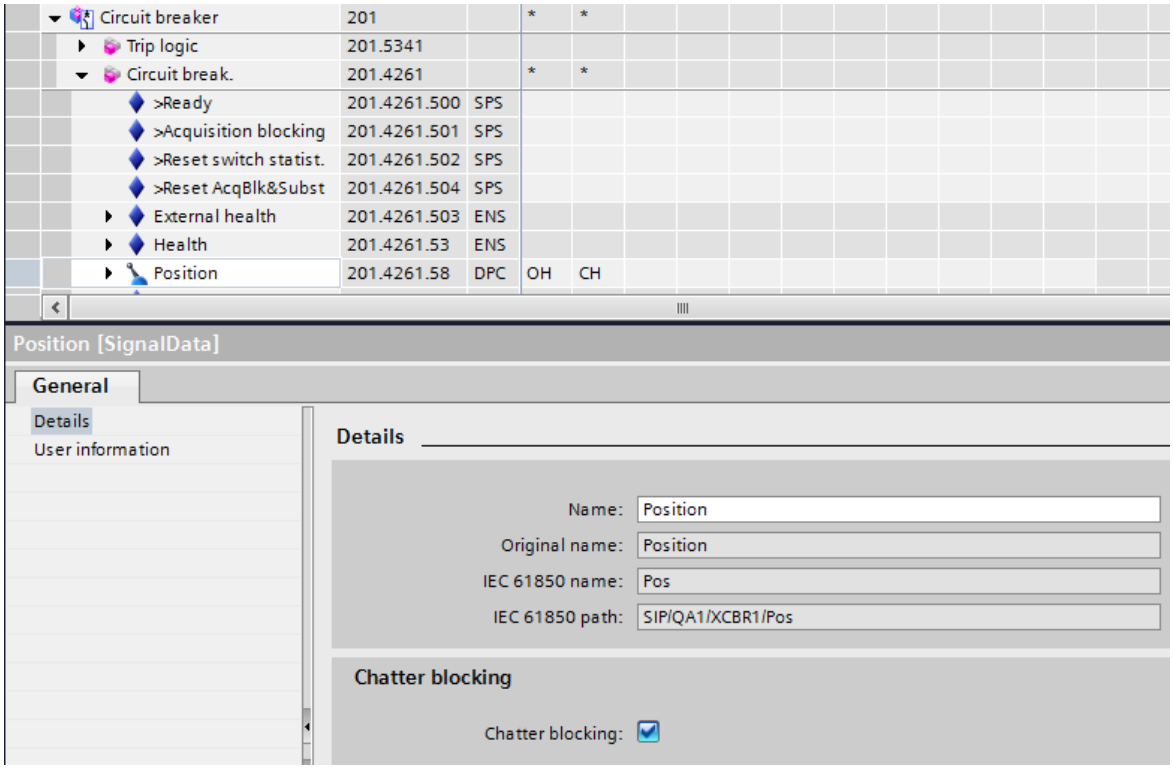


Figure 3-82 Settings for Circuit-Breaker Switch Position

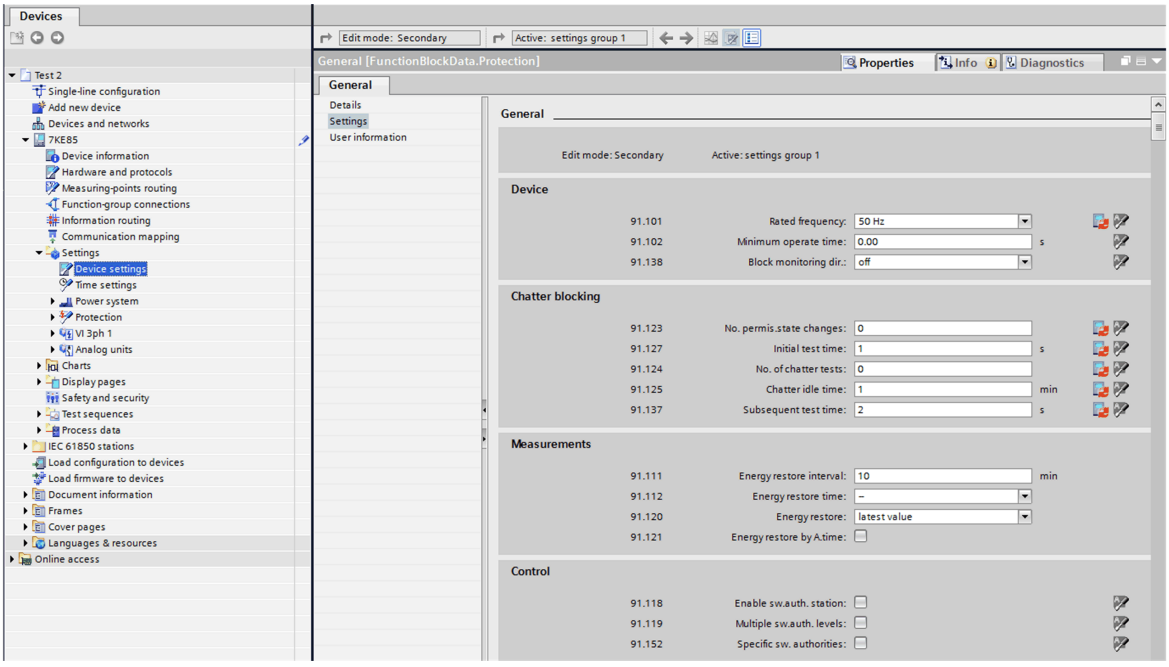
The setting range for the **Software filtering time** parameter ranges from 0 ms to 86 400 000 ms (1 day) in ms increments. The **Retrigger filter** check box can be used to select whether the software filter should be restarted by a change from 1 to 0 and back. When activated, the **Indication timestamp before filtering** check box back dates the time stamp by the set software filtering time and the fixed hardware filtering time. In this case, the time stamp corresponds to the actual status change of the signal. If you activate the **Suppress intermediate position** check box, the intermediate position is suppressed for the duration of this software filter time.

With the parameter **Spontaneous position changes filtered by**, you set how such position changes are to be filtered. Spontaneous position changes are caused by external switching commands, for

example. If the ***General software filter*** setting is selected, the general settings for software filtering of spontaneous position changes and for position changes caused by a switching command apply. The settings for spontaneous position changes can then not be edited. A separate filtering for spontaneous position changes is activated with the ***Spontaneous software filter*** setting and you can edit the settings for this.



Chatter blocking can be activated or deactivated as a parameter of the position in the **Circuit breaker** or **Disconnector** function block.

[scflatte-180315, 1, en_US]

Figure 3-83 Setting Chatter Blocking

The settings for the chatter blocking function are set centrally for the entire device in DIGSI. They are accessible as settings in the **General** function group (see the following figure).

[scparafl-291110-01.tif, 2, en_US]

Figure 3-84 Chatter-Blocking Settings

The chatter-blocking settings have the following meaning (see also *Figure 3-85* and *Figure 3-86* in the examples shown in the following):

- **`No. permis.state changes`**

  This number specifies how often the state of a signal may toggle within the chatter-test time and the chatter-checking time. If this number is exceeded, the signal will be or remains blocked.

  Enter a number from 0 to 65535 in this field. If the entry is 0, chatter blocking is essentially inactive.

- **`Initial test time`**

  During this time, the number of times a signal changes its status is checked. This time is started if chatter blocking is configured for at least one signal and this signal changes its status. If the configured number of permissible state changes is exceeded during the initial test time, the signal is temporarily blocked and the indication *`Chatter blocking`* is set.

  Enter a number between 1 and 65535 in this field. The number entered corresponds to the time in seconds. When the set time has expired, the timer restarts automatically (cycle time).

- **`No. of chatter tests`**

  This number specifies the maximum number of test cycles to be run. If the number of permissible state changes stays exceeded during the initial test time of the last test cycle, the signal is finally blocked. In this case, the indication *`Group warning`* (**Alarm handling** group) and (**Device** group) are set additionally to the *`Chatter blocking`* indication after expiry of the set number. Restarting the devices removes this block again.

  Enter a number from 0 to 32767 in this field. The value Infinite (∞) is also permissible here.

  Enter this value as character string oo.

- **`Chatter idle time`**

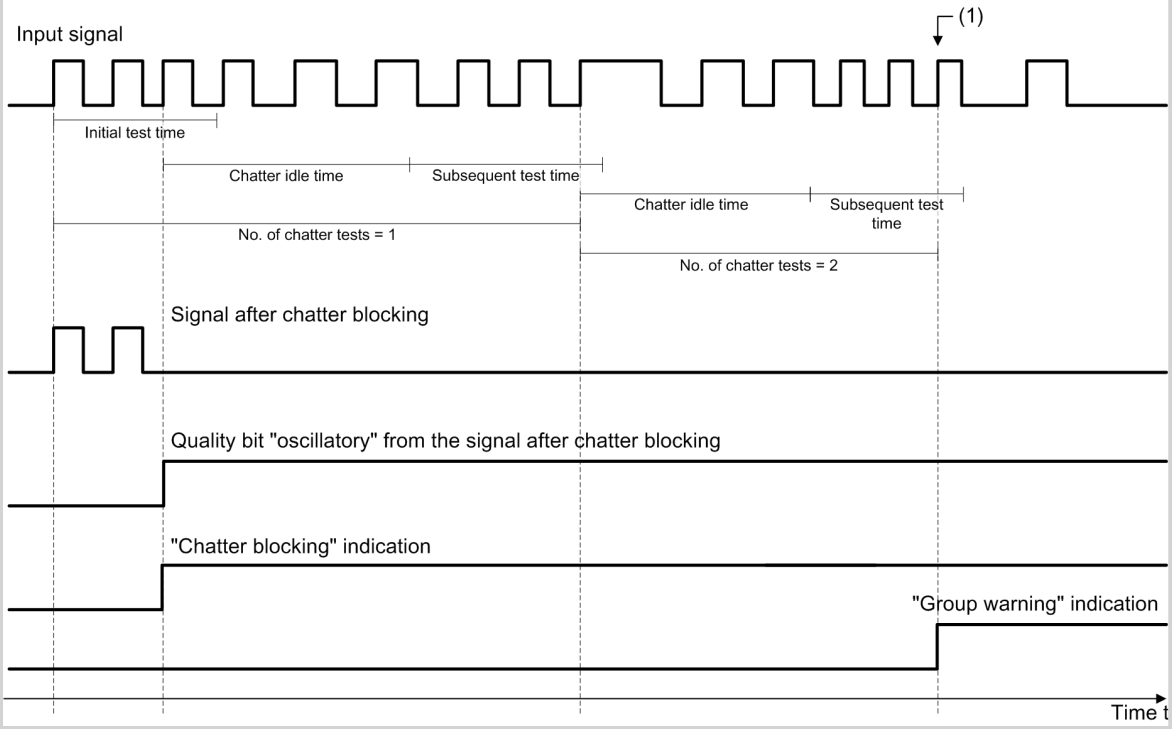
  If the number of permissible status changes for a signal is exceeded during the initial test time or the subsequent test time, the **`Chatter idle time`** starts. Within this time, this signal is blocked temporarily and the *`Chatter blocking`* indication is set. The blocked input signal is assigned the **oscillatory** quality.

  Enter a number between 1 and 65535 in this field. The number entered corresponds to the time in minutes. An entry here is only considered if the number of chatter tests does not equal 0.

- **Subsequent test time**

  During this second test time, the number of times a signal changes its status is checked once again. The time begins when the **Chatter idle time** expires. If the number of status changes is within the permissible limits, the signal is released. Otherwise, an additional dead time begins, unless the maximum number of chatter tests has been reached.

  Enter a number between 2 and 65535 in this field. The number entered corresponds to the time in seconds. An entry here is only considered if the number of chatter tests does not equal 0.



Example 1: Permanent Blocking

The chatter-blocking settings are set as follows:

- **No. permis.state changes** = 4
- **No. of chatter tests** = 2

After more than 4 state changes within the **Initial test time**, the input signal is set to the original state by the chatter blocking and the **oscillatory** quality is assigned. Additionally, a corresponding indication is added to the operational log. At the same time, the *Chatter blocking* indication is set . After expiry of the settable **Chatter idle time**, during the following **Subsequent test time**, it is checked whether the input signal is still chattering. This check is repeated, as the **No. of chatter tests** is set to 2 in this example.

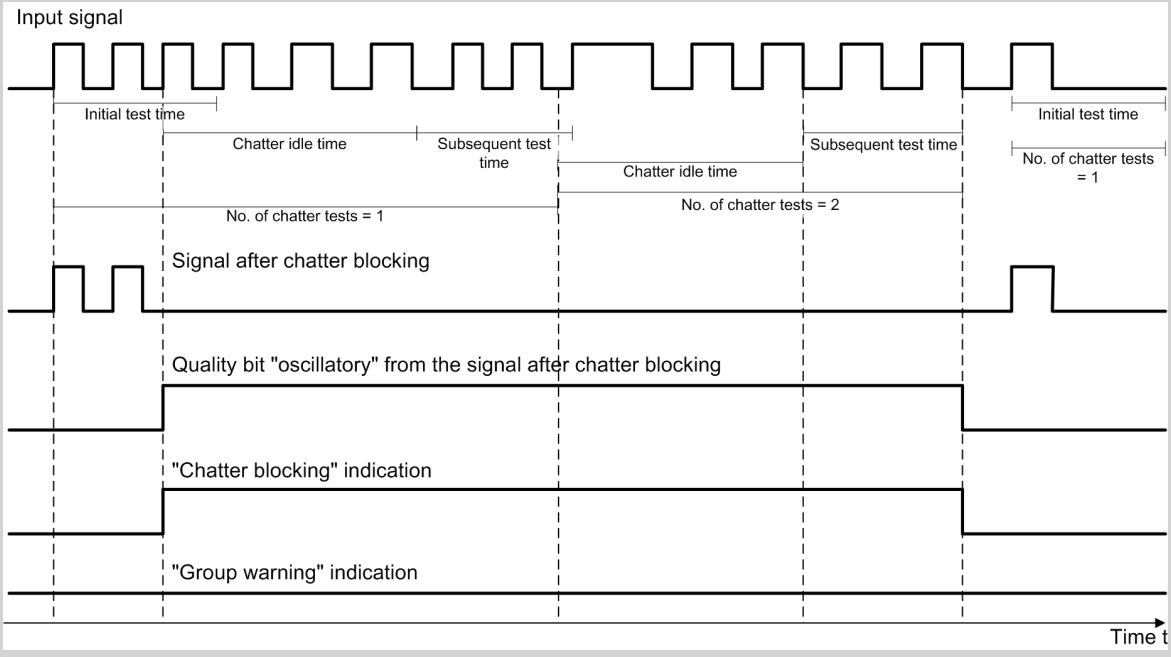
If, during the 2nd **Subsequent test time**, it has been detected that the number of state changes of the input signal exceeds the set **No. permis.state changes**, the chatter blocking detects a persistent violation of the signal stability and sets the *Group warning* indication. The original state of the signal is permanently frozen. Only a device restart removes the chatter blocking again.

[dw_chatter-block-01, 1, en_US]

Figure 3-85 Signal Change during Chatter Blocking with too Important Number of Signal State Changes During 2nd Subsequent Test Time

(1) The input signal is permanently blocked starting from this point in time.

Example 2: Temporary Blocking



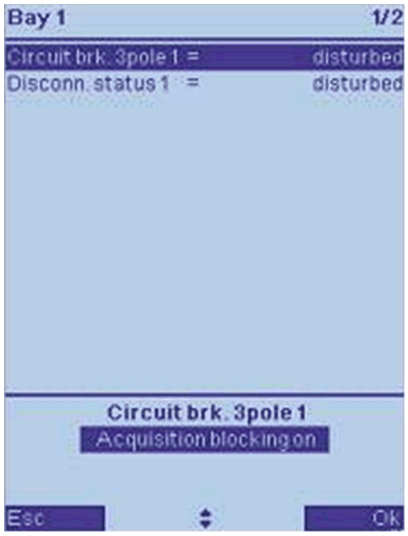
The chatter-blocking settings are set as follows:

- **No. permis.state changes** = 4
- **No. of chatter tests** = 2

After more than 4 state changes within the **Initial test time**, the input signal is set to the original state by the chatter blocking and the **oscillatory** quality is assigned. Additionally, a corresponding indication is added to the operational log. At the same time, the *Chatter blocking* indication is set. After expiry of the settable **Chatter idle time**, during the following **Subsequent test time**, it is checked whether the input signal is still chattering. This check is repeated, as the **No. of chatter tests** is set to 2 in this example.

If, during the 2nd **Subsequent test time**, it has been detected that the number of state changes of the input signal is within the set **No. permis.state changes**, the temporary blocking of state changes of the signal is removed and the actual signal state is released.

The quality bit **oscillatory** is removed and the *Chatter blocking* indication is reset. As the temporary blocking of the signal is removed, the *Group warning* indication is not set. The chatter test starts again.



[dw_chatter-block-02, 1, en_US]

Figure 3-86 Signal Change during Chatter Blocking with Permissible Number of Signal State Changes During 2nd Subsequent Test Time

3.8.2 Acquisition Blocking and Manual Updating

During commissioning, maintenance, or testing, a brief interruption of the connection between the logical signals and binary inputs may be useful. It allows you to manually update the status of a switching device that is not providing feedback correctly. Before this can take place, you must first set acquisition blocking.

Set the Acquisition blocking function in the menu of the device display **Commands > Equipment >Aq.blk man. update**. If several switching devices are available, select the appropriate switching device. When pressing the **Change** key, the confirmation ID will be queried. After entering the confirmation ID, the acquisition blocking function is switched on when **OK** is pressed.

[scerfass-280513-01.tif, 1, en_US]

Figure 3-87 Activating the Acquisition Blocking

Manual updating of the switching device is possible from within the same menu. Use the menu item **Change** to select the **Manual updating** function. Subsequently, select the updating setting of the switching device manually and acknowledge the selection by pressing **OK**. The manually updated position of the switching device will be displayed.

[scstatus-280513-01.tif, 1, en_US]

Figure 3-88 Activate Manual Updating

[scstatu2-280513-01.tif, 1, en_US]

Figure 3-89 Selecting Position

NOTE

For safety reasons, manual updating is possible only directly through the on-site operation panel of the device and not through DIGSI 5.

NOTE

Setting acquisition blocking and the subsequent manual updating are also possible via the IEC 61850 system interface.

Acquisition blocking can also be set via a binary input. This way, acquisition blocking can be set for an individual or several switching devices in a feeder simultaneously with an external toggle switch in order to disable the feeder. For this purpose, every switching device in the **Switch** function block (circuit breaker or disconnector switch) has the input signal **`>Acquisition blocking`**. This signal can also be set from the CFC.

Information			Source											Destination		
			Binary input										CFC	Binary output		
			Basismodul											Basismodul		
Signals	Number	Type	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8	2.1	2.2	2.3		1.1	1.2	1.3
(All)	(All)													(All)			
Trip logic	201.5341																
Circuit break.	201.4261		*	*											*	*	
>Ready	201.4261.500	SPS															
>Acquisition blocking	201.4261.501	SPS															
>Reset switch statist.	201.4261.502	SPS															
>Reset AcqBlk&Subst	201.4261.504	SPS															
External health	201.4261.503	ENS															

[scbeerfa-190215, 1, en_US]

Figure 3-90 Input signals *`>Acquisition Block`* and *`>Release Acquisition Block & Manual Updating`* on the Switching Device

NOTE

Interlockings are carried out with the status changes of the switching device. Remove acquisition blocking again manually. Otherwise, position changes of the switching device are not detected and interlockings are ineffective.

If the acquisition blocking and the manually updated position are set using the operation panel of the device or the system interface IEC 61850, these are retained until the acquisition blocking is manually deactivated. When you initially start the device, the acquisition blocking is deactivated.

Except for a restart, the acquisition blocking and the manually updated position are retained.

If the acquisition blocking is activated via the input signal **>Acquisition blocking**, it is retained as long as the binary input is active.

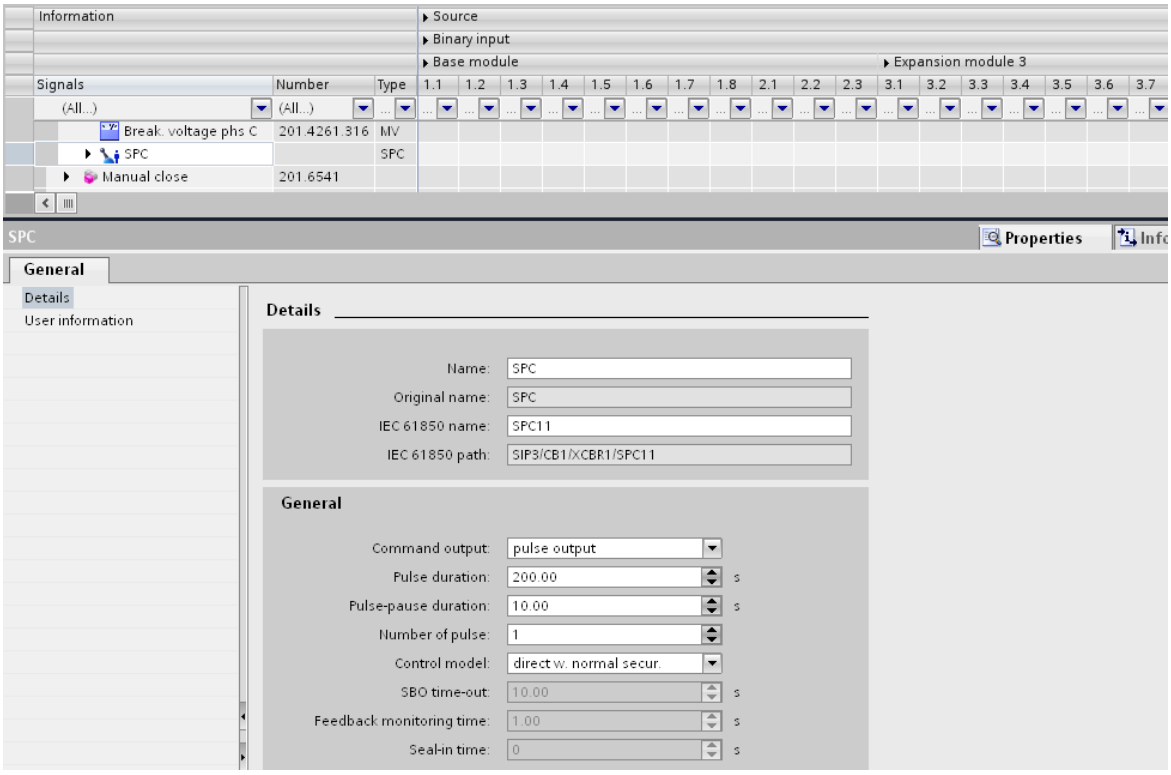
To set the acquisition blocking of a switching device, the following sources are possible:

- Operation panel of the device
- System interface IEC 61850
- Input signal **>Acquisition blocking**

All sources undergo OR operations, that is, the acquisition blocking remains set until all the sources are deactivated.

After deactivation of the acquisition blocking, the actual position of the switching device is adopted and displayed in the operation panel of the device.

NOTE



When the acquisition blocking is activated or the switching device updated manually while the entire device or the switching device is in test mode, these states are not saved. The acquisition blocking and the manual updating are not retained after a restart.

Acquisition blocking and manual update for the circuit breaker, the disconnector and the tap changer are reset by way of the **>Reset AcqBlk&Subst** binary input. Setting acquisition blocking and manual update is blocked with the input activated.

3.8.3 Persistent Commands

In addition to the switching commands, which are issued as pulse commands, and stored for the standard switching devices (circuit breaker, disconnector switch), persistent commands are also possible. In this case, a distinction must be drawn between controllables with the **Continuous output** operating mode and a stored signal output that is immune to reset.

You can change a controllable from pulse to persistent command with the **Command output** parameter.

[scbefehl-260912-01.tif, 1, en_US]

Figure 3-91 Setting the Command Type in DIGSI 5

Select ***Pulse output*** or ***Continuous output*** for the command output type. If a persistent command is selected, the Pulse parameter is irrelevant.

3.9 General Notes for Setting the Threshold Value of Protection Functions

3.9.1 Overview

You can set the threshold values of protection functions directly on the device or by using DIGSI 5.

An innovative design was implemented for the protection settings.

You can switchover the edit mode between the following setting views:

- Primary
- Secondary
- Percent

If you change settings in a setting view, DIGSI 5 calculates the settings of the 2 inactive views in the background. If you wish to save, for example, conversion to secondary values, then select the primary view. Configure all the settings and switchover to the secondary view.

Edit Mode: Primary

The parameters are set as primary values and thus refer directly to the primary system. The manual conversion on the secondary circuit omitted.

Edit Mode: Secondary

The settings refer to the secondary circuit of the transformer. This means that the settings must be converted. The secondary setting is the customary setting view. For secondary tests, the pickup values can be read directly.

Edit Mode: Percent

This setting type is beneficial for electric machines (generators, transformers, motors, and busbars). The setting values can be standardized regardless of the machine size. The reference values for the percentage settings are the rated values of the function groups, for example, rated voltage and rated current or rated apparent power . The setting values are, thus, related exclusively to the primary settings. If other reference values are used, then this is documented for the respective protection function in the application and setting notes.

If parameters are selected it may happen that they are set only in percent in all 3 setting views.

Recommendation for Setting Sequence

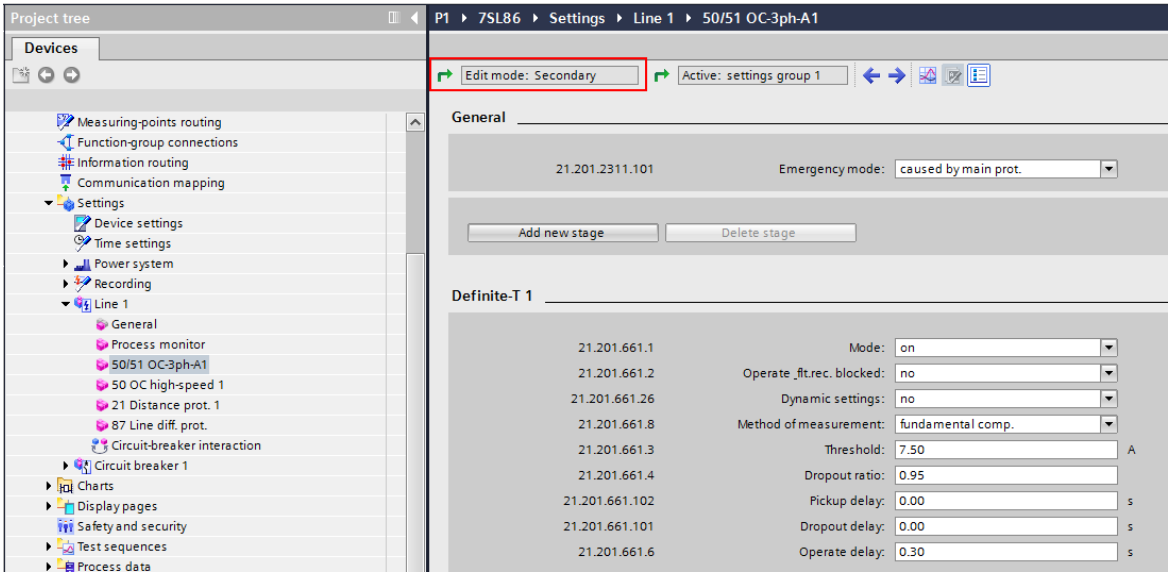
When setting the protection function, Siemens recommends the following procedure:

- First set the transformation ratios of the transformers. You can find these under **Power-system data**.
- In addition, set the reference parameters for the percent setting. You will find these parameters in function group .
- Next, set the parameter of the protection functions.

  If the transformer data have changed after completing the protection setting, remain in the setting sheet (for example, primary setting) and change the transformer data. In the background, DIGSI 5 obtains the new settings in the inactive setting views (for example, new secondary values).

The following section explains, by way of an example, how to modify the transformer ratios in DIGSI 5 using the corresponding alternatives.

3.9.2 Modifying the Transformer Ratios in DIGSI 5

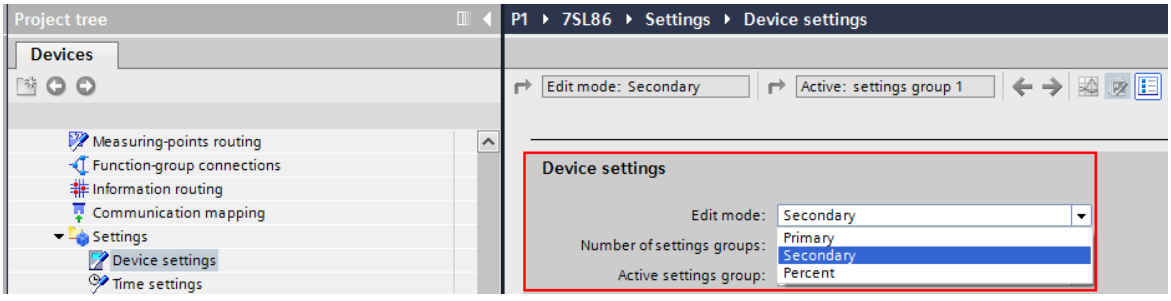


In the delivery setting, DIGSI 5 is set to the **Secondary** edit mode.

The following setting example shows how you can change the transformer ratio in DIGSI 5, and what impact this has on the settings in the setting views **Primary** and **Secondary**. The protection setting is observed in the example of the **Overcurrent protection** function.

The following output data are assumed:

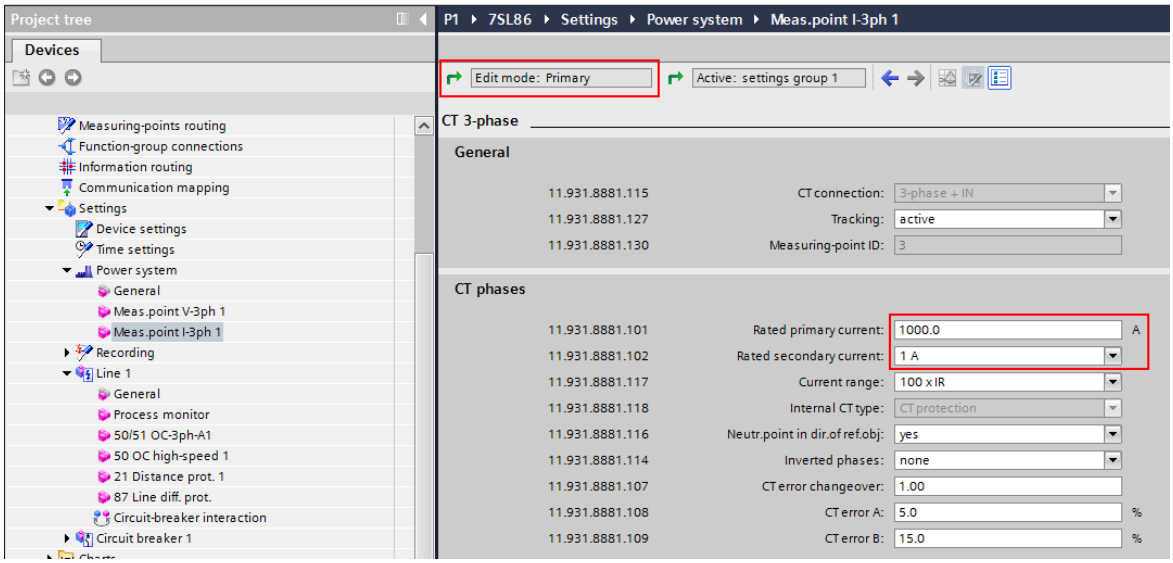
Current transformer:	1000 A/1 A
Protection pickup value:	1.5 A



The following figure shows the protection setting of the **Overcurrent protection** function in the secondary view. The threshold value of the stage is set to 1.5 A.

[scmodsek_1, 1, en_US]

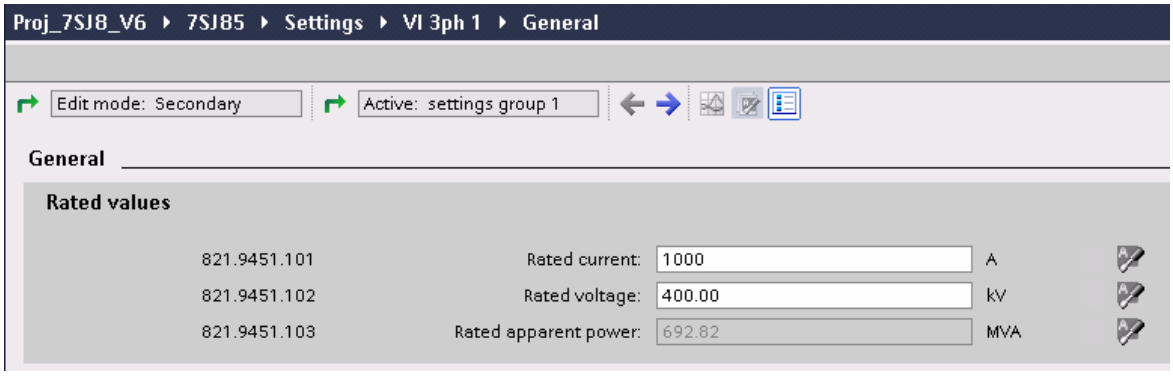
Figure 3-92 Protection Setting, Display of the Active Setting Sheet



When you click the green arrow in the setting sheet at the upper left, you get to the window for switching over to the setting view (see the following figure). Select the setting view you prefer.

[scmodums_2, 1, en_US]

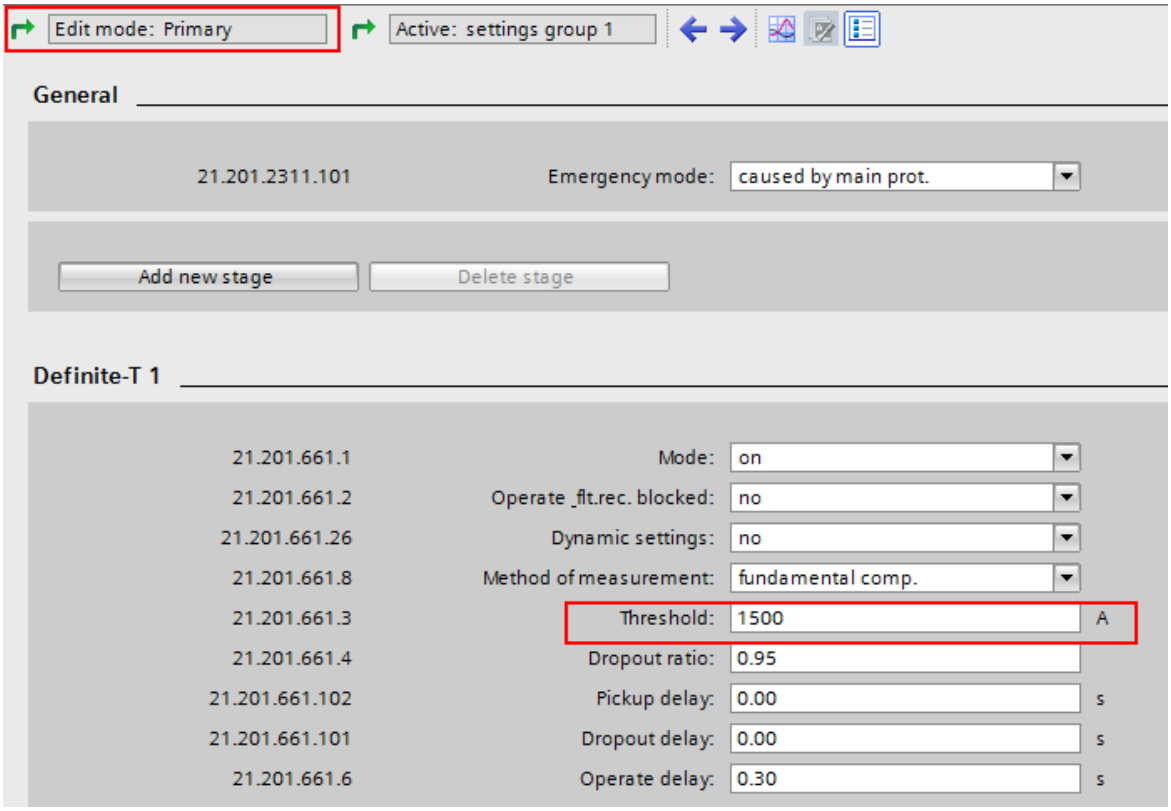
Figure 3-93 Switchover to the Desired Setting View



The following figures show the setting sequence in the **Primary** edit mode. Set the transformer data. In the example, the current transformer has a transformation ratio of 1000 A/1 A.

[scpwandl_3, 1, en_US]

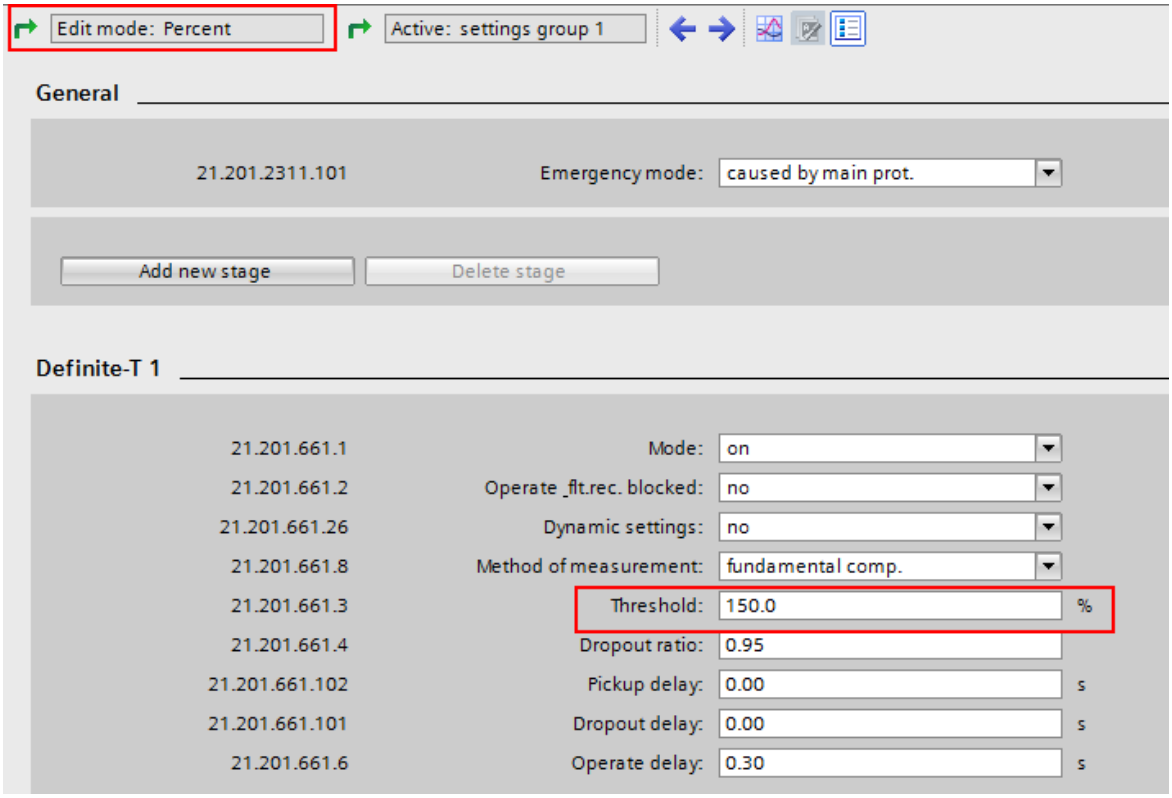
Figure 3-94 Setting Sheet:Transformer Data



In the **Voltage/current 3-phase** function group, you set the rated current and rated voltage (see the following figure). Rated current, rated voltage are the reference variables for the percent setting.

[scui3phd, 1, en_US]

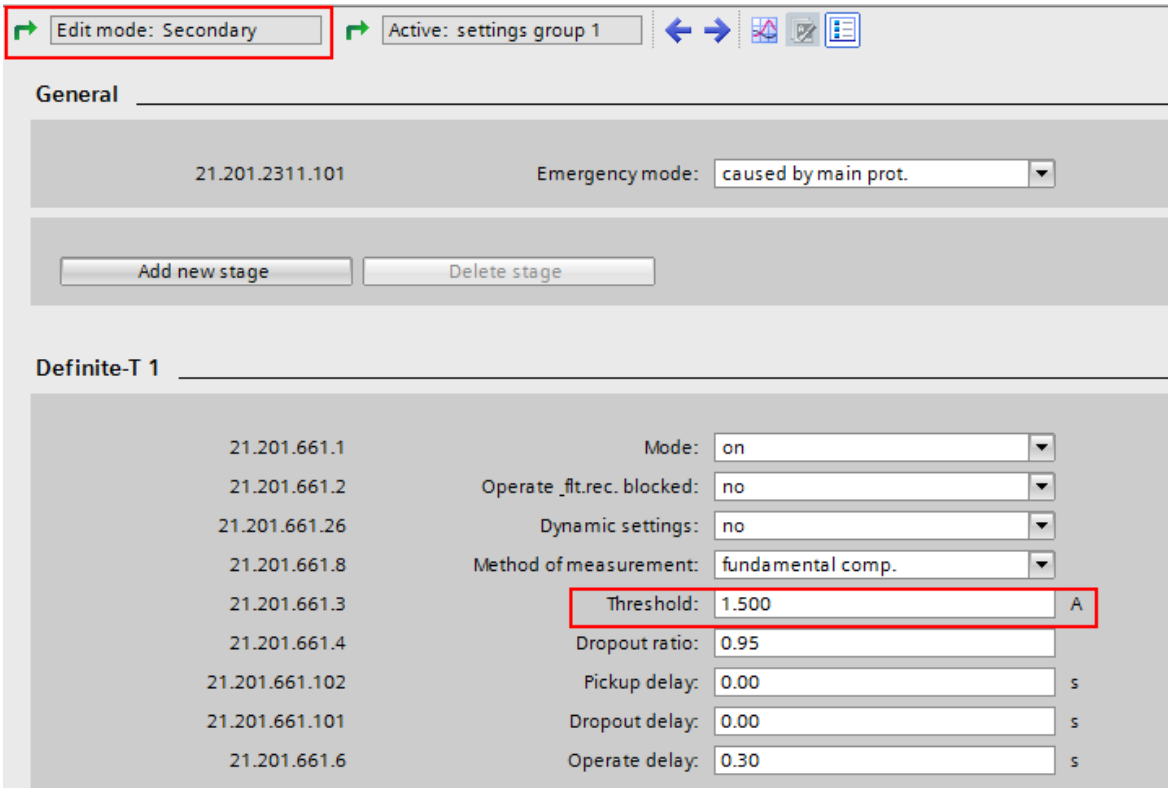
Figure 3-95 Reference Data for Percentage Settings



The following figure shows the threshold value of the **Overcurrent protection** function in the primary view at 1500 A.

[scumzpri_5, 1, en_US]

Figure 3-96 Example of the Threshold Value of the Definite Time-Overcurrent Protection (Edit Mode: Primary)

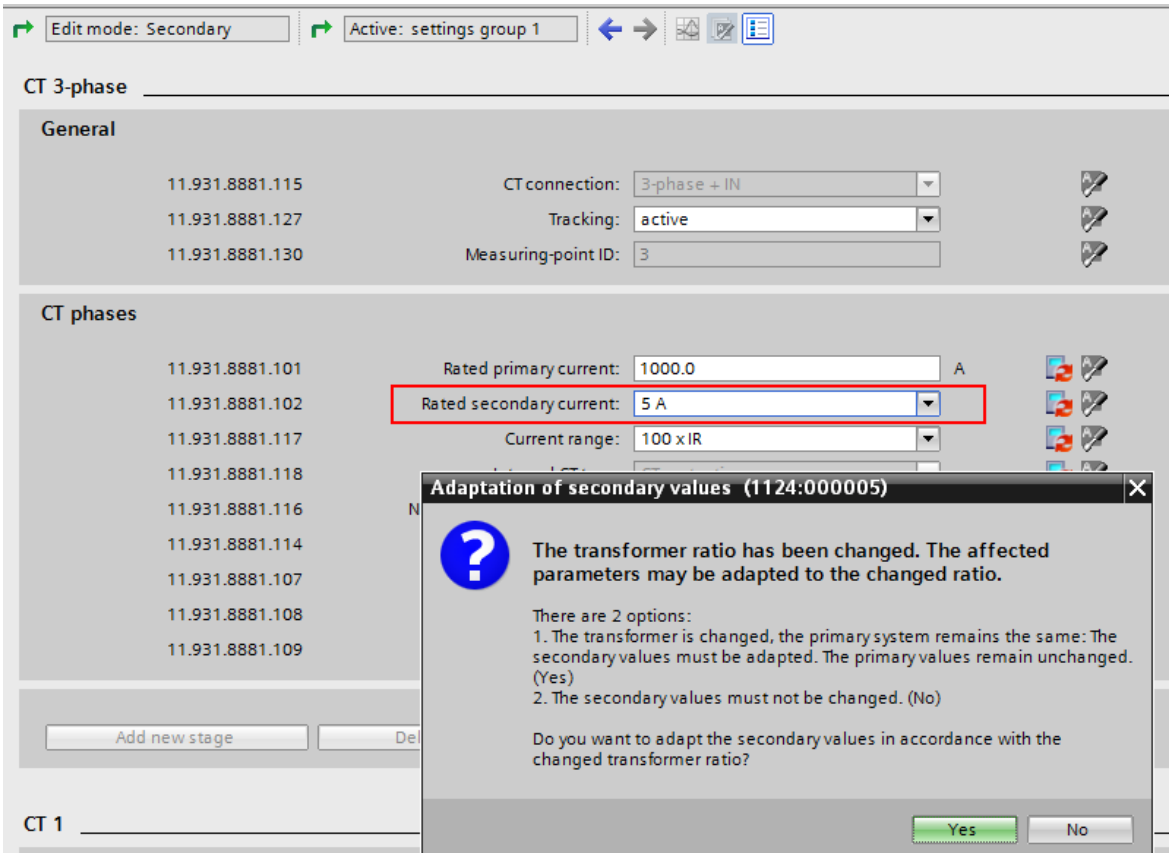


When switching over to the percent view, the result should be the following value:
1500 A/1000 A · 100 % = 150 %

[scumzpro_6, 1, en_US]

Figure 3-97 Example of the Threshold Value of the Definite Time-Overcurrent Protection (Edit Mode: Percent)

When switching over to the secondary view, the result should be the following value:
1500 A/(1000 A/1 A) = 1.5 A

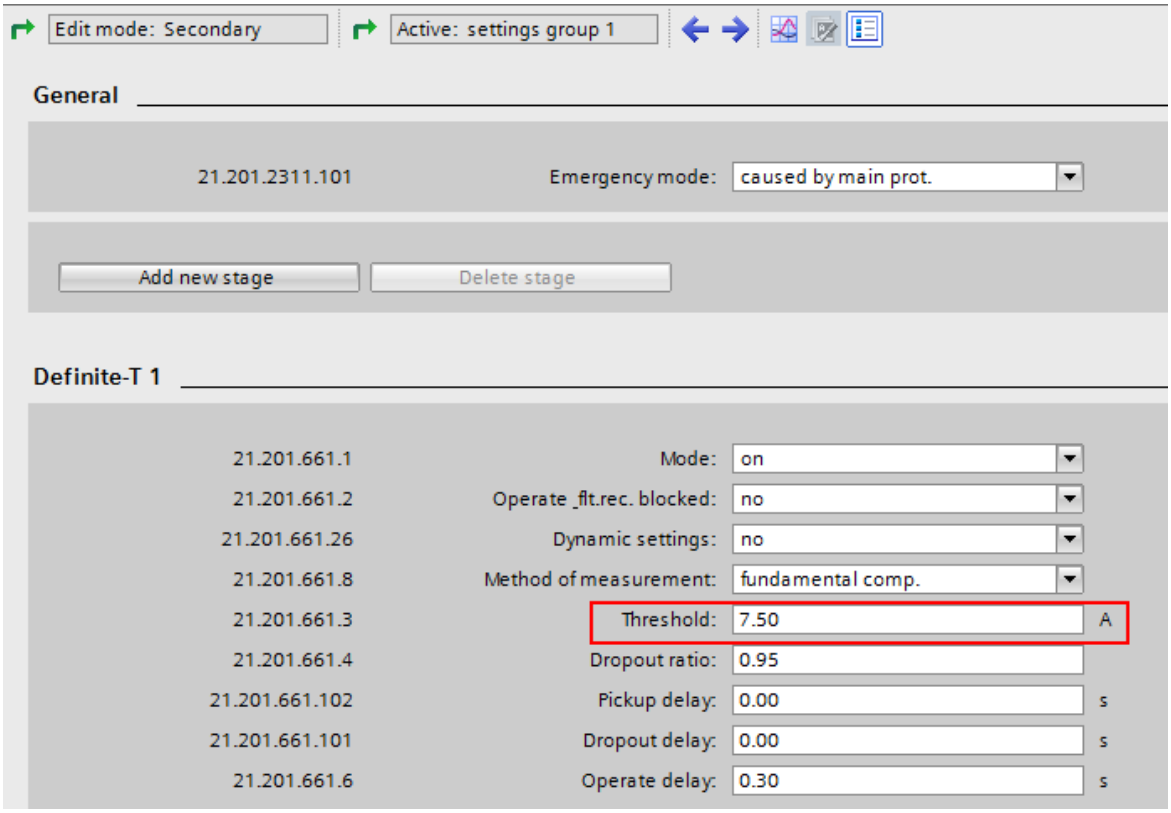


[scumzsek_7, 1, en_US]

Figure 3-98 Example of the Threshold Value of the Definite Time-Overcurrent Protection (Edit Mode: Secondary)

If you only want to work in the secondary view, DIGSI 5 supports you if the transformer ratio changes during the project phase.

In the example, the current-transformer ratio changes from 1000 A/**1 A** to 1000 A/**5 A**. Change the secondary rated current of the current transformer in the setting sheet of the transformer data from 1 A to 5 A (Edit mode: Secondary). If you change the transformer data, a window will appear (see the following figure) that will ask you for the action desired.



[scfragew_8, 1, en_US]

Figure 3-99 Query after Changing the Transformer Data (Setting View: Secondary)

If you answer the question with **Yes,** then DIGSI 5 will recalculate the pickup values (threshold values) in the active secondary view. For the new secondary transformer current 5 A, the new secondary threshold value obtained is 7.5 A (1.5 A * 5 = 7.5 A). The primary and percent values remain unchanged.

The following figure shows the newly calculated threshold value in the secondary view.

[scsekneu_9, 1, en_US]

Figure 3-100 Automatically Recalculated Secondary Values After Changes in the Transformer Data

If you have already set the settings in the secondary view by including the new transformation ratio of the transformer in the calculation, then you answer the question with **No**. In this case, the protection settings in the secondary view remain unchanged. DIGSI 5 recalculates the settings (threshold values) of the primary view. In the example, the primary threshold value is then 300 A (1.5 A * 1000 A/5 A = 300 A).

In the example, the current-transformer ratio changes from 1000 A/1 A to 1000 A/5 A. The following table summarizes the pickup values that DIGSI 5 will recalculate in the setting view. The new values (in bold) depend on the answer of your inquiry (see *Figure 3-99*).

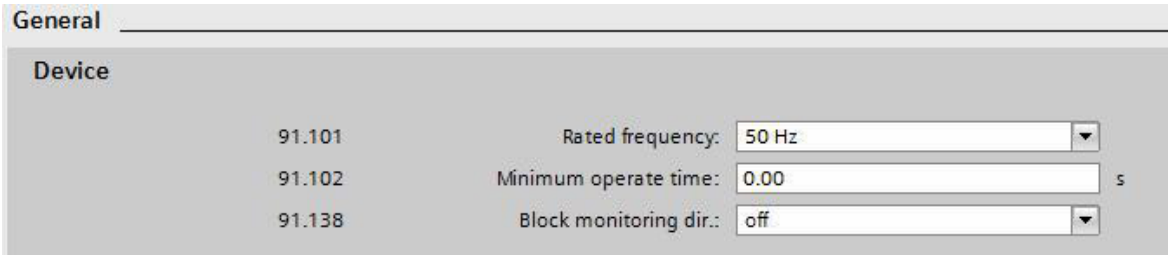
	Reply to the Question	
	Yes	**No**
Threshold value secondary (active setting view)	**7.5** A	1.5 A
Threshold value primary (covered setting view)	1500 A	**300** A

3.9.3 Changing the Transformation Ratios of the Transformer on the Device

The device is preset to the secondary value at the time of delivery. Only secondary values can be set directly on the device.

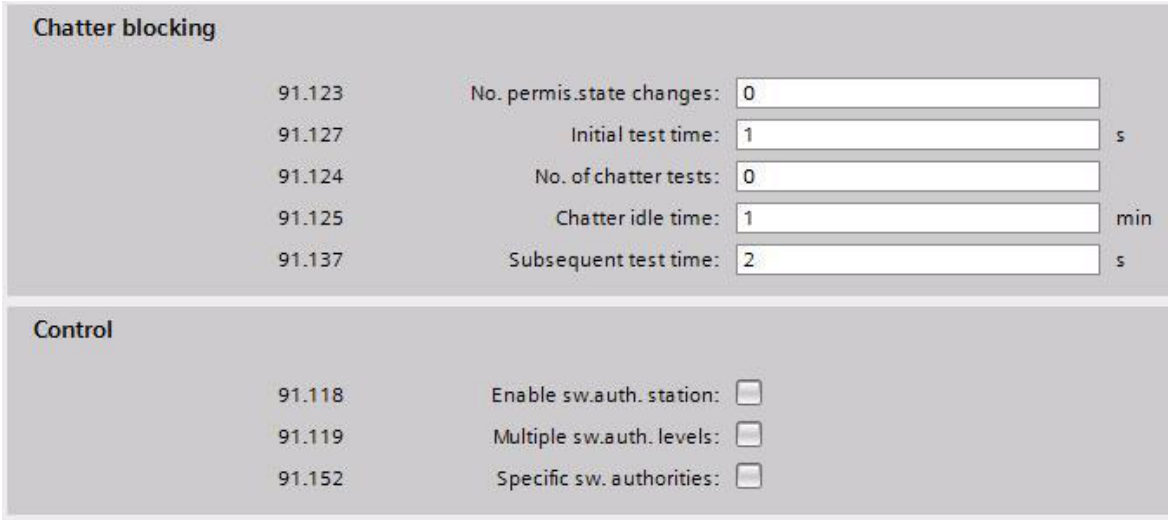
If you change transformer data directly on the device, it is not followed by a query, like in DIGSI 5 (see *Figure 3-99*). Instead, the device assumes that all settings remain unchanged in the secondary view.

NOTE



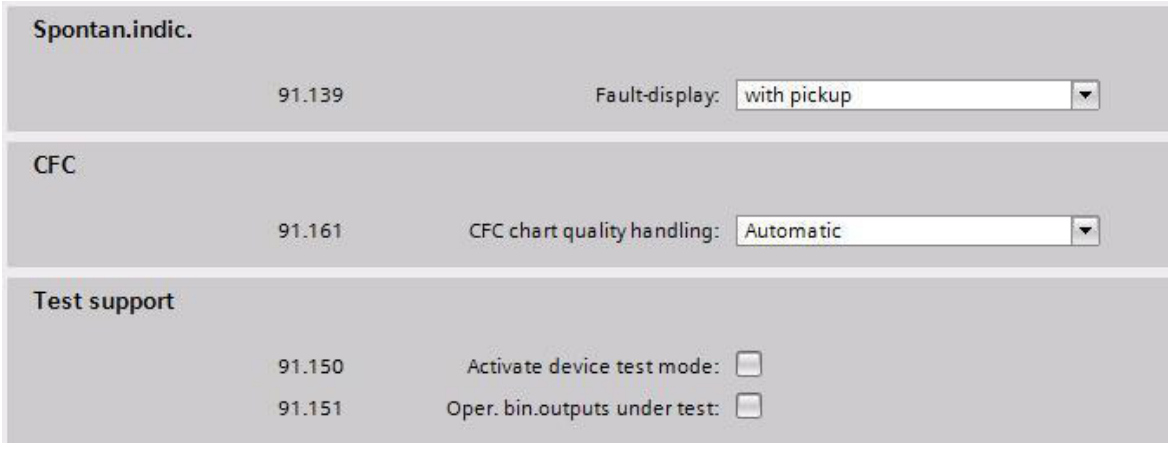
If the device works with IEC 61850 protocol, you change the transformer data only via DIGSI 5 and not directly on the device. If you change the transformer data directly on the device, the IEC 61850 configuration of the measurement and metered values can be faulty.

3.10 Device Settings



3.10.1 General Device Settings

3.10.1.1 Overview



In **Device settings** in DIGSI 5, you find the following general settings.

[scDeSeDe1-310715-01, 1, en_US]

[scDeSeAl-310715-01, 1, en_US]

[scDeSeall-260815-01, 1, en_US]

Figure 3-101 General Device Settings

The following list shows you the chapters containing the desired information.

You can find more about:

- **Chatter blocking** in chapter *3.8.1 Signal Filtering and Chatter Blocking for Input Signals* .
- **Control** in chapter *8.3 Control Functionality* .
- **Spontaneous indications** in chapter *3.1.7 Spontaneous Indication Display in DIGSI 5* .
- **CFC Quality Processing** in Chapter *3.3.3 Quality Processing/Affected by the User in CFC Charts* .

Under **Device**, you set the parameters for the device that are valid across functions.

With the **Test support**, indications issued via communication interfaces are labeled with an additional test bit, if this is supported by the protocol. With this test bit, you can determine that an indication is generated as a test and that all or individual functions of the device are in test mode. In this way, the reactions that are necessary in normal operation due to an indication can be suppressed in other devices that receive these indications. You can also permit, for example, a trip command to close an energized binary output for test purposes. Siemens recommends deactivating the **Test support** again after the test phase.

3.10.1.2 Application and Setting Notes

The major part of the settings is described in the chapters cited above. In the following sections, you can find a description of the parameters of the sections **Device**, **Spontaneous indication**, and **Test support**.

Parameter: Rated frequency

- Default setting **(_:101) Rated frequency** = ***50 Hz***

With the **Rated frequency** parameter, you set the rated frequency of the electrical power system.

Parameter: Minimum operate time

- Default setting **(_:102) Minimum operate time** = **–**

With the **Minimum operate time** parameter, you set the minimum duration for the trip command of the functions. The trip command is maintained for the set duration.

Parameter: Block monitoring dir.

- Default setting **(_:138) Block monitoring dir.** = ***off***

With the **Block monitoring dir.** parameter, you set whether indications are issued via the system interface(s) of the SIPROTEC 5 device or not.

If transmission blocking is switched on, no indications are issued via the system interface(s) of a SIPROTEC 5 device.

Parameter: Fault-display

- Default setting **(_:139) Fault-display** = ***with pickup***

With the **Fault-display** parameter, you set whether spontaneous indications are issued for a pickup or for a tripping. Keep the DIGSI 5 routing options in chapters *3.1.7 Spontaneous Indication Display in DIGSI 5* and *Table 3-5* in mind.

Parameter: Activate device test mode

- Default setting **(_:150) Activate device test mode** = inactive

With the **Activate device test mode** parameter, you activate the test mode that adds a test bit to the issued indications.

Parameter: Oper.bin.outp. under test

- Default setting **(_:151) Oper.bin.outp. under test** = inactive

If you activate the parameter **Oper.bin.outp. under test** , you can allow the closing of a binary output for test purposes. In this way, indications are issued during a device-wide test mode and the relays are either

activated or not. If an individual function is in test mode, only indications are issued and the relays are not activated.

NOTE

The device remains in test mode during every startup until you set the device back into process mode intentionally. You switch to the process mode by switching the parameterActivate device test mode to inactive again (removing the check mark).

3.10.1.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Device				
_:101	General:Rated frequency		• 50 Hz • 60 Hz	50 Hz
_:102	General:Minimum operate time		0.00 s to 60.00 s	0.00 s
_:138	General:Block monitoring dir.		• off • on	off
Spontan.indic.				
_:139	General:Fault-display		• with pickup • with trip	with pickup
Test support				
_:150	General:Activate device test mode		• 0 • 1	false
_:151	General:Oper.bin.outp. under test		• 0 • 1	false

3.10.2 Settings-Group Switching

3.10.2.1 Overview of Functions

For different applications you can save the respective function settings in so-called **Settings groups**, and if necessary enable them quickly.

You can save up to 8 different settings groups in the device. In the process, only one settings group is active at any given time. During operation, you can switch between settings groups. The source of the switchover can be selected via a parameter.

You can switchover the settings groups via the following alternatives:

- Via the on-site operation panel directly on the device
- Via an online DIGSI connection to the device
- Via binary inputs
- Via a communication connection to the substation automation technology.
  The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP or Modbus TCP can be used for switching the settings groups.

A settings group includes all switchable settings of the device. Except for a few exceptions (for example, general device settings such as rated frequency), all device settings can be switched.

Detailed information about the settings groups can be found in the Operating Manual and DIGSI 5 Online Help.

3.10.2.2 Structure of the Function

The function of the **Settings group switching** is a supervisory device function. Accordingly, the settings and indications of the settings group switching can be found in DIGSI 5 and at the on-site operation panel of the device, below the general device settings respectively.

If you want to switchover a settings group, navigate to DIGSI 5 or proceed on the on-site operation panel of the device, as follows:

- Via the project tree in DIGSI 5:
  Project -> Device -> Settings -> Device settings
- Via the on-site operation panel of the device:
  Main menu → Settings → General → Group switchover

The indications for the settings group switching can be found in the DIGSI 5 project tree under:
Project → Device → Information routing → General

3.10.2.3 Function Description

Activation

If you want to use the **Settings group switching** function, you must first set at least 2 settings groups in DIGSI 5 (parameter **Number of settings groups** > 1). You can set up a maximum of 8 settings groups. The settings groups set in DIGSI 5 are subsequently loaded into the device.

Mechanism of the Switchover

When switching over from one settings group to another, the device operation is not interrupted. With the **`Active settings group`** parameter, you are either specifying a certain settings group or you allow switching ***`via control`*** (IEC 60870-5-103, IEC 61850) or ***`via binary input`***.

Switching via Control

When using the ***`Control`*** function for switching, the settings groups can be switched via a communication connection from the substation automation technology or via a CFC chart.

The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP or Modbus TCP can be used for switching the settings groups via a communication connection.

In order to use a CFC chart for switching, you must create a new CFC chart in DIGSI 5. Create the CFC chart in the DIGSI 5 project tree under **Name of the device → Charts → Add new chart**. Link the signals that control settings group switching in the CFC chart.

Switching via Binary Input

There are 3 appropriate input signals available for switching via binary inputs. These input signals allow selection of the settings group via a binary code. If one of the 3 signals changes, the signal image present will, after 100 ms (stabilization time), result in switching over to the appropriate settings group. If only 2 settings groups must be switched over, only 1 binary input is required. The following table shows the possible binary codes (BCD) and applicable settings groups (PG).

Table 3-19 Binary Codes of the Input Signals and Applicable Settings Groups

BCD Code via Binary Inputs	PG 1	PG 2	PG 3	PG 4	PG 5	PG 6	PG 7	PG 8
>PG selection bit 3	0	0	0	0	1	1	1	1
>PG selection bit 2	0	0	1	1	0	0	1	1
>PG selection bit 1	0	1	0	1	0	1	0	1

Copying and Comparing Settings Groups

In DIGSI 5, you can copy or compare settings groups with each other.

If you want to copy settings groups, select a source and target parameter group in DIGSI 5 in the device settings, and then start the copy process. The device settings can be found in the DIGSI 5 project tree under Project → Device → Settings → Device settings.

If you want to compare settings groups, it is possible to do so in all setting sheets for settings. You will then select in addition to the active settings group, a 2nd settings group for comparison. Active setting values and the comparable values are displayed next to each other. For settings that cannot be switched over, no comparable values are displayed.

Indication of Settings Group Switchings

Every settings group shows an applicable binary indication as well as its activation and deactivation. The process of settings group switching is also logged in the log for settings changes.

3.10.2.4 Application and Setting Notes

Parameter: Number settings groups

- Default setting **(_:113) Number settings groups** = ***1***

With the **Number settings groups** parameter, you can set the number of available settings groups; you can switch between these.

Parameter: Activat. of settings group

- Default setting **(_:114) Activat. of settings group** = ***settings group 1***

With the **Activat. of settings group** parameter, you specify the settings groups that you want to activate, or the mechanisms via which the switchover is allowed. You can switchover only between the settings groups specified with the **Number settings groups** parameter. Parameter Value

Parameter Value	Description
via control	The switchover between the settings groups can only be initiated via a communication connection from a substation automation technology or via a CFC chart. The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP or Modbus TCP can be used for switching the settings groups via a communication connection.
via binary input	The switchover between the settings groups functions exclusively via the binary input signals routed to the settings group switching.
settings group 1 ... ***settings group 8***	They define the active settings groups. You can define the active settings groups in DIGSI 5, or directly on the device via the on-site operation.

3.10.2.5 Settings

4 Applications

4.1	Overview	186
4.2	Application Templates and Functional Scope for the Devices 7SJ82/7SJ85	187

4.1 Overview

The Global DIGSI 5 library provides application templates for the applications of the devices. The application template

- Supports the fast realization of complete protection solutions for applications
- Contains the basic configuration for the use case
- Contains functions and default settings for the use case

When using an application template, please note the following:

- Adapt the application template to your specific use (check/adapt default settings, delete/add functions). You can find more detailed information in the *2.1 Function Embedding in the Device*.
- Check the routing of binary outputs with respect to fast and normal relays.
- Check the CFC charts for the group-warning indications and group-fault indications.

The following describes the application templates and maximum functional scope for the devices shown in this manual.

NOTE

The availability of certain settings and setting options depends on the device type and the functions available on the device!

4.2 Application Templates and Functional Scope for the Devices 7SJ82/7SJ85

Application templates are available in **DIGSI 5** for the applications of the device 7SJ82/7SJ85. The application templates contain the basic configurations, required functions, and default settings.

The following application templates are available for the device 7SJ82 and 7SJ85 in the **DIGSI 5** function library:

- Non-directional OC (4*I)
- Non-directional OC (4*I, 4*V)
- Directional OC, grounded system
- Directional OC, resonant-grounded/isol. system
- Capacitor bank H-bridge + 1*RLC, **7SJ85 only**
- Capacitor bank MSCDN, **7SJ85 only**
- Capacitor bank H-bridge, **7SJ82 only**

To load the application templates to the device, the following minimum hardware configuration requirements must be met:

Application Template		**Hardware Configuration Minimum Requirement**
Template 1	Non-directional OC (4*I)	9 BI, 8 BO, 4 I
Template 2	Non-directional OC (4*I, 4*V)	9 BI, 8 BO, 4 I, 4 V
Template 3	Directional OC, grounded system	
Template 4	Directional OC, resonant-grounded / isol. system	
Template 5	Capacitor bank: H-bridge + 1*RLC	2 BI, 2 BO, 12 I
Template 6	Capacitor bank: MSCDN	2 BI, 2 BO, 28 I, 4 V
Template 7	Capacitor bank: H-bridge	2 BI, 2 BO, 8 I

The following table shows the functional scope and the required function points of the application templates for the device 7SJ82/7SJ85:

Table 4-1 Functional Scope of the Application Template for the Device 7SJ82/7SJ85

5 Function-Group Types

5.1	Function-Group Type Voltage-Current 3-Phase	194
5.2	Function-Group Type Voltage-Current 1-Phase	201
5.3	Function-Group Type Voltage 3-Phase	205
5.4	Function-Group Type Capacitor Bank	208
5.5	Function-Group Type Capacitor Bank Differential Protection	220
5.6	Function-Group Type Analog Units	233
5.7	Function-Group Type Circuit Breaker	272
5.8	Process Monitor	291

5.1 Function-Group Type Voltage-Current 3-Phase

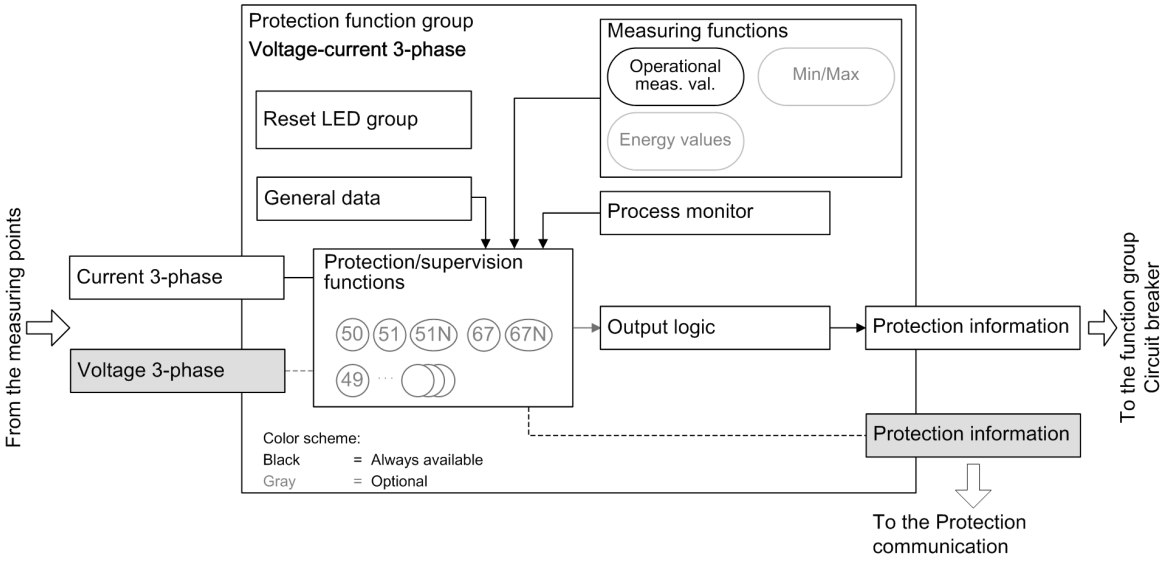
5.1.1 Overview

All functions for protection and supervision of a protected object or equipment allowing 3-phase current and voltage measurement can be used in the function group **Voltage-current 3-phase**. The function group also contains the operational measurement for the protected object or equipment (on this topic, see chapter *10 Measured Values, Energy Values, and Supervision of the Primary System*).

You will find the **Voltage-current 3-phase** function group under each device type in the Global DIGSI 5 library. You will find all protection and supervision functions that you can use for this function-group type in the function group **Voltage-current 3-phase**. These functions are described in chapter *6 Protection and Automation Functions* .

You can find additional information on the embedding of the functions in the device in chapter *2 Basic Structure of the Function* . You can find the function scope of the application templates for the various device types in the chapter *4 Applications* .

5.1.2 Structure of the Function Group



The function group always contains the following blocks:

- Protected object/equipment data (FB General)
- Operational measured values
- Process monitor
- Output logic of the function group
- Reset LED group

These blocks are essential for the function group under all circumstances, so they cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

The following figure shows the structure of the function group **Voltage-current 3-phase**.

[dwfgui3p-301112-01.tif, 4, en_US]

Figure 5-1 Structure of the Voltage-Current 3-Phase Function Group

The function group has interfaces with

- **Measuring points**
- **Circuit-breaker** function group

Interface with Measuring Points

The function group receives the required measured values via its interfaces with the measuring points. If you are using an application template, the function group is already connected to the necessary measuring points. If you add functions to the function group, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function group connections** editor. You can find more detailed information in chapter *2 Basic Structure of the Function*.

The function group has the following interfaces with the measuring points:

- **3-phase current**

  The measurands from the 3-phase power system are supplied via this interface. Depending on the connection type of the transformers, these are, for example, I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The function group must always be connected to the **I-3ph** measuring point.

  You can connect the **3-phase current** interface to a maximum of **four** 3-phase current measuring points (for example, for 1 1/2 circuit-breaker layouts). If 2 current measuring points have been connected with the **3-phase current** interface, the total current is also determined from measured values from both measuring points in the function group. All functions in the function group have access to these values.

- **3-phase voltage (optional)**

  The measurands from the 3-phase voltage system are supplied via this interface. There are various types of transformer connections possible. All values that can be calculated from the measurands are also provided via this interface. Connecting the function group to the **V 3ph** measuring point is optional.

  You can connect multiple measuring points with this interface. You can find more information in chapter *6.48 Voltage Measuring-Point Selection*.

  If you want to test or change the connection between the voltages and the V-3ph measuring point, double-click in the DIGSI 5 project tree → **(Name of the device)** on **Measuring point routing** (Connection type = 3 phase-to-ground voltage). For more information, refer to the description of the power-system data starting in chapter *6.1 Power-System Data*.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and **Circuit-breaker** function groups via the interface with the Circuit-breaker function group. This data includes, for example, the pickup and operate indications of the protection functions sent in the direction of the Circuit-breaker function group and, for example, the circuit-breaker condition information in the direction of the protection function groups.

The **Voltage-current 3-phase** function group is connected to one or more Circuit-breaker function groups. This connection generally determines:

- Which circuit breaker(s) is/are activated by the protection functions of the protection function group
- Starting the Circuit-breaker failure protection function (if available in the Circuit-breaker function group) through the protection functions of the connected protection function group
- Starting the Automatic reclosing function (AREC, if available in the Circuit-breaker function group) through the protection functions of the connected Protection function group

Besides the general allocation of the protection function group to the Circuit-breaker function groups, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** editor in the protection function group.

In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the automatic reclosing function
- Which protection functions start the Circuit-breaker failure protection function

If you are using an application template, the function groups are already connected to each other, because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2.1 Function Embedding in the Device*.

If the connection is missing, DIGSI 5 reports an inconsistency.

Protected Object/Equipment Data (FB General)

The rated voltage and rated current as well as the neutral-point treatment of the protected object or the equipment are defined here. These data apply to all functions in the **Voltage-current 3-phase** function group.

Resetting the LED Group

Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

You can find more detailed information in chapter *3.1.10 Resetting Stored Indications of the Function Group* .

Process Monitor

The process monitor is always present in the **Voltage-current 3-phase** function group and cannot be removed.

The process monitor provides the following information in the **Voltage-current 3-phase** function group:

- Current-flow criterion:
  Detection of an open/activated protected object/equipment based on the flow of leakage current
- Closure detection:
  Detection of the switching on of the protected object/equipment
- Cold-load pickup detection (optional, only for protection devices):

These data apply to all functions in the **Voltage-current 3-phase** function group.

The description of the process monitor begins in chapter *5.8 Process Monitor*.

Operational Measured Values

The operational measured values are always present in the **Voltage-current 3-phase** function group and cannot be removed.

The following table shows the operational measured values of the **Voltage-current 3-phase** function group:

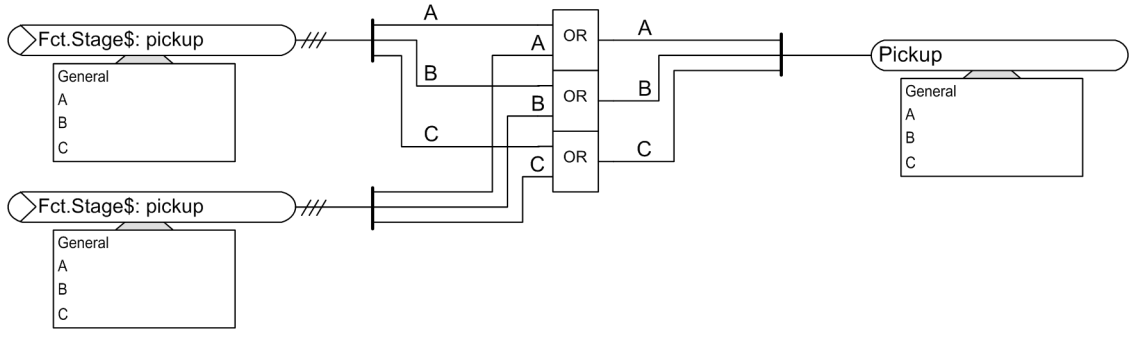
Table 5-1 Operational Measured Values of the Voltage-Current 3-Phase Function Group

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary values
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary values
I_N	Neutral-point phase current	A	A	Rated operating current of the primary values
I_{NS}	Sensitive ground current	A	mA	Rated operating current of the primary values
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Operating rated voltage of primary values/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary values
V_0	Zero-sequence voltage	kV	V	Operating rated voltage of primary values/√3
V_{NG}	Neutral-point displacement voltage	kV	V	Operating rated voltage of primary values/√3
f	Frequency	Hz	Hz	Rated frequency
P_{total}	Active power (total power)	MW	W	Active power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$

Measured Values		Primary	Secon-dary	% Referenced to
Q_{total}	Reactive power (total power)	Mvar	var	Reactive power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S_{total}	Apparent power (total power)	MVA	VA	Apparent power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active power factor	(abs)	(abs)	100 % corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	W	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	var	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	VA	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

The operational measured values are explained in more detail in chapter *10.3 Operational Measured Values* .

Inversion of Power-Related Measured and Statistical Values (FB General)

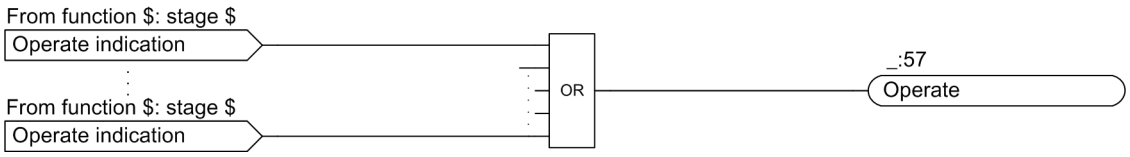


The following directional values calculated in operational measured values are defined positively in the direction of the protected object.

- Power
- Active power factor
- Energy
- Minimum, maximum values
- Average values

With the **`P, Q sign`** parameter, you can invert the sign of these operational measured values such that a power flow from the line to the busbar is displayed positively.
More information can be found in chapter *10.1 Overview of Functions*.

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions that are available in the function group separately, in a pickup logic and a trip logic, respectively. The pickup and trip logic generate the overreaching indications (group indications) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.
The pickup signals of the protection and supervision functions in the **Voltage-current 3-phase** function group are combined in a phase-selective manner and output as a group indication.

