IRES[1)]	Residual current (measured or calculated) Necessary when the operation mode "Light +current" is used

1) Can be connected to GRPOFF if "Light only" or "BI controlled" operation modes are used

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.9.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of ARCSARC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

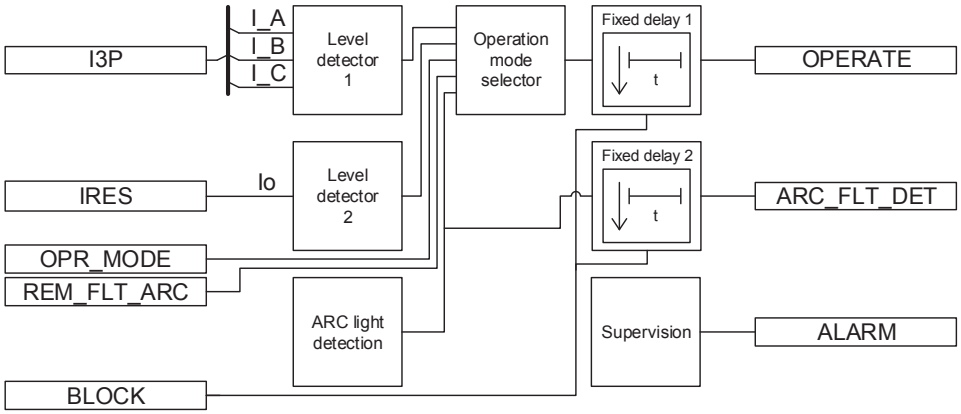

Figure 533: Functional module diagram

Level detector 1

The measured phase currents are compared phasewise to the set *Phase start value*. If the measured value exceeds the set *Phase start value*, the level detector reports the exceeding of the value to Operation mode selector.

Level detector 2

The measured residual currents are compared to the set *Ground start value*. If the measured value exceeds the set *Ground start value*, the level detector reports the exceeding of the value to Operation mode selector.

ARC light detection

ARC detection information is received directly from the relay hardware input. The detected ARC fault is directly signalled to the Operation mode selector and Fixed delay 2 modules. There are four ARC detection inputs in the protection relay. Each input is connected to a dedicated ARCSARC function.

Table 926: ARC detection inputs connected to ARCSARC

ARC input	ARC protection function
X11/ARC	ARCSARC1
X12/ARC	ARCSARC2
X13/ARC	ARCSARC3
X14/ARC	ARCSARC4

Operation mode selector

Depending on the *Operation mode* setting, Operation mode selector makes sure that all required criteria are fulfilled for a reliable decision of an arc fault situation. The operation is based on both current and light information in “Light+current” mode, on light information only in “Light only” mode or on remotely controlled information in “BI controlled” mode. When the "BI controlled" mode is in use and the `OPR_MODE`

input is activated, the operation of the function is based on light information only. When the OPR_MODE input is deactivated, the operation of the function is based on both light and current information. When the required criteria are met, Fixed delay 1 timer is activated.

Fixed delay 1

Once this timer is activated, the OPERATE signal output is activated immediately. The output is kept active for minimum 25 ms or as long as the input is activated. The BLOCK signal can be used to block the OPERATE signal.

Fixed delay 2

Once this timer is activated, the ARC_FLT_DET output is activated immediately. The output is kept active for minimum 25 ms or as long as the input is activated. The BLOCK signal can be used to block the ARC light signal output ARC_FLT_DET.

Supervision

If a faulty arc sensor is internally detected or if the connection to the arc sensor is lost, ALARM output is activated if *Sensor supervision* is set to "on".

When *Sensor supervision* is set to "off", ALARM output stays false even though the arc sensor is faulty or unconnected.

4.9.6 Application

The arc protection can be realized as a stand-alone function in a single relay or as a station-wide arc protection, including several protection relays. If realized as a station-wide arc protection, different tripping schemes can be selected for the operation of the circuit breakers of the incoming and outgoing feeders. Consequently, the relays in the station can, for example, be set to trip the circuit breaker of either the incoming or the outgoing feeder, depending on the fault location in the switchgear. For maximum safety, the relays can be set to always trip both the circuit breaker of the incoming feeder and that of the outgoing feeder.

The arc protection consists of:

- Optional arc light detection hardware with automatic backlight compensation for lens type sensors
- Light signal output ARC_FLT_DET for routing indication of locally detected light signal to another relay
- Protection stage with phase- and earth-fault current measurement.

The function detects light from an arc either locally or via a remote light signal. Locally, the light is captured either by lens type point sensors or transparent fiber loop sensors connected to the light sensor input of the relay. This captured light is guided via optical fiber to the sensor input of the relay, where it is converted to electrical signal by means of a photo diode. The optical light sensors can be placed in the various

compartments of the switchgear, for example, in the busbar compartment, the circuit breaker compartments, the bus riser and the outgoing feeder cable end compartments.

The light detected by the lens sensor inputs is compared to an automatically adjusted reference level. Each light sensor input has its own reference level. When the light exceeds the reference level of one of the inputs, the light is detected locally. When the light has been detected locally or remotely and, depending on the operation mode, if one or several phase currents exceed the set *Phase start value* limit, or the earth-fault current the set *Ground start value* limit, the arc protection stage generates an operation signal. The stage is reset in 30 ms, after all three-phase currents and the earth-fault current have fallen below the set current limits.

The light signal output from an arc protection stage `ARC_FLT_DET` is activated immediately in the detection of light in all situations. A station-wide arc protection is realized by routing the light signal outputs to output contacts connected via physical wires to the binary inputs of other relays, or by routing the light signal outputs through the communication (IEC 61850/GOOSE signaling) to the virtual inputs of other relays.

It is possible to block the tripping and the light signal output of the arc protection stage with a binary input or a signal from another function block.

Arc protection with one protection relay

In installations, with limited possibilities to realize signaling between protection relays protecting incoming and outgoing feeders, or if only the protection relay for the incoming feeder is to be exchanged, an arc protection with a less selective level can be achieved with one protection relay. In arc detection, the arc protection stage trips the circuit breaker of the incoming feeder. The maximum recommended installation distance between the two lens sensors in the busbar area is six meters and the maximum distance from a lens sensor to the end of the busbar is three meters.

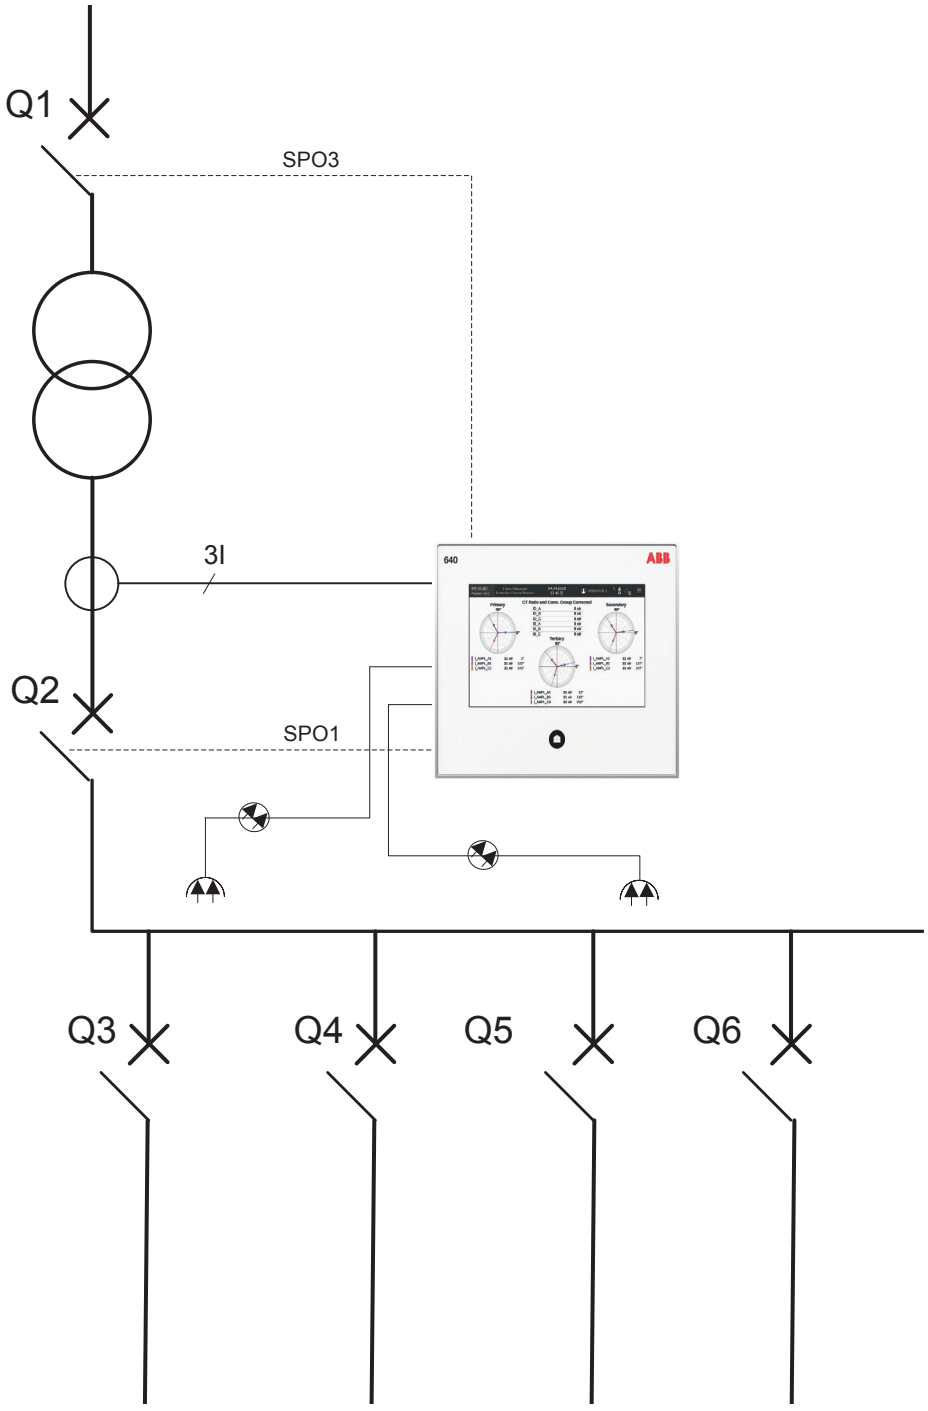

Figure 534: Arc protection with one protection relay

Arc protection with several protection relays

When using several protection relays, the protection relay protecting the outgoing feeder trips the circuit breaker of the outgoing feeder when detecting an arc at the cable terminations. If the protection relay protecting the outgoing feeder detects an arc on

the busbar or in the breaker compartment via one of the other lens sensors, it generates a signal to the protection relay protecting the incoming feeder. When detecting the signal, the protection relay protecting the incoming feeder trips the circuit breaker of the incoming feeder and generates an external trip signal to all protection relays protecting the outgoing feeders, which in turn results in tripping of all circuit breakers of the outgoing feeders. For maximum safety, the protection relays can be configured to trip all the circuit breakers regardless of where the arc is detected.

4.10.3 Functionality

The motor start-up supervision function STTPMSU is designed for protection against excessive starting time and locked rotor conditions of the motor during starting. For a good and reliable operation of the motor, the thermal stress during the motor starting is maintained within the allowed limits.

The starting of the motor is supervised by monitoring the TRMS magnitude of all the phase currents or by monitoring the status of the circuit breaker connected to the motor.

During the start-up period of the motor, STTPMSU calculates the integral of the I^2t value. If the calculated value exceeds the set value, the operate signal is activated.

STTPMSU has the provision to check the locked rotor condition of the motor using the speed switch, which means checking if the rotor is able to rotate or not. This feature operates after a predefined operating time.

STTPMSU also protects the motor from an excessive number of start-ups. Upon exceeding the specified number of start-ups within certain duration, STTPMSU blocks further starts. The restart of the motor is also inhibited after each start and continues to be inhibited for a set duration. When the lock of start of motor is enabled, STTPMSU gives the time remaining until the restart of the motor.

STTPMSU contains a blocking functionality. It is possible to block function outputs, timer or the function itself.

4.10.4 Analog input configuration

STTPMSU has one analog group input which must be properly configured.

Table 933: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.10.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of STTPMSU can be described with a module diagram. All the modules in the diagram are explained in the next sections.

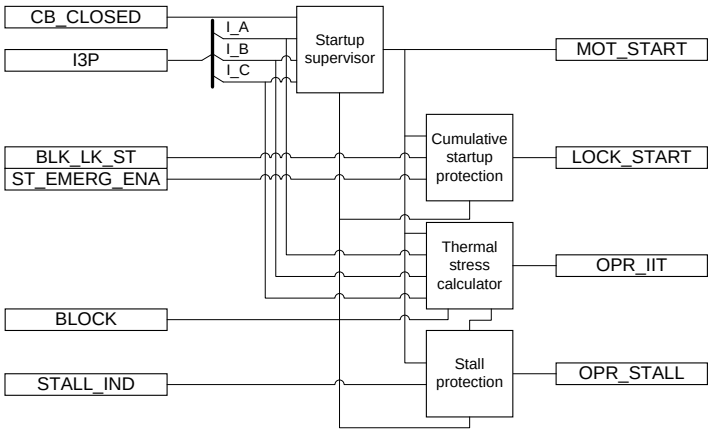

Figure 538: Functional module diagram

Startup supervisor

This module detects the starting of the motor. The starting and stalling motor conditions are detected in four different modes of operation. This is done through the *Operation mode* setting.

When the *Operation mode* setting is operated in the "IIt" mode, the function calculates the value of the thermal stress of the motor during the start-up condition. In this mode, the start-up condition is detected by monitoring the TRMS currents.

The *Operation mode* setting in the "IIt, CB" mode enables the function to calculate the value of the thermal stress when a start-up is monitored in addition to the CB_CLOSED input.

In the "IIt & stall" mode, the function calculates the thermal stress of the motor during the start-up condition. The start-up condition is detected by monitoring the TRMS currents.

In the "IIt & stall, CB" mode, the function calculates the thermal stress of the motor during the start-up condition but the start-up condition is detected by monitoring the TRMS current as well as the circuit breaker status.

In both the "IIt & stall" and "IIt & stall, CB" mode, the function also checks for motor stalling by monitoring the speed switch.

When the measured current value is used for start-up supervision in the "IIt" and "IIt & stall" modes, the module initially recognizes the de-energized condition of the motor when the values of all three phase currents are less than *Motor standstill A* for longer than 100 milliseconds. If any of the phase currents of the de-energized condition rises to a value equal to or greater than *Motor standstill A*, the MOT_START output signal is activated indicating that the motor start-up is in progress. The MOT_START output remains active until the values of all three phase currents drop below 90 percent of the set value of *Start detection A* and remain below that level for a time of *Str over delay time*, that is, until the start-up situation is over.

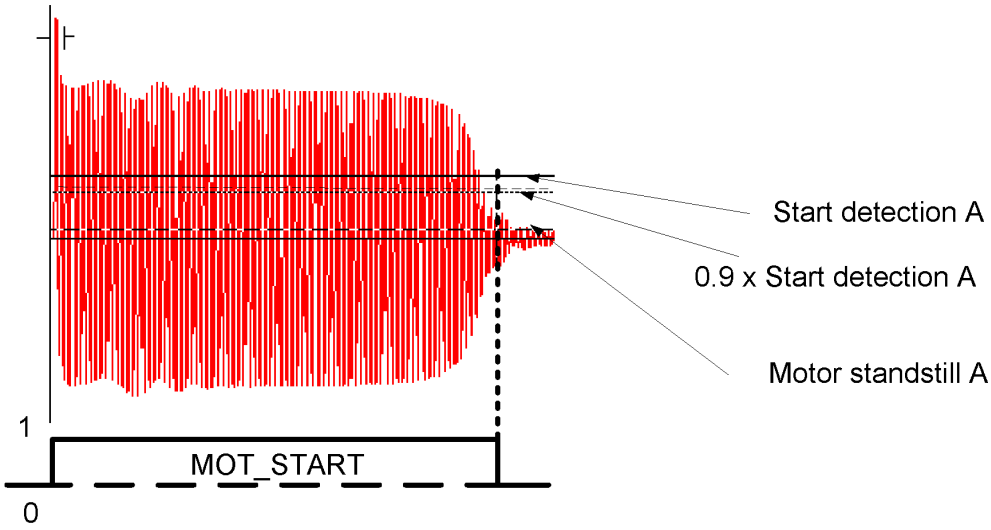

Figure 539: Functionality of start-up supervision in the "IIt and IIt&stall" mode

In case of the "IIt, CB" or "IIt & stall, CB" modes, the function initially recognizes the de-energized condition of the motor when the value of all three phase currents is below the value of the *Motor standstill A* setting for 100 milliseconds. The beginning of the motor start-up is recognized when CB is closed, that is, when the CB_CLOSED input is activated and at least one phase current value exceeds the *Motor standstill A* setting.

These two events do not take place at the same instant, that is, the CB main contact is closed first, in which case the phase current value rises above 0.1 pu and after some delay the CB auxiliary contact gives the information of the CB_CLOSED input. In some cases, the CB_CLOSED input can be active but the value of current may not be greater than the value of the *Motor standstill A* setting. To allow both possibilities, a time slot of 200 milliseconds is provided for current and the CB_CLOSED input. If both events occur during this time, the motor start-up is recognized.

The motor start-up ends either within the value of the *Str over delay time* setting from the beginning of the start-up or the opening of CB or when the CB_CLOSED input is deactivated. The operation of the MOT_START output signal in this operation mode is as illustrated in Figure 540.

This CB mode can be used in soft-started or slip ring motors for protection against a large starting current, that is, a problem in starting and so on.

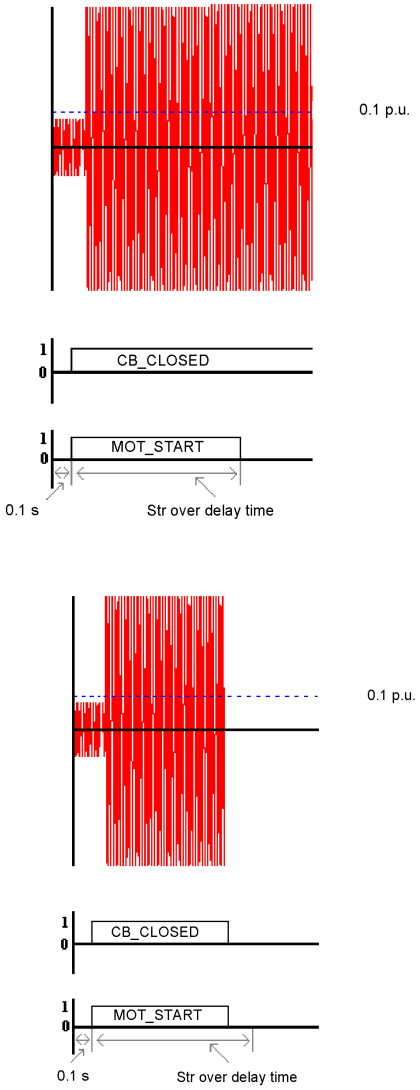

Figure 540: Functionality of start-up supervision in the "IIt, CB" mode and the "IIt and stall, CB" mode

The *Str over delay time* setting has different purposes in different modes of operation.

- In the “IIt” or “IIt & stall” modes, the aim of this setting is to check for the completion of the motor start-up period. The purpose of this time delay setting is to allow for short interruptions in the current without changing the state of the MOT_START output. In this mode of operation, the value of the setting is in the range of around 100 milliseconds.
- In the “IIt, CB” or “IIt & stall, CB” modes, the purpose of this setting is to check for the life of the protection scheme after the CB_CLOSED input has been activated. Based on the values of the phase currents, the completion of the start-up period cannot be judged. So in this mode of operation, the value of the time delay setting can even be as high as within the range of seconds, for example around 30 seconds.

The activation of the BLOCK input signal deactivates the MOT_START output.

Thermal stress calculator

Because of the high current surges during the start-up period, a thermal stress is imposed on the rotor. With less air circulation in the ventilation of the rotor before it reaches its full speed, the situation becomes even worse. Consequently, a long start-up causes a rapid heating of the rotor.

This module calculates the thermal stress developed in the motor during start-up. The heat developed during the starting can be calculated with the equation.

$$W = R_s \int_0^t i_s^2(t)\,dt$$

(Equation 237)

R_s combined rotor and stator resistance

i_s starting current of the motor

t starting time of the motor

This equation is normally represented as the integral of I²t. It is a commonly used method in protective protection relays to protect the motor from thermal stress during starting. The advantage of this method over the traditional definite time overcurrent protection is that when the motor is started with a reduced voltage as in the star-delta starting method, the starting current is lower. This allows more starting time for the motor since the module is monitoring the integral of I²t.

The module calculates the accumulated heat continuously and compares it to the limiting value obtained from the product of the square of the values of the *Motor start-up A* and *Motor start-up time* settings. When the calculated value of the thermal stress exceeds this limit, the OPR_IIT output is activated.

The module also measures the time START_TIME required by the motor to attain the rated speed and the relative thermal stress IIT_RL. The values are available in the Monitored data view.

The activation of the BLOCK input signal resets the thermal stress calculator and deactivates the OPR_IIT output.

Stall protection

This module is activated only when the selected *Operation mode* setting value is "IIt & stall" or "IIt & stall, CB".

The start-up current is specific to each motor and depends on the start-up method used, such as direct online, autotransformer and rotor resistance insertion. The start-up time is dependent on the load connected to the motor.

Based on the motor characteristics supplied by the manufacturer, this module is required if the stalling time is shorter than or too close to the starting time. In such cases, a speed switch must be used to indicate whether a motor is accelerating during start-up or not.

At motor standstill, the STALL_IND input is active. It indicates that the rotor is not rotating. When the motor is started, at certain revolution the deactivation of the STALL_IND by the speed switch indicates that the rotor is rotating. If the input is not deactivated within *Lock rotor time*, the OPR_STALL output is activated.

The module calculates the duration of the motor in stalling condition, the STALL_RL output indicating the percent ratio of the start situation and the set value of *Lock rotor time*. The value is available in the Monitored data view.

The activation of the BLOCK input signal resets the operation time and deactivates the OPR_STALL output.

Cumulative start-up protection

This module protects the motor from an excessive number of start-ups.

Whenever the motor is started, the latest value of START_TIME is added to the existing value of T_ST_CNT and the updated cumulative start-up time is available at T_ST_CNT. If the value of T_ST_CNT is greater than the value of *Cumulative time Lim*, the LOCK_START output is activated and lockout condition for the restart of motor is enabled during the time the output is active. The LOCK_START output remains high until the T_ST_CNT value reduces to a value less than the value of *Cumulative time Lim*. The start time counter reduces at the rate of the value of *Counter Red rate*.

The LOCK_START output becomes activated at the start of MOT_START. The output remains active for a period of *Restart inhibit time*.

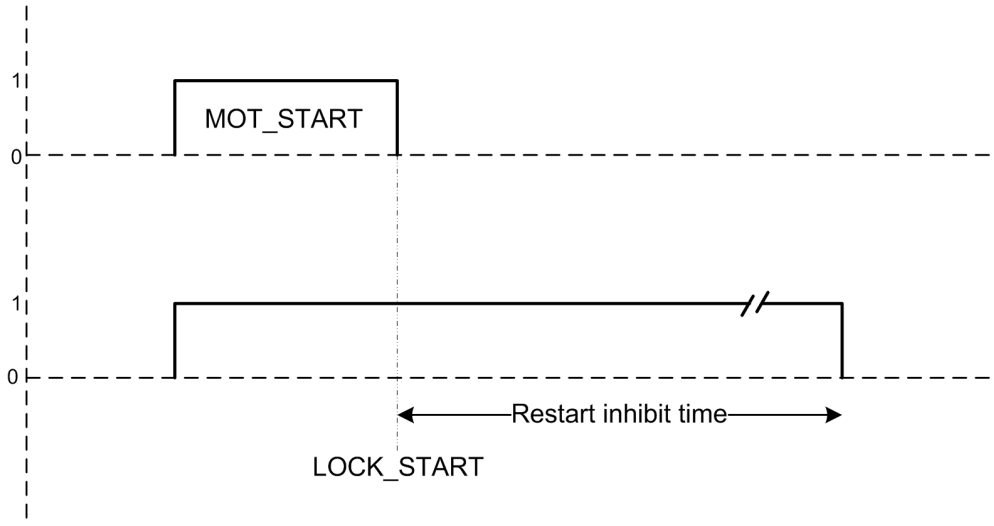

Figure 541: Time delay for cumulative start

This module also protects the motor from consecutive start-ups. When the LOCK_START output is active, T_RST_ENA shows the possible time for next restart. The value of T_RST_ENA is calculated by the difference of *Restart inhibit time* and the elapsed time from the instant LOCK_START is enabled.

When the ST_EMERG_ENA emergency start is set high, the value of the cumulative start-up time counter is set to *Cumulative time Lim* - 60s · *Emg start Red rate*. This disables LOCK_START and in turn makes the restart of the motor possible.

This module also calculates the total number of start-ups occurred, START_CNT. The value can be reset from the Clear menu.

The old *Number of motor start-ups occurred* counter value (START_CNT) can be taken into use by writing the value to the *Ini start up counter* parameter and resetting the value via the Clear menu from WHMI or LHMI.

The calculated values of T_RST_ENA, T_ST_CNT and START_CNT are available in the Monitored data view.

The activation of the BLK_LK_ST input signal deactivates the LOCK_START output. The activation of the BLOCK input signal resets the cumulative start-up counter module.

4.10.6 Application

When a motor is started, it draws a current well in excess of the motor's full-load rating throughout the period it takes for the motor to run up to the rated speed. The motor starting current decreases as the motor speed increases and the value of current remains close to the rotor-locked value for most of the acceleration period.

The full-voltage starting or the direct-on-line starting method is used out of the many methods used for starting the induction motor. If there is either an electrical or mechanical constraint, this starting method is not suitable. The full-voltage starting produces the highest starting torque. A high starting torque is generally required to start a high-inertia load to limit the acceleration time. In this method, full voltage is applied to the motor when the switch is in the "On" position. This method of starting results in a large initial current surge, which is typically four to eight times that of the full-load current drawn by the motor. If a star-delta starter is used, the value of the line current will only be about one-third of the direct-on-line starting current.

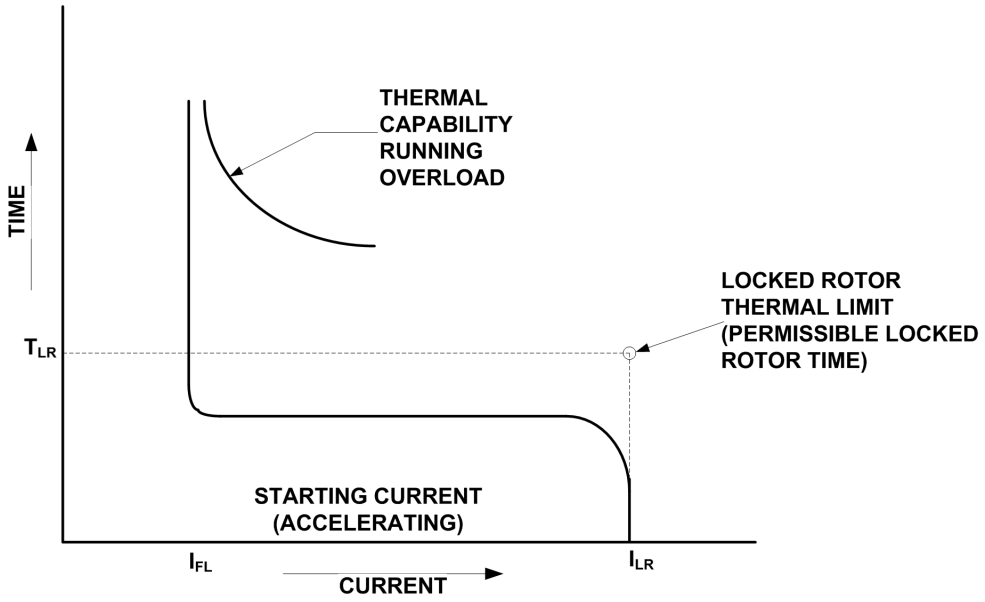

Figure 542: Typical motor starting and capability curves

The start-up supervision of a motor is an important function because of the higher thermal stress developed during starting. During the start-up, the current surge imposes a thermal strain on the rotor. This is exaggerated as the air flow for cooling is less because the fans do not rotate in their full speed. Moreover, the difference of speed between the rotating magnetic field and the rotor during the start-up time induces a high magnitude of slip current in the rotor at frequencies higher than when the motor is at full speed. The skin effect is stronger at higher frequencies and all these factors increase the losses and the generated heat. This is worse when the rotor is locked.

The starting current for slip-ring motors is less than the full load current and therefore it is advisable to use the circuit breaker in the closed position to indicate the starting for such type of motors.

The starting times vary depending on motor design and load torque characteristics. The time taken may vary from less than two seconds to more than 60 seconds. The starting time is determined for each application.

When the permissible stall time is less than the starting time of the motor, the stalling protection is used and the value of the time delay setting should be set slightly less than the permissible stall time. The speed switch on the motor shaft must be used for detecting whether the motor begins to accelerate or not. However, if the safe stall time is longer than the start-up time of the motor, the speed switch is not required.

The failure of a motor to accelerate or to reach its full nominal speed in an acceptable time when the stator is energized is caused by several types of abnormal conditions, including a mechanical failure of the motor or load bearings, low supply voltage, open circuit in one phase of a three-phase voltage supply or too high starting voltage. All these abnormal conditions result in overheating.

Repeated starts increase the temperature to a high value in the stator or rotor windings, or both, unless enough time is allowed for the heat to dissipate. To ensure a safe operation it is necessary to provide a fixed-time interval between starts or limit the number of starts within a period of time. This is why the motor manufacturers have restrictions on how many starts are allowed in a defined time interval. This function does not allow starting of the motor if the number of starts exceeds the set level in the register that calculates them. This insures that the thermal effects on the motor for consecutive starts stay within permissible levels.

For example, the motor manufacturer may state that three starts at the maximum are allowed within 4 hours and the start-up situation time is 60 seconds. By initiating three successive starts we reach the situation as illustrated. As a result, the value of the register adds up to a total of 180 seconds. Right after the third start has been initiated, the output lock of start of motor is activated and the fourth start will not be allowed, provided the time limit has been set to 121 seconds.

Furthermore, a maximum of three starts in 4 hours means that the value of the register should reach the set start time counter limit within 4 hours to allow a new start. Accordingly, the start time counter reduction should be 60 seconds in 4 hours and should thus be set to 60 s / 4 h = 15 s / h.

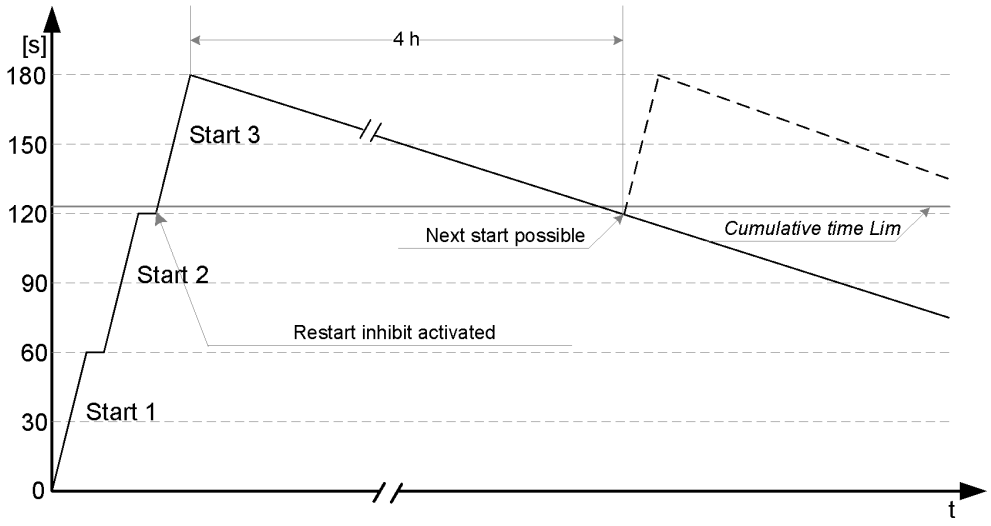

Figure 543: Typical motor-starting and capability curves

Multipurpose protection	MAPGAPC	MAP	MAP

4.11.2 Function block

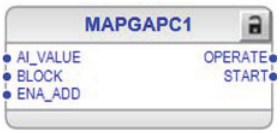

Figure 544: Function block

4.11.3 Functionality

The multipurpose protection function MAPGAPC is used as a general protection with many possible application areas as it has flexible measuring and setting facilities. The function can be used as an under- or overprotection with a settable absolute hysteresis limit. The function operates with the definite time (DT) characteristics.

The function contains a blocking functionality. It is possible to block function outputs, the definite timer or the function itself.

4.11.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of MAPGAPC can be described using a module diagram. All the modules in the diagram are explained in the next sections.

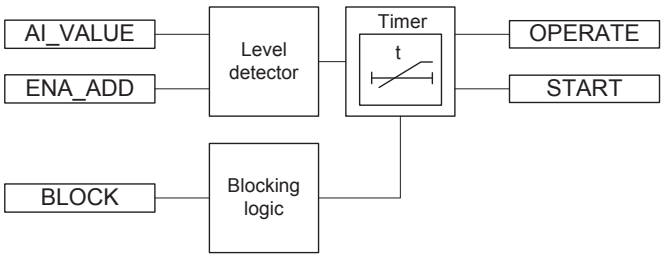

Figure 545: Functional module diagram

Level detector

Level detector compares AI_VALUE to the *Start value* setting. The *Operation mode* setting defines the direction of the level detector.

Table 942: Operation mode types

Operation mode	Description
Under	If the input signal AI_VALUE is lower than the set value of the *Start value* setting, the level detector enables the timer module.
Over	If the input signal AI_VALUE exceeds the set value of the *Start value* setting, the level detector enables the timer module.

The *Absolute hysteresis* setting can be used for preventing unnecessary oscillations if the input signal is slightly above or below the *Start value* setting. After leaving the hysteresis area, the start condition has to be fulfilled again and it is not sufficient for the signal to only return to the hysteresis area. If the ENA_ADD input is activated, the threshold value of the internal comparator is the sum of the *Start value Add* and *Start value* settings. The resulting threshold value for the comparator can be increased or decreased depending on the sign and value of the *Start value Add* setting.

Timer

Once activated, Timer activates the START output. The time characteristic is according to DT. When the operation timer has reached the value set by *Operate delay time*, the OPERATE output is activated. If the starting condition disappears before the module operates, the reset timer is activated. If the reset timer reaches the value set by *Reset delay time*, the operation timer resets and the START output is deactivated.

The timer calculates the start duration value START_DUR, which indicates the percentage ratio of the start situation and the set operation time. The value is available in the monitored data view.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting in **Configuration/System/ Blocking mode** which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the "Freeze timers" mode, the operation timer is frozen to the prevailing value, but the OPERATE output is not deactivated when blocking is activated. In the "Block all" mode, the whole function is blocked and the timers are reset. In the "Block OPERATE output" mode, the function operates normally but the OPERATE output is not activated.

4.11.5 Application

The function block can be used for any general analog signal protection, either underprotection or overprotection. The setting range is wide, allowing various protection schemes for the function. Thus, the absolute hysteresis can be set to a value that suits the application.

The temperature protection using the RTD sensors can be done using the function block. The measured temperature can be fed from the RTD sensor to the function input that detects too high temperatures in the motor bearings or windings, for example. When the ENA_ADD input is enabled, the threshold value of the internal comparator is the sum of the *Start value Add* and *Start value* settings. This allows a temporal increase or decrease of the level detector depending on the sign and value of the *Start value Add* setting, for example, when the emergency start is activated. If, for example, *Start value* is 100, *Start value Add* is 20 and the ENA_ADD input is active, the input signal needs to rise above 120 before MAPGAPC operates.

4.11.6 Signals

Table 943: MAPGAPC Input signals

Name	Type	Default	Description
AI_VALUE	FLOAT32	0.0	Analogue input value
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode
ENA_ADD	BOOLEAN	0=False	Enable start added

4.12.1.2 Function block

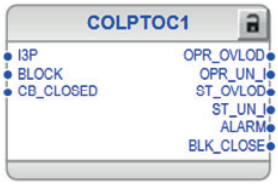

Figure 546: Function block

4.12.1.3 Functionality

The three-phase overload protection for shunt capacitor banks function COLPTOC provides single-phase, two-phase and three-phase protection against overloads caused by harmonic currents and overvoltages in shunt capacitor banks. The operation of overload and alarm is based on the peak value of the integrated current which is proportional to the voltage across the capacitor.

The overload function operates with IDMT characteristic and an alarm function operates with DT characteristic.

COLPTOC provides undercurrent protection to detect disconnection of the capacitor. COLPTOC has breaker reclosing inhibit feature to enable complete capacitor discharging before breaker reclosing after it has operated.

COLPTOC contains blocking functionality. It is possible to block the function outputs, timers or the function itself.

4.12.1.4 Analog channel configuration

COLPTOC has one analog group input which must be properly configured.

Table 950: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.12.1.5 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “on” and “off”.

The operation of COLPTOC can be described using a module diagram. All the modules in the diagram are explained in the next sections.

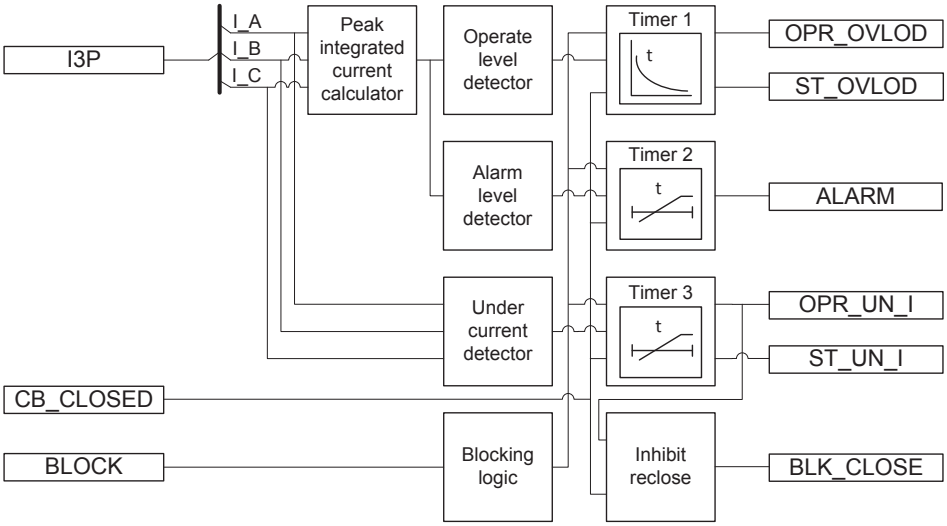

Figure 547: Functional module diagram

Peak integrated current calculator

The peak integrated current calculator calculates peak value of integrated current (I_PEAK_INT_A, I_PEAK_INT_B and I_PEAK_INT_C) which is proportional to the voltage over capacitor. The I_PEAK_INT_A, I_PEAK_INT_B and I_PEAK_INT_C values are available in monitored data view. The frequency response of the peak integrated current calculator can be seen in Figure 548.

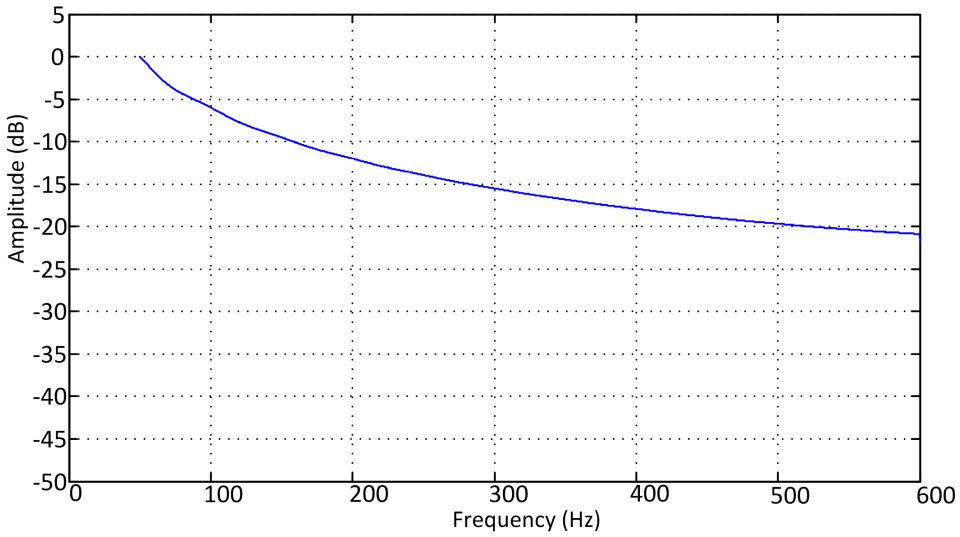

Figure 548: Frequency response of the peak integrated current calculator

Operate level detector

The Operate level detector compares `I_PEAK_INT_x` value to *Start value overload*. If the phase or phases in which `I_PEAK_INT_x` exceeds the setting matches the *Num of start phases* setting, the Operate level detector module activates the Timer 1 module.

Timer 1

Once activated, the Timer 1 module activates the `ST_OVLOD` output. The operation time depends on the overload level and *Time multiplier*. The operation time under standard characteristics is based on ANSI/IEEE 37.99 and IEC 60871-1 recommendations.

Table 951: Standard Curve characteristics for IDMT Curve

Overload value	Relay operate time(s) with k = 1	Standard
1.10	43200	IEC60871-1
1.15	1800	IEC60871-1
1.20	300	IEC60871-1
1.30	60	ANSI/IEEE37.99,IEC60871-1
1.40	15	ANSI/IEEE37.99
1.70	1	ANSI/IEEE37.99
2.20	0.120	ANSI/IEEE37.99

Operate time is based on maximum value of I_PEAK_INT_A, I_PEAK_INT_B and I_PEAK_INT_C. From maximum value calculated , operate time between any two consecutive points in the standard table is based on logarithmic interpolation.

The operate time can be scaled using the *Time multiplier* setting. The OPR_OVLOD output is activated if the overload situation lasts long enough to exceed the operation time.

The operate time for the operation overload stage is limited between 0.1 s to 43200 s (12 hours) if *Time multiplier* is used.

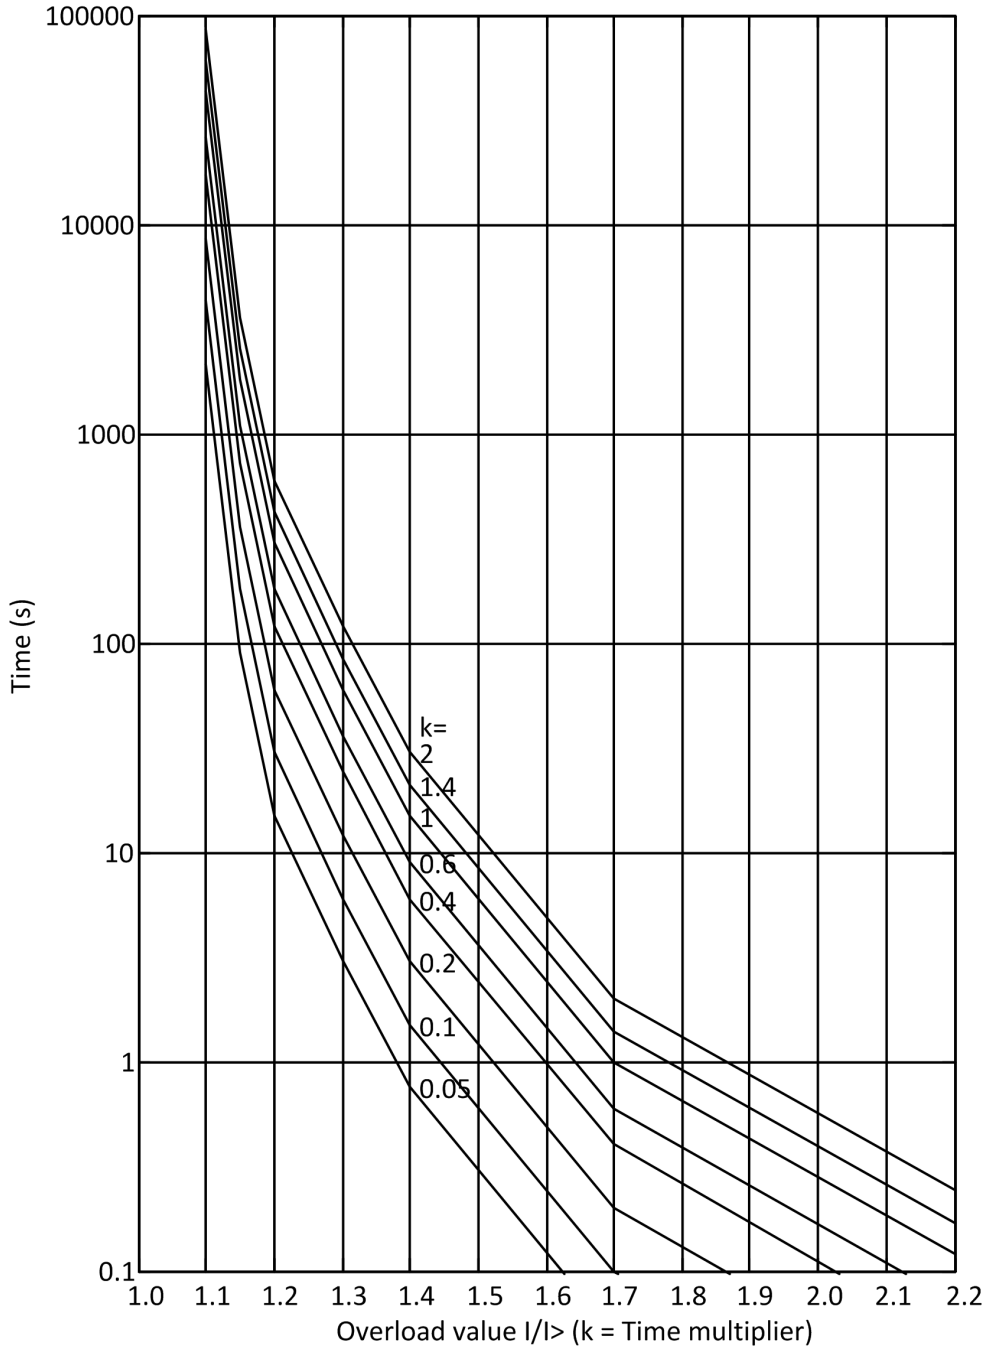

Figure 549: Inverse-time characteristic curves for overload stage

If the integrated current exceeds 1.1 times the setting *Start value overload* for a short period but does not operate as the current decreases within *Start value overload*, the output `ST_OVLOD` is kept active but the operation timer is frozen. However, if the integrated current exceeds 1.1 times the *Start value overload* setting value again, the operation timer continue from the freezing point. Thus, the operation timer is cumulative. If the integrated current exceeds 1.1 times the setting *Start value overload*

only once and remains within the *Start value overload* area for 24 hours, the operation timer and the output ST_OVLOD are reset.

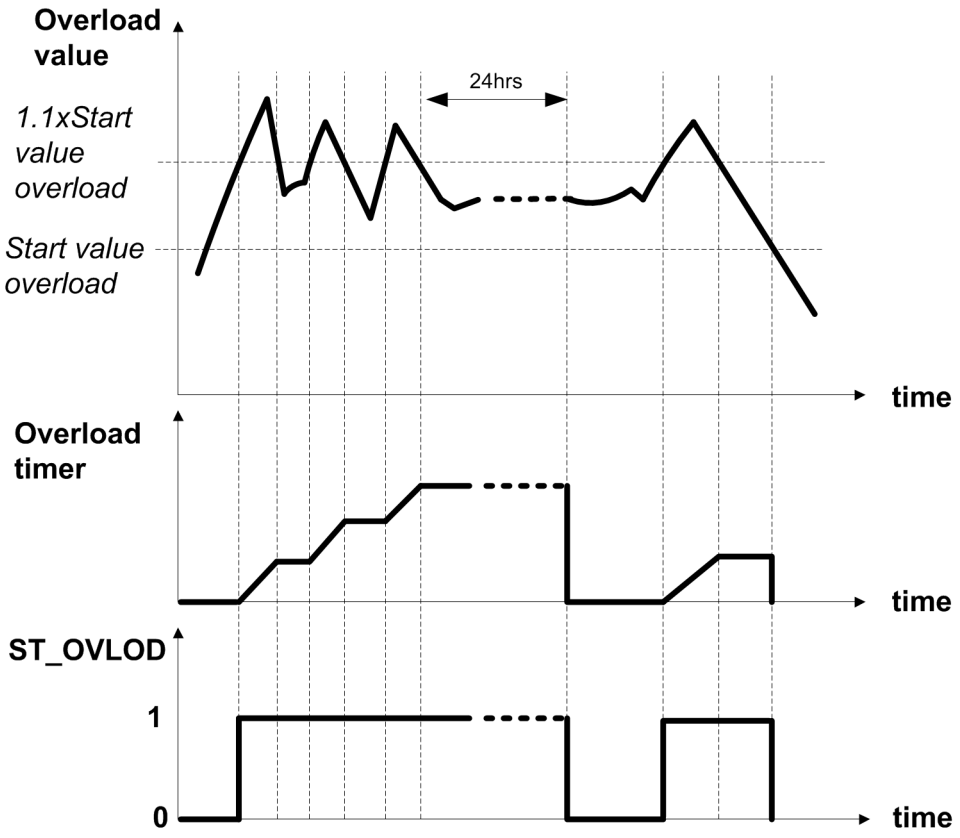

Figure 550: The behavior of the IDMT timer and the output ST_OVLOD

The ST_DUR_OVLOD output indicates the percentage ratio of the start situation and the operation time in the Timer 1 module and is available in the monitored data view.

The Timer 1 module is internally blocked for one second after the capacitor bank is connected by detecting the rising edge of the CB_CLOSED signal. The CB_CLOSED signal is True when the CB position is closed.

Alarm level detector

The Alarm level detector compares I_PEAK_INT_x value to *Alarm start value*. If the phase or phases in which I_PEAK_INT_x exceeds the setting matches the *Num of start phases* setting, the Alarm level detector module activates the Timer 2 module.

The *Num of start phases* setting is a common setting for both Operate level detector and Alarm level detector.

Timer 2

The Timer 2 characteristics are according to Definite Time (DT) .When the operation timer has reached the value of *Alarm delay time*, the ALARM output is activated.

If a drop-off situation happens, the timer is reset.

The Timer 2 module is internally blocked for one second after the capacitor bank is connected by detecting the rising edge of the CB_CLOSED signal. The CB_CLOSED signal is True when the CB position is closed.

Under current detector

The Under current detector module can be enabled by setting *Enable under current* to “Enable” and disabled by setting it to “Disable”. The Under current detector module is also disabled when CB_CLOSED is FALSE, that is, when circuit breaker is open.

