Install, Operation & Maintenance Manual

Intelligent Merging Unit 2

Preface

Introduction

This Manual and the explanatory document for the operation of IM2 or related service provide the entire information on the safe handling, commissioning and testing of IM2.

The use should be familiar with the contents of this manual and read the relevant information carefully before carrying out work on IM2.

Safety

Proper and safer operation of IM2 depend on proper transportation and handling, proper storage, installation and commissioning, and careful operation, maintenance and service. For this reason, only qualified personnel may work on or operate IM2.

Requirements for eligible employee

- Be sure to be proficient in installation, commissioning and operation of IM2 and system to which IM2 is connected.
- Be sure to be able to perform switching works safely pursuant to the approved safety engineering practices.
- Be sure to have authority to supply and disconnect power to/from IM2, and to detach, ground and label IM2.
- Be sure to complete training on management and use of safe equipment according to safety engineering.
- Be sure to complete training on emergency procedures.

Caution

- Be sure to ground the terminal of IM2 safely.
- Be sure to install IM2 an environment free from abnormal vibration within the ambient environment specified in the specification.
- Be sure to apply AC voltage and current, or power to IM2.
- Be sure to carefully check the supply voltage when connecting the output contact of IM2 to the external circuit.
- Be sure to use the linking cables carefully without applying excessive force.

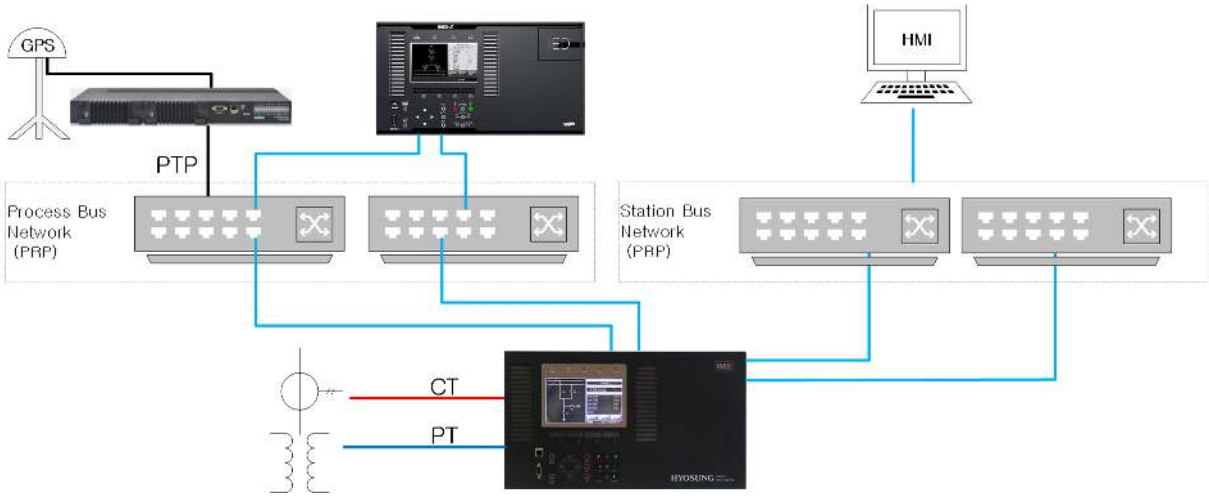
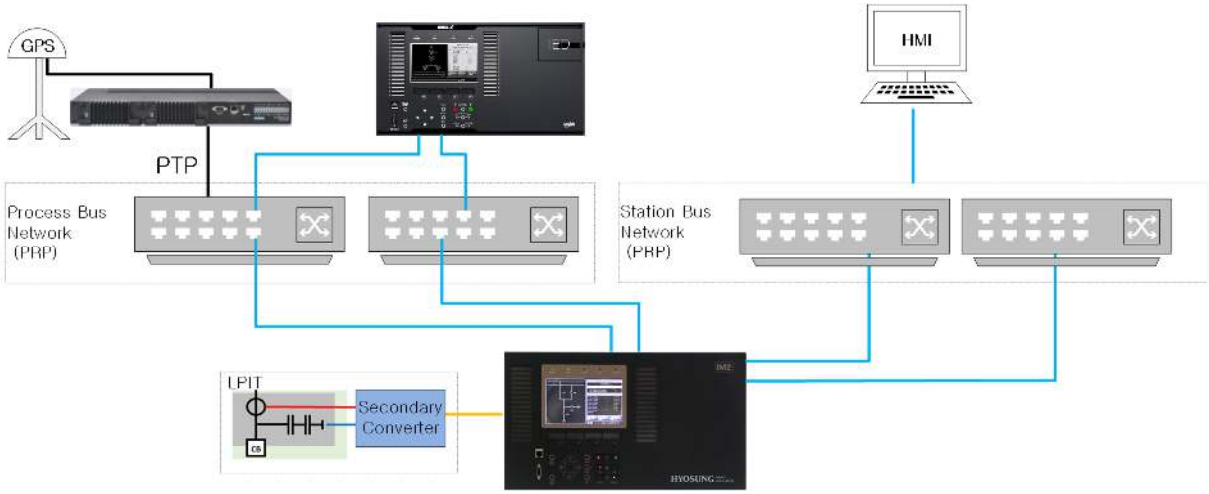
1. Introduction

1.1. Overview



- Intelligent Merging Unit 2 ("IM2") is an equipment for digital substations that receives analogue output from instrumental transformers and transmits the sampled values.
- IM2 for CT/PT receives analog signals from the conventional potential and/or current instrument transformers and transmits the sampled value packets.
- IM2 for LPIT receives the optical output digital signal of the secondary converter (SC) connected to Low Power Instrumental Transformer ("LPIT") such as Rogowski Coil and Capacitive Voltage Divider, and transmits the sampled value packets.
- IM2's sampling clock synchronization offers 2 methods: IEEE 1588v2 PTP and 1PPS. It processes PTP packets coming through the Process Bus Network for synchronizing clock, or receives 1PPS signal to synchronize with the Grand Master Time, and then maintain synchronization difference within ±2μsec, the allowable value according to IEC 61869-9.
- IM2 transmits the sampled value according to IEC 61850-9-2 standard, uses 4PT and 4CT data set defined in the IEC 61850-9-2LE guide, and supports the sampling rate defined in IEC 61850-9-2LE, as well as the sampling rate of 5760(60Hz), 4800(60Hz), 4800(50Hz), 4000(50Hz) for protection, and 15360(60Hz), 14400(60Hz), 14400(50Hz), 12800(50Hz) for measurement as defined in IEC 61869-9.
-

1.1.1. Features



- Process voltage and current signals using 24-bit high-precision, high-resolution ADC
- Process outputs from the Secondary Converter for LPIT
- Be capable of using 50/60Hz and support 80, 96 samples/cycle for protection and 80, 96, 240, 256, 288 samples/cycle for measurement
- Configure the sampled data compatible with IEC 61850-9-2LE and IEC 61869-9
- Be able to transmit up to 8 Sampled Value streams (8 Sampled Value Control Block (SVCB))
  - 4 streams for protection, 4 streams for measurement
- Support the lossless redundancy protocol, HSR/PRP
- Support the IEC61850 Report function/ & GOOSE transmitting/receiving through the Process Bus network
  - A total of 15 GOOSE Control Blocks (GOCB) (recommended)
- Support the function of the global clock synchronization
  - IEEE 1588v2 PTP
  - 1PPS BNC port
  - 1PPS jitter < ±2μsec

1.2. Connection Diagram

- The followings are configuration diagrams showing the general connection of IM2.

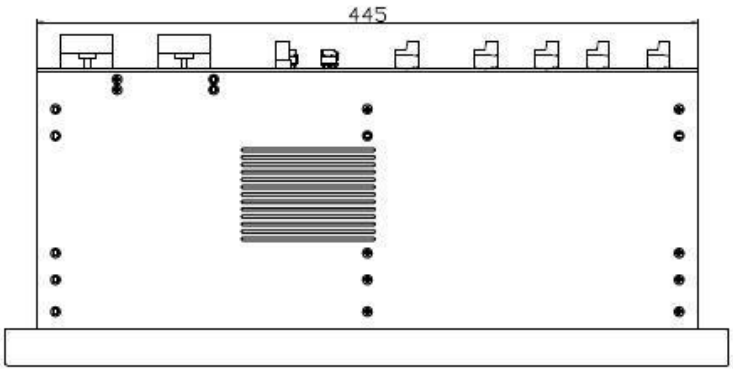
<Connection diagram example for using conventional CP/PT>

<Connection diagram example for using LPIT>

- IM2 for CT/PT is connected with CTs, PTs analog signal lines. Maximum 32 lines are connected, including maximum 12 voltages and maximum 20 currents.
- IM2 for LPIT is connected through the Secondary Converters to LPITs. Maximum 16 SCs can be connected to IM2 for LPIT, through 1 optical cable per 1 SC.
- IM2's Station/Process Bus communication ports are connected to network switching hubs that provides redundancy protocol, HSR/PRP, via optical cables, respectively. When using PTP

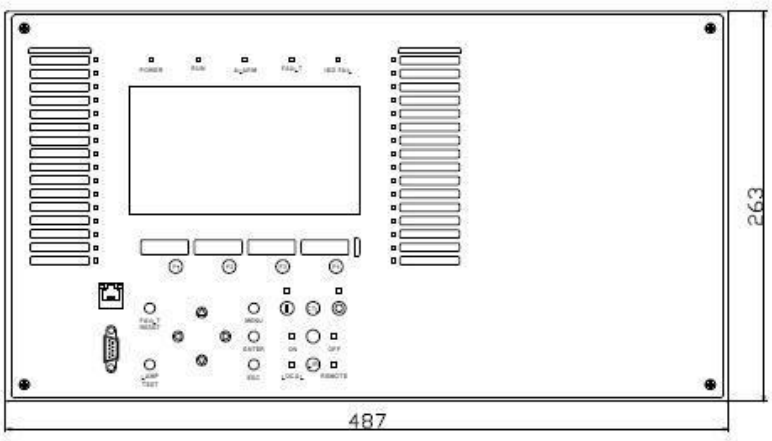
for clock synchronization, it can be used without additional connection. However, when IM2 is going to use PPS signal for synchronization, it may be needed to be connected to a PPS output device via a BNC cable.

- IED connected to Process Bus network that receives the Sampled Value can perform the functions of protection and measurement, using the sampled values transmitted by IM2.



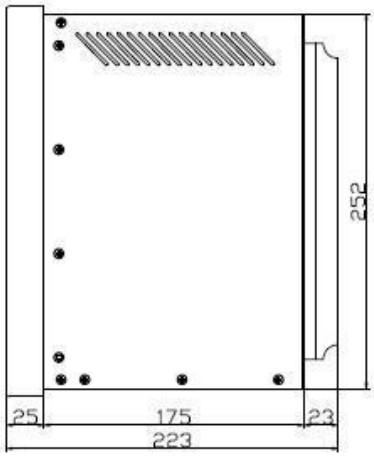
1.3. Specifications

Classification	Item	Specifications	Note
Condition of Use	Ambient temperature	-40℃ ~ +70℃	
	Relative humidity	Below 95%	
	Altitude	Below 1,000m	
Rating	Frequency	50/60Hz	
	Current	1A, 5A	
	Line voltage	100, 110, 115, 120, 200, 230V	
	Power	DC 125V (100~250V) AC 220V (100~240V) 50/60Hz	
Appearance of Product	Dimension (W x H x D)	487 x 263 x 223mm 487 x 263 x 219mm	for CT/PT for LPIT
	Type	Stand-Alone Type	
	Weight	Below 13kg Below 10kg	for CT/PT for LPIT
	Material	Aluminum	



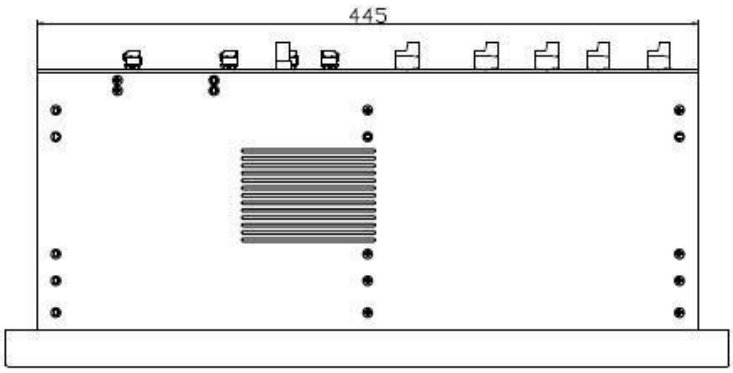
2. Appearance and Wiring

2.1. Appearance

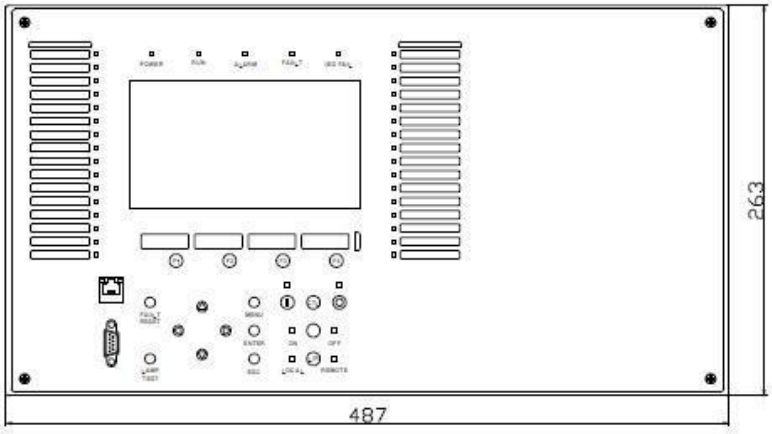


- The enclosure of IM2 is made of a fully-sealed aluminum metal case structure so as not to be affected by external interference.

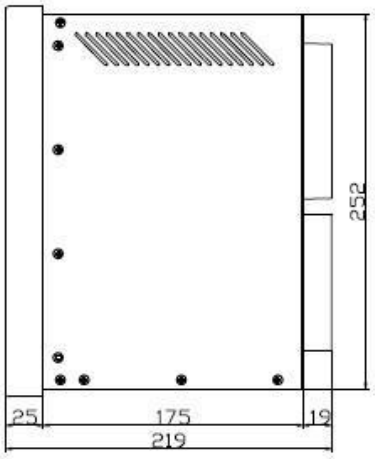
Top view



Front view

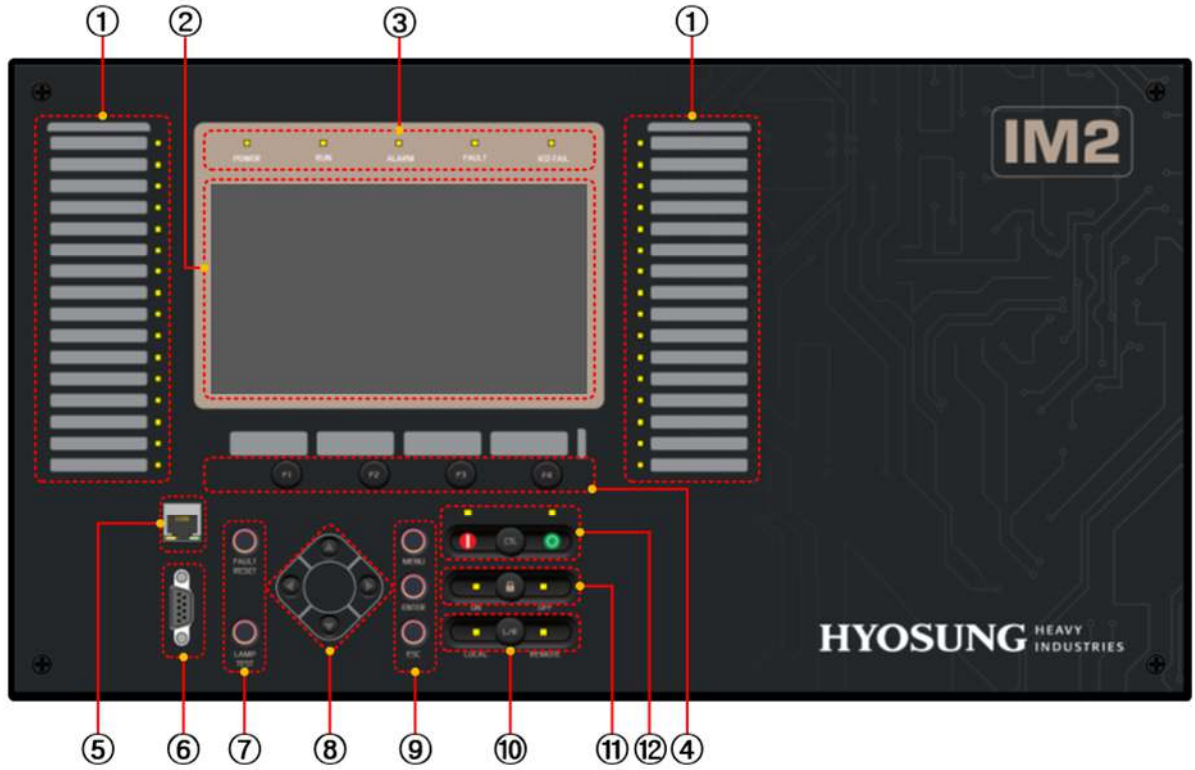


Side view



<Appearance of IM2 for CT/PT>

Top view



Front view

Side view

<Appearance of IM2 for LPIT>

2.1.1. Front Side

<Front Side of IM2 HMI>

- The description of the front side is as follows.

① LED for displaying the operational status

② TFT color graphic LCD (7") that can confirm and change the operational status and the set value

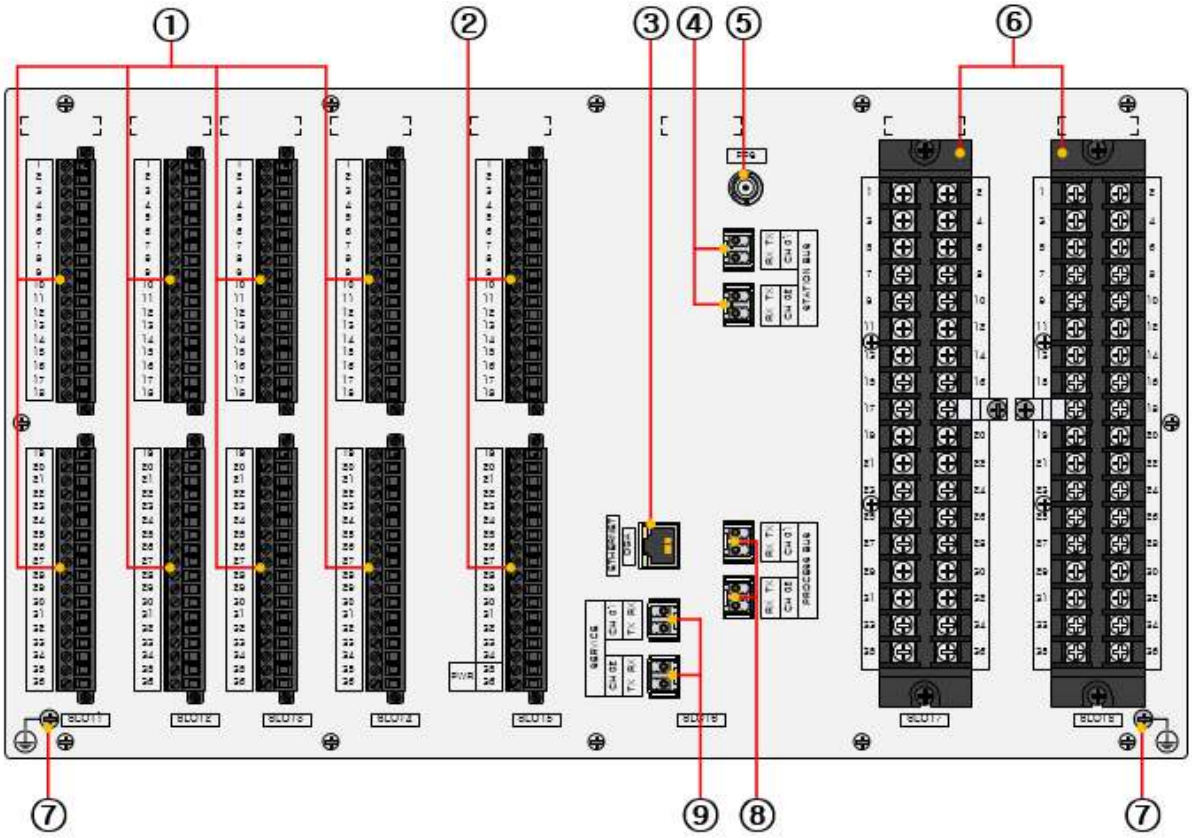
③ LED(Power) for displaying system status

④ Function button

⑤ Ethernet communication port

⑥ Console for connecting the operating software

⑦ Buttons for initializing LED status, and for testing LED



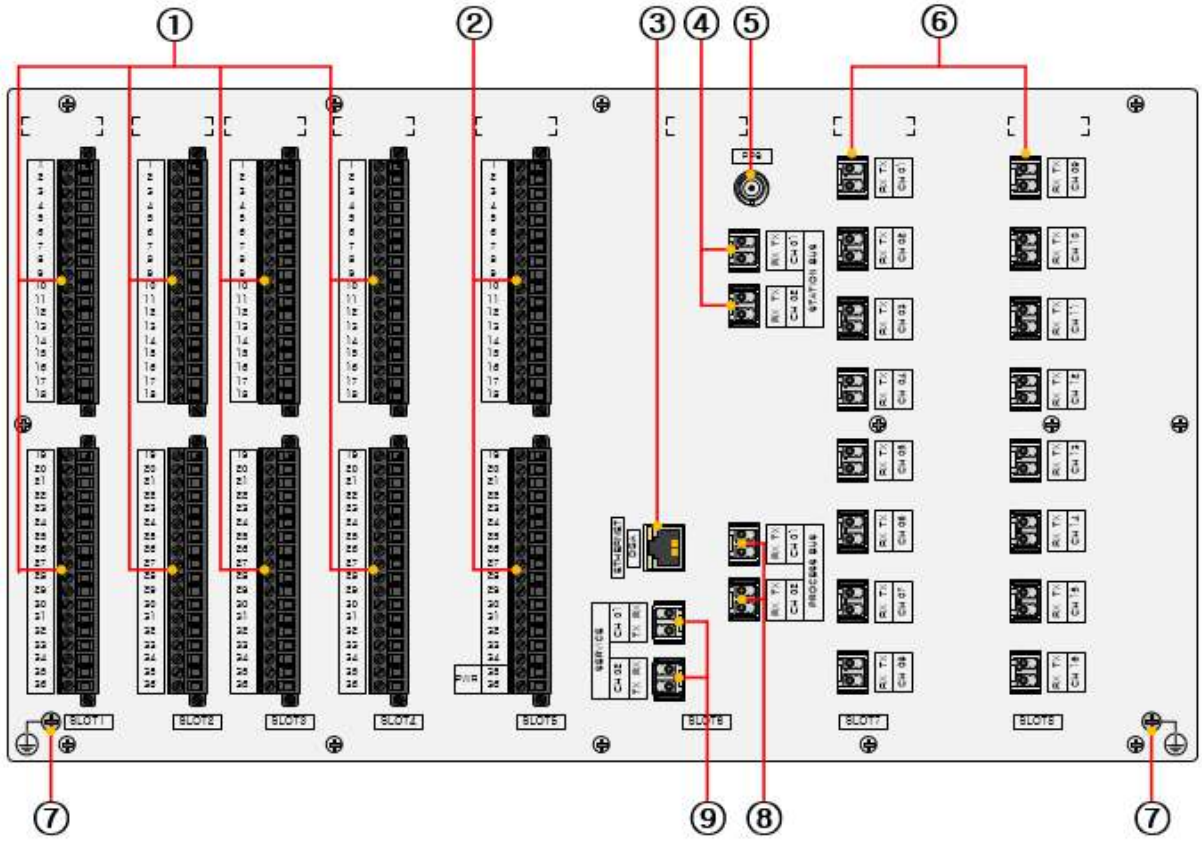
⑧ , ⑨ Buttons to move upward and downward, to select or cancel item in the menu

⑩ A button and status LED for local/remote operation

⑪ A button and status LED for operating to turn on/off interlock

⑫ A button and status LED to control device

2.1.2. Back Side (CT/PT)

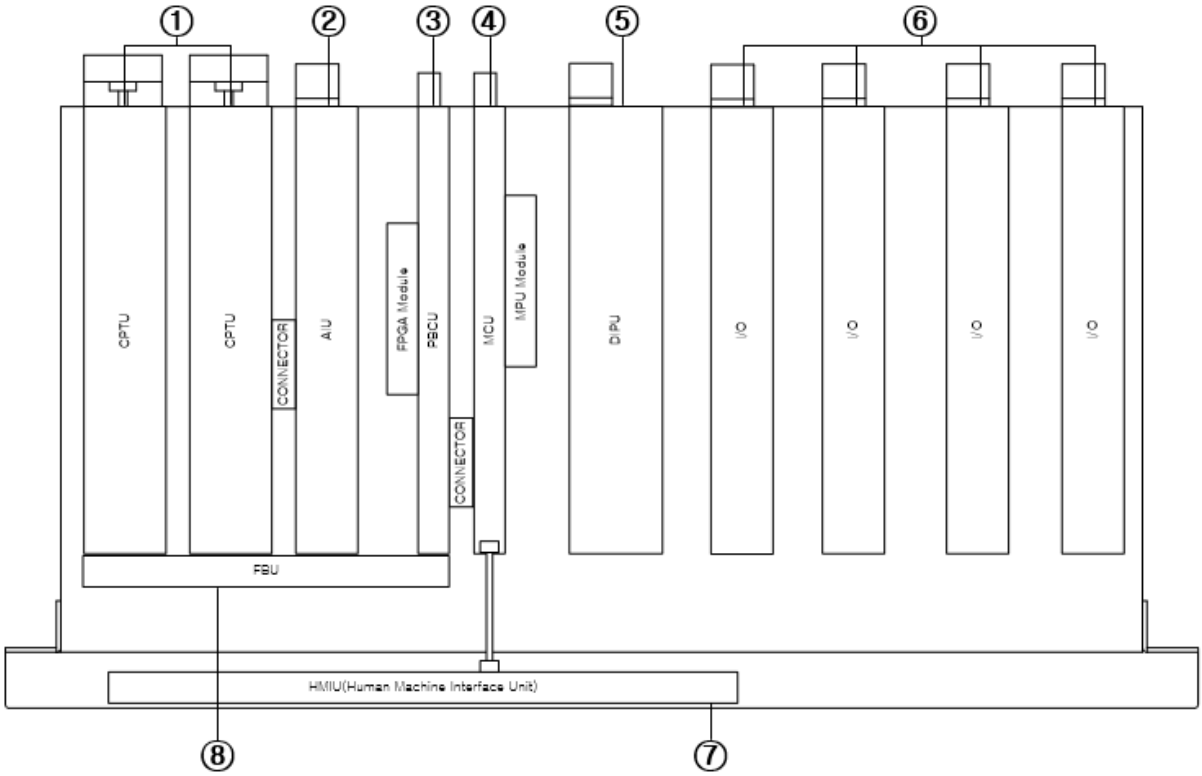


<Back side of IM2 for CT/PT>

- The back side of IM2 for CT/PT is configured as follows.

① Contact input/output terminal block
② Contact input and power input terminal block
③ Ethernet and DGA port
④ IEC 61850 Station Bus communication port (Optical)
⑤ 1PPS clock synchronization input port
⑥ Voltage/current input terminal block
⑦ Ground
⑧ IEC 61850 Process Bus communication port (Optical)
⑨ Service communication port (Optical)

2.1.3. Back Side (LPIT)



<Back side of IM2 for LPIT>

- The back side of IM2 for LPIT is configured as follows.

① Contact intput/output terminal block
② Contact input and power input terminal block
③ Ethernet and DGA port
④ IEC 61850 Station Bus communication port (Optical)
⑤ 1PPS clock synchronization input port
⑥ S/C Unit communication port (Optical)
⑦ Ground
⑧ IEC 61850 Process Bus communication port (Optical)
⑨ Service communication port (Optical)

2.1.4. Module mounting positions (for CT/PT)

<Module mounting positions>

- Modules of CPTU, AIU and PBCU are connected by FBU module, and MCU board and modules of HMIU, DIPU, I/O(DAIU, DOU, DIU) are connected via cable.

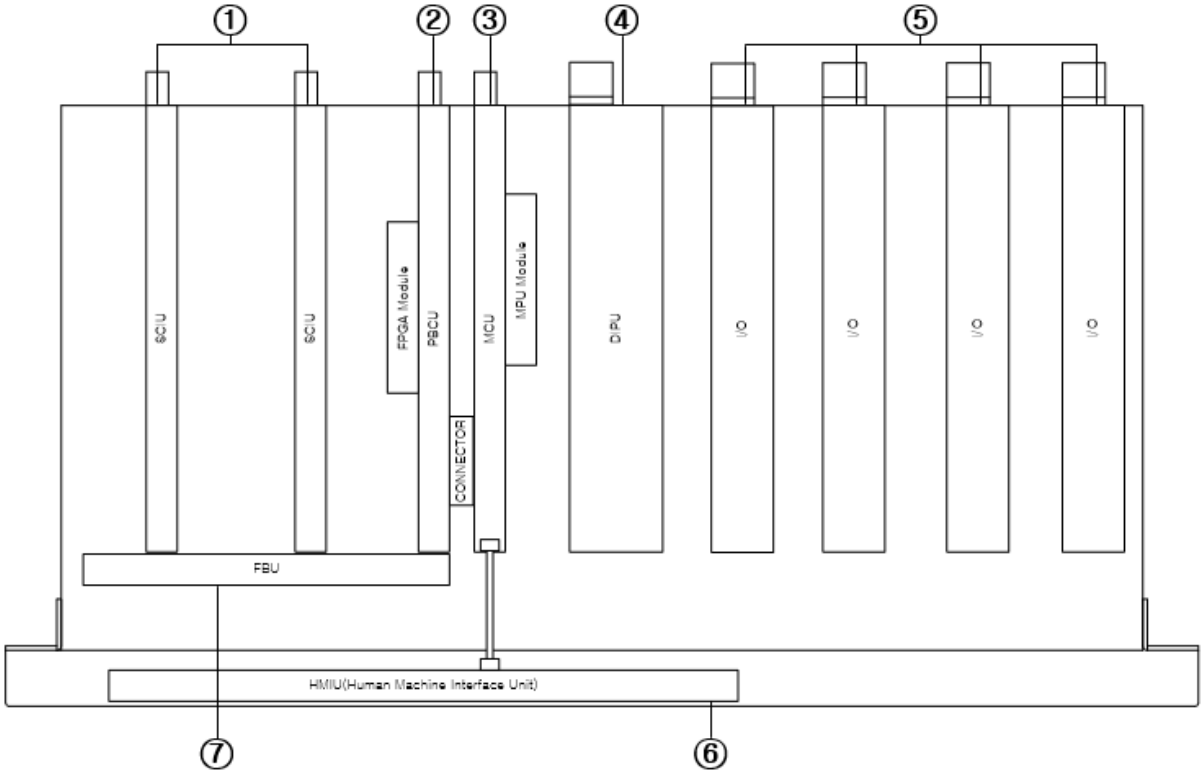
① **CPTU** module is divided into two types. CPTU-A is a module that provides input of 12 currents (CT) and 4 voltages (PT), and carries out function of inputting analog data. CPTU-B is a module that provides input of 8 currents (CT) and 8 voltages (PT), and carries out function of inputting analog data.

② **AIU** carries out digital conversion of the input analog data.

③ **PBCU** carries out function of converting the measure data into SV(Sampled Value), and then transmitting it.

④ **MCU** is a module where MPU, DSP and memory are positioned, and carries out functions of performing protection logic and processing HMI.

⑤ **DIPU** is a module that provides 26 contact input points, and carries out monitoring function, receives power and then supplies power used by each module.



⑥ **I/O** modules have three types

- **DAIU** is a module that provides 16 contact input points as well as input of 6 TDs and 2 RTDs, and carries out monitoring and measurement functions.
- **DOU** is a module that provides 17 contact output points for each module and is responsible for the control function.
- **DIU** is a module that provides 28 contact input points, and carries out monitoring function.

⑦ **HMIU** is an operator interface module that provides information to the operator via LCD and LED as well as receives input from the operator via button and touch screen, and carries out functions of setting and displaying.

⑧ **FBU** carries out interface function that connects AIU and PBCU module.

2.1.5. Module mounting positions (for LPIT)

<Module mounting positions>

- SICU and PBCU modules are connected by FBU module, and MCU board and modules of HMIU, DIPU, I/O(DAIU, DOU, DIU) are connected via cable.

① **SCIU** carries out function for inputting communication data of S/C(Secondary Converter) Unit.

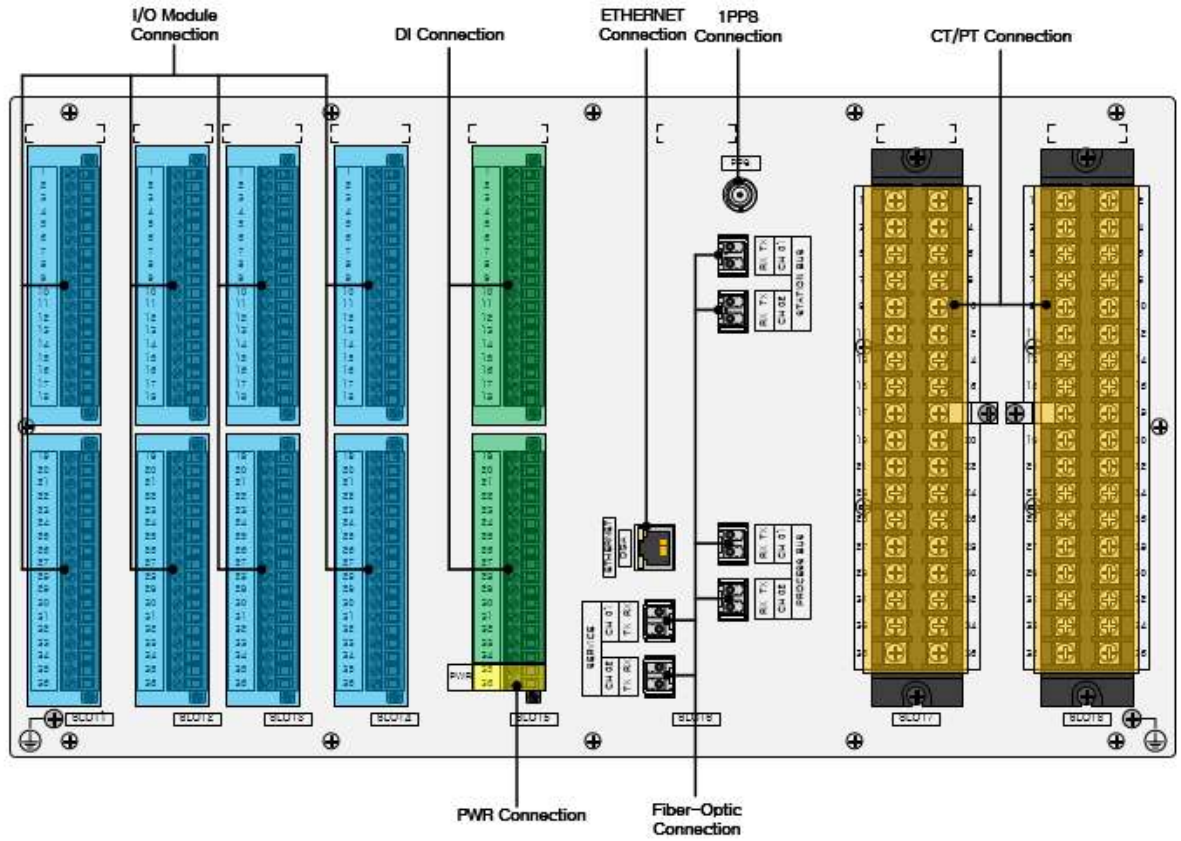
② **PBCU** carries out functions of converting measurement data into SV(Sampled Value) and transmitting it.

③ **MCU** is a module where MPU, DSP and memory are positioned, and carries out functions of performing logic and processing HMI.

④ **DIPU** is a module that provides 26 contact input points, carries out a monitoring function, and receives and provides power used by each module.

⑤ **I/O** board has three types.

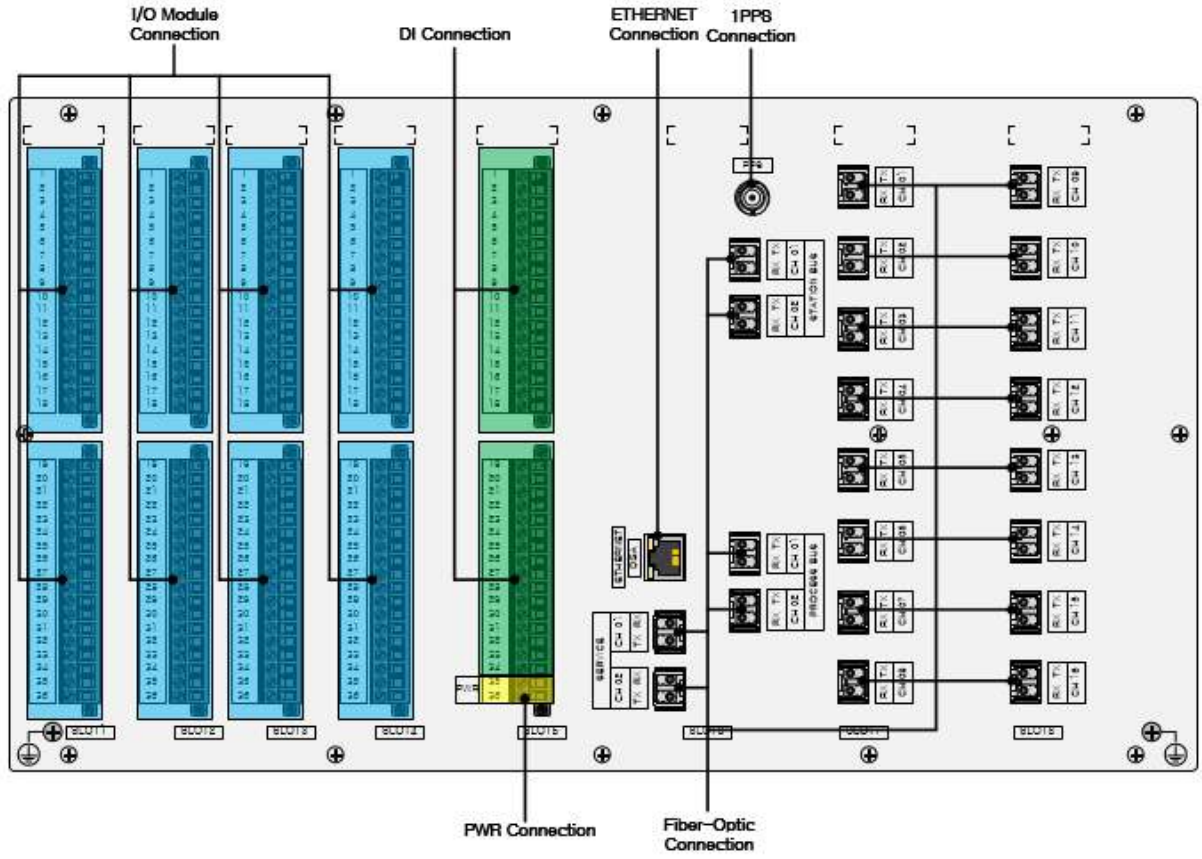
- **DAIU** is a module that provides 16 contact input points, 6 TD input and 2 RTD inputs, and carries out functions of monitoring and measurement.
- **DOU** is a module that provides 17 contact output points for each module and is responsible for the control function.
- **DIU** is a module that provides 28 contact input points, and carries out a monitoring function.



⑥ **HMIU** is an operator interface module that provides information to the operator via LCD and LED, and receives input from the operator via button and touch screen, and carries out functions of setting and displaying.

⑦ **FBU** carries out interface function that connects AIU and PBCU module.

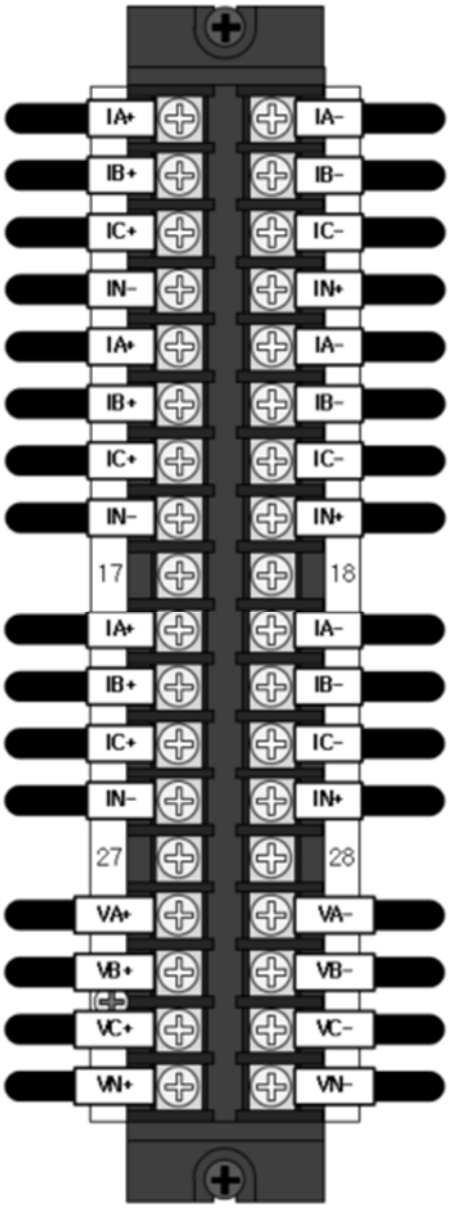
2.2. Connection



- IM2 has terminal blocks in the rear side to enable rear wiring, and is connected to the outside through the terminal block. Wiring should be made in a structure that is completely in contact with each other and does not come loose.

2.2.1. Connection Positions (for CT/PT)

<Connection positions of IM2 for CT/PT>

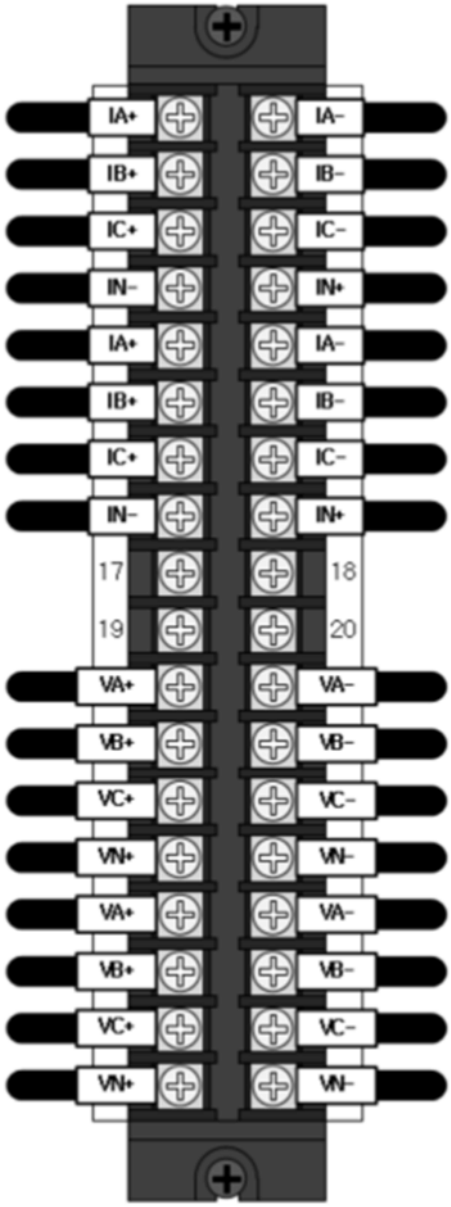


2.2.2. Connection Positions (for LPIT)

<Connection positions of IM2 for LPIT>

2.2.3. How to connect

2.2.3.1. CPTU-A Connection



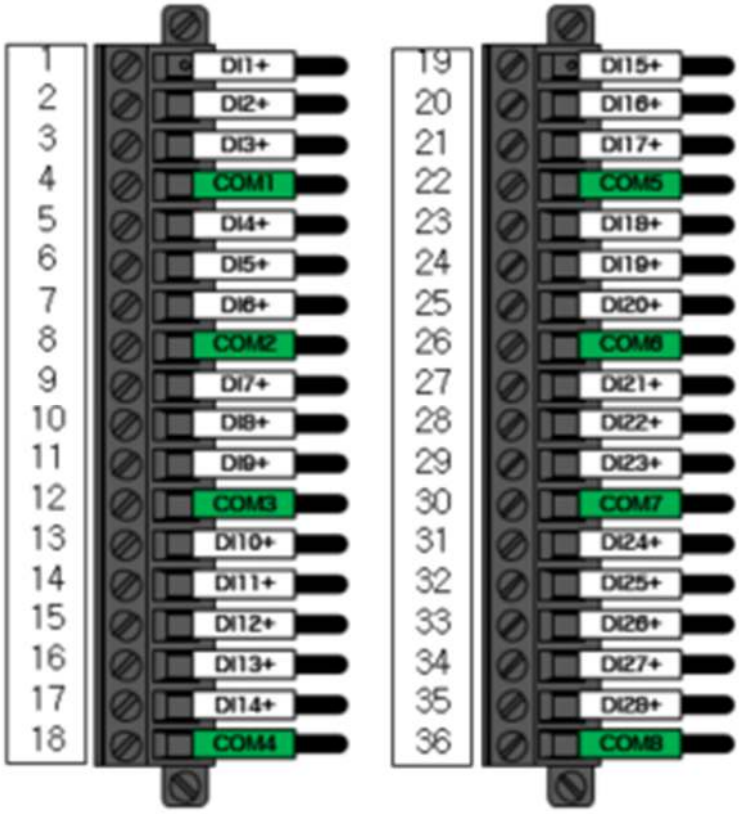
<CPTU-A cnnection>

- CT connection uses #1~#16 and #19~#26 of the CPTU-A terminal block, and the current input connection should be made as +/- pairs.
- PT connection uses #29~36 of the CPTU-A terminal block, and the input connection should be made as +/- pairs.

- Terminal block for CPTU-A connection is configured as follows.

CPTU-A	Function	CPTU-A	Function	Components
1	IA1+	2	IA1-	CT
3	IB1+	4	IB1-	
5	IC1+	6	IC1-	
7	IN1-	8	IN1+	
9	IA2+	10	IA2-	
11	IB2+	12	IB2-	
13	IC2+	14	IC2-	
15	IN2-	16	IN2+	
17	-	18	-	NC
19	IA3+	20	IA3-	CT
21	IB3+	22	IB3-	
23	IC3+	24	IC3-	
25	IN3-	26	IN3+	
27		28		NC
29	VA1+	30	VA1-	PT
31	VB1+	32	VB1-	
33	VC1+	34	VC1-	
35	VN1+	36	VN1-	

2.2.3.2. CPTU-B Connection



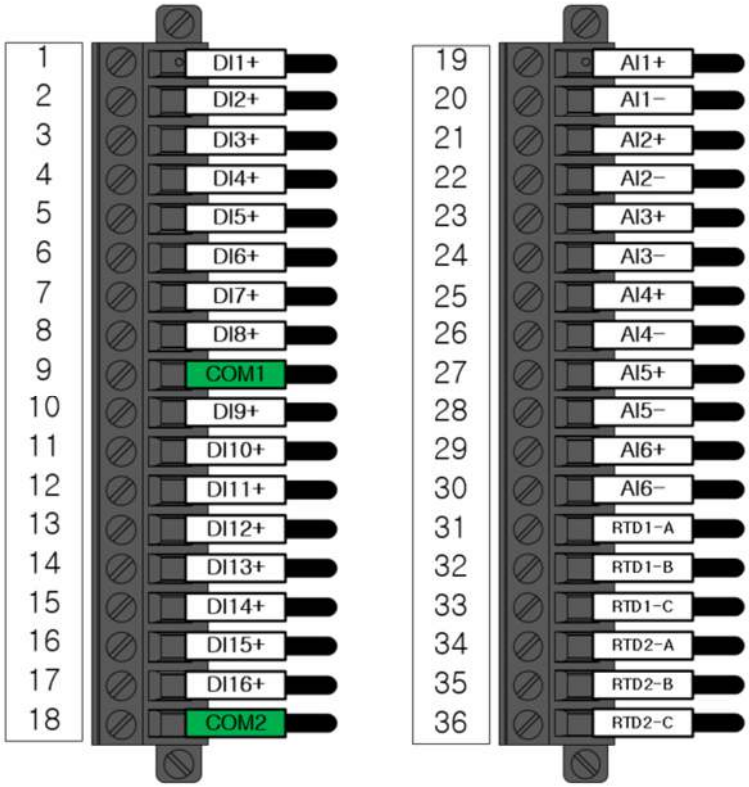
<CPTU-B Connection>

- CT connection uses #1~#16 of the CPTU-B terminal block, and the current input connection should be made as +/- pairs.
- PT connection uses #21~#36 of the CPTU-B terminal block, and the input connection should be made as +/- pairs.

- Terminal block for CPTU-B connection is configured as follows.

CPTU-B	Function	CPTU-B	Function	Components
1	IA1+	2	IA1-	CT
3	IB1+	4	IB1-	
5	IC1+	6	IC1-	
7	IN1-	8	IN1+	
9	IA2+	10	IA2-	
11	IB2+	12	IB2-	
13	IC2+	14	IC2-	
15	IN2-	16	IN2+	
17	-	18	-	NC
19	-	20	-	
21	VA1+	22	VA1-	PT
23	VB1+	24	VB1-	
25	VC1+	26	VC1-	
27	VN1+	28	VN1-	
29	VA2+	30	VA2-	
31	VB2+	32	VB2-	
33	VC2+	34	VC2-	
35	VN2+	36	VN2-	

2.2.3.3. Connection of DIU



< DIU connection>

- Connection of contact inputs in DIU uses #1~#36 of each terminal block, and is made so that 3 points or 5 points of each terminal block share one COM.

- The configuration for connecting the contact DIU terminal block is as follows.

DIU	Function	DIU	Function
1	DI1+	19	DI15+
2	DI2+	20	DI16+
3	DI3+	21	DI17+
4	DI1,2,3-	22	DI15,16,17-
5	DI4+	23	DI18+
6	DI5+	24	DI19+
7	DI6+	25	DI20+
8	DI4,5,6-	26	DI18,19,20-
9	DI7+	27	DI21+
10	DI8+	28	DI22+
11	DI9+	29	DI23+
12	DI7,8,9-	30	DI21,22,23-
13	DI10+	31	DI24+
14	DI11+	32	DI25+
15	DI12+	33	DI26+
16	DI13+	34	DI27+
17	DI14+	35	DI28+
18	DI10,11, 12,13,14-	36	DI24,25, 26,27,28-

2.2.3.4. Connection of DAIU

<DAIU connection>

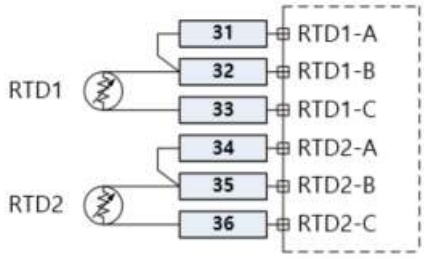
- Connection of contact inputs in DIU uses #1~18 of each terminal block, and is made so that 8 points of each terminal block share one COM.

- The configuration for connecting the contact DIU terminal block is as follows.

DAIU	Function
1	DI1+
2	DI2+
3	DI3+
4	DI4+
5	DI5+
6	DI6+
7	DI7+
8	DI8+
9	DI1,2,3,4,5,6,7,8-
10	DI9+
11	DI10+
12	DI11+
13	DI12+
14	DI13+
15	DI14+
16	D15+
17	D16+
18	DI9,10,11,12,13,14,15,16-

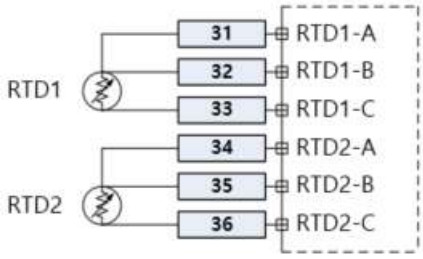
- Connection of AI in DIU uses #19~#30 of each terminal block, and the connection should be made as +/- pairs.

- The configuration for connecting the contact AI terminal block is as follows.



DAIU	Function
19	AI1+
20	AI1-
21	AI2+
22	AI2-
23	AI3+
24	AI3-
25	AI4+
26	AI4-
27	AI5+
28	AI5-
29	AI6+
30	AI6-

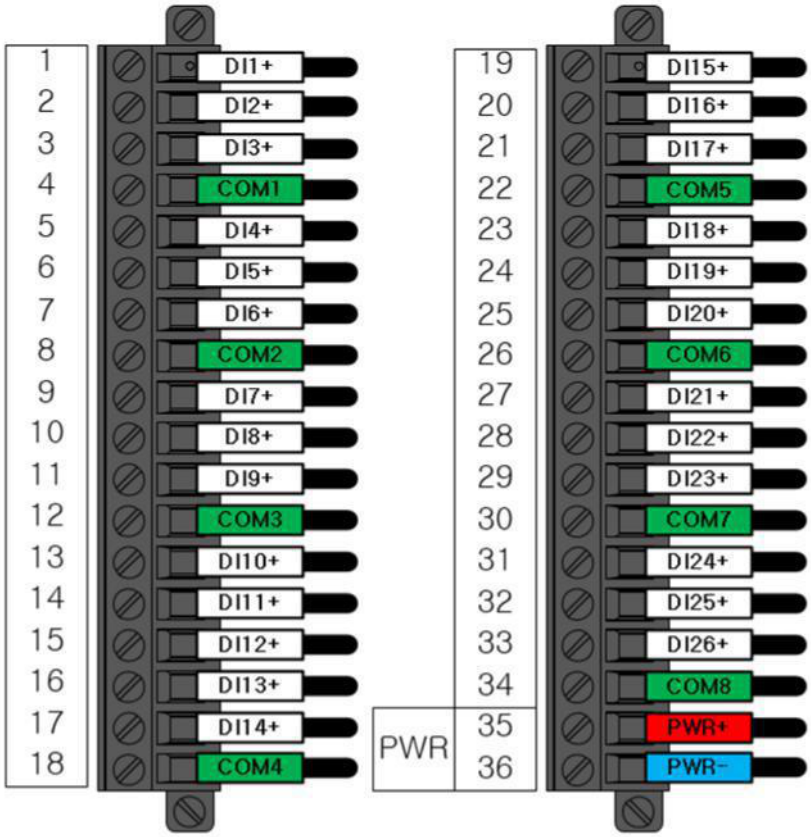
- Connection of RTD in DIU uses #31~#36 of each terminal block. #31~#33 are RTD1 [A.B.C], #34~36 are RTD2 [A,B,C] and they are connected as 2-wire or 3-wire connections.



- The configuration for connecting the RTD terminal block is as follows.

DAIU	Function
31	RTD1-A
32	RTD1-B
33	RTD1-C
34	RTD2-A
35	RTD2-B
36	RTD2-C

- The configuration for connecting the RTD sensors is as follows.



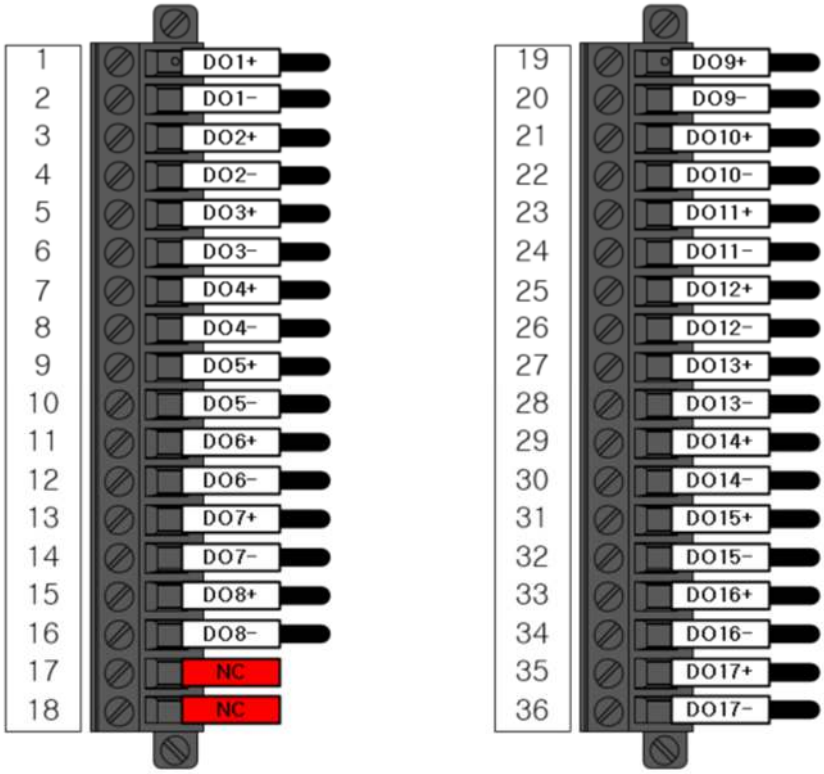
2-wire

3-wire

2.2.3.5. Connection of DIPU

< DIPU connection >

- Connection of contact input in DIPU uses #1~#36 of each terminal block, and is made so that 3 points or 5 points of each terminal block share one COM.



- The configuration for connecting the DIPU terminal block is as follows.

DIPU	Function	DIPU	Function
1	DI1+	19	DI15+
2	DI2+	20	DI16+
3	DI3+	21	DI17+
4	DI1,2,3-	22	DI15,16,17-
5	DI4+	23	DI18+
6	DI5+	24	DI19+
7	DI6+	25	DI20+
8	DI4,5,6-	26	DI18,19,20-
9	DI7+	27	DI21+
10	DI8+	28	DI22+

17	DI14+		
18	DI10,11, 12,13,14-		

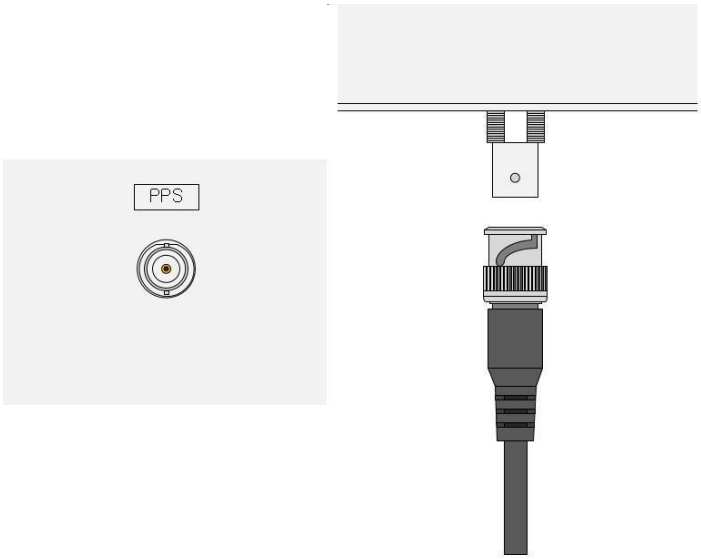
- DIPU can be used with AC and DC power supply.
- The configuration for connecting the power supply terminal block is as follows.

DIPU	Function	
35	DC125V+	AC220(L)
36	DC125V -	AC220(N)

2.2.3.6. Connection of DOU

<DOU Connection>

- Connection of AI in DOU uses #1~36 of each terminal block, and the connection is made so that there are input as +/- pairs.
- output # 35~36 point out of contacts of DOU terminal blocks are used as the basic B contact.



Be sure to check the status of the contact point B before connecting the contact output terminal block.

- The configuration for connecting the power supply terminal block is as follows.

DOU	Function	Contact
1	DO1+	
2	DO1-	
3	DO2+	
4	DO2-	
5	DO3+	
6	DO3-

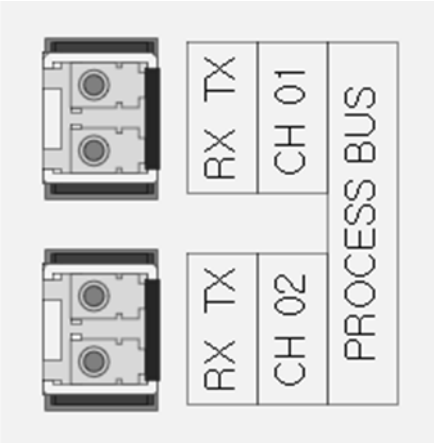
2.2.3.7. 1PPS Connection

<PPS connection>

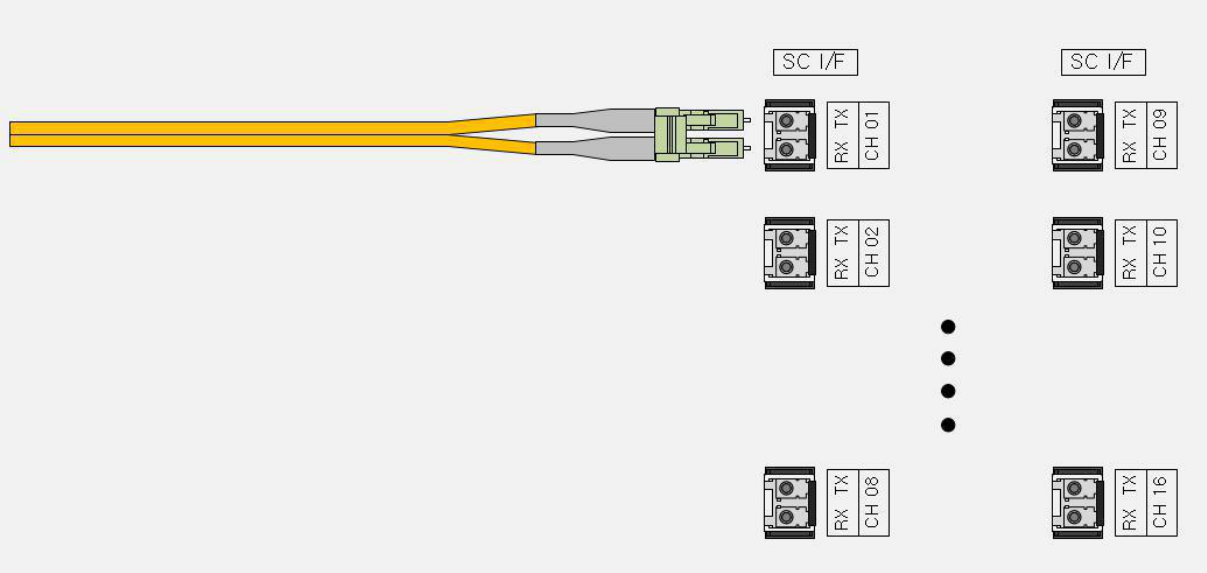
- 1PPS input cable is connected to 1PPS input port, using BNC cable.



2.2.3.8. Fiber-Optic Connection

<Fiber-optic connection>

- The optical port for connecting STATION BUS terminal (IEC 61850) and PROCESS BUS terminal consists of 2 channels (redundancy), respectively, and the optical cables are connected to CH 01 and CH 02 ports.



- SFP Specification

Classification	Description
Number of Port	2 (physical) / 1 (HSR/PRP redundant)
Figure	Rear 

Classification	Description		
Characteristics	Glass optical fiber		
Connector type	2 x duplex LC		
	Select option		
	100Base-FX	1000Base-SX 1	1000Base-SX 2
Fiber type	Multi mode (50/125μm and 62.5/125μm optical cable)		
Transmission distance	2km	550m	2km
Wave length	1310nm	850nm	1310nm
Max. Data Rate	100 Mbps	1000 Mbps	1000 Mbps
Operating Temperature	-40 ~ 85℃		
Storage Temperature	-40 ~ 85℃		
Protocol	IEC 61850-9-2LE, IEC 61869-9, limited IEC 61850-8-1 IEEE1588v2		

Do not replace SFP modules supplied by the manufacturer arbitrarily

2.2.3.9. Fiber-Optic Connection for Secondary Converter in the IM2 for LPIT

<Fiber-optic connection to SCs in IM2 for LPIT>

- Optical port for connecting Secondary Converter Unit communication consists of a total of 16 channels, and optical cable is connected as LC to ST type between Secondary Converter unit and IM2.

- SFP Specification

Classification	Description
Number of Port	8 (physical)
Characteristics	Glass optical fiber
Connector type	duplex LC
Fiber type	Multi mode (62.5 μm/125 μm optical cable)
Transmission distance	Maximum 2km
Wave length	850nm
Bit Rate	DC-50 MHz

Classification	Description
Operating Temperature	-40 ~ 85℃
Storage Temperature	-40 ~ 85℃
Protocol	Manufacturer's own protocol

Do not replace SFP modules supplied by the manufacturer arbitrarily

2.2.3.10. Wiring Feature

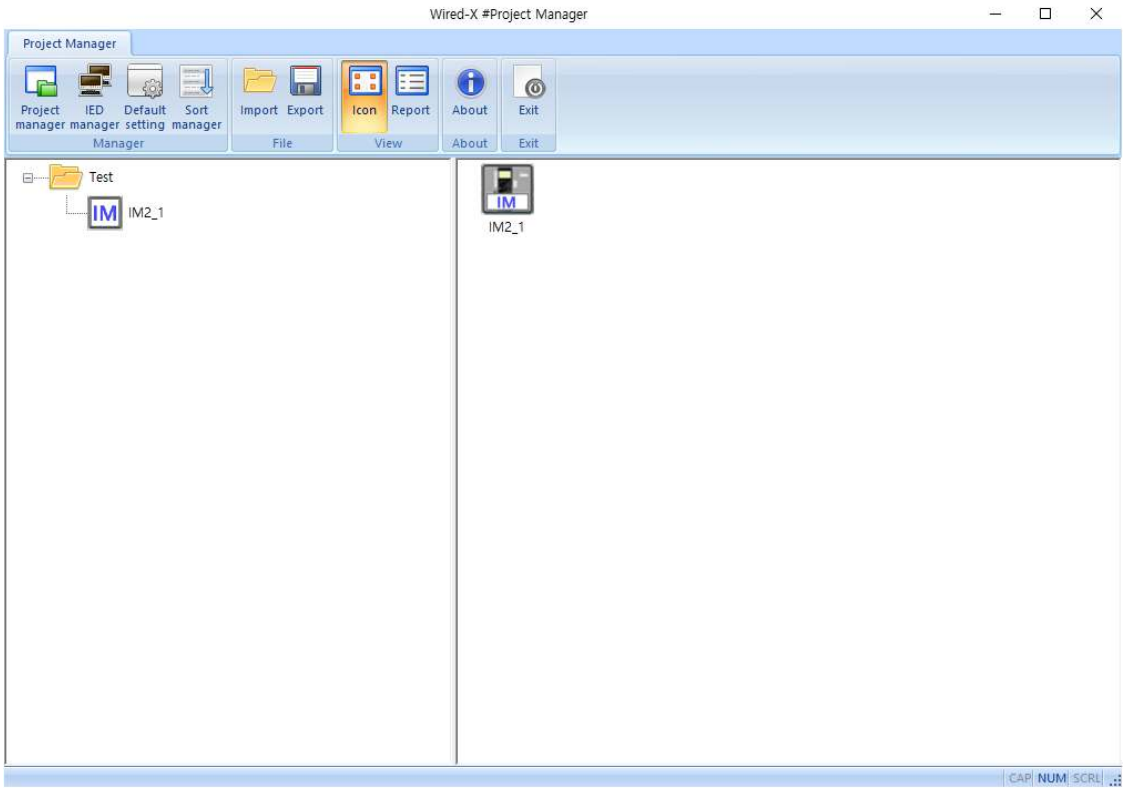
- Wiring cables used on the back side should be cables equal to or higher than the following standards.
  - Vinyl chloride insulated cable less than 450/750V that meets KSC C IEC 60227-3(2005) or IEEE 383
  - Cables for AC current circuit: copper cable of 2.5㎟ or thicker
  - Cable for power and ground-related circuit: copper cable of 2.5㎟ or thicker
  - Cable for optical communication: Multi-mode, 1310nm
  - Cable for other circuits: copper cable of 1.5㎟ or thicker
  - Treatment of wiring end: Be sure to use the ring-shaped solderless terminals with appropriate dimensions or sleeve-type solderless terminal, and mark bands and colors should be attached to facilitate wiring inspection. However, the solderless terminals must be certified by an authorized agency or conform to KSC 2620 standard.

3. Operation

3.1. Wired-X

The operating software for IM2 is installed on a Windows OS-based PC to connect to IM2 via TCP/IP over Ethernet communication service ports located at the front and the rear of IM2. The communication between the operating software and IM2 is based on request-response scheme.

<Operating software and IM2>

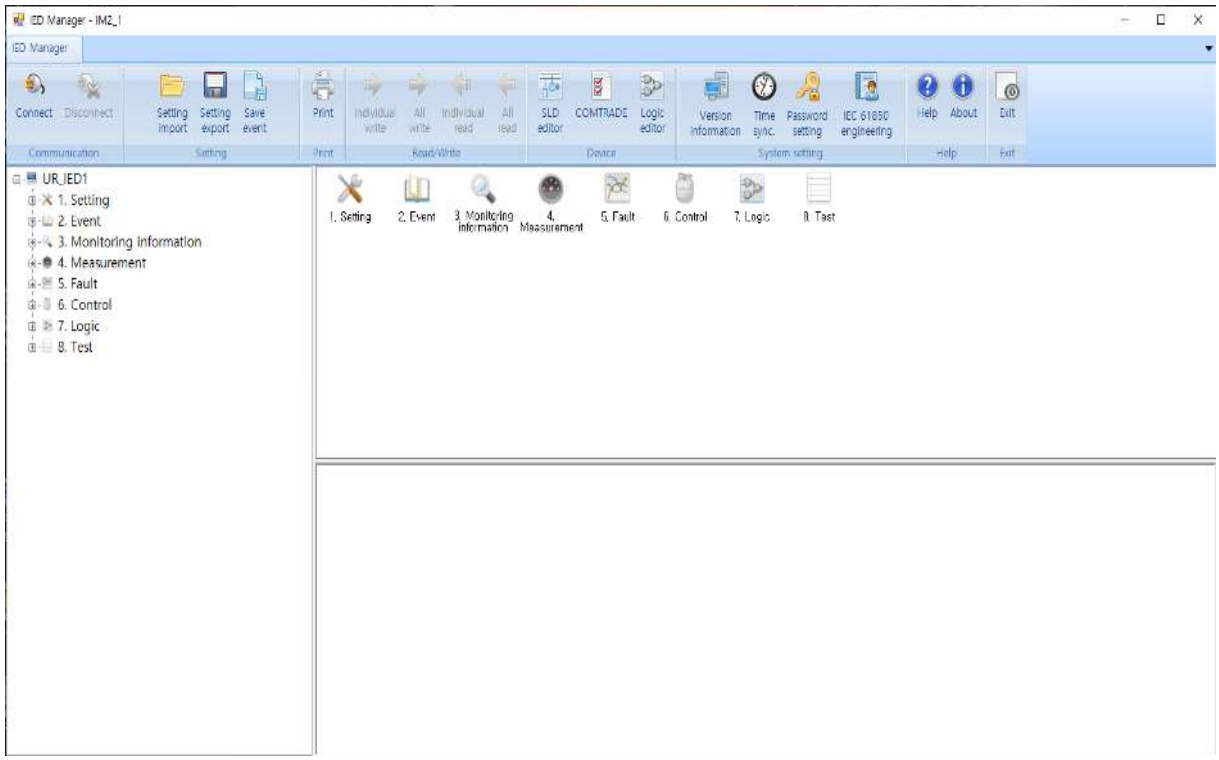


3.1.1. Software Components

Operating software consists of the following modules.

Software module	Details
Project Manager	Project management, device management
Device Manager	Device communication, event, setting, status management
IEC 61850 engineering tool	Management of IEC 61850 engineering files

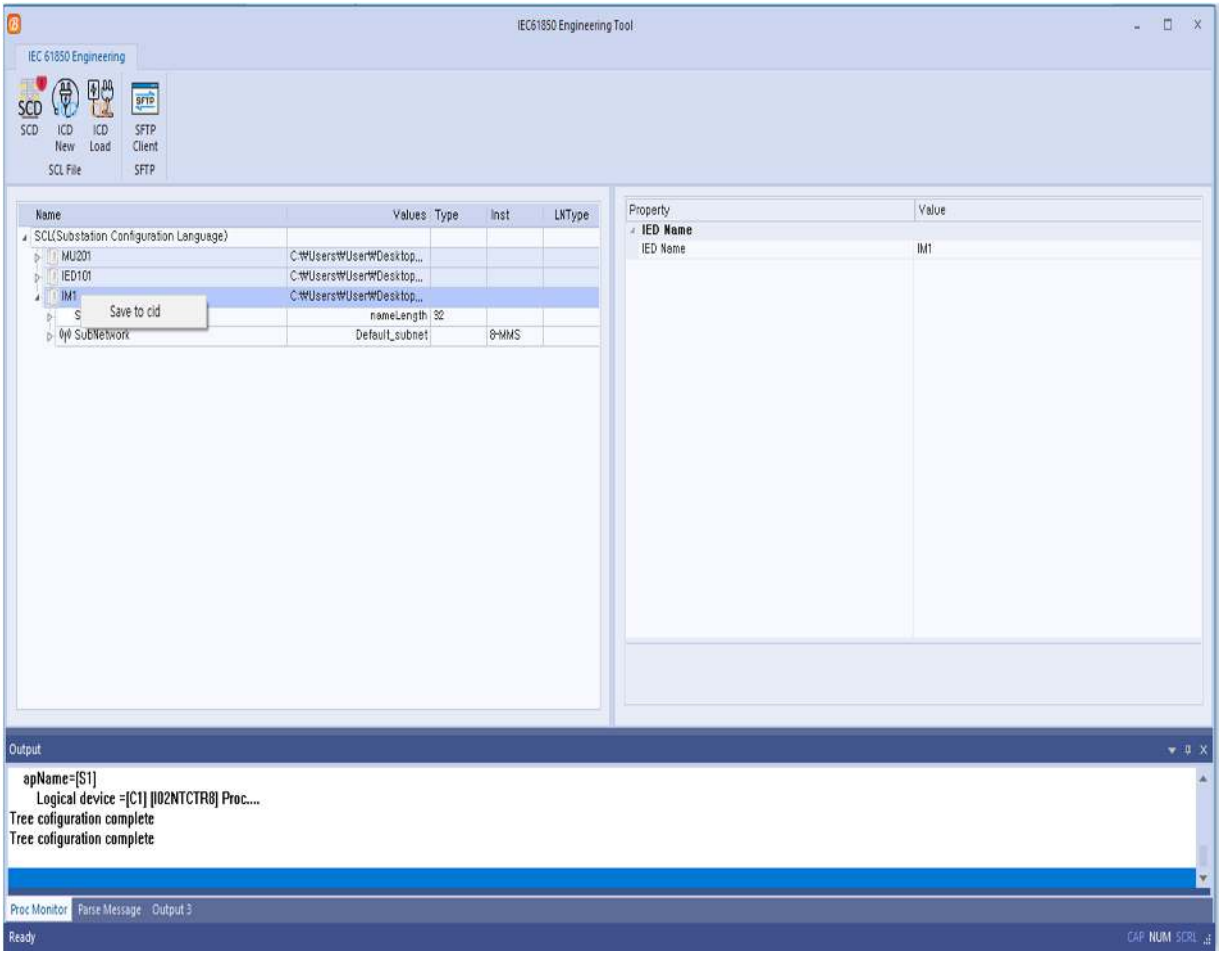
1) Project Manager



This is the window screen when the operating software is initially run, creating projects and managing devices to be used in the project by device model. Folders where data are saved, communication methods, communication settings for each device model can be managed.

<Project manager window>

2) Device Manager



The following is the Device Manager screen which appears after the connection to a device registered in the project created in the Project Manager is completed. Functions of transmitting and receiving the setting, event and history data with the device are provided. IEC 61850 engineering tool can be launched in the device manager screen.

<Device manager window>

3) IEC 61850 engineering tool

IEC 61850 engineering tool is a tool launched in the device manager, which functions to export .ICD files of devices, or import .SDC files to export .CID files. Also, it functions to upload/download the engineering files on/from devices via FTP.

<Window of IEC 61850 engineering tool>

3.1.2. Software Installation

1) Supporting Operating Systems

• Windows XP

• Windows Server 2003, 2008, 2019 Standard

• Windows Vista

• Windows 7

• Windows 8

• Windows 10

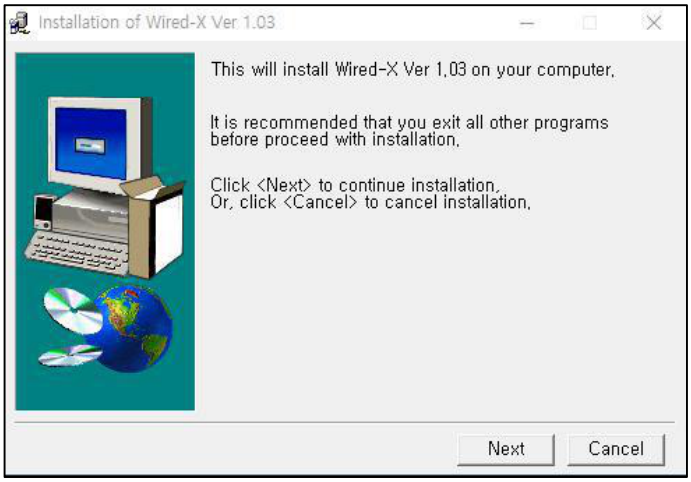
• Windows 11

2) PC requirements

• CPU: 1.5GHz or higher

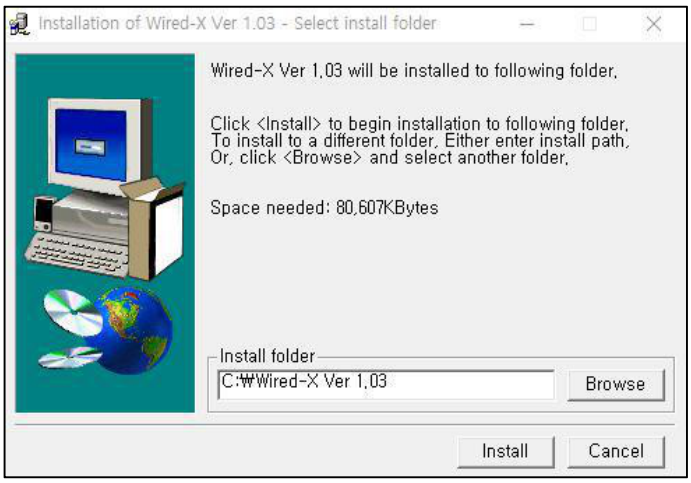
• RAM: 1GB or greater

• HDD: available space of 30GB or more



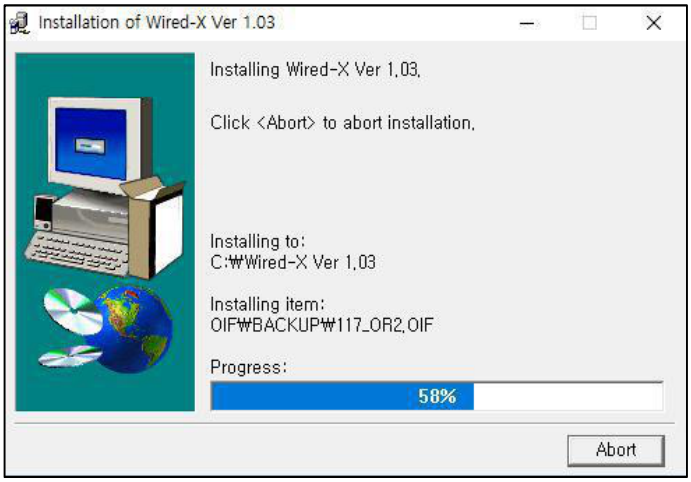
• Ethernet port

3) Installation

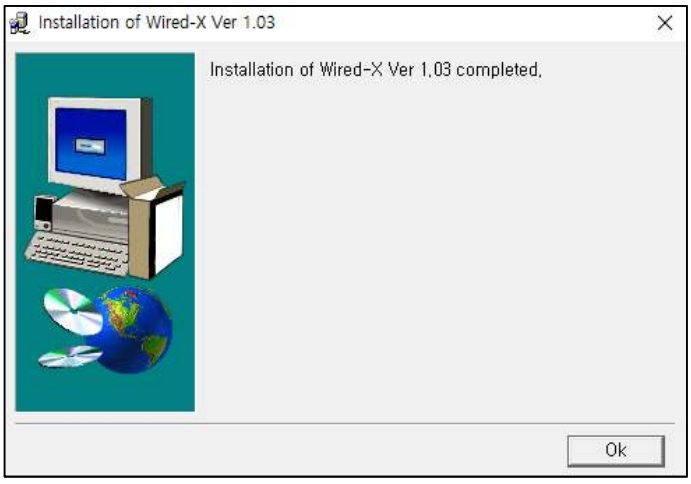


• Run "Wired-X Setup.exe" 

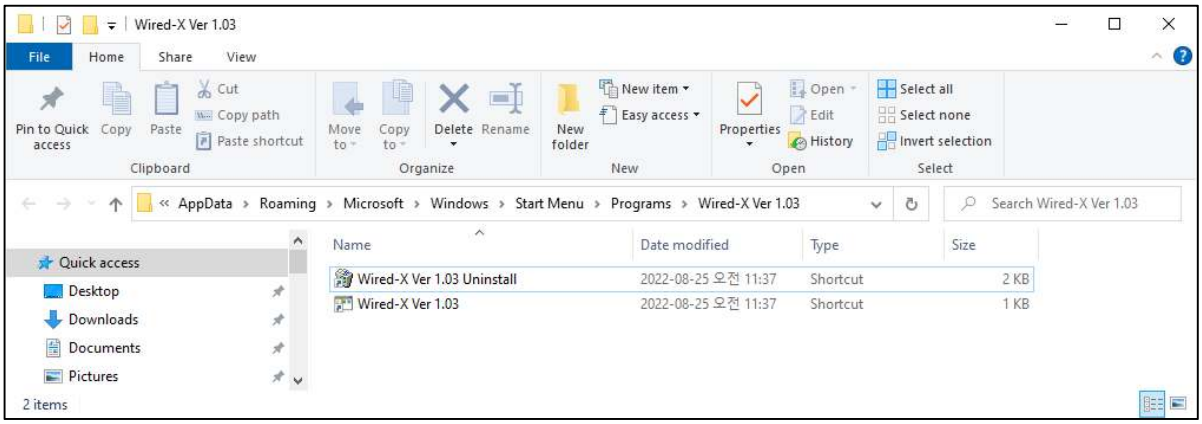
to start the installation.



• Click the "Next" button.

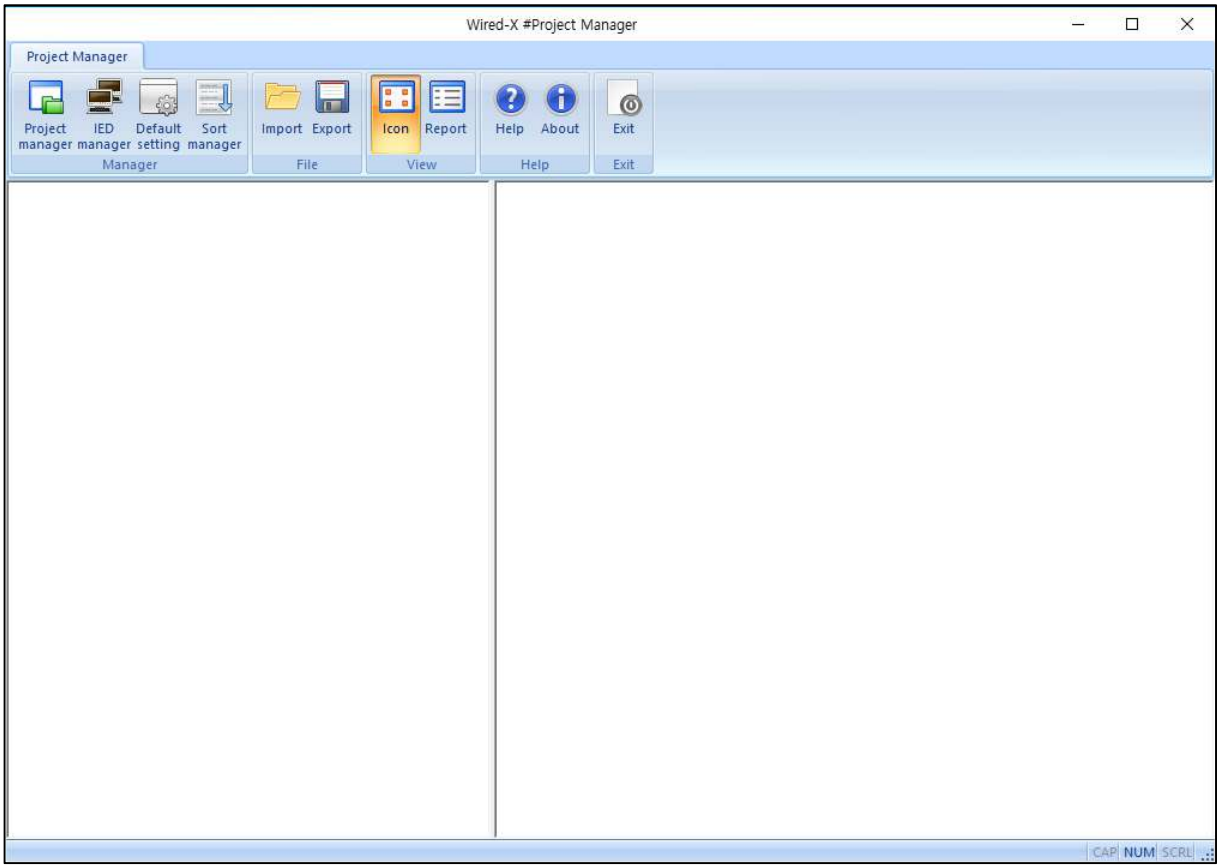


• Designate the "installation folder" and click the "Install" button.



• Installation is proceeded.

• When the installation is completed, click “Ok” button.

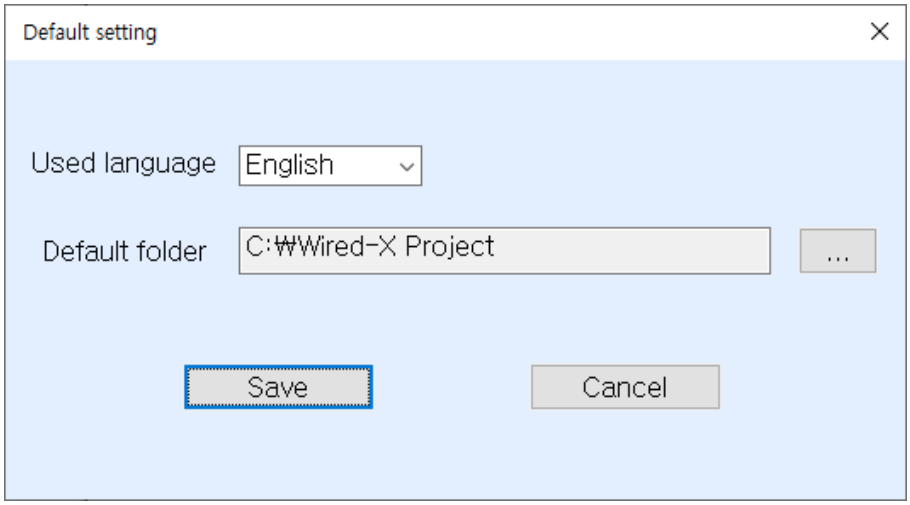


• When the installation is completed normally, the following icons are generated.

<Icons generated >

3.1.3. Running the Software

After the installation is completed, the operating software can be launched by double-clicking  icon. Below is the first screen that appears when the operating software is launched. When first launched, nothing is displayed on the screen. Project registration and device registration step should be first executed in order to being ready to make a connection to a device.



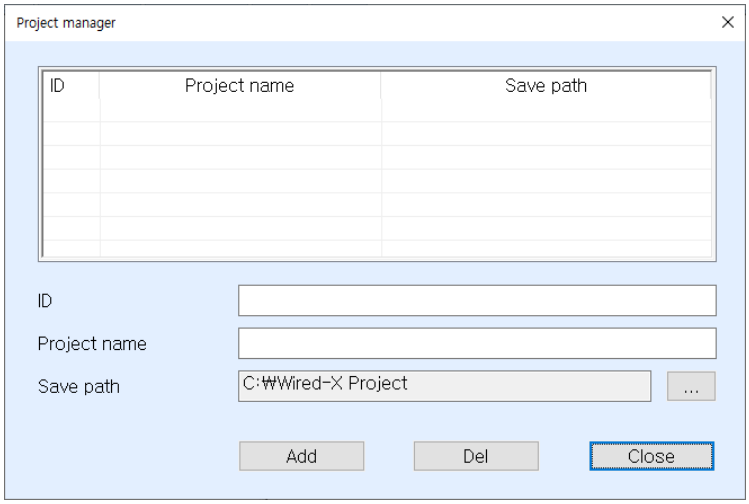
<Initial screen of the operating software (Project Manager)>

3.1.4. Environment Setting for Software

1) Save Path Setting

Set up a “default folder” that saves information on all devices to which the operating software is connected. Be sure to set up before registering project or devices. Click  icon on the toolbar.

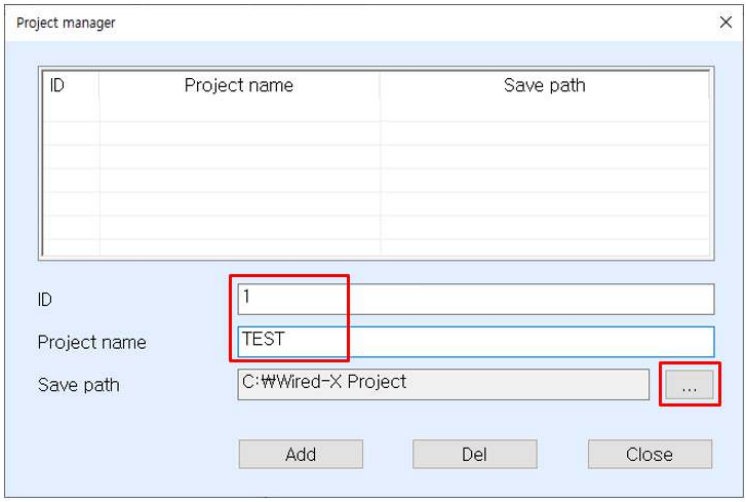
<Default setting>



The language used in the software can be changed between “Korean” and “English”. Click "..." button to select the path of default folder. The default path is "C:\Wired-X Project".

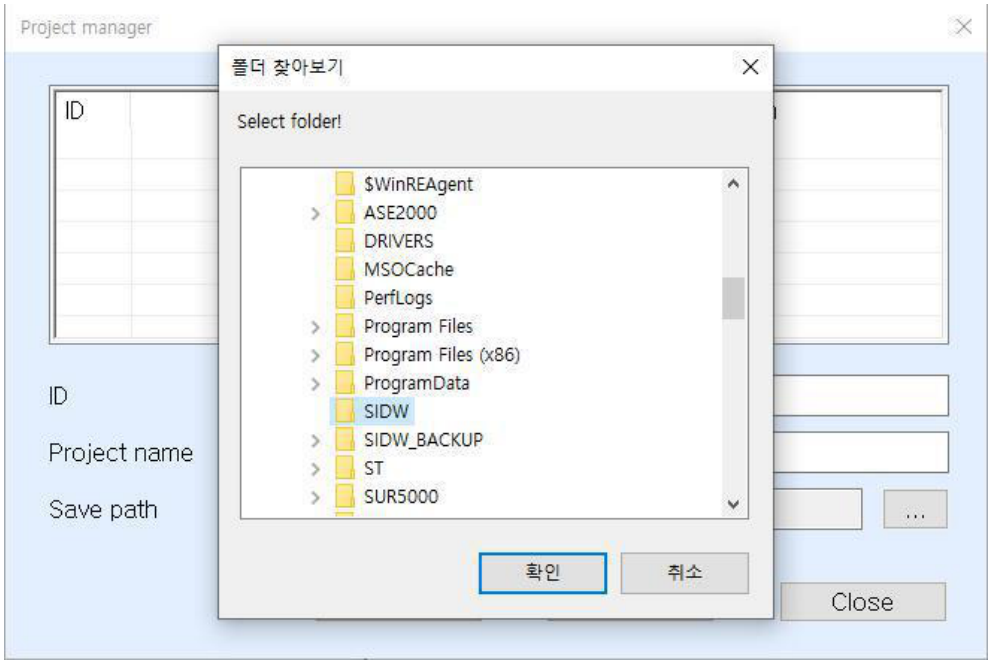
After selecting the desired folder, click "OK" button and then click “Save” button on the previous screen to complete the change of the “default folder”. The change of language takes effect after restarting the program. The information on all devices connected to and managed by the operating software is saved in the set “default folder”.

2) Registration of Project



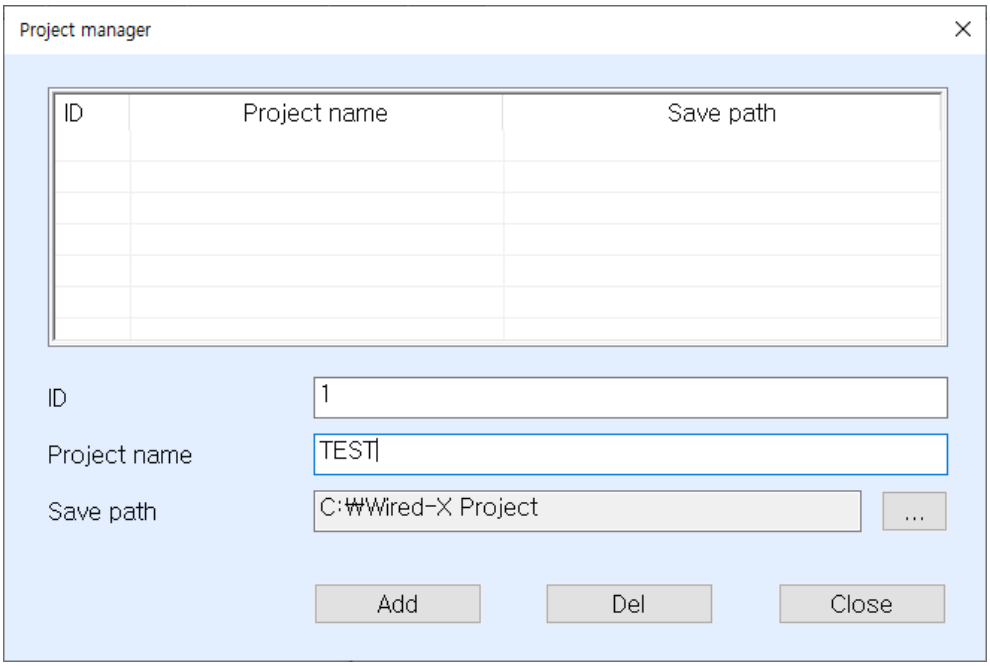
Be sure to register project in order to classify devices connected to and managed by the operating software into project units. For example, one substation can be a project.

First, click  icon on the toolbar.



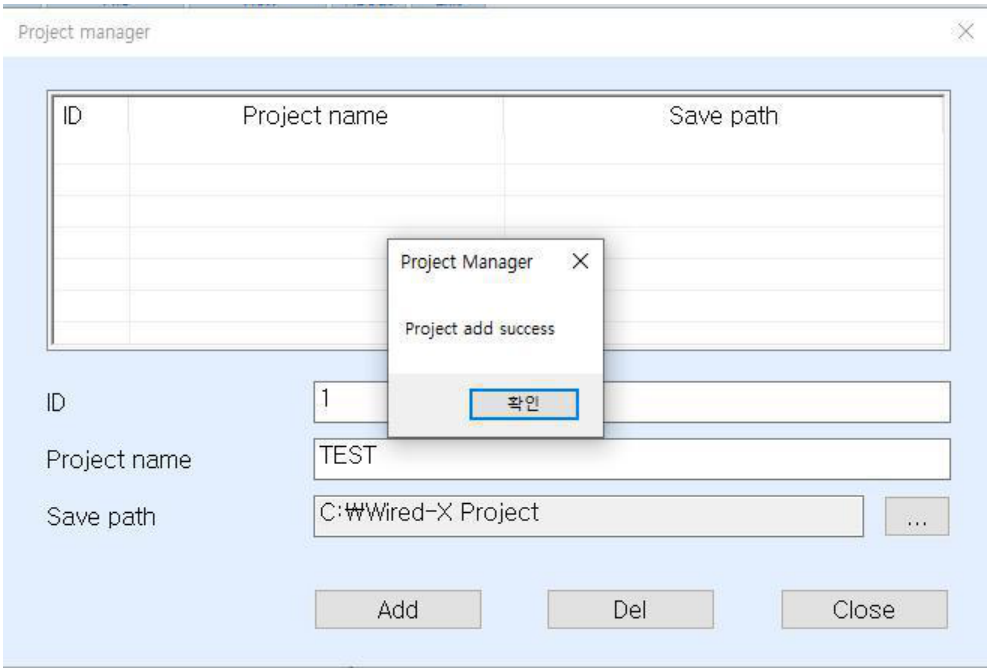
<Project Manager window>

Register projects on the window of Project Manager. Items to be registered are "Project ID", "Project Name", and "Save Path". For "Project ID", enter a numerical value that is distinct from other projects, and for “Project Name”, enter a distinguishable name (e.g., substation name). For "Save Path", select the folder where the project is saved. Check the items for registering project.



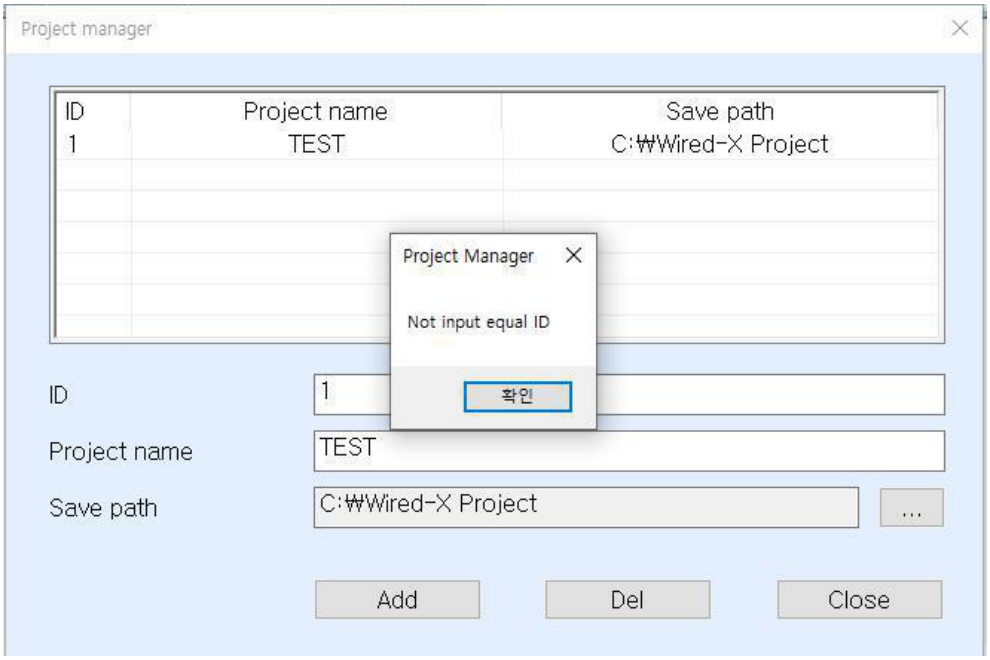
<Window for registering projects>

Select a folder where project will be saved.



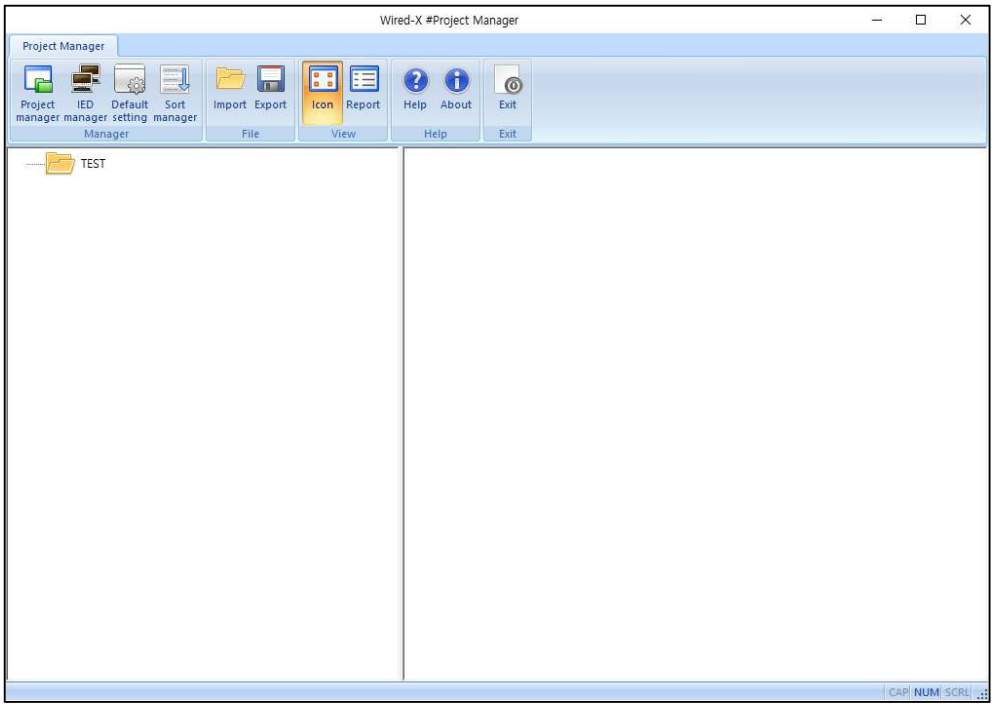
<Window for selecting save path>

Check the input items and then click “Add” button to register the project.



<Window for entering project items>

The added project details will be updated in the upper list.

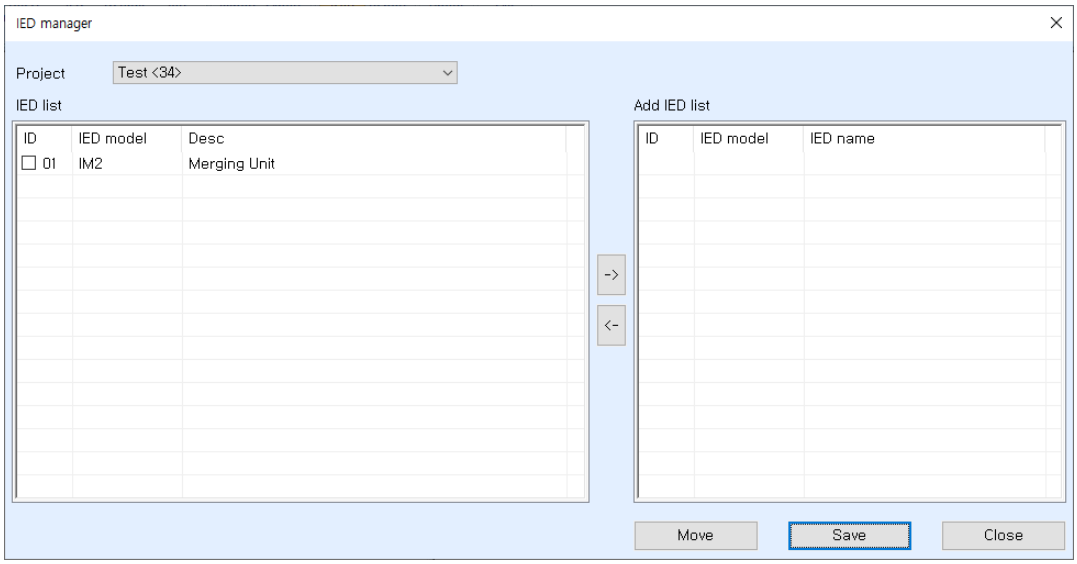


<Window that displays message of 'Project add success'>

If the ID is same as the existing value, project registration will fail.

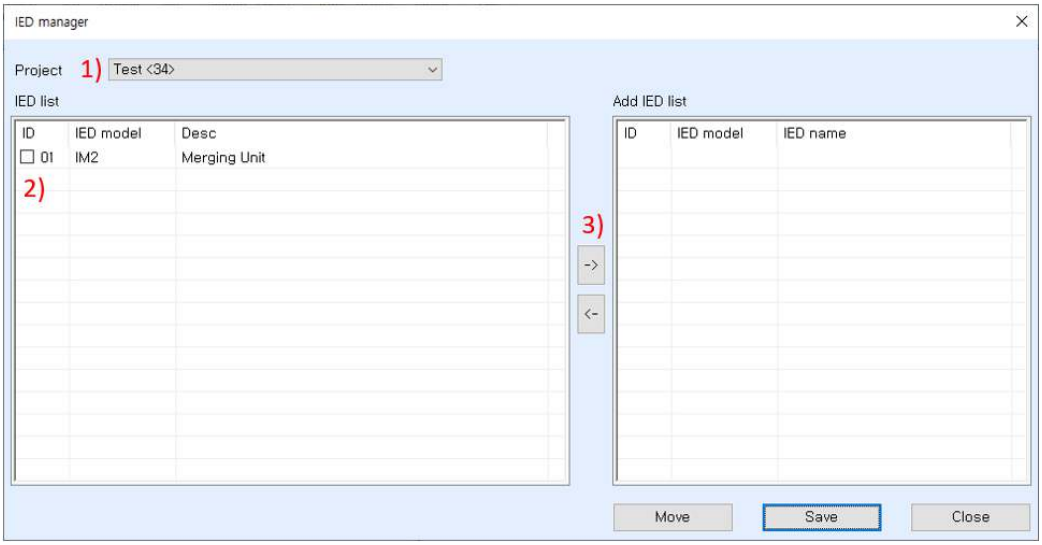
<Window that displays error message when inputting an existing ID>

After the registration process is finished, the name of the registered project is generated in the tree on the left side of the initial screen.



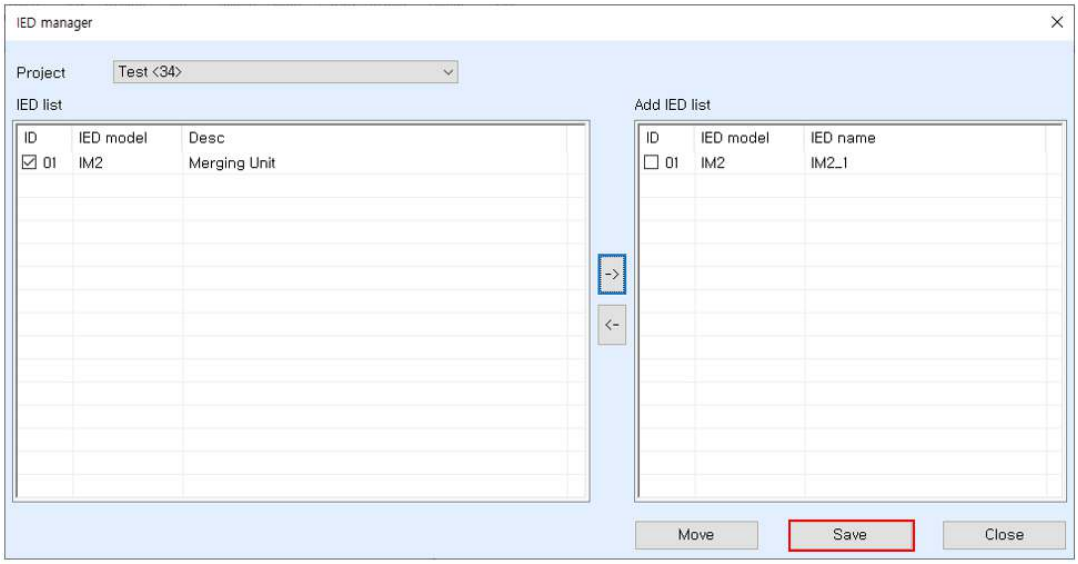
<window for checking the registered projects>

3) Registration of Devices

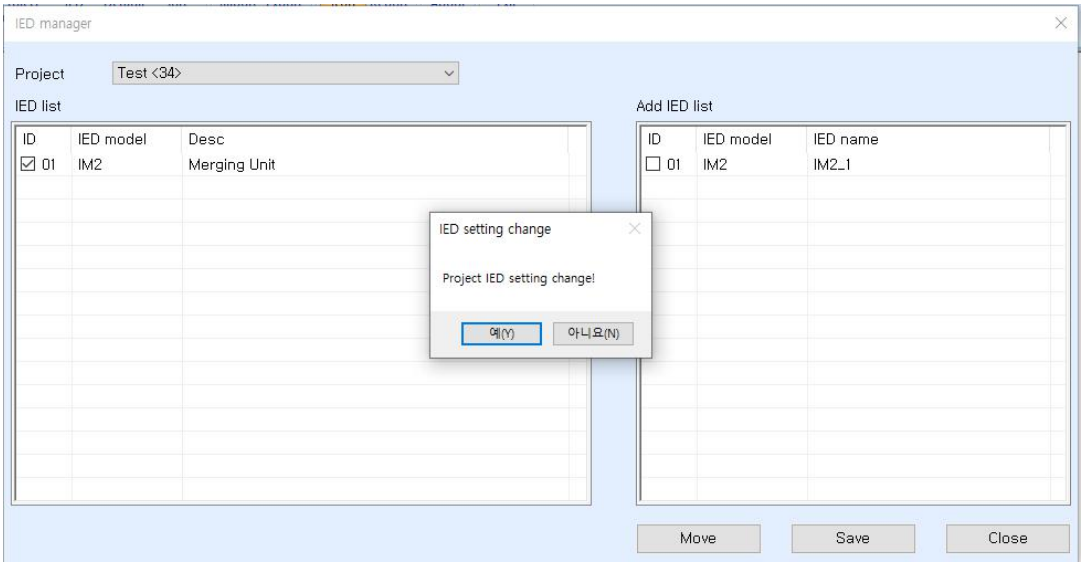


After a project is successfully registered, it is necessary to register devices for the project. For example, the IM2 devices installed in one substation can be the devices for the project.

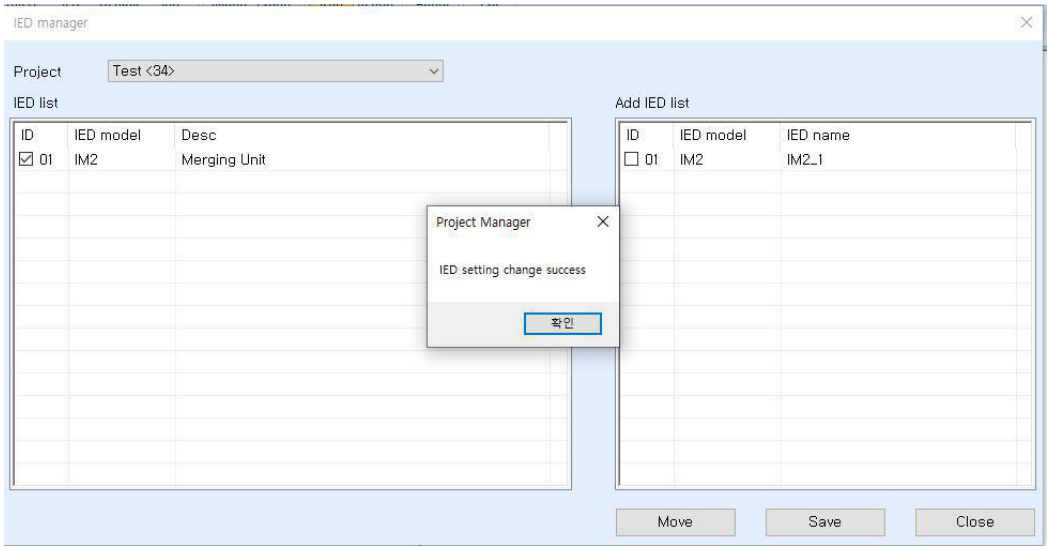
Click  icon on the toolbar.



<Manager window>

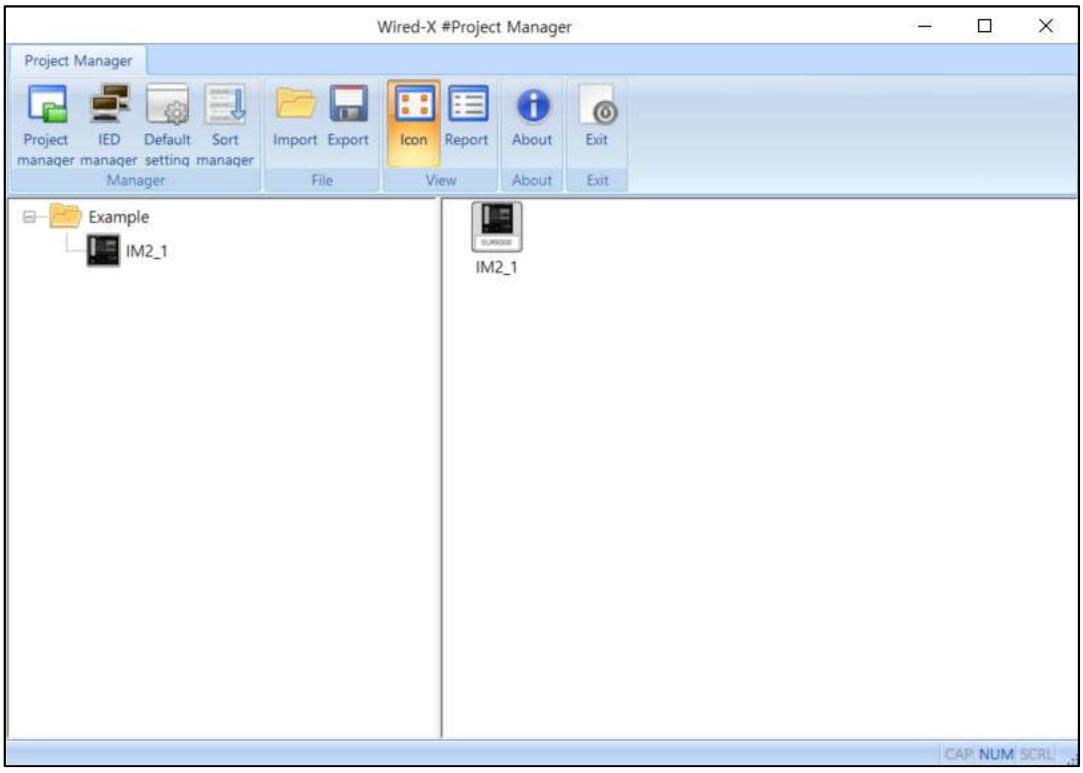


Select "Project", and then select “Device Model” to register from “Device List” on the left (multiple selections are possible), and click “-->” button to update “Registered List of Devices” on the right. Click “Save” button to complete the registration of device.



<Device registration procedure 1 – selection of item>

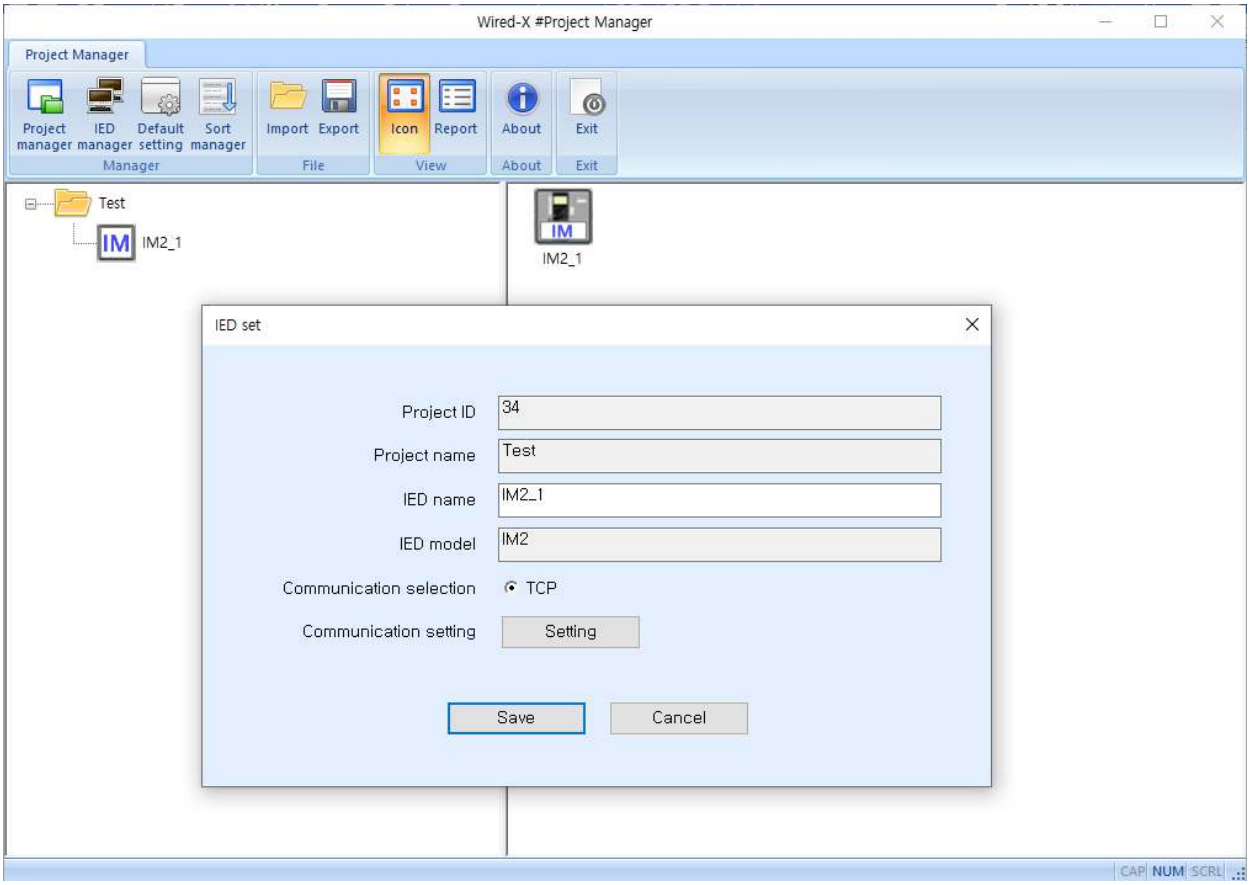
<Device registration procedure 2 – Save>



<Device registration procedure 3 – Check setting>

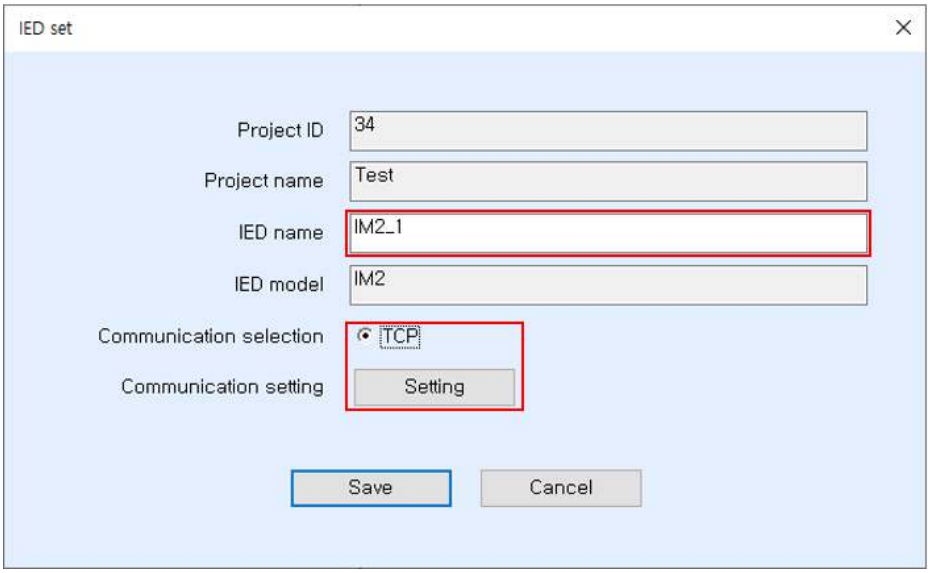
<Device registration procedure 4 – Setting completed>

When the device is registered normally and the above window is closed, the registered device is displayed below the corresponding project item on the left list as follows, and is also displayed in the right side of the screen if the project is selected.



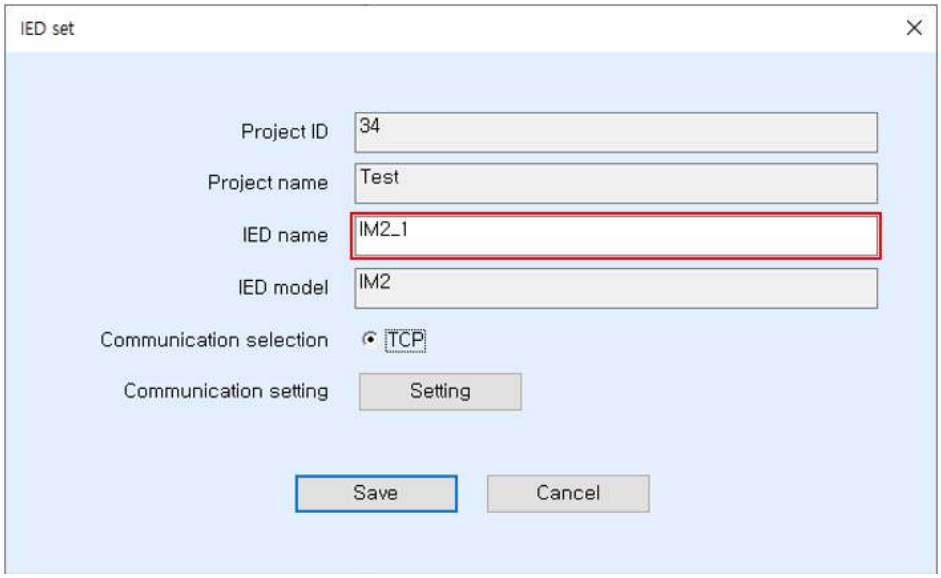
<Result of registering the device>

3.1.5. Connection to Software



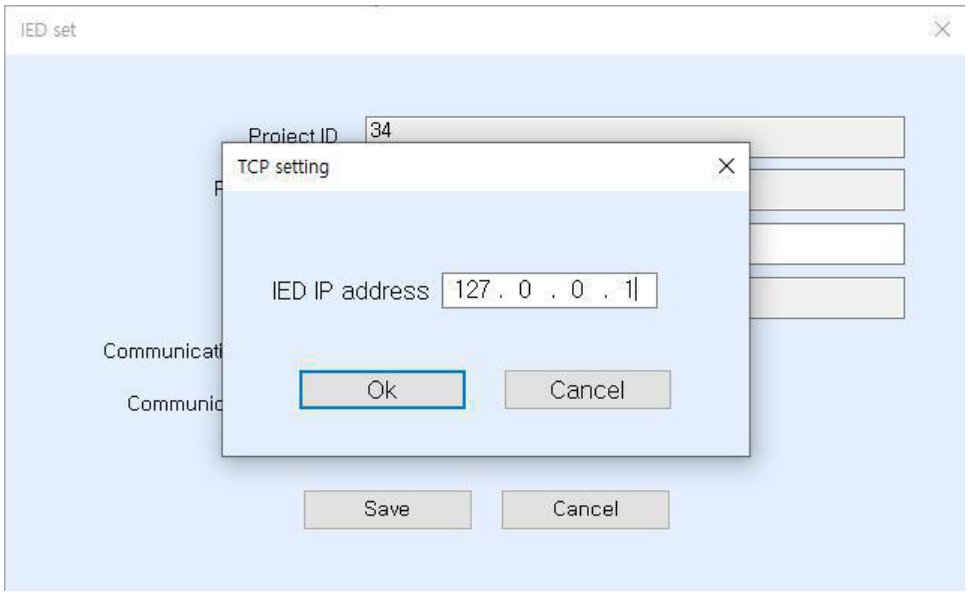
1) Setting of Connection

In order to connect the operating software to the registered device, the communication scheme and related parameters should be set up. Select the device to connect in the left or right side of the screen, click the right button on the mouse to display a window for “Device setting”.

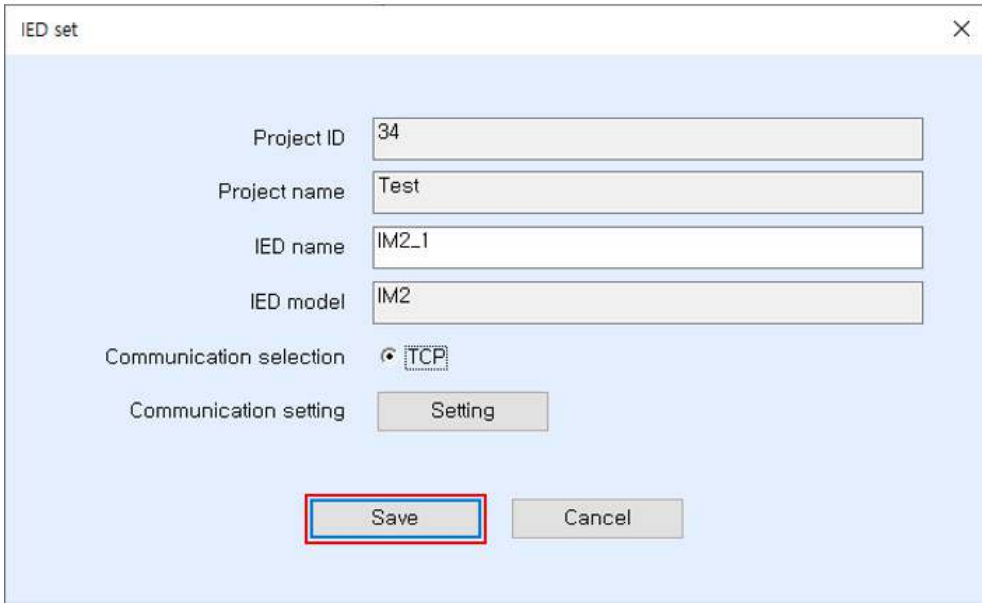


<Window for device setting>

In the above screen, “Device name”, “Communication selection” and “Communication setting” can be modified. The initial value of "Device name" is entered as the same string with the “Device model” at the time of registration, and the operator can change it. “Communication selection” is an item to select how to communicate with the device, and in such case, the setting items on the window of “Communication setting” varies depending on the selected communication scheme.



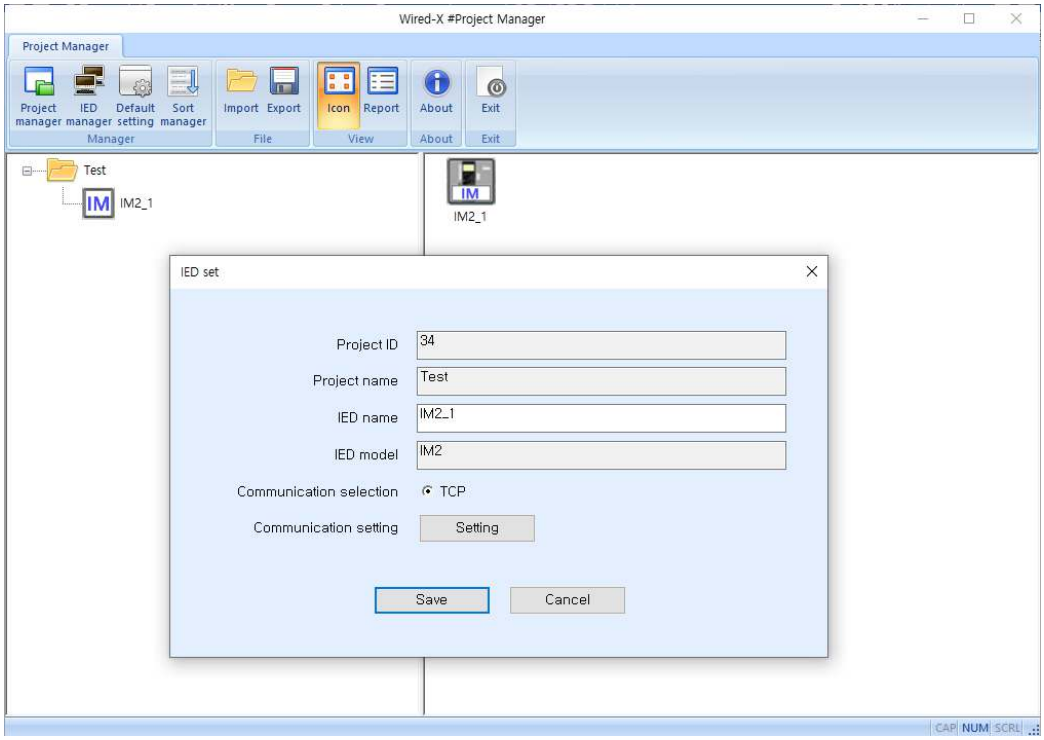
<Device setting – modifiable items>



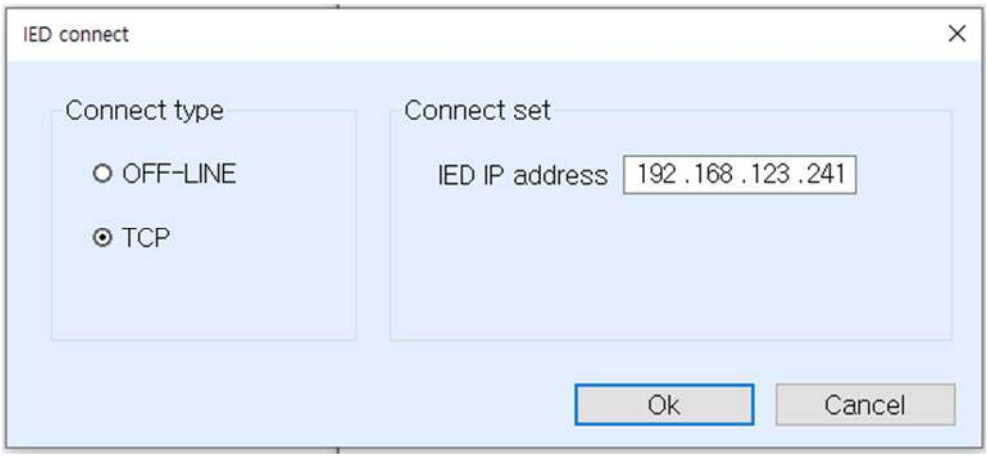
<Device name setting>

For the communication scheme, only TCP/IP is supported by IM2. In the communication setting window, the IP address of the device to connect should be correctly set. Click "OK" button after setting.

<Device setting – setting of TCP communication>

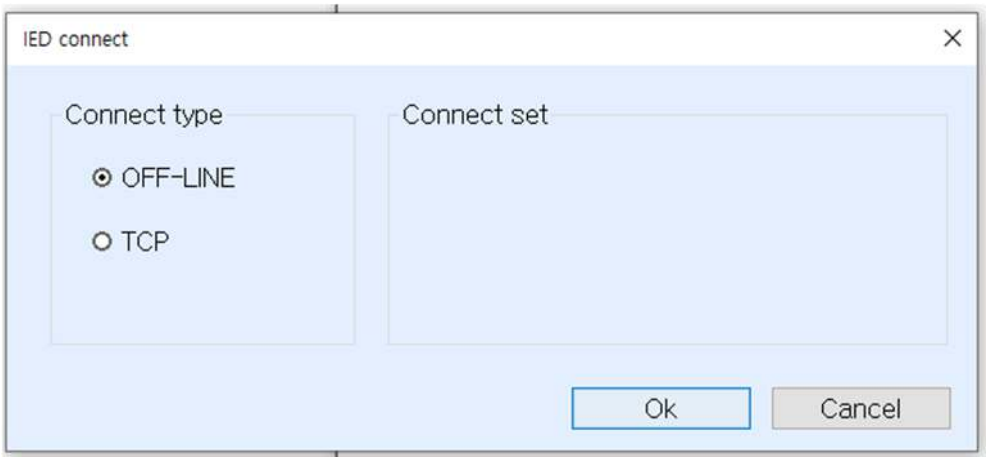


Check the set items after setting, and then click "Save" button.



<Device setting completed>

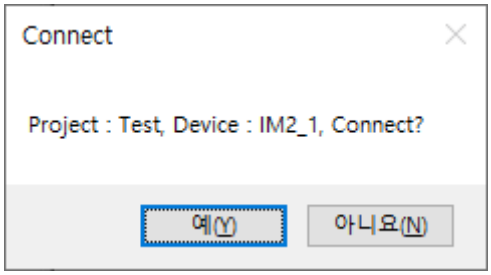
2) Connection



After setting communication parameters, double-click the device to be connected. Then, a window for device connection will be displayed.

<1st step of device connection – select and double-click the device>

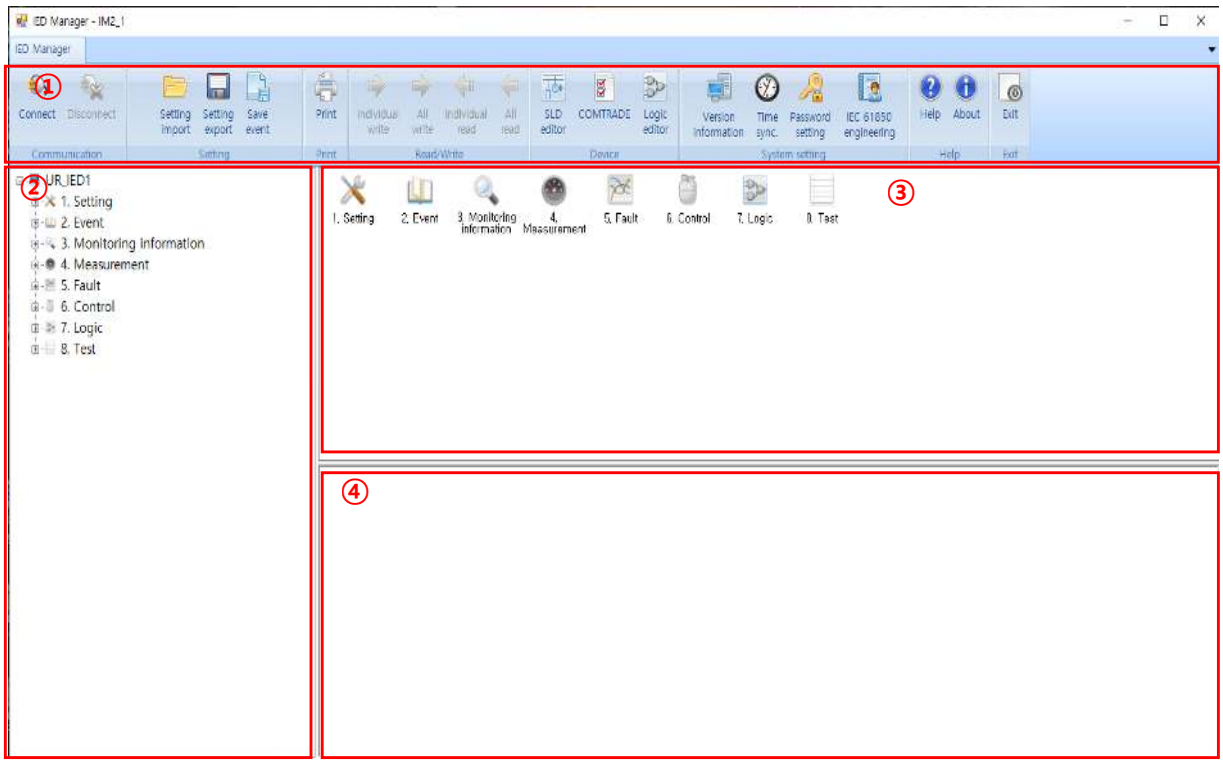
<2nd step of device connection – TCP selected>



<2nd step of device connection – off-line selected>

The connection type can be reselected in the above window. For the connection type designated in the left side of the above window, the detailed information for the type should be set in the right side of the window.

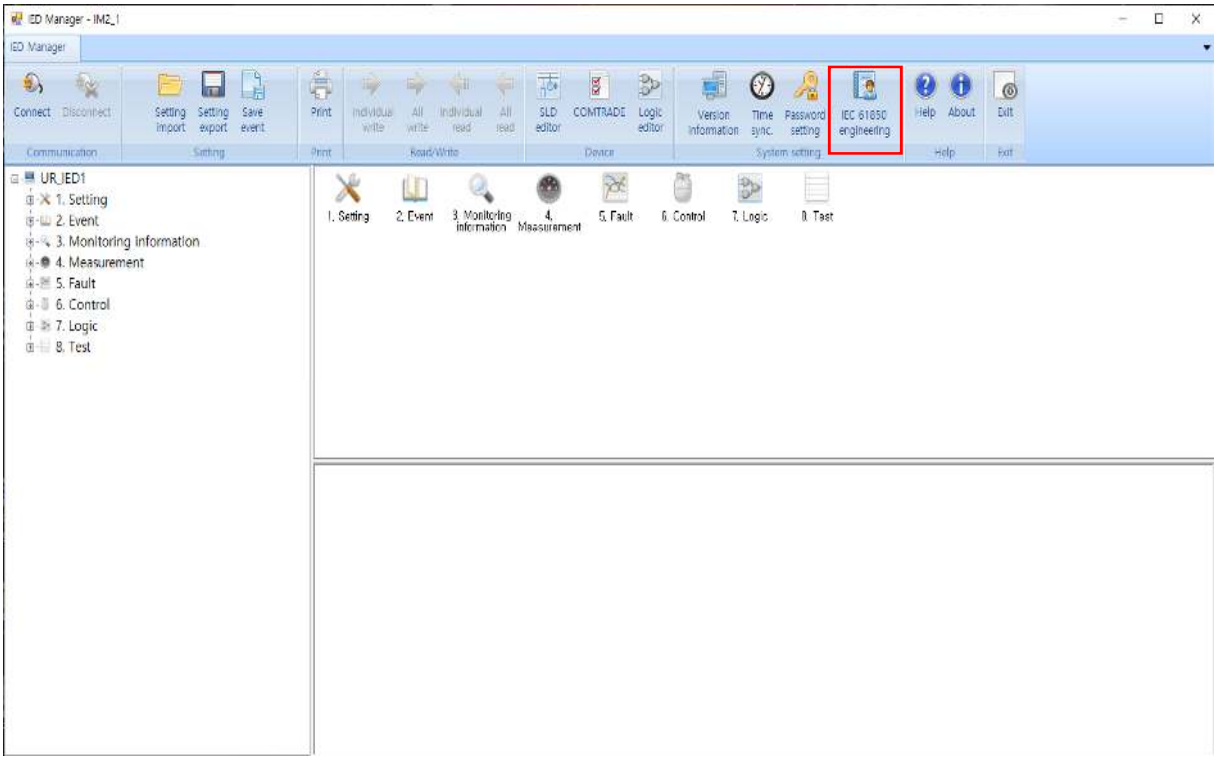
If "OFF-LINE" mode is selected, the Wired-X operates, without connecting to the device, with the information which is pre-set in the software. The values can be modified and saved also in the "OFF-LINE" mode, and it is possible to connect to the device again via TCP and read/write the values from/to the device.



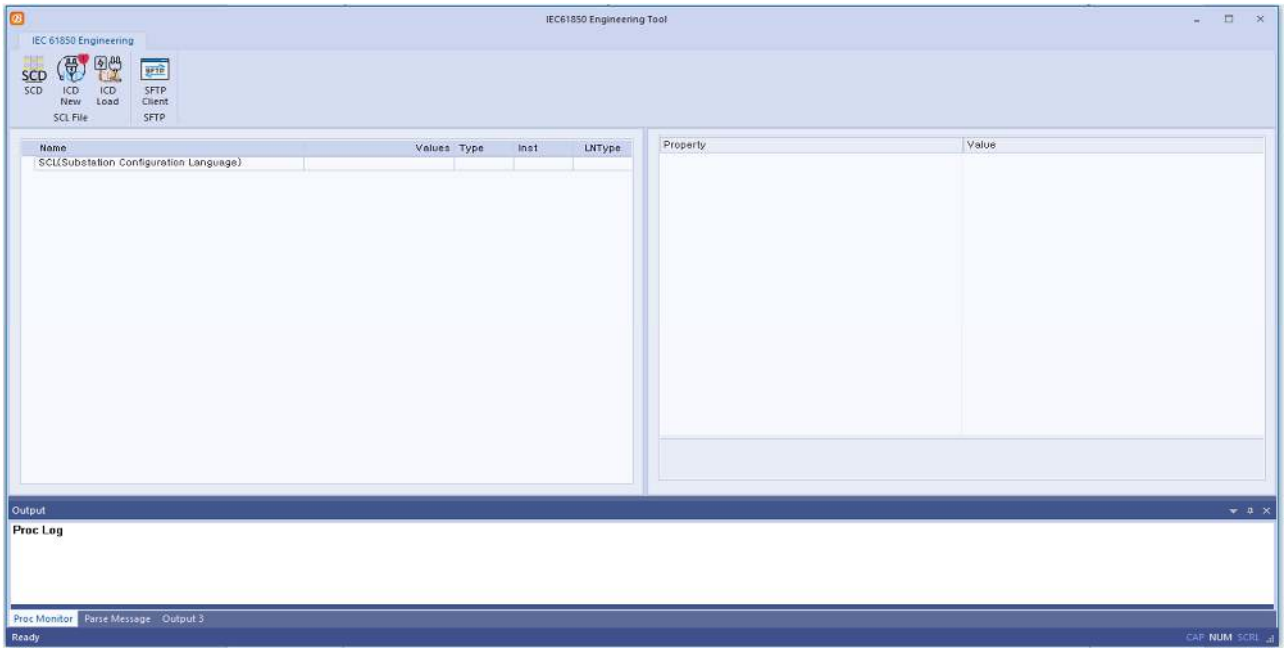
Check "Connection type", and "Connection settings", and then click "OK" button to display the confirmation window, and then click "Yes" button to connect to the device.

<3rd step of device connection – confirmation window>

When connected to the device, the software automatically reads data from the device. If the



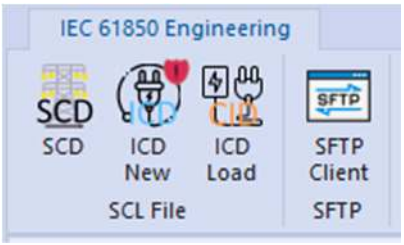
software failed to connect with the device due to some reason, a communication error message is displayed and the connection trial is terminated. If a communication error message is displayed, check the device settings again and proceed to try connection. When the connection and data synchronization with the device are completed successfully, the initial screen of the Device Manager is displayed. Device Manager view is consist of 4 area (①Main Tool Bar, ②Tree View, Detail Information View, ④Log view)



<Screen layout of the Device Manager>

3.1.6. Running IEC 61850 Engineering Tool

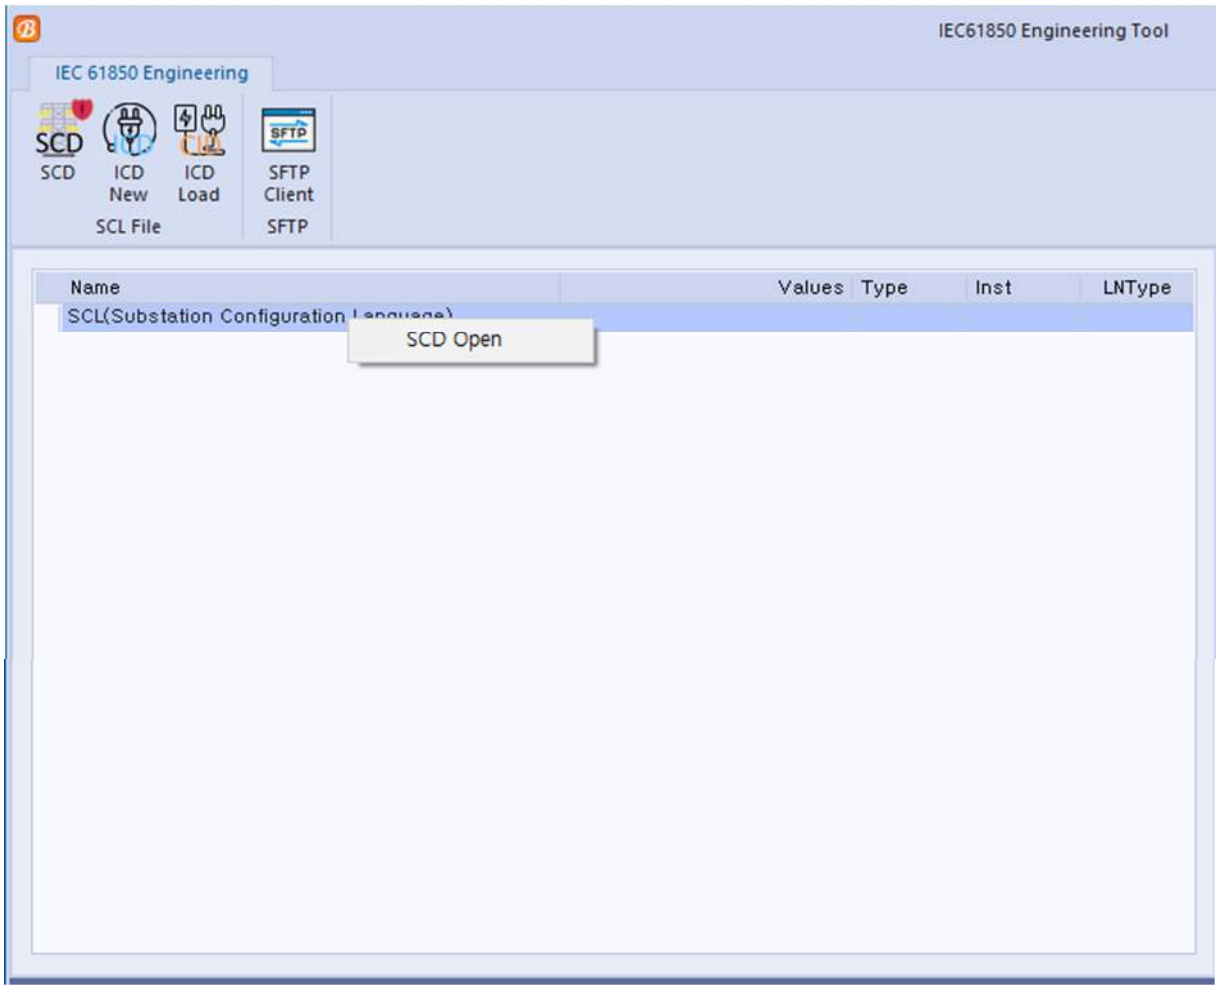
1) Running IEC61850 Engineering Tool on Wired-X



<IEC 61850 Engineering Tool Run Button>

<IEC61850 Engineering Tool>

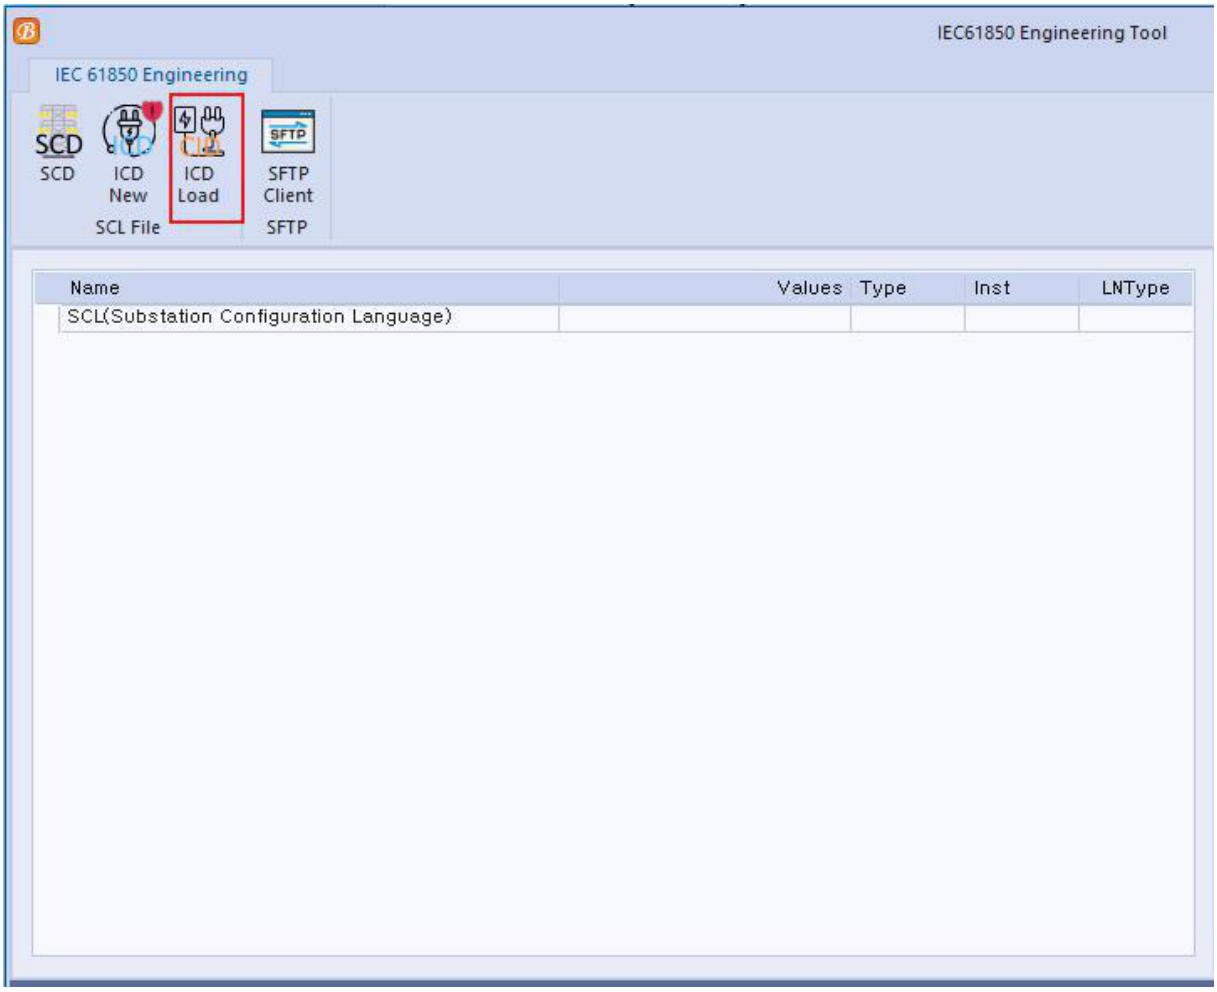
2) Basic Menu and Tools for IEC61850 Engineering Tool



Reading SCL and Connecting to SFTP can be found under the SCL File Menu.

<SCL File Menu>

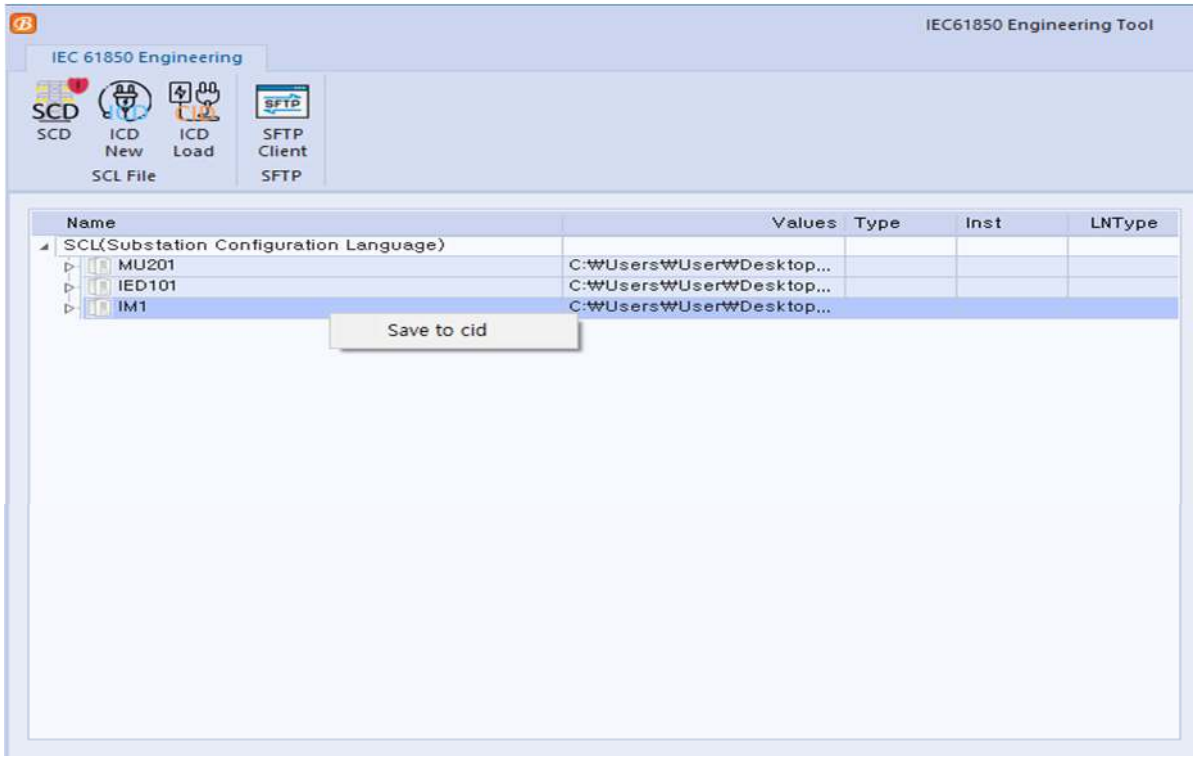
3) Opening SCD File



Click SCD under SCL File Menu, and right click on SCL to open.

<SCD File Open>

4) Loading ICD File

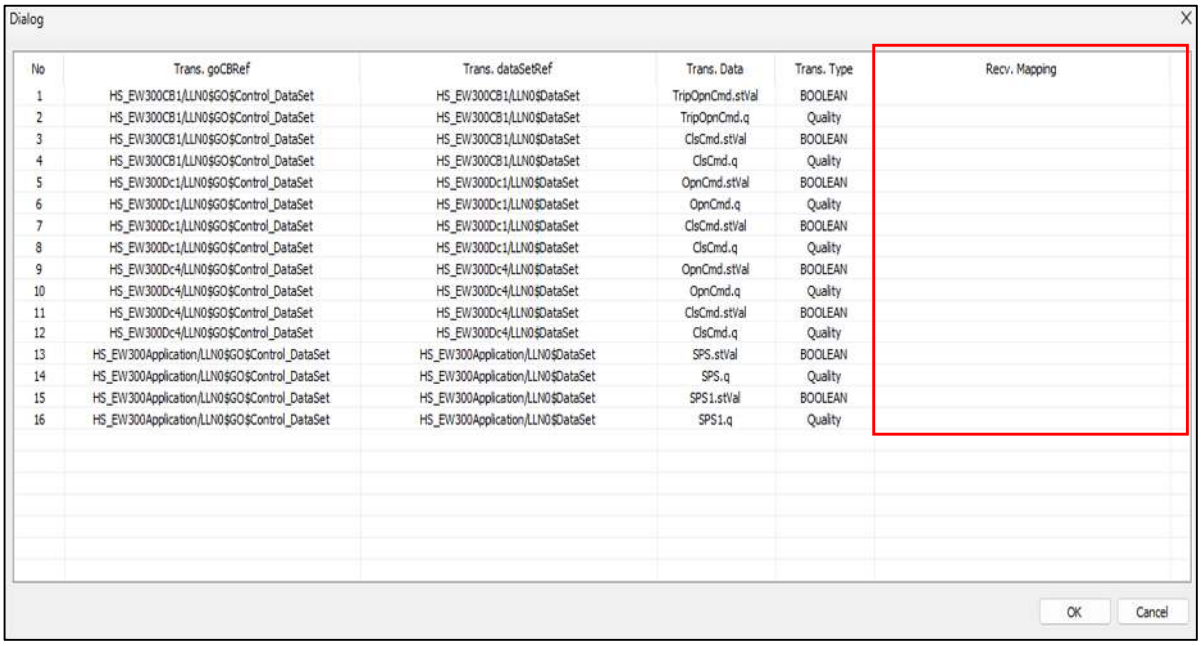


Click ICD Load under SCL File menu to load ICD File.

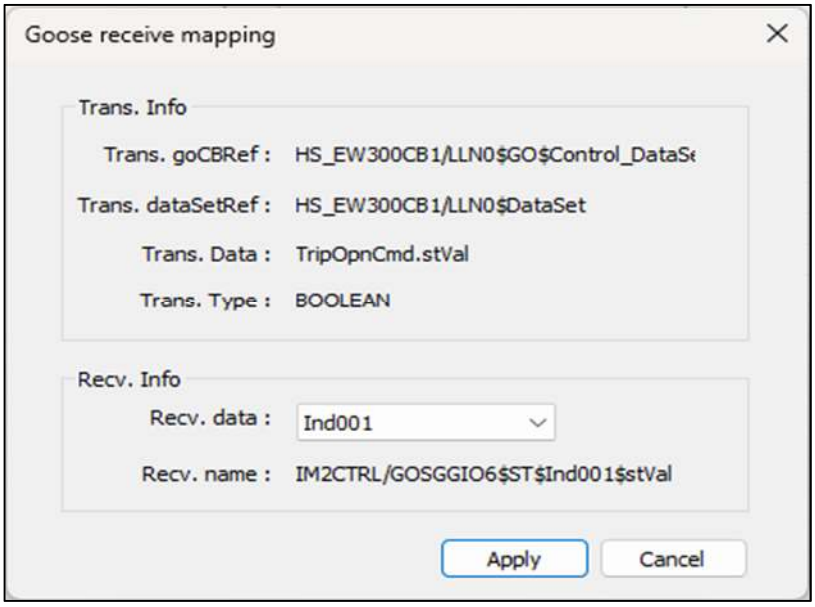
<Loading ICD File>

5) Exporting CID File

To export CID file, opening the SCD file and click on "Save to cid".

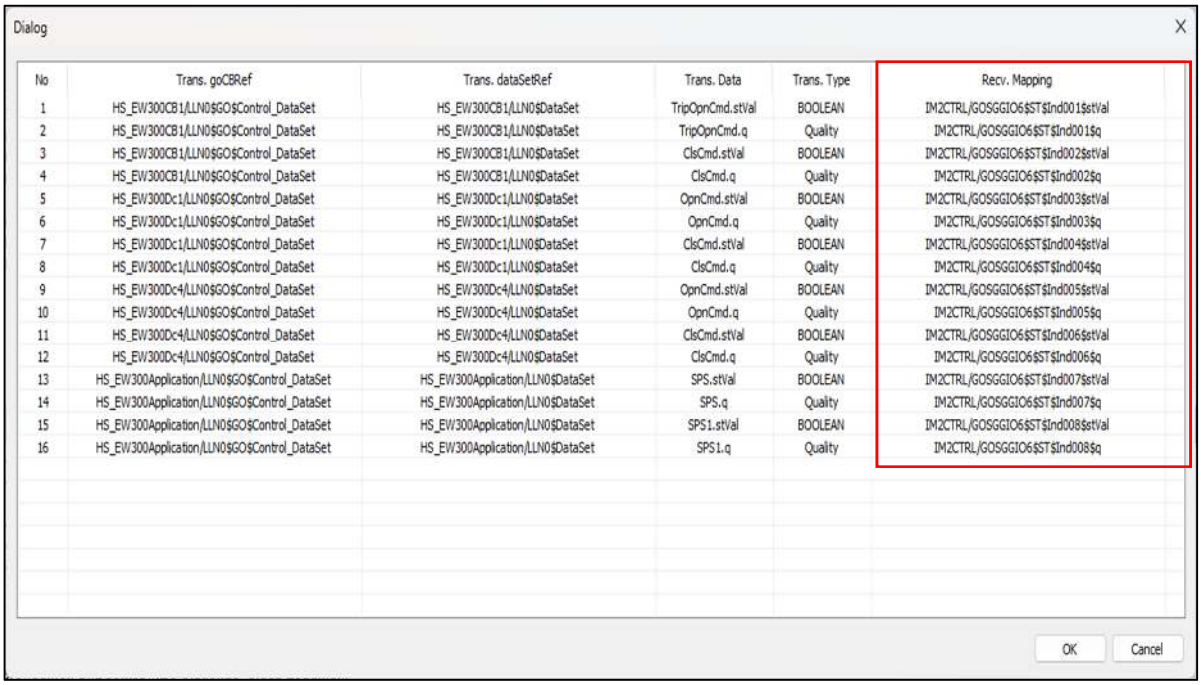


<Exporting CID File>

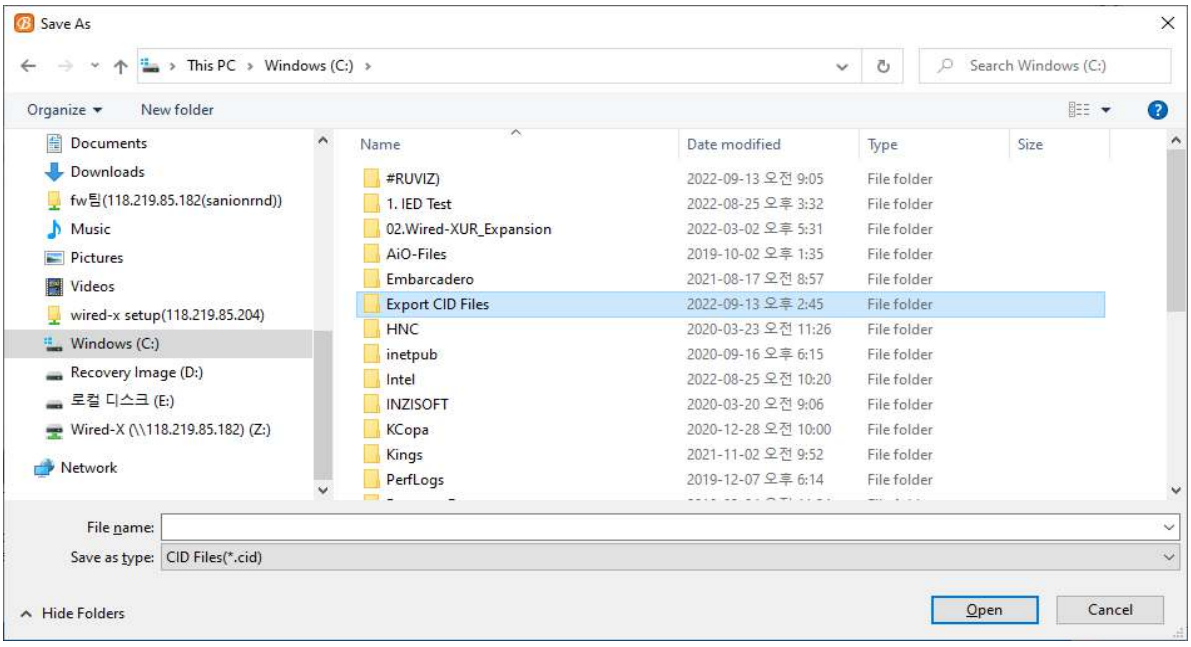


If GOOSE receive has not been mapped to IM2 in the SCD file, a window will appear, prompting you to specify the location for saving the CID file.

If you have configured the IM2 to receive GOOSE in the SCD, the GOOSE detailed mapping window will appear automatically. This is because the SCT usually only progresses the mapping to the LN level. To map to the DA level for the IM2 to receive GOOSE, follow this process.



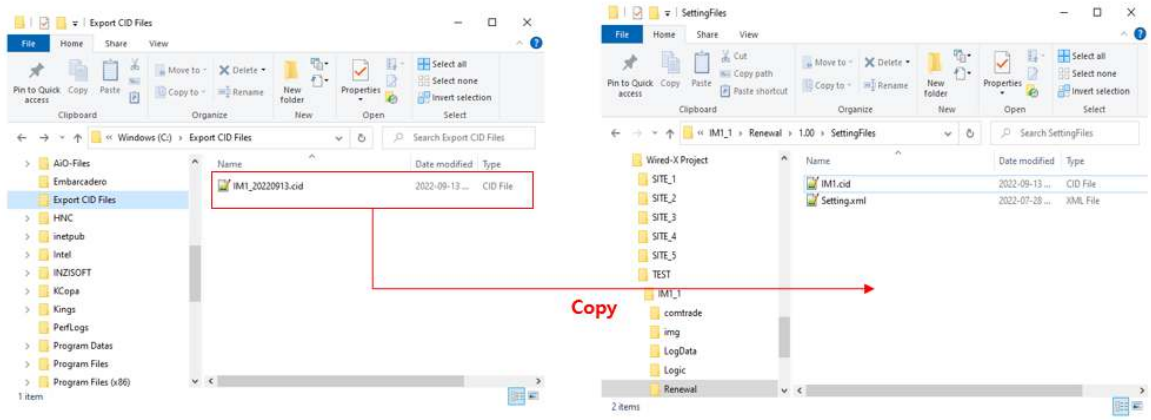
A window like the one below will pop up, and you can see that the "Recv. Mapping" column on the left is empty.



Referring to the GOOSE transmit value on the right, select and assign the value to the desired DA on IM2's GGIO6. In general, it is important to note whether it is a single point or double point.

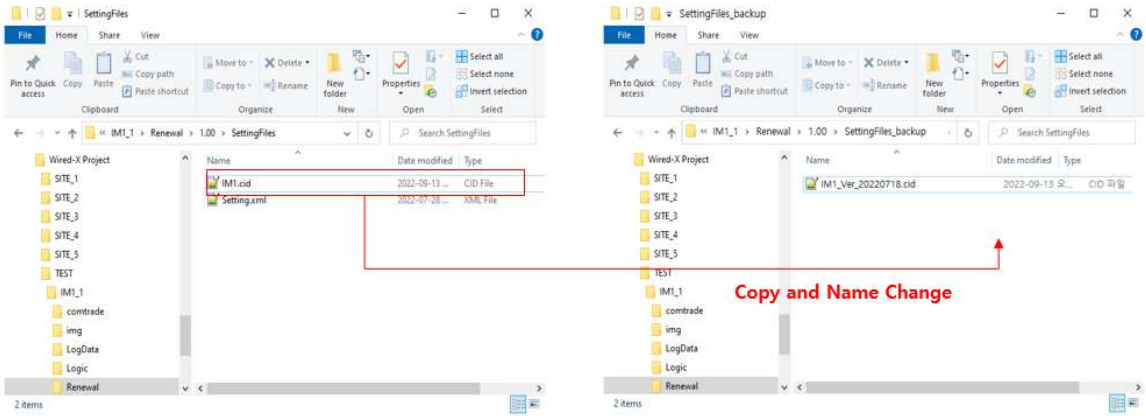
After completing all the GOOSE incoming mappings, the status displayed below should indicate completion.

Clicking the "ok" button will prompt a window to appear, asking where to save the CID file.



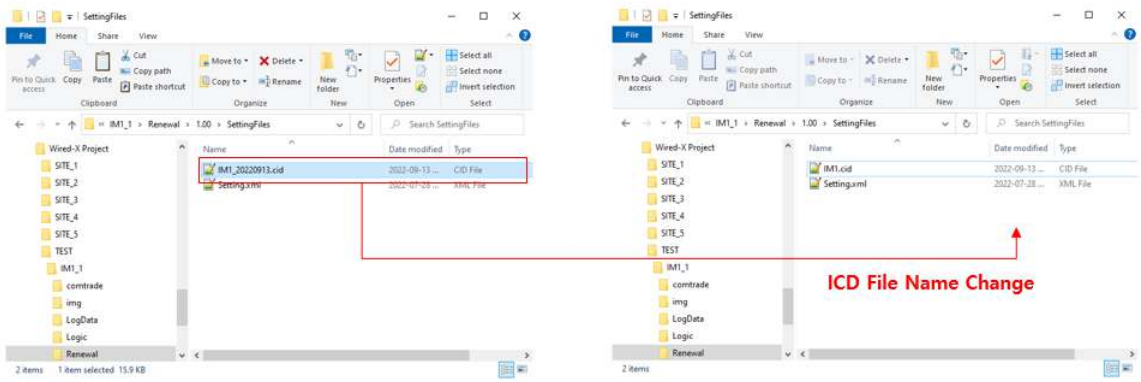
Finally, update the extracted CID file in the IM2 CID file management folder.

CID file management folder is as follows.



: Project create folder\Device name\Renewal\version\SettingFiles

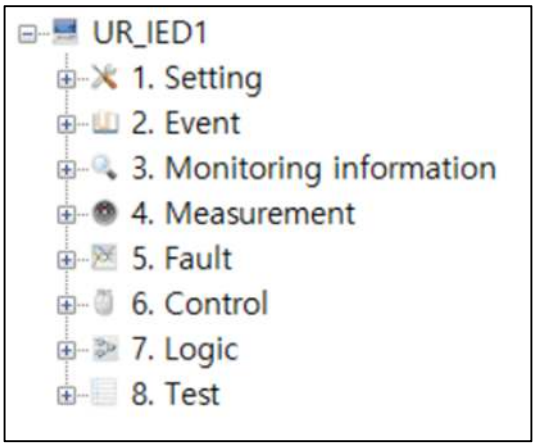
Ex. C:\Wired-X Project\IM2 Test Project\IM2_1\Renewal\1.00\SettingFiles



Step1. Copy the extracted CID file to the IM2 CID file management folder.

Step2. Copy the old CID file to the IM2 CID file backup folder and change the CID file name according to your history management rules.

Step3. Delete the old CID file and rename the CID file to be updated to “IM2.cid”. The deleted CID file cannot be recovered. Please must be back up your old CID file before proceeding.

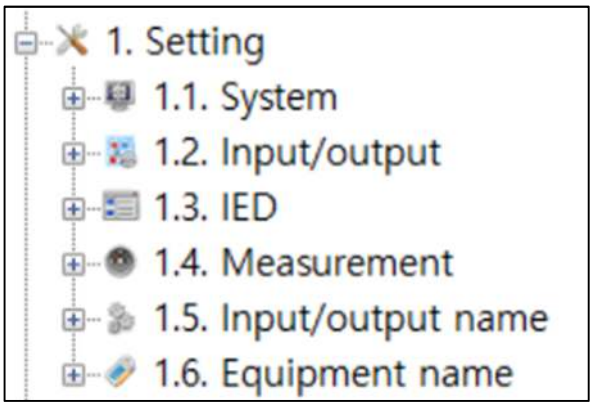


IM1_20220913.cid
Setting.xml
IM1.cid
Setting.xml
ICD File Name Change

3.2. Wired-X Menus and Settings

A description of Wired-X's menu organization and the settings available through Wired-X.

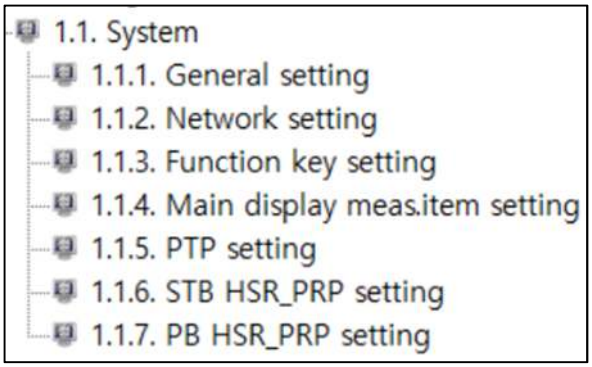
3.2.1. Menus on Wired-X



The menu organization and brief description of Wired-X is shown below.

Item	Description
1. Setting	Provide settings for IM2
2. Event	Viewing events recorded in IM2
3. Monitoring information	Check IM2's various monitoring information
4. Measurement	View the IM2's measurement information
5. Fault	Check the COMTRADE recorded in IM2
6. Control	Provide device control over Wired-X
7. Logic	Downloading and uploading user logic
8. Test	Provide simulated tests

3.2.2. Wired-X : Setting



The settings menu is divided into six sections, each of which is briefly described below.

Item	Description
1. System	General system settings for IM2
2. Input/output	Provides a mapping of physical and logical elements
3. IED	Operation related settings for IM2
4. Measurement	Select measurement sets that are displayed on the main display and "4.Measurement" on Wired-X
5. Input/output name	Modify Input/output point name
6. Equipment name	Modify the name displayed on the main display

3.2.2.1. Wired-X : Setting – System

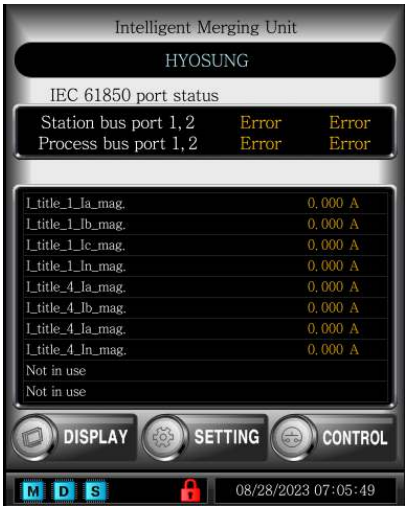
The system menu is divided into seven sections, each of which is described below.

"General setting" allows you to set general settings for IM2. The items and their values are described below.

Item	Value
Station bus time sync	PB Sync : synchronized time to PB bus time SNTP : synchronized time to SNTP server
Process bus time sync	PTP : synchronized time to PTP server PPS : synchronized internal PPS to external PPS input
Local time offset hour	-24 ~ 24 : UTC time
Local time offset minute	0 ~ 59 : UTC time
Language	English / Korean
LCD backlight time	1 ~ 180 minute
Measurement angle display	Negative / Positive
Wired-X connection port	Front port / Back port
SLD display	IEC symbol / LED symbol
SLD open LED location	Left / Right

※ SNTP and PTP cannot be used at the same time.

Network setting allows IM2 to set the IP, subnet, and gateway address of the network port, and the items are as follows.



Item		Current value	New value
Service port	IP address	10,10,10,12	
	Subnet mask	255,255,255,0	
	Default gateway	10,10,10,1	
SNTP server	IP address	203,248,240,140	
	Subnet mask	255,255,255,0	
	Default gateway	203,248,240,1	
Station bus port	IP address	10,10,10,51	
	Subnet mask	255,255,255,0	
	Default gateway	0,0,0,0	
Process bus port	IP address	192,168,37,242	
	Subnet mask	255,255,255,0	
	Default gateway	192,168,37,1	

Station & Process bus port are set by CID file.

"Function key setting" allows you to set shortcut keys from F1 to F4, and switches the screen directly to the set page.

Item	Current value	New value
F1	Control event	
F2	Counter status	
F3	Process bus GOOSE publisher	
F4	PTP information	

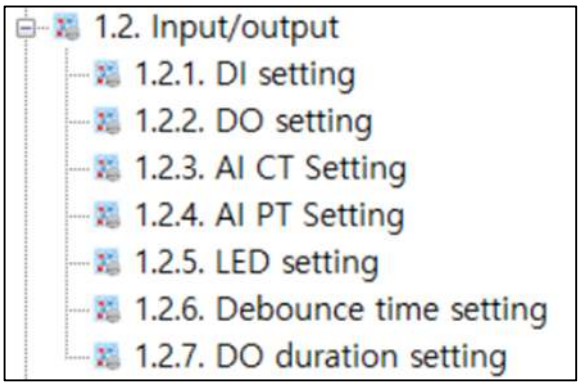
"Main display meas. Item setting" is a menu to set the measurement items to be displayed on the main LCD display shown below. Up to 10 items can be set in total.

Item	Current value	New value
Measurement item 1	I_title_1/Ia_mag	
Measurement item 2	I_title_1/Ib_mag	
Measurement item 3	I_title_1/Ic_mag	
Measurement item 4	I_title_1/In_mag	
Measurement item 5	I_title_4/Ia_mag	
Measurement item 6	I_title_4/Ib_mag	
Measurement item 7	I_title_4/Ia_mag	
Measurement item 8	I_title_4/In_mag	
Measurement item 9	Not in use	
Measurement item 10	Not in use	

"PTP settings" allows you to modify settings related to PTP and includes the following items.

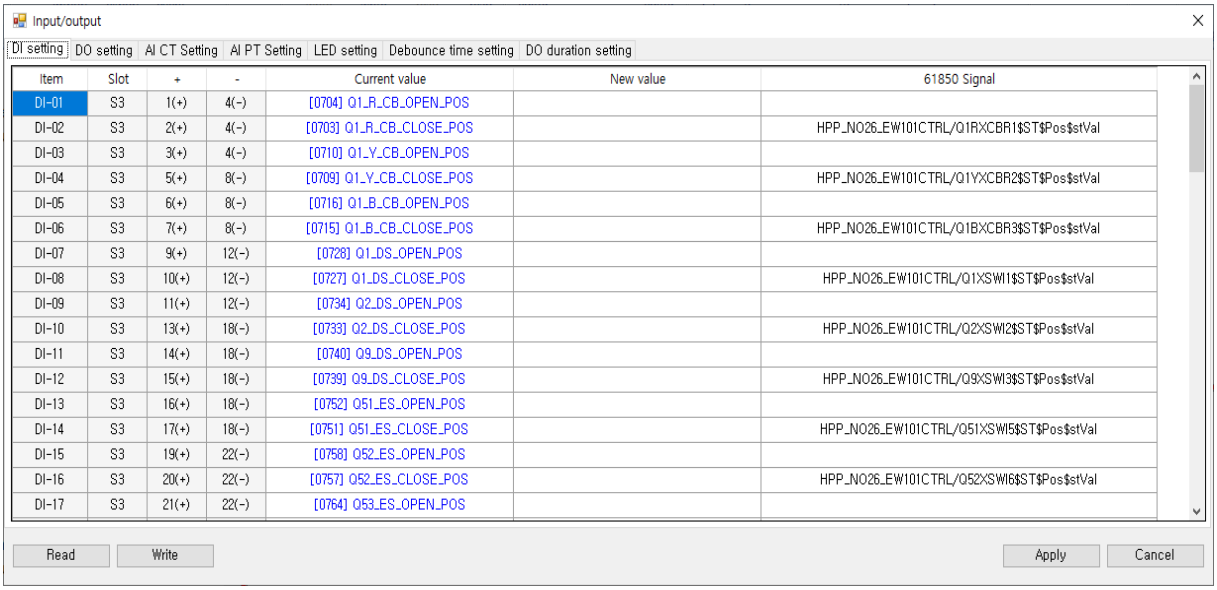
Item	Current value	New value
Delay mechanisim	P2P	
Transper mode	L2	
Slave only in use	In use	
Priority 1	128	
Priority 2	128	
Domain number	0	
Clock class	255	
Clock accuracy	25ns under	
Anounce message period	2 Sec	
Sync message period	1 MSG every sec	
Delay request period	1 MSG every sec	
PDelay request period	1 MSG every sec	
Announce timeout	3 sec	
Sync timeout	2 sec	
Transper-Receive time diff.	0 ns	
Egress latency	0 ns	
Ingress latency	0 ns	

It is recommended to use the default values. If needed, PTP specialist may change the settings as the network requirement.



"STB HSR_PRP setting" and “PB HSR_PRP setting” allow you to modify settings related to HSR/PRP and includes the following items.

Item	Current value	New value
PRP in use	In use	
PRP mode	Duplicate discard	
HSR in use	Not in use	
HSR mode	Mode H	
HSR interface	HSR-SAN	
Rsdbox LAN ID	A	
Own net ID	0	
Port A speed	1000 Mbps	
Port B speed	1000 Mbps	

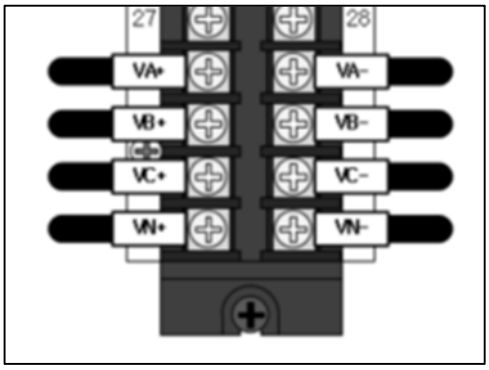


It is recommended to use the default values. If needed, HSR/PRP specialist may change the settings as the network requirement.

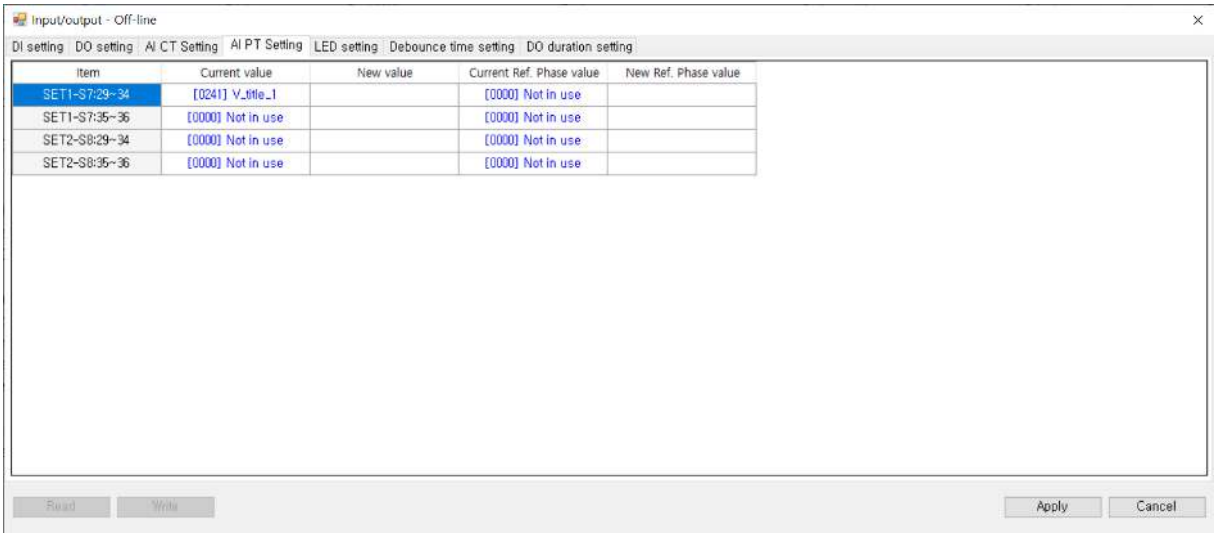
3.2.2.2. Wired-X : Setting – Input/output

The Input/out menu is divided into seven sections, each of which is described below.

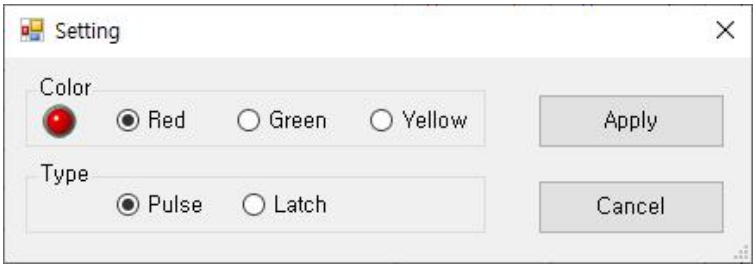
The "DI setting" allows you to map the inputs of the DI module to internal points. If the internal points related to IEC 61850 signal, it shows on the column



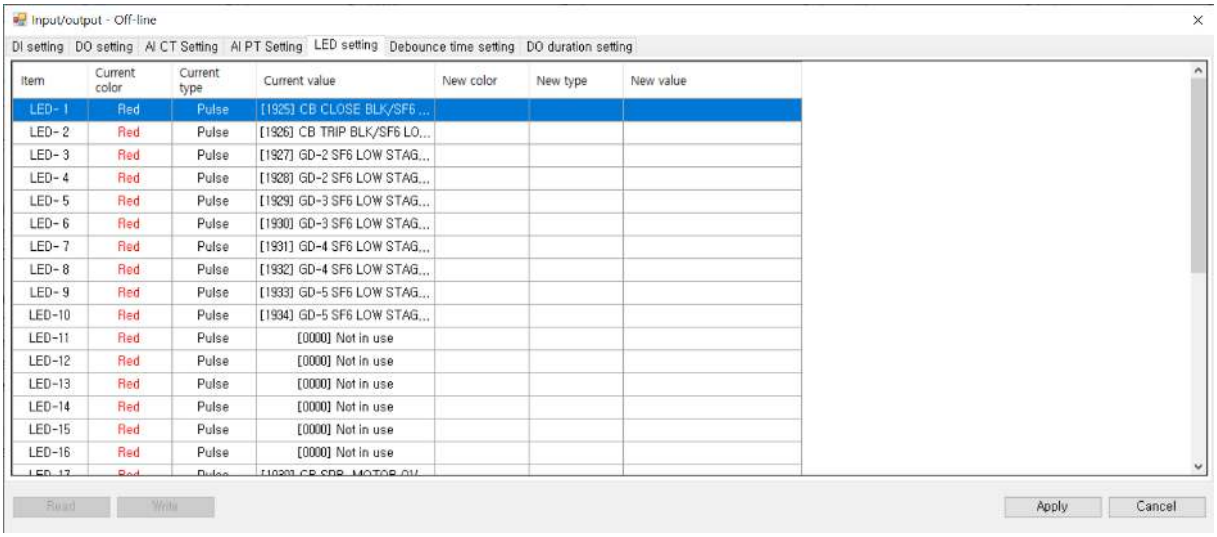
"DO setting" allows you to map the internal points to outputs of the DO module.



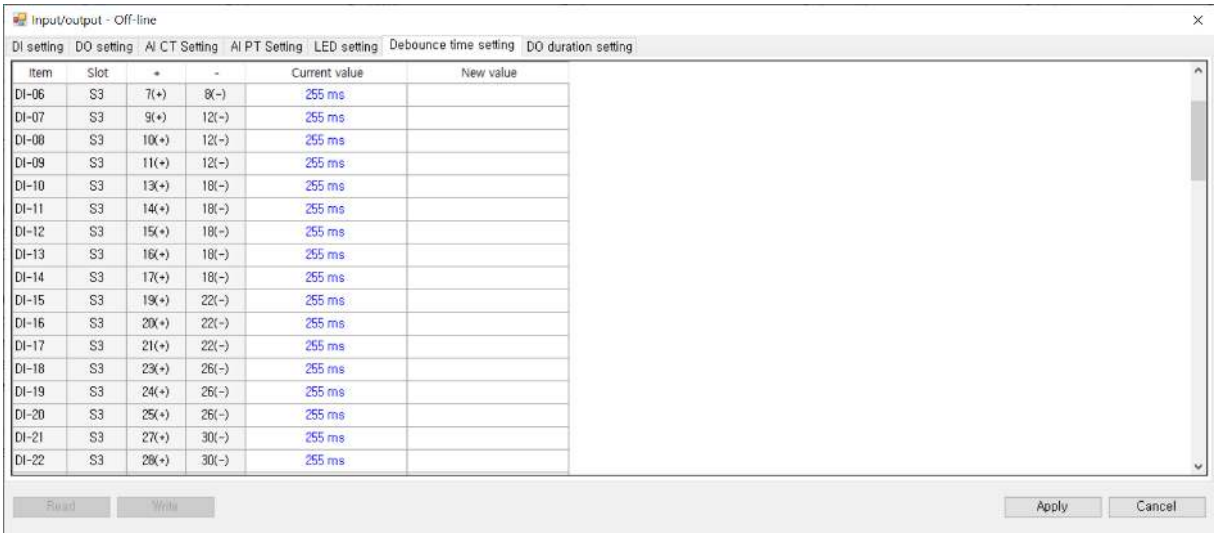
"AI CT setting" allows you to assign current inputs of CPT module to internal current set. Also, a user can set N phase as calculated (3I0) or measured (Y-Connection). The user may select reference angle of phase for display, otherwise the angle of A phase in internal voltage set #1 is the default angle.



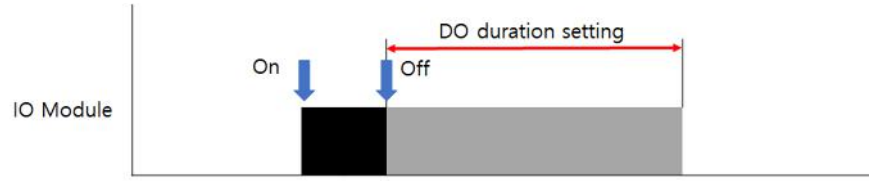
"AI PT setting" allows you to assign voltage inputs of CPT module to internal voltage set. N phase is calculated, therefore VN terminal can be assigned independently from VA,VB,VC.

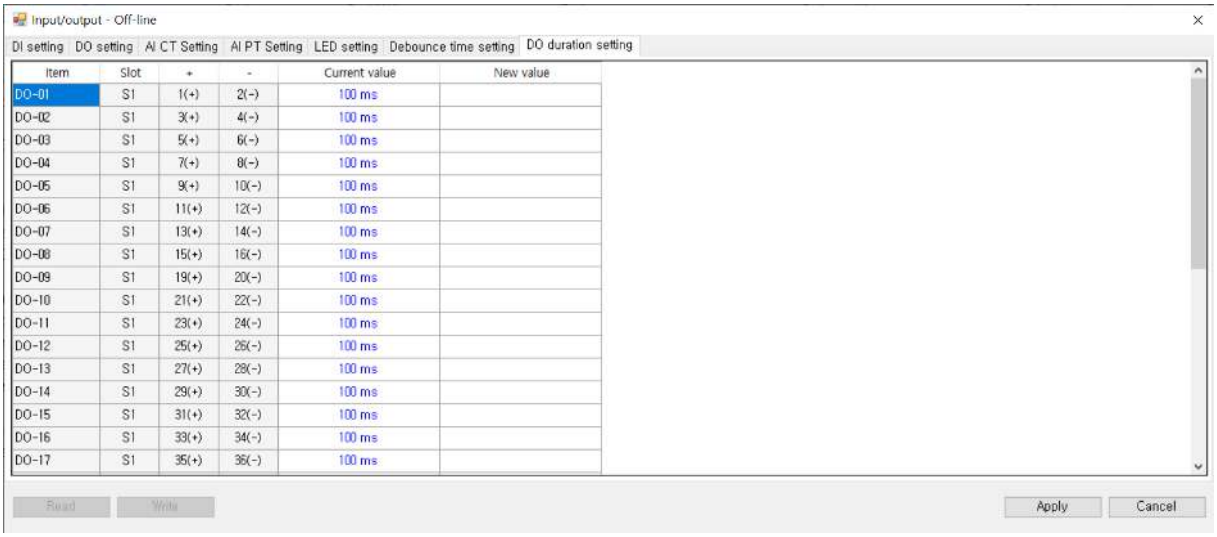


The user may select reference angle of phase for display, otherwise the angle of A phase in internal voltage set #1 is the default angle.



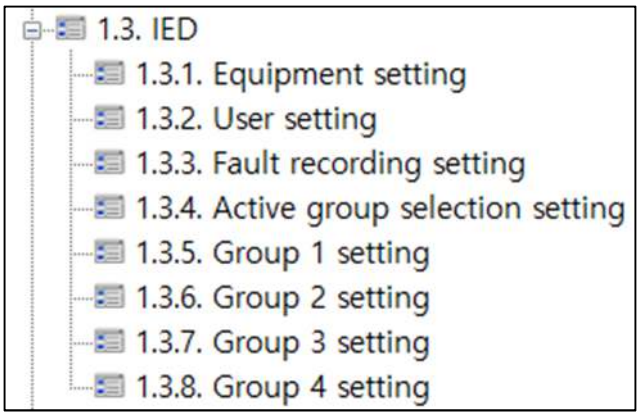
"LED setting" allows you to assign internal points to 32 LEDs. Red, green and yellow colors are provided. Pulse and latch types are provided.



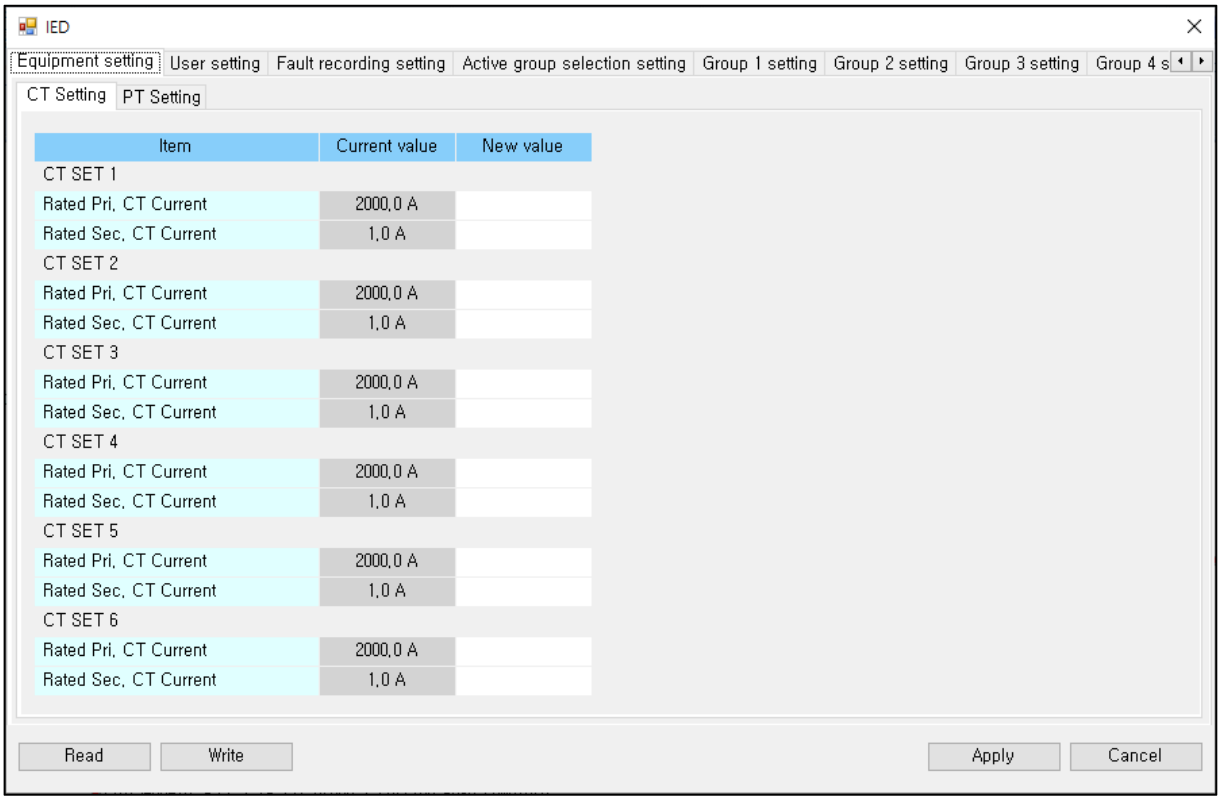


"Debounce setting" sets the debounce value to prevent mechanical chattering of the DI module inputs. Setting range is 1 ~ 255msec.

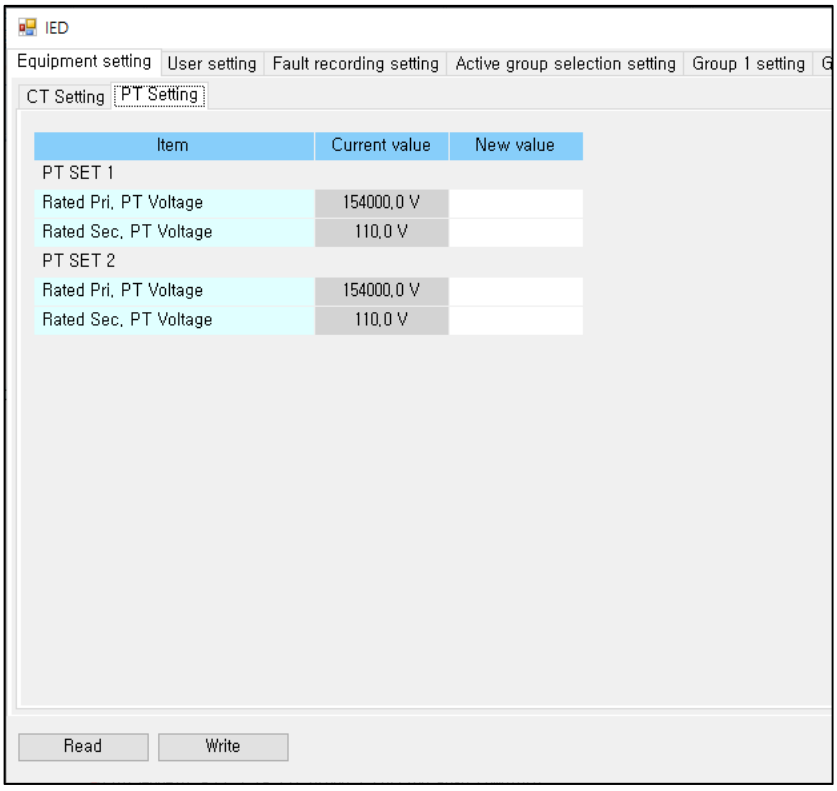
"DO duration setting" allows the output of the DO module to be maintained for a set amount of time after the internal point is turned off. Setting range is 1 ~ 10,000msec.



A pictorial representation of the description is shown below.



3.2.2.3. Wired-X : Setting – IED



The IED menu is divided into eight sections, each of which is described below.

User setting, Active group selection setting, Group 1~4 setting are emptied in factory settings. The above settings may be configured by the manufacturer to suit the site logic upon reasonable request of the site user.

"Equipment setting" sets CT/PT primary and secondary ratio that are used in the measurement display

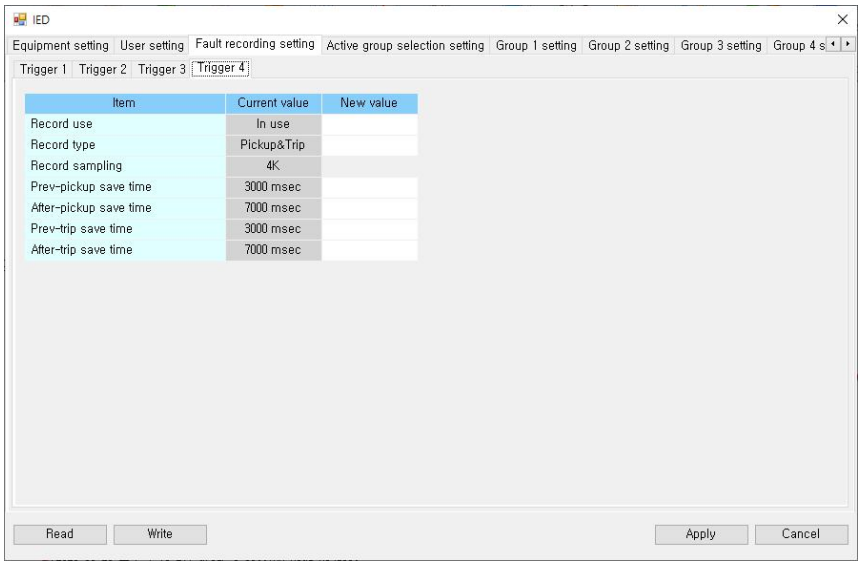
In "Fault recording setting", user can set whether to enable, how to record, and how long to record.

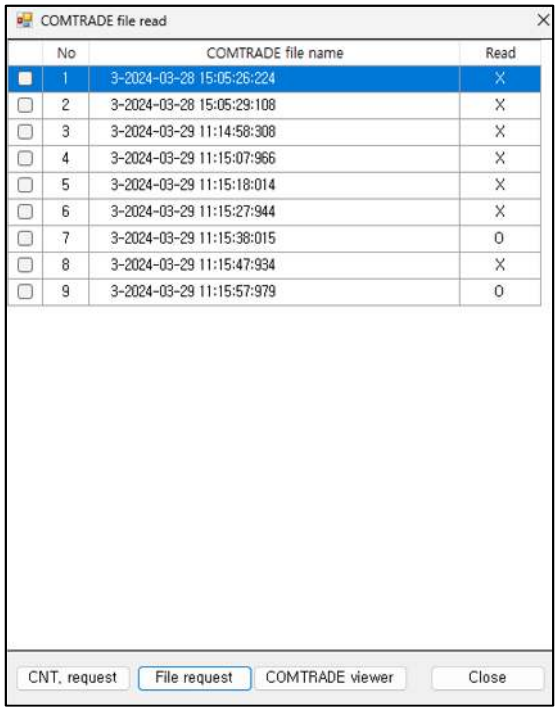
Item	Description
Record use	In use / Not in use
Record type	Internally, recording is triggered on the rising edge of the Trip and Pickup signals. Trip : Triggered only on rising edge of the trip signal. One COMTRADE file is generated. Pickup & Trip : Trip is same as the above. Pickup is only generated when the pickup signal has been maintained until "pickup after time". All conditions met two COMTRADE files are generated.
Record sampling	4.0K (50Hz) / 4.8K (60Hz). Not settable. Display only
Prev-pickup save time	Record time before the rising edge of pickup signal
After-pickup save time	Record time after the rising edge of pickup signal
Prev-trip save time	Record time before the rising edge of trip signal
Atfer-trip save time	Record time before the rising edge of trip signal

Maximum recording time is 10 seconds (10000 ms) fixed. IM2 can record 32 channels, CT & PT depending on the ordering code, and assigned DI, DO binary points from the Logic Editor. The maximum number of DAT files that can be stored is 64 fixed. If the saving DAT exceeds the maximum number, the oldest DAT files are deleted automatically.

Input Signal to triggering fault record

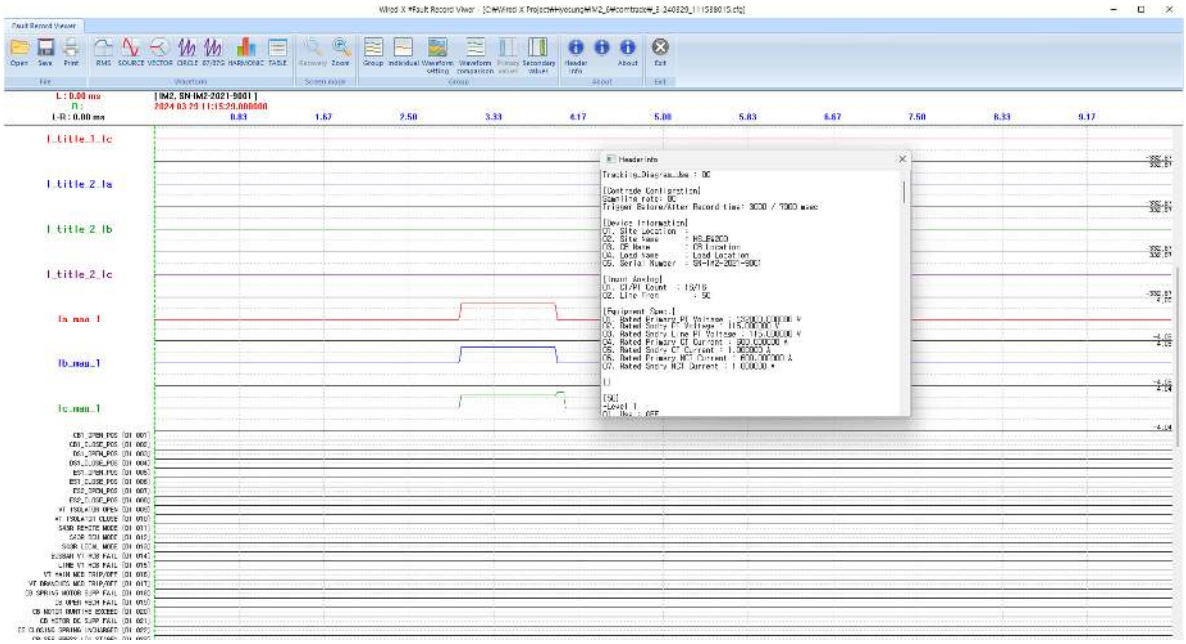


- Triggering points can be recorded by external signals. It can be set from “1.7.1. Fault recording details settings” as below. External signals can be the protection signals from other devices or the DI signals.



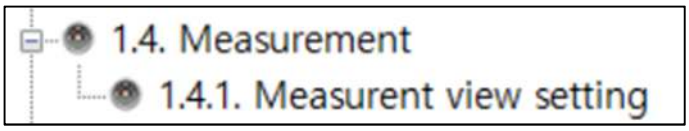
Output Signals from the fault record

- When the fault recording is done, the alarm will be shown at the front LCD as a popup screen.

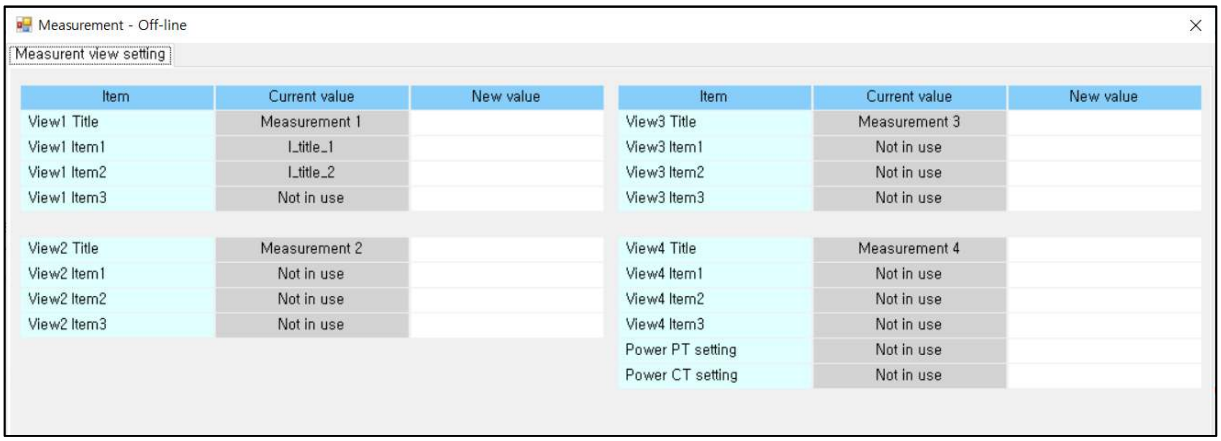


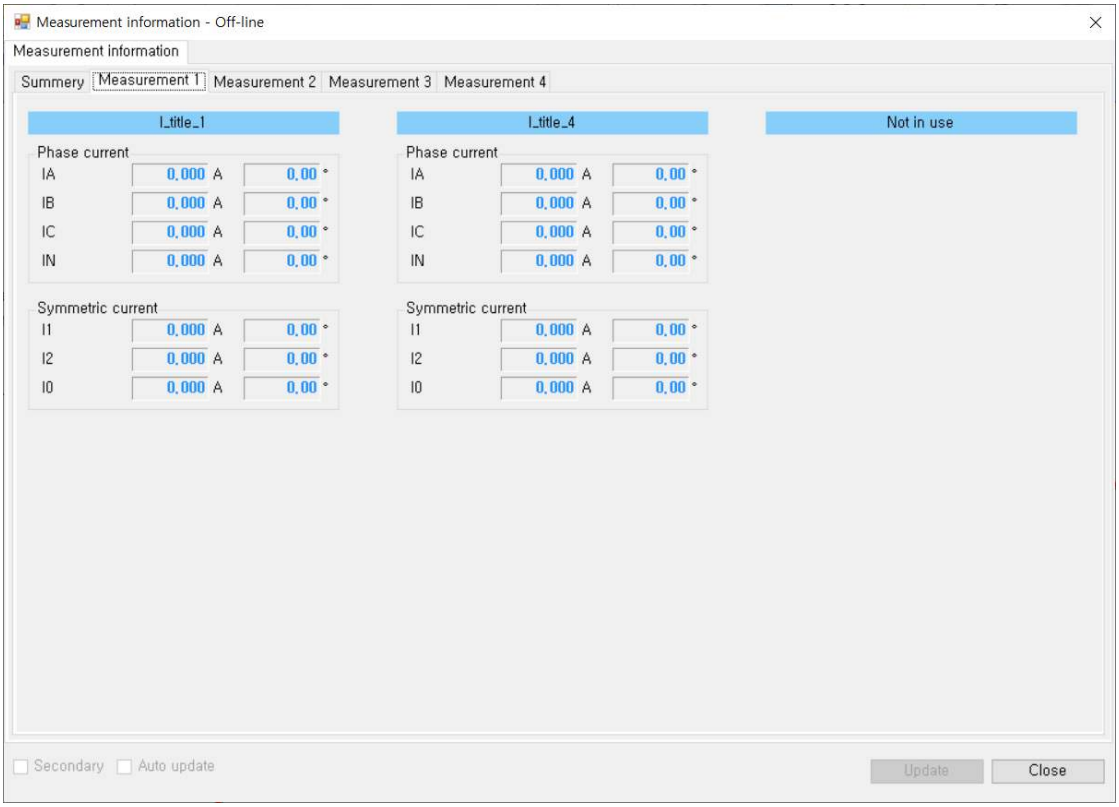
The triggering settings can be done in Wired-X as follows. It can be set in LCD also.

The details of the COMTRADE file can be analyzed in “COMTRADE” at the top of the menu. The list of COMTRADE files in the selected IM2 is shown as below.



Click on the COMTRADE viewer to see the result and analysis screen from Wired-X as below.

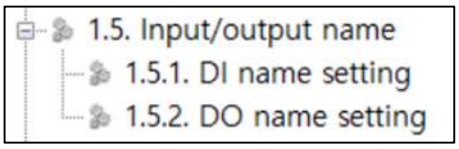


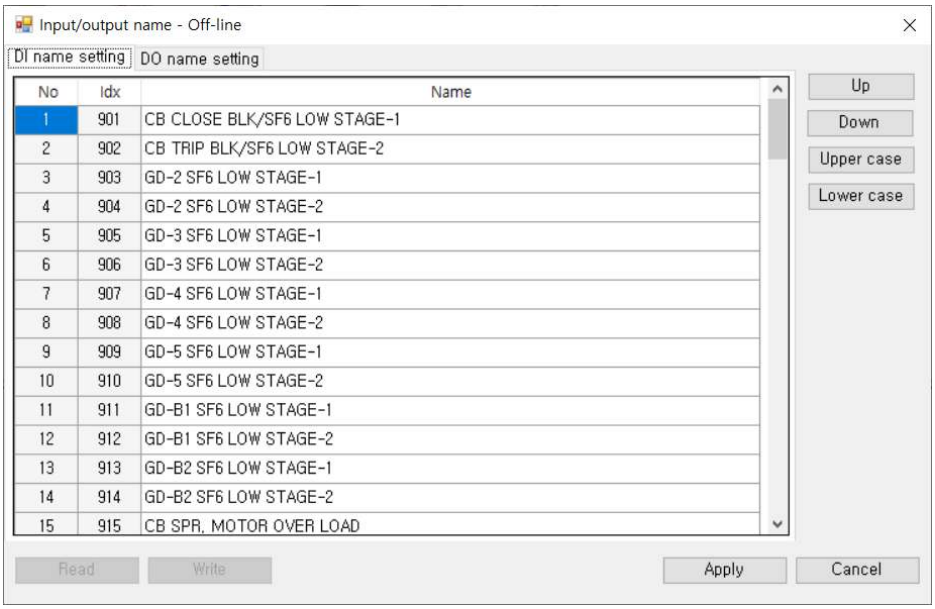


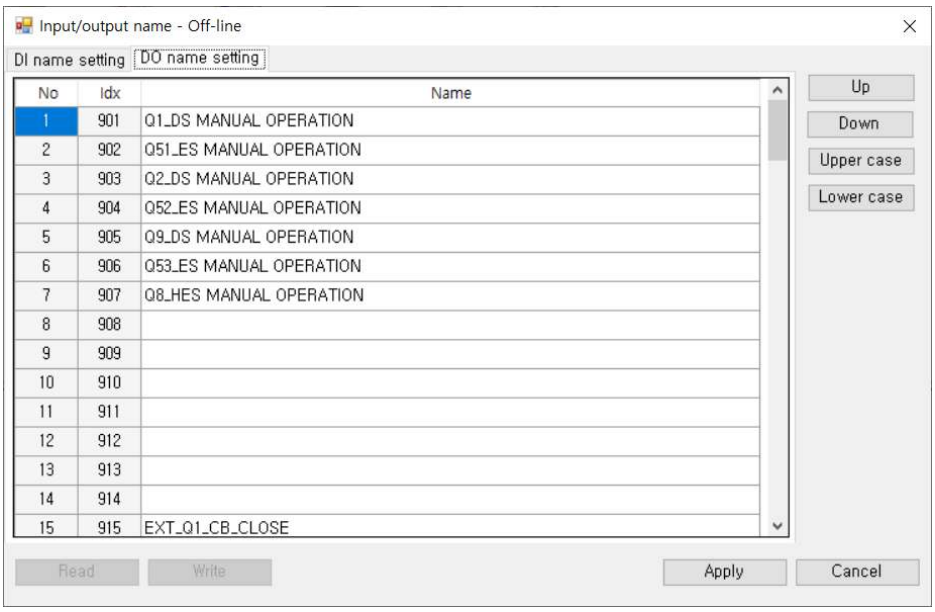
It includes analog data and DI/DO points.

3.2.2.4. Wired-X : Setting – Measurement

Select CT or PT set that will displayed on LCD & Wired-X measurement window or screen. A user may select maximum 3 sets in one window

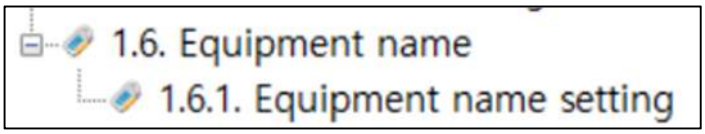


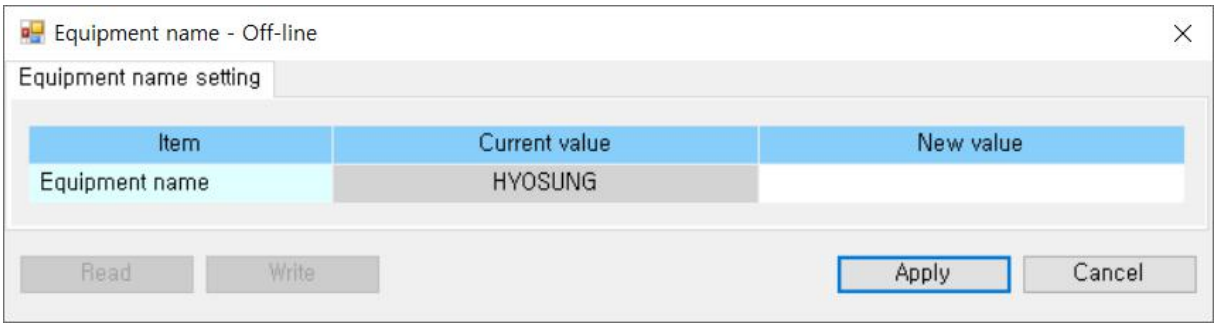




3.2.2.5. Wired-X : Setting – Input/output name

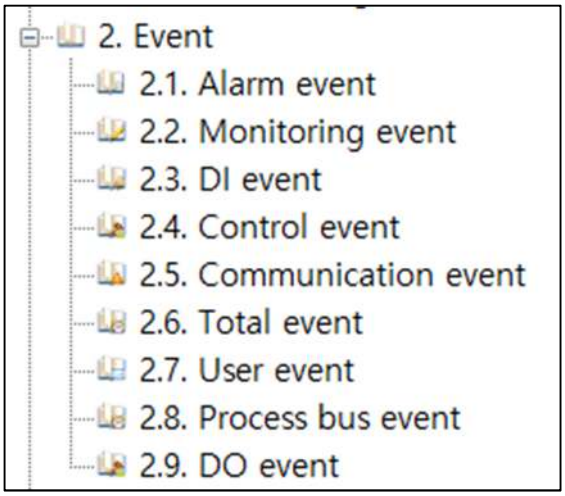
DI/DO name is set as shown in approved drawing by default. However, a user may change the name as below



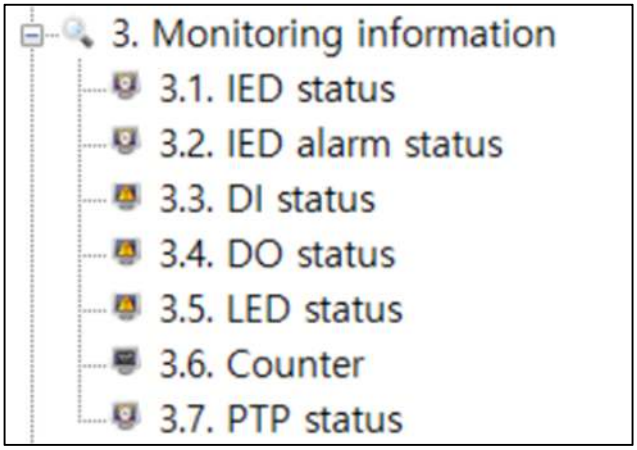


3.2.2.6. Wired-X : Setting – Equipment name

Use this setting to modify the IM2 name that will appear on the main home display.



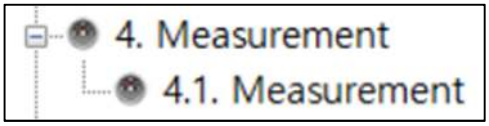
3.2.3. Wired-X : Event



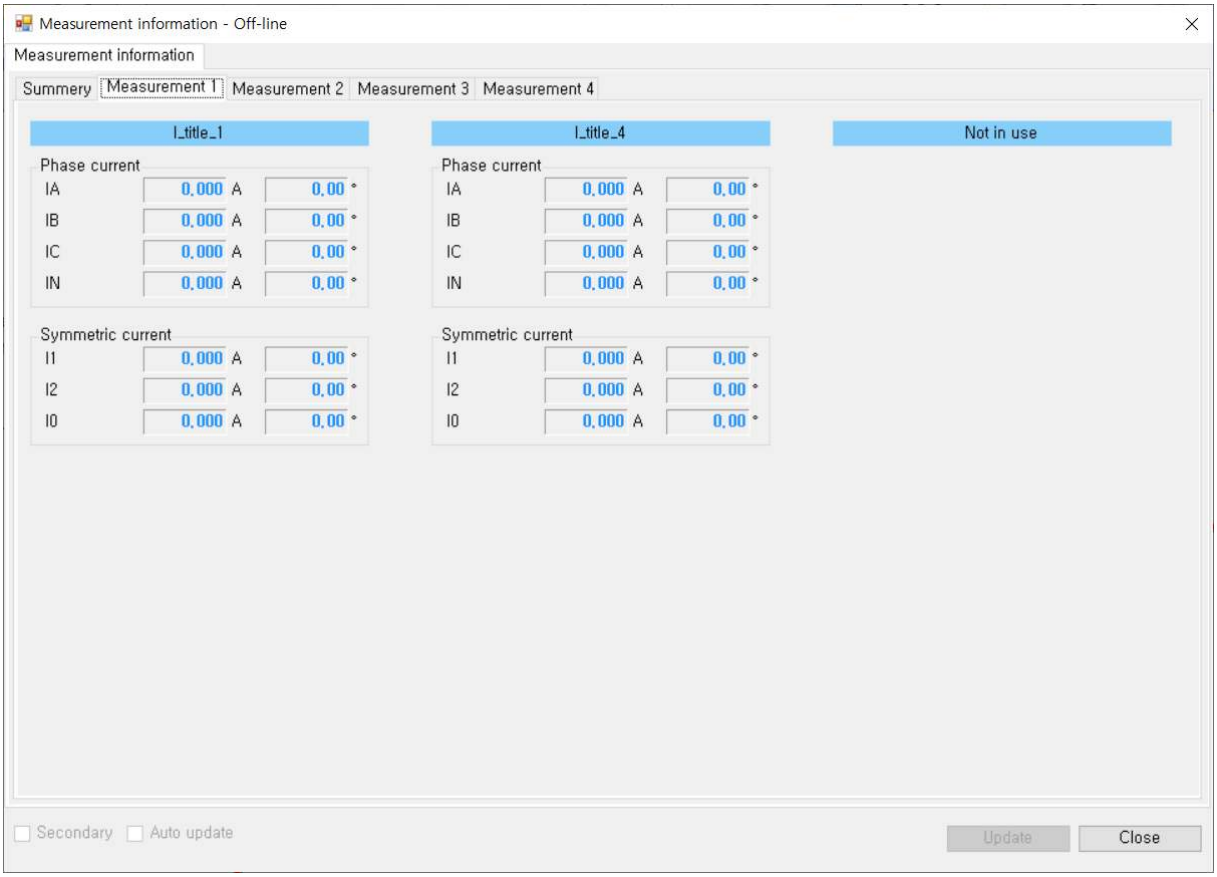
Before accessing the events recorded in IM2 using this menu, you must first read all events in IM2 through the "All read" button. There are a total of nine events, which are described below.

Event	Description
Alarm	Events logged when an alarm situation occurs in IM2
Monitoring	Events recorded by IM2's self-supervision
DI	Record event when DI status changed
Control	Record event when control happens
Communication	Internal/external communication event (Including 61850)
Total	Show all events in recorded order
User	User logic/setting related event
Process bus	Process bus related event
DO	Record event when DO status changed

3.2.4. Wired-X : Monitoring information



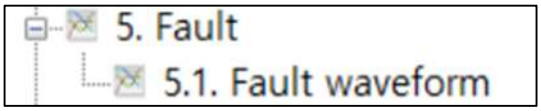
This menu enables you to monitor the up-to-date status of IM2 and the input/output status of DI/DO modules.



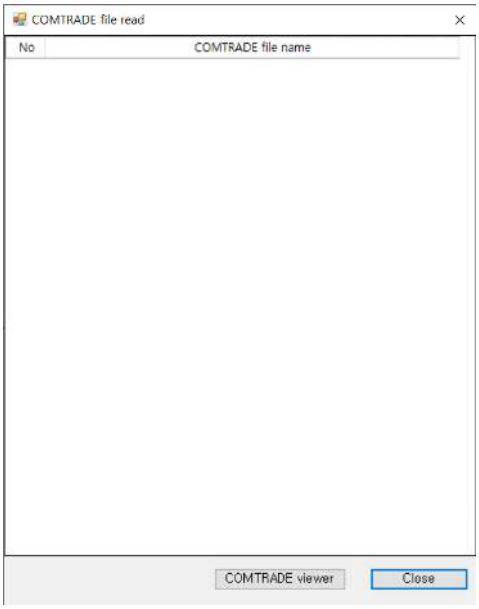
Item	Description
IED status	Shows the main status of IM2
IED alarm status	Shows the status related to the IM2 alarm (related to the Alarm LED).
DI status	Real-time input status of each terminal on the DI module
DO status	Real-time output status of each terminal on the DO module
LED status	Real-time status of each LED on the front panel
Counter	Show recorded counters of IED reset, LED reset, IED fault
PTP status	Shows real-time PTP-related status.

3.2.5. Wired-X : Measurement

The measurement sets that you configure in "view settings" will be visible on one tab. A maximum of three sets can be displayed on the tab.



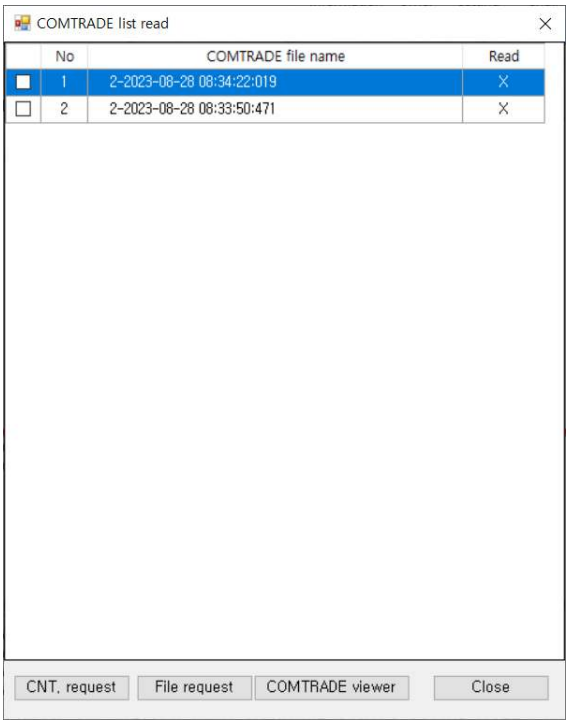
For a voltage set, the magnitude and phase of each phase, the magnitude and phase of the symmetry component, the magnitude and phase of the line to line voltage, and the frequency processed by phase A are displayed.

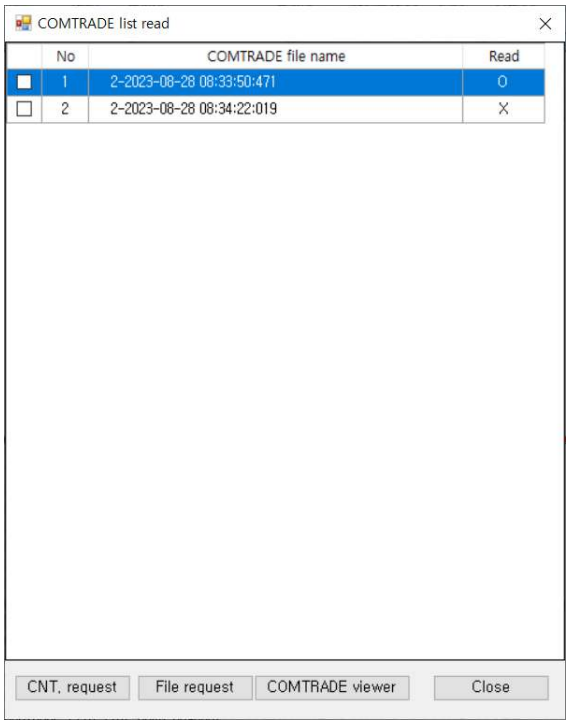


3.2.6. Wired-X : Fault

You can view the COMTRADE file stored in your PC folder via Wired-X.

Select the COMTRADE file you want to view and click the "COMTRADE viewer" button.

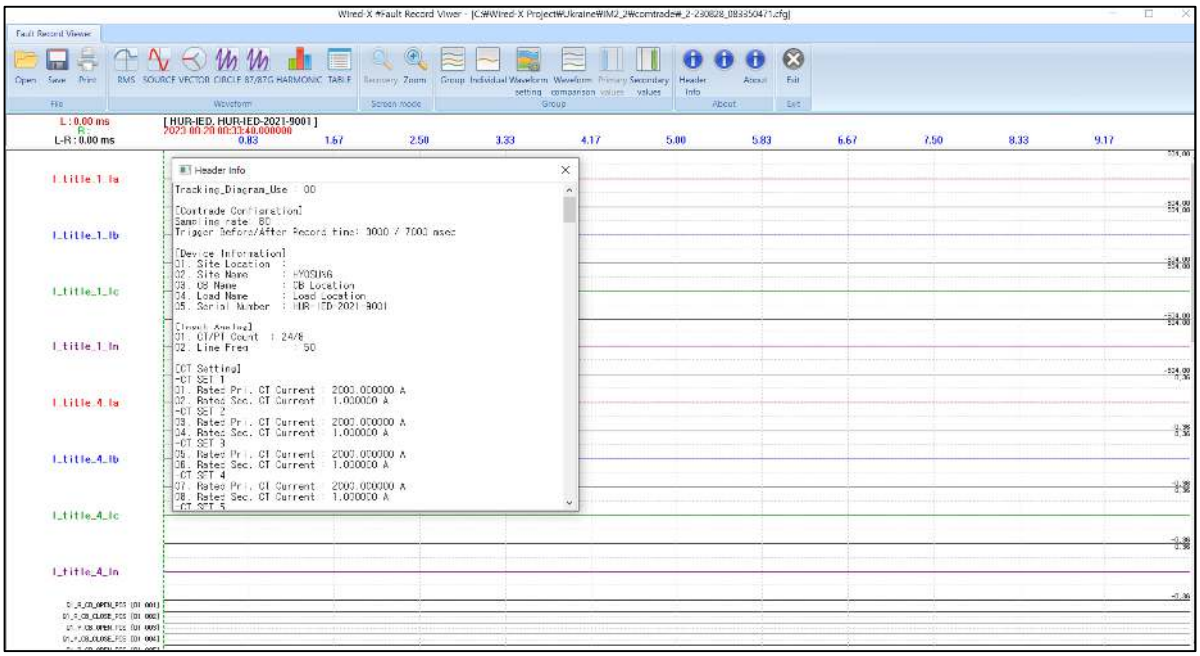




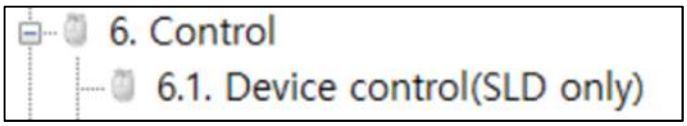
To import a COMTRADE file recorded in IM2, follow the procedure below. A user may access by clicking 

located at toolbar. Read file from COMTRADE by clicking "CNT.Request".

Click File request after selecting COMTRADE file to transfer IM2 → Wired-X

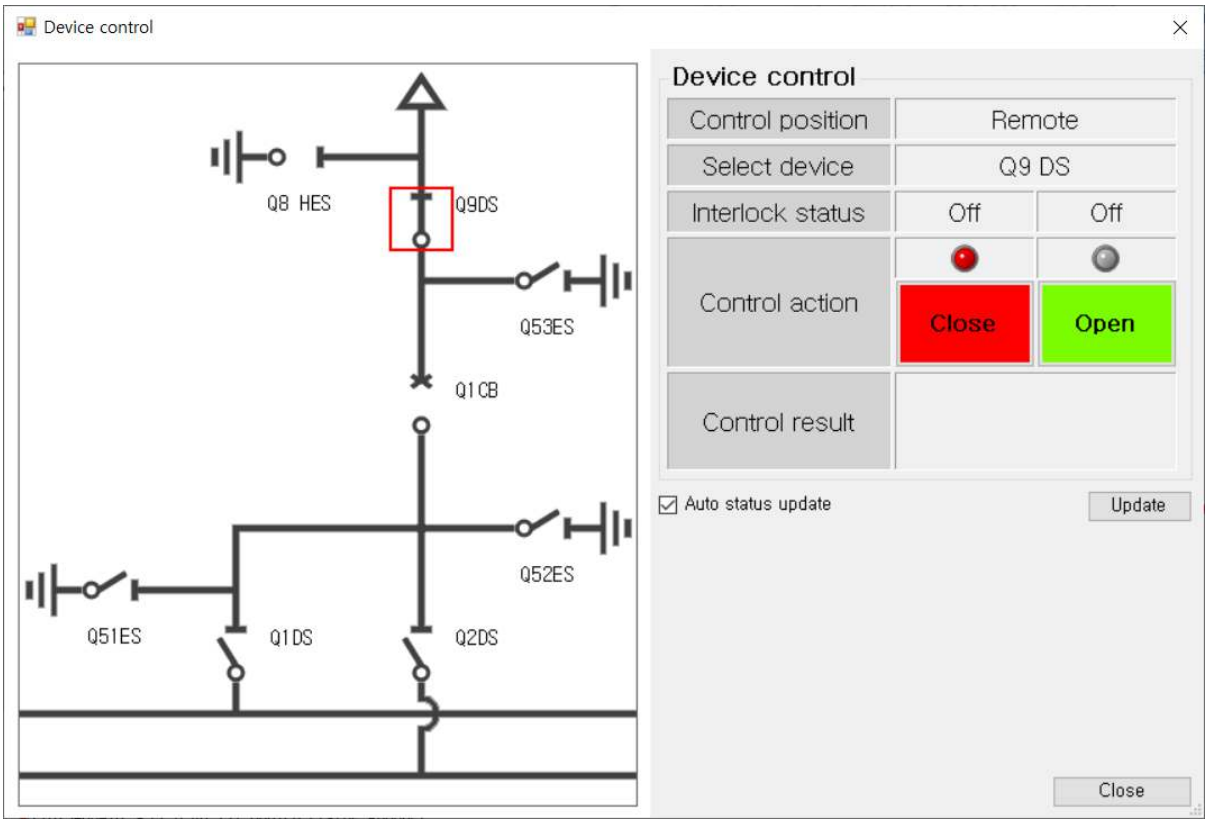


The file already read, is marked as 'O' on Read column. Already read data can be read again in offline mode



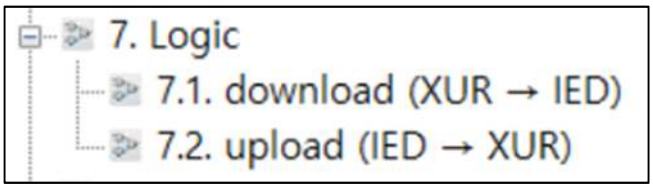
The user may check individual file by entering COMTRADE viewer.

AI CT, AI PT, DI, and DO are displayed by default.



3.2.7. Wired-X : Control

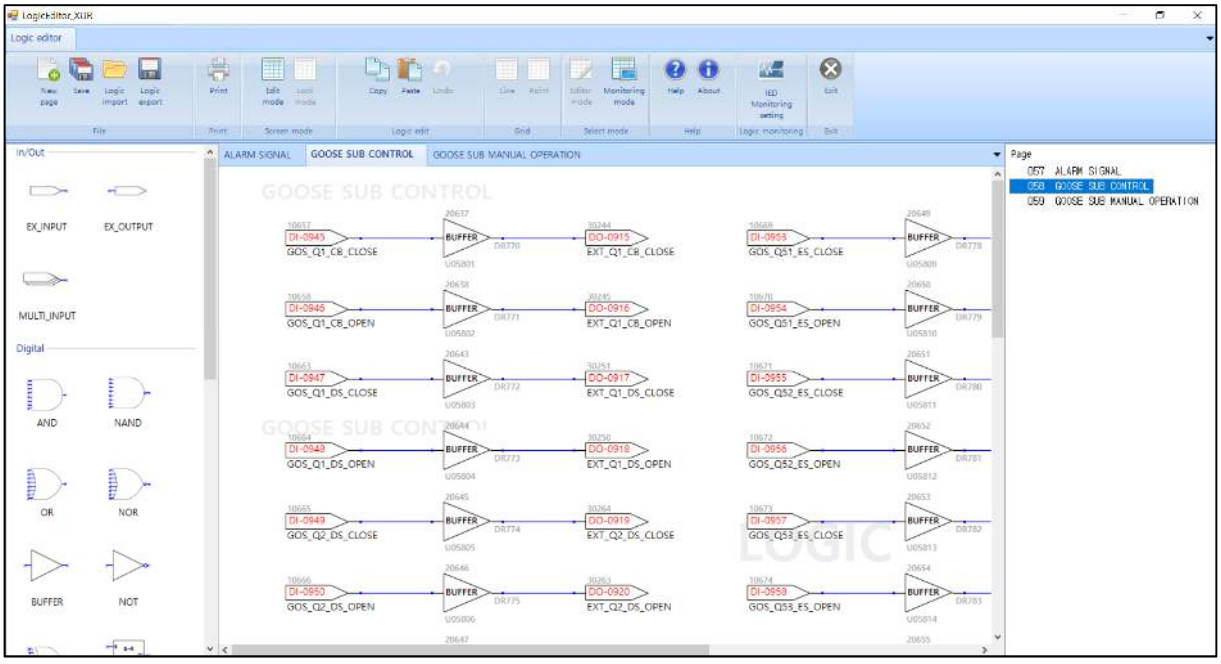
IM2 controls connected devices such as CB, ES, DS.



The source of control can be 61850 control service, Wired-X, LCD and external connected DI point. Control command will be processed correctly, if all the conditions are fulfilled.

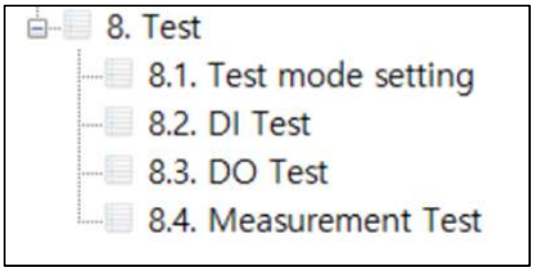
This is covered in more detail in “4.3 Function of CB/DS/ES control in SLD”

3.2.8. Wired-X : Logic



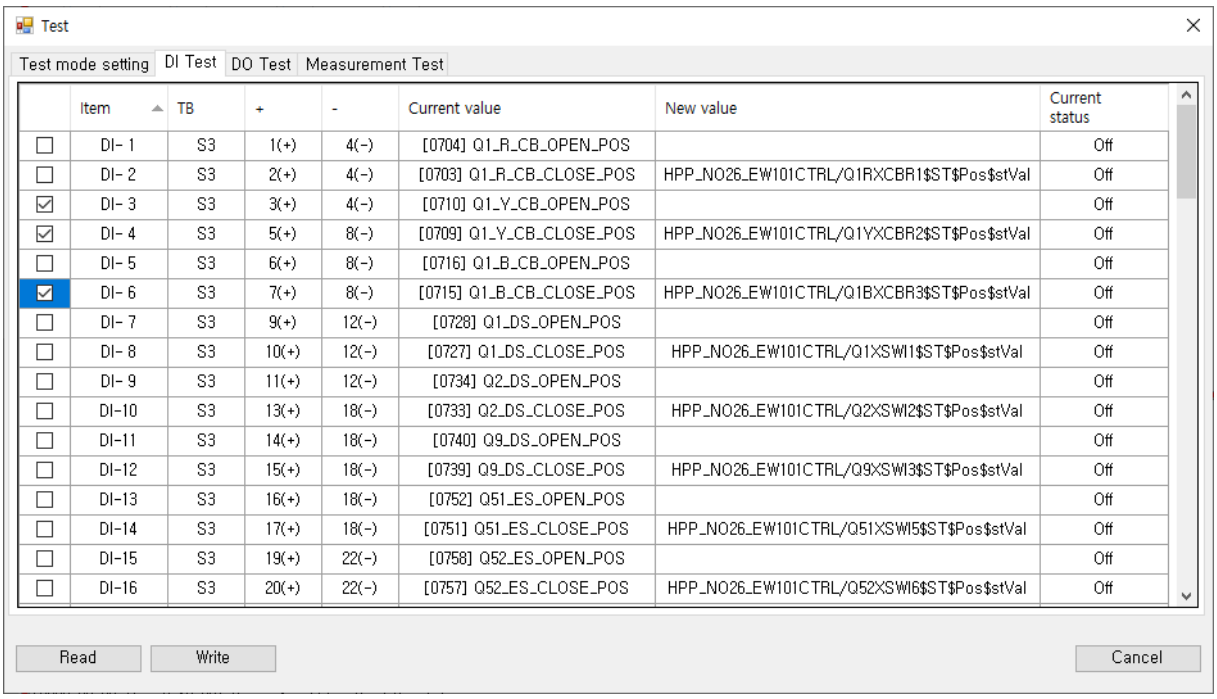
Upload/Download pre-structured logic from a manufacturer.

A user may execute the logic editor by pressing 



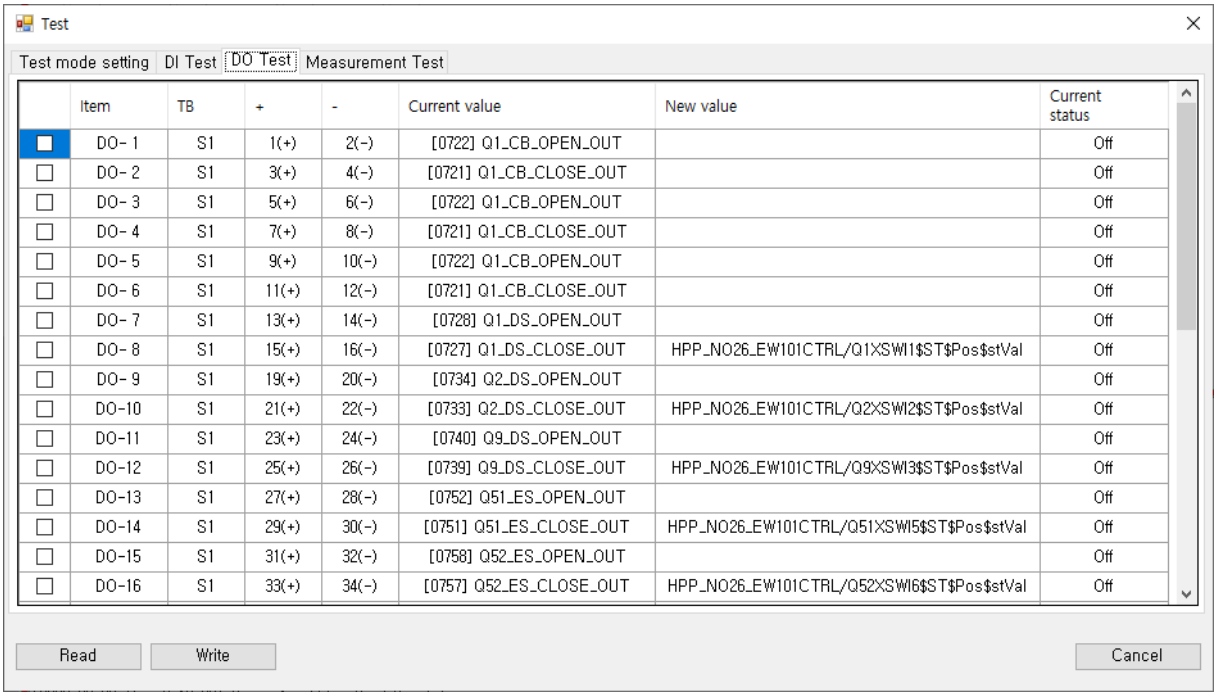
button on the toolbar

In general, the user may use GOOSE subscription data to design the logic.

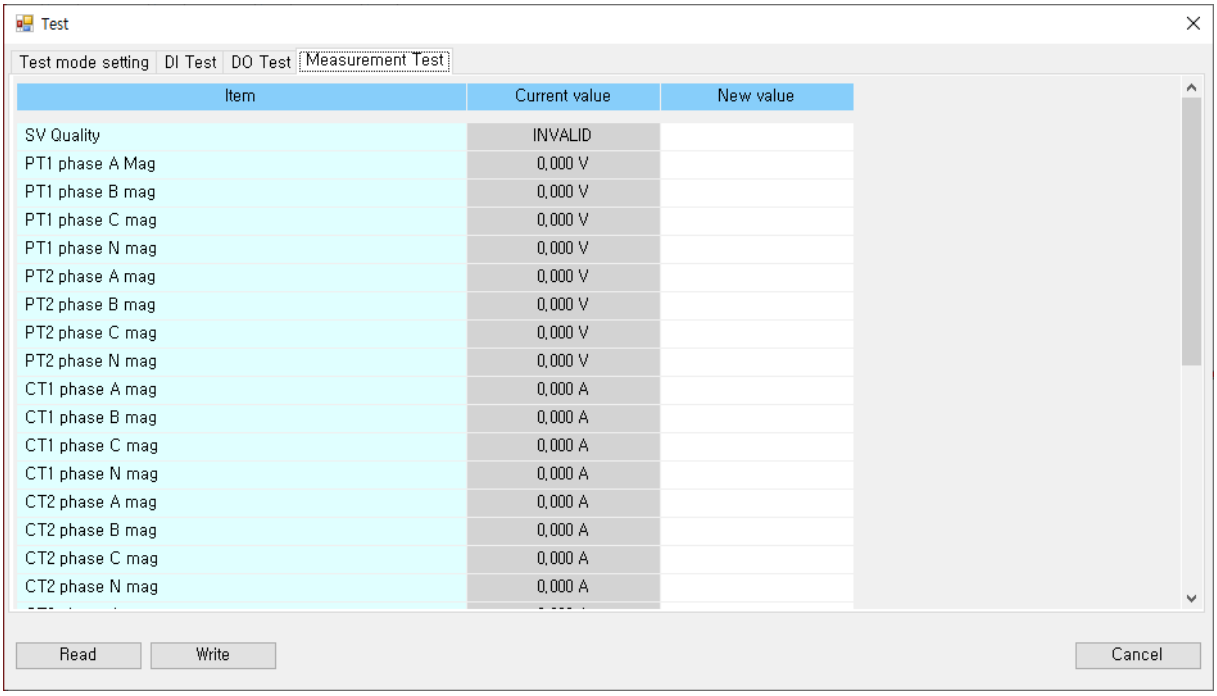


3.2.9. Wired-X : Test

A user can test DI, DO, SV without physical source connected to IM2.



Item	Description
Test mode setting	Choose whether you want to test DI, DO, and SV. When test mode is activated, the selected test values are used for input and output, while the actual DI/DO/AI inputs and outputs are ignored.
DI Test	Select a point to test as if the input were coming in virtually
DO Test	Outputs to the selected DO terminal.
Measurement Test	Used when exporting a virtual SV.



In DI Test mode, Select and configure testing DI and press “write” button.

In DO Test mode, Select and configure testing DO and press “write” button

In SV Test mode, Select and configure SV simulation test and press “write” button.

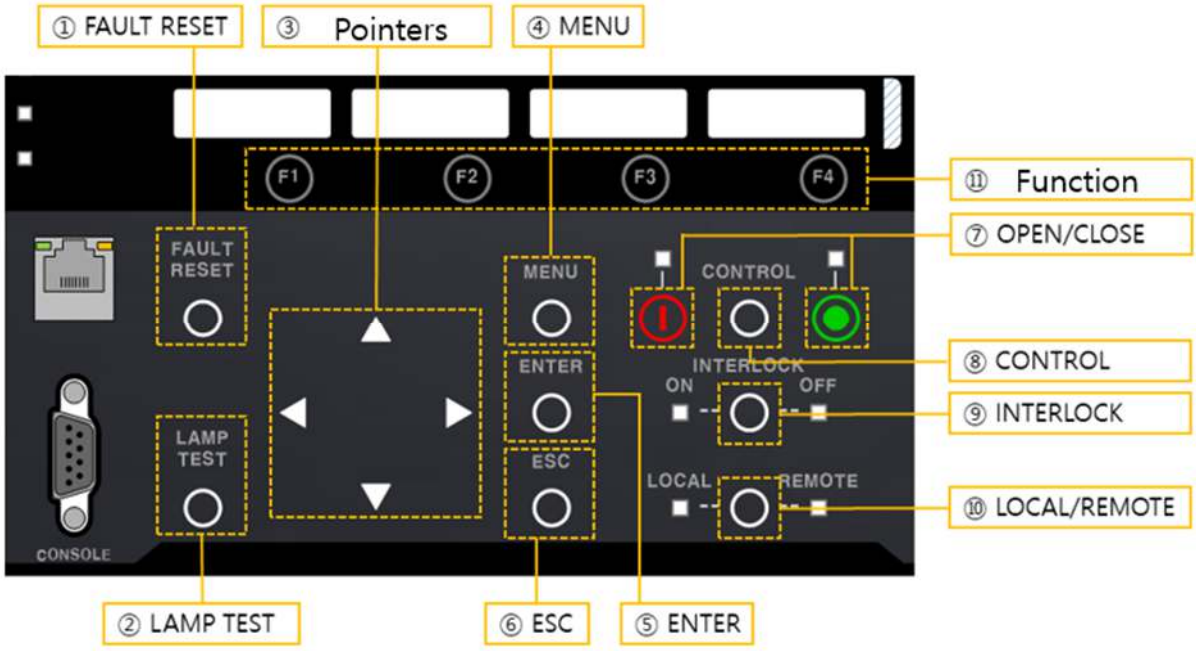
3.3. HMI Configuration

3.3.1. Overview

- HMI carries out functions of mutual information exchange between the operator and IED. It also operates so that the operator can easily recognize the operating state of IM2, and change the operating value and set value with a simple manipulation. The features of HMI are as follows.

1. The use of LCD and touch screen allows to display and process various information.

2. 4 LEDs for displaying system status and 32 LEDs for displaying operation status provide necessary information to the operator.



3. Simple manipulation allows the operator to carry out functions, such as setting and controlling IED.

4. The operator can conveniently check information and change settings on PC (operating software), using the communication port on the front.

3.3.2. Input Device

- Input device consists of a total of 18 buttons, including 4 function buttons, a button to move direction (up, down, left and right), interlock button, local/remote button and FAULT RESET button.

- Input device is configured as follows.

① FAULT RESET : a button to reset LED

② LAMP TEST : a button to test the operation of LED

③ A button to move up, down, left and right

④ MENU : a button to run menu

⑤ ENTER : a button to start the operation

⑥ ESC : a button to cancel the operation

⑦ OPEN/CLOSE : a button to run control devices at the control menu

⑧ CONTROL : a button that must be selected before operating the control device

⑨ INTERLOCK : a button to change the status of using(On)/not using (Off) interlock

⑩ LOCAL/REMOTE : a button to change Local or Remote status

⑪ Function Button : a shortcut button to move to a specific screen

- A more detailed description of button function is as follows.

① FAULT RESET

- [FAULT] The user can return LED and the operational status of LED to "Off". However, if the current operational status of LED is 'True', it does not change to 'Off'.

② LAMP TEST

- The user can run 'On/Off' of all LEDs, and check the normal status of each LED.

③ Button to move up, down, left and right

- Up/Down
  1. The user can move the cursor for selecting item up and down on a screen where the menu can be selected.
  2. During the control operation, The user can move the selected relaying element.
- Left/Right
  3. The user can move the cursor for selecting item left and right on a screen where the menu can be selected.
  4. During the control operation, You can move the selected relaying element.
  5. If the menu items consist of two or more pages, the user can move to the previous or next page.

④ MENU

- When the main menu is running, the user can move to the submenu.
- When the submenu is running, the user can move to the display, setting, and control menu in sequence.

⑤ ENTER

- The user can run the active menu or item.
- When the user intend to change the set value, the user can apply the input value.

⑥ ESC

- When the submenu is running, the user can move to the previous menu.
- When the highest menu is running, the user can move to the main screen.
- When a pop-up window is displayed, the user can close the pop-up window.
- If an item is selected on the fault event page, the user can deselect the item.

⑦ OPEN/CLOSE

- The user can run OPEN/CLOSE control operation for the selected object to be controlled.

⑧ CONTROL

- This is a button to select a control operation. Be sure to press this button first before pressing OPEN/CLOSE button in order to run the control operation.

⑨ INTERLOCK

- A User can control after selecting a device on the Control> Device Control screen.
- The user can select whether to run Interlock.
  1. When ‘not in use’(Off), the user can forcibly release the Interlock to control devices.
  2. When ‘in use’ (On), the user can activate the Interlock logic to control devices.
- Change of Interlock status
  3. Change of ‘not in use’ (Off): The user can change ‘in use’ (On) to ‘not in use’ (Off) only in the state of ‘Local', and change to ‘not in use’ (Off) only while the button is pressed.
  4. Change of ‘in use’ (On): When the button is pressed and then released, ‘not in use’ (Off) is maintained according to the set delay time of returning the set IED Interlock key, and then becomes ‘in use’ (On) automatically.
  5. However, When 'Local' status is changed to 'Remote' status, the Interlock status is automatically changed to ‘in use’ (On).

⑩ LOCAL/REMOTE

- This button assigns the position where the operator sets or controls IED.
  1. When 'Local' is selected, the user can run the setting and controlling operation in front of the IED.
  2. When 'Remote' is selected, the user can run the setting and controlling operation, using the upper-level commands or communication.

⑪ Function Buttons (F1, F2, F3, F4)

- The user can run functions set by the operator for each button.

• Display

- LED for displaying system status

◆ The types, colors and functions of LEDs for displaying system status are as shown in the table below.

Item	Color	Function
POWER	Green	LED indicating DC power is in a normal state
RUN	Green	LED indicating that power is applied and the CPU of the IED is operating normally. When IED is in normal operation, LED turns on, and when IED software or the front HMI does not operate normally, LED turns off. Also, in the event of IED_FAIL, LED turns off.
ALARM	Red	LED indicating that an abnormality has occurred in the device, and such abnormality is detected by the constant monitoring function. In the event of IED_ALARM, it turns on in red, and in the event of IED_LOCK, it blinks in red. When returning to a normal state, LED turns off.
FAULT	Red	LED indicating that a fault has been detected and protective action has been performed. If the fault is cleared, be sure to use [FAULT RESET] button on the front to turn off the light.

■ LED indicating the operational status

A total of 32 LEDs displaying the operational status are provided, and it is possible to set items the operator wants to display on each LED. It is also possible to set the operational properties of LED for each items to be displayed, such as color and display type.

■ LCD and touch screen

LCD and touch screen provides an operator interface, such as checking the set value and operational status, and changing the set value.

3.4. HMI Features

3.4.1. Functions displaying information on the operational status

- IM2 stores various information on operational state, which can be checked in the display menu.
- Up to 2000 items of event on fault, self-monitoring and control are saved, and the non-volatile memory inside the IM2 allow to store them permanently. However, since there is a limit to the number of storage and they are managed in the order of the latest record, the information on the oldest event is deleted when any events occur in excess of the maximum number.
- Up to 64 fault waveforms are stored in 4K/4.8K rate, which is identical to the samples used for protection per cycle. They are saved in the form of COMTRADE file, so the user can transmit them to the higher-level system, including the operating system of substation and SCADA, and analyze them using the operating software.
- It is possible to save fault waveform of 10 seconds long.
- The set values are saved in the nonvolatile memory inside the IM2, and therefore, preserved permanently. Data loss and damage are prevented by the use of 2 nonvolatile memories to save the set value in duplicate.
- In order to check whether all items, such as the set value related to the function, are normal during operation, the constant monitoring function checks whether the data is normal.

3.4.2. Function for Verifying Passwords

- In order for the operator to run the operation of each menu, the operator must have the authority to run such operation. Therefore, be sure to go through procedures for verifying passwords in order to check the authority before running the setting and control menus.
- The operator's authority is divided into 4 levels in total as shown below: display, setting, control and admin.

  - display authority : Information on setting and operational status inside the IM2 can be checked.
  - setting authority : All items can be set (including display authority)
  - control authority : CB, etc. can be controlled (including display authority).
  - admin authority : All items can be set and controlled.

- Password for each authority can be changed at the menu of 'setting'.

3.4.3. Operator's setting function

- The operator can set items, including time, network, the use of contract input/output, factors, holding time of controlled output and debouncing time.
- The set value of factors are individually managed in for set groups, and the group selected according to the operators' settings is applied to the operation of the factors.
- The operator's setting is possible even during normal operation of IM2, and is reflected in the operation of IM2 immediately after change.

3.4.4. Alarm for occurrence of fault event

- When a fault event occurs, the status is displayed on IM2 so that the operator can know the occurrence of a fault. The [FAULT] LED on the front is turned on, a pop-up window containing the fault details is displayed on the front LCD, and then the tray icon for occurrence of fault event on the status bar turns on.
- If the user select the 'Check' button after checking information of the pop-up window, the pop-up window disappears and the IM2's HMI function can be used normally.
- The tray icon for occurrence of fault event on the status bar turns on in the event of a fault event, and it turns off when the operator checks the fault event history in the display menu.
- In the event of a fault event, the screen is as follow.

3.4.5. Communication Port

Communication ports are provided that allow an operator to acquire data or enter information using a PC in which the operating software is installed. The role of the communication port is as follows.

- When the communication port is connected to the PC in which the operating software is installed, and acquires data of IM2, it supports the operator to easily analyze the IM2 monitoring information, or measurement data and fault information data via the operating software.
- The operator can easily enter the set value for IM2, transmit it to IM2 for application via the operating software.
- The operating software allows to acquire COMTRADE file containing the fault record from IM2, and then to analyze the fault.
- It is possible to connect the front communication port to the PC on the spot in order to update IM2 software.

4. Function

4.1. Setting standards of equipment

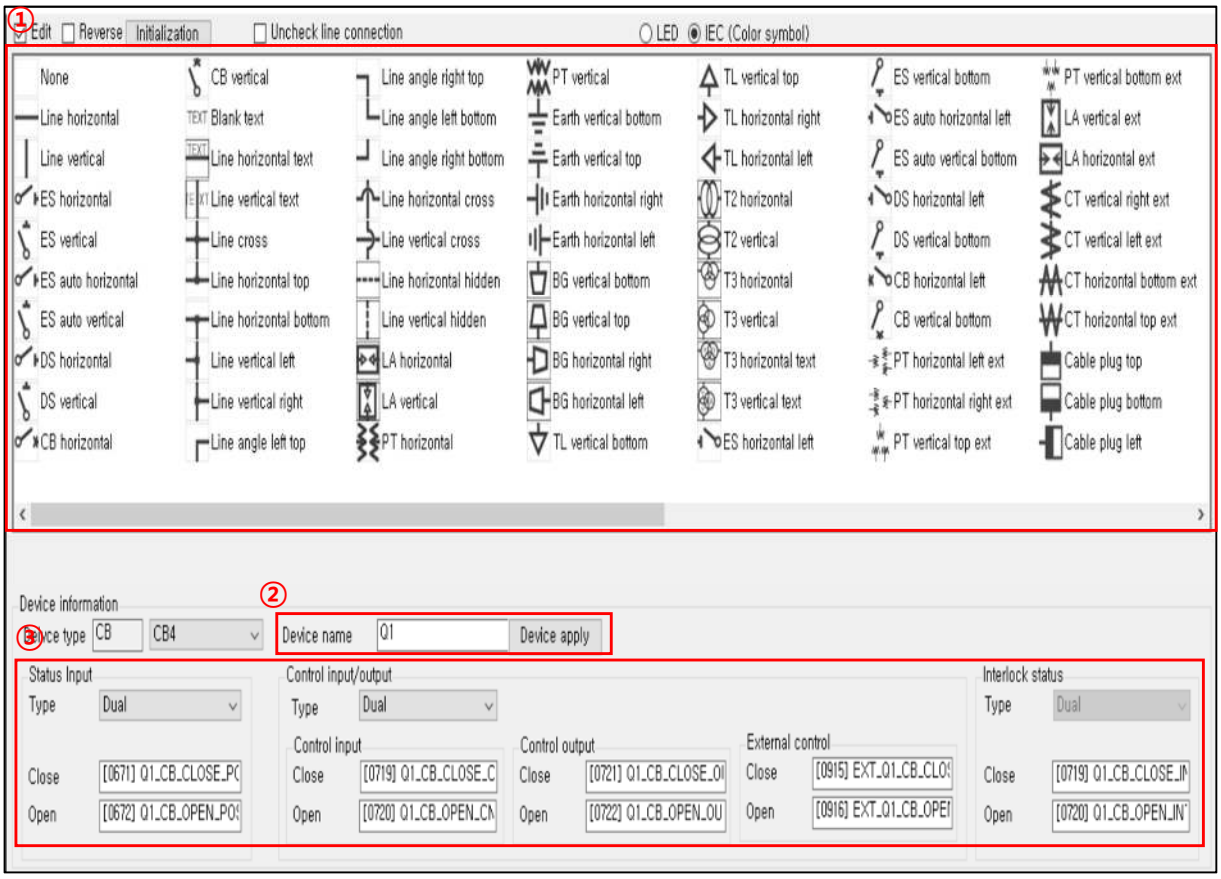
IM2 sets the rated voltage and current of the power system in which IM2 is installed. The equipment that sets the rating includes the bus PT, line PT, phase CT and N-phase CT.

Items set	Unit	Min.	Max.	Step	Default value
Rated Primary PT Voltage	V	1	2000	1	154000
Rated Secondary PT Voltage	V	1	1000	1	110
Rated Secondary Line PT Voltage	V	1	1000	1	110
Rated Primary CT Current	A	100	10000	1	2000
Rated Secondary CT Current	A	1	100	1	5
Rated Primary NCT Current	A	100	10000	1	2000
Rated Secondary NCT Current	A	1	100	1	5

4.2. Function of saving fault record

IM2 has a function to save the voltage, current signal input to IM2, and the operational result of internal logic as the fault record when internal function works. The setting items for the function of saving fault record are as shown in the table below.

Items set	Unit	Min.	Max.	Step	Default value
Use or not to use	-	Off	On	-	Off
Mode of saving fault waveform	-	Trip	Trip & pickup	-	Trip
Record Sampling	-	-	-	-	4K
Saved length of waveform before pickup occurs	msec	1	10000	1	3000
Saved length of waveform after pickup occurs	msec	1	10000	1	7000
Saved length of waveform before trip occurs	msec	1	10000	1	3000
Saved length of waveform after trip occurs	msec	1	10000	1	7000

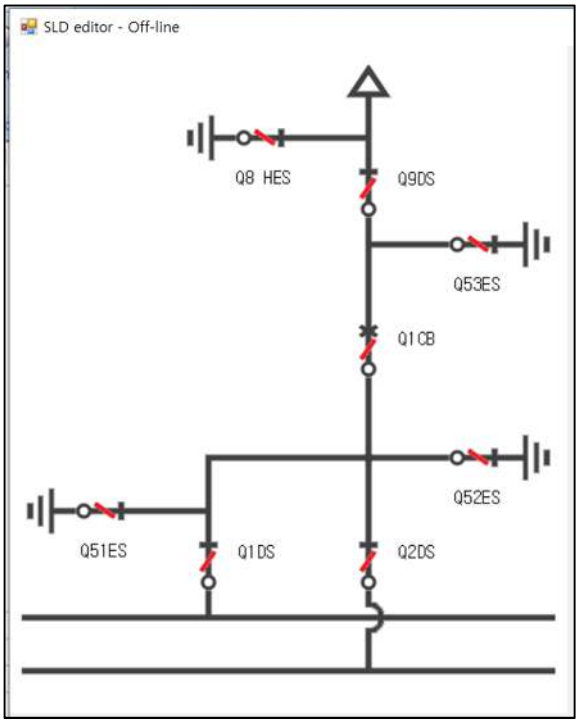


IM2 internally performs 80 samplings per cycle in order to carry out sampled value generation, therefor fault record sampling is fixed to 80 samples/cycle (=4K sample/sec(50Hz), =4.8K sample/sec(60Hz)).

4.3. Function of CB/DS/ES control in SLD

IM2 has a function to control an equipment such as CB, DS and ES in Single Line Diagram.

Wired-X provides a single line diagram editor, and a user can draw or edit SLD through the SLD editor as shown below. However, user generally do not need to modify SLD as they are designed/tested to match the approved drawings upon delivery. If you want to make a modification, please contact the manufacturer first.



① Available Symbols for SLD

② Device name as it appears on the schematic

③ Assigning points for control in SLD. ***This setting is critical and may not function properly***

if altered. Please contact the manufacturer before making any adjustments..

Below is an example of a single line diagram implemented through the Single Line Diagram Editor. A single line diagram can contain up to 4 CB symbols, 4 DS symbols, and 4 ES symbols.

- The real-time status of the current device is displayed on a single line diagram.
- The operator can change symbols indicated on the single line diagram according to the settings, and the status of the device is displayed differently according to the symbol.
- The status of the device is displayed as follows.

	The state of Open input	The state of Close input	IEC Symbol	LED Symbol
1	Off	Off		
2	On	Off		
3	Off	On		
4	On	On		

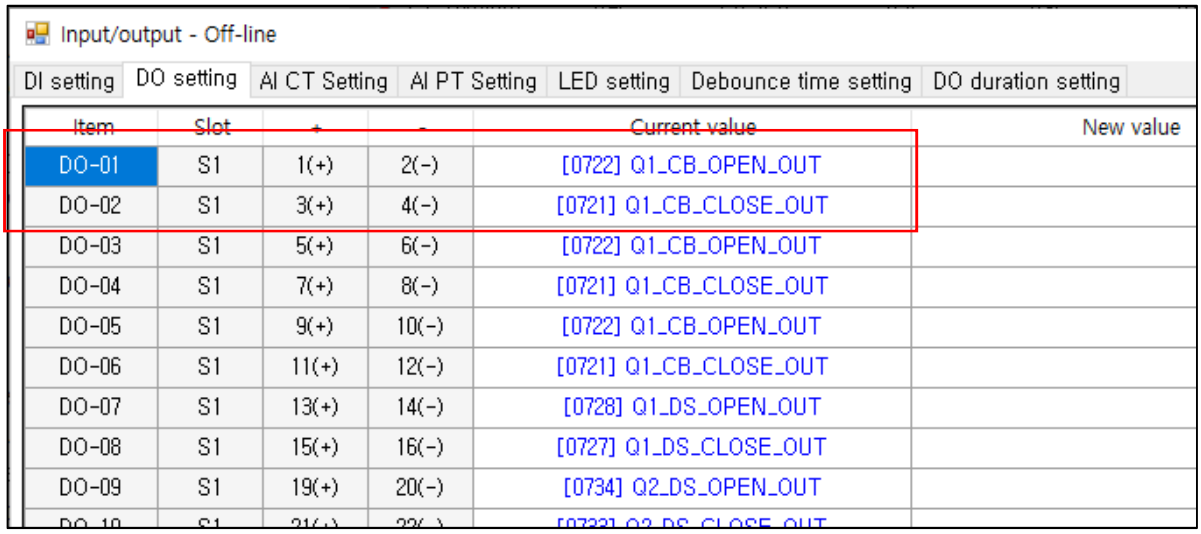
4.3.1. Control related conditions

The following conditions must be met for the control output to function properly.

- Local/Remote status
- Interlock status
- Position status /Command input
- Control output point and whether to assign a DO

Control depends on local/remote status to determine which sources are controllable, as shown below.

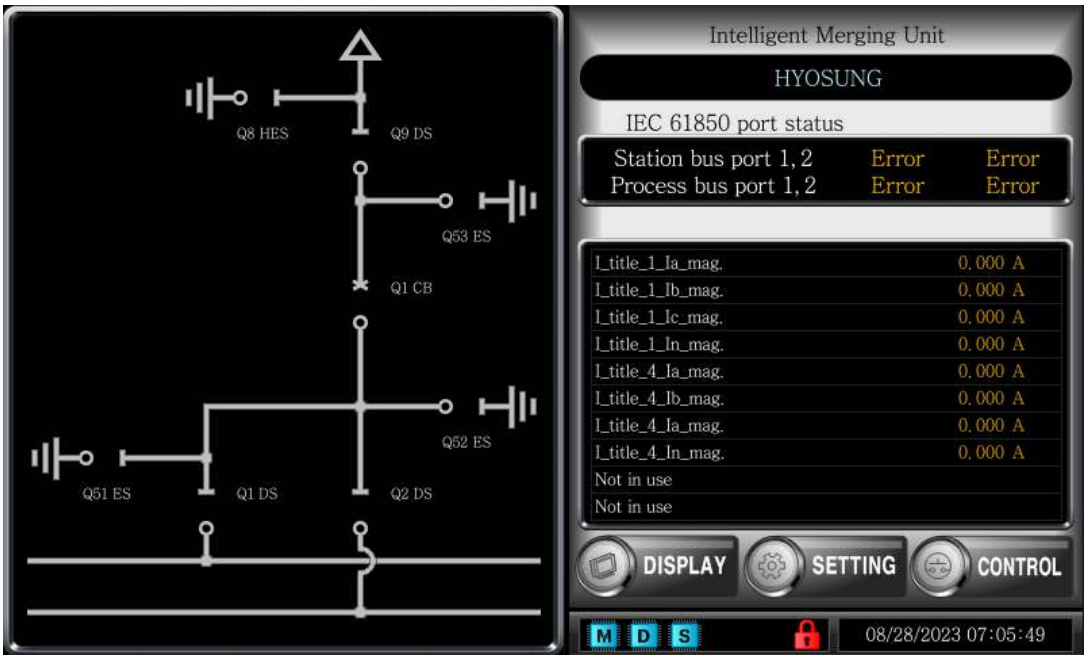
	Controllable source
Local	LCD touch panel, Button
Remote	Control input : 61850 Control Service, Wired-X External control : Internal digital points assigned to a GOOSE or DI



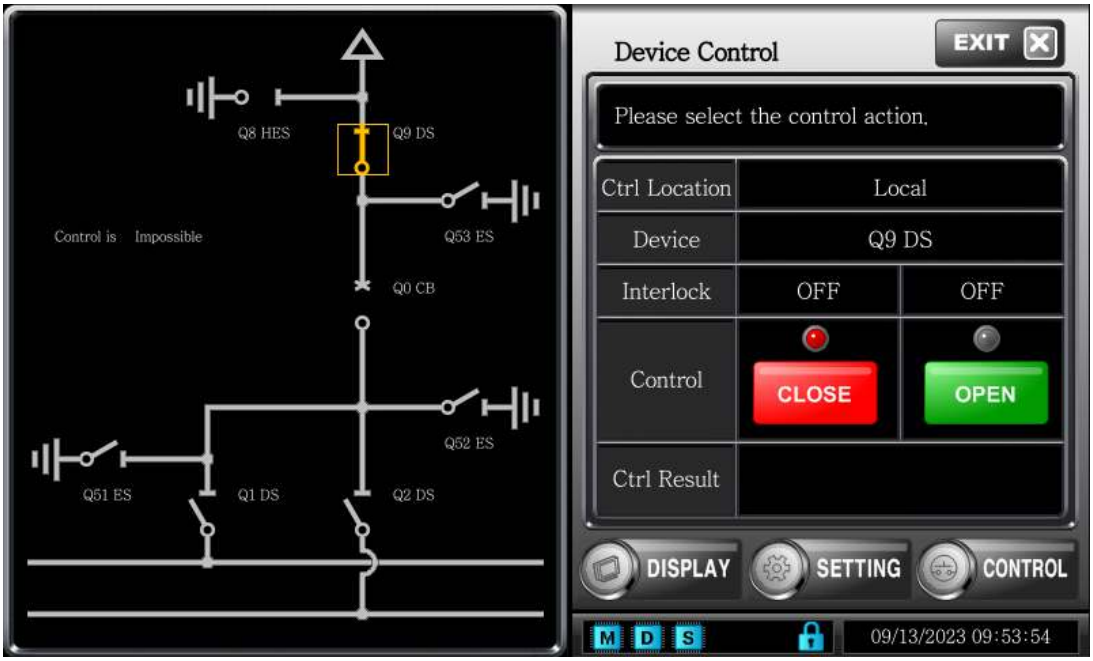
Obviously, you can't control the LCD touch panel or buttons in the Remote state, and vice versa. Check the local/remote status before executing the control action.

The Interlock status is an input that blocks the control output, preventing output when on and allowing output when off.

The position of the device and the command input must always be opposite. If a command identical to the device's position is given, no output is produced. Ex) open output occurs on close position, no output occurs on , and a failure event occurs on OPEN.

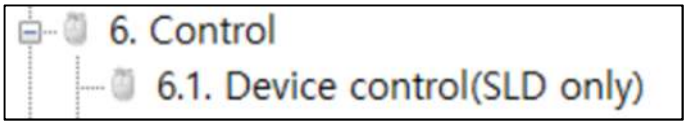


The control output point must be assigned to a DO on the DOU module. DO settings can be checked at 1.2.2 “DO setting”

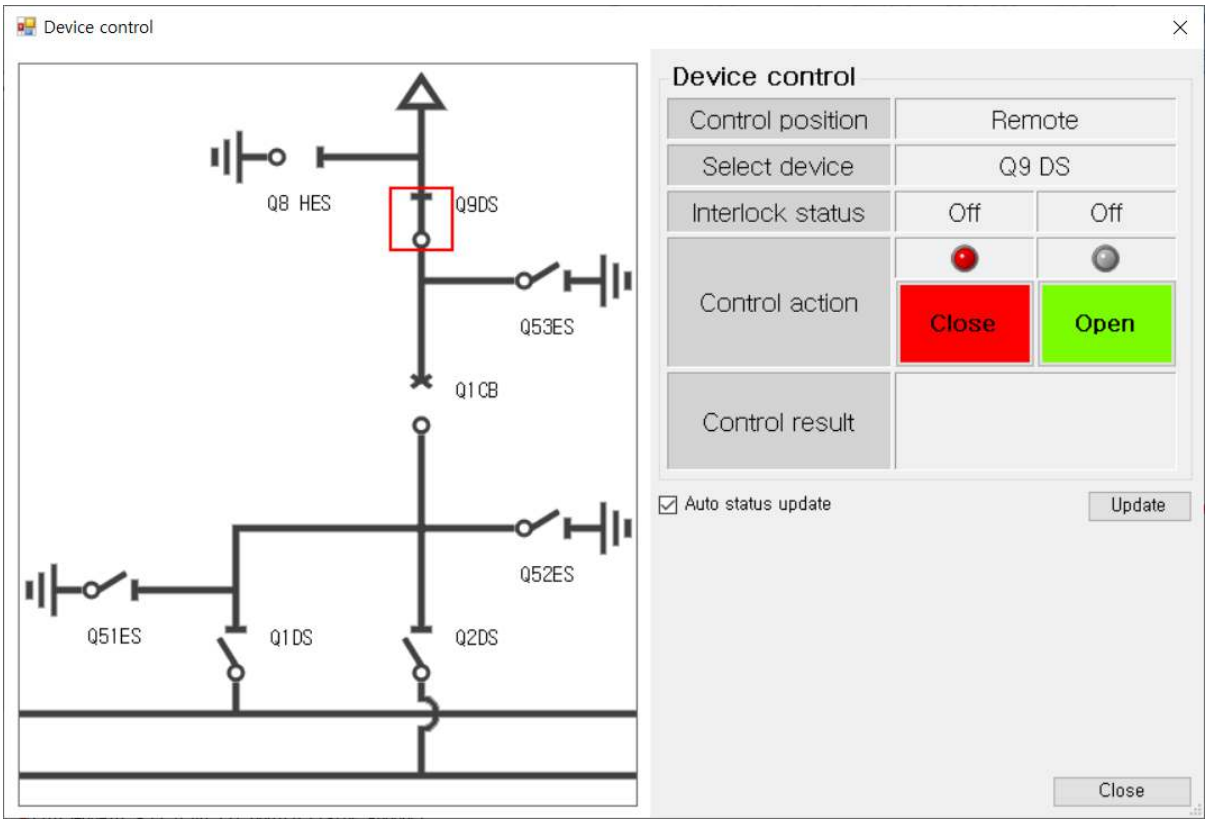


4.3.2. How to control CB/DS/ES in SLD

The conditions necessary for the control to operate have been verified, and now we will proceed to explain the actual method of operation. The IM2 can be operated in two ways: through the LCD or Wired-X. First, let's explain how to operate on the LCD.



When the device in the SLD is tapped on the Main Home screen like the above picture, a password prompt will appear. After entering the correct password, you will be directed to the control screen displayed below.



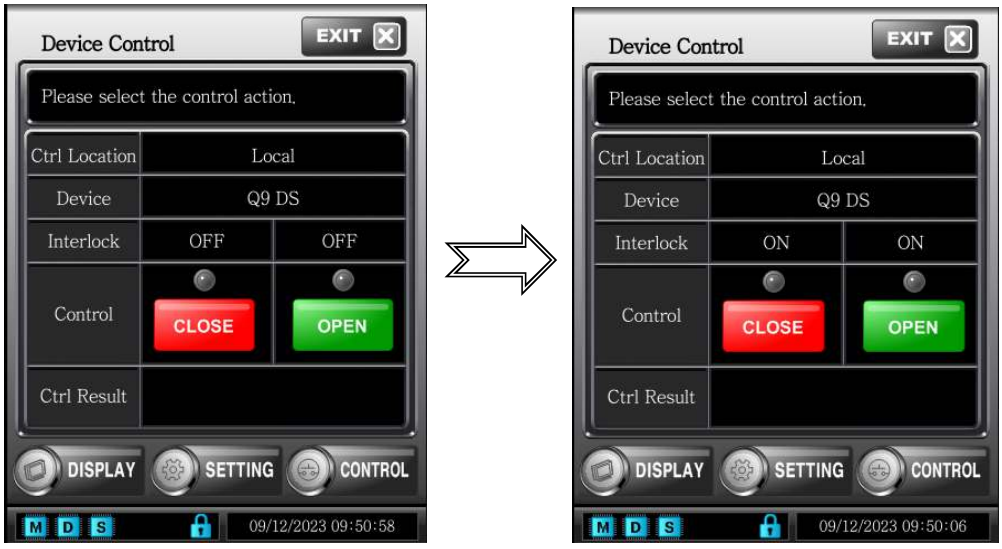
In the previous descriptions, you can see that after checking the control condition and issuing the control command, it works normally. To summarize the control conditions using the LCD/Button, we have the following:

Item	Condition
Ctrl Location	Local
Interlock	OFF
Device's Position	Open or Close

Similarly, Wired-X can control through "6. Control" after connecting to IM2 through Wired-X.

The control conditions using Wired-X are as follows

Item	Condition
Ctrl Location	Remote
Interlock	OFF
Device's Position	Open or Close



4.3.3. How to take control of CB/DS/ES in an Emergency

During an emergency, it may be necessary to take control of a device to prevent further damage. This behavior is only possible on-site in Local mode. To do so, follow these steps:

1. Select a device in SLD and enter password.
2. Press and hold "Lock" button over 3 seconds. (Releasing the button, it will revert after 3 seconds)

3. Check interlock status and confirm "OFF" to "ON".

5. Alarm & Self-Monitoring

5.1. Overview

- If the ARM lamp of this device is lit, be sure to check whether this device is free from error. Therefore, the automatic monitoring function is very important to check the status of this device in the course of startup and normal operation. A fatal error detected during automatic monitoring means that this device will be blocked and out of service. Accordingly, the power of this device must be turned off/on in order to make this device work again, or otherwise this device must be replaced.

5.2. How to classify alarms and check events

5.2.1. Description of alarm events

Alarm LED is lit upon occurrence of alarm event, and divided into [alarm element for locking the operation] and [alarm element for unlocking the operation].
When [alarm element for locking the operation] event occurs, the logic function does not work, and be sure to check it promptly and take actions because there may be problems with IM2's own hardware.

5.2.2. How to check upon occurrence of alarm event

Select "Display>Event>Alarm Event" to check the event.

5.2.3. Alarm Table

IM2 Alarm & Fail LED work in the following situations.

Status	Alarm LED	Fail LED
Operation alarm	blinking	Turn on
Non-operation alarm	Turn on	OFF
Normal & other alarm	OFF	OFF

5.2.4. How to check and inspect when alarm LED on the front of IED is turned on

1) How to check and take actions when 'Alarm event for locking the operation' occurs

- This is the case where IM2_LOCK or IM2_FAIL occurs, and if problems inside IM2 occurs, ALARM LED blinks every 1 second, and IM2 FAIL LED is turned on.

NO.	Occurrence of event	Confirmations and checklist
1	Abnormality in external power	This is an event of monitoring the control power. As this works when DC is not more than 90V and not less than 140V, be sure to check whether the power is DC 125V at the input terminal of the control power.
2	Abnormality in DSP Core	This is an event that occurs when IED's internal circuit is abnormal. When checking this event, be sure to contact the maker.
3	Abnormality in the set value	
4	DSP's failure to receive the initially set value	
5	Abnormality in measurement circuit	
6	Abnormality in ADC	
7	Abnormality in internal power	

2) How to check and take action upon occurrence of alarm event 'unlocked operation'

- This the case where IM2_ALARM elements work, and if the logic element is not locked, ALARM LED is turned on.

NO.	Event checking	Confirmations and checklist
1	Abnormality in IEC 61850 communication ※ *When IEC 61850 function is applied*	Be sure to check whether the connection of 61850 port and the optical distributor's cable linked to the rear of IM2 is normal, and whether the cables are connected mutually crosswise.
2		Be sure to check whether IEC 61850 IP for connecting to IM2 from HMI and clients is properly set. Be sure to check at "Setting>System>Network setting >IEC61850 port".
3	Abnormality in DI circuit	It operates when the state is changes more than 40 times within 1 second, so be sure to check the connection bolts on the rear of IM2 are loose.

4	Abnormality in DO circuit	This is an event that occurs when IED's internal circuit is abnormal. When checking this event, be sure to contact the maker.
5	Abnormality in DO contact	
7	Abnormality in the set value of MPU	
8	Abnormality in IEC 61850 communication process ※ *When IEC 61850 function is applied*	
9	Abnormality in IM2 event information	

3) How to check and inspect when an equipment is not controlled

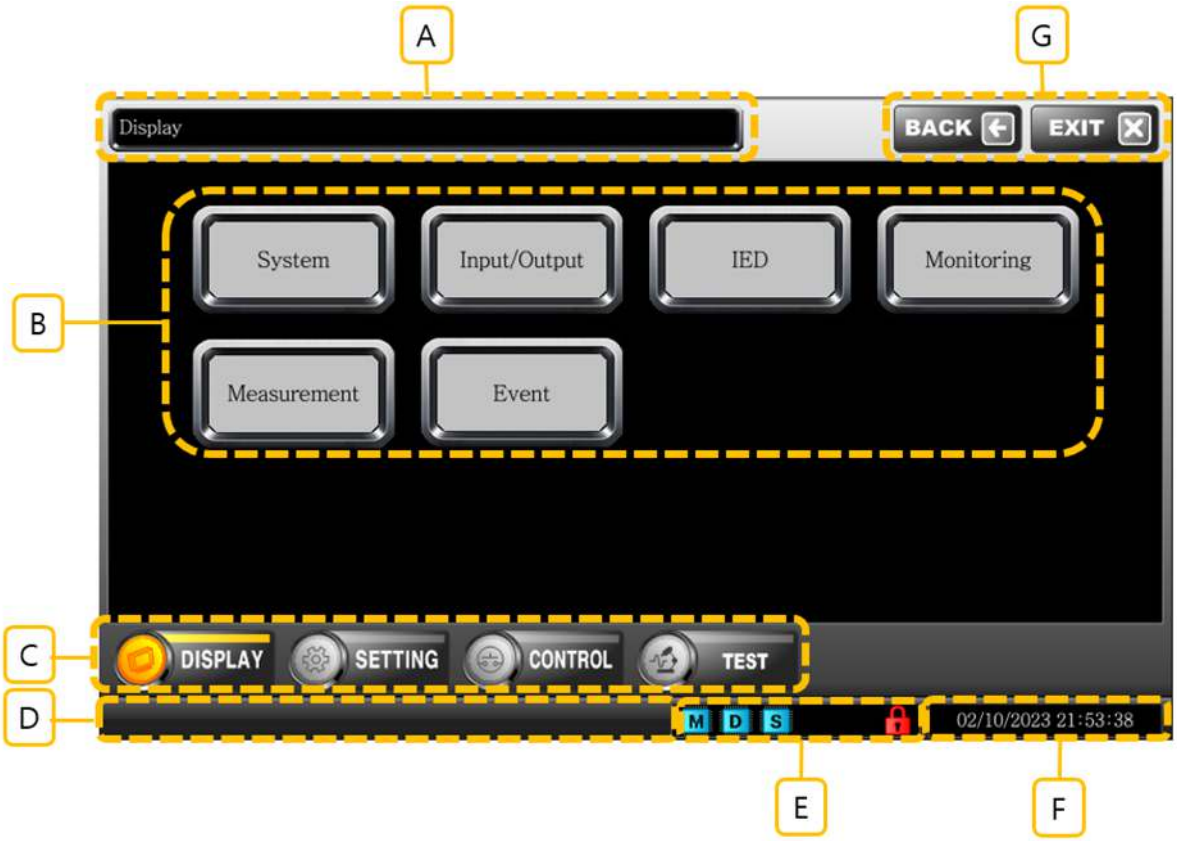
NO.	Confirmations and checklist
1	If an equipment is controlled at the site, be sure to check whether the control position is in the state of the site, and whether it is in the remote state when the equipment is controlled at a higher level, such as HMI.
2	The same control is not executed.. e.g.) When the state of inputting contact is in the state of 'CB close', 'CB close' is not controlled.
3	If the state of inputting the contact of an equipment to be controlled is not input, the equipment is not controlled. In other words, if the state of the equipment is recognized as abnormal, the equipment is not controlled. e.g.) 'CB close' can be controlled only when the state of inputting the contact is in the state of 'CB open'.
4	Be sure to check whether the interlock logic for controlling the device is applied. (Be sure to check at 'Display-Logic-Interlock) If the output of interlock logic for controlling the device is "0", the device is not controlled, so the device must be controlled after configuring the output of interlock logic as "1".

4) How to check and inspect when the connection to Wired-X communication fails

NO.	Item	Confirmations and checklist
1	When connecting to Console (serial) communication	Be sure to check whether COM port of the operator's PC matches with the Wired-X Com port. The user can check the COM port number at "My Computer>Hardware> Device Admin>Port". (How to check may vary depending on the operating system.)
2	When connecting to Ethernet communication	Be sure to check whether IP entered in IM2 is properly set. The user can check IP at "Settings>System>Network setting>Ethernet Console port".
3		Be sure to check whether the communication cable is properly connected to Ethernet port on the front of IM2.
4		Be sure to run 'Ping Test' to check whether IP assigned to IED is being used by other equipment. The user can check on the operator's PC at 'Start>Run> Enter CMD> Enter ping IP'
5		Be sure to check whether the access is blocked by the firewall on the operator's PC.

6. Display

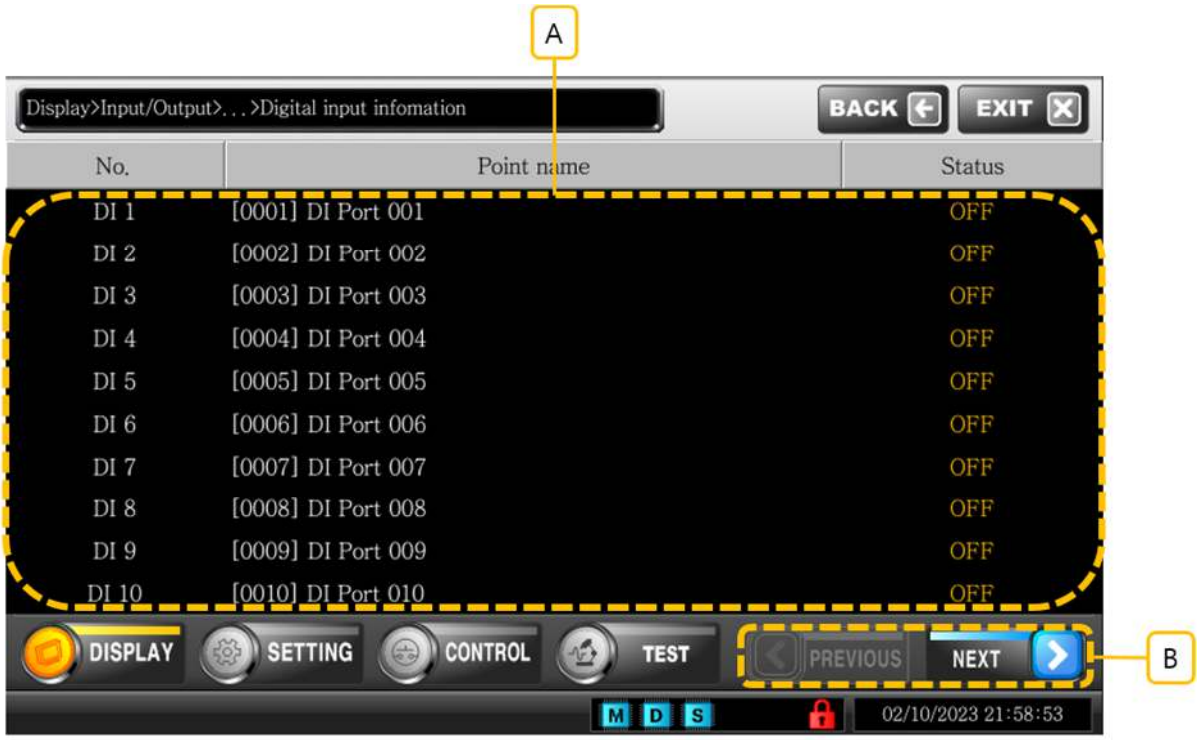
6.1. Main Screen



- The main screen displays product name, the state of IEC 61850 port, time and measurement information. The user can move to Display/Settings/Control Tab on the main screen. the mark 'lock' at the bottom of the screen indicates 'Remote/Local mode and Lock/Unlock status. The settings can be changed, using buttons on the front of IM2 (10,11). The icon, 'lock' is displayed in blue for Local mode, and in red for Remote mode, and the set value can be changed only in Local mode.

A. Single Line Diagram	: Single line diagram and equipment status are displayed.
B. Device name	: IED name
C. Facility name	: Facility name
D. the state of IEC 61850 communication	: the state of 2 ports on IEC 61850 is displayed. ※ The user can use it when applying IEC 61850.
E. Measurement data	: Key information on measurement is displayed.
F. Menu category	: All menus are classified and displayed depending on function

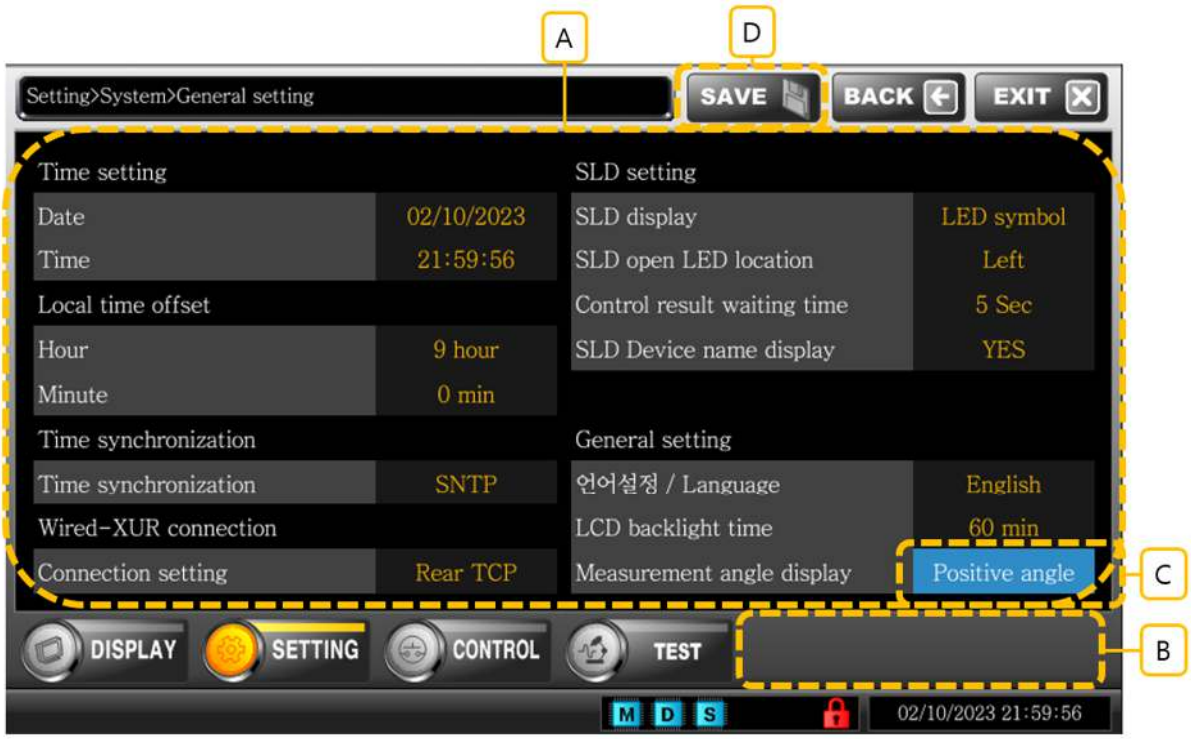
G. Time display	: information on current time is displayed
H. Tray icon	: The status of IED operation is displayed simply For details, see [Tray Icon] below.



6.1.1. Screen for selecting menu

- The configuration and meaning of the screen for selecting the detailed menu, such as display, setting and control, are as follows. The figure below is the screen for setting menu.

A.	Display of menu path	: displaying the path of the currently running menu
B.	Detailed menu	: displaying the detailed menu belonging to the menu
C.	Menu category	: Classifying and displaying all menus according to the operation
D.	Display of status	: displaying information on status
E.	Tray icon	: simply displaying the status of IED operation
F.	Display of time	: displaying information on the current time
G.	Moving backward /End button	: moving to the previous menu or main menu



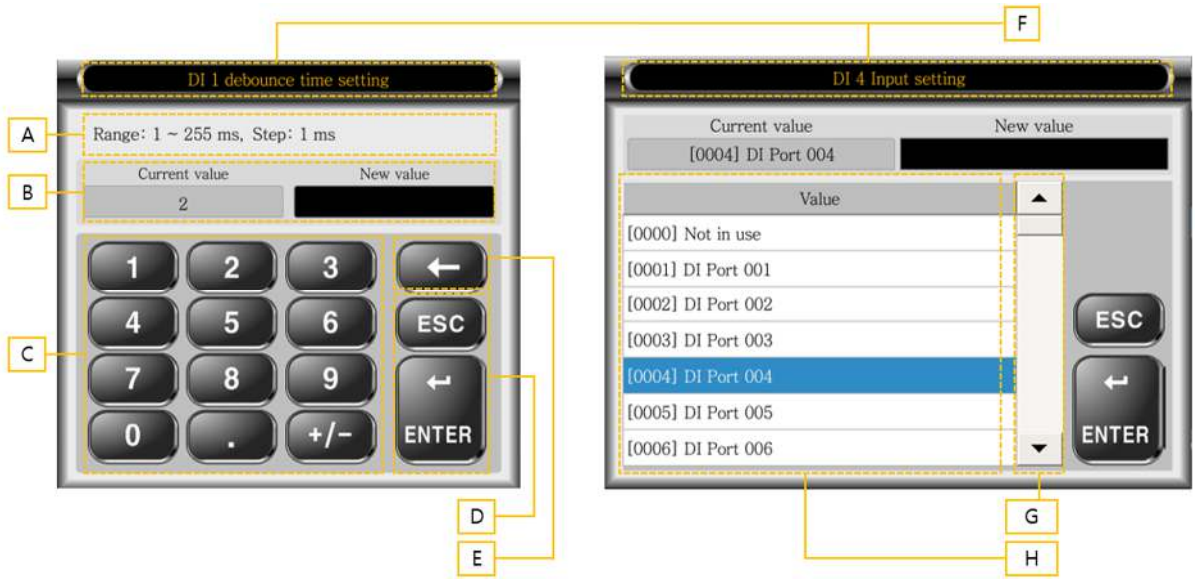
6.1.2. Screen of Display Menu

A. Detailed data : displaying the detailed data belonging to the menu

B. previous/next button : If there are 2 pages or more, a button to move page

6.1.3. Screen of menu set

A. Items set : settable items belonging to the menu



B. Previous/Next button : If there are more than 2 pages of data, a button to move page

C. Activation of menu set : Element to select and classify for running item

D. Save button : a button to save and apply the set value changed by the operator

6.1.4. Screen of pop-up window

- Pop-up windows displayed during the operation of menu is largely divided into a window with a button for entering numbers, and a window with a set list.

A.	Displaying the settable range	: Displaying the settable range, such as Min., Max. Step of the item
B.	Displaying the set value	: Displaying the existing set value and new set value entered by the operator
C.	Button to enter numbers	: Number button used to enter the set value
D.	Cancel/Confirm button	: 'Confirm' button to cancel the changed setting or to apply new input value
E.	Button to cancel input	: Button to cancel the input of new set value one by one
F.	Name of the set item	: Displaying the name of the set item
G.	Up/Down scroll	: a button to move to the previous/next item in the set list
H.	List set	: Displaying the list for the operator to select the settable item

6.1.5. Tray Icon

- Types and meanings of icons displayed on HMI are as follows.

A. MPU : Display whether MPU is normal or abnormal
- M : MPU is normal
- M : MPU processor is abnormal
- M : MPU is abnormal (None-Lock alarm)
- M : MPU is abnormal (Lock alarm)

B. DSP : Display whether DSP is normal or abnormal
- D : DSP is normal
- D : DSP processor is abnormal
- D : DSP is abnormal (None-Lock alarm)
- D : DSP is abnormal (Lock alarm)

C. IEC 61850 (STB) : Display whether IEC 61850(STB) is normal or abnormal
- S : IEC 61850 is normal
- S : IEC 61850 processor is abnormal
- S : IEC 61850 communication is abnormal
- S : IEC 61850 communication is abnormal

※ It is possible to use when applying IEC 61850.

D. Displaying fault waveform : the state of saving fault waveform
- : completing to record fault waveform

E. Interlock : Display the status of Interlock
- : Remote/ Locked
- : Local / Unlocked
- : Local / Locked

6.1.6. LED operation

- LED repeats the following process sequentially. In terms of LED display for each type, it checks and displays the data on 32 setting elements of LED individually.
- Check the displaying items set on the LED: The user can check the displaying items on LED set by the operator, and operate the LED according to the set type and color.
  1. Monitoring of the value of LED setting elements: The user can monitor data in real time, and reflect them in LED display as soon as they are changed..
  2. LED display: There is a difference in the display method for each type of LED setting. The details of the display method for each type are as follow.

Type	How to display
Pulse	It is displayed in real time according to the status value. If 'True', it is on, and if 'False', it is Off.
Latch	It monitors the status value in real time, and if 'True', LED is turned on, but even if it is changed to 'False', LED is not turned off. If the status is 'False', The user can turn off LED, using [FAULT RESET] button on the front.

6.1.7. LCD operation

- LCD repeats the following functions in order.
  1. Input on LCD: The image and status values are displayed on the LCD. The image and data name displayed on the LCD are updated only when the power is turned on for the first time or when the menu is shifted, and various status are updated and displayed ever 200ms, and the measured values are displayed every 3 second. Therefore, the operator can check the status change inside the IED in real time.
  2. Input on screen touch: The operator's screen touch is monitored, and the corresponding operation is performed. When the position, where the touch screen is pressed, is the menu button, the LCD of the selected button is changed, and when it is the button related to the saving of the settings, the changed set value is reflected inside the IED.
  3. LCD backlight: To protect the LCD, if there is no input on LCD touch or button for a set time, the LCD backlight is turned off. The backlight time can be set by the operator, and the backlight turns on again when the screen is touched or a button on the front is pressed.

6.1.8. Menu List on the Display

- The display function does not require a separate password.. That is, all operators can use the display function.
- The status of IED operation and monitoring elements are displayed, and the value set and measured by the operator can be checked..
- The menu tree on the display is as follows.

Menu on the display	Sub-menu	Sub-sub menu
System	Version information	
	General setting	
	Network information	
	Function button setting	
	Setting of measurement on the main screen	
	Board information	
	PBCU system information	
	PTP information	
	HSR/PRP information	
Input/ Output	Information on contact point	Information on input of contact point
		Information on output of contact point
	GOOSE information	Station/Process Bus GOOSE subscriber
		Station/Process Bus GOOSE publisher
		Station/Process Bus GOOSE control block
	LED information	
	Information on debouncing time	
	Information on duration of controlled output	
	Information on type of contact output	
IED (inclusion is undecided.)	Information on logic elements	
	Information on machine dimensions	
	Information on elements of saving fault record	
	Information on the set groups	
Monitoring	Status of IED operation	
	Status of IED alarm	

	Status of counter	
	Status of PBCU system	
	PTP status	
	HSR/PRP status	
Measurement (Information will be added after installing functions later)	Measurement information	Voltage: 1~3 Set
		Current: 1~3 Set
		Current: 4~5 Set
		Comprehensive information
		Information on user's measurement 1
		Information on user's measurement 2
	Transducer information	
	RTD information	
	Information on measurement inside IED	
	Electric energy	
Event	Alarm event	
	Monitoring event	
	Contact input event	
	Control event	
	Communication event	
	Fault event	
	Setting event	

6.2. Menu on the Display

6.2.1. How to run menu on the Display

1) "Move" while running the main menu on the LCD

① When moving from the main menu, which is the initial screen of IM2, to the menu on the Display, touch the "Display" button on the LCD to move to the top menu of the Display.

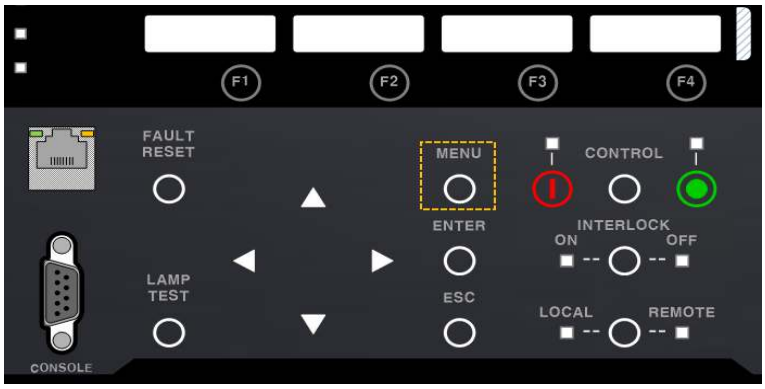
② Go to the menu of "Version Information" to check the information on IM2 version. The position of the menu of "Version Information" can be checked, referring to the menu structure of the upper Display. The menu of "Version Information" is positioned at 'Display> System>Version Information'.

③ Touch "System" button out of the buttons of the detailed menu displayed on the top menu on the display to move to the "System" menu.

④ Touch "Version Information" button out of the detailed menu buttons belonging to the System menu and go to the menu of "Version Information".

⑤ The data of [Version Information] menu are displayed on the LCD. The path of the currently running menu can be checked in the part of displaying title at the top.

※ STB of F/W version can be used when IEC 61850 is applied.

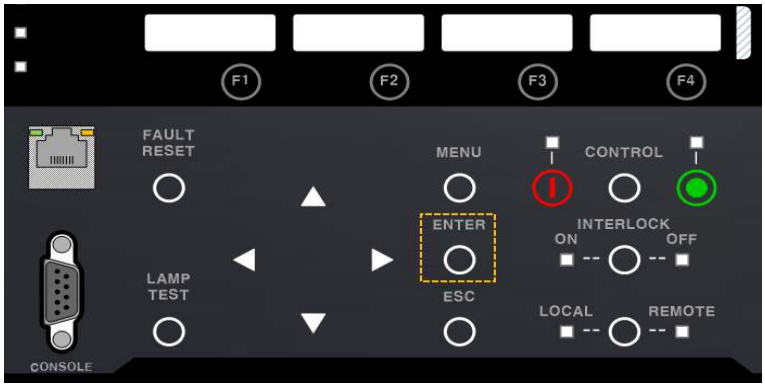


2) 'Move" while setting, controlling LCD and running test menu

① When moving to the menu on the display while other menu is running, touch "Display" menu on the LCD to go to the top menu on the display.

② Moving in the top menu on the display is the same as moving the above 'moving while the main menu on the LCD is running'.

3) Move using the front buttons



① When moving from the main menu, which is the initial screen of IM2, to the menu on the display, press the "Menu" button on the front of IM2 to go to the top menu on the display.

② To check information on IM2 version, go to the menu of "Version Information". The menu of "Version Information" is positioned at "Display>System>Version Information".

③ Use "Up, Down, Left, Right" button on the top menu of the Display to go to the "System" button among the buttons of the detailed menu. The movement of button can be checked by the indication of button selection.

④ When the button selection is activated, press "Enter" button to run the menu of "System".

⑤ Also use "Up, Down, Left, Right" menu in the "System" menu to go to "Version Information" button out of detailed menus. When the button selection is activated, press "Enter" button to run the menu of "Version Information".

⑥ The data of "Version Information" menu is displayed on the LCD.

⑦ When moving to the Display menu while other menus are running, Press "Menu" button on the front of IM2 to run. Pressing "Menu" button switches from the currently running menu to the next menu in the order of "Display" – "Setting" – "Control".

6.3. System

6.3.1. Version Information

- IM2 information and each version, including product name and model name of IM2, are displayed.

Item	Data
Product information	Product name
	Model name
	Product number
Firmware version	MPU
	DSP
	STB
Hardware version	Hardware

6.3.2. General Information

- Information is displayed, including Language of IM2, LCD backlighting time and clock synchronization.
- The generally set items are displayed as follows.

Item	Data
Time setting	Date
	Time
Offset of local time	Hour
	Minute
Clock synchronization	
How to access Wired_X	
Setting of single line diagram	Display of singled line diagram
	LED position for opening single line diagram
	Waiting time for the result of control
	Displaying the name of device on the single line diagram
General settings	Language setting / Language
	LCD backlight setting
	Displaying measurement phase

6.3.3. Information on network settings

- Communication network address of IM2 is displayed.
- IP addresses of Ethernet console port and SNTP server on the back of IED set by the operator are displayed, respectively.
- Network setting items are displayed as follows.

Item	Data
Ethernet console port	IP address
	Subnet mask
	Default gateway
SNTP server	IP address
	Subnet mask
	Default gateway
IEC 61850 port	IP address
	Subnet mask
	Default gateway

※ The settings of IEC 61850 port (IP address, subnet mask, default gateway) are applied to CID(Configured IED Description) files.

6.3.4. Information on settings of function buttons

- The operating elements of the total 4 function buttons of IM2 are displayed.

Item	Data
Settings of function button	Function button 1
	Function button 2
	Function button 3
	Function button 4

6.3.5. Information on measurement settings on the main screen

- Information on measurement items on the main screen of IM2 is displayed.
- The main screen displays up to 10 Measurement Items.

Item	Data
Measurement settings on the main screen	Measurement Item 1
	Measurement Item 2
	Measurement Item 3

	Measurement Item 4
	Measurement Item 5
	Measurement Item 6
	Measurement Item 7
	Measurement Item 8
	Measurement Item 9
	Measurement Item 10

6.3.6. Board Information

- Information on the type of AI board and IO board used by IM2 is displayed.
- Information on up to 2 AI boards and 5 IO boards is displayed.

Item	Data
AI Board	Board A
	Board B
IO Board	Board 1
	Board 2
	Board 3
	Board 4
	Board 5

6.3.7. Information on PBCU system

- Settings of clock synchronization and power of PBCU at IM2 can be checked.

Item	Data
Process Bus Live Config	PBCU On/Off
Process Bus Time Sync Mode	PTP /Local Time(RTC)
Process Bus Clock Sync Mode	PTP/PPS/GPS

6.3.8. Information on STB Time system

- Settings of clock synchronization of STB at IM2 can be checked.

Item	Data
Station Bus Time Sync Mode	SNTP/Internal Clock (PBCU)

6.3.9. PTP information

- Settings and status of PTP of IM2 can be checked.

Item	Data
Master offset	-
Path delay	-
Ingress time	-
Initial delay	-
Cumulative scaled rate offset	-
UTC offset	-
Local clock id	-
Current clock id	-
Current clock status	-
Delay Mechanism	Auto/E2E/P2P
Network Transport	UDS/UDP IPv4/UDP IPv6/IEEE 802.3/DEVICENET/CONTROLNET/PROFINET
Timestamping	Software/Hardware/Legacy H/W/One Step/P2P 1 Step
Slave Only	Enable/Disable
Priority 1	0~255
Priority 2	0~255
Domain Number	Default/ALTERNATE 1,2,3
Clock Class	0~255
Clock Accuracy	Unknown Accuracy/Within 25ns ~ >10s
Announce message period	(1 msg every 1/2/4/8 sec) / (2/4/8/16/32/64 msg every sec)
Sync. Message period	(1 msg every 1/2/4/8 sec) / (2/4/8/16/32/64 msg every sec)

Delay request message period	(1 msg every 1/2/4/8 sec) / (2/4/8/16/32/64 msg every sec)
PDelay request message period	(1 msg every 1/2/4/8 sec) / (2/4/8/16/32/64 msg every sec)
Announce receipt timeout	2~255
Sync Receipt timeout	0~255
Delay asymmetry	-2^{31}~2^{31}
Egress latency	-2^{31}~2^{31}
Ingress latency	-2^{31}~2^{31}

6.3.10. HSR/PRP Information

- The settings of communication redundancy of IM2 (HSR/PRP) are displayed.

Item	Data
Redundancy Mode	HSR/PRP
HSR Work Mode	Mode H/N/T/U
PRP Work Mode	Duplicate Discard/Duplicate Accept
HSR Ring Interface	HSR-SAN/HSR-HSR/HSR-PRP
Redundancy A Port Speed	100/1000
Redundancy B Port Speed	100/1000

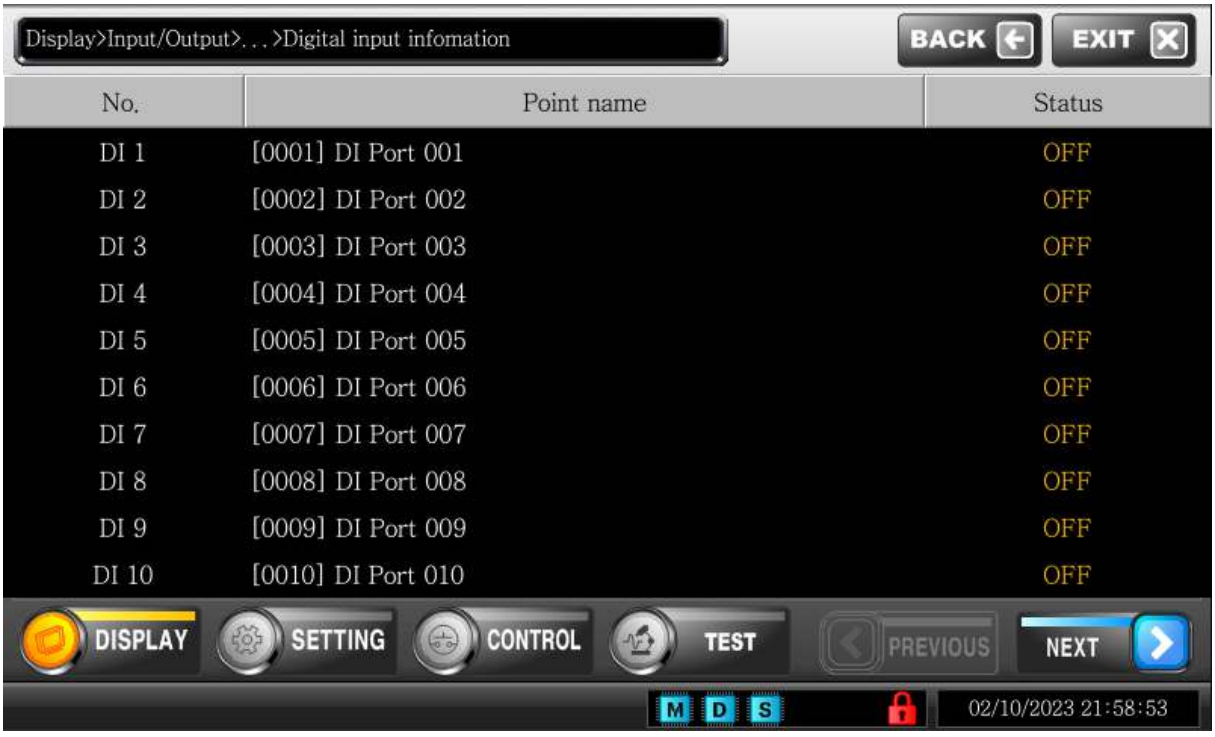
6.4. Input / Output

- Analog and digital information output/input in/from the corresponding IM2 are set in the screen below.

6.4.1. Information on contact input

- The operating value of the contact input of IM2 is displayed in real time.
- It is possible to check the status of contact input as many as the number of the mounted pointers, and the operating elements set by the operator are displayed on each number of physical point.
- Items of displaying information on contact input are as follows.

Item	Status	
Number	-	-
Point name	unused	The set point name
Status	Off	On



6.4.2. Information on contact output

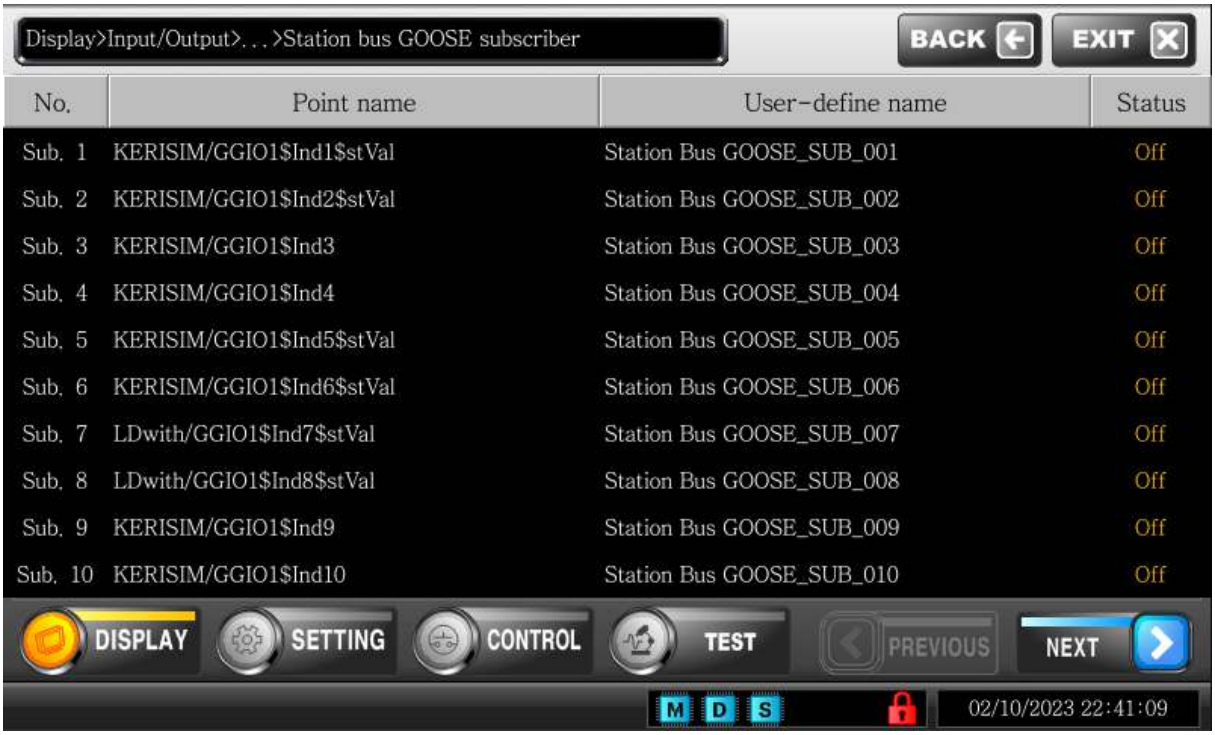
- The operating value of the contact output of IM2 is displayed in real time.

- It is possible to check the status of contact output as many as the number of the mounted pointers, and the operating elements set by the operator are displayed on each number of physical point.
- Items of displaying information on contact output are as follows.

Item	Status	
Number	-	-
Point name	unused	Name of the set point
Type of contact	Contact A	Contact B
Controlled output	OFF	ON
Status of contact	OFF	ON

- The screen displaying information on contact input/output is configured as follows.

6.4.3. GOOSE Information

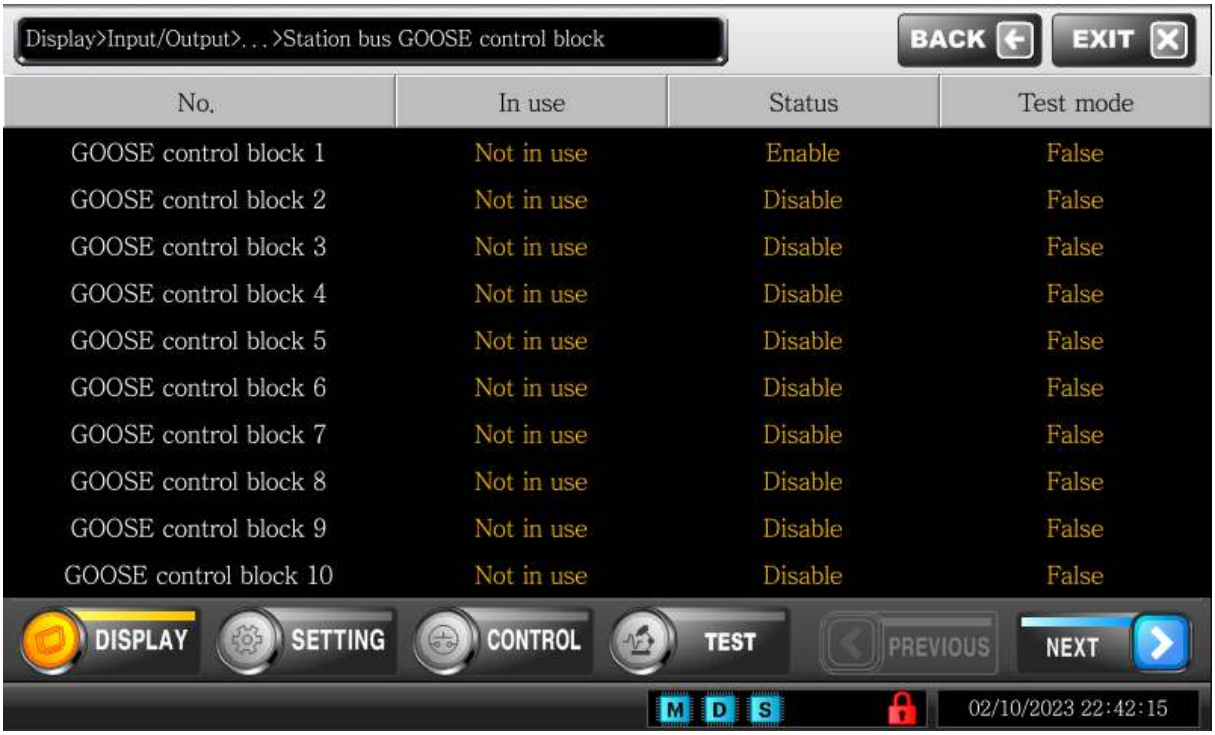


- The status of GOOSE publisher and subscriber is displayed.
- The operator can check the status of input and output of GOOSE messages in real time, and the use of each GOOSE control block.
- Items of GOOSE subscriber and publisher that can display status correspond to the elements

defined in the CID file for IEC 61850 communication.

- The point of GOOSE subscriber and publisher can additionally define "the User-defined names" via the operating software, and When a user defines 'the User-defined name", an operator can check the set point name and user-defined name together.
- It shows information on GOOSE subscriber and publisher of Station/Process Bus, respectively. The configuration of GOOSE status display in Station and Process bus is the same, so Station bus GOOSE display is shown as a representative.

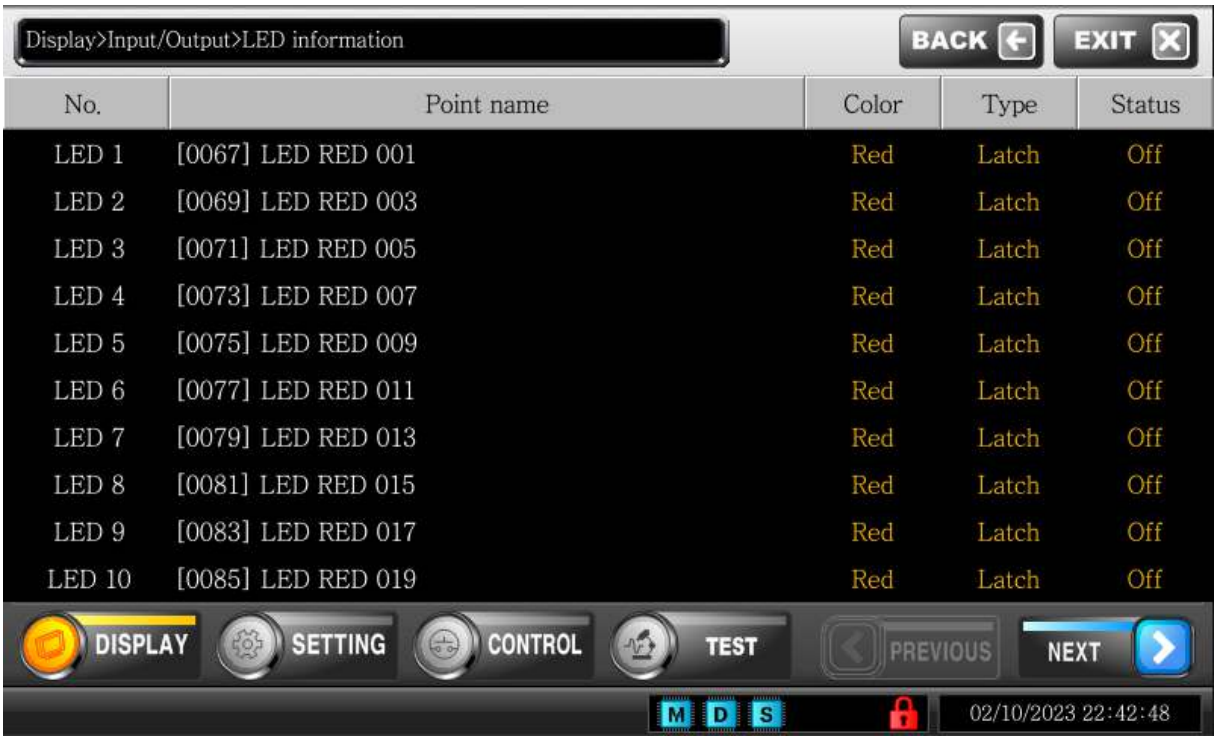
Item	Data
Station/Process Bus GOOSE subscriber	Point number
	Point name
	User-defined name
	Status
Station/Process Bus GOOSE publisher	Point number
	GoCB number
	Point name
	User-defined name
	Status
Station/Process Bus GOOSE control block	Point number
	In use or not in use
	Status
	Test mode



- The screen displaying GOOSE subscriber is configured as follows.

- GoCB number means the control block number to which the corresponding publisher point is transmitted, and GOOSE message is transmitted only when the setting of GOOSE control block is 'Enable'.
- The screen displaying GOOSE publisher is configured as follows.

- It shows the use and condition of GOOSE CB and test mode.



6.4.4. LED information

- It displays the monitoring elements and attributes of LED set using the front LCD and operating software. It displays the set value of each of the total 32 LEDs so that the operator can recognize them.
- The following Items are displayed.

Item	Status		
LED number	-	-	-
Point name	unused	Name of the set point	-
Color	Red	Green	Yellow
Type	PULSE	LATCH	-
Status	OFF	ON	

- LED operation by type
  - Operation when the type is PULSE: When LED monitoring element is turned on, and LED is turned on, and when LED monitoring element is turned off, LED is turned off .
  - Operation when the type is LATCH: When LED monitoring element is turned on, LED is turned on, and even when LED monitoring element is turned off, LED is not turned off. LED is turned out only when pressing “FAULT RESET” button on the front of HMI.
- LED information screen is configured as follows. When LED is set to ‘unused’, information on color and type is not displayed.

6.4.5. Information on Debounce Time

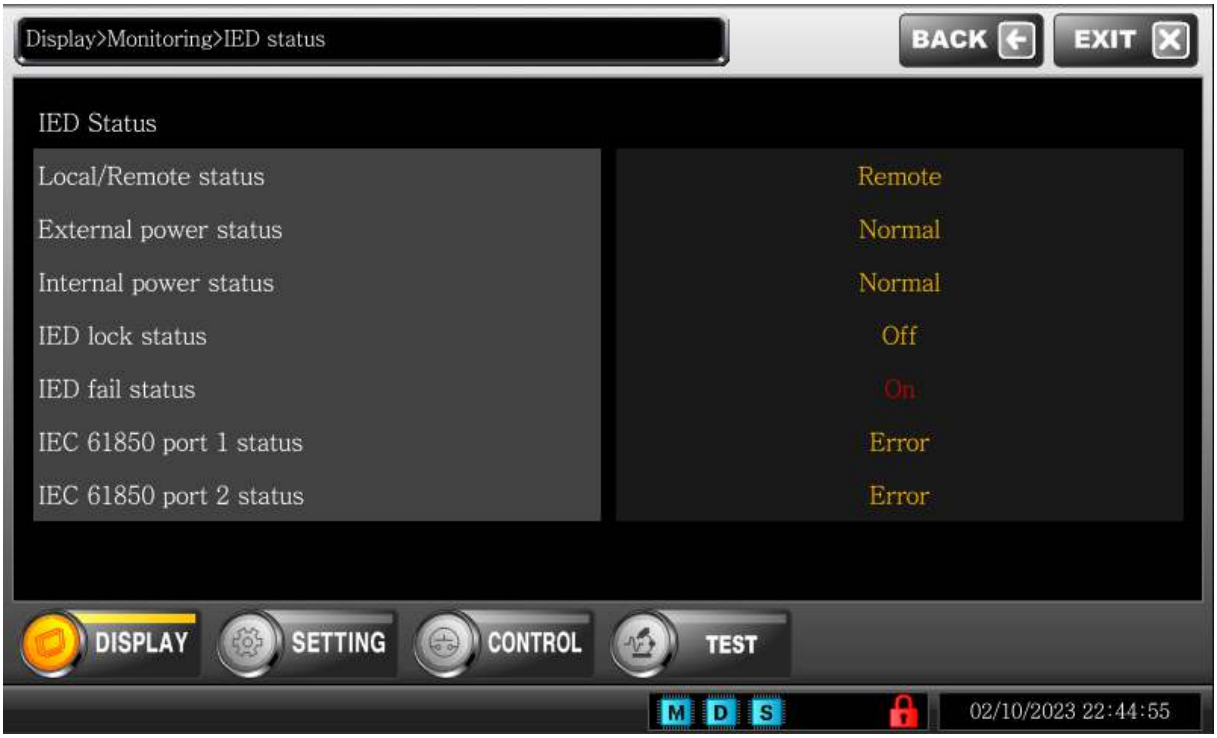
- With respect to the input contact, the debounce time for the input signal is displayed for each input contact.
- The input contact is 54 points, and the debounce time can be set in unit of 1ms from 1ms to 255ms.

6.4.6. Information on duration of control output

- When the output contact is operated, the output duration of each contact is displayed for each output contact.
- The output contact is 66 points, and the duration of the control output can be set in unit of 1ms from 1ms to 10000ms.

6.4.7. Information on the type of contact output

- When the output contact is operated, the type of contact is displayed for each output contact.
- The output contact is 66 points and the type of contact can be set to Latch and Pulse.



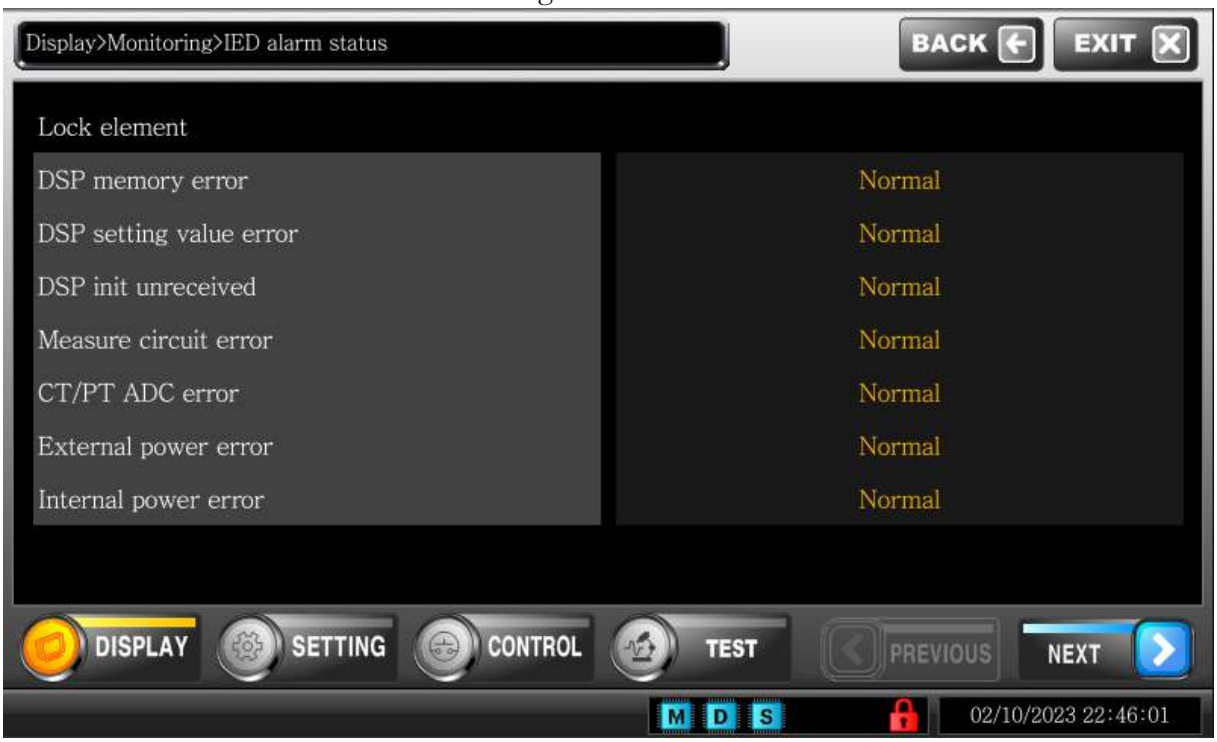
6.5. Monitoring

6.5.1. Operation Status of IED

- The operation status of IM2 is monitored in real time to check for its abnormalities.
- The operation status of IM2 displays the items below.

Item	Status	
Status of Local/Remote	Remote	Local
Status of input power	Normal	abnormal
Status of internal power	Normal	abnormal
Status of IED lock	Normal	abnormal
Status of abnormalities in IED	Normal	abnormal
Status of IEC 61850 port 1	Normal	abnormal
Status of IEC 61850 port 2	Normal	Abnormal

- The screen of IM2 operation status is configured as follows.

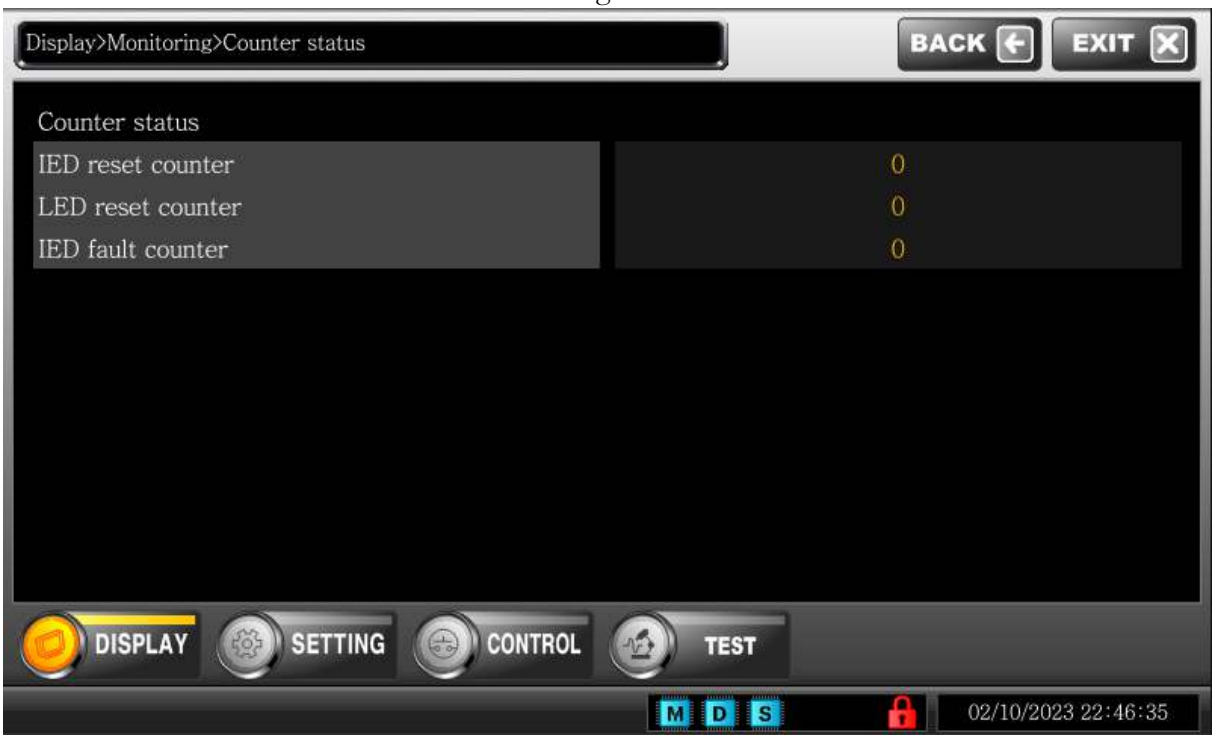


6.5.2. Alarm status of IM2

- The alarm status of IM2 is displayed in real time to determine the cause of status.