[loanrlin-150211-01.tif, 3, en_US]

Figure 5-2 Creation of the Pickup Indication of the Voltage-Current 3-Phase Function Group

The trip signals from the protection and supervision functions of the **Voltage-current 3-phase** function group always result in 3-pole tripping of the device.

[loauslin-150211-01.tif, 3, en_US]

Figure 5-3 Creation of the Operate Indication of the Voltage-Current 3-Phase Function Group

5.1.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

With this, you define which circuit-breaker(s) is/are affected by the protection functions of the Protection function group. A feasible default setting has already been provided in the application templates. You can find more information in chapter 2.

Protected Object/Equipment Data (FB General)

The set data applies to all functions in the function group.

Set the protected object/equipment data for your specific application.

Parameter: Rated current

- Default setting **(_:9451:101) Rated current** = ***1000 A***

With the **Rated current** parameter, you can set the primary rated current of the protected object or equipment. The **Rated current** parameter is significant for protection functions, as long as the current values are set in percentages. In this case it is the reference value. In addition it is the reference value for the measured values in percent.

If the device works with the IEC 61850 protocol, then you change only the setting value of the parameter via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:9451:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the protected object or equipment. The **Rated voltage** parameter is significant for protection functions, as long as the current values are set in percentages. In this case it is the reference value. In addition it is the reference value for the measured values in percent.

If the device works with the IEC 61850 protocol, then you change only the setting value of the parameter via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Power-sys. neutral point

- Default setting **(_:9451:149) Power-sys. neutral point** = ***grounded***

With the **Power-sys. neutral point** setting, you specify whether the system neutral is ***grounded*** , ***isolated*** , or ***suppress. coil grounded*** (grounded via arc-suppression coil). Currently, the parameter does not affect any protection function; only if the **Automatic reclosing function** uses the voltage measurement.

You can find more information in Chapter *6.43.1 Overview of Functions* .

Parameter: `P, Q sign`

- Default setting **`(_:9451:158) P, Q sign`** = ***`not reversed`***

The power and energy values are defined by the manufacturer such that power in the direction of the protected object is considered positive. You can also define the power output by the protected object (for example, as seen by the consumer) as positive. With the **`P, Q sign`** setting, you can invert the sign for these components. This inversion does not influence any protection function.

5.1.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
`Network data`				
_:103	General:rated apparent power		0.20 MVA to 5 000.00 MVA	692.82 MVA

NOTE

You can find more detailed information on the Process monitor in chapter *5.8 Process Monitor*.

5.1.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`Rated values`				
_:9451:101	General:Rated current		1 A to 100000 A	1000 A

5.2 Function-Group Type Voltage-Current 1-Phase

5.2.1 Overview

In the **Voltage-current 1-phase** function group, all functions can be used for protecting and for monitoring a protected object or equipment which allow a 1-phase current and voltage measurement or a zero-sequence voltage measurement via a 3-phase voltage measuring point. The function group also contains the operational measurement for the protected object or equipment (on this topic, see chapter *10 Measured Values, Energy Values, and Supervision of the Primary System*).

5.2.2 Structure of the Function Group

The **Voltage-current 1-phase** function group has interfaces to the measuring points and the **Circuit-breaker** function group.

[dw1spstr-301112-01.tif, 3, en_US]

Figure 5-4 Structure of the Voltage-current 1-Phase Function Group

Interface with Measuring Points

You connect the **Voltage-current 1-phase** function group to the current and voltage measuring points via the interfaces to the measuring points. At least one measuring point has to be connected. The other is optional. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

The function group has the following interfaces to the measuring points:

- **1-phase current**

  The 1-phase current measured values are supplied via this interface.

  You can connect multiple measuring points with the **1-phase current** interface.

- 1-phase voltage or 3-phase voltage

  You can connect the voltage interface of the function group with a 1-phase or a 3-phase measuring point. The calculated zero-sequence voltage or the measured residual voltage are available for connection with a 3-phase measuring point. The phase-to-ground voltages are not available in the function group **Voltage-current 1-phase**. You can use both connection types at the same time.

  You configure the 1-phase voltage measuring points via the voltage interface (see the following figure).

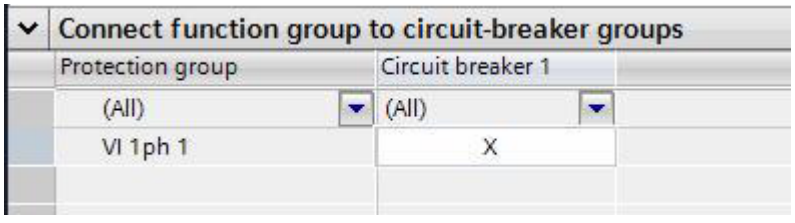
[scVI1ph_V1ph, 1, en_US]

Figure 5-5 Connecting Measuring Points to the Voltage-current 1-Phase Function Group

The converted, calculated zero-sequence voltage or measured residual voltage from the 3-phase voltage system is available via the voltage interface (see following figure).

[scVI1ph_V3ph, 1, en_US]

Figure 5-6 Connecting Measuring Points 3-Phase Voltage and 1-Phase Current to the 1-Phase Voltage-Current Function Group



You can connect the voltage interface with precisely one 3-phase voltage measuring point. 3 types of 3-phase voltage measuring-point connections are supported. With the differenct connection types, the type of voltage input also changes in line with the functions. The following table shows the characteristics of the voltage input depending on the types of connection.

Connection Type of the 3-Phase Voltage Measuring Point	**Voltage Input**
3 ph-to-gnd voltages	The zero-sequence voltage is calculated from the phase-to-ground voltages and used as a voltage input for all funtions.
3 ph-to-gnd volt. + VN	The residual voltage VN is converted to the voltage equivalent of the zero-sequence voltage. The converted voltage is used as a voltage input for functions.
3 ph-to-ph volt. + VN	

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and circuit-breaker function groups via the interface with the **Circuit-breaker** function group. In this example, the pickup and operate indications of the protection functions are exchanged in the direction of the Circuit-breaker function group.

You must connect the **Voltage-current 1-phase** function group with the **Circuit-breaker** function group. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix. If the interface is not connected, the functions operate as supervision functions in the **Voltage-current 1-phase function group**.

[sc1stspc-190214-01, 1, en_US]

Figure 5-7 Connecting Voltage-current 1-Phase Function Group with Circuit-Breaker Function Group

Fundamental Components

The fundamental components are always present in the **Voltage-current 1-phase** function group and cannot be deleted.

The following table shows the fundamental components of the **Voltage-current 1-phase** function group:

Table 5-2 Fundamental Components of the Voltage-current 1-Phase Function Group

Measured Values		Primary	Secondary	% Referring to
I	1-phase current	A	A	**Rated operating current**
V[7]	1-phase voltage	kV	V	**Rated operating voltage**
V_0 [8]	Zero-sequence voltage	kV	V	**Rated operating voltage**/√3
V_N [9]	Residual voltage	kV	V	**Rated operating voltage**/√3

5.2.3 Application and Setting Notes

NOTE

Prior to creation of the protection functions in the function group, these functions should first be connected to the appropriate **Circuit-breaker** function group.

Parameter: Rated current

- Default setting **(_:9451:101) Rated current** = ***1000 A***

The **Rated current** parameter is used to set the primary rated current. The **Rated current** specified here is the reference value for the percentage-measured values and setting values made in percentages.

Parameter: Rated voltage

- Default setting **(_:9421:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you set the primary voltage, which serves as a reference for all voltage-related % values within the **Circuit-breaker** function group.

5.2.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Range of Values	Default Setting
Rated values				
_:9421:104	General:rated apparent power		0.20 MVA to 5000.00 MVA	400.00 MVA

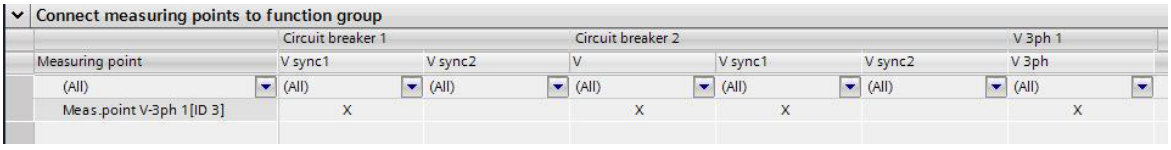
5.3 Function-Group Type Voltage 3-Phase

5.3.1 Overview

In the **Voltage 3-phase** function group, all functions can be used for protecting and for monitoring a protected object or equipment which allows a 3-phase voltage measurement. The function group also contains the operational measurement for the protected object or equipment (on this topic, see chapter *10 Measured Values, Energy Values, and Supervision of the Primary System*). Applicable functions are, for example, Voltage protection or Frequency protection.

5.3.2 Structure of the Function Group

The **Voltage 3-phase** function group has interfaces to the measuring points and the **Circuit-breaker** function group.



[dw3spann-300913, 1, en_US]

Figure 5-8 Structure of the Voltage 3-Phase Function Group

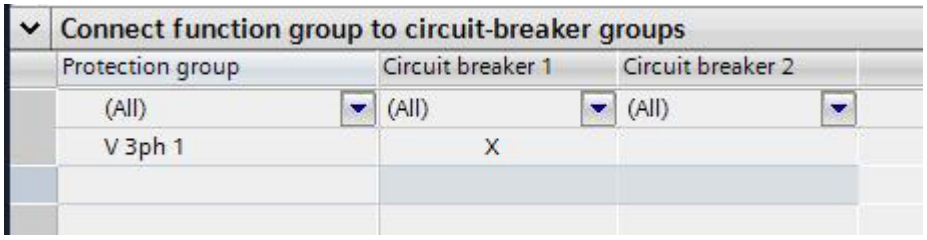
Interface with Measuring Points

You connect the **Voltage 3-phase** function group to the voltage measuring points via the interface to the measuring points. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

[sc3span1-190214-01, 1, en_US]

Figure 5-9 Connecting Measuring Points to the Voltage 3-Phase Function Group

If you add functions to the **Voltage 3-phase** function group, these are connected to the measuring point automatically.



You can connect multiple measuring points with this interface. You can find more information in chapter *6.48 Voltage Measuring-Point Selection*.

The measurands from the 3-phase voltage system are supplied via the **V 3-ph** interface. Depending on the type of transformer connections, these are, for example, V_A, V_B, V_C, V_{gnd}. All values that can be calculated from the measurands are also provided via this interface.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and circuit-breaker function groups via the interface with the **Circuit-breaker** function group. In this example, the pickup and operate indications of the protection functions are exchanged in the direction of the Circuit-breaker function group.

You must connect the **Voltage 3-phase** function group with the **Circuit-breaker** function group. This assignment can be made in DIGSI only via **Project tree** → **Connect function group**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

[sc3span2-190214-01, 1, en_US]

Figure 5-10 Connecting Voltage 3-Phase Function Group with Circuit-Breaker Function Group

Operational Measured Values

The operational measured values are always present in the **Voltage 3-phase** function group and cannot be deleted.

The following table shows the operational measured values of the **Voltage 3-phase** function group:

Table 5-3 Operational Measured Values of the Voltage 3-Phase Function Group

Measured Values		Primary	Secondary	% Referenced to
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Operating rated voltage of primary values/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary values
V_0	Zero-sequence voltage	kV	V	Operating rated voltage of primary values/√3
V_{NG}	Neutral-point displacement voltage	kV	V	Operating rated voltage of primary values/√3
f	Frequency	Hz	Hz	Rated frequency

5.3.3 Application and Setting Notes

NOTE

Before creating the protection functions in the function group, you should first connect hese functions to the appropriate **Circuit-breaker** function group.

Parameter: Rated voltage

- Default setting **(_:9421:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you set the primary rated voltage. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

5.3.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting

5.4 Function-Group Type Capacitor Bank

5.4.1 Overview

In the **Capacitor bank** function group, all the functions that are necessary for protecting and monitoring a capacitor bank can be used.

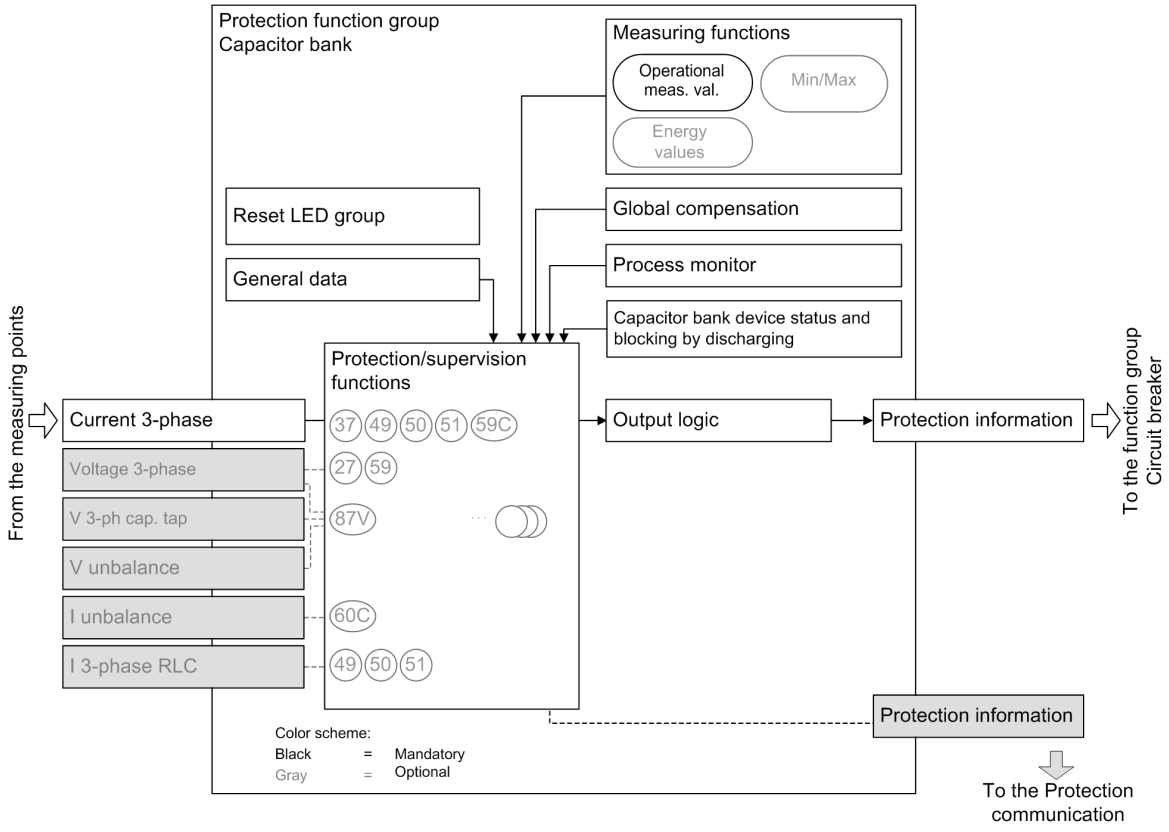
You can find the **Capacitor bank** function group under 7SJ82/7SJ85 device types in the Global DIGSI 5 Library. The **Capacitor bank** function group contains all of the protection and supervision functions that you can use for this device type.

Some of these functions are exclusively used for protecting capacitor banks, and others are universal standard functions which can be used for other protected objects as well. You find the exclusive protection functions in the directory **Capacitor-bank protection**.

[scfgcapb-250314-01, 2, en_US]

Figure 5-11 Capacitor Bank Function Group - Functional Scope for Device Type 7SJ85

For more information about the embedding of the functions in the device, refer to chapter 2. For information about the overall functional scope of the application templates for the various device types, refer to chapter 4.



5.4.2 Structure of the Function Group

The **Capacitor bank** function group always contains the following functionality:

- Protected object/equipment data (function block **General**)
- Operational measured values
- Capacitor bank device status and blocking by discharging (function block **General**)
- Process monitor
- Global compensation (function block **General**)
- Output logic of the function group
- Reset LED group

This functionality is essential for the **Capacitor bank** function group, so it cannot be loaded or deleted.

You can load the protection functions and supervision functions required for your application in the **Capacitor bank** function group. The functions are available from the Global DIGSI 5 Library. Functions that are not needed can be deleted from the function group.

[Dwstrcap-20140619-01.vsd, 2, en_US]

Figure 5-12 Structure of the Capacitor Bank Function Group

The **Capacitor bank** function group has interfaces with the following parts:

- **Measuring points**
- **Circuit-breaker** function group

Interfaces with the Measuring Points

The **Capacitor bank** function group receives the required measured values via the interfaces with the measuring points. If you are using an application template, the **Capacitor bank** function group is already connected to the specific measuring points.

You can find more detailed information in Chapter 2.

The **Capacitor bank** function group has the following 6 interfaces with the measuring points. The universal standard functions only work with the standard interfaces **3-phase current** and/or **3-phase voltage**; the other 4 interfaces are provided for the functions which are exclusively used for the capacitor banks. Please also refer to the example given below.

The **Capacitor bank** function group has the following interfaces with the measuring points:

- **3-phase current:**

  The measurands from the 3-phase current system are supplied via this interface. Depending on the connection type of the current transformers, the measurands can be for example I_A, I_B, I_C, I_N, or $3I_0$. All values that can be calculated from the measurands are also provided via this interface.

  The **Capacitor bank** function group must always be connected to the **3-phase current measuring point**. You can connect the **3-phase current measuring point** interface to the maximum of two **3-phase current measuring points**. If 2 current measuring points have been connected to the 3-phase current interface, the total current is determined by adding the measured values from both measuring points in the function group. The functions in the **Capacitor bank** function group evaluate the total current.

- **3-phase voltage** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Depending on the connection type of the voltage transformers, these can be for example V_A, V_B, V_C, V_N, or $3V_0$. All values that can be calculated from the measurands are also provided via this interface.

  The connection of the **3-phase voltage** interface is optional. This connection is only required if protection functions or supervision functions are applied, which require voltage measurements.

- **3-phase voltage CB tap** (optional):

  The measurands of a 3-phase tap voltage within a capacitor bank are supplied via this interface.

  The connection of the **3-phase voltage CB tap** interface is optional. You can connect the 3-phase voltage CB tap interface to a maximum of one **3-phase voltage measuring point**.

- **Voltage unbalance** (optional):

  The unbalanced-voltage measurands (for example, an isolated neutral point of the capacitor bank) are supplied via this interface.

  The connection of the **voltage unbalance** interface is optional. You can connect the **voltage unbalance** interface to a maximum of one **1-phase voltage measuring points**.

- **Current unbalance** (optional):

  The unbalanced-current measurands are supplied via this interface.

  The connection of the **current unbalance** interface is optional. You can connect the **current unbalance** interface to a maximum of two **3-phase current measuring points** and six **1-phase current measuring points**.The interface allows mixed connections to 3-phase current measuring point and 1-phase current measuring point; however the sum of the connections is no more than 6.

  For an overview which function are applicable on this interface, please refer to Figure 1-5.

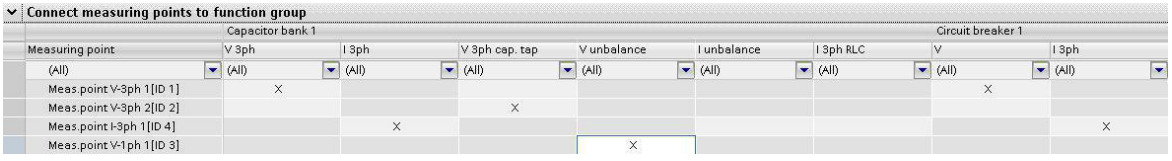
- **3-phase current RLC** (optional)

  The measurands from a tuning or filtering section (R, L, or C) of a capacitor bank are supplied via this interface.

  The connection of the **3-phase current RLC** interface is optional. You can connect the **3-phase current RLC** interface to a maximum of nine **3-phase current measuring points**.

  For an overview which function are applicable on this interface, please refer to *Figure 5-13*.

Example

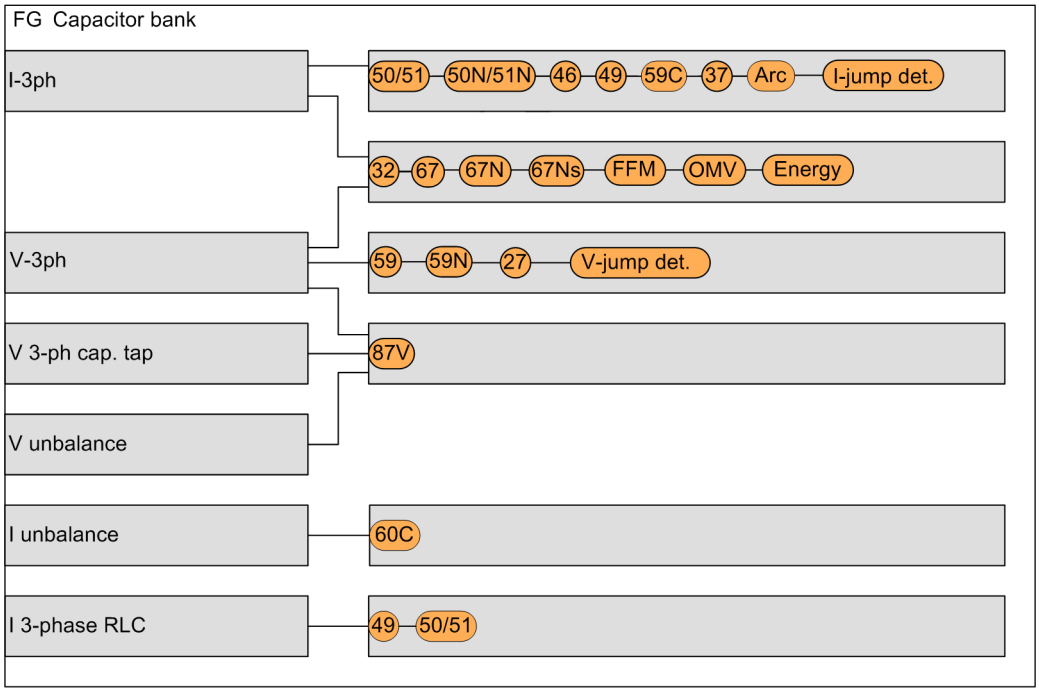


The following figure shows an example of a capacitor in H-configuration and tuning section. In the single line, the primary current and voltage measurement are shown. The required device measuring points and their connections to the function group interfaces are shown as well. In addition, it is indicated which protection function receives its measuring value from which measuring point.

[dwasscap-180713-01.tif, 2, en_US]

Figure 5-13 An Example of Assignment of Measuring Points to the Capacitor-Bank Functions

You can connect the **Capacitor bank** function group to the current and voltage measuring points via interfaces. You make this assignment in DIGSI via **Project tree → Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.



[scrconba-110314-03, 2, en_US]

Figure 5-14 Connecting Measuring Points to the Capacitor Bank Function Group

For the protection functions applied on the interfaces **3-phase current** and **3-phase voltage**, if you add these functions to the **Capacitor bank** function group, these functions will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary interface is not connected to any measuring point, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 using the **Function group connections** editor.

For the protection functions applied on the interfaces **Current unbalance** and **3-phase current**, you have to select the desired measuring points via a setting **`MP selection`**, which offers a list of all measuring points connected to the specific interface. The setting **`MP selection`** is located on the setting page of the protection function.

The following figure shows an overview of the protection functions and the interface assignment in the **Capacitor bank** function group.

27	Undervoltage protection
32	General power protection
37	Undercurrent protection
46	Negative-sequence protection
49	Overload protection
50/51	Overcurrent protection, phases
50N/51N	Overcurrent protection, ground
59	Overvoltage protection
59C	Peak overvoltage protection
59N	Overvoltage protection with zero-sequence voltage/residual voltage
60C	Current-unbalance protection

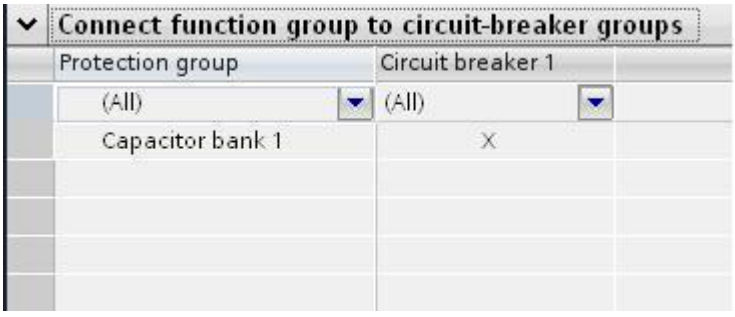
67Ns	Directional sensitive ground-fault detection
87V	Voltage-differential protection
OMV	Operational values
FFM	Fuse-failure monitor

[DwCapBank-180713-01, 4, en_US]

Figure 5-15 Overview of the Protection Functions and Interface Assignment in the Capacitor Bank Function Group

Interfaces with Circuit-Breaker Function Group



All required data are exchanged between the protection function group and the **Circuit-breaker** function group via the interface with the **Circuit-breaker** function group. These data include, for example, the pickup and operate indications of the protection functions sent in the direction of the **Circuit-breaker** function group and, for another example, the information about the circuit-breaker condition sent in the direction of the protection function group.

The **Capacitor bank** function group is connectable to a **Circuit-breaker** function group. This connection generally determines:

- Which circuit breaker is activated by the protection functions of the **Capacitor bank** function group
- Starting of the **Circuit-breaker failure protection** function (if available in the **Circuit-breaker** function group) through the protection functions of the connected **Capacitor bank** function group
- Starting of the **Automatic reclosing** function (if available in the **Circuit-breaker** function group) through the protection functions of the connected **Capacitor bank** function group

NOTE

For capacitor bank protection, the **Automatic reclosing** function is not applied in most cases. However, due to flexibility and standardization, the respective interface is offered.

[scrconb1-180713-01.tif, 1, en_US]

Figure 5-16 Connecting Capacitor Bank Function Group with Circuit-Breaker Function Group

Besides the general assignment of the **Capacitor bank** function group to the **Circuit-breaker** function group, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit breaker interaction** editor in the Capacitor bank function group.

In the detailed configuration of the interface, define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the **Circuit-breaker failure protection** function
- Which protection functions start the **Automatic reclosing** function

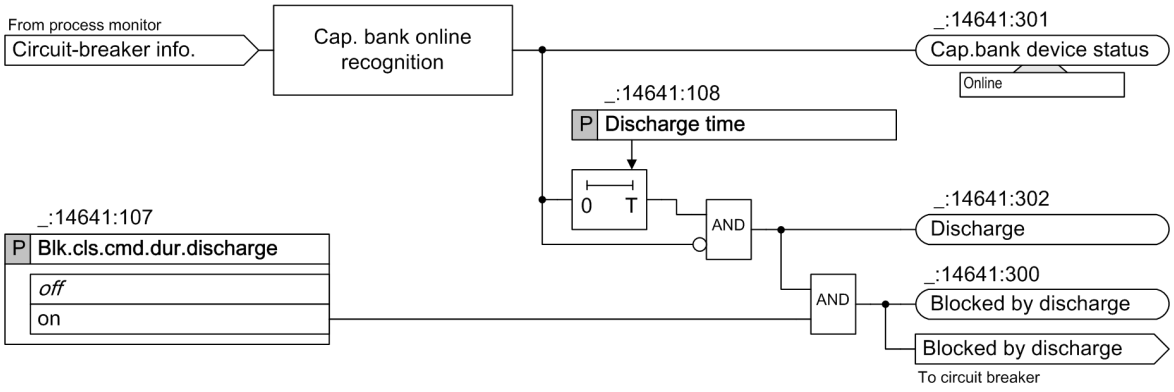
	Circuit breaker 1	
	Trip logic	50BF CB fail.1
Protection group	Trip	Start CB failure
(All)	(All)	(All)
50/51 OC-3ph-A1	X	X
Definite-T 1	X	X
Definite-T 2	X	X
Inverse-T 1	X	X

[scconcap-150713-01.tif, 2, en_US]

Figure 5-17 Connecting Protection Functions and Stage Using the Circuit-Breaker Interaction Editor

If an application template is used, the function groups have already been connected to each other because this link is essential to ensure proper operation. You can modify the link in DIGSI 5 using the **Function-group connections** editor.

You can find more information in chapter *2.1 Function Embedding in the Device*. If this link is missing, DIGSI 5 reports an inconsistency.

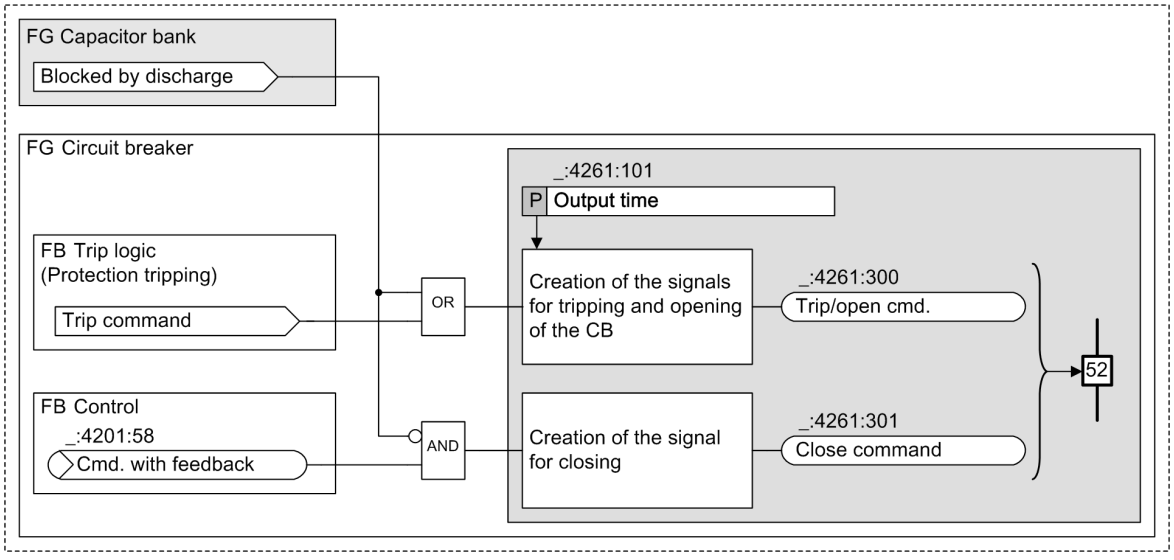


Protected Object/Equipment Data (FB General)

Capacitor-bank rated and reference data are defined as well as further protected object/equipment data. The data applies for all functions in the **Capacitor bank** function group.

For further information, refer to chapter *5.4.3 Application and Setting Notes*.

Capacitor Bank Device Status and Blocking by Discharging (FB General)



The functionality detects whether a capacitor bank is **online** or **offline**. When the status of the capacitor bank changes from **online** to **offline**, the signal *Discharge* is issued during the capacitor-bank discharging time.

[Lo-CapZap-20140617-01, 1, en_US]

Figure 5-18 Logic Diagram of Capacitor Bank Device Status and Blocking by Discharging

The device can block the closing of the circuit breaker automatically when a capacitor bank discharges. The configuration is made with the parameter **Blk.cls.cmd.dur.discharge**. If the parameter **Blk.cls.cmd.dur.discharge** is set to ***on***, the device generates a trip/open command during the discharge time and blocks closing commands additionally, see the following figure. This blocking condition is signaled via the message *Blocked by discharge*.

[Lo-discharge-20140617-01, 1, en_US]

Figure 5-19 Logic Diagram of Processing the Blocked by Discharge Signal

Global Compensation (FB General)

The **Global compensation** function block provides the binary input signal *>Compensate* to carry out the manual compensation for all functions in the FG using compensated measuring values.

In addition, the binary input signal *>Reset comp. val.* is provided to reset all compensation values for the functions using compensated measuring values.

Process Monitor

The **Process monitor** detects the current state of the protected object. It is always present in the function group and cannot be removed.

For detailed description of the **Process monitor**, refer to *5.8.1 Overview of Functions*.

Reset LED Group

The **Reset LED group** function block allows you to reset only the stored LEDs of the functions contained in the respective function group, while stored LEDs activated from functions in other function groups remain active.

For more information refer to chapter *3.1.10 Resetting Stored Indications of the Function Group* .

Operational, Fundamental, Symmetrical Components Measurements

The operational fundamental, symmetrical components and functional measurements are always available in the **Capacitor bank** function group and cannot be deleted.

Table 5-4 Operational Measured Values (True RMS) of the Function Group Capacitor Bank

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
I_N	Neutral-point phase current	A	A	Rated operating current of the primary system
$3I_0$	Residual current	A	A	Rated operating current of the primary system
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary system
V_0	Zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_{NG}	Neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P_{tot}	Active power (total power)	MW	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q_{tot}	Reactive power (total power)	MVAr	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S_{tot}	Apparent power (total power)	MVA	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100 % corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
Q_A, Q_B, Q_C	Phase-related reactive power	MVAr	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$

Table 5-5 Fundamental and Symmetrical Components Measurement Values of the Function Group Capacitor Bank

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system

Measured Values		Primary	Secondary	% Referenced to
I_N	Neutral-point phase current	A	A	Rated operating current of the primary system
$I_{seq:0}$	Zero-sequence current	A	A	Rated operating current of the primary system
$I_{seq:1}$	Positive-sequence current	A	A	Rated operating current of the primary system
$I_{seq:2}$	Negative-sequence current	A	A	Rated operating voltage of the primary system
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary system
V_N	Neutral-point phase voltage	kV	V	Rated operating voltage of the primary system/√3
$V_{seq:0}$	Zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
$V_{seq:1}$	Positive-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
$V_{seq:2}$	Negative-sequence voltage	kV	V	Rated operating voltage of the primary system/√3

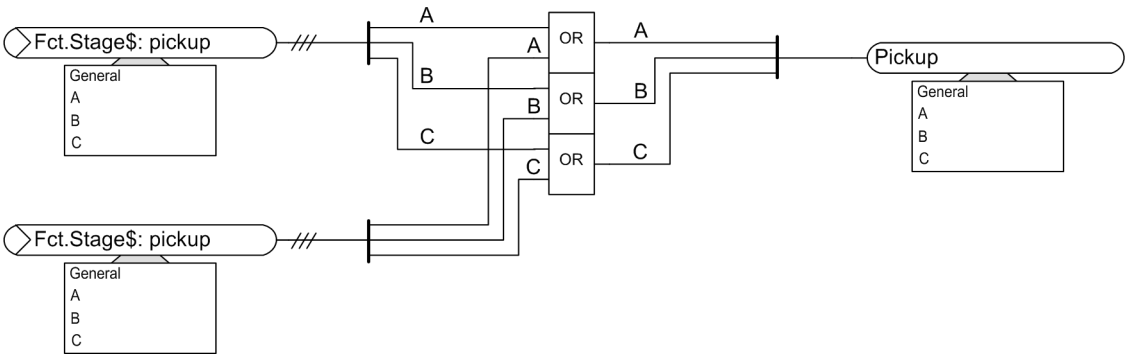
Voltage and power measurements are only available if **V-3ph measuring point** connected to the **Capacitor bank** function group.

The energy measurements are not predefined. If required, they must be loaded from the Global DIGSI 5 Library.

Inversion of Power-Related Measured and Statistical Values (FB General)

The following values calculated in operational measured values are defined positively in the direction of the protected object.

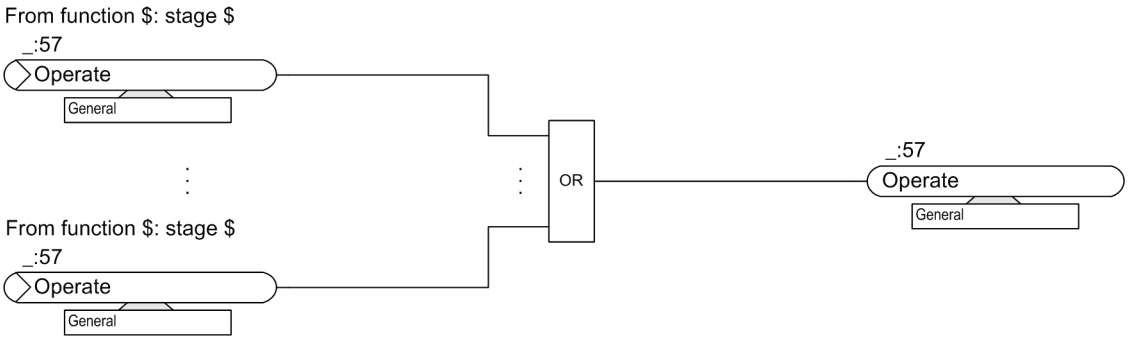
- Power
- Power factor
- Energy
- Minimum, maximum values of the power
- Average values of the power



With the **P, Q sign** setting, you can invert the sign of these operational measured values such that a power flow from the line to the busbar is displayed positively.

More information can be found in Chapter *10.1 Overview of Functions*.

Output Logic



The output logic treats the pickup and operate indications of the protection functions and supervision functions in the **Capacitor bank** function group separately, in a pickup logic and an output logic respectively. The pickup and output logics generate the group indications of the function group. These group indications are transferred to the **Circuit-breaker** function group via the **protection-information** interface and are processed further there.

The pickup and operate indications of the protection functions and the supervision functions in the **Capacitor bank** function group are combined according to the following figures of group indications.

[logepiin-230812-02.tif, 1, en_US]

Figure 5-20 Generation of the Pickup Indication of the Capacitor Bank Function Group

[logeopin-230812-02.tif, 1, en_US]

Figure 5-21 Generation of the Operate Indication of the Capacitor Bank Function Group

5.4.3 Application and Setting Notes

Interface to Circuit-Breaker Function Group

The **Capacitor bank** protection function group is linked to one **Circuit-breaker** function group. This **Circuit-breaker** function group is assigned to the circuit breaker of the capacitor bank.

Protected Object/Equipment Data (FB General)

The following application and setting notes apply for the general data. The data are configured in the function block **General** of the **Capacitor bank** function group and apply for all functions in the function group.

Parameter: `Capacitor reference curr.`

- Default setting **`(_:14641:101) Capacitor reference curr. = 1000 A`**

With the **`Capacitor reference curr.`** parameter, you set the reference current for the capacitor bank to be protected. This **`Capacitor reference curr.`** specified here is the reference value for the percentage-measured values and setting values made in percentages.

Depending on the user philosophy, the reference value could be the capacitor-bank rated current, which includes harmonics, or the capacitor-bank fundamental current.

Parameter: `Capacitor reference volt.`

- Default setting **`(_:14641:102) Capacitor reference volt. = 400.00 kV`**

With the parameter **`Capacitor reference volt.`**, you set the reference voltage of the capacitor bank to be protected. This **`Capacitor reference volt.`** specified here is the reference value for the percentage-measured values and setting values made in percentages.

Depending on the user philosophy, the reference value could be the system rated voltage (bus voltage), or the capacitor rated voltage

Parameter: `Capacitor element type`

- Default setting **`(_:14641:106) Capacitor element type`** = ***`fused`***

With the parameter **`Capacitor element type`**, you set if the capacitor elements contain internal fuses or not. This information is required in the current-unbalance protection for the fault position annunciation.

Parameter: `Blk.cls.cmd.dur.discharge`

- Default setting **`(_:14641:107) Blk.cls.cmd.dur.discharge`** = ***`off`***

With the parameter **`Blk.cls.cmd.dur.discharge`**, you set whether closing of the circuit breaker is blocked automatically or not when a capacitor bank discharges.

NOTE

If the parameter **`Blk.cls.cmd.dur.discharge`** is set to ***`on`***, the device generates a trip/open command during the discharge time.

Parameter: `Discharge time`

- Default setting **`(_:14641:108) Discharge time`** = ***`300 s`***

With the parameter **`Discharge time`**, you define capacitor-bank discharging duration. You get the value from the capacitor manufacturer.

Parameter: `Cap.-bank neutral point`

- Default setting **`(_:14641:109) Cap.-bank neutral point`** =***`isolated`***

With the parameter **`Cap.-bank neutral point`**, you can specify whether the neutral point of capacitor bank is ***`isolated`*** or ***`grounded`***. This information is required when applying the function **87V voltage differential protection**.

Parameter: `P, Q sign`

- Default setting **`(_:14611:158) P, Q sign`** =***`not reversed`***

The power and energy values are defined by the manufacturer such that power in the direction of the protected object is considered positive. You can also define the power output by the protected object as positive. With the **`P, Q sign`** parameter, you can invert the sign for these components. This inversion does not influence any protection function.

5.4.4 Write-Protected Settings

The settings listed here are primarily to aid understanding when configuring the function groups. They are calculated as a function of other settings and cannot be changed directly.

Addr.	Parameter	C	Setting Options	Default Setting
`Rated values`				
_:14641:103	General:Rated apparent power		-1.00 MVA to -1.00 MVA	0.00 MVA

NOTE

You can find more detailed information on the Process monitor in Chapter *5.7.1 Overview* .

5.4.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Rated values				
_:14641:101	General:Capacitor reference curr.		1 A to 100000 A	1000 A
_:14641:102	General:Capacitor reference volt.		0.20 kV to 1200.00 kV	400.00 kV
Cap.bank data				
_:14641:106	General:Capacitor element type		• fused • unfused	fused
_:14641:107	General:Blk.cls.cmd.dur. discharge		• off • on	off
_:14641:108	General:Discharge time		1 s to 1200 s	300 s
_:14641:109	General:Cap.-bank neutral point		• grounded • isolated	isolated
Measurements				
_:14611:158	Further settings:P, Q sign		• not reversed • reversed	not reversed

5.5 Function-Group Type Capacitor Bank Differential Protection

5.5.1 Function-Group Types

In the following graphic, you can see the structural association of the function-group types to the **Capacitor bank differential protection**.

[dwfgueca-120214-01, 2, en_US]

Figure 5-22 Function-Group Types Capacitor Bank Diff

The following function-group types are summarized in the Global DIGSI 5 library: Motor diff

- **Capacitor bank diff**
- **Capacitor bank side**

You can find the description of the function group**Capacitor bank** in chapter *5.4.1 Overview*.

The individual function-group types are stored in the **Capacitor bank diff function group** folder and can be selected. In the protection function folders, you find all protection functions which are operational in each function group. A **Capacitor bank diff** function group always includes the **Capacitor bank** and **Capacitor bank side** function groups. In total, you can assign a maximum of 3 function groups **Capacitor bank** or **Capacitor bank side** to the **Capacitor bank diff** function group.

The following table shows you the number of function-group types that can be instantiated for device 7SJ85.

Table 5-6 Function-Group Types in the Device

Device	Function-Group Type		
	Capacitor Bank Diff	Capacitor Bank	Capacitor Bank Side
7SJ85	Max. 2	Max. 9	Max. 9

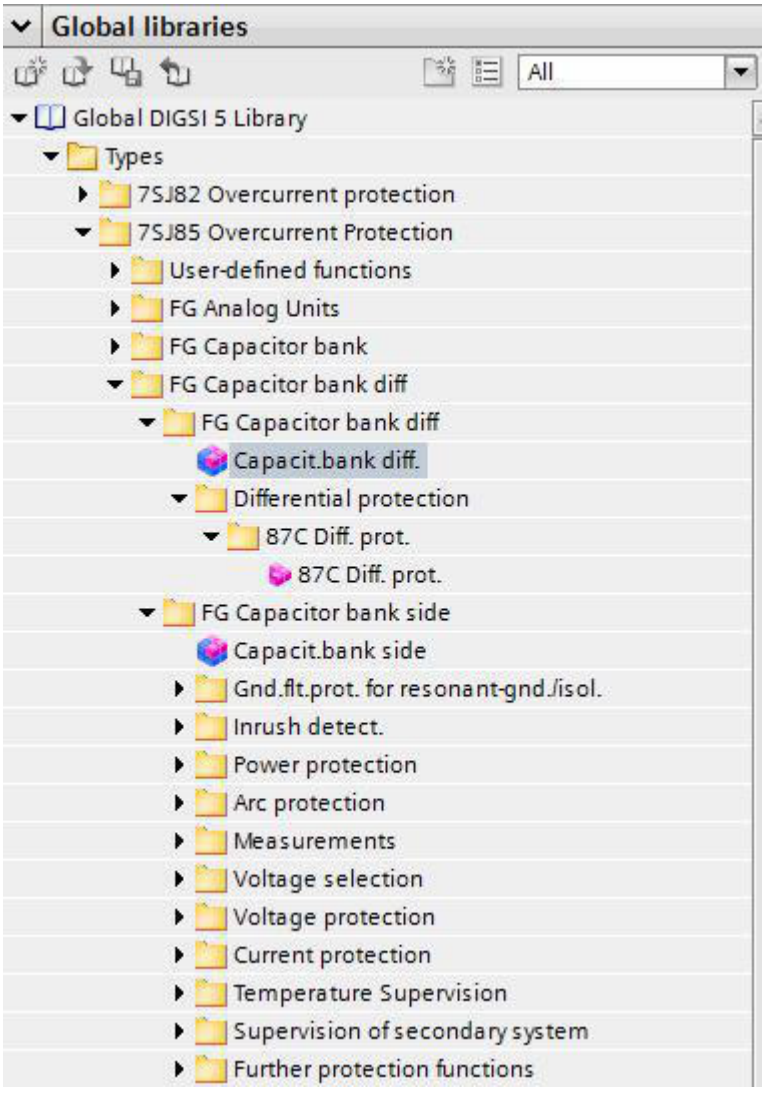
Interconnection of the function groups is necessary so that the capacitor bank differential protection functions properly. The **Circuit-breaker** function group is not listed.

Table 5-7 Assignment of Protection Function Groups to Protection Function Groups

	Capacitor Bank Diff 1
	Side (2 to 3)
Capacitor bank	X
Capacitor bank side 1	X

	Capacitor Bank Diff 1
	Side (2 to 3)
Capacitor bank side 2	X

The individual function-group types are described in the following.



5.5.2 Function-Group Type Capacitor Bank Diff

5.5.2.1 Overview

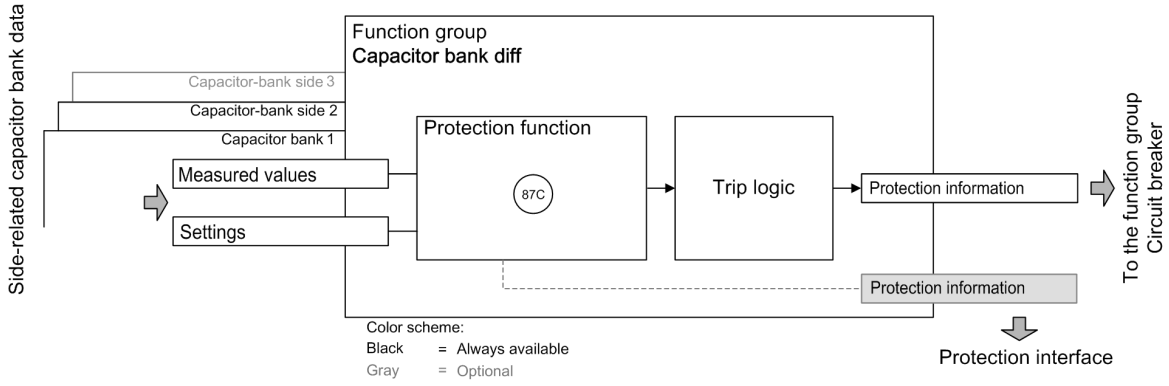
The **Capacitor bank diff.** function group contains the differential protection function and protection-function-relevant measured values.

You can find more information in the chapter *10 Measured Values, Energy Values, and Supervision of the Primary System* .

You will find the corresponding function groups and the folders with the usable protection functions in the Global DIGSI library under each device type. In the **Capacitor bank diff.** function group, you can load only the differential protection functions.

[scfgcadf-300414-01, 2, en_US]

Figure 5-23 Function Group Capacitor Bank Diff. - Functional Scope



For more information about the embedding of the functions in the device, refer to chapter *2 Basic Structure of the Function* . For application templates of the various device types, refer to chapter *4 Applications* .

5.5.2.2 Structure of the Function Group

The **Capacitor bank diff.** function group, according to *5.5.2.1 Overview* , has interfaces with the **Capacitor bank**, the **Capacitor bank side**, and the **Circuit-breaker** function groups. The **Capacitor bank diff.** function group contains the function blocks:

- Protection function (execution of the differential protection function)
- Trip logic (generation of forwarding of the operate indication)

In the **Capacitor bank diff.** function group, the differential protection function must always be available so that the protection functionality can be ensured. If you do not use an application template, load the differential protection function from the Global DIGSI library.

[dwfgcadf-030314-01, 3, en_US]

Figure 5-24 Structure of the Capacitor Bank Diff. Function Group

The **Capacitor bank diff.** function group has interfaces to the following components:

- Function group **Capacitor bank**
- Function group **Capacitor bank side**
- **Circuit-breaker** function group

Interfaces with the Circuit-Breaker Function Group

The interface with the **Circuit-breaker** function group is used to exchange all required data between the protection function group and the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the Protection function groups

You can connect the **Capacitor bank diff.** function group to one or more **Circuit-breaker** function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Capacitor bank diff.** function group
- Start of the **Circuit-breaker failure protection** function, if available in the **Circuit-breaker** function group, through the protection functions of the connected **Capacitor bank diff.** function group

Besides the general assignment of the **Capacitor bank diff.** function group to the **Circuit-breaker** function group, you can also configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 via the **Circuit-breaker interaction** Editor in the **Capacitor bank side diff.** function group.

For the detail configuration of the interface, define the following:

- Which operate indications of the protection functions are included when the trip command is generated
- Which protection functions activate the **Circuit-breaker failure protection** function

If an application template is used, the function groups are connected to each other because this link is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Function Embedding in the Device* .

Resetting the LED Group

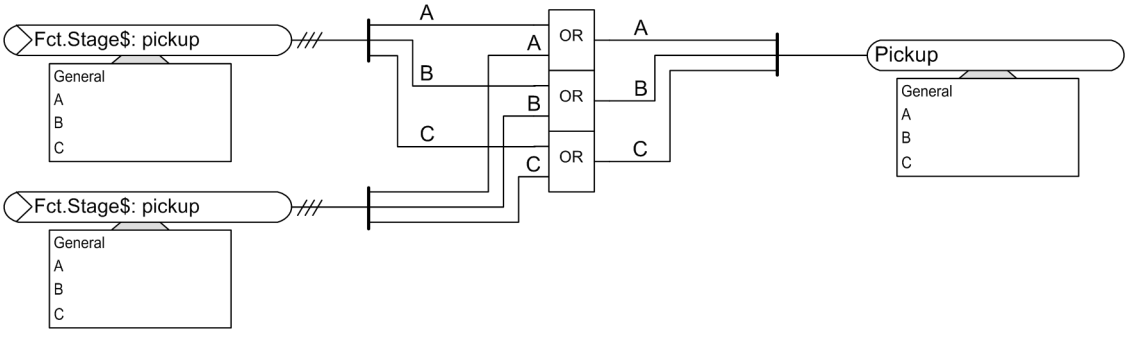
Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

Interface with Protection Communication (optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**. These are for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.5 Protection Communication* .



Capacitor-Bank Data (General)

The capacitor-bank data characterizes the data of the capacitor bank to be protected. The data relevant for the differential protection is shown. The **Capacitor bank diff.** function group takes the data from the coupled function groups **Capacitor bank** and **Capacitor bank side**.

Output Logic

The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overarching indications (group indications) of the function group. These group indications are transferred via the **Protection-information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and operate indications of the protection and supervision functions in the **Capacitor bank diff.** function group are combined into one group indication using the following numbers and outputs.

[loanrlin-150211-01.tif, 3, en_US]

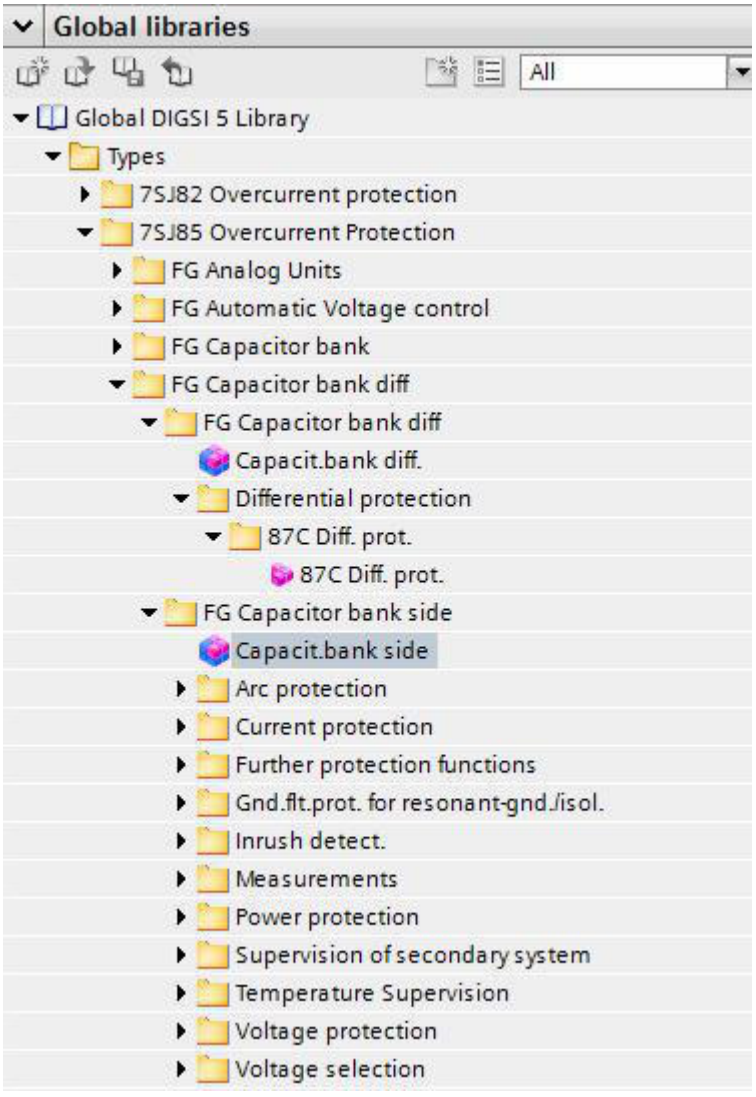
5.5.3 Function-Group Type Capacitor Bank Side



5.5.3.1 Overview

In the **Capacitor bank side** function group, all of the functions that are necessary for protecting and supervising a capacitor bank side can be used. The **Capacitor bank side** function group also contains the measuring functions.

You can find more information in chapter *10 Measured Values, Energy Values, and Supervision of the Primary System*.

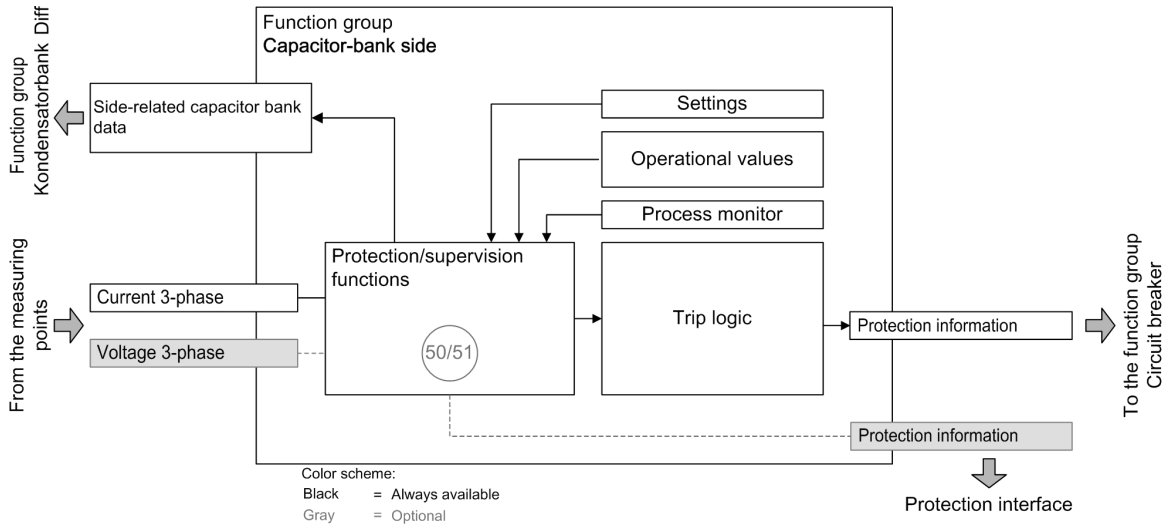
The **Capacitor bank side** function group must always have interfacing to the **Capacitor bank diff.** function group.

You will find the corresponding function groups and the folders with the usable protection functions in the Global DIGSI library under each device type. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Capacitor bank side** function group. The functions are described in chapter *6 Protection and Automation Functions* .

[scfgcasd-300414-01, 2, en_US]

Figure 5-27 Capacitor Bank Side Function Group - Functional Scope

For more information about the embedding of the functions in the device, refer to chapter *2 Basic Structure of the Function* . For application templates for the various device types, refer to chapter *4 Applications* .



5.5.3.2 Structure of the Function Group

The **Capacitor bank side** function group always contains the following function blocks:

- Side-dependent capacitor-bank data
- Operational measured values
- Process monitor
- Output logic of the function group

These blocks are required for the **Capacitor bank side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Capacitor bank side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dw_fgcabsi-201114-01, 2, en_US]

Figure 5-28 Structure of the Capacitor Bank Side Function Group

The **Capacitor bank side** function group has interfaces to the following components:

- **Measuring points**
- **Capacitor bank diff.** function group
- **Circuit-breaker** function group

Interfaces with Measuring Points

The **Capacitor bank side** function group receives the required measured values via its interfaces with the measuring points. If you are using an application template, the **Capacitor bank side** function group is connected to the necessary measuring points.

If you add functions to the **Capacitor bank side** function group, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function* .

The **Capacitor bank side** function group has the following interfaces with the measuring points:

- **3-phase current**

  The measurands from the 3-phase power system are supplied via this interface. Depending on the transformer connection type, these are for example: I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Capacitor bank side** function group must always be linked to the **I-3ph measuring point**.

  You can connect the **3-phase current** interface with a maximum of **two** 3-phase current measuring points. If 2 current measuring points have been connected to the **3-phase current** interface, the total current is also determined from measured values from both measuring points in the **Capacitor bank side** function group. All functions in the **Capacitor bank side** function group have access to these values.

- **3-phase voltage** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Different transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface.

  The connection of the **3-phase voltage** is optional. This connection is necessary only if protection or supervision functions that require voltage measurements are used.

Interfaces to the Circuit-Breaker Function Group

The interface with the **Circuit-breaker** function group is used to exchange all required data between the protection function group and the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the Protection function groups

You can connect the **Capacitor bank side** function group to one or more **Circuit-breaker** function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Capacitor bank side** function group
- Start of the **Circuit-breaker failure protection** function, if available in the **Circuit-breaker** function group, through the protection functions of the connected **Capacitor bank side** function group

Besides the general assignment of the **Capacitor bank side** function group to the **Circuit-breaker** function group, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the **Capacitor bank side** function group.

For the detail configuration of the interface, define the following:

- Which operate indications of the protection functions are included when the trip command is generated
- Which protection functions activate the **Circuit-breaker failure protection** function

If an application template is used, the function groups are connected to each other because this link is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Function Embedding in the Device* .

Interface with Protection Communication (optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.5 Protection Communication* .

Resetting the LED Group

Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

Process Monitor

The process monitor is always present in the **Capacitor bank side** function group and cannot be removed. The process monitor provides the following information in the **Capacitor bank side** function group:

- Current-flow criterion:
  Detection of an open/activated capacitor bank side based on the flow of leakage current
- Closure detection:
  Detection of closure of the capacitor bank side
- Cold-load pickup detection (optional):

This information is in the **Capacitor bank side** function group and is available to all the functions in the function group.

Operational Measured Values

The operational measured values are always present in the **Capacitor bank side** function group and cannot be deleted. If a 3-phase voltage measuring point is connected, the following table shows the total scope. If only current is connected, only the first 3 lines apply.

Table 5-8 Possible Operational Measured Values of the Capacitor Bank Side Function Group

Measured Values		Primary	Secon-dary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated residual current	A	A	Rated operating current of the primary system
I_N	Measured residual current	A	A	Rated operating current of the primary system
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating current of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_0	Calculated zero-sequence voltage	kV	V	Rated operating current of the primary system/√3
V_r	Measured neutral-point displace-ment voltage	kV	V	Rated operating current of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	MVAr	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Rated operating voltage and rated operating current of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100 % corresponds to c os φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
Q_A, Q_B, Q_C	Phase-related reactive power	MVAr	–	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

If a **V-3ph measuring point** was connected to the **Capacitor bank side** function group, voltage and phase measurements are available.

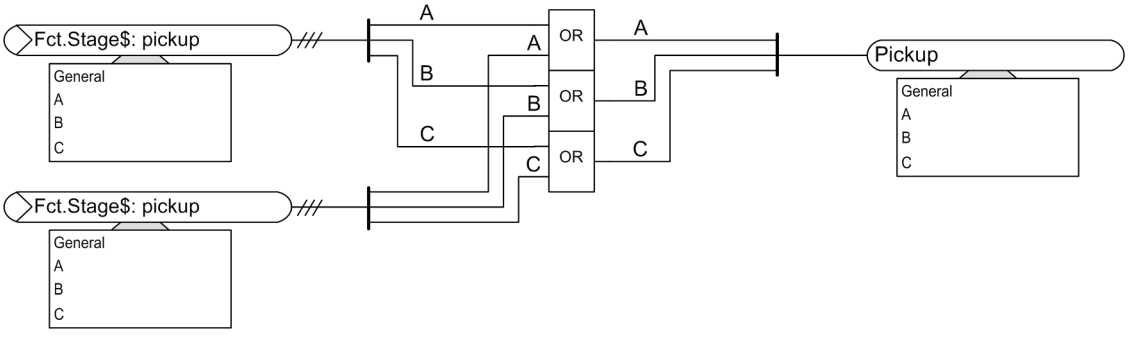
The energy measurements are not predefined. If necessary, you must load them from the Global DIGSI 5 library.

Depending on the protection and supervision functions used, additional function measurements may be available. The function values are listed in the **information list** of the appropriate protection or supervision function (see chapter *6 Protection and Automation Functions*).

NOTE

With the **`P, Q sign`** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see chapter *10.2 Structure of the Function* Structure of the Function, section Inversion of Power-Related Measured and Statistical Values):

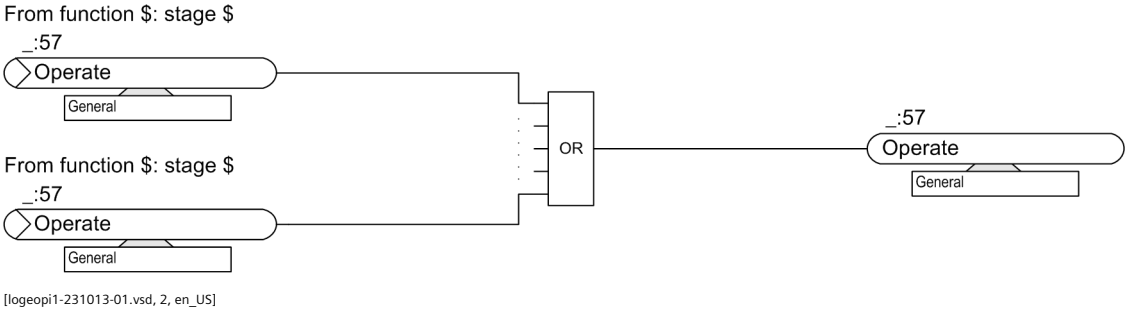
- Active power (total): P total
- Active power (phase-related): P_A, P_B, P_C
- Reactive power (total): Q total
- Reactive power (phase-related): Q_A, Q_B, Q_C



Capacitor-Bank Data (Side-Dependent)

The capacitor-bank data characterizes the data of the capacitor bank to be protected. The side-dependent capacitor-bank data applies to all of the functions in the **Capacitor bank side** function group.

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overarching indications (group indications) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and operate indications of the protection and supervision functions in the **Capacitor bank side** function group are combined into one group indication using the following numbers and outputs.

[loanrlin-150211-01.tif, 3, en_US]

Figure 5-29 Generation of Pickup Indication of the Capacitor Bank Side Function Group

[logeopi1-231013-01.vsd, 2, en_US]

Figure 5-30 Generation of Operate Indication of the Capacitor Bank Side Function Group

5.5.3.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

The **Capacitor bank side** function group is usually connected to 1 **Circuit-breaker** function group. The **Circuit-breaker** function group is assigned to the circuit breaker of the capacitor bank.

Parameter: `Rated apparent power`

- Default setting **`(_:1781:15571:103) Rated apparent power`** = ***`692.82 MVA`***.

  The **`Rated apparent power`** parameter shows the primary rated apparent power of the capacitor bank to be protected. The setting value is determined of the **`Capacitor reference volt.`** and the **`Capacitor reference curr.`** parameters.

Parameter: `Capacitor reference volt.`

- Default setting **`(_:1781:15571:102) Capacitor reference volt.`** = ***`400.00 kV`***

You can use the **`Capacitor reference volt.`** parameter to set the reference voltage of the capacitor bank to be protected. The reference voltage set here is the reference value for the percentage measured values and setting values made in percent.

Depending on user philosophy you can use the system rated voltage (busbar voltage) or the capacitor rated voltage as a reference value.

Parameter: `Capacitor reference curr.`

- Default setting **`(_:1781:15571:101) Capacitor reference curr.`** = ***`1000 A`***

You can use the **`Capacitor reference curr.`** parameter to set the reference current for the capacitor bank to be protected. The capacitor reference current set here is the reference value for the percentage measured values and setting values in percent.

For Differential protection, these values are used for absolute-value correction (rated current of the protected object).

If the capacitor bank is part of a delta connection, the value to be set here can differ from the capacitor reference current set in the **Capacitor bank** function group (by factor √3). Otherwise, set always the same values.

Depending on user philosophy, you can use the capacitor-bank rated current including the harmonics or the capacitor-bank fundamental-component current as a reference value.

Parameter: `Neutral point`

- Default setting **`(_:1781:15571:149) Neutral point`** = ***`isolated`***

With the **`Neutral point`** parameter, you specify whether the neutral point in the protection range of the differential protection is ***`grounded`*** or ***`isolated`***. If there is no neutral point in the protection zone, use the parameter ***`isolated`***. The neutral point of a capacitor bank is usually not in the protection zone. Therefore, even if the neutral point is grounded, set ***`isolated`*** here.

You can find further information in the Device manual 7UT8 Chapter 6.2.3 function description neutral point-current handling.

Parameter: `Winding configuration`

- Default setting **`(_:1781:15571:104) Winding configuration`** = ***`Y (Wye)`***

You can use the **`Winding configuration`** parameter to set ***`D (Delta)`*** for a delta connection. Another setting option is ***`Y (Wye)`*** for a star connection. The **`Winding configuration`** parameter is relevant for the Differential protection function.

Parameter: `Vector group numeral`

- Default setting **`(_:1781:15571:100) Vector group numeral`** = ***`0`***

This parameter is used to account for phase-angle rotation, which is expressed by a numeral.

Phase-angle rotation	0°	30°	60°	90°	120°	150°	180°	210°	240°	270°	300°	330°
Vector group numeral	0	1	2	3	4	5	6	7	8	9	10	11

In the function group, the following information is displayed additionally in the setting sheet:

- Side number
- Identification of the measuring points used
- Adaptation factor for the 3-phase measuring point (with reference to the side)

Each **Vector group numeral** can be set from 0 to 11 to the extent possible. Thus, for example, only even numbers are possible for the vector group Yy and Dd and only odd numbers are possible for Yd and Dy.

Parameter: Side number

- Default setting **(_:1781:14611:130) Side number** = ***not assigned***

The **Side number** parameter shows you which capacitor bank side is currently valid for the following parameters. The side number (***Side 1*** to ***Side 3***) is automatically assigned with the connection to a capacitor bank side.

Parameter: MI3ph1 usesMeasP with ID

- Default setting **(_:1781:14611:210) MI3ph1 usesMeasP with ID** = ***0***

The **MI3ph1 usesMeasP with ID** parameter shows you which 3-phase measuring point is connected to the capacitor bank side. Every measuring point is assigned a unique ID.

Parameter: MI3ph2 usesMeasP with ID

- Default setting **(_:1781:14611:211) MI3ph2 usesMeasP with ID** = ***0***

The **MI3ph2 usesMeasP with ID** parameter shows you which 3-phase measuring point is connected to the capacitor bank side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:1781:14611:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude adaptation of the phase currents of the 1st assigned measuring point. The numerical value results from the ratio of the primary rated current of the current transformer to the rated current of the side.

Parameter: CT mismatch M I-3ph 2

- Default setting **(_:1781:14611:217) CT mismatch M I-3ph 2** = ***0.000***

The **CT mismatch M I-3ph 2** parameter shows you the magnitude adaptation of the phase currents of the 2nd assigned measuring point.

5.5.3.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Range of Values	Default Setting
Rated values				
_:1781:15571:103	Rated apparent power		0.20 MVA to 5000.00 MVA	692.82 MVA

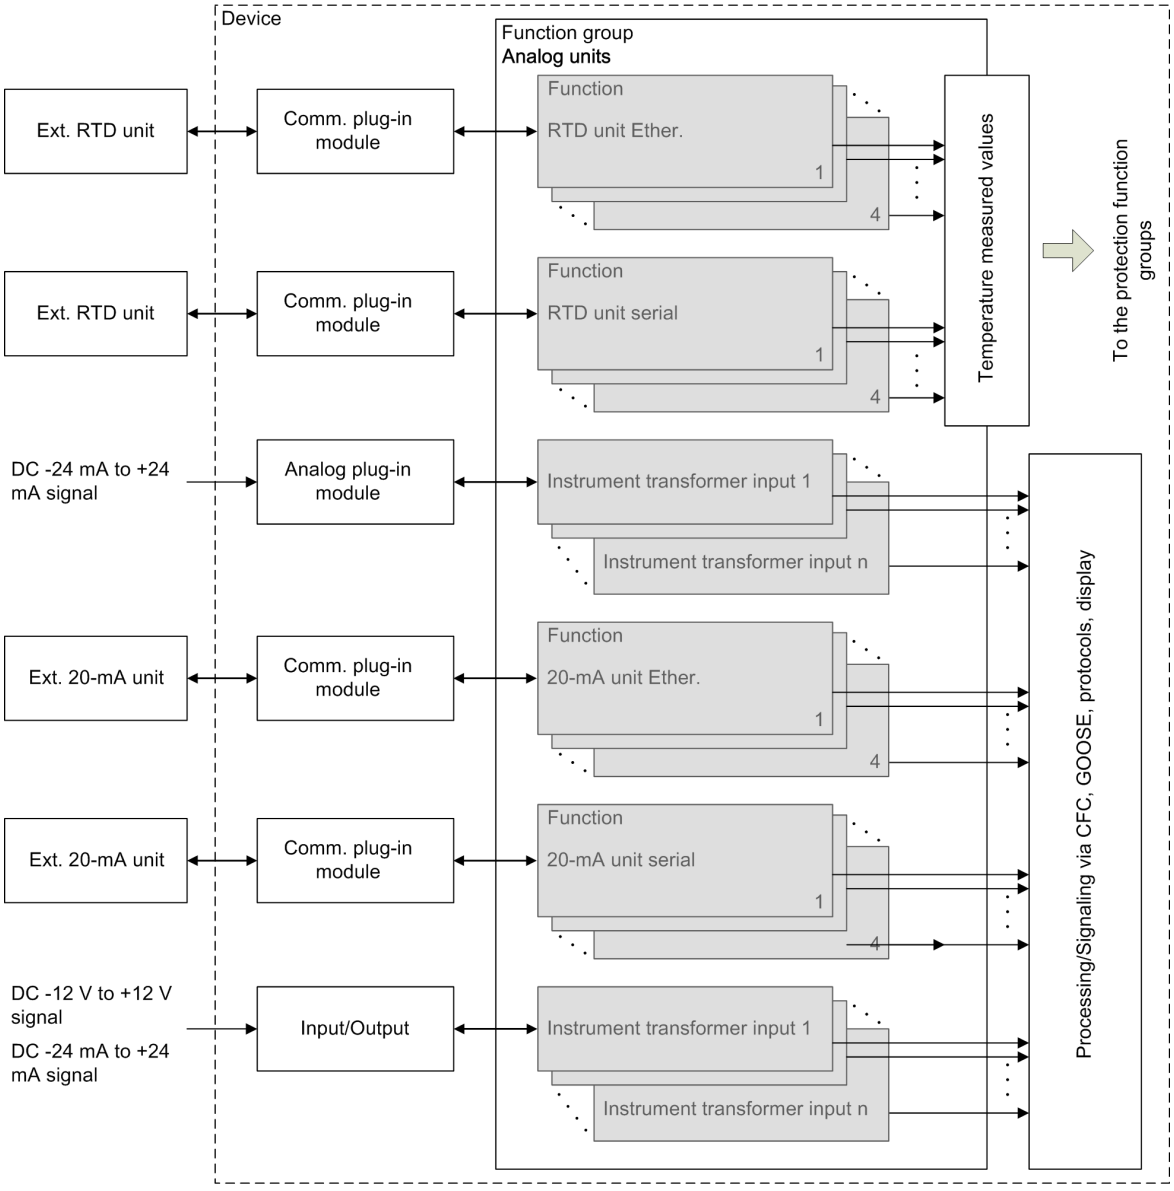
5.6 Function-Group Type Analog Units

5.6.1 Overview

The **Analog units** function group is used to map analog units and communicate with them. Analog units are external devices, such as RTD units, or analog plug-in modules, such as measuring-transducer modules.
You will find the **Analog units** function group for many device types in the Global DIGSI 5 library.



[sc20maee-190214-01, 1, en_US]

Figure 5-31 Analog Unit Function Group in DIGSI

5.6.2 Structure of the Function Group

If the device has a measuring transducer, it is automatically mapped in the **Analog units** function group. If one or more RTD units are connected to the device, you have to load one or more **RTD unit Ether.** or **RTD unit serial** functions from the Global DIGSI library in order to map the RTD units.

The following figure shows the structure of the function group.

[dwstrthe-030615-01.vsd, 1, en_US]

Figure 5-32 Structure of the Analog Unit Function Group

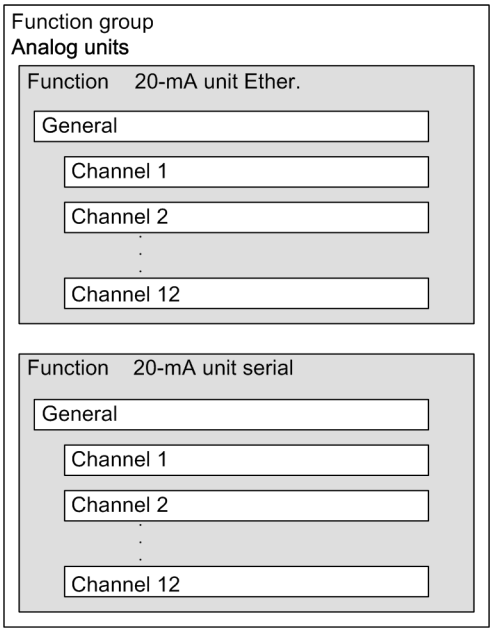
The **Analog units** function group has interfaces to protection function groups. The **Analog units** function group provides measured temperature values that come from an external RTD unit. These measured temperature values are available for all protection function groups in which a temperature monitoring function works.

The **RTD unit Ether.** function is not preconfigured by the manufacturer. A maximum of 20 function instances can work simultaneously.

The **RTD unit serial** function is set up structurally exactly in the same manner as the **RTD unit Ether.** function.

5.6.3 20-mA Unit Ethernet

5.6.3.1 Overview



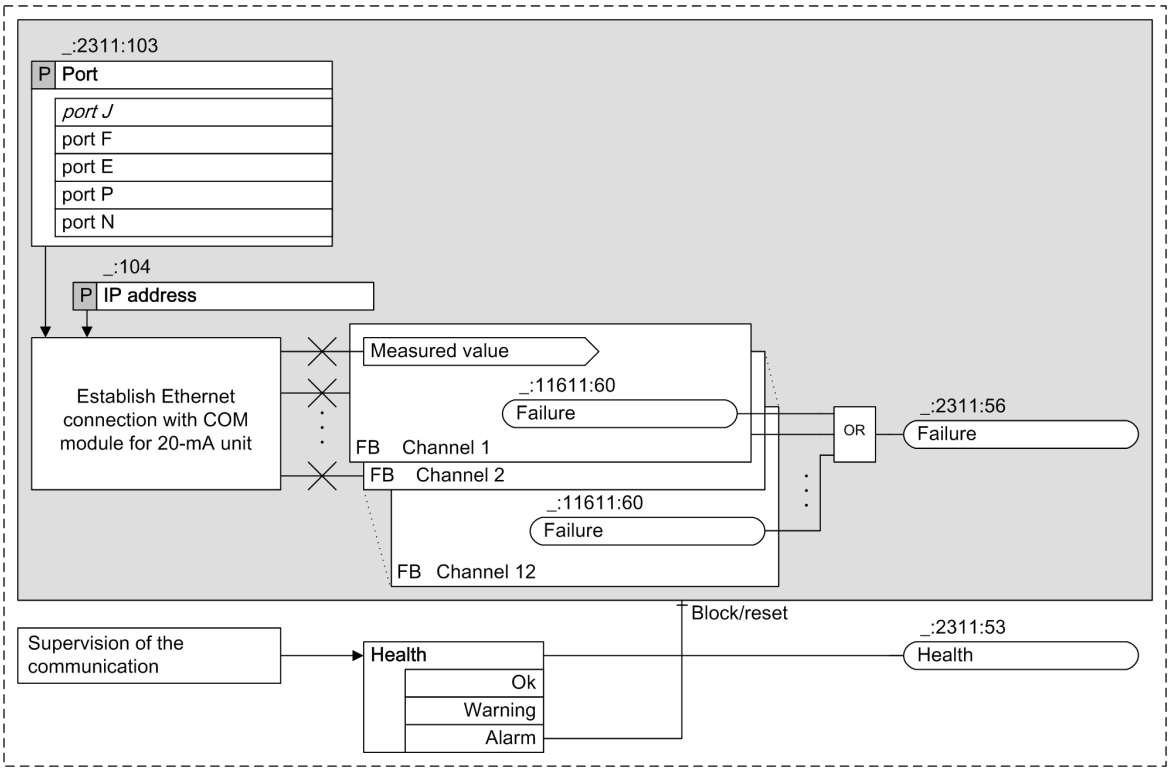
The function **20-mA unit Ether.**:

- Communicates in series with a 20-mA unit via the Slave Unit Protocol (SUP) and records the values measured by the 20-mA unit
- Transforms the measured 20-mA values into slowly changing process tags such as temperature or gas pressure
- Makes the recorded process tags available to CFC, GOOSE, protocols and the device display
- Monitors communication with the 20-mA unit

5.6.3.2 Structure of the Function

The function **20-mA unit Ether.** can work only in the function group **Analog units**. A maximum of 4 function instances can work simultaneously. Each instance contains 12 preconfigured channel function blocks.