The fundamental frequency component of phase currents is compared to the setting *Start value Un Cur*. If all the three-phase currents are below the setting *Start value Un Cur*, the Under current detector module enables the Timer 3 module.

Timer 3

Once activated, the Timer 3 module activates the ST_UN_I output. The operation is based on DT characteristics. When the operation timer has reached the value of *Un Cur delay time*, the OPR_UN_I output is activated.

If the undercurrent situation disappears, the operation timer is reset. The ST_DUR_UN_I output indicates the percentage ratio of the undercurrent start situation and the set operation time in the Timer 3 module and is available in the monitored data view.

The OPR_UN_I output is of pulse type and remains TRUE for 150 ms. After that, ST_DUR_UN_I and OPR_UN_I are deactivated and ST_DUR_UN_I is reset.

If the circuit breaker closed status signal is not detected, the constant value TRUE has to be connected to CB_CLOSED input to enable the undercurrent detector.

If the circuit breaker status signal is not connected to CB_CLOSED input, the OPR_UN_I output is activated even if the circuit breaker is open and undercurrent is detected.

Inhibit reclose

When the output OPR_UN_I becomes active or when the CB_CLOSED state changes from TRUE to FALSE, that is, when circuit breaker opens, the reclosing inhibition module activates output BLK_CLOSE.

If *Enable under current* is set to “Disable”, the reclosing inhibition operation is based purely on the CB_CLOSED input.

The behavior of the BLK_CLOSE output depends on *Reclose inhibit mode*. If *Reclose inhibit mode* is set to “Lockout”, the BLK_CLOSE output needs to be reset manually from the clearing menu parameter *COLPTOC inhibit recl*. If *Reclose inhibit mode* is set to “Non-latched”, the BLK_CLOSE output resets after the set *Reclose inhibit time* has elapsed.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting **Configuration/System/ Blocking mode** which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the operation timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, COLPTOC is executed normally but the OPR_OVLOD and OPR_UN_I outputs are not allowed to activate.

The BLOCK input does not block the BLK_CLOSE signal.

4.12.1.6 Application

The application area for three-phase overload protection function of shunt capacitor bank is the protection of power capacitor banks intended for reactive power compensation and filtering of the harmonics. Shunt capacitor banks provide a low-impedance path to harmonic currents and hence attract harmonic currents flowing in the system. Increased harmonic currents result in excessive voltage stress across the capacitor bank. According to the standards, a high-voltage capacitor shall be able to withstand 10% overload. Loading beyond that can cause damage to the capacitor bank and in turn to the system. Hence, COLPTOC is specially designed for the protection against overloads produced by harmonic currents and overvoltage.

Undercurrent protection is used to disconnect the capacitor bank from the rest of the power system when the voltage at the capacitor bank terminals is too low for too long

a period of time. To avoid an undercurrent trip operation when the capacitor bank is disconnected from the power system, the undercurrent functionality is blocked by using the capacitor bank circuit breaker status signal.

Furthermore, the reclosing inhibition feature provides protection against the reconnection of a charged capacitor to a live network. Whenever the capacitor bank circuit breaker is opened, the reclosing is inhibited for the duration of the discharge time of the capacitor. The reclosing inhibition functionality can be disabled manually or automatically. In the manual mode, the inhibition reclosing has to be manually reset and in automatic mode, the reclosing inhibitionl resets automatically after the set time.

4.12.1.7 Signals

Table 952: COLPTOC Input signals

Name	Type	Default	Description
I3P	SIGNAL	-	Three-phase currents
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode

Current unbalance protection for shunt capacitor banks	CUBPTOC	dI>C	60N

4.12.2.2 Function block

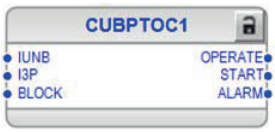

Figure 551: Function block symbol

4.12.2.3 Functionality

The current unbalance protection for shunt capacitor banks function CUBPTOC is used to protect the double-Y-connected capacitor banks from internal faults.

CUBPTOC is suitable for the protection of internally fused, externally fused and fuseless applications.

CUBPTOC has two stages of operation, that is, operation stage and alarm stage. In the operating stage, CUBPTOC starts when the measured unbalance current exceeds the set limit. The operation time characteristics can be selected to be either definite time (DT) or inverse definite minimum time (IDMT). The operation under alarm stage is either based on the DT characteristics or the faulty element counter of a capacitor bank.

CUBPTOC has a blocking functionality. It is possible to block the function outputs, timers or the function itself, if required.

4.12.2.4 Analog channel configuration

CUBPTOC has two analog group inputs which must be properly configured.

Table 961: Analog inputs

Input	Description
IUNB	Unbalance current (measured)
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 962: Special conditions

Condition	Description
IUNB measurement	The function requires that the unbalance current measurement is connected to the RESTCTR function block.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.12.2.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are “On” and “Off”. The current unbalance protection for shunt capacitor banks operates on the DFT measurement mode.

The operation of CUBPTOC can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

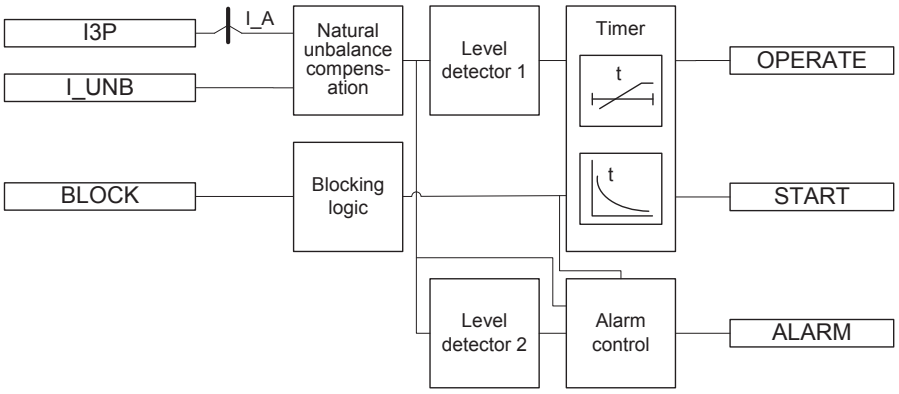

Figure 552: Functional module diagram

Natural unbalance Compensation

A standard double-Y-connected shunt capacitor bank configuration is shown in Figure 553. The fundamental frequency component of an unbalance current is measured on the common neutral connecting the two balanced parts of a shunt capacitor bank, that is, between star point 1 and star point 2.

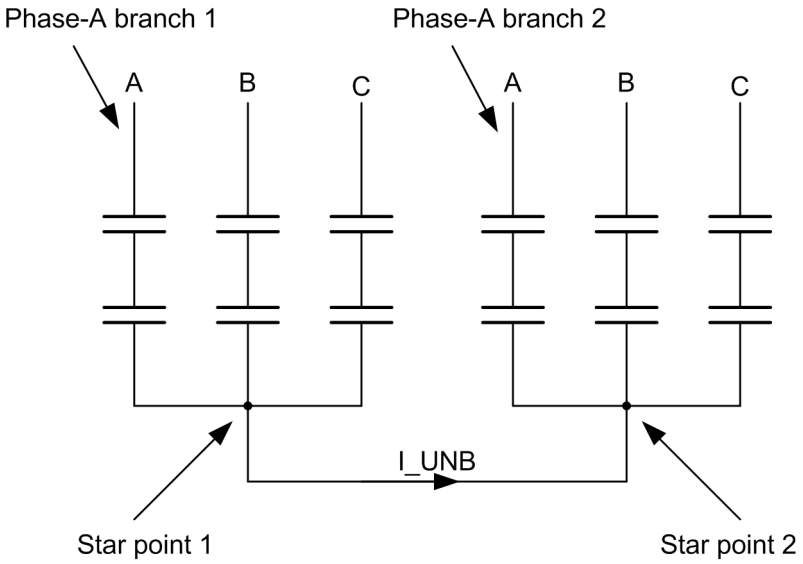

Figure 553: Double-Y-connected capacitor bank

The phase angle of the measured fundamental frequency component of the unbalance current I_UNB is synchronized by using the phase current I_A as a reference.

$$\angle\overline{I_{unb}} = \angle\overline{I_UNB} - \angle\overline{I_A}$$

(Equation 240)

In a three-phase star-connected capacitor bank circuit, there may be some amount of natural unbalance current flowing through the neutral, which is primarily due to capacitor manufacturing tolerances. The natural unbalance current must be compensated for before using the measured unbalance current for the function operation. The natural unbalance current needs to be recorded when there is no fault in the capacitor banks, and it is initiated through the command *Record unbalance*, available under menu path **Control/CUBPTOC**. By selecting *Record unbalance* with value “Record”, the measured unbalance current $\bar{I}_{Unb}$ is considered as the natural unbalance current $\bar{I}_{NatUnb}$ and is stored as a reference. The amplitude and angle of the recorded natural unbalance current I_AMPL_NAT and I_ANGL_NAT are available in the monitored data view.

Once the natural unbalance current is recorded during further executions of the function, the natural unbalance current is subtracted from the measured unbalance current $\bar{I}_{Unb}$ to obtain the compensated unbalance current $\bar{I}_{CompUnb}$ as shown in Figure 554.

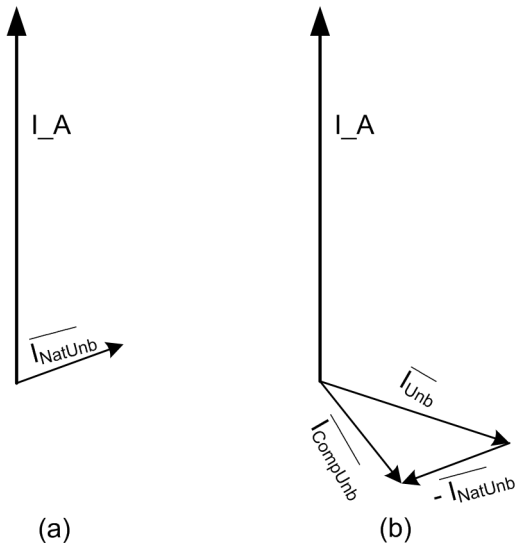

Figure 554: Natural unbalance compensation. (a) Healthy condition when the natural unbalance is recorded (b) Unbalance compensation during faulty conditions

The natural unbalance current compensation is enabled using the setting *Natural Comp Enable*. If *Natural Comp Enable* is set to “FALSE”, the unbalance current is not compensated. If *Natural Comp Enable* is set to “TRUE”, the compensated unbalance current is calculated based on the equation.

$$\bar{I}_{CompUnb} = \bar{I}_{Unb} - \bar{I}_{NatUnb}$$

(Equation 241)

The amplitude I_AMPL_COMP and the angle I_ANGL_COMP of the compensated unbalance current $\bar{I}_{CompUnb}$ are available in the monitored data view.

Level detector 1

The calculated compensated unbalance current I_AMPL_COMP is compared to the set "Start value". If I_AMPL_COMP exceeds the set "Start value", the Level detector 1 sends an enabling signal to the Timer 1 module.

Timer 1

Once activated, the Timer 1 module activates the START output. Depending on the value of the *Operating curve type* setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of *Operate delay time* in the DT mode or the maximum value defined by the inverse time curve, the OPERATE output is activated. When the user-programmable IDMT curve is selected, the operation time characteristics are defined by the parameters "Curve parameter A", *Curve parameter B*, *Curve parameter C* and *Curve parameter E*.

In a drop-off situation, that is when a fault suddenly disappears before the operate delay is exceeded, the Timer 1 reset state is activated. The functionality of the Timer 1 in the reset state depends on the combination of the Operating curve type and *Reset delay time* settings. When the DT characteristic is selected, the reset timer runs until the set *Reset delay time* value is exceeded. When the IDMT curves are selected, an immediate reset occurs. The START output is deactivated when the reset timer has elapsed.

The setting *Time multiplier* is used for scaling the IDMT operation and reset times.

The setting parameter *Minimum operate time* defines the minimum desired operation time for IDMT. The setting is applicable only when the IDMT curves are used.

The *Minimum operate time* setting should be used with great care because the operation time is according to the IDMT curve but always at least the value of the *Minimum operate time* setting.

The Timer 1 module calculates the start duration value START_DUR, which indicates the percentile ratio of the start situation and the set operation time. The value is available in the monitored data view.

In a typical double-Y-connected configuration (Figure 553), there are two branches in every phase and hence six individual counters COUNT_BR1_A, COUNT_BR2_A, COUNT_BR1_B, COUNT_BR2_B, COUNT_BR1_C and COUNT_BR2_C are maintained. Based on the phase angle of the compensated unbalance current I_ANGL_COMP, the phase and the branch of the element failure location is detected. However, the element failure location also depends on the type of capacitor banks, that is, whether internal or external fuses are used. The setting *Fuse location* is used to set the capacitor bank type as “External” or “Internal”.

For an external fuse capacitor bank, the element failure location and corresponding counters to be incremented are determined based on the phase angle of the compensated unbalance current.

Table 963: Element failure location and counters to be incremented for external fuse case

Phase angle of the compensated unbalance current (degrees)	Phase and branch of the element failure	Counters to be incremented
-15...+15	Phase-A branch 1	COUNT_BR1_A
-15...-45	Phase-A branch 1 Phase-C branch 2	COUNT_BR1_A COUNT_BR2_C
-45...-75	Phase-C branch 2	COUNT_BR2_C
-75...-105	Phase-B branch 1 Phase-C branch 2	COUNT_BR1_B COUNT_BR2_C
-105...-135	Phase-B branch 1	COUNT_BR1_B
-135...-165	Phase-B branch 1 Phase-A branch 2	COUNT_BR1_B COUNT_BR2_A
-165...-180	Phase-A branch 2	COUNT_BR2_A
+165...+180	Phase-A branch2	COUNT_BR2_A
+135...+165	Phase-C branch 1 Phase-A branch 2	COUNT_BR1_C COUNT_BR2_A
+105...+135	Phase-C branch 1	COUNT_BR1_C
+75...+105	Phase-C branch1 Phase-B branch2	COUNT_BR1_C COUNT_BR2_B
+45...+75	Phase-B branch2	COUNT_BR2_B
+15...+45	Phase-A branch1 Phase-B branch2	COUNT_BR1_A COUNT_BR2_B

If the capacitor bank is fuseless, then the setting *Fuse location* should be set to “External” and Table 963 can be used to determine the element failure location.

If the compensated unbalance current I_AMPL_COMP is greater than three times the set *Alarm value*, it is considered to be a case of blown external fuse. For the internal fuse and blown fuse cases, the element failure location and corresponding counters to be incremented are determined based on the phase angle of the compensated unbalance current.

Table 964: Element failure location and counters to be incremented for internal fuse and blown fuse case

Phase angle of the compensated unbalance current (degrees)	Phase and branch of the element failure	Counters to be incremented
-15...+15	Phase-A branch 2	COUNT_BR2_A
-15... -45	Phase-A branch 2 Phase-C branch 1	COUNT_BR2_A COUNT_BR1_C
-45...-75	Phase-C branch 1	COUNT_BR1_C

Table continues on next page

Phase angle of the compensated unbalance current (degrees)	Phase and branch of the element failure	Counters to be incremented
-75...-105	Phase-B branch 2 Phase-C branch 1	COUNT_BR2_B COUNT_BR1_C
-105...-135	Phase-B branch 2	COUNT_BR2_B
-135...-165	Phase-B branch 2 Phase-A branch 1	COUNT_BR2_B COUNT_BR1_A
-165...-180	Phase-A branch 1	COUNT_BR1_A
+165...+180	Phase-A branch 1	COUNT_BR1_A
+135...+165	Phase-C branch 2 Phase-A branch 1	COUNT_BR2_C COUNT_BR1_A
+105...+135	Phase-C branch 2	COUNT_BR2_C
+75...+105	Phase-C branch 2 Phase-B branch 1	COUNT_BR2_C COUNT_BR1_B
+45...+75	Phase-B branch 1	COUNT_BR1_B
+15...+45	Phase-A branch 2 Phase-B branch 1	COUNT_BR2_A COUNT_BR1_B

After *Alarm delay time* has elapsed, the corresponding counter value is incremented based on the magnitude of the unbalance current. If I_AMPL_COMP is less than 1.5 times the set *Alarm value*, the counter is incremented by one. Furthermore, if I_AMPL_COMP is between 1.5 and 2.5 times the set *Alarm value*, the counter is incremented by two and so on.

Normally, the setting *Alarm value* is about 0.1 percent lower than the value of the unbalance current which is caused by one faulty element. This setting value has to be chosen carefully because a slightly lower value may lead to a situation where the counters show more failures than the actual. Too high setting leads to a situation where a fault is not detected.

The counter values COUNT_BR1_A, COUNT_BR2_A, COUNT_BR1_B, COUNT_BR2_B, COUNT_BR1_C and COUNT_BR2_C are available in the monitoring data view. The total number of element failures in double-Y-connected capacitor banks, FAIL_COUNT, is available in the monitored data view.

The ALARM output is activated, when the value of FAIL_COUNT exceeds the setting *Element failure limit*.

The counter values can be reset via *CUBPTOC counters* which is located under the Clear menu.

Level detector 2

The calculated compensated unbalance current I_AMPL_COMP is compared to the set *Alarm start value*. If the I_AMPL_COMP exceeds the set *Alarm value* the Level detector 2 sends enabling signal to the Alarm control module.

Alarm control

Depending on the *Alarm mode* setting, the alarm stage operation is according to "Normal mode" or "Element counter mode".

In the "Normal mode" the time characteristic is according to DT. When the alarm timer has reached the value set by *Alarm delay time*, the ALARM output is activated. If the fault disappears before the alarm activates, the alarm timer is reset immediately.

The "Element counter mode" is used to detect faulty elements of the capacitor bank and count the number of element failures in each branch and line. On activation, this module increments the corresponding element failure counters after the set *Alarm delay time* has elapsed.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting **Configuration/System/ Blocking mode**, which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the "Freeze timers" mode, the operation timer is frozen to the prevailing value. In the "Block all" mode, the whole function is blocked and the timers are reset. In the "Block OPERATE output" mode, CUBPTOC operates normally but the OPERATE output is not activated.

4.12.2.6 Application

CUBPTOC is designed for the protection against internal faults in double-Y-connected capacitor banks. This unbalance protection detects an asymmetry in the capacitor bank caused by blown fuses or short circuits across bushings or between capacitor units and the racks in which they are mounted.

Normally, the capacitor units are designed to withstand 110 percent of the nominal voltage continuously. When an element inside a capacitor bank fails, the remaining healthier elements experience an increase in voltage across them. If the voltage exceeds the 110 percent value of the nominal voltage, it can lead to a failure of the healthier elements of the bank and in turn fail the entire capacitor bank. Since the capacitor unbalance current is directly proportional to the element failures, unbalance protection is an effective way of detecting capacitor element failures. The current unbalance protection function is usually used with the three-phase capacitor bank overload protection function to increase the sensitivity of protection for capacitor banks.

Due to the two-stage (operation and alarm stage) unbalance protection and the natural unbalance compensation facility, the protection of capacitor banks with internal fuses can be implemented with a very high degree of sensitivity. Furthermore, CUBPTOC

provides a sophisticated method of detecting the number of faulty elements in each phase by calculating the differential unbalance current.

The unbalance protection function can be used for internally fused, externally fused and fuseless shunt capacitor banks. Since a fuseless capacitor bank lacks the individual capacitor unit fuses, current unbalance protection becomes even more critical for fuseless applications.

When an individual element fails, it causes unbalance current. With an increasing number of element failures, the unbalance current increases and CUBPTOC gives an alarm. The alarm level is normally set to 50 percent of the maximum permitted level. The capacitor bank needs to be taken out of service to replace the faulty units. If this is not done, the capacitor bank is tripped when the maximum allowed unbalance current level is exceeded.

If two simultaneous faults occur in the same phase but in different branches, there is no change in the unbalance current and CUBPTOC does not detect this type of faults.

If two simultaneous faults occur in the same branch but in different phases, it may cause a phase angle equal to a situation where there is only one fault in the branch. Therefore, the element failure counters show only one fault instead of two.

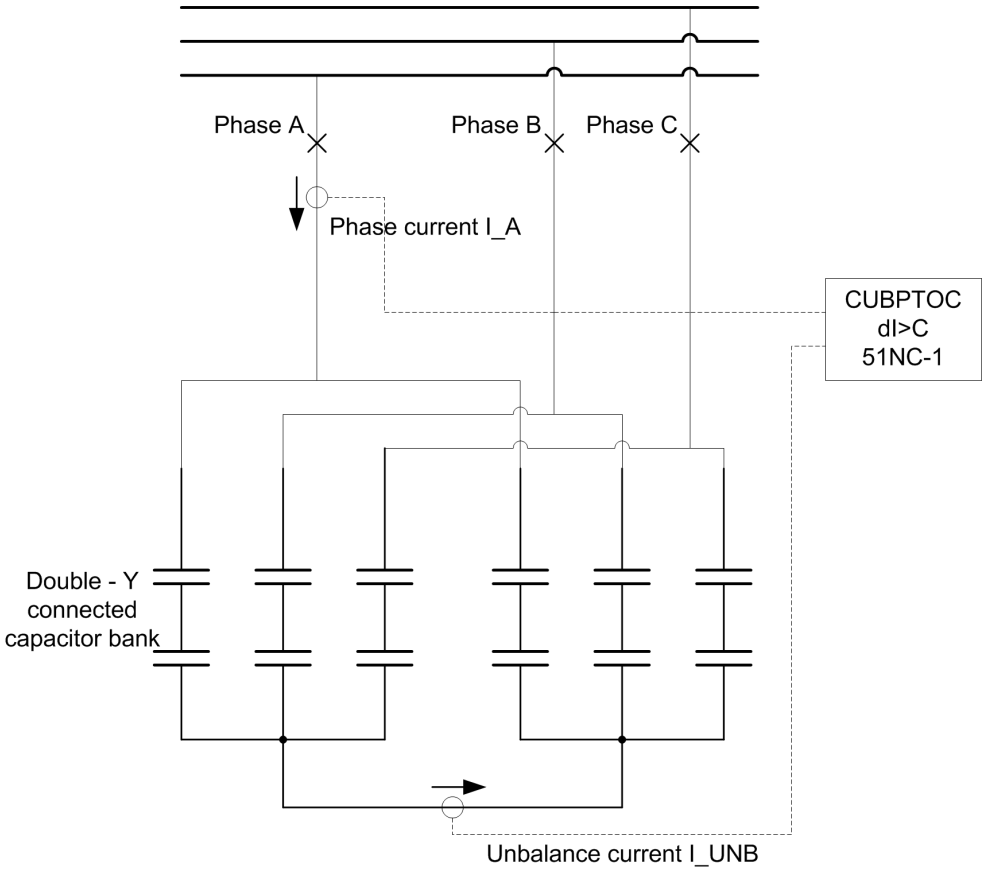

Figure 555: Example of double-Y-connected shunt capacitor bank unbalance protection

Connect the phase current analog input `I_A` and unbalance current `I_UNB` to the protection relay for the CUBPTOC function to start working.

Steps to measure natural unbalance current

1. The setting *Natural Comp Enable* must be set to “TRUE”.
2. The capacitor bank must be energized.
3. The capacitor bank compensated unbalance current `I_COM_AMPL` is observed from Monitored data.
4. The command *Record unbalance* must be activated by selecting the value “Record” which stores the unbalance reference for future unbalance calculations.
5. The compensated unbalance current (`I_COM_AMPL`) is re-checked to be approximately zero.

The natural unbalance recording should be made only during the steady-state condition and when all the capacitor bank elements are assumed to be in service.

4.12.3.2 Function block

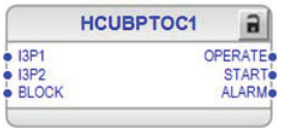

Figure 556: Function block symbol

4.12.3.3 Functionality

The three-phase current unbalance protection function for shunt capacitor banks HCUBPTOC is used to protect the H-bridge capacitor banks against internal faults. HCUBPTOC is suitable for protection of internally fused, externally fused and fuse-less capacitor bank applications.

HCUBPTOC has two stages of operation, the operation stage and alarm stage. In the operation stage, HCUBPTOC starts when the measured unbalance current exceeds the set limit. The operating time characteristics can be selected to be either definite time (DT) or inverse definite minimum time (IDMT). In the alarm stage, the alarm starts when the measured unbalance current exceeds the set alarm limit. The alarm time characteristics are based on DT.

HCUBPTOC contains blocking functionality. It is possible to block the function outputs, timers or the function itself.

4.12.3.4 Analog channel configuration

HCUBPTOC has two analog group inputs which all must be properly configured.

Table 973: Analog inputs

Input	Description
I3P1	Three-phase currents
I3P2	Three-phase unbalance currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.12.3.5 Operation principle

The function can be enabled and disabled with the Operation setting. The corresponding parameter values are “On” and “Off”.

The three-phase current unbalance protection for shunt capacitor banks operates on the DFT measurement mode. The operation of HCUBPTOC can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

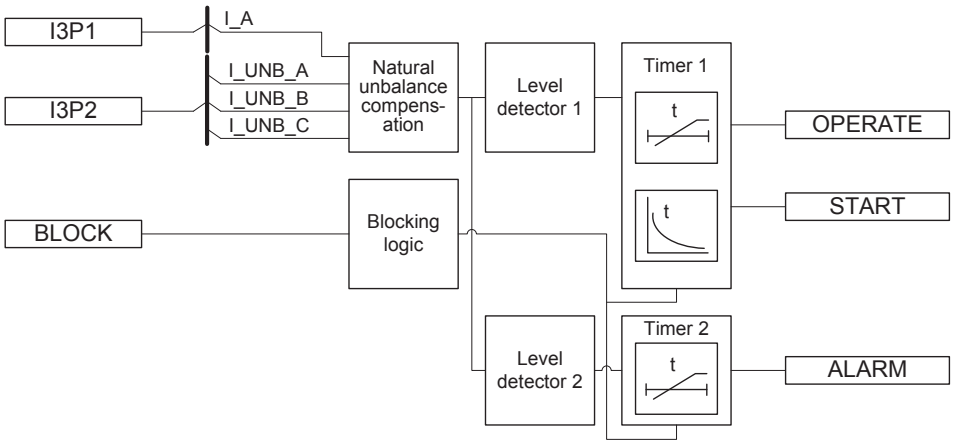

Figure 557: Function module diagram

Natural unbalance compensation

In the three-phase H-bridge-connected shunt capacitor bank configuration, the unbalance currents `I_UNB_A`, `I_UNB_B` and `I_UNB_C` are measured at the common points of the H-bridge.

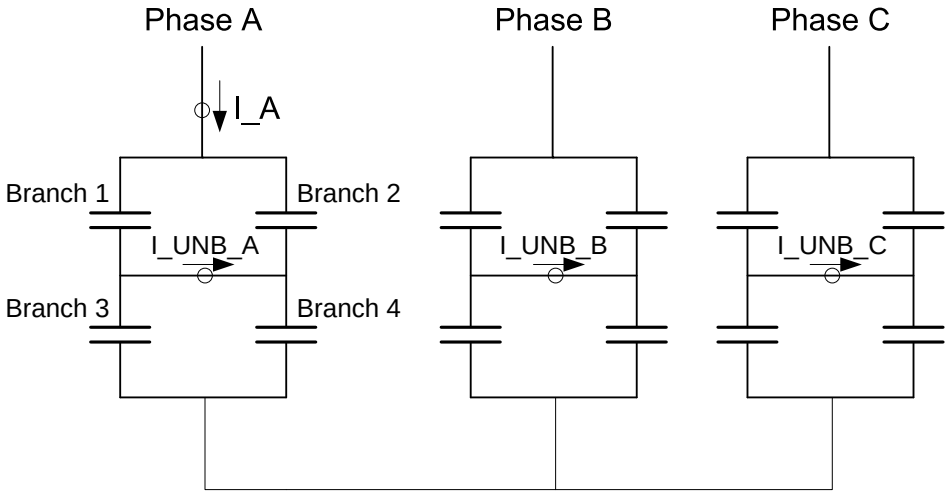

Figure 558: H-Bridge-connected capacitor bank

The phase angles of three-phase measured unbalance currents are synchronized using the phase current I_A as reference. The phase-A unbalance current phase angle can be calculated with the equation.

$$\angle\overline{I_{Unb_A}} = \angle\overline{I_UNB_A} - \angle\overline{I_A}$$

(Equation 242)

A three-phase H-bridge-connected capacitor bank circuit may have some amount of natural unbalance current flowing through the common points of H-bridge, which may primarily be due to capacitor manufacturing tolerances. Therefore, the natural unbalance current must be compensated for before using the measured unbalance current for function operation.

The natural unbalance current needs to be recorded when there is no fault in the capacitor banks, and it is initiated through the command *Record unbalance* available under menu path **Control/HCUBPTOC**. The natural unbalance currents are recorded for all the phases at the same time by setting command *Record unbalance* to “Record all phases” or each natural unbalance current can be recorded separately for individual phases by setting command *Record unbalance* to “Record phase A” or “Record phase B” or “Record phase C”. By selecting *Record unbalance* with value “Record”, the measured three-phase unbalance currents ($\overline{I}_{Unb_A}, \overline{I}_{Unb_B}, \overline{I}_{Unb_C}$) are considered the natural unbalance currents for each phase respectively and stored as a reference. The amplitude and angle of the phasewise-recorded natural unbalance currents `I_NAT_AMPL_A`, `I_NAT_ANGL_A`, `I_NAT_AMPL_B`, `I_NAT_ANGL_B`, `I_NAT_AMPL_C` and `I_NAT_ANGL_C` are available in the monitored data view.

Once a natural unbalance current is recorded, the phasewise natural unbalance current is subtracted from the corresponding phase-measured unbalance current ($\overline{I}_{Unb}$) during further executions of the function to obtain the compensated unbalance current ($\overline{I}_{CompUnb}$) .

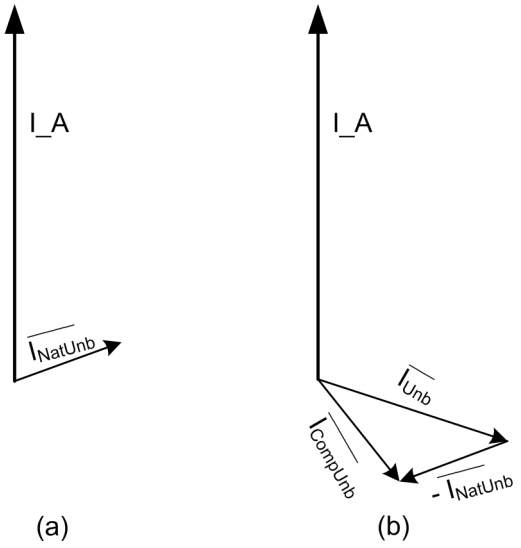

Figure 559: Natural unbalance compensation. (a) Healthy condition when the natural unbalance is recorded (b) Unbalance compensation during faulty conditions

The natural unbalance compensation for each phase is enabled based on the settings *Natural Comp Ena PhA*, *Natural Comp Ena PhB* and *Natural Comp Ena PhC* respectively. For example, if *Natural Comp Ena PhA* is set to "FALSE", the unbalance current is not compensated. If *Natural Comp Ena PhA* is set to "TRUE", the compensated unbalance current for phase A is calculated based on the equation.

$$\overline{I_{CompUnb_A}} = \overline{I_{Unb_A}} - \overline{I_{NatUnb_A}}$$

(Equation 243)

$I_{CompUnb_A}$	Phase A-compensated unbalance current
I_{Urb_A}	Phase A-measured unbalance current
I_{NatUnb_A}	Phase A-recorded natural unbalance current

The phasewise-compensated unbalance current amplitudes and angles `I_COM_AMPL_A`, `I_COM_ANGL_A`, `I_COM_AMPL_B`, `I_COM_ANGL_B`, `I_COM_AMPL_C` and `I_COM_ANGL_C` are available in the monitored data view.

The phase angles of the unbalance currents indicate the branch of a faulty element in a capacitor bank. For an internal fuse capacitor bank, the element failure branch location is determined based on the phase angle of the compensated unbalance current.

Table 974: Detection of element failure location for internal fuse capacitor bank

Name of the phase angle	Phase angle of unbalance current	Element failure branch location (Figure 558)
I_COM_ANGL_A	~+180^0	Phase A - Branch 1 or Phase A - Branch 4
I_COM_ANGL_A	~0^0	Phase A - Branch 2 or Phase A - Branch 3
I_COM_ANGL_B	~+60^0	Phase B - Branch 1 or Phase B - Branch 4
I_COM_ANGL_B	~–120^0	Phase B - Branch 2 or Phase B - Branch 3
I_COM_ANGL_C	~–60^0	Phase C - Branch 1 or Phase C - Branch 4
I_COM_ANGL_C	~+120^0	Phase C - Branch 2 or Phase C - Branch 3

If external fuses are used, the direction of an unbalance current is opposite to that of the bank where internal fuses are in use.

Table 975: Detection of element failure location for external fuse capacitor bank

Name of the phase angle	Phase angle of unbalance current	Element failure branch location (Figure 558)
I_COM_ANGL_A	~0^0	Phase A - Branch 1 or Phase A - Branch 4
I_COM_ANGL_A	~+180^0	Phase A - Branch 2 or Phase A - Branch 3
I_COM_ANGL_B	~–120^0	Phase B - Branch 1 or Phase B - Branch 4
I_COM_ANGL_B	~+60^0	Phase B - Branch 2 or Phase B - Branch 3
I_COM_ANGL_C	~+120^0	Phase C - Branch 1 or Phase C - Branch 4
I_COM_ANGL_C	~–60^0	Phase C - Branch 2 or Phase C - Branch 3

Level detector 1

The phasewise-compensated unbalance currents `I_COM_AMPL_A`, `I_COM_AMPL_B` and `I_COM_AMPL_C` are compared to the set *Start value*. If the compensated unbalance current in one or more phases exceeds the set *Start value*, the Level detector 1 module sends the enabling signal to the Timer 1 module.

Timer 1

Once activated, the Timer 1 module activates the `START` output. Depending on the value of the *Operating curve type* setting, the time characteristics are according to DT or IDMT. When the operation timer has reached the value of *Operate delay time* in the

DT mode or the maximum value defined by the inverse time curve, the OPERATE output is activated.

When the user-programmable IDMT curve is selected, the operation time characteristics are defined by the parameters *Curve parameter A*, *Curve parameter B*, *Curve parameter C* and *Curve parameter E*.

In a drop-off situation, that is, when a fault suddenly disappears before the operation delay is exceeded, the Timer 1 reset state is activated. The functionality of Timer 1 in the reset state depends on the combination of the *Operating curve type* and *Reset delay time* settings. When the DT characteristic is selected, the reset timer runs until the set *Reset delay time* value is exceeded. When the IDMT curves are selected, an immediate reset occurs. The START output is deactivated when the reset timer has elapsed.

The setting *Time multiplier* is used for scaling the IDMT operation times.

The setting parameter *Minimum operate time* defines the minimum desired operation time for IDMT. The setting is applicable only when the IDMT curves are used.

The *Minimum operate time* setting should be used with great care because the operation time is according to the IDMT curve, but always at least the value of the *Minimum operate time* setting.

Timer 1 calculates the start duration value START_DUR, which indicates the percentage ratio of the start situation and the set operation time. The value is available in the monitored data view.

Level detector 2

The phasewise-compensated unbalance currents I_COM_AMPL_A, I_COM_AMPL_B and I_COM_AMPL_C are compared to the set *Alarm start value*. If the compensated unbalance current in one or more phases exceeds the set *Alarm start value*, the Level detector 2 module sends the enabling signal to the Timer 2 module.

Timer 2

Once activated, the timer activates the alarm timer. The timer characteristic is according to DT. When the alarm timer has reached the value set by *Alarm delay time*, the ALARM output is activated.

If the fault disappears before the alarm activates, the alarm timer is reset immediately.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting **Configuration/System/ Blocking mode** which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the operation timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, HCUBPTOC operates normally but the OPERATE output is not activated.

4.12.3.6 Application

Shunt capacitor banks (SCBs) are widely used in transmission and distribution networks to produce reactive power support. Located in relevant places such as in the vicinity of load centers, SCBs have beneficial effects on power system performance: increased power factor, reduced losses, improved system capacity and better voltage level at load points.

The capacitor bank terminology ‘Bank’, ‘Unit’ and ‘Element’ is shown in Figure 560.

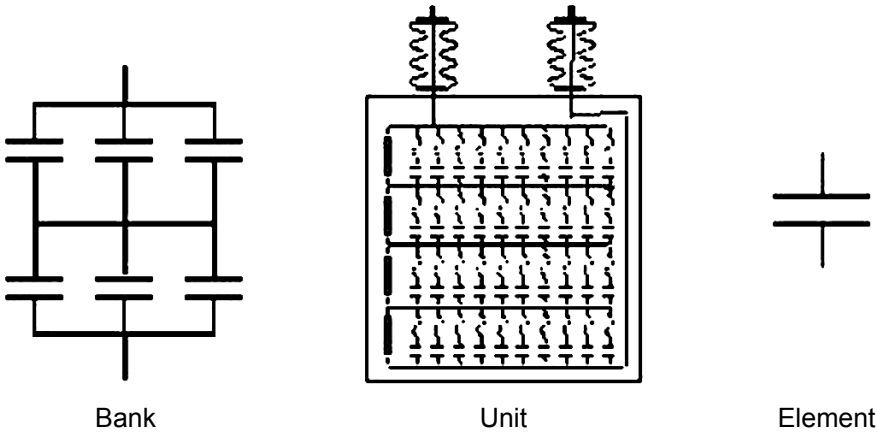

Figure 560: Bank, unit and element of a capacitor bank

HCUBPTOC is designed for the protection against internal faults in H-bridge-connected capacitor banks. This unbalance protection detects an asymmetry in the capacitor bank, caused by blown fuses or short-circuits across bushings, or between capacitor units and the racks in which they are mounted.

Normally, the capacitor units are designed to withstand 110% of the nominal voltage continuously. When an element inside a capacitor bank fails, the remaining healthy elements experience an increase in voltage across them. If the voltage exceeds 110% of the nominal voltage, it can lead to a failure of the healthy elements of the bank and in turn fail the entire capacitor bank. Since the capacitor unbalance current is directly proportional to element failures, unbalance protection is an effective way of detecting capacitor element failures. The current unbalance protection function is usually used along with the three-phase capacitor bank overload protection function to increase the sensitivity of protection for capacitor banks.

Due to the two-stage (operation and alarm stage) unbalance protection and the natural unbalance compensation facility, the protection of capacitor banks with internal fuses can be implemented with a very high degree of sensitivity.

The unbalance protection function can be used for internally fused, externally fused and fuseless shunt capacitor banks. Since a fuseless capacitor bank lacks the individual capacitor unit fuses, current unbalance protection becomes even more critical for fuseless applications.

When an individual element fails, it creates current unbalance. With an increasing number of element failures, the unbalance current increases and HCUBPTOC gives an alarm. The alarm level is normally set to 50% of the maximum permitted level. The capacitor bank then should be taken out of service to replace the faulty units. If not, the capacitor bank is tripped when the maximum allowed unbalance current level is exceeded.

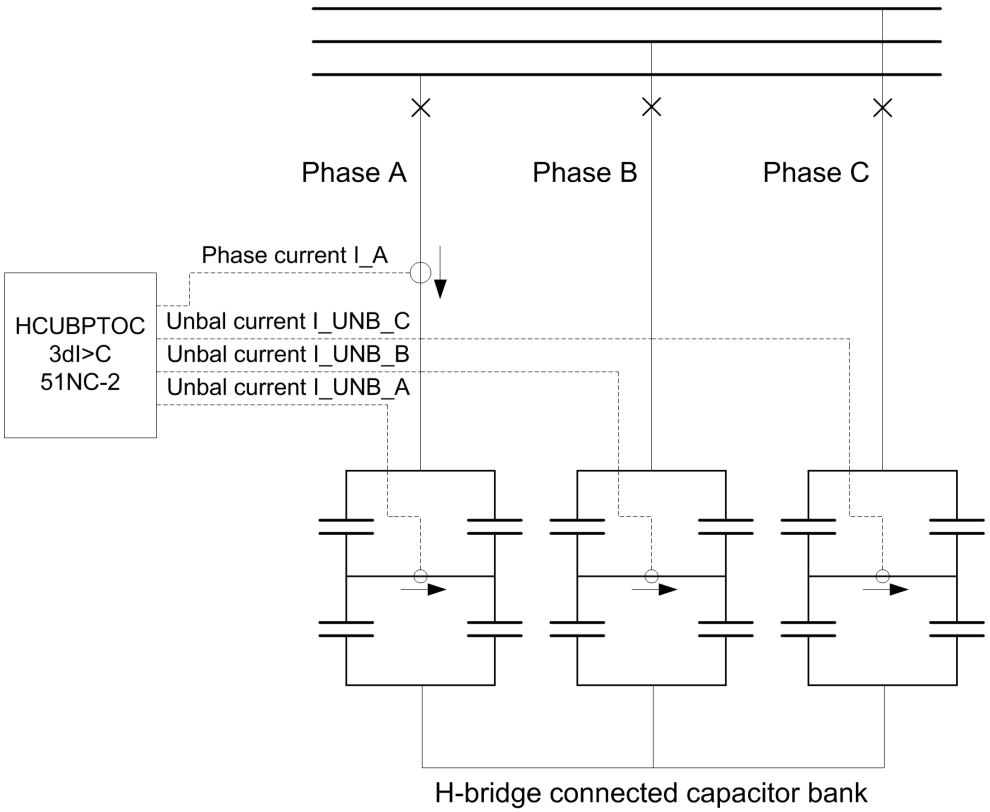

Figure 561: Application example of capacitor bank unbalance protection

The phase current analog input I_A and at least one unbalance current must be connected to the protection relay for the HCUBPTOC function to start working.

Steps to measure natural unbalance current

1. The setting *Natural Comp Enable* must be set to “TRUE”.
2. The capacitor bank must be energized.
3. The capacitor bank compensated unbalance current `I_COM_AMPL` is observed from Monitored data.
4. The command *Record unbalance* must be activated by selecting the value “Record” which stores the unbalance reference for future unbalance calculations.
5. The compensated unbalance current (`I_COM_AMPL`) is re-checked to be approximately zero.

The natural unbalance recording should be made only during the steady-state condition and when all the capacitor bank elements are assumed to be in service.

4.12.4 Shunt capacitor bank switching resonance protection, current based SRCPTOC

4.12.4.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Shunt capacitor bank switching resonance protection, current based	SRCPTOC	TD>	55ITHD

4.12.4.2 Function block

Figure 562: Function block symbol

4.12.4.3 Functionality

The shunt capacitor bank switching resonance protection, current based, function SRCPTOC is used for detecting three-phase resonance caused by capacitor switching or topology changes in the network. The operating characteristic is a definite time (DT).

SRCPTOC contains a blocking functionality. It is possible to block function outputs, timers or the function itself.

4.12.4.4 Analog input configuration

SRCPTOC has one analog group input which must be properly configured.

Table 984: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

4.12.4.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are “On” and “Off”.

The operation of SRCPTOC can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

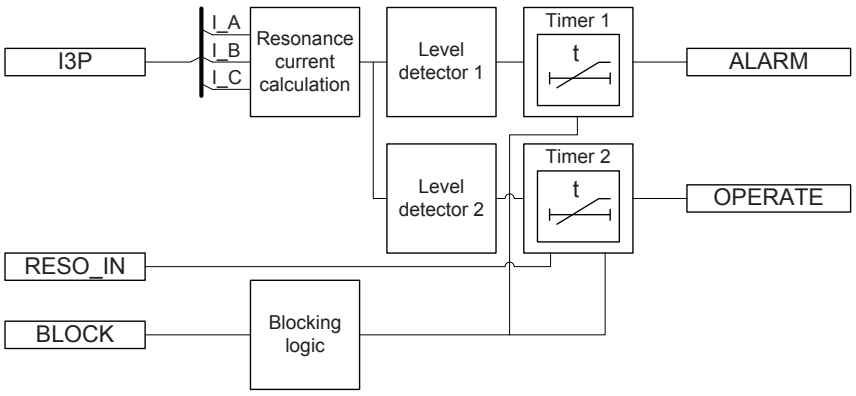

Figure 563: Functional module diagram

Resonance current calculation

This module calculates the resonance current per phase set as per setting *Tuning harmonic Num*. The resonance current for phase A is calculated with the equation.

$$I_RESO_A = \sqrt{I^2_{RMS_A} - I^2_{1_A} - I^2_{DC_A} - I^2_{K_A}}$$

(Equation 244)

I_{RMS_A}	RMS value of current in phase A (contains up to 11th harmonic)
I_{DC_A}	DC-component in phase A current
I_{1_A}	Fundamental component in phase A current
I_{K_A}	Kth harmonic component in phase A current, K is defined by setting *Tuning harmonic Num*
I_RESO_A	Calculated resonance current for phase A

The resonance current is calculated through the filter implementation. The DC and fundamental components are removed by passing the total RMS current through the High pass filter. The Kth harmonic component is removed by passing the High pass filter output through the Kth harmonic Band stop filter. The magnitude response of the High pass filter and all the harmonic Band stop filters are shown in Figure 564.

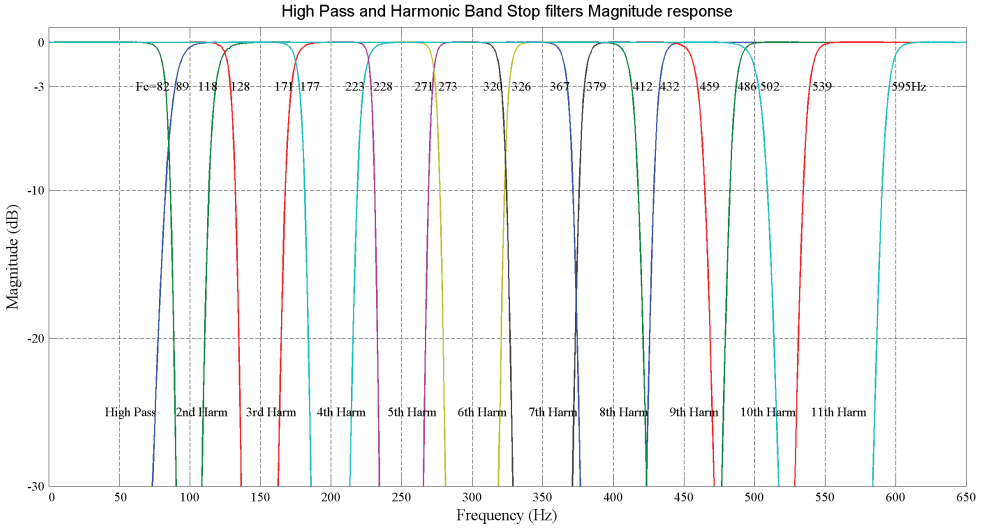

Figure 564: Magnitude response of High pass and all the harmonic Band stop filters

Similarly resonance current is calculated in the same way for phase B and phase C. Resonance currents I_RESO_A, I_RESO_B and I_RESO_C are available in the monitored data view.

The maximum of the three calculated resonance currents is further considered for calculation.

$$I_RESONANCE = Max(I_RESO_A, I_RESO_B, I_RESO_C)$$

(Equation 245)

If a capacitor bank is used only for reactive power compensation and there is no series reactor in a filter branch, the resonance protection is very important. In this case, the setting *Tuning harmonic Num* should be set to 1 because the capacitor branch is not tuned for a special frequency as in tuned filter applications. Even though *Tuning harmonic Num* is set to 1, the fundamental component is subtracted only once from I_{RMS}.

Level detector 1

The maximum calculated resonance current is compared to the set *Alarm start value*. If the calculated I_RESONANCE exceeds the set *Alarm start value*, the module sends the enabling signal to the Timer 1 module.

Level detector 2

The maximum calculated resonance current is compared to the set *Start value*. If the calculated I_RESONANCE exceeds the set *Start value*, this module sends the enabling signal to the Timer 2 module.

Timer 1

Once activated, the timer activates the alarm timer. The timer characteristic is according to DT. When the alarm timer has reached the value set by *Alarm delay time*, the ALARM output is activated.

If the fault disappears before the alarm activates, the alarm timer is reset immediately.

Timer 2

Once activated, the timer activates the operation timer. The timer characteristic is according to DT. When the operation timer has reached the value set by *Operate delay time*, the OPERATE output is activated.

If the fault disappears before the operate activates, the operation timer is reset immediately.

If the input RESO_IN becomes active, the OPERATE output is activated immediately. If the resonance protection at a higher-order filter branch has already operated, the function in lower-order filter branches can be tripped immediately using this feature.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting **Configuration/System/ Blocking mode** which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the operation timer is frozen to the prevailing value. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, SRCPTOC operates normally but the OPERATE output is not activated.

4.12.4.6 Application

Switched shunt capacitor banks are widely used by utilities and customers in industrial distribution systems to provide voltage support and to improve the power factor of a load. Capacitor steps may be switched in and out of circuits routinely as the demand for capacitive VAR compensation of a load fluctuates. Normally, automatic power factor controllers are employed which automatically switch on or off the capacitors of the capacitor bank, depending upon the prevalent reactive power requirement in the system.

One potential problem for the application of automatic power factor controllers is that it may cause harmonic resonance under certain system conditions. Capacitor switching changes the parameters of the system, which may cause the resonance frequency of the circuit to be equal to one of the frequencies of the harmonic sources prevalent in the system. Harmonic resonance, when it occurs, may result in severe voltage and current distortions, which increases losses and causes overheating of other equipment in the circuit.

A traditional way of solving the problem is to conduct a detailed system study for each individual installation and use the results to properly size the capacitors and determine the right operating range of capacitors to avoid harmonic resonance with other system components. However, this method is not economical but more time-consuming.

The capacitor switching-resonance protection function can be used as a solution to the above mentioned problem. The basis for the harmonic resonance protection is the detection of a current harmonic resonance condition caused by capacitor switching. A prolonged increase of the harmonic distortion level after a switching operation is a clear indication of such condition. When a resonant condition caused by capacitor switching occurs in a circuit, SRCPTOC detunes the circuit by taking the reverse action, that is, switching the capacitor bank off if switching it on causes resonance. If the resonance situation has been detected and SRCPTOC has switched off a capacitor bank, power factor controller should not try to switch on the capacitor bank until the switching resonance function reset.

The capacitor switching-resonance protection function can also be used to protect harmonic filters. In harmonic filter bank applications, the SRCPTOC function can be tuned to harmonic frequency for which the harmonic filter is designed to ensure that the function does not include thr tuned harmonic frequency current into the calculation of the resonance current. If there is more than one harmonic filter bank involved, each SRCPTOC tunes to the harmonic frequency of its corresponding filter bank. The interlinking between the functions can be done in such a way that if resonance occurs in a higher harmonic frequency filter bank, all the lower harmonic frequency filter banks can be tripped immediately by activating the function input RESO_IN.

The settings *Alarm start value* and *Start value* determine the portion of the total harmonic current (excluding the harmonic defined by the setting *Tuning harmonic Num*) in relation to the CT nominal value required for SRCPTOC to give alarm and operate respectively.