Alarm element for locking operation	Alarm element for 'not locking' operation
DSP memory is abnormal	DI circuit is abnormal
Set value of DSP is abnormal	DO circuit is abnormal
Initial set value of DSP is not received	DO contact is abnormal
Measurement circuit is abnormal	MPU event information is abnormal
CT/PT ADC is abnormal	The set value of MPU is abnormal
Input power is abnormal	IEC 61850 communication is abnormal
Internal power is abnormal	MPU processor is abnormal
-	DSP processor is abnormal
-	SMO processor is abnormal
-	STB processor is abnormal

- The screen of IM2 alarm status is configured as follows.

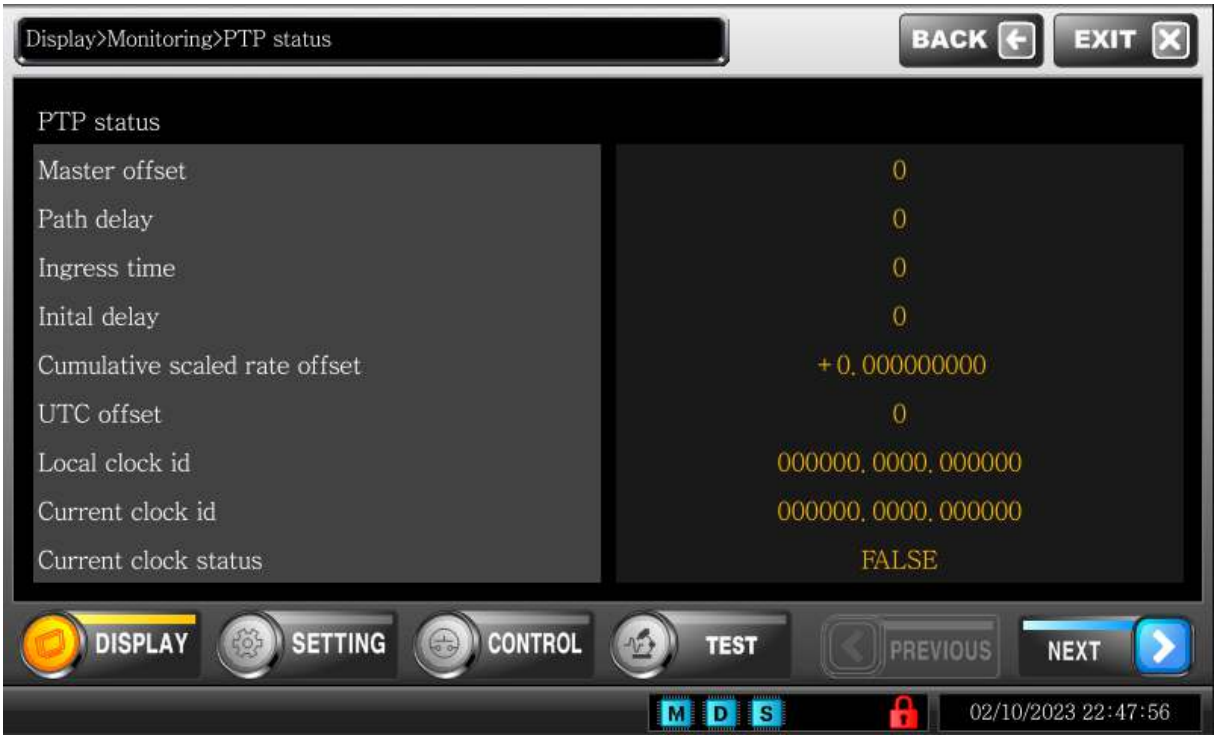


6.5.3. Status of Counter

- It displays the reset counter value of IM2. When IM2's internal reset and LED reset is operated, or failure occurs, each counter value increases.
- The status of counter displays the following items.

Item	Description
IM2 reset counter	The number of times IM2's own system has been rebooted is displayed
LED reset counter	The number of times the LED status has been initialized is displayed, using "Fault Reset" button on the front of HMI.
Counter for the occurrence of failure in IM2	The number of failures is displayed.

- The screen for the status of counter is configured as follows.



6.5.4. Status of PBCU System

- It displays the status of PBCU system.

6.5.5. PTP Status

- It displays the status and settings of PTP connected to IM2.

Display>Monitoring>PTP status
BACK
EXIT
PTP status
Announce message period
1 msg every 8 sec
Sync. message period
1 msg every 8 sec
Delay request message period
1 msg every 8 sec
Pdelay request message period
1 msg every 8 sec
Announce receipt timeout
0
Sync. receipt timeout
0
Delay asymmetry

6.5.6. HSR/PRP Status

- It displays HSR/PRP status of IM2.

6.6. Event

6.6.1. Alarm event

- Alarm event consists of items that stop the operation of IED and the user must check, out of elements that monitor the abnormal operation of IED.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The user can check in order of the latest history.
- Upon occurrence of alarm event, "ALARM" LED on the front is turned on and ALARM Data is transmitted to the upper level.
- Events include data of occurrence time for each item, event type and detailed items.

Items to be displayed	Description
Time	Event occurrence time: "YYYY/MM/DD hh:mm:ss:ms"
Type	Type of distinguishing alarm events is displayed.
Detailed Item	Detailed description according to the status that each type may have is displayed.

- For detailed items for alarm events, refer to "XI.2.A. Alarm Event".

6.6.2. Monitoring Event

- The monitoring event saves the unusual state that occurred during the operation of IM2.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The user can check in order of the latest history.
- Events include information on the occurrence time and event type for each item.

Item	Description
Time	Event occurrence time: "YYYY/MM/DD hh:mm:ss:ms"
Type	Item of event occurrence
Detailed Item	Detailed description according to the status that each type may have is displayed.

- For more details for monitoring event, refer to "XI.2.B. Monitoring Event".

6.6.3. Contact input event

- The contact input event monitors and save the status of changes in contact input point of IM2.
- Individual monitoring of the contact input point is performed, including the time of change in status, element name for the physical contact point set by the operator, and data on the status of contact input point.
- The time of change in status is monitored and saved in unit of 1ms.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The user can check in order of the latest history.
- One contact input event includes time, the name of contact input point, and information on the status of operation.

Item to be displayed	Description
Time	Event occurrence time: "YYYY/MM/DD hh:mm:ss:ms"
Point name	The element of DI operation point is displayed. The number of operated contact point and the operating element name set at the corresponding contact point are displayed.
Operation	The status of the input contact point is displayed. On(1) / Off(0)

6.6.4. Control Event

- Control event saves all control history according to the control command received from IM2.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The user can check in order of the latest history.
- One control event includes a total of 5 information: the occurrence time, position, type, object, and result of control.

Item	Description	Data
Time	Event occurrence time:	"YYYY/MM/DD hh:mm:ss:ms"
Type of control	Where the operator issued the control command	Input element (LCD, PC, 61850)
Name of control point	DO object operated by the operator	Output element
Result	Result of control action	Success
		Fail - Interlock
		Fail - Timeout

6.6.5. Communication event

- Communication event saves the CAN communication status between boards, and the history on the status of connection to the operating program.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The operator can check in order of the latest history.
- One communication event includes the occurrence time, event item and detailed item.
- Event items that can save using communication event are as follows.

Item	Data
Abnormal CAN communication occurs	CAN BUS ID
Abnormal CAN communication is released.	CAN BUS ID
Abnormal PCIF communication occurs	-
Abnormal PCIF communication is released.	-
Abnormal ADC SPI communication occurs.	ADC ID
Abnormal ADC SPI communication is released.	ADC ID
Connection to Wired-X	Access IP
Disconnection from Wired-X	Access IP

6.6.6. User event

- IM2 saves fault events when it detects faults in the system.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The operator can check in order of the latest history.
- Events include information on occurrence time for each item.
- Running the menu of fault event displays a list of fault events first, and selecting an item in the displayed list displays information on the detailed event of the selected item.

6.6.7. Setting event

- If the settings in operation is changed in IM2, it saves the setting event.
- It saves up to 2000 events, and if more than 2000 events occur, the latest event replaces the oldest event and is saved.
- The operator can check in order of the latest history.
- The event items that can be saved as the setting events are as follows.

Item to be displayed	Description
Time	Event occurrence time: "YYYY/MM/DD hh:mm:ss:ms"
Control	Position of the set change
Setting	Name of the set change
previous/changed set value	Changed value

7. Setting

7.1. Overview

- Changing the setting of IM2 affects critical operations of device, such as transmission of the sampled value, so it is recommended to set it only when it is not in operation. In addition, the setting function should be used after fully understanding the user manual.
- The current value can be checked and changed for all setting items.
- The setting function can be run only by the operator who has setting authority or admin authority. That is, a password corresponding to the authority must be entered.
- There are a settable range and unit for each item in order to prevent malfunction of IM2, and the value set by the operator is constantly monitored, but if the corresponding condition is not met, it is not applied to the internal operation of IM2.
- The set value is saved in the non-volatile memory inside IED, and can be permanently preserved.
- Saving the set value is possible only when the current status of IM2 is 'Local'.
- As soon as the operator changes and saves the set value, it is reflected in the internal operation of IM2.
- The status of IM2 must be returned to 'Remote' after the operator completes to change the set value.
- The menu tree for setting is as follows.

Menu for setting	Sub menu	Sub-sub menu
System	General setting	
	Network setting	
	Function button setting	
	Measurement setting of main screen	
	Correction of touch screen	
	Board setting	
	PBCU system setting	
	PTP setting	
	HSR/PRP setting	
Input/ Output	Contact setting	Setting of contact input
		Setting of contact output
	GOOSE setting	Setting the use of Station/Process Bus GoCB
		Setting the test mode of Station/Process Bus GoCB

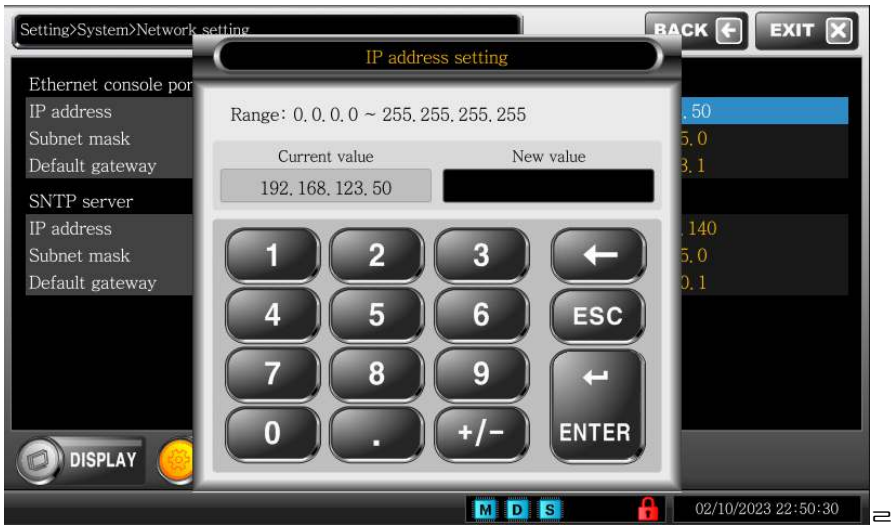
	LED setting	Setting of LED output
		Setting of LED color
		Setting of LED type
	Debounce setting	
	Setting of duration of control output	
	Setting the type of contact output	
Password	Password setting	

7.2. How to set

7.2.1. Items for setting numeric input

① When moving from the main menu, which is the initial screen of IM2, to the setting menu, touch the "Setting Menu" button on the LCD to go to the top setting menu.

② Enter password using the number button on the pop-up window for entering password, and then touch "Confirm" button.

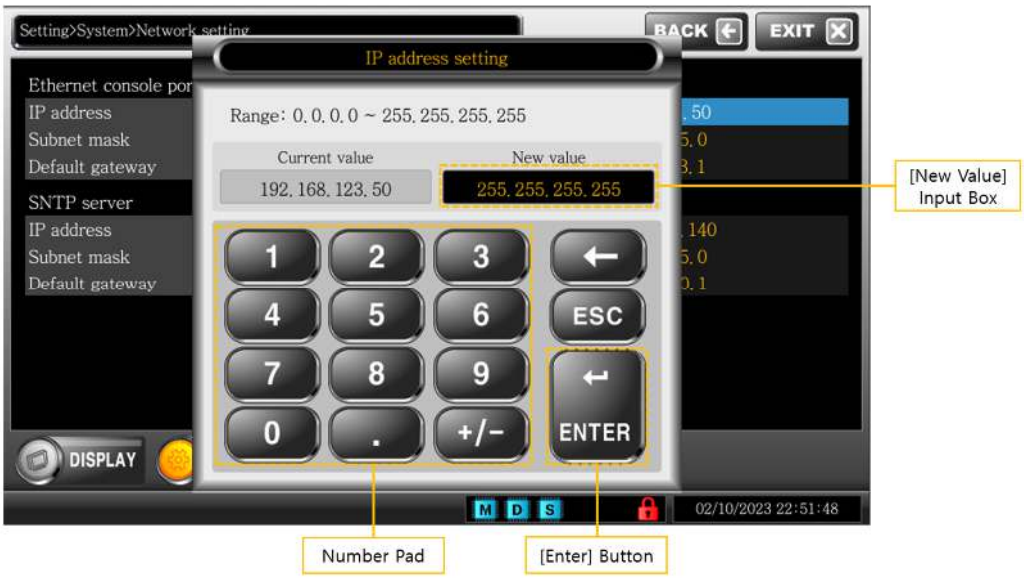


③ If the user move to the setting menu while other menu is running, touch "Setting" button on the LCD to go to the top setting menu.

④ For example, the user need to go to "Network Setting" menu to set up the device network. For checking the position of "Network Setting" menu, refer to the structure of the upper setting menu. "Network Setting" menu is positioned at 'Setting>System>Network Setting'.

⑤ Touch "System" button in the detailed menu displayed in the setting menu.

⑥ Touch "Network Setting" button to move, out of the detailed menus displayed in the system menu.

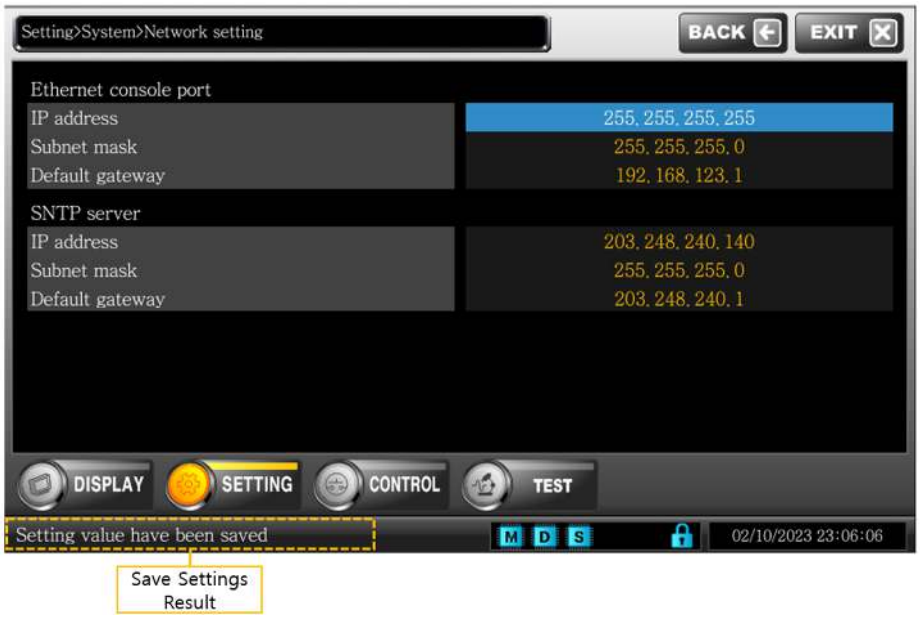


⑦ When the user touch "IP address" item out of items for setting device network, the pop-up window for setting IP address will appear.

⑧ Enter the IP addresses of device network in order from the beginning, using the number button. For example, if the user set the IP of '255.255.255.255', enter the number using the number button '2', '5', '5' and then press '.' button to go to the next input of number, and thereafter, press the number button. Enter the next numbers in the same way.

⑨ The entered setting value can be checked in the part of displaying the new setting value on the

pop-up window. Touch "Confirm" button after checking whether the entered setting value is correct.



⑩ The newly entered setting value is reflected and displayed in the "Network Setting" menu.

⑪ After completing to change the setting item, be sure to touch "Save" button at the top of the menu.

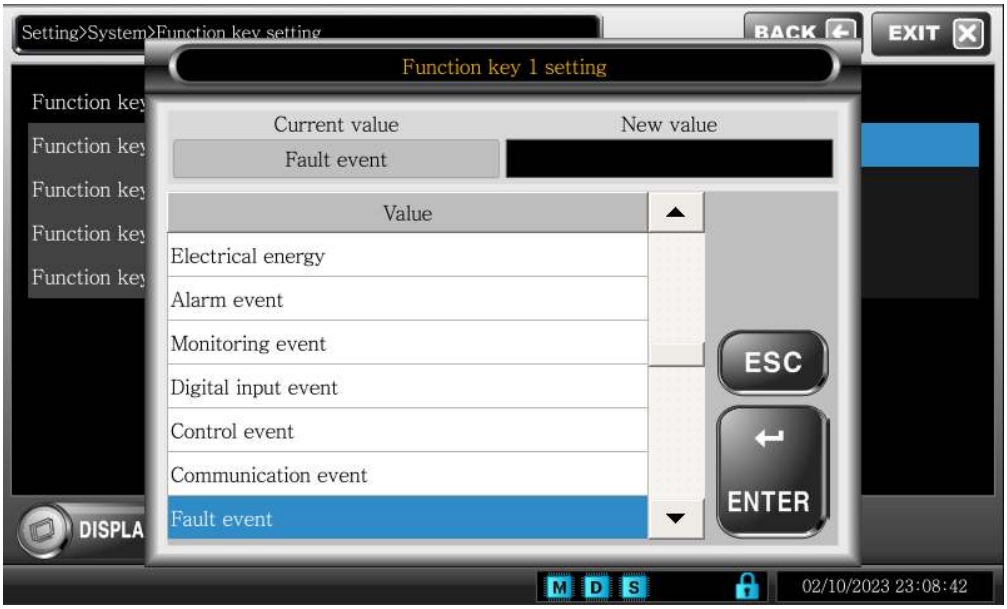
⑫ In order to prevent the erroneous operation of the reflected setting value, be sure to check once again on the pop-up window whether it is saved or not.

⑬ If the user touch “Save” button to save, the user can check the saving result in the status bar at the bottom.

⑭ If the user touch “Cancel” button, the saving is cancelled and the next operation is waited.

⑮ If the operator changes the set value, touch “Back” or “End” button to check whether the changed setting value is saved, and then move to “Back” or “End”.

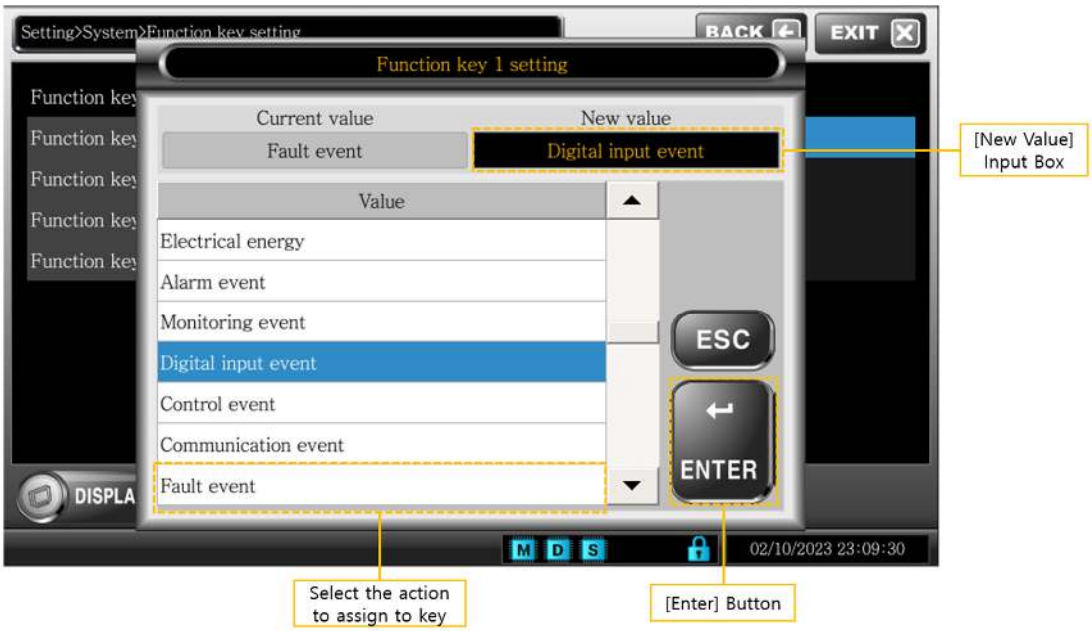
7.2.2. Items for selecting the setting list



① Move to the setting menu. “How to move” is the same as the method mentioned in the upper level ‘A) the setting of numeric input’.

② For example, in order to set the function button, the user need to go to “Setting of Function Button” menu. To check the position of “Setting of Function Button” menu, refer to the structure of the upper setting menu. “Setting of Function Button” menu is positioned at ‘Setting>System>Setting of Function Button’.

③ Touch “System” button among the detailed menus displayed in the setting menu.



④ Touch the relevant button to move, following the path from “System” menu to “Setting of Function Button” menu.

⑤ If the user touch Item “Function Button 2” out of Item for setting the function button, a pop-up window for setting appears.

⑥ The setting list is displayed on the pop-up window, and if the user touch the right scroll “Up/Down” button, the displayed list page moves.

⑦ If the user select a changed Item, the selected item will be activated. The selected setting value can be checked in the part of displaying the new setting value on the pop-up window. Be sure to check whether it is entered correctly, and then touch “Confirm” button.

⑧ The newly entered setting value is reflected and displayed in the "Setting of Function Button".

⑨ When the user complete to change the setting Item, be sure to touch "Save" button at the top of the menu.

⑩ To prevent erroneous operation of the reflected setting value, be sure to check once again on the pop-up window for checking 'Save" whether it is saved or not.

⑪ When the user touch "Confirm" button to save, the user can check the saving result in the status bar at the bottom.

7.2.3. System Menu

1) General Settings

- General settings allow the operator to set language, backlighting time, and how to synchronize clock and how to display the single line diagram.
- Date and Time: The current date and time of IED can be set.
  - Set Year (YYYY)/Month(MM)/Day (DD), Hour (hh):Minute (mm):Second (ss).
- Offset hour and minute of local time: It is the offset time to apply the time of each country to the received world standard time in synchronizing clock, etc., and basically set to "+9:00" in order to display the Korean standard time. The offset time must be changed depending on the state in which the clock synchronization system is built.
- Clock synchronization: It sets a method for synchronizing the time of IM2. The RTC clock synchronization method is used unless the setting is changed separately.
  - For clock synchronization, the user can select SNTP using server IP or clock synchronization using GPS.
- Setting of connection to Wired-X: It sets how to connect to Wired-X.
  - Wired-X can be selected as the connection method using TCP on the front/rear side, or using RS232C on the rear side.
- Display of single line diagram: If IEC symbol or LED symbol is set, the display of single line diagram on the main screen and the control screen. are changed.
- LED position for opening the single line diagram: It sets LED position for opening the single line diagram.
  - LED symbol is selected for displaying the single line diagram, and the function to change LED position of 'Open' (green)/Closed (red) is set to 'Left', 'Green (open)' is displayed at the left top of device (CB, DS, ES) symbol, and 'Red (closed)' is displayed at the right. If this function is set to 'Right', 'Red (closed)' is displayed at the left top of device (CB, DS, ES) symbol and 'Red (closed)' is displayed at the right.
- Waiting time for control result: It sets the waiting time for checking and running the result.
  - It sets time for checking the changed time of contact for checking the control result.
  - The settable range is from 1 to 60Sec, which can be set in a unit of 1Sec, and the default value is set to 5 Sec.
- Display of devices on the single line diagram: It sets whether the name of device is displayed on the single line diagram.
- Language setting/Language: It is possible to select language displayed on HMI, depending on the operator's convenience.

- LCD backlight time: It sets the time to turning off LCD backlight when the user does not touch or input on HMI LCD. If the user does not touch or input on LCD or button while setting "Backlight time", LCD backlight is turned off. When the front LCD is turned off, the screen and interlock return to the initial mode, and in such case, when selecting input of LCD touch or button, LCD backlight is turned on. However, the LCD backlight is not turned off in the state of 'Local'.
- Display of measurement phase: It sets how to display the phase value of measurement. If it is set to 'Negative angle', the phase value is displayed as ∠-359.99~∠0, and if it is set to 'Positive angle', the phase value is displayed as ∠0~∠359.99.

2) Network settings

- It can set communication port related to network communication of IM2, and information on access to network for external devices.
- It can set Ethernet console port on the front of IM2 and network of SNTP server (IP address, subnet mast, default gateway).

3) Setting the function button

- It sets whether to use a total of 4 function buttons, and their operation elements.
- It sets operation elements of each function button so that the operator can perform his/her desired function with the simple pressing of button on the front.

4) Setting the measurement on the main screen

- It sets whether to use a total of 10 measurement items, and measurement elements.
- Variable setting of items for displaying measurement can be set.
- If the user set measurement elements to be displayed on the main screen, they appear on the main screen in order.

5) Calibration of touch screen

- This is a menu to calibrate LCD touch screen, and calibrating the touch screen is in order of "Left_Top", "Right_Top", "Right_Bottom", "Left_Bottom", "Center", which is carried out, touching the center of the cross mark on the screen.

6) Board setting

- It sets the types on A and B of AI board connected to IM2.

7) Setting the PBCU system

- It can set the status and clock synchronization of PBCU.

8) PTP Setting

- For normal PTP synchronization, the following IM2 PTP settings must be compatible with PTP settings of devices connected to the starters.

9) HSR/PRP Setting

- Communication redundancy (HSR/PRP) can be set as follows. For normal operation, it must be set in the same way as devices connected to the same network.

7.2.4. Input/ Output Menu

1) Setting of contact input

- It sets the operation elements to be used for each contact point of input.
- Input contact can be set as many as the number of the mounted points, and the same operation elements cannot be set in duplicate.

2) Setting of contact output

- It sets the operation elements to be used for each contact point of output.
- Output contact can be set as many as the number of the mounted points, and the same operation elements can be set in duplicate.

※ Of elements to set the contact output in the table of the set value, some elements **must be assigned to contact B among DO points.**

3) Setting of whether to use GoCB

- In order to transmit IM2's information to GOOSE, the operator must set whether to use GOOSE control block as "Enable".
- The usable GOOSE control block is 'item in GOOSE control block' defined in the CID file for IEC 61850 communication, and can be activated in the menu to set whether to use it or not.
- Up to 15 GOOSE control blocks can be set.
- If the state of GOOSE control block is set to 'Enable', GOOSE information is transmitted to the corresponding GOOSE control block.

4) Setting of GoCB test mode

- It is set when transmitting IM2's information to GOOSE in the state of test mode.
- If the test mode for GOOSE control block is set to 'True', Test bit is set and transmitted at the time of transmitting GOOSE.
- The usable GOOSE control block is 'item in GOOSE control block' defined in the CID file for IEC 61850 communication, and can be activated in the menu to set the test mode.
- GOOSE control block is up to 20, and the test mode therefor can be set.
- Be sure not to change the test mode for GOOSE control block while IM2 is in operation.

5) Setting of LED output

- It sets monitoring elements to be applied to LED on the front of IM2 that displays a total of 32 operating status.
- It has information on color and type to be displayed on LED for each monitoring element, and information on LED setting can be checked at 'Display>Input/Output>LED Information'.

6) Setting of LED color

- It sets colors to be applied to LED on the front of IM2 that displays a total of 32 operating status.
- It has information on color and type to be displayed on LED for each monitoring element, and information on LED setting can be checked at 'Display>Input/Output>LED Information'.

7) Setting of LED type

- It sets types to be applied to LED on the front of IM2 that displays a total of 32 operating status.
- It has information on color and type to be displayed on LED for each monitoring element, and information on LED setting can be checked at 'Display>Input/Output>LED Information'.

8) Setting of debounce time

- With respect to the input contact, the debounce time for the input signal can be set for each input contact.

9) Setting the duration of control output

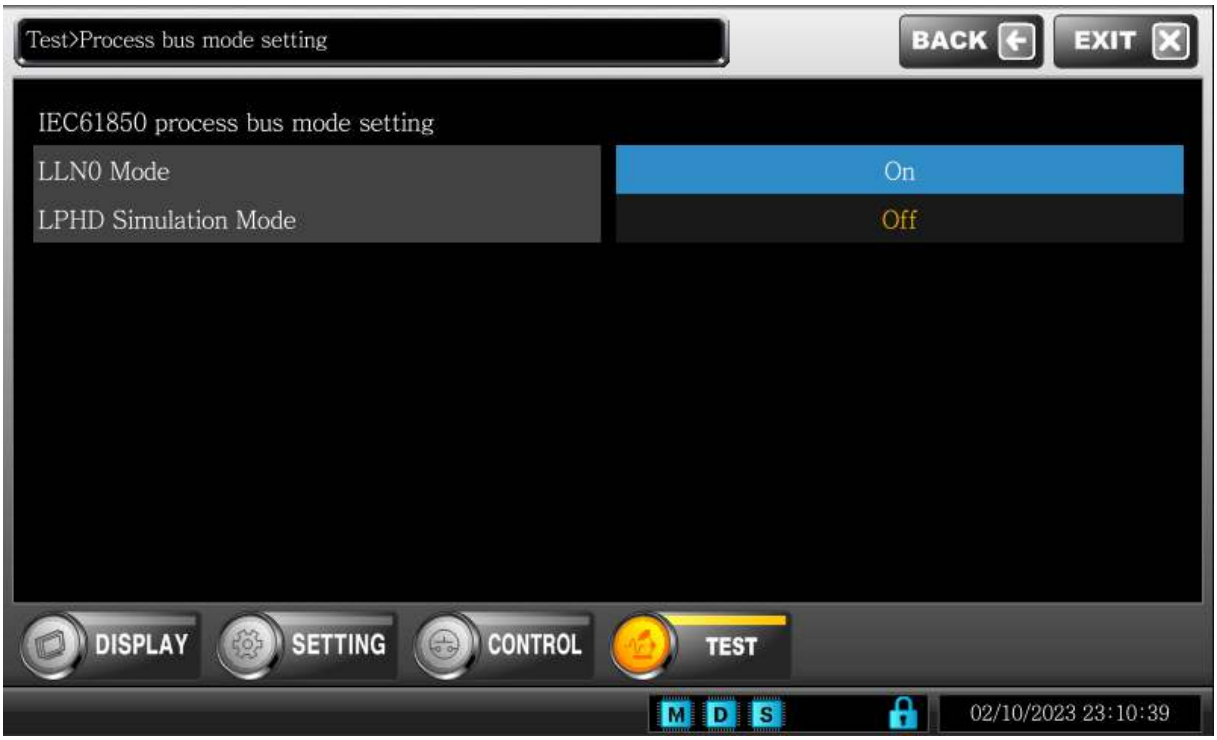
- When the output contact operates, the duration of contact output can be set for each contact output.
- If the output element is Pulse type, this duration is applied as the time when the output contact is maintained as 1.
- If the output element is Latch type, this duration is applied as the time when the output contact is maintained as 1 after the element is released.

10) Setting the type of contact output

- The set value can be set to Latch and Pulse, and its initial value is Latch.

11) Password setting

- If provide a function to set a password for each authority, such as setting, control and admin.
- Passwords are classified (setting, control, admin) in the same way as the classification of authority, and can be set after going through the procedures for verifying the password for the authority (a function that allows the user to change the password only if the password is the same when entering the existing password before changing the password).
- A password consists of four digits.
- When entering a password, numbers are not displayed, and the input value is displayed as '*'.
- If the user forgets the password after specifying it, the user should contact a manufacturer to set the password again after resetting the system.



7.3. Test

7.3.1. Outline

- In order to enter the test tab, the user should set any tab (display, setting, control) on the main screen to enter, and can see it at the bottom. In the test tab, the user can change the mode of LLN0 and LPHD according to IEC 61850 standard for each Station/Process bus.

- The contents of Station bus and Process Bus are the same as below. When LPHD mode is turned on, the simulated measurement information is updated instead of the measurement values. GOOSE, SV and MMS Report are transmitted or stopped depending on LLN0 value.

Test>Process bus mode setting

8. Installation

8.1. Overview

IM2 must be shipped, stored and installed carefully. Be sure to select an installation place where can easily connect to the communication and access the HMI on the front of IM2. Be sure to check whether the external wiring is properly connected and correctly disconnected to IM2, and pay special attention to grounding. Strictly observe the applicable guidelines contained in this Section.

8.2. Safety Guideline

Hardware of IM2 can be replaced only by the trained personnel. Always comply with the basic preventive measures to avoid damage caused by electrostatic discharge when handling IM2.

In some cases, the settings must be changed and applied as required by the engineering configuration after replacement. Therefore, the responsible personnel must be familiar with the setting of device.

8.3. Installation position and ambient conditions

IM2 must not be exposed to excessive air pollution (dust, toxic substances). In addition, be sure to avoid severe vibration, extreme temperature change, high humidity, high amplitudes and short rise time, and strong induced magnetic fields as much as possible. Excessively high temperature may materially reduce the operating life of IM2.

8.4. Conditions of cable connection

Cables of 20M or shorter must be used to obtain the precision provided by IM2. Precision is not guaranteed for cables longer than 20M.

9. Maintenance

9.1. Overview

IM2 provides alarms and events for problems occurred during filed operation, and describes countermeasures for the alarms.

If you make an mistake in settings and IM2 fails to function correctly, we will demonstrate how to restore your settings.

Once you are satisfied with the modifications you have made to the settings and IM2 is functioning correctly, I will demonstrate how to back up those settings.

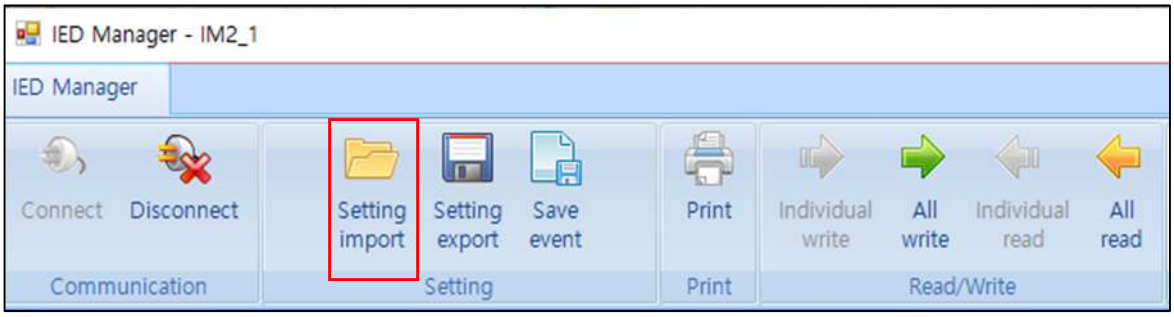
9.2. Countermeasures taken when ARM LED is turned on

The situations in which ARM LED is turned on are described in the table below, and the countermeasures can be taken as follows. In addition, a temporary network failure may be the main cause, so it may be necessary to power off/on or reset the network switch device connected to IM2.

Alarm Information	Alarm details	Troubleshooting
PTP master clock synchronization fail	PTP Fail : 1. The PTP master is not on the network. 2. Network DELAY MECHANISM is not identical to each other.	This is an alarm that occurs when the Grand Master device and PTP are not synchronized. Be sure to check whether the status and setting information of the network and the Grand Master match the device.
HSR/PRP switch Port N link down	Sampled value transport Network N port link down.	This is an alarm that occurs when a redundant port link is down. Be sure to check the status of network.
IEC61850 port link down	Communication Port all link down.	This is an alarm that occurs when all links of the redundant ports are down. Be sure to check the network status, the speed of SFP (optical module) and whether HSR/PRP matches the mode of network configuration.

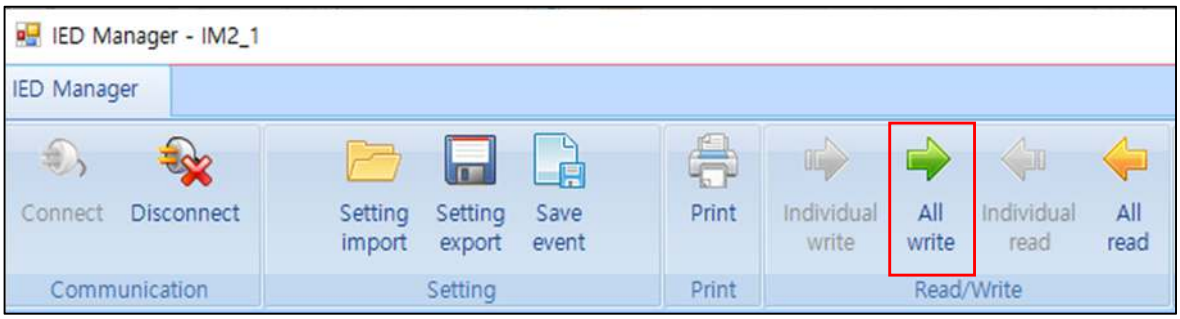
Alarm Information	Alarm details	Troubleshooting
Internal power abnormality occur	Internal power anomaly detection	This is an event that occurs when the internal circuit is abnormal. Be sure to contact the maker after checking.
ADC(N) power abnormality occur	ADC(N) reference power anomaly detection	This is an event that occurs when the internal circuit is abnormal. Be sure to contact the maker after checking.
ADC(N) status abnormality occur	ADC(N) channel status anomaly detection	This is an abnormality in internal circuit or problems with ADC. Be sure contact the maker.
External Power abnormality occur	External input power anomaly detection	This is an alarm caused by an abnormality in external power. Be sure to check the external power and contact the maker.
PPS Input abnormality occur	No 1PPS input	Be sure to check the PPS Input entered from the outside and whether a rising edge occurs every second using an oscilloscope, etc.
DPLL Synchronization Fail	Detects when the external global sync signal and internal PLL signal are out of sync.	This is an alarm that occurs when there is no input of PTP or PPS from the outside. Be sure to contact the maker. If an external global synchronizer exist, it is an internal logic problem.

<Information, type and explanation on alarm>



9.3. Countermeasures taken when COMM LED is turned off

Lights-out of COMM LED occurs when all links of redundancy (HSR/PRP) are down, so it is required to check the status of communication. Be sure to check whether the network status, the speed of SFP (optical module) matches the speed of network configuration, as well as whether the speed of HSR/PRP port is set to the same speed as the SFP, or whether the mode of network configuration is the same as the device setting.

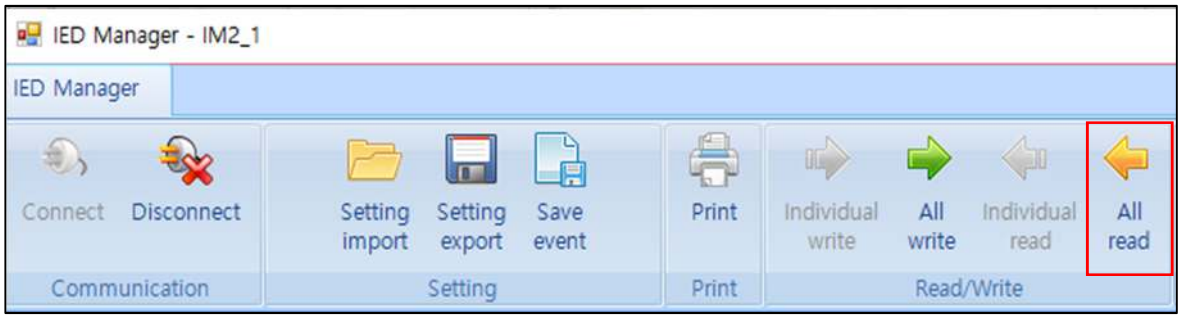


- If the network configuration is HSR, the device setting is also HSR, and if the network configuration is PRP, the device setting is also PRP.
- If the network configuration is 100Mbit/s, the speeds of SFP and Redundancy Port are also set to 100Mbit/s.

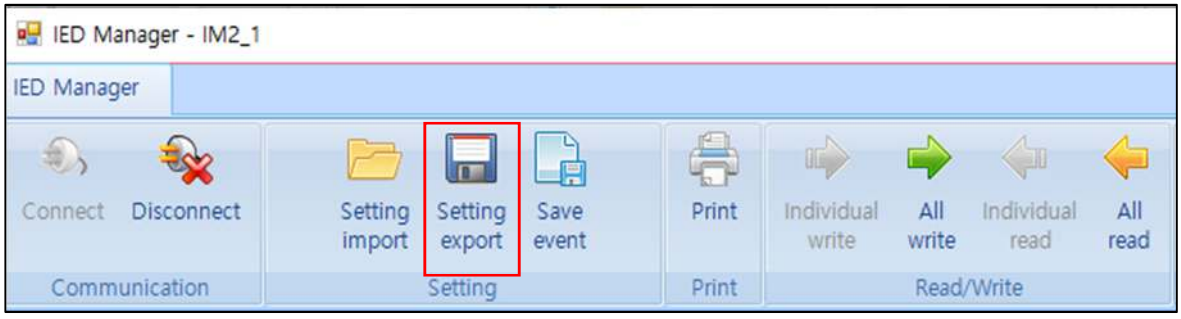
9.4. Recovery / Restore

If the IM2 is in operation and user change the settings incorrectly, causing the IM2 to behave abnormally, you can recover the IM2 to its previous settings or to the settings it had when it was shipped. (When restoring to the settings provided at delivery, any settings that have changed since delivery will need to be re-set by the user.)

Launch Wired-X and connect the IM2. Click the "Setting import" button to select a working setting file or the setting file provided at delivery, and the settings from the file will be loaded into Wired-X. (If the loaded Wired-X settings differ from the current Wired-X settings, they will be highlighted in red.)



Then, press the "All write" button to download the settings from the Wired-X to the IM2, and complete the recovery process.



9.5. Backup

You'll often change settings while running IM2. Once you have verified that IM2 is working properly with the settings you have changed, it is recommended that you back up those settings.

Firstly press the "All read" button to upload the settings from the IM2 to the Wired-X.

After pressing the "export settings" button, you will be prompted for the name and path of the file to be saved. Specify the name and path and Wired-X's settings will be saved as a file.

10. Appendix

10.1. Abbreviation

Abbreviation	Explanation
AI	Analog Input
AT	Analog Terminal
BFI	Break Failure Initiation
BRCB	Buffered Report Control Block
CB	Circuit Breaker
CB	Control Block
CBO	Check Before Operating
CID	Configured IED Description
COS	Change Of Status
CPT-AI	Current/Potential Transformer – Analog Input
CPU	Central Processing Unit
CT	Current Transformer
DI	Digital Input
IM2	Intelligent Merging Unit 2
DO	Digital Output
DPRAM	Dual-Port Random Access Memory
DS	Disconnecting Switch
DPC	Controllable Double Point
DSP	Digital Signal Processor
DT	Digital Terminal
EEPROM	Electrically Erasable Programmable Read-Only Memory
ES	Earth Switch
FA	Frame Address
FB	Function Block
FG	Frame Ground
FPGA	Field Programmable Gate Array
FT	Frame Time
FTP	File Transfer Protocol
GCB	GOOSE Control Block
GOOSE	Generic Object Oriented Substation Event
HMI	Human Machine Interface
HOC	High-set Over Current
HPI	Host-Port Interface
ICD	IED Capability Description
IEC	International Electrotechnical Commission
IED	Intelligent Electronic Device

LCD	Liquid Crystal Display
LD	Logical Device
LED	Light Emitting Diode
LN	Logical Node
MMS	Manufacturing Message Specification
MPU	Micro Processor Unit
PC	Personal Computer
RCB	Report Control Block
REF	Restricted Earth Fault
RTC	Real Time Clock
SBO	Select Before Operating
SCADA	Supervisory Control And Data Acquisition
SCD	Substation Configuration Description
SCL	Substation Configuration Language
SDRAM	Synchronous Dynamic Random Access Memory
SLD	Single Line Diagram
SMPS	Switching-Mode Power Supply
SMPU	Signal Main Processor Unit
SNTP	Simple Network Time Protocol
SPC	Controllable Single Point
SOE	Sequence Of Events
STB	STation Bus
URCB	Unbuffered Report Control Block
UTC	Universal Time Coordinated

10.2. Tables & Lists

- Time setting

Item	Unit	Min.	Max.	Step	Initial value
Year	-	2000	2099	1	-

Preface

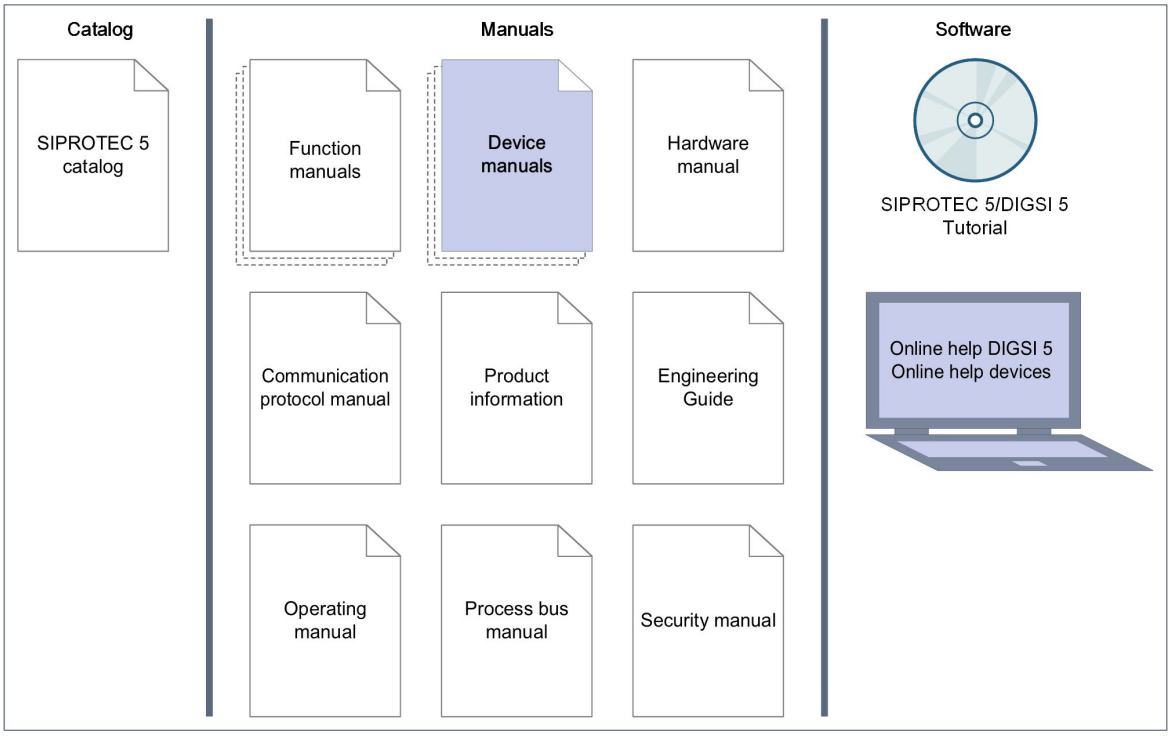
Purpose of the Manual

This manual describes the functions for transformer protection.



Target Audience

Protection system engineers, commissioning engineers, persons entrusted with the setting, testing and maintenance of automation, selective protection and control equipment, and operational crew in electrical installations and power plants.

Scope

This manual applies to the SIPROTEC 5 device family.

Further Documentation

[dw_product-overview_SIP5_device-manual, 5, en_US]

- Device manuals
  Each Device manual describes the functions and applications of a specific SIPROTEC 5 device. The printed manual and the online help for the device have the same informational structure.
- Hardware manual
  The Hardware manual describes the hardware building blocks and device combinations of the SIPROTEC 5 device family.

- Operating manual

  The Operating manual describes the basic principles and procedures for operating and assembling the devices of the SIPROTEC 5 range.

- Communication protocol manual

  The Communication protocol manual contains a description of the protocols for communication within the SIPROTEC 5 device family and to higher-level network control centers.

- Security manual

  The Security manual describes the security features of the SIPROTEC 5 devices and DIGSI 5.

- Process bus manual

  The process bus manual describes the functions and applications specific for process bus in SIPROTEC 5.

- Product information

  The Product information includes general information about device installation, technical data, limiting values for input and output modules, and conditions when preparing for operation. This document is provided with each SIPROTEC 5 device.

- Engineering Guide

  The Engineering Guide describes the essential steps when engineering with DIGSI 5. In addition, the Engineering Guide shows you how to load a planned configuration to a SIPROTEC 5 device and update the functionality of the SIPROTEC 5 device.

- DIGSI 5 online help

  The DIGSI 5 online help contains a help package for DIGSI 5 and CFC.

  The help package for DIGSI 5 includes a description of the basic operation of software, the DIGSI principles and editors. The help package for CFC includes an introduction to CFC programming, basic examples of working with CFC, and a reference chapter with all the CFC blocks available for the SIPROTEC 5 range.

- SIPROTEC 5/DIGSI 5 Tutorial

  The tutorial on the DVD contains brief information about important product features, more detailed information about the individual technical areas, as well as operating sequences with tasks based on practical operation and a brief explanation.

- SIPROTEC 5 catalog

  The SIPROTEC 5 catalog describes the system features and the devices of SIPROTEC 5.

Indication of Conformity

CE

This product complies with the directive of the Council of the European Communities on harmonization of the laws of the Member States concerning electromagnetic compatibility (EMC Directive 2014/30/EU), restriction on usage of hazardous substances in electrical and electronic equipment (RoHS Directive 2011/65/EU), and electrical equipment for use within specified voltage limits (Low Voltage Directive 2014/35/EU).

This conformity has been proved by tests performed according to the Council Directive in accordance with the product standard EN 60255-26 (for EMC directive), the standard EN IEC 63000 (for RoHS directive), and with the product standard EN 60255-27 (for Low Voltage Directive) by Siemens.

The device is designed and manufactured for application in an industrial environment.

The product conforms with the international standards of IEC 60255 and the German standard VDE 0435.

Standards

IEEE Std C 37.90

The technical data of the product is approved in accordance with UL.

For more information about the UL database, see *ul.com*

You can find the product with the **UL File Number E194016**.

Notes on Safety

This document is not a complete index of all safety measures required for operation of the equipment (module or device). However, it comprises important information that must be followed for personal safety, as well as to avoid material damage. Information is highlighted and illustrated as follows according to the degree of danger:

DANGER

DANGER means that death or severe injury **will** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid death or severe injuries.

WARNING

WARNING means that death or severe injury **may** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid death or severe injuries.

CAUTION

CAUTION means that medium-severe or slight injuries **can** occur if the specified measures are not taken.

✧ Comply with all instructions, in order to avoid moderate or minor injuries.

NOTICE

NOTICE means that property damage **can** result if the measures specified are not taken.

✧ Comply with all instructions, in order to avoid property damage.

NOTE

Important information about the product, product handling or a certain section of the documentation which must be given attention.

Qualified Electrical Engineering Personnel

Only qualified electrical engineering personnel may commission and operate the equipment (module, device) described in this document. Qualified electrical engineering personnel in the sense of this document are people who can demonstrate technical qualifications as electrical technicians. These persons may commission, isolate, ground and label devices, systems and circuits according to the standards of safety engineering.

Proper Use

The equipment (device, module) may be used only for such applications as set out in the catalogs and the technical description, and only in combination with third-party equipment recommended and approved by Siemens.

Problem-free and safe operation of the product depends on the following:

- Proper transport
- Proper storage, setup and installation
- Proper operation and maintenance

When electrical equipment is operated, hazardous voltages are inevitably present in certain parts. If proper action is not taken, death, severe injury or property damage can result:

- The equipment must be grounded at the grounding terminal before any connections are made.
- All circuit components connected to the power supply may be subject to dangerous voltage.
- Hazardous voltages may be present in equipment even after the supply voltage has been disconnected (capacitors can still be charged).
- Operation of equipment with exposed current-transformer circuits is prohibited. Before disconnecting the equipment, ensure that the current-transformer circuits are short-circuited.
- The limiting values stated in the document must not be exceeded. This must also be considered during testing and commissioning.

Selection of Used Symbols on the Device

Nr.	Symbol	Beschreibung
1		Direct current, IEC 60417, 5031
2		Alternating current, IEC 60417, 5032
3		Direct and alternating current, IEC 60417, 5033
4		Earth (ground) terminal, IEC 60417, 5017
5		Protective conductor terminal, IEC 60417, 5019

Nr.	Symbol	Beschreibung
6		Caution, risk of electric shock
7		Caution, risk of danger, ISO 7000, 0434
8		Protective insulation, IEC 60417, 5172, safety class II devices
9		Guideline 2002/96/EC for electrical and electronic devices
10		Guideline for the Eurasian market
11		Mandatory conformity mark for electronics and electrotechnical products in Morocco
12		Extra low voltage (ELV), IEC 60417, 5180, Safety Class III devices

OpenSSL

This product includes software developed by the OpenSSL Project for use in OpenSSL Toolkit (*http://www.openssl.org/*).

This product includes software written by Tim Hudson (*tjh@cryptsoft.com*).

This product includes cryptographic software written by Eric Young (*eay@cryptsoft.com*).

Table of Contents

Preface ... **3**

1 Introduction ... **51**

1.1 General ... 52

1.2 Properties of SIPROTEC 5 ... 53

1.3 Overview of Transformer Protection Devices ... 54

2 Basic Structure of the Function ... **57**

2.1 Embedding of Functions in the Device ... 58

2.2 Application Templates/Adaptation of Functional Scope ... 64

2.3 Function Control ... 66

2.4 Text Structure and Reference Number for Settings and Indications ... 72

2.5 Information Lists ... 74

3 System Functions ... **75**

3.1 Indications ... 76

3.1.1 General ... 76

3.1.2 Reading Indications on the On-Site Operation Panel ... 76

3.1.3 Reading Indications from the PC with DIGSI 5 ... 78

3.1.4 Displaying Indications ... 79

3.1.5 Logs ... 82

3.1.5.1 General ... 82

3.1.5.2 Operational Log ... 83

3.1.5.3 Fault Log ... 85

3.1.5.4 Ground-Fault Log ... 86

3.1.5.5 Setting-History Log ... 88

3.1.5.6 User Log ... 90

3.1.5.7 Communication Log ... 91

3.1.5.8 Communication-Supervision Log ... 93

3.1.5.9 Security Log ... 94

3.1.5.10 Device-Diagnosis Log ... 95

3.1.5.11 Motor-Starting Log ... 96

3.1.6 Saving and Deleting the Logs ... 98

3.1.7 Spontaneous Indication Display in DIGSI 5 ... 100

3.1.8 Spontaneous Fault Display on the On-Site Operation Panel ... 100

3.1.9 Stored Indications in the SIPROTEC 5 Device ... 102

3.1.10 Application Mode/Test Mode and Influence of Indications on Substation Automation Technology ... 103

3.1.11 Resetting Stored Indications of the Function Group ... 103

3.2 Measured-Value Acquisition ... 104

3.3 Sampling-Frequency Tracking and Frequency Tracking Groups ... 106

3.3.1 Overview ... 106

3.3.2 Sampling-Frequency Tracking ... 106
3.3.3 Frequency Tracking Groups ... 109
3.3.4 Frequency Tracking Groups – Interpretation of Measured Values ... 114
3.4 Processing Quality Attributes ... 116
3.4.1 Overview ... 116
3.4.2 Quality Processing/Affected by the User for Received GOOSE Values ... 118
3.4.3 Quality Processing/Affected by the User in CFC Charts ... 124
3.4.4 Quality Processing/Affected by the User in Internal Device Functions ... 128
3.5 Fault Recording ... 133
3.5.1 Overview of Functions ... 133
3.5.2 Structure of the Function ... 133
3.5.3 Function Description ... 133
3.5.4 Application and Setting Notes ... 137
3.5.5 Settings ... 140
3.5.6 Information List ... 141
3.6 Protection Communication ... 142
3.6.1 Overview ... 142
3.6.2 Protection Communication in the Overall System ... 143
3.6.3 Function Description ... 143
3.6.4 Available Variants for the Protection Communication ... 153
3.6.5 Classic Protection Communication ... 154
3.6.5.1 Overview ... 154
3.6.5.2 Classic Protection Communication in the Overall System ... 154
3.6.5.3 Structure of the Function Group ... 154
3.6.5.4 Configuration of the Protection Interface in DIGSI 5 ... 156
3.6.5.5 Setting Notes for the Device Combination ... 157
3.6.5.6 Setting Notes on Selecting the Communication Medium ... 160
3.6.5.7 Setting Notes for the Classic Protection Interface ... 161
3.6.5.8 Indications and Measured Values in the Classic Protection Interface ... 165
3.6.5.9 Remote Data ... 170
3.6.5.10 Constellation Measured Values for Type 1 and Type 2 ... 177
3.6.5.11 Settings ... 178
3.6.5.12 Information List ... 179
3.6.6 Advanced Protection Communication ... 181
3.6.6.1 Overview ... 181
3.6.6.2 Advanced Protection Communication in the Overall System ... 182
3.6.6.3 Structure of the FG Protection Communication ... 182
3.6.6.4 Configuration of the Advanced Protection Communication in DIGSI 5 ... 184
3.6.6.5 Setting Notes for the Protection Interface ... 188
3.6.6.6 Indications and Measured Values of the Advanced Protection Interface ... 192
3.6.6.7 Setting Notes for the Device Combination ... 195
3.6.6.8 Constellation Measured Values for Type 1 and Type 2 ... 200
3.6.6.9 Setting Notes for External Synchronization ... 202
3.6.6.10 Indications and Measured Values of the External Synchronization ... 207
3.6.6.11 Setting Notes for the Remote Data ... 208
3.6.6.12 Description Phase Swapping ... 208
3.6.6.13 Setting Notes for Phase Swapping ... 209
3.6.6.14 Settings ... 211
3.6.6.15 Information List ... 212
3.6.7 Assignment of the Protection Function Group to the FG Protection Communication ... 213
3.6.8 Application Examples and Setting Notes for IP Communication ... 214
3.6.8.1 Overview ... 214

3.6.8.2 Device Combination of 2 Devices and Redundant Communication Connection..... 214
3.6.8.3 Device Combination of 3 Devices and Only IP Communication..... 215
3.6.8.4 Device Combination of 3 Devices and Hybrid Communication Media..... 216
3.6.8.5 Device Combination of 6 Devices and Hybrid Communication Media..... 218
3.6.8.6 Unsupported Configurations..... 221
3.7 Date and Time Synchronization..... 223
3.7.1 Overview of Functions..... 223
3.7.2 Structure of the Function..... 223
3.7.3 Function Description..... 223
3.7.4 Application and Setting Notes..... 226
3.7.5 Settings..... 229
3.7.6 Information List..... 230
3.8 User-Defined Objects..... 231
3.8.1 Overview..... 231
3.8.2 Basic Data Types..... 232
3.8.3 Pulse-Metered and Energy-Metered Values..... 236
3.8.4 Additional Data Types..... 236
3.8.5 External Signals..... 236
3.9 Other Functions..... 238
3.9.1 Signal Filtering and Chatter Blocking for Input Signals..... 238
3.9.2 Acquisition Blocking and Manual Updating..... 242
3.9.3 Persistent Commands..... 244
3.9.4 Device Logout..... 245
3.9.4.1 Overview..... 245
3.9.4.2 Application and Setting Notes..... 246
3.9.4.3 Information List..... 249
3.10 General Notes for Setting the Threshold Value of Protection Functions..... 250
3.10.1 Overview..... 250
3.10.2 Modifying the Transformer Ratios in DIGSI 5..... 251
3.10.3 Changing the Transformation Ratios of the Transformer on the Device..... 257
3.11 Device Settings..... 259
3.11.1 Settings-Group Switching..... 259
3.11.1.1 Overview of Functions..... 259
3.11.1.2 Structure of the Function..... 259
3.11.1.3 Function Description..... 259
3.11.1.4 Application and Setting Notes..... 260
3.11.1.5 Settings..... 261
3.11.1.6 Information List..... 261
3.11.2 General Device Settings..... 262
3.11.2.1 Overview..... 262
3.11.2.2 Application and Setting Notes..... 263
3.11.2.3 Settings..... 265
3.11.2.4 Information List..... 268
3.11.3 Display-Page Setting..... 269
3.11.3.1 Overview..... 269
3.11.3.2 Application and Setting Notes..... 270
3.11.3.3 Settings..... 272
3.12 Using a SIPROTEC 5 Device as a Client or Merging Unit..... 273
4 Applications..... 277
4.1 Overview..... 278

4.2 Application Templates and Functional Scope of the Device 7UT82 279
4.3 Application Templates and Functional Scope of the Device 7UT85..... 282
4.4 Application Templates and Functional Scope of the Device 7UT86..... 288
4.5 Application Templates and Functional Scope of the Device 7UT87..... 298

5 Function-Group Types and Bay Proxy.....299

5.1 Overview Function Group Transformer Differential Protection.....300
5.1.1 Function-Group Types.....300
5.1.2 Function-Group Type Transformer Differential Protection.....301
5.1.2.1 Overview 301
5.1.2.2 Structure of the Function Group.....302
5.1.2.3 Information List..... 304
5.1.3 Function-Group Type Transformer Side..... 305
5.1.3.1 Overview..... 305
5.1.3.2 Structure of the Function Group.....306
5.1.3.3 Application and Setting Notes..... 310
5.1.3.4 Write-Protected Settings.....313
5.1.3.5 Settings..... 314
5.1.3.6 Information List..... 315
5.1.4 Function-Group Type Transformer Neutral Point.....315
5.1.4.1 Overview..... 315
5.1.4.2 Structure of the Function Group.....316
5.1.4.3 Application and Setting Notes..... 319
5.1.4.4 Write-Protected Settings 320
5.1.4.5 Information List..... 320
5.2 Function-Group Type Auto Transformer Differential Protection..... 322
5.2.1 Function-Group Types.....322
5.2.2 Function-Group Type Auto Transformer Differential Protection.....324
5.2.2.1 Overview 324
5.2.2.2 Structure of the Function Group.....325
5.2.2.3 Application and Setting Notes 327
5.2.2.4 Settings..... 327
5.2.2.5 Information List..... 327
5.2.3 Function-Group Type Auto Transformer Auto Side.....328
5.2.3.1 Overview..... 328
5.2.3.2 Structure of the Function Group.....329
5.2.3.3 Application and Setting Notes..... 333
5.2.3.4 Write-Protected Settings.....335
5.2.3.5 Settings..... 336
5.2.3.6 Information List..... 336
5.2.4 Function-Group Type Auto Transformer Compensation Side.....337
5.2.4.1 Overview..... 337
5.2.4.2 Structure of the Function Group.....338
5.2.4.3 Application and Setting Notes..... 342
5.2.4.4 Write-Protected Settings.....345
5.2.4.5 Settings..... 346
5.2.4.6 Information List..... 346
5.2.5 Function-Group Type Auto Transformer Ground Side.....347
5.2.5.1 Overview..... 347
5.2.5.2 Structure of the Function Group.....348
5.2.5.3 Application and Setting Notes..... 352
5.2.5.4 Write-Protected Settings.....353
5.2.5.5 Information List..... 354

5.2.6 Function-Group Type Auto Transformer Neutral Point ... 354
5.2.6.1 Overview ... 354
5.2.6.2 Structure of the Function Group ... 355
5.2.6.3 Application and Setting Notes ... 358
5.2.6.4 Write-Protected Settings ... 359
5.2.6.5 Information List ... 360
5.3 Overview Function Group Motor Differential Protection ... 361
5.3.1 Function-Group Types ... 361
5.3.2 Function-Group Type Motor Diff ... 362
5.3.2.1 Overview ... 362
5.3.2.2 Structure of the Function Group ... 363
5.3.2.3 Information List ... 365
5.3.3 Function-Group Type Motor Side ... 365
5.3.3.1 Overview ... 365
5.3.3.2 Structure of the Function Group ... 366
5.3.3.3 Application and Setting Notes ... 371
5.3.3.4 Write-Protected Settings ... 372
5.3.3.5 Settings ... 373
5.3.3.6 Information List ... 373
5.4 Overview Function Groups Generator Differential Protection ... 375
5.4.1 Overview ... 375
5.5 Function-Group Type Line ... 376
5.5.1 Overview ... 376
5.5.2 Structure of the Function Group ... 378
5.5.3 Application and Setting Notes ... 382
5.5.4 Process Monitor (FG Line) ... 389
5.5.4.1 Overview of Functions ... 389
5.5.4.2 Structure of the Function ... 389
5.5.4.3 Current-Flow Criterion ... 391
5.5.4.4 Application and Setting Notes (Current-Flow Criterion) ... 391
5.5.4.5 Settings ... 392
5.5.4.6 Circuit-Breaker Condition for the Protected Object ... 392
5.5.4.7 Closure Detection ... 392
5.5.4.8 Application and Setting Notes (Closure Detection) ... 394
5.5.4.9 Settings ... 394
5.5.4.10 Voltage Criterion (Optional) ... 395
5.5.4.11 Application and Setting Notes (Voltage Criterion) ... 395
5.5.4.12 Settings ... 396
5.5.4.13 Cold-Load Pickup Detection (Optional) ... 396
5.5.4.14 Application and Setting Notes (Cold-Load Pickup Detection) ... 397
5.5.4.15 Settings ... 398
5.5.4.16 Information List ... 398
5.5.5 Settings ... 399
5.5.6 Information List ... 399
5.6 Function-Group Type Voltage 3-Phase ... 400
5.6.1 Overview ... 400
5.6.2 Structure of the Function Group ... 400
5.6.3 Application and Setting Notes ... 401
5.6.4 Settings ... 401
5.6.5 Information List ... 402
5.7 Function-Group Type Voltage/current 1-Phase ... 403
5.7.1 Overview ... 403

5.7.2 Structure of the Function Group ... 403
5.7.3 Write-Protected Settings ... 407
5.7.4 Parameter ... 407
5.7.5 Information List ... 407
5.8 Function-Group Type Voltage/current 3-Phase ... 408
5.8.1 Overview ... 408
5.8.2 Structure of the Function Group ... 408
5.8.3 Write-Protected Settings ... 412
5.8.4 Settings ... 413
5.8.5 Information List ... 413
5.9 Function-Group Type Circuit Breaker ... 414
5.9.1 Overview ... 414
5.9.2 Structure of the Function Group ... 414
5.9.3 Application and Setting Notes ... 416
5.9.4 Settings ... 417
5.9.5 Information List ... 417
5.9.6 Trip Logic ... 418
5.9.6.1 Function Description ... 418
5.9.6.2 Application and Setting Notes ... 420
5.9.6.3 Settings ... 420
5.9.6.4 Information List ... 420
5.9.7 Circuit Breaker ... 420
5.9.7.1 Overview ... 420
5.9.7.2 Tripping, Opening and Closing the Circuit Breaker ... 421
5.9.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information ... 422
5.9.7.4 Circuit-Breaker Tripping Alarm Suppression ... 424
5.9.7.5 Tripping and Opening Information ... 425
5.9.7.6 Application and Setting Notes ... 426
5.9.7.7 Settings ... 429
5.9.7.8 Information List ... 429
5.9.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions ... 429
5.9.8.1 Overview ... 429
5.9.9 Detection Manual Closure (for AREC and Process Monitor) ... 430
5.9.9.1 Function Description ... 430
5.9.9.2 Application and Setting Notes ... 431
5.9.9.3 Settings ... 432
5.9.9.4 Information List ... 432
5.10 Function-Group Type Circuit Breaker [without Current] ... 433
5.10.1 Overview ... 433
5.10.2 Structure of the Function Group ... 433
5.10.3 Application and Setting Notes ... 435
5.10.4 Settings ... 435
5.10.5 Trip Logic ... 435
5.10.5.1 Function Description ... 435
5.10.5.2 Application and Setting Notes ... 436
5.10.5.3 Settings ... 437
5.10.5.4 Information List ... 437
5.10.6 Circuit Breaker ... 437
5.10.6.1 Overview ... 437
5.10.6.2 Tripping, Opening, and Closing the Circuit Breaker ... 437
5.10.6.3 Detection of Circuit-Breaker Auxiliary Contacts and Further Information ... 439

5.10.6.4 Circuit-Breaker Tripping Alarm Suppression ... 441
5.10.6.5 Tripping and Opening Information ... 442
5.10.6.6 Application and Setting Notes ... 442
5.10.6.7 Settings ... 445
5.10.6.8 Information List ... 445
5.10.7 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions ... 445
5.10.7.1 Overview ... 445
5.10.8 Detection Manual Closure (for Processor Monitor) ... 446
5.10.8.1 Function Description ... 446
5.10.8.2 Application and Setting Notes ... 447
5.10.8.3 Settings ... 448
5.10.8.4 Information List ... 448
5.11 Function-Group Type Analog Units ... 449
5.11.1 Overview ... 449
5.11.2 Structure of the Function Group ... 449
5.11.3 20-mA Unit Ethernet ... 451
5.11.3.1 Overview ... 451
5.11.3.2 Structure of the Function ... 451
5.11.3.3 Communication with 20-mA Unit Ethernet ... 452
5.11.3.4 Application and Setting Notes ... 453
5.11.3.5 20-mA Channel ... 453
5.11.3.6 Application and Setting Notes ... 456
5.11.3.7 Settings ... 457
5.11.3.8 Information List ... 459
5.11.4 20-mA Unit Serial ... 459
5.11.4.1 Overview ... 459
5.11.4.2 Application and Setting Notes ... 460
5.11.4.3 Settings ... 461
5.11.4.4 Information List ... 463
5.11.5 Communication with 20-mA Unit ... 463
5.11.5.1 Integration of a Serial 20-mA Unit ... 463
5.11.5.2 Integration of a 20-mA Unit Ethernet ... 466
5.11.6 V/I-Measuring-Transducer Unit with Fast Inputs ... 468
5.11.6.1 Overview ... 468
5.11.6.2 Structure of the Function ... 469
5.11.6.3 Function Description ... 469
5.11.6.4 Application and Setting Notes ... 470
5.11.6.5 Settings ... 474
5.11.6.6 Information List ... 476
5.11.7 RTD Unit Ethernet ... 476
5.11.7.1 Overview ... 476
5.11.7.2 Structure of the Function ... 476
5.11.7.3 Communication with an RTD Unit ... 477
5.11.7.4 Application and Setting Notes ... 478
5.11.7.5 Temperature Sensor ... 479
5.11.7.6 Application and Setting Notes ... 480
5.11.7.7 Settings ... 481
5.11.7.8 Information List ... 481
5.11.8 RTD Unit, Serial ... 481
5.11.8.1 Overview ... 481
5.11.8.2 Application and Setting Notes ... 481
5.11.8.3 Settings ... 482
5.11.8.4 Information List ... 482
5.11.9 Communication with RTD Unit ... 483
5.11.9.1 Integration of a Serial RTD Unit (Ziehl TR1200) ... 483

5.11.9.2 Integration of an RTD Unit Ether. (TR1200 IP) ... 485
5.11.9.3 Temperature Simulation without Sensors ... 487
5.11.10 Temperature Acquisition via Protocols ... 487
5.11.10.1 Overview ... 487
5.11.10.2 Structure of the Function ... 488
5.11.10.3 Stage Temperature Acquisition via PROFINET IO or IEC 61850 ... 488
5.11.10.4 PROFINET IO Configuration for the Temperature Acquisition ... 490
5.11.10.5 IEC 61850 Configuration for the Temperature Acquisition ... 492
5.11.10.6 Stage Temperature Acquisition via GOOSE ... 495
5.11.10.7 GOOSE Configuration for the Temperature Acquisition ... 496
5.11.10.8 Application and Setting Notes ... 508
5.11.10.9 Settings ... 509
5.11.10.10 Information List ... 509
5.11.11 LPIT Module IO240 ... 509
5.11.11.1 Overview ... 509
5.11.11.2 Structure of the Function ... 510
5.11.11.3 Function Description ... 511
5.11.11.4 Application and Setting Notes ... 512
5.11.11.5 Settings ... 517
5.11.11.6 Information List ... 519
5.12 Function-Group Recording ... 520
5.12.1 Overview ... 520
5.12.2 Structure of the Function Group ... 520
5.13 Bay Proxy ... 522
5.13.1 Overview ... 522
5.13.2 Structure of the Bay ... 523
5.13.3 Application and Setting Notes (Mode Behavior of Bay) ... 525
5.13.4 Application and Setting Notes (Bay-Related Switching Authority) ... 526
5.13.5 Application and Setting Notes (Displays and Connections for Bay) ... 527
5.13.6 Settings ... 530
5.13.7 Information List ... 531
5.14 Process Monitor ... 532
5.14.1 Overview of Functions ... 532
5.14.2 Structure of the Function ... 532
5.14.3 Current-Flow Criterion ... 533
5.14.4 Application and Setting Notes (Current-Flow Criterion) ... 534
5.14.5 Settings ... 534
5.14.6 Circuit-Breaker Condition for the Protected Object ... 535
5.14.7 Closure Detection ... 535
5.14.8 Information List ... 536
5.14.9 Cold-Load Pickup Detection (Optional) ... 536
5.14.10 Application and Setting Notes (Cold-Load Pickup Detection) ... 537
5.14.11 Settings ... 538
5.14.12 Information List ... 538

6 Protection and Automation Functions ... 539

6.1 Power-System Data ... 541
6.1.1 Overview ... 541
6.1.2 Structure of the Power-System Data ... 541
6.1.3 Application and Setting Instructions - General Settings ... 541

6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph) ... 542
6.1.5 Application and Setting Notes for Measuring-Point Current 3-Phase (I-3ph) ... 545
6.1.6 Disconnection of Measuring Points ... 548
6.1.6.1 Overview ... 548
6.1.6.2 Description ... 549
6.1.6.3 Application and Setting Notes ... 549
6.1.6.4 Settings ... 552
6.1.6.5 Information List ... 552
6.1.7 Application and Setting Notes for Line Differential Protection Settings ... 552
6.1.8 Settings ... 556
6.1.9 Information List ... 563
6.2 Transformer Differential Protection ... 567
6.2.1 Overview of Functions ... 567
6.2.2 Structure of the Function ... 567
6.2.3 Functional Description ... 568
6.2.3.1 Basic Principle of Differential Protection ... 568
6.2.3.2 Logic of the Function ... 571
6.2.3.3 Measurand Processing ... 572
6.2.3.4 Neutral-Point Current Treatment ... 575
6.2.3.5 Special Aspects of an Auto Transformer ... 578
6.2.3.6 Differential Protection Function (I-DIFF) ... 579
6.2.3.7 Differential Protection Function I-DIFF Fast ... 588
6.2.3.8 I-DIFF Unrestrained Differential Protection Function ... 592
6.2.3.9 Trip Logic of the Differential Protection ... 595
6.2.3.10 Disconnection of the Measuring Point from the Transformer Differential Protection Function ... 596
6.2.3.11 Fault Logging and Fault Recording ... 599
6.2.4 Application and Setting Notes ... 599
6.2.5 Settings ... 618
6.2.6 Information List ... 624
6.3 Differential Protection for Phase-Angle Regulating Transformer ... 626
6.3.1 Overview of Functions ... 626
6.3.2 Phase-Angle Regulating Transformers of the Single-Core PST Type ... 627
6.3.3 Application and Setting Notes for the Single-Core PST ... 631
6.3.4 Settings ... 634
6.3.5 Information List ... 635
6.3.6 Phase-Angle Regulating Transformers of the Type Special Transformer ... 635
6.3.7 Application and Setting Notes for the Special Transformer ... 637
6.3.8 Settings ... 638
6.3.9 Phase-Angle Regulating Transformers of the Two-Core PST Type ... 638
6.3.10 Application and Setting Notes for the Two-Core PST ... 641
6.3.11 Settings ... 645
6.4 Restricted Ground-Fault Protection ... 646
6.4.1 Overview of Functions ... 646
6.4.2 Structure of the Function ... 646
6.4.3 Function Description ... 647
6.4.4 Application and Setting Notes ... 654
6.4.5 Settings ... 666
6.4.6 Information List ... 667

6.5 Motor Differential Protection ... 668
6.5.1 Overview of Functions ... 668
6.5.2 Structure of the Function ... 668
6.5.3 Function Description ... 668
6.5.4 Application and Setting Notes ... 686
6.5.5 Settings ... 691
6.5.6 Information List ... 693
6.6 Generator Differential Protection ... 695
6.6.1 Overview of Functions ... 695
6.6.2 Structure of the Function ... 695
6.6.3 Function Description ... 695
6.6.4 Application and Setting Notes ... 713
6.6.5 Settings ... 717
6.6.6 Information List ... 722
6.7 Line Differential Protection ... 724
6.7.1 Overview of Functions ... 724
6.7.2 Structure of the Function ... 724
6.7.3 Function Description ... 727
6.7.4 Application and Setting Instructions - General Settings ... 732
6.7.5 Settings ... 734
6.7.6 Information List ... 735
6.7.7 Stage I-DIFF ... 736
6.7.7.1 Description ... 736
6.7.7.2 Application and Setting Notes ... 739
6.7.7.3 Settings ... 740
6.7.7.4 Information List ... 741
6.7.8 Stage I-DIFF Fast 2 ... 742
6.7.8.1 Description ... 742
6.7.8.2 Application and Setting Notes ... 745
6.7.8.3 Settings ... 746
6.7.8.4 Information List ... 747
6.7.9 Stage I-DIFF Fast ... 747
6.7.9.1 Description ... 747
6.7.9.2 Application and Setting Notes ... 749
6.7.9.3 Settings ... 749
6.7.9.4 Information List ... 749
6.7.10 Stage IN-DIFF ... 750
6.7.10.1 Description ... 750
6.7.10.2 Application and Setting Notes ... 755
6.7.10.3 Settings ... 756
6.7.10.4 Information List ... 756
6.7.11 Stage IN-DIFF unrestr ... 757
6.7.11.1 Description ... 757
6.7.11.2 Application and Setting Notes ... 761
6.7.11.3 Settings ... 762
6.7.11.4 Information List ... 763
6.7.12 Stage I2-DIFF ... 763
6.7.12.1 Description ... 763
6.7.12.2 Application and Setting Notes ... 767
6.7.12.3 Settings ... 769
6.7.12.4 Information List ... 770

6.7.13 Remote Tripping ... 770
6.7.13.1 Description ... 770
6.7.13.2 Application and Setting Notes for Remote Tripping ... 771
6.7.13.3 Settings ... 772
6.7.13.4 Information List ... 773
6.7.14 Pickup and Tripping ... 773
6.7.14.1 Pickup Logic ... 773
6.7.14.2 Trip Logic ... 774
6.7.14.3 Information List ... 774
6.7.15 Logging Off the Local Line Differential Protection ... 774
6.7.16 Charging-Current Compensation Ic-Compensation ... 777
6.7.16.1 Description ... 777
6.7.16.2 Application and Setting Notes ... 779
6.7.16.3 Settings ... 780
6.7.16.4 Information List ... 780
6.8 Stub Differential Protection ... 781
6.8.1 Overview of Functions ... 781
6.8.2 Structure of the Function ... 781
6.8.3 Function Description ... 783
6.8.4 Stage S-DIFF ... 786
6.8.4.1 Description ... 786
6.8.4.2 Application and Setting Notes ... 788
6.8.4.3 Settings ... 788
6.8.4.4 Information List ... 788
6.8.5 Stage S-DIFF Fast 2 ... 790
6.8.5.1 Description ... 790
6.8.5.2 Application and Setting Notes ... 792
6.8.5.3 Settings ... 792
6.8.5.4 Information List ... 792
6.8.6 Stage S-DIFF Fast ... 793
6.8.6.1 Description ... 793
6.8.6.2 Application and Setting Notes ... 794
6.8.6.3 Settings ... 794
6.8.6.4 Information List ... 794
6.8.7 Stage Description of the Output Logic ... 795
6.9 Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems ... 796
6.9.1 Overview of Functions ... 796
6.9.2 Structure of the Function ... 796
6.9.3 Stage Control ... 797
6.9.4 Stage with Definite-Time Characteristic Curve ... 800
6.9.4.1 Description ... 800
6.9.4.2 Application and Setting Notes ... 802
6.9.4.3 Settings ... 804
6.9.4.4 Information List ... 809
6.9.5 Stage with Inverse-Time Overcurrent Protection According to IEC and ANSI ... 811
6.9.5.1 Description ... 811
6.9.5.2 Application and Setting Notes ... 814
6.9.5.3 Settings ... 816
6.9.5.4 Information List ... 818
6.9.6 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve ... 819
6.9.6.1 Description ... 819
6.9.6.2 Application and Setting Notes ... 820
6.9.6.3 Settings ... 821

6.9.6.4 Information List ... 823
6.9.7 Stage with S0 Characteristic Curve ... 824
6.9.7.1 Description ... 824
6.9.7.2 Application and Setting Notes ... 825
6.9.7.3 Settings ... 826
6.9.7.4 Information List ... 827
6.9.8 Stage with U0 Characteristic Curve ... 828
6.9.8.1 Description ... 828
6.9.8.2 Application and Setting Notes ... 831
6.9.8.3 Settings ... 833
6.9.8.4 Information List ... 834
6.9.9 Direction Determination ... 834
6.9.9.1 Description ... 834
6.9.9.2 Application and Setting Notes ... 840
6.9.10 Phase Selection ... 842
6.9.11 Blocking of the Tripping by Device-Internal Inrush-Current Detection ... 843
6.9.11.1 Description ... 843
6.9.11.2 Application and Setting Notes ... 843
6.9.12 Signal Transmission ... 844
6.9.13 Influence of Other Functions via Dynamic Settings ... 844
6.9.13.1 Description ... 844
6.9.13.2 Application and Setting Notes ... 846
6.10 Teleprotection with Ground-Fault Protection ... 848
6.10.1 Overview of Functions ... 848
6.10.2 Structure of the Function ... 848
6.10.3 Receive Blocks ... 849
6.10.4 Permissive Overreach Transfer Trip ... 852
6.10.4.1 Description ... 852
6.10.4.2 Application and Setting Notes for the Trip Logic of the Permissive Mode ... 854
6.10.4.3 Application and Setting Notes for the Permissive Scheme ... 854
6.10.4.4 Application and Setting Notes for the Directional-Unblocking Method ... 855
6.10.4.5 Settings ... 856
6.10.4.6 Information List ... 857
6.10.5 Blocking Method ... 858
6.10.5.1 Description ... 858
6.10.5.2 Application and Setting Notes for the Blocking Method ... 860
6.10.5.3 Settings ... 861
6.10.5.4 Information List ... 862
6.10.6 Transient Blocking ... 862
6.10.6.1 Description ... 862
6.10.6.2 Application and Setting Notes for Transient Blocking ... 863
6.10.7 Sensitive Measuring Stage of Ground-Fault Protection ... 863
6.10.7.1 Description ... 863
6.10.7.2 Application and Setting Notes for the Sensitive Stage of the Ground-Fault Protection ... 864
6.11 Directional Intermittent Ground-Fault Protection ... 866
6.11.1 Overview of Functions ... 866
6.11.2 Structure of the Function ... 866
6.11.3 Stage Description ... 867
6.11.4 Application and Setting Notes ... 873
6.11.5 Settings ... 876
6.11.6 Information List ... 876

6.12 Non-Directional Intermittent Ground-Fault Protection....878
6.12.1 Overview of Functions....878
6.12.2 Structure of the Function....878
6.12.3 Stage Description....879
6.12.4 Application and Setting Notes....883
6.12.5 Settings....885
6.12.6 Information List....886
6.13 Sensitive Ground-Fault Detection....887
6.13.1 Overview of Functions....887
6.13.2 Structure of the Function....887
6.13.3 General Functionality....890
6.13.3.1 Description....890
6.13.3.2 Application and Setting Notes....893
6.13.3.3 Settings....895
6.13.3.4 Information List....895
6.13.4 Directional 3I0 Stage with Cos φ or Sin φ Measurement....896
6.13.4.1 Description....896
6.13.4.2 Application and Setting Notes....902
6.13.4.3 Settings....905
6.13.4.4 Information List....906
6.13.5 Directional Transient Ground-Fault Stage....906
6.13.5.1 Description....906
6.13.5.2 Application and Setting Notes....911
6.13.5.3 Settings....914
6.13.5.4 Information List....914
6.13.6 Directional 3I0 Stage with φ (V0,3I0) Measurement....915
6.13.6.1 Description....915
6.13.6.2 Application and Setting Notes....919
6.13.6.3 Settings....921
6.13.6.4 Information List....921
6.13.7 Directional Y0 Stage with G0 or B0 Measurement....922
6.13.7.1 Description....922
6.13.7.2 Application and Setting Notes....927
6.13.7.3 Settings....931
6.13.7.4 Information List....932
6.13.8 Directional Stage with Phasor Measurement of a Harmonic....932
6.13.8.1 Description....932
6.13.8.2 Application and Setting Notes....937
6.13.8.3 Settings....939
6.13.8.4 Information List....940
6.13.9 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage....941
6.13.9.1 Description....941
6.13.9.2 Application and Setting Notes....942
6.13.9.3 Settings....945
6.13.9.4 Information List....945
6.13.10 Non-Directional 3I0 Stage....945
6.13.10.1 Description....945
6.13.10.2 Application and Setting Notes....947
6.13.10.3 Settings....949
6.13.10.4 Information List....949
6.13.11 Non-Directional Y0 Stage....949
6.13.11.1 Description....949
6.13.11.2 Application and Setting Notes....952
6.13.11.3 Settings....953

6.13.11.4 Information List ... 953
6.13.12 Non-Directional 3I0 Harmonic Stage ... 954
6.13.12.1 Description ... 954
6.13.12.2 Application and Setting Notes ... 955
6.13.12.3 Settings ... 956
6.13.12.4 Information List ... 957
6.13.13 Pulse-Pattern Detection Stage ... 957
6.13.13.1 Description ... 957
6.13.13.2 Application and Setting Notes ... 962
6.13.13.3 Settings ... 965
6.13.13.4 Information List ... 965
6.13.14 Intermittent Ground-Fault Blocking Stage ... 966
6.13.14.1 Description ... 966
6.13.14.2 Application and Setting Notes ... 967
6.13.14.3 Settings ... 968
6.13.14.4 Information List ... 968
6.14 Echo and Tripping in the Event of Weak Infeed ... 969
6.14.1 Overview of Functions ... 969
6.14.2 Structure of the Function ... 969
6.14.3 Echo Function ... 970
6.14.4 Tripping on Weak Infeed (TWI Function) ... 974
6.14.5 Application and Setting Notes ... 974
6.14.6 Settings ... 976
6.14.7 Information List ... 976
6.15 Distance Protection ... 977
6.15.1 Overview of Functions ... 977
6.15.2 Distance Protection for Grounded Systems ... 977
6.15.2.1 Overview of Functions ... 977
6.15.2.2 Structure of the Function ... 977
6.15.2.3 Application and Setting Notes - General Settings ... 981
6.15.2.4 Settings ... 985
6.15.2.5 Information List ... 989
6.15.3 Distance Protection for Isolated/Resonant-Grounded Systems ... 991
6.15.3.1 Overview of Functions ... 991
6.15.3.2 Structure of the Function ... 991
6.15.3.3 Application and Setting Notes - General Settings ... 997
6.15.3.4 Settings ... 1000
6.15.3.5 Information List ... 1004
6.15.4 Direction Determination ... 1006
6.15.5 Pickup Method: Impedance Pickup ... 1010
6.15.5.1 Description ... 1010
6.15.5.2 Application and Setting Notes ... 1011
6.15.5.3 Settings ... 1014
6.15.5.4 Information List ... 1015
6.15.6 Zone with Quadrilateral Characteristic Curve ... 1016
6.15.6.1 Description ... 1016
6.15.6.2 Impedance Calculation ... 1018
6.15.6.3 Application and Setting Notes ... 1020
6.15.6.4 Settings ... 1024
6.15.6.5 Information List ... 1025
6.15.7 Zone with Quadrilateral Characteristic Curve and Adaptive Pickup ... 1025
6.15.7.1 Description ... 1025
6.15.7.2 Application and Setting Notes ... 1026

6.15.7.3 Settings ... 1027
6.15.7.4 Information List ... 1028
6.15.8 Zone with MHO Characteristic Curve ... 1029
6.15.8.1 Description ... 1029
6.15.8.2 Application and Setting Notes ... 1034
6.15.8.3 Settings ... 1036
6.15.8.4 Information List ... 1036
6.15.9 Zone with Circular Characteristic Curve ... 1037
6.15.9.1 Description ... 1037
6.15.9.2 Application and Setting Notes ... 1041
6.15.9.3 Settings ... 1049
6.15.9.4 Information List ... 1050
6.15.10 Release of Tripping through AREC Zone ... 1051
6.15.10.1 Description ... 1051
6.15.10.2 Application and Setting Notes ... 1053
6.15.10.3 Settings ... 1054
6.15.10.4 Information List ... 1054
6.15.11 Output Logic of the Distance Protection ... 1054
6.16 Impedance Protection ... 1056
6.16.1 Overview of Functions ... 1056
6.16.2 Structure of the Function ... 1056
6.16.3 Description ... 1056
6.16.4 Application and Setting Notes ... 1064
6.16.5 Settings ... 1071
6.16.6 Information List ... 1072
6.17 Power-Swing Blocking ... 1074
6.17.1 Overview of Functions ... 1074
6.17.2 Structure of the Function ... 1074
6.17.3 Function Description ... 1074
6.17.4 Application and Setting Notes ... 1078
6.17.5 Settings ... 1079
6.17.6 Information List ... 1079
6.18 Teleprotection with Distance Protection ... 1080
6.18.1 Overview of Functions ... 1080
6.18.2 Structure of the Function ... 1080
6.18.3 Receive Blocks ... 1081
6.18.4 Permissive Underreach Transfer Trip ... 1084
6.18.4.1 Description ... 1084
6.18.4.2 Application and Setting Notes for Permissive Underreach Transfer Trip, General ... 1086
6.18.4.3 Application and Setting Notes for the Permissive Underreach Transfer Trip via an Extended Measuring Range (Distance Protection with Underreaching and Grading-Time Shortening) ... 1087
6.18.4.4 Application and Setting Notes for the Permissive Underreach Transfer Trip via Pickup (Distance Protection with Underreaching and Remote Tripping with Release) ... 1087
6.18.4.5 Application and Setting Notes for the Direct Permissive Underreach Transfer trip ... 1088
6.18.4.6 Settings ... 1089
6.18.4.7 Information List ... 1090
6.18.5 Permissive Overreach Transfer Trip ... 1090
6.18.5.1 Description ... 1090
6.18.5.2 Application and Setting Notes for Permissive Schemes, General ... 1093

6.18.5.3 Application and Setting Notes for the Permissive Overreach Transfer Trip Scheme (Distance Protection with Overreaching and Release) ... 1094
6.18.5.4 Application and Setting Notes for the Directional-Comparison Method ... 1095
6.18.5.5 Application and Setting Notes for the Directional Unblocking Method (Distance Protection with Overreaching and Unblocking) ... 1096
6.18.5.6 Settings ... 1097
6.18.5.7 Information List ... 1098
6.18.6 Blocking Method ... 1099
6.18.6.1 Description ... 1099
6.18.6.2 Application and Setting Notes for the Blocking Method ... 1101
6.18.6.3 Settings ... 1103
6.18.6.4 Information List ... 1103
6.18.7 Reverse Interlocking ... 1104
6.18.7.1 Description ... 1104
6.18.7.2 Application and Setting Notes for Reverse Interlocking ... 1105
6.18.7.3 Settings ... 1107
6.18.7.4 Information List ... 1107
6.18.8 Transient Blocking ... 1108
6.18.8.1 Description ... 1108
6.18.8.2 Application and Setting Notes for Transient Blocking ... 1108
6.19 Universal Teleprotection with Distance Protection ... 1110
6.19.1 Overview of Functions ... 1110
6.19.2 Structure of the Function ... 1110
6.19.3 Receive Blocks ... 1112
6.19.4 Application ... 1112
6.19.5 Settings ... 1112
6.19.6 Information List ... 1114
6.20 External Trip Initiation 3-Pole ... 1117
6.20.1 Overview of Functions ... 1117
6.20.2 Structure of the Function ... 1117
6.20.3 Stage Description ... 1118
6.20.4 Application and Setting Notes ... 1118
6.20.5 Settings ... 1119
6.20.6 Information List ... 1119
6.21 External Trip Initiation with Current-Flow Criterion 3-Pole ... 1120
6.21.1 Overview of Functions ... 1120
6.21.2 Structure of the Function ... 1120
6.21.3 Stage Description ... 1121
6.21.4 Application and Setting Notes ... 1122
6.21.5 Settings ... 1122
6.21.6 Information List ... 1122
6.22 Automatic Reclosing Function ... 1124
6.22.1 Overview of Functions ... 1124
6.22.2 Structure of the Function ... 1125
6.22.3 Cooperation of the Automatic Reclosing Function and Protection Functions ... 1127
6.22.4 Cyclic Automatic Reclosing Function ... 1128
6.22.4.1 Operating Modes for Cyclic Automatic Reclosing Function ... 1128
6.22.4.2 Structure of the Cyclic Automatic Reclosing Function ... 1132
6.22.4.3 Input Logic for Operating Modes with Tripping ... 1133
6.22.4.4 Input Logic for Operating Modes with Pickup ... 1134

6.22.4.5 Start ... 1135
6.22.4.6 Cycle Control with Operating Mode 1: with Tripping/with Action Time ... 1137
6.22.4.7 Cycle Control with Operating Mode 2: With Pickup/With Action Time ... 1138
6.22.4.8 Cycle Control with Operating Mode 3: With Tripping/Without Action Time ... 1140
6.22.4.9 Cycle Control with Operating Mode 4: with Pickup/without Action Time ... 1141
6.22.4.10 Stage Release ... 1142
6.22.4.11 Dead Time for Operating Modes with Tripping ... 1143
6.22.4.12 Dead Time for Operating Modes with Pickup ... 1145
6.22.4.13 Evolving-Fault Detection During the Dead Time ... 1147
6.22.4.14 Closing Indication and Close Command ... 1149
6.22.4.15 Reclaim Time ... 1151
6.22.4.16 Circuit-Breaker Readiness and Circuit-Breaker Condition ... 1152
6.22.4.17 Blockings ... 1154
6.22.4.18 1-/3-pole Tripping of the Circuit Breaker ... 1157
6.22.4.19 Dead-Line Check (DLC) and Reduced Dead Time (RDT) ... 1158
6.22.4.20 Settings ... 1160
6.22.4.21 Information List ... 1162
6.22.5 Automatic Reclosing Function with Adaptive Dead Time (ADT) ... 1164
6.22.5.1 Description ... 1164
6.22.5.2 Settings ... 1165
6.22.5.3 Information List ... 1166
6.22.6 Automatic Reclosing Function with Secondary Arc Detection ... 1167
6.22.6.1 Description ... 1167
6.22.6.2 Application and Setting Notes for the Automatic Reclosing Function with Arc Detection ... 1170
6.22.6.3 Parameter ... 1172
6.22.6.4 Information ... 1173
6.22.7 Operation with External Automatic Reclosing Function ... 1175
6.22.7.1 Description ... 1175
6.22.7.2 Information List ... 1176
6.22.8 Control of the Internal Automatic Reclosing Function by an External Protection Device ... 1177
6.22.9 Application and Setting Notes for General Settings ... 1180
6.22.10 Application and Setting Notes for 1 Cycle of the Cyclic Automatic Reclosing Function 1188
6.23 Overcurrent Protection, Phases ... 1192
6.23.1 Overview of Functions ... 1192
6.23.2 Structure of the Function ... 1192
6.23.3 Filter for RMS Value Gain ... 1193
6.23.3.1 Description ... 1193
6.23.3.2 Application and Setting Notes ... 1195
6.23.3.3 Settings ... 1195
6.23.3.4 Information List ... 1196
6.23.4 Stage with Definite-Time Characteristic Curve ... 1197
6.23.4.1 Description ... 1197
6.23.4.2 Application and Setting Notes ... 1201
6.23.4.3 Settings ... 1205
6.23.4.4 Information List ... 1207
6.23.5 Stage with Inverse-Time Characteristic Curve ... 1209
6.23.5.1 Description ... 1209
6.23.5.2 Application and Setting Notes ... 1213
6.23.5.3 Settings ... 1216
6.23.5.4 Information List ... 1219
6.23.6 Stage with User-Defined Characteristic Curve ... 1219
6.23.6.1 Description ... 1219
6.23.6.2 Application and Setting Notes ... 1221

6.23.6.3 Settings ... 1222
6.23.6.4 Information List ... 1225
6.23.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection ... 1225
6.23.7.1 Description ... 1225
6.23.7.2 Application and Setting Notes ... 1226
6.23.8 Influence of Other Functions via Dynamic Settings ... 1227
6.23.8.1 Description ... 1227
6.23.8.2 Application and Setting Notes (Advanced Stage) ... 1228
6.24 Overcurrent Protection, Ground ... 1230
6.24.1 Overview of Functions ... 1230
6.24.2 Structure of the Function ... 1230
6.24.3 General Functionality ... 1231
6.24.3.1 Description ... 1231
6.24.3.2 Application and Setting Notes ... 1232
6.24.3.3 Settings ... 1233
6.24.4 Stage with Definite-Time Characteristic Curve ... 1234
6.24.4.1 Description ... 1234
6.24.4.2 Application and Setting Notes ... 1236
6.24.4.3 Settings ... 1239
6.24.4.4 Information List ... 1244
6.24.5 Stage with Inverse-Time Characteristic Curve ... 1245
6.24.5.1 Description ... 1245
6.24.5.2 Application and Setting Notes ... 1248
6.24.5.3 Settings ... 1249
6.24.5.4 Information List ... 1252
6.24.6 Stage with User-Defined Characteristic Curve ... 1253
6.24.6.1 Description ... 1253
6.24.6.2 Application and Setting Notes ... 1254
6.24.6.3 Settings ... 1256
6.24.6.4 Information List ... 1258
6.24.7 Blocking of the Tripping by Device-Internal Inrush-Current Detection ... 1259
6.24.7.1 Description ... 1259
6.24.7.2 Application and Setting Notes ... 1259
6.24.8 Influence of Other Functions via Dynamic Settings ... 1260
6.24.8.1 Description ... 1260
6.24.8.2 Application and Setting Notes (Advanced Stage) ... 1262
6.25 Overcurrent Protection, 1-Phase ... 1264
6.25.1 Function Overview ... 1264
6.25.2 Structure of the Function ... 1264
6.25.3 Stage with Definite-Time Characteristic Curve ... 1266
6.25.3.1 Description ... 1266
6.25.3.2 Application and Setting Notes ... 1267
6.25.3.3 Settings ... 1267
6.25.3.4 Information List ... 1268
6.25.4 Stage with Inverse-Time Characteristic Curve ... 1269
6.25.4.1 Description ... 1269
6.25.4.2 Application and Setting Notes ... 1270
6.25.4.3 Settings ... 1271
6.25.4.4 Information List ... 1272
6.25.5 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve ... 1273
6.25.5.1 Description ... 1273
6.25.5.2 Application and Setting Notes ... 1275
6.25.5.3 Settings ... 1276

6.25.5.4 Information List ... 1276
6.25.6 Stage with User-Defined Characteristic Curve ... 1277
6.25.6.1 Description ... 1277
6.25.6.2 Application and Setting Notes ... 1278
6.25.6.3 Settings ... 1279
6.25.6.4 Information List ... 1279
6.25.7 Fast Stage ... 1280
6.25.7.1 Description ... 1280
6.25.7.2 Application and Setting Notes ... 1280
6.25.7.3 Settings ... 1281
6.25.7.4 Information List ... 1281
6.25.8 Blocking of the Tripping by Device-Internal Inrush-Current Detection ... 1281
6.25.8.1 Description ... 1281
6.25.8.2 Application and Setting Notes ... 1282
6.25.9 Application Example: High-Impedance Restricted Ground-Fault Protection ... 1283
6.25.9.1 Description ... 1283
6.25.9.2 Application and Setting Notes ... 1285
6.25.10 Application Example: Tank Leakage Protection ... 1289
6.25.10.1 Description ... 1289
6.25.10.2 Application and Setting Notes ... 1290
6.26 Voltage-Dependent Overcurrent Protection, Phases ... 1291
6.26.1 Overview of Functions ... 1291
6.26.2 Structure of the Function ... 1291
6.26.3 Stage with Inverse-Time Overcurrent Protection, Voltage-Dependent ... 1292
6.26.3.1 Description ... 1292
6.26.3.2 Application and Setting Notes ... 1294
6.26.3.3 Settings ... 1296
6.26.3.4 Information List ... 1296
6.26.4 Stage with Inverse-Time Overcurrent Protection, Voltage-Released ... 1298
6.26.4.1 Description ... 1298
6.26.4.2 Application and Setting Notes ... 1299
6.26.4.3 Settings ... 1300
6.26.4.4 Information List ... 1300
6.26.5 Stage with Definite-Time Overcurrent Protection, Undervoltage Seal-In ... 1302
6.26.5.1 Description ... 1302
6.26.5.2 Application and Setting Notes ... 1303
6.26.5.3 Settings ... 1304
6.26.5.4 Information List ... 1305
6.26.6 Stage with Definite-Time Overcurrent Protection, Voltage-Released Undervoltage Seal-In ... 1306
6.26.6.1 Description ... 1306
6.26.6.2 Application and Setting Notes ... 1307
6.26.6.3 Settings ... 1309
6.26.6.4 Information List ... 1310
6.27 Directional Overcurrent Protection, Phases ... 1311
6.27.1 Overview of Functions ... 1311
6.27.2 Structure of the Function ... 1311
6.27.3 Stage Control ... 1313
6.27.3.1 Description ... 1313
6.27.3.2 Application and Setting Notes ... 1313
6.27.4 Stage with Definite-Time Characteristic Curve ... 1314
6.27.4.1 Description ... 1314
6.27.4.2 Application and Setting Notes ... 1317
6.27.4.3 Settings ... 1319

6.27.4.4 Information List ... 1324
6.27.5 Stage with Inverse-Time Characteristic Curve ... 1326
6.27.5.1 Description ... 1326
6.27.5.2 Application and Setting Notes ... 1329
6.27.5.3 Settings ... 1332
6.27.5.4 Information List ... 1334
6.27.6 Stage with User-Defined Characteristic Curve ... 1335
6.27.6.1 Description ... 1335
6.27.6.2 Application and Setting Notes ... 1336
6.27.6.3 Settings ... 1337
6.27.6.4 Information List ... 1340
6.27.7 Direction Determination ... 1340
6.27.7.1 Description ... 1340
6.27.7.2 Application and Setting Notes ... 1343
6.27.8 Influence of Other Functions via Dynamic Settings ... 1343
6.27.9 Application Notes for Parallel Lines ... 1344
6.27.10 Application Notes for Directional Comparison Protection ... 1344
6.28 Directional Overcurrent Protection, Ground ... 1346
6.28.1 Overview of Functions ... 1346
6.28.2 Structure of the Function ... 1346
6.28.3 General Functionality ... 1348
6.28.3.1 Measured-Value Selection ... 1348
6.28.3.2 Direction Determination ... 1349
6.28.3.3 Application and Setting Notes ... 1351
6.28.3.4 Settings ... 1353
6.28.3.5 Information List ... 1354
6.28.4 Stage Control ... 1354
6.28.4.1 Description ... 1354
6.28.4.2 Application and Setting Notes ... 1355
6.28.5 Stage with Definite-Time Characteristic Curve ... 1356
6.28.5.1 Description ... 1356
6.28.5.2 Application and Setting Notes ... 1359
6.28.5.3 Settings ... 1362
6.28.5.4 Information List ... 1367
6.28.6 Stage with Inverse-Time Characteristic Curve ... 1368
6.28.6.1 Description ... 1368
6.28.6.2 Application and Setting Notes ... 1372
6.28.6.3 Settings ... 1375
6.28.6.4 Information List ... 1378
6.28.7 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve ... 1379
6.28.7.1 Description ... 1379
6.28.7.2 Application and Setting Notes ... 1381
6.28.7.3 Settings ... 1382
6.28.7.4 Information List ... 1384
6.28.8 Stage with Knee-Point Characteristic Curve ... 1386
6.28.8.1 Description ... 1386
6.28.8.2 Application and Setting Notes ... 1387
6.28.8.3 Settings ... 1388
6.28.8.4 Information List ... 1389
6.28.9 Stage with User-Defined Characteristic Curve ... 1390
6.28.9.1 Description ... 1390
6.28.9.2 Application and Setting Notes ... 1391
6.28.9.3 Settings ... 1392

6.28.9.4 Information List ... 1395
6.28.10 Influence of Other Functions via Dynamic Settings ... 1396
6.29 Positive-Sequence Overcurrent Protection ... 1397
6.29.1 Overview of Functions ... 1397
6.29.2 Structure of the Function ... 1397
6.29.3 Stage with Definite-Time Characteristic Curve ... 1398
6.29.3.1 Description ... 1398
6.29.3.2 Application and Setting Notes ... 1399
6.29.3.3 Settings ... 1401
6.29.3.4 Information List ... 1401
6.29.4 Stage with Inverse-Time Characteristic Curve ... 1403
6.29.4.1 Description ... 1403
6.29.4.2 Application and Setting Notes ... 1404
6.29.4.3 Settings ... 1405
6.29.4.4 Information List ... 1405
6.30 Group Indications of Overcurrent Protection Functions ... 1407
6.30.1 Description ... 1407
6.31 Negative-Sequence Protection ... 1409
6.31.1 Overview of Functions ... 1409
6.31.2 Structure of the Function ... 1409
6.31.3 General Functionality ... 1410
6.31.3.1 Description ... 1410
6.31.3.2 Application and Setting Notes ... 1410
6.31.4 Stage with Definite-Time Characteristic Curve ... 1412
6.31.4.1 Stage Description ... 1412
6.31.4.2 Application and Setting Notes ... 1413
6.31.4.3 Settings ... 1415
6.31.4.4 Information List ... 1416
6.31.5 Stage with Inverse-Time Characteristic Curve ... 1417
6.31.5.1 Description ... 1417
6.31.5.2 Application and Settings Notes ... 1418
6.31.5.3 Settings ... 1419
6.31.5.4 Information List ... 1419
6.32 Directional Negative-Sequence Protection ... 1420
6.32.1 Overview of Functions ... 1420
6.32.2 Structure of the Function ... 1420
6.32.3 Function Description ... 1420
6.32.4 Application and Setting Notes for Direction Determination ... 1425
6.32.5 Application and Setting Notes for Stages ... 1426
6.32.6 Settings ... 1428
6.32.7 Information List ... 1429
6.33 Undercurrent Protection ... 1430
6.33.1 Overview of Functions ... 1430
6.33.2 Structure of the Function ... 1430
6.33.3 Stage Description ... 1431
6.33.4 Application and Setting Notes ... 1432
6.33.5 Settings ... 1434
6.33.6 Information List ... 1434
6.34 Overexcitation Protection ... 1436
6.34.1 Overview of Functions ... 1436

6.34.2 Structure of the Function 1436
6.34.3 Stage with Dependent Characteristic Curve (Thermal Stage) 1437
6.34.3.1 Function Description 1437
6.34.3.2 Application and Setting Notes 1440
6.34.4 Stage with Definite-Time Characteristic Curve (Time Stage) 1442
6.34.4.1 Function Description 1442
6.34.4.2 Application and Setting Notes 1442
6.34.5 Settings 1443
6.34.6 Information List 1443
6.35 Unbalanced-Load Protection 1445
6.35.1 Overview of Functions 1445
6.35.2 Structure of the Function 1445
6.35.3 Function Description 1446
6.35.4 Application and Setting Notes 1448
6.35.5 Settings 1450
6.35.6 Information List 1450
6.36 Instantaneous High-Current Tripping 1452
6.36.1 Overview of Functions 1452
6.36.2 Structure of the Function 1452
6.36.3 Standard Release Procedure 1453
6.36.4 Application and Setting Notes 1454
6.36.5 Release Procedure via Protection Interface 1455
6.36.6 Application and Setting Notes 1457
6.36.7 Settings 1457
6.36.8 Information List 1458
6.37 Overvoltage Protection with 3-Phase Voltage 1459
6.37.1 Overview of Functions 1459
6.37.2 Structure of the Function 1459
6.37.3 Stage with Definite-Time Characteristic Curve 1460
6.37.3.1 Description 1460
6.37.3.2 Application and Setting Notes 1461
6.37.3.3 Settings 1463
6.37.3.4 Information List 1464
6.37.4 Stage with Inverse-Time Characteristic Curve 1466
6.37.4.1 Description 1466
6.37.4.2 Application and Setting Notes 1469
6.37.4.3 Settings 1471
6.37.4.4 Information List 1471
6.38 Overvoltage Protection with Positive-Sequence Voltage 1472
6.38.1 Overview of Functions 1472
6.38.2 Structure of the Function 1472
6.38.3 Stage Description 1473
6.38.4 Application and Setting Notes 1473
6.38.5 Settings 1474
6.38.6 Information List 1474
6.39 Overvoltage Protection with Negative-Sequence Voltage 1476
6.39.1 Overview of Functions 1476
6.39.2 Structure of the Function 1476

6.39.3 General Functionality ... 1476
6.39.3.1 Description ... 1476
6.39.3.2 Application and Setting Notes ... 1477
6.39.3.3 Settings ... 1478
6.39.3.4 Information List ... 1478
6.39.4 Stage with Negative-Sequence Voltage ... 1479
6.39.4.1 Description ... 1479
6.39.4.2 Application and Setting Notes ... 1479
6.39.4.3 Settings ... 1481
6.39.4.4 Information List ... 1482
6.40 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage ... 1483
6.40.1 Overview of Functions ... 1483
6.40.2 Structure of the Function ... 1483
6.40.3 General Functionality ... 1483
6.40.3.1 Description ... 1483
6.40.3.2 Application and Setting Notes ... 1484
6.40.3.3 Settings ... 1485
6.40.3.4 Information List ... 1485
6.40.4 Stage with Negative-Sequence Voltage/Positive-Sequence Voltage ... 1486
6.40.4.1 Description ... 1486
6.40.4.2 Application and Setting Notes ... 1486
6.40.4.3 Settings ... 1488
6.40.4.4 Information List ... 1489
6.41 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage ... 1490
6.41.1 Overview of Functions ... 1490
6.41.2 Structure of the Function ... 1490
6.41.3 Stage with Definite-Time Characteristic Curve ... 1491
6.41.3.1 Stage Description ... 1491
6.41.3.2 Application and Setting Notes ... 1492
6.41.3.3 Settings ... 1495
6.41.3.4 Information List ... 1495
6.41.4 Stage with Inverse-Time Characteristic Curve ... 1496
6.41.4.1 Description ... 1496
6.41.4.2 Application and Setting Notes ... 1499
6.41.4.3 Settings ... 1501
6.41.4.4 Information List ... 1502
6.42 Overvoltage Protection with Any Voltage ... 1503
6.42.1 Overview of Functions ... 1503
6.42.2 Structure of the Function ... 1503
6.42.3 Stage Description ... 1504
6.42.4 Application and Setting Notes ... 1505
6.42.5 Settings ... 1507
6.42.6 Information List ... 1508
6.43 Undervoltage Protection with 3-Phase Voltage ... 1509
6.43.1 Overview of Functions ... 1509
6.43.2 Structure of the Function ... 1509
6.43.3 Stage with Definite-Time Characteristic Curve ... 1510
6.43.3.1 Description ... 1510
6.43.3.2 Application and Setting Notes ... 1512
6.43.3.3 Settings ... 1515
6.43.3.4 Information List ... 1516

6.43.4 Stage with Inverse-Time Characteristic Curve ... 1518
6.43.4.1 Description ... 1518
6.43.4.2 Application and Setting Notes ... 1522
6.43.4.3 Settings ... 1525
6.43.4.4 Information List ... 1525
6.44 Undervoltage Protection with Positive-Sequence Voltage ... 1526
6.44.1 Overview of Functions ... 1526
6.44.2 Structure of the Function ... 1526
6.44.3 Stage Description ... 1527
6.44.4 Application and Setting Notes ... 1528
6.44.5 Settings ... 1530
6.44.6 Information List ... 1531
6.45 Undervoltage Protection with Any Voltage ... 1532
6.45.1 Overview of Functions ... 1532
6.45.2 Structure of the Function ... 1532
6.45.3 Stage Description ... 1533
6.45.4 Application and Setting Notes ... 1534
6.45.5 Settings ... 1536
6.45.6 Information List ... 1537
6.46 Rate-of-Voltage-Change Protection ... 1539
6.46.1 Overview of Functions ... 1539
6.46.2 Structure of the Function ... 1539
6.46.3 General Functionality ... 1540
6.46.3.1 Description ... 1540
6.46.3.2 Application and Setting Notes ... 1540
6.46.4 Stage Description ... 1541
6.46.4.1 Description ... 1541
6.46.4.2 Application and Setting Notes ... 1542
6.46.5 Settings ... 1543
6.46.6 Information List ... 1544
6.47 Undervoltage-Controlled Reactive-Power Protection ... 1546
6.47.1 Overview of Functions ... 1546
6.47.2 Structure of the Function ... 1546
6.47.3 Protection Stage ... 1547
6.47.3.1 Description ... 1547
6.47.3.2 Application and Setting Notes ... 1548
6.47.3.3 Settings ... 1550
6.47.3.4 Information List ... 1551
6.47.4 Reclosure Stage ... 1552
6.47.4.1 Description ... 1552
6.47.4.2 Application and Setting Notes ... 1553
6.47.4.3 Settings ... 1554
6.47.4.4 Information List ... 1554
6.48 Voltage-Comparison Supervision ... 1555
6.48.1 Overview of Functions ... 1555
6.48.2 Structure of the Function ... 1555
6.48.3 Stage Description ... 1556
6.48.3.1 Description ... 1556
6.48.3.2 Application and Setting Notes ... 1559
6.48.3.3 Settings ... 1560

6.48.3.4 Information List ... 1560
6.49 Fault Locator ... 1561
6.49.1 Overview of Functions ... 1561
6.49.2 Structure of the Function ... 1561
6.49.3 Function Description ... 1562
6.49.4 Application and Setting Notes ... 1570
6.49.5 Settings ... 1575
6.49.6 Information List ... 1576
6.50 Fault Locator Plus ... 1577
6.50.1 Overview of Functions ... 1577
6.50.2 Structure of the Function ... 1577
6.50.3 Function Description ... 1579
6.50.4 Application and Setting Notes ... 1582
6.50.5 Settings ... 1589
6.50.6 Information List ... 1590
6.51 Overfrequency Protection ... 1591
6.51.1 Overview of Functions ... 1591
6.51.2 Structure of the Function ... 1591
6.51.3 Overfrequency-Protection Stage ... 1592
6.51.4 Application and Setting Notes ... 1593
6.51.5 Settings ... 1595
6.51.6 Information List ... 1595
6.52 Underfrequency Protection ... 1597
6.52.1 Overview of Functions ... 1597
6.52.2 Structure of the Function ... 1597
6.52.3 Underfrequency-Protection Stage ... 1598
6.52.4 Application and Setting Notes ... 1599
6.52.5 Settings ... 1601
6.52.6 Information List ... 1601
6.53 Underfrequency Load Shedding ... 1603
6.53.1 Overview of Functions ... 1603
6.53.2 Structure of the Function ... 1603
6.53.3 General Functionality ... 1604
6.53.3.1 Description ... 1604
6.53.3.2 Application and Setting Notes ... 1607
6.53.4 Stage Description ... 1610
6.53.4.1 Description ... 1610
6.53.4.2 Application and Setting Notes ... 1612
6.53.5 Settings ... 1613
6.53.6 Information List ... 1614
6.54 Rate of Frequency Change Protection ... 1615
6.54.1 Overview of Functions ... 1615
6.54.2 Structure of the Function ... 1615
6.54.3 General Functions (Undervoltage Test, df/dt Calculation) ... 1615
6.54.3.1 Description ... 1615
6.54.3.2 Application and Setting Notes ... 1616

6.54.4 Stage Description ... 1617
6.54.4.1 Description ... 1617
6.54.4.2 Application and Setting Notes ... 1618
6.54.4.3 Settings ... 1619
6.54.4.4 Information List ... 1619
6.55 Phase-Sequence Switchover ... 1621
6.55.1 Overview of Functions ... 1621
6.55.2 Structure of the Function ... 1621
6.55.3 Function Description ... 1621
6.55.4 Application and Setting Notes ... 1624
6.55.5 Settings ... 1625
6.55.6 Information List ... 1626
6.56 Instantaneous Tripping at Switch onto Fault ... 1627
6.56.1 Overview of Functions ... 1627
6.56.2 Structure of the Function ... 1627
6.56.3 Stage Description ... 1628
6.56.4 Application and Setting Notes ... 1628
6.56.5 Settings ... 1629
6.56.6 Information List ... 1629
6.57 Thermal Overload Protection, 3-Phase - Advanced ... 1630
6.57.1 Overview of Functions ... 1630
6.57.2 Structure of the Function ... 1630
6.57.3 Filter for RMS Value Gain ... 1630
6.57.3.1 Description ... 1630
6.57.3.2 Application and Setting Notes ... 1631
6.57.3.3 Settings ... 1632
6.57.3.4 Information List ... 1633
6.57.4 Stage with Thermal Overload Protection, 3-Phase - Advanced ... 1634
6.57.4.1 Description ... 1634
6.57.4.2 Application and Setting Notes ... 1639
6.57.4.3 Settings ... 1643
6.57.4.4 Information List ... 1644
6.58 Thermal Overload Protection, User-Defined Characteristic Curve ... 1645
6.58.1 Overview of Functions ... 1645
6.58.2 Structure of the Function ... 1645
6.58.3 Function Description ... 1645
6.58.4 Application and Setting Notes ... 1651
6.58.5 Settings ... 1654
6.58.6 Information List ... 1655
6.59 Thermal Overload Protection, 1-Phase ... 1657
6.59.1 Overview of Functions ... 1657
6.59.2 Structure of the Function ... 1657
6.59.3 Function Description ... 1658
6.59.4 Application and Setting Notes ... 1662
6.59.5 Settings ... 1666
6.59.6 Information List ... 1667
6.60 Temperature Supervision ... 1668
6.60.1 Overview of Functions ... 1668

6.60.2 Structure of the Function 1668
6.60.3 Function Description 1669
6.60.4 Application and Setting Notes 1670
6.60.5 Settings 1671
6.60.6 Information List 1675
6.61 Hotspot Calculation 1678
6.61.1 Overview of Functions 1678
6.61.2 Structure of the Function 1678
6.61.3 Function Description 1679
6.61.4 Application and Setting Notes 1684
6.61.5 Settings 1687
6.61.6 Information List 1688
6.62 Circuit-Breaker Failure Protection 1689
6.62.1 Overview of Functions 1689
6.62.2 Structure of the Function 1689
6.62.3 Function Description 1690
6.62.4 Application and Setting Notes 1697
6.62.5 Settings 1705
6.62.6 Information List 1707
6.63 Circuit-Breaker Restrike Protection 1708
6.63.1 Overview of Function 1708
6.63.2 Structure of the Function 1708
6.63.3 Function Description 1708
6.63.4 Application and Setting Notes 1712
6.63.5 Settings 1715
6.63.6 Information List 1716
6.64 Pole Discrepancy Protection 1717
6.64.1 Overview of Functions 1717
6.64.2 Structure of the Function 1717
6.64.3 Description 1717
6.64.4 Application and Setting Notes 1719
6.64.5 Settings 1720
6.64.6 Information List 1720
6.65 Out-of-Step Protection 1721
6.65.1 Overview of Functions 1721
6.65.2 Structure of the Function 1721
6.65.3 Description of a Zone 1721
6.65.4 Application and Setting Notes (System Protection) 1727
6.65.5 Settings 1736
6.65.6 Information List 1737
6.66 Arc Protection 1739
6.66.1 Overview of Function 1739
6.66.2 Structure of the Function 1739
6.66.3 Function Description 1740
6.66.4 Application and Setting Notes – General Settings 1742
6.66.5 Application and Setting Notes for the Stage 1743

6.66.6 Settings....1744
6.66.7 Information List....1746
6.66.8 Application Example for Arc Protection with Point Sensors in Operating Mode: Light Only....1747
6.66.8.1 Description....1747
6.66.8.2 Application and Setting Notes....1749
6.66.9 Application Example for Arc Protection with Point Sensors in Operating Mode: Light and Current....1750
6.66.9.1 Description....1750
6.66.9.2 Application and Setting Notes....1751
6.66.10 Application Example for Arc Protection with Point Sensors via External Trip Initiation....1752
6.66.10.1 Description....1752
6.66.10.2 Application and Setting Notes....1754
6.66.10.3 Application and Setting Notes for Variant 2 (with Feedback to Feeder Protection Devices)....1756
6.67 Power-Plant Disconnection Protection....1760
6.67.1 Overview of Functions....1760
6.67.2 Structure of the Function....1760
6.67.3 Function Description....1760
6.67.4 Application and Setting Notes....1765
6.67.5 Settings....1770
6.67.6 Information List....1770
6.68 Inrush-Current and 2nd Harmonic Detection....1772
6.68.1 Inrush-Current Detection....1772
6.68.1.1 Overview of Functions....1772
6.68.1.2 Structure of the Function....1772
6.68.1.3 Function Description....1772
6.68.1.4 Application and Setting Notes....1776
6.68.1.5 Settings....1777
6.68.1.6 Information List....1778
6.68.2 2nd Harmonic Ground Detection....1778
6.68.2.1 Overview of Functions....1778
6.68.2.2 Structure of the Function....1779
6.68.2.3 Function Description....1779
6.68.2.4 Application and Setting Notes....1780
6.68.2.5 Settings....1780
6.68.2.6 Information List....1780
6.68.3 2nd Harmonic Detection 1-Phase....1781
6.68.3.1 Overview of Functions....1781
6.68.3.2 Structure of the Function....1781
6.68.3.3 Function Description....1782
6.68.3.4 Application and Setting Notes....1783
6.68.3.5 Settings....1783
6.68.3.6 Information List....1783
6.69 Power Protection (P,Q), 3-Phase....1784
6.69.1 Overview of Functions....1784
6.69.2 Structure of the Function....1784
6.69.3 Active Power Stage....1785
6.69.4 Reactive Power Stage....1787
6.69.5 Application Example....1788
6.69.6 Setting Notes for the Active Power Stage....1789
6.69.7 Setting Notes for the Reactive Power Stage....1790

6.69.8 Settings....1791
6.69.9 Information List....1793
6.70 Reverse-Power Protection....1794
6.70.1 Overview of Functions....1794
6.70.2 Structure of the Function....1794
6.70.3 General Functionality....1795
6.70.3.1 Description....1795
6.70.3.2 Application and Setting Notes....1796
6.70.3.3 Settings....1798
6.70.3.4 Information List....1798
6.70.4 Stage Description....1799
6.70.4.1 Description....1799
6.70.4.2 Application and Setting Notes....1800
6.70.4.3 Settings....1801
6.70.4.4 Information List....1801
6.71 Voltage Measuring-Point Selection....1802
6.71.1 Overview of Functions....1802
6.71.2 Function Description....1802
6.71.3 Application and Setting Notes....1803
6.71.4 Information List....1804
6.72 Current-Jump Detection....1805
6.72.1 Overview of Functions....1805
6.72.2 Structure of the Function....1805
6.72.3 Function Description....1805
6.72.4 Application and Setting Notes....1806
6.72.5 Settings....1807
6.72.6 Information List....1807
6.73 Voltage-Jump Detection....1808
6.73.1 Overview of Functions....1808
6.73.2 Structure of the Function....1808
6.73.3 Function Description....1808
6.73.4 Application and Setting Notes....1809
6.73.5 Settings....1810
6.73.6 Information List....1810
6.74 Vector-Jump Protection....1812
6.74.1 Overview of Functions....1812
6.74.2 Structure of the Function....1812
6.74.3 General Functionality....1812
6.74.3.1 Description....1812
6.74.3.2 Application and Setting Notes....1815
6.74.3.3 Settings....1815
6.74.3.4 Information List....1815
6.74.4 Δφ Stage....1816
6.74.4.1 Description....1816
6.74.4.2 Application and Setting Notes....1817
6.74.4.3 Settings....1818
6.74.4.4 Information List....1818
6.74.5 I1 < Release Stage....1818
6.74.5.1 Description....1818
6.74.5.2 Application and Setting Notes....1819

6.74.5.3 Settings ... 1819
6.74.5.4 Information List ... 1819

7 Control Functions ... 1821

7.1 Introduction ... 1822
7.1.1 Overview ... 1822
7.1.2 Concept of Controllables ... 1822
7.2 Switching Devices ... 1825
7.2.1 General Overview ... 1825
7.2.2 Switching Device Circuit Breaker ... 1825
7.2.2.1 Structure of the Circuit-Breaker Switching Device ... 1825
7.2.2.2 Application and Setting Notes ... 1829
7.2.2.3 Connection Variants of the Circuit Breaker ... 1831
7.2.2.4 Settings ... 1839
7.2.2.5 Information List ... 1841
7.2.3 Disconnector Switching Device ... 1843
7.2.3.1 Structure of the Disconnector Switching Device ... 1843
7.2.3.2 Application and Setting Notes ... 1847
7.2.3.3 Trigger Variants of the Disconnector ... 1849
7.2.3.4 Settings ... 1852
7.2.3.5 Information List ... 1853
7.3 Switching Sequences ... 1855
7.3.1 Overview of Functions ... 1855
7.3.2 Function Description ... 1855
7.3.3 Application and Setting Notes ... 1857
7.3.4 Settings ... 1861
7.3.5 Information List ... 1861
7.4 Control Functionality ... 1862
7.4.1 Command Checks and Switchgear Interlocking Protection ... 1862
7.4.2 Command Logging ... 1883
7.4.3 Settings ... 1888
7.4.4 Information List ... 1889
7.5 Synchronization Function ... 1890
7.5.1 Overview of Functions ... 1890
7.5.2 Structure of the Function ... 1890
7.5.3 Connection and Definition ... 1891
7.5.4 General Functionality ... 1894
7.5.4.1 Description ... 1894
7.5.4.2 Application and Setting Notes ... 1898
7.5.4.3 Settings ... 1905
7.5.5 Dynamic Measuring-Point Switching ... 1906
7.5.6 Sequence of Functions ... 1908
7.5.7 Stage Synchrocheck ... 1910
7.5.7.1 Description ... 1910
7.5.7.2 Application and Setting Notes ... 1911
7.5.7.3 Settings ... 1911
7.5.7.4 Information List ... 1912
7.5.8 Stage Synchronous/Asynchronous ... 1913
7.5.8.1 Description ... 1913
7.5.8.2 Application and Setting Notes ... 1917
7.5.8.3 Settings ... 1919

7.5.8.4 Information List ... 1920
7.5.9 Expanded Checks (df/dt and Smoothing of Oscillations) ... 1921
7.5.10 Closing at De-Energized Line/Busbar ... 1922
7.5.10.1 Description ... 1922
7.5.10.2 Application and Setting Notes ... 1924
7.5.11 Direct Close Command ... 1925
7.5.12 Interaction with Control and External Triggering ... 1926
7.5.13 External Synchronization ... 1927
7.5.13.1 Description ... 1927
7.5.13.2 Application and Setting Notes (External Synchronization) ... 1930
7.5.13.3 Settings ... 1931
7.5.13.4 Information List ... 1933
7.5.14 Settings ... 1933
7.5.15 Information List ... 1935
7.6 User-Defined Function Block [Control] ... 1938
7.6.1 Overview of Functions ... 1938
7.6.2 Function Description ... 1938
7.6.3 Application and Setting Notes ... 1939
7.6.4 Settings ... 1941
7.6.5 Information List ... 1941
7.7 CFC-Chart Settings ... 1943
7.7.1 Overview of Functions ... 1943
7.7.2 Function Description ... 1943
7.7.3 Application and Setting Notes ... 1944
7.7.4 Settings ... 1944
7.7.5 Information List ... 1944
7.8 Tap Changers ... 1945
7.8.1 Function Description ... 1945
7.8.2 Application and Setting Notes ... 1949
7.8.3 Settings (Properties Dialog) ... 1956
7.8.4 Settings ... 1956
7.8.5 Information List ... 1957
7.9 Voltage Controller ... 1959
7.9.1 Overview of Functions ... 1959
7.9.2 Structure of the Function ... 1959
7.9.3 Function Description ... 1961
7.9.3.1 General ... 1961
7.9.3.2 Logic of the Function ... 1968
7.9.3.3 Control Response ... 1970
7.9.3.4 Function Supervision ... 1973
7.9.3.5 Dynamic Voltage Control (DVC) ... 1973
7.9.3.6 Line Compensation ... 1976
7.9.3.7 Limiting Values ... 1978
7.9.3.8 Blockings ... 1978
7.9.3.9 Parallel Operation ... 1979
7.9.3.10 Creating a GOOSE Later Binding for Parallel Control ... 1991
7.9.3.11 Functional Measured Values ... 1999
7.9.4 Application and Setting Notes ... 2003
7.9.4.1 General ... 2003
7.9.4.2 Controlling ... 2005

7.9.4.3 Voltage Controller ... 2006
7.9.4.4 Dynamic Voltage Control (DVC) ... 2011
7.9.4.5 Line Compensation ... 2013
7.9.4.6 Limiting Values ... 2016
7.9.4.7 Blockings ... 2017
7.9.4.8 Parallel Control ... 2018
7.9.5 Settings ... 2019
7.9.6 Information List ... 2032
7.10 Point-on-Wave Switching ... 2038

8 Supervision Functions ... 2039

8.1 Overview ... 2040
8.2 Resource-Consumption Supervision ... 2041
8.2.1 Load Model ... 2041
8.2.2 Function Points ... 2043
8.2.3 CFC Resources ... 2044
8.3 Supervision of the Secondary System ... 2046
8.3.1 Overview ... 2046
8.3.2 Measuring-Voltage Failure ... 2046
8.3.2.1 Overview of Functions ... 2046
8.3.2.2 Structure of the Function ... 2047
8.3.2.3 Unbalanced Measuring-Voltage Failure ... 2049
8.3.2.4 3-Phase Measuring-Voltage Failure ... 2050
8.3.2.5 Switching onto a 3-Phase Measuring-Voltage Failure, Low Load ... 2051
8.3.2.6 Application and Setting Notes ... 2052
8.3.2.7 Settings ... 2054
8.3.2.8 Information List ... 2054
8.3.3 Signaling-Voltage Supervision ... 2055
8.3.3.1 Overview of Functions ... 2055
8.3.3.2 Structure of the Function ... 2055
8.3.3.3 Function Description ... 2055
8.3.3.4 Application and Setting Notes ... 2057
8.3.3.5 Settings ... 2058
8.3.3.6 Information List ... 2060
8.3.4 Voltage-Transformer Circuit Breaker ... 2060
8.3.4.1 Overview of Functions ... 2060
8.3.4.2 Structure of the Function ... 2061
8.3.4.3 Function Description ... 2061
8.3.4.4 Application and Setting Notes ... 2061
8.3.4.5 Settings ... 2062
8.3.4.6 Information List ... 2062
8.3.5 Broken-Wire Detection ... 2062
8.3.5.1 Overview of Functions ... 2062
8.3.5.2 Structure of the Function ... 2062
8.3.5.3 Function Description ... 2062
8.3.5.4 Application and Setting Notes ... 2064
8.3.5.5 Settings ... 2064
8.3.5.6 Information List ... 2064
8.3.6 Voltage-Balance Supervision ... 2065
8.3.6.1 Overview of Functions ... 2065
8.3.6.2 Structure of the Function ... 2065
8.3.6.3 Function Description ... 2065
8.3.6.4 Application and Setting Notes ... 2066
8.3.6.5 Settings ... 2067

8.3.6.6 Information List ... 2067
8.3.7 Voltage-Sum Supervision ... 2067
8.3.7.1 Overview of Functions ... 2067
8.3.7.2 Structure of the Function ... 2068
8.3.7.3 Function Description ... 2068
8.3.7.4 Application and Setting Notes ... 2070
8.3.7.5 Settings ... 2070
8.3.7.6 Information List ... 2070
8.3.8 Voltage Phase-Rotation Supervision ... 2070
8.3.8.1 Overview of Functions ... 2070
8.3.8.2 Structure of the Function ... 2070
8.3.8.3 Function Description ... 2071
8.3.8.4 Application and Setting Notes ... 2072
8.3.8.5 Settings ... 2072
8.3.8.6 Information List ... 2072
8.3.9 Auxiliary Direct-Voltage Supervision ... 2072
8.3.9.1 Overview of Functions ... 2072
8.3.9.2 Structure of the Function ... 2073
8.3.9.3 Auxiliary Direct-Voltage Measurement ... 2073
8.3.9.4 Stage Description ... 2074
8.3.9.5 Application and Setting Notes ... 2075
8.3.9.6 Settings ... 2076
8.3.9.7 Information List ... 2077
8.3.10 Current-Balance Supervision ... 2077
8.3.10.1 Overview of Functions ... 2077
8.3.10.2 Structure of the Function ... 2077
8.3.10.3 Function Description ... 2078
8.3.10.4 Application and Setting Notes ... 2079
8.3.10.5 Settings ... 2080
8.3.10.6 Information List ... 2080
8.3.11 Current-Sum Supervision ... 2080
8.3.11.1 Overview of Functions ... 2080
8.3.11.2 Structure of the Function ... 2081
8.3.11.3 Function Description ... 2081
8.3.11.4 Application and Setting Notes ... 2083
8.3.11.5 Settings ... 2083
8.3.11.6 Information List ... 2084
8.3.12 Current Phase-Rotation Supervision ... 2084
8.3.12.1 Overview of Functions ... 2084
8.3.12.2 Structure of the Function ... 2084
8.3.12.3 Function Description ... 2085
8.3.12.4 Application and Setting Notes ... 2086
8.3.12.5 Settings ... 2086
8.3.12.6 Information List ... 2086
8.3.13 Saturation Detection ... 2086
8.3.13.1 Overview of Functions ... 2086
8.3.13.2 Structure of the Function ... 2087
8.3.13.3 Function Description ... 2087
8.3.13.4 Application and Setting Notes ... 2087
8.3.13.5 Settings ... 2088
8.3.14 Trip-Circuit Supervision ... 2088
8.3.14.1 Overview of Functions ... 2088
8.3.14.2 Structure of the Function ... 2088
8.3.14.3 Trip-Circuit Supervision with 2 Binary Inputs ... 2089
8.3.14.4 Trip-Circuit Supervision with 1 Binary Input ... 2090
8.3.14.5 Application and Setting Notes ... 2093

8.3.14.6 Settings ... 2094
8.3.14.7 Information List ... 2094
8.3.15 Closing-Circuit Supervision ... 2094
8.3.15.1 Overview of Functions ... 2094
8.3.15.2 Structure of the Function ... 2095
8.3.15.3 Closing-Circuit Supervision with 3 Binary Inputs ... 2095
8.3.15.4 Closing-Circuit Supervision with 2 Binary Inputs ... 2100
8.3.15.5 Closing-Circuit Supervision with 1 Binary Input ... 2101
8.3.15.6 Application and Setting Notes ... 2104
8.3.15.7 Settings ... 2104
8.3.15.8 Information List ... 2105
8.4 Supervision of the Device Hardware ... 2106
8.4.1 Overview ... 2106
8.4.2 Analog-Channel Supervision via Fast Current-Sum ... 2107
8.4.2.1 Overview of Functions ... 2107
8.4.2.2 Structure of the Function ... 2107
8.4.2.3 Function Description ... 2108
8.5 Supervision of Device Firmware ... 2111
8.6 Supervision of Hardware Configuration ... 2112
8.7 Supervision of Communication Connections ... 2113
8.8 Error Responses and Corrective Measures ... 2114
8.8.1 Overview ... 2114
8.8.2 Defect Severity 1 ... 2115
8.8.3 Defect Severity 2 ... 2119
8.8.4 Defect Severity 3 ... 2120
8.8.5 Defect Severity 4 (Group Alarm) ... 2121
8.9 Group Indications ... 2123

9 Measured Values, Energy Values, and Supervision of the Primary System ... 2125
9.1 Overview of Functions ... 2126
9.2 Structure of the Function ... 2127
9.3 Operational Measured Values ... 2129
9.4 Fundamental and Symmetrical Components ... 2131
9.5 Phasor Measurement Unit (PMU) ... 2132
9.5.1 Overview of Functions ... 2132
9.5.2 Structure of the Function Group ... 2132
9.5.3 Function Description ... 2132
9.5.4 Transmitted Data ... 2137
9.5.5 PMU Communication (IEEE C37.118) ... 2137
9.5.6 Parameterizing the PMU with DIGSI ... 2139
9.5.7 Parameterizing the PMU on the Device ... 2150
9.5.8 Application and Setting Notes ... 2151
9.5.9 Settings ... 2155
9.5.10 Information List ... 2156
9.6 Average Values ... 2157
9.6.1 Function Description of Average Values ... 2157
9.6.2 Application and Setting Notes for Average Values ... 2157
9.7 Minimum/Maximum Values ... 2160
9.7.1 Function Description of Minimum/Maximum Values ... 2160

9.7.2 Application and Setting Notes for Minimum/Maximum Values....2161
9.8 Energy Values....2162
9.8.1 Function Description of Energy Values....2162
9.8.2 Application and Setting Notes for Energy Values....2163
9.9 User-Defined Metered Values....2165
9.9.1 Function Description of Pulse-Metered Values....2165
9.9.2 Application and Setting Notes for Pulse-Metered Values....2166
9.10 Statistical Values of the Primary System....2169
9.11 Measuring Transducers....2170
9.11.1 Overview of Functions....2170
9.11.2 Structure of the Function....2170
9.11.3 Function Description....2170
9.11.4 Application and Setting Notes....2173
9.11.5 Settings....2174
9.11.6 Information List....2176
9.12 Circuit-Breaker Monitoring....2177
9.12.1 Overview of Functions....2177
9.12.2 Structure of the Function....2177
9.12.3 General Functionality....2178
9.12.3.1 Description....2178
9.12.3.2 Application and Setting Notes....2179
9.12.3.3 Settings....2180
9.12.3.4 Information List....2180
9.12.4 ΣIx Method....2181
9.12.4.1 Description....2181
9.12.4.2 Application and Setting Notes....2183
9.12.4.3 Settings....2183
9.12.4.4 Information List....2183
9.12.5 2P Method....2187
9.12.5.1 Description....2187
9.12.5.2 Application and Setting Notes....2190
9.12.5.3 Settings....2191
9.12.5.4 Information List....2192
9.12.6 I2t Method....2195
9.12.6.1 Description....2195
9.12.6.2 Application and Setting Notes....2196
9.12.6.3 Settings....2196
9.12.6.4 Information List....2196
9.12.7 Make Time....2200
9.12.7.1 Description....2200
9.12.7.2 Application and Setting Notes....2201
9.12.7.3 Settings....2201
9.12.7.4 Information List....2202
9.12.8 Break Time....2206
9.12.8.1 Description....2206
9.12.8.2 Application and Setting Notes....2207
9.12.8.3 Settings....2207
9.12.8.4 Information List....2208
9.12.9 Pole Scatter Time Open....2211
9.12.9.1 Description....2211
9.12.9.2 Application and Setting Notes....2212
9.12.9.3 Settings....2212

9.12.9.4 Information List ... 2213
9.12.10 Pole scatter time close ... 2214
9.12.10.1 Description ... 2214
9.12.10.2 Application and Setting Notes ... 2214
9.12.10.3 Settings ... 2215
9.12.10.4 Information List ... 2215
9.12.11 Mechanical Switching Time Open ... 2217
9.12.11.1 Description ... 2217
9.12.11.2 Application and Setting Notes ... 2219
9.12.11.3 Settings ... 2220
9.12.11.4 Information List ... 2221
9.12.12 Mechanical Switching Time Close ... 2225
9.12.12.1 Description ... 2225
9.12.12.2 Application and Setting Notes ... 2227
9.12.12.3 Settings ... 2228
9.12.12.4 Information List ... 2229
9.12.13 Operation counter ... 2232
9.12.13.1 Description ... 2232
9.12.13.2 Application and Setting Notes ... 2233
9.12.13.3 Settings ... 2233
9.12.13.4 Information List ... 2233
9.13 Disconnector-Switch Monitoring ... 2237
9.13.1 Overview of Functions ... 2237
9.13.2 Structure of the Function ... 2237
9.13.3 General Functionality ... 2237
9.13.3.1 Description ... 2237
9.13.3.2 Application and Setting Notes ... 2237
9.13.3.3 Settings ... 2237
9.13.3.4 Information List ... 2238
9.13.4 Mechanical Switching Time Open ... 2239
9.13.4.1 Description ... 2239
9.13.4.2 Application and Setting Notes ... 2240
9.13.4.3 Settings ... 2241
9.13.4.4 Information List ... 2241
9.13.5 Mechanical Switching Time Close ... 2242
9.13.5.1 Description ... 2242
9.13.5.2 Application and Setting Notes ... 2243
9.13.5.3 Settings ... 2244
9.13.5.4 Information List ... 2244

10 Power Quality – Basic ... 2247

10.1 Voltage Variation ... 2248
10.1.1 Overview of Functions ... 2248
10.1.2 Structure of the Function ... 2248
10.1.3 General Functionality ... 2249
10.1.3.1 Description ... 2249
10.1.4 Stage Dip ... 2249
10.1.4.1 Description ... 2249
10.1.4.2 Application and Setting Notes ... 2254
10.1.4.3 Settings ... 2254
10.1.4.4 Information List ... 2255
10.1.5 Stage Swell ... 2255
10.1.5.1 Description ... 2255
10.1.5.2 Application and Setting Notes ... 2258

10.1.5.3 Settings ... 2258
10.1.5.4 Information List ... 2259
10.1.6 Stage Interruption ... 2259
10.1.6.1 Description ... 2259
10.1.6.2 Application and Setting Notes ... 2262
10.1.6.3 Settings ... 2262
10.1.6.4 Information List ... 2263
10.2 Voltage Unbalance ... 2264
10.2.1 Overview of Functions ... 2264
10.2.2 Structure of the Function ... 2264
10.2.3 Stage V2/V1 ... 2265
10.2.3.1 Description ... 2265
10.2.3.2 Application and Setting Notes ... 2268
10.2.3.3 Settings ... 2270
10.2.3.4 Information List ... 2270
10.2.4 Stage V0/V1 ... 2271
10.2.4.1 Description ... 2271
10.2.4.2 Application and Setting Notes ... 2274
10.2.4.3 Settings ... 2275
10.2.4.4 Information List ... 2275
10.3 THD and Harmonics ... 2277
10.3.1 Overview of Functions ... 2277
10.3.2 Structure of the Function ... 2277
10.3.3 Stage Current ... 2278
10.3.3.1 Function Description ... 2278
10.3.3.2 Information List ... 2279
10.3.4 Stage Voltage ... 2279
10.3.4.1 Function Description ... 2279
10.3.4.2 Application and Setting Notes ... 2284
10.3.4.3 Settings ... 2284
10.3.4.4 Information List ... 2284
10.4 Total Demand Distortion ... 2286
10.4.1 Overview of Functions ... 2286
10.4.2 Structure of the Function ... 2286
10.4.3 Stage Current ... 2287
10.4.4 Application and Setting Notes ... 2289
10.4.5 Settings ... 2290
10.4.6 Information List ... 2290

11 Functional Tests ... 2291

11.1 General Notes ... 2292
11.2 Enabling/Disabling the Application/Test Mode for the Entire Device ... 2293
11.3 Checking System Integration ... 2295
11.4 Commissioning Notes Transformer Differential Protection ... 2297
11.4.1 Secondary Tests ... 2297
11.4.2 Primary Tests ... 2299
11.5 Generator Differential Protection ... 2309
11.5.1 Secondary Tests ... 2309
11.5.2 Primary Tests ... 2310

11.6 Commissioning Notes Motor Differential Protection....2311
11.6.1 Secondary Tests....2311
11.6.2 Primary Tests....2312
11.7 Functional Test Line Differential Protection....2313
11.7.1 Test Options and Test Modes....2313
11.7.2 Functional Test in All Devices....2314
11.7.2.1 General Information....2314
11.7.2.2 Procedure....2315
11.7.3 Functional Test in the Local Device....2315
11.7.3.1 General Information....2315
11.7.3.2 Functional Test in Case of Non-Effective Line Differential Protection in the Remote Devices – Procedure 1....2317
11.7.3.3 Functional Test in Case of Non-Effective Line Differential Protection in the Remote Devices – Procedure 2....2318
11.7.3.4 Functional Test in Case of Effective Line Differential Protection in the Remote Devices – Procedure 1....2318
11.7.3.5 Functional Test in Case of Effective Line Differential Protection in the Remote Devices – Procedure 2....2319
11.7.4 Checking the Operating Point....2321
11.7.5 Use of Test Switches....2324
11.8 Commissioning Notes for Restricted Ground-Fault Protection....2325
11.9 Direction Test of the Phase Quantities (Current and Voltage Connection)....2326
11.10 Direction Test of Ground Quantities for Directional Ground-Fault Functions....2327
11.10.1 Overview....2327
11.10.2 Directional Testing for Solid or Resistive-Grounded Systems....2327
11.10.3 Directional Testing for Isolated or Resonant-Grounded Systems....2329
11.11 Commissioning Hints for Voltage Control....2331
11.11.1 Secondary Tests....2331
11.11.1.1 General....2331
11.11.1.2 Checking the Transformer Tap Position....2331
11.11.1.3 Check of the Voltage-Control Function....2334
11.11.1.4 Further Tests....2335
11.11.1.5 Voltage-Control Function for Parallel Transformers....2338
11.11.2 Primary Tests....2343
11.12 Functional Test Protection Communication....2347
11.12.1 Checking the Protection-Data Communication....2347
11.12.2 Directional Test....2348
11.13 Functional Test for Overexcitation Protection....2349
11.14 Functional Test of Thermal Overload Protection....2350
11.15 Functional Test Hotspot Calculation....2352
11.15.1 Secondary Test....2352
11.16 Reverse-Power Protection....2353
11.16.1 Secondary Test....2353
11.16.2 Primary Test....2353
11.17 Primary and Secondary Tests of the Circuit-Breaker Failure Protection....2356
11.18 Circuit-Breaker Test....2359
11.19 Functional Test of the Inrush-Current Detection....2362
11.20 Functional Test of Transient Ground-Fault Protection....2363
11.21 Functional Test of the Trip-Circuit Supervision....2364

11.22 Functional Test for the Phase-Rotation Reversal ... 2365
11.23 Primary and Secondary Testing of the Synchronization Function ... 2366

12 Technical Data ... 2371
12.1 General Device Data ... 2374
12.1.1 Analog Inputs ... 2374
12.1.2 Supply Voltage ... 2379
12.1.3 Binary Inputs ... 2380
12.1.4 Relay Outputs ... 2381
12.1.5 Design Data ... 2383
12.2 Transformer Differential Protection ... 2388
12.3 Restricted Ground-Fault Protection ... 2391
12.4 Motor Differential Protection ... 2393
12.5 Generator Differential Protection ... 2396
12.6 Line Differential Protection ... 2399
12.7 Stub-Differential Protection ... 2402
12.8 Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems ... 2403
12.9 Teleprotection with Ground-Fault Protection ... 2408
12.10 Directional Intermittent Ground-Fault Protection ... 2409
12.11 Non-Directional Intermittent Ground-Fault Protection ... 2411
12.12 Sensitive Ground-Fault Detection ... 2413
12.12.1 General ... 2413
12.12.2 Directional 3I0 Stage with cos φ or sin φ Measurement ... 2414
12.12.3 Directional Transient Ground-Fault Stage ... 2415
12.12.4 Directional 3I0 Stage with φ(V0,3I0) Measurement ... 2416
12.12.5 Directional Y0 Stage with G0 or B0 Measurement (Admittance) ... 2417
12.12.6 Directional Stage with Phasor Measurement of a Harmonic ... 2418
12.12.7 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage ... 2419
12.12.8 Non-Directional 3I0 Stage ... 2420
12.12.9 Non-Directional Y0 Stage ... 2420
12.12.10 Non-Directional 3I0 Harmonic Stage ... 2421
12.12.11 Pulse-Pattern Detection Stage ... 2422
12.12.12 Intermittent Ground-Fault Blocking Stage ... 2423
12.13 Distance Protection ... 2425
12.14 Impedance Protection ... 2428
12.15 Power-Swing Blocking ... 2429
12.16 External Trip Initiation ... 2430
12.17 External Trip Initiation with Current-Flow Criterion ... 2431
12.18 Overcurrent Protection, Phases ... 2432
12.18.1 Stage with Definite-Time Characteristic Curve ... 2432
12.18.2 Stage with Inverse-Time Characteristic Curve ... 2434
12.18.3 Stage with User-Defined Characteristic Curve ... 2442
12.19 Overcurrent Protection, Ground ... 2446
12.19.1 Stage with Definite-Time Characteristic Curve ... 2446
12.19.2 Stage with Inverse-Time Characteristic Curve ... 2447
12.19.3 Stage with User-Defined Characteristic Curve ... 2449

12.20 Overcurrent Protection, 1-Phase ... 2451
12.20.1 Stage with Definite-Time Characteristic Curve ... 2451
12.20.2 Stage with Inverse-Time Characteristic Curve ... 2452
12.20.3 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve ... 2454
12.20.4 Stage with User-Defined Characteristic Curve ... 2456
12.21 Overcurrent Protection, 1-Phase (Fast Stage) ... 2458
12.22 Voltage-Dependent Overcurrent Protection, Phases ... 2459
12.23 Directional Overcurrent Protection, Phases ... 2462
12.23.1 Stage with Definite-Time Characteristic Curve ... 2462
12.23.2 Stage with Inverse-Time Characteristic Curve ... 2463
12.23.3 Stage with User-Defined Characteristic Curve ... 2466
12.24 Directional Overcurrent Protection, Ground ... 2469
12.24.1 Stage with Definite-Time Characteristic Curve ... 2469
12.24.2 Stage with Inverse-Time Characteristic Curve ... 2470
12.24.3 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve ... 2472
12.24.4 Stage with Knee-Point Characteristic Curve ... 2474
12.24.5 Stage with User-Defined Characteristic Curve ... 2477
12.25 Positive-Sequence Overcurrent Protection ... 2479
12.25.1 Stage with Definite-Time Characteristic Curve ... 2479
12.25.2 Stage with Inverse-Time Characteristic Curve ... 2480
12.26 Negative-Sequence Protection ... 2482
12.26.1 Stage with Definite-Time Characteristic Curve ... 2482
12.26.2 Stage with Inverse-Time Characteristic Curve ... 2483
12.27 Directional Negative-Sequence Protection with Definite-Time Delay ... 2486
12.28 Undercurrent Protection ... 2488
12.29 Overexcitation Protection ... 2490
12.30 Unbalanced-Load Protection ... 2492
12.31 Instantaneous High-Current Tripping ... 2494
12.32 Overvoltage Protection with 3-Phase Voltage ... 2495
12.33 Overvoltage Protection with Positive-Sequence Voltage ... 2497
12.34 Overvoltage Protection with Negative-Sequence Voltage ... 2498
12.35 Overvoltage Protection with Negative-Sequence Voltage/Positive-Sequence Voltage ... 2499
12.36 Overvoltage Protection with Zero-Sequence Voltage/Residual Voltage ... 2500
12.37 Overvoltage Protection with Any Voltage ... 2503
12.38 Undervoltage Protection with 3-Phase Voltage ... 2505
12.39 Undervoltage Protection with Positive-Sequence Voltage ... 2508
12.40 Undervoltage Protection with Any Voltage ... 2510
12.41 Rate-of-Voltage-Change Protection ... 2512
12.42 Undervoltage-Controlled Reactive-Power Protection ... 2514
12.43 Voltage-Comparison Supervision ... 2516
12.44 Fault Locator ... 2517
12.45 Fault Locator Plus ... 2518
12.46 Overfrequency Protection ... 2519

12.47 Underfrequency Protection ... 2520
12.48 Underfrequency Load Shedding ... 2521
12.49 Rate of Frequency Change Protection ... 2523
12.50 Instantaneous Tripping at Switch onto Fault ... 2525
12.51 Thermal Overload Protection, 3-Phase – Advanced ... 2526
12.52 Thermal Overload Protection, User-Defined Characteristic Curve ... 2530
12.53 Thermal Overload Protection, 1-Phase ... 2531
12.54 Function Group Analog Units ... 2534
12.55 Temperature Supervision ... 2535
12.56 Hotspot Calculation ... 2536
12.57 Circuit-Breaker Failure Protection ... 2538
12.58 Circuit-Breaker Restrike Protection ... 2540
12.59 Pole Discrepancy Protection ... 2541
12.60 Arc Protection ... 2542
12.61 Power-Plant Disconnection Protection ... 2543
12.62 Inrush-Current Detection ... 2545
12.63 2nd Harmonic Detection Ground ... 2547
12.64 2nd Harmonic Detection 1-Phase ... 2549
12.65 Power Protection (P,Q), 3-Phase ... 2551
12.66 Reverse-Power Protection ... 2553

1 Introduction

1.1	General	52
1.2	Properties of SIPROTEC 5	53
1.3	Overview of Transformer Protection Devices	54

1.1 General

The digital multifunctional protection and bay controllers of the SIPROTEC 5 device series are fitted with a powerful microprocessor. As a result, all tasks, from acquiring measurands to entering commands in the circuit breaker, are processed digitally.

Analog Inputs

The measuring inputs transform the currents and voltages sent by the instrument transformers and adapt them to the internal processing level of the device. A SIPROTEC 5 device consists of inputs for measuring current and voltage. The current inputs are intended for the detection of phase currents and ground current. The ground current can be detected sensitively using a core balance current transformer. In addition, phase currents can be detected very sensitively for a particularly precise measurement. The voltage inputs detect the measuring voltage of device functions requiring voltage measured values.

The analog values are digitized in the microprocessor for data processing.

Microprocessor System

All device functions are processed in the microprocessor system.

This includes, for example:

- Filtering and preparation of the measurands
- Constant monitoring of the measurands
- Monitoring of the pickup conditions for the individual protection functions
- Querying of limiting values and time sequences
- Control of signals for logic functions
- Control of open and close commands
- Recording of indications, fault data, and fault values for fault analysis
- Administration of the operating system and its functions, for example data storage, real-time clock, communication, interfaces
- External distribution of information

Binary Inputs and Outputs

Using the binary inputs and outputs, the device receives information from the system or from other devices (such as locking commands). The most important outputs include the commands to the switching devices and the indications for remote signaling of important events and states.

Front Elements

For devices with an integrated or offset operation panel, LEDs and an LC display on the front provide information on the device function and report events, states, and measured values. In conjunction with the LC display, the integrated keypad enables on-site operation of the device. All device information such as setting parameters, operating and fault indications or measured values can be displayed, and setting parameters changed. In addition, system equipment can be controlled via the user interface of the device.

Serial Interfaces

The serial interface in the front panel enables communication with a personal computer when using the DIGSI operating program. As a result, the operation of all device functions is possible. Additional interfaces on the rear are used to implement various communication protocols.

Power Supply

The individual functional units of the device are powered by an internal power supply. Brief interruptions in the supply voltage, which can occur during short circuits in the system auxiliary voltage supply, are bridged by capacitor storage (see also the Technical Data).

1.2 Properties of SIPROTEC 5

The SIPROTEC 5devices at the bay level are compact and can be installed directly in medium and high-voltage switchgear. They are characterized by comprehensive integration of protection and control functions.

General Properties

- Powerful microprocessor
- Fully digital measured-value processing and control, from sampling and digitizing of measurands to closing and tripping decisions for the circuit breaker
- Complete galvanic and interference-free isolation of the internal processing circuits from the system measuring, control, and supply circuits through instrument transformers, binary input and output modules, and DC and AC voltage converters
- Easy operation using an integrated operator and display panel, or using a connected personal computer with user interface
- Continuous display of measured and metered values at the front
- Storage of min/max measured values (slave pointer function) and storage of long-term average values
- Storage of fault indications for system incidents (faults in system) with real-time assignment and instantaneous values for fault recording
- Continuous monitoring of the measurands as well as the device hardware and software
- Communication with central control and storage devices possible via the device interface
- Battery-buffered, synchronizable clock

Modular Concept

The SIPROTEC 5 modular concept ensures the consistency and integrity of all functionalities across the entire device series. Significant features here include:

- Modular system design in hardware, software, and communication
- Functional integration of various applications, such as protection, control, and fault recorder
- The same expansion and communication modules for all devices in the family
- Innovative terminal technology with easy assembly and interchangeability and the highest possible degree of safety
- The same functions can be configured individually across the entire family of devices
- Ability to upgrade with innovations possible at all times through libraries
- Open, scalable architecture for IT integration and new functions
- Multi-layered security mechanisms in all links of the security chain
- Self-monitoring routines for reliable localization and indication of device faults
- Automatic logging of access attempts and security-critical operations on the devices and systems

Redundant Communication

SIPROTEC 5devices maintain full communication redundancy:

- Multiple redundant communication interfaces
- Redundant and independent protocols to control centers possible (such as IEC 60870-5-103 and IEC 61850, either single or redundant)
- Redundant time synchronization (such as IRIG B, SNTP or IEEE 1588).

1.3 Overview of Transformer Protection Devices

The protected object can be a power transformer in multi-winding design as well as an auto transformer. The main protection functions supplement the transformer differential protection by the restricted ground-fault protection. In addition more supplemental protection functions can be activated.

The protection device classification is oriented to the basic design of the protected object. The simplest design is a two-winding transformer with different vector group. The design can also be the simplest form of the auto transformer. After that comes the three-winding transformer with different vector-group design. The design can also be an auto transformer with stabilizing winding. The last groups are multi-winding transformers, which are often found with converter applications (for example high-voltage direct-current transmission).

An important differentiating characteristic of the devices is the ability to process the number of windings (in the following called transformer sides) and the number of measuring points. For the transformer sides, the 7UT8x offers greater flexibility. In this way, you can expand 7UT85 (two-winding transformer) to up to 3 transformer sides, and the 7UT86 (three-winding transformer) to up to 4 transformer sides using function points, if necessary. This allows greater flexibility for plant expansions or for spare parts stocking.

The following table gives you a rough overview of the 4 classes of the transformer differential protection devices.

Table 1-1 Classification of the Devices

7	UT		Essential Differentiating Characteristics
7	UT	82	Two-winding transformer (2 sides and maximum 2 measuring points)
7	UT	85	Two-winding transformer (3 sides of which 2 are free of charge and a maximum of 5 measuring points)
7	UT	86	Three-winding transformer (4 sides of which 3 are free of charge and a maximum of 7 measuring points)
7	UT	87	Multi-winding transformer (5 sides and maximum 20 measuring points)

With 7UT87, there is a special feature. Due to the maximum number of 5 sides, the simultaneous protection of 2 transformers (for example from 2 two-winding transformers) is possible through one device. More information on possibilities for use can be found in the device catalog or the application templates in chapter *4 Applications*.

Typical properties of the 4 device types are presented in the following table:

Table 1-2 Overview of the Available Measuring Points

Device	Measuring Points
7UT82	Two 1-phase current measuring points (1ph I) Two 3-phase current measuring points (3ph I)
7UT85	Five 3-phase current measuring points (3ph I) Five 1-phase current measuring points (1ph I) Five 3-phase voltage measuring points (3ph V) Five 1-phase voltage measuring points (1ph V)
7UT86	Seven 3-phase current measuring points (3ph I) Seven 1-phase current measuring points (1ph I) Seven 3-phase voltage measuring points (3ph V) Seven 1-phase voltage measuring points (1ph V)
7UT87	Twenty 3-phase current measuring points (3ph I) Twenty 1-phase current measuring points (1ph I) Twenty 3-phase voltage measuring points (3ph V) Twenty 1-phase voltage measuring points (1ph V)

Table 1-3 Properties – 7UT82

Short description	Differential protection for two-winding transformers for all voltage levels
Main protection function	1 differential protection function (standard transformer) with additional stabilization; up to 2 restricted ground-fault protection functions
Inputs and outputs	1 predefined standard variable with 8 current transformers, 7 binary inputs, 6 binary outputs
Width of housing	1/3 × 19 inches

Table 1-4 Properties – 7UT85

Short description	Differential protection for two-winding transformers for all voltage levels
Main protection function	1 differential protection function (standard or auto transformer) with additional stabilization; up to 2 restricted ground-fault protection functions
Inputs and outputs Hardware flexibility	2 predefined standard variants with 8 current transformers, 7 to 19 binary inputs, 7 to 23 binary outputs Flexible adaptable and expandable I/O quantity structure of the modular SIPROTEC 5 module
Width of housing	1/3 × 19 inches to 1/1 × 19 inches

Table 1-5 Properties – 7UT86

Short description	Differential protection for three-winding transformers for all voltage levels
Main protection function	1 differential protection function (standard) with additional stabilization; up to 3 restricted ground-fault protection functions. For auto transformer applications 2 differential protection functions can be processed in an auto transformer function group.
Inputs and outputs Hardware flexibility	2 predefined standard variants with 12 current transformers, 4 voltage transformers, 11 to 23 binary inputs, 19 to 34 binary outputs Flexible adaptable and expandable I/O quantity structure of the modular SIPROTEC 5 module
Width of housing	1/2 × 19 inches to 1/1 × 19 inches

Table 1-6 Properties – 7UT87

Short description	Differential protection for multi-winding transformers for all voltage levels
Main protection function	Up to 3 differential protection functions with additional stabilization (in different transformer function groups); up to 5 restricted ground-fault protection functions. For auto transformer applications 2 differential protection functions can be processed in an auto transformer function group.
Inputs and outputs Hardware flexibility	2 predefined standard variants with 20 current transformers, 4 voltage transformers, 15 to 27 binary inputs, 22 to 38 binary outputs Flexible adaptable and expandable I/O quantity structure of the modular SIPROTEC 5 module
Width of housing	2/3 × 19 inches to 1/1 × 19 inches

The important functional properties of the devices are:

- Transformer protection for two-winding, three-winding, and multi-winding transformers with versatile, additional protection functions
- Universal usability of the permissible measuring points
- Applicable from average up to extra-high voltage
- Protection from standard power transformers and auto transformers

- Typical properties of a transformer differential protection, such as flexible adaptation to the transformer vector group, command of closing and overexcitation processes, reliable behavior in current-transformer saturation with different degrees of saturation
- Increased sensitivity with near-neutral-point ground faults through a separate restricted ground-fault protection
- Voltage controller for the control and regulation of motor-operated tap changers
- Additional current and voltage inputs can be supplements for standard protection functions, such as overcurrent, voltage frequency, etc.
- In the standard design 2 communication modules are pluggable, as well as different logs are usable (IEC 61850, IEC 60870-5-103, DNP3 (serial+IP), Modbus RTU Slave)
- Performance automation with CFC (Continuous Function Chart)
- Secure serial protection data communication, also over great distances and all available physical media (optical fibers, two-wire connections and communication networks)
- Measurement of all relevant operating variables
- Powerful fault recording
- Consistent monitoring concept
- Auxiliary functions for simple tests and commissioning

2 Basic Structure of the Function

2.1	Embedding of Functions in the Device	58
2.2	Application Templates/Adaptation of Functional Scope	64
2.3	Function Control	66
2.4	Text Structure and Reference Number for Settings and Indications	72
2.5	Information Lists	74

2.1 Embedding of Functions in the Device

General

SIPROTEC 5 devices offer great flexibility in the handling of functions. Functions can be individually loaded into the device. Additionally, it is possible to copy functions within a device or between devices. The necessary integration of functions in the device is illustrated by the following example.

NOTE

The availability of certain settings and setting options depends on the device type and the functions available on the device!

EXAMPLE

A 1 1/2 circuit-breaker layout of the 7SA86 distance protection device serves as an example. The following protection functions are required for implementation (simplified and reduced):

- Distance protection (21)
- Overcurrent protection, phases (51)
- Circuit-breaker failure protection (50BF), for circuit breakers 1 and 2
- Basic functionality (for example handling of tripping)

Several predefined function packages that are tailored to specific applications exist for each device family. A predefined functional scope is called an **application template**. The existing application templates are offered for selection automatically when you create a new device in DIGSI 5.

EXAMPLE

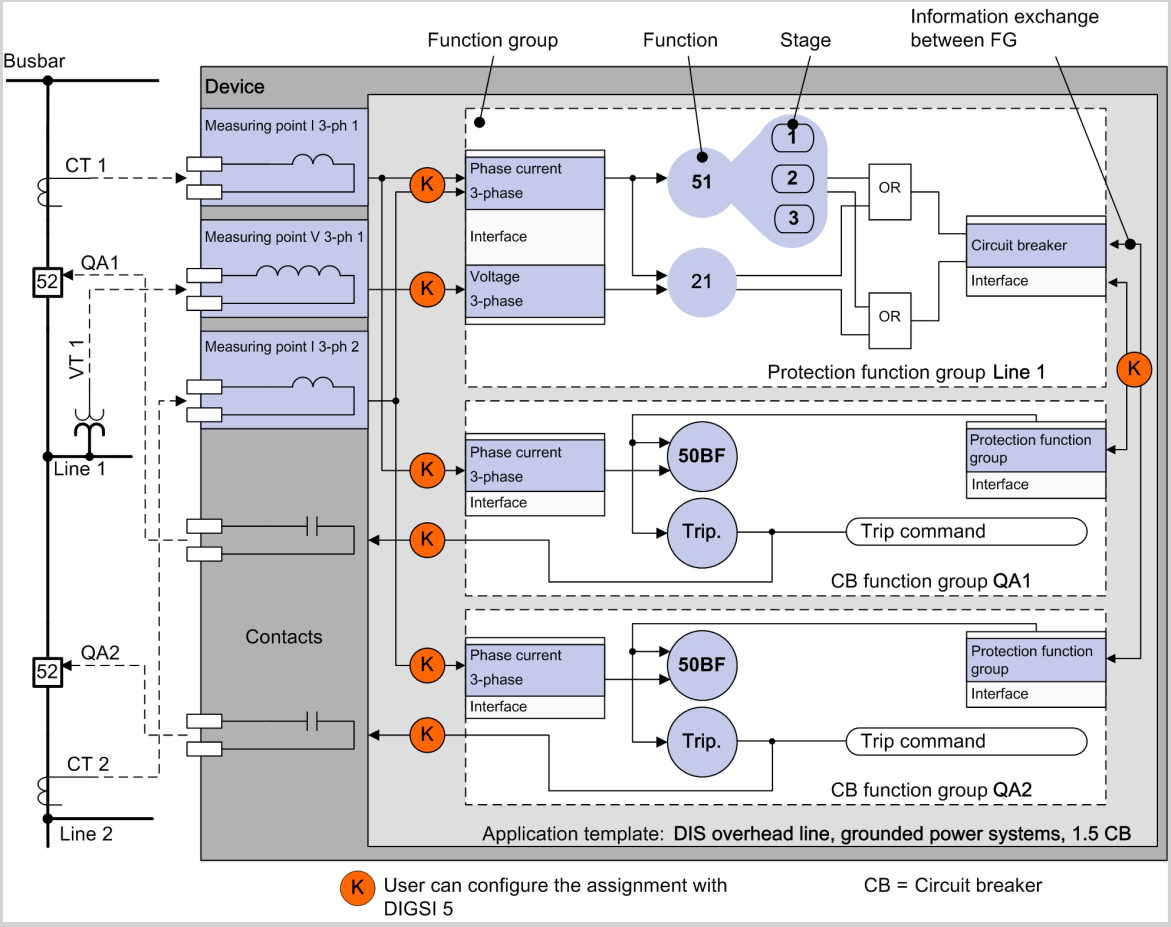
When creating the device in DIGSI 5, you must select the appropriate application template. In the example, select the application template **DIS overhead line, grounded systems, 1 1/2 circuit-breaker layout**. This application template covers the required functional scope. Selecting this application template determines the preconfigured functional scope. This can be changed as necessary (see *2.2 Application Templates/Adaptation of Functional Scope*).

Function Groups (FG)

Functions are arranged in function groups. This simplifies handling of functions (adding and copying). The function groups are assigned to primary objects, such as a line, transformer, or circuit breaker.

The function groups bundle functions with regard to the following basic tasks:

- Assignment of functions to currentand/or voltage transformers (assignment of functions to the measuring points and thus to the protected object)
- Exchange of information between function groups



When a function is copied into a function group, it automatically works with the measuring points assigned to the function group. Their output signals are also automatically included in the configured interfaces of the function group.

EXAMPLE

The selected application template **DIS overhead line, grounded systems, 1 1/2 circuit-breaker layout** comprises 3 function groups:

- Protection function group **Line 1**
- Circuit-breaker function group **QA 1**
- Circuit-breaker function group **QA 2**

The following figure shows the embedding of functions via function groups.

[dw_eifkfg, 1, en_US]

Figure 2-1 Embedding the Functions via Function Groups

Depending on the type of device, there are different types of function groups:

- Protection function groups
- Circuit-breaker function groups

Protection function groups bundle functions that are assigned to one protected object – for example to the line. Depending on the device type and nature of the protected object, there are different types of protection function groups (for example line, voltage/current 3-phase, transformer, motor, generator).

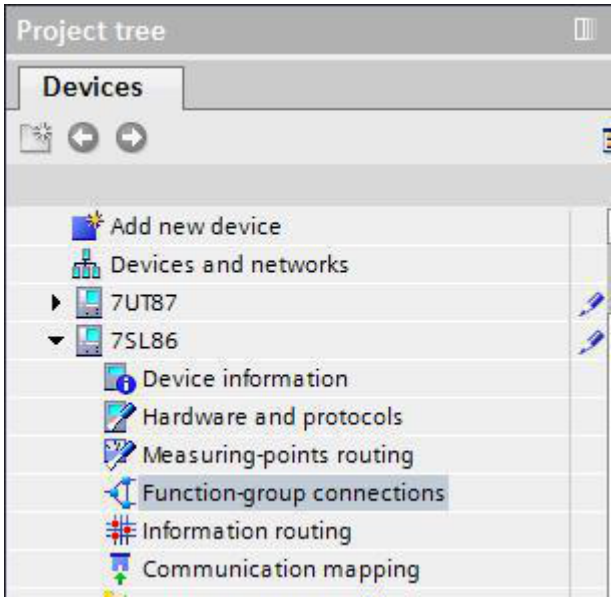
Circuit-breaker function groups bundle functions assigned to the local switches – for example, circuit breakers and disconnectors (such as processing of tripping, circuit-breaker failure protection).

The number and type of function groups differ in the respective application templates, depending on the type of the device and application. You can add, copy, or even delete function groups for a specific application. You can also adapt the functional scope within a function group according to the use case. For detailed information on this, refer to the DIGSI 5 Online Help manual.

Interface Between Function Group and Measuring Point

The function groups receive the measurands of the current and voltage transformers from measuring points. For this, the function groups are connected to 1 or more measuring points.

The number of measuring points and the assignment of function groups to the measuring points are preset by the selected application template in accordance with the specific application. Therefore, this specifies which measuring point(s) and the corresponding measurands have to be used by which function within the function group.

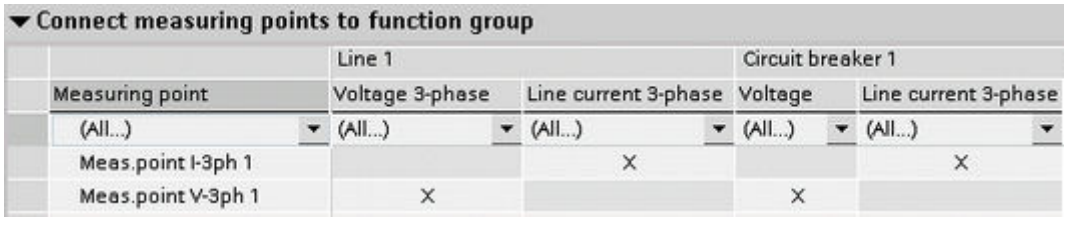


EXAMPLE

The measuring points are assigned to the function groups in the application template in *Figure 2-1* as follows:

- The protection function group **Line** is assigned to the measuring points **I-3ph 1**, **I-3ph 2**, and **V-3ph 1**. The function group therefore receives the measured values from the current transformers 1 and 2, as well as from the voltage transformer 1. The currents of measuring points **I-3ph 1** and **I-3ph 2** are geometrically added, for a feeder-related processing.
- The circuit-breaker function group **QA1** is assigned to the measuring point **I-3ph 1** and receives the measured values from current transformer 1.
- The circuit-breaker function group **QA2** is assigned to the measuring point **I-3ph 2** and receives the measured values from current transformer 2.

You can change the assignment on demand, that is, function groups can be assigned to any available measuring points of the device.



To check or change the assignment of measuring points to the function groups, double-click **Function-group connections** in the DIGSI 5 project tree.

[sc_fgverb, 1, en_US]

Figure 2-2 Project Tree in DIGSI 5 (Detail)

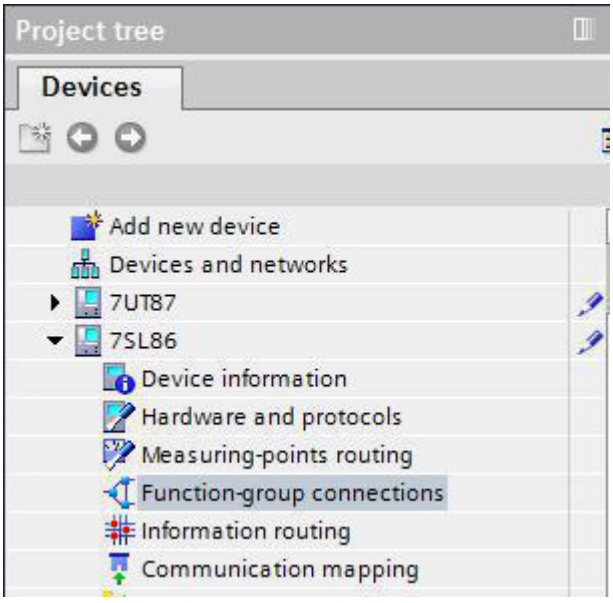
The window for routing of the measuring points opens in the working area (see the following figure, does not correspond to the example).

[scmscofg-180311-01.tif, 1, en_US]

Figure 2-3 Connecting Measuring Points and Function Groups

Interface Between Protection and Circuit-Breaker Function Groups

The protection function group(s) is/are connected to one or several circuit-breaker function groups. This connection generally determines:

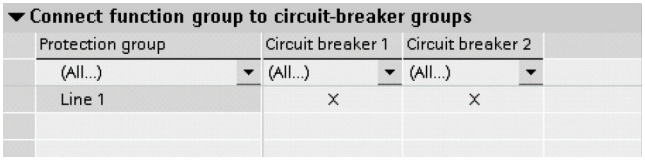


- Which circuit breaker(s) is/are started by the protection functions of the protection FG.
- Starting the **Circuit-breaker failure protection** function (if available in the Circuit-breaker function group) through the protection functions of the connected protection function group
- Starting the **Automatic reclosing** function (AREC, if available in the Circuit-breaker function group) through the protection functions of the connected protection function group

Besides the general assignment of the protection function group(s) to the circuit-breaker function groups, you can also configure the interface for specific functionalities in detail. Further information on this is included later. *Figure 2-6* shows how to reach the detail configuration. *Figure 2-7* shows the possible assignments in detail.

These definitions are also set appropriately for the specific application by the selected application template.

You can change this connection, if needed. That is, the protection function groups can be assigned to the circuit-breaker function groups as desired.

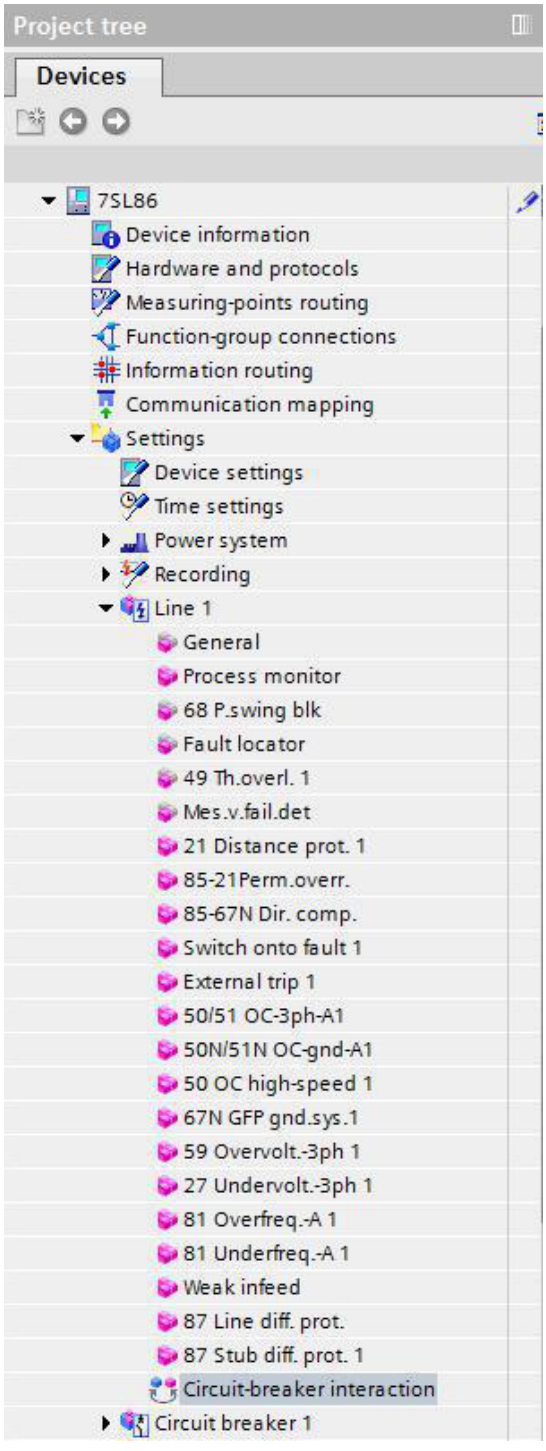


To check or change the assignment of the protection function groups to the Circuit-breaker function groups, double-click **Function group connections** in the DIGSI 5 project tree → **Name of device**.

[sc_fgverb, 1, en_US]

Figure 2-4 Project Tree in DIGSI 5 (Detail)

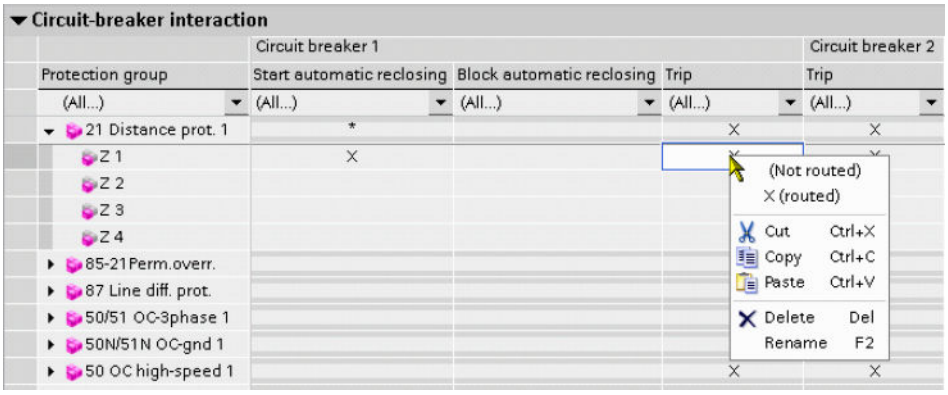
The window for general routing of the function groups opens in the working area.



[scfgcols-220211-01.tif, 1, en_US]

Figure 2-5 Connection of Protection Function Group with Circuit-Breaker Function Group

Besides the general assignment of the protection function group(s) to the circuit-breaker function groups, you can also configure the interface for specific functionalities in detail. Proceed as follows:



- Open the SIPROTEC 5 device folder in the DIGSI 5 project tree.
- Open the function settings folder in the DIGSI 5 project tree.
- Open the appropriate protection function group in the DIGSI 5 project tree, for example **Line 1**.

[sclsinta-190214-01, 1, en_US]

Figure 2-6 Project Tree in DIGSI 5 (Detail)

- Double-click **Circuit-breaker interaction** (see *Figure 2-6*).
- The window for the detailed configuration of the interface between the protection function group and the **Circuit-breaker** function group(s) opens in the working area.
- In this view, configure the interface via the context menu (right mouse button), see *Figure 2-7*.

[sc_detail, 1, en_US]

Figure 2-7 Detail Configuration of the Interface Between the Protection Function Group and the Circuit-Breaker Function Groups

In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the Automatic reclosing function
- Which protection functions block the Automatic reclosing function
- Which protection functions start the Circuit-breaker failure protection function

Functions (FN), Tripping Stages/Function Blocks (FB)

As already illustrated in *Figure 2-1*, functions are assigned to the protected objects or other primary objects via function groups.

Functions can be further subdivided. For example, protection functions often consist of multiple protection stages (for example, the Overcurrent-protection function). Other functions can contain one or more function blocks.

Each stage, each function block, and each function (without stages/function blocks) can be individually switched into specific operating modes (for example, switch on/off). This is termed function control and is explained in *2.3 Function Control*.

To adjust the functionality to the specific application, functions, stages, and function blocks can be added, copied, and deleted (see *2.2 Application Templates/Adaptation of Functional Scope*).

2.2 Application Templates/Adaptation of Functional Scope

Application Template

The application template defines the preconfigured functional scope of the device for a specific use case. A certain number of application templates is predefined for each device type. DIGSI 5 automatically offers the application templates for selection when a new device is installed. The available application templates with the respective functional scope are described in more detail in *4 Applications*.

The selection of the application template first predefines which function groups and functions are present in the device (see also *Figure 2-1* in *2.1 Embedding of Functions in the Device*).

You can adjust the functional scope to your specific application.

Adjusting the Functional Scope

Adjust the functional scope based on the selected application template. You can add, copy or delete functions, tripping stages, function blocks, or complete function groups.

In the DIGSI 5 project tree, this can be done via the following Editors:

- Single-line configuration
- Information routing
- Function settings

Siemens recommends the **Single-line configuration** Editor to adjust the functional scope.

Complete missing functionalities from the Global DIGSI 5 Library. Then, the default settings of the added functionality are active. You can copy within a device and between devices as well. Settings and routings are also copied when you copy functionalities.

NOTE

If you delete a parameterized function group, function, or stage from the device, all settings and routings will be lost. The function group, function, or tripping stage can be added again, but then the default settings are active.

In most cases, the adaptation of the functional scope consists of adding and deleting functions, stages, and function blocks. As previously described, the functions, tripping stages, and function blocks automatically connect themselves to the measuring points assigned to the function group.

In few cases, it may be necessary to add a protection or circuit-breaker function group. These newly added function groups do not contain (protection) functions. You must individually load the (protection) functions for your specific application. You must also connect the protection or circuit-breaker function group to one or more measuring points (see *2.1 Embedding of Functions in the Device*). You must connect newly added protection function groups to a circuit-breaker function group (see *2.1 Embedding of Functions in the Device*).

Functions, tripping stages, function blocks, and function groups can be added up to a certain maximum number. The maximum number can be found in the respective function and function-group descriptions.

Function Points

Function points (FP) are assigned to specific functions, but not to other functions. You can find more detailed information in the description of application templates, in *4 Applications*.

The device is supplied with the acquired function-point credit. Functions with function points can be loaded into the device only within the available function-point credit. The functional scope cannot be loaded into the device if the required number of points of the functional scope is higher than the function-point credit. You must either delete functions or upgrade the function-point credit of the device.

In addition to function-point classes (10, 20, 30, 40, 50, 75, 100 to 1400) beginning with firmware version V09.20, any function-point values in the range from 0 to 5000 are supported as a credit in the device. Thus, the precise function-point credit required can be loaded into the device by the Function-Point Manager. Alternatively, you can order classless devices with 0 points (new option beginning with V09.20) or class-bound with the required function-point class.

Extending the Function-Point Credit

You can reorder function points if the function-point credit for the device is not enough or if you have ordered a classless device with 0 points. Proceed as follows:

- Determine the function-point requirement of certain functions, for example, with DIGSI 5 or the SIPROTEC 5 Configurator.
- Create a signed license file for your device with the SIPROTEC Function-Point Manager at *www.siprotec-function-point-manager.siemens.com* or order the license file from your sales partner.
- Once you have ordered the license file using the Function-Point Manager, you can download it from there directly.
- Once you have ordered the license file from your sales partner, you will receive it by e-mail or to download.
- Use DIGSI 5 to load the signed license file onto your device. The procedure is described in the Online Help of DIGSI 5.

2.3 Function Control

Function control is used for:

- Functions that do not contain stages or function blocks
- Stages within functions
- Function blocks within functions

NOTE

Simplifying **functions** and **function control** will be discussed in the following. The description also applies to tripping stage control and function block control.

Functions can be switched to different operating modes. You use the parameter **Mode** to define whether you want a function to run (***on***) or not (***off***). In addition, you can temporarily block a function. For the purpose of commissioning, you can switch it into test mode (parameter **Mode** = ***test***).

Devices with the activated IEC 61850 allow you to switch the operating mode by using the logical node zero **LLN0**. Depending on the option **LDevice Mod controllable**[1] in DIGSI 5 under **Settings** > **Device settings**, the logical devices (as well as the child logical devices and logical nodes) can be set to one of the following operating modes:

- ***On***
- ***Off***
- ***Test***
- ***Relay blocked***
- ***Test/Relay blk.***

The following table describes the relationship between the LLN0 and the setting **LDevice Mod controllable**.

LLN0.Mod	Setting LDevice Mod controllable	
	Deactivated	Activated
Application/LLN0.Mod	Controllable	Controllable
Logical device/LLN0.Mod	Status only	Controllable
Child logical device/LLN0.Mod	Status only	Controllable
Logical node/LLN0.Mod	Status only	Controllable
_:51 Mode (controllable) of an individual tripping stage of a protection function	Controllable	Controllable

With the setting **LDevice Mod controllable** being activated, the behavior of a logical device (as well as the child logical devices and logical nodes) can be controlled also by the parameter **SetMod** (**SetMod** = ***on***: behavior = on; **SetMod** = ***off***: behavior = off) of the LLN0.

The function shows the current status – such as an *Alarm* – via the *Health* signal.

For more details, refer to the Application Notes *SIPROTEC 5 IEC 61850 Mod/Beh*.

The following explains the different operating modes and mechanisms and how you set the functions into these modes. The function control is shown in *Figure 2-8*. It is standardized for all functions. Therefore, this control is not discussed further in the individual function descriptions.

1 This parameter is only applicable if IEC 61850 is active.

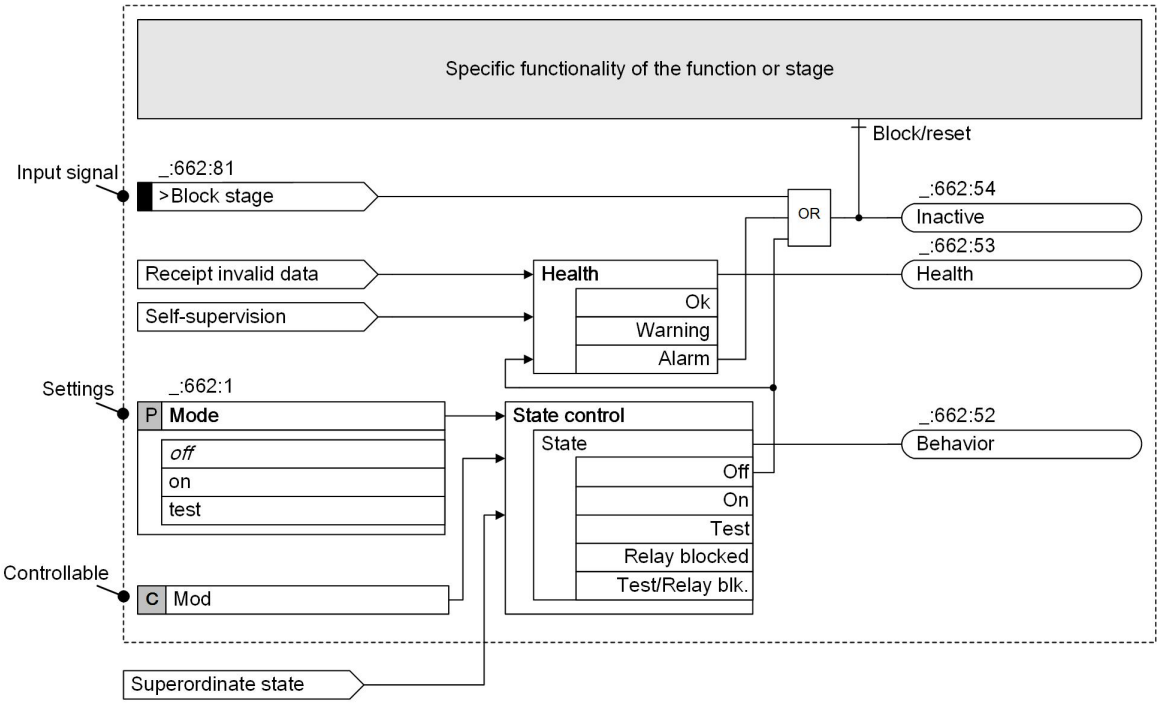


Figure 2-8 General Control of a Function

State Control

You can control the state of a function via the parameter **Mode**, the controllable **Mod** and the input **Superordinate state**.

The superordinate state is also influenced by the state of the superordinate logical devices (LD) of the IEC 61850 structure.

You set the specified operating state of the function via the parameter **Mode**. You can set the function mode to ***on***, ***off*** and ***test***. The operating principle is described in *Table 2-2*. You can set the parameter **Mode** via:

- DIGSI 5
- On-site operation at the device
- Browser-based user interface
- Certain systems control protocols (IEC 61850, IEC 60870-5-103)

You can also set the set point operating state of the function through the controllable **Mod**. You can set the function mode to ***On***, ***Off***, ***Test***, ***Relay blocked*** and ***Test/Relay blk.***. The operating principle is described in *Table 2-2*. You can set the controllable **Mod** via:

- IEC 61850-8-1
- CFC

The **superordinate state** can accept the values ***On***, ***Relay blocked*** ***Test*** and ***Test/Relay blk.***.

The state of the function resulting from the parameter **Mode**, the controllable **Mod** and the **Superordinate state** is shown in the following table. The resulting state of the function results from the combination of all sources (parameters **Mode**, Controllable **Mod** and **Superordinate state**). For simplicity, the table represents only the combination of 2 sources.

Table 2-1 Resulting State of the Function

Inputs		State of the Function
Source A	Source N	
On	On	On
On	Off	Off
On	Test	Test[2]
On	Relay blocked	Relay blocked
On	Test/Relay blk.	Test/Relay blk.
Test	On	Test[2]
Test	Off	Off
Test	Test	Test[2]
Test	Relay blocked	Test/Relay blk.
Test	Test/Relay blk.	Test/Relay blk.
Off	On	Off
Off	Off	Off
Off	Test	Off
Off	Relay blocked	Off
Off	Test/Relay blk.	Off
Relay blocked	On	Relay blocked
Relay blocked	Off	Off
Relay blocked	Test	Test/Relay blk.
Relay blocked	Relay blocked	Relay blocked
Relay blocked	Test/Relay blk.	Test/Relay blk.
Test/Relay blk.	On	Test/Relay blk.
Test/Relay blk.	Off	Off
Test/Relay blk.	Test	Test/Relay blk.
Test/Relay blk.	Relay blocked	Test/Relay blk.
Test/Relay blk.	Test/Relay blk.	Test/Relay blk.

NOTE

The browser-based user interface shows an easy-to-read list of the states of all functions if they deviate from the state ***On***.

The following table describes the possible states of a function:

2 With the parameter **(_:151) Oper.bin.outp. under test**, you define whether functions in test mode can activate relay outputs. If the parameter **(_:151) Oper.bin.outp. under test** and the test mode are activated for the entire device, all functions – including the relay outputs – are in **Test** state. If the parameter **(_:151) Oper.bin.outp. under test** is not active and the test mode is activated for the entire device, all functions – except the relay outputs – are in **Test** state. The relay outputs adopt the **Test/Relay blk.** state.

Table 2-2 Possible States of a Function

State of the Function	Explanation
On	The function is activated and operating as defined. The prerequisite is that the health of the function is ***OK***.
Relay blocked	The function is activated and operating as defined. The prerequisite is that the health of the function is ***OK***. All outputs of indications of this function to relays are blocked. **Note:** Logics outside this function block, for example, superordinate group indications, are not affected by the blocking. Their output to a relay still leads to an activation.
Off	The function is turned off. It does not create any information. The health of a disabled function always has the value ***OK***.

<table>
<tr><th>State of the Function</th><th colspan="2">Explanation</th></tr>
<tr><td>Test</td><td colspan="2">The function is set to test mode. This state supports the commissioning. All outgoing information from the function (indications and, if present, measured values) is provided with a test bit. This test bit significantly influences the further processing of the information, depending on the target.
When leaving the state Test, functions that process measured values are briefly reset for ~500 ms and blocked internally. This state is documented by the message Inactive and other function-specific messages, where appropriate.</td></tr>
<tr><td></td><td>Target of the Information</td><td>Processing</td></tr>
<tr><td></td><td>Log</td><td>The indication is labeled as Test in the log.</td></tr>
<tr><td></td><td>Binary output</td><td>An indication routed to binary outputs does not control the switching contact, unless the behavior of the binary output is in test state.</td></tr>
<tr><td></td><td>Light-emitting diode (LED)</td><td>An indication routed to the LED triggers the LED (normal processing)</td></tr>
<tr><td></td><td>CFC</td><td>Here, the behavior depends on the state of the CFC chart.
• CFC chart itself is not in test state:
The CFC chart is not triggered by a status change of information with a set test bit. The initial state of the information (state before test bit was set) is not processed during execution of the CFC chart.
• CFC chart itself is in test state:
The CFC chart continues to process the information (indication or measured value) normally. The CFC outgoing information is provided with a test bit. The definitions in this table apply to its continued processing.
A CFC chart can be set to the test state by switching the entire device to test mode or by using the CFC block CHART_STATE to switch a single CFC chart to Test mode.</td></tr>
<tr><td></td><td>Protocol</td><td>Indication and measured value are transmitted with set test bit, provided that the protocol supports this functionality.
If an object is transmitted as a GOOSE message, the test bit is set spontaneously and the GOOSE message is transmitted immediately. The receiver of the GOOSE message is automatically notified of transmitter test mode.
If an object is transmitted via the protection interface, the test bit is not transmitted. The Test state must also be transmitted as information for this state to be taken into account in the application on the receiver side. You must route the Test signal in the DIGSI 5 project tree → Device → Communication routing.
The test mode of the differential protection is dealt with separately in the application.</td></tr>
<tr><td>Test/Relay blk.</td><td colspan="2">The function works as described under Test. All output information (indications) of this function which is routed to a relay is blocked.
All output information from the function (indications and, if available, measured values) is provided with a test bit. This test bit significantly influences the further processing of the information, depending on the target.
Logics outside this function block, for example, superordinate group indications, are not affected by the blocking. If the state of these functions allows the processing of indications with a test bit (target function in the state Test or Test/Relay blk.), the output information routed to a relay continues to the control of the relays.</td></tr>
</table>

Health

Health signals if a selected function can perform its designated functionality. If so, the health is *OK*. In case the functionality is only possible in a limited way or not at all, due to state or problems within the device, the health will signal *Warning* (limited functionality) or *Alarm* (no functionality).

Internal self-monitoring can cause functions to assume the health state *Alarm* (see *8 Supervision Functions*). If a function assumes the health state *Alarm*, it is no longer active (indication *not active* is generated).

Only a few functions can signal the health state *Warning*. The health state *Warning* results from function-specific supervision and - where it occurs - it is explained in the function description. If a function assumes the *Warning* status, it will remain active, that is, the function can continue to work in a conditional manner and trip in the case of a protection function.

Not Active

The indication *Inactive* signals that a function is currently not working. The indication *Inactive* is active in the following cases:

- Function is disabled
- The function is in the health state *Alarm*
- Function is blocked by an input signal (see *Figure 2-8*)
- All protection-function steps are disabled via the *Enable protection* controllable (state = false). The indication *Protection inactive* is active.
- The function is briefly *Inactive* when exiting the state **Test**.

Blocking of the Operate Indication, No Fault Recording at Pickup

With the parameter **Blk. Op. Ind. & Fault Rec.** , you define whether a function works as a protection or a monitoring function. Further, you use this to determine the type and scope of the logging (see following table).

Parameter Value	Description
No	The function works as a protection function. It generates an operate indication and starts fault recording with pickup. During fault recording, a fault is created and logged as a fault record in the fault log.
Yes	The function works as a supervision function. The logic runs normally, but without creating the operate indication. The time-out indication is still generated and can be processed further if necessary. No fault recording starts with pickup.

NOTE

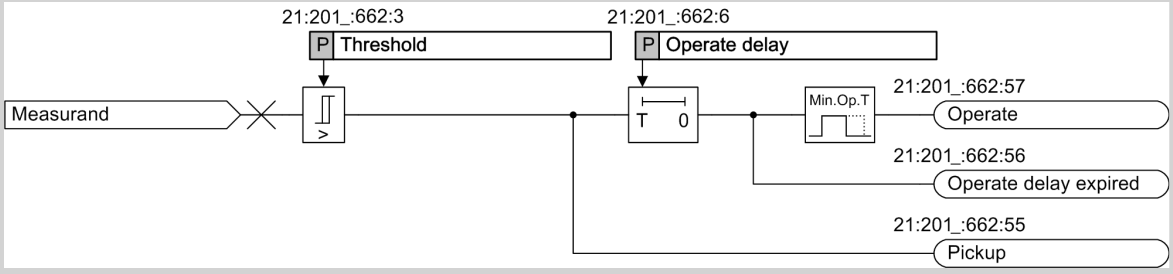
With the IEC 61850 structure editor, you can assign the logical nodes (LN) of the stages of a function to different logical devices (LD).

Always assign all LNs of a function to the same LD.

2.4 Text Structure and Reference Number for Settings and Indications

Each parameter and each indication has a unique reference number within every SIPROTEC 5 device. The reference number gives you a clear reference, for example, between an indication entry in the buffer of the device and the corresponding description in the manual. You can find the reference numbers in this document, for example, in the application and setting notes, in the logic diagrams, and in the parameter and information lists.

In order to form unique texts and reference numbers, each function group, function, function block/stage, and indication or parameter has a text and a number. This means that structured overall texts and numbers are created.



The structure of the texts and reference numbers follows the already shown in *Figure 2-1*, hierarchy:

- Function group:Function:Stage/Function Block:Indication
- Function group:Function:Stage/Function Block:Parameter

The colon serves as a structure element to separate the hierarchy levels. Depending on the functionality, not all hierarchy levels are always available. Function Group and Stage/Function block are optional. Since the function groups, functions as well as tripping stages/function blocks of the same type can be created multiple times, a so-called instance number is added to these elements.

EXAMPLE

The structure of the text and reference number is shown in the protection-function group **Line** as an example of the parameter **`Threshold value`** and the indication **`Pickup`** of the 2nd definite-time overcurrent protection stage of the function **Overcurrent protection, phases** (see *Figure 2-9*). Only one function and one function group exist in the device. The representation of the stage is simplified.

[lo_stuumz_1_en_US]

Figure 2-9 Stage of the Overcurrent Protection Function, Phases (without Representation of Stage Control)

The following table shows the texts and numbers of the hierarchy elements concerned:

	Name	Number of the Type	Instance Number
Protection function group	Line	2	1
Function	Overcurrent 3ph	20	1
Stage	Definite-time overcurrent protection	66	2
Settings	Threshold value	3	–
Indication	Pickup	55	–

The instance numbers arise as follows:

- Function group: Line **1**
  1 instance, because only one **Line** function group exists in the device
- Function: Overcurrent 3ph **1**
  1 instance, because only one **Overcurrent 3ph** function exists in the **Line** function group

- Stage: Definite-time overcurrent protection **2**

  2 instances, because 2 definite-time overcurrent protection stages exist in the **Overcurrent 3ph** function (here the 2nd instance as an example)

This results in the following texts and numbers (including the instance numbers):

Parameter:	**Number**
Line 1:Overcurrent 3-ph 1:Definite-time overcurrent protection 2:Threshold value	21:201:662:3
Indication:	**Number**
Line 1:Overcurrent 3-ph 1:Definite-time overcurrent protection 2:Pickup	21:201:662:55

The structure is simplified accordingly for parameters and indications with fewer hierarchy levels.

2.5 Information Lists

For the function groups, functions, and function blocks, settings and miscellaneous signals are defined that are shown in the settings and information lists.

The information lists merge the signals. The data type of the information may differ. Possible data types are ENS, ACD, ACT, SPS and MV.

One type is assigned to the individual data types. The following table shows the possible types:

Type	Meaning
I	**I**nput – input signal
O	**O**utput – output signal
C	**C**ontrollable – control signal

EXAMPLE:

The following table shows the types for some data types as examples:

Data Type	Type
ENS	O
ACD	O
ACT	O
SPS	I or O
SPC	C
MV	O

For further information, refer to *3.8.2 Basic Data Types*.

3 System Functions

3.1	Indications	76
3.2	Measured-Value Acquisition	104
3.3	Sampling-Frequency Tracking and Frequency Tracking Groups	106
3.4	Processing Quality Attributes	116
3.5	Fault Recording	133
3.6	Protection Communication	142
3.7	Date and Time Synchronization	223
3.8	User-Defined Objects	231
3.9	Other Functions	238
3.10	General Notes for Setting the Threshold Value of Protection Functions	250
3.11	Device Settings	259
3.12	Using a SIPROTEC 5 Device as a Client or Merging Unit	273

3.1 Indications

3.1.1 General

During operation, indications deliver information about operational states. These include:

- Measured data
- Power-system data
- Device supervisions
- Device functions
- Function procedures during testing and commissioning of the device

In addition, indications give an overview of important fault events after a failure in the system. All indications are furnished with a time stamp at the time of their occurrence.

Indications are saved in logs inside the device and are available for later analyses. The following number of indications are saved at least in the respective buffer (depending on the scope of the indications):

- Operational log 2000 indications
- Fault log 1000 indications
- Switching-device log 2000 indications
- Ground-fault log 100 indications
- User-defined log 200 indications
- Motor-starting log 200 indications

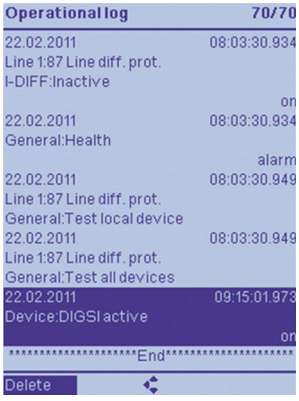
If the maximum capacity of the user-defined log or of the operational log is exhausted, the newest entries overwrite the oldest entries. If the maximum capacity of the fault log or of the ground-fault log is reached, the number of the last fault is output via the signal **Fault recording buffer is full**. You can route this signal in the information routing. If indications in the information routing of DIGSI 5 are routed to a log, then they are also saved. During a supply-voltage failure, recorded data are securely held by means of battery buffering or storage in the flash memory. You can read and analyze the log from the device with DIGSI 5. The device display and navigation using keys allow you to read and analyze the logs on site.

Indications can be output spontaneously via the communication interfaces of the device and through external request via general interrogation. In DIGSI 5, indications can be tracked spontaneously duringonline mode in a special indication window. Indications can be made accessible to higher-level control systems through mapping on various communication protocols.

NOTE

All indications are assigned to certain device functions. The text of each indication contains the corresponding function designation. You can find explanations of the meaning of indications in the corresponding device functions. However, you can also define indications yourself and group them into your own function blocks. These can be set by binary inputs or CFC logic.

Reading Indications



To read the indications of your SIPROTEC 5 device you can use the on-site operation panel of the device or a PC on which you have installed DIGSI 5. The subsequent section describes the general procedure.

3.1.2 Reading Indications on the On-Site Operation Panel

Procedure

The menus of the logs begin with a header and 2 numbers at the top right corner of the display. The number after the slash signifies the number of indications that are available. The number before the slash indicates

how many indications have just been selected or shown. The end of the indication list is closed with the entry ***END***.

[sc_oprlog, 1, en_US]

Figure 3-1 On-Site Display of an Indication List (Example: Operational Indications)

Menu Path	Log
Main menu → Indications →	Operational log Fault log Switch. device log Ground-fault log Setting-history log User log 1 User log 2 Motor-starting log Com supervision log
Main Menu → Test & Diagnosis → Log →	Device diagnosis Security log Communication log

To reach the desired log from the main menu, use the navigation keys of the on-site operation panel.

✧ Navigate inside the log using the navigation keys (top/bottom). You will find the most current indication at the top of the list. The selected indication is shown with a dark background.

Which indications can be shown in the selected log depends on the assignments in the DIGSI 5 information routing matrix or is predefined. Every indication contains date, time, and its state as additional information.

You will find information about this in chapter *3.1.5.1 General*.

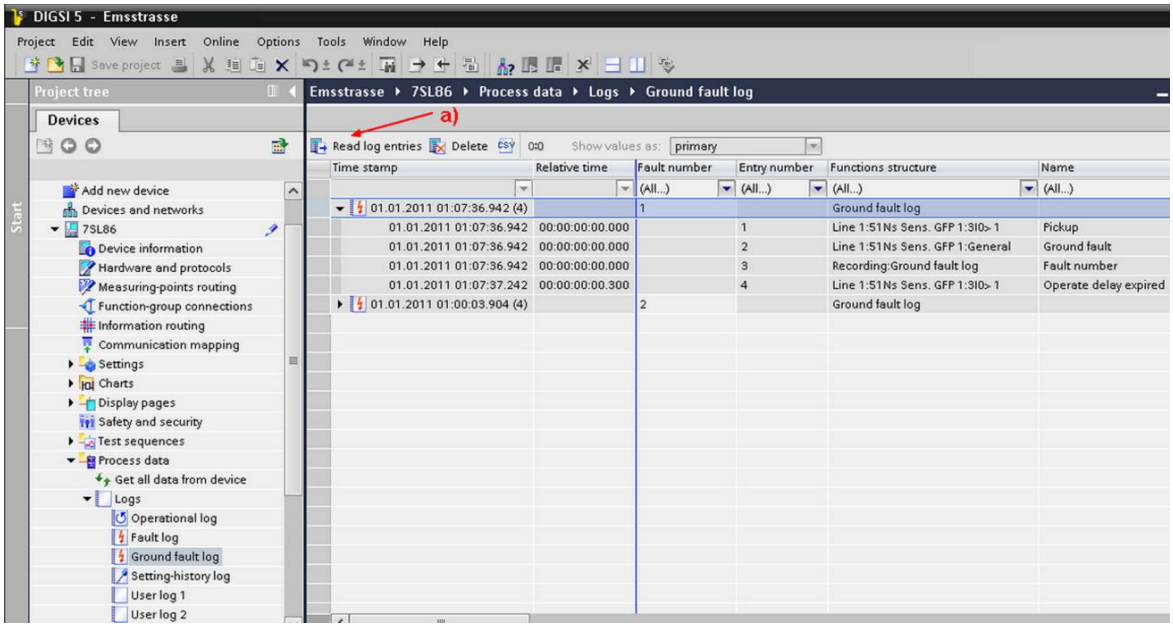
In some logs, you are given the option of deleting the entire indication list by softkey in the footer of the display. To learn more about this, read chapter *3.1.6 Saving and Deleting the Logs*.

NOTE

No password entry is necessary to read indications from the device.

3.1.3 Reading Indications from the PC with DIGSI 5

Procedure



Menu Path (Project)	Log
Project → Device → Process data → Log →	Operational log Fault log Switch. device log Ground-fault log Setting-history log User log 1 User log 2 Motor-starting log Com supervision log
Online access → Device → Device information → **Logs** tab →	Device-diagnosis log Security indications
Online access → Device → Test suite → Communication module → Hardware[3]	Communication log

To read the indications with DIGSI 5 your PC must be connected via the **USB user interface** of the on-site operation panel or via an **Ethernet interface** of the device. You can establish a direct connection to your PC via the Ethernet interfaces. It is also possible to access all connected SIPROTEC 5 devices via a data network from your DIGSI 5 PC.

✧ You reach the desired logs of the SIPROTEC 5 device using the project-tree window. If you have not created the device within a project, you can also do this via the **Online access** menu item.

After selecting the desired log, you are shown the last state of the log loaded from the device. To update, it is necessary to synchronize with the log in the device.

✧ Synchronize the log. For this purpose, click the appropriate button in the headline of the log (see the ground-fault indications example in *Figure 3-2* a)).

[sc_grfimd, 1, en_US]

Figure 3-2 DIGSI 5 Display of an Indication List (Example of Ground-Fault Log)

3 There may potentially be several communication modules to select from

You will find additional information about deleting and saving logs in chapter *3.1.6 Saving and Deleting the Logs*.

Which indications can be shown in the selected log depends on the assignments in the DIGSI 5 information routing matrix or is predefined. You will find information about this in chapter *3.1.5.1 General*.

Setting Relative Time Reference

✧ Reference the display of log entries, if needed, to the real time of a specific entry. In this way, you determine a relative time for all other indications. The real-time stamps of events remain unaffected.

3.1.4 Displaying Indications

Displayed indications are supplemented in DIGSI 5 and on the on-site operation panel with the following information:

Table 3-1 Overview of Additional Information

Indications in	DIGSI 5 Information	Device Display Information
Log for operational indications and log for user-defined and switching-device indications	Time stamp (date and time), Relative time, Entry number, Function structure, Name, Value, Quality, Cause, Number	Time stamp (date and time), Function structure, Name, Value
Log for fault indications	Time stamp (date and time), Relative time, Fault number, Entry number, Function structure, Name, Value, Quality, Cause, Number	Time stamp (date and time), Fault number, Value
Log for motor-starting indications	Time stamp (date and time), Motor-starting time, Starting current, Starting voltage, Starting duration	Time stamp (date and time), Function structure, Name, Value

Indications in	DIGSI 5 Information	Device Display Information
Log for ground-fault indications	Time stamp (date and time), Relative time, Fault number, Entry number, Function structure, Name, Value, Indication number, Quality, Cause, Number	Time stamp (date and time), Fault number, Value
Log for parameter changes	Time stamp (date and time), Relative time, Entry number, Function structure, Name, Value, Quality, Cause, Number	Time stamp (date and time), Function structure, Name, Value
Spontaneous indication window (DIGSI 5)	Time stamp (date and time), Relative time, Indication, Value, Quality, Additional Information	Time stamp (date and time), Fault number, Value
Log for safety indications[4]	Time stamp (date and time), Indication number, Indication	Time stamp (date and time), Indication
Log for device-diagnostic indications[4]	Time stamp (date and time), Indication number, Indication	Time stamp (date and time), Indication
Log for communication indications[4]	Time stamp (date and time), Indication number, Indication	Time stamp (date and time), Indication
Log for communication supervision (GOOSE)	Time stamp (date and time), Relative time, Entry number, Function structure, Name, Value, Quality, Cause, Number	Time stamp (date and time), Function structure, Name, Value

4 Only online access

Overview of Displayed Quality Attributes

If values are shown on the device display or in DIGSI, the following quality attributes are different for measured values and metered values.

Table 3-2 Measured Values

IEC 61850				Device Display/ DIGSI	Description
Detail Quality	Validity				
	Good	Invalid	Questionable		
–	X			Value	The measured value is valid.
Failure		X		Fault	The device is defective. Contact Support.
Inaccurate			X	---	The measured value was not calculated (for example, the angle between current and voltage if 1 of the 2 variables is missing).
Bad Reference			X	≈ Value	The measured value can be inaccurate (for example, outside the frequency-tracking range).
Out of Range			X	> Value	The measured value exceeds the measuring range.

Table 3-3 Metered Values

IEC 61850			Device Display/ DIGSI	Description
Validity				
Good	Invalid	Questionable		
X			Value	The metered value is invalid.
	X		---	The metered value was not calculated.
		X	≈ Value	The metered value has no reference.

Indication Columns

The following table shows the meaning of the individual columns in the log:

Indication Column	Meaning
Time stamp	Time stamp of the indication in device time using the local time zone of the device or the query time for the motor log
Relative time	Relative time to a reference entry
Error number	Number of the error that occurred in the device. This number increments continuously.
Entry number	Entry identification of buffer entries. This identification displays the sequence of buffer entries.
Indication number	Number of the indication that occurred in the device. This number increments continuously and is necessary for an analysis by Siemens.
Indication	Indication text
Function structure	Path of the signal with the signal name
Name	Signal name
Value	Current state of the command. Also pay attention to the value quality to check whether the value is up to date.

Indication Column	Meaning
Quality	The quality of the value shows the source of the value and whether the value is up to date.
Cause	Additional information such as the cause and validity
Number	DIGSI address of the signal
Motor startup time	Time of motor starting
Starting current	Current needed by the motor to start up
Starting voltage	Voltage needed by the motor to start up
Start duration	Time needed by the motor to start up

3.1.5 Logs

3.1.5.1 General

Indications are saved in logs inside the device and are available for later analyses. Different logs allow categorization of indication logging based on operating states (for example, operational and fault logs) and based on fields of application.

Table 3-4 Log Overview

Log	Logging
Operational log	Operational indications
Fault log	Fault indications
Switching-device log	Switching operation and circuit-breaker statistics
Ground-fault log	Ground-fault indications
Setting-history log	Setting changes
User-defined log	User-defined indication scope
Security log	Access with safety relevance
Device-diagnosis log	Error of the device (software, hardware) and the connection circuits
Communication log	Status of communication interfaces
Motor-starting log	Information on the motor starting
Communication-supervision log	Communication supervision (GOOSE)

Log Management

Logs have a ring structure and are automatically managed. If the maximum capacity of a log is exhausted, the oldest entries disappear before the newest entries. If the maximum capacity of the fault or ground-fault log is reached, the number of the last fault is output via the signal **Fault recording buffer is full**. You can route this signal in the information routing. If indications in the information routing of DIGSI 5 are routed to a log, then they are also saved. During a supply-voltage failure, recorded data are securely held by means of battery buffering or storage in the flash memory. You can read and analyze the log from the device with DIGSI 5. The device display and the navigation allow you to read and evaluate the logs on site using keys.

Configurability of Logs

The indication capacity to be recorded in configurable logs (for example, ground-fault log) is laid down in columns of the information routing (matrix) of DIGSI 5 specifically defined for this purpose.

Procedure

To reach the information routing of your SIPROTEC 5 device, use the project-tree window. Access is only through the project:

- Open the information routing.
  Project → Device → **Information routing**

- Select the appropriate routing column.
  Destination → Logs → Column **Ground-fault log (G)**

The routing of the selected indication is done via right click.

- Select one of the options in the list box shown:
  - Routed (X)
  - Unrouted

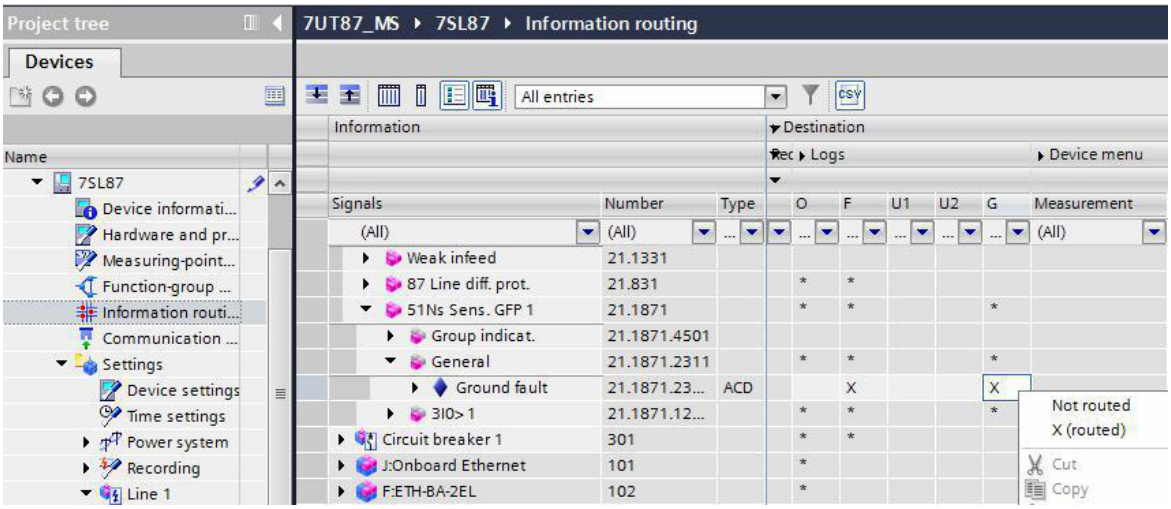


Figure 3-3 Indication Configuration in DIGSI 5 (Example: Ground-Fault Log, Column G)

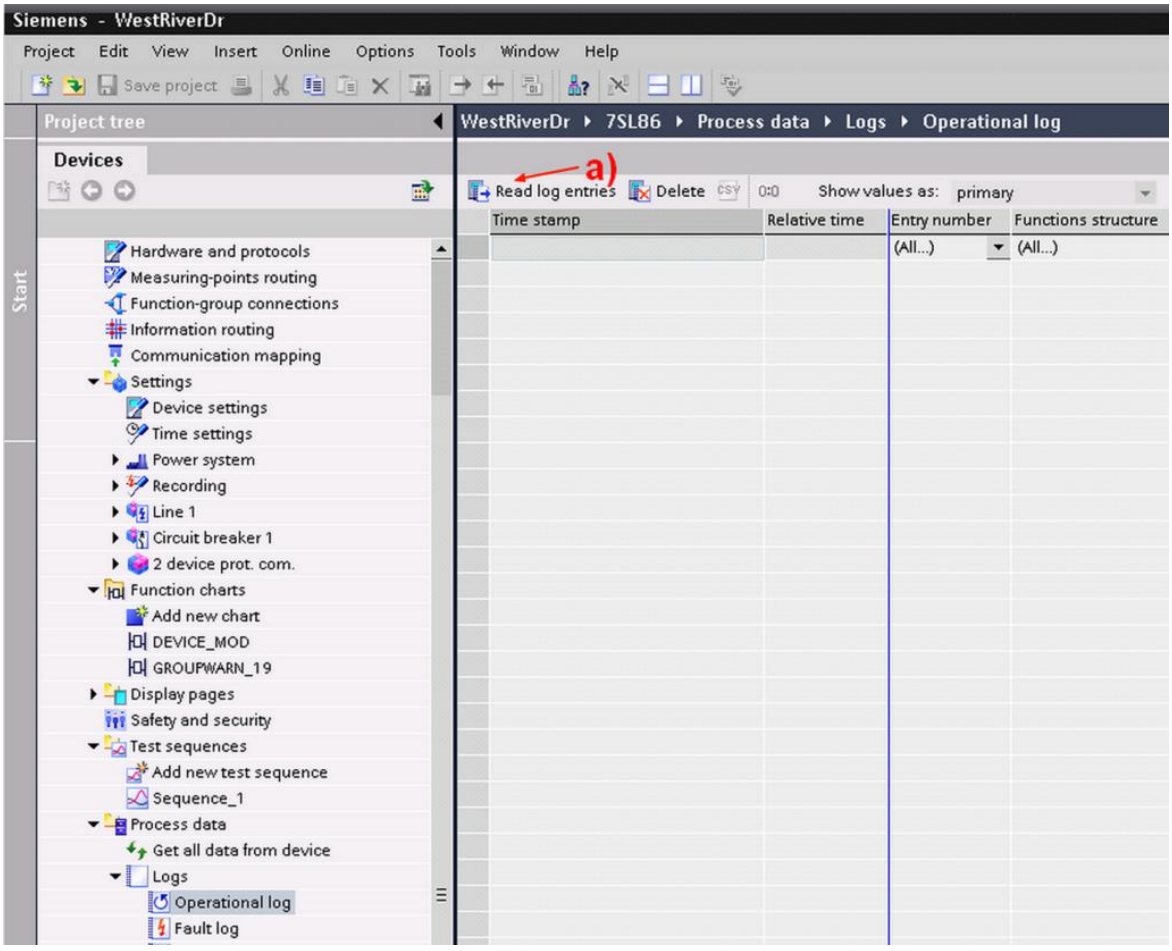
For non-configurable logs (for example, setting-history logs) scope and type of logged indications are described separately (see following chapter about logs).

3.1.5.2 Operational Log



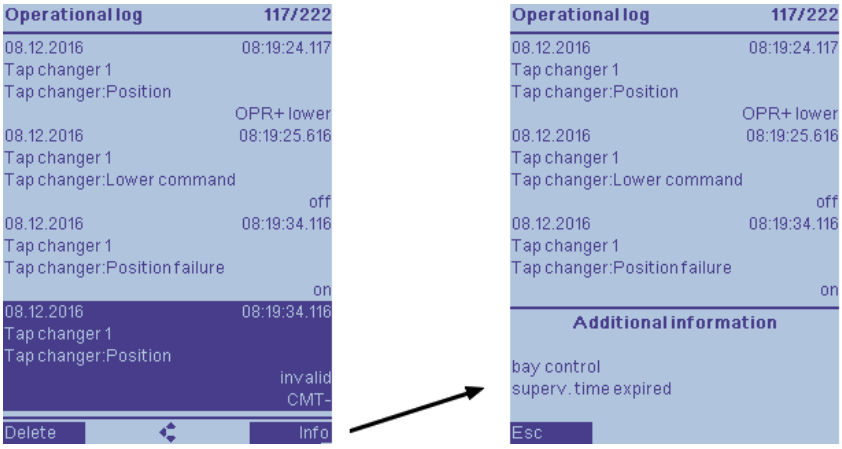
Operational indications are information that the device generates during operation. This includes information about:

- State of device functions
- Measured data
- Power-system data

Exceeding or dropping below limiting values is output as an operational indication. Short circuits in the network are indicated as an operational indication **Fault** with sequential fault number. For detailed information about the recording of system incidents, refer to the description of the fault log (chapter *3.1.5.3 Fault Log*). Up to 2000 indications can be stored in the operational log.

Reading from the PC with DIGSI 5

- To reach the operational log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **Operational log**
- The status of the operational log last loaded from the device is shown to you. To update (synchronization with the device), click the button **Read log entries** in the headline of the indication list (*Figure 3-4* a)).



[sc_betrmd, 1, en_US]

Figure 3-4 Reading the Operational Log with DIGSI 5

Reading on the Device via the On-Site Operation Panel

- To reach the operational log via the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **Operational log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.
- Using the **Info** softkey, you can retrieve auxiliary information on the entry depending on the context.

[sc_operlog1_2, en_US]

Figure 3-5 On-Site Display of an Indication List (Example: Operational Indications)

Deletability

The operational log of your SIPROTEC 5 device can be deleted. This is done usually after testing or commissioning the device. To know more about this, read chapter *3.1.6 Saving and Deleting the Logs*.

Configurability

The indication scope of the operational log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → **Operational log** column

Selected application templates and functions from the library bring with them a predefined set of operational indications which you can adjust individually at any time.

3.1.5.3 Fault Log

Fault indications are events which arise during a fault. They are logged in the fault log with real-time stamp and relative-time stamp (reference point: fault occurrence) . Faults are numbered consecutively in rising order. With fault recording engaged, a corresponding fault record with the same number exists for every fault logged in the fault log. A maximum of 128 fault logs can be stored. A maximum of 1000 indications can be recorded in each fault log.

Fault Definition

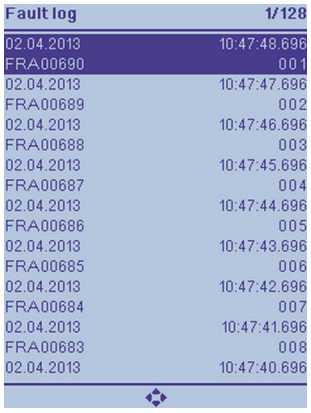
In general, a fault is started by the raising pickup of a protection function and ends with the cleared pickup after the trip command.

When using an automatic reclosing function, the complete reclosing cycle (successful or unsuccessful) is preferably integrated into the fault. If evolving faults appear within reclosing cycles, the entire clearing process is logged under one fault number even in multiple pickup cycles. Without automatic reclosing function every pickup is also recorded as its own fault.

User-defined configuration of a fault is also possible.

NOTE

The definition of the fault is done through settings of the fault recording (see Device manual). Events are logged in the fault log even when fault recording is switched off.



Apart from the recording of fault indications in the fault log, spontaneous display of fault indications of the last fault on the device display is also done. You will find details about this in chapter *3.1.8 Spontaneous Fault Display on the On-Site Operation Panel*.

Deletability

The fault log of your SIPROTEC 5 device can be deleted. For more details about this, refer to chapter *3.1.6 Saving and Deleting the Logs*.

Reading on the Device through the On-Site Operation Panel

- To reach the fault log from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **Fault logs**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[sc_faullg, 1, en_US]

Figure 3-6 Reading the Fault Log on the On-Site Operation Panel of the Device

Configurability

The indication scope of the fault log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → **Fault log** column

Selected application templates and functions from the library already bring a predefined set of operational indications with them which you can adjust individually at any time.

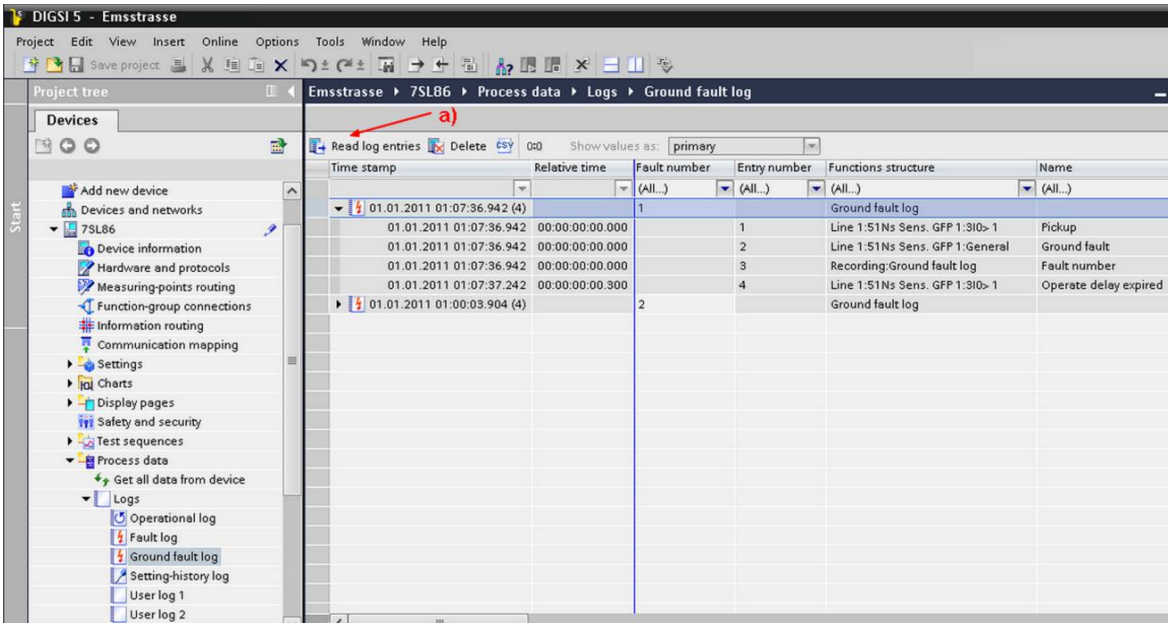
The operational measured values and the measured values of the fundamental components and symmetrical components (see Device Manual) are calculated every 9 cycles (at 50 Hz, this is every 180 ms). However, this can mean that the data are not synchronized with the sampled values of the analog channels. The recording of these measured values can be used to analyze the slowly changing processes.

3.1.5.4 Ground-Fault Log

Ground-fault indications are events which arise during a ground fault. They are logged in the ground-fault log with real-time stamp and relative-time stamp (reference point: ground-fault occurrence). Ground faults are numbered consecutively in rising order. A maximum of 10 ground-fault logs are stored, and for each ground-fault log it is guaranteed that at least 100 indications are recorded.

The following functions can start the logging of a ground fault with the raising ground-fault indication:

- **Directional sensitive ground-fault protection for deleted and isolated systems** (67Ns)
- **Sensitive ground current protection with I0** (50Ns/51Ns)
- **Intermittent ground-fault protection**



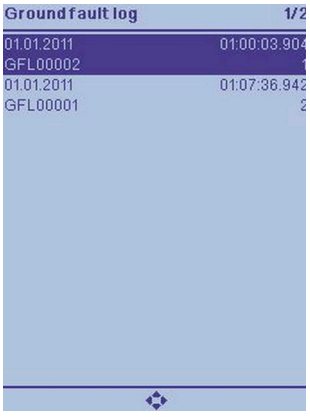
The logging ends with the clearing ground-fault indication.

Reading from the PC with DIGSI 5

- To reach the ground-fault log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process data → Logs → **Ground-fault log**

The status of the device-diagnosis log last loaded from the ground-fault log is shown to you.

- To update (synchronization with the device) click the button **Read log entries** in the headline of the indication list (*Figure 3-7* a)).



[sc_grflmd, 1, en_US]

Figure 3-7 Reading the Ground-Fault Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the ground-fault log from the main menu, use the navigation keys of the on-site operation panel.
  Main menu → Indications → **Ground-fault indication**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[scgfllg1-191012-01.tif, 1, en_US]

Figure 3-8 Reading the Ground-Fault Log on the On-Site Operation Panel of the Device

Deletability

The ground-fault log of your SIPROTEC 5 device can be deleted. Read details about this in chapter *3.1.6 Saving and Deleting the Logs*.

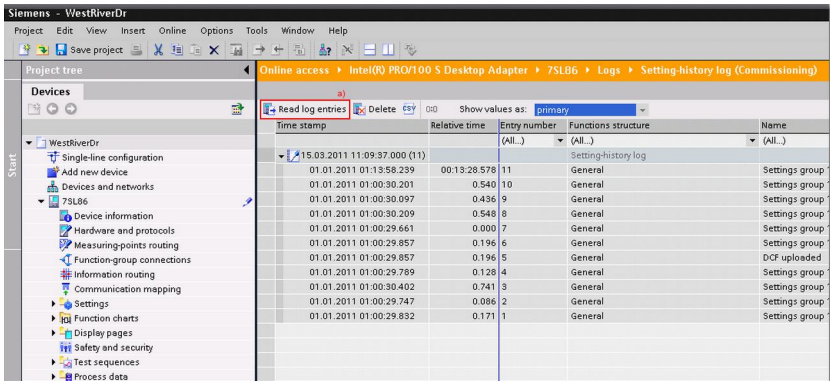
Configurability

The indication scope of the ground-fault log is configured in a specifically defined column of the information routing (matrix) of DIGSI 5:

Target → Log → Column **Ground-fault log**

Selected application templates and functions from the library already bring a predefined set of operational indications with them which you can adjust individually at any time.

3.1.5.5 Setting-History Log



All individual setting changes and the downloaded files of entire parameter sets are recorded in the log for setting changes. This enables you to determine setting changes made are associated with events logged (for example faults). On the other hand, it is possible to obtain verification with fault analyses, for example, that the current status of all settings truly corresponds to their status at the time of the fault. Up to 200 indications can be stored in the setting-history log.

Reading from the PC with DIGSI 5

- To reach the log for setting changes of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process data → Log → **Setting changes**

The status of the setting-history log last loaded from the device is shown to you.

- To update (synchronization with the device), click the **Read log entries** button in the headline of the indication list (*Figure 3-9*).

[sc_paramd, 1, en_US]

Figure 3-9 Reading the Setting-History Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the setting-history log from the main menu, use the navigation keys of the on-site operation panel.
  Main menu → Indications → **Setting changes**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[sc_hislog, 1, en_US]

Figure 3-10 Reading the Setting-History Log on the On-Site Operation Panel of the Device

Indication Categories in the Setting-History Log

For this log, there is selected information that is stored in case of successful as well as unsuccessful setting changes. The following list gives you an overview of this information.

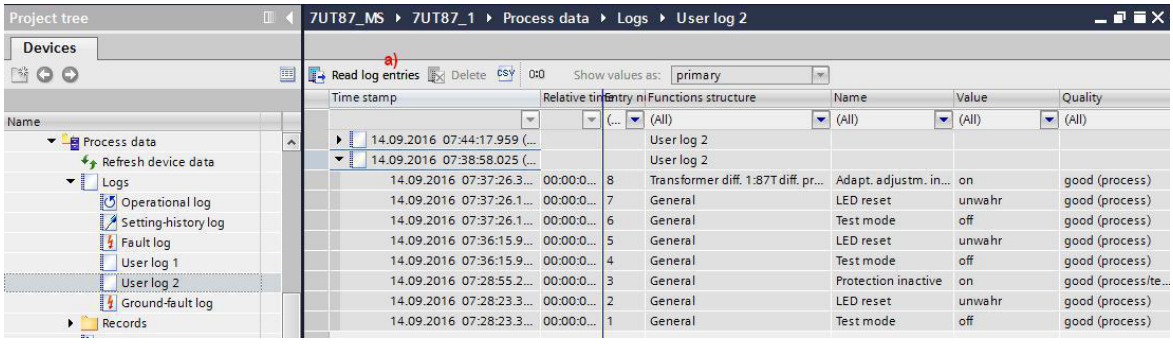
Table 3-5 Overview of Indication Types

Displayed Information	Explanation
Selection edit+	Selection of settings group to be edited
Cancelation+	Cancelling of all changes successful
SG activation+	SG activation via command successful
SG activation-	SG activation via command failed
Set+	Parameter value was changed
Confirmation+	Confirmation of change successful
Confirmation-	Confirmation of change failed
DCF uploaded	DCF loaded into device
SG 1	Settings group 1
SG 2	Settings group 2
SG 3	Settings group 3
SG 4	Settings group 4
SG 5	Settings group 5
SG 6	Settings group 6
SG 7	Settings group 7
SG 8	Settings group 8

NOTE

- The logged indications are preconfigured and cannot be changed!
- The log, which is organized as a ring buffer, cannot be deleted by the user!
- If you want to archive security-relevant information of the device without loss of information, you must regularly read this log.
- You cannot route additional indication objects to the setting-history log.

3.1.5.6 User Log



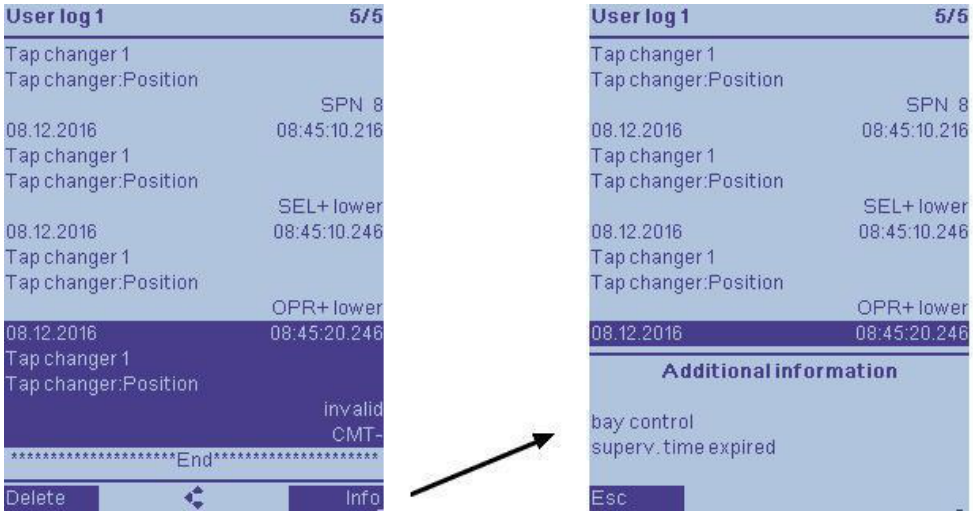
With the user-defined log (up to 2), you have the possibility of individual indication logging parallel to the operational log. This is helpful, for example, in special monitoring tasks but also in the classification into different areas of responsibility of the logs. Up to 200 indications can be stored in the user-defined log.

Reading from the PC with DIGSI 5

- To reach the user-defined log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process Data → Log → **User log 1/2**

The status of the user-defined log last loaded from the device is shown to you.

- To update (synchronization with the device), click the **Read log entries** button in the headline of the indication list (*Figure 3-11* a)).



[sc_application_md, 2, en_US]

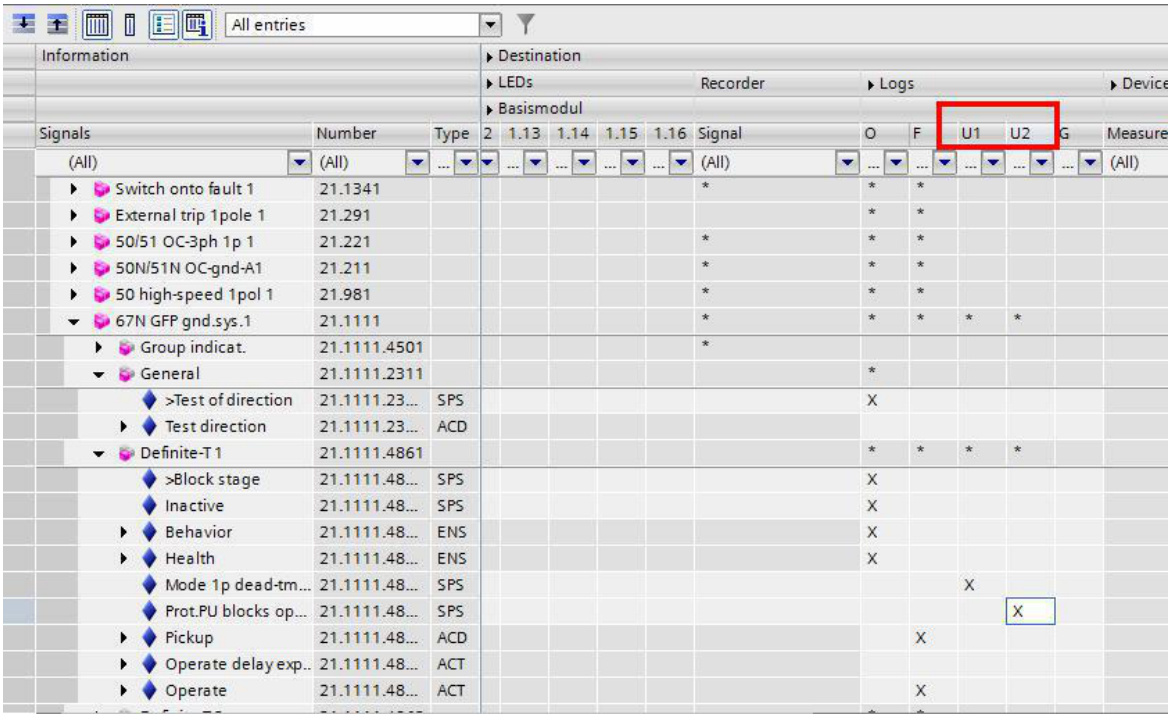
Figure 3-11 Reading the User-Defined Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach user-specific logs from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **User-defined log 1/2**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.
- Using the **Info** softkey, you can retrieve auxiliary information on the entry depending on the context.

[sc_userlog1, 1, en_US]

Figure 3-12 Reading the User-Defined Log on the On-Site Operation Panel of the Device



Deletability

The user-defined log of your SIPROTEC 5 device can be deleted. You will find details about this in chapter *3.1.6 Saving and Deleting the Logs*.

Configuration of a User-Defined Log

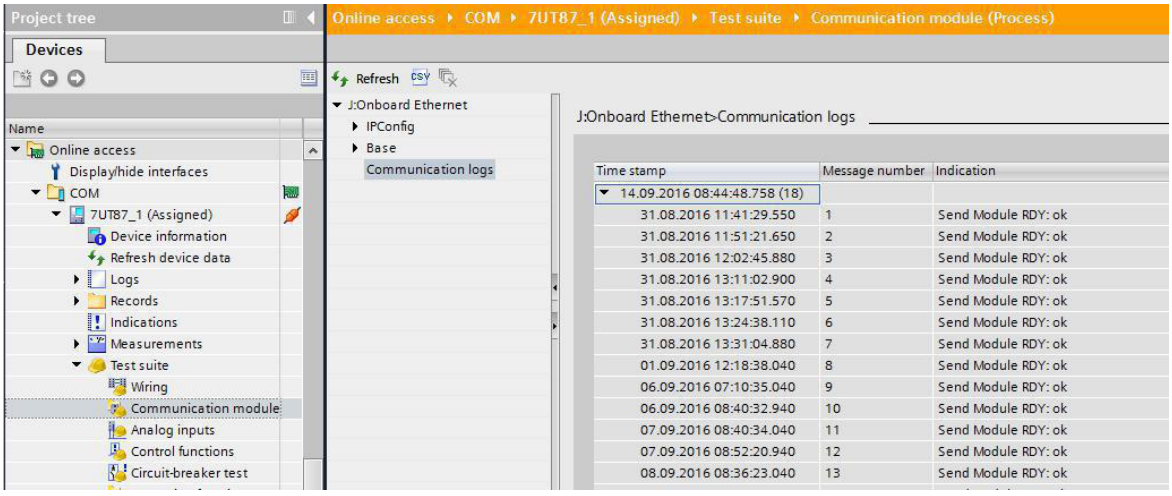
The indication capacity of a created user-defined log can be configured freely in the associated column of the information routing (matrix) of DIGSI 5:

Target → Log → U1 or U2

[sc_diu1u2, 1, en_US]

Figure 3-13 Indication Configuration in DIGSI 5 (Example: User-Defined Log U1/2)

3.1.5.7 Communication Log



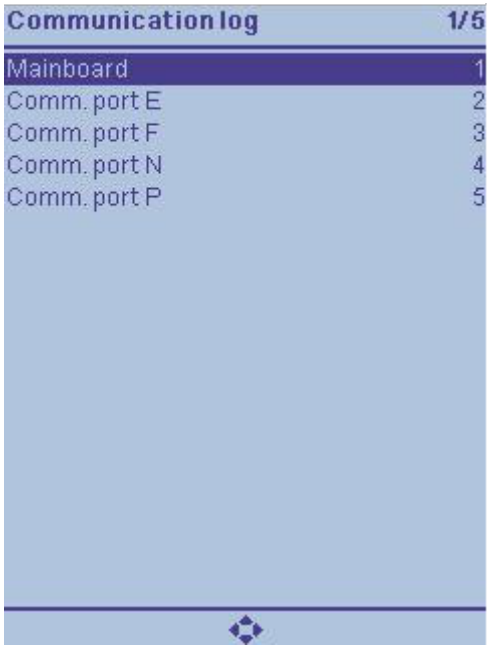
The logging of the respective status such as ensuing faults, test and diagnosis operation, and communication capacity utilizations is done for all hardware-based configured communication interfaces. Up to 500 indications can be stored in the communication log. Logging occurs separately for each communication port of the configured communication modules.

Reading from the PC with DIGSI 5

- Use the project-tree window to reach the communication logs of your SIPROTEC 5 device.
  Online access → Device → Test suite → Communication module
- Then select:
  J:Onboard Ethernet → **Communication log**

The communication log is shown to you in the state last loaded from the device.

- Before this, refresh the contents by clicking the update arrows in the headline.



[sc_compuf, 2, en_US]

Figure 3-14 Reading the Communication Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the communication log from the main menu, use the navigation keys on the on-site operation panel.
  Main Menu → Test & Diagnosis → Logs → **Communication logs**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[sc_commlg, 1, en_US]

Figure 3-15 Reading the Communication Log on the On-Site Operation Panel of the Device

Deletability

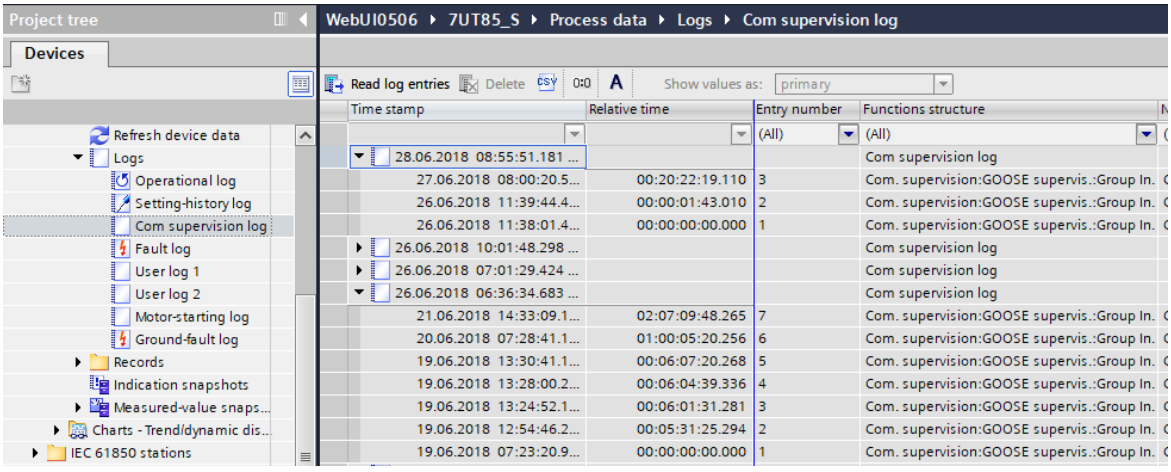
The communication logs of your SIPROTEC 5 device can be deleted. Read details about this in chapter *3.1.6 Saving and Deleting the Logs*.

Configurability

The communication logs are not freely configurable. The entries are preconfigured.

3.1.5.8 Communication-Supervision Log

The communication-supervision log is used to log communication events.
The following events are currently logged:



- Status for each GOOSE subscription (if configured)
  A log is kept of whether the GOOSE subscription has received valid messages or not.
- Aggregated status for all GOOSE subscriptions
  The status is **TRUE** if at least one GOOSE subscription does not receive any valid message.
- Subscriber in simulation mode
  GOOSE messages are processed with a simulation flag. The status is **TRUE** if at least one GOOSE subscription processes simulated messages.

Reading from the PC with DIGSI 5

- To reach the communication-supervision log of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Process data → Logs → **Com supervision log**

The status of the communication-supervision log last loaded from the device is shown.

- To update (synchronization with the device), click the button **Read log entries** in the headline of the indication list.

Reading on the Device through the On-Site Operation Panel

- To reach the communication-supervision log from the main menu, use the navigation keys on the on-site operation panel.
  Main menu → Logs → **Com supervision log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[sc_comsupervlg, 1, en_US]

Figure 3-17 Reading the Communication-Supervision Log on the On-Site Operation Panel of the Device

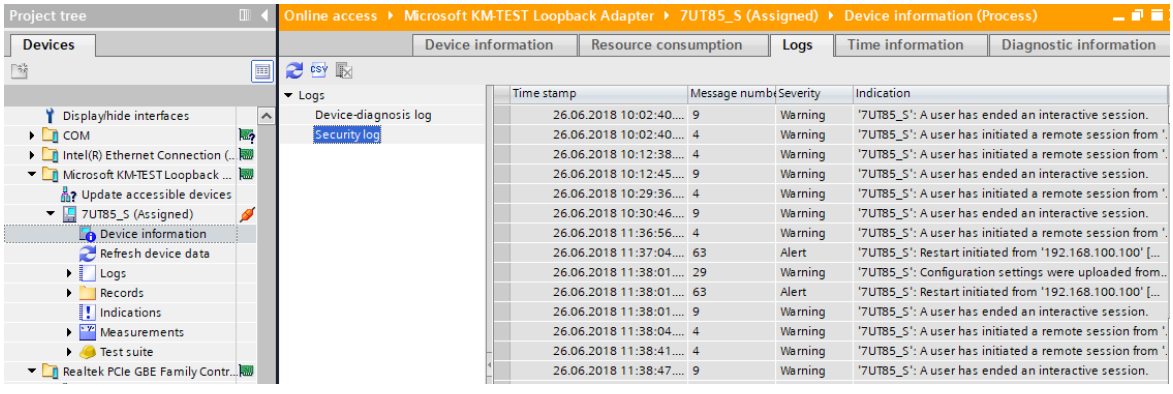
Deletability

The communication-supervision log of your SIPROTEC 5 device can be deleted. Read details about this in chapter *3.1.6 Saving and Deleting the Logs*.

Configurability

The communication-supervision log cannot be freely configured. The entries are preconfigured.

3.1.5.9 Security Log



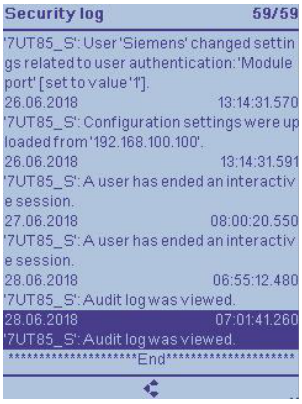
Access to areas of the device with restricted access rights is recorded in the security log. Unsuccessful and unauthorized access attempts are also recorded. Up to 2048 indications can be stored in the security log.

Reading from the PC with DIGSI 5

- To reach the security log of your SIPROTEC 5 device, use the project-tree window. The device must be in Online access.
  Project → Online access → Device → Device Information → **Logs** tab → Security logs

The state of the security log last loaded from the device is displayed.

- Before this, refresh the contents by clicking the update arrows in the headline.



[sc_secmld, 2, en_US]

Reading on the Device through the On-Site Operation Panel

- To reach the security log from the main menu, use the navigation keys of the on-site operation panel.
  Main menu → Test & Diagnosis → Logs → **Security log**
- You can navigate on the on-site operation panel using the navigation keys (top/bottom) inside the displayed indication list.

[sc_seclog, 1, en_US]

Figure 3-19 Reading the Security Log on the On-Site Operation Panel of the Device

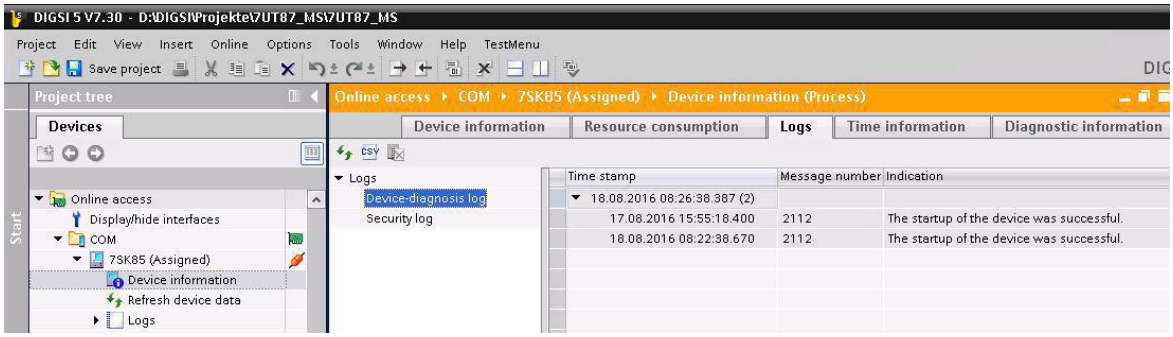
NOTE

- The logged indications are preconfigured and cannot be changed!
- This log, which is organized as a ring buffer, cannot be deleted by the user!
- If you want to archive security-relevant information of the device without loss of information, you must regularly read this log.

3.1.5.10 Device-Diagnosis Log

Concrete take-action instructions are logged and displayed in the device-diagnosis log for the following items:

- Required maintenance (for example, battery supervision)
- Identified hardware defects
- Compatibility problems



Up to 500 indications can be stored in the device-diagnosis log. In normal operation of the device, it is sufficient for diagnostic purposes to follow the entries of the operational log. This specific significance is assumed by the device-diagnosis log when the device is no longer ready for operation due to hardware defect or compatibility problems and the fallback system is active.

Reading from the PC with DIGSI 5 in Normal Operation

- To reach the device-diagnosis log of your SIPROTEC 5 device, use the project-tree window.
  Project → Online access → Device → Device information → **Logs** tab → Device-diagnosis log

The status of the device-diagnosis log last loaded from the device is shown to you.

- Before this, refresh the contents by clicking the update arrows in the headline.

NOTE

- The device-diagnosis log cannot be deleted!
- The logged indications are preconfigured and cannot be changed!

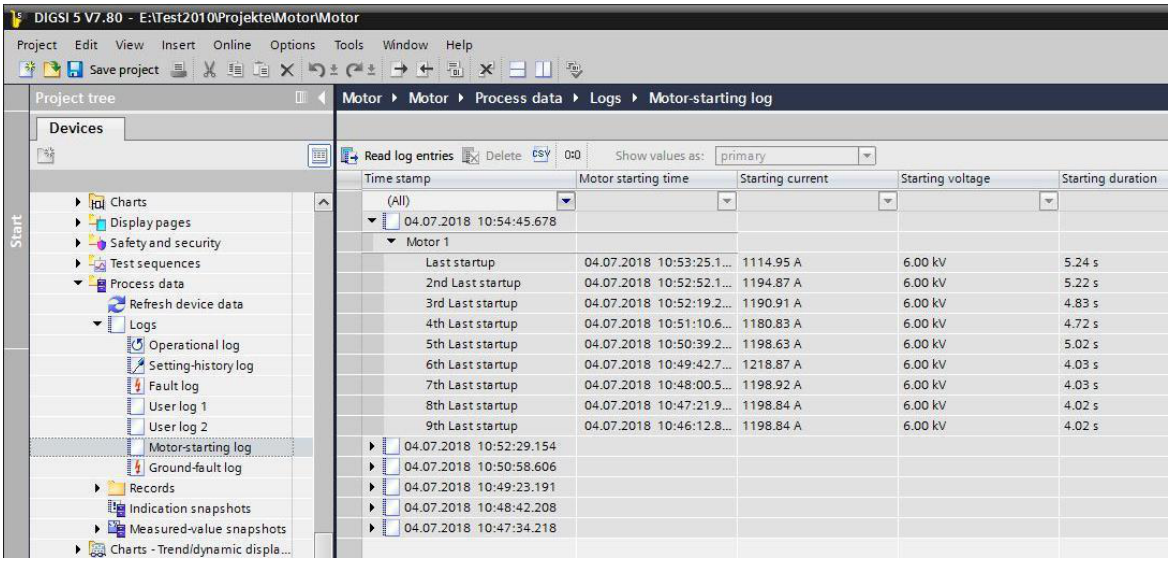
3.1.5.11 Motor-Starting Log

The motor-starting log records the starting current, starting voltage and the start duration each time a motor starts. The motor-starting current and the motor-starting voltage are displayed as primary values. Up to 200 indications can be stored in the motor-starting log.

Measurement of the motor statistics starts when the motor state changes to ***Start***. Measurement of the motor starting time ends as soon as the motor state changes to ***Standstill*** or ***Running***. The motor state is obtained from the **Motor-state detection** function.

No entry is recorded in the motor-starting log if the motor state changes to ***Start*** and the current drops below the motor starting current within 500 ms.

Table 3-6 Motor-Starting Log



Measured Values		Primary
Start duration	Motor starting time	s
Starting current	Motor-starting current (primary)	A (or kA)
Starting voltage	Motor-starting voltage (primary)	V (or kV)

Reading from the PC with DIGSI 5

- Use the project-tree window to reach the motor-starting log of your SIPROTEC 5 device.
  Project → Device → Process data → Logs → **Motor-starting log**

The state of the motor-starting log last loaded from the device is shown to you.

- To update (synchronization with the device), click the **Read log entries** button in the headline of the indication list (*Figure 3-22*).

[scmotmlp-160713-01, 2, en_US]

Figure 3-22 Reading the Motor-Starting Log with DIGSI 5

Reading on the Device through the On-Site Operation Panel

- To reach the motor-starting log from the main menu, use the navigation keys of the on-site operation panel.
  Main Menu → Indications → **Motor-starting log**
- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.

[ScMotLog-280618, 1, en_US]

Figure 3-23 Reading the Motor-Starting Log on the On-Site Operation Panel of the Device

Deletability

The motor-starting log of your SIPROTEC 5 device can be deleted. Read details about this in chapter *3.1.6 Saving and Deleting the Logs*.

Configurability

The motor-starting log is only present in the **Motor** function group. There is no column for the motor-starting log in the DIGSI information routing. The entries in the motor-starting log are preconfigured and cannot be changed.

3.1.6 Saving and Deleting the Logs

Deleting the logs of the device in the operating state is unnecessary. If storage capacity is no longer sufficient for new indications, the oldest indications are automatically overwritten with new incoming events. In order for the memory to contain information about the new faults in the future, for example, after a revision of the system, a deletion of the log makes sense. Resetting the logs is done separately for the various logs.

NOTE

Before you delete the content of a log on your SIPROTEC 5 device, save the log with DIGSI 5 on the hard disk drive of your PC.

NOTE

Not all logs of your SIPROTEC 5 device can be deleted. These limitations apply especially to logs with relevance for security and after-sales (security log, device-diagnosis log, setting-history log).

NOTE

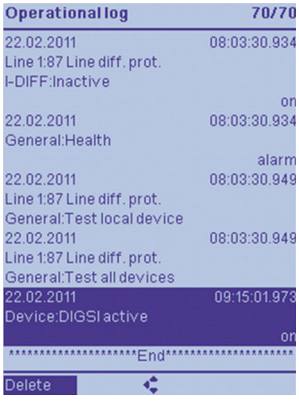
If you delete any files directly from the fault log or fault record, the error number for new fault records continues incrementing up to the maximum number 2^32. It does not reset to 0.

If you initialize flash partitioning of the fault log and fault record, the error number for new fault records resets to 0.

NOTE

If the device executes an initial start, for example after an update of the device software, the following logs are automatically deleted:

- Operational log
- Fault log
- Switching-device log
- Ground-fault log
- Setting-history log
- User-defined log
- Motor-starting log
- Communication-supervision log



Back up the deletable logs using DIGSI 5.

NOTE

If a ground fault is currently active, the ground-fault log cannot be deleted.

Deleting Logs on the On-Site Operation Panel

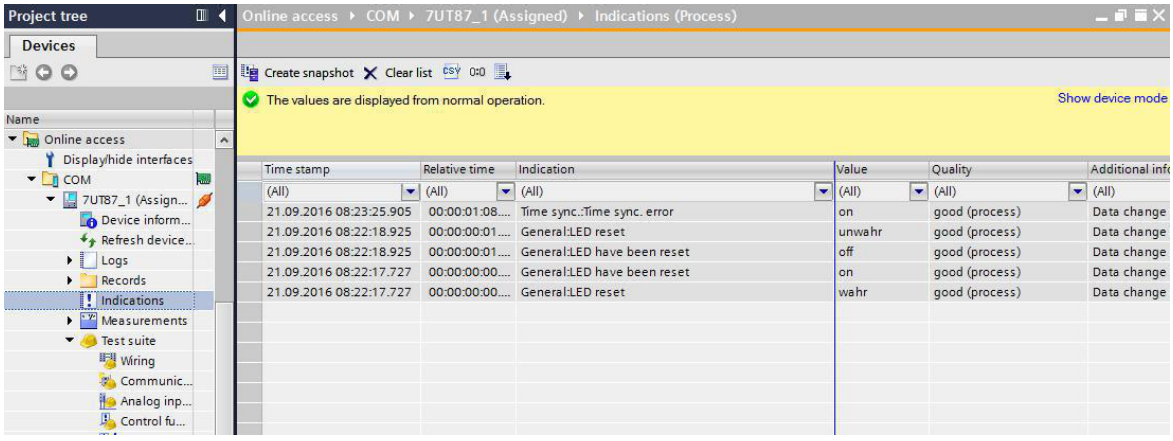
- To reach the selected log from the main menu, use the navigation keys of the on-site operation panel (example operational log):
  Main menu → Logs → **Operational log**

[sc_oprlog, 1, en_US]

Figure 3-24 Deleting the Operational Log on the On-Site Operation Panel

- You can navigate within the displayed indication list using the navigation keys (up/down) on the on-site operation panel.
- The option to delete the entire log is offered to you in the footer of the display at the bottom left. Use the softkeys below under the display to activate the command prompts. Confirm the request to **Delete**.
- After being requested, enter the password and confirm with **Enter**.
- After being requested, confirm the **Deletion of all entries** with **Ok**.

Deleting Logs from the PC with DIGSI 5



- To reach the selected log of your SIPROTEC 5 device, use the project-tree window (for example operational log).
  Project → Device → Process data → Logs → **Operational log**

3.1.7 Spontaneous Indication Display in DIGSI 5

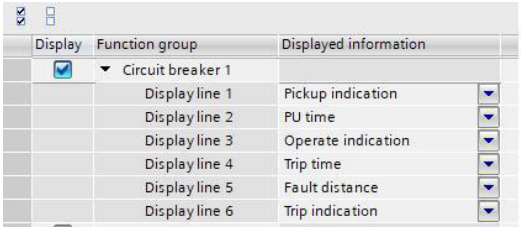
With DIGSI 5 you have the possibility of displaying all currently transmitted indications of the selected device in a special indication window.

Procedure

- Call up the spontaneous indications of your selected device in the navigation window under Online access.
- Click **Indications** in the path:
  Online access → Interface → Device → **Indications**
- The raising indications appear immediately without you having to wait for a cyclical update or initiate the manual update.

[sc_spnmld, 2, en_US]

Figure 3-25 Displaying Spontaneous Device Indications in DIGSI 5



3.1.8 Spontaneous Fault Display on the On-Site Operation Panel

After a fault, the most important data of the last fault can be displayed automatically on the device display without further operational measures. In SIPROTEC 5 devices, protected objects and even circuit breakers can be freely created and configured depending on the application (even several instances). In DIGSI 5, several spontaneous fault displays can be configured, depending on the application, with each individual one being assigned a particular circuit breaker. These displays remain stored in the device until they are manually confirmed or released by LED reset.

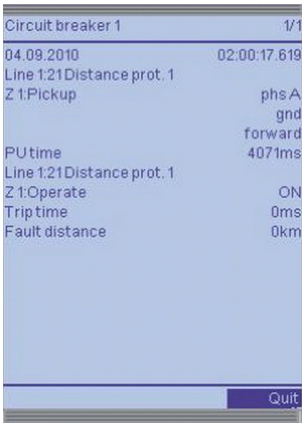
Configuration of a Spontaneous Fault Display with DIGSI 5

- To reach the **Fault-display configuration** of your SIPROTEC 5 device, use the project-tree window.
  Project → Device → Display pages → **Fault-display configuration**

- In the main window, all configured circuit breakers are displayed. A list of a maximum of 6 configurable display lines is offered for each circuit breaker. The activation of a spontaneous fault display occurs for each circuit breaker by selection via checkmark in the column **Display**.
- With the parameter **(_:139) Fault-display** (under Device → Parameter → Device settings) you determine whether spontaneous fault displays should be shown for each pickup or only pickups with the trip command.

[sc_konstf, 2, en_US]

Figure 3-26 Configuration of the Spontaneous Fault Display on the Device



For every display line the following display options can be selected:

Table 3-7 Overview of Display Options

Displayed Information	Explanation
Pickup indication	Display of the first function stage picked up in a fault, as needed with auxiliary information (phases, ground, direction)
PU time	Display of the entire pickup duration of the fault
Operate indication	Display of the first function stage triggered in a fault, as needed with auxiliary information (phases)
Trip time	Display of the operate time related to the beginning of the fault (pickup start)
Fault distance	Display of the measured fault-location distance
Operate result indication	Display of the control or switching device triggered in a fault, with auxiliary information (phases) where necessary

Acknowledgment of the Spontaneous Fault Display on the Device

After faults, the last occurred fault is always displayed to you. In cases where more than one circuit breaker is configured, several stored fault displays can be present after faults, with the latest being displayed. These displays remain stored in the device until manual acknowledgment or release by LED reset.

[sc_stfanz, 1, en_US]

Figure 3-27 Spontaneous Fault Display on the Device

Method 1: Manual acknowledgment

- Press the softkey button **Quit** in the base bar of the display. The display is irretrievably closed. Repeat this step until no further spontaneous fault displays appear.
- After completion of all confirmations the last display view is showed before the faults.

Method 2: Acknowledgment via LED reset

- An LED reset (device) causes the reset of all stored LEDs and binary output contacts of the device and also to the confirmation of all fault displays stored in the display.

You can find more details on the topic of LED reset in chapter *3.1.9 Stored Indications in the SIPROTEC 5 Device*

3.1.9 Stored Indications in the SIPROTEC 5 Device

In your SIPROTEC 5 device, you can also configure indications as **stored**. This type of configuration can be used for LEDs as well as for output contacts. The configured output (LED or contact) is activated until it is acknowledged. Acknowledgment occurs via:

- On-site operation panel
- DIGSI 5
- Binary input
- Protocol of substation automation technology

Configuration of Stored Indications with DIGSI 5

In the **Information Routing** of each device set up in DIGSI 5, you can route binary signals, among others, to LEDs and output contacts.

- To do this, proceed in the project tree to:
  Project → Device → **Information routing**
- Right-click the routing field of your binary indication in the desired LED or binary output column in the routing range of the targets.

You are offered the following options:

Table 3-8 Overview of Routing Options

Routing Options		LEDs	BOs	BIs	Description
H	(active)			X	The signal is routed as active with voltage.
L	(active)			X	The signal is routed as active without voltage.
V	(unlatched)	X	X		The signal is routed as unlatched. Activation and reset of the output (LED, BO) occurs automatically via the binary-signal value.
G	(latched)	X	X		The binary signal is latched when the output (LED) is activated. To reset, a targeted confirmation must occur.

Routing Options		LEDs	BOs	BIs	Description
NT	(conditioned latching)	X			Fault indications are stored during control of the output (LED) as a function of the parameter **(_:91:139) Fault-display**. In the event of a new fault, the previously stored states are reset. • If the fault gets terminated via a trip command from the assigned circuit breaker, the status of an indication remains as latched with the setting option ***with trip***. Without a trip command, the status is displayed before the fault (if necessary, the status of the last fault) is restored. • With the setting option ***with pickup*** the current indication image of a pickup gets stored. The image comprises all indications of functions that are effective in the event of tripping on the same circuit breaker, like the picked up function.
TL	(stored only with tripping)		X		Routing option TL (tripping stored) is only possible for the switching object circuit breaker. The output is saved with protection tripping. The contact remains activated until acknowledged. Control commands are not affected. A control command is pending above the parameterized command period until feedback has been successfully received. **Note**: You can realize the functionality of the **Lockout** (ANSI 86) by storing the output relay with the routing option TL.

3.1.10 Application Mode/Test Mode and Influence of Indications on Substation Automation Technology

With the controllable *Application mode* = ***Test*** or ***Test/Relay blk.***, you switch on or off the test mode for the entire device.

For further information, refer to *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

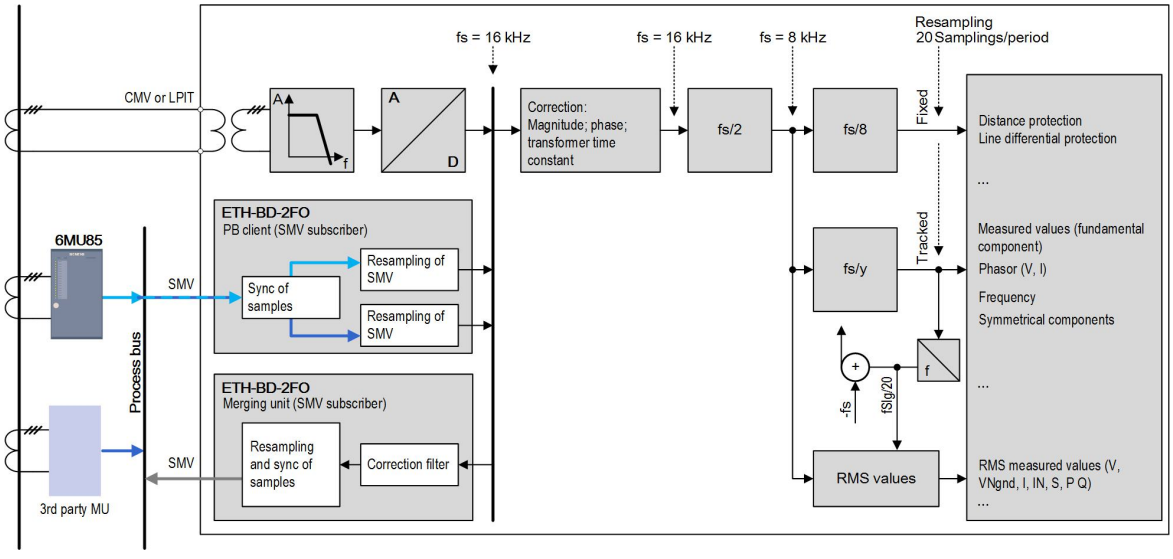
If the test mode of the device or of individual functions is switched on, the SIPROTEC 5 device marks indications sent to substation automation technology station control system with an additional test bit. This test bit makes it possible to determine that an indication was set during a test.

3.1.11 Resetting Stored Indications of the Function Group

You can configure indications of individual functions as "stored" in a function group. This type of configuration can be used for LEDs as well as for output contacts. The configured output (LED or contact) is activated until it is acknowledged.

The protection and the circuit-breaker function groups contain the block **Reset LED FG**. The block **Reset LED FG** is visible only in the Information routing under the corresponding function group in DIGSI 5. You use the binary input signal *>Reset LED* to reset the stored LEDs in the respective function group. The configured outputs (contacts) are not reset.

3.2 Measured-Value Acquisition



Basic Principle

SIPROTEC 5 devices are equipped with a powerful measured-value acquisition function. In addition to a high sampling frequency, they have a high measurand resolution. This ensures a high degree of measuring accuracy across a wide dynamic range. The 24-bit sigma/delta analog-digital converter represents the core of measured-value acquisition. In addition, the oversampling function supports the high measurand resolution. Depending on the requirements of the individual method of measurement, the sampling frequency is reduced (**Downsampling**).

In digital systems, deviations from the rated frequency lead to additional errors. In order to avoid this, 2 algorithm-dependent processes are used in all SIPROTEC 5 devices:

- Sampling-frequency tracking:
  The analog input channels are scanned for valid signals in cycles. The current power frequency is determined and the required sampling frequency is defined by using a **resampling algorithm**. The tracking is effective in the frequency range between 10 Hz and 90 Hz.
- Fixed sampling frequency – correction of the filter coefficients:
  This method operates in a limited frequency range (f_{rated} +/- 5 Hz). The power frequency is determined and, depending on the degree of the frequency deviation, the filter coefficients are corrected.

The following figure shows the basics of dealing with sampled values (SAV) in the measured-value acquisition chain. *Figure 3-28* shows to whom the various sampling frequencies are made available. In order to limit the bandwidth of the input signals, a low-pass filter (anti-aliasing filter to maintain the sampling theorem) is installed downstream. After sampling, the current input channels are adjusted. Meaning that magnitude, phase, and transformer time constant are corrected. The compensation is designed to ensure that the current transformer terminal blocks can be exchanged randomly between the devices.

[dw_meserf, 2, en_US]

Figure 3-28 Measured-Value Acquisition Chain

f_a	Sampling frequency
SMV	Sampled measured value
CMV	Conventional measured value
LPIT	Low-power instrument transformer

The internal sampling frequency of the SIPROTEC 5 devices is fixed at 16 kHz (sampling rate: 320 samplings per 50 Hz cycle). All current and voltage inputs are sampled. If magnitude, phase, and transformer time

constant are corrected, the sampling frequency is reduced to 8 kHz (160 samplings per 50-Hz cycle). This is the basic sampling frequency to which various processes, such as fault recording, RMS measured values, refer. For the RMS measurement, the measured-value window is adjusted on the basis of the power frequency. For numerous measurement and protection applications , 20 samplings per cycle are sufficient (if f_{rated} = 50 Hz): sampling every 1 ms, at f_{rated} = 60 Hz: sampling every 0.833 ms). This sampling rate is an adequate compromise between accuracy and the parallel processing of the functions (multi-functionality).

The 20 samplings per cycle will be made available to the algorithms processed in the function groups in 2 variants:

- Fixed (not resampled)
- Resampled (frequency range from 10 Hz to 90 Hz)

Depending on the algorithms (see function descriptions), the respective data flow is considered. A higher sampling frequency is used for selected methods of measurement. You can find detailed information in the corresponding function description.

NOTE

The **Power-system data** (starting in *6.1 Power-System Data*) contain the measuring points for current and voltage. Each measuring point has its own parameters.

3.3 Sampling-Frequency Tracking and Frequency Tracking Groups

3.3.1 Overview

Starting from platform version V07.80, you can merge measuring points into **Frequency tracking groups** in SIPROTEC 5 devices. The device operates with a maximum of 6 **Frequency tracking groups**.

The chapter *3.3.2 Sampling-Frequency Tracking* provides the necessary hints on the operating principle of sampling-frequency tracking and its application.

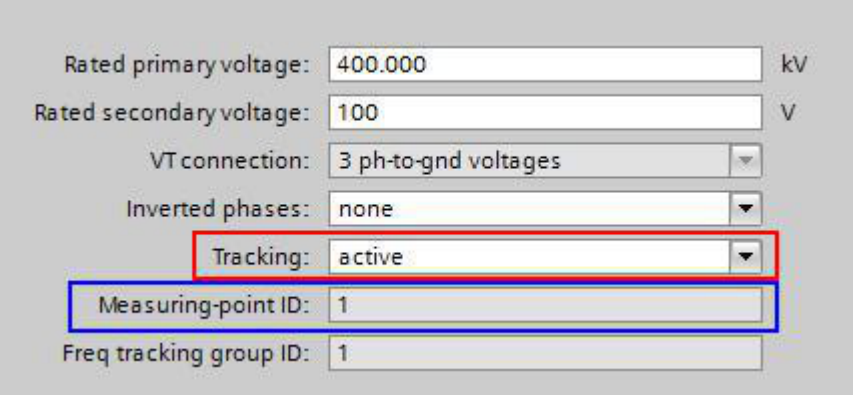
The chapter *3.3.3 Frequency Tracking Groups* describes the principle and application of frequency tracking groups.

3.3.2 Sampling-Frequency Tracking

SIPROTEC 5 devices are equipped with powerful sampling-frequency tracking as explained in *3.2 Measured-Value Acquisition* . This ensures high measuring accuracy over a wide frequency operating range (10 Hz to 90 Hz).

To determine the actual sampling frequency, the voltage and current measuring points are checked for valid input signals, the actual power frequency is determined and the tracking frequency (sampling frequency = 20 · tracking frequency) is adapted. The method is implemented in such a way that the number of samplings per actual power frequency or the frequency of the system is always constant. The number of samplings is 20 per cycle, as described in *3.2 Measured-Value Acquisition* .

During engineering, you set the parameters specifying which measuring points are used for frequency tracking. All 3-phase voltage and current measuring points and 1-phase voltage and current measuring points are allowed.



NOTE

Using a measuring point for sampling-frequency tracking requires this measuring point to be suitable for reliably determining the power frequency. This is the case, as long as the measuring point has been connected to the power system and the rated voltages and currents are measured. If the measured values for the rated voltages and currents are unavailable, sampling-frequency tracking must be switched off for this measuring point.

Examples of these kind of conditions are as follows:

- 1-phase measuring points: Measuring points that measure zero-sequence voltages or zero-sequence currents must not be used for frequency tracking.
- 3-phase measuring points: Measuring points that measure unbalanced currents and voltages for a capacitor bank must not be used for frequency tracking.

The following figure shows where you set the parameters for the corresponding measuring point and activate sampling-frequency tracking in the DIGSI 5 project tree under **Settings** → **Power-system data**.

[sc_MP_Powersys trackfreq, 1, en_US]

Figure 3-29 Using the Measuring Point to Determine the Sampling Frequency

If the parameter **Tracking** = ***active***, the measuring point is used to determine the actual tracking frequency. If the parameter **Tracking** is set to ***active*** for several measuring points, the ID of the measuring point determines the sequence in which these are checked for valid input signals. The algorithm starts with the lowest ID number, as follows:

- First, the 3-phase measuring points are scanned. If no valid voltage is found, the selected current measuring points are next. In this case, the following sequence applies:

  3-phase voltage measuring point → 3-phase current measuring point → 1-phase voltage measuring point → 1-phase current measuring point

  If a trigger signal comes from a current measuring point, the voltage measuring points are still continuously scanned for valid voltages and switched immediately if a voltage is found.
- If the true RMS value is greater than 2.5 % of the set secondary device rated value, a measuring point is valid. For example, this is 2.5 V at 100 V, 25 mA at 1 A or 125 mA at 5 A.
- A 3-phase measuring point is scanned in the sequence of phase A → phase B → phase C.
  In the case of the voltage measuring points, the phase-to-phase voltage V_{AB}, V_{BC}, and V_{CA} is always used for evaluation. The phase-to-phase voltage is calculated in the event of a phase-to-ground connection.
- The tracking frequency is tracked using different interval steps. If the tracking frequency deviates only slightly from the measured frequency, the frequency is tracked using small steps of 0.010 Hz. In the case of greater deviations, the interval is 1 Hz. To react faster in the event of larger deviations, for example in switchover conditions, tracking occurs in 5-Hz steps. When switching on measurands immediately the measured tracking frequency is used.
- If no tracking frequency can be determined, the appropriate rated frequency of the electrical power system is used as the tracking frequency. This case occurs before the measurands are switched on, after they are switched off or when the device is powered on. If the measurands are switched on, the starting frequency is the set power frequency, for example 50 Hz or 60 Hz. Since rated-frequency input variables can be assumed for most applications, the measuring algorithms start with the fixed sampling frequency, for example, 1 kHz for 50 Hz and 1.2 kHz for 60 Hz.

Figure 3-30 shows the behavior of sampling-frequency tracking across the frequency band and at the frequency limits.

The x-axis shows the actual power frequency (f_{sys}) and the y-axis shows the set tracking frequency (f_{track}). Between 10 Hz and 90 Hz, the relationship is linear. If the actual power frequency is less than 10 Hz, the tracking frequency is kept at 10 Hz. In this case, sampling occurs at 20 · 10 Hz = 200 Hz. If the power frequency is greater than 90 Hz, the tracking frequency is kept constant at 90 Hz.

If the frequency is outside the frequency operating range (10 Hz to 90 Hz), frequency tracking generates the indication ***Freq. out of range***. The individual protection functions evaluate this indication. If an overfunction can occur, the protection functions are blocked internally to avoid a failure.

You can find more detailed information on the behavior of the protection functions in *12 Technical Data*.

[dw_working-area_sampling-frequency-tracking, 2, en_US]

Figure 3-30 Operating Range of Sampling-Frequency Tracking

Siemens recommends routing the calculated power frequency (f_{sys}) and the determined tracking frequency (f_{track}) as a measured value trace in the fault record. In this way, you can document the behavior of the device in transient conditions. The following figure shows that you find the both measured values in the information routing under **Power-system data → General**:

Information			S	Destination		
			BO	LED	Recorder	
Signals	Number	Type				Signal
(All)	(All)	...				(All)
General	91					
Device	4171					
Alarm handling	5971					
Time managem.	8821					
Time sync.	8851					
Res. bin. out.	4711

f track	11.2311.323	MV				X

[sc_rout meas freq, 1, en_US]

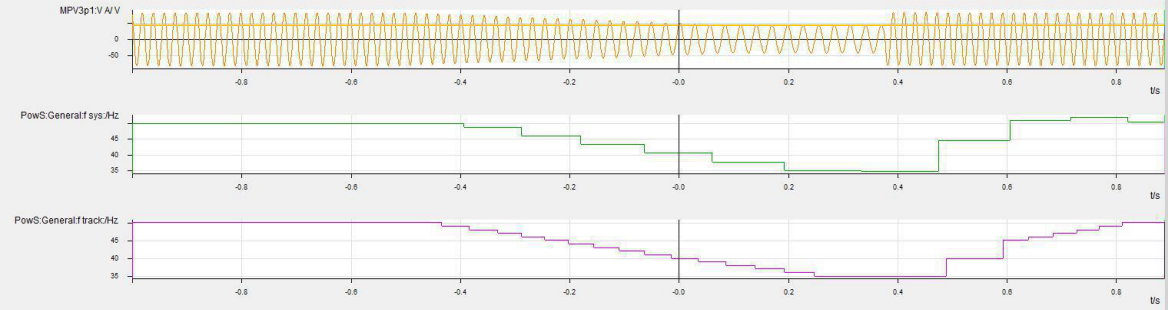

Figure 3-31 Routing of the Frequency Measured Values

EXAMPLE:

Figure 3-32 shows the behavior of sampling-frequency tracking using an example.

The voltage was reduced linearly from 57.7 V (100 V phase-to-phase) to 35 V (60.6 V phase-to-phase) and, at the same time, the frequency was reduced from 50 Hz to 35 Hz, for example motor coasting down. Then, an abrupt switch to the rated values of 57.7 V at 50 Hz was made.

The upper trace shows the power-system voltage on 1 phase (A) as an example. The center trace is the calculated power frequency and the lower trace is the determined tracking frequency. If you multiply the determined tracking frequency of the lower trace by 20, you can determine the sampling frequency.

[sc_example freqtrack, 1, en_US]

Figure 3-32 Example of Frequency Tracking and Reaction to a Step Change in the Input Variable

3.3.3 Frequency Tracking Groups

In the SIPROTEC 5 devices before platform version V07.80, sampling-frequency tracking applies to the entire device. This means that the 1st valid measuring point, for example, a 3-phase voltage measuring point, determines the selected tracking frequency based on the detected frequency.

If all measuring points in a system are galvanically coupled to each other, the power frequency is identical for all measuring points.

There are problems with electrical power system states or system states where galvanic separation is possible and measuring points of the separated system parts are connected to the SIPROTEC 5 device. For these problematic electrical power system states or system states, different frequencies are possible for a limited time. Depending on the measuring point set for tracking, the device selects which frequency to use. As a result, measuring errors and a failure of protection functions are possible.

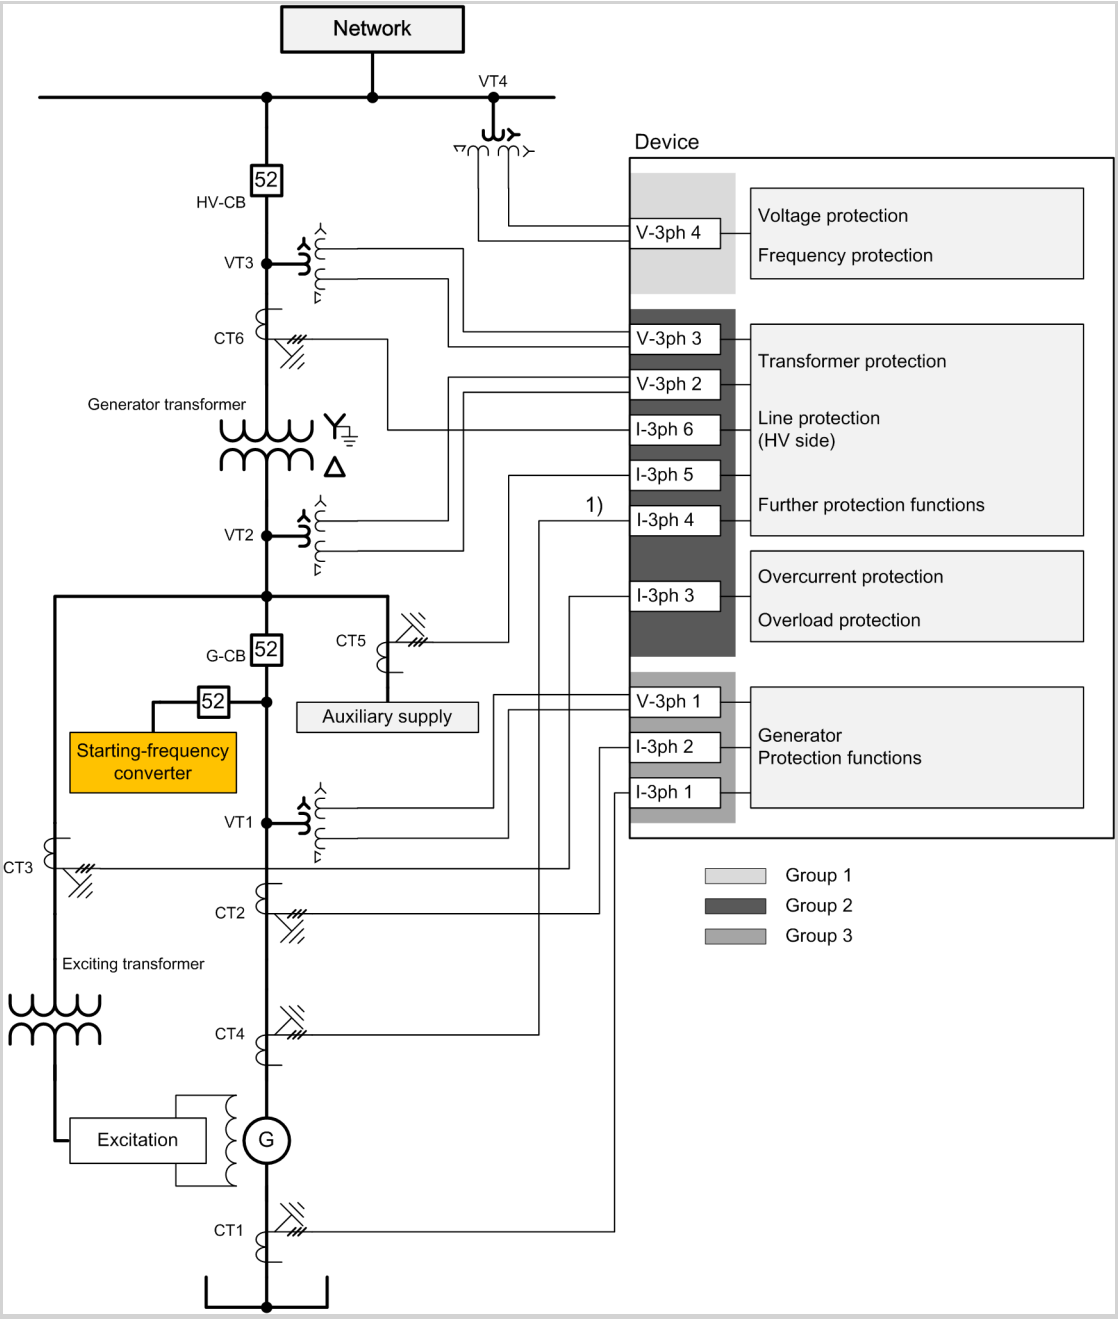
Starting with platform version V7.80, you can assign the measuring points to different frequency tracking groups. This ensures high flexibility and high measuring accuracy for a variety of applications. In this case, every frequency tracking group specifies its own sampling frequency. In the case of galvanic separation and different system frequencies, different sampling frequencies arise as a result. This occurs temporarily in systems with rotating machines, for example. A way to achieve galvanic separation is to use an open circuit breaker.

NOTE

In the measured-value acquisition chain in *Figure 3-28* in the chapter *3.2 Measured-Value Acquisition* , only the data stream designated as tracked is adapted. The data stream represented as fixed derives its sampling frequency exclusively from the set rated frequency. In this case, the constant sampling frequency of 1 kHz at f_{rated} = 50 Hz and 1.2 kHz at f_{rated} = 60 Hz is used. This applies to every measuring point, regardless of the frequency tracking group to which it is assigned.

EXAMPLE:

Figure 3-33 shows an example for the necessity of frequency tracking groups. The generator circuit breaker (GCB) and the high-voltage circuit breaker (HVCB) are the galvanic disconnection points. In this way, different switching states are possible. The device uses current measuring points (CTs 1 to 6) and voltage measuring points (VTs 1 to 4) located on different sides of the circuit breakers. In addition, it is assumed that the generator is started using a starting-frequency converter. In a gas-turbine application, the starting-frequency converter accelerates the generator from 0 Hz to about 70 % of the rated speed (roughly 35 Hz at f_{rated} = 50 Hz). After this, the gas turbine is fired up and brings the generator to the rated speed. Then, the voltage is built up to the rated voltage and synchronized. During this start-up operation, the GCB is open and the HVCB is closed. As a result, the measuring points VT 1, CTs 1, 2, 4 have a frequency that deviates from



the other measuring points during start-up operation. The other measuring points are usually at the rated frequency due of the connection to the power system.

Furthermore, protection tripping can result in a switching state where the HVCB is open and the GCB remains closed. In this case, the generator and a generator transformer can assume a frequency that deviates from the power frequency. In the event of load shedding, the generator accelerates before the speed controller intervenes. This is particularly pronounced in hydro generators.

An evaluation of the individual scenarios shows that different frequencies can occur at the different measuring points for a limited time. For this reason, 3 frequency tracking groups are necessary in this example. These groups are marked with different colors in the following figure.

NOTE

The measuring point (CT 4) marked with 1) in the following figure will be discussed later.

[dw_example_frequency-tracking-groups, 1, en_US]

Figure 3-33 Example of the Necessity of Frequency Tracking Groups

To strike a balance between application flexibility and the required computing power, the number of additional frequency tracking groups was limited to 5. Together with the basic functionality, a total of 6 frequency tracking groups are possible.

If you wish to use frequency tracking groups, use the following engineering recommendations. Before starting work, make sure you know how many frequency tracking groups are needed. Select only the required number.

If you start with an application template that you have expanded by the necessary measuring points, you must load the necessary number of additional frequency tracking groups from the Global DIGSI 5 Library into the **Power system** folder.

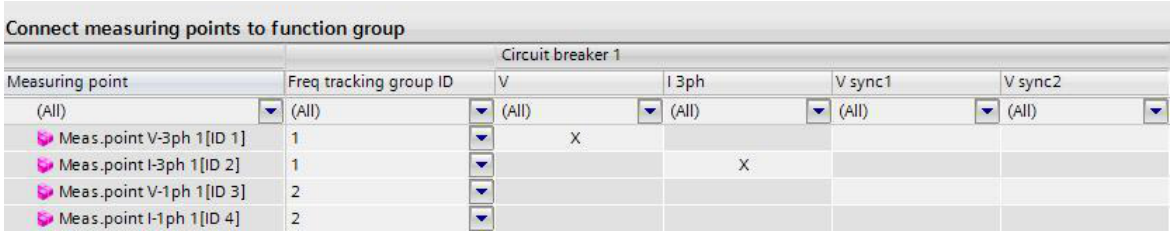
[sc_loading freq group, 1, en_US]

Figure 3-34 Loading the Required Frequency Tracking Groups

If you instantiate an additional frequency tracking group, the system automatically assigns the ID of the frequency tracking group in DIGSI using consecutive numbers. As the device already has 1 frequency tracking group, the ID numbering for additional frequency tracking groups starts with 2.

[sc_ID freqgroup, 1, en_US]

Figure 3-35 ID of the Frequency Tracking Group



NOTE

If you have activated several frequency tracking groups during engineering and you then delete a frequency tracking group again later, the assigned ID is also deleted. All other frequency tracking groups retain their assigned IDs.

Try to avoid discontinuities by deleting the frequency tracking group with the highest ID if possible.

You will find the frequency measured values and the indications of the corresponding frequency tracking group in the routing matrix (see *Figure 3-31*).

Assign the measuring points to the frequency tracking groups in the **Function-group connections** Editor. As soon as you have instantiated another frequency tracking group from the Global DIGSI 5 Library, the additional column **Frequency tracking group ID** appears in the routing matrix. In this column, you select the number of the corresponding frequency tracking group for each measuring point using the list box.

[sc_routing MP to freqgroup, 1, en_US]

Figure 3-36 Assignment of the Measuring Point to the Frequency Tracking Group

NOTE

Keep the following in mind when assigning the measuring points to the frequency tracking groups:

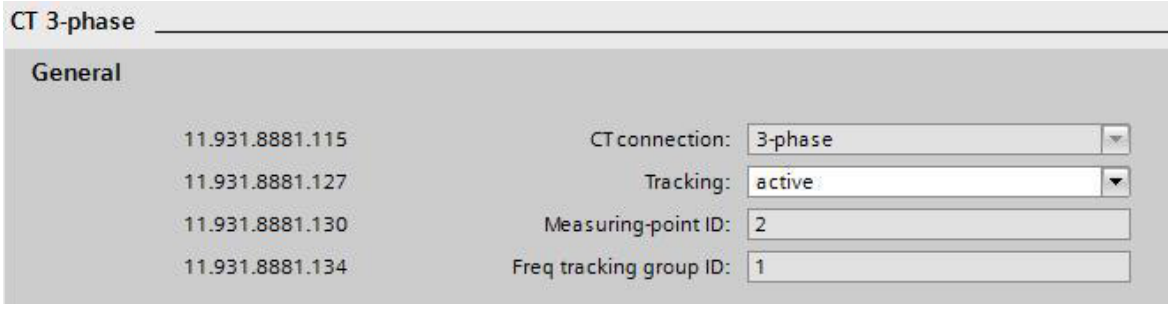
- The function groups (FGs) can operate only with 1 frequency tracking group.
- This applies also to interconnections between the function groups as for the **Transformer differential protection**.

  In the case of the **Transformer differential protection**, the **Transformer side** FG is interconnected with the **Transformer** FG and all **Transformer side** FGs of one transformer must operate in the same frequency tracking group.

  The same applies when the neutral-point current is measured using a 1-phase function group.

There are also exceptions such as the FG **Circuit breaker** (see chapter *5.9 Function-Group Type Circuit Breaker*). The voltage measured values are processed by the **Synchronization function** which operates only with a fixed sampling frequency. In this way, voltage measuring points from different frequency tracking groups can be connected.

The cited rules are checked using scripts and infractions reported during engineering.



Now, you can select the measuring points to be used to determine the tracking frequency for the appropriate frequency tracking group as explained in chapter *3.3.2 Sampling-Frequency Tracking*. If possible, use at least 1 voltage measuring point and 1 current measuring point. Give preference to 3-phase measuring points.

When the tracking frequency has been determined, all measuring points of the frequency tracking group are set to this frequency and the tracked sampling frequency is adapted.

NOTE

As described in the chapter *3.2 Measured-Value Acquisition* , the measured-value current with fixed sampling frequency is unaffected by this.

To avoid errors, the ID of the measuring point and the ID of the assigned frequency tracking group are displayed in the setting sheet of the measuring points in DIGSI 5 (see *Figure 3-37*).

[sc_MP additional setting freqgroup, 1, en_US]

Figure 3-37 Example: Settings of the 3-Phase Current Measuring Point; Additional Display of the ID for the Frequency Tracking Group

In addition, the ID of the frequency tracking group is displayed in the function group in the **General** block (see *Figure 3-38*). Here, you can also check the consistency.

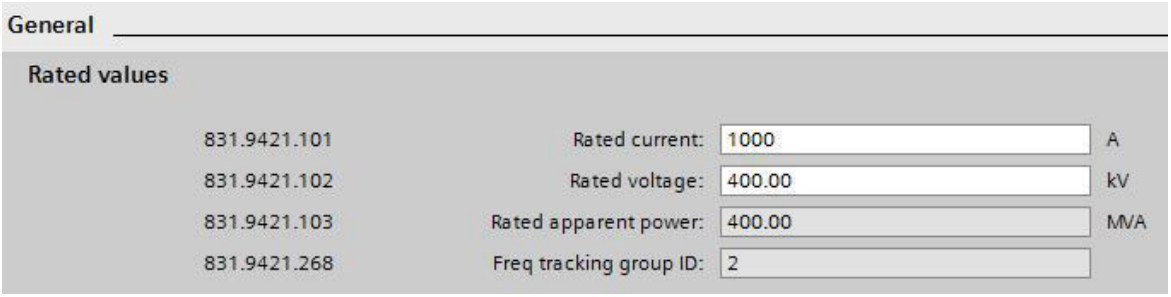


Figure 3-38 Display of the ID for the Frequency Tracking Group in the Block **General** of the Function Group

A special feature is explained using *Figure 3-33* as an example.

The measuring point marked in *Figure 3-33* with **1)** uses a current transformer that is located on the generator side but is used by the transformer differential protection. As a result, this current transformer must be assigned to the frequency tracking group 2 in accordance with the rules above. Since the generator is started using a starting-frequency converter in the application example, the frequency at this measuring point deviates from the frequency at the other measuring points of group 2. For this reason, the measuring point with CT 4 must **not** be used to determine the tracking frequency.

Depending on the application, the current of the CT 4 acts as a disturbance variable when forming the Kirchhoff's current law. As a rule, this current is not particularly strong (< 15 % of I_{rated}) so that the disturbance effect remains small. If required, you must set the differential protection to be less sensitive. Decide this for the specific application.

The following table shows the possible assignment of measuring points used to determine the tracked sampling frequency for the example. For this purpose, the parameter **`Tracking`** = ***`active`*** in the corresponding measuring point:

Frequency Tracking Group	1	2	3
Recommended measuring points for tracking	VT 4	VT 3 VT 2 CT 5	VT 1 CT 1

3.3.4 Frequency Tracking Groups – Interpretation of Measured Values

If you use frequency tracking groups, you must keep in mind special features when interpreting the measured values. The measuring points of a frequency tracking group are to be treated as decoupled for measurement purposes. This means that the complex measured values of a single function group, like phasor measured values, always match. Since phase A of the 1st measuring point is always assumed to be the reference value when representing the measured value, the phasor measured values cannot be compared between frequency tracking groups. This also applies if all measuring points are galvanically connected to one another.

NOTE

When selecting the reference variable, a voltage measuring point always takes precedence over a current measuring point. If the frequency tracking group does not contain a voltage measuring point, the 1st current measuring point is used.

EXAMPLE:

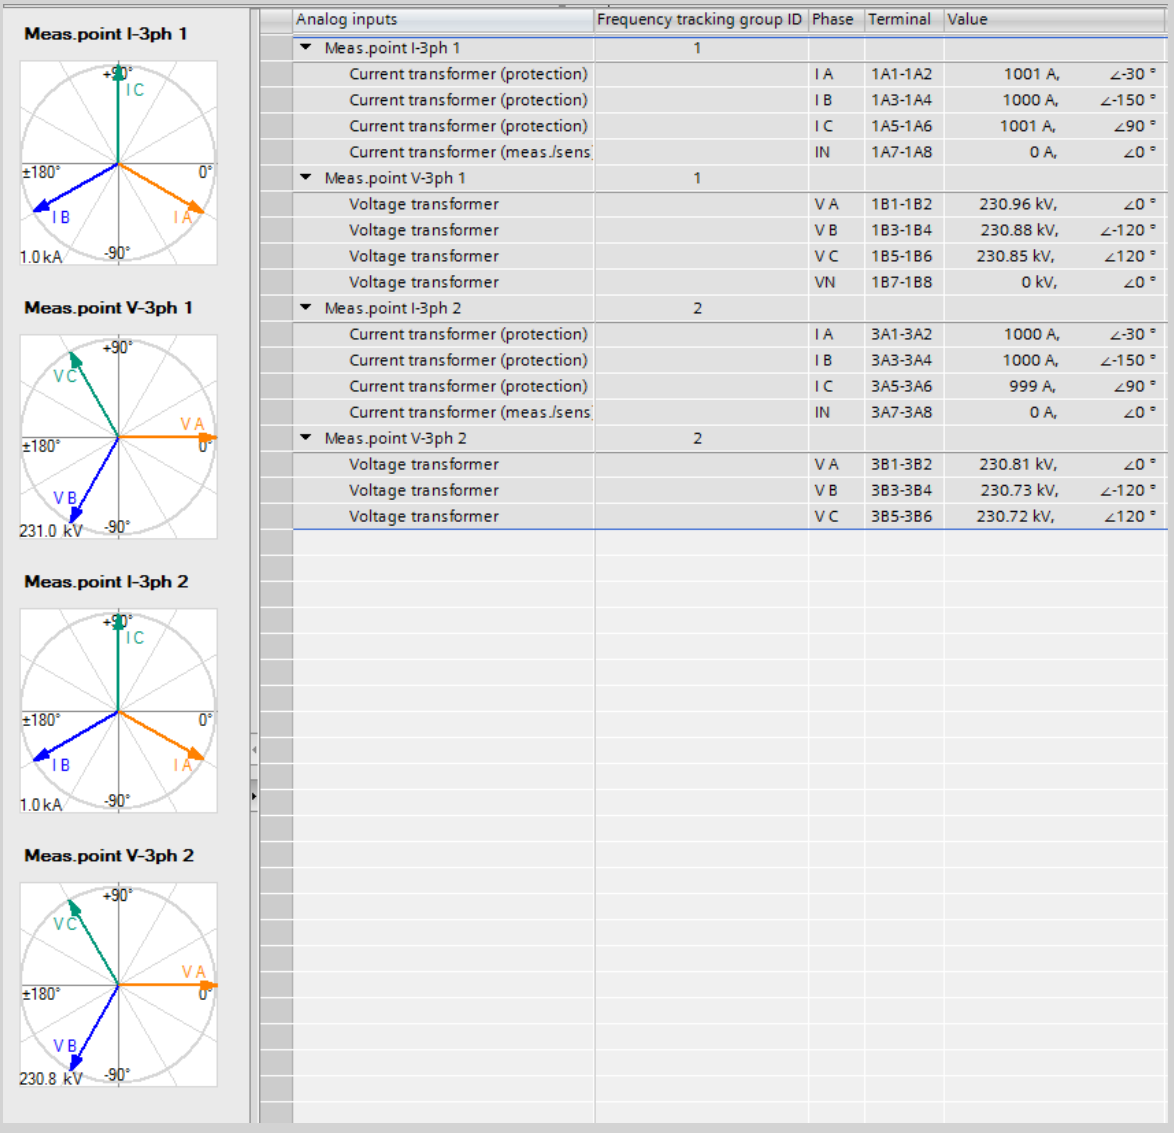

Figure 3-39 shows an example of the phasor representation of the analog measured values of the measuring points.

The phasor representation of the analog measured values of the measuring points can be found in the DIGSI 5 project tree under **Online access** → **Device** → **Test suite** → **Analog inputs**.

Each of the 2 frequency tracking groups contains one 3-phase voltage measuring point **V-3ph** and one 3-phase current measuring point **I-3ph**.

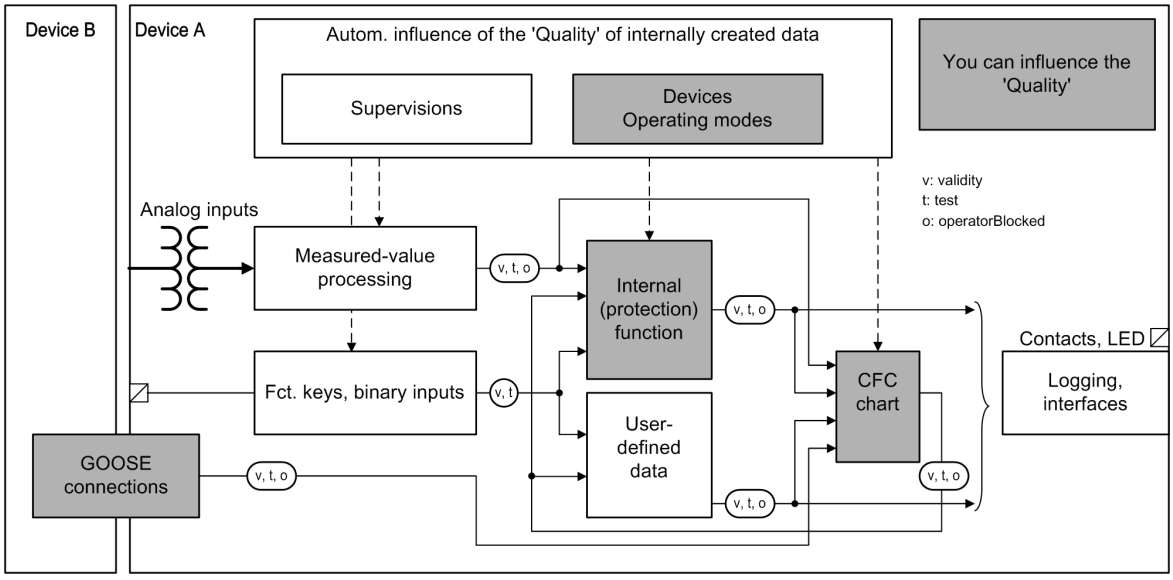
Frequency tracking group **1** contains the measuring points **V-3ph 1** and **I-3ph 1**, frequency tracking group **2** contains the measuring points **V-3ph 2** and **I-3ph 2**. The frequencies between the frequency tracking groups differ by 0.5 Hz. A phase displacement of -30° is set between the voltage and the current.

In *Figure 3-39*, you can see that the fundamental RMS measured values are identical. The phasor measured angles are shown as decoupled (see Phase angle). In this case, V_A is the reference value in the corresponding frequency tracking group. With decoupled sampling-frequency tracking, the measurement of the measurands is exact, even with a different system frequency.

Analog inputs	Frequency tracking group ID	Phase	Terminal	Value	
Meas.point I-3ph 1	1				
Current transformer (protection)		I A	1A1-1A2	1001 A,	∠-30 °
Current transformer (protection)		I B	1A3-1A4	1000 A,	∠-150 °
Current transformer (protection)		I C	1A5-1A6	1001 A,	∠90 °
Current transformer (meas./sens		IN	1A7-1A8	0 A,	∠0 °
Meas.point V-3ph 1	1				
Voltage transformer		V A	1B1-1B2	230.96 kV,	∠0 °
Voltage transformer		V B	1B3-1B4	230.88 kV,	∠-120 °
Voltage transformer		V C	1B5-1B6	230.85 kV,	∠120 °
Voltage transformer		VN	1B7-1B8	0 kV,	∠0 °
Meas.point I-3ph 2	2				
Current transformer (protection)		I A	3A1-3A2	1000 A,	∠-30 °
Current transformer (protection)		I B	3A3-3A4	1000 A,	∠-150 °
Current transformer (protection)		I C	3A5-3A6	999 A,	∠90 °
Current transformer (meas./sens		IN	3A7-3A8	0 A,	∠0 °
Meas.point V-3ph 2	2				
Voltage transformer		V A	3B1-3B2	230.81 kV,	∠0 °
Voltage transformer		V B	3B3-3B4	230.73 kV,	∠-120 °
Voltage transformer		V C	3B5-3B6	230.72 kV,	∠120 °

[sc_measured_val_DIGSI, 1, en_US]

Figure 3-39 DIGSI Online Mode: Phasor Representation of the Measuring Points with 2 Frequency Tracking Groups and a Different Frequency



If the circuit breaker in a system is closed, the measuring points are galvanically connected to one another. If you want to compare the phasor variables of all measuring points to one another when using frequency tracking groups, Siemens recommends starting a fault record. Evaluate the fault record using SIGRA in the **Phasor representation** mode. The comparison is possible here because sampled values that are not frequency-tracked are used in the fault record. If the frequency deviates from the rated frequency, the measured values differ slightly.

3.4 Processing Quality Attributes

3.4.1 Overview

The IEC 61850 standard defines certain quality attributes for data objects (DO), the so-called Quality. The SIPROTEC 5 system automatically processes some of these quality attributes. In order to handle different applications, you can influence certain quality attributes and also the values of the data objects depending on these quality attributes. This is how you can ensure the necessary functionality.

The following figure describes roughly the general data flow within a SIPROTEC 5 device. The following figure also shows at which points the quality can be influenced. The building blocks presented in the figure are described in more detail in the following.

[lo_quali1, 2, en_US]

Figure 3-40 Data Flow within a SIPROTEC 5 Device

Supported Quality Attributes

The following quality attributes are automatically processed within the SIPROTEC 5 system.

- **Validity** using the values *good* or *invalid*

  The **Validity** quality attribute shows if an object transferred via a GOOSE message is received (valid, invalid) or not received (invalid). The *invalid* state can be suppressed in the receiver device by also setting a substitute value for the object that is not received (see *3.4.2 Quality Processing/Affected by the User for Received GOOSE Values*). The substitute value is forwarded to the functions.

  If the device receives one of these values, it is replaced by the *invalid* value and thus processed further as *invalid*.

  If one of the detailed quality attributes (detailQual) has the value *TRUE*, then **Validity** is set to the *invalid* value, unless this was already done at the transmitter end.

- **Test** using the values *TRUE*, *FALSE*

  The **Test** quality attribute indicates to the receiver device that the object received via a GOOSE message was created under test conditions and not operating conditions.

- **OperatorBlocked** using the values *TRUE*, *FALSE*

  The **OperatorBlocked** quality attribute indicates whether an object transferred via GOOSE message originates from a device that is in a *functional logoff* state. When the sending device is switched off, the object is no longer being received and assumes the *invalid* state. However, since the **OperatorBlocked** quality was previously identified on the receiver device, the object can be treated differently at the receiving end (see *3.4.2 Quality Processing/Affected by the User for Received GOOSE Values*). At the receiving end, the object may be treated like a dropped signal.

- **Source** using the values *process*, *substituted*

  The **Source** quality attribute indicates whether the object was updated in the sending device.

  You can find more detailed information in *3.9.2 Acquisition Blocking and Manual Updating*.

Influencing Quality by the Operating Modes

In addition to the normal operation, the device also supports further operating modes that influence quality:

- **Test mode of the device**

  You can switch the entire device to test mode. In this case, all data objects generated in the device (state values and measured values) receive the quality attribute **Test** = *TRUE*.

  The CFC charts are also in test mode and all output data receive the quality attribute **Test** = *TRUE*.

- **Test mode for individual functions, stages, or function blocks**

  You can switch individual functions, stages, or function blocks into test mode. In this case, all data objects generated by the function, stage, or function block (state values and measured values) receive the quality attribute **Test** = *True*.

- **Functional logoff of the device**

  If you take the device out of operation and want to isolate it from the supply voltage, you can functionally log off the device ahead of time. Once you functionally log off the device, all data objects generated in the device (state values and measured values) receive the quality attribute **OperatorBlocked** = *TRUE*. This also applies to the output from CFC charts.

  If objects are transferred via a GOOSE message, the receiver devices can assess the quality. The receiver device detects a functional logoff of the transmitting device. After shutting down the sending device, the receiver device identifies that the sending device has been logged off operationally and did not fail. Now the receiving objects can automatically be set to defined states (see chapter *3.4.2 Quality Processing/Affected by the User for Received GOOSE Values*).

- **Switching off individual functions, stages, or function blocks**

  You can switch off individual functions, stages, or function blocks. In this case, all data objects generated by the function, stage, or function block (state values or measured values) receive the device-internal quality attribute **Off**. The states of the inputs and measured values remain unchanged in this case; input changes are not processed. As the quality attribute **Off** is not provided for in communication protocol IEC 61850, the data objects are transferred with the quality attribute *Invalid*.

Influencing the Quality through Hardware Supervision

Supervision functions monitor the device hardware (see *8.4 Supervision of the Device Hardware*). If the supervision functions identify failures in the data acquisition of the device, then all recorded data will receive the quality attribute **Validity** = *invalid*.

Influencing the Quality through Voltage-Transformer Circuit Breakers

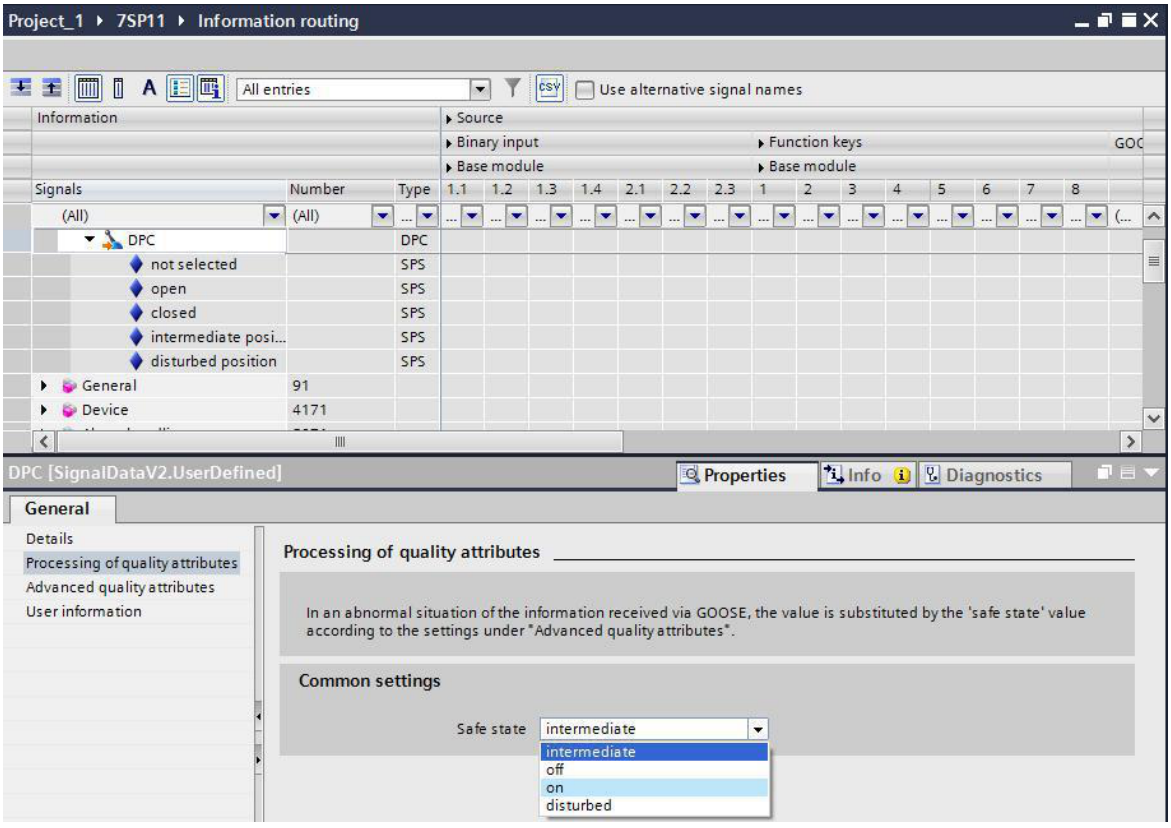
If tripping of the voltage-transformer circuit breaker is detected (see *8.3.4 Voltage-Transformer Circuit Breaker*), all recorded data will receive the quality attribute **Validity** = *invalid*.

Influencing the Quality by the User

You can influence the processing of data and their quality differently. In DIGSI 5, this is possible at the following 3 locations:

- In the **Information routing** editor for external signals from GOOSE connections
- In the CFC chart
- In the **Information routing** editor for binary input signals of device-internal functions

The following chapters describe in more detail the options regarding this influence as well as the automatic quality processing.



If a GOOSE connection is the data source of a binary input signal of a device-internal function, you can influence processing of the quality at 2 locations: at the GOOSE connection and at the input signal of the function. This is based on the following: A GOOSE date can be distributed within the receiving device to several functions. The GOOSE connection setting (influence) affects all functions. However, if different functions require customized settings, these are then set directly at the binary input signal of the function.

3.4.2 Quality Processing/Affected by the User for Received GOOSE Values

The properties of quality processing have changed with the introduction of GOOSE Later Binding. You can find information about the former quality processing in *Previous Quality Processing/Affected by the User for Received GOOSE Values, Page 122*.

In the **Information Routing** Editor, you can influence the data value and quality of all data types. The following figure shows the possible influence using the example of a DPC data type. All setting options are effective for the device receiving the data.

- In the DIGSI 5 project tree, double-click **Information Routing**.
- Select either the desired signal in the **External Signals** group or the signal of a function activated via the GOOSE column.
- Open the **Properties** window and select the **Processing Quality Attributes** sheet.

[sc_LB_GOOSE_2, 2, en_US]

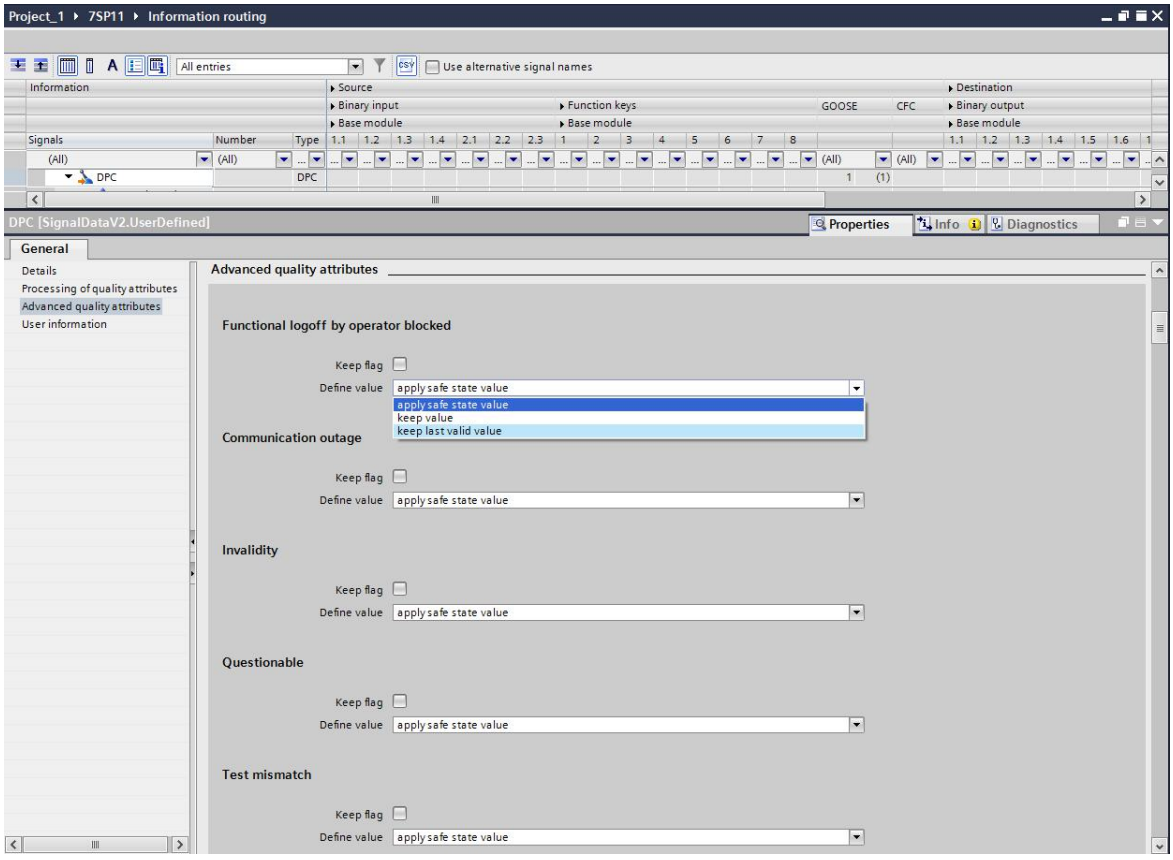


Figure 3-41 Influence Option When Linking a DPC Type Data Object

Depending on the selected data type of the object, various selection options are offered to you for the **Safe state** item in the **Common settings** section. At this point, you select the manually updated values that allow a safe operating state as soon as the data access via the communication path is disturbed.

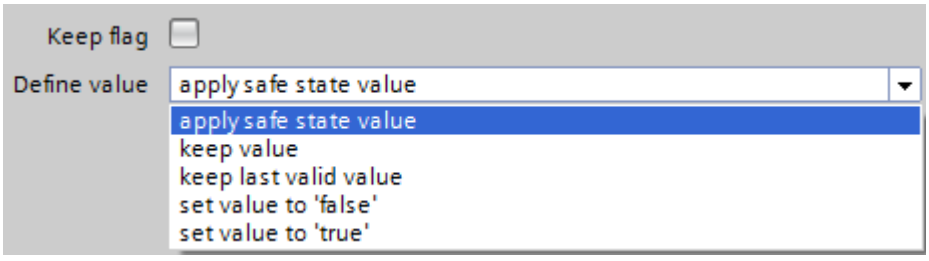
- Select the property for the selected data object.

You can also set the **Advanced quality attributes** of the data object for GOOSE Later Binding.
The following figure shows the advanced quality attributes using the example of a DPC data type.

- Open the **Properties** window and select the **Advanced quality attributes** sheet.

[sc_LB_GOOSE_1, 2, en_US]

Figure 3-42 Advanced Quality Attributes for GOOSE Later Binding



With the following advanced quality attributes, you can filter the transmitted GOOSE indications and check and set their quality. The values that have been adapted, if necessary, are forwarded to the receiver.

For the tests, you can select from the following setting options depending on the data type.

Table 3-9 Value Definitions

Setting Value	Description
Apply safe state value	The value configured in the **Safe state** is forwarded as valid to the application as soon as communication disturbance occurs.
Keep value	The disturbed quality attribute is overwritten with *good* and the received value is forwarded as valid to the application. If no value was received, the output value is assumed being in safe state.
Keep last valid value	If an invalid quality attribute is received, the last valid value is forwarded to the application. If no value has yet been received, the output value is assumed being in safe state.
Set value to "false"	Applies only to Boolean communication objects. Every invalid quality attribute causes the valid value *false* to be forwarded to the application.
Set value to "true"	Applies only to Boolean communication objects. Every invalid quality attribute causes the valid value *true* to be forwarded to the application.

These settings of the **Advanced quality attributes** apply to the advanced quality attributes listed below. The selection can vary depending on the data type.

[sc_LB_GOOSE_3, 2, en_US]

Figure 3-43 Value Definition of a Data Object of the SPS Type

You can also forward the quality attributes unchanged. To do this, you must mark the **Keep flag** check box.

NOTE

By default, the ***Keep flag*** checkbox is disabled when the signal is routed to the LED or the binary output.

Functional Logoff by Operator Blocked

You have set the *Operation mode* to *Device logoff* = *true* in the transmitting device. As a result, every indication issued from the functions and subject to *Device logoff* is transmitted with the quality information *operator blocked* and **Validity** = *good*. The receiver recognizes this for this indication and reacts according to the settings (*Table 3-9*). A different quality processing can take place only once you have set the *Operation mode* to *Device logoff* = *false* in the transmitting device.

Communication Outage

There is communication disturbance (time allowed to live) between the transmitter and the receiver indicated by the transmitter. The indication is set in accordance with the settings (*Table 3-9*).

Invalidity

The transmitting device sends this indication with the quality information **Validity** = *invalid*. The receiver recognizes this for this indication and reacts according to the settings (*Table 3-9*).

Questionable

The transmitting device sends this indication with the quality information **Validity** = *questionable*. The receiver recognizes this for this indication and reacts according to the settings (*Table 3-9*).

Test Mismatch

The transmitting device or the function in the transmitting device that issues this indication is in test mode. As a result, the indication is transmitted with the quality information *test*. The receiving function block recognizes this for this indication and reacts, depending on its own test-mode state (specified in IEC 61850-7-4 Annex A), according to the settings (*Table 3-9*).

NOTE

Follow the sequence of tests. First, the **Functional logoff by operator blocked** is tested. Then comes **Communication outage** and so on. If a case is recognized as *active*, the test chain is canceled with the configured setting for the active case.

In the case of **Invalidity**, the tests are first performed for **Functional logoff by operator blocked** (not applicable) and then for **Communication outage** (not applicable) and canceled with the configured action for **Invalidity**.

If an indication is routed into the log, manual updating of a value is also logged based on the conditions listed above and on the reason for the manual update. Manually updating a value based on the conditions listed

above causes a change in the *Health Warning* function block, inherited up to *Device health* (specified in IEC 61850-7-4).

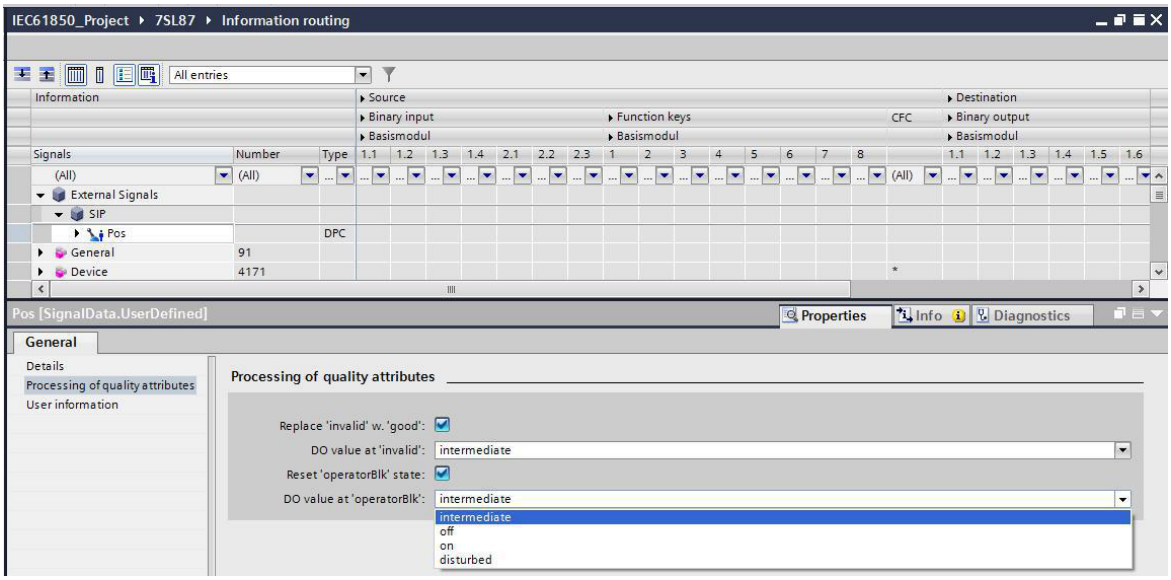
Keep Flag

The quality attributes and values indicated by the transmitter are accepted without change. Quality processing must be performed by the user via a logic diagram. The outputs of the logic diagram following the user-specific quality processing can be connected to the function-block inputs as before.

Data Substitute Values

Depending on the data type, different data substitute values must be used.

Data Type	Possible Data Substitute Values	
ACD, ACT	general	0 (False), 1 (True) The directional information is manually updated with *unknown* if the option ***Apply safe state value***, ***Set value to "false"***, and ***Set value to "true"*** are selected; or maintain the received value with the options ***Keep value*** or ***Keep last valid value*** selected. PhsA, phsB, phsC, and neut are manually updated with the same value just like how the general value is set.)
BAC, APC	mxVal	Floating-point range and range of values according to IEEE 754 (single precision)
BCR	actVal	-2^{63} to $2^{63} - 1$
CMV	mag, ang	Floating-point range and range of values according to IEEE 754 (single precision)
DPC, DPS	stVal	0, 1, 2, 3 (intermediate-state, off, on, bad-state)
INC	stVal	–2 147 483 648 to 2 147 483 647
INS	stVal	–2 147 483 648 to 2 147 483 647
ISC, BSC	valWTr.posVal	–64 to 64
	valWTr.transInd	0 (False), 1 (True)
SPC, SPS	stVal	0 (False), 1 (True)
MV	mag	Floating-point range and range of values according to IEEE 754 (single precision)



For controllable types, the following substitute values apply in addition to the settable state values or measured values:

ctlNum	=	0
stSeld	=	False
origin.orIdent	=	Substituted by quality processing
origin.orCat	=	AUTOMATIC_BAY

Previous Quality Processing/Affected by the User for Received GOOSE Values

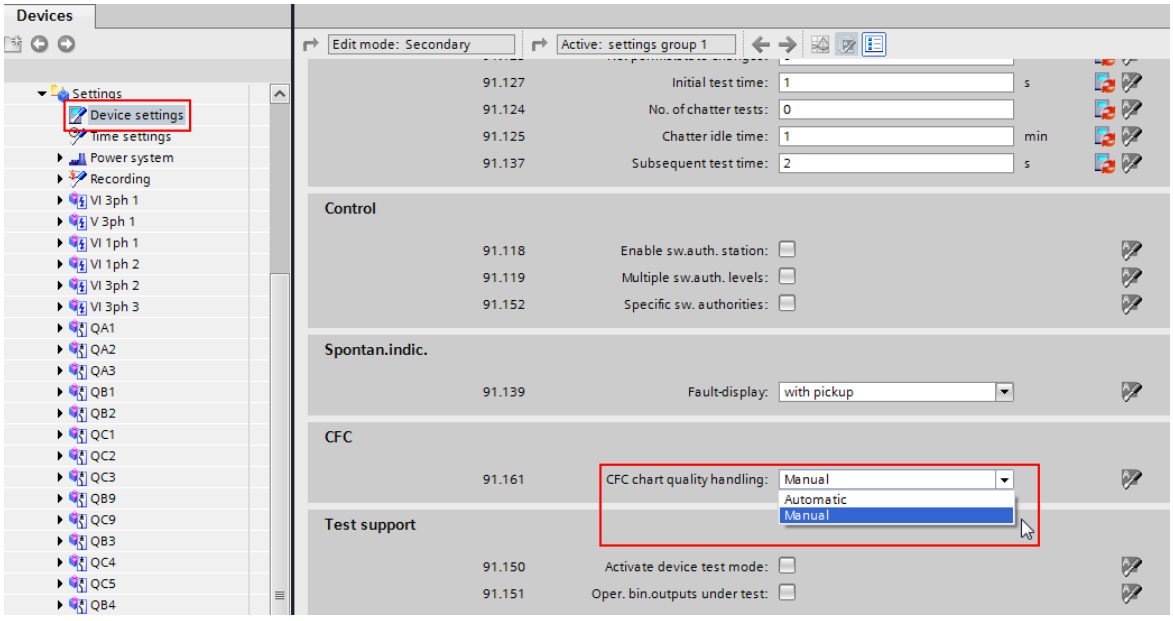
In the **Information Routing** editor, you can influence the data value and quality of all data types. The following figure shows the possible influence using the example of a DPC data type.

- In the DIGSI 5 project tree, double-click **Information Routing**.
- Select the desired signal in the **External Signals** group.
- Open the **Properties** window and select the **Processing Quality Attributes** sheet.

[sc_GOOSE values, 1, en_US]

Figure 3-44 Influence Option When Linking a DPC Type Data Object

The setting options work for the device receiving the data.



Quality Attribute: Validity	
The validity values *reserved* and *questionable* are replaced at the receiving end by the *invalid* value.	
• Check box is not set. • Check box is set and receipt of **Validity** = *good*	The validity attribute and data value are forwarded without change.
Check box is set and receipt of **Validity** = *invalid* is set (also applies to values *reserved* and *questionable*).	• The validity attribute is set to *good* and processed further using this value. • The data value is set to the defined substitute value and processed further using this substitute value.

Quality Attribute: OperatorBlocked (opBlk)	
• Check box is not set. • Check box is set and received **OperatorBlocked** = *FALSE*	The OperatorBlocked attribute and data value are forwarded without change.
Check box is set and received **OperatorBlocked** = *TRUE*	• The OperatorBlocked attribute is set to *FALSE* and processed further using this value. • The data value is set to the defined substitute value and processed further using this substitute value.

Interaction of the Quality Attribute Validity and OperatorBlocked	
OperatorBlocked check box is set and receipt of **OperatorBlocked** = *TRUE*	Regardless of whether the validity check box is set or not, and regardless of the current validity, the validity attribute is set to *good* and the substitute value of the OperatorBlocked data object is set. That is, the OperatorBlocked settings overwrite the Validity settings.
OperatorBlocked check box is not set and receipt of **OperatorBlocked** = *TRUE*	The OperatorBlocked attribute remains set and is forwarded. If the Validity check box is set and the receipt of validity = *invalid* is set, the respective data object substitute value is used. For continued signal processing and influence, it must be taken into account that in this configuration the data object substitute value for validity = *invalid* is set, but the quality attribute OperatorBlocked is not yet set.