The function **20-mA unit Ether.** contains input and output channels which can be configured independently of one another.



[dwstrfn2-150113-01.tif, 2, en_US]

Figure 5-33 Structure/Embedding of the Function

5.6.3.3 Communication with 20-mA Unit Ethernet

Logic

[lo20mtcp-150113-01.tif, 1, en_US]

Figure 5-34 Logic of the Function 20-mA Unit Ethernet

Communication with 20-mA Unit

The function is used to communicate with a 20-mA unit connected via an Ethernet connection. When a connection of the function to an external 20-mA unit via an Ethernet interface has successfully been established, the 20-mA unit sends the measured values of all connected channels to the function **20-mA unit. Ether.**. For the connection to be established successfully, specific communication settings must be specified.

You can find more detailed information in Chapter *5.6.3.4 Application and Setting Notes* .

The 20-mA measurement unit **7XV5674** is supported.

Error Responses

The following table lists the conditions under which the *Health* status transitions to the Alarm or Warning state.

Table 5-9 Error Responses

Error Description	Status Health
The function **20-mA unit Ether.** cannot establish a connection with a communication module.	Alarm
The function **20-mA unit Ether.** sends TCP settings to the communication module, which evidently would like to connect to the 20-mA unit via a serial protocol. This communication module does not establish a connection to the 20-mA unit.	Alarm
The connection between the communication module and the 20-mA unit causes a time-out indication.	Warning

Error Description	Status Health
A communication module has not received any more data from the 20-mA unit for 9 sec.	Warning

The *Failure* signal is set as soon as one of the channel function blocks reports a failure.

5.6.3.4 Application and Setting Notes

Parameter: Port

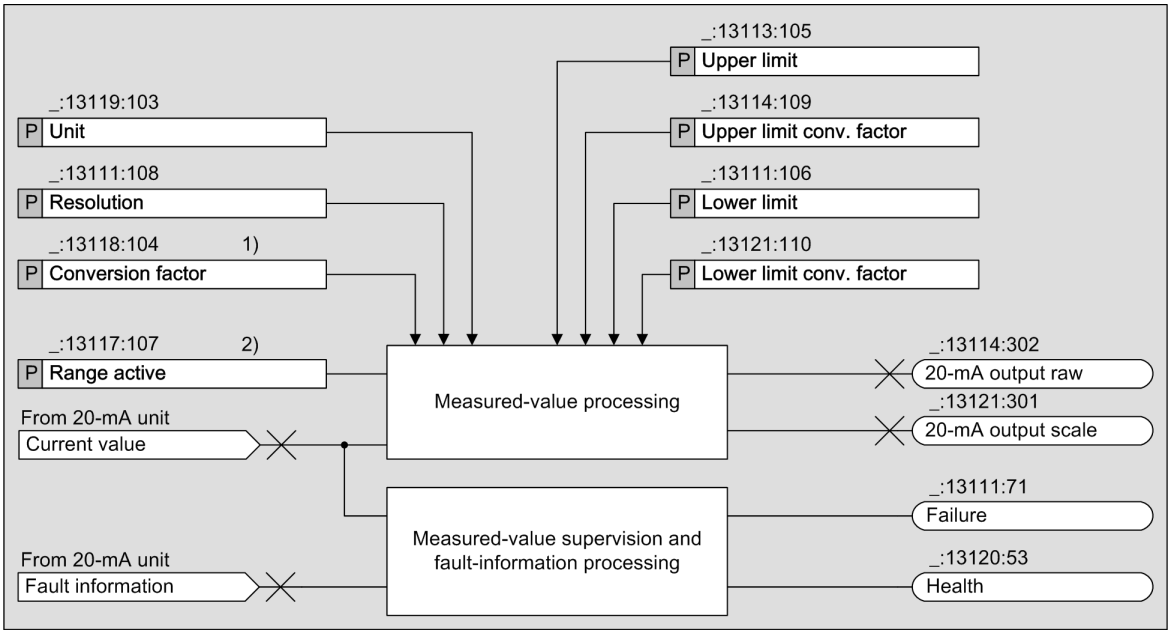
- Default setting **(_:2311:103) Port** = ***port J***

Use the **Port** setting to define the port connecting the 20-mA unit to the SIPROTEC 5 device.

Parameter: IP address

- Default setting **(_:2311:104) IP address** = ***10.16.60.1***

With the **IP address** settings, you set the IP address of the 20-mA unit connected to the communication module via the TCP protocol. You must assign each 20-mA unit an unambiguous IP address. The IP address to be set depends on your network configuration. You can set any valid IPv4 address that does not cause conflicts with other IP addresses in the network. First set an IP address for the **7XV5674 20-mA unit**. Then specify the **IP address** settings for the communication module to the same address.



Settings on the 20-mA Unit

The **7XV5674 20-mA unit**is set with a web browser on the laptop computer via the latter's Ethernet interface. Set ***Modbus TCP*** as bus protocol/operating mode.

You can find detailed notes on the settings in the 7XV5674 manual that accompanies the 20-mA unit. The documents are also available in the SIPROTEC download area *http://www.energy.siemens.com*.

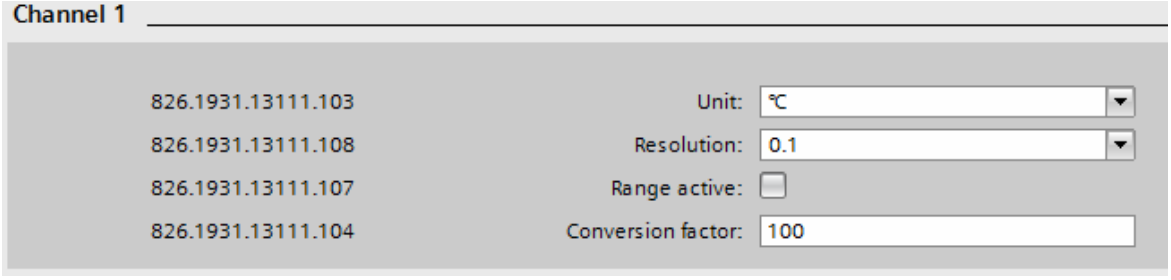
5.6.3.5 20-mA Channel

Logic

[lo20mcha-160113-01.tif, 1, en_US]

Figure 5-35 Logic Diagram of the Function 20-mA Channel

(1) If the setting **Range active** is set to ***test***, the setting **Transformation ratio** is not displayed.

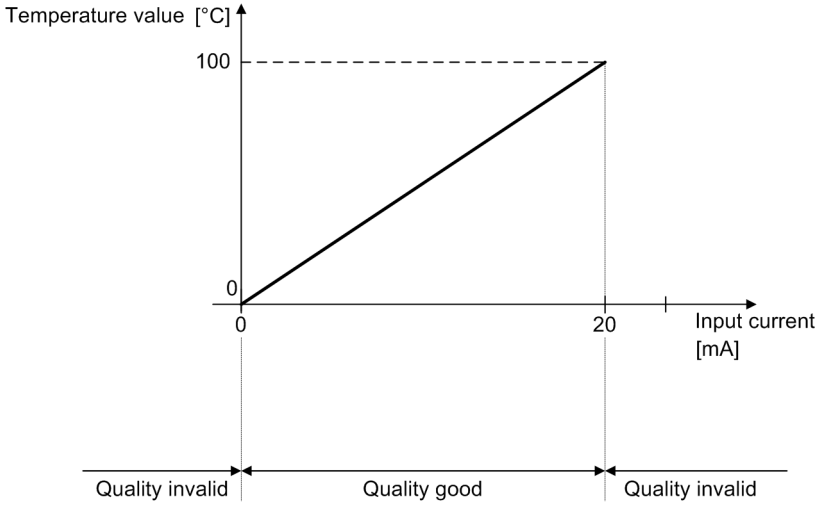


(2) If the setting **Range active** is set to ***false***, the settings **Upper limit**, **Transformation ratio upper limit**, **Lower limit** and **Transformation ratio** are not displayed.

Measured-Value Calculation

The function **20-mA channel** processes a single 20-mA current signal supplied by the 20-mA unit of the corresponding channel. The 20-mA current measured value is converted into the correct physical quantities such as temperature or pressure. In each 20-mA functional unit (Ether. and serial) there are always 12 of the 20-mA channel function blocks, even if fewer channels are connected with the 20-mA unit. The calculated values are available for further processing via CFC, GOOSE, protocols, and the display image.

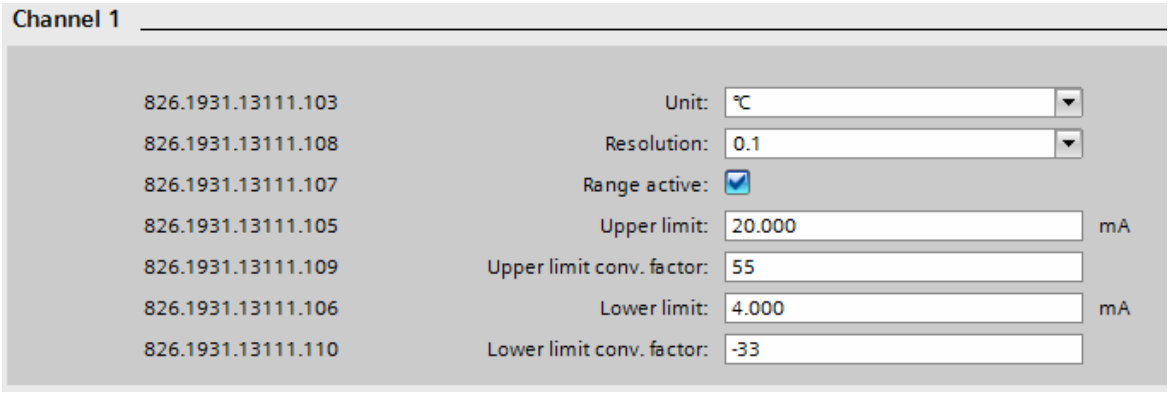
Measured-Value Processing



The 20-mA unit typically transmits a value which represents a physical quantity, such as a temperature or a pressure. Therefore, the device must contain a characteristic curve that maps the physical quantity to the 20-mA value. If you do not activate the **Range active** setting (no x in the check box), the function operates over the range 0 mA to 20 mA. If a value smaller than 0 mA or greater than 20 mA is active at the input of the 20-mA unit, the measured value is identified as invalid. The setting of the range for the scaled value goes from a usable range of 0 mA to 20 mA. The following figure shows an example.

[sckanumw-190214-01, 1, en_US]

Figure 5-36 Settings for Example 1



In this example, the measured value 0 mA means a temperature of 0 °C and the measured value 20 mA means a temperature of 100 °C. So enter as **Unit** = ***°C*** and **Conversion factor** = ***100***. The resolution (decimal place) of the temperature value can be chosen; for a decimal place, select **Resolution** = ***0.1***.

[dwknges3-020513-01.tif, 1, en_US]

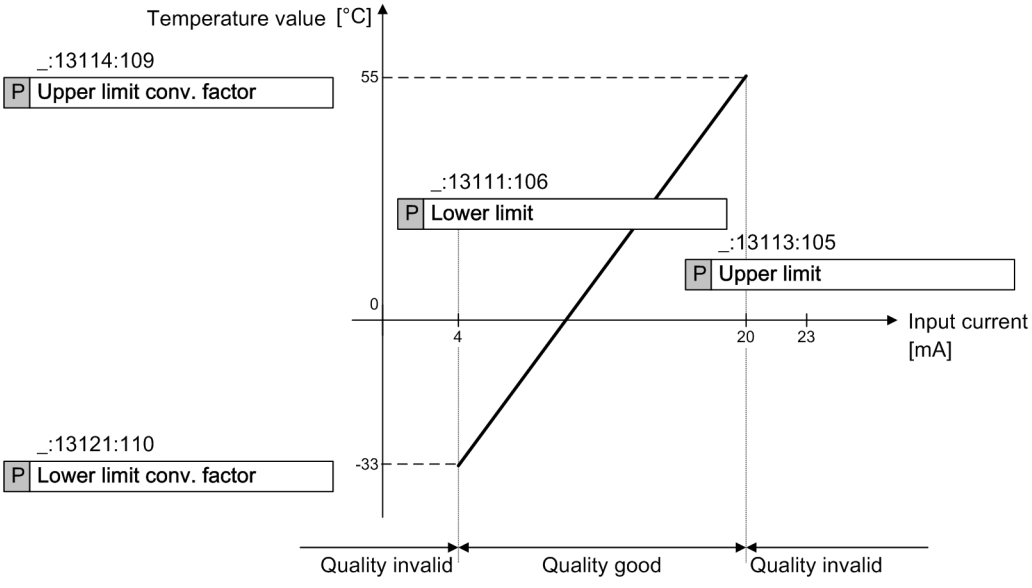


Figure 5-37 Characteristic Curve of a 20-mA Input (Example 1)

If you activate the **Range active** setting, then 4 additional parameters **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The parameters **Upper limit** and **Lower limit** indicate the range of the input current in mA. The setting **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The setting **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting. The setting of the range for the scaled value corresponds to the useable range between **Lower limit** and **Upper limit** (see following figure).

[sckanumf-190214-01, 1, en_US]

Figure 5-38 Settings for Example 2

[dwknges2-020513-01.tif, 1, en_US]

Figure 5-39 Characteristic Curve of a 20-mA Unit (Example 2)

In this example, the **Range active** setting is selected. The setting **Upper limit** is at 20 mA, the setting **Lower limit** is at 4 mA. The setting **Upper limit - Sensor** is at 55 and the setting **Lower limit - Sensor** is at -33. If the input current is smaller than 4 mA or greater than 20 mA, the quality of the scaled measured value in this example is invalid.

Each 20-mA channel makes available the scaled measured value in the information routing (these are the temperature values in the examples) and the original current measured value in mA for further processing.

The 20-mA values can be displayed in the display page and processed with CFC charts.

Error Responses

If the current input value is determined to be incorrect, the quality attribute of the output value is set to *invalid* That status for *Health* and the defect status assume the states displayed in the table.

Table 5-10 Error Responses

Error Description	Status *Health*	Error Status
The input value lies outside the given limits	OK	Yes
Channel not connected	OK	No

5.6.3.6 Application and Setting Notes

Parameter: Unit

- Default setting **(_:13111:103) Unit** = ***°C***

You use the setting **Unit** to specify which physical unit of measurement the measured values represent. The possible setting values are listed in the settings table.

Parameter: Conversion factor

- Default setting **(_:13111:104) Conversion factor** = ***100***

The **Conversion factor** setting allows you to set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:13111:108) Resolution** = ***0.1***

The **Resolution** setting is used to specify the measured value resolution.

Parameter: Range active

- Default setting **(_:13111:107) Range active** = ***false***

If you do not activate the **Range active** setting (no x in the check box), the function operates over the range -24 mA to +24 mA. The setting of the range for the scaled value goes from a usable range of -20 mA to +20 mA.

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Upper limit - Sensor**, **Lower limit**, and **Lower limit - Sensor** appear.

Parameter: Upper limit, Lower limit, Upper limit - Sensor and Lower limit - Sensor

- Default setting **(_:13111:105) Upper limit** = ***20000 mA***
- Default setting **(_:13111:109) Upper limit - Sensor** = ***100***
- Default setting **(_:13111:106) Lower limit** = ***4000 mA***
- Default setting **(_:13111:110) Lower limit - Sensor** = ***100***

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The setting **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The setting **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

The following settings and information table shows only 1 of the 12 channels, as the setting possibilities of the 12 channels do not differ.

5.6.3.7 Settings

Addr.	Parameter	C	Setting Options	Default Setting

5.6.4 20-mA Unit Serial

5.6.4.1 Overview

The function **20-mA unit Serial**:

- Provides serial communications with a 20-mA unit via the Modbus protocol and records the values measured by the 20-mA unit
- Transforms the measured 20-mA values into slowly changing process variables such as temperature or gas pressure
- Makes the recorded process tags available to CFC, GOOSE, protocols and the device display
- Monitors communication with the 20-mA unit

The function **20-mA unit Serial** is structured in the same way as the function **20-mA Unit Ether.**. The mode of operation is also identical. The only difference is that the measured values are transferred to the communication module via a serial connection instead of an Ethernet connection.

You can find more information in Chapter *5.6.3.2 Structure of the Function*.

5.6.4.2 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***Port J***

With the **Port** setting, you specify the slot for the communication module that will be used for the connection with an external 20-mA unit.

Parameter: Channel number

- Default setting **(_:2311:105) Channel number** = ***1***

A serial communication module optionally uses 2 channels. With the **Channel number** setting, you specify the channel number (1 or 2) used to connect the 20-mA unit to the device. The communication module inputs are labeled with the channel numbers.

Parameter: Slave address

- Default setting **(_:2311:106) Slave address** = *1*

Use the**Slave address** setting to define the device address of the 20-mA unit. If only one 20-mA unit is connected to the serial bus, the default value *1* can be used. Set the same device address as used with the 20-mA unit. The device address is important for distinguishing several 20-mA units that are connected to a serial bus. Set an unambiguous device address on every 20-mA unit, for example, 1, 2 and 3 when connecting 3 of the 20-mA units. On every 20-mA unit, set for the **Slave address** setting in the 3 functions **20-mA Unit Serial** the same device address for each.

Parameter: Unit

- Default setting **(_:13111:103) Unit** = *°C*

You use the setting **Unit** to specify which physical unit of measurement the measured values represent. The possible setting values are listed in the settings table.

Parameter: Conversion factor

- Default setting **(_:13111:104) Conversion factor** = *100*

The **Conversion factor** setting allows you to set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:13111:108) Resolution** = *0.1*

The **Resolution** setting is used to specify the measured value resolution.

Parameter: Range active

- Default setting **(_:13111:107) Range active** = *false*

If you do not activate the **Range active** setting (no x in the check box), the function operates over the range 0 mA to 20 mA. The setting of the range for the scaled value goes from a usable range of 0 mA to 20 mA.

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Upper limit - Sensor**, **Lower limit** and **Lower limit - Sensor** appear.

Parameter: Upper limit, Lower limit, Upper limit - Sensor and Lower limit - Sensor

- Default setting **(_:13111:105) Upper limit** = *20 mA*
- Default setting **(_:13111:109) Upper limit - Sensor** = *100*
- Default setting **(_:13111:106) Lower limit** = *4 mA*
- Default setting **(_:13111:110) Lower limit - Sensor** = *100*

If you activate the **Range active** setting, then 4 additional settings **Upper limit**, **Lower limit**, **Upper limit - Sensor** and **Lower limit - Sensor** appear. The setting **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The setting **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

The following settings and information table shows only 1 of the 12 channels, as the setting possibilities of the 12 channels do not differ.

5.6.4.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:2311:103	General:Port		• port E • port F • port J • port N • port P	port J

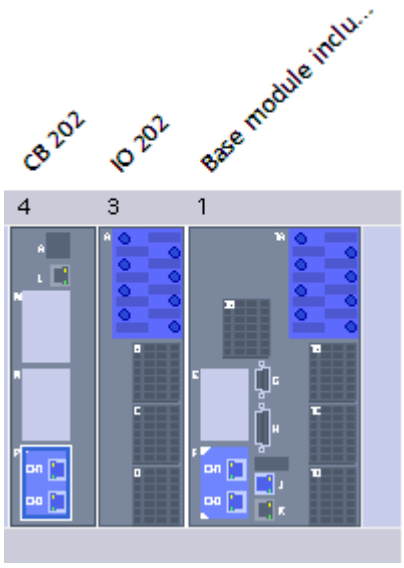
5.6.5 Communication with 20-mA Unit

5.6.5.1 Integration of a Serial 20-mA Unit

Connection of the Communication Lines

Figure 5-40 shows how to connect the 20-mA unit to the SIPROTEC 5 device. Note that Pin 1 of the RJ45 plug is connected to RTD-B and Pin 2 is connected to RTD-A.

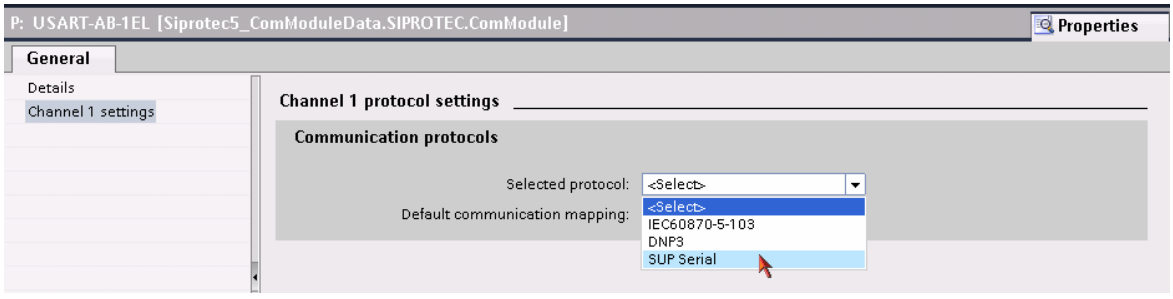


[dwve20au-150213-01.tif, 1, en_US]

Figure 5-40 Connection of the 20-mA Unit to the SIPROTEC 5 Device

Adding a USART Module

Add a USART-AB-1EL or a USART-AC-2EL USART module in DIGSI to the device. The USART module must be inserted at one of the plug-in positions for communication modules in the base module or in the CB202 expansion module (refer to the following figure).



[sc20ser3-220114-01-DE, 1, en_US]

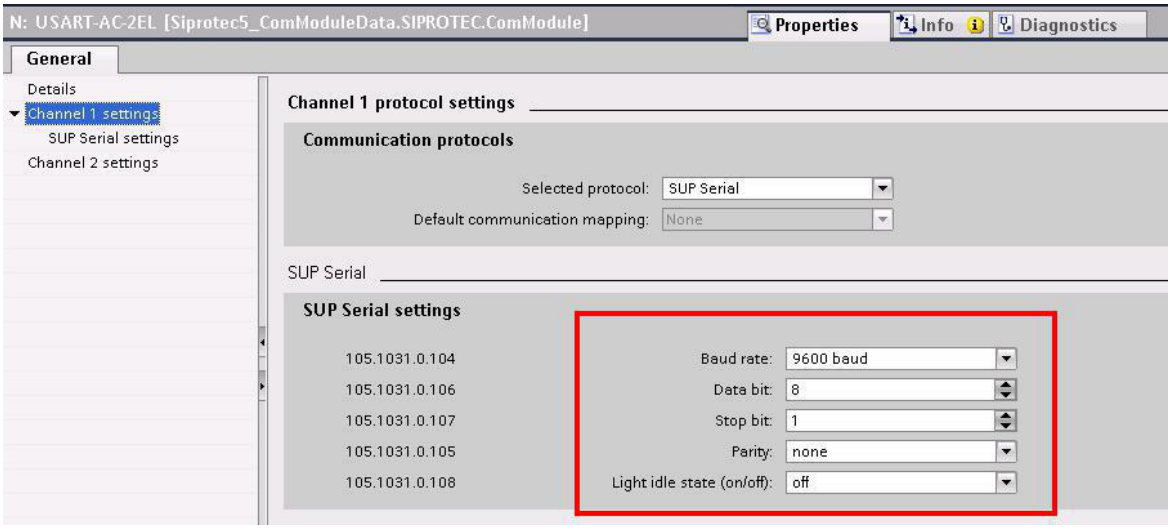
Figure 5-41 Insertion Position for a USART Module

Selecting the SUP Protocol

Select the Slave Unit Protocol (SUP). This protocol is responsible for the communication between the SIPROTEC 5 device and the 20-mA unit.

[scauser4-220114-01-DE, 1, en_US]

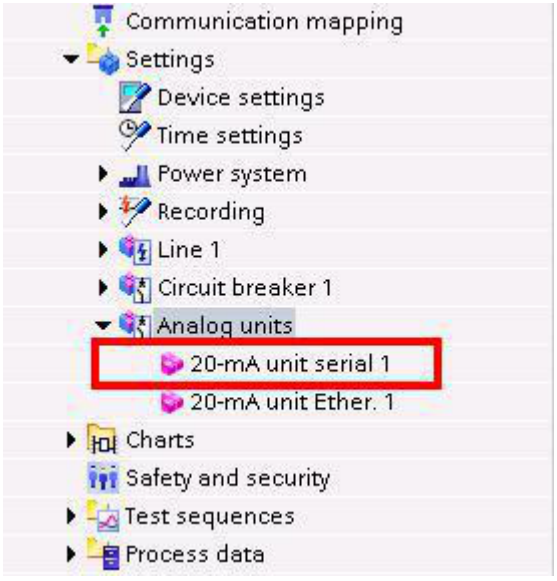
Figure 5-42 Selecting the SUP Protocol



Communication Settings

Make the communications settings for the relevant serial channels. For this, use the default settings specified by the 20-mA unit. Normally, you must adapt only the parameterization of the SIPROTEC 5 device to the settings of the 20-mA unit. Make sure that the setting values in both devices are the same. The settings of the **`Non-flickering light (on/off)`:** is not relevant for the RS485 interface.

NOTE

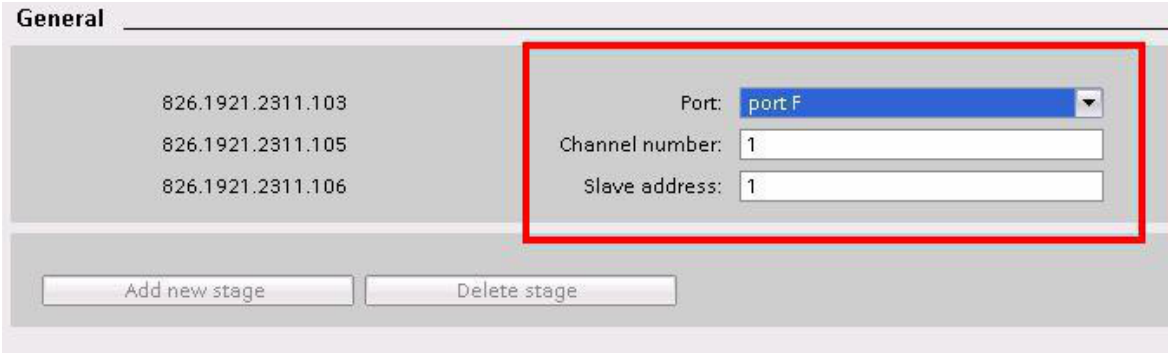


The driver for the USART module for the SUP protocol is not preinstalled as standard for the initial use of this interface (following the firmware update).

[scauser5-220114-01-DE, 1, en_US]

Figure 5-43 Making the Communication Settings

With the selection of the SUP protocol for the 20-mA unit DIGSI automatically adds the function group **Analog units** to your device configuration. You can now instantiate the function **20-mA unit serial 1** (see following figure).



[sc20ser6-220114-01-DE, 1, en_US]

Figure 5-44 Insertion of the Function 20-mA Unit Serial 1

Now, set the channel number over which the SUP protocol runs. In addition, set the slave address of the 20-mA unit. This address must be set with the same value in the 20-mA unit (refer to the following figure).

For the first use of the 20-mA unit, the following device configuration must be set on the 20-mA unit:

- Bus protocol: mod
- Device address: 1
- Baud rate: 9600
- Parity: no

[scauser7-220114-01-DE, 1, en_US]

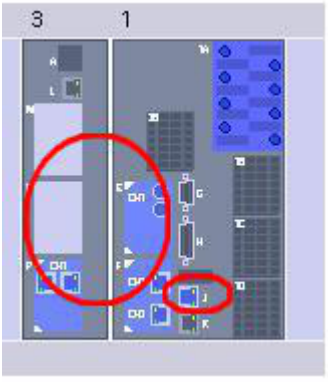


Figure 5-45 Setting the Port, Channel Number, and Device Address

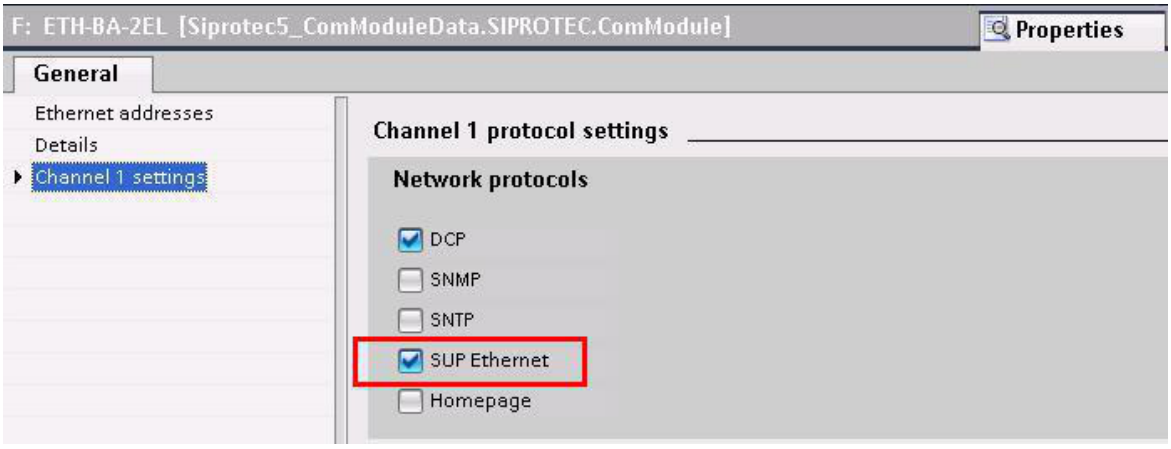
Finally, load the configuration in the device.

5.6.5.2 Integration of a 20-mA Unit Ethernet

Device Configuration

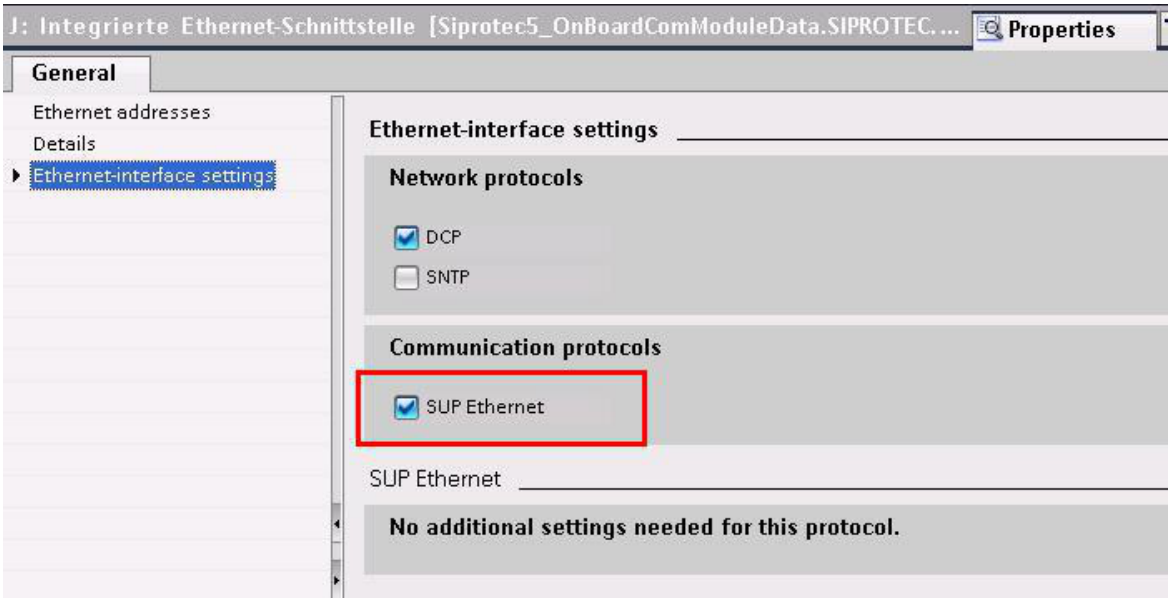
In DIGSI, insert an Ethernet module into the provided slot, thus, adding the module to the device configuration. *Figure 5-46* displays the available slots in the base module or on the expansion module CB 202. Alternatively, you can also use the integrated Ethernet interface Port J.



[scautcp1-220114-01-DE, 1, en_US]

Figure 5-46 Inserting an Ethernet Module

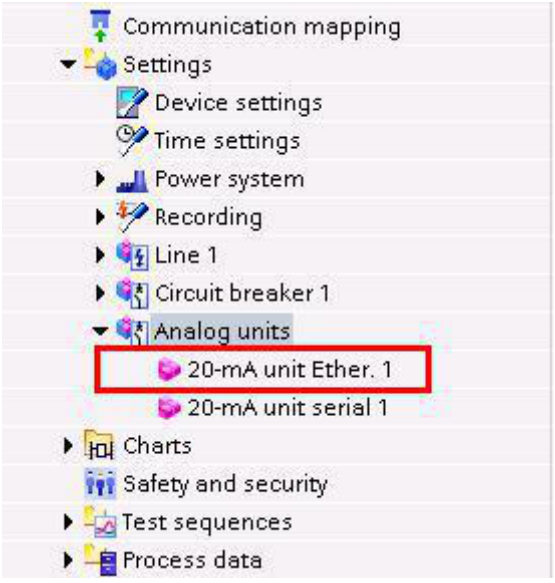
Communication Settings



Activate the SUP Ethernet protocol for the Ethernet module.

[scautcp2-220114-01-DE, 1, en_US]

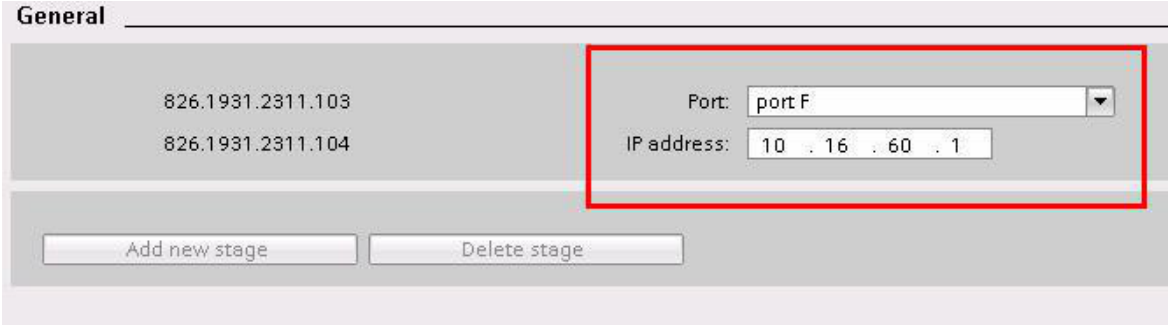
Figure 5-47 Activation of the protocol



This protocol is also available for Port J of the integrated Ethernet interface of the base module (refer to following figure).

[scautcp3-220114-01-DE, 1, en_US]

Figure 5-48 Selection of the Protocol



With the selection of the SUP protocol for the 20-mA unit, DIGSI automatically adds the **Analog units** function group and the **20-mA unit Ether.** function to your device configuration (refer to the following figure).

[sc20tcp4-220114-01-DE, 1, en_US]

Figure 5-49 Insertion of the Function 20-mA Unit Ether. 1

Now, set the port over which the SUP protocol runs. In addition, set the IP address of the 20-mA unit (refer to the following figure). This address must be set with the same value in the 20-mA unit.

[scautcp5-220114-01-DE, 1, en_US]

Figure 5-50 Setting the Port and IP Address

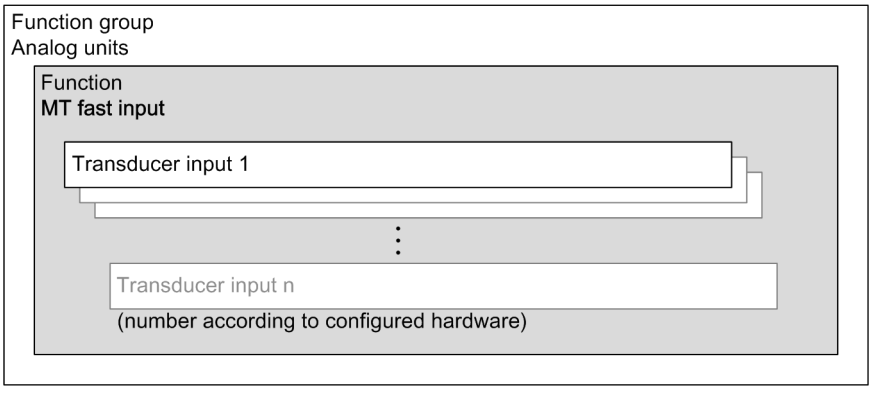
Finally, load the configuration in the device.

5.6.6 V/I-Measuring-Transducer Unit with Fast Inputs

5.6.6.1 Overview

The fast analog measuring-transducer inputs process voltage values (DC -10 V to +10 V) as well as current values (DC -20 mA to 20 mA).

The function **MT fast input**:



- Provides sampled values for recording in the fault record (the maximum sampling frequency is 8 kHz for all other SIPROTEC 5 devices). The recorded sampling frequency results from the setting of the fault-recorder function.
- Calculated measured values from the sampled values. These measured values have been deduced from the arithmetic mean values. The measuring range for the mean-value calculation is adjustable in the interval from 10 ms to 100 ms.

- Converts the measured current or voltage values into process values, for example, temperature, gas pressure, etc.
- Provides the recorded process variables for further processing by the fault recorder, the CFC, and in GOOSE-applications for transmission via communication protocols, and for visualization

The fast measuring-transducer inputs are located on the IO212 module with 8 inputs (optionally current or voltage inputs), and the IO210 module with 4 inputs (optionally current or voltage inputs).

5.6.6.2 Structure of the Function

The function **MT fast input** works in the function group **Analog units** and contains the number of available measuring-transducer inputs, depending on the hardware configuration. You can configure these channels independently from one another either as current or voltage inputs.

[dw_mu-structure, 1, en_US]

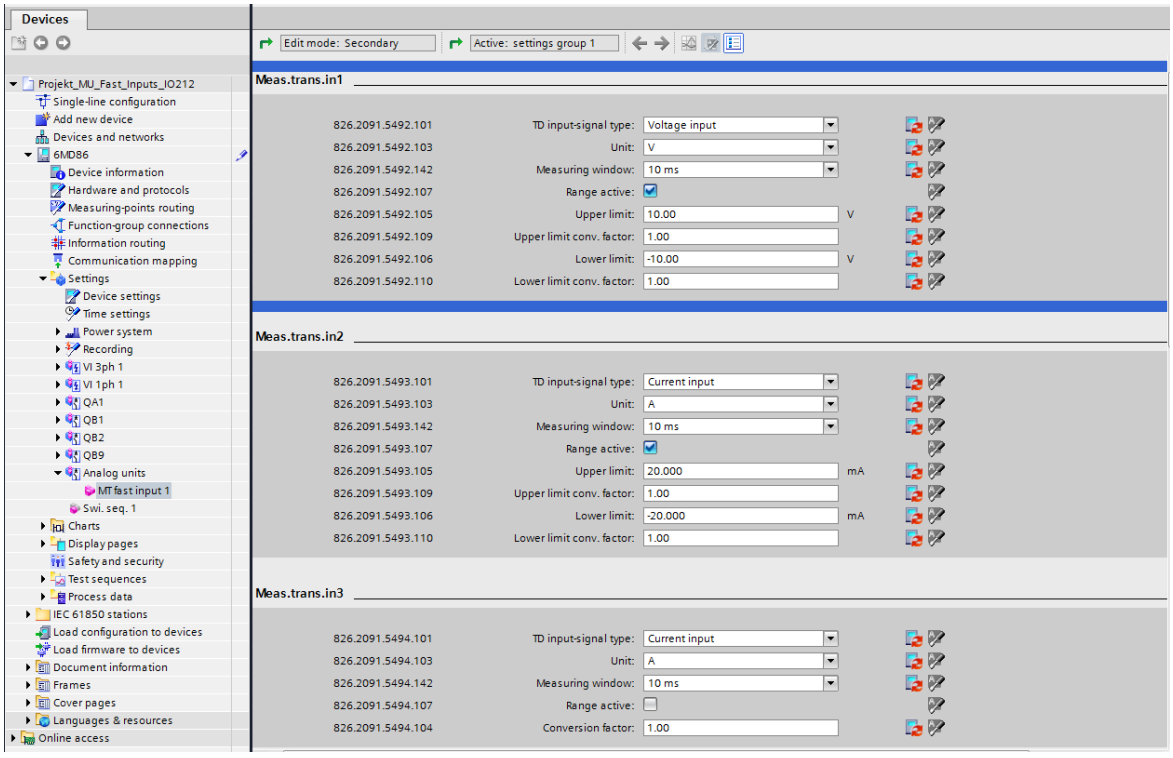


Figure 5-51 Structure/Embedding of the Function

5.6.6.3 Function Description

Once you have instantiated the **MT fast input** function, it will be visible in the project tree in the function group **Analog units**. You can find the function group **Analog units** in DIGSI in the **Settings** folder.

If you open the subdirectory **MT fast input**, you reach the setting sheet for the respective input (for more details, see Application and Setting Notes).

The hardware is designed in such a way that either a current or a voltage can be processed at each input. Use the corresponding terminals (see Hardware manual). Configure the input in accordance with the selected connection (Parameter **`TD input-signal type`**). With the parameter **`Measuring window`**, you set the measuring range with which the arithmetic mean value is determined. With the parameter **`Measuring window`**, you also determine measurement speed for the input. For example, a setting of 100 ms means that the measured value is updated every 100 ms.

[scmuio212, 1, en_US]

Figure 5-52 Parameters of the Measuring-Transducer Channels.

The fast measuring-transducer channels can be configured either as current or as voltage inputs. Apart from this, their function corresponds to the basic function of the 20-mA-channels (see chapter *5.6.3.5 20-mA Channel*).

5.6.6.4 Application and Setting Notes

Parameter: `TD input-signal type`

- Default setting **`(_:101) TD input-signal type`** = ***`Current input`***

With the parameter **`TD input-signal type`**, you determine whether the measuring-transducer input channel works as a ***`Current input`*** or as a ***`Voltage input`***.

Make sure that the selected channel has also been wired correctly (see Hardware manual, Input and Output Module IO212).

Parameter: `Unit`

- Default setting **`(_:103) Unit`** = ***`A`***

With the parameter **`Unit`**, you set the physical unit of measurement of the measured values. The possible setting values are listed in the settings table.

Parameter: `Measuring window`

- Default setting **`(_:142) Measuring window`** = ***`10 ms`***

With the parameter **`Measuring window`**, you set the measuring window that is used to determine the arithmetic mean value from the sampled values. In case of slowly varying signals, Siemens recommends setting the top value to 100 ms. With this value, a new, current measured value is provided every 100 ms for further processing.

Parameter: `Range active`

- Default setting **`(_:107) Range active`** = ***`false`***

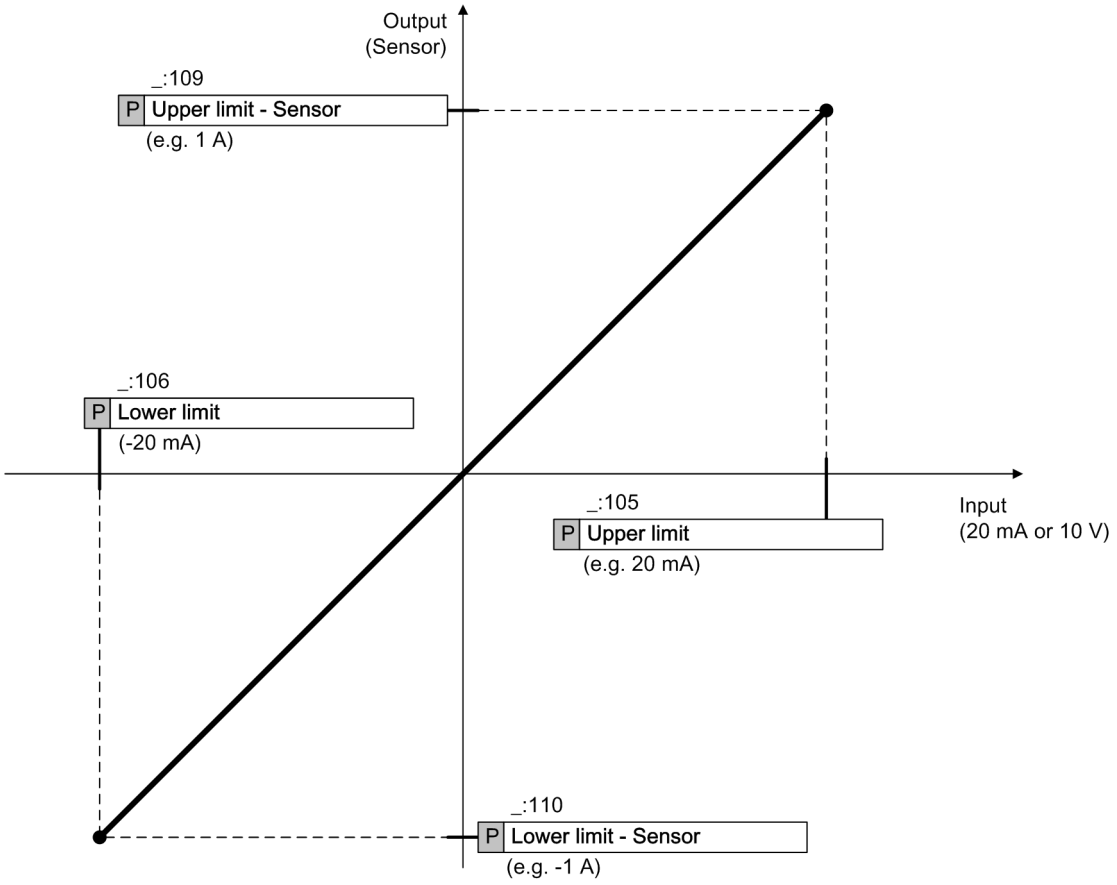
If you do not activate the **`Range active`** parameter, the function assumes a range of -20 mA to +20 mA or -10 V to +10 V. The setting of the range for the scaled value then assumes a usable range of -20 mA to +20 mA or -10 V to +10 V.

If you activate the **`Range active`** parameter, then 4 additional parameters **`Upper limit`**, **`Upper limit - Sensor`**,**`Lower limit`**, and **`Lower limit - Sensor`** appear.

Note that this setting is activated by either placing, or not placing the relevant check mark in DIGSI (see *Figure 5-52*).

Parameter: Conversion factor

- Default setting **`(_:104) Conversion factor`** = ***`1.00`***



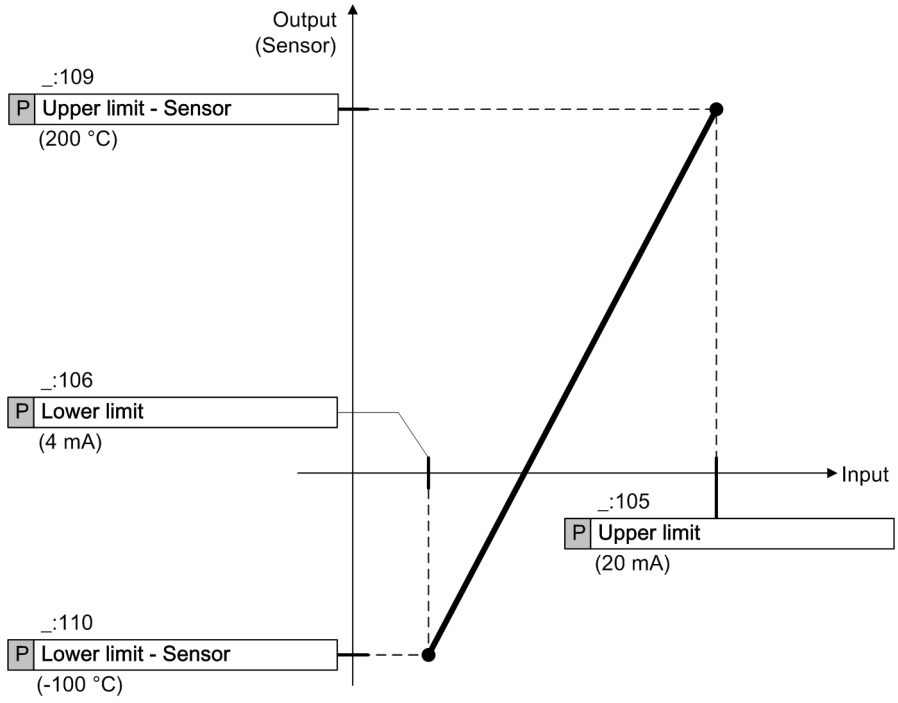
With the parameter **`Conversion factor`**, you set the conversion factor for the measuring transducer.

Parameter: Upper limit, Lower limit, Upper limit - Sensor, and Lower limit - Sensor

With the following parameters, you set the scaling of the measuring variables. By that, you can scale in an application-specific way:

- Default setting **`Upper limit`** = ***`20.00 mA`***
- Default setting **`Upper limit - Sensor`** = ***`1.00`***
- Default setting **`Lower limit`** = ***`-20.00 mA`***
- Default setting **`Lower limit - Sensor`** = ***`1.00`***

With these setting parameters, you set the operating range of the measuring transducer as well as the conversion of the values transmitted to the sensor values. Harmonize the operating range of the measuring transducer with the transmitter of the sensor. Using the free scalability of the system, you can meet different requirements. The following figure shows the setting parameters in general terms.



[dw_measured-value-scaling, 1, en_US]

Figure 5-53 Scaling Principle

Setting Example 1:

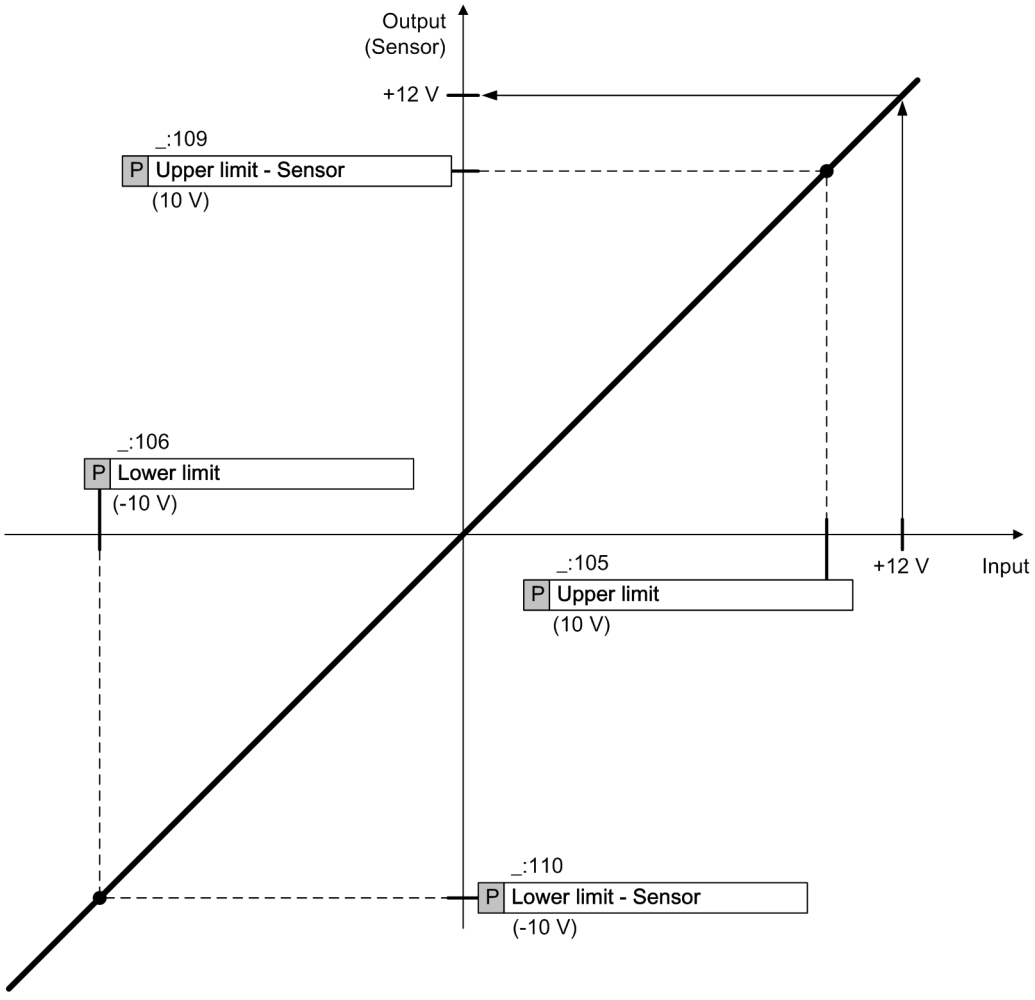
A measuring transducer transmitting a current signal of 4 mA to 20 mA is used as a transmitter. Currents well below 4 mA indicate a transmitter failure; currents around 0 mA indicate a broken wire. A sensor detecting a temperature is attached to the transmitter. The upper value corresponds to 200 °C and the lower value to -100 °C. This results in the following characteristic. In accordance with the set characteristic curve, the function calculates the sensor value from the measured current. The coefficients of the linear equation (gradient and foot point) are calculated from the set threshold and the sensor values are determined. A supplied current of 9.333 mA corresponds to a temperature of 0 °C.

[dw_measuring-transducer-characteristic, 1, en_US]

Figure 5-54 Characteristic Curve of Setting Example 1

NOTE

The hardware of the measuring transducer has been designed in such a way that measured values are transmitted and analyzed using the setting range (**`Upper limit`** or **`Lower limit`**). Therefore, special applications are possible, if necessary. The limits lie at approximately +20 mA and -20 mA or +10 V and -10 V. If the measured values are supplied above or below these limits, the quality ***`invalid`*** is assigned.



Setting Example 2:

For special applications, the transmitter sends a maximum of ±12 V. This voltage shall be issued accordingly as sensor voltage.

Set the parameters as follows:

- **`Upper limit`** = ***`10.00 V`***
- **`Upper limit - Sensor`** = ***`10.00 V`***
- **`Lower limit`** = ***`-10.00 V`***
- **`Lower limit - Sensor`** = ***`-10.00 V`***

With this setting, a signal of 12 V is issued as a 12-V measured value (see following figure).

[dw_measuring-transducer-setting, 1, en_US]

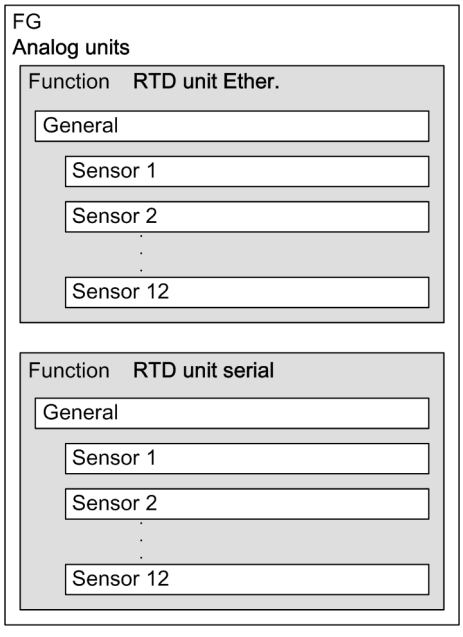
5.6.7 RTD Unit Ethernet



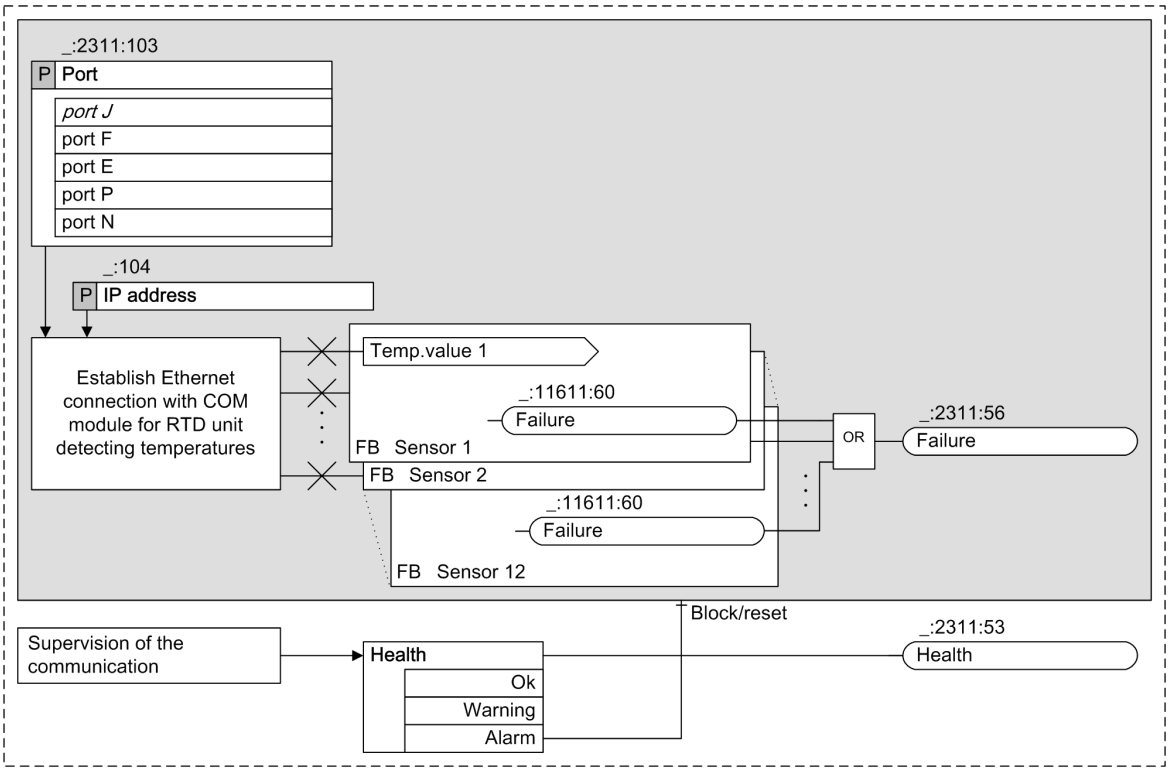
5.6.7.1 Overview

The **RTD unit Ether.** function:

- Communicates with an external RTD unit via the Slave Unit Protocol (SUP) and records the measured temperatures from the RTD unit
- Provides the captured temperatures to the temperature monitoring function
- Monitors communication with the RTD unit

5.6.7.2 Structure of the Function

The **RTD unit Ether.** function can only work in the **Analog units** function group. A maximum of 20 function instances can work simultaneously. Each instance contains 12 preconfigured sensor function blocks.



[dwstrfnc-291112-01.tif, 2, en_US]

Figure 5-56 Structure/Embedding of the Function

5.6.7.3 Communication with an RTD Unit

Logic

[lortdtcp-311012-01.tif, 1, en_US]

Figure 5-57 Logic of the RTD Unit Ether. Function

Communication with an RTD Unit

The function is used to communicate with an RTD box connected via an Ethernet connection. If the connection of the function is successfully established to the external RTD box via the Ethernet interface, the RTD box transmits the temperatures of all connected sensors to the **RTD box Ether.** function. For the connection to be established successfully, specific communication settings must be set, see chapter *5.6.7.4 Application and Setting Notes*.

The RTD box **Ziehl TR1200 IP** supports only an Ethernet connection of 10 MBit/s. A direct connection to a 100-Mbit communication module is therefore not possible. For this reason, you must connect the RTD box to the communication module via a 10/100 MBit/s autosensing switch which automatically recognizes the transmission rates and adapts them accordingly. Further information can be found in the Application and setting notes, see chapter *5.6.7.4 Application and Setting Notes*.

Error Responses

The following table lists the conditions under which the *Health* status transitions to the Alarm or Warning state.

Table 5-11 Error Responses

Error Description	Status Health
The **RTD unit Ether.** function cannot establish a connection with a communication module.	Alarm
The connection between the communication module and the RTD unit causes a time-out.	Warning

Error Description	Status Health
A communication module has not received any more data from the RTD unit for 9 sec.	Warning

The *Failure* signal is set as soon as one of the sensor function blocks reports a failure.

5.6.7.4 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***port J***

Use the **Port** parameter to define over which port the external RTD unit is connected to the SIPROTEC 5 device.

If you want to connect the external RTD unit to the integrated Ethernet interface, set the parameter **Port** = ***Port J***. If you want to connect the external RTD unit to an Ethernet plug-in module, set the parameter **Port** = ***Port F***, ***Port E***, ***Port P***, or ***Port N***.

You can connect directly the RTD unit to the device via the internal 10-Mbit Ethernet port J. If you operate the RTD unit on another port via a 100-Mbit communication module, you need an interconnected 10/100-Mbit autosensing switch, which adapts transmission rates accordingly.

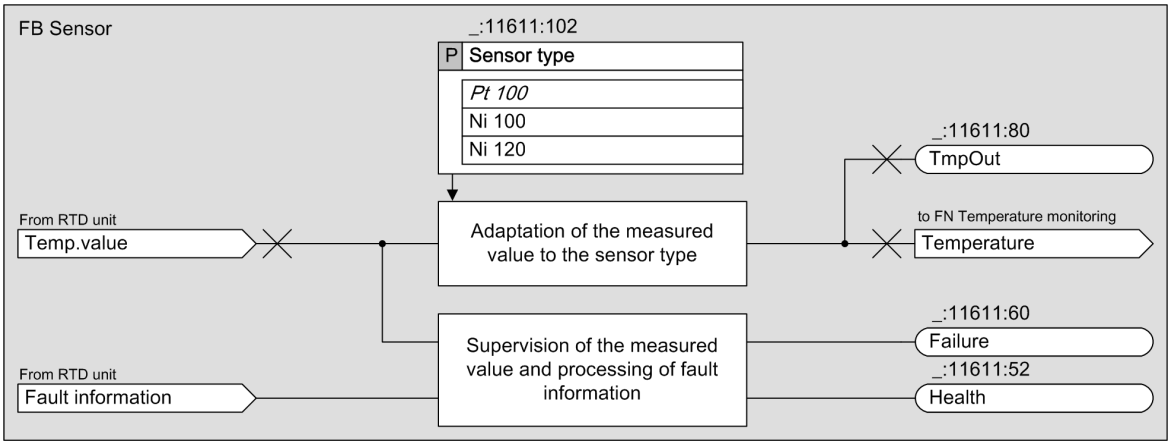
Parameter: IP address

- Default setting **(_:2311:104) IP address** = ***10.16.60.1***

With the **IP address** parameter, you set the IP address of the RTD unit connected to the communication module via the SUP protocol. Every RTD unit has to be assigned a unique IP address. The IP address to be set depends on your network configuration. You can set any valid IPv4 address that does not cause conflicts with other IP addresses in the network. Set an appropriate IP address first at the **Ziehl TR1200 IP** RTD unit. Then specify the **IP address** parameter for the communication module to the same address.

Settings on the RTD Unit

The **Ziehl TR1200 IP** RTD unit is set with the front keys or in a Web browser on a laptop computer via its Ethernet interface. Set the connection type of the sensors (3-wire connection or resistance value for 2-wire connection), the idle state of the fault-indication relay, as well as the IP interface setting.



The code lock has to be switched off for parameterization. This is only possible using the front keys of the RTD unit. The code lock is **off** (switched off) in as-delivered condition and has pin **504**.

For detailed information on the settings, refer to the TR1200 IP manual that comes with the RTD unit. The documents are also available in the SIPROTEC download area (http://www.siprotec.de) under **Accessories -> 7XV5662-xAD**.

For an Ethernet connection to a SIPROTEC 5 device communicating with the RTD unit TR1200 IP via the **SUP protocol** (Slave Unit Protocol), the **Modbus TCP** setting must be activated in the RTD unit. You can activate the Modbus TCP protocol using the function keys under the **TcP - mod** menu item or with the Web browser in the **TCP/UDP Config** tab. The **RTD** (RTD protocol) and **UDP Port** settings have no effect here. The Modbus TCP port is permanently set to 502 and cannot be changed.

5.6.7.5 Temperature Sensor

Logic

[lotmpval-311012-01.tif, 1, en_US]

Figure 5-58 Logic Diagram of the Temperature Sensor Function Block

Measured Temperature Value

The **Temperature sensor** function block processes one single measured temperature value delivered from the RTD box for the assigned sensor. 12 temperature sensor function blocks are always available in each RTD box function (both via Ethernet and serial), even if fewer sensors are connected to the RTD box.

Various temperature sensor types are supported: Pt100, Ni100, and Ni120 sensors. The function block is notified regarding the selection of connected type via the **`Sensor type`** parameter.

The function block delivers a measured temperature value in °C or °F as an output variable. The measured temperature value is available as an operational measured value and can be monitored by the **Temperature supervision** function.

Error Responses

If the measured input value is determined to be incorrect, the quality attribute of the output measured temperature value is set to *`invalid`*. The statuses for Health and Error take the statuses in accordance with the following table:

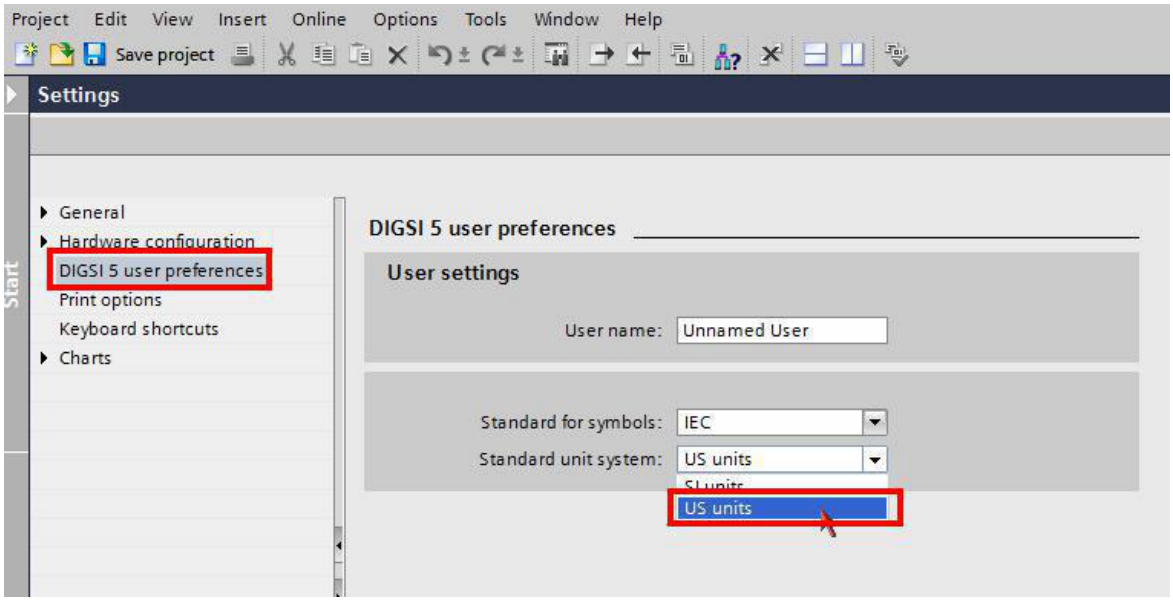
Table 5-12 Error response

Error Description	Health Status	Error Status
Sensor or line short circuited	Alarm	Yes
Sensor or line interrupted	Alarm	Yes
Measured temperature value outside the valid measuring range specified in the technical data. The valid measuring range depends on the sensor type.	Alarm	Yes
Sensor not connected	OK	No

5.6.7.6 Application and Setting Notes

Parameter: Sensor type

- Default setting **`(_:11611:102) Sensor type`** = ***`Pt 100`***



The **`Sensor type`** parameter is used to set the sensor element used. You can select between ***`Pt 100`***, ***`Ni 100`*** and ***`Ni 120`***.

Parameter: Temperature unit

To change the display and evaluation of measured temperature values from °C to °F, adapt the DIGSI user default settings accordingly.

Proceed as follows:

- In DIGSI select the menu item **Extras** --> **Settings**.
- In the **Settings** view select the menu item **DIGSI 5 User preferences**.
- Under **Standard unit system** change the setting value of the unit system used from *SI units* to *US units*.

[scfahrht-190214-01, 1, en_US]

Figure 5-59 Change of the Display Between °C and °F

The following settings and information table shows only 1 of the 12 sensors, as the setting possibilities of the 12 sensors do not differ.

5.6.8 RTD Unit, Serial

5.6.8.1 Overview

The **RTD unit serial** function:

- Communicates with an external RTD unit serial via the Slave Unit Protocol (SUP) and records the measured temperatures from the RTD unit
- Provides the captured temperatures to the temperature supervision function
- Monitors communication with the RTD unit

The **RTD unit Serial** function is set up structurally in the same manner as the **RTD unit Ether.** function. The mode of operation is also identical (see *5.6.7.3 Communication with an RTD Unit*).

5.6.8.2 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***F***

With the **Port** parameter, you set the slot for the communication module that will be used for the connection with an external RTD unit.

If you want to connect the external RTD box to an Ethernet plug-in module, set the parameter **Port** = ***Port F***, ***Port E***, ***Port P***, or ***plug-in module position***.

Parameter: Channel number

- Default setting **(_:2311:105) Channel number** = ***1***

A serial communication module optionally uses 2 channels. With the **Channel number** settings, you set the channel number (1 or 2) through which the RTD unit is connected to the device. The communication module inputs are labeled with the channel numbers.

Parameter: Slave address

- Default setting **(_:2311:106) Slave address** = ***1***

Use the **Slave address** parameter to define the device address of the RTD unit. If only one RTD unit is connected to the serial bus, the default value *1* can be used. The same device address has to be set on the RTD unit. The device address is important for distinguishing among several RTD units connected to a serial bus. Set a unique device address (for example 1, 2 and 3 when connecting 3 RTD units) for each RTD unit and the same device address for the parameter **Slave address** in the 3 **RTD unit serial** functions.

The following settings and information table shows only 1 of the 12 sensors, as the setting possibilities of the 12 sensors do not differ.

5.6.8.3 Settings

5.6.9 Communication with RTD Unit

5.6.9.1 Integration of a Serial RTD Unit (Ziehl TR1200)

Connection of the Communication Lines

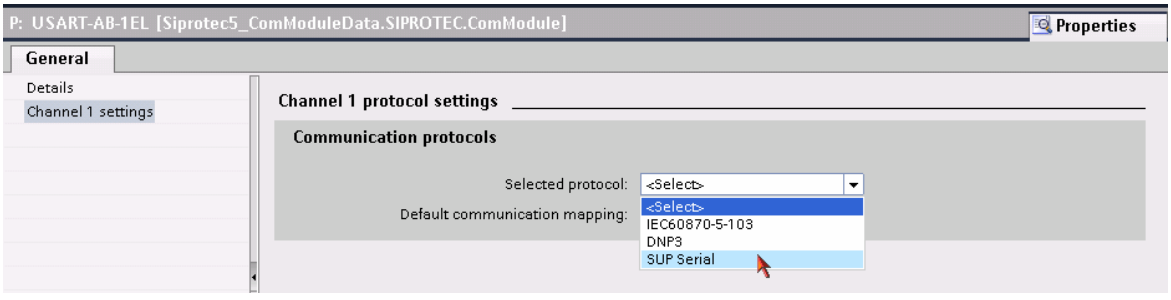
Figure 5-60 shows how you connect the RTD box to the SIPROTEC 5 device. Note that Pin 1 of the RJ45 plug is connected to RTD-B and Pin 2 is connected to RTD-A.

[dwverbau-201112-01.tif, 1, en_US]

Figure 5-60 Connection of the RTD Unit to the SIPROTEC 5 Device

Adding a USART Module

Add a USART-AB-1EL or a USART-AC-2EL USART module in DIGSI to the device. The USART module must be inserted at one of the plug-in positions for communication modules in the base module or in the CB202 expansion module (refer to the following figure).



[scauser3-190214-01, 1, en_US]

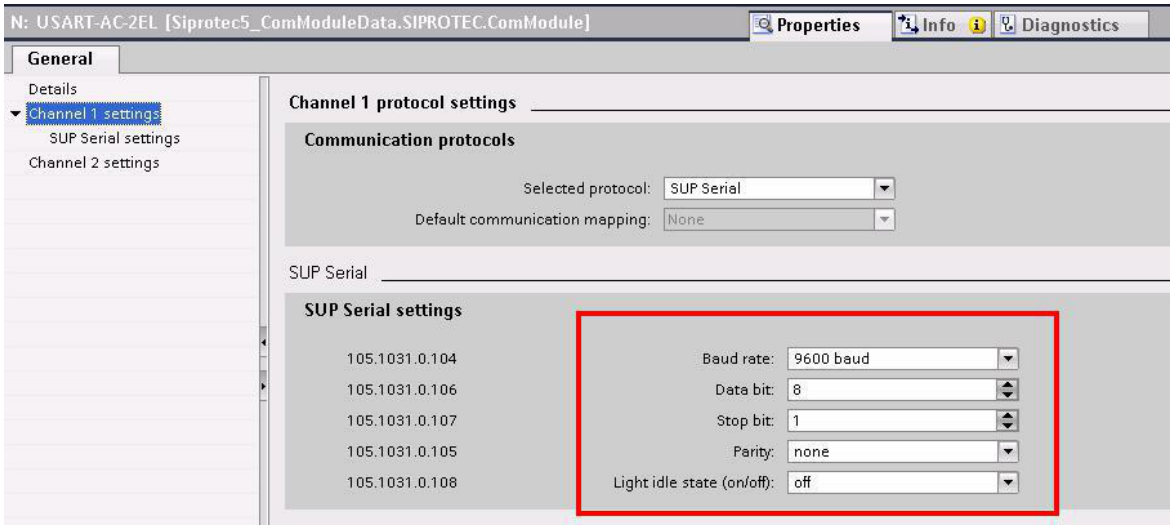
Figure 5-61 Insertion Position for a USART Module

Selecting the SUP Protocol

Select the Slave Unit Protocol (SUP). This protocol is responsible for the communication between the SIPROTEC 5 device and the RTD Unit.

[scauser4-220114-01-DE, 1, en_US]

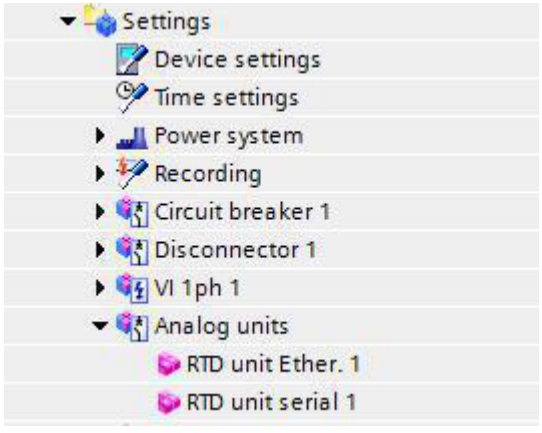
Figure 5-62 Selecting the SUP Protocol



Communication Settings

Make the communications settings for the relevant serial channels. For this, use the default settings specified by the RTD box. Normally, you must adapt only the parameterization of the SIPROTEC 5 device to the settings of the RTD box. Make sure that the setting values in both devices are the same. The settings of the **`Non-flickering light (on/off)`:** is not relevant for the RS485 interface.

NOTE

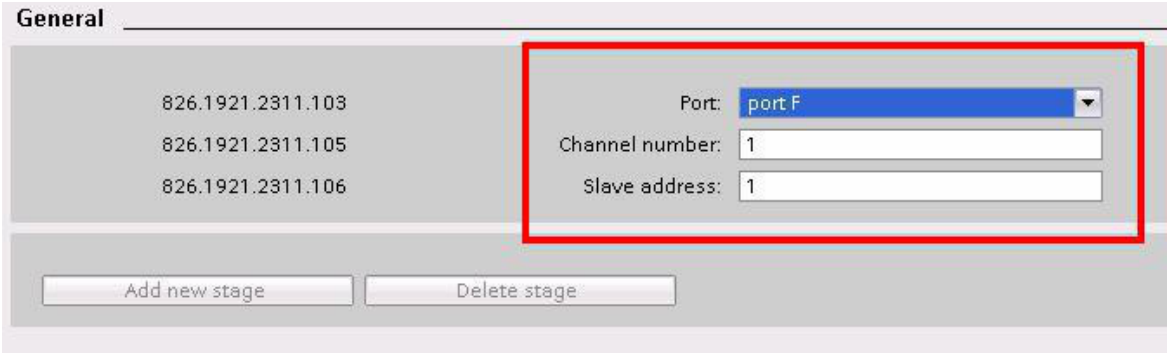


The driver for the USART module for the SUP protocol is not preinstalled as standard for the initial use of this interface (following the firmware update).

[scauser5-220114-01-DE, 1, en_US]

Figure 5-63 Making the Communication Settings

With the selection of the SUP protocol for the RTD box DIGSI automatically adds the function group **Analog units** to your device configuration. You can now instantiate the function **RTD box serial 1** (refer to the following figure).



[scauser6-190214-01, 1, en_US]

Figure 5-64 Analog-Unit Instance

Now, set the channel number over which the SUP protocol runs. In addition, set the slave address of the RTD box. This address must be set with the same value in the RTD box (refer to the following figure).