For power factor correction application

- *Tuning harmonic Num* must be set to 1.
- *Alarm start value* and *Start value* must be set according to the standard IEEE519 -1992.

For harmonic filter application

- *Tuning harmonic Num* must be set to the filter design tuning frequency.
- *Alarm start value* and *Start value* must be set according to the standard IEEE519 -1992.

Settings *Alarm start value* and *Start value* should be selected as such that in normal operation SRCPTOC should not operate.

4.12.5 Compensated neutral unbalance voltage protection CNUPTOV

4.12.5.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Compensated neutral unbalance voltage protection	CNUPTOV	CNU>	59NU

4.12.5.2 Function block

Figure 565: Function block

4.12.5.3 Functionality

The compensated neutral unbalance voltage protection function CNUPTOV detects overvoltage at the neutral point of the shunt capacitor. A blown fuse or a short-circuited capacitor element results in unbalance in the shunt capacitor bank causing increase in neutral point voltage. With CNUPTOV, an inherent capacitor bank

unbalance which results in non-zero neutral point voltage can be compensated automatically on a continuous basis.

The function starts when the fundamental (DFT) component of the compensated neutral unbalance voltage exceeds the set limit. CNUPTOV operates with the definite time (DT) characteristics.

The function contains a blocking functionality. It is possible to block function outputs, the definite timer or the function itself.

4.12.5.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of CNUPTOV can be described with a module diagram. All the modules in the diagram are explained in the next sections.

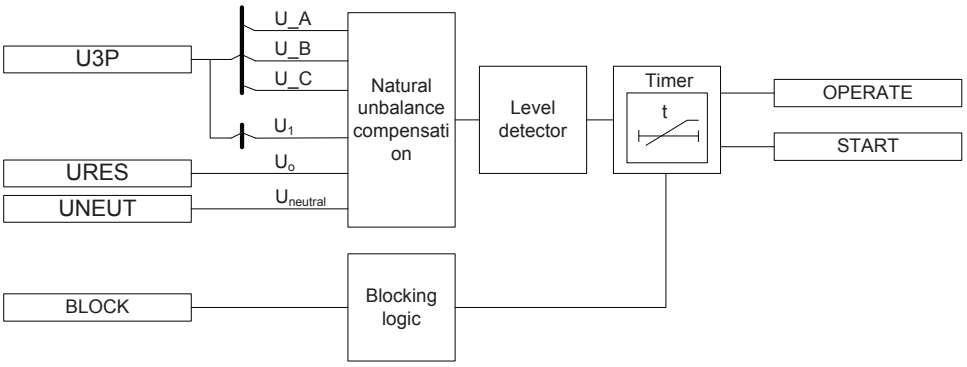

Figure 566: Functional module diagram

Natural unbalance compensation

This module calculates the natural unbalance compensation. Calculation for compensation is initiated through the command Record unbalance, available under the menu path **Control/CNUPTOV**. The function equates the operating signal to zero and calculates $\overline{U_{unb}}$ from the available known quantities. $\overline{U_{unb}}$ is memorized as $\overline{U_{unb}}(m)$. This memorized value is then used when calculating the operating quantity. For more information, see the Operating quantity section in this manual.

If the positive-sequence voltage is available at the time of memorizing the $\overline{U_{unb}}(m)$ value, the positive-sequence voltage is also memorized as $\overline{U_1}(m)$. The function then applies the revised compensation voltage to account for change in bus voltages between the moment of memorizing the compensation voltage and the time of applying it.

$$\overline{U_{unb}} = \overline{U_{unb}}(m) \cdot \frac{\overline{U_1}}{\overline{U_1}(m)}$$

(Equation 246)

Level detector

The operating signal is compared to the set *Start value*. If the operating signal exceeds the set *Start value*, Level detector sends an enabling signal to the Timer module.

Timer

Once activated, Timer activates the START output. The time characteristic is according to DT. When the operation timer has reached the value set by *Operate delay time*, the OPERATE output is activated if the operating signal persists. If a drop-off situation happens, that is, the fault disappears before the operate delay is exceeded, the timer reset state is activated. If the reset timer reaches the value set by *Reset delay time*, the operation timer resets and the START output is deactivated.

Timer calculates the start duration value START_DUR, which indicates the percentage ratio of the start situation and the set operation time. The value is available in the Monitored data view.

Blocking logic

There are three operation modes in the blocking function. The operation modes are controlled by the BLOCK input and the global setting in **Configuration/System/ Blocking mode** which selects the blocking mode. The BLOCK input can be controlled by a binary input, a horizontal communication input or an internal signal of the protection relay's program. The influence of the BLOCK signal activation is preselected with the global setting *Blocking mode*.

The *Blocking mode* setting has three blocking methods. In the “Freeze timers” mode, the operation timer is frozen to the prevailing value, but the OPERATE output is not deactivated when blocking is activated. In the “Block all” mode, the whole function is blocked and the timers are reset. In the “Block OPERATE output” mode, the function operates normally but the OPERATE output is not activated.

4.12.5.5 Operating quantity

Operating quantity in ungrounded SCB

Consider a case of a standard ungrounded shunt capacitor bank as shown in Figure 567.

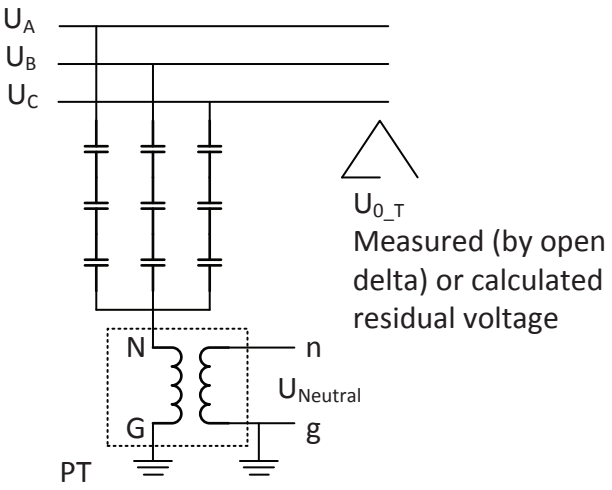

Figure 567: Ungrounded SCB

The operating signal for the compensated neutral voltage unbalance in per unit with reference to the neutral side of an ungrounded SCB is as indicated in Equation 247.

$$\text{Operating signal} = \left| \frac{\overline{U}_{Neutral}}{U_{N_sr}} - \frac{n_{Uo}}{U_{N_pr}} \cdot \overline{U}_o - \overline{U}_{unb} \right|$$

(Equation 247)

$\overline{U}_{Neutral}$ Measured shunt capacitor neutral voltage

$\overline{U}_o$ Measured open delta voltage

$\overline{U}_{unb}$ Natural unbalance compensation component

n_{Uo} Voltage ratio of open delta VT

U_{N_sr} Rated secondary voltage of neutral connected VT

U_{N_pr} Rated primary voltage of neutral connected VT

The rated *Primary voltage* and *Secondary voltage* for the neutral voltage channel $U_{Neutral}$, and for U_{N_pr} and U_{N_sr} are set in the global setting under **Configuration/ Analog inputs/Voltage (Uo,VT)**.

The operating signal setting is given as multiple of the neutral VT rated voltage.

4.12.5.6 Application

Shunt capacitor banks are provided with an unbalance protection function which is mainly used to detect problems within capacitor units using the presumed symmetry

in the impedances of the protected bank. The unbalance protection responds to unbalances in the measured signals caused by changes in the impedance of the capacitor bank.

In compensating unbalance protection, the operating signal compensates both the inherent capacitor bank unbalance and the system unbalance. The method involves measuring the residual voltage at the capacitor terminal side and at the neutral side. The terminal side's residual voltage component is obtained directly by VTs connected in open delta or by deriving open delta voltage using all three terminal side phase voltages. The neutral side's residual voltage is measured directly by connecting a VT between the neutral point and earth. It is advisable to block the function with the fuse failure function.

Example 1, ungrounded SCB

Figure 568 illustrates how much the neutral voltage changes in case of failure of some phase elements of the ungrounded SCB.

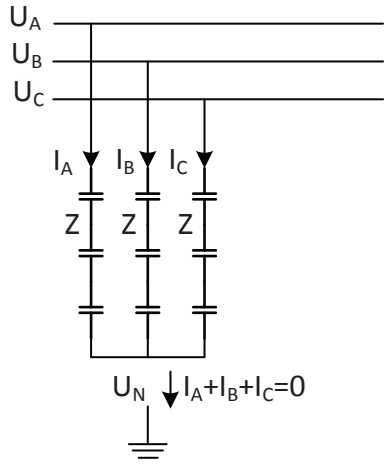

Figure 568: Ungrounded SCB

In a healthy ungrounded capacitor bank, the sum of the phase currents is

$$\bar{I}_A + \bar{I}_B + \bar{I}_C = 0$$

(Equation 248)

If the capacitor bank is symmetrical, that is, there is equal impedance in each phase, the equation can be

$$\left(\frac{\bar{U}_A - \bar{U}_N}{Z}\right) + \left(\frac{\bar{U}_B - \bar{U}_N}{Z}\right) + \left(\frac{\bar{U}_C - \bar{U}_N}{Z}\right) = 0$$

(Equation 249)

If the fault in the capacitor bank changes the phase A impedance to kZ

$$\left(\frac{\bar{U}_A - \bar{U}_N}{kZ}\right) + \left(\frac{\bar{U}_B - \bar{U}_N}{Z}\right) + \left(\frac{\bar{U}_C - \bar{U}_N}{Z}\right) = 0$$

(Equation 250)

$$\frac{\overline{U}_A}{kZ} + \frac{\overline{U}_B}{Z} + \frac{\overline{U}_C}{Z} = \overline{U}_N \cdot \left(\frac{1}{kZ} + \frac{2}{Z} \right)$$

(Equation 251)

$$\overline{U}_A + k \cdot \left(\overline{U}_B + \overline{U}_C \right) = \overline{U}_N \cdot \left(1 + 2 \cdot k \right)$$

(Equation 252)

If the system is symmetrical, that is, the system is healthy without any fault

$$\overline{U}_A + \overline{U}_B + \overline{U}_C = 0$$

(Equation 253)

Combining Equation 252 and Equation 253 results in

$$\overline{U}_A + k \cdot \left(-\overline{U}_A \right) = \overline{U}_N \cdot \left(1 + 2 \cdot k \right)$$

(Equation 254)

$$\overline{U}_N = \overline{U}_A \cdot \frac{\left(1 - k \right)}{\left(1 + 2 \cdot k \right)}$$

(Equation 255)

Considering the neutral VT ratio, per unit voltage referred to the neutral side is given by

$$\overline{U}_N = \frac{\overline{U}_A \cdot \dfrac{\left(1 - k \right)}{\left(1 + 2 \cdot k \right)}}{U_{N_pr}}$$

(Equation 256)

For example, if the impedance of the 20 kV system (U_A = 11.547 kV) capacitance drops by 5 percent, that is, k = 0.95, the neutral voltage is around 200 V according to Equation 255. If the voltage rating of a neutral VT is 20 kV/100 V, then in per unit terms refer to neutral side, the neutral voltage is around 0.01 · Un, that is, *Start value* should be set around 0.01.

In addition, assume that residual voltage (terminal side) is measured directly using an open-delta VT having ratio of $\frac{20kV}{\sqrt{3}} / \frac{100V}{\sqrt{3}} / \frac{100V}{3}$. Also, the *Primary voltage* and *Secondary voltage* settings under **Configuration/Analog inputs/Voltage (UoB,VT)** in a grounded system are set as 11.547 kV and 100 V, respectively. Similarly, if the VT connected at the neutral point has a ratio of $\frac{20kV}{\sqrt{3}} / \frac{100V}{\sqrt{3}}$, the *Primary voltage* and *Secondary voltage* settings under **Configuration/Analog inputs/Voltage (Uo,VT)** must be set as 20 kV and 100 V, respectively.

5.1 Three-phase inrush detector INRPHAR

5.1.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-phase inrush detector	INRPHAR	3I2f>	68HB

5.1.2 Function block

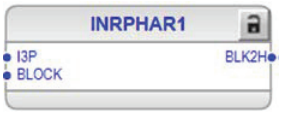

Figure 569: Function block

5.1.3 Functionality

The three-phase inrush detector function INRPHAR is used to detect transformer inrush situations in distribution networks.

Transformer inrush detection is based on the following principle: the output signal BLK2H is activated once the numerically derived ratio of second harmonic current I_2H and the fundamental frequency current I_1H exceeds the set value.

The operate time characteristic for the function is of definite time (DT) type.

The function contains a blocking functionality. Blocking deactivates all outputs and resets timers.

5.1.4 Analog channel configuration

INRPHAR has one analog group input which must be properly configured.

Table 998: Analog signals

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.1.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of INRPHAR can be described using a module diagram. All the modules in the diagram are explained in the next sections.

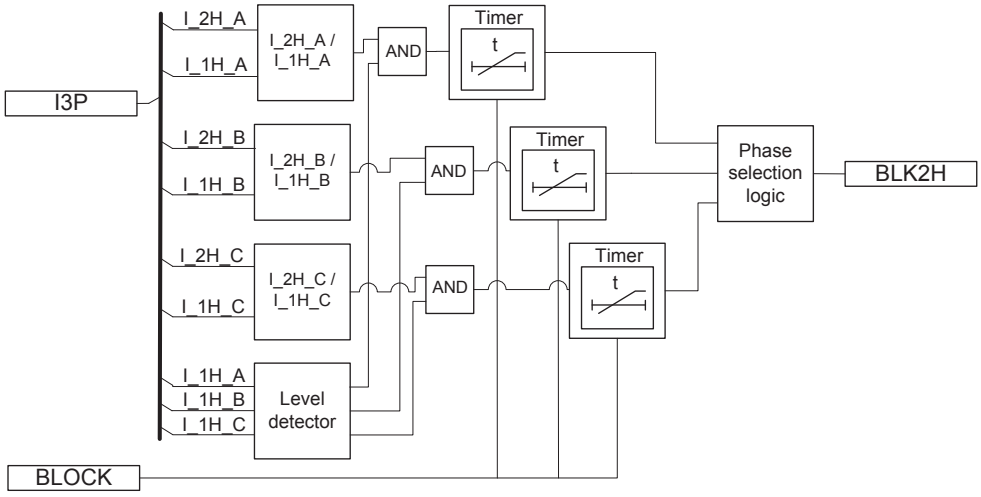

Figure 570: Functional module diagram

I_2H/I_1H

These modules calculate the ratio of the second harmonic (I_2H) and fundamental frequency (I_1H) of the phase currents. The calculated value is compared to the set *Start value*. If the calculated value exceeds the set *Start value*, the module output is activated.

Level detector

The output of the phase-specific level detector is activated when the fundamental frequency current I_1H exceeds the set *Min operate current* of the nominal current.

Timer

Once activated, Timer runs until the set *Operate delay time* value is exceeded. The time characteristics is according to DT. When the operation timer has reached the *Operate delay time* value, the Timer module output is activated. If the timer has elapsed and the inrush situation still exists, the Timer module output remains active until the I_2H/I_1H ratio drops below the set *Start value*, that is, until the inrush situation is over. If the drop-off situation occurs within the operate time up counting, the reset timer is activated. If the drop-off time exceeds *Reset delay time*, the operate timer is reset.

The BLOCK input can be controlled with a binary input, a horizontal communication input or an internal signal of the relay program. The activation of the BLOCK input prevents the BLK2H output from being activated.

Phase selection logic

This module determines the number of phases used for activating the BLK2H output. If *Num of start phases* = "1 out of 3", an inrush on any of the phases activates output BLK2H. If the set value equals "2 out of 3", an inrush or at least two phases are required to activate output BLK2H.

5.1.6 Application

Transformer protections require high stability to avoid tripping during magnetizing inrush conditions. A typical example of an inrush detector application is doubling the start value of an overcurrent protection during inrush detection.

The inrush detection function can be used to selectively block overcurrent and earth-fault function stages when the ratio of the second harmonic component to the fundamental component exceeds the set value.

Other applications of this function include the detection of inrush in lines connected to a transformer.

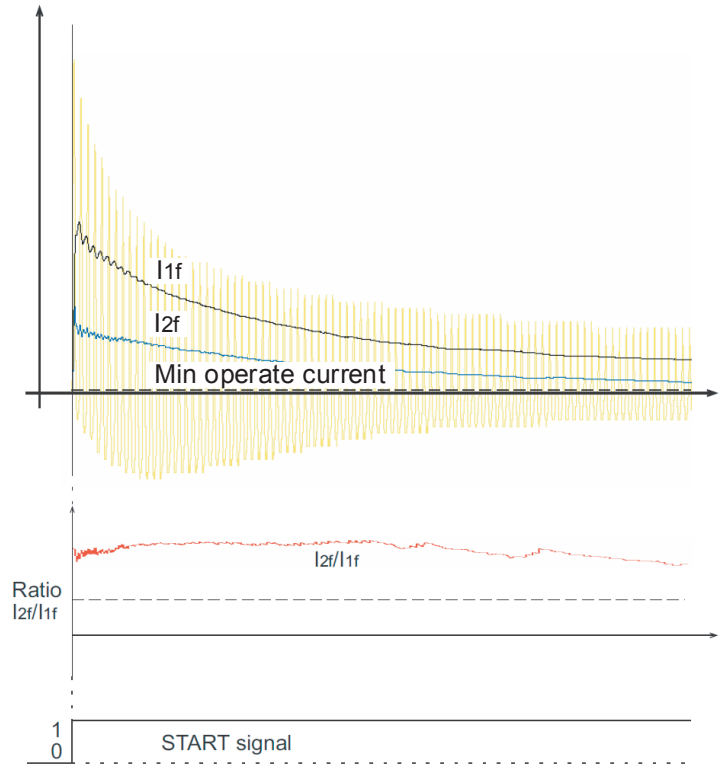

Figure 571: Inrush current in transformer

It is recommended to use the second harmonic and the waveform-based inrush blocking from the transformer differential protection function TR2PTDF if available.

Circuit breaker failure protection	CCBRBRF	3I>/Io>BF	50BF

5.2.2 Function block

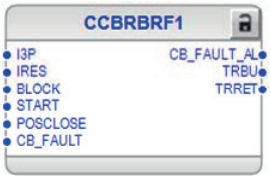

Figure 572: Function block

5.2.3 Functionality

The circuit breaker failure protection function CCBRBRF is activated by trip commands from the protection functions or through binary inputs. CCBRBRF includes a conditional or unconditional re-trip function, and also a conditional back-up trip function.

The operating values of the current measuring elements can be set within a predefined setting range. The function has two independent timers for trip purposes: a re-trip timer for the repeated tripping of its own breaker and a back-up timer for the trip logic operation for upstream breakers. A minimum trip pulse length can be set independently for the trip output.

The function contains a blocking functionality which can be used to block the function outputs.

5.2.4 Analog channel configuration

CCBRBRF has two analog group inputs which must be properly configured.

Table 1007: Analog inputs

Input	Description
I3P[1)]	Three-phase currents Necessary when *CB failure mode* is set other than "Breaker status"
IRES[1)]	Residual current (measured or calculated) Necessary when *CB failure mode* is set other than "Breaker status"

1) Can be connected to GRPOFF if *CB failure mode* is set to "Breaker status" and *CB fail retrip mode* is not set to "Current check"

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.2.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of CCBRBRF can be described using a module diagram. All the modules in the diagram are explained in the next sections. Also further information on the retrip and backup trip logics is given in sub-module diagrams.

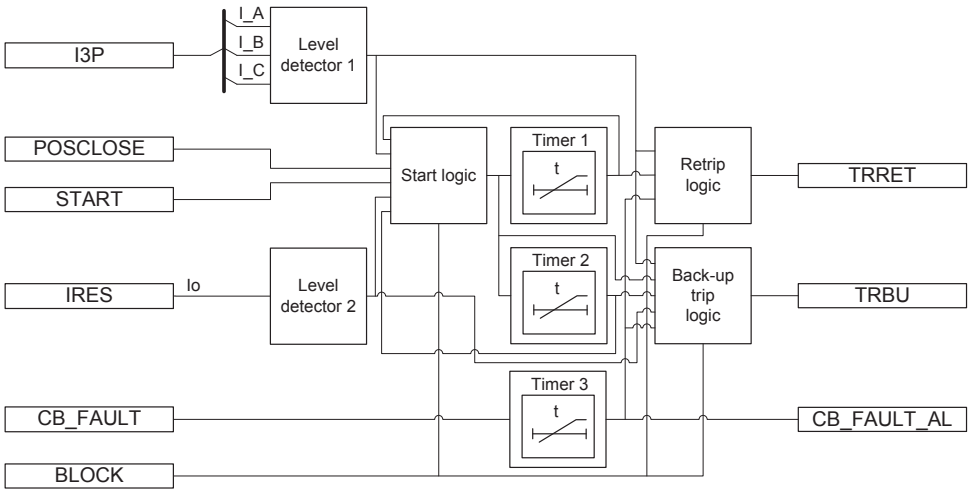

Figure 573: Functional module diagram

Level detector 1

The measured phase currents are compared phasewise to the set *Current value*. If the measured value exceeds the set *Current value*, the level detector reports the exceeding of the value to the start, retrip and backup trip logics. The parameter should be set low enough so that breaker failure situations with small fault current or high load current can be detected. The setting can be chosen in accordance with the most sensitive protection function to start the breaker failure protection.

Level detector 2

The measured residual current is compared to the set *Current value Res*. If the measured value exceeds the set *Current value Res*, the level detector reports the exceeding of the value to the start and backup trip logics. In high-impedance earthed systems, the residual current at phase-to-earth faults is normally much smaller than the short circuit currents. To detect a breaker failure at single-phase earth faults in these systems, it is necessary to measure the residual current separately. In effectively earthed systems, also the setting of the earth-fault current protection can be chosen at a relatively low current level. The current setting should be chosen in accordance with the setting of the sensitive earth-fault protection.

Start logic

Start logic is used to manage the starting of Timer 1 and Timer 2. It also resets the function after the circuit breaker failure is handled. On the rising edge of the `START` input, the enabling signal is sent to Timer 1 and Timer 2. Typically, the `START` input is activated when any protection function operates and trips the circuit breaker.

The Start logic module is reset depending on the settings *CB failure mode* and *CB failure trip mode* as shown in Table 1008. In all cases in Table 1008, however, the resetting is possible only after 150 ms from the activation of Start logic. This time is for ensuring correct operation in case of oscillation in the starting signal.

Table 1008: Start logic operation

Value of setting CB failure mode	Value of setting CB failure trip mode	Start logic reset condition
Current	1 out of 3	All phase currents drop below *Current value* setting.
	1 out of 4	All phase currents drop below *Current value* setting and the residual current drops below *Current value Res* setting.
	2 out of 4	Either of the following is true: • All phase currents drop below *Current value* setting. • The residual current drops below *Current value Res* setting and (at least) two phases are below *Current value* setting.
Breaker status	1 out of 3 1 out of 4 2 out of 4	CB is in open position.
Both(AND)	1 out of 3	Either of the following is true: • CB is in open position. • All phase currents drop below *Current value* setting.
	1 out of 4	Either of the following is true: • CB is in open position. • All phase currents drop below *Current value* setting and the residual current drops below *Current value Res* setting.
	2 out of 4	One of the following is true: • CB is in open position. • All phase currents drop below *Current value* setting. • The residual current drops below *Current value Res* setting and (at least) two phases are below *Current value* setting.
Both(OR)	1 out of 3	CB is in open position and all phase currents drop below *Current value* setting.
	1 out of 4	CB is in open position and all phase currents drop below *Current value* setting and the residual current drops below *Current value Res* setting.
	2 out of 4	CB is in open position and either of the following is true: • All phase currents drop below *Current value* setting. • The residual current drops below *Current value Res* setting and (at least) two phases are below *Current value* setting.

In addition, the function is immediately reset if:

- *Start latching mode* is set to "Level sensitive", and the START signal is deactivated. The recommended setting value is "Rising edge".
- The BLOCK input is activated.

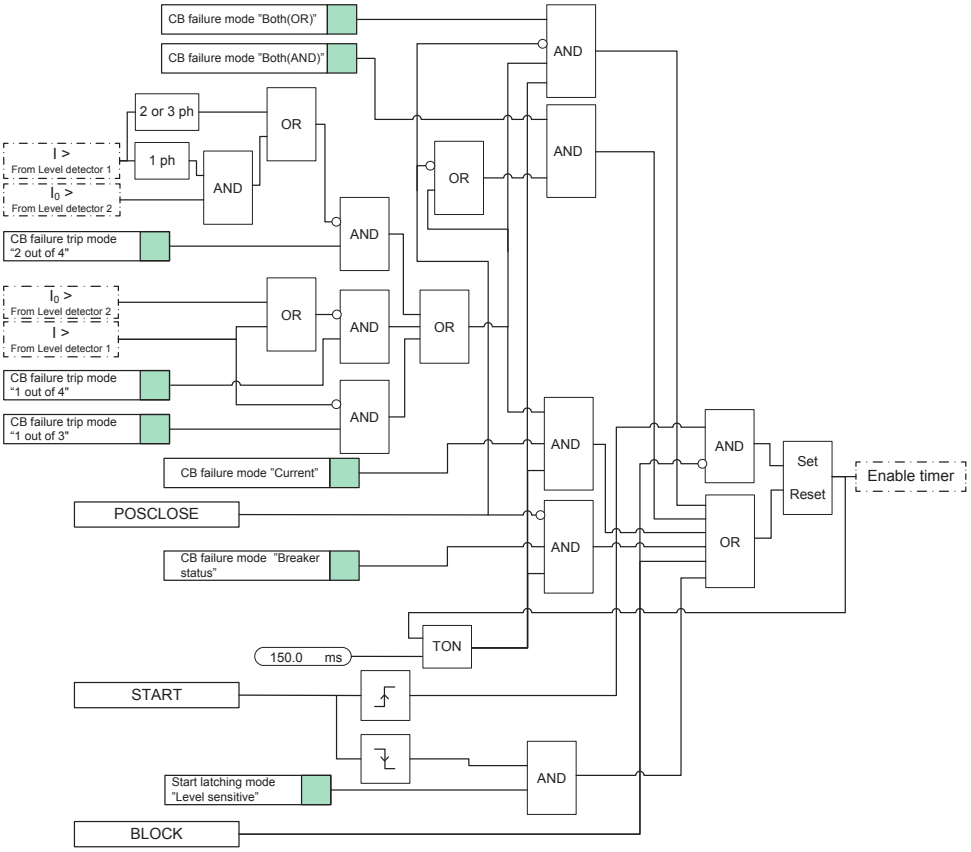

Figure 574: Start logic

Timer 1

Once activated, the timer runs until the set *Retrip time* value has elapsed. The time characteristic is according to DT. When the operation timer has reached the value set with *Retrip time*, the retrip logic is activated. A typical setting is 0...50 ms.

Timer 2

Once activated, the timer runs until the set *CB failure delay* value has elapsed. The time characteristic is according to DT. When the operation timer has reached the set maximum time value *CB failure delay*, the backup trip logic is activated. The value of this setting is made as low as possible at the same time as any unwanted operation is avoided. A typical setting is 90 - 150 ms, which is also dependent on the retrip timer.

The minimum time delay for the CB failure delay can be estimated as:

$$CBfailuredelay \geq Retriptime + t_{cbopen} + t_{BFP_reset} + t_{margin}$$

(Equation 257)

t_{cbopen} Maximum opening time for the circuit breaker

t_{BFP_reset} Maximum time for the breaker failure protection to detect the correct breaker function (the current criteria reset)

t_{margin} Safety margin

It is often required that the total fault clearance time is less than the given critical time. This time often depends on the ability to maintain transient stability in case of a fault close to a power plant.

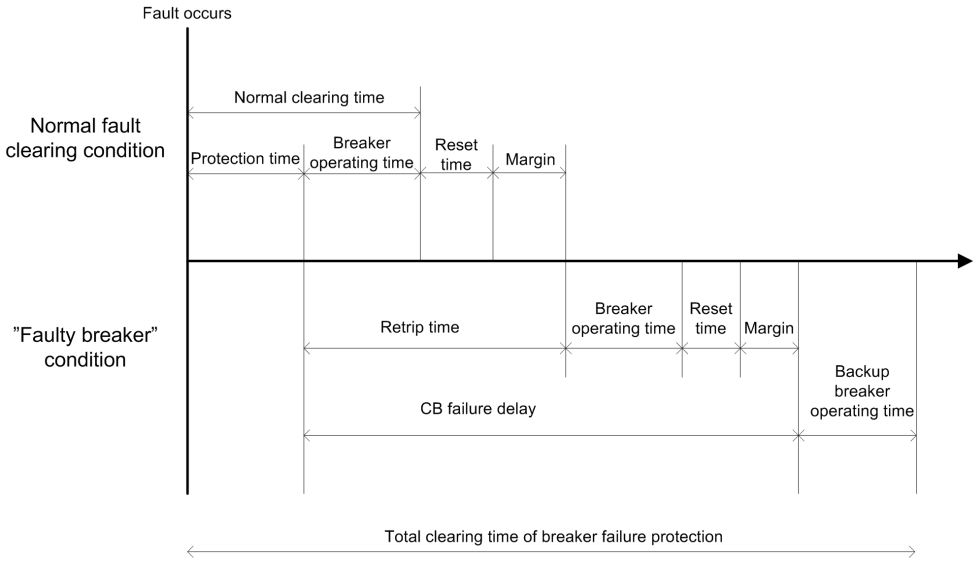

Figure 575: Timeline of the breaker failure protection

Timer 3

This module is activated by the CB_FAULT signal. Once activated, the timer runs until the set *CB fault delay* value has elapsed. The time characteristic is according to DT. When the operation timer has reached the maximum time value *CB fault delay*, the CB_FAULT_AL output is activated. After the set time, an alarm is given so that the circuit breaker can be repaired. A typical value is 5 s.

Retrip logic

Timer 1 activates Retrip logic, which can be used to give a retrip signal TRRET for the main circuit breaker. The operation of Retrip logic depends on the settings *CB failure mode* and *CB fail retrip mode* as shown in Table 1009.

Table 1009: Retrip logic operation

Value of setting CB fail retrip mode	Value of setting CB failure mode	Retrip functionality
Off	Current Breaker status Both(AND) Both(OR)	Retrip functionality switched off. TRRET is not activated.
Without Check	Current Breaker status Both(AND) Both(OR)	TRRET is activated after Timer 1 elapses.
Current check	Current	TRRET is activated after Timer 1 elapses and any phase current exceeds *Current value* setting.
	Breaker status	TRRET is activated after Timer 1 elapses and CB is in closed position.
	Both(AND)	TRRET is activated after Timer 1 elapses and CB is in closed position and any phase current exceeds *Current value* setting.
	Both(OR)	TRRET is activated after Timer 1 elapses and either of the following is true: • CB is in closed position. • Any phase current exceeds *Current value* setting.

TRRET activation is blocked if either CB_FAULT_AL output (from Timer 3) is active or the BLOCK input is activated.

Once activated, TRRET remains active for the set *Trip pulse time* or until the reasons for activation are reset. TRRET is also reset if CB_FAULT_AL or BLOCK is activated.

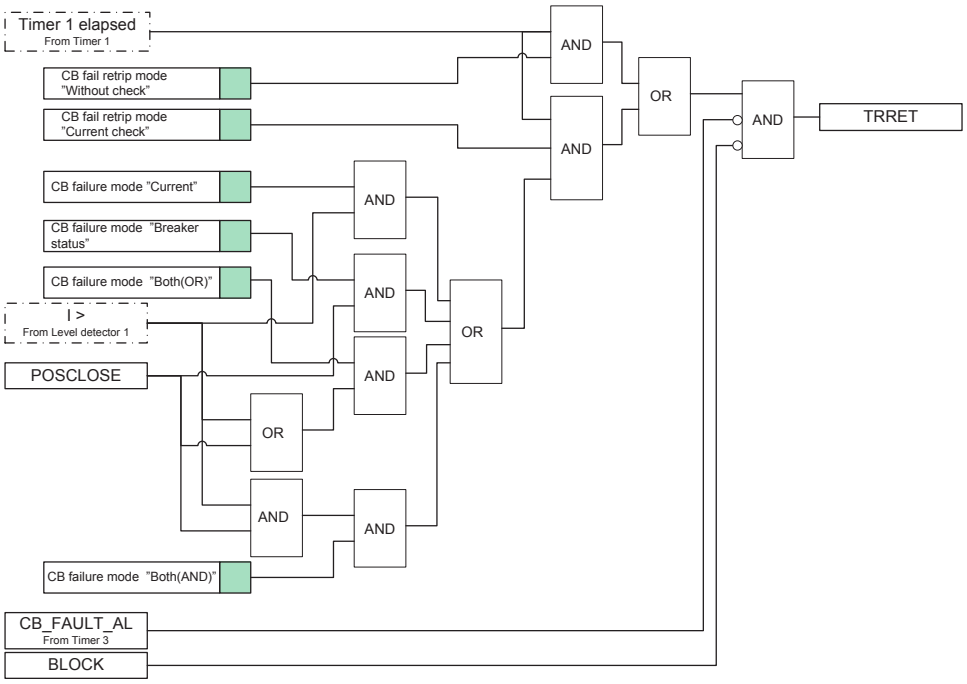

Figure 576: Retrip logic

Backup trip logic

Timer 2 activates Backup trip logic, which gives a backup trip TRBU for the upstream circuit breaker if the main circuit breaker fails to clear the fault. Backup trip logic is also activated if the timer-enabling signal from the Start logic module (rising edge of the START input detected) and CB_FAULT_AL are both active.

The operation of Backup trip logic depends on the settings *CB failure mode* and *CB failure trip mode* as shown in Table 1010.

Table 1010: Backup trip logic operation

Value of setting CB failure mode	Value of setting CB failure trip mode	Conditions for activating Backup trip logic
Current	1 out of 3	Any phase current exceeds *Current value* setting.
	1 out of 4	Either of the following is true: • Any phase current exceeds *Current value* setting. • The residual current exceeds *Current value Res* setting.
	2 out of 4	Either of the following is true: • Any phase current exceeds *Current value* setting and the residual current exceeds *Current value Res* setting. • Two or three phase currents exceed *Current value* setting.
Table continues on next page		

Value of setting CB failure mode	Value of setting CB failure trip mode	Conditions for activating Backup trip logic
Breaker status	1 out of 3 1 out of 4 2 out of 4	CB is in closed position.
Both(AND)	1 out of 3	CB is in closed position and any phase current exceeds *Current value* setting.
	1 out of 4	CB is in closed position and either of the following is true: • Any phase current exceeds *Current value* setting. • The residual current exceeds *Current value Res* setting.
	2 out of 4	CB is in closed position and either of the following is true: • Any phase current exceeds *Current value* setting and the residual current exceeds *Current value Res* setting. • Two or three phase currents exceed *Current value* setting.
Both(OR)	1 out of 3	Either of the following is true: • CB is in closed position. • Any phase current exceeds *Current value* setting.
	1 out of 4	One of the following is true: • CB is in closed position. • Any phase current exceeds *Current value* setting. • The residual current exceeds *Current value Res* setting.
	2 out of 4	One of the following is true: • CB is in closed position. • Any phase current exceeds *Current value* setting and the residual current exceeds *Current value Res* setting. • Two or three phase currents exceed *Current value* setting.

Once activated, TRBU remains active until the set *Trip pulse time* or until the reasons for activation are reset. TRRET is also reset if BLOCK is activated.

In most applications, "1 out of 3" is sufficient.

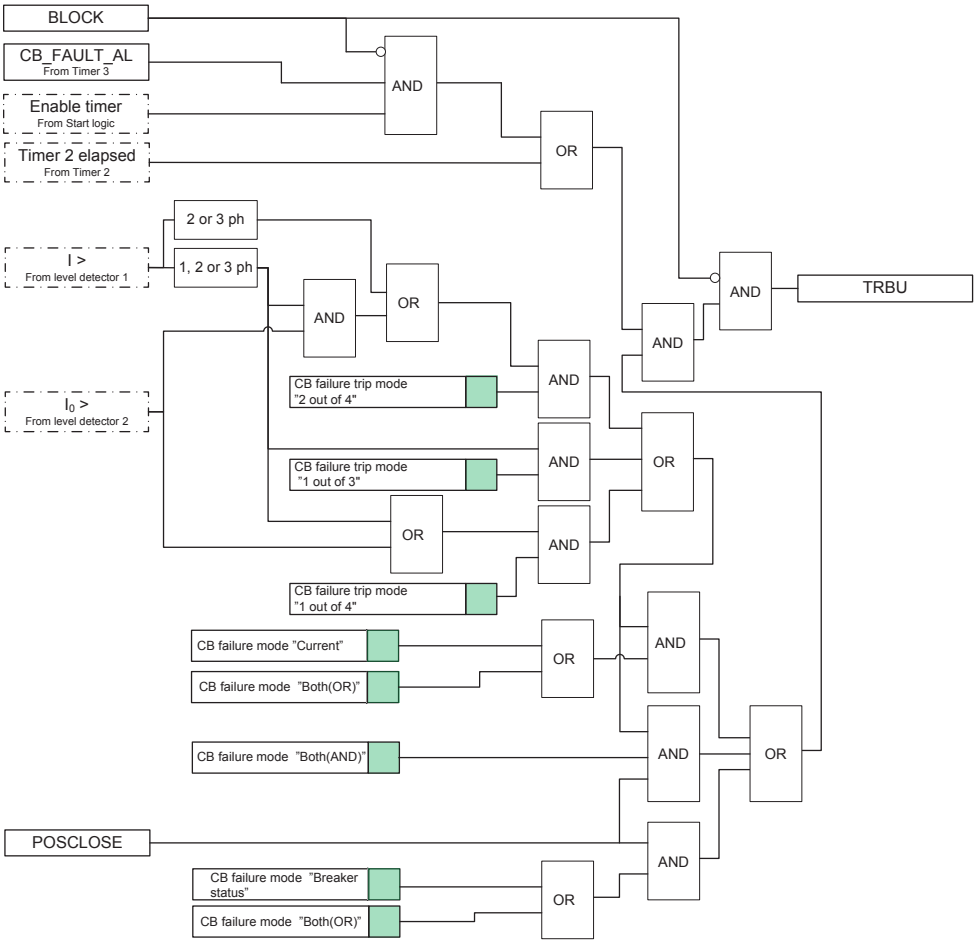

Figure 577: Backup trip logic

5.2.6 Application

The n-1 criterion is often used in the design of a fault clearance system. This means that the fault is cleared even if some component in the fault clearance system is faulty. A circuit breaker is a necessary component in the fault clearance system. For practical and economical reasons, it is not feasible to duplicate the circuit breaker for the protected component, but breaker failure protection is used instead.

The breaker failure function issues a backup trip command to up-stream circuit breakers in case the original circuit breaker fails to trip for the protected component. The detection of a failure to break the current through the breaker is made by measuring the current or by detecting the remaining trip signal (unconditional).

CCBRBRF can also retrip. This means that a second trip signal is sent to the protected circuit breaker. The retrip function is used to increase the operational reliability of the breaker. The function can also be used to avoid backup tripping of several breakers in case mistakes occur during protection relay maintenance and tests.

CCBRBRF is initiated by operating different protection functions or digital logics inside the protection relay. It is also possible to initiate the function externally through a binary input.

CCBRBRF can be blocked by using an internally assigned signal or an external signal from a binary input. This signal blocks the function of the breaker failure protection even when the timers have started or the timers are reset.

The retrip timer is initiated after the start input is set to true. When the pre-defined time setting is exceeded, CCBRBRF issues the retrip and sends a trip command, for example, to the circuit breaker's second trip coil. Both a retrip with current check and an unconditional retrip are available. When a retrip with current check is chosen, the retrip is performed only if there is a current flow through the circuit breaker.

The backup trip timer is also initiated at the same time as the retrip timer. If CCBRBRF detects a failure in tripping the fault within the set backup delay time, which is longer than the retrip time, it sends a backup trip signal to the chosen backup breakers. The circuit breakers are normally upstream breakers which feed fault current to a faulty feeder.

The backup trip always includes a current check criterion. This means that the criterion for a breaker failure is that there is a current flow through the circuit breaker after the set backup delay time.

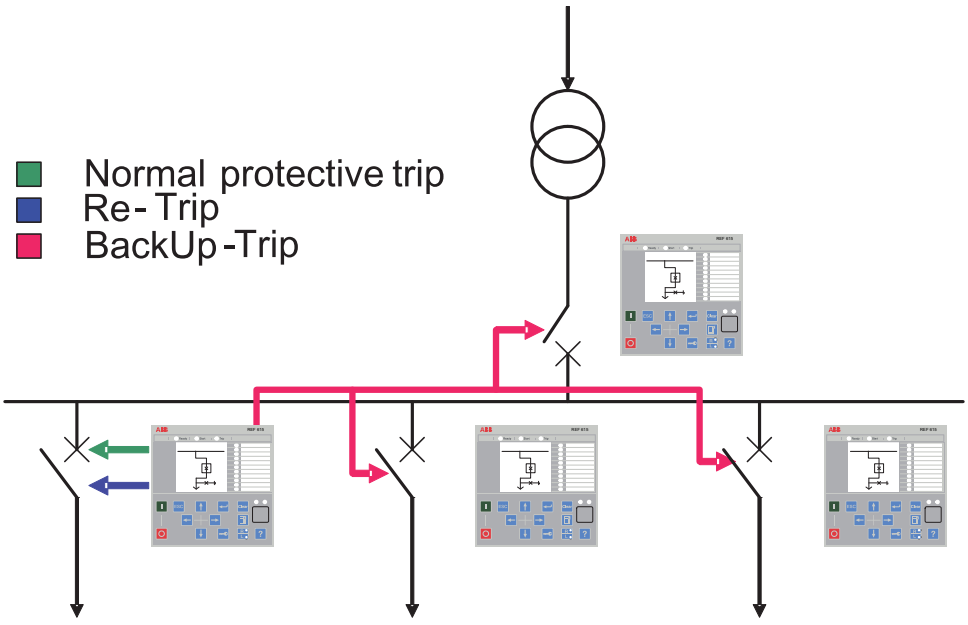

Figure 578: Typical breaker failure protection scheme in distribution substations

5.2.7 Signals

Table 1011: CCBRBRF Input signals

Name	Type	Default	Description

5.3 Master trip TRPPTRC

5.3.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Master trip	TRPPTRC	Master Trip	94/86

5.3.2 Function block

Figure 579: Function block

5.3.3 Functionality

The master trip function TRPPTRC is used as a trip command collector and handler after the protection functions. The features of this function influence the trip signal behavior of the circuit breaker. The minimum trip pulse length can be set when the non-latched mode is selected. It is also possible to select the latched or lockout mode for the trip signal.

5.3.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

When the TRPPTRC function is disabled, all trip outputs intended to go through the function to the circuit breaker trip coil are blocked.

The operation of TRPPTRC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

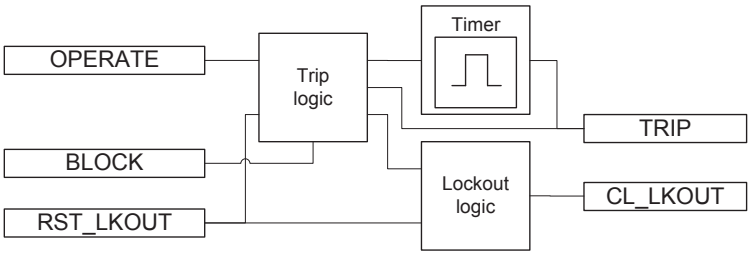

Figure 580: Functional module diagram

Timer

The duration of the TRIP output signal from TRPPTRC can be adjusted with the *Trip pulse time* setting when the "Non-latched" operation mode is used. The pulse length should be long enough to secure the opening of the breaker. For three-pole tripping, TRPPTRC has a single input OPERATE, through which all trip output signals are routed from the protection functions within the protection relay, or from external protection functions via one or more of the protection relay's binary inputs. The

function has a single trip output TRIP for connecting the function to one or more of the protection relay's binary outputs, and also to other functions within the protection relay requiring this signal.

The BLOCK input blocks the TRIP output and resets the timer.

Lockout logic

TRPPTRC is provided with possibilities to activate a lockout. When activated, the lockout can be manually reset after checking the primary fault by activating the RST_LKOUT input or from the LHMI clear menu parameter. When using the "Latched" mode, the resetting of the TRIP output can be done similarly as when using the "Lockout" mode. It is also possible to reset the "Latched" mode remotely through a separate communication parameter.

The minimum pulse trip function is not active when using the "Lockout" or "Latched" modes but only when the "Non-latched" mode is selected.

The CL_LKOUT and TRIP outputs can be blocked with the BLOCK input.

Table 1017: Operation modes for the TRPPTRC trip output

Mode	Operation
Non-latched	The *Trip pulse length* parameter gives the minimum pulse length for TRIP
Latched	TRIP is latched ; both local and remote clearing is possible.
Lockout	TRIP is locked and can be cleared only locally via menu or the RST_LKOUT input.

5.3.5 Application

All trip signals from different protection functions are routed through the trip logic. The most simplified application of the logic function is linking the trip signal and ensuring that the signal is long enough.

The tripping logic in the protection relay is intended to be used in the three-phase tripping for all fault types (3ph operating). To prevent the closing of a circuit breaker after a trip, TRPPTRC can block the CBXCBR closing.

TRPPTRC is intended to be connected to one trip coil of the corresponding circuit breaker. If tripping is needed for another trip coil or another circuit breaker which needs, for example, different trip pulse time, another trip logic function can be used. The two instances of the PTRC function are identical, only the names of the functions, TRPPTRC1 and TRPPTRC2, are different. Therefore, even if all references are made only to TRPPTRC1, they also apply to TRPPTRC2.

The inputs from the protection functions are connected to the OPERATE input. Usually, a logic block OR is required to combine the different function outputs to this input. The TRIP output is connected to the binary outputs on the IO board. This signal can also be used for other purposes within the protection relay, for example when starting the breaker failure protection.

TRPPTRC is used for simple three-phase tripping applications.

5.4 High-impedance fault detection PHIZ

5.4.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
High-impedance fault detection	PHIZ	HIF	HIZ

5.4.2 Function block

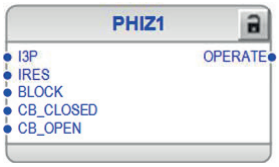

Figure 582: Function block

5.4.3 Functionality

A small percentage of earth faults have a very large impedance. They are comparable to load impedance and consequently have very little fault current. These high-

impedance faults do not pose imminent danger to power system equipment. However, they are a substantial threat to humans and properties; people can touch or get close to conductors carrying large amounts of energy.

ABB has developed a patented technology (US Patent 7,069,116 B2 June 27, 2006, US Patent 7,085,659 B2 August 1, 2006) to detect a high-impedance fault.

The high-impedance fault detection function PHIZ also contains a blocking functionality. It is possible to block function outputs.

5.4.4 Analog channel configuration

PHIZ has two analog group inputs which all must be properly configured.

Table 1022: Analog inputs

Input	Description
I3P	Three-phase currents
IRES	Residual current (measured or calculated)

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.4.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

PHIZ uses a multi-algorithm approach. Each algorithm uses various features of earth currents to detect a high-impedance fault.

Although the PHIZ algorithm is very sophisticated, the setting required to operate the function is simple. The *Security Level* setting, with the setting range of 1 to 10, is set to strike a balance between the extremes of security and dependability which together constitute the reliability of any system. The setting value “10” is more secure than “1”.

The higher the *Security Level* setting, the lower the probability of false detection, but the system might miss out some genuine fault. On the other hand, a lower setting would make the system operate more dependably for high-impedance faults in the line, but the operation is more likely for other transients in the system. There are events in electrical networks which can cause similar current waveforms like high-impedance faults. These events could then be detected by the PHIZ algorithm causing

unnecessary detections. Normally, electrical network operator does not know the existence of these events well and those can also be happening very randomly. The effect is also always dependent on event location compared to protection relay measurement location. All these facts make the PHIZ algorithm operation in certain electrical networks quite hard to measure and forecast beforehand. There is not any direct formula which can calculate the exact right setting based on known electrical network parameters.

It is hence recommended to set the value midway to “5” initially. Based on experience and confidence gained in a particular application, the setting can be moved either side. In many cases, it would be a good practice to use PHIZ as an indicative function during a piloting phase, until enough experience has been gathered and a suitable setting found.

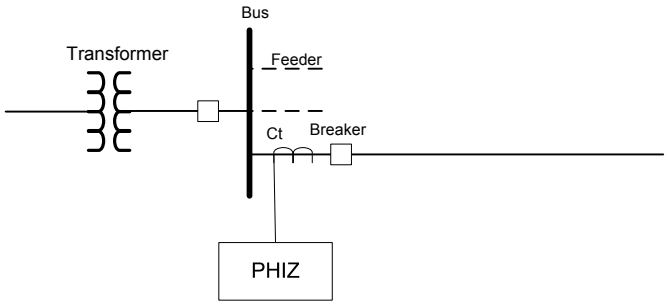

Figure 583: Electrical power system equipped with PHIZ

Power system signals are acquired, filtered and then processed by individual high-impedance fault detection algorithm. The results of these individual algorithms are further processed by a decision logic to provide the detection decision. The decision logic can be modified depending on the application requirement.

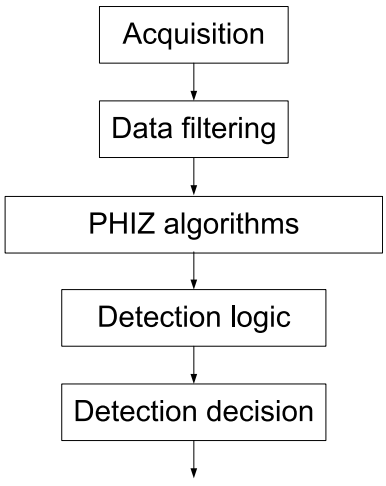

Figure 584: Block diagram of PHIZ

PHIZ is based on algorithms that use earth current signatures which are considered non-stationary, temporally volatile and of various burst duration. All harmonic and

non-harmonic components within the available data window can play a vital role in the high-impedance fault detection. A major challenge is to develop a data model that acknowledges that high-impedance faults could take place at any time within the observation window of the signal and could be delayed randomly and attenuated substantially. The model is motivated by extensive research, actual experimental observations in the laboratory, field testing and what traditionally represents an accurate depiction of a non-stationary signal with a time-dependent spectrum.

Figure 585: Validation of PHIZ on gravel

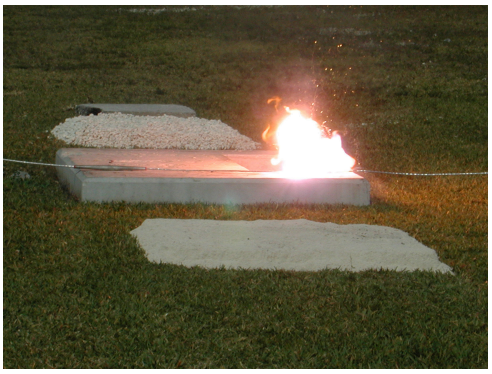

Figure 586: Validation of PHIZ on concrete

Figure 587: Validation of PHIZ on sand

Figure 588: Validation of PHIZ on grass

5.4.6 Application

PHIZ is used to detect a downed conductor dropping to a very resistive ground, causing an earth fault which is very difficult to detect by a conventional protection relay functionality. PHIZ is then targeted to be used with overhead lines. PHIZ must be used in electrical networks with efficiently grounded or isolated neutral.