3.4.3 Quality Processing/Affected by the User in CFC Charts

In DIGSI 5, you can control the quality processing of CFC charts. In the project tree, you can find the **CFC** building block (see the following figure) under **Device name** →, **Settings** → **Device settings** in the editor:

[sc_quali_cfc, 1, en_US]

Figure 3-45 Influencing CFC Quality Handling in DIGSI 5

With the **CFC chart quality handling** parameter, you control whether you want to influence the quality of CFC charts in a ***Manual*** or ***Automatic*** (default setting) manner.

If you select ***Manual***, the quality attribute of the CFC chart is always valid regardless of the quality of individual signals (**Validity** = ***good***)!

Only the **Test** quality attribute of the CFC chart is processed. If the device is in test mode or the input TEST of the CHART_STATE CFC building block is set, the quality attribute of the CFC chart is set to ***Test***.

If you select ***Automatic***, the quality processing of the CFC charts is influenced as follows:

In the case of CFC charts, a distinction has to be made between the general quality processing and certain CFC building blocks that are specifically designed for quality processing.

General Processing

Most of the CFC building blocks do not have an explicit quality processing. For these building blocks, the following general mechanisms shall apply.

Quality Attribute: Validity
If one *invalid* signal is received in the case of CFC input data, then **all** CFC output data will also be set to *invalid* if they originate from building blocks without explicit quality processing. In other words, the quality is not processed sequentially from building block to building block but the output data are set globally. This does not apply to CFC output data that originate from building blocks with explicit quality processing (see next section).

Quality Attribute: Test	
CFC chart is in **normal** state.	CFC input data with the **Test** = *TRUE* attribute are ignored. When the CFC chart is executed, then the data value that was used before the **Test** = *TRUE* attribute is used. The quality of this **old** value is also processed. This means that on the output side, the attribute **Test** = *FALSE*.
CFC chart is in **Test**[1)] state.	If the CFC chart is executed, then the attribute **Test** = *TRUE* is set for all data leaving the CFC chart. This does not depend on whether the data are formed via CFC building blocks with or without quality processing.

[1)]A CFC chart can be switched to the test state by switching the entire device to test mode or the input TEST of the CFC building block CHART_STATE is set.

Quality Attribute: OperatorBlocked	
CFC chart is in **normal** state.	In CFC charts for incoming data, the **OperatorBlocked** attribute is ignored.
CFC chart is in **functionally logged off**[1)] state .	In CFC charts for incoming data, the **OperatorBlocked** attribute is ignored. All CFC output data are labeled as functionally logged off.

[1)] This state only occurs if the device is functionally logged off. In this case, the quality attributes of all CFC outputs are labeled as **functionally logged off**.

Quality Processing Building Blocks (Condition Processing)

The first 3 building blocks (x_SPS) process the quality automatically according to the stated logic. The other building blocks are used to isolate the quality from a data object and add them back after separate logical processing.

<table>
<tr><th>Building Blocks</th><th>Description</th></tr>
<tr><td>OR_SPS

AND_SPS

NEG_SPS</td><td>The building blocks also process the supported quality attributes according to their logic. The following tables describe the logic using input values in connection with the quality attribute Validity. The input values are 0 or 1, the quality attribute Validity can have the value good (=g) or invalid (=i).
x = placeholder for the input value and quality attribute Validity</td></tr>
<tr><td></td><td>OR_SPS<table>
<tr><th>A (Value, Attribute)</th><th>B (Value, Attribute)</th><th>Q (Value, Attribute)</th></tr>
<tr><td>0, i</td><td>0, x</td><td>0, i</td></tr>
<tr><td>0, g</td><td>0, g</td><td>0, g</td></tr>
<tr><td>1, g</td><td>x, x</td><td>1, g</td></tr>
<tr><td>1, i</td><td>0, x</td><td>1, i</td></tr>
<tr><td>1, i</td><td>1, i</td><td>1, i</td></tr>
</table>The output thus has the logical value 1 with Validity = good as soon as at least 1 input has the logical value 1 with Validity = good. Otherwise, the inputs are treated according to the OR operation and the INVALID bit is OR-gated for the quality.</td></tr>
<tr><td></td><td>AND_SPS<table>
<tr><th>A (Value, Attribute)</th><th>B (Value, Attribute)</th><th>Q (Value, Attribute)</th></tr>
<tr><td>0, g</td><td>x, x</td><td>0, g</td></tr>
<tr><td>0, i</td><td>1, x</td><td>0, i</td></tr>
<tr><td>1, i</td><td>1, x</td><td>1, i</td></tr>
<tr><td>1, g</td><td>1, g</td><td>1, g</td></tr>
</table>The output thus has the logical value 0 with Validity = good as soon as at least 1 input has the logical value 0 with Validity = good. Otherwise, the inputs are treated according to the AND operation and the INVALID bit is OR-gated for the quality.</td></tr>
<tr><td></td><td>NEG_SPS<table>
<tr><th>A (Value, Attribute)</th><th>Q (Value, Attribute)</th><th></th></tr>

</table></td></tr>
<tr><td>SPLIT_SPS

SPLIT_DPS

SPLI_XMV</td><td>The building blocks isolate the data value and quality of a data object.
The requirement is that the quality is available from the input end. This is the case if the building block is interconnected with CFC input data, or is connected downstream with a quality processing building block (x_SPS). In other cases, the CFC editor does not allow a connection.</td></tr>
<tr><td>SPLIT_Q</td><td>The building block performs binary separation of the quality into good, bad (= invalid), test, off and OperatorBlocked.
These 5 attributes can then be processed individually in a binary operation. The building block must be connected downstream to a SPLIT_(DO) building block.</td></tr>
</table>

Building Blocks	Description
BUILD_Q	The building block enters a binary value for *good* and *bad* (= *invalid*) in each quality structure. Thus, with this building block the quality attributes *good* and *bad* (=*invalid*) can be set explicitly, for example, as the result of a monitoring logic. All other quality attributes are set to the default state, for instance, **Test** = *FALSE*. If, for example, the entire CFC chart is in the test state (*see Quality Attribute: Test Under General Processing*), this default status can again be overwritten on the CFC output side. The building block is normally connected downstream to a BUILD_(DO) building block.
BUILD_ACD **BUILD_ACT** **BUILD_BSC** **BUILD_DPS** **BUILD_ENS** **BUILD_SPS** **BUILD_XMV**	These building blocks merge data value and quality. The building-block output is generally used as a CFC output. Generally, the BUILD_Q building block is connected upstream from these building blocks.

CFC charts have a standard behavior in the processing of signals. If an input signal of the CFC chart has the quality *invalid*, all output signals of the CFC chart also get the quality *invalid*. This standard behavior is not desirable in some applications. If you use the building blocks for quality processing, the quality attributes of the input signals in the CFC chart are processed.

EXAMPLE: Switchgear Interlocking via GOOSE

The following conditions apply to the example:

- The interlocking condition for switchgear interlocking protection is stored in the device as a CFC chart.
- The removed device sends the release signal for the interlocking condition via a GOOSE telegram.

If the communication connection has been interrupted, the release signal (**GOOSEStr**) incoming via the GOOSE telegram gets the quality *invalid*. If the CFC chart obtains an invalid input signal, there are the following possibilities: The last signal valid before the communication interruption is used (quality = *good*) or a substitute data value with the quality *good* is used (True, False).

To do this, you have to create a separate CFC chart in addition to the interlocking plan of the switchgear interlocking. Use the building blocks for quality processing in a separate CFC chart. With the SPLIT_SPS building block, split the input signal (data type = SPS) into data value and quality information. You can then continue to process these signals separately in the CFC chart. Use the quality information as an input signal for a BUILD_SPS building block and assign the quality *good* to the signal. You obtain an SPS signal as a result, with the quality *good*. You can use this to process release messages correctly. You can process the release messages with the quality *good* in the CFC chart of the actual interlocking. Therefore, the release signal for a switch illustrated in the interlocking logic is available as a valid result with the quality *good*. The following figure shows an example of the CFC chart with the building blocks for quality processing:

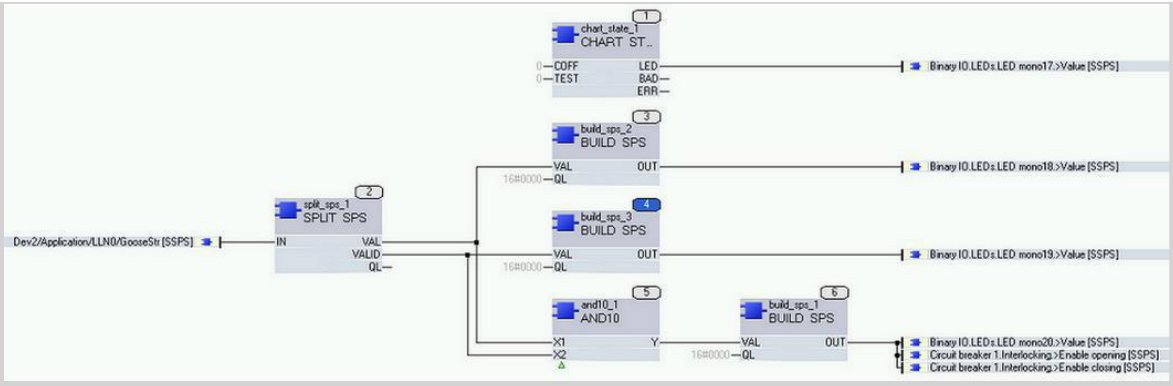

Figure 3-46 CFC Chart with Building Blocks for Quality Processing (Switchgear Interlocking via GOOSE)

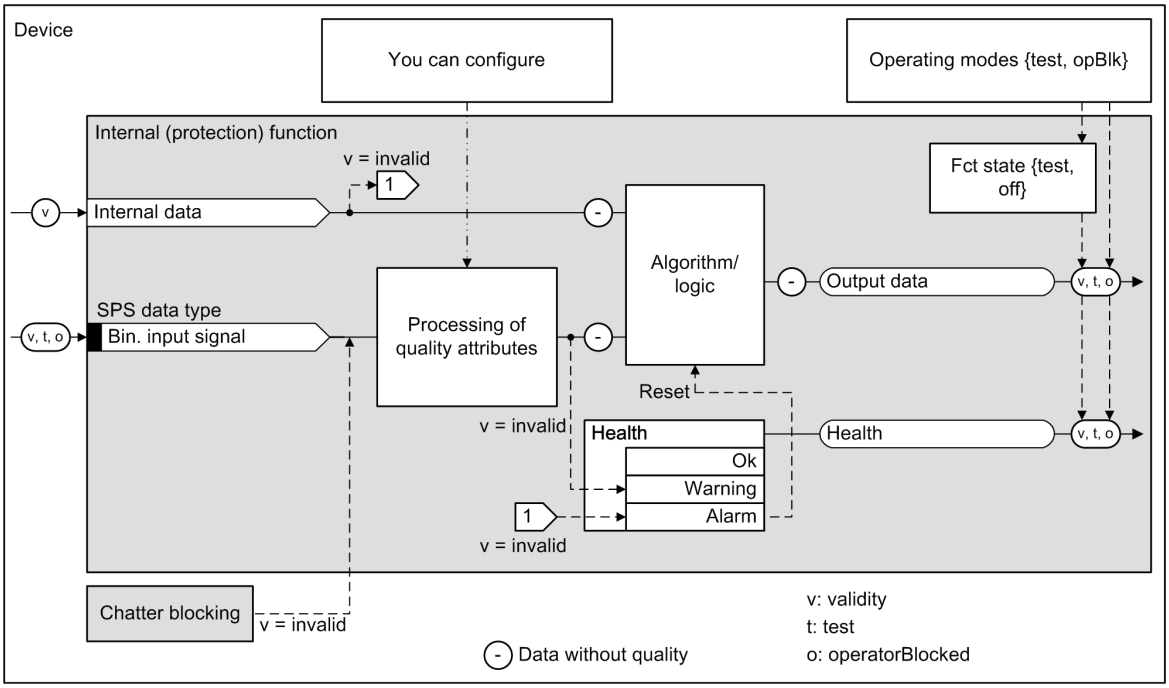
If you do not want to convert the invalid release signal to a valid signal, as described, during the communication interruption, you can also assign a defined data value to the release signal. Proceed as follows: With the SPLIT_SPS building block, split the input signal (data type = SPS) into data value and quality information. Link the VALID output of the SPLIT_SPS building block with the data value of the input signal (AND gate). This way, you can set the value to a non-risk state with the valid input signals. In the example, the output of the CFC chart is set to the value *FALSE* when the input signal is invalid.



3.4.4 Quality Processing/Affected by the User in Internal Device Functions

Figure 3-47 provides an overview for processing the quality of data objects within a device-internal function.

A function can receive internal data or input data that is routable by the user (binary input signal or double commands). The respective quality attributes supported are evaluated by the function on the input side. The attributes are not passed through the specific algorithm/the specific logic of the function. The output data are supplied with a quality that is specified by the function state and device-operating mode.

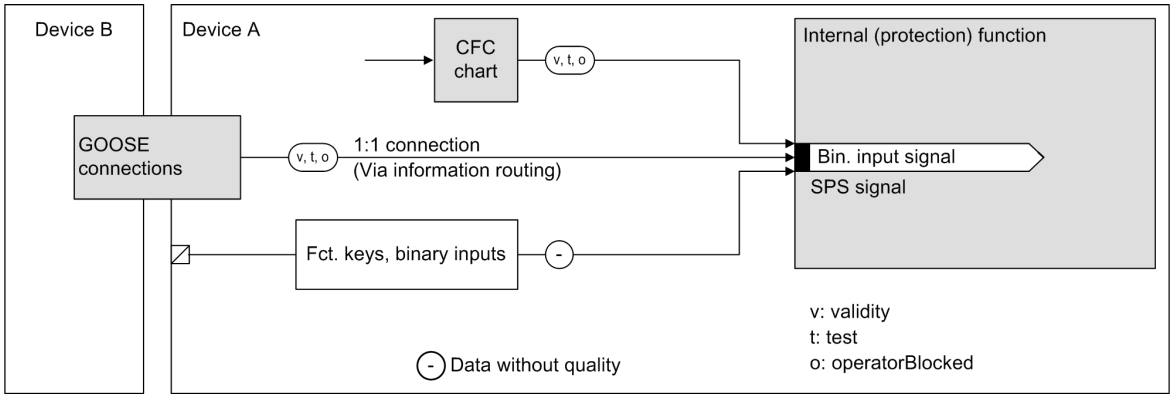
NOTE

Take into account that pickup of chatter blocking (see chapter *3.9.1 Signal Filtering and Chatter Blocking for Input Signals*) sets the corresponding **Validity** attribute to *invalid*.

[lo_quali3, 2, en_US]

Figure 3-47 Overview for Processing Quality within an Internal Function

Internal Input Data



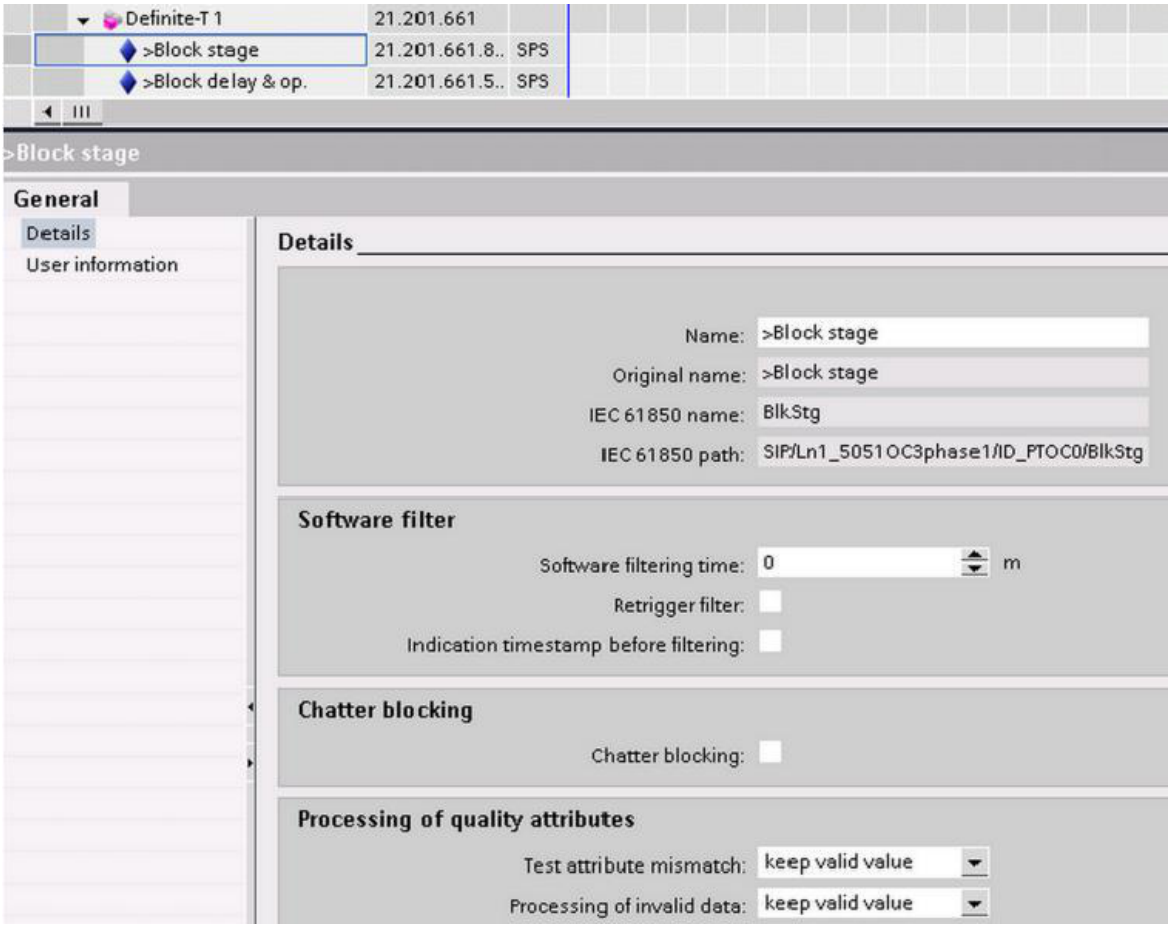
The quality processing is automatic for internal input data.

Supported Quality Attributes	Description
Validity	• At the receiving end, internal values can only be *invalid* or *good*. • If *invalid*, the function health is set to **Alarm** and the function is reset. Causes for invalid internal data are, for example: • The frequency operating range of the device was left. • The device is not calibrated. • The A/D converter monitoring identified an error.

Routable Binary Input Signals (SPS Data Type)

Figure 3-48 shows the possible sources for connecting a binary input signal. Depending on the source, different quality attributes can be set:

- CFC chart: See description in chapter *3.4.3 Quality Processing/Affected by the User in CFC Charts*
- GOOSE connection: See description in chapter *3.4.2 Quality Processing/Affected by the User for Received GOOSE Values*
- Device hardware: No quality attributes are set and supported.



[lo_quali2, 2, en_US]

Figure 3-48 Sources for Connecting a Binary Input Signal

For this signal type (SPS), you can influence the processing of the quality, see overview in *Figure 3-47*.
The following figure shows the possible influence on a binary input signal of a protection stage.

- In the DIGSI 5 project tree, double-click **Information routing**.
- In the operating range, select the desired binary input signal.
- In the **Properties** window, select the **Details** entry. There, you will find the item **Processing quality attributes**.

[sc_influence, 1, en_US]

Figure 3-49 Influence Options for a Binary Input Signal (SPS Input Signal)

Quality Attribute: Validity	
The **Validity** attribute can have the values *good* or *invalid (reserved* and *questionable* were already replaced at the input end of the device by the value *invalid*).	
The input signal source is *invalid*.	The current data value of the source signal is ignored. You can select between the following options: • Further process last valid data value of the source signal (this is the default setting with only a few exceptions) • Set the binary value to be processed further to **0**. • Set the binary value to be processed further to **1**. This configuration option is necessary to satisfy different applications. The function health switches to Warning.
The input signal source is *good*.	The source signal data value is processed further.

Quality Attribute: Test	
• The input signal source and processed function are in test state. • The input signal source is not in test state and the function to be processed is in test state.	The source signal data value is processed further.
The input signal source is in a test state and the function to be processed is in normal state.	The data value of the source signal is ignored. You can select between the following options: • Further processing of the last valid source signal data value, before the source switches to the test state (that is the default setting) • The binary value to be processed further is set to **0**. • The binary value to be processed further is set to **1**. This configuration option is necessary to satisfy different applications.

Quality Attribute OperatorBlocked
The quality cannot be influenced at this position and does not lead to a response within the logic

Output Data

The quality is not processed through the actual algorithm/logic of the function. The following table displays the conditions required to set the quality of output signals of a function.

Cause	D0 Value	Quality Attribute	
		After **internal** (to the SIPROTEC 5 system, for example, in the direction of a CFC chart)	To the IEC 61850 interface, in buffer
Functional state = **Test** (thus, result of device operating mode = **Test** or function mode = **Test**)	Unchanged	**Test** = *TRUE*	**Test** = *TRUE*
Functional state = **Off** (thus, result of device operating mode = **Off**)	Function-specific, corresponding to the definition for switched off	**Validity** = *good*	**Validity** = *invalid*

Cause	D0 Value	Quality Attribute	
Function health = **Alarm** (for example, result of invalid receive data)	Function-specific, corresponding to the definition for reset	**Validity** = *good*	**Validity** = *invalid*
Device operating mode = **functionally logged off**	Unchanged	**Validity** = *good* **OperatorBlocked** = *TRUE*	**Validity** = *good* **detailQual** = *oldData* **OperatorBlocked** = *TRUE*

3.5 Fault Recording

3.5.1 Overview of Functions

All SIPROTEC 5 devices have a fault memory in which fault recordings are kept securely. Fault recording documents operations within the power system and the way in which protection devices respond to them. You can read out fault recordings from the device and analyze them afterwards using evaluation tools such as SIGRA.

A fault record contains the following information:

- Sample values of the analog input channels
- Measured values calculated internally
- Any binary signals (for example, pickup signals and trip signals of protection functions)

You can individually configure the signals to be recorded. Furthermore, you can define the starting condition, the record duration, and the saving criterion of a recording. Fault records saved in the device are also available after a loss of auxiliary voltage.

3.5.2 Structure of the Function

The **Fault recorder** function is a central device function. Both the recording criterion and the measured-value and binary channels to be recorded are functionally preconfigured through the application templates. You are able to individually adapt the configuration in DIGSI 5. The fault recording and the fault log are subject to the same control. This ensures that real time, relative time, and numbering of the fault data are synchronized.

This means that all fault recordings function on the same real-time and relative-time basis.

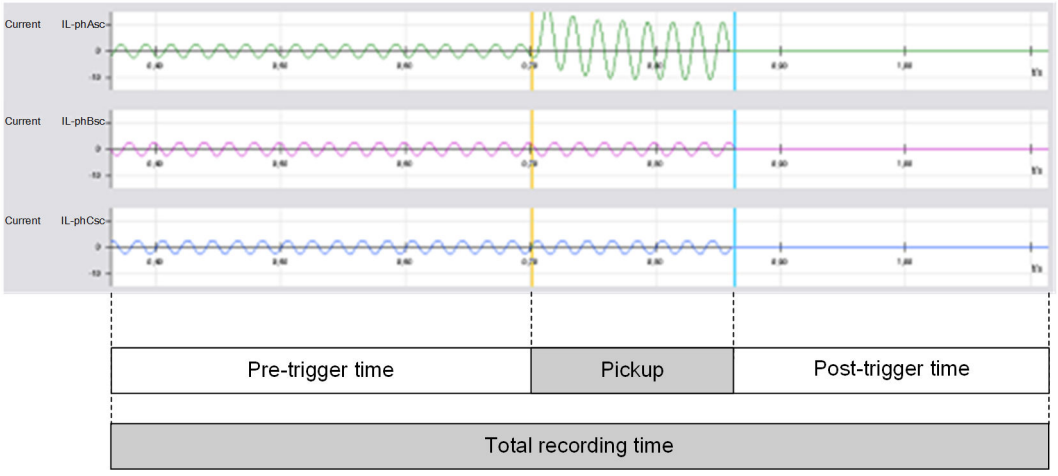
The data read out via the DIGSI-PC are saved in COMTRADE format. Fault recording data can be transferred to the substation automation technology by request in accordance with the standards via existing communication connections (such as IEC 61850, IEC 60870-5-103). The central device analyzes the data using appropriate programs.

3.5.3 Function Description

The **Fault recorder** function records the sampled values, specific to each device, of all analog inputs, the internally calculated measured values, and the binary signals. The configuration, which is predefined for each device via an application template, can be adapted individually.

NOTE

For detailed information about selecting and deleting fault records, refer to the Operating Manual (C53000-G5040-C003).



The fault memory of the device is automatically updated with every recording. When the fault memory is filled completely, the oldest recordings are overwritten automatically. Thus, the most recent recordings are always stored safely. The maximum number of recordings is 128.

Sampling Frequency

The analog measuring channels are sampled at a different sampling rate for fault recording. The **`Sampling frequency`** parameter is used to set the desired sampling frequency. Possible setting values are 1 kHz, 2 kHz, 4 kHz, and 8 kHz . This setting value applies only to fault recording and does not affect protection functions or calculated measured values.

Record Duration

The overall duration of a single fault recording comprises the total duration of the configurable recording criterion, the **Pre-trigger time** and the **Post-trigger time**. You can set the parameters for these components individually.

[dw_sigrar, 2, en_US]

Figure 3-50 Example of a Fault Recording

With the **Fault recording** parameter, you specify the start criterion of the recording.

You can set the following values:

- ***with pickup***:
  The fault recording records the complete fault until dropout. The resulting pickup signals of all function groups are taken into account.
- ***user-defined***:
  With this setting value, you can individually specify the recording criterion for the fault recording in DIGSI 5. Function-specific recording criteria can be realized in this way.

If a recording criterion reoccurs during the pickup time and post-trigger time, the recording which is active is extended to include a new post-trigger time.

For a sampling frequency of 8 kHz and 24 analog channels to be recorded, the duration of one individual fault recording can be up to 20 s.

The maximum record duration can be limited by the **Maximum record time** parameter.

In addition to starting the fault recording via the pickup, the following alternatives are possible:

- Externally via binary input signal *>External start* (for example, from an external protection device without fault recording by an object transferred via a GOOSE message)
- By way of a configurable input signal *>Manual start*, you can start fault records with a configurable length (parameter **Manual record time**).
- From DIGSI 5, you can start test fault records with a fixed length of 1 s.
- With a command from a central device via an existing communication connection (IEC 61850, IEC 60870-5-103)

NOTE

If a pickup signal is present continuously, the fault record is closed after the **Maximum record time** expires and the fault recording is not restarted!

Saving the Recording

Not every fault recording that is started actually needs to be saved. With the **Storage** parameter, you specify whether you want to save the fault recording that has started. You can also save only fault data for which the pickup of a protection function also caused a tripping . With this setting, faults beyond the self-protection range will not lead to replacing fault recordings that have already been saved.

Configuration of Signals to Be Recorded

All analog inputs of the device that have been configured (currents and voltages) are recorded as sampled channels.

Function-specific binary signals (for example, pickup and trip signals) and measured value channels can be configured individually for recording in the DIGSI information-routing matrix. For this purpose, a separate **Recorder** column is available.

You can rename the signals in the DIGSI Information-routing matrix. You can change the order of the binary signals and measured-value channels to be recorded in DIGSI under **Signal order**. You can find more detailed information on this in the DIGSI 5 Online Help, version V07.50 and higher (Order number: C53000-D5000-C001-D).

The operational measured values and the measured values of the fundamental components and symmetrical components (see the Device Manual, chapters *9.3 Operational Measured Values* and *9.4 Fundamental and Symmetrical Components*) are calculated every 9 cycles (at 50 Hz, this is every 180 ms). However, this can mean that the data are not synchronized with the sampled values of the analog channels. The recording of these measured values can be used to analyze the slowly changing processes.

Numbering and Time Stamping

All fault recordings saved are automatically numbered in ascending order and assigned a real-time stamp for the start time. The fault recording logs the fault with a relative time. The reference-time point is the start of the recording. Every fault recording has a corresponding fault log with the same number. This ensures that the fault recording can be uniquely assigned to the event log.

NOTE

When the **Fault recorder** function detects a negative time stamp of the measurand or the binary signal, an entry is added in the **Device-diagnosis log** in DIGSI. Meanwhile, the fault recording continues. The entry for an incorrect measurand or binary signal shows the prefix **Bad quality**.

Fault Memory

The device manages its available fault memory dynamically, so that the maximum recording capacity is always available. When exceeding the limits of the fault memory, the oldest recordings are automatically overwritten. This means that the most recent recordings are always available. The sampling rate, type, and number of measured value trends to be recorded are the crucial variables when it comes to restricting the length and number of recordings possible. Parallel to the sampled tracks, up to 50 tracks with function-specific measured values and up to 200 binary tracks can be recorded. The following table provides an overview of the maximum storage capacities, in seconds, for different connection variations of the protection devices.

Table 3-10 Maximum Length of All Stored Recordings

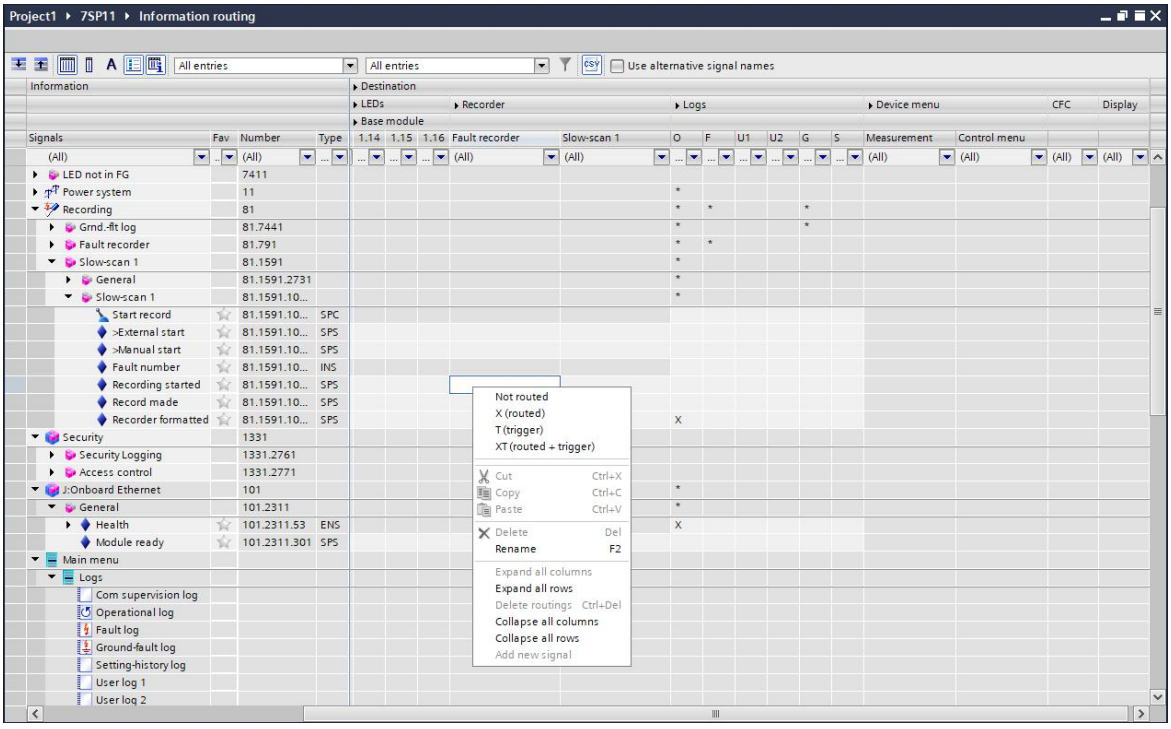
Connection Examples	Sampling 1 kHz	Sampling 2 kHz	Sampling 4 kHz	Sampling 8 kHz
Feeder: 4I, 6 measured values, 20 binary tracks	1365 s	819 s	455 s	241 s
Feeder: 4I, 4V, 20 binary tracks	1125 s	566 s	284 s	142 s

Connection Examples	Sampling 1 kHz	Sampling 2 kHz	Sampling 4 kHz	Sampling 8 kHz
Feeder: 4I, 4V, 6 measured values, 20 binary tracks	890 s	500 s	266 s	137 s
Feeder 1.5 CB: 8I, 8V, 6 measured values, 20 binary tracks	525 s	281 s	145 s	74 s

Input and Output Signals

The **Fault recorder** function provides several input signals that allow the precise starting, deleting of recordings. The output signals provide information about the function status.

In the following table, you can find input signals of the **Fault recorder** function:



Name	Type	Description
Control: Start recording	SPC	Start recording via the function key
Control: Reset memory	SPC	Delete all recording via the function key. The error numbers are reset.
Control: Delete memory	SPC	Delete all recording via the function key. The error numbers remain as is.
Control: >External start	SPS	Start recording with an external binary signal, for example, by the trip command of an external protection device. The set pre-trigger and post-trigger time are taken into account.
Control: >Manual start	SPS	Start a recording of fixed duration (parameter **`Manual record time`**) by way of an external binary signal, for example, manually via the function key or by an external binary signal.

In the following table, you can find output signals of the **Fault recorder** function:

Name	Type	Description
Control: Error number	INS	The indication of the current error number allows a unique allocation of entries in the message buffers for the recorded fault records.
Control: Recording started	SPS	Fault recording running
Control: Recording done	SPS	Fault recording done
Control: Tmax reduced	SPS	Fault recording ends before the set **`Maximum record time`** expires, because the fault log is full.
Control: Fault log is full	INS	The fault log is full.

Configuring Stored Indications Using DIGSI 5

- In the **Information Routing** of each device set up in DIGSI 5, you can route binary signals to LEDs and output contacts. To do this, open the project tree.
  Project -> Device -> **Information routing**
- Right-click the routing field of your binary indication in the desired LED or binary output column in the routing range of the targets.

[sc_FR_information routing, 1, en_US]

Figure 3-51 Routing of the Signals in the Information Routing

3.5.4 Application and Setting Notes

Parameter: Fault recording

- Recommended setting value **(_:2761:130) Fault recording** = ***with pickup***

With the **Fault recording** parameter, you define the time interval at which faults are recorded. The total record duration is defined as the duration of the fault plus the total of the parameters **Pre-trigger time**, **Post-trigger time** and is limited by the maximum record duration.

Parameter Value	Description
with pickup	The fault recording time is determined by the total number of all protection pickups. The resulting pickup signals of all function groups are considered. Note: When the post-trigger time has expired, the indications of an automatic reclosing function are not recorded. Evolving faults after expiry of the post-trigger time can result in the opening of a new fault with its own recording.
user-defined	The fault recording time is defined user-specific. Note: Specify all signals for individual definition of the fault recording time in the DIGSI 5 information-routing matrix. In the information routing matrix in the **Fault record** column, the fault recording has for this purpose a separate column **Trigger**. The record duration is calculated from the logical OR operation of all initiated, configured signals.

Parameter: Storage

- Recommended setting value **(_:2761:131) Storage** = ***always***

With the **Storage** parameter, you define the storage criterion for a fault recording that has already started.

Parameter Value	Description
always	Each fault recording that has been started is saved.
with trip	If at least one protection function issues an operate indication during the record time, any fault recording that has been started is saved.

Parameter: Maximum record time

- Default setting **(_:2761:111) Maximum record time** = ***5.00 s***

With the **Maximum record time** parameter, you configure the maximum record duration for an individual fault recording. When the time configured expires, an ongoing fault recording is canceled. This parameter merely limits the duration of the fault recording. It does not affect the logging of faults in the fault log.

Parameter: Pre-trigger time

- Recommended setting value **(_:2761:112) Pre-trigger time** = ***0.50 s***

With the **Pre-trigger time** parameter, you configure the pre-trigger time for an individual fault recording. The set pre-trigger time is prepended to the actual recording criterion for the fault recording.

Parameter: Post-trigger time

- Recommended setting value **(_:2761:113) Post-trigger time**= ***0.50 s***

With the **Post-trigger time** parameter, you configure the post-trigger time for an individual fault recording. The post-trigger time that has been configured is added to the actual recording criterion for the fault recording after the dropout.

The following table shows how the setting range changes for the **Post-trigger time** parameter depending on the **Sampling frequency**.

Sampling Frequency	Setting Range for the Post-trigger time Parameter
8 kHz	0.05 s to 4 s
4 kHz	0.05 s to 8 s
2 kHz	0.05 s to 16 s
1 kHz	0.05 s to 24 s

Parameter: Manual record time

- Recommended setting value **(_:2761:116) Manual record time** = ***0.50 s***

With the **Manual record time** parameter, you set the length of a recording if the fault recording is activated dynamically (edge-triggered) via a separately configured input signal *>Manual start*.

In this case, pre-trigger and post-trigger times do not take effect.

Parameter: Sampling frequency

- Recommended setting value **(_:2761:140) Sampling frequency** = ***8 kHz***

With the **Sampling frequency** parameter, you define the sampling frequency of fault records that you want to download via DIGSI 5. Possible setting values are 8 kHz, 4 kHz, 2 kHz, and 1 kHz.

Parameter: Sampl. freq. IEC 61850 rec.

- Recommended setting value **(_:2761:141) Sampl. freq. IEC 61850 rec.** = ***8 kHz***

With the parameter **Sampl. freq. IEC 61850 rec.**, you define the sampling frequency of the fault record that you want to download using the IEC 61850 communication protocol. Possible setting values are 8 kHz, 4 kHz, 2 kHz, and 1 kHz.

You cannot set the parameter **Sampl. freq. IEC 61850 rec.** to be greater than the set value of the parameter **Sampling frequency**. The setting options of the parameter **Sampl. freq. IEC 61850 rec.** which are greater than the set value of the parameter **Sampling frequency** are invisible.

If the size of the COMTRADE file exceeds the maximum permissible storage capacity of the device, the original recording is truncated. The truncated data are discarded.

NOTE

If you have created a fault record with a certain sampling frequency and then set the sampling frequency to a lower value, you can no longer download this fault record using the IEC 61850 communication protocol.

You must reset the sampling frequency to the original value. Then you can download the fault record again using the IEC 61850 communication protocol.

Parameter: Cal.zero.seq.cur.channel

- Default setting **(_:2761:129) Cal.zero.seq.cur.channel** = ***no***

With the **Cal.zero.seq.cur.channel** parameter, you determine whether the calculated zero-sequence current ***3I0*** or ***-3I0*** is recorded in a separate channel or not. The separate channel is visible in the DIGSI 5 Information routing under the **I 3-phase** measuring point.

The zero-sequence currents can be calculated only with the following current-transformer connection types:

- ***3-phase + IN-separate***
- ***3-phase + IN***
- ***3-phase***

Parameter Value	Description
no	The zero-sequence current calculated from the sampled values of the currents is not recorded.
-3I0	The calculated zero-sequence current ***-3I0*** is recorded for each **I 3-phase** measuring point. ***-3I0*** is calculated from the sampled current values using the following equation: -3I0 = - (I_A + I_B + I_C).
3I0	The calculated zero-sequence current ***3I0*** is recorded for each **I 3-phase** measuring point. ***3I0*** is calculated from the sampled current values using the following equation: 3I0 = (I_A + I_B + I_C).

Parameter: Cal.zero seq.volt.channel

- Default setting **(_:2761:132) Cal.zero seq.volt.channel** = ***no***

With the **Cal.zero seq.volt.channel** parameter, you determine whether the calculated zero-sequence voltage ***V0*** or ***3V0*** is recorded in a separate channel or not. The separate channel is visible in the DIGSI 5 Information routing under the **V 3-ph** measuring point.

The zero-sequence voltages can be calculated only with the following current-transformer connection types:

- ***3 ph-to-gnd volt. + VN***
- ***3 ph-to-gnd voltages***

Parameter Value	Description
no	The zero-sequence voltage calculated from the sampled voltage values is not recorded.
V0	The calculated zero-sequence voltage ***V0*** is recorded for each **V 3-ph** measuring point. ***V0*** is calculated from the sampled voltage values using the following equation: $V0 = (V_A + V_B + V_C)/3$.
3V0	The calculated zero-sequence voltage ***3V0*** is recorded for each **V 3-ph** measuring point. ***3V0*** is calculated from the sampled voltage values using the following equation: $3V0 = (V_A + V_B + V_C)$.

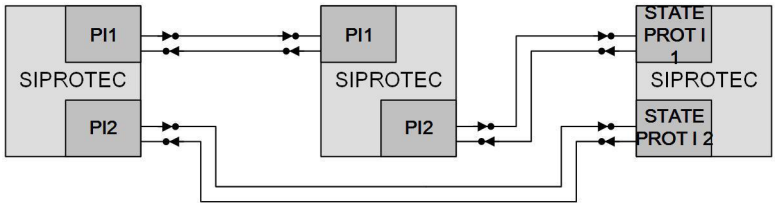
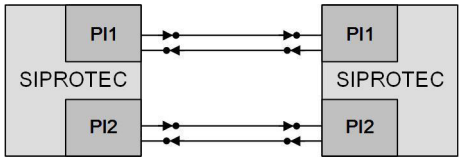
3.6 Protection Communication

3.6.1 Overview



The **Protection communication** includes all functionalities necessary for data exchange via the protection interface (PI).

Devices that communicate with each other via protection interfaces form a device combination. A device combination consists of 2 to 6 devices. The devices communicate via point-to-point connections (protection connections). In this case, a device has only one connection to another device via a protection interface (PI). With a 2nd protection interface, you can establish a connection to another device or a redundant connection to the same device. With their protection connections, the devices form a protection topology in the form of a redundant ring (ring topology) or as a chain structure (chain topology).



[dw_PDC_chain_3devices, 1, en_US]

Figure 3-52 Device Combination of 3 Devices in a Chain Topology

[dw_PDC_ring_3devices, 1, en_US]

Figure 3-53 Device Combination of 3 Devices in a Ring Topology

[dw_PDC_ring_2devices, 1, en_US]

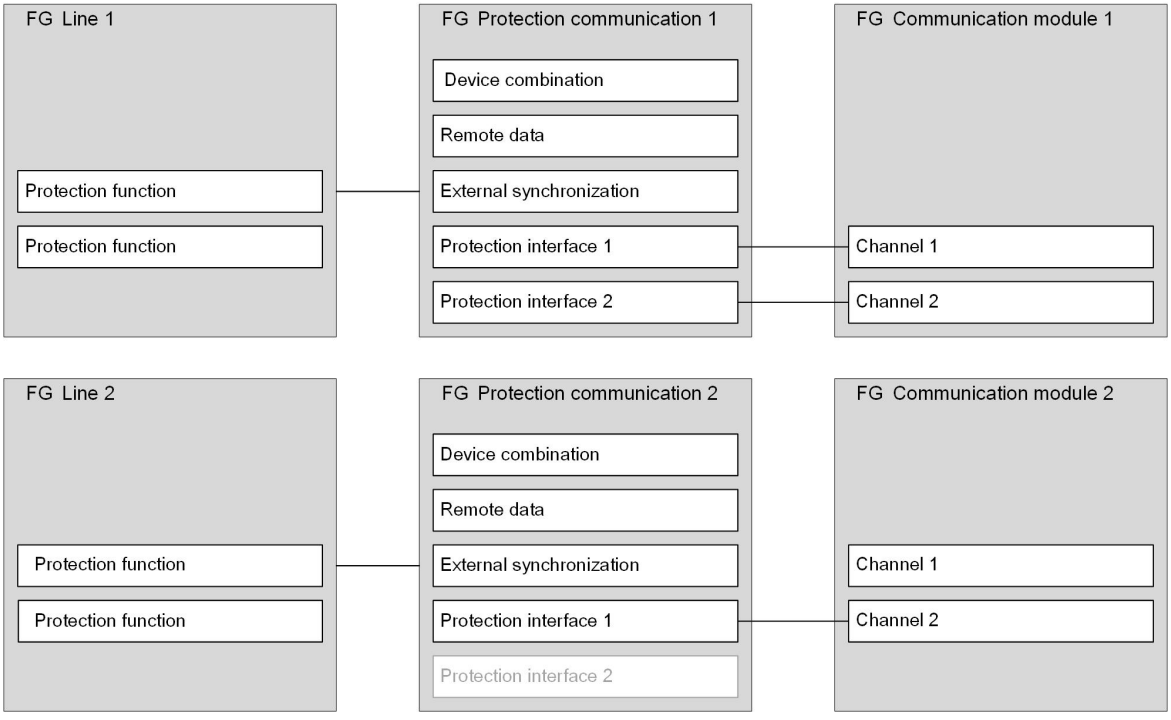
Figure 3-54 Device Combination of 2 Devices in a Ring Topology

Within a device combination, the point-to-point connections can have different bandwidths. Depending on the bandwidth, a certain amount of binary information and measured values can be transmitted bidirectionally between the devices. The connection with the lowest bandwidth defines the amount of binary information and measured values.

The following information is important for protection communication and is transmitted additionally. You cannot change this information:

- Topology data and values are exchanged for monitoring and testing the connection and displayed on the device or with DIGSI 5.
- Protection data and measured values, such as line differential protection data or binary data of the teleprotection schemes for distance protection and ground-fault protection are transmitted.
- The time synchronization of the devices is possible directly via the connection, whereby a device of the protection topology assumes the role of the timing master.

The point-to-point connection between the devices is continuously monitored for data faults and failure and the signal-transit time of the data is measured.



The protection communication is typically used for line differential protection and with the teleprotection schemes for distance protection and ground-fault protection. In SIPROTEC 5, you can configure the protection communication in all devices and use it for further protection applications. At the same time, any binary information and measured values can be transferred between the devices.

NOTE

The protection communication is compatible with the successor versions from firmware version V04.00 and higher.

3.6.2 Protection Communication in the Overall System

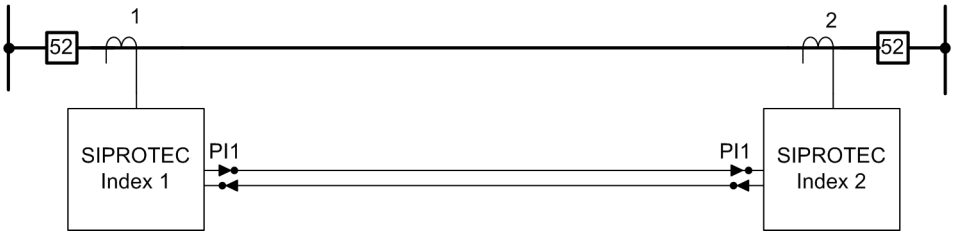
The following figure illustrates the interaction of protection communication, protection function groups, and communication modules. The **Protection communication** is integrated as follows in the overall system:

[dw_protcom_compl_system, 2, en_US]

Figure 3-55 Protection Communication in the Overall System

If protection functions want to use the protection interfaces, their superordinate protection function group, for example, the FG **Line 1**, must be connected to a **Protection communication** function group. With this connection, each protection function in the FG **Line 1** can use protection communication.

In addition, a connection must be configured between the logical protection interface in the FG **Protection communication** and a channel on the physical communication module. The physical communication module must support the protection-interface protocol.



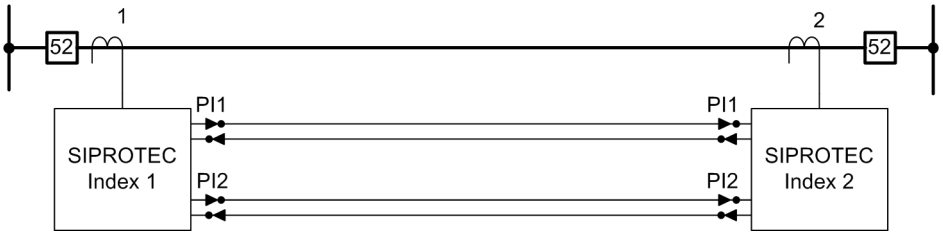
The following chapters describe the configuration of the connections.

3.6.3 Function Description

Device Combination with 2 Devices: Simple or Redundant Transmission

In a device combination with 2 devices, one protection communication with a protection interface is required per device to establish a protection connection (see next figure).

The most frequent application is the point-to-point exchange of data between 2 devices (the protection communication is of type 2), as performed by protection transmission devices. You can create a topology with up to 6 devices.



[dw_interface, 1, en_US]

Figure 3-56 Data Exchange for 2 Devices, Each with Protection Connection

NOTE

The index describes the consecutive numbering of the devices in a device combination (see parameter **`(_:5131:101) Local device is device`**).

A maximum of 2 protection interfaces per FG **Protection communication** are possible in one device, see following figure. If the **Protection communication** function groups are connected to each other in the devices via 2 protection connections of the same type, this results in 100 % redundancy regarding the transmission route. The devices then search for the communication connection with the highest bandwidth (for example, optical fiber). If this protection connection fails, the system switches over automatically to the 2nd protection connection until the 1st protection connection is available again. As the protection connection with lower bandwidth defines the maximum amount of transferable information, the same information is exchanged via both protection connections. Both protection communications in the device are then of type 1.

[dw_intera, 1, en_US]

Figure 3-57 Data Exchange for 2 Devices, Each Having 2 Protection Connections, Redundant Transmission Route

Remote Data

With the **Remote data** function, customer-specific indications and measured values can be communicated via the protection interface with settable update cycles (priorities).

There are 3 different priorities for the transmission of remote data:

- **Priority 1**: Use **Priority 1** for the transmission of fast protection signals that are transferred and updated at a maximum of every 20 ms in a telegram.
- **Priority 2**: Use **Priority 2** for the transmission of fast single-point or double-point indications that are transferred and updated at a maximum of every 40 ms.
- **Priority 3**: Use **Priority 3** for all indications, measured, and metered values that are transferred and updated a maximum of every 100 ms.

Communication Media

The communication takes place via direct fiber-optic connections, via communication networks or via 2-wire copper conductors. Siemens recommends a direct fiber-optic connection, as this offers a high transmission rate and is immune to failures in the transmission route while offering the shortest transmission time. This

also enables the transmission of a large amount of remote data in line differential protection applications and the remote control of remote devices with DIGSI 5.

The distance to be bridged and the transmission paths (communication media) available determine the settings of the protection interface. External communication converters are used for the connection to communication networks via G703.1-, X21-, or G703.6 interfaces. The connection to 2-wire copper cores also takes place via a communication converter. The C37.94 interface, for example, with 2 MBit/s, offers a direct fiber-optic connection to a multiplexer with the corresponding interface.

Table 3-11 to *Table 3-12* show examples of communication connections.

In the case of a direct connection, the transmission distance depends on the fiber type of the optical fiber. This distance can also be extended via external repeaters.

The modules in the device can be replaced from outside, so that adaptation to a transmission route is possible. In the case of the 820-nm double module USART-AE-2FO, 2 protection-interface channels can be operated on one module.

The modules can be located at slots E and F in the base device, and at slots N and P in the plug-in module assembly with integrated power supply.

When using communication converters, the connection from the device to the communication converter by a module is established via optical fibers.

Table 3-11 Plug-In Modules for Applications with Protection Communication

Plug-In Modules	Module Type: USART-AF-1LDFO	Module Type: USART-AW-2LDFO	Module Type: USART-AG-1LDFO	Module Type: USART-AU-2LDFO	Module Type: USART-AK-1LDFO	Module Type: USART-AV-2LDFO	Module Type: USART-AH-1LDFO[5]	Module Type: USART-AJ-1LDFO[6]	Module Type: USART-AX-2LDFO[7]	Module Type: USART-AY-2LDFO[8]	Module Type: ETH-BD-2FO[9]
Physical Connection											
1 x optical serial, 1300 nm, duplex LC plug, 24 km via 9/125 µm singlemode optical fiber or 4 km via 62.5/125 µm multimode optical fiber	●										
2 x optical serial, 1300 nm, duplex LC plug, 24 km via 9/125 µm singlemode optical fiber or 4 km via 62.5/125 µm multimode optical fiber		●

NOTE

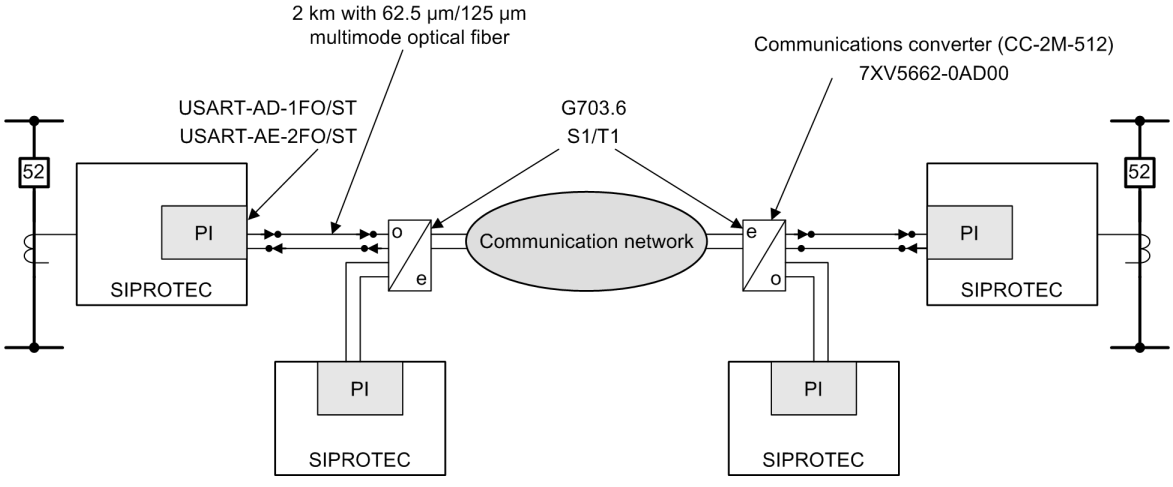
Connect two 7XV5107-0AA00 attenuators if you use the communication modules USART-AV-2LDFO or USART-AK-1LDFO for transmission routes of less than 30 km. To continue using the duplex LC plug, attach both attenuators to one end of the protection connection (see *Figure 3-61*).

[dw_single, 1, en_US]

Figure 3-62 Connection via Singlemode Optical Fiber

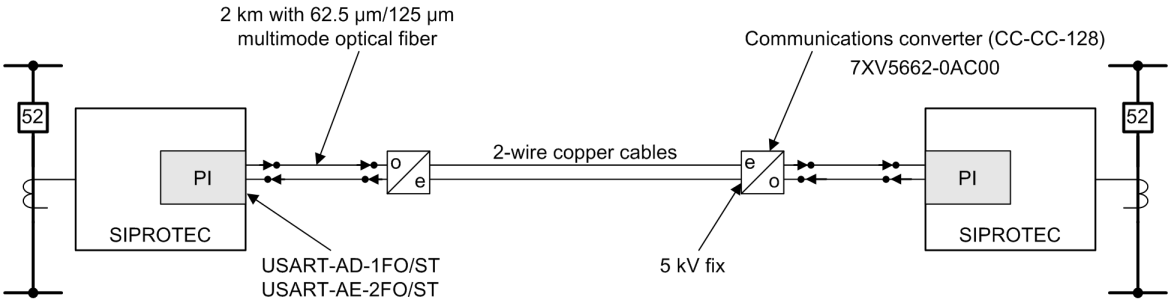


[dw_multim-05, 1, en_US]

Figure 3-63 Connection via Communication Network with a G703.1 Interface

The connection to the multiplexer is established via a communication converter with a G703.1 interface (64 kBit/s) or X21 interface (64 kBit/s to 512 kBit/s). You can set the bit rate for the KU-XG-512 (for X21), KU-XG-256 (for X21), KU-XG-128 (for X21), and KU-XG-64 (for X21 or G703.1) with the parameter **`Connection via`**.

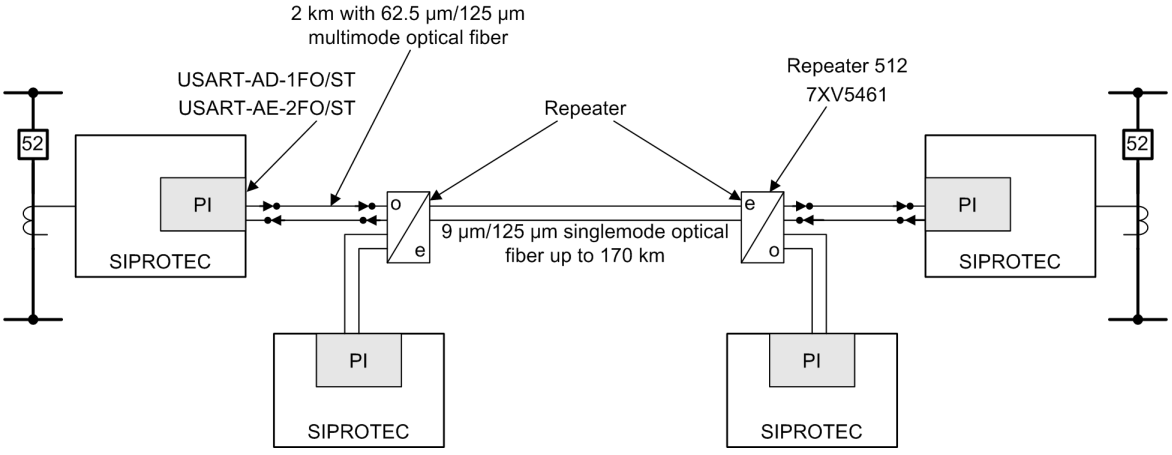
You can find more detailed information in *Table 3-13*.



[dw_multim-06, 1, en_US]

Figure 3-64 Connection via Communication Network with a G703.6 Interface

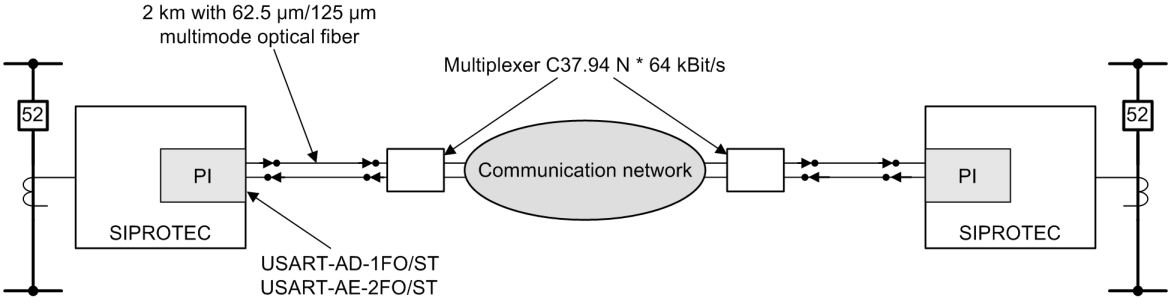
The connection to the multiplexer is established with 512 kBit/s via a communication converter with a G703.6 interface (E1 with 2 MBit/s or T1 with 1.44 MBit/s). The communication converter offers a 2nd interface for connecting an additional protection interface.



Adjust the setting for the bit rate with KU-2M-512 at 512 kBbit/s in accordance with *Table 3-13* with the parameter **`(_:105) Connection via`**.

[dw_multi_7, 1, en_US]

Figure 3-65 Connection via 2-Wire Copper Cables



The connection to a communication converter with an integrated isolation voltage of 5 kV is established with 128 kBit/s (KU-KU-128 setting in accordance with *Table 3-13*). An isolation of 20 kV of the 2-wire connection is possible via an external 7XR9516 isolating transformer.

[dw_repeat, 1, en_US]

Figure 3-66 Direct Fiber-Optic Connection via an External Repeater

The repeater offers an interface for connecting an additional protection interface. The connection to a repeater is established with 512 kBit/s (repeater 512 kBit/s setting in accordance with *Table 3-13*).

[dw_mutip8, 1, en_US]

Figure 3-67 Direct Optical Connection to a Multiplexer with a C37.94 N * 64 kBit/s Interface (Time Slot N = 1; 2 or 8)

NOTE

The redundancy of different communication connections (for the ring topology) requires rigorous separation of all devices involved in the communication. Therefore, avoid different transmission routes via the same multiplexer board, as no more substitute paths are possible if the board fails.

Supervision of the Communication

Communication is continuously monitored by the devices and displayed with indications and measured values.

If a number of defective data telegrams, or no data telegrams at all, are received, this is regarded as a **failure** in the communication as soon as a failure time of 100 ms (default setting can be changed) is exceeded. For each protection interface, a list of the measured values is shown in a window in DIGSI 5 (defective telegrams per minute/hour; transmitted and received telegrams per minute/hour, percentage fault rate per minute/hour). A corresponding failure indication is always available. If no alternative transmission route exists (as in the ring topology), the protection function operating with the protection interface is not operating and remote data is not updated on the receiver side.

If the communication is interrupted for longer than an adjustable time **Data-connection failure**, this is regarded as a communication failure. A corresponding failure indication is always available.

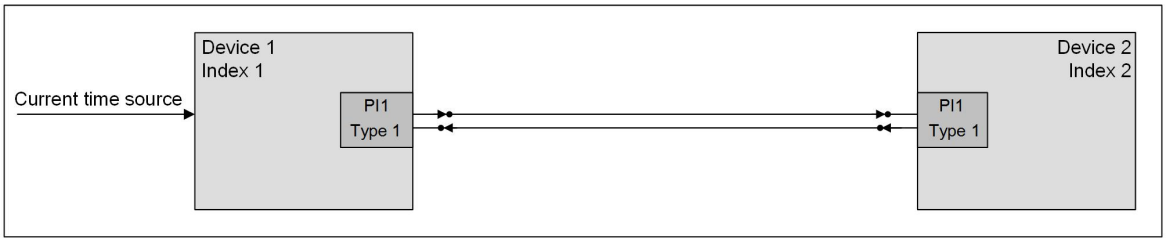
Time Synchronization via the Protection Interface, Timing Master

All devices in a device combination can synchronize their time with each other. Synchronization is carried out with millisecond accuracy. The synchronization works independently of the protection function and is used exclusively for simultaneous time keeping in the devices of a device combination.

The device you set in the parameter **(_:5131:102) Address of device 1** is the device with index 1. This device functions takes on the role of the timing master in a device combination. If the timing master is logged off and switched off, the device with the next highest device index takes on the function of the timing master. The timing master synchronizes the clocks of the other devices via the protection interfaces.

The time of the timing master itself can be synchronized via the following time sources:

- IRIG B
- DCF77
- IEEE 1588
- SNTP



For this, these time sources must be set as the 1st time source and optionally as the 2nd time source in the timing master. If available, the system switches over to the 2nd time source upon failure of the 1st time source in the timing master.

The following chapters describe how a device is set as a timing master:

- For classic protection communication, see *Parameter: Address of Device x, Page 159*.
- For advanced protection communication, see *Parameter: Device index, Page 197*.

Set the protection interface as the 1st time source in the other devices of the device combination. You can find the setting value in DIGSI 5 via the **Project tree** → **Parameters** → **Time settings** → **Timer** → **Time source 1** → ***PI***.

In this way, all events in the devices of the device combination are recorded with the same time and are time-synchronized even across different switchgears. This simplifies fault analysis and the fault records are recorded with the same time in all devices.

[dw_ti_syst, 2, en_US]

Figure 3-68 Time Synchronization in a Protection Topology

Figure 3-68 shows how device 1 with index 1 is synchronized with device 2 via the protection interface. Device 1 is the timing master, whose time is synchronized with a selectable, external time source.

Time Synchronization of the Line Differential Protection Measured Values with Millisecond Accuracy

The measured values of the devices connected via the protection interfaces are synchronized via telegram measurement with microsecond accuracy (1*10E-06 s). The protection interface displays this state with the indication *PI synchronized* RAISING.

If communications problems occur, it is possible that the measured values may not be properly synchronized. In this case, the protection interface generates the indication *PI synchronized* CLEARED. The line differential protection is blocked. This state can be corrected only manually.

NOTE

You can reset the synchronization of the protection interface directly in the device. Proceed as follows: **Device functions > x Device protection comm. > Protection interface y > Reset synchron**.

For special line differential protection applications or synchrophasor measuring devices, you can also time-synchronize the measured values with microsecond accuracy as follows:

- Via a high-precision electrical synchronization pulse (**PPS electrical**, 1-second pulse) from a satellite receiver at time-synchronization port G
- Via a high-precision optical synchronization pulse (**PPS optical**, 1-second pulse) from a satellite receiver at a USART communication module
- Via the **IEEE 1588** time-synchronization protocol

This allows you to measure and display the signal-transit time of the transmission route in transmit and receive direction separately. This lets you achieve the maximum responsivity with the line differential protection in communication networks even with differences in the signal-transit time in the transmit and receive direction (unbalanced runtimes). For the transmission of protection data in **type 2** protection communication, different signal-transit times are irrelevant.

Constellation Measured Values

Constellation measured values are measured values predefined by Siemens with the following properties:

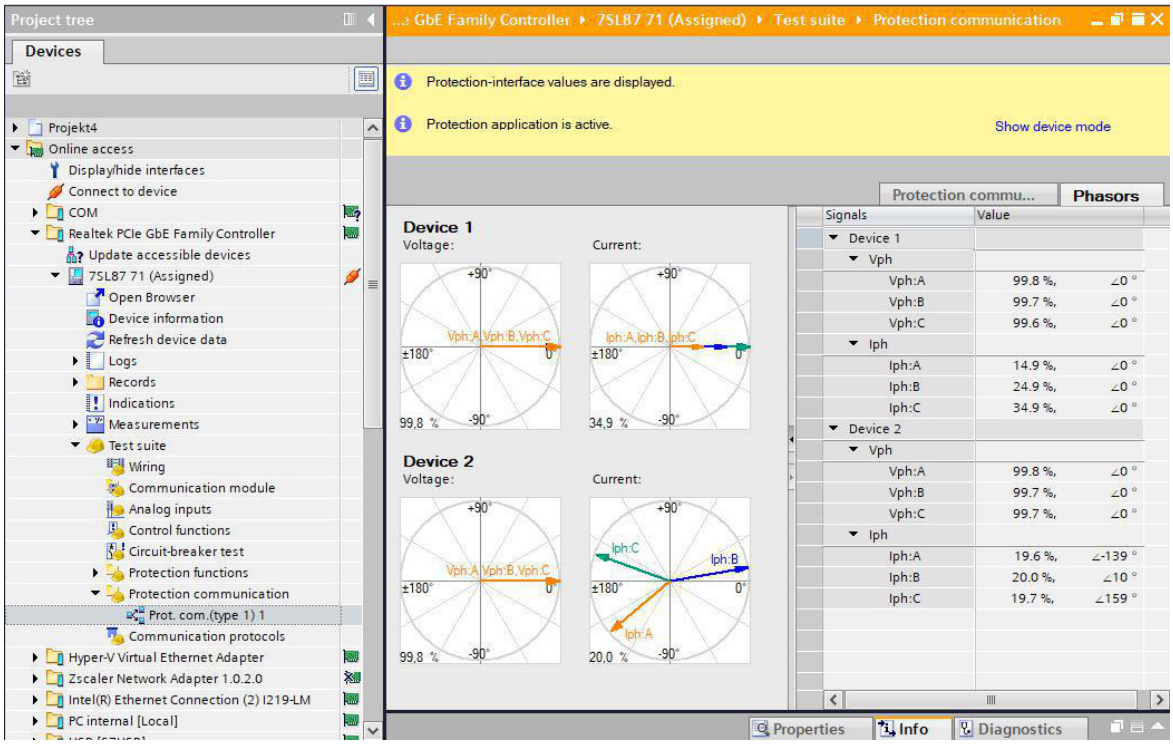
- They are synchronized in the devices in a device combination.
- They are substituted using the protection interface.
- They are available on every device.

You can view the constellation measured values with DIGSI 5.

In the device, current and voltage measured values are displayed in absolute value and phase as a percentage. 100 % conform to the rated current or the rated voltage of the line (see next figure). These measured values are recorded every 2 seconds by the devices participating in the device combination and then sent to the other respective devices. At the same time, the current and voltage values of the different devices are time-synchronous with one another.

When displaying the constellation measured values the local device is prioritized. The device connected directly with DIGSI 5 is the local device.

For the protection communication, the display of the constellation measured values differs between **Type 1** and **Type 2**.



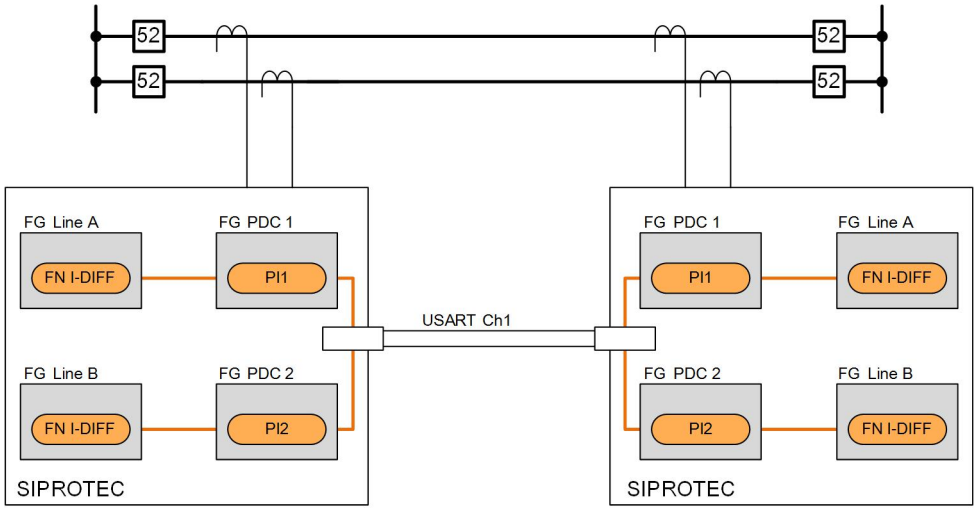
- Protection communication **Type 1**:

  The phasors of the current and voltage measured values of the local device have an angle of 0°. The angles of the measured values of the other devices relate to the local values, meaning that the angle difference to the remote ends is displayed.

- Protection communication **Type 2**:

  The voltage phasor V_A of the local device has an angle of 0°. The angles of the other local measured values and the measured values of the remote devices relate to V_A (0°).

You can find these measured values in the device under the following DIGSI mask:



[sc_const mv, 2, en_US]

Figure 3-69 Example of Constellation Measured Values with Phases

Multiplex Operation

With extended protection communication, you have the option of having a physical USART channel used by 2 logical protection interfaces. In this way, a transmission route can be double used, for example to implement **Parallel line protection** with **Line differential protection** without additional hardware. To do this, configure the channel according to chapter *3.6.6.4 Configuration of the Advanced Protection Communication in DIGSI 5*.

[dw_channel-mux, 1, en_US]

Figure 3-70 Multiplex Operation

NOTE

Note that in case of multiple use of a physical channel, the available bandwidth is divided equally between the logical protection interfaces. Therefore, this operating mode is not suitable for baud rates under 128 kBit/s.

NOTE

In case of multiple use of a physical USART connection – for example, for protection of a double line – you must provide further redundancy concepts.

3.6.4 Available Variants for the Protection Communication

The following variants are available for protection communication:

- **Classic protection communication**
  The scope of parameterization is small for the classic protection communication. The following constraints exist:
  - IP-based communication protocols are not supported.
  - Increased parameterization effort when changing the number of devices in the device combination subsequently, for example, protection of a multi-terminal line.
- **Advanced protection communication**
  The advanced protection communication provides greater flexibility and is used with IP-based communication protocols. For this purpose, the devices must be equipped with an Ethernet BD module. The following advantages also exist for devices equipped with USART communication modules:
  - Easy subsequent expansion of the number of devices in a device combination
  - Multiple function groups **Protection communication** can be instantiated
  - Multiplex operation of a physical protection connection
  - Hierarchically structured representation in DIGSI 5 project tree

For further information on the 2 variants, refer to *3.6.5 Classic Protection Communication* and *3.6.6 Advanced Protection Communication* .

NOTE

Do not confuse the 2 variants of the protection communication with type 1 and type 2 of the protection communication!

NOTE

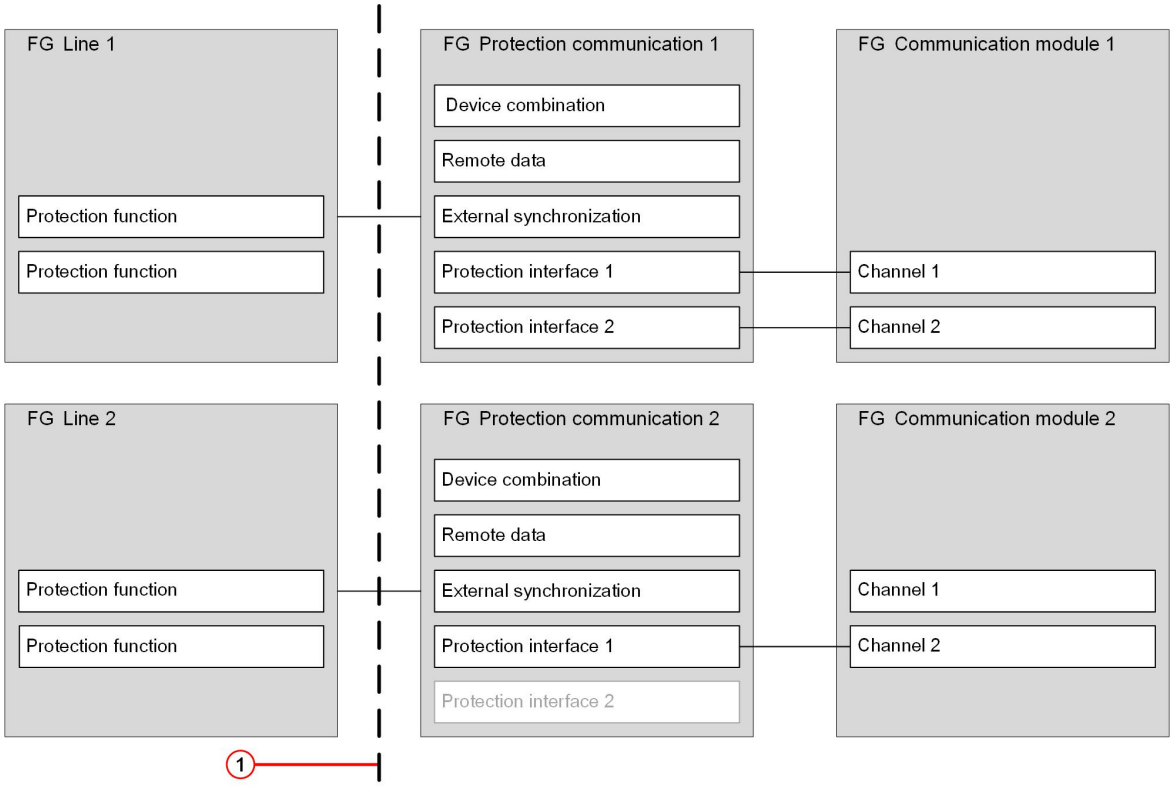
If you are unsure about the suitable variant for your use case during selection, use the advanced protection communication.

NOTE

If you want to change an existing classic protection communication to an advanced protection communication or vice versa, a window appears in DIGSI where you are asked whether you want to keep the mapping or not - that is, the communication settings or communication-information routing that has previously been set. In this case, click **No**

3.6.5 Classic Protection Communication

3.6.5.1 Overview



The classic protection communication enables the data exchange between the devices via synchronous serial point-to-point connections from 64 kBit/s to 2 mBit/s. These connections can be directly via optical fiber or via other communication media, for example, via dedicated lines or via communication networks. IP-based communication is not supported.

The function groups of the classic protection communication always support a fixed number of devices in the device combination:

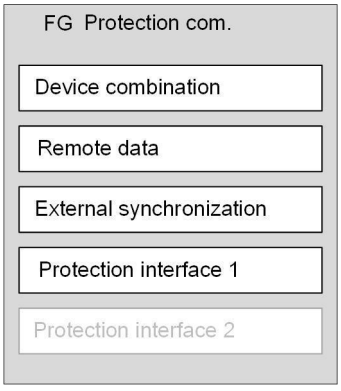
- 2-device protection communication
- 3-device protection communication
- 4-device protection communication
- 5-device protection communication
- 6-device protection communication

3.6.5.2 Classic Protection Communication in the Overall System

The classic **protection communication** is integrated as follows in the overall system:

[dw_simple_protcom_compl_system, 2, en_US]

Figure 3-71 Classic Protection Communication in the Overall System



(1) The device automatically routes the connection between the protection FG and the **Protection communication** FG in DIGSI 5.

3.6.5.3 Structure of the Function Group

If you select the communication protocol **Protection interface** and the **number of devices** on a channel in the communication module, the classic function group **Protection communication** is automatically created in the DIGSI 5 information routing.

The classic function group **Protection communication** contains the following functionalities and function blocks (FB):

- **Device combination**
- **Protection interface**
- FBs for **Remote data**
- FB **External synchronization** for the synchronization of the transferred data through an external synchronous pulse (1-second-pulse, PPS[10])

[dw_structure_FG_protcom_simple, 1, en_US]

Figure 3-72 Structure of the Classic FG Protection Communication

The function **Device combination** manages the devices that exchange data via protection communication. In the device-combination settings, you set the general settings for the device combination and the device addresses.

The function **Device combination** issues the following indications:

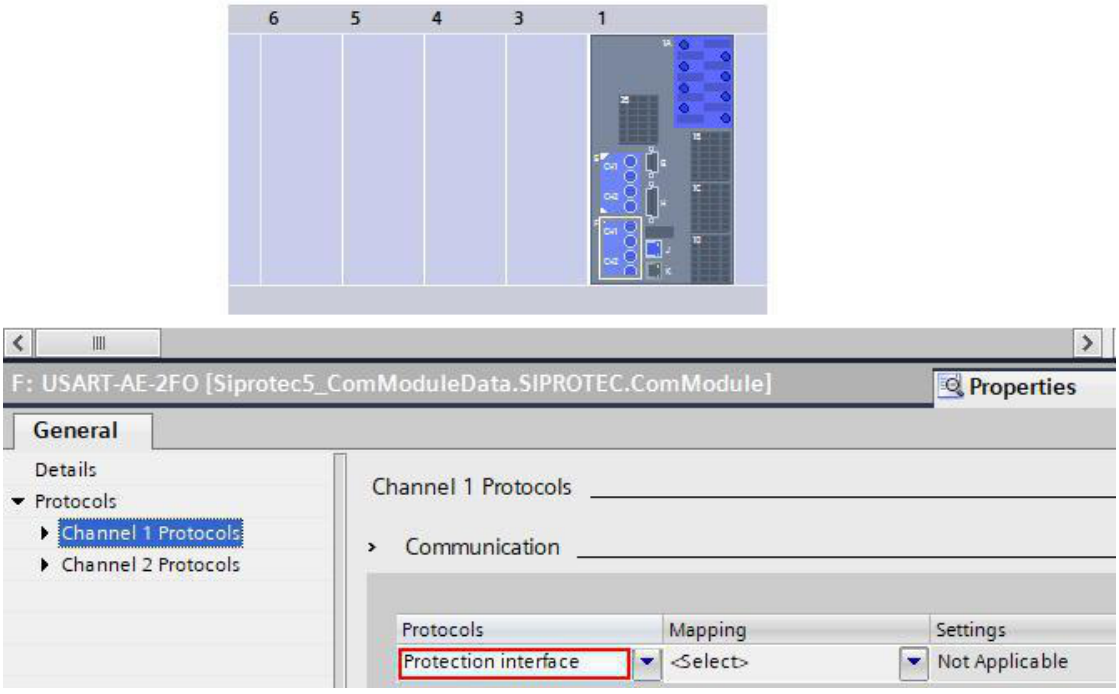
- General indications like the
  - Number of devices
  - Type and status of the device topology
- Indications of the devices in the device combination like:
  - The availability of the device
  - The state of the device, that is whether the device is logged on or off in the device combination

Measured values are transmitted via protection communication and are acquired and exchanged at the same time in the devices. The synchronization of the measured-value acquisition can be done either internally via the telegram measurement or via an external synchronous pulse (1-second pulse, PPS) using the function block **External synchronization**. The external synchronization is switched on in the function block of the protection interface. You can find the indications of the external synchronization in the function block **External synchronization**.

The function block **Remote data** is used to transfer selected and user-specific signals and measured values from the SIPROTEC 5 system. You select the signals and measured values to be transmitted in the communication mapping of DIGSI. The remote data does not issue status indications.

The function block **Protection interface** is automatically connected to a physical channel of a communication module and can therefore send signals and measured values to the neighboring device or receive them from the neighboring device. You can find the status indications of the FB **Protection interface** in the DIGSI 5 information routing in the function group **Protection communication**.

10 PPS - **P**ulse **P**er **S**econd

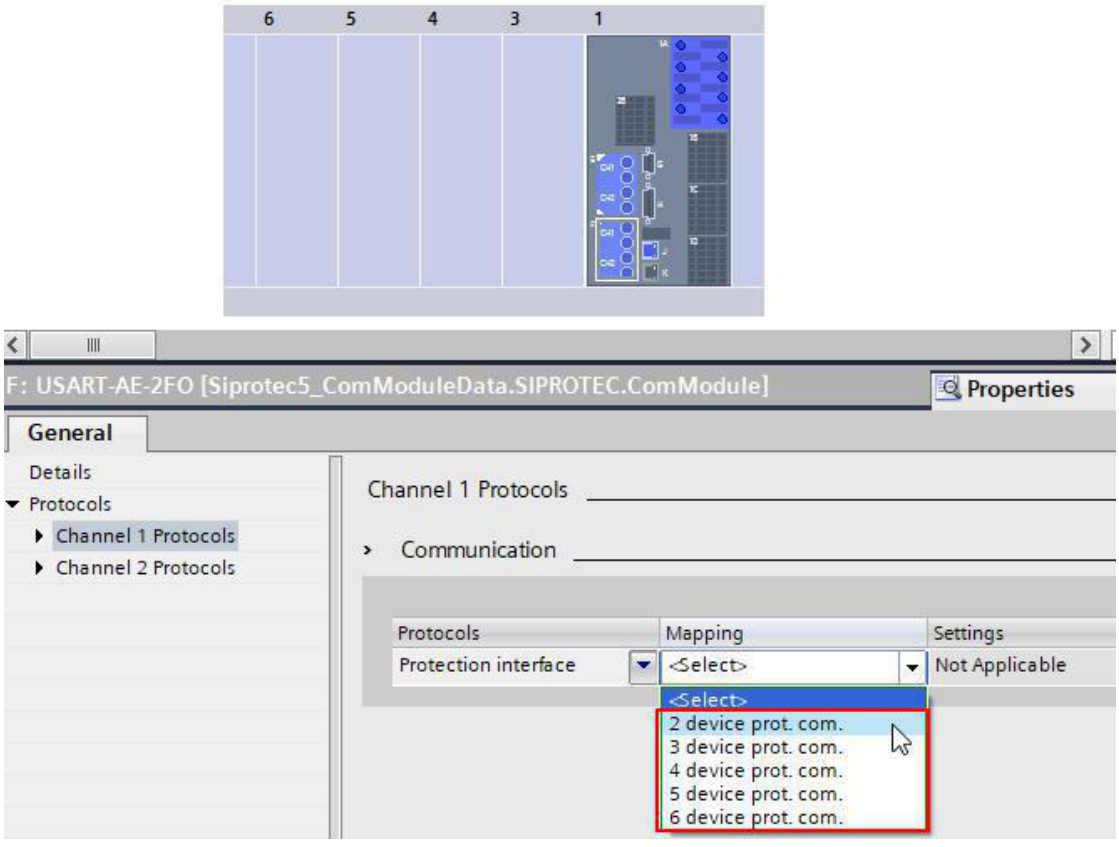


NOTE

In contrast to the protection interface in extended protection communication, the protection interface in classic protection communication is automatically connected to a physical channel of the communication module (refer to *Figure 3-71*).

3.6.5.4 Configuration of the Protection Interface in DIGSI 5

If the device is provided with modules, proceed as follows:



- Select the desired communication module in the rear view of the device.
- In the **Properties of the communication module** > **Protocols** > **Channel x Protocols**, select the ***Protection interface*** protocol.

[sc_PDC_classic_protocol, 1, en_US]

Figure 3-73 Selection of the Communication Protocol

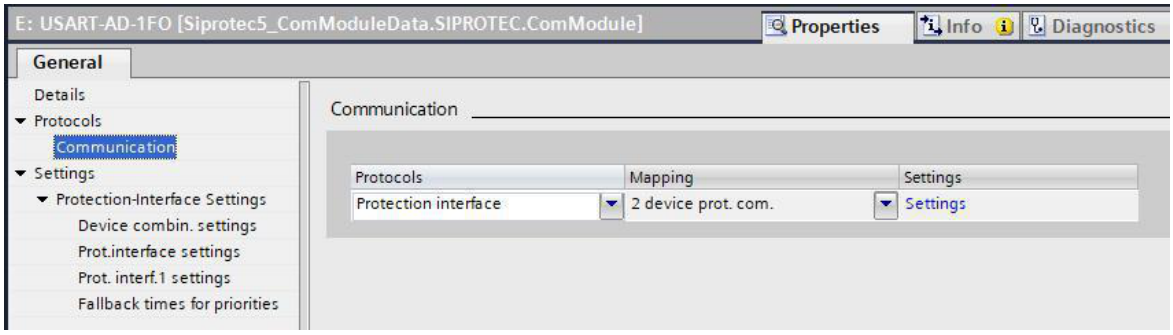
- Then select the number of devices under **Mapping** (see next figure).
  Depending on the device, the selection of device combinations can be restricted to 2 or 3 devices.
  The number of devices is an order option with regard to the line differential protection.

[sc_PDC_classic_mapping, 1, en_US]

Figure 3-74 Selecting the Device Combination

NOTE

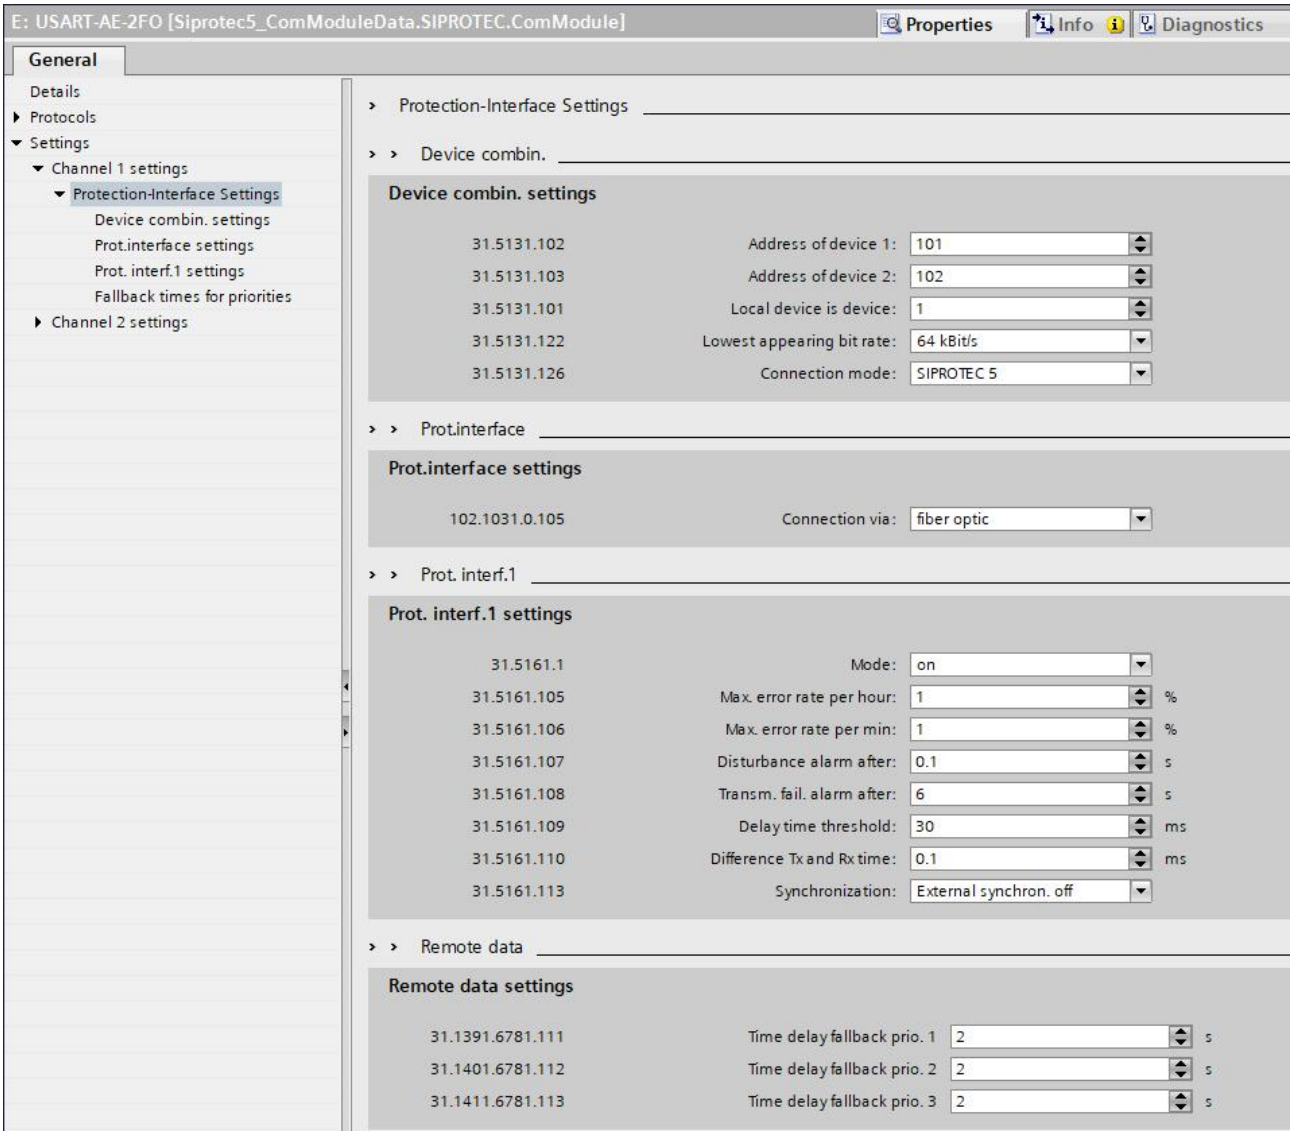
The function groups shown in *Figure 3-74* are not available in the DIGSI library.



If you use the **Line differential protection** function in combination with the classic protection communication, the device only supports 2 line ends. Under **Mapping**, select the option **2 devices prot. comm.**. If you select an option that is not permitted, DIGSI reports an inconsistency.

If the module slot is not yet provided with modules, proceed as follows:

- Select the desired communication module in the rear view of the device.
- Select the module from the catalog and drag it to a channel. Thus is the channel configured with a module. DIGSI 5 indicates whether the module can be used for protection communication under **Device Information**.
- Use the **Protocols** text box to select the ***Protection interface***, see *Figure 3-73*.
- Then use the **Mapping** text box to select the number of devices, for example **2 devices protection com.**, see *Figure 3-74*.



3.6.5.5 Setting Notes for the Device Combination

Select the communication module in the **Project tree** > **Hardware and protocols** in the **Device view**. In the properties of the communication module, you can find the setting sheets for the parameterization of the device-combination settings and the settings for protection communication.

[sc_config1, 1, en_US]

Figure 3-75 Selection of the Protocol: Communication via the Protection Interface

[sc_config, 4, en_US]

Figure 3-76 Protection-Interface Initialization and Configuration

Changes in the device-combination settings are always visible on the other channel as well. All further parameters can be set separately for individual channels.

Parameter: Address of Device x

- Default setting **(_:5131:102) Address of device 1** = ***101***
- Default setting **(_:5131:103) Address of device 2** = ***102***

With the parameters **Address of device 1** to **Address of device 2**, you give an address to each device. Set a unique and unambiguous address for each device.

NOTE

The device **1** is the timing master device in a device combination.

If all other devices in the device combination are to obtain their time from the timing master device, note the following:

- Under **Address of device 1** set the address for the timing master device.
- Parameterize the other devices such that they get their time from the timing master device via the protection connections.

  For more information, refer to *3.7.3 Function Description*. Select as the adjustable synchronization option ***Protection interface***.

  In the timing master device you must **not** set the protection interface as the synchronization source!

Parameter: Local device is device

- Default setting **(_:5131:101) Local device is device** = ***1***

With the parameter **Local device is device**, you set the index (number) of your device in the device combination. A maximum of 6 devices can be present in one device combination.

APPLICATION EXAMPLE

You have a device combination with 2 devices.

For example, in DIGSI 5, select the parameter setting **Address of device 1** with the parameter value ***101*** for device 1 and the parameter setting **Address of device 2** with the parameter value ***102*** for device 2.

Then, use the **Local device is device** parameter to set the index of the local device. The local device is the device that you parametrize.

The addresses must be set identically for all devices in the device combination. Functional protection communication requires that you also assign the same index in all devices of the device combination for a device with a unique address.

Parameter: Lowest appearing bit rate

- Default setting **(_:5131:122) Lowest appearing bit rate** = ***64 kBit/s***

With the parameter **Lowest appearing bit rate**, you set the lowest bit rate occurring in the device group. Set the lowest value in each device with a three-end constellation with 2 fiber-optic connections (2 MBit/s) and one 64 kBit/s connection with the lowest value (64 kBit/s). This value determines the maximum number of selected and self-created signals and measured values which are to be transmitted within the device combination (refer to *3.6.5.9 Remote Data*).

Apart from the default value, you can also set the following bit rates:

- ***128 kBit/s***
- ***512 kBit/s***
- ***2048 kBit/s***

NOTE

If you use optical fibers for a connection between the devices, set the value to ***2048 kBit/s***.

Connection mode

- Default setting **Connection mode** = ***SIPROTEC 5***

With the parameter **Connection mode**, you select the device type with which the SIPROTEC 5 device is to work in the device combination. As soon as a SIPROTEC 4 device works in the device combination, you must set the parameter **Connection mode** accordingly.

Parameter Value	Description
SIPROTEC 5	The SIPROTEC 5 device only works with SIPROTEC 5 devices in the device combination.
SIPROTEC 4 7SD610	The SIPROTEC 5 device works with at least one SIPROTEC 4 Differential protection device 7SD610 with firmware version V4.72 and higher in the device combination.
SIPROTEC 4 7SD5	The SIPROTEC 5 device works with at least one SIPROTEC 4 Differential protection device 7SD5x with firmware version V4.72 and higher in the device combination.
SIPROTEC 4 7SA5/6	The SIPROTEC 5 device works with at least one SIPROTEC 4 Distance protection device 7SA522 and 7SA6x with firmware version V4.72 and higher in the device combination.

3.6.5.6 Setting Notes on Selecting the Communication Medium

- Default setting **(_:105) Connection via** = ***fiber optic***

The **Connection via** parameter is used to set the bit rate required for the protection interface. Different discrete values can be entered depending on the means of communication (see following table).

Also refer to *Communication Media, Page 144*

Table 3-13 Means of Communication

Means of Communication	See	Setting Value	Bit Rate
Fiber-optic direct connection	*Figure 3-58* to *Figure 3-62*	***fiber optic***	2 MBit/s
CC-XG-512 communication converter	*Figure 3-63*	***CCXG 512 kBit/s***	512 kBit/s
CC-XG-128 communication converter	*Figure 3-63*	***CCXG 128 kBit/s***	128 kBit/s
CC-XG-64 communication converter	*Figure 3-63*	***CCXG 64 kBit/s***	64 kBit/s
Repeater 512 communication converter	*Figure 3-66*	***repeater 512 kBit/s***	512 kBit/s

3.6.5.7 Setting Notes for the Classic Protection Interface

Parameter: Max. error rate per hour

- Default setting **(_:5161:105) Max. error rate per hour** = *1.0%*

If the number of faulty telegrams per hour exceeds the value set in the parameter **Max. error rate per hour**, you receive the error message *Error rate / hour exc.*.

Parameter: Max. error rate per min

- Default setting **(_:5161:106) Max. error rate per min** = *1.0%*

If the number of faulty telegrams per minute exceeds the value set in the parameter **Max. error rate per min**, you receive the error message *Error rate / min exc.*.

Parameter: Disturbance alarm after

- Default setting **(_:5161:107) Disturbance alarm after** = *100 ms*

With the parameter **Disturbance alarm after**, you determine the time delay after which defective or missing telegrams are signaled as faulty where the indication *Status of lay. 1 and 2* is *PI data fault*.

Parameter: Transm. fail. alarm after

- Default setting **(_:5161:108) Transm. fail. alarm after** = *6.0 s*

With the parameter **Transm. fail. alarm after**, you determine the time delay after which a communication failure is signaled where the indication *Status of lay. 1 and 2* is *PI data failure*.

Parameter: Delay time threshold

- Default setting **(_:5161:109) Delay time threshold** = *30.0 ms*

The time taken to transmit and receive a signal via a protection connection is the signal-transit time. You can monitor the signal-transit time. For the **Delay time threshold**, the default setting is selected in such a way that normal communication networks do not exceed the signal-transit time. If this signal-transit time is exceeded during operation (for example upon switchover to another transmission route), the indication **Time delay exceeded** is issued.

Increased runtimes only affect the operate time, and therefore the fault-clearing time of the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.

Parameter: Difference Tx and Rx time

- Default setting **(_:5161:110) Difference Tx and Rx time** = *0.1 ms*

For time synchronization of the measured values with microsecond accuracy using telegram measurement, the signal-transit times in the send and reception direction must be approximately the same. The device monitors the signal-transit times in the send and reception direction.

With the parameter **Difference Tx and Rx time**, you set a maximum permitted signal-transit time difference between the send and reception paths (runtimes unbalanced). Set the parameter **Difference Tx and Rx time** to the maximum difference expected.

Set this value to *0* for a direct fiber-optic connection. A higher value is necessary for transmission via communication networks. Reference value: *0.1 ms* (recommended setting value).

If the difference in the signal-transit times between the send and reception path exceeds the value set, the indication *Time delay jump* is issued.

If the difference from consecutive measurements of the signal-transit times between the send and reception paths exceeds the set value and remains for more than 5 s, the indication *Time delay different* is issued. The **Line differential protection** function is no longer working properly and is *ineffective*.

NOTE

The parameter **Difference Tx and Rx time** only shows when the function **Line differential protection** is instantiated and the parameter **Synchronization** is not set to ***External synch. only***.

NOTE

If you use a multiplexer with a C37.94 interface as a means of communication, Siemens recommends a setting value of ***0.25 ms*** to ***0.6 ms***.

Parameter: Synchronization

- Default setting **(_:5161:113) Synchronization** = ***External synchron. off***

With the parameter **Synchronization**, you control the time synchronization of the measured values with microsecond accuracy.

If the SIPROTEC device operates with the external synchronization, use the **Synchronization** parameter to define how the protection is activated after restoration of the communication connection (basic state or after transmission fault). See *Figure 3-78*.

Parameter Value	Description
External synchron. off	The external synchronization is disabled: No external synchronization is performed at the protection interface. Select this setting value if you do not expect any differences between the signal-transit times in the transmission and reception directions. Then the measured values are only synchronized internally with the telegram measurement.
Telegr. and ext. synch.	Synchronization via telegram measurement and external synchronization: The measured values are synchronized internally with the telegram measurement, supported by the external synchronization. You can set the external synchronization with the parameter **External synchronization**. The synchronization is possible via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver. In this case, an existing line differential protection is only released when a new connection is established and one of the following conditions is met. • The protection connection is synchronized with the help of the external synchronization. • Symmetric signal-transit times are signaled via the binary input signal *>Sync reset* or the controllable *Reset synchronization*. This means that the signal-transit times are the same in the send and receive direction.

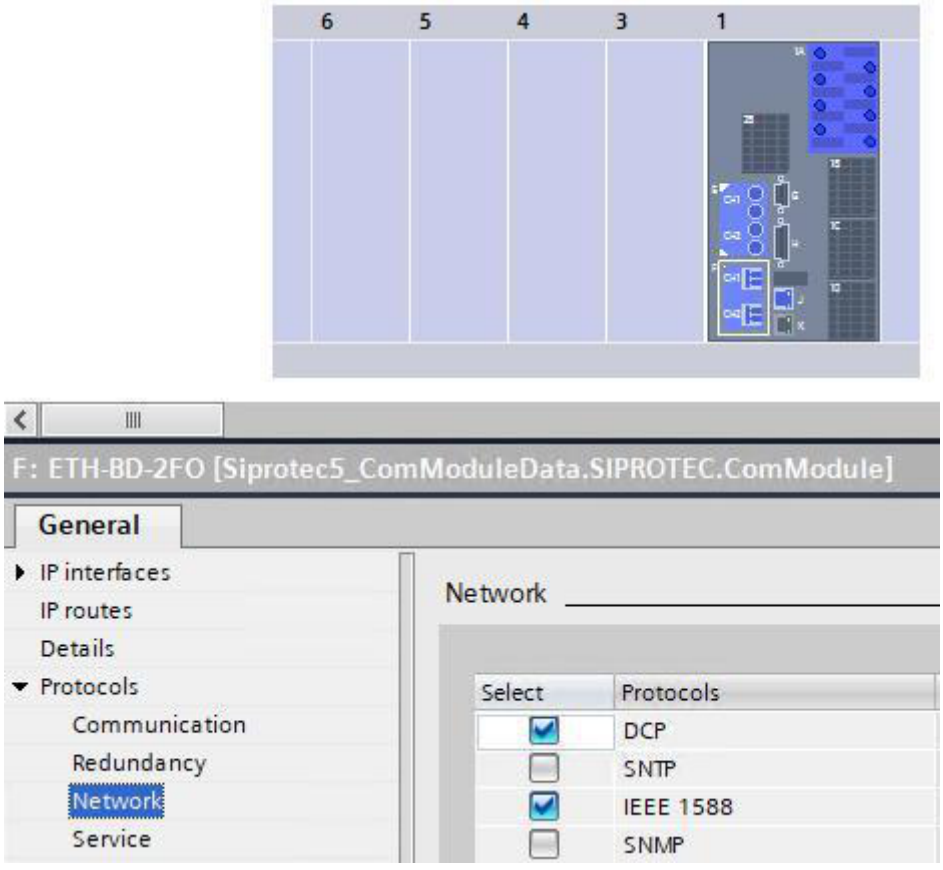
Parameter Value	Description
Telegr. or ext. synch.	Synchronization via telegram measurement or external synchronization: The measured values are synchronized internally with the telegram measurement, supported by the external synchronization. You can set the external synchronization with the parameter **External synchronization**. The synchronization is possible via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver. An available line differential protection is enabled immediately upon renewed establishment of connection (data telegrams are received). The internal synchronization is used up to synchronization.
External synch. only	External synchronization only: The measured values are synchronized only through the external synchronization. You can set the external synchronization with the parameter **External synchronization**. The synchronization is possible via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver.

Parameter: External synchronization

- Default setting **(_:5161:117) External synchronization** = ***PPS electrical (Port G)***

The parameter **External synchronization** is visible only if the parameter **Synchronization** is not set to ***External synchron. off***.

External synchronization is possible separately for each protection interface.



Parameter Value	Description
PPS electrical (Port G)	The electrical synchronous pulse of a satellite receiver (1-second-pulse, PPS[11]) is the synchronization source on the port **G**, the time synchronization interface.
IEEE 1588	The time synchronization protocol IEEE 1588 for an Ethernet-BD communication module is used for synchronization.

NOTE

The configuration option ***IEEE 1588*** is only visible if the device has an Ethernet-BD communication module and you have selected the communication protocol IEEE 1588, see following figure.

11 PPS - **P**ulse **P**er **S**econd

[sc_BD_1588, 1, en_US]

Figure 3-77 Ethernet-BD Communication Module: Selection of the IEEE 1588 Protocol

NOTE

External synchronization takes into account the signal-transit time in the transmission and reception directions. If external synchronization fails for a short time, for example, due to a receiving interference or an unfavorable satellite position for a brief period, internal synchronization via telegram measurement is still active.

NOTE

In contrast to the protection interface in extended protection communication, the protection interface in classic protection communication is automatically connected to a channel of a communication module (see *Figure 3-71*).

Parameter: Max. inaccuracy

- Default setting **(_:5161:119) Max. inaccuracy** = ***0.500 ms***

With the parameter **Max. inaccuracy**, you configure the maximum expected inaccuracy of the synchronization sourced used. The set value is only effective if the synchronization source used does not supply any information on the current inaccuracy in the synchronization signals. If you have not used any of the information on the inaccuracy of the synchronization source used, use the default setting.

NOTE

The inaccuracy of the synchronization source enters the stabilization of the **Line differential protection** as an error signal.

This means that a greater inaccuracy increases the calculated restraining quantity and makes the **Line differential protection** less sensitive.

If **IEEE 1588** is used as the synchronization source in the synchronization status ***SmpSynch*** = ***global***, accuracy values are supplied with the synchronization signals and the parameter **Max. inaccuracy** is not used. If the supplied accuracy values become invalid, the value set in the parameter **Max. inaccuracy** is used.

If the synchronization source **IEEE 1588** works in the synchronization status ***SmpSynch*** = ***local***, then the value set in the parameter **Max. inaccuracy** is used as permanently available inaccuracy.

If the synchronization source **PPS electrical (Port G)** or **PPS optical (USART)** is used, then the value set in the parameter **Max. inaccuracy** is used as permanent inaccuracy.

If a USART communication module with the **PPS** protocol and the **PPS generator**operating mode is also used as a synchronization source at the same time, the value set in the parameter **Max. inaccuracy** is used as permanent inaccuracy.

Parameter: Check synchron.-source

- Default setting **(_:5161:121) Check synchron.-source** = ***yes***

With the parameter **Check synchron.-source**, you can switch on or off the synchronization-sources check. During the check of the synchronization sources on the ends of a protection connection, a check is conducted as to whether both synchronization sources are working in the same synchronization status ***SmpSynch***.

If both synchronization sources are working in the synchronization status ***SmpSynch*** = ***global***, the check has been passed.

If both synchronization sources are working in the synchronization status ***SmpSynch*** = ***local***, that is decoupled from a global reference time, an additional check is conducted as to whether the synchronization source (***gmIdentity***) is the same. Synchronicity can only be guaranteed if the synchronization sources are the same.

If the synchronization sources display a different synchronization status, that is one displays the synchronization status ***SmpSynch*** = ***local*** and the other the synchronization status ***SmpSynch*** = ***global***, synchronization cannot be guaranteed.

Siemens recommends using the default setting **Check synchron.-source** = yes.

If you have problems with the synchronization-source check, you can switch off the synchronization-source check. Switch off the synchronization-source check only if the synchronization sources are synchronous at the end of their protection connection.

The parameter **Check synchron.-source** is visible only if the parameter **(_:5161:113) Synchronization** is set to ***External synch. only***.

NOTE

If you use **PPS electrical (port G)** as the synchronization source, the synchronization status (***SmpSynch***) is permanently set to ***global***.

If you use **PPS optical (USART)** as the synchronization source, you can use the setting (_:107) **Received. SmpSynch** to set the synchronization status to (***SmpSynch***) ***local*** or ***global***.

For synchronization with microsecond accuracy, for example with **Line differential protection**, adjust the parameter (_:107) **to Accepted. SmpSynch** = ***global***.

3.6.5.8 Indications and Measured Values in the Classic Protection Interface

Each individual protection interface provides different indications for commissioning and diagnostics of communication:

Indication *(_:5161:301) Status of lay. 1 and 2*

The indication *(_:5161:301) Status of lay. 1 and 2* informs you about the status of the connection. The following indications are possible:

Table 3-14 Status Indications Status of lay. 1 and 2

Indication	Description
initialized:	The protection interface is not connected and is in the Initial state.
PI connected:	The protection interface is connected to the protection interface of the partner device.
PI data fault:	The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:107) Disturbance alarm after** .
PI data failure:	The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:108) Transm. fail. alarm after** .
not existing:	The protection interface has not been assigned to a communication channel.

Indication *(_:5161:302) Status of lay. 3 and 4*

The indication *(_:5161:302) Status of lay. 3 and 4* informs about errors during the connection establishment. The following indications values are possible:

Status Indication	Description
no error:	No errors occurred during the connection establishment.
SW ver.incomp.:	The connection is not established because the firmware versions of the devices are incompatible. Update the firmware.
wrong dev. ID:	The connection is not established because the device address of the local device or the partner device is incorrect or set incorrectly. Check the settings for the parameters **Address of device 1** to **Address of device n** (_:5131:102 and following).
const.sett.error:	The connection is not established because the parameters are set differently. Check whether the parameter **(_:5131:122) Lowest appearing bit rate** has been set the same in all devices in the device combination.
diff.sett error:	The connection is not established because the parameters are set differently. The line differential protection settings for the connected devices are incompatible. Check whether the devices are set to operate with or without line differential protection. The rated current of the line (parameter **(_:9001:101) Rated current**) must have the same setting in all devices. With a transformer in the line, the **(_:9001:103) Rated apparent power** must be set to the same value in all devices. For further information, see *6.7 Line Differential Protection*.
net mirroring	The connection is not established. The protection interface is receiving its own data. Check the wiring.
wrong dev. idx.	The connection is not established because the device index of the local device or the partner device is incorrect. Check the setting for the parameter **(_:5131:101) Local device is device**.

Furthermore, the following output signals are available:

Output Signal	Description
(_:5161:303) Connection broken	The signal *Connection broken* indicates that during a parameterized time (parameter **(_:5161:107) Disturbance alarm after**) no telegrams or faulty telegrams were continuously received. If the indication *Connection broken* is issued, the affected protection connection is reset. This can cause the blocking of an active line differential protection or a ring topology can change to a chain topology.
(_:5161:316) Error rate / min exc.	The signal *Error rate / min exc.* indicates that the set maximum error rate per minute (parameter **(_:5161:106) Max. error rate per min**) has been exceeded. In this manner, a brief increase of the operate time and thus of the fault-clearing time is possible for the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:317) Error rate / hour exc.	The signal *Error rate / hour exc.* indicates that the set maximum error rate per hour (parameter **(_:5161:105) Max. error rate per hour**) has been exceeded. In this manner, a brief increase of the operate time and thus of the fault-clearing time is possible for the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:318) Time delay exceeded	The signal *Time delay exceeded* indicates that the threshold value for the set signal-transit time (parameter **(_:5161:109) Delay time threshold**) has been exceeded. Increased transmission times only affect the operate time, and therefore the fault-clearing time of the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:319) Time delay different	The signal *Time delay different* indicates that the threshold value for the difference in signal runtimes in the transmission and reception direction (asymmetrical runtimes) has been exceeded. The setting value results from the setting value of the parameter **(_:5161:110) Difference Tx and Rx time**. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***. If the indication *Time delay different* appears, the **Line differential protection** function is no longer working properly and is ***ineffective***.
(_:5161:320) Time delay jump	The signal *Time delay jump* indicates that the signal runtimes of the data changed abruptly. This is caused by a switchover of the communication path in the communication network. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***.
(_:5161:321) PI synchronized	The signal *PI synchronized* indicates that the synchronization with microsecond accuracy of the measured values transferred between the local device and partner device is working correctly. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***.

Output Signal	Description
(_:5161:340) Telegram lost	The signal *Telegram lost* indicates that an expected telegram has failed to arrive or a faulty telegram has been received. Reasons for this can be for example switching operations in the primary system or operations on the components of the communication network. If you want to assign the communication failures or faults to other events, route the signal *Telegram lost* temporarily into the operational log. **Note:** If the signal is constantly routed, the operational log can overflow. Siemens recommends routing the signal only for clarification of problems.
(_:5161:343) Partner	The indication shows the address of the partner device. A value of 0 means that no partner address is available.
(_:5161:323) PPS: time del. unsym.	This indication is only visible if you are working with a synchronous pulse. The indication shows that the difference in the signal runtimes between the sending and receiving path exceeds the value set with the parameter **(_:5161:110) Difference Tx and Rx time**. **Note:** The **Line differential protection** function remains ***effective***.
(_:5161:324) PI with PPS synchron.	This indication is only visible if you are working with a synchronous pulse. This indication is only visible if, in parallel to synchronization with the synchronization pulse, you are also working with the synchronization via telegram measurement. If both synchronization methods are working properly, the indication *PI with PPS synchron.* = RAISING is generated.

Measured Values of the Protection Interface

The protection interface provides the following measured value for the diagnosis of the protection-interface communication:

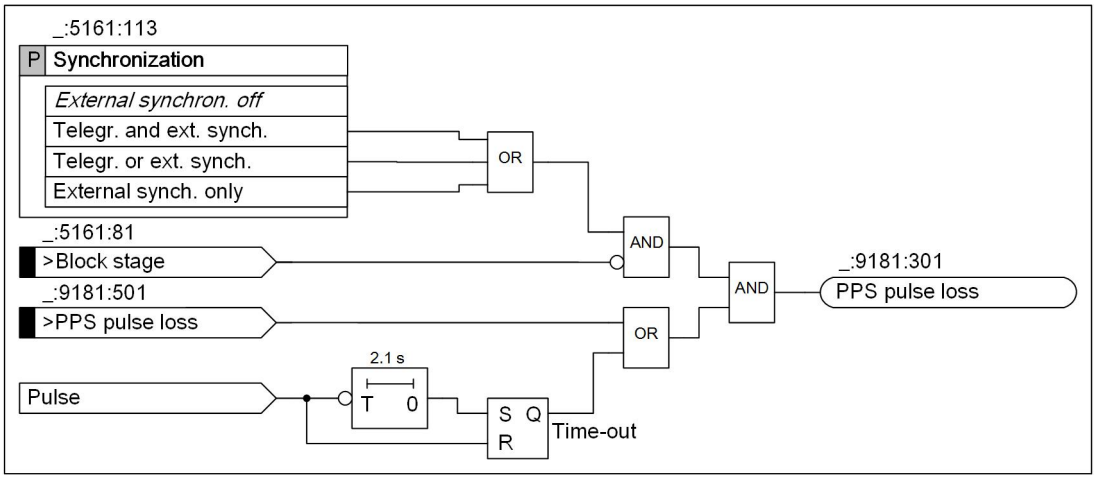
Measured Value	Description
(_:5161:308) Tx tel/h	Telegrams transmitted during the last hour
(_:5161:309) Rx tel/h	Telegrams received during the last hour
(_:5161:310) Tx tel/min	Telegrams transmitted during the last minute
(_:5161:311) Rx tel/min	Telegrams received during the last minute
(_:5161:312) Tx err/h	Transmission failure rate during the last hour
(_:5161:313) Rx err/h	Receive error rate during the last hour
(_:5161:314) Tx err/min	Transmission failure rate during the last minute
(_:5161:315) Rx err/min	Receive error rate during the last minute
(_:5161:325) Aver.Δt	Average singal runtime (average value of the runtime in transmission and reception path divided by 2, without external synchronization)
(_:5161:326) Rec. Δt	Signal runtime for reception path (with external synchronization)
(_:5161:327) Sen. Δt	Signal runtime for transmission path (with external synchronization)
(_:5161:334) Miss.tel/min	Number of telegram failures within the last minute
(_:5161:335) Miss.tel/h	Number of telegram failures within the last hour
(_:5161:336) Miss.tel/d	Number of telegram failures within the last day
(_:5161:337) Miss.tel/w	Number of telegram failures within the last week
(_:5161:338) M. loss/d	Longest lasting telegram failure within the last day
(_:5161:339) M. loss/w	Longest lasting telegram failures within the last week
(_:5161:331) Recept.	Receipt of a telegram (0 = no receipt, 1 = receipt) You can use this indication to make the telegram exchange visible in the fault record.

NOTE

You can reset the measured values of the protection interface directly in the device. Proceed as follows: **Device functions > x Device protection comm. > Protection interface y > Release measured values**.

Indications of External Synchronization

The following indications are visible only if the parameter **(_:5161:117) External synchronization** is set to ***PPS electrical (Port G)***.



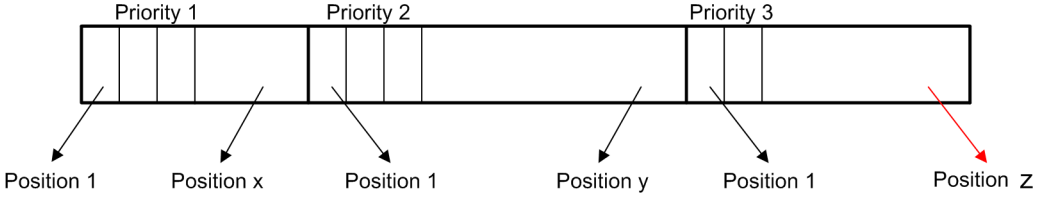
- *(_:9181:501) >PPS pulse loss*
- *(_:9181:301) PPS pulse loss*
- *(_:9181:302) PPS pulse*
- *(_:9181:303) PPS pulse OK*

The following indications are visible only if the parameter **(_:5161:117) External synchronization** is set to ***IEEE 1588***.

- *(_:304) Synchronization loss*
- *(_:305) Synchronization OK*
- *(_:306) Synchronization pulse*

Indication	Description
(_:9181:500) >Block stage	This indication shows the blocking of the external synchronization via a binary input. The external synchronization can be set to inactive through this binary input indication.
(_:9181:501) >PPS pulse loss	The binary input *(_:9181:501) >PPS pulse loss* can be used to signal an externally detected failure in the PPS synchronous pulse (for example, an error message from the satellite receiver). Setting this binary input also leads to the indication *(_:9181:301) PPS pulse loss*. The external synchronization detects immediately that there is a problem with the connected synchronization pulse. Otherwise, the problem will only be noticed after approx. 2.1 s – after the test for synchronous-pulse failure.
(_:9181:301) PPS pulse loss	This indication shows that the synchronization has failed. This can be due to the following reasons: • The input indication *(_:9181:501) >PPS pulse loss* has occurred. • The synchronous pulse has failed. • The quality of the synchronous pulse is inadequate. • There is another problem with the synchronization source. If no further PPS synchronous pulse is received within 2.1 s, the time-out monitoring responds. If no new second pulse occurs after the expiry of the monitoring time, the indication *(_:9181:301) PPS pulse loss* is issued (see *Figure 3-78*).
(_:9181:302) PPS pulse	This indication displays the synchronous pulse directly. As a rule, one pulse is generated per second. This indication works well to make the synchronous pulse visible.
(_:9181:303) PPS pulse OK	This indication shows that the synchronization is working properly.
(_:9181:304) Synchronization loss	The synchronization has failed. This can be due to a problem with the synchronization source.
(_:9181:305) Synchronization OK	The synchronization is working properly.

Indication	Description
(_:9181:306) Synchroni-zation pulse	You can use this indication to make the virtual synchronous pulse visible. As a rule, one pulse is generated per second.
(_:9181:307) Synchron. imprecise	If the set synchronization source operates in the ***global*** synchronization status (SmpSynch) and the time of the synchronization source deviates from the global time by more than 0.5 ms, the indication *Synchron. imprecise* is generated and the **Line differential protection** becomes ineffective. The indication *Synchron. imprecise* is visible only if the parameter **External synchronization** is set to ***IEEE 1588***.



[lo_pps_syn, 2, en_US]

Figure 3-78 Logic for the Generation of the Indication *PPS pulse loss*

3.6.5.9 Remote Data

Between the devices in a device combination, a data bar is exchanged which can be written or read by the devices. It can be used for exchanging various signals between the devices. For this, each signal demands a certain number of data fields.

[dw_data, 1, en_US]

Figure 3-79 Data Bar Exchanged between Devices

The data bar is divided into 3 priorities, which have different transmission rates and data volumes.

For all signals sent, the basic principle is that only pure data contents are transmitted. The quality, for example, *Valid*, is not automatically transmitted as well. If you want to transmit the quality as well, for example, for further processing of GOOSE messages, you must transmit the quality separately, for example, using CFC. If a function is in test mode, all signals of the function are provided with a test flag. If a signal with a test flag is transmitted, all signals on the receiving side are provided with a test flag. If the connection is broken, which means there are devices that cannot be reached anymore, all received signals are flagged with the quality *invalid*. Additionally, the value is set to a predefined state after a selectable dropout time or the last value received can be retained (setting ***Hold***). This can be configured separately for each received signal, refer to *Table 3-18*.

Behavior When Devices Are Logged Off or Switched Off

If you log off a device, the behavior of the remote data is not affected. A logged-off device sends remote data as well. Logged-off devices can also receive and evaluate remote data.

If you switch off a device in the device combination, the remaining devices in the device combination do not send or receive any remote data. A failsafe state is adopted for the remote data received before that, according to the settings in the communication mapping in DIGSI. The previously received values can be either retained or replaced with a dropout value.

If you switch off a logged-off device, the remaining devices keep sending or receiving remote data. The remote data of a logged-off and switched-off device is no longer available in the communication. The remaining devices behave as if the logged-off and switched-off device has never been part of the device combination.

NOTE

For **ACT** type signals, only the phase information is transmitted.

Signals that are transferred data fields of priority 1 are sent with every telegram. They are preferably used for the transmission of rapid signals, for example, release for circuit-breaker intertripping. A strictly deterministic, rapid transmission is required there.

Signals of priority 2 are transmitted with at least every 2nd telegram. For bit rates >256 kbit, there are no differences between priority 1 and priority 2.

Priority 3 signals are transmitted at least every 100 ms. This priority is used for transmission of measured and metered values. Complex values must be routed separately as the real and the imaginary part for transmission. Measured-value thresholds that lead to an updating of a measured value are set centrally as a property of the measured value. These measured-value thresholds apply with the corresponding reporting, for example, also for the transfer via IEC 61850 to a substation automation technology.

Signals which are written to a data area x under a priority on the data bar must be routed to an indication of the same type in the device reading this information. Otherwise, they are processed incorrectly on the receiving side. The data bar is organized in terms of bits. For information on the bit requirement of each signal type, refer to *Table 3-17*.

Table 3-15 and *Table 3-16* show the number of data areas in the data bar in relation to the available baud rate.

NOTE

Adjust the parameter **(_:5131:122) Lowest appearing bit rate** in each device for the protection interfaces in a device combination. This determines the number of data areas.

If, for example, in a device combination with 3 devices with a type 2 chain topology 2 devices are connected via direct optical fibers and 2 devices with a bit rate of 64 kBit/s, the 64 kBit/s section is the limiting factor for the entire device combination.

Table 3-15 Available Bits – Minimum Constellation Baud Rate 64/128 kBit/s

	Priority 1	Priority 2	Priority 3
Type 1	8 bits	24 bits	128 bits
Type 2	32 bits	64 bits	256 bits

Table 3-16 Available Bits – Minimum Constellation Baud Rate 512/2048 kBit/s

	Priority 1	Priority 2	Priority 3
Type 1	48 bits	128 bits	384 bits
Type 2	96 bits	200 bits	1024 bits

Table 3-17 Requirement in Bits

Signal Type	Size in Bits
SP (single-point indication)	1 bit
DP (double-point indication)	2 bits
IN (metered values)	32 bits
MW (measured values)[12]	32 bits
ACT	4 bits

Table 3-18 Possible Dropout Values

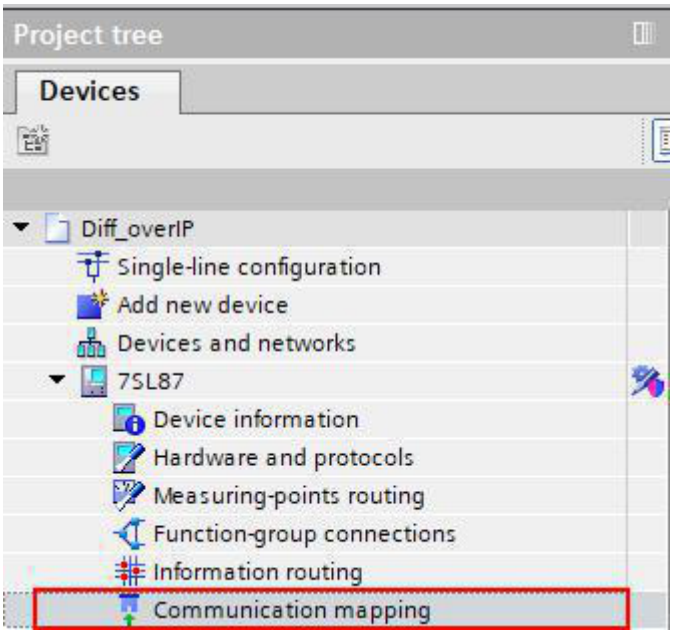
Signal Type	Dropout Thresholds
SP (single-point indication)	Outgoing, Incoming, Hold
DP (double-point indication)	On, Off, Intermediate Position, Disturbed Position, Hold
IN (metered values)	0, Hold
MW (measured values)	0, Hold
ACT	Hold

NOTE

If the protection link fails, these values can be set on the receiver side.

EXAMPLE

2 devices are connected with line differential protection via a 64-kBit channel. This is a type 1 protection communication. There are 8 bits available for priority 1. Now, for example, 4 SPS and 2 DPS can be routed:
4 x 1 Bit + 2 x 2 Bits = 8 Bits



NOTE

Measured values are transmitted as primary values.

Configuration of Remote Data in DIGSI 5:

To configure remote data, navigate in DIGSI 5 through the project tree to the communication mapping.

12 The complex phasors of a measuring point are prerouted

[sc_comm_select, 1, en_US]

Figure 3-80 Communication Mapping in DIGSI 5

Figure 3-81 to *Figure 3-85* show the routing for a type 1 protection communication.

To transmit signals to other devices, these signals must be routed in the communication matrix under **Transmit**. Binary inputs 1 and 2 are single-point indications (SPS) and are routed to bit position 1 and bit position 2 of the transmission with the highest priority (priority 1). For 64 kBit/s, for example, only 8 of these data areas are available for type 1 protection communication; they are exchanged between the devices with each telegram. Signals 3 and 4 are double-point indications (DPS), for example, a switch position that is transmitted by device 1. A double-point indication occupies 2 bit positions on the data bar. In addition, a measured and metered value are communicated with priority 3.

As a measured or metered value uses 32 bits, value 2 starts at bit position 33. DIGSI 5 shows the next free bit position.

Figure 3-83 Routing of Metered Values to Protection Communication in Device 1

Device 1 also receives signals (in the communication mapping under **Receive**, see next figure). These signals must be routed with the other devices under **Transmit**. The binary outputs 1 and 2 in device 1 receive their information via the protection communication. This is priority 1 information, which has been routed in another device to position 3 and 4 of the data bar for transmission. The secure state is predefined in the **Fallback value** column. If the protection connection fails, the single-point indication is reset to ***raising*** or **cleared** as the **fallback value** or its value is retained (***Hold***). For signals of the various priorities, you can also set a dropout time after which the reset (see following figure) to the fallback value occurs, in order to retain the original state for a short time in the event of brief interruptions. These 3 dropout times apply for all signals of one transmission priority and are set as parameters.

[sc_remotedata, 2, en_US]

Figure 3-85 Routing of Single-Point Indications (Receive) to Protection Communication in Device 1

The following figure shows the routing in the 2nd device. Binary inputs 1 and 2 are routed with priority 1 to bit positions 3 and 4 there. In device 1, bit positions 1 and 2 are already occupied (see *Figure 3-81*). If you also route the signals to bit positions 1 and 2, the signals of both devices are then connected to the corresponding bit position with a logical **OR** operation. If measured and metered values are routed in the same data areas, this results in implausible values for the receivers. As a user, you are therefore responsible for the correct routing.

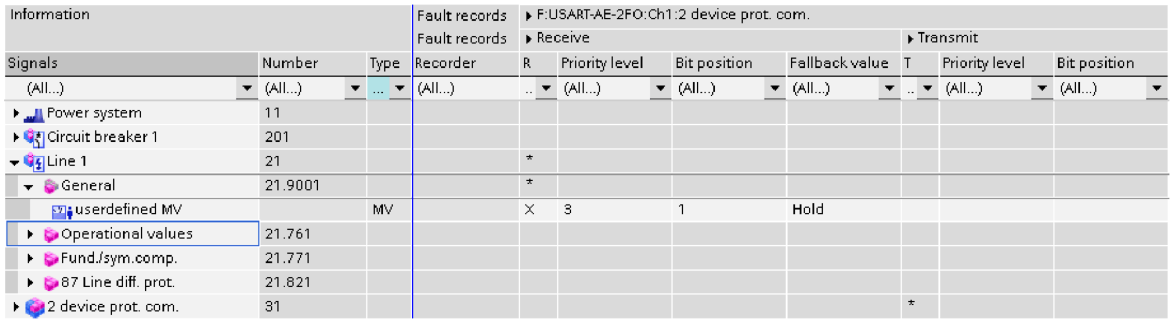
[sc_baspsr, 1, en_US]

Figure 3-86 Routing of Single-Point Indications to be Sent to Protection Communication in Device 2

The binary outputs 1 and 2 (**Receive**) in the 2nd device are connected to priority 1 signals 1 and 2 from the 1st device. This takes place via the data areas at positions 1 and 2 of the data bar, which transfer the state of the signals. Other devices can also read this information and logically link it to their internal signals. Here, too, the secure state, which is assumed when the protection connection is interrupted, is entered. This state depends on the information. With single-point indications, states 0 or 1 make sense. In the case of double-point indications, bit combinations 00, 01, 10, or 11 are possible to directly signal a disturbed position upon failure of the protection connection, for example.



Hold is used to retain the state before the failure of the protection connection.

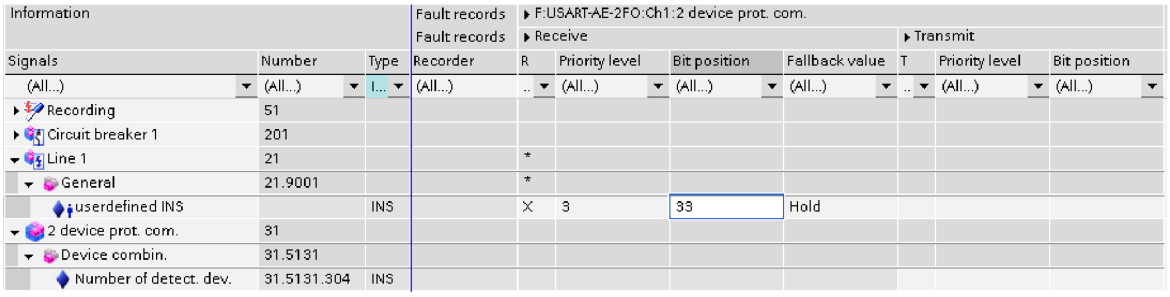

Figure 3-89 Routing of Metered Values to Protection Communication in Device 2

3.6.5.10 Constellation Measured Values for Type 1 and Type 2

NOTE

The constellation measured values are only available for the FG **Line**.

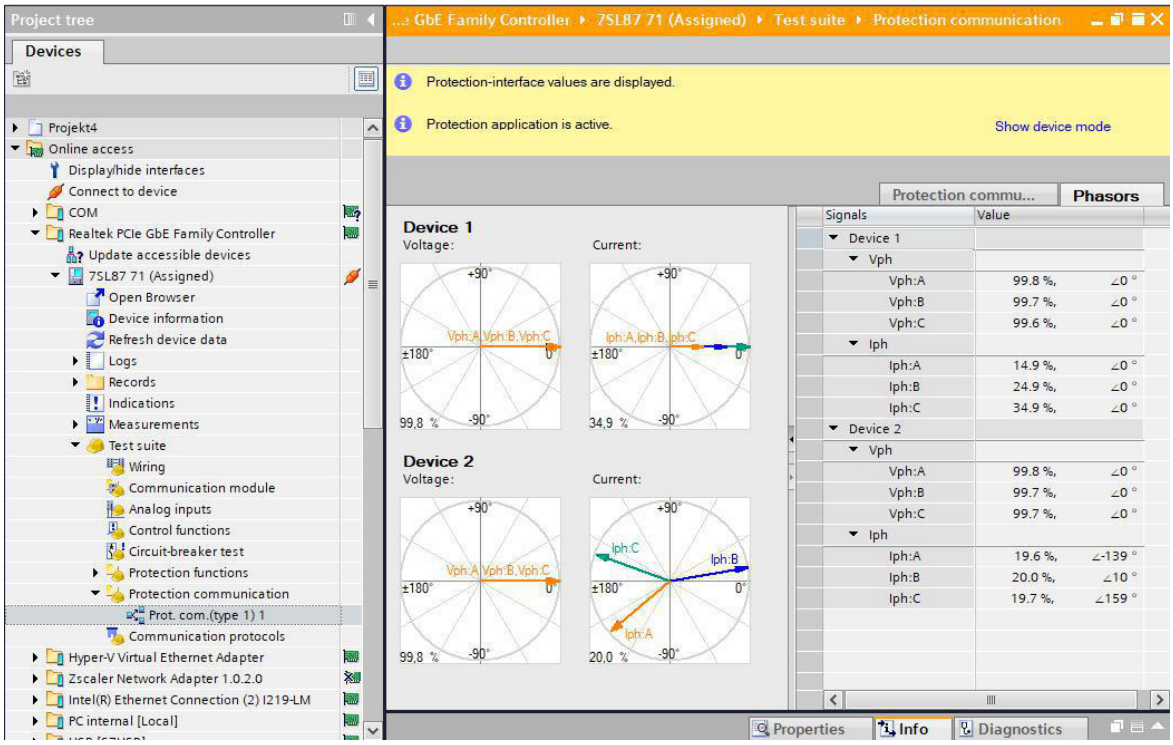
Each device in the device combination determines measured values predefined by Siemens, known as constellation measured values. You can find the constellation measured values in the DIGSI 5 information routing under the FG **n Device protection comm.** > **Constell. measured values**. The following measured values and indications are issued for each device:

Measured Value	Meaning
(_:1351:6811:302) Vph	This measured value shows the voltage of the 3 phases that is synchronized with all devices of the device combination. The absolute value and angle are issued for each phase.
(_:1351:6811:303) Iph	This measured value shows the current of the 3 phases that is synchronized with all devices of the device combination. The absolute value and angle are issued for each phase.
(_:1351:6811:300) Dev.adr.	This indication shows the device address. This allows you to assign the measured values and the circuit-breaker position in a better way.
(_:1351:6811:301) CB	This indication shows the position of the local circuit breaker and can have the following values: • *0*: The switch position of the local circuit breaker is unknown. • *1* The local circuit breaker is open. • *2* The local circuit breaker is closed.

The constellation measured values have the following properties:

- They are synchronized in the devices in a device combination.
- They are substituted using the protection interface.
- They are available on every device in the device combination.

You can view the constellation measured values with DIGSI 5.



In the device, current and voltage measured values are displayed in absolute value and phase as a percentage. 100 % conform to the rated current or the rated voltage of the line (see *Figure 3-90*). These measured values are recorded every 2 seconds by the devices and then sent to the other respective devices. At the same time, the current and voltage values of the different devices are time-synchronous with one another.

When displaying the constellation measured values, the local device is prioritized. The device connected directly with DIGSI 5 is the local device.

The angle reference depends on the type of the FG **Protection communication** used:

- Protection communication **Type 1**:
  - The angle values of the voltages show the angle difference between the local and the remote voltage. The local voltage serves as the reference with an angle of 0°.
  - The angle values of the currents show the angle difference between the local and the remote current. The local current serves as the reference with an angle of 0°.
- Protection communication **Type 2**:
  The angles of the phase-to-ground voltages and the phase currents relate to the voltage V_A of the remote device.

You can find these measured values in the device under the following DIGSI mask:

[sc_const mv, 2, en_US]

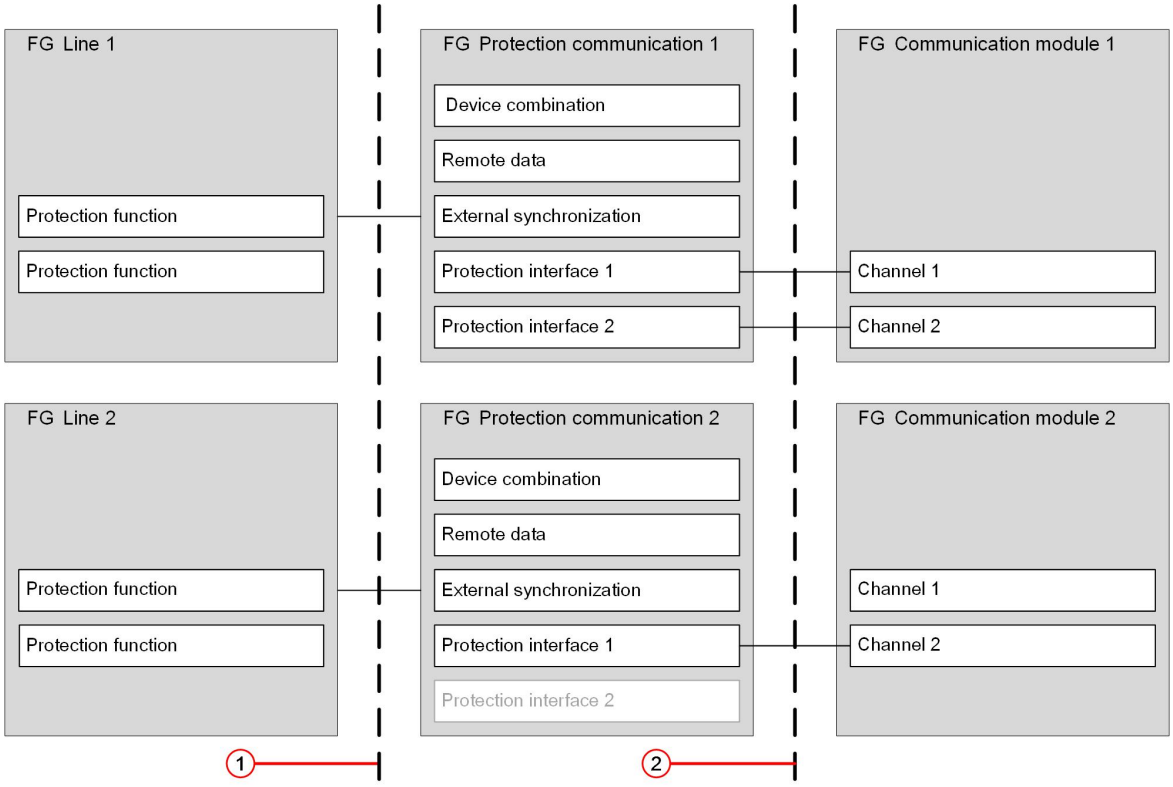
3.6.6 Advanced Protection Communication

3.6.6.1 Overview

The advanced protection communication contains all functionalities of classic protection communication. The view of parameters and indications is structured differently in DIGSI 5. In addition, the advanced protection communication supports the IP-based communication protocol.

In contrast to the classic protection communication, the advanced protection communication supports more than 2 devices in the device combination.

You can easily change the number of devices in the device combination. Further differences include support for external synchronization sources and an exchange of phase-selective information while sending and receiving.



In the DIGSI 5 library, you can find the available function groups for the advanced protection communication in the **Advanced protection communication** folder. The following function-group types can be instantiated:

- FG **Protection communication type 1 (line differential protection)**
- FG **Protection communication type 2**

For configurations with line differential protection, instantiate the FG **Protection communication type 1 (line differential protection)**. In all other cases, instantiate the FG **Protection communication type 2**.

3.6.6.2 Advanced Protection Communication in the Overall System

The **Advanced protection communication** is integrated as follows in the overall system:

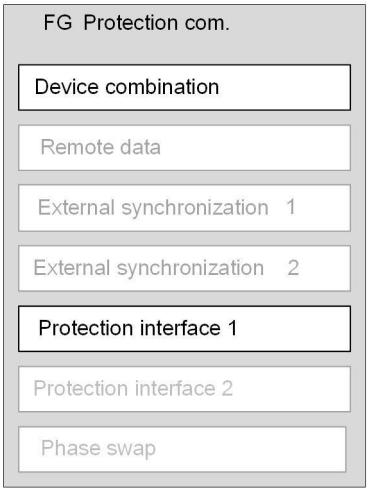
[dw_advanced_protcom_compl_system, 2, en_US]

Figure 3-91 Advanced Protection Communication in the Overall System

(1) The following applies for the FG **Line** and the FG **Voltage/Current 3-phase**: You must route the connection between the protection FG and the FG **Protection communication** in DIGSI 5.

(2) You must assign a channel to the protection interface, see *Parameter: PI assignment, Page 188*.

3.6.6.3 Structure of the FG Protection Communication



The instantiated FG **Protection communication** contains the function blocks (FB) for a protection interface and for the device combination. If you need a 2nd protection interface, add another instance.

The FG **Protection communication** contains the following functionalities and function blocks:

- FB **Device combination**
- FB for the **Protection interface**

In addition, the following FBs can be instantiated:

- A 2nd protection interface
  You can find the 2nd protection interface in the Global DIGSI 5 library under **Extended protection communication** > **Second protection interface**.
- 1 or 2 FBs for the **External synchronization** of the transmitted measured values by an external synchronization pulse (1-second pulse, PPS) or via the IEEE 1588 synchronization protocol
  You can find the FB **External synchronization** in the Global DIGSI 5 library under **Extended protection communication** > **Synchronization**.
- The FB **Remote data** is instantiated automatically, as soon as you configure remote data.
- The FB **Phase swap**

[dw_structure_FG_protcom_advanced, 2, en_US]

Figure 3-92 Structure of the FG Extended Protection Communication

Device Combination

The function **Device combination** manages the devices that exchange data via the protection communication.

The following FBs are preconfigured in the device combination:

- FB **General**
- FBs for each device in the device combination

In the **Device combination**, you configure general settings for the protection communication and the device addresses. The function **Device combination** issues the following indications:

- General indications like the
  - Amount of devices
  - Type and status of the device topology

- Indications of the devices in the device combination like:
  - The availability of the device
  - The state of the device, that is whether the device is logged on or off in the device combination
  - Measured values of the device that have been recorded and synchronized through the device combination (constellation measured values)
  - Test of the function **Line differential protection** in the device combination (only for protection communication type 1)
  - Test of the function **Line differential protection** in the local device (only for protection communication type 1)

Protection Interface

The FB **Protection interface** transmits and receives signals and measured values to/from the partner device. For this, the protection interface uses the channel of a communication module.

External Synchronization

Measured values that are acquired and exchanged in the devices at the same time, with microsecond accuracy are transmitted via the protection communication. The measured values can be synchronized as follows:

- Internally via the telegram measurement with the Ping-Pong method
- Externally via
  - An external, synchronous pulse 1-second-pulse (PPS)
  - Via the **IEEE 1588** protocol

  If you want to use an external synchronization, you must instantiate the FB **External synchronization**.

  You can use a different synchronization procedure for the 2nd protection interface than for the 1st protection interface.

Remote Data

If you want to exchange selected and user-specific data or measured values via the protection communication, you must use the **Remote data** function. If you route a specific signal or a measured value to the protection communication, the device automatically creates the **Remote data** functionality. The routed signals are then transmitted and received via the protection interface. The available bandwidth limits the amount of remote data that can be transmitted.

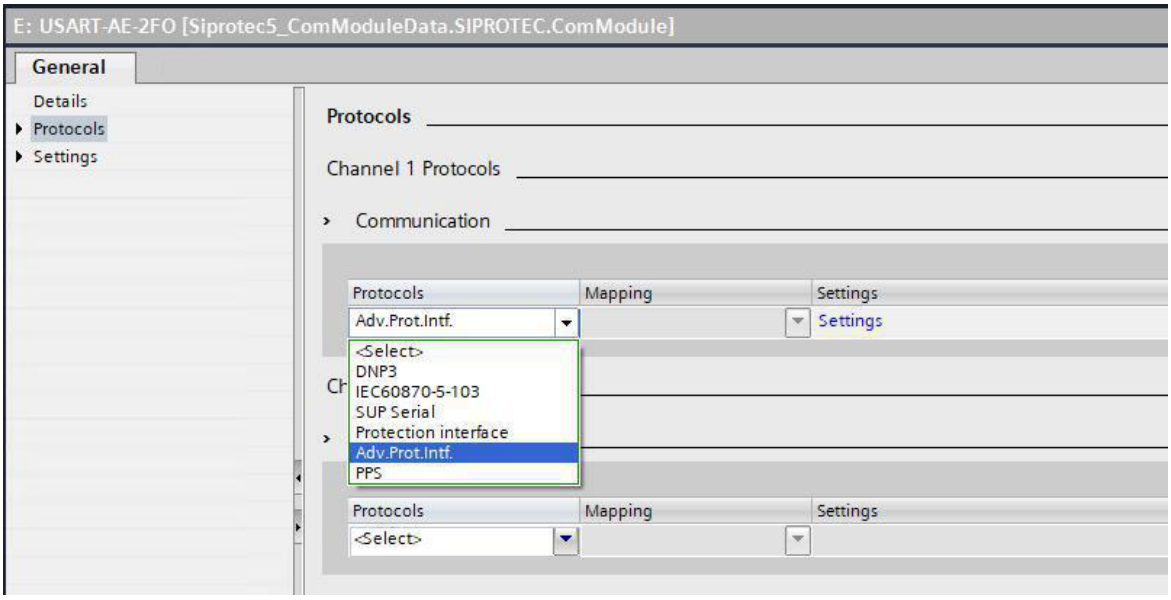
Phase Swap

If you want to exchange information via the protection communication with a device showing phases with a different sequence but with the same rotating field as your device, the SIPROTEC 5 device can swap the phase information when sending and receiving. It is no longer necessary to swap phases when connecting the current transformers.

This use case exists on some tie lines of different power-system operators.

For more information, refer to *3.6.6.12 Description Phase Swapping* and *3.6.6.13 Setting Notes for Phase Swapping*.

3.6.6.4 Configuration of the Advanced Protection Communication in DIGSI 5

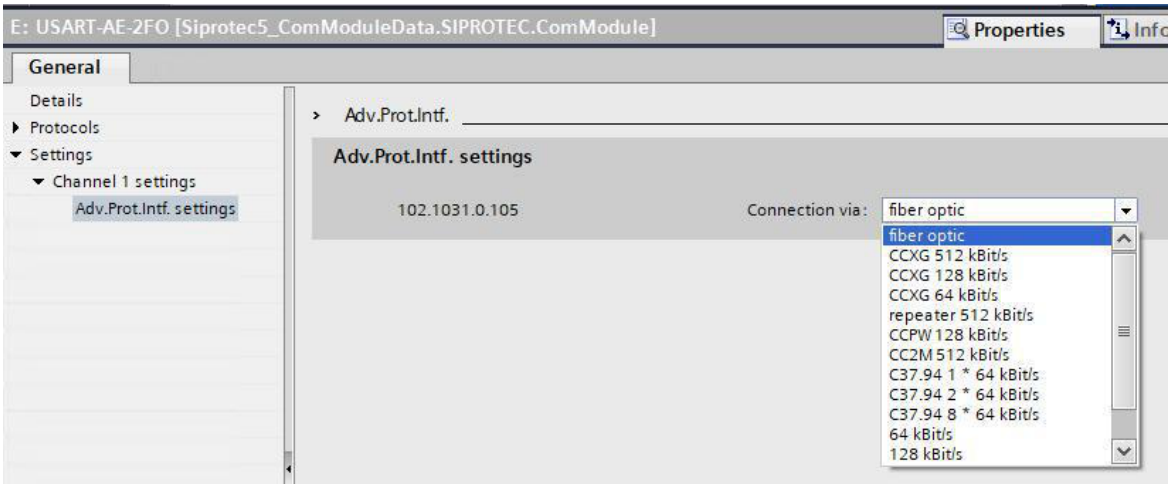


Steps during Configuration

Siemens recommends the following procedure when configuring the advanced protection communication:

- Select the desired communication module.
- Select the protocol ***Adv.Prot.Intf.***.

- The further parameterization depends on the selected communication module and is described in the following under:
  - *Advanced Protection Interface for a USART Communication Module, Page 185*
  - *Advanced Protection Interface for an Ethernet-BD Communication Module, Page 187*



Advanced Protection Interface for a USART Communication Module

[sc_USART_01, 1, en_US]

Figure 3-93 USART Communication Module: Selection of the Protocol Advanced Protection Interface

After selecting the protocol, click **Settings** in the right column to get to the connection settings of the USART protection-interface module for channel 1.

[sc_USART_02, 1, en_US]

Figure 3-94 USART Communication Module: Settings for the Advanced Protection Interface

Parameter: Connection via

- Default setting **(_:105) Connection via** = ***fiber optic***

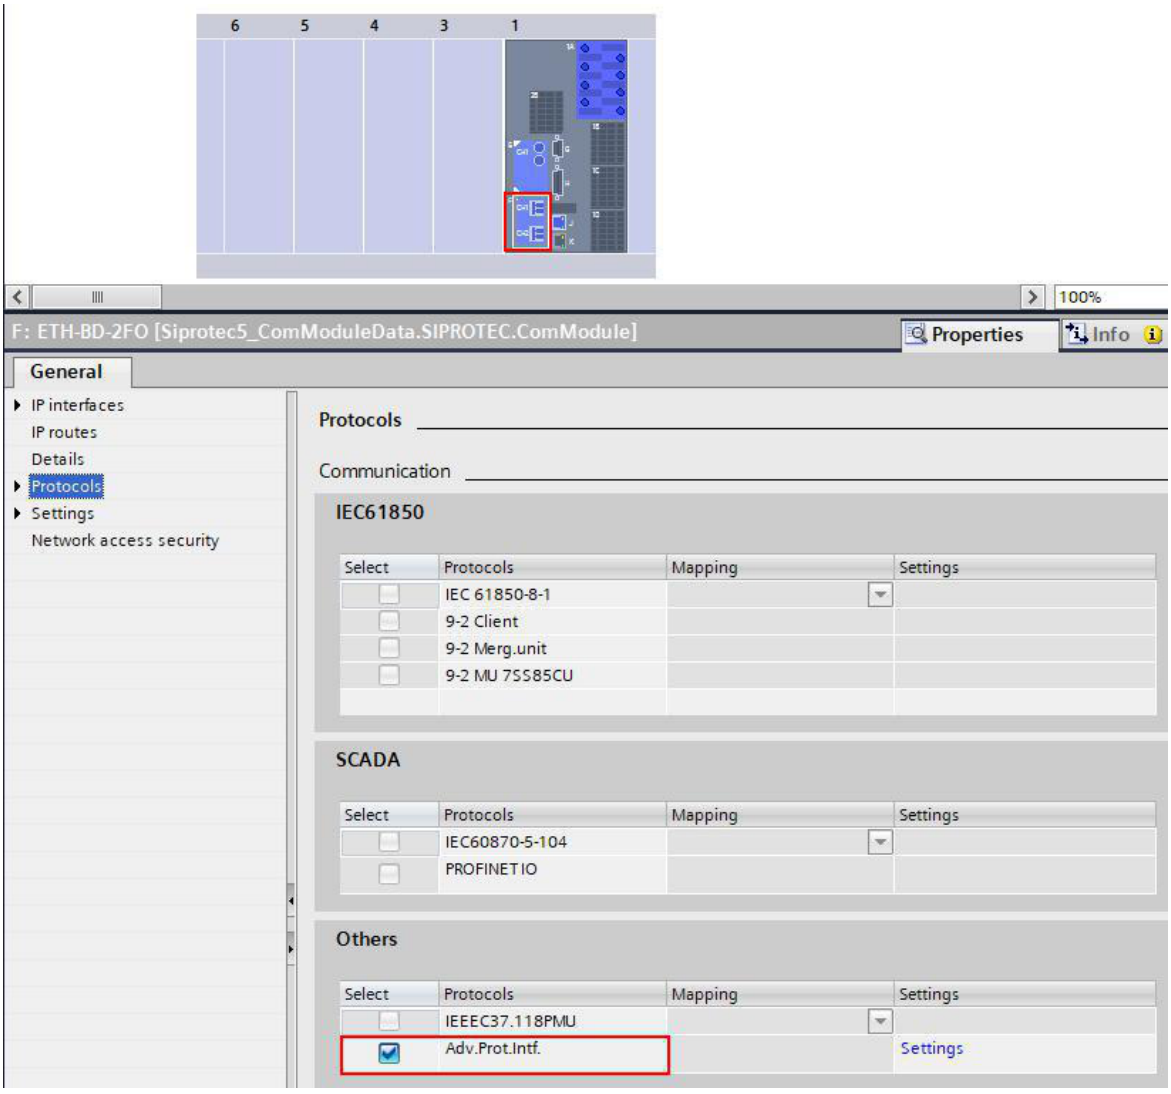
The **Connection via** parameter is used to set the bit rate required for the protection interface. Different discrete values can be entered depending on the means of communication (see following table).

Table 3-19 Communication Media

Communication Media	See	Setting Value	Bit Rate
Fiber-optic direct connection	*Figure 3-58* to *Figure 3-62*	***fiber optic***	2 MBit/s
CC-XG-512 communication converter	*Figure 3-63*	***CCXG 512 kBit/s***	512 kBit/s
CC-XG-128 communication converter	*Figure 3-63*	***CCXG 128 kBit/s***	128 kBit/s
CC-XG-64 communication converter	*Figure 3-63*	***CCXG 64 kBit/s***	64 kBit/s
Repeater 512 communication converter	*Figure 3-66*	***repeater 512 kBit/s***	512 kBit/s
CC-CC-128 communication converter	*Figure 3-65*	***CCPW 128 kBit/s***	128 kBit/s
CC-2M-512 communication converter	*Figure 3-64*	***CC2M 512 kBit/s***	512 kBit/s
Multiplexer with C37.94 interface	*Figure 3-67*	***C37.94 1 * 64 kBit/s*** ***C37.94 2 * 64 kBit/s*** ***C37.94 8 * 64 kBit/s***	64 kBit/s 128 kBit/s 512 kBit/s
Other (freely adjustable bit rates for a direct connection for special applications)		***64 kBit/s*** ***128 kBit/s*** ***512 kBit/s*** ***2048 kBit/s***	64 kBit/s 128 kBit/s 512 kBit/s 2048 kbit/s

Parameter: Multiplex operation

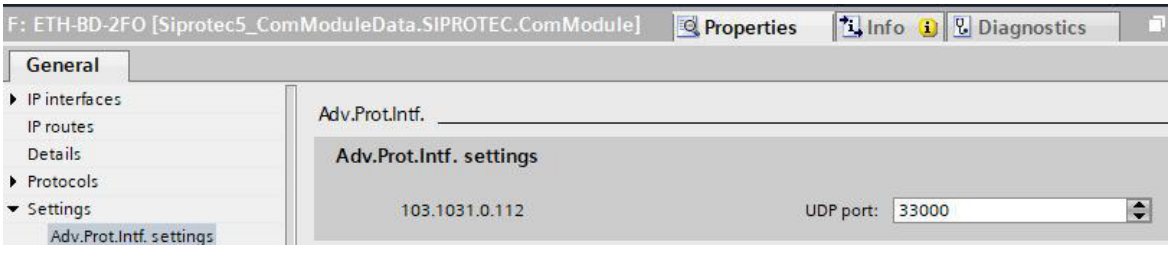
- Default setting **(_:112) Multiplex operation** = ***no***



With the parameter **Multiplex operation**, you can designate the physical channel for multiplex operation. You can then route 2 protection interfaces to this channel.
Refer to *3.6.3 Function Description*.

NOTE

For safety reasons, you cannot route 2 protection interfaces from the same device combination to one channel, as this results in apparent redundancy.



Advanced Protection Interface for an Ethernet-BD Communication Module

[sc_ETH-BD_01, 1, en_US]

Figure 3-95 Ethernet-BD Communication Module: Selection of the Protocol Advanced Protection Interface

After selecting the protocol, click **Settings** in the right column to get to the connection settings of the Ethernet-BD communication module for channel 1.

[sc_ETH-BD_02, 1, en_US]

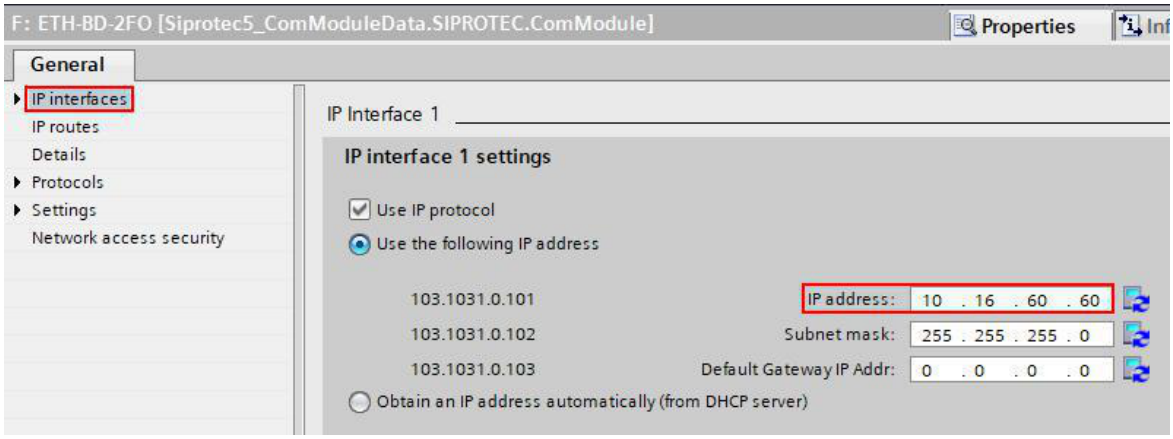


Figure 3-96 Ethernet-BD Communication Module: Settings for the Advanced Protection Interface

Parameter: UDP Port

- Default setting **`(_:112) User port`** = ***33000***

With the **UDP port** parameter, you set the value of the destination port in the UDP header of the protection-interface IP messages. You must set the same value for the parameter **UDP port** for all protection devices of a device combination that use the IP-based protection interface. Different device combinations can use the same value for the **UDP port** parameter. Normally, the default setting can always be applied. It can be necessary, for example, due to firewall policies, to configure a UDP port that differs from the default setting.

Parameterize the IP address of the Ethernet-BD communication module in the properties of the module.

[sc_IPadr, 1, en_US]

Figure 3-97 Parameterization of the IP Address for the Ethernet-BD Communication Module

The configuration and parameterization of the protection-interface communication module is now complete.

3.6.6.5 Setting Notes for the Protection Interface

The chapter provides setting notes for the logical protection interface (FB **Protection interface**).

Parameter: PI assignment

- Default setting **(_:5161:120) PI assignment** = ***Setting options depend on configuration***

In addition, you must select the channel for the protection interface in DIGSI 5 as follows: **Project tree** > **Prot. com.** > **Prot. interf.**.

In the input area under **PI assignment**, select the channel of a communication module that supports the required protection-interface protocol. As a prerequisite for this, you must have selected the protocol ***Advanced protection interface*** for the channel of the desired communication module, see *3.6.6.4 Configuration of the Advanced Protection Communication in DIGSI 5*.

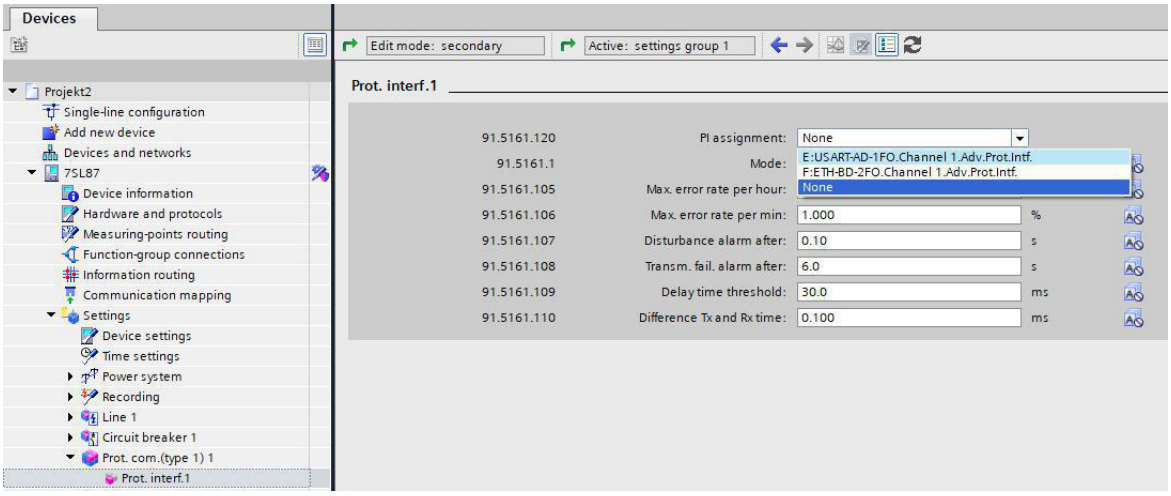

Figure 3-98 Assignment of the Protection-Interface Channel to the Protection Interface

Parameter: Max. error rate per hour

- Default setting **(_:5161:105) Max. error rate per hour** = *1.0 %*

If the number of faulty telegrams per hour exceeds the value set in the parameter **Max. error rate per hour**, you receive the error message *Error rate / hour exc.*.

Parameter: Max. error rate per min

- Default setting **(_:5161:106) Max. error rate per min** = *1.0 %*

If the number of faulty telegrams per minute exceeds the value set in the parameter **Max. error rate per min**, you receive the error message *Error rate / min exc.*.

Parameter: Disturbance alarm after

- Default setting **(_:5161:107) Disturbance alarm after** = *100 ms*

With the parameter **Disturbance alarm after**, you determine the time delay after which faulty or missing telegrams are signaled as disturbed with the indication *Status of lay. 1 and 2 = PI data fault*.

Parameter: Transm. fail. alarm after

- Default setting **(_:5161:108) Transm. fail. alarm after** = *6.0 s*

With the parameter **Transm. fail. alarm after**, you determine the time delay after which a communication failure is signaled with the indication *Status of lay. 1 and 2 = PI data failure*.

Parameter: Delay time threshold

- Default setting **(_:5161:109) Delay time threshold** = *30.0 ms*

The time taken to transmit and receive a signal via a protection connection is called the signal-transit time. You can monitor the signal-transit time. For the **Delay time threshold**, the default setting is selected in such a way that it is not exceeded by normal communication networks. If the signal-transit time is exceeded during operation (for example, upon switchover to another transmission path), the indication **Time delay exceeded** is issued.

Increased runtimes only affect the operate time, and therefore the fault-clearing time of the protection functions that use the protection interface. If you use the **Line differential protection** function, this remains in effect.

Parameter: Difference Tx and Rx time

- Default setting **(_:5161:110) Difference Tx and Rx time** = ***0.1 ms***

For a time synchronization of the measured values with microsecond accuracy by means of telegram measurement, the signal-transit times in the transmission and receive direction must be approximately the same. The device monitors the signal-transit times in the transmission and reception direction.

With the parameter **Difference Tx and Rx time**, you can set a maximum permitted signal-transit time difference between the transmission and reception paths (runtimes unbalanced). Set the parameter **Difference Tx and Rx time** to the maximum difference expected.

Set this value to ***0*** for a direct fiber-optic connection. A higher value is necessary for transmission via communication networks. ***0.1 ms*** (recommended setting value) is the reference value.

If the difference in the signal-transit times between the transmission and reception path exceeds the set value, the indication *Time delay jump* is issued.

If the difference in the signal-transit times between the transmission and reception path exceeds the set value and remains for more than 5 s, the indication *Time delay different* is issued. The **Line differential protection** function is no longer working properly and is ***ineffective***.

NOTE

The parameter **Difference Tx and Rx time** is only visible if the **Line differential protection** function is instantiated and the parameter **Synchronization** is not set to ***External synch. only***.

NOTE

If you use a multiplexer with a C37.94 interface as a communication medium, Siemens recommends a setting value of ***0.25 ms*** to ***0.6 ms***.

Parameter: Synchronization

- Default setting **(_:5161:113) Synchronization** = ***External synchron. off***

With the parameter **Synchronization**, you control the time synchronization of the measured values with microsecond accuracy.

The parameter **Synchronization** is only visible if you have instantiated the FB **External synchronization** from the Global DIGSI 5 library in the FG **Protection communication**.

If you have not instantiated the FB **External synchronization**, the measured values are time-synchronized internally with microsecond accuracy.

Parameter Value	Description
External synchron. off	The external synchronization is disabled: No external synchronization is performed on the protection interface. Select this setting value if you do not expect any differences between the signal-transit times in the transmission and reception directions. Then, the measured values are only synchronized internally with the telegram measurement.
Telegr. and ext. synch.	Synchronization via telegram measurement and external synchronization: The measured values are synchronized internally with the telegram measurement, supported by the external synchronization. The synchronization is possible via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver and configurable in the FB **External synchronization**. In this case, an existing line differential protection is only enabled when a new connection is established and one of the following conditions is met. • The protection communication link is synchronized with the help of the external synchronization. • Symmetric signal-transit times are signaled via the binary input signal *>Sync reset* or the controllable *Reset synchronization*. This means that the signal-transit times are the same in the send and receive direction.
Telegr. or ext. synch.	Telegram measurement or external synchronization: The measured values are synchronized internally with the telegram measurement, supported by the external synchronization. The synchronization is possible via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver and configurable in the FB **External synchronization**. An existing line differential protection is enabled immediately upon renewed establishment of a connection (data telegrams are received). The internal synchronization is used up to synchronization.
External synch. only	External synchronization only: The measured values are synchronized only via the external synchronization. You can set the external synchronization in the FB **External synchronization**. This enables synchronization via the IEEE 1588 protocol or via the synchronous pulse of a satellite receiver.

NOTE

If the protection interface is connected to a channel on a USART communication module (see *Parameter: PI assignment, Page 188*), the external synchronization is used to take into account the signal-transit times in the transmission and receive direction.

If the external synchronization fails for a short time, for example, due to a receiving interference or an unfavorable satellite position for a brief period, the internal synchronization via the telegram measurement is still active.

NOTE

If the protection interface is connected to a channel on an Ethernet-BD communication module (see *Parameter: PI assignment, Page 188*), the parameter **Synchronization** is permanently set to ***External synch. only***.

Parameter: FB External synchron.

- Default setting **(_:5161:117) FB External synchron.** = ***Ext. synchronization 1***

With the external synchronization, the time synchronization of the measured values with microsecond accuracy is possible through an external synchronization source.

The parameter **FB External synchron.** is only visible if you have instantiated at least 1 FB **External synchronization** from the Global DIGSI 5 library into the FG **Protection communication**. You can instantiate a maximum of 2 FBs for external synchronization.

With the parameter **FB External synchron.**, you specify whether the protection interface uses the FB **Ext. synchronization 1** or the FB **Ext. synchronization 2** for the synchronization. You parameterize the synchronization source in the corresponding FB **External synchronization**, see *3.6.6.9 Setting Notes for External Synchronization*.

NOTE

The external synchronization is possible separately for each protection interface.

Parameter: Check synchron.-source

- Default setting **(_:5161:121) Check synchron.-source** = ***yes***

With the parameter **Check synchron.-source**, you can switch the synchronization-sources check on or off. During the check of the synchronization sources on the ends of a protection connection, a check is conducted as to whether both synchronization sources are working in the same synchronization status ***SmpSynch***.

If both synchronization sources are working in the synchronization status ***SmpSynch*** = ***global***, the inspection has been passed.

If both synchronization sources are working in the synchronization status ***SmpSynch*** = ***local***, that is decoupled from a global reference time, an additional check is conducted as to whether the synchronization source (***gmIdentity***) is the same. Synchronicity can only be guaranteed if the synchronization sources are the same.

If the synchronization sources display a different synchronization status, that is one displays the synchronization status ***SmpSynch*** = ***local*** and the other the synchronization status ***SmpSynch*** = ***global***, synchronization cannot be guaranteed.

Siemens recommends using the default setting **Check synchron.-source** = ***yes***.

If you have problems with the synchronization-source check, you can switch off the synchronization-source check. Switch off the synchronization-source check only if the synchronization sources are synchronous at the end of their protection connection.

The parameter **Check synchron.-source** is visible only if the parameter **(_:5161:113) Synchronization** is set to ***External synch. only***.

NOTE

If you use **PPS electrical (port G)** as the synchronization source, the synchronization status (***SmpSynch***) is permanently set to ***global***.

If you use **PPS optical (USART)** as the synchronization source, you can use the parameter (_:107) **Received. SmpSynch** to set the synchronization status to (***SmpSynch***) ***local*** or ***global***.

For a synchronization with microsecond accuracy, for example, for the **Line differential protection**, set the parameter (_:107) **Received. SmpSynch** = ***global***.

3.6.6.6 Indications and Measured Values of the Advanced Protection Interface

Each individual protection interface provides different indications for commissioning and diagnostics of communication:

Indication ***(_:5161:301) Status of lay. 1 and 2***

The indication ***(_:5161:301) Status of lay. 1 and 2*** informs you about the status of the connection. The following indications are possible:

Table 3-20 Status Indications Status of lay. 1 and 2

Indication	Description
initialized:	The protection interface is not connected and is in the Initial state.
PI connected:	The protection interface is connected to the protection interface of the partner device.
PI data fault:	The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:107) Disturbance alarm after**.
PI data failure:	The protection interface has not received any valid telegrams for the time set in parameter **(_:5161:108) Transm. fail. alarm after**.
not existing:	The protection interface has not been assigned to a communication channel.

Indication *(_:5161:302) Status of lay. 3 and 4*

The indication *(_:5161:302) Status of lay. 3 and 4* informs about errors during the connection establishment. The following indications are possible:

Status indication	Description
no error:	No errors occurred during the connection establishment.
SW ver.incomp.:	The connection is not established because the firmware versions of the devices are incompatible. Update the firmware.
wrong dev. ID:	The connection is not established because the device address of the local device or the partner device is incorrect or set incorrectly. Check the settings for the parameters **Address of device 1** to **Address of device n** (_:5131:102 and following).
const.sett.error:	The connection is not established because the parameters are set differently. Check whether the parameter **(_:5131:122) Lowest appearing bit rate** has been set the same in all devices in the device combination.
diff.sett error:	The connection is not established because the parameters are set differently. The line differential protection settings for the connected devices are incompatible. Check whether both devices are set to operate with or without line differential protection. The rated current of the line (parameter **(_:9001:101) Rated current**) must have the same setting in all devices. With a transformer in the line, the **(_:9001:103) Rated apparent power** must be set to the same value in all devices. For further information, see *6.7 Line Differential Protection*.
net mirroring	The connection is not established. The protection interface is receiving its own data. Check the wiring.
wrong dev. idx.	The connection is not established because the device index of the local device or the partner device is incorrect. Check the setting for the parameter **(_:5131:101) Local device is device**.

Furthermore, the following output signals are available:

Output Signal	Description
(_:5161:303) Connection broken	The signal *Connection broken* indicates that during a parameterized time (parameter **(_:5161:107) Disturbance alarm after**) no telegrams or faulty telegrams were continuously received. If the indication *Connection broken* is issued, the affected protection connection is reset. This can cause the blocking of an active line differential protection or a ring topology can change to a chain topology.
(_:5161:316) Error rate / min exc.	The signal *Error rate / min exc.* indicates that the set maximum error rate per minute (Parameter **(_:5161:106) Max. error rate per min**) has been exceeded. In this manner, a brief increase of the operate time and thus of the fault-clearing time is possible for the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:317) Error rate / hour exc.	The signal *Error rate / hour exc.* indicates that the set maximum error rate per hour (Parameter **(_:5161:105) Max. error rate per hour**) has been exceeded. In this manner, a brief increase in operate time and thus the fault-clearing time is possible for the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:318) Time delay exceeded	The signal *Time delay exceeded* indicates that the threshold value for the set signal runtime (parameter **(_:5161:109) Delay time threshold**) has been exceeded. Increased runtimes only affect the operate time, and therefore the fault-clearing time of the protection functions using the protection interface. If you use the **Line differential protection** function, this remains in effect.
(_:5161:319) Time delay different	The signal *Time delay different* indicates that the threshold value for the difference in signal runtimes in the transmission and reception direction (asymmetrical runtimes) has been exceeded. The setting value results from the setting value of the parameter **(_:5161:110) Difference Tx and Rx time**. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***. If the indication *Time delay different* appears, the **Line differential protection** function is no longer working properly and is ***ineffective***.
(_:5161:320) Time delay jump	The signal *Time delay jump* indicates that the signal runtimes of the data changed abruptly. This is caused by a switchover of the communication path in the communication network. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***.
(_:5161:321) PI synchronized	The signal *PI synchronized* indicates that the synchronization with microsecond accuracy of the measured values transferred between the local device and partner device is working correctly. The indication is visible only if the parameter **(_:5161:113) Synchronization** is not set to ***External synch. only***.
(_:5161:340) Telegram lost	The signal *Telegram lost* indicates that an expected telegram has failed to arrive or a faulty telegram has been received. If you want to assign the communication failures or faults to other events, route the signal *Telegram lost* temporarily into the operational log. Such events can be switching operations in the primary system or operations on the components of the communication network. **Note:** If the signal is constantly routed, the operational log can overflow. Siemens recommends routing the signal only for clarification of problems.

Output Signal	Description
(_:5161:343) Partner	The indication shows the address of the partner device. A value of 0 means that no partner address is available.
(_:5161:323) PPS: time del. unsym.	This indication is only visible if you are working with a synchronous pulse. The indication shows that the difference in the signal runtimes between the sending and receiving path exceeds the value set with the parameter **(_:5161:110) Difference Tx and Rx time**. **Note:** The **Line differential protection** function remains ***effective***.
(_:5161:324) PI with PPS synchron.	This indication is only visible if you are working with a synchronous pulse. This indication is only visible if, in parallel to synchronization with the synchronization pulse, you are also working with the synchronization via telegram measurement. If both synchronization methods are working properly, the indication *PI with PPS synchron.* = RAISING is generated.

Measured Values of the Protection Interface

The protection interface provides the following measured value for the diagnosis of the protection-interface communication:

Measured Value	Description
(_:5161:308) Tx tel/h	Telegrams transmitted during the last hour
(_:5161:309) Rx tel/h	Telegrams received during the last hour
(_:5161:310) Tx tel/min	Telegrams transmitted during the last minute
(_:5161:311) Rx tel/min	Telegrams received during the last minute
(_:5161:312) Tx err/h	Transmission failure rate during the last hour
(_:5161:313) Rx err/h	Receive error rate during the last hour
(_:5161:314) Tx err/min	Transmission failure rate during the last minute
(_:5161:315) Rx err/min	Receive error rate during the last minute
(_:5161:325) Aver.Δt	Average signal runtime (average value of the runtime in transmission and reception direction divided by 2, without external synchronization)
(_:5161:326) Rec. Δt	Signal runtime for reception path (with external synchronization)
(_:5161:327) Sen. Δt	Signal runtime for transmission path (with external synchronization)
(_:5161:334) Miss.tel/min	Number of telegram failures within the last minute
(_:5161:335) Miss.tel/h	Number of telegram failures within the last hour
(_:5161:336) Miss.tel/d	Number of telegram failures within the last day
(_:5161:337) Miss.tel/w	Number of telegram failures within the last week
(_:5161:338) M. loss/d	Longest lasting telegram failure within the last day
(_:5161:339) M. loss/w	Longest lasting telegram failures within the last week
(_:5161:331) Recept.	Receipt of a telegram (0 = no receipt, 1 = receipt) You can use this indication to make the telegram exchange visible in the fault record.

NOTE

You can reset the measured values of the protection interface directly in the device. Proceed as follows:
Device functions > Protection comm. (Type x) > Protection interface y > Reset measured values.

3.6.6.7 Setting Notes for the Device Combination

In the **Project tree** > **Settings** > **Protection comm. (type 1)** or **Protection comm. (type 2)**, select the function block **Device combination**. In the input area, you parameterize the general settings for the device combination, instantiate the number of devices in the device combination, and set the parameters for each device. A device combination consists of at least 2 devices.

Parameter: Local device is device

- Default setting **(_:2311:101) Local device is device** = ***1***

With the **Local device is device** parameter, you set the index (number) of your device in the device combination. A maximum of 6 devices can be present in a device combination.

Parameter: Lowest appearing bit rate

- Default setting **(_:2311:122) Lowest appearing bit rate** = ***64 kBit/s***

With the parameter **Lowest appearing bit rate**, you set the lowest bit rate occurring in the device combination. This value determines the maximum number of signals and measured values to be transferred in the **Remote data** function within the device combination.

EXAMPLE:

For a device combination consisting of 3 devices in a ring topology with 2 fiber-optic connections (2 MBit/s) and a 64-kBit/s connection, set the smallest value (64 kBit/s) in each device.

Apart from the default value, you can set the following bit rates:

- ***128 kBit/s***
- ***512 kBit/s***
- ***2048 kBit/s***

NOTE

If you use optical fibers for all protection connections, set the value to ***2048 kBit/s***.

Connection mode

- Default setting **(_:2311:126) Connection mode** = ***SIPROTEC 5***

With the parameter **Connection mode**, you select the device type with which the SIPROTEC 5 device works in the device combination via the protection connections.

NOTE

As soon as a SIPROTEC 4 device is present in the device combination, the SIPROTEC 5 devices must operate in a compatibility mode. For this reason, the parameter **Connection mode** must be set to the same value in all SIPROTEC 5 devices in the device combination. Select the type of SIPROTEC 4 device from the following table:

Parameter Value	Description
SIPROTEC 5	The SIPROTEC 5 device works with a SIPROTEC 5 device in the device combination.
SIPROTEC 4 7SD610	The SIPROTEC 5 device works with a SIPROTEC 4 differential protection device 7SD610 with firmware version V4.72 and higher in the device combination.
SIPROTEC 4 7SD5	The SIPROTEC 5 device works with a SIPROTEC 4 differential protection device 7SD5x with firmware version V4.72 and higher in the device combination.
SIPROTEC 4 7SA5/6	The SIPROTEC 5 device works with a SIPROTEC 4 distance protection device 7SA522 and 7SA6x with firmware version V4.70 and higher in the device combination.

Parameter: Dev. comb. is time source

- Default setting **(_:2311:129) Dev. comb. is time source** = ***yes***

The parameter **Dev. comb. is time source** is only visible if you have instantiated several function groups **Protection comm.** and you have selected the setting value ***PI*** for the parameters **Time source 1** or **Time source 2**.

The parameter **Dev. comb. is time source** determines from which FG **Protection comm.** the time is taken over.

Parameter: Protection com.

- Default setting **(_:2311:128) Protection com.** = ***Type 1 (Line diff. prot.)***

The parameter **Protection com.** is write-protected and displays only the type of the instantiated device combination.

The device combination ***Type 1 (Line diff. prot.)*** supports the function **Line differential protection**. The device combination ***Type 2 (no Line diff. pr.)*** does not support the function **Line differential protection**.

NOTE

In the Global DIGSI 5 library, the function groups **Protection communication type 1 (line diff. protection)** and **Protection com. Type 2** are available for the advanced protection communication. When instantiating the respective function group, the corresponding type of the device combination is automatically pre-instantiated.

NOTE

If you have instantiated the FG **Protection com. Type 2**, the **Device combination Type 2** is automatically pre-instantiated in this FG and the **Line differential protection** function is not supported.

If you subsequently want to use the **Line differential protection** function in the device combination of the FG **Protection com. Type 2**, proceed as follows:

- In the DIGSI 5 project tree, delete the function block **Device combination** from the **FG protection comm. (type 2)**.
- Instantiate the function block **Device combination type 1 (line diff. protection)** from the Global DIGSI 5 library into the FG **Protection com. Type 2**.
- Parameterize the **device combination** in the input area again.
- Reroute the indications of the device combination in the DIGSI 5 information routing.

All other parameterizations and routings are retained!

Parameter: Device index

- Default setting **(_:22711:101) Device index** = ***1***
- Default setting **(_:22712:101) Device index** = ***2***
- Default setting **(_:22713:101) Device index** = ***3***
- Default setting **(_:22714:101) Device index** = ***4***
- Default setting **(_:22715:101) Device index** = ***5***
- Default setting **(_:22716:101) Device index** = ***6***

The value of the parameter **Device index** is the number of the device in the device combination. Set the device index in all devices of a device combination for the same devices in the same way. The device indices must start with 1 and be incremented continuously. DIGSI 5 assigns the device indices automatically. You can change the device indices if necessary.

NOTE

The device with the **Device index** = ***1*** is the timing-master device in a device combination.

If all other devices in the device combination are to obtain their time from the timing-master device, consider the following

- Set the **Device index** to ***1*** for the timing-master device.
- Parameterize the other devices in such a way that they get their time from the timing-master device via the protection connections.

  For more information, refer to *3.7.3 Function Description*. Select ***Protection interface*** as the adjustable synchronization option.

  In the timing-master device, you must **not** set the protection interface as the synchronization source!

Parameter: Address in Device combi.

- Default setting **(_:22711:102) Address in Device combi.** = ***101***
- Default setting **(_:22712:102) Address in Device combi.** = ***102***
- Default setting **(_:22713:102) Address in Device combi.** = ***103***
- Default setting **(_:22714:102) Address in Device combi.** = ***104***
- Default setting **(_:22715:102) Address in Device combi.** = ***105***
- Default setting **(_:22716:102) Address in Device combi.** = ***106***

With the parameter **Address in Device combi.**, you assign a unique and unambiguous address for each device.

NOTE

If the preset values do not fit, Siemens recommends the following procedure:

Define a number for the device combination that is unambiguous in your area of responsibility and that must be at least 2 digits, for example, 100. The setting value of the parameter **Address in Device combi.** is then calculated as follows: **Number in the device combination** + **Device index**.

For device **2**, this leads to **Address in Device combi.** = ***102***.

Parameter: IP Address

- Default setting **(_:22711.103) IP address** = ***0.0.0.0***
- Default setting **(_:22712.103) IP address** = ***0.0.0.0***
- Default setting **(_:22713.103) IP address** = ***0.0.0.0***
- Default setting **(_:22714.103) IP address** = ***0.0.0.0***
- Default setting **(_:22715.103) IP address** = ***0.0.0.0***
- Default setting **(_:22716.103) IP address** = ***0.0.0.0***

The IP address of the local device is taken from the settings of the Ethernet-BD communication module and displayed. The local IP address cannot be edited at this point.

NOTE

If all devices of a device combination are equipped with an Ethernet-BD communication module and use the IP communication, you must enter the IP addresses for all other devices in the device combination here. The topology detection automatically sets a ring or chain topology.

NOTE

If you have a hybrid configuration, that is not all protection connections of a device combination use the IP communication, you must observe the following when setting the IP addresses:

- The topology detection does not generate the topology automatically.
- First define the order for the communication between the devices. Define chain or ring topologies for this purpose.
  The defined topology results in the partner devices for each device, with which the device communicates directly.
  Only set the IP addresses for the partner devices that are equipped with an Ethernet-BD communication module here.
- You can find examples of the parameterization of the IP addresses in hybrid configurations in the chapters *3.6.8.4 Device Combination of 3 Devices and Hybrid Communication Media* and *3.6.8.5 Device Combination of 6 Devices and Hybrid Communication Media*.

Indications and Measured Values in the Device Combination

Indication	Meaning
(_:3321:2311:301) Status of topo. recog.	The devices form a topology via the protection connections. This indication shows the status of the topology detection and can have the following values: • *Unknown*: The topology is unknown. • *Invalid*: The detected topology is not supported. • *Transient*: The topology has just been modified. • *Valid*: The topology has been detected. The indication *Devices form* shows the type of the detected topology.
(_:3321:2311:302) Topology is	The indication shows whether all configured devices in the device combination communicate with each other via the protection connections. The indication can have the following values: • *Unknown*: The topology is unknown. • *Incomplete*: At least one device in the device combination does not communicate via the protection connections. • *Complete*: All configured devices in the device combination communicate via the protection connections.

Indication	Meaning
(_:3321:2311:303) Devices form	This indication shows the type of the detected topology that the devices in the device combination form via the protection connections. The indication can have the following values: • *Unknown topol*: The topology is unknown. • *Chain topology*: The devices and their protection connections form a chain topology. • *Ring topology* The devices and their protection connections form a ring topology.
(_:3321:2311:304) Number of detect. dev.	The indication shows the number of devices that communicate via the protection connections in the device combination.

Indication and Measured Values of the Devices

The following indications and measured values are displayed for each device in the device combination and are explained using the example of a device.

Indication	Meaning
(_:22711:300) Dev.addr.	This indication shows the address of the device.
(_:22711:318) is present	This indication shows whether the device is involved in protection communication.
(_:22711:317) is logged off	This indication shows whether the local device has been logged off. If the device has been logged off, it is no longer involved in communication via the protection interfaces. If a device has been logged off, information relevant for the protection functions is no longer exchanged.
(_:22711:301) circuit breaker	This indication shows the position of the circuit breaker and can have the following values: • *0*: The switch position of the circuit breaker is unknown. • *1* The circuit breaker is open. • *2* The circuit breaker is closed.
(_:22711:328) Line diff. test [13]	This message indicates whether the function **Line differential protection** is in the state ***Test*** or ***Test/Relay blk.***.
(_:22711:329) Local Line diff. test [13]	This message indicates whether the function **Line differential protection** is in the special test mode *Test local device*.

3.6.6.8 Constellation Measured Values for Type 1 and Type 2

NOTE

The constellation measured values are only available for the FG **Line**.

Each device in the device combination determines measured values predefined by Siemens, known as constellation measured values. You can find the constellation measured values in the DIGSI 5 information routing under the FG **Protection comm. (Type x)** > **Device combination** > **Device x**. The following measured values and indications are issued for each device:

[13] This message is only available in the FG Protection communication type 1 (line diff. protection).

Measured value	Meaning
(_:3321:22711:302) Vph	This measured value shows the voltage of the 3 phases that is synchronized with all devices of the device combination. The absolute value and angle are issued for each phase.
(_:3321:22711:303) Iph	This measured value shows the current of the 3 phases that is synchronized with all devices of the device combination. The absolute value and angle are issued for each phase.
(_:3321:22711:304) f	The measured value supplies the locally calculated frequency of the measured voltage or the current.

The constellation measured values have the following properties:

- They are synchronized in the devices in a device combination.
- They are substituted using the protection interface.
- They are available on every device.

You can view the constellation measured values with DIGSI 5.

In the device, current and voltage measured values are displayed in absolute value and phase as a percentage. 100 % conform to the rated current or the rated voltage of the line (see *Figure 3-99*). These measured values are recorded every 2 seconds by the devices involved in the device combination and then sent to the other respective devices. At the same time, the current and voltage values of the different devices are time-synchronous with one another.

When displaying the constellation measured values the local device is prioritized. The device connected directly with DIGSI 5 is the local device.

The reference of the angle information depends on whether a line differential protection has been instantiated in the FG **Line**. If a line differential protection is instantiated, the protection communication is type 1, otherwise type 2.

- Protection communication **Type 1**:
  - The angle values of the voltages show the angle difference between the local and the remote voltage. The local voltage serves as the reference with an angle of 0°.
  - The angle values of the currents show the angle difference between the local and the remote current. The local current serves as the reference with an angle of 0°.
- Protection communication **Type 2**:
  The angles of the phase-to-ground voltages and the phase currents relate to the voltage V_A of the relevant device.

You can find these measured values in the device under the following DIGSI mask:

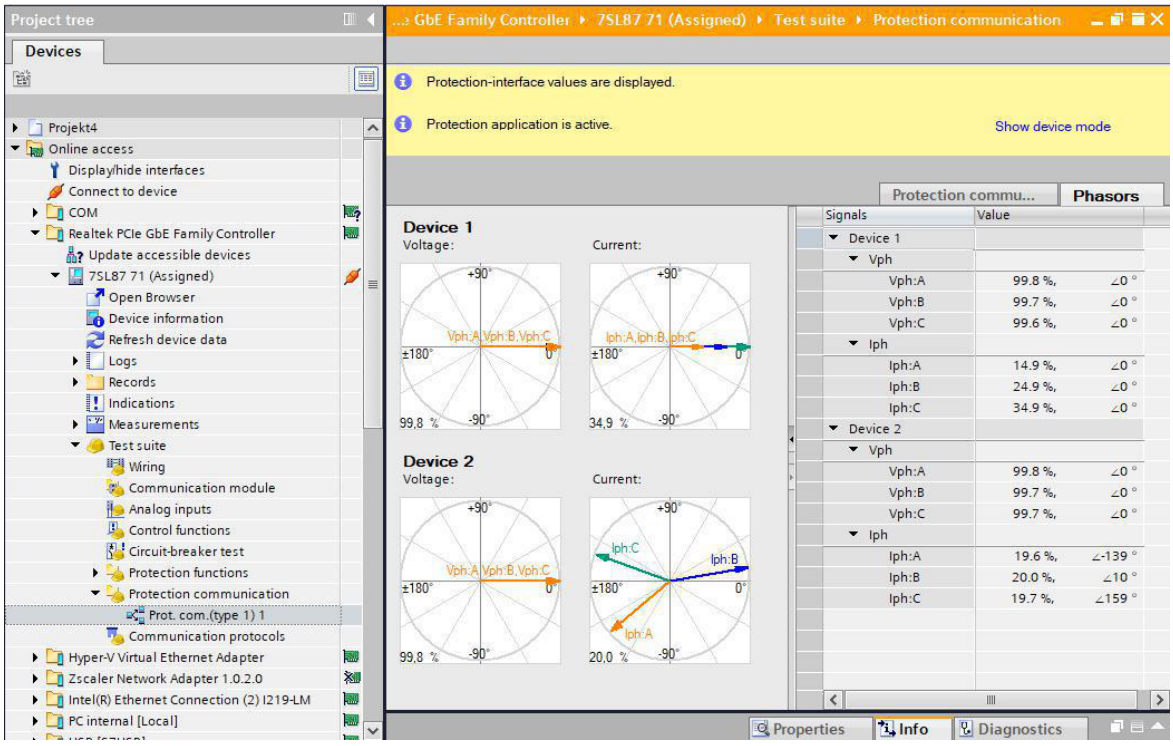

Figure 3-99 Example of Constellation Measured Values with Phases

3.6.6.9 Setting Notes for External Synchronization

With the FB **External synchronization**, you can synchronize the measured values of the devices connected via protection connections with microsecond accuracy using external synchronization sources (1*10E-06 s).

The measured values transmitted via protection communication for the line differential protection must be time-synchronized. The synchronization is possible as follows:

- Internally via telegram measurement
- Externally via the IEEE 1588 protocol
- Externally via a synchronous pulse from a satellite receiver

If you use Ethernet-BD communication modules for the protection communication of the line differential protection, the external synchronization of the measured values transmitted via the protection interface is mandatory.

If you use USART communication modules, you can synchronize the transmitted measured values either internally via telegram measurement or via external synchronization. If you do not use the external synchronization, the device automatically uses the internal synchronization.

If you want to use the external synchronization of the measured values, you must instantiate the FB **External synchronization** from the Global DIGSI 5 library into the FG **Protection comm.**. You can find the **External synchronization** in the Global DIGSI 5 library under **Advanced protection communication** > **Synchronization**.

The external synchronization is possible for line differential protection applications or synchrophasor measuring devices as follows:

- Via a high-precision electrical synchronous pulse (***PPS electrical (Port G)***, 1-second pulse) from a satellite receiver at the time-synchronization interface (Port **G**)
- Via a high-precision optical synchronous pulse (***PPS optical (USART)***, 1-second pulse) from a satellite receiver at a USART communication module
- Via the ***IEEE 1588*** time-synchronization protocol

With external synchronization, you can measure and display the signal-transit time of the transmission and receive path separately. This allows you to achieve maximum sensitivity even with unequal (unbalanced) signal-transit times in communication networks with the line differential protection. For the transmission of protection data in the **type 2** protection communication, different signal-transit times do not play a role.

If an FB **External synchronization** is instantiated, the parameter **Synchronization** is visible in the FB **Protection interf.**. With this parameter, you establish the connection between the protection interface and the type of external synchronization. See *3.6.6.5 Setting Notes for the Protection Interface*.

If you use 2 protection interfaces in the FG **Protection comm.**, you can set a different synchronization source for each protection interface if required. For this use case, you must instantiate 2 FBs **External synchronization** into the FG **Protection comm.** and set the desired synchronization source separately.

Parameter: Name of synchron. block

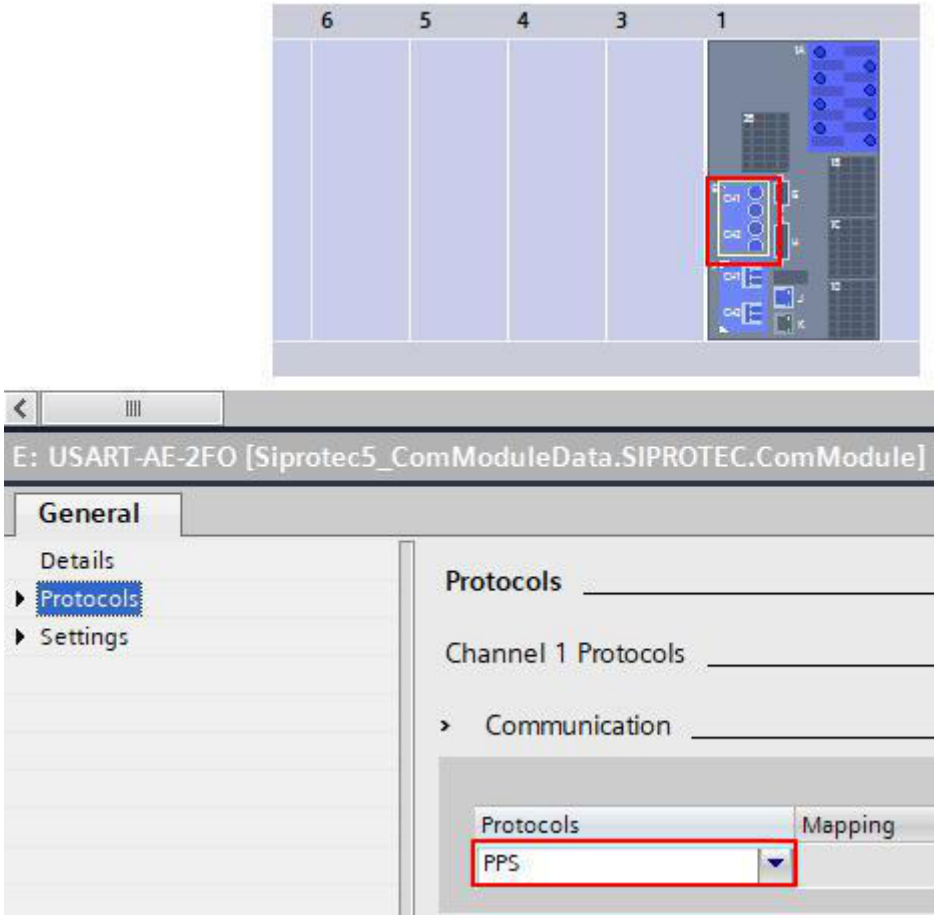
- Default setting **(_:101) Name of synchron. block** = ***Ext. synchronization 1***

The parameter **FB External synchron.** shows the name of the FB **External synchronization**.

If you have instantiated 2 FBs **External synchronization** into the FG **Protection comm.**, you can use this parameter to switch between the FB ***Ext. synchronization 1*** and the FB ***Ext. synchronization 2***.

Parameter: Synchronization source

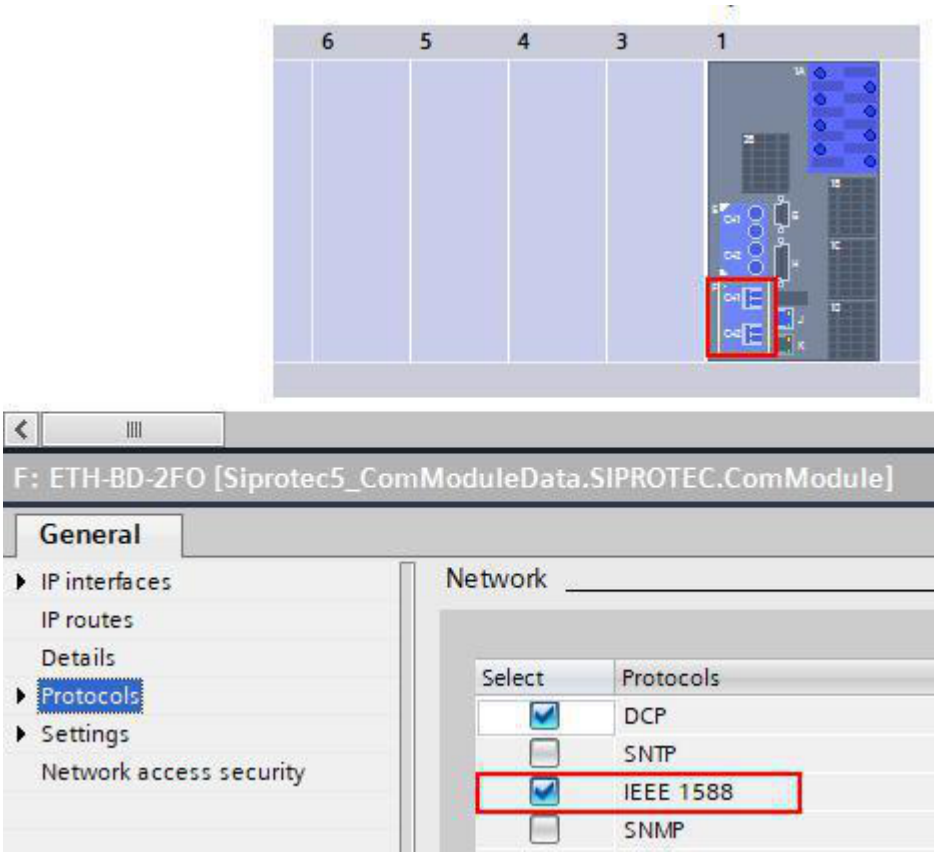
- Default setting **(_:117) Synchronization source** = ***nothing***



With the parameter **Synchronization source**, you select the desired synchronization source for the external synchronization of the measured values.

NOTE

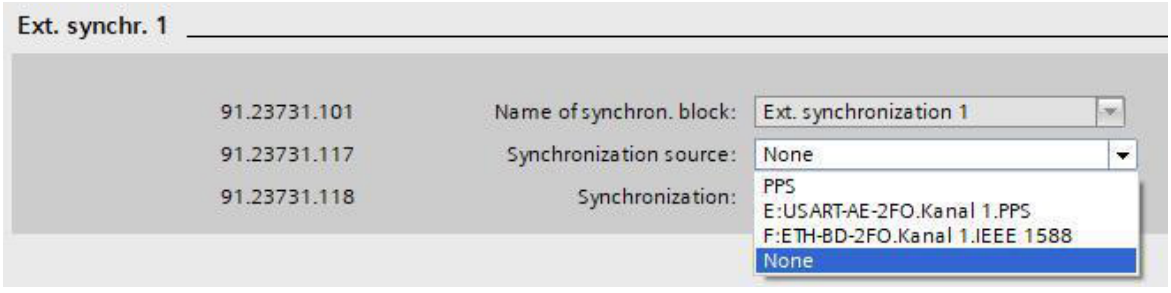
The possible setting options of the parameter **Synchronization source** depend on the configuration of the protocol for the respective channel of the communication module.



To display the selection text for the selection of an optical synchronous pulse, you must configure the protocol **PPS** on a USART communication module as follows:

[sc_PPS, 1, en_US]

Figure 3-100 Configuration of the Optical Synchronous Pulse (PPS) on a Channel of a USART Communication Module



To display the selection text for the selection of the protocol IEEE 1588, you must configure the protocol **IEEE 1588** on an Ethernet-BD communication module as follows:

[sc_1588, 1, en_US]

Figure 3-101 Configuration of the Protocol IEEE 1588 on an Ethernet-BD Communication Module

The setting options for the parameter **`Synchronization source`** then look as follows, for example:

[sc_syncopt, 1, en_US]

Figure 3-102 Possible Setting Options for the Synchronization Source

Depending on the configuration, the following synchronization sources are displayed:

Parameter Value	Description
G:Timesynchron..PPS	The electrical synchronization pulse of a satellite receiver (PPS: 1 Pulse Per Second) at the time-synchronization interface Port G is the synchronization source.
[Port]:USART-AD-1FO.Channel 1.PPS	The optical synchronization pulse of a satellite receiver (PPS: 1 Pulse Per Second) on channel 1 of a USART communication module is the synchronization source.

Parameter Value	Description
[Port]:USART-AE-2FO.Channel 2.PPS	The optical synchronization pulse of a satellite receiver (PPS: 1 Pulse Per Second) on channel 2 of a USART communication module is the synchronization source.
[Port]:ETH-BD-2FO.Channel 1.IEEE 1588	The time-synchronization standard IEEE 1588 on an Ethernet-BD communication module is the synchronization source.

NOTE

You can select different synchronization sources for the same protection connection in the devices involved, for example, the synchronization via the **IEEE 1588** protocol in device **1** and via the protocol **PPS** electrical in device **2**.

Siemens recommends using the same synchronization source for the same protection connection. If it is not possible to use the same synchronization source, check the differential current in the line differential protection in the mode **Test on all devices**. If the differential current is not in the expected range, the set synchronization sources are not synchronous to each other and therefore not usable.

NOTE

For detailed information on the communication protocols, refer to the SIPROTEC 5 manual Communication Protocols.

Parameter: Synchronization using

- Default setting **(_:118) Synchronization using** = ***nothing***

This parameter **Synchronization using** cannot be adjusted. The parameter shows further information for the selected synchronization source:

Parameter Value	Description
nothing	You have not selected any external synchronization source.
PPS electrical (Port G)	The electrical synchronization pulse of a satellite receiver (PPS: 1 Pulse Per Second) at the time-synchronization interface Port **G** is the synchronization source.
PPS optical (USART)	The optical synchronization pulse of a satellite receiver (PPS: 1 Pulse Per Second) on channel 1 of a USART communication module is the synchronization source.
IEEE 1588	The time-synchronization standard IEEE 1588 on a BD communication module is the synchronization source.

Parameter: Max. inaccuracy

- Default setting **(_:119) Max. inaccuracy** = ***0,001 ms***

With the **Max. inaccuracy** parameter, you set the maximum expected inaccuracy of the synchronization sourced used. The set value is only effective if the synchronization source used does not supply any information on the current inaccuracy in the synchronization signals. If you no information on the inaccuracy of the synchronization source used, use the default setting.

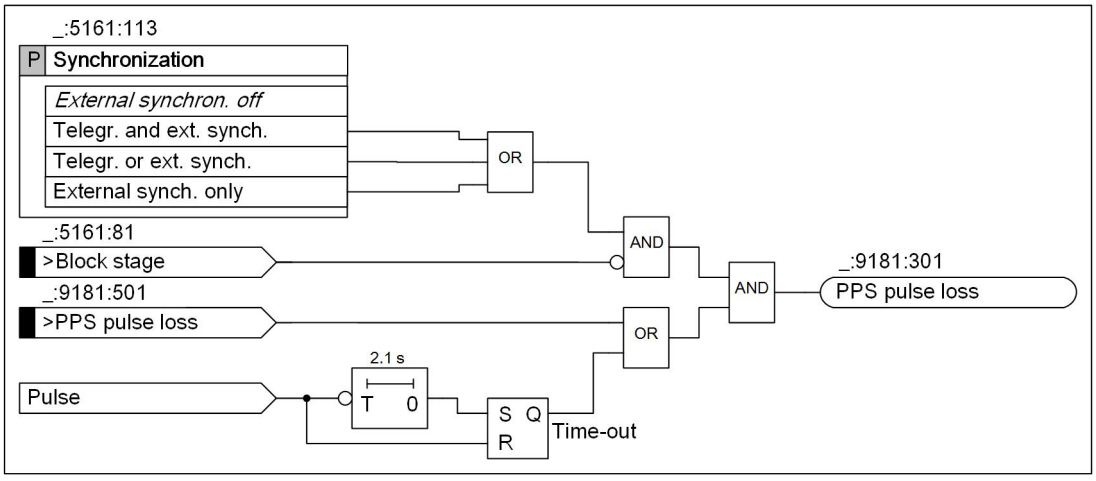
NOTE

The inaccuracy of the synchronization source enters the stabilization of the **Line differential protection** as an error signal.

This means that greater inaccuracy increases the calculated stabilization quantity and makes the **Line differential protection** less sensitive.

If **IEEE 1588** is used as the synchronization source in the synchronization status ***SmpSynch*** = ***global***, accuracy values are supplied with the synchronization signals and the parameter **Max. inaccuracy** is not

used. If the supplied accuracy values become invalid, the value set in the parameter **Max. inaccuracy** is used.



If the synchronization source **IEEE 1588** works in the synchronization status ***SmpSynch*** = ***local***, then the value set in the parameter **Max. inaccuracy** is used as permanently available inaccuracy.

If **PPS electrical (Port G)** or **PPS optical (USART)** are used as synchronization source, then the value set in the parameter **Max. inaccuracy** is used as permanently available inaccuracy.

If a USART communication module with the **PPS** protocol and the **PPS generator** operating mode is also used as a synchronization source at the same time, the value set in the parameter **Max. inaccuracy** is used as permanently available inaccuracy.

3.6.6.10 Indications and Measured Values of the External Synchronization

Indication	Description
(_:501) >PPS pulse loss	The indication *(_:501) >PPS pulse loss* is only visible with the following setting options of the parameter **(_:117) Synchronization source**: • G:Timesynchron.PPS • [Port]:USART-AD-1FO.Channel x.PPS • [Port]:USART-AE-2FO.Channel x.PPS The binary input *(_:501) >PPS pulse loss* can be used to signal an externally detected failure in the PPS synchronous pulse, for example, an error message from the satellite receiver. If the binary input *(_:501) >PPS pulse loss* is set, this leads to the indication *(_:304) Synchronization loss*. The external synchronization detects immediately that there is a problem with the connected synchronization pulse. Otherwise, the problem will only be noticed after approx. 2.1 s – after the test for synchronous-pulse failure.
(_:304) Synchronization loss	The synchronization has failed. This can be due to a problem with the synchronization source. The indication *(_:304) Synchronization loss* shows that the synchronization has failed. This can be due to the following reasons: • The input indication *(_:501) >PPS pulse loss* has occurred. • The synchronous pulse has failed. • The quality of the synchronous pulse is inadequate. • There is another problem with the synchronization source.
(_:305) Synchronization OK	The synchronization is operating correctly.
(_:306) Synchronization pulse	You can use this indication to make the synchronous pulse visible. As a rule, one pulse is generated per second.
(_:307) Synchron. imprecise	If the set synchronization source operates in the ***global*** synchronization status and the time of the synchronization source deviates from the global time by more than 0.5 ms, the indication *Synchron. imprecise* is generated and the line differential protection becomes ineffective. The indication *Synchron. imprecise* is visible if you select ***ETH-BD-2FO.Channel1.IEEE1588*** in the parameter _:103 Synchronization source. The read-only parameter **(_:118) Synchronization using** then displays ***IEEE 1588***.

[lo_pps_syn, 2, en_US]

Figure 3-103 Logic for the Generation of the Indication *>PPS pulse loss*

3.6.6.11 Setting Notes for the Remote Data

Parameter: Dropout Time Prio. x

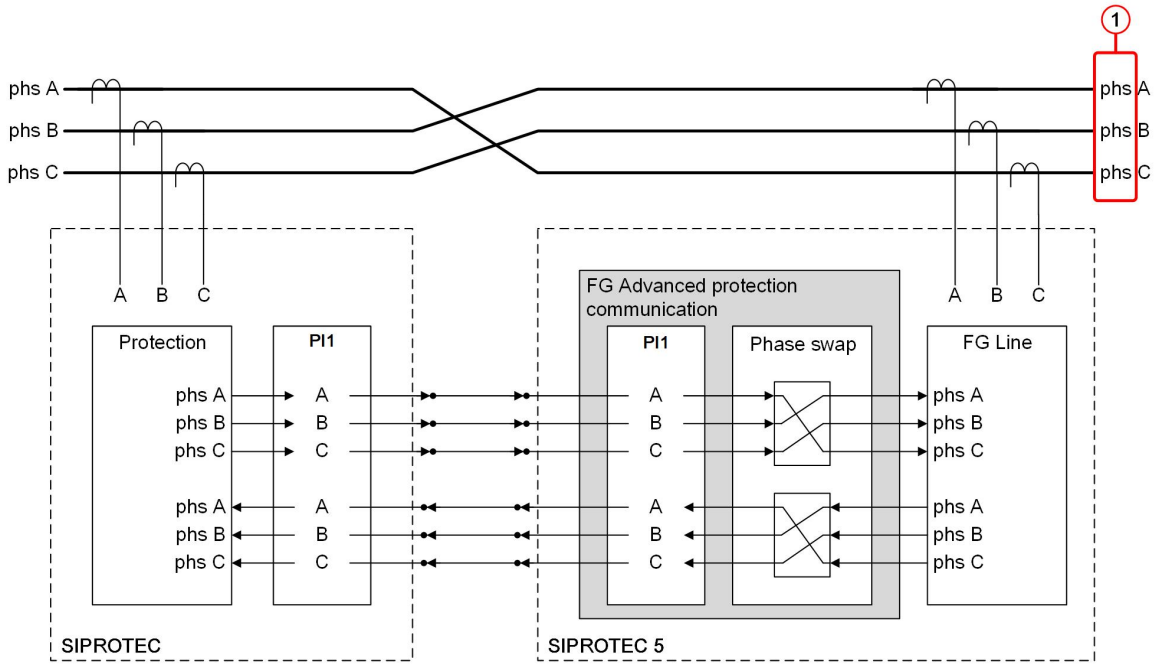
- Default setting **(_:22741:111) Dropout time prio. 1** = ***2.00 s***
- Default setting **(_:22741:112) Dropout time prio. 2** = ***2.00 s***
- Default setting **(_:22741:113) Dropout time prio. 3** = ***2.00 s***

If you use user-specific remote data, you can set how long the last received state of your remote data is held in case of a communication failure. This allows you to bridge short-term communication failures. The time can be set separately for each priority of the remote data.

For further information, refer to *3.6.5.9 Remote Data*.

3.6.6.12 Description Phase Swapping

Phase Swap



If you want to exchange information via the protection communication with a device showing phases with a different sequence but with the same rotating field as your device, the SIPROTEC 5 device can swap the phase information when sending and receiving. It is no longer necessary to swap phases when connecting the current transformers.

This use case exists on some tie lines of different power-system operators.

Figure 3-104 shows an example of the different designation of the same phases at the line ends. For example, phase **A** on the left side of the line becomes phase **C** on the right side. If a SIPROTEC 5 device is used on the right side, you can instantiate the FB **Phase swap** in the FG **Advanced protection communication**. Use the FB **Phase swap** to set how the phases are swapped when sending and receiving phase-selective information via the protection interface.

This results in the following SIPROTEC 5 device behavior:

- Connect the current and voltage transformers to the terminals **A**, **B**, and **C** of the protection device as usual.
- Connect the circuit breaker without swapping phases.
- The protection functions in both devices, such as **Line differential protection** or **Teleprotection with distance protection** cooperate without any problems.
- The phase-selective messages and measured values are displayed correctly from the point of view of the respective device.

[dw_different_phs-designation_are_compens_send-receive, 1, en_US]

Figure 3-104 Differing Phase Designations Are Compensated for while Sending and Receiving

(1) Other phase designations than at the opposite end for the same physical phase

NOTE

Phase swapping does not support the **I2-DIFF** stage of the function **Line differential protection**.

Swapping of user-specific phase-selective information sent and received using the function **Remote data** is not supported.

3.6.6.13 Setting Notes for Phase Swapping

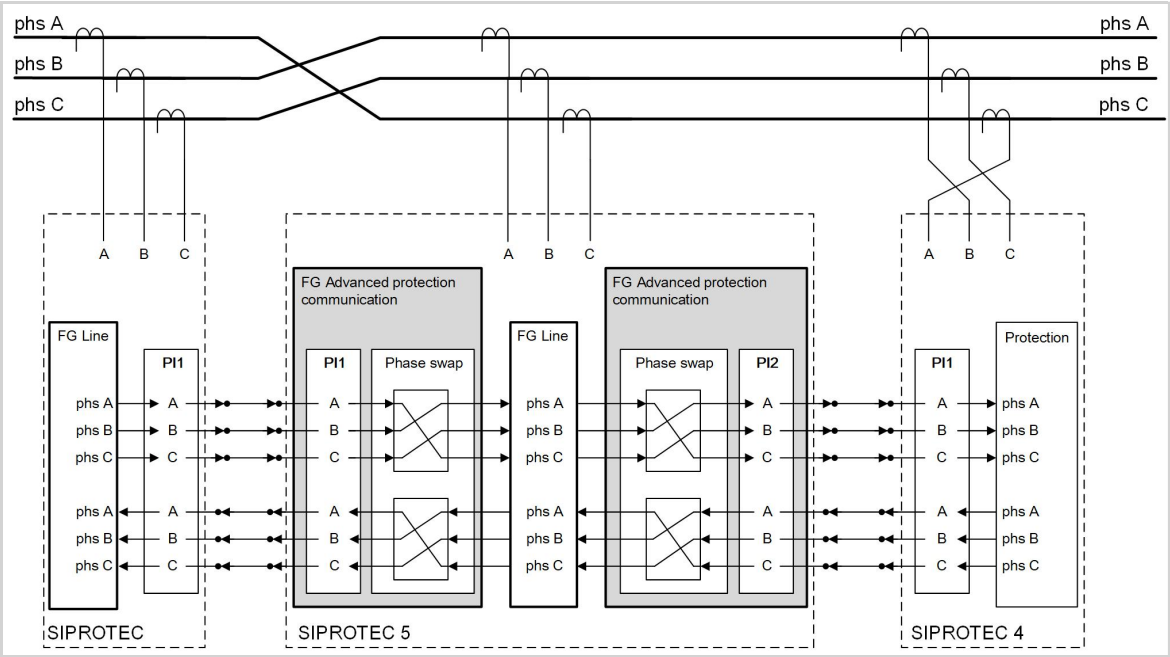
Swap in Send Direction

- Default setting **(_:101) Swap in send direction** = ***No phase swap***

With the parameter **Swap in send direction**, you select phase swapping. The phases are swapped from the send direction view. The following options are possible:

Parameter Value	Description
No phase swap	When sending phase-selective information, there is no phase swap.
A → B, B → C, C → A	The local data such as measured values and status information of the phases are swapped and sent to the neighboring device as follows: • The local data of phase **A** as data of phase **B** • The local data of phase **B** as data of phase **C** • The local data of phase **C** as data of phase **A**
A → C, B → A, C → B	The local data such as measured values and status information of the phases are swapped and sent to the neighboring device as follows: • The local data of phase **A** as data of phase **C** • The local data of phase **B** as data of phase **A** • The local data of phase **C** as data of phase **B**

Swap in Receive Direction



Depending on the setting value of the parameter **Swap in send direction**, the reverse swap direction results from the receive direction view. The read-only parameter **(_:102) Swap in receive direction** then indicates the resulting phase swap.

Parameter Value	Description
No phase swap	When receiving phase-selective information, there is no phase swap.
A → C, B → A, C → B	The data received from the neighboring device such as measured values and status information of the phases are used as follows: • The received data of phase **A** as local data of phase **C** • The received data of phase **B** as local data of phase **A** • The received data of phase **C** as local data of phase **B**
A → B, B → C, C → A	The data received from the neighboring device such as measured values and status information of the phases are used as follows: • The received data of phase **A** as local data of phase **B** • The received data of phase **B** as local data of phase **C** • The received data of phase **C** as local data of phase **A**

Examples of a Device Combination with 3 Devices:

For a device combination with more than 2 devices, you need to mentally divide the device combination into a section using the phase swap and a section not using the phase swap. In the section using the phase swap, you need to instantiate the FB **Phase swap** in the SIPROTEC 5 devices. When using SIPROTEC 4 devices, you need to swap phases when connecting the transformers and the circuit breaker.

The following figure shows a device combination with 3 devices. The device on the left can be a SIPROTEC 4 or SIPROTEC 5 device. There is a SIPROTEC 5 device in the middle and a SIPROTEC 4 device on the right side. The device in the middle swaps phases by using the FB **Phase swap**. The FB **Phase swap** is used for both protection interfaces, but it is instantiated only once for each FG **Advanced protection communication**. In the SIPROTEC 4 device on the right, you can implement the phase swap only by changing the wiring of the current and voltage transformers and of the circuit breaker. You must reinterpret the phase-selective indications accordingly.

3.6.7 Assignment of the Protection Function Group to the FG Protection Communication

If protection functions want to use the protection interfaces in a protection function group, you must route the connection of the protection function group, for example, the FG **Line 1**, with a function group **Protection communication** in DIGSI 5. Then, each protection function in the FG **Line 1** can use the protection communication.

Route the connection between the FG **Line** and the FG **Protection communication** in DIGSI 5 as follows:

Project tree > **Function-group connections** > Tab **Protection FG** ↔ **Protection FG**. Right-click to route the connection in the desired line/column.

[sc_PDC_rout1, 1, en_US]

Figure 3-106 Routing of the Connection between the Protection FG and the FG Protection Communication in DIGSI 5

NOTE

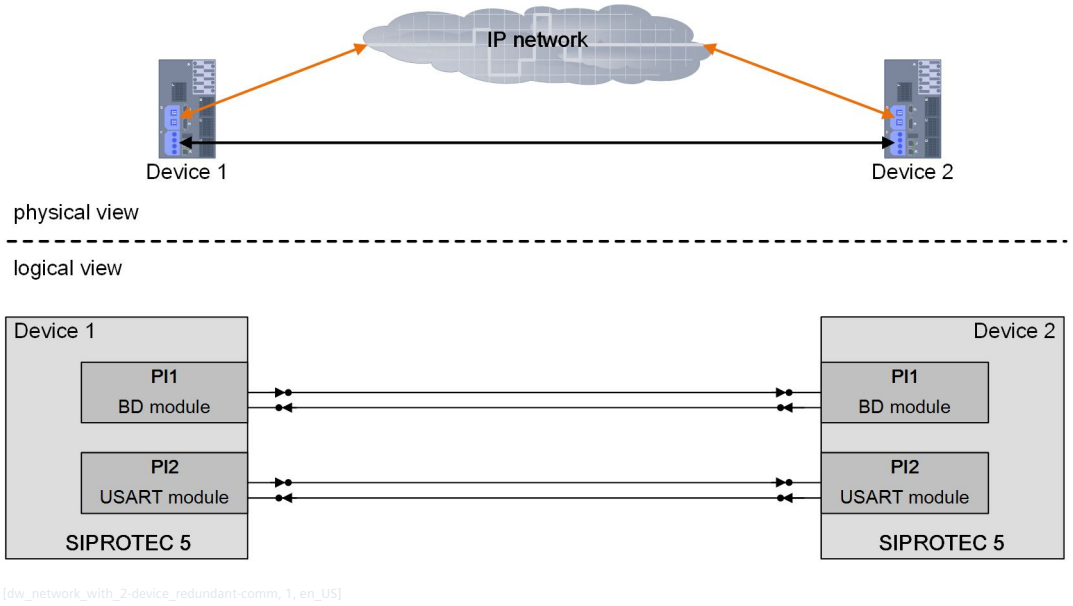
If only one protection function group and one FG **Protection communication** are instantiated in the device, DIGSI 5 connects both function groups automatically.

3.6.8 Application Examples and Setting Notes for IP Communication

3.6.8.1 Overview

The advanced protection communication supports the IP communication via MPLS[14] communication networks.

- If existing systems are to be upgraded for protection-interface communication via IP, you must retrofit an Ethernet-BD communication module in the respective SIPROTEC 5 devices.
- The protection-interface communication via IP requires an Ethernet-BD communication module per device in the device combination.
- In a device, only one Ethernet-BD communication module can be used per device combination.
- However, another device combination can use the same Ethernet-BD communication module of the device.



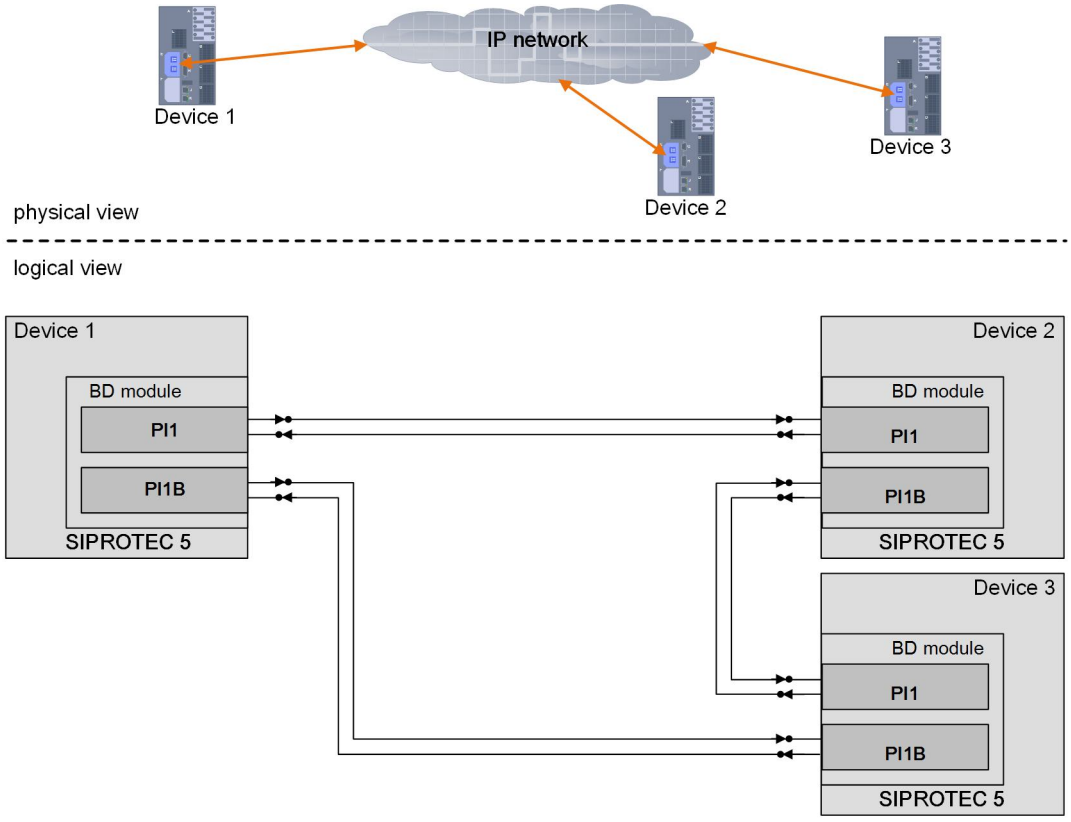
The following application examples show what you must consider when using the IP communication via MPLS communication networks.

3.6.8.2 Device Combination of 2 Devices and Redundant Communication Connection

If redundancy of the communication connection is required for a device combination consisting of 2 devices, 2 different procedures are possible:

- You can use the redundancy mechanisms of the LAN and the Ethernet-BD communication module (PRP, HSR, RSTP). In this case, the redundant communication route runs through the same Ethernet-BD communication module.
- You can set up a 2nd communication connection via a physically separate path. It is best to use a different medium for this, for example, a fiber-optic direct connection, a direct cable connection (pilot wire), or a connection based on C37.94. That is, for the 2nd communication connection, you must use another communication module in each device. The following figure shows this case from a physical and logical view:

14 MPLS = Multi-Protocol Label Switching



[dw_network_with_2-device_redundant-comm, 1, en_US]

Figure 3-107 Device Combination with 2 Devices and Redundant Communication Connection

3.6.8.3 Device Combination of 3 Devices and Only IP Communication

If you configure a device combination with 3 devices and all devices are using the IP communication, then, from the view of a device, the 2 other devices in the network are visible and reachable. For this, you configure in each device the protocol ***Advanced protection interface*** on the Ethernet-BD communication module and the **Protection interface 1**. The Ethernet-BD communication module is assigned to the **Protection interface 1**.

The special feature of this configuration is that the topology detection automatically generates a 3-device ring topology (logical view). That is, 3 point-to-point communication connections are established between the devices. In addition, another **Protection interface 1B** is automatically visible in each device, which provides the necessary 2nd communication channel for the ring topology, see the following figure:

[dw_network_with_3-device_redundant-comm, 1, en_US]

Figure 3-108 Device Combination with 3 Devices in the IP Communication Network

The **Protection interface 1B** takes over the settings of **Protection interface 1**, that is **Protection interface 1B** does not have its own settings view. The **Protection interface 1B** has its own indications and measured values, which you can see in the information routing.

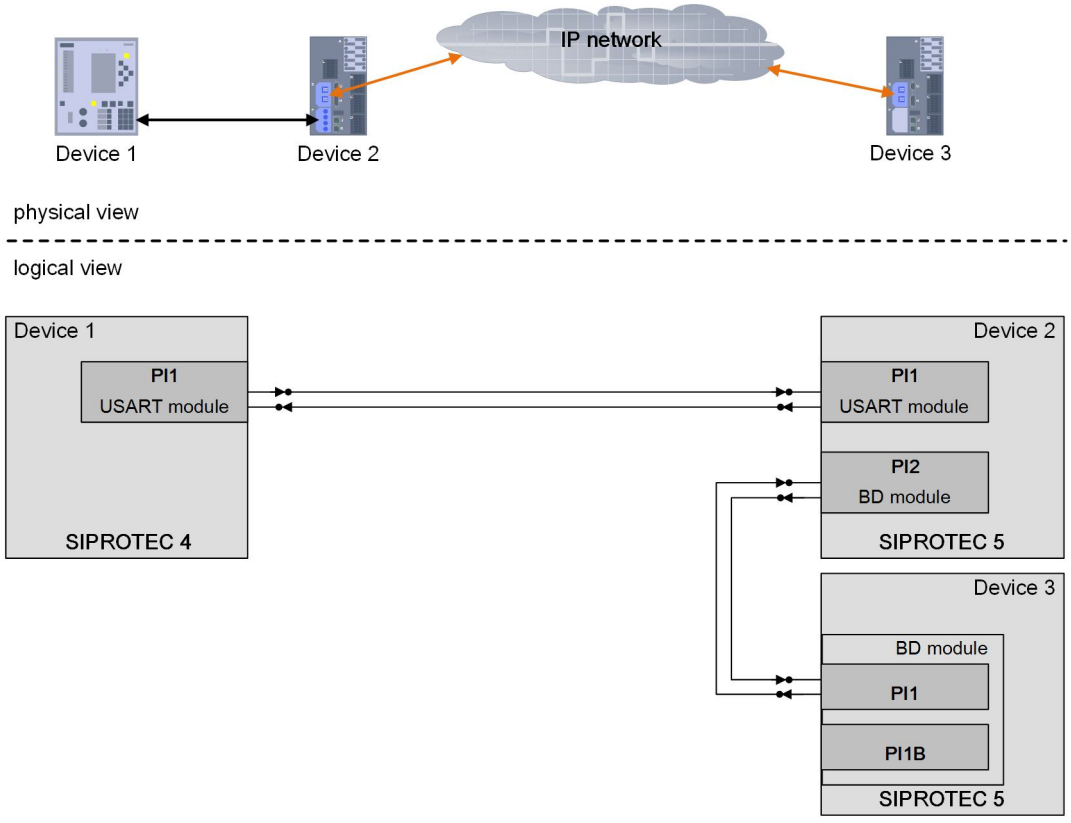
NOTE

If you use 3 devices in the device combination with IP communication, the aim of the topology detection is to form a ring topology, as in addition to a redundant connection, shorter transmission times are also possible.

If you have instantiated a 2nd protection interface, for example to establish a communication connection via another medium, the device hides the **Protection interface 1B**.

NOTE

In the following cases, the **Protection interface 1B** becomes inactive and does not have any messages or measured values:



- A 2nd protection interface is instantiated.
- Only 2 devices are present in the device combination.
- No protection interface is assigned to an Ethernet-BD communication module.

3.6.8.4 Device Combination of 3 Devices and Hybrid Communication Media

If you extend a system, it can be necessary to extend a device combination consisting of 2 existing devices by 1 device, see the following figure.

The previous 2 devices are connected to each other, for example, via a fiber-optic direct connection or via other communication media. The left device, for example, a SIPROTEC 4 device, and the middle SIPROTEC 5

device are the 2 devices previously present in the system. This device combination is to be extended by adding the right SIPROTEC 5 device. The communication between the middle and the right device is to take place via an IP communication network.

[dw_network_with_3-device_mixed-comm, 1, en_US]

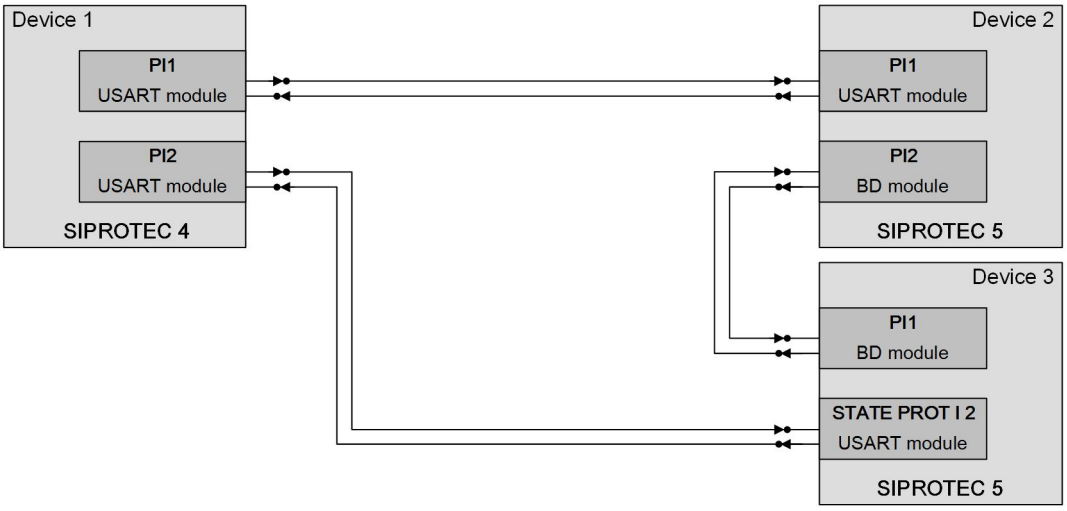


Figure 3-109 Device Combination with 3 Devices and Hybrid Communication Media

For this configuration of a 3-device chain topology, you must configure a **device combination with 3 devices** in all devices.

In the middle device, an Ethernet-BD communication module is additionally required. Configure the protocol ***Advanced protection interface*** in the properties of the Ethernet-BD communication module. Instantiate the function block **Protection interface 2** in the FG **Protection communication**. Assign the Ethernet-BD communication module to the **Protection interface 2**.

The device on the right must also have an Ethernet-BD communication module. Also configure here the protocol ***Advanced protection interface*** in the properties of the Ethernet-BD communication module and assign the Ethernet-BD communication module to the **Protection interface 1**. **Protection interface 1B** is created here as a special feature, but it is not used.

If a redundant communication connection is required for this configuration, Siemens recommends establishing a 3-device ring topology. For this purpose, you must connect the left and right devices via another communication channel. This creates the 3-device ring topology. The following figure shows this configuration:

[dw_3-device_and_mixed-comm, 1, en_US]

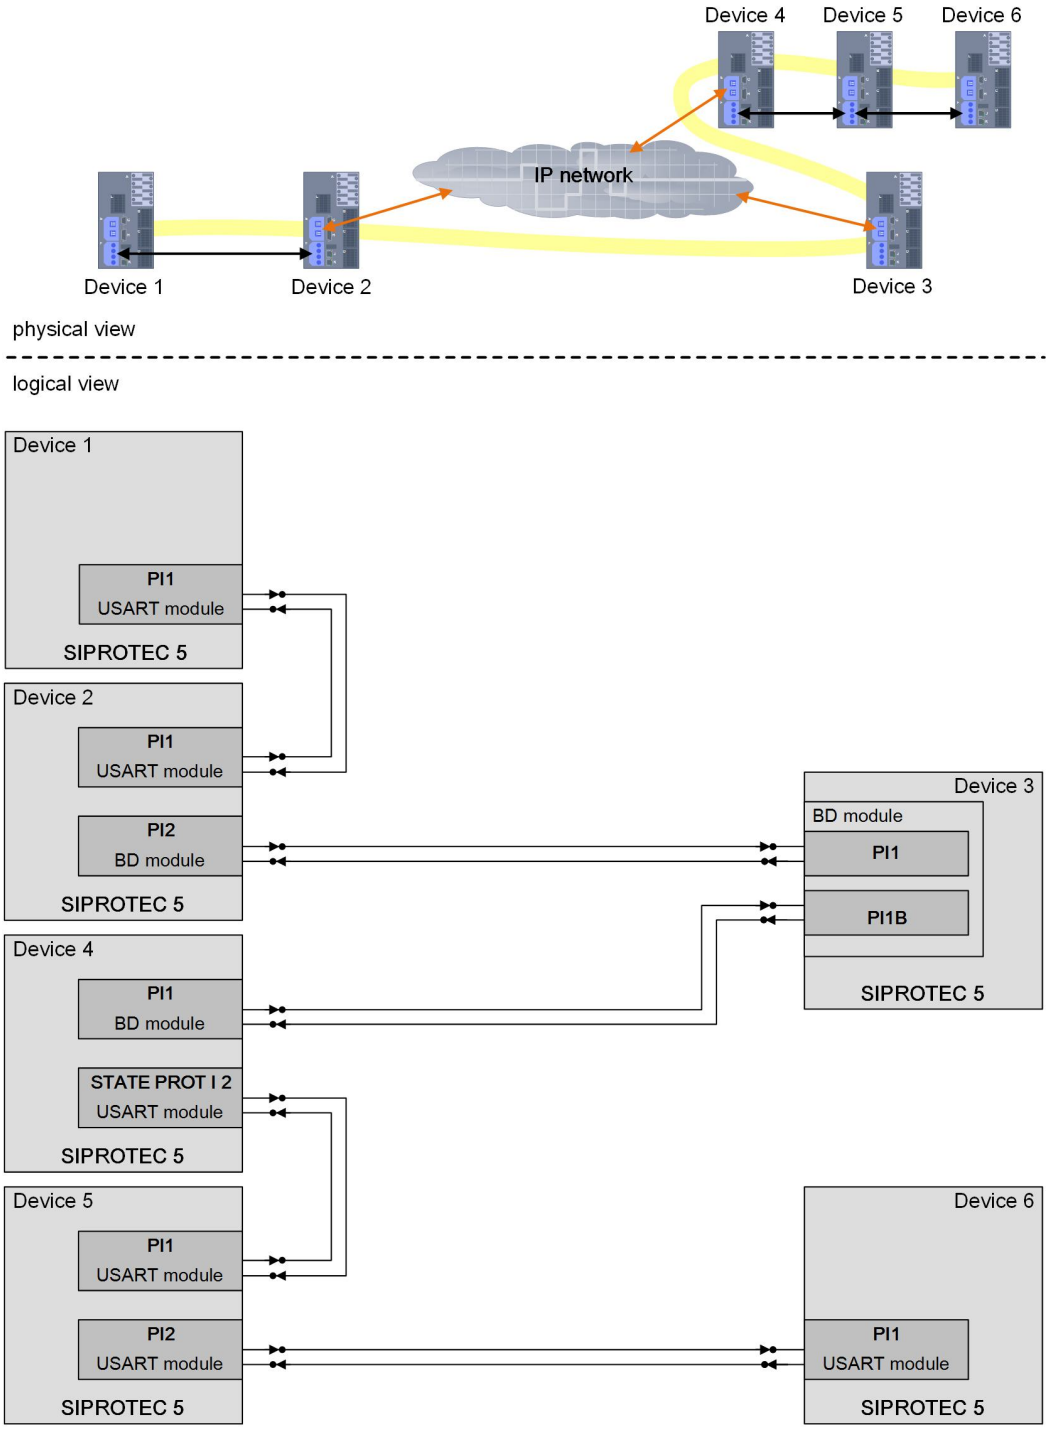
Figure 3-110 Device Combination with 3 Devices and Hybrid Communication Media and Redundant Communication Connection

The SIPROTEC 4 device (left device) does not support any IP communication. In this case, you must switch to another communication medium and retrofit a corresponding SIPROTEC 4 communication module. In any case, the communication medium used is also supported by the SIPROTEC 5 device on the right side, by retrofitting a corresponding equivalent communication module there. Configure this communication module with the protocol ***Advanced protection interface***, add an additional **Protection interface 2** to the FG **Protection communication**. Assign the **Protection interface 2** to the communication module.

3.6.8.5 Device Combination of 6 Devices and Hybrid Communication Media

IP Addresses in Hybrid Topologies

To ensure redundancy or downward compatibility, the devices also allow a mix of classic and IP-based communication media.



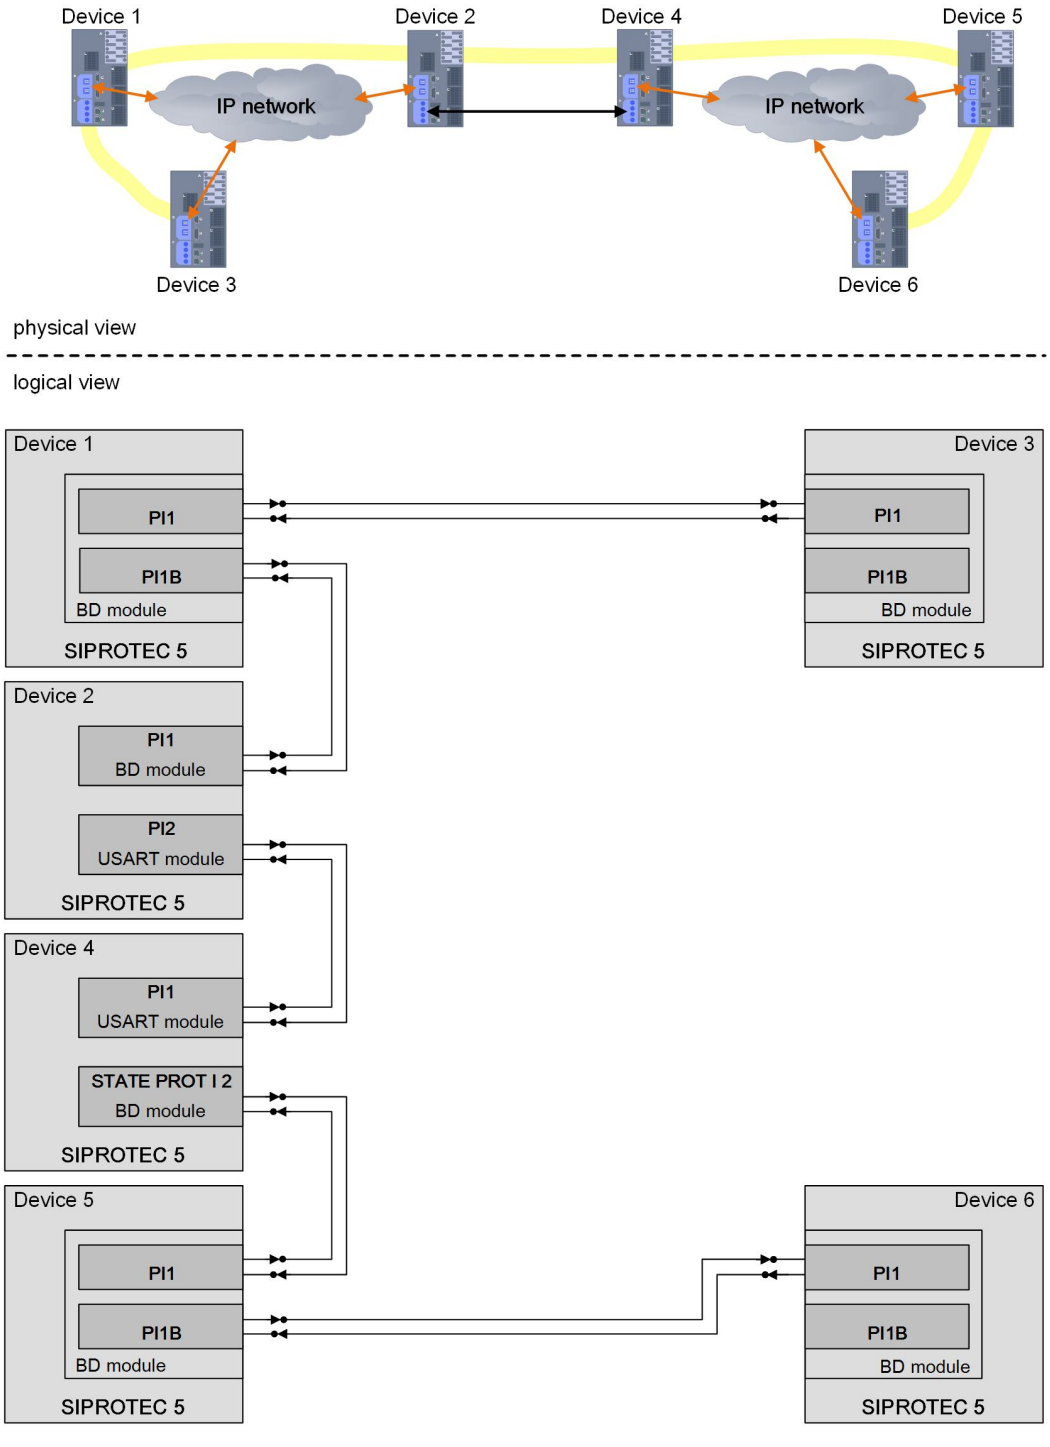
In such applications, special consideration must be given to the configuration of the IP addresses. When parametrizing the devices, you must first clarify which path the communication is to take through the network. That is, it must be clear which devices communicate with each other. To define a route, you may only configure its planned communication partners in a device. The following examples illustrate the correct IP configuration.

For device combinations with more than 3 devices and hybrid communication media, different configurations are possible. If you want to use the IP communication, consider that only one Ethernet-BD communication module per device combination is supported for the protection-interface communication.

The following figure shows a device combination with 6 devices. In the example, several devices are connected by other communication media, which form 3 device groups. The device groups are connected by an IP network. The result is a 6-device chain topology. The yellow line illustrates the communication route.

To establish this communication route, you may only parameterize the IP addresses of their direct communication partners in the devices. The following example applies:

- The devices **2** and **4** only know the IP address of device **3**.
- Device **3** only knows the IP addresses of the devices **2** and **4**.
- Leave all other IP addresses at ***0.0.0.0***.



[dw_network_with_6-device_redundant-comm, 1, en_US]

Figure 3-111 Example 1 of a Device Combination with 6 Devices

Another example shows 2 device groups whose devices are connected to each other via IP networks. The 2 device groups are connected to each other by a different communication medium. The topology detection in turn forms a 6-device chain topology.

To establish this communication route, you may only parameterize the IP addresses of their direct communication partners in the devices. The following example applies:

- Device **1** only knows the IP addresses of the devices **2** and **3**.
- The devices **2** and **3** only know the IP address of device **1**.
- Device **5** only knows the IP addresses of the devices **4** and **6**.
- The devices **4** and **6** only know the IP address of device **5**.
- Leave all other IP addresses at *0.0.0.0*.

[dw_network_with_6-device, 1, en_US]

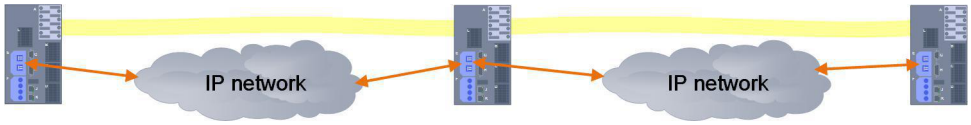


Figure 3-112 Example 2 of a Device Combination with 6 Devices

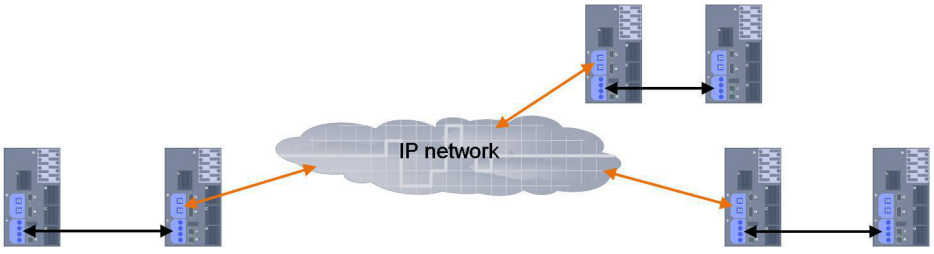
3.6.8.6 Unsupported Configurations

The following figure shows an example of a device combination with 3 devices. In the example, all devices use the IP communication. The middle device contains 2 Ethernet-BD communication modules, which are both configured with the ***Advanced protection interface*** protocol.

NOTE

You can only use 1 Ethernet-BD communication module in one device!
2 Ethernet-BD communication modules with the ***Advanced protection interface*** protocol are not supported.



[dw_non-supported-confic_network_with_3-device, 1, en_US]

Figure 3-113 Unsupported Configuration of a Device Combination with 3 Devices

NOTE

If you use the IP communication, the aim of the topology detection is to form a chain topology if there are 4 or more devices. For certain configurations, the topology detection cannot form a working chain topology.

The following figure shows an example of a device combination with 6 devices and hybrid communication media. In this case, the topology detection cannot form a functioning 6-device chain topology.

[dw_non-supported-confic_network_with_6-device, 1, en_US]

Figure 3-114 Unsupported Configuration of a Device Combination with 6 Devices

3.7 Date and Time Synchronization

3.7.1 Overview of Functions

Timely recording of process data requires precise time synchronization of the devices. The integrated date/time synchronization allows the exact chronological assignment of events to an internally managed device time that is used to time stamp events in logs, which are then transmitted to a substation automation technology or transferred via the protection interface. A clock module internal to the device and having battery backup is synchronized cyclically with the current device time so that the right device time is available and used even in case of auxiliary-voltage failure. At the same time, this permits hardware-supported monitoring of the device time.

3.7.2 Structure of the Function

The integrated date/time synchronization is a supervisory device function. Setting parameters and indications can be found in the following menus for the DIGSI and the device:

Set date and time:

- DIGSI: Online access -> Interface -> Device -> Device Information -> **Time Information**
- Device: Main menu → Device functions → **Date & Time**

Parameter:

- DIGSI: Project -> Device -> Parameter -> **Time Settings**

Indications:

- DIGSI: Project -> Device -> Information routing ->**Time keeping** or **Time Sync.**

3.7.3 Function Description

Every SIPROTEC 5 device maintains an internal device time with date. The date and time can also be set on the device via the on-site operation panel or via DIGSI 5. Within a system, or even beyond, it is usually necessary to record the time of process data accurately and to have exact time synchronization of all devices. For SIPROTEC 5 devices, the sources of time and synchronization options can be configured.

Configurable Synchronization Options:

- **None** (default setting)
  The device functions without any external time synchronization. The internal time synchronization continues to work with the help of the back-up battery even when the auxiliary voltage is shut down temporarily. The time can be adjusted manually.
- **Telegram**
  The time is synchronized via a telegram with an appropriately configured communication interface in accordance with the IEC 60870-5-103 or DNP3 protocol.
- **Connection to a radio clock**
  The time synchronization takes place with the set time telegram from an external IRIG B or DCF77 receiver via the time synchronization interface of the device.
- **Ethernet**
  The time synchronization is done via Ethernet-based SNTP protocol (Simple Network Time Protocol), for example with IEC 61850 stations or via IEEE 1588. If you enable both services during configuration of Ethernet interfaces, these protocols are available as an option for the time synchronization.

- **Protection interface**
  The time synchronization takes place via the protection interfaces configured for your SIPROTEC 5 device. Here, the timing master takes over the time management.

Configurable Time Sources:

- 2 time sources can be taken into consideration with the SIPROTEC 5 devices. For each time source, the synchronization type may be selected based on the options provided.
- **`Time source 1`** takes precedence over **`Time source 2`**, that is, **`Time source 2`** will be effective for the synchronization of the device time only if **`Time source 1`** fails. If only one time source is available and it fails, then only the internal clock continues unsynchronized. The status of the time sources is indicated.
- For every time source, it is possible to define via the **`Time zone time source 1`** parameter (or **`Time zone time source 2`**) if this source transmits its time by UTC (universal time) or if the settings correspond to the local time zone of the device.

NOTE

Make sure that the settings for the time sources coincide with the actual hardware configuration of your SIPROTEC 5 device. In any event, incorrect settings cause the status indications of time sources to pick up.

Configurable Date Format

Regardless of a feed time-synchronization source, a uniform format is maintained internally within the device. The following options are available for the customary local representation of the date format:

- Day.Month.Year: 24.12.2009
- Month/Day/Year: 12/24/2009
- Year-Month-Day: 2009-12-24

Taking Local Time Zones into Account

The internal device time is maintained in universal time (UTC). To display time stamps in DIGSI and on the device display, you can define the local time zone of the device (parameter Offset time zone for GMT), including the applicable daylight saving times (start, end, and offset of daylight saving time) using parameters. This allows the display of the local time.

NOTE

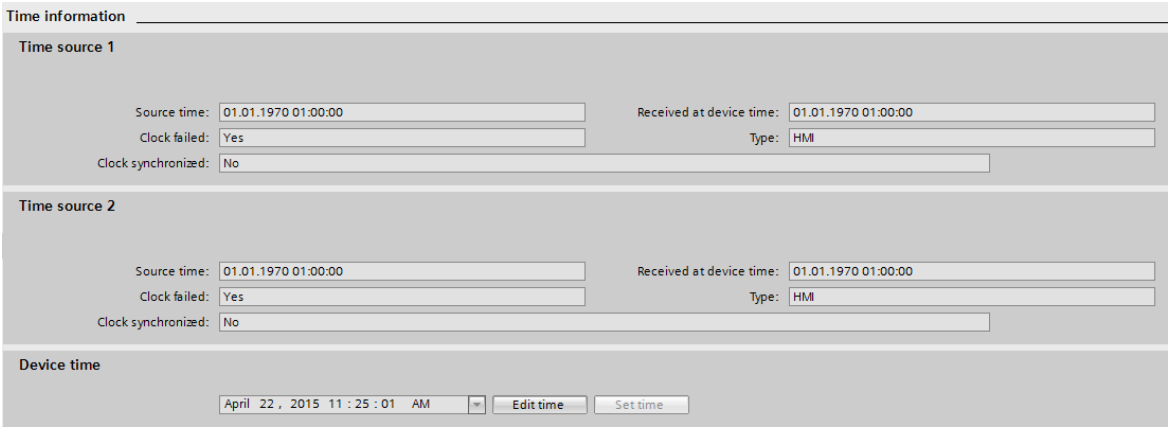
- For time sources that transmit the status of the switch to daylight saving time, this will be taken into account automatically when creating the internal device time in the UTC format. The differential time of the daylight saving time set in the device (parameter Offset daylight saving time) is taken into consideration. However, in contrast, the settings of the start of daylight saving time and end of the daylight saving times are ignored when converting into the device internal UTC format.
- For active time sources, it is not possible to set the time via the device display or DIGSI 5. An exception is setting the calendar year for active time protocol IRIG B.

Status, Supervision, and Indications of Time Management

Your SIPROTEC 5 device generates status and monitoring indications that provide important information regarding the correct configuration of the time source and the status of the internal time management during startup and device operation.

Internal time synchronization is monitored cyclically. Important synchronization processes, the status of the time sources and errors detected are reported. A device time that has become invalid will be marked accordingly so that affected functions can go to a safe state.

Indication	Description
Device: *Clock fail*	This indication signals a high difference between the internally managed time and the time of the clock module that is not permissible. The pickup of the indication can point to a defect in the clock module or to an unacceptable high drift of the system quartz crystal. The time maintained internally is marked as invalid.
Time management: *Daylight saving time*	This indication signals whether daylight saving time has been enabled.
Time management: *Clock set manually*	This indication signals that the device time has been set manually via the on-site operation panel or via DIGSI 5.
Time synchronization: *Status time source 1* *Status time source 2*	These 2 indications signal whether the active time sources are recognized as valid and active from the device point of view. When the indications pick up, it can also be an indication that an incorrect configuration of the port or channel numbers was done at the on-site operation panel.
Time synchronization: *Time sync. error*	This indication signals after the parameterized time **Fault indication after** that synchronization using an external time source has failed.
Time synchronization: *Leap second*	This indication signals that a Leap second has occurred during time synchronization using an external GPS receiver (protocol variant IRIG B 005(004) with extension according to IEEE C37.118-2005).
Time synchronization: *High accuracy*	This indication signals that the device is synchronized with an accuracy better than 1 µs The indication is only of significance when the PMU function is used.



NOTE

In case of a missing or discharged battery, the device starts without active external time synchronization with the device time 2011-01-01 00:00:00 (UTC).

For the device, DIGSI 5 provides a compact overview of the status of the time synchronization of your SIPROTEC 5 device in online mode. All displays are updated continuously. You can access the overview in the project-tree window via Online access.

DIGSI: Online access -> Interface -> Device -> Device Information -> **Time Information**

[sc_time_dg, 1, en_US]

Figure 3-115 Time Information in DIGSI

For every time source, you see the following:

- Last received time (with date)
- Receipt time of the last received time telegram
- Configured type of timer
- Indication of timer outage or failure
- Whether the device time is currently synchronized from the time source

The lower section displays the device time, which is continuously updated. If the internal device time and the infeed time source were synchronous at the time of telegram receipt, both displayed times are identical.

NOTE

All times displayed (also the time source) take into consideration the local time settings (zone and daylight saving time of the device) in the form of a numerical offset for UTC (universal time).

3.7.4 Application and Setting Notes

Parameter: Date Format

- Default setting **`Date format`** = ***`YYYY-MM-DD`***

With the parameter **`Date format`**, you define the local customary format of the date display.

Parameter Value	Description
`DD.MM.YYYY`	Day.Month.Year: Typical European display Example: 24.12.2010
`MM/DD/YYYY`	Month/Day/Year: Typical US representation Example: 12/24/2010
`YYYY-MM-DD`	Year-Month-Day: Typical Chinese display Example: 2010-12-24

Parameter: Time zone time source 1, Time zone time source 2

- Default setting **`Time zone time source 1`** = ***`local`***, **`Time zone time source 2`** = ***`local`***

With the parameters **`Time zone time source 1`** and **`Time zone time source 2`**, you define the handling of time zones of the external timer.

Parameter Value	Description
local	Local time zone and daylight saving time are considered as time zone offsets to GMT.
UTC	Time format according to UTC (universal time)

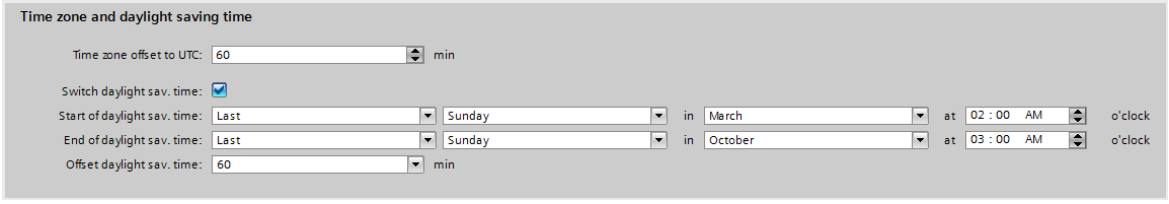
Parameter: Time source 1, Time source 2

- Default setting **Time source 1** = ***none***, **Time source 2** = ***none***

With the parameters **Time source 1** and **Time source 2**, you can configure an external timer. The prerequisite is to have the corresponding hardware configuration of the communication interfaces of your SIPROTEC 5 device. This is listed as a prefix when making a selection in DIGSI 5.

Parameter Value	Description
none	The time source is not configured.
IRIG-B	Time synchronization by an external GPS receiver: SIPROTEC 5 devices support several protocol variants of the IRIG-B standard: • **IRIG-B 002(003)** The control function bits of the signal are not occupied. The missing year is formed from the current device time. In this case, it is possible to set the year via the online access in DIGSI 5. • **IRIG-B 006(007)** The bits for the calendar year are not equal to 00. The calendar year is set automatically by the time protocol. • **IRIG-B 005(004) with extension according to IEEE C37.118-2005** If, in the time signal, other control function bits are occupied in addition to the calendar year, then the device takes the additional information into consideration for leap seconds, daylight saving time, time offset (zone, daylight saving time), and time accuracy. **Time zone time source 1** or **Time zone time source 2**: The value of this setting is not evaluated by the device, since this protocol either transmits in UTC or in the case of local time, specifies the appropriate offset to UTC in each set time telegram.
DCF77	Time synchronization by an external DCF77 receiver **Time zone time source 1** or **Time zone time source 2** = ***local*** Note: There are also clocks that generate a DCF77 signal representing UTC. In this case, UTC must be set.
PI	The time synchronization takes place via the protection interfaces configured for your SIPROTEC 5 device. Here, the timing master takes over the time management. Signal-transit times of the protection interface communication are calculated automatically. **Time zone time source 1** or **Time zone time source 2** = ***UTC*** A slave that receives a time or a SIPROTEC 5 master, receives its system time kept in UTC.

Parameter Value	Description
SNTP	The time synchronization is done via the Ethernet service SNTP (SNTP server or via IEC 61850). SIPROTEC 5 devices support both Edition1 and Edition2 in accordance with IEC 61850-7-2. In Edition2, the logical attributes LeapSecondsKnown, ClockFailure, ClockNotSynchronized, and the value TimeAccuracy are maintained in each time stamp. For Edition1, these signals contain default settings. Thus, the interoperability for substation automation technology is ensured for both editions! The SNTP service must be enabled during configuration of Ethernet interfaces so that it is available as an option for the time synchronization. **Time zone time source 1** or **Time zone time source 2** = ***UTC***
IEC 60870-5-103	The time is synchronized via telegram with an appropriately configured communication interface in accordance with the IEC 60870-5-103 protocol. **Time zone time source 1** or **Time zone time source 2** = ***local*** However, there are also T103 systems that send the UTC.
DNP3	The time is synchronized via telegram with the appropriately configured communication interface in accordance with the DNP3 protocol. 2 characteristics are supported in the process: • **Time synchronization via UTC** • **Time synchronization with local time** The daylight saving time status is not transmitted. The device assumes that the DNP3 master follows the same rules for the start and end of the daylight saving time as those that were set for the device. **Time zone time source 1** or **Time zone time source 2** = ***UTC*** is the current implementation, ***local*** concerns older implementations.
IEEE 1588	Time is synchronized via an IEEE 1588 timing master. In this case, SIPROTEC 5 devices operate as slave-only clocks. IEEE 1588 v2 is supported with P2P and Ethernet Transport. The IEEE 1588 service must be enabled during configuration of Ethernet interfaces so that it is available as an option for the time synchronization. **Time zone time source 1** or **Time zone time source 2** = ***UTC***.



Parameter: Fault indication after

- Default setting **Fault indication after** = ***600 s***

With the parameter **Fault indication after**, you set the time delay after which the unsuccessful attempts of time synchronization with external time sources configured are indicated.

Parameter: Time Zone and Daylight Saving Time

This parameter block contains all the settings for the local time zone and daylight saving time of your SIPROTEC 5 device. In addition to the individual parameters, configure the basic settings by preselecting via the option buttons or check box.

[sc_time_zo, 1, en_US]

Figure 3-116 Settings for Time Zone and Daylight Saving Time in DIGSI

Selection Button	Description
Manual settings (local time zone and daylight saving time regulation)	This setting must be selected if you want to select the local time zone and daylight saving time zone regulations of your SIPROTEC 5 device regardless of the PC settings. Input: **Offset time zone for GMT** [min] Selection: **Switchover to daylight saving time** [yes/no] via check box  • Input: **Start of daylight saving time** [Day and time] • Input: **End of daylight saving time** [Day and time] • Input: **Offset daylight saving time** [min] • Default settings as in the picture above

3.8 User-Defined Objects

3.8.1 Overview

With help from user-defined function groups and user-defined functions you can group user-defined objects, for example user-defined function blocks. 2 user-defined function blocks are available (see following figure).

[sc_udef_lib, 1, en_US]

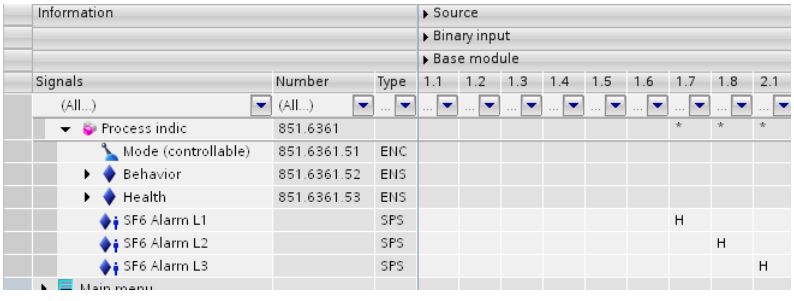

Figure 3-117 User-Defined Objects in the DIGSI 5 Library

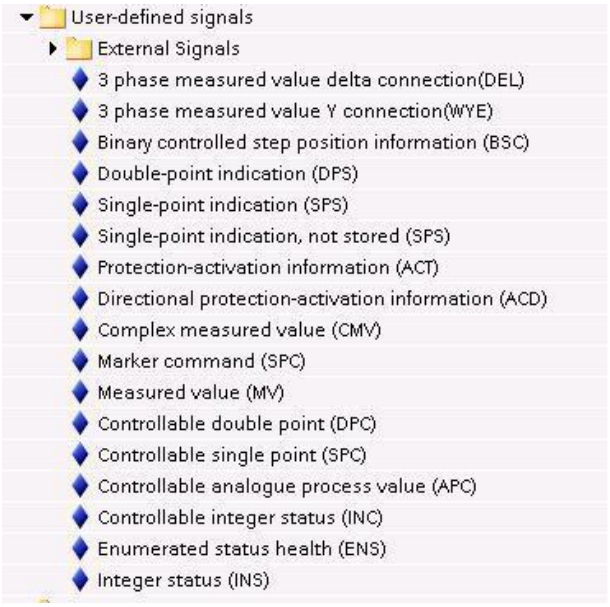
The **user-defined function block** allows you to add (see following figure) single-point indications, pickup indications, operate indications (ADC, ACT), single and double commands, commands with a controllable whole number as well as measured values. You can assign the group a superordinate name (for example **process indications** for a group of single-point indications which are read via binary inputs). This function can be deactivated using the mode. The standby mode is also analyzed or displayed.

The user-defined function blocks can be instantiated at the highest level (alongside other function groups) as well as within function groups and functions.

In addition, there is a **user-defined function block [control]**. Alongside the aforementioned possibilities presented by **user-defined function blocks**, this block offers additional tests for user-defined control signals, for example SPC or DPC.

These are described in chapter *7.6.1 Overview of Functions*.



[sc_user, 1, en_US]

Figure 3-118 Information Routing with Incorporated User-Defined Function Block: Process Indications and some Single-Point Indications

3.8.2 Basic Data Types

The following data types are available for user-defined objects in the DIGSI 5 library under the heading **User-defined signals**. Additionally, a folder for external signals is available (see chapter *3.8.5 External Signals*).

User-Defined Signals

[sc_LB_userdefsig, 1, en_US]

Figure 3-119 User-Defined Signals

Single-Point Indication (Type SPS: Single-Point Status)

The status of a binary input can be registered in the form of a single-point indication or forwarded as the binary result from a CFC chart.

EXAMPLE

Acquisition using binary input, further processing in a CFC and/or signaling using an LED.

Single-Point Indication (Type SPS unsaved: Single-Point Status Unsaved)

In contrast to **SPS** single-point indications, the state of the **SPS unsaved** indication is not maintained after the device restarts.

For this purpose, go to **Properties > Details > Initialization > Restart** and set the ***Value***.

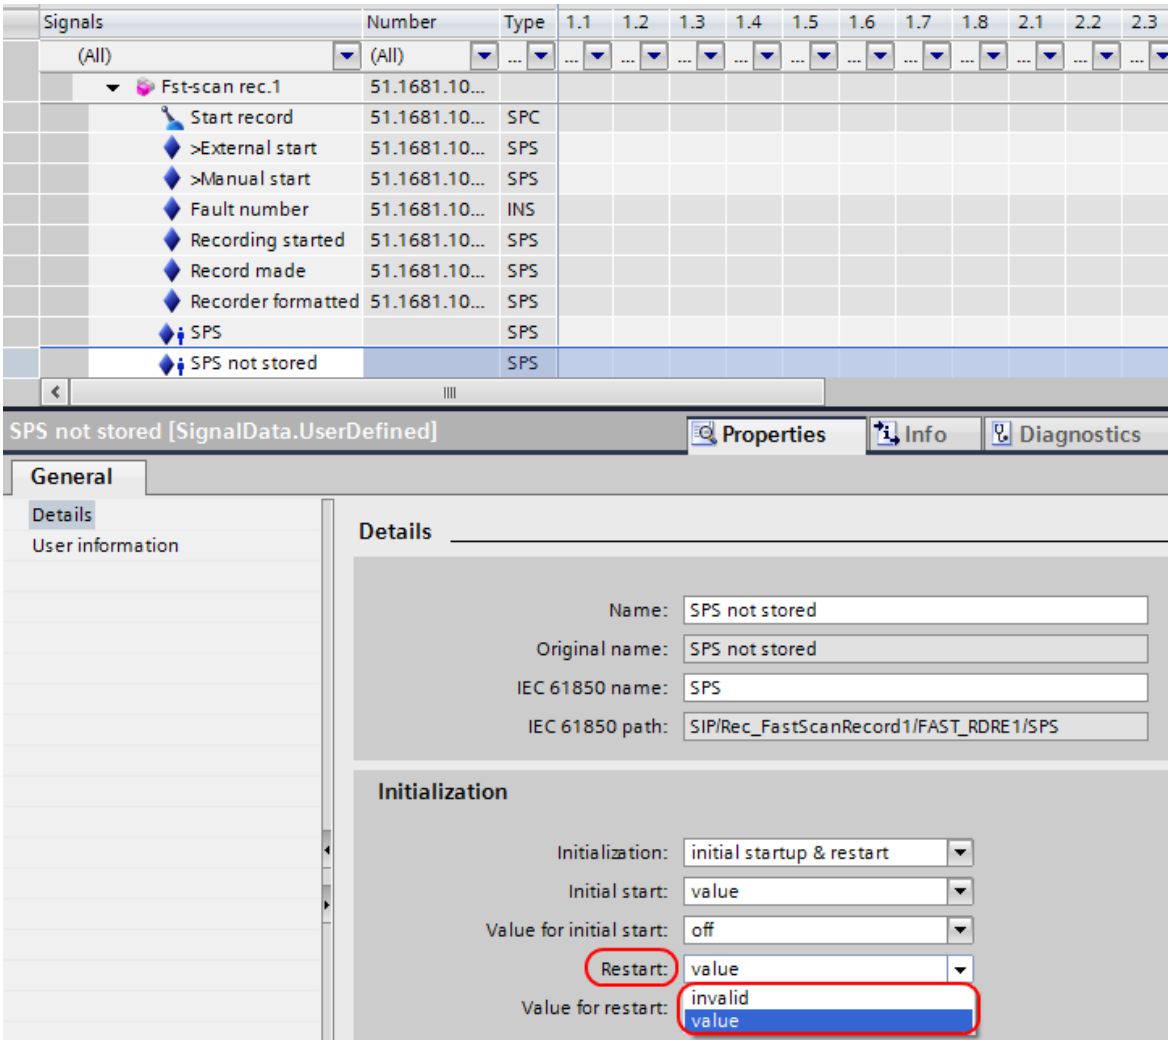


Figure 3-120 Single-Point Indication SPS Unsaved (Example: 7KE85 Fault Recorder)

Double-Point Indication (Type DPS: Double-Point Status)

When using a double-point indication, the status of 2 binary inputs can be captured simultaneously and mapped in an indication with 4 possible conditions (***ON***, ***Intermediate position***, ***OFF***, ***Disturbed position***).

EXAMPLE

Acquisition of a disconnector or circuit-breaker switch position.

Marker Command (Type SPC, Single-Point Controllable)

This data type can be used as a command without feedback for simple signaling or as an internal variable (marker).

Integer Status Value (Type INS)

The data type **INS** is used to create a whole number that represents a CFC result.

EXAMPLE

The output of the CFC block **ADD_D** can, for example, be connected with the data type **INS**. The result can be shown on the display of the device.

State of an Enumeration Value (Type ENS)

The data type **ENS** is used to create an enumerated value that represents a CFC result.

Controllable Single-Point Indication (SPC, Single-Point Controllable)

This can be used to issue a command (to one or several relays, selectable under information routing) that is monitored via a single feedback.

Command with Double-Point Feedback (DPC, Double-Point Controllable)

This can be used to issue a command (to one or several relays, selectable under information routing) that is monitored via double-point indication as feedback.

Command with a Whole Number (INC, Controllable Integer Status)

This can be used to issue a command (to one or more relays, selectable under information routing) that is monitored via a whole number as feedback.

Complex Measured Values (CMV)

This data type provides a complex measured value that can be used as a CFC result, for example.

Measured Values (MV)

This data type provides a measured value that can be used as a CFC result, for example.

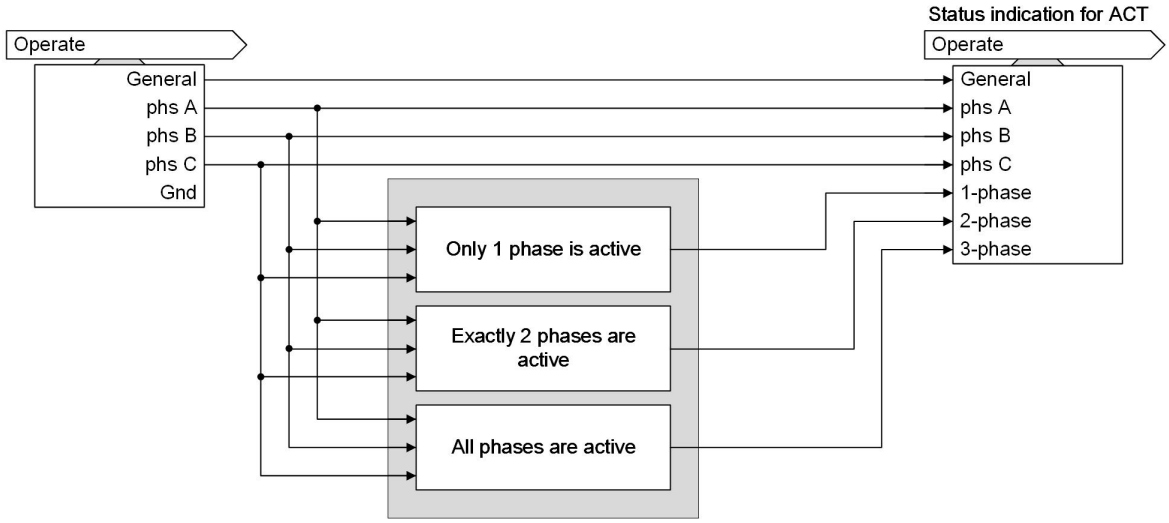
NOTE

Additional data types can be found under other headings in the DIGSI 5 library as well as in the corresponding function blocks. This applies to the following data types:

- Pulse-metered values (see **User-defined functions** in the DIGSI 5 library)
- Transformer taps
- Metered values

Phase-to-Ground Measured Values (WYE)

This data type represents the phase-to-ground measured values of a 3-phase system.



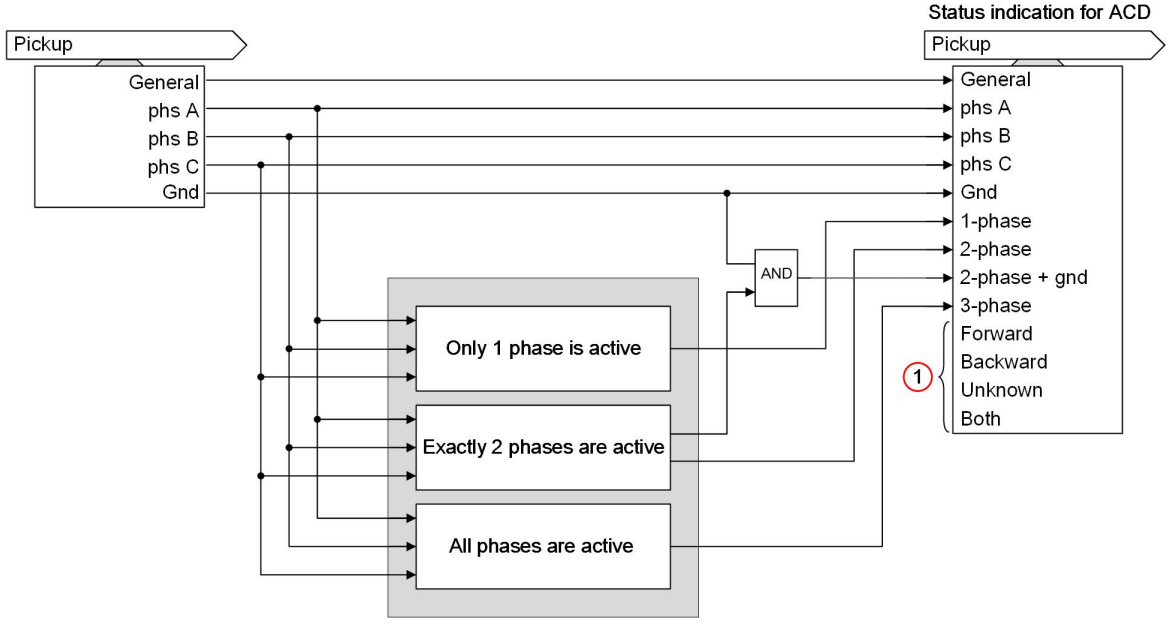
Phase-to-Phase Measured Values (DEL, Delta)

This data type represents the phase-to-phase measured values of a 3-phase system.

Protection Activation Information (ACT)

This object type is used by the protection functions for **Tripping**. It is available in the library for receiving protection information via the protection interface, which could also indicate **Tripping**.

The status indications for the **ACT** data type are built as follows:



[lo_ACT-information, 1, en_US]

Figure 3-121 Building of the Status Indications ACT

Protection Activation Information with Direction (ACD)

This object type is used by the protection functions for **Pickup**. It is available in the library for receiving protection information via the protection interface, which could also indicate **Pickup**. In addition, both ACD and ACT, can be generated and processed by CFC charts.

The status indications for the **ACD** data type are built as follows:

[lo_ACD-information, 1, en_US]

Figure 3-122 Building of the Status Indications ACD

(1) Further information, see *Table 3-21*

Table 3-21 Building of the Direction Information for the Data Type **ACD**

Direction Information	Description
forward	All picked up phases have picked up in forward direction.
backward	All picked up phases have picked up in backward direction.
unknown	The direction could not be determined for the pickup.
both	At least 1 phase has picked up in forward direction and at least 1 phase has picked up in backward direction.

3.8.3 Pulse-Metered and Energy-Metered Values

Pulse-Metered Values

Pulse-metered values are available as data type **BCR** (Binary Counter Reading) in the function group **transformer** as well as the function group**Circuit breaker**. There you will find **Pulse-metered values** under **Measured values**/**User-defined values**/**Pulse-metered value**.

The functionality and the settings of the pulse-metered values can be found in chapter *9.9.1 Function Description of Pulse-Metered Values*.

Energy Metered Values

Energy metered values no longer need to be created by the user separately. They are available as active and reactive power in each **transformer** function group for reference and output direction. The calculation is based on the current and voltage transformers associated with the transformer.

Detailed information can be found in the **transformer** function group in chapter *9.8.1 Function Description of Energy Values*

3.8.4 Additional Data Types

The following data types are also used in the system but are not available for general use as user-defined signals in the library:

- **ENC** (Enumerated Setting Controllable)
  The data type **ENC** models a command with which the user can set predefined values.
- **SEQ** (Sequence)
- **BSC** (Binary Controlled Step Position)
  The data type **BSC** can, for example, be used to control a transformer tap changer. The commands **up**, **down** can be given.

NOTE

Transformer taps are included in the **Transformer tap changer** switching element. If this switching element is created in the device, the transformer tap position is available as a data object of type **BSC** (binary controlled step position information).

3.8.5 External Signals

User-defined signals of different types (see *Figure 3-123*) are available for GOOSE Later Binding. After instantiation in a logical node, an external reference is generated during IID export and provided to a IEC 61850 system tool (for example, System Configurator) for GOOSE Later Binding (according to the Later-Binding procedure specified in IEC 61850-6).

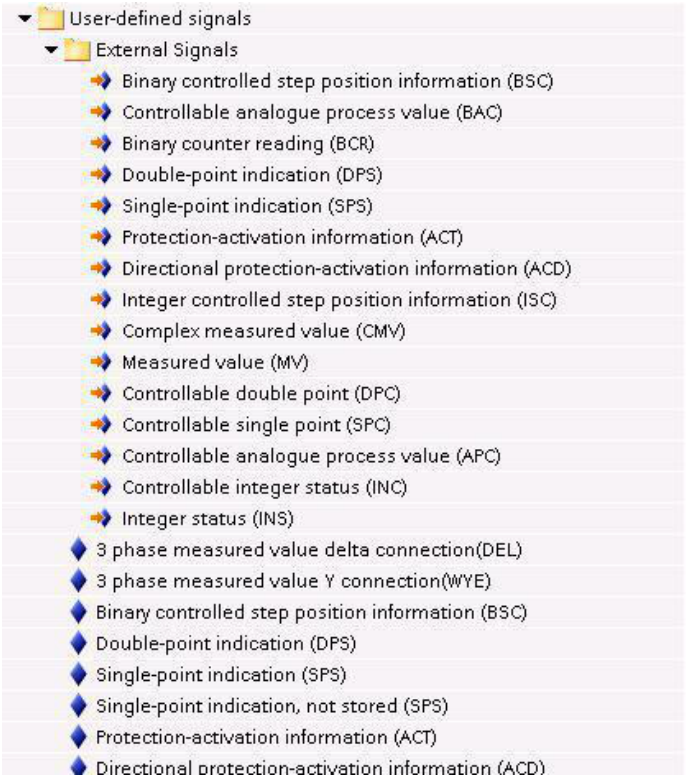


Figure 3-123 External Signals

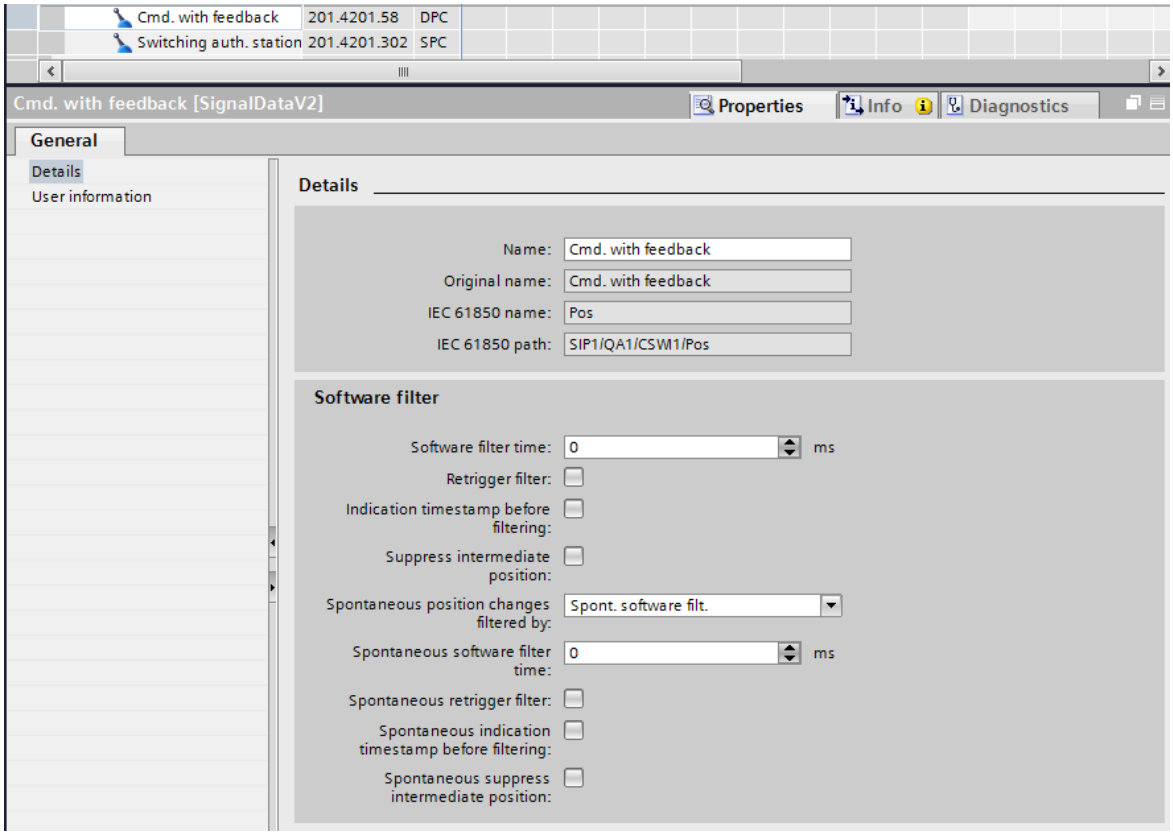
NOTE

Consider the chapter on GOOSE Later Binding in the DIGSI Online Help. User-defined signals exist as external signals and as preconfigured inputs that have been activated via the GOOSE column.

3.9 Other Functions



3.9.1 Signal Filtering and Chatter Blocking for Input Signals

Input signals can be filtered to suppress brief changes at the binary input. Chatter blocking can be used to prevent continuously changing indications from clogging the event list. After an adjustable number of changes, the indication is blocked for a certain period.

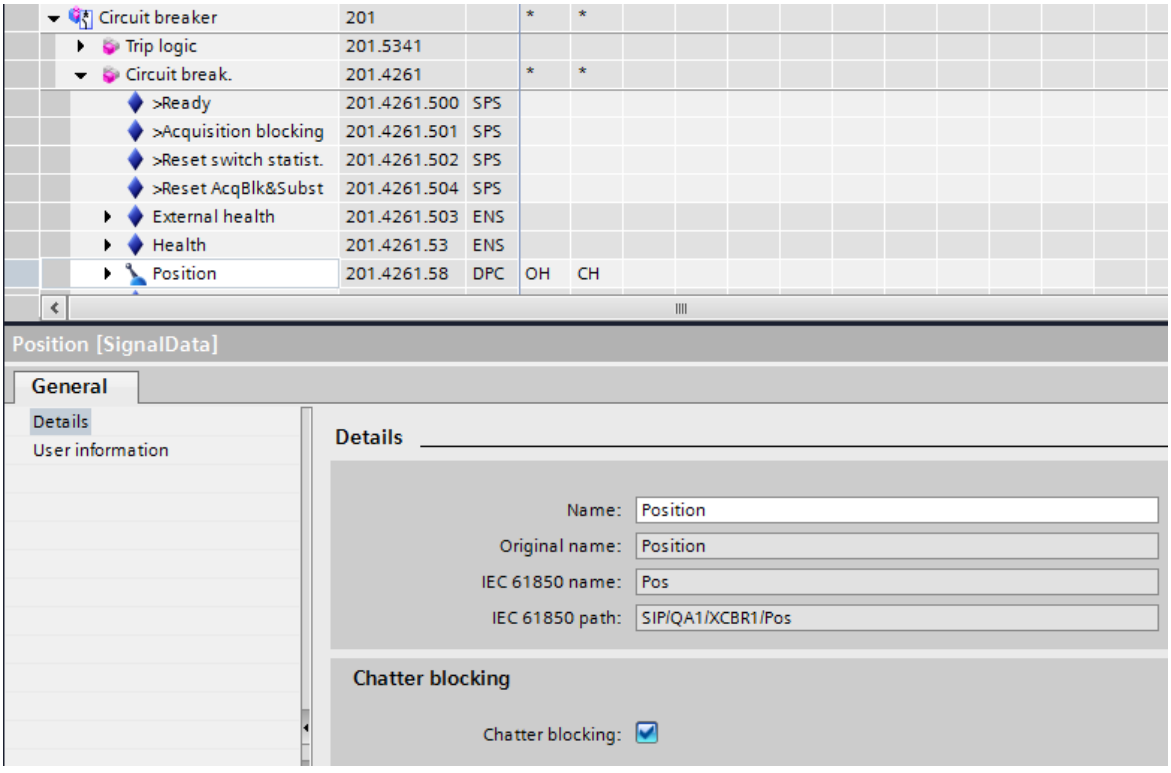
The settings for indication filtering can be found at the individual signals. The next figure shows the settings using the example of a controllable (circuit-breaker switch position).

NOTE

The software filtering time is available only for the circuit breaker and disconnector in the controllable **Cmd. with feedback** (**control** function block), as this is used for logging purposes. The controllable **position** (**circuit breaker** or **disconnector** function block) is used for interlocking conditions and must always show the unfiltered position of the switching object.

[sc_lposi, 1, en_US]

Figure 3-124 Settings for Circuit-Breaker Switch Position



The setting range for the **Software filter time** parameter ranges from 0 ms to 100 000 ms in ms increments. The **Retrigger filter** check box can be used to select whether to restart the filtering time whenever a status change is performed within the software filtering time. When activated, the **Indication timestamp before filtering** check box backdates the time stamp by the set software filtering time. In this case, the time stamp corresponds to the actual status change of the signal. If you activate the **Suppress intermediate position** check box, the intermediate position is suppressed for the duration of this software filtering time.

If you leave the software filtering time at 0 ms, the time for the suppression of the intermediate position is also 0 ms. The activated **Suppress intermediate position** check box then remains ineffective.

If you do not activate the **Suppress intermediate position** check box, the software filtering time affects the **on**, **off**, **intermediate**, and **disturbed** positions of the circuit breaker or disconnector switch.

With the parameter **Spontaneous position changes filtered by:**, you set how such position changes are to be filtered. Spontaneous position changes are caused by external switching commands, for example. If you select the ***General software filter*** setting, the general settings for software filtering of spontaneous position changes and for position changes caused by a switching command apply. The settings for spontaneous position changes then cannot be edited. A separate filtering for spontaneous position changes is activated with the ***Spontaneous software filter*** setting and you can edit the settings for this.

Chatter blocking can be activated or deactivated as an input parameter, for example as a parameter of the position in the **Circuit breaker** or **Disconnector** function block.

[sc_flatte, 1, en_US]

Figure 3-125 Setting Chatter Blocking

The settings for the chatter blocking function are set centrally for the entire device in DIGSI. They are accessible as settings in the **General** function group (see the following figure).

The chatter-blocking settings have the following meaning (see also *Figure 3-126* and *Figure 3-127* in the examples shown in the following):

- **No. permis.state changes**

  This number specifies how often the state of a signal may toggle within the chatter-test time and the chatter-checking time. If this number is exceeded, the signal will be or remains blocked.

  Enter a number from 0 to 65535 in this field. If the entry is 0, chatter blocking is essentially inactive.

- **Initial test time**

  During this time, the number of times a signal changes its status is checked. This time is started if chatter blocking is configured for at least one signal and this signal changes its status. If the configured number of permissible status changes is exceeded during the initial test time, the signal is temporarily blocked and the indication *Chatter blocking* is set.

  Enter a number from 1 to 65535 in this field. The number entered corresponds to the time in seconds. When the set time has expired, the timer restarts automatically (cycle time).

- **No. of chatter tests**

  This number specifies the maximum number of test cycles to be run. If the number of permissible status changes of the signal stays exceeded during the initial test time of the last test cycle, the signal is finally blocked. In this case, the indication *Group warning* (**Alarm handling** group and **Device** group) is set additionally to the *Chatter blocking* indication after expiry of the set number. Restarting the devices removes this block again.

  Enter a number from 0 to 32767 in this field. The value Infinite (∞) is also permissible here.

  Enter this value as character string oo.

- **Chatter idle time**

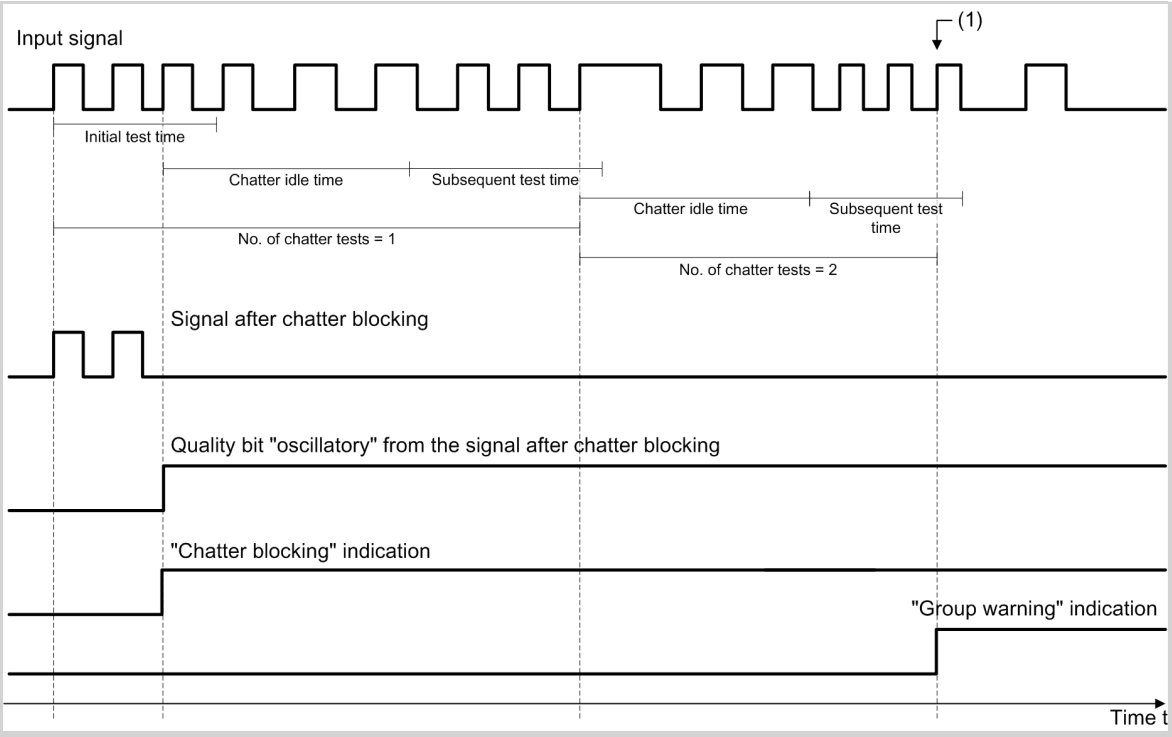
  If the number of permissible status changes for a signal is exceeded during the initial test time or the subsequent test time, the **Chatter idle time** starts. Within this time, this signal is blocked temporarily and the *Chatter blocking* indication is set. The blocked input signal is assigned the **oscillatory** quality.

  Enter a number from 1 to 65535 in this field. The number entered corresponds to the time in minutes. An entry here is only considered if the number of chatter tests does not equal to 0.

- **Subsequent test time**

  During this second test time, the number of times a signal changes its status is checked once again. The time begins when the **Chatter idle time** expires. If the number of status changes is within the permissible limits, the signal is released. Otherwise, an additional dead time begins, unless the maximum number of chatter tests has been reached.

  Enter a number from 2 to 65535 in this field. The number entered corresponds to the time in seconds. An entry here is only considered if the number of chatter tests does not equal 0.



Example 1: Permanent Blocking

The chatter-blocking settings are set as follows:

- **No. permis.state changes** = 4
- **No. of chatter tests** = 2

After more than 4 state changes within the **Initial test time**, the input signal is set to the original state by the chatter blocking and the **oscillatory** quality is assigned. Additionally, a corresponding indication is added to the operational log. At the same time, the *Chatter blocking* indication is set. After expiry of the settable **Chatter idle time**, during the following **Subsequent test time**, it is checked whether the input signal is still chattering. This check is repeated, as the **No. of chatter tests** is set to 2 in this example.

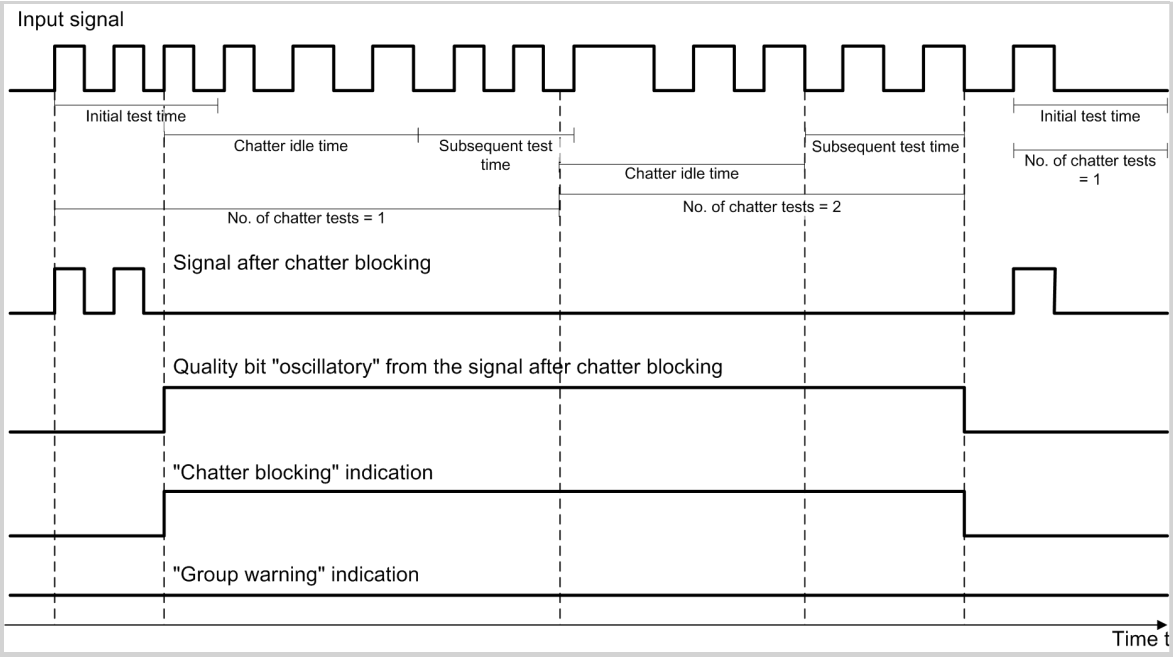
If, during the 2nd **Subsequent test time**, it has been detected that the number of status changes of the input signal exceeds the set **No. permis.state changes**, the chatter blocking detects a persistent violation of the signal stability and sets the *Group warning* indication. The original state of the signal is permanently frozen. Only a device restart removes the chatter blocking again.

[dw_chatter-block-01, 1, en_US]

Figure 3-126 Signal Change during Chatter Blocking with too Important Number of Signal State Changes During 2nd Subsequent Test Time

(1) The input signal is permanently blocked starting from this point in time.

Example 2: Temporary Blocking



The chatter-blocking settings are set as follows:

- **No. permis.state changes** = 4
- **No. of chatter tests** = 2

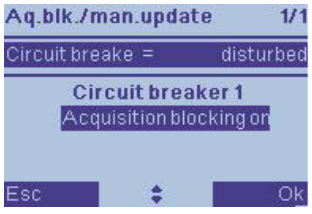
After more than 4 state changes within the **Initial test time**, the input signal is set to the original state by the chatter blocking and the **oscillatory** quality is assigned. Additionally, a corresponding indication is added to the operational log. At the same time, the *Chatter blocking* indication is set. After expiry of the settable **Chatter idle time**, during the following **Subsequent test time**, it is checked whether the input signal is still chattering. This check is repeated, as the **No. of chatter tests** is set to 2 in this example.

If, during the 2nd **Subsequent test time**, it has been detected that the number of state changes of the input signal is within the set **No. permis.state changes**, the temporary blocking of state changes of the signal is removed and the actual signal state is released.

The quality bit **oscillatory** is removed and the *Chatter blocking* indication is reset. As the temporary blocking of the signal is removed, the *Group warning* indication is not set. The chatter test starts again.

[dw_chatter-block-02, 1, en_US]

Figure 3-127 Signal Change during Chatter Blocking with Permissible Number of Signal State Changes During 2nd Subsequent Test Time



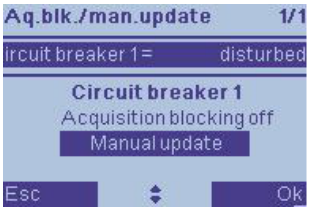
3.9.2 Acquisition Blocking and Manual Updating

During commissioning, maintenance, or testing, a brief interruption of the connection between the logical signals and binary inputs may be useful. It allows you to manually update the status of a switching device that is not providing feedback correctly. Before this can take place, you must first set acquisition blocking.

To set the acquisition blocking, proceed as follows:

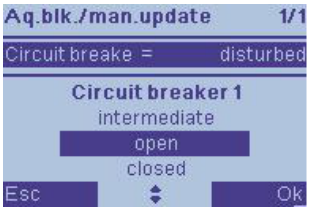
- Using the navigation keys, move in the **main menu** of the device display to **Commands→Equipment→Aq.blkman. update**.
- Select the appropriate device (for example, a circuit breaker) from among the several switching devices using the navigation keys.
- Press the **Change** softkey.
- Enter the confirmation ID (not relevant for active role-based access control (RBAC) in the device).
- Confirm the process with the softkey marked **OK** in the display.

After entering the confirmation ID (only with the RBAC inactive), acquisition blocking is switched on.



[sc_detection, 1, en_US]

Figure 3-128 Activating the Acquisition Blocking



Manual updating of the switching device is possible from within the same menu.

- Select **Manual update** (*Figure 3-129*) using the navigation keys.
- Select the switching device setting to be manually updated using the navigation keys (for example, **off**, *Figure 3-130*).
- Confirm the process with the softkey marked **Ok** in the display.

[sc_status, 1, en_US]

Figure 3-129 Activating Manual Update

[sc_statu2, 1, en_US]

Figure 3-130 Selecting Position

The manually updated position of the switching device will be displayed.

[sc_statu3, 1, en_US]

Figure 3-131 Position of the Switching Device

NOTE

For security reasons, manual updating is possible only directly through the on-site operation panel of the device and not through DIGSI 5.

NOTE

Setting acquisition blocking and the subsequent manual updating are also possible via the IEC 61850 system interface.

You can set acquisition blocking also via a binary input. If you want to put in the feeder or the switching device in revision, you can set the acquisition blocking with an external toggle switch for one or more switching devices. For this purpose, every switching device in the **Switch** function block (circuit breaker or disconnector switch) has the input signal **`>Acquisition blocking`**. This signal can also be set from the CFC.

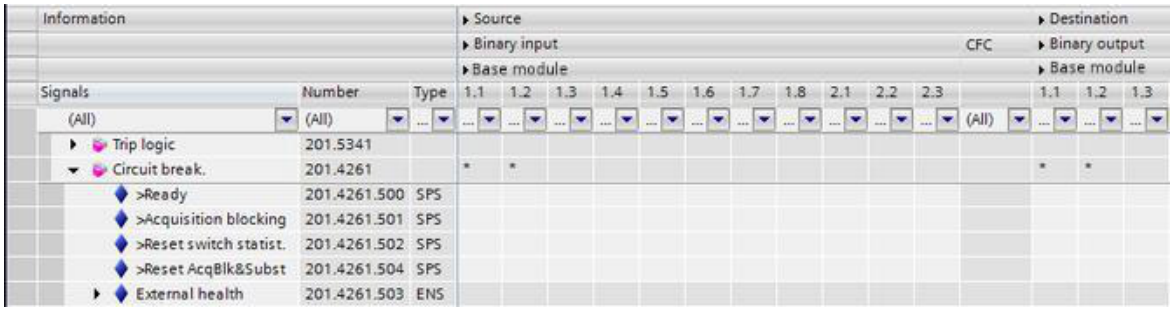


Figure 3-132 Input Signals *>Acquisition Block* and *>Release Acquisition Block & Manual Updating* on the Switching Device

NOTE

Interlockings are carried out with the status changes of the switching device. Remove acquisition blocking again manually. Otherwise, position changes of the switching device are not detected and interlockings are ineffective.

If the acquisition blocking and the manually updated position are set using the operation panel of the device or the system interface IEC 61850, these are retained until the acquisition blocking is manually deactivated. When you initially start the device, the acquisition blocking is deactivated.

Except for a restart, the acquisition blocking and the manually updated position are retained.

If the acquisition blocking is activated via the input signal **>Acquisition blocking**, it is retained as long as the binary input is active.

To set the acquisition blocking of a switching device, the following sources are possible:

- Operation panel of the device
- System interface IEC 61850
- Input signal **>Acquisition blocking**

All sources undergo OR operations, that is, the acquisition blocking remains set until all the sources are deactivated.

After deactivation of the acquisition blocking, the actual position of the switching device is adopted and displayed in the operation panel of the device.

NOTE

When the acquisition blocking is activated or the switching device updated manually while the entire device or the switching device is in application mode, these states are not saved. The acquisition blocking and the manual updating are not retained after a restart.

The acquisition blocking and the manual update for the circuit breaker, the disconnector, and the tap changer are reset by way of the **>Reset AcqBlk&Subst** binary input. Setting acquisition blocking and manual update is blocked with the input activated.

3.9.3 Persistent Commands

In addition to the switching commands, which are issued as pulse commands, and stored for the standard switching devices (circuit breaker, disconnector switch), persistent commands are also possible. In this case, a distinction must be drawn between controllables with the **Continuous output** operating mode and a stored signal output that is immune to reset.

You can change a controllable from pulse to persistent command with the **Command output** parameter.

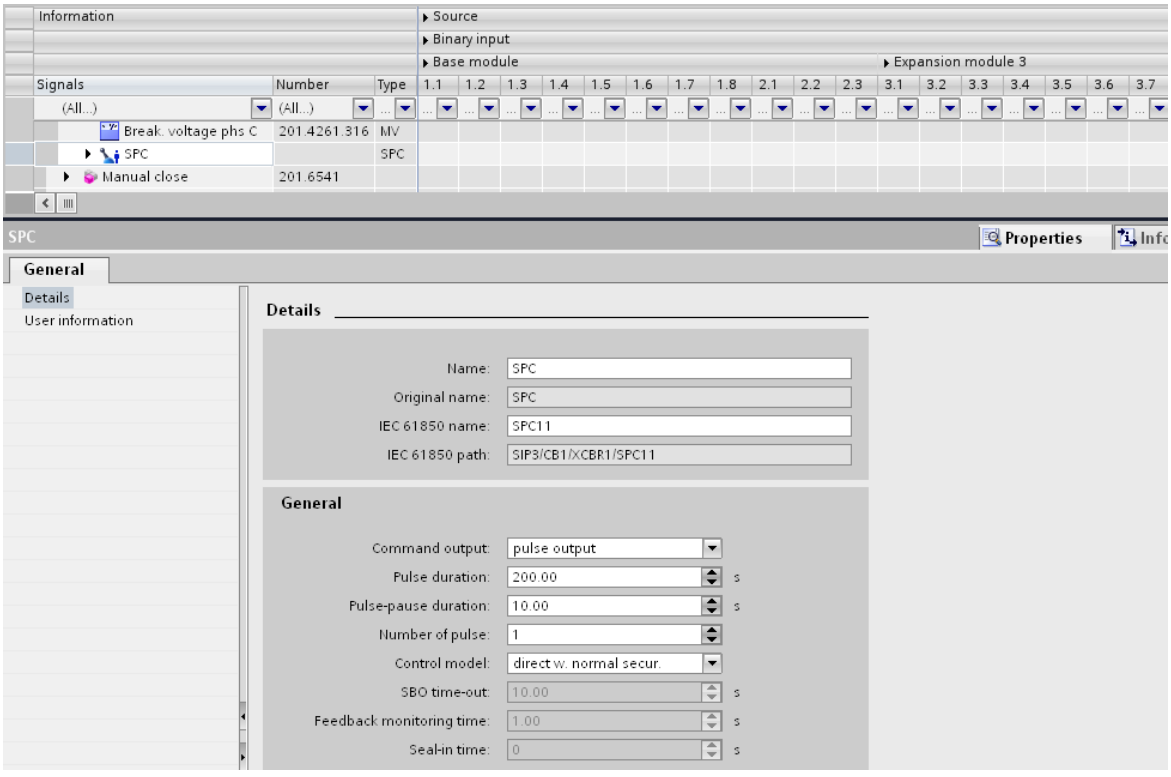

Figure 3-133 Setting the Command Type in DIGSI 5

Select ***Pulse output*** or ***Continuous output*** for the command output type. If a persistent command is selected, the Pulse parameter is irrelevant.

3.9.4 Device Logout

3.9.4.1 Overview

In the case of multibay functions, a device uses information from one or more other devices. For some applications, it may be necessary for you to remove a device with all effective functions temporarily from the plant and even to switch it off. These applications are, for example:

- Maintenance work
- System upgrades
- Testing the local protection functions, for example, the local line differential protection

The *Device logout* functionality informs the receiver devices about the imminent disconnection of the transmitter devices. To do this, the last valid received information is stored in the receiver devices and used for the multibay functions.

NOTE

If you need to remove a device temporarily from the plant, you must log off the device.

Protection functions distributed to several devices operate in a healthy manner with the remaining devices only if you have logged off the device.

You can log off the device as follows:

- Via the on-site operation panel
- Via a communication interface using the *Device logout* (*_:319*) controllable
- Via the binary inputs, general: *>Dev. funct.logout on* (*_:507*) or *>Dev. funct.logout off* (*_:508*)

You can find the controllable and the binary inputs in the DIGSI 5 project tree under **Name of the device** → **Information routing** in the working area in the **General** block.

During the log-off process, the device checks whether all conditions for a logout have been met. If the conditions for the log off have not been met, the logout is rejected.

The logout is rejected under the following conditions:

- The devices are communicating via the protection interface and switching off the device leads to an interruption in protection-interface communication.
- The **Line differential protection** function is operating in the device and the local circuit breaker is still switched on.

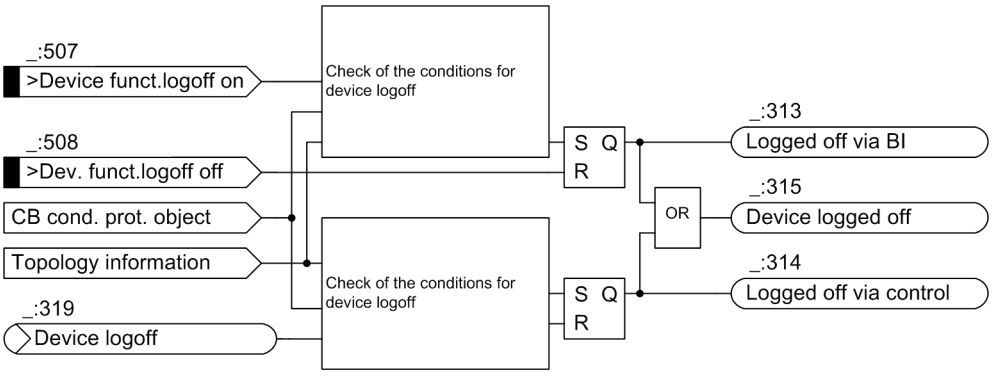
  In this case, you must switch off the local circuit breaker and repeat the log-off process for the device. After the logout, the local **Line differential protection** function is removed from the summation of the currents for the **Line differential protection** of the other devices. The **Line differential protection** function remains active in the other devices.

NOTE

The path used to log the device off is stored in the operational log.

Even if you switch off the device after logout, the *Device logged off* (_:315) state is stored.

If you want to establish the initial state again after logging off the device, you must log on the device again. To log on the device, you must use the same option used for logout. For example, if you have logged off the device via binary inputs, you must log it on again via the binary inputs. This applies in similar manner if you have logged off the device via DIGSI or via on-site operation.



3.9.4.2 Application and Setting Notes

Logoff Options for a Device

You can log a device off as follows:

- Via the on-site operation panel
- Via communication through the controllable *Device logout* (*_:319*)
- Via the binary inputs, general: *>Dev. funct.logout on* (*_:507*) or *>Dev. funct.logout off* (*_:508*)

Conditions for Logging off the Device

[lo_functional logoff device, 1, en_US]

Figure 3-134 Logic for Logging off the Device

The conditions for a successful logout of the device result from the conditions for every activated protection function.

Logoff of a Device from a Device Combination with Communication via the IEC 61850-8-1 (GOOSE) Protocol

If devices are exchanging data using the IEC 61850-8-1 (GOOSE) protocol – for example in the case of substation interlocking – for each received data point the value of this data point can be set in the receiver device when the transmitter device logs off. This value remains effective in the receiver device until the logout is canceled by the transmitter device, even if the transmitter and/or the receiver are switched off in the meantime.

Logoff of a Device from a Device Combination Using Protection Communication

If devices in a device combination communicate via the protection interface, you can only log off a device under the following conditions:

- Logging off and switching off a device in a device combination must not result in an interruption in the protection communication.
- For series-connected topologies, the device must be located at one end of the communication chain as otherwise the protection communication is interrupted when the device is logged off and switched off.

  For this reason, devices not at one of the ends in series-connected topologies cannot be logged off.

Logging Off a Device from a Protection Application with Line Differential Protection

If you are using the **Line differential protection** function, you must ensure that the functionality is still effective even after a device in a device combination is logged off and switched off. The following example describes the procedure:

EXAMPLE:

The following line formation is protected by the **Line differential protection** with 3 devices.

[dw_example logoff ldiff, 2, en_US]

Figure 3-135 Differential Protection with 3 Devices for a Line with a Feeder

In the example, the feeder is to be decommissioned for maintenance or modification work. Device 3 should therefore also be switched off. Without additional measures, the **Line differential protection** will no longer function and sends an ineffective indication.

For this use case, the **Line differential protection** function must be logged off in Device 3.

NOTE

Before logging off, you must de-energize the feeder protected by the local **Line differential protection**.

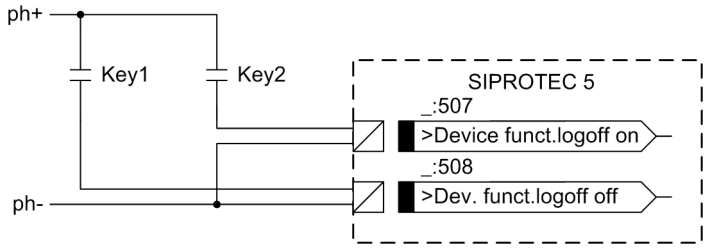
Line differential protection in device 3 can only be logged off if no current is flowing through the feeder. Device 3 checks during the log-off process whether the circuit breaker 3 is really switched off.

The **Circuit-breaker position recognition** in the function group **Circuit breaker** (CB) provides the circuit-breaker position using the internal signal *CB state protected obj.*.

If a protected object is supplied via 2 circuit breakers (CBs), for example with the 1 1/2 circuit-breaker layout, then the circuit-breaker position of the protected object must be determined with the aid of both circuit breakers. In this case, the Circuit-breaker position function block performs linking of the individual CB positions for the protected object.

If one of the following 2 conditions is met, the *CB status protected object* internal signal assumes the position *Open*:

- All connected circuit breakers signal internally the position *Open*.
- The binary input signal *>Disconnector open* is active.

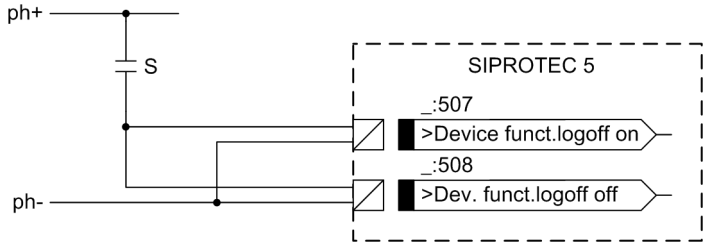


For further information refer to *5.5.4.6 Circuit-Breaker Condition for the Protected Object*.

If the **Line differential protection** is logged off in device 3, the remaining devices 1 and 2 will save this state and the total current for the Kirchoff's current law will then be calculated with the currents in devices 1 and 2 only.

If device 3 is successfully logged off, you can switch it off. The logoff of device 3 will also be saved in the remaining devices after it is switched off. If you switch device 3 on again, you must log it on again in the device combination.

Logout via Binary Inputs



The following diagrams show potential variants on how to control binary inputs. If you want to use push-buttons, switch on this function as shown in the following figure. Log off the device using the push-button **Key2**; log on the device again with the push-button **Key1**.

[lo_extta logoff device, 1, en_US]

Figure 3-136 External Push-Button Wiring for Logging off the Device

If a switch is being used for control, route the binary input *>Dev. funct.logout on* as ***H (active with voltage)*** and the binary input *>Dev. funct.logout off* as ***L (active without voltage)***. If the switch **S** is closed, the device is logged off.

[lo_extsx logoff device, 1, en_US]

Figure 3-137 External Switch Wiring for Logging off the Device

Indications

The logged-off device reports the status (*(_:315) Device logged off*) and cause of the logout.
If you have logged off the device using binary inputs, the indication *(_:313) Logged off via BI* results.
If you have logged off the device using on-site operation, via DIGSI 5 or via the protection interface,the indication *(_:314) Logged off via control* is issued.
The indications are stored in the operational log.

3.9.4.3 Information List

No.	Information	Data Class (Type)	Type
General			
_:507	General:>Dev. funct.logout on	SPS	I
_:508	General:>Dev. funct.logout off	SPS	I
_:319	General:Device logout	SPC	C
_:313	General:Logged off via BI	SPS	O
_:314	General:Logged off via control	SPS	O
_:315	General:Device logged off	SPS	O

3.10 General Notes for Setting the Threshold Value of Protection Functions

3.10.1 Overview

You can set the threshold values of protection functions directly on the device or by using DIGSI 5.

An innovative design was implemented for the protection settings.

You can switchover the edit mode between the following setting views:

- Primary
- Secondary
- Percent

If you change settings in a setting view, DIGSI 5 calculates the settings of the 2 inactive views in the background. If you wish to save, for example, conversion to secondary values, then select the primary view. Configure all the settings and switchover to the secondary view.

Edit Mode: Primary

The parameters are set as primary values and thus refer directly to the primary system. The manual conversion on the secondary circuit omitted.

Edit Mode: Secondary

The settings refer to the secondary circuit of the transformer. This means that the settings must be converted. The secondary setting is the customary setting view. For secondary tests, the pickup values can be read directly.

Edit Mode: Percent

This setting type is beneficial for electric machines (generators, transformers, motors, and busbars). The setting values can be standardized regardless of the machine size. The reference values for the percentage settings are the rated values of the function groups, for example, rated voltage and rated current or rated apparent power. The setting values are, thus, related exclusively to the primary settings. If other reference values are used, then this is documented for the respective protection function in the application and setting notes.

If parameters are selected it may happen that they are set only in percent in all 3 setting views.

Recommendation for Setting Sequence

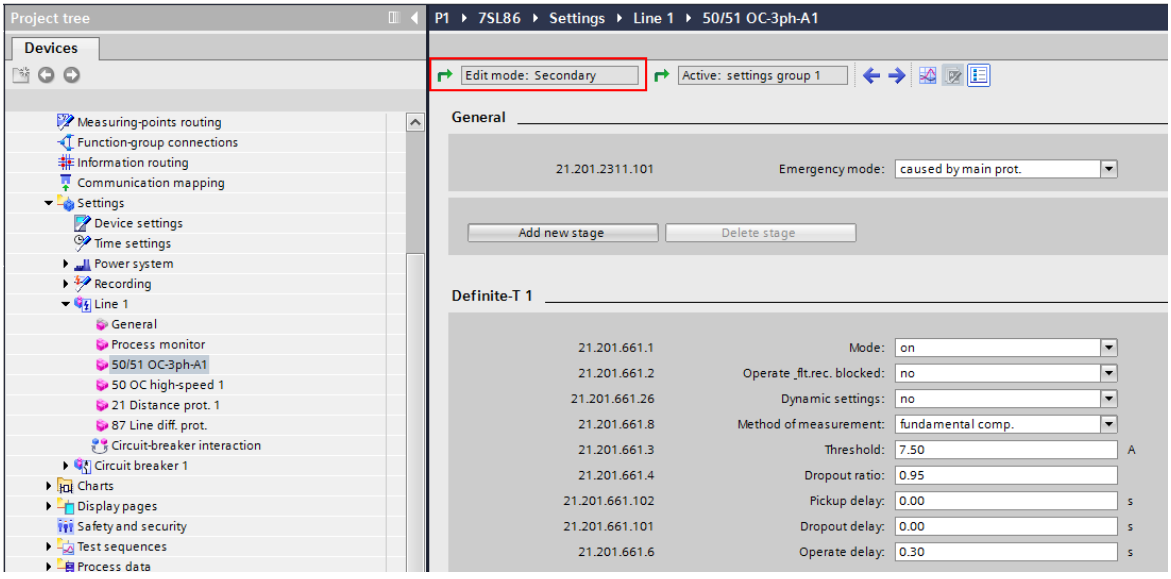
When setting the protection function, Siemens recommends the following procedure:

- First, set the transformation ratios of the transformers. You can find these under **Power-system data**.
- Subsequently, set the reference parameters for the percent setting. You will find these parameters in function group , for example, in function group **Transformer** in General Nodes under Rated Values and Coil Data..
- Next, set the parameter of the protection functions.

  If the transformer data have changed after completing the protection setting, remain in the setting sheet (for example, primary setting) and change the transformer data. In the background, DIGSI 5 obtains the new settings in the inactive setting views (for example, new secondary values).

The following section explains, by way of an example, how to modify the transformer ratios in DIGSI 5 using the corresponding alternatives.

3.10.2 Modifying the Transformer Ratios in DIGSI 5

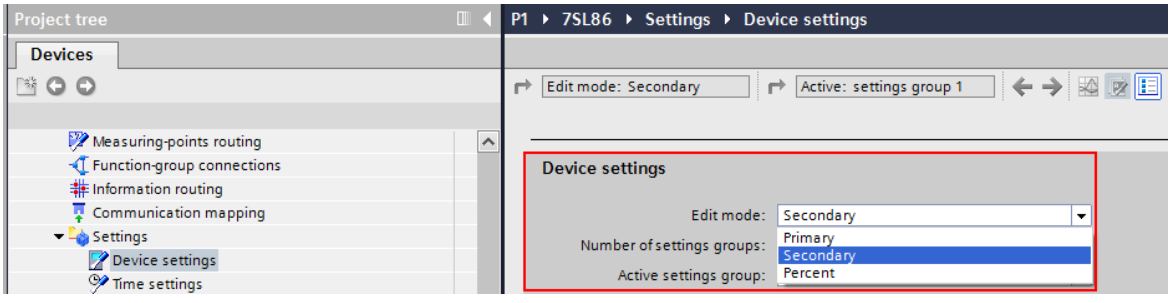


In the delivery setting, DIGSI 5 is set to the edit mode **Secondary**.

The following setting example shows how you can change the transformer ratio in DIGSI 5, and what impact this has on the settings in the setting views **Primary** and **Secondary**. The protection setting is observed in the example of the function **Overcurrent protection**.

The following output data are assumed:

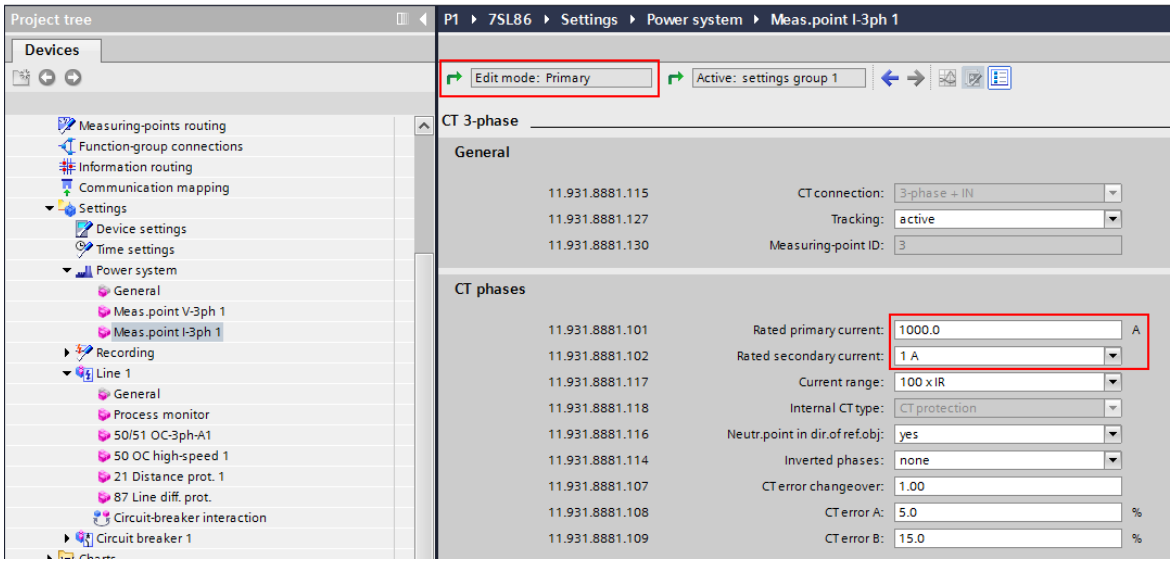
Current transformer:	1000 A/1 A
Protection pickup value:	1.5 A



The following figure shows the protection setting of the function **Overcurrent protection** in the secondary view. The threshold value of the stage is set to 1.5 A.

[scmodsek_1, 1, en_US]

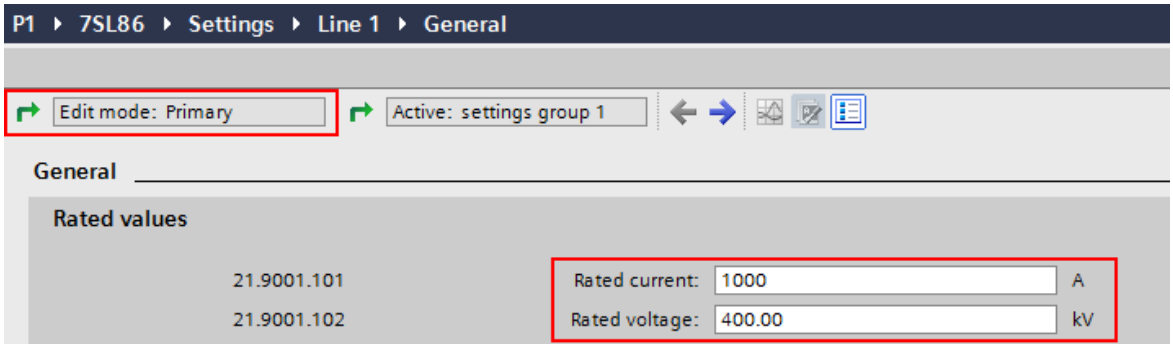
Figure 3-138 Protection Setting, Display of the Active Setting Sheet



When you click the green arrow in the setting sheet at the upper left, you get to the window for switching over to the setting view (see the following figure). Select the setting view you prefer.

[scmodums_2, 1, en_US]

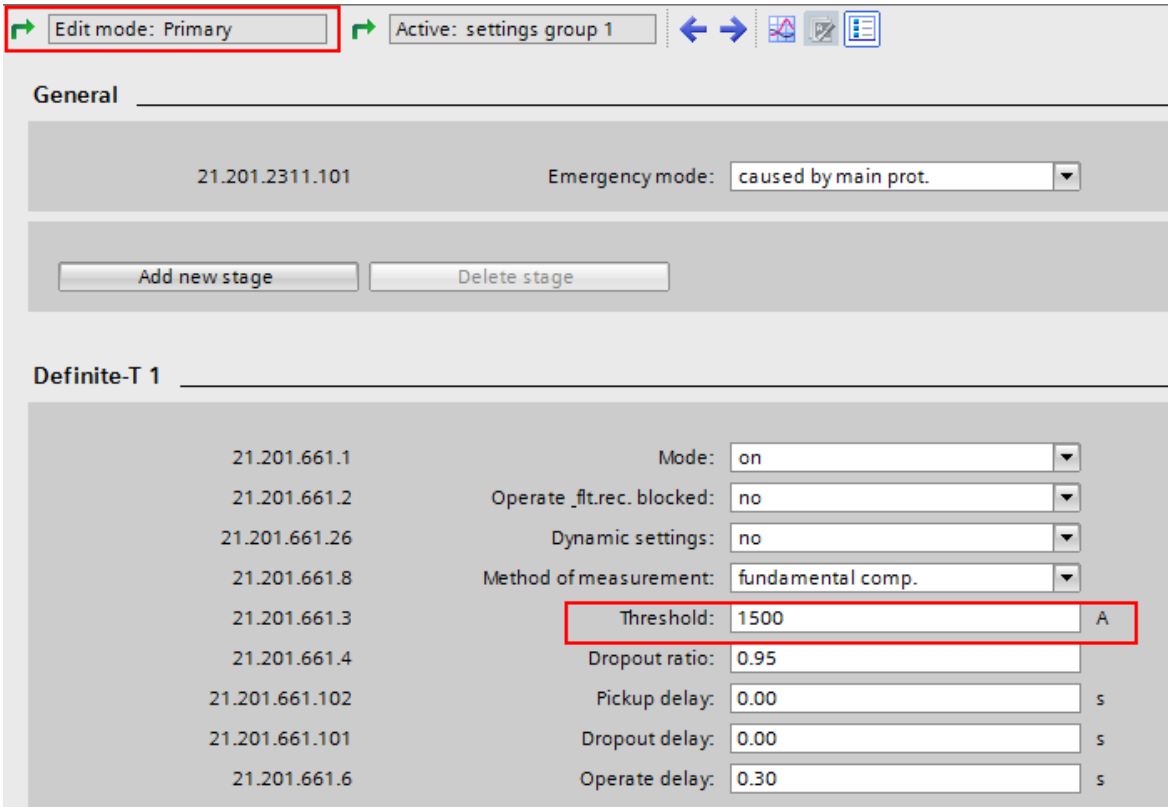
Figure 3-139 Switchover to the Desired Setting View



The following figures show the setting sequence in the edit mode **Primary**. Set the transformer data. In the example, the current transformer has a transformation ratio of 1000 A/1 A.

[scpwandl_3, 1, en_US]

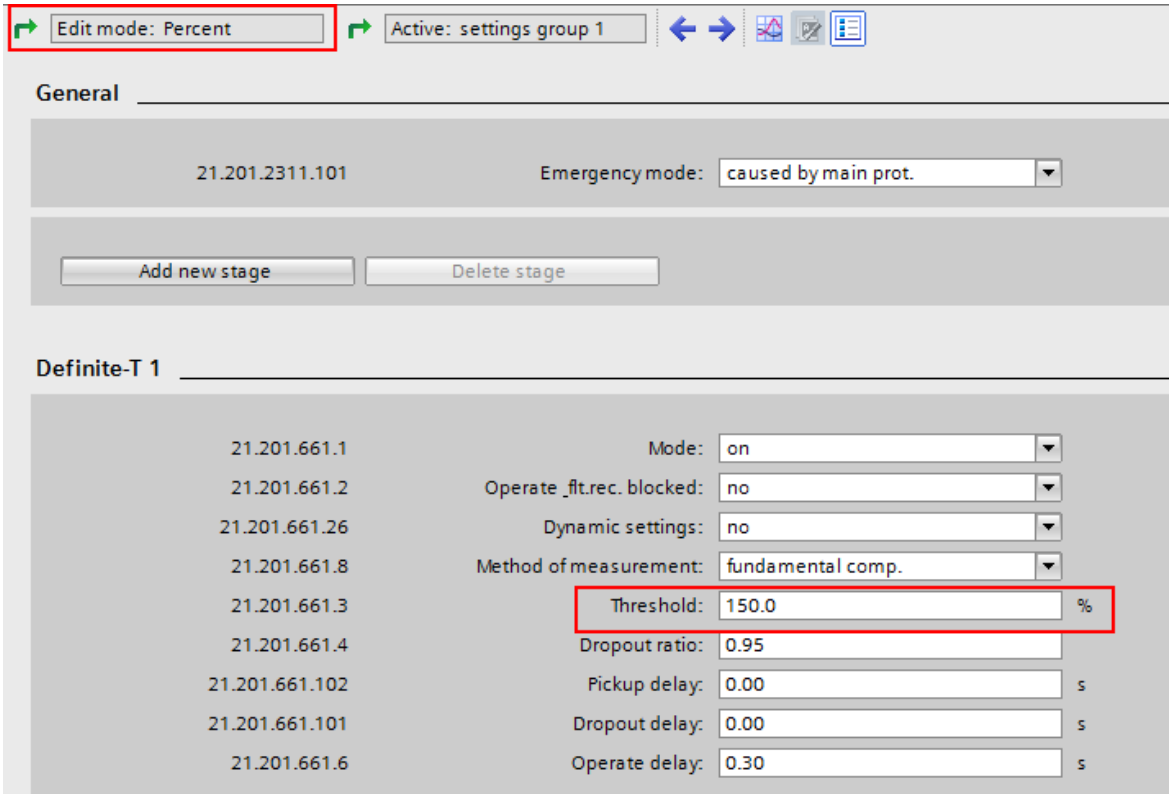
Figure 3-140 Setting Sheet: Transformer Data



In the function group **Transformer**, you set the transformer data (see following figure). Rated current, rated voltage and rated apparent power are the reference variables for the percent setting.

[scproref_4, 1, en_US]

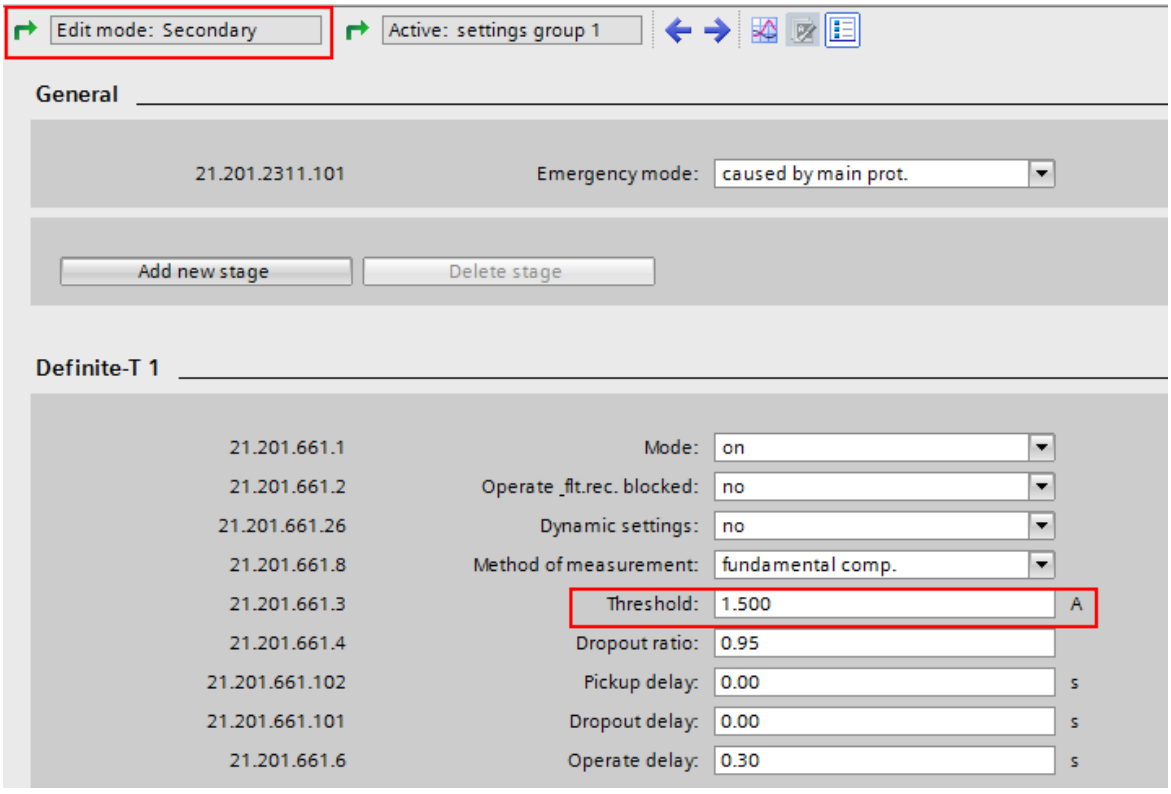
Figure 3-141 Reference Data for Percentage Settings



The following figure shows the threshold value of the function **Overcurrent protection** in the primary view at 1500 A.