The following device configuration must be set on the TR1200 RTD unit when the RTD unit is used for the first time:

- Bus protocol: mod
- Device address: 1
- Baud rate: 9600
- Parity: no

[scauser7-220114-01-DE, 1, en_US]

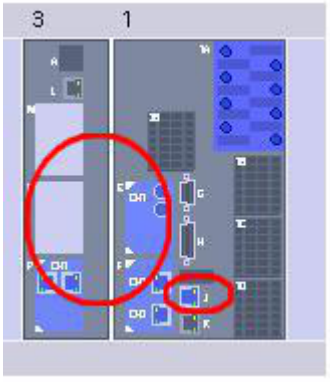


Figure 5-65 Setting the Port, Channel Number, and Slave Address

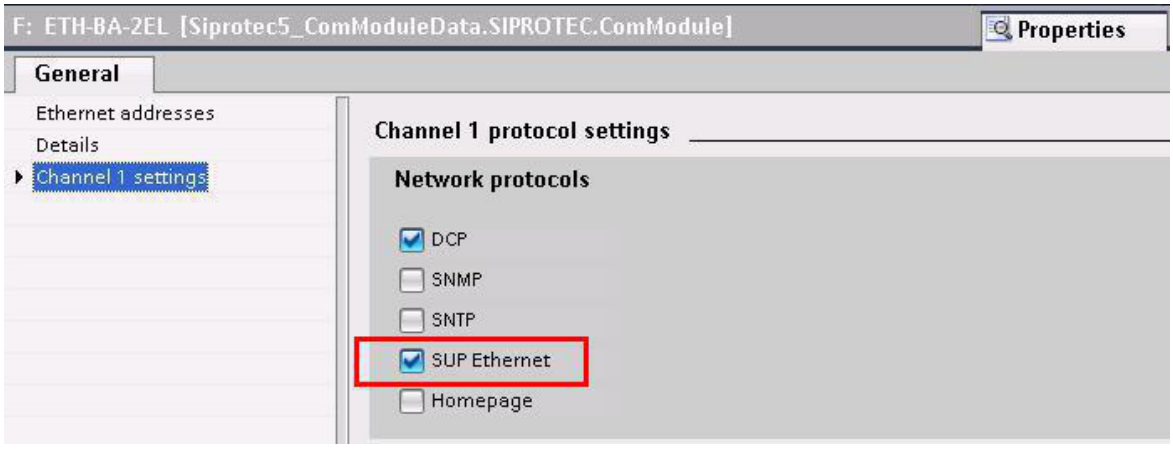
Finally, load the configuration in the device.

5.6.9.2 Integration of an RTD-Unit Ethernet (TR1200 IP)

Device Configuration

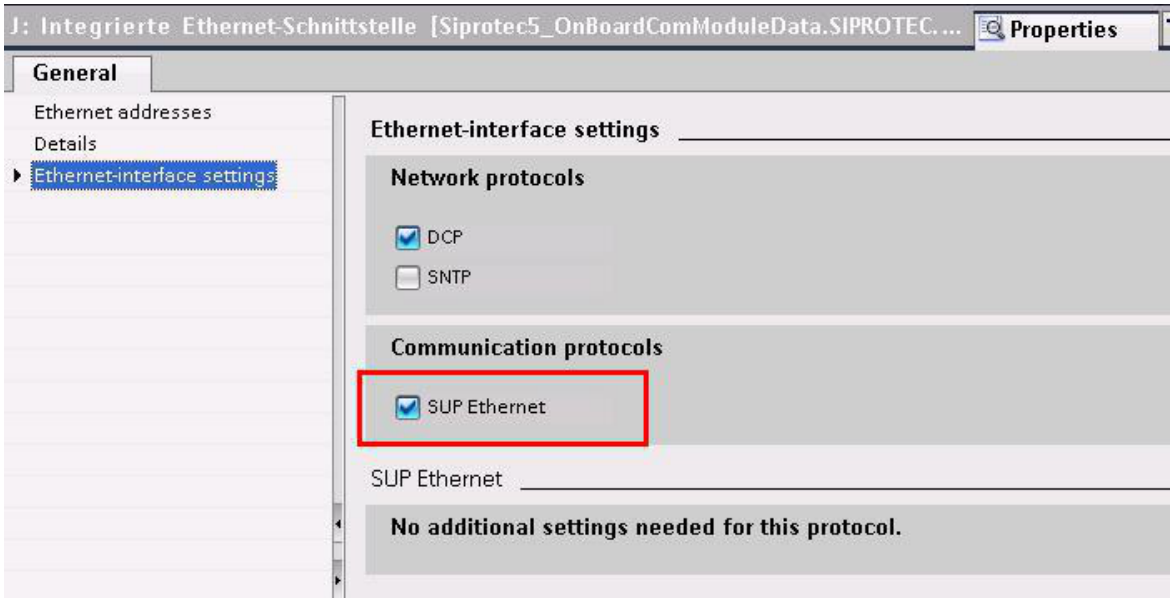
In the DIGSI, insert an Ethernet module into the provided slot, thus, adding the module to the device configuration. *Figure 5-66* displays the available slots in the base module or on the expansion module CB 202. Alternatively, you can also use the integrated Ethernet interface Port J.



[scautcp1-220114-01-DE, 1, en_US]

Figure 5-66 Inserting an Ethernet Module

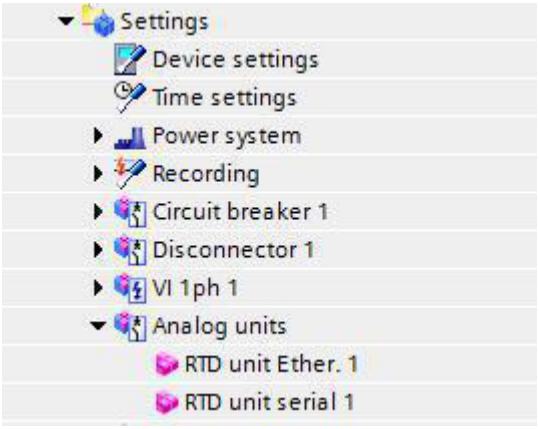
Communication Settings



Activate the SUP Ethernet protocol for the Ethernet module.

[scautcp2-220114-01-DE, 1, en_US]

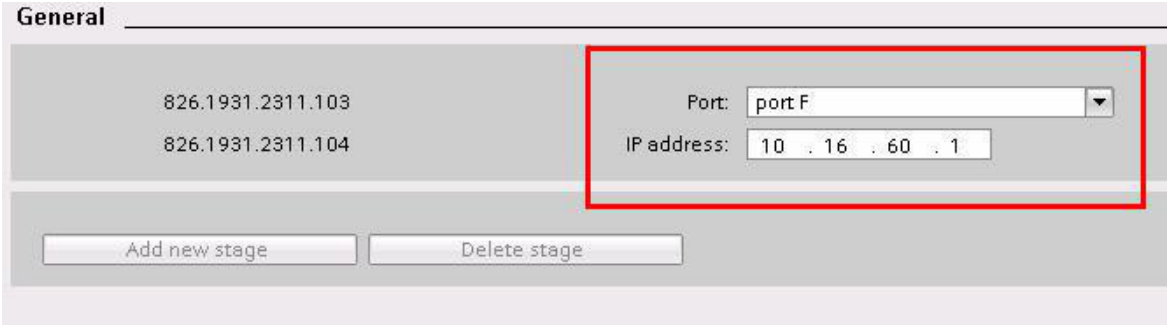
Figure 5-67 SUP Ethernet Protocol Activation



This protocol is also available for Port J of the integrated Ethernet interface of the base module (refer to following figure).

[scautcp3-220114-01-DE, 1, en_US]

Figure 5-68 SUP Ethernet Protocol Activation (base module)



With the selection of the SUP protocol for the RTD unit, DIGSI automatically adds the **Analog units** function group and the **RTD unit Ether.** function to your device configuration (refer to the following figure).

[scauser6-190214-01, 1, en_US]

Figure 5-69 Analog Unit Instance

Now, set the port over which the SUP protocol runs. In addition, set the IP address of the RTD box (refer to the following figure). This address must be set with the same value in the RTD box.

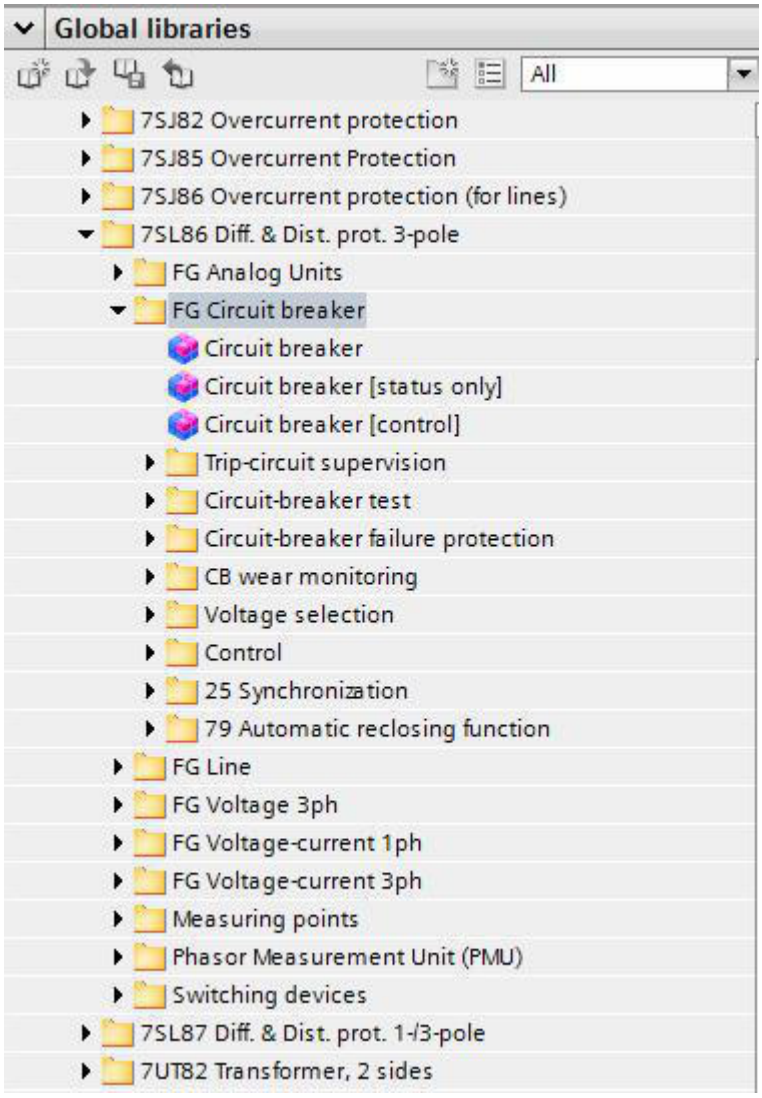
[scautcp5-220114-01-DE, 1, en_US]

Figure 5-70 Setting the Port and IP Address

Finally, load the configuration in the device.

5.6.9.3 Temperature Simulation without Sensors

Connect a resistor on the sensor terminals of the RTD unit. Using this resistor, simulate a constant temperature. The resistance value should be around 50 Ω to 200 Ω.



If you want to simulate a changeable temperature, connect an adjustable resistor of maximum 470 Ω instead of a fixed resistor.

5.7 Function-Group Type Circuit Breaker

5.7.1 Overview

The **Circuit-breaker** function group combines all the user functions that relate to a circuit breaker.

You will find the **Circuit-breaker** function group under each device type in the function library in DIGSI 5. The **Circuit-breaker** function group contains all of the protection, control, and supervision functions that you can use for this device type. The following figure shows, for example, the functional scope of the **Circuit-breaker** function group.

[scfgleis-200214-01, 1, en_US]

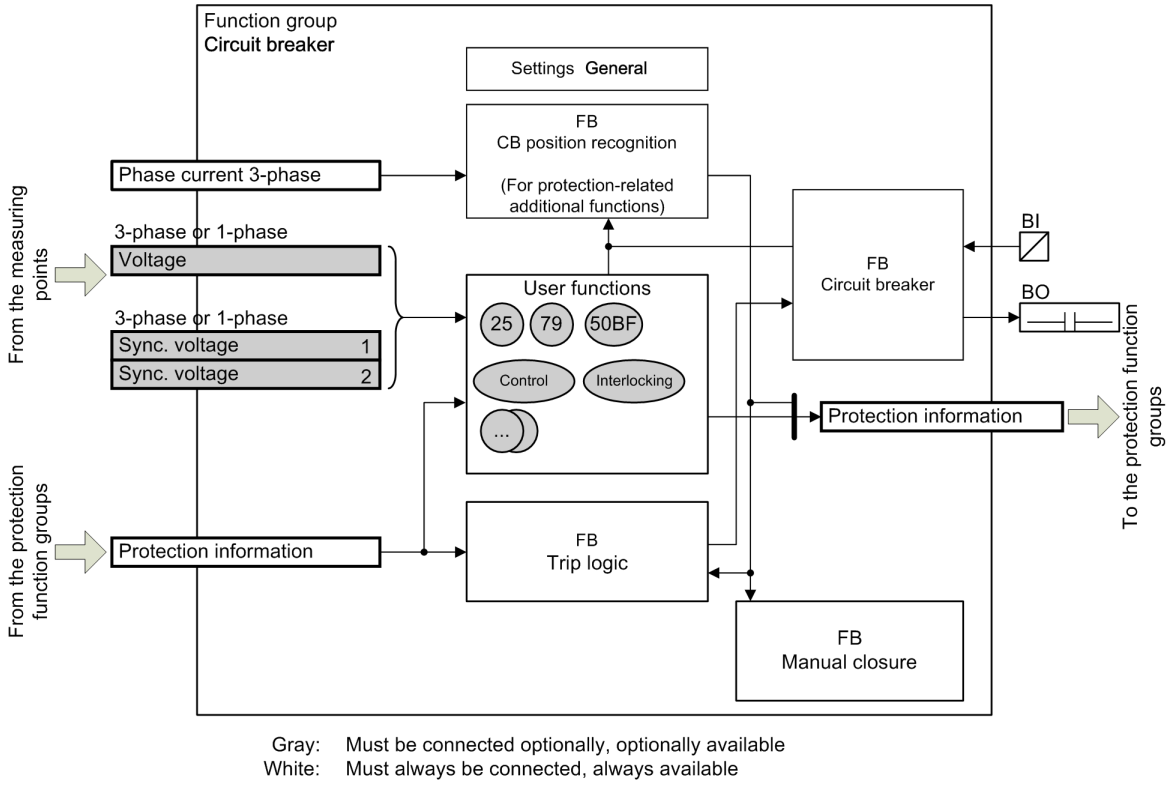
Figure 5-71 Circuit-Breaker Function Group - Example of the Functional Scope

The Circuit-breaker function group includes 3 different types of circuit breakers:

- Circuit breaker
- Circuit-breaker control
- Circuit breaker [status only]

The circuit-breaker type can accept additional basic function blocks for protection functions along with the actual circuit breaker control.

The circuit breaker [status only] is used only for acquiring the circuit-breaker switch position. This type can be used to model switches that can only be read but not controlled by the SIPROTEC 5 device.



The available functions are described in the chapters *6 Protection and Automation Functions* and *8 Control Functions*.

5.7.2 Structure of the Function Group

Besides the user functions, the **Circuit-breaker** function group contains certain functionalities that are essential for general purposes and therefore cannot be loaded or deleted:

- Trip logic
- Mapping the physical circuit breaker
- Circuit-breaker position recognition for protection functions
- Detection of manual closure
- General settings

The following figure shows the structure of the **Circuit-breaker** function group. The individual function blocks in the image are described in the following chapters.

[dwfgstru-080812-01.tif, 1, en_US]

Figure 5-72 Structure of the Circuit-Breaker Function Group

The **Circuit-breaker** function group has interfaces with:

- **Measuring points**
- Protection function groups

Interfaces with Measuring Points

The function group contains the measured values needed from the measuring points associated with this function group.

If an application template is used, the function group is connected to the measuring point of the 3-phase current because this connection is essential. It can be necessary to connect additional measuring points to the function group, depending on the nature of the user functions used. Configuration is carried out using the **Function-group connections** editor in DIGSI 5. You can find more detailed information on this in chapter *2.1 Function Embedding in the Device*.

If a user function, for example, synchronization, is used in the function group but the required measuring point has not linked to it, DIGSI 5 reports an inconsistency. This inconsistency provides an indication of the missing measuring-point connection.

The **Circuit-breaker** function group has interfaces with the following measuring points:

- **`3-phase line current`**

  The measurands from the 3-phase power system are supplied via this interface. The function group must always be connected to this measuring point.

- **`Voltage`**

  The measurands of the 3-phase voltage system or 1-phase voltage are supplied via this interface. Depending on the connection type of the transformers, in the 3-phase voltage system these are, for example, V_A, V_B, V_C of the line or feeder.

  The connection to the corresponding measuring point is necessary only if a user function that needs the measurand of the 3-phase voltage system is used, for example, to make use of the **Synchronization** or **Automatic reclosing** function.

- **`Sync. Voltage1, Sync. Voltage2`**

  A 1-phase synchronization voltage (for example, voltage of the busbar with a 1-phase connection) or a 3-phase synchronization voltage (for example, voltage of the busbar with a 3-phase connection) is supplied via this interface.

  The connection to the corresponding measuring point is necessary only if synchronization is used.

Interface with Protection-Function Groups

All required data is exchanged between the Protection and Circuit-breaker function groups via the interface with the Protection function group. This data includes, for example, the pickup and operate indications of the protection functions sent in the direction of the Circuit-breaker function group and, for example, the circuit-breaker condition information in the direction of the protection function groups.

If an application template is used, the function groups are connected to each other because this connection is essential to ensure proper operation. You can modify the connection using the **Function-group connections** editor in DIGSI 5.

You can find more detailed information in chapter *2.1 Function Embedding in the Device*.

If the connection is missing, DIGSI 5 reports an inconsistency.

Besides the general assignments of the Protection function group or groups to the Circuit-breaker function groups, you can also configure the interface for certain functionalities in detail:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Automatic reclosing** function?
- Which protection functions activate the **Circuit-breaker failure protection** function?

You can find more detailed information in chapter *2.1 Function Embedding in the Device*.

5.7.3 Application and Setting Notes

Interface with Measuring Points

The interface with the 3-phase power system must have been configured. Otherwise, DIGSI 5 supplies an inconsistency message.

If the **Synchronization** function is used, the measuring points that represent voltages V1 and V2 of the parts of the electrical power system to be synchronized must be connected.

You can find more detailed information in the chapter *8.4 Synchronization Function* .

The **Automatic reclosing** function provides the auxiliary functions **Dead-line check** and **Reduced dead time**. For these auxiliary functions, the 3-phase voltage system has to be measured. If you want to use these auxiliary functions, the measuring point of the 3-phase voltage system must be connected to the **Voltage** function group interface. This connection is also necessary if the **Automatic reclosing function with adaptive dead time** function type is used.

Interface with Protection-Function Groups

The protection-function group is connected to 2 circuit breakers (2 **Circuit-breaker** function groups) for 1 1/2 circuit-breaker layouts.

Parameter: Rated Normal Current for % Values

- Default setting **(_:2311:101) Rated normal current** = ***1000 A***

With the **Rated normal current** parameter, you set the primary current which serves as a reference for all current-related % values within the Circuit-breaker function group. This applies both for operational measured values and for setting values in %.

Enter the primary rated current of the protected object here.

If the device works with the IEC 61850 protocol, then you change only the setting value of the parameter via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated Voltage for % Values

- Default setting **(_:2311:102) Rated voltage** = ***400 kV***

With the **Rated voltage** parameter, you set the primary voltage, which serves as a reference for all voltage-related % values within the Circuit-breaker function group. This applies both for operational measured values and for setting values in %.

Enter the primary rated voltage of the protected object (for example, the line) here.

If the device works with the IEC 61850 protocol, then you change only the setting value of the parameter via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Current Threshold Circuit Breaker Open

- Default setting **(_:2311:112) Current thresh. CB open** = ***0.10 A***

With the **Current thresh. CB open** parameter, you specify the threshold value below which the circuit-breaker pole or the circuit breaker is recognized as open.

Set the **Current thresh. CB open** parameter so that the current measured when the circuit-breaker pole is open will certainly fall below the parameterized value. If parasitic currents (for example, due to induction) are excluded with the line deactivated, you can make a secondary setting of the value with a high degree of sensitivity, to ***0.05 A*** for example.

If no special requirements exist, Siemens recommends retaining the setting value of ***0.10 A*** for secondary purposes.

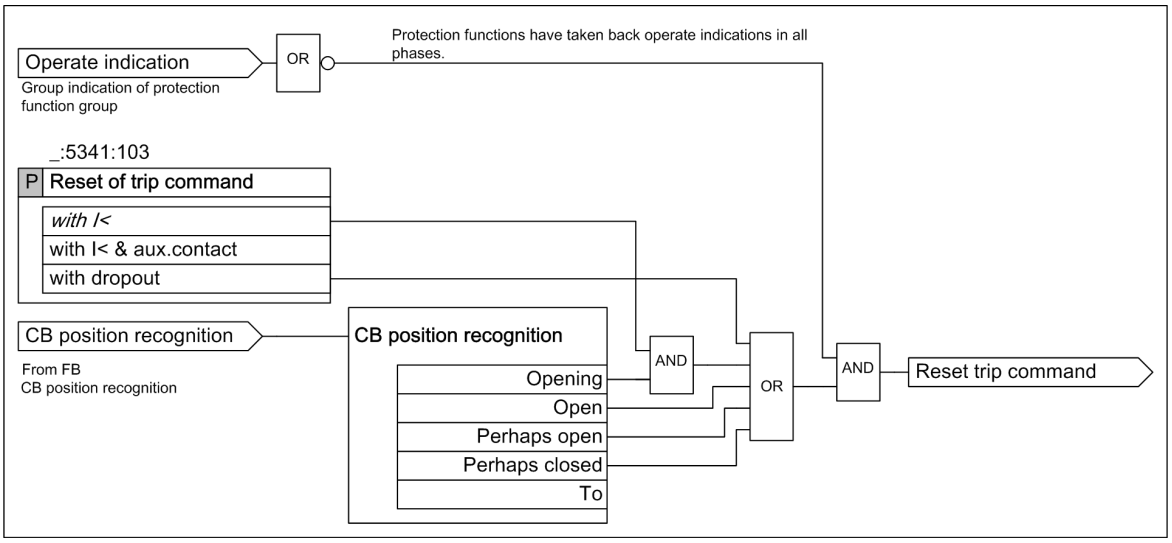
5.7.6 Trip Logic

5.7.6.1 Function Description

The **Trip logic** function block receives the group operate indication from the Protection function group or Protection function groups and forms the protection trip command that is transmitted to the **Circuit-breaker** function block.

The **Circuit-breaker** function block activates the device contact and thus causes the circuit breaker to open (see *5.7.7 Circuit Breaker*). The command output time is also effective here.



The trip logic also decides when the protection trip command is reset (see *Figure 5-74*).

[loausbef-140113-01.tif, 1, en_US]

Figure 5-73 Trip Command

Trip-Command Reset

[lobefe3p-140113-01.tif, 1, en_US]

Figure 5-74 Trip-Command Reset

Once a trip command is issued, it is stored (see *Figure 5-73*).

You determine the criteria for resetting a trip command that has been issued with the parameter **`Reset of trip command`**.

- **`with dropout`**

  The trip command is reset if the function that initiated tripping resets its operate indication. This occurs typically with dropout. Command reset of the trip command takes place regardless of verification of the circuit-breaker condition.

- **`with I<`**

- **`with I< & aux.contact`**

  For these criteria, the state of the circuit breaker is also taken into account as a further criterion in addition to the dropout of the tripping function (operate indication is reset by command). You can select whether the state is determined by means of the current (**`with I<`**) or by means of the current in conjunction with the circuit-breaker auxiliary contacts (**`with I< & aux.contact`**). The behavior of these setting options only differs in one situation of the circuit-breaker state. If the circuit breaker is in the **opening** state, the trip command is reset in the case of the option **`with I<`**, whereas it is not reset yet in the case of the option with **`with I< & aux.contact`**. The **opening** state is detected if the auxiliary contacts still detect the circuit breaker as being closed and opening is detected via the decreasing current flow.

  As long as the circuit breaker is detected unambiguously as closed (**fully closed**), the trip command will not be reset with these setting options.

  The information about the condition of the circuit breaker is supplied by the **Circuit-breaker position recognition** function block (see *5.7.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions*). The determination of the various conditions is also described in this chapter.

5.7.6.2 Application and Setting Notes

Parameter: Reset of trip command

- Recommended setting value **`(_:5341:103) Reset of trip command`** = ***`with I<`***

Parameter Value	Description
with I<	With this setting, the trip command is reset as soon as the current is removed, provided the tripping function has dropped out. The most important factor for recognition of the open circuit breaker is the current falling short of the value set in the parameter **(_:2311:112) Current thresh. CB open**.
with I< & aux.contact	For this setting not only the current has to be removed, but also the circuit-breaker auxiliary contact has to report that the circuit breaker is open. This setting assumes that the setting of the auxiliary contact has been routed via a binary input (for more information, see *5.7.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information*).
with dropout	The setting can be selected for special applications in which the trip command does not result in complete interruption of the current in every case. In this case, the trip command is reset if the pickup of the tripping protection function drops out. The setting is useful if the load current in the system cannot be interrupted during the protection device test and the test current is fed in parallel with the load current.

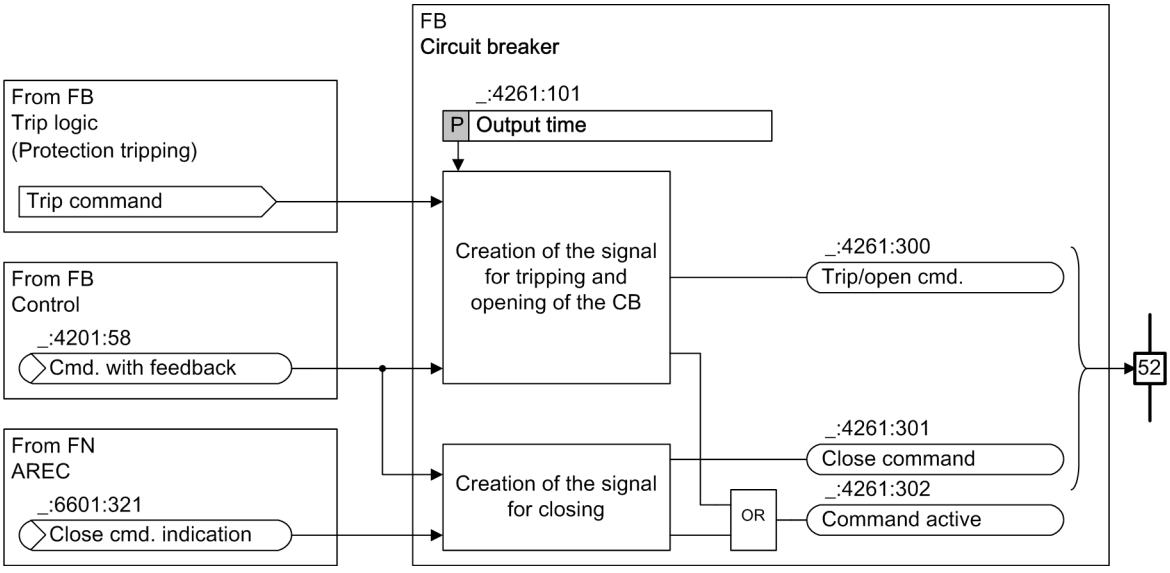
5.7.7 Circuit Breaker

5.7.7.1 Overview

The **Circuit-breaker** function block represents the physical switch in the SIPROTEC 5 device.
The basic tasks of this function block are the operation of the circuit breaker and the acquisition of the circuit-breaker auxiliary contacts and other circuit-breaker information.
The **Circuit-breaker** function block provides information about:

- Number of switching cycles
- Breaking current, breaking voltage, and breaking frequency
- Summation breaking current



5.7.7.2 Tripping, Opening, and Closing the Circuit Breaker

The circuit breaker is operated in the following situations:

- Tripping of the circuit breaker as a result of a protection trip command
- Opening of the circuit breaker as a result of control operations
- Closing of the circuit breaker as a result of automatic reclosing or control operations

Tripping is always the result of a protection function. The operate indications of the individual protection functions are summarized in the **Trip logic** function block. The trip command that causes the tripping in the **Circuit breaker** function block is generated there.

To operate the circuit breaker, the **Circuit-breaker** function block provides the output signals that must be routed to the corresponding binary outputs of the device (see *Table 5-13*).

[loausssc-090211-01.tif, 1, en_US]

Figure 5-75 Tripping, Opening, and Closing the Circuit Breaker

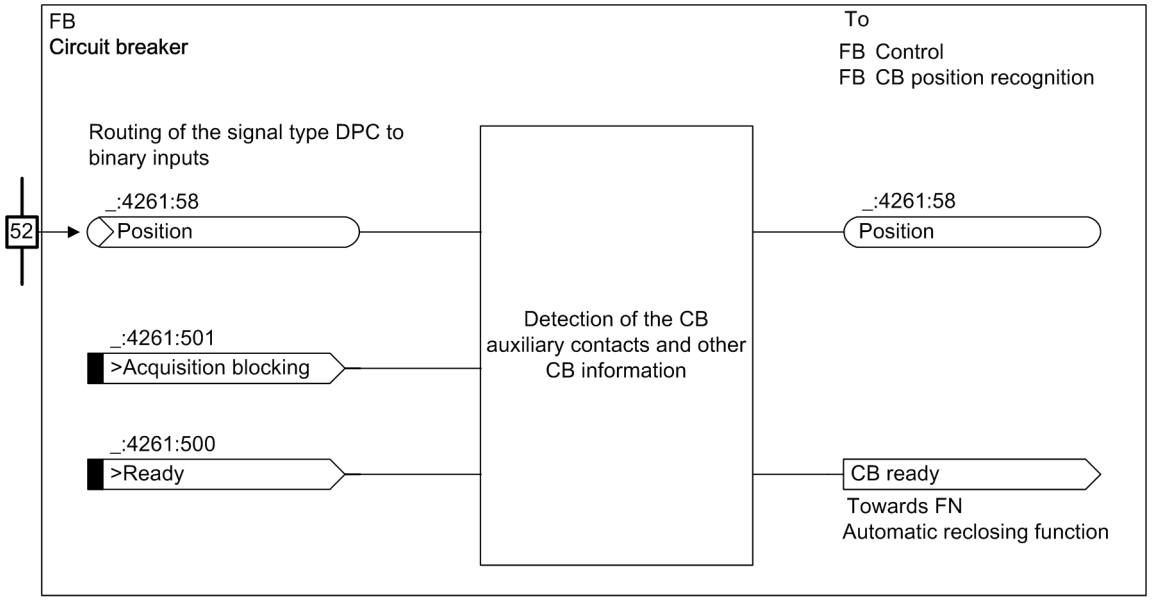


Table 5-13 Description of the Output Signals

Signal	Description	Routing Options
Trip/open cmd.	This signal executes all tripping and opening operations. The **Output time** parameter affects the signal. The signal is pending for the duration of this period, with the following exceptions: • Only when switched off by the control: The signal is canceled before expiration of the period if the auxiliary contacts report that the circuit breaker is open before expiration of the period. • Only in the event of protection tripping: The signal remains active as long as the trip command is still active after expiration of the period (see also *5.7.6.1 Function Description*). • Only in the event of protection tripping: With the routing option **Only saved in the event of tripping**, the signal remains pending until it is acknowledged manually. This only applies for protection tripping.	• Unlatched • Only saved in the event of protection tripping (not when opened)
Close command	This signal executes all closing operations. The **Output time** parameter affects the signal. The signal is pending for the duration of this period, with the following exception: The signal is canceled before expiration of the period if the auxiliary contacts report that the circuit breaker is closed before expiration of the period.	Normal routing
Command active	This signal is active as long as one of the binary outputs assigned to the signals **Trip/open cmd.** and **Close command** is active because a switching command is being executed by the control.	Normal routing

5.7.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information

To determine the circuit breaker position, the **Circuit-breaker** function block provides position signals (see next figure).

These signals are of the **Double-point indication** (DPC) type. A double-point indication can be routed to 2 binary inputs so that the open and closed circuit-breaker positions can be reliably acquired.

[loerfass-101210-01.tif, 1, en_US]

Figure 5-76 Acquisition of the Circuit-Breaker Information

Signal	Type	Description
Position	DPC	Acquisition of the circuit-breaker position The position **3-pole circuit breaker open** and/or the position **3-pole circuit breaker closed** can be acquired by routing to 1 or 2 binary inputs.

The signals must be routed to the binary input that is connected with the CB auxiliary contacts. The **open** and **closed** signals do not necessarily have to be routed in parallel. The advantage of parallel routing is that it can be used to determine an intermediate or disturbed position. On the other hand, this is not possible if only one signal is routed.

In the monitoring direction, the position signals generate the following information when the **open** and **closed** positions are acquired (see following table). This information is further processed by the **Circuit-breaker position recognition** and **Control** function blocks.

Information	Type	Description
Off	SPS	Circuit-breaker position is **opened**.
On	SPS	Circuit-breaker position is **closed**.
Intermediate position	SPS	Circuit-breaker position is in **intermediate position**.
Disturbed position	SPS	Circuit-breaker position is in **disturbed position**.
Not selected	SPS	The circuit breaker is **not selected** for a control operation.

Other input signals are:

Signal	Type	Description
>Acquisition blocking	SPS	This is used to activate acquisition blocking of the circuit-breaker auxiliary contacts (see Other Functions *3.8.3 Persistent Commands* for a description of acquisition blocking).

Signal	Type	Description
>Reset AcqBlk&Subst	SPS	This is used to reset acquisition blocking and manual update of the circuit breaker. Setting acquisition blocking and tracking is blocked with the input activated.
>Ready	SPS	The active signal indicates that the circuit breaker is ready for an **OFF-ON-OFF cycle**. The signal remains active as long as the circuit breaker is unable to trip. The signal is used in the **Automatic reclosing** and **Circuit-breaker test** functions.

Another output signal is:

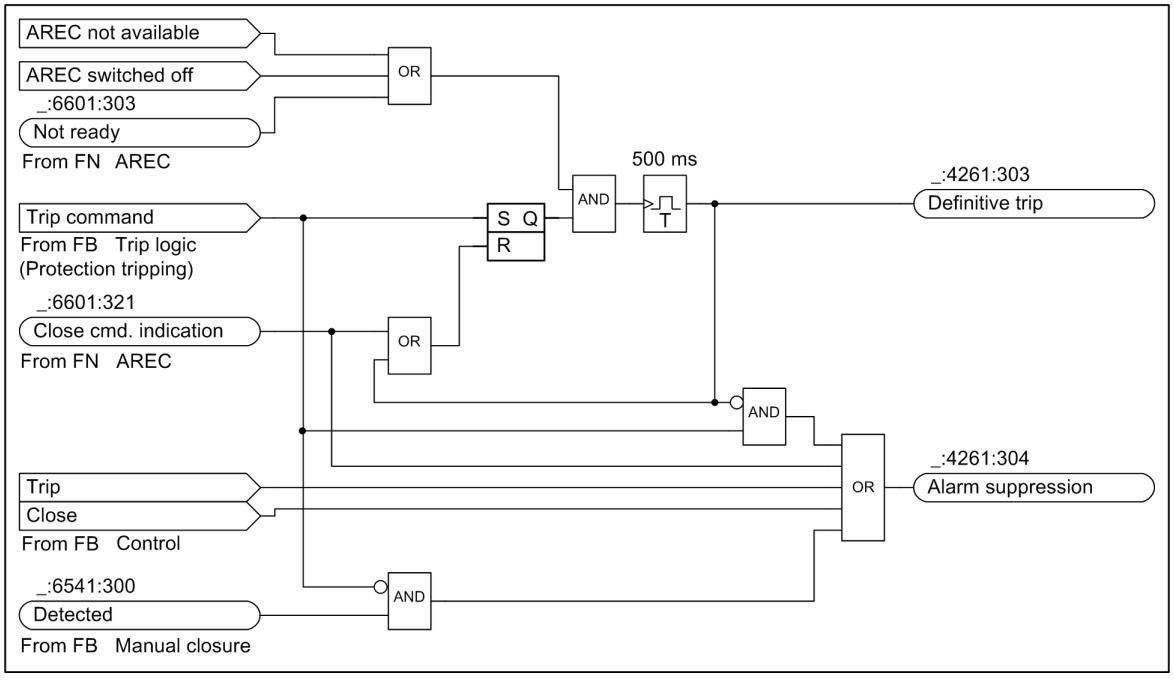
External health	SPS	This can be used to indicate the health of the physical circuit breaker. For this, you must acquire any failure information for the circuit breaker via a binary input. This failure information can set the appropriate state of the **External health** signal with a CFC chart (using the **BUILD_ENS** block). The signal has no effect on the health of the function block.

5.7.7.4 Definitive Tripping, Circuit-Breaker Tripping Alarm Suppression

Definitive Tripping

Definitive tripping is always pending whenever the **Automatic reclosing (AREC)** function does not carry out any reclosing after tripping. It follows that this is the case whenever an automatic reclosing is not present or the AREC has been switched off.

Circuit-Breaker Tripping Alarm Suppression



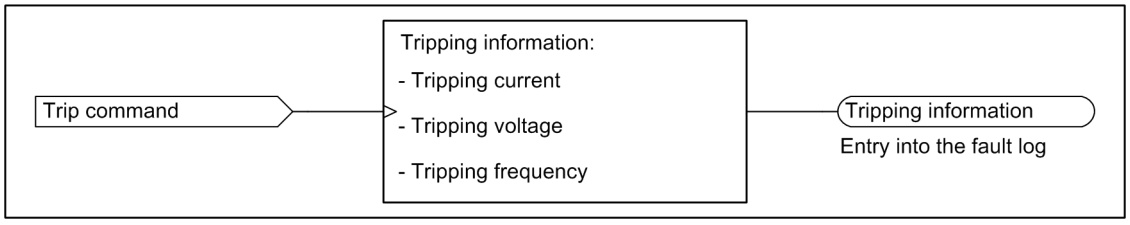
In certain systems, the user may wish to actuate an alarm (for example, a horn) when tripping (circuit-breaker tripping) occurs. This alarm should not to be issued if the circuit breaker is to be reclosed automatically after tripping or if it is to be closed or opened via the control. The alarm is only to be issued in the event of final tripping.

Depending on how the alarm is generated (for example, triggered by a fleeting contact of the circuit breaker), the **Alarm suppression** signal can be used to suppress the alarm.

The signal is generated if:

- A definitive protection tripping is not present
- The automatic reclosing function executes a closure
- The integrated control executes a closure or opening action
- External closing is detected via the **Manual close** function

For further information about its use, please refer to *5.7.9.2 Application and Setting Notes* .

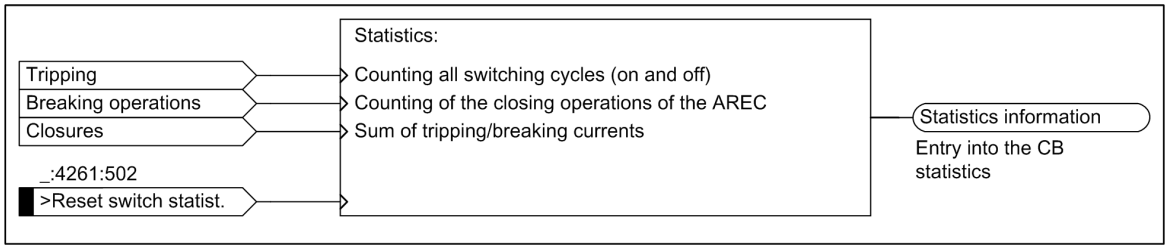


[lounterd-100611-01.tif, 1, en_US]

Figure 5-77 Definitive Tripping, Circuit-Breaker Tripping Alarm Suppression

5.7.7.5 Tripping and Opening Information

When a trip command is issued, the tripping information shown in the next figure is saved in the fault log.



[loausloe-081210-01.tif, 1, en_US]

Figure 5-78 Tripping Information

The following statistics information is saved for the circuit breaker:

- Number of switching cycles:
  All tripping, opening, and closing operations are counted.
- Number of closing operations by the automatic reclosing function
- Total of tripping and breaking currents

The statistics information can be individually set and reset via the device control. It is also possible to reset all values via the binary input signal **>Reset switch statist.**.

[lostatis-140113-01.tif, 1, en_US]

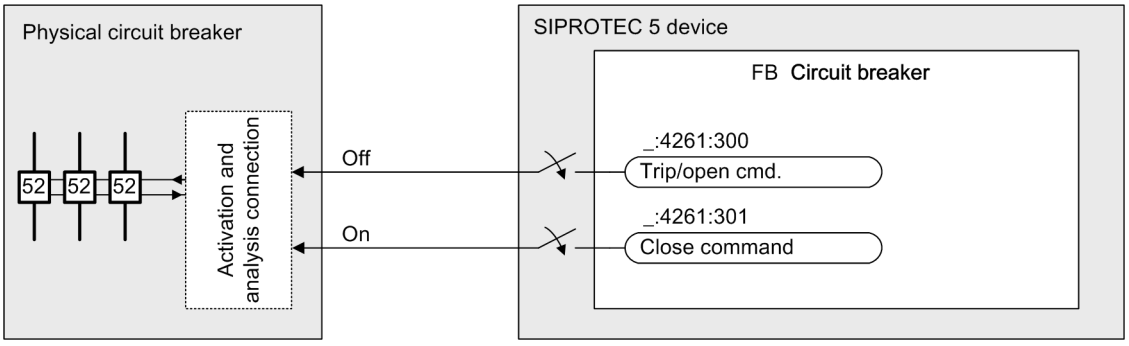


Figure 5-79 Statistics Information About the Circuit Breaker

5.7.7.6 Application and Setting Notes

Routings for Activation of the Circuit Breaker

Figure 5-80 shows the necessary routings:

- The device can execute 3-pole tripping (via the protection device).
- The device can execute 3-pole opening (via the control).
- The device can execute 3-pole closing (via AREC or via the control).

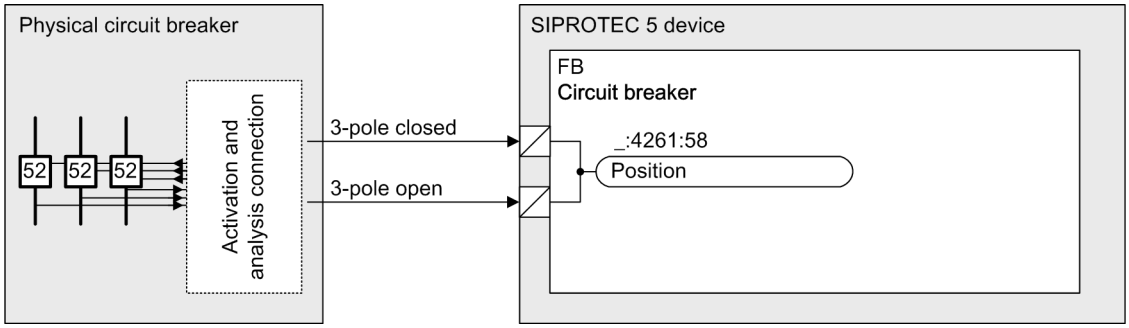
[loansteu-230311-01.tif, 1, en_US]

Figure 5-80 Activation of the Circuit Breaker

By routing the **`Trip/open cmd.`** signals to 1 or 2 binary outputs, you can carry out 1, 1.5, and 2-pole activations of the circuit breaker. You will find a detailed description of this in *8.2.2.3 Connection Variants of the Circuit Breaker*.

NOTE

Do not confuse these 1-pole, 1.5-pole, and 2-pole activations of the circuit breaker with 1-pole or 3-pole tripping of the circuit breaker.

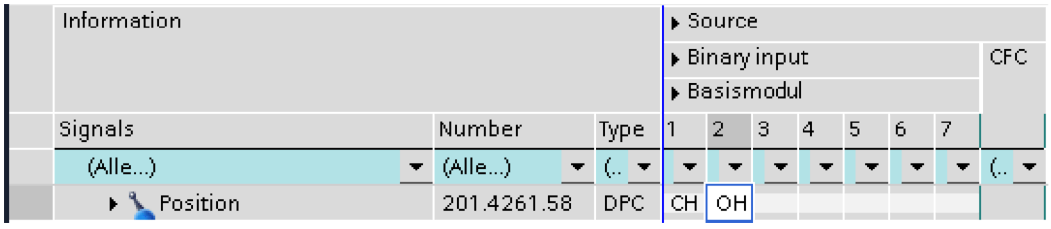


Routing for Analysis of the Circuit-Breaker Switch Position

For certain functions of the device, it is useful to detect the circuit-breaker switch position via its auxiliary contacts. These are for example:

- **Circuit-breaker position recognition** function block
- **Circuit-breaker failure protection** function
- **Control** function block

The operating principle of the auxiliary contacts is described in the individual functions.



Siemens recommends capturing the *`Circuit breaker is open in 3 poles`* and *`Circuit breaker is closed in 3 poles`* information via auxiliary contacts. This is the optimal configuration for the control functionality. For purely protection applications, it is also enough to capture just one of the 2 circuit-breaker positions.

[loauswer-230311-01.tif, 1, en_US]

Figure 5-81 Recommended Analysis of the Circuit-Breaker Switch Position when Used as a Protection and Control Device

The following diagram shows the recommended routing, in which **H** stands for **active with voltage**.

[scpolg3p-230311-01.tif, 1, en_US]

Figure 5-82 Routing for Acquisition of the Circuit-Breaker Switch Position via 2 Auxiliary Contacts

The device can also function without the analysis from the circuit-breaker auxiliary contacts, that is, routing of the auxiliary contacts is not absolutely necessary. However, this is a requirement for control functions.

Parameter: Output time

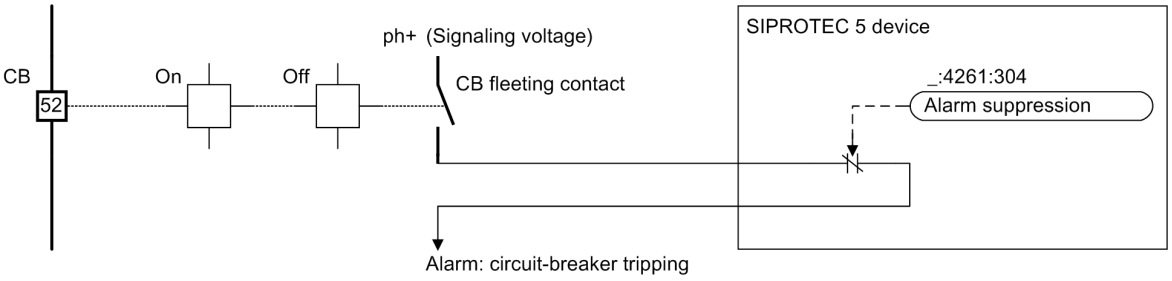
- Default setting **(_:101) Output time** = ***0.10 s***

The **Output time** parameter acts on the signals for tripping, opening, and closing of the circuit breaker.

CAUTION

Do not set a time that is too short.

If you set a time that is too short, there is a danger that the device contacts will interrupt the control circuit. If this happens, the device contacts will burn out.



✧ Set a time that is long enough to ensure that the circuit breaker reliably reaches its final position (**open** or **closed**) after a control operation.

Output Signal: Indication Suppression

Whereas in the case of feeders without an automatic reclosing function every trip command is final due to a protection function, the use of an automatic reclosing function should only cause the motion detector of the circuit breaker (fleeting contact on the circuit breaker) to trigger an alarm if tripping of the circuit breaker is definitive (see next figure for more details). Likewise, a tripping alarm should not be triggered for switching operations by the control.

For this, the alarm activation circuit should be looped via a suitably routed output contact of the device (output signal **Alarm suppression**). In the idle state and when the device is switched off, this contact is permanently closed. For this, an output contact with a break contact must be routed. The contact opens whenever the output signal **Alarm suppression** becomes active, so that tripping or a switching operation

does not cause an alarm (see the logic in *5.7.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information* for more details).

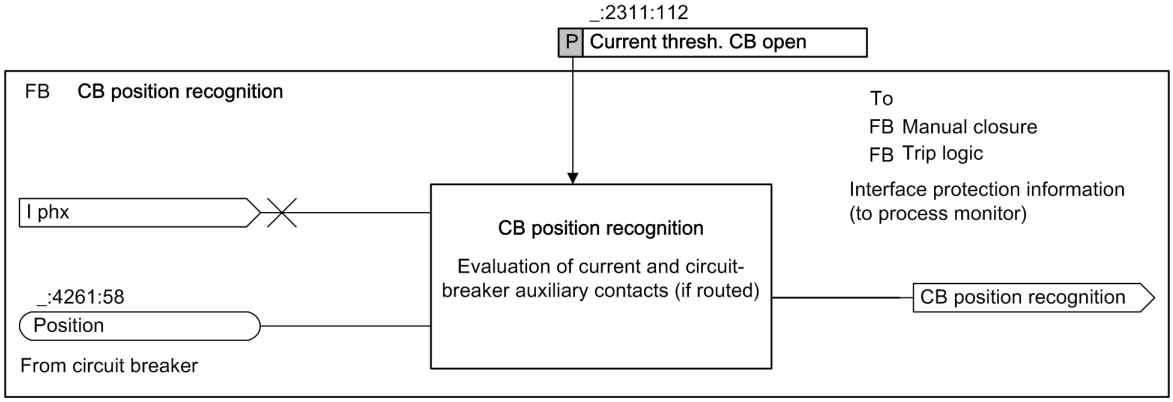
5.7.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions

5.7.8.1 Overview



This function block calculates the position of the circuit breaker from the evaluation of the auxiliary contacts and the current flow.

This information is needed in the following protection-related additional functions:

- Trip logic (see *5.7.6.1 Function Description*)
- Detection of manual closing (see *5.7.9.1 Function Description*)
- Process monitor (Standard V/I) *5.8 Process Monitor*)

Its use is described in the respective chapters.

The control does not use this information. The control evaluates the circuit-breaker auxiliary contacts.

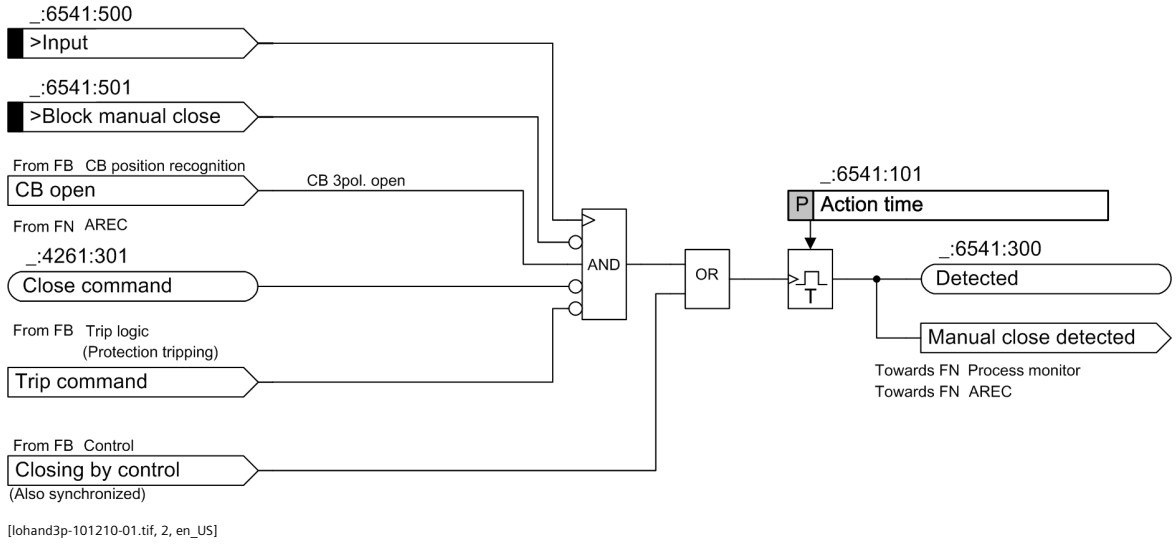
[lozust3p-070611-01.tif, 1, en_US]

Figure 5-84 Overview of the Circuit-Breaker Condition Position Function

Based on the link between the information from the auxiliary contacts and the current flow, the circuit breaker can assume the following positions:

Circuit-Breaker Condition	Description
Open	The circuit-breaker pole is detected unambiguously as **open** according to both criteria.
Closed	The circuit-breaker pole is detected unambiguously as **closed** according to both criteria.
Possibly open, possibly closed	These conditions can occur if the information is incomplete due to the routing of the auxiliary contacts and the condition can no longer be determined reliably. These **uncertain conditions** are evaluated differently by certain functions.
Opening	This is a dynamically occurring condition that results when, while a trip command is active and the auxiliary contact is still closed, the current is detected to have fallen below the threshold value because the current-flow criterion takes effect faster than the auxiliary contact can open.

5.7.9 Detection Manual Closure (for AREC and Process Monitor)



5.7.9.1 Function Description

Detection of Manual Closure (for AREC and Process Monitor)

The **Manual closure** function block detects any closure carried out by hand. This information is used in function, the **automatic reclosing (AREC)** and **Process monitor** (functions (within protection function groups).

You will find detailed information in the chapters Automatic reclosing function and Process monitor.

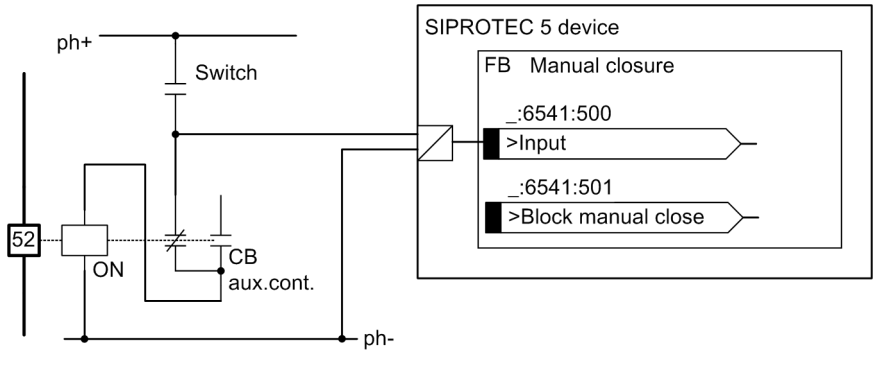
The following figure shows the logic for manual closure detection.

[lohand3p-101210-01.tif, 2, en_US]

Figure 5-85 Logic for Manual Closure Detection

External Manual Closure

An external manual closure is communicated to the device via the input signal **>Input**. The input signal can also be connected directly to the control circuit of the circuit-breaker closing coil. For this reason, detection is suppressed in the event of a close command by the AREC function. Detection via the input signal **>Input** is also blocked if the circuit breaker is closed or if a protection trip is active.



Internal Manual Closure

Manual closure is detected in all cases if a close command is transmitted by the internal control function of the device. This is possible because the control carries out plausibility checks itself and is also subject to interlocking.

5.7.9.2 Application and Setting Notes

Input Signals: >Input, >Blocking of Manual Closure

In practice, the input signal **>Input** is connected directly to the control circuit of the circuit-breaker closing coil (see following figure).

[losteuer-150113-01.tif, 1, en_US]

Figure 5-86 Connection of the Input Signal to the Control Circuit of the Circuit-Breaker Closing Coil

Every closure of the circuit breaker is recorded in the process. Therefore, detection is suppressed in the event of a close command by the internal AREC function of the device.

If external close commands are possible (actuation of the circuit breaker by other devices), which are not intended to prompt detection of a manual closure (for example, with an external reclosing device), this can be ensured in 2 ways:

- The input signal is connected in such a way that it is not activated in the event of external close commands.
- The external close command is connected to the blocking input **>Block manual close** for manual closure detection.

Parameter: Action time

- Recommended setting value **(_:101) Action time** = ***300 ms***

In order to ensure independence from manual activation of the input signal, the detection function is extended for a defined length of time using the parameter **Action time**.

Siemens recommends an action time of ***300 ms***.

5.7.9.3 Settings

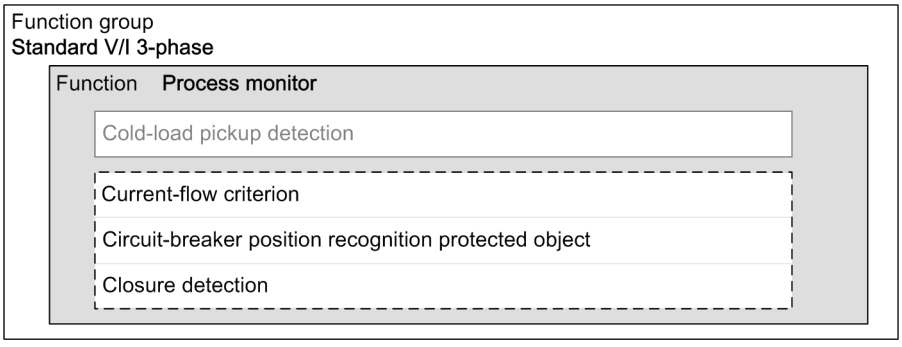
_:300	Manual close:Detected	SPS	O

5.8 Process Monitor

5.8.1 Overview of Functions



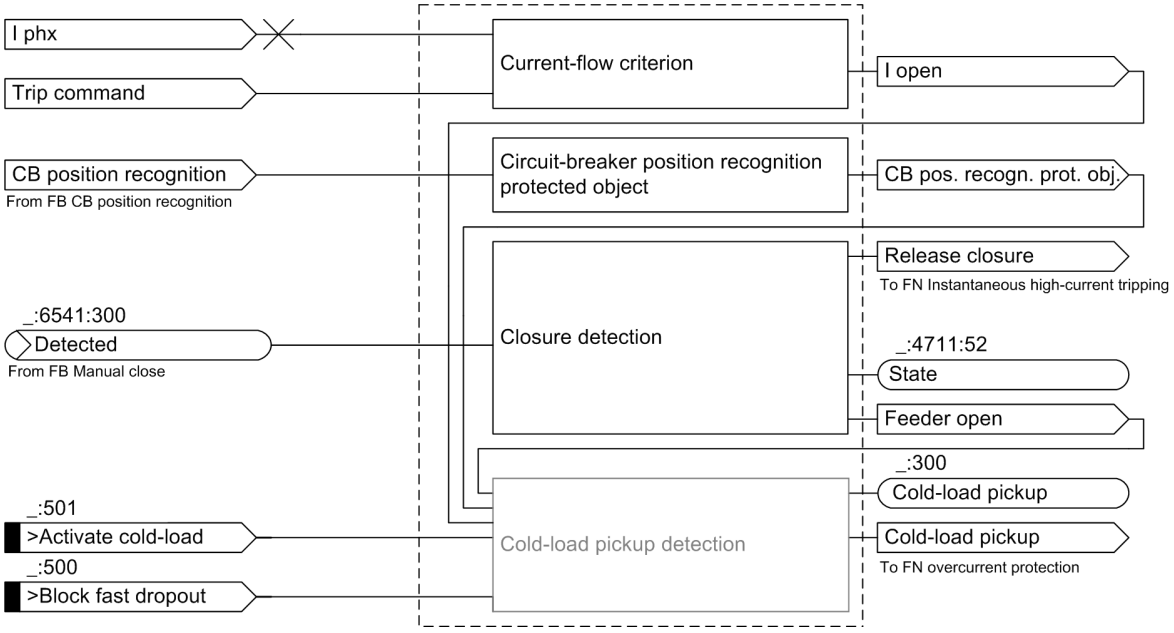
All function groups that have functions with dependencies on the state of the protected object contain a process monitor. The process monitor detects the current state of the protected object.

5.8.2 Structure of the Function

The **Process monitor** function is used in the **Standard V/I 3-phase** protection function group.

The **Process monitor** function is provided by the manufacturer with the following function blocks:

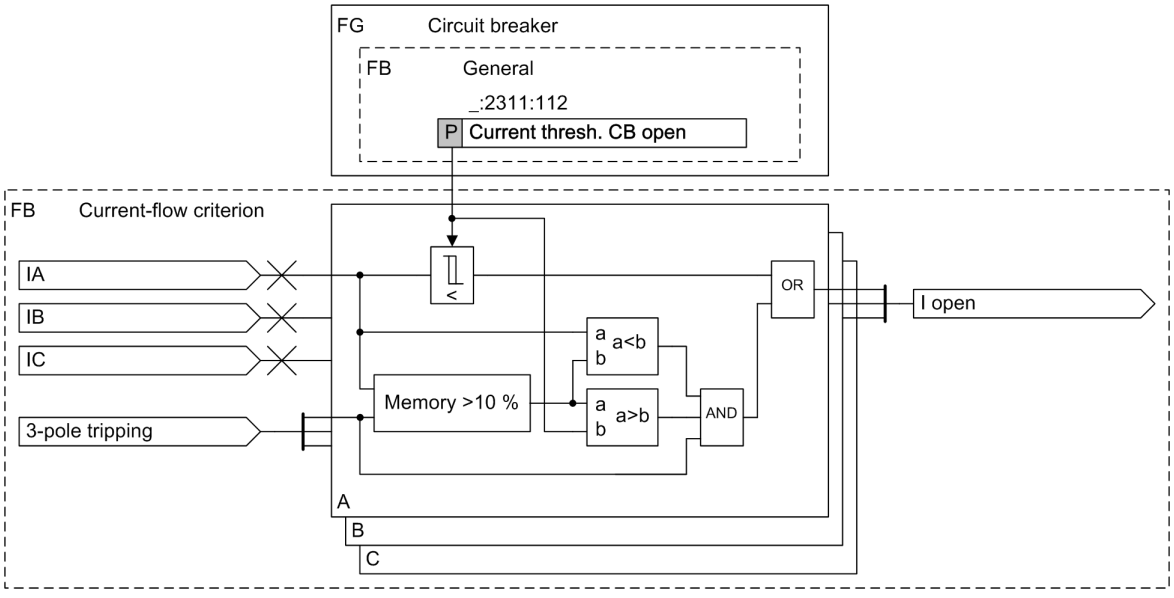
- Cold-load pickup detection (optional)
- Current-flow criterion
- Circuit-breaker condition
- Closure detection



[dwpro3pt-061212-01.tif, 2, en_US]

Figure 5-87 Structure/Embedding of the Function

You can activate the cold-load pickup detection as needed. All other stages of the process monitor run permanently in the background and are not displayed in DIGSI.



The following figure shows the relationships of the individual function blocks.

[lopro3pt-171012-01.tif, 2, en_US]

Figure 5-88 Logic Diagram of the Overall Function Process Monitor

5.8.3 Current-Flow Criterion

[loproikr-011112-01.tif, 1, en_US]

Figure 5-89 Logic Diagram of the Current-Flow Criterion Function Block

The **I open** signal of one phase is generated if one of the following conditions is met:

- A phase current falls below the set threshold of the **Current thresh. CB open** parameter. The hysteresis stabilizes the signal.
- The corresponding phase current, for example, **I A**, falls below 10 % of the phase current when the trip command arrives. If the current does not drop until after a delay due to current transformer influences, an open pole can therefore be detected quickly even after a high-current fault on the line.

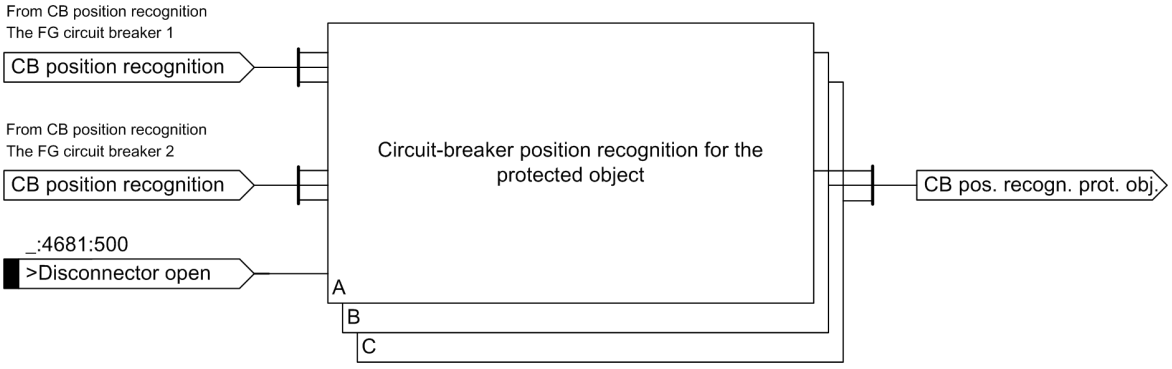
With the **Current thresh. CB open** parameter, you define the minimum current as the criterion for a deactivated line. The parameter lies in the **Circuit-breaker** function group. It acts both in the **Circuit-breaker** function group, for example circuit-breaker position recognition, and also for the process monitor in the Protection-function group.

5.8.4 Application and Setting Notes (Current-Flow Criterion)

Parameter: Current thresh. CB open

- Recommended setting value **(_:2311:112) Current thresh. CB open** = ***0.100 A***

The **Current thresh. CB open** parameter is used to define the threshold for the leakage current as the criterion for a deactivated line.



Set the **Current thresh. CB open** parameter so that the current measured when the feeder is deactivated falls below the value of the **Current thresh. CB open** parameter with certainty. The hysteresis is additionally active if the threshold is exceeded.

If parasitic currents, for example, due to induction, are ruled out when the feeder is deactivated, set the **Current thresh. CB open** parameter sensitively.

Siemens recommends a setting value of ***0.100 A***.

5.8.5 Circuit-Breaker Condition for the Protected Object

Logic

[loprolsz-140611-01.tif, 2, en_US]

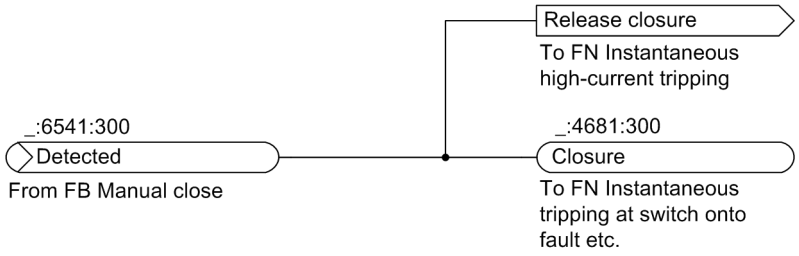
Figure 5-90 Logic Diagram of the Circuit-Breaker Condition for the Protected-Object Function Block

The circuit-breaker position recognition in the **Circuit breaker** (CB) function group provides the circuit-breaker condition by way of the internal signal *CB pos. recogn. prot. obj.*.

If a protected object is supplied via 2 circuit breakers (CBs), for example with the 1 1/2 circuit-breaker layout, then the circuit-breaker switch position of the protected object must be determined with the aid of both circuit breakers. In this case, the **Circuit-breaker position recognition for the protected object** function block connects the individual CB states. The connection provides the internal *CB pos. recogn. prot. obj.* signal to the other function blocks of the process monitor and to other functions, for example, **Trip in the event of weak infeed** and **Echo function for teleprotection method**, within the same function group.

If one of the following 2 conditions is met, the *CB pos. recogn. prot. obj.* signal is in the ***Open*** state:

- All connected circuit breakers signal the ***Open*** state internally.
- The **>Disconnector open** input is active.



If the following 2 conditions are met, the *CB pos. recogn. prot. obj.* signal is in the ***Closed*** state:

- At least one of the connected circuit breakers signals the ***Closed*** state internally.
- The **>Disconnector open** input is not active.

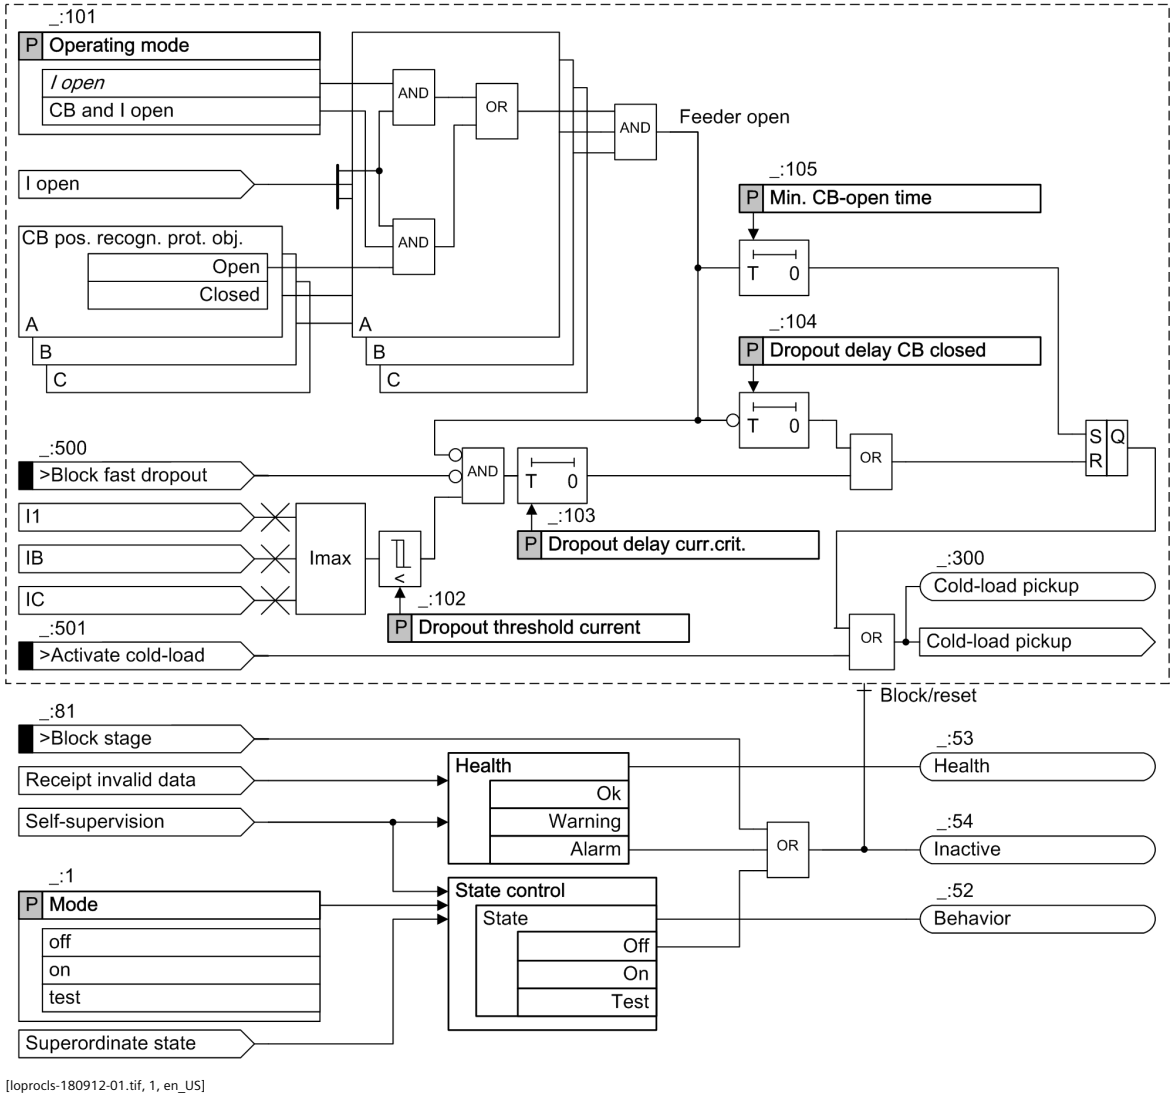
5.8.6 Closure Detection

The closure detection enables the immediate tripping of selected protection functions or protection stages when switching to short circuit or the reduction of the responsivity. The closure detection determines whether the protected object is switched on.

Logic

[loein6md-171012-01.tif, 1, en_US]

Figure 5-91 Logic Diagram of Closure Detection



For an applied binary input signal **`Detected`** (from Manual close function block), the indication **`Closure`** is active.

5.8.7 Information List

No.	Information	Data Class (Type)	Type
`Closure detec.`			
_:4681:500	Closure detec.:>Disconnector open	SPS	I
_:4681:300	Closure detec.:Closure	SPS	O

5.8.8 Cold-Load Pickup Detection (Optional)

Logic

[loprocls-180912-01.tif, 1, en_US]

Figure 5-92 Logic Diagram of the Cold-Load Pickup Detection Function Block

The **Cold-load pickup detection** function block detects that a specific time has been exceeded after deactivation of the line or protected object. If you want to connect the protected object again, you must note that an increased load-current requirement exists for a limited time after connection. This results from the nature of the load.

The **Cold-load pickup detection** function block ensures that different parameters are used for an adjustable time after connection. For example, for the time of the **`Min. CB-open time`** parameter, you can increase the threshold value of a protection function or you can select a special characteristic curve.

If the **Cold-load pickup detection** function block detects an open feeder and the set time of the **`Min. CB-open time`** parameter has expired, the indication **`>Activate cold-load`** is generated.

With the **`>Activate cold-load`** indication, you can activate a parameter set of the **Cold-load pickup** function. Via the binary input signal **`>Activate cold-load`**, you can also activate the **`>Activate cold-load`** indication directly.

If the **Cold-load pickup detection** function block detects closure and the corresponding load current, it starts the time set in the **`Dropout delay CB closed`** parameter. The **`>Activate cold-load`** indication and the activated parameter set are deactivated after this time has elapsed.

If, for the time set in the **Dropout delay curr.crit.** parameter, the maximum phase current falls below the threshold value **Dropout threshold current**, the parameter set for the **Cold-load pickup detection** function block is also deactivated. As a result, if the load current is very low, the action time **Dropout delay curr.crit.** of the **>Activate cold-load** indication can be shortened.

5.8.9 Application and Setting Notes (Cold-Load Pickup Detection)

NOTE

The settings and indications described in this chapter are only available when using the optional **Cold-load pickup detection** function block.

Parameter: Operating mode

- Default setting **(_:101) Operating mode** = ***I open***

With the **Operating mode** parameter, you set the criteria with which the Closure-detection function block operates.

Parameter Value	Description
I open	When the Current-flow criterion function block detects a clearing open condition, the decision is made for pickup. For this setting, make sure that the **Current thresh. CB open** parameter is set lower than the possible load current. If this is not the case, open is detected continuously and each fault current that exceeds the **Current thresh. CB open** parameter is interpreted as closure.
CB and I open	Closure is detected if one of the following conditions is met: • Analysis of the circuit-breaker auxiliary contact detects a clearing open condition in at least one phase. • The current-flow criterion detects a clearing open condition.

Parameter: Dropout threshold current

- Default setting **(_:102) Dropout threshold current** = ***1.00 A***

With the **Dropout threshold current** parameter, you set the threshold at which the output signal **Cold-load pickup** is deactivated when the current in at least one phase falls below this threshold.

Parameter: Dropout delay current criterion

- Default setting **(_:103) Dropout delay curr.crit.** = ***600 s***

With the **Dropout delay curr.crit.** parameter, you set the time for which the actual value must be below the **Dropout threshold current** threshold so that the output signal **Cold-load pickup** can be deactivated prematurely.

Parameter: Dropout delay CB closed

- Default setting **(_:104) Dropout delay CB closed** = ***3600 s***

With the **Dropout delay CB closed** parameter, you set the action time for the dynamic parameter set switching in the event of cold-load pickup detection.

Parameter: Min. CB open time

- Default setting **(_:105) Min. CB-open time** = ***3600 s***

With the **Min. CB-open time** parameter, you set the time after which the dynamic parameter set is activated in the event of **cold-load pickup** when the line is opened.

6.1 Power-System Data

6.1.1 Overview

The **Power-system data** are provided with each SIPROTEC 5 device and cannot be deleted. You will find them in DIGSI under **Settings** → **Power-system data**.

6.1.2 Structure of the Power-System Data

The **Power-system data** contain the block **General** and the **Measuring points** of the device. The following figure shows the structure of the **Power-system data**:

[dwandata-180912-01.tif, 2, en_US]

Figure 6-1 Structure of the Power-System Data

In order to adjust its functions to the application, the device requires some data about the power system. The necessary settings can be found in the Power-system data under **General** as well as in the **Measuring points**.

NOTE

You can find information on the supervision-function parameters in chapter *9.3 Supervision of the Secondary System*.

Type and scope of the required measuring points depend on the application. Possible measuring points are:

- Voltage 3-phase (measuring point V 3-ph)
- Current 3-phase (measuring point I 3-ph)
- Voltage 1-phase (measuring point V 1-ph)
- Current 1-phase (measuring point I 1-ph)

The measuring points have interfaces to the function groups requiring voltage and/or current measured values of the power system.

6.1.3 Application and Setting Notes – General Settings

Parameter: Phase sequence

- Recommended setting value **(_:2311:101) Phase sequence**= ***ABC***

The parameter **Phase sequence** is used to set the phase sequence (***ABC***) or (***ACB***). The setting value applies to the entire SIPROTEC 5 device.

Use the **General** function to set the settings in the power-system data.

6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph)

The following example describes the settings of the voltage measuring point **Measuring point V-3ph** (voltage 3-phase). Settings for the supervision functions are also located in the voltage measuring point. The description of these settings can be found in chapter Supervision Functions .

Parameter: Rated primary voltage

- Default setting **(_:8911:101) Rated primary voltage** = ***400.000 kV***

The **Rated primary voltage** parameter is used to set the primary rated voltage of the voltage transformer.

Parameter: Rated secondary voltage

- Default setting **(_:8911:102) Rated secondary voltage** = ***100 V***

The **Rated secondary voltage** parameter is used to set the secondary rated voltage of the voltage transformer.