Electric power lines experience faults for many reasons. In most cases, electrical faults manifest in mechanical damage, which must be repaired before returning the line to service.

Most of the electrical network faults are earth faults. Conventional protection systems based on overcurrent, impedance or other principles are suitable for detecting relatively low-impedance faults which have a relatively large fault current.

However, a small percentage of the earth faults have a very large impedance. They are comparable to load impedance and consequently have very little fault current. These high-impedance faults do not pose imminent danger to power system equipment. However, they are a considerable threat to people and property. The IEEE Power System Relay Committee working group on High Impedance Fault Detection Technology defines High Impedance Faults as those that 'do not produce enough fault current to be detectable by conventional overcurrent relays or fuses.

PHIZ always needs sensitive Io measurement.

High-impedance fault (PHIZ) detection requires a different approach than that for conventional low-impedance faults. Reliable detection of PHIZ provides safety to humans and animals. ABB has developed innovative technology for high-impedance fault detection with over ten years of research resulting in many successful field tests.

5.5 Binary signal transfer BSTGAPC

5.5.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Binary signal transfer	BSTGAPC	BST	BST

5.5.2 Function block

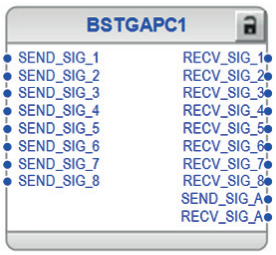

Figure 589: Function block

5.5.3 Functionality

The binary signal transfer function BSTGAPC is used for transferring binary signals between the local and remote end line differential protection relays. The function includes eight binary signals that are transferred in the protection communication telegram and can be freely configured and used for any purpose in the line differential application.

BSTGAPC transfers binary data continuously over the protection communication channel between the terminals. Each of the eight signals are bidirectional and the binary data sent locally is available remotely as a received signal.

BSTGAPC includes a minimum pulse time functionality for the received binary signals. Each received signal has its own minimum pulse time setting parameter.

BSTGAPC includes two alarm output signals. The SEND_SIG_A output signal is updated according to the status of the sent binary signals. The RECV_SIG_A output signal is updated according to the status of the received binary signals. Each signal can be separately included or excluded from the alarm logic with a setting parameter.

5.5.4 Operation principle

The *Signal 1...8 mode* setting can be used for changing the operation of the bidirectional signal channel. The signal channel can be disabled by setting the corresponding parameter value to “Not in use”. When the signal channel is disabled locally or remotely, the corresponding RECV_SIG_1...8 signal status is always false on both ends.

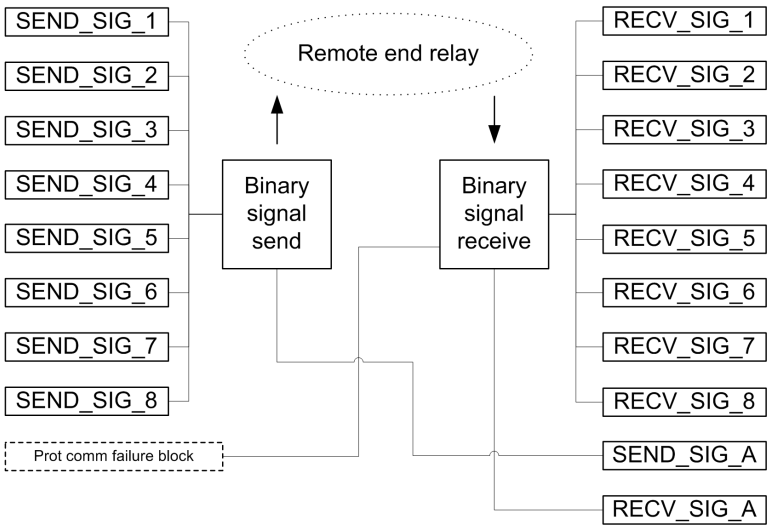

Figure 590: Functional module diagram

Binary signal send

The status of the inputs is continuously sent in the line differential protection telegrams. SEND_SIG_A can be used for alarming based on the status of SEND_SIG_1...8. By selecting the signal mode as "In use, alarm sel.", the sending status of the corresponding signal affects also the activation criteria of SEND_SIG_A. Further, in case more than one signal channels are selected into the alarm logic, the activation criteria can be defined according to "Any of selected" (OR) or "All of selected" (AND).

Binary signal receive

The function receives continuous binary data within the protection telegrams from the remote end protection relay. This received binary data status is then available as the RECV_SIG_1...8 outputs on the local end protection relay. RECV_SIG_A can be used for alarming based on the status of RECV_SIG_1...8. By selecting the signal mode as "In use, alarm sel.", the received status of the corresponding signal affects the activation criteria of RECV_SIG_A. Further, in case more than one signal channels are selected into the alarm logic, the activation criteria can be defined according to "Any of selected" (OR) or "All of selected" (AND). Each signal has also the *Pulse time 1...8* setting that defines the minimum pulse length for RECV_SIG_1...8. Also, in case the protection communication supervision detects a failure in the communication, the RECV_SIG_1...8 outputs are not set to false sooner than the minimum pulse length defined is first ensured for each signal.

5.5.5 Application

Among with the analog data, the binary data can also be exchanged with the line differential protection relays. The usage of the binary data is application specific and can vary in each separate case. The demands for the speed of the binary signals vary depending on the usage of the data. When the binary data is used as blocking signals for the line differential protection, the transfer response is extremely high. Binary signal interchange can be used in applications such as:

- Remote position indications
- Inter-tripping of the circuit breakers on both line ends
- Blocking of the line differential protection during transformer inrush or current circuit supervision failure
- Protection schemes; blocking or permissive
- Remote alarming

The figure shows the overall chain to transfer binary data in an example application. The position indication of the local circuit breaker is connected to the protection relay's input interface and is then available for the relay configuration. The circuit breaker position indication is connected to the first input of BSTGAPC which is used to send information to the remote end via communication. In the remote end, this information is handled as a remote circuit breaker open position and it is available from the first output of BSTGAPC. This way the information can be exchanged.

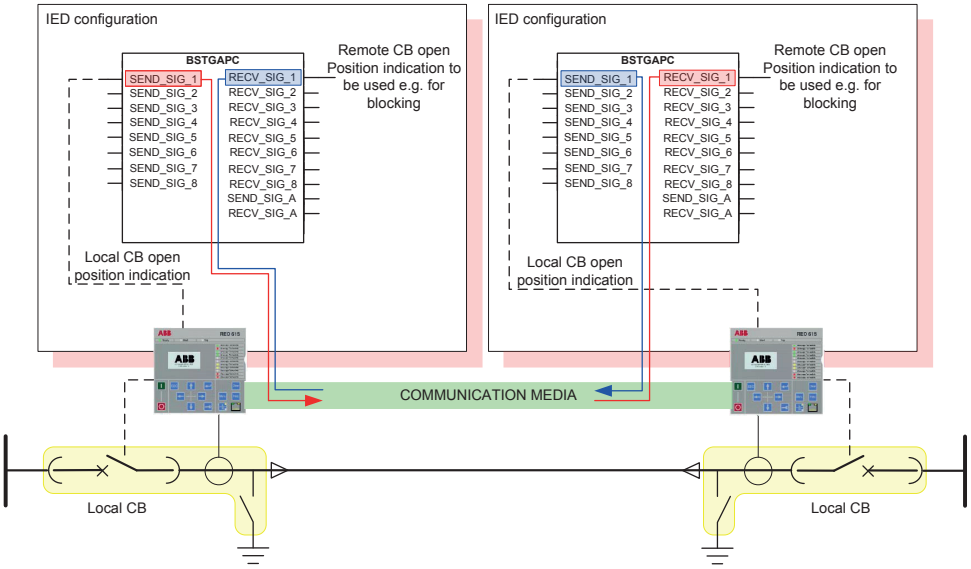

Figure 591: Example of usage of binary signal transfer for position indication change

5.5.6 Signals

Table 1028: BSTGAPC Input signals

Name	Type	Default	Description

Emergency start-up	ESMGAPC	ESTART	EST,62

5.6.2 Function block

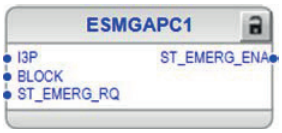

Figure 592: Function block

5.6.3 Functionality

An emergency condition can arise in cases where the motor needs to be started despite knowing that this can increase the temperature above limits or cause a thermal overload that can damage the motor. The emergency start-up function ESMGAPC allows motor start-ups during such emergency conditions. ESMGAPC is only to force the protection relay to allow the restarting of the motor. After the emergency start input is activated, the motor can be started normally. ESMGAPC itself does not actually restart the motor.

The function contains a blocking functionality. It is possible to block function outputs, timer or the function itself.

5.6.4 Analog channel configuration

ESMGAPC has one analog group input which must be properly configured.

Table 1033: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.6.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of ESMGAPC can be described using a module diagram. All the modules in the diagram are explained in the next sections.

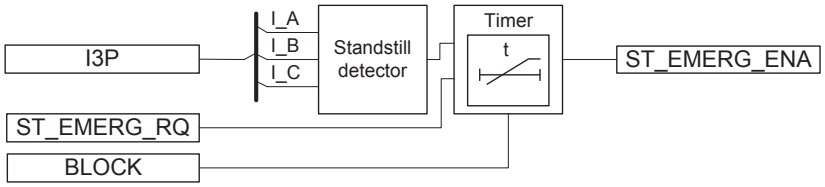

Figure 593: Functional module diagram

Standstill detector

The module detects if the motor is in a standstill condition. The standstill condition can be detected based on the phase current values. If all three phase currents are below the set value of *Motor standstill A*, the motor is considered to be in a standstill condition.

Timer

The timer is a fixed 10-minute timer that is activated when the ST_EMERG_RQ input is activated and motor standstill condition is fulfilled. Thus, the activation of the ST_EMERG_RQ input activates the ST_EMERG_ENA output, provided that the motor is in a standstill condition. The ST_EMERG_ENA output remains active for 10 minutes or as long as the ST_EMERG_RQ input is high, whichever takes longer.

The activation of the BLOCK input blocks and also resets the timer.

The function also provides the ST_EMERG_ENA output change date and time, T_ST_EMERG. The information is available in the monitored data view.

5.6.6 Application

If the motor needs to be started in an emergency condition at the risk of damaging the motor, all the external restart inhibits are ignored, allowing the motor to be restarted. Furthermore, if the calculated thermal level is higher than the restart inhibit level at an emergency start condition, the calculated thermal level is set slightly below the restart inhibit level. Also, if the register value of the cumulative start-up time counter exceeds the restart inhibit level, the value is set slightly below the restart disable value to allow at least one motor start-up.

The activation of the ST_EMERG_RQ digital input allows to perform emergency start. The protection relay is forced to a state which allows the restart of motor, and the operator can now restart the motor. A new emergency start cannot be made until the 10 minute time-out has passed or until the emergency start is released, whichever takes longer.

The last change of the emergency start output signal is recorded.

5.7 Fault locator SCEFRFLO

5.7.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Fault locator	SCEFRFLO	FLOC	FLOC

5.7.2 Function block

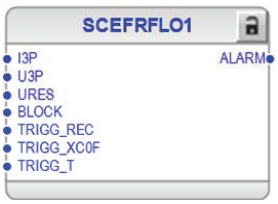

Figure 594: Function block

5.7.3 Functionality

The fault locator function SCEFRFLO provides impedance-based fault location. It is designed for radially operated distribution systems, and it can locate short circuits in all kinds of distribution networks. Earth faults can be located in effectively earthed

and in low-resistance or low-reactance earthed networks. With certain limitations, SCEFRFLO can also be used for locating an earth fault in unearthed distribution networks. Moreover, SCEFRFLO can be applied to compensated (resonant earthed) networks where an earth-fault current raising resistor is connected in parallel with the arc suppression coil. The location of the continuous low-ohmic earth fault can be determined by using the switching of the parallel resistor of the coil during an earth fault.

The fault distance calculation is based on the locally measured fundamental frequency current and voltage phasors. The full operation of SCEFRFLO requires all phase currents and phase-to-earth voltages to be measured.

The fault distance estimate is obtained when SCEFRFLO is externally or internally triggered.

5.7.4 Analog channel configuration

SCEFRFLO has three analog group inputs which must be properly configured.

Table 1040: Analog inputs

Input	Description
I3P	Three-phase currents
U3P	Three-phase voltages
URES[1)]	Residual voltage (measured) Necessary when the phase-to-phase voltages are measured and *Phase voltage Meas* is set to "Accurate"

1) Can be connected to GRPOFF if *Phase voltage Meas* is set to "Ph-to-ph without Uo"

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

There are a few special conditions which must be noted with the configuration.

Table 1041: Special conditions

Condition	Description
U3P connected real measurements	The function can work with any two phase voltage channels connected but it is recommended to connect all three voltage channels.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.7.5 Operation principle

The function can be enabled or disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of SCEFRFLO can be described with a module diagram. All the modules in the diagram are explained in the next sections.

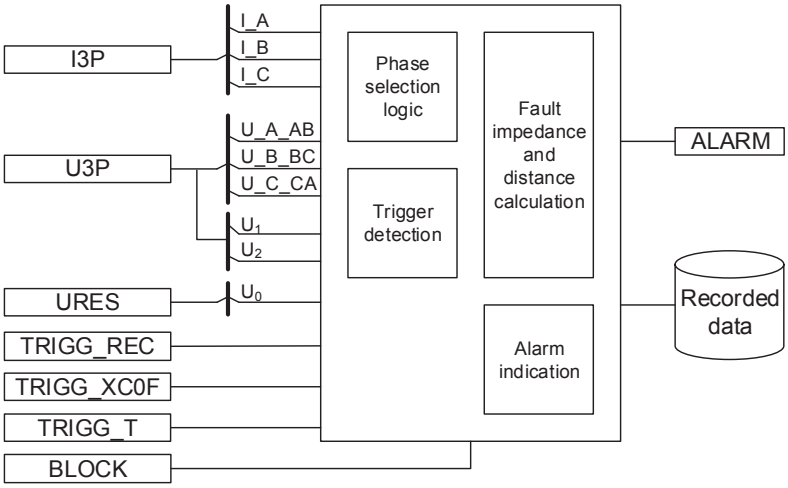

Figure 595: Functional module diagram

The fault distance calculation is done in two steps. First, the fault type is determined with the in-built Phase selection logic (PSL). Second, based on the selected impedance measuring element (fault loop) the fault distance from the measuring point to the fault location is calculated.

The phase current magnitude's minimum threshold value is 1% xIn.

Phase selection logic

Phase selection logic identifies the faulty phases based on a combined impedance and current criterion. Phase selection logic is virtually setting-free and has only one parameter, *Z Max phase load*, for discriminating a large symmetrical load from a three-phase fault. The setting *Z Max phase load* can be calculated using the equation

$$Z\,Max\,phase\,load = 0.8 \cdot \frac{U_{xy}^2}{S_{max}}$$

(Equation 258)

U_{xy} Nominal phase-to-phase voltage

S_{max} Maximum three-phase load

For example, if U_{xy} = 20 kV and S_{max} = 1 MVA, then *Z Max phase load* = 320.0 Ω.

The identification of the faulty phases is compulsory for the correct operation of SCEFRFLO. This is because only one of the impedance-measuring elements (fault loops) provides the correct result for a specific fault type. A three-phase fault is an exception and it can be calculated with any of the fault loops. The fault loop used in the fault distance calculation is indicated in the recorded data Flt loop as specified in Table 1042.

Table 1042: Fault types and corresponding fault loops

Fault type	Description	Flt loop
-	No fault	No fault
A-E	Phase A-to-earth fault	AG Fault
B-E	Phase B-to-earth fault	BG Fault
C-E	Phase C-to-earth fault	CG Fault
A-B	Phase A-to-B short circuit fault	AB Fault
B-C	Phase B-to-C short circuit fault	BC Fault
C-A	Phase C-to-A short circuit fault	CA Fault
A-B-C-(E)	Three-phase short circuit	ABC Fault

In case of two-phase-to-earth-faults (A-B-E, B-C-E or C-A-E), the selected fault loop depends on the location of the earth faults. When the faults are located at the same feeder, the corresponding phase-to-phase loop (“AB Fault”, “BC Fault” or “CA Fault”) is used for calculation. When the faults are located at different feeders, the phase-to-earth loop (“AG Fault”, “BG Fault” or “CG Fault”) corresponding to the faulty phase at the protected feeder is used for calculation.

Fault impedance and distance calculation

As soon as a fault condition is recognized by Phase selection logic, the fault distance calculation is started with one of the seven impedance-measuring elements, that is, the fault loops. SCEFRFLO uses independent algorithms for each fault type to achieve optimal performance.

The inherent result from the fault distance calculation is the ohmic fault loop impedance value.

Table 1043: The calculated impedance values available in the recorded data

Impedance value	Description
Flt phase reactance	Estimated positive sequence reactance from the substation to the fault location in primary ohms
Flt point resistance	Fault resistance value in the fault spot in primary ohms. The composition of this term depends on the fault loop as described in the following subsections.
Flt loop resistance	The total fault loop resistance from the substation to the fault location in primary ohms. Fault point resistance is included in this value. The composition of this term is different for short-circuit and earth-fault loops as described in the following subsections.
Flt loop reactance	The total fault loop reactance from the substation to the fault location in primary ohms. The composition of this term is different for short-circuit and earth-fault loops as described in the following subsections.

These impedance values can be used as such or they can be further processed in system-level fault location applications, such as distribution management system (DMS).

Fault loops “AG Fault”, “BG Fault” and “CG Fault”

Fault loops “AG Fault”, “BG Fault” and “CG Fault” are used for single-phase-to-earth faults. When the earth faults are located at different feeders, they are also applied in the case of two-phase-to-earth faults. In this case, the phase-to-earth loop (“AG Fault”, “BG Fault” or “CG Fault”) corresponding to the faulty phase at the protected feeder is used for calculation. Figure 596 shows the phase-to-earth fault loop model. The following impedances are measured and stored in the recorded data of SCEFRFLO.

$$Flt\ point\ resistance = R_{fault}$$

(Equation 259)

$$Flt\ loop\ resistance = R_1 + R_N + R_{fault}$$

(Equation 260)

$$Flt\ loop\ reactance = X_1 + X_N$$

(Equation 261)

$$Flt\ phase\ reactance = X_1$$

(Equation 262)

R_1	Estimated positive-sequence resistance from the substation to the fault location
X_1	Estimated positive-sequence reactance from the substation to the fault location
R_0	Estimated zero-sequence resistance from the substation to the fault location
X_0	Estimated zero-sequence reactance from the substation to the fault location
R_N	Estimated earth return path resistance (= (R0 – R1)/3) from the substation to the fault location
X_N	Estimated earth return path reactance (= (X0 – X1)/3) from the substation to the fault
R_{fault}	Estimated fault resistance at the fault location

The recorded data Flt phase reactance provides the estimated positive-sequence reactance from the substation to the fault location.

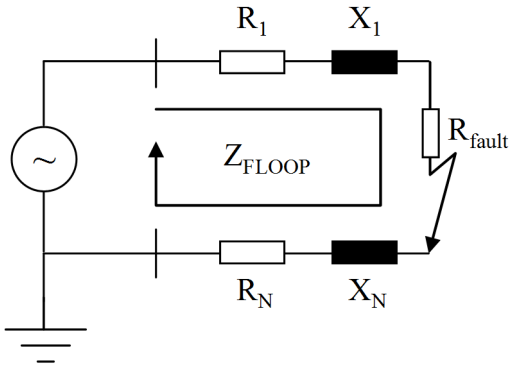

Figure 596: Fault loop impedance for phase-to-earth fault loops “AG Fault”, “BG Fault” or “CG Fault”

Setting *Flt Loc Det mode* is used for selecting between different algorithms for the calculation of the earth-fault distance. In case of compensated (resonant earthed) networks where an earth-fault current raising resistor is used, setting *Flt Loc Det mode* = "Comp, switched R" should be selected. In all other cases of system neutral point earthing (effectively earthed, low-resistance, low-reactance or unearthed networks), setting "Non-comp" should be selected.

Earth-fault distance calculation in case of non-compensated networks

In case of non-compensated networks (effectively earthed, low-resistance, low-reactance or unearthed networks), the setting *Flt Loc Det mode* is equal to "Non-comp". Furthermore, the earth-fault distance calculation algorithm is selected with setting *EF algorithm Sel*. Options for the selection are "Load compensation" and "Load modelling". For the correct operation of both algorithms, there should not be any zero-sequence current sources, for example, earthing transformers, in front of the protection relay.

The “Load compensation” algorithm uses symmetrical components to compensate for the effect of load on the measured voltages and currents. In case of radial feeders, this algorithm should be selected with low-impedance/effectively earthed systems where the fault current is fed from one side only and there are no in-feeds along the protected line.

The “Load modelling” algorithm takes into account the effect of the load in the measured currents and voltages by considering it in the fault loop model. In case of radial feeders, this algorithm can be applied with low-impedance/effectively earthed systems where the fault current is fed from one side only. The “Load modelling” algorithm has been especially designed for unearthed systems.

The “Load modelling” algorithm requires the *Equivalent load Dis* setting, that is, an equivalent load distance, as an additional parameter. The derivation and meaning of this parameter is illustrated in Figure 597, where the load is assumed to be evenly distributed along the feeder, resulting in the actual voltage drop curve as seen in the middle part of Figure 597.

In case of evenly distributed load, *Equivalent load Dis* ~ 0.5. When the load is tapped at the end of the feeder, *Equivalent load Dis* = 1.0. If the load distribution is unknown, a default value of 0.5 can be used for *Equivalent load Dis*.

The maximum value of the voltage drop, denoted as U_{drop}(real), appears at the end of the feeder. The *Equivalent load Dis* setting is the distance at which a single load tap corresponding to the total load of the feeder results in a voltage drop equal to U_{drop}(real). The dashed curve shows the voltage drop profile in this case.

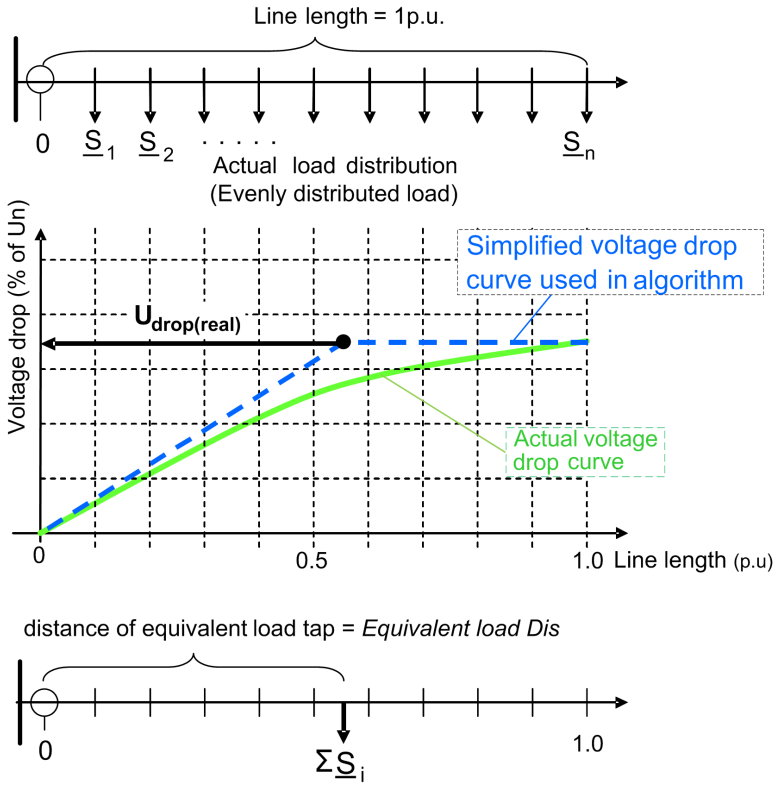

Figure 597: Description of the equivalent load distance

The exact value for *Equivalent load Dis* can be calculated based on the load flow and voltage drop calculations using data from the DMS system and the following equation.

$$Equivalent\ load\ Dis = \frac{U_{drop(real)}}{U_{drop(tap,d=1)}}$$

(Equation 263)

$U_{d(real)}$	Actual maximum voltage drop of the feeder
$U_{d(tap,d=1)}$	Fictional voltage drop if the entire load were tapped at the end (d=1) of the feeder (not drawn in Figure 597). The calculation of this value requires data from the DMS system.

Alternatively, the setting *Equivalent load Dis* can be determined by conducting a single-phase earth-fault test (R_{fault} = 0 Ω) at that point of the feeder where the maximum actual voltage drop takes place. This point is typically located at the end of the main line. The calculated value is stored in the recorded data Equivalent load Dis.

In addition, when the setting *EF algorithm Sel* is equal to "Load modelling", the *EF algorithm Cur Sel* setting determines whether the used algorithm is based on zero-sequence "Io based" or negative-sequence "I2 based" current. The difference between "Io based" and "I2 based" methods is that "I2 based" does not require the *Ph capacitive React* and *Ph leakage Ris* settings. In case of "Io based", these settings are needed to compensate for the influence of the line-charging capacitances of the protected feeder. This improves the accuracy of the fault location estimate when fault resistance is involved in the fault.

With certain restrictions, the “Load modelling” algorithm can also be applied to unearthed networks. In this case, the *EF algorithm Cur Sel* setting should be set to "Io based" and thus *Ph capacitive React* and *Ph leakage Ris* settings must be determined.

The prerequisite for the operation of SCEFRFLO in earth faults in unearthed networks is that the earth-fault current of the network corresponding to a solid fault exceeds the pre-fault load current; that is Equation 264 is valid.

$$Flt\ to\ Lod\ Cur\ ratio = \frac{\left|I_{ef(Rfault=0)}\right|}{\left|I_{Load}\right|} \geq 1$$

(Equation 264)

This ratio is estimated by SCEFRFLO and stored in the recorded data Flt to Lod Cur ratio together with the fault distance estimate.

In case of an unearthed network, sufficient fault current magnitude resulting in Flt to Lod Cur ratio >1 can be achieved, for example, with proper switching operations in the background network, if possible, which increase the fault current. If the faulty feeder is re-energized after the switching operation, a new estimate for the fault distance can be obtained. Fault resistance decreases the fault location accuracy so the resistance should not be higher than a few hundred ohms. Also, a low value of Flt to Lod Cur ratio causes inaccuracy and affects the quality of the fault distance estimate. The inaccuracies affecting the calculated fault distance estimate are reported in the recorded result quality indicator value Flt Dist quality in Table 1044.

Earth-fault distance calculation in case of compensated (resonant earthed) networks where an earth-fault current raising resistor is used

In case of compensated (resonant earthed) networks where an earth-fault current raising resistor is used, the setting *Flt Loc Det mode* is equal to "Comp, switched R". The algorithm for calculation of earth-fault distance requires a measurable change in the measured phase currents and phase-to-earth voltages during an earth fault. Such a change can be accomplished by switching on the resistor of the PAW winding (Power Auxiliary Winding) of the compensation coil during the fault.

The algorithm requires three independent time instances, which are assumed to be known by the algorithm:

- t_0 = time instance before the fault
- t_1 = time instance before the change during the earth fault
- t_2 = time instance after the change during the earth fault

The effect of loads is considered by applying “Load modelling” algorithm.

The required settings of the algorithm are:

- R1 = Positive-sequence resistance of the protected feeder [ohm, prim]
- X1 = Positive-sequence reactance of the protected feeder [ohm, prim]
- R0 = Zero-sequence resistance of the protected feeder [ohm, prim]
- X0 = Zero-sequence reactance of the protected feeder [ohm, prim]
- s = Equivalent load distance [pu]

Determining timings of changes: determination of earth fault occurrence and time instance t_0

Timing t_0 is needed to store the current and voltage phasors right before the occurrence of the earth fault. Timing t_0 is common to both triggering types (*Calculation Trg mode* either “Internal” or “External”). Pre-fault (indicating healthy network) phasors are continuously updated and stored at intervals of 300 ms until the earth fault is indicated. When the earth fault is detected (internal detection), the pre-fault phasor is stored at least 300 ms before the detection of the earth fault. This time instance before the earth fault is noted as t_0 (see Figure 598).

Determining timings of changes: determination of changes during an earth fault due to parallel resistor switching, time instances t_1 and t_2

- Time instance t_1 equals the time during earth fault, right before the switching of the parallel resistor of the coil (see Figure 598)
- Time instance t_2 equals the time during earth fault, just after the switching of the parallel resistor of the coil (see Figure 598)

In case of external triggering, time instances t_1 and t_2 are determined using input `TRIGG_T` and delay setting *Time delay*. `TRIGG_T` input should be activated when the parallel resistor is switched ON. Time instance t_1 is taken at least one fundamental cycle before `TRIGG_T` rising edge. Time instance t_2 is taken according to the set *Time delay* after the rising edge of `TRIGG_T` signal. Setting *Time delay* should be few hundreds of ms and it is needed due to oscillations in currents and voltages after the switching of the parallel resistor.

TRIGG_T activation must be given after the initial earth-fault ignition transients. Only one activation of TRIGG_T is allowed during an earth fault. However, further activations are internally disabled.

Activation of input TRIGG_REC is required in case of external triggering to record the calculated estimates for fault distance. TRIGG_REC should be activated during the earth fault after the switching of the parallel resistor.

In case of internal triggering, time instances t_1 and t_2 are determined by monitoring the change of the resistive component of Io current using admittance calculation during the earth fault and comparing the magnitude of change to setting *Zero Ris Curr change*. Time instance t_1 is taken at least one fundamental cycle before and t_2 at least one fundamental cycle after the change in the resistive component of Io exceeding the start value (setting *Zero Ris Curr change*). The value for setting *Zero Ris Curr change* should be chosen based on the rated current value of the parallel resistor with proper margin:

Zero Ris Curr change < Ipar_rated [A] · q

where q = 0.5-0.7

For example, if the rated current value of the parallel resistor is 10A@20kV and In = 100 A for Io channel, then

Zero Ris Curr change < 0.05-0.07xIn

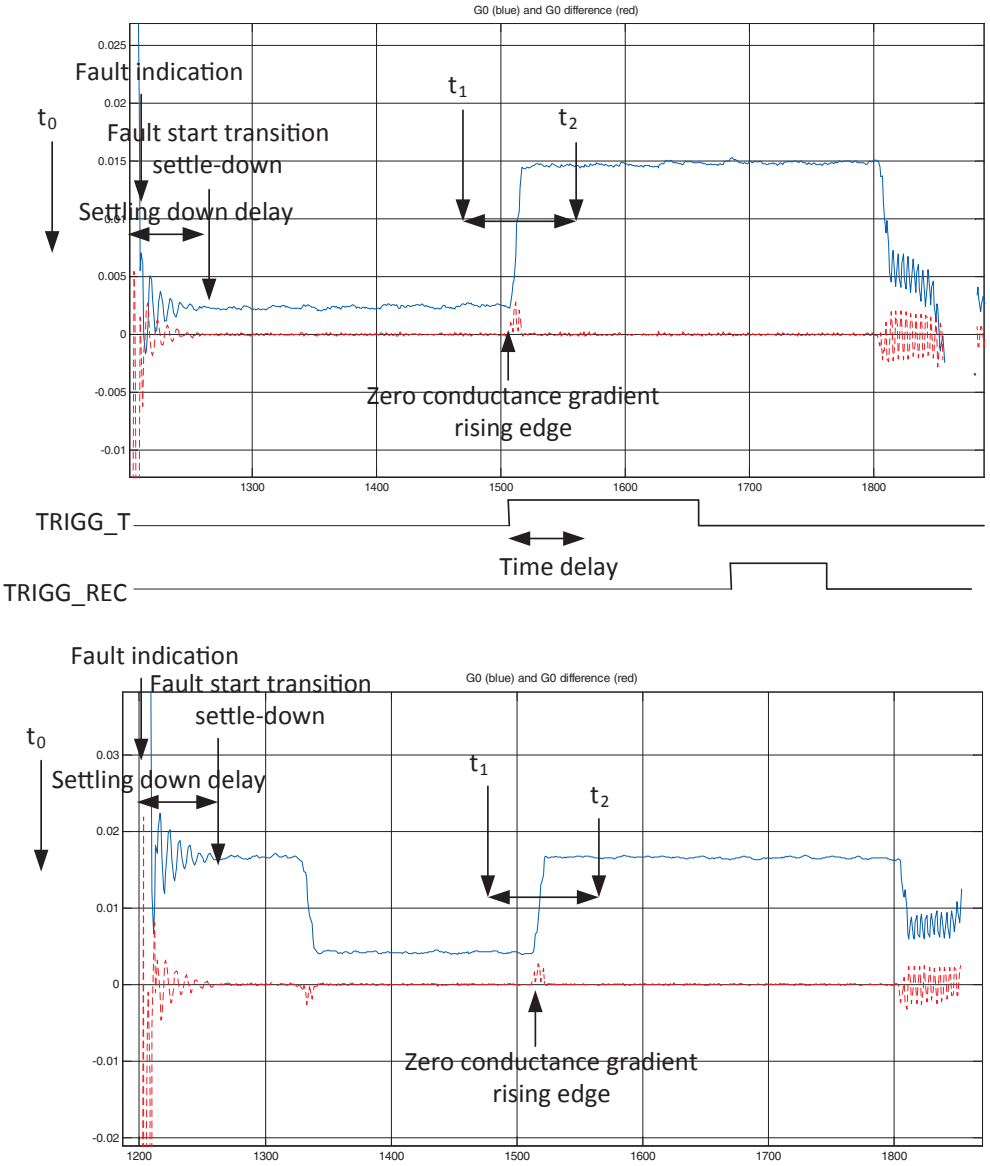

Figure 598: Fault distance estimate triggering moment definitions

Fault loops “AB Fault”, “BC Fault” and “CA Fault”

Fault loops “AB Fault”, “BC Fault” and “CA Fault” are used for phase-to-phase short circuit faults as well as in the case of a two-phase-to-earth fault if the individual earth faults are located at the same feeder. Figure 599 shows the phase-to-phase fault loop model. The following impedances are measured and stored in the recorded data of SCEFRFLO.

$$Flt\ point\ resistance = \frac{R_{fault}}{2}$$

(Equation 265)

$$Flt\ loop\ resistance = R_1 + \frac{R_{fault}}{2}$$

(Equation 266)

$$Flt\ loop\ reactance = Flt\ phase\ reactance = X_1$$

(Equation 267)

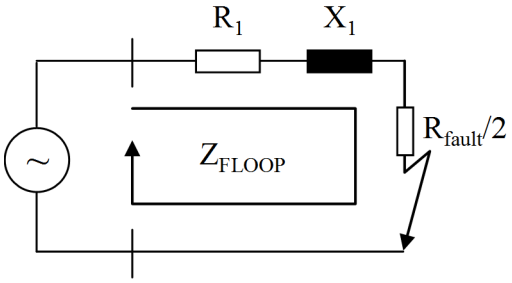

Figure 599: Fault loop impedance for phase-to-phase fault loops (“AB Fault”, “BC Fault” or “CA Fault”)

The fault distance calculation algorithm for the phase-to-phase fault loops is defined by using settings *Load Com PP loops* and *Enable simple model*. Options for the selection are "Disabled" or "Enabled".

Load compensation can be enabled or disabled with setting *Load Com PP loops*. Load compensation should be disabled only if the ratio between the fault current and load current is large or when the value of the fault distance estimate for the short circuit fault is required from each shot of an autoreclosing sequence.

The fault distance calculation is most accurate when calculated with the fault loop model. This model requires positive-sequence impedances of the protected feeder to be given as settings. If these settings are not available, valid impedance values can be calculated also without the fault loop model with setting *Enable simple model* = "Enabled". However, a valid distance estimate, that is, the conversion of measured impedance (“electrical fault distance’’) into a physical fault distance requires accurate positive-sequence impedance settings.

Fault loop “ABC Fault”

Fault loop “ABC Fault” is used exclusively for the three-phase short circuit fault. Figure 600 shows the three-phase fault loop model. The following impedances are measured and stored in the recorded data of SCEFRFLO.

$$Flt\ point\ resistance = R_{fault}$$

(Equation 268)

$$Flt\ loop\ resistance = R_1 + R_{fault}$$

(Equation 269)

$$Flt\ loop\ reactance = Flt\ phase\ reactance = X_1$$

(Equation 270)

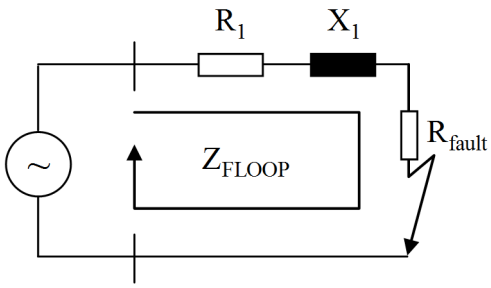

Figure 600: Fault loop impedance for a three-phase fault loop (“ABC Fault”)

The three-phase fault distance is calculated with a special measuring element using positive-sequence quantities. This is advantageous especially in case of non-transposed (asymmetric) lines, as the influence of line parameter asymmetry is reduced. If the line is non-transposed, all the phase-to-phase loops have different fault loop reactances. The use of positive-sequence quantities results in the average value of phase-to-phase loop reactances, that is, the most representative estimate in case of three-phase faults.

The fault distance calculation algorithm for the three-phase fault loop is defined with settings *Load Com PP loops* and *Enable simple model*. Options for the selection are "Disabled" or "Enabled".

Load compensation can be enabled or disabled with setting *Load Com PP loops*. The load compensation should be disabled only if the ratio between the fault current and load current is large or when the value of the fault distance estimate for the short circuit fault is required from each shot of an autoreclosing sequence.

The fault distance calculation is most accurate when the calculation is made with the fault loop model. This model requires positive sequence impedances of the protected feeder to be given as settings. If these settings are not available, valid impedance values can be calculated also without the fault loop model with setting *Enable simple model* = "Enabled". However, a valid distance estimate, that is, the conversion of measured impedance (“electrical fault distance’’) into a physical fault distance requires accurate positive-sequence impedance settings.

Estimation of fault resistance in different fault loops

The fault point resistance value provided by the impedance calculation is available in recorded data Flt point resistance and it depends on the applied fault loop as shown in Figure 601. In case of earth faults, the estimated fault point resistance includes the total fault point resistance between the faulty phase and earth, for example, the arc and earthing resistances. In case of phase-to-phase faults, the estimated fault point resistance is half of the total fault point resistance between the phases. In case of a three-phase fault, the estimated fault point resistance equals the total fault point resistance per phase, for example, the arc resistance per phase.

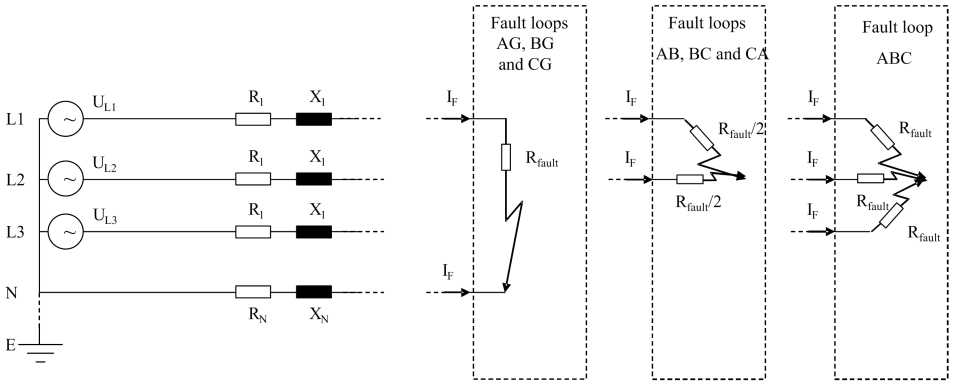

Figure 601: Definition of a physical fault point resistance in different fault loops

Steady-state asymmetry and load compensation

Power systems are never perfectly symmetrical. The asymmetry produces steady-state quantities in the form of zero-sequence and negative-sequence voltages and currents. If not compensated, these are error sources for fault distance calculation especially in case of earth faults. All earth-fault distance calculation algorithms of SCEFRFLO use the delta quantities which mitigate the effects of the steady-state asymmetry.

The load current is another error source for fault distance calculation. Its influence increases with higher fault resistance values. SCEFRFLO employs independent load compensation methods for each fault type to achieve optimal performance. The purpose of load compensation is to improve the accuracy of the fault distance calculation models by estimating the actual fault current in the fault location. Delta-quantities are used for this to mitigate the effect of load current on fault distance estimation.

For earth faults, the load compensation is done automatically inside the fault distance calculation algorithm. For short circuit faults, load compensation is enabled with setting *Load Com PP loops*. The default value is "Enabled". The parameter should be set to "Disabled" only if the ratio between the expected fault current and load current is large or when the fault distance estimate for the short circuit fault is required for each shot of an autoreclosing sequence.

The delta quantity describes the change in measured signal due to the fault.

$$\Delta x = x_{fault} + x_{pre\text{-}fault}$$

(Equation 271)

x_{fault} Signal value during fault

$x_{pre\text{-}fault}$ Signal value during healthy state just before fault

Result quality indicator

The quality of the estimated fault distance is judged and reported in recorded data as the Flt Dist quality together with the fault distance estimate. The Flt Dist quality is a bit vector indicating detected sources of inaccuracy in the fault distance estimate. If Flt Dist quality equals 1, the result is not affected by error sources. This results in good quality for the fault distance estimate. If factors affecting negatively the fault distance estimation are detected, the Flt Dist quality is according to Table 1044. In this case, the estimated fault distance (Flt distance) value is given on the HMI in parentheses.

Table 1044: Fault distance quality indicator Flt Dist quality

Value	Corresponding inaccuracy description
2	Estimation stability criterion has not been reached
4	Fault point resistance exceeds 500 Ω
8	Fault point resistance exceeds 5 × X_{loop} 1)
16	Fault point resistance exceeds 20 × X_{loop} 1)
32	Flt to Lod Cur ratio is below 1.00
64	Fault distance estimate outside tolerances (<-0.1 pu or >1.1 pu)
128	Distance estimate calculation is not done due to too low magnitudes of I or U
256	Distance estimate calculation cannot be performed (for example avoiding internal division by zero)

1) Xloop is the total loop reactance according to settings

For example, if fault point resistance exceeds 500 Ω and Flt to Lod Cur ratio is below 1.0, Flt Dist quality is “36”. As another example, if no error sources are found, but stability criterion is not met, the value of Flt Dist quality is “2”.

Impedance settings

The fault distance calculation in SCEFRFLO is based on the fault loop impedance modeling. The fault loop is parametrized with the impedance settings and these can be set at maximum for three line sections (A, B and C). Each section is enabled by entering a section length, which ranges from zero to settings *Line Len section A*, *Line Len section B* or *Line Len section C* in the order section A-> section B-> section C.

The earth-fault loops require both positive-sequence and zero-sequence impedances, for example, *R1 line section A* and *X1 line section A*, *R0 line section A* and *X0 line section A*. For the short circuit loops, only positive-sequence impedances are needed, but they can be omitted if the setting *Enable simple model* equals "Enabled".

If the impedance settings are in use, it is important that the settings closely match the impedances of the used conductor types. The impedance settings are given in primary ohms [ohm/pu] and the line section lengths in per unit [pu]. Thus, impedances can be either given in ohm/km and section length in km, or ohm/mile and section length in miles. The resulting Flt distance matches the units entered for the line section lengths.

Positive-sequence impedance values

Fault location requires accurate setting values for line impedances. Positive-sequence impedances are required both for the location of short circuits and earth faults. As data sheet impedance per unit values are generally valid only for a certain tower configuration, the values should be adjusted according to the actual installation configuration. This minimizes the fault location errors caused by inaccurate settings.

The positive-sequence reactance per unit and per phase can be calculated with an approximation equation which applies to symmetrically transposed three-phase aluminium overhead lines without ground wires.

$$X_1 \approx \omega_n \cdot 10^{-4} \left(2 \cdot \ln \frac{a_{en}}{r} + 0.5 \right) [\Omega / km]$$

(Equation 272)

ω_n $2 \cdot \pi \cdot f_n$, where f_n = fundamental frequency [Hz]

Zero-sequence impedance values

Location of earth faults requires both positive-sequence and zero-sequence impedances. For short circuit faults, zero-sequence impedances are not required.

The positive-sequence impedance per unit values for the lines are typically known or can easily be obtained from data sheets. The zero-sequence values are generally not as easy to obtain as they depend on the actual installation conditions and configurations. Sufficient accuracy can, however, be obtained with rather simple calculations using the following equations, which apply per phase for symmetrically transposed three-phase aluminium overhead lines without ground wires.

$$R_0\,[50Hz] \approx R1 + 0.14804\,[\Omega / km]$$

(Equation 274)

$$R_0\,[60Hz] \approx R1 + 0.17765\,[\Omega / km]$$

(Equation 275)

$$X_0 \approx 2 \cdot \omega_n \cdot 10^{-4} \left(3 \cdot \ln \frac{W}{r_{en}} + 0.25 \right) [\Omega / km]$$

(Equation 276)

R_1 Conductor AC resistance [Ω/km]

W $658 \sqrt{\frac{\rho_{earth}}{f_n}}$

r Radius [m] for single conductor

a_{xy} Distance [m] between phases x and y

Ph leakage Ris and *Ph capacitive React* settings

The *Ph leakage Ris* and *Ph capacitive React* settings are used for improving fault distance estimation accuracy for earth faults. They are critical for an accurate fault location in unearthed networks. In other types of networks they are less critical. The *Ph leakage Ris* setting represents the leakage losses of the protected feeder in terms of resistance per phase. The *Ph capacitive React* setting represents the total phase-to-earth capacitive reactance of the protected feeder per phase. Based on experience, a proper estimate for *Ph leakage Ris* should be about 20…40 · *Ph capacitive React*.

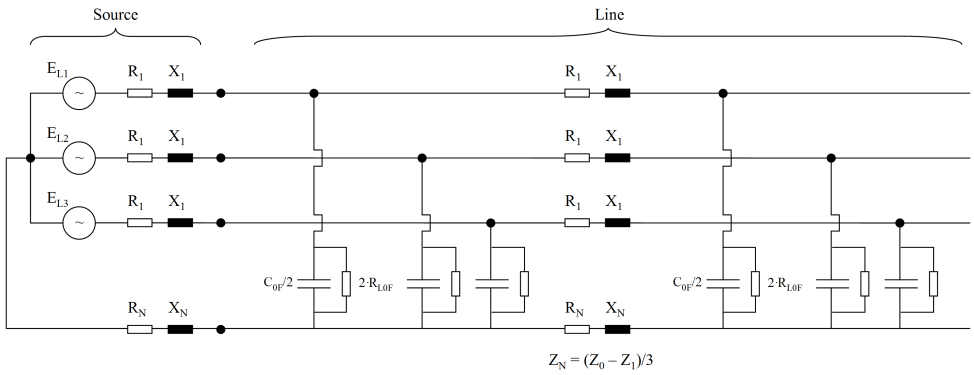

Figure 603: Equivalent diagram of the protected feeder. R_{L0F} = Ph leakage Ris.

The determination of the *Ph capacitive React* setting can be based either on network data or measurement. If the total phase-to-earth capacitance (including all branches) per phase C_{0F} of the protected feeder is known, the setting value can be calculated.

$$Ph\ capacitive\ React = \frac{1}{\left(\omega_n \cdot C_{0F}\right)}$$

(Equation 277)

In case of unearthed network, if the earth-fault current produced by the protected feeder I_{ef} is known, the setting value can be calculated.

$$Ph\ capacitive\ React = \frac{\sqrt{3} \cdot U_{xy}}{I_{ef}}$$

(Equation 278)

U_{xy} Phase-to-phase voltage

SCEFRFLO can also determine the value for the *Ph capacitive React* setting by measurements. The calculation of *Ph capacitive React* is triggered by the binary signal connected to the TRIGG_XC0F input when an earth-fault test is conducted outside the protected feeder during commissioning, for example, at the substation busbar. The *Calculation Trg mode* has to be "External". After the activation of the TRIGG_XC0F triggering input, the calculated value for setting *Ph capacitive React* is obtained from recorded data as parameter *XC0F Calc*. This value has to be manually entered for the *Ph capacitive React* setting. The calculated value matches the current switching state of the feeder so if the switching state of the protected feeder changes, the value should be updated.

Figure 604 shows an example configuration, which enables the measurement of setting *Ph capacitive React*.

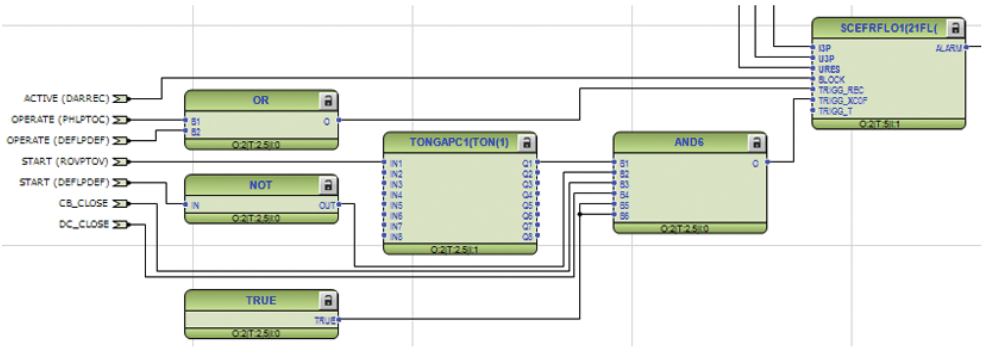

Figure 604: An example configuration, which enables the measurement of setting Ph capacitive React

If the earth fault is detected by the residual overvoltage function (START of ROVPTOV), but not seen by the forward-looking earth-fault protection function (START of DEFLPDEF), the fault is located outside the protected feeder. This is mandatory for a valid measurement of setting *Ph capacitive React*. After a set delay (TONGAPC), the input TRIGG_XC0F is activated and the parameter *XC0F Calc* in the recorded data is updated. The delay (TONGAPC) must be set longer than the start delay of the directional earth-fault function DEFLPDEF, but shorter than the minimum operating time of the directional earth-fault functions in any of the feeders. For example, if the start delay is 100 ms and the shortest operating time is 300 ms, a value of 300 ms can be used. Circuit breaker and disconnector status is used to verify that the entire feeder is measured.

Modeling a non-homogeneous line

A typical distribution feeder is built with several different types of overhead lines and cables. This means that the feeder is electrically non-homogeneous. SCEFRFLO allows the modeling of the line impedance variation in the protection relay with three line sections with independent impedance settings. This improves the accuracy of the physical fault distance conversion done in the protection relay, especially when the line impedance non-homogeneity is severe. Each section is enabled by entering a

section length, which differs from zero, to settings *Line Len section A*, *Line Len section B* or *Line Len section C* in the order section A-> section B-> section C.