[scumzpri_5, 1, en_US]

Figure 3-142 Example of the Threshold Value of the Definite-Time Overcurrent Protection Stage (Edit Mode: Primary)



When switching over to the percent view, the result should be the following value:
1500 A/1000 A · 100 % = 150 %

[scumzpro_6, 1, en_US]

Figure 3-143 Example of the Threshold Value of the Definite-Time Overcurrent Protection Stage (Edit Mode: Percent)

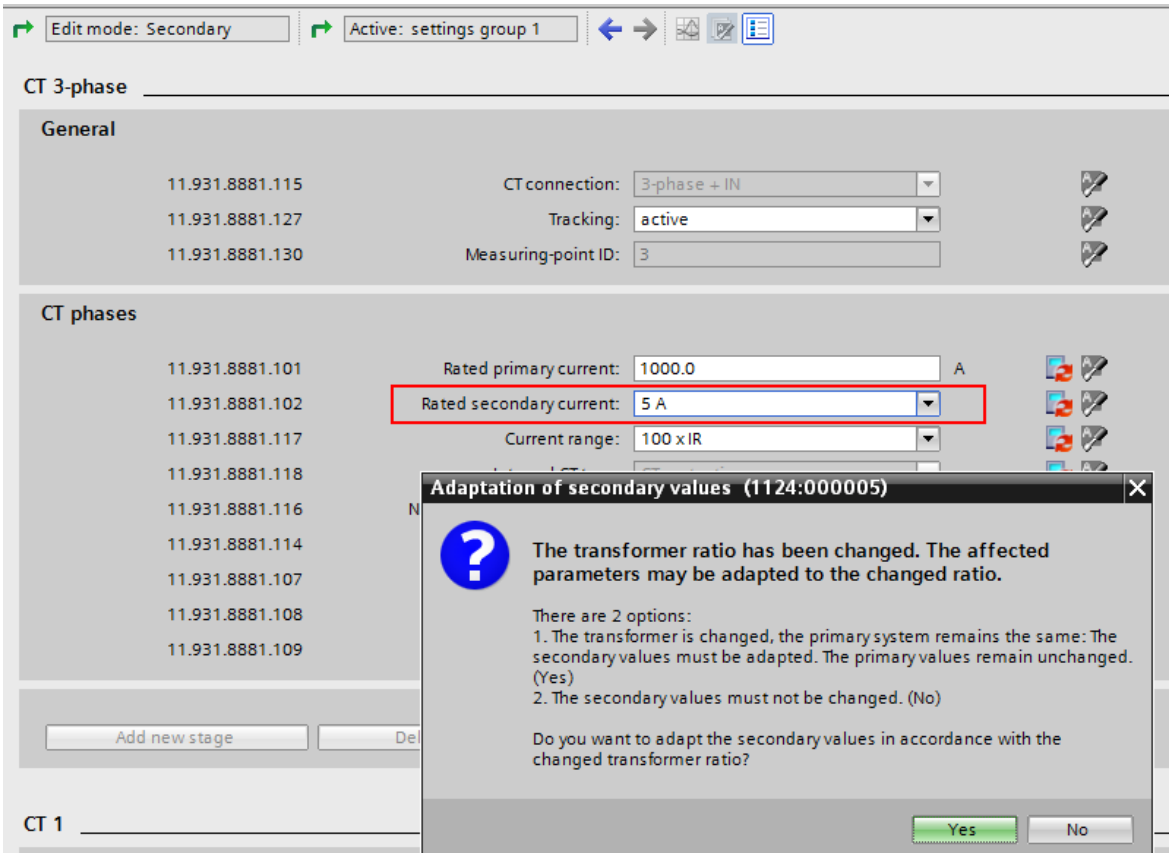
When switching over to the secondary view, the result should be the following value:
1500 A/(1000 A/1 A) = 1.5 A

[scumzsek_7, 1, en_US]

Figure 3-144 Example of the Threshold Value of the Definite-Time Overcurrent Protection Stage (Edit Mode: Secondary)

If you only want to work in the secondary view, DIGSI 5 supports you if the transformer ratio changes during the project phase.

In the example, the current-transformer ratio changes from 1000 A/**1 A** to 1000 A/**5 A**. Change the secondary rated current of the current transformer in the setting sheet of the transformer data from 1 A to 5 A (Edit mode: Secondary). If you change the transformer data, a window will appear (see the following figure) that will ask you for the action desired.



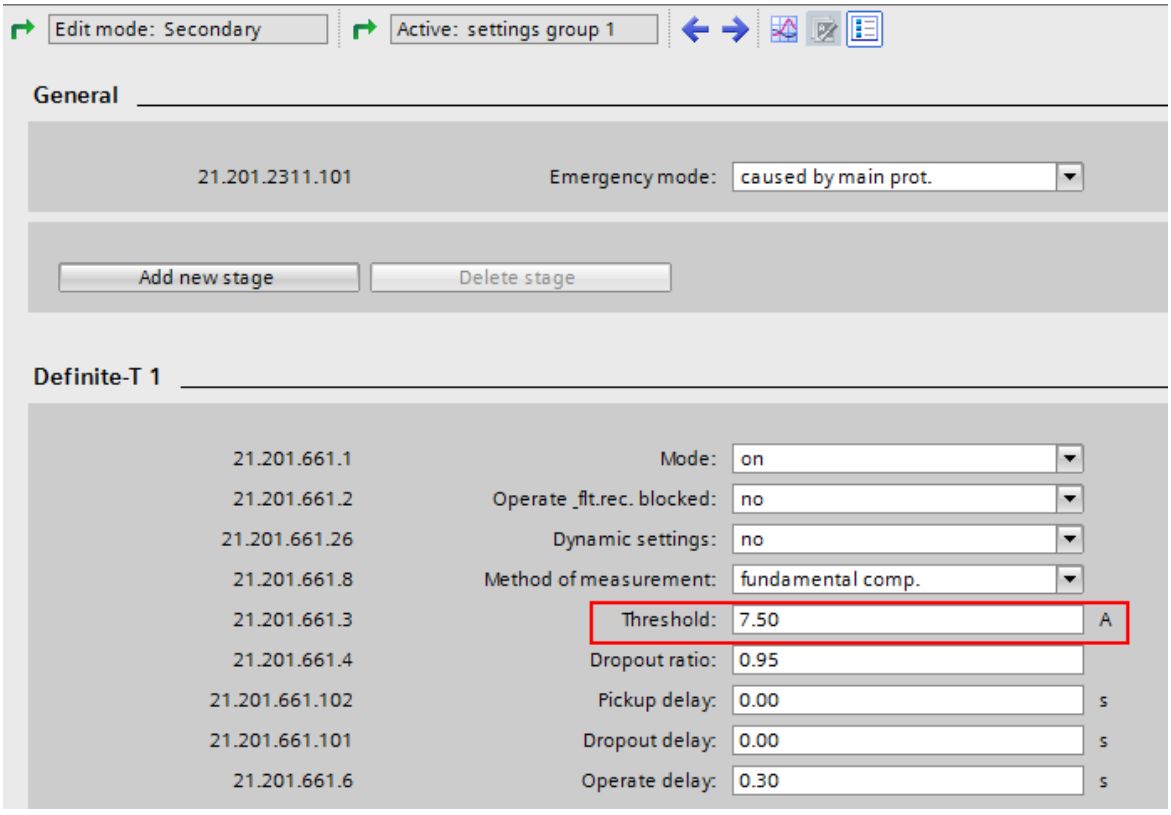


Figure 3-145 Query after Changing the Transformer Data (Setting View: Secondary)

If you answer the question with **Yes**, then DIGSI 5 will recalculate the pickup values (threshold values) in the active secondary view. For the new secondary transformer current 5 A, the new secondary threshold value obtained is 7.5 A (1.5 A * 5 = 7.5 A). The primary and percent values remain unchanged.

The following figure shows the newly calculated threshold value in the secondary view.

[scsekneu_9, 1, en_US]

Figure 3-146 Automatically Recalculated Secondary Values After Changes in the Transformer Data

If you have already set the settings in the secondary view by including the new transformation ratio of the transformer in the calculation, then answer the question with **No**. In this case, the protection settings in the secondary view remain unchanged. DIGSI 5 recalculates the settings (threshold values) of the primary view. In the example, the primary threshold value is then 300 A (1.5 A · 1000 A/5 A = 300 A).

In the example, the current-transformer ratio changes from 1000 A/1 A to 1000 A/5 A. The following table summarizes the pickup values that DIGSI 5 will recalculate in the setting view. The new values (in bold) depend on the reply to your question (refer to *Figure 3-145*).

	Reply to the Question	
	Yes	**No**
Threshold value secondary (active setting view)	**7.5** A	1.5 A
Threshold value primary (covered setting view)	1500 A	**300** A

Changing the Transformer Ratio in the Single-Line Editor

If you want to change the primary or secondary rated currents of the current transformer in the Single-Line Editor, select the current transformer. You can view and change the currents in the tab **Properties** of the object bar.

If you change the rated currents, the corresponding field has a red border to indicate currents that differ between the Single-Line Editor and the power-system data. During **synchronization** in the Single-Line Editor, these rated currents are adopted into the power-system data.

3.10.3 Changing the Transformation Ratios of the Transformer on the Device

In the delivery setting, the device is preset to secondary values. Only secondary values can be set directly on the device.

If you change transformer data directly on the device, it is not followed by a query, like in DIGSI 5 (see *Figure 3-145*). Instead, the device assumes that all settings remain unchanged in the secondary view.

NOTE

If the device works with IEC 61850 protocol, then change the transformer data only via DIGSI 5 and not directly on the device. If you change the transformer data directly on the device, the IEC 61850 configuration of the measurement and metered values can be faulty.

3.11 Device Settings

3.11.1 Settings-Group Switching

3.11.1.1 Overview of Functions

For different applications you can save the respective function settings in so-called **Settings groups**, and if necessary enable them quickly.

You can save up to 8 different settings groups in the device. In the process, only one settings group is active at any given time. During operation, you can switch between settings groups. The source of the switchover can be selected via a parameter.

You can switchover the settings groups via the following alternatives:

- Via the on-site operation panel directly on the device
- Via an online DIGSI connection to the device
- Via binary inputs
- Via a communication connection to the substation automation technology.
  The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP, or Modbus TCP can be used for switching the settings groups.

A settings group includes all switchable settings of the device. Except for a few exceptions (for example, general device settings such as rated frequency), all device settings can be switched.

For detailed information about the settings groups, refer to the *Operating Manual* and to the *DIGSI 5 Online Help*.

3.11.1.2 Structure of the Function

The function of the **Settings group switching** is a supervisory device function. Accordingly, the settings and indications of the settings group switching can be found in DIGSI 5 and at the on-site operation panel of the device, below the general device settings respectively.

If you want to switchover a settings group, navigate to DIGSI 5 or proceed on the on-site operation panel of the device, as follows:

- Via the project tree in DIGSI 5:
  Project -> Device -> Settings -> Device settings
- Via the on-site operation panel of the device:
  Main menu → Settings → General → Group switchover

The indications for the settings group switching can be found in the DIGSI 5 project tree under:
Project → Device → Information routing → General

3.11.1.3 Function Description

Activation

If you want to use the **Settings group switching** function, you must first set at least 2 settings groups in DIGSI 5 (parameter **Number of settings groups** > 1). You can set up a maximum of 8 settings groups. The settings groups set in DIGSI 5 are subsequently loaded into the device.

Mechanism of the Switchover

When switching over from one settings group to another, the device operation is not interrupted. With the parameter **Active settings group** you are either specifying a certain settings group or you allow switching ***via control*** (IEC 60870-5-103, IEC 61850) or ***via binary input***.

Switching via Control

When using the ***Control*** function for switching, the settings groups can be switched via a communication connection from the substation automation technology or via a CFC chart.

The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP, or Modbus TCP can be used for switching the settings groups via a communication connection.

In order to use a CFC chart for switching, you must create a new CFC chart in DIGSI 5. Create the CFC chart in the DIGSI 5 project tree under **Name of the device** →**Charts** →**Add new chart**. Link the signals that control settings group switching in the CFC chart.

Switching via Binary Input

There are 3 appropriate input signals available for switching via binary inputs. These input signals allow selection of the settings group via a binary code. If one of the 3 signals changes, the signal image present will, after 100 ms (stabilization time), result in switching over to the appropriate settings group. If only 2 settings groups must be switched over, only 1 binary input is required. The following table shows the possible binary codes (BCD) and applicable settings groups (PG).

Table 3-22 Binary Codes of the Input Signals and Applicable Settings Groups

BCD Code via Binary Inputs	PG 1	PG 2	PG 3	PG 4	PG 5	PG 6	PG 7	PG 8
>PG selection bit 3	0	0	0	0	1	1	1	1
>PG selection bit 2	0	0	1	1	0	0	1	1
>PG selection bit 1	0	1	0	1	0	1	0	1

Copying and Comparing Settings Groups

In DIGSI 5, you can copy or compare settings groups with each other.

If you want to copy settings groups, select a source and target parameter group in DIGSI 5 in the device settings, and then start the copy process. The device settings can be found in the DIGSI 5 project tree under Project → Device → Settings → Device settings.

If you want to compare settings groups, it is possible to do so in all setting sheets for settings. You will then select in addition to the active settings group, a 2nd settings group for comparison. Active setting values and the comparable values are displayed next to each other. For settings that cannot be switched over, no comparable values are displayed.

Indication of Settings Group Switchings

Every settings group shows an applicable binary indication as well as its activation and deactivation. The process of settings group switching is also logged in the log for settings changes.

3.11.1.4 Application and Setting Notes

Parameter: Number settings groups

- Default setting **(_:113) Number settings groups** = ***1***

With the parameter **Number settings groups**, you can set the number of available settings groups; you can switch between these.

Parameter: Activat. of settings group

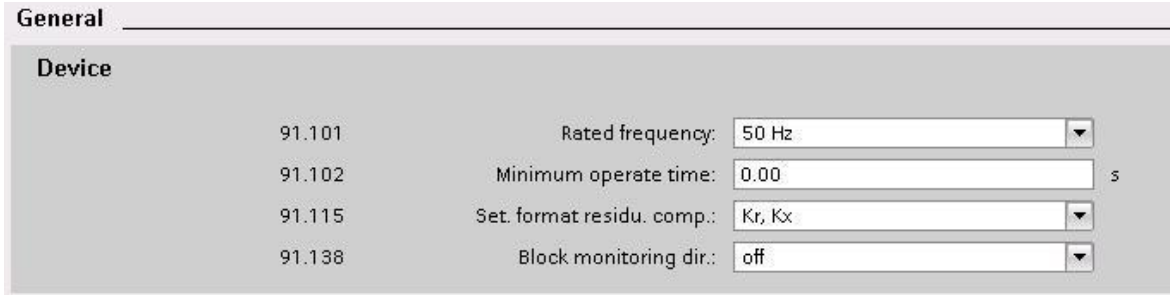
- Default setting **(_:114) Activat. of settings group** = ***settings group 1***

With the parameter **Activat. of settings group**, you specify the settings groups that you want to activate, or the mechanisms via which the switchover is allowed. You can switchover only between the settings groups specified with the parameter **Number settings groups**.

Parameter Value	Description
via control	The switchover between the settings groups can only be initiated via a communication connection from a substation automation technology or via a CFC chart. The communication protocols IEC 60870-5-103, IEC 60870-5-104, IEC 61850, DNP, or Modbus TCP can be used for switching the settings groups via a communication connection.
via binary input	The switchover between the settings groups functions exclusively via the binary input signals routed to the settings group switching.
settings group 1 ... ***settings group 8***	They define the active settings groups. You can define the active settings groups in DIGSI 5, or directly on the device via the on-site operation.

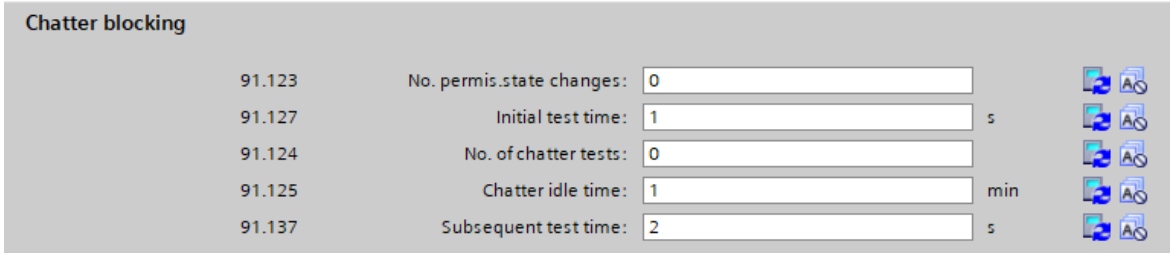
3.11.1.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Change group				
_:113	General:Number settings groups		1 to 8	1
_:114	General:Activat. of settings group		• via control • via binary input • settings group 1 • settings group 2 • settings group 3 • settings group 4 • settings group 5 • settings group 6 • settings group 7 • settings group 8	settings group 1



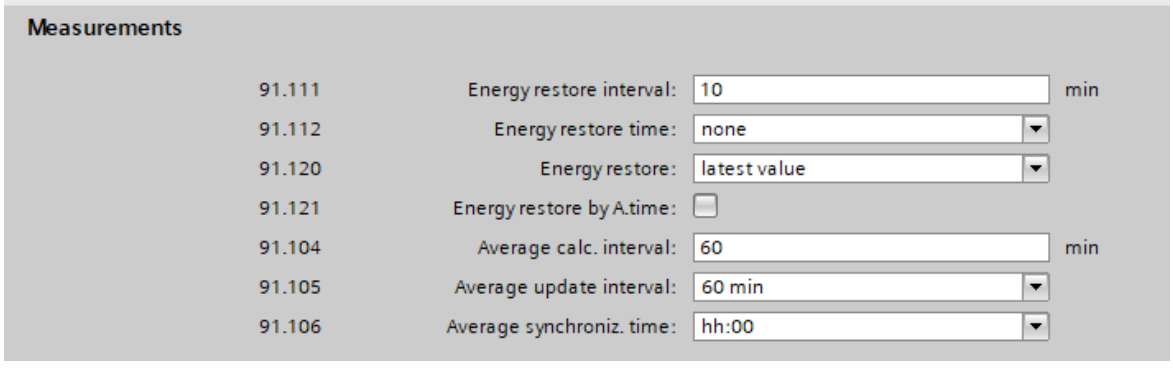
3.11.1.6 Information List

No.	Information	Data Class (Type)	Type
General			
_:500	General:>SG choice bit 1	SPS	I
_:501	General:>SG choice bit 2	SPS	I
_:502	General:>SG choice bit 3	SPS	I
_:300	General:Act. settings group 1	SPC	C
_:301	General:Act. settings group 2	SPC	C
_:302	General:Act. settings group 3	SPC	C
_:303	General:Act. settings group 4	SPC	C
_:304	General:Act. settings group 5	SPC	C
_:305	General:Act. settings group 6	SPC	C
_:306	General:Act. settings group 7	SPC	C
_:307	General:Act. settings group 8	SPC	C

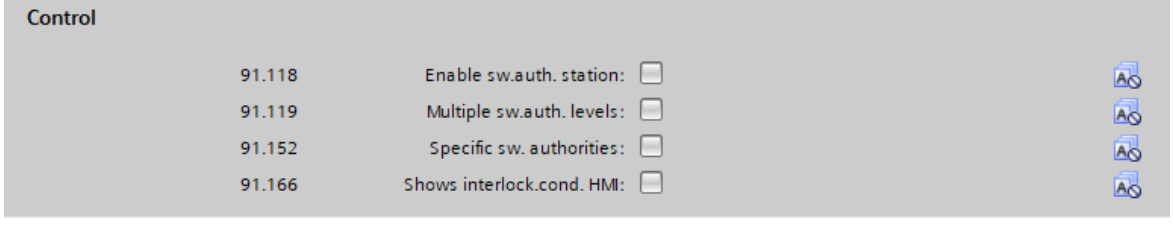


3.11.2 General Device Settings

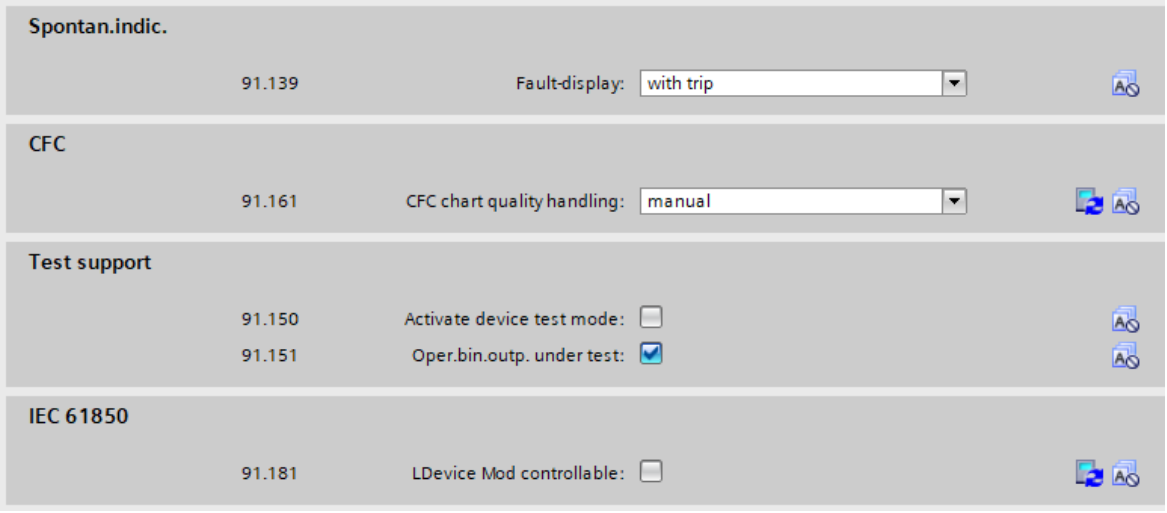
3.11.2.1 Overview



In **Device settings** in DIGSI 5, you find the following general settings.



[sc_deSeDe2, 1, en_US]



[sc_deSeAl, 4, en_US]

[sc_measurement, 1, en_US]

[sc_control, 1, en_US]

[sc_deSeBB, 2, en_US]

Figure 3-147 General Device Settings

The following list shows you the chapters containing the desired information.
You can find more about:

- **Chatter blocking** in *3.9.1 Signal Filtering and Chatter Blocking for Input Signals*.
- **Control** in *7.4 Control Functionality*.
- **Measured values** in *9.1 Overview of Functions*
- **Spontaneous indications** in *3.1.7 Spontaneous Indication Display in DIGSI 5*.
- **Continuous Function Chart Quality Treatment** in *3.4.3 Quality Processing/Affected by the User in CFC Charts*.

Under **Device**, you set the parameters for the device that are valid across functions.

With **Test support**, indications issued via communication interfaces are labeled with an additional test bit, if this is supported by the protocol. With this test bit you can determine whether an indication is generated in a test and all or individual functions of the device are in the test mode. In this manner the reactions that are necessary in normal operation due to an indication can be suppressed in other devices that receive these indications. You can also permit, for example, a trip command to close an energized binary output for test purposes. Siemens recommends deactivating the **Test support** again after the test phase.

From version **DIGSI V09.70** on, you can control the state of the logical nodes (LLN0) in a logical device (LD) under **IEC 61850** with the parameter **`LDevice Mod controllable`**. If you want to test and change the behavior of logical nodes individually, place a checkmark on the parameter **`LDevice Mod controllable`**.

3.11.2.2 Application and Setting Notes

The major portion of the settings is described in the chapters cited above. Then, the parameters on the section **Device**, **Spontaneous indication** and **Test support** are described.

Parameter: Rated frequency

- Default setting **`(_:101) Rated frequency`** = ***`50 Hz`***

With the parameter **`Rated frequency`**, you set the rated frequency of the electrical power system.

Parameter: Minimum operate time

- Default setting **`(_:102) Minimum operate time`** = ***`0.00 s`***

With the parameter **`Minimum operate time`**, you set the minimum duration for the trip command of the functions. The trip command is maintained for the set duration.

Parameter: Set. format residu. comp.

- Default setting **_:115** = ***Kr, Kx***

With the parameter **Set. format residu. comp.**, you specify the setting format for the residual compensation factors that apply across functions. You can set the residual compensation using the scalar factors ***Kr, Kx*** or as a complex factor using ***K0***.

The setting format controls the visibility of the residual compensation factors in the **Distance protection**.

Parameter: Block monitoring dir.

- Default setting **(_:138) Block monitoring dir.** = ***off***

With the parameter **Block monitoring dir.**, you set whether indications are output via the system interface(s) of the SIPROTEC 5 device or not.

If transmission blocking is switched on, no indications are output via the system interface(s) of a SIPROTEC 5 device, except via the IEC 61850 interface(s).

To avoid receiving IEC 61850 data, the corresponding IEC 61850 Client must stop the reporting or freeze the data. You can find more information in the Communication Protocols Manual (C53000-L1840-C055-3).

Parameter: Fault-display

- Default setting **(_:139) Fault-display** = ***with pickup***

With the parameter **Fault-display**, you set whether spontaneous fault indications which are signed as ***NT (conditioned latching)*** in the matrix, get stored with every pickup or only for one tripping.

Keep the DIGSI 5 routing options in chapters *3.1.7 Spontaneous Indication Display in DIGSI 5* and *3.1.9 Stored Indications in the SIPROTEC 5 Device* in mind.

Parameter: Activate device test mode

- Default setting **(_:150) Activate device test mode** = inactive

With the parameter **Activate device test mode**, you can activate the test mode for the complete device. This means that all indications generated in the device are given a test bit.

For further information, refer to *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

Apart from activating the test mode via this parameter, you can also activate the test mode using the IEC 61850-8-1 protocol. For more information, refer to the manual *SIPROTEC 5 Communication protocol*.

When the test mode is activated for the complete device, but the parameter **Oper.bin.outp. under test** is not, the routed relay outputs of the device are not activated by the generated the indications.

NOTE

The device remains in test mode during every restart until you intentionally set the device back into process mode or you have carried out an initial start.

You can set the process mode by switching the parameter **Activate device test mode** to inactive again (removing the check mark) or by deactivating the test mode again via the protocol IEC 61850-8-1.

NOTE

Besides the cross device test mode, you also have the option to place an individual function or stage into test mode depending on the supported operating modes of a function or stage. To do this, see the description of the relevant function or stage.

When you place an individual function or stage into the test mode, all indications issued by this function or stage are given a test bit.

When you activate the test mode for an individual function or stage, but not the parameter **Oper.bin.outp. under test**, the routed relay outputs of the function or stage are not activated by the generated indications.

An individual function or stage remains in the test mode during every restart until you have intentionally deactivated the test mode for this function or stage again or carried out an initial start.

Parameter: Oper.bin.outp. under test

- Default setting **(_:151) Oper.bin.outp. under test** = inactive

If you activate the parameter **Oper.bin.outp. under test**, the indications generated in the device and marked with a test bit can be issued to a routed relay output of the device, that is, you enable the relay outputs of the device to be opened and closed.

If only one individual function or stage of the device is in test mode, that is, the cross device tested mode has not been activated, only the indications of this function or stage are marked with a test bit and the routed relay outputs of the device are activated.

With the parameter **(_:151) Oper.bin.outp. under test**, you define whether the functions in ***Test*** state can activate relay outputs. If the parameter **(_:151) Oper.bin.outp. under test** and the test mode are activated for the entire device, all functions – including the relay outputs – are in ***Test*** state. If the parameter **(_:151) Oper.bin.outp. under test** is not active and the test mode is activated for the entire device, all functions – except the relay outputs – are in ***Test*** state. The relay outputs adopt the **Test/Relay blk.** state.

Output Signal: Functions in Test mode

Normally, the output signal *Functions in Test mode* is prerouted to the last LED of the device base module. If one or more protection or control functions are in test mode, the output signal *Functions in Test mode* is generated and the corresponding LED of the device lights up red.

Parameter: LDevice Mod controllable

- Default setting **(_:181) LDevice Mod controllable** = inactive

With the parameter **LDevice Mod controllable**, you control the state of the logical nodes (LLN0) in a logical device (LD). If you want to test and change the behavior of logical nodes individually, place a checkmark on the parameter **LDevice Mod controllable**.

Once the checkmark is placed, the **LLN0:Mode** can be controlled in a logical device.

3.11.2.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Device				
_:101	General:Rated frequency		• 50 Hz • 60 Hz	50 Hz

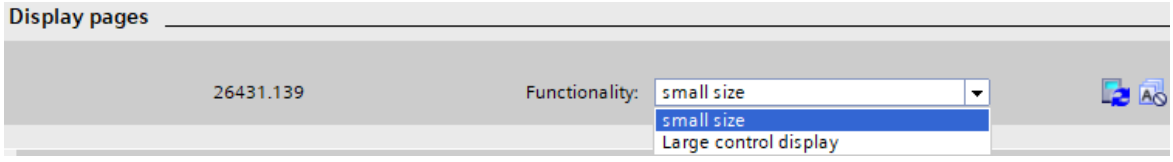
3.11.3 Display-Page Setting

3.11.3.1 Overview

Specific SIPROTEC 5 devices can be ordered with the operation-panel option **Large display, display-page size config., dual c.LEDs**. In this case, the size of the configurable display pages is settable by the user, and is function-points dependent:



- Small display pages can be configured without extra function points.
- Large display pages for large control displays require extra function points.

For devices with the operation panel **Large display, display-page size config., dual c.LEDs**, you can find the block **Display pages** in **Device settings** in DIGSI 5.

[sc_Display_page_Operation Panels, 1, en_US]

Figure 3-148 Operation Panel **Large display, display-page size config., dual c.LEDs** in DIGSI 5

[sc_Functionality_block1, 2, en_US]

Figure 3-149 Block **Display pages** in DIGSI 5

3.11.3.2 Application and Setting Notes

Parameter: Functionality

- Default setting **(_:139) Functionality** = ***small size***

With the parameter **Functionality**, you set the size of the display pages that are shown in DIGSI 5 and in the HMI.

Parameter Value	Description
small size	The size of the display page is 240 x 128 pixels. With this size, usually up to 8 operational values or very small control displays with, for example, up to 3 switches can be configured.
Large control display	The size of the display page is 240 x 320 pixels. With this size, large control displays or a large number of operational values, or a combination of both can be configured.

3.12 Using a SIPROTEC 5 Device as a Client or Merging Unit

Overview with the Distributed Busbar Protection as an Example (IEC 61850 Compliant):

- Process bus: for cross-device transmission of the measured values for current and voltage
- GOOSE: For cross-device transmission of the position information of disconnectors and circuit breakers, their trip commands and additional signals
- Distributed busbar protection
- Further information

Process Bus:

The process bus is available for the modular SIPROTEC 5 devices. The current and voltage measured values can be transmitted across devices using the process bus. Prerequisite: a ETH-BD-2FO communication module with the appropriate communication protocols. In the following figure, you can see the 7SS85 as an example of the client, and the 6MU85 and other modular SIPROTEC 5 devices as merging units.

[dw_bb8_proj-71-star, 2, en_US]

Figure 3-154 Star Structure for Distributed Busbar Protection with Merging Units Connected via Optical Fibers

Prerequisites for the Merging Units for the Distributed Busbar Protection (IEC 61850 Compliant)

You can use all modular SIPROTEC 5 devices (except the railway protection devices 7ST8x and 6MD89) and other IEC 61850 compliant devices as merging units. The following prerequisites apply:

- All clients and merging units must have the firmware version V8.0x or higher.
- All clients and merging units must be connected to the ETH-BD-2FO communication module and must use the process-bus protocols. These include:
  - Consistent use of **IEC 61850 Edition 2.x**. Siemens recommends IEC 61850 Edition 2.1.
  - Process-bus protocol **9-2 Merging Unit** for Merging Units and **9-2 Client** for clients
  - Joint time synchronization. Siemens recommends the **IEEE 1588 protocol**.
- The current and voltage transformers suitable for the target application in the client must be present in the merging units.

GOOSE:

As an alternative to using the local binary inputs and binary outputs of a SIPROTEC 5 device, you can use the inputs and outputs of other SIPROTEC 5 devices and transmit them via IEC 61850 including GOOSE.

Examples of binary routings for transmission using GOOSE.

- Circuit-breaker and disconnector position information from the transmitters to the receivers
- Circuit-breaker trip commands from the transmitter to the receivers

Distributed Busbar Protection

The distributed busbar protection is a distributed protection system with the 7SS85 as the central unit (CU) and other SIPROTEC 5 devices, the merging units (MU) as bay units.

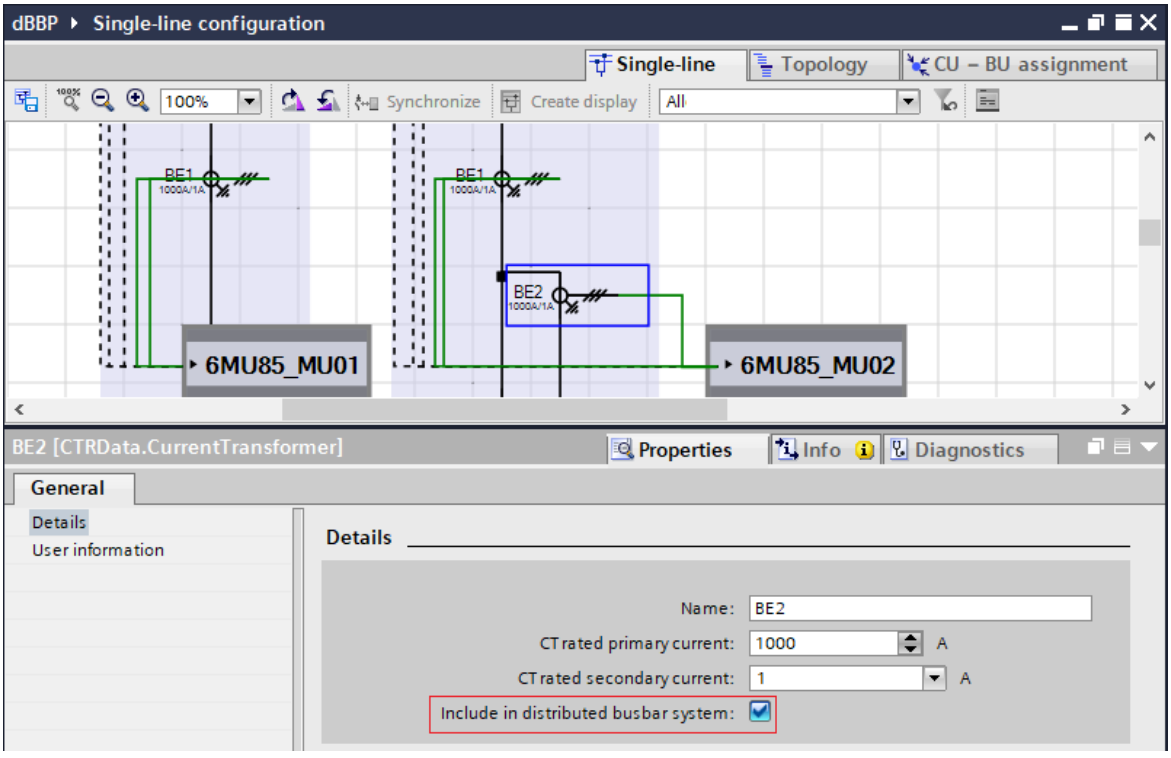
The distributed busbar protection provides the following advantages over the centralized busbar protection or the distributed busbar protection (IEC 61850 compliant):

- Transmission of current measured values (SMV) as per IEC 61850-9-2 (process bus) from the merging units
- Automatic interconnection of current measured values, disconnector-switch and circuit-breaker switch positions
- Local functional enhancements of the merging units
- Maximum number of bays and busbar zones

Functional Enhancements in the Devices

Starting with V8.40, the merging units have the following functional enhancements that are especially intended for use with the distributed busbar protection and evaluated there:

- End-fault protection (1-pole/3-pole, 3-pole)
- External tripping
- Inherent circuit-breaker failure protection
- Extension in circuit-breaker failure protection
- Measuring point out of service



NOTE

You can find these functional enhancements in the Global DIGSI 5 Library in the respective device, under **FG Circuit breaker** > **dBBP Function extensions**. You can find the function **Measuring point out of service** under **Measuring inputs** > **Current 3-phase** > **dBBP Function extensions** in the respective device.

Functional Enhancement in DIGSI 5

If a **distributed busbar protection** is present in the project, the following functional enhancements especially intended for use with the distributed busbar protection are provided in the Single-Line Editor:

- New **CU – BU assignment** tab with the **Update central unit** function.
- Additional **Include in distributed busbar system** check box for current transformers, circuit breakers, and disconnectors in the **Properties** tab.

[sc_bbp8_SLE_incl, 1, en_US]

Figure 3-155 Extension in the **Properties** Tab if the Distributed Busbar Protection is Available

Further Information

NOTE

Analog measured values, binary inputs, and binary outputs are routed across devices in the **IEC 61850 System Configurator**.

For a detailed description of how to use it as a Merging Unit/bay unit for the distributed busbar protection or distributed busbar protection (IEC 61850 compliant), refer to the **Project Engineering** chapter in the **Busbar Protection 7SS85** device manual.

For further information on the process bus, GOOSE, IEC 61850 System Configurator, descriptions of stream types, GOOSE Later Binding, VLAN priority, network redundancies, for example, PRP protocol or the sample and time synchronization using IEEE 1588, refer to the **Process Bus**, **Communication Protocols**, **IEC 61850 System Configurator** and the **DIGSI 5 Help** manuals.

4 Applications

4.1	Overview	278
4.2	Application Templates and Functional Scope of the Device 7UT82	279
4.3	Application Templates and Functional Scope of the Device 7UT85	282
4.4	Application Templates and Functional Scope of the Device 7UT86	288
4.5	Application Templates and Functional Scope of the Device 7UT87	298

4.1 Overview

The Global DIGSI 5 library provides application templates for the applications of the devices. The application template

- Supports the fast realization of complete protection solutions for applications
- Contains the basic configuration for the use case
- Contains functions and default settings for the use case

EXAMPLE, Page 58 in chapter *2 Basic Structure of the Function* provides an example for the structure of an application template.

When using an application template, note the following:

- Adapt the application template to your specific use (check/adapt default settings, delete/add functions). You can find more detailed information in the *2.1 Embedding of Functions in the Device*.
- Check the routing of binary outputs with respect to fast and normal relays.
- Check the CFC charts for the group-warning indications and group-fault indications.

Application of the devices 7UT82, 7UT85, 7UT86, and 7UT87

The transformer differential protection **7UT8x** is a selective short-circuit protection for transformers of all voltage series, for longitudinal and shunt reactors, as well as for short lines. The devices contain all functions that you need for protection from transformers and are therefore universally applicable. The main protection function of the devices is the differential protection.

The following describes the application templates and maximum functional scope for the devices 7UT82, 7UT85, 7UT86, and 7UT87.

NOTE

The availability of certain settings and setting options depends on the device type and the functions available on the device!

Number of Measuring Points

The following table shows you the maximum number of device-dependent current and voltage measuring points, which are available to you.

Table 4-1 Number of the Possible Measuring Points per Device

Device	Number of Measuring Points			
	I-3ph	I-1ph	V-3ph	V-1ph
7UT82	2	2	–	–
7UT85	5	5	5	5
7UT86	7	7	7	7
7UT87	20	20	20	20

4.2 Application Templates and Functional Scope of the Device 7UT82

Application templates are available in **DIGSI 5** for the applications of the device 7UT82. The application templates contain the basic configurations, required functions, and default settings.

The following application templates are available for the device 7UT82 in the **DIGSI 5** function library:

- Two-winding transformer basic (87T)
- Two-winding transformer (87T, 50BF, 87N)
- Motor (87M)

So that the application templates function in the device, the following minimum hardware configuration requirements must be met:

Application Templates		Hardware Configuration
Template 1	Two-winding transformer basic (87T)	7 BI, 6 BO, 8 I (base module)
Template 2	Two-winding transformer (87T, 50BF, 87N)	7 BI, 6 BO, 8 I (base module)
Template 3	Motor (87M)	7 BI, 6 BO, 8 I (base module)

The following table shows the functional scope and the required function points of the application templates for device 7UT82:

Table 4-2 Functional Scope of the Application Template for the Device 7UT82

ANSI	Function	Abbr.	Available	Template 1	Template 2	Template 3
37	Undercurrent	I<	X			
38	Temperature supervision	θ>	X			
46	Negative-sequence system overcurrent protection	I_2>, I_2/I_1>	X

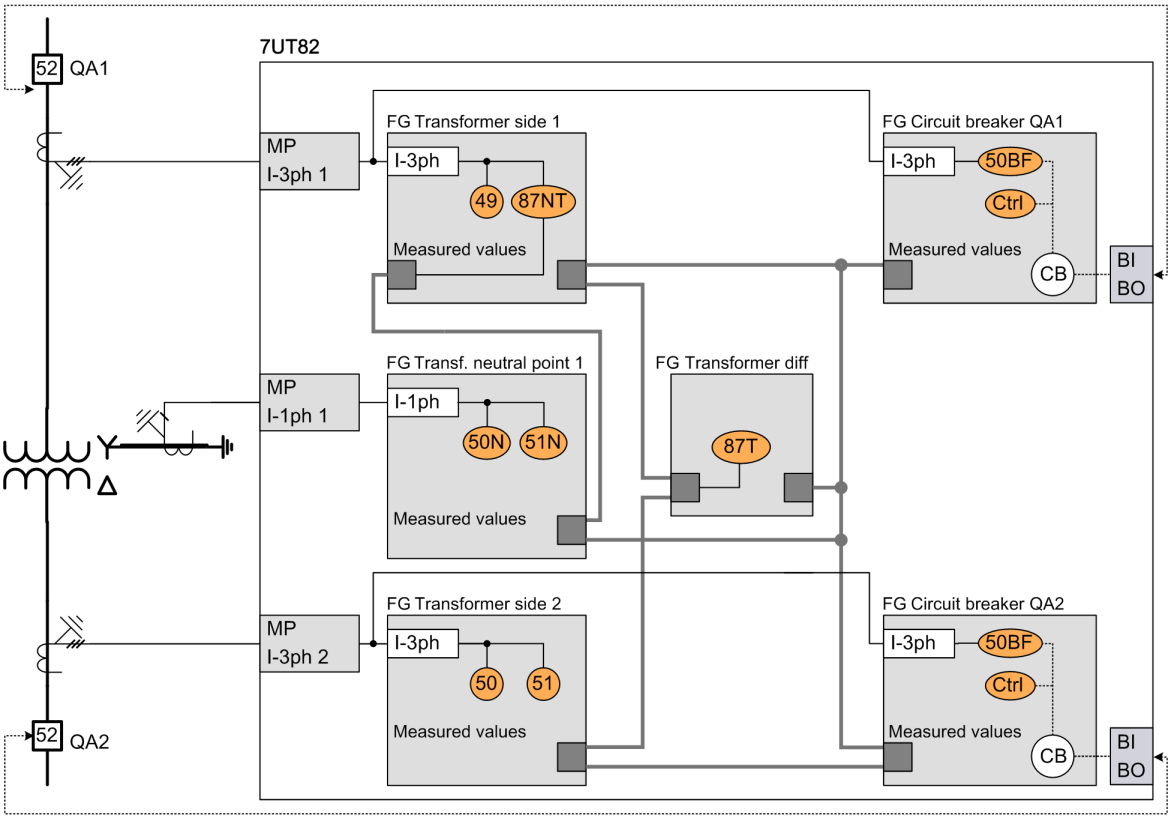
Application Template: Two-winding transformer basic (87T)

The **`Two-winding transformer basic (87T)`** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for Yd)
- Overload protection, backup protection for the downstream electrical power system

Application Template: Two-winding transformer (87T, 50BF, 87N)

The **`Two-winding transformer (87T, 50BF, 87N)`** application template is preconfigured for the following applications:



- Transformer differential protection (default setting for Yd)
- Restricted ground-fault protection on the star side
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection

Application Template: Motor (87M)

The **`Motor (87M)`** application template is preconfigured for the following applications:

- Differential motor protection
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection

The following *Figure 4-1* shows the structure of the application template **Transformer protection with restricted ground-fault protection**, the measuring points used, the function groups used, their internal circuiting, and the predefined functions.

[dwap2wik82-180314-01, 1, en_US]

Figure 4-1 Protection of a Two-Winding Transformer

4.3 Application Templates and Functional Scope of the Device 7UT85

Application templates are available in **DIGSI 5** for the applications of the device 7UT85. The application templates contain the basic configurations, required functions, and default settings.

The following application templates are available for the device 7UT85 in the **DIGSI 5** function library:

- Two-winding transformer basic (87T)
- Two-winding transformer (87T, 50BF, 87N)
- Two-winding transformer 1.5CB (87T, 50BF, 87N)
- Two-winding transformer (87T, 50BF, 90V)
- Motor (87M, 50BF, 59, 27, 81, 46, 49)

So that the application templates function in the device, the following minimum hardware configuration requirements must be met:

Application Templates		Hardware Configuration
Template 1	Two-winding transformer basic (87T)	7 BI, 7 BO, 8 I (base module)
Template 2	Two-winding transformer (87T, 50BF, 87N)	7 BI, 7 BO, 8 I (base module)
Template 3	Two-winding transformer 1.5CB (87T, 50BF, 87N)	Base module + expansion module with current inputs (for example, IO201)
Template 4	Two-winding transformer (87T, 50BF, 90V)	7 BI, 7 BO, 8 I (base module)
Template 5	Motor (87M, 50BF, 59, 27, 81, 46, 49)	7 BI, 7 BO, 8 I (base module)

The following table shows the functional scope and the required function points of the application templates for device 7UT85:

Table 4-3 Functional Scope of the Application Template for the Device 7UT85

ANSI	Function	Abbr.	Available	Template 1	Template 2	Template 3	Template 4	Template 5
21/21N	Distance protection	Z<, V<, I>, ∠ (V/I)	X

Application Template: Two-winding transformer basic (87T)

The **`Two-winding transformer basic (87T)`** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for Yd)
- Overload protection, backup protection for the downstream electrical power system

Application Template: Two-winding transformer (87T, 50BF, 87N)

The **`Two-winding transformer (87T, 50BF, 87N)`** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for Yd)
- Restricted ground-fault protection on the star side
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection

15 This function is described in the Point-on-Wave Switching Manual

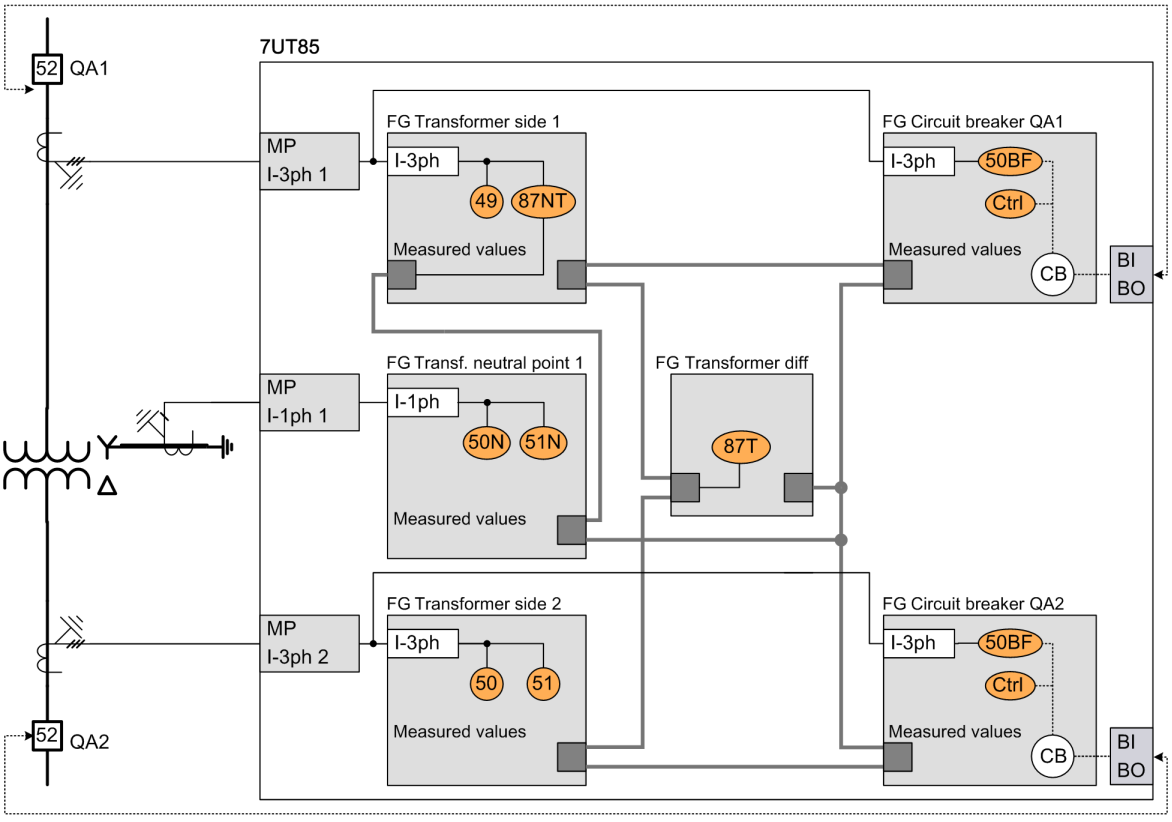
Application Template: Two-winding transformer 1.5CB (87T, 50BF, 87N)

The **Two-winding transformer 1.5CB (87T, 50BF, 87N)** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for Yd)
- Restricted ground-fault protection on the star side
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection

Application Template: Two-winding transformer (87T, 50BF, 90V)

The **Two-winding transformer (87T, 50BF, 90V)** application template is preconfigured for the following applications:



- Transformer differential protection (default setting for Yd)
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection
- Voltage controller

Application Template: Motor (87M, 50BF, 59, 27, 81, 46, 49)

The **Motor (87M, 50BF, 59, 27, 81, 46, 49)** application template is preconfigured for the following applications:

- Differential motor protection
- Overload protection, backup protection for the downstream electrical power system
- Frequency and voltage protection on the upper-voltage side
- Circuit-breaker failure protection

The following *Figure 4-2* shows the structure of the application template **Transformer protection with restricted ground-fault protection**, the measuring points used, the function groups used, their internal circuiting, and the predefined functions.

[dwap2wiklr-151013, 3, en_US]

Figure 4-2 Protection of a Two-Winding Transformer

4.4 Application Templates and Functional Scope of the Device 7UT86

Application templates are available in **DIGSI 5** for the applications of the device 7UT86. The application templates contain the basic configurations, required functions, and default settings.

The following application templates are available for the device 7UT86 in the **DIGSI 5** function library:

- Three-winding transformer basic (87T)
- Three-winding transformer 1.5CB (87T, 50BF, 87N)
- Three-winding transformer (87T, 50BF, 87N, 21)
- Auto transformer (87T, 87N, 50BF)
- Auto transformer 1.5CB (2 x 87T, 50BF, 59, 81)

The application templates for a two-winding application can also be used in a 7UT86.

You can find more information in *4.3 Application Templates and Functional Scope of the Device 7UT85*.

So that the application templates function in the device, the following minimum hardware configuration requirements must be met:

Application Templates		Hardware Configuration
Template 1	Three-winding transformer basic (87T)	11 BI, 19 BO, 12 I, 4 V
Template 2	Three-winding transformer 1.5CB (87T, 50BF, 87N)	11 BI, 19 BO, 12 I, 4 V
Template 3	Three-winding transformer (87T, 50BF, 87N, 21)	11 BI, 19 BO, 12 I, 4 V
Template 4	Auto transformer (87T, 87N, 50BF)	11 BI, 19 BO, 12 I, 4 V
Template 5	Auto transformer 1.5CB (2 x 87T, 50BF, 59, 81)	23 BI, 34 BO, 12 I, 4 V

The following table shows the functional scope and the required function points of the application templates for device 7UT86:

Table 4-4 Functional Scope of the Application Template for the Device 7UT86

ANSI	Function	Abbr.	Available	Template 1	Template 2	Template 3	Template 4	Template 5

Application Template: Three-winding transformer basic (87T)

The **`Three-winding transformer basic (87T)`** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for Ydxdy)

16 This function is described in the Point-on-Wave Switching Manual

Application Template: Three-winding transformer 1.5CB (87T, 50BF, 87N)

The **Three-winding transformer 1.5CB (87T, 50BF, 87N)** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for YNdxdx)
- Restricted ground-fault protection on the star side
- Ground current protection on the neutral side as backup protection for the electrical power system
- Overload protection
- Frequency and voltage protection on the neutral side
- Circuit-breaker failure protection

Application Template: Three-winding transformer (87T, 50BF, 87N, 21)

The **Three-winding transformer (87T, 50BF, 87N, 21)** application template is preconfigured for the following applications:

- Transformer differential protection (default setting for YNdxdx)
- Restricted ground-fault protection on the star side
- Ground current protection on the neutral side as backup protection for the electrical power system
- Overload protection
- Frequency and voltage protection on the neutral side
- Circuit-breaker failure protection
- Distance protection

Application Template: Auto transformer (87T, 87N, 50BF)

The **Auto transformer (87T, 87N, 50BF)** application template is preconfigured for the following applications:

- Transformer differential protection for the entire transformer (auto winding and stabilizing winding)
- Restricted ground-fault protection (neutral point and maximum side current)
- Overload protection, backup protection for the downstream electrical power system
- Circuit-breaker failure protection

Application Template: Auto transformer 1.5CB (2 x 87T, 50BF, 59, 81)

The **Auto transformer 1.5CB (2 x 87T, 50BF, 59, 81)** application template is preconfigured for the following applications:

- Transformer differential protection for the entire transformer (auto winding and stabilizing winding)
- Node-point protection for the auto winding for recording ground faults (3-phase recording of the neutral-point current)
- Overload protection, backup protection for the downstream electrical power system
- Frequency and voltage protection on the upper-voltage side
- Circuit-breaker failure protection

To display the different, and at the same time new, options, 5 application templates are described in detail.

Application Template: Three-Winding Transformer in a Breaker-and-a-half Layout

The 1st application is the template for protection of a three-winding transformer in a breaker-and-a-half layout. You can recognize the 3 required function groups for the transformer side, the integration of the restricted ground-fault protection as well as the internal circuiting, and selected functions. In addition, a voltage transformer is available on the upper-voltage side. Here, for example, voltage and frequency limits can be monitored. The required protection settings are made depending on the system.

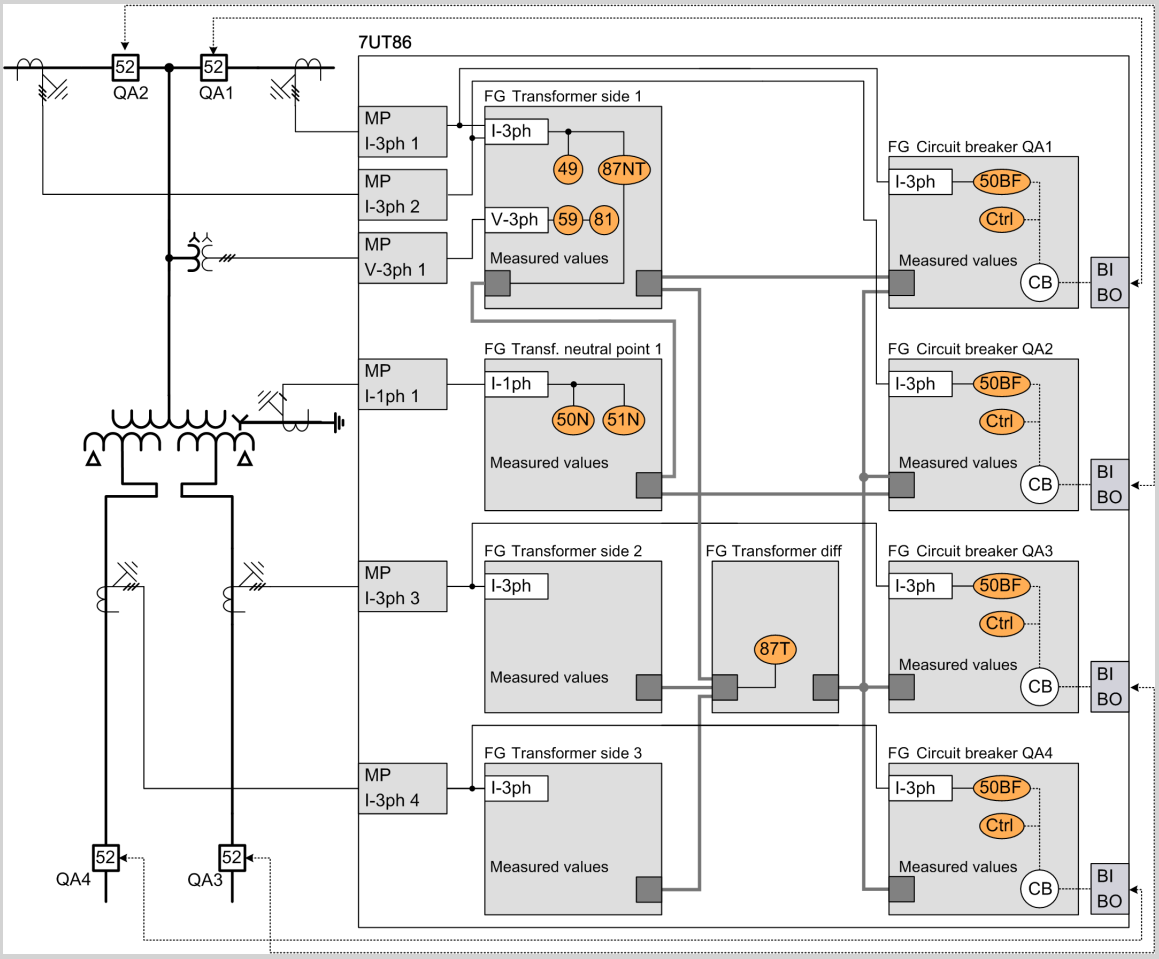

Figure 4-3 Protection of a Three-Winding Transformer

Application Template: Protection of an Auto-Transformer Bank in a Breaker-and-a-Half Layout

The 2nd application is the template for protection of an auto-transformer bank, which is connected to a breaker-and-a-half layout. The special feature of this application is that per phase the neutral-point side current is directly recorded. A separate node-point differential protection via the auto winding reliably records ground faults and winding shorts. There are 2 differential protection functions (87T and 87TNode) assigned across the entire transformer (auto and stabilizing winding). Both functions run in the **Auto transformer** function group.

Through this type of execution you have a redundant, differential protection supplemented in sensitivity. A separate restricted ground-fault protection is not required. In addition, a voltage transformer is available on the upper-voltage side. Here, for example, voltage and frequency limits can be monitored. The required protection settings are made depending on the system.

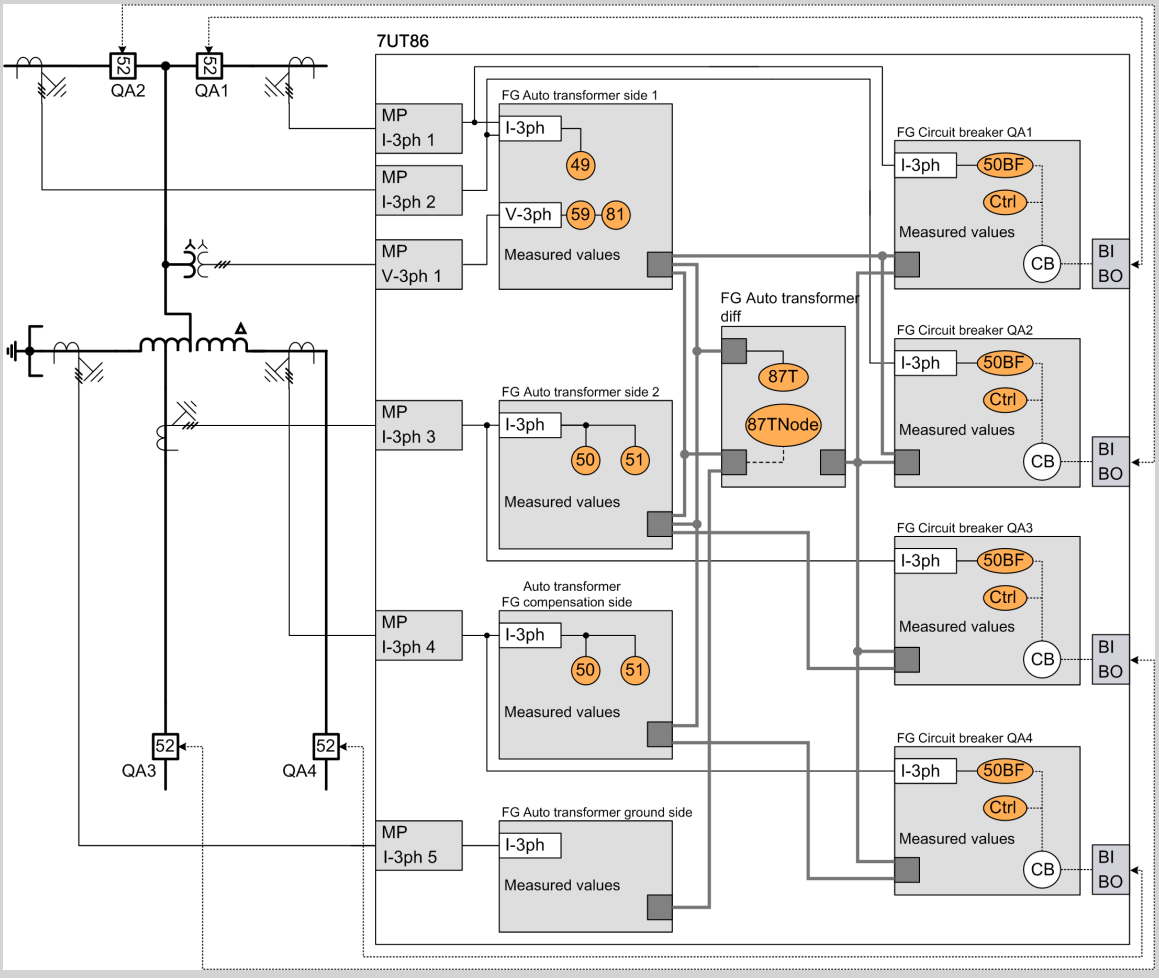

Figure 4-4 Protection of an Auto-Transformer Bank

Application Template: Motor Protection

The 3rd application is the template for motor protection. You can see the 2 function groups that are required for the motor sides as well as the circuiting, and selected functions. In addition, a voltage transformer is available on the upper-voltage side. Here, for example, voltage and frequency limits can be monitored. The required protection settings are made depending on the system.

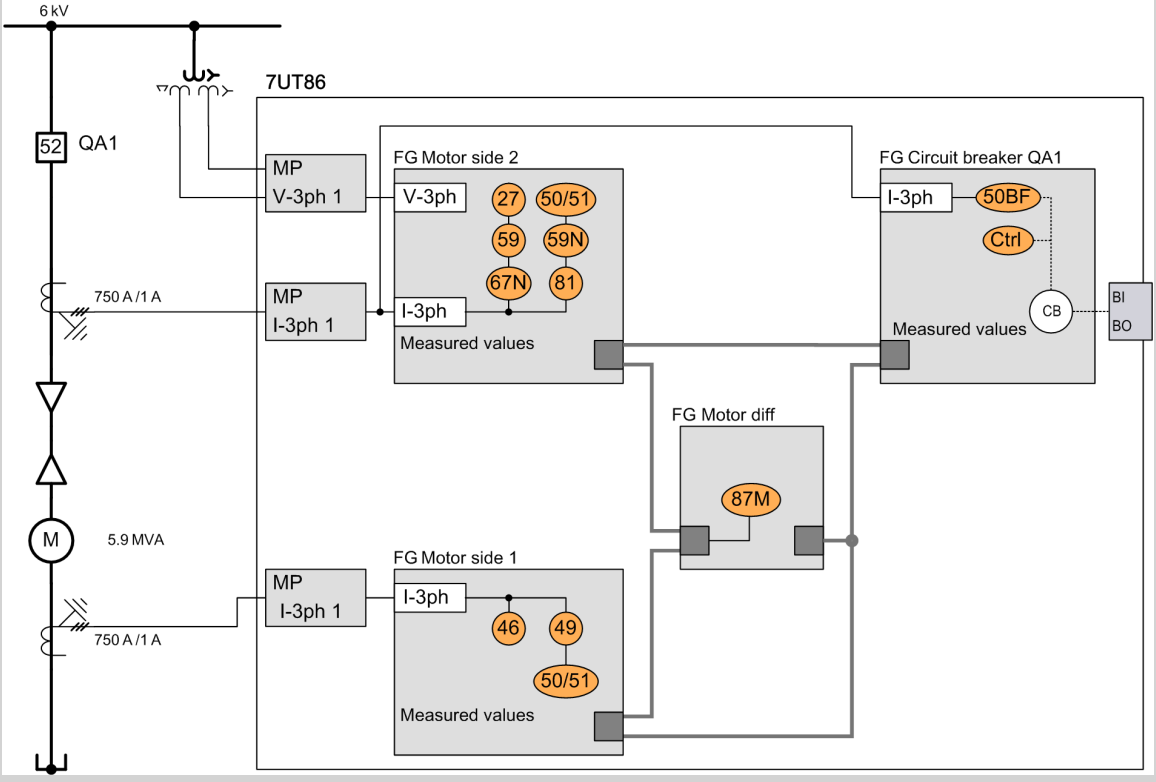

Figure 4-5 Motor Protection

Application Template: Control/Feedback Control of Power Transformers

The 4th application is the template for control/feedback control of power transformers (two-winding transformers, three-winding transformers or grid coupling transformers) and auto transformers using a motor-operated tap changer with transformer voltage regulator functionality (ANSI 90 V).

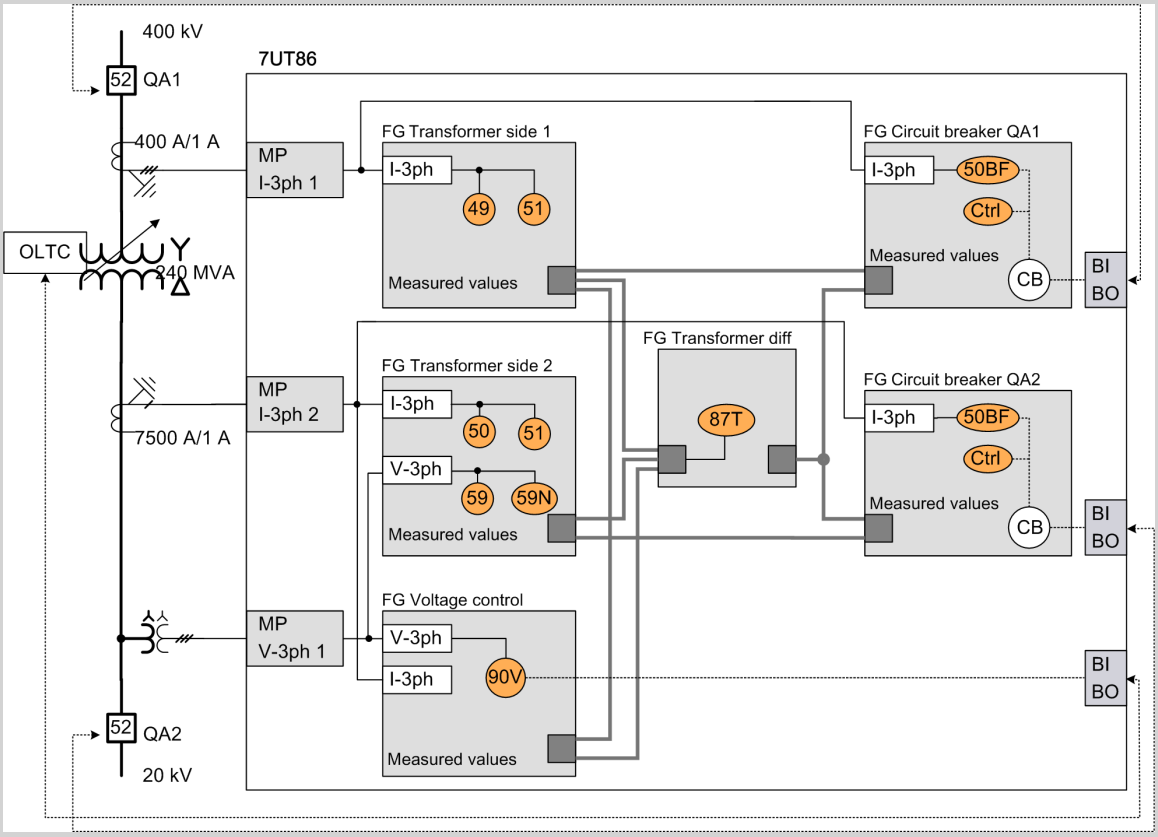

Figure 4-6 Transformer Protection with Voltage Control Functionality

Application Template: Protection of a Three-Winding Transformer with Distance Protection

The 5th application is the template for protection of a three-winding transformer. The neutral-point current of the upper-voltage side is measured and taken into account for the differential protection. In addition, restricted ground-fault protection is instantiated for the upper-voltage side. A special feature of this application is the additional protection for the feeder on the 3rd side. The distance protection used trips the circuit breaker for this feeder if there is a fault in the line. If the distance protection is only tripped at the tripping stage **Z4 non-directional** due to the power system or error conditions, circuit breaker 1 of the transformer feed is tripped.

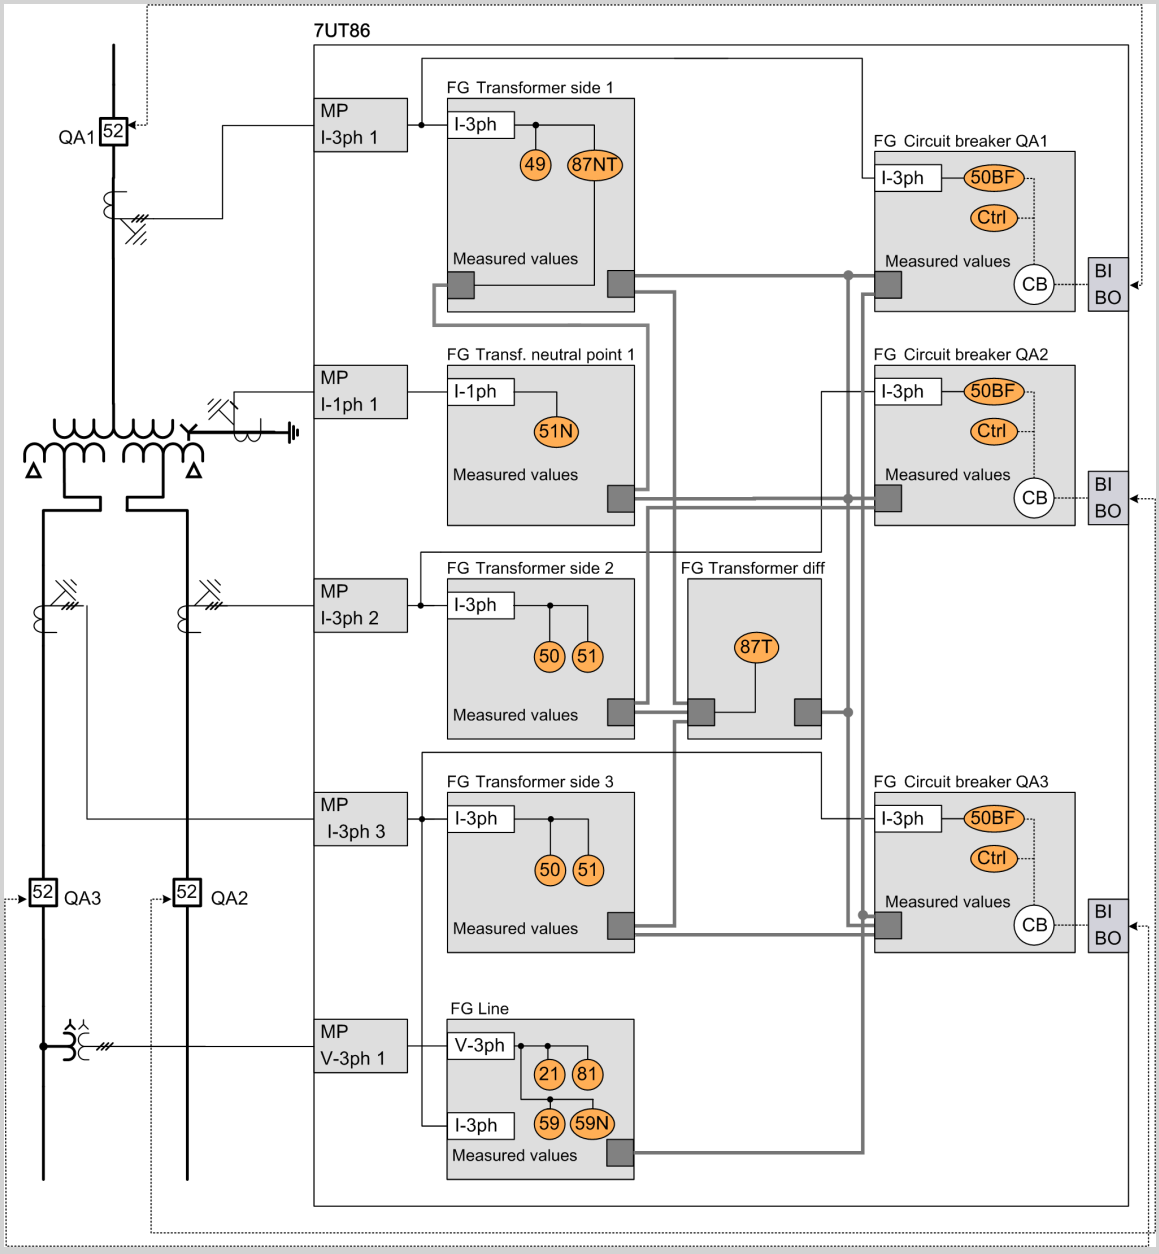

Figure 4-7 Three-Winding Transformer with Distance Protection

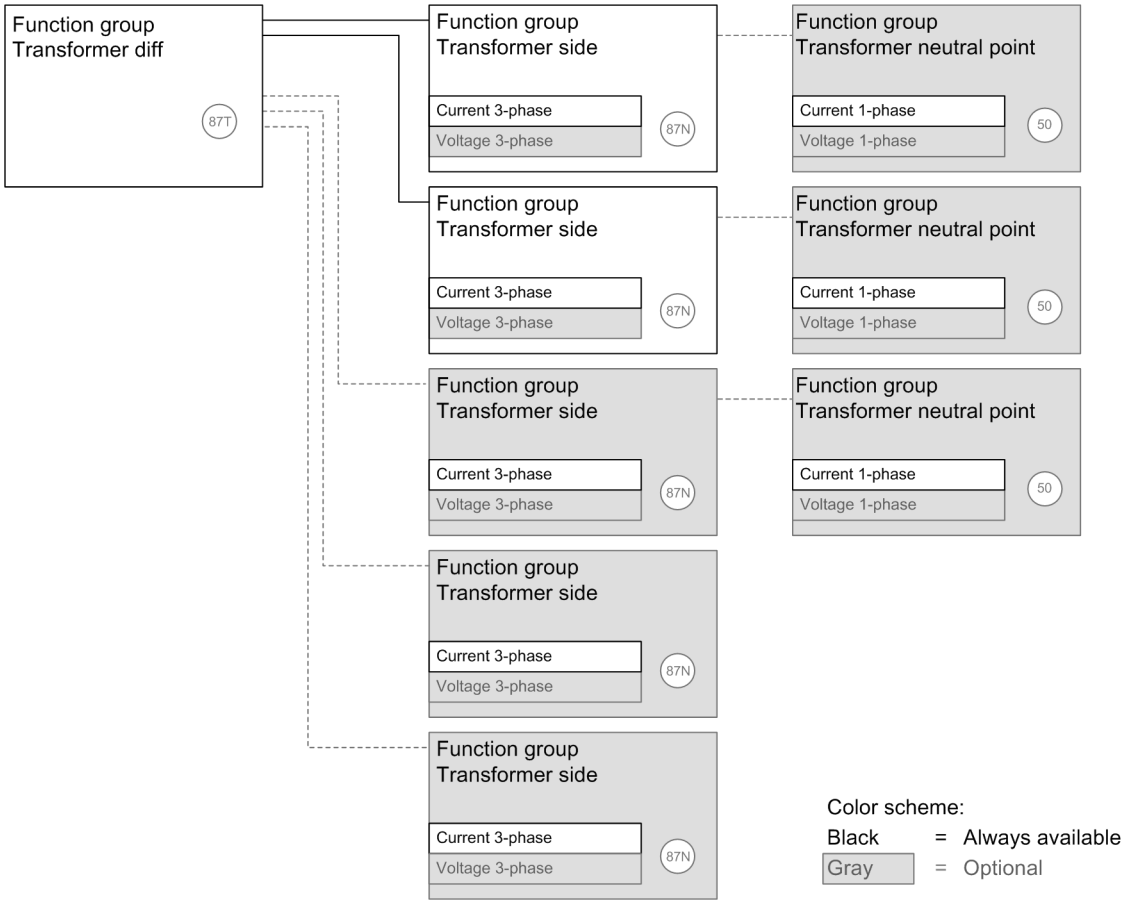
4.5 Application Templates and Functional Scope of the Device 7UT87

Application templates are available in **DIGSI 5** for the applications of the device 7UT87. The application templates contain the basic configurations, required functions, and default settings.

All application templates, which were described for the devices 7UT82, 7TUT85, and 7UT86, can be implemented in 7UT87.

Besides the functional scope of the 7UT86, the **Differential protection for phase-angle regulating transformers (Two-Core PST)** function is available.

The 7UT87 is intended for special applications (up to 5 sides and 7 measuring points), therefore, create your own application template depending on the application. Save this template with the device. To make your work easier, you can use an available template and modify it. Application suggestions can be taken from the device catalog **Transformer Differential Protection 7UT82, 7UT85, 7UT86, 7UT87**.



5 Function-Group Types and Bay Proxy

5.1	Overview Function Group Transformer Differential Protection	300

5.14	Process Monitor	532

5.1 Overview Function Group Transformer Differential Protection

5.1.1 Function-Group Types

In the following graphic, you can see the structural association of the function-group types.

[dwfguebt-291112-01.tif, 1, en_US]

Figure 5-1 Transformer Diff Function-Group Types

The following function-group types are summarized in the Global DIGSI 5 library:

- **Transf. diff.**
- **Transformer side**
- **Transf. neutral point** (transformer neutral point)

The individual function group types are stored in the **Transformer diff function group** folder and can be selected. In the protection function folders, you find all protection functions which are operational in each function group. A **Transf. diff.** function group always contains 2 **Transformer side** function groups. The **Transf. neutral point** function group can be connected if needed with the **Transformer side** function group.

The following table shows the number of function-group types that can be instantiated depending on the device (7UT82, 7UT85, 7UT86, 7UT87).

NOTE

By purchasing 70 or 120 function points, the 7UT85 and 7UT86 can be expanded to a three-winding transformer or a multi-winding transformer. Provide the respective number of measuring inputs that are required for the expansion.

Table 5-1 Function-Group Types in the Device

Device	Function-Group Type		
	Transf. Diff.	Transformer Side	Transf. Neutral-Point Function Group
7UT82	Max. 1	Max. 2	Max. 2
7UT85	Max. 1	Max. 3 (2 open)	Max. 2
7UT86	Max. 1	Max. 4 (3 open)	Max. 3
7UT87	Max. 3	Max. 7	Max. 5

In order for the transformer protection to operate properly, switching of the function group is necessary. *Table 5-2* provides an overview of those switching options that are permitted. The Circuit-breaker function group is not listed. The figures shown in the application templates (see *Figure 4-2* to *Figure 4-7*) offer a good overview of the interconnection options.

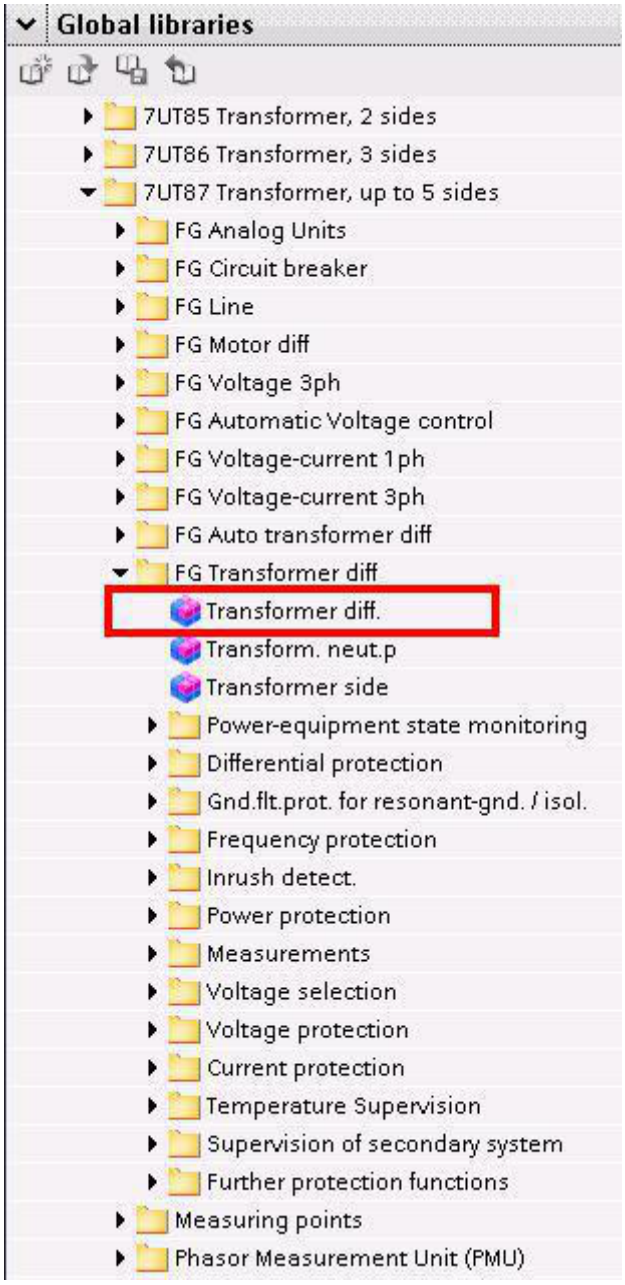
A **Transformer side** function group must always be connected with the **Transformer Diff.** function group. Depending on the application, an interconnection of the **Transf. neutral point** function group with the **Transformer side** function group is required. This is the case, for example, if a restricted ground-fault protection is used or if the neutral point current in the differential protection should be considered (zero-sequence current correction). The reverse can also be the case, that the **Transf. neutral point** needs signals from the **Transf. diff.** function group. A typical case is the inrush-current detection, which can be used for blocking a 1-phase overcurrent protection (with a short time delay set).

Table 5-2 Assignment of Protection Function Groups to Protection Function Groups

Winding	Transf. Diff. 1	Transformer Side 1	Transformer Side 2
	Side (2 ... 5)	Neutral-Point Function Group (0 ... 1)	Neutral-Point Function Group (0 ... 1)
Transformer side 1	X	-	-
Transformer side 2	X	-	-
Transformer side 3 [17]	X	-	-
Transformer side 4 [18]	X	-	-
Transformer side 5 [19]	X	-	-
Transf. neutral point 1	-	X	
Transf. neutral point 2	-		X

The individual function-group types are described in the following.

5.1.2 Function-Group Type Transformer Differential Protection



5.1.2.1 Overview

The **Transf. diff.** function group contains the differential protection function and protection function relevant measured values.

You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

You will find the corresponding function groups and also the folders with the usable protection functions in the Global DIGSI library under each device type. You can only load the Differential protection function in the **Transf. diff.** function group.

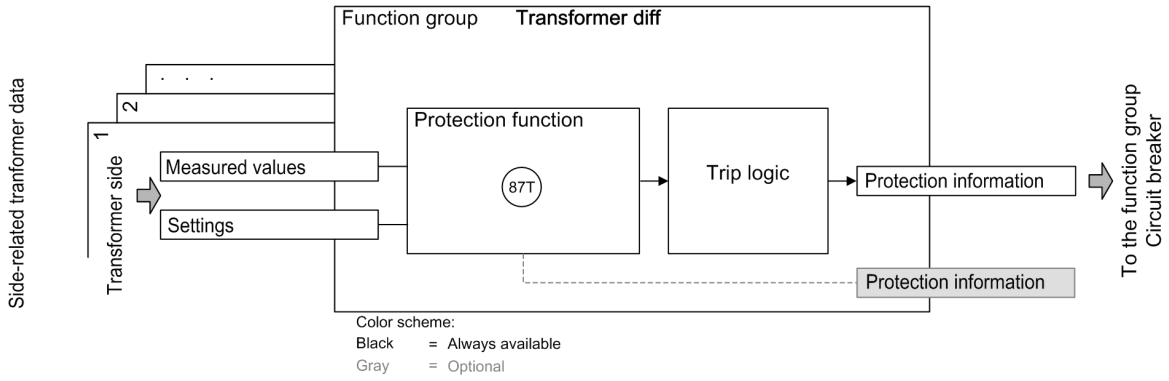
19 depending on device and application

[scpowtrf-230114-01-DE, 1, en_US]

Figure 5-2 Transformer Diff. Function Group - Functional Scope for Device Type 7UT87



For more information about the embedding of the functions in the device, please refer to chapter *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, please refer to chapter *4 Applications*.

5.1.2.2 Structure of the Function Group

The **Transf. diff.** function group according to *Figure 5-3* has interfaces with the **Transformer side** and **Circuit breaker** function groups. The **Transf. diff.** function group contains the function blocks:

- Protection function (execution of the differential protection function)
- Trip logic (generation of forwarding of the operate indication)

In order for the protection functionality to be guaranteed, the differential protection function must always be present in the **Transf. Diff.** function group. If you do not use an application template, load this from the Global DIGSI 5 library.

[dwpwrtrf-201112-01.tif, 1, en_US]

Figure 5-3 Structure of the Transformer Differential Function Group

The **Transf. diff.** function group has interfaces to the following function groups:

- **Transformer side** function group
- **Circuit-breaker** function group

Interface with the Transformer Side Function Group

The **Transf. diff.** function group receives the required measured values via the interface to the **Transformer side** function group. In addition, the required parameters are transferred.

When an application template is used, the **Transf. diff.** function group is connected with the required measuring points.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the **Transf. diff.** function group and the **Circuit-breaker** function group via the interface of the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the Protection function groups

The **Transf. diff.** function group is connected with one or more circuit-breaker function groups. This connection determines the following data:

- Which circuit breakers are activated by the protection functions of the **Transf. diff.** function group
- Start of the **Circuit-breaker failure protection** function, if available in the circuit-breaker function group, through the protection functions of the connected protection function group **Transf. diff.**

In addition to the general assignment of the **Transf. diff.** function group to the Circuit-breaker function groups, you can configure the interface in detail for specific functionalities. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** editor in the **Transf. diff.** function group.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

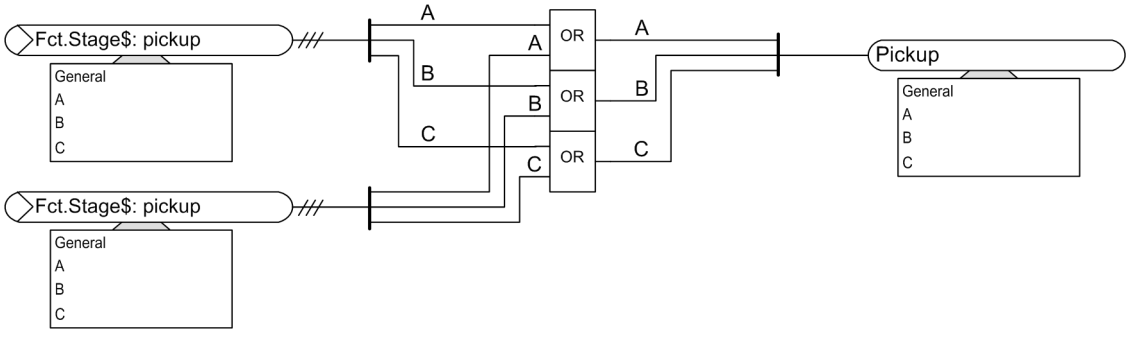
You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication** . These data are for example:

- Binary signals
- Measured values
- Complex data

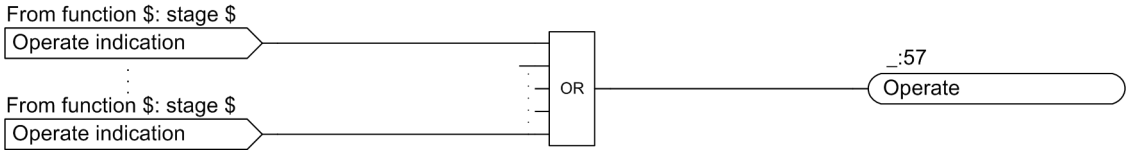
You can find more detailed information in chapter *3.6 Protection Communication*.



Transformer Data (Side-Related)

The transformer data characterize the data of the transformer to be protected. The **Transf. diff.** function group takes these data from the coupled **Transformer side** function group.

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately, in a pickup logic and an output logic respectively. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection functions in the**Transf. diff.** function group are combined phase-selectively and output as a group indication.

5.1.3 Function-Group Type Transformer Side

5.1.3.1 Overview

In the **Transformer side** function group, all of the functions that are necessary for protecting and monitoring a transformer side can be used. The **Transformer side** function group also contains the measuring functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

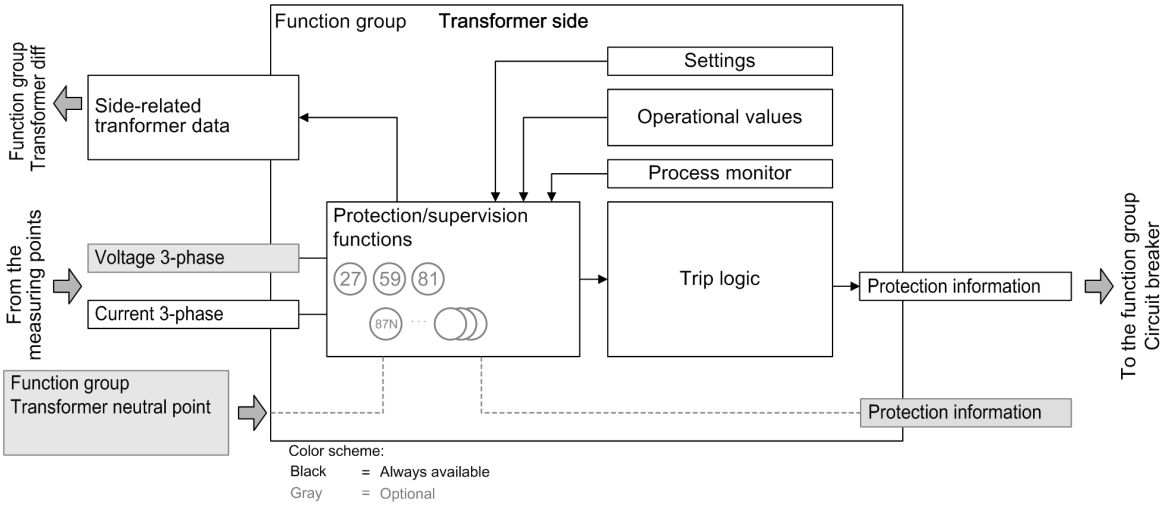
The **Transformer side** function group must always have an interfacing to the **Transformer** function group.

You will find the **Transformer side** function group and the folder with the respective protection functions under each device type in the Global DIGSI 5 library. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Transformer side** function group. The application templates show you the possible applications. The functions are described in chapter *6 Protection and Automation Functions*.

[scpowsit-230114-01-DE, 1, en_US]

Figure 5-6 Transformer Side Function Group - Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.



5.1.3.2 Structure of the Function Group

The **Transformer side** function group always contains the following function blocks:

- Side-dependent transformer data
- Operational measured values
- Process monitor
- Output logic of the function group

These blocks are required for the **Transformer side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Transformer side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwpwrsid-291112-01.tif, 1, en_US]

Figure 5-7 Structure of the Transformer Side Function Group

The **Transformer side** function group has interfaces with the following function groups: Measuring points

- **Measuring points**
- **Circuit-breaker** function group
- **Transformer diff.** function group
- **Transformer neutral point** function group

Interfaces with Measuring Points

The **Transformer side** function group receives the required measured values via its interfaces with the measuring points.

If you are using an application template, the **Transformer side** function group is connected to the necessary measuring points.

If you add functions to the **Transformer side** function group, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Transformer side** function group has the following interfaces with the measuring points:

- **`3-phase voltage`** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Different transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface.

- **3-phase current**:

  The measurands from the 3-phase power system are supplied via this interface. Depending on the transformer connection type, these are for example: I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Transformer side** function group must always be linked to the **I-3ph measuring point**.

  You can connect the **3-phase current** interface to a maximum of **four** 3-phase current measuring points, for example, for 1 1/2 circuit-breaker layouts, two 3-phase current measuring points are required. If 2 current measuring points have been connected to the **3-phase current** interface, the total current is also determined from measured values from both measuring points in the **Transformer side** function group. All functions in the **Transformer side** function group have access to these total current values.

NOTE

The other interfaces can only be connected to one measuring point each!

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the **Transformer side** function group and the **Circuit-breaker** function group via the interface of the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the Protection function groups

The **Transformer side** function group is connected to one or more circuit-breaker function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Transformer side** protection function group
- Start of the **Circuit-breaker failure protection** function, if available in the circuit-breaker function group, through the protection functions of the connected **Transformer side** protection function group

Besides the general allocation of the **Transformer side** protection function group to the circuit-breaker function groups, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** editor in the **Transformer side** function group.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Side-Dependent Transformer Data

The side dependent transformer data characterize the transformer side to be protected. The side dependent transformer data applies for all of the functions in the **Transformer side** function group.

Process Monitor

The process monitor is always present in the **Transformer side** function group and cannot be removed. The process monitor provides the following information in the **Transformer side** function group:

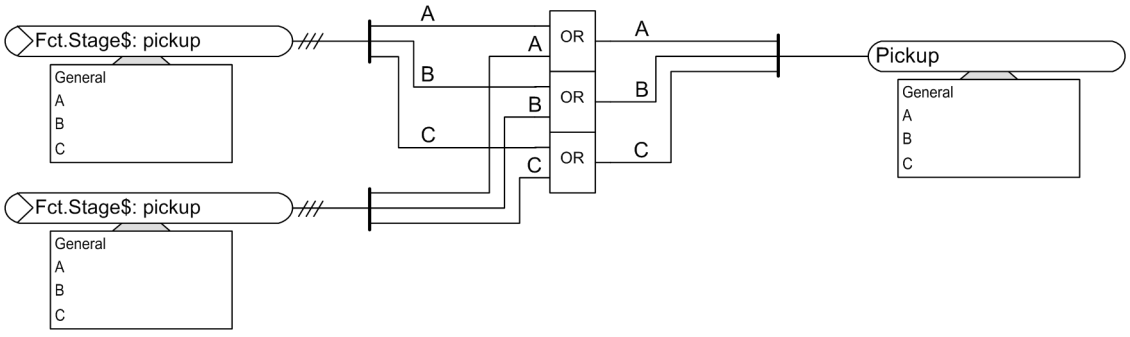
- Current-flow criterion:
  Detection of an open/activated transformer side based on the flow of leakage current
- Closure detection:
  Detection of closure of the transformer side
- Cold-load pickup detection (optional):

This information is in the **Transformer side** function group and is available to all the functions in the function group.
The description of the process monitor begins in chapter *5.14 Process Monitor*.

Operational Measured Values

The operational measured values are always present in the **Transformer side** function group and cannot be deleted. If a 3-phase voltage measuring point is connected, the following table shows the total scope. Only the first 3 lines apply for exclusive current connection.

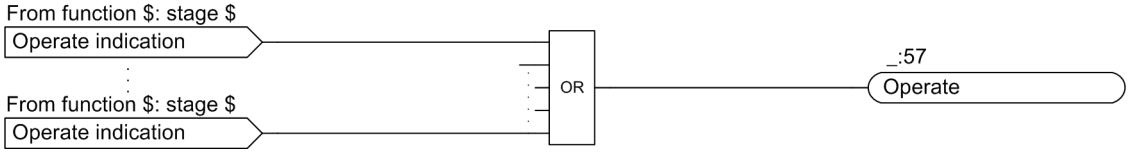
Table 5-3 Possible Operational Measured Values of the Transformer Side Function Group



Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
V_A, V_B,V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_0	Calculated zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100% corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

Measured Values		Primary	Secondary	% Referenced to
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection and supervision functions in the **Transformer side** function group are combined in a phase-selective manner and output as a group indication.

[lo_auslin, 3, en_US]

Figure 5-9 Generation of an Operate Indication of the Transformer Side Function Group

5.1.3.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

Depending on the protection function used and the circuit breakers to be activated, the connection to the corresponding **Circuit breaker** must be provided.

You can find more information in chapter *2 Basic Structure of the Function*.

Parameter: Rated apparent power

- Default setting **(_:91:103) Rated apparent power** = ***692.82 MVA***

With the **Rated apparent power** parameter, you can set the primary rated apparent power of the transformer to be protected.

NOTE

The windings for transformers with more than 2 windings can have different rated apparent powers. Here the power alone is decisive for the winding, which is assigned to the side.

The **Rated apparent power** parameter is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:91:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the transformer to be protected. The **Rated voltage** parameter is relevant for the main protection function of the device. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated current

- Default setting **(_:91:101) Rated current** = ***1000 A***

The **Rated current** parameter indicates to you the primary rated current of the transformer side. The **Rated current** parameter is relevant for the main protection function of the device. The setting value is formed from the **Rated voltage** and **Rated apparent power** parameters.

Parameter: Neutral point

- Default setting **(_:91:149) Neutral point** = ***grounded***

With the **Neutral point** parameter, you specify whether the neutral point is ***grounded*** or ***isolated***. If the neutral point is grounded via a ground current limiting (low-ohmic) or via a arc-suppression coil (high-ohmic), then also set ***grounded***. If there is a neutral point former or a surge arrester within the protection range between the neutral point and ground, the neutral point also is valid as ***grounded***.

Parameter: Winding configuration

- Default setting **(_:91:104) Winding configuration** = ***Y (Wye)***

With the **Winding configuration** parameter, you set ***Y (Wye)*** for a star connection of the transformer. Other setting options are ***D (Delta)*** for a delta connection and ***Z (Zig-Zag)*** for a zigzag connection. The **Winding configuration** parameter is relevant for the main protection function of the device.

Parameter: Vector group numeral

- Default setting **(_:91:163) Vector group numeral** = ***0***

With the **Vector group numeral** parameter, you set the vector group for the transformer to be protected. Each **Vector group numeral** from 0 to 11 can be set provided it is possible, for example, for Yy, Dd, and Dz only even numerals are possible, for Yd, Yz, and Dy only odd numerals are possible. The **Vector group numeral** parameter is relevant for the main protection function of the device.

NOTE

The device also automatically calculates the current adaptation formulas required for the winding rated currents from the rated data of the transformer to be protected and its windings. The currents are converted so that the sensitivity of the protection is based on the rated apparent power of the transformer.

Parameter: Side number

- Default setting **(_:91:130) Side number** = ***not assigned***

The **Side number** parameter shows you which transformer side is currently valid for the following parameters. The side number (***Side 1*** to ***Side 5***) is automatically assigned when connecting to a transformer side.

Parameter: MI3ph1 usesMeasP with ID

- Default setting **(_:91:210) MI3ph1 usesMeasP with ID** = ***0***

The parameters **MI3ph1 usesMeasP with ID** to **MI3ph4 usesMeasP with ID** show you which 3-phase measuring points (**MI3ph 1** to **MI3ph 4**) are connected to the transformer side. Every measuring point is assigned a unique ID.

Parameter: M I-1ph uses MeasP with ID

- Default setting **(_:91:214) M I-1ph uses MeasP with ID** = ***0***

The **M I-1ph uses MeasP with ID** parameter shows you which 1-phase measuring point is connected to the transformer side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:91:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude scaling of the phase currents of the 1st assigned measuring point. The numerical value is made up from the ratio of the primary rated current of the current transformer to the transformer rated current of the side.

Parameter: CT mismatch M I-3ph 1 IN

- Default setting **(_:91:216) CT mismatch M I-3ph 1 IN** = ***0.000***

The **CT mismatch M I-3ph 1 IN** parameter shows you the magnitude scaling of the ground current of the 1st assigned measuring point.

Parameter: CT mismatch M I-3ph 2

- Default setting **(_:91:217) CT mismatch M I-3ph 2** = ***0.000***

The **CT mismatch M I-3ph 2** parameter shows you the magnitude scaling of the phase currents of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 2 IN

- Default setting **(_:91:218) CT mismatch M I-3ph 2 IN** = ***0.000***

The **CT mismatch M I-3ph 2 IN** parameter shows you the magnitude scaling of the ground current of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 3

- Default setting **(_:91:219) CT mismatch M I-3ph 3** = ***0.000***

The **CT mismatch M I-3ph 3** parameter shows you the magnitude scaling of the phase currents of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 3 IN

- Default setting **(_:91:220) CT mismatch M I-3ph 3 IN** = ***0.000***

The **CT mismatch M I-3ph 3 IN** parameter shows you the magnitude scaling of the ground current of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 4

- Default setting **(_:91:221) CT mismatch M I-3ph 4** = ***0.000***

The **CT mismatch M I-3ph 4** parameter shows you the magnitude scaling of the phase currents of the 4th assigned measuring point.

Parameter: CT mismatch M I-3ph 4 IN

- Default setting **(_:91:222) CT mismatch M I-3ph 4 IN** = ***0.000***

The **CT mismatch M I-3ph 4 IN** parameter shows you the magnitude scaling of the ground current of the 4th assigned measuring point.

Parameter: CT mismatch M I-1ph

- Default setting **(_:91:223) CT mismatch M I-1ph** = ***0.000***

The **CT mismatch M I-1ph** parameter shows you the magnitude scaling of the transformer neutral-point current.

5.1.3.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
Rated values				
_:91:101	General:Rated current		1 A to 100 000 A	1 000 A
Side data				
_:91:130	General:Side number		• not assigned • Side 1 • Side 2 • Side 3 • Side 4 • Side 5	not assigned
_:91:210	General:MI3ph1 uses-MeasP with ID		0 to 100	0

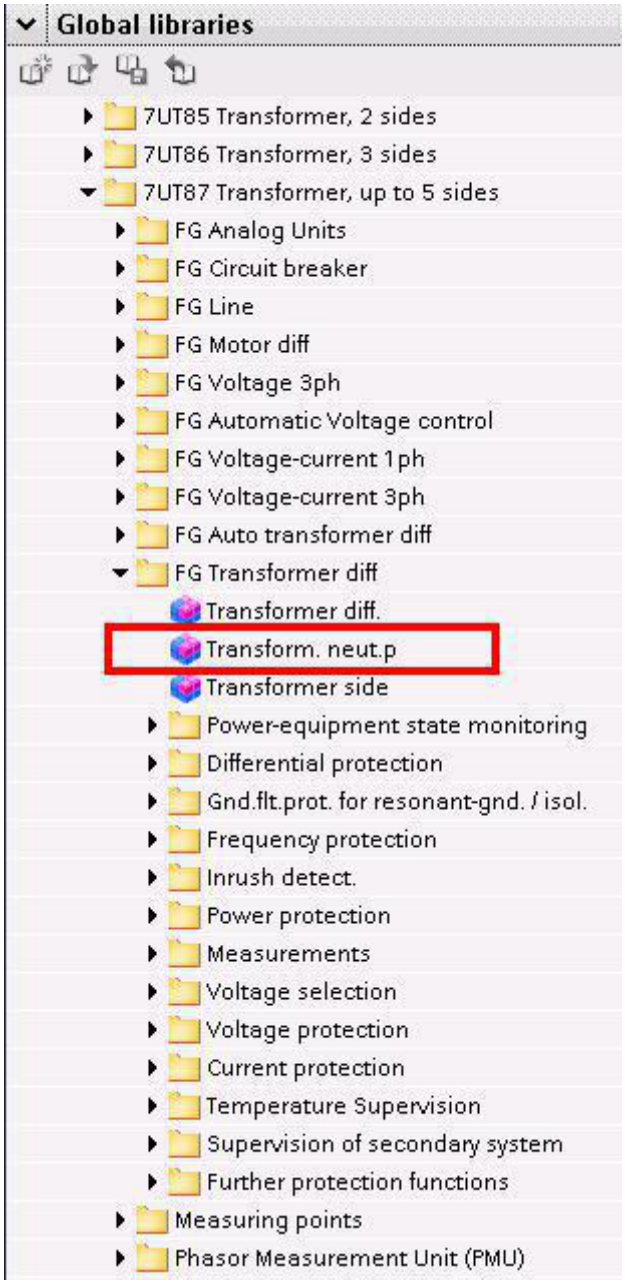
5.1.4 Function-Group Type Transformer Neutral Point

5.1.4.1 Overview



In the**Transf. neutral point** function group, all the necessary functions for protection and for supervision of a transformer are used, which are related to a neutral-point current. The **Transf. neutral point** function group also includes the measurement functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

NOTE

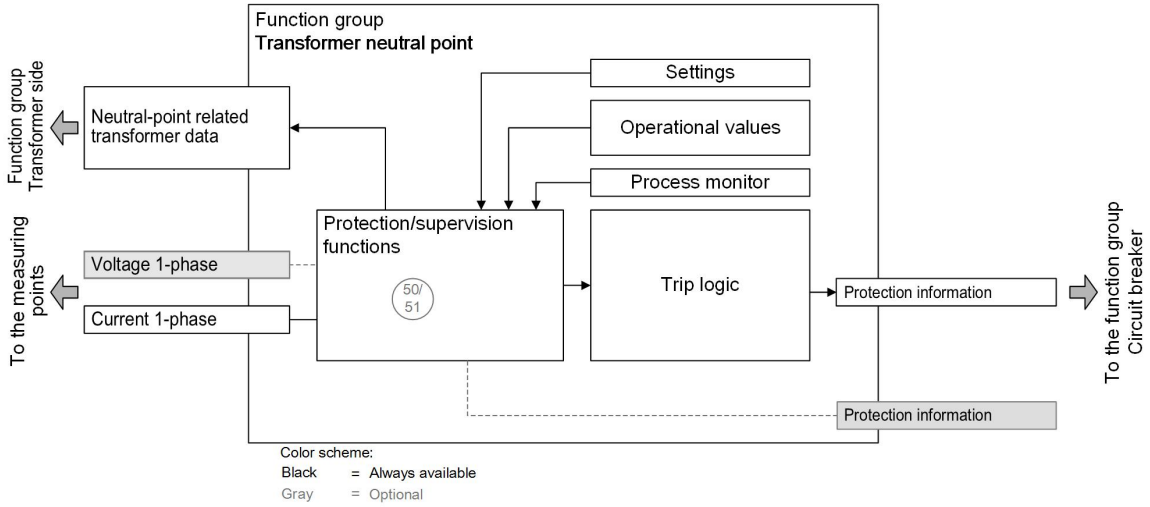
The transformer and restricted ground-fault protection do not work with sensitive ground-current transformers. Responsive transformers go to saturation too fast and generate incorrect differential currents.

In the Global DIGSI 5 library, you will find the **Transf. neutral point** function group under each device type and the folder with the respective protection functions. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Transf. neutral point** function group. Here you can only load 1-phase current functions or optional 1-phase voltage functions.The functions are described in chapter *6 Protection and Automation Functions*.

[scpowspt-230114-01-DE, 1, en_US]

Figure 5-10 Transformer Neutral Point Function Group – Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.



5.1.4.2 Structure of the Function Group

The function group **Transf. neutral point** always includes the following function blocks:

- Neutral point oriented transformer data
- Operational measured values
- Output logic of the function group

These blocks are required in the function group **Transf. neutral point** and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the function group **Transf. neutral point**. The functions are available in the function library in DIGSI 5. Functions that are not needed can be deleted from the function group.

[dwpwrstp-161012-01.tif, 2, en_US]

Figure 5-11 Structure of the Function Group Transf. Neutral Point

The function group **Transf. neutral point** has interfaces to the following function groups:

- **Measuring points**
- **Circuit breaker**
- **Transformer side**

Interfaces with Measuring Points

The function group **Transf. neutral point** receives the required measured values via its interfaces with the measuring points.

When an application template is used, the function group **Transf. neutral point** is connected with the required measuring points.

If you insert functions in the function group **Transf. neutral point**, they automatically receive the measured values of the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-Group connections** Editor.

You can find more detailed information in *2 Basic Structure of the Function*.

The function group **Transf. neutral point** has the following interfaces with the measuring points.

- **`1-phase voltage`** (optional):

  The measurands from the 1-phase voltage system are supplied via this interface. All values that can be calculated from the measurands are also provided via this interface.

  If you want to test or change the connection between the voltages and the **V-1ph measuring point** double-click **Measuring-point routing** (name of the device) in the DIGSI 5 project tree → **7UT87**.

  For more information, refer to the description of the *power-system data* starting from *6.1 Power-System Data*.

  You must connect the **`1-phase voltage`** interface with the **Measuring point V-1ph** only if functions in the function group **Transf. neutral point** work with this measurand.

- **`1-phase current`**:
  The measurands from the 1-phase current system are supplied via this interface. Depending on type of transformer connection, this is, for example I_x. All values that can be calculated from the measurands are also provided via this interface. The function group **Transf. neutral point** must always be linked with the **Measuring point I-1ph**.

NOTE

You can connect the **`1-phase current`** interface with a maximum of **one** 1-phase current measuring point.
All functions in the function group **Transformer side** have access to these values.

NOTE

If you instantiate functions in the function group **Transf. neutral point**, the function **Overcurrent protection 1ph**, the information for the inrush-current detection is taken from the assigned function group **Transformer side**.

Interface to the Function Group Circuit Breaker

Via the interface of the function group **Circuit breaker**, all necessary data is transferred between the function group **Transf. neutral point** and the function group **Circuit breaker**. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the function group circuit breaker
- Information on the circuit-breaker condition in the direction of the protection function groups

The function group **Transf. neutral point** is connected with one or more function groups Circuit breaker. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the function group **Transf. neutral point**
- Start of the function **Circuit-breaker failure protection**, if available in the function group Circuit breaker, through the protection functions of the connected protection function group **Transf. neutral point**

In addition to the general assignment of the function group **Transf. neutral point** to the function groups Circuit breaker, you can configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the function group **Transf. neutral point**.
In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the function **Circuit-breaker failure protection**?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.
You can find more detailed information in *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in *3.6 Protection Communication*.

Neutral-Point Related Transformer Data

The transformer data characterize the transformer neutral point to be protected. The transformer data applies for all of the functions in the function group **Transf. neutral point**.

Operational Measured Values

The operational measured values are always available in the function group **Transf. neutral point** and cannot be deleted.

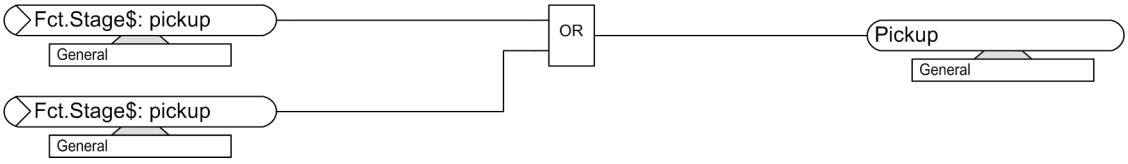


Table 5-4 Operational Measured Values of the Function Group Transformer Neutral Point

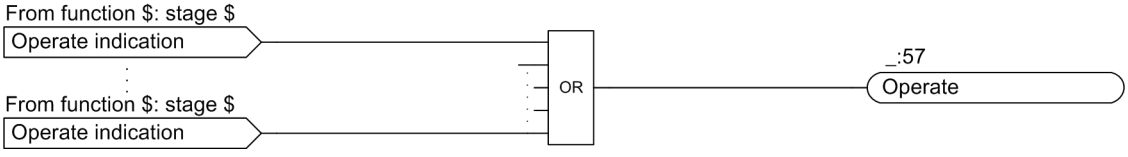
Measured Values		Primary	Secondary	% Referenced to
I	Neutral-point current	A	A	Rated operating current of the primary system
V	Voltage	kV	V	Rated operating voltage of the primary system

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the function group **Circuit breaker** and are processed further there.

The pickup and trip signals of the protection and supervision functions in the function group **Transf. neutral point** are combined phase-selectively and output as group indication.

Figure 5-13 Generation of Operate Indication of the Function Group Transf. Neutral Point

5.1.4.3 Application and Setting Notes

Parameter: Rated current (Write-Protected)

- Default setting **(_9421:104) Rated current** = ***1000 A***

The **Rated current** parameter indicates the primary rated current of the transformer to be protected. The **Rated current** can correspond to the following variables:

- Rated current of the connected transformer side
- Rated current of the reference side of the connected auto transformer

The **Rated current** cannot be changed.

Parameter: Rated voltage (Write-Protected)

- Default setting **(_:9421:105) Rated voltage** = ***400.00 kV***

The **Rated voltage** parameter indicates the primary rated voltage of the transformer to be protected. The **Rated voltage** can correspond to the following variables:

- Rated voltage of the connected transformer side
- Rated voltage of the reference side of the connected auto transformer

The **Rated voltage** cannot be changed.

Parameter: Rated apparent power

- Default setting **(_:9421:103) Rated apparent power** = ***692.82 MVA***

The **Rated apparent power** parameter indicates the calculated value from **Rated voltage** and **Rated current**. If current and voltage are available, this value is only displayed for you and cannot be changed.

Parameter: M I-1ph uses MeasP with ID

- Default setting **(_:9421:214) M I-1ph uses MeasP with ID** = ***0***

The **M I-1ph uses MeasP with ID** parameter indicates which 1-phase measuring point is connected to the transformer neutral point. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-1ph

- Default setting **(_:9421:223) CT mismatch M I-1ph** = ***0.000***

The **CT mismatch M I-1ph** parameter indicates the magnitude scaling of the transformer neutral-point current.

5.1.4.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Range of Values	Default Setting
Rated values

5.2 Function-Group Type Auto Transformer Differential Protection

5.2.1 Function-Group Types

The following figure shows the structural association of the function-group types.

[dwfguebs-291112-01.tif, 1, en_US]

Figure 5-14 Function-Group Types Auto Transformer Diff.

The following function-group types are summarized in the Global DIGSI 5 library:

- **Auto transf. diff.** (Auto transformer)
- **Auto transf. auto side** (Auto transformer auto side)
- **Auto transf. comp. side** (Auto transformer compensation side)
- **Auto transf. grd. side** (Auto transformer ground side)
- **Auto transf. neutral point** (Auto transformer neutral point)

The individual function-group types are stored in the **Auto Transformer function group** folder and can be selected. In the protection function folders, you find all protection functions which are operational in each function group. A **Transf. diff.** function group always contains 2 **Auto transf. auto side** function groups. The

Auto transf. neutral point function group can be connected if needed with the **Auto transf. comp. side** or directly with the **Auto transf. diff.** function group.

The following table shows the number of function-group types that can be instantiated depending on the device (7UT82, 7UT85, 7UT86, 7UT87).

NOTE

By purchasing 70 or 120 function points, the 7UT85 and 7UT86 can be expanded to a three-winding transformer or a multi-winding transformer. Consider to provide the respective number of measuring points that are required for the expansion.

Table 5-5 Function-Group Types in the Device

Device	Function-Group Type				
	Auto Transf. Diff.	Auto Transf. Auto Side	Auto Transf. Comp. Side	Auto Transf. Ground Side	Auto Transf. Neutral-Point Function Group
7UT82	Max. 1	Max. 2	-	-	Max. 1
7UT85	Max. 1	Max. 2	Max. 1 (not open)	Max. 1	Max. 1
7UT86	Max. 1	Max. 3 (2 open)	Max. 1	Max. 1	Max. 2
7UT87	Max. 2	Max. 5[20]	Max. 1	Max. 1	Max. 2

In order for the transformer protection to operate properly, switching of the function groups is necessary. *Table 5-6* provides an overview of those switching options that are permitted. The Circuit-breaker function group is not listed. The images shown in the application templates (see *Figure 4-2* to *Figure 4-7*) give you a good overview of the connection options.

An **Auto transf. auto side** function group must always be connected to the **Auto transf. diff.** function group. Depending on the application, a connection of the **Auto transf. neutral point** function group with the **Auto transf. comp. side** function group is required. This is the case, for example, if a restricted ground-fault protection is used or if the neutral-point current in the differential protection should be considered (zero-sequence current correction). Conversely, the **Auto transf. neutral point** function group can also require signals from the **Auto transf. diff.** function group. A typical case is the inrush-current detection, which can be used for blocking a 1-phase overcurrent protection (with a short time delay set).

Table 5-6 Assignment of Protection Function Groups to Protection Function Groups

Winding	Auto Transf. Diff. 1				Auto Transf. Comp. Side
	Auto Side (2 ... 3)	Comp. Side (0 ... 1)	Ground Side (0 ... 1)	Neutral Point Function Group (0 ... 1)	Neutral Point Function Group (0 ... 1)
Auto transf. auto side 1	X	–	–	–	–
Auto transf. auto side 2	X	–	–	–	–
Auto transformer comp. side	–	X	–	–	–
Auto transformer grd. side	–	–	X	–	–
Auto transf. neutral point 1	–	–	–	X	
Auto transf. neutral point 2	–	–	–		X

The individual function-group types are described in the following.

20 A maximum of 3 auto sides can be assigned to an auto transformer. The remaining auto sides are available for the 2nd auto transformer.

5.2.2 Function-Group Type Auto Transformer Differential Protection

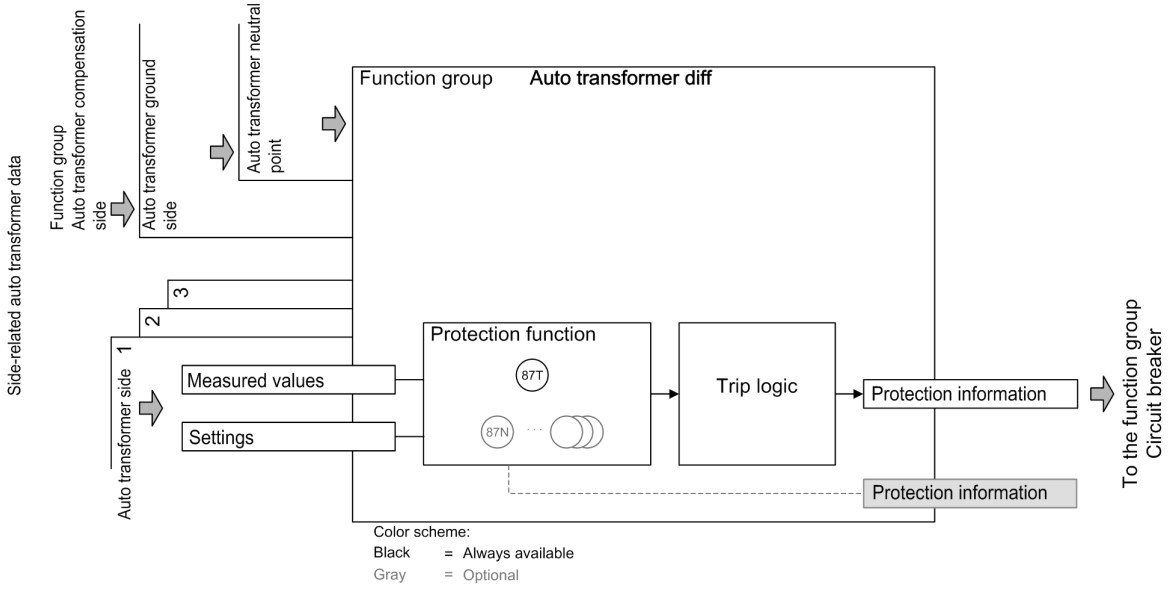
5.2.2.1 Overview

The **Auto transf. Diff.** function group contains the differential protection function and protection function relevant measured values. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

You will find the corresponding function groups and also the folders with the usable protection functions in the Global DIGSI library under each device type. You can only load the Differential protection function in the **Auto transf. diff.** function group.

[scauttrf-230114-01-DE, 1, en_US]

Figure 5-15 Auto Transformer Diff. Function Group - Functional Scope for Device Type 7UT87



For more information about the embedding of the functions in the device, refer to chapter *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, please refer to chapter *4 Applications*.

5.2.2.2 Structure of the Function Group

The **Auto transf. diff.** function group according to *Figure 5-16* has interfaces with the **Auto transf. auto side** and **Circuit-breaker** function groups. The **Auto transf. diff.** function group contains the function blocks:

- Protection function (execution of the differential protection function)
- Trip logic (generation of forwarding of the operate indication)

In order for the protection functionality to be guaranteed, the differential protection function must always be present in the **Auto transf. diff.** function group. If you do not use an application template, load this from the Global DIGSI 5 library.

[dwauttrf-201112-01.tif, 1, en_US]

Figure 5-16 Structure of the Auto Transf. Diff. Function Group

The **Auto transf. diff.** function group has interfaces to the following function groups:

- The **Auto transf. auto side** function group
- The **Auto transf. comp. side** function group
- The **Auto transf. ground side** function group
- The **Auto transf. neutral point** function group
- **Circuit-breaker** function group

Interface to the Auto Transformer Auto Side Function Group

The **Auto transf. diff.** function group receives the required measured values via the interface to the **Auto transf. auto side** function group. In addition, the required settings are transferred.

By using an application template the **Auto transf. diff.** function group is connected with the required measuring points.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and Circuit-breaker function groups via the interface with the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the Protection function groups

The **Auto transf. diff.** function group is connected with one or more circuit-breaker function groups. This connection generally determines:

- Which circuit breakers are activated by the protection functions of the **Auto transf. diff.** function group
- Start of the **Circuit-breaker failure protection** function, if available in the Circuit-breaker function group via the protection functions of the connected **Auto transf. diff.** function group.

In addition to the general assignment of the **Auto transf. diff.** function group to the Circuit-breaker function groups, you can configure the interface in detail for specific functionalities. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the **Auto transf. diff.** function group.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

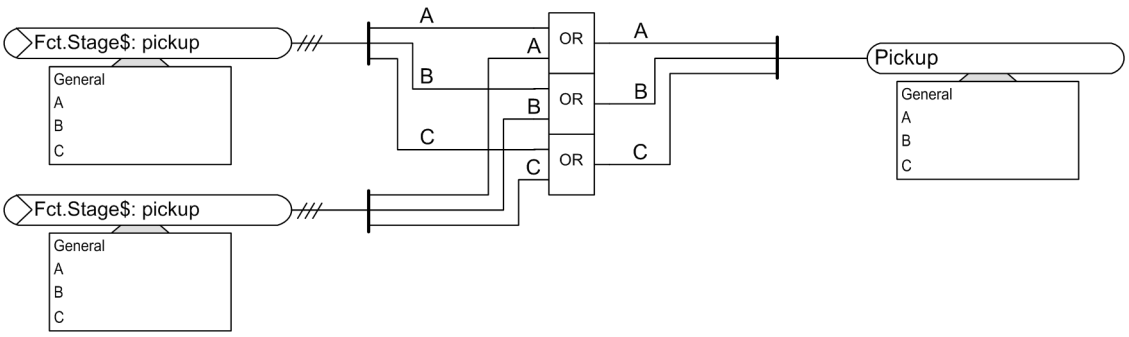
Interface with Protection Communication (Optional)

All required data is exchanged between the Protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

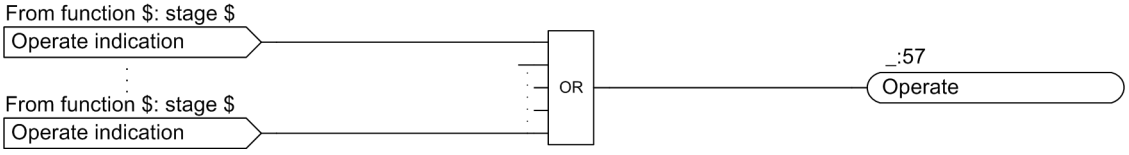
Auto Transformer Data (Side-Related)



The auto transformer data characterize the auto transformer to be protected. The **Auto transf. diff.** function group takes these data from the coupled function groups.

- **Auto transf. auto side** function group
- **Auto transf. comp. side** function group
- **Auto transf. ground side** function group
- **Auto transf. neutral point** function group

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection and supervision functions in the **Auto transf. diff.** function group are combined phase-selectively and output as a group indication.

[lo_auslin, 3, en_US]

Figure 5-18 Generation of Operate Indication of the Auto Transformer Diff. Function Group

5.2.2.3 Application and Setting Notes

Parameter: Neutral point

- Default setting **(_:91:149) Neutral point** = ***grounded***

With the **Neutral point** parameter, you specify whether the neutral point of the auto transformer is ***grounded*** or ***isolated***.

NOTE

The **Neutral point** parameter is only visible or changeable if you have connected the **Auto transformer Diff.** function group with the **Auto transf. neutral point**.function group.

5.2.2.4 Settings

5.2.3 Function-Group Type Auto Transformer Auto Side

5.2.3.1 Overview

In the **Auto transf. auto side** function group all functions required for protection and supervision of an auto transformer auto side can be used. The **Auto transf. auto side** function group also includes the measurement functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

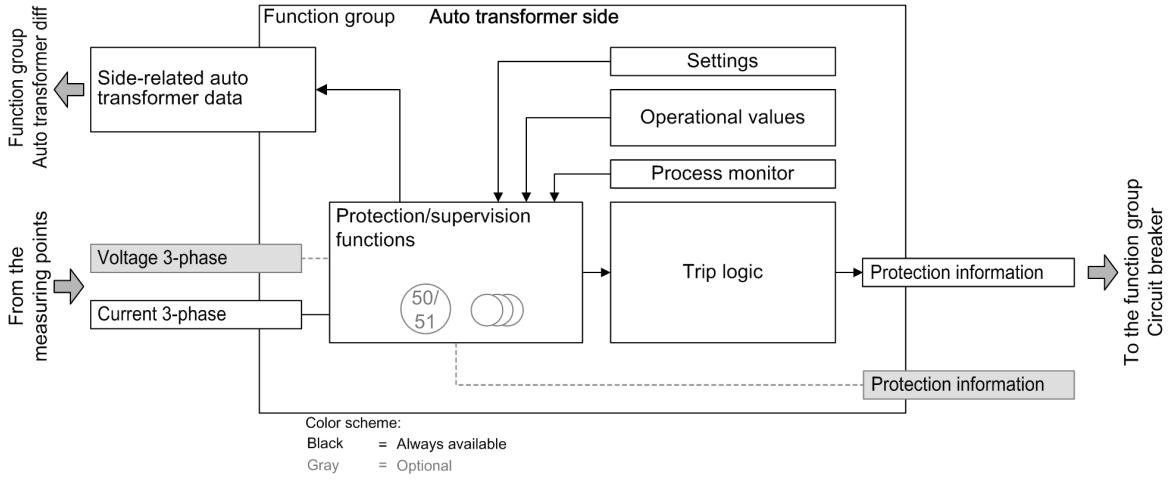
The **Auto transf. auto side** function group must always have a link to the **Auto transformer** function group.

In the Global DIGSI 5 library, you will find the **Auto transf. auto side** function group under each device type and the folder with the respective protection functions. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Auto transf. auto side**. The functions are described in chapter *6 Protection and Automation Functions*.

[scautspr-230114-01-DE, 1, en_US]

Figure 5-19 Auto Transformer Auto Side Function Group – Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.



5.2.3.2 Structure of the Function Group

The **Auto transf. auto side** function group always includes the following function blocks:

- Side-dependent auto transformer data
- Operational measured values
- Process monitor
- Output logic of the function group

These blocks are required in the **Auto transf. auto side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Auto transf. auto side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwautsid-201112-01.tif, 1, en_US]

Figure 5-20 Structure of the Auto Transf. Auto Side Function Group

The **Auto transf. auto side** function group has interfaces to the following function groups:

- **Measuring points**
- **Circuit-breaker** function group
- **Auto transformer** function group

Interfaces with Measuring Points

The **Auto transf. auto side** function group receives the required measured values via its interfaces with the measuring points.

By using an application template the **Auto transf. auto side** function group is connected with the required measuring points.

If you insert functions in the **Auto transf. auto side** function group, they automatically receive the measured values of the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Auto transf. auto side** function group has the following interfaces with the measuring points.

- **`3-phase voltage`** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Different transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface.

- **3-phase current**:

  The measurands from the 3-phase power system are supplied via this interface. Depending on the transformer connection type, these are for example: I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Auto transf. auto side** function group must always be connected with the **Measuring point I-3ph**.

  You can connect the **3-phase current** interface to a maximum of **four** 3-phase current measuring points, for example, for 1 1/2 circuit-breaker layouts, two 3-phase current measuring points are required. If 2 current measuring points are connected with the **3-phase current** interface, in the **Auto transf. auto side** function group the total current is additionally formed from the measured values of both measuring points. All functions of the **Auto transf. auto side** function group have access to these values.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and circuit-breaker function groups via the interface with the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the protection function groups

The **Auto transf. auto side** function group is connected with one or more Circuit-breaker function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Auto transf. auto side** function group
- Start of the **Circuit-breaker failure protection** function, if available in the Circuit-breaker function group, through the protection functions of the connected **Auto transf. auto side** function group

In addition to the general assignment of the **Auto transf. auto side** protection function group to the circuit-breaker function groups, you can configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** editor in the **Auto transf. auto side** function groups.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Side-Dependent Auto Transformer Data

The auto transformer data characterize the auto transformer auto side to be protected. The side-related auto transformer data applies for all of the functions in the **Auto transf. auto side** function group.

Process Monitor

The process monitor is always available in the **Auto transf. auto side** function group and cannot be removed. The process monitor makes the following information available in the **Auto transf. auto side** function group:

- Current-flow criterion:
  Detection of an open/activated auto transformer auto side based on the flow of leakage current
- Closure detection:
  Recognition of the switching on of the auto transformer auto side
- Cold-load pickup detection (optional):

This information is available in the **Auto transf. auto side** function group for all the functions included in it.

The description of the process monitor begins in chapter *5.14 Process Monitor*.

Operational Measured Values

The operational measured values are always available in the **Auto transf. auto side** function group and cannot be deleted. If a 3-phase voltage measuring point is connected, the following table shows the total scope. Only the first 3 lines apply for exclusive current connection.

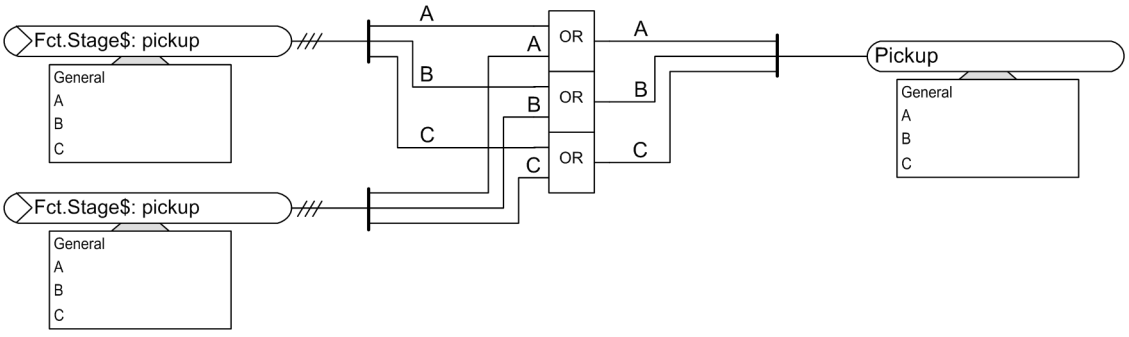


Table 5-7 Possible Operational Measured Values of the Auto Transformer Auto Side Function Group

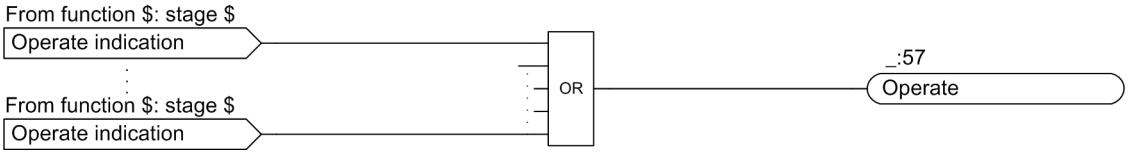
Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
V_A, V_B,V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_0	Calculated zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100% corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection-information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection and supervision functions in the **Auto transf. auto side** function group are combined phase-selectively and output as group indication.

Figure 5-22 Generation of Operate Indication of the Auto Transformer Auto Side Function Group

5.2.3.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

Depending on the protection function used and the circuit breakers to be activated, the connection to the corresponding **Circuit breaker** must be provided.

You can find more information in chapter *2 Basic Structure of the Function*.

Parameter: Rated apparent power

- Default setting **(_:91:103) Rated apparent power** = ***692.82 MVA***

With the **Rated apparent power** parameter, you can set the primary rated apparent power for the auto transformer to be protected. The **Rated apparent power** parameter is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:91:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the auto transformer to be protected. The **Rated voltage** parameter is relevant for the main protection function of the device. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated current

- Default setting **(_:91:101) Rated current** = ***1000 A***

The **Rated current** parameter indicates to you the primary rated current of the auto transformer auto side. The **Rated current** parameter is relevant for the main protection function of the device. The setting value is formed from the **Rated voltage** and **Rated apparent power** parameters.

NOTE

The device also automatically calculates the current adaptation formulas required for the winding rated currents from the rated data of the auto transformer to be protected and its windings. The currents are converted so that the sensitivity of the protection is based on the rated apparent power of the auto transformer.

Parameter: Side number

- Default setting **(_:91:130) Side number** = ***not assigned***

The **Side number** parameter shows you which auto transformer auto side is currently valid for the following parameters. The side number (***Side 1*** to ***Side 5***) is automatically assigned with the connection to an auto transformer auto side.

Parameter: MI3ph1 usesMeasP with ID

- Default setting **(_:91:210) MI3ph1 usesMeasP with ID** = ***0***

The parameters **MI3ph1 usesMeasP with ID** to **MI3ph4 usesMeasP with ID** show you which 3-phase measuring points (**MI3ph 1** to **MI3ph 4**) are connected to the auto transformer auto side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:91:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude scaling of the phase currents of the 1st assigned measuring point. The numerical value is made up from the ratio of the primary rated current of the current transformer to the auto transformer rated current of the side.

Parameter: CT mismatch M I-3ph 1 IN

- Default setting **(_:91:216) CT mismatch M I-3ph 1 IN** = ***0.000***

The **CT mismatch M I-3ph 1 IN** parameter shows you the magnitude scaling of the ground current of the 1st assigned measuring point.

Parameter: CT mismatch M I-3ph 2

- Default setting **(_:91:217) CT mismatch M I-3ph 2** = ***0.000***

The **CT mismatch M I-3ph 2** parameter shows you the magnitude scaling of the phase currents of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 2 IN

- Default setting **(_:91:218) CT mismatch M I-3ph 2 IN** = ***0.000***

The **CT mismatch M I-3ph 2 IN** parameter shows you the magnitude scaling of the ground current of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 3

- Default setting **(_:91:219) CT mismatch M I-3ph 3** = ***0.000***

The **CT mismatch M I-3ph 3** parameter shows you the magnitude scaling of the phase currents of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 3 IN

- Default setting **(_:91:220) CT mismatch M I-3ph 3 IN** = ***0.000***

The **CT mismatch M I-3ph 3 IN** parameter shows you the magnitude scaling of the ground current of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 4

- Default setting **(_:91:221) CT mismatch M I-3ph 4** = ***0.000***

The **CT mismatch M I-3ph 4** parameter shows you the magnitude scaling of the phase currents of the 4th assigned measuring point.

Parameter: CT mismatch M I-3ph 4 IN

- Default setting **(_:91:222) CT mismatch M I-3ph 4 IN** = ***0.000***

The **CT mismatch M I-3ph 4 IN** parameter shows you the magnitude scaling of the ground current of the 4th assigned measuring point.

5.2.3.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
Rated values				
_:91:101	General:Rated current		1 A to 100 000 A	1 000 A
Side data				
_:91:130	General:Side number		• not assigned • Side 1 • Side 2 • Side 3 • Side 4 • Side 5	not assigned
_:91:210	General:MI3ph1 uses-MeasP with ID		0 to 100	0
_:91:211	General:MI3ph2 uses-MeasP with ID		0 to 100	0
_:91:212	General:MI3ph3 uses-MeasP with ID		0 to 100	0
_:91:213	General:MI3ph4 uses-MeasP with ID		0 to 100	0
_:91:215	General:CT mismatch M I-3ph 1		0.000 to 100.000	0.000

Addr.	Parameters	C	Range of Values	Default Setting
_:91:216	General:CT mismatch M I-3ph 1 IN		0.000 to 100.000	0.000
_:91:217	General:CT mismatch M I-3ph 2		0.000 to 100.000	0.000
_:91:218	General:CT mismatch M I-3ph 2 IN		0.000 to 100.000	0.000
_:91:219	General:CT mismatch M I-3ph 3		0.000 to 100.000	0.000
_:91:220	General:CT mismatch M I-3ph 3 IN		0.000 to 100.000	0.000
_:91:221	General:CT mismatch M I-3ph 4		0.000 to 100.000	0.000
_:91:222	General:CT mismatch M I-3ph 4 IN		0.000 to 100.000	0.000

NOTE

You can find more detailed information on the Process monitor in chapter *5.14 Process Monitor*.

5.2.3.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Rated values				
_:91:103	General:Rated apparent power		0.20 MVA to 5000.00 MVA	692.82 MVA
_:91:102	General:Rated voltage		0.40 kVto 800.00 kV	400.00 kV
Measurements				
_:91:158	General:P, Q sign		• not reversed • reversed	not reversed

5.2.4 Function-Group Type Auto Transformer Compensation Side

5.2.4.1 Overview

In the **Auto transf. comp. side** all the functions required for protection and supervision of an auto transformer compensation side can be used. The **Auto transf. comp. side** also includes the measurement functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

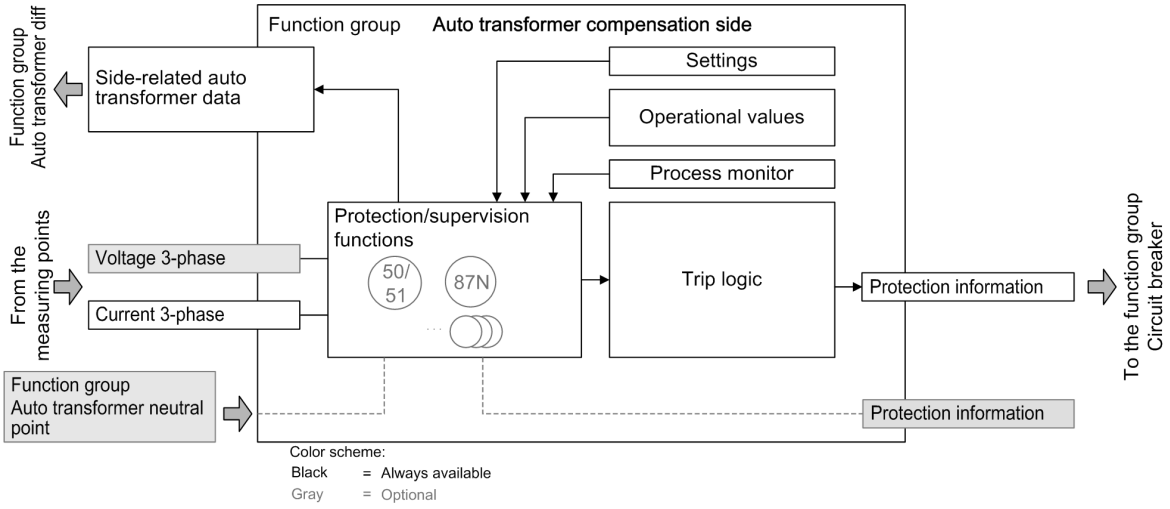
The **Auto transf. comp. side** must always have a link to the **Auto transformer** function group.

In the Global DIGSI 5 library, you will find the **Auto transf. comp. side** function group under each device type and the folders with the respective protection functions. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Auto transf. comp. side** function group. The functions are described in chapter *6 Protection and Automation Functions*.

[scautcmp-230114-01-DE, 1, en_US]

Figure 5-23 Auto Transformer Comp. Side Function Group - Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to chapter *4 Applications*.



5.2.4.2 Structure of the Function Group

The **Auto transf. comp. side** function group always contains the following function blocks:

- Side-dependent auto transformer data
- Operational measured values
- Process monitor
- Output logic of the function group

These blocks are required for the **Auto transf. comp. side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Auto transf. comp. side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwautcsd-291112-01.tif, 1, en_US]

Figure 5-24 Structure of the Auto Transf. Comp. Side Function Group

The **Auto transf. comp. side** function group has interfaces to the following function groups:

- **Measuring points**
- **Circuit-breaker** function group
- **Auto transf. diff.** function group
- **Auto transf. neutral point** function group

Interfaces with Measuring Points

The **Auto transf. comp. side** function group receives the required measured values via its interfaces with the measuring points.

By using an application template the **Auto transf. comp. side** function group is connected with the required measuring points.

If you insert functions in the **Auto transf. comp. side** function group, they automatically receive the measured values of the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Auto transf. comp. side** function group has the following interfaces with the measuring points:

- **`3-phase voltage`** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Different transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface.

- **3-phase current**:

  The measurands from the 3-phase power system are supplied via this interface. Depending on the transformer connection type, these are for example: I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Auto transf. comp. side** function group must always be linked to the **I-3ph measuring point**.

  You can connect the **3-phase current** interface to a maximum of **four** 3-phase current measuring points, for example, for 1 1/2 circuit-breaker layouts, two 3-phase current measuring points are required. If 2 current measuring points are connected with the **3-phase current** interface, in the **Auto transf. comp. side** function group the total current is additionally formed from the measured values of both measuring points. All functions of the **Auto transf. comp. side** function group have access to these values.

NOTE

The other interfaces can only be connected to one measuring point each!

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and circuit-breaker function groups via the interface with the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the protection function groups

The **Auto transf. comp. side** function group is connected with one or more Circuit-breaker function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Auto transf. comp. side** function group.
- Start of the **Circuit-breaker failure protection** function (if available in the Circuit-breaker function group) through the protection functions of the connected **Auto transf. comp. side** function group

In addition to the general assignment of the **Auto transf. comp. side** function group to the Circuit-breaker function groups, you can configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** editor in the **Auto transf. comp. side** function group.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Side-Dependent Auto Transformer Data

The auto transformer data characterize the auto transformer compensation side to be protected. The auto transformer data applies for all of the functions in the **Auto transf. comp. side** function group.

Process Monitor

The process monitor is always available in the **Auto transf. comp. side** function group and cannot be removed. The process monitor makes the following information available in the **Auto transf. comp. side** function group:

- Current-flow criterion:
  Recognition of an open/closed auto transf. comp. side based on the flowing leakage current
- Closure detection:
  Recognition of the switching on of the auto transf. comp. side
- Cold-load pickup detection (optional):

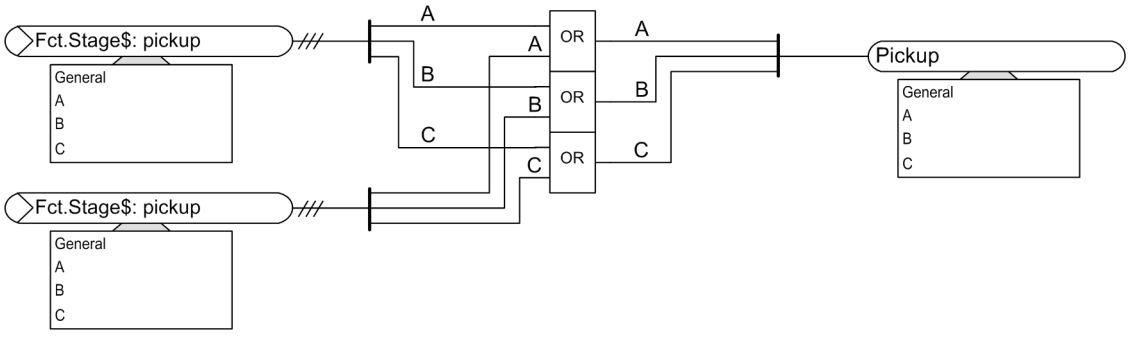
This information is available in the **Auto transf. comp. side** function group for all the functions included in it.

The description of the process monitor begins in chapter *5.14 Process Monitor*.

Operational Measured Values

The operational measured values are always available in the **Auto transf. comp. side** function group and cannot be deleted. If a 3-phase voltage measuring point is connected, the following table shows the total scope. Only the first 3 lines apply for exclusive current connection.

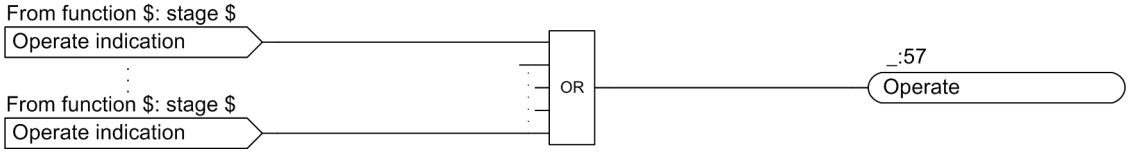
Table 5-8 Possible Operational Measured Values of the Auto Transformer Comp. Side Function Group



Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
V_A, V_B,V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_0	Calculated zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100 % corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

Measured Values		Primary	Secondary	% Referenced to
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection and supervision functions in the **Auto transf. comp. side** function group are combined phase-selectively and output as group indication.

[lo_auslin, 3, en_US]

Figure 5-26 Generation of Operate Indication of the Auto Transformer Comp. Side Function Group

5.2.4.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

Depending on the protection function used and the circuit breakers to be activated, the connection to the corresponding **Circuit breaker** must be provided.

You can find more information in chapter *2 Basic Structure of the Function*.

Parameter: Rated apparent power

- Default setting **(_:91:103) Rated apparent power** = ***692.82 MVA***

With the **Rated apparent power** parameter, you can set the primary rated apparent power for the auto transformer to be protected. The **Rated apparent power** parameter is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:91:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the auto transformer to be protected. The **Rated voltage** parameter is relevant for the main protection functions of the device. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated current

- Default setting **(_:91:101) Rated current** = ***1000 A***

The **Rated current** parameter indicates to you the primary rated current of the auto transformer. The **Rated current** parameter is relevant for the main protection function of the device. The setting value is formed from the **Rated voltage** and **Rated apparent power** parameters.

Parameter: Neutral point

- Default setting **(_:91:149) Neutral point** = ***isolated***

With the **Neutral point** parameter, you specify whether the neutral point is ***grounded*** or ***isolated***.

Parameter: Winding configuration

- Default setting **(_:91:104) Winding configuration** = ***D (Delta)***

With the **Winding configuration** parameter, you set ***D (Delta)*** for a delta connection of the auto transformer. Other setting options are ***Y (Wye)*** for a star connection and ***Z (Zig-Zag)*** for a zigzag connection. The **Winding configuration** parameter is relevant for the main protection function.

Parameter: Vector group numeral

- Default setting **(_:91:163) Vector group numeral** = ***1***

With the **Vector group numeral** parameter you set the vector group for the auto transformer to be protected. Every **Vector group numeral** from 0 to 11 can be set provided it is possible, for example, for Yy, Dd, and Dz only even numerals are possible, for Yd, Yz, and Dy only odd numerals. The **Vector group numeral** parameter is relevant for the main protection function.

NOTE

The device automatically calculates the current adaptation formulas required for the winding rated currents from the rated data of the auto transformer to be protected and its windings. The currents are converted so that the sensitivity of the protection is based on the rated apparent power of the auto transformer.

Parameter: Side number

- Default setting **(_:91:130) Side number** = ***not assigned***

The **Side number** parameter shows you which auto transformer side is currently valid for the following parameters. The side number (***Side 1*** to ***Side 5***) is automatically assigned with the connection to an auto transformer side.

Parameter: MI3ph1 usesMeasP with ID

- Default setting **(_:91:210) MI3ph1 usesMeasP with ID** = ***0***

The parameters **MI3ph1 usesMeasP with ID** to **MI3ph4 usesMeasP with ID** show you which 3-phase measuring points (**MI3ph 1** to **MI3ph 4**) are connected to the auto transformer compensation side. Every measuring point is assigned a unique ID.

Parameter: M I-1ph uses MeasP with ID

- Default setting **(_:91:214) M I-1ph uses MeasP with ID** = ***0***

The **M I-1ph uses MeasP with ID** parameter shows you which 1-phase measuring point is connected to the auto transformer compensation side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:91:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude scaling of the phase currents of the 1st assigned measuring point. The numerical value is made up from the ratio of the primary rated current of the current transformer to the auto transformer rated current of the compensation side.

Parameter: CT mismatch M I-3ph 1 IN

- Default setting **(_:91:216) CT mismatch M I-3ph 1 IN** = ***0.000***

The **CT mismatch M I-3ph 1 IN** parameter shows you the magnitude scaling of the ground current of the 1st assigned measuring point.

Parameter: CT mismatch M I-3ph 2

- Default setting **(_:91:217) CT mismatch M I-3ph 2** = ***0.000***

The **CT mismatch M I-3ph 2** parameter shows you the magnitude scaling of the phase currents of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 2 IN

- Default setting **(_:91:218) CT mismatch M I-3ph 2 IN** = ***0.000***

The **CT mismatch M I-3ph 2 IN** parameter shows you the magnitude scaling of the ground current of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 3

- Default setting **(_:91:219) CT mismatch M I-3ph 3** = ***0.000***

The **CT mismatch M I-3ph 3** parameter shows you the magnitude scaling of the phase currents of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 3 IN

- Default setting **(_:91:220) CT mismatch M I-3ph 3 IN** = ***0.000***

The **CT mismatch M I-3ph 3 IN** parameter shows you the magnitude scaling of the ground current of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 4

- Default setting **(_:91:221) CT mismatch M I-3ph 4** = ***0.000***

The **CT mismatch M I-3ph 4** parameter shows you the magnitude scaling of the phase currents of the 4th assigned measuring point.

Parameter: CT mismatch M I-3ph 4 IN

- Default setting **(_:91:222) CT mismatch M I-3ph 4 IN** = *0.000*

The **CT mismatch M I-3ph 4 IN** parameter shows you the magnitude scaling of the ground current of the 4th assigned measuring point.

Parameter: CT mismatch M I-1ph

- Default setting **(_:91:223) CT mismatch M I-1ph** = *0.000*

The **CT mismatch M I-1ph** parameter shows you the magnitude scaling of the auto transformer neutral-point current.

5.2.4.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
Rated values				
_:91:101	General:Rated current		1 A to 100 000 A	1 000 A
Side data				
_:91:130	General:Side number		• not assigned • Side 1 • Side 2 • Side 3 • Side 4 • Side 5	not assigned
_:91:210	General:MI3ph1 uses-MeasP with ID		0 to 100	0
_:91:211	General:MI3ph2 uses-MeasP with ID		0 to 100	0
_:91:212	General:MI3ph3 uses-MeasP with ID		0 to 100	0
_:91:213	General:MI3ph4 uses-MeasP with ID		0 to 100	0
_:91:214	General:M I-1ph uses MeasP with ID		0 to 100	0
_:91:215	General:CT mismatch M I-3ph 1		0.000 to 100.000	0.000
_:91:216	General:CT mismatch M I-3ph 1 IN		0.000 to 100.000	0.000
_:91:217	General:CT mismatch M I-3ph 2		0.000 to 100.000	0.000
_:91:218	General:CT mismatch M I-3ph 2 IN		0.000 to 100.000	0.000
_:91:219	General:CT mismatch M I-3ph 3		0.000 to 100.000	0.000
_:91:220	General:CT mismatch M I-3ph 3 IN		0.000 to 100.000	0.000
_:91:221	General:CT mismatch M I-3ph 4		0.000 to 100.000	0.000

Addr.	Parameters	C	Range of Values	Default Setting
_:91:222	General:CT mismatch M I-3ph 3 IN		0.000 to 100.000	0.000
_:91:223	General:CT mismatch M I-1ph		0.000 to 100.000	0.000

NOTE

You can find more detailed information on the Process monitor in chapter *5.14 Process Monitor*.

5.2.4.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Rated values				
_:91:103	General:Rated apparent power		0.20 MVA to 5000.00 MVA	692.82 MVA

5.2.5 Function-Group Type Auto Transformer Ground Side

5.2.5.1 Overview

In the **Auto transf. ground side** function group all the functions required for protection and supervision of an auto transformer ground side can be used. The **Auto transf. ground side** function group also includes the measurement functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

The **Auto transf. ground side** function group must always have a link to the **Auto transf.** function group.

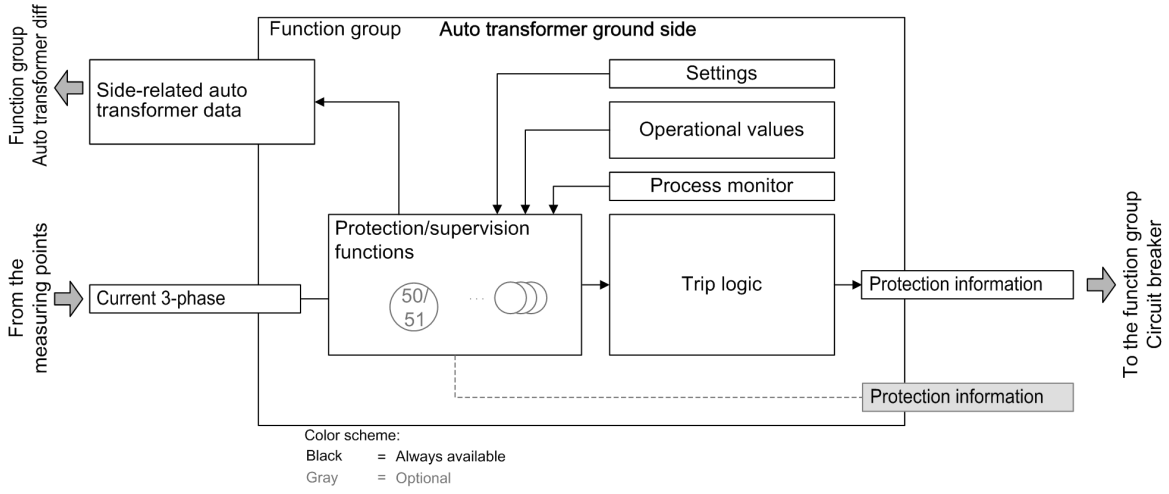
In the Global DIGSI 5 library, you will find the **Auto transf. ground side** function group under each device type and the folders with the respective protection functions. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Auto transf. ground side** function group.The functions are described in chapter *6 Protection and Automation Functions*.

[scautgrd-230114-01-DE, 1, en_US]

Figure 5-27 Auto Transformer Comp. Ground Side Function Group - Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.

5.2.5.2 Structure of the Function Group



The **Auto transf. ground side** function group always includes the following function blocks:

- Protection and supervision functions
- Auto transformer data
- Operational measured values

- Process monitor
- Output logic of the function group

These blocks are required in the **Auto transf. ground side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Auto transf. ground side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwautesd-201112-01.tif, 1, en_US]

Figure 5-28 Structure of the Auto Transformer Ground Side Function Group

The **Auto transf. ground side** function group has interfaces to the following function groups:

- **Measuring points**
- **Circuit-breaker** function group
- **Auto transf. diff.**function group

Interfaces with Measuring Points

The **Auto transf. ground side** function group receives the required measured values via its interfaces with the measuring points.

By using an application template the **Auto transf. ground side** function group is connected with the required measuring points.

If you insert functions in the **Auto transf. ground side** function group, they automatically receive the measured values of the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Auto transf. ground side** function group has the following interface with the measuring points:

- **`3-phase current`**:

  The measurands from the 3-phase power system are supplied via this interface. Depending on the connection type of the transformers, these are for example I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Auto transf. ground side** function group must always be linked to the **I-3ph measuring point**.

  All functions of the **Auto transf. ground side** function group have access to these values.

NOTE

You can connect the **3-phase current** interface with a maximum of **one** 3-phase current measuring point.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and Circuit-breaker function groups via the interface with the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the protection function groups

The **Auto transf. ground side** function group is connected with one or more Circuit-breaker function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Auto transf. ground side** function group
- Start of the **Circuit-breaker failure protection** function, if available in the Circuit-breaker function group, through the protection functions of the connected **Auto transf. ground side** function group

In addition to the general assignment of the **Auto transf. ground side** function group to the circuit-breaker function groups, you can configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the **Auto transf. ground side** function group.
In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.
You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Side-Dependent Auto Transformer Data

The auto transformer data characterize the auto transformer ground side to be protected. The auto transformer data applies for all of the functions in the **Auto transf. ground side** function group.

Process Monitor

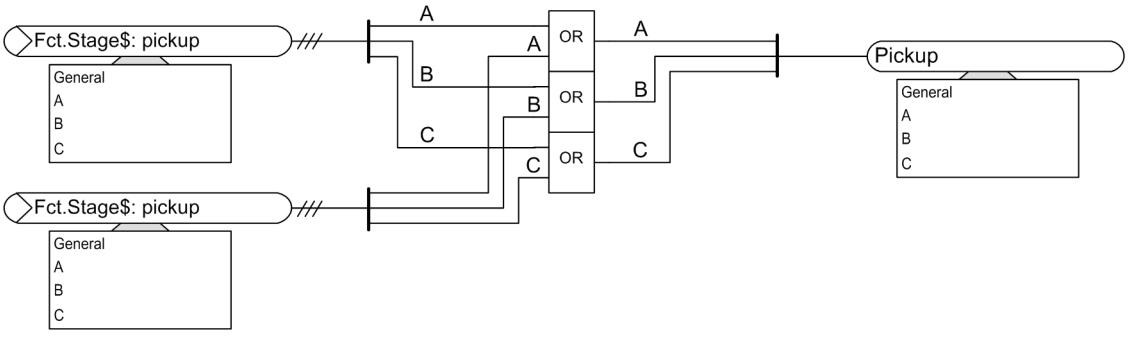
The process monitor is always available in the **Auto transf. ground side** function group and cannot be removed. The process monitor makes the following information available in the **Auto transf. ground side** function group:

- Current-flow criterion:
  Recognition of an open/closed auto transf. ground side based on the flowing leakage current

- Closure detection:
  Recognition of the switching on of the auto transf. ground side
- Cold-load pickup detection (optional):

This information is available in the **Auto transf. ground side** function group for all the functions included in it.
The description of the process monitor begins in chapter *5.14 Process Monitor*.

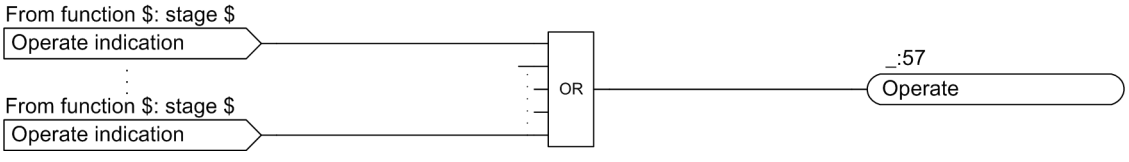
Operational Measured Values



The operational measured values are always available in the **Auto transf. ground side** function group and cannot be deleted.

Table 5-9 Possible Operational Measured Values of the Auto Transformer Ground Side Function Group

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
f	Frequency	Hz	Hz	Rated frequency



Output Logic

The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.
The pickup and trip signals of the protection and supervision functions in the **Auto transf. ground side** function group are combined phase-selectively and output as group indication.

[lo_anrlin, 3, en_US]

Figure 5-29 Generation of Pickup Indication of the Auto Transformer Ground Side Function Group

[lo_auslin, 3, en_US]

Figure 5-30 Generation of Operate Indication of the Auto Transformer Ground Side Function Group

5.2.5.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

Depending on the protection function used and the circuit breakers to be activated, the connection to the corresponding **Circuit breaker** must be provided.

You can find more information in chapter *2 Basic Structure of the Function*.

Parameter: Rated apparent power

- Default setting **(_:91:103) Rated apparent power** = ***692.82 MVA***

With the **Rated apparent power** parameter, you can set the primary rated apparent power for the auto transformer to be protected. The **Rated apparent power** parameter is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:91:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the auto transformer to be protected. The **Rated voltage** parameter is relevant for the main protection function of the device. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated current

- Default setting **(_:91:101) Rated current** = ***1000 A***

The **Rated current** parameter indicates to you the primary rated current of the auto transformer side. The **Rated current** parameter is relevant for the main protection function of the device. The setting value is formed from the **Rated voltage** and **Rated apparent power** parameters.

NOTE

The device automatically calculates the current adaptation formulas required for the winding rated currents from the rated data of the auto transformer to be protected and its windings. The currents are converted so that the sensitivity of the protection is based on the rated apparent power of the auto transformer.

Parameter: Side number

- Default setting **(_:91:130) Side number** = ***not assigned***

The **Side number** parameter shows you which auto transformer side is currently valid for the following parameters. The side number (***Side 1*** to ***Side 5***) is automatically assigned with the connection to an auto transformer side.

Parameter: MI3ph1 usesMeasP with ID

- Default setting **(_:91:210) MI3ph1 usesMeasP with ID** = ***0***

The **MI3ph1 usesMeasP with ID** parameter shows you which 3-phase measuring point (**MI3ph 1**) is connected to the auto transformer side. The measuring point is assigned a unique ID.

Parameter: M I-1ph uses MeasP with ID

- Default setting **(_:91:214) M I-1ph uses MeasP with ID** = ***0***

The **M I-1ph uses MeasP with ID** parameter shows you which 1-phase measuring point is connected to the auto transformer side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:91:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude scaling of the phase currents of the 1st assigned measuring point. The numerical value is made up from the ratio of the primary rated current of the current transformer to the auto transformer rated current of the ground side.

Parameter: CT mismatch M I-3ph 1 IN

- Default setting **(_:91:216) CT mismatch M I-3ph 1 IN** = ***0.000***

The **CT mismatch M I-3ph 1 IN** parameter shows you the magnitude scaling of the ground current of the 1st assigned measuring point.

5.2.5.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
Rated values

5.2.6 Function-Group Type Auto Transformer Neutral Point

5.2.6.1 Overview

In the **Auto transf. neutral point** function group all the necessary functions for protection and for supervision of an auto transformer are used, which are related to a neutral-point current. The **Auto transf. neutral point** also includes the measurement functions. You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

NOTE

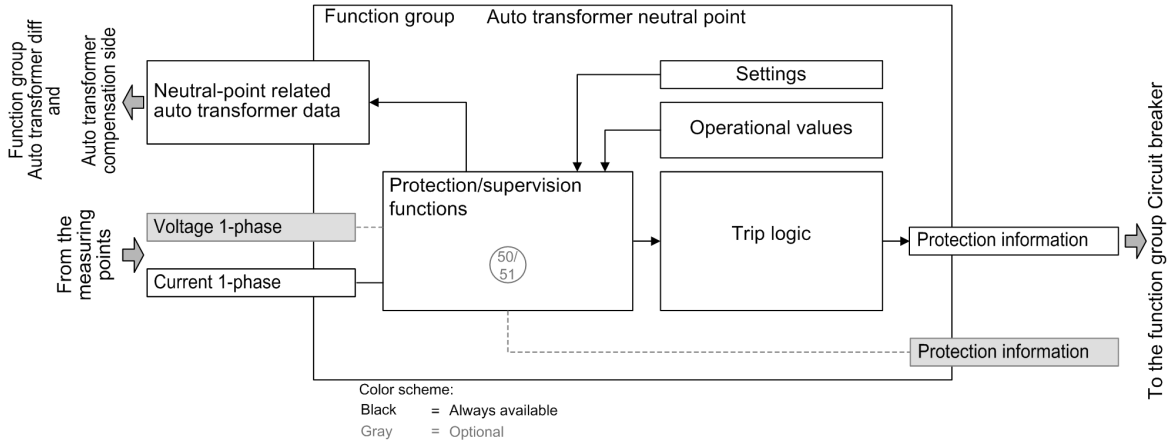
The transformer and restricted ground-fault protection do not work with responsive ground-current transformers. Responsive transformers go to saturation too fast and generate incorrect differential currents.

In the Global DIGSI 5 library, you will find the **Auto transf. neutral point** function group under each device type and the folders with the respective protection functions. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Auto transf. neutral point** function group. Here you can only load 1-phase current functions or optional 1-phase voltage functions. The functions are described in chapter *6 Protection and Automation Functions*.

[scautspt-230114-01-DE, 1, en_US]

Figure 5-31 Auto Transformer Comp. Neutral Point Function Group - Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.



5.2.6.2 Structure of the Function Group

The **Auto transf. neutral point** function group always includes the following function blocks:

- Neutral-point related auto transformer data
- Operational measured values
- Output logic of the function group

These blocks are required in the **Auto transf. neutral point** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Auto transf. neutral point** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwautspk-201112-01.tif, 1, en_US]

Figure 5-32 Structure of the Auto Transf. Neutral Point Function Group

The **Auto transf. neutral point** function group has interfaces to the following function groups:

- **Measuring points**
- **Circuit-breaker** function group
- **Auto transf. diff.** function group
- **Auto transformer comp. side** function group

Interfaces with Measuring Points

The **Auto transf. neutral point** receives the required measured values via its interfaces with the measuring points.

By using an application template the **Auto transf. neutral point** function group is connected with the required measuring points.

If you insert functions in the **Auto transf. neutral point** function group, they automatically receive the measured values of the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Auto transf. neutral point** function group has the following interfaces with the measuring points:

- **`1-phase voltage`** (optional):

  The measurands from the 1-phase voltage system are supplied via this interface. All values that can be calculated from the measurands are also provided via this interface.

  You have to connect the **`1-phase voltage`** interface with the **Measuring point V-1ph** only if the functions in the **Auto transf. neutral point** function group work with this measurand.

- **`1-phase current`**:

  The measurands from the 1-phase power system are supplied via this interface. Depending on the connection type for the transformers, this is for example I_x. All values that can be calculated from the measurands are also provided via this interface. The **Auto transf. neutral point** must always be linked with the **Measuring point I-1ph** .

NOTE

You can connect the **`1-phase current`** interface with a maximum of **one** 1-phase current measuring point.

All functions of the **Auto transf. auto side** function group have access to these values.

NOTE

If you instantiate in the **Auto transf. neutral point** function group, the **Overcurrent protection 1ph** function, the information for the inrush-current detection is taken from the assigned **Auto transf. auto side** function group.

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and Circuit-breaker function groups via the interface with the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the protection function groups

The **Auto transf. neutral point** function group is connected with one or more Circuit-breaker function groups. This connection generally determines:

- Which circuit breakers are activated by the protection functions of the **Auto transf. neutral point** function group
- Start of the **Circuit-breaker failure protection** function, if available in the Circuit-breaker function group, through the protection functions of the connected **Auto transf. neutral point** function group

In addition to the general assignment of the **Auto transf. neutral point** function group to the Circuit-breaker function groups, you can configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the **Auto transf. neutral point** function group.

In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Circuit-breaker failure protection** function?

If an application template is used, the function groups are connected to each other because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.

You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Neutral-Point Related Auto Transformer Data

The auto transformer data characterize the auto transformer neutral point to be protected. The auto transformer data applies for all of the functions in the **Auto transf. neutral point** function group.

Operational Measured Values

The operational measured values are always available in the **Auto transf. neutral point** function group and cannot be deleted.

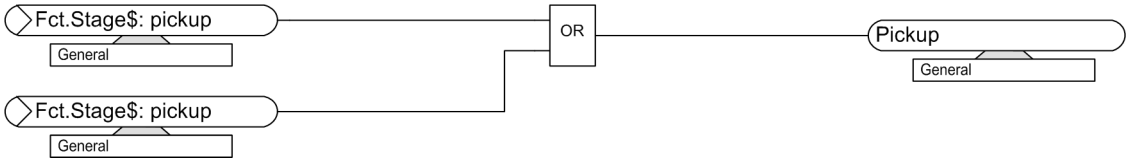


Table 5-10 Operational Measured Values of the Auto Transf. Neutral Point Function Group

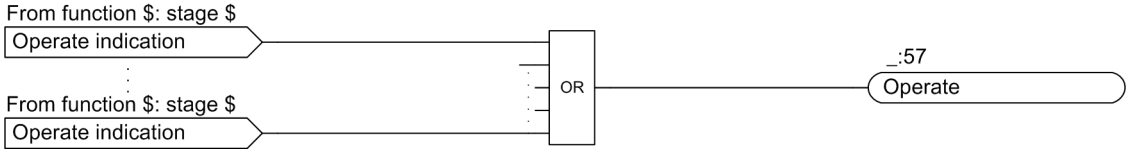
Measured Values		Primary	Secondary	% Referenced to
I	Neutral-point current	A	A	Rated operating current of the primary system
V	Voltage	kV	V	Rated operating voltage of the primary system

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately, in a pickup logic and an output logic respectively. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection-information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and trip signals of the protection and supervision functions in the **Auto transf. neutral point** are combined phase-selectively and output as group indication.

Figure 5-33 Generation of Pickup Indication of the Auto Transf. Neutral Point Function Group

[lo_auslin, 3, en_US]

Figure 5-34 Generation of Operate Indication of the Auto Transf. Neutral Point Function Group

5.2.6.3 Application and Setting Notes

Parameter: Rated current

- Default setting **(_:9421:101) Rated current** = ***1000 A***

With the **Rated current** parameter, you can set the primary rated current for the auto transformer to be protected. The **Rated current** parameter is relevant for the main protection function of the device. The **Rated current** specified here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

The **(_:9421:101) Rated current** parameter is not visible with a circuiting of the **Auto transformer compensation side** or **Auto transformer diff.** function groups with a **Auto transformer auto side** function group. Instead the write-protected parameter **(_:9421:104) Rated current** is displayed.

The **(_:9421:102) Rated voltage** parameter behaves the same with this circuiting. In its place the **(_:9421:105) Rated voltage** parameter is displayed.

Parameter: Rated current (write-protected)

- Default setting **(_9421:104) Rated current** = ***1000 A***

The **Rated current** parameter indicates to you the primary rated current of the auto transformer to be protected. The **Rated current** can correspond to the following variables:

- Rated current of the connected transformer side
- Rated current of the reference side of the connected auto transformer

The **Rated current** cannot be changed.

Parameter: Rated voltage

- Default setting **(_:9421:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage of the auto transformer to be protected. The **Rated voltage** parameter is relevant for the main protection function of the device. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

Parameter: Rated voltage (write-protected)

- Default setting **(_:9421:105) Rated voltage** = ***400.00 kV***

The **Rated voltage** parameter indicates to you the primary rated voltage of the auto transformer to be protected. The **Rated voltage** can correspond to the following variables:

- Rated voltage of the connected transformer side
- Rated voltage of the reference side of the connected auto transformer

The **Rated voltage** cannot be changed.

Parameter: Rated apparent power

- Default setting **(_:9421:103) Rated apparent power** = ***692.82 MVA***

The **Rated apparent power** parameter indicates to you the calculated value from **Rated voltage** and **Rated current**. If current and voltage are available, this value is only displayed for you and cannot be changed.

Parameter: M I-1ph uses MeasP with ID

- Default setting **(_:9421:214) M I-1ph uses MeasP with ID** = ***0***

The **M I-1ph uses MeasP with ID** parameter shows you which 1-phase measuring point is connected to the transformer neutral point. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-1ph

- Default setting **(_:9421:223) CT mismatch M I-1ph** = ***0.000***

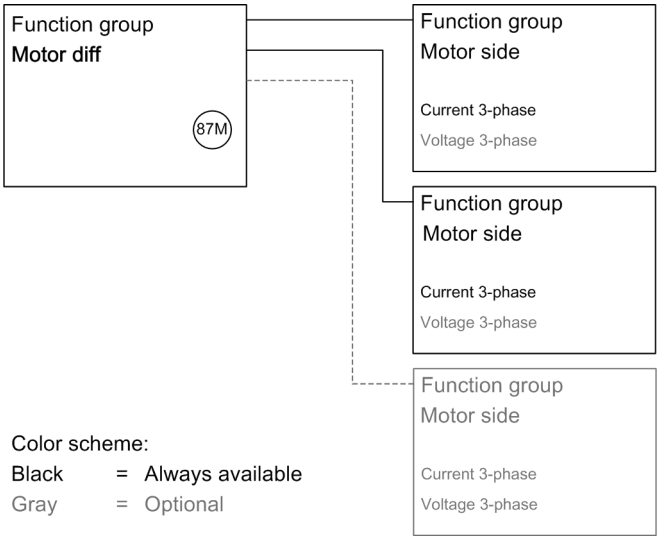
The **CT mismatch M I-1ph** parameter shows you the magnitude scaling of the auto transformer neutral-point current.

5.2.6.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Range of Values	Default Setting
Rated values				
_:9421:101	General:Rated current		1 A to 100 000 A	1 000 A
_:9421:102	General:Rated voltage		0.20 kV to 1 200.00 kV	400 kV

Addr.	Parameter	C	Range of Values	Default Setting
_:9421:103	General:Rated apparent power		0.20 MVA to 5 000.00 MVA	692.82 MVA
_:9421:104	General:Rated current		1 A to 100 000 A	1 000 A
_:9421:105	General:Rated voltage		0.20 kV to 1 200.00 kV	400 kV
Power-system data				
_:9421:214	General:M I-1ph uses MeasP with ID		0 to 100	0
_:9421:223	General:CT mismatch M I-1ph		0.00 to 100.00	0.000



5.2.6.5 Information List

No.	Information	Data Class (Type)	Type

5.3 Overview Function Group Motor Differential Protection

5.3.1 Function-Group Types

In the following figure, you can see the structural association of the function-group types **Motor differential**

[dwfguest-040713-01.vsd, 1, en_US]

Figure 5-35 Function-Group Types Motor differential

The following function-group types are summarized in the Global DIGSI 5 library:

- **Motor differential**
- **Motor side**

The individual function-group types are stored under the folder **FG Motor diff** and can be selected. In the protection function folders, you find all protection functions which are operational in each function group. One function group **Motor differential** always has 2 function groups **Motor side** ; at a maximum, you can assign a total of 3 function groups **Motor side** to the function group **Motor differential** .

The following table shows the number of function-group types that can be instantiated depending on the device (7UT82, 7UT85, 7UT86, 7UT87).

Table 5-11 Function-Group Types in the Device

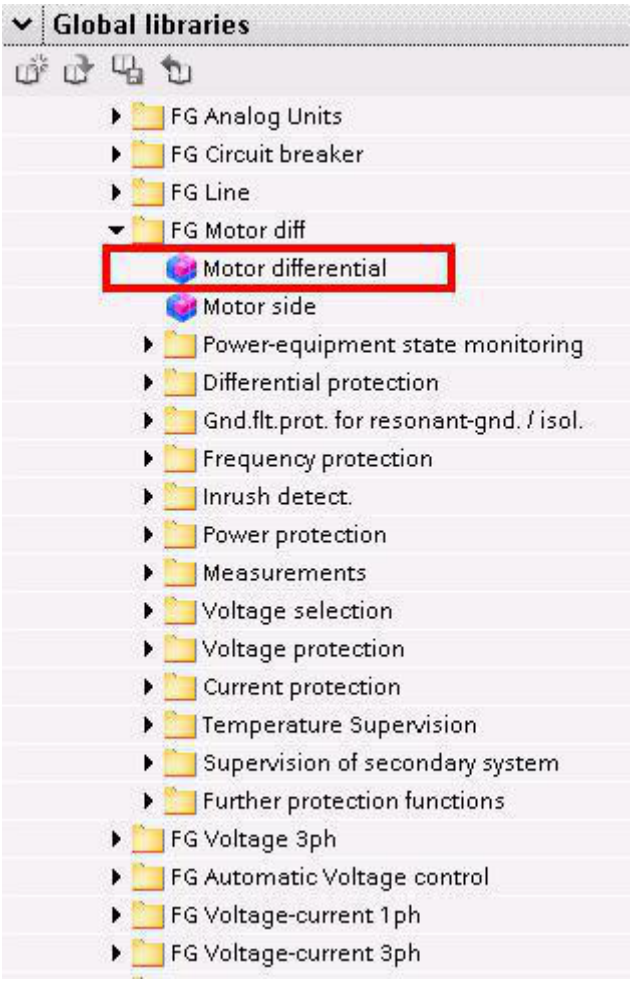
Device	Function-Group Type	
	Motor differential	Motor side
7UT82	Max. 1	Max. 2
7UT85	Max. 2	Max. 4
7UT86	Max. 2	Max. 5
7UT87	Max. 3	Max. 7

Interconnection of the function groups is necessary so that the Motor differential protection functions properly. The Circuit-breaker function group is not listed. The figure shown in the application template (refer to *Figure 4-5*) offers a good overview of the interconnection options.

Table 5-12 Assignment of Protection Function Groups to Protection Function Groups

	Motor differential 1
	Side (2 ... 3)
Motor side 1	X
Motor side 2	X

The individual function-group types are described in the following.



5.3.2 Function-Group Type Motor Diff

5.3.2.1 Overview

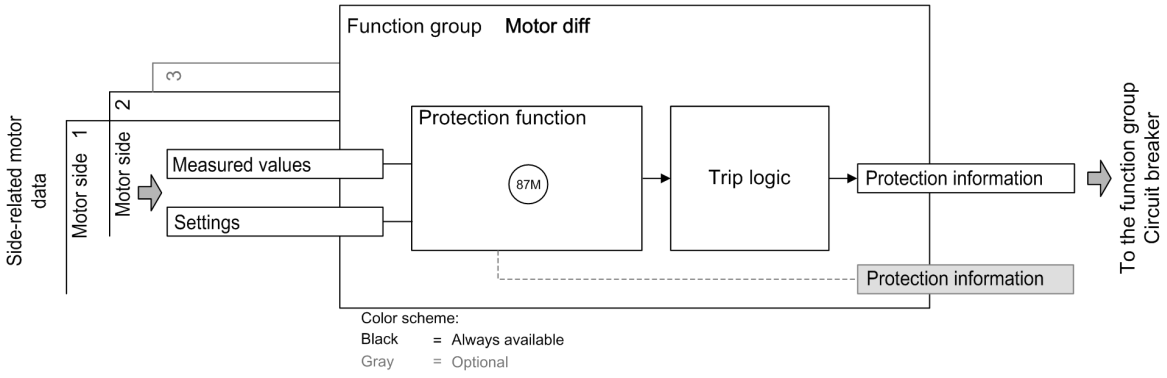
The **Motor diff.** function group contains the differential protection function and protection-function-relevant measured values.

You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

You will find the corresponding function groups and also the folders with the usable protection functions in the Global DIGSI library under each device type. You can load only the differential protection function in the **Motor diff.** function group.

[scfgmodi-240114-01-DE, 1, en_US]

Figure 5-36 Motor Differential Protection Function Group - Functional Scope



For more information about the embedding of the functions in the device, refer to chapter *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to chapter *4 Applications*.

5.3.2.2 Structure of the Function Group

The **Motor diff.** function group according to *5.3.2.1 Overview* has interfaces with the **Motor side** and **Circuit-breaker** function groups. The **Motor diff.** function group contains the function blocks:

- Protection function (execution of the differential protection function)
- Trip logic (generation of forwarding of the operate indication)

In the **Motor diff.** function group, the differential protection function must always be available so that the protection functionality can be ensured. If you do not use an application template, load this from the Global DIGSI 5 library.

[dwfgmodz-211013-01.tif, 1, en_US]

Figure 5-37 Structure of the Motor Differential Protection Function Group

The **Motor diff.** function group has interfaces to the following components:

- **Motor side** function group
- **Circuit-breaker** function group

Interfaces to the Circuit-Breaker Function Group

All required data is exchanged between the **Motor diff.** function group and the **Circuit-breaker** function group via the interface of the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the **Circuit-breaker** function group
- Information on the circuit-breaker condition in the direction of the protection function groups

You can connect the **Motor diff.** function group to one or more **Circuit-breaker** function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Motor diff.** function group
- Start of the **Circuit-breaker failure protection** function, if available in the **Circuit-breaker** function group, through the protection functions of the connected **Motor diff.** function group

Besides the general assignment of the **Motor diff.** function group to the **Circuit-breaker** function groups, you can also configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 via the **Circuit-breaker interaction** Editor in the **Motor diff.** function group.
In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the **Circuit-breaker failure protection** function

If you are using an application template, the function groups are already connected to each other, because this connection is essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.
You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

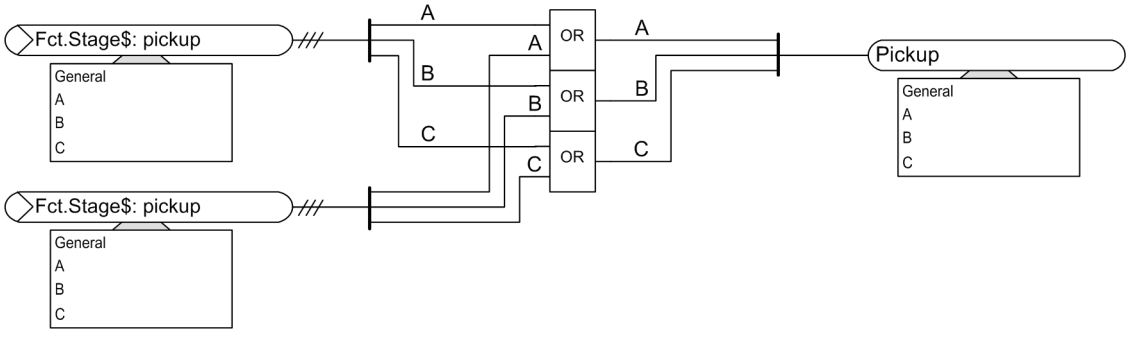
Resetting the LED Group

Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

Interface with Protection Communication (Optional)

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**. These data are for example:

- Binary signals
- Measured values
- Complex data



You can find more detailed information in chapter *3.6 Protection Communication*.

Motor Data (General)

The motor data characterizes the data of the motor to be protected. The data relevant for the differential protection is shown. The **Motor diff.** function group takes these data from the coupled function group **Motor side** function groups.

Output Logic

The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection-information** interface to the **Circuit-breaker** function group and are processed further there.
The pickup and operate indications of the protection and supervision functions in the **Motor diff.** function group are combined into one group indication using the following numbers and outputs.

[lo_anrlin, 3, en_US]

Figure 5-38 Generation of Pickup Indication of the Motor Differential Protection Function Group

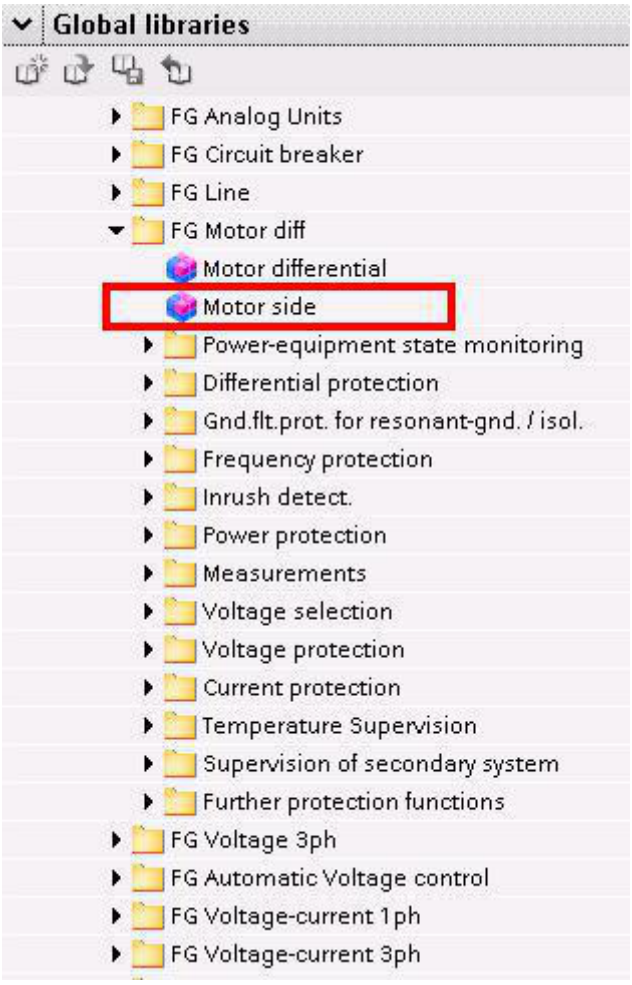
5.3.3 Function-Group Type Motor Side



5.3.3.1 Overview

In the **Motor side** function group, all of the functions that are necessary for protecting and supervising a motor side can be used. The **Motor side** function group also contains the measuring functions.

You can find more information in chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*.

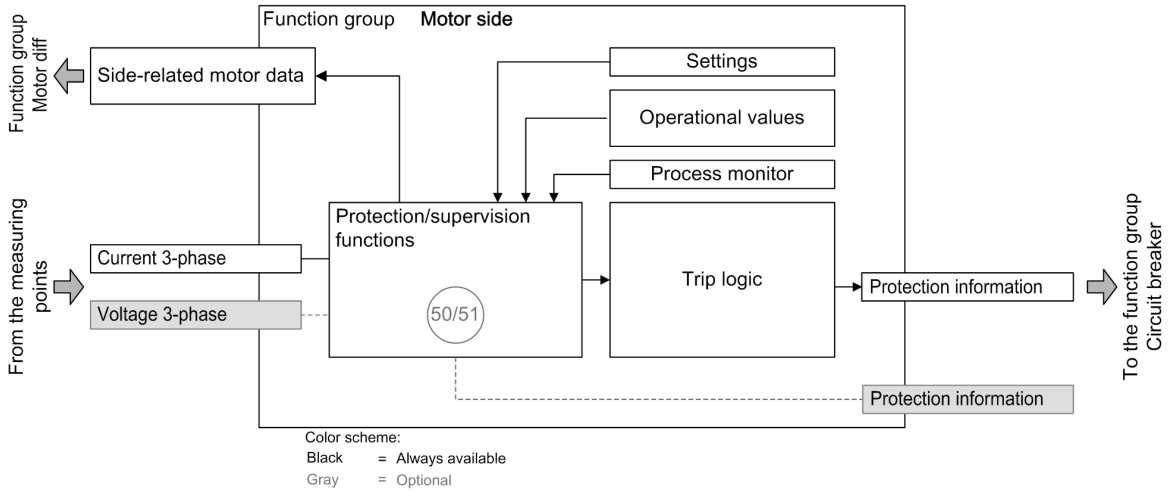
The **Motor side** function group must always have interfacing to the **Motor diff.** function group.

You will find the corresponding function groups and also the folders with the usable protection functions in the Global DIGSI 5 library under each device type. Depending on the connected measuring points, you can load the respective protection and supervision functions in the **Motor side** function group. The functions are described in chapter *6 Protection and Automation Functions*.

[scfgmosd-240114-01-DE, 1, en_US]

Figure 5-40 Motor Side Function Group - Functional Scope

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.



5.3.3.2 Structure of the Function Group

The **Motor side** function group always contains the following function blocks:

- Side-dependent motor data
- Operational measured values
- Process monitor
- Trip logic of the function group

These blocks are required for the **Motor side** function group and therefore cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the **Motor side** function group. The functions are available in the Global DIGSI 5 library. Functions that are not needed can be deleted from the function group.

[dwfgmosi-030713-01.tif, 1, en_US]

Figure 5-41 Structure of the Motor Side Function Group

The **Motor side** function group has interfaces to the following components:

- **Measuring points**
- **Motor diff.** function group
- **Circuit-breaker** function group

Interfaces with Measuring Points

The **Motor side** function group receives the required measured values via its interfaces with the measuring points. If you are using an application template, the **Motor side** function group is already connected to the necessary measuring points.

If you add functions to the **Motor side** function group, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

You can find more detailed information in chapter *2 Basic Structure of the Function*.

The **Motor side** function group has the following interfaces with the measuring points:

- **`3-phase current`**

  The measurands from the 3-phase power system are supplied via this interface. Depending on the transformer connection type, these are for example: I_A, I_B, I_C, I_N, or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The **Motor side** function group must always be connected to the **I-3ph measuring point**.

  You can connect the **`3-phase current`** interface to a maximum of **four** 3-phase current measuring points, for example, for 1 1/2 circuit-breaker layouts, two 3-phase current measuring points are required. If 2 current measuring points have been connected to the **3-phase current** interface, the total current is also determined from measured values from both measuring points in the **Motor side** function group. All functions in the **Motor side** function group have access to these values.

- **`3-phase voltage`** (optional):

  The measurands from the 3-phase voltage system are supplied via this interface. Different transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface.

  Connection of the **3-phase voltage** interface is optional. This connection is necessary only if protection or supervision functions that require voltage measurements are used.

Interfaces to the Circuit-Breaker Function Group

All required data is exchanged between the **Motor side** function group and the **Circuit-breaker** function group via the interface of the **Circuit-breaker** function group. The following data is required:

- Pickup and operate indications of the protection functions in the direction of the Circuit-breaker function group
- Information on the circuit-breaker condition in the direction of the protection function groups

You can connect the **Motor side** function group to one or more **Circuit-breaker** function groups. This connection determines the following:

- Which circuit breakers are activated by the protection functions of the **Motor side** function group
- Start of the **Circuit-breaker failure protection** function, if available in the **Circuit-breaker** function group, through the protection functions of the connected **Motor side** function group

Besides the general assignment of the **Motor side** function group to the **Circuit-breaker** function group, you can also configure the interface for specific functionalities in detail. Configure the details in DIGSI 5 via the **Circuit-breaker interaction** Editor in the **Motor side** function group.
In the detail configuration of the interface, you define the following:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the **Circuit-breaker failure protection** function

If you are using an application template, the function groups are already connected to each other, because this connection is essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. If the connection is missing, DIGSI 5 reports an inconsistency.
You can find more detailed information in chapter *2.1 Embedding of Functions in the Device*.

Interface with Protection Communication (Optional)

All required data is exchanged between the Protection function group and the protection communication via the interface with **Protection communication**, for example:

- Binary signals
- Measured values
- Complex data

You can find more detailed information in chapter *3.6 Protection Communication*.

Resetting the LED Group

Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

Process Monitor

The process monitor is always present in the **Motor side** function group and cannot be removed. The process monitor provides the following information in the **Motor side** function group:

- Current-flow criterion:
  Detection of an open/activated motor side based on the flow of leakage current
- Closure detection:
  Detection of closure of the motor side
- Cold-load pickup detection (optional):

This information is in the **Motor side** function group and is available to all the functions in the function group.
The description of the process monitor begins in chapter *5.14 Process Monitor*.

Operational Measured Values

The operational measured values are always present in the **Motor side** function group and cannot be deleted. If a 3-phase voltage measuring point is connected, the following table shows the total scope. Only the first 3 lines apply for exclusive current connection.

Table 5-13 Possible Operational Measured Values of the Motor Side Function Group

Measured Values		Primary	Secondary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Measured zero-sequence current	A	A	Rated operating current of the primary system
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary system
V_0	Calculated zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_N	Measured neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated frequency
P	Active power (total power)	MW	–	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100% corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

If a **V-3ph measuring point** was connected to the **Motor side** function group, voltage and phase measurements are available.

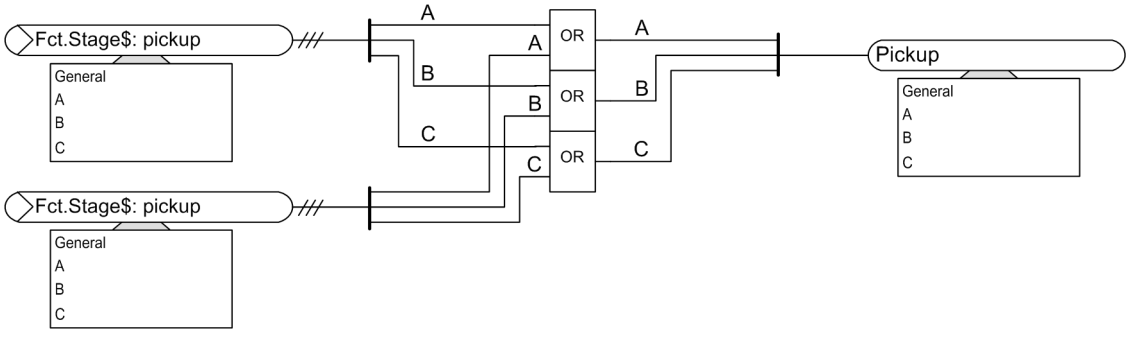
The energy measurements are not predefined. If necessary, you must load them from the Global DIGSI 5 library.

Depending on the protection and supervision functions used, additional function measurements can be available. The function values are listed in the **Information list** for the relevant protection or supervision function (refer to *6 Protection and Automation Functions* and *8 Supervision Functions*).

NOTE

With the **`P, Q sign`** parameter in the function block **General**, the sign of the following measured values of the respective function group can be inverted (see chapter *9.2 Structure of the Function* Structure of the Function, section Inversion of Output-Related Measured and Statistical Values):

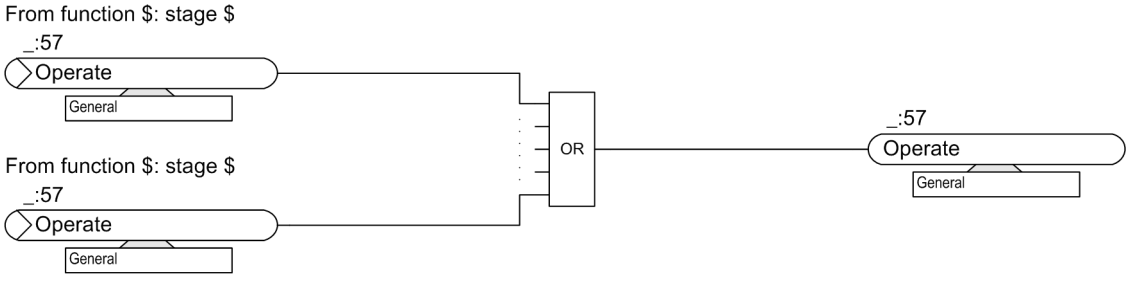
- Active power (total): P total
- Active power (phase-related): P_A, P_B, P_C
- Reactive power (total): Q total
- Reactive power (phase-related): Q_A, Q_B, and Q_C



Motor Data (Side-Related)

The motor data characterizes the data of the motor to be protected. The side-dependent motor data applies for all of the functions in the **Motor side** function group.

Output Logic



The output logic treats the pickup and trip signals of the protection and supervision functions in the function group separately. Pickup logic and output logic are each assigned to the signals. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection-information** interface to the **Circuit-breaker** function group and are processed further there.

The pickup and operate indications of the protection and supervision functions in the **Motor side** function group are combined into one group indication using the following numbers and outputs.

[lo_anrlin, 3, en_US]

Figure 5-42 Generation of Pickup Indication of the Motor Side Function Group

[lo_geopi1-231013-01, 2, en_US]

Figure 5-43 Generation of Operate Indication of the Motor Side Function Group

5.3.3.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

The **Motor side** function group is usually connected to 1 **Circuit-breaker** function group. The **Circuit-breaker** function group is assigned to the circuit breaker of the motor.

Parameter: `Rated apparent power`

- Default setting **`(_:1781:14671:103) Rated apparent power`** = ***`692.82 MVA`***

With the **`Rated apparent power`** parameter, you can set the primary rated apparent power for the motor to be protected. The **`Rated apparent power`** parameter is relevant for the main protection function of the device. The **`Rated apparent power`** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: `Motor rated voltage`

- Default setting **`(_:1781:14671:102) Motor rated voltage`** = ***`400.00 kV`***

With the **`Motor rated voltage`** parameter, you can set the primary rated apparent power for the motor to be protected. The **`Motor rated voltage`** parameter is relevant for the main protection function of the device. The **`Motor rated voltage`** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: `Motor rated current`

- Default setting **`(_:1781:14671:101) Motor rated current`** = ***`1000 A`***

The **`Motor rated current`** parameter shows you the primary rated current of the motor side. The**`Motor rated current`** parameter is relevant for the main protection function of the device. The setting value is formed from the **`Motor rated voltage`** and **`Rated apparent power`** parameters.

NOTE

The device also automatically calculates the current adaptation formulas required for the winding rated currents from the rated data of the motor to be protected and its windings. The currents are converted so that the sensitivity of the protection is based on the rated apparent power of the motor.

Parameter: `Side number`

- Default setting **`(_:1781:14611:130) Side number`** = ***`not assigned`***

The **`Side number`** parameter shows you which motor side is currently valid for the following settings. The side number (***`Side 1`*** to ***`Side 3`***) is automatically assigned with the connection to a motor side.

Parameter: `MI3ph1 usesMeasP with ID`

- Default setting **`(_:1781:14611:210) MI3ph1 usesMeasP with ID`** = ***`0`***

The parameters **MI3ph1 usesMeasP with ID** to **MI3ph4 usesMeasP with ID** show you which 3-phase measuring points (**MI3ph 1** to **MI3ph 4**) are connected to the motor side. Every measuring point is assigned a unique ID.

Parameter: CT mismatch M I-3ph 1

- Default setting **(_:1781:14611:215) CT mismatch M I-3ph 1** = ***0.000***

The **CT mismatch M I-3ph 1** parameter shows you the magnitude adaptation of the phase currents of the 1st assigned measuring point. The numerical value is made up from the ratio of the primary rated current of the current transformer to the motor rated current of the side.

Parameter: CT mismatch M I-3ph 1 IN

- Default setting **(_:1781:14611:216) CT mismatch M I-3ph 1 IN** = ***0.000***

The **CT mismatch M I-3ph 1 IN** parameter shows you the magnitude adaptation of the ground current of the 1st assigned measuring point.

Parameter: CT mismatch M I-3ph 2

- Default setting **(_:1781:14611:217) CT mismatch M I-3ph 2** = ***0.000***

The **CT mismatch M I-3ph 2** parameter shows you the magnitude adaptation of the phase currents of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 2 IN

- Default setting **(_:1781:14611:218) CT mismatch M I-3ph 2 IN** = ***0.000***

The **CT mismatch M I-3ph 2 IN** parameter shows you the magnitude adaptation of the ground current of the 2nd assigned measuring point.

Parameter: CT mismatch M I-3ph 3

- Default setting **(_:1781:14611:219) CT mismatch M I-3ph 3** = ***0.000***

The **CT mismatch M I-3ph 3** parameter shows you the magnitude adaptation of the phase currents of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 3 IN

- Default setting **(_:1781:14611:220) CT mismatch M I-3ph 3 IN** = ***0.000***

The **CT mismatch M I-3ph 3 IN** parameter shows you the magnitude adaptation of the ground current of the 3rd assigned measuring point.

Parameter: CT mismatch M I-3ph 4

- Default setting **(_:1781:14611:221) CT mismatch M I-3ph 4** = ***0.000***

The **CT mismatch M I-3ph 4** parameter shows you the magnitude adaptation of the phase currents of the 4th assigned measuring point.

Parameter: CT mismatch M I-3ph 4 IN

- Default setting **(_:1781:14611:222) CT mismatch M I-3ph 4 IN** = ***0.000***

The **CT mismatch M I-3ph 4 IN** parameter shows you the magnitude adaptation of the ground current of the 4th assigned measuring point.

5.3.3.4 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Range of Values	Default Setting
Rated values				
_:1781:14671:101	Motor rated current		1 A to 100 000 A	1000 A
Side data

5.4 Overview Function Groups Generator Differential Protection

5.4.1 Overview

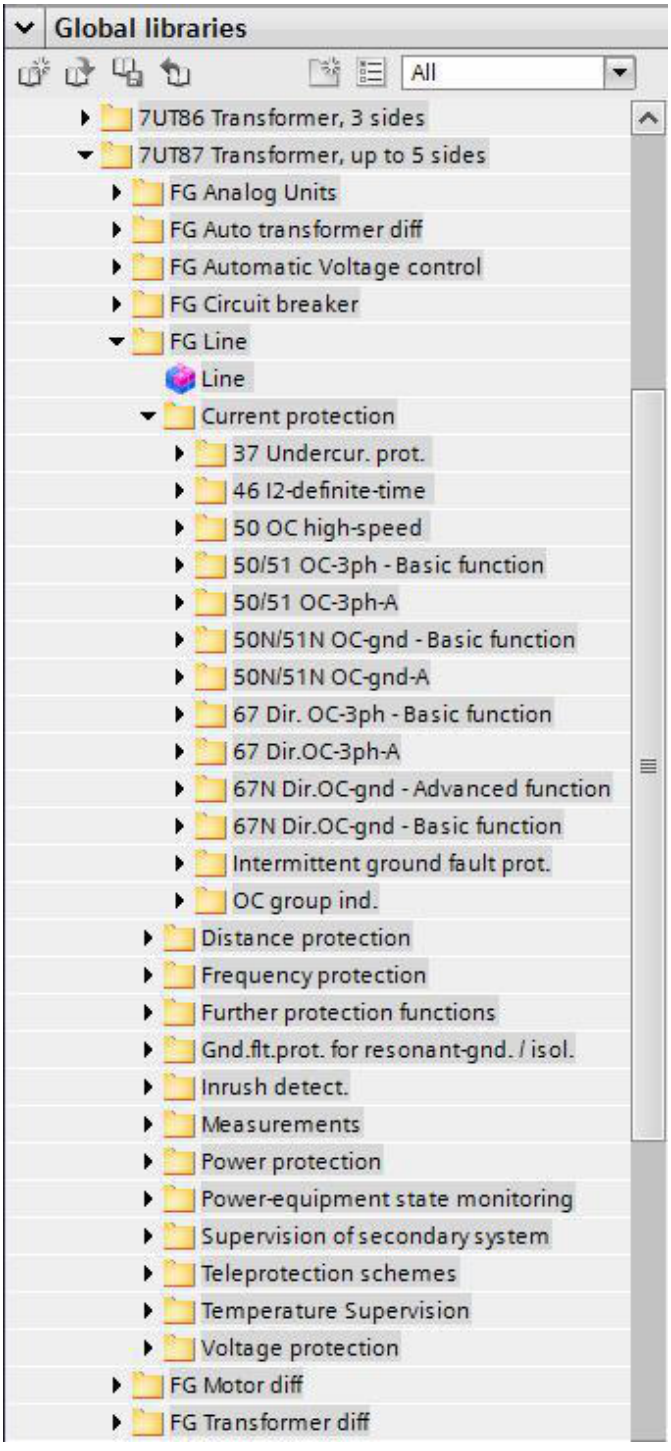
NOTE

This chapter gives you a short overview of the function group Generator differential protection. You can find descriptions of the 3 listed function-group types and the Generator differential protection function in the generator protection manual (C53000-G5040-C027).

- **Generator Diff** function-group type
- **Generator Side** function-group type
- **Generator Stator** function-group type

The **Generator Diff** function-group type contains the Differential protection function and protection-function-relevant measured values.

Generator-specific protection and supervision functions can operate in the **Generator Side** and **Generator Stator** function-group types. The scope depends on the type of protection concept selected. The **Generator Side** and **Generator Stator** function-group types also contain measuring functions.



You can find the corresponding function groups and the folders with the usable protection functions in the Global DIGSI 5 library under each device type. For example, you can load the Differential protection function in the **Generator Diff** function-group type.

5.5 Function-Group Type Line

5.5.1 Overview

In the **Line** function group, all of the functions that are necessary for protecting and monitoring a line can be used. The **Line** function group also contains the measuring functions (for more information, see *9 Measured Values, Energy Values, and Supervision of the Primary System*).

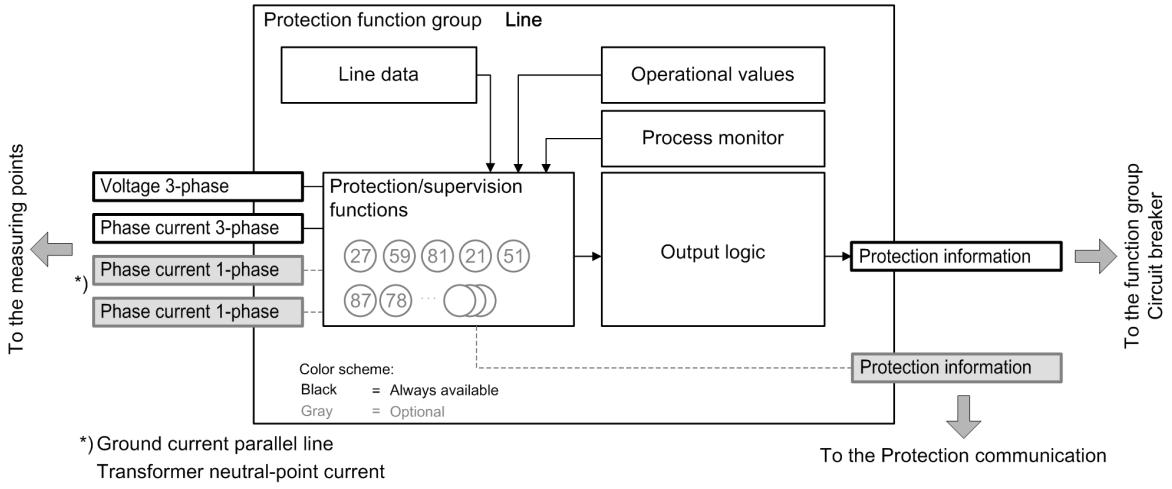
You can find the **Line** function group under each device type in the function library in DIGSI 5. The **Line** function group contains all of the protection and supervision functions that you can use for this device type.These functions are described in *6 Protection and Automation Functions*. The following figure shows the functional scope of the **Line** function group using the example of a device.

[scprutli-221013-01, 1, en_US]

Figure 5-44 Function Group Line – Functional Scope for Device Type 7UT87

For more information about the embedding of the functions in the device, refer to *2 Basic Structure of the Function*. For information about the overall functional scope of the application templates for the various device types, refer to *4 Applications*.

5.5.2 Structure of the Function Group



The **Line** function group always contains the following blocks:

- Line data
- Operational measurement
- Process monitor
- Output logic of the function group

These blocks are essential for the function group **Line**, so they cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the function group **Line**. The functions are available in the function library in DIGSI 5. Functions that are not needed can be deleted from the function group.

The following figure shows the structure of the **Line** function group:

[dwfgline-160812-01.tif, 1, en_US]

Figure 5-45 Structure of the Function Group Line

The **Line** function group has interfaces with

- **Measuring points**
- **Circuit-breaker** function group
- **Protection communication**

Interfaces with Measuring Points

The function group **Line** receives the required measured values via its interfaces with the measuring points.

If you are using an application template, the function group **Line** is already connected to the necessary measuring points.

If you add functions to the function group **Line**, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor.

For further information, refer to *2 Basic Structure of the Function*.

The function group **Line** has the following interfaces with the measuring points:

- **3-Phase Voltage**:
  The measurands from the 3-phase voltage system are supplied via this interface. Various transformer connection types are possible. All values that can be calculated from the measurands are also provided via this interface. The function group Line must always be connected to the **V-3ph measuring point**.
  If you want to use the **Distance protection** in the function group **Line**, you must connect the 3 phase-to-ground voltages to the **V-3ph measuring point**. If you want to test or change the connection between the voltages and the **V-3ph measuring point**, double-click **Measuring-point routing** in the DIGSI 5 project tree → **7SL86** (name of device) (connection type = 3 phase-to-ground voltage).
  For further information, refer to the description of the *Power-system data* starting from *6.1.1 Overview*.
- **3-phase phase current**:
  The measurands from the 3-phase power system are supplied via this interface. Depending on the connection type of the transformers, these are, for example, I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The Line function group must always be connected to the **I-3ph measuring point**.
  You can connect the **3-phase phase current** interface to a **maximum of two** 3-phase current measuring points (for example, for 1 1/2 circuit-breaker layouts). If 2 current measuring points have been connected to the **3-phase phase current** interface, the total current is also determined from measured values from both measuring points in the function group **Line**. All functions in the **Line** function group have access to these values.
- **Ground current parallel line**:
  If the device measures the ground current in the parallel line, this 1-phase measurand of the **Line** function group is provided via this interface.
  You only have to connect the **Ground current parallel line** interface to the **I-1ph measuring point** if functions in the **Line** function group are working with this measurand.
- **Transformer neutral-point current**:
  If the device measures the ground current in the transformer neutral point, this 1-phase measurand of the **Line** function group is provided via this interface.
  You only have to connect the **Transformer neutral-point current** interface to the **I-1ph measuring point** if functions in the **Line** function group are working with this measurand.

NOTE

You can connect the interface **3-phase phase current** to **at most two** 3-phase current measuring points (for example, for 1 1/2 circuit-breaker layouts).
The other interfaces can only be connected to one measuring point each!

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the protection and **Circuit-breaker** function groups via the interface with the Circuit-breaker function group. This data includes, for example, the pickup and operate indications of the protection functions sent in the direction of the circuit-breaker function group and, for example, the circuit-breaker position information in the direction of the protection function groups.

The **Line** function group is connected to one or more circuit-breaker function groups. This connection generally determines:

- Which circuit breaker(s) is/are activated by the protection functions of the protection function group **Line**
- Start of the function **Circuit-breaker failure protection** (if available in the function group Circuit-breaker) through the protection functions of the connected protection function group **Line**
- Start of the function **Automatic reclosing** (AREC if available in the function group Circuit-breaker) through the protection functions of the connected protection function group **Line**

Besides the general allocation of the protection function group **Line** to the circuit-breaker function groups, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the function group **Line**.

In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the automatic reclosing function
- Which protection functions start the circuit-breaker failure protection function

If you are using an application template, the function groups are already connected to each other, because this connection is essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor. For more detailed information, refer to *2.1 Embedding of Functions in the Device*. If the connection is missing, DIGSI 5 reports an inconsistency.

Interface with Protection Communication

All required data is exchanged between the protection function group and the protection communication via the interface with **Protection communication**. These are, for example, binary signals, measured values and complex data. Functions such as differential protection or teleprotection scheme exchange information with other protection devices via the protection interface.

If an application template is used, the protection function group and protection communication are already connected to each other because this connection is absolutely essential to ensure proper operation.

For further information, refer to *3.6 Protection Communication*.

If this connection is missing, DIGSI 5 reports an inconsistency.

Line Data

The line data characterizes the line that is to be protected. The line data applies for all of the functions in the function group **Line**.

Process Monitor

The process monitor is always present in the function group **Line** and cannot be removed. The process monitor provides the following information in the function group **Line**:

- Current-flow criterion:
  Detection of an open/closed line based on the flow of minimum current
- Voltage criterion (optional):
  Detection of an open/closed line based on the minimum voltage present
- Closure detection:
  Detection of closure of the line
- Cold-load pickup detection (optional):
  Detection of a transient state of the network after a long period of disconnection (such as a blackout) followed by automatic reclosing

This information is in the function group **Line** and all is available to all the functions in the function group. The description of the process monitor begins in *5.5.4 Process Monitor (FG Line)*.

Operational Measured Values

The operational measured values are always present in the **Line** function group and cannot be deleted.

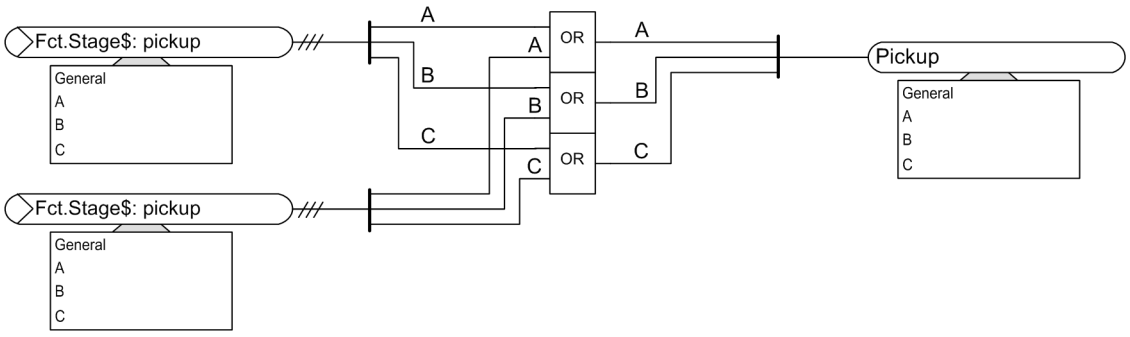
The following table shows the operational measured values of the **Line** function group:

Table 5-14 Operational Measured Values of the Function Group Line

Measured Values		Primary	Secon-dary	% Reference to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary system
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary system
I_N	Neutral-point phase current	A	A	Rated operating current of the primary system
I_{NS}	Sensitive ground current	A	mA	Rated operating current of the primary system
V_A, V_B,V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary system/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary system
V_0	Zero-sequence voltage	kV	V	Rated operating voltage of the primary system/√3
V_{NE}	Neutral-point displacement voltage	kV	V	Rated operating voltage of the primary system/√3
f	Frequency	Hz	Hz	Rated Frequency
P	Active power (total power)	MW	–	Active power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q	Reactive power (total power)	Mvar	–	Reactive power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S	Apparent power (total power)	MVA	–	Apparent power of the primary system $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100% corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	–	Apparent power of the phase $V_{rated\ Lx} \cdot I_{rated\ Lx}$

Inversion of Power-Related Measured and Statistical Values (FB General)

The following directional values calculated in operational measured values are defined positively in the direction of the protected object.

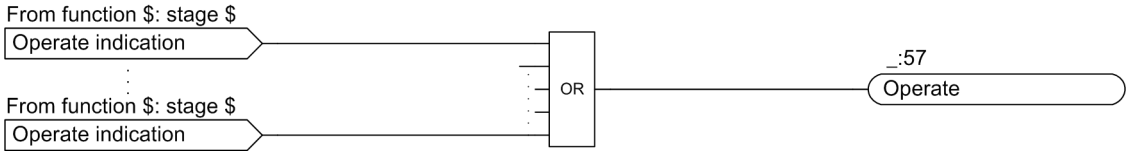


- Power
- Power factor
- Energy
- Minimum, maximum values
- Mean values

With the **`P, Q sign`** parameter, you can invert the sign of these operational measured values such that a power flow from the line to the busbar is displayed positively.
For further information, refer to *9.1 Overview of Functions*.

Output Logic

The output logic treats the pick up and operate indications of the protection and supervision functions in the function group separately, in either a pickup logic or an output logic. The pickup and output logic generate the overreaching indications (group signals) of the function group. These group indications are transferred via the **Protection information** interface to the function group **Circuit breaker** and are processed further there.



The pickup indications of the protection and supervision functions in the function group **Line**are combined phase-segregated and output as a group indication.

[lo_anrlin, 3, en_US]

Figure 5-46 Generation of Pickup Indication of the Function Group Line

The operate indications from the protection functions of the function group **Line** always result in 3-pole tripping of the device.

[lo_auslin, 3, en_US]

Figure 5-47 Generation of an Operate Indication of the Function Group Line

5.5.3 Application and Setting Notes

Interface to the Circuit-Breaker Function Group

The **Line** protection function group is linked to 2 circuit breakers (2 Circuit-breaker function groups) for the breaker-and-a-half layout.

You can find more information in chapter *2 Basic Structure of the Function*.

Line Data

The following application and setting instructions apply for the line data. The line data are configured in the **Line** function group and apply for all functions in the function group.

NOTE

Specify the line data for your specific application!

Parameter: Rated current

- Default setting **(_:9001:101) Rated current** = ***1000 A***

With the **Rated current** parameter, you can set the primary rated current for the line to be protected. The **Rated current** parameter is relevant for the **Differential-protection** function. The **Rated current** specified here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the optional function block **Transformer** has been instantiated in the**Line Differential Protection** function, the parameter **Rated apparent power** can be set. The parameter **Rated current** is then calculated internally and is displayed as a write-protected parameter.

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated voltage

- Default setting **(_:9001:102) Rated voltage** = ***400 kV***

With the **Rated voltage** parameter, you can set the primary rated voltage for the line to be protected. The **Rated voltage** parameter is relevant for the **Differential-protection**, **Distance-protection**, and **Voltage-protection** functions. The **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Rated apparent power

- Default setting _:9001:103 **Rated apparent power** = ***692.8 MVA***

NOTE

The parameter **Rated apparent power** is only configurable if the optional function block **Transformer** has been instantiated in the **Line Differential Protection** function.

If the function block **Transformer** has not been instantiated, the **Rated apparent power** is calculated internally from parameters **Rated current** and **Rated voltage** and is displayed as a write-protected parameter.

With the **Rated apparent power** parameter, you can set the primary rated apparent power of the protected transformer. The **Rated apparent power** parameter is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Neutral point

- Default setting **(_:9001:149) Neutral point** = ***grounded***

With the **Neutral point** parameter, you specify whether the system-neutral point is ***grounded***, ***isolated*** or ***suppress. coil grounded*** (grounded via arc-suppression coil).

Parameter: C1 per length unit

- Default setting **(_:9001:112) C1 per length unit** = ***0.010 µF/km***

With the **C1 per length unit** parameter, you specify the capacitance per unit length in the positive-sequence system for the line to be protected. You set the **C1 per length unit** parameter as a relative value in µF/km or µF/miles. The capacitance per unit length in the positive-sequence system is identical to the operating capacitance c_b'. The **C1 per length unit** parameter is relevant for the **Differential protection**, **Overvoltage protection with positive-sequence system and compounding** and **Fault locator** functions.

Parameter: C0 per length unit

- Default setting **(_:9001:148) C0 per length unit** = ***0.010 µF/km***

With the **C0 per length unit** parameter, you specify the capacitance per unit length in the zero-sequence system for the line to be protected. You set the **C0 per length unit** parameter as a relative value in µF/km or µF/miles. The capacitance per unit length in the zero-sequence system is identical to the ground capacitance c_{gnd}'. The **C0 per length unit** parameter is relevant for the **Differential protection** and **Fault locator** functions.

EXAMPLE

110-kV single-phase liquid-filled cable 3 · 185 mm² Cu with the data:

$c_b = c_{gnd} = 0.27$ µF/km

The setting value for the parameters **C1 per length unit** and **C0 per length unit** is 0.27 µF/km.

Parameter: X per length unit

- Default setting **(_:9001:113) X per length unit** = ***0.0525 Ω/km***

With the **X per length unit** parameter, you set the reactance per unit length for the line to be protected. You set the **X per length unit** parameter as a relative value in Ω/km or Ω/miles. The **X per length unit** parameter is relevant for the **Distance protection, Differential protection**, **Overvoltage protection with positive-sequence system and compounding**, and **Fault locator** functions.

Parameter: Line length

- Default setting **(_:9001:114) Line length** = ***60 km***

With the **Line length** parameter, you can set the length of the line to be protected as a unit of length in km or miles. The **Line length** parameter is relevant for the **Distance protection, Differential protection**, **Overvoltage protection with positive-sequence system and compounding**, **Fault locator** and **Fault locator plus** functions.

Parameter: Line angle

- Default setting **(_:9001:108) Line angle** = ***85°***

The **Line angle** parameter is relevant for the **Distance protection**, **Differential protection**, **Overvoltage protection with positive-sequence system and compounding**, **Fault locator** and **Fault locator plus** functions. Calculate the setting value for the parameter **Line angle** from the line constants for the line to be protected as follows:

$$\tan\varphi = \frac{X_L}{R_L} \qquad \text{or} \qquad \varphi = \arctan\left(\frac{X_L}{R_L}\right)$$

{fo_lwinkl, 1, en_US}

where:

R_L	Resistance of the line to be protected
X_L	Reactance of the line to be protected

EXAMPLE

110-kV overhead line 150 mm² with the data

$R'_1 = 0.19$ Ω/km

$X'_1 = 0.42$ Ω/km

You calculate the setting value for the line angle as follows:

$$\tan \varphi = \frac{X_L}{R_L} = \frac{X'_1}{R'_1} = \frac{0.42\ \Omega/\mathrm{km}}{0.19\ \Omega/\mathrm{km}} = 2.21$$

[fo_tan_phi, 1, en_US]

$$\arctan(2.21) = 65.7°$$

[fo_arctan_phi, 1, en_US]

Parameter: Kr and Kx

- Default setting **(_:9001:104) Kr** = ***1.0***
- Default setting **(_:9001:105) Kx** = ***1.0***

NOTE

The visibility of the **Kr** and **Kx** parameters depends on the selected setting format of the residual compensation factors. The parameters **Kr** and **Kx** only become visible after you have set the parameter **Set. format residu. comp.** = ***Kr, Kx*** for the device.

The **Kr** and **Kx** parameters are used to set the residual compensation factors as scalar values. The **Kr** and **Kx** parameters are relevant for the **Distance protection** and **Fault locator** functions.

NOTE

You can overwrite the residual compensation factors specified here in the distance-protection zones with specific parameters for each zone.

Calculate the setting values for the parameters **Kr** and **Kx** from the line data as follows:

Resistance ratio	Reactance ratio
$Kr = \frac{R_{gnd}}{R_L} = \frac{1}{3} \cdot \left(\frac{R_0}{R_1} - 1 \right)$	$Kx = \frac{X_{gnd}}{X_L} = \frac{1}{3} \cdot \left(\frac{X_0}{X_1} - 1 \right)$

where:

R_0	Zero-sequence system resistance of the line
X_0	Zero-sequence system reactance of the line
R_1	Positive-sequence system resistance of the line
X_1	Positive-sequence system reactance of the line

This data can either be used for the entire line or as length-related values, since the quotients are length-independent. You can calculate the data both from the primary values and from the secondary values.

EXAMPLE

110-kV overhead line 150 mm² with the data:

R_1/s	0.19 Ω/km positive-sequence system resistance
X_1/s	0.42 Ω/km positive-sequence system reactance
R_0/s	0.53 Ω/km zero-sequence system resistance
X_0/s	1.19 Ω/km zero-sequence system reactance
s	Line length

You receive the following setting values for the parameters **Kr** and **Kx**:

$$k_r = \frac{R_{Gnd}}{R_L} = \frac{1}{3} \cdot \left(\frac{R_0}{R_1} - 1\right) = \frac{1}{3} \cdot \left(\frac{0.53\ \Omega/km}{0.19\ \Omega/km} - 1\right) = 0.60$$

[fo_kr, 1, en_US]

$$k_x = \frac{X_{Gnd}}{X_L} = \frac{1}{3} \cdot \left(\frac{X_0}{X_1} - 1\right) = \frac{1}{3} \cdot \left(\frac{1.19\ \Omega/km}{0.42\ \Omega/km} - 1\right) = 0.61$$

[fo_kx, 1, en_US]

Parameter: K0 and Angle (K0)

- Default setting **(_:9001:118) K0** = ***1.000***
- Default setting **(_:9001:150) Angle (K0)** = ***0.00°***

NOTE

The visibility of the **K0** and **Angle (K0)** parameters depends on the selected setting format of the residual compensation factors. The parameters **K0** and **Angle (K0)** only become visible after you have set the parameter **Set. format residu. comp.** = ***K0*** for the device.

The **K0** and **Angle (K0)** parameters are used to set the complex grounding-resistance factor. The **K0** and **Angle (K0)** parameters are relevant for the **Distance protection**, **Fault locator** and **Fault locator plus** functions.

NOTE

You can overwrite the residual compensation factors specified here in the distance-protection zones with local parameters for each zone.

Make sure that the line angle is set correctly because the device needs the line angle for calculation of the compensation components from the K0 factor. The complex grounding-resistance factor is defined by the value and the angle. You can calculate the complex grounding-resistance factor from the line data as follows:

$$K_0 = \left|\frac{\underline{Z}_{Gnd}}{\underline{Z}_L}\right| = \left|\frac{1}{3} \cdot \left(\frac{\underline{Z}_0}{\underline{Z}_1} - 1\right)\right|$$

[fo_K01, 1, en_US]

where:

$\underline{Z}_0$	(complex) zero-sequence impedance
$\underline{Z}_1$	(complex) positive-sequence impedance

This data can either be used for the entire line or as length-related values, since the quotients are length-independent. The data can be calculated both from the primary values and from the secondary values.

For overhead lines, you can use the values for the calculation because the angles of the zero-sequence system and the positive-sequence system differ only slightly. For cables, however, significant angular differences can occur, as the following example illustrates.

EXAMPLE

110-kV single-phase liquid filled cable 3 · 185 mm² Cu with the data:

Z_1/s	$0.408 \cdot e^{j73^\circ}$ Ω/km positive-sequence impedance
Z_0/s	$0.632 \cdot e^{j18.4^\circ}$ Ω/km zero-sequence impedance
s	Line length

The values for calculation of the grounding-resistance factor K0 are:

$$\frac{\underline{Z}_0}{\underline{Z}_1} = \frac{0.632}{0.408} \cdot e^{j(18.4° - 73°)} = 1.55 \cdot e^{-j\,54.6°} = 1.55 \cdot (0.579 - j\,0.815) = 0.898 - j\,1.263$$

[fo_1_k0, 1, en_US]

$$k_0 = \left|\frac{1}{3} \cdot \left(\frac{\underline{Z}_0}{\underline{Z}_1} - 1\right)\right| = \left|\frac{1}{3} \cdot (0.898 - j\,1.263 - 1)\right| = \left|\frac{1}{3} \cdot (-0.102 - j\,1.263)\right|$$

[fo_2_k0, 1, en_US]

The setting value of the parameter **K0** is calculated from:

$$k_0 = \left|\frac{1}{3} \cdot \sqrt{(-0.102^2) + (-1.263^2)}\right| = 0.42$$

[fo_3_k0, 1, en_US]

When determining the angle, take note of the quadrant of the result. The following table lists the quadrants and the angle range obtained from the operational signs of the real and imaginary parts of K0.

Real Part	Imaginary Part	tan Phi (K0)	Quadrant/Range		Calculation Method
+	+	+	I	0° to 90°	arc tan (|Im| / |Re|)
+	-	-	IV	-90° to 0°	–arc tan (|Im| / |Re|)
-	-	+	III	-90° to -180°	arc tan (|Im| / |Re|) –180°
-	+	-	II	+90° to +180°	–arc tan (|Im| / |Re|) +180°

In this example, the following setting value for the **Angle (K0)** parameter is obtained:

$$\varphi(K_0) = \arctan\left(\frac{1.263}{0.102}\right) - 180° = -94.6°$$

[fo_phi_K0, 1, en_US]

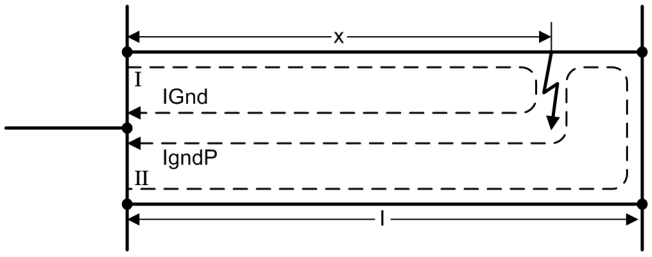
Parameter: KmR and KmX

- Default setting **(_:9001:106) KmR** = ***0.00***
- Default setting **(_:9001:107) KmX** = ***0.00***

The **KmR** and **KmX** parameters are used to set the coupling impedance for parallel-line compensation. The **KmR** parameter (= R0m/3RL) is used to set the coupling resistance. The **KmX** parameter (= X0m/3XL) is used to set the coupling reactance. The **KmR** and **KmX** parameters are only relevant for the **Distance-protection** function.

Parameter: Km0 and Angle (Km0)

- Default setting **(_:9001:124) Km0** = ***0.00***
- Default setting **(_:9001:125) Angle (Km0)** = ***0.00°***



Use the parameters **Km0** (= Z0m/3ZL) and **Angle (Km0)** to set the coupling impedance for parallel-line compensation as a complex value in quantity and angle. The **Km0** parameter allows you to set the value for the coupling-impedance factor. The **Angle (Km0)** parameter allows you to set the angle of the coupling-impedance factor. The **Km0** and **Angle (Km0)** parameters are only relevant for the **Distance-protection** function.

Parameter: Gnd.curr.ratio(MutComp)

- Recommended setting value **(_:9001:109) Gnd.curr.ratio(MutComp)** = ***85 %***

The **Gnd.curr.ratio(MutComp)** parameter is only relevant for the **Distance protection** and single-ended **Fault locator** functions. With the **Gnd.curr.ratio(MutComp)** parameter, you define the ground-current balance for parallel-line compensation. This parameter is important for parallel-line compensation in the event of ground faults outside of the line to be protected.

For the ground-current balance of the distance protection, the setting value returns the current ratio I_{Gnd}/I_{gndP} for the protection device at installation site II (see *Figure 5-48*).

[dwparkomrw-161013, 1, en_US]

Figure 5-48 Range of Parallel-Line Compensation at II

Parallel-line compensation is only carried out if the ground current of the line to be protected (I_{Gnd}) is greater than the ground current of the parallel line (I_{gndP}) evaluated with the parameter **Gnd.curr.ratio(MutComp)**.

Siemens recommends retaining the default setting **Gnd.curr.ratio(MutComp)** = ***85 %*** . In highly unbalanced system conditions and if the coupling factor is very small (XM/XL less than 0.4), a smaller value may be advisable.

Parameter: CT saturation detection

- Default setting **(_:9001:119) CT saturation detection** = ***no***

With the parameter **CT saturation detection**, you specify whether the device is to work with saturation detection or not. The saturation detection detects measuring errors due to saturation of the current transformers and switches over the method of measurement for distance measurement. The **CT saturation detection** parameter is only relevant for the **Distance-protection** function.

Parameter: CT saturation threshold

- Default setting **(_:9001:120) CT saturation threshold** = ***10 A***

The **CT saturation threshold** parameter allows you to set the current threshold for the saturation detection. If the set value is exceeded, saturation detection becomes active. If the saturation detection detects a current-transformer saturation, the device switches over the method of measurement for distance measurement. Calculate the setting value for the parameter **CT saturation threshold** according to the following formula:

$$I_{sat} > = \frac{n'}{5} \cdot I_{rated}$$

[fo1isaet-041210-01.tif, 1, en_US]

where:

$$n' = n \cdot \frac{S_N + S_i}{S' + S_i}$$ Effective overcurrent factor

S_N	Rated burden of the current transformers [VA]
S_i	Inherent burden of the current transformers [VA]
S'	Actually connected burden (protection device + secondary lines)

NOTE

The parameter **CT saturation threshold** only becomes visible when you have set the parameter **CT saturation detection** = ***yes***.

Parameter: Series compensation

- Default setting **(_:9001:111) Series compensation** = ***no***

Use the parameter **Series compensation** to specify whether the line to be protected is to work with or without series compensation. The **Series compensation** parameter is relevant for the **Distance-protection** and **Directional ground-fault protection** functions. To ensure that the direction determination functions correctly in applications for or in the vicinity of series-compensated lines, set the parameter **Series compensation** = ***yes***.

Parameter: Series capacit. reactance

- Default setting **(_:9001:110) Series capacit. reactance** = ***0 Ω***

The **Series capacit. reactance** parameter is used to define the positive-sequence system reactance of the series capacitor. The reactance of the series capacitor is calculated as follows from the capacitance of the capacitor (c_s):

$$X = \frac{1}{2\pi f \cdot c_s}$$

[foforcse-060509-01.tif, 1, en_US]

The **Series capacit. reactance** parameter is only relevant for the **Directional ground-fault protection** function.

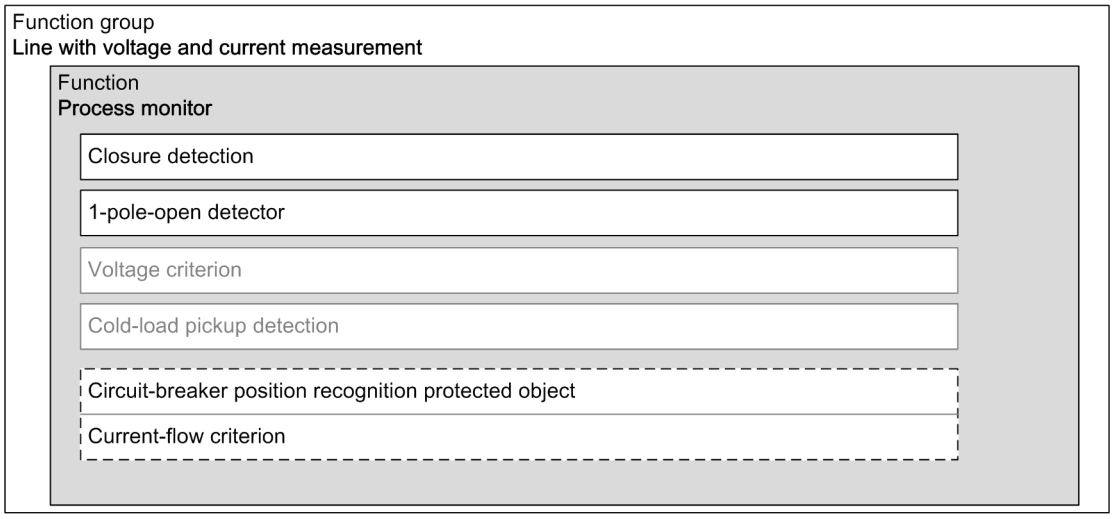
Parameter: P, Q sign

- Default setting **(_:9001:158) P, Q sign** = ***not reversed***

The power and energy values are designed by the manufacturer such that power in the direction of the protected object is considered positive. You can also positively define the power dissipation through the protected object (for example, as seen by the consumer). With the **P, Q sign** parameter, you can invert the sign for these components. This inversion does not influence any protection function.

5.5.4 Process Monitor (FG Line)

5.5.4.1 Overview of Functions



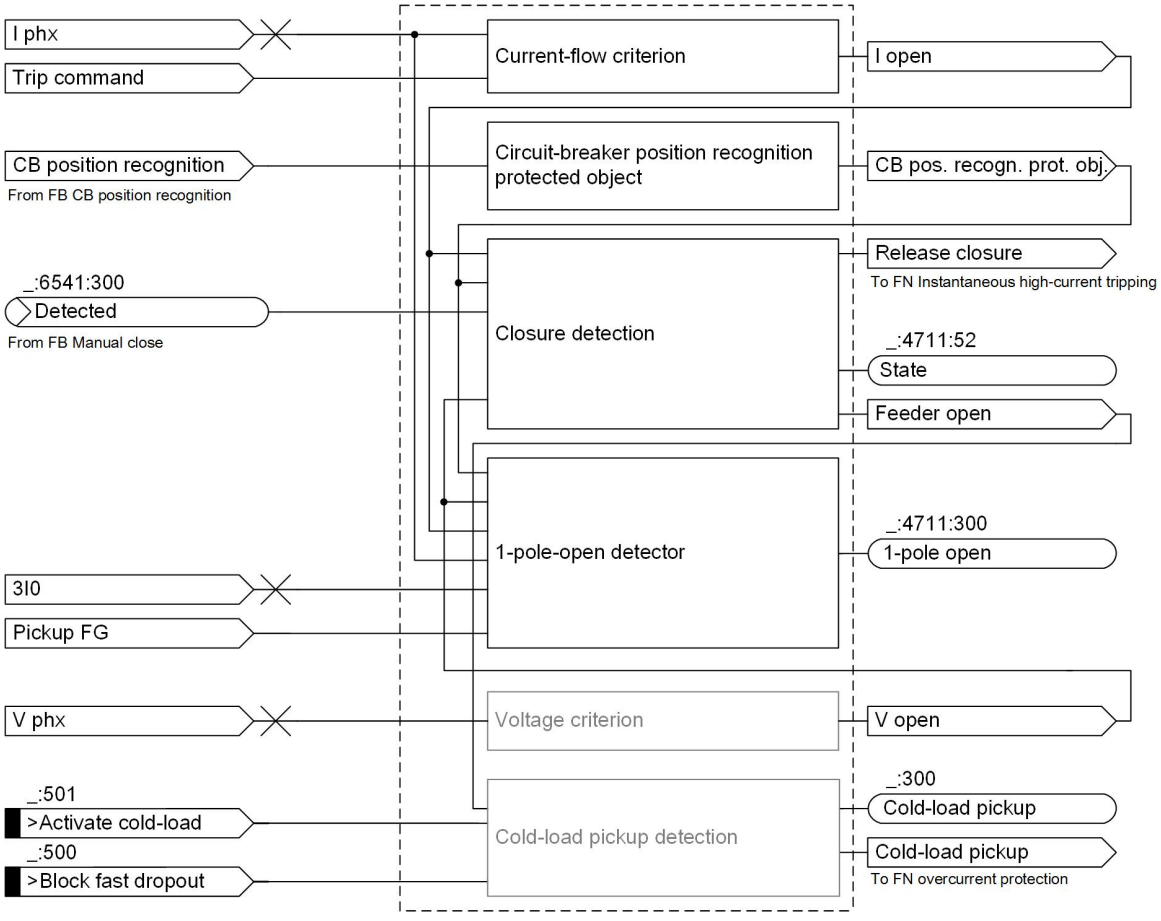
All function groups that have functions with dependencies on the state of the protected object contain a process monitor. The process monitor detects the current state of the protected object.

5.5.4.2 Structure of the Function

The **Process monitor** function is used in the **Line** protection function group with voltage and current measurement.

The **Process monitor** function is preconfigured by the manufacturer with the following function blocks:

- Closure detection
- 1-pole-open detector
- Cold-load pickup detection (optional)
- Voltage criterion (optional)
- Circuit-breaker condition
- Current-flow criterion

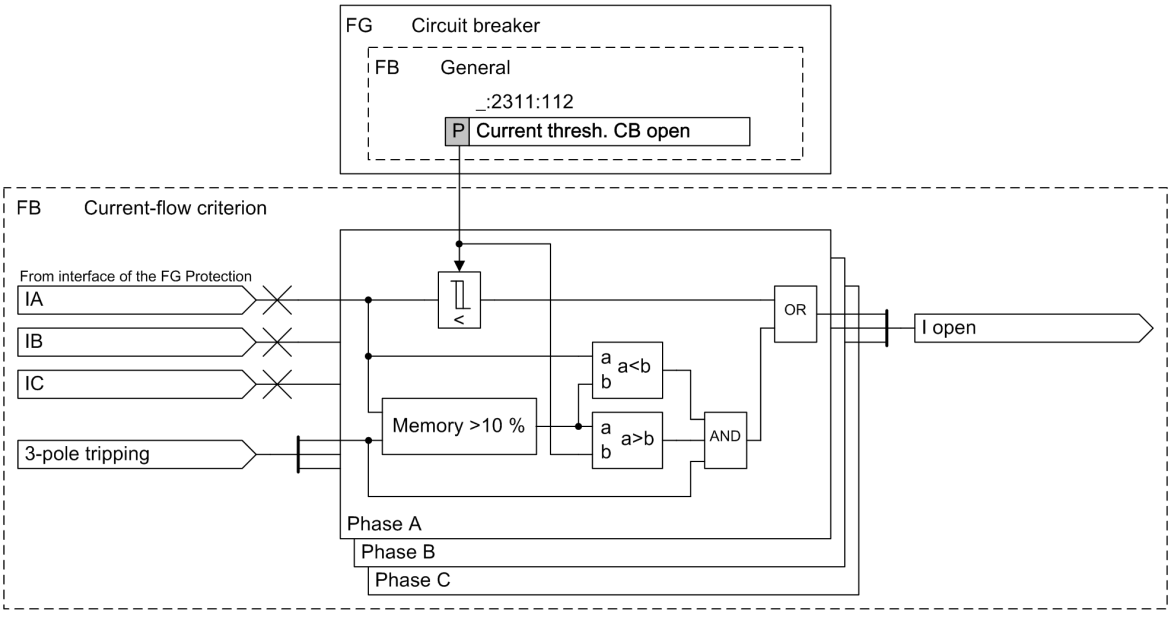


[dwpro1p1-050612-01.tif, 3, en_US]

Figure 5-49 Structure/Embedding of the Function

You can switch the voltage criterion and the cold-load pickup detection as necessary. The circuit-breaker position recognition and the current-flow criterion run permanently in the background and are not displayed in DIGSI.

The following figure shows the relationships of the individual function blocks.



[lopro1p1-171012-01.tif, 3, en_US]

Figure 5-50 Logic Diagram of the Overall Function Process Monitor

5.5.4.3 Current-Flow Criterion

Logic

[lo_proikr, 2, en_US]

Figure 5-51 Logic Diagram of the Current-Flow Criterion Function Block

The phase currents are provided via the interface to the protection function group.

The **I open** signal of one phase is generated if one of the following conditions is met:

- A phase current falls below the set threshold of the **Current thresh. CB open** parameter. The hysteresis stabilizes the signal.
- The corresponding phase current, for example, **I A**, falls below 10 % of the phase current when the trip command arrives. If the current does not drop until after a delay due to current transformer influences, an open pole can therefore be detected quickly even after a high-current fault on the line.

With the **Current thresh. CB open** parameter, you define the minimum current as the criterion for a deactivated line. The parameter lies in the **Circuit-breaker** function group. It acts both in the **Circuit-breaker** function group, for example circuit-breaker position recognition, and also for the process monitor in the protection function group.

If a protection function group with integrated process monitor is connected to several **Circuit breaker** FGs, the **Current thresh. CB open** parameter is present in each FG **Circuit breaker**. The smallest setting value of the parameter **Current thresh. CB open** is used.

5.5.4.4 Application and Setting Notes (Current-Flow Criterion)

Parameter: Current thresh. CB open

- Recommended setting value **(_:2311:112) Current thresh. CB open** = ***0.100 A***

The **Current thresh. CB open** parameter is used to define the threshold for the leakage current as the criterion for a deactivated line.

Set the **Current thresh. CB open** parameter so that the current measured when the feeder is deactivated falls below the value of the **Current thresh. CB open** parameter with certainty. The hysteresis is additionally active if the threshold is exceeded.

If parasitic currents, for example, due to induction, are ruled out when the feeder is deactivated, set the **Current thresh. CB open** parameter sensitively.

Siemens recommends a setting value of ***0.100 A***.

5.5.4.5 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Breaker settings				
_:2311:112	General:Current thresh. CB open	1 A @ 100 Irated	0.030 A to 10.000 A	0.100 A
		5 A @ 100 Irated	0.15 A to 50.00 A	0.50 A
		1 A @ 50 Irated	0.030 A to 10.000 A	0.100 A
		5 A @ 50 Irated	0.15 A to 50.00 A	0.50 A
		1 A @ 1.6 Irated	0.001 A to 1.600 A	0.100 A
		5 A @ 1.6 Irated	0.005 A to 8.000 A	0.500 A
_:2311:136	General:Op. mode BFP		• unbalancing • I> query	unbalancing

5.5.4.6 Circuit-Breaker Condition for the Protected Object

Logic

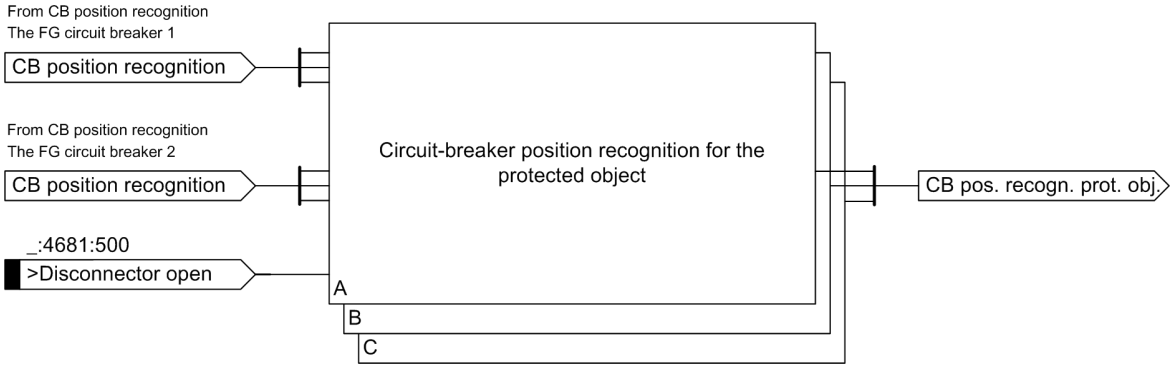


Figure 5-52 Logic Diagram of the Circuit-Breaker Condition for the Protected-Object Function Block

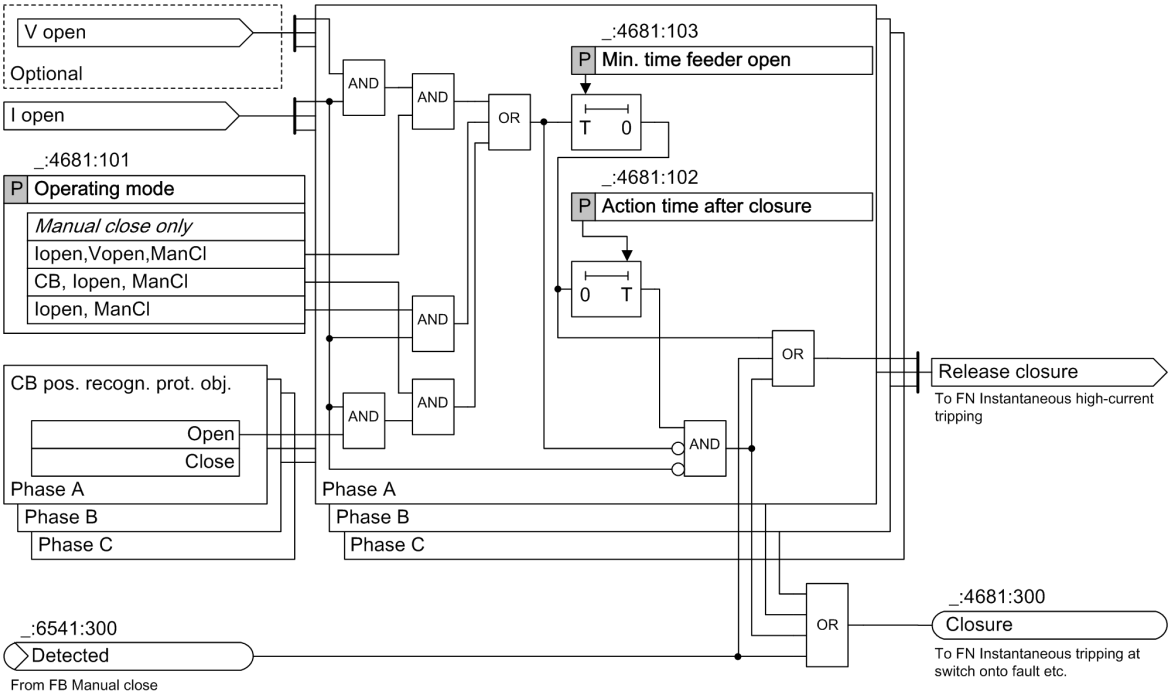
The circuit-breaker position recognition in the **Circuit-breaker** (CB) function group provides the circuit-breaker condition by way of the internal signal ***CB pos. recogn. prot. obj.***.

If a protected object is supplied via 2 circuit breakers (CBs), for example with the 1 1/2 circuit-breaker layout, then the circuit-breaker switch position of the protected object must be determined with the aid of both circuit breakers. In this case, the **Circuit-breaker position recognition for the protected object** function block connects the individual CB states. The connection provides the internal ***CB pos. recogn. prot. obj.*** signal to the other function blocks of the process monitor and to other functions, for example, **Trip in the event of weak infeed** and **Echo function for teleprotection method**, within the same function group.

If one of the following 2 conditions is met, the ***CB pos. recogn. prot. obj.*** signal is in the ***Open*** state:

- All connected circuit breakers signal the ***Open*** state internally.
- The **>Disconnector open** input is active.



If the following 2 conditions are met, the ***CB pos. recogn. prot. obj.*** signal is in the ***Closed*** state:

- At least one of the connected circuit breakers signals the ***Closed*** state internally.
- The **>Disconnector open** input is not active.

5.5.4.7 Closure Detection

Logic

The closure detection enables the immediate tripping of selected protection functions or protection stages when switching to short circuit or the reduction of the responsivity. The closure detection determines whether the protected object is switched on.

[loproein-121012-01.tif, 2, en_US]

Figure 5-53 Logic Diagram of the Closure-Detection Function Block

For an applied binary input signal **Detected** (from function block Manual close), the indication **Closure** is always active. The indication **Closure** can also be activated via the measurand. In addition, the protected object must be switched off for at least the time **Min. time feeder open**.

This time is started as follows depending on the **Operating mode** parameter:

- For parameter **Operating mode** = ***Iopen,Vopen,ManCl***:
  If the current-flow criterion and the voltage criterion are detected open-circuited.
- For parameter **Operating mode** = ***CB, Iopen, ManCl***:
  If the circuit-breaker auxiliary contact(s) and the current-flow criterion are detected as open-circuited.
- For parameter **Operating mode** = ***Iopen, ManCl***:
  If the current-flow criterion is detected as open-circuited.

If the protected object is detected as switched off, the phase-segregated internal output signal **Release (Closure)** is formed. The **Instantaneous high-current tripping** function can trip immediately, for example with the **Release (Closure)** signal in the event of connection to a short circuit.

If all the following conditions are active, the **Closure** indication is activated via the measurands.

- The protected object is switched off for at least the time **Min. time feeder open**.
- The time **Action time after closure** is running.
- The current-flow criterion no longer detects the state open-circuited.

The time **Action time after closure** is started depending on the **Operating mode** parameter:

- For parameter **Operating mode** = ***Iopen,Vopen,ManCl***:
  If the current-flow criterion or the voltage criterion is no longer detected open-circuited.
- For parameter **Operating mode** = ***CB, Iopen, ManCl***:
  If the circuit-breaker auxiliary contact(s) or the current-flow criterion are no longer detected as open-circuited.
- For parameter **Operating mode** = ***Iopen, ManCl***:
  If the current-flow criterion is no longer detected as open-circuited.

5.5.4.8 Application and Setting Notes (Closure Detection)

Parameter: Operating mode

- Default setting **(_:4681:101) Operating mode**=***Manual close only***

With the **Operating mode** parameter, you set the criteria with which the **Closure-detection** function block operates.

Parameter Value	Description
Manual close only	The detection of feeder closure is exclusively decided using the binary input signal **Detected** (from Manual close function block). Siemens recommends this setting, if both of the following conditions are met: • The binary input signal **Manual On** is available on the side of the system. • A closure detection must not happen due to an additional current and voltage measurement, for example, after an automatic reclosing.
Iopen,Vopen,ManCl	The closure detection is done additionally with the current and voltage measurement. If the voltage transformers are installed at the busbar side or if there is no voltage connected, you must not use this setting.
CB, Iopen, ManCl	The closure detection is done additionally with the current measurement and with the evaluation of connected circuit breaker position contacts.
Iopen, ManCl	The closure detection is done additionally with the current measurement. For this setting, make sure that the **Current thresh. CB open** parameter is set lower than the lowest possible load current. If this is not ensured, open-circuit is detected continuously and each current value that exceeds the **Current thresh. CB open** parameter is interpreted as closure.

Parameter: Min. time feeder open

- Recommended setting value **(_:4681:103) Min. time feeder open** = ***0.25 s***

To avoid incorrect closure detection, the protected object must be switched off for the minimum time of **Min. time feeder open** before the **Closure** indication can become active. You define the duration of the release delay with the **Min. time feeder open** parameter.

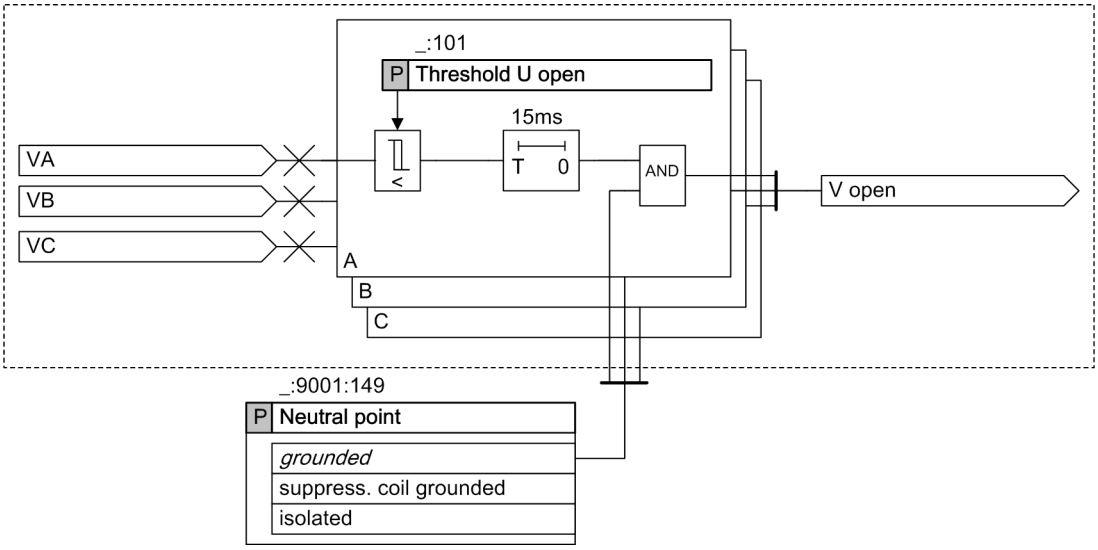
Siemens recommends a setting value of ***0.25 s***.

Parameter: Action time after closure

- Recommended setting value **(_:4681:102) Action time after closure** = ***0.05 s***

The **Closure** indication signals detected closure. With the **Action time after closure** parameter, you set the **Closure** indication to a defined length.

Siemens recommends a setting value of ***0.05 s***.



5.5.4.9 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Closure detec.				
_:4681:101	Closure detec.:Operating mode		• Manual close only • Iopen,Vopen,ManCl • CB, Iopen, ManCl • Iopen, ManCl	Manual close only

Addr.	Parameter	C	Setting Options	Default Setting
_:4681:102	Closure detec.:Action time after closure		0.01 s to 60.00 s	0.05 s
_:4681:103	Closure detec.:Min. time feeder open		0.05 s to 60.00 s	0.25 s

5.5.4.10 Voltage Criterion (Optional)

Logic

[loproure-020211-01.tif, 1, en_US]

Figure 5-54 Logic Diagram of the Voltage-Criterion Function Block

If you want to test closure detection or an open-pole detector via a voltage, you need a voltage transformer installed on the line side and electrical power systems with a grounded neutral point. In this case, add the **Voltage criterion** function block to the process monitor.

If the voltage transformers are installed on the busbar side or if there is no voltage connected, you must not use the voltage criterion to detect a deactivated phase.

With the **(_:101) Threshold U open** parameter, you define the residual voltage as the criterion for a deactivated line. If the phase-to-ground voltage falls below the value of the **Threshold U open** parameter, the **V open** signal is generated. The function stabilizes the signal with a hysteresis and a delay of the rising edge of the signal. The falling edge of the signal is forwarded without delay.

5.5.4.11 Application and Setting Notes (Voltage Criterion)

Parameter: Threshold U open

NOTE

The **Threshold U open** parameter is available only when the optional **Voltage criterion** function block is used. Use this parameter only with a voltage transformer installed on the line side and in electrical power systems with a grounded neutral point.

- Recommended setting value **(_:101) Threshold U open** = ***30.000 V***

With the **Threshold U open** parameter, you define the threshold for the leakage voltage as the criterion for a deactivated feeder.

Set the **Threshold U open** parameter so that the voltage measured when the feeder is deactivated falls below the value of the **Threshold U open** parameter with certainty. The hysteresis is additionally active

if the threshold is exceeded. The value of the **Threshold U open** parameter must lie below the minimum expected phase-to-ground voltage. The voltage transformers must be connected on the line side.

Due to possible parasitic voltages (for example, due to capacitive coupling in), do not set the value of the **Threshold U open** too sensitively.

Siemens recommends a setting value of ***30.000 V***.

5.5.4.12 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Volt.criterion				
_:101	Volt.criterion:Threshold U open		0.300 V to 170.000 V	30.000 V

5.5.4.13 Cold-Load Pickup Detection (Optional)

Logic

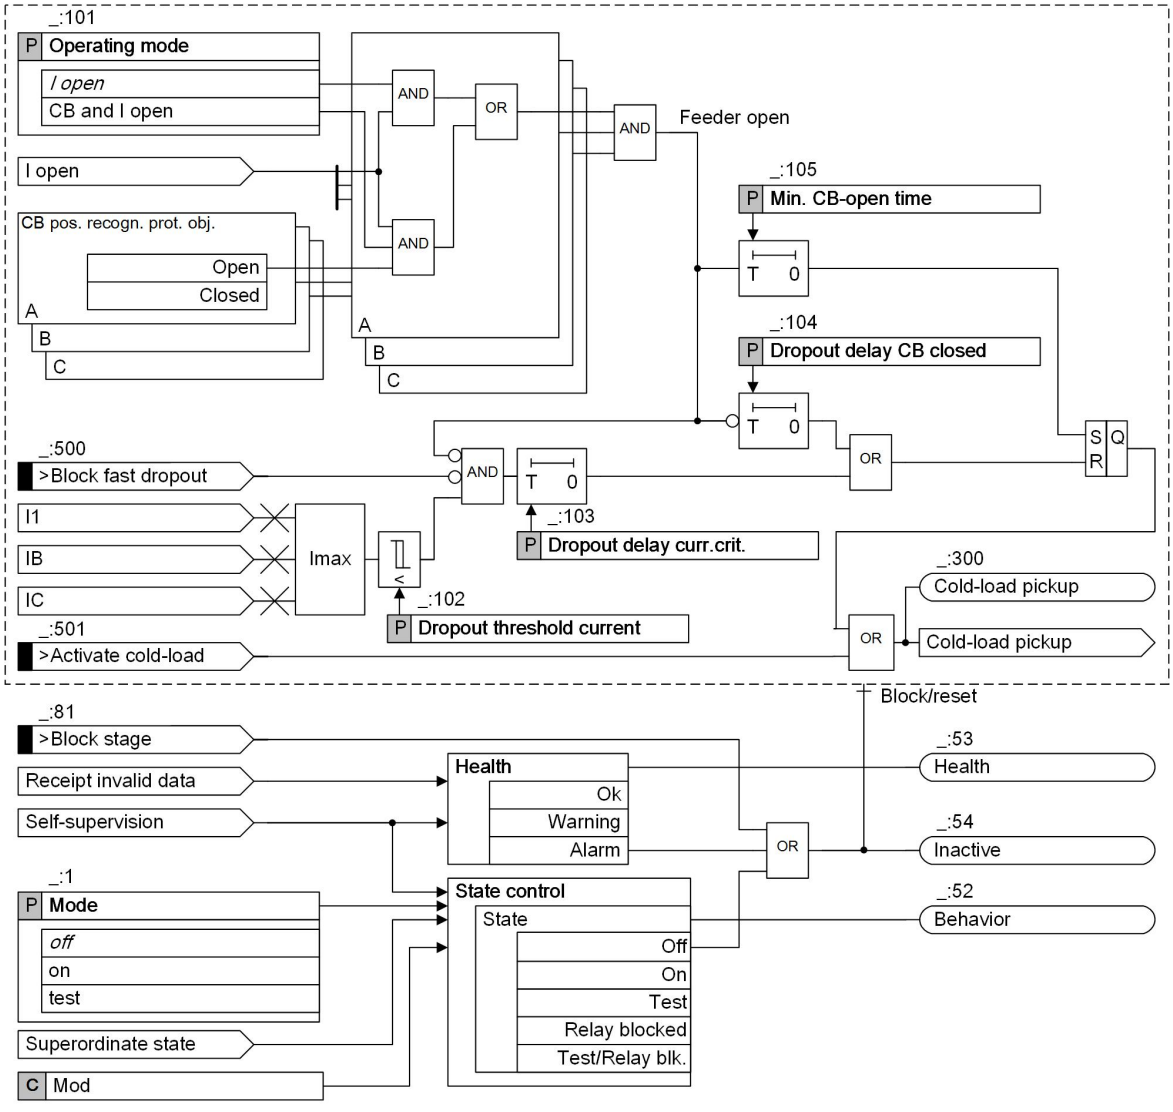


Figure 5-55 Logic Diagram of the Cold-Load Pickup Detection Function Block

The **Cold-load pickup detection** function block detects that a specific time has been exceeded after deactivation of the line or protected object. If you want to connect the protected object again, you must note that an increased load-current requirement exists for a limited time after connection. This results from the nature of the load.

The **Cold-load pickup detection** function block ensures that different parameters are used for an adjustable time after connection. For example, for the time of the **Min. CB-open time** parameter, you can increase the threshold value of a protection function or you can select a special characteristic curve.

If the **Cold-load pickup detection** function block detects an open feeder and the set time of the **Min. CB-open time** parameter has expired, the indication **>Activate cold-load** is generated.

With the **>Activate cold-load** indication, you can activate a parameter set of the **Cold-load pickup** function. Via the binary input signal **>Activate cold-load**, you can also activate the **>Activate cold-load** indication directly.

If the **Cold-load pickup detection** function block detects closure and the corresponding load current, it starts the time set in the **Dropout delay CB closed** parameter. The **>Activate cold-load** indication and the activated parameter set are deactivated after this time has elapsed.

If, for the time set in the **Dropout delay curr.crit.** parameter, the maximum phase current falls below the threshold value **Dropout threshold current**, the parameter set for the **Cold-load pickup detection** function block is also deactivated. As a result, if the load current is very low, the action time **Dropout delay curr.crit.** of the **>Activate cold-load** indication can be shortened.

5.5.4.14 Application and Setting Notes (Cold-Load Pickup Detection)

NOTE

The settings and indications described in this chapter are only available when using the optional **Cold-load pickup detection** function block.

Parameter: Operating mode

- Default setting **(_:101) Operating mode** = ***I open***

With the **Operating mode** parameter, you set the criteria with which the Closure-detection function block operates.

Parameter Value	Description
I open	When the Current-flow criterion function block detects a clearing open condition, the decision is made for pickup. For this setting, make sure that the **Current thresh. CB open** parameter is set lower than the possible load current. If this is not the case, open is detected continuously and each fault current that exceeds the **Current thresh. CB open** parameter is interpreted as closure.
CB and I open	Closure is detected if one of the following conditions is met: • Analysis of the circuit-breaker auxiliary contact detects a clearing open condition in at least one phase. • The current-flow criterion detects a clearing open condition.

Parameter: Dropout threshold current

- Default setting **(_:102) Dropout threshold current** = ***1.00 A***

With the **Dropout threshold current** parameter, you set the threshold at which the output signal **Cold-load pickup** is deactivated when the current in at least one phase falls below this threshold.

Parameter: Dropout delay current criterion

- Default setting **(_:103) Dropout delay curr.crit.** = ***600 s***

With the **Dropout delay curr.crit.** parameter, you set the time for which the actual value must be below the **Dropout threshold current** threshold so that the output signal **Cold-load pickup** can be deactivated prematurely.

Parameter: Dropout delay CB closed

- Default setting **(_:104) Dropout delay CB closed** = ***3600 s***

With the **Dropout delay CB closed** parameter, you set the action time for the dynamic parameter set switching in the event of cold-load pickup detection.

Parameter: Min. CB open time

- Default setting **(_:105) Min. CB-open time** = ***3600 s***

With the **Min. CB-open time** parameter, you set the time after which the dynamic parameter set is activated in the event of **cold-load pickup** when the line is opened.

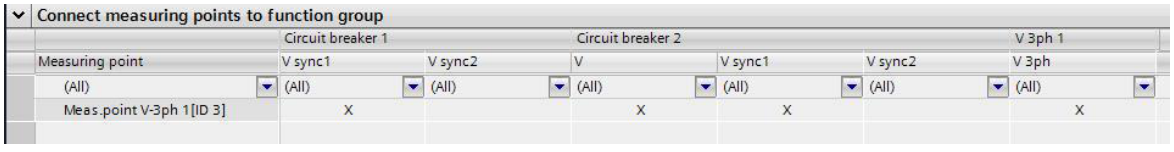
5.6 Function-Group Type Voltage 3-Phase

5.6.1 Overview

In the **Voltage 3-phase** function group, all functions can be used for protecting and for monitoring a protected object or equipment which allows a 3-phase voltage measurement. The function group also contains the operational measurement for the protected object or equipment (on this topic, see chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*). Applicable functions are, for example, Voltage protection or Frequency protection.

5.6.2 Structure of the Function Group

The function group **Voltage 3-phase** has interfaces to the measuring points and the function group **Circuit breaker**.



[dw_3phase_voltage, 1, en_US]

Figure 5-56 Structure of the Function Group Voltage 3-Phase

Interface with Measuring Points

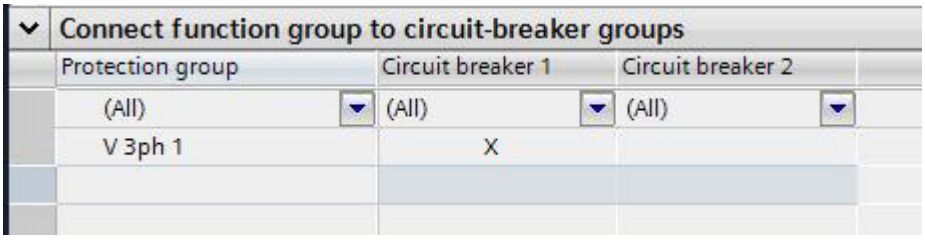
You connect the function group **Voltage 3-phase** to the voltage measuring points via the interface to the measuring points. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

[sc_3_voltage1, 1, en_US]

Figure 5-57 Connecting Measuring Points to the Voltage 3-Phase Function Group

If you add functions to the function group **Voltage 3-phase**, these are connected to the measuring point automatically.

You can connect multiple measuring points with this interface. For more information, refer to chapter *6.71 Voltage Measuring-Point Selection*.



The measurands from the 3-phase voltage system are supplied via the interface **V 3-ph**. Depending on the connection type of the transformers, for example, V_A, V_B, V_C, V_{gnd}. All values that can be calculated from the measurands are also provided via this interface.

Interface to the Function Group Circuit Breaker

All required data is exchanged between the function group **Voltage 3-phase** and the function group **Circuit breaker** via the interface of the function group **Circuit breaker**.

In this example, the pickup and operate indications of the protection functions are exchanged in the direction of the function group Circuit breaker.

You must connect the function group **Voltage 3-phase** with the function group **Circuit breaker**. This assignment can be made in DIGSI only via **Project tree** → **Connect function group**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

[sc_3_voltage2, 1, en_US]

Figure 5-58 Connecting the Function Group Voltage 3-Phase with the Function Group Circuit Breaker

Operational Measured Values

The operational measured values are always present in the function group **Voltage 3-phase** and cannot be deleted.

The following table shows the operational measured values of the function group **Voltage 3-phase**:

Table 5-15 Operational Measured Values of the Voltage 3-Phase Function Group

Measured Values		Primary	Secondary	% with respect to
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Operating rated voltage of primary values/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltage	kV	V	Rated operating voltage of the primary values
V_0	Zero-sequence voltage	kV	V	Operating rated voltage of primary values/√3
V_{NG}	Neutral-point displacement voltage	kV	V	Operating rated voltage of primary values/√3
f	Frequency	Hz	Hz	Rated frequency

5.6.3 Application and Setting Notes

NOTE

Before creating the protection functions in the function group, you should connect them to the appropriate **Circuit-breaker** function group.

Parameter: Rated voltage

- Default setting **(_:9421:102) Rated voltage** = ***400.00 kV***

With the **Rated voltage** parameter, you set the primary rated voltage. The parameter **Rated voltage** set here is the reference value for the percentage-measured values and setting values made in percentages.

5.6.4 Settings

5.7 Function-Group Type Voltage/current 1-Phase

5.7.1 Overview

In the **Voltage-current 1-phase** function group, all functions can be used for protecting and for monitoring a protection object or equipment that allow a 1-phase current and voltage measurement or a zero-sequence voltage measurement via the 3-phase voltage measuring point. The function group also contains the operational measurement for the protected object or equipment (see chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*).

5.7.2 Structure of the Function Group

The function group **Voltage-current 1-phase** has interfaces to the measuring points and the function group **Circuit breaker**.

[dw_1spstr, 1, en_US]

Figure 5-59 Structure of the Function Group Voltage-Current 1-Phase

Interface with Measuring Points

You connect the function group **Voltage-current 1-phase** to the current and voltage measuring points via the interfaces to the measuring points. At least one measuring point has to be connected. The other is optional. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix.

The function group has the following interfaces to the measuring points:

- **1-phase current**

  The 1-phase current measured values are provided via this interface.

  You can only connect a 1-phase current measuring point to the interface **1-phase current**.

- **Voltage 1-phase** or **Voltage 3-phase**

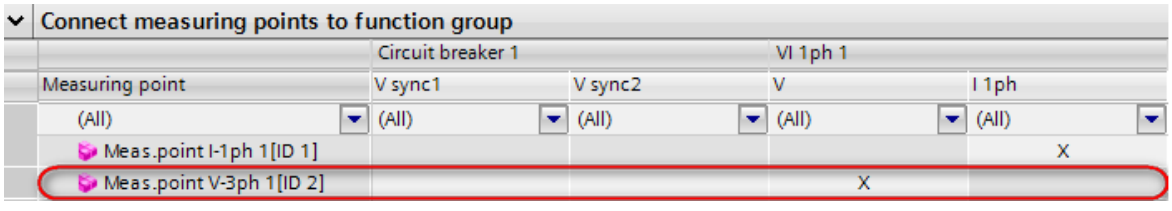
  You can connect the voltage interface of the function group **Voltage-current 1-phase** with a 1-phase or a 3-phase measuring point. The calculated zero-sequence voltage or the measured residual voltage is available for connection with a 3-phase measuring point. The phase-to-ground voltages are not available in the function group **Voltage-current 1-phase**. You can use both connection types at the same time.

  You configure the 1-phase voltage measuring points via the voltage interface (see the following figure).

[scVI1ph_V1ph, 1, en_US]

Figure 5-60 Connecting Measuring Points to the Function Group Voltage-Current 1-Phase

If you select the voltage type ***VN broken-delta*** for the 1-phase voltage measuring point in the measuring point routing (see the following figure), the device measures the residual voltage V_N at the broken-delta winding. The residual voltage is converted into the voltage equivalent of the zero-sequence voltage. This converted voltage is used as the voltage input for all functions in the function group **Voltage-current 1-phase**.



[scvnopen, 1, en_US]

Figure 5-61 Selection of the ***VN broken-delta*** Voltage Type for the 1-Phase Voltage Measuring Point

The zero-sequence voltage calculated from the 3-phase voltage system or the measured residual voltage is available via the voltage interface (see the following figure).

The zero-sequence voltage calculated from the 3-phase voltage system is available via the voltage interface (see the following figure).

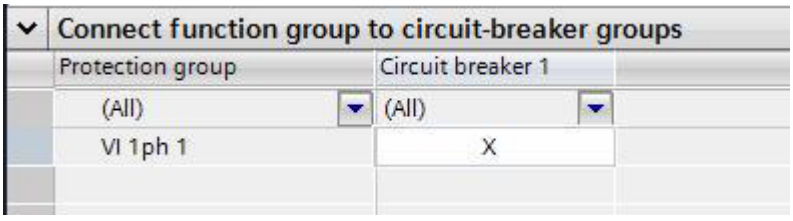
[scVI1ph_V3ph, 1, en_US]

Figure 5-62 Connecting Measuring Points 3-Phase Voltage and 1-Phase Current to the Function Group 1-Phase Voltage-Current

You can connect the voltage interface of the function group **Voltage-current 1-phase** with precisely one 3-phase voltage measuring point. 3 types of 3-phase voltage measuring-point connection are supported.

With the different connection types, the type of voltage input for the functions in the function group **Voltage-current 1-phase** also changes.

The following table shows the properties of the voltage input for the function group **Voltage-current 1-phase** depending on the connection types.



Connection Type of the 3-Phase Voltage Measuring Point	Voltage Input
3 ph-to-gnd voltages	The zero-sequence voltage is calculated from the phase-to-ground voltages and used as a voltage input for all functions.
3 ph-to-gnd volt. + VN	The residual voltage VN is converted into the voltage equivalent of the zero-sequence voltage. This converted voltage is used as a voltage input for functions.
3 ph-to-ph volt. + VN	

Interface to the Circuit-Breaker Function Group

All required data is exchanged between the function group **Voltage-current 1-phase** and the function group **Circuit breaker** via the interface of the function group **Circuit breaker**.

In this example, the pickup and operate indications of the protection functions are exchanged in the direction of the Circuit-breaker function group.

You must connect the function group **Voltage-current 1-phase** with the function group **Circuit breaker**. This assignment can only be made in DIGSI via **Project tree** → **Function group connections**. To connect the interfaces, set a cross at the intersection between the row and column in the matrix. If the interface is not connected, the functions operate as supervision functions in the function group **Voltage-current 1-phase**.

[sc_1stspc, 1, en_US]

Figure 5-63 Connecting Function Group Voltage-Current 1-Phase with Function Group Circuit Breaker

Fundamental Components

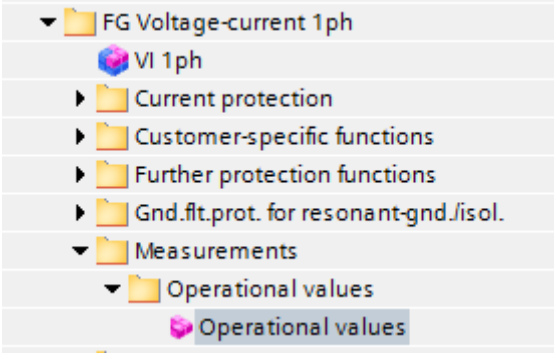
The fundamental components are always present in the function group **Voltage-current 1-phase** and cannot be deleted.

The following table shows the fundamental components of the function group **Voltage-current 1-phase**:

Table 5-16 Fundamental Components of the Function Group Voltage-Current 1-Phase

Measured Values		Primary	Secondary	% Referring to
I	1-phase current	A	A	Parameter **Rated operating current**
V[21]	1-phase voltage	kV	V	Parameter **Rated operating voltage**
V_0[22]	Zero-sequence voltage	kV	V	Parameter **Rated operating voltage**/√3
V_N[23]	Residual voltage	kV	V	Parameter **Rated operating voltage**/√3

21 The 1-phase voltage V is only visible if it is connected to a 1-phase voltage measuring point.



22 The zero-sequence voltage V0 is only visible if it is connected to a 3-phase voltage measuring point with the connection type 3-phase phase-to-ground voltage.

23 The residual voltage VN is only visible if it is connected to a 3-phase voltage measuring point with the connection type 3-phase phase-to-ground voltage + VN or 3-phase phase-to-phase voltage + VN.

You can find the parameters **Rated operating current** and **Rated operating voltage** in the function block **General** of the function group **Voltage-current 1-phase**.

Operational Measured Values

The operational measured values are not preconfigured in the function group **Voltage-current 1-phase**. You can instantiate them in the function group or delete them from the function group. You can find the operational measured values in the DIGSI library, in the folder **FG Voltage-current 1-phase** under **Measurements** → **Operational values**.

[scui1pom, 1, en_US]

Figure 5-64 Operational Measured Values

Table 5-17 Operational Measured Values of the Function Group Voltage-Current 1-Phase

Measured Values		Primary	Secondary	% Referring to
I	1-phase current	A	A	Parameter **Rated operating current**
V[24]	1-phase voltage	kV	V	Parameter **Rated operating voltage**
V_N[25]	Residual Voltage	kV	V	Parameter **Rated operating voltage**/√3
V_0[26]	Zero-sequence voltage	kV	V	Parameter **Rated operating voltage**/√3
f	Frequency	Hz	Hz	Parameter **Rated frequency**
P	Active power	MW	W	Parameter **Rated apparent power**
Q	Reactive power	Mvar	var	Parameter **Rated apparent power**

You can find the parameters **Rated operating current**, **Rated operating voltage**, and **Rated apparent power** in the function block **General** of the function group **Voltage-current 1-phase**. You can find the parameter **Rated frequency** in the function block **General** of the **Device settings**.

NOTE

The frequency can be calculated from the voltage or current measured value.

The active and reactive power are only displayed if the voltage and the 1-phase current are connected to the function group. If the connected voltage is a phase-to-ground voltage (VA, VB , VC) or any voltage Vx, the specific power values are displayed. Otherwise the power is displayed as not available.

24 V is only visible if it is connected to a 1-phase voltage measuring point.

25 VN is only visible if it is connected to a 3-phase voltage measuring point of the type 3 ph-to-gnd volt. + VN or 3 ph-to-ph volt. + VN.

26 V0 is only visible if it is connected to a 3-phase voltage measuring point of the type 3 ph-to-gnd voltages.

5.7.3 Write-Protected Settings

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameter	C	Setting Options	Default Setting

5.8 Function-Group Type Voltage/current 3-Phase

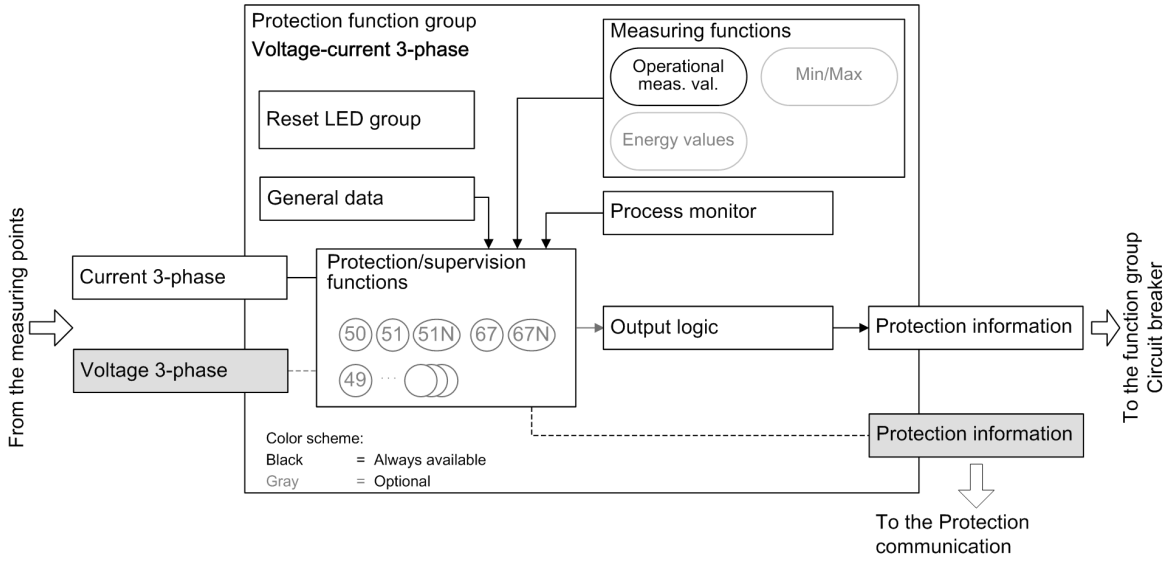
5.8.1 Overview

In the **Voltage-current 3-phase** function group, you can use all the functions for protection and supervision of a protected object or equipment that allows 3-phase current and voltage measurement. The function group also contains the operational measurement for the protected object or equipment (on this topic, see chapter *9 Measured Values, Energy Values, and Supervision of the Primary System*).

You will find the **Voltage-current 3-phase** function group under each device type in the Global DIGSI 5 library. You will find all protection and supervision functions that you can use for this function-group type in the function group **Voltage-current 3-phase**. These functions are described in chapter *6 Protection and Automation Functions*.

For more information about the embedding of the functions in the device, refer to chapter *2 Basic Structure of the Function*. For information regarding the functional scope of the application templates for the various device types, refer to chapter *4 Applications*.

5.8.2 Structure of the Function Group



The function group always contains the following blocks:

- Protected object/equipment data (FB General)
- Operational measured values
- Process monitor
- Output logic of the function group
- Reset the LED group

These blocks are essential for the function group under all circumstances, so they cannot be loaded or deleted.

You can load the protection and supervision functions required for your application in the function group. The functions are available in the function library in DIGSI 5. Functions that are not needed can be deleted from the function group.

The following figure shows the structure of the function group **Voltage-current 3-phase**:

[dw_fg_ui3p, 4, en_US]

Figure 5-65 Structure of the Voltage-Current 3-Phase Function Group

The function group has interfaces with:

- **Measuring points**
- Function group **Circuit breaker**

Interface with Measuring Points

The function group receives the required measured values via its interfaces with the measuring points. If you are using an application template, the function group is already connected to the necessary measuring points. If you add functions to the function group, they will automatically receive the measured values from the correct measuring points. If you add protection functions to the function group but the necessary measuring point is not connected, DIGSI 5 reports an inconsistency. Configure the measuring points in DIGSI 5 via the **Function-group connections** Editor. For more detailed information, refer to *2 Basic Structure of the Function*.

The function group has the following interfaces with the measuring points:

- **3-phase voltage**

  The measurands from the 3-phase voltage system are supplied via this interface. There are various types of transformer connections possible. All values that can be calculated from the measurands are also provided via this interface. The function group must always be linked to the **V-3ph** measuring point.

  You can connect multiple measuring points with this interface. For more information, refer to *6.71 Voltage Measuring-Point Selection*.

  If you want to test or change the connection between the voltages and the V-3ph measuring point, double-click in the DIGSI 5 project tree **(Name of the device)** > **Measuring point routing** (Connection type = 3 phase-to-ground voltage). For more information, refer to the description of the power-system data starting with *6.1 Power-System Data*.

- **3-phase current**

  The measurands from the 3-phase current system are supplied via this interface. Depending on the connection type of the transformers, these are, for example, I_A, I_B, I_C, I_N or $3I_0$. All values that can be calculated from the measurands are also provided via this interface. The function group must always be connected to the **I-3ph** measuring point.

  You can connect the **3-phase current** interface to a maximum of **four** 3-phase current measuring points, (for example, for 1 1/2 circuit-breaker layouts). If 2 current measuring points have been connected with the **3-phase current** interface, the total current is also determined from measured values from both measuring points in the function group. All functions in the function group have access to these values.

Interface to the Circuit-Breaker Function Group

All required data are exchanged between the function groups **Voltage-current 3-phase** and **Circuit breaker** via the interface of the **Circuit-breaker** function group.

This data includes, for example, the pickup and operate indications of the protection functions sent in the direction of the Circuit-breaker function group and, for example, the circuit-breaker position information in the direction of the protection function groups.

The **Voltage-current 3-phase** function group is connected to one or more Circuit-breaker function groups. This connection generally determines:

- Which circuit breaker(s) is/are activated by the protection functions of the protection function group
- Starting the Circuit-breaker failure protection function (if available in the Circuit-breaker function group) through the protection functions of the connected protection function group
- Starting the Automatic reclosing function (AREC, if available in the Circuit-breaker function group) through the protection functions of the connected Protection function group

Besides the general allocation of the protection function group to the Circuit-breaker function groups, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the protection function group.

In the detail configuration of the interface, you define:

- Which operate indications of the protection functions go into the generation of the trip command
- Which protection functions start the Automatic reclosing function
- Which protection functions start the Circuit-breaker failure protection function

If you are using an application template, the function groups are already connected to each other, because this connection is absolutely essential to ensure proper operation. You can modify the connection in DIGSI 5 via the **Function-group connections** Editor.

For more information, refer to *2.1 Embedding of Functions in the Device*.

If the connection is missing, DIGSI 5 reports an inconsistency.

Protected Object/Equipment Data (FB General)

The rated voltage and rated current as well as the neutral-point treatment of the protected object or the equipment are defined here. These data apply to all functions in the **Voltage-current 3-phase** function group.

Resetting the LED Group

Using the **Reset the LED group** function, you can reset the stored LEDs of the functions in one specific function group while the activated, stored LEDs of other functions in other function groups remain activated.

For more detailed information, refer to *3.1.11 Resetting Stored Indications of the Function Group* .

Process Monitor

The process monitor is always present in the **Voltage-current 3-phase** function group and cannot be removed.

The process monitor provides the following information in the **Voltage-current 3-phase** function group:

- Current-flow criterion:
  Detection of an open/activated protected object/equipment based on the flow of leakage current
- Closure detection:
  Detection of the switching on of the protected object/equipment
- Cold-load pickup detection (optional, only for protection devices):

This information applies to all functions available in the **Voltage-current 3-phase** function group.

The description of the process monitor begins with *5.14 Process Monitor*.

Operational Measured Values

The operational measured values are always present in the **Voltage-current 3-phase** function group and cannot be deleted.

The following table shows the operational measured values of the **Voltage-current 3-phase** function group:

Table 5-18 Operational Measured Values of the Voltage-Current 3-Phase Function Group

Measured Values		Primary	Secon-dary	% Referenced to
I_A, I_B, I_C	Phase currents	A	A	Rated operating current of the primary values
3I0	Calculated zero-sequence current	A	A	Rated operating current of the primary values
I_N	Neutral-point phase current	A	A	Rated operating current of the primary values
I_{NS}	Sensitive ground current	A	mA	Rated operating current of the primary values
V_A, V_B, V_C	Phase-to-ground voltages	kV	V	Rated operating voltage of the primary values/√3
V_{AB}, V_{BC}, V_{CA}	Phase-to-phase voltages	kV	V	Rated operating voltage of the primary values

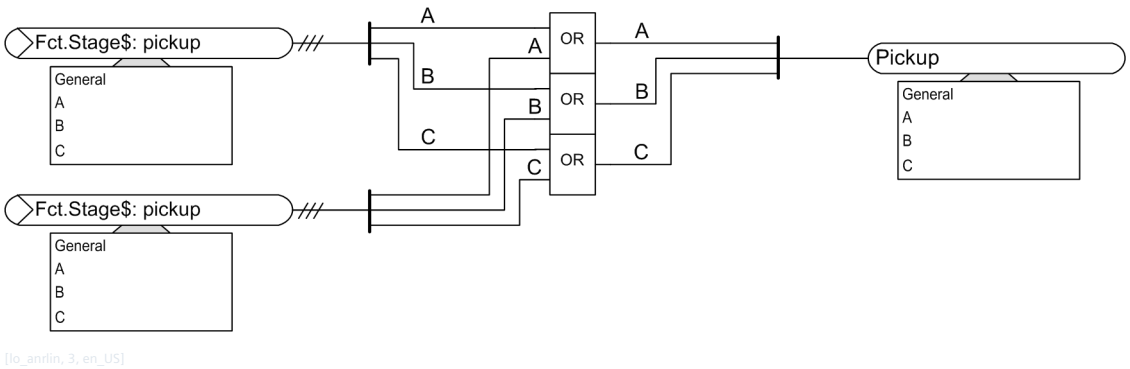
Measured Values		Primary	Secon-dary	% Referenced to
V_0	Zero-sequence voltage	kV	V	Rated operating voltage of the primary values/√3
V_{NG}	Neutral-point displacement voltage	kV	V	Rated operating voltage of the primary values/√3
f	Frequency	Hz	Hz	Rated frequency
P_{total}	Active power (total power)	MW	W	Active power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Q_{total}	Reactive power (total power)	Mvar	var	Reactive power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
S_{total}	Apparent power (total power)	MVA	VA	Apparent power of the primary values $\sqrt{3} \cdot V_{rated} \cdot I_{rated}$
Cos φ	Active factor	(abs)	(abs)	100 % corresponds to cos φ = 1
P_A, P_B, P_C	Phase-related active power	MW	W	Active power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
Q_A, Q_B, Q_C	Phase-related reactive power	Mvar	var	Reactive power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$
S_A, S_B, S_C	Phase-related apparent power	MVA	VA	Apparent power of the phase $V_{rated\ phsx} \cdot I_{rated\ phsx}$

For a more detailed explanation of the operational measured values, refer to *9.3 Operational Measured Values*.

Inversion of Power-Related Measured and Statistical Values (FB General)

The following directional values calculated in operational measured values are defined positively in the direction of the protected object.

- Power
- Active factor
- Energy
- Minimum, maximum values
- Average values

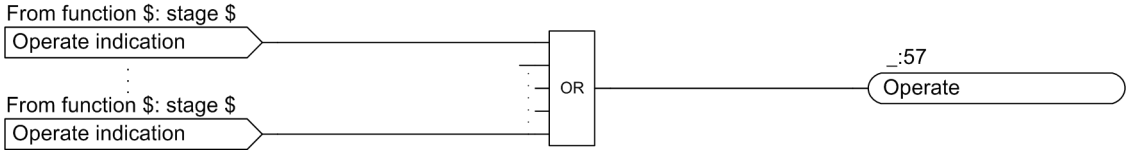


With the parameter **`P, Q sign`**, you can invert the sign of these operational measured values such that a power flow from the line to the busbar is displayed positively.

For more information on this, refer to *9.1 Overview of Functions*.

Output Logic

The output logic treats the pickup and trip signals of the protection and supervision functions that are available in the function group separately, in a pickup logic and a trip logic, respectively. The pickup and trip logic generate the overreaching indications (group indications) of the function group. These group indications are transferred via the **Protection information** interface to the **Circuit-breaker** function group and are processed further there.



The pickup signals of the protection and supervision functions in the **Voltage-current 3-phase** function group are combined in a phase-selective manner and output as a group indication.

[lo_anrlin, 3, en_US]

Figure 5-66 Creation of the Pickup Indication of the Voltage-Current 3-Phase Function Group

The trip signals from the protection and supervision functions of the **Voltage-current 3-phase** function group always result in 3-pole tripping of the device.

[lo_auslin, 3, en_US]

Figure 5-67 Creation of the Operate Indication of the Voltage-Current 3-Phase Function Group

5.8.3 Write-Protected Settings

Parameter: Rated apparent power

- Default setting (_:103) **Rated apparent power** = ***692.82 MVA***

With the parameter **Rated apparent power**, you can set the primary rated apparent power for the auto transformer to be protected. The parameter **Rated apparent power** is relevant for the main protection function of the device. The **Rated apparent power** set here is the reference value for the percentage-measured values and setting values made in percentages.

NOTE

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

The settings listed here are used primarily for understanding during configuration of the function groups. They are calculated on the basis of other settings and cannot be directly changed.

Addr.	Parameters	C	Range of Values	Default Setting
Network data				
_:103	General:rated apparent power		0.20 MVA to 5 000.00 MVA	692.82 MVA

NOTE

For more detailed information on the process monitor, refer to *5.14 Process Monitor*.

5.8.4 Settings

5.9 Function-Group Type Circuit Breaker

5.9.1 Overview

The **Circuit-breaker** function group combines all the user functions that relate to a circuit breaker.

You will find the **Circuit-breaker** function group under each device type in the function library in DIGSI 5. The **Circuit-breaker** function group contains all of the protection, control, and supervision functions that you can use for this device type. The following figure shows, for example, the functional scope of the **Circuit-breaker** function group.

[sc_cb2typ, 1, en_US]

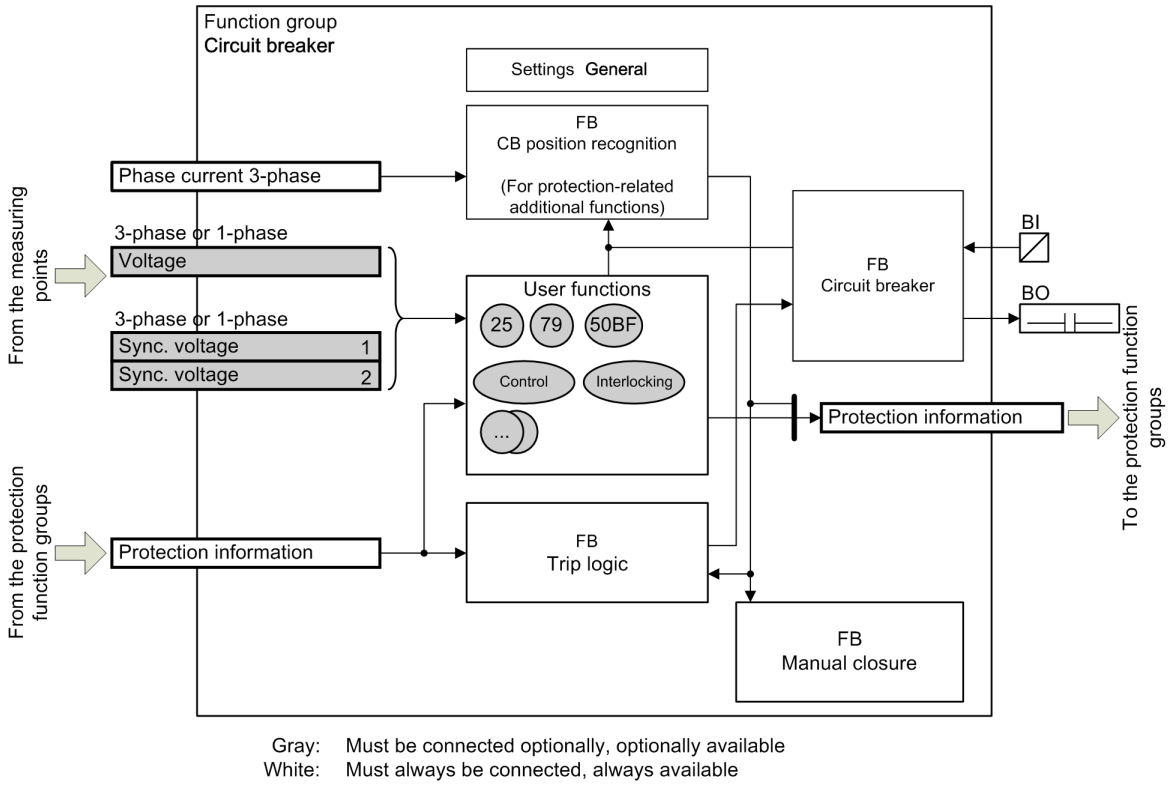
Figure 5-68 Circuit-Breaker Function Group – Example of the Functional Scope

The Circuit-breaker function group includes 2 different types of circuit breakers:

- Circuit breaker
- Circuit breaker [status only]

The type circuit breaker can accept additional basic function blocks for protection functions along with the actual circuit-breaker control.

The type circuit breaker [status only] is used only for acquiring the circuit-breaker switch position. This type can be used to model switches that can only be read but not controlled by the SIPROTEC 5 device.



The available functions are described in *6 Protection and Automation Functions* and *7 Control Functions*.

5.9.2 Structure of the Function Group

Besides the user functions, the **Circuit-breaker** function group contains certain functionalities that are essential for general purposes and therefore cannot be loaded or deleted:

- Trip logic
- Mapping the physical circuit breaker
- Circuit-breaker position recognition for protection functions
- Detection of manual closure
- General settings

The following figure shows the structure of the **Circuit-breaker** function group. The individual function blocks in the image are described in the following chapters.

[dw_fg_stru, 1, en_US]

Figure 5-69 Structure of the Circuit-Breaker Function Group

The **Circuit-breaker** function group has interfaces with:

- Measuring points
- Protection function groups (for example the protection function group **Transformer** or **Auto transformer** as well as side-related function groups)

Interfaces with Measuring Points

The function group contains the measured values needed from the measuring points associated with this function group.

If an application template is used, the function group is connected to the measuring point of the 3-phase current because this connection is essential. It can be necessary to connect additional measuring points to the function group, depending on the nature of the user functions used. The configuration is done via the **Function-group connections** editor in DIGSI 5. You can find more detailed information on this in *2.1 Embedding of Functions in the Device*.

If a user function, for example, synchronization, is used in the function group but the required measuring point has not linked to it, DIGSI 5 reports an inconsistency. This inconsistency provides an indication of the missing measuring-point connection.

The function group **Circuit breaker** has interfaces with the following measuring points:

- **3-phase line current**
  The measurands from the 3-phase current system are supplied via this interface. The function group must always be connected to this measuring point.

- **Voltage**

  The measurands from the 3-phase voltage system are supplied via this interface. Depending on the connection type of the transformers, in the 3-phase voltage system these are, for example, V_A, V_B, V_C of the line or the feeder. The connection of the function group to this measuring point is optional.

- **Sync. Voltage1, Sync. Voltage2**

  A 1-phase synchronization voltage (for example, voltage of the busbar with a 1-phase connection) or a 3-phase synchronization voltage (for example, voltage of the busbar with a 3-phase connection) is supplied via this interface.

  The connection to the corresponding measuring point is necessary only if synchronization is used.

Interface with Protection-Function Groups

All required data are exchanged between the protection function group and the function groups **Circuit breaker** via the interfaces of the function group **Circuit breaker**. This data includes, for example, the pickup and operate indications of the protection functions sent in the direction of the function group circuit-breaker and, for example, the circuit-breaker position information in the direction of the protection function groups.

If an application template is used, the function groups are connected to each other because this connection is essential to ensure proper operation. You can modify the connection using the **Function-group connections** Editor in DIGSI 5.

You can find more detailed information in *2.1 Embedding of Functions in the Device*.

If the linkage is missing, DIGSI 5 reports an inconsistency.

Besides the general assignments of the protection function group or groups to the Circuit-breaker function groups, you can also configure the interface for certain functionalities in detail:

- Which operate indications of the protection functions are included when the trip command is generated?
- Which protection functions activate the **Automatic reclosing** function?
- Which protection functions activate the **Circuit-breaker failure protection** function?

You can find more detailed information in *2.1 Embedding of Functions in the Device*.

5.9.3 Application and Setting Notes

Interface with Measuring Points

The interface with the 3-phase current system must have been configured. Otherwise, DIGSI 5 supplies an inconsistency message.

If the function **Synchronization** is used, the measuring points that represent voltages V1 and V2 of the power-supply units to be synchronized must be connected.

For further information refer to *7.5 Synchronization Function*.

The function **Automatic reclosing** provides the auxiliary functions **Dead-line check** and **Reduced dead time**. For these auxiliary functions, the 3-phase voltage system has to be measured. If you want to use these auxiliary functions, the measuring point of the 3-phase voltage system must be connected to the function-group interface **Voltage**. This connection is also necessary if the function type **Automatic reclosing function with adaptive dead time** is used.

Interface with Protection-Function Groups

The protection-function group **Transformer** is connected to 2 circuit breakers (2 function groups **Circuit breaker**) for 1 1/2 circuit-breaker layouts.

Parameter: I Reference for % Values

- Default setting **(_:2311:101) Rated normal current** = ***1000.00 A***

With the parameter **Rated normal current**, you set the primary current, which serves as a reference for all current-related % values within the function group Circuit breaker. This applies both for operational measured values and for setting values in %.

Enter the primary rated current of the protected object (for example, the transformer) here.

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: V Reference for % Values

- Default setting **(_:2311:102) Rated voltage** = ***400.00 kV***

With the parameter **Rated voltage**, you set the primary voltage, which serves as a reference for all voltage-related % values within the function group Circuit breaker. This applies both for operational measured values and for setting values in %.

Enter the primary rated voltage of the protected object (for example, the line) here.

If the device works with the IEC 61850 protocol, then you change the setting value of the parameter only via DIGSI 5 and not directly on the device. If you change the setting value directly on the device, then the IEC 61850 configuration of the metered values can be faulty.

Parameter: Current Threshold Circuit Breaker Open

- Default setting **(_:2311:112) Current thresh. CB open** = ***0.10 A***

With the parameter **Current thresh. CB open**, you specify the current threshold below which the circuit-breaker pole or the circuit breaker is recognized as open.

Set the parameter **Current thresh. CB open** so that the current measured when the circuit-breaker pole is open will certainly fall below the parameterized value. If parasitic currents (for example, due to induction) are excluded with the line deactivated, you can make a secondary setting of the value with a high degree of sensitivity, to ***0.05 A*** for example.

If no special requirements exist, Siemens recommends retaining the setting value of ***0.10 A*** for secondary purposes.

5.9.4 Settings

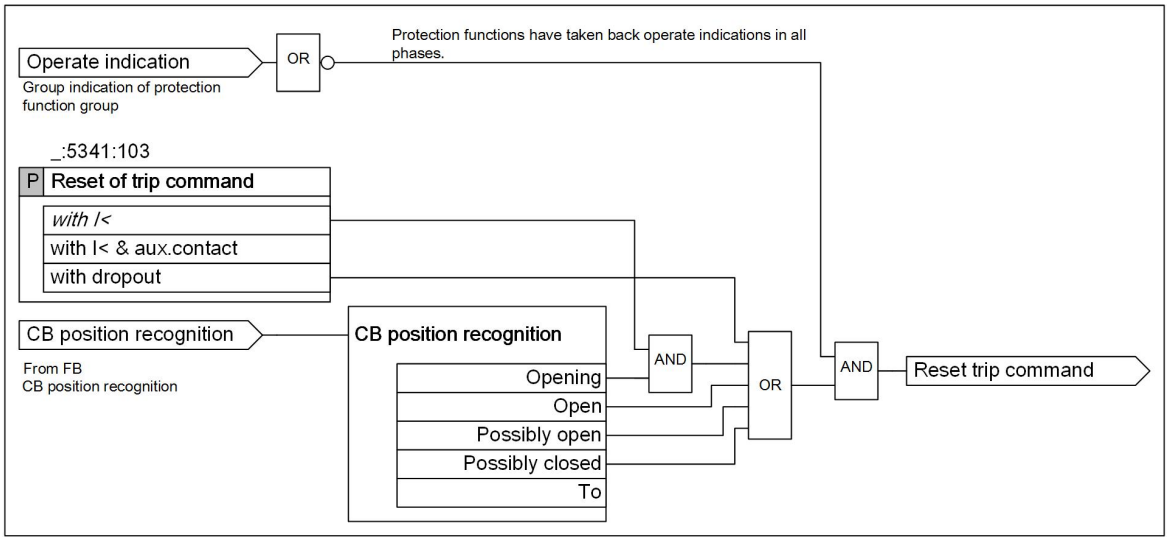
5.9.6 Trip Logic

5.9.6.1 Function Description

The **Trip logic** function block receives the group operate indication from the Protection function group or Protection function groups and forms the protection trip command that is transmitted to the **Circuit-breaker** function block.

The **Circuit-breaker** function block activates the device contact and thus causes the circuit breaker to open (see *5.9.7 Circuit Breaker*). The command output time is also effective here.



The trip logic also decides when the protection trip command is reset (see *Figure 5-71*).

[lo_ausbef, 1, en_US]

Figure 5-70 Trip Command

Trip-Command Reset

[lo_befe3p, 1, en_US]

Figure 5-71 Trip-Command Reset

Once a trip command is issued, it is stored (see *Figure 5-70*).

You determine the criteria for resetting a trip command that has been issued with the parameter **`Reset of trip command`**. The following setting options are possible:

- **`with dropout`**
  If the function that initiated tripping resets its operate indication the trip command is reset. This occurs typically with dropout. Command reset of the trip command takes place regardless of verification of the circuit-breaker condition.
- **`with I<`**
- **`with I< & aux.contact`**
  For these criteria, the state of the circuit breaker is also taken into account as a further criterion in addition to the dropout of the tripping function (operate indication is reset by command). You can select whether the state is determined by means of the current (**`with I<`**) or by means of the current in conjunction with the circuit-breaker auxiliary contacts (**`with I< & aux.contact`**). The behavior of these setting options only differs in one situation of the circuit-breaker state. If the circuit breaker is in the **opening** state, the trip command is reset in the case of the option **`with I<`**, whereas it is not reset yet in the case of the option with **`with I< & aux.contact`**. The **opening** state is detected if the auxiliary contacts still detect the circuit breaker as being closed and opening is detected via the decreasing current flow.
  As long as the circuit breaker is detected unambiguously as closed (**fully closed**), the trip command will not be reset with these setting options.
  The information about the condition of the circuit breaker and the determination of the various conditions is supplied by the **Circuit-breaker position recognition** function block. You can find further information in chapter *5.9.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions*.

5.9.6.2 Application and Setting Notes

Parameter: Reset of trip command

- Recommended setting value **(_:5341:103) Reset of trip command** = ***with I<***

Parameter Value	Description
with I<	The trip command is reset under the following conditions: • Dropout of the tripping function • The current falls short of the value set in the parameter **(_:2311:112) Current thresh. CB open**
with I< & aux.contact	The trip command is reset under the following conditions: • The current falls short of the value set in the parameter **(_:2311:112) Current thresh. CB open** • The circuit-breaker auxiliary contact reports that the circuit breaker is open. This setting assumes that the setting of the auxiliary contact has been routed via a binary input (for more information, see *5.9.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information*).
with dropout	If the load current in the system cannot be interrupted during the protection device test and the test current is fed in parallel with the load current this setting is useful. The setting can be selected for special applications in which the trip command does not result in complete interruption of the current in every case. In this case, the trip command is reset if the pickup of the tripping protection function drops out.

5.9.7 Circuit Breaker

5.9.7.1 Overview

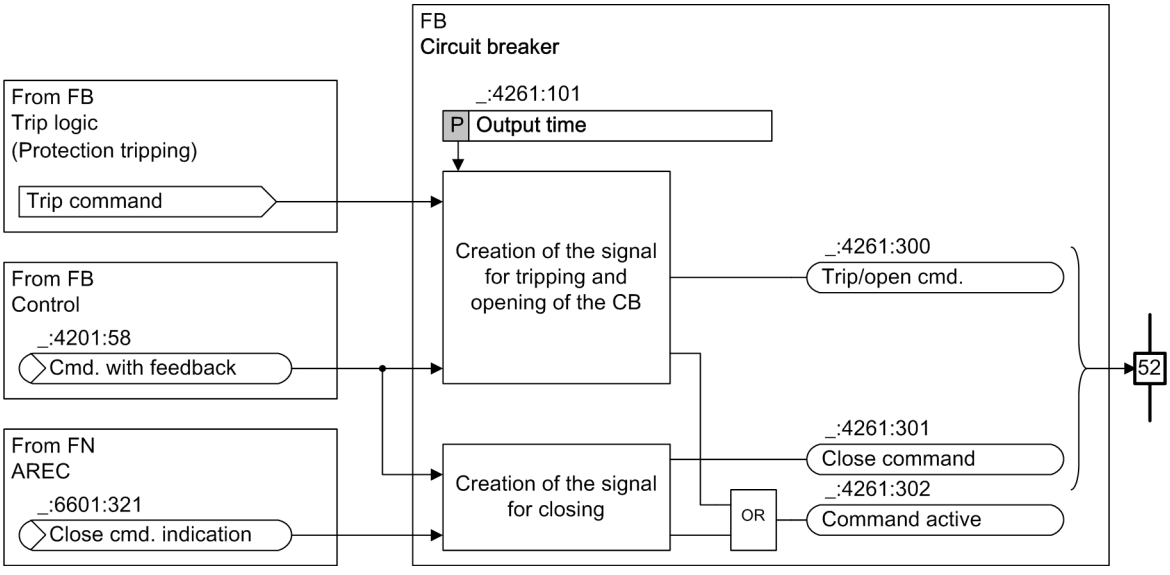
The function block **Circuit breaker** represents the physical switch in the SIPROTEC 5 device.

The basic tasks of this function block are:

- Operation of the circuit breaker (CB)
- Acquisition of the circuit-breaker auxiliary contacts
- Acquisition of other circuit-breaker information

The function block **Circuit breaker** provides the following information:

- Number of switching cycles
- Breaking current, breaking voltage, and breaking frequency
- Summation breaking current



5.9.7.2 Tripping, Opening and Closing the Circuit Breaker

The circuit breaker is operated in the following situations:

- Tripping of the circuit breaker as a result of a protection trip command
- Opening of the circuit breaker as a result of control operations
- Closing of the circuit breaker as a result of an automatic reclosing or of control operations

Tripping is always the result of a protection function. The operate indications of the individual protection functions are summarized in the **Trip logic** function block. The trip command that causes the tripping in the function block **Circuit breaker** is generated there.

For the operational handling of the circuit breaker, the function block **Circuit breaker** provides the output signals that must be routed to the corresponding binary outputs of the device (see *Table 5-19*).

[lo_ausssc, 1, en_US]

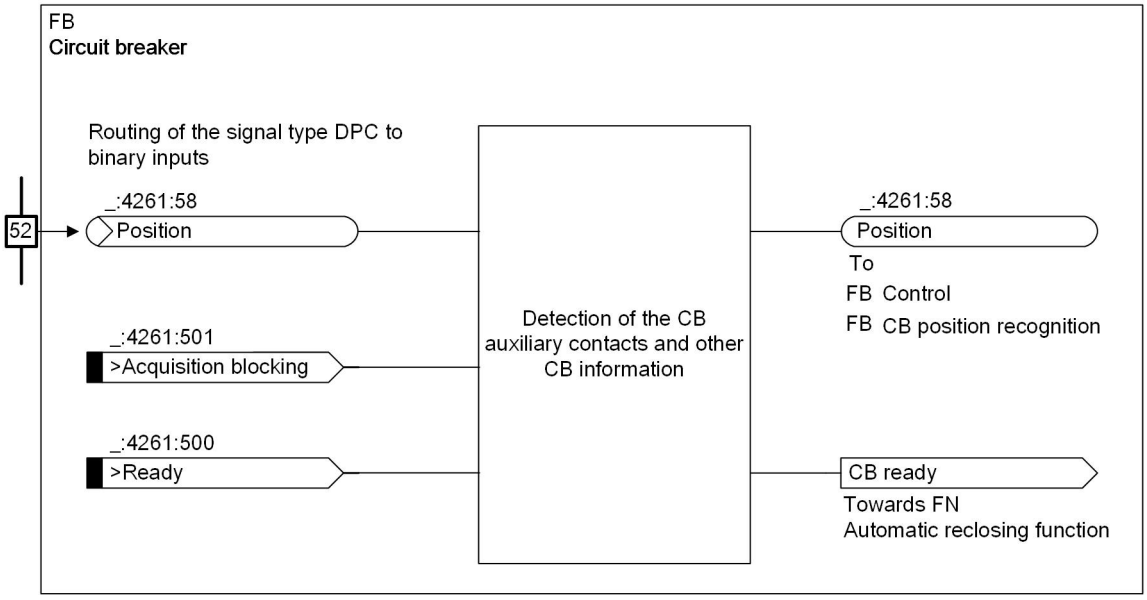


Figure 5-72 Tripping, Opening, and Closing the Circuit Breaker

Table 5-19 Description of the Output Signals

Signal	Description	Routing Options
Trip/open cmd.	This signal executes all tripping and opening operations. The **Output time** parameter affects the signal. The signal is pending for the duration of the output time, with the following exceptions: • **Only when switched off by the control:** The signal is reset before expiration of the period if the auxiliary contacts report that the circuit breaker is open before expiration of the period. • **Only in the event of protection tripping:** – The signal remains active as long as the trip command is still active after expiration of the period (see also *5.9.6.1 Function Description*). If the trip signal is no longer active and the auxiliary contacts report that the circuit breaker is open before expiration of the period, the signal is canceled before expiration of the period. – With the routing option **Only saved in the event of tripping**, the signal remains pending until it is acknowledged manually. This only applies for protection tripping.	• Unlatched • Only saved in the event of protection tripping (not when opened)
Close command	This signal executes all closing operations. The **Output time** parameter affects the signal. The signal is pending for the duration of the output time, with the following exception: The signal is canceled before expiration of the period if the auxiliary contacts report that the circuit breaker is closed before expiration of the period.	Normal routing
Command active	This signal is active if one of the following binary outputs is active: • **Trip/open cmd.** • **Close command** The binary outputs are active as long as a switching command is being executed by the control.	Normal routing

5.9.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information

To determine the circuit-breaker position, the function block **Circuit breaker** provides position signals. These signals are of the **Double-point indication** (DPC) type. A double-point indication can be routed to 2 binary inputs so that the open and closed circuit-breaker switch positions can be reliably acquired.

[lo_erfass, 2, en_US]

Figure 5-73 Acquisition of the Circuit-Breaker Information

Signal	Type	Description
Position	DPC	Acquisition of the circuit-breaker switch position The switch position CB 3-pole **open** and/or the position CB 3-pole **closed** can be detected by routing to 1 or 2 binary inputs.

The signals must be routed to the binary input that is with the CB auxiliary contacts. The **open** and **closed** signals do not necessarily have to be routed in parallel. The advantage of parallel routing is that it can be used to determine an intermediate or disturbed position. If you route only one signal (**open** or **closed**), you cannot determine an intermediate position or a disturbed position.

In the monitoring direction, the position signals generate the following information when the **open** and **closed** positions are detected (see following table). This information is further processed by the **Circuit-breaker position recognition** and **Control** function blocks.

Information	Type	Description
Open	SPS	The circuit-breaker switch position is **opened**.
Closed	SPS	The circuit-breaker switch position is **closed**.
Intermediate position	SPS	The circuit-breaker switch position is in the **intermediate position**. The signal **open** and the signal **closed** have not been set.
Disturbed position	SPS	The circuit-breaker switch position is in the **disturbed position**. The signal **open** and the signal **closed** have been set simultaneously.
Not selected	SPS	The circuit breaker is **not selected** for a control operation.

The following table shows the additional input signals:

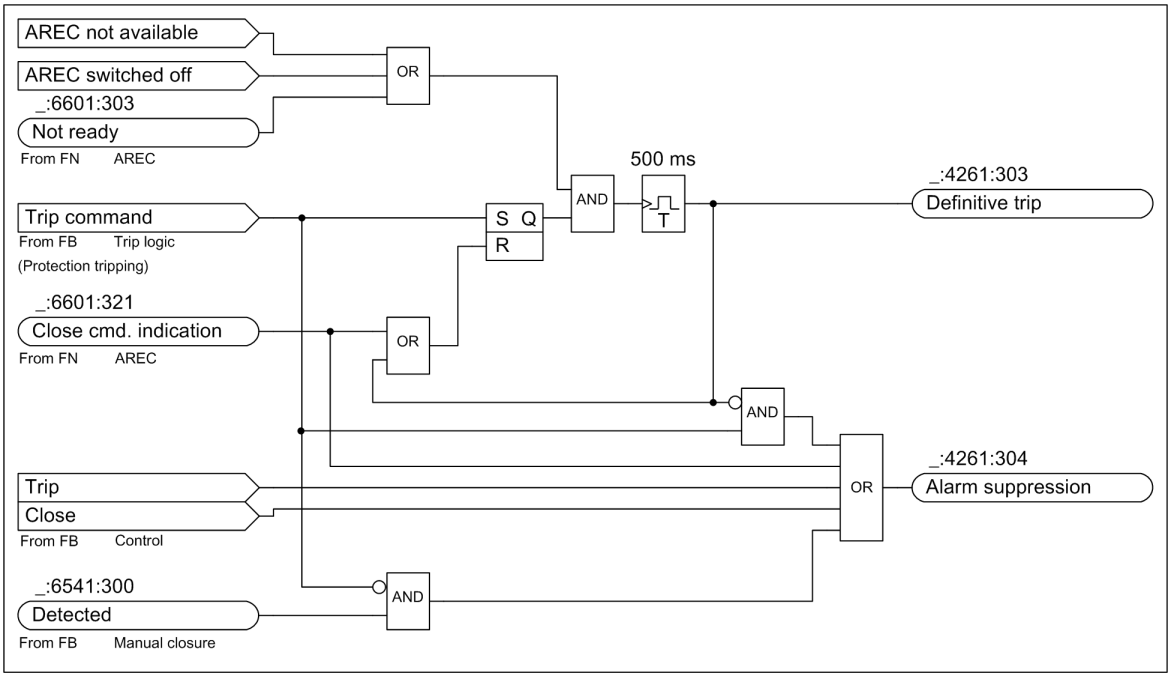
Signal	Type	Description
>Acquisition blocking	SPS	This is used to activate acquisition blocking of the circuit-breaker auxiliary contacts (see *Other Functions 3.9.3 Persistent Commands* for a description of acquisition blocking).
>Reset AcqBlk&Subst	SPS	This is used to reset acquisition blocking and manual update of the circuit breaker. If the signal is active, acquisition blocking and manual update are reset.
>Ready	SPS	The active signal indicates that the circuit breaker is ready for an **Open-Closed-Open** cycle. The signal remains active as long as the circuit breaker is unable to trip. The signal is used in the **Automatic reclosing** and **Circuit-breaker test** functions.

The following table shows one additional output signal:

Signal	Type	Description
External health	ENS	This can be used to indicate the health of the physical circuit breaker. For this, all failure information of the circuit breaker must be detected via a binary input. This failure information can set the appropriate state of the **External health** signal with a CFC chart (using the **BUILD_ENS** block). The signal has no effect on the health of the function block.

5.9.7.4 Circuit-Breaker Tripping Alarm Suppression

Circuit-Breaker Tripping Alarm Suppression



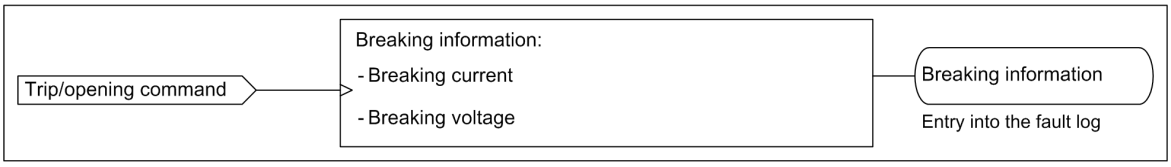
In certain systems, the user may wish to actuate an alarm (for example, a horn) when tripping (circuit-breaker tripping) occurs. This alarm should not be issued if it is to be reclosed automatically after tripping, or if it is to be closed or opened via the control. The alarm is only to be issued in the event of definitive tripping.

Depending on how the alarm is generated (for example, triggered by a fleeting contact of the circuit breaker), the *Alarm suppression* signal can be used to suppress the alarm.

If one of the following conditions is met, the *Alarm suppression* signal is generated:

- The definitive protection tripping is not present.
- The integrated automatic reclosing function executes a closure.
- The integrated control executes a closure or opening action.
- The function **Manual close** detects an external closing.

For further information about its use, refer to *5.9.9.2 Application and Setting Notes*.

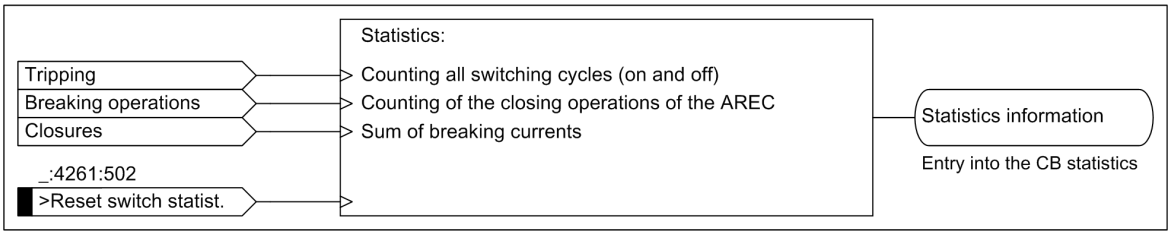


[lo_unterd, 2, en_US]

Figure 5-74 Definitive Tripping and Circuit-Breaker Tripping Alarm Suppression

5.9.7.5 Tripping and Opening Information

When a trip or opening command is issued, the breaking information shown in the next figure is saved in the fault log.



[lo_ausloe, 2, en_US]

Figure 5-75 Breaking Information

The following statistics information is saved for the circuit breaker:

- Number of switching cycles:
  All tripping, opening, and closing operations are counted.
- Number of closing operations by the automatic reclosing function
- Total of breaking currents

The statistics information can be individually set and reset via the device control. It is also possible to reset all values via the binary input signal **`>Reset switch statist.`**.

[lo_statistics information circuit-breaker, 2, en_US]

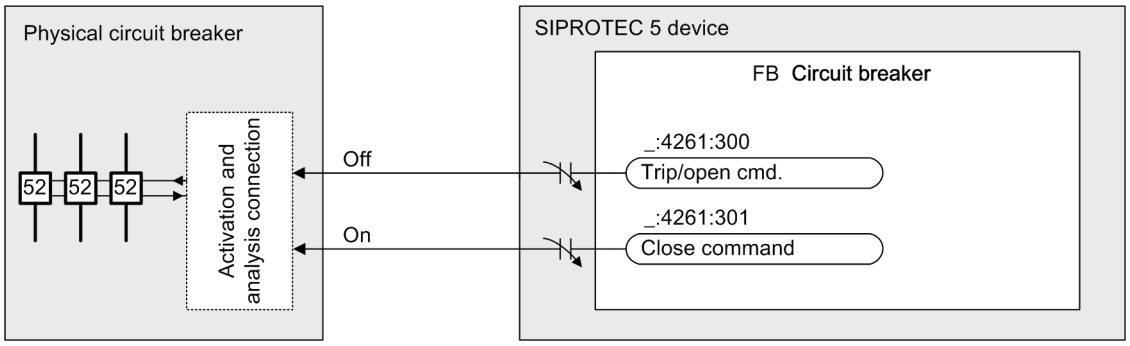


Figure 5-76 Statistics Information About the Circuit Breaker

5.9.7.6 Application and Setting Notes

Routings for Activation of the Circuit Breaker

Figure 5-77 shows the necessary routings for the device:

- 3-pole tripping via the protection
- 3-pole opening via the control

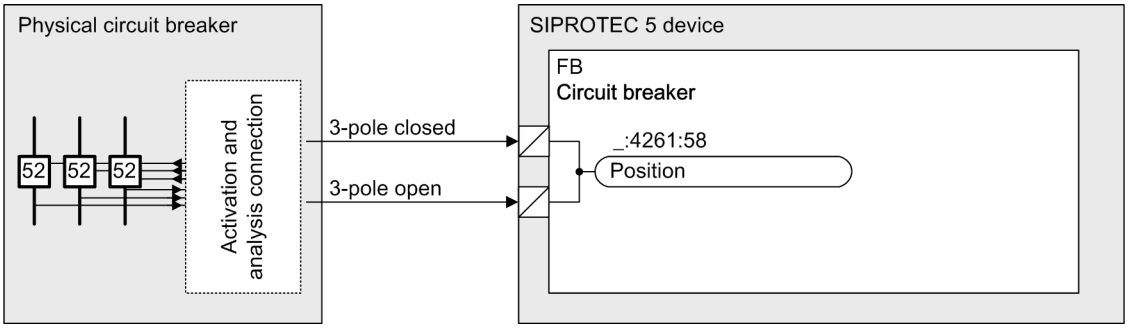
[lo_ansteu, 2, en_US]

Figure 5-77 Activation of the Circuit Breaker

By routing the **`Trip/open cmd.`** signals to 1 or 2 binary outputs, you can carry out 1-pole, 1.5-pole, and 2-pole activations of the circuit breaker. You can find a detailed description of this in chapter *7.2.2.3 Connection Variants of the Circuit Breaker*.

NOTE

Do not confuse these 1-pole, 1.5-pole, and 2-pole activations of the circuit breaker with 1-pole or 3-pole tripping of the circuit breaker.

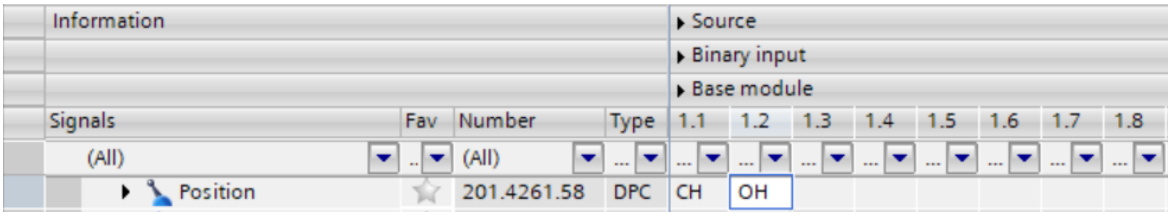


Routing to Evaluate the Circuit-Breaker Switch Position

For certain functions of the device, it is useful to detect the circuit-breaker switch position via its auxiliary contacts. The following shows a number of examples:

- **Circuit-breaker position recognition** function block
- **Circuit-breaker failure protection** function
- **Control** function block

The operating principle of the auxiliary contacts is described in the individual functions.



Siemens recommends capturing the information *`Circuit breaker is open in 3 poles`* and *`Circuit breaker is closed in 3 poles`* via auxiliary contacts. This is the optimal configuration for the control functionality. For purely protection applications, it is also sufficient to acquire just one of the 2 circuit-breaker switch positions. When used as a protection and control device, Siemens recommends the following evaluation of the circuit-breaker switch position:

[lo_evaluation2, 1, en_US]

Figure 5-78 Recommended Evaluation of the Circuit-Breaker Switch Position

The following diagram shows the recommended routing, in which **OH** stands for **active with voltage**.

[sc_polg3p, 1, en_US]

Figure 5-79 Routing for Acquisition of the Circuit-Breaker Switch Position via 2 Auxiliary Contacts

The device can also function without the analysis from the circuit-breaker auxiliary contacts, that is, routing of the auxiliary contacts is not absolutely necessary. However, this is a requirement for control functions.

Parameter: Output Time

- Default setting **(_:101) Output time** = ***0.10 s***

The **Output time** parameter acts on the signals for tripping, opening, and closing of the circuit breaker.

CAUTION

Do not set a time that is too short.

If you set a time that is too short, there is a danger that the device contacts will interrupt the control circuit. If this happens, the device contacts will burn out.

✧ Set a time that is long enough to ensure that the circuit breaker reliably reaches its final position (**open** or **closed**) after a control operation.

Parameter: Indicat. of breaking values

- Default setting **(_:105) Indicat. of breaking values** = ***always***

With the parameter **Indicat. of breaking values**, you specify whether the measured values are to be reported if the circuit breaker is opened via the control function.

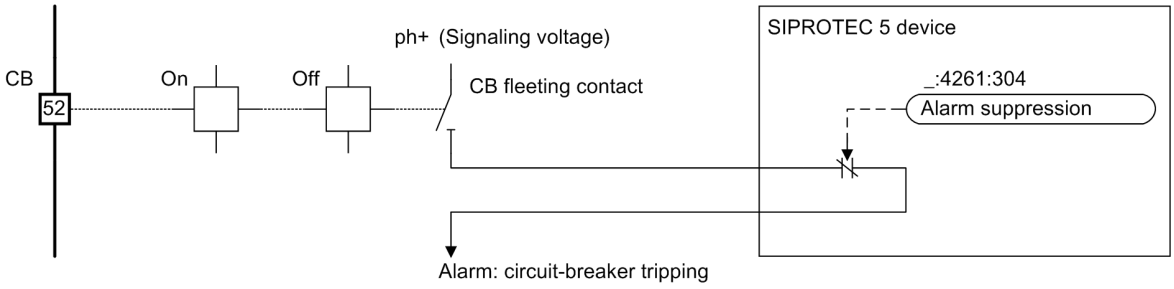
Parameter Value	Description
always	With this setting, the measured values are reported if the circuit breaker is opened either via the control function or via the trip command of a protection function.
with trip	With this setting, the measured values are only reported if the circuit breaker is opened via the trip command of a protection function.

Measured Values

When a protection function opens the circuit breaker, the following measured values can be stored in the fault log:

- *Break.-current phs A*
- *Break.-current phs B*
- *Break.-current phs C*
- *Break. current 3I0/IN*
- *Break. voltage phs A*
- *Break. voltage phs B*
- *Break. voltage phs C*

The measured value *Break. current 3I0/IN* is the neutral-point current. Dependent on the connection type of the **measuring point I-3ph** that is connected with the function group **Circuit breaker**, the neutral-point current differs as follows:



Connection Type of the Measuring Point I-3ph	Neutral-Point Current
3-phase	Calculated zero-sequence current $3I_0$
3-phase + IN 3-phase + IN-separate 3ph,2prim.CT + IN-sep 2ph, 2p. CT + IN-sep	Measured neutral-point current I_N If the secondary ground current exceeds the linear section of the sensitive measuring input (1.6 Irated) with sensitive current transformers, the neutral-point current of the measured I_N is switched to the calculated $3I_0$.

Output Signal: Indication Suppression

Whereas in the case of feeders without an automatic reclosing function every trip command is final due to a protection function, the use of an automatic reclosing function should only cause the motion detector of the circuit breaker (fleeting contact on the circuit breaker) to trigger an alarm if tripping of the circuit breaker is definitive (see next figure for more details). Likewise, a tripping alarm should not be triggered for switching operations by the control.

For this, the alarm activation circuit should be looped via a suitably routed output contact of the device (output signal **Alarm suppression**). In the idle state and when the device is switched off, this contact is always closed. For this, an output contact with a break contact must be routed. The contact opens whenever the output signal **Alarm suppression** becomes active, so that tripping or a switching operation does not cause an alarm.

You can find more detailed information in the logic in *5.9.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information*.

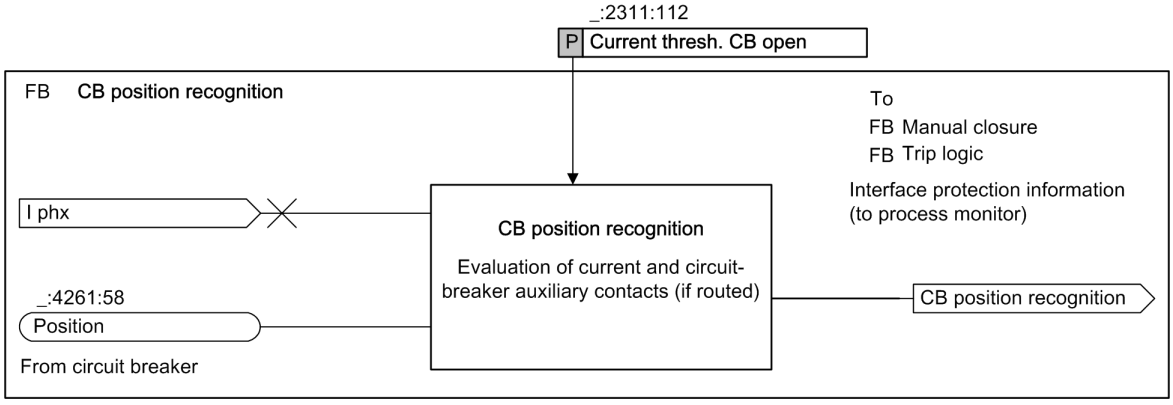
5.9.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions

5.9.8.1 Overview



This function block calculates the position of the circuit breaker from the evaluation of the auxiliary contacts and the current flow.

This information is needed in the following protection-related additional functions:

- Trip logic (see *5.9.6.1 Function Description*)
- Detection of manual closing (see *5.9.9.1 Function Description*)
- Process monitor (see Process monitor (Line Function group) *5.5.4 Process Monitor (FG Line)* or Process monitor (Standard V/I) *5.14 Process Monitor*)

The specified chapters describe the way the protection-related additional functions are processing the information of this function block.

The control does not use this information. The control evaluates the circuit-breaker auxiliary contacts.

[lo_zust3p, 1, en_US]

Figure 5-81 Overview of the Circuit-Breaker Condition Position Function

Based on the link between the information from the auxiliary contacts and the current flow, shown in *Figure 5-81*, the circuit breaker can assume the following positions. The following table shows the possible circuit-breaker conditions:

Circuit-Breaker Condition	Description
Open	The circuit-breaker pole is detected unambiguously as ***open*** according to both criteria.
Closed	The circuit-breaker pole is detected unambiguously as ***closed*** according to both criteria.
Possibly open, possibly closed	These conditions can occur if the information is incomplete due to the routing of the auxiliary contacts and the condition can no longer be determined reliably. These ***uncertain conditions*** are evaluated differently by certain functions.
Opening	This is a dynamically occurring condition that results when, while a trip command is active and the auxiliary contact is still closed, the current is detected to have fallen below the threshold value. The reason for that is that the current-flow criterion takes effect faster than the auxiliary contact can open.

5.9.9 Detection Manual Closure (for AREC and Process Monitor)

5.9.9.1 Function Description

Detection of Manual Closure (for Process Monitor)

The **Manual closure** function block detects any closure carried out by hand. This information is used in the **Process monitor** functions (within protection function groups).

The following figure shows the logic for manual closure detection.