Parameter: Matching ratio Vph / VN

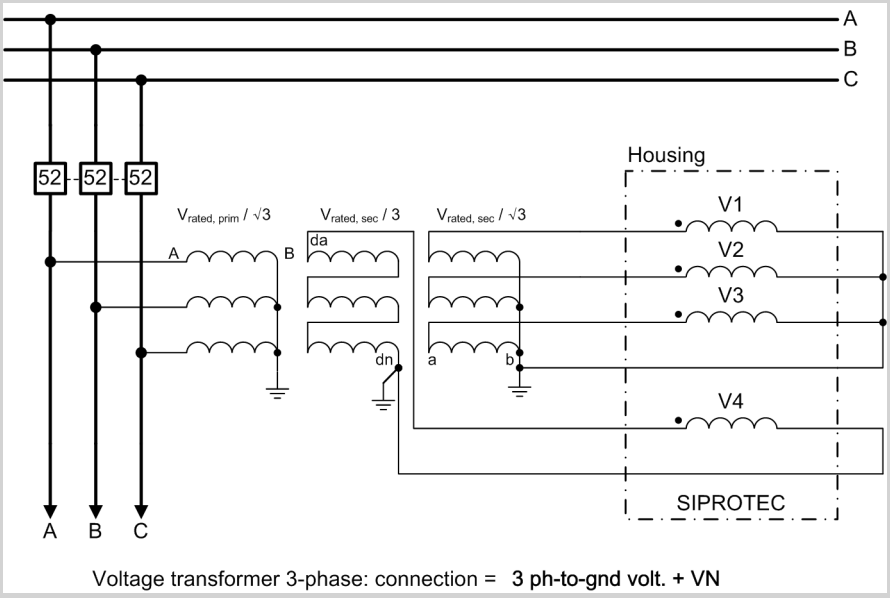
- Default setting **(_:8911:103) Matching ratio Vph / VN** = ***1.73***

With the parameter **Matching ratio Vph / VN**, you set the deviation between the calculated zero-sequence voltage and the residual voltage measured directly via a measuring input. The different transmission ratio of the voltage transformers is the cause for the deviation (see *Figure 6-2*).

The **Matching ratio Vph / VN** is equal to the ratio $3V_{0\,sec}/V_{N\,sec}$

with

$V_{0\,sec}$	Calculated zero-sequence voltage
$V_{N\,sec}$	Measured residual voltage



The zero voltage is calculated as phase-to-ground voltages. The residual voltage is measured on the open delta winding of the voltage transformer. For 1-phase voltage transformers, the residual voltage is measured in the generator or the transformer neutral point.

NOTE

The measurement residual voltage $V_{N\,sec}$ is converted to a zero-sequence voltage in the device as follows:

$$V_{0\,sec} = V_{N\,sec} \cdot \frac{\text{Matching ratio Vph/VN}}{3}$$

EXAMPLE 1:

[dw_bsp1uwdl_anpassfaktor, 2, en_US]

Figure 6-2 3-Phase Voltage Transformer: Connection = 3 Phase-to-Ground Voltage + VN

If the connection type of the voltage transformer is ***3 ph-to-gnd volt. + VN*** (parameter: **VT connection**) and the voltage input V4 is connected to the broken-delta winding of the voltage transformer (da/dn), the **Matching ratio Vph / VN** is as follows:

When changing the neutral point according to *Figure 6-2* , this results in the following values:

- The calculated secondary zero-sequence voltage $V_{0\ sec}$ is equal to the secondary phase-to-ground voltage. Expressed as secondary transformer rated voltage, then $V_{rated\ sec}/\sqrt{3}$.
- The measured residual voltage on the open delta winding is the sum of the voltage drops on the 3 sides. Expressed with the side ratio, the result is $V_{N,\ sec} = 3\ V_{rated,sec}/3$.

Calculate the **Matching ratio Vph / VN** parameter as follows:

$$\text{Matching ratio } \frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\ sec}}{V_{N\ sec}} = \frac{3 \cdot \frac{V_{nom\ sec}}{\sqrt{3}}}{3 \cdot \frac{V_{nom\ sec}}{3}} = \frac{3}{\sqrt{3}} = \sqrt{3} = 1.73$$

[fo_bsp1, 1, en_US]

Set **Matching ratio Vph / VN** = ***1.73***.

In **example 1** $V_{rated\ sec}$, the phase-to-ground voltage and the secondary voltage on the open delta winding were identical. If these voltages are different, use the actual numerical values in the calculation.

EXAMPLE 2:

Phase-to-ground voltage	$V_{rated\ sec}$ = 100 V
Broken-delta winding (for example, grounding transformer in generator protection)	$V_{rated\ sec}$ = 500 V The voltage input of the device is designed for a continuous operation using 230 V max. Therefore, the voltage on the open delta winding (500 V) is reduced to a 5:2 ratio, using an Ohmic divider. In order to calculate the matching factor, the secondary voltage of 200 V will be applied.

Calculate the **Matching ratio Vph / VN** parameter as follows:

$$\text{Matching ratio}\ \frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\ \text{sec}}}{V_{\text{N sec}}} = \frac{3 \cdot \frac{V_{\text{nom sec}}}{\sqrt{3}}}{3 \cdot \frac{V_{\text{nom sec}}}{3}} = \frac{3 \cdot \frac{100\ \text{V}}{\sqrt{3}}}{3 \cdot \frac{200\ \text{V}}{3}} = \frac{3}{2 \cdot \sqrt{3}} = \frac{\sqrt{3}}{2} = 0.866$$

[fo_bsp2, 1, en_US]

Set **Matching ratio Vph / VN** = ***0.866***.

Interpretation of the result:

The zero-sequence voltage calculated from the phase-to-ground voltage is 57.73 V (= 100V/√3). The measured residual voltage is 200 V. The calculated adaptation factor is 0.866. The measured residual voltage is converted to a zero-sequence voltage inside the device:

$$V_{0\ \text{sec}} = V_{\text{N sec}} \cdot \frac{\text{Matching ratio Vph/VN}}{3} = 200\ \text{V} \cdot \frac{0.866}{3} = 57.73\ \text{V}$$

[fo_umrechnung2, 2, en_US]

NOTE

During the ground-fault test, the set adaptation factor can be checked by comparing the operational measured values. The operational measured values contain the calculated zero-sequence voltage $V_{0\ \text{sec}}$ and the measured residual voltage $V_{\text{N sec}}$. Proceed with the compilation as follows:

$$\text{Matching ratio.}\frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\ \text{sec}}}{V_{\text{N sec}}}$$

The **Matching ratio Vph / VN** parameter is significant for the following functions:

- Overvoltage protection with zero-sequence voltage/residual voltage
- Measured-value supervision
- Scaling of the faulty and measured values

Parameter: VT connection

- Default setting **(_:8911:104) VT connection** = ***3 ph-to-gnd volt. + VN***

The parameter **VT connection** shows the connection type of the voltage transformer for the 3-phase voltage measuring point. The parameter can be found in the DIGSI 5 project tree under **Name of the device** → **Settings** → **Power-system data** → **Measuring point V 3-phase**. You cannot change the connection type of the voltage transformer in the power-system data.

You can change the connection type of the voltage transformer only under measuring point routing in DIGSI 5. Under **Name of the device** → **Measuring-points routing** → **Voltage measuring points**, select the desired connection type under **Connection type**. The following types of connections are possible:

- ***3 ph-to-gnd volt. + VN***
- ***3 ph-to-gnd voltages***
- ***3 ph-to-ph volt. + VN***
- ***3 ph-to-ph voltages***
- ***2 ph-to-ph volt. + VN***
- ***2 ph-to-ph voltages***
- ***2 ph-to-gnd volt. + VN***
- ***2 ph-to-gnd voltages***

Depending on the connection type selected, you must route the measured values to the terminals of the voltage measuring point in DIGSI 5. You can find connection examples for voltage transformers in the chapters

A.8 Connection Examples for Voltage Transformers for 7SJ85 and *A.9 Connection Examples for Voltage Transformers for 7SJ82*. The connection examples provide assistance when selecting the type of connection.

Parameter: Inverted phases

- Default setting **(_:8911:106) Inverted phases** = ***none***

The **Inverted phases** parameter is intended for special applications, for example, pumped-storage hydropower plants (see chapter Phase-rotation reversal). This default setting may be retained for power-system protection applications.

Parameter: Tracking

- Default setting **(_:8911:111) Tracking** = ***active***

The **Tracking** parameter is used to determine whether the measuring channels of this measuring point shall be used to determine the sampling frequency.

The sampling frequency of the device is adjusted to the power frequency. The device selects a measuring channel, through which the sampling frequency is determined. Preferably, this should be a voltage metering channel. This validity of the signal is monitored (minimum level, frequency range). If these values are invalid, the device switches to another channel (etc.). Once switched to a current channel, the system automatically switches back to this channel if a voltage channel is valid again.

Parameter Value	Description
active	If the parameter **Tracking** = ***active*** has been set, the measuring point will be included when determining the sampling frequency. If possible, only the 3-phase measuring points shall be considered. Siemens recommends using the default setting. **Note:** If the parameter **Tracking** = ***active*** , the determined sampling frequency applies to all functions in the device that do not use fixed sampling rates.
inactive	If the channels of the measuring point are not to be considered for determining the sampling frequency, please select the setting value ***inactive***.

Parameter: Magnitude correction

- Default setting **(_:3811:103) Magnitude correction** = ***1.000***

When using the **Magnitude correction** parameter, the magnitude (magnitude correction) is adjusted for the voltage input. This allows you to correct the tolerances of the primary current transformer phase-selectively. The magnitude correction may be required for highly precise measurements. Use a comparison measurement to determine the setting value (for example, a high-precision measuring-voltage transformer). If a primary correction is not necessary, retain the default setting.

NOTE

The **Magnitude correction** parameter has nothing to do with the internal adjustment of the input circuit.

6.1.5 Application and Setting Notes for Measuring Point Current 3-Phase (I-3ph)

The following example describes the settings for the current **Measuring point I 3-ph** (Current 3-phase). The supervision function settings are also located in the current measuring point. The description of these settings can be found in chapter *9 Supervision Functions*.

Parameter: CT connection

- Default setting **(_:8881:115) CT connection** = ***3-phase + IN-separate***

The parameter **CT connection** shows the connection type of the current transformer for the 3-phase current measuring point. The parameter can be found in the DIGSI 5 project tree under **Name of the device → Settings → Power-system data → Measuring point I 3-phase**. You cannot change the connection type of the current transformer in the **Power-system data**.

You can change the connection type of the current transformer only under measuring point routing in DIGSI 5. Under **Name of the device → Measuring point routing → Current measuring points**, select the desired connection type under Connection type. The following types of connections are possible:

- ***3-phase + IN-separate***
- ***3-phase + IN***
- ***3-phase***
- ***3-phase, 2 primary CT***
- ***3ph,2prim.CT + IN-sep***
- ***2ph, 2p. CT + IN-sep***

Depending on the connection type selected, you must route the measured values to the terminals of the current measuring point in DIGSI 5. You can find connection examples for current transformers in chapter *A.7 Connection Examples for Current Transformers* . The connection examples provide assistance when selecting the type of connection.

Parameter: Tracking

- Default setting **(_:8881:127) Tracking** = ***active***

With the parameter**Tracking**, you specify whether you would like to work with the sampling-frequency tracking function.

Parameter Value	Description
active	If the parameter **Tracking** = ***active*** has been set, the measuring point will be included when determining the sampling frequency. If possible, only the 3-phase measuring points shall be considered. Siemens recommends using the default setting. **Note:** If the parameter **Tracking** = ***active***, the determined sampling frequency applies to all functions in the device not using fixed sampling rates.
inactive	If the channels of the measuring point are not to be considered for determining the sampling frequency, please select the setting value ***inactive***.

Parameter: Rated primary current

- Default setting **(_:8881:101) Rated primary current** = ***1000 A***

With the **Rated primary current** parameter, the active rated primary current of the current transformer is set.

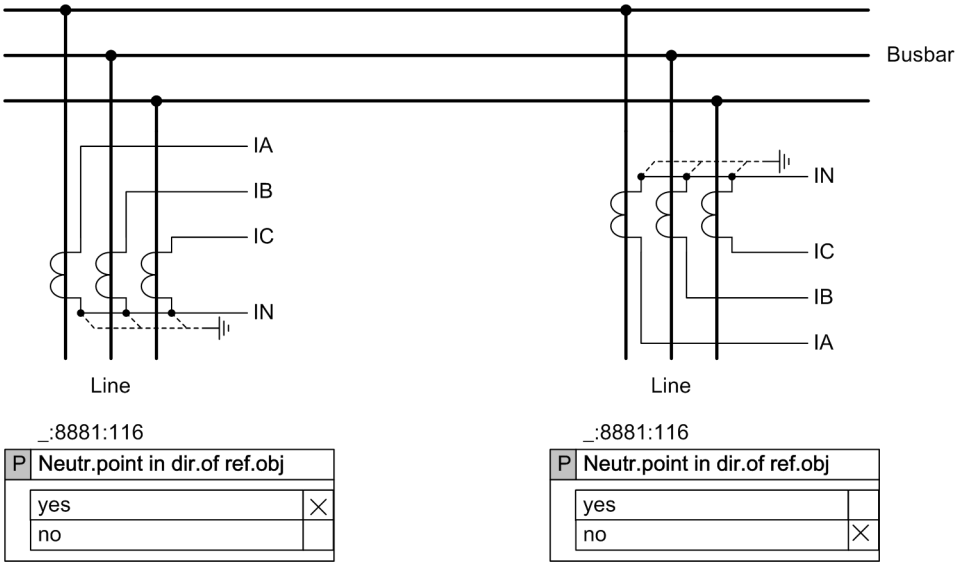
Parameter: Rated secondary current

- Default setting **(_:8881:102) Rated secondary current** = ***1 A***

With the **Rated secondary current** parameter, you set the current rated secondary current of the current transformer.

Parameter: Current range

- Default setting 7SJ82 **(_:8881:117) Current range** = ***50 x IR***
- Default setting 7SJ85 **(_:8881:117) Current range** = ***100 x IR***



The **Current range** parameter allows you to set the dynamic range for the current input. Please retain the default setting for power-system protection applications. The current measuring range 1.6 x Irated applies for the connection type ***3-phase + IN-separate*** and the sensitive current input or for the measuring inputs.

Parameter: Neutr.point in dir.of ref.obj

- Default setting **(_:8881:116) Neutr.point in dir.of ref.obj** = ***yes***

The **Neutr.point in dir.of ref.obj** parameter is used to set the direction of the neutral point of the current transformer (see following figure). Often, the neutral point of the current transformer is determined by the direction of the protected object (for example, in the direction of the line, cable, transformer). For this reason, the default setting of the parameter was defined as ***yes***.

When switching the parameter, the direction of the phase currents and of the ground current IN or IN-separate is rotated device-internally.

[dwpolstromwdl-251013, 1, en_US]

Figure 6-3 Polarity of Current Transformers

Parameter: Inverted phases

- Default setting **(_:8881:114) Inverted phases** = ***none***

The **Inverted phases** parameter is intended for special applications, for example, pumped-reservoir plants (see Chapter Phase-rotation reversal). This default setting may be retained for power-system protection applications.

Parameter: Magnitude correction

- Default setting **(_:3841:103) Magnitude correction** = ***1.000***

When using the **Magnitude correction** parameter, you adjust the amplitude (amplitude correction) for the current input. This allows you to correct the tolerances of the primary current transformer phase-selectively. The magnitude correction may be required for highly precise measurements. Use a comparison measurement to determine the setting value (for example, a high-precision measuring-voltage transformer). If a primary correction is not necessary, retain the default setting.

NOTE

The **Magnitude correction** parameter has nothing to do with the internal adjustment of the input circuit.

Note Regarding Routable Data

Indications for the current rotating field and the information pertaining to the sampling-frequency tracking can be found in **Information routing** under **Power-system data** → **General** in DIGSI 5. The indication *Freq.out of oper.range* means that the frequency operating range has been exceeded. Either the

frequency is out of range (10 Hz to 80 Hz) or the input signals are too small for a manual update. Should this condition occur, the system switches the update frequency to a sampling rate that corresponds to the rated frequency.

Furthermore, there are 2 additional measured frequency values available. The measured value *f sys* displays the current system frequency, and the measured value *f track* displays the sampling frequency currently set. Siemens recommends routing both measured values as fault-recording channel.

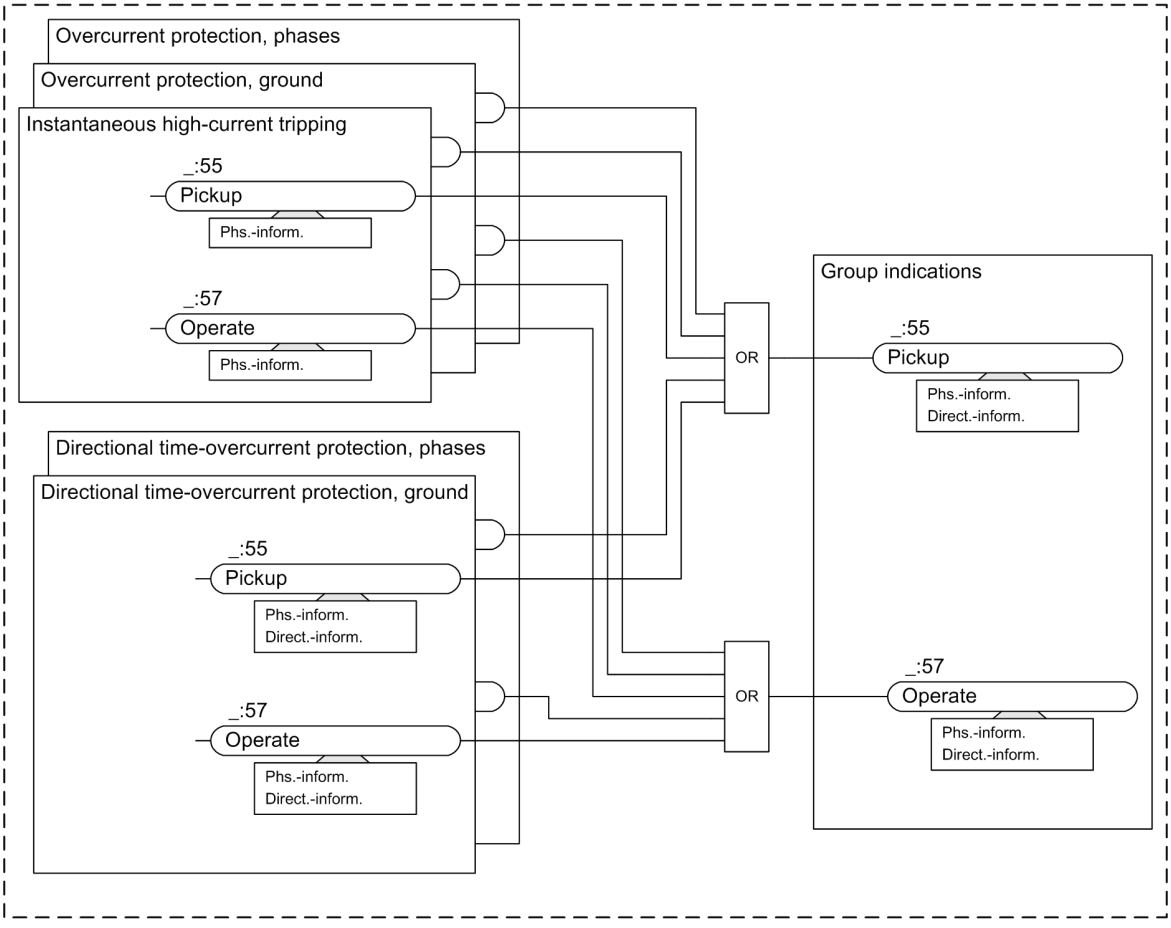
6.2 Group Indications of Overcurrent Protection Functions

6.2.1 Description



The function block **Group indications of the overcurrent protection functions** uses the pickup and operate indications of the following functions:

- Overcurrent Protection, Phases
- Overcurrent Protection, Ground
- Directional time-overcurrent protection, phases
- Directional Overcurrent Protection, Ground
- Instantaneous High-Current Tripping

The group indications of the overcurrent protection are generated by a logical OR of the stage-selective pickup and operate indications of the functions listed above (see also *Figure 6-4*):

- **`Pickup`**
- **`Operate`**

The pickup and operate indications are output, where present, with direction information.

[loocgri2-271112-01.tif, 2, en_US]

Figure 6-4 Logic Diagram of the Overcurrent Protection Group Indications

6.3 Overcurrent Protection, Phases

6.3.1 Overview of Functions

The **Overcurrent protection, phases** function (ANSI 50/51):

- Detects short circuits in electrical equipment
- Can be used as backup overcurrent protection in addition to the main protection

6.3.2 Structure of the Function

The **Overcurrent protection, phases** function is used in protection function groups. 2 kinds of functions are available for the 3-phase overcurrent protection:

- **Overcurrent protection, phases – advanced** (50/51 OC-3ph-A)
- **Overcurrent protection, phases – basic** (50/51 OC-3ph-B)

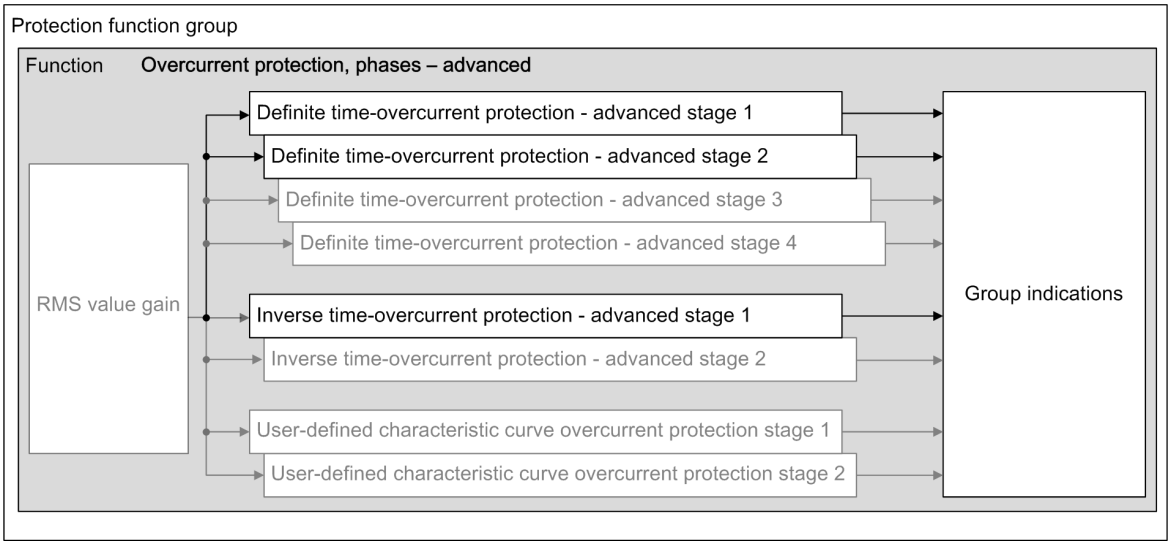
The Basic function type is provided for standard applications. The Advanced function type offers more functionality and is provided for more complex applications.

Both function types are preconfigured by the manufacturer with 2 **Definite time-overcurrent protection** stages and with 1 **Inverse time-overcurrent protection** stage.

In the **Overcurrent protection, phase– advanced** function type, the following stages can be operated simultaneously:

- Maximum of 4 stages **Definite time-overcurrent protection – advanced**
- 2 stages **Inverse time-overcurrent protection – advanced**
- 2 stages **User-defined overcurrent protection characteristic curve**

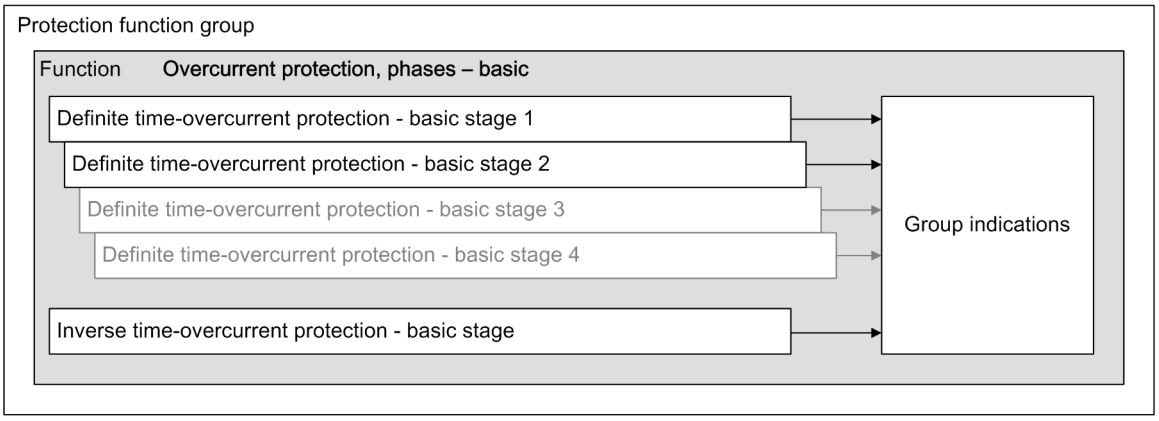
In the **Overcurrent protection, phases – basic** function type, the following stages can be operated simultaneously:



- Maximum of 4 stages **Definite time-overcurrent protection – basic**
- 1 stage **Inverse time-overcurrent protection – basic**

Stages that are not preconfigured are shown in gray in the following figures. Apart from the tripping delay characteristic, the stages are identical in structure.

The optional function block **Filter** offered in the advanced function allows to gain harmonics or to compensate the amplitude attenuation for the RMS value.



The group-indication output logic generates the following group indications of the protection function by the logical OR of the stage-selective indications:

- **`Pickup`**
- **`Operate`**

[dw_ocp_ad with Filter.tif, 1, en_US]

Figure 6-5 Structure/Embedding of the Function Overcurrent Protection, Phases – Advanced

[dwocpbp1-210113-01.tif, 2, en_US]

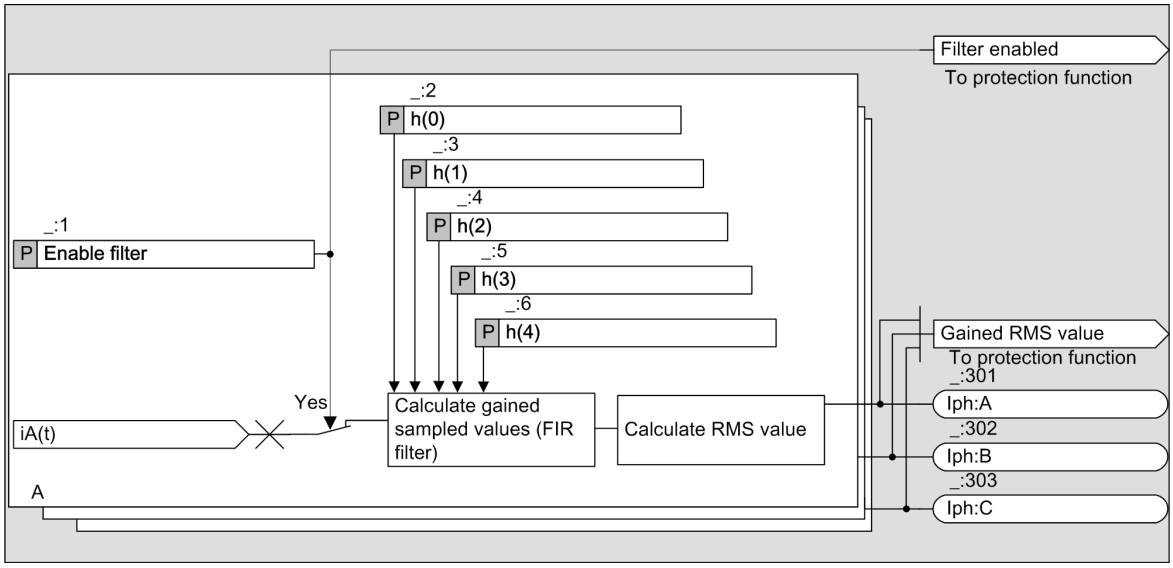
Figure 6-6 Structure/Embedding the Function Overcurrent Protection, Phases – Basic

If the device-internal functions listed in the following are present in the device, these functions can influence the pickup values and tripping delays of the stages or block the stages. The stage can also be affected by an external source via a binary input signal.

- Automatic reclosing (AREC)
- Cold-load pickup detection
- Binary input signal

If the device is equipped with an **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer-inrush currents (available in both function types).

6.3.3 Filter for RMS Value Gain



6.3.3.1 Description

The function block **Filter** can be used to adapt the RMS value for 2 means:

- To gain harmonics in a defined way. Higher harmonics can stress the protected object thermally more than lower harmonics. This is the case for reactors applied in AC filters. In addition, the amplitude attenuation of higher frequencies due to the anti-aliasing filter of the device is automatically compensated by the filter
- To only compensate the amplitude attenuation of higher frequencies due to the anti-aliasing filter

The filter gain (amplitude response) is realized by a 9-order FIR filter.

Logic

[lo_TOLP_FilterStage, 1, en_US]

Figure 6-7 Logic Diagram of the Function Block Filter

The FIR filter gains the 8-kHz sampled values according to the set filter coefficients. Afterwards, the RMS value is calculated. The symmetrical 9-order filter coefficients are set via the values of the respective parameters **`h(0)`**, **`h(1)`**, **`h(2)`**, **`h(3)`**, and **`h(4)`**.

NOTE

A FIR-filter configuration tool is provided as an auxiliary PC tool. With this PC tool, the coefficients h(0), h(1), h(2), h(3), h(4) of the FIR filter are generated according to the required gain factors (amplitude response). The tool can be obtained from the SIPROTEC download area. For more information about the tool, refer to the tool help function.

The gained RMS value is delivered to the protection stages only when the function block **Filter** is instantiated and the parameter **`Enable filter`** is set as ***`yes`***. Otherwise, the normal RMS value is used.

Functional Measured Values

Values	Description	Primary	Secondary	% Referenced to
Iph:A	Gained RMS measured value of current A	kA	A	Parameter **`Rated current`**
Iph:B	Gained RMS measured value of current B	kA	A	Parameter **`Rated current`**

Values	Description	Primary	Secondary	% Referenced to
Iph:C	Gained RMS measured value of current C	kA	A	Parameter **Rated current**

You can find the parameter **Rated current** in the **FB General** of function groups where the **Overcurrent protection, phases – advanced** function is used.

If the parameter **Enable filter** is set to ***no***, the functional measured values are shown as ---.

6.3.3.2 Application and Setting Notes

Parameter: Enable filter

- Default setting **(_:1) Enable filter** = ***no***.

With the parameter **Enable filter**, you set whether the **Filter** is enabled.

Parameter Value	Description
yes	If gained RMS values should be used in one of the protection stages, set parameter **Enable filter** = ***yes***.
no	If no gained RMS values are needed, set the parameter **Enable filter** = ***no***.

Parameter: h(0),h(1),h(2),h(3),h(4)

- Default setting **(_:2) h(0)** = ***0.000***
- Default setting **(_:3) h(1)** = ***0.000***
- Default setting **(_:4) h(2)** = ***0.000***
- Default setting **(_:5) h(3)** = ***0.000***
- Default setting **(_:6) h(4)** = ***1.000***

With the default value of the coefficients, the filter has no effect and no gain is applied.

If the filter shall be applied to adapt the RMS value calculation to a specific protection object such as a reactor, the reactor manufacturer has to provide the required amplitude response (gain factors) for the reactor. To determine the coefficients h(0) to h(4) for the FIR filter, you must enter the gain factors into the auxiliary PC tool which is available in the SIPROTEC download area. The 5 required coefficients are generated by the tool. They have to be entered manually as settings to configure the filter. The amplitude attenuation of higher frequencies due to the anti aliasing filter of the device is automatically taken into account and compensated by the filter.

To only compensate the attenuation of higher frequencies by the device, set the following coefficients in the filter.

Rated Frequency	Filter Coefficients for Only Compensating the Device Amplitude Attenuation
50 Hz	h(0) = -0.002 h(1) = -0.012 h(2) = 0.045 h(3) = -0.110 h(4) = 1.151
60 Hz	h(0) = -0.005 h(1) = -0.020 h(2) = 0.058 h(3) = -0.128 h(4) = 1.170

6.3.3.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting

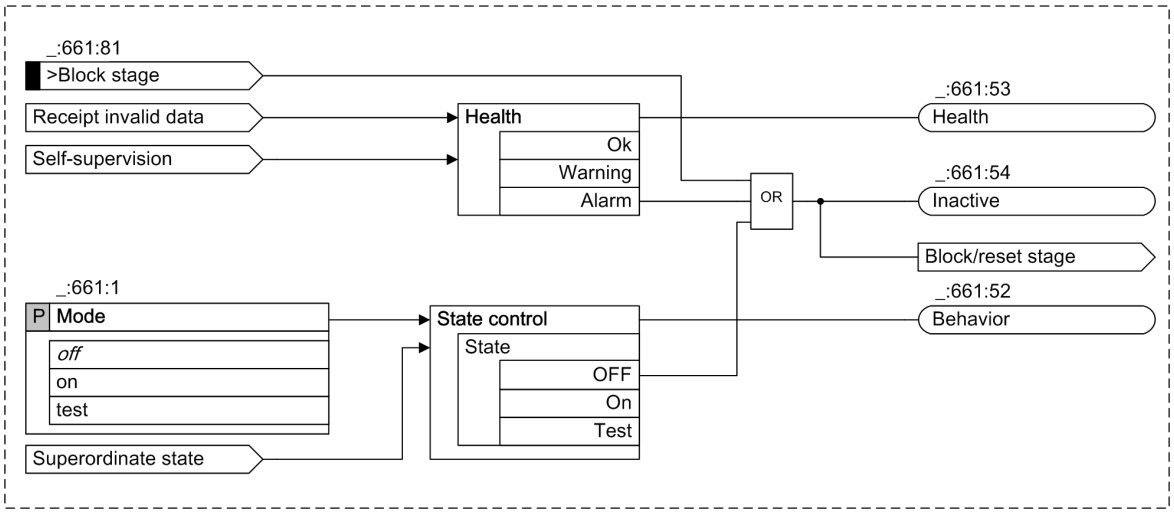
6.3.4 Stage with Definite-Time Characteristic Curve

6.3.4.1 Description



Logic of the Basic Stage

[loocp3b1-280113-01.tif, 3, en_US]

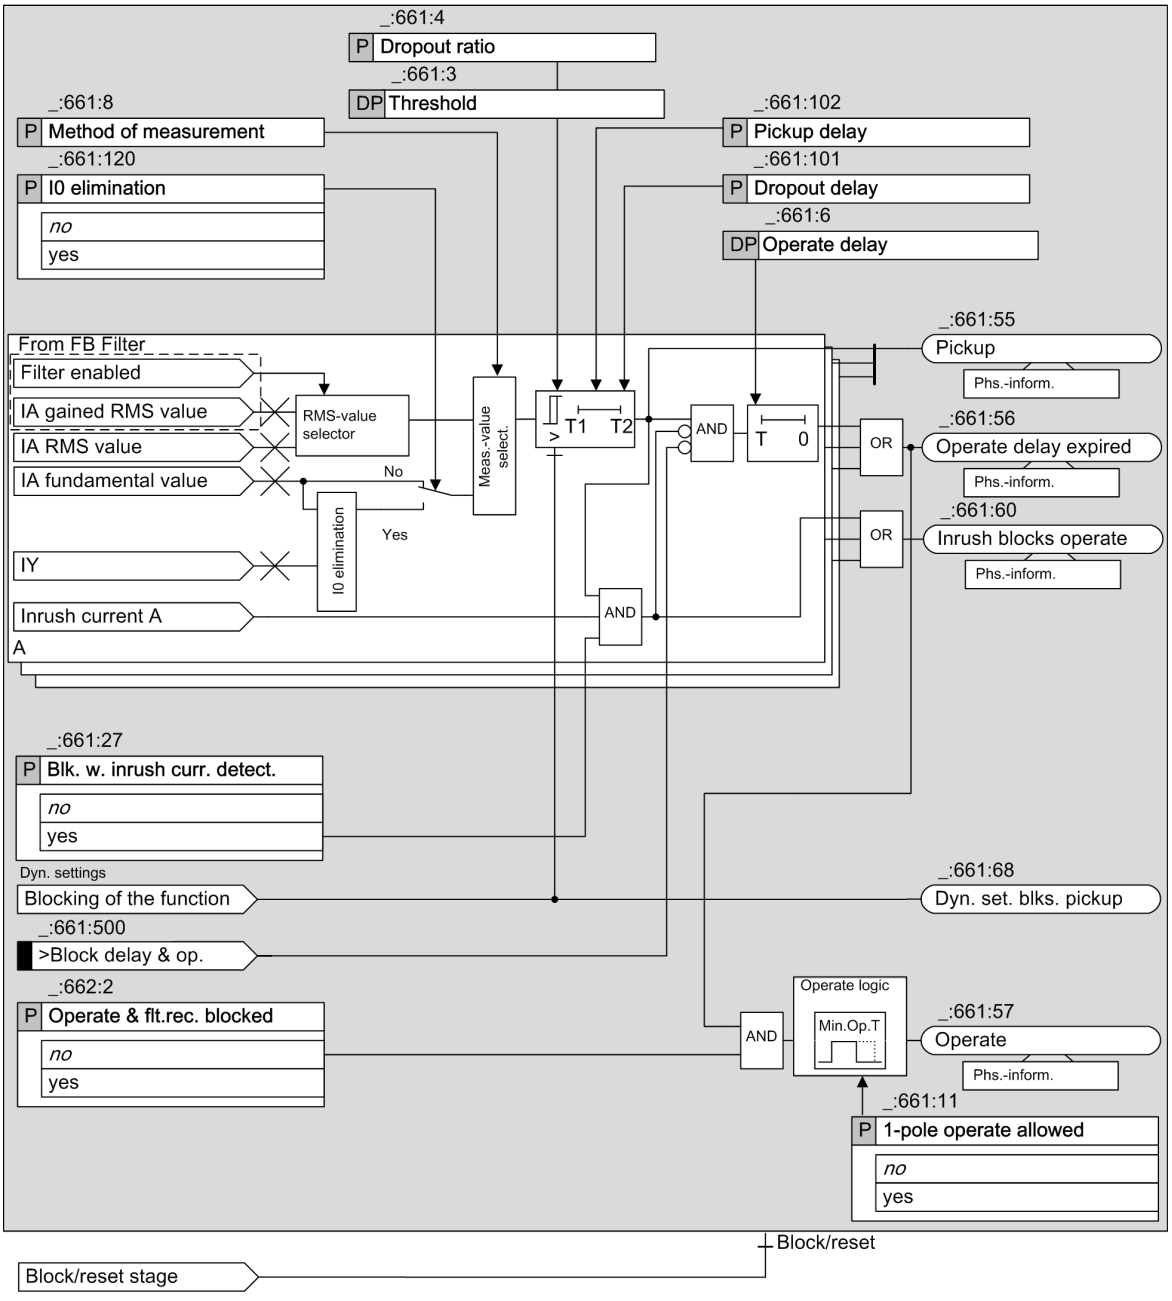


Figure 6-8 Logic Diagram of the Definite Time-Overcurrent Protection (Phases) – Basic

Logic of the Advanced Stage

[lo_OCP_Adv_UMZ_StageControl, 1, en_US]

Figure 6-9 Logic Diagram of the Stage Control

[loocp3p1-310511-01.tif, 3, en_US]

Figure 6-10 Logic Diagram of the Definite Time-Overcurrent Protection (Phases) – Advanced

Method of measurement (Basic and Advanced Stage)

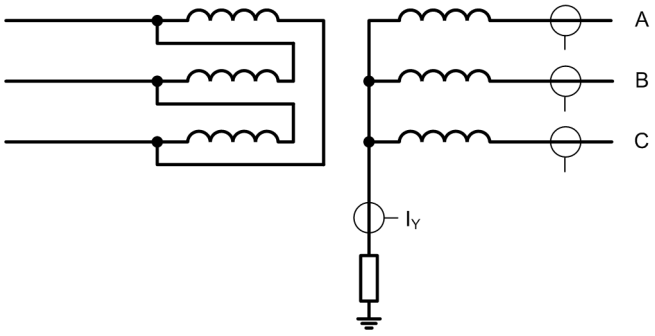
You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the calculated ***RMS value***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

RMS-Value Selection (Advanced Stage)

If ***RMS value*** is selected as the method of measurement, the protection function supports 2 kinds of RMS measurement.

- Normal RMS value
- Gained RMS value from the function block **Filter**

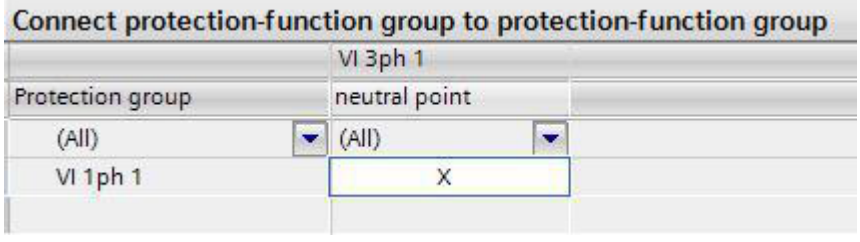


If the function block **Filter** is configured and if you have enabled the filter, the gained RMS value is automatically used.

NOTE

When the function block **Filter** is applied, only one 3-phase current measuring point is allowed to be connected to the 3-phase current interface of the function group.

I0 Elimination (Advanced Stage)



In order to increase the sensitivity for the phase-to-phase faults on the transformer low-voltage side, use the I0 elimination of the phase currents for the overcurrent-protection application on one transformer.
In order to determine the I0 elimination of the phase currents, the transformer neutral point current I_Y must be measured.

[dwsgaocp-230414-01, 1, en_US]

Figure 6-11 I0 Elimination Principle

The transformer neutral point current I_Y is measured via a 1-phase current measuring point that is connected to the **Voltage/current 1-phase**. The function group **Voltage/current 1-phase** must be connected to the function group **Voltage/current 3-phase** in which the function **Overcurrent protection, phases** is being used.

[sccpfoint-230414-01, 1, en_US]

Figure 6-12 Connection of the Voltage/Current 1-Phase Function Group with the Neutral Point Input of the Voltage/Current 3-Phase Function Group

In case of an I0 elimination, the following calculations result:

$\underline{I}_{A\text{-elim.}} = \underline{I}_A - 1/3\ \underline{I}_Y$

$\underline{I}_{B\text{-elim.}} = \underline{I}_B - 1/3\ \underline{I}_Y$

$\underline{I}_{C\text{-elim.}} = \underline{I}_C - 1/3\ \underline{I}_Y$

The phase current $\underline{I}_{phx\text{-elim.}}$ is necessary for the following protection process.

If the **Method of measurement** parameter is set to ***fundamental comp.***, the I0 elimination is applied.

The currents $I_{phx\text{-}elim.}$ are available as functional values.

Pickup delay (Advanced Stage)

If the current exceeds the threshold value, the pickup delay is generated. If the threshold remains exceeded during the pickup delay time, the pickup signal is generated.

Dropout Delay (Advanced Stage)

If the value falls below the dropout threshold, the pickup dropout can be delayed. The pickup is maintained for the specified time. The tripping delay continues to run. If the time delay expires while the pickup is still maintained, the stage operates.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Via the binary input signal **>Block stage** from an external or internal source
- Via the functionality of the **dynamic settings** (only available in the Advanced function type, see subtitle **Influence of other functions via dynamic settings** and chapter *6.3.8.1 Description*).

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.3.7.1 Description* .

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic Reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.3.8.1 Description* .

6.3.4.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:661:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value*** parameter Value

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: `Threshold` , `Operate delay`

- Default setting **`(_:661:3) Threshold`** = ***`1.500 A`*** (for the 1st stage)
- Default setting **`(_:661:6) Operate delay`** = ***`0.30 s`*** (for the 1st stage)

Set the **`Threshold`** and **`Operate delay`** parameters for the specific application.

The following details apply to a 2-stage characteristic curve (1st stage = definite time-overcurrent protection stage and 2nd stage = high-current stage).

1st stage (overcurrent stage):

The setting depends on the maximum occurring operating current. Pickup by overload must be excluded since overcurrent protection operates with short tripping times as short-circuit protection and not as overload protection. Therefore, set the **`Threshold`** parameter for lines to approx. 10 %, for transformers and motors to approx. 20% above the maximum load that is expected.

EXAMPLE

Overcurrent-protection stage: 110-kV overhead line, 150 mm² cross-section

Maximum transmittable power	
P_{max}	= 120 MVA
Correspondingly	
I_{max}	= 630 A
Current transformer	= 600 A/5 A
Safety factor	= 1.1

Settings in primary and secondary values result in the setting values:

Threshold value 1st stage (primary)	$= 1.1 \cdot 630\ A = 693\ A$
Threshold value 1st stage (secondary)	$= 1.1 \cdot \frac{630\ A}{600\ A} \cdot 5\ A = 5.8\ A$

[foocpph1-030311-01.tif, 2, en_US]

The **`Operate delay`** to be set is derived from the time-grading schedule that has been prepared for the system.

2nd stage (high-current stage):

This tripping stage can also be used for current grading. This applies in the case of very long lines with low source impedance or ahead of high reactances (for example, transformers, shunt reactors). Set the **`Threshold`** parameter to ensure that the stage does not pick up in case of a short circuit at the end of the line.

Set the **`Operate delay`** parameter to ***`0`*** or to a low value.

Siemens recommends that the threshold values be determined with a system analysis. The following example illustrates the principle of grading with a current threshold on a long line.

EXAMPLE

High-current stage: 110-kV overhead line, 150 mm² cross-section

s (length)	= 60 km
Z_L/s	= 0.46 Ω/km

Ratio of zero-sequence impedance and positive-sequence impedance of the line: $Z_{L0}/Z_{L1} = 4$

Short-circuit power at the beginning of the line:

S_{sc}'	= 2.5 GVA

Ratio of zero-sequence impedance and positive-sequence impedance of the source impedance at the beginning of the line: $Z_{P0}/Z_{P1} = 2$

Current transformer = 600 A/5 A

Resulting in the following values for the line impedance Z_L and the source impedance Z_P:

$$Z_L = 0.46\ \Omega/\mathrm{km} \cdot 60\mathrm{km} = 27.6\ \Omega$$

[fo_OCP002_030311, 1, en_US]

$$Z_P = \frac{110\ \mathrm{kV}^2}{2500\ \mathrm{MVA}} = 4.84\ \Omega$$

[fo_OCP003_030311, 1, en_US]

The 3-phase short-circuit current at the end of the line is $I_{sc\ end}$:

$$I_{sc\ end} = \frac{1.1 \cdot V_{rated}}{\sqrt{3} \cdot (Z_P + Z_L)} = \frac{1.1 \cdot 110\ kV}{\sqrt{3} \cdot (4.84\ \Omega + 27.6\ \Omega)} = 2150\ A$$

[fo_ocpph4_030311, 1, en_US]

The settings in primary and secondary values result in the following setting values which include a safety margin of 10 %:

Threshold value 2nd stage (primary) = $1.1 \cdot 2150\ \mathrm{A} = 2365\ \mathrm{A}$

Threshold value 2nd stage (secondary) = $1.1 \cdot \frac{2150\ \mathrm{A}}{600\ \mathrm{A}} \cdot 5\ \mathrm{A} = 19.7\ \mathrm{A}$

[foocp004-030311-01.tif, 2, en_US]

If short-circuit currents exceed 2365 A (primary) or 19.7 A (secondary), there is a short circuit on the line to be protected. The overcurrent protection can cut off this short circuit immediately.

Note: The amounts in the calculation example are accurate enough for overhead lines. If the source impedance and line impedance have different angles, you have to use complex numbers to calculate the **Threshold** .

Parameter: I0 elimination

- Default setting **(_:661:120) I0 elimination** = ***no***

This parameter is not visible in the basic stage.

The I0 elimination in phase currents for overcurrent-protection applications can be used in a transformer. This increases the sensitivity for the phase-to-phase fault on the transformer low-voltage side. The following conditions must be fulfilled:

- The transformer neutral point current I_Y is measured and is available for the protection function group.
- The parameter **Method of measurement** is set to ***fundamental comp.*** .

With the **I0 elimination** parameter, you can switch the I0 elimination function on or off.

Parameter: Pickup delay

- Default setting **(_:661:102) Pickup delay** = ***0.00 s***

This parameter is not visible in the basic stage.

For special applications, it is desirable that a short exceeding of the current threshold does not lead to the pickup of the stage and start fault logging and recording. If this stage is used as a thermal overload function, that is considered a special application.

When using the **Pickup delay** parameter, a time interval is defined during which a pickup is not triggered if the current threshold is exceeded.

For all short-circuit protection applications, this value is 0.00 s as a default.

Parameter: `Dropout delay`

- Recommended setting value **`(_:661:101) Dropout delay`** = ***`0.00 s`***

This parameter is not visible in the basic stage.

Siemens recommends to use the default setting ***`0`*** since the dropout of a protection stage must be done as fast as possible.

You can use the **`Dropout delay`** parameter ≠ ***`0`*** to obtain a uniform dropout behavior if you use it together with an electromechanical relay. This is required for time grading. The dropout time of the electromechanical relay must be known for this purpose. Subtract the dropout time of your own device (see Technical Data) and set the result.

Parameter: `Dropout ratio`

- Recommended setting value **`(_:661:4) Dropout ratio`** = ***`0.95`***

This parameter is not visible in the basic stage.

The recommended set value of ***`0.95`*** is appropriate for most applications.

To achieve high-precision measurements, the setting value of the parameter **`Dropout ratio`** can be reduced, for example, to ***`0.98`***. If you expect highly fluctuating measurands at the response threshold, you can increase the setting value of the parameter **`Dropout ratio`**. This avoids chattering of the tripping stage.

Parameter: `1-pole operate allowed`

- Default setting **`(_:661:11) 1-pole operate allowed`** = ***`no`***

The parameter must be set for the specific application.

Parameter Value	Description
`no`	The stage always operates 3-pole.
`yes`	The stage operates phase-selectively. However, tripping by the device (generated in the tripping logic of the function group **Circuit-breaker**) is always 3-pole because the device does not support phase-selective tripping.

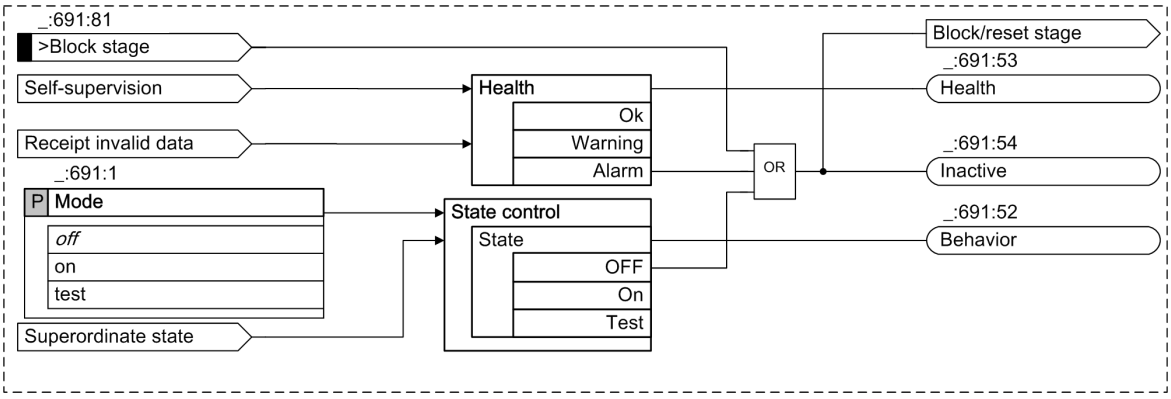
6.3.5 Stage with Inverse-Time Characteristic Curve

6.3.5.1 Description



Logic of the Basic Stage

[loocp3b2-280113-01.tif, 2, en_US]

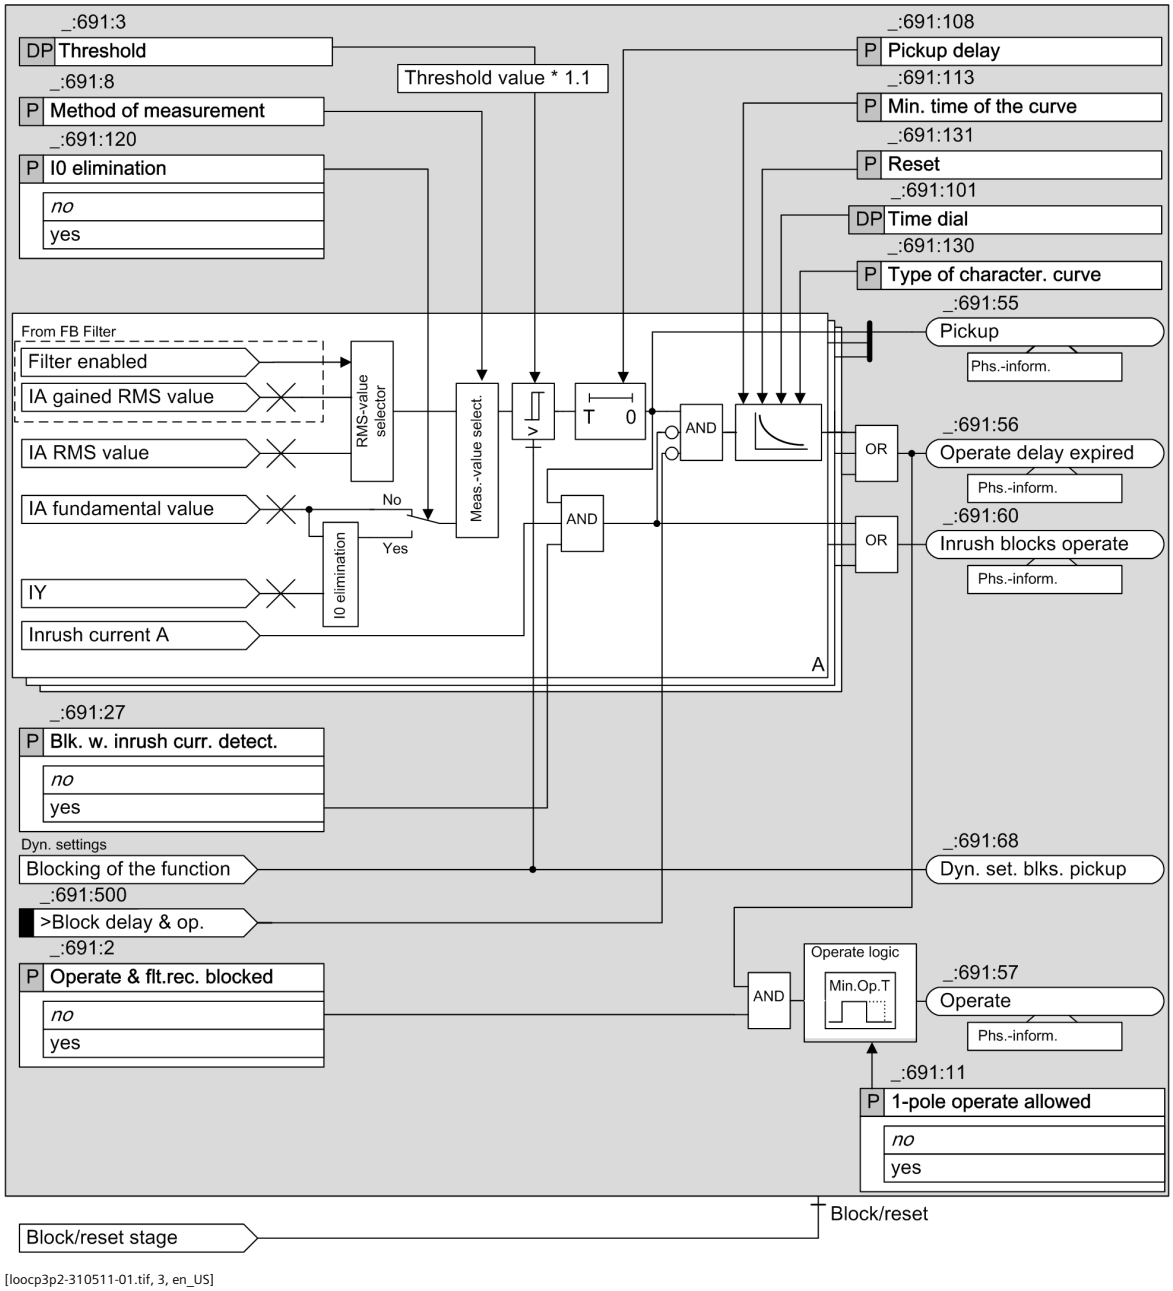


Figure 6-13 Logic Diagram of the Inverse Time-Overcurrent Protection (Phases) – Basic

Logic of the Advanced Stage

[lo_Stage Control, 1, en_US]

Figure 6-14 Logic Diagram of the Stage Control

[loocp3p2-310511-01.tif, 3, en_US]

Figure 6-15 Logic Diagram of the Inverse Time-Overcurrent Protection (Phases) – Advanced

RMS-Value Selection (Advanced Stage)

If ***RMS value*** is selected as the method of measurement, the protection function supports 2 kinds of RMS measurement.

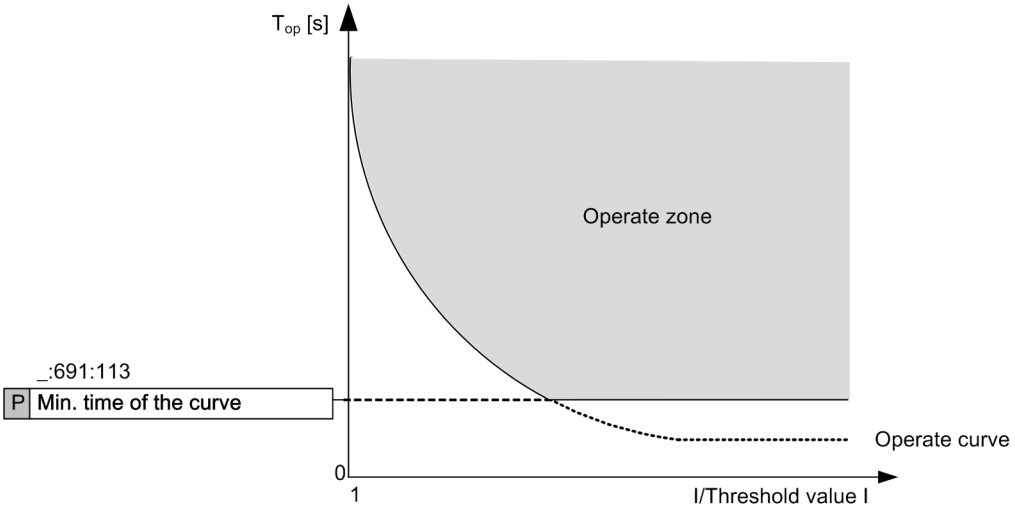
- Normal RMS value
- Gained RMS value from the function block **Filter**

If the function block **Filter** is configured and if youSelf practise_LG_OCP_Inverse time_Advanced, 1, en_US have enabled the filter, the gained RMS value is automatically used.

NOTE

When the function blcok **Filter** is applied, only one 3-phase current measuring point is allowed to be connected to the 3-phase current interface of the function group.

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve according to IEC and ANSI (Basic and Advanced Stage)



When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrating method of measurement summarizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls below the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

Minimum Time of the Curve (Advanced Stage)

With the parameter **`Min. time of the curve`**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time.

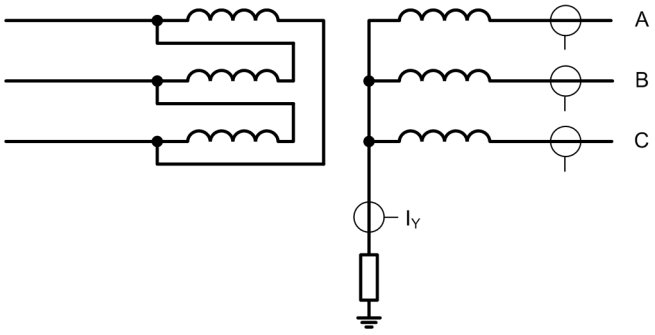
[DwOcp3Mi_20140715-01, 1, en_US]

Figure 6-16 Minimum Operating Time of the Curve

Additional Time Delay (Advanced Stage)

With the parameter **`Additional time delay`**, you define a definite-time delay in addition to the inverse-time delay. With this setting, the whole curve is shifted on the time axis by this additional definite time.

Method of Measurement (Basic and Advanced Stage)

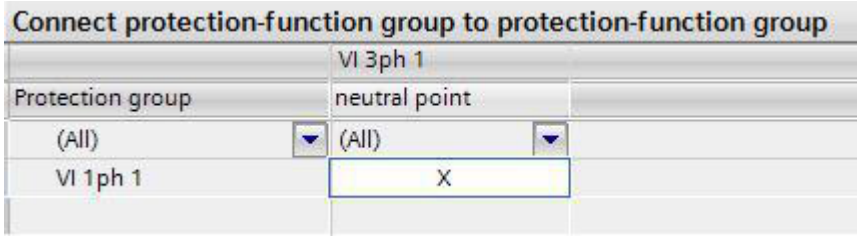


You use the **`Method of measurement`** parameter to define whether the stage uses the ***`fundamental comp.`*** or the calculated ***`RMS value`***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

I0 Elimination (Advanced Stage)

In order to increase the sensitivity for the phase-to-phase fault on the transformer low-voltage side, use the I0 elimination of the phase currents for the overcurrent-protection applications on one transformer.



In order to determine the I0 elimination of the phase currents, the transformer neutral point current I_Y must be measured.

[dwsgaocp-230414-01, 1, en_US]

Figure 6-17 I0 Elimination Principle

The transformer neutral point current I_Y is measured via a 1-phase current measuring point that is connected to the **Voltage/current 1-phase**. The function group **Voltage/current 1-phase** must be connected to the function group **Voltage/current 3-phase** in which the function **Overcurrent protection, phases** is used.

[sccpfoint-230414-01, 1, en_US]

Figure 6-18 Connection of the Function Group Voltage/Current 1-Phase with the Neutral Point Input of the Voltage/Current 3-Phase Function Group

In case of an I0 elimination, the following calculations must be considered:

$\underline{I}_{A\text{-elim.}} = \underline{I}_A - 1/3\ \underline{I}_Y$

$\underline{I}_{B\text{-elim.}} = \underline{I}_B - 1/3\ \underline{I}_Y$

$\underline{I}_{C\text{-elim.}} = \underline{I}_C - 1/3\ \underline{I}_Y$

The phase current $\underline{I}_{phx\text{-elim.}}$ is necessary for the following protection process.

If the **`Method of measurement`** parameter is set to ***`fundamental comp.`***, the I0 elimination is operating.

The currents $\underline{I}_{phx\text{-elim.}}$ are available as functional values.

Pickup Delay (Advanced Stage)

If the current exceeds the threshold value, the pickup delay starts. If the threshold is exceeded during the pickup delay time, the pickup signal is generated.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Via the binary input signal **`>Block stage`** from an external or internal source
- Via the functionality of the **`dynamic settings`** (only available in the Advanced function type, see subtitle **Influence of other functions via dynamic settings** and chapter *6.3.8.1 Description*).

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.3.7.1 Description* .

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic Reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.3.8.1 Description* .

6.3.5.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:691:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value*** Parameter Value

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Type of character. curve

- Default setting **(_:691:130) Type of character. curve** = ***IEC normal inverse***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **Type of character. curve** required for your specific application. For more information about the parameter **Type of character. curve**, refer to chapter *12.5.2 Stage with Inverse-Time Characteristic Curve*.

Parameter: Min. time of the curve

- Default setting **(_:691:113) Min. time of the curve** = ***0.00 s***

This parameter is only available in the advanced stage.

With the parameter **Min. time of the curve**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time. If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

NOTE

If the set value is smaller than the smallest possible time delay of the inverse-time characteristic curve, the parameter has no influence on the delay time.

Parameter: Additional time delay

- Default setting **(_:691:115) Additional time delay** = ***0.00 s***

With the parameter **Additional time delay**, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic time.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

Parameter: Threshold

- Default setting **(_:691:3) Threshold** = ***1.500 A***

Set the **Threshold** and **Type of character. curve** parameters for the specific application.

The setting depends on the maximum occurring operating current. Pickup by overload must be excluded since overcurrent protection operates with short tripping times as short-circuit protection and not as overload protection. Set the **Threshold** parameter for lines to approx. 10 %, for transformers and motors to approx. 20 % above the maximum expected load.

Note that a safety margin is set between pickup value and threshold value. The stage only picks up at approx. 10 % above the **Threshold**.

EXAMPLE

Overcurrent-protection stage: 110-kV overhead line, 150 mm² cross-section

Maximum transmittable power	
P_{max}	= 120 MVA
Correspondingly	
I_{max}	= 630 A
Current transformer	= 600 A/5 A

Settings in primary and secondary values result in the setting values:

Threshold value I> (primary) = 630 A

$$\text{Threshold value I> (secondary)} = \frac{630\ \text{A}}{600\ \text{A}} \cdot 5\ \text{A} = 5.25\ \text{A}$$

[foocp005-030311-01.tif, 2, en_US]

Parameter: I0 elimination

- Default setting **(_:661:120) I0 elimination** = ***no***

This parameter is not visible in the basic stage.

The I0 elimination in phase currents for overcurrent-protection applications can be used in a transformer. This increases the sensitivity for the phase-to-phase faults on the low-voltage side of the transformer. The following conditions must be fulfilled:

- The transformer neutral point current I_Y is measured and is available for the protection function group.
- The parameter **Method of measurement** is set to ***fundamental comp.***.

With the **I0 elimination** setting, you can switch the I0 elimination function on or off.

Parameter: `Pickup delay`

- Default setting **`(_:661:102) Pickup delay`** = ***`0.00 s`***

This parameter is not visible in the basic stage.

For special applications it is desirable if the current threshold is briefly exceeded, that this will not lead to the pickup of the stage and starts fault logging or recording. If this stage is used as a thermal overload function, that is considered a special application.

When using the **`Pickup delay`** parameter, a time interval is defined during which a pickup is not trigger if the current threshold is exceeded.

For all short-circuit protection applications, this value is 0.00 s and is considered as a default.

Parameter: `Time dial`

- Default setting **`(_:691:101) Time dial`** = ***`1.00`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The set value for the **`Time dial`** parameter is derived from the time-grading chart that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the parameter **`Time dial`** at ***`1`*** (default setting).

Parameter: `Reset`

- Default setting **`(_:691:131) Reset`** = ***`disk emulation`***

You use the **`Reset`** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

Parameter: `1-pole operate allowed`

- Default setting **`(_:691:11) 1-pole operate allowed`** = ***`no`***

The parameter must be set for the specific application.

Parameter Value	Description
`no`	The stage always operates 3-pole.
`yes`	The stage operates phase-selectively. However, tripping by the device (generated in the tripping logic of the function group **Circuit-breaker**) is always 3-pole because the device does not support phase-selective tripping.

6.3.6 Stage with User-Defined Characteristic Curve

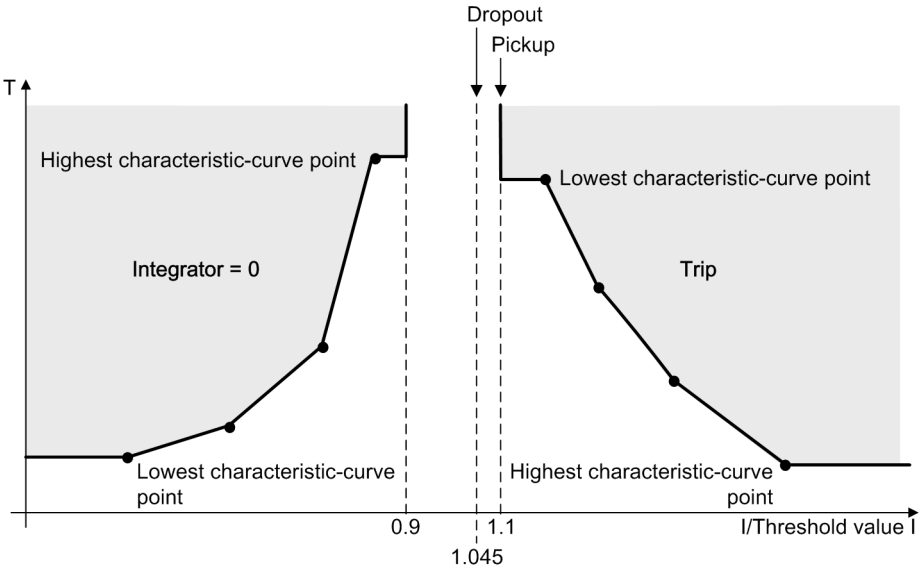
6.3.6.1 Description

This stage is only available in the advanced function type.

This stage is structured the same way as the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.3.5.1 Description*). The only difference is that you can define the characteristic curve as desired.

User-Defined Characteristic Curve

With the user-defined characteristic curve, you can define the operate curve point by point using up to 30 value pairs of current and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.



Pickup and Dropout Behavior with the User-Defined Characteristic Curve

When the input variable exceeds the threshold value by 1.1 times, the characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The

dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

[dwocpken-140611-02.tif, 1, en_US]

Figure 6-19 Pickup Behavior and Dropout Behavior when Using a User-Defined Characteristic Curve

NOTE

The currents that are lower than the current value of the smallest characteristic-curve point do not extend the operate time. The pickup characteristic runs in parallel to the current axis up to the smallest characteristic-curve point. Currents that are larger than the current value of the largest characteristic-curve point do not reduce the operate time. The pickup characteristic runs in parallel to the current axis from the largest characteristic-curve point.

6.3.6.2 Application and Setting Notes

This stage is structured the same way as the **Inverse time-overcurrent protection – advanced** stage. The only difference is that you can define the characteristic curve as desired. This chapter provides only application and setting notes for setting characteristic curves.

Parameter: `Current/time value pairs` (from the operate curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to shift the characteristic curve.

Set the time value in seconds. The characteristic curve is shifted via the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The set value for the **Time dial** parameter is derived from the time-grading chart that has been prepared for the electrical power system. Where no time grading and therefore no displacement of the characteristic curve is required, leave the **Time dial** parameter at ***1***.

Parameter: Reset

- Default setting **(_:110) Reset** = ***disk emulation***

You use the **Reset** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	In the case of this setting, a dropout characteristic curve has to be set in addition to the operate curve. Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Use this setting if the dropout is not to be performed after disk emulation but an instantaneous dropout is desired.

Parameter: Current/time value pairs (of the dropout characteristic curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **Threshold** parameter to ***1.00*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to shift the characteristic curve.

Set the time value in seconds. The characteristic curve is shifted via the **Time dial** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: 1-pole operate allowed

- Default setting **(_:11) 1-pole operate allowed** = ***no***

The parameter must be set for the specific application.

Parameter Value	Description
no	The stage always operates 3-pole.
yes	The stage operates phase-selectively. However, tripping by the device (generated in the tripping logic of the function group **Circuit breaker**) is always 3-pole because the device does not support phase-selective tripping.

6.3.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection

6.3.7.1 Description

With the **`Blk. w. inrush curr. detect.`** parameter, you can define whether tripping of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking, the stage picks up. The start of the tripping delay and the trip signal are blocked. The function signals this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started. After that time, the stage operates. The following figure only shows the part of the stage (exemplified by definite time-overcurrent protection stage 1) that illustrates the influence of the blocking. Only if the central function **Inrush-current detection** (see chapter *12.10 Inrush-Current Detection*) is in effect can the blocking be set.

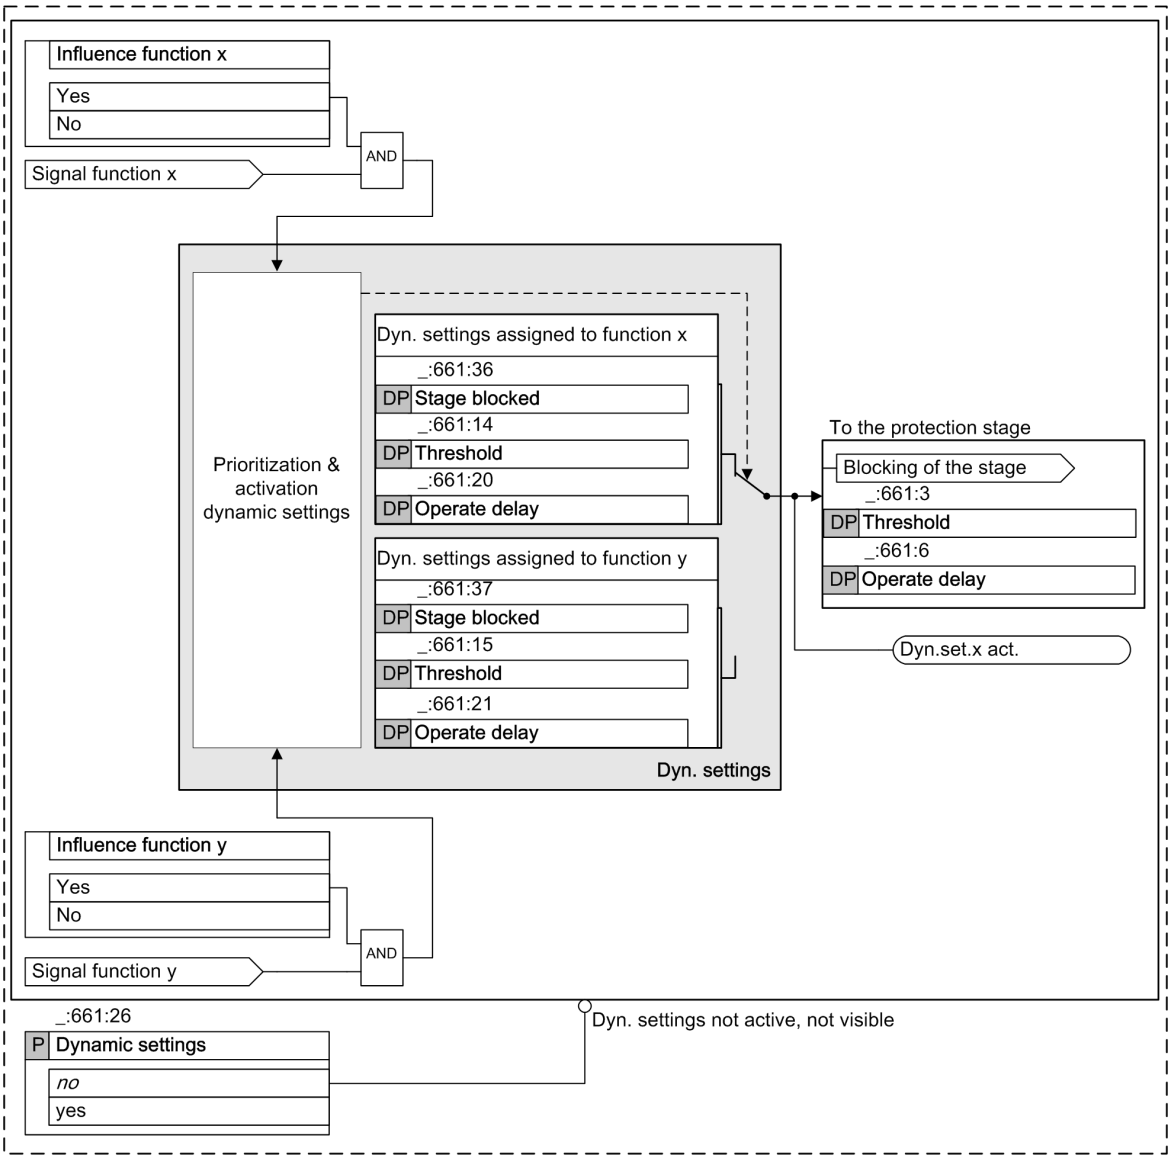
[loocp3pha-210812-01.vsd, 1, en_US]

Figure 6-20 Part-Logic Diagram on the Influence of Inrush-Current Detection Exemplified by the 1st Definite Time-Overcurrent Protection Stage

6.3.7.2 Application and Setting Notes

Parameter: **`Blk. w. inrush curr. detect.`**

- Default setting **`(_:661:27) Blk. w. inrush curr. detect.`** = ***`no`***



Parameter Value	Description
`no`	The transformer inrush current detection does not affect the stage. Select this setting in the following cases: • In cases where the device is not used on transformers. • In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This, for example, applies to the high-current stage that is set such according to the short-circuit voltage V_{sc} of the transformer that it only picks up on faults from the high-voltage side. The transformer-inrush current cannot become larger than the maximum transmittable short-circuit current.
`yes`	When the transformer inrush current detection detects an inrush current that would lead to a tripping of the stage, the start of the time delay and tripping of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

6.3.8 Influence of Other Functions via Dynamic Settings

6.3.8.1 Description

The parameters **`Threshold`** and **`Operate delay`** used for tripping are so-called **`dynamic settings`**. Depending on other functions, the settings of these parameters can be changed dynamically (see

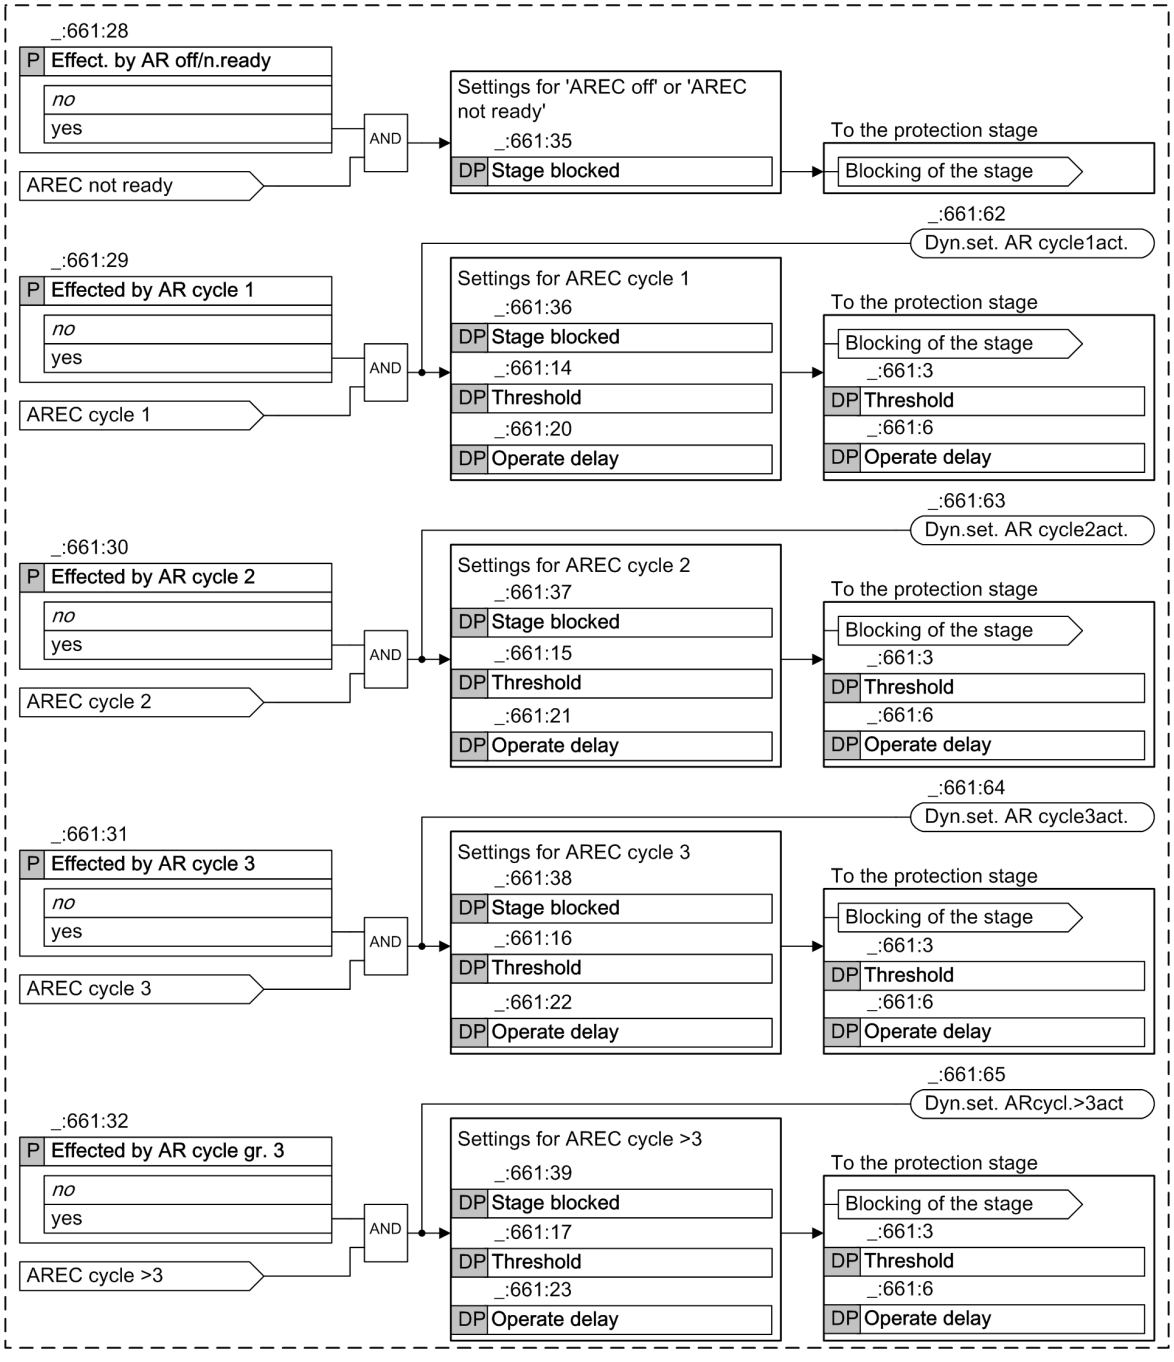
Figure 6-21). Depending on other functions, the stage can also be blocked dynamically. This functionality is only available in function type Advanced.