The impedance model with one line section is enabled by setting *Line Len section A* to differ from zero. In this case, the impedance settings *R1 line section A*, *X1 line section A*, *R0 line section A* and *X0 line section A* are used for the fault distance calculation and for conversion from reactance to physical fault distance. This option should be used only in the case of a homogeneous line, that is, when the protected feeder consists of only one conductor type.

The impedance model with two line sections is enabled by setting both *Line Len section A* and *Line Len section B* to differ from zero. In this case, the impedance settings *R1 line section A*, *X1 line section A*, *R0 line section A*, *X0 line section A*, *R1 line section B*, *X1 line section B*, *R0 line section B* and *X0 line section B* are used for the fault distance calculation and for conversion from reactance to physical fault distance. This option should be used in the case of a non-homogeneous line when the protected feeder consists of two types of conductors.

The impedance model with three line sections is enabled by setting *Line Len section A*, *Line Len section B* and *Line Len section C* to differ from zero. In this case, the impedance settings *R1 line section A*, *X1 line section A*, *R0 line section A*, *X0 line section A*, *R1 line section B*, *X1 line section B*, *R0 line section B*, *X0 line section B*, *R1 line section C*, *X1 line section C*, *R0 line section C* and *X0 line section C* are used for the fault distance calculation and for conversion from reactance to physical fault distance. This option should be used in the case of a non-homogeneous line when the protected feeder consists of more than two types of conductors.

The effect of line impedance non-homogeneity on the conversion of fault loop reactance into physical fault distance is demonstrated in the example shown in Figure 605 with a 10-km-long feeder with three line types. The total line impedance for the 10 km line is R1 = 6.602 Ω (0.660 Ω/km) and X1 = 3.405 Ω (0.341 Ω/km), consisting of the following sections and impedance values.

- 4 km of PAS 150 (R1 = 0.236 Ω/km, X1 = 0.276 Ω/km)
- 3 km of Al/Fe 54/9 Raven (R1 = 0.536 Ω/km, X1 = 0.369 Ω/km)
- 3 km of Al/Fe 21/4 Swan (R1 = 1.350 Ω/km, X1 = 0.398 Ω/km)

The non-homogeneity of feeder impedance can be illustrated by drawing the protected feeder in RX-diagram (in the impedance plane), as shown in Figure 605.

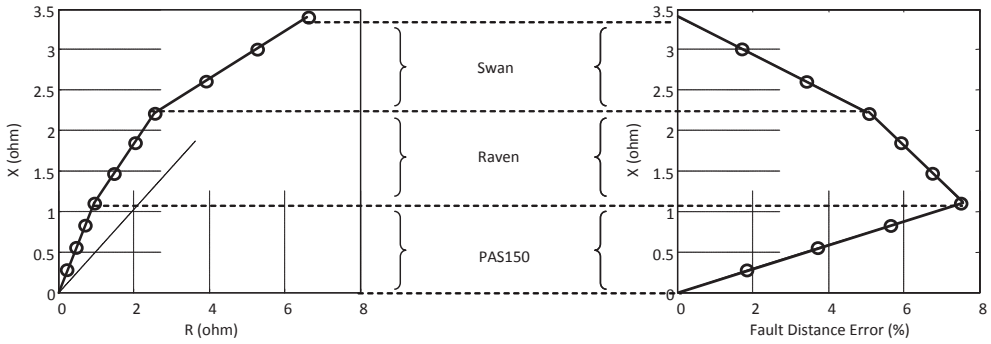

Figure 605: Example impedance diagram of an electrically non-homogeneous feeder (left), and the resulting error in fault distance if the measured fault loop reactance is converted into physical fault distance by using only one line section parameters (right).

In Figure 605 the feeder is modeled either with one or three line sections with parameters given in Table 1048.

Table 1048: Impedance settings

Parameter	Impedance model with one section	Impedance model with three sections
R1 line section A	0.660 Ω/pu	0.236 Ω/pu
X1 line section A	0.341 Ω/pu	0.276 Ω/pu
Line Len section A	10.000 pu	4.000 pu
R1 line section B	N/A	0.536 Ω/pu
X1 line section B	N/A	0.369 Ω/pu
Line Len section B	0.000 pu	3.000 pu
R1 line section C	N/A	1.350 Ω/pu
X1 line section C	N/A	0.398 Ω/pu
Line Len section C	0.000 pu	3.000 pu

Figure 605 illustrates the error when converting the measured fault loop reactance into physical fault distance. The fault location is varied from 1 km to 10 km in 1 km steps (marked with circles). An error of nearly eight per cent at maximum is created by the conversion procedure when modeling a non-homogenous line with only one section. By using impedance model with three line sections, there is no error in the conversion.

The previous example assumed a short circuit fault and thus, only positive-sequence impedance settings were used. The results, however, also apply to earth faults.

Taps or spurs in the feeder

If the protected feeder consists of taps or spurs, the measured fault impedance corresponds to several physical fault locations (for example, A or B in Figure 606). The actual fault location must be identified using additional information, for example, short circuit current indicators placed on tapping points.

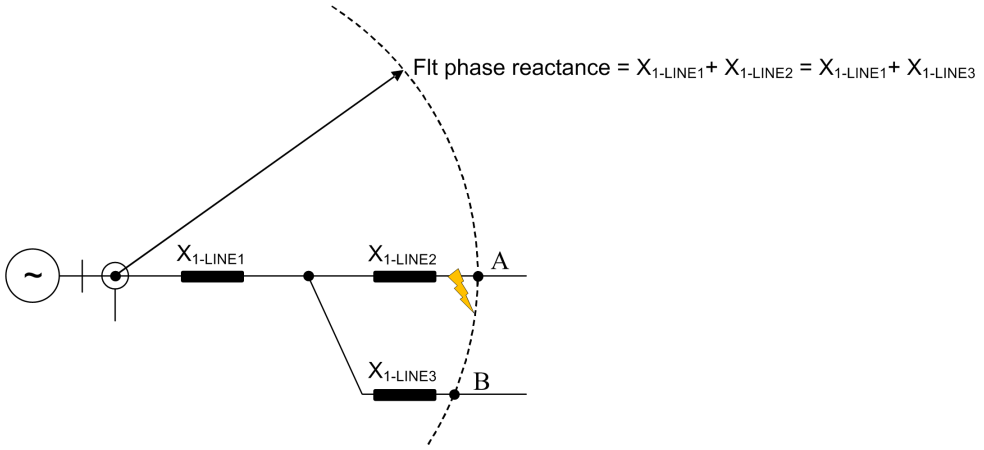

Figure 606: Fault on a distribution line with spurs

Trigger detection

The fault distance estimate is obtained when SCEFRFLO is triggered. The triggering method is defined with setting *Calculation Trg mode*. The options for selection are "External" or "Internal", where the default value is "External". The TRIGG_OUT event indicates the fault distance value recording moment. The fault distance estimate, Flt distance, together with the time stamp of actual triggering are saved in the recorded data of SCEFRFLO.

- In case of external triggering, an external trigger signal should be connected to the TRIGG_REC input. The triggering signal is typically a trip signal from a protective function. At triggering moment the fault distance is stored into recorded data. It is important that triggering be timed suitably to provide sufficient time for the distance estimation calculation before tripping of the feeder circuit breaker.
- In case of internal triggering, the TRIGG_REC input is not used for triggering. Instead, the trigger signal is created internally so that the estimation is started when Phase selection logic detects a fault and the estimate is triggered when its value has stabilized sufficiently. This is judged by maximum variation in fault distance estimate and defined with setting *Distance estimate Va* (in the same unit as the fault distance estimate). When successive estimates during one fundamental cycle are within “final value ± *Distance estimate Va*”, the fault distance estimate (mean of successive estimates) is recorded. If the stabilization criterion has not been fulfilled, the fault distance estimate is given right before the fault ends. Phase selection logic is a non-directional function so internal triggering should not be used when directionality is required.

Generally, SCEFRFLO requires a minimum of two fundamental cycles of measuring time after the fault occurrence. Figure 607 illustrates the typical behavior of fault distance estimate of SCEFRFLO as a function of time.

- Immediately after the fault occurrence, the estimate is affected by initial fault transients in voltages and currents.
- Approximately one fundamental cycle after the fault occurrence, the fault distance estimate starts to approach the final value.
- Approximately two fundamental cycles after the fault occurrence, the stability criterion for fault distance estimate is fulfilled and the TRIGG_OUT event is sent. The recorded data values are stored at this moment.

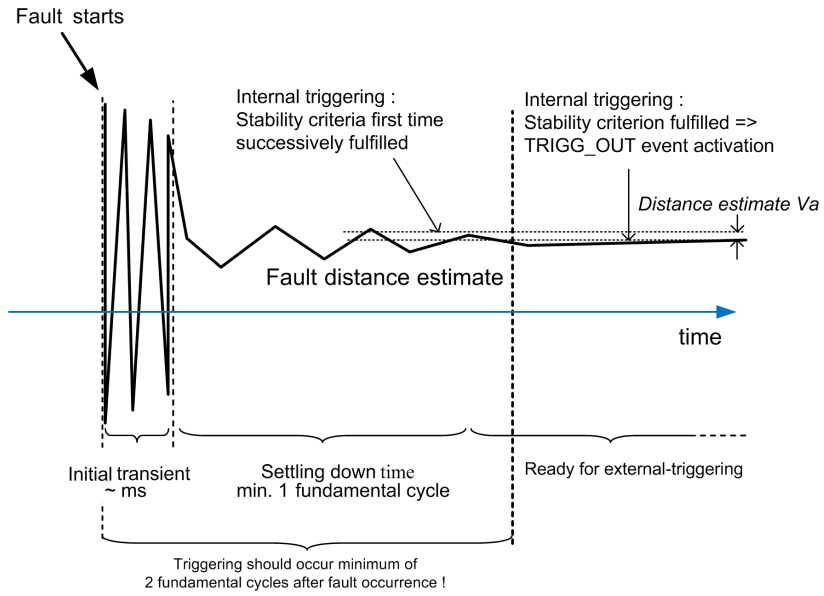

Figure 607: The behavior of fault distance estimate in time

Alarm indication

SCEFRFLO contains an alarm output for the calculated fault distance. If the calculated fault distance FLT_DISTANCE is between the settings *Low alarm Dis limit* and *High alarm Dis limit*, the ALARM output is activated. If setting *High alarm Dis limit* has been set below *Low alarm Dis limit*, the ALARM operation is inverted: the ALARM output is activated if *High alarm Dis limit* is undershot or *Low alarm Dis limit* is exceeded. The default value for both is zero so that no distance estimate activates ALARM.

The ALARM output can be used, for example, in regions with waterways or other places where knowledge of certain fault locations is of high importance.

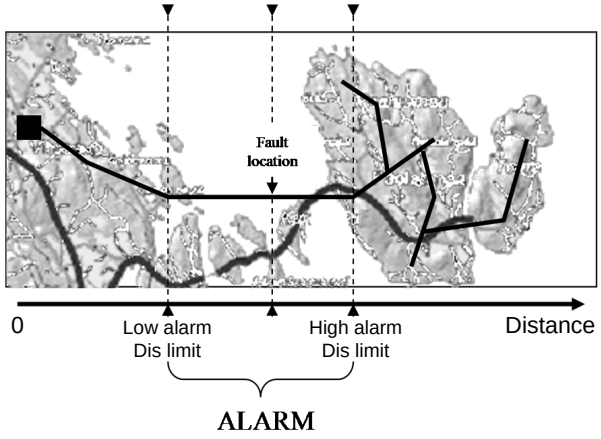

Figure 608: An example of the ALARM output use

Recorded data

All the information required for a later fault analysis is recorded to SCEFRFLO recorded data. In the protection relay, recorded data is found in **Monitoring/ Recorded data/Other protection/SCEFRFLO**.

SCEFRFLO has also monitored data values which are used for the readout of continuous calculation values. Table 1049 shows which of the recorded data values are available as continuous monitoring values during a fault.

Table 1049: Recorded and monitored data values

Recorded data	Monitored data
Flt loop	FAULT_LOOP
Flt distance	FLT_DISTANCE
Flt Dist quality	FLT_DIST_Q
Flt loop resistance	RFLOOP
Flt loop reactance	XFLOOP
Flt phase reactance	XFPHASE

Flt to Lod Cur ratio	IFLT_PER_ILD
Equivalent load Dis	S_CALC
XC0F Calc	XC0F_CALC

5.7.6 Measurement modes

The full operation of SCEFRFLO requires that all three phase-to-earth voltages are measured. The voltages can be measured with conventional voltage transformers or voltage dividers connected between the phase and earth (*VT connection* is set to "Wye"). Another alternative is to measure phase-to-phase voltages (*VT connection* is

set to "Delta") and residual voltage (Uo). Both alternatives are covered by setting the configuration parameter *Phase voltage Meas* to "Accurate".

The function can operate correctly with only two phase-to-earth voltages if the residual voltage is also measured and connected to the source UTVTR which provides the phase-to-earth voltages to the function. In this case, the missing phase-to-earth voltage is correctly calculated internally in the relay. If the measured residual voltage is connected to SCEFRFLO input URES, *Phase voltage Meas* can be set to "Accurate".

When the *Phase voltage Meas* setting is set to "Ph-to-ph without Uo" and only phase-to-phase voltages are available (but not Uo), only short-circuit measuring loops (fault loops “AB Fault”, “BC Fault”, “CA Fault” or “ABC Fault”) can be measured accurately. In this case, the earth-fault loops (fault loops “AG Fault”, “BG Fault” or “CG Fault”) cannot provide correct fault distance estimates and the triggering of the function in case of an earth fault is automatically disabled. The situation is similar if only two phase-to-earth voltages are measured and the measured residual voltage is not connected to SCEFRFLO.

5.7.7 Application

The main objective of the feeder terminals is a fast, selective and reliable operation in case of faults inside the protected feeder. In addition, information on the distance to the fault point is very important for those involved in operation and maintenance. Reliable information on the fault location greatly decreases the downtime of the protected feeders and increases the total availability of a power system.

SCEFRFLO provides impedance-based fault location. It is designed for radially operated distribution systems and is applicable for locating short circuits in all kinds of distribution networks. Earth faults can be located in effectively earthed and low-resistance/low-reactance earthed networks. With certain limitations, SCEFRFLO can also be used for locating an earth fault in unearthed distribution networks.

Configuration example

A typical configuration example for SCEFRFLO triggering is illustrated in Figure 604 where external triggering is applied, that is, *Calculation Trg mode* is set to "External".

The OPERATE signal from the non-directional overcurrent function PHLPTOC is used to provide an indication of a short circuit fault. The OPERATE signal from the directional earth-fault function DEFLPDEF is used to provide an indication of an earth fault at the protected feeder.

SCEFRFLO with the autoreclosing function

When SCEFRFLO is used with the autoreclosing sequence, the distance estimate from the first trip is typically the most accurate one. The fault distance estimates from successive trips are possible but accuracy can be decreased due to inaccurate load compensation. During the dead time of an autoreclosing sequence, the load condition of the feeder is uncertain.

The triggering of SCEFRFLO can also be inhibited during the autoreclosing sequence. This is achieved by connecting the signal ACTIVE from the autoreclosing function DARREC, which indicates that the autoreclosing sequence is in progress, to the BLOCK input of SCEFRFLO. Blocking of the SCEFRFLO triggering is indicated during the autoreclosing sequence when the load compensation or steady-state asymmetry elimination is based on the delta quantities. This applies to the short circuit faults when *Load Com PP loops* is set to "Enabled" or, to earth faults, when *EF algorithm Sel* is set to "Load compensation" or "Load modelling".

Switch-onto-fault protection	CVPSOF	CVPSOF	SOFT

5.8.2 Function block

Figure 609: Function block

5.8.3 Functionality

The switch-onto-fault function CVPSOF is a complementary function, especially to the distance protection function (DSTPDIS), but it can also be used to complement the non-directional or directional overcurrent protection functions (PHxPTOC, DPHxPDOC).

CVPSOF accelerates the operation of the protection ensuring a fast trip when the breaker is closed onto faulted feeder or bus. Without CVPSOF the measured voltages may be too small for the impedance zones or the directional overcurrent stages to operate reliably. This condition exists when the voltage transformers are located in the feeder or the bus side to be energized and therefore the voltage memory required for a correct directional measurement is not available.

5.8.4 Analog channel configuration

CVPSOF has two analog group inputs which must be properly configured.

Table 1058: Analog inputs

Input	Description
I3P[1)]	Three-phase currents Necessary when *Operation mode* is other than "Start"
U3P[2)]	Three-phase voltages Necessary when *Operation mode* is other than "Start"

1) Can be connected to GRPOFF if *Operation mode* is set to "Start" and *Automatic SOTF Ini* is set to "DLD disabled" or "Voltage"
2) Can be connected to GRPOFF if *Operation mode* is set to "Start" and *Automatic SOTF Ini* is set to "DLD disabled" or "Current"

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

There are a few special conditions which must be noted with the configuration.

Table 1059: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two phase voltage channels connected but it is recommended to connect all three voltage channels.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.8.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of CVPSOF can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

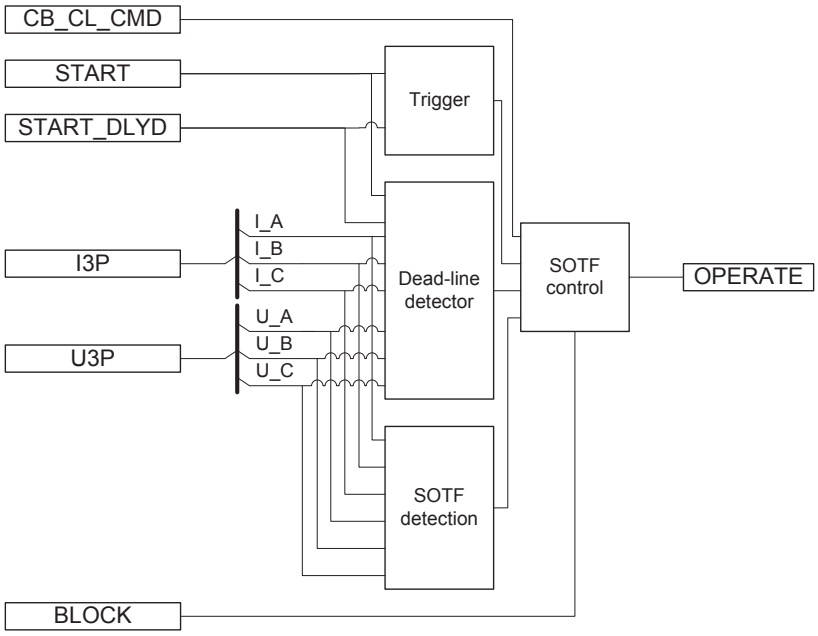

Figure 610: Functional module diagram

Trigger

This module is used for detecting a possible fault immediately after circuit breaker closing. The use of external protection function, typically the start signal from a non-directional distance zone or overcurrent stage, is required for fault indication. The START and START_DLYD inputs are available for the purpose.

- The START input has no delay. Thus, a switch-onto-fault situation is immediately signalled to SOTF control.
- START_DLYD is used when an additional delay is required to start the signal. The switch-onto-fault situation is signalled to the SOTF control after the set *Operate delay time*.

Dead-line detector

The dead line detection should be used only when the voltage transformers are located on the line side of the circuit breaker.

The *Automatic SOTF Ini* setting is used to configure the internal dead line detection function.

Table 1060: Options for dead line detection

Automatic SOTF Ini	Description
DLD disabled	The dead line detection function is disabled. This operation mode must be applied when voltage transformers are located on the bus side of the circuit breaker.
Voltage	The dead line detection function is enabled and based solely on the undervoltage condition. A dead line condition is declared, if all the phase voltages are below the *Voltage dead Lin Val* setting. The dead line is detected if the dead line condition is declared and simultaneously no fault is detected by the START and START_DLYD inputs . The dead line condition is signalled to the SOTF control after the delay defined with the *Dead line time* setting.
Current	The dead line detection function is enabled and based solely on the undercurrent condition. A dead line condition is declared, if all the phase currents are below the *Current dead Lin Val* setting. The dead line is detected if the dead line condition is declared and simultaneously no fault is detected by the START and START_DLYD inputs. The dead line condition is signalled to the SOTF control after delay defined with the *Dead line time* setting.
Current & Voltage	The dead line detection function is enabled and based on undercurrent and undervoltage condition. A dead line condition is declared, if all the phase currents are below the *Current dead Lin Val* setting and simultaneously all phase voltages are below the *Voltage dead Lin Val* setting. The dead line is detected if the dead line condition is declared and simultaneously no fault is detected by the START and START_DLYD inputs. The dead line condition is signalled to the SOTF control after delay defined with the *Dead line time* setting.

SOTF detection

The purpose of this module is to detect the switch onto fault situation based on the current and voltage measurements. If the voltage, in any of the phases, is below the *Voltage dead Lin Val* setting and simultaneously the current in the same phase exceeds the *Current dead Lin Val* setting, the SOTF situation is signalled to SOTF control module after the set *Cur voltage Det time*.

SOTF control

The SOTF control module needs to be activated before the operation is possible in the switch-onto-fault situation. There are two ways to activate the SOTF control module.

- By CB_CL_CMD (circuit breaker closing command)
- By the dead line condition received from the dead line detection module

Dead line detection should be used only when the voltage transformers are located on the line side of the circuit breaker.

When the CB_CL_CMD input is activated or the dead line condition is detected, the SOTF control module becomes active. The reset timer is started when CB_CL_CMD is inactivated or the dead line condition disappears. Thus, the module becomes inactive after the set *SOTF reset time* is exceeded.

When the SOTF control module is active, the *Operation mode* setting defines the operation criteria for the detection of a switch-onto-fault condition. The detection can be based on the external start signals from the distance or overcurrent functions, on the measured internal voltage and current levels, or on both.

Table 1061: Options for SOTF detection

Operation mode	Description
Start	The OPERATE output is activated immediately after a signal from the trigger module. This indicates that the breaker is closed onto fault.
Current & Voltage	The OPERATE output is activated immediately after a signal from the SOTF detection module. This indicates that the breaker is closed onto fault. This operation mode can be used, for example, if the non-directional distance zone is not available.
Both	The OPERATE output is activated immediately after a signal from the trigger or SOTF detection modules. This indicates that the breaker is closed onto fault.

The OPERATE output can be blocked by activating the BLOCK input.

5.8.6 Application

The operation of CVPSOF is generally based on the non-directional distance zone or the non-directional overcurrent stage. When the feeder-side voltage transformers are used for providing the polarization quantity for the distance or directional overcurrent protection, the use of non-directional impedance or current based protection for starting CVPSOF secures a fast switch-onto-fault tripping in the close-in three-phase short circuits. The non-directional protection provides a fast fault clearance when the protection is used for energizing a bus from the feeder with a short circuit fault in it. Other protection functions, like time delayed zero-sequence overcurrent functions, can be connected to CVPSOF to increase the dependability of the scheme. The other main advantage of using CVPSOF is that it typically accelerates the tripping in case of energizing a feeder onto a fault. Without CVPSOF, this tripping is normally performed by the normal time-graded protection or alternatively by the time-delayed local backup protection, for which operating times are considerably longer than with CVPSOF tripping.

An internal dead line detection check is provided to activate the function when the voltage transformers are located on the feeder side. An initiation by the dead line detection is highly recommended for the busbar configurations where more than one circuit breaker at one feeder end can energize the protected feeder or the feeder can also be energized from the other end.

Setting guidelines

Input START: If a distance zone is used for starting the switch-onto-fault function, the zone has to be set to cover the entire protected feeder with a safety margin of minimum 20 percent. If the non-directional zone is not available, the internal *Current & Voltage* criterion or the start signal from the GFC function can be used instead. If a non-directional overcurrent is used for starting, the current setting must not be higher than what is required for the non-delayed and dependable tripping for a close-in three-phase fault during minimum source conditions. If the short-circuit current along the feeder is considerably higher than the maximum load currents, it is possible that the whole feeder length is covered by CVPSOF tripping. If it is required to delay the tripping, for example, due to high inrush currents, the starting signal can be connected to the START_DLYD input instead.

The *Current dead Lin Val* setting parameter is set to 20 percent of the base current by default. The parameter must be set with a sufficient margin of 15...20 percent under the minimum expected load current. The setting must still exceed the maximum charging current of a feeder.

The *Voltage dead Lin Val* setting parameter is set to 70 percent of the base voltage by default. This is a suitable setting in most cases, but it is recommended to check the suitability in the actual application.

The *Cur voltage Det time* setting parameter is set to 0.02 seconds by default. This is suitable in most applications. This delay can be coordinated, for example, with the dead time settings of the AR shots to prevent the release of CVPSOF by the dead line detection function when the high-speed autoreclosing is in progress.

The *Dead line time* setting parameter is set to 0.2 seconds by default. This is suitable in most applications. The delay must not be set too short to avoid unwanted activations during the transients in the system.

The *SOTF reset time* setting parameter is set to 1 second by default. This is suitable for most applications.

5.9 Local acceleration logic DSTPLAL

5.9.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Local acceleration logic	DSTPLAL	LAL	21LAL

5.9.2 Function block

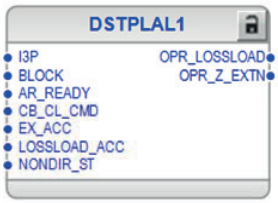

Figure 611: Function block

5.9.3 Functionality

The local acceleration logic function DSTPLAL is a complementary function to the distance protection function DSTPDIS. DSTPLAL is not intended for a stand-alone use.

The main purpose of DSTPLAL is to achieve a fast fault clearing which is independent of the fault location on the protected feeder when no communication channel is available between the local and remote terminals. DSTPLAL enables a fast fault clearing during certain conditions, but the function cannot completely replace the communication scheme logic.

DSTPLAL can be controlled either by the autorecloser (zone extension logic) or by monitoring the loss of load currents (the loss of load logic). Both operation modes are enabled independently.

5.9.4 Analog channel configuration

DSTPLAL has one analog group input which must be properly configured.

Table 1068: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.9.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of DSTPLAL can be described with a module diagram. All the modules in the diagram are explained in the next sections.

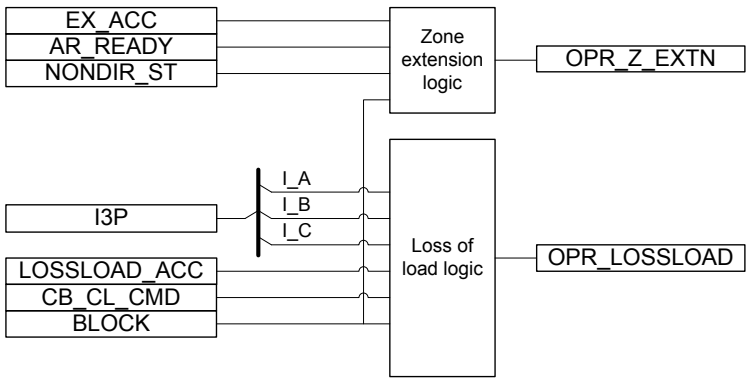

Figure 612: Functional module diagram

Zone extension logic

Zone extension logic is enabled with *Operation mode* = "Zone extension".

When the zone extension operation mode is enabled, the autoreclosing function DARREC enables a fast fault clearance that covers the entire length of the protected feeder. This is achieved by allowing a time-delayed overreaching zone to trip instantaneously when a fault occurs. For this purpose, one of the DSTPDIS zones can be configured with an independently set reach.

After the overreaching zone instantaneously trips, the autoreclosing sequence starts. If the fault is transient, the system may get restored in the first shot of AR. However, in case of a persistent fault only the first trip of the AR sequence is accelerated by Zone extension logic. During the rest of the sequence, Zone extension logic is blocked and AR initiation is performed selectively by the time-graded distance zones.

If the fault is located on the adjacent feeder or bus within the reach of the overreaching zone, tripping and AR initiation take place in an external fault.

Zone extension logic can be described using a module diagram.

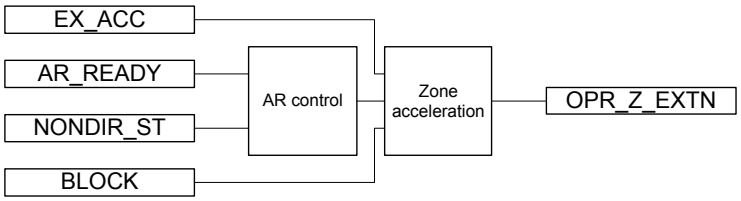

Figure 613: Functional module diagram of Zone extension logic

AR control

The AR control module supervises the zone acceleration by monitoring the status of the AR_READY and NONDIR_ST input signals. The READY output signal from the autorecloser (AR) function, which indicates the status of the autoreclosing, is connected to the AR_READY input. The start signal from the non-directional zone is connected to the NONDIR_ST input. If the non-directional zone is not available for this, then the start output from the overreaching zone with the biggest reach or GFC can be used instead.

The permission for zone acceleration is given if AR_READY = TRUE, that is, the AR function is ready to start a new AR sequence. If the set reclaim time of the AR function expires before the fault is cleared, the NONDIR_ST input signal is used to block the activation of the zone acceleration. This ensures that the accelerated trip followed by the AR initiation is not repeated for the same fault regardless of the reclaim time setting and the reach of the overreaching zone connected to the EX_ACC input. Otherwise, this could lead to pumping of the circuit breaker, that is, the repetition of the first shot without being able to complete the desired AR sequence.

The AR control module blocks the Zone acceleration module after the initiation of the first shot until the AR sequence has been completed, that is, until the AR_READY input signal changes its state back from FALSE to TRUE.

Zone acceleration

The start signal from the overreaching zone whose operation is to be accelerated is connected to the EX_ACC input. When the EX_ACC input is activated and, simultaneously, the AR control module gives permission for acceleration, the operate signal from Zone extension logic is obtained from the OPR_Z_EXTN output, which is used to trip the circuit breaker and initiate the autoreclosing (the AR shot).

The activation of the BLOCK input blocks the OPR_Z_EXTN output.

Loss of load logic

Loss of load logic is enabled with *Operation mode* = "Loss of load".

When the loss of load operation mode is enabled, a time-delayed overreaching zone is allowed to trip instantaneously if the loss of load current condition is detected.

The loss of load function does not operate in case of a three-phase fault as all the phases are faulty. Therefore, none of the current values drops below the *Minimum current* setting, meaning that the loss of load current condition cannot be detected.

Loss of load logic can be described using a module diagram.

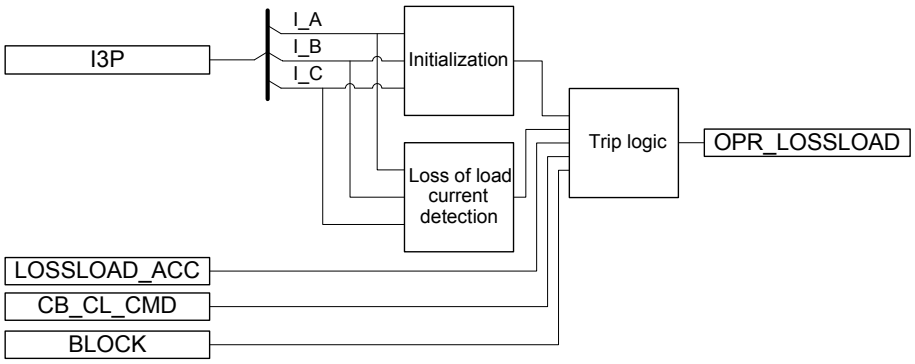

Figure 614: Functional module diagram of Loss of load logic

Initialization

The Initialization module gives an enabling signal to the Trip logic module when the values of all three phase currents are above the set value of *Load current value* for

more than the time set with *Load release on time*. The enabling signal has a drop-off delay defined with the *Load release off Tm* setting.

Loss of load current detection

The Loss of load current detection module gives an enabling signal to the Trip logic module if any of the phase current values drops below the *Minimum current* setting due to a remote end breaker opening and, simultaneously, the value of at least one phase current exceeds the value of the *Load current value* setting due to a fault. Such a condition has to be valid for longer than the *Minimum current time* setting.

Trip logic

The operate signal is obtained from the OPR_LOSSLOAD output if the enable signal is received from both Initialization and Loss of load current detection modules and, simultaneously, a fault is seen by the overreaching zone connected to the LOSSLOAD_ACC input.

The activation of the BLOCK input blocks the OPR_LOSSLOAD output. Temporary blocking is achieved using the circuit breaker's close command pulse connected to the CB_CL_CMD input. It is used to prevent an unwanted operation due to initial transients after the breaker is closed, for example, in case of inrush currents.

5.9.6 Application

DSTPLAL is used in those applications where the conventional communication scheme logic cannot be applied (when no communication channel is available), but the user still requires a fast clearance for the faults on the entire feeder.

DSTPLAL enables a fast fault clearing during certain conditions, but it is unable to replace the communication scheme logic due to a possible lack of selectivity during the first trip and AR initiation and also as the loss of load logic cannot operate for three-phase faults. DSTPLAL is controlled either by the autoreclosing (Zone extension logic) or by monitoring the loss of load current (Loss of load logic).

Zone extension logic

The zone extension operation mode can be applied when the autoreclosing function DARREC is in operation. When the zone extension is enabled, DARREC is used to enable the fast fault clearance independent of the fault location on the protected feeder. This is achieved by allowing a time-delayed overreaching zone to trip instantly when a fault occurs. Also, if there are tapped loads on the protected feeder, it is required to set a dedicated zone to initiate one or two shots as fast as possible before the protection devices of these taps clear. If the fault is still present after these shots, further tripping is delayed in accordance with the other zones so that the operation becomes slower than the protection of the load taps, enabling it to clear. The final tripping that ends the sequence is always performed selectively according to the time grading of the zones.

If the fault is located on the adjacent feeder or bus within the reach of the overreaching zone, the tripping and the AR initiation take place during an external fault.

Setting guidelines

The *Load current value* setting must be set below the minimum three-phase load current during the healthy state. A security factor of 0.5 is used:

$$\textit{Load current value} = 0.5 \cdot I_{minload}$$

$I_{minload}$ minimum load current during normal operation conditions

The loss of load function is released after *Load release on time* is elapsed and the load current in all three phases is above the *Load current value* setting. If the current values drop below the *Load current value* setting, the release condition stays activated until the drop-out delay time has expired (the *Load release off Tm* setting). The value of *Load release off Tm* is by default set to "0.3 s". The *Load release on time* setting is used to increase the security of the loss of load function, for example, in the case of transient inrush currents during the energizing of a power transformer. When there is no need for delaying the release, the *Load release on time* is set to zero in applications.

The *Minimum current* setting is used to detect the loss of load condition in healthy phases during the fault. The *Minimum current* setting is set to a value higher than the maximum current flowing in the healthy phases during the fault when the breaker at the remote end has been opened and the load flowing through has therefore been disconnected. This current can be, for example, due to the charging current of the phases or the load current of the tapped loads. The *Minimum current* setting value is set below the *Load current value* setting. By default, the *Minimum current* setting value is set to "0.05 pu".

The *Minimum current time* setting is used to provide the start delay for the loss of load current detection to avoid an unwanted release of the function. The value of *Minimum current time* is by default set to "0.2 s".

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Scheme communication logic	DSOCPSCH	CL	85 21SCHLGC

5.10.2 Function block

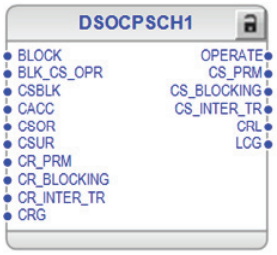

Figure 615: Function block

5.10.3 Functionality

The scheme communication logic function DSOCPSCH is used to achieve instantaneous fault clearing independent of the fault location on the protected feeder. Several communication scheme types are available.

- Direct underreaching transfer trip DUTT
- Permissive underreaching transfer trip PUTT
- Permissive overreaching transfer trip POTT
- Directional comparison blocking scheme DCB

The directional comparison unblocking scheme DCUB can also be implemented by complementing the permissive schemes with an additional logic called the unblocking function, which is also included in DSOCPSCH.

If the permissive overreach scheme is used, some of the power system conditions require additional special logic circuits, such as the current reversal and weak-end infeed logic function CRWPSCH.

5.10.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of DSOCPSCH can be described with a module diagram. All the modules in the diagram are explained in the next sections.

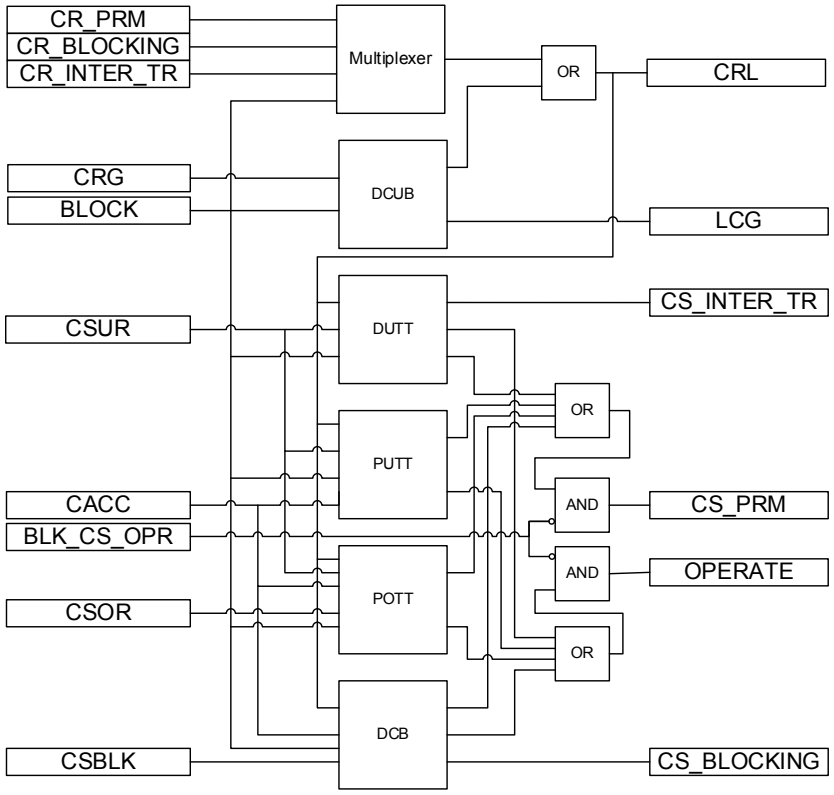

Figure 616: Functional module diagram

The applied communication scheme logic in DSOCPSCH is selected with the *Scheme type* setting.

Table 1074: Communication scheme based on the Scheme type value

Scheme type value	Communication scheme
"Intertrip"	DUTT
"Permissive Underreach"	PUTT
"Permissive Overreach"	POTT
"Blocking"	DCB

The unblocking scheme (DCUB) is enabled with the *Unblock Mode* setting.

Multiplexer

The multiplexer connects an input signal to an output based on the value of the *Scheme type* setting.

Table 1075: Connected inputs based on the Scheme type value

Scheme type value	Inputs connected to an output
"Intertrip"	CR_INTER_TR
"Permissive Underreach" or "Permissive Overreach"	CR_PRM
"Blocking"	CR_BLOCKING

Direct underreaching transfer trip scheme DUTT

The direct intertrip scheme is enabled with *Scheme type* = "Intertrip".

In the direct intertrip scheme, the start signal from the underreaching zone Z1 is connected to the CSUR input to create a carrier send CS_INTER_TR signal. The duration of the CSUR input signal is prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration for the CS_INTER_TR signal.

The local circuit breaker is directly tripped (activation of the OPERATE output) with the carrier received CR_INTER_TR signal after a settable pick-up delay *Coordination Time* has elapsed without further local criteria.

The unblocking function (*Unblock Mode* = "Permanent" and *Unblock Mode* = "Time window") must not be enabled with the DUTT scheme, as the lost guard signal results in an immediate trip of the local circuit breaker.

The activation of the BLOCK input totally blocks the direct intertrip scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

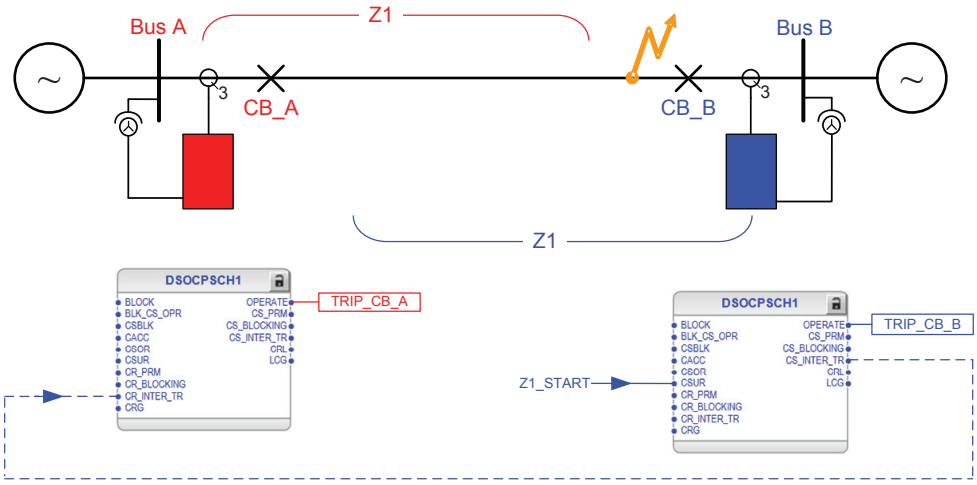

Figure 617: Simplified functional diagram of the direct intertrip scheme

Permissive underreaching transfer trip scheme PUTT

The permissive underreach scheme is enabled with *Scheme type* = "Permissive Underreach".

In the permissive underreach scheme, the start signal from the underreaching zone Z1 is connected to the CSUR input to create a CS_PRM signal. The duration of the CSUR input signal can be prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_PRM signal.

In the permissive underreach scheme, the CR_PRM signal, or the CRL signal if the unblocking function is enabled, is used to allow the overreaching zone Z2 to trip (activation of the OPERATE output) after the pick-up delay *Coordination Time*. The start signal from the overreaching zone Z2 is connected to the CACC input.

Activating the BLOCK input totally blocks the permissive underreach scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

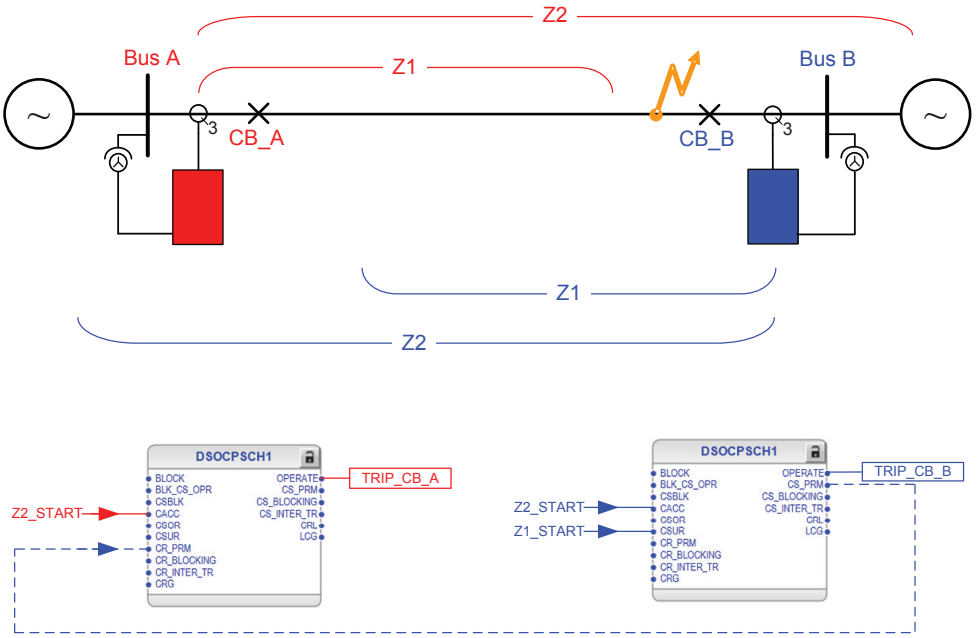

Figure 618: Simplified functional diagram of the permissive underreach scheme

Permissive overrreaching transfer trip scheme POTT

The permissive overreach scheme is enabled with *Scheme type* = "Permissive Overreach".

In this scheme, the start signal from the overreaching zone Z2 is connected to the CSOR input to create a CS_PRM signal. The CS_PRM signal can also be issued simultaneously from the underreaching zone Z1. In this case, the start signal from the underreaching zone Z1 is connected to the CSUR input. The duration of the CSUR input signal is prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_PRM signal.

In case of parallel feeders, and when the external current reversal logic (CRWPSCH) is enabled, the CS_PRM signal is not prolonged and the value of *Carrier Min Dur* is set to zero to secure correct operation.

In the permissive overreach scheme, the received signal CR_PRM, or CRL if the unblocking function is enabled, is used to allow the overreaching zone Z2 to trip (activation of the OPERATE output) after the settable pick-up delay *Coordination Time*. The start signal from the overreaching zone is connected to the CACC input.

Activating the BLOCK input totally blocks the permissive overreach scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

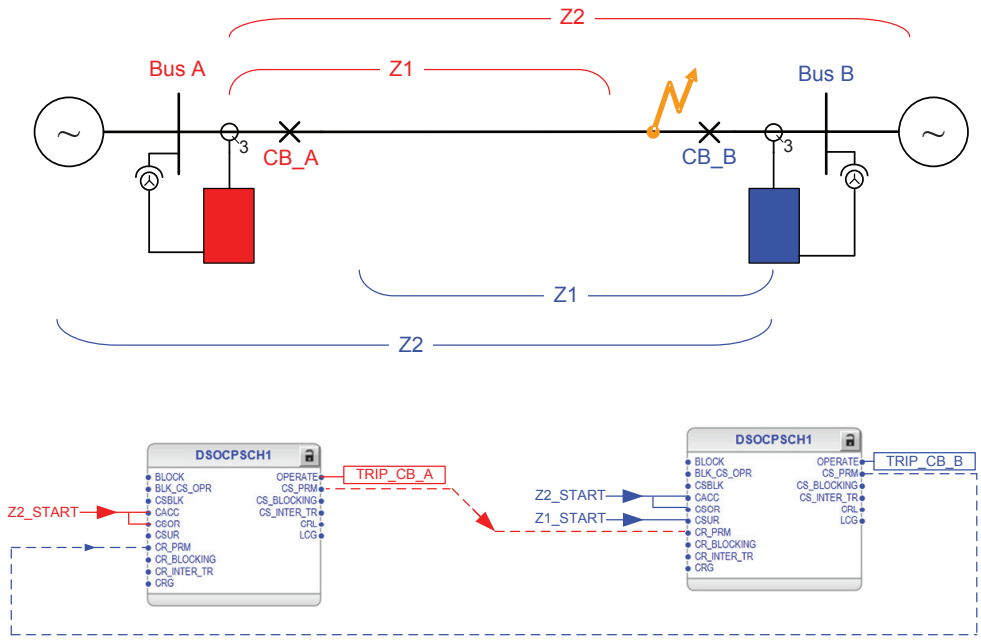

Figure 619: Simplified functional diagram of the permissive overreach scheme

Directional comparison blocking scheme DCB

The directional comparison blocking scheme is enabled with *Scheme type* = "Blocking".

In the blocking scheme, the start signal from the reverse-looking zone Z3 is connected to the CSBLK input to create a CS_BLOCKING signal. The starting of the reverse-looking zone indicates that the fault is located outside the protected feeder. The duration of the CSBLK input signal can be prolonged with the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_BLOCKING signal.

The blocking scheme is mainly used to allow the overreaching zone Z2 to trip (activation of the OPERATE output) after the settable *Coordination Time* has elapsed, and if no blocking signal is received from the remote terminal. To prevent a false trip in case of an external fault, the block signal CR_BLOCKING must be received before the *Coordination Time* has elapsed. The start signal from the overreaching zone Z2 is connected to the CACC input.

The *Coordination Time* setting in the blocking scheme depends, for example, on the communication system delay and on the terminal's response times in transmitting the CS_BLOCKING signal to the other feeder end. The *Coordination Time* setting must not be zero.

Activating the BLOCK input totally blocks the directional comparison blocking scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

In Figure 620, in case of internal faults, the CS_BLOCKING signal is not sent because the fault is not sent as it is not seen by the reverse-looking zones (Z3).

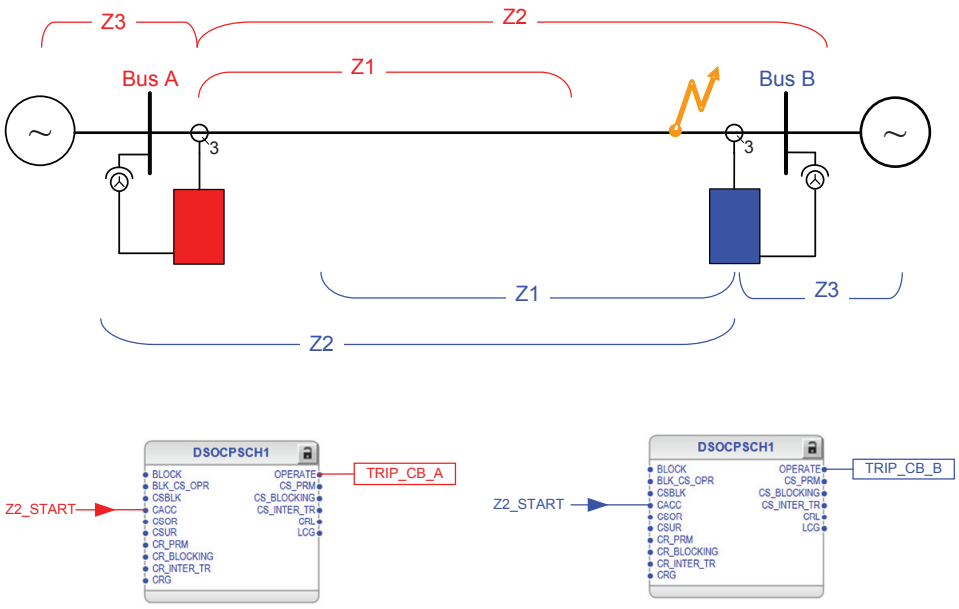

Figure 620: Simplified functional diagram of the blocking scheme, internal fault

In Figure 621, in case of external faults, the protection relay at bus B sees the fault in the reverse direction and sends a blocking signal CS_BLOCKING to the protection relay at bus A. There is no CB operation at either end.