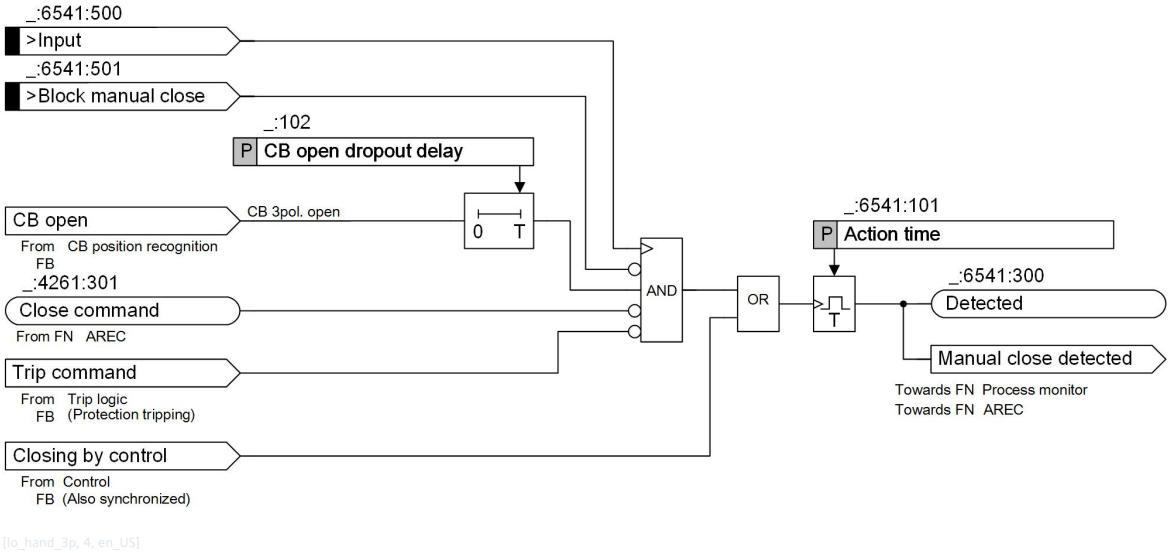


Figure 5-82 Logic for Manual Closure Detection

External Manual Closure

An external manual closure is communicated to the device via the input signal **>Input**. The input signal can also be connected directly to the control circuit of the circuit-breaker closing coil. Detection via the input signal **>Input** is also blocked if the circuit breaker is closed or if a protection trip is active.

Internal Manual Closure

Manual closure is detected in all cases if a close command is transmitted by the internal control function of the device. This is possible because the control carries out plausibility checks itself and is also subject to interlocking.

5.9.9.2 Application and Setting Notes

Input Signals: >Input, >Blocking of Manual Closure

In practice, the input signal **>Input** is connected directly to the control circuit of the circuit-breaker closing coil (see following figure).

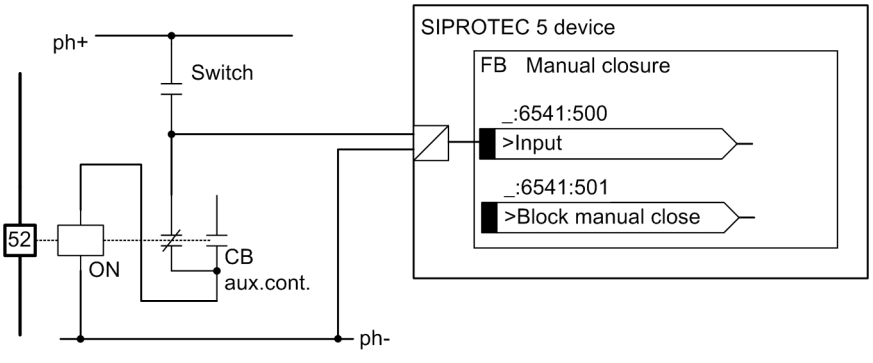

Figure 5-83 Connection of the Input Signal to the Control Circuit of the Circuit-Breaker Closing Coil

Every closure of the circuit breaker is recorded in the process.

If external close commands are possible (actuation of the circuit breaker by other devices), which are not intended to promptly detect a manual closure, this can be ensured in 2 ways:

- The input signal is connected in such a way that it is not activated in the event of external close commands.
- The external close command is connected to the blocking input **>Block manual close** for manual closure detection.

Parameter: Action time

- Recommended setting value **(_:101) Action time** = ***0.30 s***

In order to ensure independence from manual activation of the input signal, the detection function is extended for a defined length of time using the parameter **Action time**.

Siemens recommends an action time of ***0.30 s***.

Parameter: CB open dropout delay

- Default setting **(_:102) CB open dropout delay** = ***0.00 s***

With the **CB open dropout delay** parameter, you can maintain the effectiveness of internal indication *CB open* for the set time. If the input signal **>Input** becomes active after external delayed manual closure, the indication *(_:300) Detected* is output as long as the dropout delay is effective.

5.9.9.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting

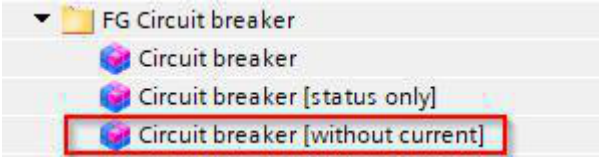
5.10 Function-Group Type Circuit Breaker [without Current]



5.10.1 Overview

The function group **Circuit breaker [without current]** is a circuit-breaker function group that does not measure the primary current of the circuit breaker. For the applications that do not need to monitor the current information of circuit breakers, the function group **Circuit breaker [without current]** is a good option.

The function group **Circuit breaker [without current]** is also suitable for sending tripping signals to external equipment, for example, excitation system, turbine controller, and transformer fire-fighting system.

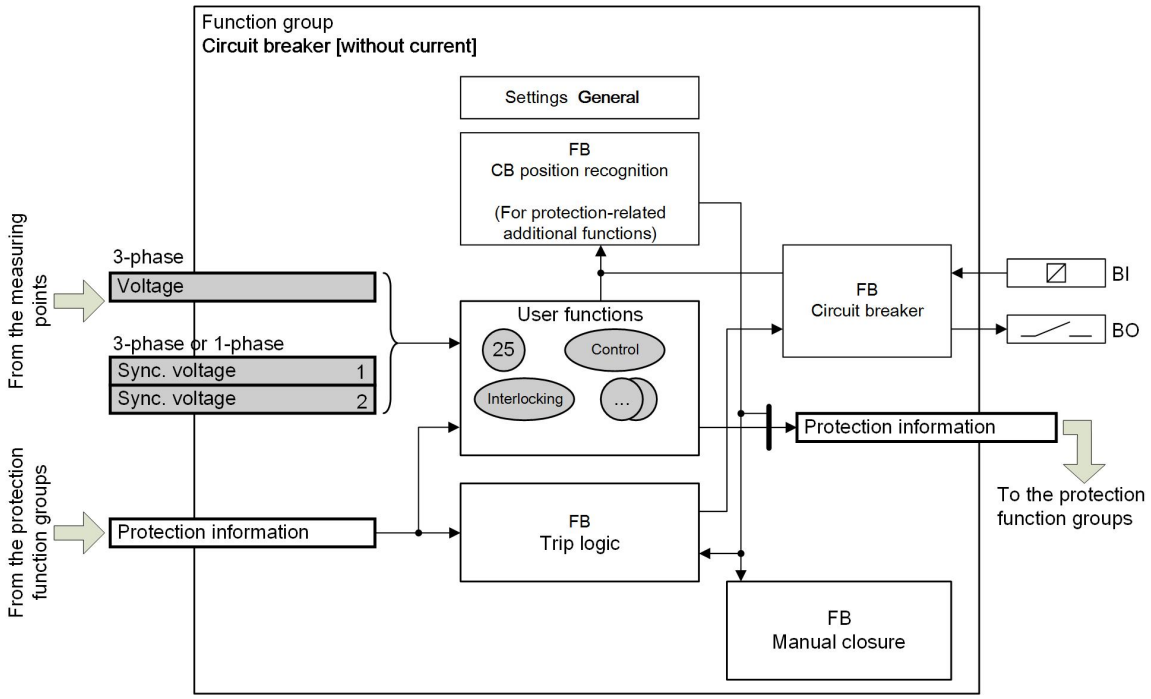
The advantage of the function group **Circuit breaker [without current]** is the usage with the matrix **Circuit-breaker interaction**. You can easily create a tripping concept for the unit protection.

You can find the function group **Circuit breaker [without current]** under the device types in the Global DIGSI 5 Library.

[sc_fg cb without I_7ut_7um, 1, en_US]

Figure 5-84 Function Group Circuit Breaker [without Current]

The following functions are available in the function group **Circuit breaker [without current]**:



- Circuit-breaker control
- Circuit-breaker interlocking
- Circuit-breaker test
- Synchronization
- External synchronization
- Trip-circuit supervision
- Closing-circuit supervision
- Voltage measuring-point selection

5.10.2 Structure of the Function Group

Besides the user functions, the function group **Circuit breaker [without current]** contains certain functionalities that are essential for general purposes. These functionalities cannot be loaded or deleted:

- Trip logic
- Mapping the physical circuit breaker
- Circuit-breaker position recognition for protection functions
- Detection of manual closure
- General settings

The following figure shows the structure of the function group **Circuit breaker [without current]**. The individual function blocks in the figure are described in the following chapters.

[dw_fg_stru, 1, en_US]

Figure 5-85 Structure of the Function-Group Type Circuit breaker [without current]

Gray: Optionally connected

The function group **Circuit breaker [without current]** has interfaces with the following items:

- Measuring points
- Function groups

Interfaces with Measuring Points

The function group receives the required measured values from the measuring points which are connected to this function group.

If a user function, for example, the function **Synchronization**, is used in the function group, but the required measuring point is not linked to the function group, DIGSI 5 reports an inconsistency. This inconsistency provides an indication of the missing measuring-point connection.

The function group **Circuit breaker [without current]** has interfaces with the following measuring points:

- **3-phase voltage**

  The measurands of the 3-phase voltage system are supplied via this interface. The voltages are different due to the different connection types of the voltage transformers, for example, V_A, V_B, and V_C in one 3-phase voltage system, but V_{AB}, V_{BC}, and V_{CA} in another 3-phase voltage system.

  The connection to the corresponding measuring point is necessary only if a function that needs the measurand of the 3-phase voltage system is used.

- **Sync. voltage1, Sync. voltage2**

  A 1-phase synchronization voltage (for example, voltage of the busbar with a 1-phase connection) or a 3-phase synchronization voltage (for example, voltage of the busbar with a 3-phase connection) is supplied via this interface.

  The connection to the corresponding measuring point is necessary only if the function **Synchronization** is used.

Interface with Function Groups

All required data is exchanged between the function group **Circuit breaker [without current]** and the other function groups via the interfaces of the function group **Circuit breaker [without current]**. This data includes, for example, the circuit-breaker position information in the direction of the other function groups.

If an application template is used, the function groups are connected to each other because this connection is essential to ensure proper operation. You can modify the connection using the Editor **Function-group connections** in DIGSI 5. If the connection is missing, DIGSI 5 reports an inconsistency.

Besides the general assignments of other function groups to the circuit-breaker function groups, you can assign the protection functions to the desired circuit-breaker function groups for the tripping operation in the Editor **Circuit-breaker interaction** under the corresponding protection function group.

For more information, refer to *2.1 Embedding of Functions in the Device*.

5.10.3 Application and Setting Notes

Interface with Measuring Points

If the function **Synchronization** is used, the measuring points that represent voltages V1 and V2 of the parts of the electrical power systems to be synchronized must be connected.

You can find more detailed information in *7.5 Synchronization Function*.

Parameter: `Rated voltage`

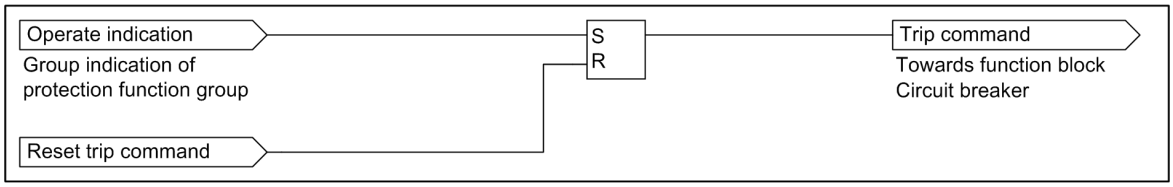
- Default setting `(_:2311:102) Rated voltage` = ***400.00 kV***

With the parameter **`Rated voltage`**, you set the primary rated voltage of the protected object. The primary rated voltage serves as a reference for all voltage-related % values within the function group **Circuit breaker [without current]**. This setting applies both for the operational measured values and for the setting values in %.

If the device works with the IEC 61850 protocol, you can only change the setting value of the parameter via DIGSI 5. If you change the setting value directly on the device, the IEC 61850 configuration of the metered values can be faulty.

5.10.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Ref. for %-values				
_:2311:102	General:Rated voltage		0.10 kV to 1200.00 kV	400.00 kV

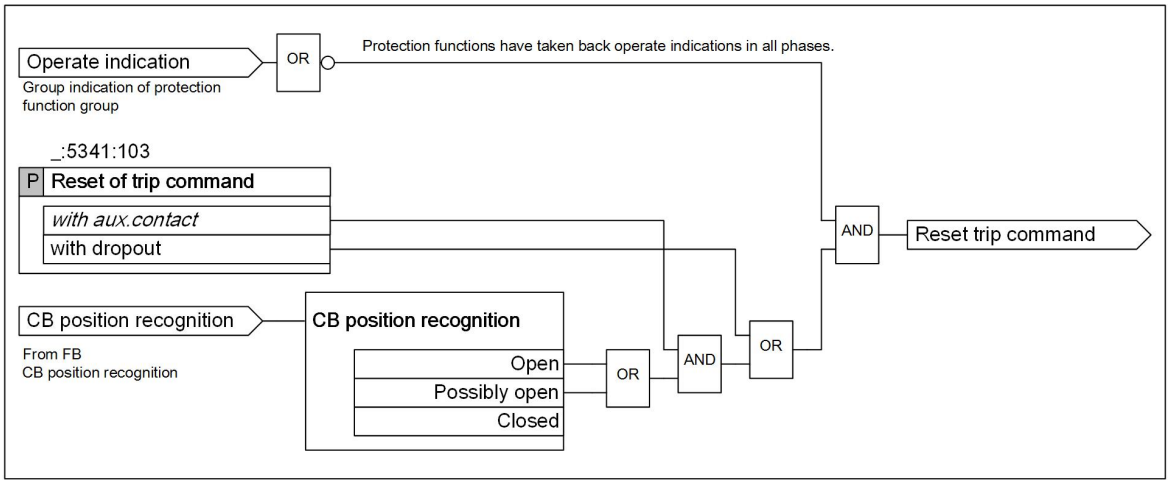


5.10.5 Trip Logic

5.10.5.1 Function Description

The **Trip logic** function block receives the operate group indication from the protection function groups and forms the protection trip command that is transmitted to the **Circuit-breaker** function block.

The **Circuit-breaker** function block activates the device contact and thus causes the circuit breaker to open (see *5.9.7 Circuit Breaker*). The command output time is also effective here.



The trip logic also decides when the protection trip command is reset (see *Figure 5-87*).

[lo_ausbef, 1, en_US]

Figure 5-86 Trip Command

Trip-Command Reset

[lo_befe3p_4CB_without_I, 1, en_US]

Figure 5-87 Trip-Command Reset

Once a trip command is issued, it is stored (see *Figure 5-86*).

You determine the criteria for resetting a trip command that has been issued with the parameter **Reset of trip command**. The following setting options are possible:

- ***with dropout***

  If the function that initiated tripping resets its operate indication the trip command is reset. This occurs typically with dropout. Command reset of the trip command takes place regardless of verification of the circuit-breaker condition.

- ***with aux.contact***

  For this criteria, the state of the circuit breaker is also taken into account as a further criterion in addition to the dropout of the tripping function (operate indication is reset). The state is determined by the circuit-breaker auxiliary contacts (***with aux.contact***).

  As long as the circuit breaker is detected unambiguously as closed (**fully closed**), the trip command will not be reset with this setting option.

  The information about the condition of the circuit breaker and the determination of the various conditions is supplied by the **Circuit-breaker position recognition** function block. You can find further information in chapter *5.9.8 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions*.

5.10.5.2 Application and Setting Notes

Parameter: Reset of trip command

- Default setting **(_:5341:103) Reset of trip command** = ***with aux.contact***

Parameter Value	Description
with aux.contact	The trip command is reset if the state of the circuit-breaker auxiliary contact indicates that the circuit breaker is open. This setting assumes that the setting of the auxiliary contact has been routed via a binary input. For more information, refer to *5.10.6.3 Detection of Circuit-Breaker Auxiliary Contacts and Further Information*.
with dropout	The trip command is reset if the pickup of the tripping protection function drops out.

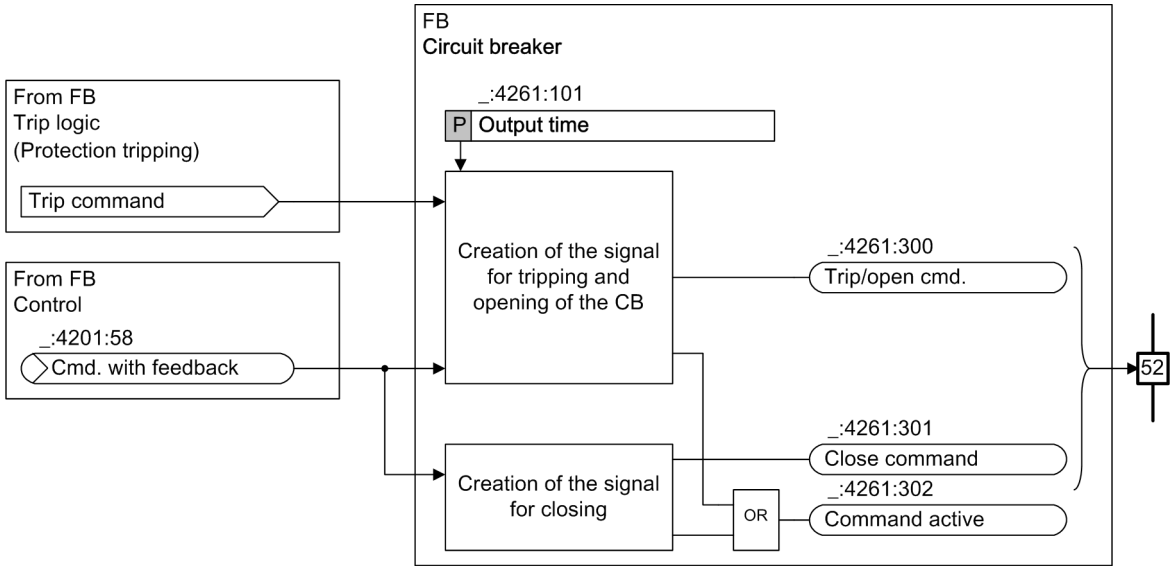
5.10.6 Circuit Breaker

5.10.6.1 Overview

The function block **Circuit breaker** represents the physical switch in the SIPROTEC 5 device.
The basic tasks of this function block are:

- Operation of the circuit breaker
- Acquisition of the circuit-breaker auxiliary contacts
- Acquistion of other circuit-breaker information

The function block **Circuit breaker** provides the following information:



- Number of switching cycles
- Breaking voltage and breaking frequency

5.10.6.2 Tripping, Opening, and Closing the Circuit Breaker

The circuit breaker is operated in the following situations:

- Tripping of the circuit breaker as a result of a protection trip command
- Opening of the circuit breaker as a result of control operations
- Closing of the circuit breaker as a result of control operations

Tripping is always the result of a protection function. The operate indications of the individual protection functions are summarized in the **Trip logic** function block. The trip command that causes the tripping in the function block **Circuit breaker** is generated there.
To operate the circuit breaker, the **Circuit-breaker** function block provides the output signals that must be routed to the corresponding binary outputs of the device (see *Table 5-19*).

[lo_CB_tripping-opening-closing, 1, en_US]

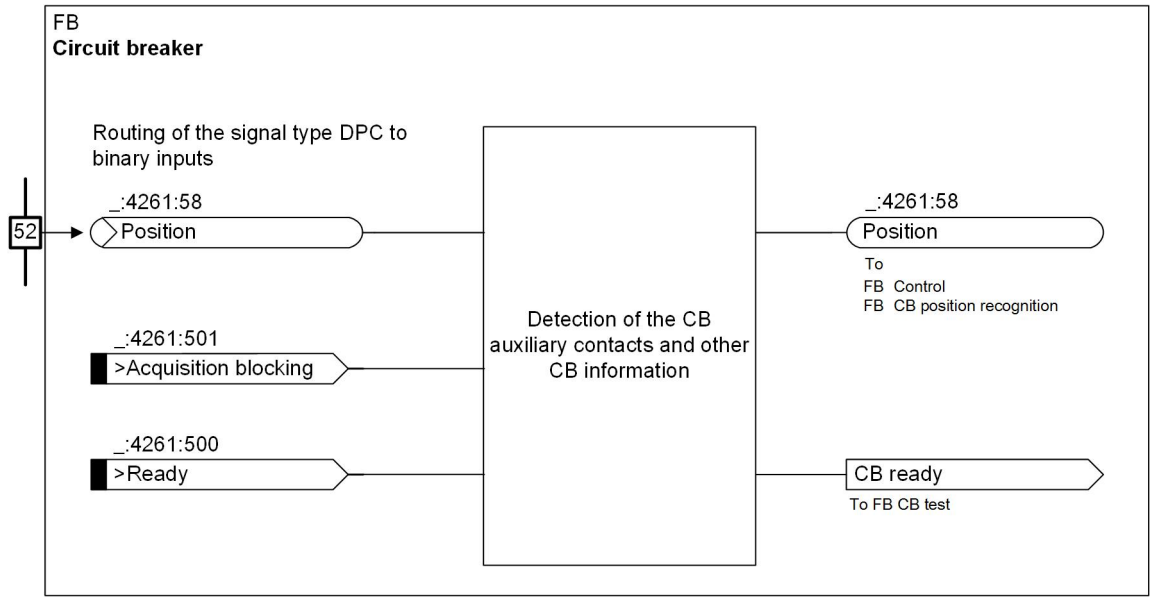


Figure 5-88 Tripping, Opening, and Closing the Circuit Breaker

Table 5-20 Description of the Output Signals

Signal	Description	Routing Options
Trip/open cmd.	This signal executes all tripping and opening operations. The **Output time** parameter affects the signal. The signal is pending for the duration of the output time, with the following exceptions: • **Only when switched off by the control:** The signal is reset before expiration of the period if the auxiliary contacts report that the circuit breaker is open before expiration of the period. • **Only in the event of protection tripping:** – The signal remains active as long as the trip command is still active after expiration of the period (see also *5.9.6.1 Function Description*). If the trip signal is no longer active and the auxiliary contacts report that the circuit breaker is open before expiration of the period, the signal is canceled before expiration of the period. – With the routing option **Only saved in the event of tripping**, the signal remains pending until it is acknowledged manually. This only applies for protection tripping.	• Unlatched • Only saved in the event of protection tripping (not when opened)
Close command	This signal executes all closing operations. The **Output time** parameter affects the signal. The signal is pending for the duration of the output time, with the following exception: The signal is canceled before expiration of the period if the auxiliary contacts report that the circuit breaker is closed before expiration of the period.	Normal routing
Command active	This signal is active if one of the following binary outputs is active: • **Trip/open cmd.** • **Close command** The binary outputs are active as long as a switching command is being executed by the control.	Normal routing

5.10.6.3 Detection of Circuit-Breaker Auxiliary Contacts and Further Information

To determine the circuit-breaker position, the function block **Circuit breaker** provides position signals. These signals are of the **Double-point indication** (DPC) type. A double-point indication can be routed to 2 binary inputs so that the open and closed circuit-breaker switch positions can be reliably acquired.

[lo_erfass_4CB_withoout_1, 1, en_US]

Figure 5-89 Acquisition of the Circuit-Breaker Information

Signal	Type	Description
Position	DPC	Acquisition of the circuit-breaker switch position The switch position CB 3-pole **open** and/or the position CB 3-pole **closed** can be detected by routing to 1 or 2 binary inputs.

The signals must be routed to the binary input that is with the CB auxiliary contacts. The **open** and **closed** signals do not necessarily have to be routed in parallel. The advantage of parallel routing is that it can be used to determine an intermediate or disturbed position. If you route only one signal (**open** or **closed**), you cannot determine an intermediate position or a disturbed position.

In the monitoring direction, the position signals generate the following information when the **open** and **closed** positions are detected (see following table). This information is further processed by the **Circuit-breaker position recognition** and **Control** function blocks.

Information	Type	Description
Open	SPS	The circuit-breaker switch position is **opened**.
Closed	SPS	The circuit-breaker switch position is **closed**.
Intermediate position	SPS	The circuit-breaker switch position is in the **intermediate position**. The signal **open** and the signal **closed** have not been set.
Disturbed position	SPS	The circuit-breaker switch position is in the **disturbed position**. The signal **open** and the signal **closed** have been set simultaneously.
Not selected	SPS	The circuit breaker is **not selected** for a control operation.

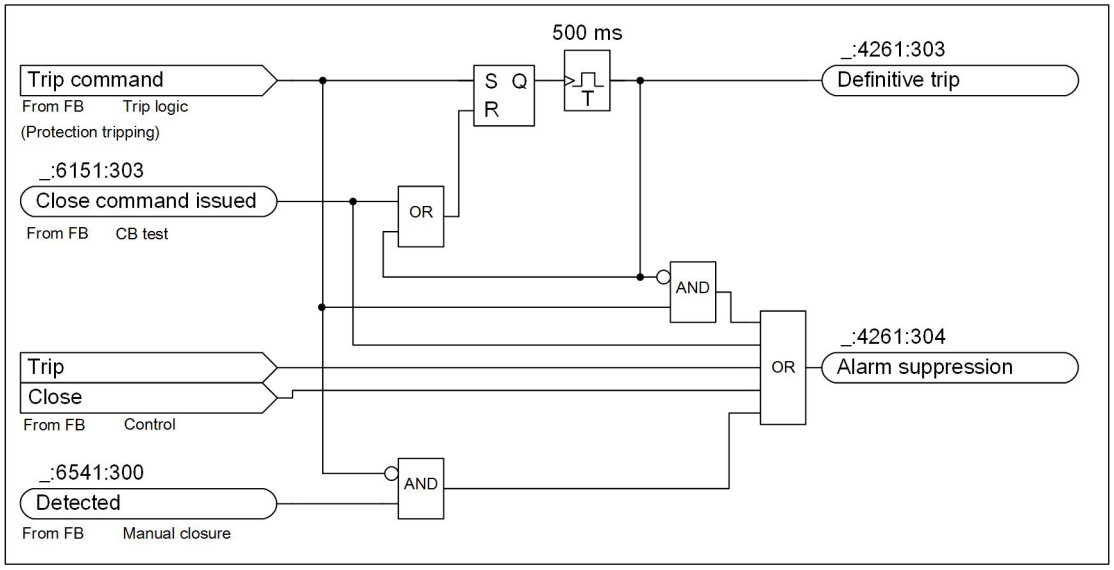
The following table shows the additional input signals:

Signal	Type	Description
>Acquisition blocking	SPS	This is used to activate acquisition blocking of the circuit-breaker auxiliary contacts (see *Other Functions 3.9.3 Persistent Commands* for a description of acquisition blocking).
>Reset AcqBlk&Subst	SPS	This is used to reset acquisition blocking and manual update of the circuit breaker. If the signal is active, acquisition blocking and manual update are reset.
>Ready	SPS	The active signal indicates that the circuit breaker is ready for an **Open-Closed-Open** cycle. The signal remains active as long as the circuit breaker is unable to trip. The signal is used in the **Circuit-breaker test** function.

The following table shows one additional output signal:

Signal	Type	Description
External health	ENS	This can be used to indicate the health of the physical circuit breaker. For this, all failure information of the circuit breaker must be detected via a binary input. This failure information can set the appropriate state of the **External health** signal with a CFC chart (using the **BUILD_ENS** block). The signal has no effect on the health of the function block.

5.10.6.4 Circuit-Breaker Tripping Alarm Suppression



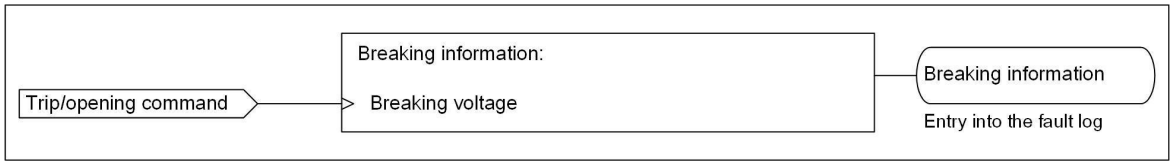
Circuit-Breaker Tripping Alarm Suppression

In certain systems, you possibly want to actuate an alarm (for example, a horn) when tripping (circuit-breaker tripping) occurs. This alarm should not to be issued if the control is used to switch on or off. The alarm is only to be issued in the event of final tripping.

Depending on how the alarm is generated (for example, triggered by a fleeting contact of the circuit breaker), the *Alarm suppression* signal can be used to suppress the alarm.

If one of the following conditions is met, the *Alarm suppression* signal is generated:

- The definitive protection tripping is not present.
- A close command is issued via the **Circuit-breaker test** function.
- The integrated control executes a closure or opening action.
- External closing is detected via the **Manual close** function.

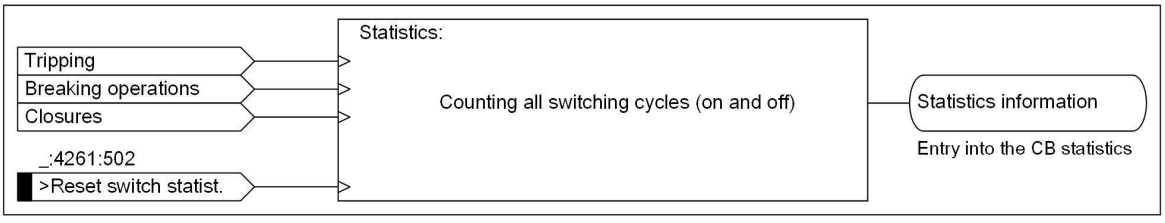


[lo_unterd_4CB_without_I, 2, en_US]

Figure 5-90 Definitive Tripping and Circuit-Breaker Tripping Alarm Suppression

5.10.6.5 Tripping and Opening Information

When a trip or opening command is issued, the breaking information shown in the next figure is saved in the fault log.



[lo_ausloe_4CB_without_I, 1, en_US]

Figure 5-91 Breaking Information

The number of switching cycles is saved for the circuit breaker as the statistics information. All tripping, opening, and closing operations are counted.

The statistics information can be individually set and reset via the device control. It is also possible to reset all values via the binary input signal **>Reset switch statist.**.

[lo_statistics information CB_4CB_without_I, 1, en_US]

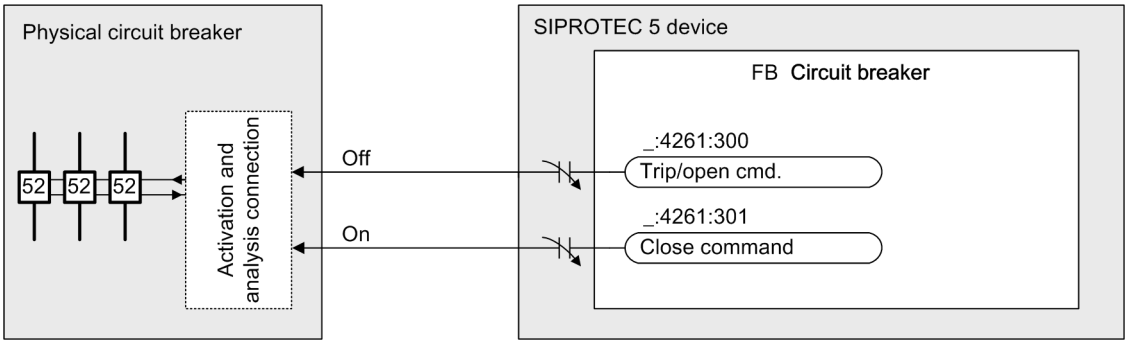


Figure 5-92 Statistics Information about the Circuit Breaker

5.10.6.6 Application and Setting Notes

Routings for Activation of the Circuit Breaker

Figure 5-93 shows the necessary routings for the device:

- 3-pole tripping via the protection
- 3-pole opening via the control

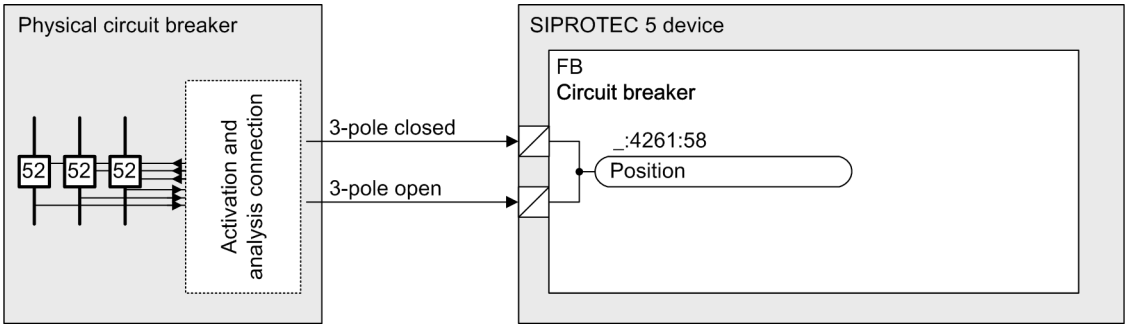
[lo_ansteu, 2, en_US]

Figure 5-93 Activation of the Circuit Breaker

By routing the **`Trip/open cmd.`** signals to 1 or 2 binary outputs, you can carry out 1-pole, 1.5-pole, and 2-pole activations of the circuit breaker. You can find a detailed description of this in chapter *7.2.2.3 Connection Variants of the Circuit Breaker*.

NOTE

Do not confuse these 1-pole, 1.5-pole, and 2-pole activations of the circuit breaker with 1-pole or 3-pole tripping of the circuit breaker.



Routing for Analysis of the Circuit-Breaker Switch Position

For certain functions of the device, it is useful to detect the circuit-breaker switch position via its auxiliary contacts. The following shows a number of examples:

- Function block **Circuit-breaker position recognition**
- Function block **Control**

The operating principle of the auxiliary contacts is described in the individual functions.

Siemens recommends detecting the *`Circuit breaker is open in 3 poles`* and *`Circuit breaker is closed in 3 poles`* information via auxiliary contacts. This is the optimal configuration for the control functionality. For purely protection applications, it is also sufficient to detect just one of the 2 circuit-breaker switch positions. When used as a protection and control device, Siemens recommends the following analysis of the circuit-breaker switch position:

[lo_evaluation2, 1, en_US]

Figure 5-94 Recommended Analysis of the Circuit-Breaker Switch Position

The following figure shows the recommended routing, in which **OH** stands for **active with voltage**.

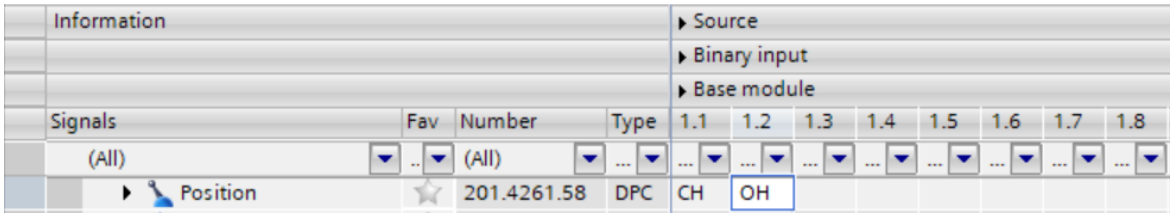


Figure 5-95 Routing for Acquisition of the Circuit-Breaker Switch Position via 2 Auxiliary Contacts

The device can also function without the analysis from the circuit-breaker auxiliary contacts, that is, routing of the auxiliary contacts is not absolutely necessary. However, this is a requirement for the control functions.

Parameter: Output Time

- Default setting **(_:101) Output time** = ***0.10 s***

The **Output time** parameter acts on the signals for tripping, opening, and closing of the circuit breaker.

CAUTION

Do not set a time that is too short.

If you set a time that is too short, there is a danger that the device contacts will interrupt the control circuit. If this happens, the device contacts will burn out.

✧ Set a time that is long enough to ensure that the circuit breaker reliably reaches its final position (**open** or **closed**) after a control operation.

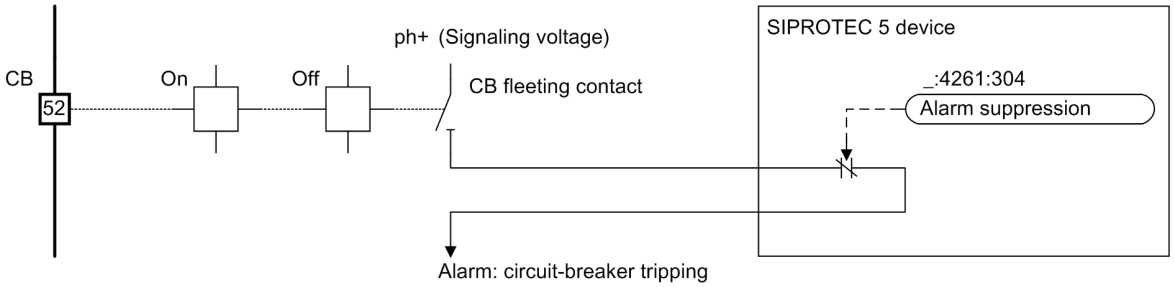
Parameter: Indicat. of breaking values

- Default setting **(_:105) Indicat. of breaking values** = ***always***

With the parameter **Indicat. of breaking values**, you specify whether the measured values are to be reported if the circuit breaker is opened via the control function.

Parameter Value	Description
always	With this setting, the measured values are reported if the circuit breaker is opened either via the control function or via the trip command of a protection function.
with trip	With this setting, the measured values are only reported if the circuit breaker is opened via the trip command of a protection function.

Measured Values



When a protection function opens the circuit breaker, the following measured values can be stored in the fault log:

- *Break. voltage phs A*
- *Break. voltage phs B*
- *Break. voltage phs C*

Output Signal: Indication Suppression

For this, the alarm activation circuit should be looped via a suitably routed output contact of the device (output signal **Alarm suppression**). In the idle state and when the device is switched off, this contact is always closed. For this, an output contact with a break contact must be routed. The contact opens whenever the output signal **Alarm suppression** becomes active, so that tripping or a switching operation does not cause an alarm.

You can find more detailed information in the logic in *5.9.7.3 Acquisition of Circuit-Breaker Auxiliary Contacts and Further Information*.

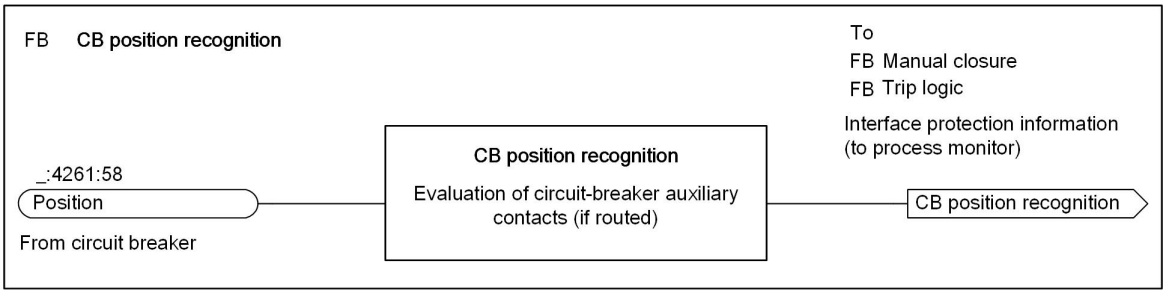
5.10.7 Circuit-Breaker Position Recognition for Protection-Related Auxiliary Functions



5.10.7.1 Overview

This function block calculates the position of the circuit breaker from the evaluation of the auxiliary contacts.

This information is needed in the following protection-related additional functions:

- Trip logic (see *5.10.5.1 Function Description*)
- Detection of manual closing (see *5.10.8.1 Function Description*)
- Process monitor (Standard V/I) (see *5.14 Process Monitor*)

The specified chapters describe the way the protection-related additional functions are processing the information of this function block.
The control does not use this information. The control evaluates the circuit-breaker auxiliary contacts.

[lo_zust3p_4CB_without_I, 1, en_US]

Figure 5-97 Overview of the Circuit-Breaker Position Recognition

Based on the link between the information from the auxiliary contacts, shown in *Figure 5-81*, the circuit breaker can assume the following positions. The following table shows the possible circuit-breaker positions:

Circuit-Breaker Position	Description
Open	The circuit-breaker pole is detected unambiguously as ***open*** according to both criteria.
Closed	The circuit-breaker pole is detected unambiguously as ***closed*** according to both criteria.
Possibly open	This condition occurs if the information is incomplete due to the routing of the auxiliary contacts and the condition can no longer be determined reliably. This uncertain condition is evaluated differently by certain functions.

5.10.8 Detection Manual Closure (for Processor Monitor)

5.10.8.1 Function Description

Detection of Manual Closure (for Process Monitor)

The **Manual closure** function block detects any closure carried out by hand. This information is used in the **Process monitor** functions (within protection function groups).
The following figure shows the logic for manual closure detection.

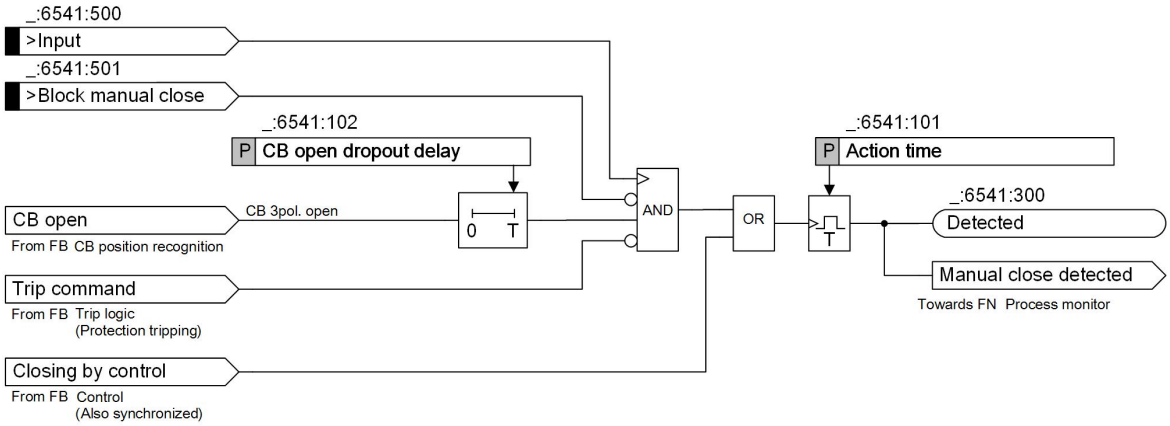


Figure 5-98 Logic for Manual Closure Detection

External Manual Closure

An external manual closure is communicated to the device via the input signal **>Input**. The input signal can also be connected directly to the control circuit of the circuit-breaker closing coil. Detection via the input signal **>Input** is also blocked if the circuit breaker is closed or if a protection trip is active.

Internal Manual Closure

Manual closure is detected in all cases if a close command is transmitted by the internal control function of the device. This is possible because the control carries out plausibility checks itself and is also subject to interlocking.

5.10.8.2 Application and Setting Notes

Input Signals: >Input, >Blocking of Manual Closure

In practice, the input signal **>Input** is connected directly to the control circuit of the circuit-breaker closing coil (see following figure).

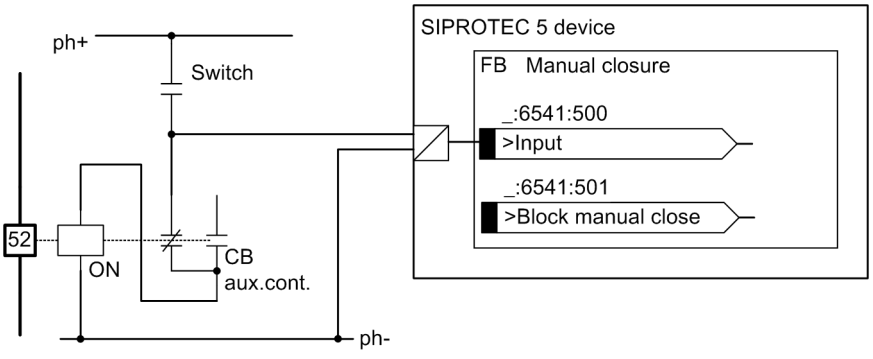

Figure 5-99 Connection of the Input Signal to the Control Circuit of the Circuit-Breaker Closing Coil

Every closure of the circuit breaker is recorded in the process.

If external close commands are possible (actuation of the circuit breaker by other devices), which are not intended to promptly detect a manual closure, this can be ensured in 2 ways:

- The input signal is connected in such a way that it is not activated in the event of external close commands.
- The external close command is connected to the blocking input **>Block manual close** for manual closure detection.

Parameter: Action time

- Recommended setting value **(_:101) Action time** = ***0.30 s***

In order to ensure independence from manual activation of the input signal, the detection function is extended for a defined length of time using the parameter **Action time**.

Siemens recommends an action time of ***0.30 s***.

Parameter: CB open dropout delay

- Default setting **(_:102) CB open dropout delay** = ***0.00 s***

With the **CB open dropout delay** parameter, you can maintain the effectiveness of internal indication *CB open* for the set time. If the input signal **>Input** becomes active after external delayed manual closure, the indication *(_:300) Detected* is output as long as the dropout delay is effective.

5.10.8.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting

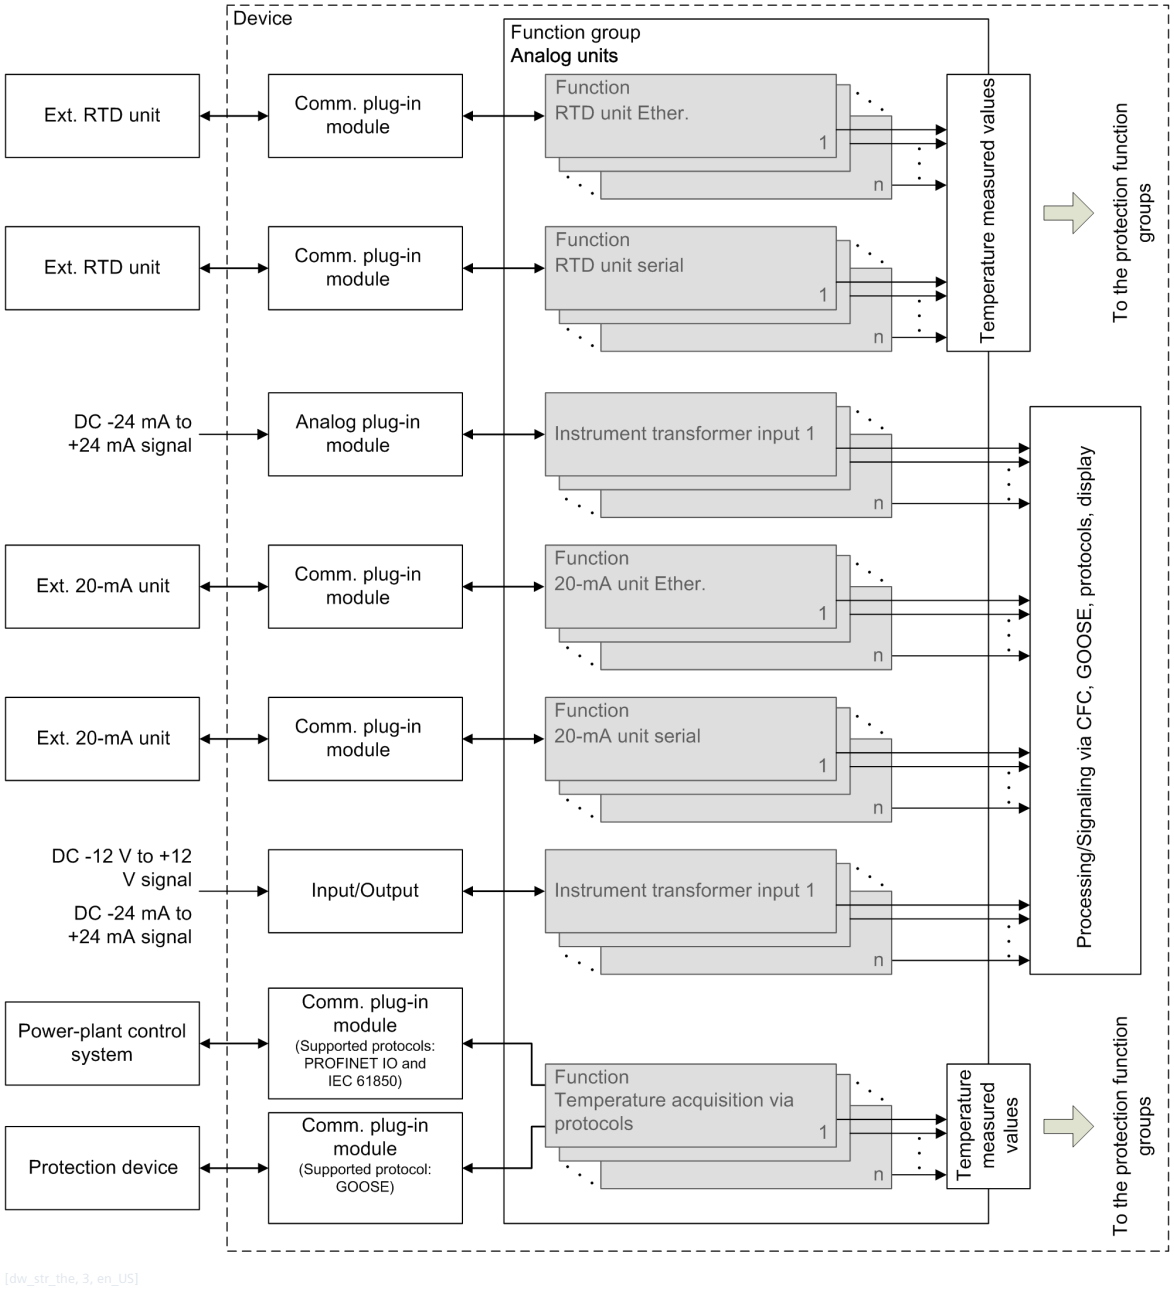
5.11 Function-Group Type Analog Units

5.11.1 Overview

The function group **Analog units** is used to map analog units and communicate with them. Analog units are external devices, such as RTD units, or analog plug-in modules or measuring-transducer modules.
You can find the function group **Analog units** for many device types in the Global DIGSI 5 library.



[sc_20_maee, 3, en_US]

Figure 5-100 Analog Unit Function Group in DIGSI

5.11.2 Structure of the Function Group

If the device has a measuring transducer, it is automatically mapped in the function group **Analog units**. If one or more RTD units are connected to the device, you have to load one or more **RTD unit Ether.** or **RTD unit serial** functions from the Global DIGSI 5 library in order to map the RTD units.
If the device is connected to a power-plant control system or another protection device, you must load one or more **Temperature acquisition via protocols** functions from the Global DIGSI 5 library to form the protocols.
The following figure shows the structure of the function group.

[dw_str_the, 3, en_US]

Figure 5-101 Structure of the Function Group Analog Unit

Gray: Optionally wired, optionally available
White: Always wired, always available

The function group **Analog units** has interfaces to protection function groups. The function group **Analog units** provides, for example, measured temperature values that come from an external RTD unit , a measuring transducer or via protocols. These measured temperature values are available for all protection function groups in which a temperature monitoring function works.

The function **RTD unit Ether.** is not preconfigured by the manufacturer. A maximum of 20 function instances can operate simultaneously.

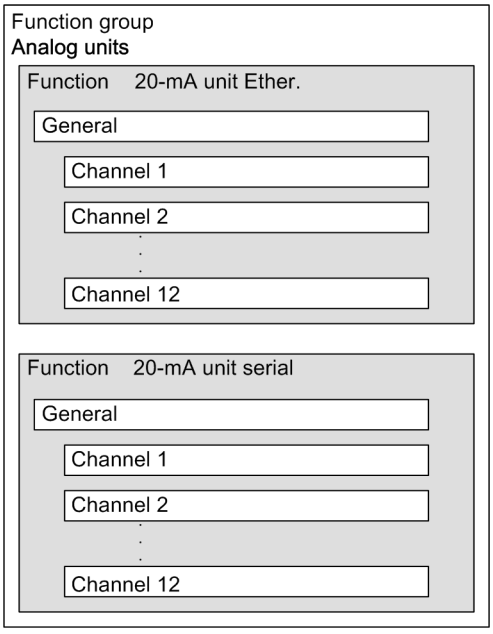
The structure of the function **RTD unit serial** is identical to the structure of the function **RTD unit Ether.**.

The function **20-mA unit Ether.** is not preconfigured by the manufacturer. A maximum of 4 function instances can operate simultaneously. The structure of the function **20 mA serial unit** is identical to the structure of the function **20-mA unit Ether.**.

The function **Temperature acquisition via protocols** has 2 stage types: The **Temperature acquisition via PROFINET IO or IEC 61850** and the **Temperature acquisition via GOOSE**. One instance of the **Temperature acquisition via PROFINET IO or IEC 61850** is preconfigured by the manufacturer. A maximum of 12 instances can operate simultaneously for both stage types.

5.11.3 20-mA Unit Ethernet

5.11.3.1 Overview



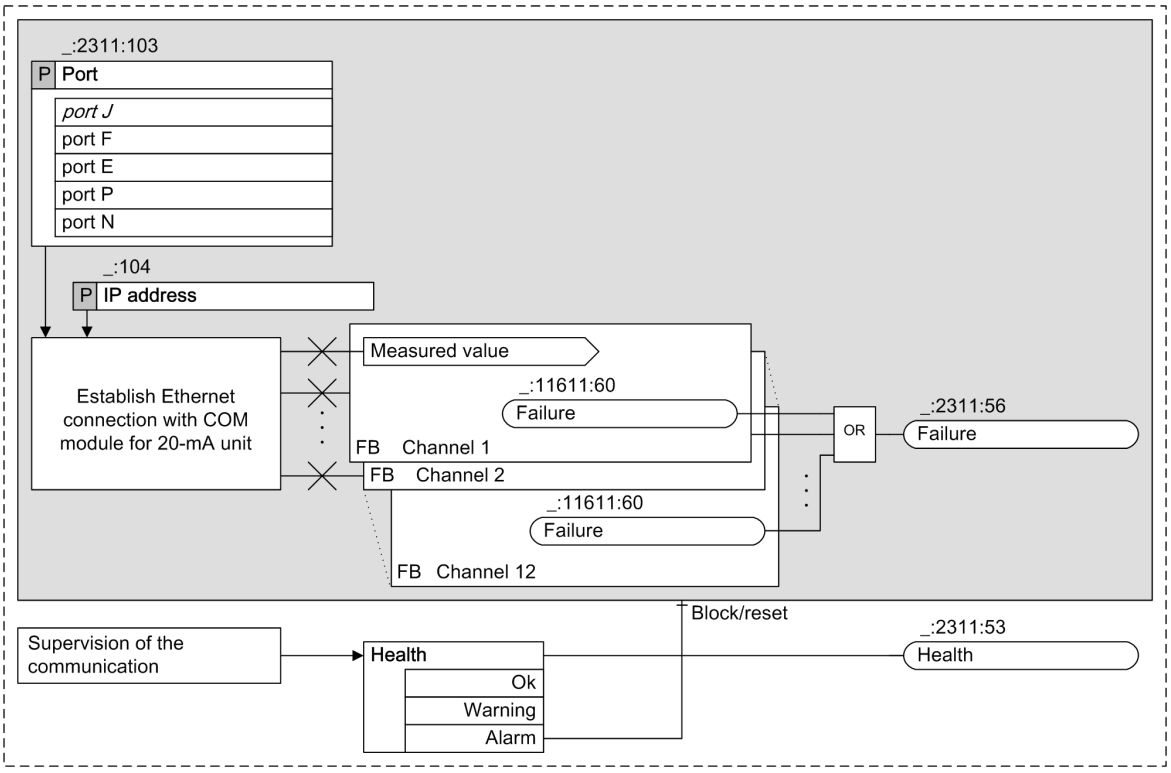
The function **20-mA unit Ether.**:

- Communicates in series with a 20-mA unit via the Slave Unit Protocol (SUP) and records the values measured by the 20-mA unit
- Transforms the measured 20-mA values into slowly changing process tags such as temperature or gas pressure
- Makes the recorded process tags available to CFC, GOOSE, protocols and the device display
- Monitors communication with the 20-mA unit

5.11.3.2 Structure of the Function

The function **20-mA unit Ether.** can only work in the function group **Analog units**. A maximum of 4 function instances can work simultaneously. Each instance contains 12 preconfigured channel function blocks.

The function **20-mA unit Ether.** contains input and output channels which can be configured independently of one another.



[dw_str_fn2, 2, en_US]

Figure 5-102 Structure/Embedding of the Function

5.11.3.3 Communication with 20-mA Unit Ethernet

Logic

[lo_20mtcp_1, en_US]

Figure 5-103 Logic of the Function 20-mA Unit Ethernet

Communication with 20-mA Unit

The function is used to communicate with a 20-mA unit connected via an Ethernet connection. When a connection of the function to an external 20-mA unit via an Ethernet interface has successfully been established, the 20-mA unit sends the measured values of all connected channels to the function **20-mA unit. Ether.**. For the connection to be established successfully, specific communication settings must be specified.

You can find more detailed information in *5.11.3.4 Application and Setting Notes*.

The 20-mA measuring unit **7XV5674** is supported.

Error Responses

The following table lists the conditions under which the status *Health* transitions to the Alarm or Warning state.

Table 5-21 Error Responses

Error Description	Status Health
The function **20-mA unit Ether.** cannot establish a connection witha communication module.	Alarm
The function **20-mA unit Ether.** sends TCP settings to the communication module, which evidently would like to connect to the 20-mA unit via a serial protocol. This communication module does not establish a connection to the 20-mA unit.	Alarm

Error Description	Status Health
The connection between the communication module and the 20-mA unit causes a time-out indication.	Warning
A communication module has not received any more data from the 20-mA unit for 9 sec.	Warning

The signal *Failure* is issued as soon as one of the channel function blocks reports a failure.

5.11.3.4 Application and Setting Notes

Parameter: Port

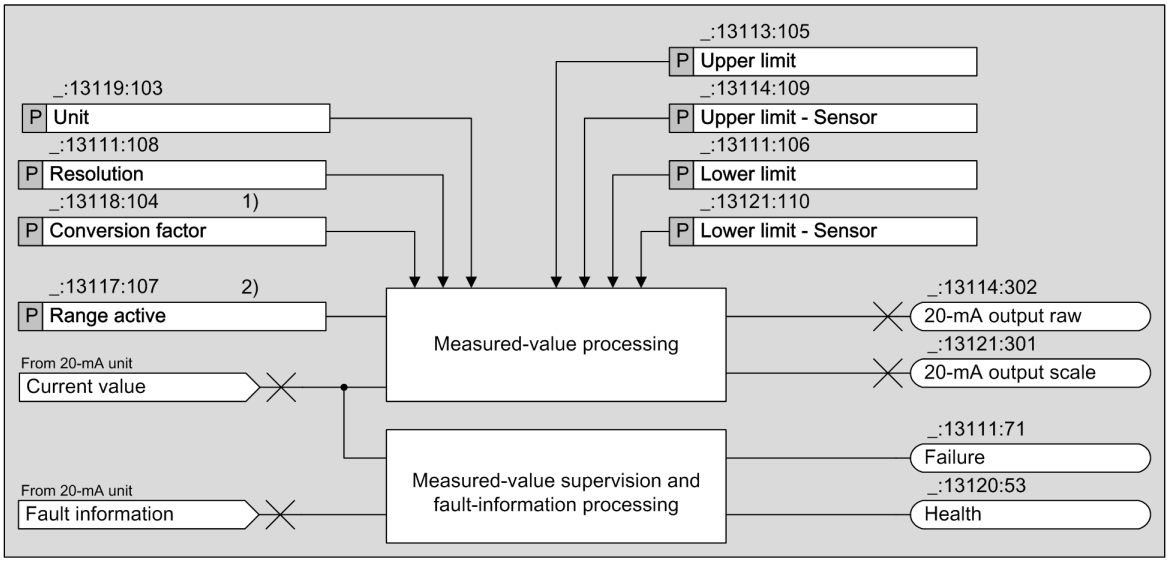
- Default setting **(_:2311:103) Port** = ***port J***

With the parameter **Port**, you define the port connecting the 20-mA unit to the SIPROTEC 5 device.

Parameter: IP address

- Default setting **(_:2311:104) IP address** = ***10.16.60.1***

With the parameter **IP address**, you set the IP address of the 20-mA unit connected to the communication module via the TCP protocol. You must assign each 20-mA unit an unambiguous IP address. The IP address to be set depends on your network configuration. You can set any valid IPv4 address that does not cause conflicts with other IP addresses in the network. First set an IP address for the **7XV5674 20-mA unit**. Then specify the parameter **IP address** for the communication module to the same address.



Settings on the 20-mA Unit

Set the **7XV5674 20-mA unit** with a Web browser on the laptop computer via the latter's Ethernet interface. Set ***Modbus TCP*** as a bus protocol/operating mode.

You can find detailed notes on the settings in the 7XV5674 manual that accompanies the 20-mA unit. The documents are also available in the SIPROTEC download area (*www.support.industry.siemens.com*).

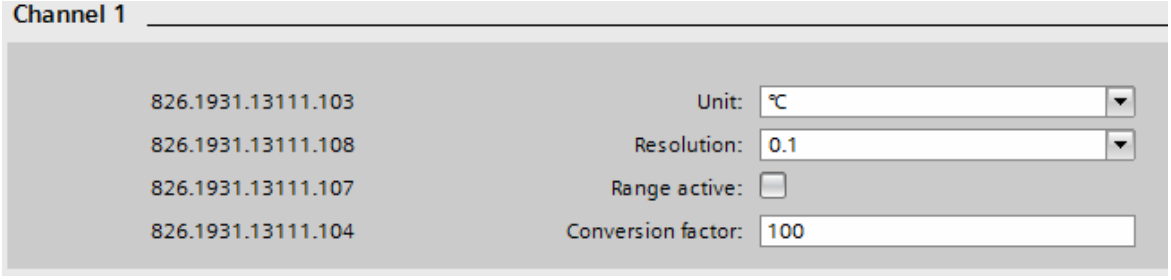
5.11.3.5 20-mA Channel

Logic

[lo_20mcha, 1, en_US]

Figure 5-104 Logic Diagram of the Function 20-mA Channel

(1) If the setting **Range active** is set to ***test***, the setting **Transformation ratio** is not displayed.

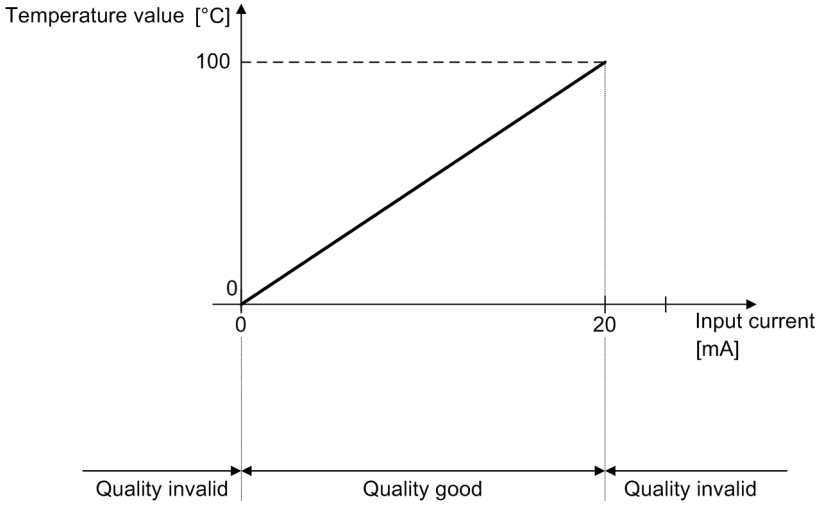


(2) If the setting **Range active** is set to ***false***, the settings **Upper limit**, **Transformation ratio upper limit**, **Lower limit** and **Transformation ratio** are not displayed.

Measured-Value Calculation

The function **20-mA channel** processes a single 20-mA current signal supplied by the 20-mA unit of the corresponding channel. The 20-mA current measured value is converted into the correct physical quantities such as temperature or pressure. In each 20-mA functional unit (Ether. and serial) there are always 12 of the 20-mA channel function blocks, even if fewer channels are connected with the 20-mA unit. The calculated values are available for further processing via CFC, GOOSE, protocols, and the display image.

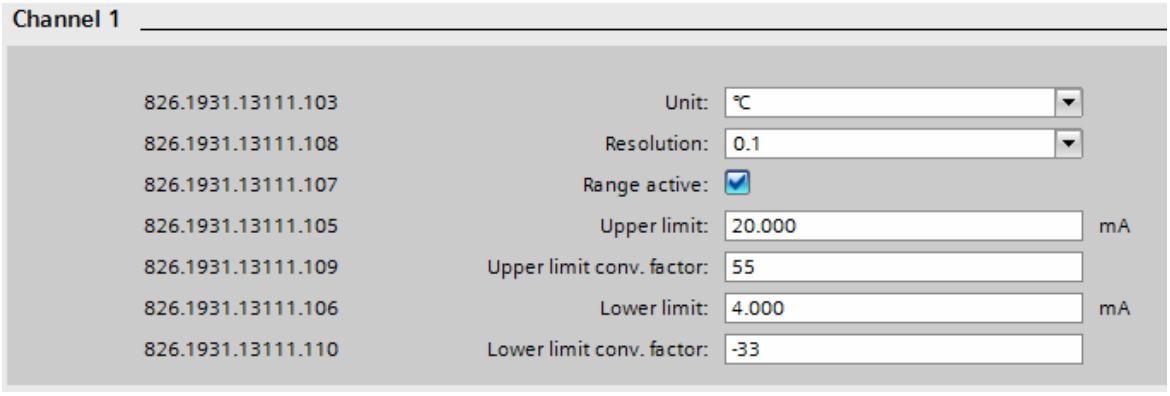
Measured-Value Processing



The 20-mA unit typically transmits a value which represents a physical quantity, such as a temperature or a pressure. Therefore, the device must contain a characteristic curve that maps the physical quantity to the 20-mA value. If you do not activate the **Range active** setting (no x in the check box), the function operates over the range 0 mA to 20 mA. If a value smaller than 0 mA or greater than 20 mA is active at the input of the 20-mA unit, the measured value is identified as invalid. The setting of the range for the scaled value goes from a usable range of 0 mA to 20 mA. The following figure shows an example.

[sckanumw-190214-01, 1, en_US]

Figure 5-105 Settings for Example 1



In this example, the measured value 0 mA means a temperature of 0 °C and the measured value 20 mA means a temperature of 100 °C. So enter as **Unit** = ***°C*** and **Conversion factor** = ***100***. The resolution (decimal place) of the temperature value can be chosen; for a decimal place, select **Resolution** = ***0.1***.

[dw_knges3, 1, en_US]

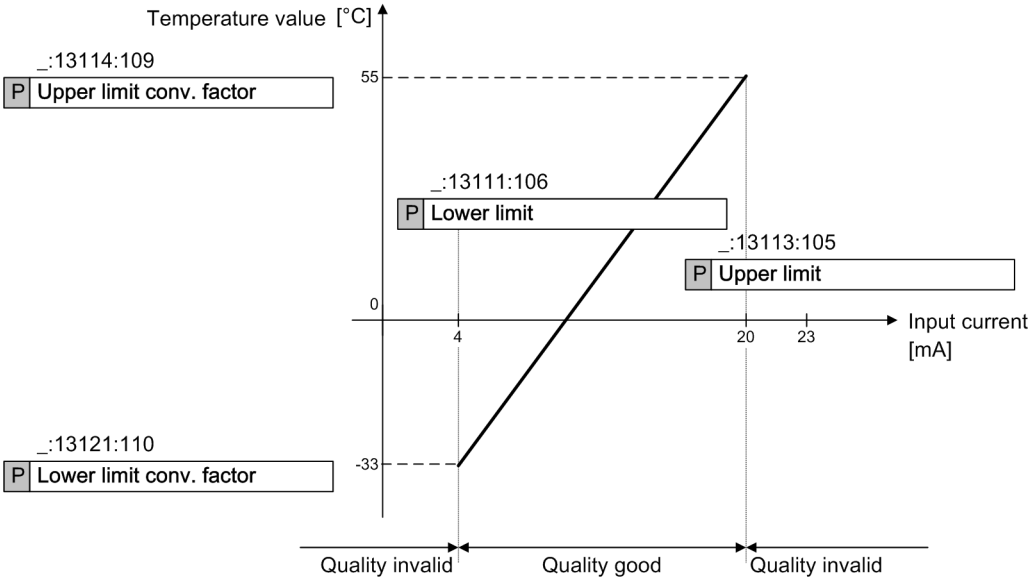


Figure 5-106 Characteristic Curve of a 20-mA Input (Example 1)

If you activate the **Range active** setting, then 4 additional parameters **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The parameters **Upper limit** and **Lower limit** indicate the range of the input current in mA. The setting **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The setting **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting. The setting of the range for the scaled value corresponds to the useable range between **Lower limit** and **Upper limit** (see following figure).

[sckanumf-190214-01, 1, en_US]

Figure 5-107 Settings for Example 2

[dw_knges2, 1, en_US]

Figure 5-108 Characteristic Curve of a 20-mA Unit (Example 2)

In this example, the **Range active** setting is selected. The setting **Upper limit** is at 20 mA, the setting **Lower limit** is at 4 mA. The setting **Upper limit - Sensor** is at 55 and the setting **Lower limit - Sensor** is at -33. If the input current is smaller than 4 mA or greater than 20 mA, the quality of the scaled measured value in this example is invalid.

Each 20-mA channel makes available the scaled measured value in the information routing (these are the temperature values in the examples) and the original current measured value in mA for further processing.

The 20-mA values can be displayed in the display page and processed with CFC charts.

Error Responses

If the current input value is determined to be incorrect, the quality attribute of the output value is set to *invalid* That status for *Health* and the defect status assume the states displayed in the table.

Table 5-22 Error Responses

Error Description	Status *Health*	Error Status
The input value lies outside the given limits	OK	Yes
Channel not connected	OK	No

5.11.3.6 Application and Setting Notes

Parameter: Unit

- Default setting **(_:13111:103) Unit** = ***°C***

With the **Unit** parameter, you set the physical unit of measurement the measured values. The possible setting values are listed in the settings table.

Parameter: Conversion factor

- Default setting **(_:13111:104) Conversion factor** = ***100***

With the **Conversion factor** parameter, you set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:13111:108) Resolution** = ***0.1***

With the **Resolution** parameter, you set the resolution of the scaled values.

Parameter: Range active

- Default setting **(_:13111:107) Range active** = ***false***

If you do not activate the parameter **Range active** (no x in the check box), the function operates over the range 0 mA to 20 mA. The setting of the range for the scaled value goes from a usable range of 0 mA to 20 mA.

If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**, **Upper limit - Sensor**, **Lower limit**, and **Lower limit - Sensor** appear.

Parameter: Upper limitLower limitUpper limit - Sensor and Lower limit - Sensor

- Default setting **(_:13111:105) Upper limit** = ***20.000 mA***
- Default setting **(_:13111:109) Upper limit - Sensor** = ***100***
- Default setting **(_:13111:106) Lower limit** = ***4.000 mA***
- Default setting **(_:13111:110) Lower limit - Sensor** = ***100***

If you activate the parameter **Range active** , the 4 additional parameters **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The parameter **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The parameter **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

The following settings and information table shows only 1 of the 12 channels, as the setting possibilities of the 12 channels do not differ.

5.11.4 20-mA Unit Serial

5.11.4.1 Overview

The function **20-mA unit Serial**:

- Provides serial communications with a 20-mA unit via the Modbus protocol and records the values measured by the 20-mA unit
- Transforms the measured 20-mA values into slowly changing process variables such as temperature or gas pressure
- Makes the recorded process tags available to CFC, GOOSE, protocols and the device display
- Monitors communication with the 20-mA unit

The function **20-mA unit Serial** is structured in the same way as the function **20-mA Unit Ether.**. The mode of operation is also identical. The only difference is that the measured values are transferred to the communication module via a serial connection instead of an Ethernet connection.

You can find more information in Chapter *5.11.3.2 Structure of the Function*.

5.11.4.2 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***Port J***

With the parameter **Port**, you specify the slot for the communication module that will be used for the connection with an external 20-mA unit.

Parameter: Channel number

- Default setting **(_:2311:105) Channel number** = ***1***

A serial communication module optionally uses 2 channels. With the parameter **Channel number**, you specify the channel number (1 or 2) used to connect the 20-mA unit to the device. The communication module inputs are labeled with the channel numbers.

Parameter: Slave address

- Default setting **(_:2311:106) Slave address** = ***1***

With the parameter **Slave address**, you define the device address of the 20-mA unit. If only one 20-mA unit is connected to the serial bus, the default value *1* can be used. Set the same device address as used with the 20-mA unit. The device address is important for distinguishing several 20-mA units that are connected to a serial bus. Set an unambiguous device address on every 20-mA unit, for example, 1, 2 and 3 when connecting 3 of the 20-mA units. On every 20-mA unit, set for the parameter **Slave address** in the 3 functions **20-mA Unit Serial**.

Parameter: Unit

- Default setting **(_:13111:103) Unit** = ***°C***

With the parameter **Unit**, you set the physical unit of measurement the measured values. The possible setting values are listed in the settings table.

Parameter: Conversion factor

- Default setting **(_:13111:104) Conversion factor** = ***100***

With the parameter **Conversion factor**, you set the conversion factor for the measuring transducer.

Parameter: Resolution

- Default setting **(_:13111:108) Resolution** = ***0.1***

With the parameter **Resolution**, you set the resolution of the scaled values.

Parameter: Range active

- Default setting **(_:13111:107) Range active** = ***false***

If you do not activate the parameter **Range active** (no x in the check box), the function operates over the range 0 mA to 20 mA. The setting of the range for the scaled value goes from a usable range of 0 mA to 20 mA.
If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**, **Upper limit - Sensor**, **Lower limit**, and **Lower limit - Sensor** appear.

Parameter: Upper limit, Lower limit, Upper limit - Sensor, and Lower limit - Sensor

- Default setting **(_:13111:105) Upper limit** = ***20 mA***
- Default setting **(_:13111:109) Upper limit - Sensor** = ***100***
- Default setting **(_:13111:106) Lower limit** = ***4 mA***
- Default setting **(_:13111:110) Lower limit - Sensor** = ***100***

If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**, **Lower limit**, **Upper limit - Sensor**, and **Lower limit - Sensor** appear. The parameter **Upper limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Upper limit** setting. The parameter **Lower limit - Sensor** is the calculated measured value if the input current corresponds to the value in the **Lower limit** setting.

The following settings and information table shows only 1 of the 12 channels, as the setting possibilities of the 12 channels do not differ.

5.11.4.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:2311:103	General:Port		• port F • port E • port J • port N • port P	port J

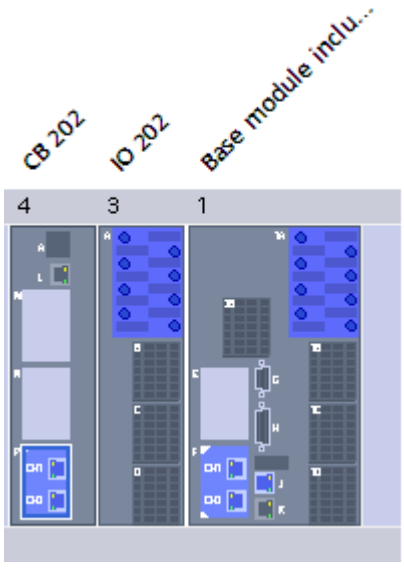
5.11.5 Communication with 20-mA Unit

5.11.5.1 Integration of a Serial 20-mA Unit

Connection of the Communication Lines

Figure 5-109 shows how to connect the 20-mA unit to the SIPROTEC 5 device. Note that Pin 1 of the RJ45 plug is connected to RTD-B and Pin 2 is connected to RTD-A.

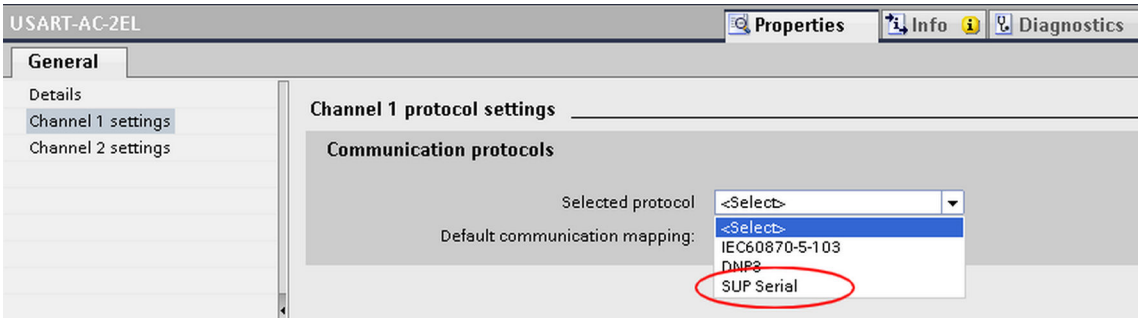


[dwve20au-150213-01.tif, 1, en_US]

Figure 5-109 Connection of the 20-mA Unit to the SIPROTEC 5 Device

Adding a USART Module

Add a USART-AB-1EL or a USART-AC-2EL USART module in DIGSI to the device. The USART module must be inserted at one of the plug-in positions for communication modules in the base module or in the CB202 expansion module (refer to the following figure).



[sc20ser3-220114-01-DE, 1, en_US]

Figure 5-110 Insertion Position for a USART Module

Selecting the SUP Protocol

Select the Slave Unit Protocol (SUP). This protocol is responsible for the communication between the SIPROTEC 5 device and the 20-mA unit.

[scauser4-301012-01.tif, 1, en_US]

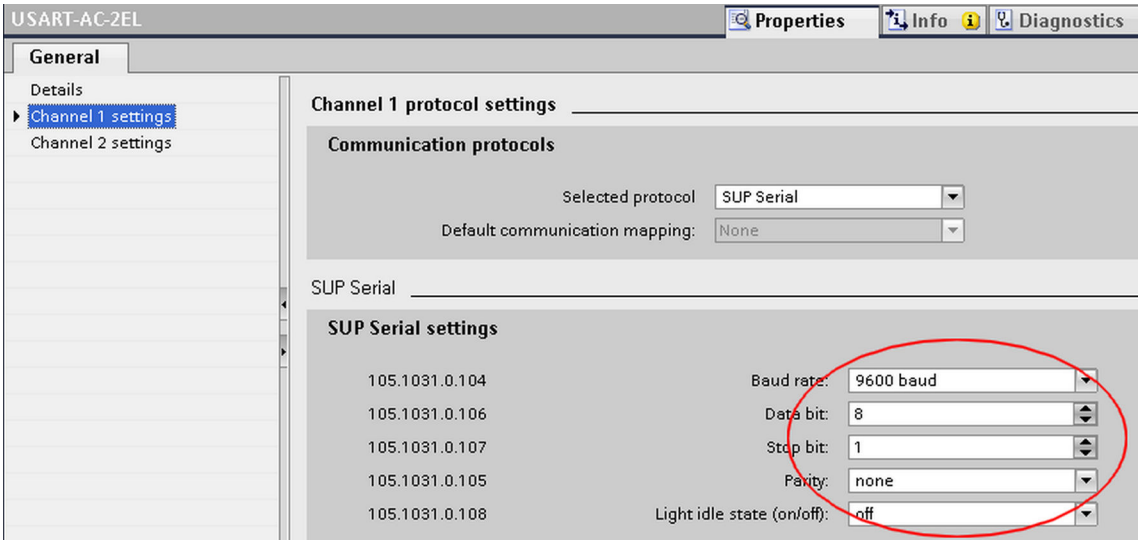


Figure 5-111 Selecting the SUP Protocol

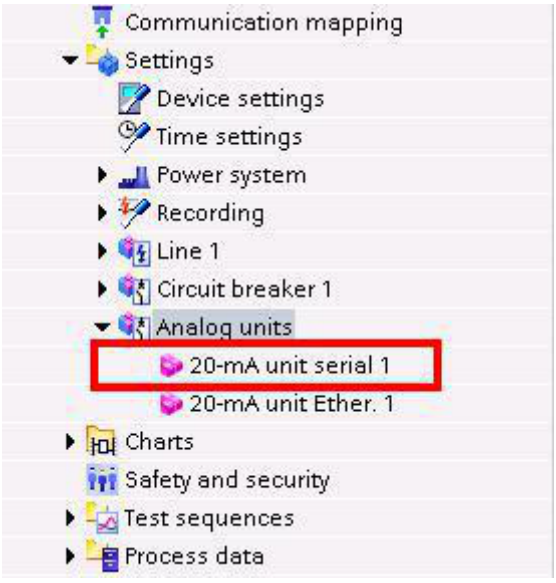
Communication Settings

Make the communications settings for the relevant serial channels. For this, use the default settings specified by the 20-mA unit. Normally, you must adapt only the parameterization of the SIPROTEC 5 device to the settings of the 20-mA unit. Make sure that the setting values in both devices are the same. The setting of the parameter **`Non-flickering light (on/off)`:** is not relevant for the RS485 interface.

NOTE



The driver for the USART module for the SUP protocol is not preinstalled as standard for the initial use of this interface (following the firmware update).

[scauser5-301012-01.tif, 1, en_US]

Figure 5-112 Making the Communication Settings

With the selection of the SUP protocol for the 20-mA unit DIGSI automatically adds the function group **Analog units** to your device configuration. You can now instantiate the function **20-mA unit serial 1** (see the following figure).

[sc20ser6-220114-01-DE, 1, en_US]

Figure 5-113 Insertion of the Function 20-mA Unit Serial 1

Now, set the channel number over which the SUP protocol runs. In addition, set the slave address of the 20-mA unit. This address must be set with the same value in the 20-mA unit (refer to the following figure).
For the first use of the 20-mA unit, the following device configuration must be set on the 20-mA unit:

- Bus protocol: mod
- Device address: 1
- Baud rate: 9600
- Parity: no

[scauser7-220114-01-DE, 1, en_US]

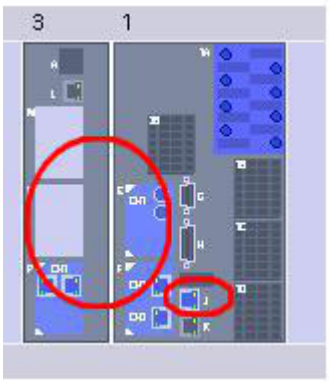


Figure 5-114 Setting the Port, Channel Number, and Device Address

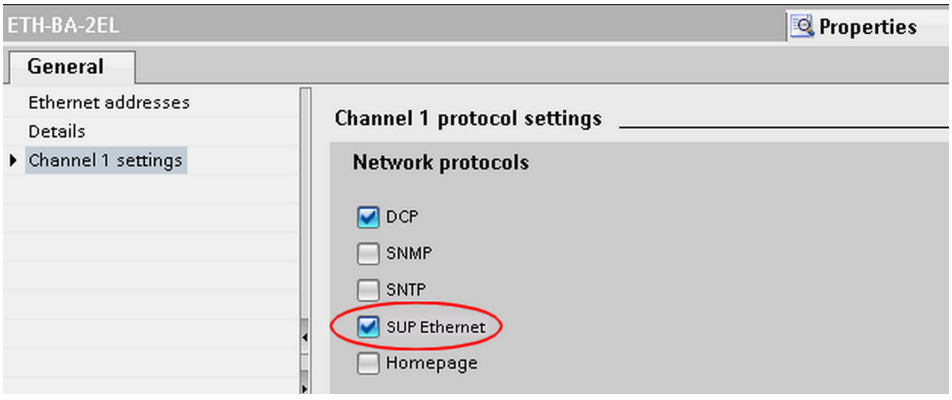
Finally, load the configuration in the device.

5.11.5.2 Integration of a 20-mA Unit Ethernet

Device Configuration

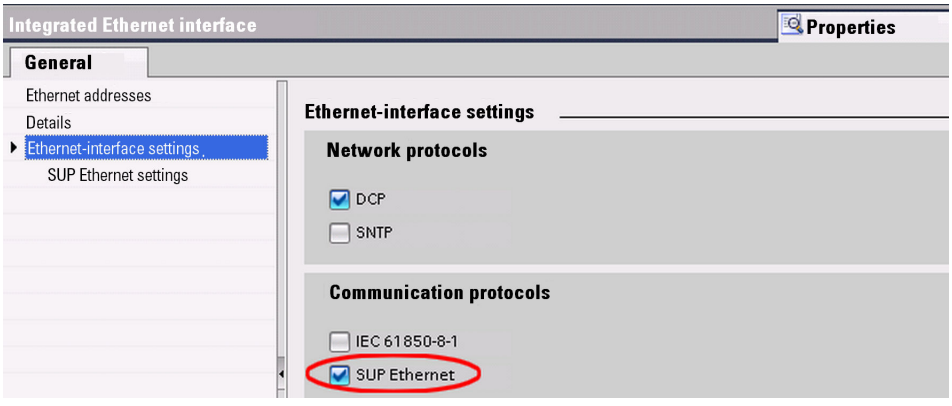
In DIGSI, insert an Ethernet module into the provided slot, thus adding the module to the device configuration. *Figure 5-115* displays the available slots in the base module or on the expansion module CB202. Alternatively, you can also use the integrated Ethernet interface Port J.



[sc_autcp1, 1, en_US]

Figure 5-115 Inserting an Ethernet Module

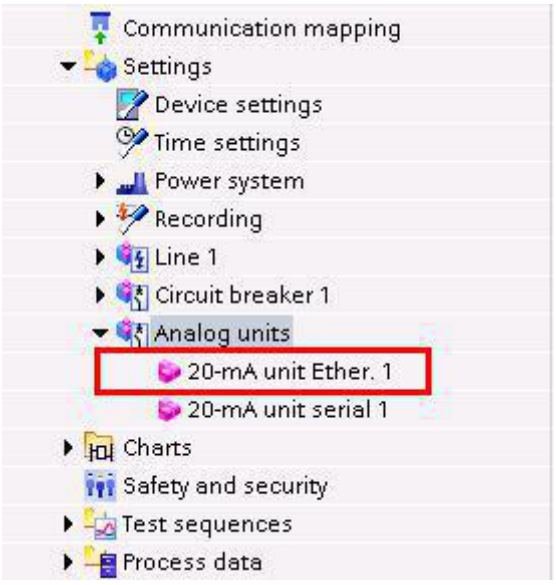
Communication Settings



Activate the SUP Ethernet protocol for the Ethernet module.

[sc_autcp2, 1, en_US]

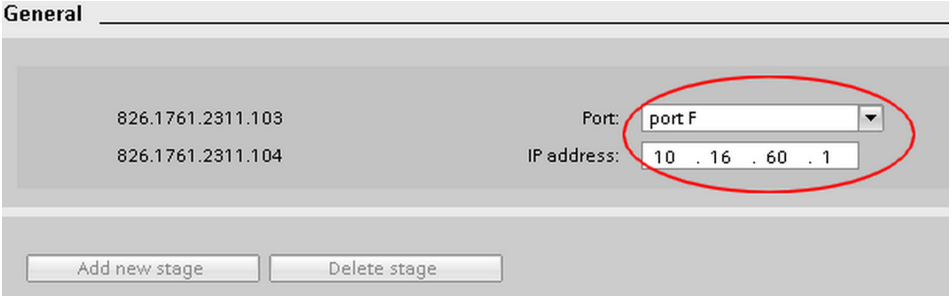
Figure 5-116 Activation of the Protocol



This protocol is also available for Port J of the integrated Ethernet interface of the base module (refer to following figure).

[sc_autcp3, 1, en_US]

Figure 5-117 Selection of the Protocol



With the selection of the SUP protocol for the 20-mA unit, DIGSI automatically adds the **Analog units** function group and the **20-mA unit Ether. 1** function to your device configuration (refer to the following figure).

[sc_20tcp4, 1, en_US]

Figure 5-118 Insertion of the Function 20-mA Unit Ether. 1

Now, set the port over which the SUP protocol runs. In addition, set the IP address of the 20-mA unit (refer to the following figure). This address must be set with the same value in the 20-mA unit.

[sc_autcp5, 1, en_US]

Figure 5-119 Setting the Port and IP Address

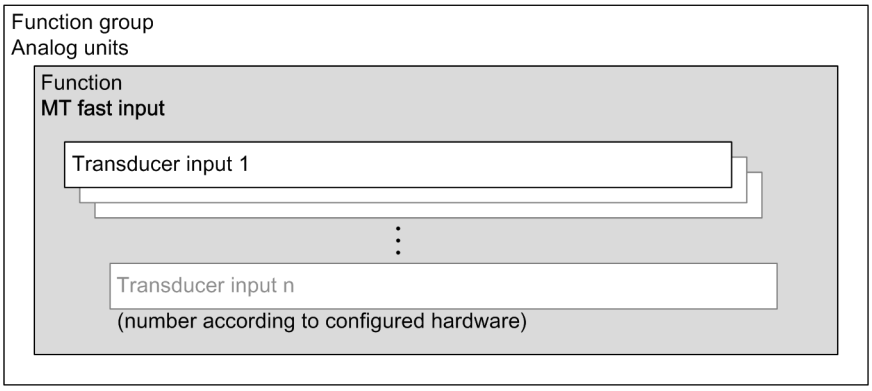
Finally, load the configuration in the device.

5.11.6 V/I-Measuring-Transducer Unit with Fast Inputs

5.11.6.1 Overview

The fast analog measuring-transducer inputs process voltage values (DC -10 V to +10 V) as well as current values (DC -20 mA to 20 mA).

The function **MT fast input**:



- Provides sampled values for recording in the fault record (the maximum sampling frequency is 8 kHz for all other SIPROTEC 5 devices). The recorded sampling frequency results from the setting of the fault-recorder function.
- Calculated measured values from the sampled values. These measured values have been deduced from the arithmetic mean values. The measuring range for the mean-value calculation is adjustable in the interval from 10 ms to 100 ms.

- Converts the measured current or voltage values into process values, for example, temperature, gas pressure, etc.
- Provides the recorded process variables for further processing by the fault recorder, the CFC, and in GOOSE-applications for transmission via communication protocols, and for visualization

The fast measuring-transducer inputs are located on the IO212 module with 8 inputs (optionally current or voltage inputs), and the IO210 module with 4 inputs (optionally current or voltage inputs).

5.11.6.2 Structure of the Function

The function **MT fast input** works in the function group **Analog units** and contains the number of available measuring-transducer inputs, depending on the hardware configuration. You can configure these channels independently from one another either as current or voltage inputs.

[dw_mu-structure, 1, en_US]

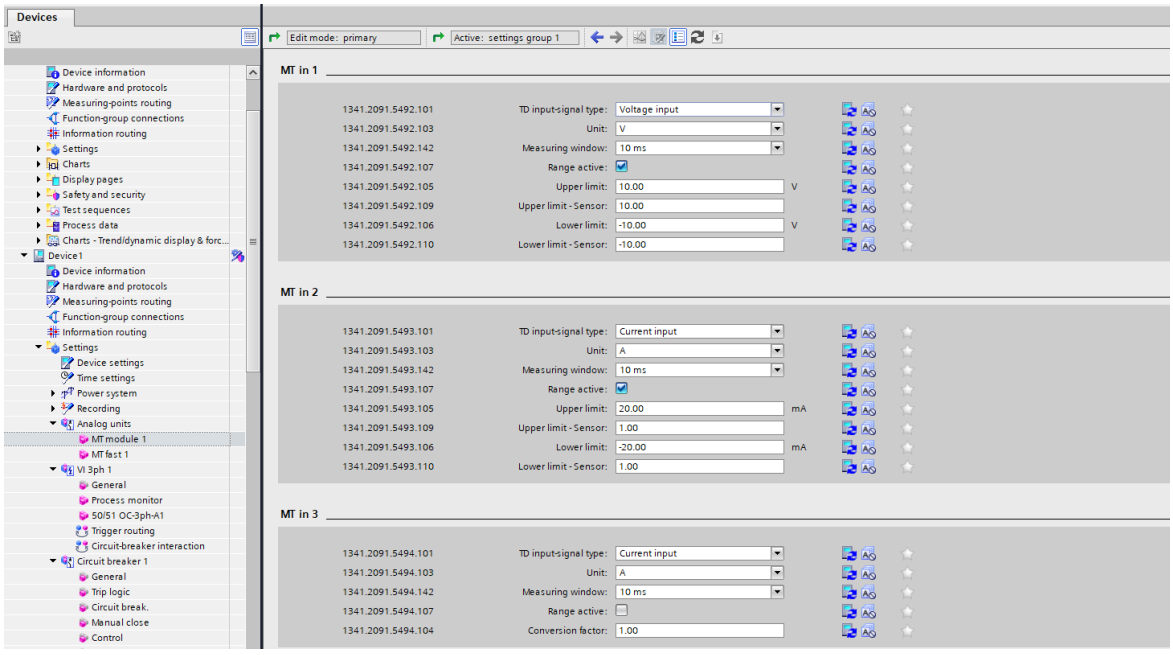


Figure 5-120 Structure/Embedding of the Function

5.11.6.3 Function Description

Once you have instantiated the **MT fast input** function, it will be visible in the project tree in the function group **Analog units**. You can find the function group **Analog units** in DIGSI in the **Settings** folder.

If you open the subdirectory **MT fast input**, you reach the setting sheet for the respective input (for more details, see *5.11.6.4 Application and Setting Notes*).

The hardware is designed in such a way that either a current or a voltage can be processed at each input. Use the corresponding terminals (see Hardware manual). Configure the input in accordance with the selected connection (Parameter **`TD input-signal type`**). With the parameter **`Measuring window`**, you set the measuring range with which the arithmetic mean value is determined. With the parameter **`Measuring window`**, you also determine measurement speed for the input. For example, a setting of 100 ms means that the measured value is updated every 100 ms.

[scmuio212, 2, en_US]

Figure 5-121 Parameters of the Measuring-Transducer Channels.

The fast measuring-transducer channels can be configured either as current or as voltage inputs. Apart from this, their function corresponds to the basic function of the 20-mA channels (see chapter *5.11.3.5 20-mA Channel*).

5.11.6.4 Application and Setting Notes

Parameter: `TD input-signal type`

- Default setting **`(_:101) TD input-signal type`** = ***`Current input`***

With the parameter **`TD input-signal type`**, you determine whether the measuring-transducer input channel works as a ***`Current input`*** or as a ***`Voltage input`***.

Make sure that the selected channel has also been wired correctly (see *Hardware manual, Input and Output Module IO212)*.

Parameter: `Unit`

- Default setting **`(_:103) Unit`** = ***`A`***

With the parameter **`Unit`**, you set the physical unit of measurement of the measured values. The possible setting values are listed in the settings table.

Parameter: `Measuring window`

- Default setting **`(_:142) Measuring window`** = ***`10 ms`***

With the parameter **`Measuring window`**, you set the measuring window that is used to determine the arithmetic mean value from the sampled values. In case of slowly varying signals, Siemens recommends setting the top value to 100 ms. With this value, a new, current measured value is provided every 100 ms for further processing.

Parameter: `Range active`

- Default setting **`(_:107) Range active`** = ***`false`***

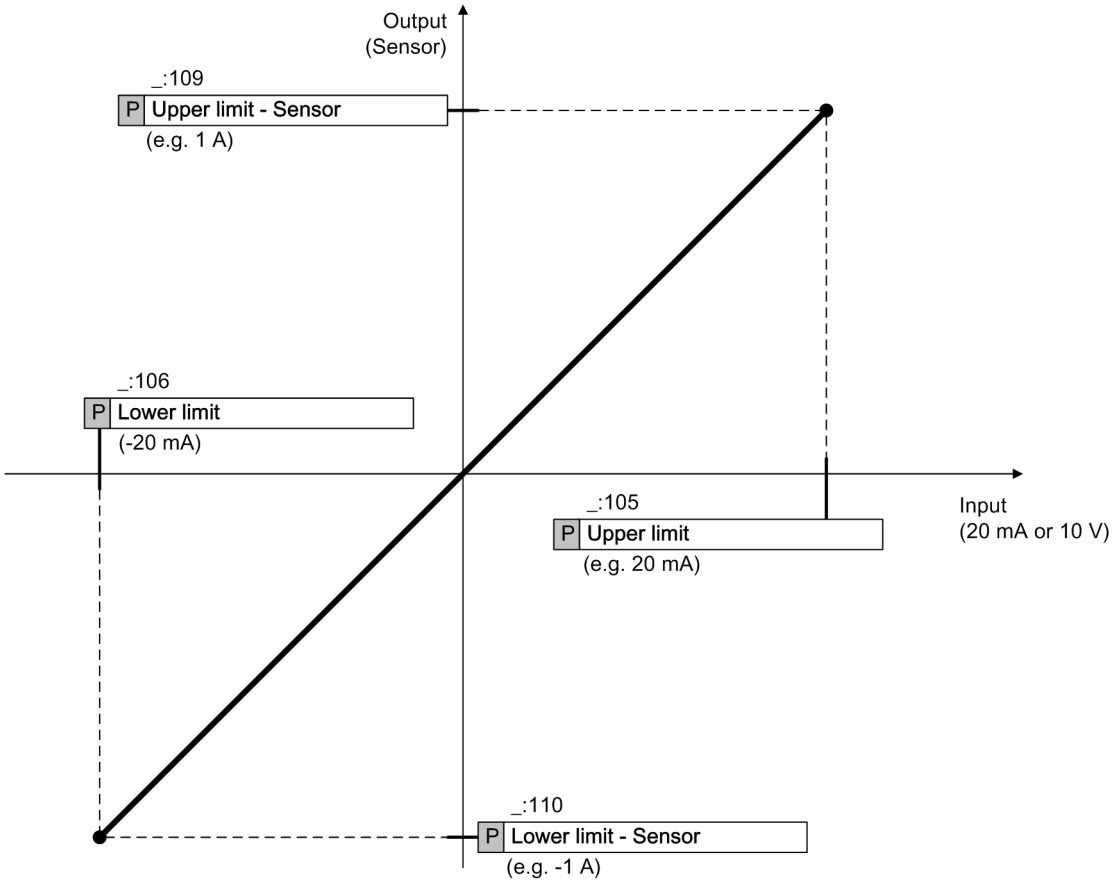
If you do not activate the **Range active** parameter, the function assumes a range of -20 mA to +20 mA or -10 V to +10 V. The setting of the range for the scaled value then assumes a usable range of -20 mA to +20 mA or -10 V to +10 V.

If you activate the parameter **Range active**, the 4 additional parameters **Upper limit**,**Upper limit - Sensor**, **Lower limit**, and **Lower limit - Sensor** appear.

Note that this setting is activated by either placing, or not placing the relevant check mark in DIGSI (see *Figure 5-121*).

Parameter: Conversion factor

- Default setting **(_:104) Conversion factor** = ***1.00***



With the parameter **Conversion factor**, you set the conversion factor for the measuring transducer.

Parameter: Upper limit, Upper limit - Sensor, Lower limit, and Lower limit - Sensor

With the following parameters, you set the scaling of the measuring variables. By that, you can scale in an application-specific way:

- Default setting **Upper limit** = ***20.00 mA***
- Default setting **Upper limit - Sensor** = ***1.00***
- Default setting **Lower limit** = ***-20.00 mA***
- Default setting **Lower limit - Sensor** = ***1.00***

With these setting parameters, you set the operating range of the measuring transducer as well as the conversion of the values transmitted to the sensor values. Harmonize the operating range of the measuring transducer with the transmitter of the sensor. Using the free scalability of the system, you can meet different requirements. The following figure shows the setting parameters in general terms.

[dw_measured-value-scaling, 1, en_US]

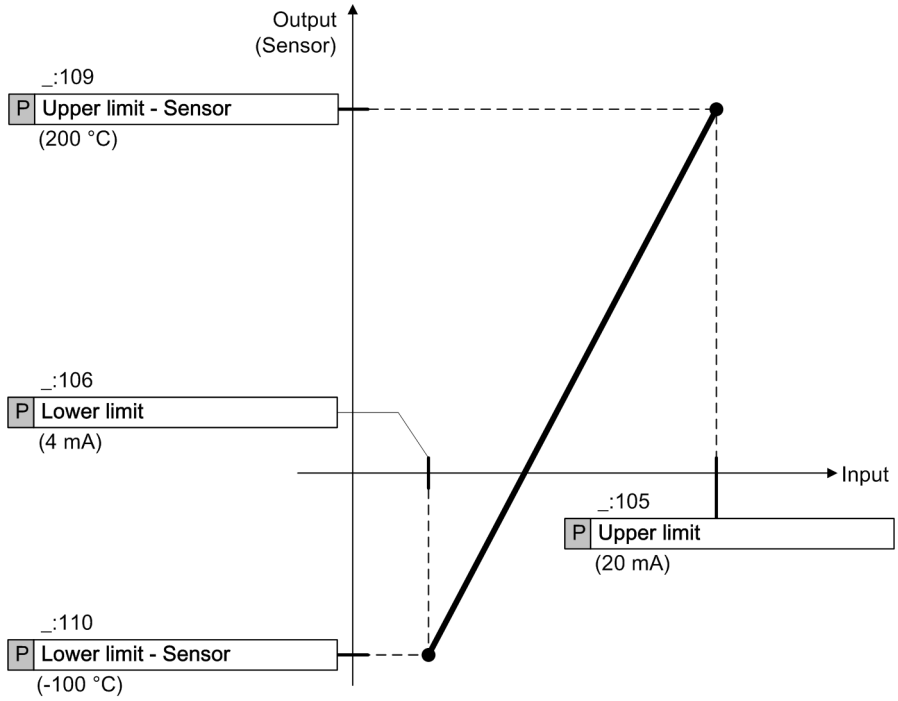


Figure 5-122 Scaling Principle

If you keep the preset limiting values, the following conditions are possible:

- If the input current is < 2.000 mA
  The function issues the indication *Broken wire* and the quality of the output value is invalid. The functions that use the output value as the measured value can be deactivated.
- If the input current is > 2.500 mA
  The indication *Broken wire* drops out.

Setting Example 1:

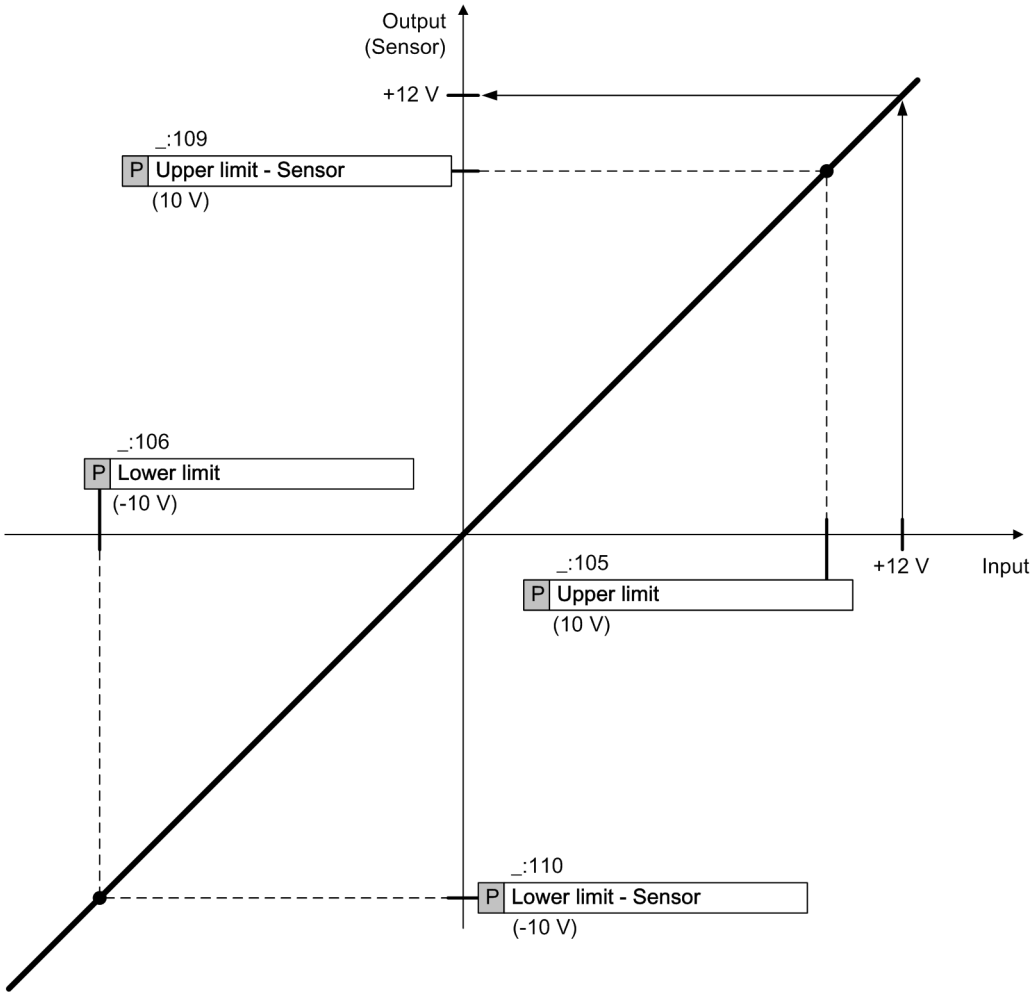
A measuring transducer transmitting a current signal of 4 mA to 20 mA is used as a transmitter. Currents well below -25.6 mA or above +25.6 mA indicate a transmitter failure. A sensor detecting a temperature is attached to the transmitter. The upper value corresponds to 200 °C and the lower value to -100 °C. This results in the following characteristic. In accordance with the set characteristic curve, the function calculates the sensor value from the measured current. The coefficients of the linear equation (gradient and foot point) are calculated from the set threshold and the sensor values are determined. A supplied current of 9.333 mA corresponds to a temperature of 0 °C.

[dw_measuring-transducer-characteristic, 1, en_US]

Figure 5-123 Characteristic Curve of Setting Example 1

NOTE

The hardware of the measuring transducer has been designed in such a way that measured values are transmitted and analyzed using the setting range (**`Upper limit`** or**`Lower limit`**). Therefore, special applications are possible, if necessary. The limits are at approx. +20 mA and -20 mA or +10 V and -10 V.



Setting Example 2:

For special applications, the transmitter sends a maximum of ±12 V. This voltage shall be issued accordingly as sensor voltage.

Set the parameters as follows:

- **`Upper limit`** = ***`10.00 V`***
- **`Upper limit - Sensor`** = ***`10.00 V`***
- **`Lower limit`** = ***`-10.00 V`***
- **`Lower limit - Sensor`** = ***`-10.00 V`***

With this setting, a signal of 12 V is issued as a 12-V measured value (see following figure).

[dw_measuring-transducer-setting, 1, en_US]

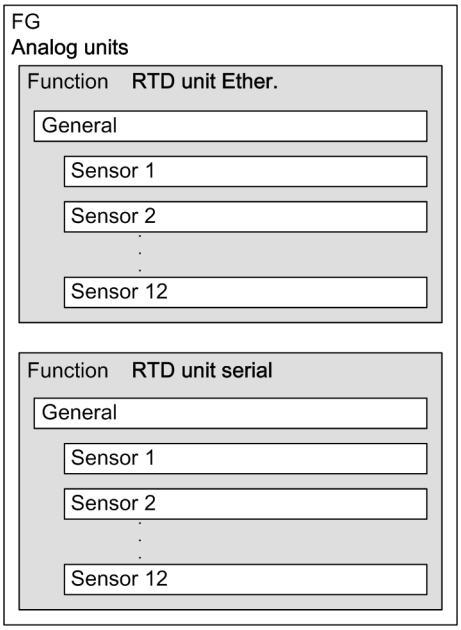
5.11.7 RTD Unit Ethernet



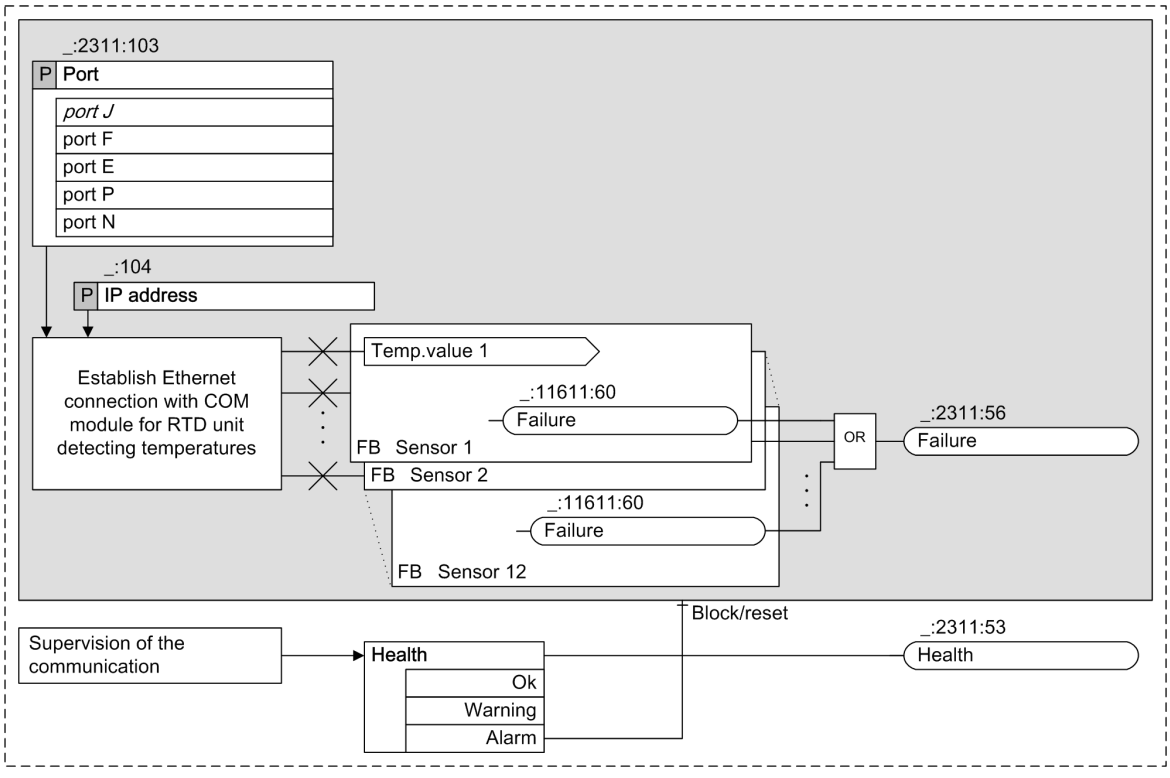
5.11.7.1 Overview

The **RTD unit Ether.** function:

- Communicates with an external RTD unit via the Slave Unit Protocol (SUP) and records the measured temperatures from the RTD unit
- Provides the captured temperatures to the temperature monitoring function
- Monitors communication with the RTD unit

5.11.7.2 Structure of the Function

The **RTD unit Ether.** function can only work in the **Analog units** function group. A maximum of 20 function instances can work simultaneously. Each instance contains 12 preconfigured sensor function blocks.



[dw_str_fnc, 2, en_US]

Figure 5-125 Structure/Embedding of the Function

5.11.7.3 Communication with an RTD Unit

Logic

[lo_rtdtcp, 1, en_US]

Figure 5-126 Logic of the RTD Unit Ether. Function

Communication with an RTD Unit

The function is used to communicate with an RTD unit connected via an Ethernet connection. If the connection of the function is successfully established to the external RTD unit via the Ethernet interface, the RTD unit transmits the temperatures of all connected sensors to the **RTD unit Ether.** function. For the connection to be established successfully, specific communication settings must be set, see chapter *5.11.7.4 Application and Setting Notes*.

The RTD unit **Ziehl TR1200 IP** supports only an Ethernet connection of 10 MBit/s. A direct connection to a 100-Mbit communication module is therefore not possible. For this reason, you must connect the RTD unit to the communication module via a 10/100 MBit/s autosensing switch which automatically recognizes the transmission rates and adapts them accordingly. Further information can be found in the Application and setting notes, see chapter *5.11.7.4 Application and Setting Notes*.

Error Responses

The following table lists the conditions under which the *Health* status transitions to the Alarm or Warning state.

Table 5-23 Error Responses

Error Description	Status Health
The **RTD unit Ether.** function cannot establish a connection with a communication module.	Alarm
The connection between the communication module and the RTD unit causes a time-out.	Warning
A communication module has not received any more data from the RTD unit for 9 sec.	Warning

The *Failure* signal is issued as soon as one of the sensor function blocks reports a failure.

5.11.7.4 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***port J***

Use the **Port** parameter to define over which port the external RTD unit is connected to the SIPROTEC 5 device.

If you want to connect the external RTD unit to the integrated Ethernet interface, set the parameter **Port** = ***Port J***. If you want to connect the external RTD unit to an Ethernet plug-in module, set the parameter **Port** = ***Port F***, ***Port E***, ***Port P***, or ***Port N***.

You can connect directly the RTD unit to the device via the internal 10-Mbit Ethernet port J. If you operate the RTD unit on another port via a 100-Mbit communication module, you need an interconnected 10/100-Mbit autosensing switch, which adapts transmission rates accordingly.

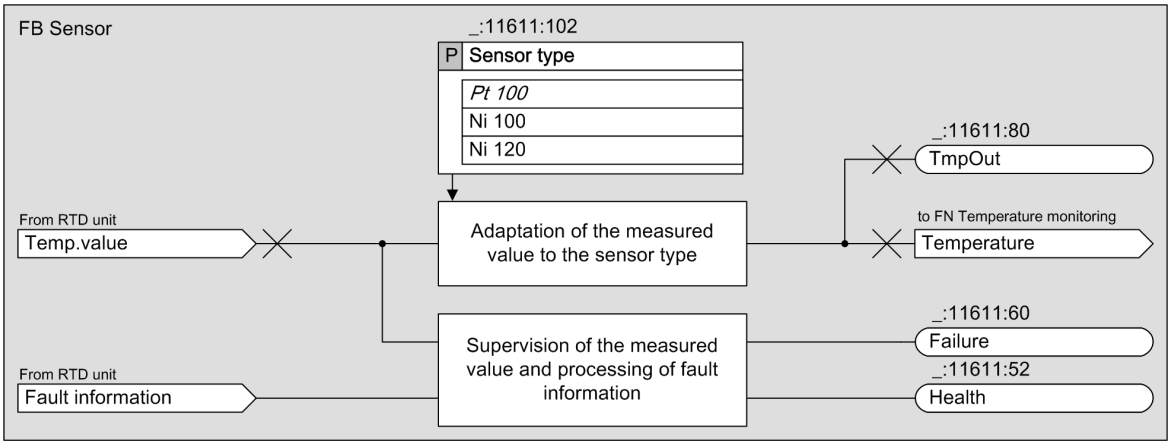
Parameter: IP address

- Default setting **(_:2311:104) IP address** = ***10.16.60.1***

With the parameter **IP address**, you set the IP address of the RTD unit connected to the communication module via the SUP protocol. Every RTD unit has to be assigned a unique IP address. The IP address to be set depends on your network configuration. You can set any valid IPv4 address that does not cause conflicts with other IP addresses in the network. Set an appropriate IP address first at the **Ziehl TR1200 IP** RTD unit. Then specify the parameter **IP address** for the communication module to the same address.

Settings on the RTD Unit

The **Ziehl TR1200 IP** RTD unit is set with the front keys or in a Web browser on a laptop computer via its Ethernet interface. Set the connection type of the sensors (3-wire connection or resistance value for 2-wire connection), the idle state of the fault-indication relay, as well as the IP interface setting.



The code lock has to be switched off for parameterization. This is only possible using the front keys of the RTD unit. The code lock is **off** (switched off) in as-delivered condition and has pin **504**.

For detailed information on the settings, refer to the TR1200 IP manual that comes with the RTD unit. The documents are also available in the SIPROTEC download area (http://www.siprotec.de) under **Accessories -> 7XV5662-xAD**.

For an Ethernet connection to a SIPROTEC 5 device communicating with the RTD unit TR1200 IP via the **SUP protocol** (Slave Unit Protocol), the **`Modbus TCP`** setting must be activated in the RTD unit. You can activate the Modbus TCP protocol using the function keys under the **tcP.** → **Mod / on** menu item or with the Web browser in the **TCP/UDP Config** tab. The **RTD** (RTD protocol) and **UDP Port** settings have no effect here. The Modbus TCP port is permanently set to 502 and cannot be changed.

5.11.7.5 Temperature Sensor

Logic

[lo_tmpval, 1, en_US]

Figure 5-127 Logic Diagram of the Temperature Sensor Function Block

Measured Temperature Value

The **Temperature sensor** function block processes one single measured temperature value delivered from the RTD unit for the assigned sensor. 12 temperature sensor function blocks are always available in each RTD unit function (both via Ethernet and serial), even if fewer sensors are connected to the RTD unit.

Various temperature sensor types are supported: Pt100, Ni100, and Ni120 sensors. The function block is notified regarding the selection of connected type via the **`Sensor type`** parameter.

The function block delivers a measured temperature value in °C or °F as an output variable. The measured temperature value is available as an operational measured value and can be monitored by the **Temperature supervision** function.

Error Responses

If the measured input value is determined to be incorrect, the quality attribute of the output measured temperature value is set to *`invalid`*. The statuses for Health and Error take the statuses in accordance with the following table:

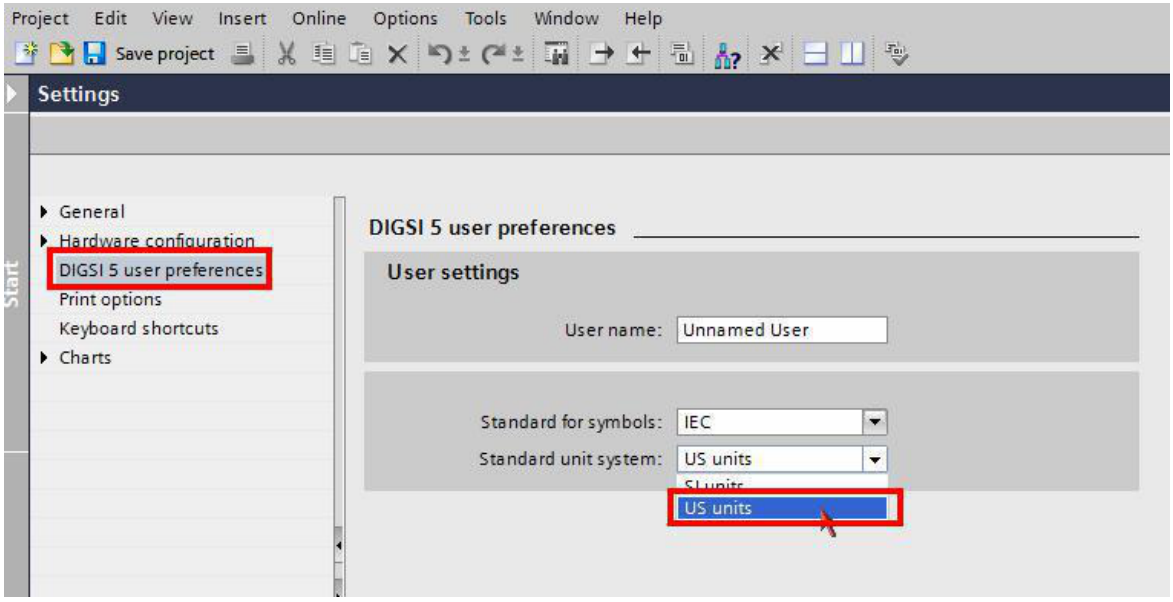
Table 5-24 Error response

Error Description	Health Status	Error Status
Sensor or line short circuited	Alarm	Yes
Sensor or line interrupted	Alarm	Yes

Error Description	Health Status	Error Status
Measured temperature value outside the valid measuring range specified in the technical data. The valid measuring range depends on the sensor type.	Alarm	Yes
Sensor not connected	OK	No

5.11.7.6 Application and Setting Notes

Parameter: Sensor type



- Default setting **(_:11611:102) Sensor type** = ***Pt 100***

The **Sensor type** parameter is used to set the sensor element used. You can select between ***Pt 100***, ***Ni 100*** and ***Ni 120***.

Parameter: Temperature unit

To change the display and evaluation of measured temperature values from °C to °F, adapt the DIGSI user default settings accordingly.
Proceed as follows:

- In DIGSI select the menu item **Extras** --> **Settings**.
- In the **Settings** view select the menu item **DIGSI 5 User preferences**.
- Under **Standard unit system** change the setting value of the unit system used from ***SI units*** to ***US units***.

[scfahrht-190214-01, 1, en_US]

Figure 5-128 Change of the Display Between °C and °F

The following settings and information table shows only 1 of the 12 sensors, as the setting possibilities of the 12 sensors do not differ.

5.11.8 RTD Unit, Serial

5.11.8.1 Overview

The **RTD unit serial** function:

- Communicates with an external RTD unit serial via the Slave Unit Protocol (SUP) and records the measured temperatures from the RTD unit
- Provides the captured temperatures to the temperature supervision function
- Monitors communication with the RTD unit

The **RTD unit Serial** function is set up structurally in the same manner as the **RTD unit Ether.** function. The mode of operation is also identical (see *5.11.7.3 Communication with an RTD Unit*).

5.11.8.2 Application and Setting Notes

Parameter: Port

- Default setting **(_:2311:103) Port** = ***F***

With the parameter **Port**, you set the slot for the communication module that will be used for the connection with an external RTD unit.

If you want to connect the external RTD unit to an Ethernet plug-in module, set the parameter **Port** = ***Port F***, ***Port E***, ***Port P***, or ***plug-in module position***.

Parameter: Channel number

- Default setting **(_:2311:105) Channel number** = *1*

A serial communication module optionally uses 2 channels. With the parameter **Channel number**, you set the channel number (1 or 2) through which the RTD unit is connected to the device. The communication module inputs are labeled with the channel numbers.

Parameter: Slave address

- Default setting **(_:2311:106) Slave address** = *1*

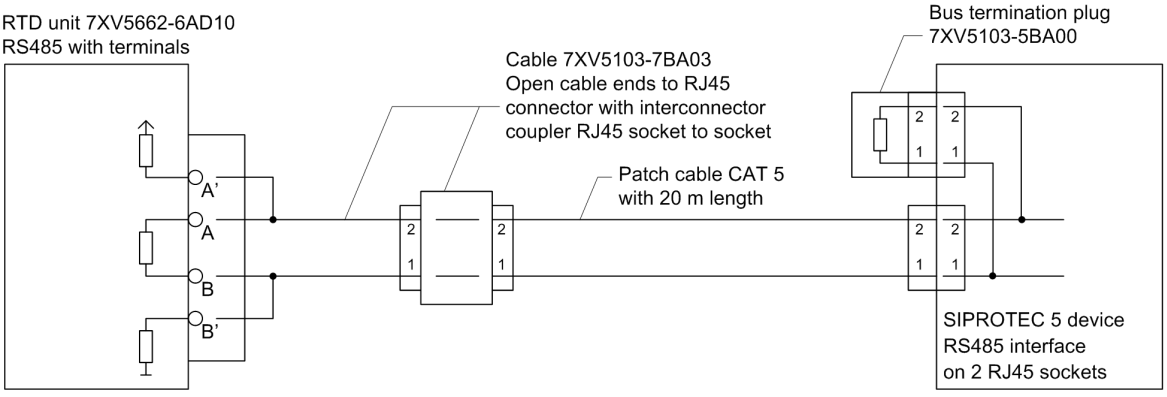
With the parameter **Slave address**, you define the device address of the RTD unit. If only one RTD unit is connected to the serial bus, the default value *1* can be used. The same device address has to be set on the RTD unit. The device address is important for distinguishing among several RTD units connected to a serial bus. Set a unique device address (for example 1, 2, and 3 when connecting 3 RTD units) for each RTD unit and the same device address for the parameter **Slave address** in the 3 **RTD unit serial** functions.

The following settings and information table shows only 1 of the 12 sensors, as the setting possibilities of the 12 sensors do not differ.

5.11.8.3 Settings

Addr.	Parameter	C	Setting Options	Default Setting
General				
_:2311:103	General:Port		• port F • port E • port J • port N • port P	port J
_:2311:105	General:Channel number		1 to 2	1
_:2311:106	General:Slave address		1 to 247	1
Sensor 1				
_:11611:102	Sensor 1:Sensor type		• Pt 100 • Ni 100 • Ni 120	Pt 100

5.11.8.4 Information List



No.	Information	Data Class (Type)	Type
General			
_:2311:52	General:Behavior	ENS	O
_:2311:53	General:Health	ENS	O
_:2311:56	General:Failure	SPS	O
Sensor 1			
_:11611:51	Sensor 1:Behavior	ENS	O
_:11611:52	Sensor 1:Health	ENS	O
_:11611:60	Sensor 1:Failure	SPS	O
_:11611:80	Sensor 1:TmpOut	MV	O

5.11.9 Communication with RTD Unit

5.11.9.1 Integration of a Serial RTD Unit (Ziehl TR1200)

Connection of the Communication Lines

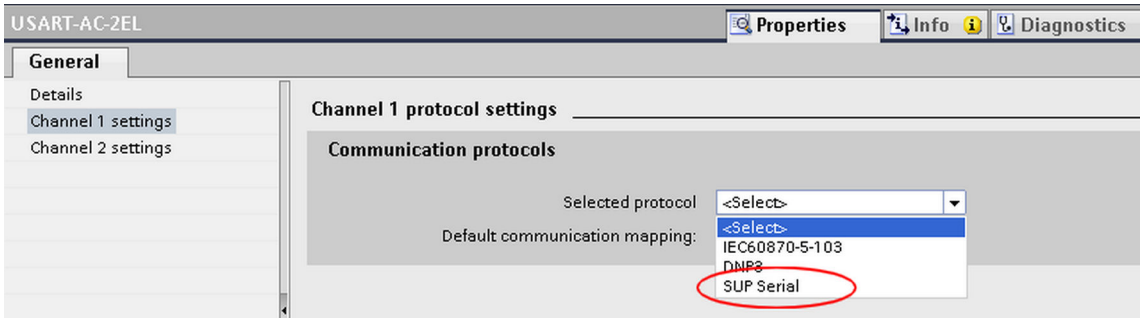
Figure 5-129 shows how you connect the RTD unit to the SIPROTEC 5 device. Note that Pin 1 of the RJ45 plug is connected to RTD-B and Pin 2 is connected to RTD-A.

[dwverbau-201112-01.tif, 1, en_US]

Figure 5-129 Connection of the RTD Unit to the SIPROTEC 5 Device

Adding a USART Module

Add a USART-AB-1EL or a USART-AC-2EL USART module in DIGSI to the device. The USART module must be inserted at one of the plug-in positions for communication modules in the base module or in the CB202 expansion module (refer to the following figure).



[scauser3-190214-01, 1, en_US]

Figure 5-130 Insertion Position for a USART Module

Selecting the SUP Protocol

Select the Slave Unit Protocol (SUP). This protocol is responsible for the communication between the SIPROTEC 5 device and the RTD Unit.

[scauser4-301012-01.tif, 1, en_US]

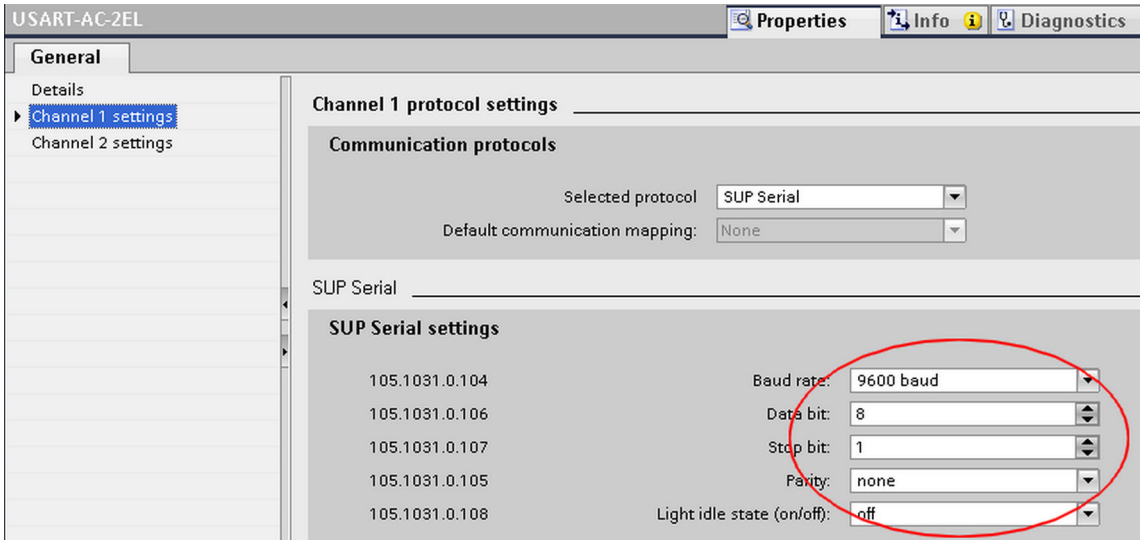


Figure 5-131 Selecting the SUP Protocol

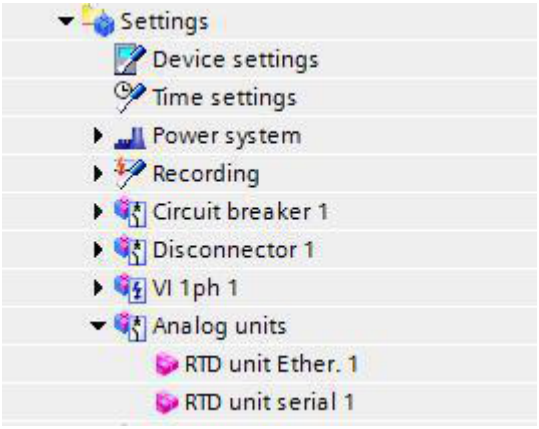
Communication Settings

Make the communications settings for the relevant serial channels. For this, use the default settings specified by the RTD box. Normally, you must adapt only the parameterization of the SIPROTEC 5 device to the settings of the RTD box. Make sure that the setting values in both devices are the same. The setting of the parameter **`Non-flickering light (on/off)`**: is not relevant for the RS485 interface.

NOTE



The driver for the USART module for the SUP protocol is not preinstalled as standard for the initial use of this interface (following the firmware update).

[scauser5-301012-01.tif, 1, en_US]

Figure 5-132 Making the Communication Settings

With the selection of the SUP protocol for the RTD box DIGSI automatically adds the function group **Analog units** to your device configuration. You can now instantiate the function **RTD unit serial 1** (refer to the following figure).

[sc_auser6, 1, en_US]

Figure 5-133 Analog-Unit Instance

Now, set the channel number over which the SUP protocol runs. In addition, set the slave address of the RTD unit. This address must be set with the same value in the RTD box (refer to the following figure).
The following device configuration must be set on the TR1200 RTD unit when the RTD unit is used for the first time:

- Bus protocol: mod
- Device address: 1
- Baud rate: 9600
- Parity: no

[scauser7-220114-01-DE, 1, en_US]

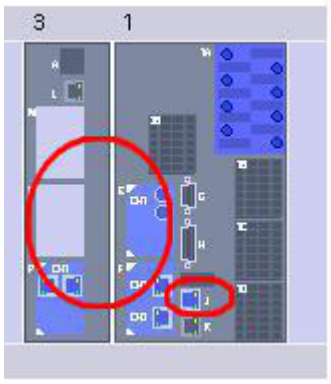


Figure 5-134 Setting the Port, Channel Number, and Slave Address

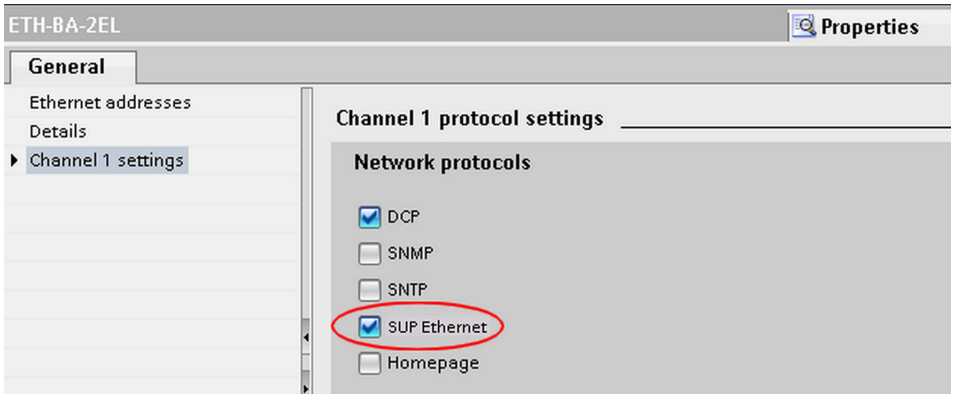
Finally, load the configuration in the device.

5.11.9.2 Integration of an RTD Unit Ether. (TR1200 IP)

Device Configuration

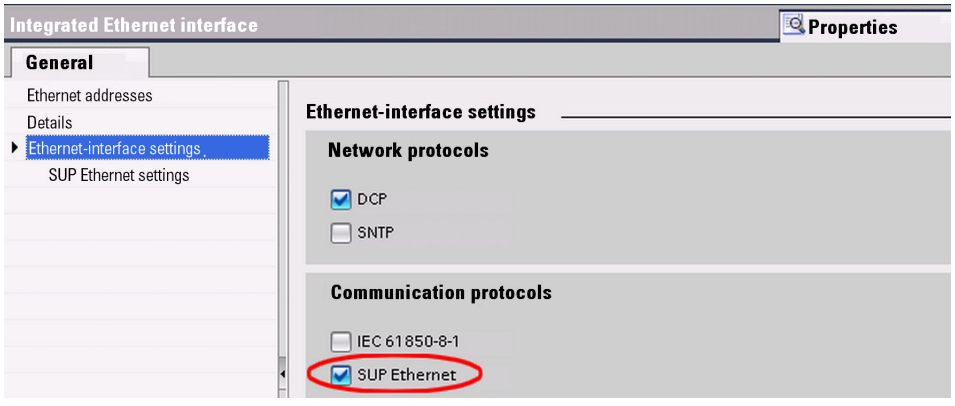
In the DIGSI, insert an Ethernet module into the provided slot, thus adding the module to the device configuration. *Figure 5-135* displays the available slots in the base module or on the expansion module CB202. Alternatively, you can also use the integrated Ethernet interface port J.



[sc_autcp1, 1, en_US]

Figure 5-135 Inserting an Ethernet Module

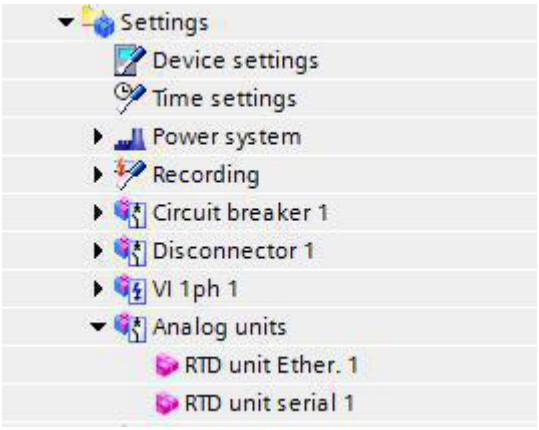
Communication Settings



Activate the SUP Ethernet protocol for the Ethernet module.

[sc_autcp2, 1, en_US]

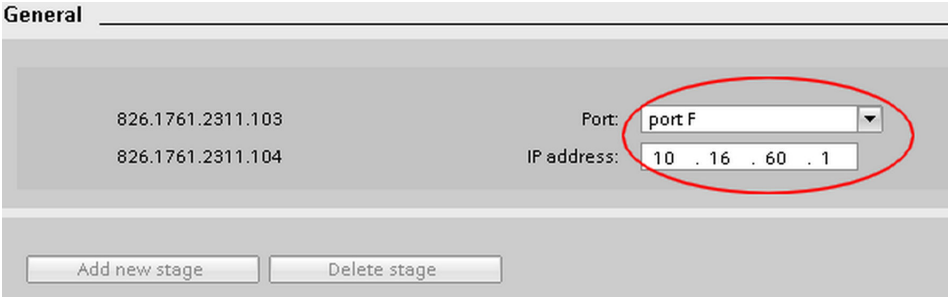
Figure 5-136 SUP Ethernet Protocol Activation



This protocol is also available for Port J of the integrated Ethernet interface of the base module (refer to following figure).

[sc_autcp3, 1, en_US]

Figure 5-137 SUP Ethernet Protocol Activation (Base Module)



With the selection of the SUP protocol for the RTD unit, DIGSI automatically adds the **Analog units** function group and the **RTD unit Ether.** function to your device configuration (refer to the following figure).

[sc_auser6, 1, en_US]

Figure 5-138 Analog Unit Instance

Now, set the port over which the SUP protocol runs. In addition, set the IP address of the RTD unit (refer to the following figure). This address must be set with the same value in the RTD unit.

[sc_autcp5, 1, en_US]

Figure 5-139 Setting the Port and IP Address

Finally, load the configuration in the device.

5.11.9.3 Temperature Simulation without Sensors

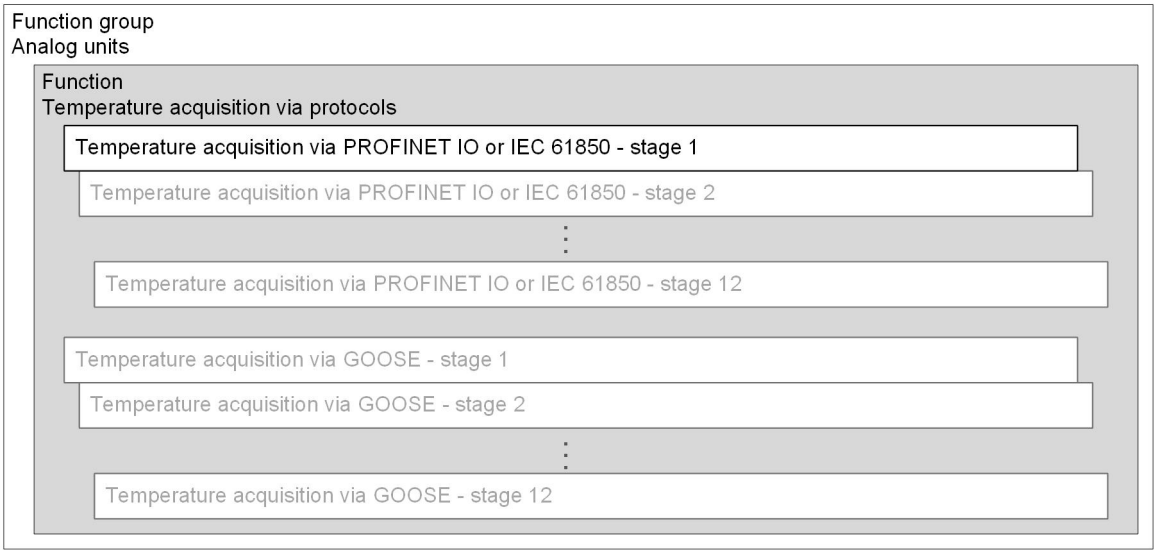
Connect a resistor on the sensor terminals of the RTD unit. Using this resistor, simulate a constant temperature. The resistance value should be around 50 Ω to 200 Ω.

If you want to simulate a changeable temperature, connect an adjustable resistor of maximum 470 Ω instead of a fixed resistor.

5.11.10 Temperature Acquisition via Protocols

5.11.10.1 Overview

The function **Temperature acquisition via protocols**:



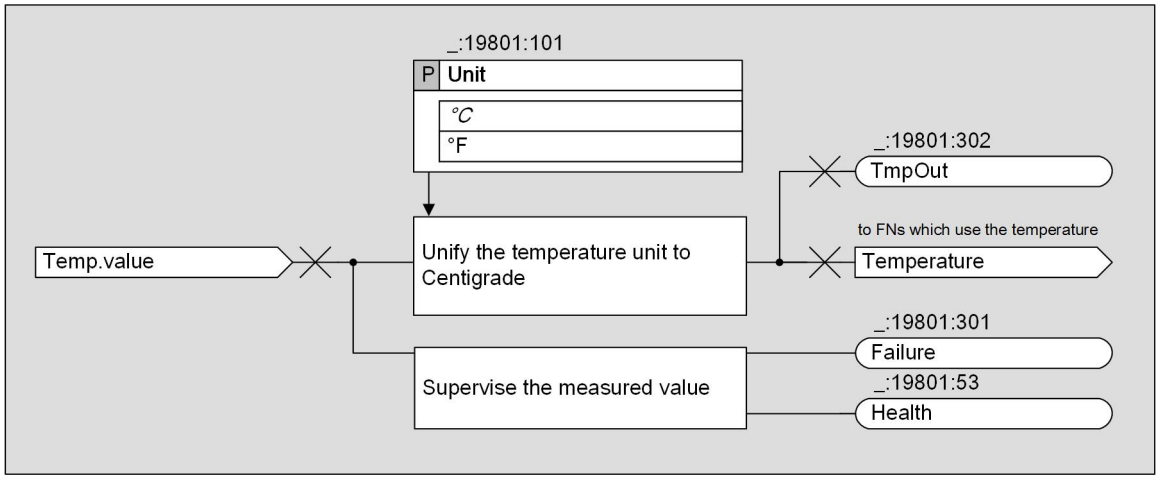
- Obtains the temperature from a power-plant control system or from another protection device
- Processes the temperature, for example, supervises the temperature in the CFC
- Transfers the temperature to other protection devices

5.11.10.2 Structure of the Function

The function **Temperature acquisition via protocols** can work only in the function group **Analog units**. In this function, the following stages can operate simultaneously:

- 12 stages **Temperature acquisition via PROFINET IO or IEC 61850**
  The stage can obtain the temperature from a power-plant control system via the PROFINET IO protocol or the IEC 61850 protocol.
- 12 stages **Temperature acquisition via GOOSE**
  The stage can obtain the temperature from another SIPROTEC 5 protection device via the GOOSE protocol.

The function **Temperature acquisition via protocols** comes factory-set with 1 stage **Temperature acquisition via PROFINET IO or IEC 61850**.



[dw_structure_TmpviaProt, 1, en_US]

Figure 5-140 Structure/Embedding of the Function

5.11.10.3 Stage Temperature Acquisition via PROFINET IO or IEC 61850

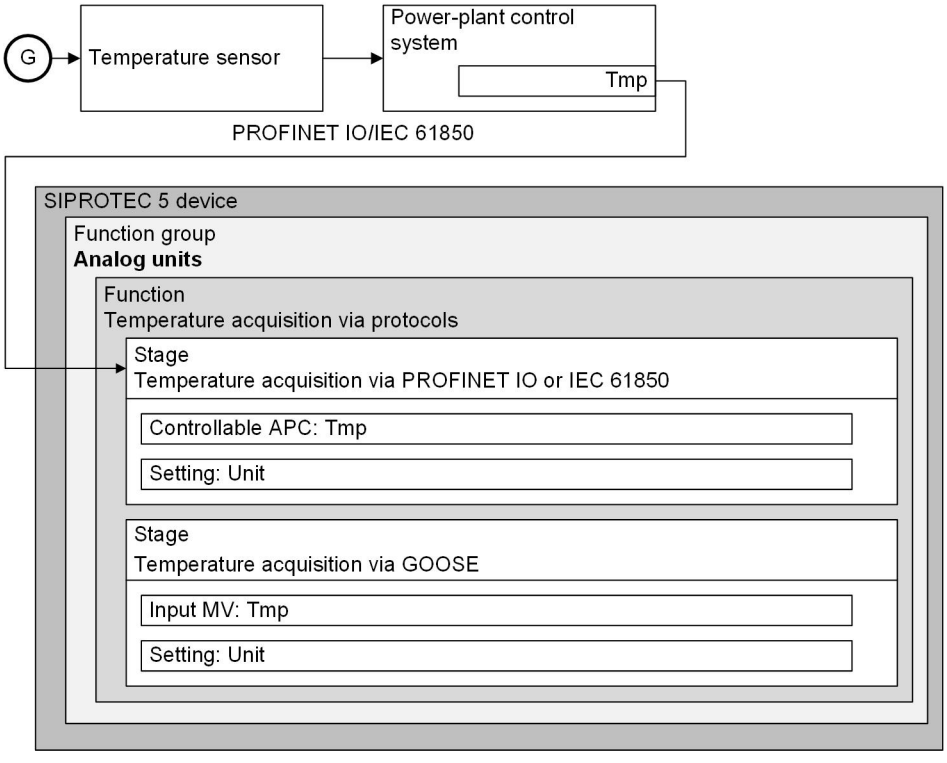
Logic

[lo_tmpval, 1, en_US]

Figure 5-141 Logic Diagram of the Stage

The stage **Temperature acquisition via PROFINET IO or IEC 61850** supports 2 protocols:

- PROFINET IO protocol
  If you set the PROFINET IO protocol for the temperature acquisition, you can only get the analog value.
- IEC 61850 protocol
  If you set the IEC 61850 protocol for the temperature acquisition, you get the analog value, the quality, and the time stamp.



Invalid Temperature Indication

If the received temperature is invalid, the failure indication *Temperature failure* is issued.

Stage Application

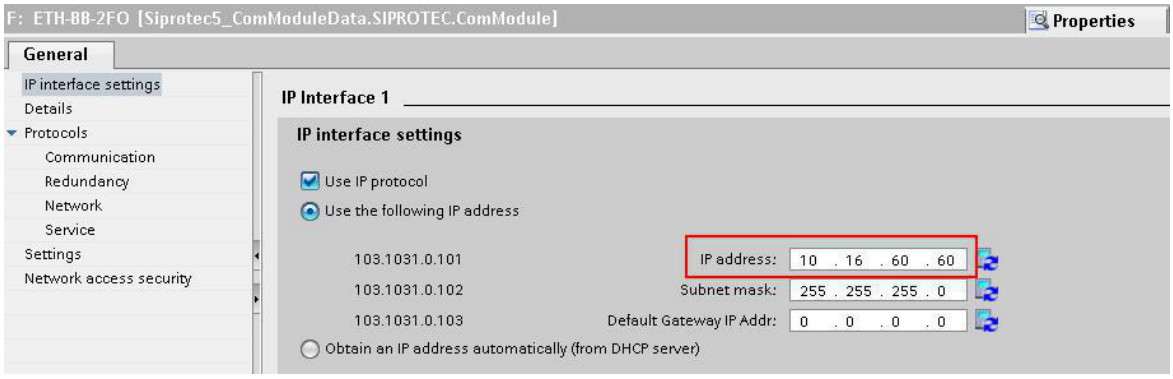
You can use the stage **Temperature acquisition via PROFINET IO or IEC 61850** for the following purposes:

- Acquire the cold-gas temperature from the power-plant control system
- Process the received cold-gas temperature value
- Send the processed cold-gas temperature value to other functions for further processing

[dw_app-example_IEC, 1, en_US]

Figure 5-142 Application Example

The following table explains the data.

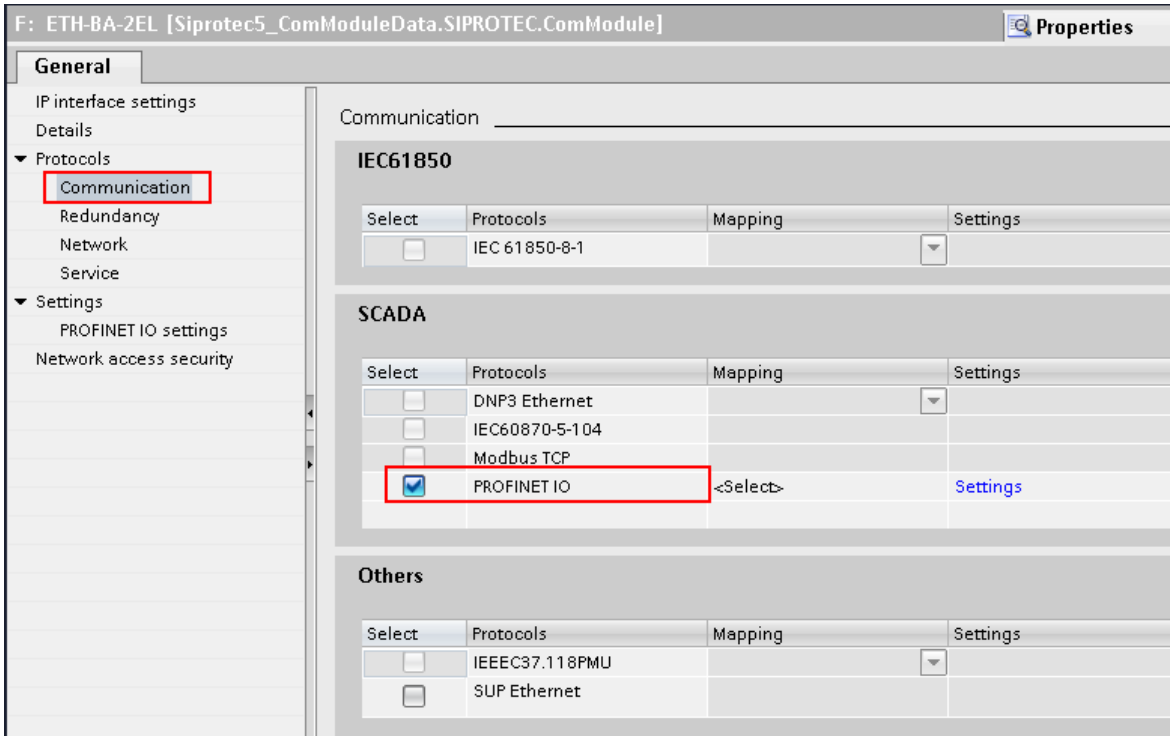


Data Name	Description
Tmp	With this variable, you can set the PROFINET IO protocol or the IEC 61850 protocol for the temperature acquisition. In the stage **Temperature acquisition via PROFINET IO or IEC 61850**, the data type is APC.
Unit	With this parameter, you can select the unit **°F** or **°C** for the temperature which is acquired from the power-plant control system.

5.11.10.4 PROFINET IO Configuration for the Temperature Acquisition

With the stage **Temperature acquisition via PROFINET IO or IEC 61850**, to acquire the cold-gas temperature via the PROFINET IO protocol, the following configurations are necessary.

IP-Address Configuration and Protocol Selection



- ✧ In the project tree, navigate to your device and double-click **Hardware and protocols**.
- ✧ In the **Device view** tab, select an Ethernet communication module for which you want to configure the PROFINET IO protocol.
- ✧ In the **Properties** tab of the communication module, select **General** > **IP interface settings**.
- ✧ Set the **IP address** for the communication module.

[sc_PROFINET IP, 2, en_US]

Figure 5-143 IP-Address Configuration

- ✧ Select **General** > **Protocols** > **Communication**.
- ✧ Under **SCADA**, select the item ***PROFINET IO***.

[sc_PROFINET_IO, 2, en_US]

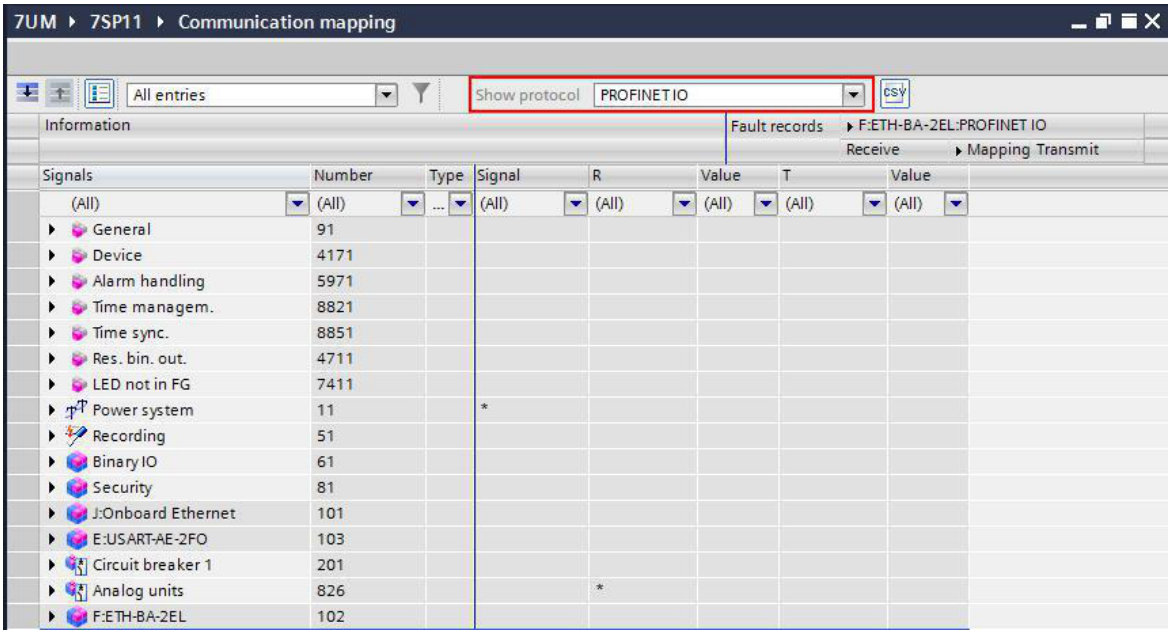


Figure 5-144 Protocol Selection

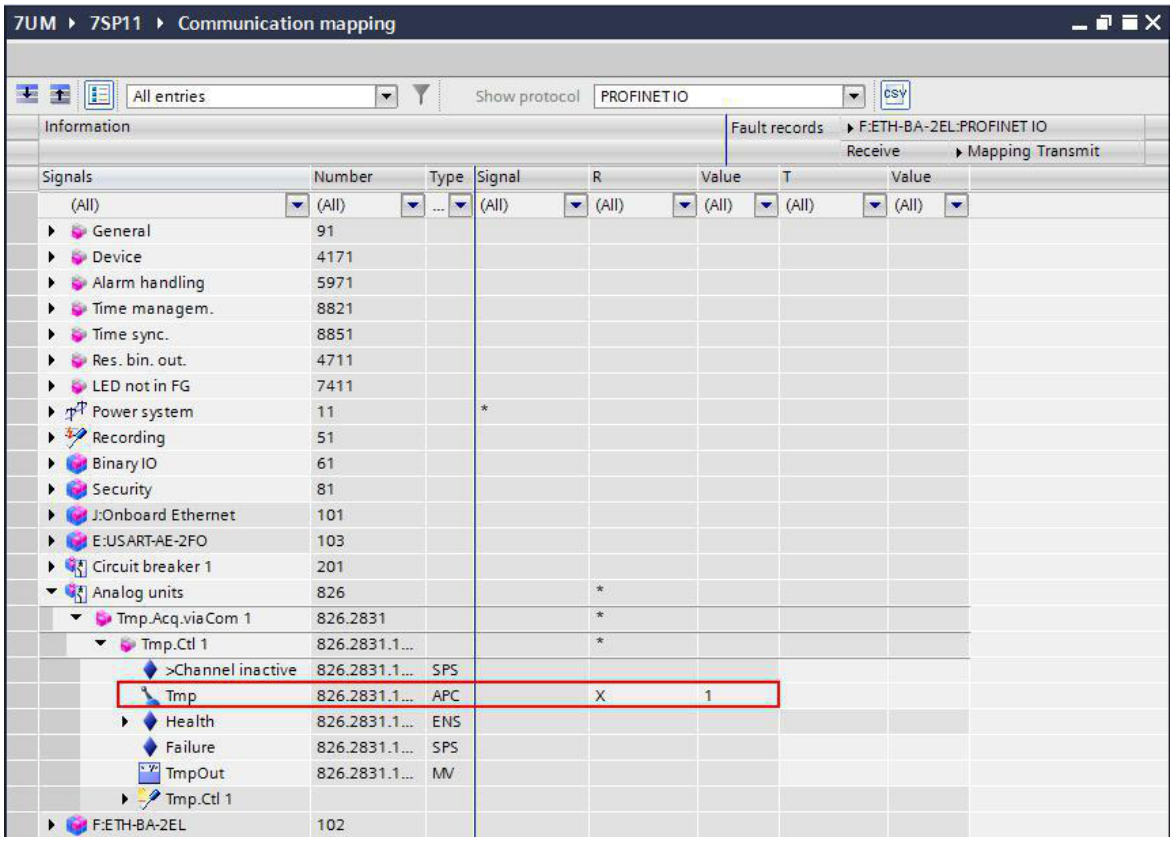
Function Instantiation

- ✧ In the project tree, navigate to your device and select **Settings** > **Analog units**.
  If there is no function group **Analog units**, instantiate one.
- ✧ Instantiate the function **Tmp.Acq.viaCom** in the function group **Analog units**.

Signal Mapping and Configuration



- ✧ In the project tree, navigate to your device and double-click **Communication mapping**.
- ✧ In the **Communication mapping** matrix, set **Show protocol** to ***PROFINET IO***.

[sc_PROFI_Filter, 2, en_US]

Figure 5-145 Protocol Filter

- ✧ In the column **Signals**, select **Analog units** > **Tmp.Acq.viaCom 1** > **Tmp.Ctl 1**.
- ✧ Route the data *Tmp* in column **R** and set the value to ***1***.

[sc_PROFI_Setting, 1, en_US]

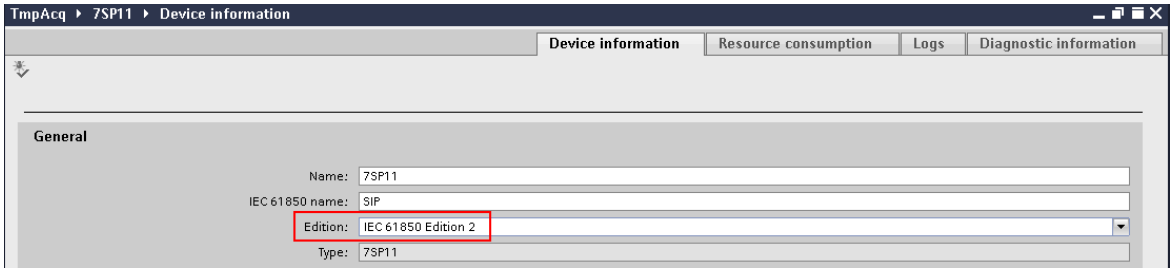


Figure 5-146 Signal Configuration

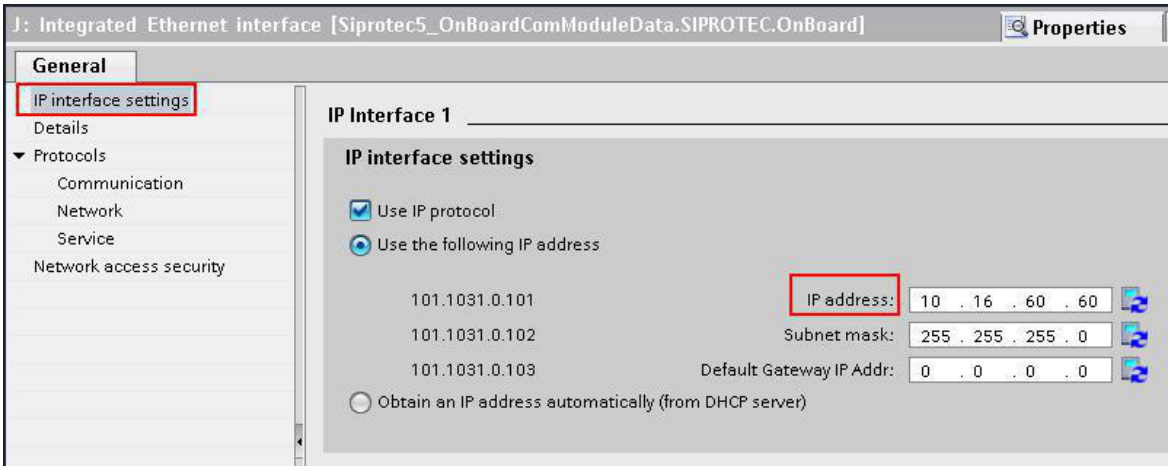
5.11.10.5 IEC 61850 Configuration for the Temperature Acquisition

With the stage **Temperature acquisition via PROFINET IO or IEC 61850**, to acquire the cold-gas temperature via the IEC 61850 protocol, the following configurations are necessary.

IEC 61850 Edition Selection

- ✧ In the project tree, navigate to your device and double-click **Device information**.
- ✧ In the **Device information** tab, set the parameter **`Edition`** to ***`IEC 61850 Edition 2`*** or a higher edition.

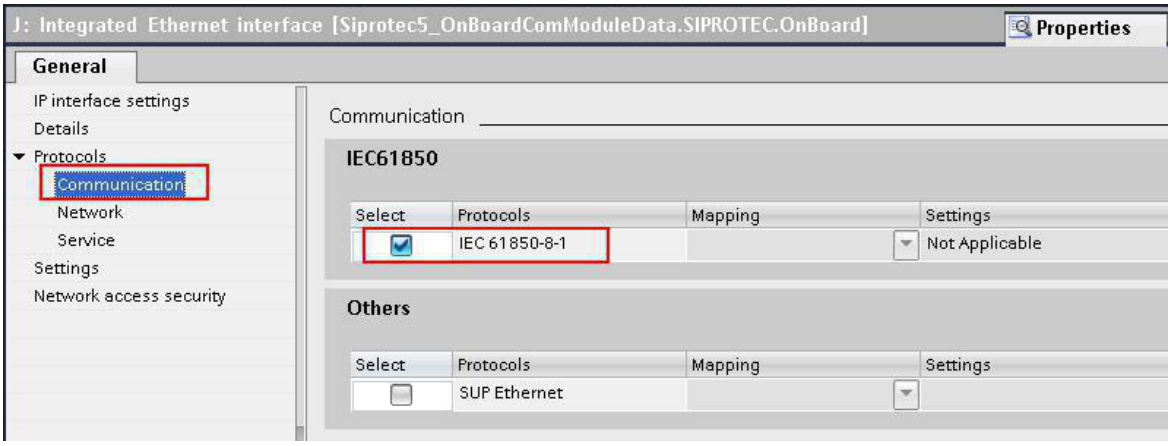


[sc_iec_edition, 1, en_US]

Figure 5-147 IEC 61850 Edition

IP-Address Configuration and Protocol Selection

- ✧ In the project tree, navigate to your device and double-click **Hardware and protocols**.
- ✧ In the **Device view** tab, select the communication module for which you want to configure the IEC 61850 protocol.

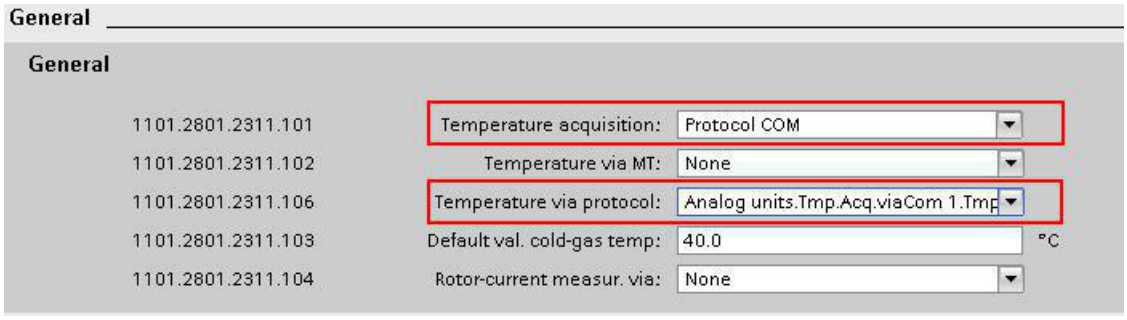


- ✧ In the **Properties** tab of the communication module, select **General** > **IP interface settings**.
- ✧ Set the **IP address** for the communication module.

[sc_iec_61850_ip, 2, en_US]

Figure 5-148 IP-Address Configuration

- ✧ Select **General** > **Protocols** > **Communication**.
- ✧ Under **IEC61850**, select the item ***IEC 61850-8-1***.

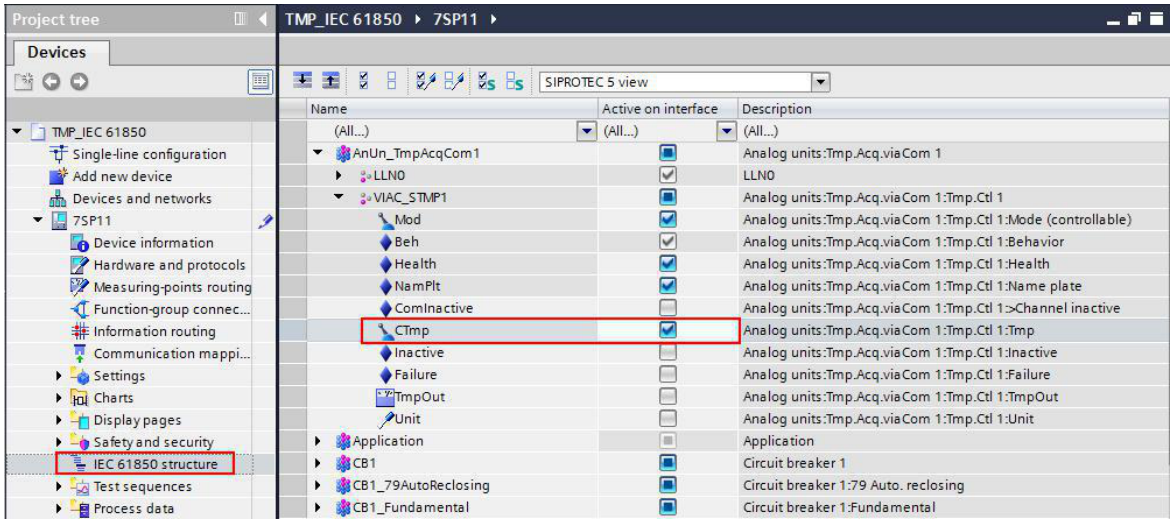


[sc_iec_61850_sel, 2, en_US]

Figure 5-149 Protocol Selection

Function Instantiation

- ✧ In the project tree, navigate to your device and select **Settings** > **Analog units**.
  If there is no function group **Analog units**, instantiate one.
- ✧ Instantiate the function **Tmp.Acq.viaCom** in the function group **Analog units**.
- ✧ Instantiate the function that requires the cold-gas temperature in the corresponding function group.
  The function **49R RotorTOLP** is taken as an example in the following steps.
- ✧ Under **General** of the function **49R RotorTOLP**, set the parameter **`Temperature acquisition`** to ***`Protocol COM`***.
- ✧ Set the parameter **`Temperature via protocol`** to ***`Analog units.Tmp.Acq.viaCom 1.Tmp.Ctl 1`***.



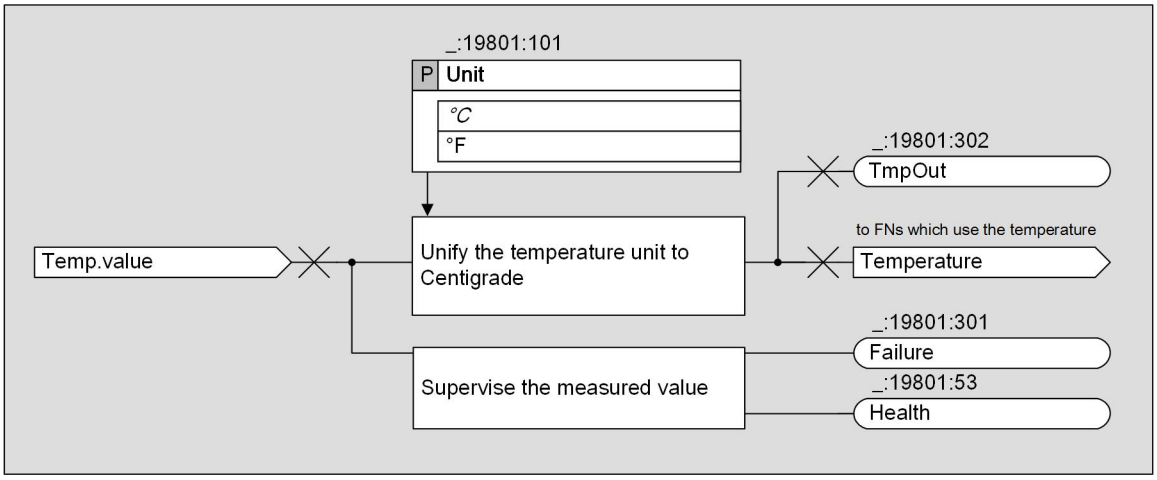
[sc_iec_61850_3, 2, en_US]

Figure 5-150 Parameter Configuration

Configuration in the IEC 61850 structure

✧ In the project tree, navigate to your device and double-click **IEC 61850 structure**.

✧ In the column **Name**, select **AnUn_TmpAcqCom 1** > **VIAC_STMP1** > **CTmp**.



[sc_iec_61850_cgt, 1, en_US]

Figure 5-151 Data Selection

5.11.10.6 Stage Temperature Acquisition via GOOSE

Logic

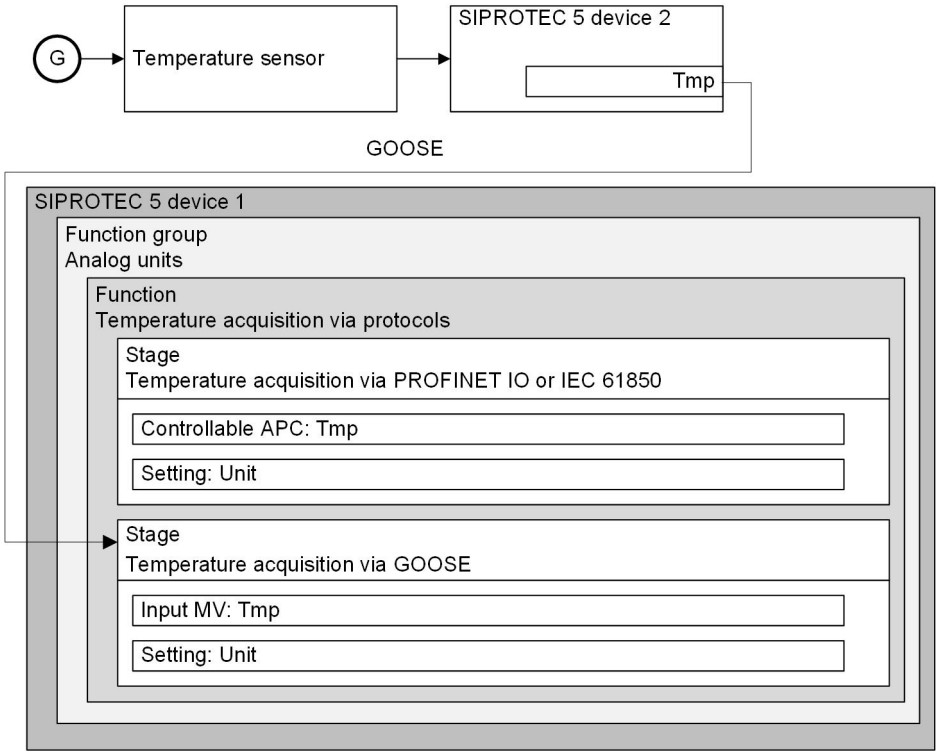
[lo_tmpval, 1, en_US]

Figure 5-152 Logic Diagram of the Stage

Invalid Temperature Indication

If the received temperature is invalid, the failure indication *Temperature failure* is issued.

Stage Application



The following terms are used for the stage **Temperature acquisition via GOOSE**:

- Source device
  SIPROTEC 5 protection device that provides data
- Target device
  SIPROTEC 5 protection device that requests data from the source device

In the target device, you can use the stage **Temperature acquisition via GOOSE** for the following purposes:

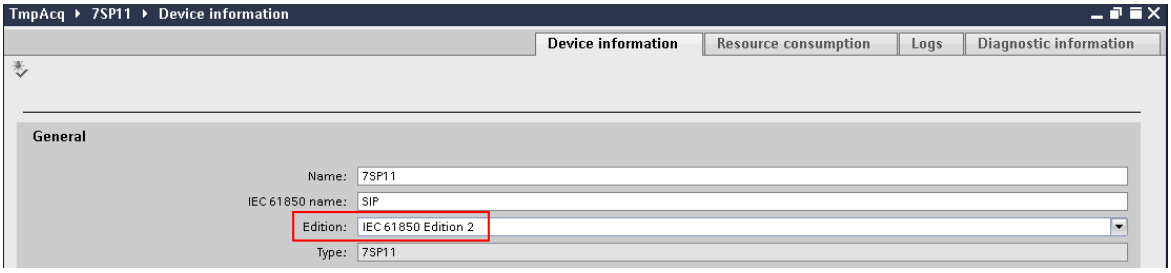
- Acquire the cold-gas temperature from the source device
- Process the received cold-gas temperature value
- Send the processed cold-gas temperature value to other functions for further processing

In the following figure, the source device is SIPROTEC 5 device 2 and the target device is SIPROTEC 5 device 1.

[dw_app-example_GOOSE, 2, en_US]

Figure 5-153 Application Example

The following table explains the data.



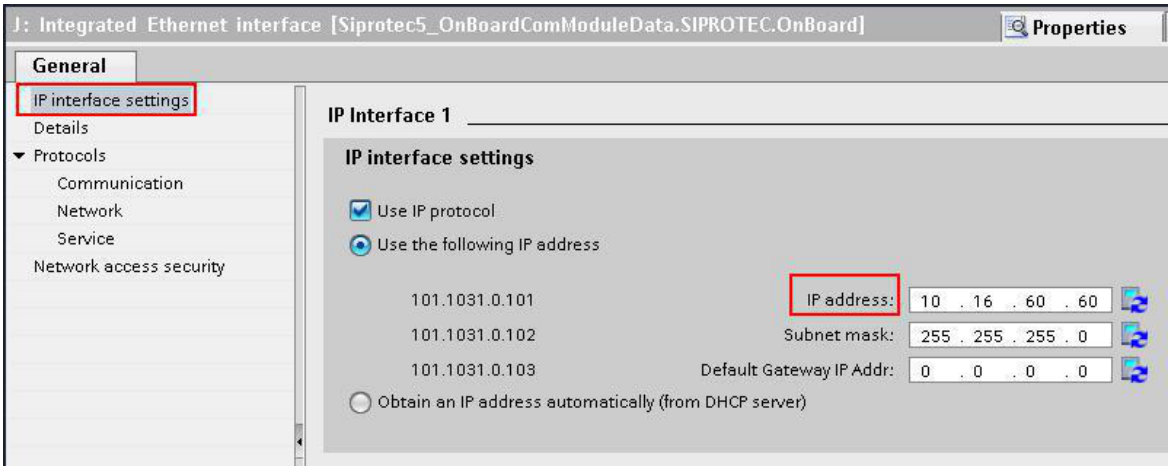
Data Name	Description
Tmp	With this variable, you can set the GOOSE protocol for the temperature acquisition. In the stage **Temperature acquisition via GOOSE**, the input measured value with a COM template is designed to acquire the data from another SIPROTEC 5 protection device.
Unit	With this parameter, you can select the unit ***°F*** or ***°C*** for the temperature which is acquired from another SIPROTEC 5 protection device.

5.11.10.7 GOOSE Configuration for the Temperature Acquisition

To acquire the cold-gas temperature with the stage **Temperature acquisition via GOOSE**, the following configurations are necessary.

IEC 61850 Edition Selection – Source Device

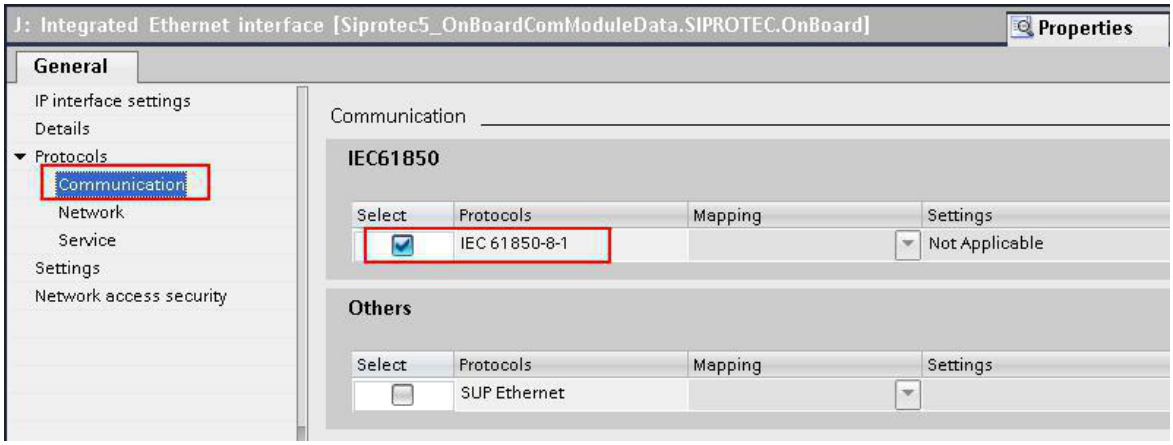
- ✧ In the project tree, select the source device and double-click **Device information**.
- ✧ In the **Device information** tab, set the parameter **Edition** to ***IEC 61850 Edition 2*** or a higher edition.



[sc_iec_edition, 1, en_US]

Figure 5-154 IEC 61850 Edition

IP-Address Configuration and Protocol Selection – Source Device

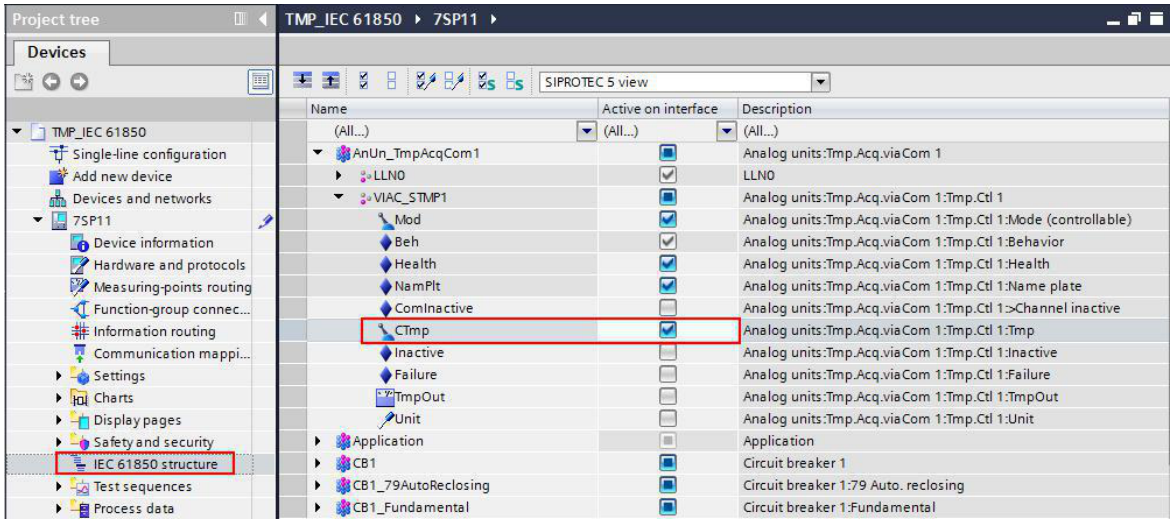


- ✧ In the project tree, select the source device and double-click **Hardware and protocols**.
- ✧ In the **Device view** tab, select the communication module for which you want to configure the IEC 61850 protocol.
- ✧ In the **Properties** tab of the communication module, select **General** > **IP interface settings**.
- ✧ Set the **IP address** for the communication module.

[sc_iec_61850_ip, 2, en_US]

Figure 5-155 IP-Address Configuration

- ✧ Select **General** > **Protocols** > **Communication**.
- ✧ Under **IEC61850**, select the item ***IEC 61850-8-1***.

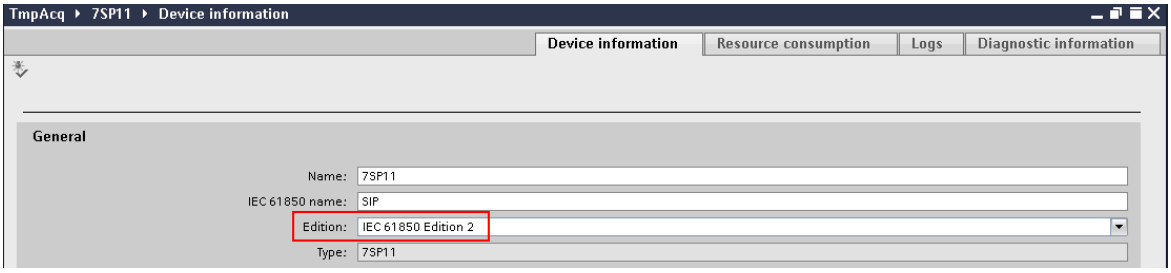


[sc_iec_61850_sel, 2, en_US]

Figure 5-156 Protocol Selection

Configuration in IEC 61850 structure – Source Device

- ✧ In the project tree, select the source device and double-click **IEC 61850 structure**.
- ✧ In the column **Name**, select **AnUn_TmpAcqCom 1** > **VIAC_STMP1** > **CTmp**.



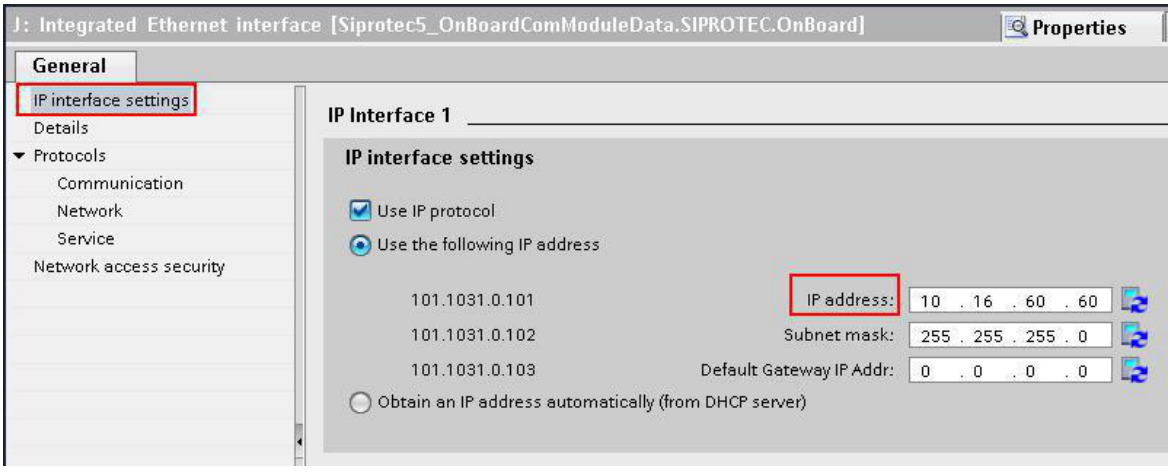
[sc_iec_61850_cgt, 1, en_US]

Figure 5-157 Data Selection

Now, the device can be used to send the cold-gas temperature to other devices.

IEC 61850 Edition Selection – Target Device

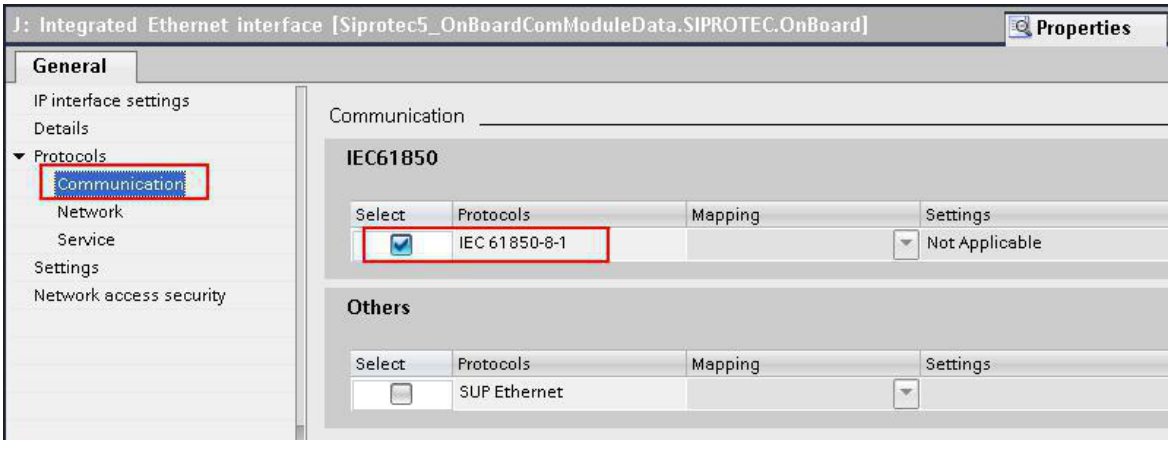
- ✧ In the project tree, select the target device and double-click **Device information**.
- ✧ In the **Device information** tab, set the parameter **`Edition`** to ***`IEC 61850 Edition 2`*** or a higher edition.



[sc_iec_edition, 1, en_US]

Figure 5-158 IEC 61850 Edition

IP-Address Configuration and Protocol Selection – Target Device



- ✧ In the project tree, select the target device and double-click **Hardware and protocols**.
- ✧ In the **Device view** tab, select the communication module for which you want to configure GOOSE.
- ✧ In the **Properties** tab of the communication module, select **General** > **IP interface settings**.
- ✧ Set the **IP address** for the communication module.

[sc_iec_61850_ip, 2, en_US]

Figure 5-159 IP-Address Configuration

- ✧ Select **Protocols** > **Communication** > **IEC 61850-8-1**.

[sc_iec_61850_sel, 2, en_US]

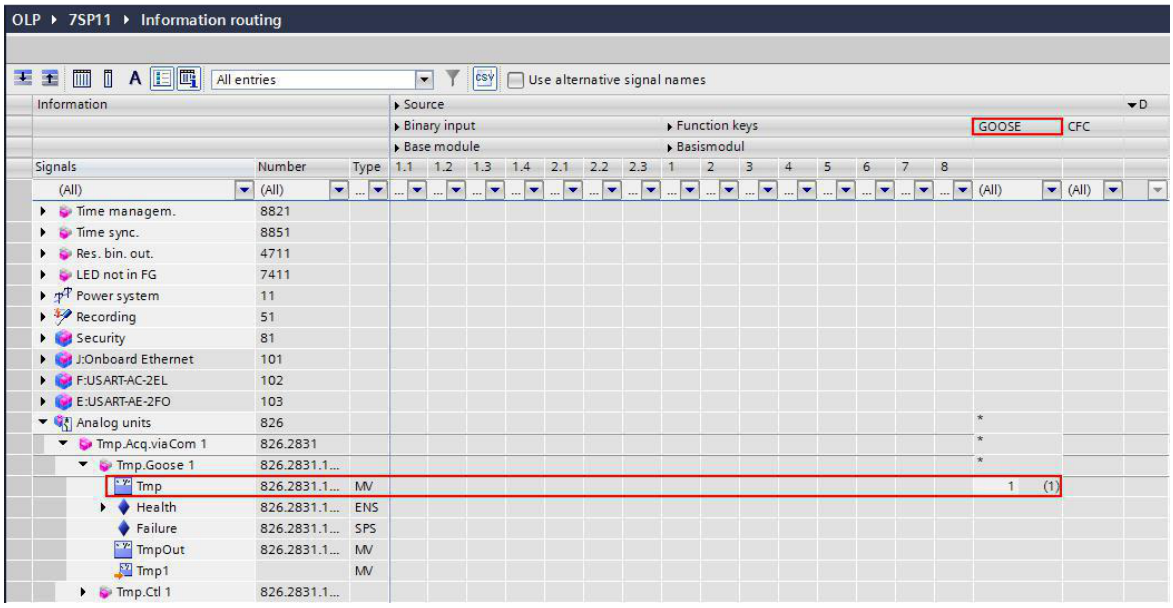


Figure 5-160 Protocol Selection

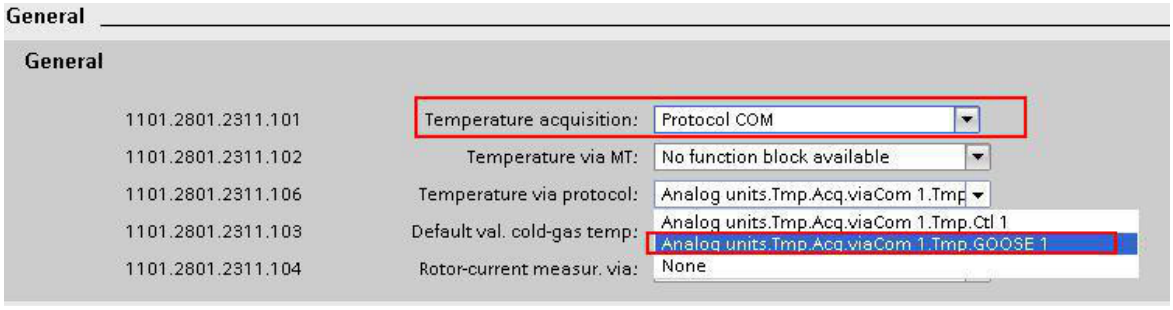
Function Instantiation – Target Device

- ✧ In the project tree, select the target device and select **Settings** > **Analog units**.
  If there is no function group **Analog units**, instantiate one.
- ✧ Instantiate the function **Tmp.Acq.viaCom** in the function group **Analog units**.
- ✧ Instantiate the stage **Tmp.GOOSE** in the function **Tmp.Acq.viaCom**.

Configuration in Information Routing – Target Device

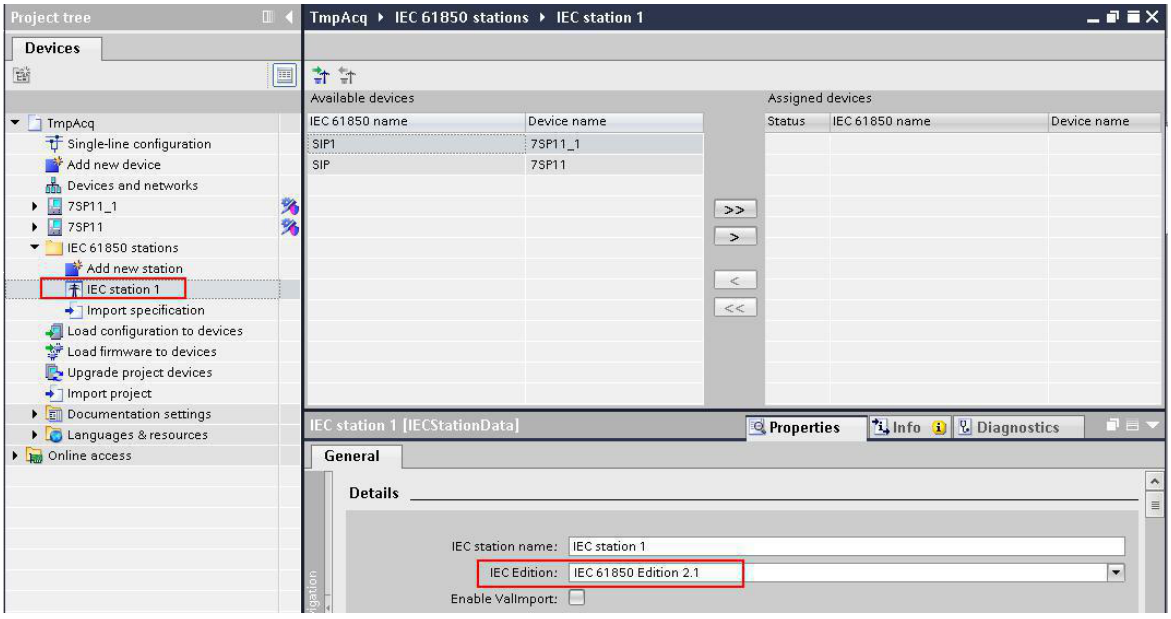


- ✧ In the project tree, select the target device and double-click **Information routing**.
- ✧ In the column **Signals**, select **Analog units** > **Tmp.Acq.viaCom 1** > **Tmp.Goose 1**.
- ✧ Set the value to ***1*** in the column **GOOSE** for the data **Tmp**.

[sc_station_10, 1, en_US]

Configuration of the Protection Function – Target Device

- ✧ Instantiate the function that requires the cold-gas temperature in the corresponding function group.
  The function **49R RotorTOLP** is taken as an example in the following steps.
- ✧ Under **General** of the function **49R RotorTOLP**, set the parameters **`Temperature acquisition`** to ***`Protocol COM`***.
- ✧ Set the parameter **`Temperature via protocol`** to ***`Analog units.Tmp.Acq.viaCom 1.Tmp.GOOSE 1`*** .

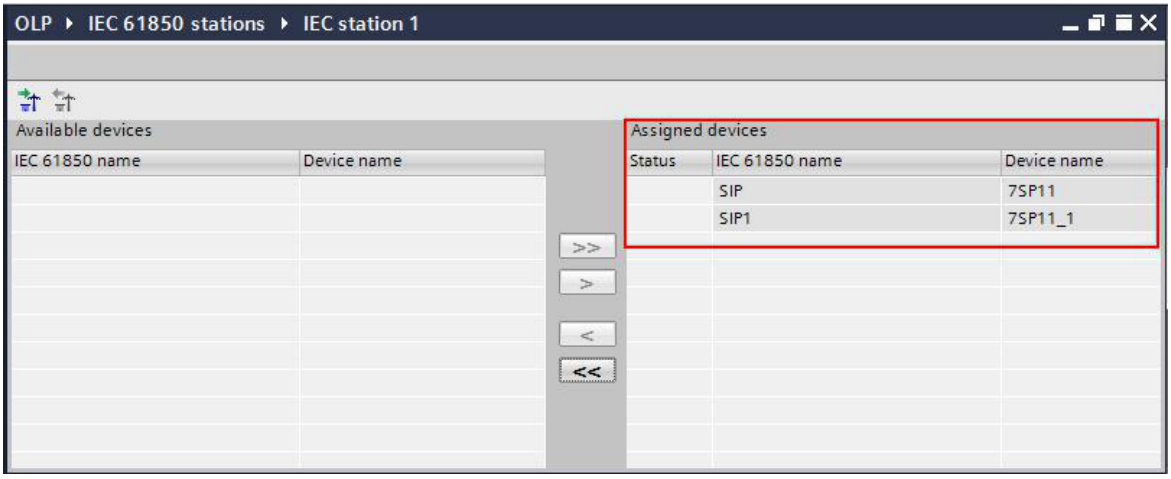


[sc_GOOSE_CGT, 2, en_US]

Figure 5-161 Parameter Configuration

Connection of the Source Device and the Target Device

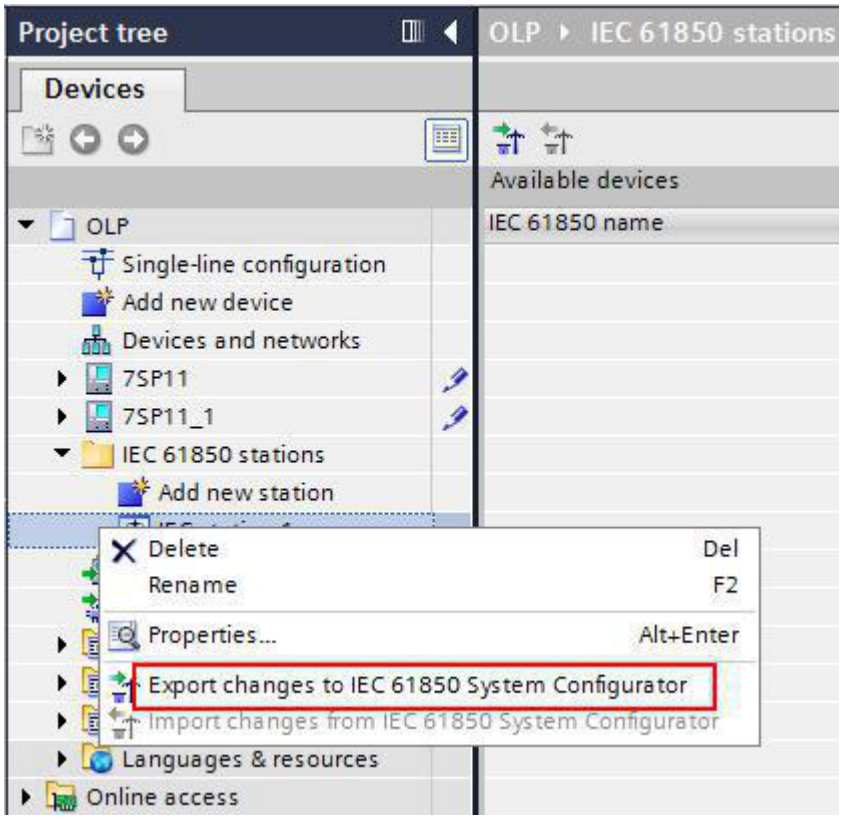
✧ In the project tree, select **IEC 61850 stations** > **IEC station 1**.
If there is no station, double-click **Add new station** and create one.



✧ Double-click **IEC station 1** and set the parameter **`IEC Edition`** to ***`IEC 61850 Edition 2`*** or a higher edition in the **Properties** tab.

[sc_iec_station, 2, en_US]

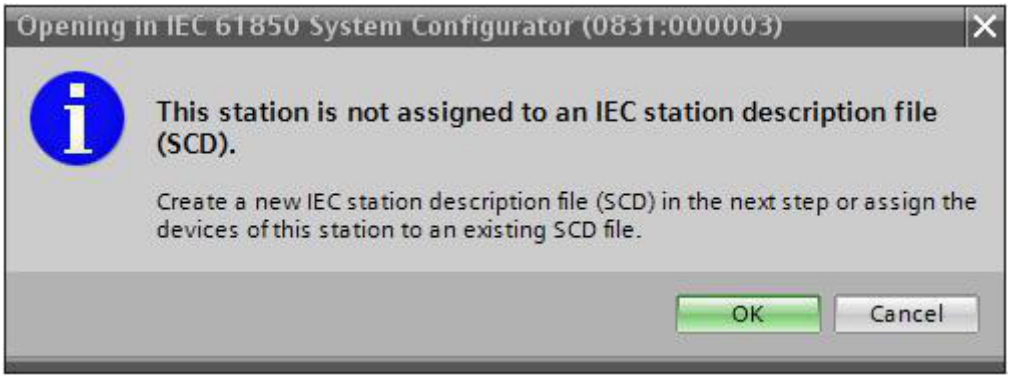
Figure 5-162 IEC 61850 Edition



✧ Assign the available devices to the IEC station.

[sc_device_assign, 1, en_US]

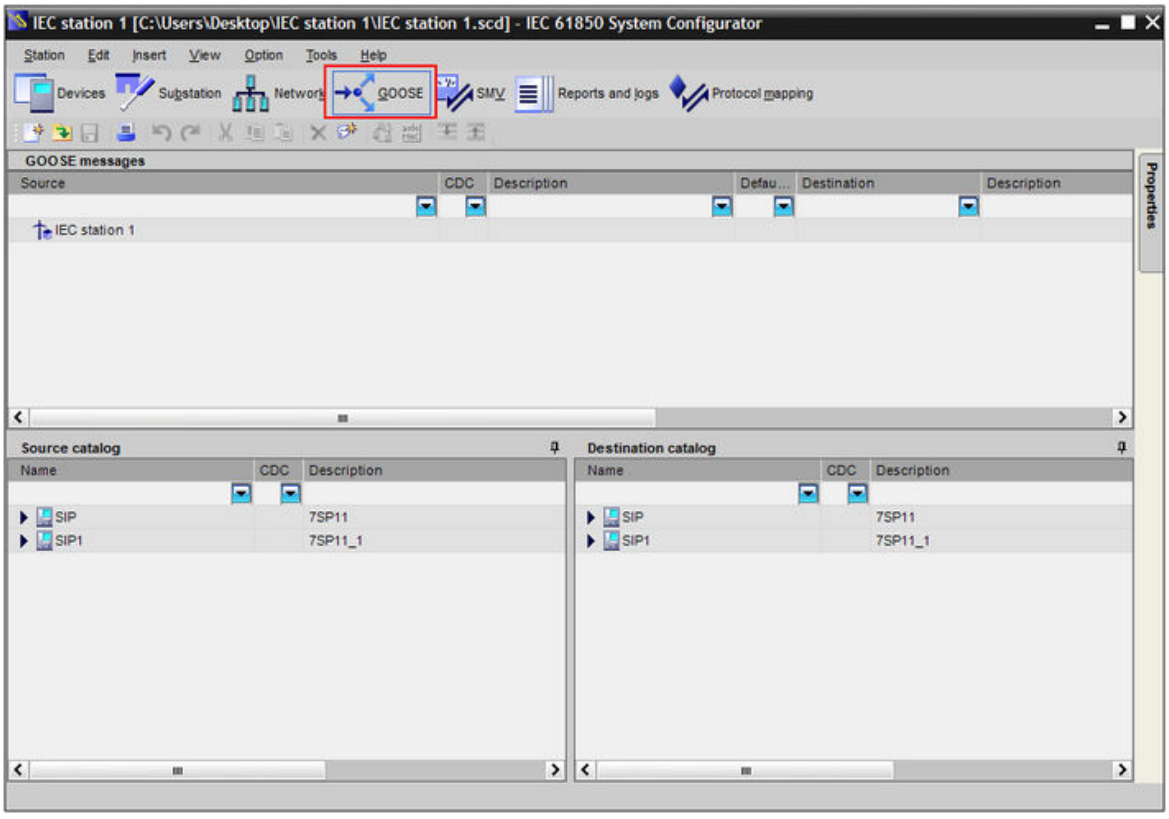
Figure 5-163 Device Assignment



✧ Right-click the station and select **Export changes to IEC 61850 System Configurator** in the context menu.

[sc_export_IEC, 1, en_US]

Figure 5-164 Export Changes to IEC 61850 System Configurator

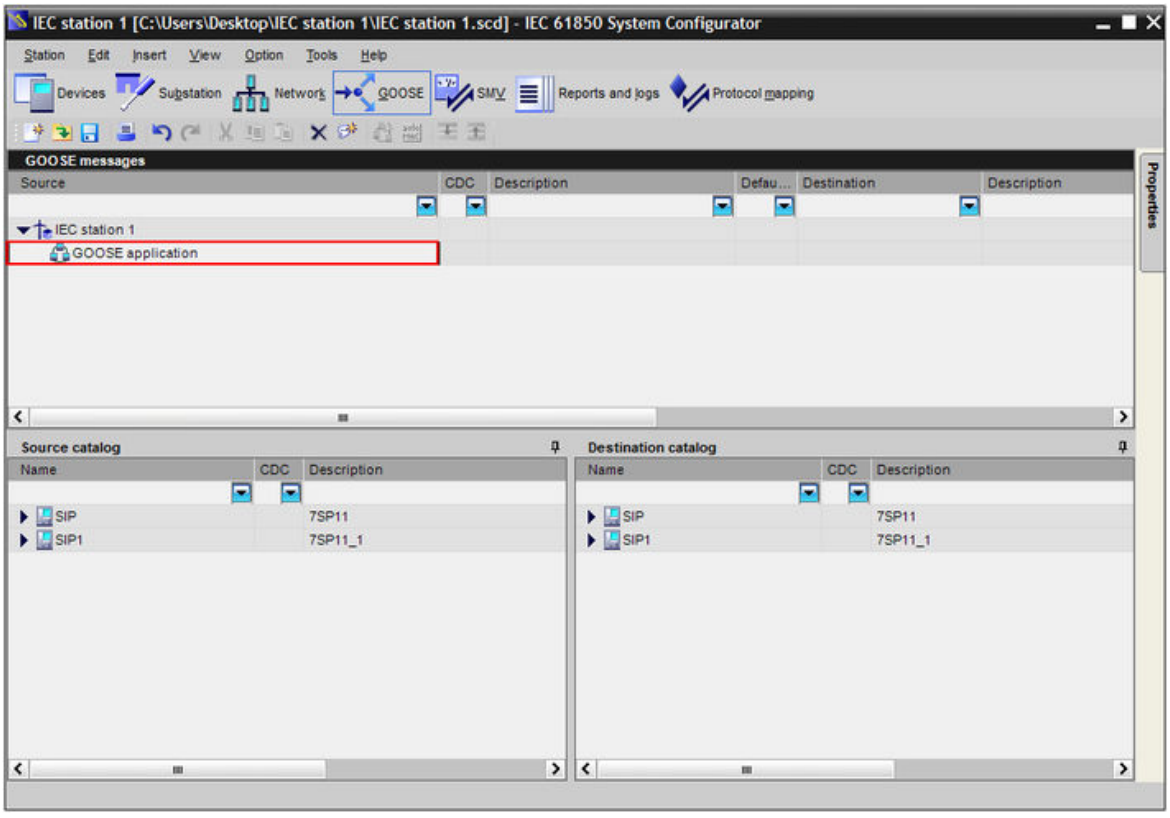


✧ If the following dialog appears, click **OK** and save the SCD file to a folder.

[sc_iec_confim, 1, en_US]

Figure 5-165 SCD File Creation

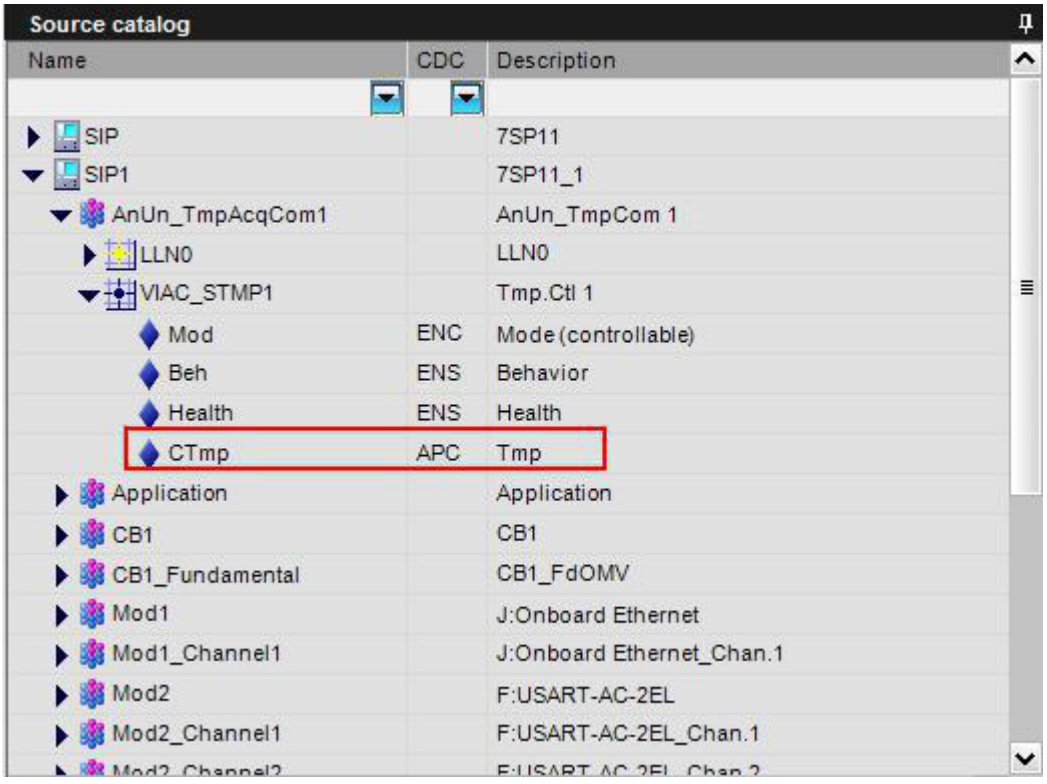
✧ In the opened **IEC 61850 System Configurator** window, select **GOOSE** in the toolbar.



[sc_station_01, 2, en_US]

Figure 5-166 GOOSE-Function Selection

✧ In the **GOOSE messages** view, right-click the IEC station and select **GOOSE application** in the context menu.



The **GOOSE application** is listed under the IEC station.

[sc_station_02, 2, en_US]

Figure 5-167 GOOSE Application Creation

✧ In the **Source catalog** area, navigate to the source device and select **AnUn_TmpAcqCom 1** > **VIAC_STMP1** > **CTmp**.

[sc_station_03, 1, en_US]

Figure 5-168 Source-Data Selection

✧ Drag the data **CTmp** and drop it to **GOOSE application** in the **GOOSE messages** view.

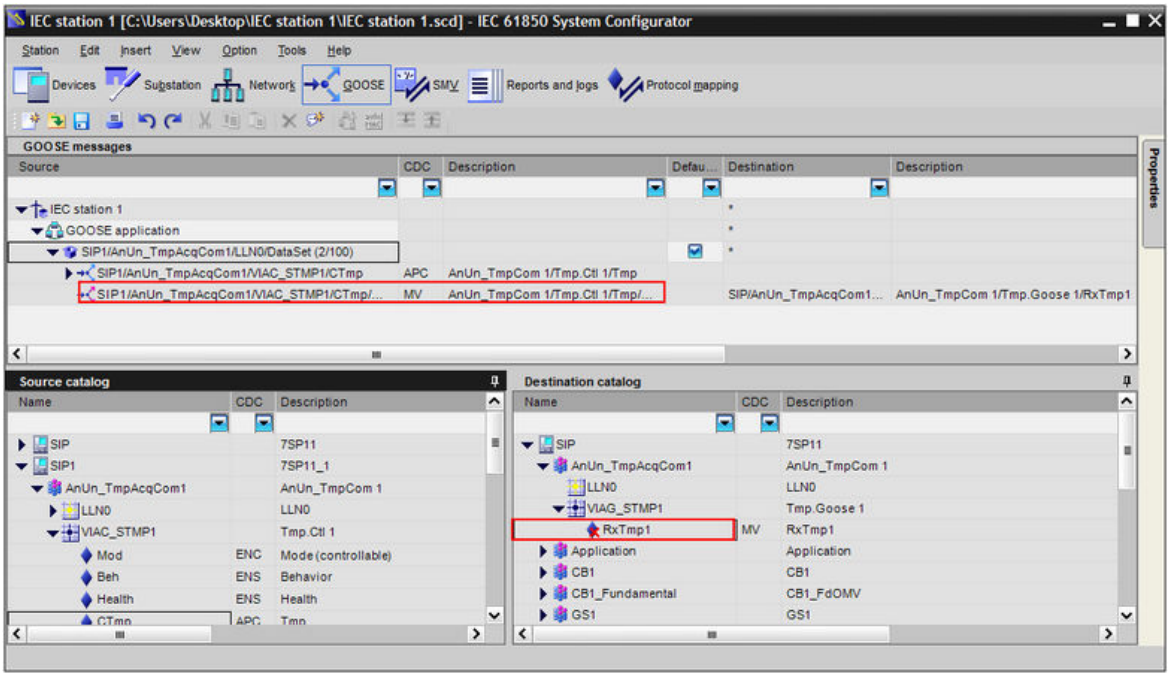
You can see the assigned source data.

[sc_station_04, 1, en_US]

Figure 5-169 Source-Data Assignment

✧ Unfold the assigned source data.

✧ In the **Destination catalog** area, navigate to the target device and select **AnUn_TmpAcqCom1** > **RxTmp1**.

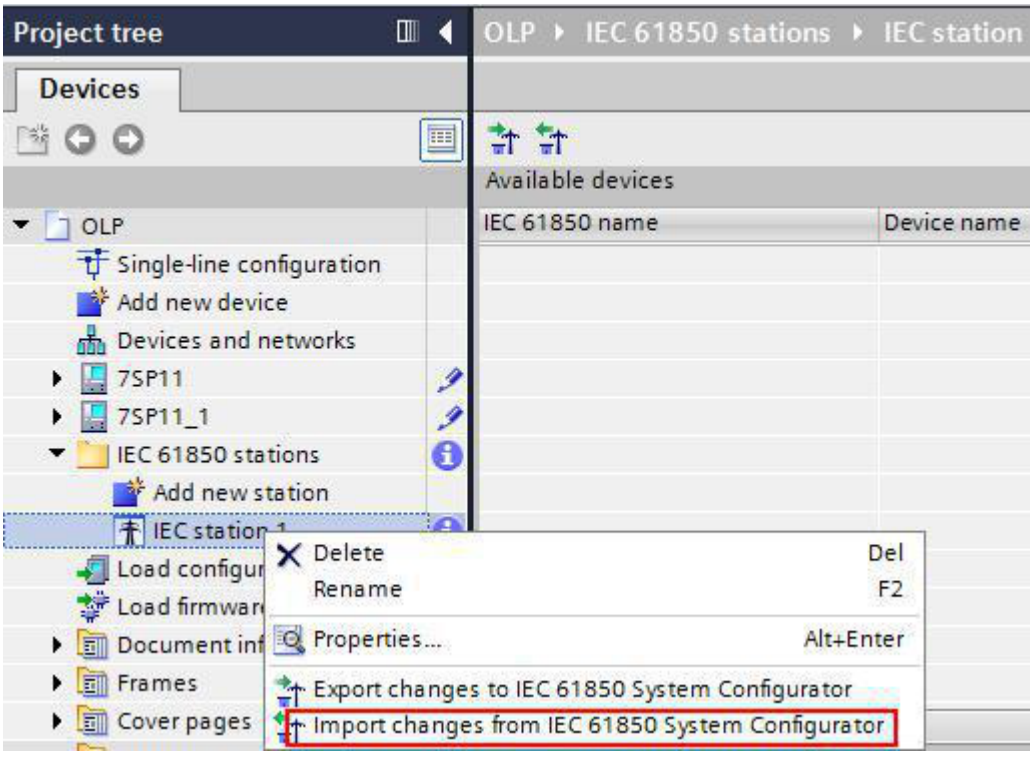


[sc_station_06, 1, en_US]

Figure 5-170 Target-Data Selection

✧ Drag the data **RxTmp1** and drop it to the assigned source data.

Now, the target data is connected with the source data.



[sc_station_11, 2, en_US]

Figure 5-171 Destination-Data Assignment

✧ Save the configurations.

✧ In DIGSI 5 in the project tree, right-click the IEC station and select **Import changes from IEC 61850 System Configurator** in the context menu.

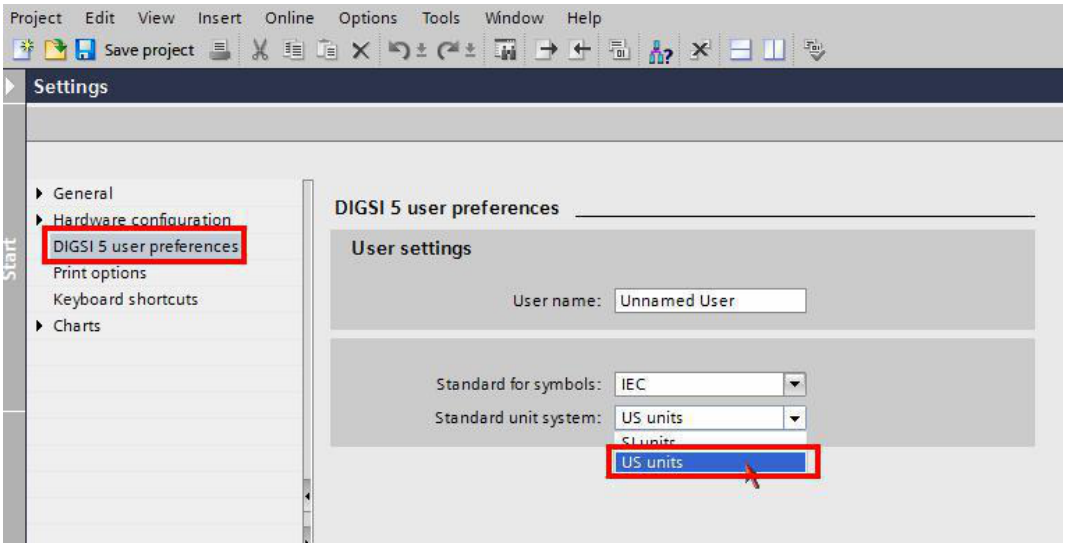
[sc_station_08, 1, en_US]

Figure 5-172 Import Changes from IEC 61850 System Configurator

If the following dialog appears, the source device and the target device are successfully connected.

[sc_End, 1, en_US]

Figure 5-173 Successful Device Connection

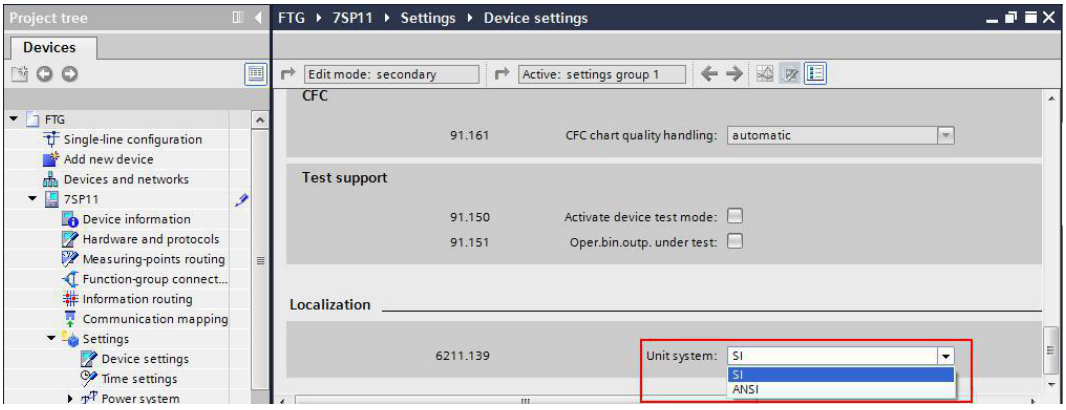


✧ Click **OK** to finish the connection.

5.11.10.8 Application and Setting Notes

Change of the Temperature Unit

Commonly, the temperature unit °C is used in the display and evaluation of measured temperature values.



- To change the temperature unit from °C to °F for all devices in the current DIGSI project, proceed as follows:
  - In DIGSI, select the menu item **Options** > **Settings**.
  - In the **Settings** view, select the menu item **DIGSI 5 user preferences**.
  - Set the parameter **`Standard unit system`** to ***`US units`***.

[scfahrht-190214-01, 1, en_US]

Figure 5-174 Change of the Temperature Unit between °C and °F for all Devices

- To change the temperature unit from °C to °F for 1 device, proceed as follows:
  - In the project tree, navigate to your device and select **Settings** > **Device settings**.
  - In the **Device settings** view, navigate to the menu item **Localization**.
  - Set the parameter **`Unit system`** to ***`ANSI`***.

[sc_SITmp, 1, en_US]

Figure 5-175 Change of the Temperature Unit between °C and °F for 1 Device

NOTE

If the parameter **Unit system** is set to ***ANSI***, only the unit of the measuring values and parameters changes to °F.

The unit of the following data is still °C:

- Other temperature data in the device
- The temperature thresholds in DCF

Parameter: Unit

- Default setting **(_:19801:101) Unit** = ***°C***

You use the setting **Unit** to specify which physical unit of the source data the measured values represent. The possible setting values are listed in the settings table.

5.11.10.9 Settings

Addr.	Parameter	C	Setting Options	Default Setting

5.11.11 LPIT Module IO240

5.11.11.1 Overview

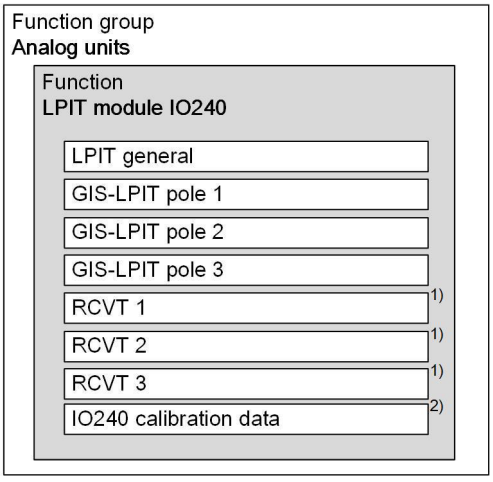
The input module IO240 for the low-power instrument transformer in the gas insulated switchgear (GIS-LPIT) and for the resistive-capacitive voltage transformer (RCVT) from Siemens Energy (**LPIT module IO240**):

- Measures temperature values, voltage values, and current values
- Provides an interface for SIPROTEC 5 modular devices to connect to Siemens Energy GIS-LPIT (GIS-LPVT and GIS-LPCT) and RCVT
- Converts current values into primary values
- Converts voltage values into primary values according to the sensor type (GIS-LPVT or RCVT)
- Provides primary values for protection functions, the voltage measurement, and the current measurement

The input module IO240 is available in a hardware variant of the 6MU85 device as part of the 1/3 base module or as an expansion module for installation in modular SIPROTEC 5 devices.

NOTE

Due to the higher power demand of the IO240 boards, a maximum of 2 IO240 modules are allowed per device row and totally a maximum of 4 IO240 modules are allowed in a SIPROTEC 5 device. This limitation also applies to the case that 1 of the IO240 modules is used in the 1/3 basic housing.



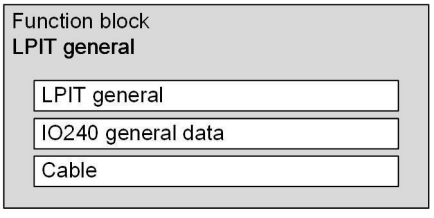
For more information on the use and configuration of the IO240 module combined with the connected LPIT, refer to the *Application Note APN-090 IO240 and LPITs*.

5.11.11.2 Structure of the Function

The function **LPIT module IO240** works in the function group **Analog units**.

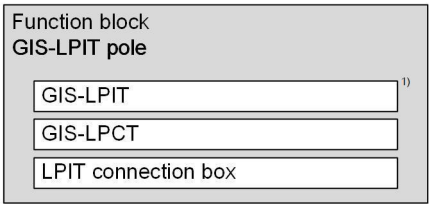
The function **LPIT module IO240** contains the following function blocks:

- 3 for **GIS-LPIT pole**
- 3 for **RCVT**
- 1 for **IO240 calibration data**



[dw_strIO240, 4, en_US]

Figure 5-176 Structure of the Function LPIT module IO240



(1) It is available when the parameter **`Use RCVT as volt. sensor`** under **LPIT General** is checked.

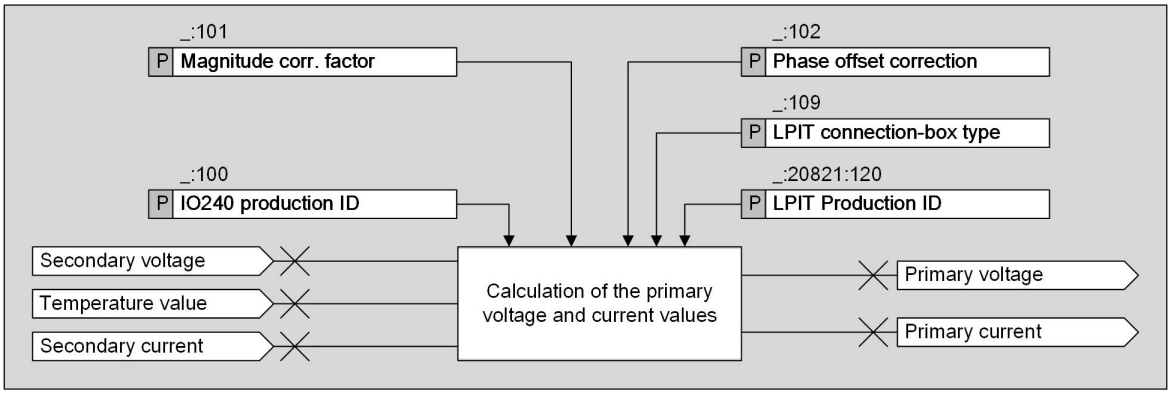
(2) It is available when the parameter **`Use cal. data IO240 board`** under **IO240 general data** is checked.

[dw_strIO240_LPIT General, 4, en_US]

Figure 5-177 Structure of the Function Block LPIT general

[dw_strIO240_LPIT Sensor, 5, en_US]

Figure 5-178 Structure of the Function Block GIS-LPIT pole



(1) It is available when the parameter **GIS-LPIT type** under **LPIT General** is set to ***LPIT 1-phase***.

5.11.11.3 Function Description

Once you have instantiated the **LPIT module IO240**, it is visible in the project tree in the function group **Analog units**. You can find the function group **Analog units** in the folder **Settings** of the device in the DIGSI 5 project tree.

If you open the subdirectory **LPIT-IO240**, you reach the setting sheet for the function blocks **LPIT General**, **GIS-LPIT pole**, **RCVT**, and **IO240 cal.data**. For more information, refer to *5.11.11.4 Application and Setting Notes* and *5.11.11.5 Settings*.

Logic of the LPIT Module IO240

[lo_IO240_logic_diagram, 4, en_US]

Figure 5-179 Logic of the LPIT Module IO240

NOTE

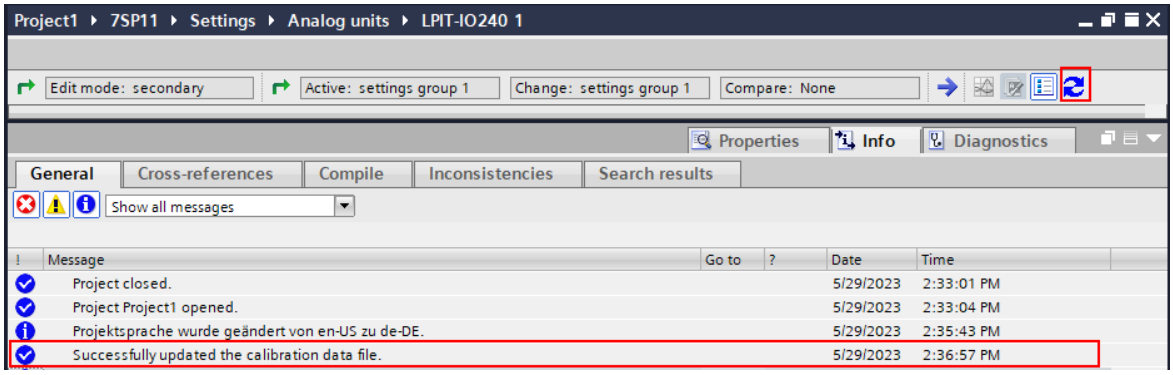
The parameter **IO240 production ID** is only used for calculation when the parameter **Use cal. data IO240 board** in the function block **IO240 general data** is checked.

The parameters **Magnitude corr. factor** and **Phase offset correction** are only used for calculation when the parameter **Use RCVT as volt. sensor** in the function block **LPIT General** is checked.

Calculation of the Primary Values

When RCVT is not used, the **LPIT module IO240** obtains the temperature values and secondary values from the GIS-LPIT sensor. When RCVT is used, the **LPIT module IO240** obtains the temperature values and secondary-current values from the GIS-LPIT sensor, and the secondary-voltage values from the RCVT sensor. The secondary values are converted into the corresponding primary values based on the settings in the function blocks **LPIT general**, **GIS-LPIT pole**, **RCVT**, and **IO240 calibration data**. The primary values are then internally provided to the device for the measurement functions or protection functions, and can be optionally published as sampled measured values.

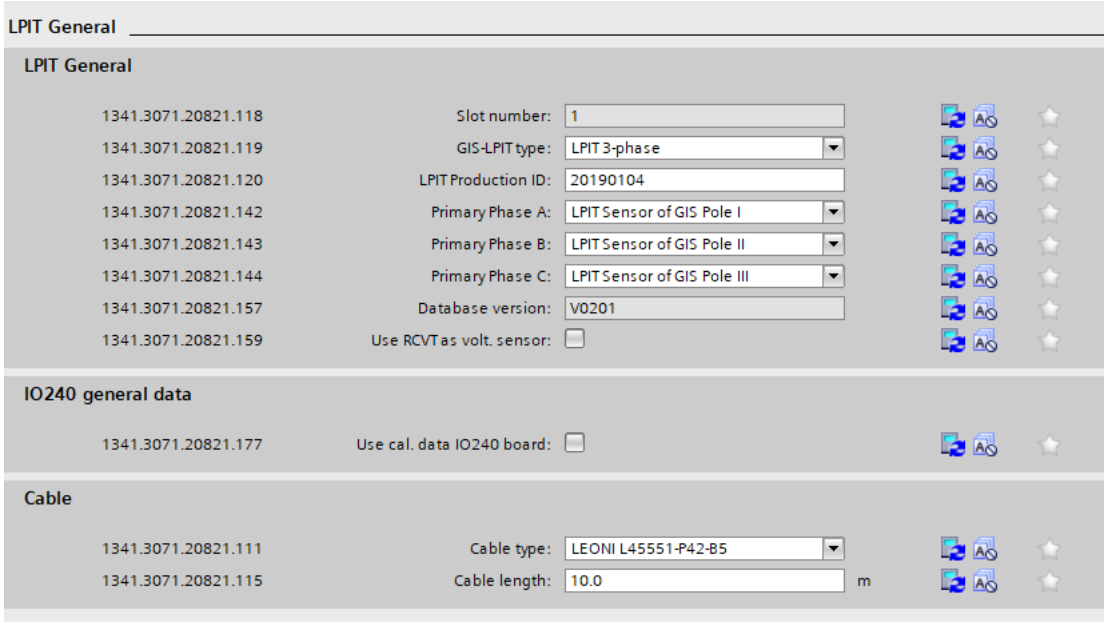
Temperature Value of the GIS-LPIT Sensor



The **LPIT module IO240** measures the temperature value of the GIS-LPIT sensor via the PT100 sensors of the GIS-LPIT. The temperature is used to compensate the temperature influence of the measured secondary values. This allows an accurate calculation of the primary values. The measured resistance of the PT100 sensor and the resulting temperature are available as information in the device for further use, such as customized logic charts (CFC) and recording. The resistance and temperature values are shown on the HMI.

If RCVT is used as the voltage input, the temperature value of the GIS-LPIT sensor has no influence on the voltage measurement.

5.11.11.4 Application and Setting Notes



Calibration Data

The calibration data of the GIS-LPIT sensor, the GIS-LPIT connection box, and the IO240 board are stored in a cloud storage. Therefore, the calibration data for DIGSI are available independently from the DIGSI 5 version and can be updated for newly produced GIS-LPIT and IO240 board. To update the local copy of the calibration data file, you can click the refresh button  . The feedback of a successful or unsuccessful update of the calibration data file is given in the **Info** tab.

[sc_refresh button and message, 2, en_US]

Settings of the LPIT General

[sc_LPIT_General, 3, en_US]

Figure 5-180 Settings of the LPIT General

Parameter: `Slot number`

The parameter specifies the mounting location of the IO240 board in the SIPROTEC 5 device and is used to identify the board mounting location when multiple IO240 boards are used in a device.

Parameter: `GIS-LPIT type`

- Default setting **`(_:20821:119) GIS-LPIT type`** = ***`LPIT 3-phase`***

With the parameter **`GIS-LPIT type`**, you set the GIS type used.

Parameter Value	Connection to the LPIT Module IO240	GIS-LPIT Sensor Type
`LPIT 3-phase`	Rogowski coil Capacitive voltage sensor	3-phase encapsulated (8DN8-5, 8DN8-6, 8VN1)
`3-phase without LPVT`	Rogowski coil	
`LPIT 1-phase`	Rogowski coil Capacitive voltage sensor	1-phase encapsulated
`1-phase without LPVT`	Rogowski coil	

Parameter: `LPIT Production ID`

To load the calibration data of your GIS-LPIT sensor from the calibration data file, enter the corresponding GIS-LPIT production ID. You can find the GIS-LPIT Production ID at the GIS-LPIT sensor name plate.

NOTE

Each **LPIT Production ID** is unique.

Parameter: `Primary Phase A`, `Primary Phase B`, `Primary Phase C`

- Default setting **`(_:142) Primary Phase A`** = ***`LPIT Sensor of GIS Pole I`***
- Default setting **`(_:143) Primary Phase B`** = ***`LPIT Sensor of GIS Pole II`***
- Default setting **`(_:144) Primary Phase C`** = ***`LPIT Sensor of GIS Pole III`***

With these parameters, you define the mapping relationship between the primary phase and the LPIT sensor of GIS pole, according to the physical connection. The **LPIT module IO240** takes the settings of the corresponding LPIT sensor of GIS pole for each phase.

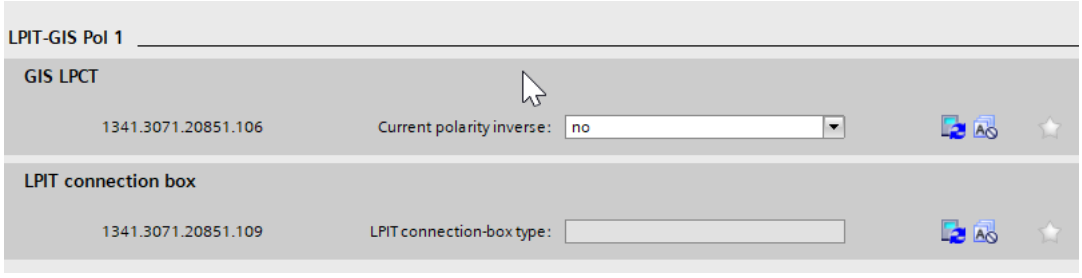
Parameter: `Use RCVT as volt. sensor`

- Default setting: the parameter **`(_:20281:159) Use RCVT as volt. sensor`** is unchecked.

With the parameter **`Use RCVT as volt. sensor`**, you decide whether to use the GIS-LPVT or RCVT as the voltage sensor type for the primary-voltage measurement. When this parameter is checked, the 3 function blocks for **RCVTs** are available and all the settings related to GIS-LPVT are invisible.

Parameter: `Crosstalk RCVT 1 to 2`, `Crosstalk RCVT 2 to 1`, `Crosstalk RCVT 2 to 3`, `Crosstalk RCVT 3 to 2`, `Crosstalk RCVT 3 to 1`, `Crosstalk RCVT 1 to 3`

- Default setting **`(_:160) Crosstalk RCVT 1 to 2`** = ***`0.000 %`***
- Default setting **`(_:161) Crosstalk RCVT 2 to 1`** = ***`0.000 %`***
- Default setting **`(_:162) Crosstalk RCVT 2 to 3`** = ***`0.000 %`***
- Default setting **`(_:163) Crosstalk RCVT 3 to 2`** = ***`0.000 %`***
- Default setting **`(_:164) Crosstalk RCVT 3 to 1`** = ***`0.000 %`***
- Default setting **`(_:165) Crosstalk RCVT 1 to 3`** = ***`0.000 %`***



With these parameters, you configure the mutual influence of crosstalk from the RCVT in one phase to the one in another phase.

Parameter: `Use cal. data IO240 board`

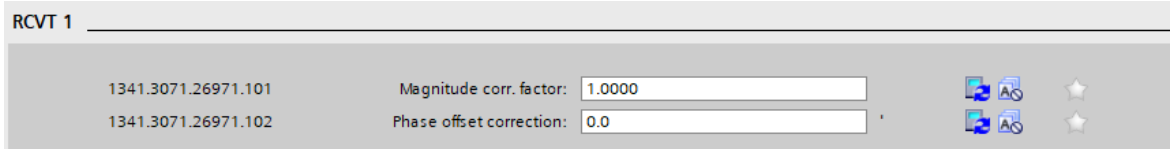
- Default setting: the parameter **`(_:20821:177) Use cal. data IO240 board`** is unchecked.

With the parameter **`Use cal. data IO240 board`**, you decide whether to use the calibration data of the IO240 board for the primary-value calculation to achieve measuring accuracy class 0.1. When this parameter is checked, the function block **IO240 cal.data** is available.

Settings of the LPIT-GIS Pole

[sc_LPIT-GIS_pole, 2, en_US]

Figure 5-181 Settings of the LPIT-GIS Pole, Example



Parameter: `Current polarity inverse`

With this parameter, you confirm whether the polarity of the physically-connected current is inversed. If the current polarity is inversely connected, set this parameter to ***`yes`***.

Parameter: `LPIT connection-box type`

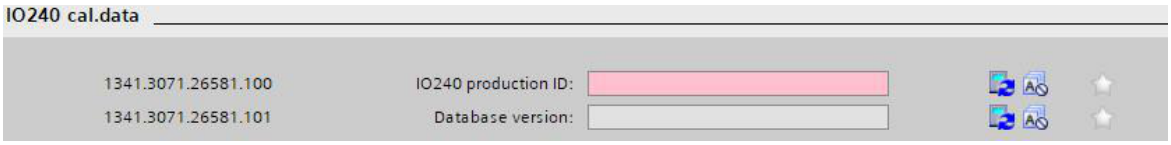
After the GIS-LPIT production ID is entered, the type of the LPIT connection box is visible in DIGSI. It is not configurable.

Settings of the RCVT Sensors

[sc_settings_RCVT, 1, en_US]

Figure 5-182 Settings of the RCVT

Parameter: `Magnitude corr. factor`, `Phase offset correction`

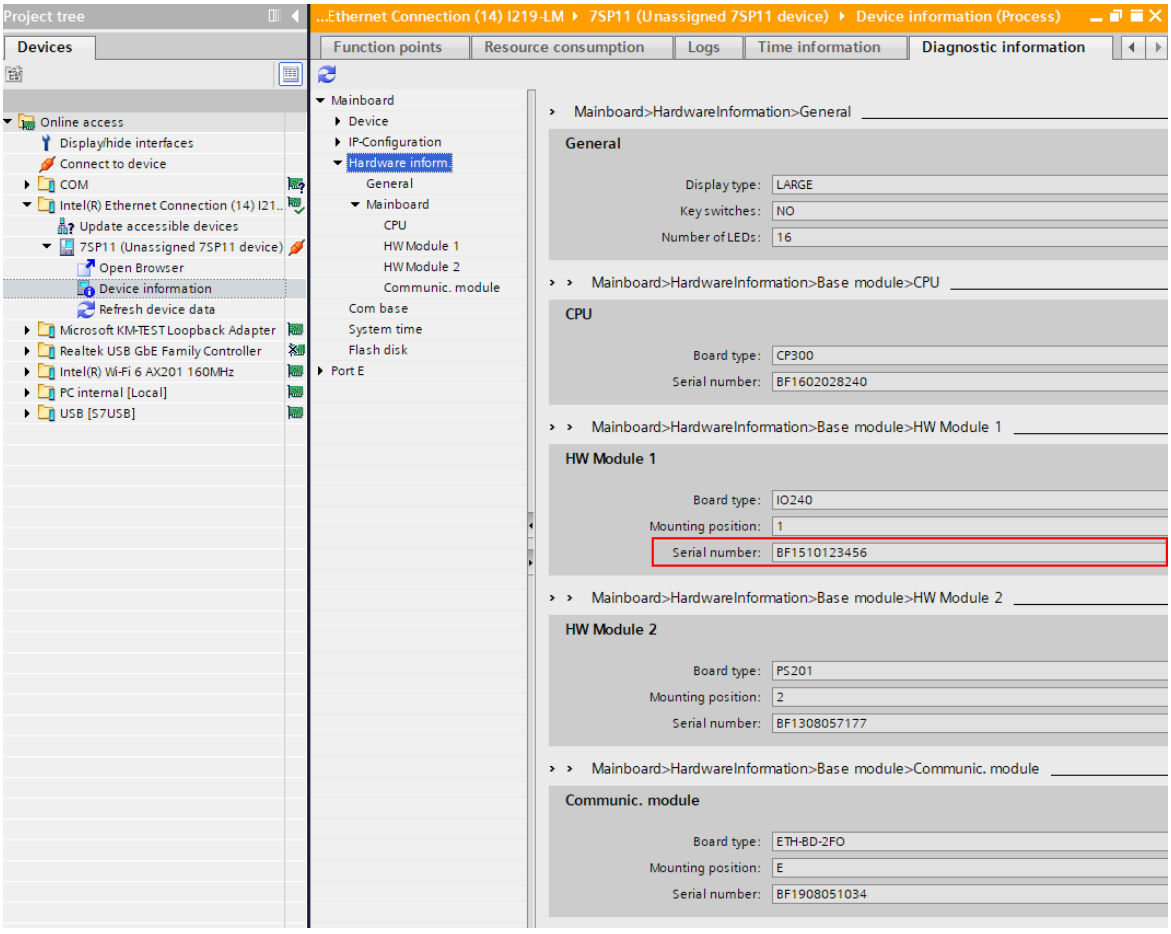


- Default setting **`(_:101) Magnitude corr. factor`** = ***`1.0000`***
  With the parameter **`Magnitude corr. factor`**, you adjust the magnitude for the voltage input.
- Default setting **`(_:102) Phase offset correction`** = ***`0.0 '`***
  With the parameter **`Phase offset correction`**, you adjust the phase angle for the voltage input.

These parameters allow you to correct the tolerances of the primary-voltage transformer phase-selectively. Magnitude correction and phase-offset correction are probably required for high-precision measurements.

Settings of the IO240 Calibration Data

To achieve the measuring accuracy class 0.1, the calibration data of the IO240 board used are required. The board-specific calibration data can be ordered separately from the supplier of the LPIT sensor.



In the function block **IO240 cal.data**, there are 2 parameters **`IO240 production ID`** and **`Database version`**.

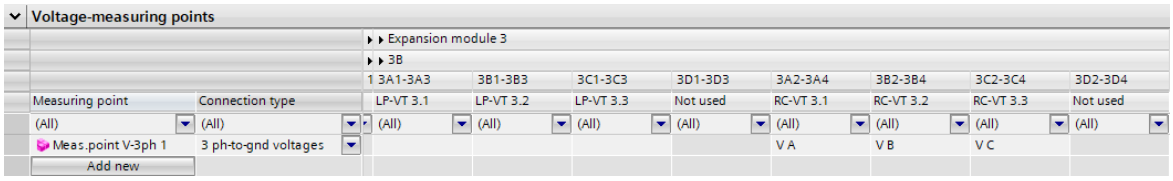
[sc_IO240 cal. data, 1, en_US]

Figure 5-183 Settings of the IO240 Calibration Data

For the parameter **`IO240 production ID`**, you must enter the value manually. You can find the production ID of the IO240 board in DIGSI 5 via **Online access** > **Device information** > **Hardware inform.** > HW module with the board type: IO240. You can also get the production ID of the specific IO240 board from the LPIT supplier.

[sc_IO240_production_ID, 1, en_US]

Figure 5-184 IO240 Production ID



After the production ID is entered, the corresponding version of database is visible in DIGSI. The version is not configurable.

Measuring-Points Routing

The **LPIT module IO240** only supports the ***`3 ph-to-gnd voltages`*** connection type of voltage and the ***`3-phase`*** connection type of current in the **Measuring-points routing**.

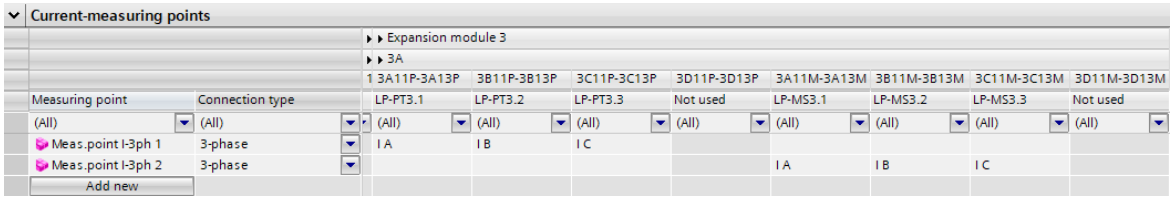
2 groups of 3-phase voltage measuring channels with different voltage-transformer types derived from the connected voltage sensor are available in the **Measuring-points routing**. For each **LPIT module IO240**, you can only route 1 group of the 3-phase voltage measuring channels according to the connected voltage sensor,

either GIS-LPVT or RCVT. The measuring-points routing must be consistent with the configuration of the parameter **`Use RCVT as volt. sensor`**. Otherwise, DIGSI 5 reports an inconsistency.

[sc_IO240 voltage connection type, 3, en_US]

Figure 5-185 IO240 Voltage Connection Type

NOTE



The voltages in the following channels are for the GIS-LPVT sensor:

- LP-VT3.1
- LP-VT3.2
- LP-VT3.3

The voltages in the following channels are for the RCVT sensor:

- RC-VT3.1
- RC-VT3.2
- RC-VT3.3

2 groups of 3-phase current measuring channels with different measuring ranges derived from the connected Rogowski coil are available in the **Measuring-points routing**. The protection channel supplies a dynamic range of 100 times the rated primary current of the assigned current measuring point. The measuring channel supplies a dynamic range of 1.6 times the rated primary current of the assigned measuring point, with higher accuracy than the protection channel. The rated primary current must be set accordingly in the settings for the current measuring points. The settings for the current measuring points can be found in the device settings under **Settings** and **Power System**.

[sc_IO240 current connection type, 3, en_US]

Figure 5-186 IO240 Current Connection Type

NOTE

The currents in the following channels are for the protection function:

- LP-PT3.1
- LP-PT3.2
- LP-PT3.3

The currents in the following channels are for the measurement function:

- LP-MS3.1
- LP-MS3.2
- LP-MS3.3

Measuring Point Voltage 3-Phase (V-3ph)

For the voltage measuring points of the **LPIT module IO240**, the value of the parameter **`Rated secondary voltage`** is the basis for the configuration of the parameters in secondary values. When connected to the GIS-LPVT sensor, the rated secondary voltage is preset permanently to a virtual voltage of 100 V and is invisible in DIGSI. When connected to the RCVT sensor, the rated secondary voltage is preset permanently to a real voltage of 100 V, which is visible and read-only in DIGSI.

For more information on the measuring point voltage 3-phase (V-3ph), refer to *6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph)*.

Measuring Point Current 3-Phase (I-3ph)

For the current measuring point of the **LPIT module IO240** for both the protection and measuring channels, the rated secondary current is preset permanently to a virtual current of 1 A. This value is the basis for the parameterization of the settings in secondary values. The parameter **`Rated secondary current`** is invisible in DIGSI.

For more information on the measuring point current 3-phase (I-3ph), refer to *6.1.5 Application and Setting Notes for Measuring-Point Current 3-Phase (I-3ph)*.

Avoiding Unauthorized Access to IO240 Terminals

For revenue metering, to protect the measurement chain against unauthorized access, you have the following options:

- Use a shield cover; if necessary a sealing can be applied.
- Extend the shield cover with an optional microswitch (product code P1X596).

Application of the Optional Microswitch

After connection of the 2 leads from the microswitch to the terminals D9 and D10, the IO240 module can detect an opening of the shield cover and report it via SCADA communication. When the connected microswitch is actuated, the information *`(_:76) Shield cover`* changes the status. The information can be further processed via the information routing and reported to the control system, for example.

For more information on the installation, refer to the *SIPROTEC 5 Hardware manual*.

5.11.11.5 Settings

Addr.	Parameter	Setting Options	Default Setting
`LPIT General`			
_:118	LPIT General:Slot number	1 to 12 Not settable	Physical slot number of the IO240 board connection

5.12 Function-Group Recording

5.12.1 Overview

The device has a flash memory in which records can be saved. The recording documents operations within the power system and how devices respond to them. You can read out records from the device and analyze them. Depending on the recorder, the records are available in different file formats (see the following table).

Table 5-25 File Format Used by Individual Recorders

Interface	File Format	FR[29]	SSR[30]	CR[31]	TR[32]

5.12.2 Structure of the Function Group

The **Recording** function group consists of the following functionalities:

- **General** function block
- **Fault recorder** function
- **Slow-scan recorder** function
- **Continuous recorder** function
- **Trend recorder** function

The following figure shows the structure of the **Recording** function group. The function blocks are described in the following chapters.

29 FR: Protection fault recorder
30 SSR: Slow-scan recorder
31 CR: Continuous recorder
32 TR: Trend recorder

[dw_fg_recorder, 4, en_US]

Figure 5-187 Structure of the Recording Function Group

NOTE

If you want to use one of the following functions, the device must be equipped with the CP300, CP150, or CP050 CPU printed circuit board assembly:

- Slow-scan recorder
- Continuous recorder
- Trend recorder

The function group **Protection Recording** is a central device function. The recording criterion, measured-value channels, and binary channels to be recorded are functionally preconfigured through the application templates. You can individually adapt the configuration in DIGSI 5 after enabling Recorder Routing functions.

For more information on the **Fault recorder** function, refer to **Fault Recording**, starting at *3.5.1 Overview of Functions* .

For more information on the function group **Recording**, refer to the *SIPROTEC 5 Protection Recording manual* (C53000-H5040-C089).

5.13 Bay Proxy

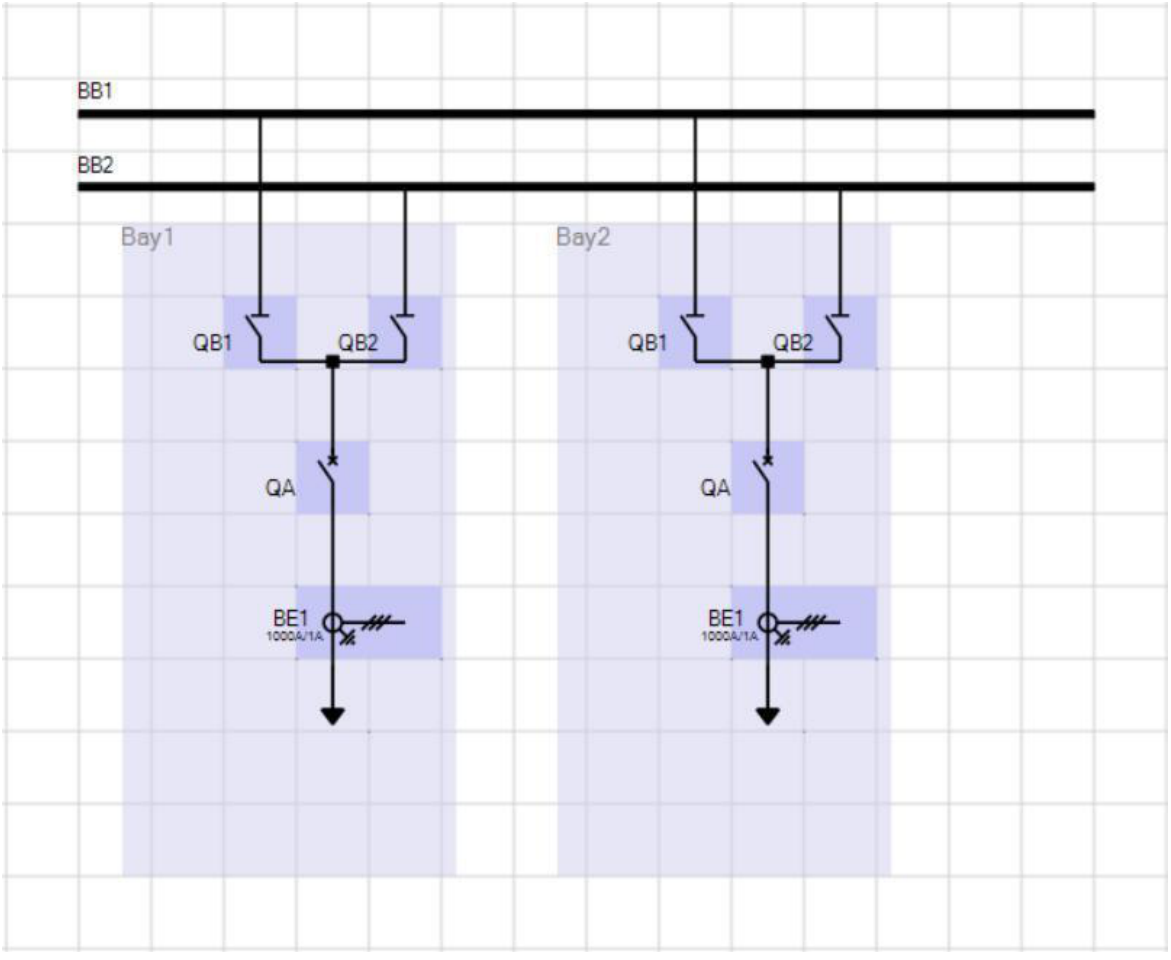
5.13.1 Overview

In a substation, the **Bay** represents a feeder, a line, a transformer, or a coupler. The **Bay** comprises function groups such as **Voltage/current 3-phase**, **Circuit breaker**, and **Disconnector**. For the complete list of supported function groups, refer to *5.13.2 Structure of the Bay*.

SIPROTEC 5 can protect multiple feeders in one device. To have a clear structure and additional configuration and testing benefits, you can group the functions groups inside **Bays**.

NOTE

This functionality is available for SIPROTEC 5 modular devices.



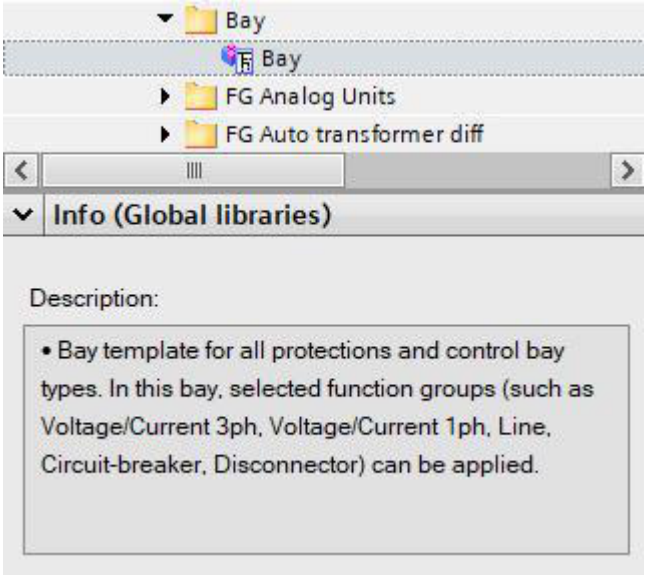


Figure 5-188 Example of Bays

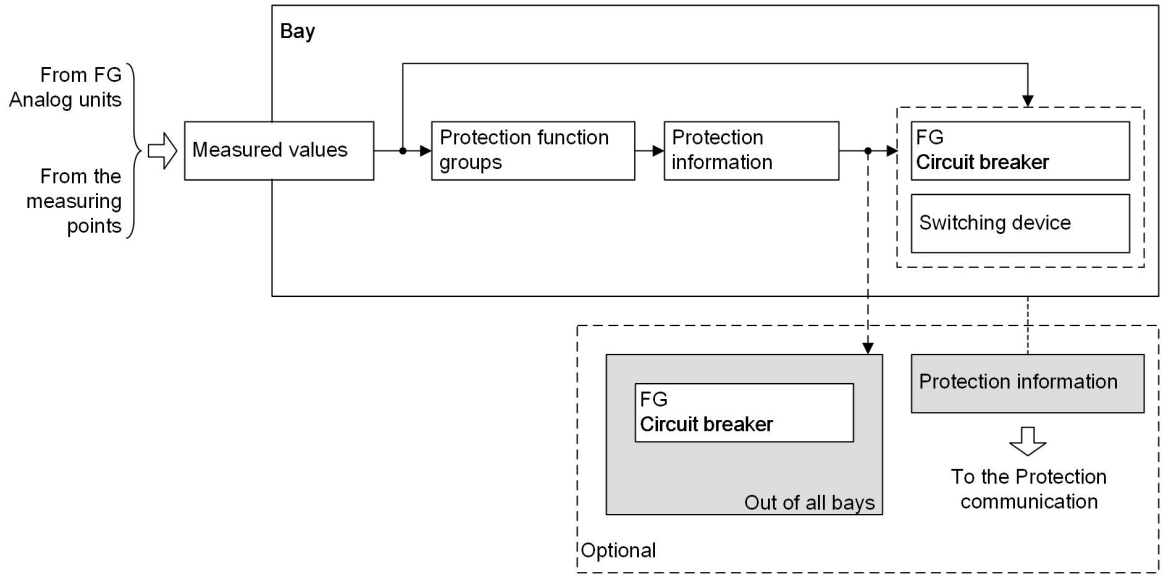
NOTE

The single-line diagram is not mandatory for the **Bay**.

5.13.2 Structure of the Bay

You can find the **Bay** under the device in the Global DIGSI 5 Library.



[sc_AOMBay, 3, en_US]

You can instantiate the following function groups under the **Bay**:

- FG **Circuit breaker**
  - **Circuit breaker**
  - **Circuit breaker [status only]**
- FG **Voltage/current 1-phase**
- FG **Voltage/current 3-phase**
- FG **Voltage 3-phase**
- FG **Line**
- FG **Transformer diff**
  - **Transformer diff**
  - **Transformer side**
  - **Transformer neutral point**
- FG **Auto transformer diff**
  - **Auto transformer diff**
  - **Auto transformer side**
  - **Auto transformer compensation side**
  - **Auto transformer ground side**
  - **Auto transformer neutral point**
- FG **Voltage controller**
  - **Voltage control grid coupling transformer**
  - **Voltage control three-winding transformer**
  - **Voltage control two-winding transformer**

- Switching device
  - **Disconnector**
  - **Disconnector [status only]**
  - **Tap changer**
- User-defined function group

[dw_structure AOM Bay Universal, 1, en_US]

Figure 5-189 Structure of the Bay

The **Bay** has interfaces to:

- Measuring points
- Function group **Analog units**
- Function group **Circuit breaker**
- Protection communication

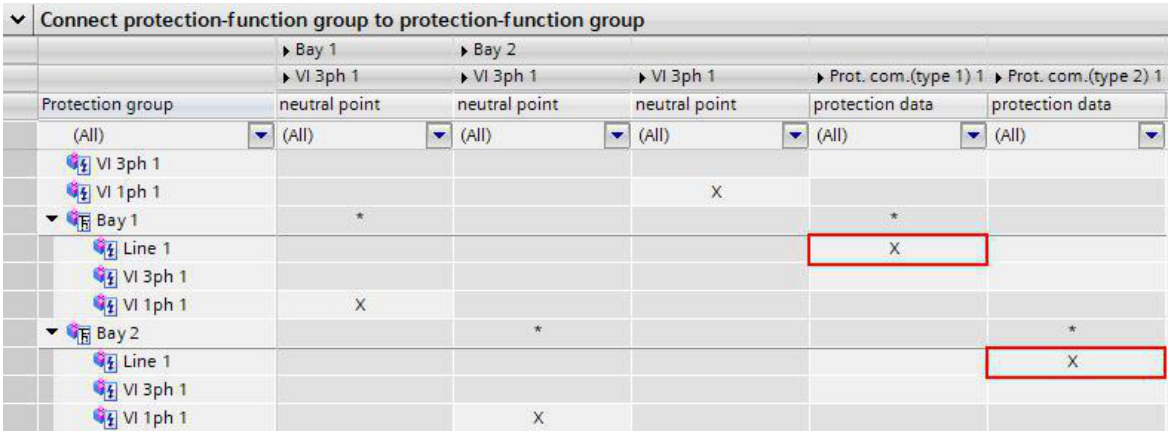
Interfaces with Measuring Points and Function Group Analog Units

The function groups in the **Bay** receive the required measured values via the interfaces with the measuring points and via the interfaces with the function group **Analog units**.

For details, refer to the descriptions of the specific function-group types.

Interface with the Function Group Circuit Breaker

All required data is exchanged between the function groups in the **Bay** and the function group **Circuit breaker** out of **Bays** via the interface of this function group **Circuit breaker**.



For details, refer to the descriptions of the specific function-group types.

Interface with Protection Communication

All required data is exchanged between the protection function group and the protection communication via the interface with the **Protection communication**. These data are for example:

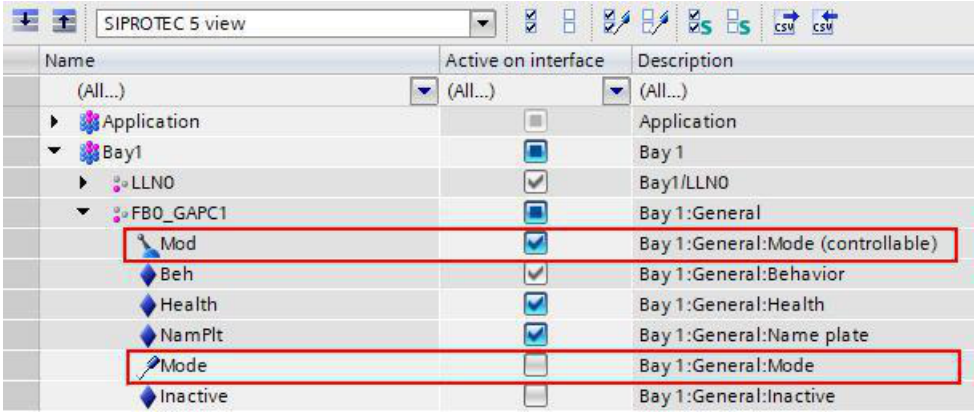
- Binary signals
- Measured values
- Complex data

The protection communication is typically used for line differential protection and with the teleprotection schemes for distance protection and ground-fault protection. If you want to use the function **Line differential protection** in a **Bay**, you must configure the protection interface for the function group **Line**.

[sc_Protection_interface_Line_AOMBay, 2, en_US]

Figure 5-190 Example of Configuring the Protection Interfaces

For more details, see *3.6 Protection Communication*.



5.13.3 Application and Setting Notes (Mode Behavior of Bay)

Parameter: Mode

- Default setting **(_:1) Mode** = ***on***

A **Bay**, including all functions under the **Bay**, can be switched to different operating modes. With the parameter **Mode**, you define whether you want a **Bay** to run (***on***) or not (***off***). In addition, you can temporarily block a **Bay** or switch it into test mode for commissioning (parameter **Mode** = ***test***).

Additionally, the state of the **Bay** can be influenced using the controllable **Mod** in the IEC 61850 representation. The **Mode (controllable)** in the DIGSI 5 Information routing supports the states ***On***, ***Off***, ***Test***, ***Relay blocked***, and ***Test/Relay blk.***

[sc_Mode(controllable), 2, en_US]

Figure 5-191 Controllable **Mod** and parameter **Mode** in the IEC 61850 structure

The **overall device state** can have the values ***On***, ***Relay blocked***, ***Test***, and ***Test/Relay blk.***.

The states of the **Bay** resulting from the parameter **Mode**, the controllable **Mod**, and the **overall device state** are shown in the following table. The resulting state of the **Bay** results from the combination of all sources (parameter **Mode**, controllable **Mod**, and **overall device state**). As a simplification, the table only shows the combination of 2 sources.

Table 5-26 Resulting State of the Bay

Inputs		State of the Bay
Device	Bay	
On	On	On
	Relay blocked	Relay blocked
	Test	Test[33]
	Test/Relay blk.	Test/Relay blk.
	Off	Off
Relay blocked	On	Relay blocked
	Relay blocked	Relay blocked
	Test	Test/Relay blk.
	Test/Relay blk.	Test/Relay blk.
	Off	Off
Test	On	Test[33]
	Relay blocked	Test/Relay blk.
	Test	Test[33]
	Test/Relay blk.	Test/Relay blk.
	Off	Off
Test/Relay blk.	On	Test/Relay blk.
	Relay blocked	Test/Relay blk.
	Test	Test/Relay blk.
	Test/Relay blk.	Test/Relay blk.
	Off	Off

For more information about function state control, refer to *2.3 Function Control*.

5.13.4 Application and Setting Notes (Bay-Related Switching Authority)

Parameter: Bay-related sw.auth.

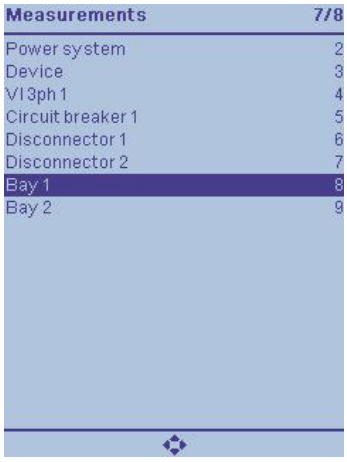
- Default setting **(_:151) Bay-related sw.auth.** = ***false***

When activating the parameter **Bay-related sw.auth.**, an individual switching authority as well as an individual switching mode for this bay are configured. They are valid for all switching devices in the bay provided no own **Swi.dev. related sw.auth.**, is activated. Additional signals are displayed in the information routing (see also *7.4.1 Command Checks and Switchgear Interlocking Protection*).

Parameter: Specific sw. authorities

- Default setting **(_:152) Specific sw. authorities** = ***false***

You can enable additional options for the switching authority check. For more information about these options, see *Specific Switching Authority, Page 1869*.

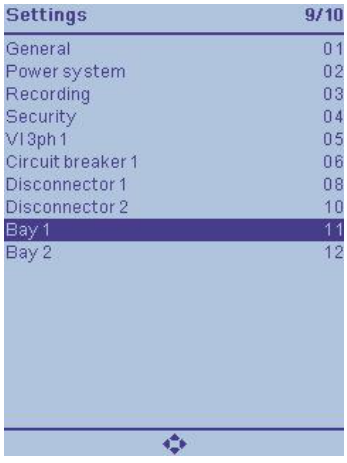


[33] With the parameter **(_:151) Oper.bin.outp. under test**, you can set whether the relay outputs are to be activated by functions in the **Test** state. If this parameter is deactivated (default setting), the **Test** state of a function is changed to **Test/Relay blk.**.

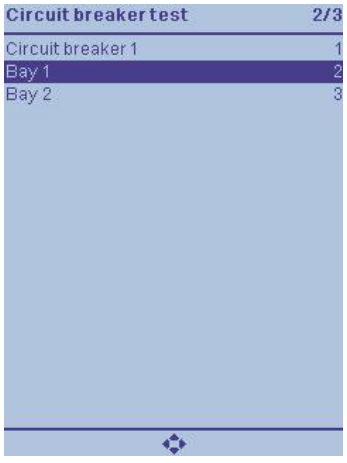
5.13.5 Application and Setting Notes (Displays and Connections for Bay)

Displays for the Bay on the On-Site Operation Panel

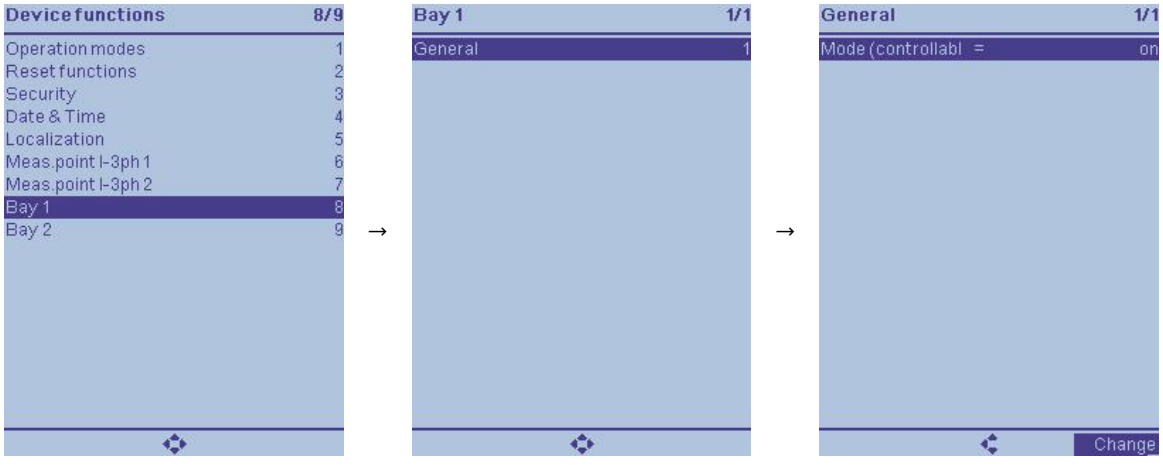
If **Bays** are instantiated, the displays contain the **Bay** menu items on the on-site operation panel, as shown in the following example screenshots.



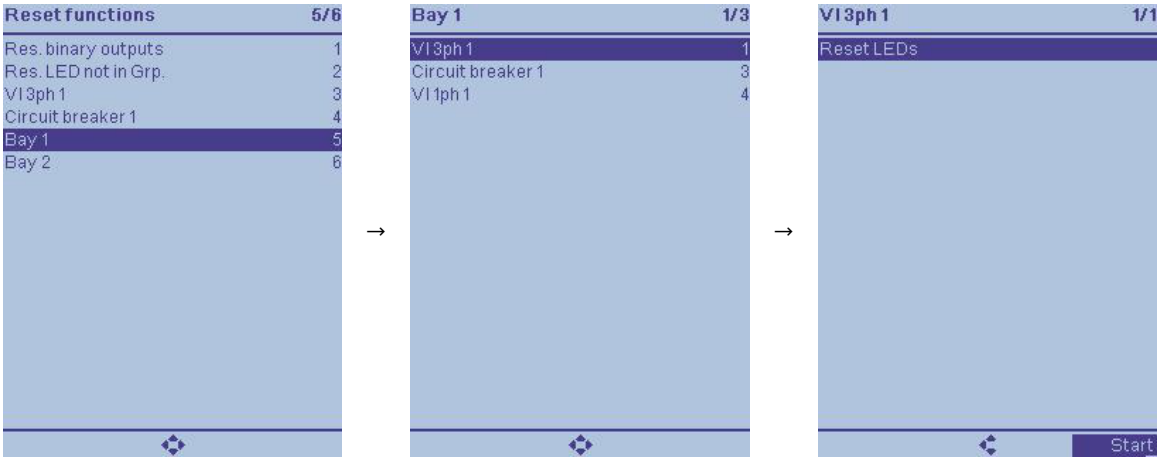
- Measurements



- Control



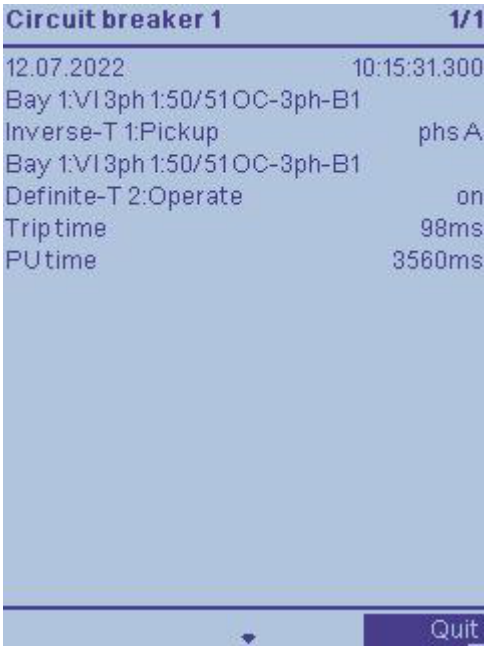
- Settings



- Circuit breaker test

- Device functions

- Reset functions



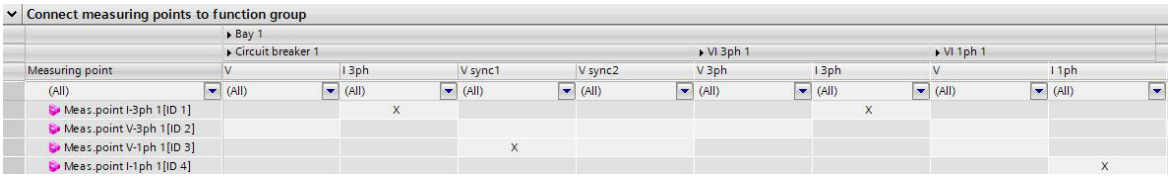
Fault Display for the Bay

For the **Bay**, the configuration of the fault display with DIGSI 5 and the acknowledgment of the fault display on the on-site operation panel are as follows:

Display	Function group	Displayed information
☑	Circuit breaker 1	
	Display line 1	Pickup indication
	Display line 2	Operate indication
	Display line 3	Trip time
	Display line 4	PU time
	Display line 5	No alarm
	Display line 6	No alarm
	Bay 1	
☑	Circuit breaker 1	
	Display line 1	Pickup indication
	Display line 2	Operate indication
	Display line 3	Trip time
	Display line 4	PU time
	Display line 5	No alarm
	Display line 6	No alarm

[sc_fault_display_configure_AOMBay, 2, en_US]

Figure 5-192 Configuration of the Fault Display for the Bay with DIGSI 5

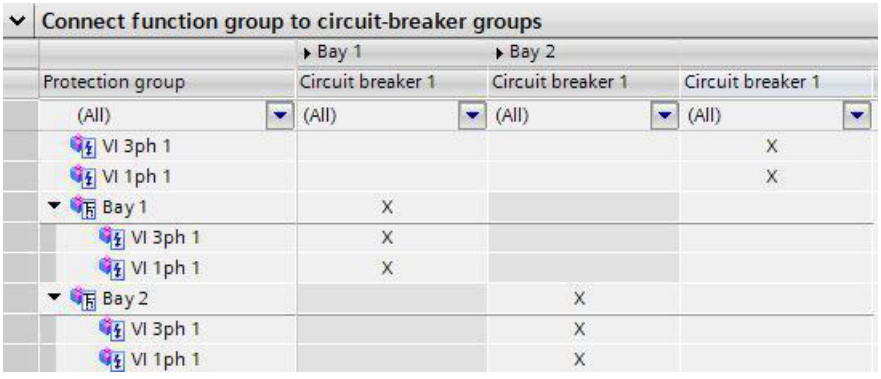


[sc_fault_display_ack_AOMBay, 2, en_US]

Figure 5-193 Fault Display for the Bay on the On-Site Operation Panel

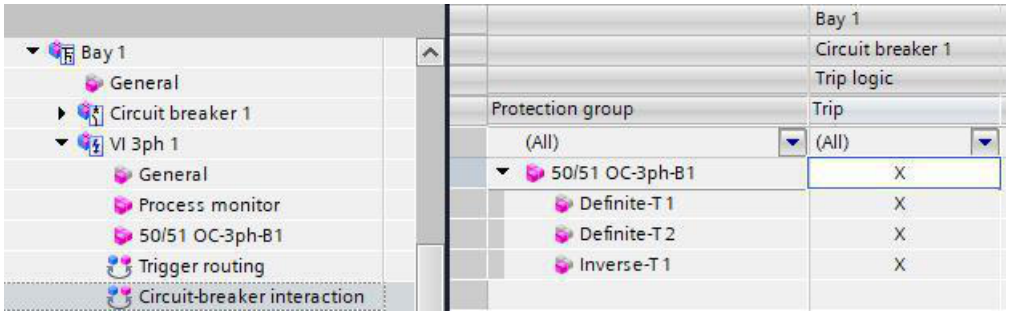
For more information about fault display, refer to *3.1.8 Spontaneous Fault Display on the On-Site Operation Panel* .

Connecting Measuring Points to Function Groups in a Bay



Under **Function-group connections** > **Connect measuring points to function group**, you can connect measuring points to the function groups in a **Bay**, as shown in the following figure.

[Connecting measuring points to function groups in a bay, 2, en_US]

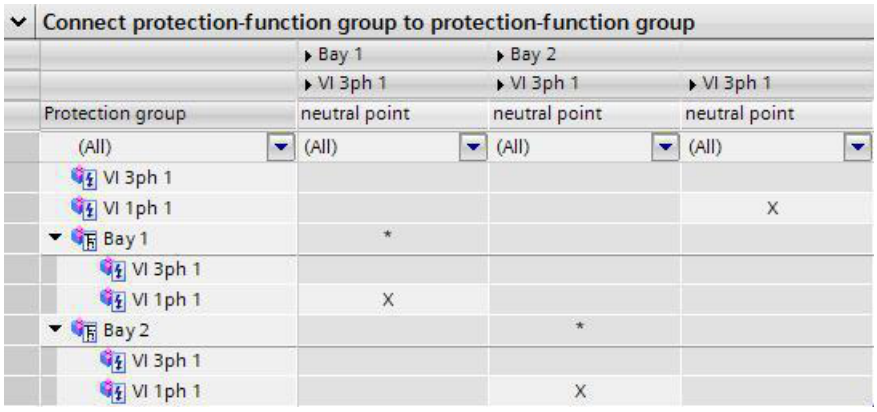


Connecting Function Groups in a Bay to Circuit Breakers

Under **Function-group connections** > **Connect function group to circuit-breaker groups**, you can connect protection function groups in a **Bay** to function groups **Circuit breaker** in the **Bay** or out of **Bays**, as shown in the following figure.

[Connecting function groups in a bay to circuit breakers, 2, en_US]

Besides the general allocation of the protection function groups to the function groups **Circuit breaker**, you can also configure the interface for certain functionalities in detail. Configure the details in DIGSI 5 using the **Circuit-breaker interaction** Editor in the protection function groups, as shown in the following figure.



[Circuit-breaker interaction, 2, en_US]

In the preceding figure, the routable function groups **Circuit breaker** are those connected under **Function-group connections** > **Connect function group to circuit-breaker groups**.

Connecting Function Groups in the Same Bay

Under **Function-group connections** > **Connect protection-function group to protection-function group**, you can connect function groups to other function groups in the same **Bay**, as shown in the following figure. You cannot connect a function group in a **Bay** to a function group out of the **Bay**.

[Connecting function groups in the same bay, 2, en_US]

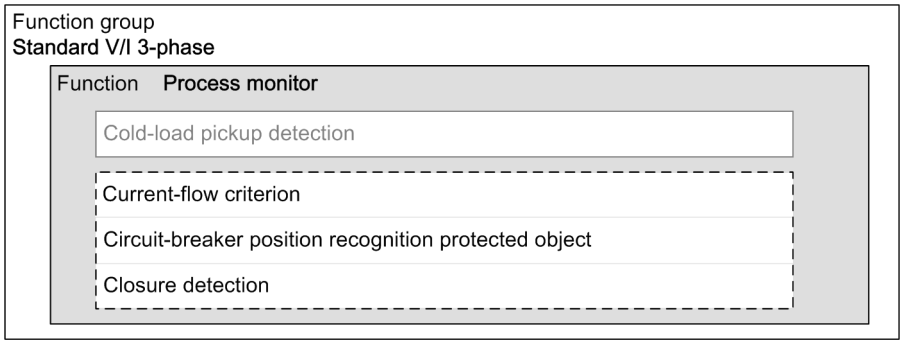
5.14 Process Monitor

5.14.1 Overview of Functions

All function groups that have functions with dependencies on the state of the protected object contain a process monitor. The process monitor detects the current state of the protected object.



5.14.2 Structure of the Function

The **Process monitor** function is used in the following protection function groups with current measurement:

- **Transformer side**
- **Auto transf. auto side**
- **Auto Transf. comp. side**
- **Auto transf. ground side**
- **Motor Side**
- **Standard V/I**

The **Process monitor** function is provided by the manufacturer with the following function blocks:

- Cold-load pickup detection (optional)
- Current-flow criterion
- Circuit-breaker condition
- Closure detection

[dw_pro3pt, 2, en_US]

Figure 5-194 Structure/Embedding of the Function

You can activate the cold-load pickup detection as needed. All other stages of the process monitor run permanently in the background and are not displayed in DIGSI.

The following figure shows the relationships of the individual function blocks.

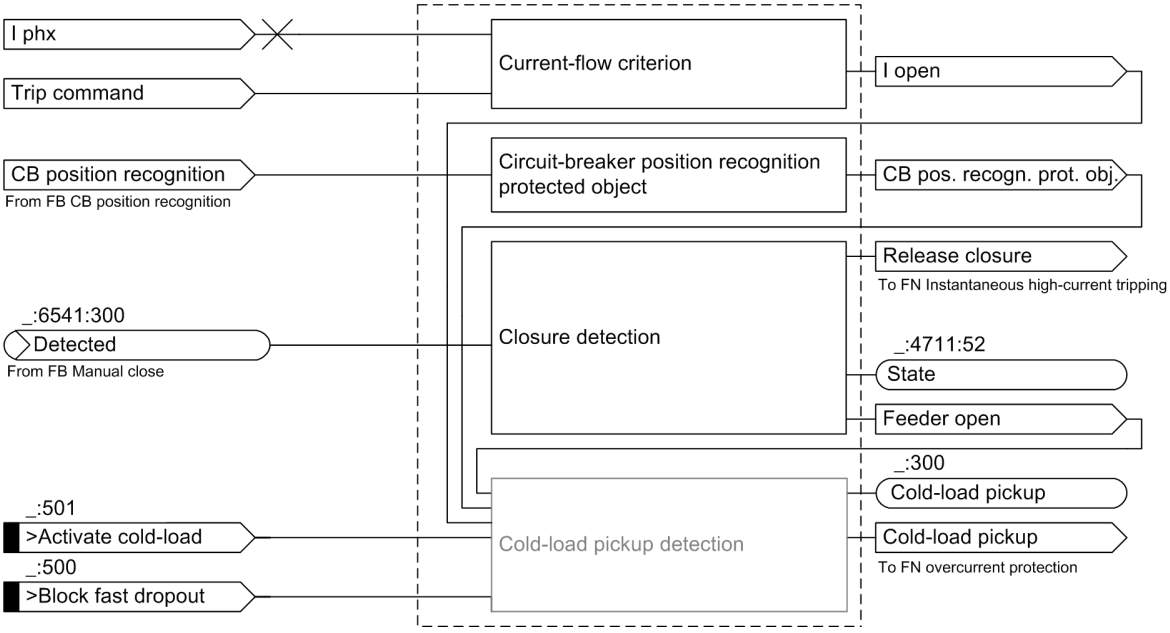


Figure 5-195 Logic Diagram of the Overall Function Process Monitor

5.14.3 Current-Flow Criterion

Logic

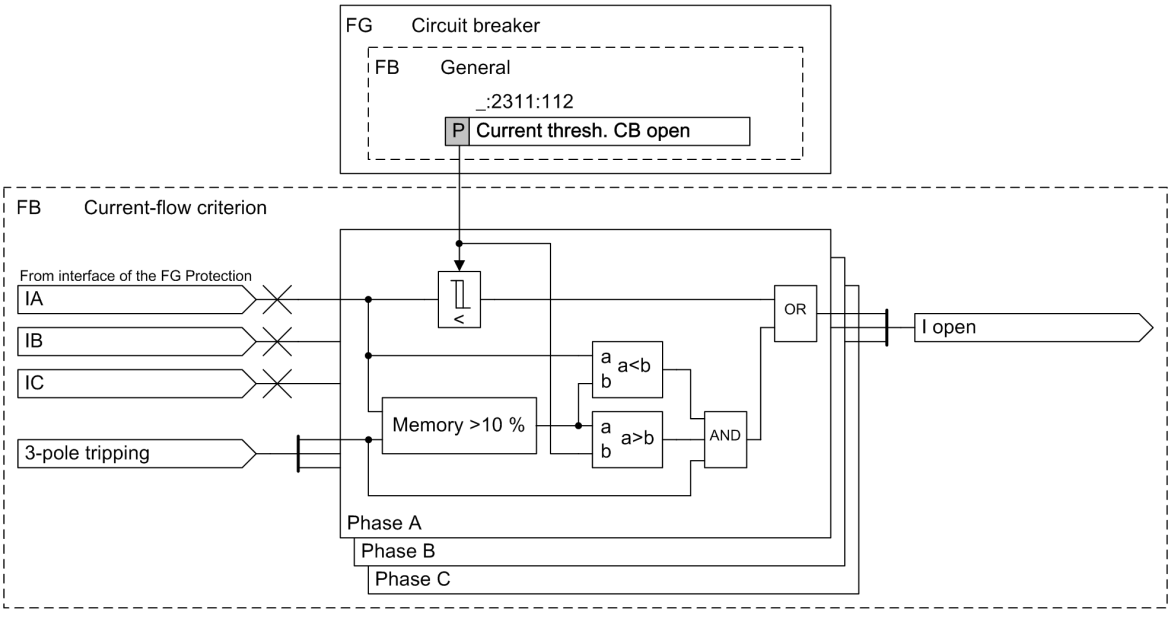

Figure 5-196 Logic Diagram of the Current-Flow Criterion Function Block

The phase currents are provided via the interface to the protection function group.

The **I open** signal of one phase is generated if one of the following conditions is met:

- A phase current falls below the set threshold of the **Current thresh. CB open** parameter. The hysteresis stabilizes the signal.
- The corresponding phase current, for example, **I A**, falls below 10 % of the phase current when the trip command arrives. If the current does not drop until after a delay due to current transformer influences, an open pole can therefore be detected quickly even after a high-current fault on the line.

With the **Current thresh. CB open** parameter, you define the minimum current as the criterion for a deactivated line. The parameter lies in the **Circuit-breaker** function group. It acts both in the **Circuit-breaker** function group, for example circuit-breaker position recognition, and also for the process monitor in the protection function group.

If a protection function group with integrated process monitor is connected to several **Circuit breaker** FGs, the **Current thresh. CB open** parameter is present in each FG **Circuit breaker**. The smallest setting value of the parameter **Current thresh. CB open** is used.

5.14.4 Application and Setting Notes (Current-Flow Criterion)

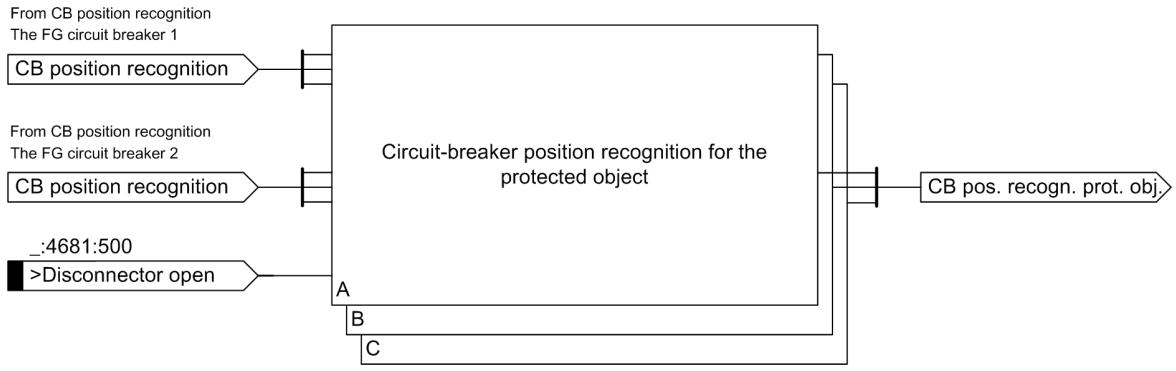
Parameter: Current thresh. CB open

- Recommended setting value **(_:2311:112) Current thresh. CB open** = ***0.100 A***

The **Current thresh. CB open** parameter is used to define the threshold for the leakage current as the criterion for a deactivated line.

Set the **Current thresh. CB open** parameter so that the current measured when the feeder is deactivated falls below the value of the **Current thresh. CB open** parameter with certainty. The hysteresis is additionally active if the threshold is exceeded.

If parasitic currents, for example, due to induction, are ruled out when the feeder is deactivated, set the **Current thresh. CB open** parameter sensitively.



Siemens recommends a setting value of ***0.100 A***.

5.14.5 Settings

5.14.6 Circuit-Breaker Condition for the Protected Object

Logic

[lo_prolsz, 2, en_US]

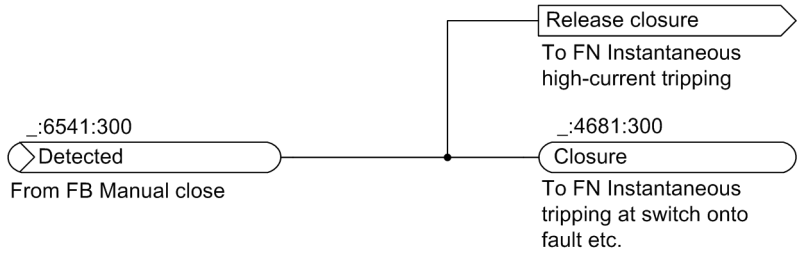
Figure 5-197 Logic Diagram of the Circuit-Breaker Condition for the Protected-Object Function Block

The circuit-breaker position recognition in the **Circuit-breaker** (CB) function group provides the circuit-breaker condition by way of the internal signal *CB pos. recogn. prot. obj.*.

If a protected object is supplied via 2 circuit breakers (CBs), for example with the 1 1/2 circuit-breaker layout, then the circuit-breaker switch position of the protected object must be determined with the aid of both circuit breakers. In this case, the **Circuit-breaker position recognition for the protected object** function block connects the individual CB states. The connection provides the internal *CB pos. recogn. prot. obj.* signal to the other function blocks of the process monitor and to other functions, for example, **Trip in the event of weak infeed** and **Echo function for teleprotection method**, within the same function group.

If one of the following 2 conditions is met, the *CB pos. recogn. prot. obj.* signal is in the ***Open*** state:

- All connected circuit breakers signal the ***Open*** state internally.
- The **>Disconnector open** input is active.



If the following 2 conditions are met, the *CB pos. recogn. prot. obj.* signal is in the ***Closed*** state:

- At least one of the connected circuit breakers signals the ***Closed*** state internally.
- The **>Disconnector open** input is not active.

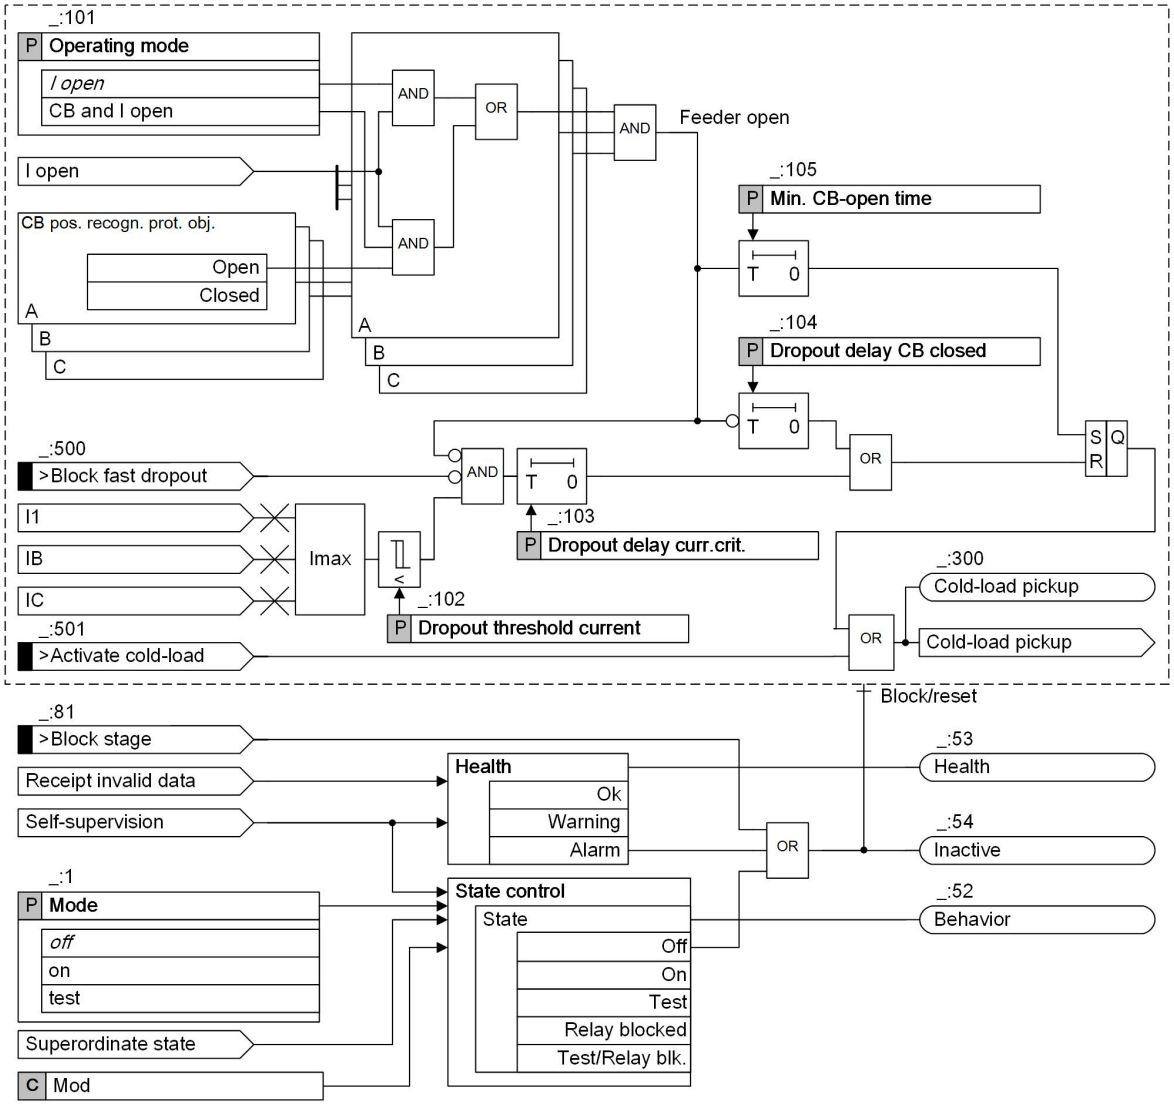
5.14.7 Closure Detection

The closure detection enables the immediate tripping of selected protection functions or protection stages when switching to a short circuit or the reduction of the responsivity. The closure detection determines whether the protected object is switched on.

Logic

[lo_ein_6md, 1, en_US]

Figure 5-198 Logic Diagram of Closure Detection



For an applied binary input signal **(_:6541:300) Detected** (from function block Manual close), the indication **(_:4681:300) Closure** is active.

5.14.9 Cold-Load Pickup Detection (Optional)

Logic

[lo_pro_cls, 2, en_US]

Figure 5-199 Logic Diagram of the Cold-Load Pickup Detection Function Block

The **Cold-load pickup detection** function block detects that a specific time has been exceeded after deactivation of the line or protected object. If you want to connect the protected object again, you must note that an increased load-current requirement exists for a limited time after connection. This results from the nature of the load.

The **Cold-load pickup detection** function block ensures that different parameters are used for an adjustable time after connection. For example, for the time of the **Min. CB-open time** parameter, you can increase the threshold value of a protection function or you can select a special characteristic curve.

If the **Cold-load pickup detection** function block detects an open feeder and the set time of the **Min. CB-open time** parameter has expired, the indication **>Activate cold-load** is generated.

With the **>Activate cold-load** indication, you can activate a parameter set of the **Cold-load pickup** function. Via the binary input signal **>Activate cold-load**, you can also activate the **>Activate cold-load** indication directly.

If the **Cold-load pickup detection** function block detects closure and the corresponding load current, it starts the time set in the **Dropout delay CB closed** parameter. The **>Activate cold-load** indication and the activated parameter set are deactivated after this time has elapsed.

If, for the time set in the **Dropout delay curr.crit.** parameter, the maximum phase current falls below the threshold value **Dropout threshold current**, the parameter set for the **Cold-load pickup detection** function block is also deactivated. As a result, if the load current is very low, the action time **Dropout delay curr.crit.** of the **>Activate cold-load** indication can be shortened.

5.14.10 Application and Setting Notes (Cold-Load Pickup Detection)

NOTE

The settings and indications described in this chapter are only available when using the optional **Cold-load pickup detection** function block.

Parameter: Operating mode

- Default setting **(_:101) Operating mode** = ***I open***

With the **Operating mode** parameter, you set the criteria with which the Closure-detection function block operates.

Parameter Value	Description
I open	When the Current-flow criterion function block detects a clearing open condition, the decision is made for pickup. For this setting, make sure that the **Current thresh. CB open** parameter is set lower than the possible load current. If this is not the case, open is detected continuously and each fault current that exceeds the **Current thresh. CB open** parameter is interpreted as closure.
CB and I open	Closure is detected if one of the following conditions is met: • Analysis of the circuit-breaker auxiliary contact detects a clearing open condition in at least one phase. • The current-flow criterion detects a clearing open condition.

Parameter: Dropout threshold current

- Default setting **(_:102) Dropout threshold current** = ***1.00 A***

With the **Dropout threshold current** parameter, you set the threshold at which the output signal **Cold-load pickup** is deactivated when the current in at least one phase falls below this threshold.

Parameter: Dropout delay current criterion

- Default setting **(_:103) Dropout delay curr.crit.** = ***600 s***

With the **Dropout delay curr.crit.** parameter, you set the time for which the actual value must be below the **Dropout threshold current** threshold so that the output signal **Cold-load pickup** can be deactivated prematurely.

Parameter: Dropout delay CB closed

- Default setting **(_:104) Dropout delay CB closed** = ***3600 s***

With the **Dropout delay CB closed** parameter, you set the action time for the dynamic parameter set switching in the event of cold-load pickup detection.

Parameter: Min. CB open time

- Default setting **(_:105) Min. CB-open time** = ***3600 s***

With the **Min. CB-open time** parameter, you set the time after which the dynamic parameter set is activated in the event of **cold-load pickup** when the line is opened.

6.1 Power-System Data

6.1.1 Overview

The **Power-system data** are provided with each SIPROTEC 5 device and cannot be deleted. You will find them in DIGSI under **Settings** → **Power system**.

6.1.2 Structure of the Power-System Data

The **Power-system data** contain the block **General** and the **Measuring points** of the device. The following figure shows the structure of the **Power-system data**:

[dw_system data, 2, en_US]

Figure 6-1 Structure of the Power-System Data

In order to adjust its functions to the application, the device requires some data about the power system. The necessary settings can be found in the Power-system data under **General** as well as in the **Measuring points**.

NOTE

You can find information on the supervision-function parameters in *8.3 Supervision of the Secondary System*.

Type and scope of the required measuring points depend on the application. Possible measuring points are:

- Voltage 3-phase (measuring point V 3-ph)
- Current 3-phase (measuring point I 3-ph)
- Voltage 1-phase (measuring point V 1-ph)
- Current 1-phase (measuring point I 1-ph)

The measuring points have interfaces to the function groups, which require voltage and/or current measured values of the power system.

6.1.3 Application and Setting Instructions - General Settings

Parameter: Phase sequence

- Recommended setting value **(_:2311:101) Phase sequence** = ***ABC***

The parameter **Phase sequence** is used to set the phase sequence (***ABC***) or (***ACB***). The setting value applies to the entire SIPROTEC 5 device.

Use the **General** function to set the settings in the power-system data.

You can find detailed information about phase-rotation reversal in chapter *6.55 Phase-Sequence Switchover*.

6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph)

The following example describes the settings of the voltage measuring point **Measuring point V-3ph** (Voltage 3-phase). The **V-1ph measuring point** has only a subset of the parameters described here. The description of the parameter is also valid for the **V-1ph measuring point**.

Parameter: Rated primary voltage

- Default setting **(_:8911:101) Rated primary voltage** = ***400 kV***

With the parameter **Rated primary voltage**, you set the primary rated voltage of the voltage transformer.

Parameter: Rated secondary voltage

- Default setting **(_:8911:102) Rated secondary voltage** = ***100 V***

With the parameter **Rated secondary voltage**, you set the secondary rated voltage of the voltage transformer.

Parameter: Matching ratio Vph / VN

- Default setting **(_:8911:103) Matching ratio Vph / VN** = ***1.73***

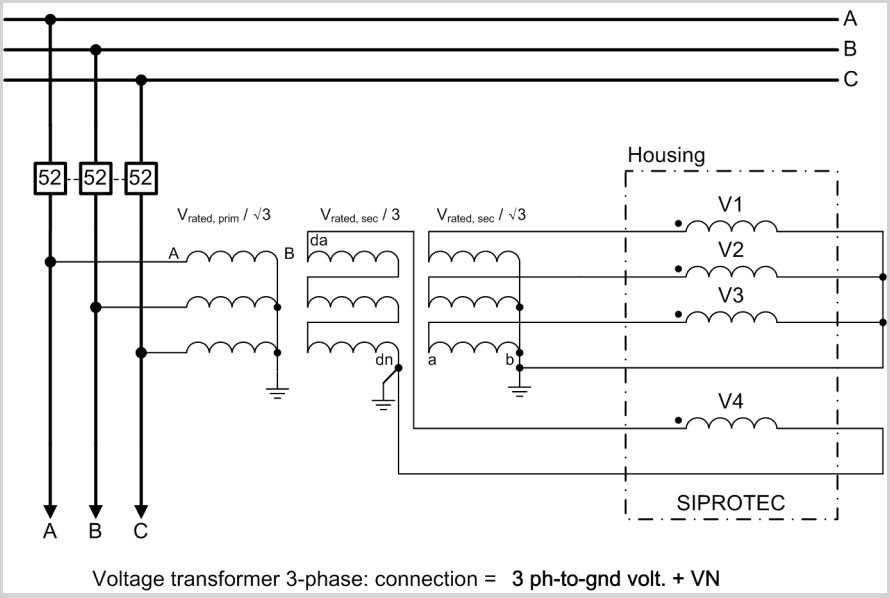
With the parameter **Matching ratio Vph / VN**, you set the deviation between the calculated zero-sequence voltage and the residual voltage measured directly via a measuring input. The different ratio of the voltage transformers is the cause for the deviation (see *Figure 6-2*).

The **Matching ratio Vph / VN** is equal to the ratio $3V_{0\,sec}/V_{N\,sec}$

with

$V_{0\,sec}$	Calculated zero-sequence voltage
$V_{N\,sec}$	Measured residual voltage

The zero-sequence voltage is calculated as phase-to-ground voltages. The residual voltage is measured on the broken-delta winding of the voltage transformer. For 1-phase voltage transformers the residual voltage is measured in the generator or the transformer neutral point.



NOTE

The measured residual voltage $V_{N\,sec}$ is converted to a zero-sequence voltage in the device as follows:

$$V_{0\,sec} = V_{N\,sec} \cdot \frac{\text{Matching ratio Vph/VN}}{3}$$

EXAMPLE 1:

[dw_bsp1uwdl_anpassfaktor, 2, en_US]

Figure 6-2 3-Phase Voltage Transformer: Connection = 3 Phase-to-Ground Voltage + VN

When the type of connection for the voltage transformer is ***3 ph-to-gnd volt. + VN*** (parameter: **VT connection**) and the voltage input V4 is connected to the broken-delta winding of the voltage transformer (da/dn), the **Matching ratio Vph / VN** is as follows:

When changing the neutral point according to *Figure 6-2*, this results in the following values:

- The calculated secondary zero-sequence voltage $V_{0\,sec}$ is equal to the secondary phase-to-ground voltage. Expressed as secondary transformer rated voltage, then $V_{rated,sec}/\sqrt{3}$.
- The measured residual voltage on the broken-delta winding is the sum of the voltage drops on the 3 sides. Expressed with the side ratio, the result is $V_{N,\,sec} = 3\ V_{rated,sec}/3$.

Calculate the **Matching ratio Vph / VN** parameter as follows:

$$\text{Matching ratio } \frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\,sec}}{V_{N\,sec}} = \frac{3 \cdot \frac{V_{rated\ sec}}{\sqrt{3}}}{3 \cdot \frac{V_{rated\ sec}}{3}} = \frac{3}{\sqrt{3}} = \sqrt{3} = 1.73$$

[fo_example_1, 2, en_US]

Set **Matching ratio Vph / VN** = ***1.73***.

In **example 1** $V_{rated\,sec}$, the phase-to-ground voltage and the secondary voltage on the broken-delta winding were identical. If these voltages are different, use the actual numerical values in the calculation.

EXAMPLE 2:

Phase-to-ground voltage	$V_{rated\,sec} = 100$ V
Broken-delta winding (for example, grounding transformer in generator protection)	$V_{rated\,sec} = 500$ V The voltage input of the device is designed for a continuous operation, using 230 V max. Therefore, the voltage on the broken-delta winding (500 V) is reduced to a 5:2 ratio, using an ohmic divider. In order to calculate the matching factor, the secondary voltage of 200 V will be applied.

Calculate the **Matching ratio Vph / VN** parameter as follows:

$$\text{Matching ratio } \frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\,\text{sec}}}{V_{\text{N sec}}} = \frac{3 \cdot \frac{V_{\text{rated sec}}}{\sqrt{3}}}{3 \cdot \frac{V_{\text{rated sec}}}{3}} = \frac{3 \cdot \frac{100\ \text{V}}{\sqrt{3}}}{3 \cdot \frac{200\ \text{V}}{3}} = \frac{3}{2 \cdot \sqrt{3}} = \frac{\sqrt{3}}{2} = 0.866$$

[fo_example_2, 1, en_US]

Set **Matching ratio Vph / VN** = ***0.866***.

Interpretation of the result:

The zero-sequence voltage calculated from the phase-to-ground voltage is 57.73 V (= 100V/√3). The measured residual voltage is 200 V. The calculated matching factor is 0.866. The measured residual voltage is converted to a zero-sequence voltage inside the device:

$$V_{0\,\text{sec}} = V_{\text{N sec}} \cdot \frac{\text{Matching ratio Vph/VN}}{3} = 200\ \text{V} \cdot \frac{0.866}{3} = 57.73\ \text{V}$$

[fo_conversion2, 2, en_US]

NOTE

During the ground-fault test, the set matching factor can be checked by comparing the operational measured values. The operational measured values contain the calculated zero-sequence voltage $V_{0\,\text{sec}}$ and the measured residual voltage $V_{\text{N sec}}$. Proceed with the compilation as follows:

$$\text{Matching ratio.} \frac{\text{Vph}}{\text{VN}} = \frac{3 \cdot V_{0\,\text{sec}}}{V_{\text{N sec}}}$$

The **Matching ratio Vph / VN** parameter is significant for the following functions of the device:

- Overvoltage protection with zero-sequence/residual voltage
- Measured-value supervision
- Scaling of the faulty and measured values

Parameter: VT connection

- Default setting **(_:8911:104) VT connection** = ***3 ph-to-gnd volt. + VN***

The parameter **VT connection** shows the connection type of the voltage transformer for the 3-phase voltage measuring point. The parameter can be found in the DIGSI 5 project tree under **Name of the device** → **Parameter** → **Power-system data** → **Measuring point V 3-phase**. You cannot change the connection type of the voltage transformer in the power-system data.

You can change the connection type of the voltage transformer only under measuring point routing in DIGSI 5. Under **Name of the device** → **Measuring point routing** → **Voltage measuring points**, select the desired connection type under **Connection type**. The following types of connections are possible:

- ***3 ph-to-gnd volt. + VN***
- ***3 ph-to-gnd voltages***
- ***3 ph-to-ph volt. + VN***
- ***3 ph-to-ph voltages***
- ***2 ph-to-ph volt. + VN***
- ***2 ph-to-ph voltages***

Depending on the connection type selected, you must route the measured values to the terminals of the voltage measuring point in DIGSI 5. You can find connection examples for voltage transformers in *A.10 Connection Examples of Voltage Transformers for Modular Devices*. The connection examples provide assistance when selecting the type of connection.

Parameter: Inverted phases

- Default setting **(_:8911:106) Inverted phases** = ***none***

The **Inverted phases** parameter is intended for special applications, for example, pumped-storage hydropower plants (see *6.55 Phase-Sequence Switchover*). This default setting can be retained for power-system protection applications.

Parameter: Tracking

- Default setting **(_:8911:111) Tracking** = ***active***

The **Tracking** parameter is used to determine whether the measuring channels of this measuring point shall be used to determine the sampling frequency.

The sampling frequency of the device is adjusted to the power frequency. The device selects a measuring channel, through which the sampling frequency is determined. Preferably, this should be a voltage metering channel. This validity of the signal is monitored (minimum level, frequency range). If these values are invalid, the device switches to another channel (etc.). Once switched to a current channel, the system automatically switches back to this channel if a voltage channel is valid again.

Parameter Value	Description
active	If the parameter **Tracking** = ***active*** has been set, the measuring point will be included when determining the sampling frequency. If possible, only the 3-phase measuring points shall be considered. Siemens recommends using the default setting. **Note:** Note that, during sampling-frequency tracking, the entire device is set to the determined sampling frequency. That is to say, all of the measuring point channels work with the determined main sampling frequency. Please keep this in mind when working with the device.
inactive	If the channels of the measuring point are not to be considered for determining the sampling frequency, select the setting value ***inactive***.

Parameter: Magnitude correction

- Default setting **(_:3811:103) Magnitude correction** = ***1.000***

With the **Magnitude correction** parameter, you adjust the amplitude (magnitude correction) for the voltage input. This allows you to correct the tolerances of the primary current transformer phase-selectively. The magnitude correction can be required for highly precise measurements. Use a comparison measurement to determine the setting value (for example, a high-precision measuring-voltage transformer). If a primary correction is not necessary, retain the default setting.

NOTE

The **Magnitude correction** parameter has nothing to do with the internal adjustment of the input circuit.

6.1.5 Application and Setting Notes for Measuring-Point Current 3-Phase (I-3ph)

The following example describes the settings for the current measuring points **Measuring point I-3ph** (Current 3-phase). The **I-1ph measuring point** has only a subset of the parameters described here. The description of the parameter is also valid for the **I-1ph measuring point**.

Parameter: CT connection

- Default setting **(_:8881:115) CT connection** = ***3-phase + IN-separate***

The parameter **CT connection** shows the connection type of the current transformer for the 3-phase current measuring point. The parameter can be found in the DIGSI 5 project tree under **Name of the device**

→ **Parameter** → **Power-system data** → **Measuring point I 3-phase**. You cannot change the connection type of the current transformer in the power-system data.

You can change the connection type of the current transformer only under measuring point routing in DIGSI 5. Under **Name of the device** → **Measuring point routing** → **Current measuring points**, select the desired connection type under Connection type. The following types of connections are possible:

- ***3-phase + IN-separate***
- ***3-phase + IN***
- ***3-phase***
- ***3-phase, 2 primary CT***
- ***3ph,2prim.CT + IN-sep***

Depending on the connection type selected, you must route the measured values to the terminals of the current measuring point in DIGSI 5. You can find connection examples for current transformers in chapter *A.9 Connection Examples for Current Transformers*. The connection examples provide assistance when selecting the type of connection.

Parameter: `Tracking`

- Default setting **`(_:8881:127) Tracking`** = ***`active`***

With the parameter **`Tracking`**, you specify whether you would like to work with the manual updating function of the sampling frequency.

Parameter Value	Description
`active`	If the parameter **`Tracking`** = ***`active`*** has been set, the measuring point will be included when determining the sampling frequency. If possible, only the 3-phase measuring points shall be considered. Siemens recommends using the default setting. **Note:** During the manual updating of the sampling frequency, the entire device adjusts itself to different sampling frequencies corresponding to the frequency tracking groups. That is to say, the channels of the measuring points work with the determined sampling frequency of the frequency tracking groups. Keep this in mind when working with the device.
`inactive`	If the channels of the measuring point are not to be considered for determining the sampling frequency, please select the setting value ***`inactive`***.

Parameter: Rated primary current

- Default setting **`(_:8881:101) Rated primary current`** = ***`1000 A`***

With the **`Rated primary current`** parameter, you set the active rated primary current of the current transformer.

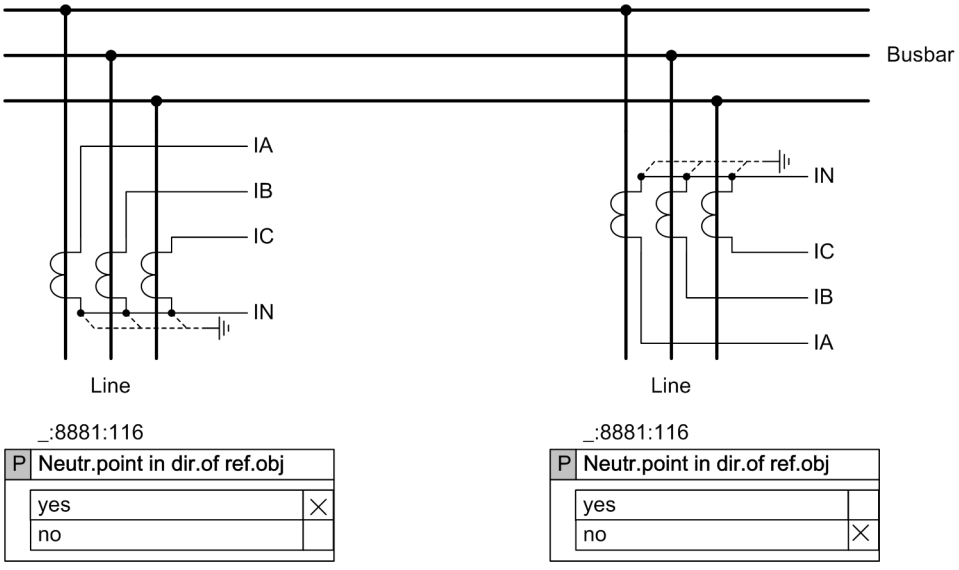
Parameter: Rated secondary current

- Default setting **`(_:8881:102) Rated secondary current`** = ***`1 A`***

With the **`Rated secondary current`** parameter, you set the active rated secondary current of the current transformer.

Parameter: Current range

- Default setting **`(_:8881:117) Current range`** = ***`100 x IR`***



The **`Current range`** parameter allows you to set the dynamic range for the current input. Retain the default setting for power-system protection applications. The setting value for the sensitive current input and the measuring current input is 1.6 x I_{rated}.

Parameter: Neutr.point in dir.of ref.obj

- Default setting **(_:8881:116) Neutr.point in dir.of ref.obj** = ***yes***

The **Neutr.point in dir.of ref.obj** parameter is used to set the direction of the neutral point of the current transformer (see the following figure). Often, the neutral point of the current transformer is determined by the direction of the protected object (for example, in the direction of the line, cable, transformer). For this reason, the default setting of the parameter was defined as ***yes***.

When switching the parameter, the direction of the phase currents and of the ground current IN or IN-separate is changed device-internally.

[dw_polstromwdl, 1, en_US]

Figure 6-3 Polarity of Current Transformers

Parameter: Inverted phases

- Default setting **(_:8881:114) Inverted phases** = ***none***

The **Inverted phases** parameter is intended for special applications, for example, pumped-storage hydropower plants (see chapter *6.55 Phase-Sequence Switchover*). This default setting can be retained for power-system protection applications.

Parameter: CT error changeover

- Default setting **(_:8881:107) CT error changeover** = ***1.00***

The **CT error changeover** parameter is only relevant for the Line differential protection function. The **CT error changeover** parameter defines the transition range of the transformer fault from low to higher currents.

Parameter: CT error A

- Default setting **(_:8881:108) CT error A** = ***5.0***

The **CT error A** parameter considers the transformer fault at rated current plus a safety margin.

Parameter: CT error B

- Default setting **(_:8881:109) CT error B** = ***15.0***

The **CT error B** parameter considers the transformer fault at rated overcurrent factor plus a safety margin. It is the number preceding the letter P of the transformer data.

Parameter: Magnitude correction

- Default setting **(_:3841:103) Magnitude correction** = *1.000*

When using the **Magnitude correction** parameter, you adjust the amplitude (amplitude correction) for the current input. This allows you to correct the tolerances of the primary current transformer phase-selectively. The magnitude correction may be required for highly precise measurements. Use a comparison measurement to determine the setting value (for example, a high-precision measuring-voltage transformer). If a primary correction is not necessary, retain the default setting.

NOTE

The **Magnitude correction** parameter has nothing to do with the internal adjustment of the input circuit.

Note Regarding Routable Information

Indications for the current rotating field and the information pertaining to the manual updating can be found in **Information routing** under **Power-system data** → **General** in DIGSI 5. The indication *Freq.out of oper.range* means that the frequency operating range has been exceeded. Either the frequency is out of range (10 Hz to 90 Hz) or the input signals are too small for a manual update. Should this condition occur, the system switches the update frequency to a sampling rate that corresponds to the rated frequency.

Furthermore, there are 2 additional measured frequency values available. The measured value *f sys* displays the current system frequency, and the measured value *f track* displays the sampling frequency currently set. Siemens recommends routing both measured values as fault-recording channel.

6.1.6 Disconnection of Measuring Points

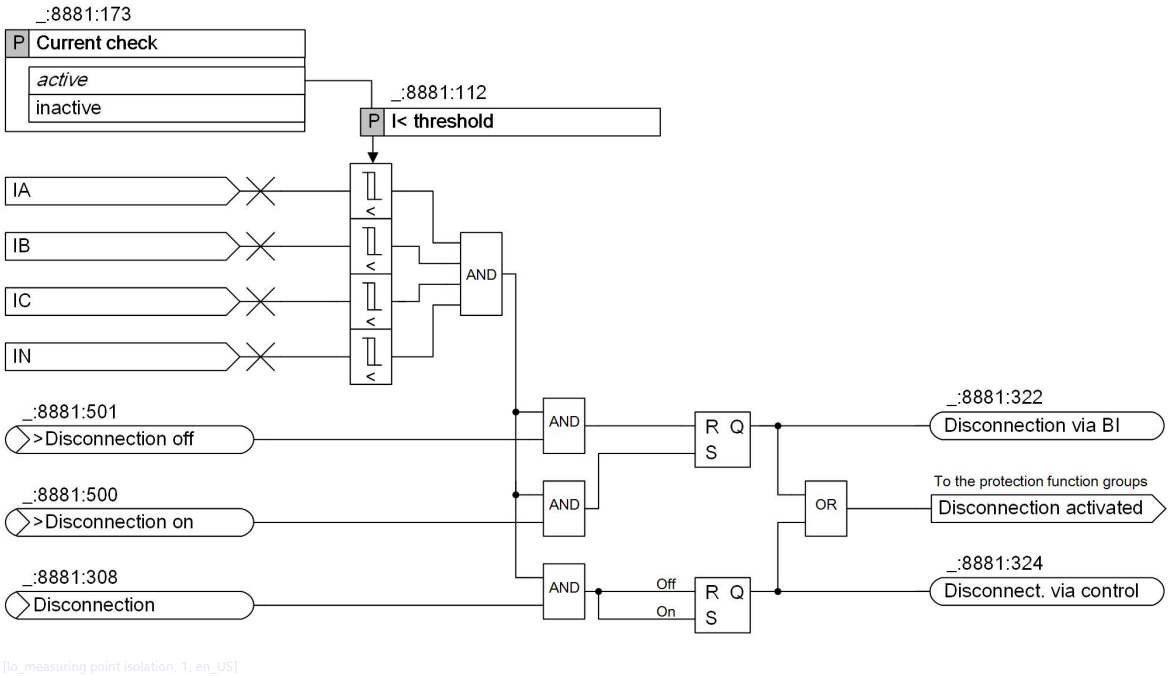
6.1.6.1 Overview

Maintenance work or specific operating and switching states of the power system can require disconnection of measuring point. Therefore, it is sometimes necessary to take individual measuring points out of processing, for example, to prevent an unwanted tripping of the Differential protection. With the **Disconnection of measuring points** functionality, you can disconnect the connection of the **Measuring point I-3ph** to a protection function group.

If the measuring point has been disconnected, you can carry out any work without influencing the work of the protection functions that are assigned to the measuring point. Once the measuring point has been disconnected, the Differential protection, for example, does not take the measured values of this measuring point into account anymore for calculating the differential current.

An exception applies for the following protection functions of the FG **Line**:

- Distance Protection with Classic Method
- Distance Protection with Reactance Method (RMD)
- Power-Swing Blocking
- Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems (67N)
- Measuring-voltage failure detection



NOTE

If one of the current measuring points is disconnected, the mentioned protection functions of the FG **Line** switch to the *Alarm* state and are not active.

There is another exception for the disconnection of measuring points for the FG **Circuit breaker**: If the FG **Circuit breaker** is connected to a disconnected measuring point, the functional measured values are indicated as usual and used by the functions in the FG **Circuit breaker**. That is, the disconnection does not set the functional measured values to 0. If a circuit-breaker failure detection is instantiated in the FG **Circuit breaker**, Siemens recommends blocking the function for current tests.

6.1.6.2 Description

Logic

[lo_measuring point isolation, 1, en_US]

Figure 6-4 Logic of the Disconnection of Measuring Point

You can find the signals for the **Disconnection of measuring points** in the Information routing matrix in DIGSI under **Settings** → **Power system** → **Meas.point I-3ph**.

The following signals are available for activating the **Measuring point I-3ph**:

- The binary inputs *(_:8881:500) >Disconnection on* and *(_:8881:501) >Disconnection off*
- The controllable *(_:8881:308) Disconnection*

You can control whether the **Measuring point I-3ph** may only be disconnected if the measured currents fall below the set threshold value. The measuring point can also be disconnected without checking the threshold value. If you want to disconnect the measuring point without threshold-value check, consider that no currents are flowing anymore in the primary plant.

Disconnection messages are also available after a restart of the device. The device stores the disconnection efficacy in NVRAM[34] The last information on disconnection remains available, even if the auxiliary voltage fails. When the auxiliary voltage returns, the device compares the stored state with that of the binary inputs.

6.1.6.3 Application and Setting Notes

Parameter: Current check

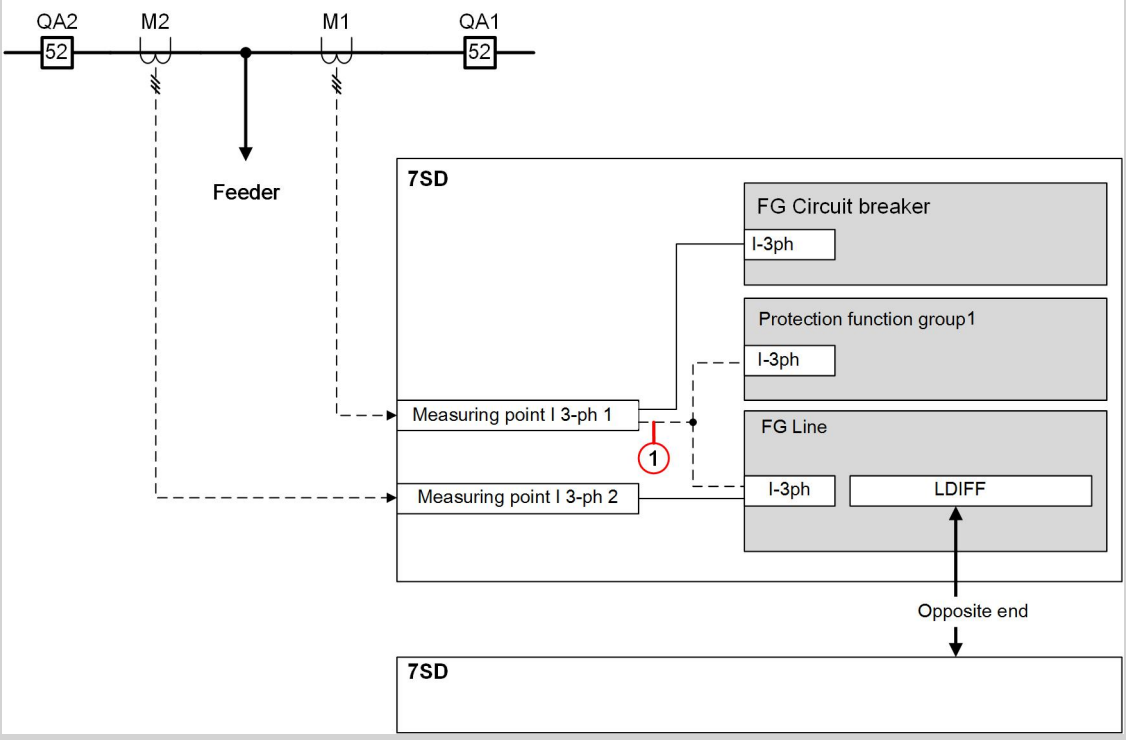
- Default setting **(_:8881:173) Current check** = ***active***

With the **Current check** parameter, you can set whether you want to compare the RMS values of the phase currents IA, IB, IC and of the measured zero-sequence current IN with a threshold value.

34 NVRAM = Non-Volatile Random Access Memory; RAM, which does not lose the stored data, even when there is no power.

Parameter Value	Description
active	The RMS values of the phase currents IA, IB, IC and of the measured zero-sequence current IN are compared to the setting value of the parameter **I< threshold**. The **Measuring point I-3ph** can only be activated if the current measured values fall below the threshold value.
inactive	The RMS values of the phase currents IA, IB, IC and of the measured zero-sequence current IN are not compared to the setting value of the parameter **I< threshold**.

Parameter: I< threshold



- Default setting **(_:8881:112) I< threshold** = ***0.100 A***

With the **I< threshold** parameter, you set the threshold for disconnection of a measuring point. If the current measured values fall below the threshold value, the **Measuring point I-3ph** can be activated.

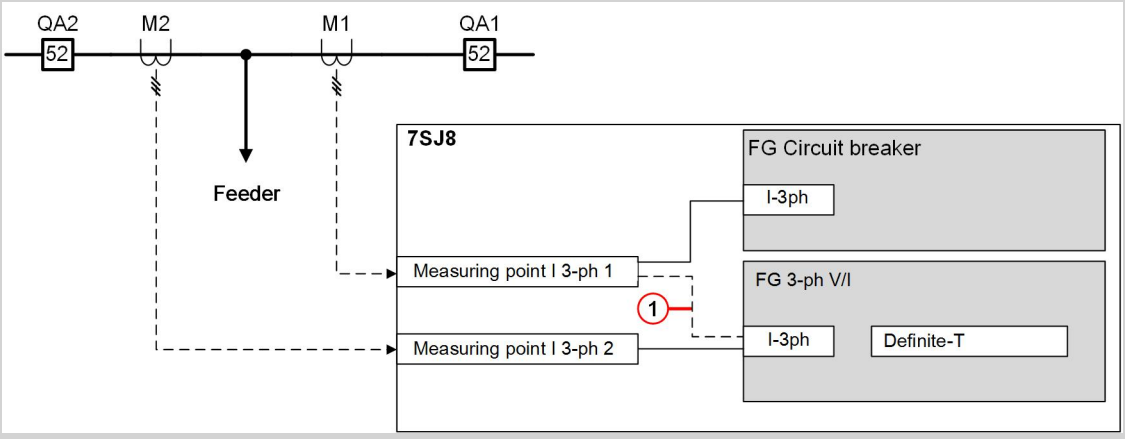
Set the **I< threshold** parameter so that the measured current will certainly fall below the parameterized value, for example, if the circuit-breaker pole is open. If parasitic currents, for example, due to induction, are not possible with the line/feeder deactivated, you can make a secondary setting of the value with a high degree of sensitivity, to 0.050 A for example. If no special requirements exist, Siemens recommends retaining the setting value of 0.100 A for secondary purposes.

EXAMPLE

Temporary Disconnection of a Connection of a Current Measuring Point to a Protection Function Group, Using the Example of a Line Differential Protection

[dw_similar-application_7SD_with_2-MU, 1, en_US]

Figure 6-5 Possible Disconnection of Measuring Point for the Line Differential Protection



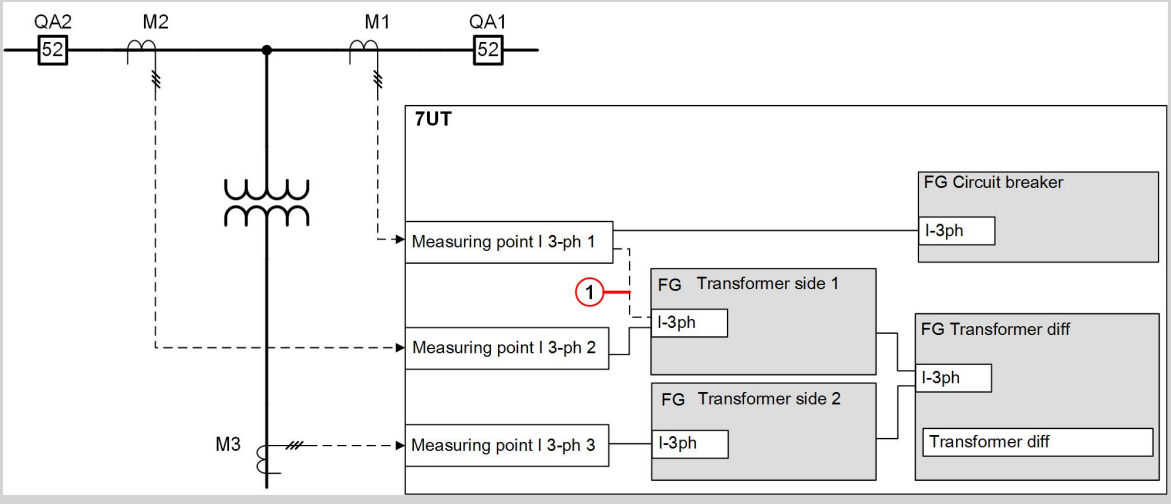
(1) Temporary disconnection of the connection to the **Measuring point I-3ph 1** for the FG **Line** and to the Protection Function Group 1

NOTE

If you disconnect the **Measuring point I-3ph 1**, you must make sure that no currents flows into the feeder via **M1**. Otherwise, this leads to an unwanted tripping of the **Line differential protection** function.

EXAMPLE

Temporary Disconnection of a Connection of a Current Measuring Point to the Protection Function Group 3-ph Voltage/Current



[dw_similar-application_7SJ8_with_2-MU_1_en_US]

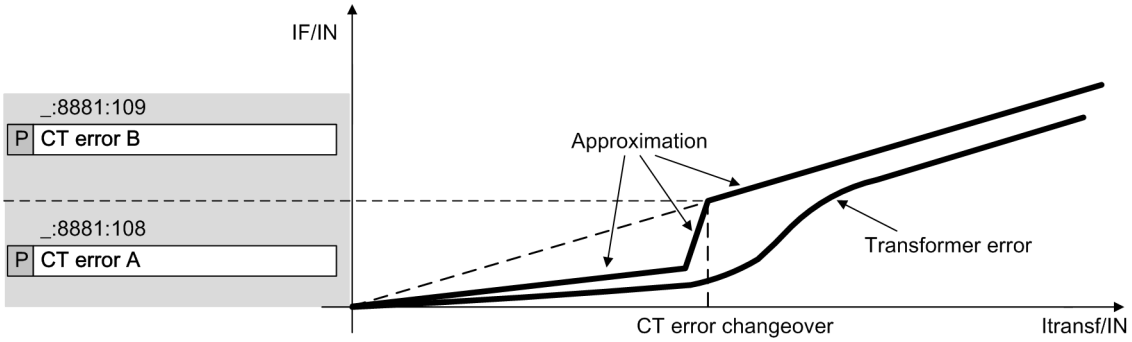
6.1.7 Application and Setting Notes for Line Differential Protection Settings

NOTE



The following parameters are only important for the **Line differential protection** function. You can find these parameters in the DIGSI 5 project tree under **Device name** (for example, **7SL86**) → **Settings** → **Power-system data** under **Measuring point I-3ph**.

Current-Transformer Characteristic Curve

The basic principle of the Differential protection function assumes that all currents flowing into a healthy protected object add up to 0. If the sets of current transformers indicate different transformation errors at the line ends in the overcurrent range, the secondarily measured sum of the current may reach a significant magnitude during external short circuits and the high flow of current resulting from this fact. This may simulate an internal short circuit.

The adaptive stabilization method of the line differential protection considers the erroneous behavior during current-transformer transmission errors. For this reason, the measuring error protection must be known with regard to the value of the current transformed by the current transformer. To do this, set the characteristic data of the current transformer and the secondary circuits. In many cases, the default setting can be main-

tained. It considers the data of the most unfavorable protection current transformer. By using the following settings, the Line differential protection function approximates the characteristic curve of the transformer error and calculates the stabilization value.

[dwctfail-310111-01.tif, 2, en_US]

Figure 6-8 Transmission Behavior of the Current Transformer

Parameter: CT error changeover

- Default setting **(_:8881:107) CT error changeover** = ***1.00***

The **CT error changeover** parameter defines the transition range of the transformer error from low to higher currents.

$$\text{CT error changeover} = \frac{n'}{n} = \frac{P_N + P_i}{P' + P_i}$$

[fofueber-090311-01.tif, 1, en_US]

with

n'	Operational overcurrent factor (effective overcurrent factor)
n	Rated overcurrent factor of the current transformer (index following the letter "P")
P_N	Rated burden of the current transformer at rated current in [VA]
P_i	Inherent burden of the current transformers at rated current in [VA]
P'	Actually connected burden (devices and secondary lines) at rated current in [VA]

The rated overcurrent factor **n** and the rated power $\mathbf{P_N}$ of the current transformer can be found on the name plate of the current transformer. These values refer to the specified conditions (rated current, rated burden).