[loocp3dpa-030311-01.vsd, 1, en_US]

Figure 6-21 Principle of the Dynamic Settings Exemplified by 1st Definite Time-Overcurrent Protection Stage

If available in the device, the following functionalities can affect the overcurrent-protection stages:

Functionalities	Priority
Automatic reclosing (AREC)	Priority 1
Cold-load pickup detection	Priority 2
Binary input signal	Priority 3



These functionalities generate signals that change the settings of the dynamic settings of the overcurrent-protection stage or block it, if required. In the latter case, the settings of the **Threshold** and **Operate delay** parameters are of no relevance. Within the overcurrent-protection stage, each of these signals is provided with a configuration parameter **Influence of function ...** and its own dynamic settings (**Operate delay** and **Threshold**). The configuration settings are used to set whether the signal shall be active or not, this means whether the dynamic settings shall be activated or not. If one of these signals (for

example, signal function x) becomes active and is to take effect, these settings become dynamic, that is, instantly active. This means that the setting assigned to the signal replaces the standard setting. If the signal becomes inactive, the standard settings apply again. The activation of the dynamic settings is reported.

Where several signals are active in parallel, the priority specified above shall apply. This means that a signal with priority 2 precedes that of priority 3. The settings assigned to signal 2 become active.

The functionality of the dynamic settings can be disabled. In this case, the settings assigned to the signals are not visible and are without effect.

Link to the Device-Internal Function *Automatic Reclosing (Advanced Stage)*

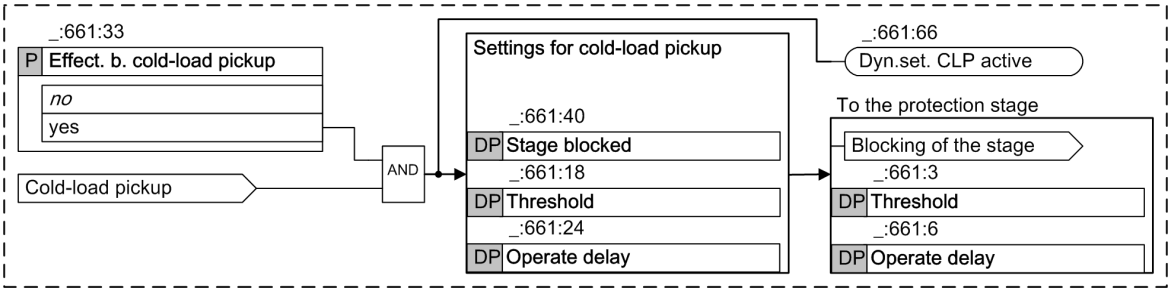
[loocp3awe-040311-01, 1, en_US]

Figure 6-22 Influence of the AREC Signals on the Overcurrent-Protection Stage

Several AREC signals can affect the setting for the **Threshold** and **Operate delay** parameters of the protection stage and its blocking.

- AREC is ready for reclosing 1 (= Automatic reclosing cycle 1)
- AREC is ready for reclosing 2 (= Automatic reclosing cycle 2)
- AREC is ready for reclosing 3 (= Automatic reclosing cycle 3)
- AREC is ready for reclosing 4 (= Automatic reclosing cycle >3)

The following signal can only block the protection stage:



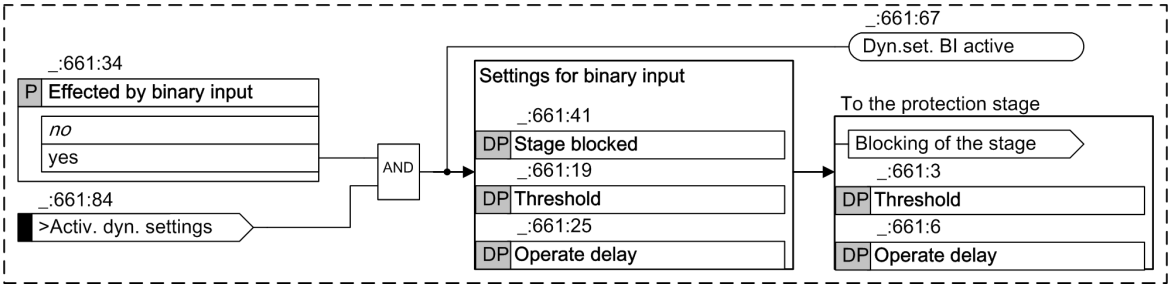
- AREC is not ready or switched off (= Automatic reclosing off / not ready)

This means that if the AREC is ready and the protection stage is in the idle state, the settings for **AREC cycle 1** are active and not the standard settings. The standard settings are active in the case of **AREC off/not ready**.

The influence can be activated for each signal individually. You also have to set the **Threshold** and **Operate delay** or **Stage blocked** parameters, which take effect when the signal is active.

The way AREC signals are generated is described in chapter *6.43.1 Overview of Functions*.

Link to the Device-Internal Function *Cold-Load Pickup Detection (Advanced Stage)*



[loocp3kal-030311-01.vsd, 1, en_US]

Figure 6-23 Influence of the Cold-Load Pickup Detection on the Overcurrent-Protection Stage

In the case of cold-load pickup, you have the option to change the settings for the **Threshold** and **Operate delay** parameters of the protection level. You can also block the level. To do so, you must activate the influence of the cold-load pickup. You also have to set the **Threshold** and **Operate delay** or assign settings to **Stage blocked**, which take effect when the signal is active.

The way signals are generated **Cold-load pickup** is described in chapter *5.8.1 Overview of Functions*.

Link to an External *Function via a Binary Input Signal (Advanced Stage)*

[loocp3bin-030311-01.vsd, 1, en_US]

Figure 6-24 Influence of the Binary Input on the Overcurrent-Protection Stage

You can use the binary input signal **>Activ. dyn. settings** to change the settings for the **Threshold** and the **Operate delay** parameters of the protection stage. You can also block the level. To do so, you must activate the influence of the binary input. You also have to set the **Threshold** and **Operate delay** or assign settings to **Stage blocked**, which take effect when the signal is active.

6.3.8.2 Application and Setting Notes (Advanced Stage)

Parameter: `Dynamic settings`

- Default setting **`(_:661:26) Dynamic settings`** = ***no***

Parameter Value	Description
no	The influence on the overcurrent-protection stage by device-internal or external functions is not necessary.
yes	If a device-internal function (automatic reclosing function or cold-load pickup detection) or an external function should affect the overcurrent-protection stage (such as change the setting of the threshold value or time delay, blocking of the stage), the setting must be changed to ***yes***. This makes the configuration parameters **`Influence of function...`** as well as the dynamic settings **`Threshold`**, **`Operate delay`** and **`Stage blocked`** of the stage visible and enables the settings to be set for the specific influence.

Influence of AREC

The example of how the overcurrent stage (1st stage) can be used as a fast stage before automatic reclosing describes the influence exerted by AREC.

The setting of the overcurrent stage (1st stage) results from the time-grading schedule. Additionally, it is to be used as fast stage before an automatic reclosing. Because a fast disconnection of the short-circuit current takes priority over the selectivity prior to reclosing, the tripping delay can be set to ***0*** or a very small value. To achieve the selectivity, the final disconnection must be done with the grading time.

AREC is set to 2 reclosings. A secondary **`Threshold`** of ***1.5 A*** and a **`Operate delay`** of ***600 ms*** are assumed (according to the time-grading schedule) for the overcurrent-protection stage. The standard settings of the stage are set to these values.

To realize the application, the configuration settings **`Effected by AR cycle 1`** and **`Effected by AR cycle 2`** are changed in the example to ***yes*** (= influenced). This activates the **`AR cycle 1`** and **`AR cycle 2`** input signals within the stage. When they become active, they switch to the assigned dynamic settings.

The two dynamic settings **`Operate delay`** assigned to these input signals (sources of influence) are set to the time delay ***0*** (instantaneous tripping). The two dynamic settings **`Threshold`** assigned to these input signals are set to the normal threshold value of ***1.5 A***.

If the threshold value (***1.5 A***) is exceeded before AREC 1 and AREC 2, the overcurrent-protection stage trips instantaneously. If the fault still exists after AREC 2 (unsuccessful AREC), the stage trips with the time delay of ***600 ms*** according to the time-grading schedule.

Influence of External Devices

The influence of an external device can also be configured. The above is an example of how the overcurrent-protection stage (1st stage) can be used as a fast stage before automatic reclosing, in which case the AREC function is performed by an external device.

To realize the application, the configuration setting **`Effected by binary input`** must be changed to ***yes*** (= influenced). This activates the **`>Activ. dyn. settings`** input signal within the stage. When the input signal becomes active, it switches to the assigned dynamic settings. The external device must provide the **`Cycle 1`** and **`Cycle 2`** signals or, alternatively, the **`AR ready`** signal. The signals must be connected with the binary input signal **`>Activ. dyn. settings`**.

The dynamic setting **`Operate delay`**, which is assigned to the input signal (source of influence) **`>Activ. dyn. settings`**, is set to the time delay ***0*** (instantaneous tripping). The dynamic setting **`Threshold`** assigned to this input signal is set to the normal threshold value of ***1.5 A***.

If the threshold value (***1.5 A***) is exceeded before AREC 1 and AREC 2, the overcurrent-protection stage trips instantaneously. If the fault still exists after AREC 2 (unsuccessful AREC), the stage trips with the time delay of ***600 ms*** according to the time-grading schedule.

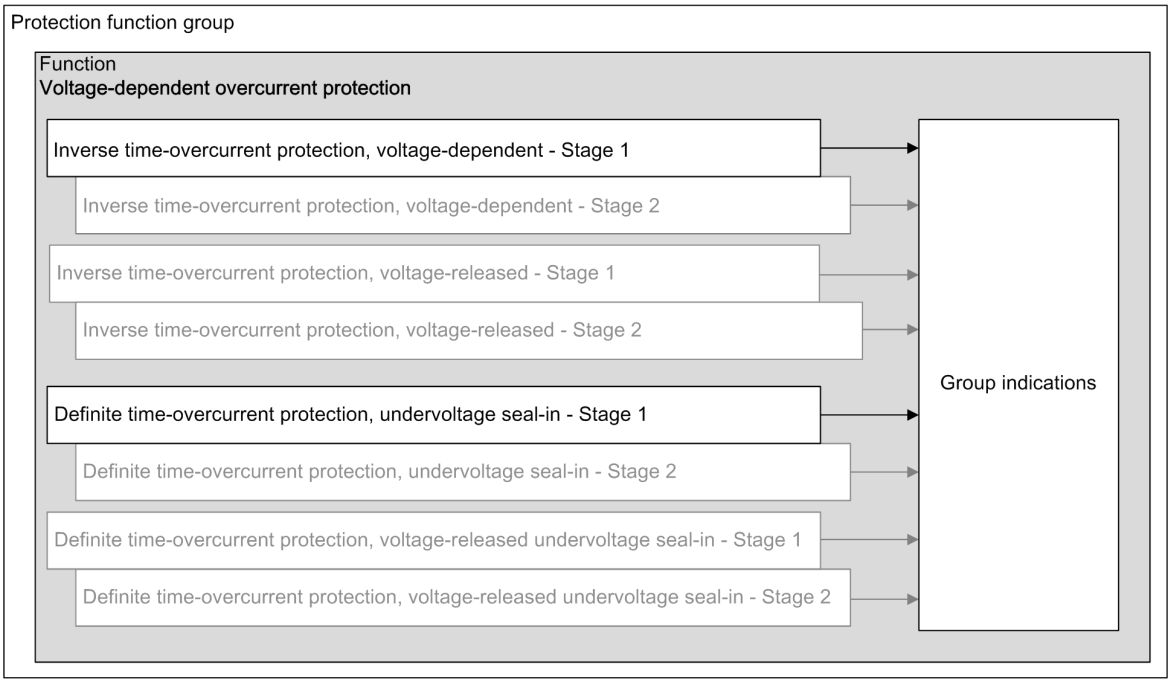
6.4 Voltage-Dependent Overcurrent Protection, Phases

6.4.1 Overview of Functions

The **Voltage-dependent overcurrent protection** (ANSI 51V) function:

- Detects short circuits affecting electric equipment
- Can be used for special network conditions where the overcurrent pickup level should be decreased depending on the fault voltage
- Can be used for generators where the excitation voltage is derived from the machine terminals and the overcurrent pickup should be kept depending on the fault voltages

6.4.2 Structure of the Function



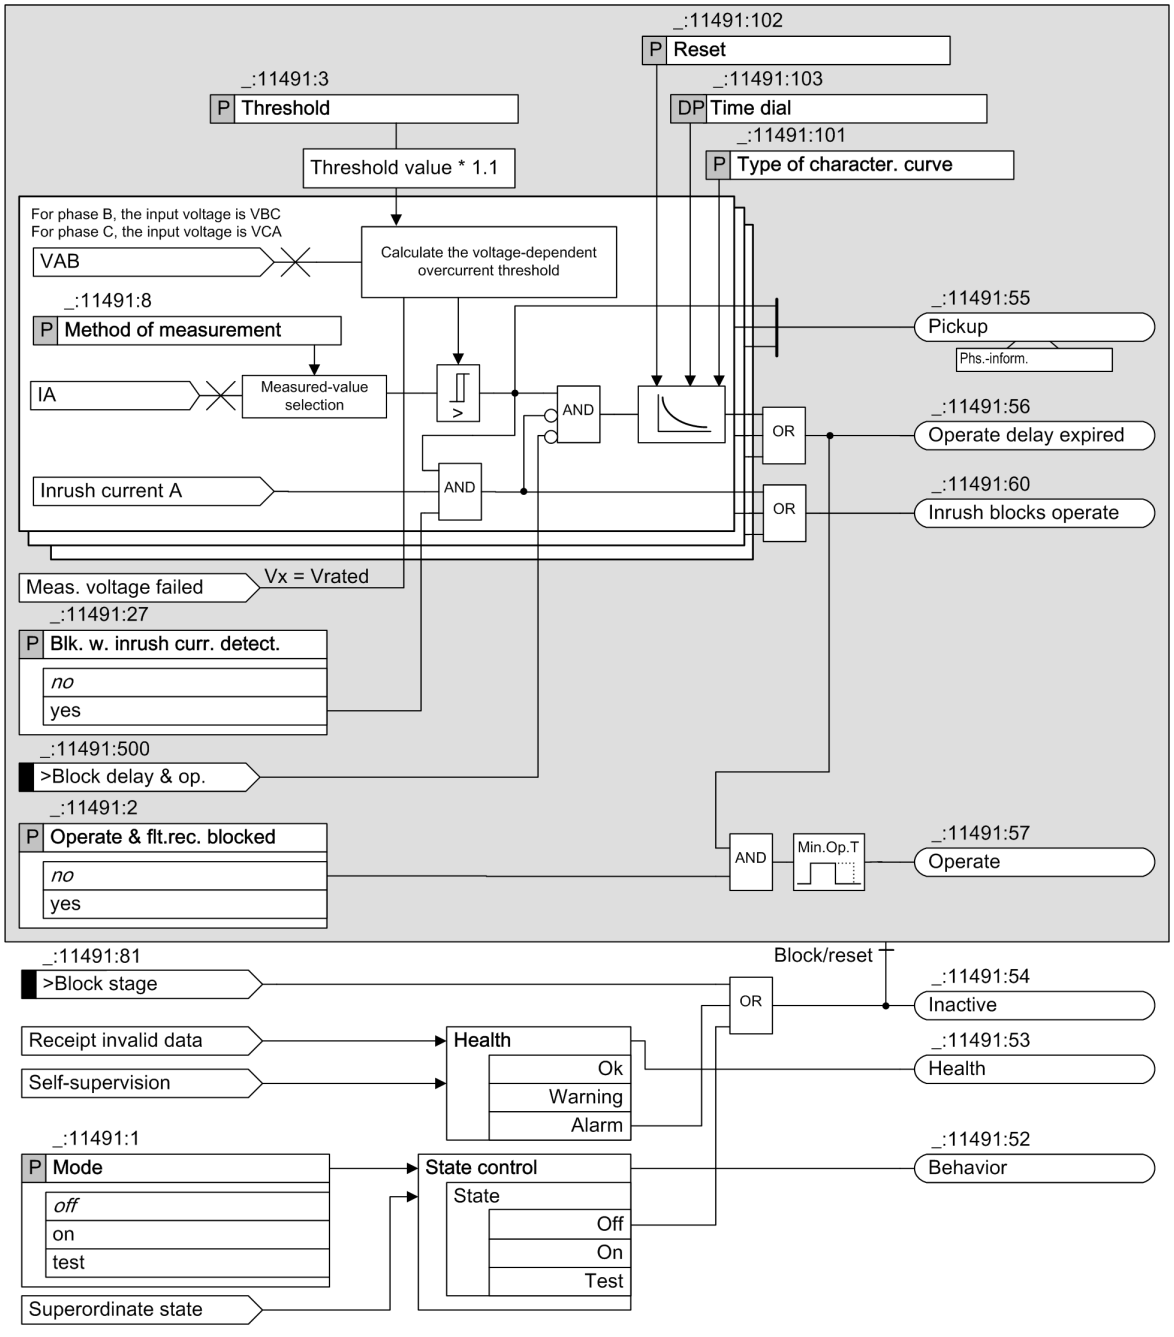
The **Voltage-dependent overcurrent protection** function is used in protection function groups with 3-phase current and voltage measurement.

The function **Voltage-dependent overcurrent protection** comes with the following factory-set stages:

- Inverse time-overcurrent protection, voltage-dependent stage
- Definite time-overcurrent protection, undervoltage seal-in stage

In this function, the following stages can operate simultaneously:

- A maximum of 2 inverse time-overcurrent protection, voltage-dependent stages
- A maximum of 2 inverse time-overcurrent protection, voltage-released stages
- A maximum of 2 definite time-overcurrent protection, undervoltage seal-in stages
- A maximum of 2 definite time-overcurrent protection, voltage-released undervoltage seal-in stages



[dwstuvol-210713-03_Release.vsd, 2, en_US]

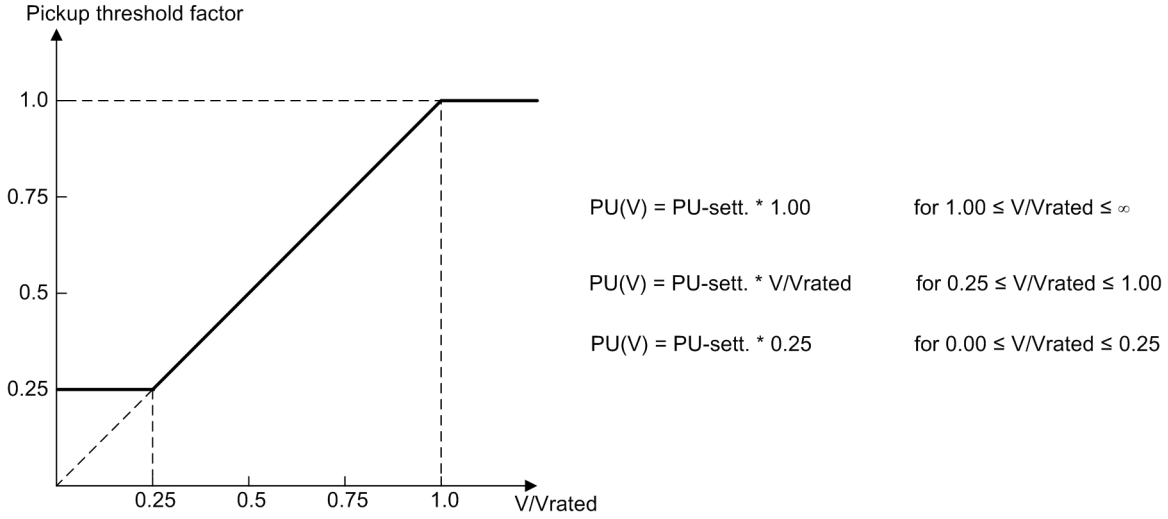
6.4.3 Stage with Inverse Time-Overcurrent Protection, Voltage-Dependent

6.4.3.1 Description

Logic of the Stage

[lovoldep-210713-01.tif, 1, en_US]

Figure 6-26 Logic Diagram of the Inverse Time-Overcurrent Protection, Voltage-Dependent



Method of Measurement

You use the **`Method of measurement`** parameter to define whether the stage uses the *`fundamental comp.`* (standard method) or the calculated *`RMS value`*.

- Measurement of the fundamental comp.:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Voltage-Dependent Pickup Threshold

The pickup threshold of the overcurrent stage depends on the voltage magnitude. A lower voltage decreases the current pickup value (see *Figure 6-27*). In the range between V/V_{rated} = 1.00 to 0.25 a linear, directly proportional dependence is realized.

[dwvolpic-220713-01.tif, 1, en_US]

Figure 6-27 Voltage Influence of the Pickup Threshold

With:

V	=	Measured phase-to-phase voltage
V_{rated}	=	Rated voltage (parameter Rated voltage in the function block General of the protection function group)
PU sett.	=	Pickup threshold setting (parameter address: _11491:3)
PU(V)	=	Applied pickup threshold according to the voltage influence

The minimum current pickup threshold value is 0.03 * Irated. This value cannot be decreased any further even not by voltage-dependent pickup threshold factor.

Decreasing the pickup threshold is carried out phase-selectively. The assignment of voltages to current-carrying phases is shown in *Table 6-1*.

Table 6-1 Controlling Voltages in Relation to the Fault Current

Current	Controlling Voltage
I_A	V_{AB}
I_B	V_{BC}
I_C	V_{CA}

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve According to IEC and ANSI

When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls below the pickup value by 1.045 times (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to the characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is started from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical data.

Influence On the Operate Curve

The current pickup threshold is decreased proportional to the voltage decrease. Consequently, for a constant current I the I/Threshold-value ratio is increased and the operate time is reduced. Compared with the standard curves represented in the **Technical Data**, the operate curve shifts to the left side as the voltage decreases.

Measuring-Voltage Failure Detection

In case of a measuring-voltage failure detection the input voltage value is automatically set to V_{rated}, so that the pickup threshold factor will be 1.

Blocking of the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.3.7.1 Description* .

6.4.3.2 Application and Setting Notes

Parameter: **Blk. w. inrush curr. detect.**

- Default setting **(_:11491:27) Blk. w. inrush curr. detect.** = ***no***

Parameter Value	Description
no	The transformer inrush-current detection does not affect the stage. Select this setting in the following cases: • In cases where the device is not used on transformers. • In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This applies, for example, to the high-current stage that is set according to the short-circuit voltage Vsc of the transformer in such a way that the stage only picks up on faults from the high-voltage side. The transformer-inrush current cannot become larger than the maximum transmittable short-circuit current.
yes	When the transformer inrush-current detection detects an inrush current that would lead to a tripping of the stage, the start of the time delay and tripping of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

Parameter: Method of measurement

- Recommended setting value **(_:11491:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the *fundamental comp.* (standard method) or the calculated *RMS value*.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard process.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks).

Parameter: Threshold

- Default setting **(_:11491:3) Threshold** = ***1.500 A***

The recommended setting value of 1.500 A is suitable for most applications.

Set the **Threshold** and **Type of character. curve** parameters for the specific application.

The setting depends on the maximum occurring operating current. Pickup by overload must be excluded since overcurrent protection operates with short tripping times as short-circuit protection and not as overload protection.

Set the **Threshold** parameter for lines to approx.10 %, for transformers and motors to approx. 20 % above the maximum expected load.

Note that a safety margin is set between pickup value and threshold value. The stage only picks up at approx. 10 % above the **Threshold**.

Parameter Type of character. curve

- Default setting **(_:11491:101) Type of character. curve** = ***IEC normal inverse***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **Type of character. curve** required for your specific application.

Parameter: Reset

- Default setting **(_:11491:102) Reset** = ***disk emulation***

The **Reset** parameter allows you to define whether the stage decreases according to the dropout characteristic curve (behavior of a disk emulation = rotor disc) or instantaneously.

Parameter Value	Description
disk emulation	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Select this setting if the dropout does not have to be performed after a disk emulation and an instantaneous dropout is desired instead.

Parameter: Time dial

- Default setting **(_:11491:103) Time dial** = ***1***

You can use the **Time dial** parameter to displace the characteristic curve in the time direction.

The setting value for the **Time dial** parameter is derived from the time-grading chart that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the parameter **Time dial** at 1 (default setting).

6.4.4 Stage with Inverse Time-Overcurrent Protection, Voltage-Released

6.4.4.1 Description

Logic of the Stage

[lovolrel-210713-01.tif, 1, en_US]

Figure 6-28 Logic Diagram of the Inverse Time-Overcurrent Protection, Voltage-Released

This stage is structured in the same way as the Inverse time-overcurrent, voltage-dependent stage (see chapter *6.4.3.1 Description*). The only differences are the conditions for the pickup and the influence on the operate curve.

Measuring-Element Release

When the controlling voltage drops below the setting **Undervoltage threshold**, the respective measuring element is released.

The release of the measuring elements is carried out phase-selectively. The assignment of voltages to current-carrying phases is shown in *Figure 6-27*.

Blocking of the Stage with Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In case of a blocking, the picked up stage is reset. The following blocking options are available for the stage:

- From an internal source upon pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker

The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

6.4.4.2 Application and Setting Notes

This stage is structured in the same way as the **Inverse time-overcurrent, voltage-dependent** stage. The only differences are the conditions for the pickup and the influence on the operate curve. This chapter only provides the application and setting notes for the setting **Blk. by meas.-volt. failure** and **Undervoltage threshold**. For guidance on the other parameters of this stage, refer to chapter *6.4.3.2 Application and Setting Notes*.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You can use the **Blk. by meas.-volt. failure** parameter to control the response of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal **Measuring-voltage failure detection** function is configured and switched on.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
no	The overcurrent-protection stage is not blocked when a measuring-voltage failure is detected.
yes	The overcurrent-protection stage is blocked when a measuring-voltage failure is detected. Siemens recommends using the default setting, as correct operation of the stage cannot be guaranteed if a measuring-voltage failure occurs.

Parameter: Undervoltage threshold

- Default setting **(_:104) Undervoltage threshold** = ***75.0 V***

When the controlling voltage is below the set value, the inverse time-overcurrent stage is released.

The parameter is set to a value just below the lowest phase-to-phase voltage admissible during operation, for example, from 75 % to 80 % of V_{rated}.

6.4.5 Stage with Definite Time-Overcurrent Protection, Undervoltage Seal-In

6.4.5.1 Description

Logic of the Stage

[lo_Seal-in_20150215, 2, en_US]

Figure 6-29 Logic Diagram of the Definite Time-Overcurrent Protection, Undervoltage Seal-in

Undervoltage Seal-In

In generators where the excitation voltage is derived from the machine terminals, the short-circuit current decreases quickly in the event of close-in faults (for example, in a generator or a generator-transformer range). The current decreases to a value below the current threshold within a few seconds because of the absence of the excitation voltage. To avoid a dropout of the relay, the positive-sequence voltages are used as an additional criterion for detecting a short-circuit fault.

The pickup signal is maintained for a settable seal-in time **Duration of V-seal-in time**, if the positive-sequence voltage falls below a settable threshold **V-seal-in threshold** after an overcurrent pickup, even if the current falls below the threshold again. If the voltage recovers before the seal-in time has elapsed, or if the undervoltage seal-in is blocked via a binary input *>Block V-seal-in*, the signal *Pickup I>+V-seal-in* drops out immediately.

You can switch off the undervoltage seal-in via the parameter **State of V-seal-in**.

Blocking of the Undervoltage Seal-in with Measuring-Voltage Failure

The **Undervoltage seal-in** can be blocked if a measuring-voltage failure occurs. In case of a blocking, the pickup signal *Pickup I>+V-seal-in* drops out immediately. The following blocking options are available for the **Undervoltage seal-in**:

- From an internal source upon pickup of the **Measuring-voltage failure detection** function.
- From an external source via the binary input signal *>Open* of the function block **VT miniature CB**, which links in the tripping of the voltage-transformer circuit breaker.

The parameter **Blk. by meas.-volt. failure** can be used to control the measuring-voltage failure detection. The **Undervoltage seal-in** remains unaffected if the parameter **Blk. by meas.-volt. failure** is switched off.

6.4.5.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:16951:2) Operate & flt.rec. blocked** = ***no***

With the parameter **Operate & flt.rec. blocked**, you can block the operate indication, the fault recording, and the fault log.

Parameter: Threshold

- Default setting **(_:16951:3) Threshold** = ***1.350 A***

The setting is mainly determined by the maximum operating current.

Pickup by overload must be excluded since the protection may trip if a short operate delay time is set. Set the **Threshold** parameter for generators to a value between 20 % and 30 %, for transformers and motors approx. 40 % above the expected peak load.

Parameter: Operate delay

- Default setting **(_:16951:6) Operate delay** = ***3.00 s***

The parameter **Operate delay** must be coordinated with the time grading of the network protection to guarantee the selectivity. Practical time delays are between 1 s to 2 s.

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:16951:10) Blk. by meas.-volt. failure** = ***yes***

With the parameter **Blk. by meas.-volt. failure**, you can activate (***yes***) or deactivate (***no***) the blocking by the **Measuring voltage failure detection** function. The recommended setting is the default setting.

Parameter: State of V-seal-in

- Default setting **(_:16951:101) State of V-seal-in** = ***off***

With the parameter **State of V-seal-in**, the seal-in functionality can be activated (switched ***on***). Siemens recommends this setting if the excitation transformer is connected to the main lead of the generator.

Parameter: V-seal-in threshold

- Default setting **(_:16951:102) V-seal-in threshold** = ***46.2 V***

The **V-seal-in threshold** (positive-sequence voltage) is set to a value below the lowest phase-to-phase voltage admissible during an operation, for example 80 % of the rated voltage of a generator. The positive-sequence voltage is evaluated. The practicable value for a voltage transformer with a rated secondary voltage of 100 V is 46.2 V.

The following table shows an example of a specification:

Threshold	1.4 * $I_{rated, Gen}$		
Operate delay	3.00 s		
Undervoltage seal-in	0.8 * $V_{rated, Gen}$		
Duration of V-seal-in time	4.00 s		
Dropout ratio	0.95		
Rated current $I_{rated, Gen}$	483 A	Rated voltage $V_{rated, Gen}$	6.3 kV
Rated current $I_{rated, VT, prim}$	500 A	Rated voltage $V_{rated, VT, prim}$	6.3 kV
Rated current $I_{rated, VT, sec}$	1 A	Rated voltage $V_{rated, VT, sec}$	100 V

The following secondary setting values result from this specification:

$$\text{Threshold} = \frac{1.4 \times I_{\text{rated ,Gen}}}{I_{\text{rated ,CT,prim}}} \times I_{\text{rated ,VT,sec}} = \frac{1.4 \times 483\ \text{A}}{500\ \text{A}} \times 1\ \text{A} = 1.35\ \text{A}$$

[fo_OCP_UVSI_threshold, 1, en_US]

$$\text{Undervoltage seal} - \text{in} = \frac{0.8 \times V_{\text{rated ,Gen}}}{V_{\text{rated ,VT,prim}}} \times \frac{V_{\text{reated ,VT,sec}}}{\sqrt{3}} = \frac{0.8 \times 6.3\ \text{kV}}{6.3\ \text{kV}} \times \frac{100\ \text{V}}{\sqrt{3}} = 46.200\ \text{V}$$

[fo_OCP_UVSI_Seal-in, 1, en_US]

Parameter: Duration of V-seal-in time

- Default setting **(_:16951:104) Duration of V-seal-in time** = ***4.00 s***

The parameter **Duration of V-seal-in time** limits the pickup seal-in induced by an overcurrent or undervoltage. The value must be set higher than the value of the parameter **Operate delay**. The difference shall be greater than 0.5 s. In the default setting, a difference of 1 s is used.

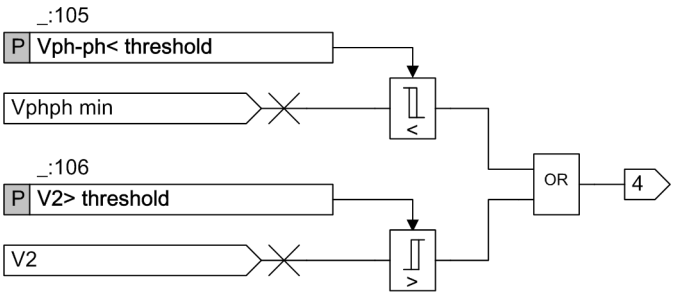
6.4.6 Stage with Definite Time-Overcurrent Protection, Voltage-Released Undervoltage Seal-In

6.4.6.1 Description



Logic of the Stage

[lo_Seal-in_Rel20150215, 2, en_US]

Figure 6-30 Logic Diagram of the Definite Time-Overcurrent Protection, Voltage-Released Undervoltage Seal-in, Part 1

Signal 4 in the following figure refers to *Figure 6-30*.

[lo_Seal-in_Rel2, 1, en_US]

Figure 6-31 Logic Diagram of the Definite Time-Overcurrent Protection, Voltage-Released Undervoltage Seal-in, Part 2

Voltage Release

In addition to the current criterion with undervoltage seal-in, a voltage-released logic must be present to issue the indication *Pickup*. The voltage-released logic monitors the negative-sequence voltage and phase-to-phase voltages respectively for detecting unsymmetrical faults and symmetrical faults. With the voltage-released logic, the setting value of the parameter **Threshold** can be reduced in a certain range and the reliability and sensibility of this function can be improved correspondingly.

Undervoltage Seal-In

In generators where the excitation voltage is derived from the machine terminals, the short-circuit current decreases quickly in the event of close-in faults (for example, in a generator or a generator-transformer range). The current decreases to a value below the current threshold within a few seconds because of the absence of the excitation voltage. To avoid a dropout of the relay, the positive-sequence voltages are used as an additional criterion for detecting a short-circuit fault.

The pickup signal is maintained for a settable seal-in time **Duration of V-seal-in time**, if the positive-sequence voltage falls below a settable threshold **V-seal-in threshold** after an overcurrent pickup, even if the current falls below the threshold again. If the voltage recovers before the seal-in time has elapsed, or if the undervoltage seal-in is blocked via a binary input *>Block V-seal-in*, the signal *Pickup I>+V-seal-in* drops out immediately.

You can switch off the undervoltage seal-in via the parameter **State of V-seal-in**.

Blocking of the Undervoltage Seal-in with Measuring-Voltage Failure

The **Undervoltage seal-in** can be blocked if a measuring-voltage failure occurs. In case of a blocking, the pickup signal *Pickup I>+V-seal-in* drops out immediately. The following blocking options are available for the **Undervoltage seal-in**:

- From an internal source upon pickup of the **Measuring-voltage failure detection** function.
- From an external source via the binary input signal *>Open* of the function block **VT miniature CB**, which links in the tripping of the voltage-transformer circuit breaker.

The parameter **Blk. by meas.-volt. failure** can be used to control the measuring-voltage failure detection. The **Undervoltage seal-in** ramains unaffectecd if the parameter **Blk. by meas.-volt. failure** is switched off.

6.4.6.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = *no*

With the parameter **Operate & flt.rec. blocked**, you can block the operate indication, the fault recording, and the fault log.

Parameter: Threshold

- Default setting **(_:3) Threshold** = ***1.350 A***

The setting is mainly determined by the maximum operating current.

Pickup by overload must be excluded since the protection may trip if a short operate delay time is set. Set the **Threshold** parameter for generators to a value between 20 % and 30 %, for transformers and motors approx. 40 % above the expected peak load.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***3.00 s***

The parameter **Operate delay** must be coordinated with the time grading of the network protection to guarantee the selectivity. Practical time delays are between 1 s to 2 s.

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:10) Blk. by meas.-volt. failure** = ***yes***

With the parameter **Blk. by meas.-volt. failure**, you can activate (***yes***) or deactivate (***no***) the blocking by the **Measuring voltage failure detection** function. The recommended setting is the default setting.

Parameter: State of V-seal-in

- Default setting **(_:101) State of V-seal-in** = ***off***

With the parameter **State of V-seal-in**, the seal-in functionality can be activated (switched ***on***). Siemens recommends this setting if the excitation transformer is connected to the main lead of the generator.

Parameter: V-seal-in threshold

- Default setting **(_:102) V-seal-in threshold** = ***46.2 V***

The **V-seal-in threshold** (positive-sequence voltage) is set to a value below the lowest phase-to-phase voltage admissible during an operation, for example 80 % of the rated voltage of a generator. The positive-sequence voltage is evaluated. The practicable value for a voltage transformer with a rated secondary voltage of 100 V is 46.2 V.

The following table shows an example of a specification:

Threshold	1.4 * $I_{rated, Gen}$		
Operate delay	3.00 s		
Undervoltage seal-in	0.8 * $V_{rated, Gen}$		
Duration of V-seal-in time	4.00 s		
Dropout ratio	0.95		
Rated current $I_{rated, Gen}$	483 A	Rated voltage $V_{rated, Gen}$	6.3 kV
Rated current $I_{rated, VT, prim}$	500 A	Rated voltage $V_{rated, VT, prim}$	6.3 kV
Rated current $I_{rated, VT, sec}$	1 A	Rated voltage $V_{rated, VT, sec}$	100 V

The following secondary setting values result from this specification:

$$\text{Threshold} = \frac{1.4 \times I_{rated\ ,Gen}}{I_{rated\ ,CT,prim}} \times I_{rated\ ,VT,sec} = \frac{1.4 \times 483\ \text{A}}{500\ \text{A}} \times 1\ \text{A} = 1.35\ \text{A}$$

[fo_OCP_UVSI_threshold, 1, en_US]

$$\text{Undervoltage seal} - \text{in} = \frac{0.8 \times V_{rated\ ,Gen}}{V_{rated\ ,VT,prim}} \times \frac{V_{reated\ ,VT,sec}}{\sqrt{3}} = \frac{0.8 \times 6.3\ \text{kV}}{6.3\ \text{kV}} \times \frac{100\ \text{V}}{\sqrt{3}} = 46.200\ \text{V}$$

[fo_OCP_UVSI_Seal-in, 1, en_US]

Parameter: Duration of V-seal-in time

- Default setting **(_:104) Duration of V-seal-in time** = ***4.00 s***

The parameter **Duration of V-seal-in time** limits the pickup seal-in induced by an overcurrent or undervoltage. The value must be set higher than the value of the parameter **Operate delay**. The difference shall be greater than 0.5 s. In the default setting, a difference of 1 s is used.

Parameter: Vph-ph< threshold

- Default setting **(_:105) Vph-ph< threshold** = ***60.000 V***

With the parameter **Vph-ph< threshold**, you can set the threshold at which the output signal *Voltage release* is activated when the minimum phase-to-phase voltage falls below this threshold.

Parameter: V2> threshold

- Default setting **(_:106) V2> threshold** = ***4.600 V***

With the parameter **V2> threshold**, you can set the threshold at which the output signal *Voltage release* is issued when V2 exceeds the threshold.

6.5 Overcurrent Protection, Ground

6.5.1 Overview of Functions

The **Overcurrent protection, ground** function (ANSI 50N/51N):

- Detects short circuits in electrical equipment
- Can be used as backup overcurrent protection in addition to the main protection

6.5.2 Structure of the Function

The **Overcurrent protection, ground** function is used in protection function groups. 2 kinds of functions are available for the 3-phase overcurrent protection:

- **Overcurrent protection, ground – advanced** (50N/51N OC-gnd-A)
- **Overcurrent protection, ground – basic** (50N/51N OC-gnd-B)

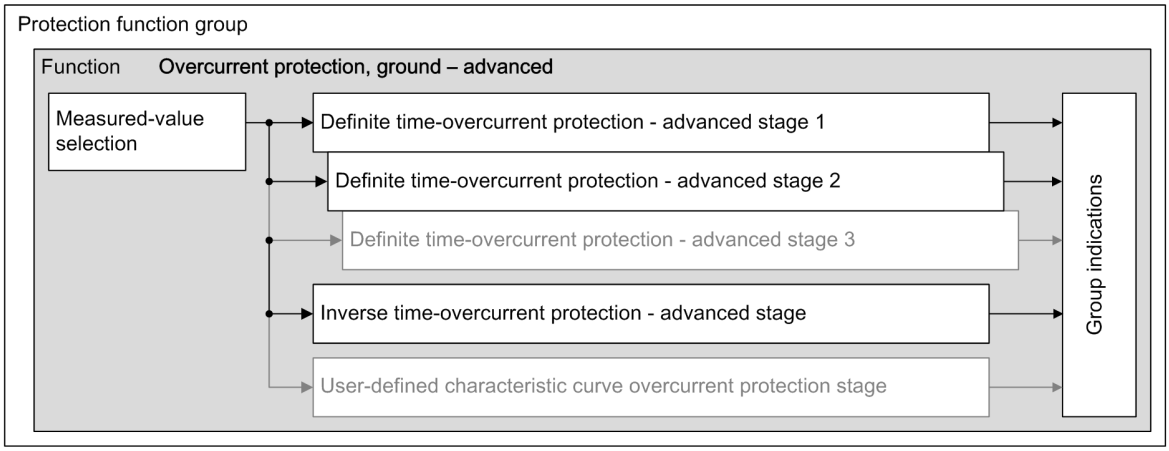
The function type Basic is provided for standard applications. The function type Advanced offers more functionality and is provided for more complex applications.

Both function types are pre-configured by the manufacturer with 2 **Definite time-overcurrent protection** stages and with 1 **Inverse time-overcurrent protection** stage.

In the function type **Overcurrent protection, ground – advanced** the following stages can be operated simultaneously:

- Maximum of 3 stages **Definite time-overcurrent protection – advanced**
- 1 stage **Inverse time-overcurrent protection – advanced**
- 1 stage **User-defined characteristic curve overcurrent protection**

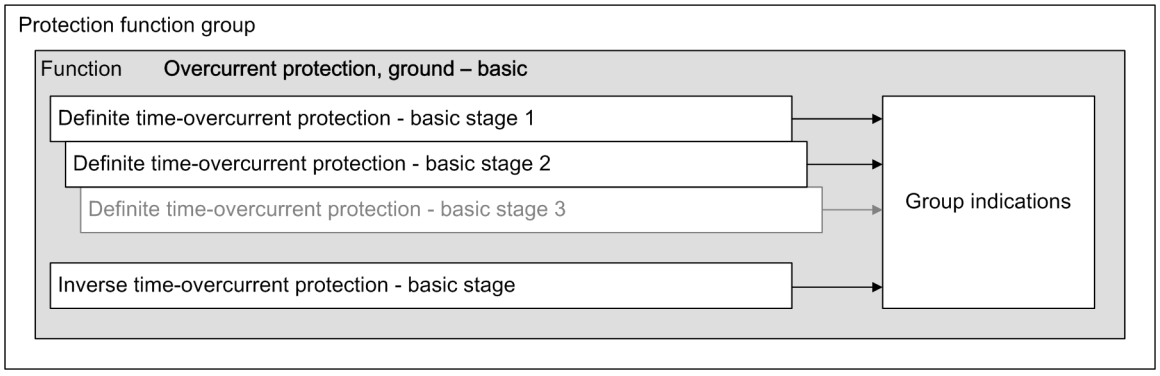
In the function type **Overcurrent protection, ground – basic** the following stages can be operated simultaneously:



- Maximum of 3 stages **Definite time-overcurrent protection – basic**
- 1 stage **Inverse time-overcurrent protection – basic**

The non-preconfigured stages are shown in gray in the following figures. Apart from the tripping delay characteristic, the stages are identical in structure.

The measured-value selection (only advanced stage) is general functionality and has a uniform effect on the stages (see *Figure 6-32* and chapter *6.5.3.1 Description*). This ensures that all stages of the function receive the same measured current value.



The group-indication output logic generates the following group indications of the protection function by the logical OR of the stage-selective indications:

- **`Pickup`**
- **`Operate`**

[dwocpga2-060213-01.tif, 4, en_US]

Figure 6-32 Structure/Embedding the Function Overcurrent Protection, Ground – Advanced

[dwocpgb1-060213-01.tif, 3, en_US]

Figure 6-33 Structure/Embedding the Function Overcurrent Protection, Ground – Basic

If the following listed, device-internal functions are present in the device, these functions can influence the pickup values and tripping delays of the stages or block the stages. The stage can also be affected by an external source via a binary input signal.

- Automatic reclosing (AREC)
- Cold-load pickup detection
- Binary input signal

If the device is equipped with an **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer-inrush currents (available in both function types).

6.5.3 General Functionality

6.5.3.1 Description

Measured-Value Selection

The function provides the option to select between the values ***IN measured*** or ***3I0 calculated***.

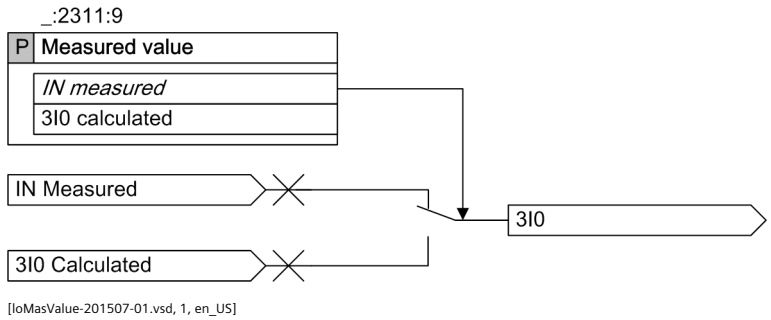


Figure 6-34 Logic Diagram of Measured-Value Selection

Both options are only available for the current-transformer connection types ***3-phase + IN*** and ***3-phase + IN-separate***. For other connection types respectively, only one option is possible. If you select an option that is not allowed, an inconsistency message is given.

Depending on the CT secondary rated current, the CT connection type, and the selected setting, the secondary threshold setting range varies according to the following table.

Table 6-2 Threshold Setting Range

Connection Type	Measured Value	CT Terminal Type	Threshold Setting Range (rated I-sec.: ph = 1 A, IN = 1 A)	Threshold Setting Range (rated I-sec.: ph = 1 A, IN = 5 A)	Threshold Setting Range (rated I-sec.: ph = 5 A, IN = 1 A)	Threshold Setting Range (rated I-sec.: ph = 5 A, IN = 5 A)
3ph + IN	3I0 calculated	4 * Protection	0.030 A to 35.000 A	N/A	N/A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	N/A	N/A	0.005 A to 8.000 A
	IN measured	4 * Protection	0.030 A to 35.000 A	N/A	N/A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	N/A	N/A	0.005 A to 8.000 A
3ph + IN-separate	3I0 calculated	4 * Protection	0.030 A to 35.000 A	0.030 A to 35.000 A	0.15 A to 175.00 A	0.15 A to 175.00 A
		3 * Protection, 1 * sen.	0.030 A to 35.000 A	0.030 A to 35.000 A	0.15 A to 175.00 A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	0.001 A to 1.600 A	0.005 A to 8.000 A	0.005 A to 8.000 A
	IN measured	4 * Protection	0.030 A to 35.000 A	0.15 A to 175.00 A	0.030 A to 35.000 A	0.15 A to 175.00 A
		3 * Protection, 1 * sen.	0.001 A to 1.600 A	0.005 A to 8.000 A	0.001 A to 1.600 A	0.005 A to 8.000 A
		4 * Measurement	0.001 A to 1.600 A	0.005 A to 8.000 A	0.001 A to 1.600 A	0.005 A to 8.000 A

6.5.3.2 Application and Setting Notes

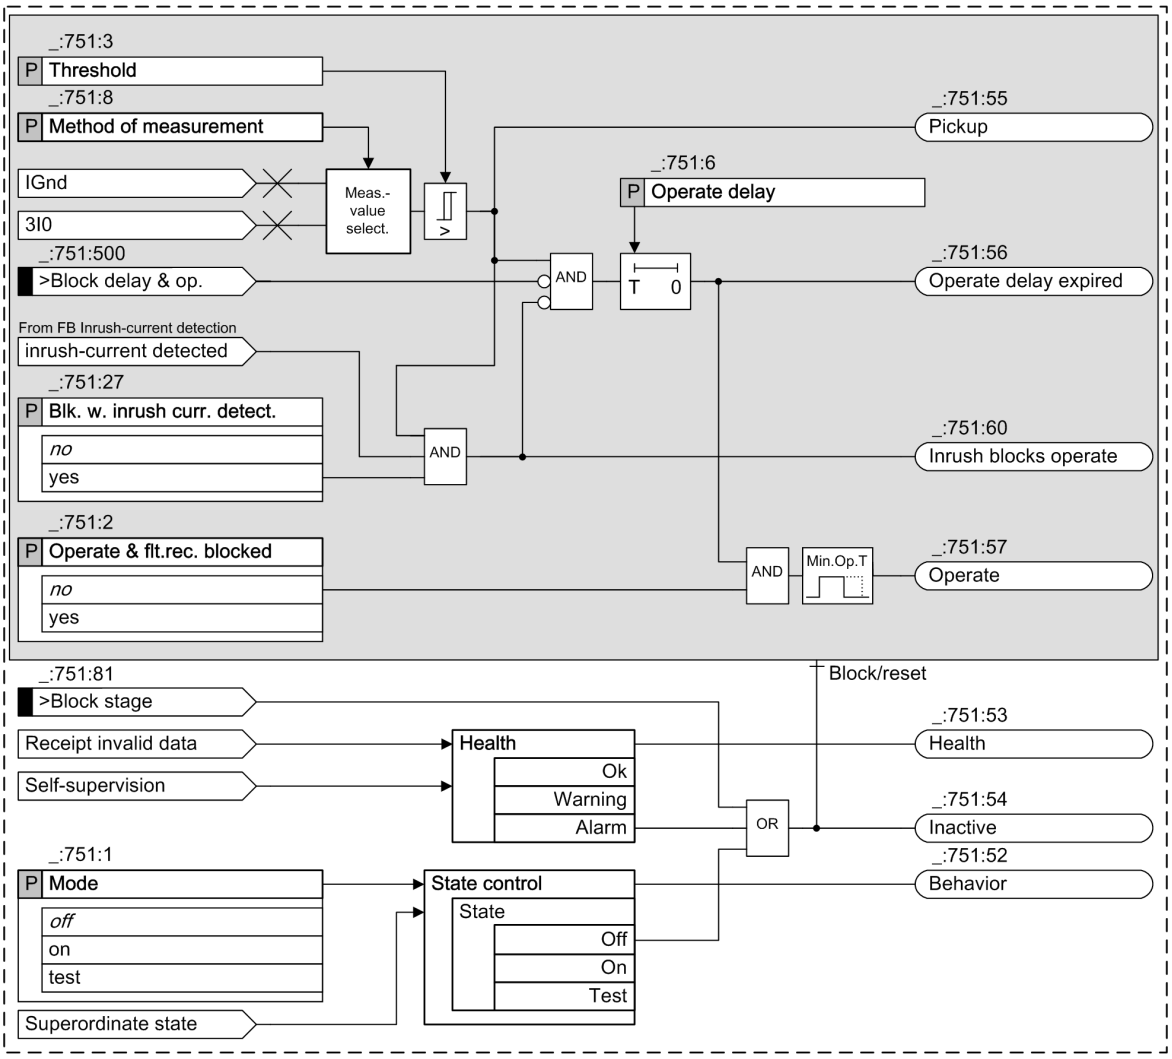
Parameter: `Measured value`

- Recommended setting value **`Measured value`** = ***`IN Measured`***

This parameter is not available in the basic function.

Parameter Value	Description

IN Measured	The function operates with the measured ground current IN. This is the recommended setting unless there is a specific reason to use the calculated zero-sequence current 3I0.
3I0 Calculated	The function operates with the calculated zero sequence current 3I0. This setting option can be used when applying a redundant 50N/51N function for safety reasons.



6.5.3.3 Settings

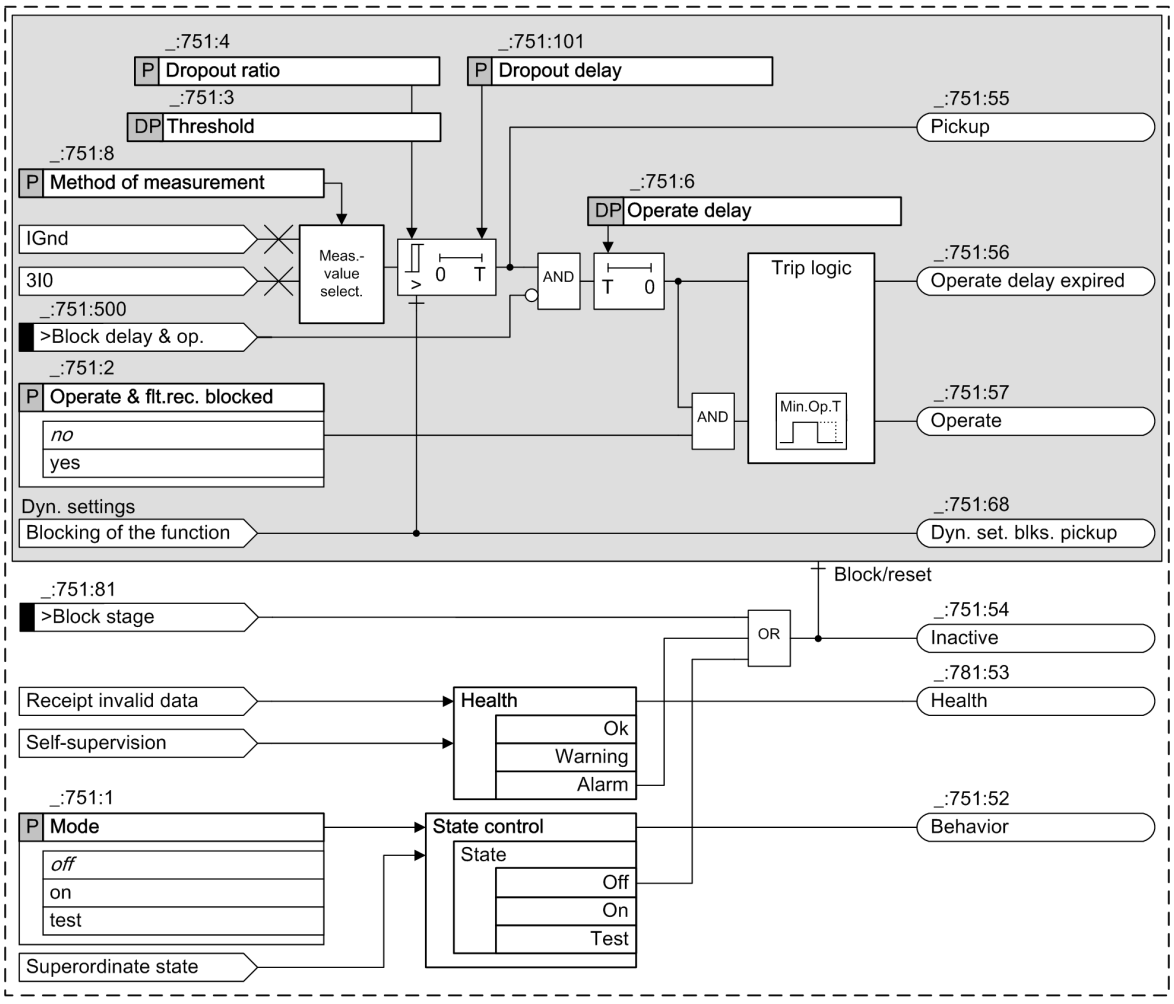
6.5.4 Stage with Definite-Time Characteristic Curve

6.5.4.1 Description



Logic of the Basic Stage

[loocpgb1-060213-01.tif, 2, en_US]

Figure 6-35 Logic Diagram of the Definite Time-Overcurrent Protection (Ground) – Basic

Logic of the Advanced Stage

[loocpgn1-291112-01.tif, 1, en_US]

Figure 6-36 Logic Diagram of the Definite Time-Overcurrent Protection (Ground) – Advanced

Method of Measurement (Basic and Advanced Stage)

You use the **`Method of measurement`** parameter to define whether the stage uses the ***`fundamental comp.`*** or the calculated ***`RMS value`***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Dropout Delay (Advanced Stage)

If the value falls below the dropout threshold, the pickup dropout can be delayed. The pickup is maintained for the specified time. The tripping delay continues to run. If the time delay expires while the pickup is still maintained, the stage operates.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Via the binary input signal **>Block stage** from an external or internal source
- Via the functionality of the **dynamic settings** (see chapter **Influence of other functions via dynamic settings** and section *6.5.8.1 Description*).

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.5.7.1 Description*.

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.5.8.1 Description* .

6.5.4.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:751:8) Method of measurement** = ***fundamental comp.***

The **Method of measurement** parameter allows you to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Threshold, Operate delay

- Default setting **(_:751:3) Threshold** = ***1.20 A*** (for the first stage)
- Default setting **(_:751:6) Operate delay** = ***0.300 s*** (for the first stage)

Set the **Threshold** and **Operate delay** parameters for the specific application.

The following details apply to a 2-stage characteristic curve (1st stage = definite time-overcurrent protection stage and 2nd stage = high-current stage).

1st stage (overcurrent stage):

The setting depends on the minimal occurring ground-fault current. This must be determined.

The **Operate delay** to be set is derived from the time-grading schedule that has been prepared for the system.

2nd stage (high-current stage):

This tripping stage can also be used for current grading. This applies in the case of very long lines with low source impedance or ahead of high reactances (for example, transformers, shunt reactors). Set the **Threshold** parameter to ensure that the stage does not pick up in case of a short-circuit at the end of the line.

Set the **Operate delay** parameter to ***0*** or to a low value.

Siemens recommends that the threshold values be determined with a system analysis. The following example illustrates the principle of grading with a current threshold on a long line.

EXAMPLE

High-current stage: 110-kV overhead line, 150 mm² cross-section

s (length)	= 60 km
Z_L/s	= 0.46 Ω/km

Ratio of zero-sequence impedance and positive-sequence impedance of the line: $Z_{L0}/Z_{L1} = 4$

Short-circuit power at the beginning of the line:

S_{sc}'	= 2.5 GVA

Ratio of zero-sequence impedance and positive-sequence impedance of the source impedance at the beginning of the line: $Z_{P0}/Z_{P1} = 2$

Current transformer	= 600 A/5 A

Resulting in the following values for the line impedance Z_L and the source impedance Z_P:

$$Z_L = 0.46\ \Omega/\mathrm{km} \cdot 60\mathrm{km} = 27.6\ \Omega$$

[fo_OCP002_030311, 1, en_US]

$$Z_P = \frac{110\ \mathrm{kV}^2}{2500\ \mathrm{MVA}} = 4.84\ \Omega$$

[fo_OCP003_030311, 1, en_US]

The 1-pole short-circuit current at the end of the line is $I_{scG\ end}$:

$$I_{sc\ gnd\ end} = \frac{1.1 \cdot V_N \cdot 3}{\sqrt{3} \cdot \left[Z_P \cdot \left(2 + \frac{Z_{P0}}{Z_{P1}}\right) + Z_L \cdot (2 + \frac{Z_{L0}}{Z_{L1}})\right]} = \frac{1.1 \cdot 110\mathrm{kV} \cdot 3}{\sqrt{3} \cdot [4.84\ \Omega \cdot (2+2) + 27.6\ \Omega \cdot (2+4)]} = 1133\ \mathrm{A}$$

[fo_ocp005_030311, 1, en_US]

The settings in primary and secondary values result in the following setting values which include a safety margin of 10 %:

$$\text{Threshold value 2nd stage (primary)} = 1.1 \cdot 1133\ \mathrm{A} = 1246.3\ \mathrm{A}$$

$$\text{Threshold value 2nd stage (secondary)} = 1.1 \cdot \frac{1133\ \mathrm{A}}{600\ \mathrm{A}} \cdot 5\ \mathrm{A} = 10.39\ \mathrm{A}$$

[foocpgr4-030311-01.tif, 3, en_US]

In case of short-circuit currents exceeding 1246 A (primary) or 10.39 A (secondary) there is a short-circuit on the line to be protected. The overcurrent protection can cut off this short circuit immediately.

Note: The amounts in the calculation example are accurate enough for overhead lines. If the source impedance, line impedance and zero-sequence impedance have very different angles, you have use complex numbers to calculate the **Threshold**.

Parameter: `Dropout delay`

- Recommended setting value **`(_:751:101) Dropout delay`** = ***0***

This parameter is not visible in the basic stage.

Siemens recommends to use the default setting ***0*** since the dropout of a protection stage must be done as fast as possible.

You can use the **`Dropout delay`** parameter ≠ ***0*** to obtain a uniform dropout behavior if you use it together with an electromechanical relay. This is required for time grading. The dropout time of the electromechanical relay must be known for this purpose. Subtract the dropout time of your own device (see Technical Data) and set the result.

Parameter: `Dropout ratio`

- Recommended setting value **`(_:751:4) Dropout ratio`** = ***0.95***

This parameter is not visible in the basic stage.

The recommended set value of ***0.95*** is appropriate for most applications.

To achieve high-precision measurements, the setting value of the parameter **`Dropout ratio`** can be reduced, for example, to ***0.98***. If you expect highly fluctuating measurands at the response threshold, you can increase the setting value of the parameter **`Dropout ratio`**. This avoids chattering of the tripping stage.

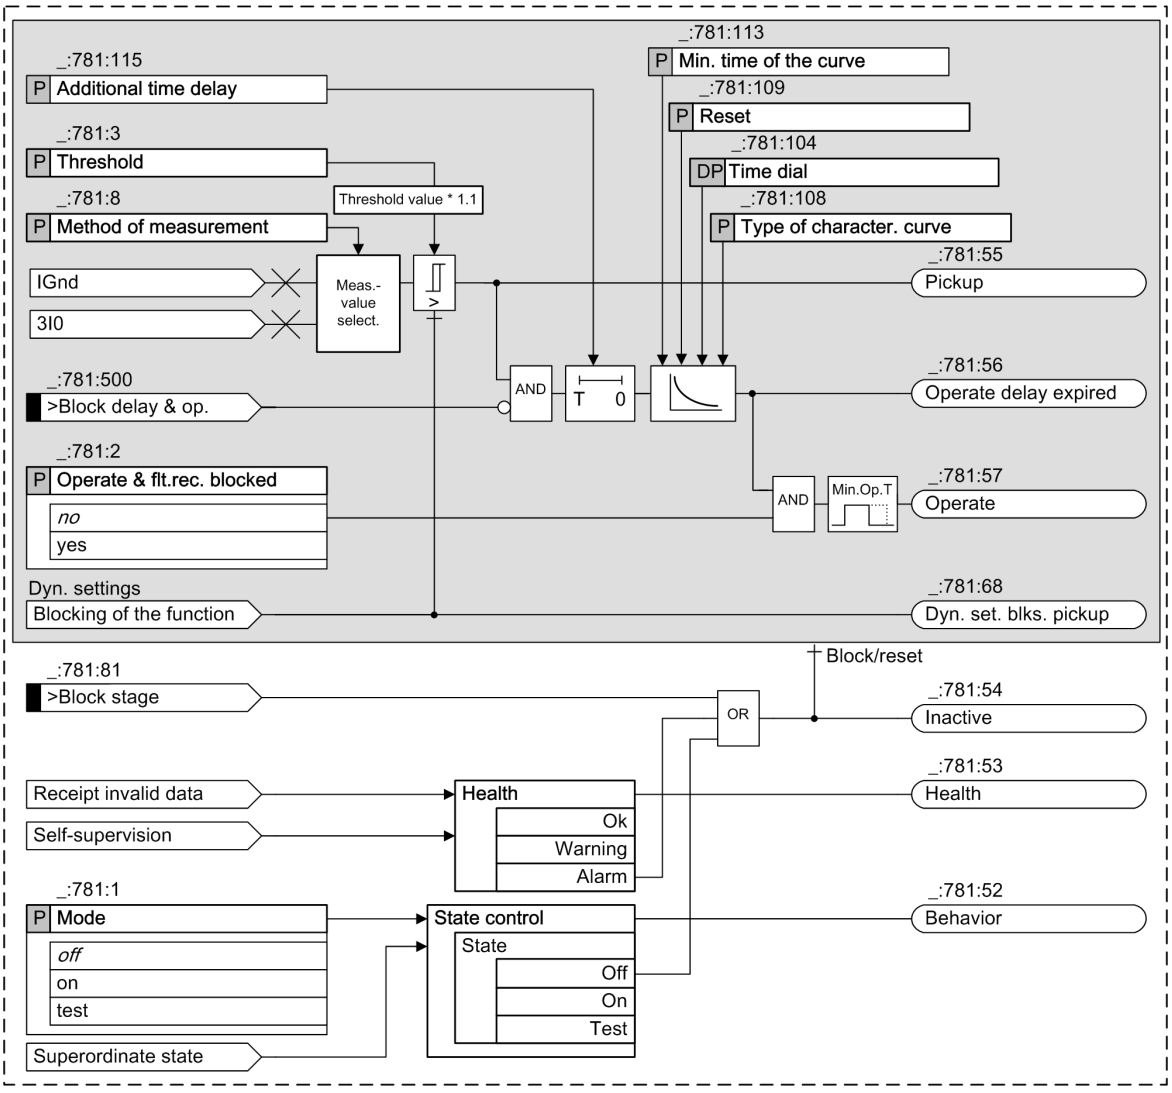
6.5.5 Stage with Inverse-Time Characteristic Curve

6.5.5.1 Description



Logic of the Basic Stage

[loocpgr2-070213-01.tif, 3, en_US]

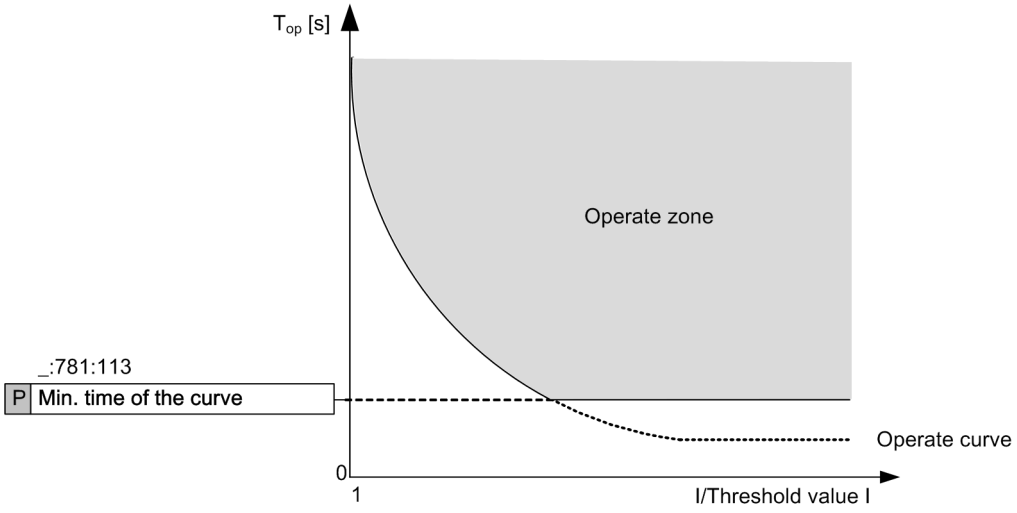
Figure 6-37 Logic Diagram of the Inverse Time-Overcurrent Protection (Ground) – Basic

Logic of the Advanced Stage

[loocpgn2-291112-01.tif, 2, en_US]

Figure 6-38 Logic Diagram of the Inverse Time-Overcurrent Protection (Ground) – Advanced

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve according to IEC and ANSI (Basic and Advanced Stage)



When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

Minimum Time of the Curve (Advanced Stage)

With the parameter **Min. time of the curve**, you define the minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time.

[Dwocpgr3Mi_20140716-01, 1, en_US]

Figure 6-39 Minimum Operating Time of the Curve

Additional Time Delay (Advanced Stage)

With the parameter **Additional time delay**, you define a definite-time delay in addition to the inverse-time delay. With this setting, the whole curve is shifted on the time axis by this additional definite time.

Method of Measurement (Basic and Advanced Stage)

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the calculated ***RMS value***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Via the binary input signal **>Block stage** from an external or internal source
- Via the functionality of the **dynamic settings** (see subtitle **Influence of other functions via dynamic settings** and chapter *6.5.8.1 Description*).

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.5.7.1 Description*.

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.5.8.1 Description* .

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic reclosing
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.5.8.1 Description* .

6.5.5.2 Application and Setting Notes

Parameter: `Method of measurement`

- Recommended setting value **`(_:781:8) Method of measurement`** = ***`fundamental comp.`***

You use the **`Method of measurement`** parameter to define whether the stage uses the ***`fundamental comp.`*** (standard method) or the calculated ***`RMS value`***.

Parameter Value	Description
`fundamental comp.`	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
`RMS value`	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **`threshold value`** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Type of character. curve

- Default setting **`(_:781:108) Type of character. curve`** = ***`IEC normal inverse`***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **`Type of character. curve`** required for your specific application. For more information about the parameter **`Type of character. curve`**, refer to chapter*12.7.2 Stage with Inverse-Time Characteristic Curve*.

Parameter: `Min. time of the curve`

- Default setting **`(_:781:113) Min. time of the curve`** = ***`0.00 s`***

This parameter is only available in the advanced stage.

With the parameter **`Min. time of the curve`**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time. If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

NOTE

If the set value is smaller than the smallest possible time delay of the inverse-time characteristic curve, the parameter has no influence on the delay time.

Parameter: `Additional time delay`

- Recommended setting value **`(_:781:115) Additional time delay`** = ***`0.00 s`***

With the parameter **`Additional time delay`**, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommend keeping the default setting of 0 s.

Parameter: `Threshold`

- Default setting **`(_:781:3) Threshold`** = ***`1.20 A`***

The setting depends on the minimal occurring ground-fault current. This must be determined.

Parameter: `Time dial`

- Default setting **`(_:781:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The set value for the **`Time dial`** parameter is derived from the time-grading chart that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the **`Time dial`** parameter at ***`1`***.

Parameter: `Reset`

- Default setting **`(_:781:109) Reset`** = ***`disk emulation`***

You use the **`Reset`** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

6.5.6 Stage with User-Defined Characteristic Curve

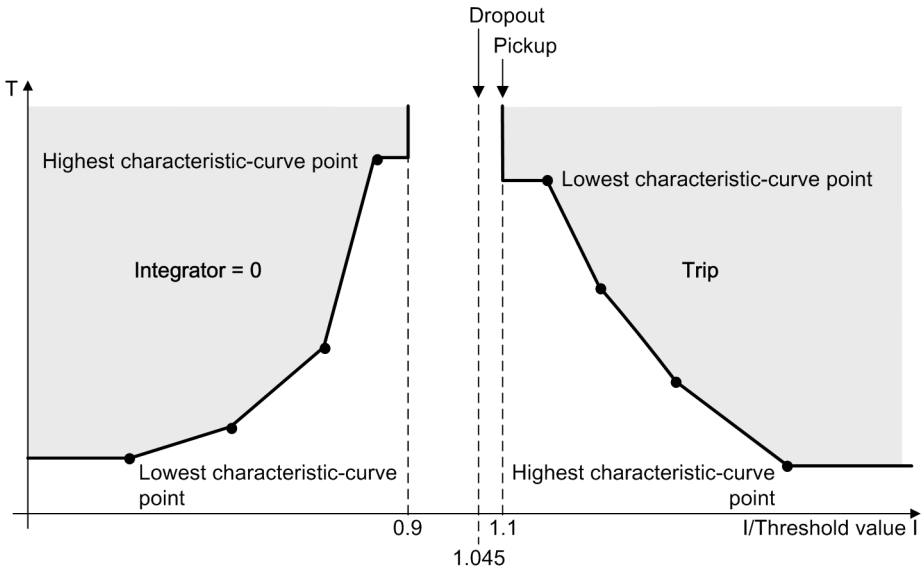
6.5.6.1 Description

This stage is only available in the advanced function type.

This stage is structured the same way as the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.5.5.1 Description*). The only difference is that you can define the characteristic curve as desired.

User-Defined Characteristic Curve

With the user-defined characteristic curve, you can define the operate curve point by point using up to 30 value pairs of current and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.



Pickup and Dropout Behavior with the User-Defined Characteristic Curve

When the input variable exceeds the threshold value by 1.1 times, the characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The following figure shows the pickup and dropout behavior when a user-defined characteristic curve is used.

[dwocpken-140611-02.tif, 1, en_US]

Figure 6-40 Pickup Behavior and Dropout Behavior when Using a User-Defined Characteristic Curve

NOTE

Note that the currents that are lower than the current value of the smallest characteristic-curve point do not extend the operate time. The pickup characteristic runs in parallel to the current axis up to the smallest characteristic-curve point. Currents that are larger than the current value of the largest characteristic-curve point do not reduce the operate time. The pickup characteristic runs in parallel to the current axis from the largest characteristic-curve point.

6.5.6.2 Application and Setting Notes

This stage is structured the same way as the **Inverse time-overcurrent protection – advanced** stage. The only difference is that the user can define the characteristic curve as desired. This chapter only provides application and setting notes for setting characteristic curves. For guidance on the other parameters of the stage, see chapter *6.5.5.2 Application and Setting Notes* .

Parameter: `Current/time value pairs` (from the operate curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The set value for the **Time dial** parameter is derived from the time-grading chart that has been prepared for the electrical power system. Where no time grading and therefore no displacement of the characteristic curve is required, leave the parameter **Time dial** at ***1*** (default setting).

Parameter: Reset

- Default setting **(_:110) Reset** = ***disk emulation***

You use the **Reset** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	In the case of this setting, a dropout characteristic curve has to be set in addition to the operate curve. Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

Parameter: Current/time value pairs (of the dropout characteristic curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **Threshold** parameter to ***1.00*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **Time dial** parameter.

NOTE

The value pairs must be entered in continuous order.

6.5.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection

6.5.7.1 Description

With the **Blk. w. inrush curr. detect.** parameter, you can define whether tripping of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking, the stage picks up. The start of the tripping delay and the trip signal are blocked. The function signals this through a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started. After that time, the stage operates. The following figure only shows the part of the stage (exemplified by definite time-overcurrent protection stage 1) that illustrates the influence of the inrush-current detection. Only if the central function **Inrush-current detection** (see section *12.10 Inrush-Current Detection*) is in effect can the blocking be set.