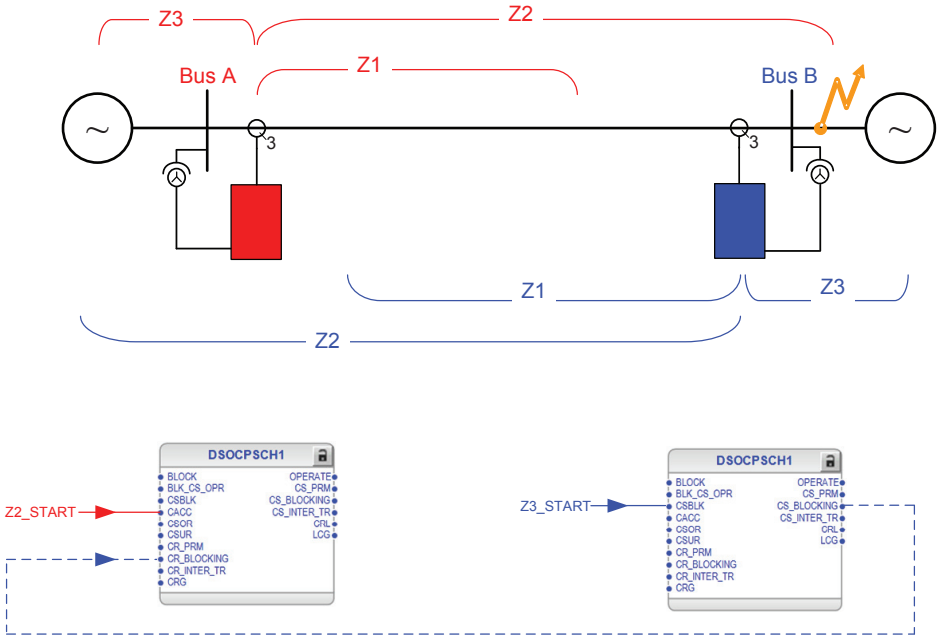

Figure 621: Simplified functional diagram of the blocking scheme, external fault

The unblocking function used with the blocking function provides a possibility to supervise the communication channel. In this case, the CRL output signal is used as a local blocking signal.

The operation mode *Unblock Mode* = "Time window" is not recommended as the blocking is activated only for 150 ms after the guard signal disappears. This results in an unwanted operation of the protection.

Directional comparison unblocking scheme DCUB

The unblocking function is a complementary logic which can be used together with the permissive communication schemes. In the unblocking scheme, the dependability of the permissive schemes is improved by using the loss of guard signal from the communication equipment to create a CRL output signal locally. This enables the permissive scheme to operate even if the communication channel is interrupted or lost.

The unblocking function uses a carrier guard signal which must always be present. The absence of the CRG signal for a time longer than the value of the *Loss of carrier time* setting generates a logical CRL signal. A communication failure shorter than the value of the *Loss of carrier time* setting is always ignored.

The unblocking function is configured with the *Unblock Mode* setting.

- *Unblock Mode* = "Off": The unblocking function is disabled.
- *Unblock Mode* = "Permanent": If the CRG signal disappears for a longer time than defined in the *Loss of carrier time* setting, the logical CRL signal is generated. The CRL output signal remains active until the CRG signal reappears. The communication failure is not signaled by the LCG output.
- *Unblock Mode* = "Time window": If the CRG signal disappears for a longer time than defined in the *Loss of carrier time* setting, the CRL output signal is generated. The CRL output signal remains active for 150 ms, after which a communication failure is signaled by the LCG output. The LCG output is reset 200 ms after the CRG signal reappears. The purpose of this mode is to ensure tripping during a fixed delay of 150 ms after the loss of communication due to possible consequences of an internal fault. After this time, the accelerated tripping is allowed only if the CR_PRM signal is received again.

With operation modes *Unblock Mode* = "Permanent" and *Unblock Mode* = "Time window", the created CRL output signal is internally ORed with the CR_PRM input to allow the permissive scheme to operate even when the communication channel has been interrupted or lost. The CRL and LCG output signals are also available as outputs for monitoring purposes. Activating the BLOCK input blocks the CRL and LCG outputs.

5.10.5 Application

To achieve fast fault clearing on the part of the protected feeder not covered by the instantaneous zone Z1, the stepped distance protection function can be used with DSOCPSCH.

Applying DSOCPSCH requires a communication channel capable of transmitting an "On" or "Off" signal in each direction. To enable fast tripping, the most important requirement for the communication channel is the communication speed.

The performance of DSOCPSCH is directly related to the communication channel speed, and to the security against false or lost signals. Therefore, dedicated communication channels are recommended. With short distances of up to a few kilometers, a typical communication media is a simple pilot wire based on auxiliary power. With distances of up to 50 km with the integrated communication interface or up to 150 km with external equipment, fibre-optic cables using digital data transmission can be used. To avoid false signals causing unwanted operation, the security of the communication channel should be emphasized. Also, the dependability of the communication channel should be considered to ensure that the signals are reliably transmitted during the power system faults.

DSOCPSCH supports five communication schemes.

- Direct underreaching transfer trip DUTT
- Permissive underreaching transfer trip PUTT
- Permissive overreaching transfer trip POTT
- Directional comparison blocking scheme DCB
- Directional comparison unblocking scheme DCUB

Depending on whether the communication channel is used for sending a block or a trip signal, the communication schemes can be divided into blocking schemes and permissive schemes.

In permissive schemes, the trip signals of the distance zones are interchanged between the terminals to receive a permission to trip during an internal fault. The tripping of the local terminal depends on both the starting of its own forward-looking zone and on the received signal from the opposite terminal. In the underreaching scheme, no signals are sent during an external fault. During an external fault, a trip signal is also sent to the opposite terminal if the fault is seen in the forward direction and the overreaching scheme is used. However, in case of external faults, tripping is always blocked because either no signal is received as the opposite terminal sees a reverse fault or because the signal is received but the fault is seen in the reverse direction. In either case, the blocking is not dependent on the received signal so a lost communication channel does not result in false operation.

In the blocking scheme, a blocking signal is sent to the opposite terminal if the fault is locally seen in the reverse direction, that is, during an external fault. Thus, the blocking is dependent on the received signal, and there is typically a need to delay the tripping of the terminal receiving the blocking signal. This delay depends, for

example, on the response times of the communication channel and terminals. During an internal fault, there is no signal transmission between the terminals, so the tripping does not depend on the received signal from the opposite terminal.

In conclusion, compared to the blocking schemes, the permissive schemes are inherently faster and have better security [1] against false tripping, since tripping in an external fault is not possible in case of a channel interruption. In a blocking scheme, a lost communication channel and a simultaneous external fault may lead to a false operation of the protection if the communication channel is not supervised. On the other hand, as the fast trip of the permissive scheme depends on the received signal, its dependability [2] is lower than that of the blocking scheme.

The unblocking scheme enhances the dependability of the permissive scheme. If the communication channel is interrupted and, simultaneously, a fault occurs in the forward direction, tripping is still possible either during a fixed time interval, counting from the beginning of the interruption, or for as long as the communication channel is lost. This is achieved by connecting the supervision output of the implemented communication functionality to the dedicated carrier guard signal input of DSOCPSCH. In general, the unblocking scheme provides better security than the blocking scheme because tripping in external faults is only possible if the fault occurs within the fixed time interval after the beginning of the channel interruption.

The direct transfer trip scheme uses the underreaching zone to trip the local breaker and to transfer the trip signal to a remote terminal. The remote terminal operates immediately based on the received transfer trip signal, without any additional conditions. This scheme is very simple, but the security is low as a spurious signal results in false operation of the protection.

Direct underreaching transfer trip DUTT

In some applications, there is a need to trip the remote-end breaker immediately because of fault detection by the local measurements. This applies, for example, when the transformers or reactors are connected to the system without circuit breakers, or for remote tripping after the operation of the local breaker failure protection (CBFP).

In the direct intertrip scheme (DUTT), the carrier send signal `CS_INTER_TR` is initiated by an underreaching zone, or by the tripping signal from an external protection relay, such as transformer or reactor protection. At the remote end, the received signal initiates a breaker trip immediately without any further local protection criteria. To limit the risk of an unwanted trip due to spurious sending of signals, the trip can be delayed by the *Coordination Time* setting, which should be set to 10...30 ms, depending on the type of the communication channel. The communication channel operating in direct intertripping applications should be secure and dependable.

Setting guidelines for the intertrip scheme DUTT

Scheme type = "Intertrip"

[1] The ability to block operation in case of an external fault
[2] The ability to operate in case of an internal fault

Coordination Time = "0.050" s (10 ms + maximal transmission time)

Carrier Min Dur = "0.1" s

Permissive underreaching transfer trip PUTT

In the permissive underreach scheme, the permission to trip is obtained locally from the underreaching zone and sent to the remote end. The received signal is combined with the local fault indication from the overreaching zone resulting in a trip command after a settable pick-up delay *Coordination Time*.

The protection relay of either feeder end sends a permissive signal to trip the other end. The communication channel must be able to receive and transmit at the same time. In permissive schemes, the communication channel must be fast and secure, but also dependable. Inadequate security causes unwanted tripping for the external faults. Inadequate speed or dependability causes delayed tripping for internal faults.

The `CS_PRM` signal is issued based on the underreaching zone Z1.

The underreach scheme is not applicable on short feeder lengths because the impedance measurement cannot easily distinguish between the internal and external faults in such cases.

The underreaching zones Z1 at the local and remote ends must overlap to prevent a gap between the protection zones, where the faults are not detected. If the underreaching zone does not meet the required sensitivity, for example, the fault infeed from a remote end, the blocking or permissive overreach scheme is considered.

To achieve an instantaneous trip, the carrier received signal `CR_PRM` must be received when the overreaching zone Z2 is still starting. In some cases, due to a fault in current distribution, the overreaching zone can operate only after the fault has been cleared by the remote terminal. In this case, there is a risk that if the remote terminal is tripped directly by, for example, zone Z1, the `CS_PRM` signal issued by the zone resets before the overreaching zone of the local end terminal has operated. To assure a sufficient duration of the `CR_PRM` signal, the `CS_PRM` signal can be prolonged by the time *Carrier Min Dur*. The recommended value of the *Carrier Min Dur* setting is "0.1" s.

The received communication signal is combined with the output from the local overreaching zone. Therefore, there is less concern about a false signal causing an incorrect trip, and therefore the timer *Coordination Time* is set to "0". A communication channel failure does not affect the selectivity, but delays the tripping at the other end for certain fault locations.

Setting guidelines for the permissive underreach scheme PUTT

Scheme type = "Permissive Underreach"

Coordination Time = "0" s

Carrier Min Dur = "0.1" s

Permissive overreaching transfer trip POTT

In the permissive overreach scheme, the permission to trip is obtained locally from an overreaching zone and sent to the remote end. The received signal is then combined with the local fault indication from the overreaching zone, resulting in a trip command after a settable pick-up delay *Coordination Time*.

The protection relay at either end of the feeder sends a permissive signal to trip the other end. Therefore the communication channel must be able to receive and transmit at the same time. The communication on permissive schemes should be fast and secure.

The CS_PRM signal is issued based on the overreaching zone Z2.

The permissive overreach scheme can be used for all feeder types and lengths.

In the permissive overreach scheme, the communication channel plays an essential role in obtaining a fast tripping at both ends. Typically, a lost communication channel does not cause false tripping. However, it delays the operation of the protection for the faults anywhere on the feeder.

The communication channel for a permissive overreach scheme must be fast and secure, but also dependable. Inadequate security can cause unwanted tripping for external faults. Inadequate speed or dependability can cause delayed tripping for internal faults.

In the permissive overreaching scheme, the CS_PRM signal can be issued in parallel both from the overreaching and underreaching zones. The CS_PRM signal from the overreaching zone must not be prolonged, while the CS_PRM signal from the underreaching zone must typically be prolonged. In parallel feeder applications, the scheme typically needs to be complemented by the current reversal logic. To ensure the correct operation in this case, the CS_PRM signal must not be prolonged (*Carrier Min Dur* = "0" s). There is no need to delay the tripping while receiving the carrier signal, so the timer *Coordination Time* is set to "0".

Setting guidelines for the permissive overreaching transfer trip scheme POTT

Scheme type = "Permissive Overreach"

Coordination Time = "0" s

Carrier Min Dur = "0.1" s

Carrier Min Dur = "0" s (in case of parallel lines and current reversal logic)

Directional comparison blocking scheme DCB

In the blocking scheme, the reverse-looking zone Z3 is used for sending a block signal to the remote end to block the overreaching zone.

The blocking scheme is very dependable because it operates on faults anywhere on the protected feeder, even if the communication channel is out of service. Conversely, it

is less secure than a permissive scheme because it trips for the external faults within the reach of the overreaching local zone if the communication channel is out of service and no block signal is received.

Inadequate speed or low dependability of the communication channel can cause spurious tripping for external faults.

To secure that the blocking signal arrives before the local overreaching zone trips, the trip is delayed by the *Coordination Time* setting. This setting must be set longer than the sum of the maximal transmission time of the channel and the start and response times of the protection relays sending and receiving the CS_BLOCKING signal. A security margin of at least 10 ms should be considered. The time delay *Carrier Min Dur* for prolonging the CS_BLOCKING signal is set to "0".

Setting guidelines for the blocking scheme DCB

Scheme type = "Blocking"

Coordination Time = "0.1" s (10 ms + maximal transmission time)

Carrier Min Dur = "0" s

Directional comparison unblocking scheme DCUB

Metallic communication paths unfavorably affected by fault-generated noise or by other electrical phenomena, such as lightning, are not suitable for conventional permissive schemes that rely on the signal transmitted during a fault in the protected feeder. Principally, the communication media must be properly shielded or otherwise designed to provide an adequate performance during such conditions.

The unblocking scheme can be used to overcome the lower dependability of permissive schemes. The function is used in older, less reliable communication, where the signal has to be sent through the primary fault. The unblocking function uses a carrier guard signal CRG which must always be present, even when no CR_PRM signal is received. Due to the absence of the CRG signal during the security time, the *Loss of carrier time* setting is used as a CR_PRM signal. This also enables a permissive scheme to operate when the communication channel is temporarily lost during an internal fault.

Setting guidelines for the unblocking scheme DCUB

The unblocking function is configured with the *Unblock Mode* setting.

- *Unblock Mode* = "Off": The unblocking function is disabled.
- *Unblock Mode* = "Permanent": If the CRG signal disappears for a longer time than defined in the *Loss of carrier time* setting, a logical carrier received signal CRL is generated. The CRL signal remains active until the CRG signal is present. The communication failure is not signalled by the LCG output. The *Loss of carrier time* setting is set to "35" ms.
- *Unblock Mode* = "Time window": If the CRG signal disappears for a longer time period than the *Loss of carrier time* setting, a CRL signal is generated. The CRL signal remains active for 150 ms, after which a communication failure is signalled

by the LCG output. The value of the LCG output is reset 200 ms after the CRG signal reappears. The *Loss of carrier time* setting is set to "35" ms.

5.10.6 Signals

Table 1076: DSOCPSCH Input signals

Name	Type	Default	Description
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode
BLK_CS_OPR	BOOLEAN	0=False	Signal for blocking CS and Operate in all schemes
CSBLK	BOOLEAN	0=False	Reverse directed distance protection zone signal for requesting activation of TxBlk
CACC	BOOLEAN	0=False	Permissive distance protection zone signal
CSOR	BOOLEAN	0=False	Overreaching distance protection zone signal
CSUR	BOOLEAN	0=False	Underreaching distance protection zone signal
CR_PRM	BOOLEAN	0=False	Received teleprotection permissive from the other side
CR_BLOCKING	BOOLEAN	0=False	Received teleprotection blocking from the other side
CR_INTER_TR	BOOLEAN	0=False	Received direct trip from the other side
CRG	BOOLEAN	0=False	Carrier guard signal received

Table 1077: DSOCPSCH Output signals

Name	Type	Description
OPERATE	BOOLEAN	Operate
CS_PRM	BOOLEAN	Permissive transmitted to the other side
CS_BLOCKING	BOOLEAN	Blocking transmitted to the other side
CS_INTER_TR	BOOLEAN	Direct trip transmitted to the other side
CRL	BOOLEAN	Carrier received after unblock logic
LCG	BOOLEAN	Loss of guard

Communication logic for residual overcurrent	RESCPSCH	CLN	85 67G/N SCHLGC

5.11.2 Function block

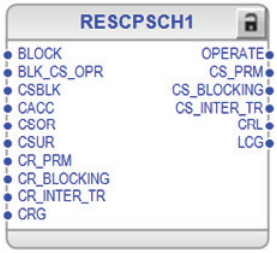

Figure 622: Function block

5.11.3 Functionality

The communication logic for residual overcurrent function RESCPSCH is used to achieve instantaneous fault clearing independent of the fault location on the protected feeder. There are four available communication scheme types.

- Direct underreaching transfer trip DUTT
- Permissive underreaching transfer trip PUTT
- Permissive overreaching transfer trip POTT
- Directional comparison blocking scheme DCB

The directional comparison unblocking scheme DCUB can also be provided by complementing the permissive schemes with an additional logic called the unblocking function, which is also included in RESCPSCH.

If the permissive overreaching scheme is used, some of the power system conditions require additional special logic circuits, such as the current reversal and weak-end infeed logic for residual overcurrent function RCRWPSCH.

5.11.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of RESCPSCH can be described with a module diagram. All the modules in the diagram are explained in the next sections.

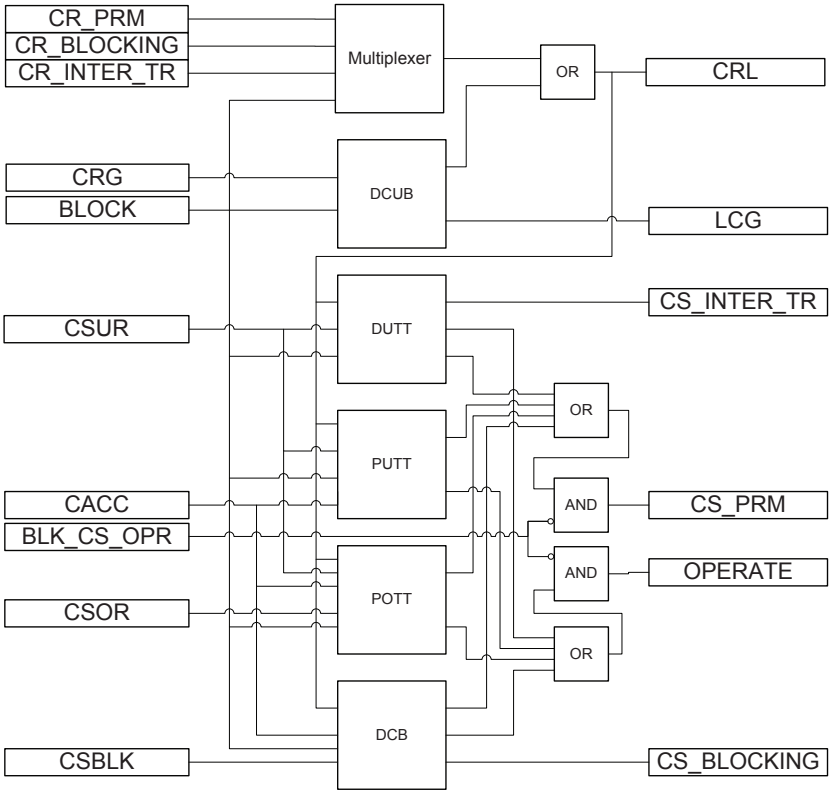

Figure 623: Functional module diagram

The applied communication scheme logic in RESCPSCH is selected with the *Scheme type* setting.

Table 1082: Communication scheme based on the Scheme type value

Scheme type value	Communication scheme
"Intertrip"	DUTT
"Permissive Underreach"	PUTT
"Permissive Overreach"	POTT
"Blocking"	DCB

The unblocking scheme (DCUB) is enabled with the *Unblock mode* setting.

Multiplexer

The multiplexer connects an input signal to an output based on the value of the *Scheme type* setting.

Table 1083: Connected inputs based on the Scheme type value

Scheme type value	Inputs connected to an output
"Intertrip"	CR_INTER_TR
"Permissive Underreach" or "Permissive Overreach"	CR_PRM
"Blocking"	CR_BLOCKING

Direct underreaching transfer trip scheme DUTT

The direct intertrip scheme is enabled with *Scheme type* = "Intertrip".

In the direct intertrip scheme, the start signal from the underreaching (instantaneous) residual overcurrent function DEFHPDEF is connected to the CSUR input to create a carrier send CS_INTER_TR signal. The duration of the CSUR input signal can be prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration for the CS_INTER_TR signal.

The local circuit breaker is directly tripped (activation of the OPERATE output) with the carrier received CR_INTER_TR signal after a settable pick-up delay *Coordination time* has elapsed without further local criteria.

The unblocking function (*Unblock mode* = "Permanent" and *Unblock mode* = "Time window") must not be enabled with the DUTT scheme, as the lost guard signal results in an immediate trip of the local circuit breaker.

The activation of the BLOCK input totally blocks the direct intertrip scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

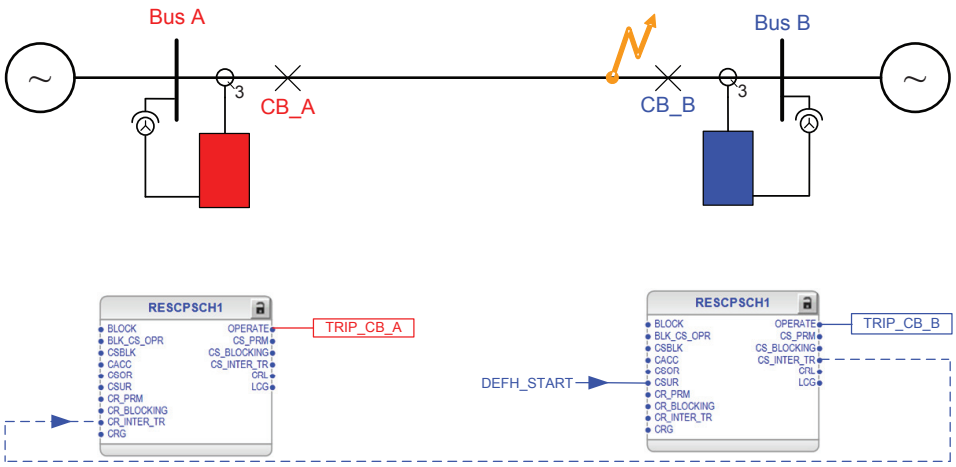

Figure 624: Simplified functional diagram of the direct intertrip scheme

Permissive underreaching transfer trip scheme PUTT

The permissive underreach scheme is enabled with *Scheme type* = "Permissive Underreach".

In the permissive underreach scheme, the start signal from the underreaching (instantaneous) residual overcurrent function DEFHPDEF is connected to the CSUR input to create a CS_PRM signal. The duration of the CSUR input signal can be prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_PRM signal.

In the permissive underreach scheme, the CR_PRM signal or CRL signal, if the unblocking function is enabled, is used to allow the overreaching residual overcurrent function DEFLPDEF to trip (activation of the OPERATE output) after the pick-up delay *Coordination time*. The start signal from the overreaching function is connected to the CACC input. A general start signal in the forward direction can also be connected to the CACC input.

The CS_PRM signal is also generated if the CR_PRM signal is received and the local carrier acceleration signal CACC is active.

Activating the BLOCK input totally blocks the permissive underreach scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

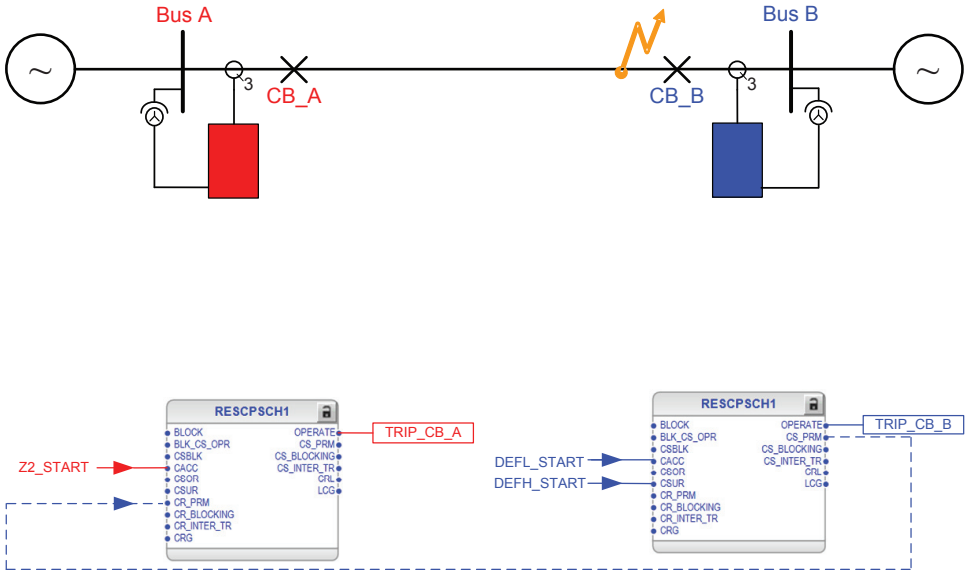

Figure 625: Simplified functional diagram of the permissive underreach scheme

Permissive overrreaching transfer trip scheme POTT

The permissive overreach scheme is enabled with *Scheme type* = "Permissive Overreach".

In this scheme, the START signal from the overreaching residual overcurrent function DEFLPDEF is connected to the CSOR input to create a CS_PRM signal. The CS_PRM signal can also be issued simultaneously from the underreaching residual overcurrent function DEFHPDEF. In this case, the start signal from the underreaching function is connected to the CSUR input. The duration of the CSUR input signal can be prolonged by the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_PRM signal.

In case of parallel feeders, when the external current reversal logic (RCRWPSCH) is enabled, the CS_PRM signal is not prolonged and the value of *Carrier Min Dur* is set to zero to secure correct operation.

In the permissive overreach scheme, the received signal CR_PRM or CRL, if the unblocking function is enabled, is used to allow the overreaching residual overcurrent function DEFLPDEF to trip (activation of the OPERATE output) after the settable pick-up delay *Coordination time*. The start signal from the overreaching zone is connected to the CACC input.

The CS_PRM signal is also generated if the CR_PRM signal is received and the local carrier acceleration signal CACC is active.

Activating the BLOCK input totally blocks the permissive overreach scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

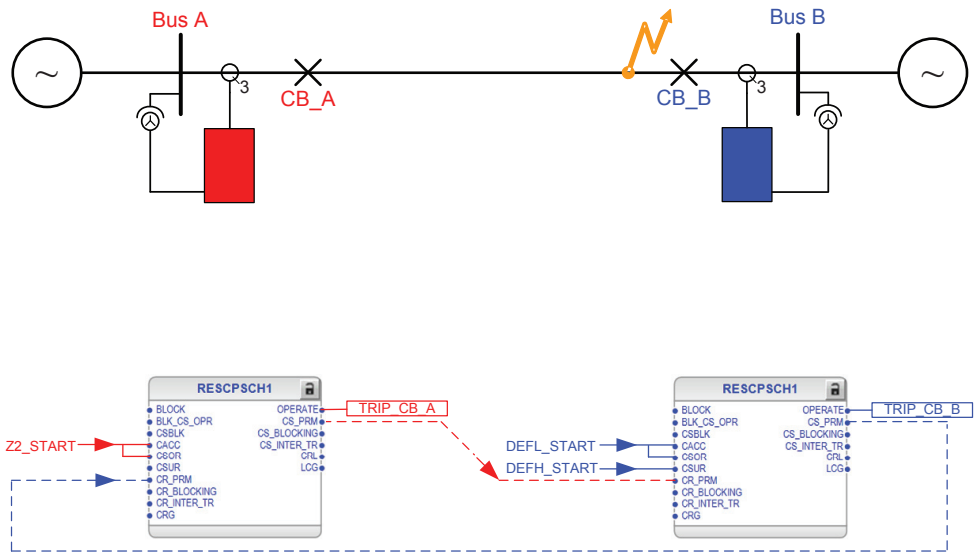

Figure 626: Simplified functional diagram of the permissive overreach scheme

Directional comparison blocking scheme DCB

The directional comparison blocking scheme is enabled with *Scheme type* = "Blocking".

In the blocking scheme, the START signal from the reverse-looking residual overcurrent function DEFLPDEF set to operate for the reverse direction earth fault, is connected to the CSBLK input to create a CS_BLOCKING signal. The starting of the reverse-looking function indicates that the fault is located outside the protected feeder. The duration of the CSBLK input signal can be prolonged with the *Carrier Min Dur* setting to ensure a sufficient duration of the CS_BLOCKING signal.

The blocking scheme is mainly used to allow the forward-looking overreaching residual overcurrent function to trip (activation of the OPERATE output) after the settable *Coordination time*, and if no block signal is received from the remote terminal. To prevent a false trip in case of external faults, the CR_BLOCKING signal must be received before the *Coordination time* has elapsed. The start signal from the overreaching residual overcurrent function DEFLPDEF is connected to the CACC input.

The *Coordination time* setting in the blocking scheme depends, for example, on the communication system delay and on the terminal's response times in transmitting a CS_BLOCKING signal to the other feeder end. The *Coordination time* setting must not be zero.

Activating the BLOCK input totally blocks the directional comparison blocking scheme. The CS_PRM and OPERATE outputs can be blocked by the BLK_CS_OPR input.

In Figure 627, in case of internal faults, the CS_BLOCKING signal is not sent as the fault is not seen by the reverse-looking overreaching function.

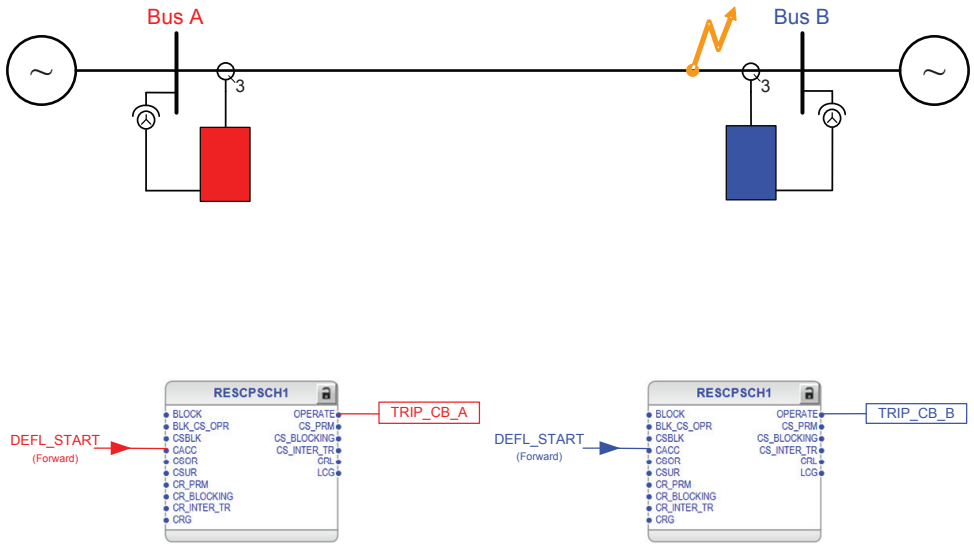

Figure 627: Simplified functional diagram of the blocking scheme, internal fault

In Figure 628, in case of external faults, the protection relay at bus B sees the fault in the reverse direction and sends a blocking signal CS_BLOCKING to the protection relay at bus A. There is no CB operation at either end.

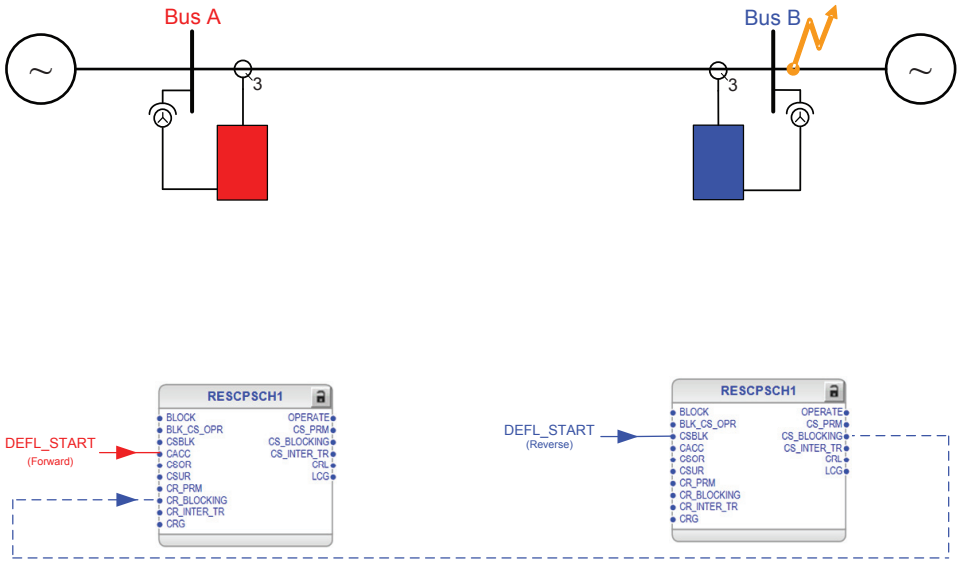

Figure 628: Simplified functional diagram of the blocking scheme, external fault

The unblocking function used with the blocking function provides a possibility to supervise the communication channel. In this case, the CRL output signal is used as a local blocking signal.

The operation mode *Unblock mode* = "Time window" is not recommended as the blocking is activated only for 150 ms after the guard signal disappears. This results in an unwanted operation of the protection.

Directional comparison unblocking scheme DCUB

The unblocking function is a complementary logic which can be used together with the permissive communication schemes. In the unblocking scheme, the dependability of the permissive schemes is improved by using the loss of guard signal from the communication equipment to create a CRL output signal locally. This enables the permissive scheme to operate even if the communication channel is interrupted or lost.

The unblocking function uses a carrier guard signal which must always be present. The absence of the CRG signal for a time longer than the value of the *Loss of carrier time* setting generates a logical CRL signal. A communication failure shorter than the value of the *Loss of carrier time* setting is always ignored.

The unblocking function is configured with the *Unblock mode* setting.

- *Unblock mode* = "Off": The unblocking function is disabled.
- *Unblock mode* = "Permanent": If the CRG signal disappears for a longer time than defined in the *Loss of carrier time* setting, the logical CRL signal is generated. The CRL output signal remains active until the CRG signal reappears. The communication failure is not signaled by the LCG output.
- *Unblock mode* = "Time window": If the CRG signal disappears for a longer time than defined in the *Loss of carrier time* setting, the CRL output signal is generated. The CRL output signal remains active for 150 ms, after which a communication failure is signaled by the LCG output. The LCG output is reset 200 ms after the CRG signal is present again. The purpose of this mode is to ensure tripping during a fixed delay of 150 ms after the loss of communication due to possible consequences of an internal fault. After this time, the accelerated tripping is allowed only if the CR_PRM signal is received again.

With operation modes *Unblock mode* = "Permanent" and *Unblock mode* = "Time window", the created CRL output signal is internally ORed with the CR_PRM input to allow the permissive scheme to operate even when the communication channel has been interrupted or lost. The values of CRL and LCG output signals are also available through the Monitored data view. Activating the BLOCK input blocks the CRL and LCG outputs.

5.11.5 Application

To achieve fast fault clearing on the part of the protected feeder not covered by the instantaneous step of the residual overcurrent protection, the directional residual overcurrent protection can be used with RESCPSCH.

Applying RESCPSCH requires a communication channel capable of transmitting an "On" or "Off" signal in each direction. To enable fast tripping, the most important requirement for communication is the communication speed.

The performance of RESCPSCH is directly related to the communication channel speed, and to the security against false or lost signals. Therefore, dedicated communication channels are recommended. With short distances of up to a few kilometers, a typical communication media is a simple pilot wire based on auxiliary power. With distances of up to 150 km, fibre-optic cables using digital data transmission can be used. To avoid false signals that could cause unwanted operation, the security of the communication channel should be emphasized. Also, the dependability of the communication channel should be considered to ensure that the signals are reliably transmitted during power system faults.

RESCPSCH supports five communication schemes.

- Direct underreaching transfer trip DUTT
- Permissive underreaching transfer trip PUTT
- Permissive overreaching transfer trip POTT
- Directional comparison blocking scheme DCB
- Directional comparison unblocking scheme DCUB

Depending on whether the communication channel is used for sending a block or a trip signal, the communication schemes can be divided into blocking schemes and permissive schemes.

In permissive schemes, the trip signals of the directional residual overcurrent protection are interchanged between the terminals to receive a permission to trip during an internal fault. The tripping of the local terminal depends on both the starting of its own forward-looking function and the received signal from the opposite terminal. In the underreaching scheme, no signals are sent during an external fault. A trip signal is sent to the opposite terminal during an external fault if the fault is seen in the forward direction and the overreaching scheme is used. However, in case of external faults, tripping is always blocked because either no signal is received as the opposite terminal sees a reverse fault or the signal is received but locally the fault is seen in the reverse direction. In either case, the blocking is not dependent on the received signal so a lost communication channel does not result in false operation.

In the blocking scheme, a blocking signal is sent to the opposite terminal if the fault is locally seen in the reverse direction, that is, during an external fault. Thus, the blocking is dependent on the received signal, and there is typically a need to delay the tripping of the terminal receiving the blocking signal. This delay depends, for example, on the response times of the communication channel and terminals. During an internal fault, there is no signal transmission between the terminals, so the tripping does not depend on the received signal from the opposite terminal.

In conclusion, permissive schemes are inherently faster and have better security [3] against false tripping than a blocking scheme, since tripping in an external fault is not

[3] The ability to block operation in case of an external fault

possible in case of a channel interruption. In a blocking scheme, a lost communication channel and a simultaneous external fault may lead to a false operation of the protection if the communication channel is not supervised. On the other hand, as the fast trip of the permissive scheme depends on a received signal, its dependability [4] is lower than that of the blocking scheme.

The unblocking scheme enhances the dependability of the permissive scheme. If the communication channel is interrupted and, simultaneously, a fault occurs in the forward direction, tripping is still possible either during a fixed time interval after the beginning of the interruption or as long as the communication channel is lost. This is achieved by connecting the supervision output of the implemented communication functionality to the dedicated carrier guard signal input of RESCPSCH. In general, the unblocking scheme provides better security than the blocking scheme because tripping in external faults is only possible if the fault occurs within the fixed time interval after the beginning of the channel interruption.

The direct transfer trip scheme uses the underreaching function to trip the local breaker and to transfer the trip signal to the remote terminal. The remote terminal operates immediately based on the received transfer trip signal, without any additional conditions. This scheme is very simple, but its security is low as a spurious signal results in false operation of the protection.

Direct underreaching transfer trip DUTT

In some applications, there is a need to trip the remote end breaker immediately because of fault detection by the local measurements. This applies, for example, when the transformers or reactors are connected to the system without circuit breakers, or for remote tripping following the operation of the local breaker failure protection (CBFP).

In the direct intertrip scheme (DUTT), the carrier send signal `CS_INTER_TR` is initiated by the underreaching or the tripping signal of an external protection relay, such as transformer or reactor protection. At the remote end, the received signal initiates the breaker trip immediately without any further local protection criteria. To limit the risk of an unwanted trip due to spurious sending of signals, the trip can be delayed by the *Coordination time* setting, which should be set to 10...30 ms, depending on the type of the communication channel. The communication channel operating in direct intertripping applications should be secure and dependable.

Setting guidelines for the intertrip scheme DUTT

Scheme type = "Intertrip"

Coordination time = "0.050" s (10 ms + maximal transmission time)

Carrier Min Dur = "0.1" s

[4] The ability to operate in case of an internal fault

Permissive underreaching transfer trip PUTT

In the permissive underreach scheme, a permission to trip is obtained locally from the underreaching function and sent to the remote end. The received signal is then combined with the local fault indication from the overreaching function resulting in a trip command after a settable pick-up delay *Coordination time*.

The protection relay of either feeder end sends a permissive signal to trip the other end. The communication channel must be able to receive and transmit at the same time. In permissive schemes, the communication channel must be fast and secure, but also dependable. Inadequate security causes unwanted tripping for external faults. Inadequate speed or dependability causes delayed tripping for internal faults.

The CS_PRM signal is issued based on the underreaching residual overcurrent protection function.

The permissive scheme is not applicable on short feeder lengths because the residual overcurrent protection cannot easily distinguish between the internal and external faults in such cases.

The residual overcurrent function may start only at one end due to the system conditions such as weak zero-sequence source at one end, or high fault resistance. However, fast tripping from both ends can be achieved by connecting a general forward start signal to CACC. So, even if the local overreaching residual overcurrent function has not picked up, the local OPERATE output is activated. The function also generates a CS_PRM signal by combining the carrier received CR_PRM signal from a remote end and also the local activation of CACC, giving the permission to a remote function to trip instantaneously.

The CR_PRM signal must be received when the overreaching residual overcurrent protection is still active to achieve an instantaneous trip. In some cases, due to the fault current distribution, the overreaching protection can operate only after the fault has been cleared by the remote terminal. In this case, there is a risk that if the remote terminal is tripped directly by the instantaneous underreaching function, the CS_PRM signal that it issues resets before the overreaching function of the local end terminal is operated. To ensure a sufficient duration of the CR_PRM signal, the CS_PRM signal can be prolonged by time *Carrier Min Dur*. The recommended value of the *Carrier Min Dur* setting is "0.1" s.

The received communication signal is combined with the output from the local overreaching function. Therefore, there is less concern about a false signal causing an incorrect trip. Therefore, the timer *Coordination time* can be set to "0". A communication channel failure does not affect the selectivity, but delays the tripping at the other end for certain fault locations.

Setting guidelines for the permissive underreach scheme PUTT

Scheme type = "Permissive Underreach"

Coordination time = "0" s

Carrier Min Dur = "0.1" s

Permissive overreaching transfer trip POTT

In the permissive overreach scheme, the permission to trip is obtained locally from an overreaching function and sent to the remote end. The received signal is then combined with the local fault indication from the overreaching function, resulting in a trip command after a settable pick-up delay *Coordination time*.

The protection relay at either end of the feeder sends a permissive signal to trip the other end. Therefore the communication channel must be able to receive and transmit at the same time. A general requirement for the communication on permissive schemes is that it should be fast and secure.

In the permissive overreach scheme, the CS_PRM signal is issued based on the start of the overreaching residual overcurrent function.

The residual overcurrent function may start at one end due to the system conditions such as weak zero-sequence source at one end, or high fault resistance. However, fast tripping from both ends can be achieved by connecting a general forward start signal to CACC. So, even if the local overreaching residual overcurrent function has not picked up, the local OPERATE is activated. The function also generates a CS_PRM signal by combining the CR_PRM signal from a remote end and local activation of CACC, giving permission to the remote function to trip instantaneously.

The permissive overreach scheme can be used for all feeder types and lengths.

In the permissive overreach scheme, the communication channel is essential for obtaining fast tripping at both ends. Typically, a lost communication channel does not cause false tripping, but it delays the operation of the protection for the faults on the feeder.

The communication channel for a permissive overreach scheme must be fast and secure, but also dependable. Inadequate security can cause unwanted tripping for external faults. Inadequate speed or dependability can cause delayed tripping for internal faults.

In the permissive overreaching scheme, the CS_PRM signal can be issued in parallel both from the overreaching and underreaching functions. The CS_PRM signal from the overreaching function must not be prolonged, while the CS_PRM signal from the underreaching function must typically be prolonged. In parallel feeder applications, the scheme typically needs to be complemented by the current reversal logic. To ensure a correct operation in this case, the CS_PRM signal must not be prolonged (*Carrier Min Dur* = "0" s). There is no need to delay the tripping when receiving the carrier signal, so the time *Coordination time* is set to "0".

Setting guidelines for the permissive overreaching transfer trip scheme POTT

Scheme type = "Permissive Overreach"

Coordination time = "0" s

Carrier Min Dur = "0.1" s

Carrier Min Dur = "0" s (in case of parallel lines and current reversal logic)

Directional comparison blocking scheme DCB

In the blocking scheme, the reverse-looking residual overcurrent function is used for sending a block signal to the remote end to block the overreaching forward-looking residual overcurrent function.

The blocking scheme is very dependable because it operates for faults anywhere on the protected feeder, even if the communication channel is out of service. Conversely, it is less secure than a permissive scheme because it trips for the external faults within the reach of the overreaching local function if the communication channel is out of service and no block signal is received.

Inadequate speed or low dependability of the communication channel can cause spurious tripping for external faults.

To secure that the blocking signal arrives before the local overreaching function trips, the trip is delayed by the *Coordination time* setting. This setting must be set longer than the sum of the maximal transmission time of the channel and the start and response times of the protection relays sending and receiving the `CS_PRM` signal. A security margin of at least 10 ms should be considered. The time delay *Carrier Min Dur* for prolonging the `CS_PRM` signal is set to "0".

Setting guidelines for the blocking scheme

Scheme type = "Blocking"

Coordination time = "0.1" s (10 ms + maximal transmission time)

Carrier Min Dur = "0" s

Directional comparison unblocking scheme DCUB

Metallic communication paths adversely affected by fault-generated noise or by other electrical phenomena, such as lightning, are not suitable for conventional permissive schemes that rely on signal transmission during a fault in the protected feeder. Principally, the communication media must be properly shielded or otherwise designed to provide an adequate performance during such conditions.

The unblocking scheme can be used to overcome the lower dependability of permissive schemes. The function is used in older, less reliable communication, where the signal has to be sent through the primary fault. The unblocking function uses a carrier guard signal `CRG` which must always be present, even when no `CR_PRM` signal is received. Due to the absence of the `CRG` signal during the security time, the *Loss of carrier time* setting is used as a `CR_PRM` signal. This also enables a permissive scheme to operate when the communication channel is temporarily lost during an internal fault.

Setting guidelines for the unblocking scheme

- *Unblock mode* = "Off": The unblocking function is disabled.
- *Unblock mode* = "Permanent": If the CRG signal disappears for a longer time period than defined in the *Loss of carrier time* setting, a logical carrier received signal CRL is generated. The CRL signal remains active until the CRG signal is present. The communication failure is not signalled by the LCG output. The *Loss of carrier time* setting is set to "35" ms.
- *Unblock mode* = "Time window": If the CRG signal disappears for a longer time period than the *Loss of carrier time* setting, a CRL signal is generated. The CRL signal remains active for 150 ms, after which a communication failure is signalled by the LCG output. The value of the LCG output is reset 200 ms after the CRG signal reappears. The *Loss of carrier time* setting is set to "35" ms.

5.11.6 Signals

Table 1084: RESCPSCH Input signals

Name	Type	Default	Description
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode
BLK_CS_OPR	BOOLEAN	0=False	Signal for blocking CS and OPR in all schemes
CSBLK	BOOLEAN	0=False	Reverse residual overcurrent signal for Carrier Send
CACC	BOOLEAN	0=False	Signal to be used for tripping by Communication Scheme
CSOR	BOOLEAN	0=False	Overreaching residual overcurrent signal for Carrier Send
CSUR	BOOLEAN	0=False	Underreaching residual overcurrent signal for Carrier Send
CR_PRM	BOOLEAN	0=False	Received teleprotection permissive from the other side
CR_BLOCKING	BOOLEAN	0=False	Received teleprotection blocking from the other side
CR_INTER_TR	BOOLEAN	0=False	Received direct trip from the other side
CRG	BOOLEAN	0=False	Carrier guard signal received

Table 1085: RESCPSCH Output signals

Name	Type	Description
OPERATE	BOOLEAN	Operate
CS_PRM	BOOLEAN	Permissive transmitted to the other side
CS_BLOCKING	BOOLEAN	Blocking transmitted to the other side
CS_INTER_TR	BOOLEAN	Direct trip transmitted to the other side
CRL	BOOLEAN	Carrier received after unblock logic
LCG	BOOLEAN	Loss of guard

Current reversal and weak-end infeed logic	CRWPSCH	CLCRW	85 21CREV,WEI

5.12.2 Function block

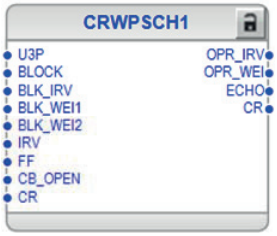

Figure 629: Function block

5.12.3 Functionality

The current reversal and weak-end infeed logic function CRWPSCH can be used when the scheme communication logic DSOCPSCH requires additional logics to operate correctly in all power system conditions.

In parallel feeder applications, the fault current direction on the healthy feeder can change when the circuit breaker on the faulty feeder opens to clear the fault. This can lead to an unwanted operation of the distance protection on the healthy parallel feeder when DSOCPSCH is used with the permissive overreach scheme. The main purpose of the current reversal logic is to prevent such unwanted operations.

The permissive communication schemes can operate only when the protection in the remote terminal can detect the fault. This detection requires sufficient minimum fault current. If such current is not available due to a too weak remote end source, the weak-end infeed logic can be used to overcome the situation and trip the remote end breaker.

5.12.4 Analog channel configuration

CRWPSCH has one analog group input which must be properly configured.

Table 1090: Analog inputs

Input	Description
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1091: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two phases connected but it is recommended to connect all three voltage channels.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.12.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of CRWPSCH can be described with a module diagram. All the modules in the diagram are explained in the next sections.

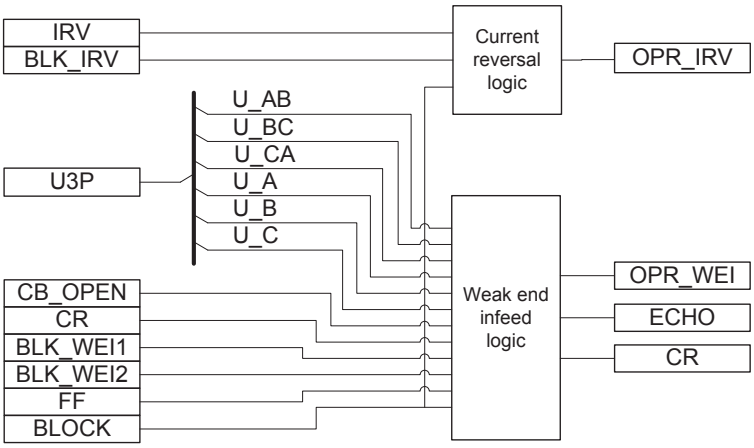

Figure 630: Functional module diagram

Current reversal logic

Current reversal logic is enabled by changing the value of the *Reversal mode* setting to "On".

This logic uses the start signal of the reverse-looking zone (Z3) connected to the IRV input, which is used to recognize the fault in the reverse direction, that is, in the parallel feeder. When the reverse zone is activated after a start delay (the *Reversal time* setting), the logic is ready to issue an OPR_IRV output signal. The OPR_IRV signal is connected to the BLK_CS_OPR input of DSOCPSCH in order to block the sending of the carrier send signal (CS) and the activation of the OPERATE output of the communication logic. The OPR_IRV signal has a drop-off delay defined with the *Reversal reset time* setting.

An internal 10 ms drop-off timer enables the current reversal logic to be activated for the short-duration input signals even if the *Reversal reset time* setting is set to zero.

The BLK_IRV input is used to block the activation of the OPR_IRV output. The BLK_IRV input is typically connected to the forward-looking zone start signals within the terminal. General blocking is achieved by activating the BLOCK input.

Weak-end infeed logic

Weak-end infeed logic is used to activate the distance protection function when the fault current infeed is too low due to, for example, high source impedance or fault current distribution between sources. When activated, the CR signal is logically combined with the local criteria to initiate the tripping of the weak-end breaker. The received signal is echoed back to accelerate the tripping in the opposite end with the stronger source.