EXAMPLE:

Current transformer per VDE 0414/Part 1 or IEC 60044

Current transformer 10P10; 30 VA → n = 10; P_N = 30 VA

Current transformer 10P20; 20 VA → n = 20; P_N = 20 VA

The operational overcurrent factor **n'** is the result of the rated data and the actual secondary burden **P'**.

Under normal circumstances, the inherent burden of the current transformer is documented in the test report. If this value is unknown, the inherent burden Pi can be approximated and determined from the DC resistance Ri of the secondary winding:

$$P_i = R_i \cdot I^2_{rated}$$

[foeigbue-090311-01.tif, 1, en_US]

You can find the Siemens setting recommendation in *Table 6-1*.

Parameter: CT error A

- Default setting **(_:8881:108) CT error A** = ***5.0***

The **CT error A** parameter considers the transformer error at rated current plus a safety margin. According to VDE 0414/Part 1 or IEC 60044, at a primary rated current F1, the **CT error A** is equal to the measured current deviation.

Example:

Current transformer 5P:	3 %
Current transformer 10P:	5 %

You can find the Siemens setting recommendations in *Table 6-1*.

Parameter: CT error B

- Default setting **(_:8881:109) CT error B** = ***15.0***

The **CT error B** parameter considers the transformer error during rated overcurrent factor in addition to the safety margin. It is the number preceding the letter **P** of the transformer data.
You can find the Siemens setting recommendation in *Table 6-1*.

Setting Recommendations for General Protection Current Transformers

The following table lists general protection current transformers with characteristic data, including associated setting recommendations:

Table 6-1 Setting Recommendations for Current-Transformer Data

Transformer Class	STANDARD	Ratio Error at Rated Current	Angle Error at Rated Current	Fault at Rated Overcurrent Factor	Fault Transition[35]	CT error A[35]	CT error B[35]
5P	IEC 60044-1	1.0 %	± 60 min	≤ 5 %	1.50	3.0 %	10.0 %
10P		3.0 %	_	≤ 10 %	1.50	5.0 %	15.0 %
TPX		0.5 %	± 30 min	ϵ ≤ 10 %	1.50	1.0 %	15.0 %
TPY		1.0 %	± 30 min	ϵ ≤ 10 %	1.50	3.0 %	15.0 %
TPZ		1.0 %	180 min ± 18 min	ϵ ≤ 10 % (only I ≈)	1.50	6.0 %	20.0 %
PX	IEC 60044-1 OV: Class X				1.50	3.0 %	10.0 %
C100 to C800	ANSI				1.50	5.0 %	15.0 %
5TPE	IEC 61869-10	1.0 %	± 60 min	≤ 5 %	1.50	5.0 %	15.0 %
Low-power current transformer	IEC 61869-6	< 1 %	< ± 30 min	< 1 %	1.50	3.0 %	3.0 %
Optical current transformer	IEC 61869-6	< 1 %	< ± 30 min	< 1 %	1.50	3.0 %	3.0 %

35 Setting recommendation for the parameter

EXAMPLE:

Current transformer	5P10; 20 VA
Ratio $\ddot{U}_I$	600 A/5 A
Inherent burden	2 VA
Secondary lines	4 mm^2 copper (Cu)
Specific resistance of Cu	0.0175 Ω mm^2/m
Length	20 m
I_{rated}	5 A
Burden at 5 A	0.1 VA

The resistance of the secondary lines is calculated as follows:

$$R_l = 2 \cdot 0.0175 \frac{\Omega \cdot mm^2}{m} \cdot \frac{20\ m}{4\ mm^2} = 0.175\ \Omega$$

[fo_rl, 1, en_US]

The worst-case scenario has been assumed for the calculation, whereby during a 1-pole error the current flows back and forth across the secondary lines (factor 2). This follows that the power at a rated current of I_{rated} = 5 A can be calculated as:

$$P_i = 0.0175\ \Omega \cdot (5\ A) \cdot 2 = 4.375\ VA$$

[fo_pi, 1, en_US]

The entire connected burden comprises the burden of the supply lines and the burden of the device, and is calculated as follows:

$$P' = 4.375\ VA + 2 \cdot 0.1\ VA = 4.575\ VA$$

[fo_pges, 1, en_US]

The ratio of the overcurrent factors is calculated as follows:

$$\text{CT error changeover} = \frac{n'}{n} = \frac{P_N + P_i}{P' + P_i} = \frac{20\ VA + 2\ VA}{4.575\ VA + 2\ VA} = 3.35$$

[fo_fehlerueb, 1, en_US]

According to *Table 6-1*, Siemens recommends the following setting values:

CT error changeover	= 1.50
CT error A	= 3.0 %
CT error B	= 10.0 %

Transformer with Voltage Control

If the power transformer with voltage control is within the protection range, please observe the following: A differential current occurs already during stationary operation. This differential current depends on the current and the position of the tap changer. This is a current-proportional error. For this reason, it should be dealt with as an additional current-transformer error.

Calculate the max. deviation along the limit of the control range (referring to the mean current of the control range). Add the max. deviation to the calculated transformer errors A and B. Implement this correction only for the end that is facing the controlled side of the transformer.

EXAMPLE:

For a transformer YNd5, 35 MV, 110 kV/25 kV, Y-side controlled ± 10 %

This results in the following values:

Rated current at rated voltage	= 184 A
Rated current at V_{rated} + 10% I_{min}	= 167 A
Rated current at V_{rated} - 10% I_{max}	= 202 A

For the controlled side of the transformer, the following mean current is determined:

$$I_{mean} = \frac{I_{min} + I_{max}}{2} = \frac{167\,A + 202\,A}{2} = 184.5\,A$$

[foimittl-090311-01.tif, 1, en_US]

The max. deviation of this mean current is:

$$\delta_{max} = \frac{I_{max} + I_{mean}}{I_{mean}} = \frac{202\,A - 184.5\,A}{184.5\,A} = 0.095 = 9.5\,\%$$

[fodelmax-090311-01.tif, 1, en_US]

Add this max. deviation to the transformer errors **`CT error A`** and **`CT error B`** determined as described above. Ensure that this deviation due to voltage control relates to the mean current at rated apparent power and not to the rated current at the rated voltage.

6.2 Transformer Differential Protection

6.2.1 Overview of Functions

The function **Transformer differential protection** (ANSI 87T):

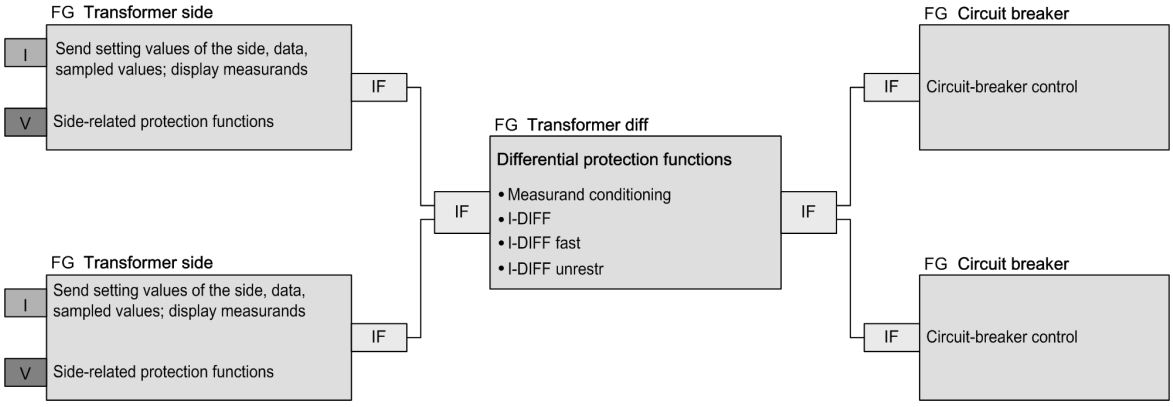
- Detects ground faults and multiphase short-circuits in transformers, reactors, short lines, as wells as generators and motors
- Is appropriate for block protection for generator-transformer blocks, transformer-reactor combinations or transformer-neutral reactors
- Has available the necessary stabilization methods in the event of connection and overexcitation processes
- Is stable in the event of external short-circuits with current transformer saturation through intelligent saturation recognition methods
- Triggers safely in the case of internal high-current faults through an additional high-current stage

Depending on the basic type of the device selected, can protect different system configurations. In the simplest implementation (7UT82), this is a two-winding transformer. The 7UT85 protects a two-winding transformer or an auto transformer. The 7UT86 processes 3 sides or 3 measuring points. In a function group, 2 differential protection functions can run in parallel for auto-transformer applications and 2-core phase-angle regulating transformers. In the maximum implementation (7UT87), up to 5 sides or a maximum of 7 measuring points can be processed. Furthermore, the 7UT87 can process 3 function groups **Transformer differential protection**.

6.2.2 Structure of the Function

The function **Transformer differential protection** is used in the protection function group **Transformer** or **Auto Transformer**. The function depends upon application in the corresponding application template preconfigured by the manufacturer or can be copied during the engineering into the corresponding function group.

The function **Transformer differential protection** consists of the stages **I-DIFF** and **I-DIFF fast**. In addition, the stage **I-DIFF unrestr** is available. You can select this stage from the function catalog and copy it into the function **Transformer differential protection**. The stages can be blocked, in addition you can switch the stages on and off.



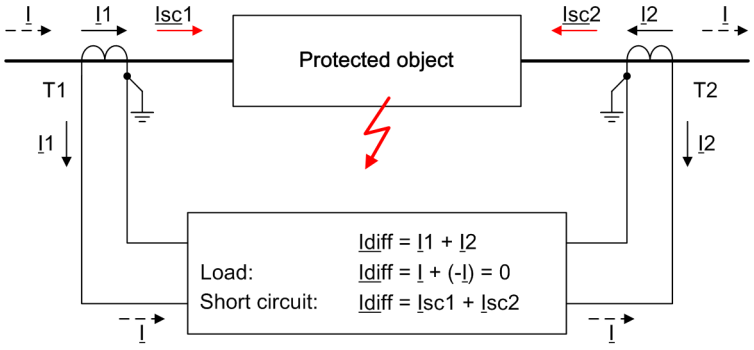
The following actions are performed in the function group **Transformer side**:

- Accept side-related protection settings
- Perform side-related calculations
- Send all data (setting values, included currents) to the function group **Transformer**
- Accept necessary settings for adapting differential protection to the current tap changer setting

The number of instances of the function **Transformer differential protection** is limited as follows in the device types and in the function groups:

Device	Max. Number of Instances of the Function Transformer Differential Protection per		
	Device	FG Transformer diff	FG Auto transformer diff
7UT82	1	1	1
7UT85	1	1	1
7UT86	2	2	2
7UT87	3	2	2

Side-related protection functions can run in the function group **Transformer side**, for example, restricted ground-fault protection, overload protection, overcurrent protection.



[dweinbfk-170712-01.tif, 2, en_US]

Figure 6-9 Structure/Embedding of the Function

6.2.3 Functional Description

6.2.3.1 Basic Principle of Differential Protection

Differential protection is based on a current comparison (set of nodal representation according to Kirchhoff, however, accounting for the current ratio of the transformer). When comparing the current, use is made of the fact that a protected object uses the same current I in a non-faulty operating state on both sides (dotted in *Figure 6-10*). This current flows into the range being observed on one side and leaves it again on the other side. A current differential is a sure indication of a fault within the protected object. The calculation of the difference is determined through the current direction definition. The current direction is defined as positive to the protected object. The current difference results from the vector addition of the currents.

[dwprin2s-170712-01.tif, 1, en_US]

Figure 6-10 Basic Principle of Differential Protection Using the Example of 2 Sides

For safe operation, additional functions are required. The implementation of these additional functions is described in Chapter *6.2.3.6 Differential Protection Function (I-DIFF)*.

Current Stabilization

If very large currents flow through the protection range in the case of external faults, with different transmission behavior of the transformers **W1** and **W2** (*Figure 6-10*) a corresponding differential current I_{diff} occurs.

When this is larger than the corresponding pickup threshold, the device can issue a trip command, even though no fault is present in the protection range. Such a malfunction of the protection is avoided by the restraint current ($I_{rest.}$) and is implemented in the form of a characteristic curve $I_{diff} = f(I_{rest.})$.

The largest current of 2 or more measuring points of the protected object is used for stabilization.

The definition for 2 measuring points is:

A trip or differential current is

$I_{diff} = (\underline{I}_1 + \underline{I}_2)$

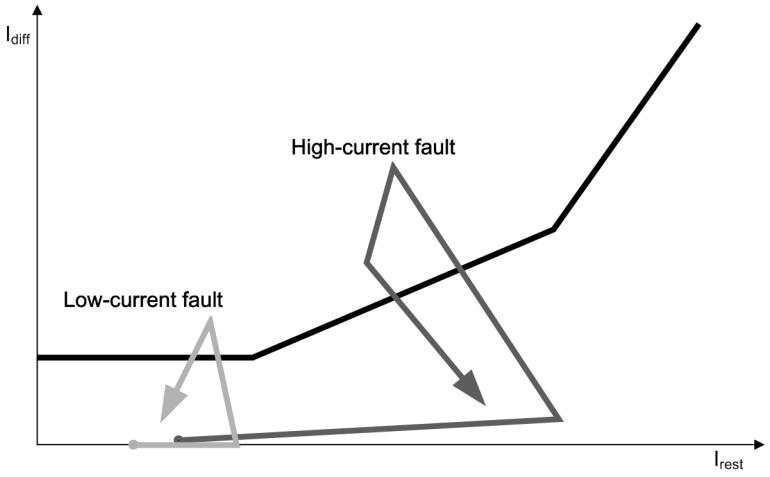
as well as a restraint current of

$I_{rest.} = Max (|\underline{I}_1| ; |\underline{I}_2|)$

For more than 2 measuring points this definition is expanded. This restraint method allows a reliable trip decision for more than 2 measuring points and different feeding behavior for internal short circuits.

$I_{rest.} = Max (|\underline{I}_1| ; |\underline{I}_2| ; ... |\underline{I}_n|)$

To clarify the effect 3 important operating states are observed with ideal and adapted measurands.



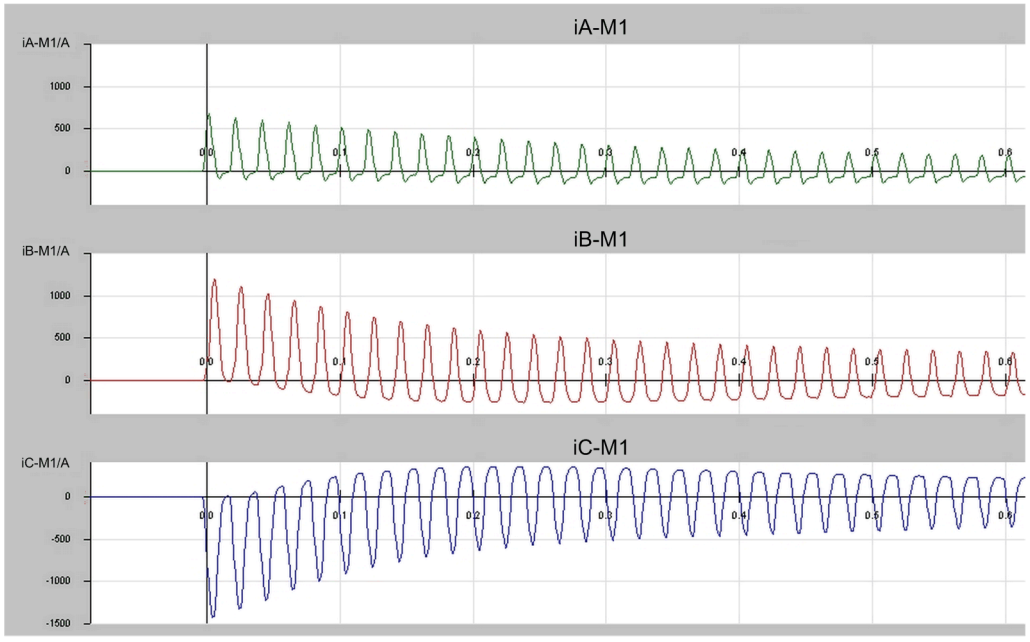
- Through fault current in healthy operation or external short circuit:
  $\underline{I}_1$ flows into the protection range, $\underline{I}_2$ flows out of the protection range, that is, negative compared with the prefix definition, thus $\underline{I}_2 = -\underline{I}_1$;
  in addition $|\underline{I}_2| = |\underline{I}_1|$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 - \underline{I}_1| = 0$
  $I_{rest} = Max (|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$
  No tripping quantity ($I_{diff} = 0$); the stabilization ($I_{rest.}$) corresponds to the flowing current.
- Internal short circuit, feed from both sides with equal amount of currents, for example:
  Then $\underline{I}_2 = \underline{I}_1$; In addition $|\underline{I}_2| = |\underline{I}_1|$;
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + \underline{I}_1| = 2 \cdot |\underline{I}_1|$
  $I_{rest} = Max (|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$
  The tripping quantity (I_{diff}) is twice as large as the short-circuit current and the restraining quantity ($I_{rest.}$).
- Internal short circuit, feed only from one side:
  Then $\underline{I}_2 = 0$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + 0| = |\underline{I}_1|$
  $I_{rest} = Max (|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1|$
  The tripping quantity (I_{diff}) and the restraining quantity ($I_{rest.}$) are the same size and correspond to the short-circuit current.

Additional Stabilization with External Short Circuits

In case of an external short circuit, high short-circuit currents flowing through can lead to current transformer saturation. This saturation can be more or less strongly pronounced at the measuring points, and in this way simulate a differential current. The differential current can lie in the tripping range of the characteristic curve for a certain time and lead to unwanted tripping without any particular measures. In accordance with *Figure 6-11* there are 2 typical scenarios:

- High-current, external short circuit
  First, the current on both sides is transferred and leads to a large restraint current. After this, a transformer becomes saturated, resulting in a differential current I_{diff} that can exceed the operate curve. Simultaneously, the restraint current $I_{rest.}$ drops out. Once the transformer is no longer saturated, the differential current decreases and falls below the characteristic curve.
- Low-current, external short circuit
  Current transformers can also become saturated through the large direct-current time constant (switching of transformers, motors), but small currents flowing. This manifests itself as a phase angle rotation of the current. Exceeding the characteristic curve in a non-stabilized area is possible.

Intelligent saturation detection methods capture this state and lead to a temporally limited blocking of the Differential protection function.

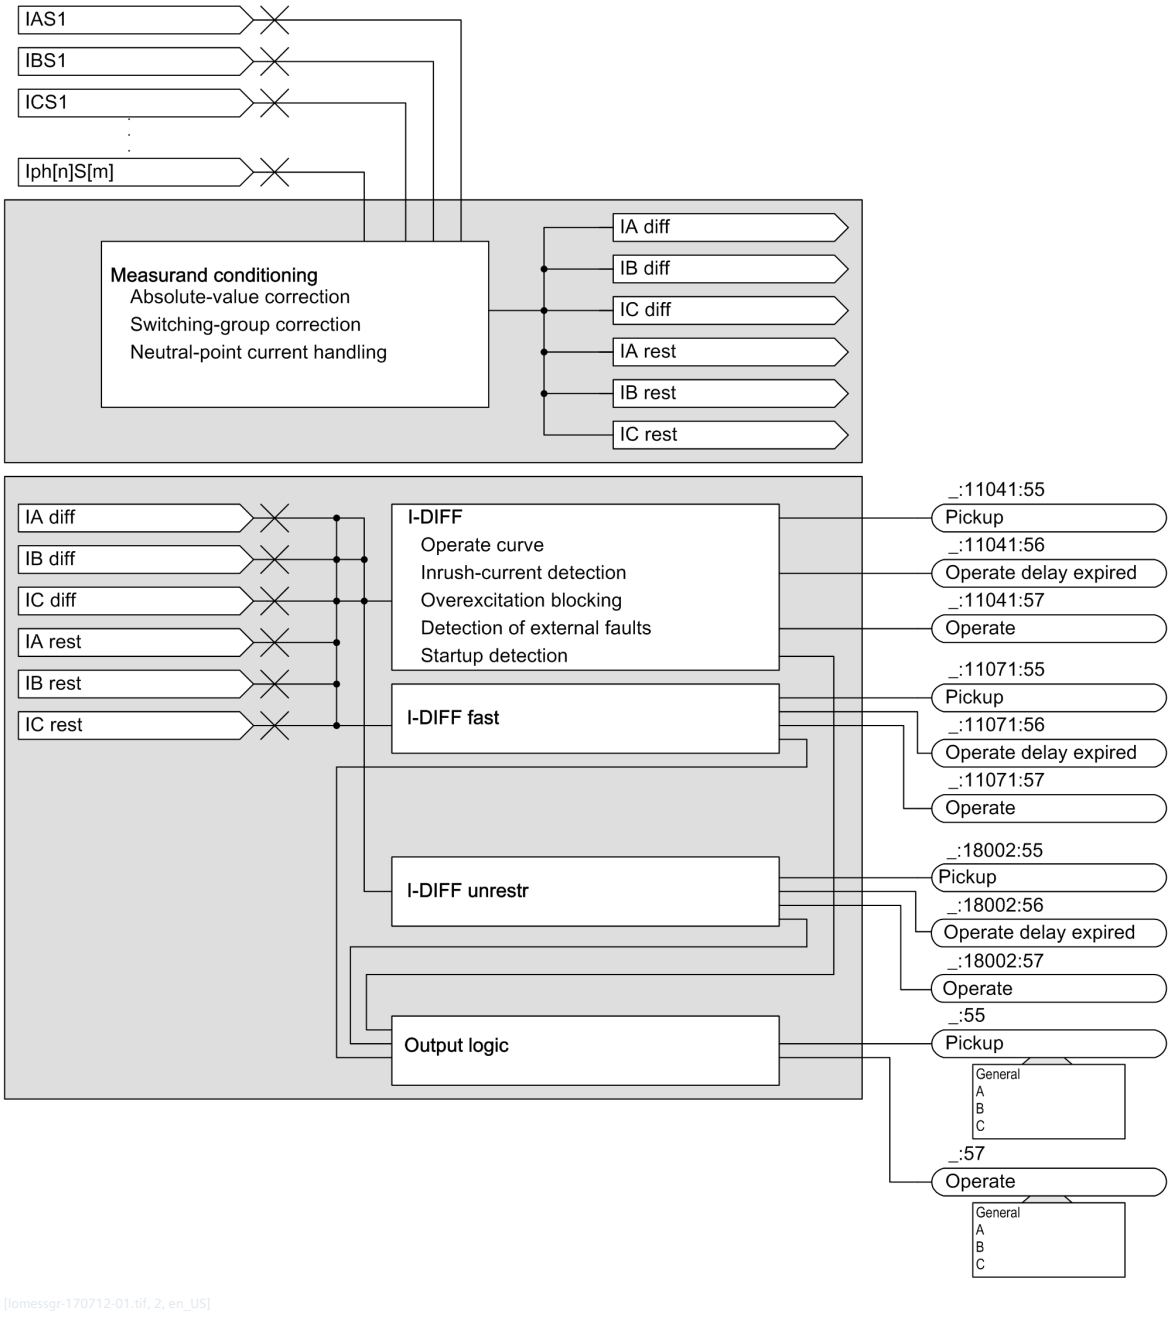


[dwislauf-170712-01.tif, 1, en_US]

Figure 6-11 Principle Current Course in External Short Circuit and Temporary Current Transformer Saturation on One Side

Inrush Current and Overexcitation Stabilization

When a transformer is switched on, an inrush current with a DC component flows, since the flow cannot change itself erratically. The inrush current develops in all phases and appears immediately as differential current. The direct-current time constant can amount to several seconds with large transformers. The following figure shows a typical situation.

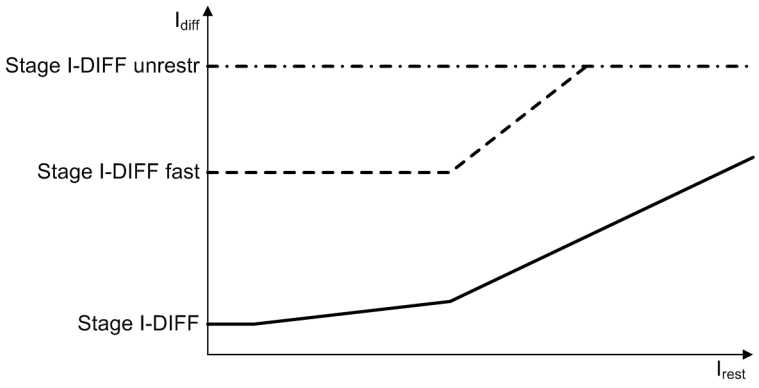


[dwscreen-170712-01.tif, 1, en_US]

Figure 6-12 Typical Inrush Current Curve

If a transformer is operated with too high of a voltage, it can be modulated up into the non-linear part of the magnetization characteristic curve. An increased magnetizing current results, which manifests itself as an increased differential current and can lead to an overfunction.

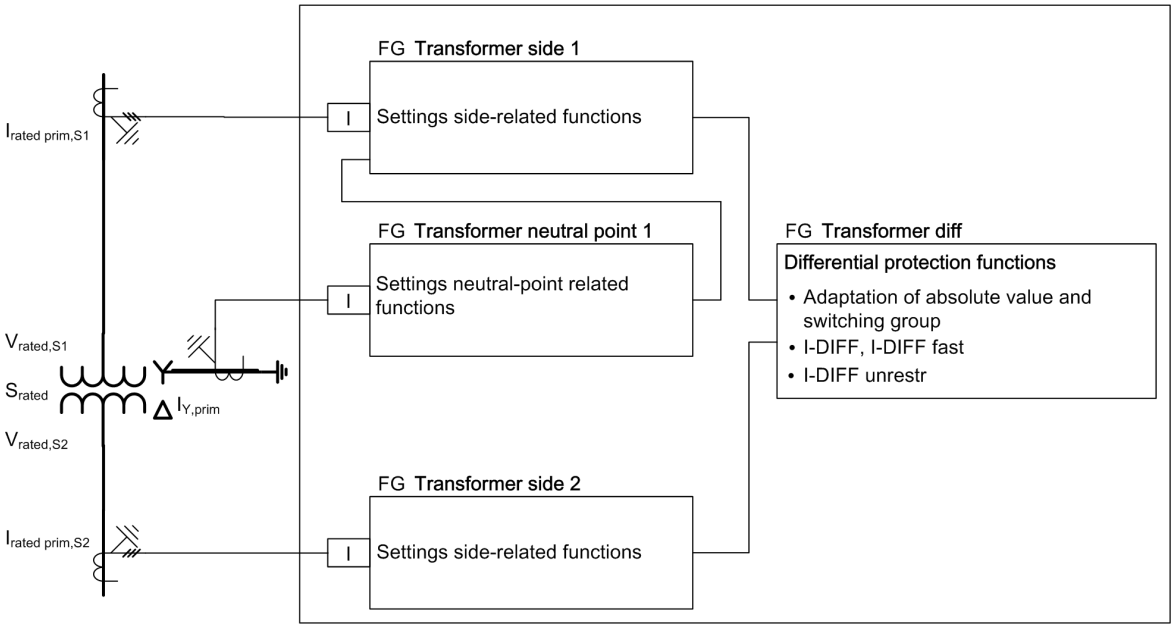
For this reason, additional functions are required which block the differential protection with closure and overexcitation processes.



6.2.3.2 Logic of the Function

[lomessgr-170712-01.tif, 2, en_US]

Figure 6-13 Logic Diagram of the Transformer Differential Protection Function



The interaction of the I-DIFF, I-DIFF fast and I-DIFF unrestrained tripping stages is shown in the operate curve below.

[dw_charac_function_trans-dif, 1, en_US]

Figure 6-14 Operate Curve of the Transformer Differential Protection Function

In the following, the essential components of differential protection are described in detail. The two-winding implementation, the basic structure of which shows *Figure 6-15*, serves as an example. The connection is between the phase current transformers and the neutral-point current transformer. Additionally, both relevant function groups for differential protection are represented.

[dw2wtyd5-170712-01.tif, 2, en_US]

Figure 6-15 Connection and Basic Structure for the Example of a Two-Winding Transformer Yd5

6.2.3.3 Measurand Processing

Absolute-Value Correction

Since the current transformers cannot be adapted exactly to the rated currents of the protected object with regard to their primary rated data, a standardization to the nominal sizes of the protected object takes place. The conversion occurs every sampling time (thus, for instantaneous values). The differential protection function processes 20 sampled values per period. In addition, the sampled values tracked are used. A high degree of accuracy can be attained over the entire tracking range (from 10 Hz to 90 Hz).

The IDIFF-fast tripping and the IDIFF-unrestrained tripping stages work on non-frequency tracked values and thus, implement fast operate times at low frequencies.

The absolute value is adapted via the following formula:

$$i^{*}_{phsx} = k\, i_{phsx}$$

$$\text{with } k = \frac{I_{\text{rated prim, Sx}}}{I_{\text{rated obj, Sx}}} = \frac{I_{\text{rated prim, Sx}}}{\frac{S_{\text{rated, ref}}}{V_{\text{rated, Sx}}\sqrt{3}}}$$

[fobetr07-170712-01.tif, 1, en_US]

i_{phsx}*	Adapted instantaneous value per phase (x = 1, 2, 3)
i_{phsx}	Instantaneous value per phase (x = 1, 2, 3)
k	Correction value per measuring point
$I_{\text{rated prim,Sx}}$	Primary transformer rated current per measuring point
$S_{\text{rated,ref}}$	Reference power (maximum rated apparent power of the protected object)
$V_{\text{rated,Sx}}$	Rated voltage of the respective side (measuring point) of the protected object

NOTE

The largest power is used as reference winding with a multi-winding transformer. If several windings have the same absolute value of power, then, the highest current winding is selected as the reference winding. The absolute value of the neutral-point transformer is also adapted according to the previous formula. In this case, the absolute value should be adapted to the side with the greatest power.

Tap-Changer Adaptation

If a tap changer is present and is allocated to a transformer side, the side currents are also adapted to the current tap-changer position. In order to activate this functionality, the settings must be made in the **Transformer side** function group. You can find a more detailed description of the parameters **`Tap changer`**, **`Basic position`** and **`Volt. diff. adjacent taps`** are in the Application and Setting Instructions, subtitle Parameters: Tap changer.

Make the stage setting that corresponds to the rated voltage and the setting for the stage voltage. With these settings, an adjustment factor is calculated for each existing tap-changer position.

$$k_{(i)} = k_{\text{Base position}} \cdot \left(1 + \frac{\left(\text{Pos}_{(1)} - \text{BasPos}\right) \cdot \Delta V}{V_{\text{rated}}}\right)$$

[foBasPo1-231013-01, 1, en_US]

with

$\text{Pos}_{(i)}$	Existing tap-changer position
BasPos	Basic position of the tap changer
ΔV	Voltage difference of a stage
V_{rated}	Rated voltage
$k_{\text{Base position}}$	Corresponds to the correction value for each measuring point

When the sliding contact of the motor drive is activated by the tap changer, the previous stage remains active until the running contact signals the end of the motor run.

If capture of the current tap-changer position malfunctions, a higher operate curve takes effect. In this case, 2 measures become effective:

1. Calculation of an average adjustment factor

$$k_{\text{ref}} = k_{\text{Base position}} \cdot \frac{V_{\text{ref}}}{V_{\text{rated}}}$$

[foBasPo2-231013-01, 1, en_US]

$$V_{ref} = \frac{2}{\frac{1}{V_{min}} + \frac{1}{V_{max}}}$$

[foBasPo3-231013-01, 1, en_US]

2. Non-sensitive setting of the operate curve with factor k_{tcr}

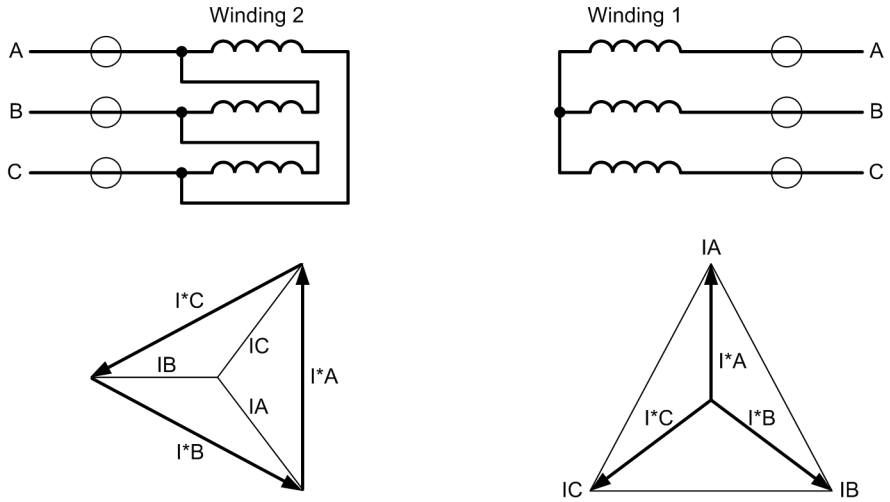
$$k_{tcr} = \frac{V_{max} - V_{min}}{V_{max} + V_{min}}$$

[foBasPo4-231013-01, 1, en_US]

Vector-Group Correction

The vector groups of the transformer sides arise from the different side-wise coupling of the transformer windings to the transformer core as well as its configuration (Y, D, Z). The measured currents can therefore not be used directly for summation. The vector-group correction replicates the magnetic coupling of the transformer coils and makes the measured currents comparable. The correction occurs such that each side is converted to vector group 0. Since you are in the 3-phase system, the conversion occurs via matrices which are stored for the respective vector-group type. The general description is given in the following formula. In the same calculation step, the absolute value is corrected:

$$\begin{bmatrix} i_A^* \\ i_B^* \\ i_C^* \end{bmatrix} = k * M_{SG} * \begin{bmatrix} i_A \\ i_B \\ i_C \end{bmatrix}$$



[foscha08-170712-01.tif, 1, en_US]

with

i_{phx}*	Adapted instantaneous value per phase (x = 1, 2, 3)
i_{phx}	Instantaneous value per phase (x = 1, 2, 3)
k	Correction of absolute value per measuring point
M_{SG}	Correction matrix

The following example (*Figure 6-16*) shows the conversion. The neutral point is insulated against *Figure 6-15*, such that no zero-sequence current (short-circuit current) can arise in case of an external fault and can therefore not cause a faulty measurement.

In the example, the currents are processed directly. On the delta side, the conversion takes place into a vector group 0. If the measured zero-sequence current is also taken into account while using this matrix with the present neutral reactor, a higher sensitivity with regard to the usual elimination matrix can be attained (see *Figure 6-19*).

[dwyd5001-030912-01.tif, 1, en_US]

$$\begin{pmatrix} I_A^* \\ I_B^* \\ I_C^* \end{pmatrix} = \frac{1}{3} \cdot \begin{pmatrix} 1-\sqrt{3} & 1 & 1+\sqrt{3} \\ 1+\sqrt{3} & 1-\sqrt{3} & 1 \\ 1 & 1+\sqrt{3} & 1-\sqrt{3} \end{pmatrix} \cdot \begin{pmatrix} IA \\ IB \\ IC \end{pmatrix} \qquad \begin{pmatrix} I_A^* \\ I_B^* \\ I_C^* \end{pmatrix} = 1 \cdot \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} IA \\ IB \\ IC \end{pmatrix}$$

Figure 6-16 Vector-Group Adaptation with the Example of Yd5 without Accounting for the Absolute-Value Adaptation

6.2.3.4 Neutral-Point Current Treatment

Considering the Neutral-Point Current

If the neutral point of a transformer winding is grounded, a current can also flow into the protection range in the case of a ground fault via this neutral point. For a complete summation, this current must be included. In *Figure 6-17* an outflowing zero-sequence current, for example, a fault occurs on the right side in the phase currents ($-I_C = -3I_0$). This corresponds to the current flowing into the neutral point ($I_Y = 3I_0$), such that the currents enter into the sum.

[dwsgayd5-170712-01.tif, 1, en_US]

Figure 6-17 Vector-Group Adaptation with the Example of Yd5

The complete matrix equation for the grounded side (Y side) with inclusion of all currents flowing in is, in this case:

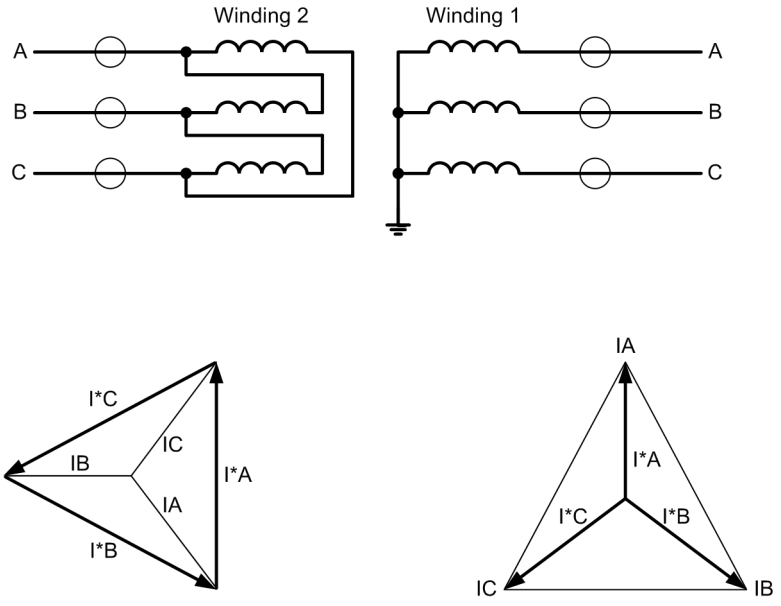
$$\begin{pmatrix} I_A^* \\ I_B^* \\ I_C^* \end{pmatrix} = 1 \cdot \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} I_A \\ I_B \\ I_C \end{pmatrix} + \frac{1}{3} \cdot \begin{pmatrix} I_Y \\ I_Y \\ I_Y \end{pmatrix}$$

[foanpa11-170712-01.tif, 1, en_US]

$\underline{I}_{St}$ corresponds to $-3\underline{I}_0$ with current flowing. With a ground fault **within** the transformer area, the zero-sequence current goes in as a result ($\underline{I}_0 = 1/3\ \underline{I}_Y$). With a ground fault **outside**, however, the zero-sequence current falls out, since the zero-sequence current measured on the terminals $3\underline{I}_0 = (\underline{I}_A + \underline{I}_B + \underline{I}_C)$ (negative here) removes the neutral-point current $\underline{I}_Y$. Given this, nearly complete sensitivity is guaranteed for internal ground faults, while the zero-sequence current is automatically eliminated in case of an external ground fault.
If the following conditions are satisfied, the neutral-point current is accounted for:

- In the function group **Transformer side**, the parameter **`Neutral point`** = ***`grounded`*** is set.
- The function group **Transformer neutral point** is connected with the measuring point and the function group **Transformer side** (see *Figure 6-15*).
- In the function group **Transformer**, the parameter **`Meas. gnd. current side 1`** = ***`yes`*** is set.

You can attain increased sensitivity for ground faults in the protection range by using restricted ground-fault protection (see chapter *6.4 Restricted Ground-Fault Protection*).



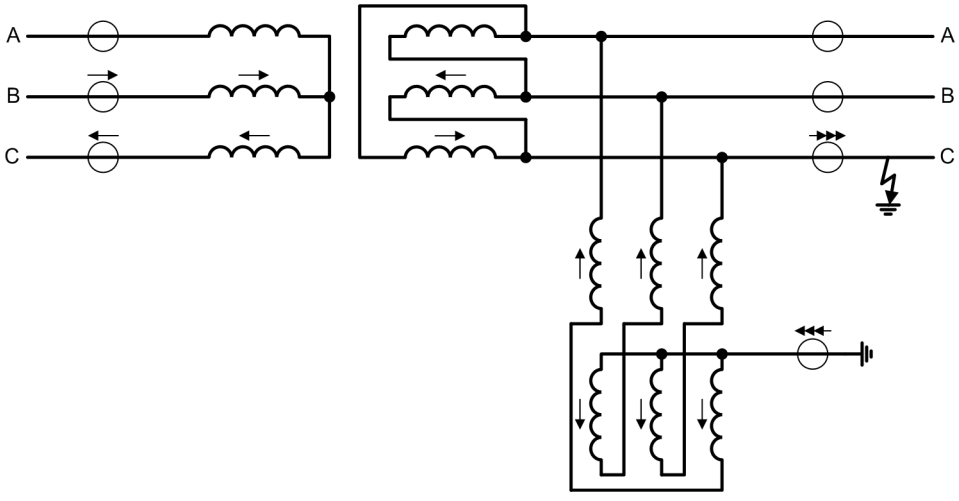
NOTE

In order to enable the proper function of the differential protection, the neutral-point transformer must be designed correspondingly strong (almost saturation-free). Interior 1-pole short circuits can lead to too high neutral-point currents. The harmonic resulting from a saturation can lead to a blocking of the tripping by the inrush-current detection. In addition a saturation when tripping can result in no unambiguous fault situation, that is unaffected phases also signal a tripping.

Neutral-Point Current is not Measured

Often the neutral-point current is not accessible, however, or is not coupled into the differential protection. Then, in accordance with *Figure 6-16*, a complete summation across all currents flowing into the protected object is not possible, since $\underline{I}_Y$ does not go in. So that the zero-sequence current in the phase currents ($-\underline{I}_C = -3\underline{I}_0$) does not lead to a faulty differential current, it must be eliminated.

The *Figure 6-18* shows an example of the vector group YNd5 with grounded neutral point on the Y side.
On the left side (delta side) of *Figure 6-18*, the zero-sequence current drops out automatically through formation of the differential current. Even in the transformer itself, no zero-sequence current is possible outside of the delta winding. If the neutral-point current cannot be measured, the zero-sequence current on the right side must be eliminated. This results from the matrix equation, for example, for:
$\underline{I}^*_A$: $1/3\ (2\ \underline{I}_A - 1\ \underline{I}_B - 1\ \underline{I}_C) = 1/3\ (3\ \underline{I}_A - \underline{I}_A - \underline{I}_B - \underline{I}_C) = 1/3\ (3\ \underline{I}_A - 3\ \underline{I}_0) = (\underline{I}_A - \underline{I}_0)$
By eliminating the zero-sequence current, fault currents are rendered harmless without special external measures. The fault currents also flow as a consequence of grounding in the protection range (transformer neutral point or neutral reactor) with ground faults in the power system via the current transformer. In *Figure 6-18* a zero-sequence current arises on the right side during an external fault, for example, but not on the left side. A comparison of the currents without zero-sequence current elimination and without inclusion of the neutral-point current, leads to a false result (differential current despite fault being external).



[dwyd5002-120120-01.tif, 1, en_US]

$$\begin{pmatrix} I_A^* \\ I_B^* \\ I_C^* \end{pmatrix} = \frac{1}{\sqrt{3}} \cdot \begin{pmatrix} -1 & 0 & 1 \\ 1 & -1 & 0 \\ 0 & 1 & -1 \end{pmatrix} \cdot \begin{pmatrix} I_A \\ I_B \\ I_C \end{pmatrix} \qquad \begin{pmatrix} I_A^* \\ I_B^* \\ I_C^* \end{pmatrix} = \frac{1}{3} \cdot \begin{pmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{pmatrix} \cdot \begin{pmatrix} I_A \\ I_B \\ I_C \end{pmatrix}$$

[foyd5002-170712-01.tif, 2, en_US]

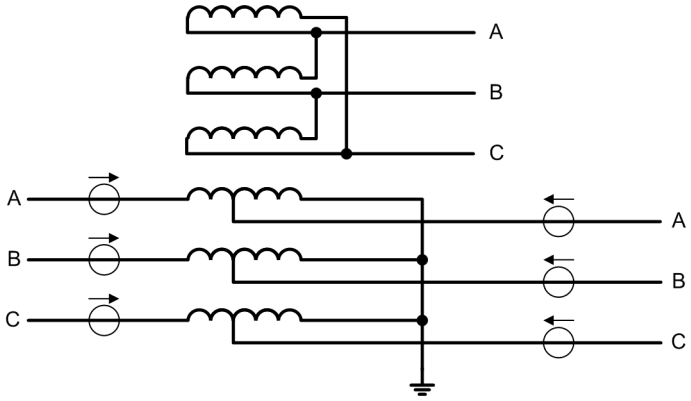
Figure 6-18 Vector-Group Adaptation for the Example of YNd5

Figure 6-19 shows an example of a ground fault on a delta side outside of the protection range with a neutral reactor (zigzag reactors) within the protection range. Here, too, a zero-sequence current arises on the right side, but not on the left side. If the neutral reactor is outside of the protection range (current transformer between power transformer and neutral reactor), then the zero-sequence current is harmless, since it does not flow through a measuring point (current transformer).

[dwtstern-120120-01.tif, 1, en_US]

Figure 6-19 Example of Ground Fault Outside of the Grounding Transformer within the Protection Range with Current Distribution

Zero-sequence current elimination has the disadvantage that the differential protection is less sensitive with ground faults in the protection range of the grounded side around the zero-sequence current. Since the



zero-sequence current makes up 1/3 of the short-circuit current, a sensitivity of 2/3 is achieved. If there is no neutral-point grounding present in the protection range or the neutral-point current can be captured (*Figure 6-17*), the zero-sequence current elimination is unnecessary (see *Figure 6-16*). In order to not recognize an electric breakdown as an internal fault with a connected **surge arrester on the neutral point** you must make do without this advantage.

If, in the function group **Transformer side**, the parameter **`Neutral point`** = ***`grounded`*** is set and no neutral-point current is coupled into the function group (see *Figure 6-15*), then the zero-sequence current elimination always takes place. If a neutral-point current is coupled into the function group **Transformer side** (for example, for the restricted ground-fault protection) and in the function group **Transformer**, the parameter **`Meas. gnd. current side 1`** = ***`no`*** is present, then a zero-sequence current elimination is also performed. If **`Neutral point`** = ***`isolated`*** is set, the phase currents are processed directly, without the zero-sequence currents being taken into account. If nothing is connected to the neutral point, make this setting.

6.2.3.5 Special Aspects of an Auto Transformer

In order to make the resulting currents for the differential protection comparable, all currents refer to the auto winding (= side of the protected object) with the largest rated apparent power. This is designated **rated power of the protected object**. If the highest rated apparent power occurs multiple times, the side with the higher rated current is selected as the reference side.

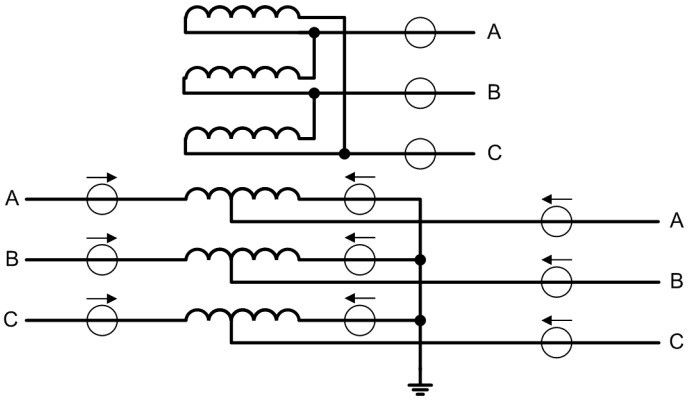
With auto transformers, there is only the vector group for the auto-transformer winding Y(N)y0 (*Figure 6-20*). Neutral-point grounding affects all auto-transformer windings connected to the parts of the electrical power system (upper-voltage and undervoltage). With a ground fault, coupling between the 2 parts of the electrical power system occurs via the common neutral-point grounding.

[dwstern1-040912-01.tif, 1, en_US]

Figure 6-20 Auto Transformer with Grounded Neutral Point

Here, too, the neutral-point current $I_{rest.}$ is necessary for a complete treatment of all currents flowing into the protected area. If the neutral point is not accessible, the residual current from the two phase currents must be eliminated. This means that the matrix with the residual current elimination is used on both sides. As with separated windings, differential protection with ground faults in the protection range is then reduced in sensitivity to 2/3 of the fault current. The residual current amounts to 1/3 of the short-circuit current.

If the neutral-point current is accessible and connected to the device, all currents flowing into the protection range are available. The residual current in the phases then enters into the sum with outward-lying ground faults through the neutral-point current. With an inward-lying ground fault, the full sensitivity of differential protection is thereby guaranteed.



In order to attain an even higher sensitivity with ground faults in the protection range with the help of the neutral-point current, you can use the restricted ground-fault protection.

If, in the case of an auto transformer, three 1-phase auto transformers are interconnected, it is possible to attain a good ground fault sensitivity. With this arrangement, the 1-phase ground fault is the most likely fault. Short-circuits between the phases are excluded due to spatial separation. Here you can create current differential protection through each winding which captures the sum of all currents flowing to the node (the winding).

The requirements for this are that you configure an auto transformer with a 3-phase current connection for the grounding side and set the parameter **(_:2311:186) Protection Mode** = ***Current node*** .

NOTE

The differential protection function records no stabilizing winding with ***Current node*** . A stabilizing winding must be additionally protected.

[dwtspstr-040912-01.tif, 1, en_US]

Figure 6-21 Auto Transformer Bank with Current Transformer in the Neutral-Point Feed

6.2.3.6 Differential Protection Function (I-DIFF)

A differential current per phase based on the instantaneous value variables is calculated from the processed currents (see section *6.2.3.3 Measurand Processing*). The direction of current flow is defined as to the **protected object as positive**. The fundamental component contribution to the differential current (I_{diff}) is calculated via a Fourier filter (filter length = 1 period (20 sampled values)).

If the neutral-point current is connected, it is accounted for in the differential current as well as in the restraint current. This state of affairs is not represented for the reason of simplification in the following formulas. The currents of that measuring point whose RMS value is the largest are used as restraint current. Neutral or zero-sequence currents are also accounted for. If, for example, the current collapses at a measuring point as a consequence of current-transformer saturation, the measuring point that has the largest current is automatically switched to at the point in time of the calculation.

NOTE

Differential protection does not work with sensitive ground-current transformers. Since sensitive transformers can go into saturation too quickly, false differential currents arise.

$$i_{diff,phsx} = \sum_{m=1}^{N} i^{*}_{phsx,Mm} \rightarrow I_{diff,phsx} = FIR(i_{diff,phsx})$$

$$I_{phsx,Mm} = \sqrt{\frac{1}{n}\sum_{k=1}^{n} i^{*2}_{phsx,Mm}(k)}$$

$$I_{rest,phsx} = \underset{m=1}{\overset{N}{MAX}}\, I_{phsx,Mm}$$

with

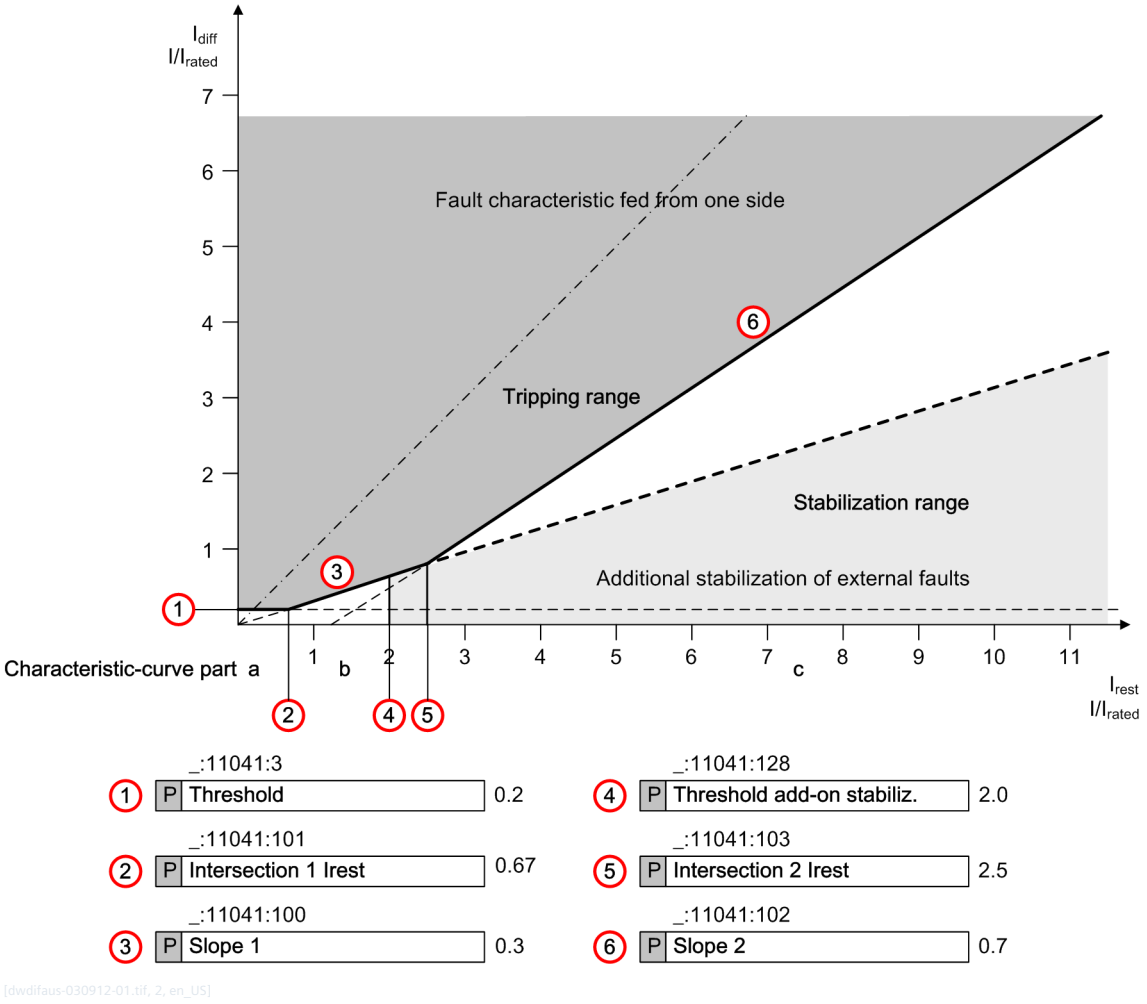
x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points
n	Number of samples per period (n = 20)

FIR	Fourier filter
MAX	Maximum value determination

Pickup Characteristic

The *Figure 6-22* shows the pickup characteristic of the 7UT8x. The characteristic curve branch **a** represents the sensitivity threshold of the differential protection (parameter **Threshold**) and considers constant fault currents like magnetizing currents.

The characteristic branch **b** (parameter **Intersection 1 Irest** and **Slope 1**) considers current-proportional faults under normal operating conditions.



These faults can occur for the following reasons:

- Transformation errors in the current transformer and the input transformer of the device
- Adaptation deviations and tap changers in transformers with voltage control (but only if the tap-changer position is not taken into account in the differential protection)

The characteristic curve branch **c** (parameter **Intersection 2 Irest** and **Slope 2**) secures the differential protection from overfunction in case of high-current external faults and transformer saturation. In this area, transformer saturation can arise due to high short-circuit currents, and because of this a higher differential current results.

To avoid overfunction with external faults with current-transformer saturation (also see *Figure 6-11*), a logic is implemented that uses the characteristic curve **additional stabilization of external faults**. If the operating point is located in the additional stabilization area and exceeds the operate curve from there, then the logic becomes active, and blocks the differential protection.

The additional stabilization range is derived from the parameters **Threshold add-on stabiliz.** and **Slope 1**.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-22 Pickup Characteristic of the Differential Protection

If the differential current multiplied by the dropout ratio of 0.7 does not reach the pickup characteristic, the pickup drops out.

Inrush-Current Detection

The inrush-current detection evaluates the calculated instantaneous values of the differential current. The inrush current develops with Sympathetic Inrush – connection of a parallel transformer or Recovery Inrush – inrush current subsequent to returning voltage after a fault in the system in the differential current considerably higher than in the side currents. An assignment to the corresponding blocking phases is possible only in the differential current due to the vector-group correction.

The inrush-current detection is activated when the pickup characteristic is exceeded. It is deactivated when it is blocked by an external fault.

For inrush-current detection, 2 methods working in parallel are used:

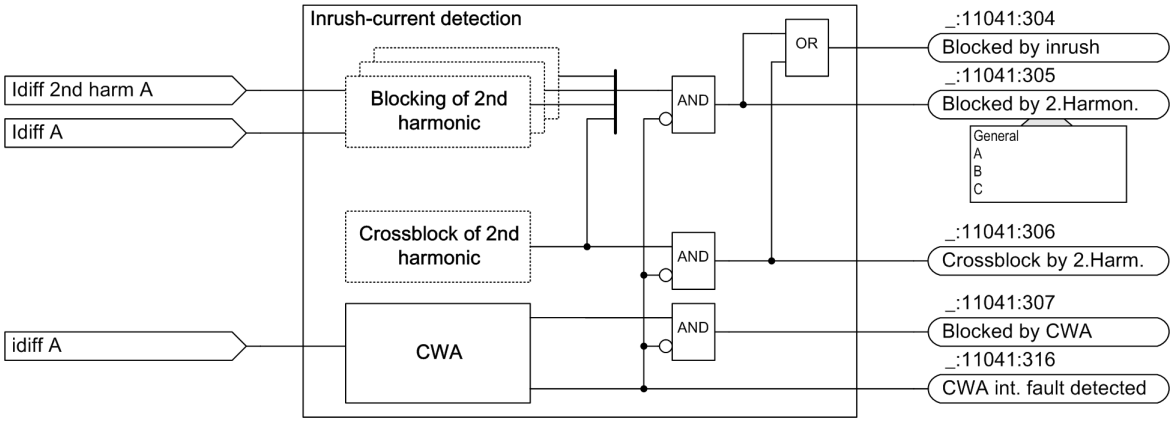
- **Component of the 2nd harmonic relative to the fundamental component in the differential current ($I_{2nd\ harm}/I_{1st\ harm}$)**

  As also shown in *Figure 6-12*, the 2nd harmonic is clearly pronounced in the inrush current. If the component of the 2nd harmonic exceeds the set threshold value (parameter: **`2nd harmonic content`**), a phase-segregated blocking occurs. The harmonics develop differently in the different phases. If exceeding of the 2nd harmonic is detected in a phase, it can be necessary to block all phases simultaneously. This blocking must be limited with regard to time and is controlled by the parameter **`Crossblock. time 2nd har.`**. The correct positioning of the filter windows is controlled by the internal pickup.

- **Curve form analysis (current wave shape analysis – CWA)**

  The occurrence of flat areas in the current course is typical for a connection process (see *Figure 6-23*). If these flat areas occur in all 3 phases at the same point in time, this is a typical characteristic of the connection process. The method works as a supplement to the 2nd harmonic and covers cases that are not controlled through the 2nd harmonic. Based on the method of measurement, the blocking always affects all phases simultaneously. The method has internal, firmly-set thresholds available.

  If the CWA method does not find any flat areas precisely one period after fault inception, an **Internal fault** is detected, the 2nd harmonic and the CWA inrush-current method are blocked and the **`CWA int. fault detected`** indication is output. In this way, blocking or delayed tripping of the differential protection by the 2nd harmonic is prevented during the connection process with internal faults or current-transformer saturation.



If you want only one method to be active, the other method can be changed to inactive. The parameters **`Blocking with 2. harmonic`** = ***no*** or **`Blocking with CWA`** = ***no*** serve this end.

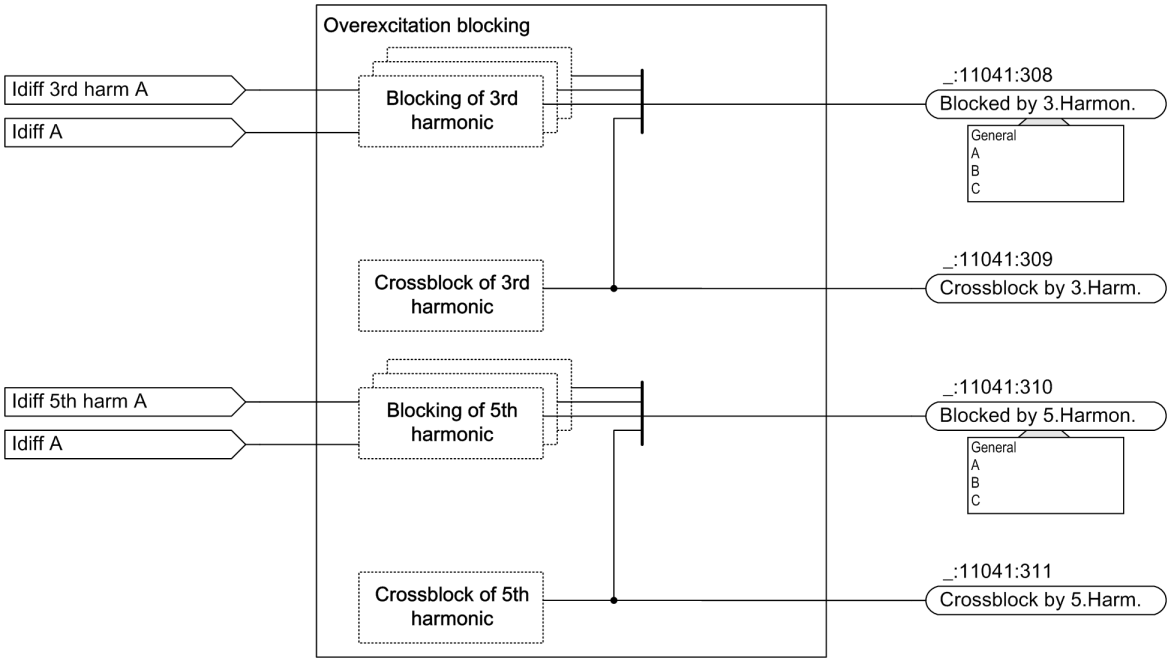
Figure 6-23 Inrush Current with Pronounced Flat Areas

Figure 6-24 shows the logical input and output signals.

[loblkein-170712-01.tif, 2, en_US]

Figure 6-24 Logic Inrush-Current Detection



Blocking of Overexcitation

Stationary overexcitation is characterized by odd-numbered harmonics. Here the 3rd or 5th harmonic is suited to stabilization. Since with transformers, the 3rd harmonic is eliminated, for example, in the case of a delta winding, the 5th harmonic is used. The overexcitation blocking is activated when the pickup characteristic is exceeded. It is deactivated when it is blocked by an external fault.

Odd-numbered harmonics, which are not present with an internal short circuit, also play a role in converter transformers.

The shares of the 3rd and 5th harmonics in relation to the fundamental component are determined from the instantaneous values of the differential current via Fourier filters. If the threshold value (**3rd harmonics content** or **5th harmonics content**) is exceeded, a phase-selective blocking occurs. It is also possible here to block all 3 phases simultaneously via the crossblock function (parameter: **Crossblock. time 3rd har.** or **Crossblock. time 5th har.**). Contrary to the 2nd harmonic, the overexcitation stabilization becomes inactive if the differential current (fundamental component value) exceeds a limiting value (parameter: **Limit Idiff 3., 5. harmonics**).

The *Figure 6-25* shows the logical input and output signals.

[lofehler-170712-01.tif, 1, en_US]

Figure 6-25 Behavior under Different Fault Conditions

Detection of External Short Circuits

To reliably detect external short circuits with current-transformer saturation, the measurand curve is evaluated in the Diff.-Rest level with a detector. The detector has 2 essential tasks:

- **Blocking in the case of an unambiguous high-current external short circuit**

  The differential current and the restraint current are monitored on a phase basis in the Diff/Restr level immediately after fault inception. To ensure the stability of the saturation detection for low saturation-free times of the primary current transformer, estimated values based on the difference quotients of the instantaneous values are used.

  If the estimated restraint current exceeds the **Threshold add-on stabiliz.** parameter and the expected value of the differential current of all phases are in the additional stabilization range (parameter **Slope 1**) (*Figure 6-22*) simultaneously, the detector is active and the indication *Blocked by ext. fault phsx* appears. The tripping of the Differential protection function is blocked.

  If an external short circuit arises and is cleared by the protection responsible for it, the additional stabilization drops out. If the dropout ratio (0.7) of the RMS value of the restraint current does not reach the parameter **Threshold add-on stabiliz.** (*Figure 6-22*), the additional stabilization drops out. The indication *Blocked by ext. fault phsx* is reset.

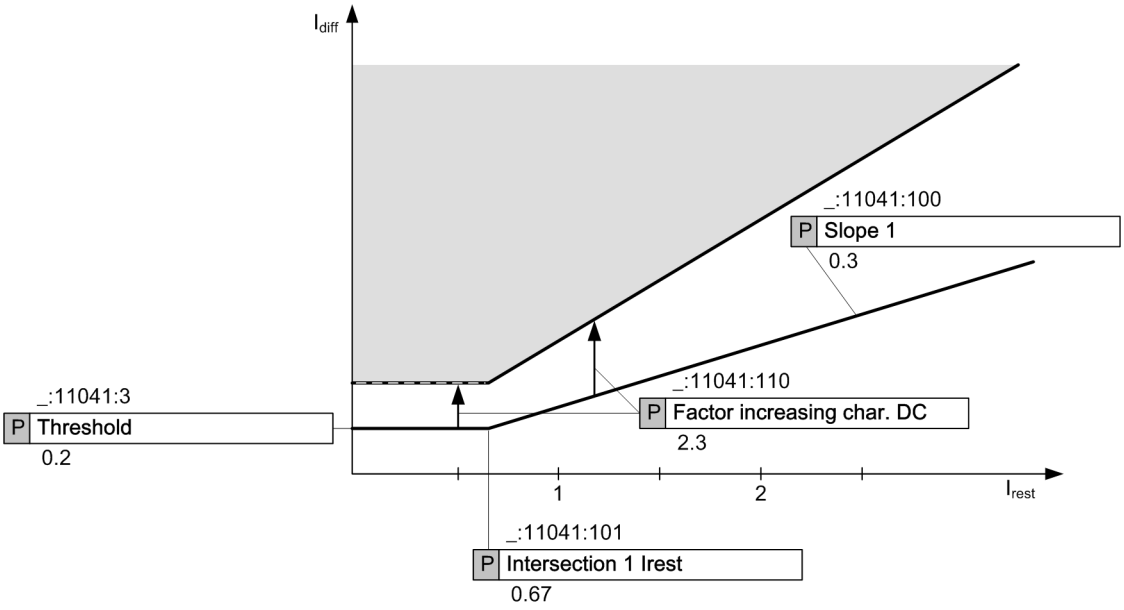
  If the differential current exceeds **Slope 1** as a result of transformer saturation, that is, there is a pickup phsx, the blocking is limited in time (parameter: **Time of add-on stabiliz.**).

  Starting with the indication *Blocked by ext. fault phsx* the other phases can be blocked with it via the parameter **Crossblk. time add-on st.**. If differential currents spread to the other phases through the vector-group correction or zero-sequence current elimination subsequent to transformer saturation, this blocking is necessary.

- **Removal of the blocking with a change in fault location from external to internal**

  An internal short circuit can arise as a consequence of an external short circuit. This fault-location change must be recognized and the blocking must be removed. The critical case is a short circuit with current-transformer saturation. The saturation detection examines here the instantaneous values of the differential current. With transformer saturation the instantaneous values do not reach an internal threshold in the saturation-free time. If this threshold is permanently exceeded and a pickup is present in the corresponding phase, an internal error is assumed. The other phases are also examined during the parameterization with crossblock.

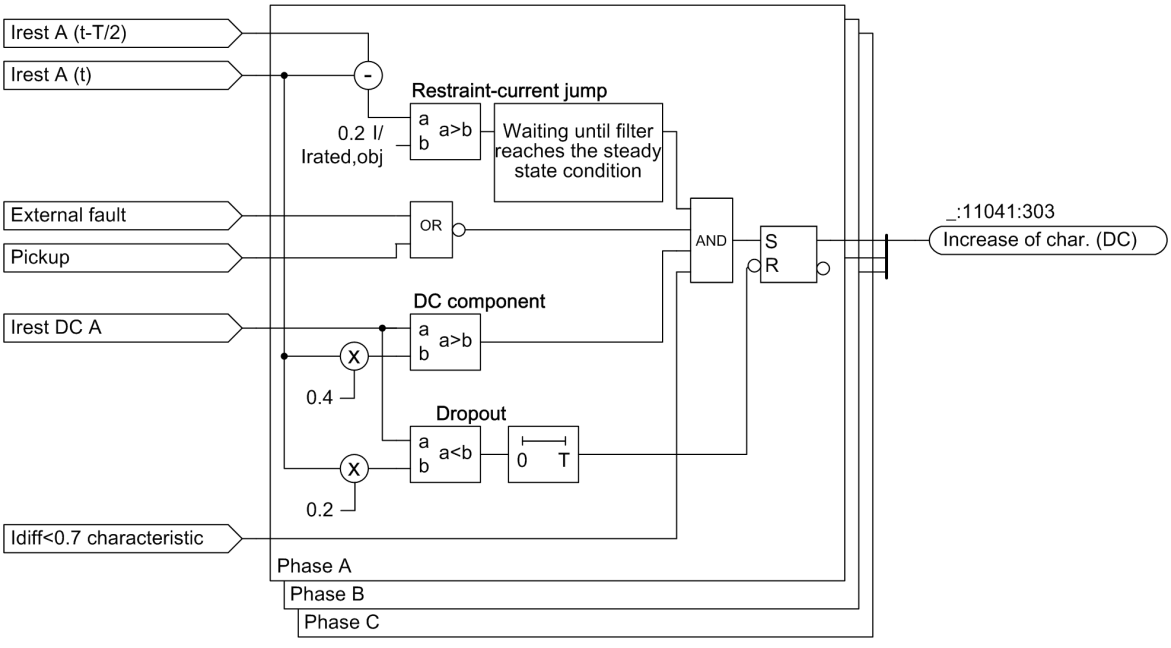
  The blocking of the tripping (including crossblock) is removed and the indication *Blocked by ext. fault phsx* is reset.



DC-Component Detection

In accordance with *Figure 6-11* low-current external faults with large DC components can also lead to exceeding of the operate curve. The additional stabilization area is not attained, however.
To avoid an overfunction, the following steps are taken:

- The restraint current $I_{rest.;phsx}$ is monitored for a jump.
- If the jump occurs, the DC component is calculated, with a temporal delay (1 period), from the instantaneous value of the restraint current (current at the measuring point with the largest current) $i_{rest.,phsx} = i_{phsx,Mm}$. The result is $I_{rest.DC,phsx}$. This current is compared to the restraint current $I_{rest.,phsx}$ and is checked for exceeding of the internal threshold.
- The differential current $I_{Diff,phsx}$ must lie below the dropout characteristic curve (characteristic curve · 0.7) in all 3 phases.
- If the first 3 points lead to positive results, then the operate curve is raised by the parameter **Factor increasing char.** with a default setting of ***2.3***. Here, only the threshold value and the slope 1 are raised (see *Figure 6-26*). The indication *Increase of char. (DC)* is issued. If the product of parameters **Factor increasing char.** and **Slope 1** exceeds **0.85**, the maximum increase of the raised **Slope 1** is limited to 0.85.
- As additional criterion, the pickup indication *Pickup* (internal fault is present) or the indication of the additional stabilization *Blocked by ext. fault phsx* (high-current external fault) is interrogated. If one of the 2 conditions is present, the characteristic curve increase is stopped. A retroactive pickup no longer resets the characteristic curve increase. A pickup with DC-component detection occurs only if the raised operate curve is exceeded.



If the DC component $I_{rest.DC,phsx}$ falls below the internal dropout threshold, the dropout delay is determined as follows:

It is assumed that the de- and re-magnetization of the transformer last equally long. The magnetization is at the highest at the point in time in which the internal dropout threshold is attained. The time is measured from the start of the DC-component detection until the internal dropout threshold is reached. Added to this time are 5 periods and from this, the dropout delay is derived. Following this, the characteristic curve increase is reset to the original value. *Figure 6-27* shows the overall logic.

Figure 6-26 Increasing the Characteristic Curve after DC Detection

[lodcerkn-170712-01.tif, 3, en_US]

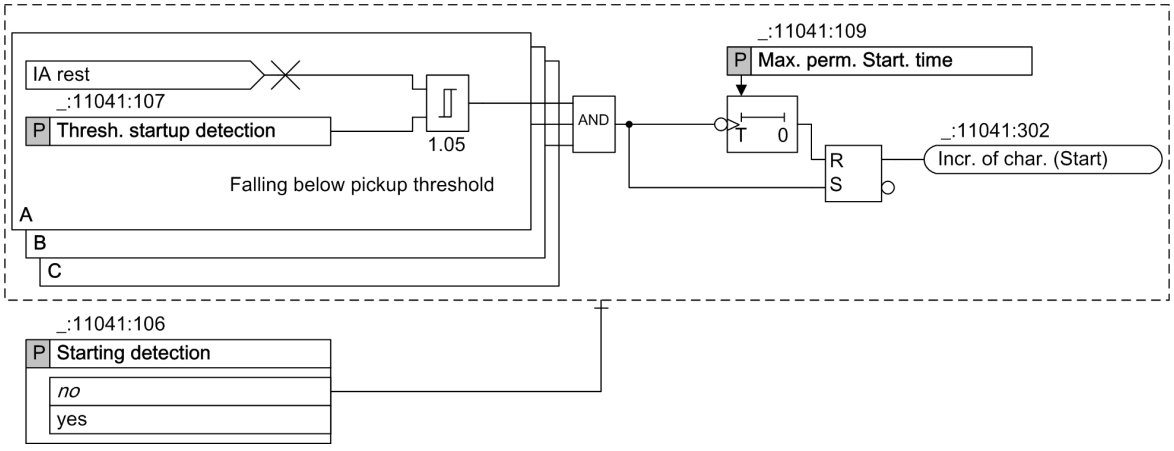

Figure 6-27 Logic DC Detection

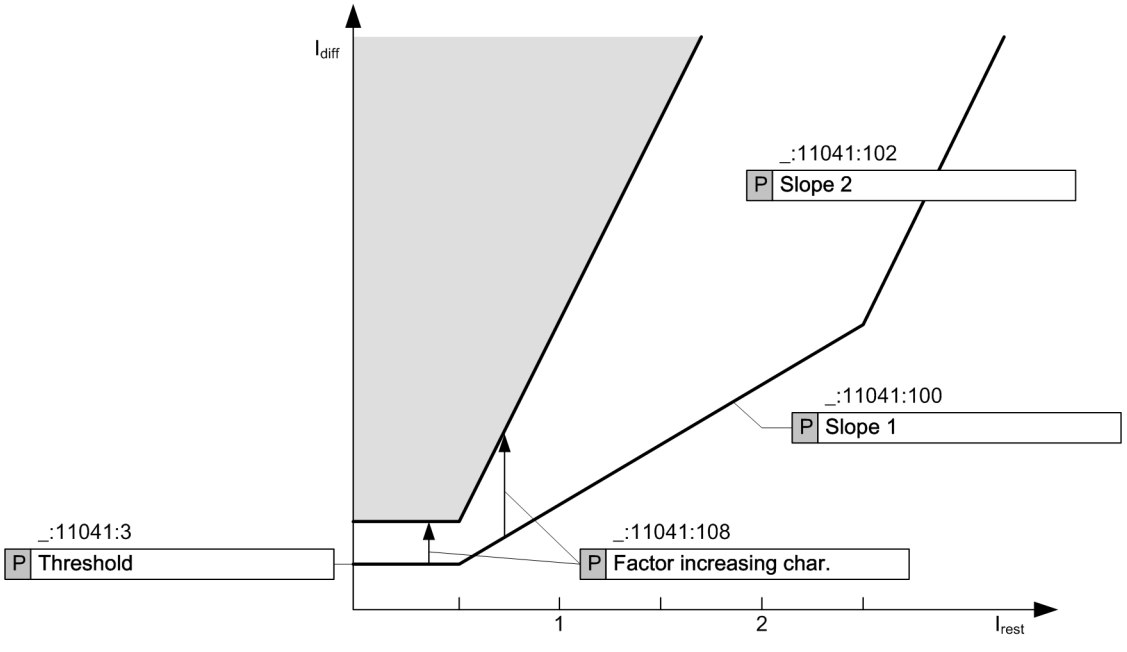
Startup Detection

The startup detection is particularly useful in the case of motors. In contrast to transformers, the inrush current with motors is a flowing current. Differential currents can arise, however, by the current transformers having different residual magnetization and being supplied with current act different operating points of their hysteresis. These differential currents are low in fact, but with sensitive setting of the differential protection can lead to overfunction.



As additional security against overfunction when switching in a previously protected object that carries no current, you can use the pickup-value increase at startup. If the restraint current falls below a settable value in all phases **`Thresh. startup detection`** the pickup-value increase is activated. The pickup value **`Threshold`** and **`Slope 1`** are raised by the set value in accordance with paramete **`Factor increasing char.`**. As a rule here, **`Slope 1`** cannot exceed a value of 0.85.

If the parameter **`Thresh. startup detection`** is exceeded, dropout occurs and a timing element (parameter: **`Max. perm. Start. time`**) is activated. Once this time has elapsed, the characteristic curve that was increased in all phases is reset to its source value. *Figure 6-28* shows the logic diagram of the startup detection and *Figure 6-29* the increased characteristic curve.

[loanlauf-170712-01.tif, 3, en_US]

Figure 6-28 Logic Startup Detection

[dwanlken-201112-01.tif, 1, en_US]

Figure 6-29 Characteristic Curve Increase at Startup

Trip Logic of the Differential Protection Function I-DIFF

Figure 6-30 shows the trip logic. If the characteristic curve is exceeded (see *Figure 6-22*) a pickup occurs. Redirection of the information for tripping can be blocked by the additional functions.

Blocking is possible through use of the following influencing variables:

- Detection of a connection process (2nd harmonic and CWA method)
- Identification of further harmonics (3rd and 5th harmonics (overexcitation detection))
- Detection of external short circuits that can simulate an internal short circuit through transformer saturation

Additionally, the **Crossblock** mechanisms operate with blocking functions, depending on the settings.

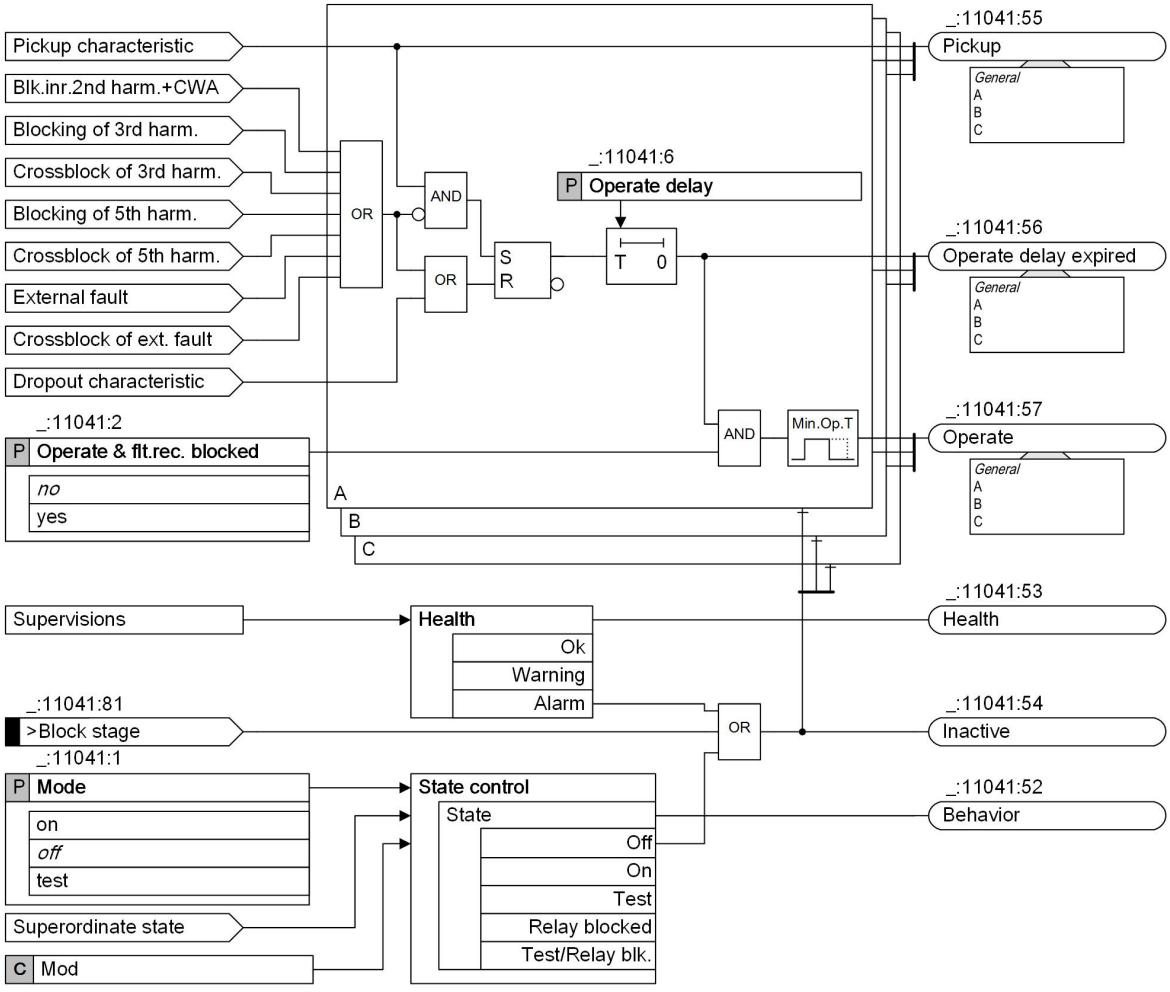


Figure 6-30 Trip Logic of I-DIFF

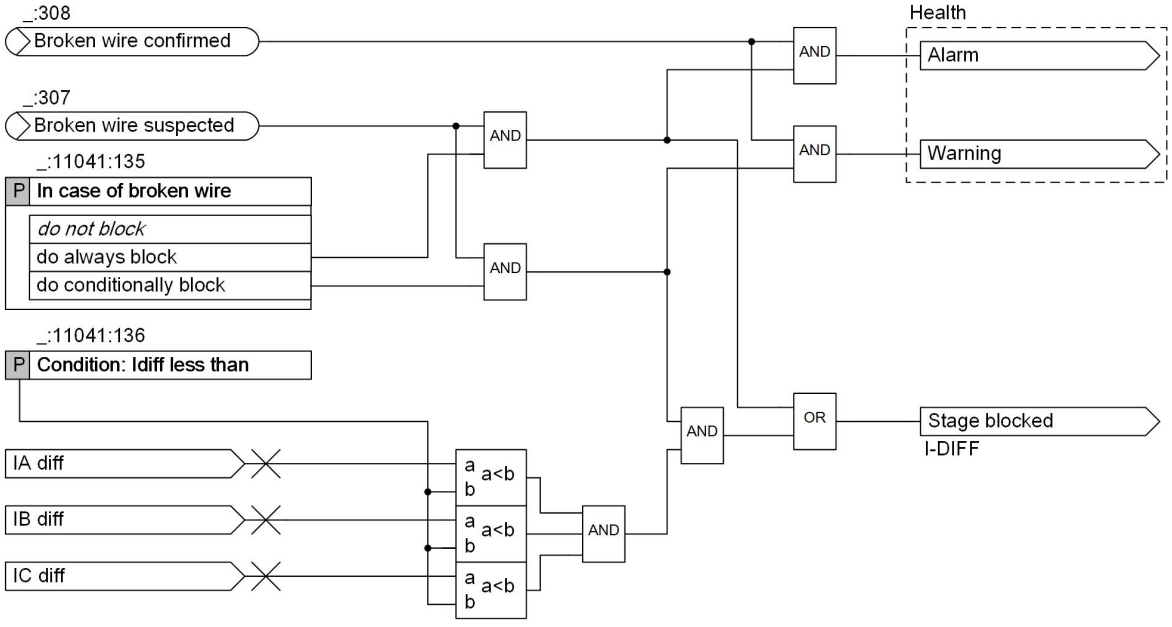
Reaction to Broken Wire in the Secondary System



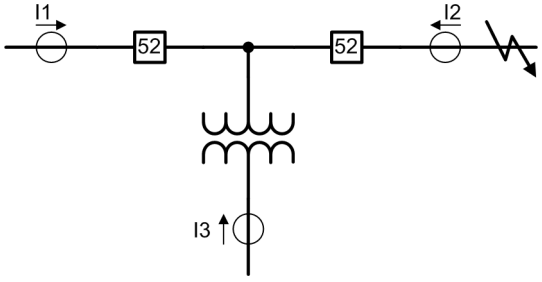
During steady-state operation, the function **Broken-wire detection** in the current measuring point detects interruptions in the secondary circuit of the current transformers, refer to *8.3.5 Broken-Wire Detection*.

Inherent to the working principle of protection functions that evaluate a current difference, interruptions in the secondary circuit cause unwanted tripping. With the **Broken-wire detection** and a corresponding parameterization in the stage **I-DIFF**, you can immediately block the stage **I-DIFF** in the function **Transformer differential protection** if a wire break is suspected.

If the **Broken-wire detection** is switched on in at least one current measuring point on a transformer side and the parameter **(_:5581:101) Mode of blocking** is set to ***blocking***, the parameters **(_:11041:135)**

In case of broken wire and **(_:11041:136) Condition: Idiff less than** are visible in the stage **I-DIFF**. These 2 parameters control the reaction of the stage **I-DIFF** to a wire break.

With the parameter **In case of broken wire**, you specify whether the stage **I-DIFF** is supposed to ***do not block***, ***do always block***, or ***do conditionally block*** in case of a wire break in the secondary system. If the parameter **In case of broken wire** is set to ***do conditionally block***, the blocking of the stage **I-DIFF** depends on the level of the differential current. The stage **I-DIFF** is only blocked if the differential current is less than the value set in the parameter **Condition: Idiff less than**.



[lo_broken_wire_tdiff, 1, en_US]

Figure 6-31 Logic of the Wire-Break Blocking in the Stage **I-DIFF**

6.2.3.7 Differential Protection Function I-DIFF Fast

As a supplement to the differential protection function I-DIFF, the function I-DIFF fast is available. The main task consists in switching off high-current internal short circuits in the shortest amount of time. The method controls current-transformer saturation and is stable with external transverse faults (see *Figure 6-32*).

[dwextfeh-170712-01.tif, 1, en_US]

Figure 6-32 External Fault in a 1 1/2 Circuit-Breaker Layout

Metrologically, 2 methods are combined:

- Instantaneous-value method
- Filter-based method

Instantaneous-Value Method

Through the instantaneous-values method, an immediate evaluation of the sampled values of the differential $i_{Diff}(t)$ and restraint current $i_{rest}(t)$ occurs. The absolute-value and vector-group adapted currents (i*) are also

the basis. The currents are defined positively to the node. The restraint current is the maximum current of all measuring points. The instantaneous values are formed via an estimation method from 2 sampled values.

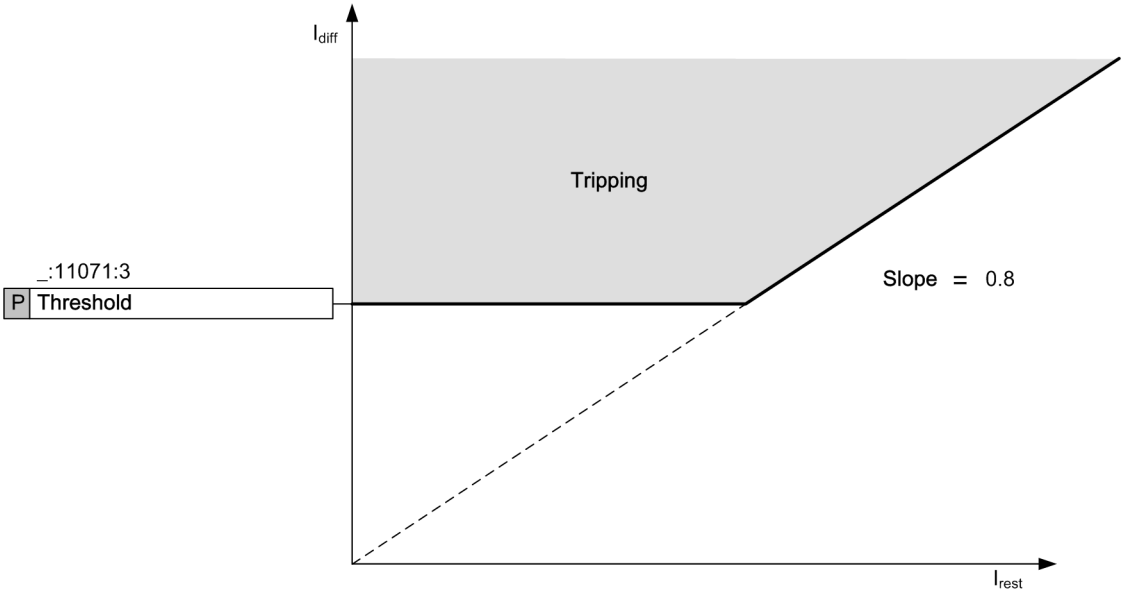
$$i_{diff,phsx}(t) = \left| \sum_{m=1}^{N} i^{*}_{phsx,Mm}(t) \right|$$

$$i_{rest,phsx}(t) = \frac{N}{2} \cdot \underset{m=1}{\overset{N}{MAX}} \left| i^{*}_{phsx,Mm}(t) \right|$$

[fomome27-170712-01.tif, 1, en_US]

where

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points



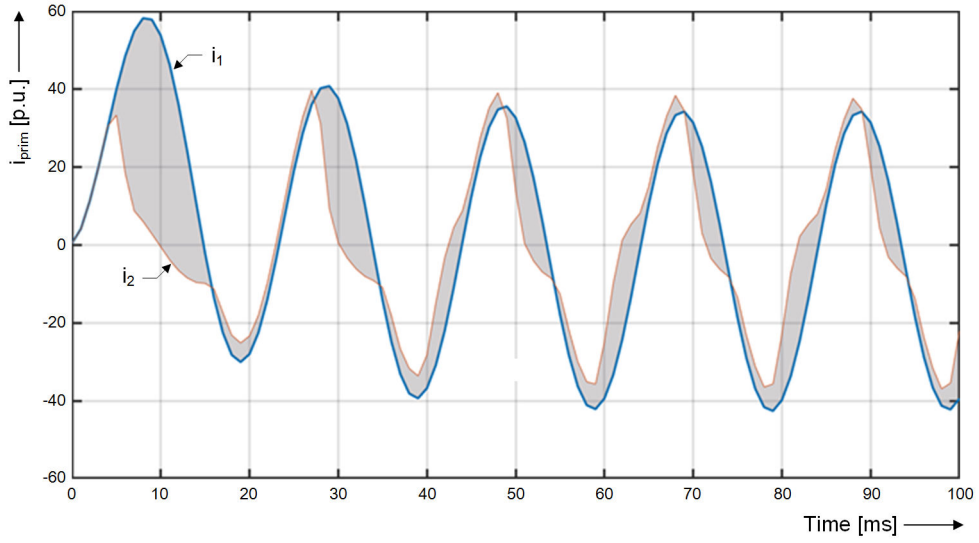
The evaluation of the restraint current is used for stabilization in the event of high-current external short circuits with transformer saturation (see *Figure 6-32*).

Figure 6-33 shows the operate curve. The parameter **Threshold** is set to the maximum fault current to be expected when switching on the transformer (see *Parameter: **Threshold** (Setting the Characteristic-Curve Parameters), Page 604*). The slope of the characteristic curve is fixed at 0.8.

In the algorithm, the following conditions are processed:

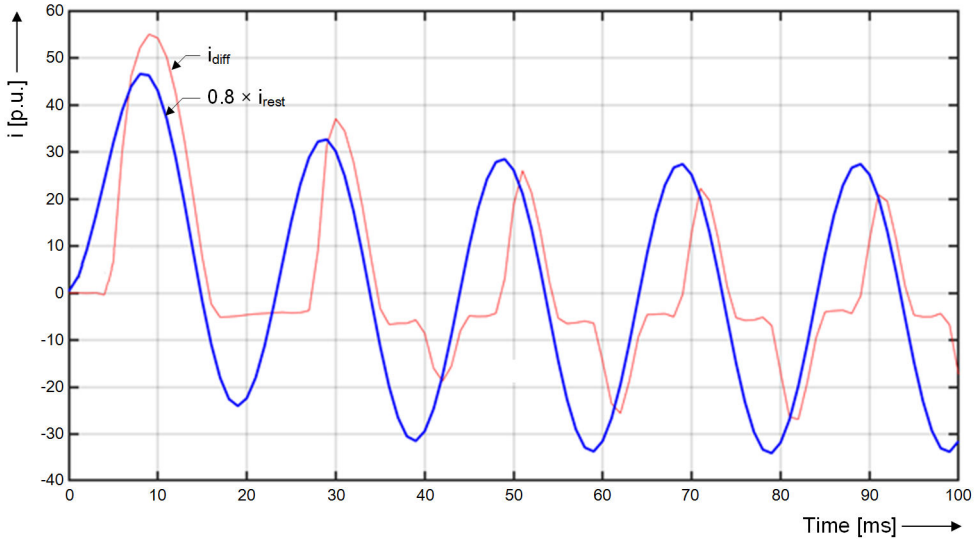
- Condition 1: The increase of the restraint current $di_{rest.}(t)/dt$ is determined continuously and compared with an internal threshold value.
- Condition 2: After that, a comparison determines whether the differential-current instantaneous value is larger than the restraint current (characteristic curve **Slope** in *Figure 6-33*): $i_{diff}(t) > 0.8 \cdot i_{rest.}(t)$.
- Condition 3: After that, a comparison determines whether the differential-current instantaneous value exceeds the parameter **Threshold**.

When all conditions are met, tripping occurs immediately. If the 1st condition is recognized and not the 2nd condition, then the instantaneous-value function is blocked for 300 ms.



[dwidfast-300114-01.tif, 1, en_US]

Figure 6-33 Characteristic Curve of I-DIFF Fast

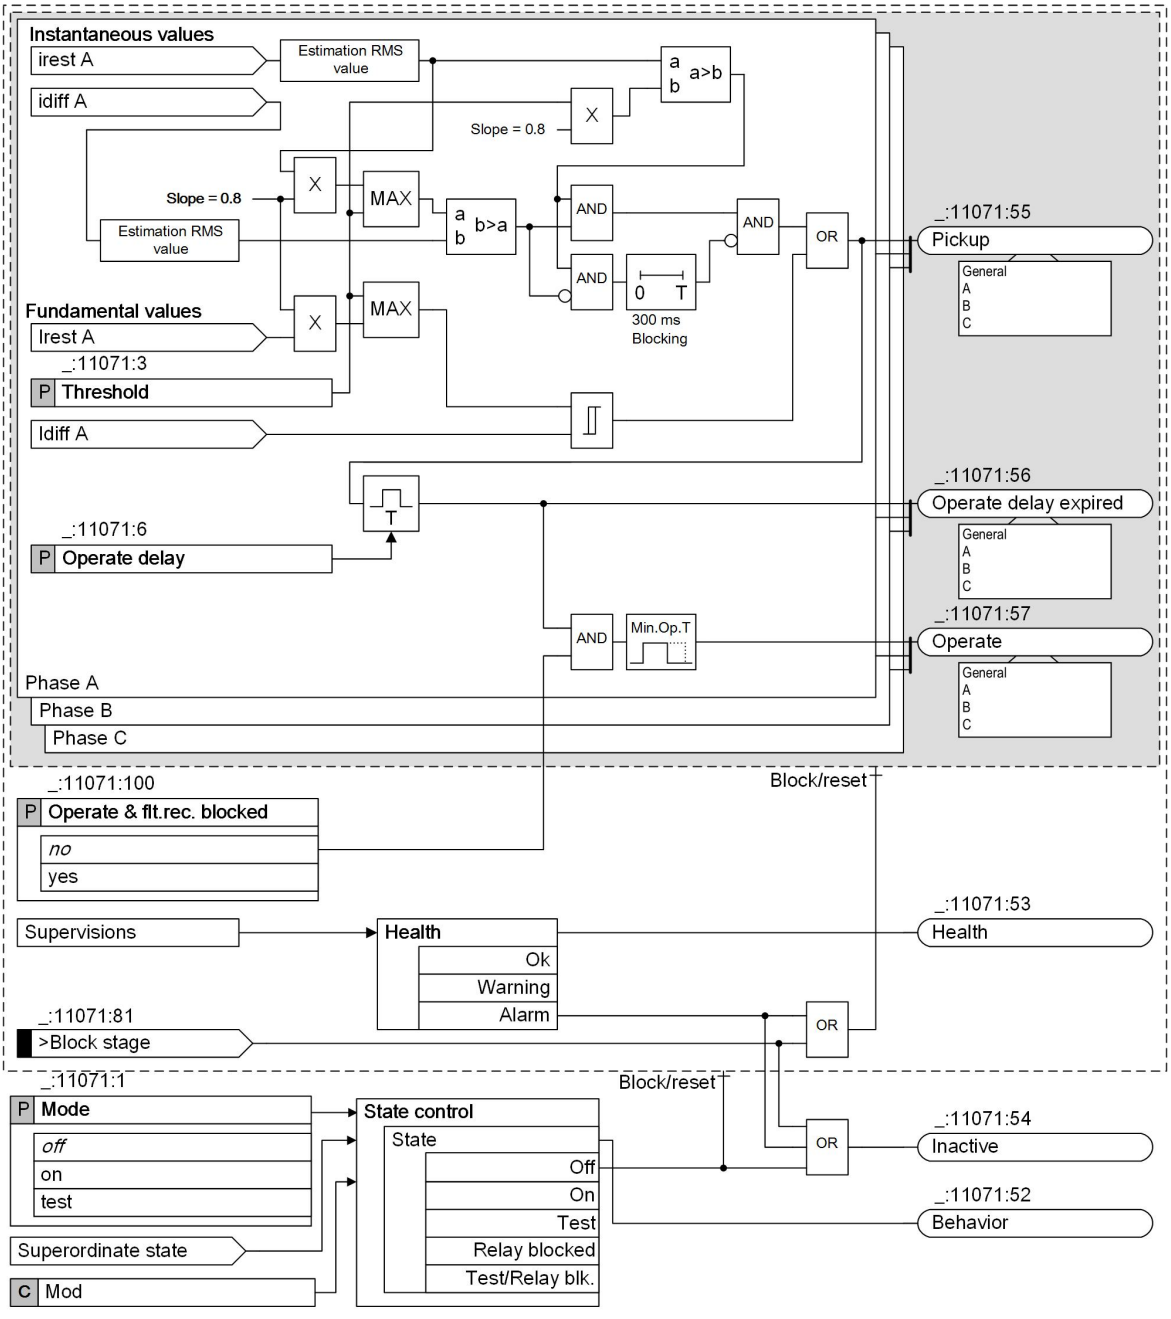


Behavior in the event of a high-current external fault with transformer saturation

The following example in *Figure 6-34* shows a high-current fault with transformer saturation. The short-circuit current with DC component flows through a protected object, for example, a busbar with a 1 1/2 circuit-breaker layout. The current flows through 2 current transformers, where the i1 current is properly transmitted through one of them, and transformer saturation occurs for the other one after a few milliseconds. The range between the flows of the i1 and i2 currents is the differential current that has been measured by the protection device. The differential current and restraint current flow $i_{rest}(t)$ multiplied by factor 0.8 is shown in *Figure 6-35*. Condition 1 is met when the restraint current rises quickly when the $di_{rest}(t)/dt$ fault occurs. At this point, condition 2 is thoroughly checked to determine whether the differential-current instantaneous value is greater than 0.8 of the restraint-current instantaneous value. The evaluation is carried out within a max. of 1/8 of a system period once the fault occurs. As the differential current, and thereby condition 2, has not been met in the event of heavy transformer saturation, the instantaneous-value method for the I-DIFF fast stage is blocked for 300 ms.

[dwinnfel-201112-01.tif, 2, en_US]

Figure 6-34 Curve Plot for Primary Currents in the Event of an External Short Circuit with Transformer Saturation



[dwextfel-170712-01.tif, 2, en_US]

Figure 6-35 Curve Plot for the Differential Current and Restraint Current i_{rest} · 0.8 in the Event of an External Short Circuit with Transformer Saturation

Fundamental-Component Method

Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} and the stabilization value (maximum current of a measuring point) $I_{rest.}$ are ordered in the operate curve *Figure 6-33* and the trip decision is made.

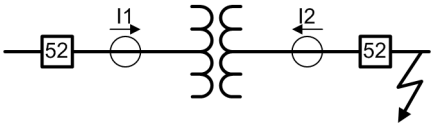
Figure 6-36 shows the overall logic.

[lo_id_fast, 4, en_US]

Figure 6-36 Logic of the Differential Protection Function I-DIFF Fast

6.2.3.8 I-DIFF Unrestrained Differential Protection Function

When protected objects with a high longitudinal impedance (transformer, generator, reactor) are protected without busbar sections, the I-DIFF unrestrained differential protection stage can be used as an alternative to the I-DIFF Fast protection stage. This stage does not control transformer saturation. Therefore, the setting value of this stage must be adjusted to the maximum short-circuit current that flows through this protected object.



High-current faults in the protection range can always be switched off immediately without consideration of the restraint currents if, due to the current magnitude, it is determined that an external fault is not involved. In the case of protected objects with a large intrinsic longitudinal impedance (transformer, generator, reactor), a current can be found that is never exceeded by a flowing short-circuit current.

For a transformer, that is, for example, the (primary) value:

$$\frac{1}{u_{sc\ transf}} \cdot I_{Ntransf}$$

[fo_diff_current_error, 1, en_US]

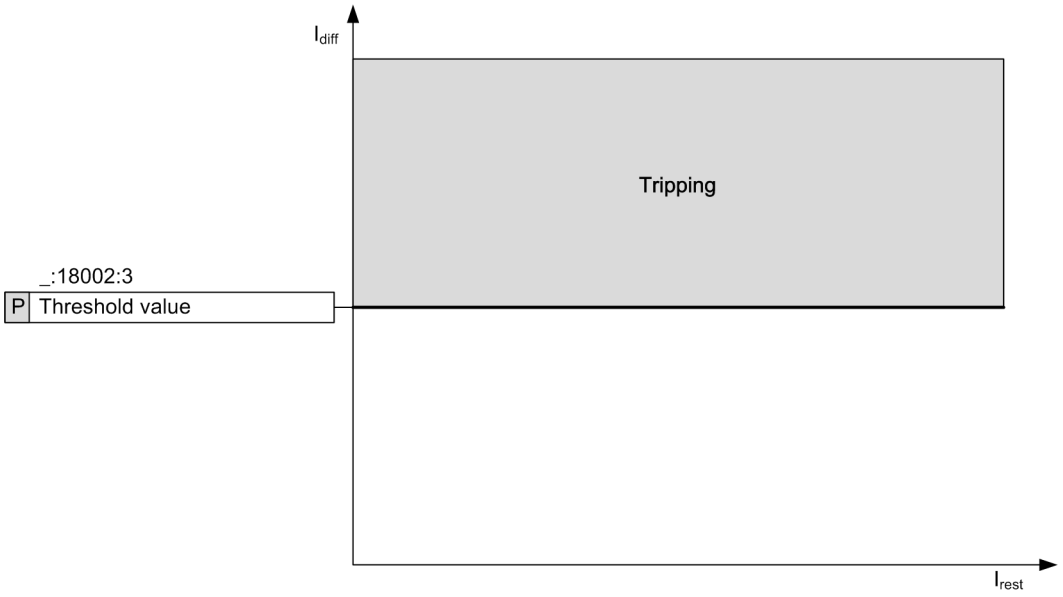
The I-DIFF unrestrained stage also acts if, for example, due to current-transformer saturation because of a DC component in the short-circuit current, a 2nd harmonic occurs. The inrush-current detection could interpret this as the closed-circuit current.

[dwextfehzw-100117-01, 1, en_US]

Figure 6-37 External Fault in a Two-Winding Transformer

The I-DIFF unrestrained protection stage operates both with the fundamental component of the differential protection and with instantaneous values.

Metrologically, 2 methods are combined:

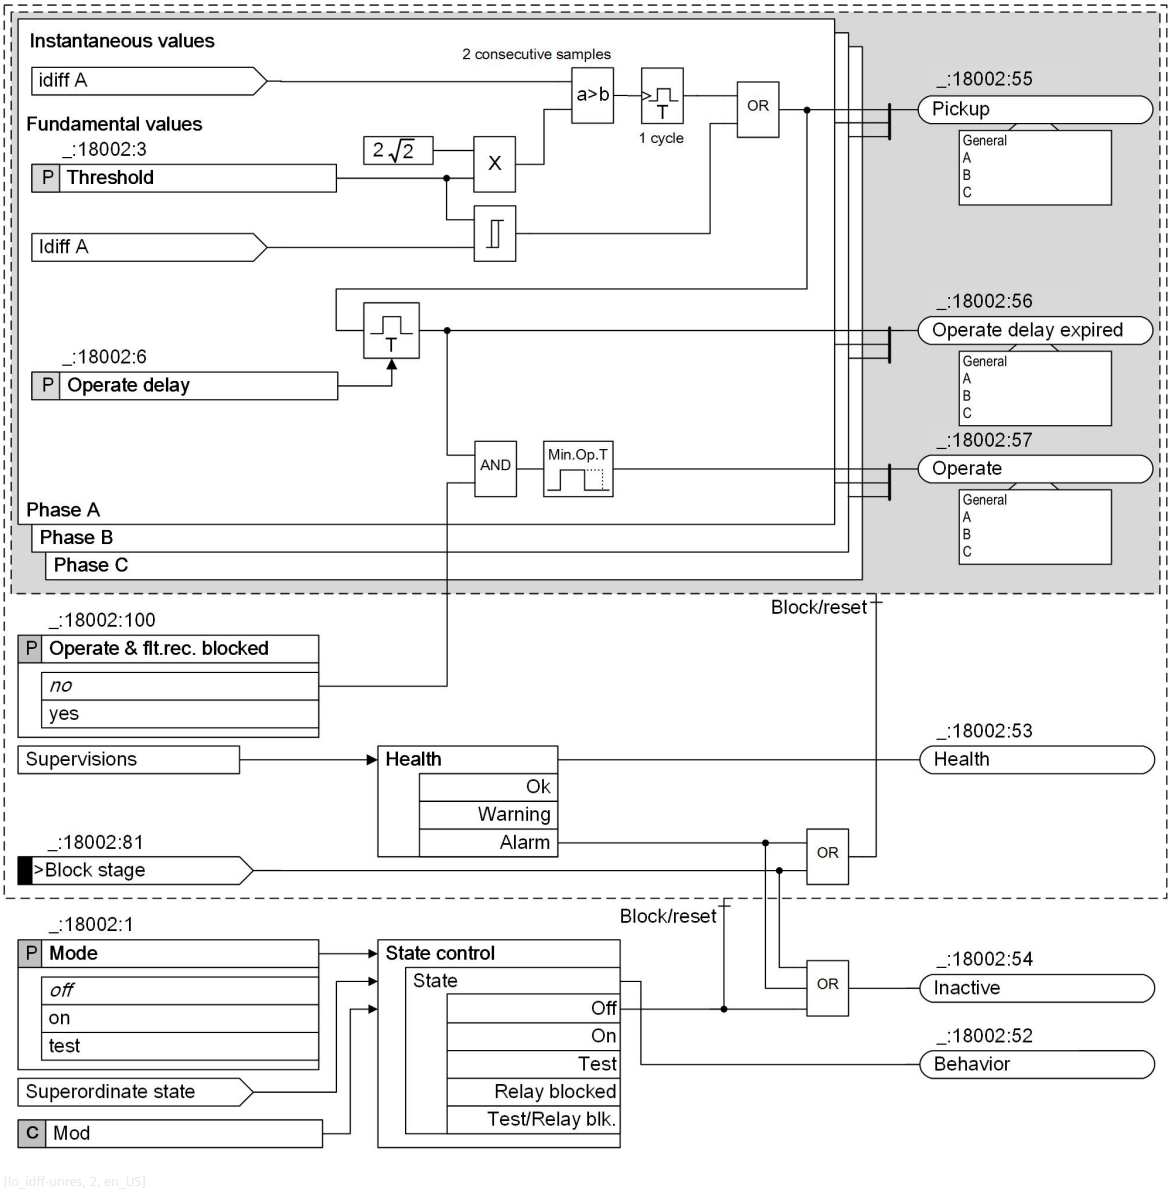


- Instantaneous-value method
- Filter-based method

Instantaneous-Value Method

With the instantaneous-values method, an immediate evaluation of the sampled values of the differential current $i_{Diff}(t)$ occurs. The instantaneous-value stage only works above $2 \cdot \sqrt{2}$ of the setting value due to a potential full shift in the short-circuit current once the fault occurs. The absolute-value and vector-group adapted currents (i*) are also the basis. If the fundamental component is greatly damped by current transformer saturation, the instantaneous-value method ensures quick tripping.

Fundamental-Component Method



Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} is ordered in the operate curve *Figure 6-38* and the trip decision is made.

Functional Measured Values

Measured Value	Description
_:2311:300 A, B, C	Differential current
_:2311:301 A, B, C	Restraint current

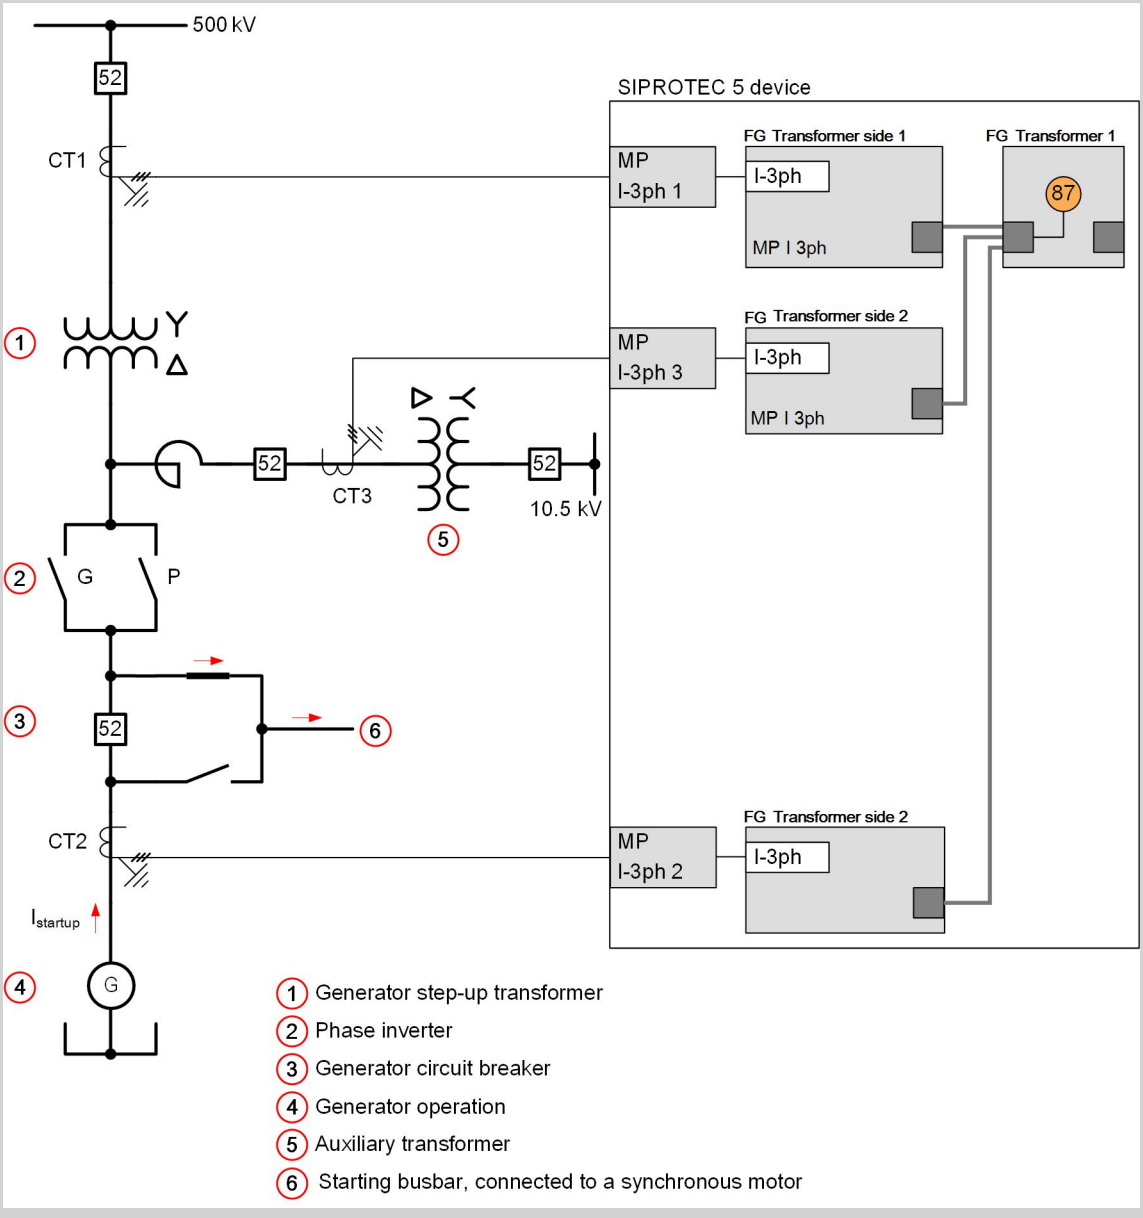
6.2.3.10 Disconnection of the Measuring Point from the Transformer Differential Protection Function

For special applications, for example, in a pumped-storage hydropower plant, an individual measuring point must be disconnected from but then reconnected to the **Transformer differential protection** function under different specific operating conditions.

The disconnection and reconnection can be automatically and reliably achieved by the **Current transformer disconnection** function. The following example describes a mixed application of the functions **Transformer differential protection** and **Current transformer disconnection**.

Transformer Differential Protection in a Pumped-Storage Hydropower Plant

In a pumped-storage hydropower plant, the synchronous machine can operate in the pump operation mode (for example, the generator in the following figure) and in the pump startup mode (for example, the motor in *Figure 6-42*).



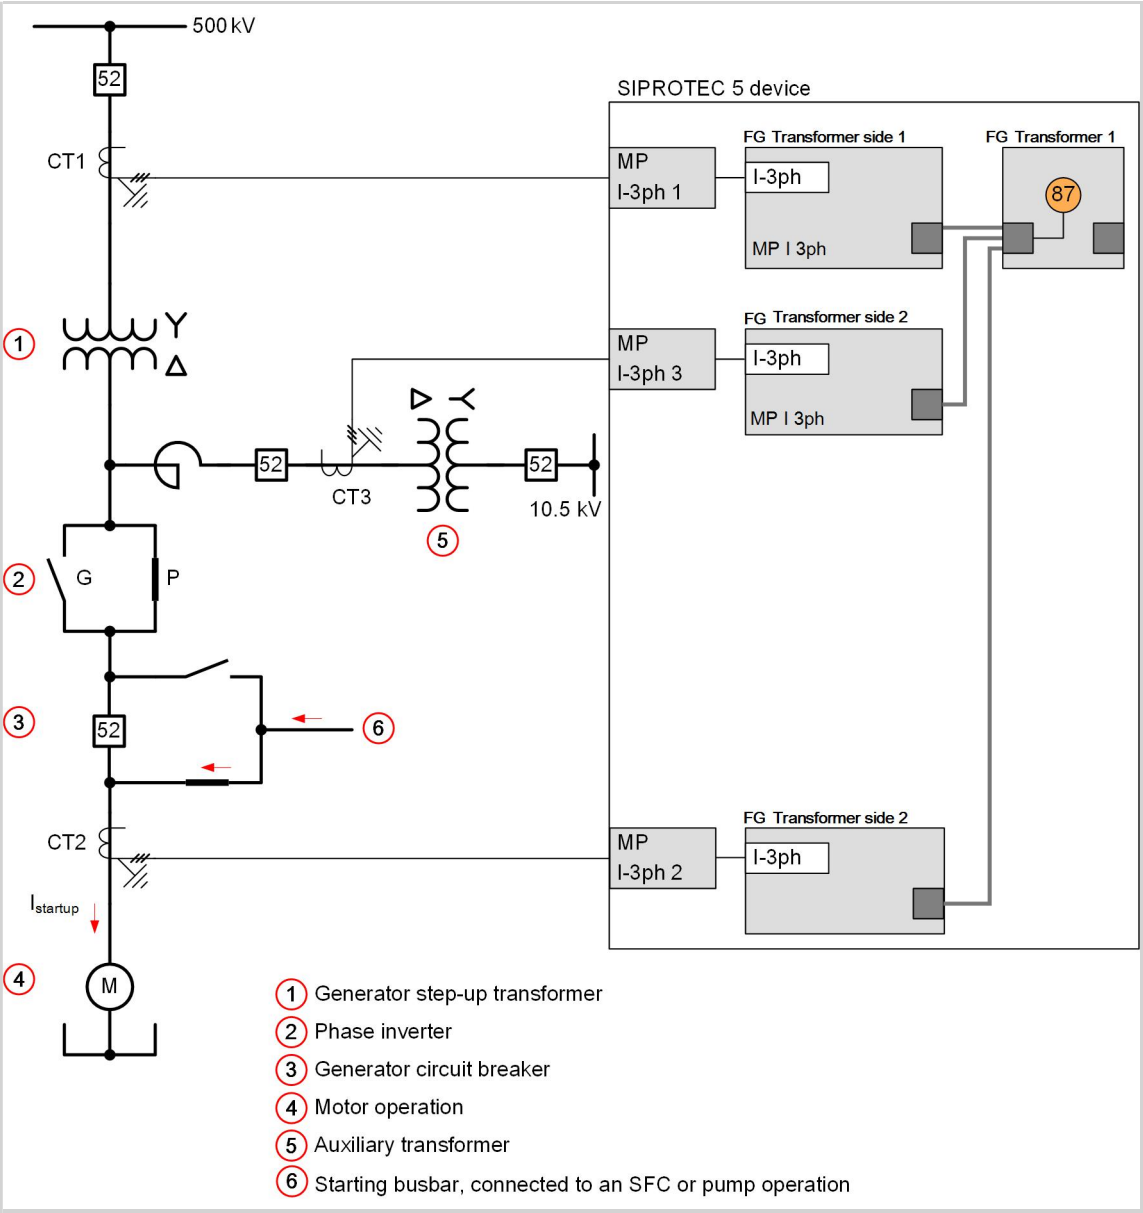


Figure 6-41 Pump Operation Mode

If the generator acts as pump operation, it feeds the starting current $I_{startup}$ into the starting busbar with a frequency change from 0 Hz to the rated value.

[lo_Pp_Startup, 1, en_US]

Figure 6-42 Pump Startup Mode

In the pump startup mode, the motor is excited and connected to the starting busbar during the startup. It is started up via an external-current infeed from a static-frequency converter (SFC) or pump operation. The motor runs from a speed of 0 to the rated value, and then, it is connected to the power grid by a paralleling device. During the speedup of the motor, the frequency of the injected starting current $I_{startup}$ changes from 0 Hz to the rated value.

The synchronous machine is connected to the power grid via a generator step-up transformer (GSUT). The GSUT is protected by the **Transformer differential protection** function (ANSI 87T) and detects short circuits and ground faults. In the pump operation mode or the pump startup mode, the synchronous machine is disconnected from the GSUT via a phase inverter or a generator circuit breaker (GCB). On the one hand, according to the Kirchhoff's law, to avoid overfunction, the measured current $I_{startup}$ from CT2 must be disconnected from the **Transformer differential protection** function. On the other hand, in the pump startup mode, after the motor is connected to the power grid, the measured current $I_{startup}$ from CT2 must be reconnected to the **Transformer differential protection** function. The disconnection and reconnection are realized by the **Current transformer disconnection** function.

The following figure shows an example of a logic diagram for this application.

NOTE

Disconnection or reconnection of the current transformer has a direct impact on the **Transformer differential protection** function. To avoid overfunction caused by the disturbance of binary input signals *>Disconnection on* and *>Disconnection off*, Siemens recommends not activating *>Disconnection on* and *>Disconnection off* with external single-point binary inputs. Siemens recommends using a CFC logic with double-point binary inputs.

In case of overfunction caused by power loss of device and binary input signals at the same time, do not obtain the binary input signal *>Disconnection off* from the **NOT** logic of the binary input signal *>Disconnection on*.

6.2.3.11 Fault Logging and Fault Recording

A fault is opened with every protection pickup. This means that a fault log and a fault recording are started. Saving of the fault record depends on the setting (see *3.5.3 Function Description*). Since pickup and tripping are the same in differential protection, the recording setting can be used with the pickup function. To enable fault recording even with an external short circuit, along with the exceedance of the characteristic curve, a fault record is opened in case of blocking by an external short circuit or from characteristic curve increase through DC-component recognition. This has the advantage that you can evaluate the transformer transfer method of the current transformers very well in case of a fault.

6.2.4 Application and Setting Notes

Selected applications for differential protection are described in the following. Setting instructions for the necessary setting parameters are given for these applications.

Protection of a Two-Winding Transformer

As an example a transformer in the vector group YNd5 is selected, whose neutral side is solidly grounded. If different settings are produced by different variants (vector group, grounding), reference to them is made for the corresponding setting parameters. *Figure 6-43* shows the basic structure with the typical system parameters. The function is operational in the devices 7UT82, 7UT85, 7UT86, and 7UT87.

NOTE

Also, observe the connection of the current transformer *A.8 Requirements for Current Transformers* in the Appendix.

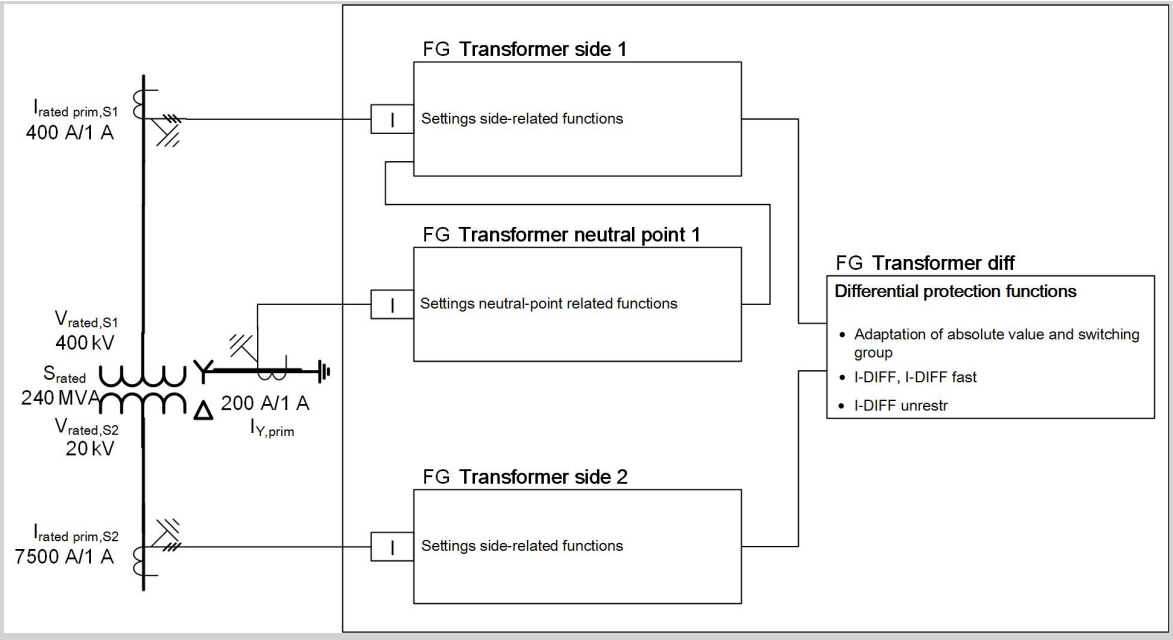

Figure 6-43 Connection of a Two-Winding Transformer

In the example, a 7UT85 is selected.

2 measuring inputs are interconnected on the 3-phase measuring points of side 1 and side 2. The measuring points must be interconnected with the corresponding function groups.

Figure 6-44 shows the corresponding screenshot from DIGSI 5.

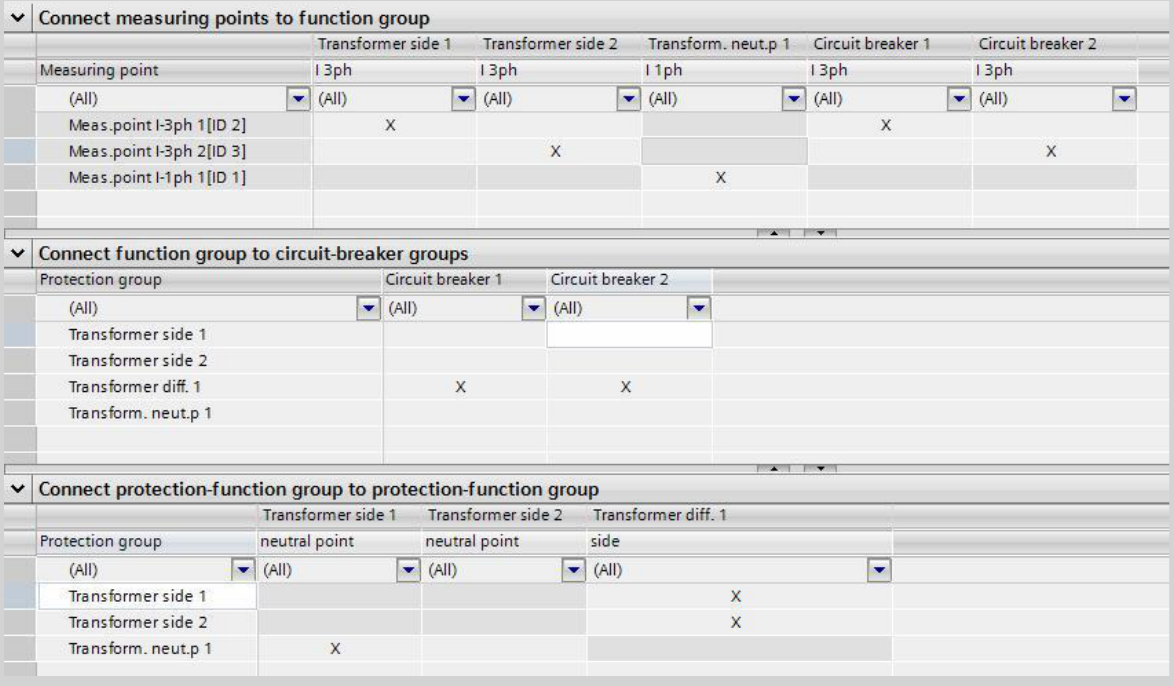

Figure 6-44 Internal Circuiting in DIGSI 5

Transformer Side Function Group

Go to the function group **Transformer side** and make the following settings:

NOTE

Ensure that the correct transformer data is set at the measuring points.

NOTE

Keep in mind that the matching factors in each case are calculated from the primary transformer current and a reference rated current. For a standard transformer and an auto transformer, the reference rated current of each side is the rated current of the reference side transformed on the individual side. The matching factors are calculated and displayed as write-protected parameters. Only the matching factors used appear in the menu.

The matching factor for one transformer side is calculated by the equation below:

$$\text{CT ratio}_{(m)} = \frac{I_{\text{rated transf. (m)}}}{I_{\text{rated (m)}}}$$

The reference current $I_{\text{rated (m)}}$ is the rated current of the transformer side and is calculated using:

$$I_{\text{rated (m)}} = \frac{S_{\text{rated (m)}}}{\sqrt{3} \cdot V_{\text{rated (m)}}}$$

with

CT ratio	Matching factor
$I_{\text{rated transf.}}$	Primary rated current of the current transformer
I_{rated}	Rated current of the transformer side
S_{rated}	Rated apparent power
V_{rated}	Rated voltage of the transformer side
m	Measuring point

Parameter: `Rated apparent power`

- Default setting **`(_:91:103) Rated apparent power`** = ***`240 MVA`***

With this parameter, you set the rated apparent power of the appropriate side. The setting value for both sides is the same with a two-winding transformer.

Parameter: `Rated voltage`

- Default setting **`(_:91:102) Rated voltage`** = ***`400 kV`***

With this parameter, you set the rated voltage of the appropriate side. For side 1, it is 400 kV. Set 20 kV for side 2 in the example.

If a transformer with tap changers is used, do not use the actual rated voltage, but set a medium-sized voltage as **`Rated voltage`**. Use the following relationship to calculate the voltage:

$$V_{\text{ref}} = 2\frac{V_{\text{max}} \cdot V_{\text{min}}}{V_{\text{max}} + V_{\text{min}}}$$

[fonensei-170712-01.tif, 1, en_US]

V_{ref}	Voltage to be set
V_{max}	Voltage at upper tap position
V_{min}	Voltage at lower tap position

The calculated rated current of the side is displayed as additional information. In the example, this is a value of 346 A (240 MVA/(√3 · 400 kV) = 346.4 A).

Parameter: `Neutral point`

- Default setting **`(_:91:149) Neutral point`** = ***`grounded`***

This parameter is important for zero-sequence current treatment. In the example, the transformer is solidly grounded on side 1. For this reason, set ***`grounded`***. For side 2 (delta side) set ***`isolated`***. If a neutral reactor is located within the protection range of the transformer differential protection on the delta side, set ***`grounded`***. If a star winding is not grounded, then set ***`isolated`***.

NOTE

If a star winding is implemented to be insulated with regard to the neutral-point treatment and a surge arrester is connected, then to avoid overfunction of the differential protection, the setting ***`grounded`*** is recommended. If the surge arrester picks up, then it grounds the neutral point.

Parameter: `Winding configuration`

- Default setting **`(_:91:104) Winding configuration`** = ***`Y (Wye)`***

You set the circuiting of the windings with this parameter. Side 1 is interconnected in the star. For this reason, set ***`Y (Wye)`***. For side 2, which is interconnected in the delta, you must set a ***`D (Delta)`***. If the windings are interconnected in zigzag, set a ***`Z (Zig-Zag)`***.

Parameter: `Vector group numeral`

- Default setting **`(_:91:163) Vector group numeral`** = ***`0`***

This parameter is used to account for phase-angle rotation, which is expressed by a number.

Phase-angle rotation	0°	-30°	-60°	-90°	-120°	-150°	-180°	-210°	-240°	-270°	-300°	-330°
Vector group numeral	0	1	2	3	4	5	6	7	8	9	10	11

In the example, a transformer YNd5 is used. For this transformer, side 1 gets the Vector group numeral 0 and side 2 the Vector group numeral 5.

In the function group, the following information is displayed additionally in the setting sheet:

- Side number
- Identification of the measuring points used
- Matching factor for the 3-phase measuring point (with reference to the side)
- Matching factor for the measuring point at the neutral point (with reference to the side)

You can set each Vector group numeral from 0 to 11 to the extent possible. Thus, for example, only even numbers are possible for the vector group Yy, Dd, and Dz and only odd numbers are possible for Yd, Yz, and Dy.

Parameter: `Tap changer`

- Default setting **`(_:91:44) Tap changer`** = ***`No function block has been selected`***

When using this parameter, the transformer side is assigned to a tap changer. If a tap changer is assigned, other parameters also become visible. You can use a separate tap changer or the tap changer in the voltage controller.

[sctssdi2-260913-01, 2, en_US]

Figure 6-45 Settings in DIGSI 5

Parameter: `Basic position`

- Default setting **`(_:91:138) Basic position`** = ***8***

With the parameter **`Basic position`** you specify the stage at which the voltage matches the rated voltage of the transformer side.

Parameter: `Volt. diff. adjacent taps`

- Default setting **`(_:91:139) Volt. diff. adjacent taps`** = ***0.000***

With the parameter **`Volt. diff. adjacent taps`**, you set the voltage difference of a stage under idle conditions.

Function Group Transformer DIFF

Make the following settings in the function group **Transformer Diff** for the function I-DIFF:

NOTE

Keep in mind that the matching factors in each case are calculated from the primary transformer current and the object rated current. For a standard transformer, the object rated current of the side is the rated current of the reference side transformed on the individual side. The matching factors are calculated and displayed as write-protected parameters. Only the matching factors used appear in the menu.

The matching factor for one transformer side is calculated by the equation below:

$$\text{CT ratio}_{(m)} = \frac{I_{\text{rated transf. (m)}}}{I_{\text{rated obj.}}}$$

The reference current $I_{\text{rated obj.}}$ is the rated current of the transformer side and is calculated using:

$$I_{\text{rated obj.}} = \frac{S_{\text{rated obj.}}}{\sqrt{3} \cdot V_{\text{rated obj.}}}$$

with

CT ratio	Matching factor
$I_{\text{rated transf.}}$	Primary rated current of the current transformer
$I_{\text{rated obj.}}$	Rated current of the transformer side
$S_{\text{rated obj.}}$	Rated apparent power
$V_{\text{rated obj.}}$	Rated voltage of the transformer side
m	Measuring point

Tap Changer

In the **General** setting sheet in DIGSI 5, you specify whether the adaptation of the differential protection to the current tap-changer position is to be used. Make the setting and allocation in the transformer side.

Parameter: `Use tap-changer position`

- Default setting **`(_:2311:187) Use tap-changer position`** = ***yes***

With setting ***yes***, you adapt the differential protection function to the current tap-changer position.

NOTE

- In the properties dialog Position of the tap changer, enable the parameter **`Moving contact (highest binary input)`**. Set the parameter **`Supervision behavior`** of the tap changer to ***`warning`*** or ***`alarm block`***.

Zero-Sequence Current Treatment

You set how the ground current is handled on the **General** setting sheet in DIGSI 5. On **Transformer Side 1**, the neutral point of the transformer is set as grounded. In this way, the protection function knows that the zero-sequence current is to be accounted for. With the following parameter, you can set the treatment of the zero-sequence current.

NOTE

In the Appendix, also note the requirements for current transformers of the differential protection *A.8 Requirements for Current Transformers* .

Parameter: `Meas. gnd. current side 1`

- Default setting **`(_:2311:100) Meas. gnd. current side 1`** = ***`no`***

With the setting ***yes*** a zero-sequence current correction is performed. The setting ***no*** causes the elimination of the zero-sequence current. With the zero-sequence current correction, a higher sensitivity is attained in the case of 1-pole ground faults. If the neutral point current transformer should be taken into consideration in the differential protection, set ***yes***.

NOTE

For this application, design the neutral point current transformer appropriately strong (almost saturation-free over approx. 30 ms).

More information on this in *6.2.3.1 Basic Principle of Differential Protection*, section **Neutral point current handling**.

Parameter: `Threshold` (Setting the Characteristic-Curve Parameters)

- Default setting **`(_:11041:3) Threshold`** = ***`0.2 I/Irated,obj`***

With this parameter, you set the pickup threshold for the differential current. This is the total current flowing into the protection range during a short circuit, regardless of how it is distributed on the sides of the protected object. The **`Threshold`** is referenced to the rated current of the protected object. With transformers, a sensitive setting can by selected since a relatively small magnetizing current arises as a constant fault current. The default setting of ***`0.2 I/Irated,obj`*** is a practical value between sensitivity and possible disturbing influence.

If the transformer sets are of similar construction in the case of reactors, generators and motors (identical in transmission behavior), a more sensitive setting is possible.

In the event of a very pronounced deviation of the current-transformer rated currents from the rated current of the protected object or with several measuring points, expect greater measuring tolerances. If loads with large time constants (external transformers, motors) are connected, transmission problems (for example, through remanence) can arise with currents in the rated current range with a closed iron core transformer (p-cores). In this case, Siemens recommends an increased setting value of 0.3 I/Irated,obj.

If the position of the tap changer cannot or should not be taken into account in the differential protection, set the pickup value slightly higher than the default setting. Use the following relationship for estimation.

Threshold value$_{New}$ = threshold value + (k_{StS} · Intersection 1 Irest) I/Irated,obj

$$k_{StS} = \frac{V_{max} - V_{min}}{V_{max} + V_{min}} = \frac{(100\,\% + St_{max}) - (100\,\% + St_{min})}{(100\,\% + St_{max}) + (100\,\% + St_{min})}$$

[fokorwr2-180912-01.tif, 1, en_US]

k_{StS} Correction value to account for the tap changer

Example: Tap changer $St_{max} = +12\,\%$, $St_{min} = -12\,\%$.

$$k_{StS} = \frac{(100\,\% + 12\,\%) - (100\,\% - 12\,\%)}{(100\,\% + 12\,\%) + (100\,\% - 12\,\%)} = 0.12$$

[fokorwr3-180912-01.tif, 2, en_US]

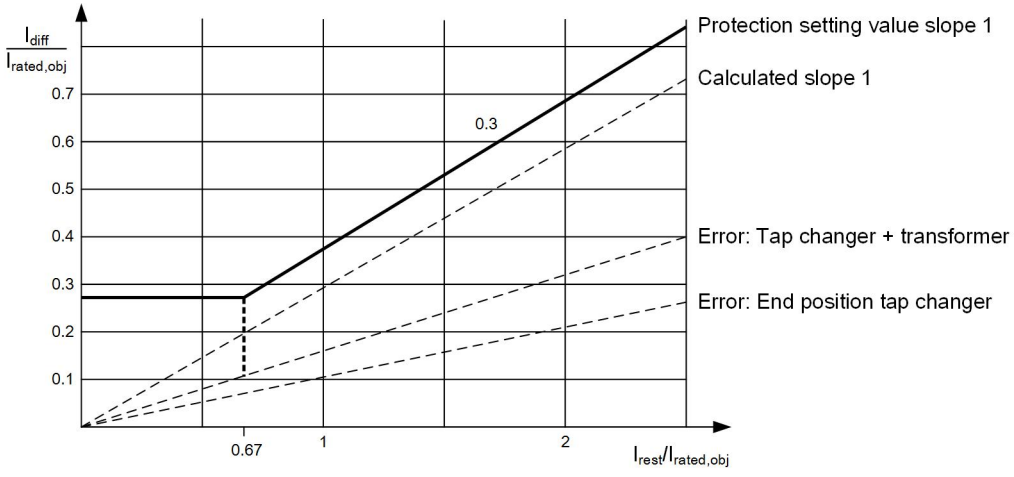
Threshold value$_{New}$ = 0.20 I/Irated,obj + (0.12 · 0.67) I/Irated,obj ≈ ***0.28 I/Irated,obj***

Parameter: `Slope 1`

- Default setting **`(_:11041:100) Slope 1`** = ***0.3***

NOTE

The stabilization method has been changed from that in SIPROTEC 4 (7UT6x, 7UM62). For this reason, select a higher slope (also see *6.2.3.1 Basic Principle of Differential Protection*).



If the position of the tap changer cannot or should not be taken into account in the differential protection, check the increase.

The Slope 1 should be approximately 2 times higher than the current-proportional fault currents, which are caused by transformer transmission faults and non-adaption of a tap changer. In general, you can use a factor of 1.2 for the transformer fault currents.

`Slope 1New` = 2 · 1.2 · k_{StS}

for example **`Slope 1New`** = 2.4 · 0.12 = 0.288

However, you should set a slope of at least ***0.3***. *Figure 6-46* illustrates the situation.

[dwstgsfs-261012-01.tif, 3, en_US]

Figure 6-46 Setting Slope 1 with Tap Changer

Parameter: `Intersection 1 Irest`

- Default setting **`(_:11041:101) Intersection 1 Irest`** = ***0.67 I/Irated,obj***

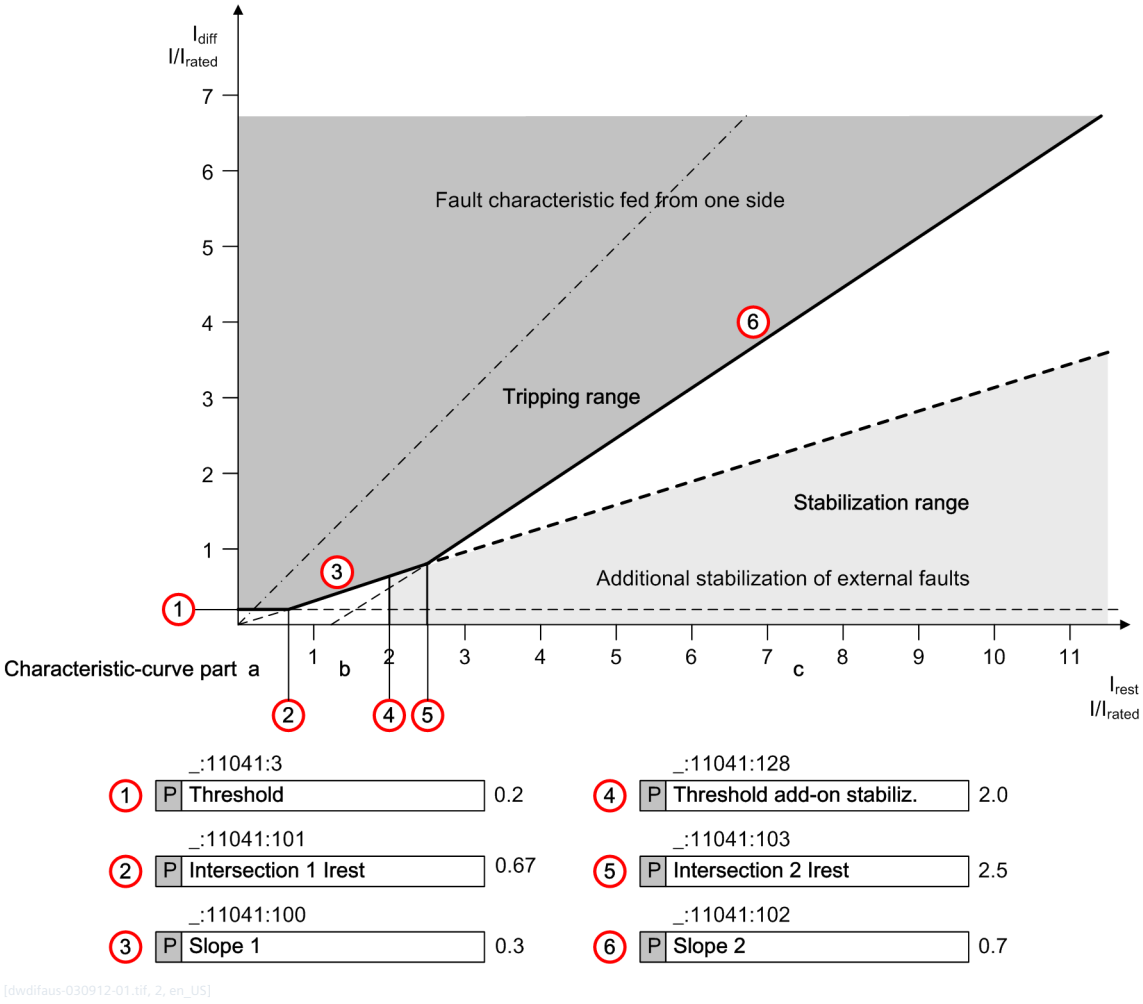
The maximum current of the measuring point is used as restraint current. If you have to expect dynamic transmission faults of the current transformer even with small currents, Siemens recommends keeping the default setting of 0.67.

The setting of the parameter **Intersection 1 Irest** determines the end of the horizontal section with the threshold value I Diff>. Therefore also take into account the formula in the setting notes for the threshold value I Diff>.

Parameter: Intersection 2 Irest

- Default setting **(_:11041:103) Intersection 2 Irest** = ***2.5 I/Irated,obj***

NOTE



If excessive current flows are cause to expect transmission problems for the current transformer, set the **Slope 2** to a higher value.

When using the parameter **Intersection 2 Irest**, you determine at which restraint current the **Slope 2** will start. The default setting ***2.5 I/Irated,obj*** is a practical value.

Parameter: Slope 2

- Default setting **(_:11041:102) Slope 2** = ***0.7***

With the parameter **Slope 2**, an overfunction of the differential protection is avoided with high-current external faults as a consequence of current-transformer transmission faults (for example, due to saturation). A value greater than or equal to double the value of **Slope 1** is practical. As the default setting, ***0.7*** was selected.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-47 Characteristic Curve with the Default Settings

Parameter: `Starting detection`

- Default setting **`(_:11041:106) Starting detection`** = ***no***

If motors are operated by a transformer to be protected, Siemens recommends the activation of the startup detection. The startup detection prevents an overfunction caused by the startup currents of the motors. Siemens recommends this also for the protection of power-compensating reactors. In this case, set the default setting **`Starting detection`** = ***yes***.

Parameter: `Thresh. startup detection`

- Default setting **`(_:11041:107) Thresh. startup detection`** = ***0.1 I/Irated,obj***

If the restraint current falls below this threshold value, the subsequently set characteristic curve increase becomes effective with activated function. For this application, Siemens recommends a default setting of ***0.1 I/Irated,obj***.

Parameter: `Factor increasing char.`

- Default setting **`(_:11041:108) Factor increasing char.`** = ***2.0***

Change the default setting value in the case of application. A setting to the value 2.0 has proven itself to be sufficient for many applications. For this reason, the recommended setting value is **`Factor increasing char.`** = ***2.0***.

Parameter: `Max. perm. Start. time`

- Default setting **`(_:11041:109) Max. perm. Start. time`** = ***`5.0 s`***

The setting value must lie above the maximum permissible start time of the connected motors. Find the start time in the motor data sheets (for example, **Locked Rotor** time). To ensure tripping through the motor protection (starting-time supervision) and avoid overfunctions, select a somewhat longer time (factor 1.2).

Parameter: `Factor increasing char. DC` (DC-Component Detection)

- Default setting **`(_:11041:110) Factor increasing char. DC`** = ***`2.3`***

DC-component detection is always active. As a result of the DC components, transmission problems can arise (for example, phase-angle rotations) in current transformers with small currents flowing. For this reason, the **`Threshold`** and the **`Slope 1`** are raised by the set factor. The default setting of 2.3 has proven itself with numerous applications.

Parameter: `Blocking with 2. harmonic` (Inrush-Current Detection)

- Default setting **`(_:11041:115) Blocking with 2. harmonic`** = ***`yes`***

Always activate inrush-current detection with transformer applications.

Parameter: `2nd harmonic content`

- Default setting **`(_:11041:116) 2nd harmonic content`** = ***`15 %`***

For many practical applications, the default setting value of ***`15 %`*** has proven useful. In exceptional cases, the setting value can be decreased with a small proportion of 2nd harmonic. Avoid a setting under 10 %, however. With an internal fault and current-transformer saturation, a proportion of 2nd harmonic also arises. Too sensitive of a setting leads to a blocking of the protection function.

Parameter: `Crossblock. time 2nd har.`

- Default setting **`(_:11041:117) Crossblock. time 2nd har.`** = ***`0 s`***

Since the inrush currents develop differently in the 3 phases, the pickup value, for example, is not attained in a phase, but the differential current exceeds the characteristic curve. Corrective action creates a mutual blocking. If a time unequal to 0 s is set, the crossblock function works. If an overfunction arises, the setting cannot be made until commissioning takes place. Do not set the duration for an excessive amount of time. Practical values showed a setting between 3 and 5 periods.

Parameter: `Blocking with CWA`

- Default setting **`(_:11041:118) Blocking with CWA`** = ***`yes`***

In accordance with the application sheet, an additional, supplementary method is used for the inrush-current detection. Siemens recommends using the default setting. If you wish to perform the inrush-current detection only when monitoring the 2nd harmonic, you can switch off the CWA method (**`Blocking with CWA`** = ***`no`***).

NOTE

When using a shunt reactor, Siemens recommends deactivating the CWA process, since the process results in a false pickup in the event of an external fault. The background is that the CWA-internal fault detection deactivates the blocking of the 2nd harmonic in the differential protection.

Parameter: `Blocking with 3rd harm.` (Overexcitation Blocking)

- Default setting **`(_:11041:121) Blocking with 3rd harm.`** = ***`no`***

Blocking with the 3rd harmonic is intended for special applications, for example, when supplying power to blast furnaces. Even with standard transformers, the 3rd harmonic can arise in a case of overexcitation, but this is eliminated through the delta winding. For this reason, using the 5th harmonic is preferred.

Parameter: 3rd harmonics content

- Default setting **(_:11041:122) 3rd harmonics content** = ***30 %***

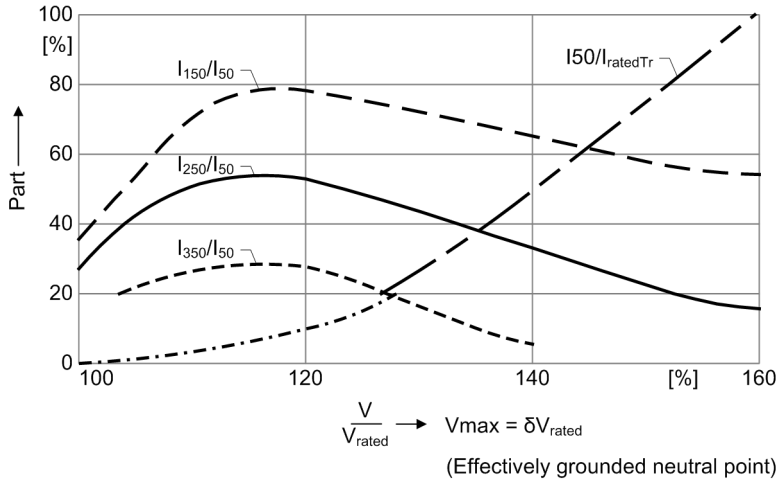
For many practical applications, the default setting value of ***30 %*** has proven useful. Also see explanations for setting the 5th harmonic.

Parameter: Crossblock. time 3rd har.

- Default setting **(_:11041:123) Crossblock. time 3rd har.** = ***0 s***

See explanation of inrush-current detection.

Parameter: Blocking with 5th harm.



- Default setting **(_:11041:124) Blocking with 5th harm.** = ***no***

If you expect higher overvoltages that can bring about a failure of the differential protection, change the default setting (also see explanations below) and activate the functionality (**Blocking with 5th harm.** = ***yes***).

Parameter: 5th harmonics content

- Default setting **(_:11041:125) 5th harmonics content** = ***30 %***

For many practical applications, the default setting value of 30 % has proven useful. It can be derived from the *Figure 6-48* in the graphic shown. The voltage is represented on the x-axis, and the percentage of the individual measurable variables on the y-axis. On the curve $I_{50}/I_{ratedTr}$ you can see that the pickup value of the differential protection can be exceeded in case of overvoltage. If you assume 140 % [V/V_{rated}] as the maximum overvoltage, you can read from the curve I_{250}/I_{50}, that the proportion of the 5th harmonic still amounts to approx. 35 %. A setting value of ***30 %*** is therefore sufficient.

[dwanhaub-170712-01.tif, 1, en_US]

Figure 6-48 Part of the Harmonic in Case of Overexcitation

Parameter: Crossblock. time 5th har.

- Default setting **(_:11041:126) Crossblock. time 5th har.** = ***0 s***

You can leave the default setting as is. If problems arise during system operation, you can take corrective measures by setting an appropriate time. You can derive the necessary time from the fault record by evaluating the proportion of the harmonic.

Parameter: Limit Idiff 3., 5. harmonics

- Default setting **(_:11041:127) Limit Idiff 3., 5. harmonics** = ***1.5 I/Irated,obj***

If large differential currents arise, you can assume an internal fault. To avoid a subfunction of the differential protection, overexcitation blocking is inhibited from the threshold value on. Distorted fault currents produce predominantly odd-numbered harmonics in case of an internal fault. In accordance with *Figure 6-48*, a possible differential current is caused that lies below the rated current due to overexcitation. On the other hand, distorted fault currents arise only with currents far above the rated current. Therefore, ***1.5 I/Irated,obj*** is a practical setting value.

Detection of External Faults

In *Figure 6-47*, the range **Add-on stabilization with external fault** is represented. The range is described by the parameters **Threshold add-on stabiliz.** and **Slope 1**. With an external short circuit, the differential currents can increase beyond this range and reach into the tripping area. With the following parameters, time-limited blocking can be performed.

Parameter: Threshold add-on stabiliz.

- Default setting **(_:11041:128) Threshold add-on stabiliz.** = ***2.0***

The parameter **Threshold add-on stabiliz.** allows you to set the pickup value for the additional stabilization. Due to the selected method of measurement, a setting value of 2 is practical. The additional stabilization range is limited by the parameters **Threshold add-on stabiliz.** and **Slope 1**.

Parameter: Time of add-on stabiliz.

- Default setting **(_:11041:129) Time of add-on stabiliz.** = ***0.3 s***

As orientation for the setting value, you can use the operate time of the external feeder protection. Additionally, take into account the break time of the circuit breaker. Thus, the following calculation rule results:

$t_{Z\text{-rest}} \geq t_{Trip.,ext\ protection} + t_{Trip,circuit\ breaker}$

The default value is a practical value. You must adapt the value appropriately to use. The value 0 deactivates the detection of external faults.

Parameter: Crossblk. time add-on st.

- Default setting **(_:11041:130) Crossblk. time add-on st.** = ***0.3 s***

As a consequence of the vector-group correction and zero-sequence current elimination, the differential currents can spread to the other phases in case of transformer saturation. For this reason, Siemens recommends the activation of the crossblock function with a corresponding setting of the time. The set time must be identical to the time that is set for the duration of the additional stabilization.

Broken wire action in the Stage I-DIFF

If the **Broken-wire detection** is switched on in at least one current measuring point on a transformer side and the parameter **(_:5581:101) Mode of blocking** is set to ***blocking***, the parameters **(_:11041:135) In case of broken wire** and **(_:11041:136) Condition: Idiff less than** are visible in the stage **I-DIFF**. These 2 parameters control the reaction of the stage **I-DIFF** to a wire break.

Parameter: In case of broken wire

- Default setting **(_:11041:135) In case of broken wire** = ***do not block***

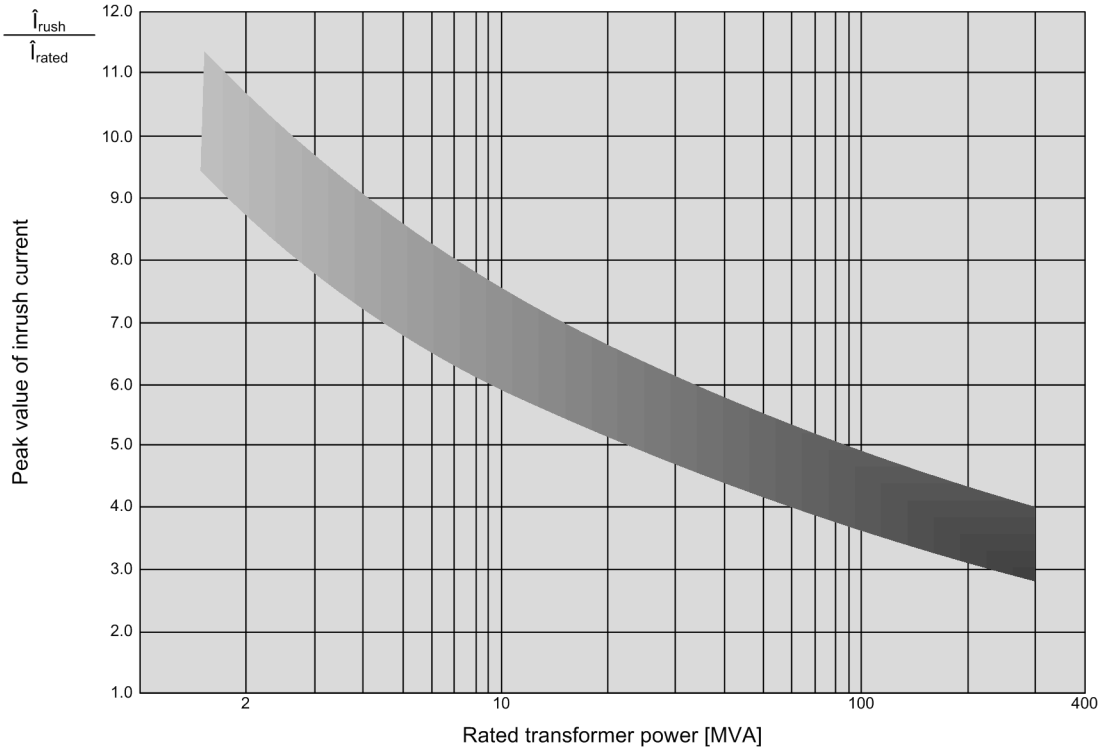
With the parameter **In case of broken wire**, you specify whether the stage **I-DIFF** is supposed to ***do not block***, ***do always block***, or ***do conditionally block*** in case of a wire break in the secondary system.

Parameter: Condition: Idiff less than

- Default setting **(_:11041:136) Condition: Idiff less than** = ***1.20 I/IrObj***

If the parameter **In case of broken wire** is set to ***do conditionally block***, the blocking of the stage **I-DIFF** depends on the level of the differential current. The stage **I-DIFF** is only blocked if the differential

current is less than the value set in the parameter **Condition: Idiff less than**. If the differential current exceeds the set value, the blocking of the stage **I-DIFF** is canceled.



Protection Stage I-DIFF Fast

The task of this protection stage is the fast detection of high-current internal faults (see also *6.2.3.1 Basic Principle of Differential Protection*). For this reason, the protection stage must always be activated.

Parameter: Threshold

- Default setting **(_:11071:3) Threshold** = ***7.5 I/Irated,obj***

The **Threshold** must exceed the expected inrush current. The inrush current depends on the construction, the core material, and the impedances of the transformer. There are typical power-dependent values. Use the graphic below for estimating purposes (*Figure 6-49*).
In the case of transformers with a low power rating (<10 MVA) the inrush current can lie above the default setting value of ***7.5 I/Irated,obj***.

[Dw-Nennleistung-Transf-060214, 1, en_US]

Figure 6-49 Transformer Inrush Currents, Typical Data

Example:
At a power of 100 MVA, a value of approx. 4.5 I/Irated,obj. is derived from *Figure 6-49*. For this application, reduce the default setting from 7.5 I/Irated,obj to the determined value.

Protection Stage I-DIFF Unrestrained

The task of this protection stage is the fast detection of high-current internal faults (also refer to *6.2.3.8 I-DIFF Unrestrained Differential Protection Function*).

Parameter: Threshold

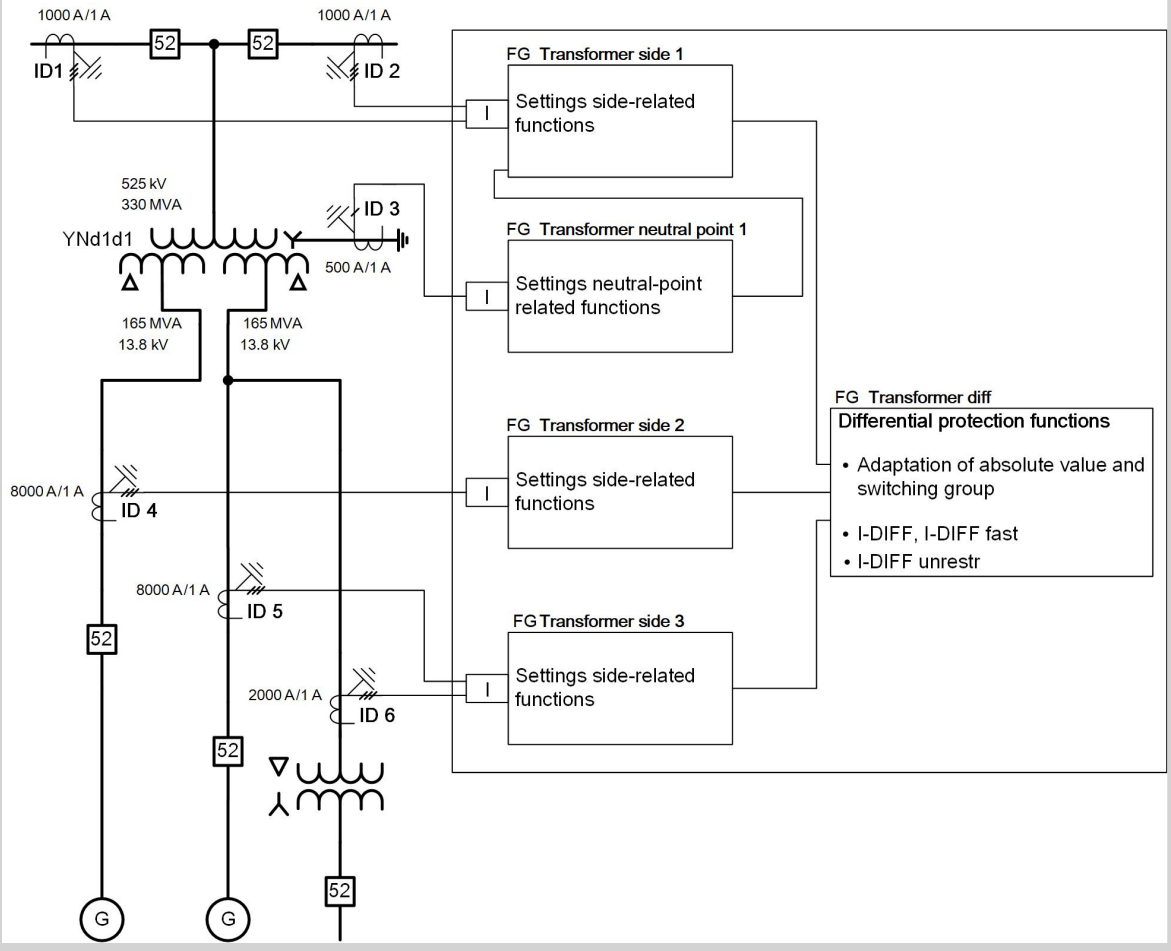
- Default setting **(_:18002:3) Threshold** = ***10.0 I/Irated,obj***

To set the parameter **Threshold** correctly, you must take into account the short-circuit impedance of the system and the protected object as well as the maximum inrush current.

Protection of a Three-Winding Transformer with Several Measuring Points

In this complex example, the main focus is on the configuration. A three-winding transformer YNd1d1, which is connected on the upper-voltage side to a breaker-and-a-half layout, is protected. A generator feeds in power on the delta side, while a generator also supplies its own power. On the upper-voltage side, the transformer is solidly grounded. As can be seen in *Figure 6-50*, five 3-phase measuring points and one 1-phase measuring point is required. A 1-phase overcurrent protection is located in the 1-phase measuring point as ground current backup protection. So that the restricted ground-fault protection found there can process the neutral-point current, circuiting with the **Transformer side 1** is required. The individual measuring points are described by ID1 to ID6. Furthermore, 3 function groups **Transformer side**, 1 function group **Transformer neutral point**, and the function group **Transformer** are required.

The functionality is available in the devices 7UT86 and 7UT87.



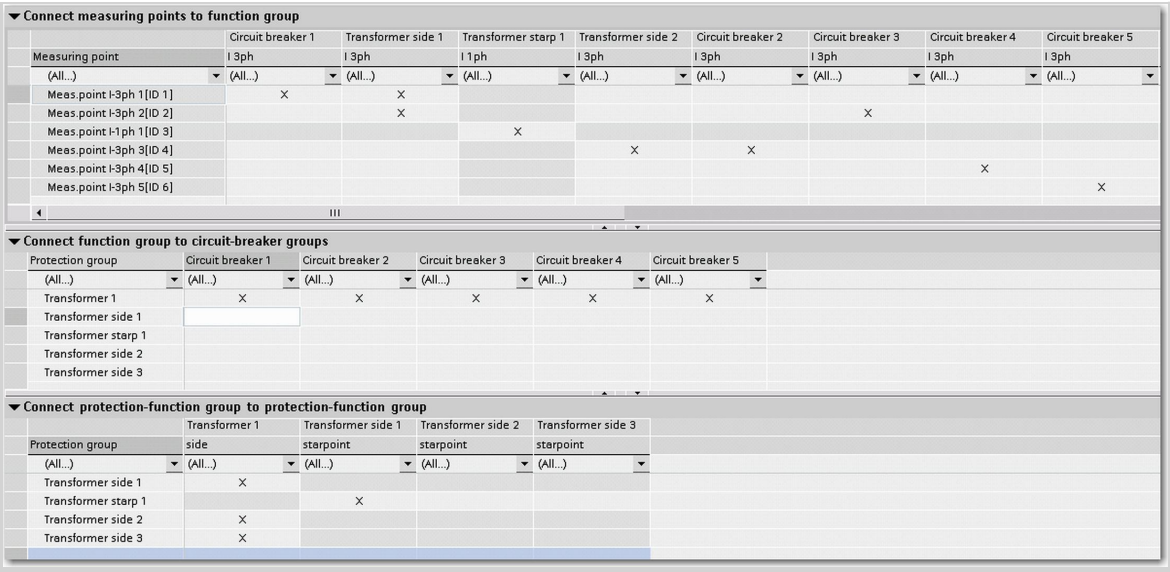


Figure 6-50 Connection of a Three-Winding Transformer with Several Measuring Points

Figure 6-50 shows you the measuring point assignment to the function groups and the circuiting of the function groups among one another from DIGSI 5. Since a total of 5 circuit breakers are operated, 5 function groups **Circuit Breaker** are present.

[ScTrDfFG-230216, 1, en_US]

Figure 6-51 Circuiting of the Measuring Points and Function Groups (Principle)

Make the settings in the function group **Transformer side**, using the procedure described for the two-winding transformer. Ensure that the transformer data with the measuring points have been set. The following screenshot shows the settings for the function group **Transformer side 1** (upper-voltage side).

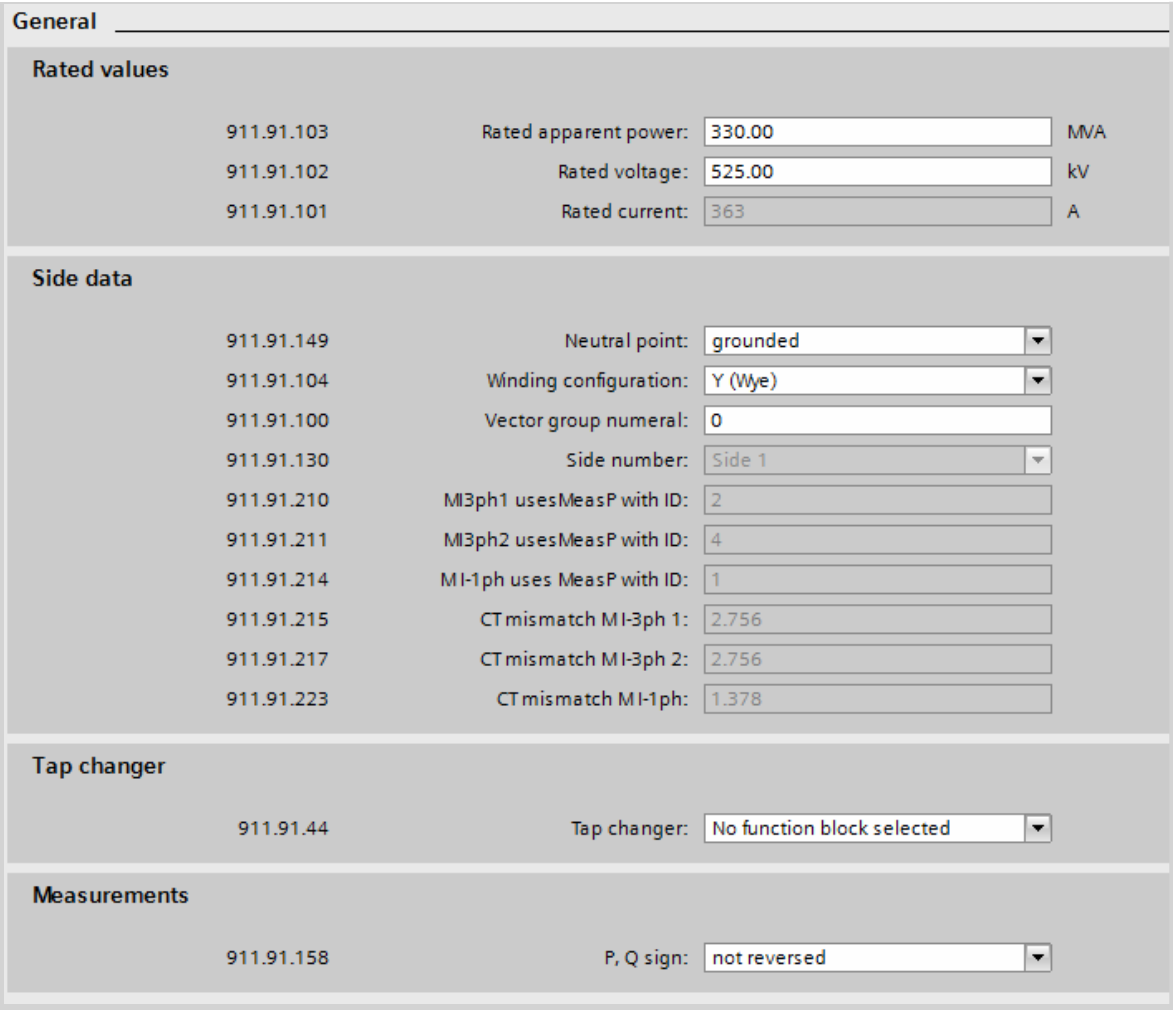

Figure 6-52 Setting the Function Group Transformer Side 1

Besides the standard data of the transformer side, additional information is stored. These are colored gray.
The following values are displayed:

- Side number of the transformer side
- IDs of the assigned measuring points
- Side-related matching factors for the current correction

NOTE

Ensure that the current correction factors refer to the side.

The rated current of the side amounts to 363 A and phase current transformers of 1000 A/1 A are present. The matching factor results in 1000 A/363 A = 2.76. For the neutral point transformer 500 A/363 A = 1.38 is the result.
Analog to the two-winding transformer, the identical setting parameters for the function group **Transformer** may be used. *Figure 6-53* to *Figure 6-55* show the appropriate setting sheet for the stage I-DIFF.

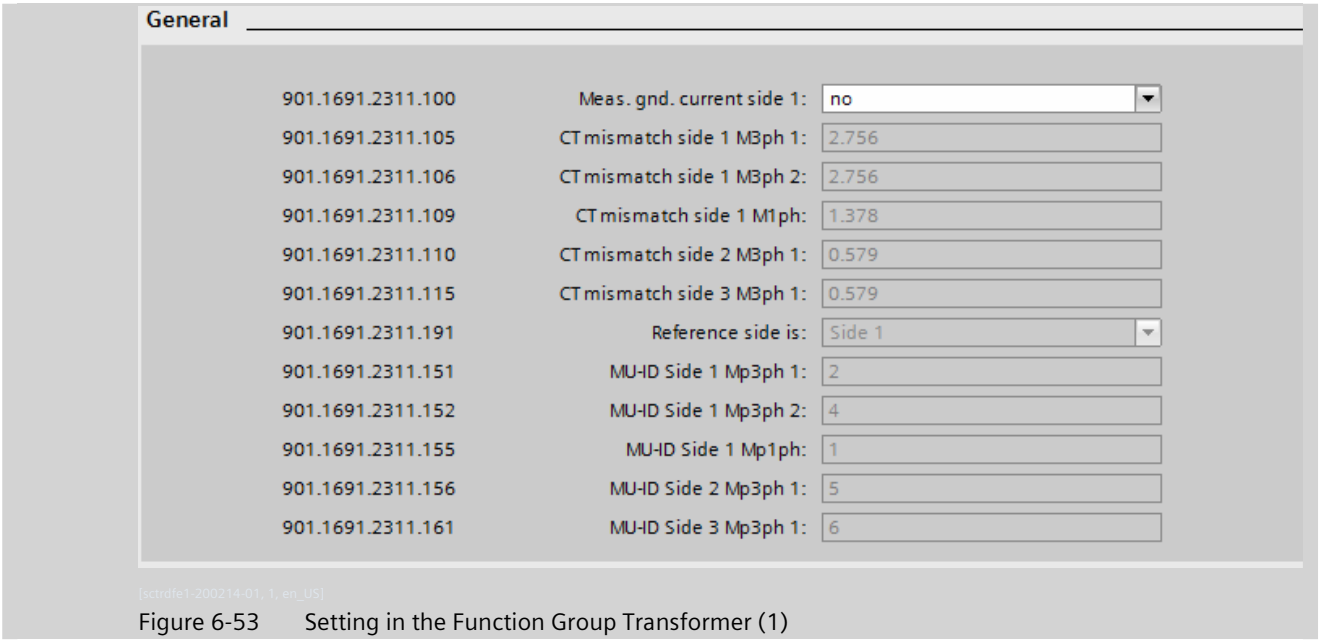

Figure 6-53 Setting in the Function Group Transformer (1)

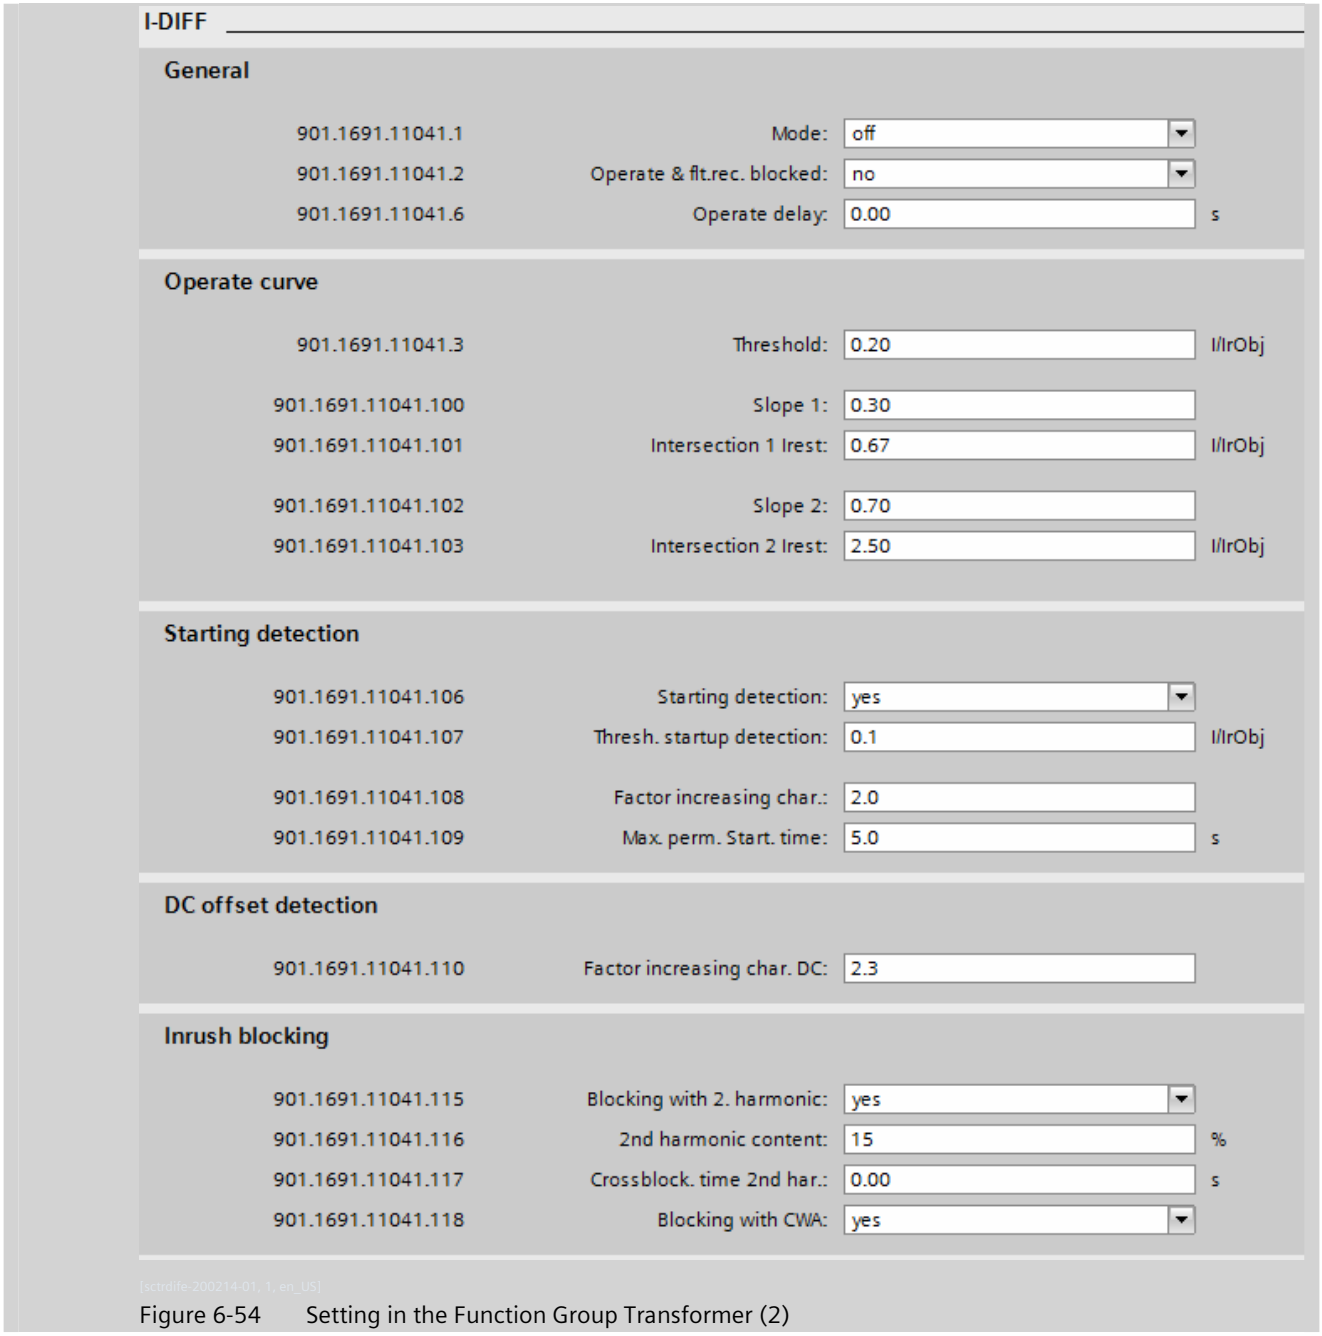

Figure 6-54 Setting in the Function Group Transformer (2)

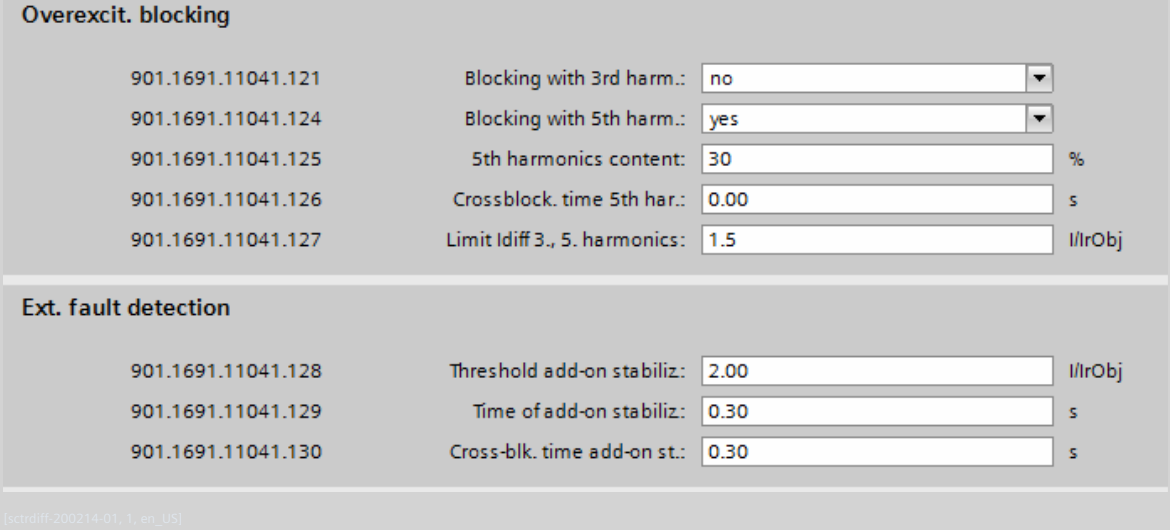

Figure 6-55 Setting in the Function Group Transformer (3)

You set how the ground current is handled on the **General** setting sheet. On transformer side (*Figure 6-52*), the neutral point of the transformer is set as grounded. In this way, the protection function knows that the zero-sequence current is to be accounted for. With the following parameter, you can set the treatment of the zero-sequence current.

Parameter: `Meas. gnd. current side 1`

- Default setting `(_:2311:100) Meas. gnd. current side 1` = ***no***

With the setting ***yes*** a zero-sequence current correction is performed. The setting ***no*** causes the elimination of the zero-sequence current. With the zero-sequence current correction, a higher sensitivity is attained in the case of 1-pole ground faults. If the neutral-point current transformer and the differential protection are connected, you must set ***yes***. Ensure beforehand that you have set the transformer data with the measuring points.

For further explanations for zero-sequence current handling, refer to *6.2.3.1 Basic Principle of Differential Protection*.

Additionally, the correction factors that the differential protection uses for current adaptation are shown under **General**. The currents are based on the transformed rated current of the reference side.

NOTE

The reference side is the side with the highest rated apparent power. If this should be several sides, the largest side rated current is selected from these.

Since side 1 is the side with the greatest power, the matching factors are identical to those in the function group **Transformer Side**. For side 2, the following adaptation results:

I_{Ref} = (330 MVA/(13.8 kV · √3)) = 13 806 A; 8000 A/13 806 A = 0.58. Since 2 measuring points with different primary rated currents are connected on side 3, 2 different matching factors result. For the 2 000 A transformer, that is 2 000 A/13 806 A = 0.14.

Protection of an Auto Transformer with Stabilizing Winding

In addition to the configuration, this example focuses on protection-relevant implementation. A transformer bank is protected with a stabilizing winding that is connected on the upper-voltage side to a breaker-and-a-half layout. *Figure 6-56* shows the system connection and the internal circuiting of the function groups. Altogether, four 3-phase voltage measuring points are processed. The auto transformer also has a 3-phase current transformer (ID4) at the neutral point. Differential protection which treats the auto transformer as a pure node can be realized additionally. You thereby attain a higher sensitivity in faults near the neutral point;

on the basis of how the transformer bank is set up, these are 1-pole ground faults. Settings instructions are given below.

NOTE

This supplemented protection function does not record the stabilizing windings!

In contrary to this, the conventional differential protection function also takes into consideration the stabilizing winding. The measuring points ID1, ID2, ID3, and ID5 are processed. The protection function is identical to the function of the standard transformer. You can read settings instructions below. The function is operational in the devices 7UT86 and 7UT87.

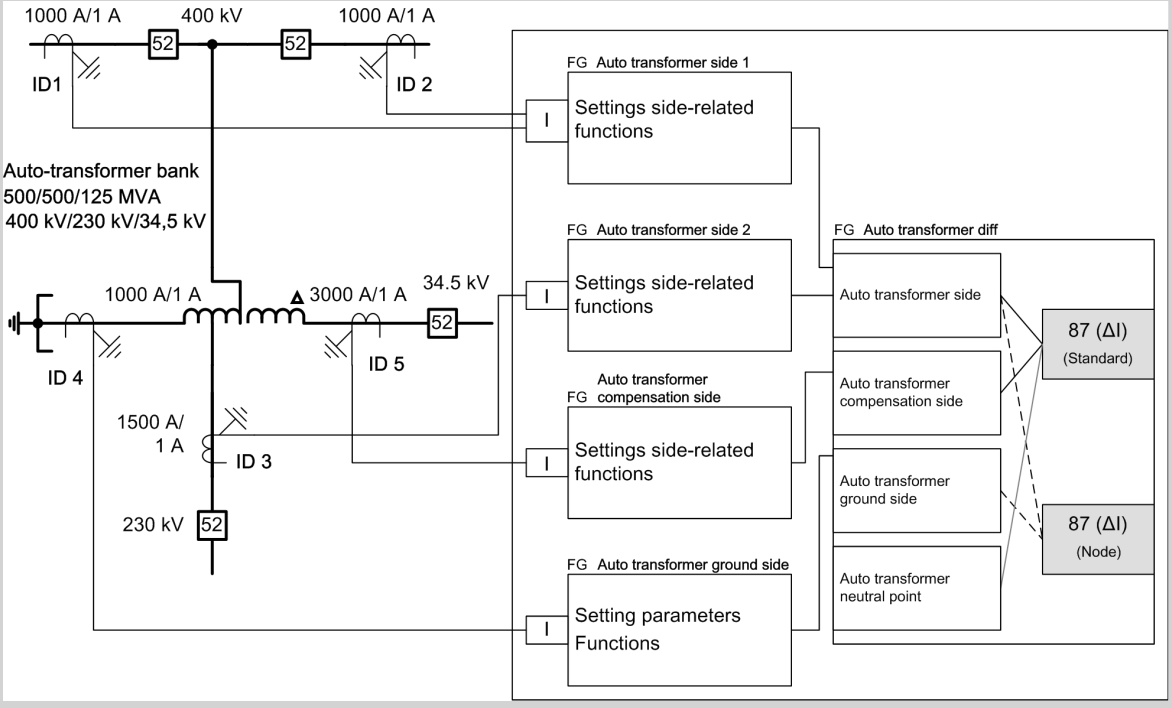

Figure 6-56 Connection of an Auto-Transformer Bank with Stabilizing Winding and Several Measuring Points

From *Figure 6-56* it can be seen that 4 function groups are required side-specifically. The connection of the measuring points to this and the side-specific settings occur. The differential protection functions are processed in the function group **Auto transformer diff**. The 2 differential protection functions run in parallel in the application. *Figure 6-56* also shows the circuiting of the function groups to the different interfaces of the function group **Auto transformer diff**. The auto-transformer/neutral point interface is used for applications where a 1-phase current transformer is present at the neutral point. In this application, connect the current transformer with a function group **Auto transformer neutral point**.

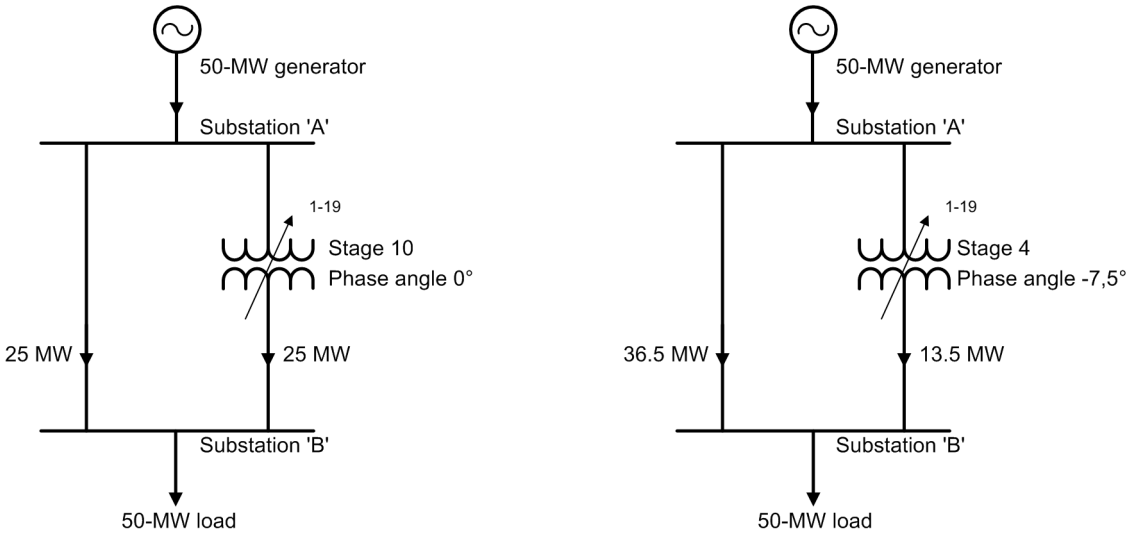
6.3 Differential Protection for Phase-Angle Regulating Transformer



6.3.1 Overview of Functions

The function **Differential protection for phase-angle regulating transformers** (PST) supplements the existing function **Transformer differential protection** (ANSI 87T). You can find the structure of the function in chapter *6.2.2 Structure of the Function*.

Phase-angle regulating transformers are used to control the reactive-power flow and active-power flow in high-voltage power systems. The objective is to achieve voltage stability, a uniform load dispatching in parallel transmission lines, and to prevent unbalanced current in the meshes of the transmission systems.

The main function of the phase-angle regulating transformer is to alter the effective phase displacement between the input and output voltage of a transmission line. This function controls the amount of current that can be transmitted by a single line.

In order to apply an introduced voltage boost to influence the active-power flow, phase-angle regulating transformers are integrated into the electrical power system in series. This situation arises, for example, if an increase in the transmission capacity is required due to the installation of an additional line. By using selective control of the angle between the current and the voltage in a line, both lines can be used up to their projected load limit.

[dw_PST_DIFF_01, 1, en_US]

Figure 6-57 Power Distribution between 2 Lines when Using Different Phase-Angle Values

The control of the power flow or the energy-flow direction at the tie-point of 2 electrical power systems is another typical application.

To parameterize the Transformer differential protection for the phase-angle regulating transformer application, add a corresponding function block from the DIGSI 5 library to the function group **Transf.Diff** .

[sc_PST_DIFF_08, 1, en_US]

Figure 6-58 Instances of the Phase-Angle Regulating Transformer

There are 3 function blocks available for the adaptation to the various types of phase-angle regulating transformers:

Sing.-core PST — Phase-angle regulating transformers of the single-core transformer type

These transformers contain all necessary windings on a 3-phase transformer core. When the angle is adjusted, the absolute value of the voltage does not change linearly. To compensate for the change in the absolute value of the voltage, an additional voltage controller (transformer with in-phase regulation) is usually required.

Spec. transf. — Special transformers

Special transformers are transformers with a fixed interconnection of the windings. This will result in a vector-group number that is not an integer value (for example, SG 0.25 = 7.5°). They can be used, for instance, as inverter transformers. When the rectified currents from several windings are joined with shifted phase displacements, the result is reduced ripple of the direct current.

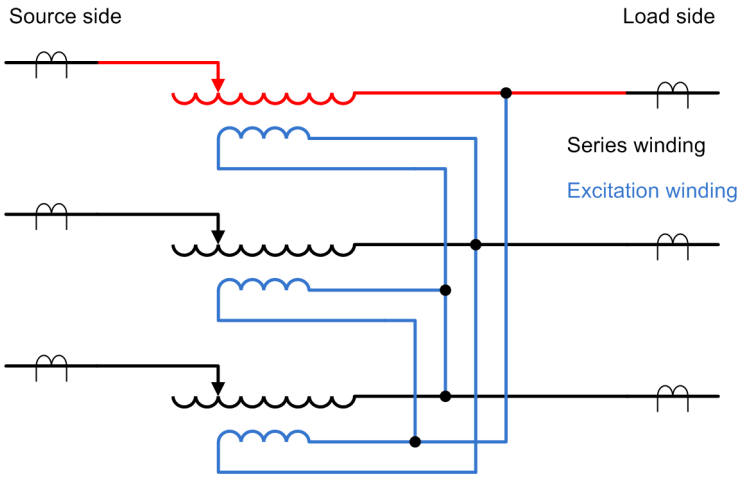
Two-core PST — Phase-angle regulating transformers of the two-core transformer type

These transformers connect the phase-shifted voltage via an adjustable shunt transformer. Therefore, the tap changer does not carry the load current and is suitable for higher power levels. The absolute value of the voltage ratio does not change with the angle.

The number of function blocks of the **phase-angle regulating transformer** is limited as follows in the device types:

Device	Sing.-core PST	Spec. transf.	Two-core PST
7UT82	1	1	0
7UT85	1	1	0
7UT86	1	1	1
7UT87	3	3	3

The transformer differential protection automatically considers the resulting change in the absolute value and change in angle. Therefore, the changes do not need to be taken into consideration in the pickup-characteristic settings for the differential protection.



The switch makes it possible to change between negative and positive no-load phase displacement even under full load. In this case, blocking of the stage I-DIFF of the differential protection is adjustable.

6.3.2 Phase-Angle Regulating Transformers of the Single-Core PST Type

The phase-angle regulating transformer of the type single-core PST consists of a 3-phase series winding and a 3-phase excitation winding. The excitation winding uses a delta connection and induces the voltage ΔV in the series winding. The excitation winding is installed on the same transformer core.

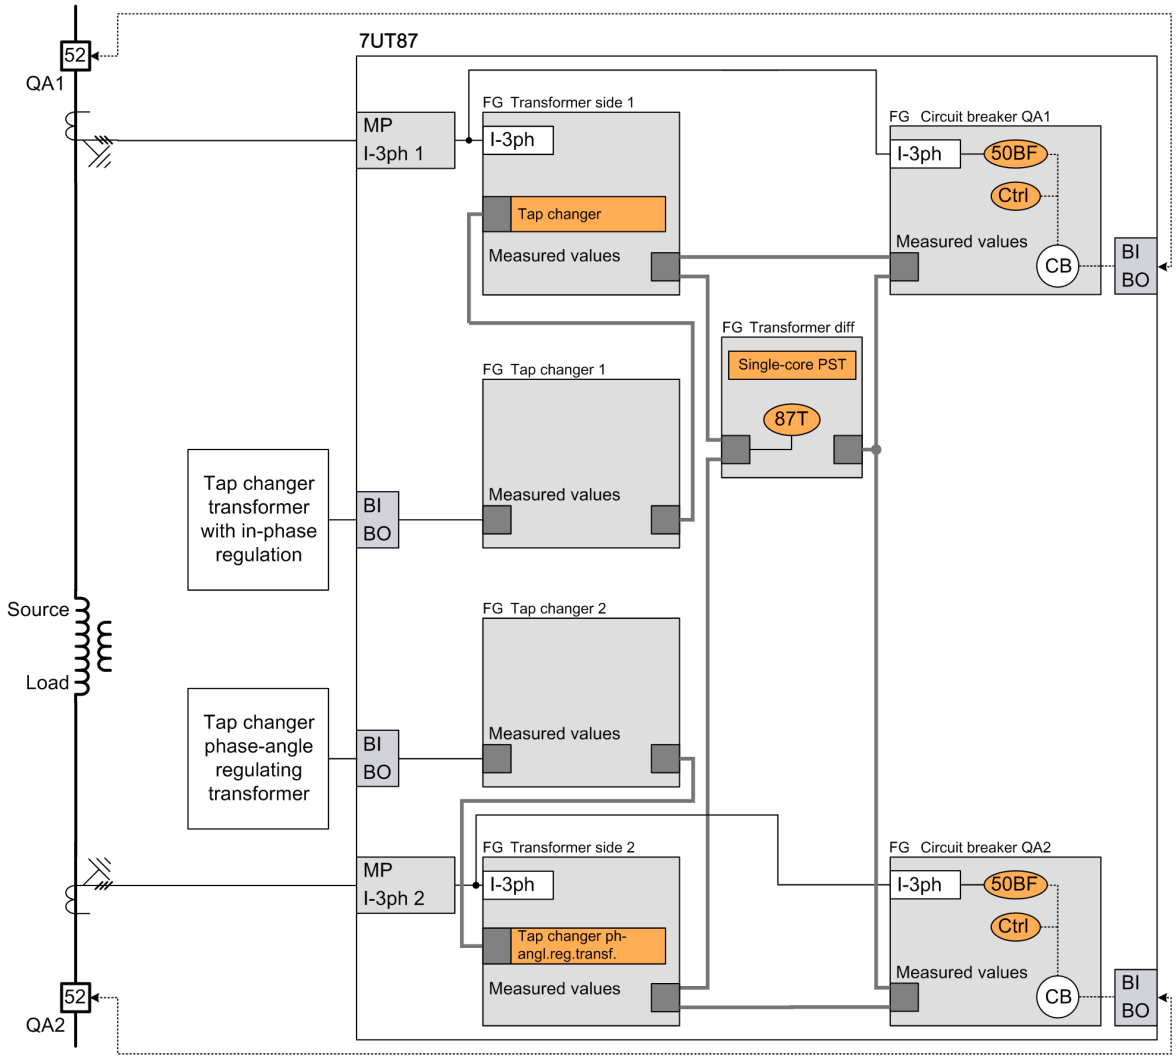
You can use one or several tap changers to change the phase displacement and the output voltage of the transformer.

The differential protection of this transformer requires information regarding the position of the tap changer, information about the no-load voltage, and the angle of the respective stage. The following figure shows the corresponding connection of an asymmetrical single-core transformer scheme, Single-core PST.

[dw_PST_DIFF_02, 1, en_US]

Figure 6-59 Asymmetrical Single-Core Transformer Scheme, Single-Core PST

Configure the differential protection for the phase-angle regulating transformers by adding the **Sing.-core PST** function block to the **Transformer diff.** function.

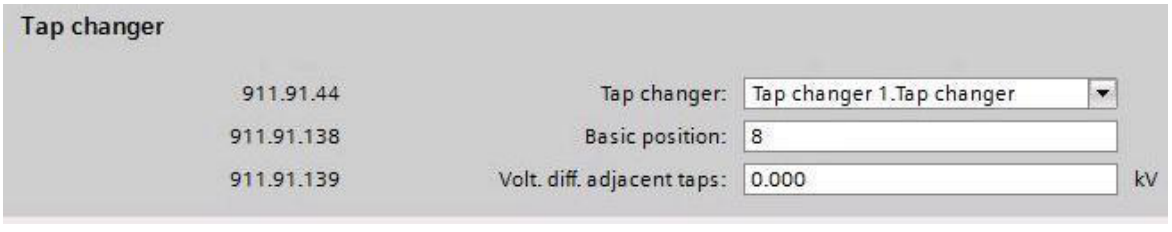


[sc_PST_DIFF_07, 1, en_US]

Figure 6-60 Instance of the Single-Core PST Function Block

After instantiation of the **Sing.-core PST** function block, additional required parameters are displayed in the **Transformer side** function group and in the **Transformer diff.** function group.

The tap changers for the phase-angle regulation and the in-phase regulation are assigned in the transformer side. The phase-angle regulating transformer tap changer detects the voltage and the angle for each tap-changer position.



If using asymmetrical phase-angle regulating transformers, changing the phase angle also affects the voltage. Therefore, a second tap changer may be required in order to compensate for the changed absolute value of the voltage. This additional tap changer collects the information required to correct the voltage of the transformer with in-phase regulation.

[dw_PST_DIFF_03, 2, en_US]

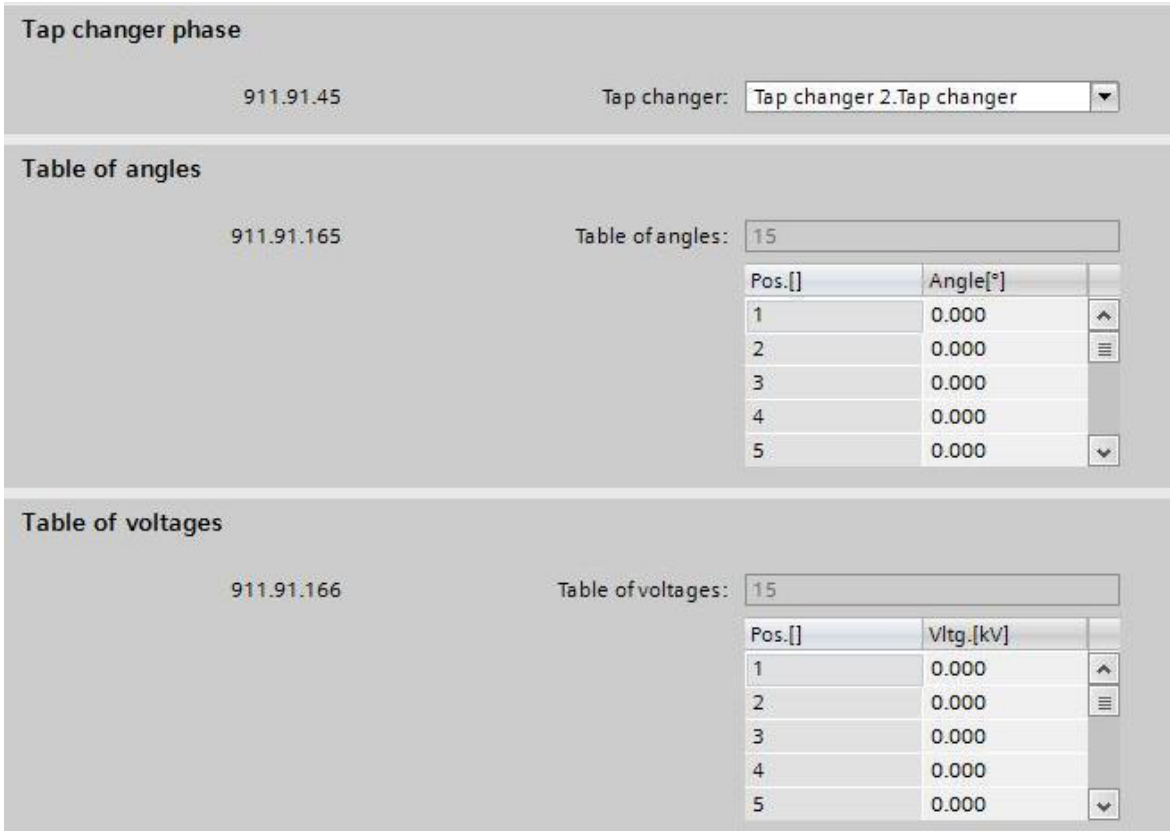


Figure 6-61 Logic of the Single-Core PST Function Block

The *Figure 6-62* and the *Figure 6-63* show the settings for adaptation to the tap changers of the transformer sides 1 and 2. Additional settings of the tap changer are described in chapter *7.8 Tap Changers*.

[sc_PST_Diff_20_b, 1, en_US]

Figure 6-62 Setting of the Tap Changer Transformer Side 1

[sc_PST_Diff_20_a, 1, en_US]

Figure 6-63 Setting of the Tap Changer for Transformer Side 2

You can use the set table values to adjust the differential protection to the control of the transformer. This prevents additional differential currents that are caused by different tap-changer positions.

Set the software filtering time for the binary inputs of the tap changer. This software filtering time avoids the fact that the transient states in the binary image of the tap-changer position lead to an incorrect adaptation of the differential protection during the transition from one stage to the next. When you set the software filtering time, you must take into consideration the runtime of the tap changer. If the motor-driven contact of the tap changer is also detected, you can select a small value for the software filtering time.

In case of a failure or a loss of tap-changer information, for example, in case of an inadmissible combination of values of the tap-changer position, the I-DIFF stage of the differential protection is blocked. The I-DIFF fast stage remains active.

If the phase-angle regulating transformer is equipped with a tap changer for the in-phase regulation in addition to the phase-angle regulation or quadrature regulation, you can consider both tap changers in the differential protection.

AR Switch

The Advanced-Retard switch (AR switch) toggles the direction of the no-load phase displacement without interruption of the load current.

With the parameter **`Use AR switch`** in the **`Sing.-core PST`** function block, you determine how the differential protection responds when changing the AR switch.

In order to prevent an overfunction of the transformer differential protection, blocking of the transformer differential protection is adjustable. The blocking must be selected for the time that is required by the AR switch to reach a new position. Blocking applies only to the I-DIFF stage. The I-DIFF fast stage is not blocked.

6.3.3 Application and Setting Notes for the Single-Core PST

The following text describes the settings required for the application of the differential protection for the phase-angle regulating transformer of the single-core transformer type. You can find the general setting information for the transformer differential protection in *6.2.4 Application and Setting Notes*.

Transformer Side Function Group

After the instantiation of the **Single-core PST** function block, additional parameters for the setting of the tap changers are displayed.

NOTE

Ensure that the correct transformer data are set at the measuring points.

NOTE

Consider that only one tap changer can be parameterized on one transformer side.

Parameters for the Tap Changer Transformer with In-Phase Regulation

In the **Transformer side** function group, to set the **tap changer**, enter the following settings for the **transformer with in-phase regulation** tap changer.

Parameter: `Tap changer`

- Default setting **`(_:91:44) Tap changer`** = ***none***

With the **`Tap changer`** parameter, you assign a tap changer to the transformer side. This tap changer is used to detect the in-phase regulation. If a tap changer is assigned, other parameters also become visible. You can use a separate tap changer or the tap changer in the voltage controller.

Parameter: `Basic position`

- Default setting **`(_:91:138) Basic position`** = ***8***

With the **`Basic position`** parameter, you determine the position of the tap changer for the in-phase regulation at which the transformer operates at the rated voltage.

Parameter: `Volt. diff. adjacent taps`

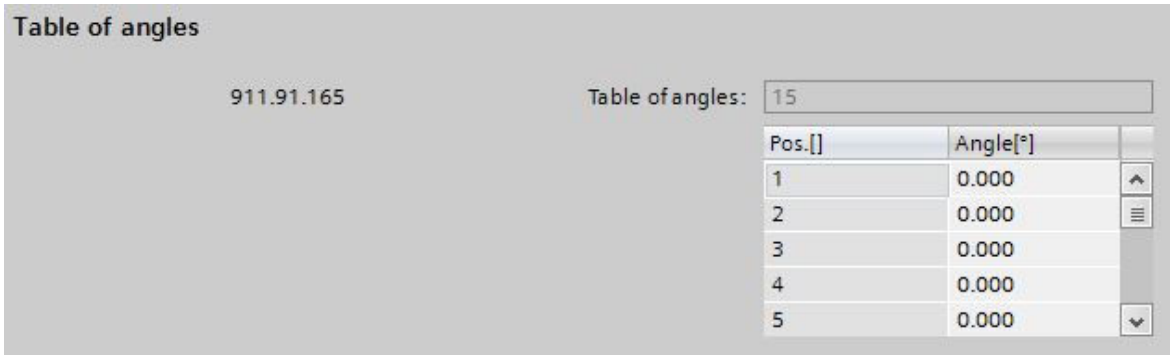
- Default setting **`(_:91:139) Volt. diff. adjacent taps`** = ***0.000 kV***

With the **`Volt. diff. adjacent taps`** parameter, you set the voltage difference of a stage under no-load conditions.

Parameters for the Phase-Angle Regulating Transformer Tap Changer

In the **Transformer side** function group, to set the **tap changer**, enter the following settings for the **phase-angle regulating transformer** tap changer.

Parameter: `Tap changer`

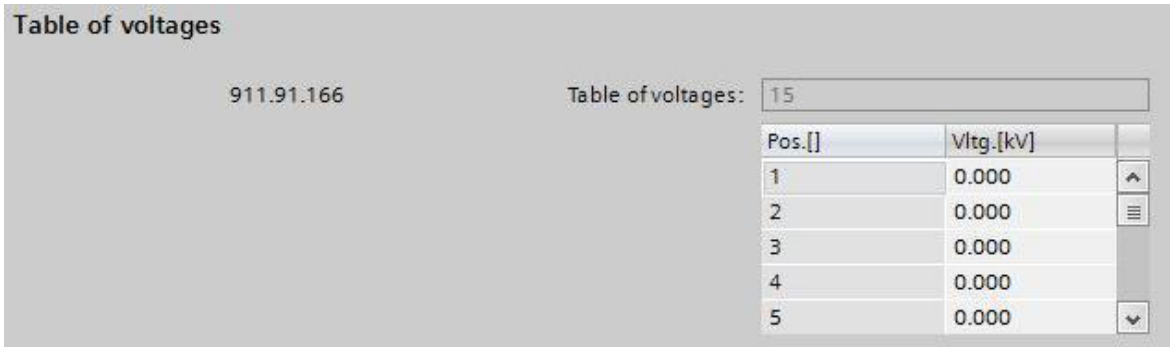


- Default setting **`(_:91:45) Tap changer`** = ***none***

With the **`Tap changer`** parameter, you assign a tap changer to the transformer side. This tap changer is used to detect the phase-angle regulation.

NOTE

You must parameterize this tap changer when using the application phase-angle regulating transformer of the single-core PST type.



Parameter: `Table of Angles`

[sc_PST_DIFF_01, 1, en_US]

Figure 6-64 Table Display of the Angles in DIGSI

Parameter: `Table of Voltages`

[sc_PST_DIFF_02, 1, en_US]

Figure 6-65 Table Display of the Voltages in DIGSI

Function Group Transformer Diff.

In the **Transformer. diff.** function group and in the **`Sing.-core PST`** function block, make the following settings.

Parameter: `Use AR switch`

- Default setting **`(_:101) Use AR switch`** = ***`no`***

With the **`Use AR switch`** parameter, you define whether the differential protection considers the switchover of the AR switch. When using the setting ***`Block function`***, the parameter **`(_:102) Blocking time ARS`** is visible.

Parameter: `Blocking time ARS`

- Default setting **`(_:102) Blocking time ARS`** = ***`12.00 s`***

With the **`Blocking time ARS`** parameter, you determine how long the I-DIFF stage of the differential protection will be blocked during the switchover of the AR switch. This blocking function is necessary in order to avoid an overfunction of the differential protection. In order for the AR switch to reach its new position safely, you must select a sufficient blocking time.

NOTE

If you have assigned a transformer neutral point to a grounded side with a user-defined vector-group number, Siemens recommends not to use the measured 1-phase current of the neutral point in the differential-protection calculation.

Example:

Transformer example: Single-Core PST 90°

Information provided by the manufacturer:

Type:	Three-legged core with stabilizing winding. The stabilizing winding cannot be accessed from the outside.
Power	200 MVA
Rated voltages:	110 kV/110 kV ±10° (± 13 stages)
Frequency:	50 Hz
Phase angle:	No-load state: ±10° (position 1 = -10°, position 14 = 0°, position 27 = +10°) Full load: position 1 = -13°, position 14 = 2.4°, position 27 = +7°)

Stage	No-Load Phase Angle [°]	No-Load Output Voltage [kV]
1	-10.00°	111.70 kV
2	-9.24°	111.45 kV
3	-8.49°	111.22 kV
4	-7.72°	111.01 kV
5	-6.96°	110.82 kV
6	-6.19°	110.65 kV
7	-5.42°	110.49 kV
8	-4.65°	110.36 kV
9	-3.88°	110.25 kV
10	-3.11°	110.16 kV
11	-2.33°	110.09 kV
12	-1.55°	110.04 kV
13	-0.78°	110.01 kV
14	**0.00°**	**110.00 kV**
15	0.78°	110.01 kV
16	1.55°	110.04 kV
17	2.33°	110.09 kV
18	3.11°	110.16 kV
19	3.88°	110.25 kV
20	4.65°	110.36 kV
21	5.42°	110.49 kV
22	6.19°	110.65 kV
23	6.96°	110.82 kV
24	7.72°	111.01 kV
25	8.49°	111.22 kV
26	9.24°	111.45 kV
27	10.00°	111.70 kV

Parameterization of the function block:

- Set the parameters for a 2-sided transformer (for example with the application template: two-winding transformer, basic).
- Set the parameters for the tap changer.
- Set the parameters for the **Sing.-core PST** function block in the current **Transformer diff.** function group.

Tap-changer settings:

- Set the required motor monitoring time of the motor runtime.
  The setting for the highest tap-changer position is not required for the quadrature regulation tap changer. In this case, the tap changer is not considered.
- You set the additional settings for the tap changer in the Information routing found in the Properties dialog for the tap-changer position. To adjust the settings, follow the information of the manufacturer.
  These settings include:
  - Offset of the tap display: 0
  - Number of tap positions: 27
  - Tap coding type: Binary
  - Motor run signal: Activate the detection of the motor run signal if this signal is available.
  - Software filtering time: Set the software filtering time on the basis of the runtime needed by the tap changer to change the position from one stage to the adjacent stage.
- Route the position of the tap changer to the corresponding binary inputs.

Settings for the transformer sides:

- Set the rated data of transformer side 1 according to the documentation of the manufacturer:
  - Rated apparent power: 200 MVA
  - Rated voltage: 110 kV
  - Vector-group number: 0
- Set the rated data of transformer side 2 according to the documentation of the manufacturer:
  - Rated apparent power: 200 MVA
  - Rated voltage: 110 kV
- Set the parameters of the **Tap changer** as a **Tap changer phase**. Subsequently, the tables for the position, angles, and voltages settings become visible.
- Set the angles and the voltages of the individual stages of the tap changer according to the table in the documentation of the manufacturer.

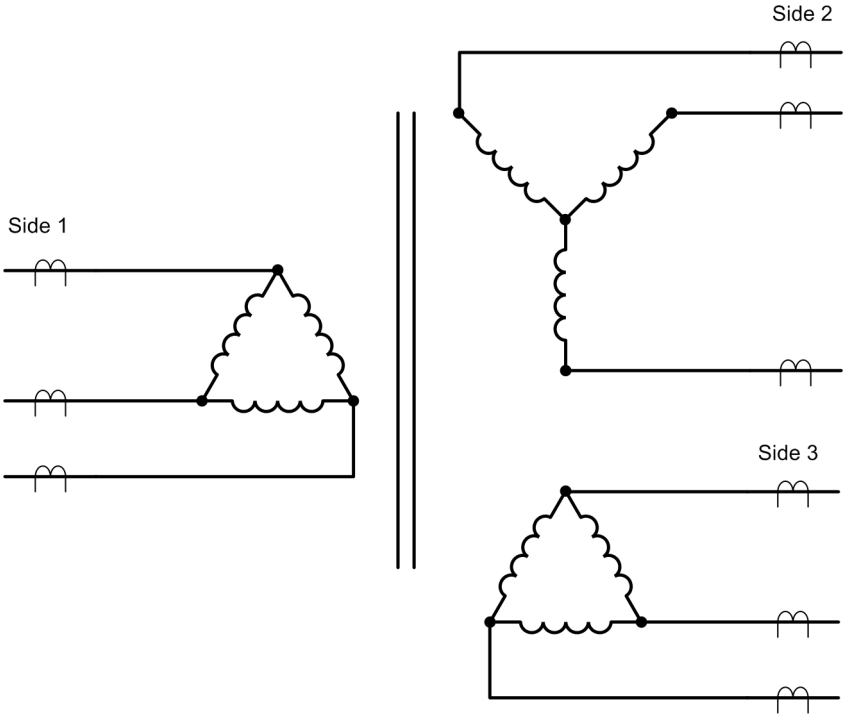
Settings for the transformer differential protection:

- Set the **Sing.-core PST** function block:
  - **Use AR switch**: ***no***

    For phase-angle regulating transformers of the single-core type, this setting can be selected frequently, since switching can occur without interruption at 0°.

6.3.4 Settings

Addr.	Parameter	C	Setting Options	Default Setting
Tap changer				
_:91:138	General:Basic position		-128 to 127	8



Addr.	Parameter	C	Setting Options	Default Setting
_:91:139	General:Volt. diff. adjacent taps		0.000 kV to 800.000 kV	0.000 kV
_:91:44	General:Tap changer		Setting options depend on configuration	
_:91:45	General:Tap changer		Setting options depend on configuration	
Sing.-core PST				
_:101	Sing.-core PST:Use AR switch		• no • Block function	no
_:102	Sing.-core PST:Blocking time ARS		0.00 s to 60.00 s	12.00 s

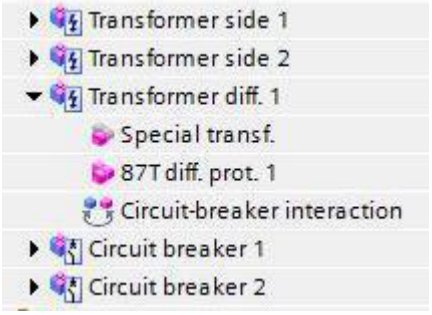
No.	Information	Data Class (Type)	Type
General			
_:90	Sing.-core PST:>AR switch	DPS	I

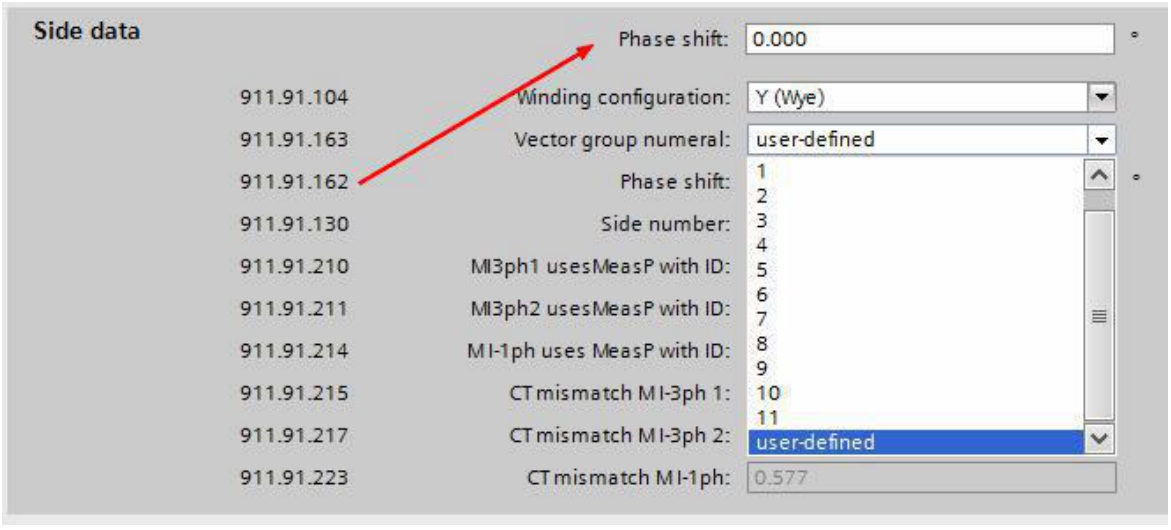
6.3.6 Phase-Angle Regulating Transformers of the Type Special Transformer



The term special transformer refers to industrial-type transformers. Their windings are interconnected in such a way that a phase displacement that is different to 30°, for example ±7.5°, is possible. Special transformers can be used, for example, to supply power to electrical drives, frequency converters, and rectifiers. When joining the rectified currents from several windings with shifted phase displacements, the result is reduced ripple of the direct current.

[dw_PST_DIFF_04, 1, en_US]

Figure 6-66 Basic Scheme of a Special Transformer



Configure the differential protection for special transformers by adding the **Transformer diff.** function to the **Special transformer** function block.

[sc_PST_DIFF_03, 1, en_US]

Figure 6-67 Instance of the Special Transformer Function Block

After instantiation of the **Special transformer** function block in the **Transformer diff.** function group, the setting range of the parameter **(_:91:163) Vector group numeral** will be extended by the ***user-defined*** setting in the assigned **Transformer side** function group. If you select this setting option, the additional parameter **(_:91:162) Phase shift** is visible. You can set this parameter in a range of values from -180.000° to +180.000°. The **Special transformer** function block has no settings of its own.

[sctrstst-180215-01, 1, en_US]

Figure 6-68 Settings for the Transformer Side

You can combine the special transformer and a transformer with in-phase regulation for adaptive adjustment of the transformer differential protection.

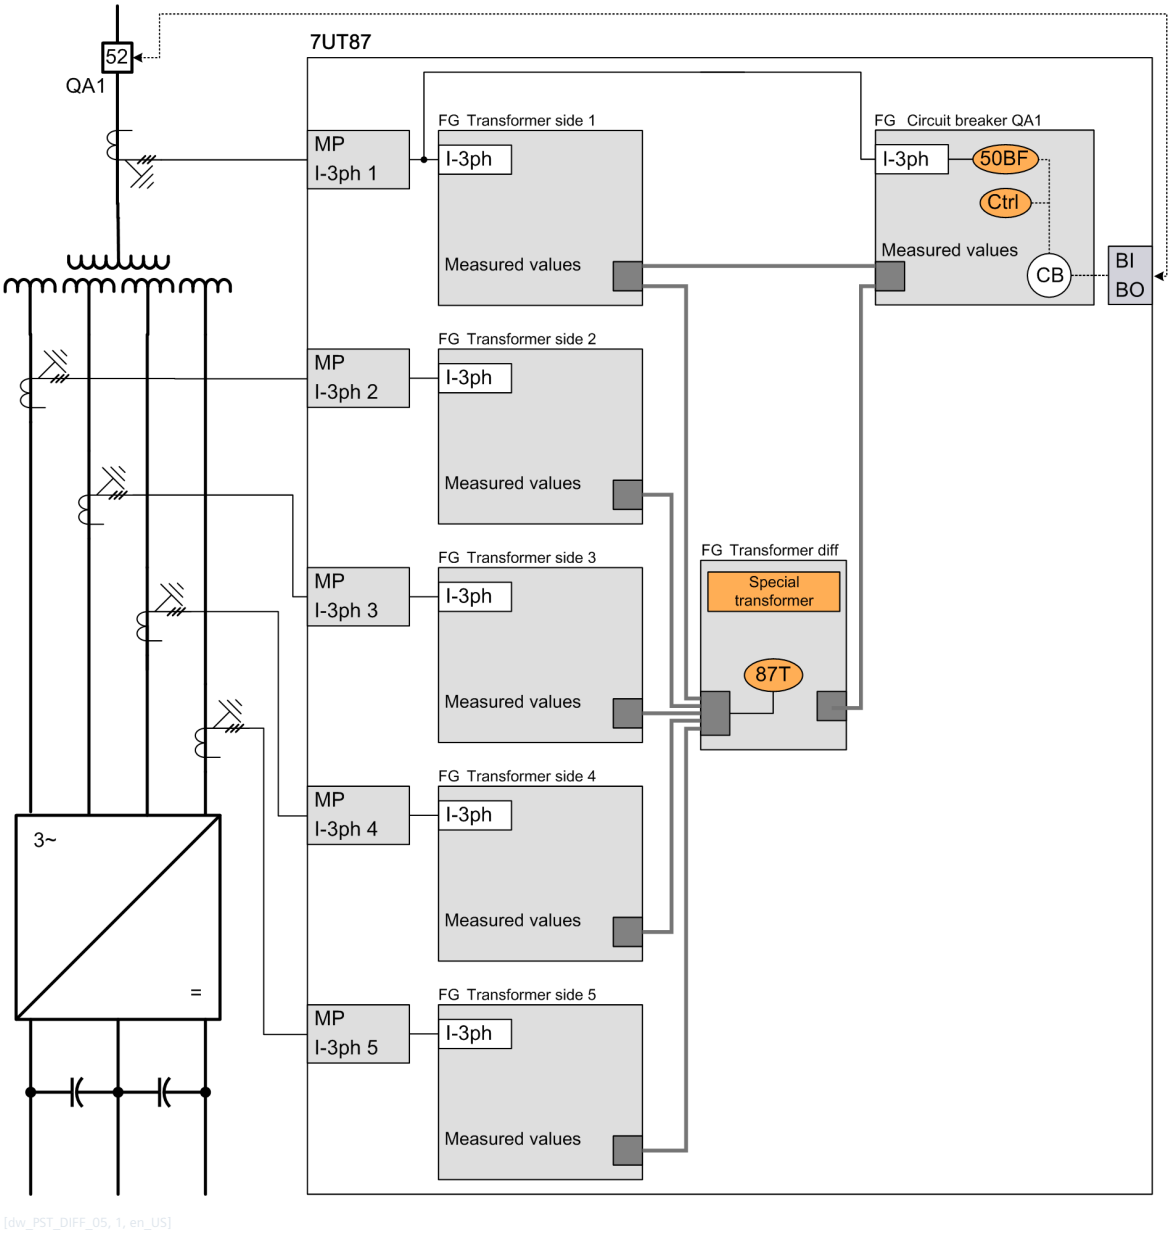


Figure 6-69 Logic of the Special Transformer Function Block

6.3.7 Application and Setting Notes for the Special Transformer

The following text describes the settings required for the application of the differential protection for the phase-angle regulating transformer of the special transformer type. You can find the general setting information for the transformer differential protection in chapter *6.2.4 Application and Setting Notes*.

Parameter: (_:91:163) Vector group numeral

- Default setting **Vector group numeral** = *0*

With the **Vector group numeral** parameter, you set the vector-group number of the transformer side. To use special transformers, select the ***user-defined*** setting. If you select this setting, the parameter **(_:91:162) Phase shift** is displayed.

Parameter: (_:91:162) Phase shift

- Default setting **Phase shift** = *0*

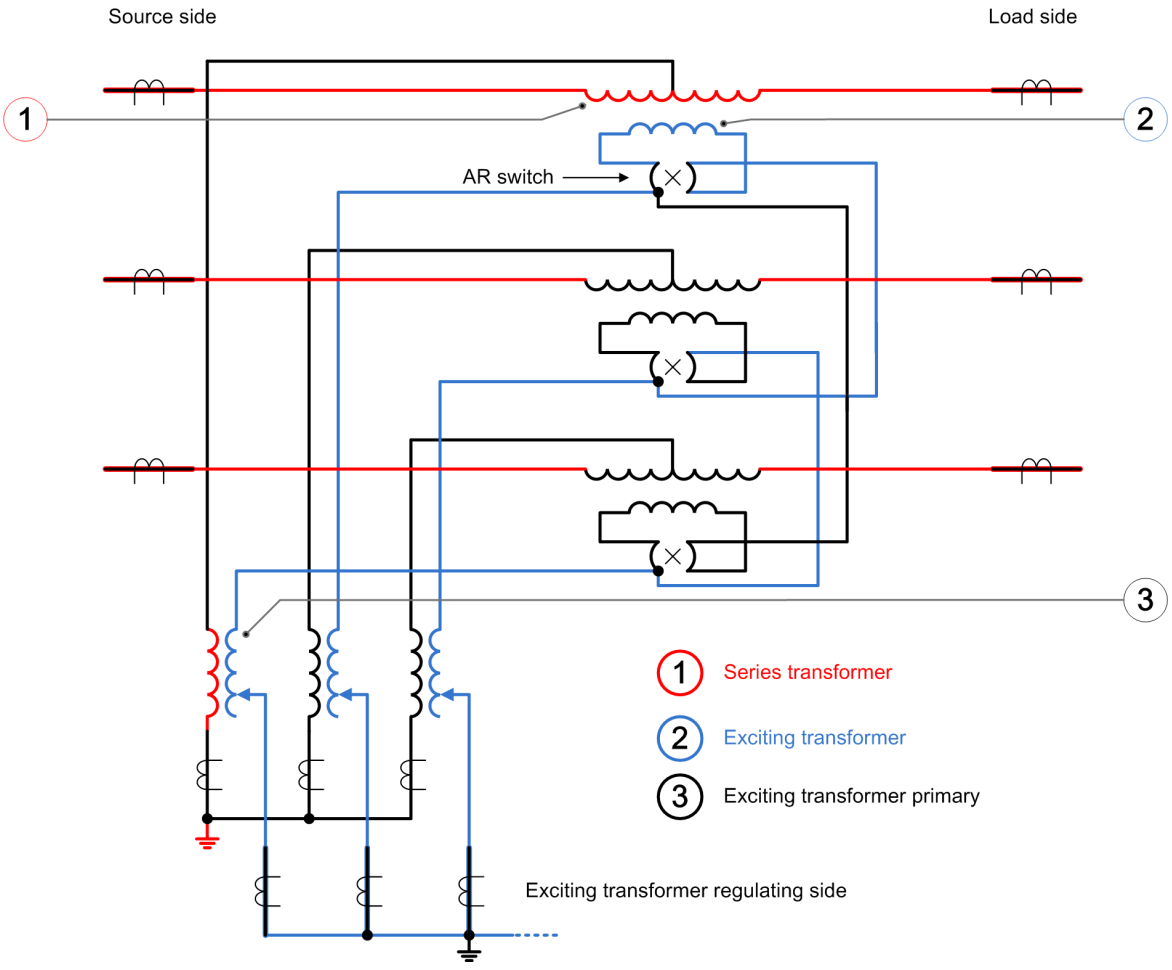
With the **Phase shift** parameter, you set the phase displacement of the transformer side

NOTE

If you have assigned a transformer neutral point to a grounded side with a user-defined vector-group number, Siemens recommends not to use the measured 1-phase current of the neutral point in the differential protection calculation.

6.3.8 Settings

Addr.	Parameter	C	Setting Options	Default Setting
_:91:104	General:Winding configuration		• Y (Wye) • D (Delta) • Z (Zig-Zag)	Y (Wye)
_:91:163	General:Vector group numeral		• 0 • 1 • 2 • 3 • 4 • 5 • 6 • 7 • 8 • 9 • 10 • 11 • user-defined	0
_:91:162	General:Phase shift		-180.000 ° to 180.000 °	0.000 °

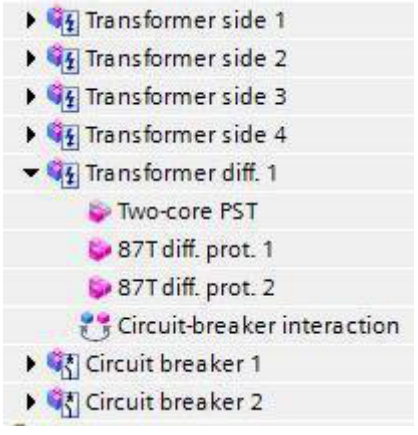


6.3.9 Phase-Angle Regulating Transformers of the Two-Core PST Type

The phase-angle regulating transformer of the two-core transformer type (Two-Core PST) consists of a 3-phase series transformer and a 3-phase exciting transformer. The voltage generated by the exciting transformer can be set as a series voltage ΔV and can be coupled to the delta winding of the series transformer. Series and exciting transformers can be integrated in a single tank or in separate tanks.

A protection system with 2 differential protection functions has established itself for the differential protection of this transformer (see IEC 62032, IEEE Std C57.135 and IEEE C37.245):

- Primary differential protection (ANSI 87P)
- Secondary differential protection (ANSI 87S)

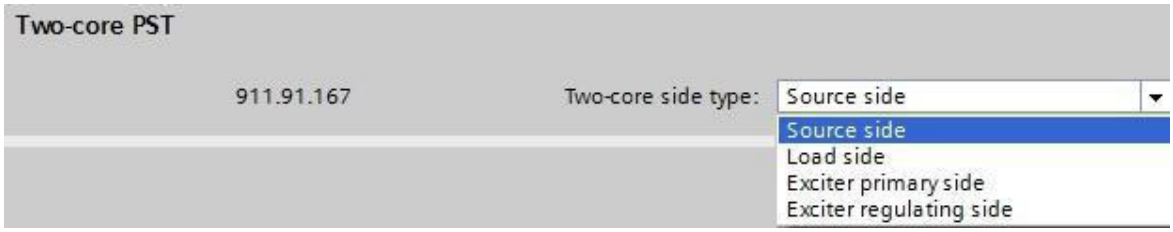


For this protection system, the connections of 4 current measuring points are required. Connect those points with 4 transformer sides.

[dw_PST_DIFF_06, 2, en_US]

Figure 6-70 Symmetrical Two-Core Transformer Scheme, Two-Core PST

Configure the differential protection for the phase-angle regulating transformer by adding the function group **Two-Core PST** function block to the **Transf. diff.** function group.

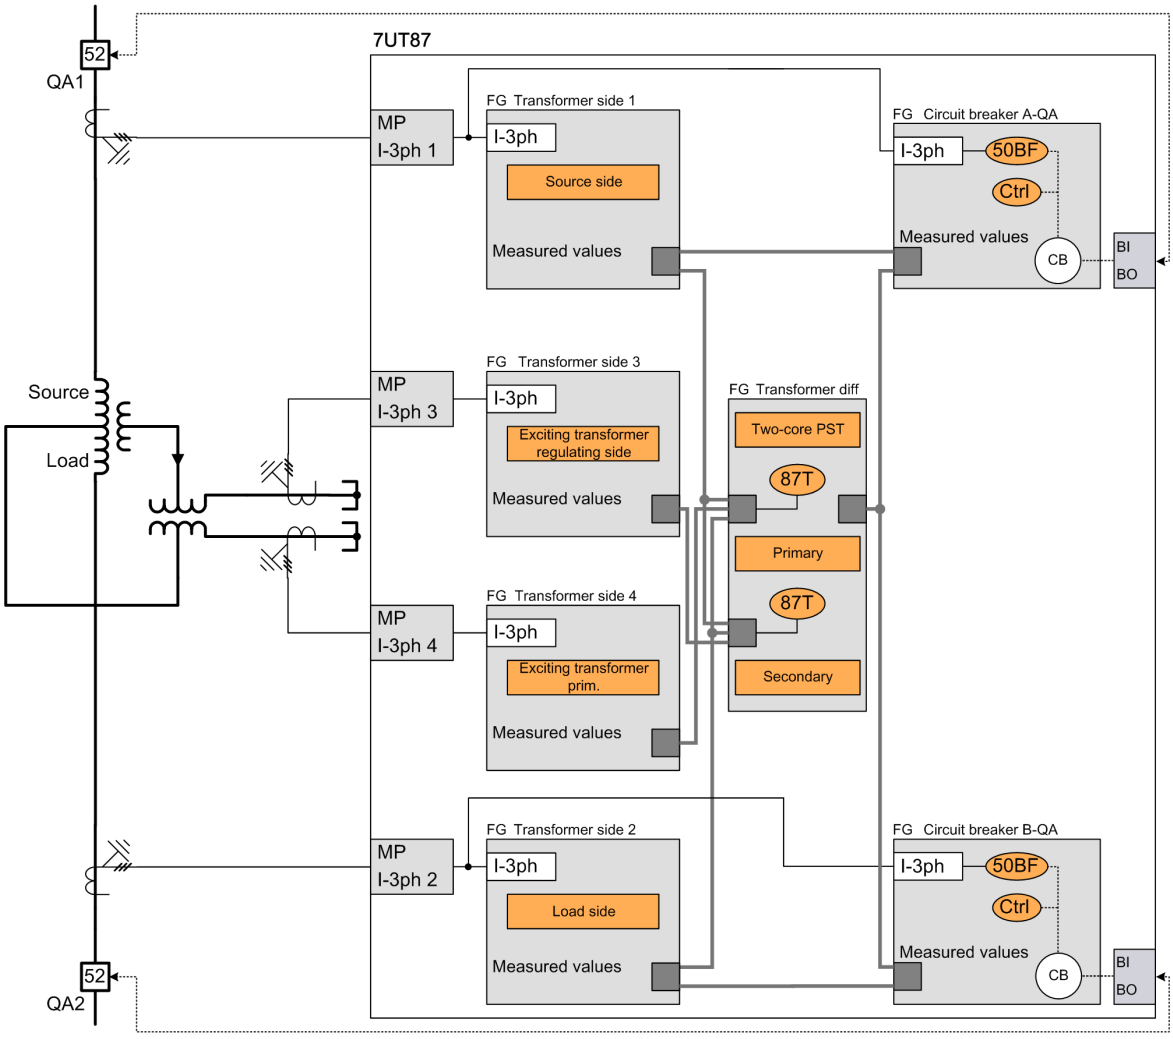


[sc_PST_DIFF_12, 1, en_US]

Figure 6-71 Instance of the Two-Core PST Function Block

After instantiation of the function block **Two-core PST**, additional parameters are displayed on the transformer sides. With the parameter **`(_:91:167) Two-core side type`**, you specify the type of the side.

All 4 sides of the phase-angle regulating transformer must be of different types. This is tested when setting the transformer sides.



[sc_PST_DIFF_11, 1, en_US]

Figure 6-72 Setting the Transformer Sides

NOTE

Parameterization of the tap changer is not required for the application Two-core PST phase-angle regulating transformer application. Therefore, you must set the parameter **`Tap changer`** to ***No***.

[dw_PST_DIFF_07, 3, en_US]

Figure 6-73 Logic of the Function Block Two-Core PST

Advanced-Retard Switch

The Advanced-Retard switch (AR switch) toggles the direction of the no-load phase displacement without interruption of the load current.

With the parameter **Use AR switch** in the function block **Two-core PST**, you specify how the differential protection responds when changing the Advanced-Retard switch.

In order to prevent an overfunction of the transformer differential protection, blocking of the transformer differential protection is adjustable. The blocking must be selected for the time that is required by the AR switch to reach a new position. Blocking applies only to the stage **I-DIFF**. The stage **I-DIFF fast** is not blocked.

In addition to blocking the differential protection functions, a further switchover of the vector group number (0 and 6) can be required. This is necessary when positioning the switch in the triangle of the delta winding, since the direction of the electric current in the measuring points of the excitation winding (regulating side) is inverted.

6.3.10 Application and Setting Notes for the Two-Core PST

The following text describes the settings required for the application of the differential protection for the phase-angle regulating transformer of the two-core transformer type. You can find the general setting information for the transformer differential protection in chapter *6.2.4 Application and Setting Notes*.

You cannot combine the Two-Core PST with a transformer with in-phase regulation for adaptive adjustment of the transformer differential protection.

Transformer Side Function Group

After the instantiation of **Two-core PST** function block, additional parameters for the setting of the tap changers are displayed.

Go to the **Transformer side** function group and make the following settings.

NOTE

Ensure that the correct transformer data are set at the measuring points.

Parameter: Two-core side type

- Default setting **(_:91:167) Two-core side type** = ***Source side***

With the **Two-core side type** parameter, you set the following side types: ***Source side***, ***Load side***, ***Exciter primary side*** and ***Exciter regulating side*** .

To use the phase-angle regulating transformer of the two-core transformer type with both protection functions ***87T primary prot*** and ***87T secondary prot***, all 4 sides are required.

The tap-changer position information is not required for the protection scheme.

NOTE

The setting of the neutral-point grounding is not available, since it must not be changed in this protection scheme (see IEC 62032 / IEEE Std C57.135). The appropriate values are used in the device in accordance with the type of side.

The settings of both parameters **rated apparent power** and **rated voltage** on the exciting-unit side do not affect the differential protection. In order for them to function correctly, they must be derived in the device from the information received from the other sides. However, these settings may be required for additional but only side-relevant protection functions.

Parameter: (_:91:163) Vector group numeral

- Default setting **Vector group numeral** = ***0***

The **Vector group numeral** parameter is only visible and required for the regulating side of the exciting transformer. This setting is applicable for the forward direction of the switch when setting the parameter **Use AR switch** = ***Block fct. & switch VG***. If another setting is select, the parameter applies to both switch positions.

Function Group Transformer Diff.

A phase-angle regulating transformer of the Two-Core PST type can only be protected completely by using 2 differential protection functions. To do this, instantiate the **Transformer diff.** function twice in the **Transformer diff.** function group.

Make the following settings in the **Transformer diff.** function of the **Transformer diff.** function group:

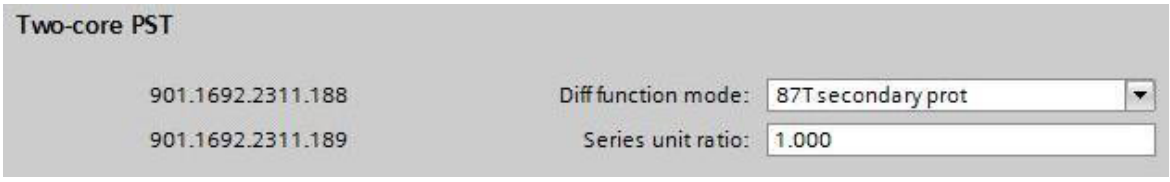
Parameter: Diff function mode

- Default setting **(_:2311:188) Diff function mode** = ***87T primary prot***

With the parameter **Diff function mode**, you assign an operating mode to the differential protection.

Parameter Value	Description
87T primary prot	In the primary protection operating mode, this protection function uses primarily the source side, load side, and the exciting-transformer primary side. The regulating side of the exciting transformer is ignored.
87T secondary prot	In the secondary protection operating mode, this protection function preferably uses the source side, the load side, and the regulating side of the exciting transformer. The primary side of the exciting transformer is ignored.

Parameter: Series unit ratio



- Default setting **(_:2311:189) Series unit ratio** = ***1.000***

With the parameter **Series unit ratio**, you set the winding number ratio of the series transformer:

$$K = \frac{n_{Source} + n_{Load}}{n_{Delta}}$$

[fo_PST_DIFF_01, 1, en_US]

You can also generate this ratio with the information about the no-load voltage of the windings.

[sc_PST_DIFF_13, 1, en_US]

Figure 6-74 Setting the Winding Ratio in DIGSI

Two-Core PST Function Block

Make the following settings in the **Two-core PST** function block in the **Transformer diff.** function group:

Parameter: Use AR switch

- Default setting **(_:101) Use AR switch** = ***no***

With the parameter **Use AR switch**, you define whether the differential protection considers the switchover of the AR switch.

Parameter Value	Description
no	No consideration of the AR switch
Block function	During AR switchover, the I-DIFF differential protection stage is blocked.
Block fct. & switch VG	During AR switchover, the I-DIFF differential protection stage is blocked and the vector group of the regulating side of the exciting transformer is switched internally.

[sc_PST_DIFF_10, 1, en_US]

Figure 6-75 Setting the AR Switch in DIGSI

When installing the switch in the triangle of the delta winding, the direction of the current in the measuring points of the excitation winding (regulating side) is inverted. Therefore, you must also switch the vector-group number (0 or 6).

When the switch changes the activation of the excitation winding (regulating side), the current through the measuring point on this side does not change in most cases. This depends on the installation location of the transformer. In this case, you can set the parameter **Use AR switch** to ***no***. If you still face short-term differential current during the switchover phase, you can use the ***Block function*** setting to avoid an unwanted tripping of the **87T secondary** function.

If you set the parameter to ***Block function*** or ***Block fct. & switch VG***, the parameter **(_:102) Blocking time ARS** becomes visible and you can use it to set the blocking time of the I-DIFF stage of the transformer differential protection ***87T secondary prot***. During the blocking time, the stage switches to the ***not active*** condition. If the switch has not reached a valid position after the time has elapsed, the I-DIFF stage switches to the **Alarm** condition. In this condition, you must route the input signals of the switch.

Since the protection must block immediately, no software filtering time is available for the switch. The blocking time is not triggered.

The transformer differential protection ***87T primary prot*** remains unaffected by this parameter.

In order to ensure the proper detection of the AR switch condition by the binary inputs *>Switch*, a connection as double-point indication is provided. This will detect and report intermediate positions and disturbed positions.

If only one binary input is available, you can proceed with the conversion in the CFC by using the **Build_DSP** converter building block. The DSP position **closed** indicates a forward direction. The DSP position **open** indicates a reverse direction.

Parameter: (_:102) Blocking time ARS

- Default setting **Blocking time ARS** = ***12.00 s***

With the **Blocking time ARS** parameter, you determine how long the I-DIFF stage of the differential protection will be blocked during the switchover of the AR switch. This time is necessary in order to prevent an overfunction of the differential protection. In order for the AR switch to reach its new position safely, you must select a sufficient blocking time. Typically, this time is 12 s.

Example:

Transformer example: Two-core PST	
Information provided by the manufacturer:	
Rated voltage/rated power:	410 kV/1200 MVA
Frequency:	50 Hz
Number of tap positions:	±32 positions

Rated voltage of the winding parts source side/load side of the series transformer:	2x 41.1 kV
Rated voltage of the secondary winding of the series transformer:	105.8 kV
Output of the exciting transformer:	410 MVA
Rated voltage of the primary excitation winding:	410 kV
Rated voltage of the control winding:	105.8 kV

The AR switch toggles the forward and reverse direction of the delta winding (secondary windings of the series transformer). Therefore, you must switch the vector group of the regulating side of the exciting transformer between the vector-group number 0 and 6.

Parameterization of the function block:

- Set the parameters for a 4-sided transformer, for example, with the application template for a three-winding transformer as basis and extend it.
- Set the parameters for the **Two-core PST** function block in the available **Transformer diff.** function group.
- Set the parameters for a 2nd Differential protection function in the **Transformer Diff.** function group.
  Capturing the information for the tap changer is not required for the protection scheme.

Settings for the transformer sides:

- Transformer side 1:
  - **Two-core side type**: ***Source side***
  - Rated apparent power: 1200 MVA
  - Rated voltage: 410 kV
- Transformer side 2:
  - **Two-core side type**: ***Load side***
  - Rated apparent power: 1200 MVA
  - Rated voltage: 410 kV
- Transformer side 3:
  - **Two-core side type**: ***Exciter primary side***
  - Rated apparent power: 410 MVA (affects only the reference-side selection in the differential protection)
  - Rated voltage: 410 kV (affects only the reference-side selection in the differential protection)
- Transformer side 4:
  - **Two-core side type**: ***Exciter regulating side***
  - Rated apparent power: 410 MVA (does not affect the differential protection)
  - Rated voltage: 105.8 kV (does not affect the differential protection)
  - Vector-group number: 0 (information about the vector-group number for the forward direction)

Settings for the transformer differential protection:

- **Two-Core PST** function block:
  - Parameter **(_:101) Use AR switch** = ***Block fct. & switch VG***
  - Parameter **(_:102) Blocking time ARS** = ***12 s***

  If the AR switch toggles its position, the I-DIFF stage of the differential protection will be blocked for the set time. If the AR switch has not reached a valid position after the time has elapsed, the function switches to the **Alarm** condition.

- **Transformer diff. 1**:
  - **Operating mode Diff**:***87T primary differential protection***
- **Transformer diff. 2**:
  - **Operating mode Diff**: ***87T secondary differential protection***
  - Series-transformer ratio: 0.777 (2 x 41.1 kV/105.8 kV)
- Information routing:
  - Route the binary-input signal **>Toggle switch**.
    Since the protection must block immediately, no software filtering time is available for the switch. The blocking time is not triggered.

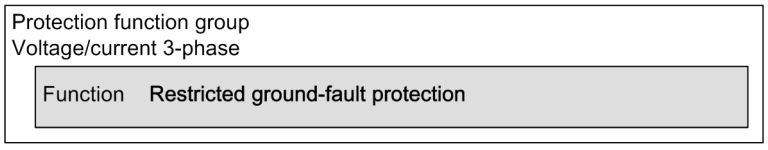
6.4 Restricted Ground-Fault Protection

6.4.1 Overview of Functions



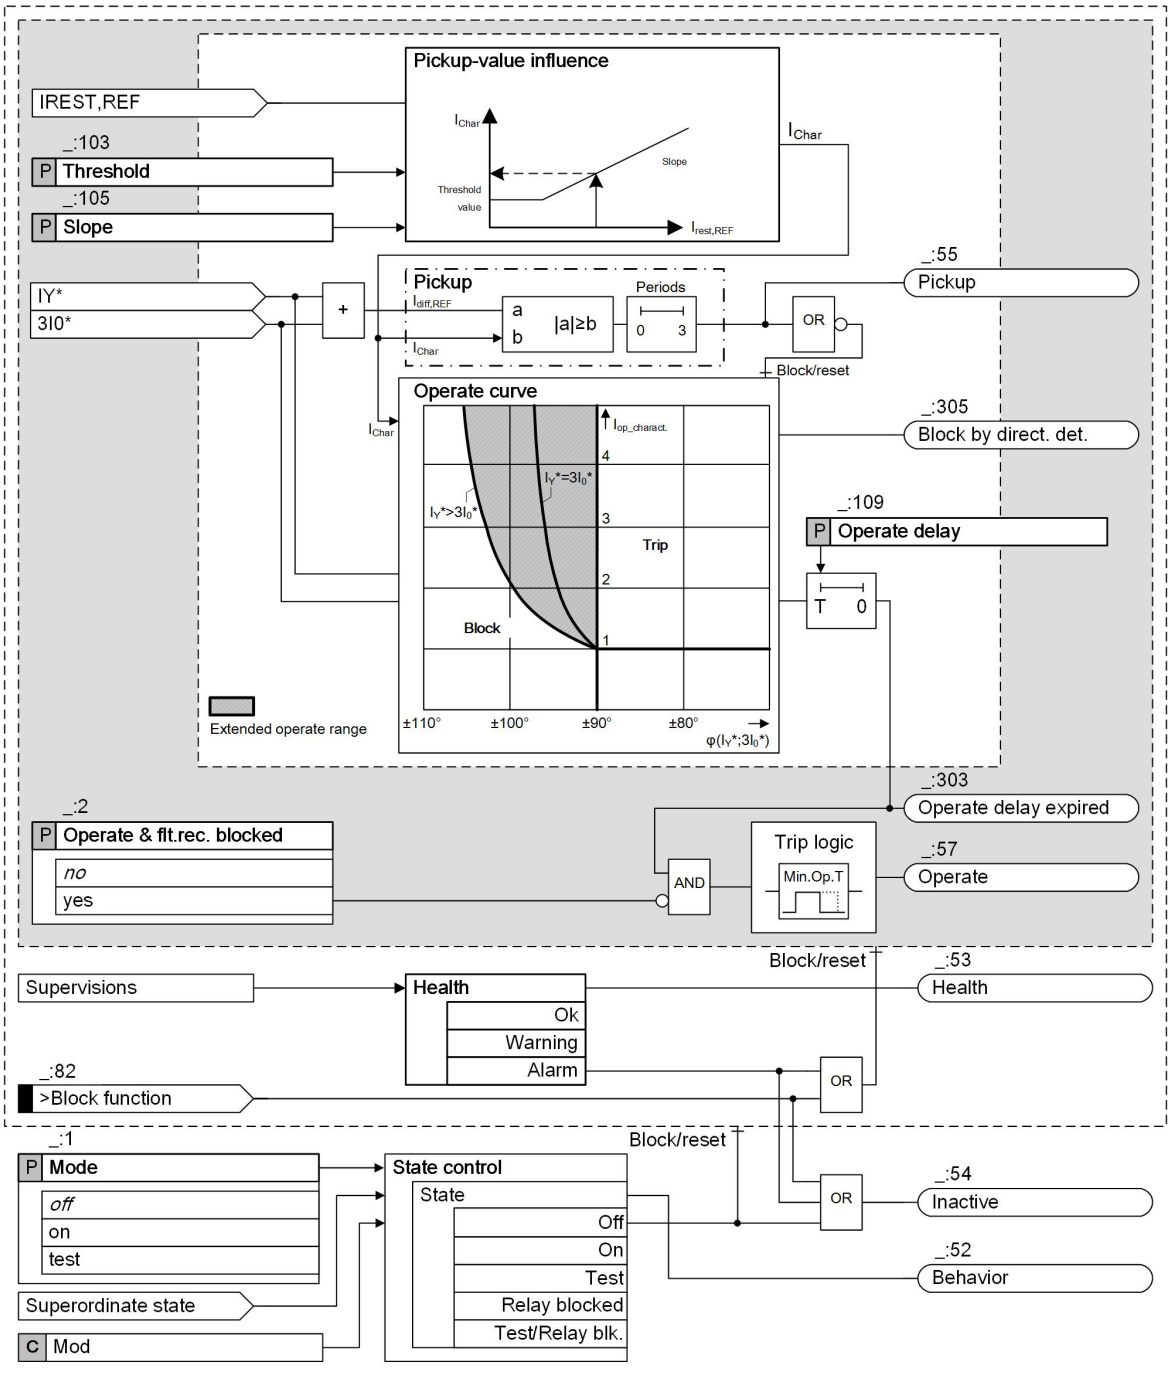
The **Restricted ground-fault protection** function (ANSI 87N, REF):

- Detects ground faults in transformers, shunt reactors, neutral reactors, or rotating machinery in which the neutral point is grounded.
- Has high sensitivity to ground faults near the neutral point.
- Is supplemental main protection to longitudinal differential protection.
- Protects grounding transformers in the protection range. It is required that a current transformer be used in the case of neutral point feed, that is, between neutral point and grounding conductor. The neutral point transformer and the phase current transformer define the protection range.
- Automatically adapts itself to the highest-amperage side with auto transformers, and thereby prevents overfunction in the event of external ground faults.

6.4.2 Structure of the Function

The function **Restricted ground-fault protection** is used in the protection function group **Transformer side** or **Auto transformer** . Furthermore, you can use the function in the stabilizing winding of the auto transformer as well as in the function **Standard UI**. The function depends upon application in the corresponding application template preconfigured by the manufacturer or can be copied during the engineering into the corresponding function group.

The function **Restricted ground-fault protection** is stepless.

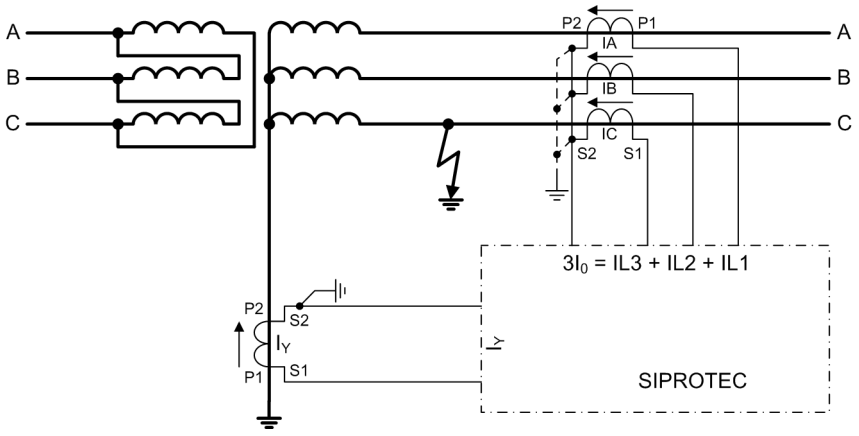


[dw_stru_pt, 2, en_US]

Figure 6-76 Structure/Embedding of the Function

6.4.3 Function Description

Logic of the Function



[lo_reffkt, 4, en_US]

Figure 6-77 Logic Diagram of the Restricted Ground-Fault Protection Function

The protection function processes the neutral-point current $\underline{I}_Y$* and the zero-sequence current 3 $\underline{I}_0$ calculated from the phase currents (see following figure). The amount-adapted (compensated) currents are described by the * symbol. They are normalized to the rated object current of the respective side. The protection range extends exclusively over the transformer winding, including current transformer.

In case of an internal ground fault, the zero-sequence currents flow to the fault location. With an external ground fault, the fault current inverts itself in the phase current transformers. In this way, the direction of current flow serves as the decisive criterion for an internal fault.

[dw_grdpri, 2, en_US]

Figure 6-78 Basic Principle of the Function

NOTE

Consider the polarity of the current transformers. It must be set in accordance with the connection type. Connect the neutral point to the 3-pole measuring points on the device side using the even-numbered terminals.

The protection function operates in 3 steps according to the logic diagram *Figure 6-77*:

- Effect of pickup value:
  Increasing the set pickup threshold using the restraint current. This prevents overfunction in the event of high-current external ground faults.
- Pickup:
  If the calculated current $I_{Diff,REF}$ exceeds the adapted pickup threshold, pickup starts.
- Operate curve based on phase-angle difference:
  The angle difference between the neutral-point current (I_y*) and the calculated zero-sequence current ($3I_0$*) in the operate curve is taken into consideration to differentiate between internal and external faults.

Effect of Pickup Value

The restraint current ($I_{Rest,REF}$) is calculated from the measured currents. The reference arrows are defined as positive when pointing to the protected object (see *Figure 6-78*). Consider that the neutral-point current (I_Y) detected using the 1-phase measuring point is displayed as positive in the fault record and in the DIGSI 5 Test Suite if the current flows from the protected object to ground.

NOTE

The following calculation applies to the configurations with one current measuring point for the side. In a special case of 2 current measuring points per side, the calculation of the restraint current must be performed in greater detail.

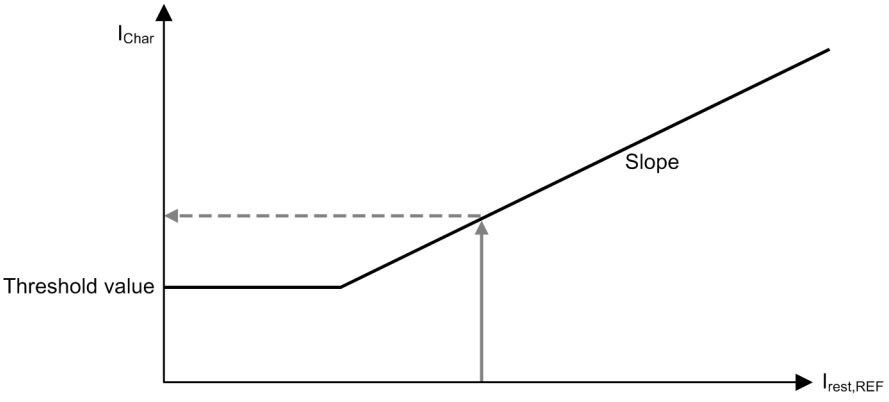
$\underline{I}_Y^* = k_{yx} \cdot 3\underline{I}_y$

$3\underline{I}_0^* = k_{sx} \cdot (\underline{I}_A + \underline{I}_B + \underline{I}_C)$

with

$k_{yx} = I_{N,transformerY}/I_{N,side}$ with the secondary current measured in the neutral point (Y)

$k_{sx} = I_{N,transformerS}/I_{N,side}$ with the secondary current measured on the transformer side (S)



$I_{Diff,REF} = |\underline{I}_Y^* + 3\underline{I}_0^*|$

$I_{Rest,REF} = |\underline{I}_Y^*| + |\underline{I}_A^*| + |\underline{I}_B^*| + |\underline{I}_C^*|$ with all currents normalized to the rated object current

where:

$\underline{I}_Y$	Measured zero-sequence current at neutral point
k_{yx}	Factor for magnitude adaptation (neutral point)
k_{sx}	Factor for magnitude adaptation (side)
$I_{N,transformer}$	Primary transformer rated current
$I_{N,side}$	Primary rated current of the transformer side (rated object current)
$I_{Diff,REF}$	Differential current
$I_{Rest,REF}$	Restraint current

Using the calculated restraint current, a current I_{Char} which represents the pickup value for the tripping is determined from the characteristic curve (*Figure 6-79*). In this way, the protection function is stabilized in the event of external, multiphase ground faults, for example, a 2-pole ground fault. This means that the protection function becomes less sensitive.
If the **`Slope = 0`** is set here (as an exception), the set **`Threshold`** of the operate curve is passed regardless of the restraint current.

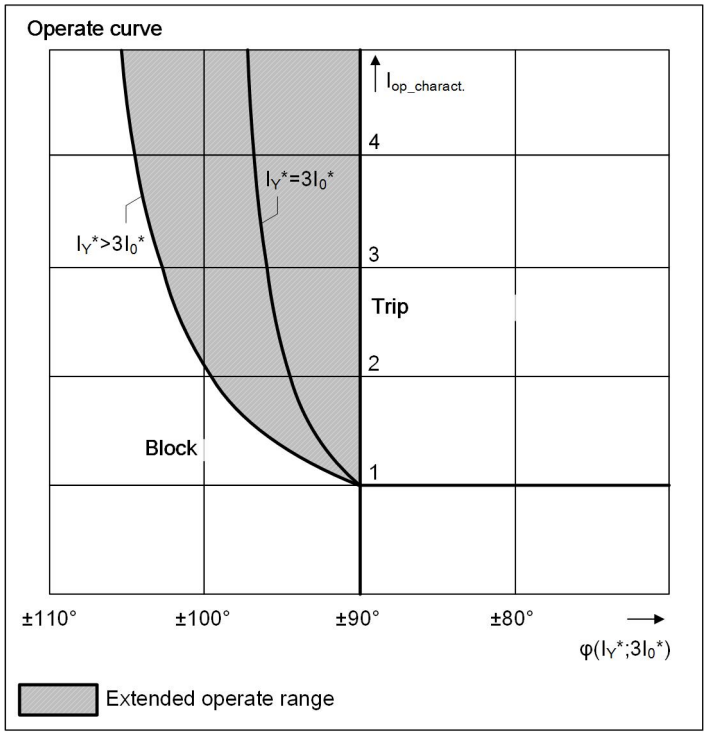
[dw_stab_ke, 2, en_US]

Figure 6-79 Stabilized Characteristic Curve

The ratio between the neutral-point current and the value for the current I_{Char} determined from *Figure 6-79* is observed in the operate curve.

$$I_{op_charact.} = \frac{|I_Y^*|}{I_{Char}}$$

[fo_trip current, 1, en_US]



Pickup

If the $I_{Diff,REF}$ calculated differential current exceeds the calculated current I_{Char} (see *Figure 6-77*), pickup occurs and the internal processing is enabled. The pickup is indicated.

Operate Curve Based on Phase-Angle Difference

The operate curve represented in the following figure consists of 2 parts. In the right part of the characteristic curve (angle magnitude ≤ 90°), you will find the case of an **internal ground fault**. Under ideal conditions, the angle between the evaluated currents ($\angle(\underline{I}_Y^*, 3\underline{I}_0^*)$) equals 0 in the event of an internal fault. In the right section of the characteristic curve (internal fault), the trip threshold for the current $I_{op_charact.}$ is >1.

If the measured current on the transformer side yields only a very small $3I_0$* amount, there is no sense in determining the angle difference. If, in the event of an internal fault, a small $3I_0$* current simulates an angle error due to a measuring error, the **extended operate range** allows reliable tripping with an angle difference of >90°.

[dw_ausken, 3, en_US]

Figure 6-80 Operate Curve Depending on the Phase Angle

NOTE

The characteristic curve shown in *Figure 6-80* shows the limit of the tripping range with the angle criterion. The **extended operate range** is shown symbolically for 2 conditions:

- Condition 1: $|\underline{I}_Y^*| = |3\underline{I}_0^*|$
- Condition 2: $|\underline{I}_Y^*| = 3 \cdot |3\underline{I}_0^*|$

The characteristic curve $|\underline{I}_Y^*| = |3\underline{I}_0^*|$ is the angle limit of the extended operate range for this condition.

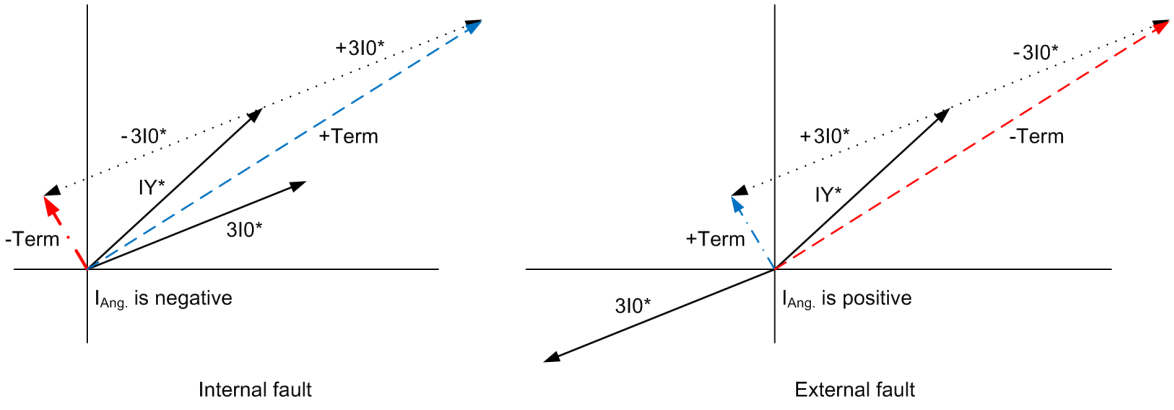
In the event of an external fault with $|\underline{I}_Y^*| = |3\underline{I}_0^*|$, the phase angle is between $\underline{I}_Y^*$ and $3\underline{I}_0^* \approx 180°$.

If a measuring error now changes the angle and this angle error is <80°, unwanted tripping does not occur. In *Figure 6-80*, that is the section to the left of 100°.

If, for example, the ratio is $|\underline{I}_Y^*| >> |3\underline{I}_0^*|$, tripping is theoretically not possible for an angle difference of 180°. This is the case if no fault current is flowing on the transformer side and the current $3I_0$* results from a measuring error. With the **extended operate range**, internal faults are cleared in a secured way.

In case of an **external ground fault**, the zero-sequence current calculated from the phase currents reverses by 180°. The phase angle between the zero-sequence currents thus ($\angle(\underline{I}_Y^*, 3\underline{I}_0^*)$) equals ± 180°. They are located in the left part of the operate curve and detect a clearly increased tripping limit.

As specified in *Figure 6-80*, the characteristic-curve limit with regard to the angle specification on the x-axis depends on the ratio $|\underline{I}_Y^*|$ to $|3\underline{I}_0^*|$. If the amounts differ, the characteristic curve shifts.



The current $I_{Angle,REF}$ for the **Angle decision** is determined from the following subtraction and summation:

$I_{Angle,REF} = |\underline{I}_Y^* - 3\underline{I}_0^*| - |\underline{I}_Y^* + 3\underline{I}_0^*|$

The resulting current $I_{Angle,REF}$ results from the respective fault conditions, which are illustrated in the following figure. With an internal fault (angle difference ≈ 0°) a value results for $I_{Angle,REF}$ that has a negative sign. The sign remains negative, even when angle errors occur. The amount of $I_{Angle,REF}$ decreases.

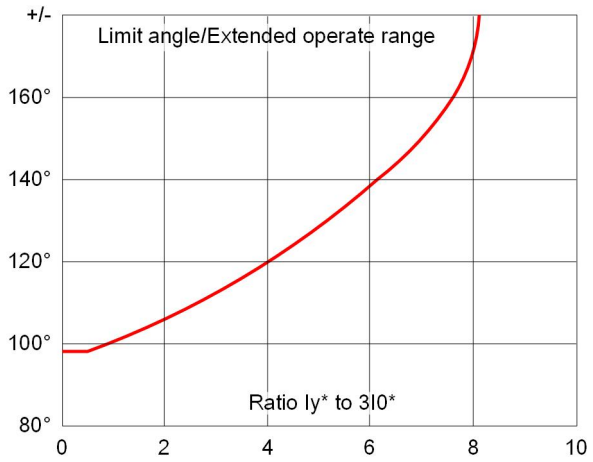
With an external short circuit (≈180°), the value of $I_{Angle,REF}$ becomes positive. The current $I_{Angle,REF}$ remains positive, even if an angle error occurs. The amount also decreases.

The following figure shows this for $I_{Angle,REF}$ = (-Term) - (+Term).

[dw_angle-decision_for_external-faults, 1, en_US]

Figure 6-81 Angle Decision in Internal and External Faults

For tripping to occur, the neutral-point current $\underline{I}_Y$* must reach the value $I_{REF,Trip}$.



The following table shows the relationship between angle magnitude φ($\underline{I}_Y$*, 3$\underline{I}_0$*), angle dimension $I_{Angle,REF}$, and trip variable $I_{REF,Trip}$

Angle Magnitude φ($\underline{I}_Y$*, 3$\underline{I}_0$*)	Angle Dimension $I_{Angle,REF}$	Trip Variable $I_{REF,Trip}$	Comments
0° < φ ≤ 90°	$I_{Angle,REF}$ = 0	$I_{REF,Trip} = \lvert\underline{I}_Y^*\rvert$	Internal fault
90° < φ < 180°	$I_{Angle,REF}$ > 0	$I_{REF,Trip}$ = max (0, $\lvert\underline{I}_Y^*\rvert$ - $k_{REF}I_{Angle,REF}$)	Normal operation or external fault

where:

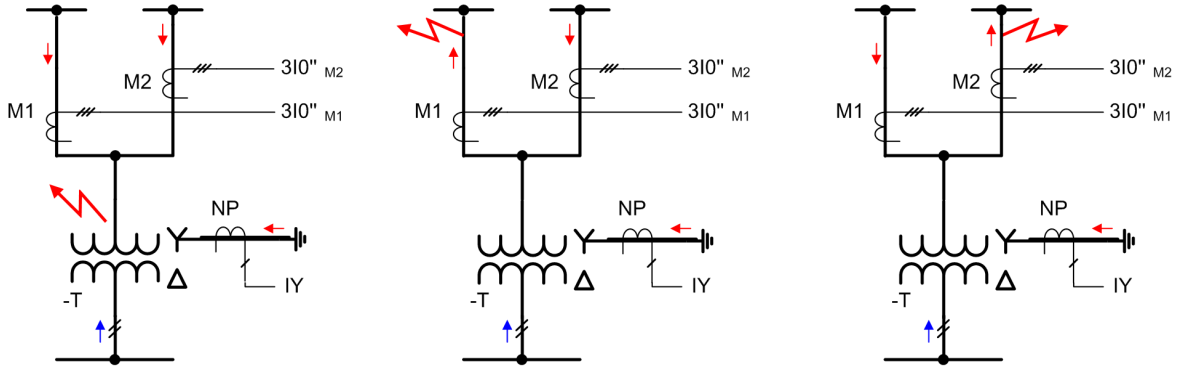
k_{REF} Factor (permanently set to 4.05657)
With this value, the limit angle at $\lvert\underline{I}_Y^*\rvert = \lvert 3\underline{I}_0^*\rvert$ is precisely 100°. No tripping is possible from this angle on.

The following figure shows an example of the effect on the **extended operate** by the different ratio $\underline{I}_Y$* to $3\underline{I}_0$* ($I_{rest,REF}$ is not considered in the representation).

[dw_angle_trip_relationship, 1, en_US]

Figure 6-82 Ratio $\underline{I}_Y$* to $3\underline{I}_0$*

Tripping is possible for each angle from a ratio of $\underline{I}_Y$* to $3\underline{I}_0$* > 8.2.



Processing of Several Measuring Points on One Side

If several measuring points are present on one side of a star winding, as with a 1 1/2 circuit-breaker layout, the angle decision occurs separately for each measuring point. The maximum current $I_{Angle,REF}$ is used to establish the tripping decision.

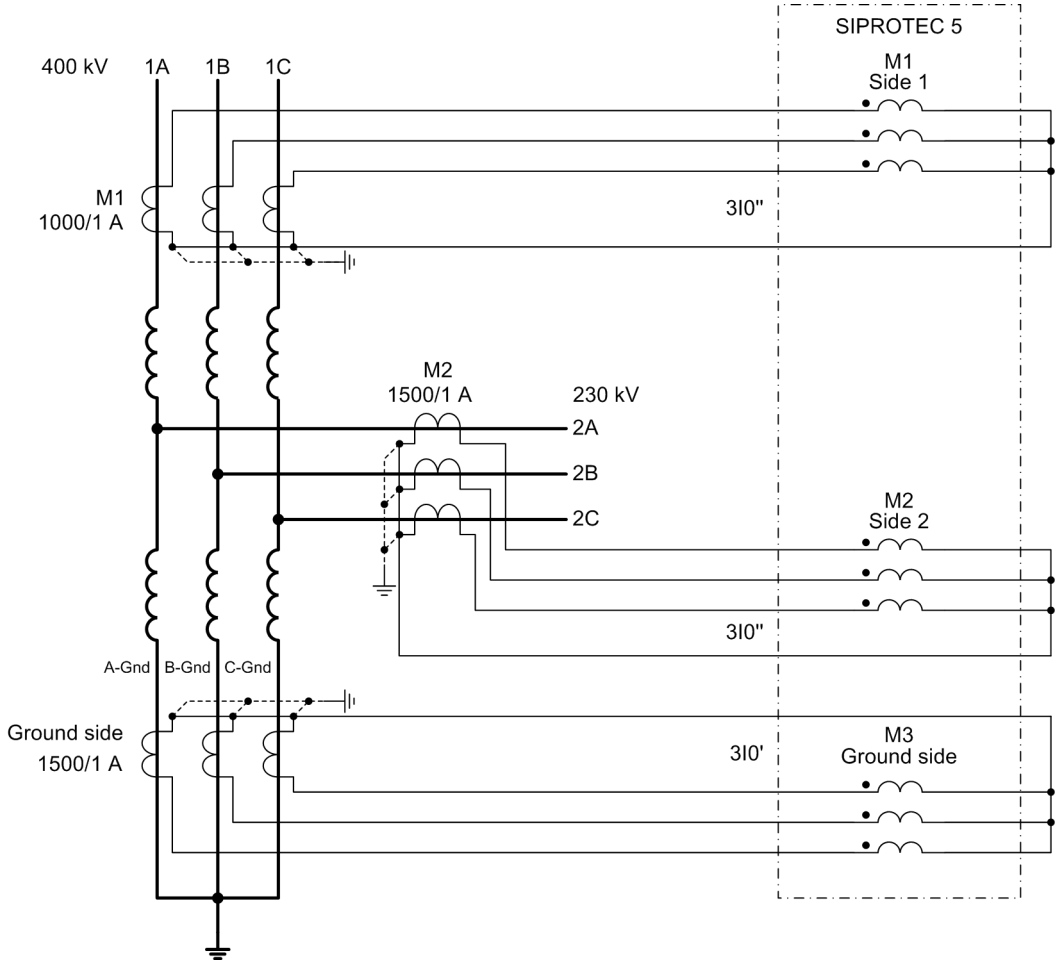
NOTE

With an external fault, the current $I_{Angle,REF}$ is always > 0.

The following figure shows the behavior under different fault conditions.
Also observe that the restraint current ($I_{Rest.,REF}$) always results from the sum of all currents (phase currents of the measuring points and the neutral-point current). For pickup, the differential current $I_{Diff,REF}$ is necessary. This differential current results from the geometric sum of all adapted zero-sequence currents. The zero-sequence currents of the measuring points on the outgoing side and of the neutral-point current are meant here.

$I_{Ang, REFM1} \leq 0, \Delta\varphi_{_M1} = 0°$
$I_{Ang, REFM2} \leq 0, \Delta\varphi_{_M2} = 0°$
$I_{REF, Trip} = I_{Char}$

$I_{Ang, REFM1} \geq 0, \Delta\varphi_{_M1} = 180°$
$I_{Ang, REFM2} \leq 0, \Delta\varphi_{_M2} = 0°$
$I_{REF, Trip} = I_{Char} + k * I_{Ang, REFM1}$



$I_{Ang, REFM1} \leq 0, \Delta\varphi_{_M1} = 0°$
$I_{Ang, REFM2} \geq 0, \Delta\varphi_{_M2} = 180°$
$I_{REF, Trip} = I_{Char} + k * I_{Ang, REFM2}$

[dw_fehler, 2, en_US]

Figure 6-83 Behavior under Different Fault Conditions

Processing a Ground Side for Auto Transformer

Instead of a 1-phase neutral point, with an auto transformer, a 3-phase ground side can also be used.

[dw_autraf, 1, en_US]

Figure 6-84 Connecting a Ground Side on the Auto Transformer

NOTE

The largest rated object current from both sides of the auto transformer is used as a reference current ($I_{N,side}$) for an auto transformer. It is the rated object current on the 230-kV side in *Figure 6-84*.

In this case, the neutral-point current is calculated as the sum of the phase currents of the ground side as follows:

$\underline{I}_Y^* = k_{my} \cdot (\underline{I}_{Gnd,A} + \underline{I}_{Gnd,B} + \underline{I}_{Gnd,C})$

with

$k_{my} = I_{NY,transformer}/I_{N,\ M2\ side}$

The following applies for the restraint current:

$I_{Rest,REF} = |\underline{I}_{Gnd,A}^*| + |\underline{I}_{Gnd,B}^*| + |\underline{I}_{Gnd,C}^*| + |\underline{I}_{M1A}^*| + |\underline{I}_{M1B}^*| + |\underline{I}_{M1C}^*| + |\underline{I}_{M2A}^*| + |\underline{I}_{M2B}^*| + |\underline{I}_{M2C}^*|$

NOTE

If both the 1-phase neutral point and the 3-phase ground side are connected, the restricted ground-fault protection uses only the 1-phase neutral point. The 3-phase ground side is not considered.

Functional Measured Values

Measured Value	Description
(_:306) I REF,operate	Operate quantity of the restricted ground-fault protection from the angle criterion and can be displayed in the fault record
(_:307) I Angle,REF	Stabilizing value (angle) of the restricted ground-fault protection from the angle criterion and can be displayed in the fault record
(_:311) I REF,Trip operate	Operate quantity of the restricted ground-fault protection when OFF; will be issued in the log
(_:312) I angle,REF operate	Stabilizing value of the restricted ground-fault protection when OFF; will be issued in the log
(_:301) I diff.	Differential current; can be displayed in the fault record
(_:302) I restr.	Restraint current; can be displayed in the fault record

You can find the measured values for the **Restricted ground-fault protection** under the following device menu items:

- Main menu → Measurements → function → Function values → 87N REF

6.4.4 Application and Setting Notes

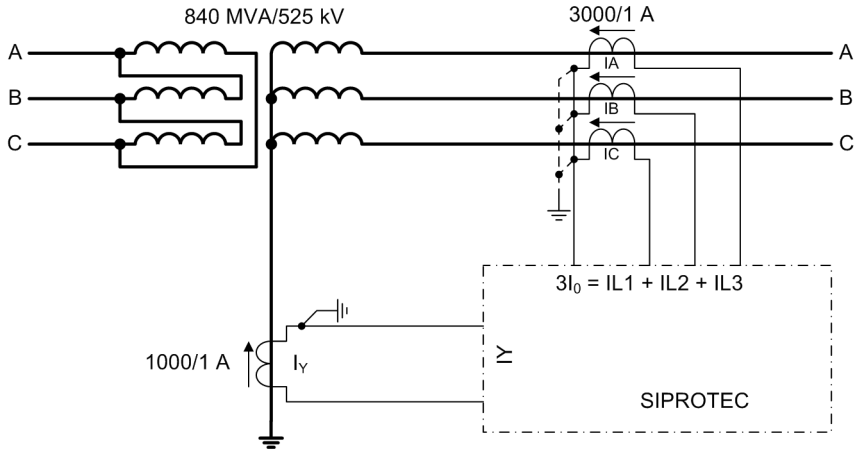
NOTE

You can determine the setting limits for the threshold values as follows (the adaption is done automatically and a setting is only possible within the permissible range):

Lower limit:

Threshold value ≥ max {*0.05 I/Irated,S*; *0.05 I/Irated,S* * $I_{prim\ transf.\ max}$ / $I_{rated,\ protected\ object}$}

Upper limit:



Threshold value ≤ min {*2.00 I/Irated,S*; *100.00 I/Irated,S* * $I_{prim\ transf.\ max}$ / $I_{rated,\ protected\ object}$}

The value ***0.05 I/Irated,S*** is the minimum possible setting value and ***2.00 I/Irated,S*** the maximum possible. $I_{prim,transf.\ max}$ is the largest transformer current and $I_{rated,protected\ object}$ the protected object rated current (reference current) ***100.00 I/Irated,S*** is the upper measurement limit.

The adaptation of the setting limits is done automatically. In addition, a setting is prevented outside of these limits.

In the following, typical applications are described for the restricted ground-fault protection.

Protection of a Solidly Grounded Star Winding (Y Side)

[dw_anster, 3, en_US]

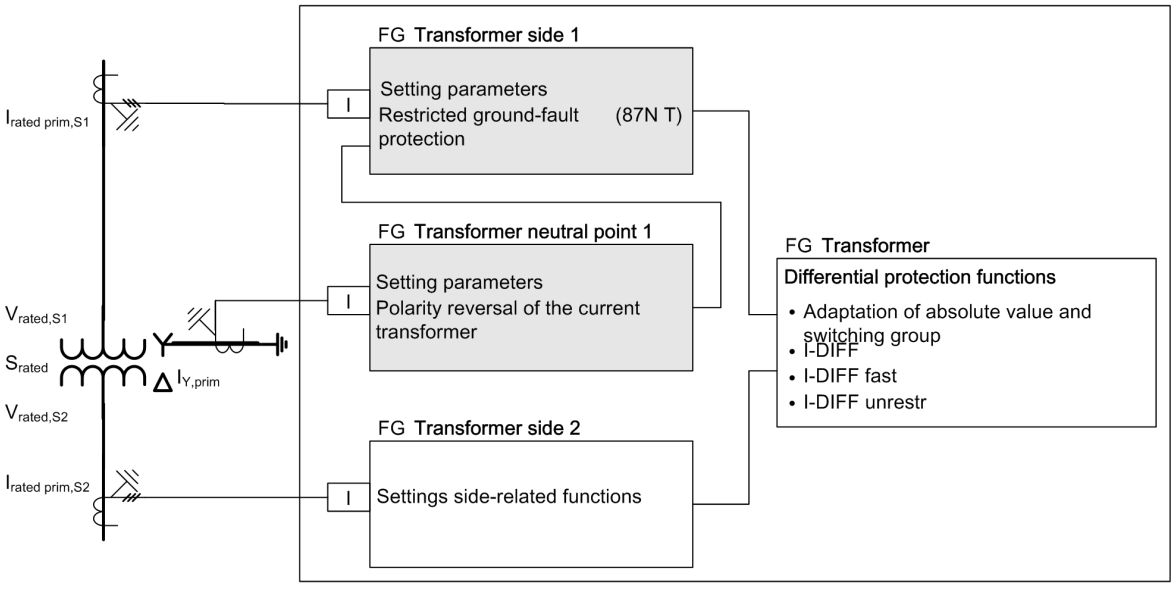


Figure 6-85 Application Star Side

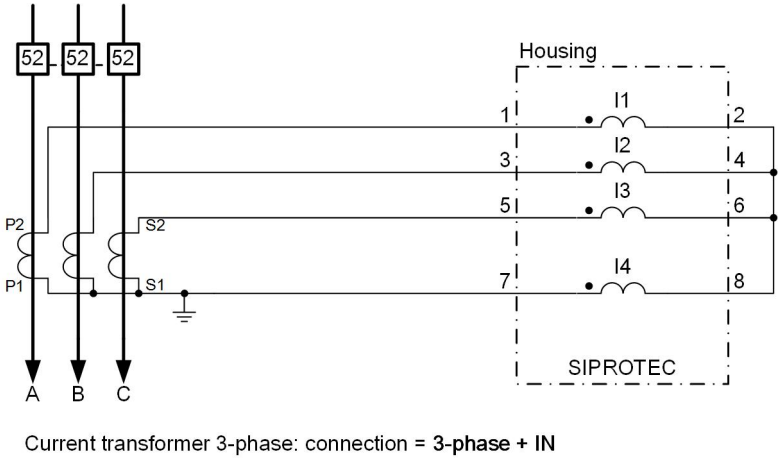
This application is a standard application. Here the phase currents of one side and the neutral-point current are processed. The function is located in the **Transformer Side** function group.

The following figure shows the structural division of the function. The restricted ground-fault protection gets its measurands from the current transformers, which are connected to the **Transformer side** function group. The neutral-point current is guided via the **Transformer neutral point** function group to the **Transformer side** function group. The current I_y measured at the neutral point is inverted by 180° in the fault record (COMTRADE). This is due to the fact that, for a Holmgreen connection, the summation current flows via the terminal with an even connection number, and for a 1-phase connection, it flows via the terminal with an uneven connection number. To be compatible with SIPROTEC 4 (including reference arrow definition of the restricted ground-fault protection), in addition to the magnitude scaling of the neutral-point current, a rotation of the polarity (phase rotation by 180°) is also carried out in the function group **Transformer neutral point**.

NOTE

The fault record indicates the analog traces according to the connection. For this reason, the neutral-point current is shown rotated by 180° in comparison to SIPROTEC 4. This is due to the fact that, for a Holmgreen connection, the summation current flows via the terminal with an even connection number, and for a 1-phase connection, it flows via the terminal with an uneven connection number.

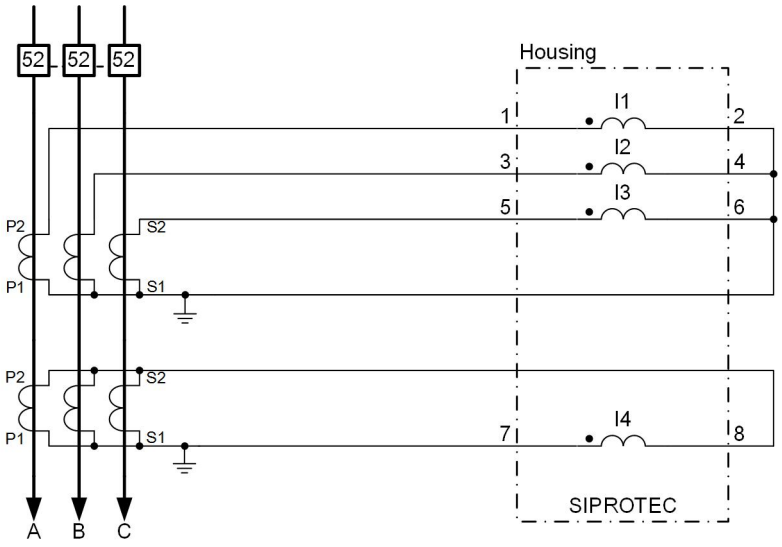


[dw_2wtyde, 3, en_US]

Figure 6-86 Function Group Structure of the Restricted Ground-Fault Protection

Explanations on the Connection and Current-Direction Definition

Uniform reference arrows and transformer burdens are defined for the SIPROTEC 5 device series. These agreements also apply to the transformer protection devices. The special handling of the neutral-point current described previously is a result of this.



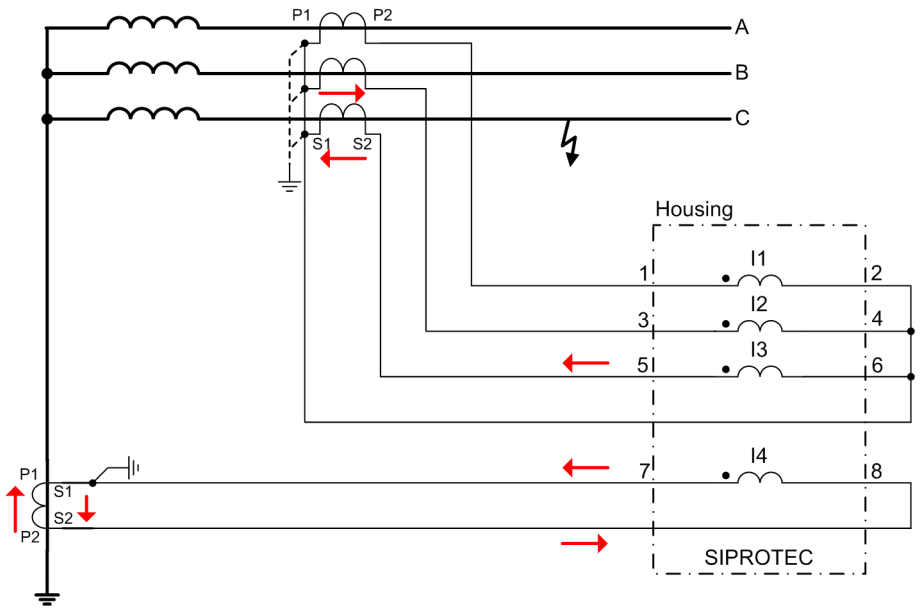
Due to the current definition, the current in the direction of the protected object is always positive. For the 3-phase current-transformer connection, the representation in *Figure 6-87* and *Figure 6-88* applies. For a Holmgreen connection, the summation current is always generated with the neutral point at the terminals with even numbers. If a separate I_N is detected (*Figure 6-88*), for example, with a core balance current transformer, the current I4 must have the same directional mode as in *Figure 6-87* with Holmgreen. The protected object is located to the right or left of the transformer set. The polarity in case of a 3-phase transformer connection is set with the neutral point (in the direction of the protected object or not). The following basic connections result from this.

[ti_phase_2, 4, en_US]

Figure 6-87 Current-Transformer Connection (1) According to Definition

or

Current transformer 3-phase: connection = **3-phase + IN-separate**



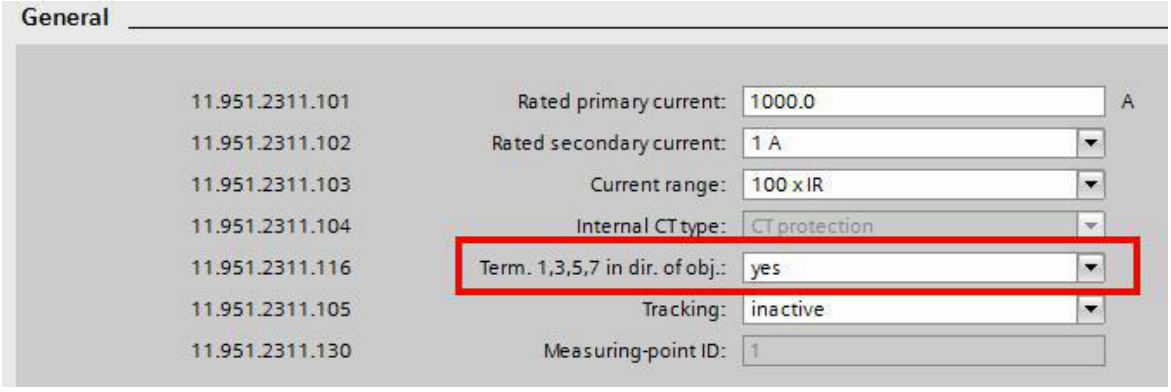
[tileite4-260313-01.tif, 4, en_US]

Figure 6-88 Current-Transformer Connection (2) According to Definition

The following connection is defined for the transformer according to *Figure 6-89*. The current flow for an external ground fault is entered at the same time. It is recognized that the secondary currents each flow from the device. From this, a differential current ($I_{Diff,REF} = |\underline{I}_Y + \underline{I}_A + \underline{I}_B + \underline{I}_C| = |-\underline{I}_4 - \underline{I}_3|$) results, according to the reference arrow definition for the restricted ground-fault protection (positive to the protected object) with an external ground fault. To prevent that, the neutral-point current is rotated in the **Transformer neutral-point** function group. It follows that: $I_{Diff, REF} = |\underline{I}_4 - \underline{I}_3| = 0$.

NOTE

Consider the current-transformer requirements in *A.8 Requirements for Current Transformers* .



Current transformer 3-phase: connection = **3-phase**

Current transformer 1-phase: connection = **IN**

[dw_stwnas, 2, en_US]

Figure 6-89 Current-Transformer Connection on the Transformer

The setting of the 1-phase measuring point based on the definition is carried out as follows:

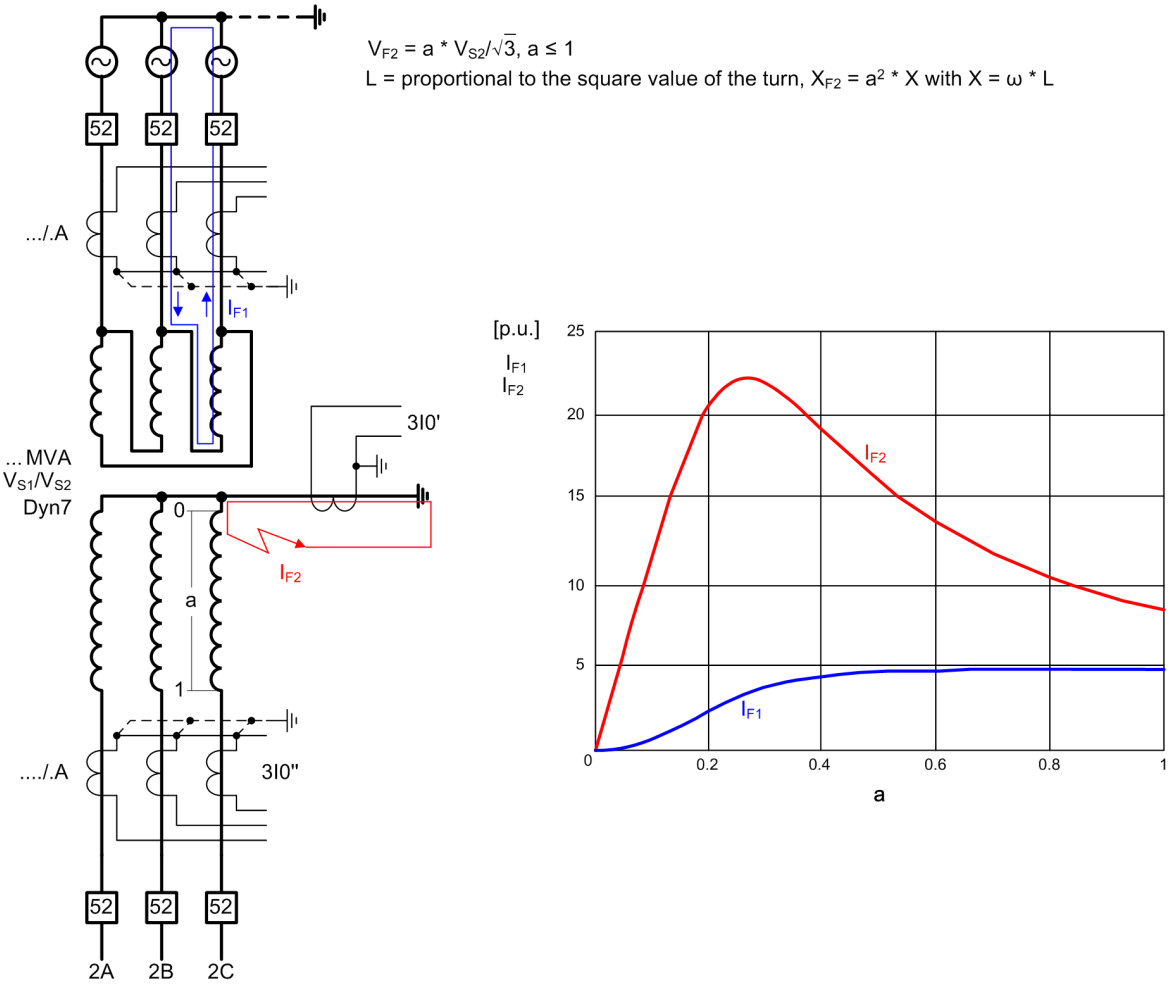
[scedsall-200214-01, 1, en_US]

Figure 6-90 DIGSI 5 Setting

The point in *Figure 6-89* describes the polarity of the current transformer. At the same time, the current terminal is designed so that this side is fed out on an odd number terminal point. Since in the SIPROTEC 5 system each current transformer can be assigned a 1-phase measuring point, the odd number terminal points are named in the setting parameters. According to *Figure 6-89*, the setting must be ***yes***.

- Default setting **(_:115) terminal 1,3,5,7 in dir.obj.** = ***yes***

The polarity of the 3-phase transformer connection is always configured on the side of the terminals with even numbers for orientation of the neutral point.



Threshold Value

The following view can be used to derive the threshold value. The transformer is supplied, for example, via the delta winding and a 1-pole ground fault occurs on the star side.

NOTE

For estimation of the short-circuit current, note that the inductance changes quadratically with the winding and linearly with the voltage.

The right part in the following figure represents the fault current as a function of the fault location. The fault current curve I_{F1} shows that the longitudinal differential protection with faults near the neutral point has sensitivity problems due to the sinking current. On the other hand, the neutral-point current I_{F2} is sufficiently large. There is therefore no need to set the **Threshold** (current through the neutral point transformer) to sensitive.

[dw_f1pole, 2, en_US]

Figure 6-91 Principal Fault Current Curves with a 1-Pole Ground Fault

- Recommended setting value **(_:103) Threshold** = ***0.2 I/Irated,S***

The previously mentioned setting limits must be maintained during the setting process (refer to the following example):

$$\text{Threshold value} \geq 0.05\ \text{I/Irated, S} \cdot \frac{I_{CT\ max,prim}}{I_{rated,side}}$$

[fo_schwe1, 1, en_US]

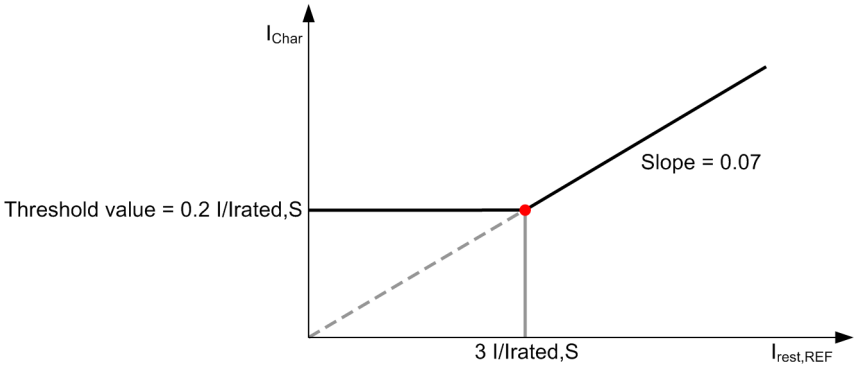
The following lower limiting value results from the data from *Figure 6-85*:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{3000\,\text{A}}{924\,\text{A}} = 0.162\ \text{I/Irated,S}$$

$$\text{with } I_{\text{object,side}} = \frac{S_{\text{rated}}}{\sqrt{3}\,V_{\text{rated}}} = \frac{840\,\text{MVA}}{\sqrt{3}\,525\,\text{kV}} = 924\,\text{A}$$

[fo_schwe2, 1, en_US]

The recommended setting value of ***0.2 I/Irated,S*** lies above it.



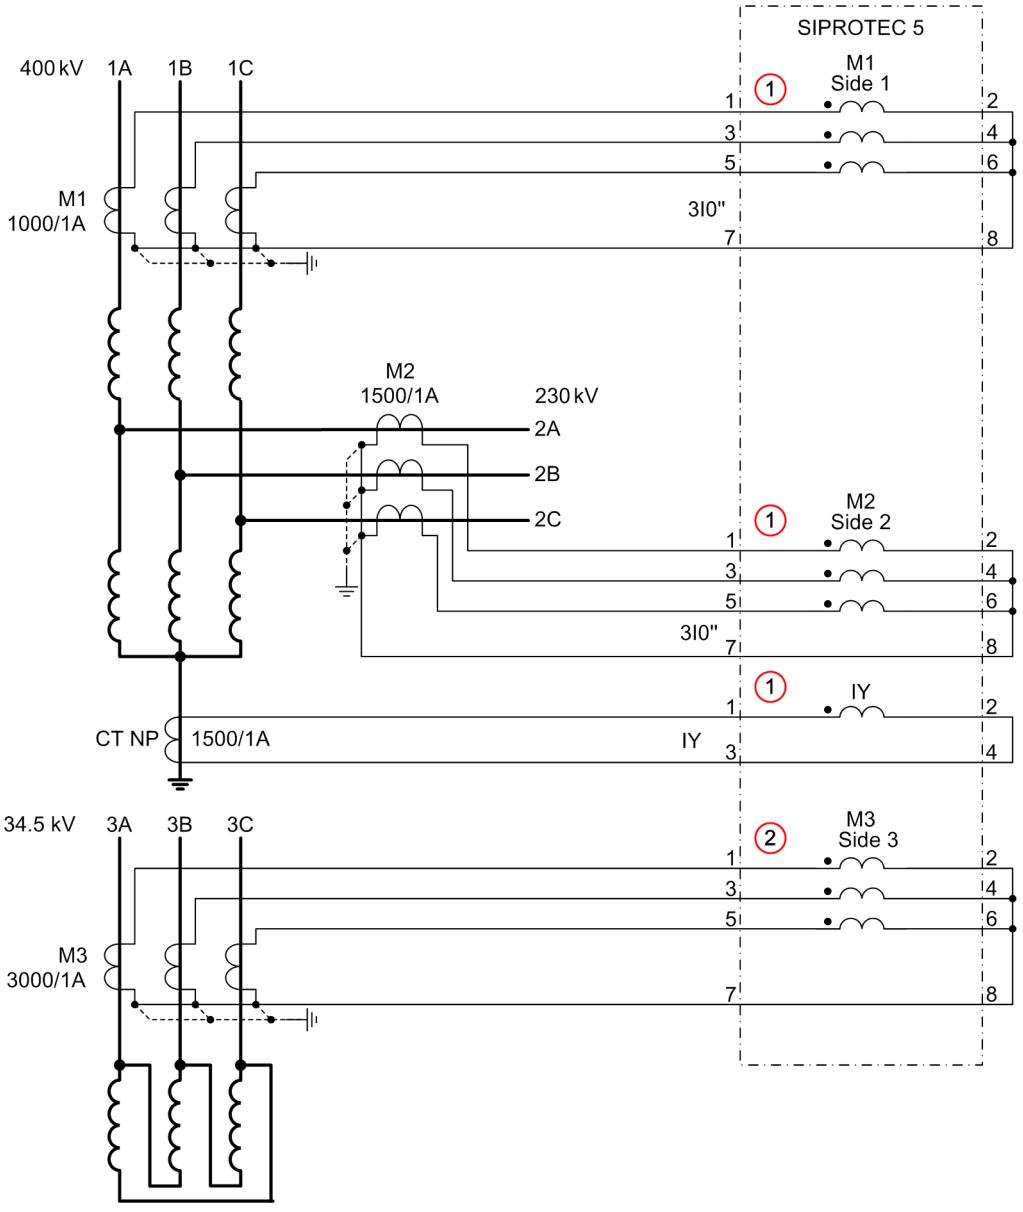
- Recommended setting value **(_:105) Slope** = ***0.07***

You can stabilize the protection function with external multiphase short-circuits to ground with the parameter **Slope**. To determine the setting value, no pickup value increase can occur up to the rated current. After this, the gradient must be active. To derive the gradient, it is assumed that continuation of the straight line must go through the coordinate origin (see *Figure 6-92*). Determine the intersection from the threshold value and the restraint current at rated current. Calculate the gradient as follows:

$$I_{\text{rest,REF}} = \left|I_0^*\right| + \left|I_A\right| + \left|I_B\right| + \left|I_C\right| = 0 + 3\ \text{I/Irated, S} = 3\ \text{I/Irated, S}$$

$$\text{Slope} = \frac{\text{Threshold value}}{I_{\text{rest,REF}}} = \frac{0.2\ \text{I/Irated, S}}{3\ \text{I/Irated, S}} = 0.07$$

[fo_stbref, 2, en_US]



[dw_steiga, 3, en_US]

Figure 6-92 Derivation of the Setting Value for the Gradient

If you have several measuring points on an outgoing side (see *Figure 6-83*), Siemens recommends using the value **3 I/Irated,S** in the intersection calculation for the restraint current. In the load case, the maximum transformer rated current flows on one side.

If, however, several measuring points are on the supply side (for example, breaker-and-a-half layout), Siemens recommends including all phase currents in the intersection calculation, in order to avoid too strong a stabilization. With 2 measuring points, a value of **6 I/Irated,S** results as intersection with the threshold value. The slope becomes flatter (**0.2 I/Irated,S/6 I/Irated,S = 0.03**).

Protection of an Auto Transformer

[dw_sp_tran, 2, en_US]

Figure 6-93 Activation and Application Example of an Auto Transformer (500 MVA: 400 kV, 230 kV; 125 MVA: 34.5 kV)

(1) Base module

(2) Expansion module

For an auto transformer, the highest side rated current is used for normalization. In the example (*Figure 6-93*), the measuring point is M2 (230-kV side). For this side, a rated current of 500 MVA/(√(3) · 230 kV) = 1255 A results. The primary transformer rated current is 1500 A. With this, you can calculate the minimum permissible pickup value.

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{I_{\text{CT max,prim}}}{I_{\text{object,side}}} = 0.05\ \text{I/Irated,S} \cdot \frac{1500\text{A}}{1255\text{A}} = 0.06\ \text{I/rated,S}$$

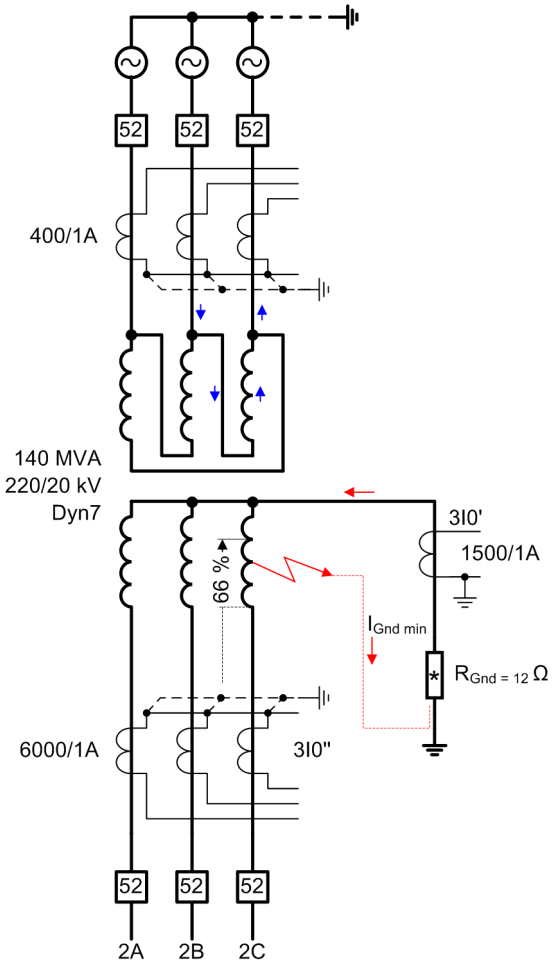
[fo_scwe01, 1, en_US]

Siemens recommends a setting value of **0.2 I/Irated,S**.

- Recommended setting value **(_:103) Threshold** = ***0.2 I/Irated,S***

To determine the **Slope**, the restraint current of both sides (400 kV and 230 kV) must be used. The rated current is used as starting value for the gradient. Since side 2 (230 kV) is the reference side for the normalization, the value of the 400-kV side must be adapted to this rated current. The adaptation factor results from the inverse ratio (230 kV/400 kV). The following restraint current goes into the calculation:

$$I_{rest,REF} = 3\ I/Irated,S2 + 3\frac{230\,kV}{400\,kV}\ I/Irated,S2 = 3\ I/Irated,S2 + 1.725\ I/Irated,S2 = 4.73\ I/Irated,S$$



$$Slope = \frac{Threshold\ value}{I_{rest,REF}} = \frac{0.2\ I/Irated,S}{4.73\ I/Irated,S} \approx 0.042$$

[fo_stbrst, 2, en_US]

Siemens recommends using the setting value 0.07.

- Recommended setting value **(_:105) Slope** = ***0.07***

Protection of a Resistance-Grounded Star Winding (Y Side)

[dw_ref_spa, 1, en_US]

Figure 6-94 Application with Resistance-Grounded Neutral Point

The pickup values can be derived from the example data in *Figure 6-94*. As side rated value, the following results:

140 MVA/(√3 · 20 kV) = 4042 A

The following threshold value results as lower limit:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{6000\,\text{A}}{4042\,\text{A}} = 0.07422\ \text{I/Irated,S}$$

$$\text{with } I_{\text{object,side}} = \frac{S_{\text{rated}}}{\sqrt{3} \cdot V_{\text{rated}}} = \frac{840\text{MVA}}{\sqrt{3} \cdot 525\text{kV}} = 924\text{A}$$

[fo_schwe3, 1, en_US]

So that the function is responsive, select a setting value of 0.08 I/Irated,S.

- Recommended setting value **(_:103) Threshold** = ***0.08 I/Irated,S***

As slope, the following results:

$$\text{Slope} = \frac{\text{Threshold value}}{I_{\text{rest,REF}}} = \frac{0.08\ \text{I/Irated,S}}{3\ \text{I/Irated,S}} \approx 0.03$$

[fo_steig1, 2, en_US]

- Recommended setting value **(_:105) Slope** = ***0.03***

Because of the grounding resistance R_E reduced protection range results. This can be estimated as follows: The grounding resistance is much larger than the winding reactance, thus the following maximum ground current results:

$I_{\text{gnd max}} = 20\ \text{kV}/(\sqrt{3} \cdot 12\ \Omega) = 962\ \text{A}$

You can determine the minimum tripping current from the setting value:

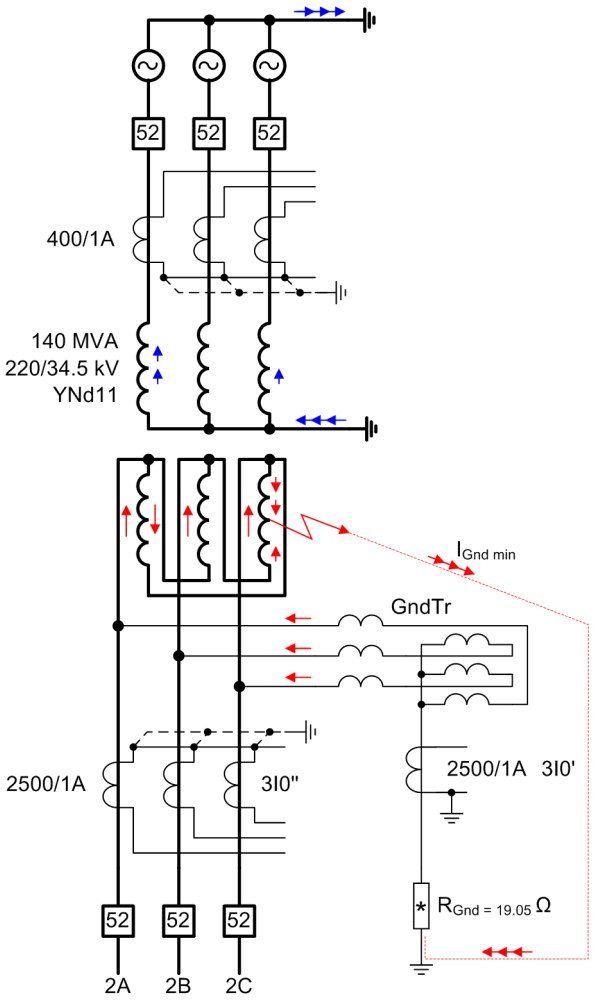
$I_{\text{gnd min}}$ = side rated current * threshold value = 4042 A · 0.08 = 323 A

Thus, the following protection range results:

$$\text{Protection range} = 1 - \frac{I_{\text{gnd min}}}{I_{\text{gnd max}}} = 1 - \frac{323\,\text{A}}{962\,\text{A}} = 0.664$$

[fo_schwe4, 1, en_US]

The attainable protection range amounts to approx. 66.4 %. In order to capture ground faults near the neutral point, it is also recommended to connect a sensitive ground current protection to the neutral point transformer. You must coordinate its operate time with the line protection.



NOTE

Ensure that the protection range further limits itself with larger neutral-point resistances, or the restricted ground-fault protection can no longer be used.

Protection with Neutral Reactors on the Delta Side

To produce ground currents on the delta side of a transformer, neutral reactors (zigzag reactors) are used. A resistance for ground current limitation can also be present. In this case, the resistance is much greater than the reactor and delta reactance of the transformer. The following figure shows a typical implementation. The restricted ground-fault protection works between output-sided phase current transformers and the current transformer in the neutral point of the neutral reactor.

In the example, the fault current curve with the ground fault in a delta winding is also represented. The fault location at which the lowest fault current flows can also be seen. This current influences the protection setting set close.

[dw_strpkt, 1, en_US]

Figure 6-95 Application with Neutral Reactor

As side rated value, the following results:

140 MVA/($\sqrt{3}$ · 34.5 kV) = 2343 A

You can thus define the lower limit for the threshold value:

$$\text{Threshold value} \geq 0.05\ \text{I/Irated,S} \cdot \frac{2500\ \text{A}}{2343\ \text{A}} = 0.06\ \text{I/Irated,S}$$

[fo_schwe5, 1, en_US]

If the fault is in the middle of the winding, as shown in *Figure 6-95*, the minimum ground current will arise. The driving voltage is:

$V_{gnd\ min} = V_{rated,S2}/(2\sqrt{3}) = 34.5\ kV/(2\sqrt{3}) = 9.96\ kV$

The following minimum ground current results:

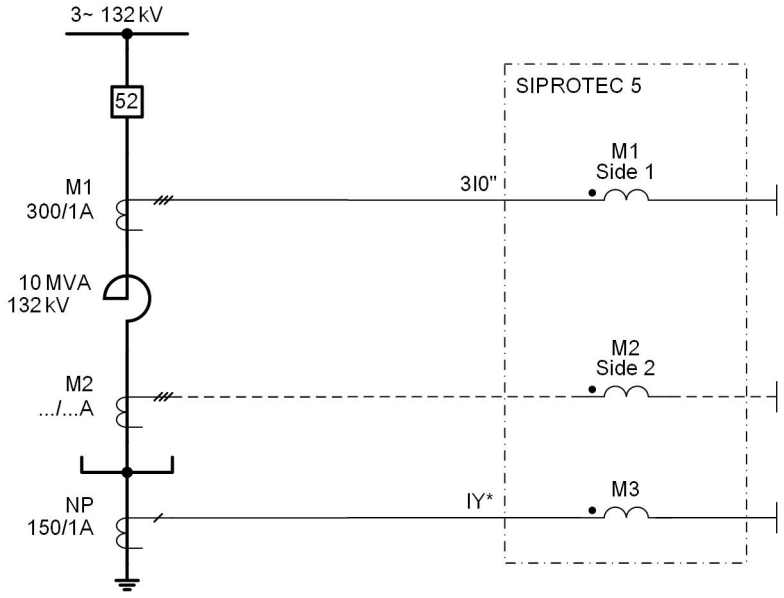
$I_{gnd\ min} = V_{gnd\ min}/R_{gnd} = 9.96\ kV/19.05\ \Omega = 523\ A$

With reference to the side rated current, the relationship is:

$I_{gnd\ min}/I_{rated,S} = 523\ A/2343\ A = 0.223$

With a safety margin of 2, 0.223/2 = 0.1115 is the result. Select this value as threshold value (rounded: 0.12 I/Irated,S).

- Recommended setting value **(_:103) Threshold** = ***0.12 I/Irated,S***



As slope, the following results:

$$\text{Slope} = \frac{\text{Threshold value}}{I_{rest,REF}} = \frac{0.12\ I/I_{rated,S}}{3\ I/I_{rated,S}} \approx 0.04$$

[fo_steig2, 2, en_US]

- Recommended setting value **(_:105) Slope** = ***0.04***

Protection of a Shunt Reactor

[dw_anquer, 2, en_US]

Figure 6-96 Application with Neutral Reactor

As side rated value, the following results:
10 MVA/(√3 · 132 kV) = 43.7 A
You can thus define the lower limit for the threshold value:

$$\text{Threshold value} \geq 0.05\ I/I_{rated,S} \cdot \frac{300\ A}{43.7\ A} = 0.343\ I/I_{rated,S}$$

[fo_schwe6, 1, en_US]

Select 0.35 I/Irated,S as threshold value.

- Recommended setting value **(_:103) Threshold** = ***0.35 I/Irated,S***

There are no fault currents which could potentially lead to a current-transformer saturation flowing through the protection range of the shunt reactor. The characteristic curve therefore does not require an increased value for stabilization (parameter **(_:11041:100) Slope 1**). You can set the operate curve very flat since there are no transient faults due to magnetization, transformer tap changers, or transformer faults. Siemens recommends a minimum slope of 0.05.

- Recommended setting value **(_:105) Slope** = ***0.05***

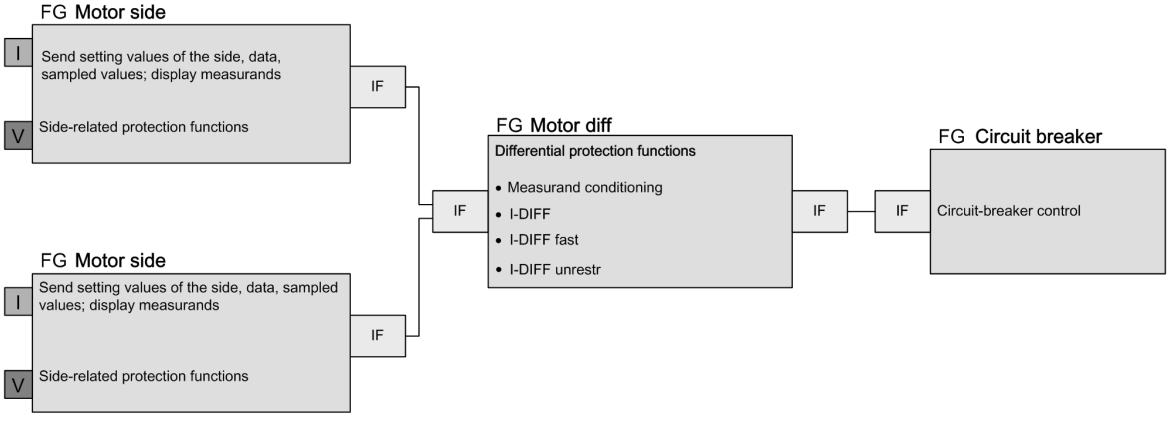
6.5 Motor Differential Protection

6.5.1 Overview of Functions

The **Motor Differential Protection** function (ANSI 87M):

- Detects ground faults and multiphase short circuits in motors
- Detects ground faults during the operation of motors using mains with a grounded neutral point
- Is stable during startup processes with current-transformer saturation through intelligent saturation recognition methods
- Triggers safely in the case of internal high-current faults through an additional high-current stage

6.5.2 Structure of the Function



The **Motor differential protection** function is used in the **Motor diff** protection function group. The function depends upon application in the corresponding application template preconfigured by the manufacturer or can be copied during the engineering into the corresponding function group.

The **Motor differential protection** function consists of the 2 tripping stages I-DIFF and I-DIFF fast. In addition, the I-DIFF unrestrained tripping stage is available. You can select this tripping stage from the function catalog and copy it into the **Motor differential protection** function. The tripping stages can be blocked, in addition you can switch the tripping stages on and off.

In the function group **Motor Side**:

- The side-related protection settings are performed
- The side-related calculations are performed
- All data (setting values, detected currents) are relayed to the **Motor** function group

Motor side-related protection functions can run in the **Motor Side** function group, for example overload protection, overcurrent protection, etc.

[dweimbfk-190712-01.tif, 2, en_US]

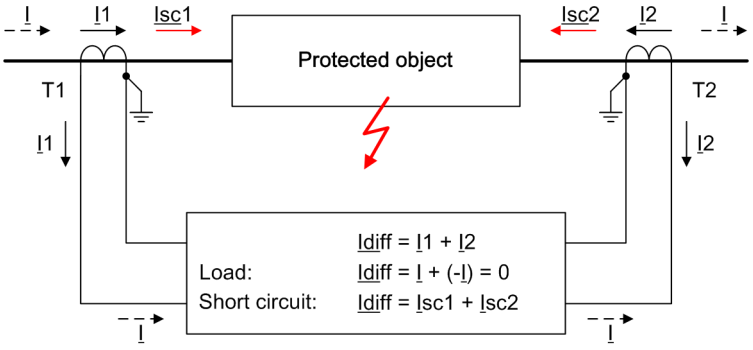


Figure 6-97 Structure/Embedding of the Function

6.5.3 Function Description

Basic Principle of Differential Protection

Differential protection is based on a comparison of currents (Kirchhoff current law). When comparing the current, use is made of the fact that a protected object uses the same current I in a non-faulty operating state on both sides (dotted in *Figure 6-98*). This current flows into the range being observed on one side and leaves

it again on the other side. A current differential is a sure indication of a fault within the protected object. The calculation of the difference is determined through the current-direction definition. The current direction is defined as positive to the protected object. The current difference results from the vector addition of the currents.

[dwprin2s-170712-01.tif, 1, en_US]

Figure 6-98 Basic Principle of Differential Protection Using the Example of 2 Sides

For safe operation, additional functions are required. The implementation of these additional functions is described in chapter *I-DIFF Differential Protection Function, Page 672*.

Current Stabilization

If very large currents flow through the protection range in the case of external faults, with different transmission behavior of the transformers **T1** and **T2** (*Figure 6-98*), a corresponding differential current I_{diff} occurs. When this is larger than the corresponding pickup threshold, the device can issue a trip command, even though no fault is present in the protection range. Such a malfunction of the protection is avoided by the restraint current (I_{rest}) and is implemented in the form of a characteristic curve $I_{diff} = f(I_{rest})$.

The largest current of 2 or more measuring points of the protected object is used for stabilization.

The definition for 2 measuring points is:

A trip or differential current is

$I_{diff} = (\underline{I}_1 + \underline{I}_2)$

as well as a restraint current of

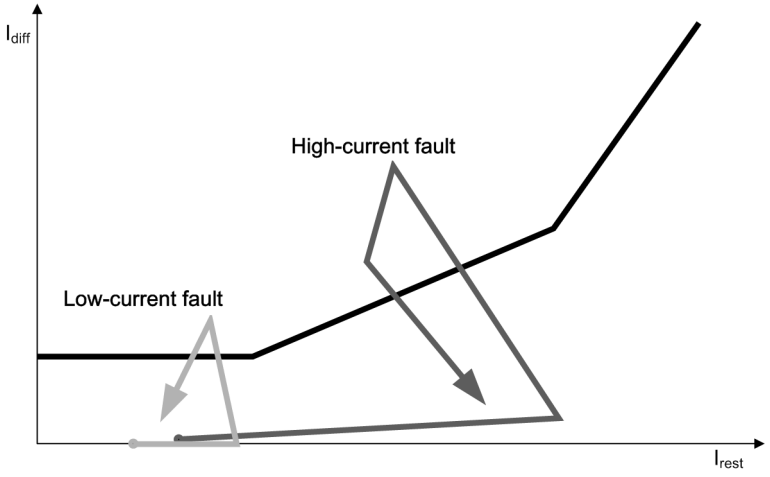
$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|)$

For more than 2 measuring points, this definition is expanded. This restraint method allows a reliable trip decision for more than 2 measuring points and different feeding behavior for internal short circuits.

$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2| ; \ldots |\underline{I}_n|)$

To clarify the effect, 3 important operating states are observed with ideal and adapted measurands.

- Through fault current in healthy operation or externally caused error:
  $\underline{I}_1$ flows into the protection range, $\underline{I}_2$ flows out of the protection range, that is, negative compared with the prefix definition, thus $\underline{I}_2 = -\underline{I}_1$;
  in addition $|\underline{I}_2| = |\underline{I}_1|$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 - \underline{I}_1| = 0$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$
  No tripping quantity ($I_{diff} = 0$); the stabilization (I_{rest}) corresponds to the flowing current.
- Internal short circuit, feed from both sides with equal amount of currents, for example:
  Then $\underline{I}_2 = \underline{I}_1$; In addition $|\underline{I}_2| = |\underline{I}_1|$;
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + \underline{I}_1| = 2 \cdot |\underline{I}_1|$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$
  The tripping quantity (I_{diff}) is twice as large as the short-circuit current and the restraining quantity (I_{rest}).

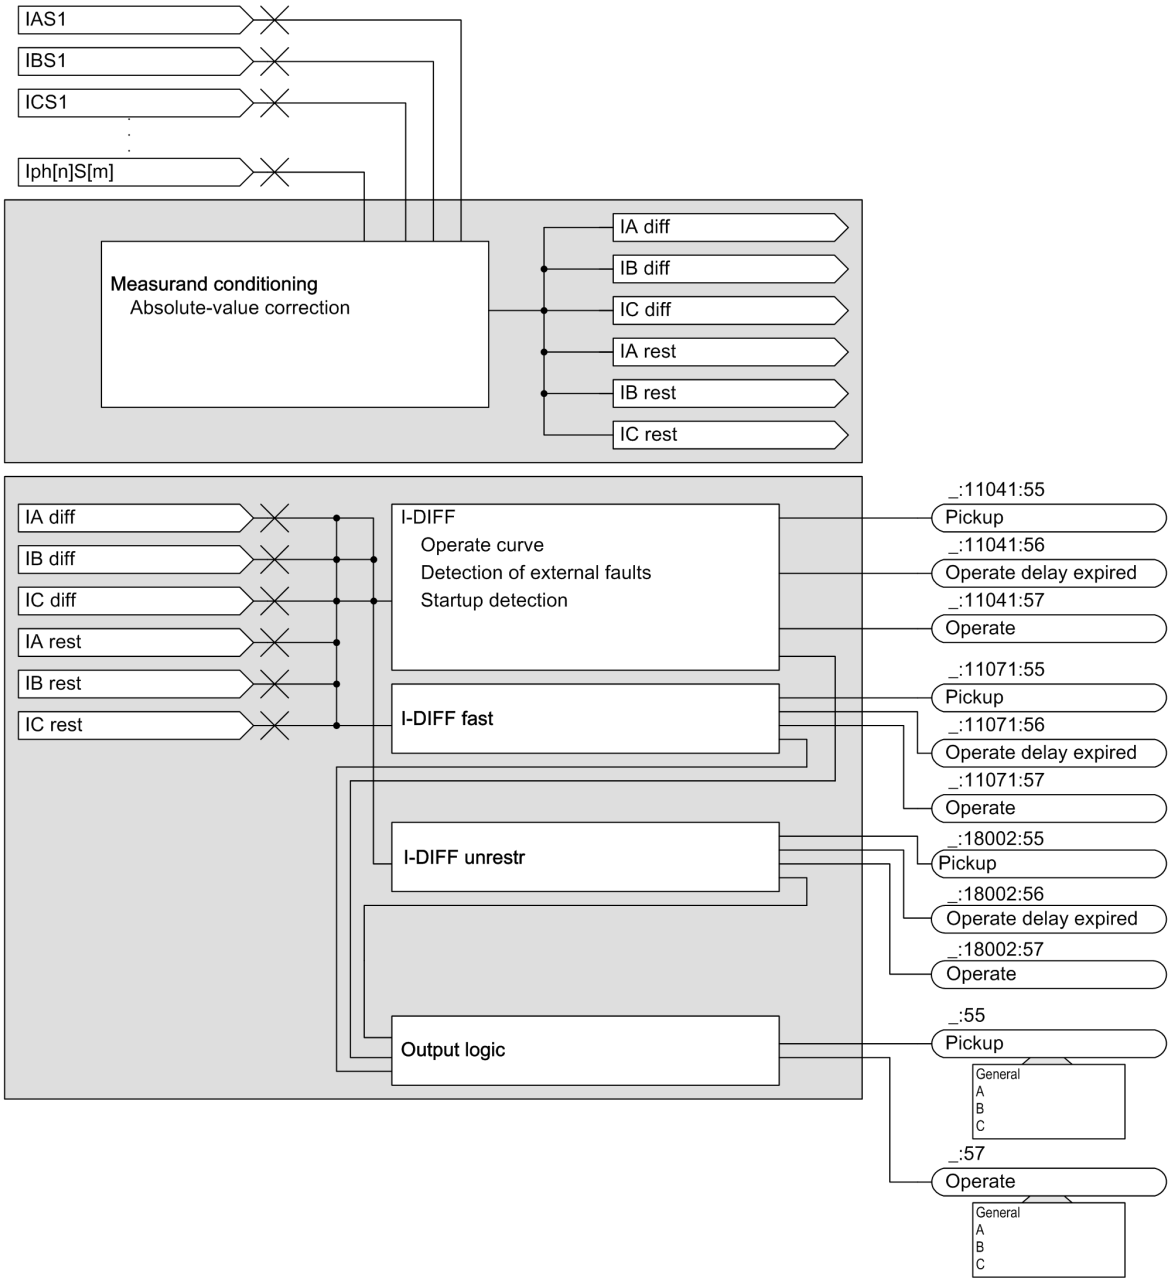


- Internal short circuit, feed only from one side:
  Then $\underline{I}_2 = 0$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + 0| = |\underline{I}_1|$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1|$
  The tripping quantity (I_{diff}) and the restraining quantity (I_{rest}) are of the same size and correspond to the short-circuit current.

Additional Stabilization with External Short Circuits

In case of an external short circuit, high short-circuit currents flowing through can lead to current-transformer saturation. This saturation can be more or less strongly pronounced at the measuring points, and in this way simulate a differential current. The differential current can lie in the tripping range of the characteristic curve for a certain time and lead to unwanted tripping without any particular measures. In accordance with *Figure 6-99*, there are 2 typical scenarios:

- High-current, external short circuit
  First, the current on both sides is transferred and leads to a large restraint current. After this, a transformer becomes saturated, resulting in a differential current I_{diff} that can exceed the operate curve. Simultaneously, the restraint current I_{rest} drops. Once the transformer is no longer saturated, the differential current decreases and falls below the characteristic curve.
- Low-current, external short circuit
  Current transformers can also become saturated through the large direct-current time constant (switching of transformers, motors), but small currents flowing through. This manifests itself as a phase-angle rotation of the current. Exceeding the characteristic curve in a non-stabilized area is possible.



Intelligent saturation-detection methods capture this state and lead to a temporally limited blocking of the Differential protection function.

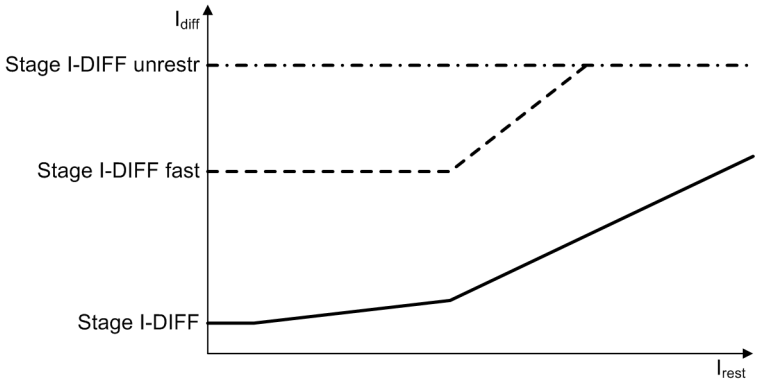
Figure 6-99 Principle Current Course in External Short Circuit and Temporary Current-Transformer Saturation on One Side



Logic of the Function

[lomesmgr-190713-01.tif, 2, en_US]

Figure 6-100 Logic Diagram of the Differential Protection Function

The interaction of the I-DIFF, I-DIFF fast, and I-DIFF unrestrained tripping stages is shown in the following operate curve.

[dw_charac_function_trans-dif, 1, en_US]

Figure 6-101 Operate Curve of the Differential Protection Function

In the following, the essential components of differential protection are described in detail.

Measurand Processing

Amount Correction

Since the current transformers cannot be adapted exactly to the rated currents of the protected object with regard to their primary rated data, a standardization to the nominal sizes of the protected object takes place. The conversion occurs every sampling time (thus, for instantaneous values). The differential protection function processes 20 sampled values per period. In addition, the sampled values tracked are used. A high degree of accuracy can be attained over the entire tracking range (from 10 Hz to 90 Hz).

The IDIFF-fast tripping and the IDIFF-unrestrained tripping stages work on non-frequency tracked values and thus, implement fast operate times at low frequencies.

The amount is adapted via the following formula:

$$i^{*}_{phsx} = k\, i_{phsx}$$

$$\text{with } k = \frac{I_{rated\,prim,\,Sx}}{I_{rated\,obj,\,Sx}} = \frac{I_{rated\,prim,\,Sx}}{\frac{S_{rated,\,ref}}{V_{rated,\,Sx}\sqrt{3}}}$$

[fobetr07-170712-01.tif, 1, en_US]

i_{phsx}*	Adapted instantaneous value per phase (x = A, B, C)
i_{phsx}	Instantaneous value per phase (x = A, B, C)
k	Correction value per measuring point
$I_{rated\ prim,Sx}$	Primary transformer rated current per measuring point
$I_{rated\ obj,Sx}$	Primary rated current of the protected object
$S_{rated,ref}$	Reference power (maximum rated apparent power of the protected object)
$V_{rated,Sx}$	Rated voltage of the respective side (measuring point) of the protected object

I-DIFF Differential Protection Function

A differential current per phase based on the instantaneous value variables is calculated from the processed currents (see section Measurand Processing). The direction of current flow is defined as to the **protected object as positive**. The fundamental component contribution to the differential current (I_{diff}) is calculated via a Fourier filter (filter length = 1 period (20 sampled values)).