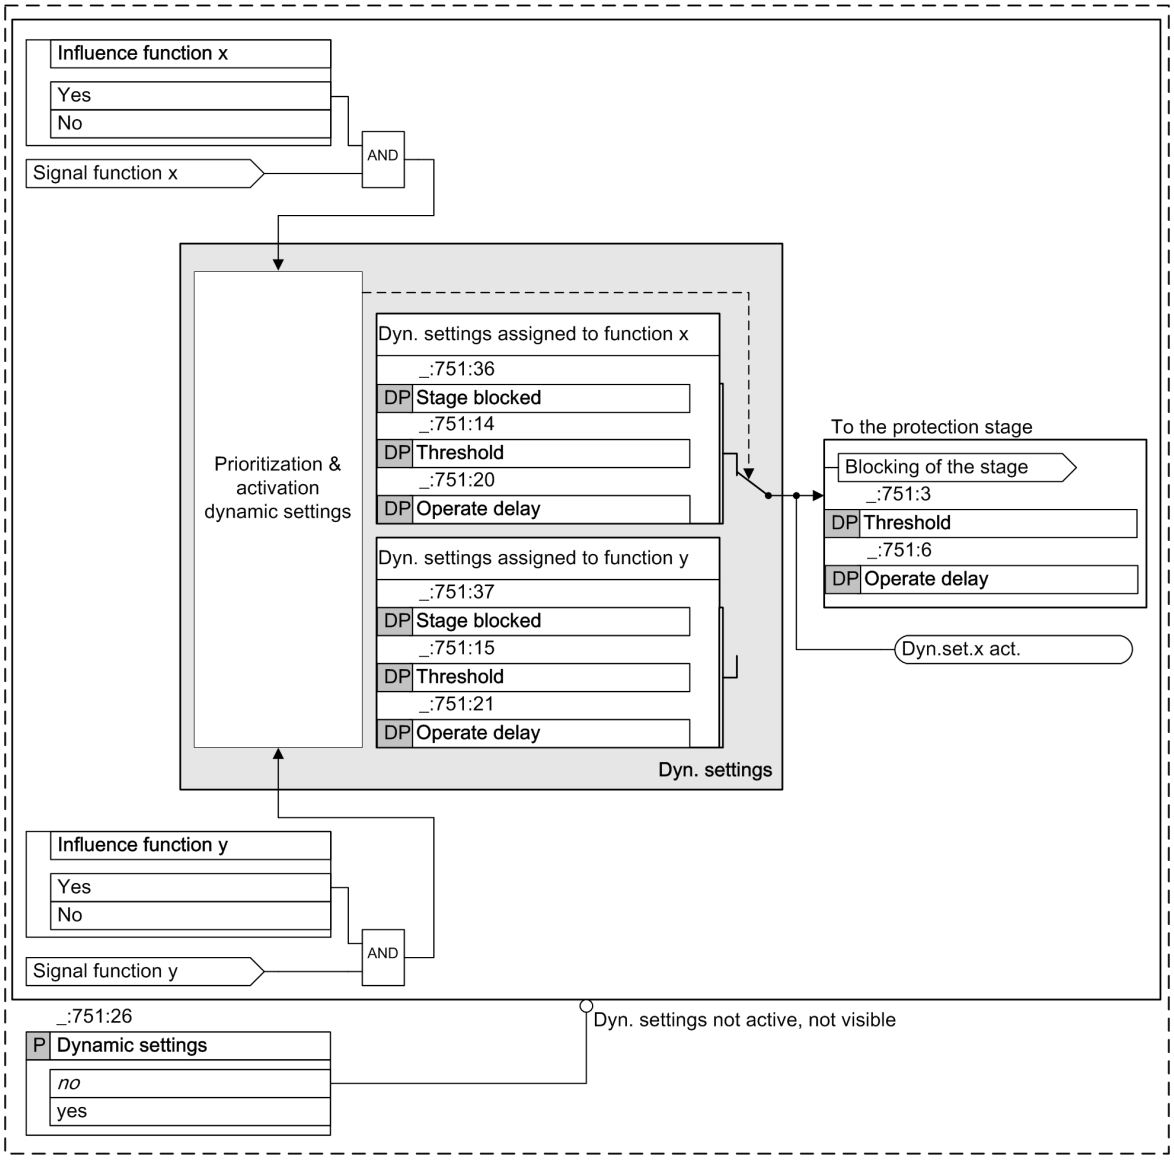
[loocpgrd-210812-01.tif, 1, en_US]

Figure 6-41 Part-Logic Diagram on the Influence of Inrush-Current Detection Exemplified by the 1st Definite Time-Overcurrent Protection Stage

6.5.7.2 Application and Setting Notes

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:751:27) Blk. w. inrush curr. detect.** = ***no***



Parameter Value	Description
no	The transformer inrush current detection does not affect the stage. Select this setting in the following cases: • In cases where the device is not used on transformers. • In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This, for example, applies to the high-current stage that is set such according to the short-circuit voltage V_{sc} of the transformer that it only picks up on faults from the high-voltage side. The transformer-inrush current cannot become larger than the maximum transmittable short-circuit current.

Parameter Value	Description
yes	When the transformer inrush current detection detects an inrush current that would lead to a tripping of the stage, the start of the time delay and tripping of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

6.5.8 Influence of Other Functions via Dynamic Settings

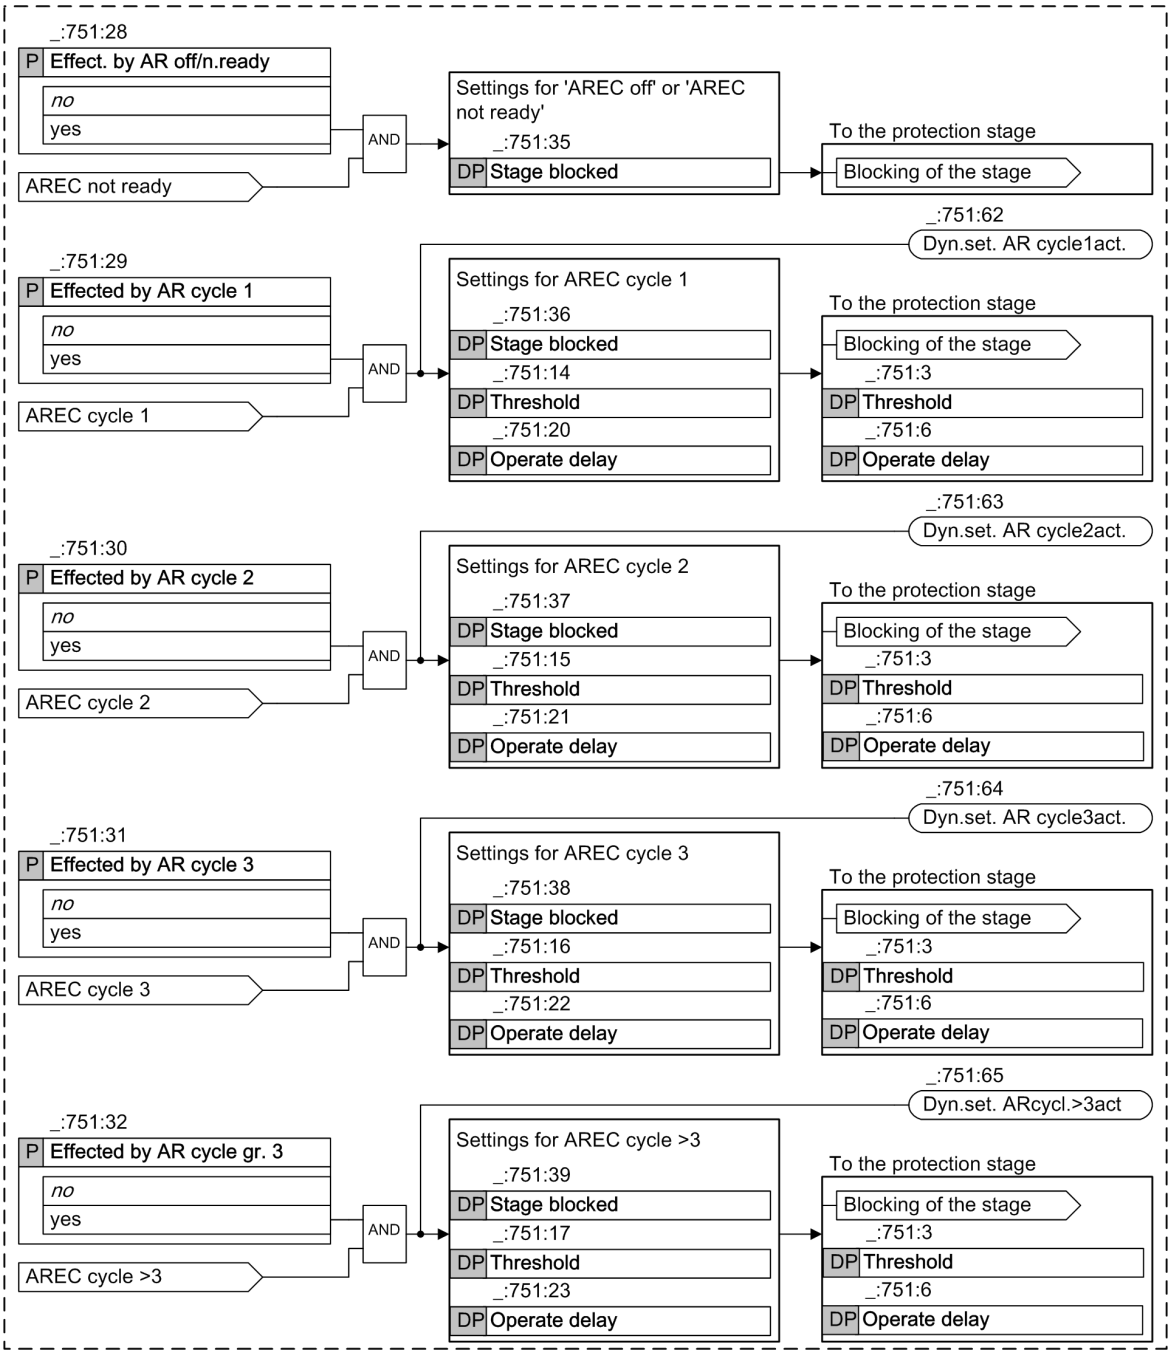
6.5.8.1 Description

The **Threshold** and **Operate delay** settings used for tripping are so-called **dynamic settings**. Depending on other functions, the settings of these parameters can be changed dynamically. Depending on other functions, the stage can also be blocked dynamically. This functionality is only available in function type Advanced.

[loocpgnd-030311-01.vsd, 1, en_US]

Figure 6-42 Principle of the Dynamic Settings in the Example of 1st Definite Time-Overcurrent Protection Stage

If available in the device, the following functionalities can affect the overcurrent-protection stages:



Functionalities	Priority
Automatic reclosing (AREC)	Priority 1
Cold-load pickup detection	Priority 2
Binary input signal	Priority 3

These functionalities generate signals that change the settings of the dynamic settings of the overcurrent-protection stage or block it, if required. In the latter case, the settings for the **Threshold** and the **Operate delay** are of no relevance. Within the overcurrent-protection stage, each of these signals is provided with a configuration parameter **Influence of function ...** and its own dynamic settings (**Operate delay** and **Threshold**). The configuration settings are used to set whether the signal shall be active or not, this means whether the dynamic settings shall be activated or not. If one of these signals (for example, signal function x) becomes active and is to take effect, these parameter settings become dynamic, that is, instantly active. This means that the setting assigned to the signal replaces the standard setting. If the signal becomes inactive, the standard settings apply again. The activation of the dynamic settings is reported.

Where several signals are active in parallel, the priority specified above shall apply. This means that a signal with priority 2 precedes that of priority 3. The settings assigned to signal 2 become active.

The functionality of the dynamic settings can be disabled. In this case, the settings assigned to the signals are not visible and are without effect.

Link to the Device-Internal Function *Automatic Reclosing (Advanced Stage)*

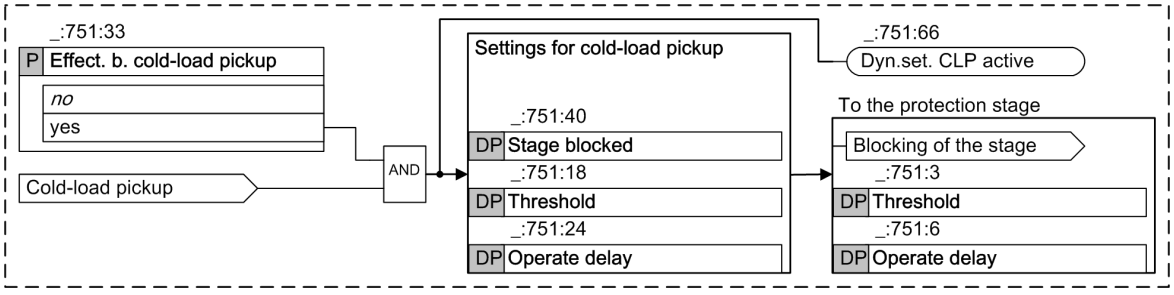
[loocpgrnd-040311-01.vsd, 1, en_US]

Figure 6-43 Influence of the AREC Signals on the Overcurrent-Protection Stage

Several AREC signals can affect the setting for the **Threshold** and the **Operate delay** of the protection stage and its blocking.

- AREC is ready for reclosing 1 (= Automatic reclosing cycle 1)
- AREC is ready for reclosing 2 (= Automatic reclosing cycle 2)
- AREC is ready for reclosing 3 (= Automatic reclosing cycle 3)
- AREC is ready for reclosing 4 (= Automatic reclosing cycle >3)

The following signal can only block the protection stage:



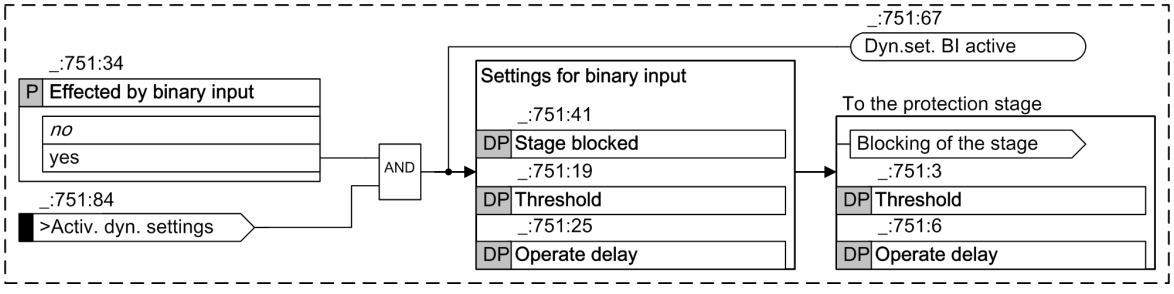
- AREC is not ready or switched off (= Automatic reclosing off / not ready)

This means that if the AREC is ready and the protection stage is in the idle state, the settings for **AREC cycle 1** are active and not the standard settings. The standard settings are active in the case of **AREC off/not ready**.

The influence can be activated for each signal individually. You also have to set the **Threshold** and **Operate delay** or **Stage blocked** parameters, which take effect when the signal is active.

The way AREC signals are generated is described in chapter *6.43.1 Overview of Functions*.

Link to the Device-Internal Function *Cold-Load Pickup Detection (Advanced Stage)*



[loocpkalgnd-030311-01.vsd, 1, en_US]

Figure 6-44 Influence of the Cold-Load Pickup Detection on the Overcurrent-Protection Stage

You have the option of changing the settings for the **Threshold** and the **Operate delay** of the protection stage for a cold-load pick-up. You can also block the stage. To do so, you must activate the influence of the cold-load pickup. You also have to set the **Threshold** and **Operate delay** or assign settings to **Stage blocked**, which take effect when the signal is active.

The way signals are generated **Cold-load pickup** is described in chapter *5.8.8 Cold-Load Pickup Detection (Optional)* .

Link to an External *Function via a Binary Input Signal (Advanced Stage)*

[loocpbingnd-030311-01.vsd, 1, en_US]

Figure 6-45 Influence of the Binary Input on the Overcurrent-Protection Stage

You can use the binary input signal **>Activ. dyn. settings** to change the settings for the **Threshold** and the **Operate delay** of the protection stage. You can also block the stage. To do so, you must activate the influence of the binary input. You also have to set the **Threshold** and **Operate delay** or assign settings to **Stage blocked**, which take effect when the signal is active.

6.5.8.2 Application and Setting Notes (Advanced Stage)

Binary Input Signal: `Dynamic settings`

- Default setting **`(_:751:26) Dynamic settings`** = ***`no`***

Parameter Value	Description
`no`	The influence on the overcurrent-protection stage by device-internal or external functions is not necessary.
`yes`	If a device-internal function (automatic reclosing function or cold-load pickup detection) or an external function should affect the overcurrent-protection stage (such as change the setting of the threshold value or time delay, blocking of the stage), the setting must be changed to ***`yes`***. This makes the configuration parameters **`Influence of function...`** as well as the dynamic settings **`Threshold`**, **`Operate delay`** and **`Stage blocked`** of the stage visible and enables the settings to be set for the specific influence.

Influence of AREC

The example of how the overcurrent-protection stage (1st stage) can be used as a fast stage before automatic reclosing describes the influence exerted by AREC.

The setting of the overcurrent level (1st level) results from the time-grading schedule. It is to be used as fast stage before an automatic reclosing. Because fast disconnection of the short-circuit current takes priority over the selectivity prior to reclosing, the **`Operate delay`** parameter can be set to ***`0`*** or to a very low value. To achieve the selectivity, the final disconnection must be done with the grading time.

AREC is set to 2 reclosings. A secondary **`Threshold`** of ***`1.5 A`*** and a **`Operate delay`** of ***`600 ms`*** are assumed (according to the time-grading schedule) for the overcurrent-protection stage. The standard settings of the stage are set to these values.

To realize the application, the configuration settings **`Effected by AR cycle 1`** and **`Effected by AR cycle 2`** are changed in the example to ***`yes`*** (= influenced). This activates the **`AR cycle 1`** and **`AR cycle 2`** input signals within the stage. When they become active, they switch to the assigned dynamic settings.

The two dynamic settings **`Operate delay`** assigned to these input signals (sources of influence) are set to the time delay ***`0`*** (instantaneous tripping). The two dynamic settings **`Threshold`** assigned to these input signals are set to the normal threshold value of ***`1.5 A`***.

If the threshold value (***`1.5 A`***) is exceeded before AREC 1 and AREC 2, the overcurrent-protection stage trips instantaneously. If the fault still exists after AREC 2 (unsuccessful AREC), the stage trips with the time delay of ***`600 ms`*** according to the time-grading schedule.

Influence of External Devices

The influence of an external device can also be configured. The above is an example of how the overcurrent-protection stage (1st stage) can be used as a fast stage before automatic reclosing, in which case the AREC function is performed by an external device.

To realize the application, the configuration setting **`Effected by binary input`** must be changed to ***`yes`*** (= influenced). This activates the **`>Activ. dyn. settings`** input signal within the stage. When the input signal becomes active, it switches to the assigned dynamic settings. The external device must provide the **`Cycle 1`** and **`Cycle 2`** signals or, alternatively, an AREC ready signal. The signals must be connected with the binary input signal **`>Activ. dyn. settings`**.

The dynamic setting **`Operate delay`**, which is assigned to the input signal (source of influence) **`>Activ. dyn. settings`**, is set to the time delay ***`0`*** (instantaneous tripping). The dynamic setting **`Threshold`** assigned to this input signal is set to the normal threshold value of ***`1.5 A`***.

If the threshold value (***`1.5 A`***) is exceeded before AREC 1 and AREC 2, the overcurrent-protection stage trips instantaneously. If the fault still exists after AREC 2 (unsuccessful AREC), the stage trips with the time delay of ***`600 ms`*** according to the time-grading schedule.

6.6 Directional Overcurrent Protection, Phases

6.6.1 Overview of Functions

The **Directional time-overcurrent protection, phases** (ANSI 67):

- Detects short circuits at electrical equipment
- Can be used as backup overcurrent protection in addition to the main protection
- Ensures selective fault detection for parallel lines or transformers with infeed at one end
- Ensures selective fault detection in cable runs with infeed at both ends or in lines connected to form ring topologies

6.6.2 Structure of the Function

The **Directional time-overcurrent protection, phases** function is used in protection function groups. 2 function types are offered:

- **Directional time-overcurrent protection, phases - advanced** (67 Dir.OC-3ph-A)
- **Directional time-overcurrent protection, phases - basic** (67 Dir.OC-3ph-B)

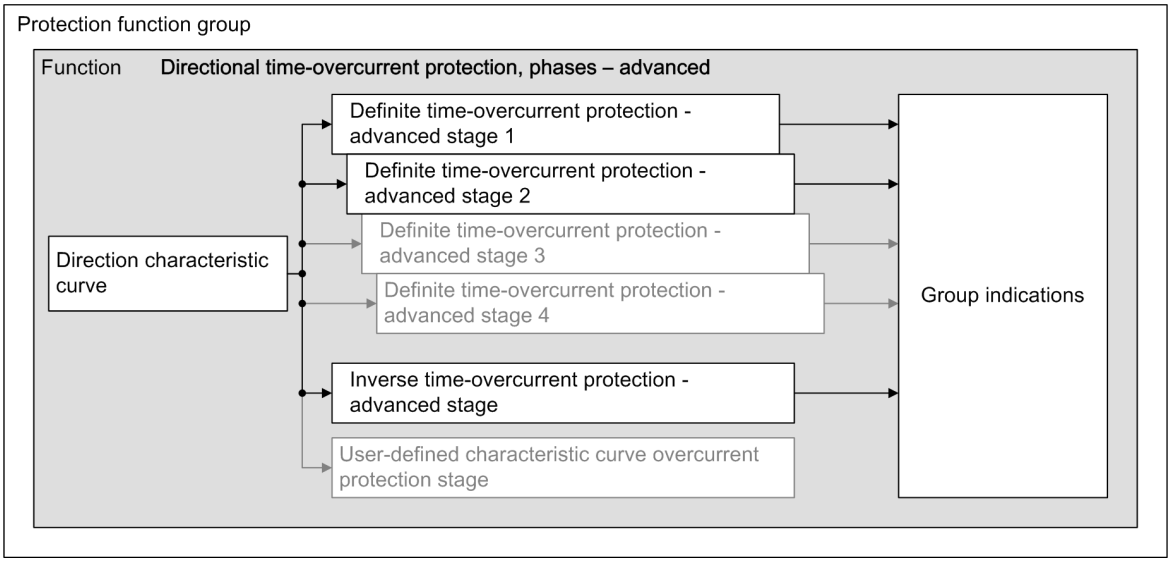
The Basic function type is provided for standard applications. The Advanced function type offers more functionality and is provided for more complex applications.

Both function types are preconfigured by the manufacturer with 2 **directional, definite time-overcurrent protection** stages and with 1 **directional inverse time-overcurrent protection** stage.

In the advanced function type **Directional time-overcurrent protection, phases – advanced** the following stages can be operated simultaneously:

- Maximum of 4 stages **Definite time-overcurrent protection – advanced**
- 1 stage **Inverse time-overcurrent protection – advanced**
- 1 stage **User-defined overcurrent protection characteristic curve**

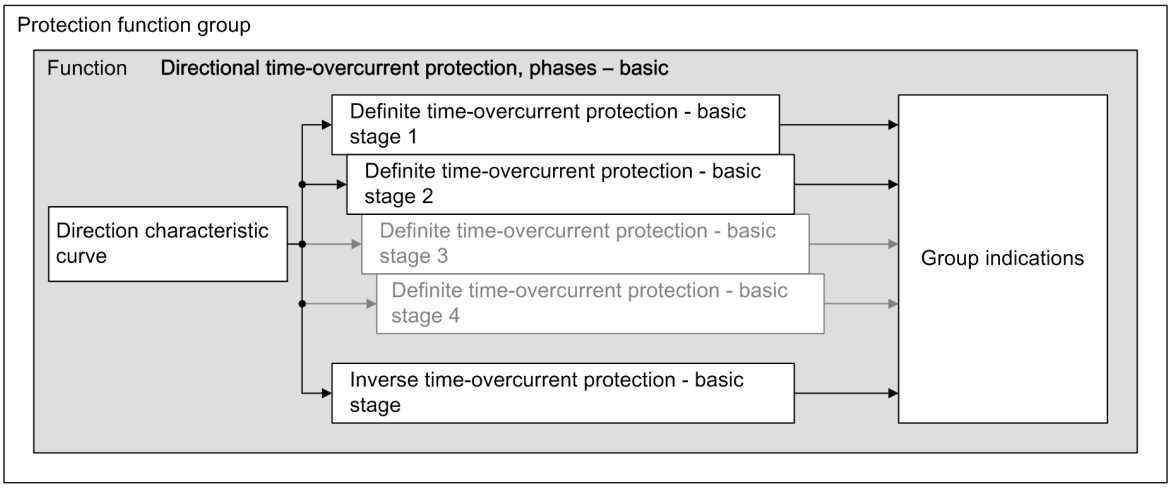
In the Basic function type **Directional time-overcurrent protection, phases – basic** the following stages can be operated simultaneously:



- Maximum of 4 stages **Definite time-overcurrent protection – basic**
- 1 stage **Inverse time-overcurrent protection – basic**

Stages that are not preconfigured are shown in gray in the following figures. Apart from the tripping delay characteristic, the stages are identical in structure.

The direction determination occurs on function level and has the same effects in all stages (see following figure and chapter *6.6.7.1 Description*). In this way, it is ensured that all stages of a function receive the same direction result. Every stage can be set to the forward or reverse direction.



The group-indication output logic generates the following group indications of the protection function by the logical OR of the stage-selective indications:

- **`Pickup`**
- **`Operate`**

[dwdiocan-050213-01.tif, 3, en_US]

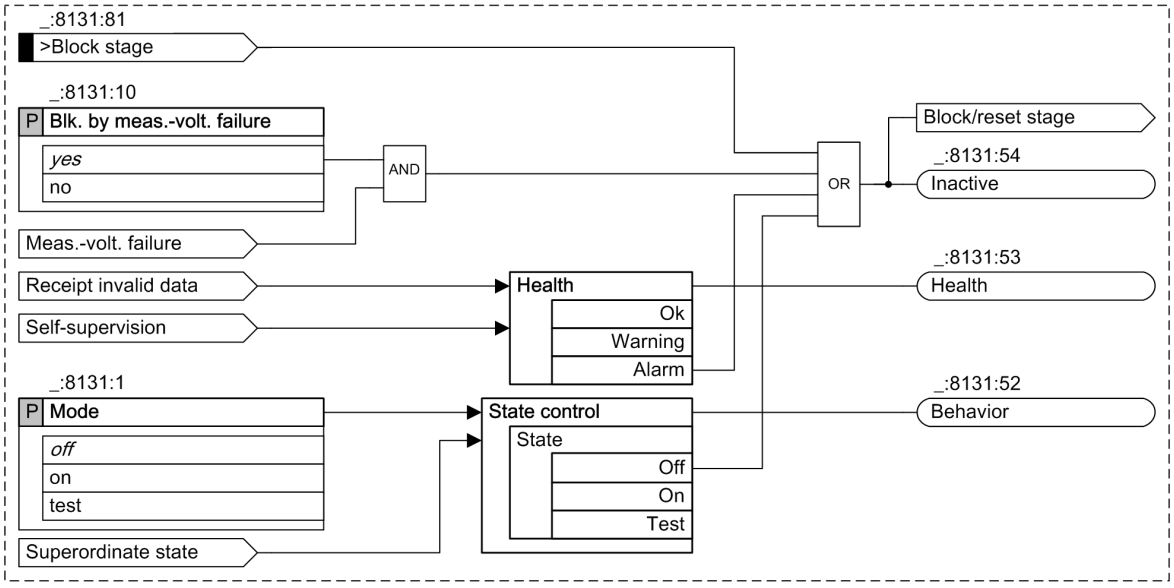
Figure 6-46 Structure/Embedding the Function Directional Time-Overcurrent Protection, Phases – Advanced

[dwdiocba-050213-01.tif, 4, en_US]

Figure 6-47 Structure/Embedding the Function Directional Time-Overcurrent Protection, Phases – Basic

If the device-internal functions listed in the following are present in the device, these functions can influence the pickup values and tripping delays of the stages or block the stages. The stage can also be affected by an external source via a binary input signal.

- Automatic reclosing (AREC)
- Cold-load pickup detection
- Binary input signal



If the device is equipped with the **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer-inrush currents.

6.6.3 Stage Control

6.6.3.1 Description

Logic

The following figure represents the stage control. It applies to all types of stages.

[lodocpn2-291112-01.tif, 1, en_US]

Figure 6-48 Stage-Control Logic Diagram

Blocking of the Stage with Measuring-Voltage Failure (Basic and Advanced Stage)

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function (see chapter *9.3.2.1 Overview of Functions*)
- From an external source via the binary input signal **>Open** of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker

The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.

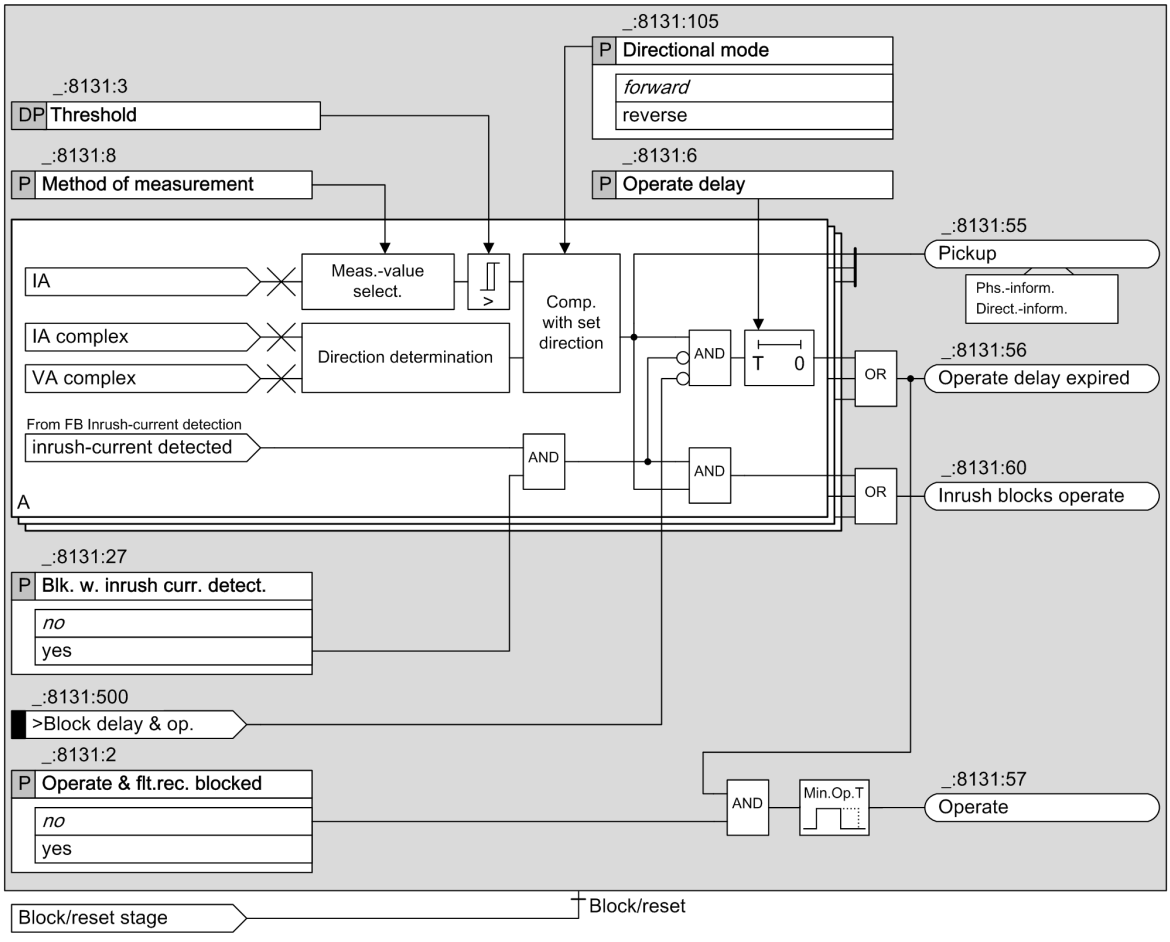
6.6.3.2 Application and Setting Notes

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:8131:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following two conditions is met:

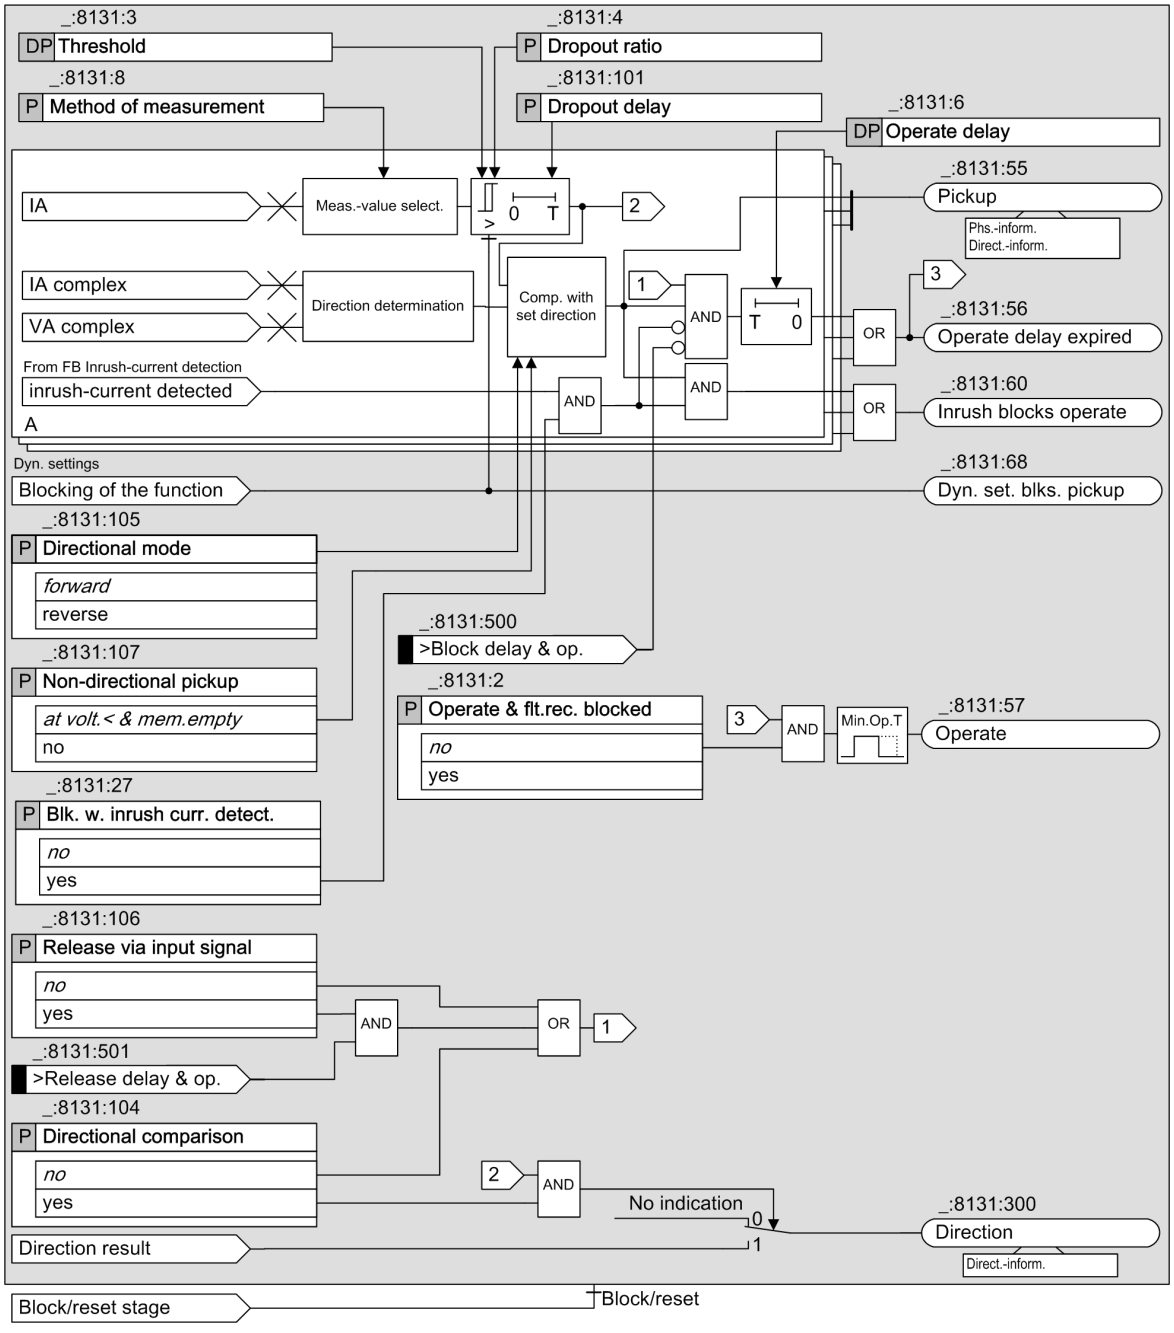


- The device-internal supervision function **Measuring-voltage failure detection** is configured and switched on.
- The binary input signal **>Open** of the function block **VTCB** is connected to the voltage-transformer circuit breaker (see chapter *9.3.4.1 Overview of Functions*).

Parameter Value	Description
yes	The directional overcurrent-protection stage is blocked. Siemens recommends that you retain the default setting, as correct direction determination cannot be guaranteed if a measuring-voltage failure occurs.
no	The directional overcurrent-protection stage is not blocked.

6.6.4 Stage with Definite-Time Characteristic Curve

6.6.4.1 Description



Logic of the Basic Stage

[lodocg6b-060213-01.tif, 2, en_US]

Figure 6-49 Logic Diagram of the Directional, Definite Time-Overcurrent Protection, Phases - Basic

Logic of the Advanced Stage

[lodocp31-141013, 1, en_US]

Figure 6-50 Logic Diagram of the Directional, Definite Time-Overcurrent Protection, Phases - Advanced

Directional mode (Basic and Advanced Stage)

You use the **`Directional mode`** parameter to define whether the stage works in a forward or reverse direction.

Direction determination itself works across stages (see section *6.6.7.1 Description*).

Non-Directional Pickup, Voltage Memory (Basic and Advanced Stage)

If a 3-phase close-up fault occurs, all 3 phase-to-ground voltages drop to almost 0. If this happens, direction determination can fall back on a voltage memory (see chapter l *6.6.7.1 Description*). If no voltage measure-

ments which can be used to determine the direction are available in the voltage memory, the basic stage generally picks up without direction determination, that is non-directionally. For the advanced stage, the response can be defined via the **Non-directional pickup** parameter. With the ***at volt.< & mem.empty*** setting, the function picks up in such a situation without direction determination. With the ***no*** setting, the function does not pick up.

Directional Comparison Protection (Advanced Stage)

The stage can be used for directional comparison protection. This is set using the **Directional comparison** parameter. With the ***yes*** setting, the function uses the threshold value violation to determine the direction (forward or reverse) and reports the indication **Direction** . The direction indicated is independent of the directional mode set for the stage.

The **Release via input signal** setting and the **>Release delay & op.** input signal are available with directional comparison protection. If the **Release via input signal** parameter is set to ***yes*** , the start of the time delay, and therefore the tripping of the stage, are only enabled if the **>Release delay & op.** input signal is active.

Method of measurement (Basic and Advanced Stage)

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the calculated ***RMS value*** .

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Dropout delay (Advanced Stage)

If the value falls below the dropout threshold, the pickup dropout can be delayed. The pickup is maintained for the specified time. The tripping delay continues to run. If the time delay expires while the pickup is still maintained, the stage operates.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Externally or internally via the binary input signal **>Block stage** (see chapter *6.6.3.1 Description*)
- Measuring-voltage failure (see chapter *6.6.3.1 Description*)
- Via the dynamic settings function (only provided in the Advanced function type, see chapter **Influence of other functions via dynamic settings** and chapter *6.3.8.1 Description*)

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and the fault logging and recording takes place.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.3.7.1 Description* .

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.3.8.1 Description* .

6.6.4.2 Application and Setting Notes

Parameter: **Directional mode**

- Default setting **(_:8131:105) Directional mode** = ***forward***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
forward	Select this setting if the stage is to work in a forward direction (in the direction of the line).
reverse	Select this setting if the stage is to work in a reverse direction (in the direction of the busbar).

Parameter: **Method of measurement**

- Recommended setting value **(_:8131:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: **Directional comparison**, **Release via input signal**

- Default setting **(_:8131:104) Directional comparison** = ***no***
- Default setting **(_:8131:106) Release via input signal** = ***no***

These 2 parameters are not visible in the basic stage.

You use these parameters to define whether the stage is to be used for directional comparison protection. Directional comparison protection is performed via the **Direction** and **>Release delay & op.** signals.

Parameter Value	Description
no	The stage is not used for directional comparison protection.

Parameter Value	Description
yes	If the **Directional comparison** parameter is set to ***yes***, the **Release via input signal** parameter, the **Direction** output signal, and the **>Release delay & op.** input signal become available. If the **Release via input signal** parameter is set to ***yes***, the start of the time delay, and therefore also the operate signal of the stage, are only enabled if the **>Release delay & op.** input signal is active. The **>Release delay & op.** input signal must be connected to the release information from the opposite end (forward information from the **Direction** output signal); see also the application example in chapter *6.6.10 Application Notes for Directional Comparison Protection* .

Parameter: Non-directional pickup

- Recommended setting value **(_:8131:107) Non-directional pickup** = ***at volt.< & mem.empty***

This parameter is not visible in the basic stage.

Parameter Value	Description
at volt.< & mem.empty	Select this setting if the stage is to pick up in a non-directional manner if the voltage memory is empty and determining of direction has to be performed at low voltages (3-phase close-up fault). An empty voltage memory may exist, for example, if there is a voltage transformer at the line end and the circuit breaker (CB) trips. Siemens recommends using the default setting.
no	Select this setting if determining of direction is required under all circumstances, that is, even in the event of pickup on a 3-phase close-up fault.

Parameter: Threshold

- Default setting **(_:8131:3) Threshold** = ***1.50 A*** (for the first stage)

The same considerations apply to setting the threshold value as for non-directional overcurrent protection. For further information, refer to section *6.3.4.2 Application and Setting Notes* .

Parameter: Operate delay

- Default setting **(_:8131:6) Operate delay** = ***0.300 s*** (for the 1st stage)

The Operate delay to be set is derived from the time-grading schedule that has been prepared for the system.

Typical examples of grading times are provided in the chapters *6.6.9 Application Notes for Parallel Lines and Cable Runs with Infeed at Both Ends* and *6.6.10 Application Notes for Directional Comparison Protection* .

Parameter: Dropout ratio

- Recommended setting value **(_:8131:4) Dropout ratio** = ***0.95***

This parameter is not visible in the basic stage.

The recommended set value of 0.95 is appropriate for most applications.

For high-precision measurements, the setting value of the **Dropout ratio** parameter can be reduced, for example to 0.98. If you expect heavily fluctuating measurands at the response threshold, you can increase the setting value of the **Dropout ratio** parameter. This avoids chattering of the tripping stage.

Parameter: Dropout delay

- Recommended setting value **(_:8131:101) Dropout delay** = ***0 s***

This parameter is not visible in the basic stage.

Siemens recommends using this setting value, since the dropout of a protection stage must be performed as fast as possible.

You can use the **Dropout delay** parameter ≠ ***0 s*** to obtain a uniform dropout behavior if you use it together with an electromechanical relay. This is required for time grading. The dropout time of the electromechanical relay must be known for this purpose. Subtract the dropout time of your own device (see Technical Data) and set the result.

6.6.4.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:2311:102	General:Rotation angle of ref. volt.		-180 ° to 180 °	45 °

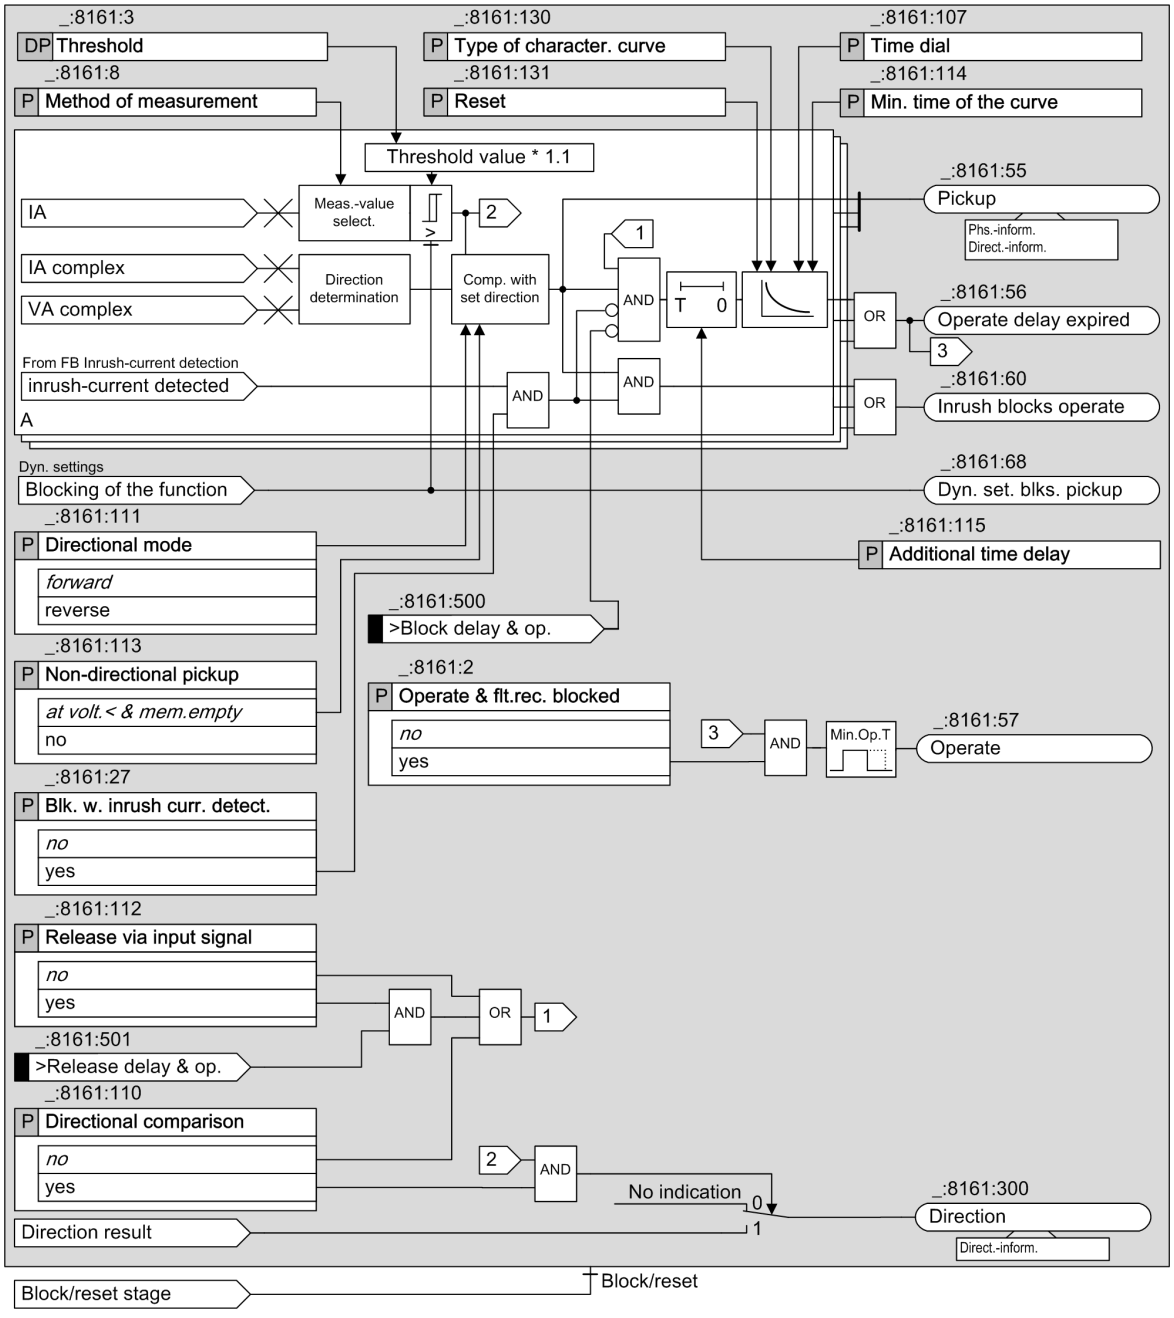
6.6.5 Stage with Inverse-Time Characteristic Curve

6.6.5.1 Description



Logic of the Basic Stage

[lodoci6b-060213-01.tif, 2, en_US]

Figure 6-51 Logic Diagram of the Directional, Inverse Time-Overcurrent Protection, Phases - Basic

Logic of the Advanced Stage

[lodocp33-121013, 2, en_US]

Figure 6-52 Logic Diagram of the Directional, Inverse Time-Overcurrent Protection, Phases - Advanced

Directional mode (Basic and Advanced Stage)

You use the **`Directional mode`** parameter to define whether the stage works in a forward or reverse direction.

The direction determination works across stages (see chapter *6.6.7.1 Description*).

`Non-directional pickup`, Voltage Memory (Basic and Advanced Stage)

If a 3-phase close-up fault occurs, all 3 phase-to-ground voltages drop to almost 0. If this happens, direction determination can fall back on a voltage memory (see chapter *6.6.7.1 Description*). If no voltage measurements which can be used to determine the direction are available in the voltage memory, the basic stage

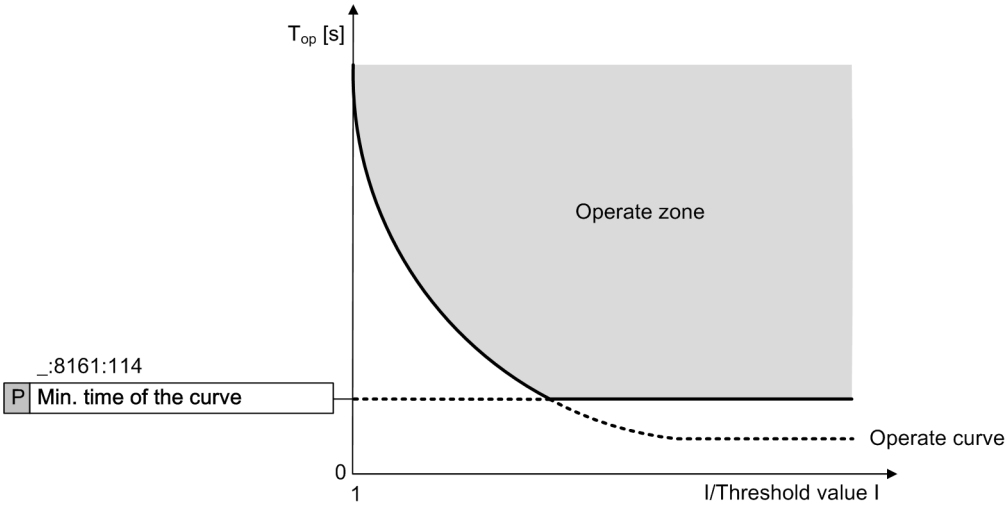
generally picks up without direction determination, that is non-directionally. For the advanced stage, the response can be defined via the **Non-directional pickup** parameter. With the ***at volt.< & mem.empty*** setting, the function picks up in such a situation without direction determination. With the ***no*** setting, the function does not pick up.

Directional Comparison Protection (Advanced Stage)

The stage can be used for directional comparison protection. This is set using the **Directional comparison** parameter. With the ***yes*** setting, the function uses the threshold value violation to determine the direction (forward or reverse) and reports the indication **Direction**. The direction indicated is independent of the directional mode set for the stage.

The **Release via input signal** setting and the **>Release delay & op.** input signal are available with directional comparison protection. If the **Release via input signal** parameter is set to ***yes***, the start of the time delay, and therefore the tripping of the stage, are only enabled if the **>Release delay & op.** input signal is active.

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve according to IEC and ANSI (Basic and Advanced Stage)



When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrating method of measurement summarizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls below the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

Minimum Time of the Curve (Advanced Stage)

With the parameter **Min. time of the curve**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time.

[DwDocp01_040715-01.vsd, 1, en_US]

Figure 6-53 Minimum Operating Time of the Curve

Additional Time Delay (Advanced Stage)

With the parameter **Additional time delay**, you define a definite-time delay in addition to the inverse-time delay. With this setting, the whole curve is shifted on the time axis by this additional definite time.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Externally or internally via the binary input signal **>Block stage** (see chapter *6.6.3.1 Description*)
- Measuring-voltage failure (see chapter *6.6.3.1 Description*)
- Via the functionality of the **dynamic settings** (only in the advanced function type, see subtitle **Influence of other functions via dynamic settings** and chapter *6.3.8.1 Description*).

Blocking of the Time Delay (Basic and Advanced Stage)

You can use the binary input signal **>Block delay & op.** to prevent the start of the time delay and thus also the operate signal. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Operate Delay and the Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.3.7.1 Description* .

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can influence the overcurrent-protection stages:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.3.8.1 Description* .

6.6.5.2 Application and Setting Notes

Parameter: Directional mode

- Default setting **(_:8161:111) Directional mode** = ***forward***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
forward	Select this setting if the stage is to work in a forward direction (in the direction of the line).
reverse	Select this setting if the stage is to work in a reverse direction (in the direction of the busbar).

Parameter: Method of measurement

- Recommended setting value **(_:8161:8) Method of measurement** = ***fundamental comp.***

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.

Parameter Value	Description
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks). For this method of measurement, do not set the **threshold value** of the stage to less than 0.1 $I_{rated,sec}$.

Parameter: Directional comparison, Release via input signal

- Default setting **(_:8161:110) Directional comparison** = ***no***
- Default setting **(_:8161:112) Release via input signal** = ***no***

These 2 parameters are not visible in the basic stage.

You use these parameters to define whether the stage is to be used for directional comparison protection. Directional comparison protection is performed via the **Direction** and **>Release delay & op.** signals.

Parameter Value	Description
no	The stage is not used for directional comparison protection.
yes	If the **Directional comparison** parameter is set to ***yes***, the **Release via input signal** parameter, the **Direction** output signal, and the **>Release delay & op.** input signal become available. If the **Release via input signal** parameter is set to ***yes***, the start of the time delay, and therefore also the operate signal of the stage, are only enabled if the **>Release delay & op.** input signal is active. The **>Release delay & op.** input signal must be connected to the release information from the opposite end (forward information from the **Direction** output signal); see also the application example in chapter *6.6.10 Application Notes for Directional Comparison Protection* .

Parameter: Non-directional pickup

- Recommended setting value **(_:8161:113) Non-directional pickup** = ***at volt.< & mem.empty***

This parameter is not visible in the basic stage.

Parameter Value	Description
at volt.< & mem.empty	Select this setting if the stage is to pick up in a non-directional manner if the voltage memory is empty and determining of direction has to be performed at low voltages (3-phase close-up fault). An empty voltage memory may exist, for example, if there is a voltage transformer at the line end and the CB trips. Siemens recommends using the default setting.
no	Select this setting if determining of direction is required under all circumstances, that is, even in the event of pickup on a 3-phase close-up fault.

Parameter: Type of character. curve

- Default setting **(_:8161:130) Type of character. curve** = ***IEC normal inverse***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **Type of character. curve** required for your specific application.

Parameter: Min. time of the curve

- Default setting **(_:8161:114) Min. time of the curve** = ***0.00 s***

This parameter is only available in the advanced stage.

With the parameter **Min. time of the curve**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time. If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

NOTE

If the set value is smaller than the smallest possible time delay of the inverse-time characteristic curve, the parameter has no influence on the delay time.

Parameter: Additional time delay

- Default setting **(_:8161:115) Additional time delay** = ***0.00 s***

With the parameter **Additional time delay**, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

Parameter: Threshold

- Default setting **(_:8161:3) Threshold** = ***1.50 A***

The same considerations apply to setting the threshold value as for non-directional overcurrent protection. Therefore, refer to chapter *6.3.5.2 Application and Setting Notes* for further information.

Parameter: Time dial

- Default setting **(_:8161:101) Time dial** = ***1***

Use the **Time dial** parameter to displace the characteristic curve in the time direction.

The set value for the **Time dial** parameter is derived from the time-grading chart that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the **Time dial** parameter at ***1*** (default setting).

Parameter: Reset

- Default setting **(_:8161:131) Reset** = ***disk emulation***

You use the **Reset** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

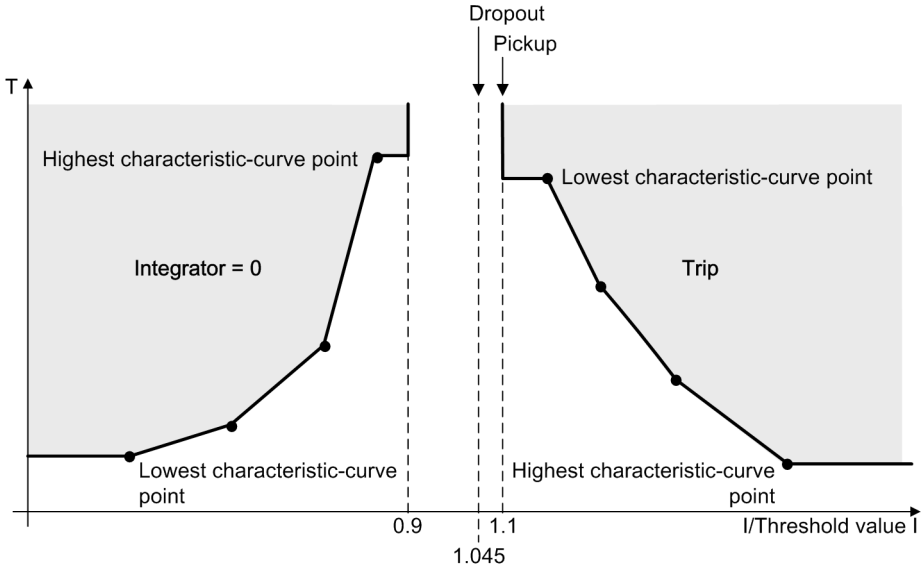
6.6.6 Stage with User-Defined Characteristic Curve

6.6.6.1 Description

The structure of this stage is identical to that of the advanced stage with directional inverse-time characteristic curve (*6.6.4.1 Description*). The only difference is that you can define the characteristic curve as desired.

User-Defined Characteristic Curve



With the directional, user-defined characteristic curve, you can define the tripping curve point by point using up to 30 value pairs of current and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.

Pickup and Dropout Behavior with User-Defined Characteristic Curve

When the input variable exceeds the threshold value by 1.1 times, the characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

[dwocpken-140611-02.tif, 1, en_US]

Figure 6-54 Pickup and Dropout Behavior when Using a Directional User-Defined Characteristic Curve

NOTE

Note that the currents that are lower than the current value of the smallest characteristic-curve point do not extend the operate time. The pickup characteristic runs in parallel to the current axis up to the smallest characteristic-curve point. Currents that are larger than the current value of the largest characteristic-curve point do not reduce the operate time. The pickup characteristic runs in parallel to the current axis from the largest characteristic-curve point.

6.6.6.2 Application and Setting Notes

This stage is structured in the same way as the stage with a directional inverse-time characteristic curve. The only difference is that you can define the characteristic curve as desired. This chapter only provides application and setting notes for setting characteristic curves.

Parameter: `Current/time value pairs` (from the operate curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

Use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The set value for the **`Time dial`** parameter is derived from the time-grading chart that has been prepared for the electrical power system. Where no time grading and therefore no displacement of the characteristic curve is required, leave the **`Time dial`** parameter set to ***`1`***.

Parameter: `Reset`

- Default setting **`(_:115) Reset`** = ***`disk emulation`***

You use the **`Reset`** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	In the case of this setting, a dropout characteristic curve has to be set in addition to the operate curve. Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

Parameter: `Current/time value pairs` (of the dropout characteristic curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting depends on the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold value setting afterwards if you want to displace the characteristic curve.

Set the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

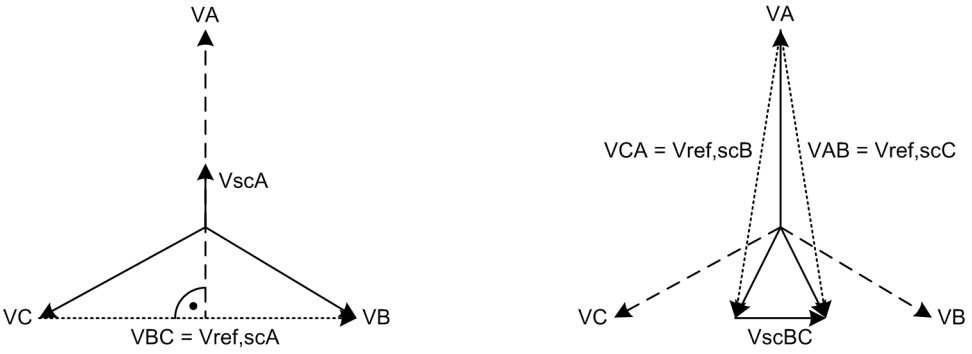
6.6.7 Direction Determination

6.6.7.1 Description

General

Every phase has a separate direction-measuring element. If the threshold value in a phase is exceeded, the direction determination is started for this phase. If there are multiphase short circuits, all measuring elements involved perform direction determination independently. If one of the determined directions matches the set direction, the stage picks up (see descriptions of the stage logic).



The direction is determined by calculating the phase angle between the short-circuit current and a reference voltage.

Measurands for Direction Determining

The directional measuring element uses the short-circuit current of the phase concerned and the cross-polarized phase-to-phase voltage (as the reference voltage) to determine the direction. This means that the direction can still be determined unambiguously and correctly, even if the short-circuit voltages collapse completely when a 1 or 2-phase fault occurs (close-up fault).

The phase-to-phase voltages are calculated when phase-to-ground voltages are connected.

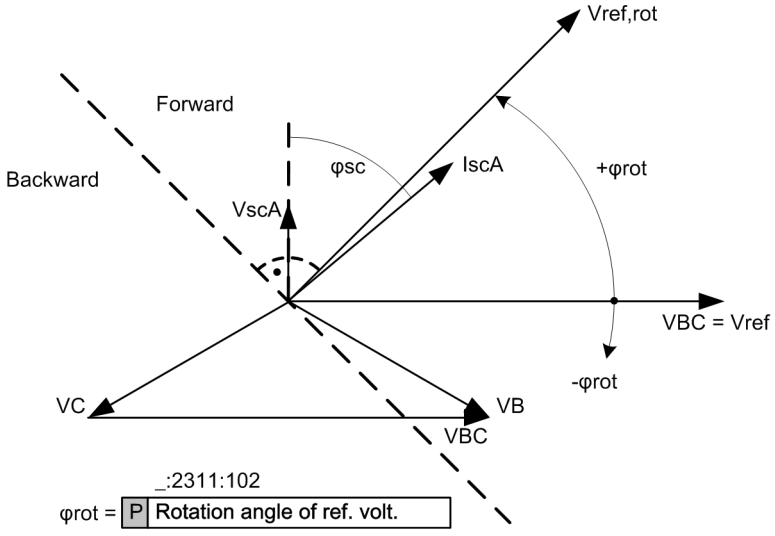
The cross-polarized voltage (reference voltage) is vertical in relation to the short-circuit voltages for 1-phase-to-ground faults (*Figure 6-55*, left). For 2-phase short circuits, the position of the reference voltages changes up to 30°, depending on the extent to which the short-circuit voltages collapse (*Figure 6-55*, right).

[dwdocp02-240611-01.tif, 1, en_US]

Figure 6-55 Cross-Polarized Voltages for Direction Determination

The following table shows how measurands are assigned for direction-determination purposes in the event of different types of fault.

Table 6-3 Measurands for Direction Determining



Threshold-Value Exceeding	Measuring Element							
	A		B		C		Ground	
	Current	Voltage	Current	Voltage	Current	Voltage	Current	Voltage

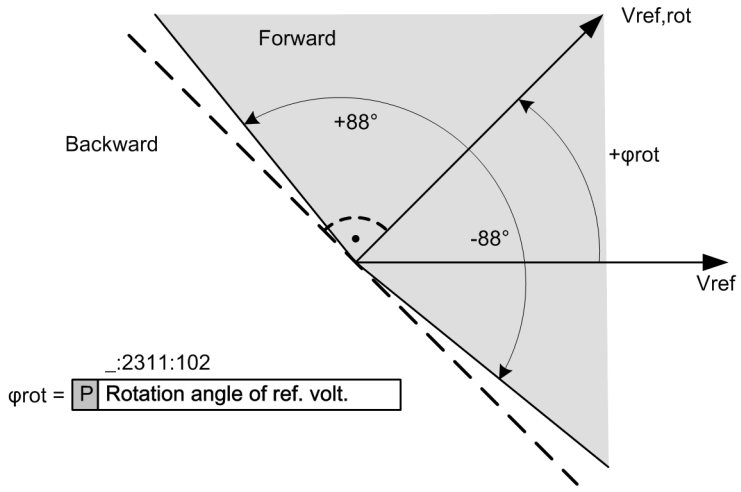
A, B, Gnd	I_A	V_{BC}	I_B	V_{CA}	–	–	I_r	V_0
B, C, Gnd	–	–	I_B	V_{CA}	I_C	V_{AB}	I_r	V_0
A, C, Gnd	I_A	V_{BC}	–	–	I_C	V_{AB}	I_r	V_0
A, B, C	I_A	V_{BC}	I_B	V_{CA}	I_C	V_{AB}	–	–
A, B, C, Gnd	I_A	V_{BC}	I_B	V_{CA}	I_C	V_{AB}	I_r	V_0

Voltage Memory

Saved voltages are used if, when a 3-pole close-up fault occurs, the measuring voltages are not sufficient for reliable direction determination. Insofar as and as long as no sufficient measuring voltage is available after the storage time (2 s) has elapsed, the detected direction is retained. If the memory does not contain any voltages (when closing onto a short circuit, for example), the behavior of the stage is defined using the **Non-directional pickup** parameter.

Direction Determination



As mentioned in the **General** section, the direction is determined by calculating the phase angle between short-circuit current and reference voltage. To take different system conditions and applications into account, the reference voltage can be rotated through an adjustable angle (**Rotation angle of ref. volt.** parameter). This moves the vector of the rotated reference voltage close to the vector of the short-circuit current. Consequently, the result of direction determination is as reliable as possible. *Figure 6-56* illustrates the relationship based on a 1-phase ground fault in phase A. The short-circuit current I_{kL1} lags the short-circuit voltage by the short-circuit angle φ_k. The reference voltage, in this case V_{BC} for measuring element A, is rotated positively (counterclockwise) by the setting value of the **Rotation angle of ref. volt.** parameter. In the scenario illustrated here, the rotation is +45°.

[dwdocp33-070611-01.tif, 2, en_US]

Figure 6-56 Rotation of the Reference Voltage, Phase-Measuring Element

The rotated reference voltage defines the forward and reverse range; see *Figure 6-57*. The forward range is calculated as ±88° around the rotated reference voltage $V_{ref,rot}$. If the short-circuit current vector is located in this range, the device decides on the forward direction. In the mirrored range, the device decides on the backward direction. In the intermediate range, the direction is undetermined.

[dwdocp34-240611-01.tif, 2, en_US]

Figure 6-57 Forward Characteristic of the Directional Function, Phase-Measuring Element

Direction Determination for Test Purposes

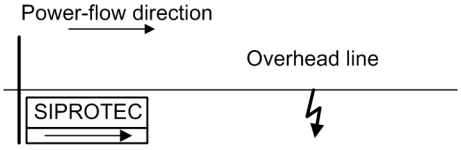
If you activate the binary input signal **>Test of direction**, the direction is determined and indicated even without the current threshold being exceeded in one of the stages. The direction can be determined as soon as current and voltage are greater than approx. 7 % of their secondary rated values.

6.6.7.2 Application and Setting Notes

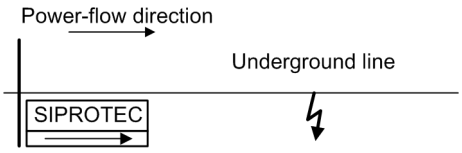
Parameter: Rotation angle of ref. volt.

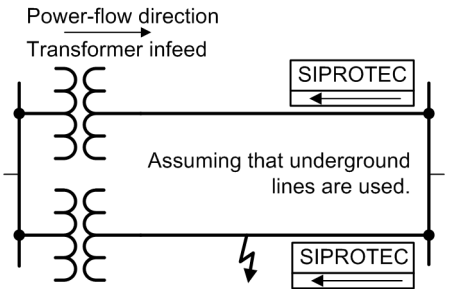
- Default setting **(_:2311:102) Rotation angle of ref. volt.** = ***45°***

The directional characteristic, that is, the position of the **forward** and **reverse** ranges, is set with the **Rotation angle of ref. volt.** parameter. The short-circuit angle is typically to be found in a range from 30° to 60° inductive. Therefore, in most cases, the default setting of +45° can be retained to position the reference voltage, as it ensures a reliable directional result.



Some example settings for special applications appear in the following (*Table 6-4*). Please note that for phase-to-ground faults (PG faults), the reference voltage (fault-free voltage) is vertical in relation to the short-circuit voltage. This results in the following setting for the rotation angle:





Rotation angle of ref. volt. = 90 - φsh phase-measuring elements (PG faults)

Please also note that for phase-to-phase faults, the reference voltage is rotated between 0° (distant fault) and 30° (close-up fault) dependent upon the collapse of the faulted voltage (see *Figure 6-56*). You can take this into account with an average value of 15°.

Rotation angle of ref. volt. = 90 - φsh - 15° phase-measuring elements (PP faults)

Table 6-4 Example settings

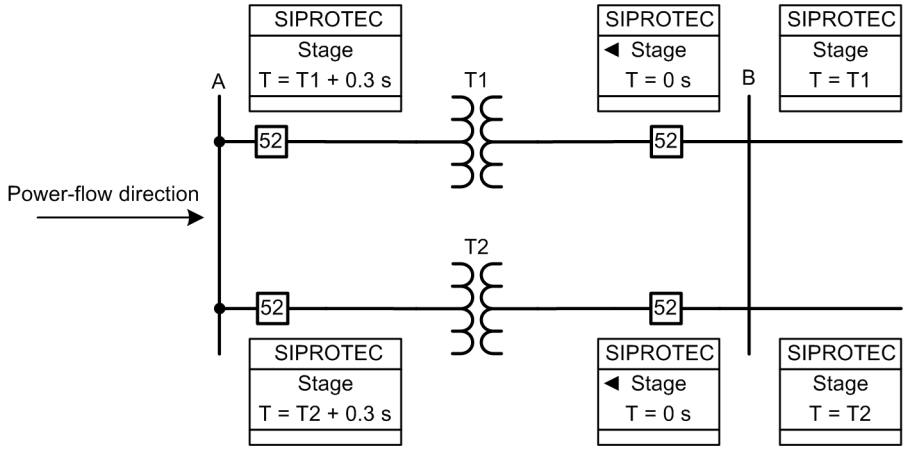
Application	φsh typical	Setting Rotation angle of ref. volt.
	60°	Range 30° to 0° for PP faults Selected: 15°

Application	φsh typical	Setting **Rotation angle of ref. volt.**
	30°	Range 60° to 30° for PP faults Selected: 45°
	30°	Range 60° to 30° for PP faults Selected: 45°

Input signal: >Test of direction

If you activate the binary input signal **>Test of direction**, the direction is determined and indicated even without the current threshold being exceeded in one of the stages. This provides an easy means of checking the direction during commissioning, without changing the threshold values of the stages.

6.6.8 Influence of Other Functions via Dynamic Settings



The influence of these functions via dynamic settings is described in chapter *6.3.8.1 Description* and chapter *6.3.8.2 Application and Setting Notes (Advanced Stage)* .

6.6.9 Application Notes for Parallel Lines and Cable Runs with Infeed at Both Ends

Parallel Lines or Transformers

In parallel lines or transformers with infeed at one end (see *Figure 6-58*), if there is no directional measuring element, a fault on feeder T1 will also trip the other feeder T2. In contrast, a directional measuring element in the devices on busbar B prevents the tripping of the circuit-breaker in the parallel feeder. Therefore, in *Figure 6-58*, directional time-overcurrent protection is used in the places marked with direction arrows. Please note that the forward direction of the protection device represents the direction towards the object to be protected. This does not have to be the same as the power direction of normal load flow.

Set time grading in opposition to the load flow with increasing time. As load can only flow in one direction, you can set the directional devices without time delay.

[dwdocp05-240611-01.tif, 1, en_US]

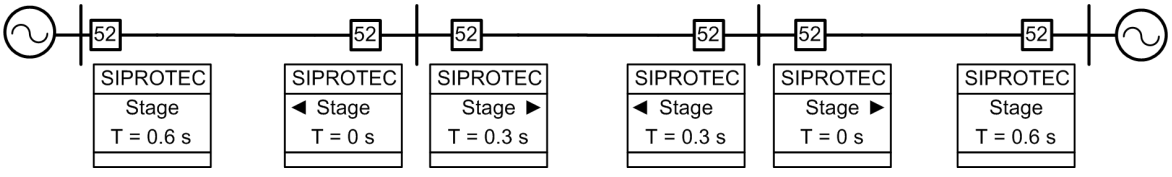


Figure 6-58 Parallel Line with Transformers

Legend for *Figure 6-58*

Stage ►:	Directional stage, **forward** direction set
Stage:	Non-directional stage
T:	Grading time

Cable Runs with Infeed at Both Ends

Cable runs with infeed at both ends and lines connected to form ring topologies also require that you supplement overcurrent protection with the directional criterion. *Figure 6-59* shows a ring system implementation, with the 2 infeeds shown merging in the ring to form a single infeed. For the directional devices whose forward direction matches the power-flow direction, set time grading in opposition to the power flow with increasing time. As power flow from both ends is possible, grading has to be set at both ends.

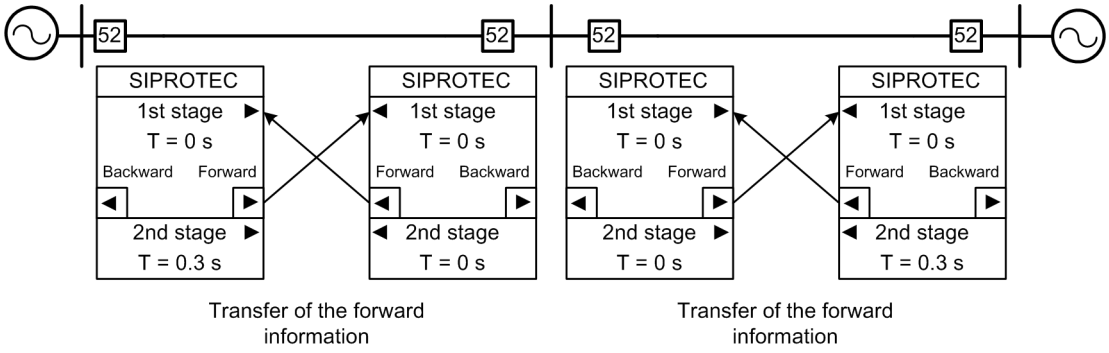
6.6.10 Application Notes for Directional Comparison Protection

The direction determination of directional time-overcurrent protection can be used to implement directional comparison protection for cable runs with infeed at both ends. Directional comparison protection is used for the selective isolation of a faulted line section (for example, subsections of closed rings). Sections are isolated in fast time, that is, they do not suffer the disadvantage of long grading times.

This technique requires that directional information can be exchanged between the individual protection stations. You can implement this information exchange using a communication channel (protection interface or IEC 61850 GOOSE) or with pilot wires for signal transmission via an auxiliary voltage loop.



Protection Principle

The protection principle is shown in *Figure 6-60*. 2 devices (one at the start of the line and the other at the end of the line) work together in each line section. The information **fault in forward direction** is transferred between them. A directional definite time-overcurrent protection level is in operation in both devices in the forward direction (1st level). However, this level is not enabled in the idle state. The level is only released when the information **fault in forward direction** is received from the opposite end. If the enabled level also defines the fault in the forward direction, the fault must be on this line section and the level trips immediately. As this protection principle works with an enable procedure (and not with a blocking procedure), there is no need to delay the level.

A second directional definite time-overcurrent protection stage with standard time grading works in parallel with the first stage as a selective backup stage. This ensures full selectivity of protection in the following situations:

- Infeed at one end or weak infeed at one end: In this case, no release signal is generated.
- Failure of the communication route: In this case, the release signal is not transmitted.

To provide selective protection in fast time for busbars between the line sections also, you can combine this protection principle with the principle of reverse interlocking. This principle is not discussed in further detail in this document.

[dwdocp07-240611-01.tif, 1, en_US]

Figure 6-60 Selectivity through Directional Comparison Protection

Legend for *Figure 6-60*

Stage ►:	Stage is set in the **forward** direction; stage 1 is instantaneous, stage 2 is graded
►, ◄:	If a threshold value is exceeded, the stage indicates the direction (forward or reverse)

If you are using a communication channel, the protocol-transmission methods detect if the channel is interrupted. If you are using pilot wires, we recommend operation based on a closed-circuit connection. The device uses a function chart to check and indicate if the binary input is dead for an unexpectedly long period. In contrast with the blocking procedure, overfunction is not possible if communication is lost. Therefore, a loss of communication is not critical where this procedure is concerned, although it must be detected and indicated.

Directional comparison protection can also be implemented as a blocking procedure. This procedure works under all system switching states, i.e. also with infeed at one end (or weak infeed). However, to use it you must delay the stage (typically by 100 ms) so that the blocking signal is received in time under all circumstances. It is also essential that you monitor the communication channel to avoid overfunction in the event of failure followed by a system incident.

Configuration of the Stage, Function Chart

To configure the stage, proceed as follows:

- The **`Directional mode`** parameter of both stages must be set to ***`forward`***
- The **`Directional comparison`** and **`Release via input signal`** parameters of the first stage must be set to ***`yes`***. This is so that the first stage is only released if the **`>Release delay & op.`** input signal is active. Furthermore, the direction is indicated if a threshold value is exceeded.
- The first stage can be set without a time delay. The second stage has to be graded

- The information ***forward*** from the **Direction** signal in the first stage must be transmitted to the opposite end. The routing is determined by the type of transmission
- A function chart has to be implemented at the receive end to link the received (***forward*** information) and release signals, dependent upon the type of transmission.