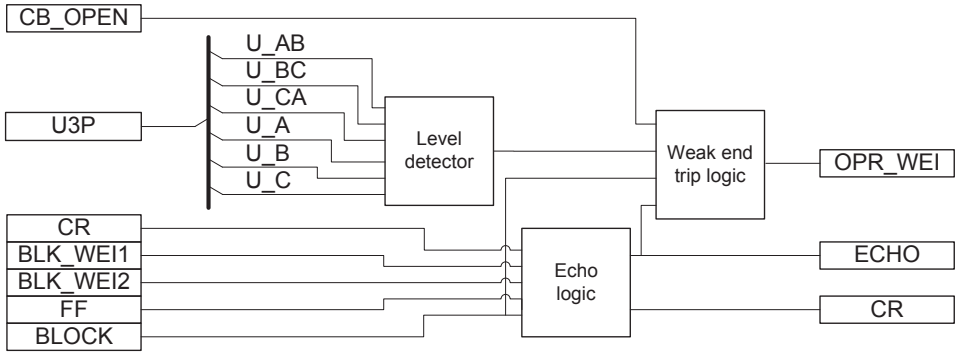

Figure 631: Functional module diagram of weak-end infeed logic

The WEI logic is enabled using the *Wei mode* setting.

- If *Wei mode*= "Off", the WEI logic is disabled.
- If *Wei mode*= "Echo", the WEI logic is enabled without Level detector.
- If *Wei mode*= "Echo and Operate", the WEI logic is enabled with Level detector.

Level detector

Both phase-to-earth and phase-to-phase voltages are monitored. The undervoltage criteria are applied to the phase-to-phase voltages with the *PPV level for Wei* setting and to the phase-to-earth voltages with the *PhV level for Wei*. Level detector sends an enable signal for a phase to Weak-end trip logic when one or more voltages are below the corresponding settings. Level detector blocks the enable signal if all three-phase voltages are above the set value more than 100 ms. This is to avoid sending an unnecessary operate signal if the breaker is already open.

Echo logic

Echo logic returns the received carrier signal with the ECHO output when it receives a CR signal if no fault has been detected by the forward- and reverse-looking zones and the duration of CR is longer than the coordination time delay (setting *Wei Crd time*). The received carrier receive signal is also given as the CR output.

When the WEI logic is enabled at both feeder ends, a spurious signal can be looped round by Echo logic. To avoid a continuous lockup of the system, the duration of the echoed signal is limited to 200 ms.

The ECHO and CR outputs can be blocked by activating the BLOCK input. The FF, BLK_WEI1 and BLK_WEI2 inputs can be used to block the ECHO output. The FF input is usually connected to the functional output of the fuse failure function, and the BLK_WEI1 input is typically connected to the start signals of the forward and reverse directional residual overcurrent functions within the terminal. The BLK_WEI2 signal has an in-built 200 ms drop-off delay. The BLK_WEI2 input is usually connected to all the fault detection functions within the terminal except the residual overvoltage function.

Weak-end trip logic

Weak-end trip logic is activated if it receives an enable signal from Level detector and ECHO output of Echo logic is activated. Then a general trip signal OPR_WEI is activated. The activation of the CB_OPEN input blocks the tripping.

The OPR_WEI output can be blocked by activating the BLOCK input.

5.12.6 Application

Current reversal logic

In parallel feeder applications, when the overreaching permissive communication schemes are used, unselective tripping may result due to the current reversal. Such a condition can occur in the healthy feeder when the fault is cleared in the faulty feeder. The tripping of the healthy parallel feeder may lead to losing the connection between the two buses. To avoid this situation, the current reversal logic (transient blocking logic) can be used.

Assume that Relay A1, Relay A2, Relay B1 and Relay B2 are equipped with DSOCPSCH and the permissive overreach scheme is enabled. A fault occurs at Feeder 1 close to bus B. Relay A2 at the healthy Feeder 2 recognizes the fault in the forward direction within the overreaching zone Z2 and sends a CS signal to Relay B2 according to the POTT scheme. Relay B2 does not recognize the fault in the forward direction and does not operate even though a permissive CR signal is received from Relay A2. Moreover, Relay B2 does not send a permissive signal to Relay A2.

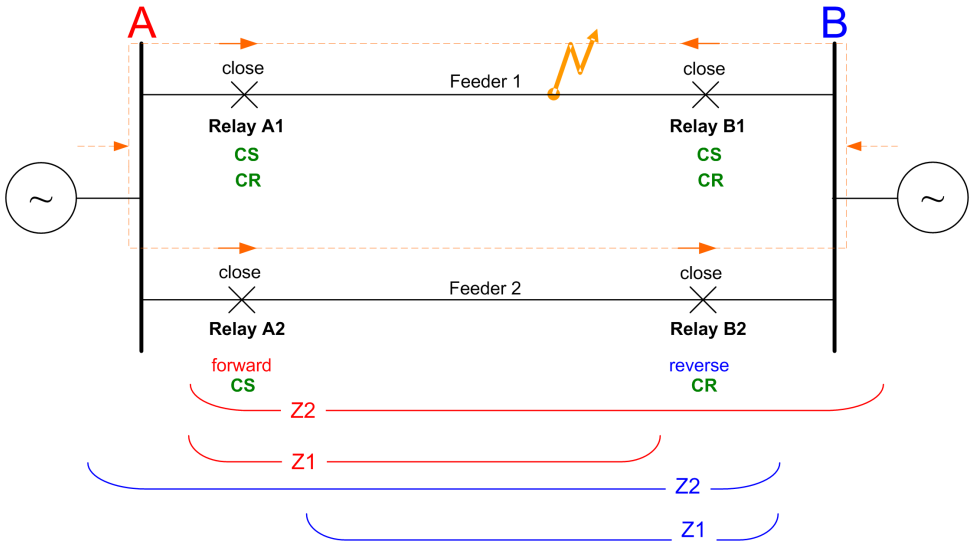

Figure 632: The fault occurs at one of the parallel lines.

The faulty feeder (Feeder 1) is not simultaneously tripped at both ends and it might occur that, for example, the circuit breaker closer to the fault at Relay B1 is tripped faster than the breaker at bus A due to the direct operation of the zone Z1 of Relay B1. Thus, when the breaker at Relay B1 opens, the direction of the fault current at the healthy feeder (Feeder 2) is reversed.

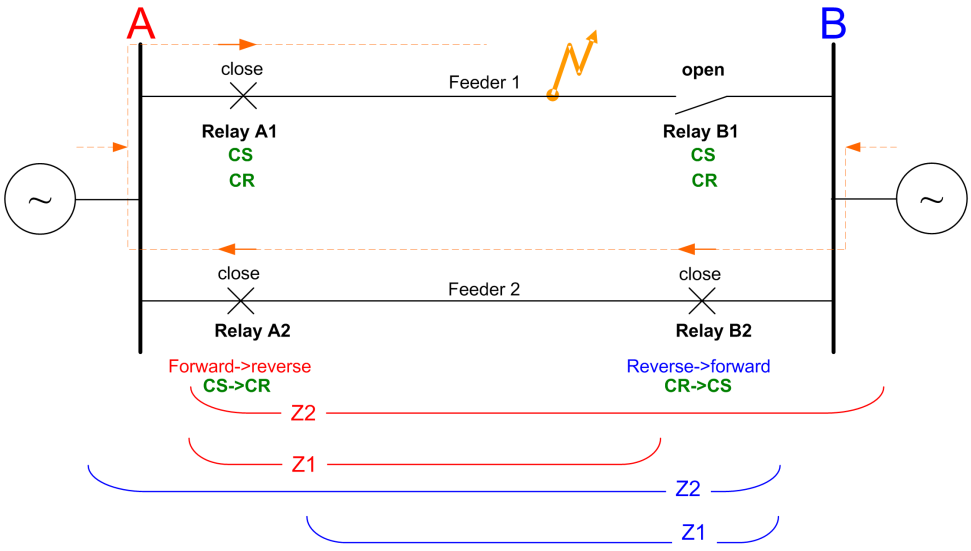

Figure 633: The circuit breaker at Relay B1 opens and creates a current reversal condition

Relay A2 is still sending the CS signal because of the reset time delay of the forward zone of Relay A2 when the overreaching zone of Relay B2 starts to recognize the fault in the forward direction. Relay B2 can malfunction and trip the breaker of the healthy feeder.

This problem can be solved by using the reverse-looking zone (Z3) to recognize the fault in reverse direction and temporarily block the operation of DSOCPSCH due to the current reversal condition. This is used in CRWPSCH.

Weak-end infeed logic

Avoid using the WEI function at both feeder ends. It can only be enabled at the weak end.

The weak-end infeed logic should be used only in permissive schemes.

Setting guidelines for current reversal logic

Setting *Reversal reset time*: Set the *Reversal reset time* setting to the maximum reset time of the communication channel. A minimum setting of 40 ms is recommended. A long *Reversal reset time* setting increases the security against unwanted tripping, but delays the fault clearing if the fault develops in one feeder and involves the other. However, the probability of this type of fault is small.

Setting *Reversal time*: Set the start delay *Reversal time* setting to less than 80 percent of the breaker operate time, but to a minimum of 20 ms.

Setting guidelines for weak-end infeed logic

The WEI function returns the received carrier signal with the ECHO output when it receives the carrier signal (CR) if no fault has been detected by forward- and reverse-looking zones and the signal duration is longer than the *Wei Crd time* coordination time delay setting. Set the *Wei Crd time* = "0.010" s to avoid the spurious carrier received signals that activate the WEI logic and cause unwanted communication.

Set the voltage criteria *PPV level for Wei* and *PhV level for Wei* for the weak-end trip to 70 percent of the system's base voltage. The setting should be below the minimum operate voltage of the system but above the voltage that occurs for a fault on the protected feeder. The phase-to-phase elements must be verified not to operate for the phase-to-earth faults.

5.13.2 Function block

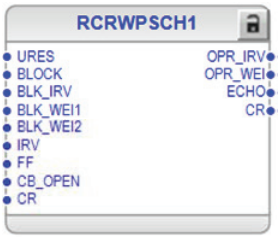

Figure 634: Function block

5.13.3 Functionality

The current reversal and weak-end infeed logic for residual overcurrent function RCRWPSCH can be used when the communication logic for residual overcurrent RESCPSCH requires additional logics to operate correctly in all power system conditions.

In parallel feeder applications, the direction of the fault current on the healthy feeder can change when the circuit breaker on the faulty feeder opens to clear the fault. This can lead to an unwanted operation of the residual overcurrent protection on the healthy parallel feeder when RESCPSCH with the permissive overreach scheme is used. The main purpose of the current reversal logic is to prevent such unwanted operations.

The permissive communication schemes can operate only when the protection in the remote terminal can detect the fault. This detection requires sufficient minimum fault current. If such current is not available due to too weak a remote end source, the WEI logic can be used to overcome the situation and trip the remote end breaker.

5.13.4 Analog channel configuration

RCRWPSCH has one analog group input which must be properly configured.

Table 1097: Analog inputs

Input	Description
URES[1)]	Residual voltage (measured or calculated) Necessary when *Wei mode* is set to "Echo and Operate"

1) Can be connected to GRPOFF if *Wei mode* is set to "Off" or "Echo"

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

There are a few special conditions which must be noted with the configuration.

Table 1098: Special conditions

Condition	Description
URES calculated	The function requires that all three voltage channels are connected to calculate the residual voltage. Setting *VT connection* must be "Wye" in that particular UTVTR.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.13.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of RCRWPSCH can be described with a module diagram. All the modules in the diagram are explained in the next sections.

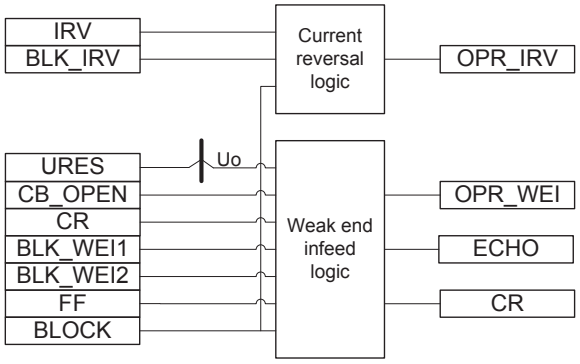

Figure 635: Functional module diagram

Current reversal logic

Current reversal logic is enabled by changing the value of the *Reversal mode* setting to "On".

Current reversal logic uses the start signal of the reverse directional residual overcurrent function connected to the IRV input, which is used to recognize the fault in the reverse direction, that is, in the parallel feeder. When the reverse directional residual overcurrent function is activated, the logic is ready to issue an OPR_IRV output signal after a start delay (setting *Reversal time*). The OPR_IRV signal is connected to the BLK_CS_OPR input of the scheme communication logic function to block the sending of the carrier send signal (CS) and the activation of the OPERATE output of the communication logic. The OPR_IRV signal has a drop-off delay defined with the *Reversal reset time* setting.

An internal 10 ms drop-off timer is provided which ensures the current reversal logic is activated for short-duration input signals, even if the *Reversal reset time* setting is set to zero.

The BLK_IRV input is used to block the activation of the OPR_IRV output. The BLK_IRV input is typically connected to the start signals of the forward-looking residual overcurrent function in the terminal. General blocking is achieved by activating the BLOCK input.

Weak-end infeed (WEI) logic

The WEI logic is used to activate the residual overcurrent protection function when the fault current infeed is too low due to, for example, high source impedance or fault current distribution between sources. When activated, the carrier receive (CR) signal is logically combined with the local criteria to initiate the tripping of the weak-end breaker. The received signal is also echoed back to accelerate the tripping at the opposite end with the stronger source.

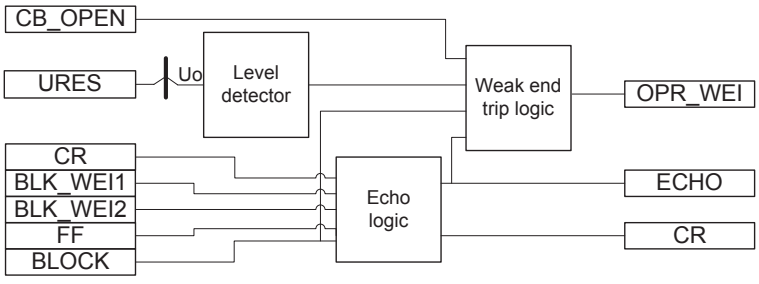

Figure 636: Functional module diagram of Weak-end infeed logic

The WEI logic is enabled using the *Wei mode* setting.

- If *Wei mode* = "Off", the WEI logic is disabled.
- If *Wei mode* = "Echo", the WEI logic is enabled without Level detector.
- If *Wei mode* = "Echo and Operate", the WEI logic is enabled with Level detector.

Level detector

Level detector sends an enabling signal to Weak-end trip logic when the residual voltage is above the *Residual voltage Val* setting.

Echo logic

Echo logic returns the received carrier signal with the ECHO output when it receives a carrier receive signal (CR) if no fault has been detected by the forward and reverse directional residual overcurrent functions and the duration of CR is longer than the coordination time delay (the setting *Wei Crd time*). The received carrier receive signal is also given as the CR output.

When the WEI logic is enabled at both feeder ends, a spurious signal can be looped round by Echo logic. To avoid a continuous lockup of the system, the duration of the echoed signal is limited to 200 ms.

The ECHO and CR outputs can be blocked by activating the BLOCK input. The FF, BLK_WEI1 and BLK_WEI2 inputs can be used to block the ECHO output. The FF input is usually connected to the functional output of the fuse failure function, and the BLK_WEI1 input is typically connected to the start signals of the forward and reverse directional residual overcurrent functions in the terminal. The BLK_WEI2 signal has an in-built 200 ms drop-off delay and is usually connected to all the fault detection functions in the terminal except the residual overvoltage function.

Weak-end trip logic

Weak-end trip logic is activated if it receives an enable signal from Level detector and ECHO output of Echo logic is activated. Then a general trip signal OPR_WEI is activated. The activation of the CB_OPEN input blocks the tripping.

The OPR_WEI output can be blocked by activating the BLOCK input.

5.13.6 Application

Current reversal logic

When the overreaching permissive communication schemes are used in parallel feeder applications, the current reversal can result in unselective tripping. Such a condition can occur in the healthy feeder when the fault is cleared in the faulty feeder. The tripping of the healthy parallel feeder can lead to losing the connection between the two buses. To avoid this situation, the current reversal logic (transient blocking logic) can be used.

In the current reversal condition, the relays Relay A1, Relay A2, Relay B1 and Relay B2 can be equipped with the scheme communication logic RESCPSCH and the permissive overreach scheme can be enabled.

A fault occurs at Feeder 1 close to bus B. Relay A2 at the healthy feeder 2 recognizes the fault in the forward direction and sends a CS signal to Relay B2 according to the PUTT scheme. Relay B2 does not recognize the fault in the forward direction and hence does not send a permissive signal to Relay A2.

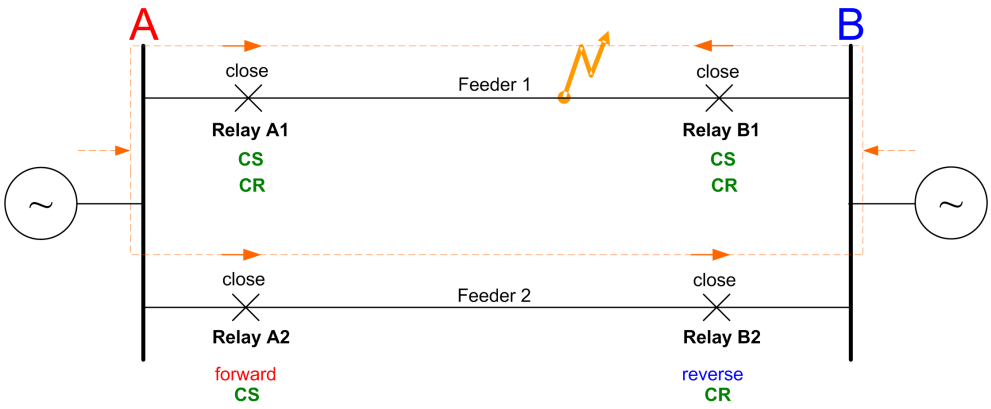

Figure 637: Fault occurs at one of the parallel lines. CS=carrier signal sending, CR=carrier signal receiving

The faulty feeder (Feeder 1) is not simultaneously tripped at both ends and, for example, the circuit breaker closer to the fault at Relay B1 may be tripped faster than the breaker at bus A. As a result, when the breaker at Relay B1 opens, the direction of the fault current at the healthy feeder (Feeder 2) is reversed.

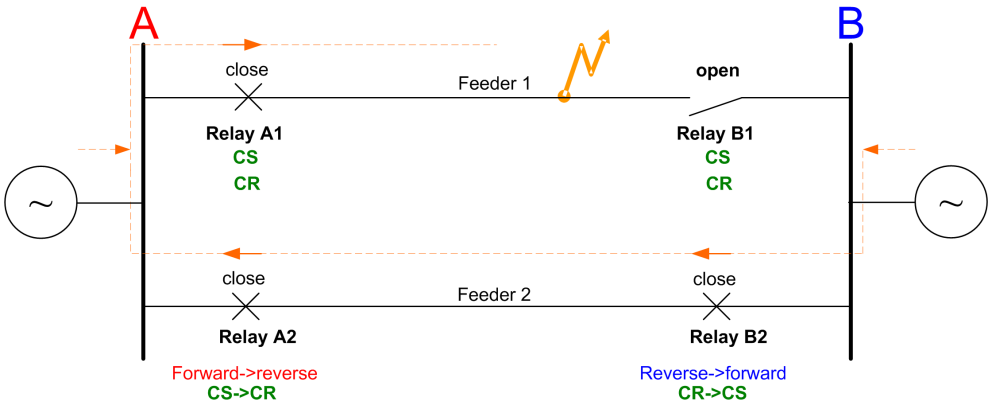

Figure 638: Circuit breaker at Relay B1 opens and creates a current reversal condition. CS=carrier signal sending, CR=carrier signal receiving.

Relay A2 still sends the CS signal because of the reset time delay of the forward direction residual overcurrent function of Relay A2. When Relay B2 starts to recognize the fault in the forward direction, Relay B2 can malfunction and trip the breaker of the healthy feeder.

This problem can be solved using the reverse directional residual overcurrent function to recognize the fault in reverse direction and temporarily block the operation of the scheme communication logic due to the current reversal condition. This is used in RCRWPSCH.

Weak-end infeed (WEI) logic

Do not use the WEI function at both feeder ends. It can only be enabled at the weak end.

The WEI logic is recommended to be used only in the permissive schemes.

Setting guidelines for current reversal logic

Reversal reset time: This setting can be set to the maximum reset time of the communication channel. A minimum setting of 40 ms is recommended. A long *Reversal reset time* setting increases the security against unwanted tripping, but delays the fault clearing if the fault develops from one feeder to involve the other. However, the probability of this type of fault is small.

Reversal time: Set the start delay reversal time below 80 percent of the breaker operate time, but to a minimum of 20 ms.

Setting guidelines for Weak-end infeed (WEI) logic

The WEI logic returns the received carrier signal with the ECHO output when it receives the carrier signal (CR) if no fault has been detected by the forward and reverse directional measuring elements and the duration is longer than the *Wei Crd time* coordination time delay setting. To prevent the spurious carrier receive signals from activating the WEI logic and causing unwanted communication, the *Wei Crd time* setting can be set to "0.010 s".

5.13.7 Signals

Table 1099: RCRWPSCH Input signals

Name	Type	Default	Description
URES	SIGNAL	-	Residual voltage
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode
BLK_IRV	BOOLEAN	0=False	Block of current reversal function
BLK_WEI1	BOOLEAN	0=False	Block of WEI Logic
BLK_WEI2	BOOLEAN	0=False	Block of WEI logic due to operation of other protections
IRV	BOOLEAN	0=False	Activation of current reversal logic
FF	BOOLEAN	0=False	Block of trip from WEI logic through fuse-failure function

5.14.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-phase power directional element	DPSRDIR	I1->	67P-TC

5.14.2 Function block

Figure 639: Function block

5.14.3 Functionality

The three-phase power directional element function DPSRDIR is used to detect positive-sequence power direction. The output of the function is used for blocking or releasing other functions in protection scheme.

The directional positive-sequence power protection contains a blocking functionality which blocks function output and resets Timer.

DPSRDIR executes on the direction of positive-sequence power and not the value. If overpower or underpower is needed, refer to DOPPDPR and DUPPDPR. DPSRDIR is generally used for directional controls.

5.14.4 Analog channel configuration

DPSRDIR has two analog group inputs which must be properly configured.

Table 1104: Analog inputs

Input	Description
I3P	Three-phase currents
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1105: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two phase voltage channels connected but it is recommended to connect all three voltage channels.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.14.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of DPSRDIR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

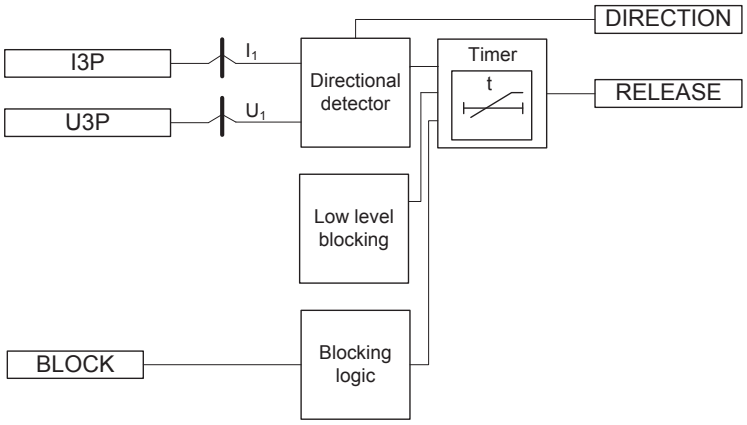

Figure 640: Functional module diagram

Directional detector

The Directional detector module compares the angle of the positive-sequence current I1 to the angle of the positive-sequence voltage V1. Using the positive-sequence voltage angle as reference, the positive-sequence current angle is compared to the *Characteristic angle* setting. If the angular difference is within the operating sector selected with the *Directional mode* setting, the On signal is sent to Timer.

The operating sector is defined by the setting *Min forward angle*, *Max forward angle*, *Min reverse angle* and *Max reverse angle*. The options that can be selected for the *Directional mode* setting are “Forward” and “Reverse”.

The sector limits are always given as positive degree values.

The *Characteristic angle* setting is also known as Relay Characteristic Angle (RCA), Relay Base Angle or Maximum Torque Line.

Figure 641: Configurable directional settings

Low-level blocking

For a reliable operation, signal levels should be greater than the minimum level. If they are not greater than the minimum level, Timer is blocked. If the amplitude of the positive-sequence current is greater than the *Min trip current* value and the positive-sequence voltage amplitude is greater than the *Min trip voltage* value, the On signal is sent to Timer.

Timer

Once activated, the internal operating timer is started. The Timer characteristic is according to definite time DT. When Timer has reached the value of *Release delay time*, the RELEASE output is activated. If a drop-off situation happens, that is, if the operating current moves outside the operating sector or signal amplitudes drop below the minimum level before *Release delay time* is exceeded, the Timer reset state is activated. If the drop-off continues for more than *Reset delay time*, Timer is deactivated.

Blocking logic

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates the RELEASE output and resets Timer.

5.14.6 Application

The three-phase power directional element function DPSRDIR improves the possibility to obtain a selective function of the overcurrent protection in meshed networks. DPSRDIR is used to block or release other overcurrent protection functions.

Neutral power directional element	DNZSRDIR	I2->, Io->	67N-TC

5.15.2 Function block

Figure 642: Function block

5.15.3 Functionality

Neutral power directional element function DNZSRDIR is used to detect negative or residual power direction. The output of the function is used for blocking or releasing other functions in protection scheme.

In negative-sequence voltage selection, if the angle difference between negative-sequence voltage and negative-sequence current is in a predefined direction (either in forward or reverse direction), DNZSRDIR gives a release signal after a definite time delay.

In residual voltage selection, if the angle difference between residual voltage and residual current is in a predefined direction (either in forward or reverse direction), DNZSRDIR gives release signal after a definite time delay.

This function contains a blocking functionality which blocks the function output and resets Timer.

DNZSRDIR executes on the direction of either negative-sequence or zero-sequence power and not the value. The function is generally used for directional controls.

5.15.4 Analog channel configuration

DNZSRDIR has four analog group inputs which must be properly configured.

Table 1112: Analog inputs

Input	Description
I3P[1)]	Three-phase currents Necessary when *PoI quantity* is "Neg. seq. volt."
IRES[2)]	Residual current (measured or calculated) Necessary when *PoI quantity* is "Zero seq. volt."
U3P[1)]	Three-phase voltages Necessary when *PoI quantity* is "Neg. seq. volt."
URES[2)]	Residual voltage (measured or calculated) Necessary when *PoI quantity* is "Zero seq. volt."

1) Can be connected to GRPOFF if *PoI quantity* is set to "Zero seq. volt."
2) Can be connected to GRPOFF if *PoI quantity* is set to "Neg. seq. volt."

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

There are a few special conditions which must be noted with the configuration.

Table 1113: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two phase voltage channels connected but it is recommended to connect all three voltage channels.
URES calculated	The function requires that all three voltage channels are connected to calculate residual voltage. Setting *VT connection* must be "Wye" in that particular UTVTR.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

5.15.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of DNZSRDIR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

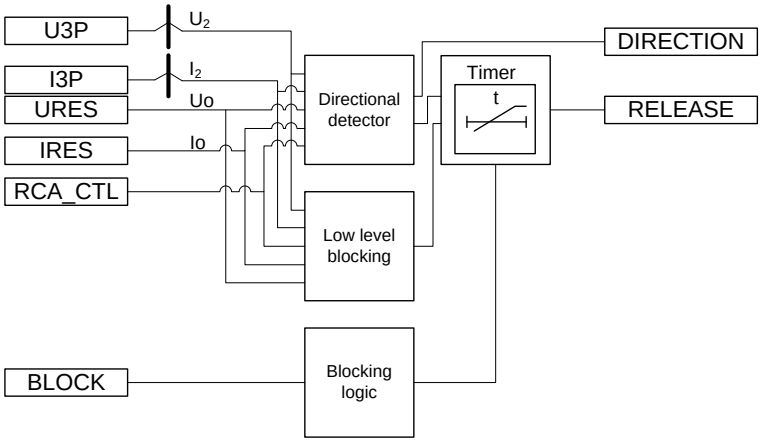

Figure 643: Functional module diagram

Directional detector

When "Neg. seq. volt." selection is made using the *Pol quantity* setting, the Directional detector module compares the angle of the negative-sequence current (I_2) to the negative-sequence voltage ($-U_2$). Using the negative-sequence voltage angle as the reference, the negative-sequence current angle is compared to the *Characteristic angle* setting. If the angle difference is within the operating sector selected by *Direction mode* setting, the Enable signal is sent to Timer.

The value of *Characteristic angle* should be chosen in such way that all the faults in the operating direction are seen in the operating zone and all the faults in the opposite direction are seen in the backward zone.

The operating sector is defined by the settings *Max forward angle*, *Max reverse angle*, *Min forward angle* and *Min reverse angle*. The options that can be selected for *Directional mode* settings are “Forward” and “Reverse”.

Characteristic angle is also known as Relay Characteristic Angle RCA, Relay Base Angle or Maximum Torque Line.

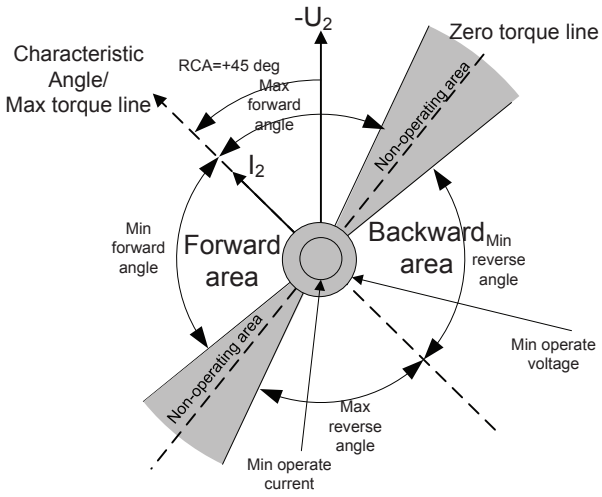

Figure 644: Configurable directional setting when "Neg. seq. volt." selection is made using the Pol quantity setting

When *Zero seq. volt.* voltage selection is made using *Pol quantity* setting, the directional detector module compares the angle of the residual current to the residual voltage. Using the residual voltage as reference, the residual current angle is compared to the *Characteristic angle* setting. If the angle difference is within the operating sector selected by the *Directional mode* setting, the Enable signal is sent to Timer.

The polarizing quantity (residual voltage) is inverted because of switched voltage measurement cables, the correction can be done by setting the *Pol reversal* setting to "True", which rotates the polarizing quantity by 180 degrees.

The directional characteristic for the measured or calculated residual power is same.

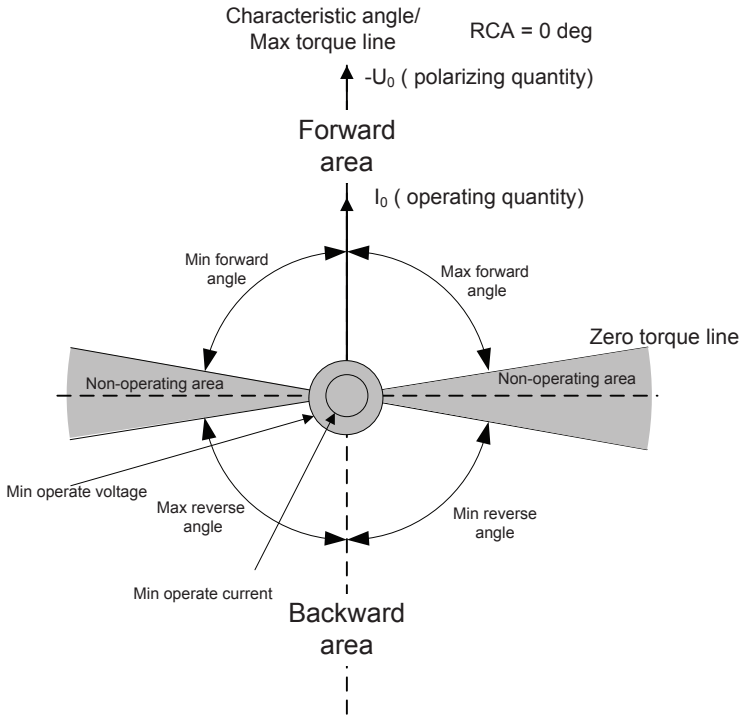

Figure 645: Configurable directional setting for Zero seq. volt. (residual voltage) using the Pol quantity setting

The *Characteristic angle* setting is done based on method of grounding employed in the network. For example, in case of an isolated network, *Characteristic angle* is set to -90°, and in case of a compensated network, *Characteristic angle* is set to 0° and 60° for solidly grounded systems. In general *Characteristic angle* is selected so that it matches close to the expected fault angle value, which results in maximum sensitivity. *Characteristic angle* can be set anywhere between -179° to +180°. The figures show examples of the operating area with RCA set to +60° and -90°, respectively.

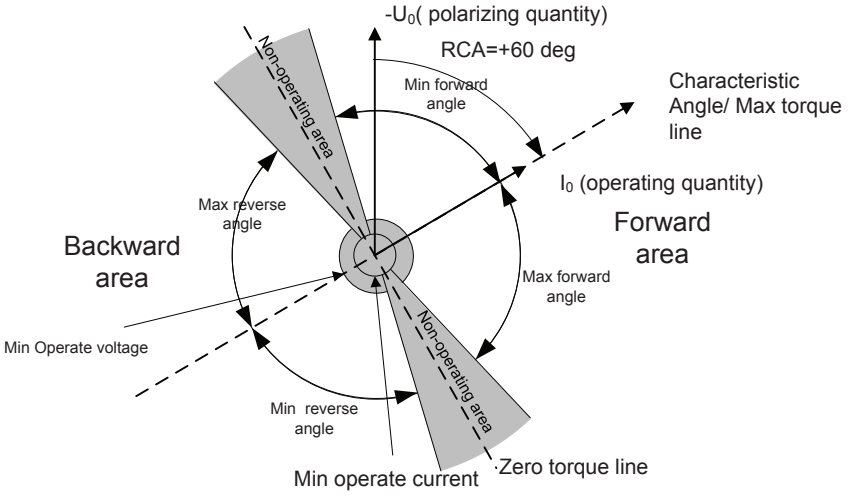

Figure 646: Configurable directional characteristics (RCA =+60˚) for a solidly earthed network

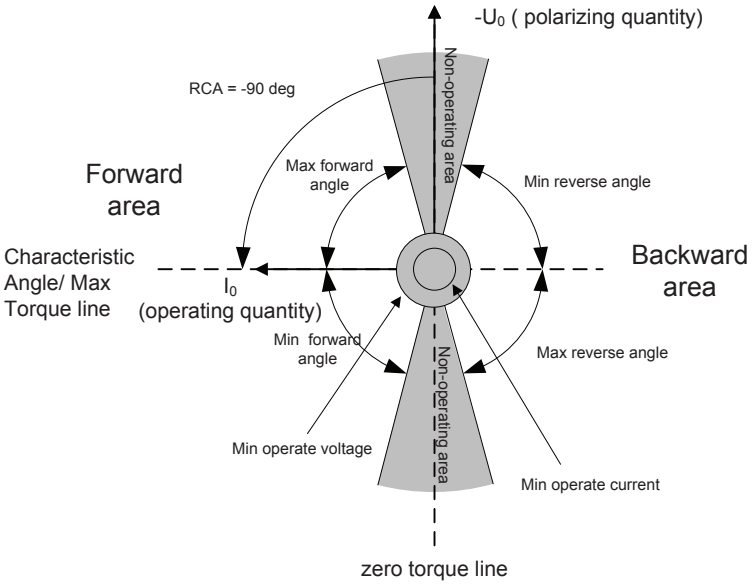

Figure 647: Configurable directional characteristics (RCA = -90˚) for an isolated network

Characteristic angle should be set to a positive value if the operating signal lags the polarizing quantity -VG or -VN, respectively, and a negative value if operating signal leads the polarizing quantity, respectively.

Table 1114: Recommended Characteristic angle setting for different network

Type of network	Characteristic angle recommended
Compensated network	0°
Solidly grounded network	+60°
Isolated network	-90°

The *Characteristic angle* setting is adjusted to the operation according to the method of neutral-point grounding, so that in an isolated network *Characteristic angle* is -90° and in a compensated network 0°. In addition, *Characteristic angle* can be changed via the control signal RCA_CTL, in which case the alternatives are -90° and 0°. The operation of the RCA_CTL input depends on the *Characteristic angle* setting.

The Peterson coil or the grounding resistor may be temporarily out of operation. To keep the protection scheme selective, it is necessary to update the *Characteristic angle* settings accordingly. This is done with an auxiliary input in the relay which receives a signal from an auxiliary switch of the disconnector of the Peterson coil in compensated networks or of the grounding resistor in grounded network as a result the *Characteristic angle* is set automatically to suit the earthing method.

Table 1115: Characteristic angle control for the RCA_CTL condition

Characteristic angle Setting	RCA_CTL=FALSE	RCA_CTL=TRUE
-90°	*Characteristic angle* =-90°	*Characteristic angle* = 0°
0°	*Characteristic angle* = 0°	*Characteristic angle* =-90°

When the phase angle criterion is used, the DIRECTION output indicates on which operating sector the negative or residual power is measured.

Low-level blocking

For a reliable operation, signal levels should be greater than the minimum level. If they are not greater than the minimum level, Timer is blocked.

In the "Neg. seq. volt." polarization selection using the *Pol quantity* setting, if the amplitude of the negative-sequence current is greater than the *Min operate current* value and the negative-sequence voltage amplitude is greater than the *Min operate voltage* value, the Enable signal is sent to Timer.

In the "Zero seq. volt." polarization selection using *Pol quantity*, if the amplitude of the residual current is greater than the *Min operate current* value and residual voltage amplitude is greater than the *Min operate voltage* value, the Enable signal is sent to Timer.

Timer

Once activated, the internal operating timer is started. The Timer characteristic is according to DT. When Timer has reached the value of *Release delay time*, the RELEASE output is activated. If a drop-off situation happens, that is, if the operating

current moves out of the operating sector or signal amplitudes drop below the minimum levels, before *Release delay time* is exceeded, the Timer reset state is activated. If the drop-off continues for more than *Reset delay time*, Timer is deactivated.

Blocking logic

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates RELEASE output and resets Timer.

5.15.6 Application

The neutral power directional element function DNZSRDIR improves the possibility to obtain selective function of the overcurrent protection in meshed networks. DNZSRDIR is used to block or release other overcurrent protection functions.

Section 6 Supervision functions

6.1 Trip circuit supervision TCSSCBR

6.1.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Trip circuit supervision	TCSSCBR	TCS	TCM

6.1.2 Function block

Figure 648: Function block

6.1.3 Functionality

The trip circuit supervision function TCSSCBR is designed to supervise the control circuit of the circuit breaker. The invalidity of a control circuit is detected by using a dedicated output contact that contains the supervision functionality. The failure of a circuit is reported to the corresponding function block in the relay configuration.

The function starts and operates when TCSSCBR detects a trip circuit failure. The operating time characteristic for the function is DT. The function operates after a predefined operating time and resets when the fault disappears.

The function contains a blocking functionality. Blocking deactivates the ALARM output and resets the timer.

6.1.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of TCSSCBR can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

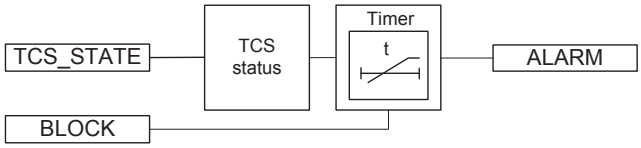

Figure 649: Functional module diagram

TCS status

This module receives the trip circuit status from the hardware. A detected failure in the trip circuit activates the timer.

Timer

Once activated, the timer runs until the set value of *Operate delay time* has elapsed. The time characteristic is according to DT. When the operation timer has reached the maximum time value, the `ALARM` output is activated. If a drop-off situation occurs during the operate time up counting, the fixed 0.5 s reset timer is activated. After that time, the operation timer is reset.

The `BLOCK` input can be controlled with a binary input, a horizontal communication input or an internal signal of the relay program. The activation of the `BLOCK` input prevents the `ALARM` output to be activated.

6.1.5 Application

TCSSCBR detects faults in the electrical control circuit of the circuit breaker. The function can supervise both open and closed coil circuits. This supervision is necessary to find out the vitality of the control circuits continuously.

Figure 650 shows an application of the trip circuit supervision function use. Example of both mechanical (on the left) and static (on the right) outputs TCS connections are shown.

The mechanical outputs (PODPx) are used in both AC or DC circuits, and polarity is insignificant. The static outputs (SPOx) can be used in DC only and polarity must be correct.

The best solution is to connect an external R_{ext} shunt resistor in parallel with the circuit breaker internal contact as shown with the dashed line. This way, although the circuit breaker auxiliary contact is open, TCS can see the trip circuit through R_{ext}. The R_{ext} resistor should have such a resistance that the current through the circuit breaker coil remains small, that is, it does not harm or overload the circuit breaker's trip coil if the trip is latched/locked-out.

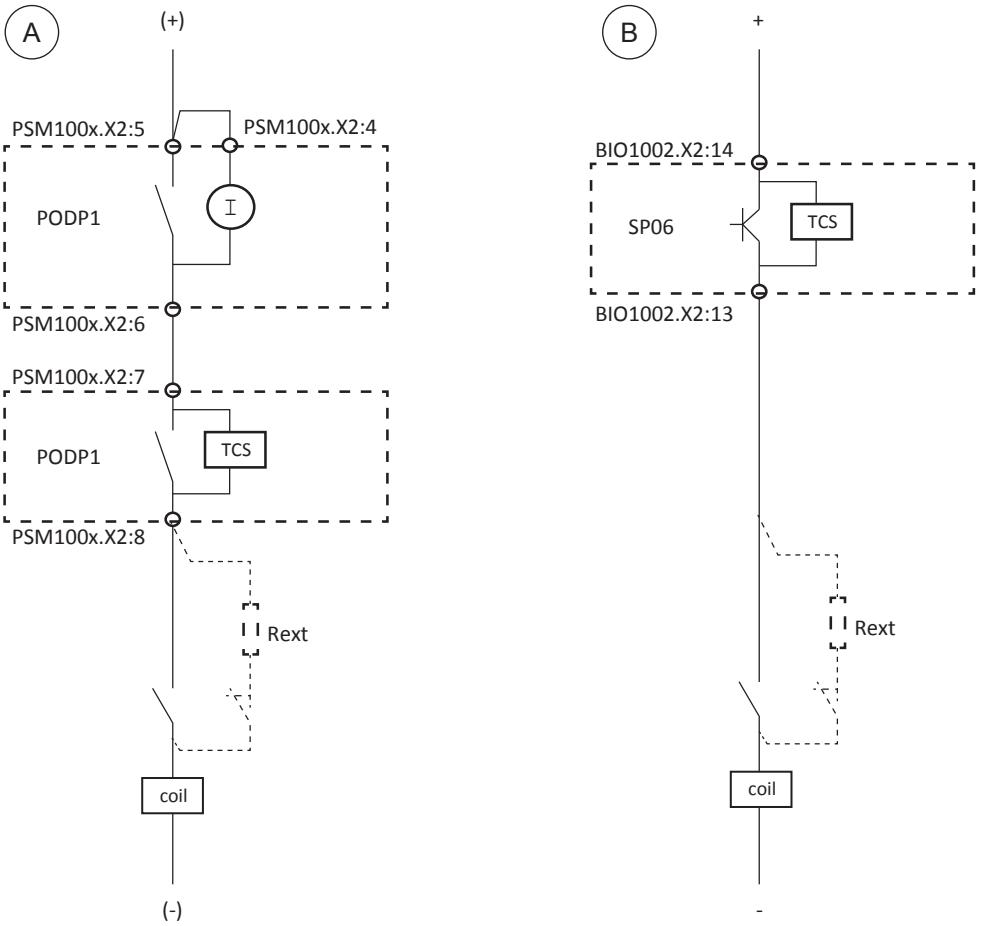

Figure 650: Operating principle of the trip-circuit supervision, single-pole connection

If TCS is required only in a closed position, the external shunt resistance can be omitted. When the circuit breaker is in the open position, TCS sees the situation as a faulty circuit. One way to avoid TCS operation in this situation is to block the supervision function whenever the circuit breaker is open.

It is also recommended to block the supervision function when the trip output is active. Otherwise, TCS issues an alarm if the trip remains active over the set TCS *Operate delay time*.

Figure 651 shows a double-pole connection of the trip circuit supervision. For the static output, this requires using SPO5 or SPO6 output in series of the circuit.

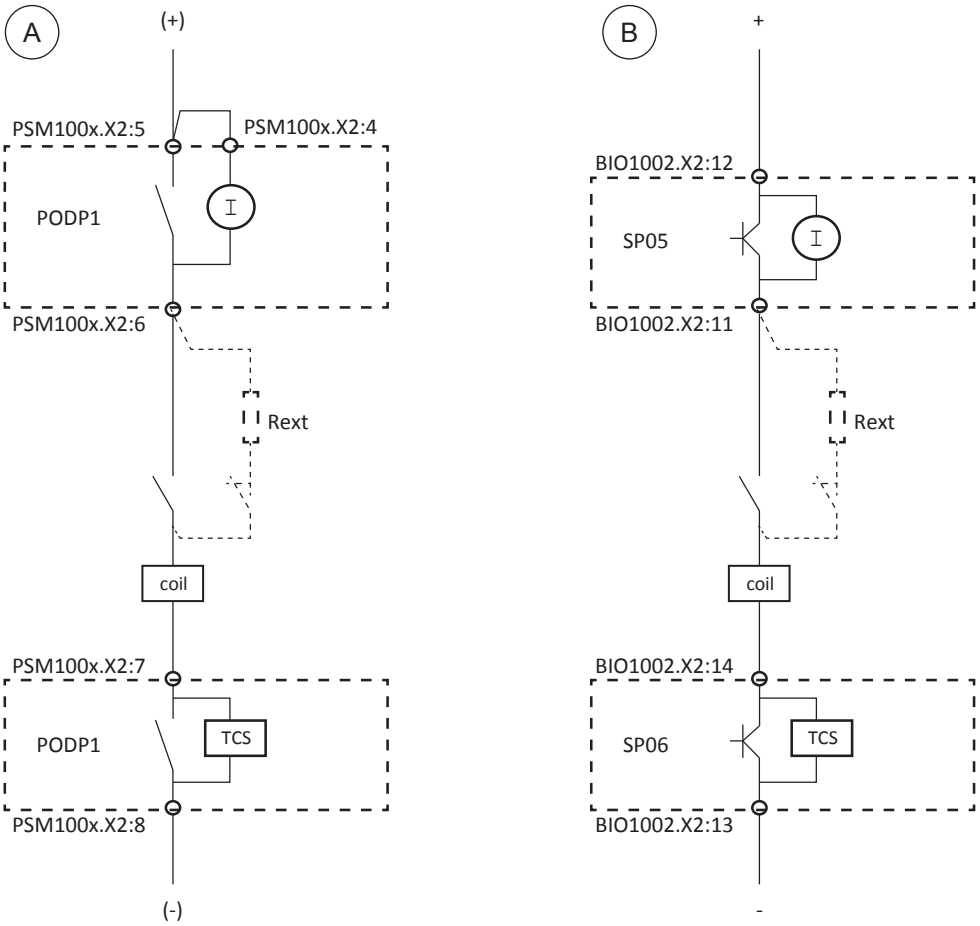

Figure 651: Operating principle of the trip-circuit supervision, double-pole connection

Trip circuit supervision and other trip contacts

It is typical that the trip circuit contains more than one trip contact in parallel, for example in transformer feeders where the trip of a Buchholz relay is connected in parallel with the feeder terminal and other relays involved. The supervising current cannot detect if one or all the other contacts connected in parallel are not connected properly.

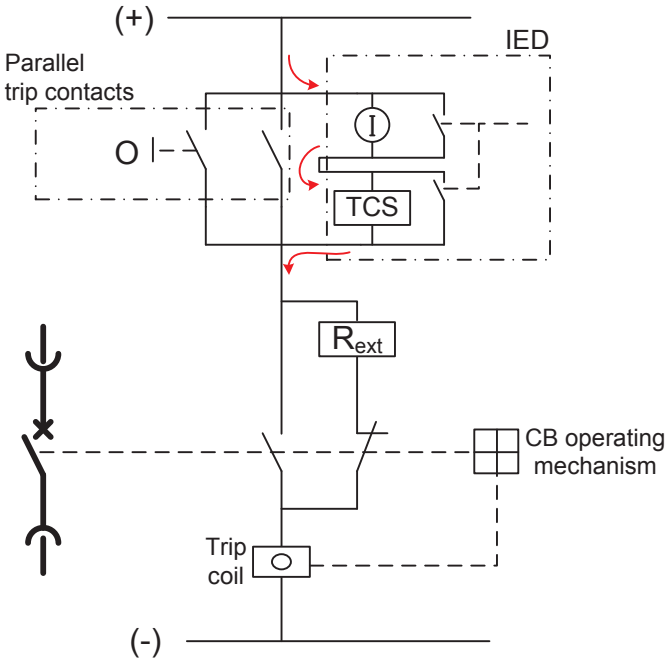

Figure 652: Constant test current flow in parallel trip contacts and trip circuit supervision

In case of parallel trip contacts, the recommended way to do the wiring is that the TCS test current flows through all wires and joints.

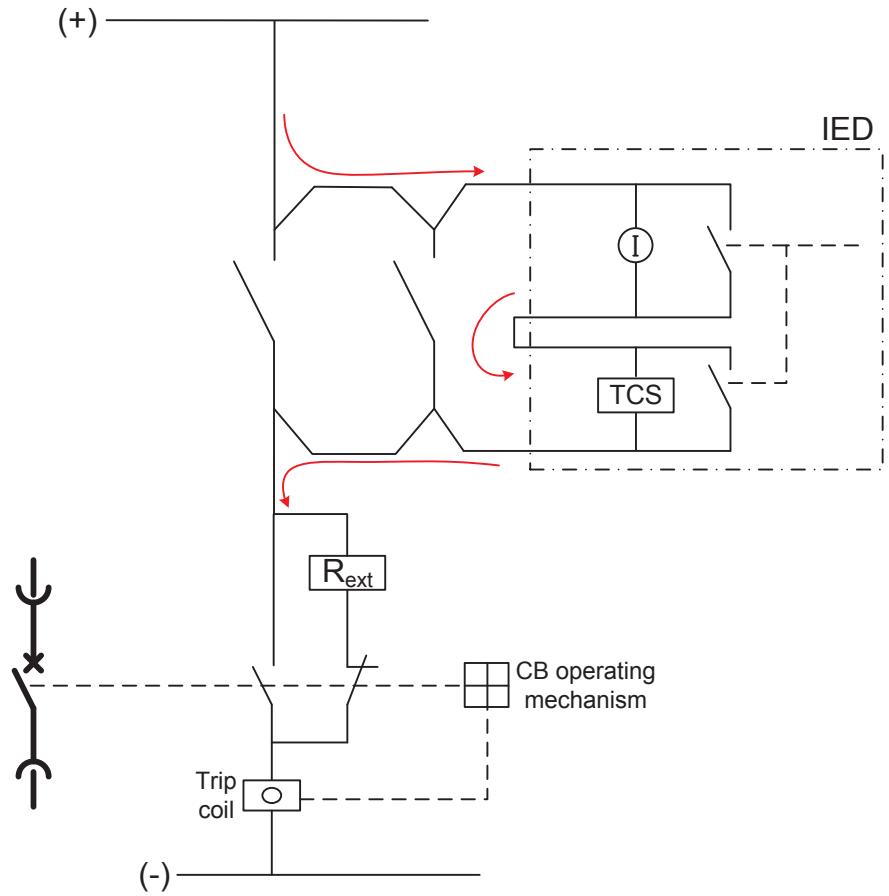

Figure 653: Improved connection for parallel trip contacts where the test current flows through all wires and joints

Several trip circuit supervision functions parallel in circuit

Not only the trip circuit often have parallel trip contacts, it is also possible that the circuit has multiple TCS circuits in parallel. Each TCS circuit causes its own supervising current to flow through the monitored coil and the actual coil current is a sum of all TCS currents. This must be taken into consideration when determining the resistance of R_{ext}.