The currents of that measuring point whose RMS value is the largest are used as restraint current. If, for example, the current collapses at a measuring point as a consequence of current-transformer saturation,

the measuring point that has the largest current is automatically switched to at the point in time of the calculation.

$$i_{diff,phsx} = \sum_{m=1}^{N} i^{*}_{phsx,Mm} \rightarrow I_{diff,phsx} = FIR(i_{diff,phsx})$$

$$I_{phsx,Mm} = \sqrt{\frac{1}{n}\sum_{k=1}^{n} i^{*2}_{phsx,Mm}(k)}$$

$$I_{rest,phsx} = \underset{m=1}{\overset{N}{MAX}}\, I_{phsx,Mm}$$

[fogrds16-170712-01.tif, 1, en_US]

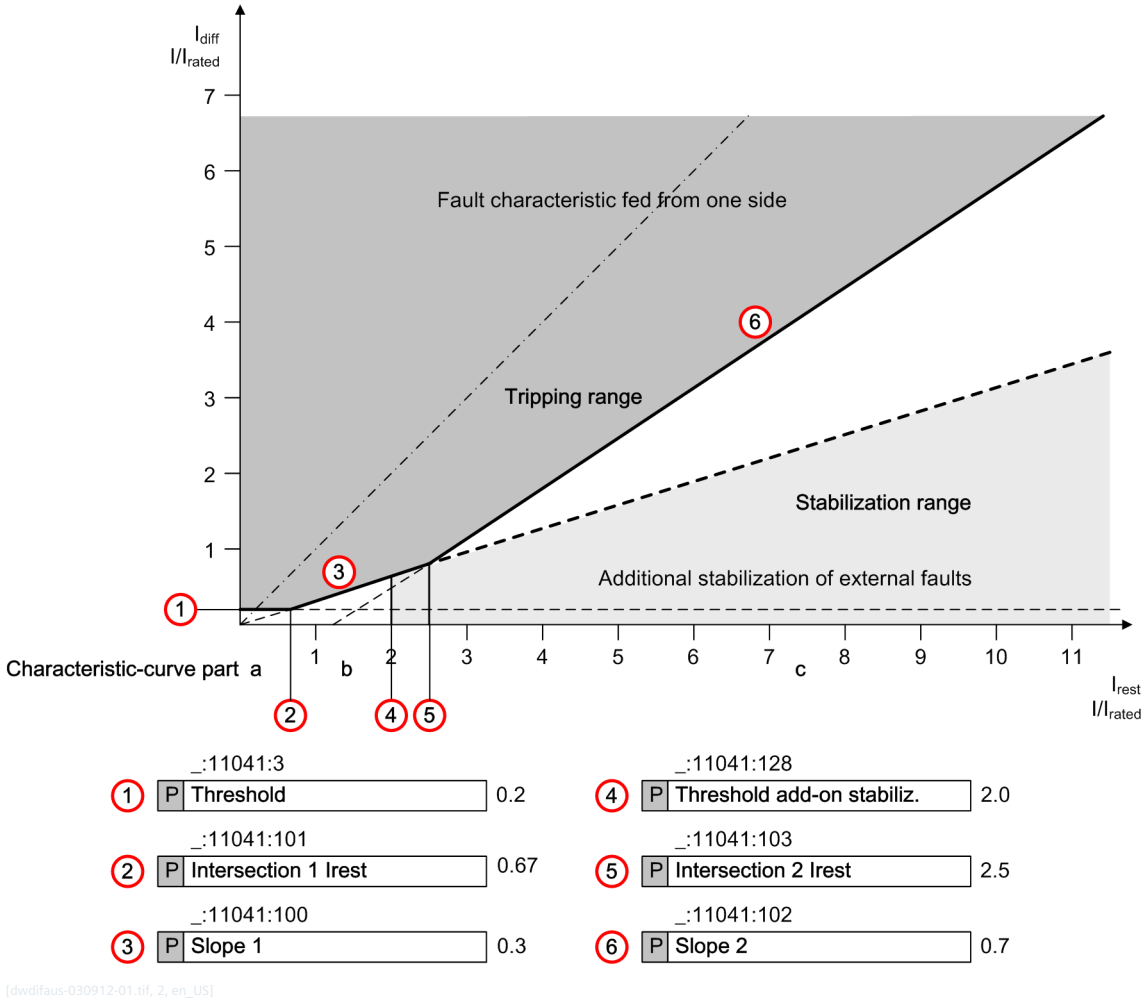
With

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points
n	Number of samples per period (n = 20)
FIR	Fourier filter
MAX	Maximum value determination

Pickup Characteristic

Figure 6-102 shows the pickup characteristic of the differential protection. The characteristic curve branch **a** represents the sensitivity threshold of the differential protection (parameter **`Threshold`**) and considers constant fault currents like magnetizing currents.

The characteristic branch **b** (parameter **`Intersection 1 Irest`** and **`Slope 1`**) considers current-proportional faults under normal operating conditions.



These faults can occur for the following reasons:

- Transformation errors in the current transformer and the input transformer of the device
- Adaptation deviations

The characteristic curve branch **c** (parameter **`Intersection 2 Irest`** and **`Slope 2`**) protects the differential protection against overfunction in case of high-current external faults and transformer saturation. In this range, transformer saturation can arise due to high short-circuit currents, and because of this, a higher differential current results.

In order to avoid overfunction in the event of external faults with current-transformer saturation, a logic is implemented that uses the characteristic curve **Additional stabilization of external faults**. If the operating point is located in the additional stabilization range and exceeds the operate curve from there, then the logic becomes active and blocks the differential protection.

The additional stabilization range is derived from the **`Threshold add-on stabiliz.`** and **`Slope 1`** parameters.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-102 Pickup Characteristic of the Differential Protection

If the differential current multiplied by the dropout ratio of 0.7 does not reach the pickup characteristic, the pickup drops out.

Detection of External Faults

To detect external faults with transformer saturation in a reliable way, the measurand curve is evaluated in the Diff.-Rest level by means of a detector. An external fault can occur if the motor feeds back to an external short circuit or if the motor starts up.

The detector has 2 essential tasks:

- **Blocking in the case of a definite high-current external fault**

  The differential current and the restraint current are monitored on a phase basis in the Diff/Restr level immediately after fault inception. To ensure the stability of the saturation detection for low saturation-free times of the primary current transformer, estimated values based on the difference quotients of the instantaneous values are used.

  If the estimated restraint current exceeds the **Threshold add-on stabiliz.** parameter and the expected value of the differential current of all phases is in the additional stabilization range (parameter **Slope 1**) (*Figure 6-102*) at the same time, the detector is active and the indication *Blocked by ext. fault phsx* appears. The tripping of the Differential protection function is blocked.

  If an external fault arises and is cleared by the protection responsible for it, the additional stabilization drops out. If the dropout ratio (0.7) of the RMS value of the restraint current does not reach the **Threshold add-on stabiliz.** parameter (*Figure 6-102*), the additional stabilization drops out. The indication *Blocked by ext. fault phsx* is reset.

  If the differential current exceeds **Slope 1** as a result of transformer saturation, that is, there is a pickup phsx, the blocking is limited in time (parameter: **Time of add-on stabiliz.**).

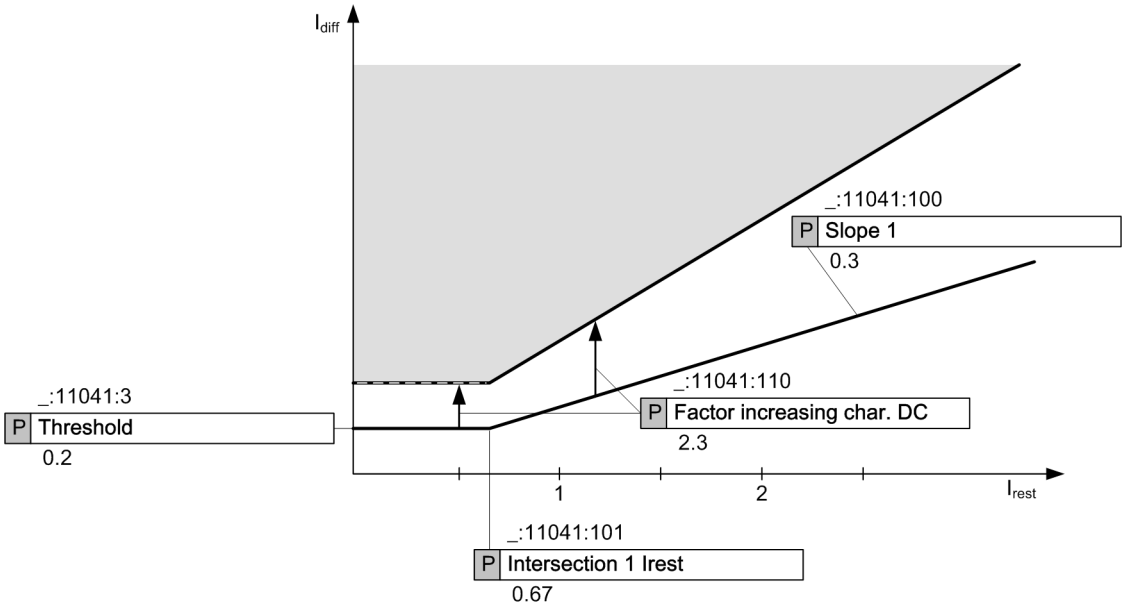
  Starting with the indication *Blocked by ext. fault phsx*, the other phases can be blocked with it via the **Crossblk. time add-on st.** parameter. If differential currents due to transformer saturation spread to the other phases through the vector-group correction or residual current elimination, this blocking is necessary.

- **Removal of the blocking with a change in fault location from external to internal**

  An internal fault can arise as a consequence of an external fault. This fault change must be recognized and the blocking must be removed. The critical case is a short-circuit with current-transformer saturation. The saturation detection examines here the instantaneous values of the differential current. With transformer saturation, the instantaneous values fall below an internal threshold in the saturation-free time. If this threshold is permanently exceeded and a pickup is present in the corresponding phase, an internal error is assumed. The other phases are also examined during the parameterization with crossblock.

  The blocking of the tripping is removed and the indication *Blocked by ext. fault phsx* is reset.

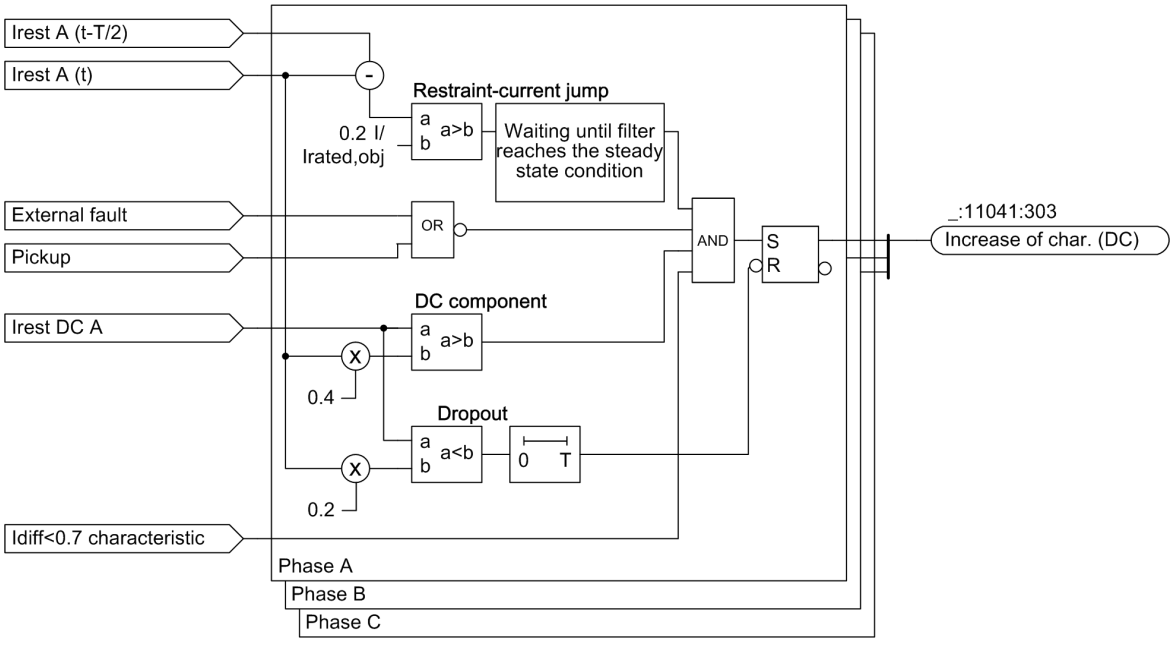
DC-Component Detection



Low-current external faults with large DC components can also lead to exceeding of the operate curve. The additional stabilization range is not attained, however.

To avoid an overfunction, the following steps are taken:

- The restraint current $I_{rest.;phsx}$ is monitored for a jump.
- If the jump occurs, the DC component is calculated, with a temporal delay (1 period), from the instantaneous value of the restraint current (current at the measuring point with the largest current) $i_{rest.,phsx} = i_{phsx,Mm}$. The result is $I_{rest.DC,phsx}$. This current is compared to the restraint current $I_{rest.,\ phsx}$ and is checked for exceeding of the internal threshold.
- The differential current $I_{diff,phsx}$ must lie below the dropout characteristic curve (characteristic curve · 0.7) in all 3 phases.
- If the first 3 points lead to positive results, then the operate curve is raised by the parameter **Factor increasing char.** with a default setting of ***2.3***. Here, only the threshold value and the slope 1 are raised (see *Figure 6-103*). The indication *Increase of char. (DC)* is output. If the product of parameter **Factor increasing char.** and **Slope 1** exceeds **0.85**, the maximum increase of the raised **Slope 1** is limited to 0.85.
- As additional criterion, the pickup indication *Pickup* (internal fault is present) or the indication of the additional stabilization *Blocked by ext. fault phsx* (high-current external fault) is interrogated. If one of the 2 conditions is present, the characteristic-curve increase is stopped. A retroactive pickup no longer resets the characteristic-curve increase. A pickup with DC-component detection occurs only if the raised operate curve is exceeded.



If the DC component $I_{rest.DC,phsx}$ falls below the internal dropout threshold, the dropout delay is determined as follows:

It is assumed that the de- and re-magnetization of the transformer last equally long. The magnetization is at the highest at the point in time in which the internal dropout threshold is attained. The time is measured from the start of the DC-component detection until the internal dropout threshold is reached. Added to this time are 5 periods and from this, the dropout delay is derived. Following this, the characteristic-curve increase is reset to the original value. *Figure 6-104* shows the overall logic.

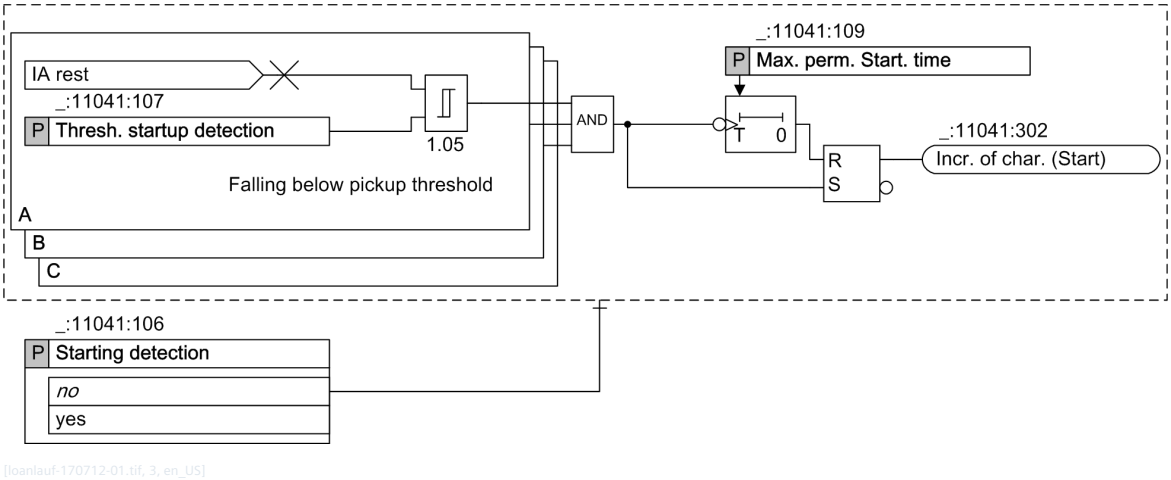
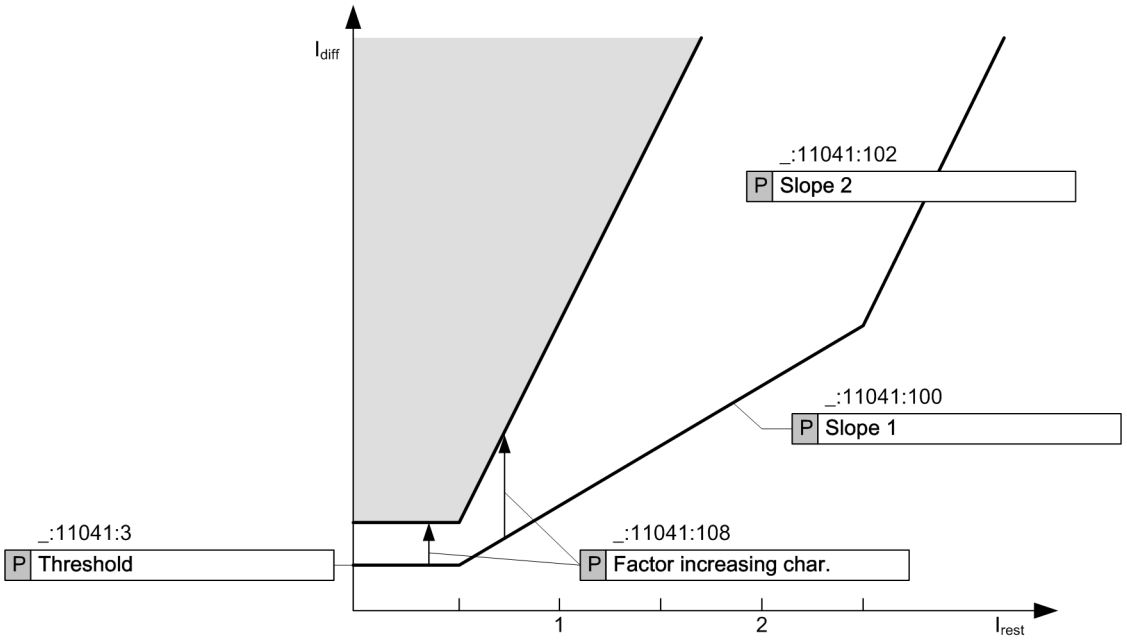
Figure 6-104 Logic DC Detection



Startup Detection

The startup detection is particularly useful in the case of motors. In contrast to transformers, the inrush current with motors is a flowing current. Differential currents can arise, however, by the current transformers having different residual magnetization and being supplied with current at different operating points of their hysteresis. These differential currents are low in fact, but they can lead to overfunction with sensitive setting of the differential protection.

With generators, the motor startup can also lead to higher currents. With the startup detection, you can make the protection somewhat less sensitive for a specific period of time and avoid overfunction. As a result you achieve a comparable effect to that of DC-component detection.



As additional security against overfunction when switching in a previously protected object that carries no current, you can use the pickup-value increase at startup. If the restraint current falls below a settable value **Thresh. startup detection** in all phases, the pickup-value increase is activated. The pickup value **Threshold** and **Slope 1** are raised by the set value in accordance with parameter **Factor increasing char.**. As a rule here, **Slope 1** cannot exceed a value of 0.85.

If the parameter **Thresh. startup detection** is exceeded, dropout occurs and a timing element (parameter: **Max. perm. Start. time**) is activated. Once this time has elapsed, the characteristic curve that was increased in all phases is reset to its original value. *Figure 6-105* shows the logic diagram of the startup detection and *Figure 6-106* the increased characteristic curve.

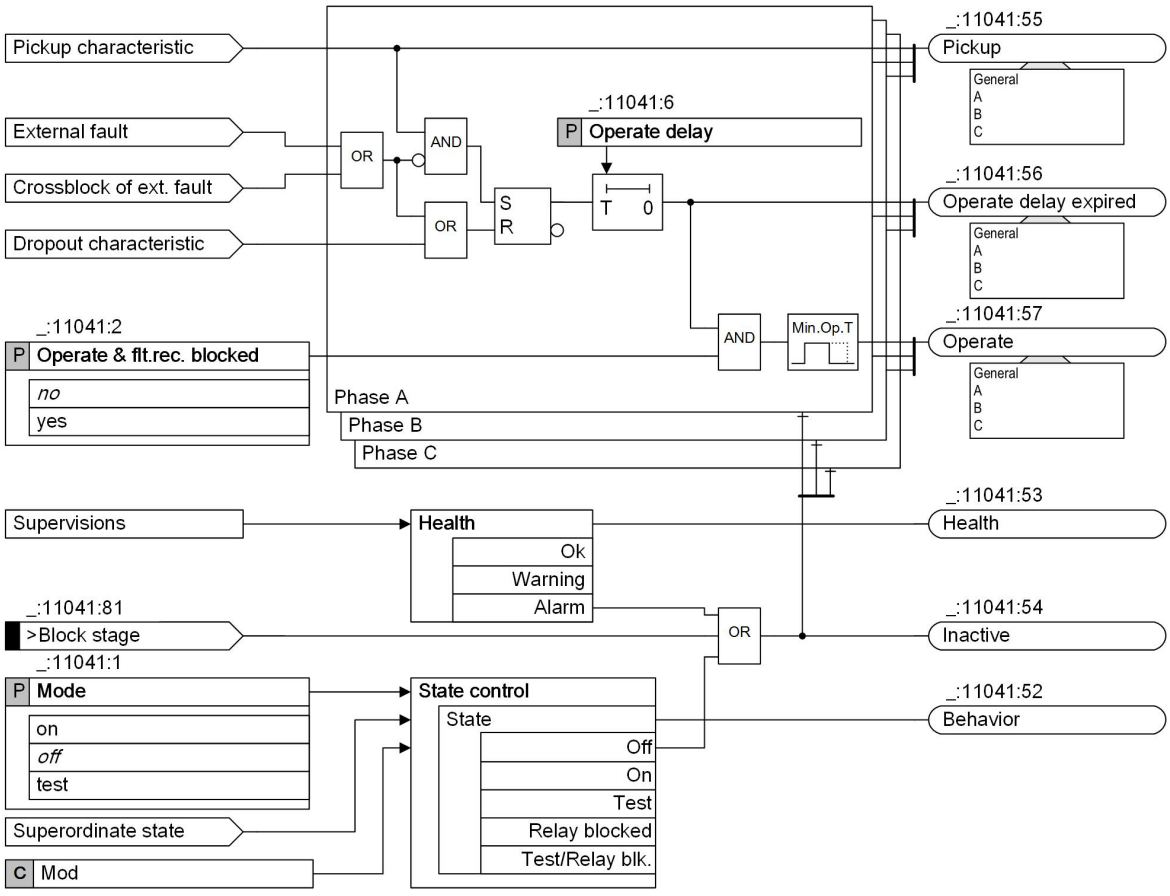
Figure 6-106 Characteristic-Curve Increase at Startup



Trip Logic of the Differential Protection Function I-DIFF

Figure 6-107 shows the trip logic. If the characteristic curve is exceeded (see *Figure 6-102*) a pickup occurs. Redirection of the information for tripping can be blocked by the additional functions.

Blocking is possible through use of the following influencing variables:

- Recognition of external faults that can simulate an internal fault through transformer saturation

In addition, in case of blocking due to an *external error*, a **crossblock** mechanism comes into effect.

[lo_aus_mid, 2, en_US]

Figure 6-107 Trip Logic of I-DIFF

I-DIFF Fast Differential Protection Function

As a supplement to the I-DIFF differential protection function, the function I-DIFF fast is available. The main task consists in switching off high-current internal faults in the shortest amount of time. The method controls current-transformer saturation and is stable in the event of external transverse faults (integration in breaker-and-a-half arrangements).

Metrologically, 2 methods are combined:

- Instantaneous-value method
- Filter-based method

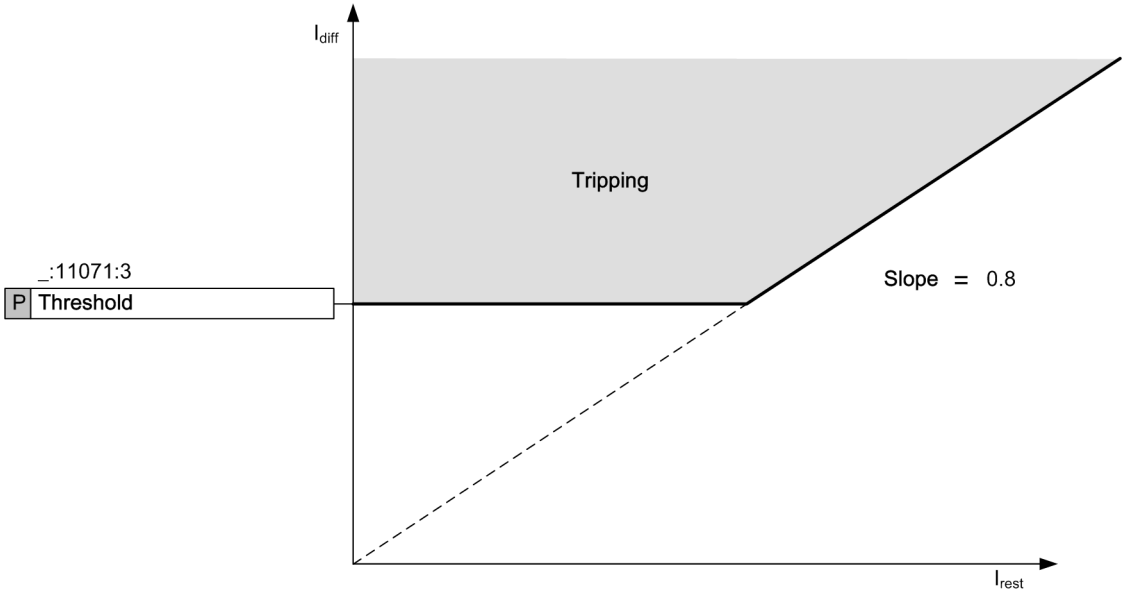
Instantaneous-Value Method

Through the instantaneous-values method, an immediate evaluation of the sampled values of the differential $i_{Diff}(t)$ and restraint current $i_{rest}(t)$ occurs. The absolute-value and vector-group adapted currents (i*) are also the basis. The currents are defined positively to the node. The restraint current is the maximum current of all measuring points.

$$i_{diff,phsx}(t) = \left| \sum_{m=1}^{N} i^{*}_{phsx,Mm}(t) \right|$$

$$i_{rest,phsx}(t) = \max_{m=1}^{N} \left| i^{*}_{phsx,Mm}(t) \right|$$

[fomome27-170712-01.tif, 1, en_US]

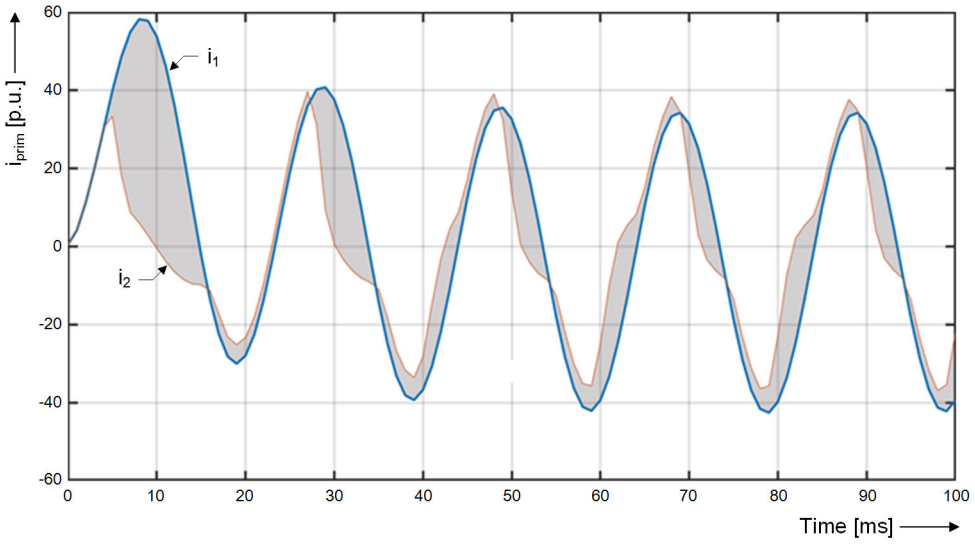


where

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points

The evaluation of the restraint current is used to recognize saturated, high-current external faults.
Figure 6-108 shows the operate curve. The parameter **Threshold** is set here such that it lies over the maximum fault current flowing. The slope of the characteristic curve is fixed at 0.8.
In the algorithm, the following conditions are processed:

- Condition 1: The increase of the restraint current $di_{rest}(t)/dt$ is determined continuously and compared with an internal threshold value.
- Condition 2: After that, a comparison determines whether the differential current is larger than the restraint current (characteristic curve **Slope** in *Figure 6-108*): $i_{diff}(t) > 0.8 \cdot i_{rest}(t)$.
- Condition 3: After that, a comparison determines whether the differential current exceeds the parameter **Threshold**.



When all conditions are met, tripping occurs immediately. If the 1st condition is recognized and not the 2nd condition, then the function is blocked for 300 ms.

[dwidfast-300114-01.tif, 1, en_US]

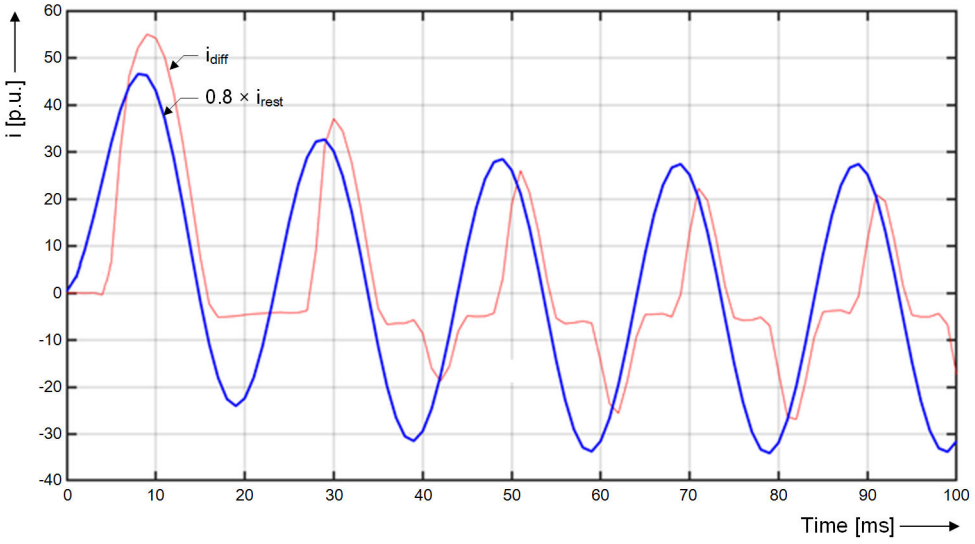


Figure 6-108 I-DIFF Fast Characteristic Curve

The 2 following figures show the behavior during an internal and an external fault. It is typical for the internal fault (*Figure 6-109*) that the differential current rises more quickly than the restraint current. After a few sampled values, the trip signal is issued. In case of an external fault, a differential current arises only after transformer saturation occurs. You can always assume, however, that the current is transferred a few milliseconds after occurrence of the fault. In accordance with *Figure 6-111*, the restraint current is larger than the differential current after occurrence of the fault, but condition 2 is not met and the function is therefore blocked.

[dwextfel-170712-01.tif, 2, en_US]

Figure 6-110 Curve Plot for External Fault with Transformer Saturation (k= 0.65)

Fundamental-Component Method

Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} and the stabilization value (maximum current of a measuring point) $I_{rest.}$ are ordered in the operate curve according to *Figure 6-108* and the trip decision is made.

Figure 6-111 shows the overall logic.

[lo_id_fast, 4, en_US]

Figure 6-111 Logic of the I-DIFF Fast Differential Protection Function

I-DIFF Unrestrained Differential Protection Function

In addition to the I-DIFF and I-DIFF fast differential protection function, the function I-DIFF unrestrained is available. The main task of this function consists in switching off high-current internal short circuits in the shortest amount of time. The method controls current-transformer saturation.

High-current faults in the protection range can always be switched off immediately without consideration of the restraint currents if, due to the current magnitude, it is determined that an external fault is not involved. In the case of protected objects with a large intrinsic longitudinal impedance (transformer, generator, reactor), a current can be found that is never exceeded by a flowing short-circuit current.

For a transformer, for example, the (primary) value is:

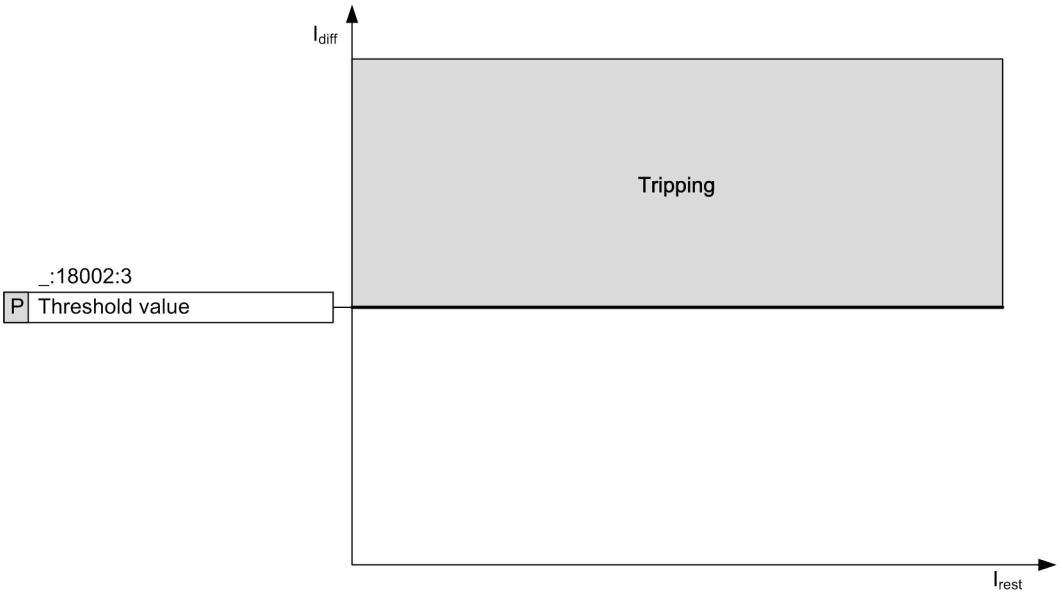
$$\frac{1}{v_{sc\ transf.}} \cdot I_{N\ transf.}$$

[fo_Idiff-error, 1, en_US]

The I-DIFF unrestrained stage also acts if, for example, due to current-transformer saturation because of a DC component in the short-circuit current, a 2nd harmonic occurs. The inrush-current detection could interpret this as the closed-circuit current.

The I-DIFF unrestrained protection stage operates both with the fundamental component of the differential protection and with the instantaneous value.

Metrologically, 2 methods are combined:

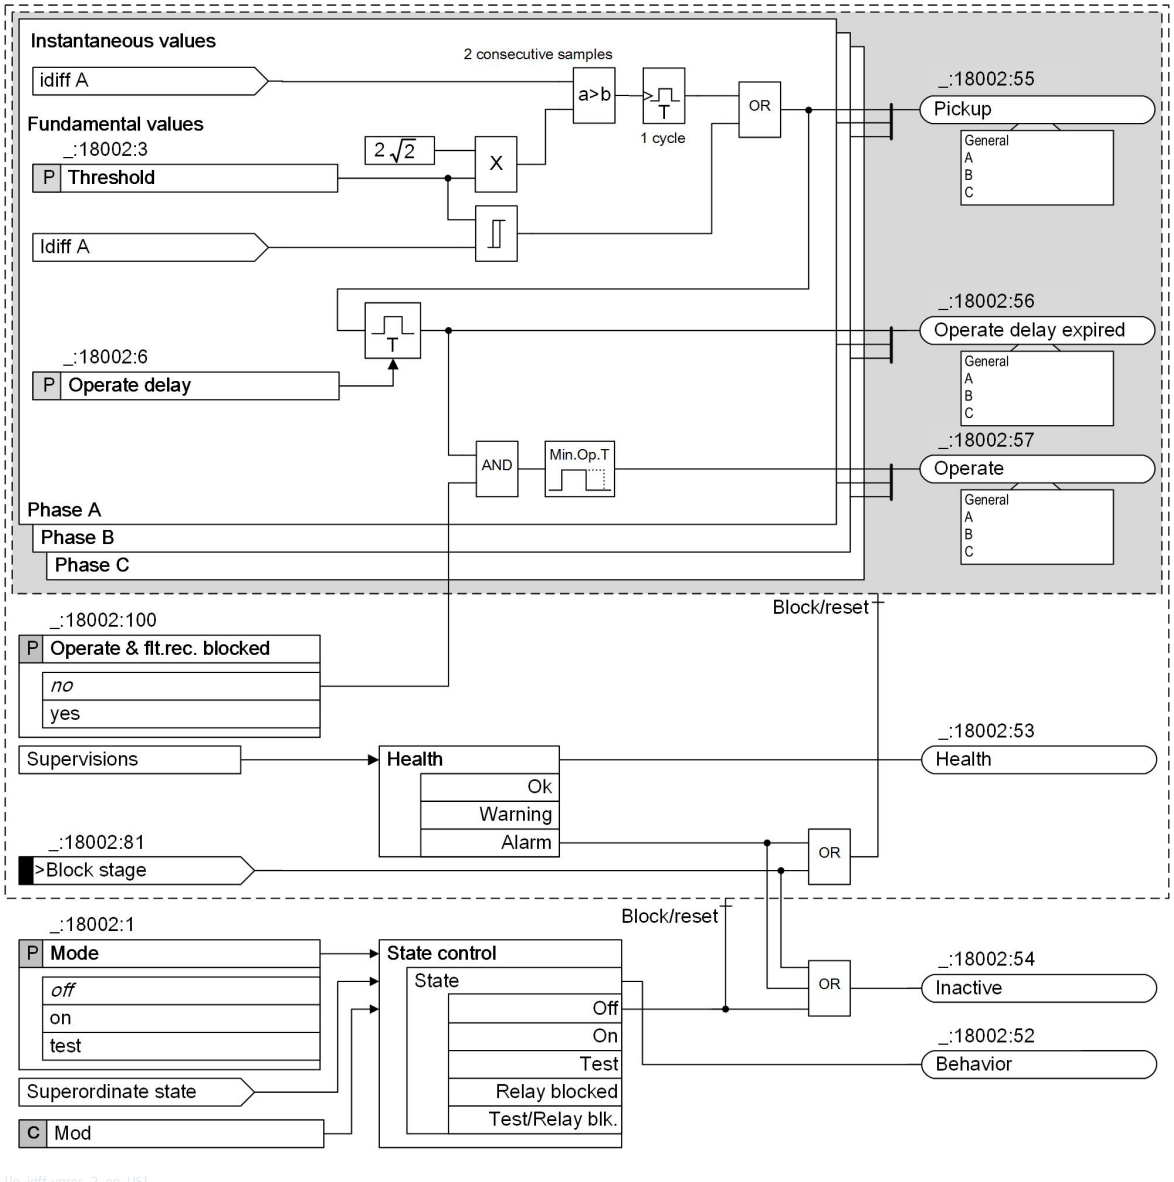


- Instantaneous-value method
- Filter-based method

Instantaneous-Value Method

With the instantaneous-values method, an immediate evaluation of the sampled values of the differential current $i_{Diff}(t)$ occurs. The absolute-value and vector-group adapted currents (i*) are also the basis.

Fundamental-Component Method



Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} is ordered in the operate curve *Figure 6-112* and the trip decision is made.

Figure 6-113 Logic of the I-DIFF Unrestrained Differential Protection Function

Trip Logic of the Differential Protection

A common trip signal is formed from the subfunctions I-DIFF, I-DIFF fast, and I-DIFF unrestrained. *Figure 6-114* shows the corresponding logic.

[lo_gesamt, 3, en_US]

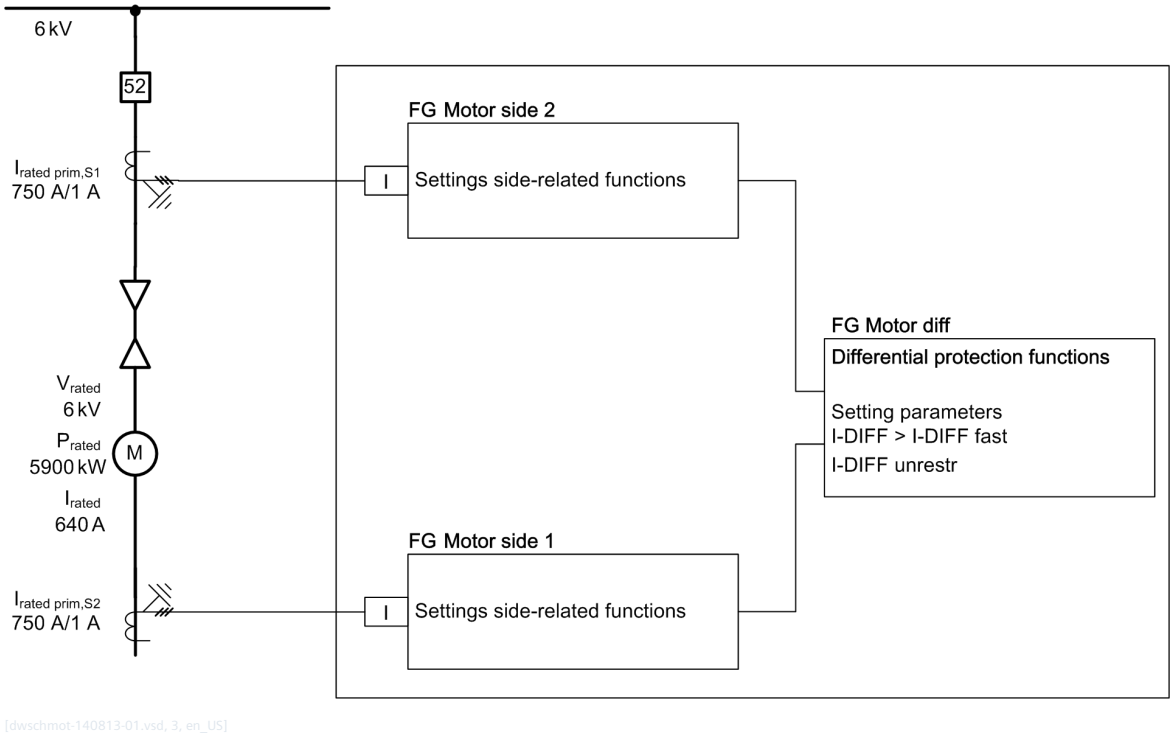
Figure 6-114 Overall Trip Logic

Fault Logging and Fault Recording

A fault is opened with every protection pickup. This means that a fault log and a fault recording are started. Saving of the fault record depends on the setting (see *3.5.3 Function Description*). Since pickup and tripping are the same in differential protection, the recording setting can be used with the pickup function. To enable fault recording even with external errors, along with the exceedance of the characteristic curve, a fault record is opened in case of a blocking by an external error or in case of a characteristic-curve increase through a DC-component detection. This has the advantage that you can evaluate the transformer transfer method of the current transformers very well in case of a fault.

6.5.4 Application and Setting Notes

Setting information for the required setting parameters is provided for a typical motor protection application. *Figure 6-115* shows a typical motor protection application. For motors with a power of more than 1 MW to 2 MW, Siemens recommends the use of differential protection. This prevents damage in the event of tripping in case of a short circuit. The application assumes that a current-transformer set is available at the motor neutral point. The **Motor differential protection** is operational in the devices 7UT82, 7UT85, 7UT86, and 7UT87.



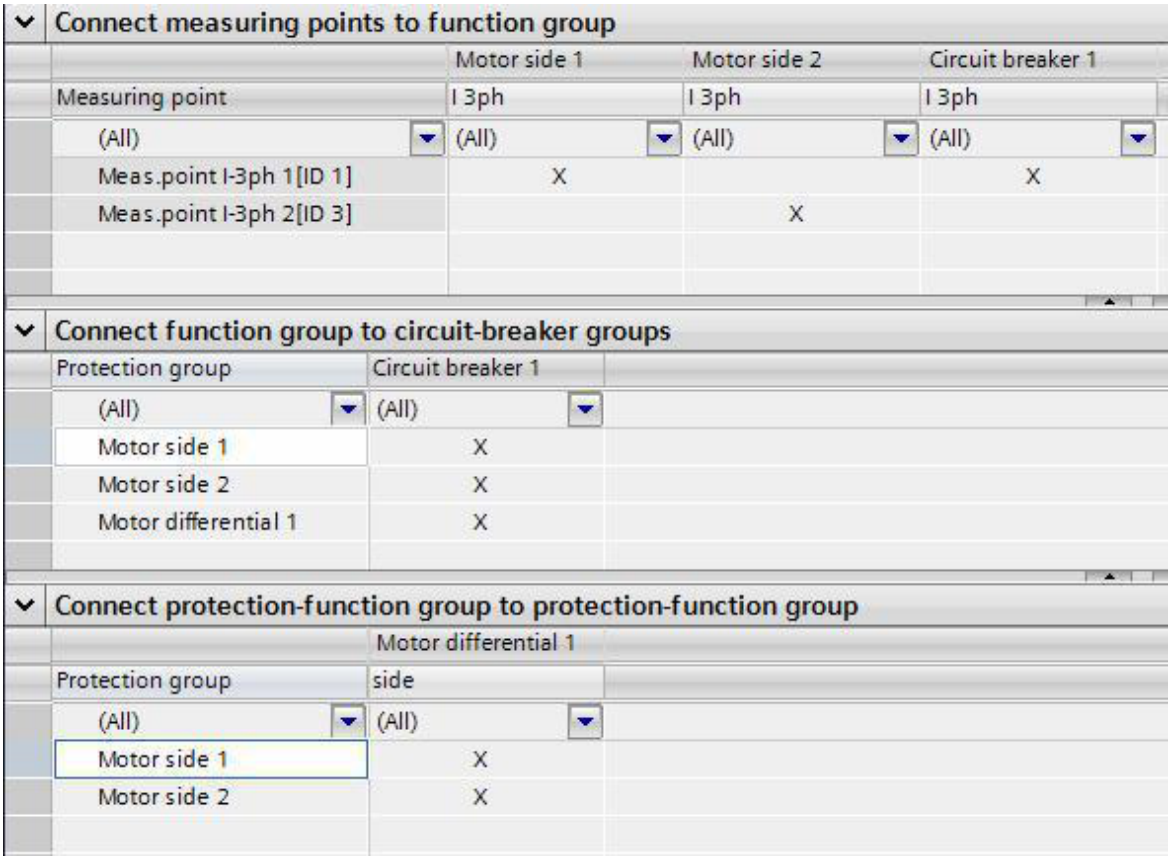


Figure 6-115 Connection Example

In the example, a 7UT85 is selected. Here, 2 measuring inputs are interconnected on the 3-phase measuring points of side 1 and side 2. The measuring points must be interconnected with the corresponding function groups.

Figure 6-116 shows the corresponding screenshot from DIGSI 5.

[scmesveb-200214-01, 1, en_US]

Figure 6-116 Internal Interconnection in DIGSI 5

Motor Side Function Group

In the **Motor side** function group, make the following settings:

NOTE

Ensure that the correct transformer data are set at the measuring points.

Parameter: `Rated apparent power`

- Default setting **`(_:14671:103) Rated apparent power`** = ***`6.65 MVA`***
  With this parameter, you set the rated apparent power of the motor. For a motor with 2 sides, the setting value is the same for both sides.

Parameter: `Motor rated voltage`

- Default setting **`(_:14671:102) Motor rated voltage`** = ***`6 kV`***
  With this parameter, you set the motor rated voltage of the motor. This is 6 kV in this example.

Motor Diff. Function Group

Make the following settings in the **Motor Diff.** function group for the I-Diff function:

Parameter: `Threshold` (Setting the Characteristic-Curve Parameters)

- Default setting **`(_:11041:3) Threshold`** = ***`0.20 I/Irated,obj`***

With this parameter, you set the pickup threshold for the differential current. This is the total current flowing into the protection range during a short circuit, regardless of how it is distributed on the sides of the protected object. The pickup value is relative to the rated current of the protected object. The default setting of ***0.20 I/Irated,obj*** is a practical value between sensitivity and possible disturbing influence.

Parameter: `Intersection 1 Irest`

- Default setting **`(_:11041:101) Intersection 1 Irest`** = ***0.67 I/Irated,obj***

The maximum current of the measuring point is used as restraint current. If you have to expect dynamic transmission faults of the current transformer even with small currents, half of the rated current is an appropriate setting value.

Parameter: `Slope 1`

- Default setting **`(_:11041:100) Slope 1`** = ***0.30***

With the **`Slope 1`**, you avoid an overfunction of the differential protection with low-current external faults as a consequence of current-transformer transmission faults (stationary and dynamic faults). The default setting of ***0.30*** is sufficient for many applications.

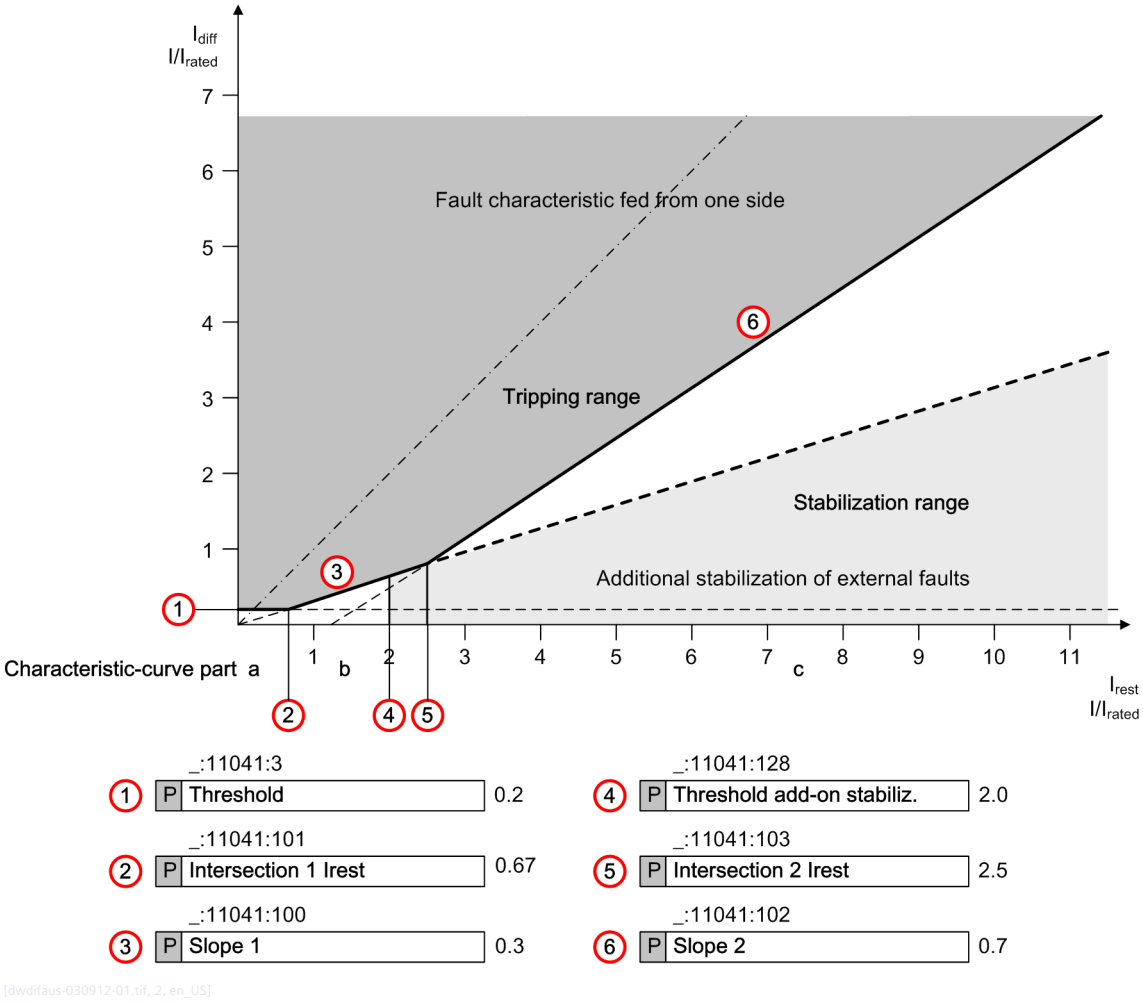
NOTE

The stabilization method has been changed from that in SIPROTEC 4 (7UT6x, 7UM62). For this reason, select a higher slope (also see *6.5.3 Function Description*).

Parameter: `Intersection 2 Irest`

- Default setting **`(_:11041:103) Intersection 2 Irest`** = ***2.50 I/Irated,obj***

NOTE



If you expect transmission problems with current transformers with larger currents flowing through, then the **`Slope 2`** must be selected to be larger.

The parameter **`Intersection 2 Irest`** determines from which restraint current the **`Slope 2`** begins. The default setting ***2.50 I/Irated,obj*** is a practical value.

Parameter: `Slope 2`

- Default setting **`(_:11041:102) Slope 2`** = ***0.70***

With the parameter **`Slope 2`**, an overfunction of the differential protection is avoided with high-current external faults as a consequence of current-transformer transmission faults (for example, due to saturation). A value greater than or equal to double the value of **`Slope 1`** is practical. As the default setting, ***0.70*** was selected.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-117 Characteristic Curve with the Default Settings

Parameter: `Starting detection`

- Default setting **`(_:11041:106) Starting detection`** = ***`yes`***

To avoid overfunction due to the motor starting current, Siemens recommends activating startup detection for motor-protection applications. This is also recommended for protecting common-mode reactors. In this case, set the default setting **`Starting detection`** = ***`yes`***.

Parameter: `Thresh. startup detection`

- Default setting **`(_:11041:107) Thresh. startup detection`** = ***`0.1 I/Irated,obj`***

If the restraint current falls below this threshold value, the subsequently set characteristic-curve increase becomes effective with activated function. The default setting value of ***`0.1 I/Irated,obj`*** is recommended for the application.

Parameter: `Factor increasing char.`

- Default setting **`(_:11041:108) Factor increasing char.`** = ***`1.0`***

Change the default setting value in the case of application. An increase to the value 2.0 has proven itself to be sufficient for many applications.

Parameter: `Max. perm. Start. time`

- Default setting **`(_:11041:109) Max. perm. Start. time`** = ***`5.0 s`***

The setting value must lie above the maximum permissible starting time of the connected motor. Refer to the motor data sheets for the starting time (for example, **Locked Rotor** time). To guarantee tripping through the motor protection (starting time monitoring) and avoid overfunctions, select a somewhat longer time (factor 1.2 or higher). For the motor in the example, a rated torque for 6.5 s was assumed for 90 % rated voltage. The setting value should be larger than 1.2 * 6.5 s = 7.8 s. Siemens recommends a setting value of 10 s.

Parameter: `Factor increasing char. DC` (DC-Component Detection)

- Default setting **`(_:11041:110) Factor increasing char. DC`** = ***`2.3`***

DC-component detection is always active. As a result of the DC components, transmission problems can arise (for example, phase-angle rotations) in current transformers with small currents flowing. For this reason, the **`Threshold`** and the **`Slope 1`** are raised by the set factor. The default setting of 2.3 has proven itself with numerous applications.

Detection of External Faults

In *Figure 6-117*, the range **Add-on stabilization with external fault** is represented. The range is described by the parameters **`Add-on stabilization threshold value`** and **`Slope 1`**. With an external short circuit, the differential currents can increase beyond this range and reach into the tripping area. With the following parameters, time-limited blocking can be performed.

Parameter: `Threshold add-on stabiliz.`

- Default setting **`(_:11041:128) Threshold add-on stabiliz.`** = ***`2.00 I/Irated,obj`***

The **`Threshold add-on stabiliz.`** parameter allows you to set the pickup value for the additional stabilization. Due to the selected method of measurement, a setting value of ***`2.00 I/Irated,obj`*** is practical. The additional stabilization range is limited by the parameters **`Threshold add-on stabiliz.`** and **`Slope 1`**.

Parameter: `Time of add-on stabiliz.`

- Default setting **`(_:11041:129) Time of add-on stabiliz.`** = ***`0.30 s`***

As orientation for the setting value, you can use the operate time of the external feeder protection. Additionally, take into account the break time of the circuit breaker. Thus, the following calculation method results:

$t_{Z\text{-rest}} \geq t_{Trip,ext\ protection} + t_{Trip,circuit\ breaker}$

The default value is a practical value. You must adapt the value appropriately to use. The value 0 s deactivates the recognition of external faults.

Parameter: `Crossblk. time add-on st.`

- Default setting **`(_:11041:130) Crossblk. time add-on st.`** = ***`0.30 s`***

The additional stabilization acts separately on each phase. However, it can be extended to block all phases. Siemens recommends the activation of the crossblock function with a corresponding setting of the time. The set time must be identical to the time that is set for the duration of the additional stabilization.

Protection Stage I-DIFF Fast

The task of this protection stage is the fast detection of high-current internal faults (see also *I-DIFF Fast Differential Protection Function, Page 679*). For this reason, the protection stage must always be activated.

Parameter: `Threshold`

- Default setting **`(_:11071:3) Threshold`** = ***`7.5 I/Irated,obj`***

Siemens recommends setting the threshold value greater or equal to the starting current. For example, if the starting current of the motor is 5.6 $I/I_{rated,motor}$, set the threshold value to 6.0 $I/I_{rated,obj}$.

Protection Stage I-DIFF Unrestrained

The task of this protection stage is the fast detection of high-current internal faults (see also *I-DIFF Unrestrained Differential Protection Function, Page 682*).

Parameter: `Threshold`

- Default setting **`(_:18002:3) Threshold`** = ***`10.0 I/Irated,obj`***

Use the description of the protection stage **I-DIFF fast** (*Protection Stage I-DIFF Fast, Page 690*) for setting the threshold value.

6.6 Generator Differential Protection

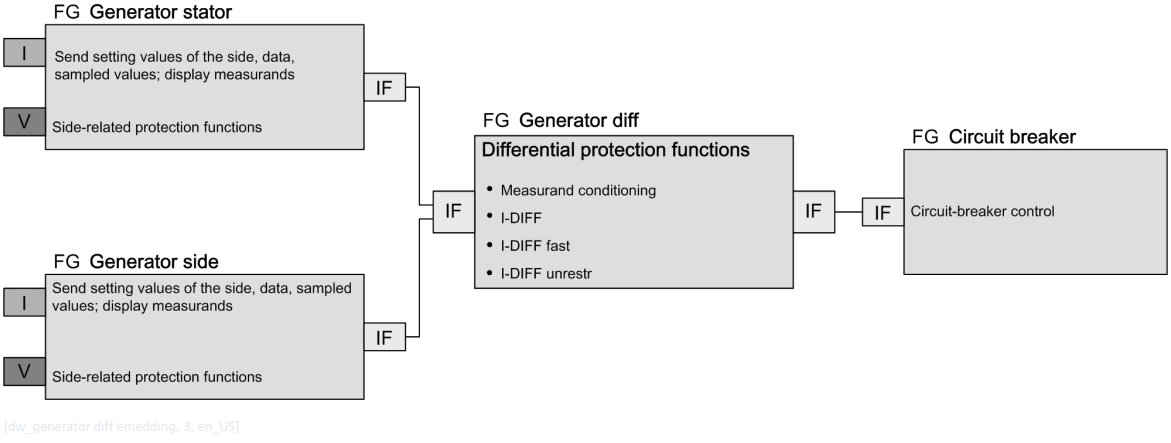
6.6.1 Overview of Functions

The **Generator differential protection** function (ANSI 87G):

- Detects short circuits in generators
- Detects ground faults in generators with a grounded neutral point (typical for low voltage)
- Is stable in the event of external short-circuits with current-transformer saturation through intelligent saturation-detection methods
- Triggers safely in the case of internal high-current faults through an additional high-current stage

6.6.2 Structure of the Function

The **Generator differential protection** function is used in the **Generator Diff** protection function group. The function depends upon application in the corresponding application template preconfigured by the manufacturer or can be copied during the engineering into the corresponding function group.



The **Generator differential protection** function consists of the 2 tripping stages I-DIFF and I-DIFF fast. In addition, the I-DIFF unrestrained tripping stage is available. You can select this tripping stage from the function catalog and copy it into the **Generator differential protection** function. The tripping stages can be blocked, in addition you can switch the tripping stages on and off.

In the function groups **Generator side** and **Generator stator**:

- The side-related protection settings are performed
- The side-related calculations are performed
- All data (setting values, detected currents) are relayed to the **Generator diff** function group

The side-related protection functions can run in the **Generator side** function group, for example overload protection, overcurrent protection, etc.

The majority of the typical generator protection functions are located in the **Generator stator** function group. These work with the neutral-point side current transformers.

[dw_generator diff emedding, 3, en_US]

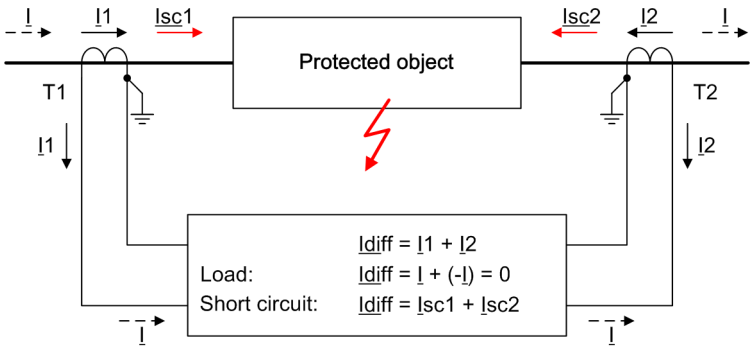


Figure 6-118 Embedding of the Function

6.6.3 Function Description

Basic Principle of Differential Protection

Differential protection is based on a comparison of currents (Kirchhoff current law). When comparing the current, use is made of the fact that a protected object uses the same current I in a non-faulty operating state

on both sides (dotted in *Figure 6-98*). This current flows into the range being observed on one side and leaves it again on the other side. A current differential is a sure indication of a fault within the protected object. The calculation of the difference is determined through the current-direction definition. The current direction is defined as positive to the protected object. The current difference results from the vector addition of the currents.

[dwprin2s-170712-01.tif, 1, en_US]

Figure 6-119 Basic Principle of Differential Protection Using the Example of 2 Sides

For safe operation, additional functions are required. The implementation of these additional functions is described in chapter *I-DIFF Differential Protection Function, Page 672*.

Current Stabilization

If very large currents flow through the protection range in the case of external faults, with different transmission behavior of the transformers **T1** and **T2** (*Figure 6-98*), a corresponding differential current I_{diff} occurs. When this is larger than the corresponding pickup threshold, the device can issue a trip command, even though no fault is present in the protection range. Such a malfunction of the protection is avoided by the restraint current (I_{rest}) and is implemented in the form of a characteristic curve $I_{diff} = f(I_{rest})$.

The largest current of 2 or more measuring points of the protected object is used for stabilization.

The definition for 2 measuring points is:

A trip or differential current is

$I_{diff} = (\underline{I}_1 + \underline{I}_2)$

as well as a restraint current of

$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|)$

For more than 2 measuring points, this definition is expanded. This restraint method allows a reliable trip decision for more than 2 measuring points and different feeding behavior for internal short circuits.

$I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2| ; \ldots |\underline{I}_n|)$

To clarify the effect, 3 important operating states are observed with ideal and adapted measurands.

- Through fault current in healthy operation or externally caused error:

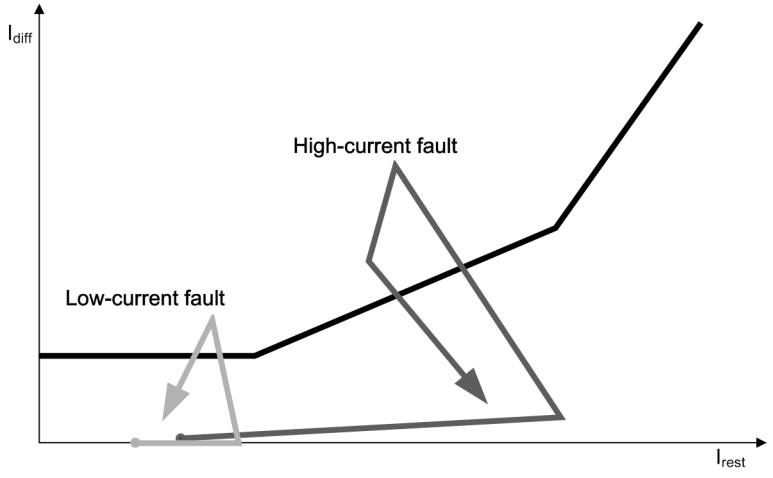
  $\underline{I}_1$ flows into the protection range, $\underline{I}_2$ flows out of the protection range, that is, negative compared with the prefix definition, thus $\underline{I}_2 = -\underline{I}_1$;

  in addition $|\underline{I}_2| = |\underline{I}_1|$

  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 - \underline{I}_1| = 0$

  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$

  No tripping quantity ($I_{diff} = 0$); the stabilization (I_{rest}) corresponds to the flowing current.

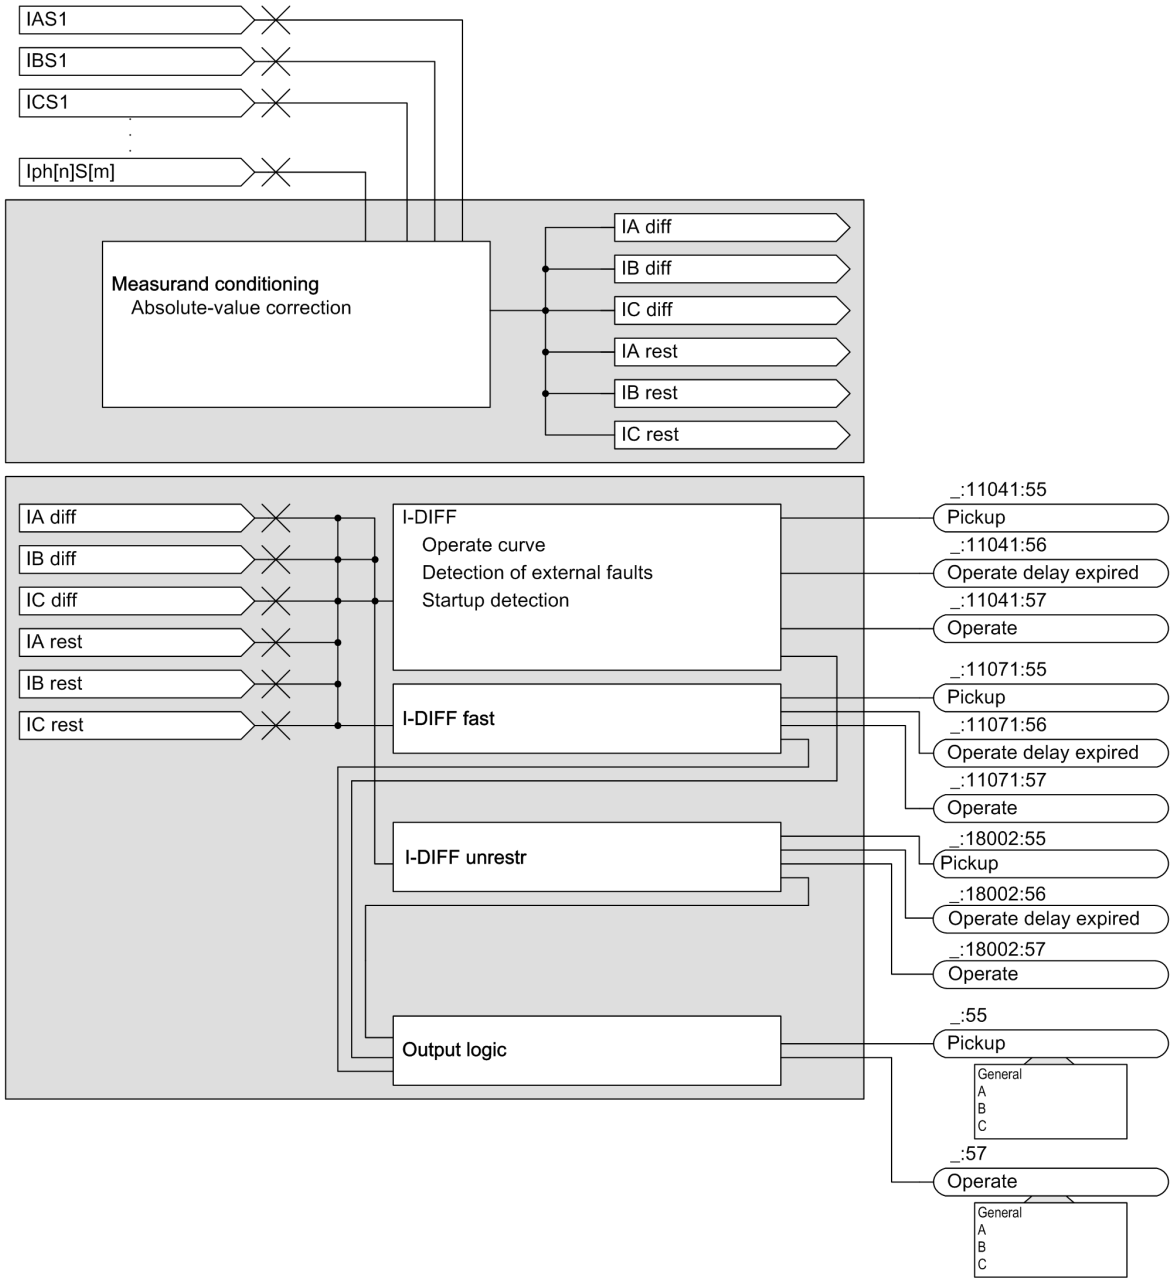


- Internal short circuit, feed from both sides with equal amount of currents, for example:
  Then $\underline{I}_2 = \underline{I}_1$; In addition $|\underline{I}_2| = |\underline{I}_1|$;
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + \underline{I}_1| = 2 \cdot |\underline{I}_1|$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1| = |\underline{I}_2|$
  The tripping quantity (I_{diff}) is twice as large as the short-circuit current and the restraining quantity (I_{rest}).
- Internal short circuit, feed only from one side:
  Then $\underline{I}_2 = 0$
  $I_{diff} = |\underline{I}_1 + \underline{I}_2| = |\underline{I}_1 + 0| = |\underline{I}_1|$
  $I_{rest} = \text{Max}\,(|\underline{I}_1| ; |\underline{I}_2|) = |\underline{I}_1|$
  The tripping quantity (I_{diff}) and the restraining quantity (I_{rest}) are of the same size and correspond to the short-circuit current.

Additional Stabilization with External Short Circuits

In case of an external short circuit, high short-circuit currents flowing through can lead to current-transformer saturation. This saturation can be more or less strongly pronounced at the measuring points, and in this way simulate a differential current. The differential current can lie in the tripping range of the characteristic curve for a certain time and lead to unwanted tripping without any particular measures. In accordance with *Figure 6-99*, there are 2 typical scenarios:

- High-current, external short circuit
  First, the current on both sides is transferred and leads to a large restraint current. After this, a transformer becomes saturated, resulting in a differential current I_{diff} that can exceed the operate curve. Simultaneously, the restraint current I_{rest} drops. Once the transformer is no longer saturated, the differential current decreases and falls below the characteristic curve.
- Low-current, external short circuit
  Current transformers can also become saturated through the large direct-current time constant (switching of transformers, motors), but small currents flowing through. This manifests itself as a phase-angle rotation of the current. Exceeding the characteristic curve in a non-stabilized area is possible.



Intelligent saturation-detection methods capture this state and lead to a temporally limited blocking of the Differential protection function.

Logic of the Function

[lomesmgr-190713-01.tif, 2, en_US]

Figure 6-121 Logic Diagram of the Differential Protection Function

The interaction of the I-DIFF, I-DIFF fast, and I-DIFF unrestrained tripping stages is shown in the following operate curve.

[dw_charac_function_trans-dif, 1, en_US]

Figure 6-122 Operate Curve of the Differential Protection Function

In the following, the essential components of differential protection are described in detail.

Measurand Processing

Amount Correction

Since the current transformers cannot be adapted exactly to the rated currents of the protected object with regard to their primary rated data, a standardization to the nominal sizes of the protected object takes place. The conversion occurs every sampling time (thus, for instantaneous values). The differential protection function processes 20 sampled values per period. In addition, the sampled values tracked are used. A high degree of accuracy can be attained over the entire tracking range (from 10 Hz to 90 Hz).

The IDIFF-fast tripping and the IDIFF-unrestrained tripping stages work on non-frequency tracked values and thus, implement fast operate times at low frequencies.

The amount is adapted via the following formula:

$$i^{*}_{phsx} = k\, i_{phsx}$$

$$\text{with } k = \frac{I_{rated\,prim,\,Sx}}{I_{rated\,obj,\,Sx}} = \frac{I_{rated\,prim,\,Sx}}{\frac{S_{rated,\,ref}}{V_{rated,\,Sx}\sqrt{3}}}$$

[fobetr07-170712-01.tif, 1, en_US]

i_{phsx}*	Adapted instantaneous value per phase (x = A, B, C)
i_{phsx}	Instantaneous value per phase (x = A, B, C)
k	Correction value per measuring point
$I_{rated\ prim,Sx}$	Primary transformer rated current per measuring point
$I_{rated\ obj,Sx}$	Primary rated current of the protected object
$S_{rated,ref}$	Reference power (maximum rated apparent power of the protected object)
$V_{rated,Sx}$	Rated voltage of the respective side (measuring point) of the protected object

I-DIFF Differential Protection Function

A differential current per phase based on the instantaneous value variables is calculated from the processed currents (see section Measurand Processing). The direction of current flow is defined as to the **protected object as positive**. The fundamental component contribution to the differential current (I_{diff}) is calculated via a Fourier filter (filter length = 1 period (20 sampled values)).

The currents of that measuring point whose RMS value is the largest are used as restraint current. If, for example, the current collapses at a measuring point as a consequence of current-transformer saturation,

the measuring point that has the largest current is automatically switched to at the point in time of the calculation.

$$i_{diff,phsx} = \sum_{m=1}^{N} i^{*}_{phsx,Mm} \rightarrow I_{diff,phsx} = FIR(i_{diff,phsx})$$

$$I_{phsx,Mm} = \sqrt{\frac{1}{n}\sum_{k=1}^{n} i^{*2}_{phsx,Mm}(k)}$$

$$I_{rest,phsx} = \underset{m=1}{\overset{N}{MAX}}\, I_{phsx,Mm}$$

[fogrds16-170712-01.tif, 1, en_US]

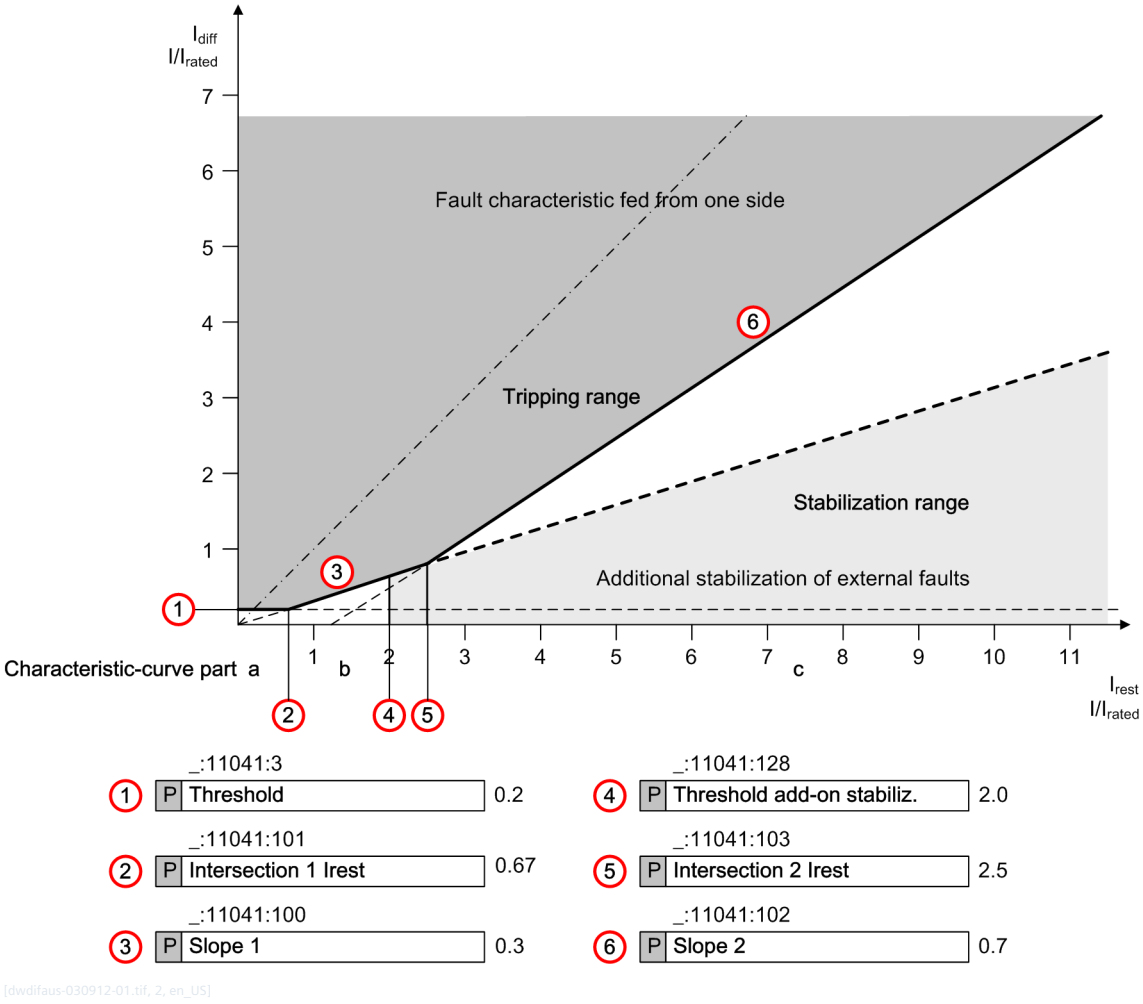
With

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points
n	Number of samples per period (n = 20)
FIR	Fourier filter
MAX	Maximum value determination

Pickup Characteristic

Figure 6-102 shows the pickup characteristic of the differential protection. The characteristic curve branch **a** represents the sensitivity threshold of the differential protection (parameter **Threshold**) and considers constant fault currents like magnetizing currents.

The characteristic branch **b** (parameter **Intersection 1 Irest** and **Slope 1**) considers current-proportional faults under normal operating conditions.



These faults can occur for the following reasons:

- Transformation errors in the current transformer and the input transformer of the device
- Adaptation deviations

The characteristic curve branch **c** (parameter **Intersection 2 Irest** and **Slope 2**) protects the differential protection against overfunction in case of high-current external faults and transformer saturation. In this range, transformer saturation can arise due to high short-circuit currents, and because of this, a higher differential current results.

In order to avoid overfunction in the event of external faults with current-transformer saturation, a logic is implemented that uses the characteristic curve **Additional stabilization of external faults**. If the operating point is located in the additional stabilization range and exceeds the operate curve from there, then the logic becomes active and blocks the differential protection.

The additional stabilization range is derived from the **Threshold add-on stabiliz.** and **Slope 1** parameters.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-123 Pickup Characteristic of the Differential Protection

If the differential current multiplied by the dropout ratio of 0.7 does not reach the pickup characteristic, the pickup drops out.

Detection of External Faults

To detect external faults with transformer saturation in a reliable way, the measurand curve is evaluated in the Diff.-Rest level by means of a detector. An external fault can occur if the motor feeds back to an external short circuit or if the motor starts up.

The detector has 2 essential tasks:

- **Blocking in the case of a definite high-current external fault**

  The differential current and the restraint current are monitored on a phase basis in the Diff/Restr level immediately after fault inception. To ensure the stability of the saturation detection for low saturation-free times of the primary current transformer, estimated values based on the difference quotients of the instantaneous values are used.

  If the estimated restraint current exceeds the **Threshold add-on stabiliz.** parameter and the expected value of the differential current of all phases is in the additional stabilization range (parameter **Slope 1**) (*Figure 6-102*) at the same time, the detector is active and the indication *Blocked by ext. fault phsx* appears. The tripping of the Differential protection function is blocked.

  If an external fault arises and is cleared by the protection responsible for it, the additional stabilization drops out. If the dropout ratio (0.7) of the RMS value of the restraint current does not reach the **Threshold add-on stabiliz.** parameter (*Figure 6-102*), the additional stabilization drops out. The indication *Blocked by ext. fault phsx* is reset.

  If the differential current exceeds **Slope 1** as a result of transformer saturation, that is, there is a pickup phsx, the blocking is limited in time (parameter: **Time of add-on stabiliz.**).

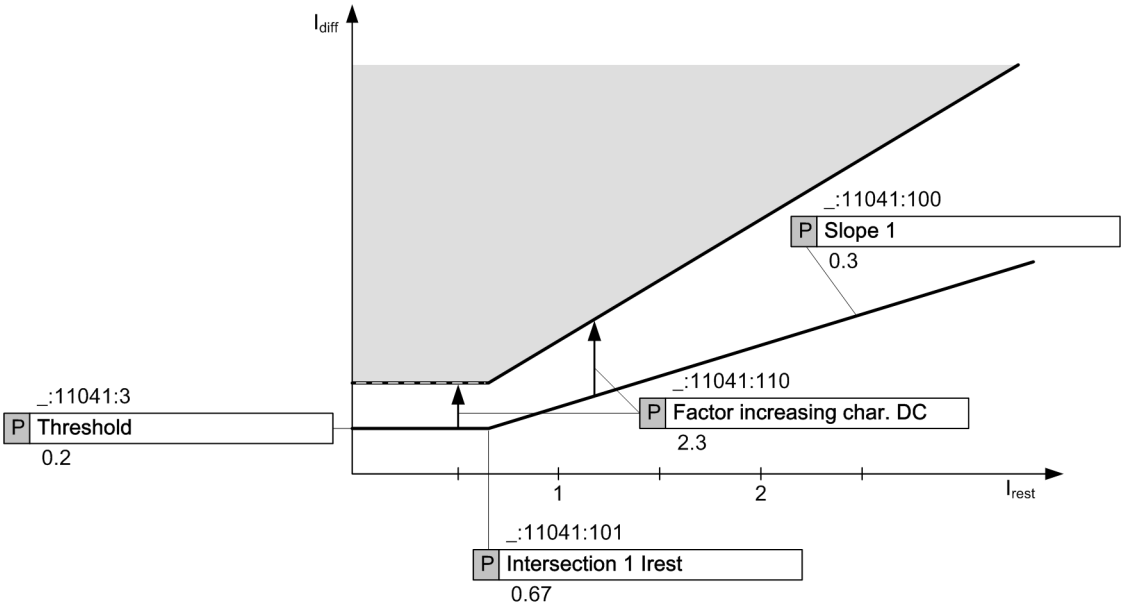
  Starting with the indication *Blocked by ext. fault phsx*, the other phases can be blocked with it via the **Crossblk. time add-on st.** parameter. If differential currents due to transformer saturation spread to the other phases through the vector-group correction or residual current elimination, this blocking is necessary.

- **Removal of the blocking with a change in fault location from external to internal**

  An internal fault can arise as a consequence of an external fault. This fault change must be recognized and the blocking must be removed. The critical case is a short-circuit with current-transformer saturation. The saturation detection examines here the instantaneous values of the differential current. With transformer saturation, the instantaneous values fall below an internal threshold in the saturation-free time. If this threshold is permanently exceeded and a pickup is present in the corresponding phase, an internal error is assumed. The other phases are also examined during the parameterization with crossblock.

  The blocking of the tripping is removed and the indication *Blocked by ext. fault phsx* is reset.

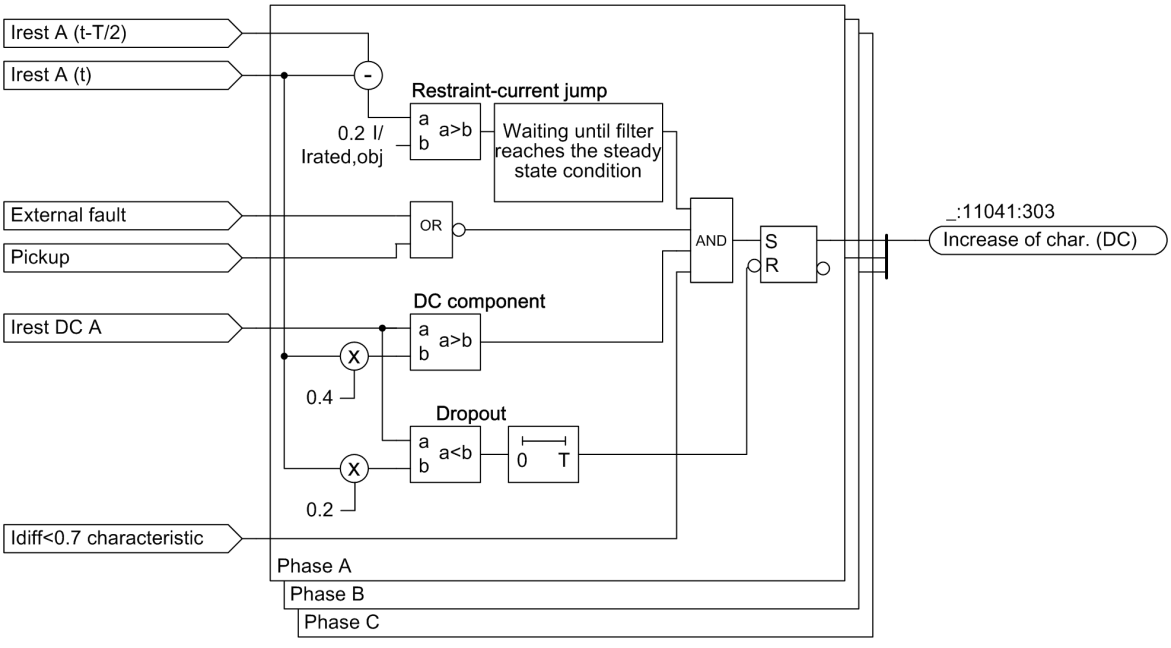
DC-Component Detection



Low-current external faults with large DC components can also lead to exceeding of the operate curve. The additional stabilization range is not attained, however.

To avoid an overfunction, the following steps are taken:

- The restraint current $I_{rest.;phsx}$ is monitored for a jump.
- If the jump occurs, the DC component is calculated, with a temporal delay (1 period), from the instantaneous value of the restraint current (current at the measuring point with the largest current) $i_{rest.,phsx} = i_{phsx,Mm}$. The result is $I_{rest.DC,phsx}$. This current is compared to the restraint current $I_{rest.,\ phsx}$ and is checked for exceeding of the internal threshold.
- The differential current $I_{diff,phsx}$ must lie below the dropout characteristic curve (characteristic curve · 0.7) in all 3 phases.
- If the first 3 points lead to positive results, then the operate curve is raised by the parameter **Factor increasing char.** with a default setting of ***2.3***. Here, only the threshold value and the slope 1 are raised (see *Figure 6-103*). The indication *Increase of char. (DC)* is output. If the product of parameter **Factor increasing char.** and **Slope 1** exceeds **0.85**, the maximum increase of the raised **Slope 1** is limited to 0.85.
- As additional criterion, the pickup indication *Pickup* (internal fault is present) or the indication of the additional stabilization *Blocked by ext. fault phsx* (high-current external fault) is interrogated. If one of the 2 conditions is present, the characteristic-curve increase is stopped. A retroactive pickup no longer resets the characteristic-curve increase. A pickup with DC-component detection occurs only if the raised operate curve is exceeded.



If the DC component $I_{rest.DC,phsx}$ falls below the internal dropout threshold, the dropout delay is determined as follows:

It is assumed that the de- and re-magnetization of the transformer last equally long. The magnetization is at the highest at the point in time in which the internal dropout threshold is attained. The time is measured from the start of the DC-component detection until the internal dropout threshold is reached. Added to this time are 5 periods and from this, the dropout delay is derived. Following this, the characteristic-curve increase is reset to the original value. *Figure 6-104* shows the overall logic.

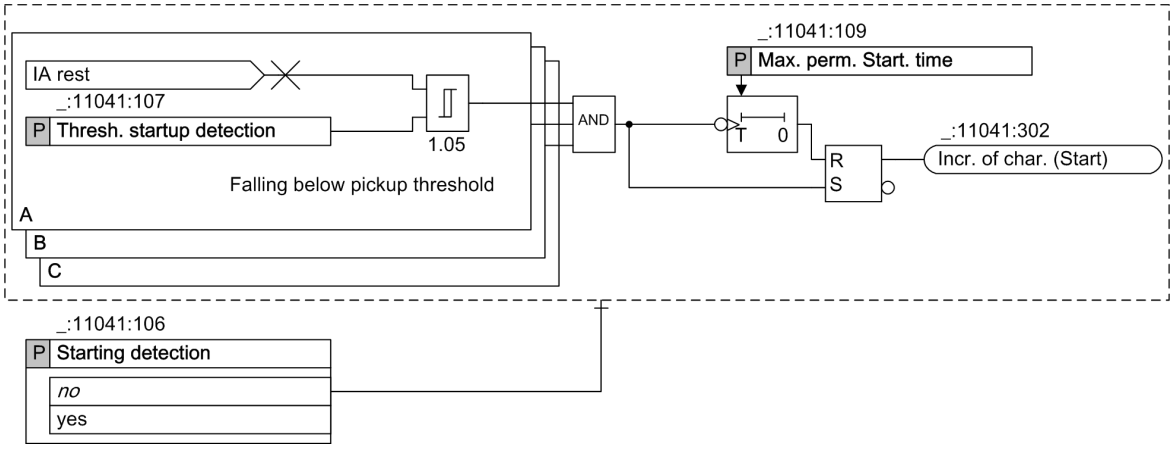
Figure 6-124 Increasing the Characteristic Curve after DC Detection

[lodcerkn-170712-01.tif, 3, en_US]

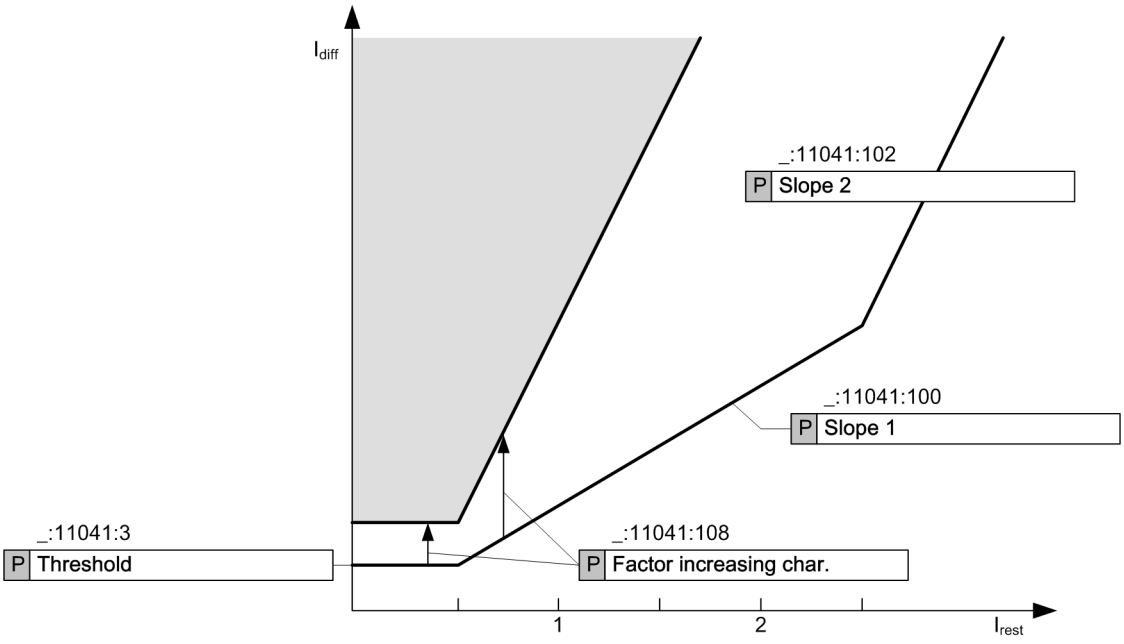
Figure 6-125 Logic DC Detection



Startup Detection

The startup detection is particularly useful in the case of motors. In contrast to transformers, the inrush current with motors is a flowing current. Differential currents can arise, however, by the current transformers having different residual magnetization and being supplied with current at different operating points of their hysteresis. These differential currents are low in fact, but they can lead to overfunction with sensitive setting of the differential protection.

With generators, the motor startup can also lead to higher currents. With the startup detection, you can make the protection somewhat less sensitive for a specific period of time and avoid overfunction. As a result you achieve a comparable effect to that of DC-component detection.



As additional security against overfunction when switching in a previously protected object that carries no current, you can use the pickup-value increase at startup. If the restraint current falls below a settable value **`Thresh. startup detection`** in all phases, the pickup-value increase is activated. The pickup value **`Threshold`** and **`Slope 1`** are raised by the set value in accordance with parameter **`Factor increasing char.`**. As a rule here, **`Slope 1`** cannot exceed a value of 0.85.

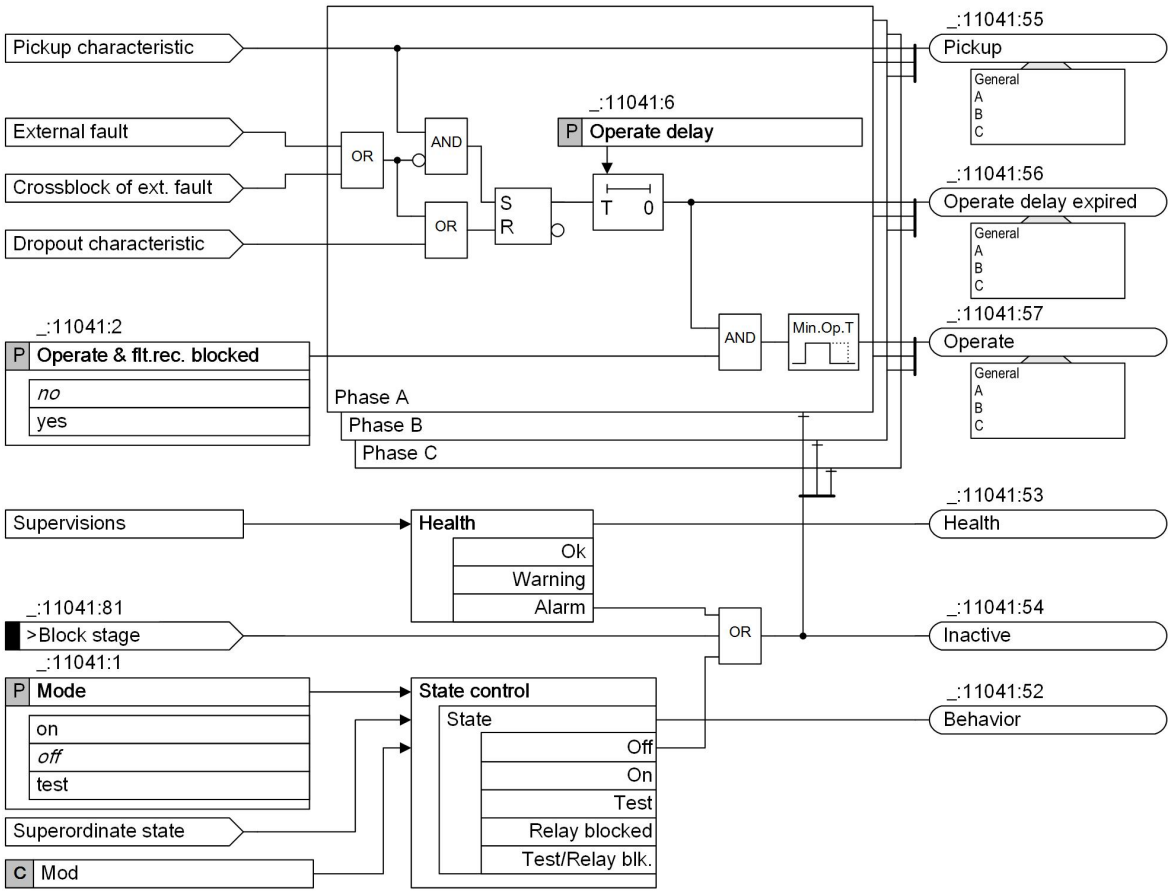
If the parameter **`Thresh. startup detection`** is exceeded, dropout occurs and a timing element (parameter: **`Max. perm. Start. time`**) is activated. Once this time has elapsed, the characteristic curve that was increased in all phases is reset to its original value. *Figure 6-105* shows the logic diagram of the startup detection and *Figure 6-106* the increased characteristic curve.

[loanlauf-170712-01.tif, 3, en_US]

Figure 6-126 Logic Startup Detection

[dwanlken-201112-01.tif, 1, en_US]

Figure 6-127 Characteristic-Curve Increase at Startup



Trip Logic of the Differential Protection Function I-DIFF

Figure 6-107 shows the trip logic. If the characteristic curve is exceeded (see *Figure 6-102*) a pickup occurs. Redirection of the information for tripping can be blocked by the additional functions.

Blocking is possible through use of the following influencing variables:

- Recognition of external faults that can simulate an internal fault through transformer saturation

In addition, in case of blocking due to an *external error*, a **crossblock** mechanism comes into effect.

[lo_aus_mid, 2, en_US]

Figure 6-128 Trip Logic of I-DIFF

I-DIFF Fast Differential Protection Function

As a supplement to the I-DIFF differential protection function, the function I-DIFF fast is available. The main task consists in switching off high-current internal faults in the shortest amount of time. The method controls current-transformer saturation and is stable in the event of external transverse faults (integration in breaker-and-a-half arrangements).

Metrologically, 2 methods are combined:

- Instantaneous-value method
- Filter-based method

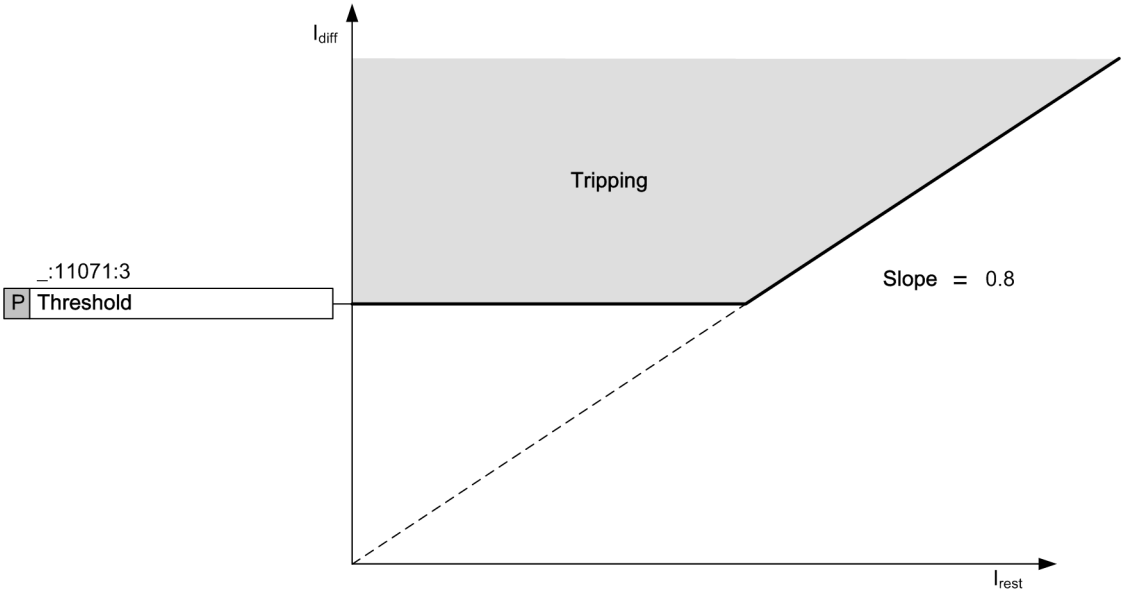
Instantaneous-Value Method

Through the instantaneous-values method, an immediate evaluation of the sampled values of the differential $i_{Diff}(t)$ and restraint current $i_{rest}(t)$ occurs. The absolute-value and vector-group adapted currents (i*) are also the basis. The currents are defined positively to the node. The restraint current is the maximum current of all measuring points.

$$i_{diff,phsx}(t) = \left| \sum_{m=1}^{N} i^{*}_{phsx,Mm}(t) \right|$$

$$i_{rest,phsx}(t) = \max_{m=1}^{N} \left| i^{*}_{phsx,Mm}(t) \right|$$

[fomome27-170712-01.tif, 1, en_US]

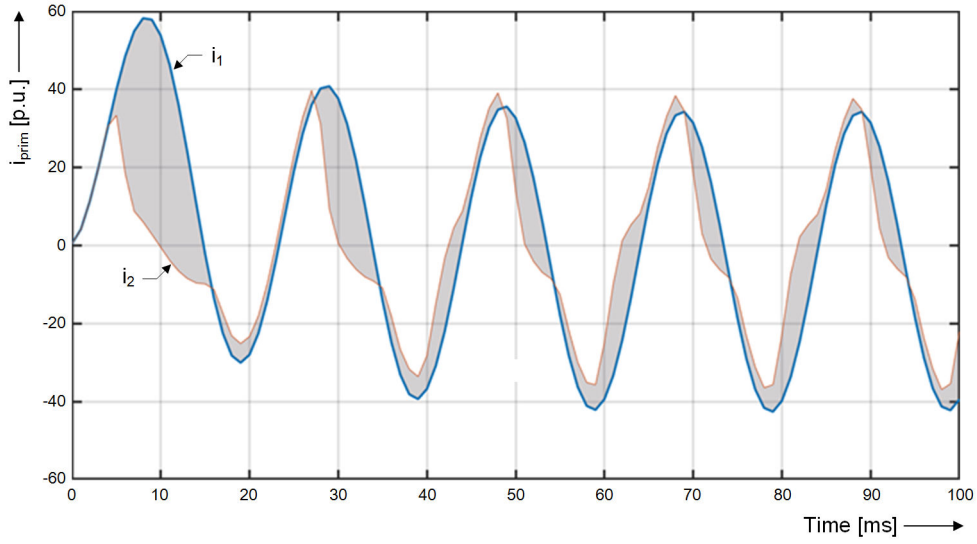


where

x	Variable (1, 2, 3) for the phase currents (A, B, C)
m	Variable (1, 2, ..., N) for the measuring points
N	Number of measuring points

The evaluation of the restraint current is used to recognize saturated, high-current external faults.
Figure 6-108 shows the operate curve. The parameter **Threshold** is set here such that it lies over the maximum fault current flowing. The slope of the characteristic curve is fixed at 0.8.
In the algorithm, the following conditions are processed:

- Condition 1: The increase of the restraint current $di_{rest}(t)/dt$ is determined continuously and compared with an internal threshold value.
- Condition 2: After that, a comparison determines whether the differential current is larger than the restraint current (characteristic curve **Slope** in *Figure 6-108*): $i_{diff}(t) > 0.8 \cdot i_{rest}(t)$.
- Condition 3: After that, a comparison determines whether the differential current exceeds the parameter **Threshold**.



When all conditions are met, tripping occurs immediately. If the 1st condition is recognized and not the 2nd condition, then the function is blocked for 300 ms.

[dwidfast-300114-01.tif, 1, en_US]

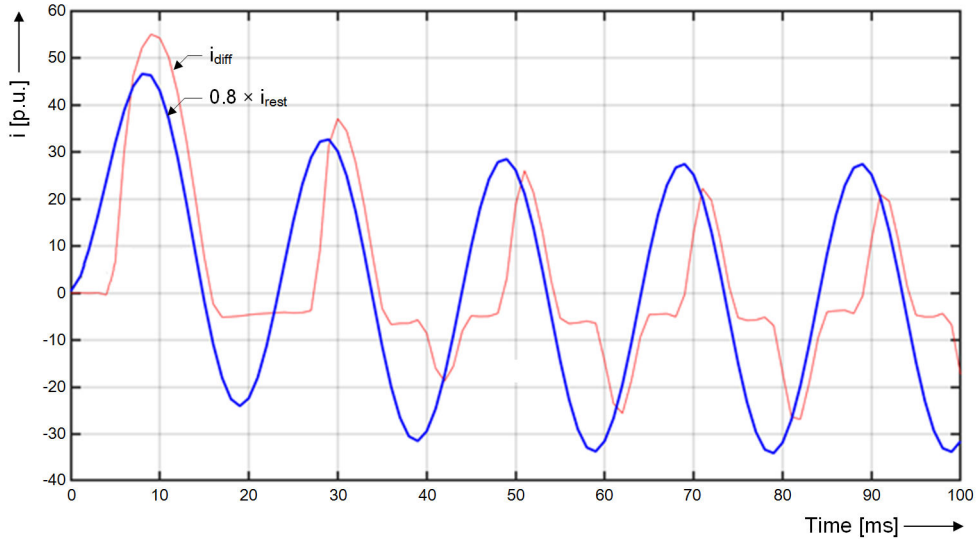


Figure 6-129 I-DIFF Fast Characteristic Curve

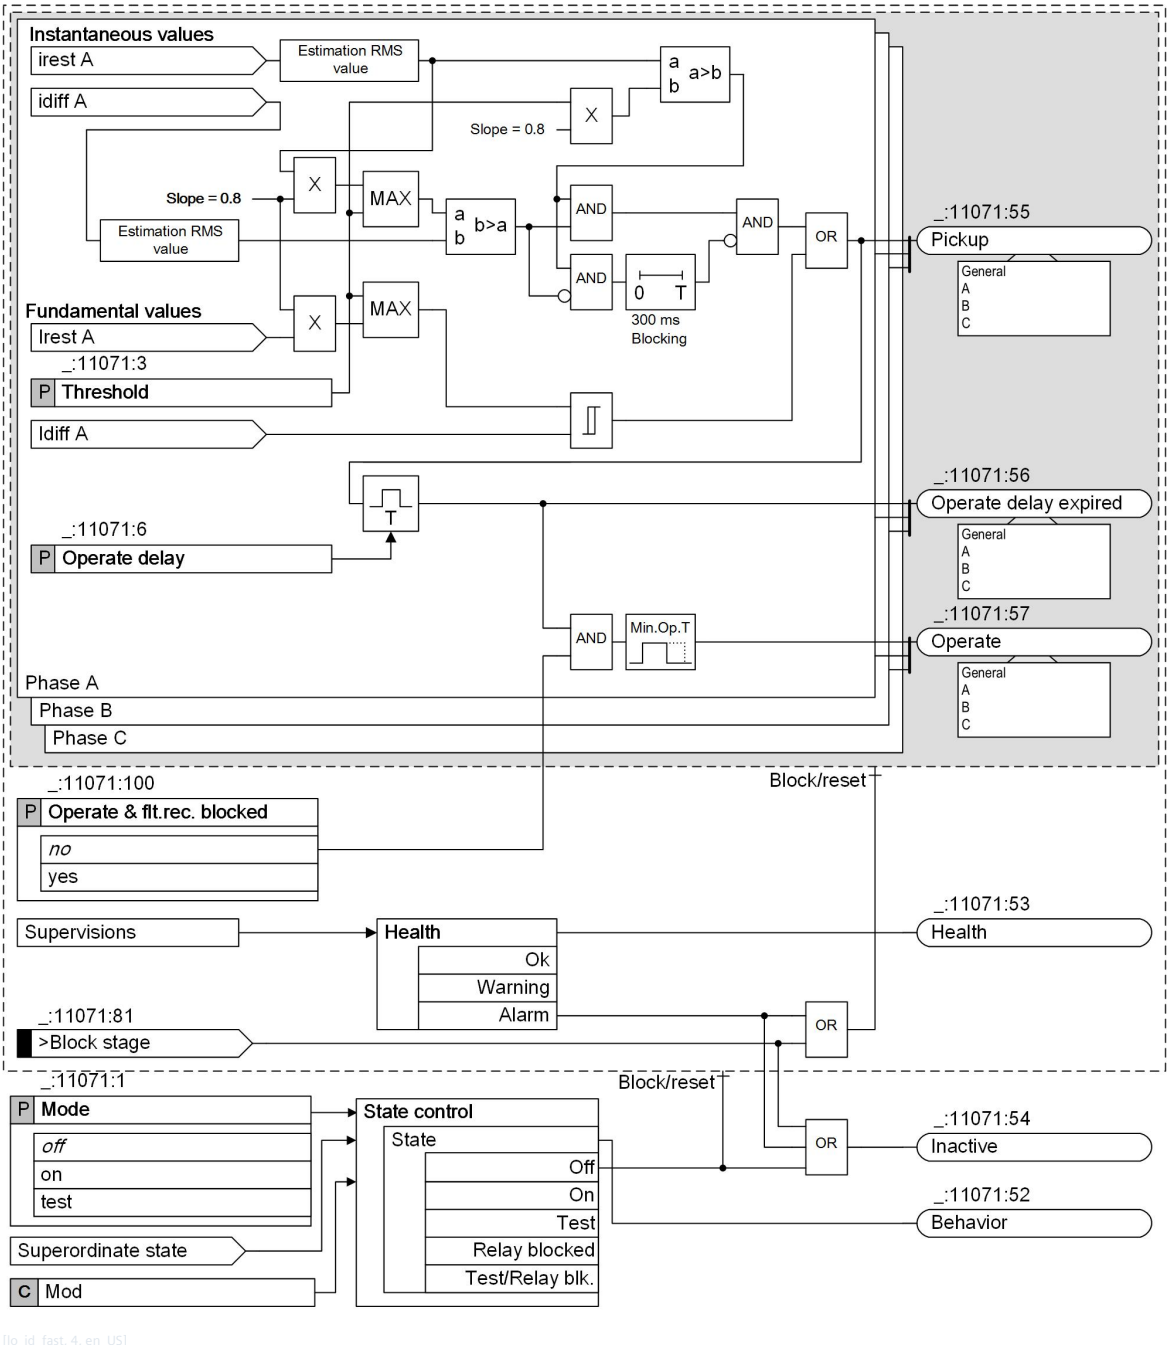
The 2 following figures show the behavior during an internal and an external fault. It is typical for the internal fault (*Figure 6-109*) that the differential current rises more quickly than the restraint current. After a few sampled values, the trip signal is issued. In case of an external fault, a differential current arises only after transformer saturation occurs. You can always assume, however, that the current is transferred a few milliseconds after occurrence of the fault. In accordance with *Figure 6-111*, the restraint current is larger than the differential current after occurrence of the fault, but condition 2 is not met and the function is therefore blocked.

[dwinnfel-201112-01.tif, 2, en_US]

Figure 6-130 Curve Plot for Internal Fault with Transformer Saturation (k= 0.65)



[dwextfel-170712-01.tif, 2, en_US]

Figure 6-131 Curve Plot for External Fault with Transformer Saturation (k= 0.65)

Fundamental-Component Method

Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} and the stabilization value (maximum current of a measuring point) $I_{rest.}$ are ordered in the operate curve according to *Figure 6-108* and the trip decision is made.

Figure 6-111 shows the overall logic.

[lo_id_fast, 4, en_US]

Figure 6-132 Logic of the I-DIFF Fast Differential Protection Function

I-DIFF Unrestrained Differential Protection Function

In addition to the I-DIFF and I-DIFF fast differential protection function, the function I-DIFF unrestrained is available. The main task of this function consists in switching off high-current internal short circuits in the shortest amount of time. The method controls current-transformer saturation.

High-current faults in the protection range can always be switched off immediately without consideration of the restraint currents if, due to the current magnitude, it is determined that an external fault is not involved. In the case of protected objects with a large intrinsic longitudinal impedance (transformer, generator, reactor), a current can be found that is never exceeded by a flowing short-circuit current.

For a transformer, for example, the (primary) value is:

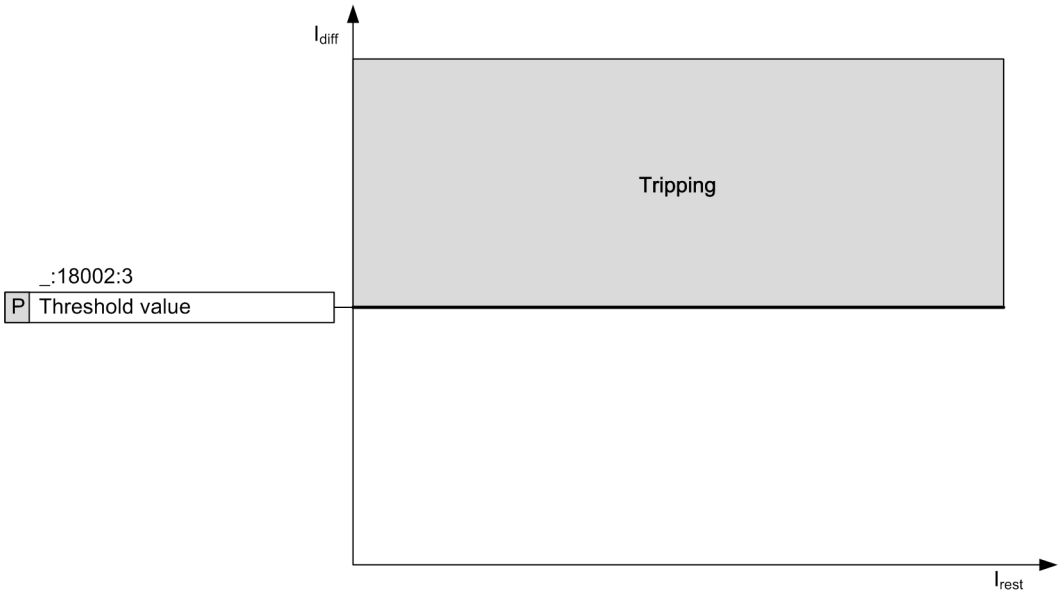
$$\frac{1}{v_{sc\ transf.}} \cdot I_{N\ transf.}$$

[fo_Idiff-error, 1, en_US]

The I-DIFF unrestrained stage also acts if, for example, due to current-transformer saturation because of a DC component in the short-circuit current, a 2nd harmonic occurs. The inrush-current detection could interpret this as the closed-circuit current.

The I-DIFF unrestrained protection stage operates both with the fundamental component of the differential protection and with the instantaneous value.

Metrologically, 2 methods are combined:

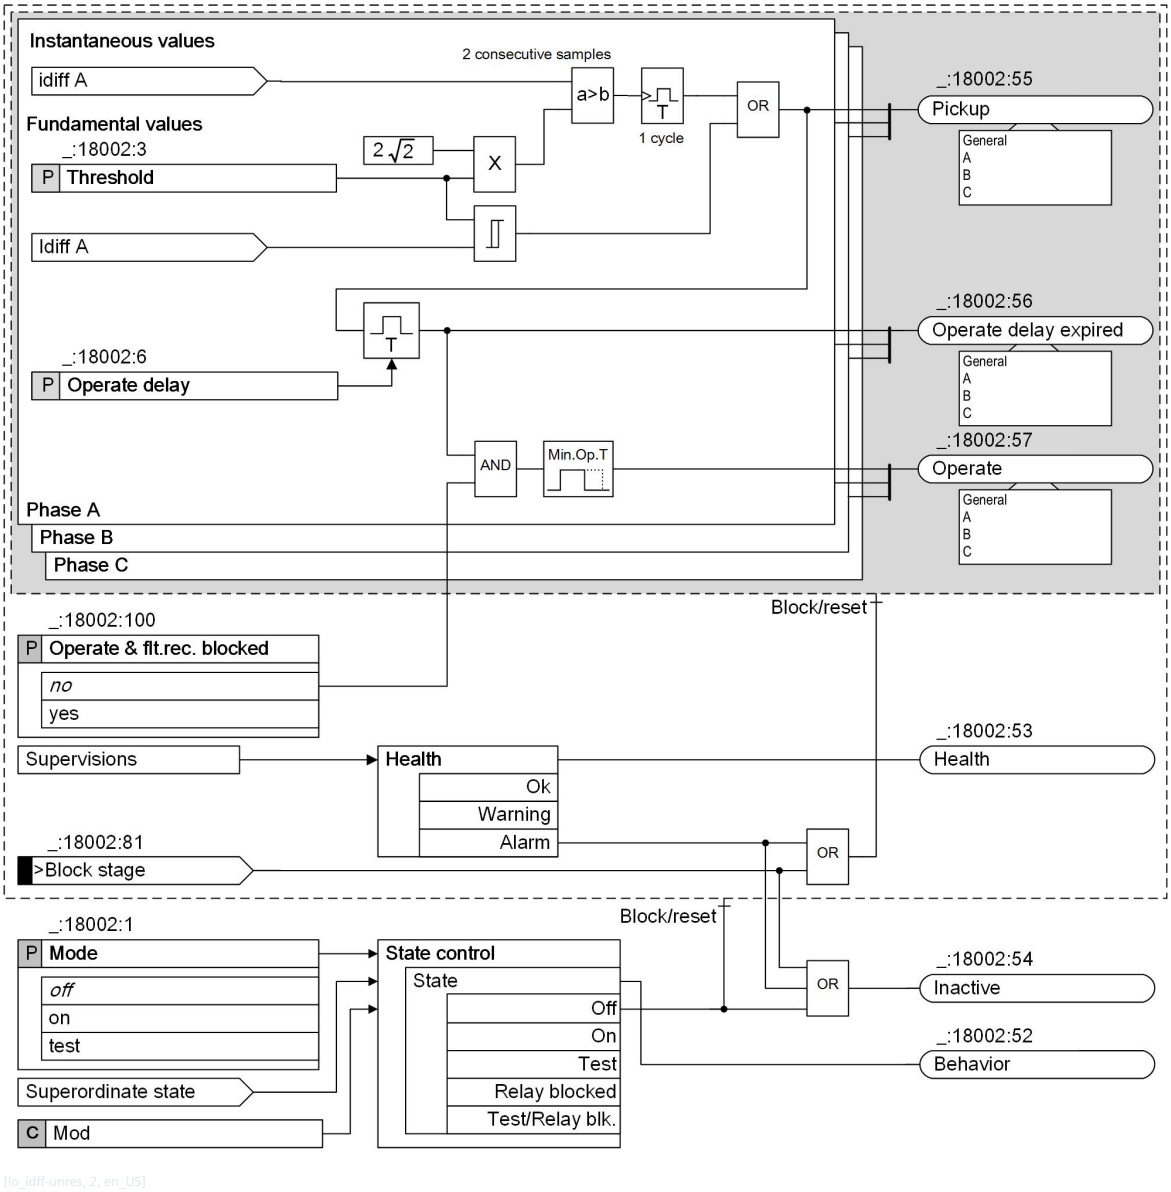


- Instantaneous-value method
- Filter-based method

Instantaneous-Value Method

With the instantaneous-values method, an immediate evaluation of the sampled values of the differential current $i_{Diff}(t)$ occurs. The absolute-value and vector-group adapted currents (i*) are also the basis.

Fundamental-Component Method



Parallel to the instantaneous-value method, the fundamental component works with a temporal delay. Here, the same measured values are processed as with the I-DIFF method. The fundamental component of the differential current I_{diff} is ordered in the operate curve *Figure 6-112* and the trip decision is made.

Trip Logic of the Differential Protection

A common trip signal is formed from the subfunctions I-DIFF, I-DIFF fast, and I-DIFF unrestrained. *Figure 6-114* shows the corresponding logic.

[lo_gesamt, 3, en_US]

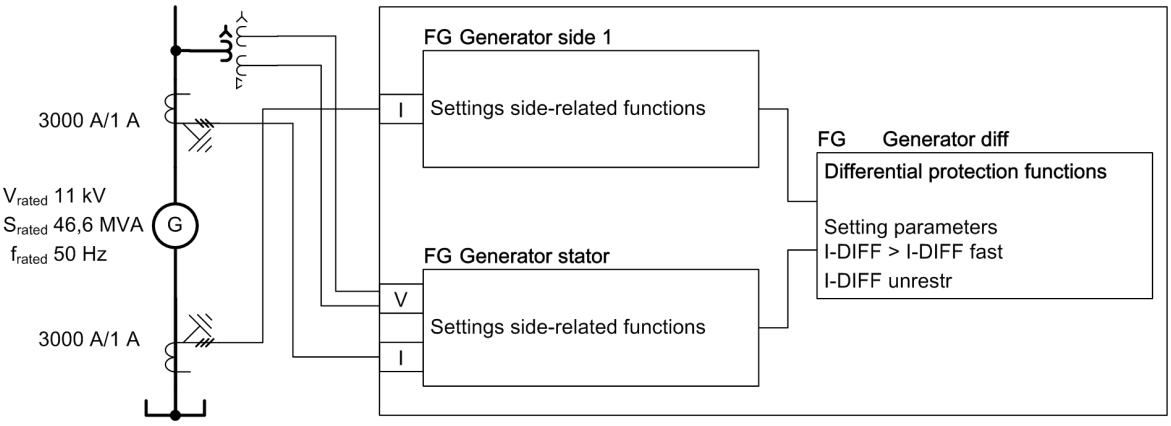

Figure 6-135 Overall Trip Logic

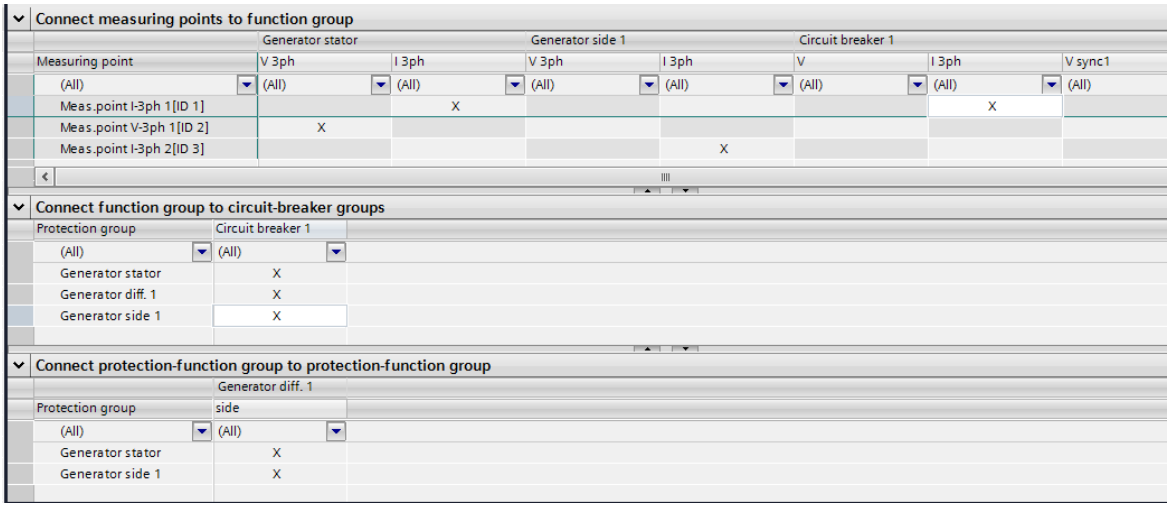
Fault Logging and Fault Recording

A fault is opened with every protection pickup. This means that a fault log and a fault recording are started. Saving of the fault record depends on the setting (see *3.5.3 Function Description*). Since pickup and tripping are the same in differential protection, the recording setting can be used with the pickup function. To enable fault recording even with external errors, along with the exceedance of the characteristic curve, a fault record is opened in case of a blocking by an external error or in case of a characteristic-curve increase through a DC-component detection. This has the advantage that you can evaluate the transformer transfer method of the current transformers very well in case of a fault.

6.6.4 Application and Setting Notes

This chapter provides setting information for the required setting parameters for a typical generator protection application. *Figure 6-136* shows a typical generator protection application. This prevents significant damage to the generator in the event of tripping in case of a short circuit. Therefore, the **Generator differential protection** also makes sense for less powerful generators (< 5 MVA).



[dw_generator diff connection example, 3, en_US]

Figure 6-136 Connection Example

The connection example refers to an application in the 7UM85. The 3-phase current measuring points are connected to the function groups **Generator side 1** and **Generator stator**. The differential protection function runs in the **Generator diff** function group.

The following screenshot from DIGSI 5 shows the connection of the measuring points as well as the connection of the function groups.

[sc_generator_diff_switch_Digsi, 1, en_US]

Figure 6-137 Internal Interconnection in DIGSI 5

Generator Side and Generator Stator Function Groups

Make the following settings in the function groups **Generator side** and **Generator stator**. They are needed for scaling the currents and processing the differential protection.

NOTE

Ensure that the correct transformer data are set at the measuring points.

The data in the example are for the following current transformers: 3 000 A/1 A

Parameter: `Rated apparent power`

- Default setting **`(_:14671:103) Rated apparent power`** = ***`46.60 MVA`***

  With this parameter, you can set the rated apparent power of the generator. With one generator, the setting value for both function groups (sides) is the same.

Parameter: `Rated voltage`

- Default setting **`(_:14671:102) Rated voltage`** = ***`11 kV`***

  With this parameter, you can set the rated voltage of the generator. The rated voltage is 11 kV in this example. The setting is the same for both function groups.

Generator Diff Function Group

Make the following settings in the **Generator diff** function group for the Idiff function:

Parameter: `Threshold` (Setting the Characteristic-Curve Parameters)

- Default setting **`(_:11041:3) Threshold`** = ***`0.2 I/Irated,obj`***

You set the pickup threshold for the differential current with this parameter. This is the total current flowing into the protection range during a short circuit, regardless of how it is distributed on the sides of the protected object. The pickup value is relative to the rated current of the protected object. The default setting of ***`0.2 I/Irated,obj`*** is a practical value between sensitivity and possible disturbing influence.

Parameter: `Intersection 1 Irest`

- Default setting **`(_:11041:101) Intersection 1 Irest`** = ***`0.67 I/Irated,obj`***

The maximum current of the measuring point is used as restraint current. If you have to expect dynamic transmission faults of the current transformer even with small currents, half of the rated current is an appropriate setting value.

Parameter: `Slope 1`

- Default setting **`(_:11041:100) Slope 1`** = ***`0.3`***

With the **`Slope 1`** you avoid an overfunction of the differential protection with low-current external faults as a consequence of current-transformer transmission faults (stationary and dynamic faults). The default setting of ***`0.3`*** is sufficient for many applications.

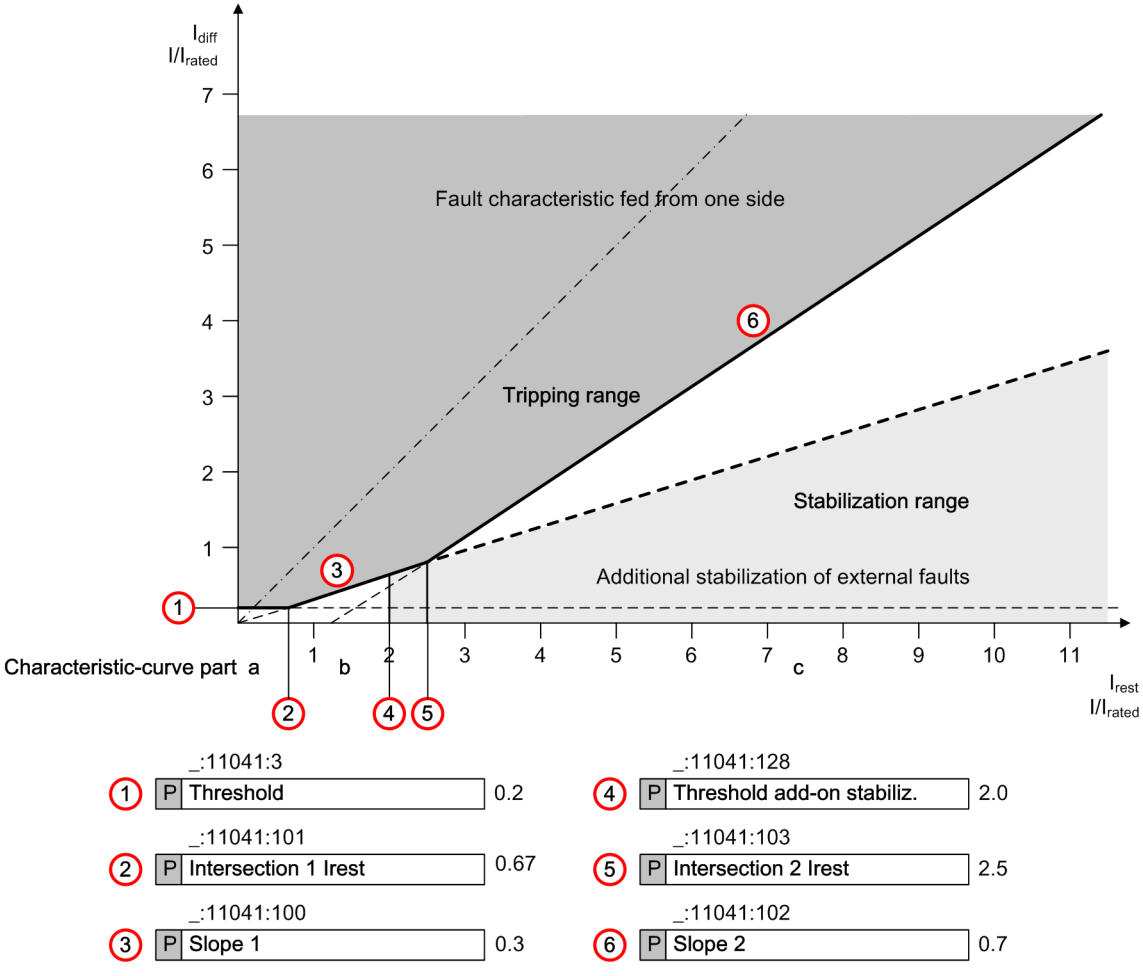
NOTE

The stabilization method has been changed from that in SIPROTEC 4 (7UT6x, 7UM62). For this reason, select a higher slope (also see *6.6.3 Function Description*).

Parameter: `Intersection 2 Irest`

- Default setting **`(_:11041:103) Intersection 2 Irest`** = ***`2.5 I/Irated,obj`***

The parameter **`Intersection 2 Irest`** determines from which restraint current the **`Slope 2`** begins. The default setting ***`2.5 I/Irated,obj`*** is a practical value.



Parameter: `Slope 2`

- Default setting **`(_:11041:102) Slope 2`** = ***`0.7`***

With the **`Slope 2`** parameter, an overfunction of the differential protection is avoided with high-current external faults as a consequence of current-transformer transmission faults (for example, due to saturation). A value greater than or equal to double the value of **`Slope 1`** is practical. As the default setting, ***`0.7`*** was selected.

NOTE

If excessive current flows are cause to expect transmission problems for the current transformers, set the **Slope 2** to a higher value.

[dwdifaus-030912-01.tif, 2, en_US]

Figure 6-138 Characteristic Curve with the Default Settings

Parameter: Starting detection

- Default setting **(_:11041:106) Starting detection** = ***yes***

If the generator feeds into busbars to which motors are also connected, Siemens recommends the activation of the startup detection for generator protection applications, since the motor starting currents can influence the transmission behavior of the current transformers. In this case, set the parameter **Starting detection** to ***yes***.

Parameter: Thresh. startup detection

- Default setting **(_:11041:107) Thresh. startup detection** = ***0.1 I/Irated,obj***

If the restraint current falls below this threshold value, the subsequently set characteristic-curve increase becomes effective with activated function. Increase the default setting of ***0.1 I/Irated,obj*** for generator protection corresponding to your operating conditions. Adjust the parameter **Thresh. startup detection** to the lower load limit (possible order of magnitude, for example, ***0.4 I/Irated,obj***).

Parameter: `Factor increasing char.`

- Default setting **`(_:11041:108) Factor increasing char.`** = ***`1.0`***

Change the default setting value in the case of application. An increase to the value 2.0 has proven itself to be sufficient for many applications.

Parameter: `Max. perm. Start. time`

- Default setting **`(_:11041:109) Max. perm. Start. time`** = ***`5.0 s`***

The setting value must lie above the maximum permissible start time of the connected motor. Refer to the motor data sheets for the start time (for example, **Locked Rotor** time). To guarantee tripping through the motor protection (starting-time supervision) and avoid overfunctions, select a somewhat longer time (factor 1.2 or higher). For the motor in the example, a start time of 6.5 s was assumed at 90 % rated voltage and rated torque. The setting value should be larger than 1.2 * 6.5 s = 7.8 s. Siemens recommends a setting value of 10 s.

Parameter: `Factor increasing char. DC` (DC-Component Detection)

- Default setting **`(_:11041:110) Factor increasing char. DC`** = DC-Component Detection

DC-component detection is always active. As a result of the DC components, transmission problems can arise (for example, phase-angle rotations) in current transformers with small currents flowing. For this reason, the **`Threshold`** and the **`Slope 1`** are increased by the set factor. The default setting of 2.0 has proven itself with numerous applications.

Detection of External Faults

In *Figure 6-138*, the range **Add-on stabilization with external fault** is represented. The range is described by the parameters **`Add-on stabilization threshold value`** and **`Slope 1`**. With an external short circuit, the differential currents can increase beyond this range and reach into the tripping area. With the following parameters, time-limited blocking can be performed.

Parameter: `Threshold add-on stabiliz.`

- Default setting **`(_:11041:128) Threshold add-on stabiliz.`** = ***`2.0`***

The **`Threshold add-on stabiliz.`** parameter allows you to set the pickup value for the additional stabilization. Due to the selected method of measurement, a setting value of 2 is practical. The additional stabilization range is limited by the parameters **`Threshold add-on stabiliz.`** and **`Slope 1`**.

Parameter: `Time of add-on stabiliz.`

- Default setting **`(_:11041:129) Time of add-on stabiliz.`** = ***`0.3 s`***

As orientation for the setting value, you can use the operate time of the external feeder protection. Additionally, take into account the break time of the circuit breaker. Thus, the following calculation method results:

$t_{Z\ rest.} \geq t_{trip,\ ext\ protection} + t_{trip,\ circuit\ breaker}$

The default value is a practical value. You must adapt the value appropriately to use. The value 0 deactivates the detection of external faults.

Parameter: `Crossblk. time add-on st.`

- Default setting **`(_:11041:130) Crossblk. time add-on st.`** = ***`0.3 s`***

The additional stabilization acts separately on each phase. However, it can be extended to block all phases. Siemens recommends the activation of the crossblock function with a corresponding setting of the time. The set time must be identical to the time that is set for the duration of the additional stabilization.

Protection Stage I-DIFF Fast

The task of this protection stage is the fast detection of high-current internal faults (see also *6.6.3 Function Description*). For this reason, the protection stage must always be activated.

Parameter: `Threshold`

- Default setting **`(_:11071:3) Threshold`** = ***`7.5 I/Irated,obj`***

If there are internal faults in the generator with simultaneous network operation, you can assume a current feed from both the generator and the network side. If there is an external fault, current is only fed from the generator. The subtransient and then direct-axis transient reactance takes effect at fault inception. If you assume that the transformers are nearly identical and do not saturate immediately, you can use the direct-axis subtransient reactance to estimate the maximum fault current. The current-transformer design is based on this fault current.

With the assumption described (saturation not the same), you set the stage via the transient short-circuit current.

Idiff fast > 1.1/xd' ·$I_{rated,\ generator}$

Values for xd' from 0.15 through 0.35 result in setting values from approx. 3 $I_{rated,\ generator}$ to 7 $I_{rated,\ generator}$.

Example:

Direct-axis transient reactance xd' (saturated) = 0.19

This results in a transient current of 1.1/0.19 · $I_{rated,\ generator}$ = 5.79 $I_{rated,\ generator}$ = 5.79 $I_{rated,\ obj}$

For the parameter **`(_:11071:3) Threshold`**, you can use the default setting of ***`7.5 I/Irated,obj`***.

Protection Stage I-DIFF Unrestrained

The task of this protection stage is the fast detection of high-current internal faults (see also *I-DIFF Unrestrained Differential Protection Function, Page 682*).

Parameter: `Threshold`

- Default setting **`(_:18002:3) Threshold`** = ***`10.0 I/Irated,obj`***

Use the description of the protection stage **I-DIFF fast** (*Protection Stage I-DIFF Fast, Page 716*) to set the threshold value.

6.7 Line Differential Protection

6.7.1 Overview of Functions

Line differential protection (ANSI 87L):

- Is a selective short-circuit protection for overhead lines, cables, and busbars with single-side and multi-side infeed in radial, looped, or meshed systems
- Allows instantaneous tripping on line ends if short circuits occur
- Works strictly phase-selectively
- Becomes more sensitive when using charging-current compensation (Ic compensat.)
- Allows separate protection of the ground path
- Allows separate protection by monitoring the negative-sequence current

NOTE

When using Line differential protection functions in transformer differential protection, the current transformer requirements of the line protection must be considered. These can be found in the Line Protection manual (C53000-G5040-C010).

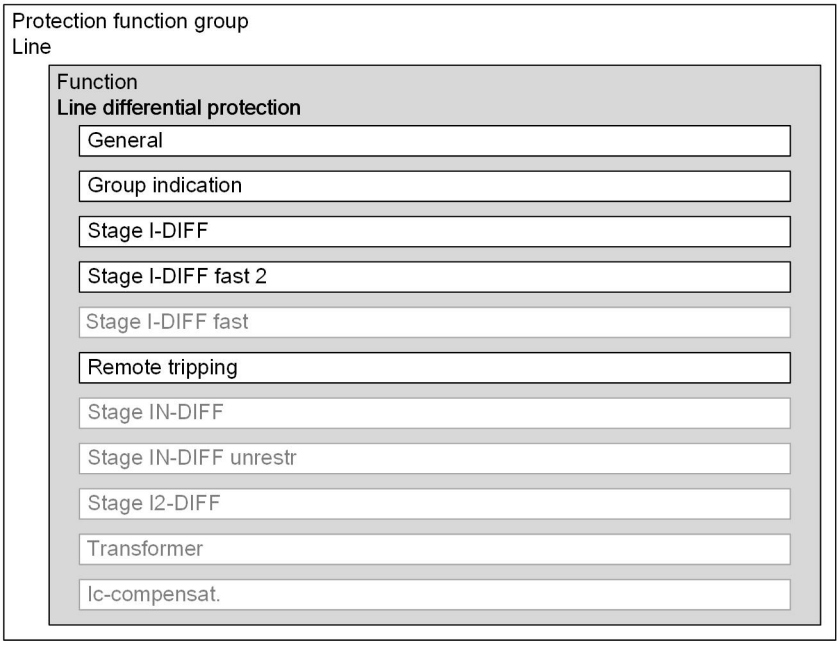
6.7.2 Structure of the Function

The function **Line differential protection** is used in the function group **Line**.
The function **Line differential protection** is preconfigured at the factory with the function block (FB) **General** , the stage **I-DIFF**, and the stage **I-DIFF fast 2**.
Additional stage types are available in the Global DIGSI 5 library:

- The stage **I-DIFF fast** as an alternative for the stage **I-DIFF fast 2**.
- The stage **IN-DIFF** for separate protection of the ground path.
- The stage **IN-DIFF unrest** for separate protection of the ground path.
- The stage **I2-DIFF** for separate monitoring of the negative-sequence current.

NOTE

Keep in mind that the same stage types must be instantiated in all devices of the device combination. That is, when using the stage **I-DIFF fast**, this stage must be instantiated in all devices of the device combination.

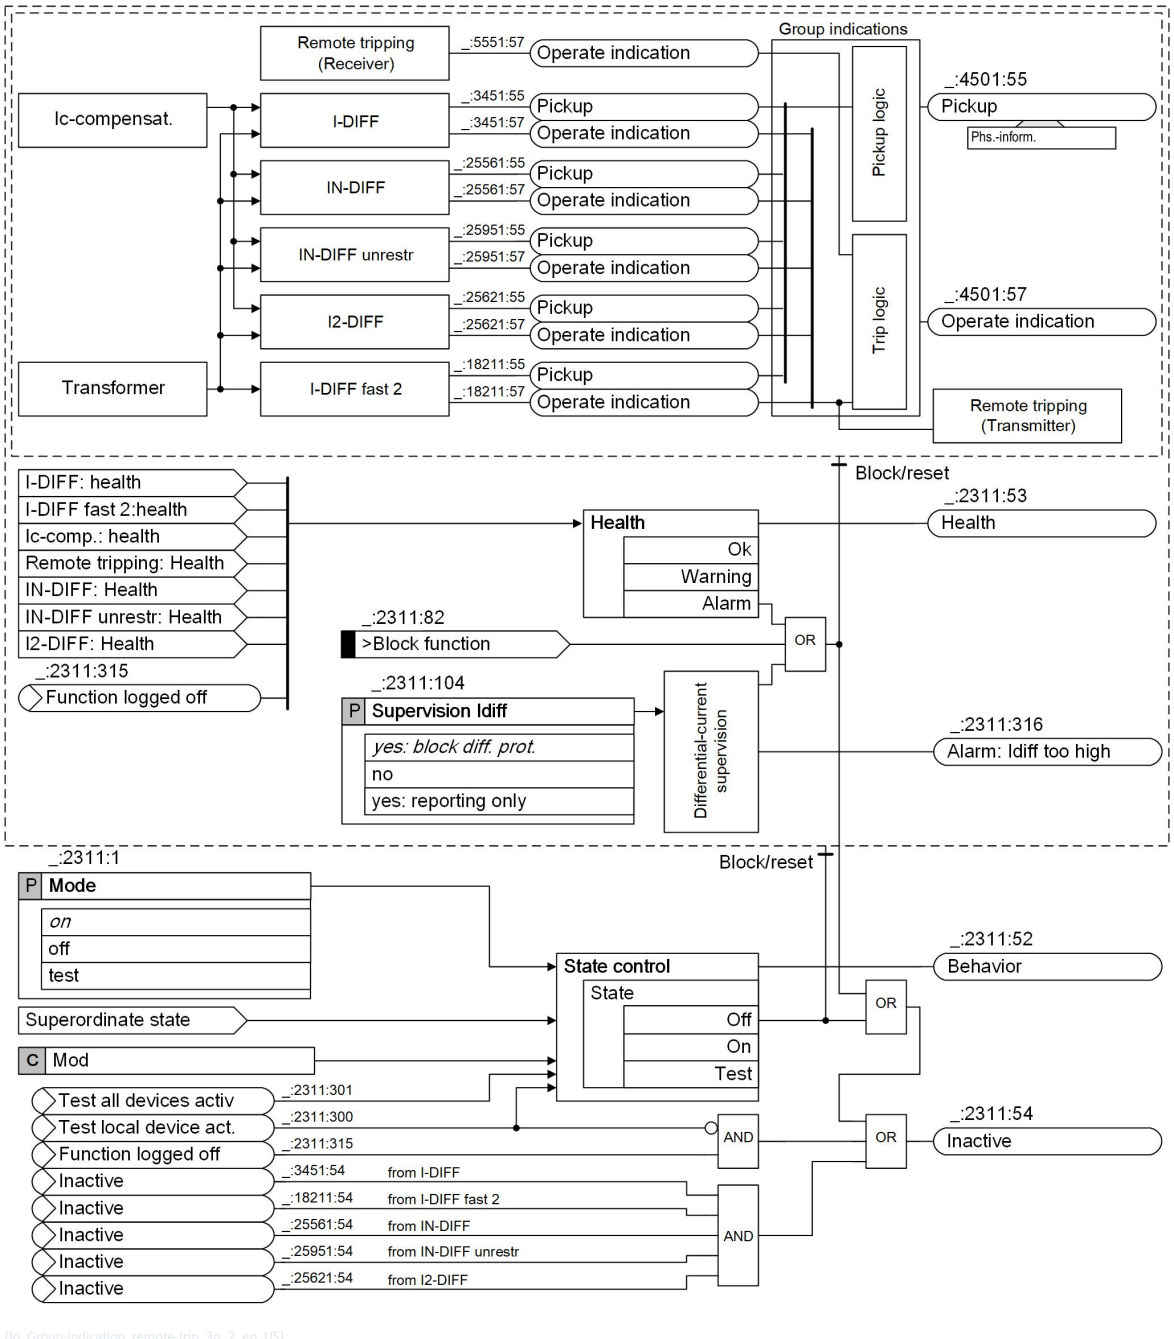


Also note that the devices can be operated either with the stage **I-DIFF fast 2** or with the stage **I-DIFF fast**. Parallel operation of the 2 stages is not possible.

When commissioning communication via the protection interface, it is checked whether the same stage types are instantiated in all devices of the device combination. If different stage types are instantiated in the devices, communication via the protection interface is not possible. In this case, the protection interface issues the diagnostic indication *(_:5161:302) Status of lay. 3 and 4 = Diff. Param. Error* in that case.

For further information, refer to *3.6.5.8 Indications and Measured Values in the Classic Protection Interface* and *3.6.6.6 Indications and Measured Values of the Advanced Protection Interface*.

The function blocks **Ic-compensat.** and **Transformer** are available in the Global DIGSI 5 library for special applications and can be instantiated into the function.



The protection function is structured in that way that the settings in the FB **General** are valid for all stages.

[dw_diff-structur_LP, 1, en_US]

Figure 6-139 Structure/Embedding of the Function

Overall Logic

[lo_Group-indication_remote-trip_3p, 2, en_US]

Figure 6-140 Logic Diagram of the Function Line Differential Protection, Overall Logic

Mode of Operation

The function **Line differential protection** is composed of several subfunctions.

The core of differential protection consists of the 2 stages **I-DIFF** and **I-DIFF fast 2**. Both work in parallel and ensure high sensitivity or fast tripping, depending on the severity of the fault.

For special applications where a ground differential protection is required, the stages **IN-DIFF** and/or **IN-DIFF unrest** can be used.

With the stage **I2-DIFF**, a negative-sequence differential protection can also be used.

The output signals of these stages are pickup and trip signals, which are routed to the pickup logic and the trip logic, resulting in the corresponding protection indications.

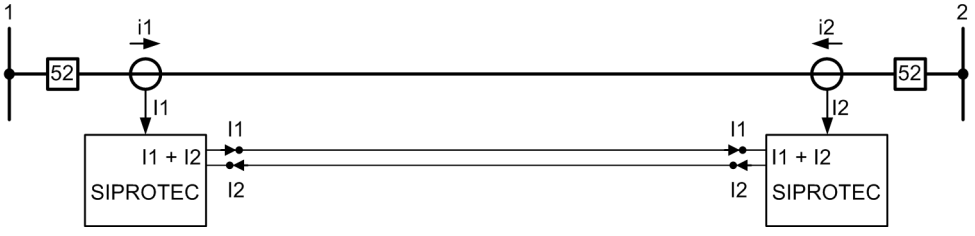
The functionality **Remote tripping** transmits the internally generated trip group indication to the remote devices in the device combination. In addition, the functionality **Remote tripping** receives the trip group indications of the remote devices and transmits these indications to the trip logic. For more detailed information, refer to *6.7.13 Remote Tripping*.

The optional FB **Ic-compensat.** contains the charging-current compensation. The FB **Ic-compensat.** is assigned exclusively to the sensitive stage **I-DIFF** and ensures maximum sensitivity even with high capacitive charging currents.

The optional FB **Transformer** is required to protect a transformer in the protection range. The additional FB **Transformer** guarantees that amplitudes and phase angle of the measured currents at the line ends will be evaluated correctly.

6.7.3 Function Description

The line differential protection operates on the basis of current comparison (Kirchhoff's current law). For this a device has to be installed at each end of the area to be protected. The devices exchange their measurands via communication connections. Each device performs the current comparison with these measurands and trips the assigned circuit breaker, if there is a short circuit in the protection range. The current transformers selectively delimit the protection range.



Apart from normal lines, the Line differential protection can also protect lines with a transformer in block connection. By using the function **Inrush-current detection** and the adaptive method of measurement for the line differential protection, the stages can be stabilized to prevent tripping that may be caused by transformer inrush currents.

Measured-Value Transmission

If the protected object is spatially connected – as is the case with generators, transformers, busbars – the measurands can be processed directly. The processing is different for lines where the protection range extends from one station to another. To enable the measurands from all line ends to be processed at each line end, these measurands must be transferred in a suitable form. In this way, the tripping condition can be checked at each line end, and the respective local circuit breaker can be tripped in case of a fault.

The measurands are encrypted and transmitted in digital telegrams via communication channels. For this purpose, each device features at least one interface for protection-data communication, called the protection interface in the following.

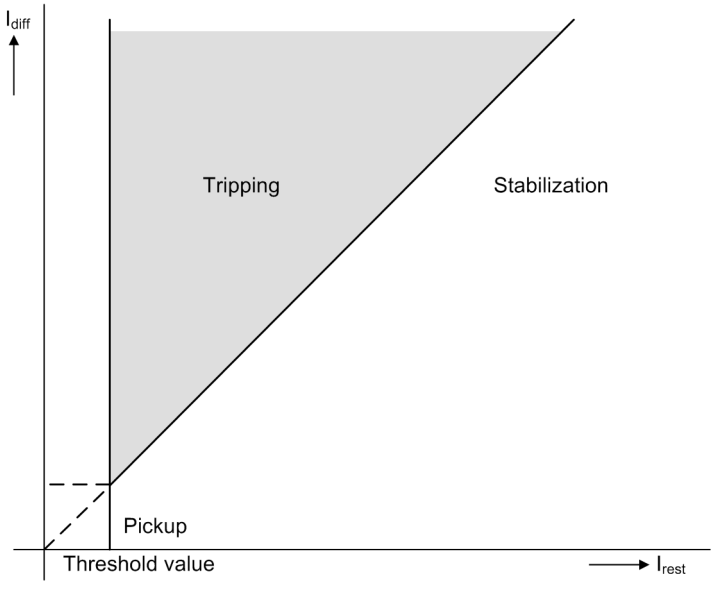
Figure 6-141 shows this principle for a line with 2 ends. Each device detects the local current and sends information on its magnitude and phase relation to the opposite end. Thus, each device can add the currents from all ends and further process them.

[dwdiff2e-150211-01.tif, 2, en_US]

Figure 6-141 Differential Protection for a Line with 2 Ends

Measured-Value Synchronization

The devices detect the local currents asynchronously. This means that each device detects, digitizes, and preprocesses the associated currents from the current transformers at its own random processor clock. If the currents of 2 or more line ends are to be compared, all currents must be processed with the same time base. All devices in the device combination exchange their time status with each telegram. The device whose address is entered first in the device-combination configuration in the protection interface functions as **timing master**, meaning it specifies the time frame. Each device can thus calculate the time offset due to the transmission and processing times relative to the **timing master**.



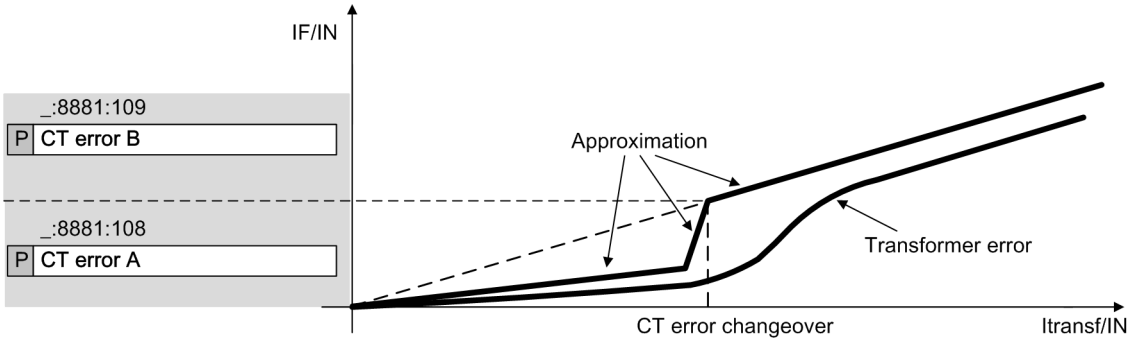
To achieve a sufficiently exact synchronization of the measured values, the current values are additionally provided with a **time stamp** before they are transmitted from one device to the others in digital telegrams. The time stamp allows a statement on the time at which the transmitted current values were valid. The receiving devices can thus carry out a fine synchronization based on the time stamp and their own time management. This means that currents detected at the same time (< 5 µs tolerance) are compared with each other.

The devices use the time stamp in the measured-data telegram to monitor the transfer times in real time and take each of these into account at the respective receiving end. The frequency of the measurands is decisive for precise calculation of the complex phasors. So that the phasor comparison is synchronous, the devices also measure the frequency of the measurands constantly and feed these into the calculation when needed. If the device is connected to voltage transformers and if at least one voltage is available in sufficient magnitude, the frequency is determined from this voltage. Otherwise, the measured currents are used as the basis for frequency determination. The devices exchange the determined frequencies with one another via the communication routes. Under these conditions, all devices operate with the updated frequency.

Adaptive Self-Stabilization

The basic principle of the differential protection is based on the precondition that, during uninterrupted operation, the sum of all currents flowing into the protected object equals 0. This applies to the primary system and only there if the shunt components of current, which occur from the capacitance of the lines or the magnetization currents of the transformers and shunt reactors, are negligible. In contrast, the secondary currents offered to the devices via the current transformers contain measuring fault originating from the measuring fault of the current transformers and the input circuits of the devices themselves. Even transmission faults such as signal jitter can cause measurand deviations.

All these influences mean that even in healthy operation the sum of the currents processed in the devices is not exactly 0. The differential protection is stabilized against these influences. A special method of **Adaptive self-stabilization** is applied in this context to ensure the highest possible sensitivity of the differential protection. The function calculates a restraint current I_{rest} for this purpose.



[dwanspre-150211-01.tif, 1, en_US]

Figure 6-142 Operate Curve of the Differential Protection

Current-Transformer Faults

In order to take into account the influences of current-transformer faults, each device calculates the current-transformer fault on an adaptive basis. This value results from an estimated calculation of the possible local transformer faults based on the data of the local current transformers and the magnitude of the locally measured currents.

[dwctfail-310111-01.tif, 2, en_US]

Figure 6-143 Approximation of the Current-Transformer Faults

The basis for this are the transformer data of the connected current transformers that must be entered individually for each device. Since each device transmits its estimated faults to the other devices in the device combination, each device is able to determine the sum of possible faults and use them for stabilization.

Other Measuring Faults

Other measuring faults, which can occur in the device itself due to hardware tolerances, calculation tolerances, time deviations, or the **quality** of the measurands such as harmonics and frequency deviations, are also estimated by the device and automatically increase the local self-stabilization value on an adaptive basis. The permissible variances of the transmission and processing times are also taken into account.

Time deviations are caused by residual faults when performing synchronization of the measurands, runtime variance or similar. GPS synchronization is used to prevent possible increases in self-stabilization in case of runtime jumps.

If an influencing variable cannot be detected – for example, the frequency because no adequate measurands are available – the device assumes the rated values by definition. In the frequency example, this means the following: If the frequency cannot be determined because no sufficient measurands are available, the device uses the rated frequency. But since the actual frequency can deviate from the rated frequency within the permissible range (±20 %), the stabilization is automatically increased correspondingly. As soon as the frequency has been determined (100 ms max. after applying a usable measurand), the stabilization is decreased again. In practice, this has an effect if no measurand is available in the range to be protected before the occurrence of a short-circuit, for example when switching a line with line-side voltage transformers onto a fault. Since the frequency is not yet known at that time, the stabilization is increased at first until the actual frequency is determined. This can lead to a tripping delay, but only at the pickup threshold, for example, in the case of very low-current faults.

Stages of Line Differential Protection

The Line differential protection has 2 preconfigured stages:

- The stage **I-DIFF** works with accurate measurement. Maximum sensitivity can be achieved with this stage. You cannot delete this stage.

  The stage **I-DIFF** can cooperate with the **Current comparison** stage of the Line differential protection of the SIPROTEC 4 devices 7SD5x and 7SD61x.

- The stage **I-DIFF fast 2** works in parallel with the stage **I-DIFF**. A very fast algorithm enables tripping decisions to be made very quickly in the event of high-current faults.

  If the stage **I-DIFF fast 2** is instantiated, the **Saturation detection** block is visible with the parameter **CT saturation threshold** in the **Measuring point Current 3-phase**.

- The stage **I-DIFF fast** is available in the DIGSI 5 library as an alternative to the stage **I-DIFF fast 2**. If you want to instantiate this stage, you must first delete the stage **I-DIFF fast 2**.
  If the stage **I-DIFF fast** is instantiated, the **Saturation detection** block is not visible with the parameter **CT saturation threshold** in the current measuring point.
  The stage **I-DIFF fast** also works in parallel with the stage **I-DIFF**. A very fast algorithm enables tripping decisions to be made very quickly in the event of high-current faults.
  The stage **I-DIFF fast** can cooperate with the stage **Fast charge comparison** of the Line differential protection of the SIPROTEC 4 devices 7SD5x and 7SD61x.
- The stage **IN-DIFF** operates with high-accuracy measurement either with the separately measured ground current I_N or with the calculated zero-sequence current 3I0. With this stage, you can achieve the maximum sensitivity.
- The stage **IN-DIFF unrest** operates with high-accuracy measurement either with the separately measured ground current I_N or with the calculated zero-sequence current 3I0. With this stage, you cannot achieve the maximum sensitivity because the adaptive self-stabilization is not used here.
- The stage **I2-DIFF** operates with high-accuracy measurement with the measured negative-sequence current I2. With this stage, you can achieve the maximum sensitivity.

Inrush-Current Detection

If the protection range extends beyond a transformer, a high inrush current, which flows into the protection range but does not leave it again, has to be expected when connecting the transformer. The inrush current can reach a multiple of the rated current and is characterized by a relatively high content of 2nd harmonic (twice the rated frequency), which is missing almost completely in the case of a short circuit.

The algorithm of the Line differential protection recognizes the inrush currents. Temporarily, the adaptive stabilization function provides an elevated restraint current, preventing any unwanted tripping.

If the function **Inrush-current detection** is present in the device, inrush currents will be detected correctly. For this, the function block **Inrush detect.** from the DIGSI 5 function library must be instantiated and enabled. High inrush currents can lead to an overfunction. Inrush-current detection prevents overfunction by blocking the affected phases or all phases using the crossblock function.

Charging-Current Compensation

Distributed line or phase capacities cause a permanently capacitive charging current. This charging current has to be taken into account by the pickup values of the differential-protection stages. In cables, this charging current can reach considerable values. The charging-current compensation serves to improve the sensitivity so that maximum sensitivity can be protected even at high charging currents. For this, the function block **Ic-compensat.** from the DIGSI 5 function library must be instantiated and enabled.

Monitoring the Differential Current

The process of adaptive self-stabilization is based on the fact that differential current faults that are caused by disturbing influences can be compensated by supplementary restraints. Thus, the process provides the highest possible sensitivity for the differential protection.

The additional dynamic monitoring of the differential current is meaningful, since there are interfering effects that cannot be detected by the device. This includes stationary or slowly building unbalances in the transmission times in the protection interface communication over communication networks. Without external GPS time synchronization, the runtime monitoring function cannot capture the unbalances in transmission times. Therefore, the received measured values cannot be synchronized precisely and high currents passing through may cause tripping.

During operation (load operation), the behavior of the differential and restraint current must be monitored to this effect, and whether in spite of a restraining quantity the differential current approaches the operate curve in an unexpected manner and without recognizing jumps in runtime. Monitoring is based on a characteristic curve located at 80 % of the characteristic curve of the stage **I-DIFF**. If the differential current exceeds the monitoring characteristic curve (parameter **Supervision Idiff** = ***yes: block diff. prot.***) and a current jump is not present, the Line differential protection is blocked after 1 s and the indication *Alarm:*

Idiff too high is output. In addition, a fault record is initiated in all differential protection devices (see *6.7.2 Structure of the Function*).

During commissioning, ensure that the differential current in the operate curve is defined primarily by the charging current and the transformer error (DIGSI 5 Test Suite). If the differential-current supervision function picks up during commissioning, check first whether the setting recommendation for stage **I-DIFF** was followed. If the stage **I-DIFF** is set correctly, pickup indicates a stationary unbalance of the signal-transmission times. It is the responsibility of the network operator to apply suitable measures to eliminate the causes.

Remote Tripping

Additionally to the measured values, the function **Line differential protection** transfers the locally generated operate indication to the Line differential protection functions of the remote devices in the device combination. The remote devices then generate an operate indication if the local **Line differential protection** has not yet generated an operate indication. This can occur under pickup conditions at the pickup threshold (see *6.7.2 Structure of the Function*).

Emergency Mode

NOTE

When the protection device is in emergency mode, the function **Line differential protection** does not work.

If the **Line differential protection** is the main protection function in the protection device, the **Line differential protection** can activate the emergency mode of the device. The emergency mode is activated if one of the following conditions is met:

- Protection-interface communication is disturbed.
- Line differential protection is blocked via the binary input *(_:2311:82) >Block function*.

When emergency mode is active, the function **Overcurrent protection** can work as an emergency function, for example.

If the functions **Line differential protection** and **Distance protection** are instantiated simultaneously, you can set the distance protection zones in such a way that in case of a line differential protection outage, the blocking of the distance protection zones is disabled. The blocking of the distance protection zones is disabled if one of the following conditions is met:

- Protection-interface communication is disturbed.
- Line differential protection is blocked via the binary input *(_:2311:82) >Block function*.
- Line differential protection is disabled.
- Line differential protection is in test operation mode *(_:2311:308) Test all devices*.

Constellation Measured Values

Refer to *Constellation Measured Values , Page 151*

6.7.4 Application and Setting Instructions - General Settings

NOTE

Keep the following hints in mind so that the line differential protection operates correctly on all line ends:

- Set the rated current of the line (parameter **(_:9001:101) Rated current**) to the same value at both ends of the line.
  The rated apparent power is internally calculated for both ends of the line and is displayed as the write-protected parameter **(_:9001:103) Rated apparent power**.
- If you have instantiated the **Transformer** function block in the line differential protection, set the parameter **(_:9001:103) Rated apparent power** to the same value at both ends. The rated current is internally calculated for both ends of the line and is displayed as the write-protected parameter **(_:9001:101) Rated current**.

If the parameters **Rated current** and **Rated apparent power** are set in a different way in the devices of the device combination, the Line differential protection does not operate correctly and the indication *Diff. Param. Err.* is issued.
For further information, refer to *3.6.5.8 Indications and Measured Values in the Classic Protection Interface* and *3.6.6.6 Indications and Measured Values of the Advanced Protection Interface*.

NOTE

To stabilize the line differential protection against current-transformer errors, the parameters for the phase currents **(_:8881:107) CT error changeover**, **(_:8881:108) CT error A** and **(_:8881:109) CT error B** as well as the parameters for the ground current IN **(_:8881:110) CT error changeover**, **(_:8881:111) CT error A** and **(_:8881:147) CT error B** are relevant for the current measuring points in the power-system data. These parameters are used exclusively by the function **Line differential protection**.

Parameter: Min. current for release

- Default setting **(_:2311:102) Min. current for release** = *0.00 A*

With the parameter **Min. current for release**, you specify the minimum local current required for release of the local operate indication.

Parameter: Supervision Idiff

- Recommended setting value **(_:2311:104) Supervision Idiff** = *yes: block diff. prot.*

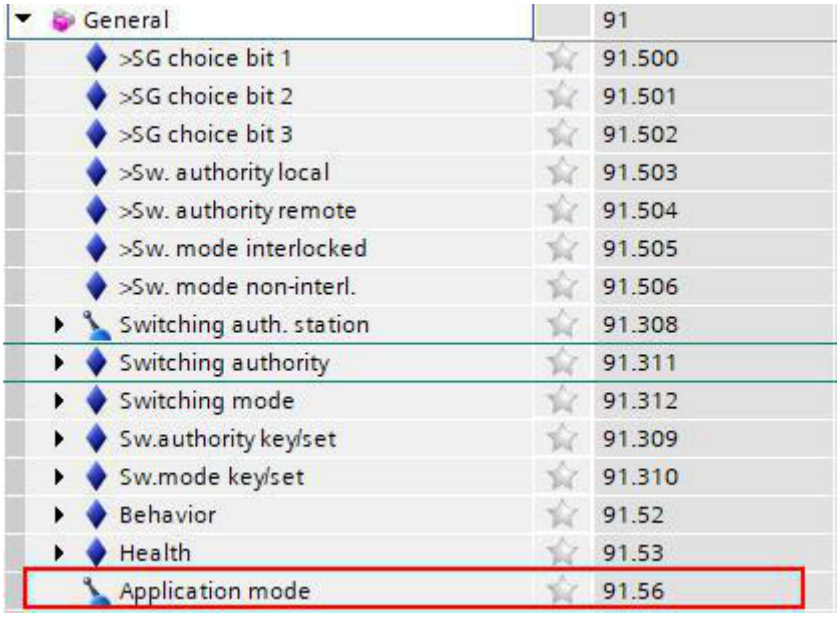
When using the parameter **Supervision Idiff**, you specify whether the line differential protection function operates with or without differential-current supervision.

Parameter Value	Description
no	The differential current is not monitored.
yes: reporting only	The differential current is monitored. If the differential current exceeds the supervision threshold and a current jump is not present, the indication *Alarm: Idiff too high* is issued after 1 s.
yes: block diff. prot.	The differential current is monitored. If the differential current exceeds the supervision threshold and there is no current jump, the line differential protection is blocked after 1 s and the indication *Alarm: Idiff too high* is issued.

Parameter: Action on Behavior = test

- Default setting **(_:2311:108) Action on Behavior = test** = *Test loc. device autom.*

With the parameter **Action on Behavior = test**, you specify whether the special test mode ***Test local device*** for the function **Line differential protection** is switched on automatically or not after the test mode has been switched on for the entire device via the controllable *Application mode*.

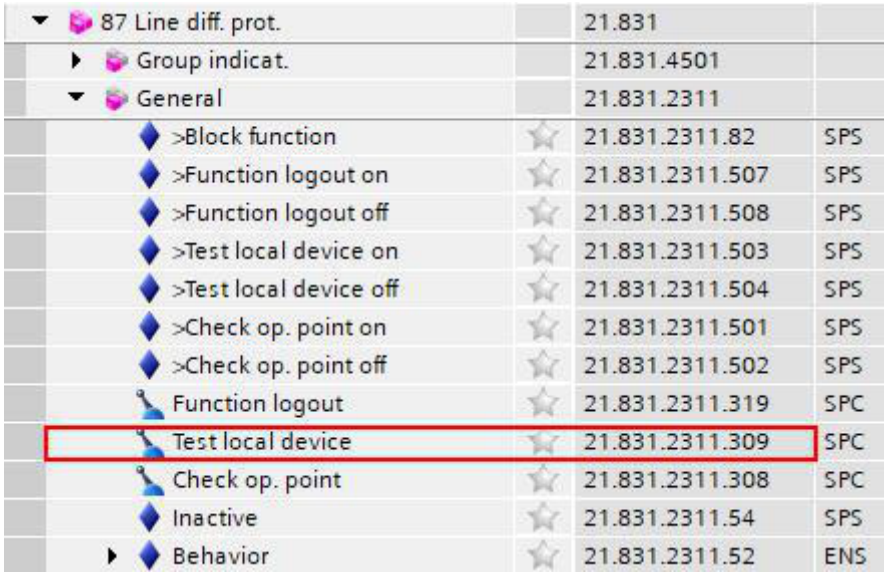


Parameter Value	Description
Test loc. device autom.	If the test mode is switched on for the entire device via the controllable *Application mode*, the special test mode ***Test local device*** is switched on automatically for the function **Line differential protection**. If you use a test switch for testing the local function **Line differential protection** that activates the test mode for the entire device as well as the test mode ***Test local device*** in one switching procedure, this setting option is useful.
Test loc. device man.	With this setting option, the function **Line differential protection** is not automatically switched to the test mode ***Test local device***.

If you switch the entire device to test mode, all protection functions automatically adopt the state ***Test*** or ***Test/Relay blk.***. Protection functions that work only with local measurands can now be tested.

For further information, refer to *Parameter: Activate device test mode , Page 264* and *11.2 Enabling/Disabling the Application/Test Mode for the Entire Device*.

The function **Line differential protection** additionally requires the measurands of the remote devices. Therefore, you must also switch on the test mode for the entire device in the remote devices so that the line differential protection in the remote devices changes to the state ***Test*** or ***Test/Relay blk.***. Only then is it possible to test the entire function **Line differential protection**.



If you want to test the function **Line differential protection** only in the local device, first switch the entire device to test mode using the controllable *(_:56) Application mode*.

[sc_Applicationmode, 1, en_US]

Figure 6-144 Switching on the Test Mode for the Entire Device with the Controllable *Application mode*

Then switch on the special test mode ***Test local device*** with the controllable *(_:2311:309) Test local device* in the function **Line differential protection**.

[sc_Ldiff_testmode_controllable, 1, en_US]

Figure 6-145 Switching on the Special Test Mode for the Function **Line Differential Protection** with the Controllable *Ctrl:Test local device*

In this operating mode, the function **Line differential protection** interprets the local currents as differential currents. These currents are not transmitted to the line differential protection functions of the remote devices. Hence, the line differential protection functions of the remote devices are not effective.

For further information, refer to *11.7 Functional Test Line Differential Protection*.

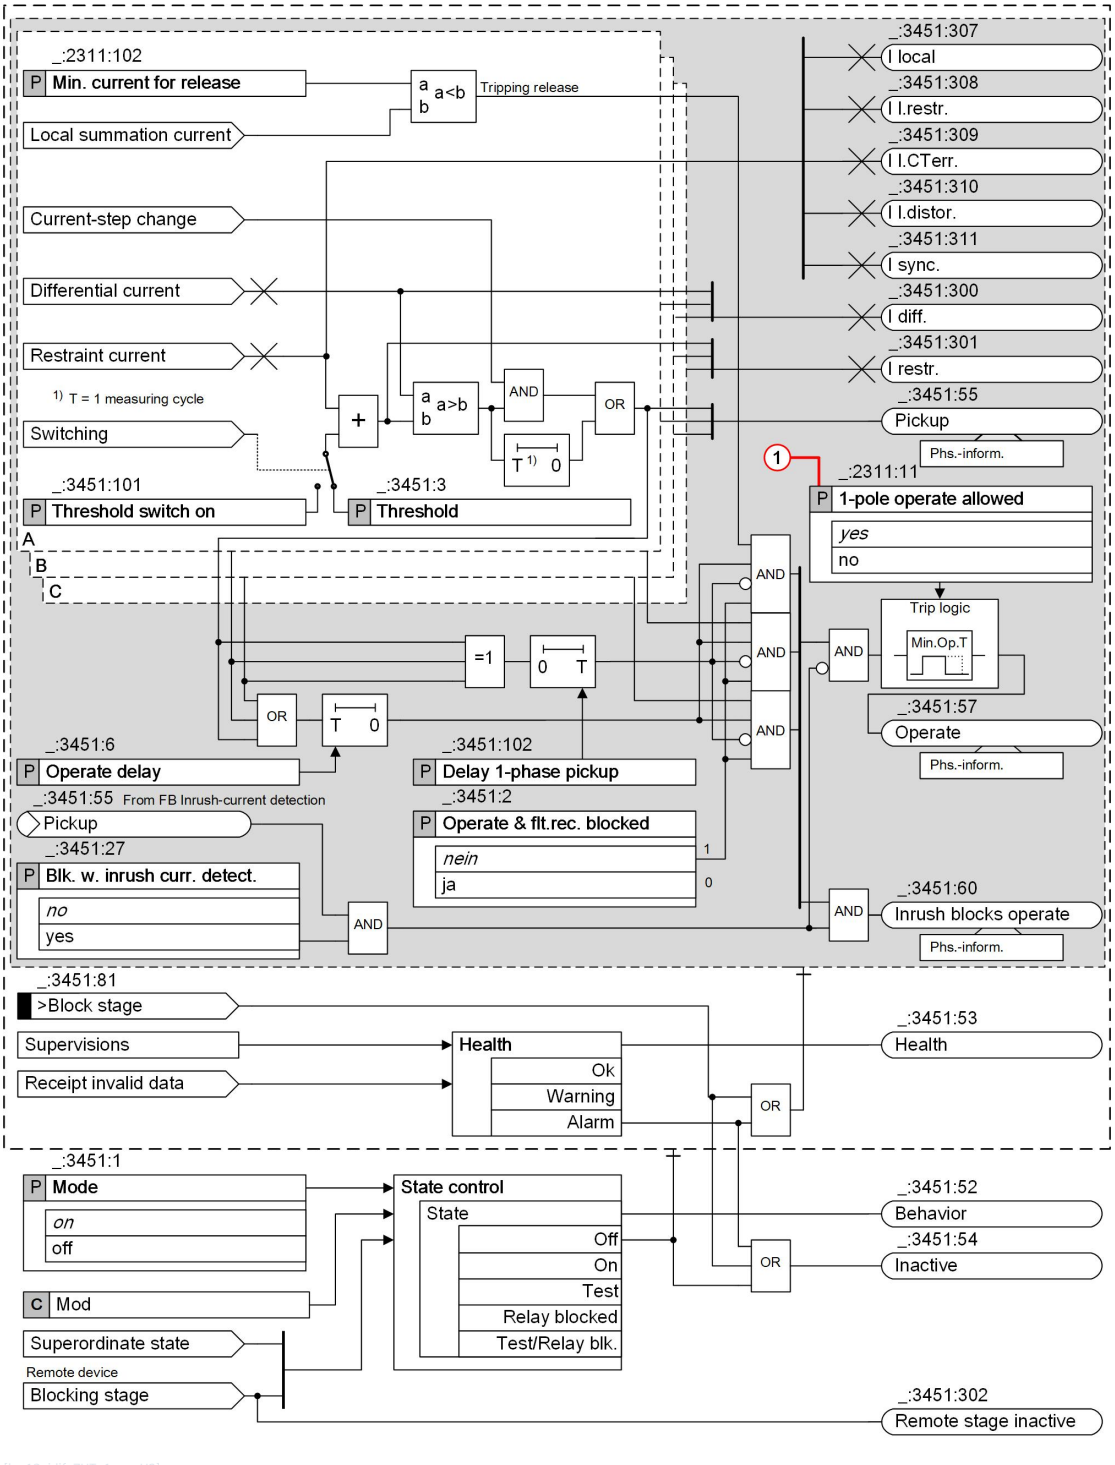
6.7.7 Stage I-DIFF



6.7.7.1 Description

Logic of the Stage

[loijump, 2, en_US]

Figure 6-146 Logic of the Stage **I-DIFF**, Part 1

[lo_13_idif_7UT, 1, en_US]

Figure 6-147 Logic of the Stage **I-DIFF**, Part 2

(1) The parameter is only available if the function **Line differential protection 1-pole/3-pole** is instantiated in the device.

Mode of Operation

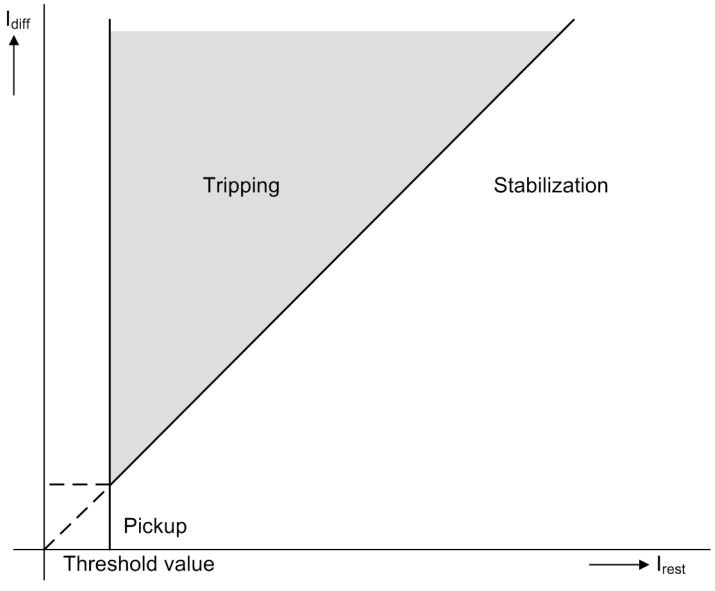
The stage **I-DIFF** is the sensitive stage of differential protection. The principle of the stage **I-DIFF** is comparison of the current phasor. Usable current phasors are available after 1 period has elapsed following the occurrence

of a fault event. The stage **I-DIFF fast 2**, which operates in parallel, is responsible for fast tripping in the event of high-current faults.

The measurands are analyzed separately for each phase. Each device calculates an I_{diff} differential current from the sum of the current phasors which are calculated at each end of the protected object and transmitted to the other ends. Its value corresponds to the fault current which the differential-protection system sees, ideally that is the short-circuit current. In correct operation, it is small and corresponds to the capacitive charging current in lines in a first approximation. If charging-current compensation is active, the maximum sensitivity is achieved and the pickup value can be set considerably smaller.

The I_{rest} restraint current counteracts the differential current. The restraint current results from the sum of the maximum measuring faults at the ends of the protected object and is calculated adaptively from the current measurands and the set substation settings. To this end, the maximum fault of the current transformers in the rated range or the short-circuit current range is multiplied by the presently flowing current at each end of the protected object and transmitted to the other ends together with the determined internal faults. This means that the restraint current I_{rest} always reflects the maximum possible measuring faults in the differential-protection system.

Optional functions such as **charging-current compensation** (increased sensitivity) and **transformer in the protection range** are automatically considered when the differential and stabilization currents are calculated.



Pickup of the Stage

The pickup characteristic of the differential protection (see *Figure 6-148*) results from the stabilization characteristic curve $I_{diff} = I_{rest}$ (45° line) which is cut below the setting value of the parameter **Threshold**. It complies with the equation

I_{rest} = **Threshold** + Σ (current-transformer error and other measuring errors).

If the measured differential current exceeds the pickup threshold (**Threshold**) and the maximum possible measuring errors, there is an internal fault (dimmed area in *Figure 6-148*).

In case of an internal fault, you can define an additional criterion for local tripping release using the parameter **Min. current for release**.

[dwanspre-150211-01.tif, 1, en_US]

Figure 6-148 Pickup Characteristic of the Stage I-DIFF

Pickup upon Switching

When switching on longer, unloaded cables, overhead lines, and resonant-grounded lines, pronounced higher-frequency compensating processes can occur. These are strongly dampened by digital filters of the differential protection. With the parameter **Thresh. switch onto fault**, you can prevent single-end pickup of the line differential protection in case of switching. The parameter **Thresh. switch onto**

fault always becomes effective as soon as a device in the device combination has detected that its end is switched after a dead time. All devices in the device combination are then changed over to this pickup value for the duration of the closure detection (parameter: **Action time after closure**). For more detailed information, refer to *5.5.4.7 Closure Detection*.

In addition, for the switching of transformers and shunt reactors, the device features an **Inrush-current detection** function via which blocking of the affected phase of the differential protection is possible. For more detailed information, refer to *6.68.1 Inrush-Current Detection*.

Inrush-Current Detection

You can find the **Inrush-current detection** function in the Global DIGSI 5 library under **Line FG** → **Inrush detect.**. Add this functionality to the **Line** function group (under **DIGSI 5 project tree** →**Name of the device** → **Settings** →**Line**).

The parameter **Blk. w. inrush curr. detect.** now also appears in the stage **I-DIFF** of the Line differential protection.

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (, fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

Measured Value of the I-DIFF Stage

In order to clarify failures, the **I-DIFF** stage provides the following measured values:

Measured Value	Description
(_:3451:300) I diff.	Differential current
(_:3451:301) I restr.	Restraint current (overall restraint)
(_:3451:307) I local	Value of local current phasor
(_:3451:308) I l.restr.	Local restraint current
(_:3451:309) I l.cTerr.	Partial component of the local restraint current that considers the transformer fault.
(_:3451:310) I l.distor.	Subcomponent of the local restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabilization.
(_:3451:311) I sync.	Subcomponents of the overall restraint that are caused by faults during the time synchronization of the current phasor.

The measured values are available in the fault record. You can read out fault recordings from the device and analyze them afterwards using evaluation tools such as SIGRA. The device display shows only *I diff.* and *I restr.*. In order to find the measured values on the device, go to **Main menu** → **Measurements** → **Line x** → **Functional measured values** → **Line differential protection** → **I-DIFF**.

For detailed information about selecting and deleting fault recordings, refer to the *Operating Manual*.

6.7.7.2 Application and Setting Notes

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:3451:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the tripping is blocked during the detection of an inrush current. If the inrush-current detection blocks tripping of the stage **I-DIFF**, the indication *Inrush blocks operate* is generated.

Parameter: `Threshold`

- Recommended setting value **`(_:3451:3) Threshold`** = ***`0.300 A`***

With the **`Threshold`** parameter, you set the pickup threshold for the stage **I-DIFF**. The total current flowing into the protection range during a short circuit is decisive, that is, the total fault current, regardless of how it divides among the ends of the protected object.

Parameter: `Thresh. switch onto fault`

- Recommended setting value **`(_:3451:101) Thresh. switch onto fault`** = ***`0.300 A`***

With the **`Thresh. switch onto fault`** parameter, you set the pickup threshold for the stage **I-DIFF** during a detected connection.

A setting of 3 times to 4 times the stationary charging current generally ensures the stability of the protection when switching.

Approximately at the same time, all devices in the device combination use the pickup threshold increased with the **`Thresh. switch onto fault`** parameter during the set **`(_:4681:102) Action time after closure`**. For further information, refer to *5.5.4.7 Closure Detection*.

If you set the parameter in exactly the same way as the parameter **`Threshold`**, the parameter **`Thresh. switch onto fault`** is ineffective.

Parameter: `Delay 1-phase pickup`

- Recommended setting value **`(_:3451:102) Delay 1-phase pickup`** = ***`0.04 s`***

If the differential protection is used in an isolated or resonant-grounded system, it has to be ensured that tripping due to the fault-ignition oscillation of a simple ground fault is prevented. With the **`Delay 1-phase pickup`** parameter, you delay the pickup in case of a simple ground fault.

In extended, resonant-grounded systems, Siemens recommends using a higher setting value.

NOTE

This parameter is only effective for **resonant-grounded/isolated** neutral-point treatment!

Parameter: `Operate delay`

- Recommended setting value **`(_:3451:6) Operate delay`** = ***`0.00 s`***

In special cases, it can be advantageous to delay the tripping of the differential protection with an additional time stage, for example for reverse interlocking. The time delay is started when the stage **I-DIFF** picks up.

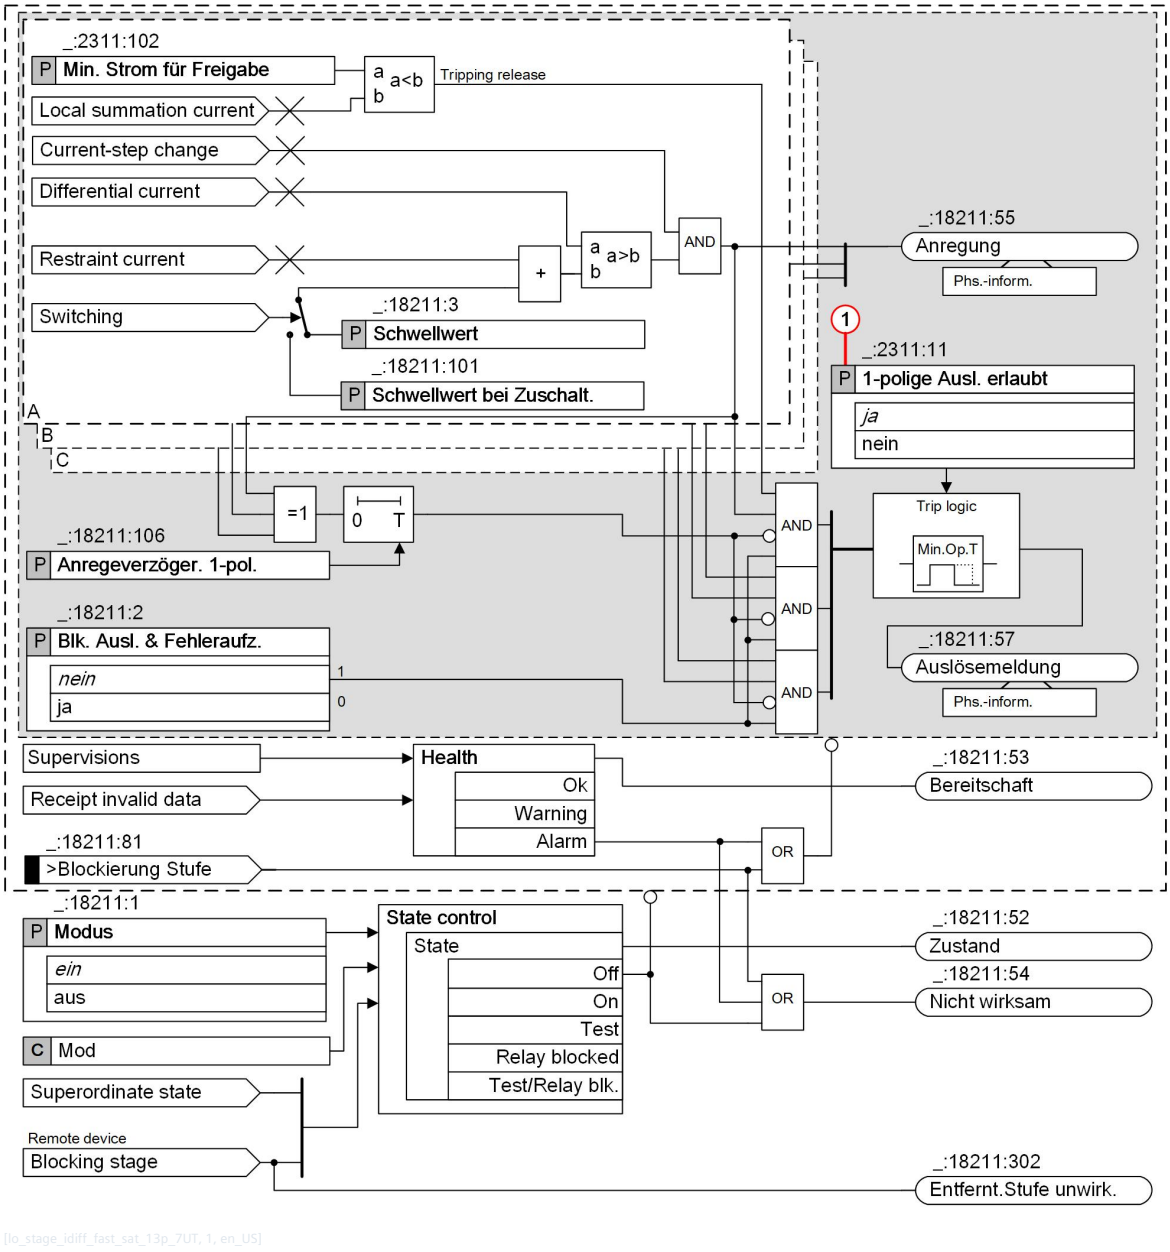
6.7.8 Stage I-DIFF Fast 2



6.7.8.1 Description

Logic of the Stage

[loijump, 2, en_US]

Figure 6-149 Logic of the Stage I-DIFF fast 2, Part 1

[lo_stage_idiff_fast_sat_13p_7UT, 1, en_US]

Figure 6-150 Logic of the Stage I-DIFF fast 2, Continued

(1) The parameter is only available if the function **Line differential protection 1-pole/3-pole** is instantiated in the device.

NOTE

If you want to use the stage **I-DIFF fast 2**, the device must be equipped with the **CP300** CPU printed circuit board assembly.

The differential-protection procedure of the stage **I-DIFF fast 2** has been improved compared to the procedure of the stage **I-DIFF fast**.

The new differential-protection procedure has the following properties:

- The lower limit of the setting range was reduced. As a result, the pickup threshold can be set with more sensitivity.
- Improved stability against transformer-saturation effects during special faults

- Shorter operate times
- Improved behavior during faults with a change from external to internal errors

Mode of Operation

The **I-DIFF fast 2** stage is the differential-protection stage that is optimized for fast tripping times when high-current faults occur. It is superimposed on the **I-DIFF** stage. The measurands are analyzed separately for each phase. Fast tripping for high-current faults is achieved with a procedure based on filtered instantaneous values. During this procedure, stabilization to prevent signal distortion (for example, current-transformer saturation), which can occur during external high-current faults, is not possible. For this reason, a decision for internal or external faults must be made before the potential saturation appears. It is assumed that the current transformers do not yet go into saturation at least for 5 ms after fault inception.

If you use the **I-DIFF fast 2** stage, the **Saturat. det.** block is visible in the measuring point **Current 3-phase** with the **CT saturation threshold** parameter. For this, the **CT saturation threshold** must be set so that transformer saturation does not occur until the currents exceed the setting value.

You can find more detailed information in chapter *8.3.13 Saturation Detection*.

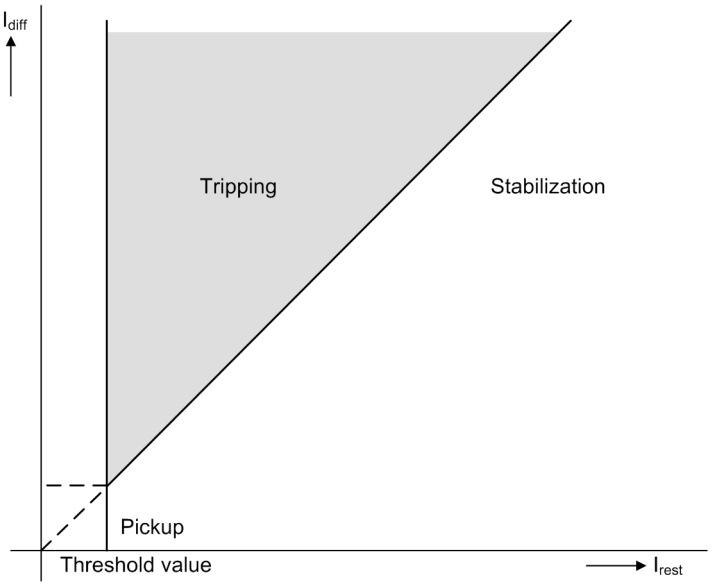
If saturation occurs for one or more current transformers that limit the protection range, the **I-DIFF fast 2** stage is blocked and an erroneous pickup due to transformer saturation is avoided. Normally, the **I-DIFF fast 2** stage is set higher than the rated current. In this way, the influence of charging currents and cross-flow currents of transformers (fixed and transient) is suppressed.

Otherwise, the **I-DIFF fast 2** stage works in the same way as the sensitive **I-DIFF** stage. Each device calculates an I_{diff} differential current for each phase from the sum of the filtered instantaneous values, which are calculated at each end of the protected object and transmitted to the other ends. Its amount corresponds to the fault current calculated by the differential-protection system, ideally that is the short-circuit current. In correct operation, it is small and corresponds to the capacitive charging current in lines in a first approximation.

The I_{rest} restraint current counteracts the differential current. The restraint current results from the sum of the maximum measuring faults at the ends of the protected object and is calculated adaptively from the current measurands and the set substation parameters. To this end, the maximum fault of the current transformers in the rated range or the short-circuit current range is multiplied by the presently flowing current at each end of the protected object and transmitted to the other ends together with the determined internal faults. This means that the restraint current I_{rest} always reflects the maximum possible measuring faults in the differential-protection system.

The option of a transformer in the protection range is automatically considered when the differential and stabilization currents are calculated. An activated charging-current compensation has no effect on the **I-DIFF fast 2** stage.

Pickup of the Stage



The decisive element is the RMS value of the current. Like for the **I-DIFF** stage, the pickup characteristic (see *Figure 6-151*) results from the stabilization characteristic curve $I_{diff} = I_{rest}$ (45° line) which is cut below the setting value of the parameter **Threshold**. It complies with the equation:

I_{rest} = **Threshold** + Σ(I · **CT error B** + other measuring errors)

For further information, refer to *6.1.7 Application and Setting Notes for Line Differential Protection Settings*.

If the measured differential current exceeds the sum from pickup threshold (**Threshold**) and maximum possible measuring error, there is an internal error (see *Figure 6-151*).

In case of an internal error, you can define an additional criterion for local tripping release using the parameter **Min. current for release**.

[dwanspre-150211-01.tif, 1, en_US]

Figure 6-151 Pickup Characteristic of the I-DIFF fast 2 Stage

Pickup upon Switching

When switching on longer, unloaded cables, overhead lines, and resonant-grounded lines, pronounced higher-frequency compensating processes can occur.

As the **Threshold** of the **I-DIFF fast 2** stage must be set significantly higher than the **Threshold** of the **I-DIFF** stage, switching procedures do not lead to an erroneous pickup of the **I-DIFF fast 2** stage.

For the switching procedures mentioned above, it may be worthwhile to set the **Thresh. switch onto fault** parameter higher than the **Threshold** parameter. This reliably prevents erroneous pickup of the **I-DIFF fast 2** stage. The parameter **Thresh. switch onto fault** always becomes effective as soon as a device in the device combination has detected that its end is switched after a dead time. All devices in the device combination are then changed over to this pickup value for the duration of the closure detection (**Action time after closure** parameter).

You can find more detailed information in chapter *5.5.4.7 Closure Detection*.

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

6.7.8.2 Application and Setting Notes

Parameter: Threshold

- Recommended setting value **(_:3481:3) Threshold** = ***1.000 A***

With the **Threshold** parameter, you set the pickup threshold for the stage **I-DIFF fast 2**.

This stage responds very quickly. For this reason, pickup during capacitive charging currents (in the case of lines) and inductive magnetization currents for transformers or shunt reactors – including during switching procedures - must be excluded. This also applies when charging-current compensation is switched on, because this is not effective for the stage **I-DIFF fast 2**. Set the pickup value to a value greater then the load current ($1.2 \cdot I_{rated}$ to $2 \cdot I_{rated}$).

In resonant-grounded systems, the value must not fall below the value of the not resonant-grounded ground-fault current. This value results from the total capacitive ground-fault current without taking into consideration the arc-suppression coil. Since the arc-suppression coil has to compensate for approximately the total

capacitive ground-fault current, its approximate rated current can be taken as a basis. For transformers, set $I_{rated\ transf.}/V_{k\ transf.}$

A final dynamic check of the pickup thresholds is performed during commissioning.

Parameter: `Thresh. switch onto fault`

- Recommended setting value **`(_:3481:101) Thresh. switch onto fault`** = ***`1.000 A`***

With the **`Thresh. switch onto fault`** parameter, you set the pickup threshold for the stage **`I-DIFF fast 2`** during a detected switching.

If bushing-type transformers are used for a transformer in the line section to be protected, leakage fluxes through the bushing-type transformers can occur during reclosure after an external fault. These leakage fluxes can corrupt the secondary current and lead to an overfunction of the stage **`I-DIFF fast 2`**. If bushing-type transformers are used, Siemens recommends setting the pickup value in the case of switching to 2 to 3 times the setting value of the threshold value of the stage.

Approximately at the same time, all devices in the device combination use the pickup threshold increased with the parameter **`Thresh. switch onto fault`** during the set **`(_:4681:102) Action time after closure`**. For further information, refer to *5.5.4.7 Closure Detection*.

If you set the parameter to the same value as the parameter **`Threshold`**, the parameter **`Thresh. switch onto fault`** is not effective.

Parameter: `Delay 1-phase pickup`

- Recommended setting value **`(_:3481:106) Delay 1-phase pickup`** = ***`0.04 s`***

If the differential protection is used in an isolated or resonant-grounded system, it must be ensured that tripping due to the starting oscillation of a single ground fault is prevented. With the parameter **`Delay 1-phase pickup`**, you delay the pickup in case of a single ground fault.

Siemens recommends a higher setting value in extended resonant-grounded systems.

NOTE

This parameter is only effective for **resonant-grounded or isolated** neutral-point treatment!

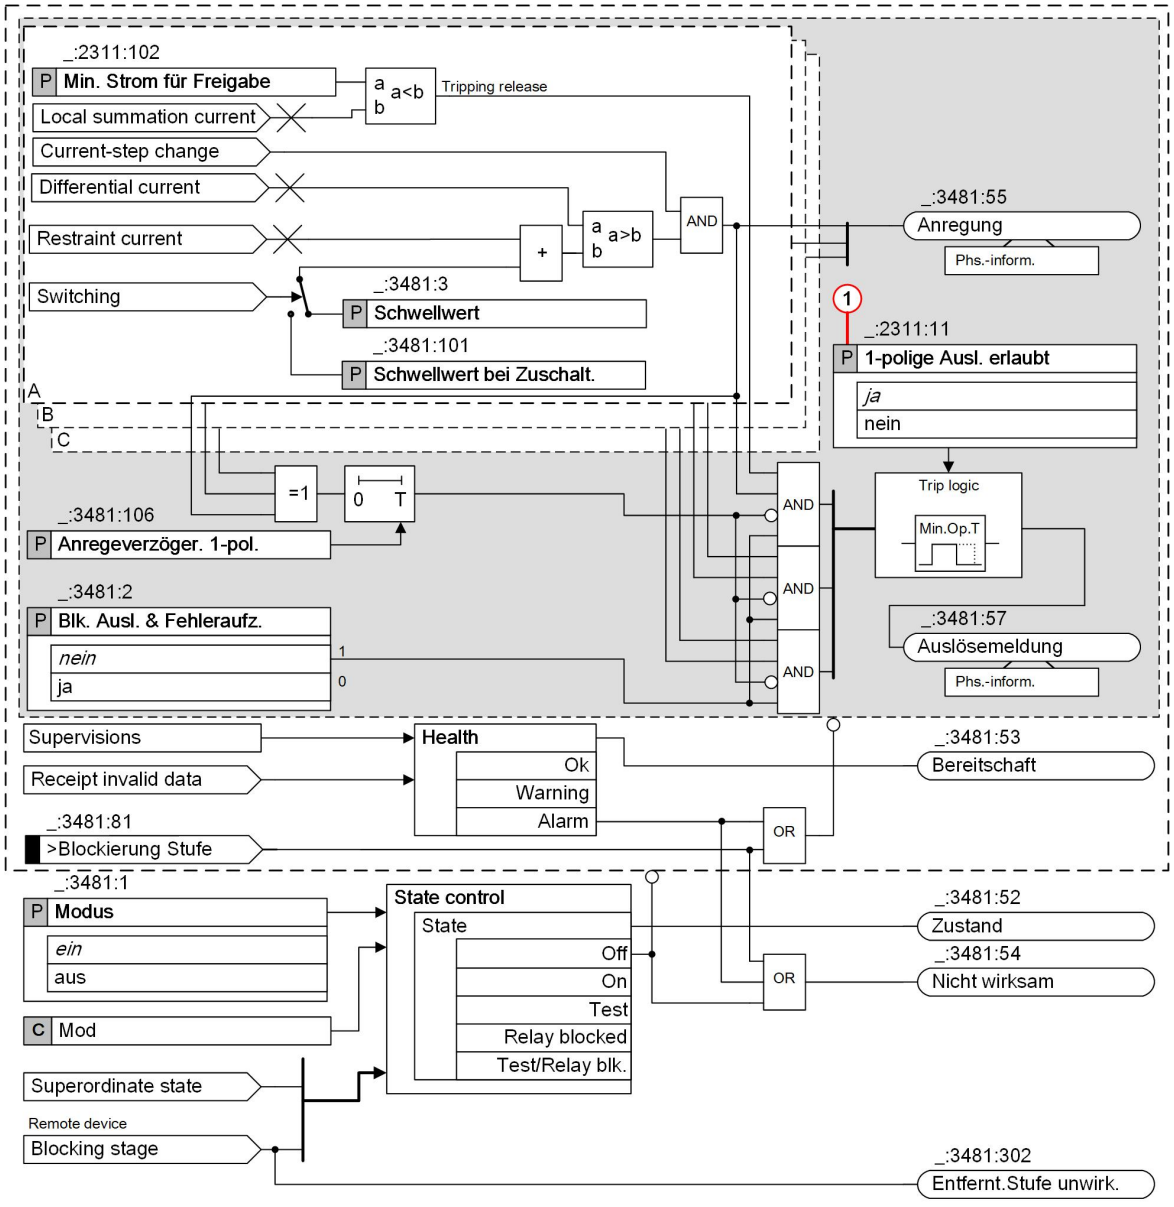
6.7.9 Stage I-DIFF Fast



6.7.9.1 Description

Logic of the Stage

[loijump, 2, en_US]

Figure 6-152 Logic of the Stage **I-DIFF fast**, Part 1

[lo_13_idfs_7UT, 1, en_US]

Figure 6-153 Logic of the Stage **I-DIFF**, Part 2

(1) The parameter is only available if the function **Line differential protection 1-pole/3-pole** is instantiated in the device.

NOTE

Siemens recommends:

Use the stage **I-DIFF fast** only if you want to expand an existing line differential protection device combination and you want to retain the existing protection procedure.

NOTE

If you load an application template starting from the **V07.50** platform into a device with the **CP200** CPU printed circuit board assembly, keep the following in mind:

- Starting with the V07.50 platform, the **I-DIFF fast 2** stage is preinstantiated in the **Line differential protection** function.
- The consistency check in DIGSI 5 reports an error for devices with the **CP200** CPU printed circuit board assembly.
- Replace the stage **I-DIFF fast 2** with the stage **I-DIFF fast**.

The stage **I-DIFF fast** is essentially identical to the stage **I-DIFF fast 2**.

In contrast to the differential-protection procedure of the stage **I-DIFF fast 2**, the procedure of the stage **I-DIFF fast** requires a time of at least 5 ms free of saturation from the current transformer. Starting at a certain current flow (> 2.5 · I_{rated}, local measurement), the system immediately determines an external fault and the stage **I-DIFF fast** is blocked. If saturation occurs for one or more current transformers limiting the protection range, the stage **I-DIFF fast** is blocked and unwanted tripping due to transformer saturation is avoided.

6.7.9.2 Application and Setting Notes

The **I-DIFF fast** stage is essentially identical to the **I-DIFF fast 2** stage.

If you want to use the **I-DIFF fast** stage, you must delete the preinstantiated **I-DIFF fast 2** stage if necessary. After this, you can instantiate the **I-DIFF fast** stage.

If you use the **I-DIFF fast** stage, the **Current-transformer saturation** block is not present in the **Measuring point Current 3-phase**.

You can find the application and setting notes for the **I-DIFF fast 2** stage in chapter *6.7.8.2 Application and Setting Notes*.

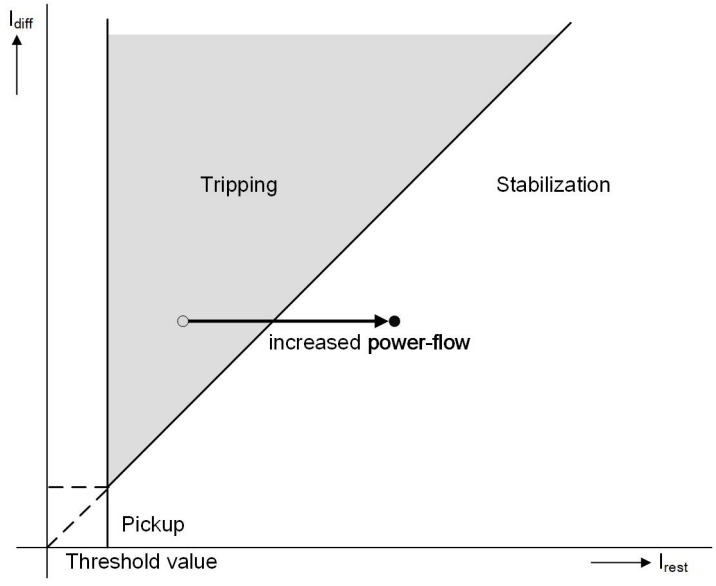
6.7.10 Stage IN-DIFF

6.7.10.1 Description



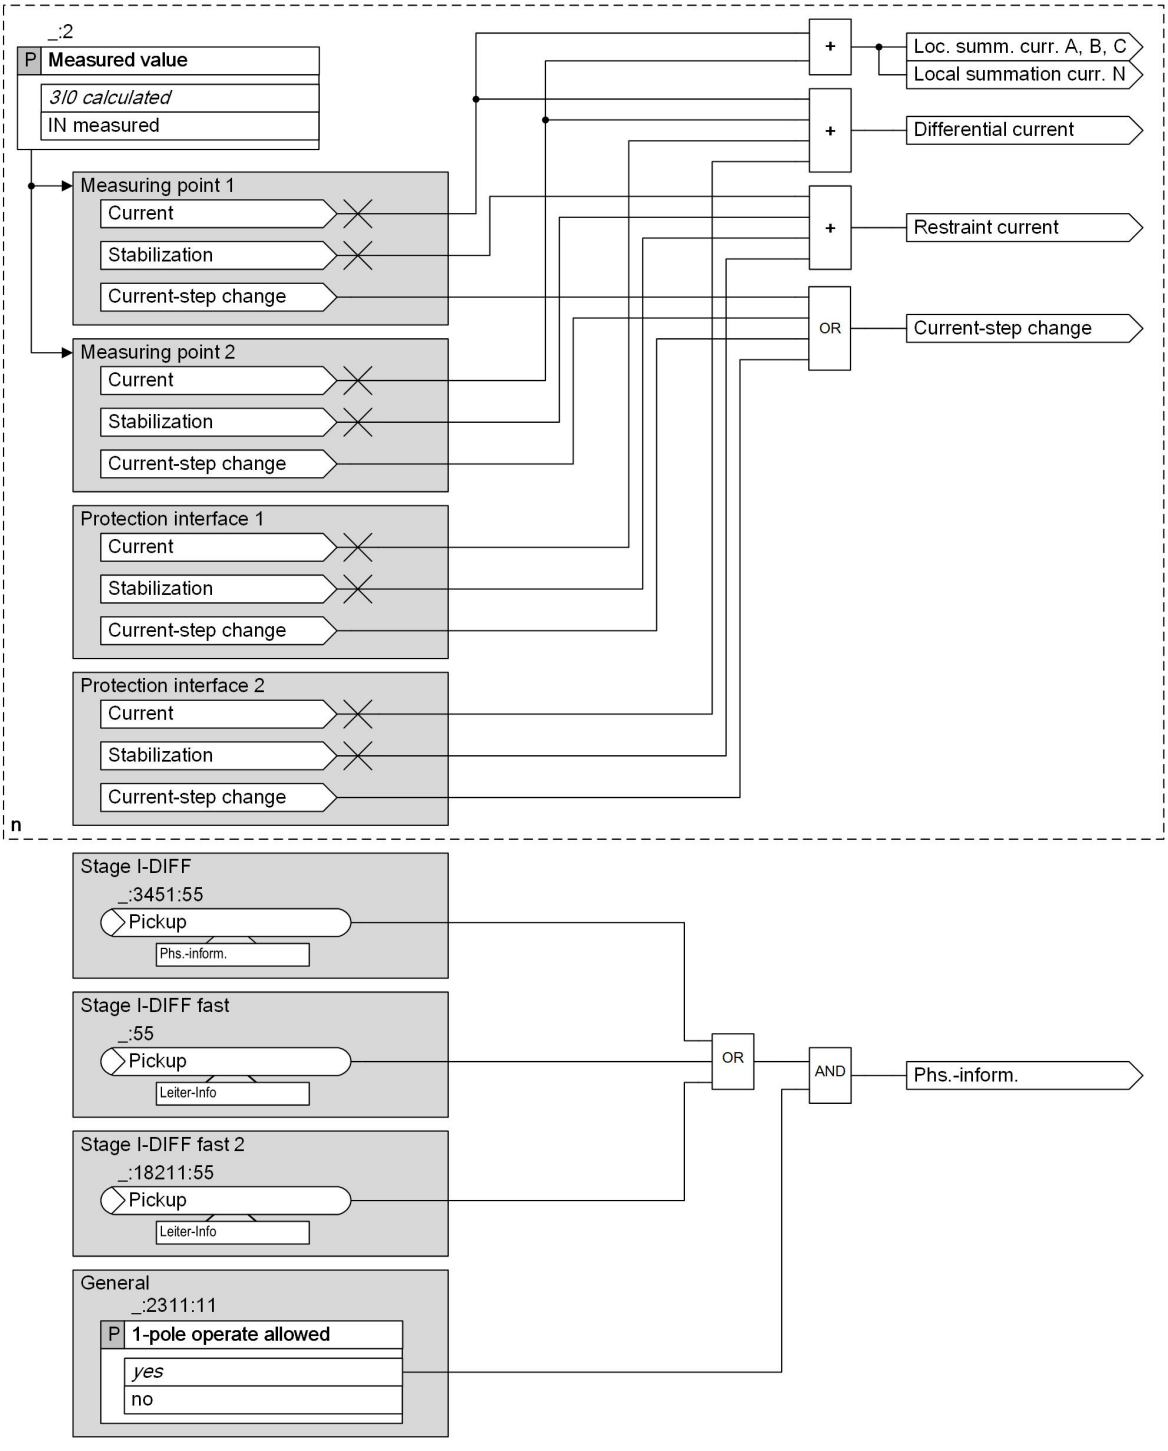
The ground-current differential protection (ANSI 87LN):

- Is a selective ground-fault protection for overhead lines, cables, and busbars with single-side and multi-side infeed in radial, ring, or meshed systems
- Allows fast tripping of short circuits with ground at 2 to 6 line ends
- Allows protection of a transformer in the protection range of the line
- Becomes more sensitive when using the charging-current compensation (Ic compensat.)
- Either the measured ground current IN or the calculated zero-sequence current 3I0 can be set as the leading measured quantity.

NOTE

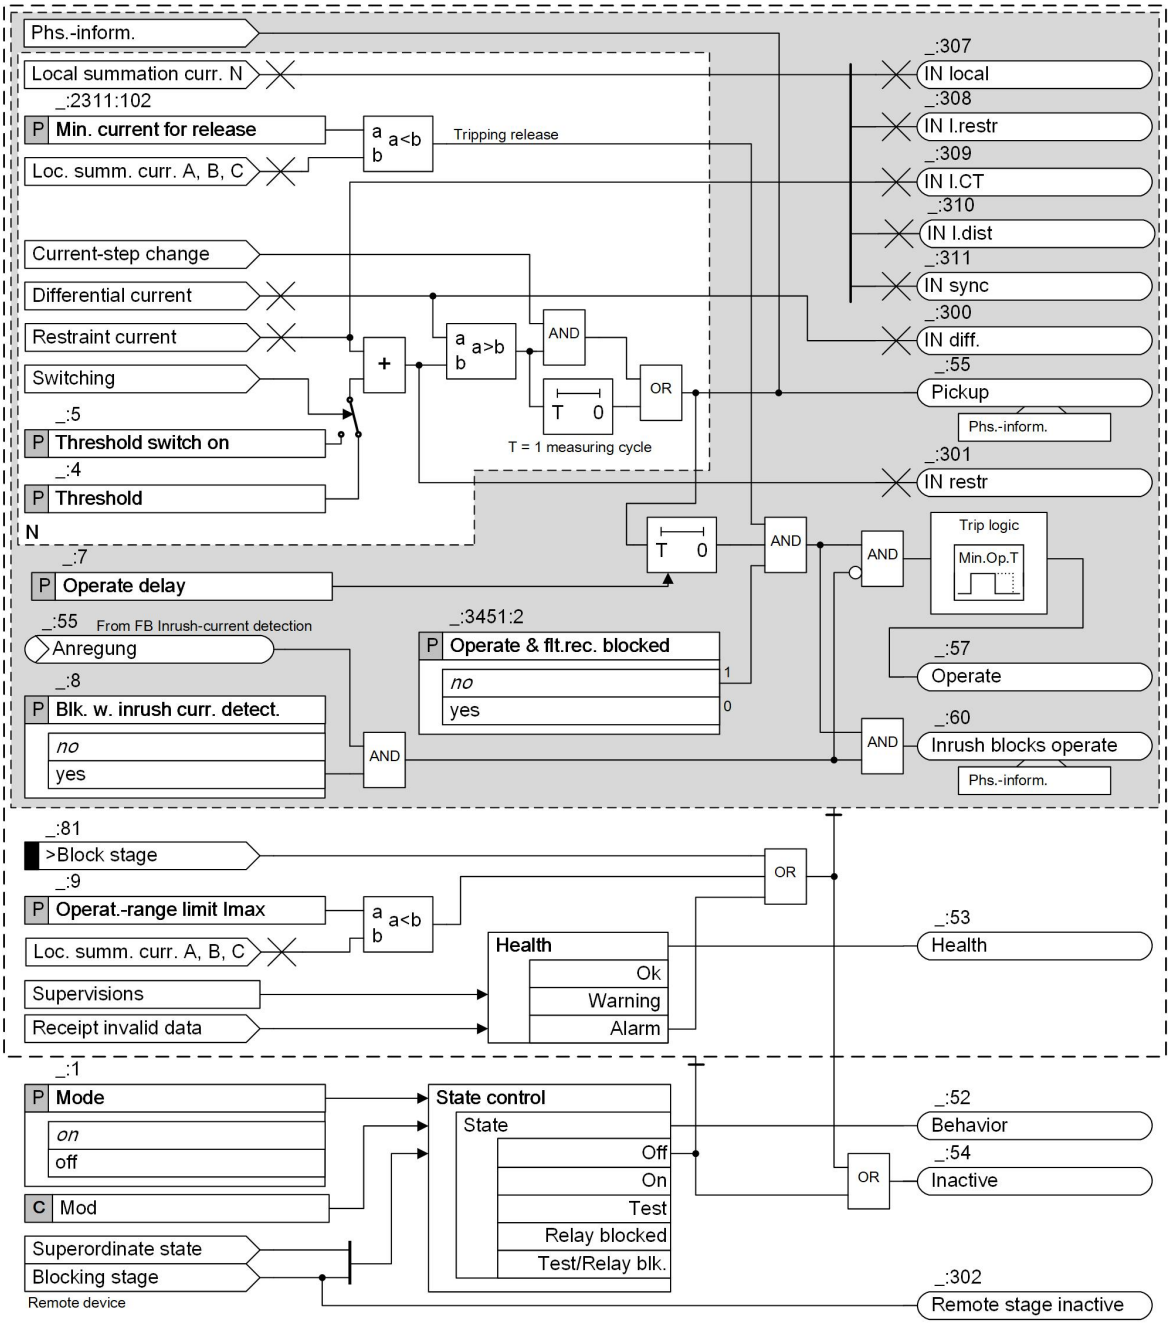
For the use of the stage **IN-DIFF**, a baud rate of at least 512 Kbit/s is required.

The ground current is independent of balanced power flows that occur. For the stage **I-DIFF**, an increased load current causes an increased restraint, see the following figure. This causes the protection with the stage **I-DIFF** to become more insensitive. If the power flow is high, in rare cases, the stage **I-DIFF** may not reliably detect ground faults with high contact resistance.



[dw_pickup characteristic_more_load, 2, en_US]

Figure 6-154 Shift of the Operating Point of the Stage **I-DIFF** in Case of a Fault with High Load Current



The stage **IN-DIFF** can use the measured ground current IN as the leading measured quantity and thus operate independently of different balanced power flows. The restraining quantity IN_{rest}, derived from the ground current IN, is thus also independent of balanced power-flow changes. In the cases described in the preceding sections, the stage **IN-DIFF** can be more sensitive than the stage **I-DIFF** and reliably detect the fault.

Logic of the Stage

[lo_meas-value_310_2, en_US]

Figure 6-155 Logic of the Stage **IN-DIFF**, Part 1

[lo_stage IN-diff phs-N_part2, 1, en_US]

Figure 6-156 Logic of the Stage **IN-DIFF**, Part 2

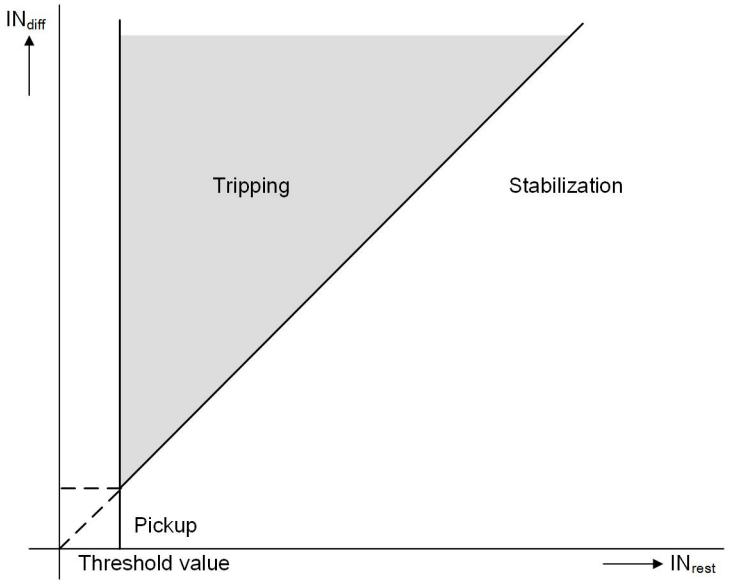
Mode of Operation

The stage **IN-DIFF** is the sensitive stage of the differential protection for the ground path. The principle of the stage **IN-DIFF** is a comparison of the ground-current phasors. Each device calculates a differential current IN_{diff} from the sum of the ground-current phasors at each end of the protected object and transmits the calculated value to the remaining ends. The amount corresponds to the fault current which the differential-protection system sees – ideally, this is the short-circuit current. In healthy unbalanced operation, it is small and corresponds to the capacitive charging current to ground in lines in a first approximation. If the charging-current compensation is active, the maximum sensitivity is achieved and the pickup value can be set considerably smaller. The ground differential current is counteracted by the ground restraint current IN_{rest}. The restraint

current results from the sum of the maximum measuring faults at the ends of the protected object and is calculated adaptively from the current measurands and the set substation parameters.

If ***IN measured*** is set as the measured value, the fault of the ground-current transformer in the rated range or in the short-circuit current range is multiplied by the ground current presently flowing at each end of the protected object and transferred to the other ends together with the determined internal faults. If ***3I0 calculated*** is set as the measured value, the fault of the phase current transformers in the rated range and in the short-circuit current range is multiplied by the maximum current presently flowing in one phase at each end of the protected object and transferred to the other ends together with the determined internal faults.

This means that the ground restraint current IN_{rest} is an image of the maximum possible measuring fault of the differential-protection system. Optional functions such as **Charging-current compensation** (increased sensitivity) and the **Transformer in the protection range** are automatically considered when the ground differential currents and the ground restraint currents are calculated.



Pickup of the Stage

The pickup characteristic of the differential protection (see *Figure 6-157*) results from the stabilization characteristic curve $I_{diff} = I_{rest}$ (45° line) which is cut below the setting value of the parameter **Threshold**. It corresponds to the following equation:

IN_{rest} = **Threshold** + Σ (current-transformer error and other measuring errors).

If the measured differential current exceeds the sum of the pickup threshold (threshold) and the maximum possible measuring error, there is an internal fault (dimmed area in *Figure 6-157*).

In case of an internal fault, you can define an additional criterion for local tripping release using the parameter **Min. current for release**.

[dw_pickup characteristic_INdiff_INstab, 1, en_US]

Figure 6-157 Pickup Characteristic of the Stage **IN-DIFF**

If the stage **IN-DIFF** detects a fault in the ground path, the stage generates the pickup signal with the ground information. If the ground-current differential protection picks up, the pickup signal of the stage **IN-DIFF** takes over the phase information from the stages **I-DIFF**, **I-DIFF fast 2**, and **I-DIFF fast**.

Pickup upon Switching

When switching on longer, unloaded cables, overhead lines, and resonant-grounded lines, pronounced higher-frequency compensating processes can occur. These are strongly dampened by digital filters of the differential protection. With the parameter **Threshold switch on**, you can prevent a pickup of the line differential protection in case of switching.

The parameter **Threshold switch on** always becomes effective as soon as a device in the device combination has detected that its end is switched after a dead time. All devices in the device combination are then changed over to this pickup value for the duration of the closure detection (parameter: **Action time after closure**).

For more detailed information, refer to *5.5.4.7 Closure Detection*.

In addition, for the switching of transformers and shunt reactors, the device features a function **Inrush-current detection** via which blocking of the affected phase of the differential protection is possible.

For more detailed information, refer to *6.68.1.1 Overview of Functions*.

Inrush-Current Detection

You can find the function **Inrush-current detection** in the DIGSI 5 function library under **Line FG > Inrush detect.**. Add this functionality to the function group **Line** (under **DIGSI 5 project tree > Name of the device > Settings > Line**). The parameter **Blk. w. inrush curr. detect.** now also appears in the stage **IN-DIFF** of the Line differential protection.

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

Measured Values of the Stage IN-DIFF

In order to clarify failures, the stage **IN-DIFF** provides the following measured values:

Measured Value	Description
(_:300) IN diff.	• If the stage **IN-DIFF** operates with the measured ground current IN, the measured value corresponds to the ground differential current. • If the stage **IN-DIFF** operates with the calculated zero-sequence current 3I0, the measured value corresponds to the zero-sequence current difference.
(_:301) IN restr	Ground restraint current (overall restraint)
(_:307) IN local	• If the stage **IN-DIFF** operates with the measured ground current IN, the measured value corresponds to the amount of the local ground current IN. • If the stage **IN-DIFF** operates with the calculated zero-sequence current 3I0, the measured value corresponds to the amount of the local zero-sequence current 3I0.
(_:308) IN l.restr	Local ground restraint current
(_:309) IN l.CT	Partial component of the local ground restraint current that considers the transformer fault. If you set the connection type ***3-phase*** or ***3-phase + IN*** in the measuring-points routing of the **Measuring point I-3ph**, the largest transformer fault occurring in A, B, or C is considered. If you set the connection type ***3-phase + IN-separate*** in the measuring-points routing of the **Measuring point I-3ph**, the transformer fault of the separate ground-current transformer is considered.
(_:310) IN l.dist	Subcomponent of the local ground restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabilization.
(_:311) IN sync	Subcomponent of the overall restraint that is caused by faults during the time synchronization of the ground current phasors.

The measured values are available in the fault record. You can read out fault recordings from the device and analyze them afterwards using evaluation tools such as SIGRA. The device display shows only *IN diff.* and *IN restr*. In order to find the measured values on the device, go to **Main menu > Measurements > Line x > Functional measured values > Line differential protection > IN-DIFF**.

For detailed information about selecting and deleting fault recordings, refer to the Operating Manual.

6.7.10.2 Application and Setting Notes

Parameter: `Measured value`

- Default setting **`(_:2) Measured value`** = ***3I0 calculated***

With the parameter **`Measured value`**, you set whether the stage **IN-DIFF** operates with the zero-sequence current 3I0 calculated from the phase currents or with the directly measured ground current IN. Phasor measured values are determined based on the set measured value and transmitted to the opposite ends.

On the other hand, the phasor measured values received from the opposite ends are used to calculate a differential zero-sequence current or a differential ground current. At one end of the line, you can set the parameter **`Measured value`** to ***3I0 calculated*** and at a second end of the line to ***IN measured***.

NOTE

For power systems with isolated neutral point, the setting value of the parameter **`Measured value`** = ***IN measured*** is not possible.

Parameter: `Blk. w. inrush curr. detect.`

- Recommended setting value **`(_:8) Blk. w. inrush curr. detect.`** = ***no***

With the parameter **`Blk. w. inrush curr. detect.`**, you determine whether the tripping is blocked during the detection of an inrush current. If the inrush-current detection blocks tripping of the stage **IN-DIFF**, the indication *Inrush blocks operate* is generated. Inrush-current detection is based on the phase currents.

Parameter: `Threshold`

- Recommended setting value **`(_:4) Threshold`** = ***0.300 A***

With the parameter **`Threshold`**, you set the pickup threshold for the stage **IN-DIFF**. The total current flowing into the protection range during a short circuit is decisive, that is the total fault current. This applies regardless of how it divides among the ends of the protected object.

If you set the parameter **`Measured value`** = ***3I0 calculated***, the stage **IN-DIFF** compares the calculated zero-sequence current 3I0 with the **`Threshold`**.

If you set the parameter **`Measured value`** = ***IN measured***, the stage **IN-DIFF** compares the measured ground current IN with the **`Threshold`**.

Parameter: `Threshold switch on`

- Recommended setting value **`(_:5) Threshold switch on`** = ***0.300 A***

With the parameter **`Threshold switch on`**, you set the pickup threshold for the stage **IN-DIFF** during a detected connection.

A setting of 3 times to 4 times the stationary charging current ensures the stability of the protection when switching.

Approximately at the same time, all devices in the device combination use the pickup threshold increased with the parameter **`Thresh. switch onto fault`** during the set **`(_:4681:102) Action time after closure`**. For more information, refer to *5.5.4.7 Closure Detection*.

If you set the parameter **`Threshold switch on`** in exactly the same way as the parameter **`Threshold`**, the parameter **`Threshold switch on`** is ineffective.

Parameter: **Operate delay**

- Recommended setting value **(_:7) Operate delay** = *0.00 s*

In special cases, it can be advantageous to delay the tripping of the differential protection with an additional time stage, for example for a reverse interlocking. If the stage **IN-DIFF** stage picks up, the time delay starts.

If you set **Operate delay** = ∞, the stage **IN-DIFF** will not trip.

Parameter: **Operat.-range limit Imax**

- Recommended setting value **(_:9) Operat.-range limit Imax** = *2.500 A*

With the parameter **Operat.-range limit Imax**, you set up to which maximum local current the stage **IN-DIFF** operates. In case of local currents above this threshold, the stage is blocked and the indication *Local current too high* is issued.

If the **IN-DIFF** stage has issued an operate indication and the local current subsequently exceeds the set **Operat.-range limit Imax**, the tripping remains in force. The tripping stage will not be blocked.

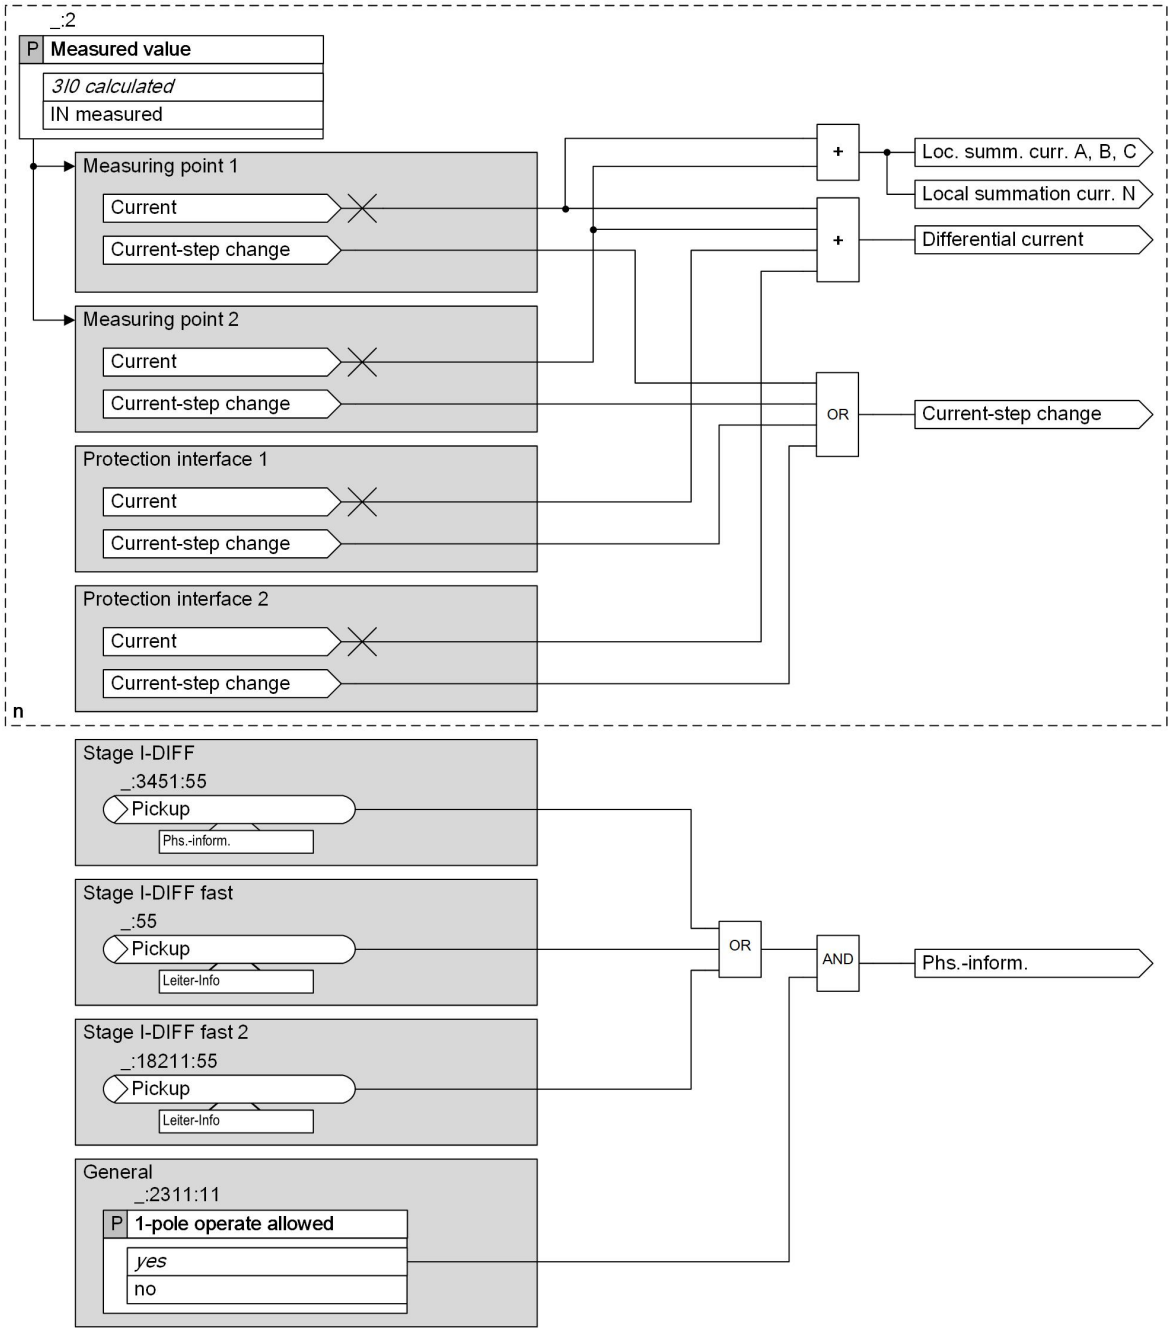
6.7.11 Stage IN-DIFF unrestr

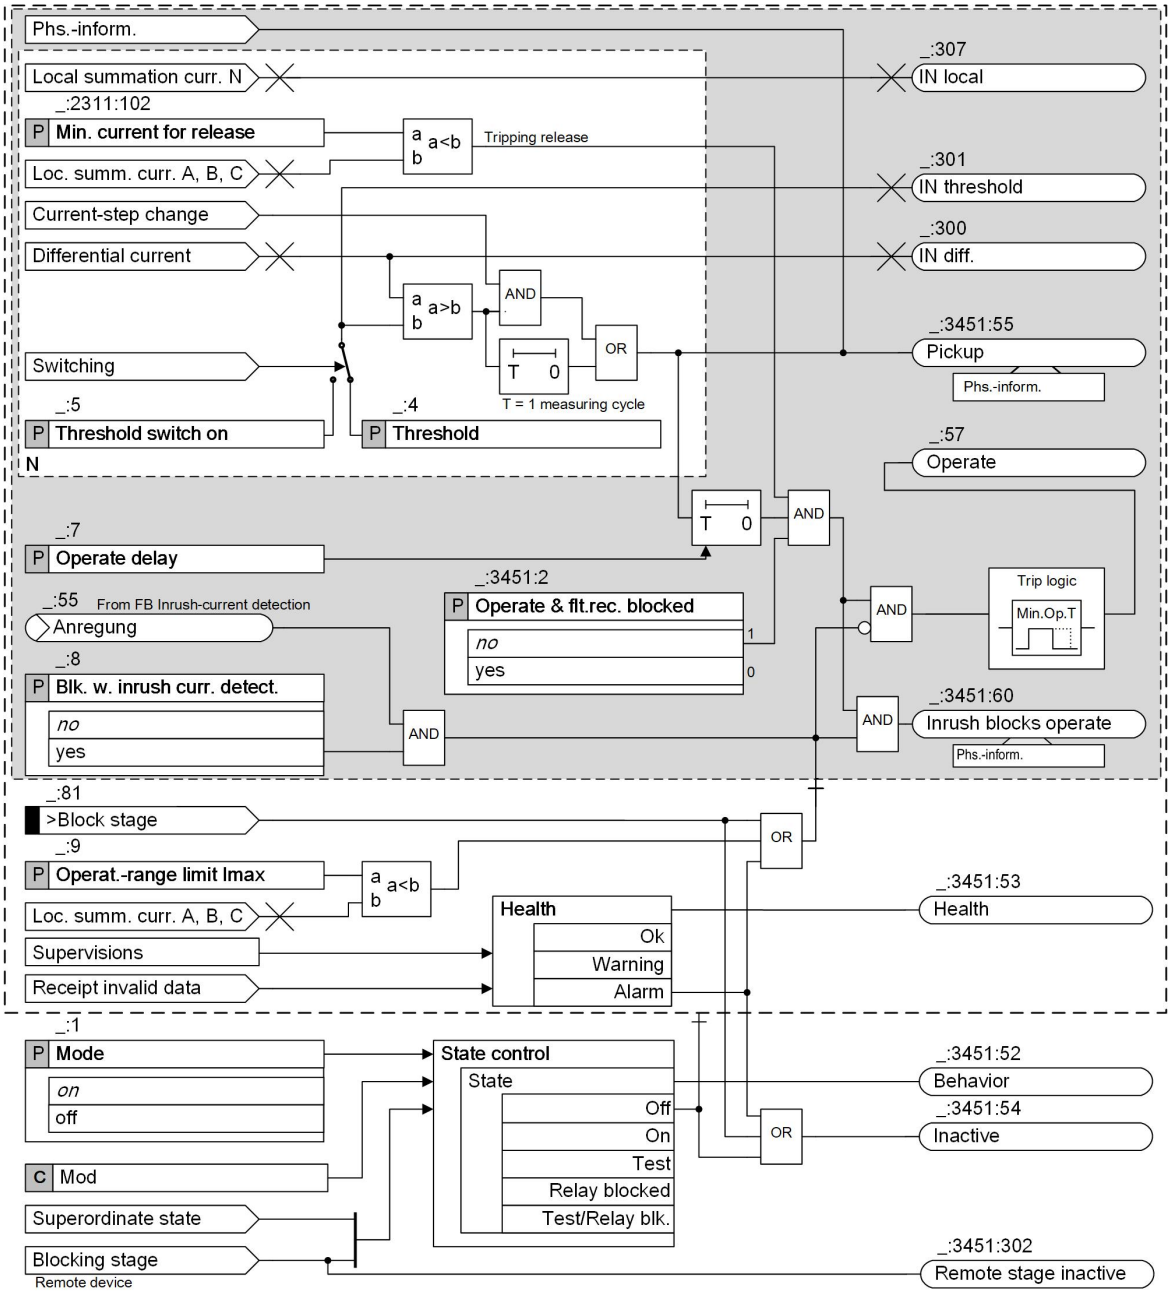
6.7.11.1 Description

The ground current differential protection (ANSI 87LN):



- Is a selective ground-fault protection for overhead lines, cables, and busbars with single-side and multi-side infeed in radial, ring, or meshed power systems
- Allows fast tripping of short circuits with ground at 2 to 6 line ends
- Permits protection of a transformer in the protection range of the line
- Is an unrestraint differential protection that only operates with a parameterizable threshold value
- The charging-current compensation (Ic compensat.) can be used to reduce the differential currents.
- Either the measured ground current IN or the calculated zero-sequence current 3I0 can be set as the leading measured quantity.

NOTE



For the use of the stage **IN-DIFF unrest**, a baud rate of at least 512 Kbit/s is required.

Logic of the Stage

[lo_IN-DIFF-unstab, 2, en_US]

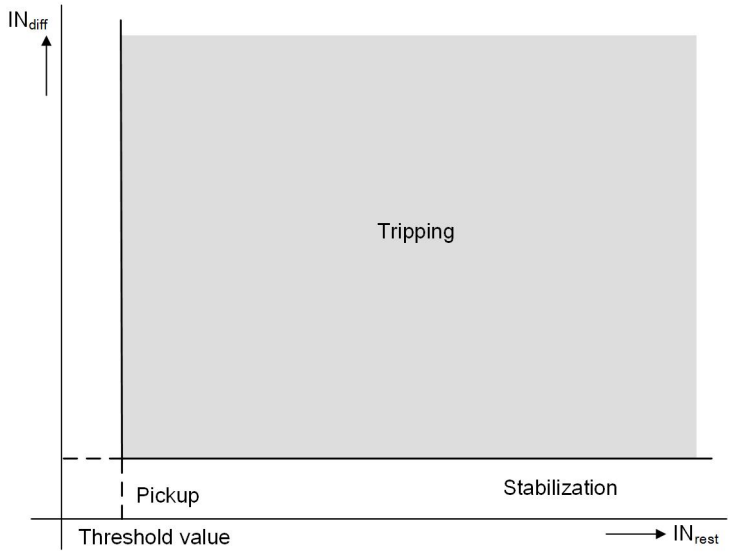
Figure 6-158 Logic of the Stage **IN-DIFF unrest**, Part 1

[lo_stage IN-diff-unstab phs-N, 2, en_US]

Figure 6-159 Logic of the Stage **IN-DIFF unrest**, Part 2

Mode of Operation

The stage **IN-DIFF unrest** is the stage of the differential protection for the neutral path. The principle of the stage **IN-DIFF unrest** is a comparison of the ground current phasors. Each device calculates an IN_{diff} differential current from the sum of the ground current phasors which are calculated at each end of the protected object and transmitted to the other ends. The amount of the differential current equals the fault current that the differential protection system sees. In the ideal case, it equals the short-circuit current. In healthy unbalanced operation, the amount of the differential current is small and corresponds to the capacitive charging current to ground in lines in a first approximation. If charging-current compensation is active, the maximum sensitivity is achieved and the pickup value can be set considerably smaller.



In contrast to the stage **IN-DIFF**, the stage **IN-DIFF unrest** operates without the restraint current I_{rest}. This means, the only criterion for pickup is that the differential current must exceed the parameter **`Threshold`**.

Optional functions such as **Charging-current compensation** (increased sensitivity) and **Transformer in the protection range** are automatically considered when the differential currents are calculated.

Pickup of the Stage

The stage **IN-DIFF unrest** picks up as soon as the differential current exceeds the setting value of the parameter **`Threshold`** (refer to *Figure 6-160*). This means that an internal error has occurred.

In case of an internal error, you can define an additional criterion for local tripping release using the parameter **`Min. current for release`**.

[dw_pickup characteristic_INdiff_INstab_01, 1, en_US]

Figure 6-160 Pickup Characteristic of the Stage **IN-DIFF unrest**

If the stage **IN-DIFF unrest** detects a fault in the neutral path, the stage generates the pickup signal with the ground information. When the ground-current differential protection picks up, the pickup signal of the stage **IN-DIFF unrest** takes over the phase information from the stages **I-DIFF**, **I-DIFF fast 2**, and **I-DIFF fast**.

Pick up upon Switching

When switching on longer, unloaded cables, overhead lines, and resonant-grounded lines, pronounced higher-frequency compensating processes can occur. These are strongly dampened by digital filters of the differential protection. You can ensure the pickup of the line differential protection is prevented when switching using the parameter **`Threshold switch on`**.

The parameter **`Threshold switch on`** always becomes effective as soon as a device in the device combination has detected that its end has been switched after a dead pause. All devices in the device combination are then changed over to this pickup value for the duration of the closure detection (parameter: **`Action time after closure`**).

For more information, refer to *5.5.4.7 Closure Detection*.

In addition, for the switching of transformers and shunt reactors, the device additionally features an **Inrush-current detection** function that can impose the blocking of the differential protection.

For more information, refer to *6.68.1.1 Overview of Functions*.

Inrush-Current Detection

You can find the function **Inrush-current detection** under **Line FG > Inrush-current det.** in the DIGSI 5 function library. Add this functionality to the function group **Line** (under **DIGSI 5 project tree > Name of the device > Parameter > Line**). In the stage **IN-DIFF unrest** of the line differential protection the parameter **`Blk. w. inrush curr. detect.`** now also appears.

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

Measured Values of the Stage IN-DIFF unrest

To clarify faults, the stage **IN-DIFF unrest** provides the following measured values:

Measured Value	Description
(_:300) IN diff.	• If the stage **IN-DIFF unrest** operates with the measured ground current IN, the measured value corresponds to the ground differential current. • If the stage **IN-DIFF unrest** operates with the calculated zero-sequence current 3I0, the measured value corresponds to the zero-sequence current difference.
(_:301) IN threshold	Threshold value (pickup value)
(_:307) IN local	Amount of local ground-current phasor

The measured values are available in the fault record. You can read out the fault recordings from the device and analyze them afterwards using evaluation tools such as SIGRA. Only *IN diff.* and *IN threshold* are visible on the device display. To find the measured values on the device, go to **Main menu > Measured values > Line x > Functional measured values > Line differential protection → IN-DIFF unrest**.

For detailed information about selecting and deleting fault recordings, refer to the Operating Manual.

6.7.11.2 Application and Setting Notes

Parameter: Measured value

- Default setting **(_:2) Measured value** = ***3I0 calculated***

With the parameter **Measured value**, you set whether the stage **IN-DIFF unrest** should operate with the zero-sequence current 3I0 calculated from the phase currents or with the directly measured ground current IN. Phasor measured values are determined based on the set measured value and transmitted to the opposite ends.

On the other hand, the phasor measured values received from the opposite ends are used to calculate a differential zero-sequence current or a differential ground current. At one end of the line, you can set the parameter **Measured value** to ***3I0 calculated*** and at a second end of the line, you can select the setting ***IN measured***.

NOTE

For systems with isolated neutral point, the setting value of the parameter **Measured value** = ***IN measured*** is not possible.

Parameter: Blk. w. inrush curr. detect.

- Recommended setting value **(_:8) Blk. w. inrush curr. detect.** = ***no***

With the parameter **Blk. w. inrush curr. detect.**, you determine whether the tripping is blocked during the detection of an inrush current. If the inrush-current detection blocks tripping of the stage **IN-DIFF unrest**, the indication *Inrush blocks operate* is generated. The inrush-current detection is based on the phase currents.

Parameter: Threshold

- Recommended setting value **(_:4) Threshold** = ***0.300 A***

With the parameter **Threshold**, you set the pickup threshold for the stage **IN-DIFF unrest**. The total current flowing into the protection range during a short circuit, that is the total fault current, is decisive. This applies regardless of how it divides among the ends of the protected object.

Parameter: Threshold switch on

- Recommended setting value **(_:5) Threshold switch on** = *0.300 A*

With the parameter **Threshold switch on**, you set the pickup threshold for the stage **IN-DIFF unrest** during a detected connection.

A setting of 3 times to 4 times the stationary charging current generally ensures the stability of the protection when switching.

Approximately at the same time, all devices in the device combination use the pickup threshold increased with the parameter **Thresh. switch onto fault** during the set **(_:4681:102) Action time after closure**. For further information, refer to *5.5.4.7 Closure Detection*.

If you set the parameter **Threshold switch on** in exactly the same way as the parameter **Threshold**, the parameter **Threshold switch on** is ineffective.

Parameter: Operate delay

- Recommended setting value **(_:7) Operate delay** = *0.00 s*

In special cases, it can be advantageous to delay the tripping of the differential protection with an additional time stage, for example for a reverse interlocking. If the stage **IN-DIFF unrest** picks up, the time delay starts.

If you set the **Operate delay** = ∞, the stage **IN-DIFF unrest** does not trip.

Parameter: Operat.-range limit Imax

- Recommended setting value **(_:9) Operat.-range limit Imax** = *2.500 A*

With this parameter, you set up to which maximum local current the stage **IN-DIFF unrest** operates. In case of local currents above this threshold, the stage is blocked and the indication *Local current too high* is issued.

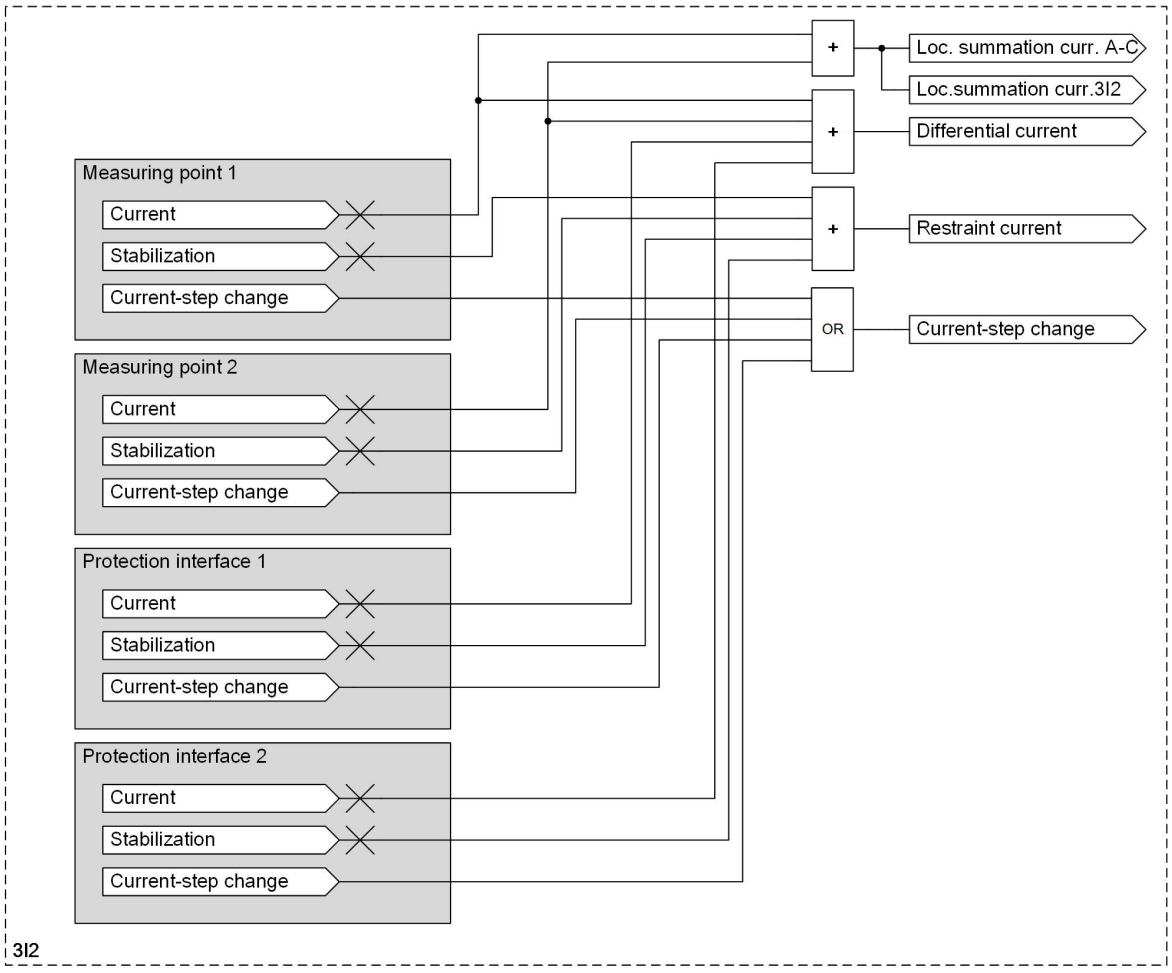
6.7.12 Stage I2-DIFF

6.7.12.1 Description

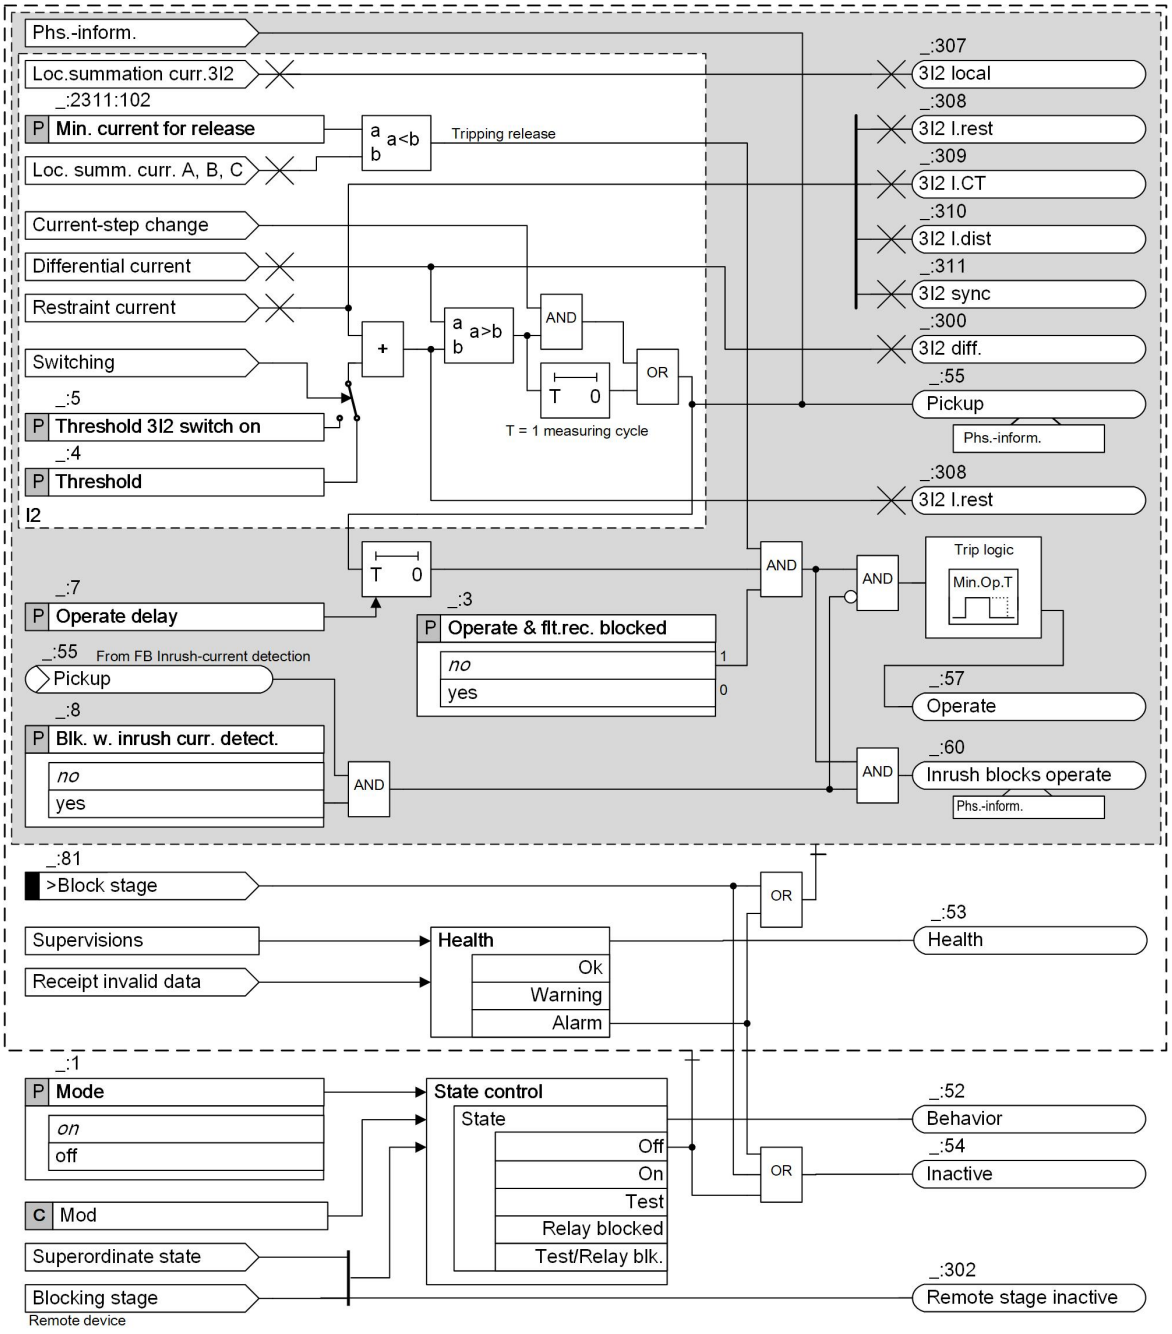
The negative-sequence differential protection (ANSI 87LQ):

- Is a selective short-circuit protection for overhead lines, cables, and busbars with single-side and multi-side infeed in radial, ring, or meshed systems
- Allows fast tripping of 1-pole or 2-pole short circuits at 2 to 6 line ends
- Allows protection of a transformer in the protection range of the line
- Gets more sensitive when using the charging-current compensation (Ic compensat.)



NOTE

For the use of the **I2-DIFF** stage, a baud rate of at least 512 Kbit/s is required.



The stage **I2-DIFF** monitors the calculated negative-sequence current I2. As a result, the influence of load currents on the method of measurement is low for all unbalanced errors. Pure phase-to-phase errors have no effect on the ground path and are not detected by the stage **IN-DIFF**. These faults are recorded by the stage **I2-DIFF**.

Logic of the Stage

[lo_meas-value_310_02, 1, en_US]

Figure 6-161 Logic of the Stage **I2-DIFF**, Part 1

[lo_stage 3I2 phs-I2, 2, en_US]

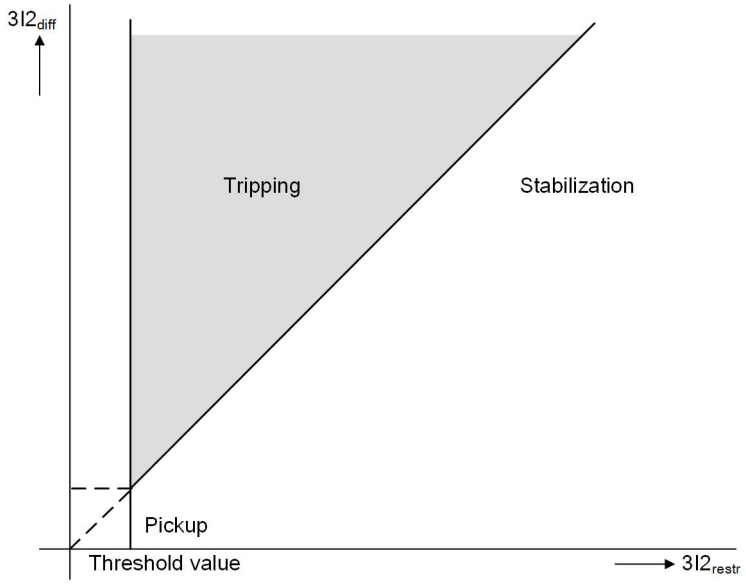
Figure 6-162 Logic of the Stage **I2-DIFF**, Part 2

Mode of Operation

The stage **I2-DIFF** is the sensitive stage of the differential protection using the negative-sequence system. The principle of the stage **I2-DIFF** is a comparison of the negative-sequence current phasors. Each device calculates a differential current $3I2_{diff}$ from the sum of the negative-sequence current phasors which are calculated at each end of the protected object and transmitted to the other ends. The amount of the differential current corresponds to the fault current that the differential-protection system sees. In the ideal case, it corresponds to the short-circuit current. In healthy balanced operation, the differential current is 0. If the charging-current compensation is active, the maximum sensitivity is achieved and the pickup value can be set considerably smaller.

The $3I2_{rest}$ restraint current counteracts the differential current. The restraint current results from the sum of the maximum measuring faults at the ends of the protected object and is calculated adaptively from the current measurands and the set substation settings. To this end, the fault of the phase current transformers in the rated range or the short-circuit current range is multiplied by the maximum presently flowing current in one phase at each end of the protected object and transmitted to the other ends together with the determined internal faults. This means that the restraint current $3I2_{rest}$ reflects the maximum possible measuring fault in the differential-protection system.

Optional functions such as **Charging-current compensation** (increased sensitivity) and **Transformer in the protection range** are automatically considered when the differential currents are calculated.



Pickup of the Stage

The pickup characteristic of the differential protection (see *Figure 6-163*) results from the restraint characteristic curve $3I2_{diff} = 3I2_{rest}$ (45 ° line) which is cut below the setting value of the **`Threshold 3I2`** parameter. It corresponds to the following equation:

$3I2_{rest}$ = **`Threshold 3I2`** + Σ(current-transformer error and other measuring errors)

If the measured differential current exceeds the pickup threshold (**`Threshold 3I2`**) and the maximum possible measuring faults, there is an internal fault (dimmed area in *Figure 6-163*).

In case of an internal fault, you can define an additional criterion for local tripping release using the parameter **`Min. current for release`**.

[dw_pickup characteristic_3I2diff_3I2stab_new, 1, en_US]

Figure 6-163 Pickup Characteristic of the Stage **I2-DIFF**

Pickup upon Switching

When switching on longer, unloaded cables, overhead lines, and resonant-grounded lines, pronounced higher-frequency compensating processes can occur. These are strongly dampened by digital filters of the differential protection. With the parameter **`Threshold 3I2 switch on`**, you can prevent a pickup of the line differential protection in case of switching.

The parameter **`Threshold 3I2 switch on`** always becomes effective as soon as a device in the device combination has detected that its end is switched after a dead time. All devices in the device combination are then changed over to this pickup value for the duration of the closure detection (parameter: **`Min. current for release`**).

For more information, refer to *5.5.4.7 Closure Detection*.

In addition, for the switching of transformers and shunt reactors, the device features an **Inrush-current detection** function via which blocking of the differential protection is possible.

For more information, refer to *6.68.1.1 Overview of Functions*.

Inrush-Current Detection

You can find the **Inrush-current detection** function in the Global DIGSI 5 library under **Line FG > Inrush detect.**. Add this functionality to the **Line** function group (under **DIGSI 5 project tree >Name of the device > Settings >Line**). In the stage **I2-DIFF** of the line differential protection, the parameter **Blk. w. inrush curr. detect.** appears additionally.

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

Measured Values of the Stage I2-DIFF

To clarify failures, the stage **I2-DIFF** provides the following measured values:

Measured Value	Description
(_:300) 3I2 diff.	Negative-sequence differential current
(_:301) 3I2 restr	Negative-sequence restraint current (overall restraint)
(_:307) 3I2 local	Amount of local negative-sequence current phasor
(_:308) 3I2 l.rest	Local negative-sequence restraint current
(_:309) 3I2 l.CT	Partial component of the local restraint current that considers the transformer fault.
(_:310) 3I2 l.dist	Subcomponent of the local negative-sequence restraint current that considers the fault caused by signal distortion. Each deviation of the signal form from the sinus shape is interpreted as a signal distortion. The deviation between the actual signal form and the sinus shape will be converted to a percentage of the stabilization.
(_:311) 3I2 sync	Subcomponents of the overall restraint that are caused by faults during the time synchronization of the current phasor.

The measured values are available in the fault record. You can read out fault recordings from the device and analyze them afterwards using evaluation tools such as **SIGRA**. The device display shows only *3I2 diff.* and *3I2 restr*. To find the measured values on the device, go to **Main menu > Measurements > Line x > Functional measured values > Line differential protection > I2-DIFF**.

For detailed information about selecting and deleting fault recordings, refer to the Operating Manual.

6.7.12.2 Application and Setting Notes

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:8) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the tripping is blocked during the detection of an inrush current. If the inrush-current detection blocks tripping of the stage **I2-DIFF**, the indication *Inrush blocks operate* is generated. Inrush-current detection is based on the phase currents.

Parameter: Threshold 3I2

- Recommended setting value **(_:4) Threshold 3I2** = ***0.300 A***

With the **Threshold 3I2** parameter, you set the pickup threshold for the stage **I2-DIFF**. Here, the total current flowing into the protection range during a short circuit is decisive. This applies regardless of how the current is divided among the ends of the protected object.

Parameter: `Threshold 3I2 switch on`

- Recommended setting value **`Threshold 3I2 switch on`** = ***`0.300 A`***

With the **`(_:5) Threshold 3I2 switch on`** parameter, you set the pickup threshold for the stage **I2-DIFF** during a detected connection.

A setting of 3 times to 4 times the stationary charging current ensures the stability of the protection when switching.

Approximately at the same time, all devices in the device combination use the pickup threshold increased with the **`Thresh. switch onto fault`** parameter during the set **`(_:4681:102) Action time after closure`**. For further information, refer to *5.5.4.7 Closure Detection*.

If you set the parameter **`Threshold 3I2 switch on`** exactly in the same way as the parameter **`Threshold 3I2`**, the parameter **`Threshold 3I2 switch on`** is ineffective.

Parameter: `Operate delay`

- Recommended setting value **`(_:7) Operate delay`** = ***`0.00 s`***

In special cases, it can be advantageous to delay the tripping of the differential protection with an additional time stage, for example for a reverse interlocking. The time delay is started when the stage **I2-DIFF** picks up.

If you set **`Operate delay`** = ∞, the **I2-DIFF** stage will not trip.

Example

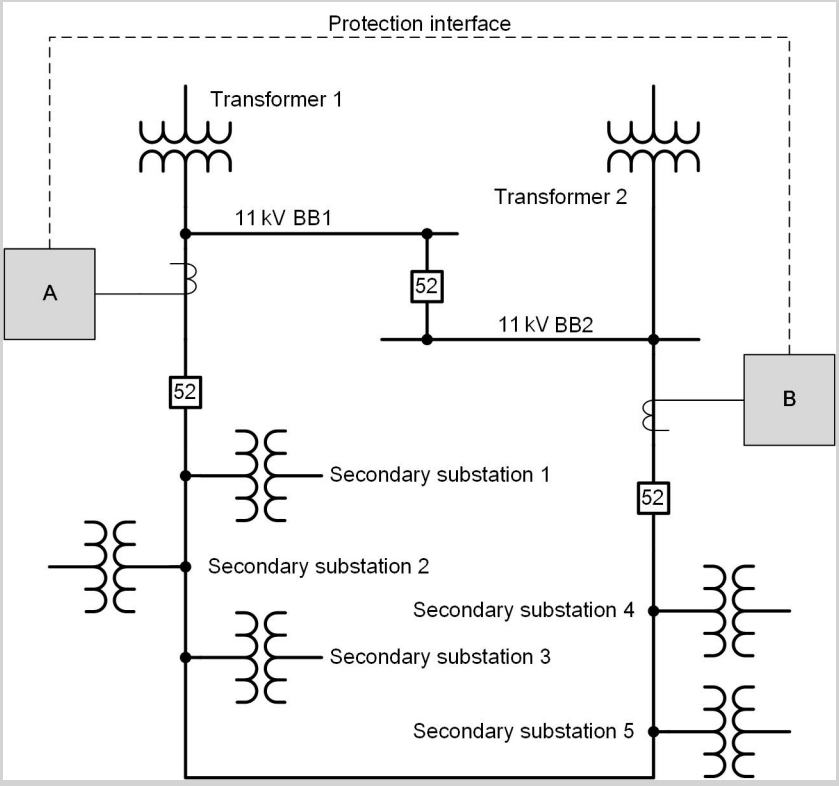
The ring feeder in the *Figure 6-164* is protected with the sensitive stage **I2-DIFF**. In healthy operation, the negative-sequence differential current **$3I2_{diff}$** occurs at 1st place because of the unbalanced load current in the transformers of the secondary substations. As a rule, the proportion I2 in the load current is less than 5 %.

In the example, the transformers of the secondary substations each have a rated apparent power of 1500 kVA. Thus, the maximum outgoing load current and the negative-sequence differential current **$3I2_{diff}$** are calculated as follows:

$$I_{Load_sum} = 5 \cdot \frac{1500\,\text{kVA}}{\sqrt{3} \cdot 11\,\text{kV}} = 394\,\text{A}$$

[fo_sum_current_i_load, 1, en_US]

Due to unbalance, a maximum of 5 % I2 is assumed:



$$3I2_{load} = 3 \cdot 5\,\% \cdot I_{load_{sum}} = 3 \cdot 0.05 \cdot 394\,\text{A} = 59.1\,\text{A}$$

[fo_3I2_Load, 1, en_US]

The **`Threshold 3I2`** with a safety margin of 20 % is set as follows:

$$\text{Threshold } 3I2 = 1.2 \cdot 3I2_{load} = 1.2 \cdot 59.1\,\text{A} = 71\,\text{A prim}$$

[fo_3I2_Load_Thresh, 1, en_US]

[dw_ring-example_1, en_US]

Figure 6-164 Example Ring Feeder

Tripping delay

If a fuse at the secondary substations allows selective fault clearing, the stage **I2-DIFF** must be delayed. A grading time of 300 ms is sufficient:

`Operate delay` = ***`0.30 s`***

When switching on, the inrush current can be higher than the maximum load current. To avoid overfunction, the threshold is adjusted when switching on. Assumed, the maximum inrush current is 400 % of the rated current. The pickup threshold of the stage **I2-DIFF** is increased by 400 %:

`Threshold 3I2 switch on` = ***`400 %`*** · **`Threshold 3I2`** = ***`4`*** · 71 A = 284 A prim

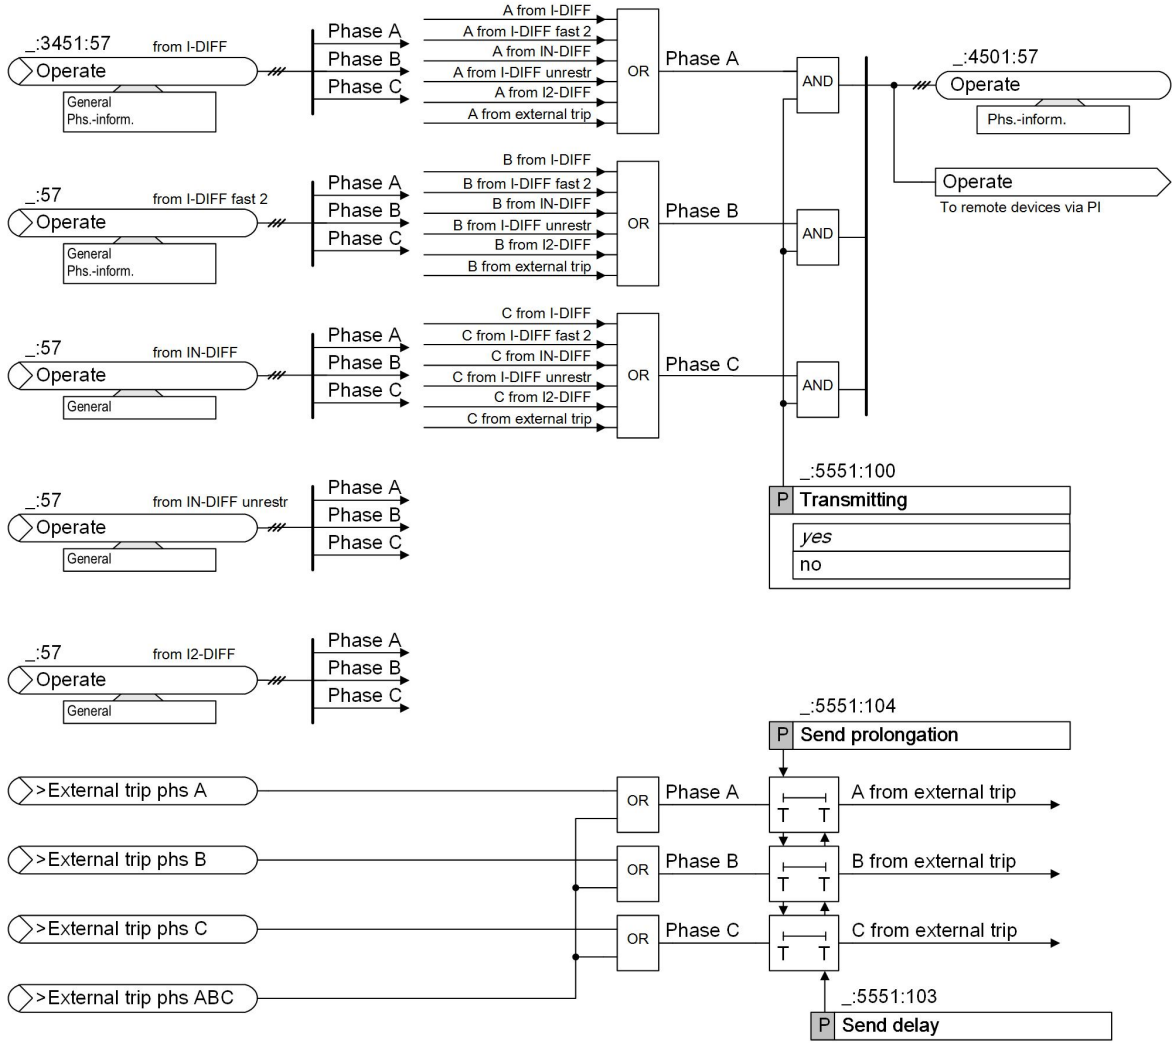
6.7.13 Remote Tripping

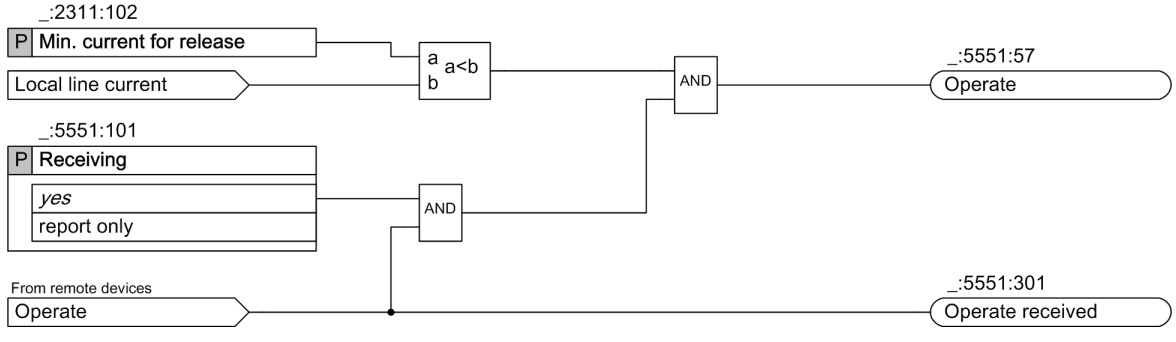
6.7.13.1 Description



The function **Line differential protection** contains the functionality **remote tripping**.

Remote tripping forms the phase-segregated operate indication *(_:5551:300) Operate transmitted* by the OR operation of the operate indications in the stages **I-DIFF**, **I-DIFF fast 2**, **IN-DIFF**, **IN-DIFF unrest**, and **I2-DIFF** and transmits it to the Line differential protection functions of the remote devices in the device combination

If a device receives a remote operate indication from a remote device, the **remote tripping** functionality generates the indication *(_:5551:57) Operate*.



You can find the **remote tripping** indications in the DIGSI 5 information routing under **Line** →**Line differential protection**→ **Remote tripping**.

Logic of the Stage

[lo_Group-indication_operate-send, 1, en_US]

Figure 6-165 Logic of the Transmit Direction

[lo_receive_direction_3pol, 1, en_US]

Figure 6-166 Logic of the Receive Direction

6.7.13.2 Application and Setting Notes for Remote Tripping

Parameter: `Transmitting`

- Recommended setting value **`(_:5551:100) Transmitting`** = ***on***

With the **Transmitting** parameter, you set whether the remote operate indications of the line differential protection are transmitted by way of the protection interface or not.

Parameter Value	Description
on	The functionality **Remote tripping** forms the indication *(_:5551:300) Operate transmitted* by the OR operation of the operate indications of the following stages: • **I-DIFF** • **I-DIFF fast 2** • **I-DIFF fast** • **IN-DIFF** • **IN-DIFF unrest** • **I2-DIFF** The functionality **Remote tripping** sends the indication *Operate transmitted* to the Line differential protection functions of the remote devices in the device combination via the protection interface.
off	The functionality **Remote tripping** does not transmit the remote operate indication via the protection interface.

Parameter: Receiving

- Recommended setting value **(_:5551:101) Receiving** = ***yes***

With the **Receiving** parameter, you control the behavior of the device when a remote operate indication is received from a remote device.

Parameter Value	Description
yes	With this setting option, the indications *(_:5551:301) Operate received* and *(_:5551:57) Operate* are generated.
report only	With this setting option, the *(_:5551:57) Operate* is not generated.

Parameter: Send delay and Send prolongation

- Default setting **(_:5551:103) Send delay** = *0.02 s*
- Default setting **(_:5551:104) Send prolongation** = *0.00 s*

With the routing of the binary signal >External trip phs ABC, you can generate a remote operate indication and transmit it to the remote devices of the device combination.

With the **Send delay** parameter, you delay transmission of the remote operate indication by the set time.

With the **Send prolongation** parameter, you extend transmission of the remote operate indication by the set time.

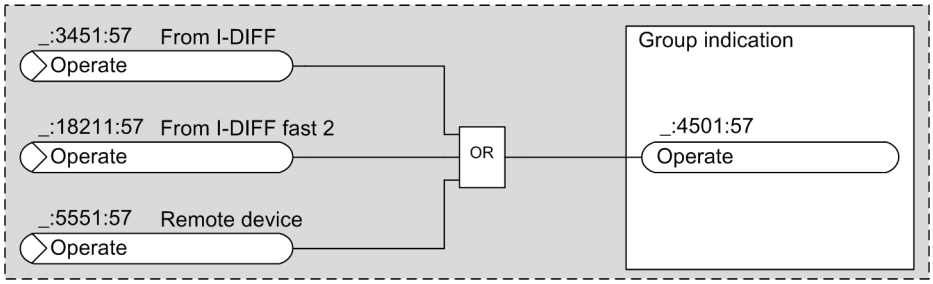
6.7.14 Pickup and Tripping

6.7.14.1 Pickup Logic

The pickup logic combines the pickup indications of the stages **I-DIFF**, **I-DIFF fast 2**, **I-DIFF fast**, **IN-DIFF**, **IN-DIFF unrest**, and **I2-DIFF** in a phase-segregated manner and forms the pickup group indication of the function **Line differential protection**.



[lo_Group-indication_pickup, 1, en_US]

Figure 6-167 Pickup Logic

6.7.14.2 Trip Logic

The trip logic combines the operate indications of the stages **I-DIFF**, **I-DIFF fast 2**, **IN-DIFF**, **IN-DIFF unrest**, **I2-DIFF** and the **remote tripping** and forms the tripping group indication of the function **Line differential protection**.
If you have instantiated the FG **Circuit breaker**, the function **Line differential protection** trips in a 3-pole way.

[loauslo3-100311-01.tif, 4, en_US]

6.7.15 Logging Off the Local Line Differential Protection

For some applications, it may be necessary to remove and log off the local Line differential protection from the device combination of the line differential protection. These applications include, for example:

- Maintenance work
- System expansion
- Testing the local line differential protection

EXAMPLE:

The following line formation is protected by the line differential protection with 3 devices.

[dw_example logoff ldiff, 2, en_US]

Figure 6-169 Differential Protection with 3 Devices for a Line with a Feeder

In the example, the feeder is to be decommissioned for maintenance or modification work. Device 3 should therefore also be switched off. Without additional measures, the line differential protection will no longer function and will send an indication that it is ineffective.

For this use case, the **Line differential protection** function must be logged off in device 3. The Line differential protection in device 3 can only be logged off if no current is flowing through the feeder. During the log-off process, device 3 checks whether the circuit breaker 3 is really open. If the Line differential protection is logged off in device 3, this is saved in the remaining devices 1 and 2 and Kirchhoff's current law will then be calculated only with the currents of the devices 1 and 2.

If device 3 is successfully logged off, you can switch it off. The logoff of device 3 is saved in the remaining devices after it is switched off. If you switch device 3 back on, log on to the device combination again.

NOTE

Before logging off, you must switch off the feeder protected by the local line differential protection.

Logoff Options of the Line Differential Protection

You can log off the **Line differential protection** function as follows:

- In DIGSI online mode via the operating dialog **Online accesses > Interface > Device > Device information, Test and operation, Functional logout**
- Via the on-site operation panel under **Device functions > Line n > Line diff. protection > Log off function**
- Via communication with the controllable *(_:2311:319) Function logout*
- Via the binary inputs *(_:2311:507) >Function logout on* or *(_:2311:508) >Function logout off*

  You can find the binary inputs in the DIGSI information routing at the function **Line differential protection** under **General**.

Conditions for Logging off the Function

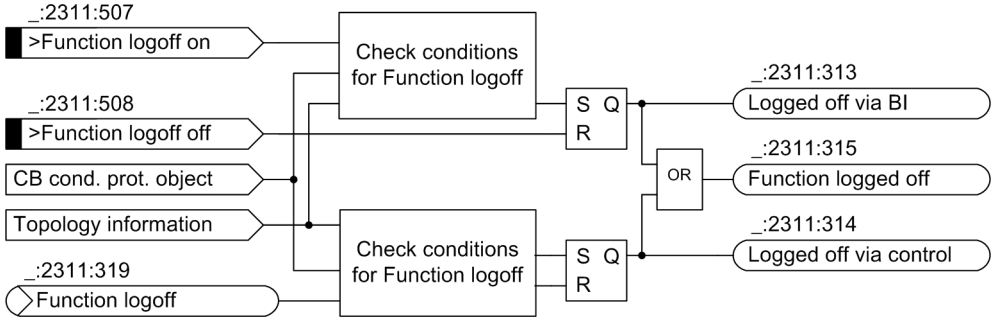

Figure 6-170 Logic for Logging off the Function

The following conditions must be fulfilled before the function is logged off:

- The current flow at the circuit breaker must be stopped. You must switch off the feeder protected by the local line differential protection.

  The locally measured current of the logged-off line end no longer flows into the sum of the currents. The function then only sums up the currents from the line ends that have not been logged off.

- The circuit-breaker position recognition in the **Circuit-breaker** function group (CB) provides the circuit-breaker condition via the internal signal *CB state protected obj.*.

  If a protected object is supplied via 2 circuit breakers (CBs), for example, in case of a breaker-and-a-half layout, then the CB state of the protected object must be determined with both circuit breakers. In this case, the **Circuit-breaker condition for the protected object** function block performs the connection of the individual CB conditions.

  If one of the following 2 conditions is met, the *CB state protected obj.* internal signal is in the ***Open*** state:

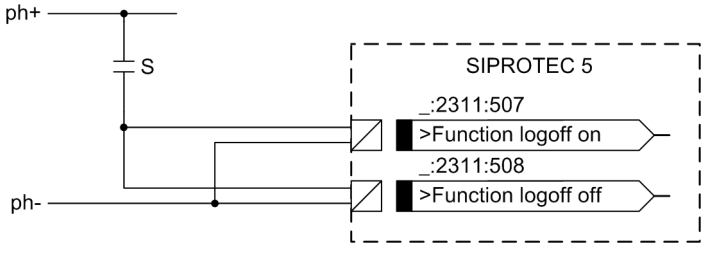
  – All connected circuit breakers signal the ***Open*** state.

  – The input **>Disconnector open** is active.

  For more detailed information, refer to *5.5.4.6 Circuit-Breaker Condition for the Protected Object*.

- Monitoring the communication topology in the device combination is only important if more than 2 devices are communicating via the protection interface. A function can only be logged off if this does not disturb the communication between the remaining devices in the device combination.

The logged-off local line differential protection can also be activated for test purposes (see *11.7 Functional Test Line Differential Protection*). This has no influence or impact on the running protection interface communication.



The following diagrams show potential variants on how to control binary inputs. If you would like to use push-buttons, switch on these push-buttons as shown in the following figure. With the push-button **Key2**, you log off the function using; with the push-button **Key1**, you log the function on again.

[loexttx3-140311-01.tif, 1, en_US]

Figure 6-171 External Push-Button Wiring for Logging off the Local Line Differential Protection

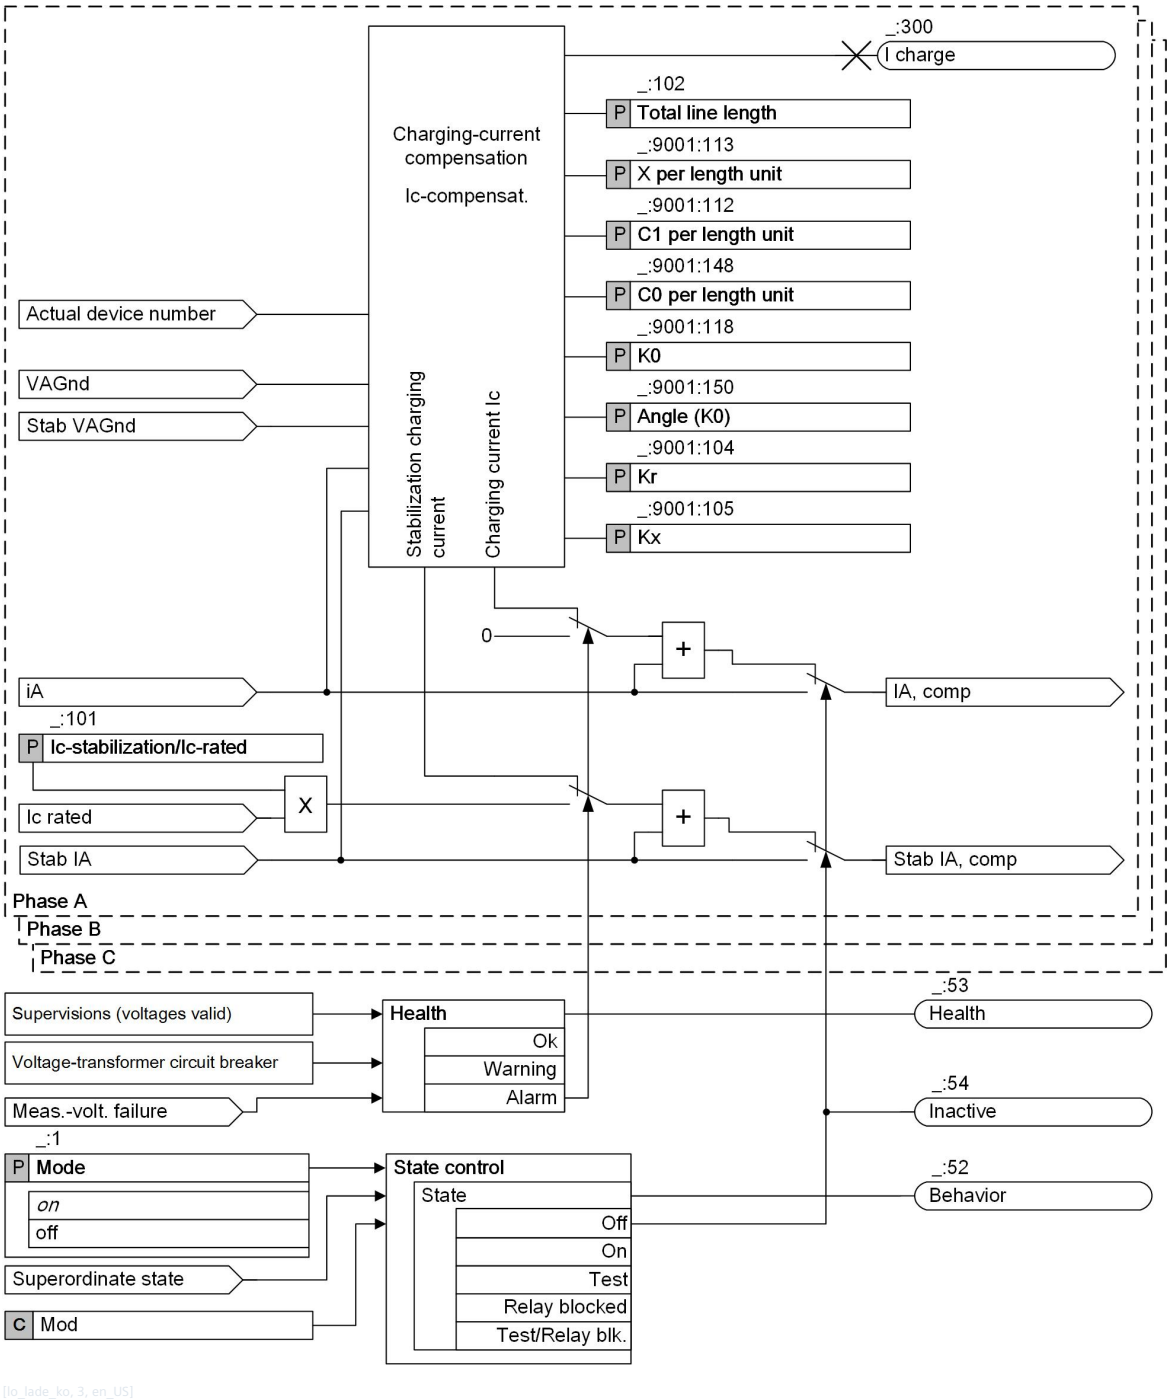
If a control switch is used, route the binary input *>Function logout on* as ***H (active with voltage)*** and the binary input *>Function logout off* as ***L (active without voltage)***. If the switch **S** is closed, the function is logged off.

[loextsx4-020412-01.tif, 1, en_US]

Figure 6-172 External Switch Wiring for Logging off the Local Line Differential Protection

Indications

The logged-off function reports the status (*Function logged off*) and the cause of the logoff.



If you have logged off the function via binary inputs, the indication *Logged off via BI* is issued.

If you have logged off the function via on-site operation, DIGSI 5, or the protection interface, the indication *Logged off via control* is issued.

6.7.16 Charging-Current Compensation Ic-Compensation

6.7.16.1 Description

Logic of the Stage

[lo_lade_ko, 3, en_US]

Figure 6-173 Charging-Current Compensation

Mode of Operation

The optional FB **Ic-compensat.** is available for charging-current compensation. The FB **Ic-compensat.** is assigned to the stages **I-DIFF**, **IN-DIFF**, **IN-DIFF unrestr**, and **I2-DIFF** and increases the sensitivity of the stages even with high capacitive charging currents.

The charging current is caused by the capacitances of the overhead line or the cable and flows through the ground capacitance of the line. Due to the phase-to-ground and phase-to-phase capacitances, charging currents are flowing even in correct operation, which cause a difference of the currents at the ends of the protection range. In cables or long lines, the capacitive charging currents can reach considerable values. If the feeder-side transformer voltages are connected to the devices, the influence of the capacitive charging currents can be compensated for by calculation. The charging-current compensation specifies the actual charging current. If there are lines with 2 ends, each device performs half the charging-current compensation. When using .

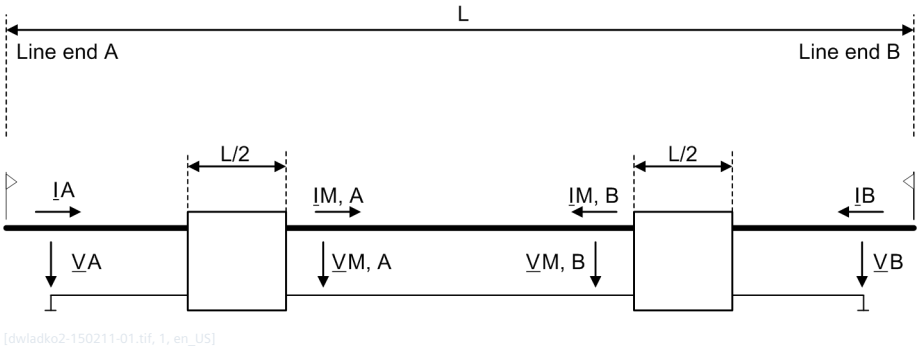


Figure 6-174 Charging-Current Compensation for a Line with 2 Ends (1-Phase System)

For correct operation, stationary charging currents can be regarded as almost constant since they only depend on the voltage and line capacitances. If you are working without charging-current compensation, take into account the charging currents in the pickup value of the **I-DIFF** stage. With charging-current compensation, this does not have to be taken into account here. With charging-current compensation, the stationary magnetizing currents are considered before quadrature-axis reactances. For transient inrush currents, the devices are provided with separate inrush-current detection.

NOTE

If you wish to work with the charging-current compensation, consider the following:

- The local voltage transformers must be connected to the line!
- Monitor the voltage with the **Measuring-voltage failure detection** function. If the **Measuring-voltage failure detection** is not present in the **Line** function group, add the function to the **Line** function group from the Global DIGSI 5 library.

  You can find the **Measuring-voltage failure detection** function in the Global DIGSI 5 library under **FG Line → Supervision of secondary system → Mes.v.fail.det**.

If a transformer or common-mode reactors are located in the line section to be protected, charging-current compensation must not be activated!

6.7.16.2 Application and Setting Notes

The rated current **Ic-rated** is the capacitive charging current to be expected for the entire line and is the result of the setting values of the following parameters:

Parameters	Description
(_:101) Rated frequency	Rated frequency of the device You can find the parameter in DIGSI 5 under **Settings** → **Device settings**.
(_:9001:102) Rated voltage **(_:9001:112) C1 per length unit** **(_:9001:148) C0 per length unit** **(_:9001:113) X per length unit** **(_:9001:104) Kr** **(_:9001:105) Kx** **(_:9001:118) K0** **(_:9001:150) Angle (K0)**	Rated voltage of the line Capacitance per unit length of the line Reactance per unit length of the line Residual compensation factors You can find the parameters in DIGSI 5 under **Settings** → **FG Line** → **General**.
(_:102) Total line length	Overall length of the line as a parameter of the charging-current compensation You can find the parameter in DIGSI 5 under **Settings** → **FG Line** → **Line diff. prot.** in the FB **Ic-compensat.**.

For verification purposes, the rated charging current is displayed as a write-protected parameter in the function block **Ic-compensat.** (**(_:110) Rated charging current**).

In the following cases, no charging current can be calculated:

- The voltages are not connected.
- The voltages are connected, but the internal supervision functions **Voltage-transformer circuit breaker** or **Measuring-voltage failure detection** (Fuse Failure Monitor) detect a loss of voltage.

If one of the 2 cases occurs, the charging-current compensation remains responsible for the line; however, it must return to the conventional stabilization method (see parameter **Ic-stabilization/Ic-rated**).

NOTE

Before switching off the charging-current compensation with the parameter **Mode**, you must increase the **Threshold** of the **I-DIFF** stage to 2 to 3 times **Ic-rated** of the line distance portion. Otherwise, undesired tripping might occur.

NOTE

You must enter additional line parameters for charging-current compensation. These include the following parameters:

- The **Rated frequency**
- The **Rated voltage** of the line
- Capacitance per unit length of the line (**C1 per length unit**, **C0 per length unit**)
- The residual compensation factors (**Kr**, **Kx**, **K0**, **Angle (K0)**)
- The **Total line length**

Parameter: Ic-stabilization/Ic-rated

- Recommended setting value **(_:101) Ic-stabilization/Ic-rated** = *1.5*

It is only possible to set the **I-DIFF** stage more sensitively by using the charging-current compensation (FB **Ic-compensat.**). If you use the charging-current compensation, set the **Threshold** of the **I-DIFF** stage to 1· Ic-rated.

In case of an outage or lack of voltages, it must be ensured that the **Threshold** of the **I-DIFF** stage is increased again to 2 to 3 times Ic-rated. Do this with the parameter **Ic-stabilization/Ic-rated**.

With the **Ic-stabilization/Ic-rated** parameter, you set the stabilization charging current/rated current ratio. The setting value of the parameter **Ic-stabilization/Ic-rated** increases the stabilization of the **I-DIFF** stage by an additional component (stabilization charging current).

EXAMPLE:

In case of an outage or lack of voltages, the **Threshold** of the **I-DIFF** stage is to be increased to 2.5 times Ic-rated. The threshold of the **I-DIFF** stage is set to 1 · Ic-rated.

If you want to increase the threshold of the **I-DIFF** stage to 2.5 times, set the parameter **Ic-stabilization/Ic-rated** = 1.5.

In case of an outage of lack of voltages, both setting values are added to 2.5.

Since the charging current of the device must only be considered for the respective portion of the line, each device will in fact increase its normal stabilization by a value of **Ic-stabilization/Ic-rated** divided by the number of devices.

Parameter: Total line length

- Default setting **(_:102) Total line length** = ***100.0 km***

The parameter **Total line length** considers the entire length of the protected line . Thus, the overall capacity of the line and the resulting charging current of the line can be determined.

6.8 Stub Differential Protection

6.8.1 Overview of Functions

The Stub differential protection (ANSI 87STUB):

- Is a selective, 2-step short-circuit protection for a line stub that can be tripped by a disconnector switch. It is important in 1 1/2 circuit-breaker layouts.
- Detects short circuits that lie between the current transformers and the feeder disconnector switch QB.
- Operates strictly phase-segregated and permits 3-pole instantaneous high-speed tripping

The stub differential protection operates on the basis of current comparison. To do this, the current transformers that selectively limit the line range are connected to the device using 2 configured, 3-phase current measurement locations. The feedback of the disconnector's position (open) activates the stub differential protection

[dwstubap-150211-01.tif, 1, en_US]

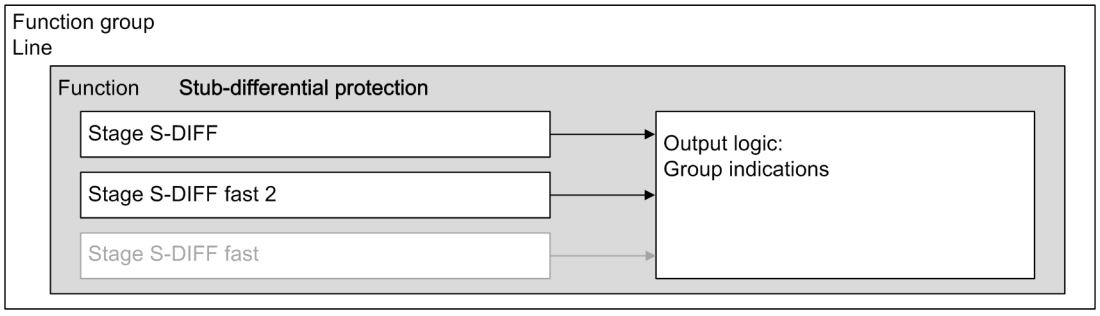

Figure 6-175 Stub Differential Protection on a 1 1/2 Circuit-Breaker Layout

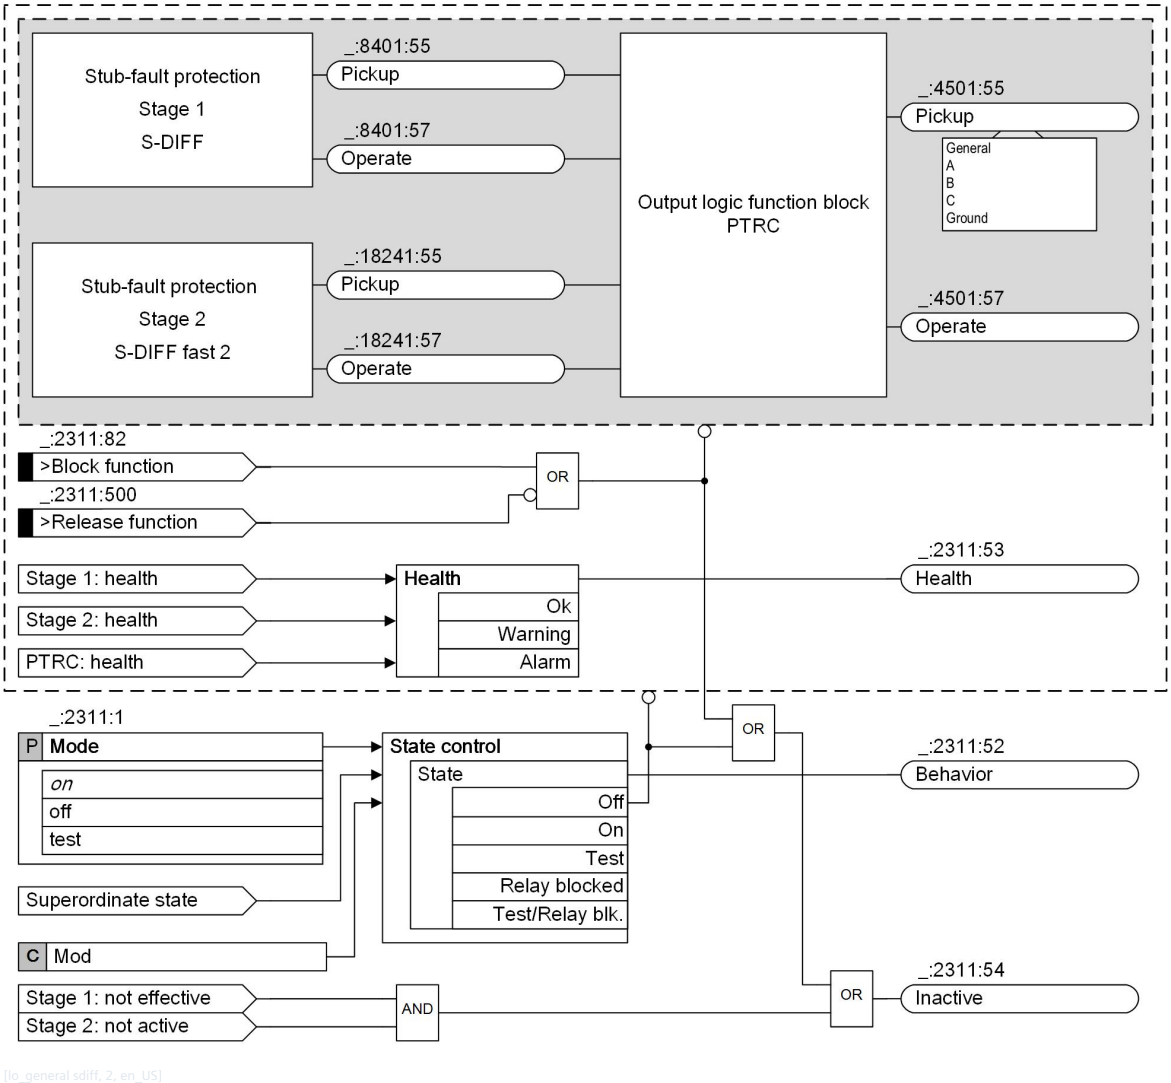
6.8.2 Structure of the Function

The **Stub-differential protection** function is used in the **Line** function group.

The **Stub-differential protection** function is preconfigured at the factory with the **S-DIFF** stage and the **S-DIFF fast 2** stage.

As an alternative to the **S-DIFF fast 2** stage, the **S-DIFF fast** stage is available in the Global DIGSI 5 library.



[dwstubeb-150211-01.tif, 2, en_US]

Figure 6-176 Embedding the Stub-Differential Protection

Mode of Operation

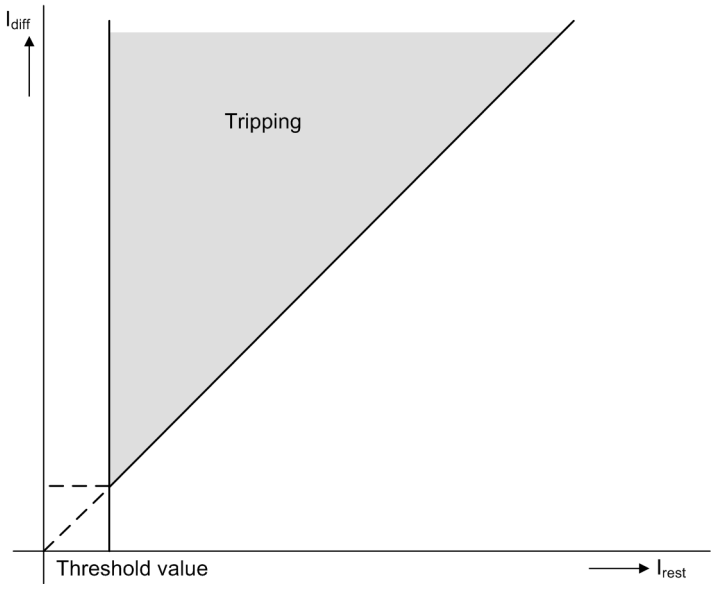
The **Stub-differential protection** function is composed of the **S-DIFF** stage and the **S-DIFF fast 2** stage. Both will also be referred to in the following sections as function blocks. Both stages work in parallel and ensure high sensitivity or fast tripping, depending on the severity of the fault. A release binary input (*>Release function*) switches the stub-differential protection to active. This binary input reports the position **open** to the feeder disconnector switch. The output signals of these stages are pickup and operate signals, which are routed to the output logic, resulting in the corresponding protection indications.

Overall Logic

[lo_general sdiff, 2, en_US]

Figure 6-177 General Logic of the Stub-Differential Protection

6.8.3 Function Description



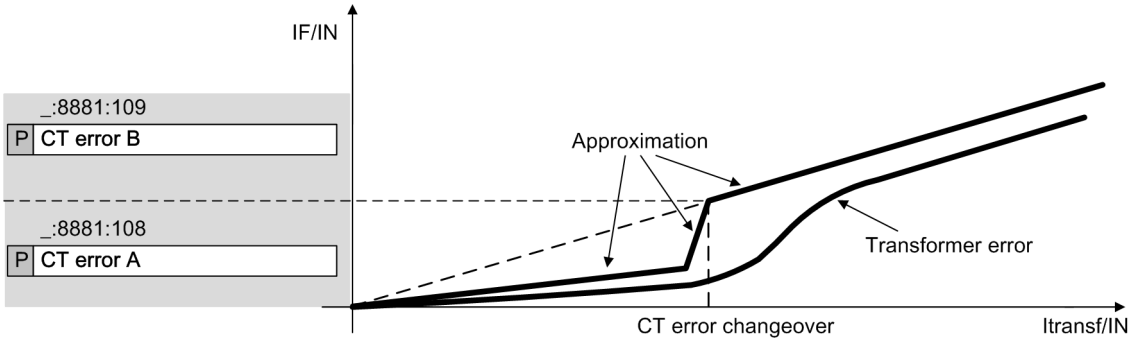
Adaptive Self-Stabilization

The basic principle of differential protection rests on the precondition that, during an uninterrupted operation, the sum of all currents flowing into the protected object equal 0. Secondary currents detected by the device are tainted with measuring errors that are caused by the transmission behavior of the current transformer and the input circuits of the device. All these influences mean that even in healthy operation the sum of the currents processed in the devices is not exactly 0. The differential protection is stabilized against these influences. A special method of adaptive self-stabilization is used in this context to ensure the highest possible sensitivity of the differential protection.

The stabilization variable Irest is calculated from the sum of the potential faults:

Irest = **Threshold** + Σ(current-transformer errors and other measuring errors).

If the measured differential current exceeds the pickup threshold and the maximum possible measuring error, there is an internal fault (shaded area in *Figure 6-178*). With the adaptive approach it is no longer necessary to assign parameters for a characteristic curve.



[dwanstub-150211-01.tif, 1, en_US]

Figure 6-178 Operate Curve of the Stub-Differential Protection

Current-Transformer Errors

In order to take into account the influences of current-transformer errors, an adaptive self-stabilization value I_{fault} is calculated for each measuring point. This is the result of the sum of all current-transformer errors, which in turn are the result of the current-transformer data and the degree of currents measured on the transformer.

[dwctfail-310111-01.tif, 2, en_US]

Figure 6-179 Approximation of the Current-Transformer Errors

The set parameters of the transformer data apply to the configured current inputs on the device.

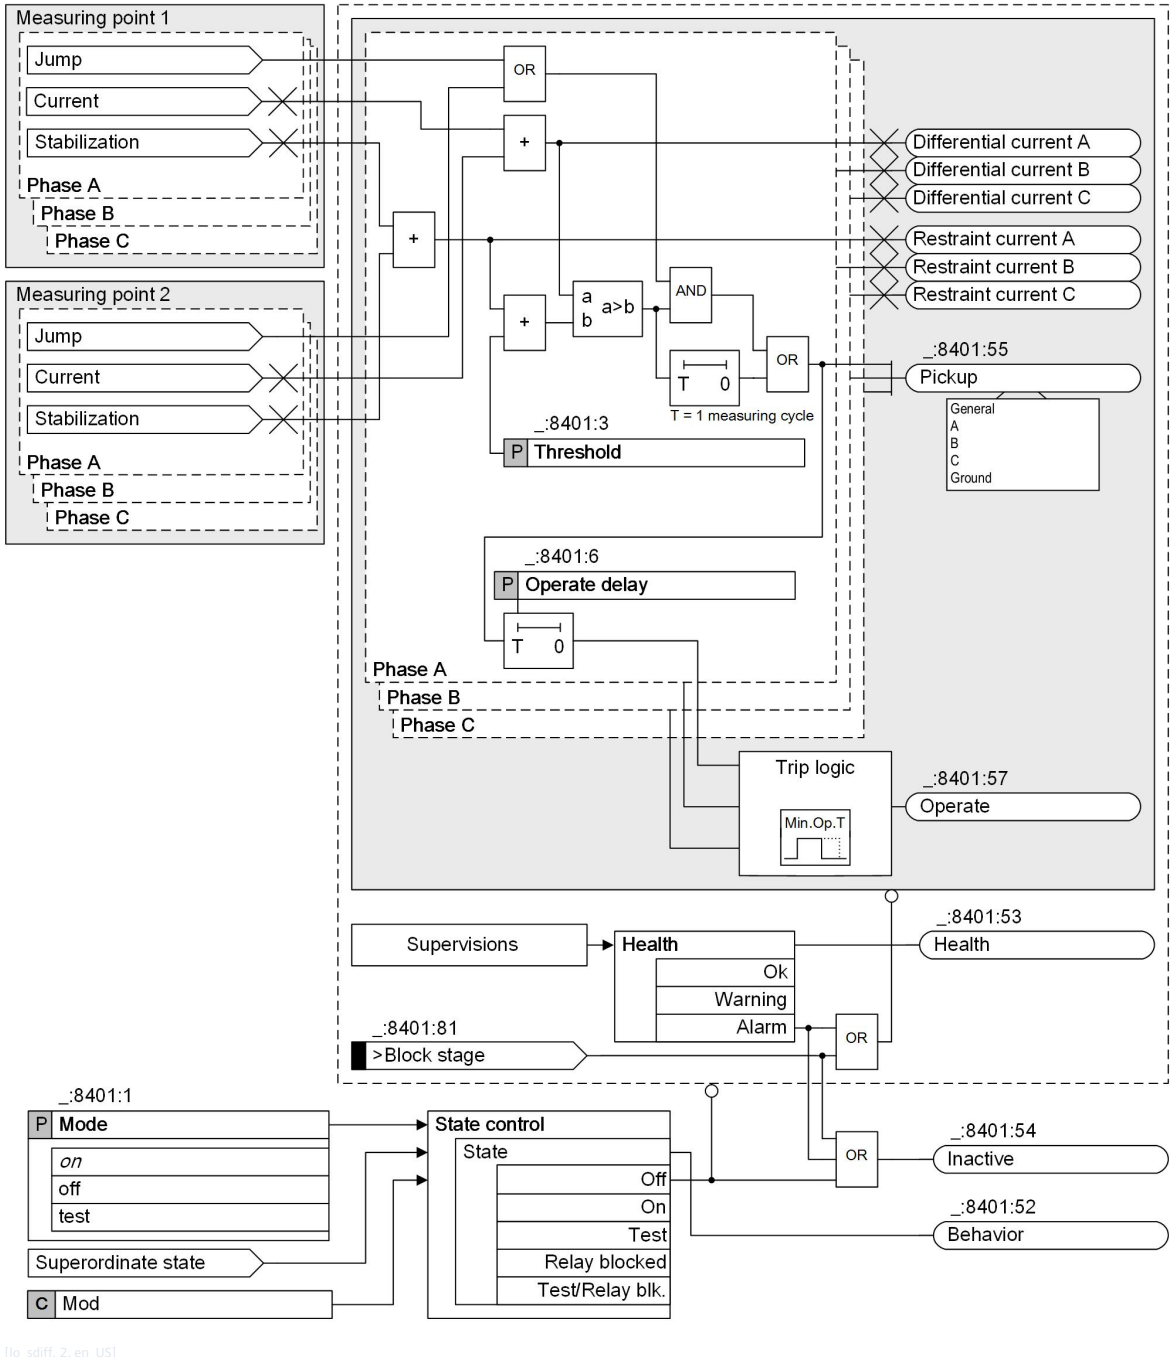
Other Measuring Faults

Additional measuring faults will also be estimated by the device and local self-stabilizing variables will be automatically increased.

Such measuring faults can be caused by

- Hardware and computation tolerances by the device itself
- Based on the **Quality** of the measurands such as harmonic components and frequency deviations.

Stages of the Stub-Differential Protection



The stub-differential protection has 2 preconfigured stages:

- The **S-DIFF** stage works with very accurate measurement. Maximum sensitivity can be achieved with this stage. You cannot delete this stage.
- The **S-DIFF fast 2** stage works in parallel with the **S-DIFF** stage. A very fast algorithm enables tripping decisions to be made very quickly in the event of high-current faults.
  If the **S-DIFF fast 2** stage is instantiated, the **Saturation detection** block is visible with the **CT saturation threshold** parameter in the **Measuring point Current 3-phase**.
- The **S-DIFF fast** stage is available in the Global DIGSI 5 library as an alternative to the **S-DIFF fast 2** stage. If you want to instantiate this stage, you must first delete the **S-DIFF fast 2** stage.
  If the **S-DIFF fast** stage is instantiated, the **Saturation detection** block is not visible with the **CT saturation threshold** parameter in the current measuring point.
  The **S-DIFF fast** stage also works in parallel with the **S-DIFF** stage. A very fast algorithm enables tripping decisions to be made very quickly in the event of high-current faults.

6.8.4 Stage S-DIFF

6.8.4.1 Description

Logic of the Stage

[lo_sdiff, 2, en_US]

Figure 6-180 Logic of the Stage S-DIFF

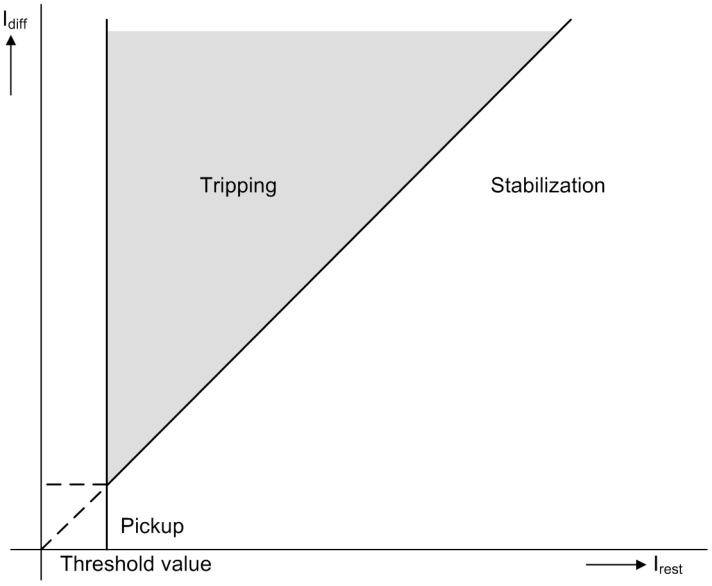
Mode of Operation

The stage **S-DIFF** is the sensitive stage of the stub-differential protection. It is based on the principle of current phasor calculation. Usable current phasors are available after 1 period has elapsed following the

occurrence of a fault event. The stage **S-DIFF fast 2**, which operates in parallel, is responsible for fast tripping in the event of high-current errors.

All measurands are evaluated separately for each phase. The device calculates a differential current from the sum of the current phasors on the measuring inputs. The sum of the differential current is equal to the fault current, which is detected by the differential-protection system. Ideally, this is the short-circuit current. In correct operation, it is small and corresponds to the capacitive charging current in a first approximation.

The restraint current counteracts the differential current. The restraint current results from the sum of the maximum measuring errors at the ends of the protected object and is calculated adaptively from the current measurands and the set substation settings. To do this, the maximum error of the current transformers in the rated range or the short-circuit current range is multiplied with the straight flowing currents of the current transformer of the protected object.



Pickup of the Stage

The pickup characteristic of the stub differential protection (see *Figure 6-181*) results from the stabilization characteristic curve Stubdif = Irest (45° line) which is cut below the setting value of the parameter **(_:8401:3) Threshold**.

It complies with the following equation:

Irest = **Threshold** + Σ(current-transformer errors and other measuring errors).

If the calculated differential current exceeds the pickup threshold and the maximum possible measuring error, there is an internal error (shaded area in *Figure 6-181*).

[dwanspre-150211-01.tif, 1, en_US]

Figure 6-181 Pickup Characteristic of the Stage S-DIFF

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

6.8.4.2 Application and Setting Notes

Parameter: Threshold

- Recommended setting value: **(_:8401:3) Threshold** = ***0.300 A***

  The pickup threshold of the differential current is set using this parameter. The total current flowing into the protection range during a short circuit is the important criterion. This is the overall fault current, regardless how the ends of the protected object are divided.

Parameter: Operate delay

- Recommended setting value: **(_:8401:6) Operate delay** = ***0.00 s***

  In special cases, it can be advantageous to delay the tripping of the stub differential protection with an additional time stage, for example for reverse interlocking. The time delay is started when an internal fault has been detected (***(_:8401:55) Pickup***).

6.8.5 Stage S-DIFF Fast 2

6.8.5.1 Description

Logic of the Stage

[lo_stage_sdiff_schn2, 2, en_US]

Figure 6-182 Logic of the Stage S-DIFF fast 2

NOTE

If you want to use the **S-DIFF fast 2** stage, the device must be equipped with the **CP300** CPU printed circuit board assembly.

Method of Operation

The stage **S-DIFF fast 2** is optimized for fast operate times during high-current faults. It is superimposed on the stage **S-DIFF**. The measurands are analyzed separately for each phase. Fast tripping for high-current faults is achieved with a procedure based on filtered instantaneous values. During this procedure, stabilization to prevent signal distortion (for example, current-transformer saturation), which may occur during high-current external faults, is not possible. For this reason, a decision for internal or external faults must be made before the potential saturation occurs. It is assumed that the current transformers do not yet go into saturation at least for the duration of one integration interval (5 ms) after fault inception.

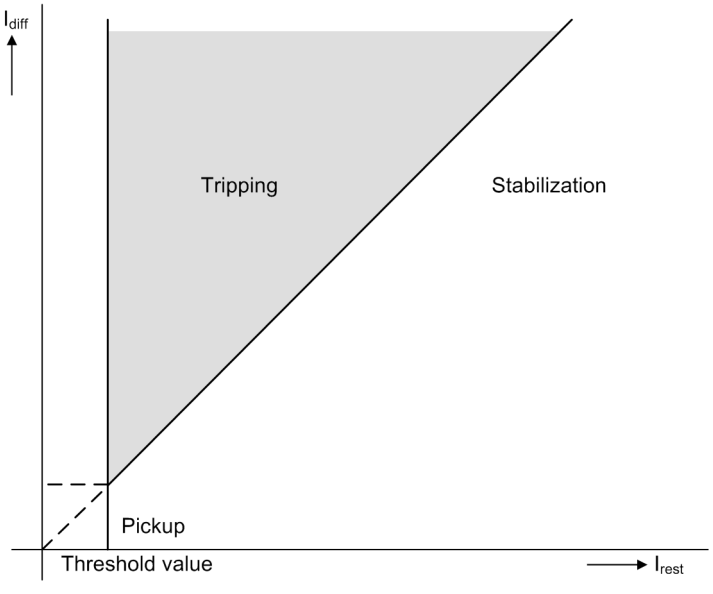
If you use the stage **S-DIFF fast 2**, the block **Saturat. det.** is visible with the parameter **CT saturation threshold** in the measuring point **Current 3-phase**. With this, the **CT saturation threshold** must be set so that transformer saturation does not occur until the currents exceed the setting value.

For more detailed information, refer to *8.3.13 Saturation Detection*.

If saturation occurs for one or more current transformers limiting the protection range, the stage **S-DIFF fast 2** is blocked and an erroneous pickup is avoided due to transformer saturation.

Normally, the stage **S-DIFF fast 2** is set higher than the rated current. Otherwise, the stage **S-DIFF fast 2** works in the same way as the sensitive stage **S-DIFF**. Each device calculates a differential current for each phase from the sum of the filtered instantaneous values, which are calculated at each end of the protected object. The value of the differential current corresponds to the fault current, which is detected by the differential-protection system. Ideally, this is the short-circuit current. In correct operation, it is small and corresponds to the capacitive charging current in lines in a first approximation.

The restraint current counteracts the differential current. The restraint current results from the sum of the maximum measuring faults at the ends of the protected object and is calculated adaptively from the current measurands and the set substation parameters. To this end, the maximum error of the current transformers in the rated range or the short-circuit current range is multiplied with the presently flowing currents on each end of the protected object.



Pickup of the Stage

Like for the stage **S-DIFF**, the pickup characteristic (refer to *Figure 6-183*) results from the stabilization characteristic curve S-DIFF = Irest (45° line), which is cut below the setting value of the parameter **Threshold**.

It complies with the equation

Irest = **Threshold** + Σ(current-transformer errors and other measuring errors).

If the calculated differential current exceeds the pickup threshold and the maximum possible measuring error, there is an internal error (dimmed area in the following figure).

[dwanspre-150211-01.tif, 1, en_US]

Figure 6-183 Pickup Characteristic of the Stage S-DIFF fast 2

Fault Behavior

The indication *Health* is set to ***Alarm*** when fast measured-value monitoring functions (fast sum I, analog-digital converter) signal a fault or when invalid data are received via the protection interface. The validity of the currents used as well as the validity of the data received via the protection interface are monitored continuously. If persistent faults are detected, **Health** is set to ***Alarm*** and **Inactive** is set to ***Yes***.

6.8.5.2 Application and Setting Notes

Parameter: Threshold

- Recommended setting value: **(_:18241:3) Threshold** = ***1.000 A***

  With this parameter, you set the pickup threshold of the differential current. This pickup threshold must be primarily equal on all ends of the protected object.

  This stage responds very quickly. For this reason, a pickup with capacitive charging currents and inductive magnetization currents as with transformers or shunt reactors – including during switching procedures – must be excluded. Set the pickup value to a value greater then the load current ($1.2 \cdot I_{rated}$ to $2 \cdot I_{rated}$).

6.8.5.3 Settings

6.8.6 Stage S-DIFF Fast

6.8.6.1 Description

Logic of the Stage

[lo_stubi2, 2, en_US]

Figure 6-184 Logic of the S-DIFF fast

The **S-DIFF fast** stage is essentially identical to the **S-DIFF fast 2** stage.

If you want to use the **S-DIFF fast** stage, you must delete the preinstantiated **S-DIFF fast 2** stage first. After this, you can instantiate **S-DIFF fast**.

If you use the **S-DIFF fast** stage, the **Saturat. det.** block is not available in the measuring point **Current**.

You can find the description of the **S-DIFF fast 2** in chapter *6.8.5.1 Description*.

6.8.6.2 Application and Setting Notes

The **S-DIFF fast** stage is essentially identical to the **S-DIFF fast 2** stage.

If you want to use the **S-DIFF fast** stage, you must delete the preinstantiated **S-DIFF fast 2** stage first. After this, you can instantiate the **S-DIFF fast** stage.

If you use the **S-DIFF fast** stage, the **Saturat. det.** block is not available in the measuring point **Current**.

You can find the description of the **S-DIFF fast 2** stage in chapter *6.8.5 Stage S-DIFF Fast 2*.

Parameter: Threshold

- Recommended setting value: **(_:8431:3) Threshold** = ***1.000 A***

  This parameter sets the pickup threshold of the differential current, which must be primarily equal on all ends of the protected object.

  This stage responds very quickly. For this reason, pickup during capacitive charging currents and inductive magnetization currents (for transformers or shunt reactors) – including during switching procedures - must be excluded. The pickup value should be set higher than the load current (max. $1.2 \cdot I_{rated}$ to $2 \cdot I_{rated}$).

6.8.7 Stage Description of the Output Logic

Output Logic

[lo_stubag, 3, en_US]

Figure 6-185 Output Logic

6.9 Ground-Fault Protection for High-Resistance Ground Faults in Grounded Systems

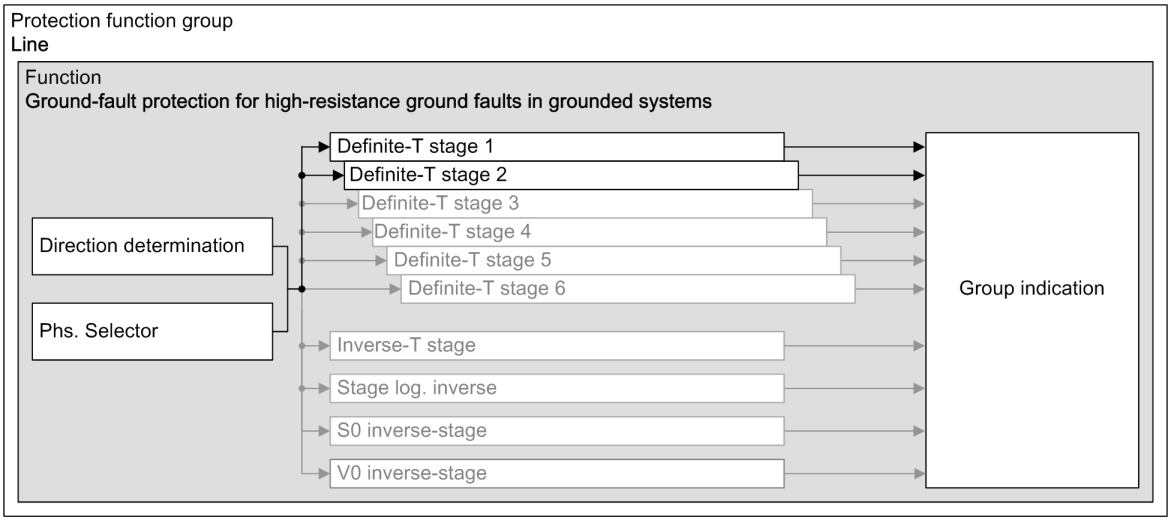
6.9.1 Overview of Functions

The **Ground-fault protection for high-resistance ground faults in grounded-neutral systems** function (ANSI 67N):

- Detects high-resistance ground faults in electric equipment in grounded systems
- Detects short circuits phase selectively

6.9.2 Structure of the Function

The **Ground-fault protection for high-resistance ground faults in grounded systems** function is used in the **Line** protection function group. The function is preconfigured at the factory to have 2 stages with definite-time delay (definite time-overcurrent protection stages). Within the function, maximum 6 definite time-overcurrent protection stages can be operated as well as 1 simultaneously by each inverse type. A maximum of 2 functions can be operated within the function group.



The following stage types are available:

- Ground-fault protection with definite-time delay (definite-time overcurrent protection)
- Ground fault protection with definite-time delay according to IEC and ANSI (AMZ-3I0-IEC/ANSI)
- Ground fault protection with definite-time delay with logarithmic inverse characteristic (AMZ-3I0-log)
- Ground-fault protection with zero-sequence power-dependent delay (S0 inverse)
- Ground-fault protection with zero-sequence voltage-dependent delay (V0 inverse)

The process for direction determination and phase selection is on the function level and has a uniform effect on the stages (see *Figure 6-186* and section *6.9.9.1 Description*). In this way, it is ensured that all stages of a function receive the same direction result. Each stage can be set non-directional or directional – forwards or reverse.

The group-indications output logic (see *Figure 6-186*) generates the following group indications for the entire **Ground-fault protection** function by logic OR from the stage-selective indications:

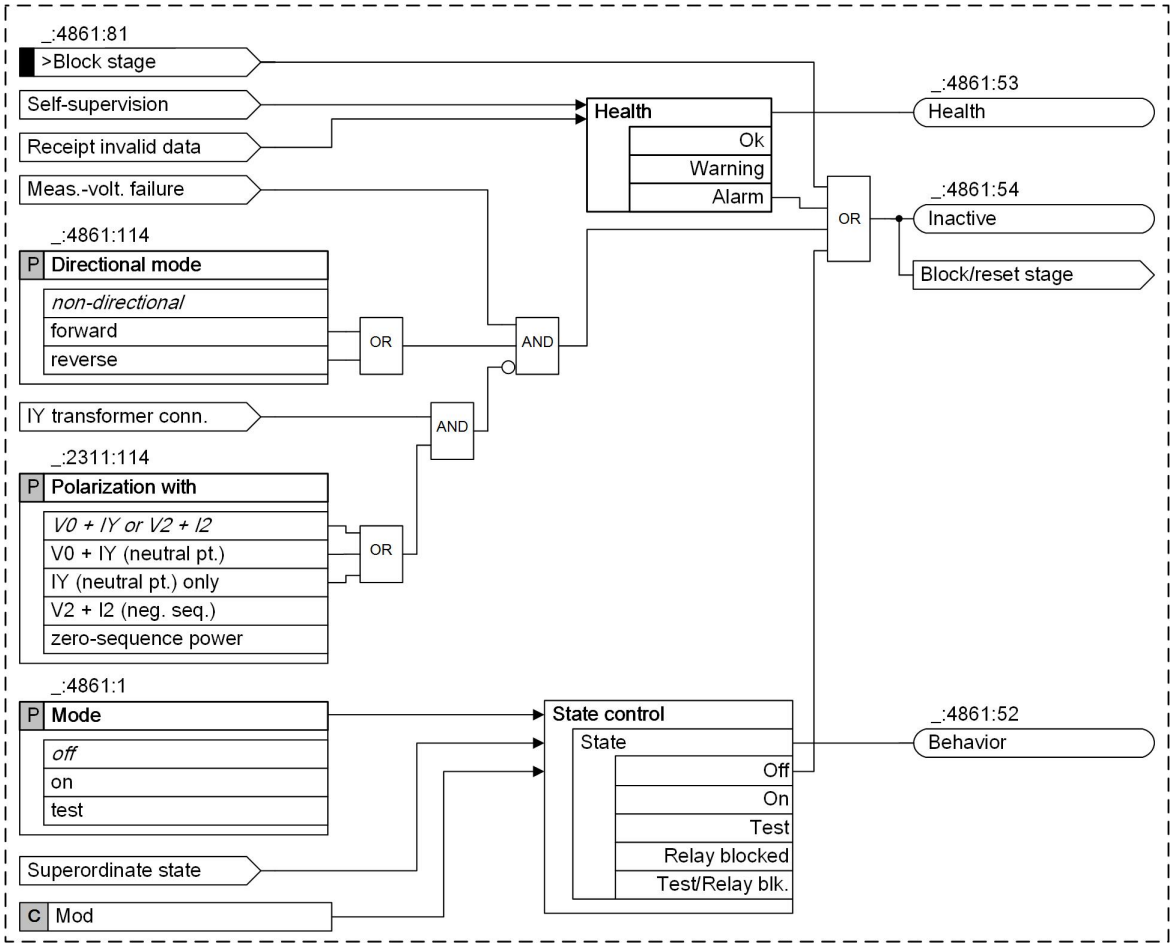
- **`Pickup`**
- **`Operate delay expired`**
- **`Operate`**

[dwgfpstr-030311-01.tif, 2, en_US]

Figure 6-186 Structure/Embedding of the Function

If the following listed, device-internal functions are present in the device, these functions can influence the pickup values and time delays of the stages or block the stages. The stage can also be affected from outside via a binary input signal.

- Automatic reclosing (AREC)
- Binary input signal



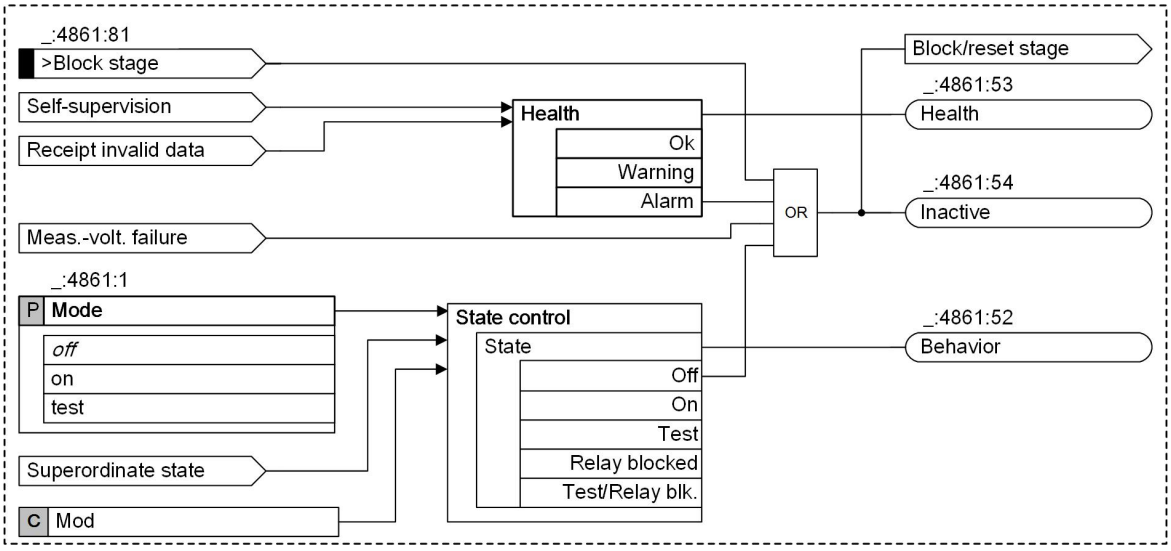
Automatic reclosing (AREC) If the device is equipped with an **Inrush-current detection** function, the stages can be stabilized against tripping due to transformer-inrush currents (see section *6.9.11.1 Description*).

The stages can be used for directional-comparison protection via the **Teleprotection method with ground-fault protection** function, if necessary (see chapter *6.10.1 Overview of Functions*).

6.9.3 Stage Control

Logic

The following figure represents a stage control. It applies for the stage types definite-time overcurrent protection, inverse-time overcurrent protection according to IEC and ANSI and inverse-time overcurrent protection with logarithmic inverse characteristic.



[lo_ggfp_02, 2, en_US]

Figure 6-187 Stage Control for the Stages Types Definite Time-Overcurrent Protection, Inverse-Time Overcurrent Protection, and Logarithmic Inverse

Besides the universally applicable stage control, the stage is blocked in the case of a measuring-voltage failure, insofar as the stage works directionally, and the transformer neutral-point current is not connected.

The following figure shows the stage control for the stage types S0 inverse and V0 inverse.

[lo_ggfp_12, 2, en_US]

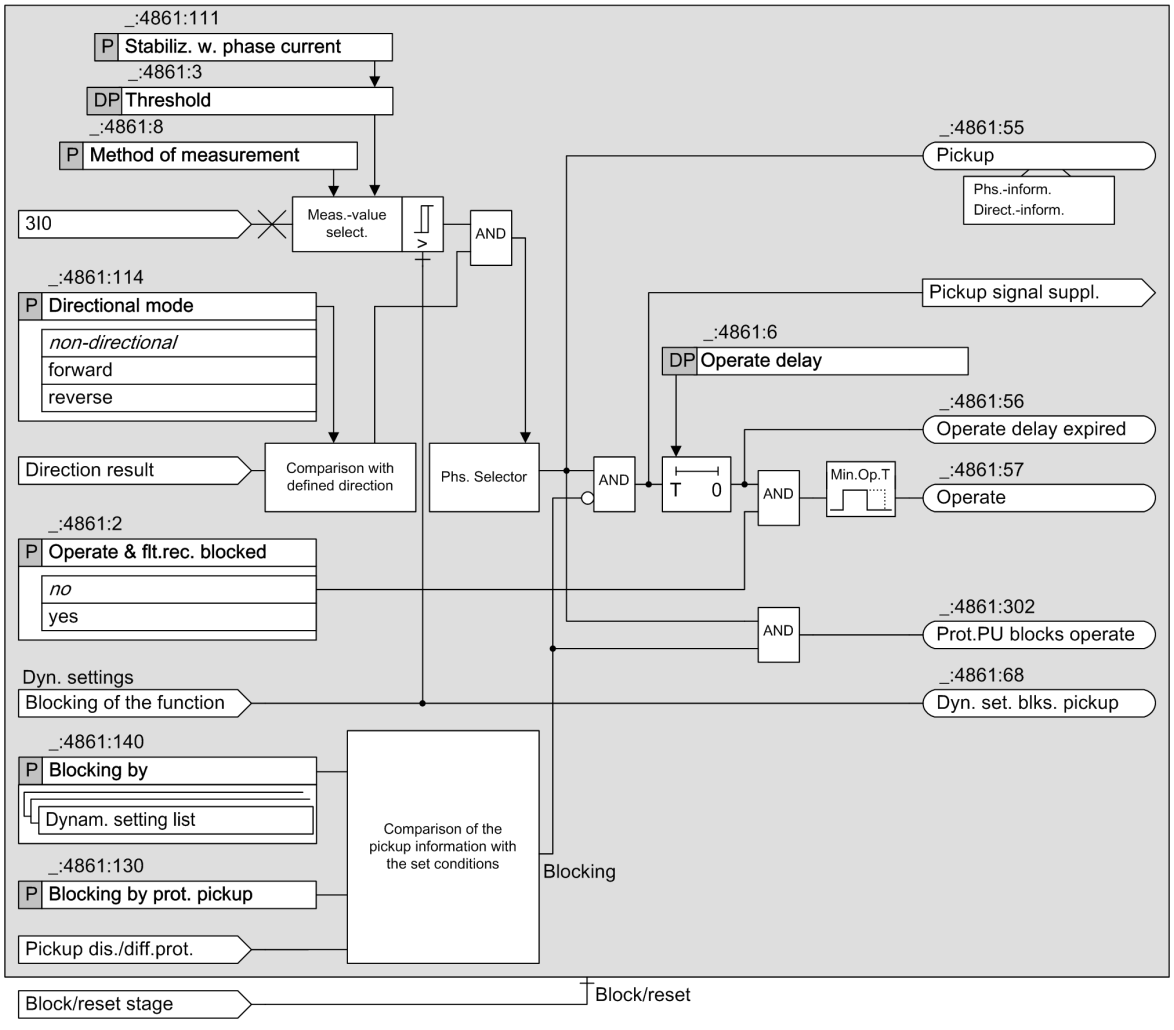


Figure 6-188 Stage Control for the Stage Types S0 Inverse and V0 Inverse

Besides the universally applicable stage control, the stages is also blocked upon a measuring-voltage failure.