6.7 Directional Overcurrent Protection, Ground

6.7.1 Overview of Functions

The **Directional time-overcurrent protection, ground** function (ANSI 67N):

- Detects short circuits to ground affecting electric equipment
- Ensures selective ground fault detection for parallel lines or transformers with infeed at one end
- Ensures selective ground fault detection in cable runs with infeed at both ends or in lines connected to form ring topologies

6.7.2 Structure of the Function

The **Directional time-overcurrent protection, ground** function can be used in protection function groups which provide zero-sequence current and zero-sequence voltage measurements. 2 function types are offered:

- **Directional time-overcurrent protection, ground – advanced** (67N Dir.OC-gnd-A)
- **Directional time-overcurrent protection, ground – basic** (67N Dir.OC-gnd-B)

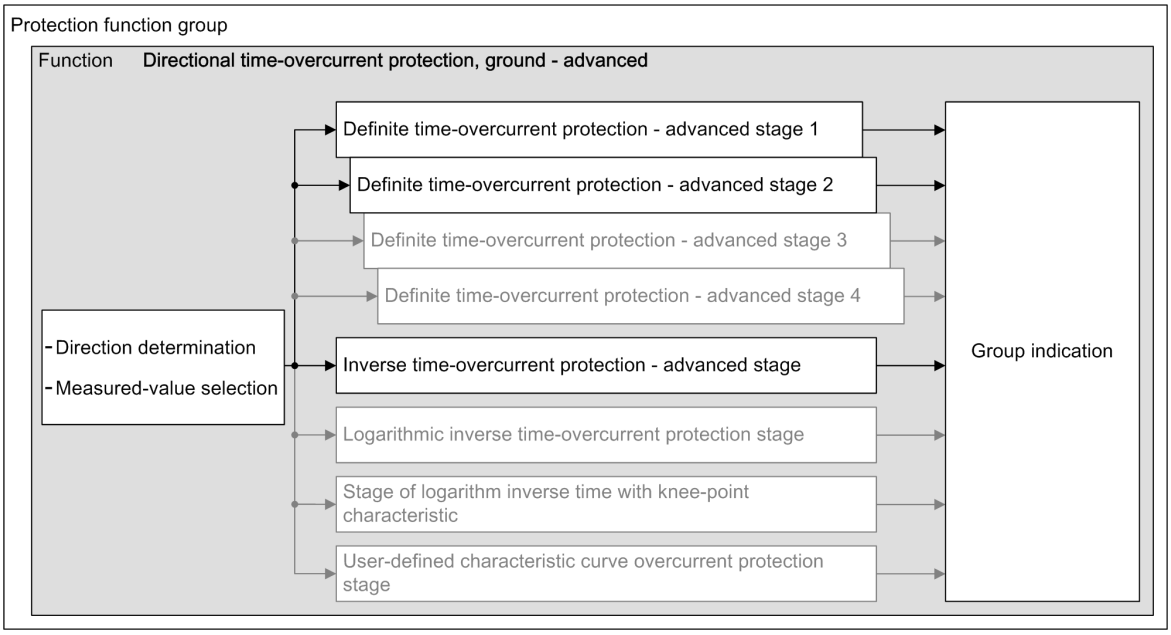
The basic function type shall be used for standard applications. The advanced function type provides more functionalities and is intended for more sophisticated applications.

Both function types are preconfigured by the manufacturer with 2 **Definite time-overcurrent protection** stages and 1 **Inverse time-overcurrent protection** stage.

In the advanced function type **Directional time-overcurrent protection, ground – advanced**, the following stages can operate simultaneously:

- A maximum of 4 **Definite time-overcurrent protection – advanced** stages
- 1 **Inverse time-overcurrent protection – advanced** stage
- 1 **Logarithmic inverse time-overcurrent protection** stage
- 1 **Logarithmic inverse time with knee-point overcurrent protection** stage
- 1 **User-defined characteristic curve overcurrent protection** stage

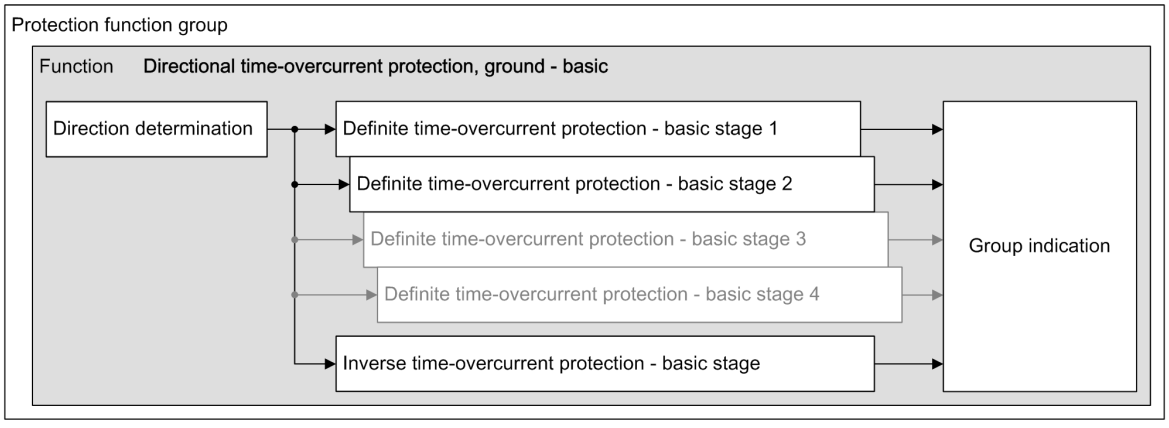
In the basic function type **Directional time-overcurrent protection, ground – basic**, the following stages can operate simultaneously:



- A maximum of 4 **Definite time-overcurrent protection – basic** stages
- 1 **Inverse time-overcurrent protection – basic** stage

Referring to *Figure 6-61* and *Figure 6-62*, the stages not preconfigured are shown in gray. Apart from the operate-delay characteristic curve, the stages are similar in structure.

The general functionallity includes the direction determination and the measured-value selection (only advanced function). They take place on the functional level and have a uniform effect on the stages (see *Figure 6-61* and chapter General Functionality. This ensures that all stages of the function receive the same measured current value and the same direction result. Each stage can be set to work in forward or reverse direction.



The group indication output logic generates the following group indications for the protection function by the logic OR from the stage-selective indications:

- Pickup
- Operate

[dwrdirad-300913, 2, en_US]

Figure 6-61 Structure/Embedding of the Function Directional Time-Overcurrent Protection, Ground – Advanced

[dwrdirba-300913, 1, en_US]

Figure 6-62 Structure/Embedding of the Function Directional Time-Overcurrent Protection, Ground – Basic

If the following listed device-internal functions are present in the device, these functions can influence the pickup values and operate delays of the stages or block the stages. The stage can also be affected by an external source via a binary input signal.

- Automatic reclosing (AREC)
- Cold-load pickup detection
- Binary input signal

If the device is equipped with the **Inrush-current detection** function, the stages can be stabilized against operate due to transformer-inrush currents.

6.7.3 General Functionality

6.7.3.1 Measured-Value Selection

Logic

The function provides the option to select between the values ***IN measured*** or ***3I0 calculated***.

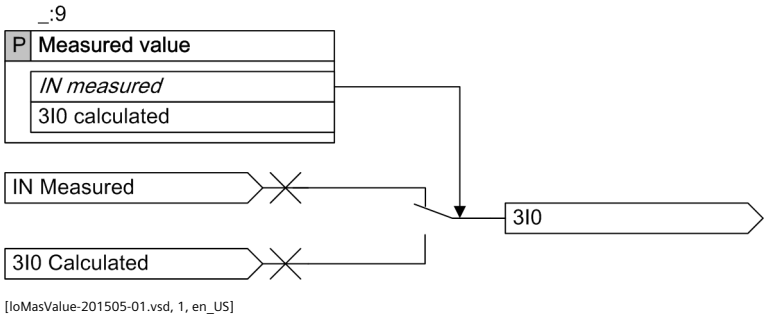


Figure 6-63 Logic Diagram of Measured-Value Selection

Both options are only available for the current-transformer connection types ***3-phase + IN*** and ***3-phase + IN-separate***. For other connection types respectively, only one option is possible. If you select an option that is not allowed, an inconsistency message is given.

Depending on the CT secondary rated current, the CT connection type, and the selected setting, the secondary threshold setting range varies according to the following table.

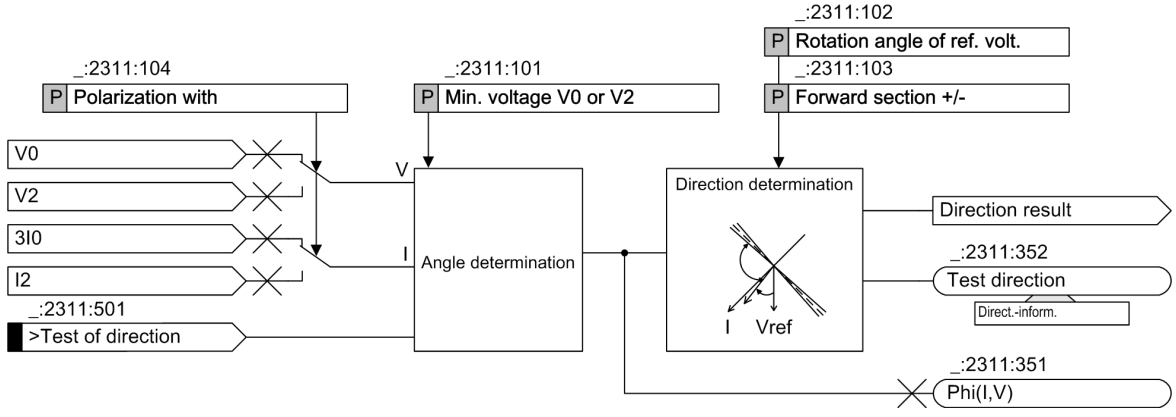

Table 6-5 Threshold Setting Range

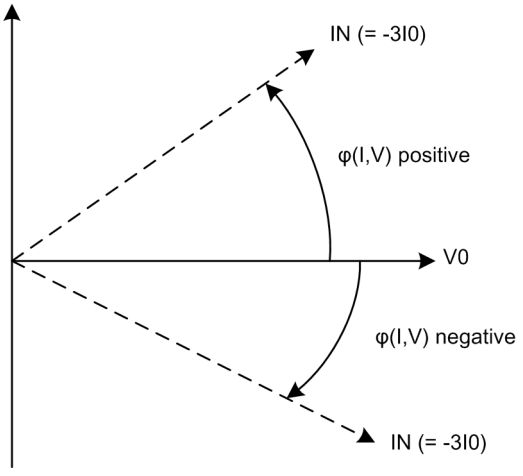
Connection Type	Measured Value	CT Terminal Type	Threshold Setting Range (rated I-sec.: ph = 1 A, IN = 1 A)	Threshold Setting Range (rated I-sec.: ph = 1 A, IN = 5 A)	Threshold Setting Range (rated I-sec.: ph = 5 A, IN = 1 A)	Threshold Setting Range (rated I-sec.: ph = 5 A, IN = 5 A)
3ph + IN	3I0 calculated	4 * Protection	0.030 A to 35.000 A	N/A	N/A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	N/A	N/A	0.005 A to 8.000 A
	IN measured	4 * Protection	0.030 A to 35.000 A	N/A	N/A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	N/A	N/A	0.005 A to 8.000 A
3ph + IN-separate	3I0 calculated	4 * Protection	0.030 A to 35.000 A	0.030 A to 35.000 A	0.15 A to 175.00 A	0.15 A to 175.00 A
		3 * Protection, 1 * sen.	0.030 A to 35.000 A	0.030 A to 35.000 A	0.15 A to 175.00 A	0.15 A to 175.00 A
		4 * Measurement	0.001 A to 1.600 A	0.001 A to 1.600 A	0.005 A to 8.000 A	0.005 A to 8.000 A
	IN measured	4 * Protection	0.030 A to 35.000 A	0.15 A to 175.00 A	0.030 A to 35.000 A	0.15 A to 175.00 A
		3 * Protection, 1 * sen.	0.001 A to 1.600 A	0.005 A to 8.000 A	0.001 A to 1.600 A	0.005 A to 8.000 A
		4 * Measurement	0.001 A to 1.600 A	0.005 A to 8.000 A	0.001 A to 1.600 A	0.005 A to 8.000 A

6.7.3.2 Direction Determination

Logic of Direction Determination

The following figure represents the logic of the direction determination. It applies to all types of stages.



[lodirdet-280812-01.tif, 1, en_US]

Figure 6-64 Logic Diagram of Direction Determination

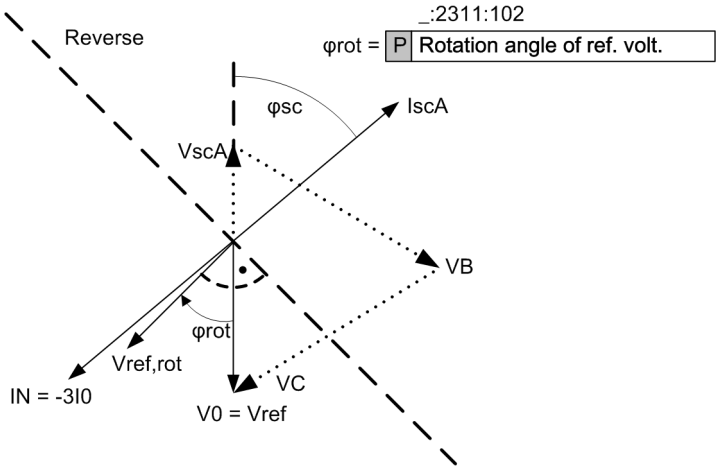
Measurand for the Direction Determination

With the parameter **`Polarization with`** you define whether the direction determination is calculated with the zero-sequence components 3I0 and V0 or with the negative-sequence components I2 and V2, which are present during faults in the network.

The angle between IN (=-3I0) and V0 (respectively -I2 and V2) in case of using the negative-sequence components is available as a functional measured value. This value is only present during faults in the network.

[DwUlkenn-240812-01.vsd, 1, en_US]

Figure 6-65 Measured-Value Definition

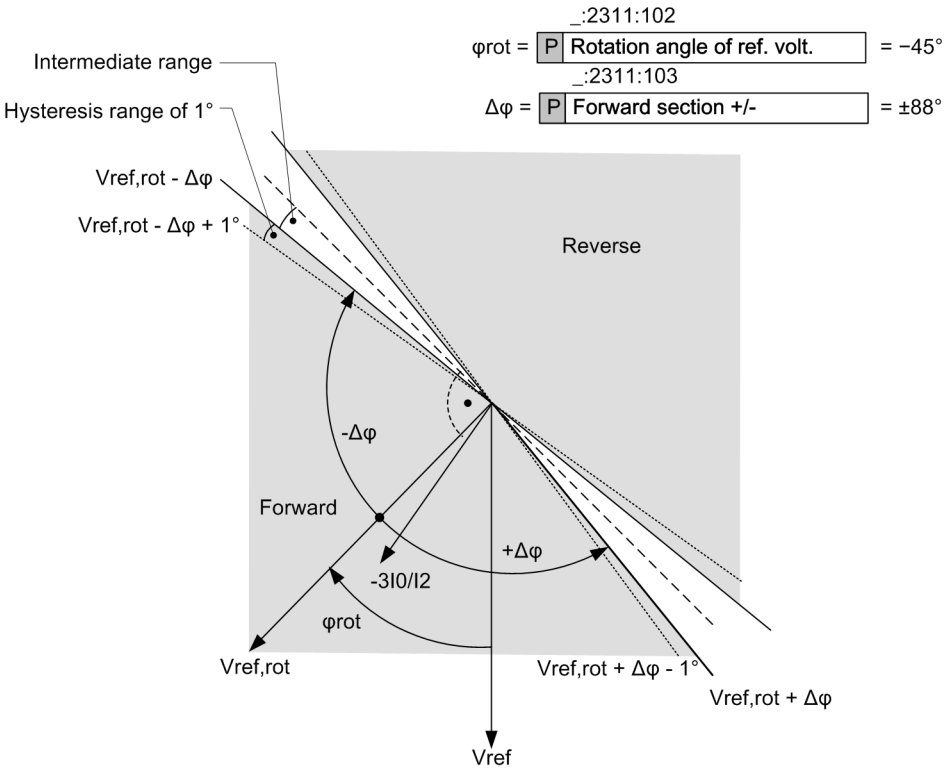


Start of the Direction Determination

If the zero-sequence current 3I0 exceeds the pickup threshold of a stage and the selected voltage (V0 or V2) exceeds the parameter **`Min. voltage V0 or V2`** as well, the direction determination is started.

Direction Determination with Zero-Sequence Values

The direction is determined by calculating the phase angle between the short-circuit current -3I0 and the rotated reference voltage **Vref, rot**. Contrary to the **Directional time-overcurrent protection, phase** function, which works with the healthy voltage as reference voltage, the fault voltage V0 itself is the reference voltage for the **Directional time-overcurrent protection, ground** function. To take different system condi-



tions and applications into account, the reference voltage V0 can be rotated through an adjustable angle (parameter **Rotation angle of ref. volt.**). This moves the vector of the rotated reference voltage close to the vector of the short-circuit current -3I0. Consequently, the result of direction determination is as reliable as possible. *Figure 6-66* illustrates the relationship based on a 1-phase-to-ground fault in phase A. The fault current has a phase displacement of 180° to the fault current IscA and lags the fault voltage by the fault angle φsc. The reference voltage V0 is rotated by φrot which is -45°.

[dwroreze-300913, 2, en_US]

Figure 6-66 Rotation of the Reference Voltage, Directional Time-Overcurrent Protection, Ground Function with Zero-Sequence Values

The rotated reference voltage **Vref, rot** and the parameter **Forward section +/-** define the forward and reverse ranges, see *Figure 6-67* . The forward range is calculated as ± Δφ° around the rotated reference voltage **Vref, rot**. Δφ is set with the parameter **Forward section +/-** . If the short-circuit current vector -3I0 is located in this range, the device decides on the forward direction. In the mirrored range, the device decides on the reverse direction. In the intermediate range, the direction is undetermined.

[dwforrev-281013, 2, en_US]

Figure 6-67 Forward/Reverse Characteristic of the Directional Time-Overcurrent Protection, Ground Function

Direction Determination with Negative-Sequence Values

The method works in the same way as for zero-sequence values. Instead of 3I0 and V0, the negative-sequence values I2 and V2 are used for determining the direction.

Direction Determination for Test Purposes

If you activate the binary input signal *>Test of direction* , the direction is determined and indicated even without the current threshold being exceeded in one of the stages. The direction can be determined as soon as the zero-sequence current 3I0 and the zero-sequence voltage V0 exceeds approx. 7 % of the secondary rated values of phase current and voltage.

6.7.3.3 Application and Setting Notes

Parameter: `Measured value`

- Recommended setting value **`(_:9) Measured value`** = ***`IN Measured`***

This parameter is not available in the basic function.

Parameter Value	Description
`IN Measured`	The function operates with the measured ground current IN. This is the recommended setting unless there is a specific reason to use the calculated zero-sequence current 3I0.
`3I0 Calculated`	The function operates with the calculated zero-sequence current 3I0. This setting option can be used when applying a redundant 50N/51N function for safety reasons.

Parameter: **Min. voltage V0 or V2**

- Recommended setting value **(_:2311:101) Min. voltage V0 or V2** = ***2 V***

This parameter is not available in the basic function. The basic function uses a fixed value of 2 V.

You use the **Min. voltage V0 or V2** parameter to define the minimum zero-sequence voltage or negative-sequence voltage for the direction determination. The minimum voltage must be set greater than the maximum operational unbalance plus the voltage-transformer measuring errors.

As the measuring error of the individual voltage transformer is not added up, the critical measuring-error influence is the unbalance of the primary system.

Siemens recommends observing the operational zero-sequence voltage V0 of the protected object (for example, the line) via the operational measured values of the device and providing the maximum value with a certainty of 50 %.

EXAMPLE

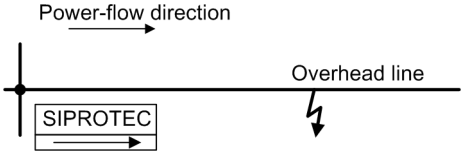
Maximum operational measured value of zero-sequence voltage V0 = 0.5 Vsec

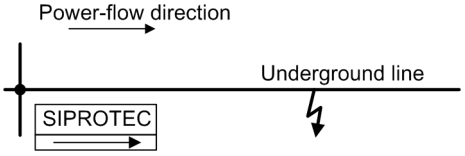
Min. voltage V0 or V2 = 1.5 * 0.5 V = 0.75Vsec

If you have no information about maximum operational unbalance, Siemens recommends using the default setting.

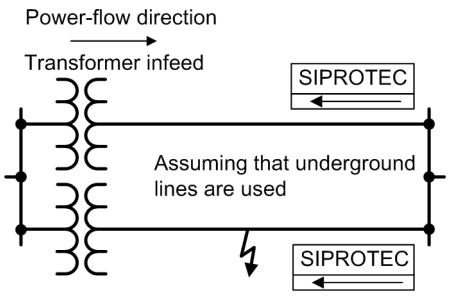
Parameter: **Rotation angle of ref. volt.** / **Forward section +/-**

- Recommended setting value **(_:2311:102) Rotation angle of ref. volt.** = ***-45°***
- Recommended setting value **(_:2311:103) Forward section +/-** = ***88°***





The parameter **Forward section +/-** is not available in the basic function. The basic function uses a fixed value of 88°.



The direction characteristic, that is, the area of the forward and reverse ranges, is set with the **Rotation angle of ref. volt.** and the **Forward section +/-** parameters. The short-circuit angle is typically to be found in a range from -30° to -60° inductively. Therefore, in most cases, the default setting of -45° can be retained to position the reference voltage, as it ensures a reliable directional result.

Some example settings for special applications appear below *Table 6-6*. Note that for 1-phase-to-ground faults (PG faults), the reference voltage is the zero-sequence voltage V0. This results in the following setting for the rotation angle:

Rotation angle of ref. volt. = -φk ground-measuring elements (PG faults)

Table 6-6 Example Settings

Application	φk Typical	Setting **Rotation angle of ref. volt.**
	60°	-60°
	30°	-30°

	30°	-30°

Parameter: `Polarization with`

- Recommended setting value **`(_:2311:104) Polarization with`** = ***`zero sequence`***

This parameter is not available in the basic function. The basic function uses always zero-sequence components for the direction determination.

You use the parameter **`Polarization with`** to select the values for the direction determination.

Parameter Value	Description
`zero sequence`	Select ***`zero sequence`*** to determine the direction via the zero-sequence components V0 and 3I0. Siemens recommends using the zero-sequence components for the direction determination.
`negative sequence`	Select ***`negative sequence`*** to determine the direction via the negative-sequence components V2 and I2. The negative-sequence system can be used in case of danger that the zero-sequence voltage is too small due to unfavorable zero-sequence impedance conditions or that a parallel line influences the zero-sequence system.

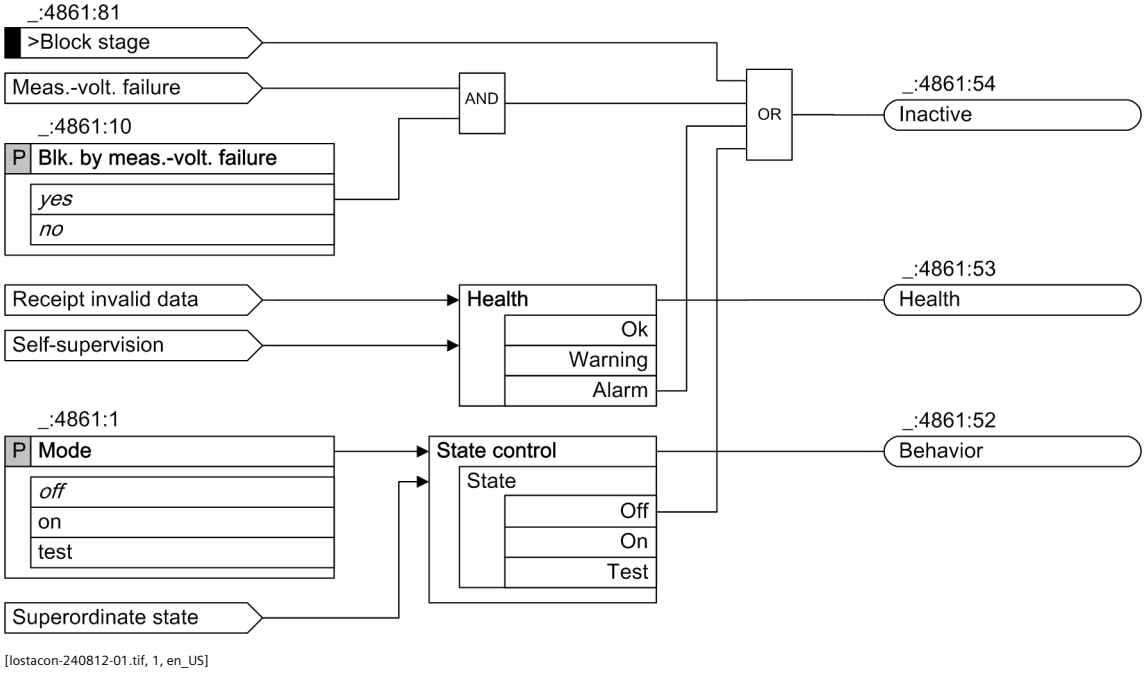
Input Signal: *`>Test of direction`*

If you activate the binary input signal *`>Test of direction`*, the direction is determined and indicated even without the current threshold being exceeded in one of the stages. This provides an easy means of checking the direction during commissioning, without changing the threshold values of the stages.

6.7.3.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting
`General`				
_:9	General:Measured value		• 3I0 calculated • IN measured	IN measured
_:101	General:Min. voltage V0 or V2		0.150 V to 20.000 V	2.000 V
_:102	General:Rotation angle of ref. volt.		-180 ° to 180 °	-45 °
_:103	General:Forward section +/-		0 ° to 90 °	88 °
_:104	General:Polarization with		• zero sequence • negative sequence	zero sequence

6.7.3.5 Information List



No.	Information	Data Class (Type)	Type
General			
_:2311:501	General:>Test of direction		I
_:2311:352	General:Test direction		O
_:2311:351	General:Phi(I,V)		O

6.7.4 Stage Control

6.7.4.1 Description

Logic

The following figure represents the stage control. It applies to all types of stages.

[lostacon-240812-01.tif, 1, en_US]

Figure 6-68 Logic Diagram of the Stage Control

Blocking of Stage in Case of Measuring-Voltage Failure

The stages can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From an internal source on the pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Voltage-transformer circuit breaker**, which links to the trip of the voltage-transformer circuit breaker

The **`Blk. by meas.-volt. failure`** parameter can be set to either block or not block the stage when the **Measuring-voltage failure detection** function picks up.

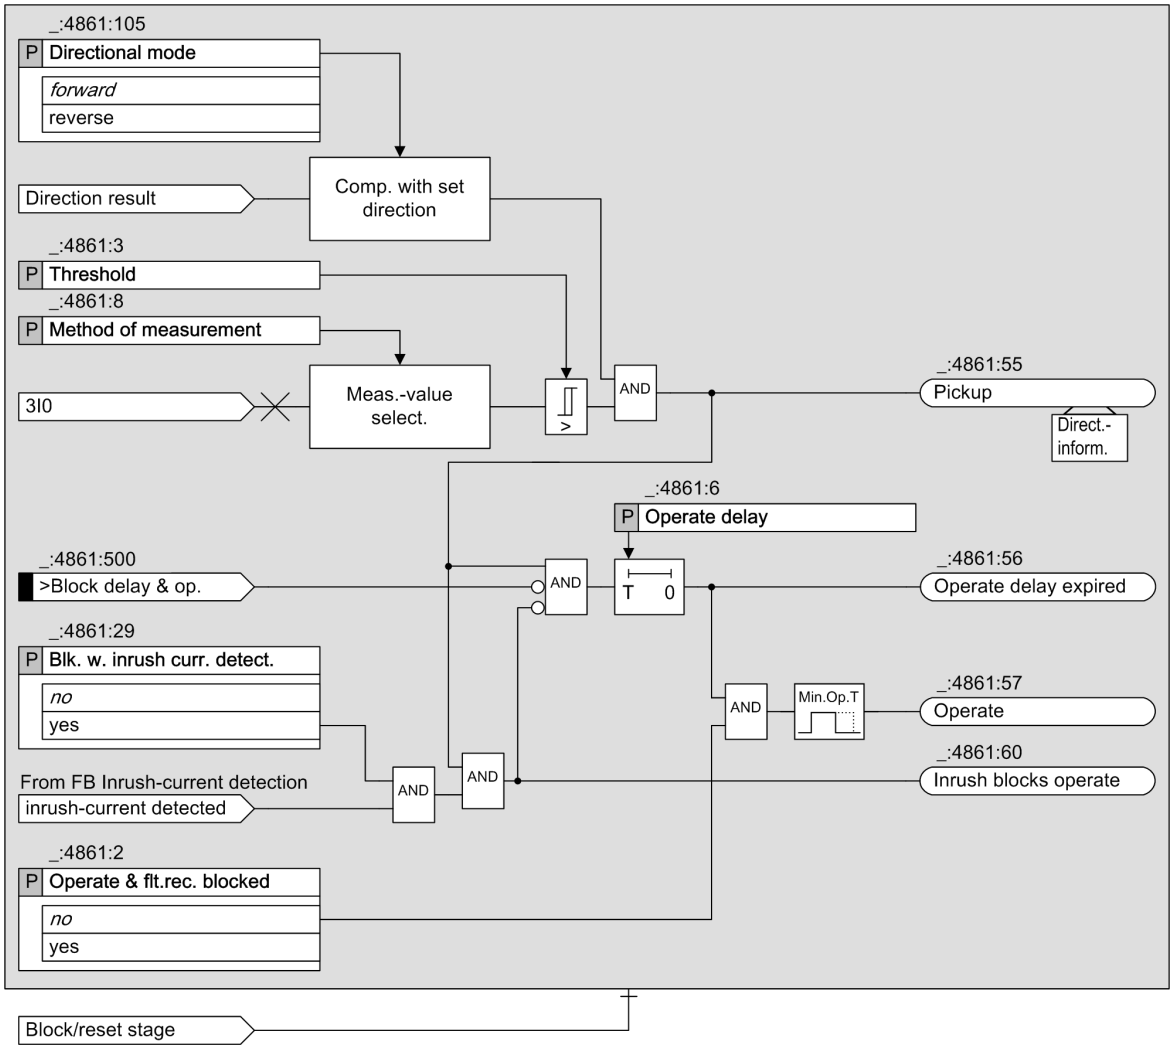
6.7.4.2 Application and Setting Notes

Parameter: **`Blk. by meas.-volt. failure`**

- Recommended setting value **`(_:4861:10) Blk. by meas.-volt. failure`** = ***`yes`***

You can use the **Blk. by meas.-volt. failure** parameter to control the response of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

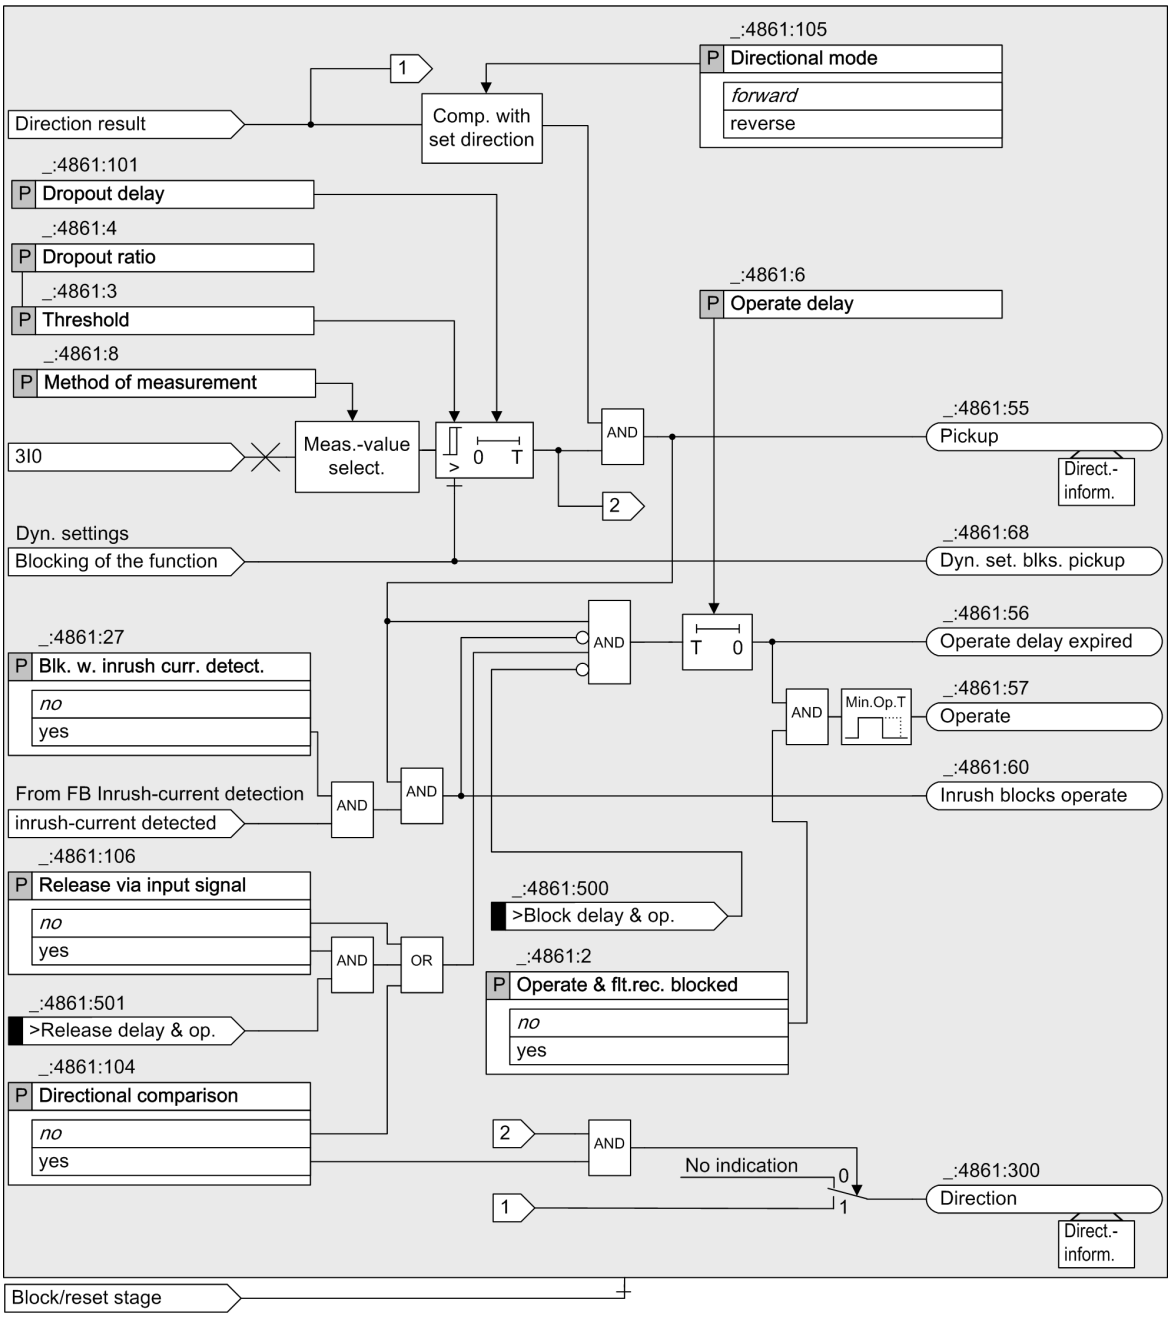


- The device-internal **Measuring-voltage failure detection** function is configured and switched on.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The directional overcurrent-protection stage is blocked when a measuring-voltage failure is detected. Siemens recommends using the default setting, as correct direction determination cannot be guaranteed if a measuring-voltage failure occurs.
no	The directional overcurrent-protection stage is not blocked when a measuring-voltage failure is detected.

6.7.5 Stage with Definite-Time Characteristic Curve

6.7.5.1 Description



Logic of the Basic Stage

[lodirovb-280812-02.tif, 1, en_US]

Figure 6-69 Logic Diagram of the Directional Definite Time-Overcurrent Protection, Ground – Basic

Logic of the Advanced Stage

[lodirova-280812-02.tif, 1, en_US]

Figure 6-70 Logic Diagram of the Directional Definite Time-Overcurrent Protection, Ground – Advanced

Measurand (Basic and Advanced Stage)

The function uses the zero-sequence current (3I0) as a criterion for the ground fault.

Depending on the parameter setting connection type of the **Measuring point I-3ph**, the zero-sequence current is measured or calculated. Depending on the applied CT terminal type, the 3I0 **`Threshold`** range varies according to the following table.

Table 6-7 Threshold Setting Range

Connection Type of the Measuring Point I-3ph	Ground Current	CT Terminal Type	Threshold Setting Range (Secondary)
3-phase	Calculated	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
x + IN x + IN-separate	Measured	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.001 A to 1.600 A
		4 * Measurement	0.001 A to 1.600 A

Method of Measurement (Basic and Advanced Stage)

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

- Measurement of the fundamental component:
  This measuring procedure processes the sampled current values and filters out the fundamental components numerically.
- Measurement of the RMS value:
  This measuring procedure determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Directional Mode (Basic and Advanced Stage)

You can use the **Directional mode** parameter to define whether the stage works in a forward or reverse direction.
The direction determination works across all stages (see chapter *6.7.3.2 Direction Determination*).

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Externally or internally via the binary input signal *>Block stage* (see chapter *6.7.4.1 Description*)
- Measuring-voltage failure (see chapter *6.7.4.1 Description*)
- Via the dynamic settings functionality (only available in the advanced function type, see **Influence of Other Functions via Dynamic Settings** and chapter *6.7.10 Influence of Other Functions via Dynamic Settings*)

Blocking of the Operate Delay (Basic and Advanced Stage)

You can use the binary input signal *>Block delay & op.* to prevent the start of the operate delay and thus also the generation of the operate signal. A running operate delay is reset. The pickup is indicated. Fault logging and fault recording take place.

Blocking of the Operate Delay and Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter *6.5.7.1 Description*

Dropout Delay (Advanced Stage)

In case of undershooting of the dropout threshold, the dropout can be delayed. The pickup is maintained for the specified time. The operate delay continues to run. If the operate delay expires while the pickup is still maintained, the stage operates.

Directional Comparison Protection (Advanced Stage)

The stage can be used for directional comparison protection. This is set using the **Directional comparison** parameter. With the ***yes*** setting, the direction indication *Direction* is released and the direction (forward or reverse) is determined, if the current exceeds the threshold of the stage. The direction indicated is independent of the directional mode set for the stage.

The **Release via input signal** parameter and the *>Release delay & op.* input signal are available with directional comparison protection. If the **Release via input signal** parameter is set to ***yes***, the start of the operate delay, and therefore the operate signal of the stage, are only enabled when the *>Release delay & op.* input signal is active.

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can exert an influence on the overcurrent-protection stage:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.7.10 Influence of Other Functions via Dynamic Settings*.

6.7.5.2 Application and Setting Notes

Parameter: Directional mode

- Default setting **(_:4861:105) Directional mode** = ***forward***

You can use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
forward	Select this setting if the stage is to work in forward direction (in the direction of the line).
reverse	Select this setting if the stage is to work in reverse direction (in the direction of the busbar).

Parameter: Method of measurement

- Recommended setting value **(_:4861:8) Method of measurement** = ***fundamental comp.***

You can use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard process.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks).

Parameter: Directional comparison, Release via input signal

- Default setting **(_:4861:104) Directional comparison** = ***no***
- Default setting **(_:4861:106) Release via input signal** = ***no***

The parameters **Directional comparison** and **Release via input signal** are not visible for the basic stage.

You can use these settings to define whether the stage is to be used for directional comparison protection. Directional comparison protection is performed via the *Direction* and *>Release delay & op.* signals.

Parameter Value	Description

no	The stage is not used for directional comparison protection.
yes	If the **Directional comparison** parameter is set to ***yes***, the **Release via input signal** parameter, the *Direction* output signal, and the *>Release delay & op.* input signal become available. If the **Release via input signal** parameter is set to ***yes***, the starts of the operate delay and operate signal are only enabled when the *>Release delay & op.* input signal is active. The *>Release delay & op.* input signal must be connected to the enable information from the opposite end (forward information from the *Direction* output signal). See also the application example in chapter *6.6.10 Application Notes for Directional Comparison Protection*

Parameter: **Dynamic settings**

- Default setting **(_:4861:26) Dynamic settings** = ***no***

This parameter is not visible for the basic stage.

Parameter Value	Description
no	The influence on the overcurrent-protection stage by device-internal or external functions is not necessary.
yes	If a device-internal function (**Automatic reclosing** or **Cold-load pickup detection**) or an external function should affect the overcurrent-protection stage (such as change the setting of the threshold value or operate delay, blocking of the stage), the setting must be changed to ***yes***. This makes the configuration parameters effected by **Auto reclosing**/**Cold-load PU**/**Binary input** as well as the dynamic settings **Threshold**, **Operate delay**, and **Stage blocked** of the stage visible and enables the settings to be set for the specific influence.

For further setting notes, refer to chapter *6.5.8.2 Application and Setting Notes (Advanced Stage)* of the function **Overcurrent Protection, Ground**.

Parameter: **Blk. w. inrush curr. detect.**

- Default setting **(_:4861:27) Blk. w. inrush curr. detect.** = ***no***

Parameter Value	Description
no	The transformer inrush-current detection does not affect the stage. Select this setting in the following cases: • In cases where the device is not used on transformers. • In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This applies, for example, to the high-current stage that is set according to the short-circuit voltage Vsc of the transformer in such a way that the stage only picks up on faults from the high-voltage side. The transformer inrush current cannot become larger than the maximum transmittable short-circuit current.
yes	When the transformer inrush-current detection detects an inrush current that would lead to an operate of the stage, the start of the operate delay and operate of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

Parameter: Threshold

- Default setting **(_:4861:3) Threshold** = ***1.20 A***

For setting the threshold value, the same considerations apply as for the non-directional time-overcurrent protection function.

For further information, refer to chapter *6.5.4.2 Application and Setting Notes* .

Parameter: Dropout ratio

- Recommended setting value **(_:4861:4) Dropout ratio** = ***0.95***

This parameter is not visible for the basic stage.

The recommended setting value of ***0.95*** is appropriate for most applications.

For high-precision measurements, the setting value of the **Dropout ratio** parameter can be reduced, for example to 0.98. If you expect highly fluctuating measurands at the pickup threshold, you can increase the setting value of the **Dropout ratio** parameter. This avoids chattering of the stage.

Parameter: Dropout delay

- Recommended setting value **(_:4861:101) Dropout delay** = ***0 s***

This parameter is not visible for the basic stage.

Siemens recommends using the dropout delay of 0 s, since the dropout of a protection stage must be performed as fast as possible.

You can use the **Dropout delay** parameter ≠ ***0 s*** to obtain a uniform dropout behavior if you use it together with an electromechanical relay. This is required for time grading. The dropout time of the electromechanical relay must be known for this purpose. Subtract the dropout time of your own device (see Technical data) and set the result.

Parameter: Operate delay

- Default setting **(_:4861:6) Operate delay** = ***0.300 s*** (for the 1st stage)

The **Operate delay** to be set is derived from the time-grading chart that has been prepared for the system.

Typical examples of grading times are provided in sections *6.6.9 Application Notes for Parallel Lines and Cable Runs with Infeed at Both Ends* and *6.6.10 Application Notes for Directional Comparison Protection* .

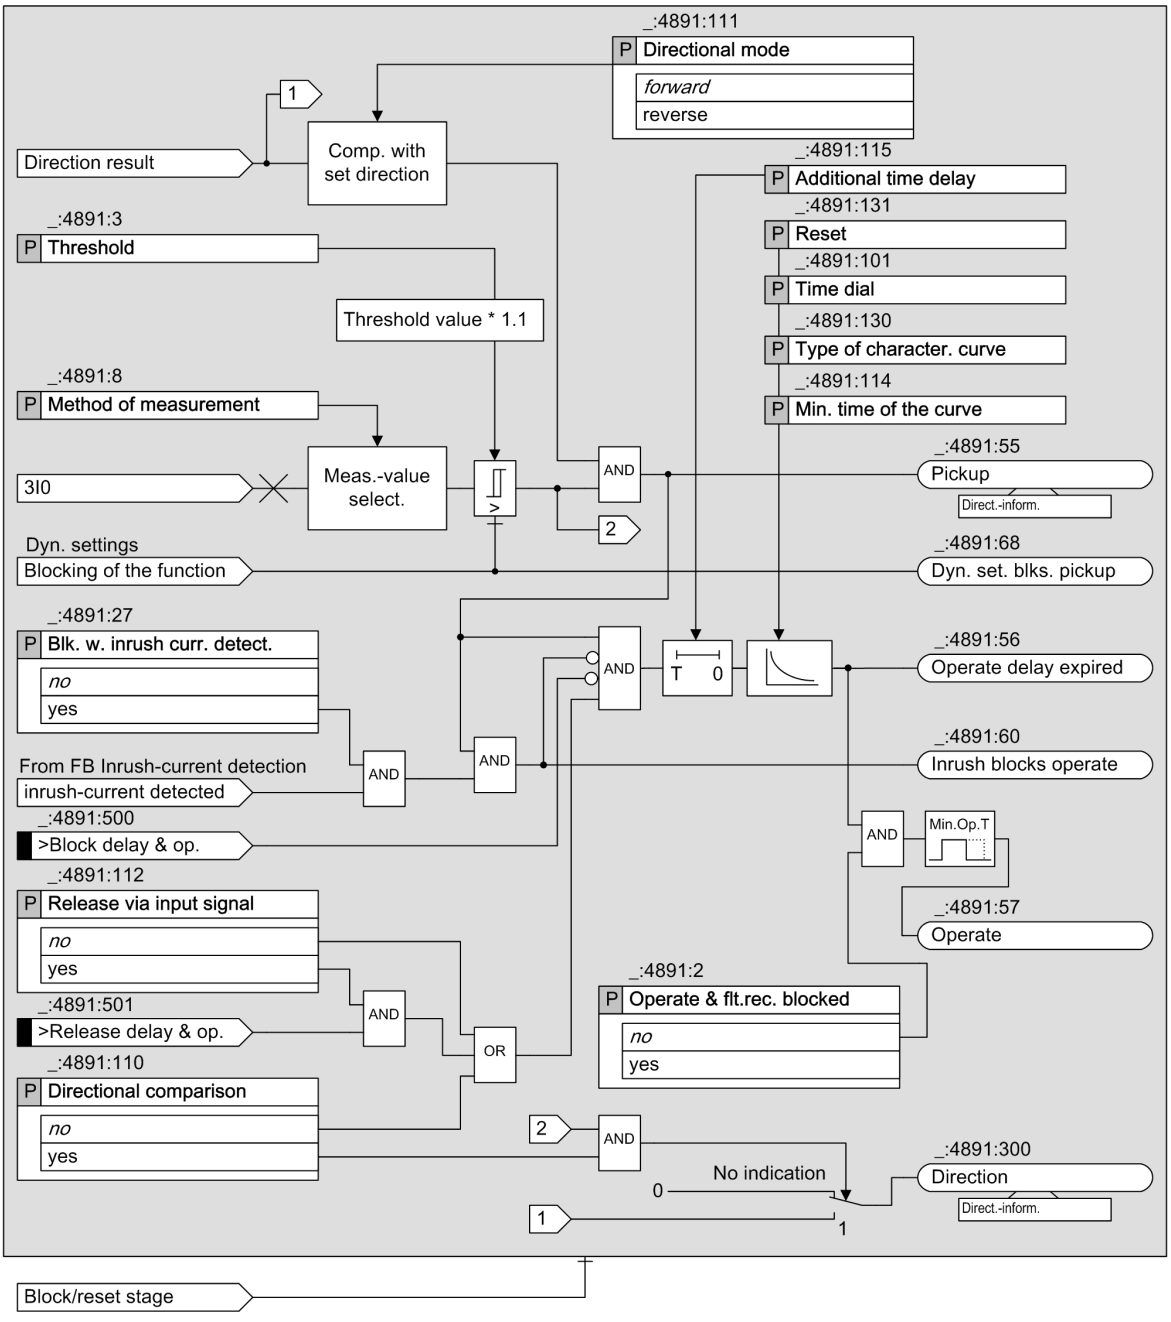
6.7.6 Stage with Inverse-Time Characteristic Curve

6.7.6.1 Description



Logic of the Basic Stage

[lodiinvb-280812-02.tif, 2, en_US]

Figure 6-71 Logic Diagram of the Directional Inverse Time-Overcurrent Protection, Ground – Basic

Logic of the Advanced Stage

[lodiinva-280812-02.tif, 2, en_US]

Figure 6-72 Logic Diagram of the Directional Inverse Time-Overcurrent Protection, Ground – Advanced

Measurand (Basic and Advanced Stage)

The function uses the zero-sequence current (3I0) as a criterion for the ground fault.

Depending on the parameter setting connection type of the **Measuring point I-3ph**, the zero-sequence current is measured or calculated. Depending on the applied CT terminal type, the 3I0 **`Threshold`** range varies according to the following table.

Table 6-8 Threshold Setting Range

Connection Type of the Measuring Point I-3ph	Ground Current	CT Terminal Type	Threshold Setting Range (Secondary)
3-phase	Calculated	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.030 A to 35.000 A
		4 * Measurement	0.001 A to 1.600 A
x + IN x + IN-separate	Measured	4 * Protection	0.030 A to 35.000 A
		3 * Protection, 1* sensitive	0.001 A to 1.600 A
		4 * Measurement	0.001 A to 1.600 A

Method of Measurement (Basic and Advanced Stage)

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

- Measurement of the fundamental component:

  This measuring procedure processes the sampled current values and filters out the fundamental components numerically.

- Measurement of the RMS value:

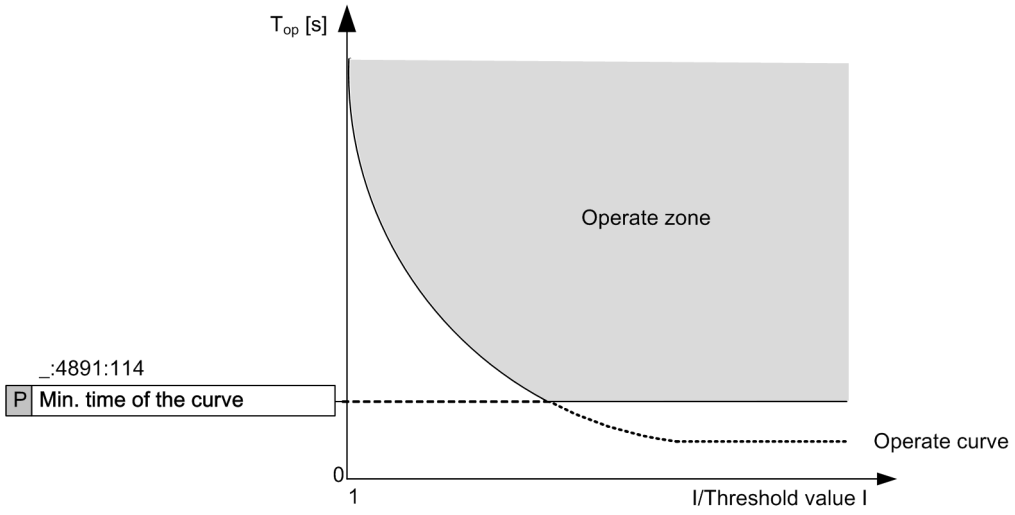
  This measuring procedure determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Directional Mode (Basic and Advanced Stage)

You can use the **Directional mode** parameter to define whether the stage works in a forward or reverse direction.

The direction determination works across all stages (see chapter *6.7.3.2 Direction Determination*).

Pickup and Dropout Behavior of the Inverse-Time Characteristic Curve According to IEC and ANSI (Basic and Advanced Stage)



When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrated measuring procedure totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls below the threshold value by a factor of 1.045 (0.95 × 1.1× threshold value), the dropout starts. The pickup will be indicated as clearing. You can influence the dropout behavior via adjustable parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is started from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical data.

Minimum Time of the Curve (Advanced Stage)

With the parameter **Min. time of the curve**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time.

[DwMinTime_20140708-01.vsd, 1, en_US]

Figure 6-73 Minimum Operating Time of the Curve

Additional Time Delay (Advanced Stage)

With the parameter **Additional time delay**, you define a definite-time delay in addition to the inverse-time delay. With this setting, the whole curve is shifted on the time axis by this additional definite time.

Blocking of the Stage (Basic and Advanced Stage)

The following blockings reset the picked up stage completely:

- Externally or internally via the binary input signal *>Block stage* (see chapter *6.7.4.1 Description*)
- Measuring-voltage failure (see chapter *6.7.4.1 Description*)
- Via the dynamic settings functionality (only available in the advanced function type, see **Influence of Other Functions via Dynamic Settings** and chapter *6.7.10 Influence of Other Functions via Dynamic Settings*)

Blocking of the Operate Delay (Basic and Advanced Stage)

You can use the binary input signal *>Block delay & op.* to prevent the start of the operate delay and thus also the generation of the operate signal. A running operate delay is reset. The pickup is indicated. Fault logging and fault recording take place.

Blocking of the Operate Delay and Operate Signal via the Device-Internal Inrush-Current Detection Function (Basic and Advanced Stage)

Blocking of the operate delay and the operate signal via the device-internal **Inrush-current detection** function is described in chapter Blocking of the Tripping by Device-Internal Inrush-Current Detection

For more information, refer to *6.5.7.1 Description*.

Directional Comparison Protection (Advanced Stage)

The stage can be used for directional comparison protection. This is set using the **Directional comparison** parameter. With the ***yes*** setting, the direction indication *Direction* is released and the direction (forward or reverse) is determined, if the current exceeds the threshold of the stage. The direction indicated is independent of the directional mode set for the stage.

The **Release via input signal** parameter and the *>Release delay & op.* input signal are available with directional comparison protection. If the **Release via input signal** parameter is set to ***yes***, the start of the operate delay, and therefore the operate signal of the stage, are only enabled when the *>Release delay & op.* input signal is active.

Influence of Other Functions via Dynamic Settings (Advanced Stage)

If available in the device, the following functions can exert an influence on the overcurrent-protection stage:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.7.10 Influence of Other Functions via Dynamic Settings*.

6.7.6.2 Application and Setting Notes

Parameter: Directional mode

- Default setting **(_:4891:111) Directional mode** = ***forward***

You can use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
forward	Select this setting if the stage is to work in forward direction (in the direction of the line).
reverse	Select this setting if the stage is to work in reverse direction (in the direction of the busbar).

Parameter: Method of measurement

- Recommended setting value **(_:4891:8) Method of measurement** = ***fundamental comp.***

You can use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** (standard method) or the calculated ***RMS value***.

Parameter Value	Description
fundamental comp.	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard process.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example, at capacitor banks).

Parameter: Directional comparison, Release via input signal

- Default setting **(_:4891:110) Directional comparison** = ***no***
- Default setting **(_:4891:112) Release via input signal** = ***no***

The parameters **Directional comparison** and **Release via input signal** are not visible for the basic stage.

You can use these settings to define whether the stage is to be used for directional comparison protection. Directional comparison protection is performed via the *Direction* and *>Release delay & op.* signals.

Parameter Value	Description
no	The stage is not used for directional comparison protection.

Parameter Value	Description
yes	If the **Directional comparison** parameter is set to ***yes***, the **Release via input signal** parameter, the *Direction* output signal, and the *>Release delay & op.* input signal become available. If the **Release via input signal** parameter is set to ***yes***, the starts of the operate delay and operate signal are only enabled when the *>Release delay & op.* input signal is active. The *>Release delay & op.* input signal must be connected to the release information from the opposite end (forward information from the *Direction* output signal). See also the application example in chapter *6.6.10 Application Notes for Directional Comparison Protection* .

Parameter: **Dynamic settings**

- Default setting **(_:4891:26) Dynamic settings** = ***no***

This parameter is not visible for the basic stage.

Parameter Value	Description
no	The influence on the overcurrent-protection stage by device-internal or external functions is not necessary.
yes	If a device-internal function (**Automatic reclosing** or **Cold-load pickup detection**) or an external function should affect the overcurrent-protection stage (such as change the setting of the threshold value or operate delay, blocking of the stage), the setting must be changed to ***yes***. This makes the configuration parameters effected by **Auto reclosing**/**Cold-load PU**/**Binary input** as well as the dynamic settings **Threshold**, **Time dial**, and **Stage blocked** of the stage visible and enables the settings to be set for the specific influence.

For further setting notes, refer to chapter *6.5.8.2 Application and Setting Notes (Advanced Stage)* of the function **Overcurrent Protection, Ground**.

Parameter: **Blk. w. inrush curr. detect.**

- Default setting **(_:4891:27) Blk. w. inrush curr. detect.** = ***no***

Parameter Value	Description
no	The transformer inrush-current detection does not affect the stage. Select this setting in the following cases: • In cases where the device is not used on transformers. • In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This applies, for example, to the high-current stage that is set according to the short-circuit voltage V_{sc} of the transformer in such a way that the stage only picks up on faults from the high-voltage side. The transformer inrush current cannot become larger than the maximum transmittable shortcircuit current.

Parameter Value	Description
yes	When the transformer inrush-current detection detects an inrush current that would lead to an operate of the stage, the start of the operate delay and operate of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

Parameter: `Min. time of the curve`

- Default setting **`(_:4891:114) Min. time of the curve`** = ***`0.00 s`***

This parameter is only available in the advanced stage.

With the parameter **`Min. time of the curve`**, you define a minimum operate delay time. The operate delay time of inverse-time characteristic curve never falls below the minimum operate delay time. If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommends keeping the default setting of 0 s.

NOTE

If the set value is smaller than the smallest possible time delay of the inverse-time characteristic curve, the parameter has no influence on the delay time.

Parameter: `Additional time delay`

- Default setting **`(_:4891:115) Additional time delay`** = ***`0.00 s`***

With the parameter **`Additional time delay`**, you define a definite-time delay in addition to the inverse-time delay.

If the setting is left on its default value of 0 s, this parameter has no effect on the inverse-time characteristic curve.

This parameter is only required for time coordination in recloser schemes. For all other applications, Siemens recommend keeping the default setting of 0 s.

Parameter: `Threshold`

- Default setting **`(_:4891:3) Threshold`** = ***`1.20 A`***

The setting depends on the minimal occurring ground-fault current. This must be detected.

Consider that a safety margin is set between pickup value and threshold value. The stage only picks up at approx. 10 % above the **`Threshold`**.

Parameter: `Type of character. curve`

- Default setting **`(_:4891:130) Type of character. curve`** = ***`IEC normal inverse`***

The device offers all the usual inverse-time characteristic curves according to IEC and ANSI. Select the **`Type of character. curve`** required for your specific application.

Parameter: `Time dial`

- Default setting **`(_:4891:101) Time dial`** = ***`1`***

You can use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The setting value for the **`Time dial`** parameter is derived from the time-grading chart that has been prepared for the electrical power system.

Where no time grading and therefore no displacement of the characteristic curve is required, leave the **Time dial** parameter at ***1*** (default setting).

Parameter: Reset

- Default setting **(_:4891:131) Reset** = ***disk emulation***

You can use the **Reset** parameter setting to define whether the stage decreases according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	Select this setting if the device is coordinated with electromechanical devices or other devices which perform a dropout after a disk emulation.
instantaneous	Select this setting if the dropout does not have to be performed after a disk emulation and an instantaneous dropout is desired instead.

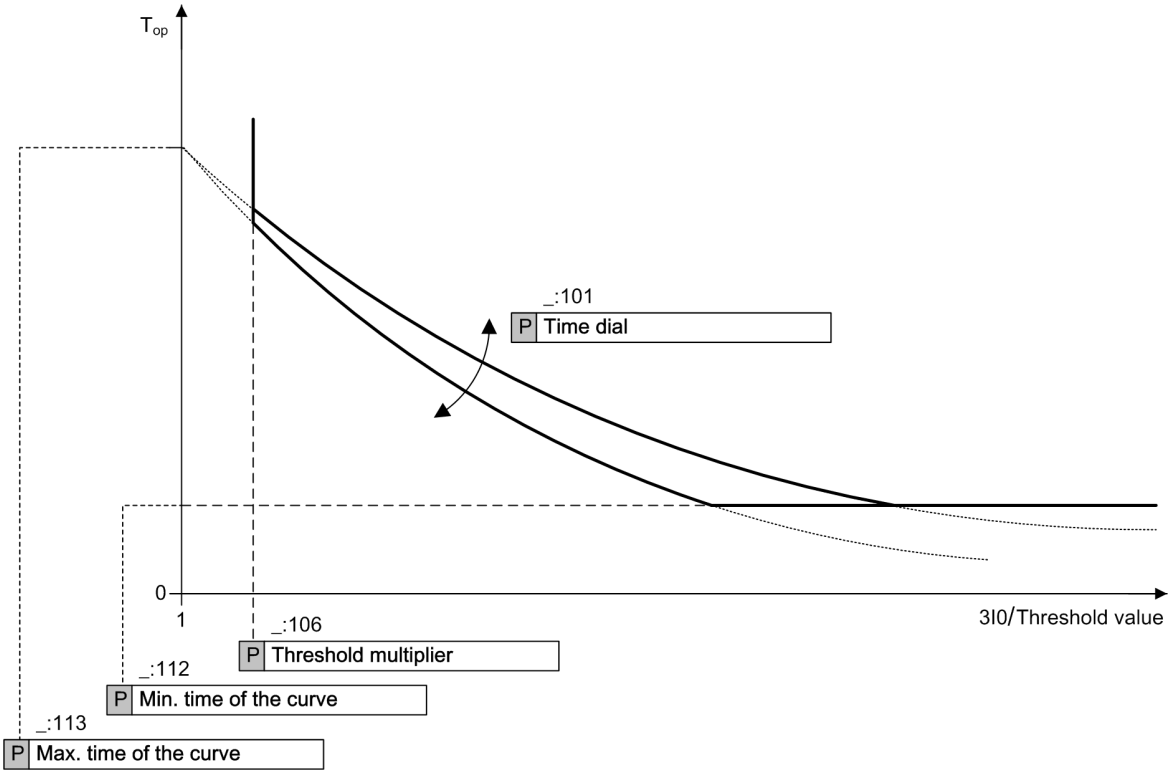
6.7.7 Stage with Inverse Time-Overcurrent Protection with Logarithmic-Inverse Characteristic Curve

6.7.7.1 Description

Logic of the Stage

[lodiloin-280812-02.tif, 1, en_US]

Figure 6-74 Logic Diagram of the Directional Logarithmic Inverse Time-Overcurrent Protection, Ground



Apart from the operate curve, this type of stage is identical to the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.7.6.1 Description*).

This section will only discuss the nature of the operate curve. For further functionality, refer to chapter *6.7.6.1 Description*.

Operate Curve

If the function picks up, the logarithmic inverse-time characteristic curve is processed. A time value T_{op} is calculated for every input value exceeding 95 % of the pickup value. An integrator accumulates the value 1/ T_{op}. If the accumulated integral reaches the fixed value 1, the stage operates.

The curve used to calculate the time value T_{op} is shown in the following figure. The **Threshold multiplier** parameter defines the beginning of the characteristic curve. The **Max. time of the curve** determines the initial value of the characteristic curve. The **Time dial** parameter changes the slope of the characteristic curve. At high currents, the **Min. time of the curve** parameter indicates the lower time limit.

[dwloginv-300913, 2, en_US]

Figure 6-75 Operate Curve of Logarithmic Inverse-Time Characteristic

The time to operate is calculated with the following formula:

$$T_{op} = T_{max} - T_d \ln\left(\frac{3I0}{I_{thresh} \times I_{mul}}\right)$$

[fomula01-240812-01.tif, 1, en_US]

Where

T_{max}	Maximum time of the curve (parameter **Max. time of the curve**)
T_d	Time dial (parameter **Time dial**)
T_{op}	Operate time
3I0	Measured zero-sequence current
I_{thresh}	Threshold value (parameter **Threshold**)
I_{mul}	Threshold multiplier (parameter **Threshold multiplier**)

If the calculated time is less than T_{min} (parameter **Min. time of the curve**), T_{min} is used.

6.7.7.2 Application and Setting Notes

Apart from the operate curve, this type of stage is identical to the ground-fault protection type with inverse-time delay according to IEC and ANSI (advanced function type) (see chapter *6.7.6.1 Description*).

This section only discusses the nature of the operate curve. For further functionality, refer to chapter *6.7.6.2 Application and Setting Notes*.

Stage Type Selection

If the operate delay is to be dependent on the current level according to a logarithmic characteristic curve, select this stage type.

Dynamic Settings: `Threshold`

- Default setting **`(_:3) Threshold`** = ***`1.20 A`***

Define the pickup value corresponding to the application. In doing so, for time-graded stages, the settings of the superordinate and of the subordinate stages in the time-grading chart must be taken into consideration.

Parameter: `Threshold multiplier`

- Default setting **`(_:116) Threshold multiplier`** = ***`1.1`***

You can use the **`Threshold multiplier`** parameter to define the beginning of the characteristic curve on the current axis (in relation to the threshold value).

General information cannot be provided. Define the value corresponding to the application.

EXAMPLE

`Threshold` (Secondary current)	I_{thresh} = 1.2 A
`Threshold multiplier`	I_{mul} = 1.1
Pickup value (Secondary current)	I_{PU} = 1.2 A ×1.1 = 1.32 A

Dynamic Settings: `Time dial`

- Default setting **`(_:6) Time dial`** = ***`1.250 s`***

You can use the **`Time dial`** parameter to change the slope of the characteristic curve.

General information cannot be provided. Define the value corresponding to the application.

Parameter: `Max. time of the curve`

- Default setting **`(_:114) Max. time of the curve`** = ***`5.800 s`***

The parameter **`Max. time of the curve`** determines the initial value of the characteristic curve (for 3I0 = **`Threshold`**).

General information cannot be provided. Define the value corresponding to the application.

Parameter: `Min. time of the curve`

- Default setting **`(_:113) Min. time of the curve`** = ***`1.200 s`***

The parameter **`Min. time of the curve`** determines the lower time limit (at high currents).

General information cannot be provided. Define the value corresponding to the application.

Parameter: `Additional time delay`

- Recommended setting value **`(_:115) Additional time delay`** = ***`0 s`***

You can set an additional current-independent time delay. This additional delay is intended for special applications.

Siemens recommends setting this time to ***0 s*** so that it has no effect.

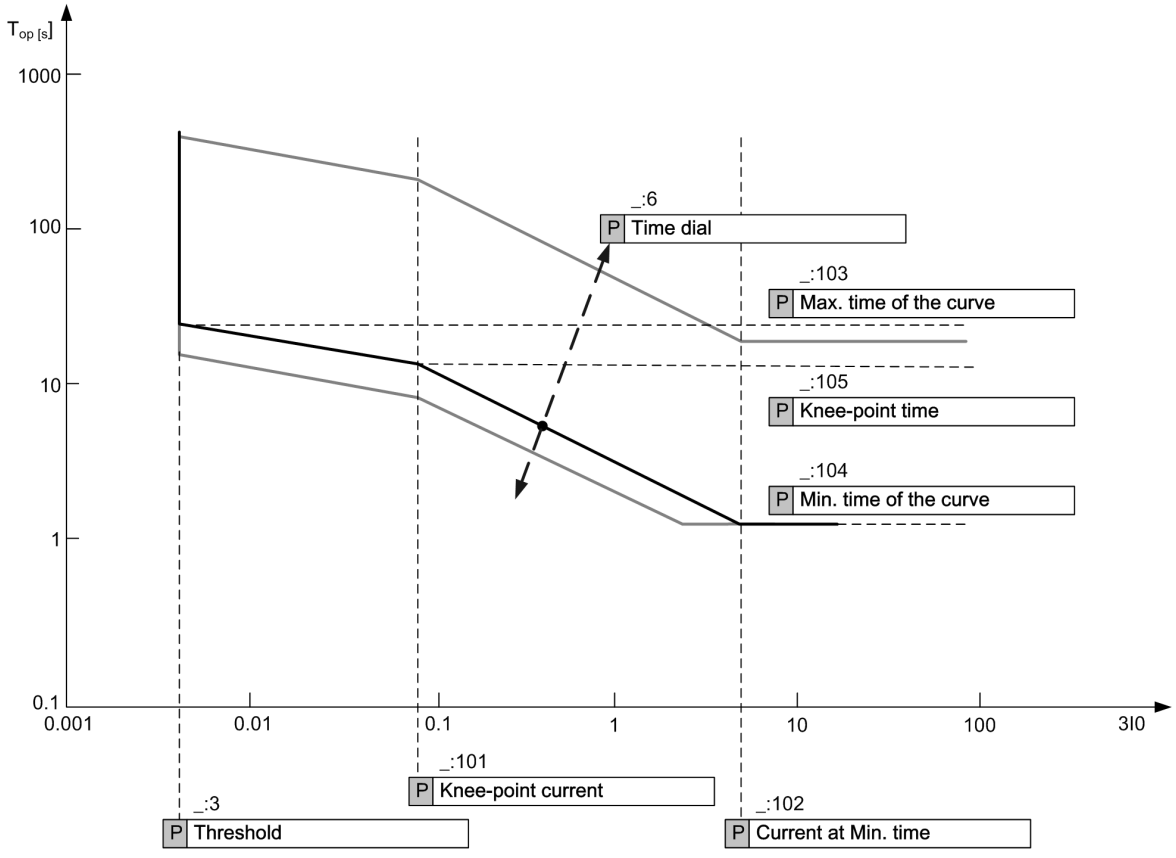
6.7.8 Stage Description Knee-Point Characteristic Curve

6.7.8.1 Description

Logic of the Stage

[lodilokn-280812-02.tif, 2, en_US]

Figure 6-76 Logic Diagram of the Directional Logarithmic Inverse Time with Knee-Point Overcurrent Protection, Ground



Apart from the operate curve, this type of stage is almost identical to the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.7.6.1 Description*). The only difference is that the dynamic settings change functionality is not available.

This section only discusses the nature of the operate curve. For further functionality, refer to chapter *6.7.6.1 Description*.

Operate Curve

If the function picks up, the logarithmic inverse-time characteristic curve is processed. A time value T_{op} is calculated for every input value exceeding 95 % of the threshold value. An integrator accumulates the value $1/T_{op}$. If the accumulated integral reaches the fixed value 1, the stage operates.

The curve used to calculate the time value T_{op} is shown in the following graphic. The curve is composed of 2 sections with different slops. 7 parameters are used to define the logarithmic inverse time with knee-point characteristic curve. The parameter **Max. time of the curve** determines the initial time value of the characteristic curve, and relates to the 3I0 **Threshold** value. The transition point is defined by parameter **Knee-point current** and parameter **Knee-point time**. The parameter **Min. time of the curve** indicates the lower time limit, and parameter **Current at Min. time** determines the current value at **Min. time of the curve**. The parameter **Time dial** servers as a time factor to the operate time.

[dwloinkn-300913, 2, en_US]

Figure 6-77 Operate Curve of the Logarithmic Inverse Time with Knee-Point Characteristic (In the Example of **Threshold** = ***0.004 A***)

6.7.8.2 Application and Setting Notes

Apart from the operate curve, this type of stage is almost identical to the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.7.6.1 Description*). The only difference is that the dynamic settings change functionality is not available.

This section only discusses the nature of the operate curve. For further functionality, refer to chapter *6.7.6.2 Application and Setting Notes*.

Parameter: Threshold

- Default setting **(_:3) Threshold** = ***1.20 A***

You can use the **Threshold** parameter to define the pickup value of the stage corresponding to the specific application.

Parameter: Time dial

- Default setting **(_:6) Time dial** = *0.2*

You can use the **Time dial** parameter to displace the operate curve in the time direction.

General information cannot be provided. Define the value corresponding to the application.

Parameter: Knee-point

- Default setting **(_:101) Knee-point current** = *1.300 A*
- Default setting **(_:105) Knee-point time** = *23.60 s*

You use the **Knee-point current** parameter and the **Knee-point time** parameter to define the knee-point of the operate curve.

General information cannot be provided. Define the values corresponding to the application.

Parameter: Minimum Time of the Operate Curve

- Default setting **(_:104) Min. time of the curve** = *0.80 s*
- Default setting **(_:102) Current at Min. time** = *1.500 A*

Via the parameters **Min. time of the curve** and **Current at Min. time**, the point of the operate curve is defined where higher currents do no longer cause shorter operate times.

General information cannot be provided. Define the value corresponding to the application.

Parameter: Maximum Time of the Operate Curve

- Default setting **(_:103) Max. time of the curve** = *93.00 s*

You can use the parameter **Max. time of the curve** to determine the initial value of the operate curve (for 3I0 = **Threshold**).

General information cannot be provided. Define the value corresponding to the application.

6.7.9 Stage with User-Defined Characteristic Curve

6.7.9.1 Description

Logic of the Stage

[lodirusr-280812-02.tif, 1, en_US]

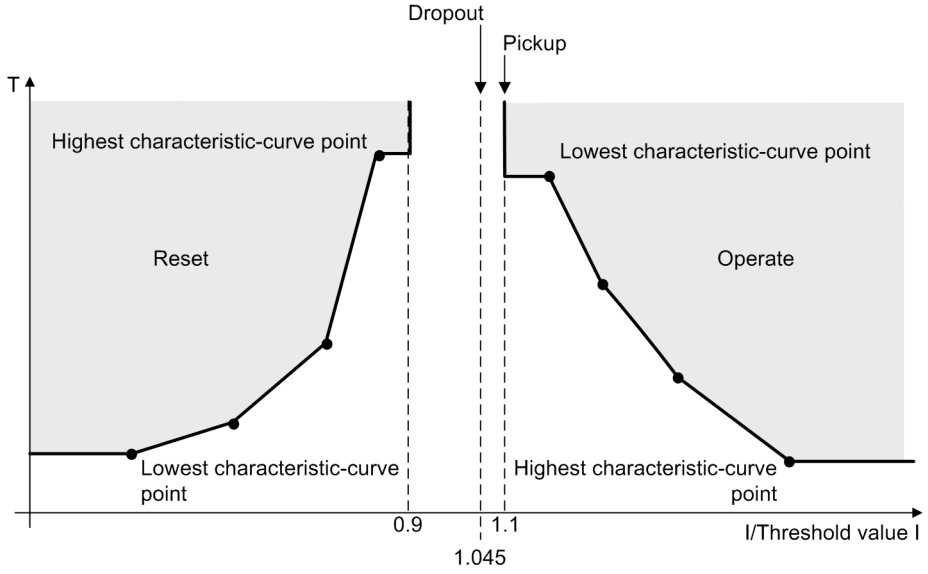
Figure 6-78 Logic Diagram of the Directional User-Defined Characteristic Curve Overcurrent Protection, Ground

This stage is structured in the same way as the **Inverse time-overcurrent protection – advanced** stage (see chapter *6.7.6.1 Description*). The only difference is that you can define the characteristic curve.

This section only discusses the nature of the operate curve. For further functionality, refer to chapter *6.7.6.1 Description*.

User-Defined Characteristic Curve

With the directional, user-defined characteristic curve, you can define the operate curve point by point using up to 30 value pairs of current and time. The device uses linear interpolation to calculate the characteristic curve from these values. You can also define a dropout characteristic curve if you wish.



Pickup and Dropout Behavior with User-Defined Characteristic Curves

When the input variable exceeds the threshold value by 1.1 times, the characteristic curve is processed.

An integrating method of measurement totalizes the weighted time. The weighted time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the threshold value by a factor of 1.045 (0.95 × 1.1× threshold value), the dropout is started. The pickup will be indicated as outgoing. You can influence the dropout behavior via setting parameters. You can select between instantaneous dropout (totalized time is deleted) or dropout according to the characteristic curve (reduction of totalized time depending on the characteristic curve). The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is started from 0.9 of the set threshold value.

The following figure shows the pickup behavior and dropout behavior when a directional user-defined characteristic curve is used.

[dwpidrbe-300913, 1, en_US]

Figure 6-79 Pickup and Dropout Behavior when Using a User-Defined Characteristic Curve

NOTE

Note that the currents that are lower than the current value of the smallest characteristic-curve point do not extend the operate time. The pickup characteristic runs in parallel to the current axis up to the smallest characteristic-curve point. Currents that are larger than the current value of the largest characteristic-curve point do not reduce the operate time. The pickup characteristic runs in parallel to the current axis from the largest characteristic-curve point.

6.7.9.2 Application and Setting Notes

This stage is structured in the same way as the **Inverse time-overcurrent protection – advanced** stage. The only difference is that you can define the characteristic curve as required. This section only provides application and setting notes for setting the characteristic curves. For guidance on the other parameters of the stage, see chapter *6.7.6.2 Application and Setting Notes*.

Parameter: `Current/time value pairs` (of the Operate Curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting follows the characteristic curve you want to realize.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold setting afterwards if you want to displace the characteristic curve.

Specify the time value in seconds. The characteristic curve is displaced using the **`Time dial`** parameter.

NOTE

The value pairs must be entered in continuous order.

Parameter: `Time dial`

- Default setting **`(_:101) Time dial`** = ***`1`***

You can use the **`Time dial`** parameter to displace the characteristic curve in the time direction.

The setting value for the **`Time dial`**parameter is derived from the time-grading chart that has been prepared for the system. Where no grading and therefore no displacement of the characteristic curve is required, leave the **`Time dial`** set to ***`1`***.

Parameter: `Reset`

- Default setting **`(_:110) Reset`** = ***`disk emulation`***

The **`Reset`** parameter is used to define whether the stage drops out according to the dropout characteristic curve (behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
`disk emulation`	Both operate curve and a dropout characteristic curve have to be specified with this setting. Use this setting if the device is coordinated with electromechanical devices or other devices performing dropout after disk emulation.
`instantaneous`	Use this setting if the dropout is not to be performed after disk emulation, that is, if instantaneous dropout is required.

Parameter: `Current/time value pairs` (of the Dropout Curve)

Use these settings to define the characteristic curve. Set a current/time value pair for each characteristic-curve point. The setting is determined by the characteristic curve you want to achieve.

Set the current value as a multiple of the threshold value. Siemens recommends that you set the **`Threshold`** parameter to ***`1.00`*** in order to obtain a simple relation. You can change the threshold setting afterwards if you want to displace the characteristic curve.

Specify the time value in seconds. The characteristic curve is displaced using the **`Time dial`**parameter.

NOTE

The value pairs must be entered in continuous order.