6.9.4 Stage with Definite-Time Characteristic Curve

6.9.4.1 Description

Logic of a Stage

[loggfp31-160611-01.tif, 1, en_US]

Figure 6-189 Logic Diagram for Ground-Fault Protection with Definite Time-Overcurrent Protection

Measurand

The residual current is used as a measurand. The residual current is calculated according to its definition equation

$$\underline{3I0} = \underline{I_A} + \underline{I_B} + \underline{I_C}$$

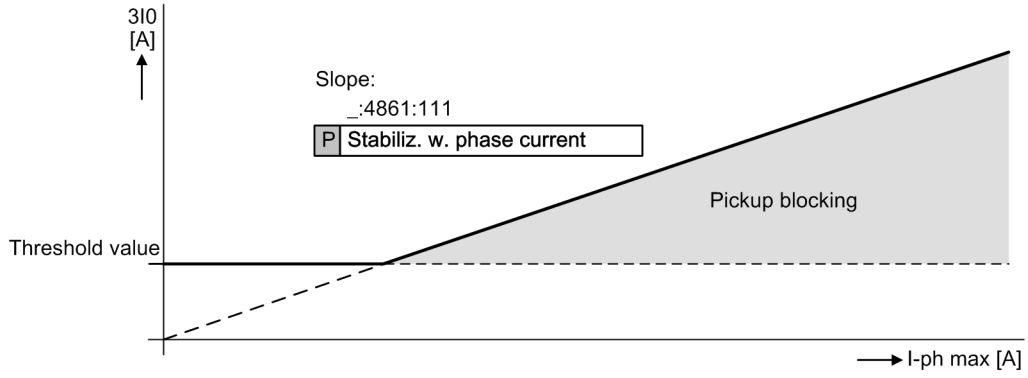
from the sum of the 3 phase currents. Depending on the use of the current inputs of the device, the residual current can be measured or calculated.

If you connect a current input in the neutral-point feed of the current transformer or to a separate ground-current transformer of the line to be protected, the ground current (residual current) will be directly available to the device.

If the device is equipped with a sensitive current input I_{Nsens}, the device will use this ground current (residual current). The linear range of this measuring input ends at an amplitude of approx. 1.5 A. At higher currents, the device automatically switches to analysis of the residual current calculated from the phase currents.

If the ground current is not present in the device as a directly measured variable, the device will calculate the zero current from the conductor currents.

Method of Measurement



The **Method of measurement** parameter is used to select the relevant measuring procedure, depending on the application:

- Measurement of the fundamental component over 1 cycle filter (standard filter)
  This measuring procedure processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the fundamental component over 2 cycle filters
  This measuring procedure processes the sampled current values and filters out the fundamental component numerically. Harmonics and transient faults are damped particularly strongly over the extended filter length in comparison to the standard filter. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see Technical specifications).

Stabilization with Phase Currents

In grounded systems, unbalanced line and load ratios cause a residual current in normal operational applications. Likewise, different current-transformer faults lead to a secondary residual current. The amplitude of this undesirable residual current increases as the phase current increases. An undesirable residual current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases as phase currents rise (see following graphic).

You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

[logfpsta-030311-01.tif, 1, en_US]

Figure 6-190 Stabilization with Phase Currents

Directional mode

You use the **Directional mode** parameter to define whether the stage works in a forward or reverse direction. Non-directional operation is also possible.

The direction determination works across stages (see chapter *6.9.9.1 Description*).

Phase Selection

Phase Selection Depending on the distribution of the currents and voltages, the phase selection detects if a 1-phase (determination of the affected phase) or multiphase short circuit is present (see Chapter *6.9.10 Phase Selection*).

Pickup for Signal Supplement

The **Teleprotection method with ground-fault protection** function can be used to apply the stage for directional comparison protection as well. The stage provides the internal signal **signal supplement**

pickup for this. Complete the necessary settings in the function **Teleprotection method with ground-fault protection** (see chapter *6.10.1 Overview of Functions*).

Blocking of the Stage Pickup

The following blockings suppress the pickup of the stage and fully reset the picked up stage:

- Externally or internally via the binary input signal **>Block stage** (see also *Figure 6-187* and *Figure 6-188*)
- Via the functionality of the dynamic settings (see section *6.9.13.1 Description*)

The blocking cause is indicated.

Blocking of the Tripping by Pickup of the Distance Protection or Differential Protection Function

The pickup of the main protection function (differential protection) can block the level tripping. You can perform this setting via 2 parameters:

- Parameter **Blocking by**

  This parameter is used to select the differential at whose pickup the blocking is to occur.
- Parameter **Blocking by prot. pickup**

  The parameter is also used to set whether blocking is to occur upon pickup of the main protection. This also applies if you have selected one or more zones/stages from the **Blocking by** parameter.

Blocking of the Tripping via the Device-Internal Inrush-Current Detection Function

Blocking of tripping via the device-internal **Inrush-current detection** function is described in section *6.9.11.1 Description*.

Influence of Other Functions via Dynamic Settings

If the following functions are present in the device, they can affect the dynamic settings **Threshold** and **Operate delay** of the level:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.9.13.1 Description*.

6.9.4.2 Application and Setting Notes

Stage-Type Selection

If the tripping delay is to be independent of the current level, select the stage type Definite time-overcurrent protection.

A multi-stage Definite time-overcurrent protection function is realized by the parallel operation of several definite time-overcurrent protection stages.

Parameter: Blocking by the Main Protection

- Default setting **(_:4861:140) Blocking by** = none
- Default setting **(_:4861:130) Blocking by prot. pickup** = ***every pickup***

If you wish to give the selective fault clarification by the main protection function (for example, differential protection) priority over tripping by ground-fault protection, you can define this via both parameters. The **Blocking by** parameter is used to select the zones or levels of the main protection function(s), upon whose pickup the ground-fault protection is to be blocked.

The **Blocking by prot. pickup** parameter is used to set whether a blocking of the tripping is to be activated upon excitation of the main protection.

Parameter Value	Description
every pickup	Blocking at every pickup
no pickup	No blocking at pickup of the main protection function

Parameter: Directional mode

- Default setting **(_:4861:114) Directional mode** = ***non-directional***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
non-directional	If the stage is to work in the forward and reverse direction (in the direction of the line and busbar), then select this setting. The stage also works with this setting if no direction measurement is possible, for example, owing to lower or no polarization voltage.
forward	Select these settings if the stage is only to work in a forward direction (in direction of the line).
reverse	Select this setting if the level is only to work in the reverse direction (in the direction of the busbar).

Parameter: Method of measurement

- Recommended setting value **(_:4861:8) Method of measurement** = ***1-cycle filter***

Use the **Method of measurement** parameter to define whether the measurand is determined via 1 or 2 cycle filters.

Parameter Value	Description
1-cycle filter	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.
2-cycle filter	To implement a particularly strong attenuation of harmonics and transient faults, select the setting 2 cycle filter. Please note that in this case the pickup time of the tripping level increases slightly (see Technical specifications).

Parameter: Stabilization with phase currents

- Recommended setting value **(_:4861:111) Stabiliz. w. phase current** = ***10 %***

In grounded systems, unbalanced line and load ratios cause a residual current in normal operational applications. Likewise, different current-transformer faults lead to a secondary residual current. The amplitude of this undesirable residual current increases as the phase current increases. An undesirable residual current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases as phase currents rise. You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

Siemens recommends a setting of 10 % under normal conditions.

Dynamic parameter: Threshold

- Default setting **(_:4861:3) Threshold** = ***1500 A***

Define the pickup value corresponding to the application.

At a very sensitive setting, you must ensure that a residual current due to unbalance (for example, untwisted line) does not cause the level to respond.

Dynamic parameter: Operate delay

- Default setting **(_:4861:6) Operate delay** = ***300 ms***

The Operate delay to be set is derived from the time grading chart for ground faults that has been prepared for the network.

When selecting the current and time setting, note whether stage tripping is direction-dependent and whether signal transmission is used. See also chapter *6.10.1 Overview of Functions*.

If you use a stage direction independently and with signal transmission, it can also have a non-delayed effect during the release process. Parameterize a short delay for the blocking method equal to the signal-transmission time plus a reserve of approx. 20 ms.

6.9.5 Stage with Inverse-Time Overcurrent Protection According to IEC and ANSI

6.9.5.1 Description

Logic of the Stage

[loggfp32-300511-01.tif, 1, en_US]

Figure 6-191 Logic Diagram for Ground-Fault Protection with Definite-Time Delay According to IEC and ANSI (AMZ-3I0-IEC/ANSI)

Measurands

The residual current is used as a measurand. The residual current is calculated according to its definition equation

$$\underline{3I0} = \underline{I_A} + \underline{I_B} + \underline{I_C}$$

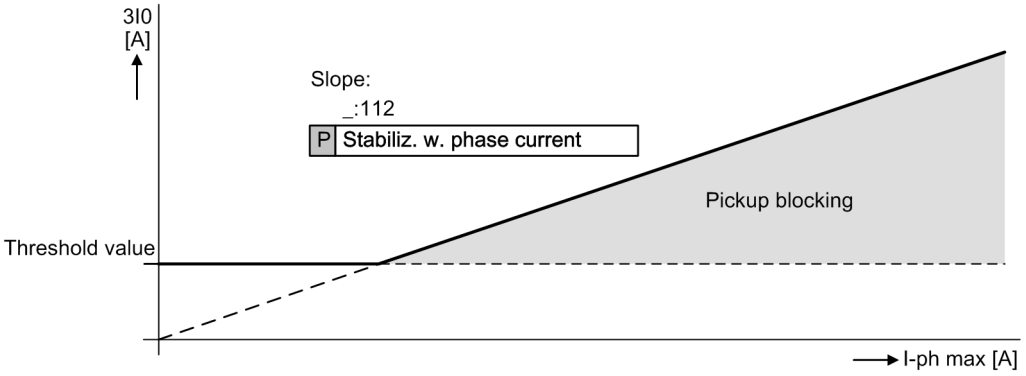
from the sum of the 3 phase currents. Depending on the use of the current inputs of the device, the residual current can be measured or calculated.

If you connect a current input in the neutral-point feed of the current transformer or to a separate ground-current transformer of the line to be protected, the ground current (residual current) will be directly available to the device.

If the device is equipped with a sensitive current input I_{Nsens}, the device will use this current. The linear range of this measuring input ends at an amplitude of approx. 1.6 A. At higher currents, the device automatically switches to analysis of the residual current calculated from the phase currents.

If the ground current is not present in the device as a directly measured variable, the device will calculate the residual current from the phase currents.

Method of Measurement



The **Method of measurement** parameter is used to select the relevant method of measurement, depending on the application:

- Measurement of the fundamental component via 1-cycle filter (standard filter)
  This measuring procedure processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the fundamental component via 2-cycle filter
  This measuring procedure processes the sampled current values and filters out the fundamental component numerically. Harmonics and transient faults are damped particularly strongly over the extended filter length in comparison to the standard filter. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see Technical specifications).

Stabilization with Phase Currents

In grounded systems, unbalanced line and load ratios cause a residual current in normal operational applications. Likewise, different current-transformer faults lead to a secondary residual current. The amplitude of this undesirable residual current increases as the phase current increases. An undesirable residual current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases as phase currents rise (see following graphic).

You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

[loggfpst-030810-01.tif, 1, en_US]

Figure 6-192 Stabilization with Phase Currents

Directional mode

You use the **Directional mode** parameter to define whether the stage works in a forward or reverse direction. Non-directional operation is also possible.

The direction determination works across stages (see chapter *6.9.9.1 Description*).

Phase Selection

The phase selection detects whether a 1-pole (determination of the relevant conductor) or a multiphase short circuit is present via the distribution of the currents and voltages (see section *6.9.10 Phase Selection*).

Pickup for Signal Supplement

The **Teleprotection method with ground-fault protection** function can be used to apply the stage for directional comparison protection as well. The stage provides the internal signal **`signal supplement pickup`** for this. Complete the necessary settings in the function **Teleprotection-transmission method with ground-fault protection** (see chapter *6.10.1 Overview of Functions*).

Pickup, Dropout, and Tripping Behavior of the Dependent Characteristic Curve According to IEC and ANSI

When the input variable exceeds the threshold value by a factor of 1.1, the inverse-time characteristic curve is processed. An integrating method of measurement totalizes the weighted time. This time results from the characteristic curve. For this, the time that is associated with the present current value is determined from the characteristic curve. Once the weighted time exceeds the value 1, the stage operates.

When the measured value falls short of the pickup value by a factor of 1.045 (0.95 x 1.1 x threshold value), the dropout is started. The pickup will be indicated as clearing. You can influence the dropout behavior via setting parameters. You can select between the following options:

- Non-delayed dropout: The summed time is deleted.
- Dropout according to characteristic curve: The summed time is reduced in relation to the characteristic curve.

The dropout according to characteristic curve (disk emulation) is the same as turning back a rotor disk. The weighted reduction of the time is initiated from 0.9 of the set threshold value.

The characteristic curve and associated formulas are shown in the Technical Data.

The execution of the characteristic curve after exceeding 1.1 times the threshold value can be delayed by a constant time (**`Additional time delay`** parameter).

Blocking of the Stage Pickup

The following blockings suppress the pickup of the stage and fully reset the picked up stage:

- Externally or internally via the binary input signal **`>Block stage`** (see also *Figure 6-187* and *Figure 6-187*)
- Via the functionality of the dynamic settings (see section *6.9.13.1 Description*)
  The blocking cause is indicated.

Blocking of the Tripping by Pickup of the Differential Protection Function

The pickup of the main protection function (differential protection) can block the stage tripping. You can perform this setting via 2 parameters:

- Parameter **`Blocking by`**
  This parameter is used to select the differential at whose pickup the blocking is to occur.
- Parameter **`Blocking by prot. pickup`**
  The parameter is also used to set whether blocking is to occur upon pickup of the main protection. This also applies if you have selected one or more zones/stages from the **`Blocking by`** parameter.

Blocking of the Tripping via the Device-Internal Inrush-Current Detection Function

Blocking of the tripping via the device-internal inrush-current detection is described in section *6.9.11.1 Description*.

Influence of Other Functions via Dynamic Settings

If the following functions are present in the device, they can affect the dynamic settings **`Threshold`** and **`Time dial`** of the level:

- Automatic reclosing
- Cold-load pickup detection
- Binary input signal

The influence of these functions via dynamic settings is described in chapter *6.9.13.1 Description*.

6.9.5.2 Application and Setting Notes

Stage-Type Selection

If the tripping delay is to be dependent on the current stage according to the IEC or ANSI standard, select this type of stage.

Parameter: Blocking by the Main Protection

- Default setting **(_:140) Blocking by** = none
- Default setting **(_:131) Blocking by prot. pickup** = ***every pickup***

If you wish to give the selective fault clarification by the main protection function (for example, differential protection) priority over tripping by ground-fault protection, you can define this via both parameters. The **Blocking by** parameter is used to select the zones or levels of the main protection function(s), upon whose pickup the ground-fault protection is to be blocked.

The **Blocking by prot. pickup** parameter is used to set whether a blocking of the tripping is to be activated upon excitation of the main protection.

Parameter Value	Description
every pickup	Blocking at every pickup
no pickup	No blocking at pickup of the main protection function

Parameter: Directional mode

- Default setting **(_:115) Directional mode** = ***non-directional***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
non-directional	If the stage is to work in the forward and reverse direction (in the direction of the line and busbar), then select this setting. The stage also works with this setting if no direction measurement is possible, for example, owing to lower or no polarization voltage.
forward	Select these settings if the stage is only to work in a forward direction (in direction of the line).
reverse	Select this setting if the level is only to work in the reverse direction (in the direction of the busbar).

Parameter: Method of measurement

- Recommended setting value **(_:8) Method of measurement** = ***1-cycle filter***

Use the **Method of measurement** parameter to define whether the measurand is determined via a 1 or 2 cycle filter.

Parameter Value	Description
1-cycle filter	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.
2-cycle filter	To implement a particularly strong attenuation of harmonics and transient faults, select the setting 2 cycle filter. Please note that in this case the pickup time of the tripping level increases slightly (see Technical specifications).

Parameter: Stabilization with phase currents

- Recommended setting value **(_:112) Stabiliz. w. phase current** = ***10*** **%**

In grounded systems, unbalanced line and load ratios cause a residual current in normal operational applications. Likewise, different current-transformer faults lead to a secondary residual current. The amplitude of this undesirable residual current increases as the phase current increases. An undesirable residual current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases as phase currents rise. You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

Siemens recommends a setting of 10% under normal conditions.

Dynamic Parameter: Threshold

- Default setting **(_:3) Threshold** = ***1500 A***

Define the pickup value corresponding to the application.

At a very sensitive setting, you must ensure that a residual current due to unbalance (for example, untwisted line) does not cause the level to respond.

Parameter: Type of character. curve

- Default setting **(_:133) Type of character. curve** = ***IEC normal inverse***

Select the type of characteristic curve specified for the system. The characteristic curves and the associated formulas are shown in the Technical Data.

Dynamic Parameter: Time dial

- Default setting **(_:106) Time dial** = ***1.00***

The time multiplier is derived from the grading chart for ground faults established for the system.

When selecting the current and time setting, note whether stage tripping is direction-dependent and whether signal transmission is used. See also section *6.10.2 Structure of the Function*.

If you use a stage direction independently and with signal transmission, it can also have a non-delayed effect during the release process. Parameterize a short delay for the blocking method equal to the signal-transmission time plus a reserve of approx. 20 ms.

Parameter: Additional time delay

- Recommended setting value **(_:132) Additional time delay** = ***0 s***

This additional delay is intended for special applications.

Siemens recommends setting this time to 0 so that it has no effect.

Parameter: Reset

- Default setting **(_:134) Reset** = ***instantaneous***

You use the **Reset** parameter to define whether the stage drops out according to the dropout characteristic curve (in accordance with the behavior of a disk emulation = rotor disk) or instantaneously.

Parameter Value	Description
disk emulation	Use this setting if the device is coordinated with electromechanical devices or other devices, performing a dropout after disk emulation.
instantaneous	Use this setting if the dropout is not to be performed after disk emulation and an instantaneous dropout is desired instead.

6.9.6 Stage with Inverse-Time Overcurrent Protection with Logarithmic-Inverse Characteristic Curve

6.9.6.1 Description

Logic of the Stage

[loggfp33-300511-01.tif, 1, en_US]

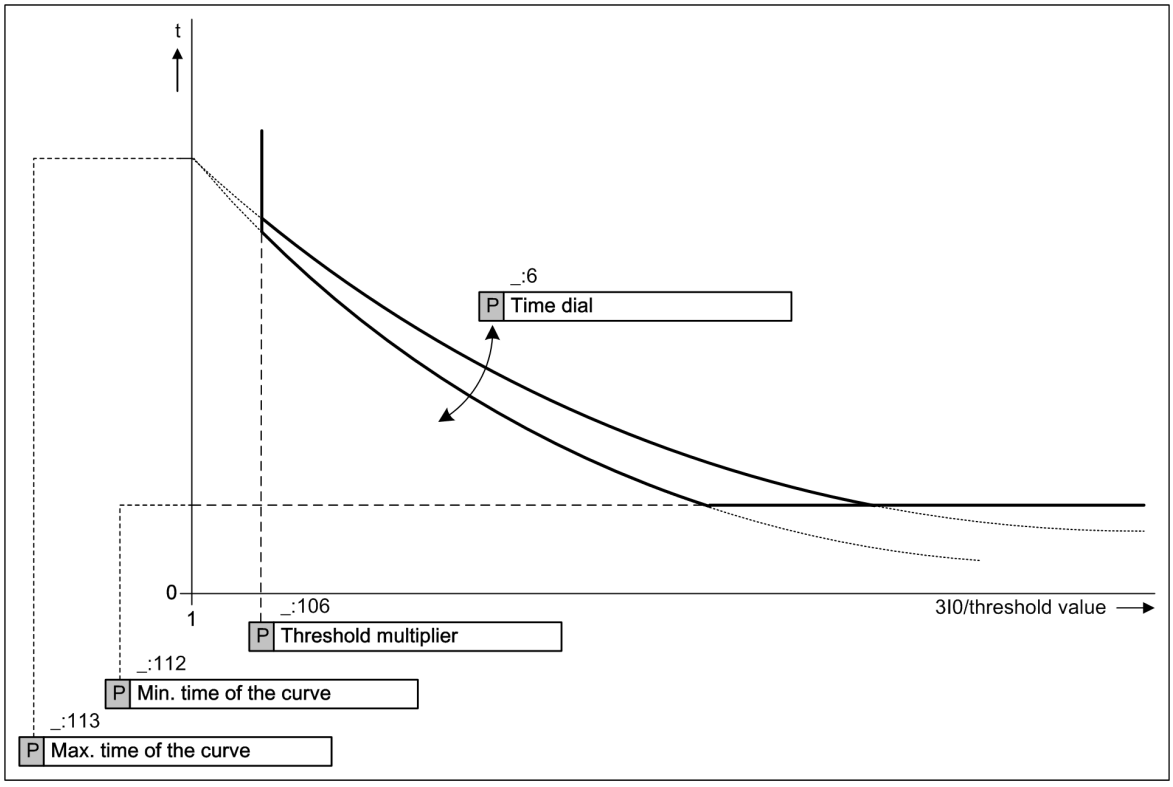

Figure 6-193 Logic Diagram for Ground-Fault Protection with Inverse Time-Overcurrent Protection with Logarithmic Inverse Characteristic Curve (AMZ-3I0-Log)

Apart from the operate curve, this type of stage is identical to the ground-fault protection type with inverse time-overcurrent protection according to IEC and ANSI (AMZ-3I0-IEC/ANSI) (see section *6.9.5.1 Description*). This section will only discuss the nature of the operate curve. For the further functionality, Siemens refers to section *6.9.5.1 Description* .

Operate Curve

Figure 6-194 shows the effect of the characteristic curve parameters qualitatively.

The **Threshold** parameter setting is the reference value for all current values. At the same time, the **Threshold multiplier** parameter maps the beginning of the characteristic curve, that is, the lower operating range on the current axis in relation to the threshold value. The time value **Max. time of the curve** determines the initial value of the characteristic curve (for 3I0 = threshold value). The **Time dial** parameter changes the slope of the characteristic curve. At high currents, the **Min. time of the curve** parameter indicates the lower time limit.

[loggfp04-030810-01.tif, 1, en_US]

Figure 6-194 Operate Curve

6.9.6.2 Application and Setting Notes

Apart from the characteristic curve, this type of stage is identical to the ground-fault protection type with inverse-time delay according to IEC and ANSI (AMZ-3I0-IEC/ANSI) (see section *6.9.5.1 Description*).

This section will only discuss the nature of the operate curve. For the further functionality, Siemens refers to section *6.9.5.2 Application and Setting Notes* .

Stage-Type Selection

If the operate delay is to be dependent on the current stage according to a logarithmic characteristic curve, select this stage type.

Dynamic Parameter: Threshold

- Default setting **(_:3) Threshold** = ***1500 A***

Define the pickup value corresponding to the application. In doing so, for the time-graded stages, the setting for the superordinate and subordinate stages must be taken into account in the grading chart.

Parameter: Threshold multiplier

- Default setting **(_:106) Threshold multiplier** = ***1.1***

You can use the **Threshold multiplier** parameter to define the beginning of the characteristic curve on the current axis (in relation to the threshold value).

General information cannot be provided. Define the value corresponding to the application.

Dynamic Parameter: Time dial

- Default setting **(_:106) Time dial** = ***300 ms***

You can use the **Time dial** parameter to change the slope of the characteristic curve.
General information cannot be provided. Define the value corresponding to the application.

Parameter: Max. time of the curve

- Default setting **(_:113) Max. time of the curve** = ***1.200 s***

The time value **Max. time of the curve** determines the initial value of the characteristic curve (for 3I0 = **Threshold**).
General information cannot be provided. Define the value corresponding to the application.

Parameter: Min. time of the curve

- Default setting **(_:112) Min. time of the curve** = ***1.200 s***

The time value **Min. time of the curve** determines the lower time limit (at high currents).
General information cannot be provided. Define the value corresponding to the application.

6.9.7 Stage with S0 Characteristic Curve

6.9.7.1 Description

Logic of the Stage

[loggfp34-160611-01.tif, 2, en_US]

Figure 6-195 Logic Diagram for Ground-Fault Protection with Zero-Sequence Power-Dependent Delay (S0 Inverse)

Apart from the operate curve, this type of stage is identical to the ground-fault protection type with inverse time-overcurrent protection according to IEC and ANSI (AMZ-3I0-IEC/ANSI) (see section *6.9.5.1 Description*).

This section will only discuss the nature of the operate curve. For the further functionality, Siemens refers to section *6.9.5.1 Description* .

Operate Curve

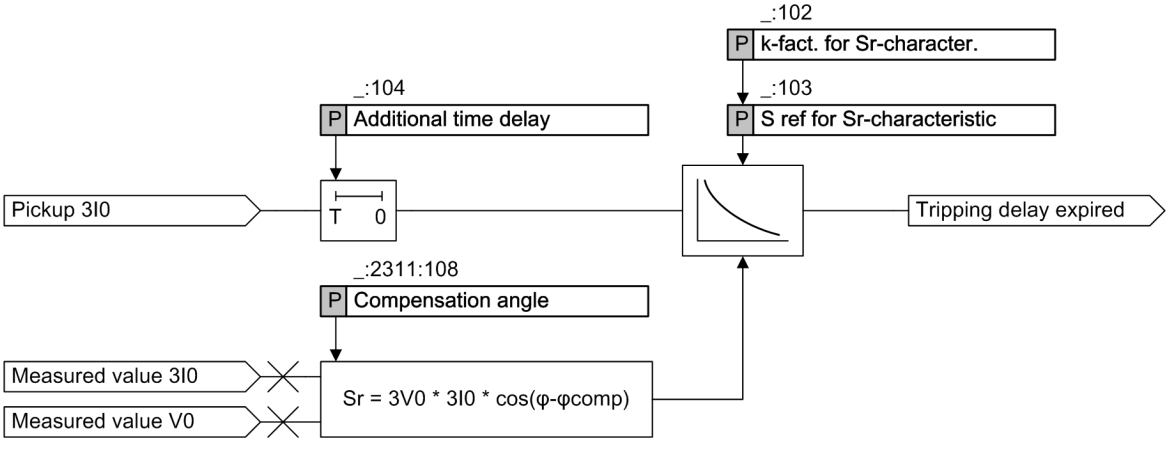
Figure 6-196 shows the operate curve of the stage.

The zero-sequence system power protection operates according to a power-dependent operate curve.

The zero-sequence system power is calculated from the zero-sequence voltage and the zero-sequence system current. The Sr component in the direction of an adjustable compensation angle φ_{comp} is definitive. This component is designated as a compensated zero power:

$S_r = 3I0 \cdot 3V0 \cdot \cos(\varphi\text{-}\varphi_{comp})$ with $\varphi = \varphi_{V0} - \varphi_{I0}$

φ_{comp} therefore indicates the direction of maximum sensitivity ($\cos(\varphi - \varphi_{comp}) = 1$, if $\varphi = \varphi_{comp}$). The power calculation automatically contains the direction via its sign information. Reversing the signs also allows the power for the reverse direction to be determined. *Figure 6-202* represents the direction-characteristic curve.



The operate time results according to the equation:

$$t = k \cdot \frac{S_{ref}}{S_r}$$

[fogfp003-300511-01.tif, 1, en_US]

The power-time characteristic curve can be shifted with the reference value S_{ref} (**`S ref for Sr-charac-teristic`** = basic value for the inverse characteristic curve for $\varphi = \varphi_{comp}$) in power direction. The power-time characteristic curve can be shifted in the time direction by the factor **`k-fact. for Sr-character.`**.

You can set additional power-dependent delays with the time setting **`Additional time delay`**.

[loggfp11-250111-01.tif, 1, en_US]

Figure 6-196 Operate Curve

6.9.7.2 Application and Setting Notes

Apart from the characteristic curve, this type of stage is identical to the ground-fault protection type with inverse-time delay according to IEC and ANSI (AMZ-3I0-IEC/ANSI) (see section *6.9.5.1 Description*).

This section will only discuss the nature of the operate curve. For the further functionality, Siemens refers to section *6.9.5.2 Application and Setting Notes* .

Stage-Type Selection

If the tripping delay is to be dependent on the zero power according to an inverse characteristic curve, select this stage type.

Parameter: Compensation angle

- Default setting **`(_:2311:108) Compensation angle`** = ***255°***

The **Compensation angle** setting is used to define the direction of maximum sensitivity.

General information cannot be provided. Define the value corresponding to the application.

Parameter: k-fact. for Sr-character.

- Default setting **(_:102) k-fact. for Sr-character.** = ***0.500 s***

The **k-fact. for Sr-character.** parameter can be used to shift the power-time characteristic curve on the time line.

General information cannot be provided. Define the value corresponding to the application.

Parameter: S ref for Sr-characteristic

- Default setting **(_:103) S ref for Sr-characteristic** = ***10 VA***

The **S ref for Sr-characteristic** parameter can be used to shift the power-time characteristic curve on the power axis.

General information cannot be provided. Define the value corresponding to the application.

Parameter: Additional time delay

- Default setting **(_:104) Additional time delay** = ***1.200 s***

You can set additional power-dependent delays with the **Additional time delay** parameter.

General information cannot be provided. Define the value corresponding to the application.

6.9.8 Stage with U0 Characteristic Curve

6.9.8.1 Description

Logic of the Stage

[lo gfp stage V0 invers 3-ph, 1, en_US]

Figure 6-197 Logic Diagram for Ground-Fault Protection with Zero-Sequence Voltage-Dependent Delay (V0 inverse)

Measurands

The device measures the residual voltage. The measured voltage is converted to the zero-sequence voltage $\underline{V}_0$. If the residual voltage is not available to the device as a measurand from the broken-delta winding, the zero-sequence voltage $\underline{V}_0$ is calculated from the measured phase-to-ground voltages $\underline{V}_A$, $\underline{V}_B$, and $\underline{V}_C$ using the definition equation:

$$\underline{V}0 = \frac{1}{3}\left(\underline{V}_A + \underline{V}_B + \underline{V}_C\right)$$

[fo_U0 nullspannung, 1, en_US]

The zero-sequence current is used as a measurand. Based on its definition equation, the zero-sequence current is derived from the sum of the 3 phase currents:

$$3\underline{I}0 = \underline{I}_A + \underline{I}_B + \underline{I}_C$$

[fo_I0 nullstrom, 1, en_US]

Depending on the use of the current inputs of the device, the zero-sequence current can be measured or calculated.

If you connect a current input to the neutral-point feed of the current transformer or to a separate ground-current transformer of the line to be protected, the ground current (zero-sequence current) will be directly available to the device.

If the device is equipped with a sensitive current input I_{Nsens}, the device will use this current. The linear range of this measuring input ends at an amplitude of approx. 1.6 A. At higher currents, the device automatically switches to analysis of the zero-sequence current calculated from the phase currents.

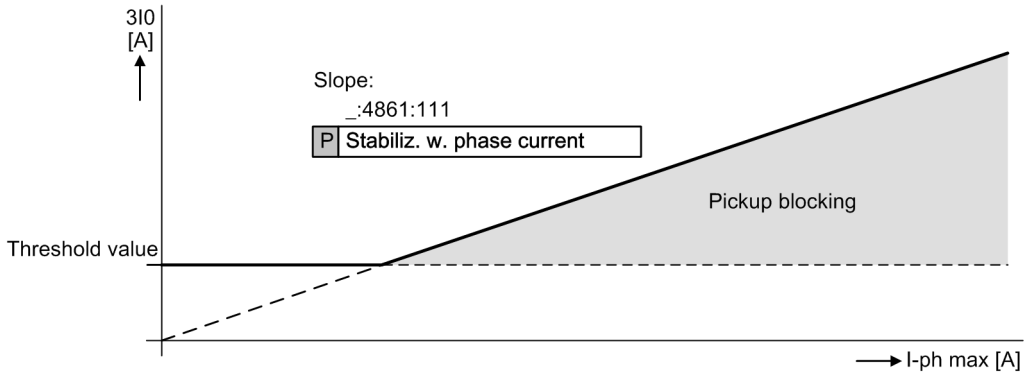
If the ground current is not present in the device as a directly measured variable, the device will calculate the zero-sequence current from the phase currents.

Method of Measurement

The **`Method of measurement`** parameter is used to select the relevant measuring procedure, depending on the application:

- Measurement of the fundamental component via 1-cycle filter (standard filter)

  This measuring procedure processes the sampled current values and filters out the fundamental component numerically.



- Measurement of the fundamental component via 2-cycle filter

  This measuring procedure processes the sampled current values and filters out the fundamental component numerically. Harmonics and transient faults are damped particularly strongly over the extended filter length in comparison to the standard filter. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see Technical specifications).

Stabilization with Phase Currents

In grounded systems, unbalanced line and load ratios cause a zero-sequence current in normal operational applications. Likewise, different current-transformer errors lead to a secondary zero-sequence current. The amplitude of this undesirable zero-sequence current increases as the phase current increases. An undesirable zero-sequence current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases with rising phase currents (see next figure).

You can change the stabilization factor (= gradient) via the **`Stabiliz. w. phase current`** parameter.

[logfpsta-030311-01.tif, 1, en_US]

Figure 6-198 Stabilization with Phase Currents

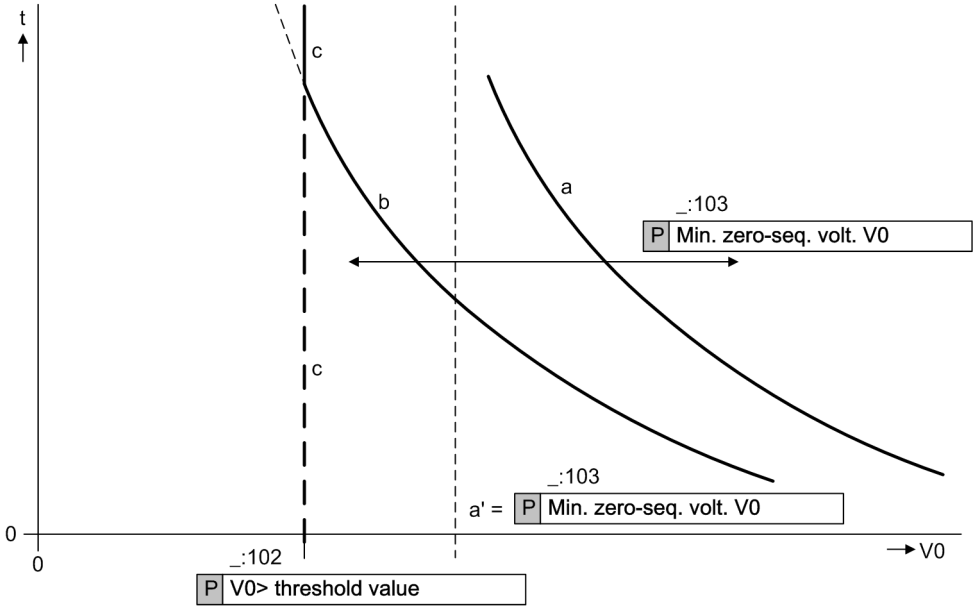
Directional mode

You use the **`Directional mode`** parameter to define whether the stage works in a forward or reverse direction. Non-directional operation is also possible.

The direction determination works across stages (see *6.9.9.1 Description*).

Voltage-Dependent Operate Curve

The voltage-dependent operate curve is based on the following formula:



$$t = \frac{2\ s}{0.25 \cdot V_0/[V] - V_{0\,min}/[V]}$$

[fo_U0 kennl, 1, en_US]

with

V_0	Actually occurring zero-sequence voltage
$V_{0\,min}$	Setting value of the parameter **`Min. zero-seq. volt. V0`**

The following figure shows the voltage-dependent characteristic curve of the **V0 inverse** stage:

[dw-GFP-kennl, 1, en_US]

Figure 6-199 Parameter of the Voltage-Dependent Characteristic Curve of the V0 Inverse Stage (without Additional Times)

The operate time depends on the value of the zero-sequence voltage. In meshed, grounded systems, the zero-sequence voltage increases towards the point of the ground fault. Due to the inverse characteristic curve, the operate time decreases with rising zero-sequence voltage.

The **V0> threshold value** parameter defines the lower voltage limit (dotted line **c** in *Figure 6-199*). The lower voltage limit **c** cuts off the characteristic curve **b**.

The **Min. zero-seq. volt. V0** parameter shifts the voltage-dependent characteristic curves in the direction of V0.

The **Time delay directional** parameter shifts the voltage-dependent characteristic curves in the direction of time.

The setting value of the **Min. zero-seq. volt. V0** parameter is the asymptote **a´** of characteristic curve **a** for $t \rightarrow \infty$.

Processing the inverse characteristic curve after exceeding the threshold value **V0> threshold value**, can be delayed by the time set in the **Time delay directional** parameter.

Blocking of the Stage Pickup

In the event of blocking, the picked up stage will be reset. Blocking is possible externally or internally via the binary input signal **>Block stage** (see also *Figure 6-188*).

Blocking the Tripping via the Device-Internal Inrush-Current Detection Function

Blocking of the tripping via the device-internal inrush-current detection is described in *6.9.11.1 Description*.

6.9.8.2 Application and Setting Notes

Stage-Type Selection

If the tripping delay is to be dependent on the zero-sequence voltage according to an inverse characteristic curve, select this stage type.

Parameter: Directional mode

- Default setting **(_:108) Directional mode** = ***forward***

You use the **Directional mode** parameter to define the directional mode of the stage.

Parameter Value	Description
forward	Select this setting if the stage is only to work in a forward direction (in direction of the line).
reverse	Select this setting if the stage is only to work in the reverse direction (in the direction of the busbar).
non-directional	Select this setting if the stage is to work in the forward and reverse direction (in the direction of the line and busbar). The stage also works with this setting if no direction measurement is possible, for example, owing to lower or no polarization voltage.

Parameter: Method of measurement

- Default setting **(_:8) Method of measurement** = ***1-cycle filter***

Use the **Method of measurement** parameter to define whether the measurand is determined via a 1- or 2-cycle filter.

Parameter Value	Description
1-cycle filter	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.
2-cycle filter	To implement a particularly strong attenuation of harmonics and transient faults, select the setting 2-cycle filter. Note that in this case, the pickup time of the stage increases slightly (see Technical specifications).

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:109) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the **V0-inverse stage** is blocked or not blocked during the detection of the transformer inrush current.

The **Blk. w. inrush curr. detect.** parameter is visible only when the **Inrush-current detection** function is available in the application.

Related Topics

6.9.11.2 Application and Setting Notes

Parameter: Blocking by the Main Protection

- Default setting **(_:140) Blocking by** = none
- Default setting **(_:111) Blocking by prot. pickup** = ***every pickup***

If you wish to give the selective fault clarification by the main protection function (for example, differential or distance protection) priority over tripping by ground-fault protection, you can define this via both parameters. The **Blocking by** parameter is used to select the zones or stages of the main protection function(s), upon whose pickup the ground-fault protection is to be blocked.

The **Blocking by prot. pickup** parameter can be used to define the type of pickup, which leads to the blocking.

Parameter Value	Description
every pickup	Blocking at every pickup
no pickup	No blocking at pickup of the main protection function

Parameter: Hold mode 1p dead time

- Default setting **(_:106) Hold mode 1p dead time** = ***0.040 s***

With the **Hold mode 1p dead time** parameter you define the time by which the behavior during a 1-pole dead time is extended.

At all line ends, there is no simultaneous switch-in after a 1-pole dead time. Thus, the device-internal signal for a 1-pole dead time must be retained for a certain time after the switch-in (end of the 1-pole dead time) until the other end or ends have securely switched in. The time to be set here corresponds to the maximum time between the connection of the 1st circuit breaker and the connection of the last circuit breaker at all ends of the feeder after a 1-pole dead time.

Parameter: Stabiliz. w. phase current

- Default setting **(_:105) Stabiliz. w. phase current** = ***10 %***

In grounded systems, unbalanced line and load ratios cause a residual current in normal operational applications. Likewise, different current-transformer faults lead to a secondary residual current. The amplitude of this undesirable residual current increases as the phase current increases. An undesirable residual current can lead to false pickup and unwanted tripping at low setting values for the ground-current stages. To avoid false pickup and unwanted tripping, the ground-current stages are stabilized with the phase currents. The threshold value increases as phase currents rise. You can change the stabilization factor (= gradient) via the **Stabiliz. w. phase current** parameter.

Siemens recommends a setting of 10 % under normal conditions.

Parameter: Threshold 3I0

- Default setting **(_:101) Threshold 3I0** = ***1.000 A***

With the **Threshold 3I0** parameter, you define the pickup value for the zero-sequence current. Set the **Threshold 3I0** lower than the minimum ground-fault current.
Define the pickup value corresponding to the application.

Parameter: V0> threshold value

- Default setting **(_:102) V0> threshold value** = ***1.667 V***

With the **V0> threshold value** parameter, you set the lower voltage limit of the voltage-dependent operate curve (see *Figure 6-199*). The lower voltage limit cuts off the characteristic curve.

Parameter: Min. zero-seq. volt. V0

- Default setting **(_:103) Min. zero-seq. volt. V0** = ***0.200 V***

With the **Min. zero-seq. volt. V0** parameter, you shift the voltage-dependent characteristic curves in the direction of V0 (see *Figure 6-199*).

Parameter: Time delay directional

- Default setting **(_:104) Time delay directional** = ***0.90 s***

With the **Time delay directional** parameter, you shift the voltage-dependent characteristic curve in the direction of time (see *Figure 6-199*).

Parameter: Time delay non-direct.

- Default setting **(_:112) Time delay non-direct.** = ***1.20 s***

With the **Time delay non-direct.** parameter, you can set additional direction-independent time delays. The level of the zero-sequence voltage does not affect the previously set time delay.
Define the value corresponding to the application.

6.9.9 Direction Determination

6.9.9.1 Description

The direction determination works across stages. Various methods are available for determining the direction and for increasing the accuracy of the determination.

The following diagram shows which variables and settings are used for direction determination.

[logfpri1-010311-01.tif, 1, en_US]

Figure 6-200 Logic Diagram for Direction Determination

Method for Direction Determination

Use the **Direct. determination with** parameter to define the method and variables with which the direction determination works:

- ***V0 + IY or V2 + I2*** (direction determination with zero-sequence system/transformer neutral-point current or negative-sequence system)
- ***V0 + IY (neutral pt.)*** (direction determination with zero-sequence system/transformer neutral-point current)
- ***IY (neutral pt.) only*** (direction determination with transformer neutral-point current)
- ***V2 + I2 (neg. seq.)*** (direction determination with negative-sequence system)
- ***zero-sequence power*** (direction determination with zero-system power)

The individual methods are described in more detail below.

The device automatically selects a suitable method with the ***V0 + IY or V2 + I2*** setting.

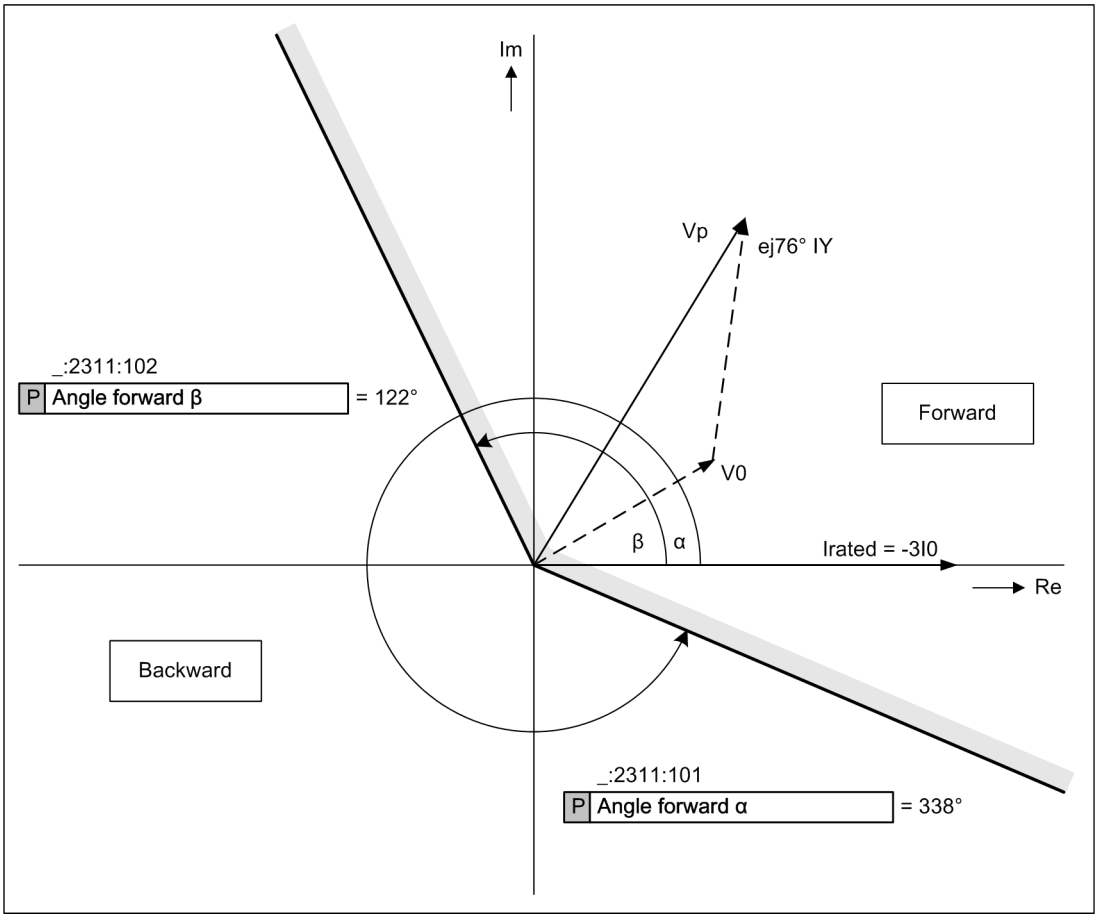
Direction Determination with Current/Voltage Zero-Sequence Variables/Transformer Neutral-Point Current

The forward and backward area is defined by the 2 parameters **Angle forward β** and **Angle forward α** (see also *Figure 6-202*). The reference for the 2 angles that must be set is the positive real axis. The angles are defined positively in a mathematical sense (that is, counterclockwise). The area between the limit angle α, starting in a mathematically positive direction, and the limit angle β is the forward area. The remaining area is the backward area.

The direction is determined from the measuring current I_N and a reference voltage Vp. If no transformer neutral-point current is connected to the device, the reference voltage Vp is the zero-sequence voltage V0.

The zero-sequence voltage is calculated from its definition equation:

$$\underline{V}0 = \frac{1}{3}\left(\underline{V}_A + \underline{V}_B + \underline{V}_C\right)$$



Depending on the device connection, it is measured or calculated. If a voltage input is connected at the broken-delta winding V_{dadn} of a voltage-transformer set, the device will use this voltage with consideration of the **Matching ratio Vph / VN** (see *8.3.7.3 Function Description*). Otherwise the device calculates the zero-sequence voltage from the phase-to-ground voltages.

If the neutral-point current IY of a grounded transformer (supply transformer) is connected, the reference voltage V_P is the sum of the zero-sequence voltage V0 and a variable proportional to the neutral-point current IY (see *Figure 6-201*). This corresponds to 20 V at the rated current. With the setting ***IY (neutral pt.) only***, V_P is only derived from the transformer neutral-point current.

To determine the direction, the device sets the measuring current I_N (= -3I0) to the real axis. If the phasor of the reference voltage V_P is within the defined forward area, the device determines the direction as **forward**. In other cases, the device determines the direction as **backward**.

As a prerequisite for direction determination, the adjustable minimum variables for the zero-sequence voltage or the transformer neutral-point current must be exceeded (parameters **Min. zero-seq. voltage V0** and **Min. neutral-point curr. IY**).

If the device detects a fault in the voltage-transformer secondary circuit, the direction determination is prevented with V0. If the transformer neutral-point current is connected to the device, the direction can be determined via this.

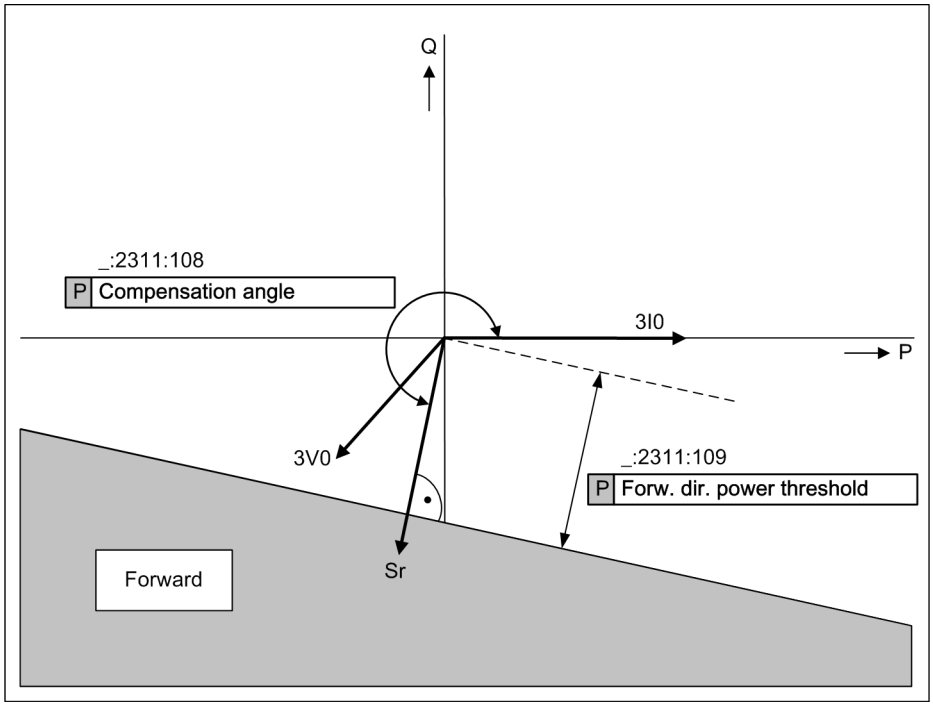
[logfpri2-010311-01.tif, 1, en_US]

Figure 6-201 Phasor Diagram for Direction Determination with Zero-Sequence System Variables

Direction Determination with Negative-Sequence System Variables

This method works in the same way as the direction determination with zero-sequence system current and zero-sequence system voltage. Instead of 3I0 and V0, the negative-sequence system variables I2 and V2 are used for the measurement. These measurands must also have a **`Min. neg.-seq. voltage V2`** and a **`Min. neg.-seq. current I2`**.

Direction Determination with Zero-Sequence System Power



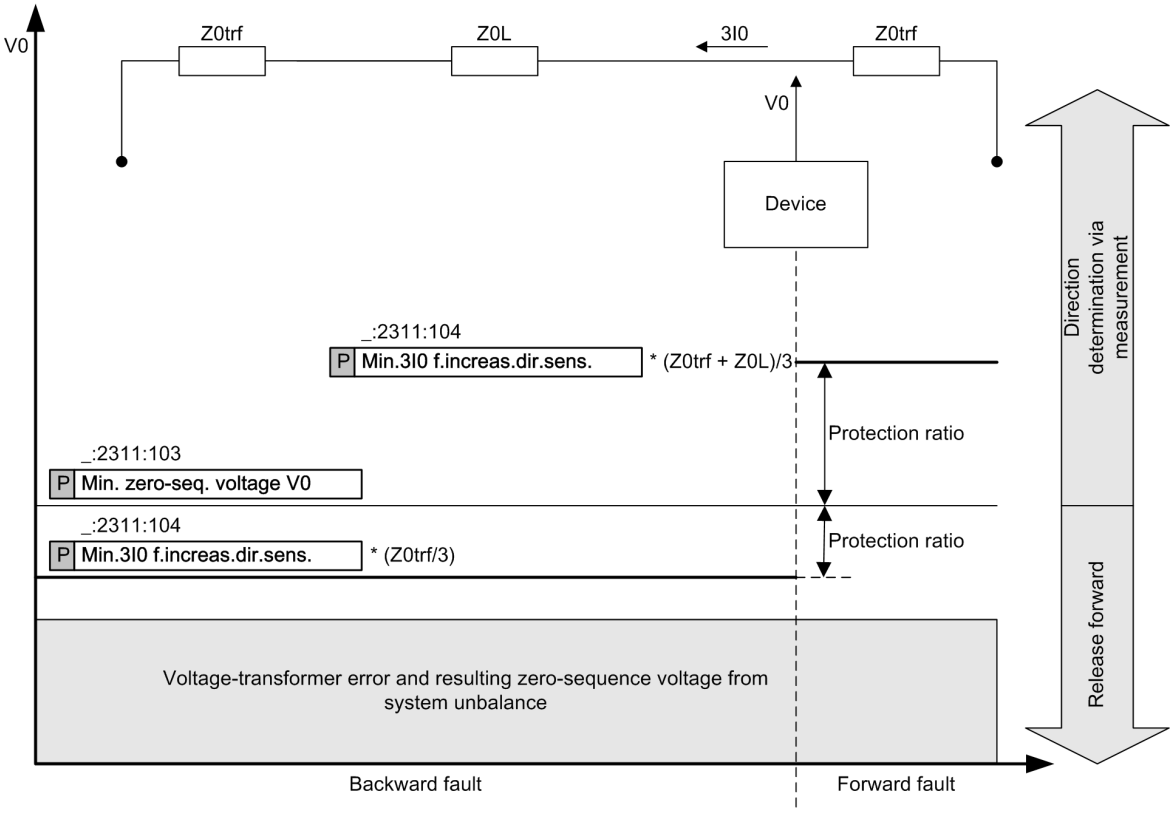
The zero-sequence system power can also be used for the direction determination. The sign of the compensated zero-sequence system power is then crucial. This is the component mentioned in *6.9.7.1 Description* under operate curve S_r of the zero-sequence system power in the direction of an adjustable compensation angle φ_{comp}, that is, $S_r = 3I0 \cdot 3V0 \cdot \cos(\varphi - \varphi_{comp})$.

The direction determination yields:

- Forward, if S_r positive and $|S_r| >$ **`Forw. dir. power threshold`**
- Backward, if S_r negative and $|S_r| >$ **`Forw. dir. power threshold`**

Determining the direction requires a minimum residual voltage that can be set as **`Min. zero-seq. voltage V0`**. Another prerequisite is that the compensated zero power must have an adjustable minimum value (parameter **`Forw. dir. power threshold`**). If the device detects a fault in the voltage-transformer secondary circuit (binary input of voltage transformer miniature circuit breaker dropped out, measuring-voltage failure detection) or a 1-pole dead time, the direction determination is prevented.

The following figure shows an example of the direction-characteristic curve.



[logfpri4-010311-01.tif, 1, en_US]

Figure 6-202 Direction-Characteristic Curve for Direction Determination with Zero-Sequence System Power

Increased Directional Sensitivity at Low V0 Voltage

The following figure shows the principle for increasing the directional sensitivity.

[logfpri5-010311-01.tif, 1, en_US]

Figure 6-203 Principle of Increased Directional Sensitivity at Low V0 Voltage

The V0 voltage at a ground fault with direction = backward is determined with the following equation:

$V0_{F0=backward} = I0 \cdot (Z0_{trf} + Z0L)$

This equation can be used to determine a I0 threshold with corresponding V0 threshold. If the I0 threshold is exceeded, the measured V0 voltage at a backward fault must exceed the corresponding V0 threshold. If the I0 threshold is exceeded and the measured V0 voltage is less than the V0 threshold, the direction = forward can thus be determined.

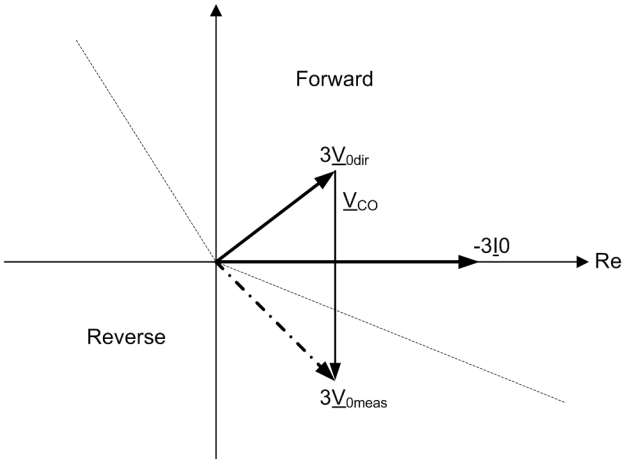
The method can improve the directional sensitivity in the case of long lines (large Z0L).

Switch on this functionality via the **`Dir.reslt=forw.at V0<min`** parameter.

If the measured V0 voltage falls below the minimum value **`Min. zero-seq. voltage V0`** and 3I0 exceeds the current threshold **`Min.3I0 f.increas.dir.sens.`**, the decision is for forward.

Direction Determination for Lines with Series Compensation

The direction determination/direction-characteristic curve of the ground-fault protection is based on the assumption of a mainly inductive zero-sequence impedance. In case of a series-compensated line this assumption does not apply anymore. According to the degree of compensation, the zero-sequence impedance is more or less influenced regarding its capacity. If the capacitor is located on the busbar side of the voltage transformer the situation is especially unfavorable.



In case of a series compensation on the line you can adjust the direction of the measured zero-sequence voltage V_{0meas}. Perform the adjustment with the **`Dir.corr.at ser.comp.lines`** parameter. Set the data necessary for the adjustment (reactance of the capacitor bank) in the function group **Line** (see chapter *5.5.3 Application and Setting Notes*).

In case of faults on the protected line, the zero-sequence voltage with series compensation consists of 2 components: the voltage drop on the source impedance (mainly inductive) and the voltage drop on the series capacitor.

If the capacity of the series capacitor is known (and constant), the voltage drop on the series capacitor can be determined according to the following formula:

$\underline{V}_{C0} = -jX_{C0} \cdot 3\underline{I}_0$ with

X_{C0} Parameter **`Series capacit. reactance`** in the function group **Line**

[dw_corr_series_comp_direction_with-0, 1, en_US]

Figure 6-204 Adjustment of the Series Compensation for Direction Determination with Zero-Sequence System

The voltage drop on the series capacitor $\underline{V}_{C0}$ is subtracted from the measured voltage $3\underline{V}_{0meas}$. The resulting voltage $3\underline{V}_{0Dir}$ is then assigned to the direction-characteristic curve of the ground-fault protection (see *Figure 6-204*).

6.9.9.2 Application and Setting Notes

Parameter: Direct. determination with

- Recommended setting value **(_:2311:114) Direct. determination with** = ***V0 + IY or V2 + I2***

NOTE

If you use a teleprotection scheme with ground-fault protection, you must ensure that the direction measurement at all line ends is carried out using the same procedure. The setting for parameter **Direct. determination with** must be the same. If a device is used at a line end that does not have all the setting options, then you must limit the direction measurement to a single procedure that is possible at all line ends, for example, only V0 (setting option ***V0 + IY (neutral pt.)***).

Parameter Value	Description
V0 + IY or V2 + I2	The default setting ***V0 + IY or V2 + I2*** is universal. The device automatically selects the best (largest) measured value for direction determination. You can also use this setting if the transformer neutral-point current IY is not connected to the device. Siemens recommends using this setting (see note on Teleprotection Scheme).
V0 + IY (neutral pt.)	If the direction determination is to be deliberately excluded via negative-sequence variables (V2 and I2), select this setting. You can also use this setting irrespective of whether the transformer neutral-point current IY is connected to the device or not. If the transformer neutral-point current is not connected to the device, the direction measurement only operates with V0. For the teleprotection scheme, it can be necessary to carry out the direction measurement with the zero-sequence system alone if a device only provides this option at the opposite end.
IY (neutral pt.) only	This setting can be advisable if a transformer neutral-point current IY is reliably available at the device input at any time. The direction determination is then not affected by faults in the secondary circuit of the voltage converter. It also works if there is a fault in the voltage-transformer secondary circuit. However, this setting requires that ground-fault currents are at least predominantly fed via the transformer whose neutral-point current is measured.
V2 + I2 (neg. seq.)	Select this setting if you only wish to determine the direction with the negative-sequence variables I2 and V2. If zero-sequence voltages occur during ground faults, which are too low for evaluation of the zero-sequence variables, direction determination with negative-sequence variables is advantageous. Direction determination with negative-sequence variables is also advantageous if, for example, parallel lines falsify the zero-sequence variables through mutual coupling. You can also use these settings if the zero-sequence voltage is not available in the device.
zero-sequence power	This setting is intended for special applications.

Parameter: Limit angle of the forwards range

- Recommended setting value **(_:2311:102) Angle forward β** = ***122°***
- Recommended setting value **(_:2311:101) Angle forward α** = ***338°***

You can use the **Angle forward β** and **Angle forward α** parameters to alter the position of the direction-characteristic curve for all methods based on the angular measurement between the measuring and reference value. Only the method for determining the direction via the zero-sequece power is excluded.

Siemens recommends using the default settings, as the function reliably determines the direction of ground faults with this.

Parameter: Directional Correction with Series Compensation

- Recommended setting value **(_:2311:116) Dir.corr.at ser.comp.lines** = ***no***

Parameter Value	Description
no	If no series compensation is used on the line, set this parameter to ***no***.
yes	If a series compensation is used on the line, set this parameter to ***yes***. Direction determination is then corrected using V0.

Parameter: Minimum zero-sequence voltage V0

- Default setting **(_:2311:103) Min. zero-seq. voltage V0** = ***0.15 V***

You can use the **Min. zero-seq. voltage V0** parameter to define the minimum zero-sequence voltage for the direction determination with V0. The minimum zero-sequence voltage V0 must be set greater than the maximum operational unbalance (zero-sequence system) plus voltage-transformer measuring errors. As the measuring error of the individual voltage transformers in the zero-sequence system is not added up, the critical measuring error influence is the unbalance of the primary system.

Siemens recommends observing the operational zero-sequence voltage V0 of the protected object (for example, the line) via the operational measured values of the device and providing the maximum value with a certainty of 20 %.

Min. zero-seq. voltage V0 = 1.2 · max. operational measured value of voltage zero-sequence voltage V0

Example:

Max. operational measured value of voltage zero-sequence voltage V0 = 0.5 Vsec

Min. zero-seq. voltage V0 = 1.2 0.5 V = 0.60 Vsec

The setting value refers to the zero-sequence voltage V0 according to the definition equation and not to 3V0, as with the SIPROTEC 4 devices.

Parameter: Minimum neutral point current IY

- Recommended setting value **(_:2311:105) Min. neutral-point curr. IY** = ***0.05 A***

The **Min. neutral-point curr. IY** parameter is used to set the lower threshold for the reference current from the neutral point of a supply transformer. You can set the value relatively sensitive (see recommended setting value), as the neutral-point current detection is naturally accurate.

Parameter: Minimum negative-sequence variables V2 and I2

- Recommended setting value **(_:2311:107) Min. neg.-seq. voltage V2** = ***0.7 V***
- Recommended setting value **(_:2311:106) Min. neg.-seq. current I2** = ***0.05 A***

You can use the parameters to define the minimum negative-sequence variables for determining the direction with V2 and I2. The set limiting values must not be exceeded by operational unbalances.

Parameter: Compensation angle

- Recommended setting value **(_:2311:108) Compensation angle** = ***255°***

The **Compensation angle** parameter is used to set the angle of the maximum sensitivity, $\cos(\varphi - \varphi_{comp}) = 1$, if $\varphi = \varphi_{comp}$.

The default setting 255° therefore corresponds to a zero-sequence impedance angle of 75° (255° – 180°). Siemens recommends using the default settings, as the direction of ground faults is determined reliably with this.

Parameter: Forward dir. power threshold

- Default setting **(_:2311:109) Forw. dir. power threshold** = ***0.3 VA***

You can use the **Forw. dir. power threshold** parameter to define the value of the compensated zero-sequence power, above which the direction is detected as forward. To ensure direction determination even at low zero-sequence powers, this value is to be below the reference power **S ref for Sr-characteristic** (see chapter *6.9.7.1 Description*).

Parameter: Direction result = forward at V0 < minimum zero-sequence voltage

- Default setting **(_:2311:115) Dir.reslt=forw.at V0<min** = ***no***

With long lines it can be the case that the zero-sequence voltage at a remote fault is too low on the line to be protected. This is due to the high ratio between the zero-sequence impedance of the line and the supply (source). If the setting for the **Min. zero-seq. voltage V0** parameter is fallen below, it will no longer be possible to determine the direction by angular measurement. In the case of reverse faults in long lines, the zero-sequence voltage cannot drop so sharply if the set 3I0 threshold value (**Min.3I0 f.increas.dir.sens.** parameter) is exceeded.

Parameter Value	Description
no	If the direction has to remain undetermined under the described condition and a stage pickup is not therefore possible in a directional stage, you should select the setting ***no***.
yes	If the direction has to be automatically detected as forwards under the described condition, you should select the setting ***yes***.

Parameter: Minimum zero-sequence current 3I0 for increased directional sensitivity

- Default setting **(_:2311:104) Min.3I0 f.increas.dir.sens.** = ***0.05 A***

You only have to set the **Min.3I0 f.increas.dir.sens.** parameter if the **Dir.reslt=forw.at V0<min** parameter has been set to ***yes***.

Then calculate the setting value with the following equation (see also *Figure 6-203*):

$$\text{Min.3I0 f.increas.dir.sens.} = SM \cdot \frac{3 \cdot V0}{(Z0L + Z0_{trf})}$$

[fofrbest-060110-01.tif, 1, en_US]

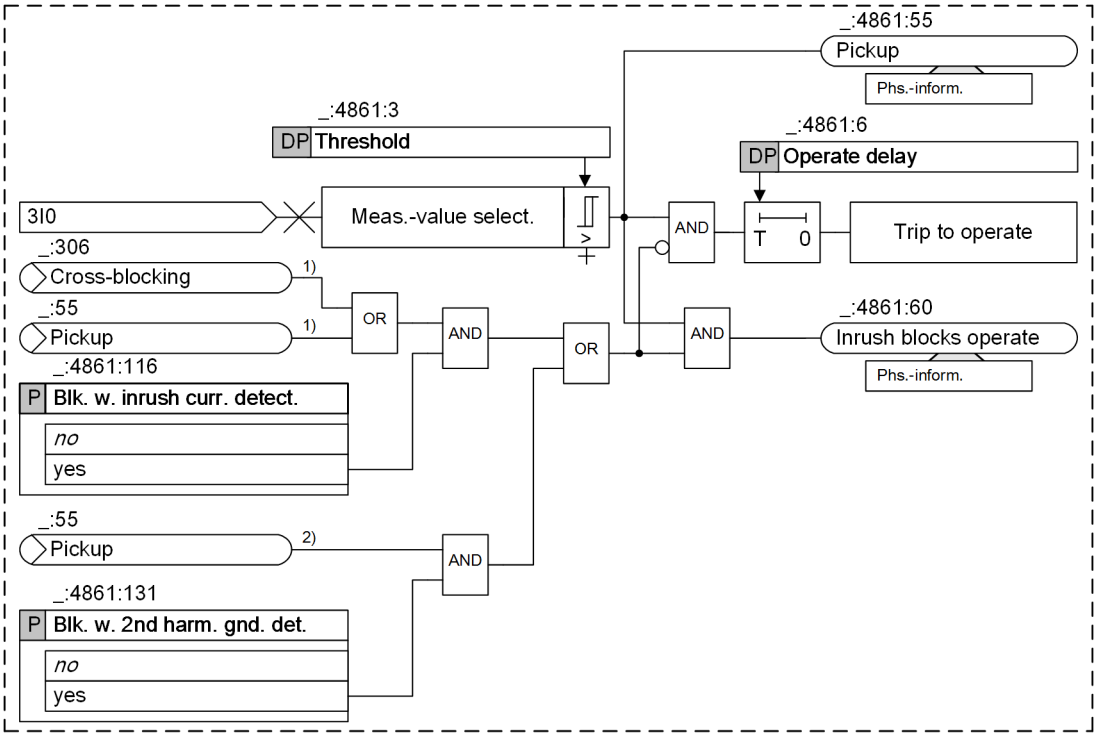
In this equation, V0 is the setting value for the **Min. zero-seq. voltage V0** parameter. SM is a reserve (for example, 1.2).

6.9.10 Phase Selection

As the ground-fault protection works with the zero-sequence or negative-sequence values, direct determination of the ground fault is not possible. The phase selection detects whether a 1-pole or multiphase short circuit has occurred with the distribution of the currents. The phase selection detects which phase is affected in the case of a 1-phase short circuit. The affected phase is reported via the pickup. The stages always initiate 3-pole tripping.

The phase selection filters the negative-sequence and the zero-sequence out of the phase currents. The fault type, that is, whether a 1-pole or multiphase short circuit has occurred, is determined from the phase displacement between the negative-sequence current and the zero-sequence current. The phase currents, purged of the load current, are also evaluated from this. This utilizes the fact that, in the case of a 1-phase short circuit, the healthy conductors can only conduct either no fault currents at all or only in-phase fault currents.

The phase selection has an action time of approx. 40 ms. If the phase selection is unable to make a decision in this time, 3-phase is signaled.



6.9.11 Blocking of the Tripping by Device-Internal Inrush-Current Detection

6.9.11.1 Description

With the **Blk. w. inrush curr. detect.** parameter, you define whether tripping of the stage should be blocked when a threshold-value violation occurs due to an inrush current. In case of a blocking, the stage picks up. The **S0 invers** and the **V0 invers** stages do not pick up. The start of the time delay and tripping are blocked. The stage signals this by way of a corresponding indication. If the blocking drops out and the threshold value of the stage is still exceeded, the time delay is started. After that time, the stage operates.

With the **Blk. w. 2nd harm. gnd. det.** parameter, you define whether the operate indication of the stage should be blocked when a threshold value is exceeded due to a detected 2nd harmonic in the ground current. If the conditions for the 2nd harmonic to ground and the start condition for the protection function have been satisfied, inrush-current blocking is active. In case of a blocking and if the start conditions have been satisfied, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

The following figure only shows the part of the stage (exemplified by the 1st definite-time overcurrent protection stage) that illustrates the influence of the inrush-current detection. The blocking can only be adjusted if the **Inrush-current detection** function is active.

[loggfp13-260111-01.tif, 2, en_US]

Figure 6-205 Part of the Logic Diagram on the Influence of Inrush-Current Detection Exemplified by the 1st Definite-Time Overcurrent Protection Stage

(1) From the function block Inrush-current detection

(2) From the function block 2nd harmonic detection ground

6.9.11.2 Application and Setting Notes

Parameter: Blocking w. inrush-current detection

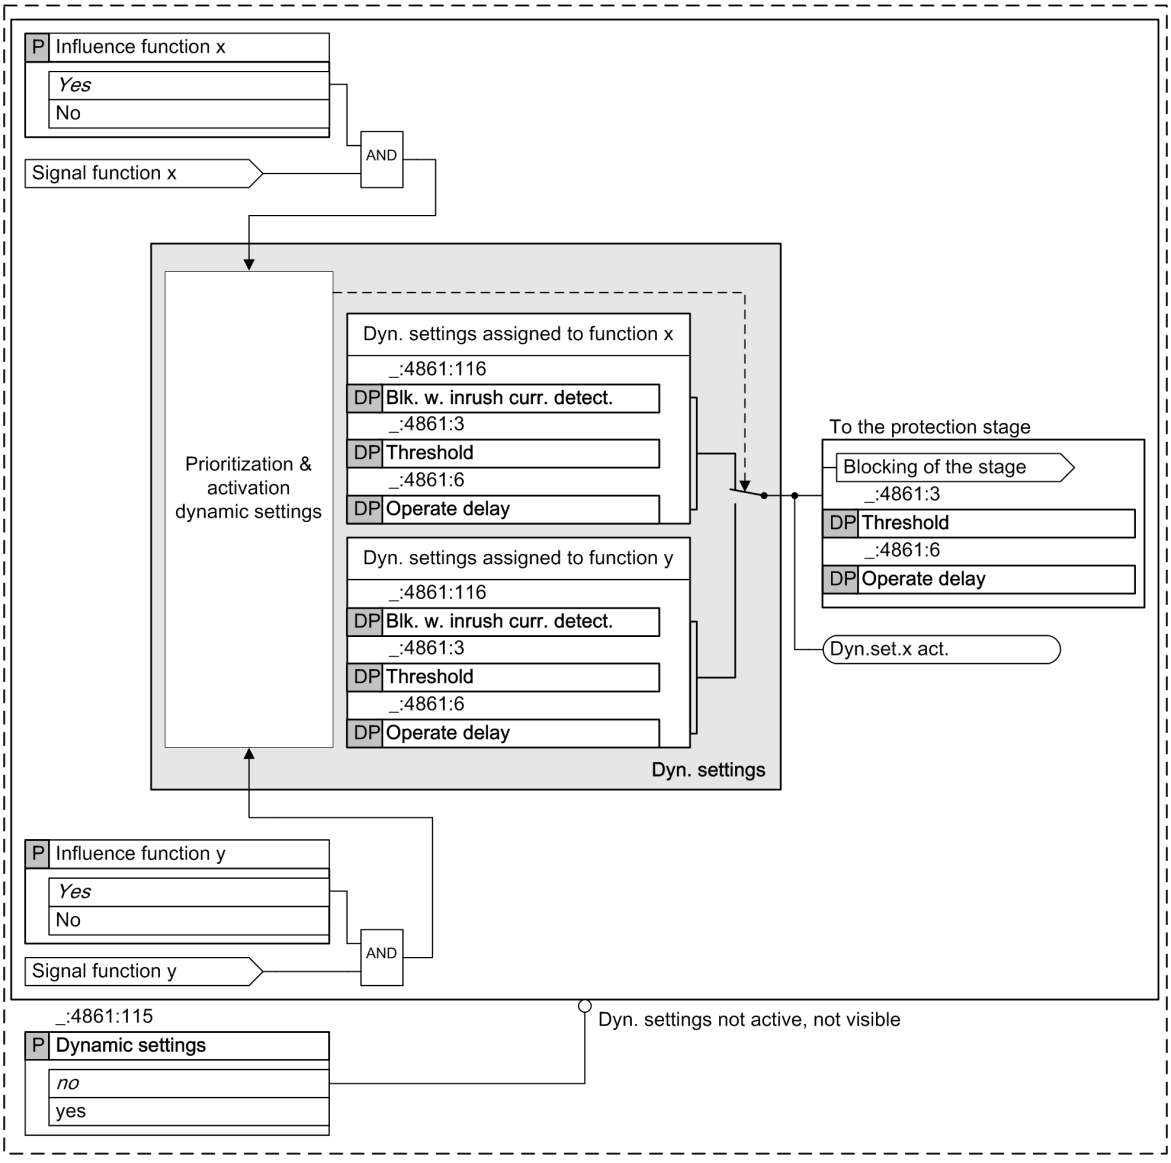
- Default setting **(_:4861:116) Blk. w. inrush curr. detect.** = ***no***

Parameter Value	Description
no	The transformer inrush-current detection does not affect the stage. Select this setting in the following cases: 1) In cases where the device is not used on transformers. 2) In cases where the device is used on transformers and the threshold value of the stage is set above the maximum inrush current of the transformer. This typically applies for the high-current stage. The high-current stage is set corresponding to the short-circuit voltage V_{sc} of the transformer so that it only responds to high-voltage side faults. The transformer inrush current cannot become larger than the maximum transmittable short-circuit current.
yes	When the transformer inrush-current detection detects an inrush current that can lead to a tripping of the stage, the start of the time delay and tripping of the stage are blocked. Select this setting if the device is used on transformers and the threshold value of the stage is set below the maximum inrush current of the transformer. This applies to the overcurrent-protection stage, which is used as a backup stage with grading time for faults on the undervoltage side of the transformer.

Parameter: Blk. w. 2nd harm. gnd. det.

- Default setting **(_:4861:131) Blk. w. 2nd harm. gnd. det.** = ***no***

Parameter Value	Description
no	If no 3I0/IN current flow is expected, due to current-transformer saturation above the trip threshold value, select this setting.
yes	If an 3I0/IN current flow is expected due to current-transformer saturation above the trip threshold value, blocking must be activated. This supplies the stability for the following conditions: • Current-transformer saturation without inrush current, because a saturated signal also contains a 2nd harmonic component • Phase inrush current which leads to current-transformer saturation and therefore results in the inrush current of the 2nd harmonic is also being present in the parasitic 3I0 current.



6.9.12 Signal Transmission

You can extend the ground-fault protection by means of the integrated signal-transmission logic for directional comparison protection. You can find more detailed information on the possible transmission methods and their function in section *6.10.2 Structure of the Function*.

6.9.13 Influence of Other Functions via Dynamic Settings

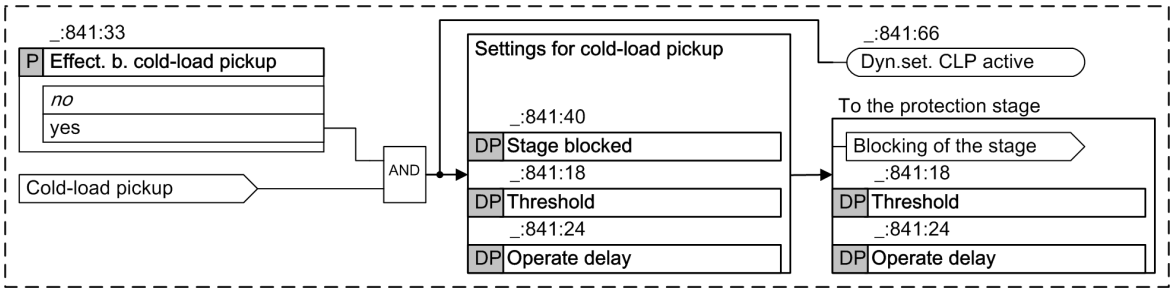
6.9.13.1 Description

The parameters **Threshold** and **Operate delay** of the tripping are so-called dynamic parameters (DP). Depending on other functions, the settings of these parameters can be changed dynamically (see *Figure 6-206*). Depending on other functions, the stage can also be blocked dynamically.

[lodynpar-260111-01.tif, 2, en_US]

Figure 6-206 Principle of the Dynamic Parameters in the Example of 1st Definite Time-Overcurrent Protection Stage

If the following functionalities are available in the device, they can affect the overcurrent-protection stages:



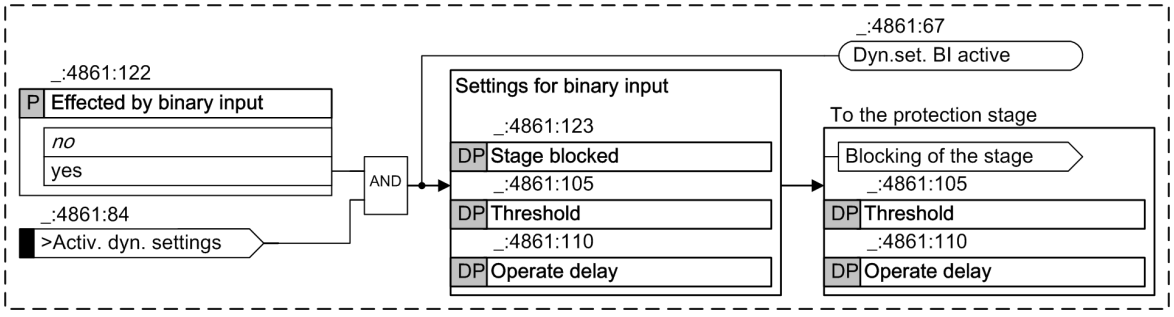
Functionalities	Priority
Automatic reclosing (AREC)	Priority 1
Cold-load pickup detection	Priority 2
Binary input signal	Priority 3

These functionalities generate signals that change the settings of the dynamic settings of the protection stage or block it, if necessary. In the latter case, the settings for the threshold value and time delay are of no relevance. To each of the signals, the overcurrent-protection stage provides a configuration parameter **`Affected by function ...`** and own dynamic parameters (**`Operate delay`** and **`Threshold`**). The configuration parameters are used to set whether the signal shall be active or not, that is, whether the dynamic settings should be activated or not. If one of these signals (for example, signal function x) becomes active and is to take effect, these parameter settings become dynamic, that is, instantly active. This means that the setting assigned to the signal replaces the standard setting. If the signal becomes inactive, the standard settings apply again. The activation of the dynamic parameter is reported.

Where several signals are active in parallel, the specified priority applies. This means that a signal with priority 1 precedes that of priority 2. The parameters assigned to signal 1 become active.

The functionality of the dynamic parameters can be disabled. In this case, the parameters assigned to the signals are not visible and are without effect.

Link to the Device-Internal Function *Cold-Load Pickup Detection*



[logfpkal-300511-01.tif, 1, en_US]

Figure 6-207 Influence of the Cold-Load Pickup Detection on the Overcurrent-Protection Stage

In the case of cold-load pickup, you have the option to change the settings for the **Threshold** and **Operate delay** parameters of the protection stage. You can also block the stage. To do so, you must activate the influence of the cold-load pickup. You also have to set the parameters for the **Threshold** and **Operate delay** or **Stage blocked** settings, which take effect when the signal is active.

The way the **Cold-load pickup** signal is generated is described in chapter *5.5.4.1 Overview of Functions*.

Link to an External *Function via a Binary Input Signal*

[loeinbin-270111-01.tif, 1, en_US]

Figure 6-208 Influence of the Binary Input on the Overcurrent-Protection Stage

You can use the binary input signal **>Activ. dyn. settings** to change the settings for the **Threshold** and the **Operate delay** of the protection stage. You can also block the stage. To do so, you must activate the influence of the binary input. You also have to set the parameters for the **Threshold** and **Operate delay** or **Stage blocked** settings, which take effect when the signal is active.

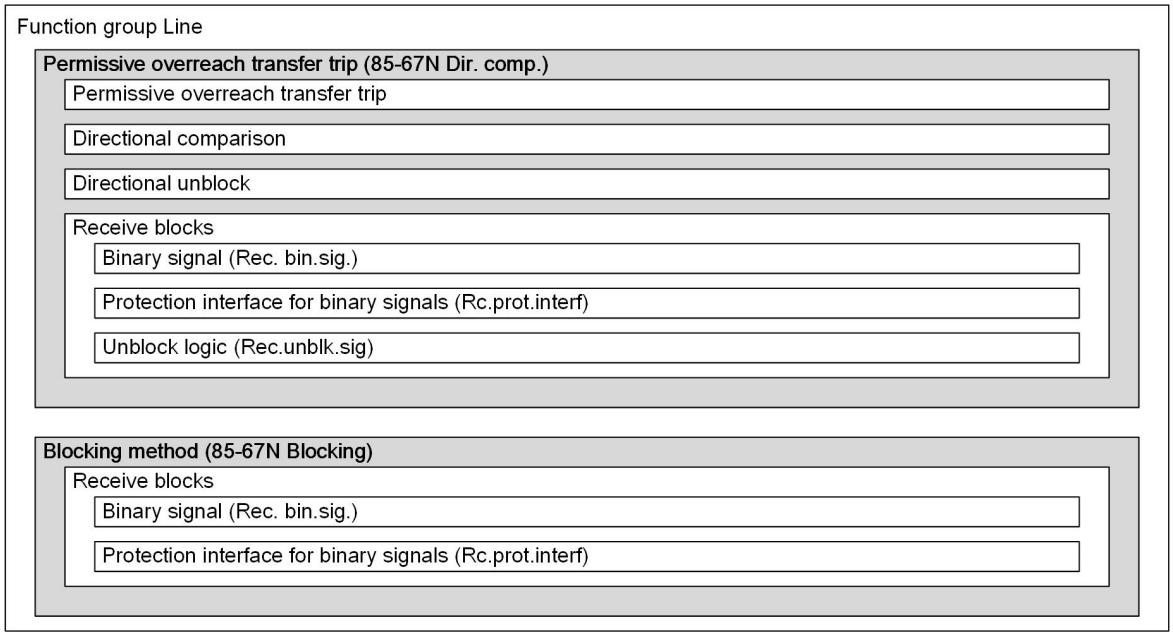
6.9.13.2 Application and Setting Notes

Parameter: Dynamic settings

- Default setting **(_:4861:115) Dynamic settings** = ***no***

Parameter Value	Description
no	The influence on the protection stage by device-internal or external functions is not necessary.
yes	If a device-internal function (for example, Automatic reclosing function) or an external function is to affect the protection stage (for example, change to the setting of the threshold value or the time delay, blocking of the stage), it is necessary to set it to ***yes***. In this way, the configuration parameters **Affected by function...** as well as the dynamic settings **Threshold**, **Operate delay** and **Stage blocked** of the stage are visible and you can parameterize the specific influence.

Further application and setting notes can be found in the Overcurrent protection, phases and function in section *6.23.8.2 Application and Setting Notes (Advanced Stage)* .



6.10 Teleprotection with Ground-Fault Protection

6.10.1 Overview of Functions

Information is exchanged with the remote station so that the ground-fault protection switches off immediately and selectively on the entire line for all errors. You can implement the teleprotection through reception and transmission contacts or through a digital communication connection.

6.10.2 Structure of the Function

The **Teleprotection schemes** are used in protection function groups with a voltage-measuring point in combination with the Ground-fault protection function. The schemes of the function illustrated in the following figure are available.

[dw_fkt-line_EF_Freigabe-Blockierverfahren, 1, en_US]

Figure 6-209 Structure/Embedding of the Function

Figure 6-210 displays the function control and the function blocks.

The transmission logic analyzes the pickup signals of the ground-fault protection and creates the respective transmission signal for the transmission to the other line end.

The receipt signal from the other line end is coupled either through:

- Binary input (FB **Rec. bin.sig.**)
- Unblock logic (FB **Rec.unblk.sig**)
- Communication (FB **Rec. PI**)

To protect the ends of multi-terminal lines, the function blocks **Rec. bin.sig.** and **Rec.unblk.sig** are available multiple times, once for each removed line end.

The stage parameterized for the teleprotection scheme delivers the pickup information. This pickup information is combined with the reception information for the trip condition. If the trip condition is fulfilled, the teleprotection scheme creates the operate indication.

A trip signal results through the simultaneous presence of a pickup and a release signal.

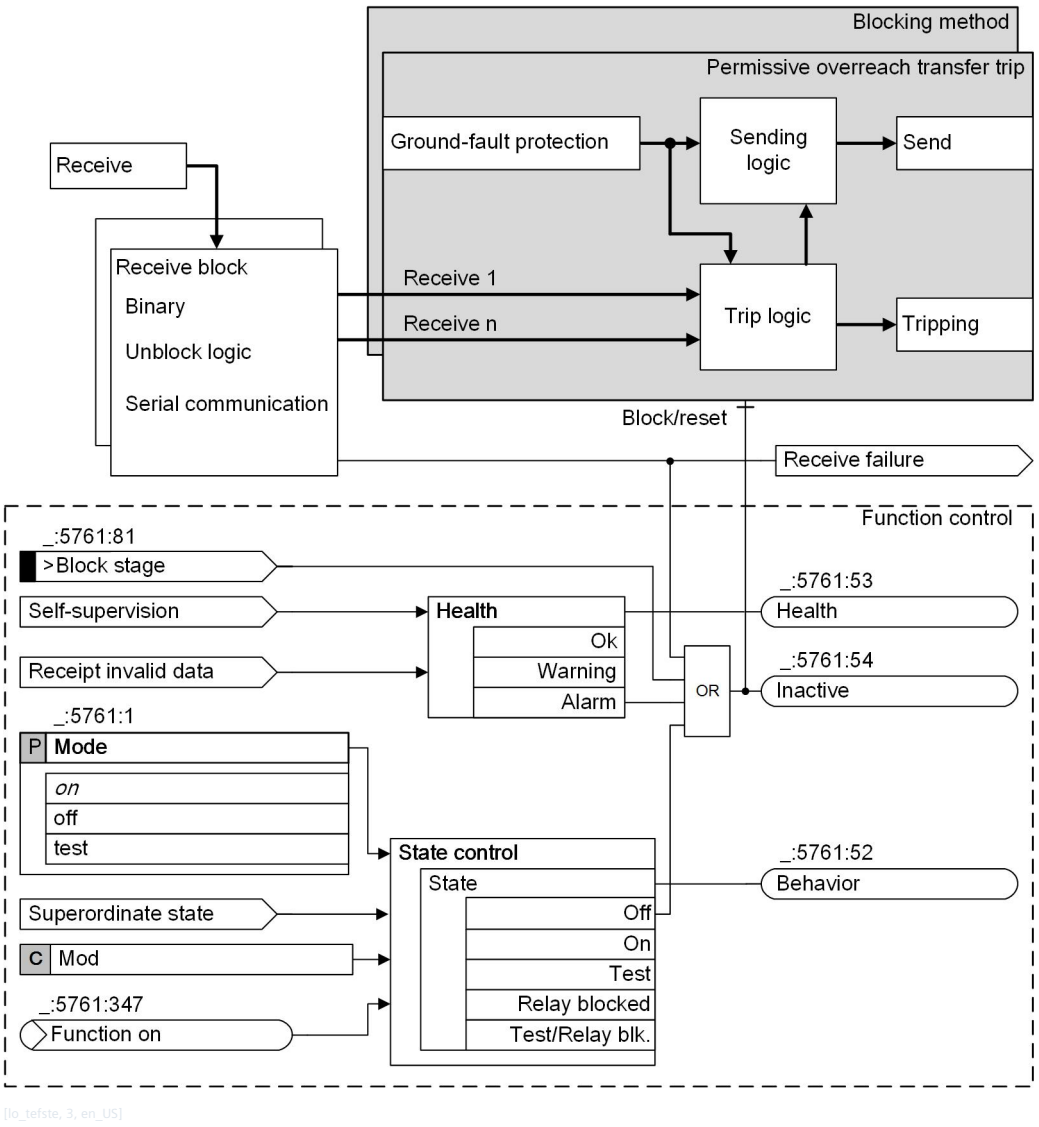


Figure 6-210 Function Blocks and Function Control

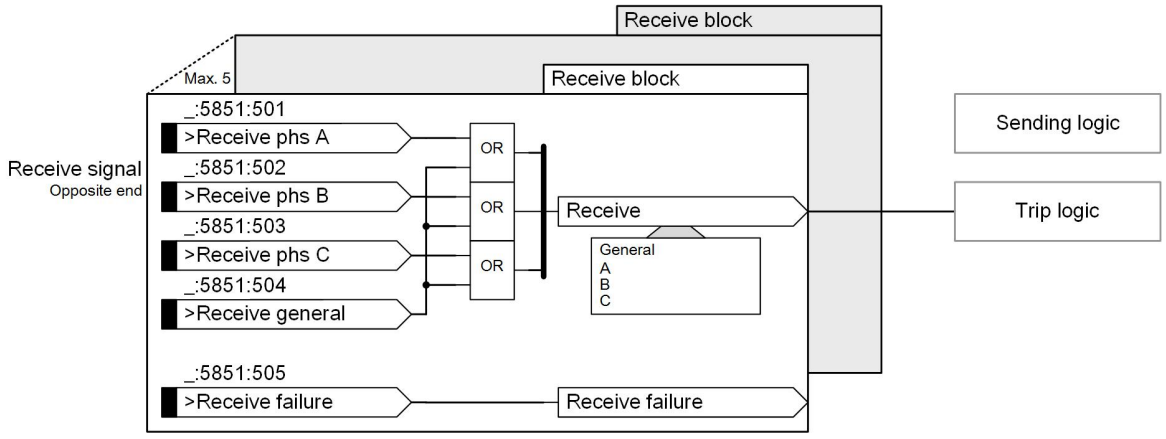


In the following, the individual function blocks for the teleprotection scheme are described. You can find detailed information about function control in *2.3 Function Control*.

6.10.3 Receive Blocks

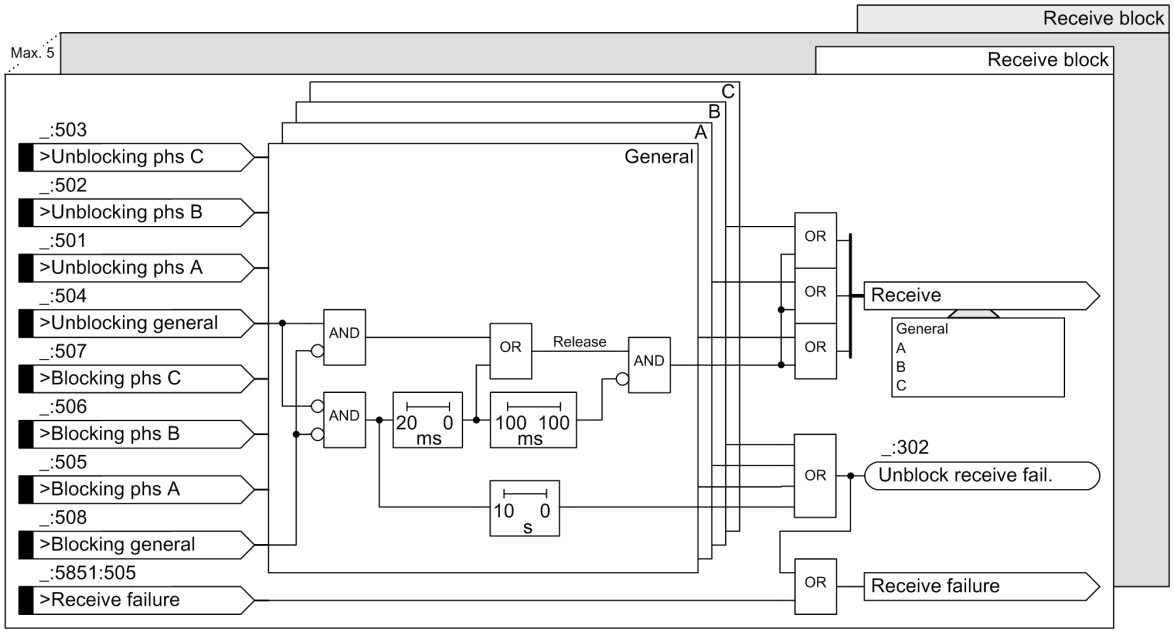
For the coupling of reception signals from opposite ends, the receive-block types **`Rec. bin.sig.`**, **`Rec.unblk.sig`**, and **`Rec. PI`** are available. The teleprotection schemes described in the following can be operated with the suitable receive blocks as needed.

A mixture between a line end connected through a protection interface and a binary connected line end is not possible.

Binary Receive Block (in DIGSI 5: `Rec. bin.sig.`)

[lotprxbi-100611-01.tif, 2, en_US]

Figure 6-211 Logic Diagram of the Receive Block:`Rec. bin.sig.`



If the communication occurs through binary signals, this reception logic is used. If a teleprotection scheme is configured, for example, with 3 ends in total, 2 function blocks `Rec. bin.sig.` are required.

For applications with 1-pole trip, the selectivity for double ground faults can be improved on parallel lines if 3-phase-selective transmission signals can be transferred per communication direction. The receipt signals can thus be used phase-specifically for A, B, and C or in general as individual signals.

For common-phase teleprotection, the signal **`>Receive general`** is used, for phase-selective teleprotection the 3 signals **`>Receive phs A`**, **`>Receive phs B`**, and **`>Receive phs C`**.

The binary input **`>Receive failure`** affects the status indications of the function control, see *Figure 6-210*.

Receive Block Unblock (in DIGSI 5: `Rec.unblk.sig`)

[lotpsunb-140611-01.tif, 1, en_US]

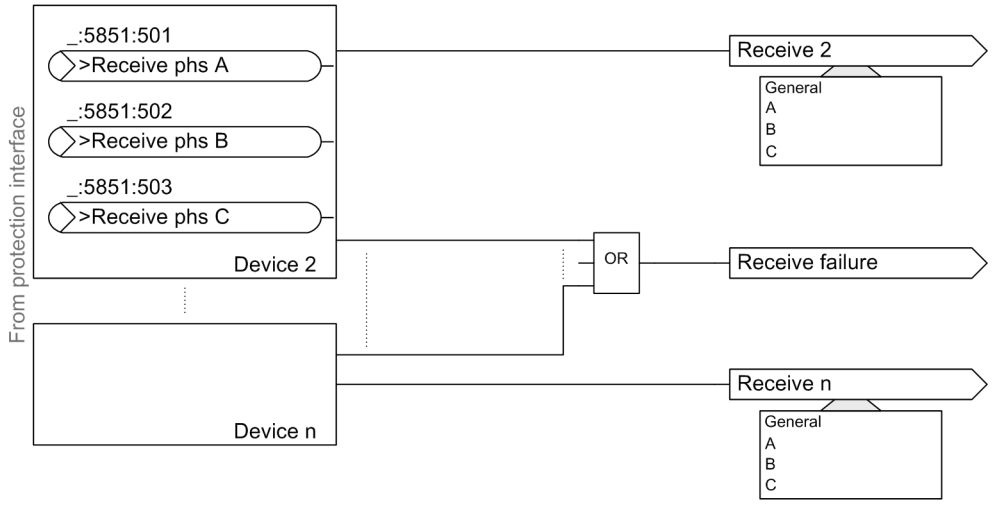
Figure 6-212 Logic Diagram of the Receive Block: `Rec.unblk.sig`

You can use the teleprotection schemes optionally with the unblocking method. The difference to the conventional binary receipt is that a trip is also then possible if a release signal arrives from the opposite end.

The unblocking method is preferred under the following conditions:

- With long lines
- If the signal is transmitted via PLC (power-line carrier transmission) through the line that is to be protected
- If the attenuation of the transmission signal at the fault location can be so large that the reception from the other line end is not provided

For transmission of the signal, 2 signal frequencies are required, which are sent from the transmission signal of the protection device. If the transmission device has channel monitoring, a monitoring frequency (blocking frequency) can be switched to a working frequency (unblocking frequency). During the idle state or during an external error, the monitoring frequency is transmitted, which signalizes the binary input *>Blocking general* (or during phase-selective teleprotection to the binary inputs *>Blocking phs A*, *>Blocking phs B* and *>Blocking phs C*) of the unblocking logic.



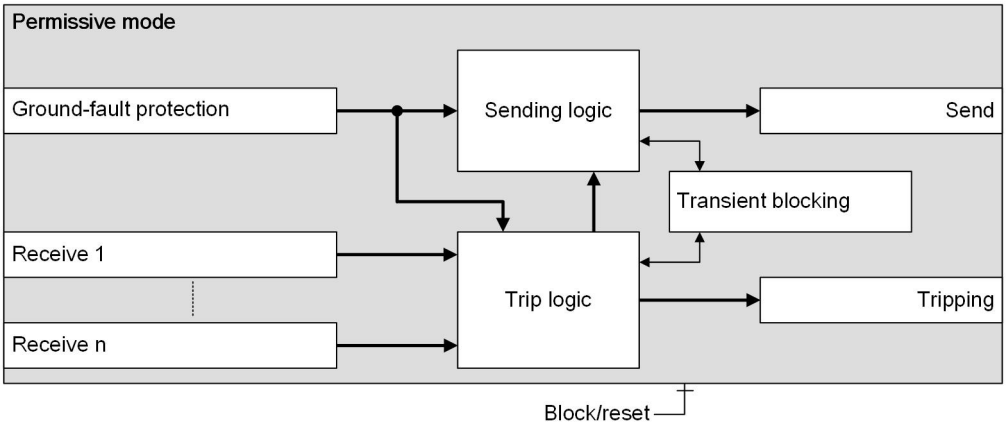
If in the event of a fault due to the transmission signal from the opposite line end the working frequency is received healthy, the receipt signal *>Unblocking general* will appear at the binary input of the unblocking logic. During phase-selective teleprotection, instead of *>Unblocking general* the 3 receive signals *>Unblocking phs A*, *>Unblocking phs B*, and *>Unblocking phs C* are used. Subsequently, the blocking signal *>Blocking general* disappears. During the phase-selective teleprotection, the 3 blocking signals *>Blocking phs A*, *>Blocking phs B*, and *>Blocking phs C* are used. With this, the signal *>Unblocking general* (or the respective signals *>Unblocking phs A*, *>Unblocking phs B*, and *>Unblocking phs C*) are transmitted and the reception of the trip logic of the teleprotection scheme is approved.

A short circuit on the line can cause an attenuation or reflection of the signal and the signal to be transmitted no longer reaches the other line end. In this state both binary inputs *>Unblocking general* and *>Blocking general* are not active. After a time delay of 20 ms, the release is still created and forwarded to the receipt logic. The release is then retracted over the time stage after a further 100 ms.

If the signals continue to receive without disruptions, the release is possible again after a dropout delay of 100 ms.

If the device does not receive any of the signals for 10 s, the indication *Unblock receive fail.* is generated. This indication affects the status indications of the function control, see *Figure 6-210*.

Receive Block Protection Interface (in DIGSI 5: `Rec. PI`)



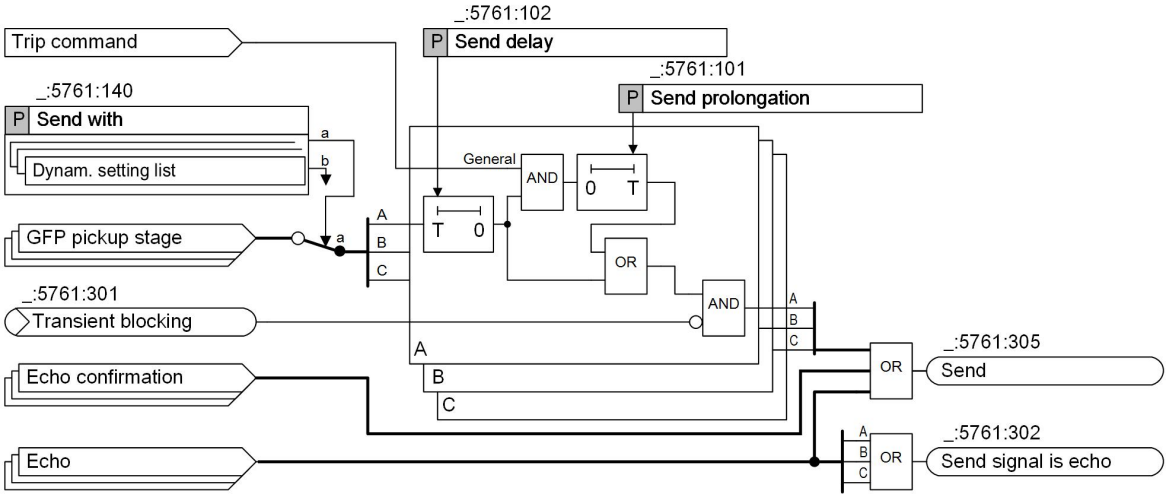
[lotprxws-310511-01.tif, 1, en_US]

Figure 6-213 Logic Diagram of the Receive Block: **`Rec. PI`**

If the communication takes place via a protection interface (digital), this receipt logic is used. Independent of the number of configured devices, only one function block is always **`Rec. PI`** required. The number and the identity of the devices that participate in the teleprotection scheme for protection of the line configuration can be set in the function group **Protection communication** under **System configuration**.

6.10.4 Permissive Overreach Transfer Trip

6.10.4.1 Description



[dwtevgve-100611-01.tif, 2, en_US]

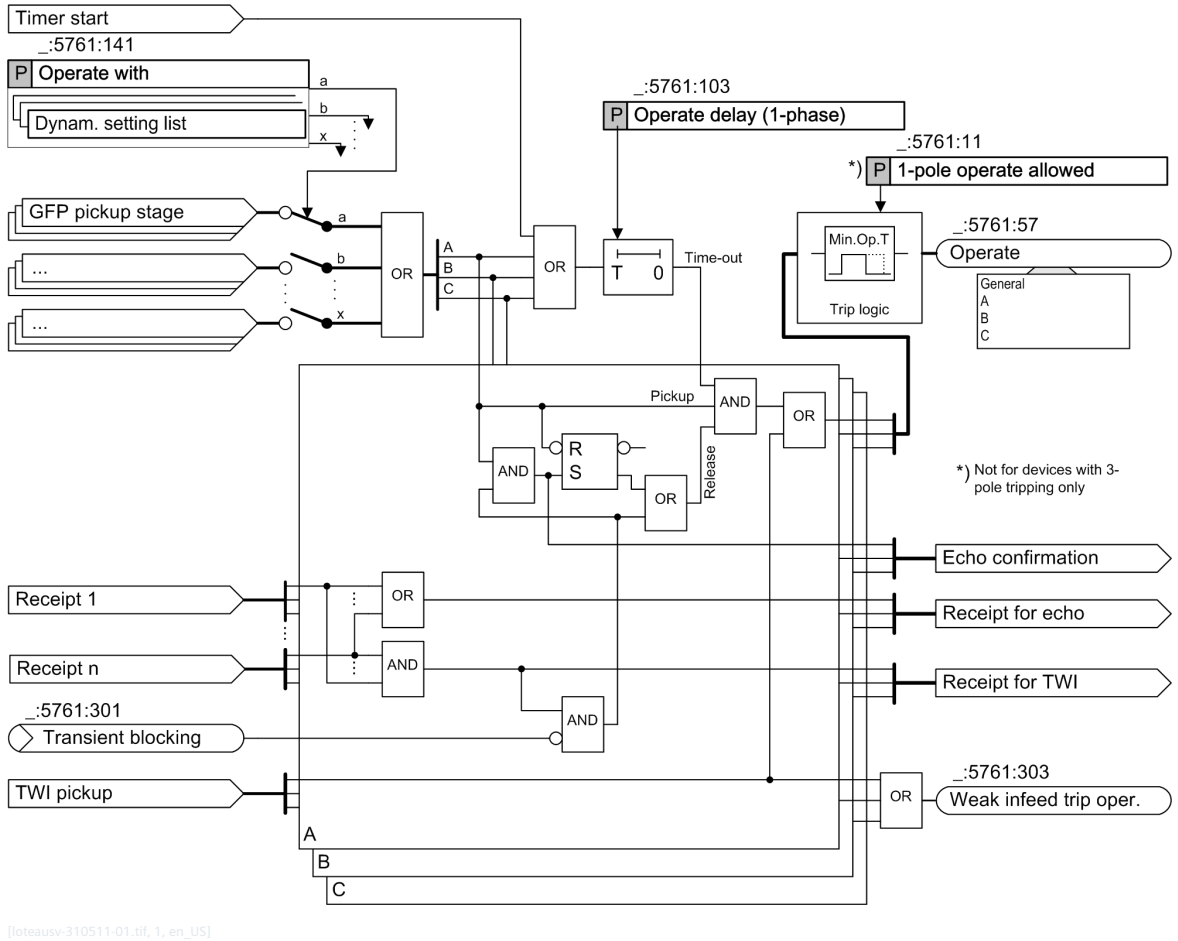
Figure 6-214 Function Block: **85-67N Dir. comp.**

If the ground-fault protection recognizes a fault in a forward direction, a send signal will be sent to the opposite end. If the fault is also recognized in the forward direction, the received signal in the device on the opposite end will lead to an increased trip.

Sending Logic Permissive Mode

[loteseve-310511-01.tif, 3, en_US]

Figure 6-215 Sending Logic for Permissive Mode



With the parameters **Send with**, you can select which stage of the ground-fault protection affects the send signal. The send condition is fulfilled if the selected stage - or stages - are picked up in a forward direction.
If the protection has already submitted a trip command, the send signal can be prolongated by a set time **(_:5761:101) Send prolongation**. This allows for the release of the other cable end even if the short circuit is very quickly switched off. With this, pickup differences between the cable ends and signal delays can be considered.

If needed, the send signal can be delayed with **(_:5761:102) Send delay**.

The transient blocking (signal *Transient blocking*) provides additional security from fault signals due to transient oscillations caused by a change of direction after disconnection of external faults (for example, on parallel lines). You can find a detailed description in *6.10.6.1 Description*. No send signal is sent in the event of transient blocking.

For applications with 1-pole operate, the selectivity of the permissive mode for double faults can be improved on parallel lines if 3 phase-selective send signals are transmitted per communication direction. Send and reception signals can thus be used phase-specifically for L1, L2 and L3 or phase-jointly as individual signals (general).

Trip Logic Permissive Mode

[loteausv-310511-01.tif, 1, en_US]

Figure 6-216 Trip Logic for Permissive Mode

The ground-fault protection provides the pickup information to the teleprotection scheme. The trip for the affected stage is attended to by that teleprotection scheme with which the ground-fault protection collaborates.

If a reception signal is present, the stage set through the parameter **(_:5761:141) Operate with** will be released for tripping. The trip can be delayed. You can set the time delay under **Send delay**.

With the parameter **(_:5761:11) 1-pole operate allowed**, the tripping logic can allow for 1-pole trip in 1-/3-pole trip devices. This parameter does not apply to devices that only have 3-pole trip.

If the permissive mode for the protection of a line configuration with more than 2 ends is used, the reception signals from all line ends are combined for the operate with AND.

A trip signal results from the simultaneous presence of

- Stage pickup
- Release signal
- Expired time

For applications with delayed trip, a non-recurring receipt signal is only kept until the stage pickup returns. Through this, it is guaranteed that the release signal is also present if the time-out of the corresponding time delay releases the trip and the send signal of the protection of the opposite end is no longer imminent.

The transient blocking (signal *Transient blocking*) prevents the release of the tripping in the permissive mode. It ensures additional security from fault signals due to transient oscillations caused by a change of direction after disconnection of external faults (for example on parallel lines). You can find the detailed description in *6.10.6.1 Description*.

Measures in the Event of Weak Infeed

If no or only a weak infeed is available at a line end, the protection does not pick up the phase information or it does so incorrectly. With this, neither a trip command nor a send signal can be sent. With the permissive mode, the line end cannot be tripped quickly with increased infeed because no release signal is transferred from the end with the weak infeed.

In order to allow for a quick disconnection on both cable ends in such cases, the teleprotection schemes have special measures:

- For the trip of the cable end with a strong infeed, the echo function can be made effective with a weak infeed.
- In order for the cable end to also be tripped with a weak infeed, the teleprotection schemes have a function for trip with weak infeed.

The functions are described in detail in the chapter **Echo and Tripping in the event of weak infeed**.

6.10.4.2 Application and Setting Notes for the Trip Logic of the Permissive Mode

The various permissive modes can be implemented by using both parameters **Send with** and **Operate with** . Additionally, you must observe the selection of the reception block.

The following methods can be ordered:

Methods	Parameter: Send with	Parameter: Operate with
85-67N Dir. comp.	One or multiple stages	One or multiple stages
Ground-fault unblock procedure (Rec.unblk.sig as a reception block)	One or multiple stages	One or multiple stages

Parameter: Send prolongation

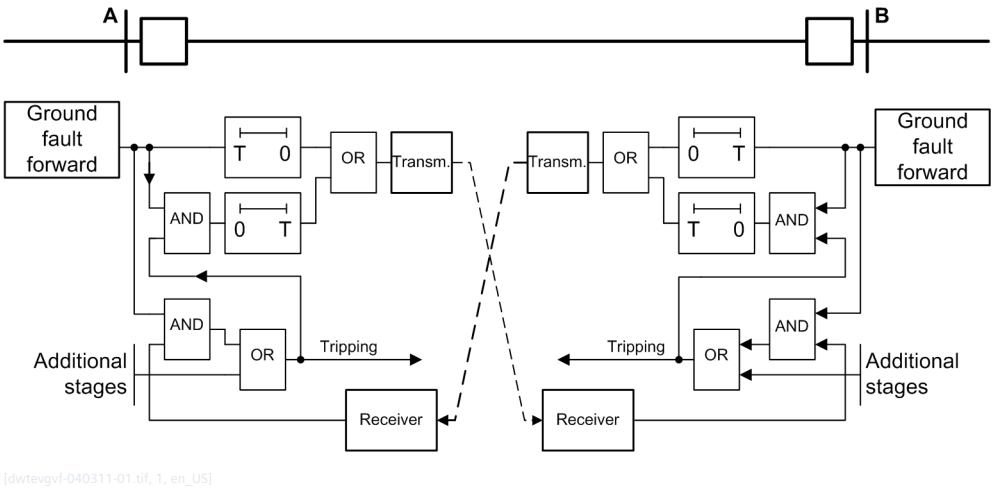
- Recommended setting value **(_:5761:101) Send prolongation** = ***0.05 s***

With the parameter **Send prolongation** in the transmission logic, you can compare the differences in the pickup times for both line ends. If SIPROTEC devices are used on all line ends, Siemens recommends the setting value ***0.05 s***.

Parameter: Send delay

- Recommended setting value **(_:5761:102) Send delay** = ***0.00 s***

With the parameter **Send delay**, you can set an additional tripping delay. Since the teleprotection scheme should lead to rapid and selective tripping, Siemens recommends the setting value ***0.00 s***.



Parameter: 1-pole operate allowed

- Recommended setting value **(_:5761:11) 1-pole operate allowed** = ***yes***

With the parameter **1-pole operate allowed**, you allow 1-pole tripping of the teleprotection scheme for 1-phase faults or multi-phase faults and 1-phase reception. In devices with 1-pole tripping, Siemens recommends the setting ***yes***. In devices with 3-pole trip, this parameter does not apply.

6.10.4.3 Application and Setting Notes for the Permissive Scheme

If the ground-fault protection recognizes an error in the cable direction after a pickup, it will transmit a release signal to the opposite end. If the opposite end receives the release signal and also recognizes a fault in the cable direction, the trip signal is created.

[dwtevgvf-040311-01.tif, 1, en_US]

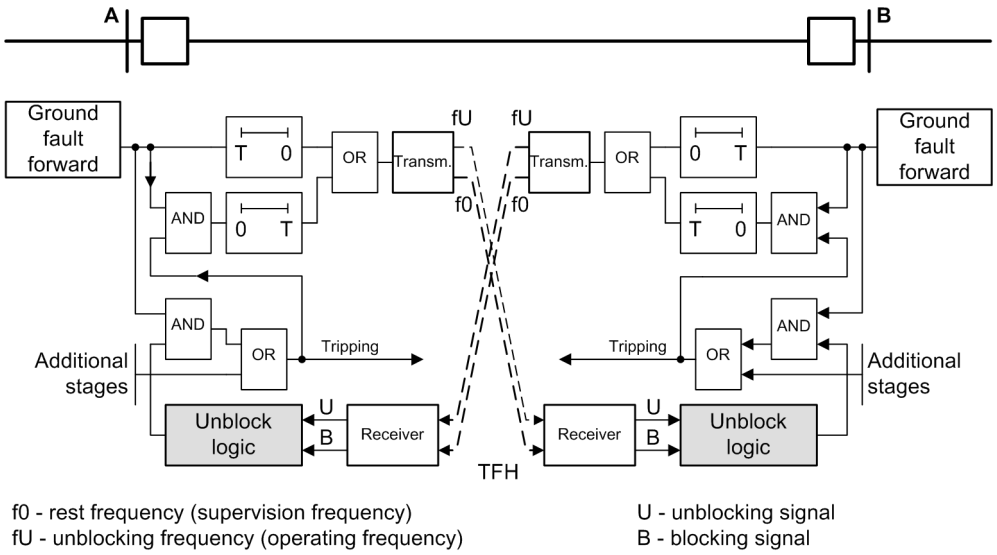
Figure 6-217 Function Scheme of the Permissive Scheme

With the following settings, you can configure the permissive schemes:

Parameter: `Send with`

- Recommended setting value **`(_:5761:140) Send with`** = ***`ground-fault stage`***

With the parameter **`Send with`**, you select one or multiple stages of the ground-fault protection as transmission criteria. The selection texts of the stages are identical with the labels that you assign to them in the ground-fault protection.



Parameter: `(_:5761:141) Operate with`

- Recommended setting value **`(_:5761:141) Operate with`** = ***`ground-fault stage`***

With the parameter **`Operate with`**, you select the stage or the stages of the ground-fault protection that leads to tripping during signal reception. The selection texts of the stages are identical with the labels that you assign to them in the ground-fault protection.

6.10.4.4 Application and Setting Notes for the Directional-Unblocking Method

The directional-unblocking method corresponds with the permissive scheme with a preset function block **`Rec.unblk.sig`**. Thus, unlike the permissive scheme, tripping is also possible without a permissive signal from the opposite end. The directional-unblocking method cannot be operated with a communication through a protection interface (WS) due to its function.

[dwteublv-040311-01.tif, 1, en_US]

Figure 6-218 Function Scheme of the Directional-Unblocking Method

With the following settings, you can configure the directional-unblocking method:

Parameter: `Send with`

- Recommended setting value **`(_:5761:140) Send with`** = ***`ground-fault stage`***

With the parameter **`Send with`**, you select one or multiple stages of the ground-fault protection as transmission criteria. The selection texts of the stages are identical with the labels that you assign to them in the ground-fault protection.

Parameter: `Operate with`

- Recommended setting value **`(_:5761:141) Operate with`** = ***`ground-fault stage`***

With the parameter **`Operate with`**, you select the stage or the stages of the ground-fault protection that leads to an operate during signal reception. The selection texts of the stages are identical with the labels that you assign to them in the ground-fault protection.

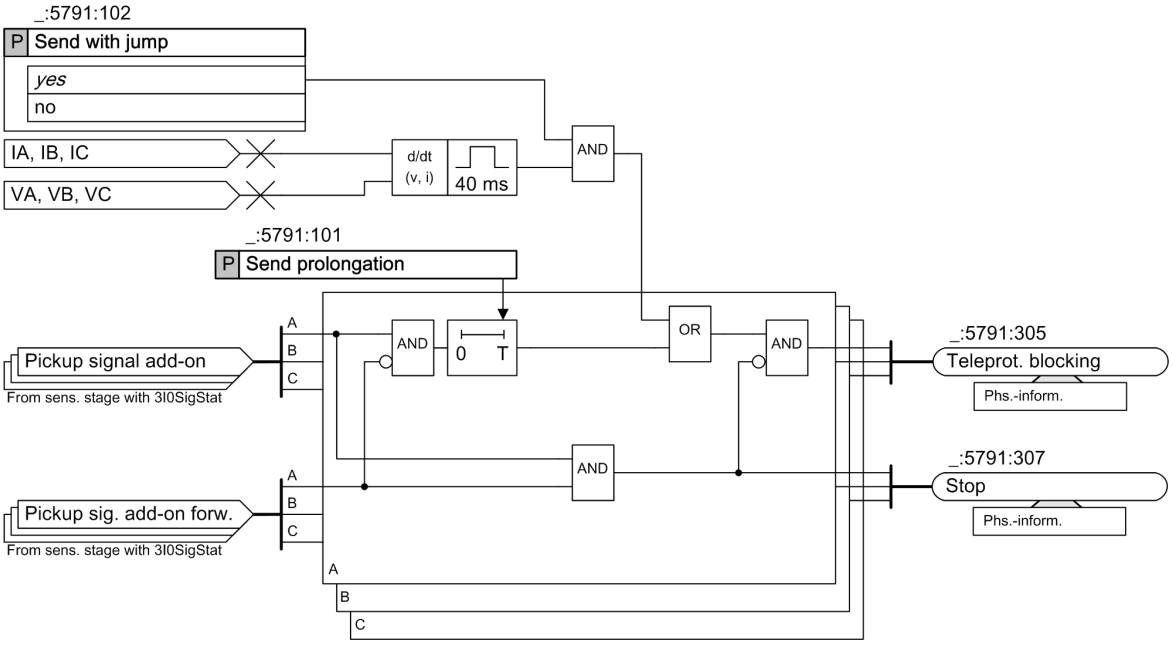
6.10.5 Blocking Method

6.10.5.1 Description



[dwtefblo-100611-01.tif, 1, en_US]

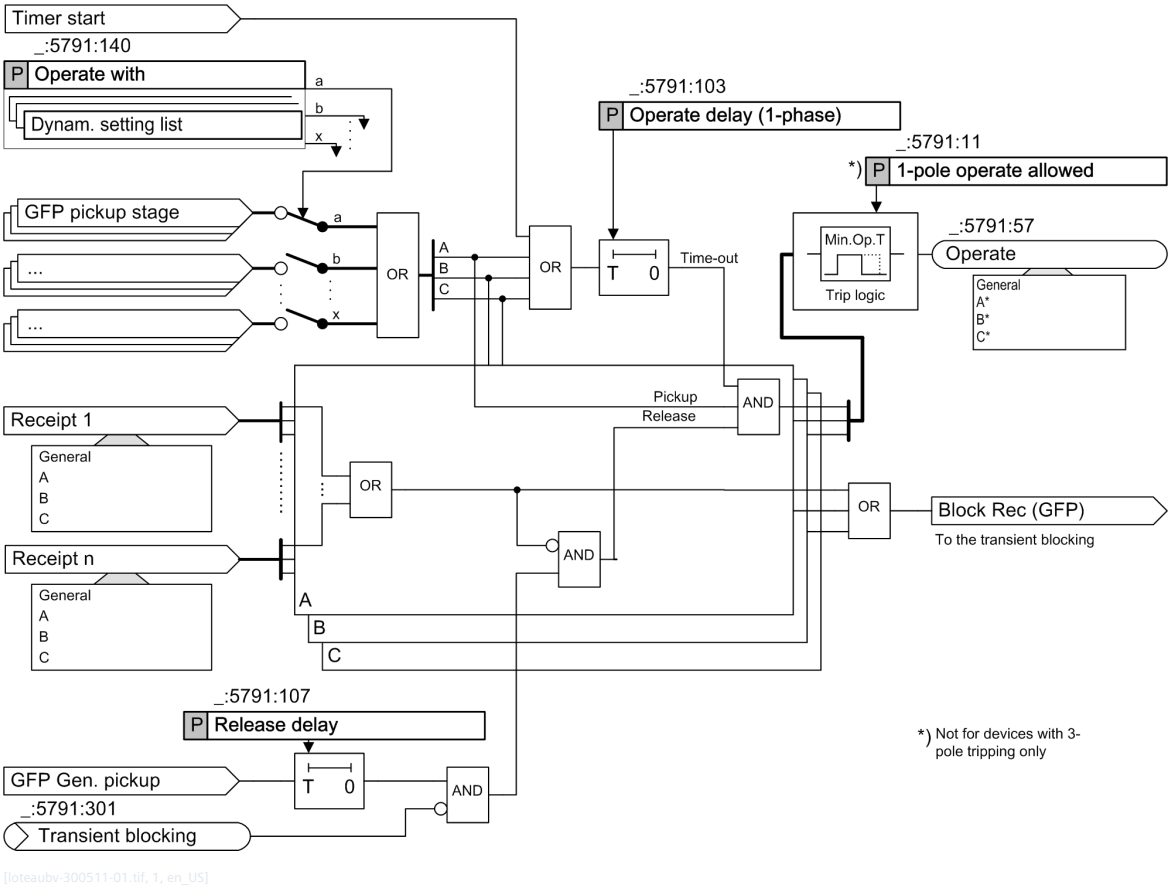
Figure 6-219 Function Block: **85-67N Block.**

If the protection function recognizes a ground fault in the backward direction, the blocking signal is sent to the opposite end (signal **Blocking**). If the protection device does not receive a blocking signal at the receiving line end, it generates the trip signal after a short time delay.

Sending Logic Blocking Method

[lotesblk-040311-01.tif, 1, en_US]

Figure 6-220 Sending Logic for the Blocking Method



The blocking signal is created in the event of pickup of the ground-fault protection in the **backward** or **non-directional** direction. The threshold value for creation of the blocking signal is the percentage of the threshold value of the level that affects tripping in the blocking procedure. The percentage is set with the parameter **(_:5761:104) 3I0 threshold rev./forw.** in the teleprotection scheme. For further information, refer to *6.10.7.1 Description*.

The logic is designed in a phase-selective manner. With the parameter **(_:5791:101) Send prolongation**, you can extend the blocking signal. Even if the error has already been cleared up locally, the opposite end can continue to be blocked through this.

The blocking signal can also be sent immediately with jump detection (parameter **(_:5791:102) Send with jump**). If the communication channel can react very quickly to the absence of the blocking signal, you can use this jump signal, because the jump signal appears for every jump in the dimensions. If the ground-fault protection detects an error in the forward direction, the blocking signal is immediately stopped and the indication *Stop* is created.

For applications with 1-pole trip, the selectiveness of the blocking method for double faults can be improved on parallel lines if 3 phase-selective transmission signals are transferred per communication direction. Transmission and reception signals can therefore be used phase-specifically for A, B, and C or phase-jointly as individual signals.

Trip Logic Blocking Method

[loteaubv-300511-01.tif, 1, en_US]

Figure 6-221 Trip Logic for the Blocking Method

The ground-fault protection provides the pickup information to the teleprotection scheme. The trip for the affected stage is attended to by that teleprotection scheme with which the ground-fault protection collaborates.

If a reception signal is present, the zone set through the parameter **(_:5791:140) Operate with** will be released for tripping. The trip of the blocking method must be delayed due to possible differences in the pickup times of the devices at both cable ends and because of the transmission time. You can set the time delay with the parameter **(_:5791:107) Release delay**.

The tripping can be delayed. You can set the time delay under **(_:5761:102) Send delay**.

The operate indication results for the simultaneous presence

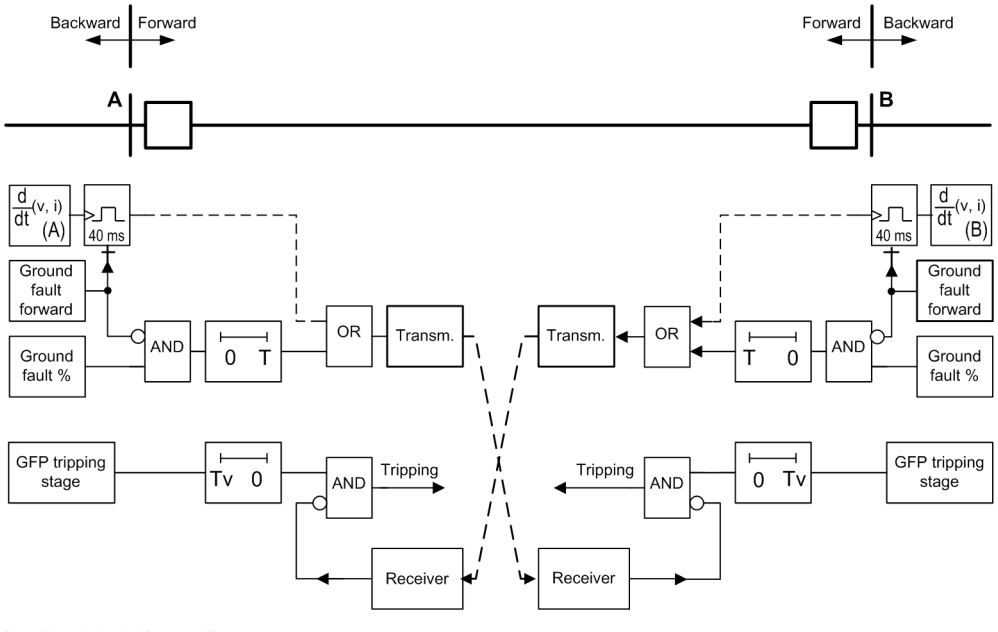
- of the stage pickup of the ground-fault protection
- of the internal release signal
- of the time expirations

No release of the trip occurs for an upcoming reception signal. In order to make sure that the pickup of the selected stage(s) does not switch the exterior errors on the opposite end, the trip is blocked for upcoming reception signals.

If the blocking method for the protection of a line configuration with more than 2 ends is used, the reception signals from all cable ends are combined with OR.

With the parameter **(_:5791:11) 1-pole operate allowed**, the trip logic can allow for 1-pole trip in 1-/3-pole trip devices. This parameter does not apply to devices that only have 3-pole trip.

Measures in the Event of Weak Infeed



For the blocking procedure, there is not possibility, depending on the procedure, to achieve a trip command release through the opposite end with a weak infeed. The advantage of the blocking procedure is instead that there can be a trip on the infeed end without a release, because the end not being fed in cannot form a blocking signal.

6.10.5.2 Application and Setting Notes for the Blocking Method

The blocking method is often used:

- If the signal is transmitted with TFH through the protected line and if the attenuation of the transmission signal at the fault location is so large that the reception from the other cable end cannot be guaranteed.
- For the protection of line configurations with more than 2 ends with different infeed

If the ground-fault protection recognizes an error in a backward direction, a blocking signal is transmitted. If the other cable end does not receive a blocking signal, the ground-fault protection trips in a forward direction in the case of a ground-fault current. Since no release signal is required by the opposite end, single infeed short circuits are quickly switched off with the blocking method.

[dwteblve-140611-01.tif, 1, en_US]

Figure 6-222 Function Scheme of the Blocking Method

Parameter: Send with jump

- Recommended setting value **(_:5791:102) Send with jump** = ***Yes***

With the parameter **Send with jump**, you can set if the blocking signal is sent without delay with the jump detection. Siemens recommends using the fast blocking with jump and retaining the setting.

Parameter: Send prolongation

- Recommended setting value **(_:5791:101) Send prolongation** = ***0.05 s***

With the settings **T SENDEVERL.** in the transmission logic, you can compare the differences in the pickup times for both cable ends. If SIPROTEC devices are used on all cable ends, Siemens recommends the setting value ***0.05 s***.

Parameter: Operate with

- Recommended setting value **(_:5791:140) Operate with** = ***ground-fault stage***

With the parameter **Operate with**, you can select the ground-fault stage.

Parameter: Release delay

- Recommended setting value **(_:5791:107) Release delay** = ***0.020 s***

With the parameter **Release delay**, you must set the release delay after a pickup. The trip of the blocking method must be delayed due to possible differences in the pickup times of the devices at both cable ends and because of the transmission time. Siemens recommends a setting of ***0.020 s***.

6.10.6 Transient Blocking

6.10.6.1 Description

The transient blocking provides additional security from fault signals due to transient oscillations caused by a change of direction after disconnection of external faults (for example on parallel lines).

[lotetrbl-310511-01.tif, 1, en_US]

Figure 6-223 Logic Diagram of the Transient Blocking

If a pickup in the reverse direction or non-directionally is present (non-forward fault), the transient blocking occurs after a waiting period (**(_:5791:105) Trans. blk. pickup delay**). After the omission of the blocking criteria, the transient blocking will be maintained for a set time (**(_:5791:106) Trans. blk. dropout delay**).

6.10.6.2 Application and Setting Notes for Transient Blocking

Parameter: `Trans. block. with`

- Default setting **`(_:5791:141) Trans. block. with`** = ***`DIS: TrBlock XBlk`***

Set the parameter **`Trans. block. with`** to ***`DIS: TrBlock XBlk`***, if the teleprotection scheme for distance protection works on the same communication channel as a teleprotection scheme for the ground-fault protection. Set the parameter to ***`invalid`*** if you are using separate communication channels. If no teleprotection scheme for distance protection is used, parameter setting will not be possible and the link will be automatically deactivated.

Parameter: `Trans. blk. pickup delay`

- Recommended setting value **`(_:5791:105) Trans. blk. pickup delay`** = ***`0.04 s`***

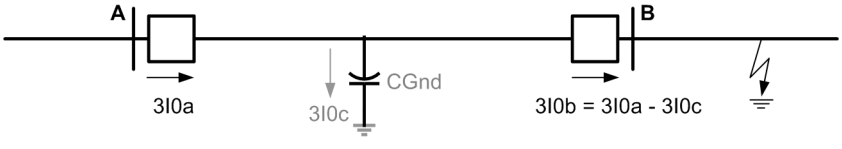
With the parameter **`Trans. blk. pickup delay`**, you set how long a reverse or non-directional pickup should remain before the transient blocking occurs. Siemens recommends a setting of ***`0.04 s`***.

NOTE

The time **`Trans. blk. pickup delay`** may not be set to 0. This makes sure that the transient-blocking time **`Trans. blk. dropout delay`** is not already started if the directional information comes in a delayed manner compared to the function pickup. Depending on the time of the circuit breaker on the parallel line or the circuit breaker lying in a reverse direction, settings between 10 ms and 40 ms are recommended.

Parameter: `Trans. blk. dropout delay`

- Recommended setting value **`(_:5791:106) Trans. blk. dropout delay`** = ***`0.05 s`***

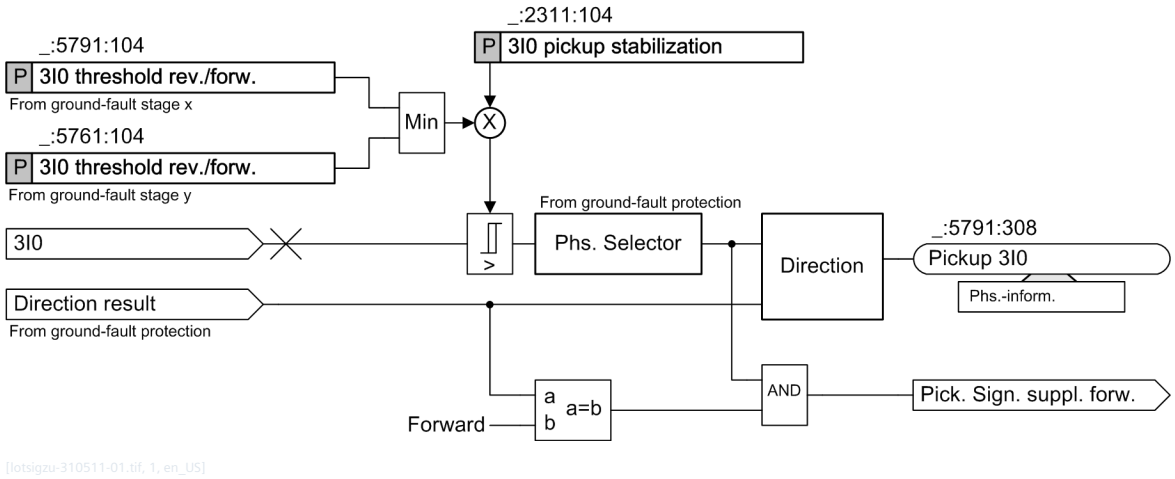


With the parameter **`Trans. blk. dropout delay`**, you determine the duration of the transient blocking. The time must be set longer than the duration of the transient compensation methods for the occurrence or switching of exterior short circuits.

6.10.7 Sensitive Measuring Stage of Ground-Fault Protection

6.10.7.1 Description

In order to avoid a faulty echo during permissive schemes, it must be ensured that an external ground fault with a flowing ground-fault current is detected at both line ends. During the blocking method and for the transient blocking, a secure blocking signal must be created under these conditions.



If the error is not detected in a ground fault in accordance with *Figure 6-224* the protection in B, this would be interpreted as an error fed-in from A. With permissive schemes, protection B would send an echo signal. For the blocking procedure and for the transient blocking, the required blocking signal would not be created. The consequence would be a faulty trip of the ground-fault protection in A.

[dwt3i0v1-040311-01.tif, 1, en_US]

Figure 6-224 Possible Current Distribution with an External Ground-Fault

The teleprotection scheme with ground-fault protection therefore has a sensitive ground-current stage **`(_:5791:104) 3I0 threshold rev./forw.`**.

[lotsigzu-310511-01.tif, 1, en_US]

Figure 6-225 Logic of the Sensitive Ground-Fault Protection

With the permissive scheme, the sensitive ground-current stage has an effect on the echo function and the transient blocking. If the stage for the recognition of a backward fault in B is always more sensitive than the stage pickup of the ground-fault protection, which sees an error from the other line end A in a forward direction, no fault echo signal can result and the transient blocking will also work correctly.

With the blocking method, the sensitive ground-current stage is the threshold from which the blocking signal is created if there are reverse errors. For this application, it also applies that the recognition of a reverse error in B must be more sensitive than the stage pickup of the ground-fault protection, which sees the error from the other cable end A in a forward direction. Thus, the blocking signal sent from B leads to the required blocking of the trip ground-current stage on the cable end A.

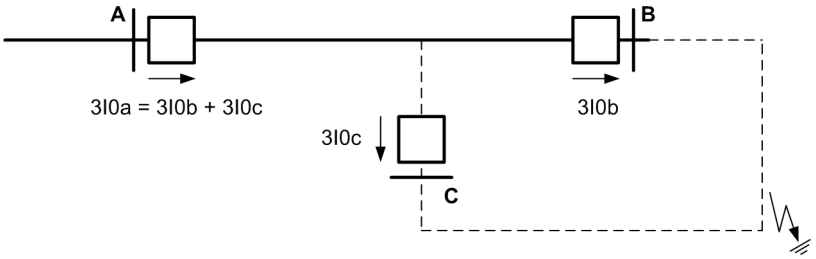
The setting value for the sensitive ground-current stage is a percent value. For permissive schemes, it automatically relates to the threshold value of the stage or the stages of the ground-fault protection, which are connected with the permissive scheme via the parameter **Send with**.

During the blocking method, the percentage setting value automatically relates to the stage or stages of the ground-fault protection, which are connected with the blocking method via the parameter **Operate with**.

6.10.7.2 Application and Setting Notes for the Sensitive Stage of the Ground-Fault Protection

Parameter: 3I0 threshold rev./forw.

- Default setting **(_:5761:104) 3I0 threshold rev./forw.** and **(_:5791:104) 3I0 threshold rev./forw.** = *75%*



With the parameter **3I0 threshold rev./forw.**, you can set the threshold value for the ground-fault signal addition stage in a ratio to the thresholds of the ground-fault stages selected under **Send with**

The sensitive stage of the ground-fault protection must be more sensitive than the ground-current stage that works with the transmission or trip stage in order for the teleprotection method to function correctly. The sensitive stage must be set in a more sensitive manner depending on the size of the capacitive ground current (3I0c in *Figure 6-224*). Normally, 70 % to 80 % of the setting for the ground-current stage is adequate for overhead lines. Siemens recommends the setting of 75 % for this application.

For cables or very long overhead lines, if the capacitive currents in the event of a ground fault have the same dimensions as the ground-fault currents, the echo function should be avoided or it should only be used for open circuit-breakers; the blocking procedure should then not be used at all.

For lines with 3 ends (feeder), it must be considered that the ground-fault current is unevenly distributed over the ends of the line in the event of an external ground fault. The critical case is illustrated in *Figure 6-226*. In the least favorable case, the ground current flowing from A divides itself half and half over line ends B and C. The setting value **3I0 threshold rev./forw.** significant for the echo or the blocking signal, must therefore be below half of the response value of the ground-current stage used for signal transmission. Additionally, the considerations described above apply with regard to the capacitive ground current, which is not dealt with in *Figure 6-226*. The conditions are more convenient for a ground-current distribution different

than assumed here, because then one of the 2 ground currents 3I0b or 3I0c must be greater than in the previous consideration.

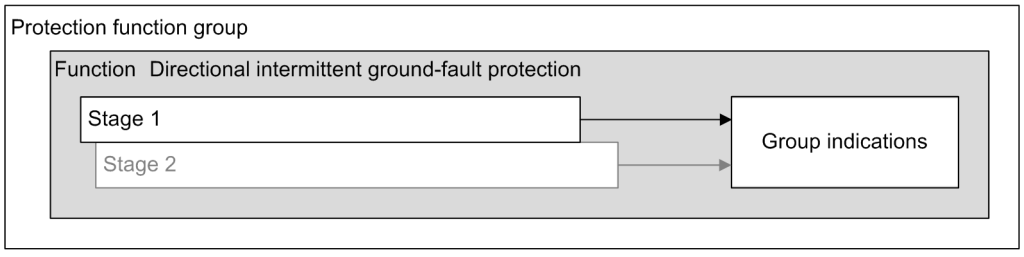
[dwt3i0v2-040311-01.tif, 1, en_US]

Figure 6-226 Possible Inconvenient Current Distribution through a Teed Feeder in the Event of an External Ground Fault

6.11 Directional Intermittent Ground-Fault Protection

6.11.1 Overview of Functions

The function **Directional intermittent ground-fault protection**:



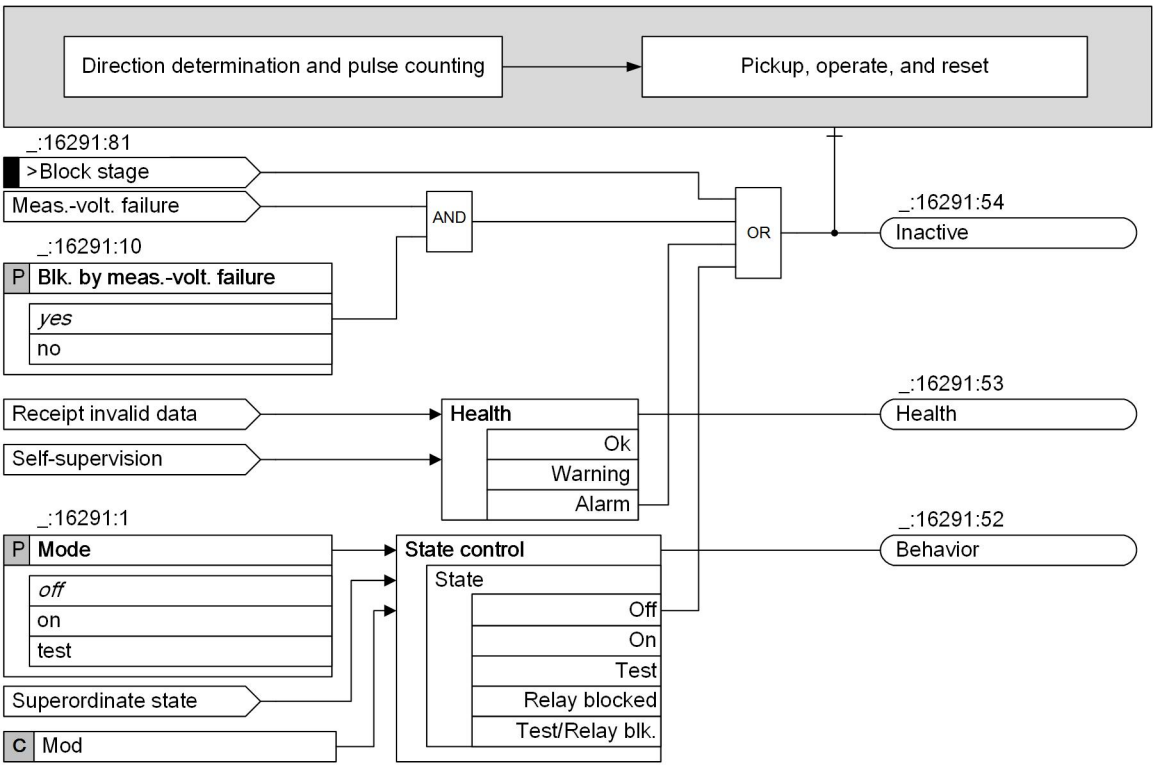
- Detects the intermittent ground faults in grounded, compensated, or isolated cable systems selectively
- Can be operated in 2 different modes:
  - Operate only by counting directional ground-current pulses
  - Operate by integration of the fault current in combination with a directional criterion by counting directional ground-current pulses

The intermittent ground faults in cable systems are frequently caused by weak insulation or water ingress in cable joints. The ground faults are characterized by the following properties:

- Intermittent ground faults show very short high ground-current pulses (up to several hundred amperes) with a duration of less than 1 ms.
- Intermittent ground faults are self-extinguishing and reignite within one half period up to several periods, depending on the power-system conditions and the fault type.
- Intermittent ground faults can persist over longer periods (several seconds to minutes) and develop to static ground faults.

6.11.2 Structure of the Function

The function **Directional intermittent ground-fault protection** can be used in protection function groups with current and voltage measurement. The function is preconfigured by the manufacturer with 1 stage, and a maximum of 2 stages can be operated simultaneously.



[dw_structure_dirl_GFP, 1, en_US]

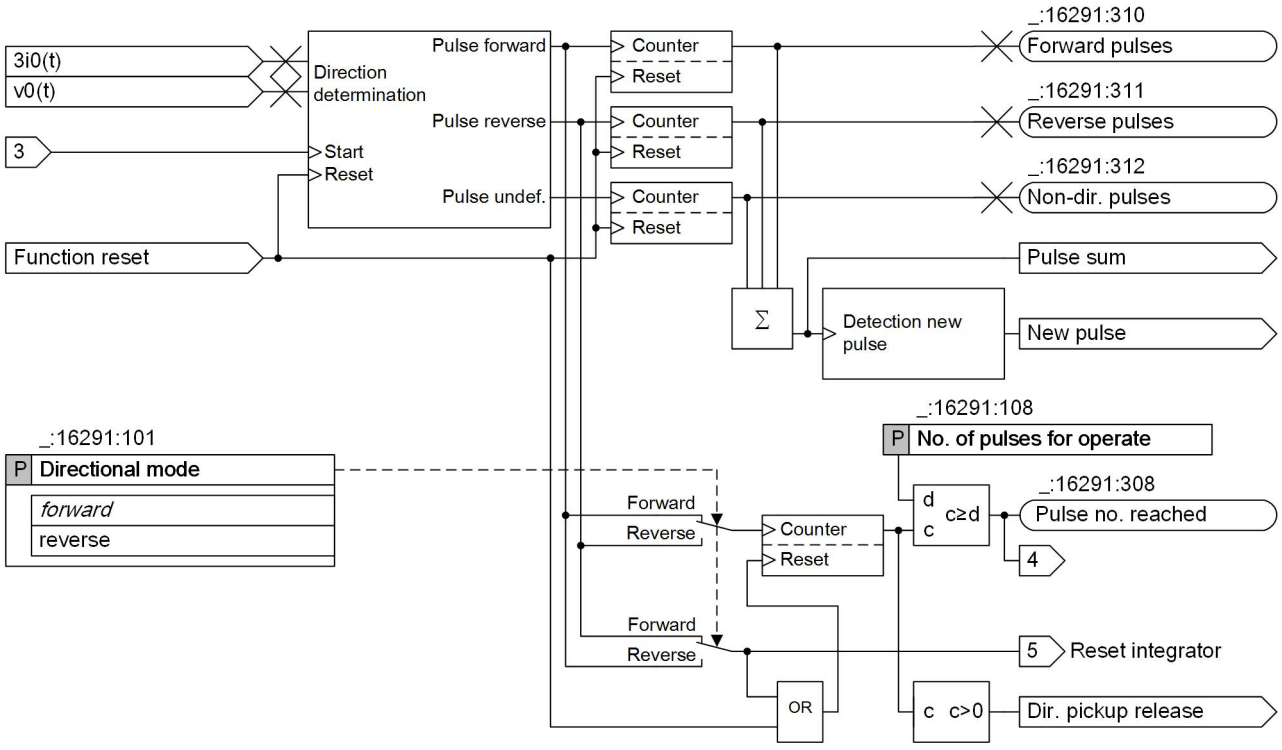
Figure 6-227 Structure/Embedding of the Function

6.11.3 Stage Description

Overview

[lo_overview, 2, en_US]

Figure 6-228 Logic of the Directional Intermittent Ground-Fault Protection



Blocking of the Stage with Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From an internal source upon pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **`Volt.-transf. c. b.`**, which links in the tripping of the voltage-transformer circuit breaker

The **`Blk. by meas.-volt. failure`** parameter can be set so that the measuring-voltage failure detection blocks the stage or does not block it.

Logic for Direction Determination and Pulse Counting

[lo_int_dir1, 3, en_US]

Figure 6-229 Logic Diagram of Direction Determination and Pulse Counting

(1) The input signal 3 is from *Figure 6-230*.

Measurement Values for Direction Determination

The function **Directional intermittent ground-fault protection** determines the direction of the ground-current pulse by comparing the maximum 3I0 and the VN changing trend of the ground-current pulse.

The zero-sequence voltage v0(t) can either be measured via the voltage input VN or can be calculated from the sum of 3 phase-to-ground voltages. The measured value depends on the parameter **Connection type** of the measuring point V-3ph.

The intermittent ground-fault current 3i0(t) can either be measured via the ground-current input IN or via the sensitive ground-current input I_{NS}. It can also be calculated from the sum of the 3 phase currents. The current value and its setting range depend on the parameter **Connection type** of the measuring point I-3ph.

Table 6-2 Threshold Setting Range with Different Connection Types

Connection Type of the Measuring Point I-3ph	Current Threshold 3I0/IN	CT Terminal Type	Threshold Setting Range (Secondary)[36]
3-phase	Calculated 3I0[37]	4 x Protection	0.030 A to 35.000 A
		3 x Protection, 1 x sensitive	0.030 A to 35.000 A
		4 x Measurement	0.001 A to 1.600 A

36 These values apply for a secondary rated current of 1 A. The values need to be multiplied by 5 when the secondary rated current is 5 A.

37 If the connection type is without IN, such as 3-phase, the current threshold value is a calculated 3I0 value.

Connection Type of the Measuring Point I-3ph	Current Threshold 3I0/IN	CT Terminal Type	Threshold Setting Range (Secondary)[36]
3-phase + IN 3-phase + IN-separate	Measured IN[38]	4 x Protection	0.030 A to 35.000 A
		4 x Measurement	0.001 A to 1.600 A
	Measured IN and calculated 3I0 when IN > 1.6 A	3 x Protection, 1 x sensitive	0.001 A to 35.000 A

Direction Determination and Pulse Counting

When the RMS value of 3I0 exceeds the set threshold value (signal no. 3 in *Figure 6-229*), the direction determination process is started and is continuously carried out until the function resets. At first, the current pulse (current peak) detection takes place. If a current pulse is detected, the direction determination for this pulse is carried out.

The direction is determined by the maximum 3I0 and the VN changing trend of the ground-current pulse. The plus or minus sign of the maximum 3I0 is compared to the plus or minus sign of the VN changing trend, resulting in the directional decision ***forward*** or ***reverse***. If the VN changing trend is smaller than 0.03 V_{rated} or if the maximum 3I0 is smaller than 0.1 I_{rated}, the direction is undefined.

During the ongoing intermittent ground fault, the directional results for all current pulses are counted.

Directional Mode and Directional Pulse Counter Criterion

The parameter **Directional mode** defines whether the function operates in ***forward*** or in ***reverse*** direction. The pulses in the specified direction are counted. If the pulse counter reaches the threshold value set in the parameter **No. of pulses for operate**, the signal *Pulse no. reached* is issued. Depending on the operating mode (***Counter*** or ***Integrator and counter***) of the function, the signal can immediately cause the operate of the function (***Counter*** mode) or it is processed as directional release criteria (***Integrator and counter*** operating mode). Refer to the further description in the following sections.

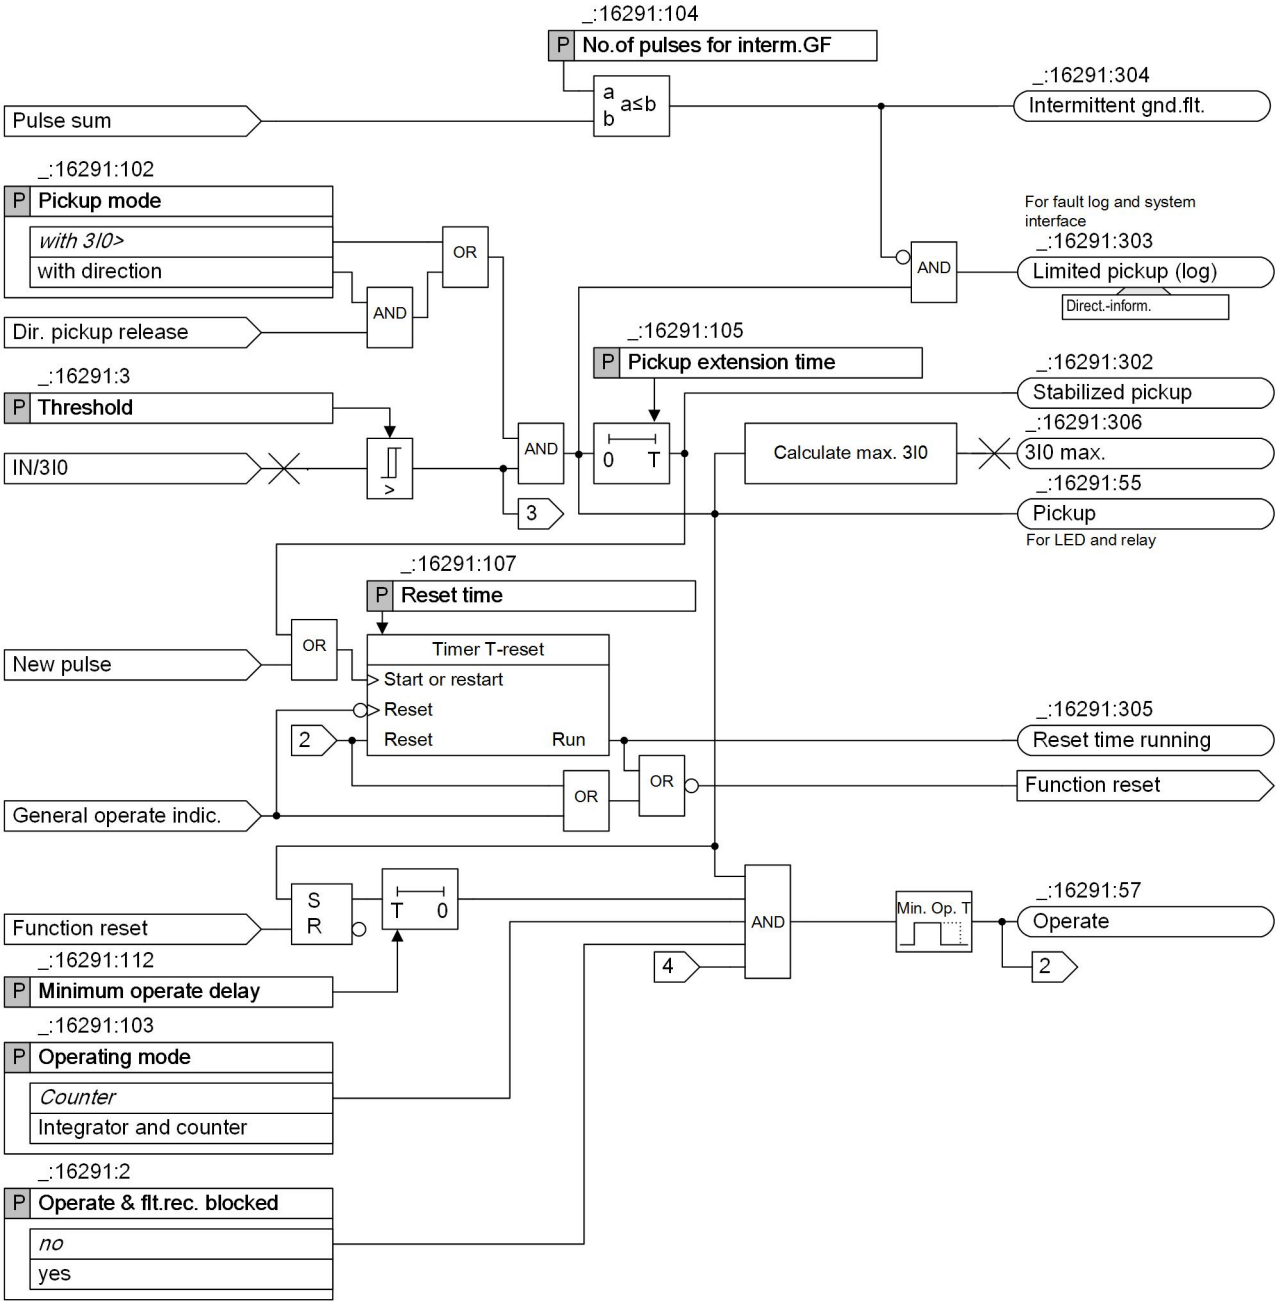
The directional pulse counter is reset when a different direction than the set **Directional mode** is detected. An undefined direction result does not reset the counter.

Operating Mode

2 different functional operating modes are available: ***Counter*** and ***Integrator and counter***. You can select the different operating modes using the parameter **Operating mode**.

- Operating mode ***Counter***:

  Many ground-current pulses of intermittent ground faults can result in a damage of the protected object. In this mode, the criterion for operate is only the number of directional current pulses. This is similar to the SIPROTEC 4 implementation.



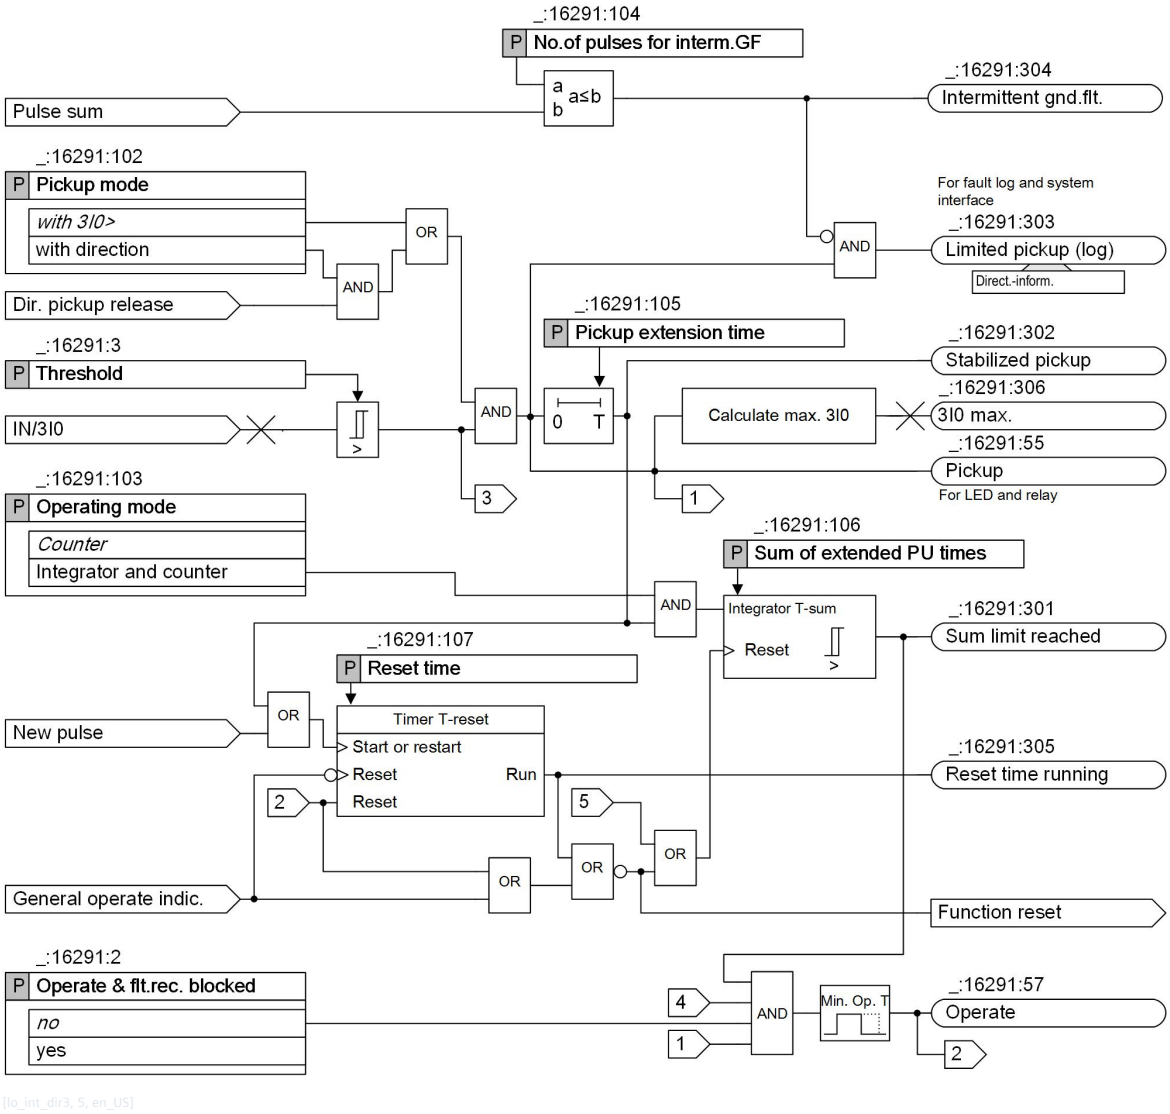
- Operating mode ***Integrator and counter***:

  An intermittent ground fault can result in thermal stress on the protected object. The magnitude and the duration of the ground-current pulses are decisive for the thermal stress. In order to calculate the thermal stress, the stage sums up the duration of the stabilized pickups with an integrator. If the integration value reaches the threshold value, one criterion for the operate is fulfilled. The 2nd criterion for the operate is the ground-fault direction. The ground-fault direction is determined by counting the directional ground-current pulses.

36 These values apply for a secondary rated current of 1 A. The values need to be multiplied by 5 when the secondary rated current is 5 A.

38 If the connection type is with IN, such as 3-phase + IN, the current threshold value is a measured IN value.

Pickup, Operate, and Reset logic for the Counter Mode



[lo_int_dir2, 4, en_US]

Figure 6-230 Pickup, Operate, and Reset Logic in Operating Mode Counter

(1) The internal signal 4 is from *Figure 6-229*.

Pickup, Operate, and Reset logic for the Integrator and Counter Mode

[lo_int_dir3, 5, en_US]

Figure 6-231 Pickup, Operate, and Reset Logic in Operating Mode Integrator and Counter

(1) The internal signal 4 and 5 are from *Figure 6-229*.

Measurement Value for Pickup and Integration

The stage calculates the RMS value of 3I0 since this value takes into account the higher-order harmonic components and the direct component (DC). Both components contribute to the thermal load.

Pickup, Limited Pickup, and Stabilized Pickup

Whenever 3I0 exceeds **`Threshold`**, the stage issues the signal *`Pickup`*. The signal is intended to be applied for LED and relay output.

`Stabilized pickup` is formed by prolonging the pickup indication by a settable time **`Pickup extension time`**. This stabilization is especially important for the coordination with the existing static or electromechanical overcurrent protection.

The *`Limited pickup (log)`* signal is intend to be applied for logging and communication interface. The *`Limited pickup (log)`* signal will be entered in the fault log and reported via the system interface unless the *`Intermittent gnd.flt.`* indication is given. This behavior prevents a burst of indications.

Intermittent Ground-Fault Indication

The stage counts the 3I0 pulses. If the sum of forward pulse counts, reverse counts, and directional undefined counts is equal to or greater than **No.of pulses for interm.GF**, the signal *Intermittent gnd.flt.* is issued.

If the signal *Intermittent gnd.flt.* is issued, the pickup indications of some protection functions will be restraint to avoid an indication burst during an intermittent ground fault.

Operate

The conditions for issuing the signal *Operate* depend on the operating mode.

Operating Mode	Conditions for Issuing the Operate Signal
Counter	• The current-pulse counter reached the **No. of pulses for operate**, which is signaled via the *Pulse no. reached* indication. • The timer **Minimum operate delay** expired. The timer is started with the first pickup and is reset when the function resets. • The pickup is active, which is signaled via the *Pickup* indication.
Integrator and counter	• The 3I0 current integration value reaches the predefined **Sum of extended PU times**, which is signaled via the *Sum limit reached* indication. • The current-pulse counter reached the **No. of pulses for operate**, which is signaled via the *Pulse no. reached* indication. • The pickup is active, which is signaled via the *Pickup* indication.

When an opposite current pulse against the setting **Directional mode** is detected, the **Integrator T-sum** and the **Counter** are reset.

Reset Time for the Definition of the Interval between Independent Ground Faults

If there is a long interval between independent ground faults or if the ground fault extinguishes and does not restrike again within a long time, the function must not operate. The interval between ground faults is monitored with the reset time. If a ground fault occurs, the **Timer T-reset** with the setting **Reset time** and the **Integrator T-sum** are launched simultaneously. Unlike the integrator, each new ground-current pulse restarts the reset time with its initial value. If the **Timer T-reset** expires, that is, no new ground fault was detected during that period, all memories and the stage logics are reset. The **Timer T-reset** thus determines the time during which the next ground fault must occur to be processed yet as intermittent ground fault in connection with the previous fault. A ground fault that occurs later is considered as a new ground-fault event.

Reset Conditions

Under one of the following 2 conditions, **Timer T-reset** is reset:

- The intermittent ground-fault protection stage operates.
- The general operate indication is going.

Under one of the following conditions, **Integrator T-sum** and **Counter** are reset and the whole stage is reset and returns to its idle state:

- The **Timer T-reset** expires without an operate signal of this stage or another function was issued.
- The operate signal of the intermittent ground-fault protection stage is going.
- The general operate indication is going without the operate signal of the intermittent ground-fault protection stage issued.

Maximum Value 3I0 of the Ground Fault

The stage records the maximum RMS value of 3I0 during the intermittent ground fault.The statistic value *3I0 max.* is a percentage value calculated through dividing the primary maximum RMS value by the rated current value of the protected object. If the function resets or operates, this value is logged via the signal *3I0 max.*.

Fault Log and Fault Recording

You can select between the ground-fault log without fault recording or the normal fault log with fault recording. If you set the parameter **Operate & flt.rec. blocked** to ***yes***, the operate of the stage and fault recording are blocked and the information automatically appears in the ground-fault log. Otherwise, the operate and fault recording are not blocked and the information appears in the normal fault log.

Start and Stop of Fault Recording, Fault Logging, and General Pickup

The *Stabilized pickup* signal initiates fault recording, fault logging, and the general pickup of the function group. The fault recording starts according to the pre-trigger time before the *Stabilized pickup* signal rises.

With the reset condition of this stage, the fault recording, fault logging, and the general pickup of the function group are terminated.

Influence on Other Functions to Avoid a Burst of Indications

In this case, the function uses the same mechanism as the **Non-directional intermittent ground-fault protection**. For more information, refer to chapter *Influence on Other Functions to Avoid a Burst of Signals, Page 882*.

6.11.4 Application and Setting Notes

No Start of the Automatic Reclosing Function

Automatic reclosing is not an effective measure against intermittent ground faults. For this reason, the function **Directional intermittent ground-fault protection** is not intended to start the Automatic reclosing function.

Routing of Pickup Signals

The signal *Pickup* is supposed to be routed to an LED and a relay. The signal *Limited pickup (log)* is only reported to the fault log and communication interface until the signal *Intermittent gnd.flt.* is issued. This scheme prevents a burst of indications.

NOTE

To avoid a burst of indications, do not route the signal *Pickup* to the operational log and to the fault log.

Parameter: Threshold

- Default setting **(_:16291:3) Threshold** = ***1.00 A***

With the parameter **Threshold**, you set the threshold value of the ground current 3I0, measured as RMS value.

A rather sensitive setting is possible to respond also to short ground faults since the pickup time shortens as the ground-fault current increases.

Parameter: Directional mode

- Default setting **(_:16291:101) Directional mode** = ***forward***

With the parameter **Directional mode**, you define if the function operates in *forward* or in *reverse* direction.

Parameter: Pickup mode

- Default setting **(_:16291:102) Pickup mode** = ***with 3I0>***

With the parameter **Pickup mode**, you define under which conditions pickup is detected and fault logging and recording start:

- When the parameter **Pickup mode** is set to ***with 3I0>***, the signal *Pickup* is released without considering the ground fault direction. The signal *Pickup* is issued once the IN/3I0 exceeds the threshold value.
- When the parameter **Pickup mode** is set to ***with direction***, the signal *Pickup* is issued when at least one pulse direction is the same as the direction specified by the set value of parameter **Directional mode**.

Parameter: **Operating mode**

- Default setting **(_:16291:103) Operating mode** = ***Counter***

With the parameter **Operating mode**, you define if the function operates in ***Counter*** or in ***Integrator and counter*** mode.

Operating Mode	Application and Setting Notes
Counter	The number of directional pulses is the determining operate criterion. This is a simple method which is similar to the implementation in the 7SJ SIPROTEC 4 devices. Siemens recommends using this method if no time grading or only simple time grading between protection devices (time grading of only 2 or 3 devices) is required. Time grading is then carried out by increasing the parameter value **No. of pulses for operate** towards the infeed.
Integrator and counter	The integrator and the counter are the determining operate criteria while the counter criterion is only used for the direction determination. The integrator works in the same way as for the non-directional intermittent ground fault function. This allows the same time-grading principles as for the non-directional intermittent ground fault function. Refer to this function for more description.

Parameter: **No.of pulses for interm.GF**

- Default setting **(_:16291:104) No.of pulses for interm.GF** = ***3***

With the parameter **No.of pulses for interm.GF**, you set the total number of pulse counts (***forward***, ***reverse*** and ***non-dir. pulses***) at which the ground fault is considered to be intermittent. Siemens recommends using the default setting.

Parameter: **Pickup extension time**

- Default setting **(_:16291:105) Pickup extension time** = ***0.10 s***

With the parameter **Pickup extension time**, you get a prolonged and thus stabilized pickup signal. This stabilization is especially important for the coordination with existing static or electromechanical overcurrent protections.

Parameter: **No. of pulses for operate**

- Default setting **(_:16291:108) No. of pulses for operate** = ***5***

The pulses in the specified direction from **Directional mode** are counted. If the pulse counter reaches the set value of the parameter **No. of pulses for operate**, the directional counter criterion is fulfilled.

The setting of parameter **No. of pulses for operate** depends on the **Operating mode**.

Operating Mode	Application and Setting Notes
Counter	The number of directional pulses is the determining operate criterion. Thus do not set the value for parameter **No. of pulses for operate** too small. Consider that a permanent intermittent ground fault will cause many current pulses. If no time-grading considerations are required, Siemens recommends using a value in the range of 10 to 20.
Integrator and counter	The integrator and the counter are the determining operate criteria while the counter criterion is only used for the direction determination. The value for parameter **No. of pulses for operate** to fulfill the directional criterion can be set to a rather small value in the range of 3 to 5.

Parameter: Sum of extended PU times

- Default setting **(_:16291:106) Sum of extended PU times** = ***20.00 s***

This parameter is only relevant in the operating mode ***Integrator and counter***.

With the parameter **Sum of extended PU times**, you set the threshold value for the integrator. If the integration reaches **Sum of extended PU times**, the stage operates if the signal *Pulse no. reached* and the pickup state is present.

The parameter **Sum of extended PU times** represents one of the 5 selectivity criteria (ground-fault direction, pickup threshold, pickup extension time, reset time, and integrator threshold value) for coordination of the relays on subordinate devices. It is comparable to the time grading of the overcurrent protection.

The **Sum of extended PU times** has the shortest summation time in the radial system for the device that is closest to the intermittent ground fault and that picks up.

Parameter: Reset time

- Default setting **(_:16291:107) Reset time** = ***300 s***

With the parameter **Reset time**, you can define the maximum interval between 2 adjacent ground faults. If the interval is larger than the **Reset time**, the counter and integrator are reset.

The parameter **Reset time** must be much higher than the operate value of the **Sum of extended PU times**.

NOTE

Siemens recommends setting the parameter **Reset time** to a value not lower than 40 ms. A too low value will lead to a risk that the intermittent ground-fault protection function never picks up.

Parameter: Operate & flt.rec. blocked

- Default setting **(_:16291:2) Operate & flt.rec. blocked** = ***no***

With the parameter **Operate & flt.rec. blocked**, you can block the operate indication, the fault recording, and the fault log. In this case, a ground-fault log is created instead of the fault log.

Parameter: Minimum operate delay

- Default setting **(_:16291:112) Minimum operate delay** = ***0.00 s***

This parameter is only relevant in the operating mode ***Counter***.

The parameter **Minimum operate delay** is used to avoid too fast tripping in case of frequent restriking (for example, restriking occurs every 30 ms).

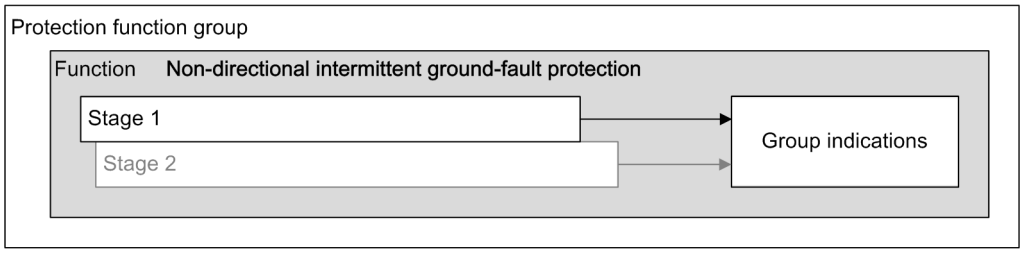
6.12 Non-Directional Intermittent Ground-Fault Protection

6.12.1 Overview of Functions

A typical characteristic of intermittent ground faults is that they often extinguish automatically and strike again after some time. The fault duration can last between a few milliseconds and many seconds. Thus, such faults are not detected at all or not selectively by the ordinary overcurrent protection. If pulse durations are extremely short, not all protection devices in a short-circuit path can pick up. Thus, selective tripping is not ensured.



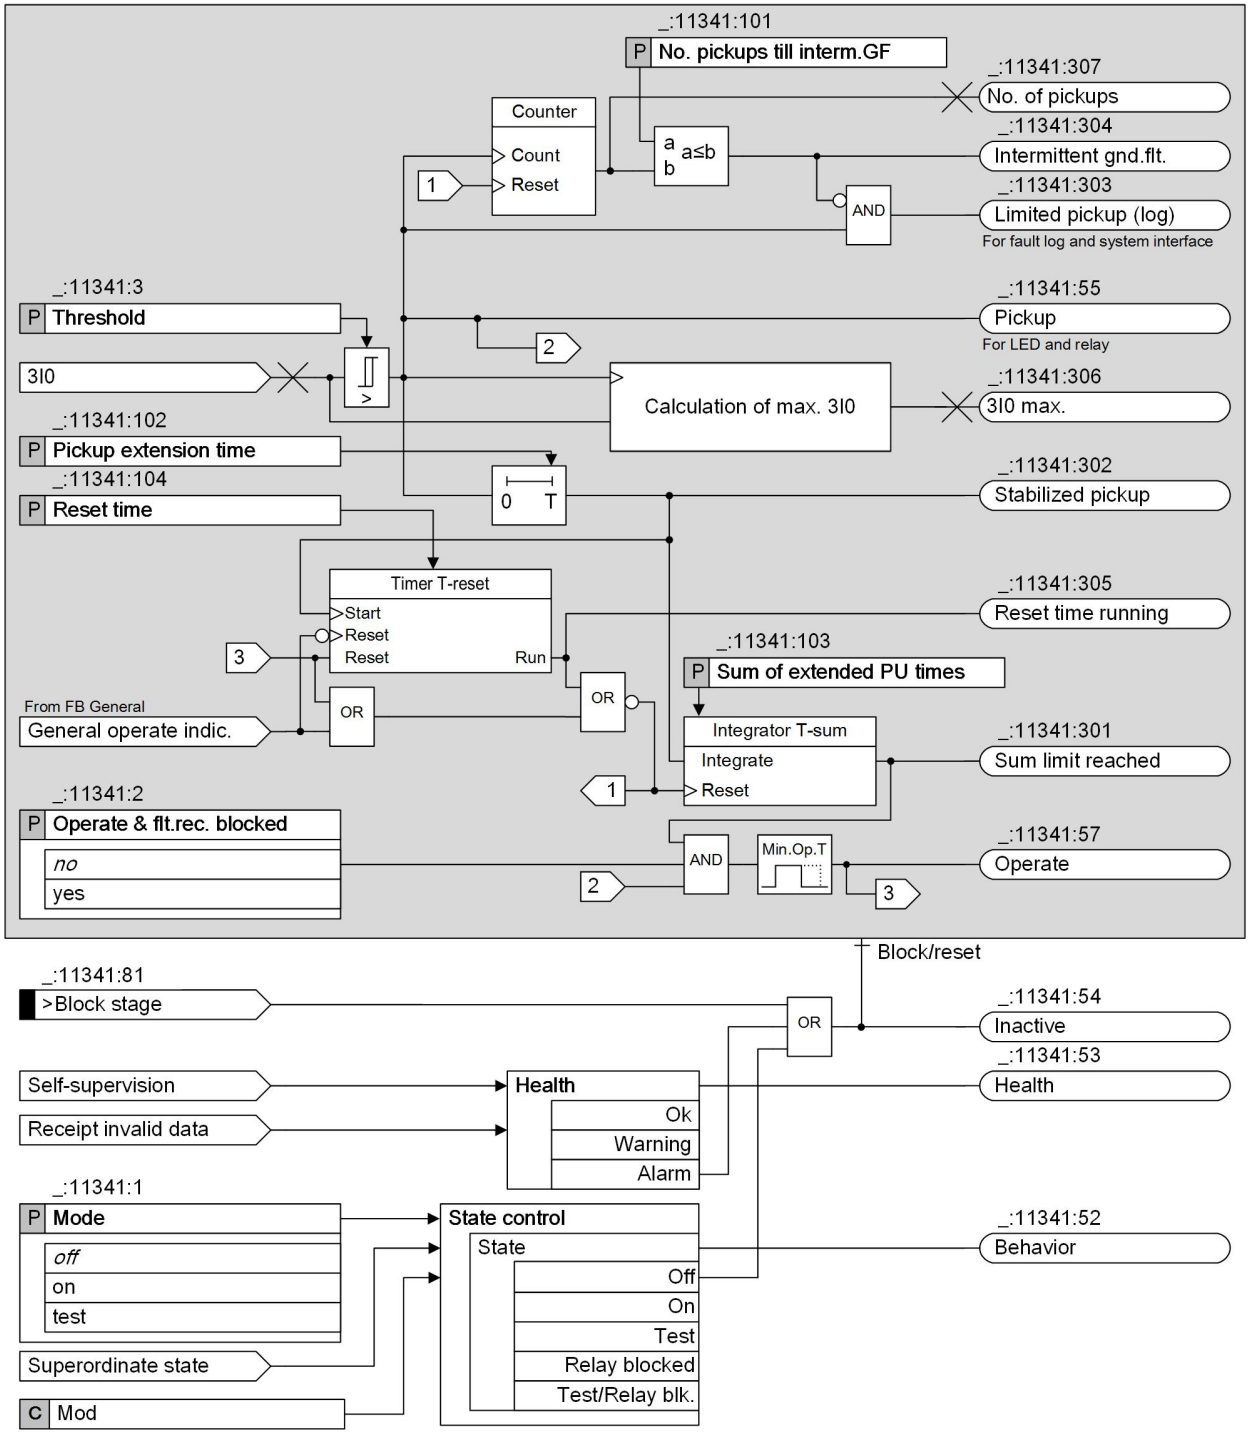
Due to the time delay of the overcurrent protection function, such faults are too short to initiate switching off the faulted cable. The short-circuit protection can clear such ground faults selectively only if the ground faults have become permanent.

But such intermittent ground faults already bear the risk of damaging the equipment thermally. This is why SIPROTEC 5 devices feature a protection function that is able to detect such intermittent ground faults and accumulates their duration. If the sum reaches a configurable value within a certain time, the limit of the thermal rating has been reached. If intermittent ground faults are distributed over a long period or if the ground fault disappears and does not restrike after some time, the equipment under load is expected to cool down. Tripping is not necessary in this case.

The function **Non-directional intermittent ground-fault protection** is used to protect against intermittent ground faults which occur, for example, in cables due to poor insulation or water ingress in cable joints.

6.12.2 Structure of the Function

The function **Non-directional intermittent ground-fault protection** can be used in protection function groups with current measurement. The function comes factory-set with 1 stage, and a maximum of 2 stages can be operated simultaneously. The non-preconfigured stages are shown in gray in the following figure.



[dw_int_GFP, 1, en_US]

Figure 6-232 Structure/Embedding of the Function

6.12.3 Stage Description

Logic

[lo_Intnon, 2, en_US]

Figure 6-233 Logic of the Non-Directional Intermittent Ground-Fault Protection

Measured Value 3I0

The intermittent ground-fault current 3I0 can either be measured via the standard ground-current input IN or via the sensitive ground-current input I_{NS}. It can also be calculated from the sum of the 3-phase currents. The current value and its setting range depend on the parameter **Connection type** of the measuring point I-3ph.

Table 6-3 Threshold Setting Range with Different Connection Types

Connection Type of the Measuring Point I-3ph	Current Threshold 3I0/IN	CT Terminal Type	Setting Range Threshold Value (Secondary)[39]
3-phase	Calculated 3I0[40]	4 x Protection	0.030 A to 35.000 A
		3 x Protection, 1 x sensitive	0.030 A to 35.000 A
		4 x Measurement	0.001 A to 1.600 A
3-phase + IN 3-phase + IN-separate	Measured IN[41]	4 x Protection	0.030 A to 35.000 A
		4 x Measurement	0.001 A to 1.600 A
	Measured IN and calculated 3I0 when IN > 1.6 A	3 x Protection, 1 x sensitive	0.001 A to 35.000 A

Method of Measurement

The stage calculates the RMS value of 3I0 since this value takes into account the higher-order harmonics components and the direct component (DC). Both components contribute to the thermal load.

Maximum 3I0 of the Fault

The stage records the maximum RMS value of 3I0 during the intermittent ground fault. The statistical value *3I0 max.* is a percentage value calculated through dividing the primary maximum RMS value by the rated current value of the protected object. With the coming operate signal, this value is logged via the information *3I0 max.*.

Pickup and Intermittent Ground-Fault Indication

When 3I0 exceeds the threshold value, the pickup signals *Pickup* and *Limited pickup (log)* are issued. The stage generates the signal *Stabilized pickup* by extending the *Pickup* for a defined time (parameter **Pickup extension time**).

The stage counts the signals *Pickup*. If the counted number reaches the configured **No. pickups till interm.GF**, the signal *Intermittent gnd.flt.* is issued. The signal *Limited pickup (log)* is not issued anymore after the issue of the signal *Intermittent gnd.flt.*.

39 These values apply for a secondary rated current of 1 A. The values need to be multiplied by 5 when the secondary rated current is 5 A.

40 If the connection type is without IN, such as 3-phase, the current threshold value is a calculated 3I0 value.

41 If the connection type is with IN, such as 3-phase + IN, the current threshold value is a measured IN value.

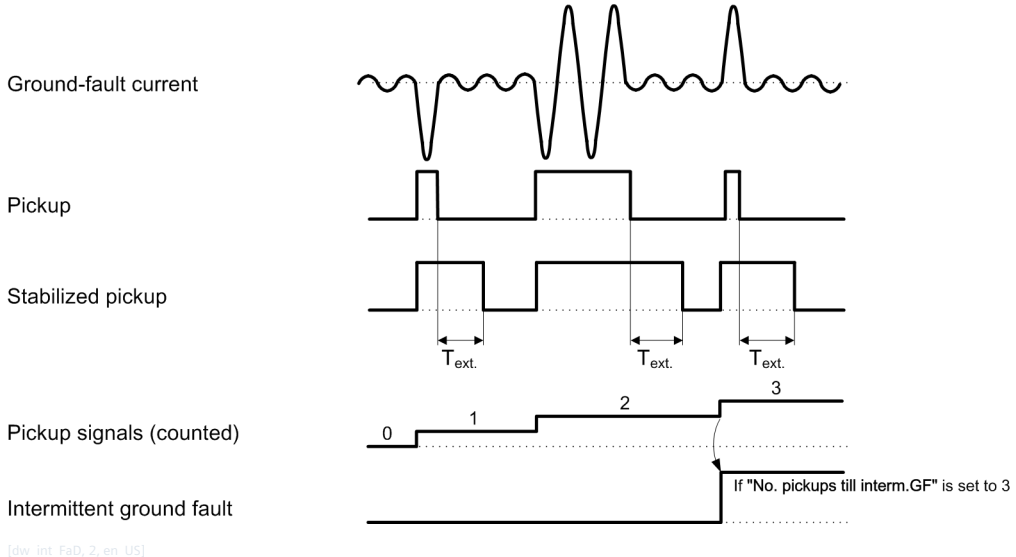


Figure 6-234 Fault Detection of the Intermittent Ground-Fault Protection

$T_{ext.}$ Defined time for extending the signal *Pickup*

Number of Pickups

The stage counts the number of signals *Pickup* during the intermittent ground fault. With the operate of the stage this number is logged via the information *No. of pickups*.

Accumulation of the Intermittent Ground-Fault Current and Issuing the Operate Signal

An intermittent ground fault can result in thermal stress on the protected equipment. The magnitude and the duration of the ground-fault current are decisive for the thermal stress. In order to calculate the thermal stress, the stage sums up the duration of the stabilized pickups with a sum of times. If the integration value reaches the predefined **Sum of extended PU times**, the limit of the thermal load is reached. The stage issues the signal *Sum limit reached* and operates when the signal *Pickup* is active.

Reset Timer for the Definition of the Interval between Independent Ground Faults

If there is a large interval between independent ground faults or if ground fault extinguishes and does not restrike again within a larger time, the stressed equipment can cool down. In this case, an operation is not necessary. The interval between ground faults is monitored with the reset timer. If a ground fault occurs, the **Timer T-reset** with its setting **Reset time** is launched simultaneously with **Integrator T-sum**. Unlike the integrator, each new ground fault restarts the reset timer with its initial value. If **Timer T-reset** expires, that is, no new ground fault was detected during that period, all memories and the stage logics are reset. **Timer T-reset** thus determines the time during which the next ground fault must occur to be processed yet as intermittent ground fault in connection with the previous fault. A ground fault that occurs later is considered as a new fault event.

Reset Conditions

Under one of the following 2 conditions, **Timer T-reset** is reset.

- The Intermittent ground-fault protection stage operates.
- The general operate indication is going.

Under one of the following conditions, **Integrator T-sum** and **Counter** are reset and the whole stage is reset and returns to its idle state.

- **Timer T-reset** expires without an operate signal of this stage or another function was issued.
- The operate signal of the intermittent ground-fault protection stage is going.
- The general operate indication is going without the operate signal of the intermittent ground-fault protection stage issued.

Fault Log and Fault Recording

You can select between the ground-fault log without fault recording or the normal fault log with fault recording. If you set the parameter **Operate & flt.rec. blocked** to ***yes***, the operate of the stage and fault recording are blocked and the information automatically appears in the ground-fault log. Otherwise, the operate and fault recording are not blocked and the information appears in the normal fault log.

Start & Stop of Fault Recording, Fault Logging, and General Pickup

The signal *Stabilized pickup* initiates the fault recording, fault logging, and the general pickup of the function group. The fault recording starts according to the pre-trigger time before the signal *Stabilized pickup* rises.

With the reset condition of this stage, the fault recording, fault logging, and the general pickup of the function group are terminated.

Influence on Other Functions to Avoid a Burst of Signals

Intermittent ground faults may cause other functions, based on overcurrent measurement, to pick up, which may result in a burst of signals. In order to avoid an overflow of the fault log, a special mechanism is applied to the signals of these functions after detection of an intermittent ground fault (signal *Intermittent gnd.flt.*).

The special mechanism is applied for the following listed functions and other functions are not influenced:

- Overcurrent protection, phases
- Overcurrent protection, ground
- Directional overcurrent protection, phases
- Directional overcurrent protection, ground
- Overcurrent protection, 1-phase
- Negative-sequence protection with definite-time characteristic curve
- Directional negative-sequence protection with definite-time delay
- Directional overcurrent-protection stage with cos phi or sin phi measurement
- Directional overcurrent-protection stage with 3I0-phi (V,I) measurement
- Sensitive ground-current protection with 3I0

If a function picks up, normally its output signals are sent directly to the information targets, for example, the pickup signal is written to the fault log. To avoid overflow of logs due to intermittent ground faults, a special log buffer mechanism is used. If one of the preceding functions or stages picks up after an intermittent ground fault has been detected (signal *Intermittent gnd.flt.* has been issued), its output signals are processed as shown in the following 2 tables.

Table 6-4 Processing of the Signal Status Changes

Processing of Signal Status Changes	Description
Special buffering mechanism	The status changes of signals are written to a special buffer. This buffer can store the latest change for each signal. With the pickup signal as example, if one of the preceding protection functions or stages picks up during an active signal *Intermittent gnd.flt.*, the pickup signal is not written in the fault log anymore unless one of the preceding functions operates. After the operation, the buffered signals are written to the information target with the original time stamp. This measure ensures that a pickup signal, although delayed, is always signaled in association with each operate command.
Discard	The signal status changes are discarded.
Pass through	The signal is forwarded to the information target without restriction. Special buffering does not apply for specific information targets as protection measure, for example, reverse interlocking, need these signals for proper operation.

Table 6-5 Information Target with Different Processing of Signal Status Changes

Information Target		Processing of Signal Status Changes
Processing of Signal Status Changes	Operational log Fault log Ground-fault log User-defined log	Special buffering mechanism
Communication interface	IEC 61850-8-1 Client/Server IEC 60870-5-103/104 DNP V3.0	Special buffering mechanism
Automatic reclosing function		Discard
Circuit-breaker failure protection		Discard
Group indications		Discard(1)
Protection interface	PDI	Pass through
IEC 61850-8-1 GOOSE		Pass through
CFC		Pass through
LEDs		Pass through
Binary output		Pass through
Fault recorder		Pass through

(1) Note for reverse-interlocking applications: To ensure that the interlocking signal is not discarded during an intermittent ground fault, Siemens recommends using the individual pickup signals of the function stages instead of the group indications for reverse-interlocking applications in combination with the intermittent ground-fault protection function.

6.12.4 Application and Setting Notes

No Start of the Automatic Reclosing Function

Automatic reclosing is not an effective measure against intermittent ground faults as the protection function only operates after repeated detection of a fault or after the integration value reaches the predefined **Sum of**

extended PU times. Besides this, its basic design is to prevent thermal overload. For these reasons, the intermittent ground-fault protection function is not intended to start the automatic reclosing function.

Rooting of Pickup Signals

The signal *Pickup* is supposed to be routed to LED and relay. The signal *Limited pickup (log)* is only reported to the fault log and communication interface before the signal *Intermittent gnd.flt.* is issued. This scheme prevents a burst of messages.

NOTE

To avoid a burst of messages, do not route the signal *Pickup* to the operational log and fault log.

Parameter: Threshold

- Default setting **(_:11341:3) Threshold** = ***1.00 A***

With the parameter **Threshold**, you set the threshold value of the ground current 3I0, measured as RMS value.
A rather sensitive setting is possible to respond also to short ground faults since the pickup time shortens as the ground-fault current increases.

Parameter: No. pickups till interm.GF

- Default setting **(_:11341:101) No. pickups till interm.GF** = ***3***

With the parameter **No. pickups till interm.GF**, you set the number of counted *Pickup* signals after which the ground fault is considered as intermittent.

Parameter: Pickup extension time

- Default setting **(_:11341:102) Pickup extension time** = ***0.10 s***

You can get a stabilized pickup signal with the parameter **Pickup extension time**. This stabilization is especially important for the coordination with existing static or electromechanical overcurrent protections.

Parameter: Sum of extended PU times

- Default setting **(_:11341:103) Sum of extended PU times** = ***20 s***

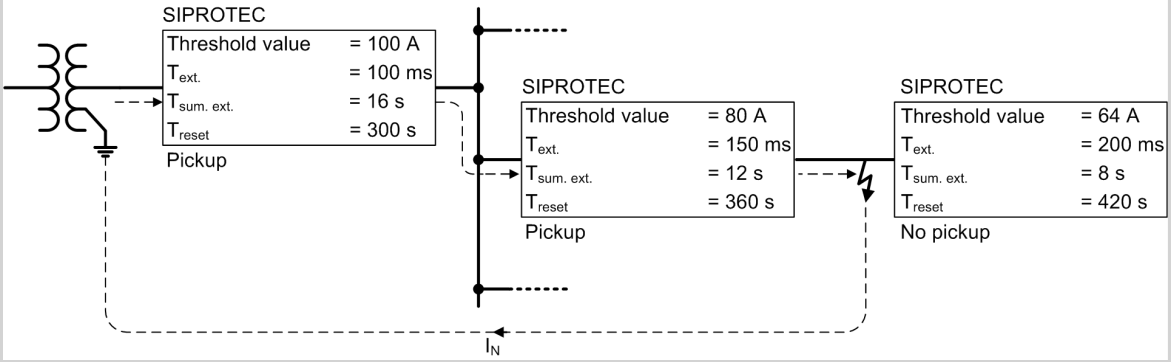
With the parameter **Sum of extended PU times**, you set the threshold value for the integrator. If the integration reaches **Sum of extended PU times**, the stage operates if the pickup state is present.
This **Sum of extended PU times** represents one of the 4 selectivity criteria (pickup threshold, pickup extension time, reset time, and integrator threshold value) for coordination of the relays on adjacent feeders. It is comparable to the time grading of the overcurrent protection. The protection in the radial system which is closest to the intermittent fault and picks up, has the shortest summation time **Sum of extended PU times**.

Parameter: Reset time

- Default setting **(_:11341:104) Reset time** = ***300 s***

With the parameter **Reset time**, you can define the maximum interval between 2 adjacent ground faults. If the interval is larger than the **Reset time**, the counter and integrator are reset.
The parameter **Reset time** must be much higher than the operate value of the **Sum of extended PU times**.

NOTE



Siemens recommends setting the parameter **Reset time** to a value not lower than 40 ms. A too low value will lead to a risk that the intermittent ground-fault protection function never picks up.

Parameter: `Operate & flt.rec. blocked`

- Default setting **`(_:11341:2) Operate & flt.rec. blocked`** = ***no***

You can block the operate indication, the fault recording, and the fault log with the parameter **`Operate & flt.rec. blocked`**. In this case, a ground-fault log is created instead of the fault log.

6.13 Sensitive Ground-Fault Detection

6.13.1 Overview of Functions

2 functions are available for ground-fault detection: a directional one and a non-directional one.

The **Directional sensitive ground-fault detection** (ANSI 67Ns) serves:

- For directional detection of permanent ground faults in isolated or resonant-grounded systems
- For directional detection of fast extinguishing transient ground faults in isolated or resonant-grounded systems
- For determination of the faulty phase
- For detection of high-impedance ground faults in effectively (solidly) or low-impedance (semi-solidly) grounded systems

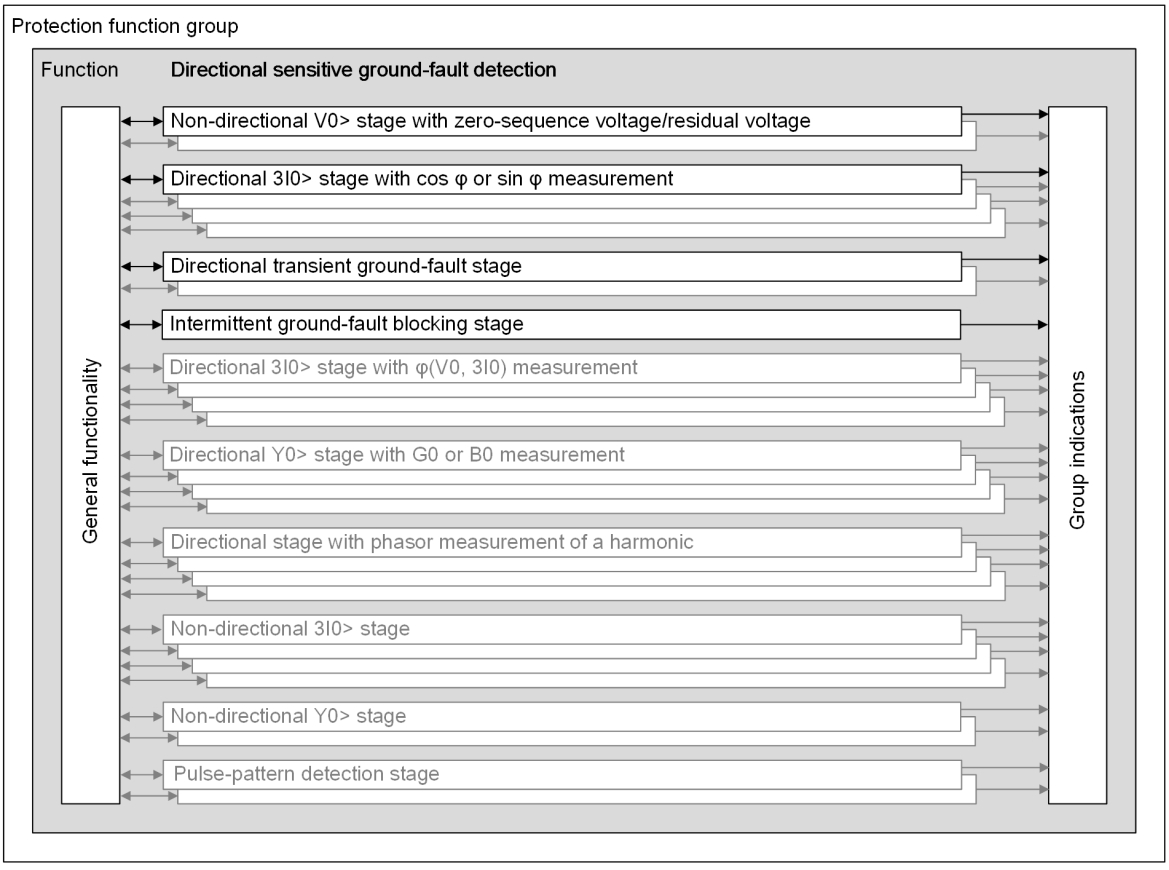
The **Non-directional sensitive ground-fault detection** (ANSI 51Ns) serves:

- For ground-fault detection in isolated or resonant-grounded systems
- For detection of high-impedance ground faults in effectively (solidly) or low-impedance (semi-solidly) grounded systems

6.13.2 Structure of the Function

Directional Sensitive Ground-Fault Detection

The **Directional sensitive ground-fault detection** function can be used in protection function groups that make current and voltage zero-sequence systems (3I0 and V0) available. The function comes factory-set with a non-directional **V0> stage with zero-sequence voltage/residual voltage**, a directional **3I0> stage with cos φ or sin φ measurement**, a directional **transient ground-fault stage**, and an **intermittent ground-fault blocking stage**.



The following stages can be operated simultaneously within the function:

- 2 non-directional **V0> stages with zero-sequence voltage/residual voltage**
- 4 directional **3I0> stages with cos φ or sin φ measurement**
- 2 directional **transient ground-fault stages**
- 4 directional **3I0> stages with φ(V0, 3I0) measurement**
- 4 directional **Y0> stages with G0 or B0 measurement** (admittance method)
- 4 directional **stages with phasor measurement of a harmonic**
- 4 non-directional **3I0> stages**
- 2 non-directional **Y0> stages**
- 2 non-directional **pulse-pattern detection stages**
- 1 **intermittent ground-fault blocking stage**

The general functionality works across stages on the function level.

The group-indications output logic generates the following group indications of the entire function by the logical OR from the stage-selective indications:

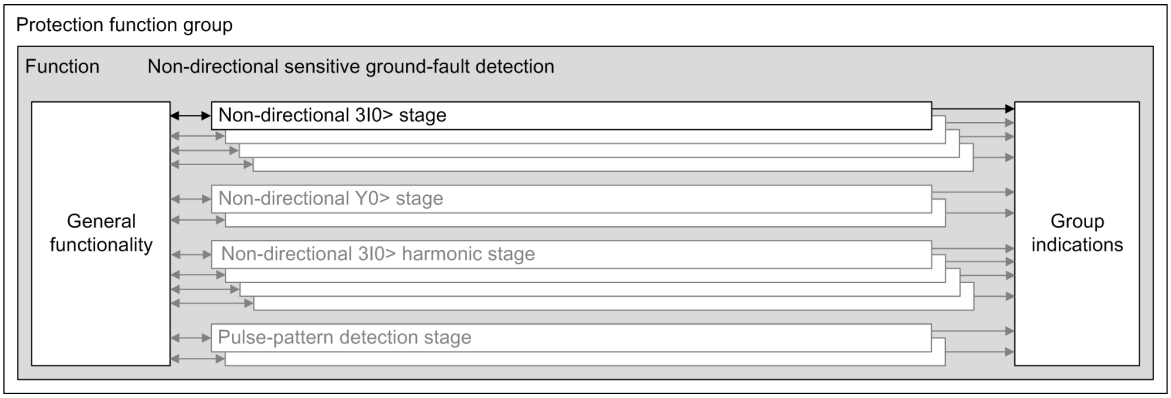
- Pickup
- Operate indication

[dw_str_GFP, 6, en_US]

Figure 6-236 Structure/Embedding of the Directional Function in Protection Function Groups

Non-Directional Sensitive Ground-Fault Detection

The **Non-directional sensitive ground-fault detection** function can be used in protection function groups that only make the zero-sequence system (3I0) available. The function comes factory-set with a non-directional **3I0> stage**.



The following stages can be operated simultaneously within the function:

- 4 non-directional **3I0> stages**
- 2 non-directional **Y0> stages**
- 4 non-directional **3I0> harmonic stages**
- 2 non-directional **pulse-pattern detection stages**

The general functionality works across stages on the function level.

The group-indications output logic generates the following group indications of the entire function by the logical OR from the stage-selective indications:

- Pickup
- Operate indication

[lo_gfp_non, 6, en_US]

Figure 6-239 Logic Diagram of the Cross-Stage Functionality of the Non-Directional Function

Operational Measured Value φ(I,V)

The function block calculates the angle between IN and V0 and makes the angle available as function measured value *Phi(I,V)*.

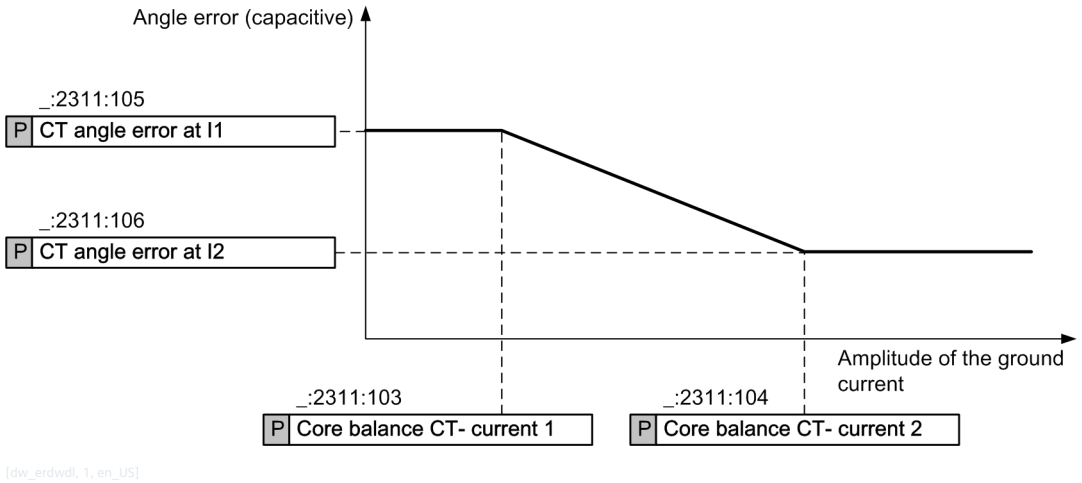
[dw_ph_I_N_U0, 1, en_US]

Figure 6-240 Sign Definition for the Measured Value

Network Topology

The parameter **Network topology** parameter is only used in the **Directional transient ground-fault** stage.

With this parameter, the algorithm of the directional transient ground-fault stage adopts its processing of an operational 3I0.



Fault-Extinction Detection

The extinction of the fault is characterized by the fact that the zero-sequence voltage subsides. Depending on the system conditions and fault characteristics, this process can last several 100 ms. If a continuously falling zero-sequence voltage is detected during the set time **Decay time V0**, then the fault is considered extinguished. The signal *Flt. extinction det.* is issued.

Thus, the possibility exists, for example, to block the stage **3I0>** with cos φ or sin φ measurement directly after the fault extinction, in order to avoid an overfunction during the subsiding process with a very sensitive setting of the stage.

Angle-Error Compensation

The high reactive power factor in the arc-suppression-coil-ground system and the unavoidable air-gap of the core balance current transformer often make necessary a compensation of the angle error of the core balance current transformer. Using the characteristic shown in the following figure, the device approaches the angle error of the core balance current transformer with sufficient precision.

[dw_erdwdl, 1, en_US]

Figure 6-241 Correction of the Transmission Characteristic Curve of a Core Balance Current Transformer

Ground-Fault Indication, Stabilization at Intermittent Ground Fault

The indication *Ground fault* indicates the ground fault and manages the ground-fault log (see *Ground-Fault Log, Page 892*). The corresponding information of the stages used is accessed for the generation of this indication.

The indication *Ground fault* contains the direction information, independent of the parameterized working direction of a stage. The indication is thus suited for transfer to a station.

To avoid a flood of indications in case of an intermittent ground fault, a maximum of 30 status changes of this indication is logged per ground fault. An intermittent ground fault must be treated as one ground fault so that the stabilization can take action. This is ensured with the parameter **Dropout delay**, by the dropout of the indication *Ground fault* being delayed. If the next ignition of the ground fault takes place during the dropout delay, the indication does not drop out and the log remains open.

NOTE

The *Ground fault* indication in the general stage must be routed into the ground-fault log. If not, you can meet a flood of ground-fault logs when an intermittent ground fault occurs.

Ground-Fault Log

Ground faults can be recorded in a designated buffer, the ground-fault log. As long as the **Operate & flt.rec. blocked** parameter is set to ***yes***, all indications routed into the ground-fault log are written in the ground-fault log.

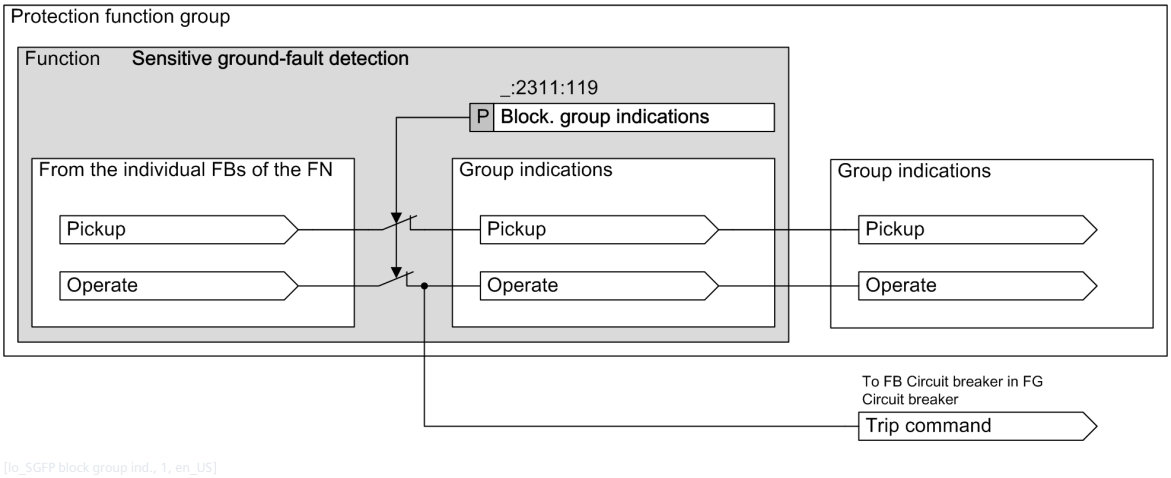
The criterion for opening the ground-fault log is the raising of any indication which is routed to the ground-fault log, for example, the indication *Ground fault* . The criterion for closing is the clearing of all routed indications.

Related Topics

You can find general notes on the ground-fault login chapter **Indications** under *3.1.5.4 Ground-Fault Log*.

Value Indications in Log and Real-Time Functional Values

If the value indications listed in *Table 6-6* can be calculated, they are written into the log (ground-fault log or fault log) at the time of the 1st raising ground-fault indication and the 1st operate indication of any stage.



The function also provides some real-time functional values, as described in *Table 6-6*.

Table 6-6 Value Indications in Log and Real-Time Functional Values

Value Indication in Log	Real-Time Functional Value	Description
IN	–	Neutral-point current IN
IN active	IN act.	Active component IN
IN reactive	IN react.	Reactive component IN
V0	–	Zero-sequence voltage V0
Phi(IN, V0)	Phi(I,V)	Angle between IN and V0 Refer to *Operational Measured Value φ(I,V) , Page 891*.

If the ground current is measured via a sensitive input and the measured value exceeds the measuring range of 1.6 · I_{rated}, the function switches from the measured IN value to the calculated 3I0 value and the 3I0 values are displayed.

Group-Indication Blocking

[lo_SGFP block group ind., 1, en_US]

Figure 6-242 Logic Diagram of the Group-Indication Blocking of the Directional and Non-Directional Functions

By setting the **`Block. group indications`** parameter to ***`yes`***, the following indications are blocked:

- The group indications of the function and the corresponding group indications of the function group
- The trip command from the function **Sensitive ground-fault detection** to the FB **Circuit breaker**

Fault recording and logging are not affected by the setting.

6.13.3.2 Application and Setting Notes

Indication: *`Ground fault`*

To indicate the ground fault and its direction via the protocol, Siemens recommends using the indication *`(_:2311:302) Ground fault`*. The indication contains the direction information, independent of the parameterized working direction of a stage. And this indication is also stabilized against a flood of indications in case of an intermittent ground fault.

Parameter: `Decay time V0`

- Recommended setting value **`(_:2311:101) Decay time V0`** = *`0.10 s`*

With the **`Decay time V0`** parameter, you specify the time slot for the detection of a fault extinction. If V0 continuously falls within this time, fault extinction is detected and the indication *`Flt. extinction det.`* is issued.

Siemens recommends using the default setting.

Parameter: `Dropout delay`

- Recommended setting value **`(_:2311:102) Dropout delay`** = ***`1.00 s`***

To avoid chattering of the indication *Ground fault* during an intermittent ground fault and thus a frequent opening and closing of the ground-fault log, the dropout of the indication *Ground fault* (and thus the closing of the log) can be delayed by the **`Dropout delay`**.

Siemens recommends using the default setting.

Using the default setting ensures that no flood of indications arises in case of an intermittent ground fault for the indication *Ground fault*. The intermittent ground fault is then treated as a ground fault, and the stabilization of the indication *Ground fault* can thus take action.

Angle-Error Compensation of the Core Balance Current Transformer

- Default setting **`(_:2311:103) Core balance CT- current 1`** = ***`0.050 A`***
- Default setting **`(_:2311:104) Core balance CT- current 2`** = ***`1.000 A`***
- Default setting **`(_:2311:105) CT angle error at I1`** = ***`0.0°`***
- Default setting **`(_:2311:106) CT angle error at I2`** = ***`0.0°`***

The high reactive-power factor in the arc-suppression-coil-ground system and the unavoidable air gap of the core balance current transformer often make necessary a compensation of the angle error of the core balance current transformer. For the burden actually connected, the maximum angle error **`CT angle error at I1`** and the corresponding secondary current **`Core balance CT- current 1`** as well as a further operating point **`CT angle error at I2`**/**`Core balance CT- current 2`** are entered, from which point the angle error no longer changes appreciably.

In the isolated or grounded system, angle compensation is not necessary.

Parameter: `Block. group indications`

- Default setting **`(_:2311:119) Block. group indications`** = ***`no`***

The **`Block. group indications`** parameter supports in applying the **Sensitive ground-fault detection** function as a supervision function. If you set this parameter to ***`yes`***, the following indications are blocked:

- The group indications of the function and the corresponding group indications of the function group are blocked.

  Consequently, the group-indications of the function group are then related to short-circuit protection functions and can be forwarded to a station controller in the meaning of short-circuit protection.
- The trip command from the **Directional sensitive ground-fault detection** function to the FB **Circuit breaker** is blocked.

Fault recording and logging are not affected by the setting.

Parameter: `Network topology`

- Default setting **`(_:2311:121) Network topology`** = ***`ring/meshed`***

This parameter is only used in the **Directional transient ground-fault** stage.

With the **`Network topology`** parameter, you set the network topology with reference to the network section to be protected by the individual device.

Network Topology	Description
`ring/meshed`	The device is applied in a meshed system or a closed feeder ring.
`radial`	The device is applied in a single feeder with radial topology. This setting has to be also selected if parallel feeders are closed rings, as long as the own feeder is single.

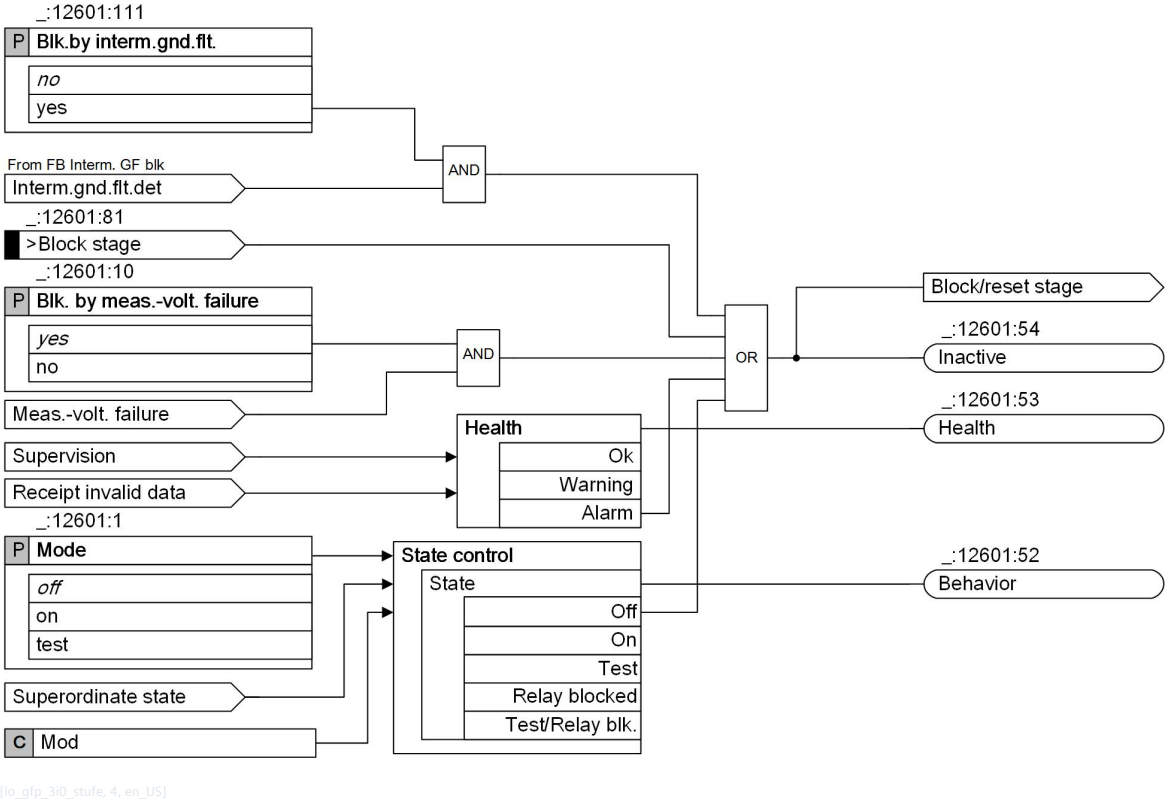
6.13.4 Directional 3I0 Stage with Cos φ or Sin φ Measurement

6.13.4.1 Description

Logic



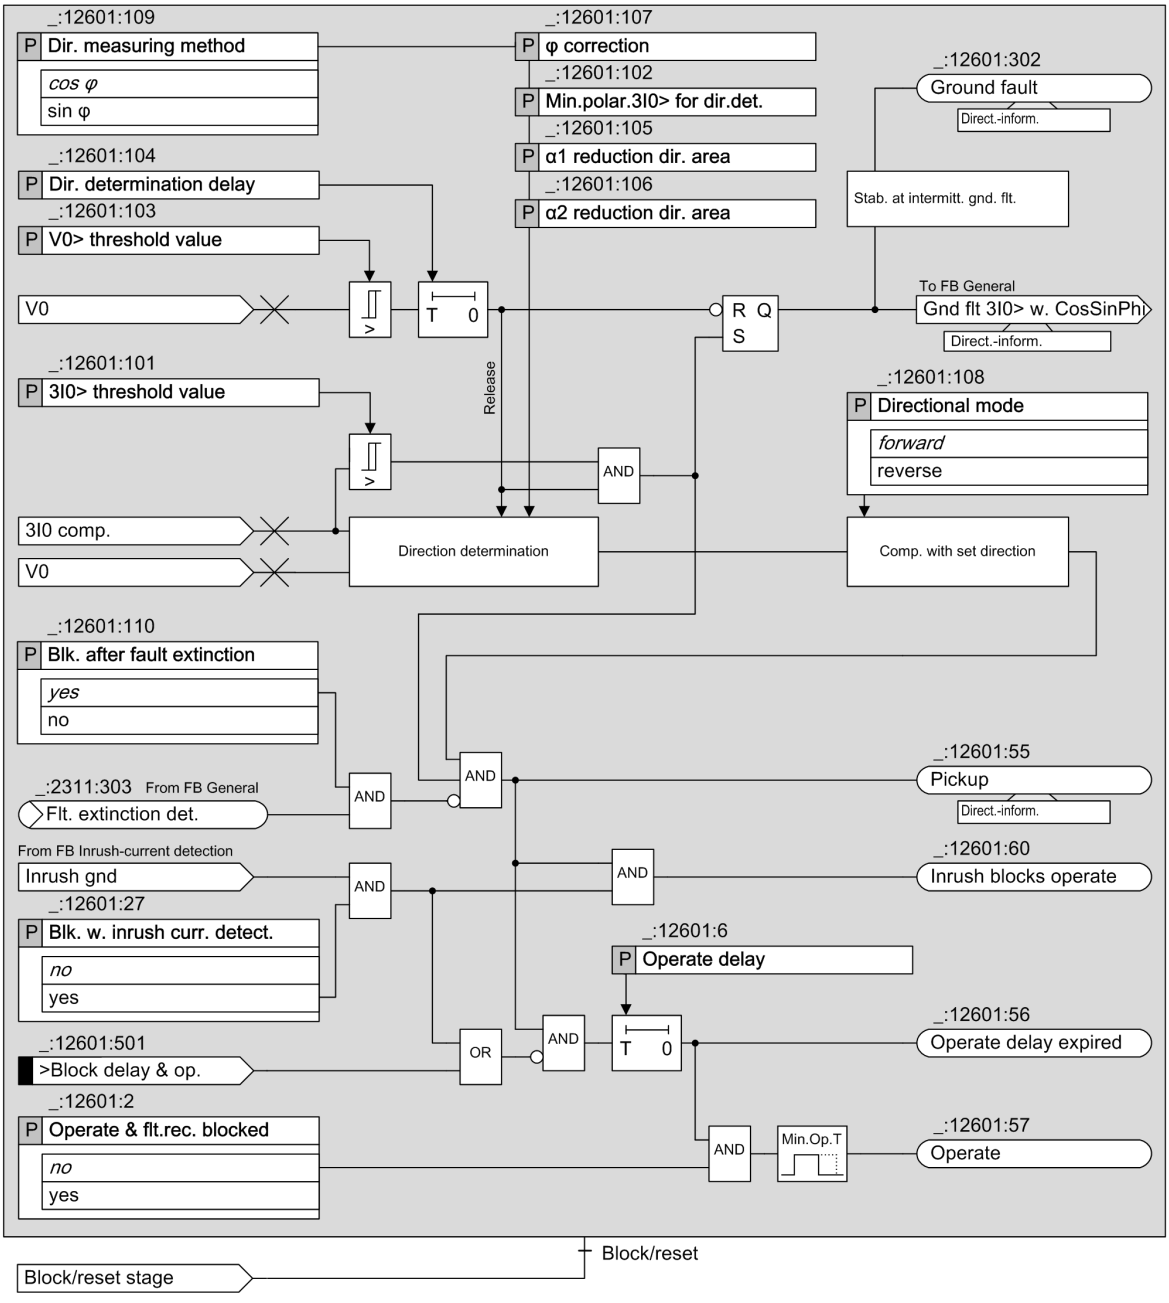


Figure 6-243 Logic Diagram of the Stage Control

[lo_gfp_3i0f, 5, en_US]

Figure 6-244 Logic Diagram of the Directional 3I0 Stage with Cos φ or Sin φ Measurement

Measured Value V0, Method of Measurement

The device can measure the residual voltage at the broken-delta winding. The measured voltage VN is converted to a value with reference to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, Method of Measurement

The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary

ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

Depending on the setting of the **Connection type** parameter of the measuring point **I-3ph** as well as the current terminal block used, the following different linearity and settings ranges result in addition to the common application:

Connection Type of the Measuring Point I-3ph	Current Threshold 3I0/IN	Current Terminal Block	3I0 Threshold Value Settings Range (Secondary) [42]
3-phase	Calculated 3I0[43]	4 × protection	0.030 A to 35.000 A
		3 × protection, 1 × sensitive	0.030 A to 35.000 A
		4 × measurement	0.001 A to 1.600 A
3-phase + IN 3-phase + IN-separate 2ph, 2p. CT + 2 IN-sep	Measured IN[44]	4 × protection	0.030 A to 35.000 A
		4 × measurement	0.001 A to 1.600 A
	Measured IN and calculated 3I0 when IN > 1.6 A	3 × protection, 1 × sensitive	0.001 A to 35.000 A
3ph,2prim.CT + IN-sep 2ph, 2p. CT + IN-sep	Measured IN	4 × protection	0.030 A to 35.000 A
		4 × measurement	0.001 A to 1.600 A
		3 × protection, 1 × sensitive	0.001 A to 1.600 A

With the use of the function within a 1-phase function group and therefore at a 1-phase measuring point **I-1ph**, the following different linearity and settings ranges result:

Measuring Point I-1ph	Current Threshold	Current Terminal Block	3I0 Threshold Value Settings Range (Secondary) [45]
	Measured	Sensitive	0.001 A to 1.600 A
		Protection	0.030 A to 35.000 A

The method of measurement processes the sampled current values and filters out the fundamental component numerically.

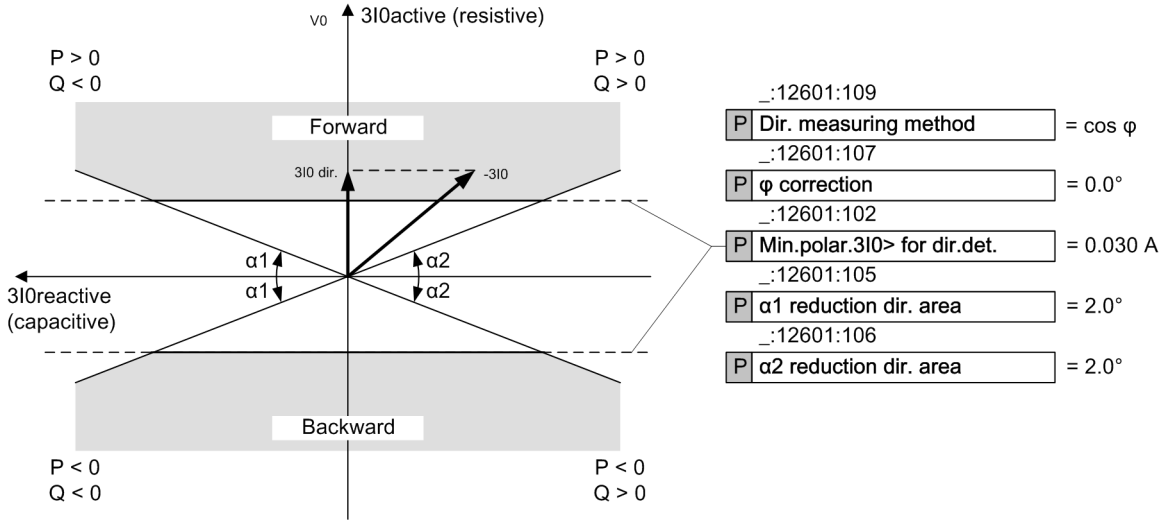
The methods of measurement are characterized by high accuracy and by insensitivity to harmonics, especially the 3rd and 5th harmonics frequently present in the ground-fault (residual) current.

Ground-Fault Detection, Pickup

If the absolute value of the ground current 3I0 exceeds the threshold value **3I0> threshold value** and the absolute value of the zero-sequence voltage V0 exceeds the threshold value **V0> threshold value**, the stage recognizes the ground fault. The direction determination (see the next paragraph) is started when the V0 threshold value is exceeded. The direction result is indicated via the *Ground fault* signal (in the **General** function block). If the direction result equals the parameterized direction (parameter **Directional mode**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The result form the direction determination is only valid if the absolute value of the ground current 3I0 has also exceeded its threshold value.



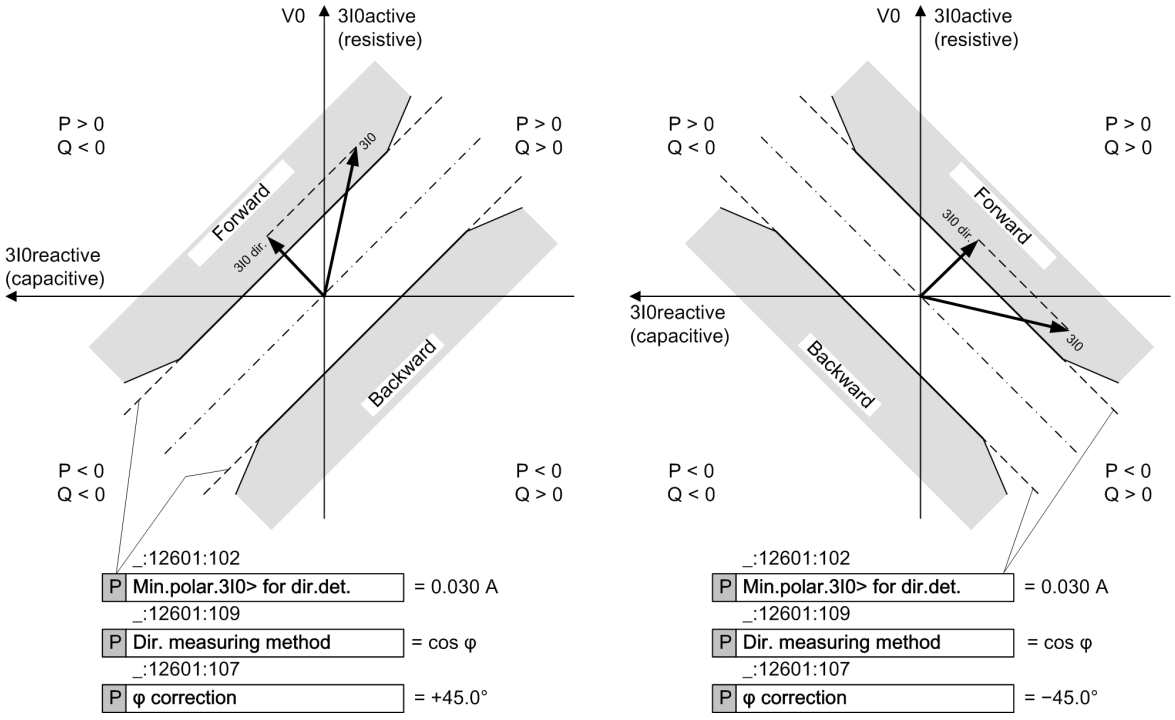
42 These values apply for a secondary rated current of 1 A. For a secondary rated current of 5 A, the values must be multiplied by 5.

43 If the connection type is without IN, such as 3-phase, the current threshold value is a calculated 3I0 value.

44 If the connection type is with IN, such as 3-phase + IN, the current threshold value is a measured IN value.

45 These values apply for a secondary rated current of 1 A. For a secondary rated current of 5 A, the values must be multiplied by 5.

The following figure shows an example of the direction determination in the complex phasor diagram for the cos-φ direction measurement method with a correction value of the direction straight lines from 0 (parameter **φ correction**). The example is suitable for the determination of the ground-fault direction in an arc-suppression-coil-ground system where the variable 3I0 · cos φ is decisive for the direction determination.



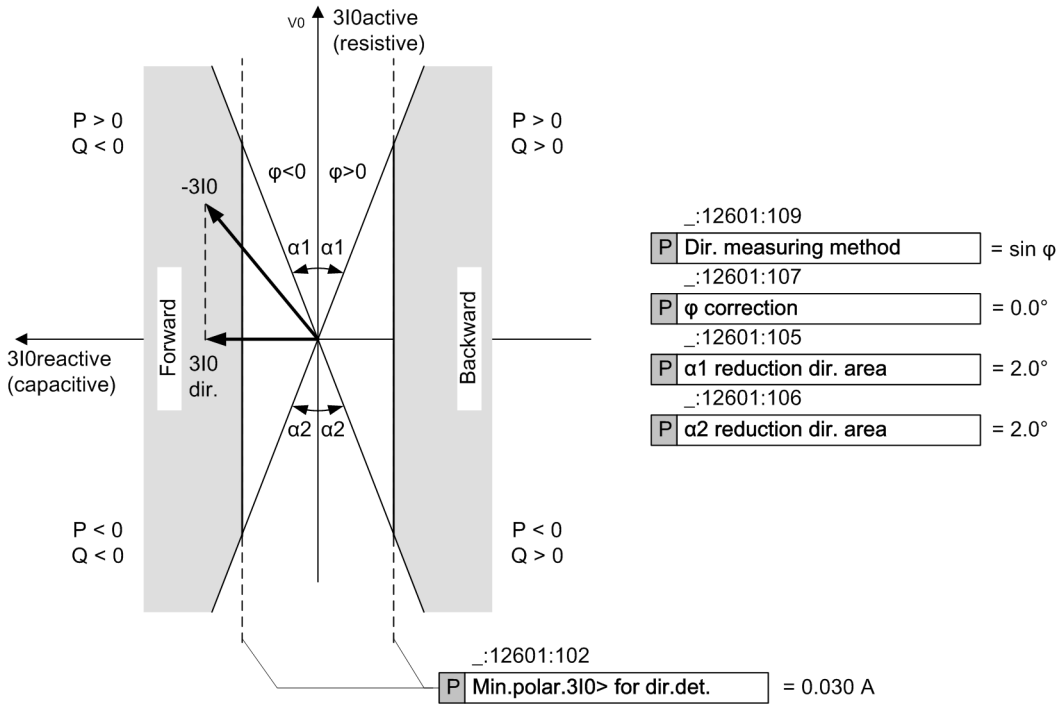
[dw_cosphi, 3, en_US]

Figure 6-245 Direction-Characteristic Curve with Cos φ Measurement

The zero-sequence voltage V0 is basically the reference value for the real axis. The axis of symmetry of the direction-characteristic curve coincides with the 3I0reactive axis for this example. For the direction determination, basically the portion of the current vertical to the set direction-characteristic curve (= axis of symmetry) is decisive (3I0 dir.). In this example, this is the active portion 3I0active of the current 3I0. The current 3I0dir. (here = 3I0active) is calculated and compared with the setting value **Min.polar.3I0> for dir.det.**. If the current 3I0 dir. exceeds the positive setting value, the direction is forward. If the current 3I0 dir. exceeds the negative setting value, the direction is backward. In the range in between, the direction is undetermined.

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you can limit the forward and backward ranges as shown in the figure. With this, the direction determination is secured in case of high currents in the direction of the axis of symmetry.

The symmetry axis can be turned via a correction angle **φ correction** parameter) in a range of ±45°. Through this, it is possible, for example, to attain the greatest sensitivity in grounded systems in the resistive-inductive range with a -45° turn. In the case of electric machines in busbar connection on the isolated system, the greatest sensitivity in the resistive-capacitive range can be attained with a rotation of +45°.



[dw_phicor, 2, en_US]

Figure 6-246 Turning the Direction-Characteristic Curves with Cos φ Measurement with Angle Correction

If you set the **Dir. measuring method** parameter to ***sin φ*** and the **φ correction** parameter to ***0***, the symmetry axis of the direction-characteristic curve coincides with the 3I0active axis and the V0 axis. Since the portion of the current vertical to the direction-characteristic curve (= axis of symmetry) is decisive (3I0dir.), here, the current 3I0reactive is included in the direction determination. If the current 3I0dir. (here = 3I0reactive) exceeds the negative setting value **Min.polar.3I0> for dir.det.**, the direction is forward. If the current 3I0dir. exceeds the positive setting value, the direction is backward. In the range in between, the direction is undetermined.

This direction measurement thus is appropriate for the determination of ground-fault direction in isolated systems.

[dw_sin_phi, 4, en_US]

Figure 6-247 Direction-Characteristic Curve with Sin φ Measurement

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Voltage-transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that Measuring-voltage failure detection blocks the stage or does not block it.

Blocking the Stage in Case of an Intermittent Ground Fault

In case of an intermittent ground fault, the stage can be blocked upon receiving the internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage. In the event of blocking, the picked-up stage will be reset.

After the release of the blocking, the timer **Dir. determination delay** is newly started and must expire before a new ground fault or pickup is annunciated.

With the **Blk.by interm.gnd.flt.** parameter, you can enable or disable the blocking of the stage in case of an intermittent ground fault.

Blocking the Pickup with Detection of the Fault Extinction

Using the evaluation of the instantaneous value developing of the zero-sequence voltage, the fault extinction can be recognized faster than via the dropout of the V0 fundamental-component value under the pickup value. The pickup of the stage is blocked with the fast detection of the fault extinction. With this, the pickups

are avoided due to the decay procedure in the zero-sequence system after the fault extinction. With the **Blk. after fault extinction** parameter, you enable or disable this accelerated detection of the fault extinction.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Tripping by Device-Internal Inrush-Current Detection

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

6.13.4.2 Application and Setting Notes

Parameter: Operate & flt.rec. blocked

- Default setting **(_:12601:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:12601:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: Blk. w. inrush curr. detect.

- Recommended setting value **(_:12601:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains unaffected by a switching-on procedure.

Parameter: Blk.by interm.gnd.flt.

- Default setting **(_:12601:111) Blk.by interm.gnd.flt.** = ***no***

With the **Blk.by interm.gnd.flt.** parameter, you specify whether the stage is blocked upon receiving an internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage.

During intermittent ground faults, stages designed for detecting permanent ground faults (based on continuous RMS measurement) tend to generate a flood of signals and probably even temporary wrong directional information. This can be avoided by blocking these stages in case of an intermittent ground fault.

If intermittent ground faults in your network are probable, Siemens recommends enabling the blocking.

Parameter: `Blk. after fault extinction`

- Recommended setting value **`(_:12601:110) Blk. after fault extinction`** = ***`yes`***

If the **`Blk. after fault extinction`** parameter is set to ***`yes`***, the pickup is blocked after detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. Siemens recommends using the default setting.

Parameter: `Directional mode`

- Default setting **`(_:12601:108) Directional mode`** = ***`forward`***

When a fault is detected, the selection of the parameter **`Directional mode`** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: `Dir. measuring method, φ correction, Min.polar.3I0> for dir.det., 3I0> threshold value`

- Default setting **`(_:12601:109) Dir. measuring method`** = ***`cos φ`***
- Default setting **`(_:12601:107) φ correction`** = ***`0.0°`***
- Default setting **`(_:12601:102) Min.polar.3I0> for dir.det.`** = ***`0.030 A`***
- Default setting **`(_:12601:101) 3I0> threshold value`** = ***`0.050 A`***

These parameters are used to define the direction characteristic of the stage. The direction characteristic to use is dependent on the neutral-point treatment of the system.

Note that, for the direction determination, basically only a portion of the current vertical to the set direction-characteristic curve (3I0dir.) is decisive, refer to *6.13.4.1 Description*. This portion of the current is compared to the threshold value **`Min.polar.3I0> for dir.det.`**. In contrast, the absolute value of the current 3I0 is compared with the **`3I0> threshold value`** parameter.

System Type/ Neutral-Point Treatment	Description
Arc-suppression coil grounded	In the arc-suppression-coil-ground system, the watt-metric residual current 3I0 · cos φ of the arc-suppression coil is decisive for the direction determination. To evaluate the watt-metric residual current, set the parameters as follows: • **Dir. measuring method** = ***cos φ*** • **φ correction** = ***0.0°*** The direction determination for a ground fault is made more difficult in that a much larger capacitive or inductive reactive current is superimposed on the small watt-metric residual current. Therefore, depending on the system configuration and the fault evaluation, the total ground current supplied to the device can vary considerably in its values regarding the magnitude and the phase angle. However, the device should only evaluate the active component of the ground-fault current. This requires extremely high accuracy, particularly regarding the phase-angle measurement of all the instrument transformers. Furthermore, the device must not be set to operate too sensitively. A reliable direction measurement can only be expected with connection to a core balance current transformer. For the setting of the **Min.polar.3I0> for dir.det.** parameter, the rule of thumb is: Set the pickup value only to half of the expected measuring current as only the watt-metric residual current can be put into use. The **3I0> threshold value** parameter can also be set to half of the expected measuring current, whereby here the entire zero-sequence current can be put to use.
Isolated	In the isolated system, the capacitive ground reactive current 3I0 · sin φ is decisive for the direction determination. To evaluate the capacitive ground reactive current, set the parameters as follows: • **Dir. measuring method** = ***sin φ*** • **φ correction** = ***0.0°*** In an isolated system, the capacitive ground-fault currents of the entire electrically connected system flow through the measuring point in case of a ground fault. The ground current of the faulty feeder is compensated in the measuring point. As the pickup value of the **Min.polar.3I0> for dir.det.** and **3I0> threshold value** parameters, select about half of this capacitive ground-fault current flowing via the measuring point.
Resistance-Grounded	In the resistance-grounded system, the ohmic-inductive ground-fault current is decisive for the direction determination. To evaluate this short-circuit current, set the parameters as follows: • **Dir. measuring method** = ***cos φ*** • **φ correction** = ***-45.0°*** Set the **Min.polar.3I0> for dir.det.** and **3I0> threshold value** parameters to a value below the minimum ground-fault current to be expected.

Parameter: α1 reduction dir. area, α2 reduction dir. area

- Recommended setting value **(_:12601:105) α1 reduction dir. area** = ***2°***
- Recommended setting value **(_:12601:106) α2 reduction dir. area** = ***2°***

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you specify the angle for the limitation of the direction range. Siemens recommends using the default setting of 2°.

In an arc-suppression-coil-ground system in feeders with a very large reactive current, it can be practical to set a somewhat larger angle α1 to avoid a false pickup based on transformer and algorithm tolerances.

Parameter: V0> threshold value

- Default setting **(_:12601:103) V0> threshold value** = ***30.000 V***

The **V0> threshold value** parameter allows you to set the zero-sequence voltage sensitivity of the stage. Set the threshold value smaller than the minimum absolute value of the zero-sequence voltage V0 that must still be detected.

Parameter: Dir. determination delay

- Default setting **(_:12601:104) Dir. determination delay** = ***0.00 s***

The start of the ground fault normally shows a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: Operate delay

- Default setting **(_:12601:6) Operate delay** = ***2.0 s***

The **Operate delay** parameter determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

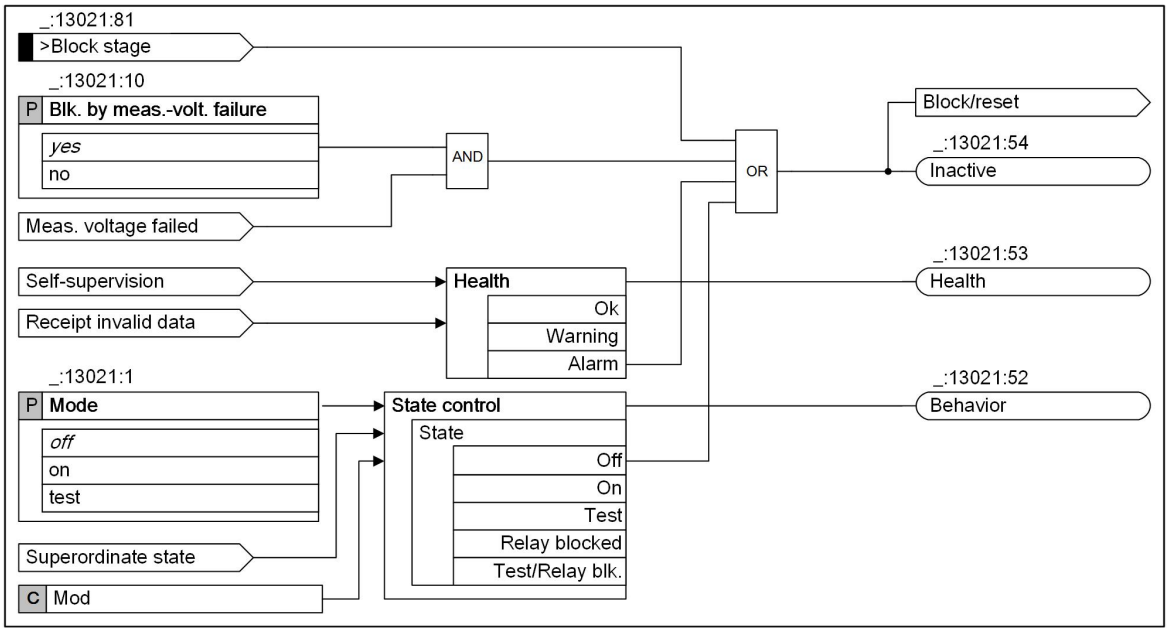
6.13.5 Directional Transient Ground-Fault Stage

6.13.5.1 Description



Overview

Ground faults occurring in arc-suppression-coil-ground systems often extinguish a short time after the ignition, mostly within a few milliseconds. Such transient occurrences are called transient ground faults. In order to detect the ground-fault direction, based on these transient occurrences, a special method of measurement is required that can also capture high frequencies. Conventional methods based on phasor calculations are not suitable. Even for ground faults lasting for a short time, usually, a high-frequency charging process occurs in healthy phases. The transient charging process is evaluated by an energy-integrating method to determine the ground-fault direction. This method ensures high sensitivity and positive stability against parasitic signals in the zero-sequence system.

Since permanent ground faults also start with the transient charging process in healthy phases, those errors will be detected as well.

This stage is most suitable for the use in closed loops or meshed systems. Operational, circulating zero-sequence currents are eliminated and therefore, cannot affect the directional result.

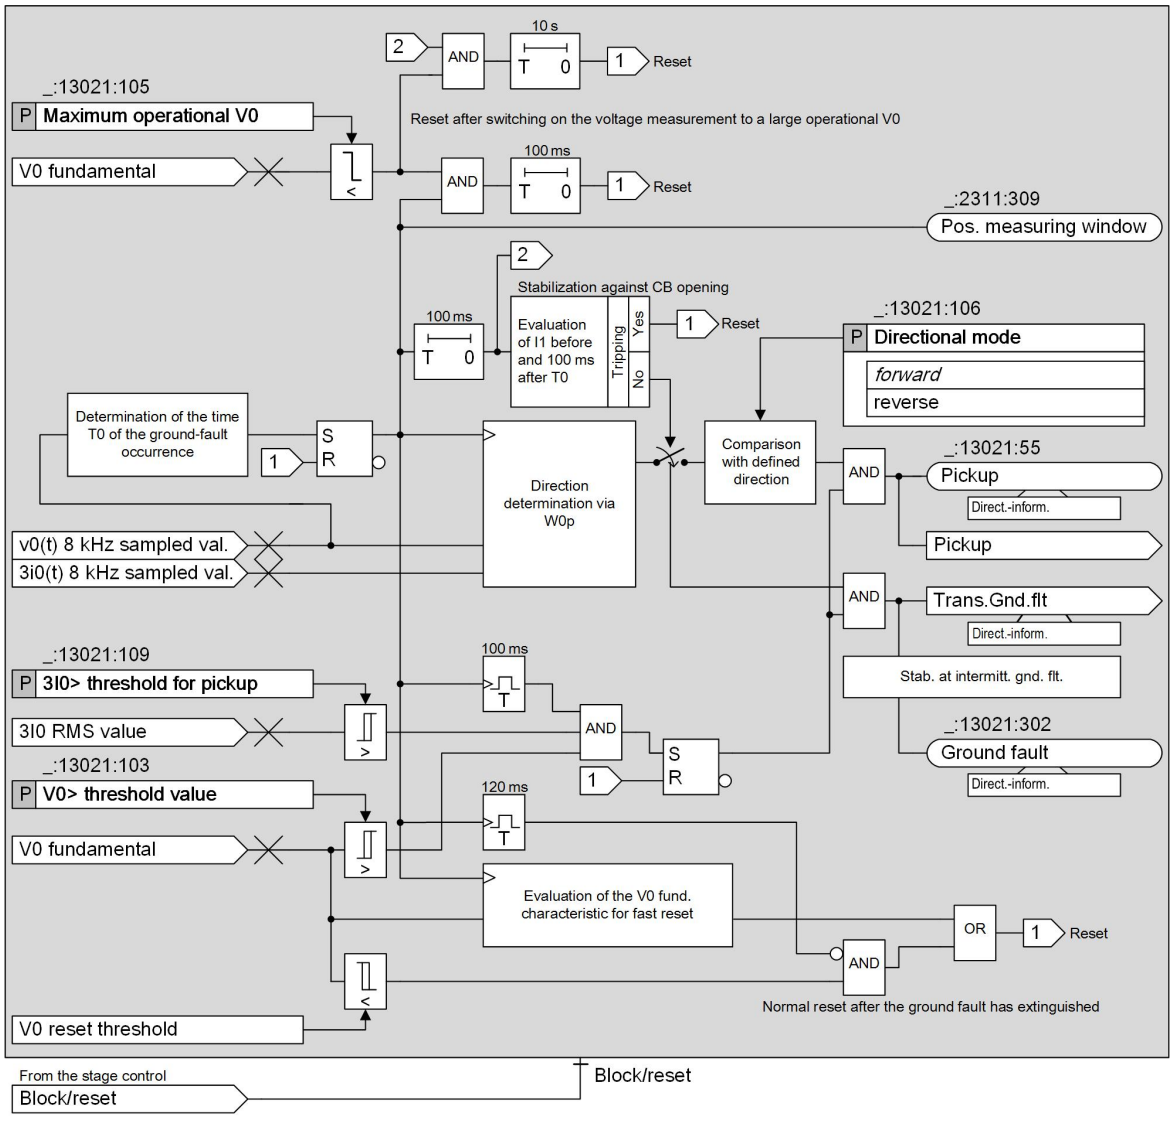
Stage-Control Logic

[lo_stu_wis, 3, en_US]

Figure 6-248 Logic Diagram of the Stage Control

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.



Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Volt.-transf. c. b.**, which links in the tripping of the voltage-transformer circuit breaker.

The **`Blk. by meas.-volt. failure`** parameter can be set so that **measuring-voltage failure detection** blocks the stage or not.

Logic of the Transient Ground-Fault Functionality

[lo_wisfut, 10, en_US]

Figure 6-249 Logic Diagram of the Directional Transient Ground-Fault Stage

Measured Values, Method of Measurement

The zero-sequence voltage and zero-sequence current are measured directly or calculated from the phase variables. When measuring directly, the following is detected:

- Zero-sequence voltage on the broken-delta winding
- Zero-sequence current via Holmgreen connection or via core balance current transformer

The voltage measured on the broken-delta winding will be converted to the zero-sequence voltage V_0.

The instantaneous values of the zero-sequence voltage v0(t) that are sampled at a high frequency (8 kHz) serve to determine the point in time of the ground fault occurrence T0.

The instantaneous values of the zero-sequence voltage v0(t) and the ground current 3i0(t), which are sampled at a high frequency (8 kHz), are the basis for direction determination.

The fundamental-component values of the zero-sequence voltage V0 serve to release the directional result and the pickup as well as a criterion for the stabilization against switching operations.

The positive-sequence system (if it exists as a measured value) serves as an additional criterion for the stabilization against switching operations.

The fundamental-component value of V0 and the true RMS value of 3I0 will be used for the pickup and the optional trip logic.

Operational, meaning circulating zero-sequence currents, can occur in closed loops or meshed systems. This type of zero-sequence current is also present in case of a failure and can falsify the directional result. Therefore, an operational zero-sequence current is eliminated.

Determining the Time of the Ground-Fault Ignition

The algorithm uses the evaluation of the instantaneous values of the zero-sequence voltage to verify continuously whether a ground fault occurred. This takes place regardless of whether the set threshold value for V0 is exceeded. If a ground fault occurs, the measuring window for determining the direction is positioned and the direction determination is performed. The position of the measuring window is logged via the indication *Pos. measuring window* (in FB **General**). The precise identification of the time T0 at which the ground fault occurs is decisive for the correct direction determination.

Determination of Direction, Method of Measurement

The active energy of the zero-sequence system is calculated for the direction determination. Once the ground-fault occurrence has been detected, the active energy will be calculated across approximately 1 cycle frequency. If the active energy of the zero-sequence system is negative, a forward fault is present; otherwise it is a backward fault.

Directional Ground-Fault Signal, Pickup

Determining the time of the ground-fault ignition and the direction is always done with maximum sensitivity. With the parameters **V0> threshold value** and **3I0> threshold for pickup**, you define the sensitivity for the indication of the direction and the pickup of the stage.

If both of the following conditions are met, the direction result will be reported:

- The fundamental-component value of the zero-sequence voltage V0 exceeds the **V0> threshold value** within 100 ms after detecting the ground-fault ignition.
- The true RMS value of the zero-sequence current 3I0 exceeds the **3I0> threshold for pickup**.

In this way, high-impedance ground faults are also reported in which the zero-sequence system values rise only slowly, and, for this reason, the occurrence of the ground fault is detected noticeably earlier than the exceedance of the parameterized threshold value.

The direction result will be reported to the function via the *(_:2311:302) Ground fault* of the function block **General information**. This indication is reported irrespective of the parameterized direction of the function.

If the determined direction corresponds with the parameterized direction (parameter **Directional mode**), a pickup occurs.

Reset of the Algorithm

To allow a new directional measurement, the algorithm needs to be reset. The normal reset takes place when all the following conditions are met:

- The fundamental component of the zero-sequence voltage V0 drops below the V0 reset threshold. This reset threshold is a small device-internal V0 threshold. It is also depending on an operational V0 and is thus a dynamic threshold. The threshold value is 2.0 V secondary without dynamic influence.
- The duration of 120 ms after T0 has expired.

Stabilization against Switching Operations

Switching operations in the system to be protected can cause transient signals in the zero-sequence system. The stage is stabilized against possible overfunction due to switching operations.

The following mechanisms are applied:

- The fundamental-component value of the zero-sequence voltage V0 is usually only marginal influenced by switching operations and is thus a good criterion for distinguishing the ground fault from a switching operation. The condition that the fundamental-component value must exceed the **`V0> threshold value`** for reporting the direction result effectively suppresses the influence of switching operations.

  For rare cases in which high zero-sequence voltages occur over longer time ranges after switching off the feeder or line, a criterion based on the positive-sequence current is also effective. This criterion compares the positive-sequence current before and after the transient event and thus detects a disconnection. In case of disconnection, the direction result is not reported.

  Through stabilization mechanisms, the direction result is reported 100 ms after the ground-fault ignition. Thus a pickup occurs with a 100-ms delay.

  If the stage is used in a 1-phase function group, the additional criterion via the positive-sequence current is not effective.

- The function detects transient ground faults using the zero-sequence voltage. In systems with operational zero-sequence voltages, if the measuring voltage is switched on, the function can internally be started. If the fundamental-component value of the zero-sequence voltage does not exceed the threshold of the **`Maximum operational V0`** parameter in a time slot of 100 ms after the function start, the function is reset internally. For an unexpected case where the function is started due to a switching transient event, a further reset criterion exists to ensure that the function does not permanently remain in the start condition. After the time of 100 ms, if the fundamental-component value is continuously less than the **`Maximum operational V0`** threshold for 10 s, the function is reset as well.

Trip Logic

[lo_auswis, 4, en_US]

Figure 6-250 Trip Logic Diagram

In many applications, the transient ground-fault stage is used only to indicate the direction. In this case, the trip logic is not required and remains disabled. However, this stage can also be used to trip a permanent ground fault. For this, you enable the optional trip logic with the **Operate functionality** parameter. If the fundamental-component value of V0 and the true RMS value of 3I0 exceed the set threshold values, the tripping delay (**Operate delay** parameter) starts with the pickup. If the parameter **Operate & flt.rec. blocked** is set to ***no***, the stage operates when the tripping delay expires.

An intermittent ground fault has the characteristics of periodical extinction and reignition within one half period up to several periods. You can find more information in chapter *6.11.1 Overview of Functions*. Due to the tripping delay and the too short fault durations (contact to ground), reliable tripping is not possible. To ensure reliable tripping under such conditions, the parameter **Dropout delay** can be used. When the fault extinguishes, the fundamental-component value of V0 and the true RMS value of 3I0 drop below the threshold values. A dropout can be delayed for a time specified with the **Dropout delay** parameter. The tripping delay continues to run. If the time delay expires within the dropout delay, the stage operates.
You can set the **Dropout delay** according to the application. The default setting is 0 s. The setting of the dropout delay does not affect the direction determination. When the fault reignites, a new direction determination takes place if the function has dropped out before. If the determined direction is opposite to the parameterized direction or is unknown, the tripping delay is reset immediately.

Blocking the Tripping Delay with Detection of the Fault Extinction

Using the evaluation of the instantaneous value cycle of the zero-sequence voltage, the fault extinction of the ground fault can be detected faster than via the dropout of the V0 fundamental-component value under the pickup value. The fast detection of the fault extinction (see function block **General information**) blocks the tripping delay after the dropout delay expires. With the parameter **Blk. after fault extinction**, this accelerated blocking mechanism can be enabled or disabled.

6.13.5.2 Application and Setting Notes

Parameter: Operate functionality

- Default setting **(_:13021:108) Operate functionality** = ***no***

If the transient ground-fault stage is used only to indicate the direction, this optional trip logic is not required and remains disabled. If the transient ground-fault stage is used to trip permanent faults as well, this optional trip logic must be enabled. Pickup of the stage will initiate the tripping delay.

Parameter: Operate & flt.rec. blocked

- Default setting **(_:13021:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:13021:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.
A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: **Blk. after fault extinction**

- Recommended setting value **(_:13021:107) Blk. after fault extinction** = ***yes***

If the **Blk. after fault extinction** parameter is set to ***yes***, the tripping delay is reset after the detection of the fault extinction. Therefore, if the tripping delay is set for a short time, the possibility of an overfunction is avoided. The reason for an overfunction is a slower attenuation in the zero-sequence system following the fault extinction. Siemens recommends keeping this default setting if the stage is used for tripping.

To protect against intermittent ground faults, the stage uses the parameter **Dropout delay** to delay a dropout due to fault extinction. If you are using the stage for protection against intermittent ground faults, disable the blocking.

Parameter: **Directional mode**

- Default setting **(_:13021:106) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: **V0> threshold value**

- Default setting **(_:13021:103) V0> threshold value** = ***15.000 V***

With the parameter **V0> threshold value**, you define the sensitivity for the indication of the direction and the pickup of the stage.

Note that the sensitivity of the direction determination itself is not influenced. The direction determination always works with maximum sensitivity.

If high-resistive ground faults must also be reported, very sensitive settings are possible, for example, **V0> threshold value** = ***5 V*** secondary.

Parameter: **Maximum operational V0**

- Recommended setting value **(_:13021:105) Maximum operational V0** = ***3.000 V***

With the parameter **Maximum operational V0**, you define the maximum operational zero-sequence voltage V0. If the fundamental-component value of the zero-sequence voltage V0 does not exceed the parameter **Maximum operational V0** in a time slot of 100 ms after the function has started, the stage is reset.

The setting is made with reference to the zero-sequence voltage V0 according to its definition.

Network Structure	Description
Radial network	In radial networks, operational zero-sequence voltages are rather small. Siemens recommends using the default value of 3.000 V.
Ring network, meshed network	Greater operational zero-sequence voltages can occur in ring or meshed networks. The secondary operational zero-sequence voltages can be determined by reading the residual voltage $V_{N\,sec}$ or the zero-sequence voltage $V_{0\,sec}$ under the symmetrical components from the device or via DIGSI. In case you read the secondary residual voltage $V_{N\,sec}$, you convert it to $V_{0\,sec}$ with the **Matching ratio Vph / VN** parameter. For more information, see also *6.1.4 Application and Setting Notes for Measuring-Point Voltage 3-Phase (V-3ph)*. If $V_{0\,sec}$ is greater than 2.5 V, the value of **Maximum operational V0** shall be increased to $V_{0\,sec} \cdot 1.2$. Example: $V_{N\,sec}$ = 5.000 V **Matching ratio Vph / VN** = $\sqrt{3}$ $V_{0\,sec}$ = 5.000 V · $\sqrt{3}$ / 3 = 2.887 V **Maximum operational V0** = 2.887 V · 1.2 = 3.464 V In most cases, the operational zero-sequence voltages are smaller than 2.500 V. Siemens recommends using the default value of 3.000 V.

Parameter: 3I0> threshold for pickup

- Default setting **(_:13021:109) 3I0> threshold for pickup** = ***0.000 A***

With the parameter **3I0> threshold for pickup**, you define the sensitivity for the indication of the direction and the pickup of the stage.

In ring or meshed systems, you can use this parameter to reduce the number of ground-fault reporting devices. The parameter needs to be set according to the user experience on the specific network. For radial systems, normally you can keep the default value of 0 A which sets this parameter to inactive.

Parameter: 3I0> threshold for operate

- Default setting **(_:13021:104) 3I0> threshold for operate** = ***0.030 A***

The setting is significant only for optional trip logic for switching off permanent ground faults. Select the setting such that the static ground-fault current exceeds the threshold value. You can disable this criterion by setting the value to 0 A.

Parameter: Dropout delay

- Default setting **(_:13021:7) Dropout delay** = ***0.00 s***

The parameter **Dropout delay** allows you to use the function also as a protection against intermittent ground faults. With the parameter **Dropout delay**, the dropout of the pickup state after fault extinction is delayed or held until the next ignition. Thus, the operate delay can go on and trip the fault.

Set the time to a value within which the new ignition can still be assigned to the previous fault. Typical values are in a range between several hundred milliseconds and a few seconds.

Parameter: Operate delay

- Default setting **(_:13021:6) Operate delay** = ***0.50 s***

The **Operate delay** parameter determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

The setting of the **Operate delay** depends on the specific application. Ensure that the pickup is delayed by 100 ms regarding the time of the ground-fault ignition.

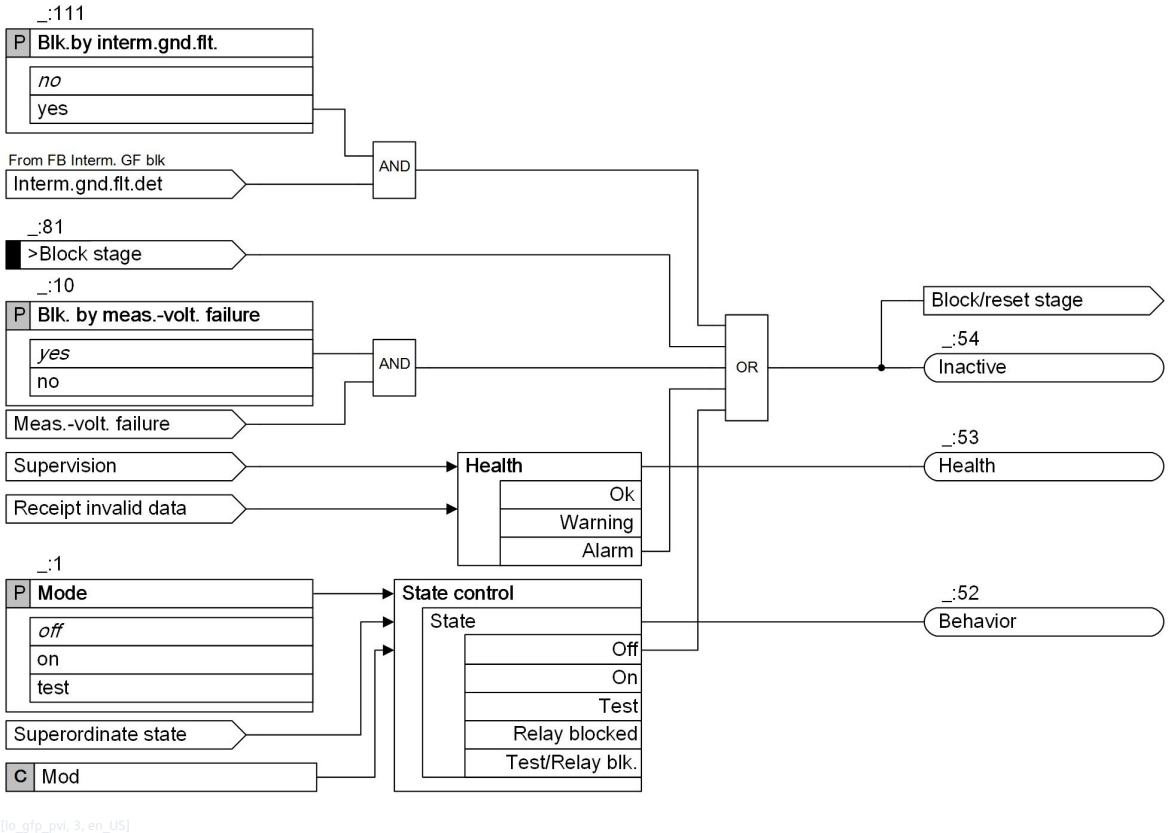
6.13.6 Directional 3I0 Stage with φ (V0,3I0) Measurement

6.13.6.1 Description

Logic



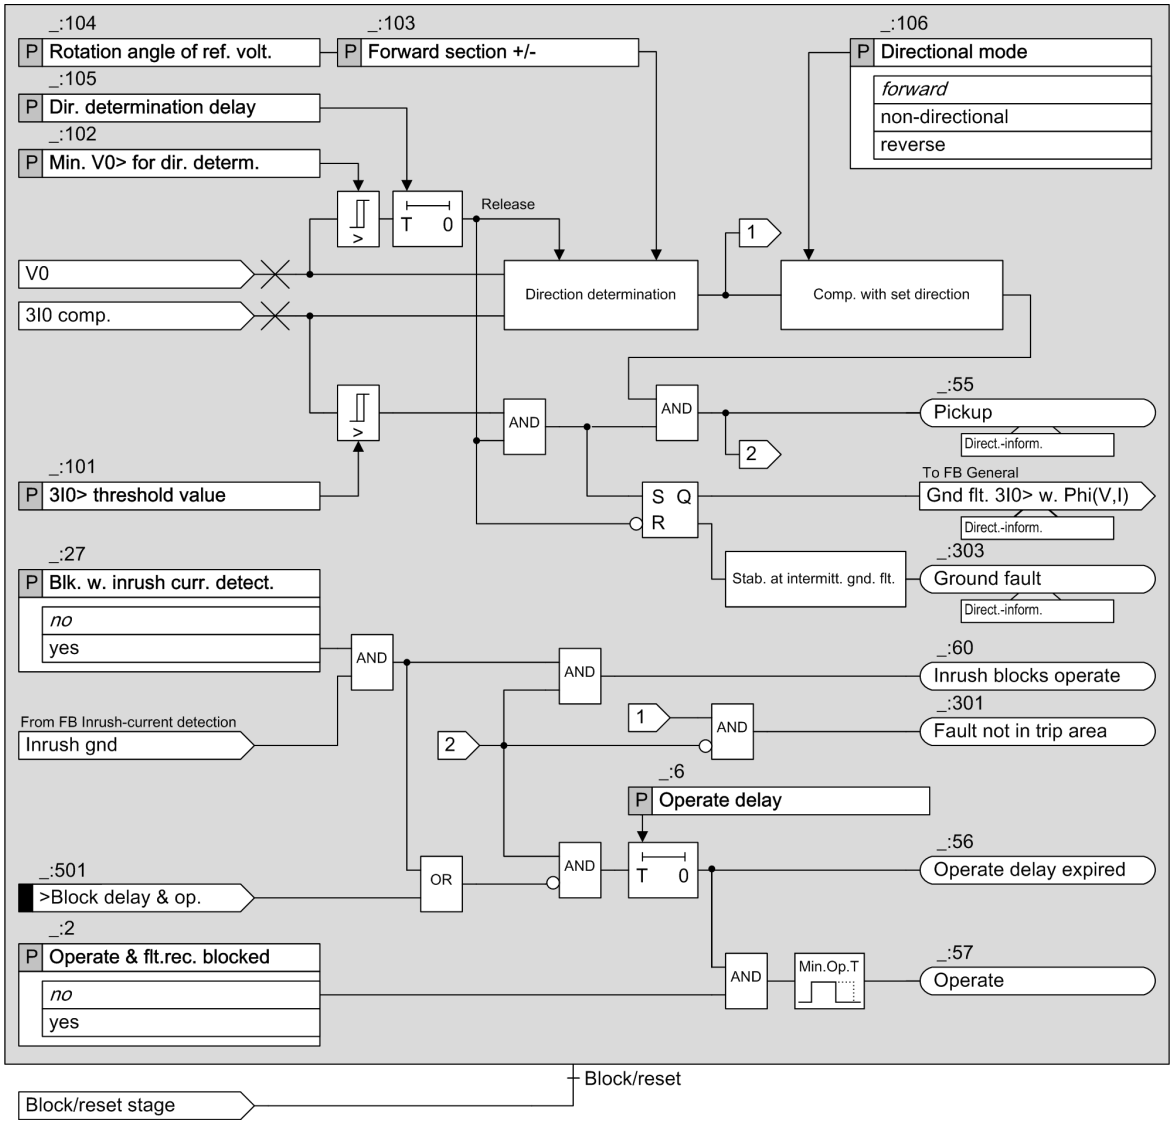


Figure 6-251 Logic Diagram of the Stage Control

[lo_dir sensGFP 3I0 phi VI, 1, en_US]

Figure 6-252 Logic Diagram of the Directional 3I0 Stage with φ (V0,3I0) Measurement

Measured Value V0, Method of Measurement

The device can measure the residual voltage at the broken-delta winding. The measured voltage is converted to a value with reference to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages VA, VB, and VC using the defining equation.

This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, Method of Measurement

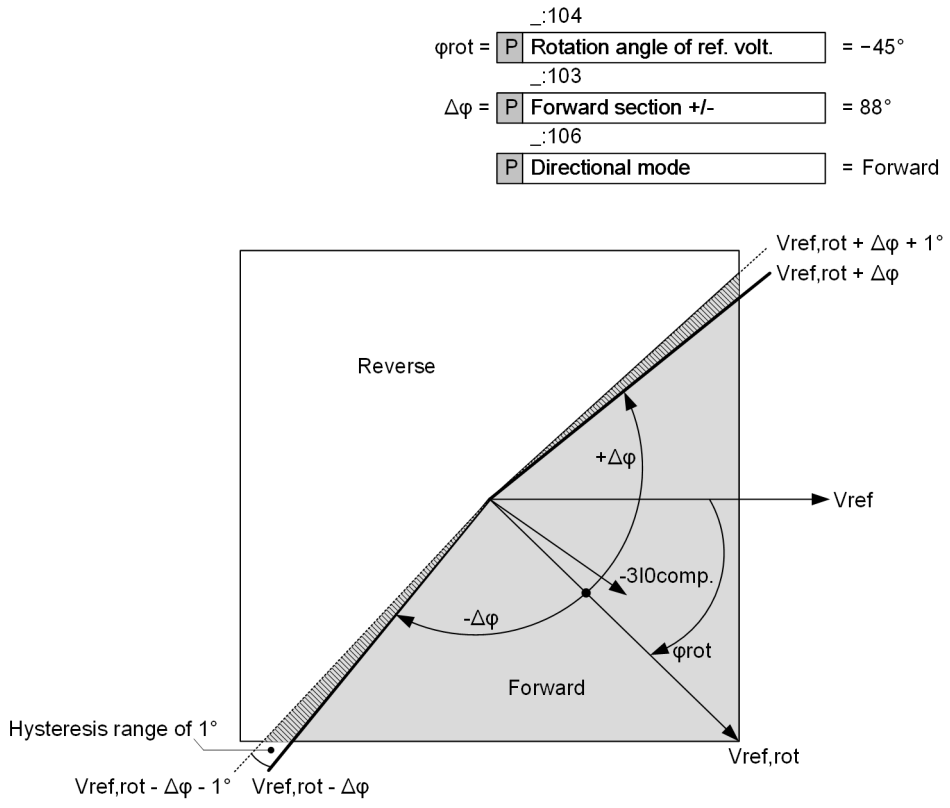
The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

The method of measurement processes the sampled current values and filters out the fundamental component numerically.

Depending on the connection type of the measuring point and on the current terminal blocks used, different linearity and setting ranges result. You can find more information in chapter *Measured Value 3I0, Method of Measurement , Page 897*.

Ground-Fault Detection, Pickup

If the absolute value of the ground current 3I0 vector exceeds the threshold value **3I0> threshold value** and the absolute value of the zero-sequence voltage V0 vector exceeds the threshold value **Min. V0> for dir. determ.**, the stage detects the ground fault. The direction determination (see in the following paragraph) is started when the zero-sequence voltage exceeds the threshold. The result from the direction determination is only valid if the absolute value of the ground current 3I0 vector has also exceeded its threshold value. The direction result is indicated via the *Ground fault* signal (in the **General** function block).



As long as the direction result equals the parameterization direction (parameter **Directional mode**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands.

The direction is determined via the determination of the phase angle between the angle-error compensated ground current 3I0com. and the rotated zero-sequence voltage V0, indicated in the following as reference voltage $V_{ref,rot}$. To take different system conditions and applications into account, the reference voltage can be rotated through an adjustable angle (**Rotation angle of ref. volt.** parameter). This moves the vector of the rotated reference voltage close to the vector ground current -3I0com. Consequently, the result of direction determination is as reliable as possible.

The rotated reference voltage $V_{ref,rot}$ and the **Forward section +/-** parameter define the forward and reverse area. The forward area results as range ± Δφ around the rotated reference voltage $V_{ref,rot}$. The value ± Δφ is set with the **Forward section +/-** parameter. The remaining area besides the forward area is the reverse area. Between the forward and reverse area, a hysteresis is defined, refer to *Figure 6-253*.

[dw_dirrot, 1, en_US]

Figure 6-253 Directional Characteristic in Forward Mode

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>open* of the function block **Voltage-transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that **measuring-voltage failure detection** blocks the stage or not.

Blocking the Stage in Case of an Intermittent Ground Fault

In case of an intermittent ground fault, the stage can be blocked upon receiving the internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage. In the event of blocking, the picked-up stage will be reset.

After the release of the blocking, the timer **Dir. determination delay** is newly started and must expire before a new ground fault or pickup is annunciated.

With the **Blk.by interm.gnd.flt.** parameter, you can enable or disable the blocking of the stage in case of an intermittent ground fault.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Tripping by Device-Internal Inrush-Current Detection

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

6.13.6.2 Application and Setting Notes

Parameter: **Operate & flt.rec. blocked**

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

You can block the operate indication, the fault recording, and the fault log with the **Operate & flt.rec. blocked** parameter. In this case, a ground-fault log is created instead of the fault log.

Parameter: **Blk. by meas.-volt. failure**

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: **Blk. w. inrush curr. detect.**

- Recommended setting value **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains unaffected by a switching-on procedure.

Parameter: **Blk.by interm.gnd.flt.**

- Default setting **(_:111) Blk.by interm.gnd.flt.** = ***no***

With the **Blk.by interm.gnd.flt.** parameter, you specify whether the stage is blocked upon receiving an internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage.

During intermittent ground faults, stages designed for detecting permanent ground faults (based on continuous RMS measurement) tend to generate a flood of signals and probably even temporary wrong directional information. This can be avoided by blocking these stages in case of an intermittent ground fault.

If intermittent ground faults in your network are probable, Siemens recommends enabling the blocking.

Parameter: Directional mode

- Default setting **(_:106) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or reverse direction.

When the parameter **Directional mode** is set as ***non-directional***, the direction determination is not considered. The pickup condition depends only on the absolute values 3I0 and V0 and the respective thresholds. The forward direction is the direction towards the motor.

Parameter: Rotation angle of ref. volt.,Forward section +/-

- Default setting **(_:104) Rotation angle of ref. volt.** = ***-45°***
- Default setting **(_:103) Forward section +/-** = ***88°***

With the **Rotation angle of ref. volt.** and **Forward section +/-** parameters, you set the direction characteristic, that is, the areas of forward and reverse. With this, you set the direction characteristic according to the system conditions and the neutral-point treatment.

Typical settings for the **Rotation angle of ref. volt.** parameter are:

- Arc-suppression-coil-ground system: 0°
- Isolated system: +45° to +90°
- Grounded system: -45°

The **Forward section +/-** parameter can normally be left at its default setting. A reduction of the forward area by a few degrees is practical, for example, in an arc-suppression-coil-ground system with long cable feeders, that generate high capacitive fault currents.

NOTE

In isolated networks, the setting is near +90°.

The generator protection is also an isolated system. However, to take into account the loading resistor in the busbar connection of the generator, the setting is near +45°.

Parameter: Min. V0> for dir. determ.

- Default setting **(_:102) Min. V0> for dir. determ.** = ***2.000 V***

With the **Min. V0> for dir. determ.** parameter, you determine the minimum voltage V0 necessary for the release of the direction determination that must be attained within the time delay **Dir. determination delay**.

Parameter: 3I0> threshold value

- Default setting **(_:101) 3I0> threshold value** = ***0.050 A***

The **3I0> threshold value** parameter allows you to set the ground-current sensitivity of the stage. Set the threshold value lower than the minimum absolute value of the ground-fault current 3I0 that must still be detected.

Parameter: Dir. determination delay

- Default setting **(_:105) Dir. determination delay** = ***0.10 s***

The start of the ground fault normally shows a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: `Operate delay`

- Default setting **`(_:6) Operate delay`** = ***`0.50 s`***

The **`Operate delay`** parameter determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

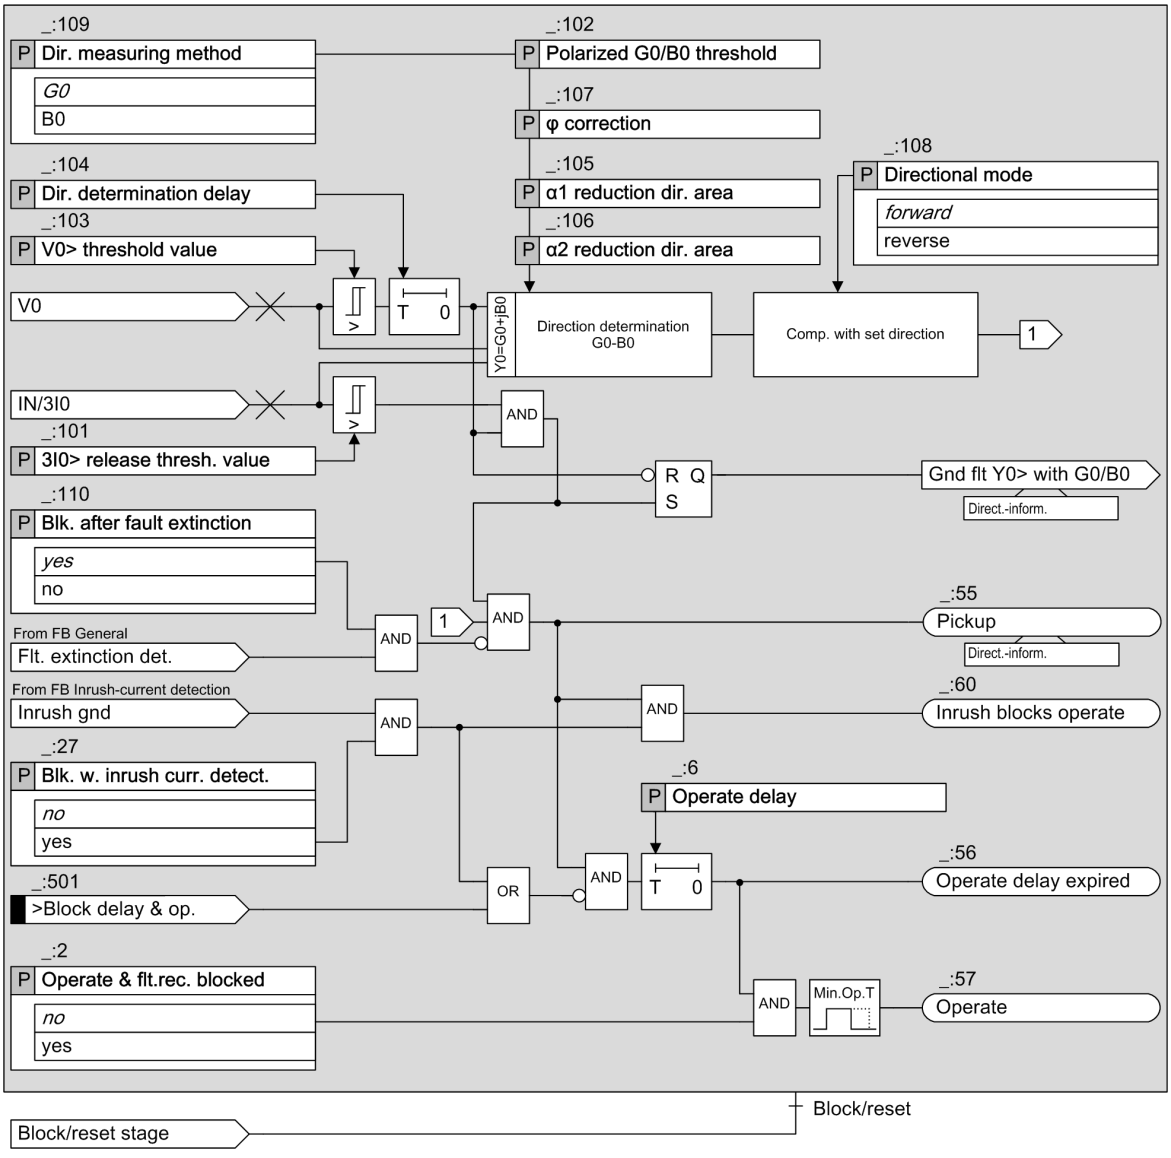
6.13.7 Directional Y0 Stage with G0 or B0 Measurement



6.13.7.1 Description

Logic

{lo_stage_control_Y0G080, 3, en_US}

Figure 6-254 Logic Diagram of the Stage Control

{lo_Y0_G0_B0, 6, en_US}

Figure 6-255 Logic Diagram of the Directional Y0 Stage with G0 or B0 Measurement

Measured Value V0, Method of Measurement

The device can measure the residual voltage at the broken-delta winding. The measured voltage VN is converted to a value with reference to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages VA, VB, and VC using the definition equation.

The method of measurement processes the sampled voltage values and filters out the fundamental component numerically.

Measured Value 3I0, Method of Measurement

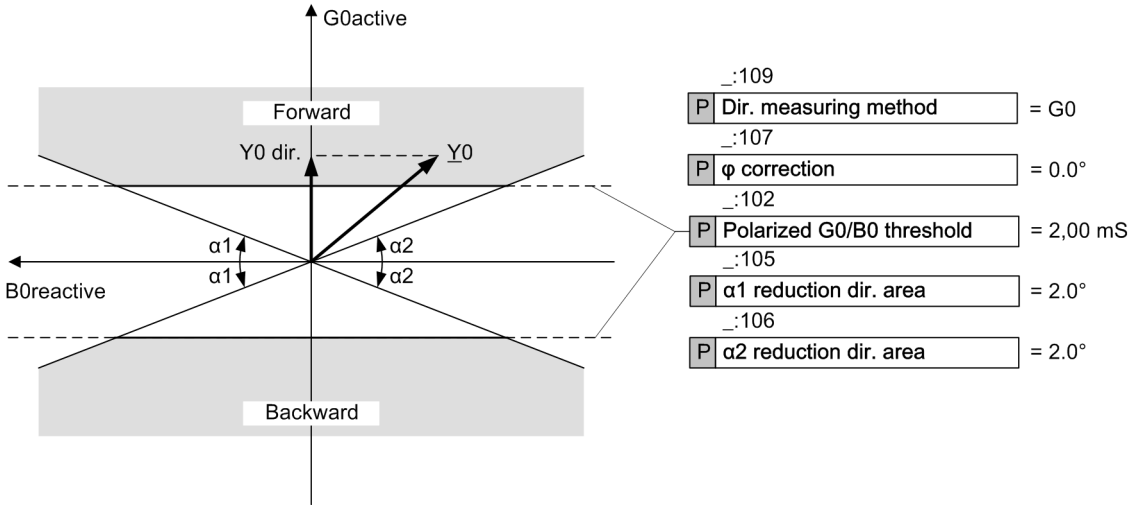
The function usually evaluates the ground current 3I0 sensitively measured via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 calculated from the phase currents. This results in a very large linearity and settings range.

The method of measurement processes the sampled current values and filters out the fundamental component numerically. The methods of measurement are characterized by high accuracy and by insensitivity to harmonics, especially the 3rd and 5th harmonics frequently present in the ground-fault (residual) current.

Depending on the connection type of the measuring point as well as the current terminal blocks used, different linearity and setting ranges result. You can find more information in section *Measured Value 3I0, Method of Measurement , Page 897*.

Y0, G0, B0

The fundamental-component values of V0 and 3I0 are used to calculate the admittance Y0 = G0 + jB0. You can choose to use G0 or B0 to determine the direction.



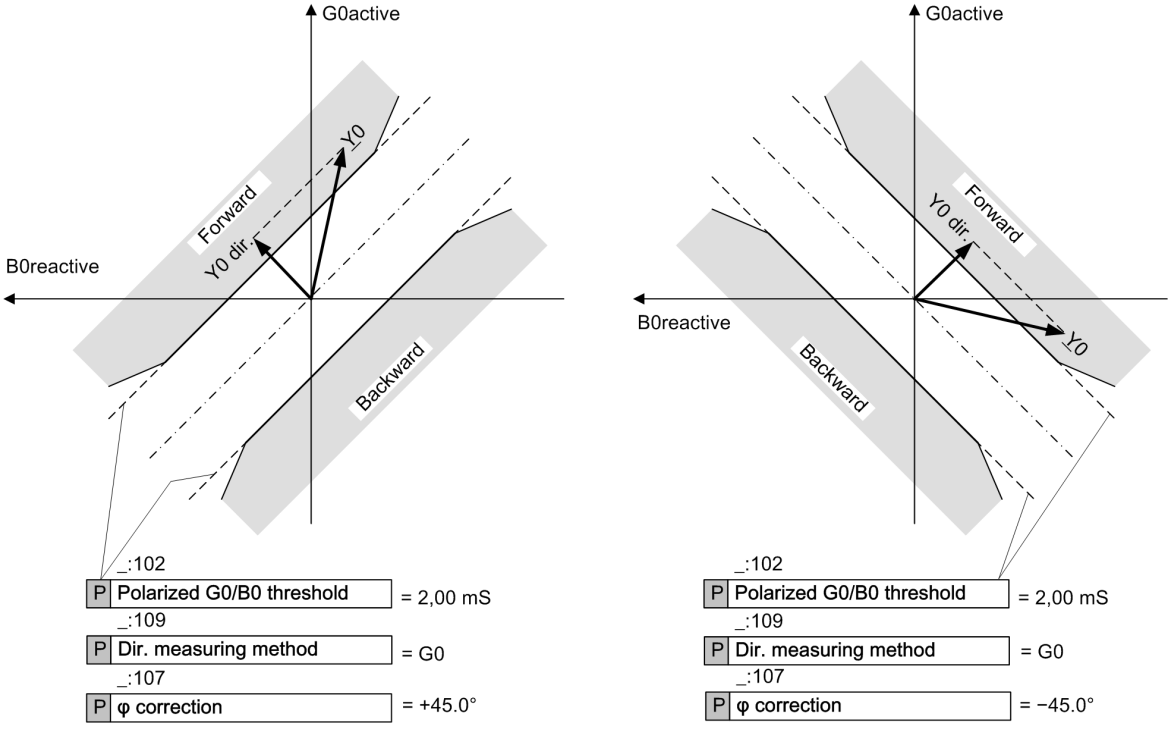
Ground-Fault Detection, Pickup

If the absolute value of the ground current 3I0 exceeds the threshold value **`3I0> release thresh. value`** and the absolute value of the zero-sequence voltage V0 exceeds the threshold value **`V0> threshold value`**, the stage recognizes the ground fault. The calculation of G0 or B0 is started with exceeding the threshold values and then, the direction determination (see the following) is performed. The direction result is indicated via the *`Ground fault`* signal (in the **General** function block). If the direction result equals the parameterized direction (parameter **`Directional mode`**), the stage picks up.

Direction Determination

Exceeding the threshold values by the zero-sequence voltage V0 is a criterion for the ground fault. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **`Dir. determination delay`** parameter to achieve steady-state measurands. The result from the direction determination is only valid if the absolute value of the ground current 3I0 has also exceeded its release threshold value.

The following figure shows an example of the direction determination in the complex phasor diagram for the G0 direction measurement method with a correction value of the direction straight line from 0 (Parameter **`φ correction`**). The example is suitable for the determination of the ground-fault direction in an arc-suppression-coil-ground system where the value G0 is decisive for the direction determination.



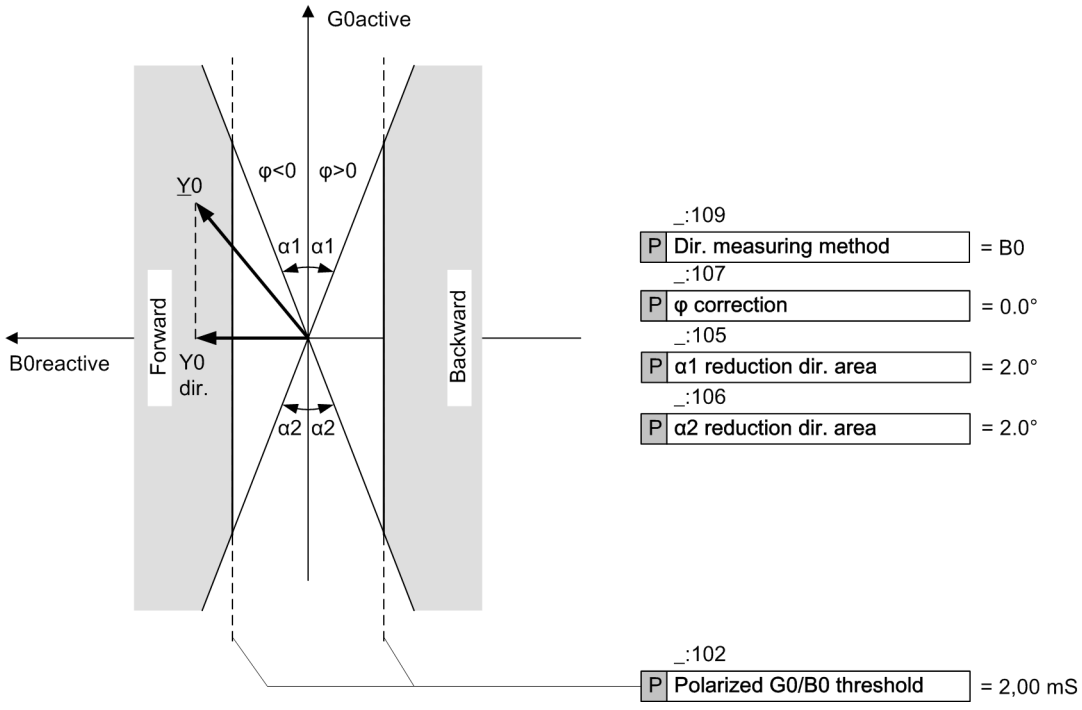
[dw_Y0_dire, 1, en_US]

Figure 6-256 Direction-Characteristic Curve for the G0 Measurement

The zero-sequence voltage V0 is generally the reference value for the real axis and is identical to the G0 axis. The axis of symmetry of the direction-characteristic curve coincides with the B0 (reactive) axis for this example. For the direction determination, the component of the admittance perpendicular to the set direction-characteristic curve (= axis of symmetry) is decisive G0dir (=Y0dir). In this example, this is the active component **G0active** of the admittance Y0. The conductance G0dir. (here = G0active) is calculated and compared with the setting value **`Polarized G0/B0 threshold`**. If the conductance G0dir. exceeds the positive setting value, the direction is forward. If the conductance G0dir. exceeds the negative setting value, the direction is backward. In the range in between, the direction is undetermined.

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you can limit the forward and backward ranges as shown in *Figure 6-257*. With this, the direction determination is secured in case of high currents in the direction of the axis of symmetry.

The symmetry axis can be turned via a correction angle (**φ correction** parameter) in a range of ±45. Through this, it is possible, for example, to attain the greatest sensitivity in grounded systems in the resistive-inductive range with a -45° turn. In the case of electric machines in busbar connection on the isolated system, the greatest sensitivity in the resistive-capacitive range can be attained with a turn of +45° (see following figure).



[dw_Y0_meas, 1, en_US]

Figure 6-257 Turning the Direction-Characteristic Curves with G0 Measurement with Angle Correction

If you set the **Dir. measuring method** parameter to B0 and the **φ correction** parameter to ***0***, the axis of symmetry of the direction-characteristic curve coincides with the G0 and V0 axes. Since the component of the admittance Y0 perpendicular to the direction-characteristic curve (= axis of symmetry) is decisive (B0dir. (=Y0dir.)), here, the susceptance B0 (reactive) is used in the direction determination. If the susceptance B0dir. (B0reactive) exceeds the negative setting value **Polarized G0/B0 threshold**, the direction is forward. If the susceptance B0dir. exceeds the positive setting value, the direction is backward. In the range in between, the direction is undetermined.

This direction measurement thus is appropriate for the determination of ground-fault direction in isolated systems.

[dw_si_co_Y0, 1, en_US]

Figure 6-258 Direction-Characteristic Curve for the B0 Measurement

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>open* of the function block **Voltage-transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker.

The **Blk. by meas.-volt. failure** parameter can be set so that Measuring-voltage failure detection blocks the stage or does not block it.

Blocking the Stage in Case of an Intermittent Ground Fault

In case of an intermittent ground fault, the stage can be blocked upon receiving the internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage. In the event of blocking, the picked-up stage will be reset.

After the release of the blocking, the timer **Dir. determination delay** is newly started and must expire before a new ground fault or pickup is annunciated.

With the **Blk.by interm.gnd.flt.** parameter, you can enable or disable the blocking of the stage in case of an intermittent ground fault.

Blocking the Pickup with Detection of the Fault Extinction

Using the evaluation of the instantaneous value developing of the zero-sequence voltage, the fault extinction can be recognized faster than via the dropout of the V0 fundamental-component value under the pickup value. The pickup of the stage is blocked with the fast detection of the fault extinction. With this, the pickups

are avoided due to the decay procedure in the zero-sequence system after the fault extinction. With the **Blk. after fault extinction** parameter, you enable or disable this accelerated detection of the fault extinction.

Blocking of the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Tripping by Device-Internal Inrush-Current Detection

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

6.13.7.2 Application and Setting Notes

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: Blk. w. inrush curr. detect.

- Recommended setting value **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you specify whether the operate is blocked during detection of an inrush current.

Siemens recommends disabling the blocking. The fundamental component of the zero-sequence voltage is a reliable criterion for the ground fault and remains untouched by a switching-on procedure.

Parameter: Blk.by interm.gnd.flt.

- Default setting **(_:111) Blk.by interm.gnd.flt.** = ***no***

With the **Blk.by interm.gnd.flt.** parameter, you specify whether the stage is blocked upon receiving an internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage.

During intermittent ground faults, stages designed for detecting permanent ground faults (based on continuous RMS measurement) tend to generate a flood of signals and probably even temporary wrong directional information. This can be avoided by blocking these stages in case of an intermittent ground fault.

If intermittent ground faults in your network are probable, Siemens recommends enabling the blocking.

Parameter: **Blk. after fault extinction**

- Recommended setting value **(_:110) Blk. after fault extinction** = ***yes***

If the **Blk. after fault extinction** parameter is set to ***yes***, the pickup is blocked after detection of the fault extinction. With this, the pickups are avoided due to the decay procedure in the zero-sequence system after the fault extinction. Siemens recommends using the default setting.

Parameter: **Directional mode**

- Default setting **(_:108) Directional mode** = ***forward***

When a fault is detected, the selection of the parameter **Directional mode** defines whether the pickup of the stage occurs in forward or backward direction.

Parameter: **Dir. measuring method, φ correction, Polarized G0/B0 threshold, 3I0> release thresh. value**

- Default setting **(_:109) Dir. measuring method** = ***G0***
- Default setting **(_:107) φ correction** = ***0.0°***
- Default setting **(_:102) Polarized G0/B0 threshold** = ***2.00 mS***
- Default setting **(_:101) 3I0> release thresh. value** = ***0.002 A***

These parameters are used to define the direction characteristic of the stage. The direction characteristic to use is dependent on the neutral-point treatment of the system.

Note that, for the direction determination, basically only the component of the admittance perpendicular to the set direction-characteristic curve is decisive, see also *6.13.7.1 Description*. This admittance component is compared to the threshold value **Polarized G0/B0 threshold**. In contrast, the absolute value of the current 3I0 is compared with the **3I0> release thresh. value** parameter.

System Type/ Neutral-Point Treatment	Description
Grounded	In the arc-suppression-coil-ground system, the watt-metric residual current 3I0 · cos φ of the arc-suppression coil is decisive for the direction determination. To evaluate the watt-metric residual current, set the parameters as follows: • **Dir. measuring method** = *G0* • **φ correction** = *0.0°* The direction determination for a ground fault is made more difficult in that a much larger reactive current of capacitive or inductive character is superimposed on the small watt-metric residual current. Therefore, depending on the system configuration and the fault evaluation, the total ground current supplied to the device can vary considerably in its values regarding the magnitude and the phase angle. However, the device should only evaluate the active component of the ground-fault current. This requires extremely high accuracy, particularly regarding the phase-angle measurement of all the instrument transformers. Furthermore, the device must not be set to operate too sensitively. A reliable direction measurement can only be expected with connection to a core balance current transformer. For the setting of the **Polarized G0/B0 threshold** parameter, the following formula applies: $G0 > k_s \frac{I_{0active}}{\sqrt{3}V_{rated}} + \frac{I_{0min}}{V0>}$ where: k_s: Safety margin, k_s = 1.2 (cable networks), k_s = 2.0 (overhead lines) $I_{0active}$: Active component of the ground-fault current (watt-metric residual current) of the protected line V_{rated}: Secondary rated voltage in the healthy case I_{0min}: Min. ground current in the healthy case, 5 mA to 10 mA (core balance current transformer), 50 mA to 100 mA (Holmgreen transformer) V0>: Pickup threshold of the residual voltage ≈ $0.1\sqrt{3}V_{rated}$ If a parallel resistor Rp is used on the arc-suppression coil, the threshold value G0 must also be smaller than: $G0 \leq \frac{1}{k_s} \frac{I_{Rp}}{\sqrt{3}V_{rated}}$ where: k_s: Safety margin ≥ 1.5 I_{Rp}: Secondary rated current of the parallel resistor V_{rated}: Secondary rated voltage in the healthy case The **3I0> release thresh. value** parameter can be set to half of the expected measuring current and here, the entire zero-sequence current can be put to use.
Isolated	In the isolated system, the capacitive ground reactive current 3I0 · sin φ is decisive for the direction determination. To evaluate the capacitive ground reactive current, set the parameters as follows: • **Dir. measuring method** = *B0* • **φ correction** = *0.0°* In isolated systems, a ground fault allows the capacitive ground-fault currents of the entire electrically connected system, except for the ground current in the faulty cable itself, to flow through the measuring point as the latter flows directly away from the

System Type/ Neutral-Point Treatment	Description
	fault location (that is, not via the measuring point). The following formula can be used to determine the pickup value of the **Polarized G0/B0 threshold** parameter. $B0 \geq \frac{I_{0min}}{V0>}$ where: I_{0min}: Ground current in the healthy case V0>: Pickup threshold of the residual voltage ≈ $0.02\sqrt{3}V_{rated}$ In healthy operation, B0 ≤ 0. For the **3I0> release thresh. value** parameter, select around half of this capacitive ground-fault current flowing via the measuring point.
Resistance-Grounded	In the resistance-grounded system, the ohmic-inductive ground-fault current is decisive for the direction determination. To evaluate this short-circuit current, set the parameters as follows: • **Dir. measuring method** = *G0* • **φ correction**= *-45.0°* For the setting of the **Polarized G0/B0 threshold** parameter, the rule of thumb is: Set the pickup value according to the following formula where only the active ground-fault current can be put into use. $G0 > k_s \frac{I_{0active}}{\sqrt{3}V_{rated}} + \frac{I_{0min}}{V0>}$ where: k_s: Safety margin, k_s = 1.2 (cable networks), k_s = 2.0 (overhead lines) $I_{0active}$: Active component of the ground-fault current of the protected line V_{rated}: Secondary rated voltage in the healthy case I_{0min}: Min. ground current in the healthy case, 5 mA to 10 mA (core balance current transformer), 50 mA to 100 mA (Holmgreen transformer) V0>: Pickup threshold of the residual voltage ≈ $0.02\sqrt{3}V_{rated}$ The **3I0> release thresh. value** parameter must be set to a value below the minimum expected ground-fault current.

Parameter: **α1 reduction dir. area, α2 reduction dir. area**

- Recommended setting value **(_:105) α1 reduction dir. area** = *2°*
- Recommended setting value **(_:106) α2 reduction dir. area** = *2°*

With the **α1 reduction dir. area** and **α2 reduction dir. area** parameters, you specify the angle for the limitation of the direction range. Siemens recommends using the default setting of 2°.

In an arc-suppression-coil-ground system in feeders with a very large reactive current, it can be practical to set a somewhat larger angle α1 to avoid a false pickup based on transformer and algorithm tolerances.

Parameter: **V0> threshold value**

- Default setting **(_:103) V0> threshold value** = *30.000 V*

The **V0> threshold value** parameter allows you to set the zero-sequence voltage sensitivity of the stage. The threshold value must be smaller than the minimum amount of the zero-sequence voltage V0 which must still be detected.

Parameter: `Dir. determination delay`

- Default setting **`(_:104) Dir. determination delay`** = ***`0.10 s`***

The start of the ground fault normally indicates a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed for this reason from the occurrence of the zero-sequence voltage with the **`Dir. determination delay`** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: `Operate delay`

- Default setting **`(_:6) Operate delay`** = ***`2.0 s`***

The **`Operate delay`** parameter determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

6.13.8 Directional Stage with Phasor Measurement of a Harmonic

6.13.8.1 Description

The **Directional stage with phasor measurement of a harmonic** is based on a continuous measuring direction-determination method. The stage determines the direction via the 3rd, 5th, or 7th harmonic phasors of the zero-sequence voltage V0 and current 3I0.

Logic

[lo_sensGFP V0 dir harmonic, 3, en_US]

Figure 6-259 Logic Diagram of the Directional Stage with Phasor Measurement of a Harmonic

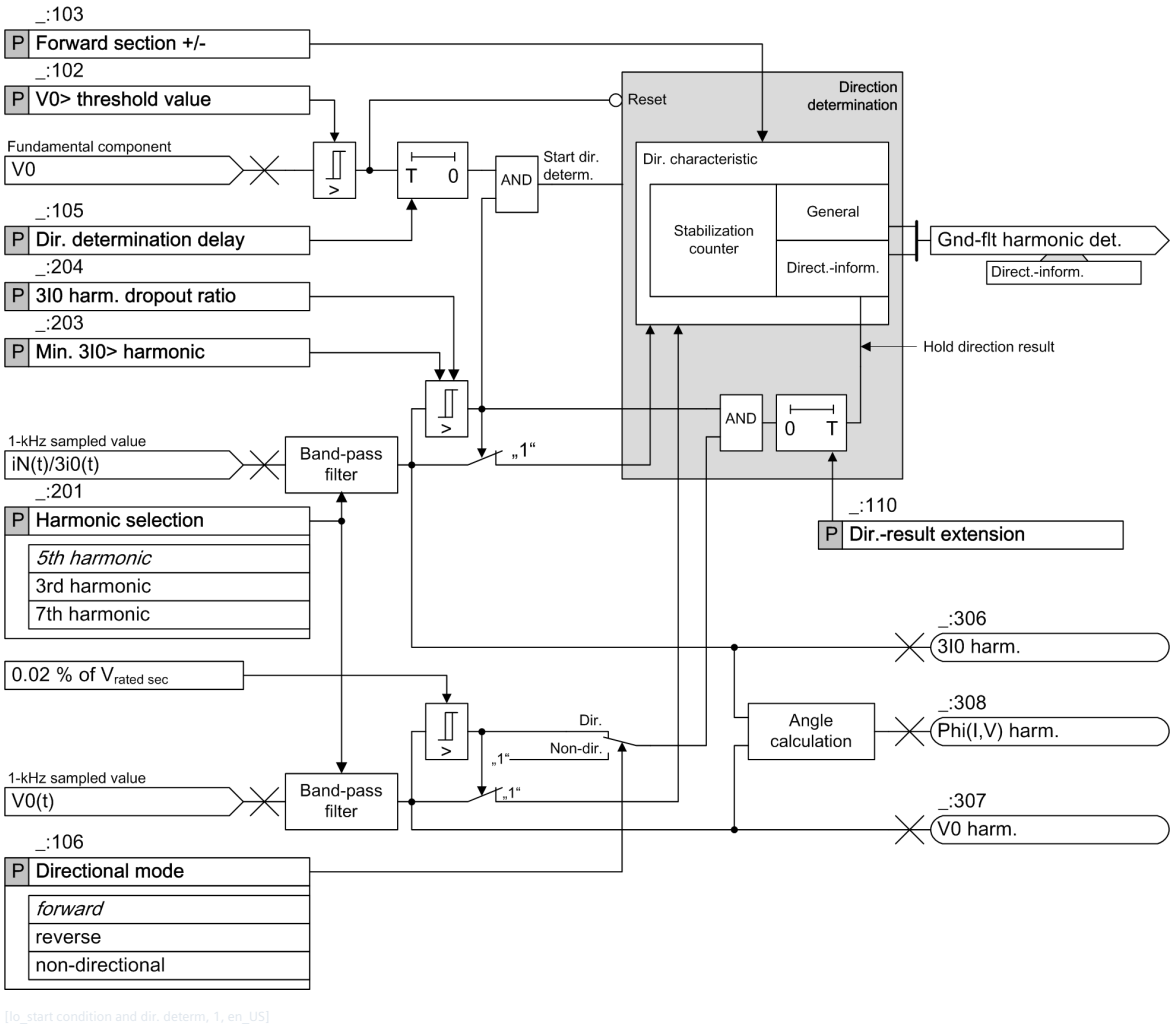

Figure 6-260 Logic Diagram of the Start Conditions and of the Direction Determination

Measured Values, Methods of Measurement

The device can measure the residual voltage at the broken-delta winding. The measured voltage is converted to a value with reference to the zero-sequence voltage V0. If the residual voltage is not available to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

For the measured value 3I0 and the method of measurement, you can find more information in section *Measured Value 3I0, Method of Measurement , Page 897*.

The function uses the fundamental-component value of V0 and the 3rd, 5th, or 7th harmonic phasor of V0 and 3I0 for direction determination. The specific harmonic phasor to be used is determined by the **`Harmonic selection`** setting.

Ground-Fault Detection, Pickup

If the fundamental-component value of the zero-sequence voltage V0 exceeds the threshold **`V0> threshold value`**, the stage detects the ground fault and the timer **`Dir. determination delay`** starts.

If the following 2 conditions are met, the ground-fault signaling and direction determination start:

- The fundamental-component value of the zero-sequence voltage V0 keeps exceeding the threshold **`V0> threshold value`** during the period of the timer **`Dir. determination delay`**.
- The absolute value of the zero-sequence harmonic current 3I0harm. exceeds the threshold **`Min. 3I0> harmonic`** when the timer **`Dir. determination delay`** expires.

To carry out the direction determination, the following condition must also be met in addition to the preceding 2 conditions:

The zero-sequence harmonic voltage V0harm. must exceed the threshold which is 0.02 % of the secondary rated voltage of the voltage transformer. If this condition is not met, the direction result is **unknown**.

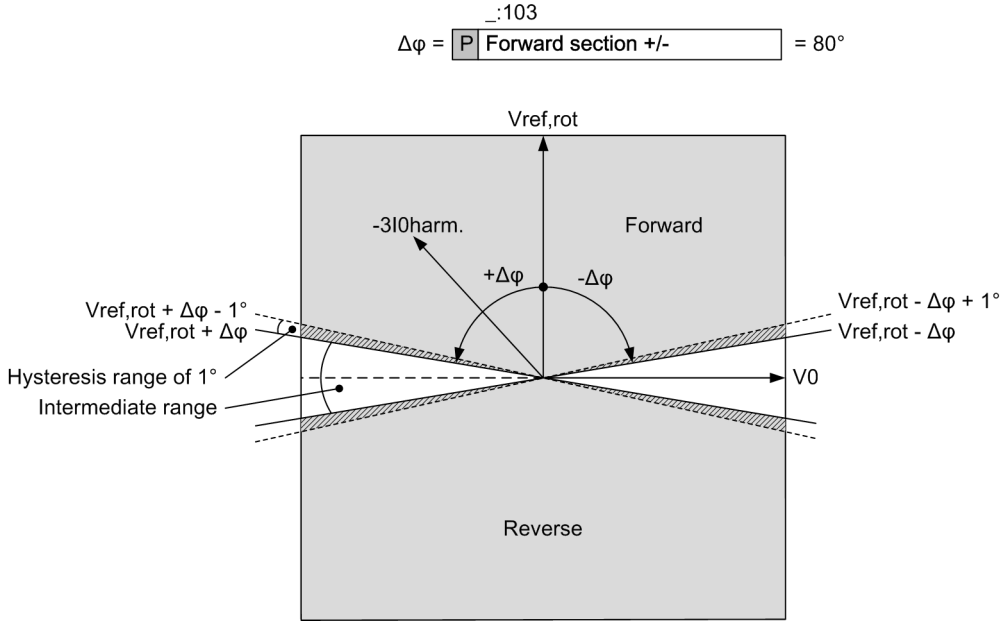
The direction result is indicated via the *Ground fault* signal.

The stage pickup depends on the direction result and on the **Directional mode** parameter:

- If the **Directional mode** parameter is set as ***forward*** or ***reverse***, the stage picks up when the direction result equals the parameterized direction, and the *Pickup* is signaled with the determined direction.
- If the **Directional mode** parameter is set as ***non-directional***, the stage picks up regardless of the direction result, and the *Pickup* is signaled with the **unknown** information.

Direction Determination

With the **Harmonic selection** parameter, you can select the 3rd, 5th, or 7th harmonic phasor for direction determination. The direction is determined via the calculation of the phase angle between the following values:



- Zero-sequence harmonic current 3I0harm.
- Rotated zero-sequence harmonic voltage V0harm., indicated in the following as reference voltage $V_{ref,rot}$

The reference voltage is rotated by the angle +90° in relation to V0. This provides the maximum security for the direction determination assuming that 3I0harm. is a reactive current.

The rotated reference voltage $V_{ref,rot}$ and the **Forward section +/-** parameter define the forward and reverse area. For details, refer to *Figure 6-261*.

The areas in the following figure are as follows:

- The forward area results as range ± Δφ around the rotated reference voltage $V_{ref,rot}$. You can set the value ± Δφ with the **Forward section +/-** parameter. If the vector of the secondary ground current -3I0harm. lies within this area, the direction result is forward.
- The mirror area of the forward area is the reverse area. If the vector of the secondary ground current -3I0harm. lies within this area, the direction result is reverse.
- In the intermediate range, the direction is **unknown**.

[dw_sensGFP V0 dir harmonic, 1, en_US]

Figure 6-261 Direction Characteristic

Stabilization Counter

To determine a reliable direction result, the function uses a stabilization counter. For indicating a direction result, the determined direction must be stable for 4 successive measuring cycles. The cycle time is 10 ms.

Direction-Result Extension

With the timer **Dir.-result extension**, you can extend the last determined direction result if the conditions for a further direction determination are no longer met. The last direction result is held until the conditions for a further direction determination are met again (timer is reset) or until the timer expires. The behavior of the direction-result extension varies according to the setting of the **Directional mode** parameter:

- **Directional mode** = ***forward*** or ***reverse***

  As soon as the zero-sequence harmonic current 3I0harm. or the zero-sequence harmonic voltage V0harm. falls below its respective dropout value, the timer **Dir.-result extension** starts. If the direction result equals the setting of the **Directional mode** parameter, the last *Pickup* signal is also extended.

  If both 3I0harm. and V0harm. exceed their thresholds again, the timer **Dir.-result extension** is reset immediately and the direction determination is carried out again.

- **Directional mode** = ***non-directional***

  As soon as the zero-sequence harmonic current 3I0harm. falls below its dropout value, the timer **Dir.-result extension** starts.

  In this directional mode, the *Pickup* is signaled only with the direction information *unknown* regardless of the actual direction that is indicated via the *Ground fault* signal. Therefore, the *Pickup* signal with the *unknown* information is extended.

  If 3I0harm. exceeds its threshold again, the timer **Dir.-result extension** is reset immediately and the direction determination is carried out again.

Measured Value Display

After the timer **Dir. determination delay** expires and the V0 fundamental-component value keeps exceeding the **V0> threshold value**, the following measured values are issued:

- *V0 harm.*
- *3I0 harm.*
- *Phi(I,V) harm.*

These measured values are displayed as **---** if 3I0harm. or V0harm. is smaller than 0.005 % of the rated secondary current or voltage.

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Stage in Case of Measuring-Voltage Failure

The stage can be blocked if a measuring-voltage failure occurs. In the event of blocking, the picked up stage will be reset.

The following blocking options are available for the stage:

- From inside on pickup of the **Measuring-voltage failure detection** function
- From an external source via the binary input signal *>Open* of the function block **Voltage-transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker

The **Blk. by meas.-volt. failure** parameter can be set so that the **Measuring-voltage failure detection** blocks the stage or not.

Blocking the Stage in Case of an Intermittent Ground Fault

In case of an intermittent ground fault, the stage can be blocked upon receiving the internal signal *Interm.gnd.flt.det* from the **Intermittent ground-fault blocking** stage. In the event of blocking, the picked-up stage will be reset.

After the release of the blocking, the timer **Dir. determination delay** is newly started and must expire before a new ground fault or pickup is annunciated.

With the **Blk.by interm.gnd.flt.** parameter, you can enable or disable the blocking of the stage in case of an intermittent ground fault.

6.13.8.2 Application and Setting Notes

Parameter: V0> threshold value

- Default setting **(_:102) V0> threshold value** = ***20.000 V***

The **V0> threshold value** parameter allows you to set the zero-sequence (fundamental) voltage sensitivity of the stage. Set the threshold value smaller than the minimum absolute value of the zero-sequence voltage V0 that must still be detected. Typical values are in the range of 15 V to 25 V.

Parameter: Dir. determination delay

- Default setting **(_:105) Dir. determination delay** = ***0.00 s***

The start of the ground fault normally shows a significant transient behavior. This can lead to an incorrect direction decision. The direction determination can be delayed from the occurrence of the zero-sequence voltage with the **Dir. determination delay** parameter to achieve steady-state measurands. The duration of the transient cycle is determined from the system conditions and the respective fault characteristics. If you have no knowledge of a suitable time delay, Siemens recommends keeping the default setting.

Parameter: Forward section +/-

- Default setting **(_:103) Forward section +/-** = ***80°***

With the **Forward section +/-** parameter, you set the direction characteristic, that is, the forward and reverse areas.

The **Forward section +/-** parameter can normally be left at its default setting. With reducing the forward area, you can provide more security for the direction result, but on the other hand, you increase the probability of an underfunction.

Parameter: Dir.-result extension

- Default setting **(_:110) Dir.-result extension** = ***5.00 s***

With the **Dir.-result extension** parameter, you define the time for extending the last determined direction result if the conditions for further direction determination are no longer met.

This timer can be used to generate a stable direction indication under fluctuating zero-sequence harmonics. A stable direction indication again can be required for the implementation of a prioritization schema between different parallel working detection methods (stages).

Parameter: Harmonic selection

- Default setting **(_:201) Harmonic selection** = ***5th harmonic***

With the **Harmonic selection** parameter, you select to use the 3rd, 5th, or 7th harmonic phasor of the zero-sequence voltage V0 and of the zero-sequence current 3I0 for direction determination.

Parameter: Min. 3I0> harmonic

- Default setting **(_:203) Min. 3I0> harmonic** = ***0.030 A***

With the **Min. 3I0> harmonic** parameter, you define the threshold value of the zero-sequence harmonic current 3I0harm. for detecting the ground fault and for starting direction determination. For more information, see also *Ground-Fault Detection, Pickup, Page 934*.

This parameter needs to be set according to the experience from the specific network. This requires the analysis of permanent ground faults from the network. If such information is unavailable, Siemens recommends a rather low setting in the area of 5 mA to 10 mA secondary.

Parameter: 3I0 harm. dropout ratio

- Default setting **(_:204) 3I0 harm. dropout ratio** = ***0.60***

With the **3I0 harm. dropout ratio** parameter, you define the dropout threshold for the **Min. 3I0> harmonic** parameter.

Lowering this dropout threshold enlarges the range and the period of direction determination under fluctuating zero-sequence harmonics. Siemens recommends using the default setting.

Parameter: Directional mode

- Default setting **(_:106) Directional mode** = ***forward***

With the **Directional mode** parameter, you define for which direction result the function generates the pickup state:

- If the **Directional mode** parameter is set as ***forward*** or ***reverse***, the stage picks up when the direction result equals the parameterized direction, and the *Pickup* is signaled with the determined direction.
- If the **Directional mode** parameter is set as ***non-directional***, the stage picks up regardless of the direction result, and the *Pickup* is signaled with the **unknown** information.

Parameter: Operate delay

- Default setting **(_:6) Operate delay** = ***1.00 s***

The **Operate delay** parameter determines the time during which the pickup conditions must be met to issue the operate indication. The operate indication is issued when this time expires.

NOTE

When both the **Operate delay** and the **Dir.-result extension** are applied, the **Operate delay** should usually be set to a considerably greater value than the **Dir.-result extension**. If the **Operate delay** is less than the **Dir.-result extension**, the function will operate for each fault regardless of the fault duration, as long as the fault direction equals the set direction.

Parameter: Operate & flt.rec. blocked

- Default setting **(_:2) Operate & flt.rec. blocked** = ***no***

With the **Operate & flt.rec. blocked** parameter, you block the operate indication, the fault recording, and the fault log. In this case, a ground-fault log is created instead of the fault log.

Parameter: Blk. by meas.-volt. failure

- Default setting **(_:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: **`Blk.by interm.gnd.flt.`**

- Default setting **`(_:111) Blk.by interm.gnd.flt.`** = ***no***

With the **`Blk.by interm.gnd.flt.`** parameter, you specify whether the stage is blocked upon receiving an internal signal *`Interm.gnd.flt.det`* from the **Intermittent ground-fault blocking** stage.

During intermittent ground faults, stages designed for detecting permanent ground faults (based on continuous RMS measurement) tend to generate a flood of signals and probably even temporary wrong directional information. This can be avoided by blocking these stages in case of an intermittent ground fault.

If intermittent ground faults in your network are probable, Siemens recommends enabling the blocking.

6.13.9 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

6.13.9.1 Description

Logic

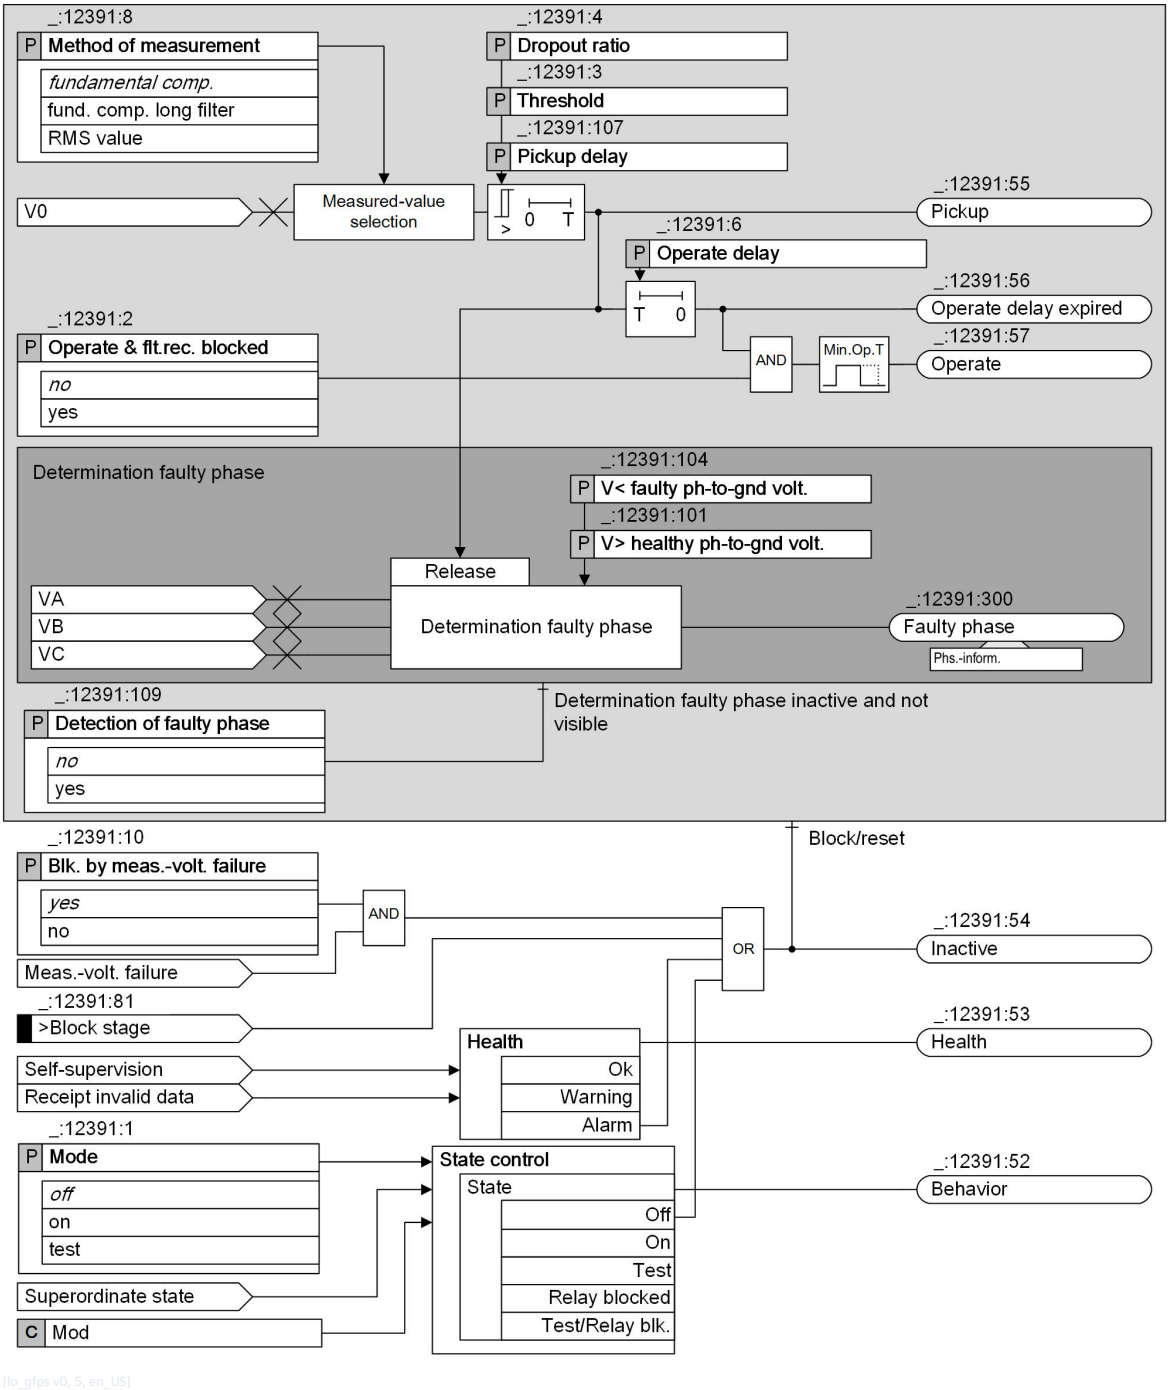

Figure 6-262 Logic Diagram of the Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage

Measured Value, Method of Measurement

The device can measure the residual voltage at the broken-delta winding. The measured voltage VN is converted to a value with reference to the zero-sequence voltage V0. If the residual voltage is not available

to the device as a measurand, the zero-sequence voltage V0 is calculated from the measured phase-to-ground voltages V_A, V_B, and V_C using the defining equation.

Use the **Method of measurement** parameter to select the relevant method of measurement, depending on the application:

- Measurement of the fundamental component (standard filter):
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically.
- Measurement of the RMS value (true RMS):
  This method of measurement determines the voltage amplitude from the sampled values according to the defining equation of the RMS value.
- Measurement of the fundamental component over 2 cycle filters with triangular window:
  This method of measurement processes the sampled voltage values and filters out the fundamental component numerically. The extended filter length compared to the standard filter and the use of the triangular window results in a particularly strong attenuation of harmonics and transient faults. The extended filter length causes the pickup time to increase slightly compared to the standard filter (see *12.12.7 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage*).

Pickup, Dropout

The stage compares the **Threshold** with the zero-sequence voltage V0. The **Pickup delay** parameter allows you to delay the pickup of the stage depending on the residual voltage.

With the **Dropout ratio** parameter, you can define the ratio of the dropout value to the **Threshold**.

Determination of the Faulty Phase

With the **Detection of faulty phase** parameter, you can enable or disable the determination of the ground-fault phase. Determining is released when the stage picks up. If 2 phases exceed the threshold value **V> healthy ph-to-gnd volt.** and one phase falls below the threshold value **V< faulty ph-to-gnd volt.**, the last phase is determined to be faulty and is signaled as such.

Blocking the Stage

In the event of blocking, the picked up stage will be reset. The following blocking options are available for the stage:

- Via the binary input signal **>Block stage** from an external or internal source
- From inside on pickup of the **measuring-voltage failure detection** function. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or does not block it.
- From an external source via the binary input signal *>open* of the function block **Voltage-transformer circuit breaker**, which links in the tripping of the voltage-transformer circuit breaker. The **Blk. by meas.-volt. failure** parameter can be set so that measuring-voltage failure detection blocks the stage or not.

6.13.9.2 Application and Setting Notes

Parameter: Method of measurement

- Recommended setting value **(_:12391:8) Method of measurement** = ***fundamental comp.***

The **Method of measurement** parameter allows you to define whether the function works with the fundamental component or the calculated RMS value.

Parameter Value	Description
fundamental comp.	This method of measurement suppresses the harmonics or transient voltage peaks. Siemens recommends using this setting as the standard method.
RMS value	Select this method of measurement if you want the stage to take harmonics into account (for example at capacitor banks).
fund. comp. long filter	To implement particularly strong damping of harmonics and transient faults, select this method of measurement. At 2 periods, the length of the filter is longer than that of the standard filter. Note that in this case the pickup time of the stage increases slightly (see *12.12.7 Non-Directional V0 Stage with Zero-Sequence Voltage/Residual Voltage*).

Parameter: `Pickup delay`

- Recommended setting value **`(_:12391:107) Pickup delay`** = ***`0 ms`***

The **`Pickup delay`** parameter allows you to delay the analysis of the measurand (to generate the pickup) depending on the occurrence of the residual voltage. A pickup delay can be necessary if high transients are anticipated after fault inception due to high line and ground capacitances.

Siemens recommends using the default setting **`Pickup delay`** = ***`0 ms`***.

Parameter: `Threshold`

- Default setting **`(_:12391:3) Threshold`** = ***`30 V`***

The threshold value of the function is set as the zero-sequence voltage V0. The device calculates the zero-sequence voltage V0 either from the residual voltage measured via the broken-delta winding or from the 3 phase-to-ground voltages.

The setting value depends on the system grounding:

- Since virtually the full residual voltage occurs during ground faults in isolated or arc-suppression-coil-grounded systems, the setting value is uncritical there. Siemens recommends setting the value between 20 V and 40 V. A higher sensitivity (= lower threshold value) can be necessary for high fault resistances.
- Siemens recommends setting a more sensitive (smaller) value in grounded systems. This value must be higher than the maximum residual voltage anticipated during operation caused by system unbalances.

EXAMPLE

For an isolated system

The residual voltage is measured via the broken-delta winding:

- If the ground fault is fully unbalanced, a residual voltage of 100 V is present at the device terminals.
- The threshold value should be set so that the stage picks up on 50 % of the full residual voltage.
- At full residual voltage, the zero-sequence voltage is 100 V/$\sqrt{3}$ = 57.7 V
  Setting value: 0.5 · 57.7 V = 28.9 V ≈ 30 V

Parameter: `Dropout ratio`

- Recommended setting value **`(_:12391:4) Dropout ratio`** = ***`0.95`***

The recommended setting value of ***`0.95`*** is appropriate for most applications. To achieve high measurement precision, the dropout ratio can be reduced to 0.98, for example.

Parameter: `Operate delay`

- Default setting **`(_:12391:6) Operate delay`** = ***`3.00 s`***

The **Operate delay** allows you to prevent transient residual voltages from initiating a trip. The setting depends on the specific application.

Parameter: Blk. by meas.-volt. failure

- Recommended setting value **(_:12391:10) Blk. by meas.-volt. failure** = ***yes***

You use the **Blk. by meas.-volt. failure** parameter to control the behavior of the stage when a measuring-voltage failure is detected.

A measuring-voltage failure can only be detected if one of the following 2 conditions is met:

- The device-internal supervision function **Measuring-voltage failure detection** is configured and enabled.
- The binary input signal *>Open* of the function block **Voltage-transformer circuit breaker** is connected to the voltage-transformer circuit breaker.

Parameter Value	Description
yes	The protection stage is blocked (= default setting). If V0 is calculated from the phase-to-ground voltages, Siemens recommends using the blocking.
no	The protection stage is not blocked. If V0 is obtained from the VN measurement of a broken-delta winding, Siemens recommends not using the blocking.

Parameter: Detection of faulty phase

- Default setting **(_:12391:109) Detection of faulty phase** = ***no***

The **Detection of faulty phase** parameter controls how the stage responds to determine which phase is affected by the ground fault.

Parameter Value	Description
no	The phase affected by the ground fault is not determined. Select the default setting if you do not want to use the stage to detect ground faults, for example for applications in grounded systems.
yes	After a pickup by the residual voltage, the device tries to determine which phase is affected by the ground fault. Select this setting for applications in isolated or arc-suppression-coil-grounded systems.

Parameter: V< faulty ph-to-gnd volt.

- Default setting **(_:12391:104) V< faulty ph-to-gnd volt.** = ***30 V***

Set the threshold value for determining which phase is affected by the ground fault in the **V< faulty ph-to-gnd volt.** parameter. The setting value is a phase-to-ground quantity.

The set value must be smaller than the minimum phase-to-ground voltage occurring during operation. Siemens recommends using the default setting **V< faulty ph-to-gnd volt.** = ***30 V***.

Parameter: V> healthy ph-to-gnd volt.

- Default setting **(_:12391:101) V> healthy ph-to-gnd volt.** = ***70 V***

Set the threshold value for the 2 healthy phases in the **V> healthy ph-to-gnd volt.** parameter. The setting value is a phase-to-ground measurand.

The set value must be above the maximum phase-to-ground voltage occurring during operation, but below the minimum phase-to-phase voltage present during operation. At V_{rated} = 100 V, the value has to be set to 70 V, for example. Siemens recommends using the default setting **V> healthy ph-to-gnd volt.** = ***70 V***.

Operation as Supervision Function

If you want the stage to have a reporting effect only, the generation of the operate indication and fault logging can be disabled via the **`Operate & flt.rec. blocked`** parameter.

6.13.10 Non-Directional 3I0 Stage

6.13.10.1 Description

In the **Directional sensitive ground-fault detection** function, the **Non-directional 3I0 stage** also works on demand.

Logic

[lo_sensitive ground-current protection 3I0, 3, en_US]

Figure 6-263 Logic Diagram of the Non-Directional 3I0 Stage

Measured Value 3I0

The function usually evaluates the sensitively measured ground current 3I0 via a core balance current transformer. Since the linearity range of the sensitive measuring input ends at approx. 1.6 A, for larger secondary ground currents, the function switches to the 3I0 current calculated from the phase currents. This results in a very large linearity and settings range.

Depending on the connection type of the measuring point as well as the current terminal blocks used, different linearity and setting ranges result. You can find more information in section *Measured Value 3I0, Method of Measurement , Page 897*.

Method of Measurement

You use the **Method of measurement** parameter to define whether the stage uses the ***fundamental comp.*** or the calculated ***RMS value***.

- Measurement of the fundamental component:
  This method of measurement processes the sampled current values and filters out the fundamental component numerically.
- Measurement of the RMS value:
  This method of measurement determines the current amplitude from the sampled values according to the defining equation of the RMS value. Harmonics are included in the analysis.

Blocking the Stage via Binary Input Signal

You can block the stage externally or internally via the binary input signal *>Block stage*. In the event of blocking, the picked up stage will be reset.

Blocking the Time Delay

You can use the binary input signal *>Block delay & op.* to prevent the start of the time delay and thus also the operate indication. A running time delay is reset. The pickup is indicated and a fault record is opened.

Blocking of the Tripping by Device-Internal Inrush-Current Detection

The **Blk. w. inrush curr. detect.** parameter allows you to define whether the operate indication of the stage should be blocked when a threshold value is exceeded due to an inrush current. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

The **Blk. w. 2nd harm. gnd. det.** parameter allows you to define whether the operate indication of the stage should be blocked when the detected 2nd harmonic component of the ground current exceeds a threshold value. In case of a blocking and fulfilled pickup conditions, the stage picks up. The start of the time delay and the operate indication are blocked. The function indicates this through a corresponding indication. If the blocking drops out and the pickup conditions are still met, the time delay is started. After that time, the stage operates.

6.13.10.2 Application and Setting Notes

Parameter: Blk. w. inrush curr. detect.

- Default setting **(_:27) Blk. w. inrush curr. detect.** = ***no***

With the **Blk. w. inrush curr. detect.** parameter, you determine whether the tripping is blocked during the detection of an inrush current.

Parameter: Blk. w. 2nd harm. gnd. det.

- Default setting **(_:103) Blk. w. 2nd harm. gnd. det.** = ***no***

Parameter Value	Description
no	If no 3I0/IN current flow due to CT saturation with a level above the pickup threshold is expected, select this setting.
yes	If 3I0/IN current flow due to CT saturation with a level above the pickup threshold is expected, the blocking must be activated. This provides stability for the following conditions: • CT saturation without inrush current since a saturated signal also contains 2nd-harmonic content • Phase inrush current that leads to CT saturation and therefore causes 2nd-harmonic inrush current being present also in the parasitic 3I0 current

Parameter: `Method of measurement`

- Recommended setting value **`(_:8) Method of measurement`** = ***`fundamental comp.`***

With the **`Method of measurement`** parameter, you define whether the stage uses the ***`fundamental comp.`*** (standard method) or the calculated ***`RMS value`***.

Parameter Value	Description
`fundamental comp.`	Select this method of measurement if harmonics or transient current peaks are to be suppressed. Siemens recommends using this method as the standard method.