Setting the TCS function in a protection relay not-in-use does not typically affect the supervising current injection.

Trip circuit supervision with auxiliary relays

Many retrofit projects are carried out partially, that is, the old electromechanical relays are replaced with new ones but the circuit breaker is not replaced. This creates a problem that the coil current of an old type circuit breaker can be too high for the protection relay trip contact to break.

The circuit breaker coil current is normally cut by an internal contact of the circuit breaker. In case of a circuit breaker failure, there is a risk that the protection relay trip contact is destroyed since the contact is obliged to disconnect high level of electromagnetic energy accumulated in the trip coil.

An auxiliary relay can be used between the protection relay trip contact and the circuit breaker coil. This way the breaking capacity question is solved, but the TCS circuit in the protection relay monitors the healthy auxiliary relay coil, not the circuit breaker coil. The separate trip circuit supervision relay is applicable for this to supervise the trip coil of the circuit breaker.

Dimensioning of the external resistor

Under normal operating conditions, the applied external voltage is divided between the relay's internal circuit and the external trip circuit so that at the minimum 20 V (15...20 V) remains over the relay's internal circuit. Should the external circuit's resistance be too high or the internal circuit's too low, for example due to welded relay contacts, a fault is detected.

Mathematically, the operation condition can be expressed as:

$$U_C - U_D - I_C \cdot (R_s + R_{ext}) \geq 20V \quad AC / DC$$

(Equation 279)

U_c	Operating voltage over the supervised trip circuit
U_D	Voltage drop over internal 3 mA current drain, about 6.5 V
I_c	Measuring current through the trip circuit, appr. 1.5 mA (0.99...1.72 mA)
R_{ext}	External shunt resistance
R_s	Trip coil resistance

If the external shunt resistance is used, it has to be calculated not to interfere with the functionality of the supervision or the trip coil. Too high a resistance causes too high a voltage drop, jeopardizing the requirement of at least 20 V over the internal circuit, while a resistance too low can enable false operations of the trip coil.

Table 1122: Values recommended for the external resistor R_{ext}

Operating voltage U_c	Shunt resistor R_{ext}
48 V AC/DC	1.2 kΩ, 5 W
60 V AC/DC	5.6 kΩ, 5 W
110...130 V AC/DC	22 kΩ, 5 W
220...250 V AC/DC	33 kΩ, 5 W

Due to the requirement that the voltage over the TCS contact must be 20 V or higher, the correct operation is not guaranteed with auxiliary operating voltages lower than 48 V DC because of the voltage drop in U_D and R_{ext} and the operating coil or even voltage

drop of the feeding auxiliary voltage system which can cause too low voltage values over the TCS contact. In this case, erroneous alarming can occur.

At lower (<48 V DC) auxiliary circuit operating voltages, it is recommend either to use the static output and single-pole connection (as then there is no internal current drain and $U_D = 0$ V), or not to use R_{ext} and block TCS when the circuit breaker is open.

Using power output contacts without trip circuit supervision

In case of mechanical outputs, if TCS is not used, the internal current drain (PSM100x.X2:4, PSM100x.X2:9 and PSM100x.X2:14 in PODP1, PODP2 and PODP2 outputs, respectively) can be left unconnected. The output can then be used as a normal power output.

Incorrect connections and use of trip circuit supervision

Although the TCS circuit in the PODP1, PODP2 and PODP2 outputs consists of two separate contacts, it must be noted that those are designed to be used as series connected to guarantee the breaking capacity given in the technical manual of the protection relay. Figure 654 shows incorrect usage of a TCS circuit when only one of the contacts is used.

6.2 Current circuit supervision CCSPVC

6.2.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Current circuit supervision	CCSPVC	MCS 3I	CCM

6.2.2 Function block

Figure 655: Function block

6.2.3 Functionality

The current circuit supervision function CCSPVC is used for monitoring current transformer secondary circuits.

CCSPVC calculates internally the sum of phase currents (I_A, I_B and I_C) and compares the sum against the measured single reference current (I_REF). The reference current must originate from other three-phase CT cores than the phase currents (I_A, I_B and I_C) and it is to be externally summated, that is, outside the protection relay.

CCSPVC detects a fault in the measurement circuit and issues an alarm or blocks the protection functions to avoid unwanted tripping.

It must be remembered that the blocking of protection functions at an occurring open CT circuit means that the situation remains unchanged and extremely high voltages stress the secondary circuit.

6.2.4 Analog channel configuration

CCSPVC has two analog group inputs which must be properly configured.

Table 1128: Analog inputs

Input	Description
I3P	Three-phase currents
IRES	Residual current (measured)

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1129: Special conditions

Condition	Description
IRES measured	In case IRES needs to be derived, the function requires that all CT cores, except for the one used for phase current measurement, must be used and summed externally.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

6.2.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of CCSPVC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

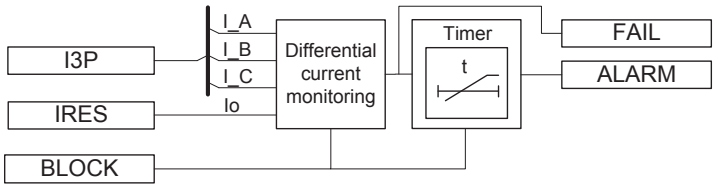

Figure 656: Functional module diagram

Differential current monitoring

Differential current monitoring supervises the difference between the summed phase currents I_A, I_B and I_C and the reference current I_REF.

The current operating characteristics can be selected with the *Start value* setting. When the highest phase current is less than 1.0 × In, the differential current limit is defined with *Start value*. When the highest phase current is more than 1.0 × In, the differential current limit is calculated with the equation.

$$MAX(I_A, I_B, I_C) \cdot Start\,value$$

(Equation 280)

The differential current is limited to 1.0 × In.

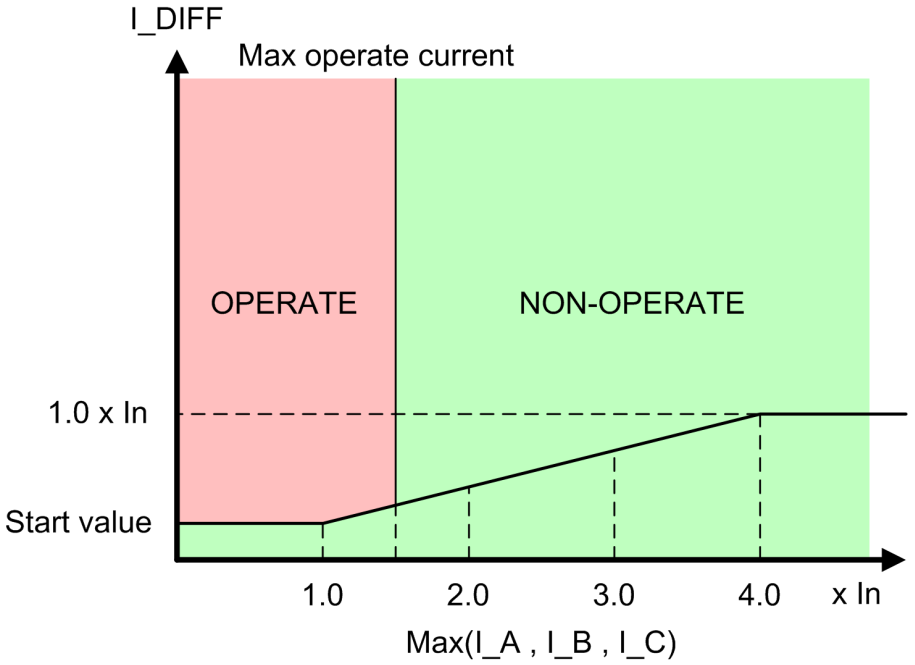

Figure 657: CCSPVC operating characteristics

When the differential current I_DIFF is in the operating region, the FAIL output is activated.

The function is internally blocked if any phase current is higher than the set *Max operate current*. When the internal blocking activates, the FAIL output is deactivated immediately. The internal blocking is used for avoiding false operation during a fault situation when the current transformers are saturated due to high fault currents.

The value of the differential current is available in the monitored data view on the LHMI or through other communication tools. The value is calculated with the equation.

$$I_DIFF = \left|\overline{I_A} + \overline{I_B} + \overline{I_C}\right| - \left|\overline{I_REF}\right|$$

(Equation 281)

The *Start value* setting is given in units of ×In of the phase current transformer. The possible difference in the phase and reference current transformer ratios is internally compensated by scaling I_REF with the value derived from the *Primary current* setting values. These setting parameters can be found in the Basic functions section.

The activation of the BLOCK input deactivates the FAIL output immediately.

Timer

The timer is activated with the FAIL signal. The ALARM output is activated after a fixed 200 ms delay. FAIL needs to be active during the delay.

When the internal blocking is activated, the FAIL output deactivates immediately. However, the ALARM output deactivates after a fixed delay of three seconds.

The function resets when the differential current is below the start value and the highest phase current is more than 5 percent of the nominal current (0.05 × In).

If the current falls to zero when the FAIL or ALARM outputs are active, the deactivation of these outputs is prevented.

The activation of the BLOCK input deactivates the ALARM output.

6.2.6 Application

Open or short-circuited current transformer cores can cause unwanted operation in many protection functions such as differential, earth-fault current and negative-sequence current functions. When currents from two independent three-phase sets of CTs or CT cores measuring the same primary currents are available, reliable current circuit supervision can be arranged by comparing the currents from the two sets. When an error in any CT circuit is detected, the protection functions concerned can be blocked and an alarm given.

In case of high currents, the unequal transient saturation of CT cores with a different remanence or saturation factor can result in differences in the secondary currents from the two CT cores. An unwanted blocking of protection functions during the transient stage must then be avoided.

The supervision function must be sensitive and have a short operation time to prevent unwanted tripping from fast-acting, sensitive numerical protections in case of faulty CT secondary circuits.

Open CT circuits create extremely high voltages in the circuits, which may damage the insulation and cause further problems. This must be taken into consideration especially when the protection functions are blocked.

When the reference current is not connected to the protection relay, the function should be turned off. Otherwise, the FAIL output is activated when unbalance occurs in the phase currents even if there was nothing wrong with the measurement circuit.

Reference current measured with core-balanced current transformer

CCSPVC compares the sum of phase currents to the current measured with the core-balanced CT.

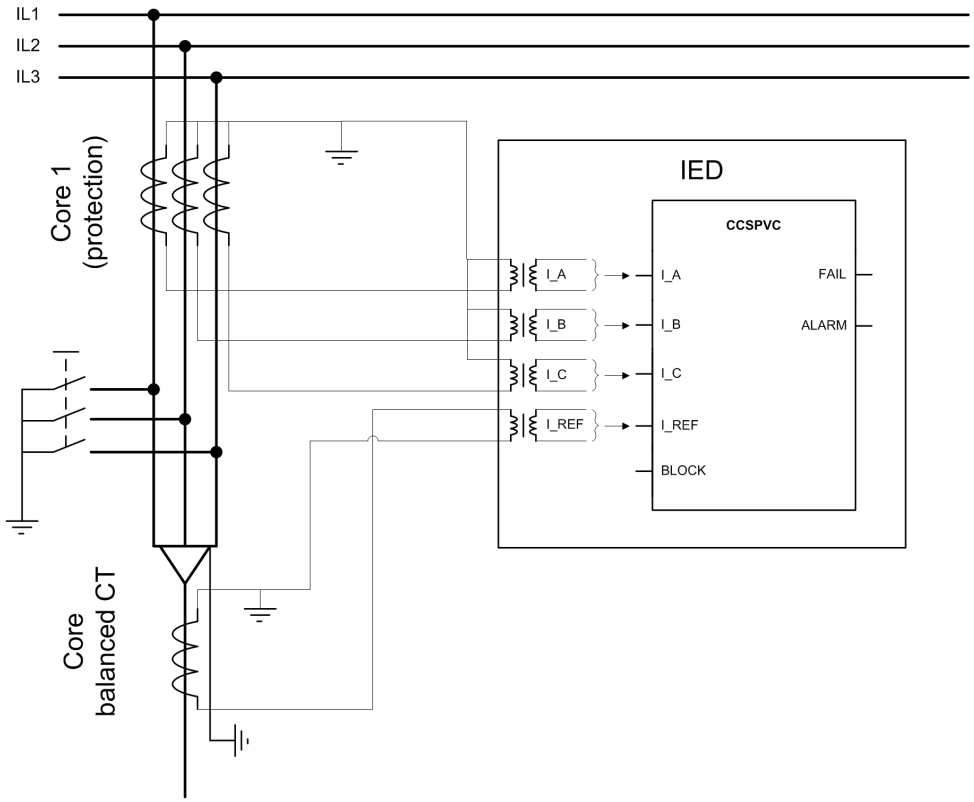

Figure 658: Connection diagram for reference current measurement with core-balanced current transformer

Current measurement with two independent three-phase sets of CT cores

Figure 659 and Figure 660 show diagrams of connections where the reference current is measured with two independent three-phase sets of CT cores.

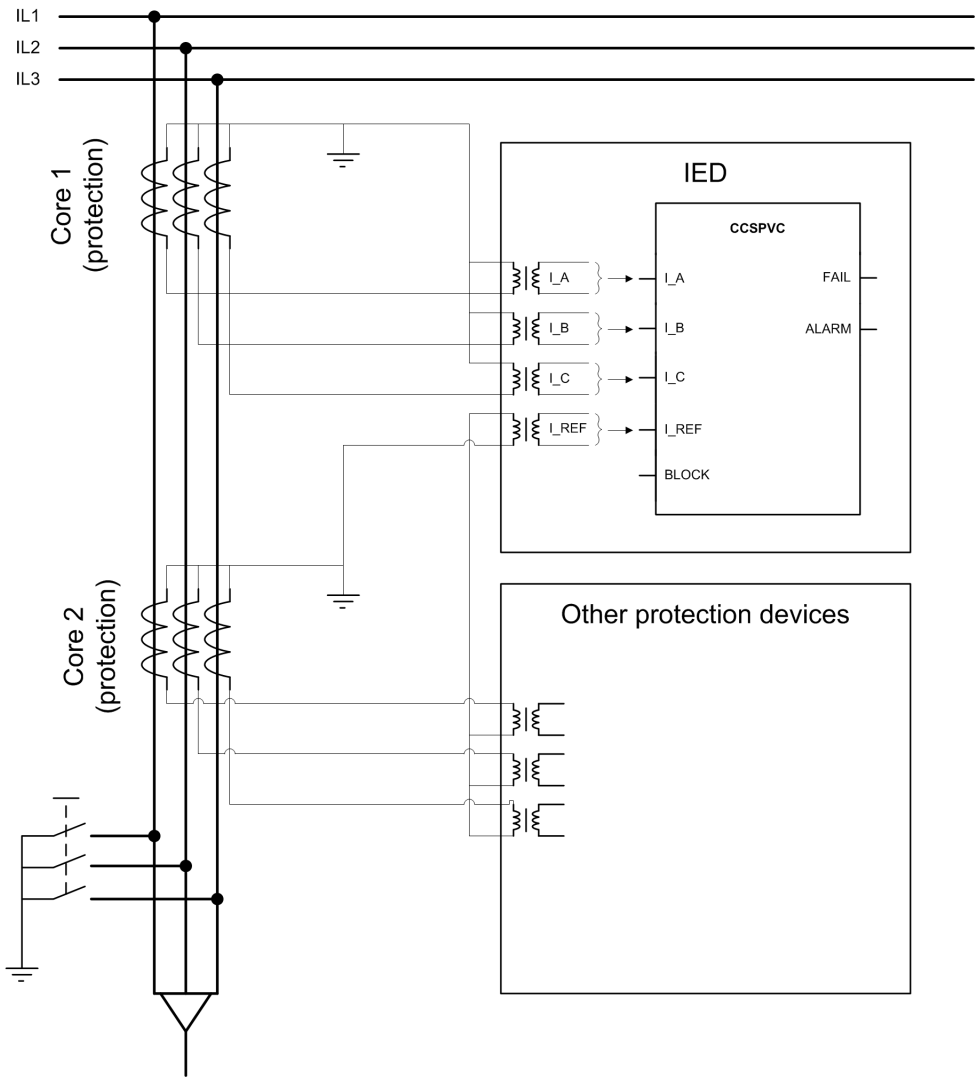

Figure 659: Connection diagram for current circuit supervision with two sets of three-phase current transformer protection cores

When using the measurement core for reference current measurement, it should be noted that the saturation level of the measurement core is much lower than with the protection core. This should be taken into account when setting the current circuit supervision function.

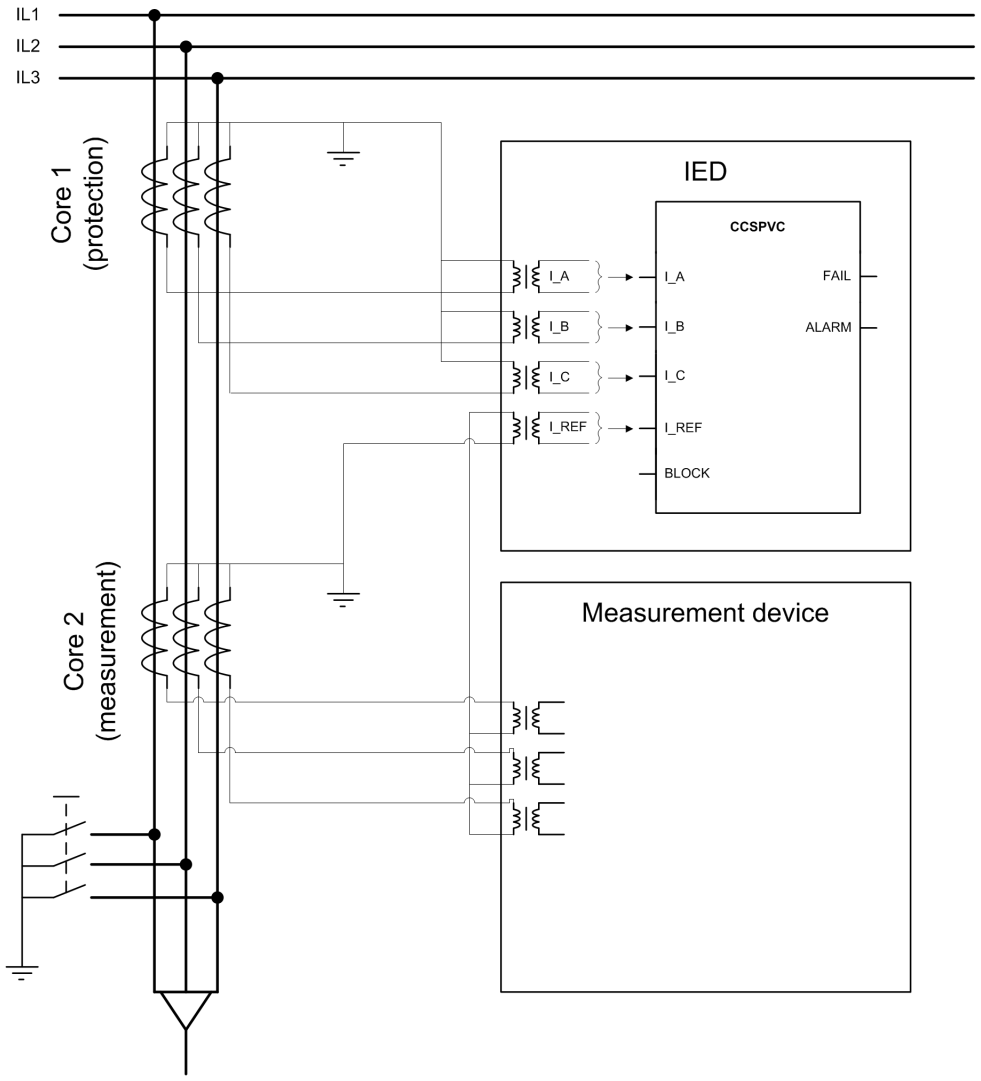

Figure 660: Connection diagram for current circuit supervision with two sets of three-phase current transformer cores (protection and measurement)

Example of incorrect connection

The currents must be measured with two independent cores, that is, the phase currents must be measured with a different core than the reference current. A connection diagram shows an example of a case where the phase currents and the reference currents are measured from the same core.

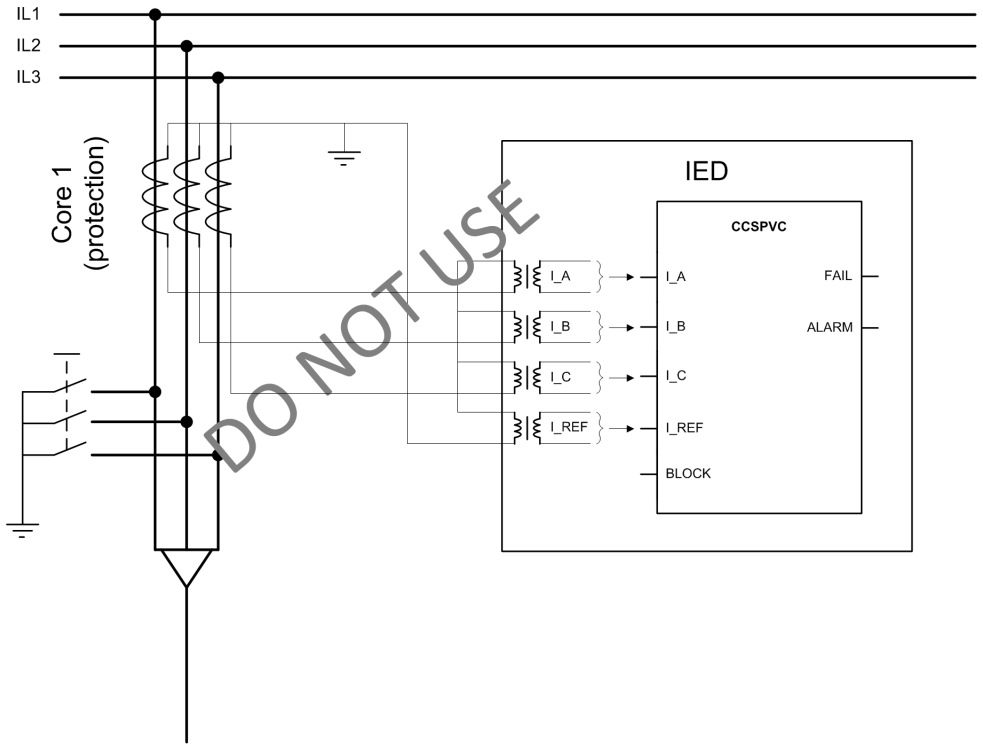

Figure 661: Example of incorrect reference current connection

6.3.2 Function block

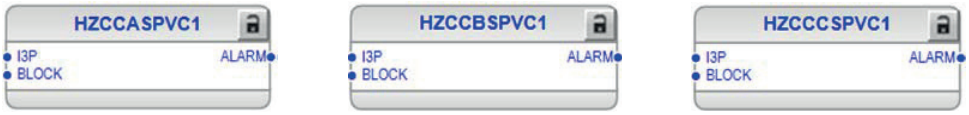

Figure 662: Function block

6.3.3 Functionality

The current transformer supervision for high-impedance protection scheme function HZCCxSPVC is a dedicated phase-segregated supervision function to be used along with the high-impedance differential protection for detecting the broken CT secondary wires. The differential current is taken as an input for the protection relay. During normal CT condition, the value of the differential current is zero. However, when the CT is broken, the secondary differential current starts flowing and it is used for generating alarms.

To avoid maloperation, HZCCxSPVC should have a sensitive setting, compared to the high-impedance differential protection. The function is likely to start under through-fault conditions. However, by incorporating a high time delay (3 s or more), the downstream protection clears the fault before an alarm is generated.

HZCCxSPVC generates an alarm when the differential current exceeds the set limit. The function operates within the DT characteristic.

HZCCxSPVC contains a blocking functionality. It is possible to block the function output, Timer or the whole function.

6.3.4 Analog channel configuration

HZCCxSPVC has one analog group input which must be properly configured.

Table 1136: Analog signals

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

6.3.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of HZCCxSPVC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

The module diagram illustrates all the phases of the function. However, the functionality is described only for phase A. The functionality for phase B and C is identical.

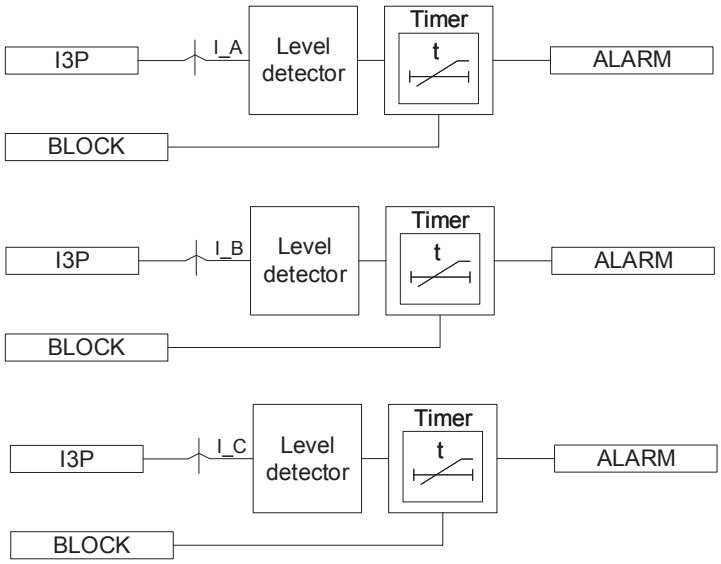

Figure 663: Functional module diagram

Level detector

This module compares the differential current I_A to the set *Start value*. The timer module is activated if the differential current exceeds the value set in the *Start value* setting.

Timer

The time characteristic is according to DT. When the alarm timer reaches the value set by *Alarm delay time*, the ALARM output is activated. If the fault disappears before the module generates an alarm signal, the reset timer is activated. If the reset timer reaches the value set by *Reset delay time*, the alarm timer resets. The activation of the BLOCK signal resets the Timer and deactivates the ALARM output.

Lockout logic

HZCCxSPVC is provided with the possibility to activate a lockout for the ALARM output depending on the *Alarm output mode* setting. In the "Lockout" mode, the ALARM must be reset manually from the LHMI Clear menu after checking the CT secondary circuit. In the "Non-latched" mode, the ALARM output functions normally, that is, it resets as soon as the fault is cleared.

6.3.6 Measuring modes

The function operates on two alternative measurement modes, DFT and Peak-to-Peak. The measurement mode is selected using the *Measurement mode* setting.

6.3.7 Application

HZCCxSPVC is a dedicated phase-segregated supervision function to be used along with the high-impedance differential protection for detecting the broken CT secondary wires. The operation principle of HZCCxSPVC is similar to the high-impedance differential protection function HIxPDIF. However, the current setting of HZCCxSPVC is set to be much more sensitive than HIxPDIF and it operates with a higher time delay. A typical example of the HZCCxSPVC *Start value* setting is 0.1 pu with an *Alarm delay time* of 3 s or more.

As the current setting of HZCCxSPVC is more sensitive than the actual differential stage, it can start internally under the through-fault conditions; however, a sufficient time delay prevents false alarm. If the bus wire is broken, differential current arises depending on the load of the feeder with the broken bus wire.

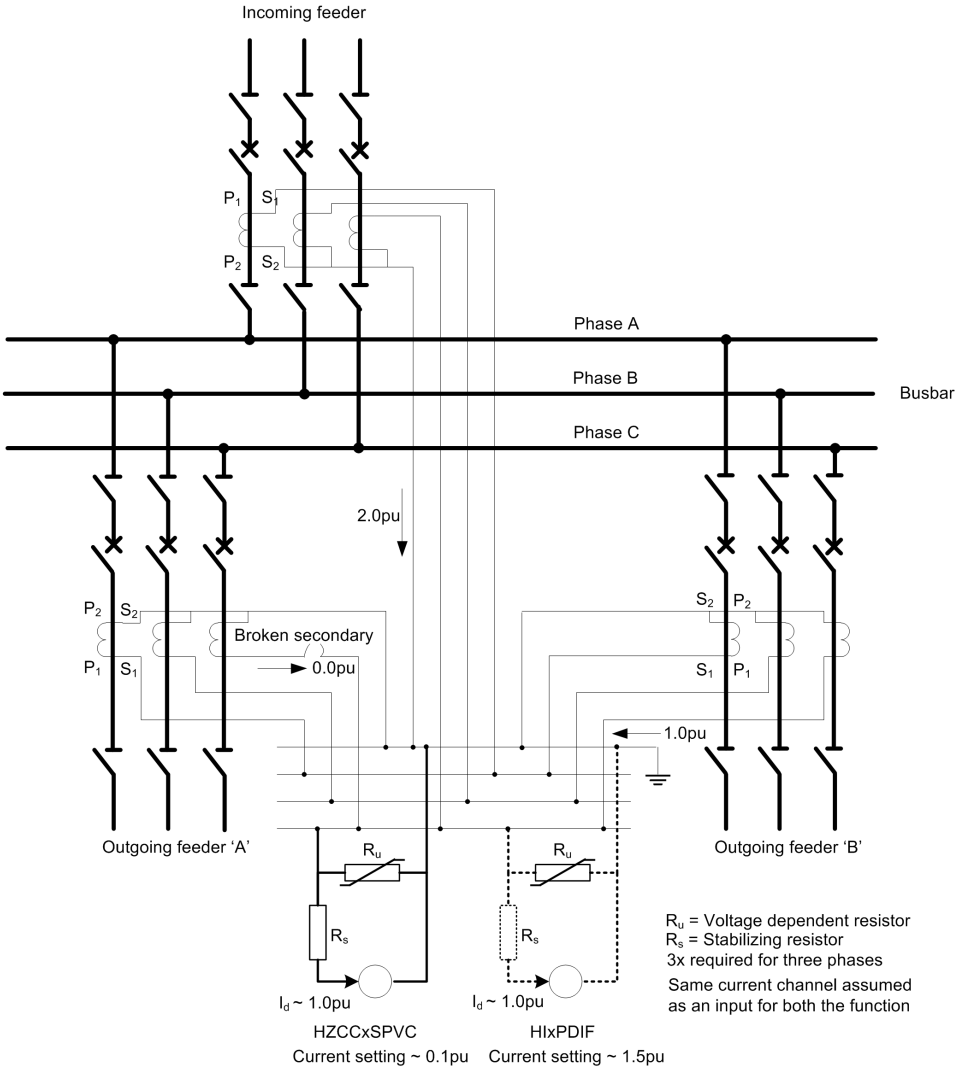

Figure 664: Broken secondary detection by HZCCxSPVC

In the example, the incoming feeder is carrying a load of 2.0 pu and both outgoing feeders carry an equal load of 1.0 pu However, both HIxPDIF and HZCCxSPVC consider the current as an increased differential or unbalance current because of the broken CT wire in phase C. Both HIxPDIF and HZCCxSPVC receive the differential current of approximately 1.0 pu The main differential protection HIxPDIF cannot operate because of the higher current setting.

All CTs must have the same ratio.

The ALARM output of the CT supervision function can be used to energize an auxiliary relay which can short-circuit the current CT wires, making the busbar differential protection inoperative. This arrangement does not prevent unwanted operation of HIxPDIF if the start setting is below the rated load. For example, if the start setting for HIxPDIF in the example is set as 0.8 pu HIxPDIF will operate before HZCCxSPVC.

6.4 Protection communication supervision PCSITPC

6.4.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Protection communication supervision	PCSITPC	PCS	PCS

6.4.2 Function block

Figure 665: Function block

6.4.3 Functionality

The protection communication supervision function PCSITPC monitors the protection communication channel. PCSITPC blocks the line differential protection functions when interference in the protection communication channel is detected. The blocking takes place automatically for the LNPLDF and BSTGAPC functions which are dependent on the continuous availability of the protection communication channel.

The protection communication channel is continuously monitored by PCSITPC. The function detects missing or delayed protection telegrams. Protection telegrams are used for transferring the sampled analog and other protection related data. Missing or

delayed protection telegrams can jeopardize the demand operate speed of the differential protection.

When a short-term interference is detected in the protection communication channel, the function issues a warning and the line differential functions are automatically internally blocked. PCSITPC reacts fast for the protection communication interferences. The blocking takes place at the latest when a communication interruption lasting for two fundamental network periods is detected. When a severe and long lasting interference or total interruption in the protection communication channel is detected, an alarm is issued (after a five-second delay). The protection communication supervision quality status is exchanged continuously online by the local and remote PCSITPC instances. This ensures that both local and remote ends protection blocking is issued coordinately. This further enhances the security of the line differential protection by forcing both line end protection relays to the same blocking state during a protection communication interference, even in cases where the interference is detected with only one line end protection relay. There is also the *Reset delay time* settings parameter available which is used for changing the required interference-free time before releasing the line-differential protection back in operation after a blocking due to an interference in communication.

6.4.4 Operation principle

The operation of protection communication supervision can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

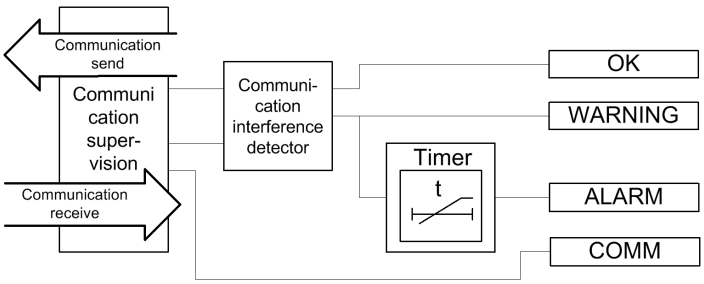

Figure 666: Functional module diagram

Communication supervision

The protection communication is supervised because the differential calculation is dependent on the refreshing of new analog phasor samples from the remote terminal within the protection telegram. The new protection telegram also updates the status of the binary signals sent by the remote terminal. The calculation of the differential current is based on comparing the remote and local terminal measured current samples. It is therefore essential that the protection communication telegrams are supervised and the result of the sample latency calculation can be used further in the differential current calculation. When the communication is able to receive telegrams correctly from the remote end via the communication media, the communication is assumed to be operating correctly and the `COMM` output is kept active.

Communication interference detector

The communication interference detector is continuously measuring and observing the sample latency of the protection telegrams. This value is also available as monitored data. The function provides three output signals of which only the corresponding one is active at a time depending on if the protection communication supervision is in OK, WARNING or ALARM. The OK state indicates the correct operation of the protection. The WARNING state indicates that the protection is internally blocked due to detected interference. The WARNING state is switched to ALARM if the interference lasts for a longer period. The protection communication supervision can sometimes be in the WAITING state. This state indicates that the terminal is waiting for the communication to start or restart from the remote end terminal.

Timer

Once activated with the WARNING signal, the timer has a constant time delay value of five seconds. If the communication failure exists after the delay, the ALARM output is activated.

6.4.5 Application

Communication principle

Analog samples, trip-, start- and user programmable signals are transferred in each protection telegram and the exchange of these protection telegrams is done eight times per power system cycle (every 2.5 ms when F_n = 50 Hz).

Master-Master communication arrangement is used in the two-terminal line differential solution. Current samples are sent from both line ends and the protection algorithms are also executed on both line ends. The direct-intertrip, however, ensures that both ends are always operated simultaneously.

Time synchronization

In numerical line differential protection, the current samples from the protections which are located geographically apart from each other must be time coordinated so that the current samples from both ends of the protected line can be compared without introducing irrelevant errors. The time coordination requires an extremely high accuracy.

As an example, an inaccuracy of 0.1 ms in a 50 Hz system gives a maximum amplitude error of approximately around 3 percent. An inaccuracy of 1 ms gives a maximum amplitude error of approximately 31 percent. The corresponding figures for a 60 Hz system are 4 and 38 percent respectively.

In the protection relay, the time coordination is done with an echo method. The protection relays create their own time reference between each other so that the system clocks do not need to synchronize.

The figure shows that in the time synchronization the transmission time to send a message from station B to station A, T1→T2, and the time to receive a message from A to B, T4→T5, are measured. The station A protection relay delay from the sampling to the start of send, T3→T4, and the local delay from receive to the station B protection relay sampling T5→T6 time, are also measured for the station B protection relay, and vice versa. This way the time alignment factor for the local and remote samples is achieved.

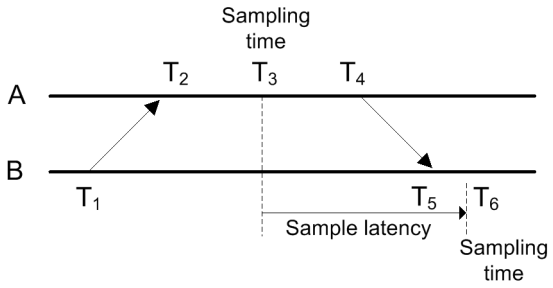

Figure 667: Measuring sampling latency

$$P_d = \frac{(T_2 - T_1) + (T_5 - T_4)}{2}$$

(Equation 282)

$$S_d = P_d + (T_4 - T_3) + (T_6 - T_5)$$

(Equation 283)

The sampling latency S_d is calculated for each telegram on both ends. The algorithm assumes that the one-way propagation delay P_d is equal for both directions.

The echo method without GPS can be used in telecommunication transmission networks as long as delay symmetry exists, that is, the sending and receiving delays are equal.

6.4.6 Signals

6.5 Fuse failure supervision SEQSPVC

6.5.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Fuse failure supervision	SEQSPVC	FUSEF	VCM, 60

6.5.2 Function block

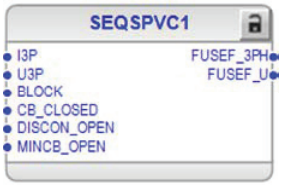

Figure 668: Function block

6.5.3 Functionality

The fuse failure supervision function SEQSPVC is used to block the voltage-measuring functions when failure occurs in the secondary circuits between the voltage transformer (or combi sensor or voltage sensor) and protection relay to avoid misoperations of the voltage protection functions.

SEQSPVC has two algorithms, a negative sequence-based algorithm and a delta current and delta voltage algorithm.

A criterion based on the delta current and the delta voltage measurements can be activated to detect three-phase fuse failures which usually are more associated with the voltage transformer switching during station operations.

6.5.4 Analog channel configuration

SEQSPVC has two analog group inputs which all must be properly configured.

Table 1156: Analog inputs

Input	Description
I3P	Three-phase currents
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1157: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two voltage channels connected but it is recommended to connect all three voltage channels.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

6.5.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of SEQSPVC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

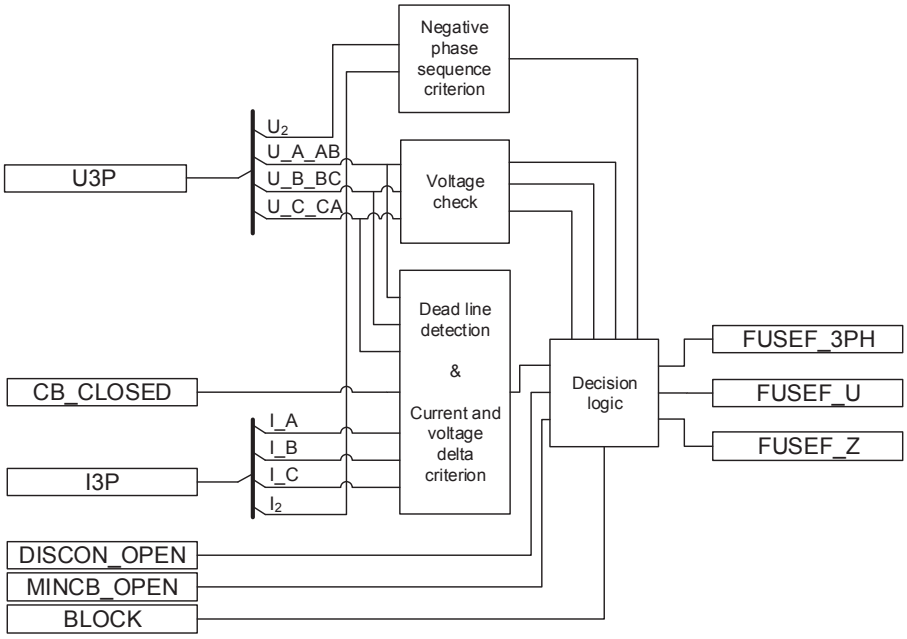

Figure 669: Functional module diagram

Negative phase-sequence criterion

A fuse failure based on the negative-sequence criterion is detected if the measured negative-sequence voltage exceeds the set *Neg Seq voltage Lev* value and the measured negative-sequence current is below the set *Neg Seq current Lev* value. The detected fuse failure is reported to the decision logic module.

Voltage check

The phase voltage magnitude is checked when deciding whether the fuse failure is a three, two or a single-phase fault.

The module makes a phase-specific comparison between each voltage input and the *Seal in voltage* setting. If the input voltage is lower than the setting, the corresponding phase is reported to the decision logic module.

Current and voltage delta criterion

The delta function can be activated by setting the *Change rate enable* parameter to "True". Once the function is activated, it operates in parallel with the negative sequence-based algorithm. The current and voltage are continuously measured in all three phases to calculate:

- Change of voltage dU/dt
- Change of current dI/dt

The calculated delta quantities are compared to the respective set values of the *Current change rate* and *Voltage change rate* settings.

The delta current and delta voltage algorithms detect a fuse failure if there is a sufficient negative change in the voltage amplitude without a sufficient change in the current amplitude in each phase separately. This is performed when the circuit breaker is closed. Information about the circuit breaker position is connected to the `CB_CLOSED` input.

There are two conditions for activating the current and voltage delta function.

- The magnitude of dU/dt exceeds the corresponding value of the *Voltage change rate* setting and magnitude of dI/dt is below the value of the *Current change rate* setting in any phase at the same time due to the closure of the circuit breaker (`CB_CLOSED` = TRUE).
- The magnitude of dU/dt exceeds the value of the *Voltage change rate* setting and the magnitude of dI/dt is below the *Current change rate* setting in any phase at the same time and the magnitude of the phase current in the same phase exceeds the *Min Op current delta* setting.

The first condition requires the delta criterion to be fulfilled in any phase at the same time as the circuit breaker is closed. Opening the circuit breaker at one end and energizing the line from the other end onto a fault could lead to an improper operation of SEQSPVC with an open breaker. If this is considered to be an important disadvantage, the `CB_CLOSED` input is to be connected to FALSE. In this way only the second criterion can activate the delta function.

The second condition requires the delta criterion to be fulfilled in one phase together with a high current for the same phase. The measured phase current is used to reduce the risk of a false fuse failure detection. If the current on the protected line is low, a voltage drop in the system (not caused by the fuse failure) is not followed by a current change and a false fuse failure can occur. To prevent this, the minimum phase current criterion is checked.

The fuse failure detection is active until the voltages return above the *Min Op voltage delta* setting. If a voltage in a phase is below the *Min Op voltage delta* setting, a new

fuse failure detection for that phase is not possible until the voltage returns above the setting value.

Decision logic

If voltages are Wye-connected, it is recommended to scale the default values of voltage-based settings with 1/sqrt(3) because the default setting values apply for Delta-connected settings.

The fuse failure detection outputs FUSEF_U and FUSEF_3PH are controlled according to the detection criteria or external signals.

Table 1158: Fuse failure output control

Fuse failure detection criterion	Conditions and function response
Negative-sequence criterion	If a fuse failure is detected based on the negative sequence criterion, the FUSEF_U output is activated.
	If the fuse failure detection is active for more than five seconds and at the same time all the phase voltage values are below the set value of the *Seal in voltage* setting with *Enable seal in* turned to "True", the function activates the FUSE_3PH output signal.
	The FUSEF_U output signal is also activated if all the phase voltages are above the *Seal in voltage* setting for more than 60 seconds and at the same time the negative sequence voltage is above *Neg Seq voltage Lev* for more than 5 seconds, all the phase currents are below the *Current dead Lin Val* setting and the circuit breaker is closed, that is,CB_CLOSED is TRUE.
Current and voltage delta function criterion	If the current and voltage delta criterion detects a fuse failure condition, but all the voltages are not below the *Seal in voltage* setting, only the FUSEF_U output is activated.
	If the fuse failure detection is active for more than five seconds and at the same time all the phase voltage values are below the set value of the *Seal in voltage* setting with *Enable seal in* turned to "True", the function activates the FUSE_3PH output signal.
External fuse failure detection	The MINCB_OPEN input signal is supposed to be connected through a protection relay binary input to the N.C. auxiliary contact of the miniature circuit breaker protecting the VT secondary circuit. The MINCB_OPEN signal sets the FUSEF_U output signal to block all the voltage-related functions when MCB is in the open state.
	The DISCON_OPEN input signal is supposed to be connected through a protection relay binary input to the N.C. auxiliary contact of the line disconnector. The DISCON_OPEN signal sets the FUSEF_U output signal to block the voltage-related functions when the line disconnector is in the open state.

It is recommended to always set *Enable seal in* to "True". This secures that the blocked protection functions remain blocked until normal voltage conditions are restored if the fuse failure has been active for 5 seconds, that is, the fuse failure outputs are deactivated when the normal voltage conditions are restored.

The activation of the BLOCK input deactivates both FUSEF_U and FUSEF_3PH outputs.

6.5.6 Application

Some protection functions operate on the basis of the measured voltage value in the protection relay point. These functions can fail if there is a fault in the measuring circuits between the voltage transformer (or combi sensor or voltage sensor) and protection relay.

A fault in the voltage-measuring circuit is called a fuse failure. This term is misleading since a blown fuse is just one of the many possible reasons for a broken circuit. Since incorrectly measured voltage can result in a faulty operation of some of the protection functions, it is important to detect the fuse failures. A fast fuse failure detection is one of the means to block voltage-based functions before they operate.

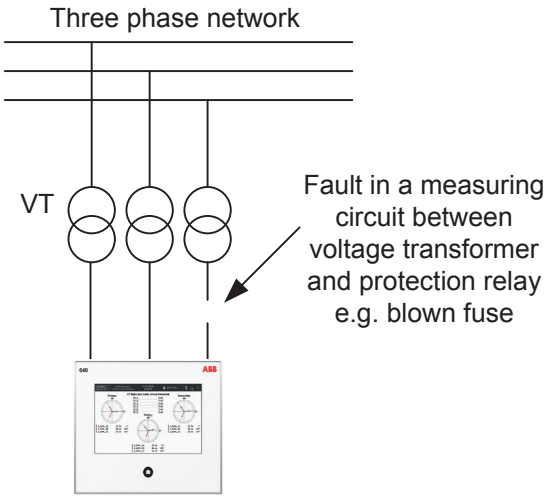

Figure 670: Fault in a circuit from the voltage transformer to the protection relay

A fuse failure occurs due to blown fuses, broken wires or intended substation operations. The negative sequence component-based function can be used to detect different types of single-phase or two-phase fuse failures. However, at least one of the three circuits from the voltage transformers must be intact. The supporting delta-based function can also detect a fuse failure due to three-phase interruptions.

In the negative sequence component-based part of the function, a fuse failure is detected by comparing the calculated value of the negative sequence component voltage to the negative sequence component current. The sequence entities are

calculated from the measured current and voltage data for all three phases. The purpose of this function is to block voltage-dependent functions when a fuse failure is detected. Since the voltage dependence differs between these functions, SEQSPVC has two outputs for this purpose.

6.6 Runtime counter for machines and devices MDSOPT

6.6.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Runtime counter for machines and devices	MDSOPT	OPTS	OPTM

6.6.2 Function block

Figure 671: Function block

6.6.3 Functionality

The runtime counter for machines and devices function MDSOPT calculates and presents the accumulated operation time of a machine or device as the output. The unit of time for accumulation is hour. The function generates a warning and an alarm when the accumulated operation time exceeds the set limits. It utilizes a binary input to indicate the active operation condition.

The accumulated operation time is one of the parameters for scheduling a service on the equipment like motors. It indicates the use of the machine and hence the mechanical wear and tear. Generally, the equipment manufacturers provide a maintenance schedule based on the number of hours of service.

6.6.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of MDSOPT can be described using a module diagram. All the modules in the diagram are explained in the next sections.

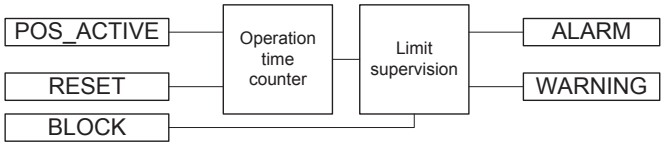

Figure 672: Functional module diagram

Operation time counter

This module counts the operation time. When POS_ACTIVE is active, the count is continuously added to the time duration until it is deactivated. At any time the OPR_TIME output is the total duration for which POS_ACTIVE is active. The unit of time duration count for OPR_TIME is hour. The value is available through the Monitored data view.

The OPR_TIME output is a continuously increasing value and it is stored in a nonvolatile memory. When POS_ACTIVE is active, the OPR_TIME count starts

increasing from the previous value. The count of OPR_TIME saturates at the final value of 299999, that is, no further increment is possible. The activation of RESET can reset the count to the *Initial value* setting.

Limit supervision

This module compares the motor run-time count to the set values of *Warning value* and *Alarm value* to generate the WARNING and ALARM outputs respectively when the counts exceed the levels.

The activation of the WARNING and ALARM outputs depends on the *Operating time mode* setting. Both WARNING and ALARM occur immediately after the conditions are met if *Operating time mode* is set to “Immediate”. If *Operating time mode* is set to “Timed Warn”, WARNING is activated within the next 24 hours at the time of the day set using the *Operating time hour* setting. If *Operating time mode* is set to “Timed Warn Alm”, the WARNING and ALARM outputs are activated at the time of day set using *Operating time hour*.

The *Operating time hour* setting is used to set the hour of day in Coordinated Universal Time (UTC). The setting has to be adjusted according to the local time and local daylight-saving time.

The function contains a blocking functionality. Activation of the BLOCK input blocks both WARNING and ALARM.

6.6.5 Application

The machine operating time since commissioning indicates the use of the machine. For example, the mechanical wear and lubrication requirement for the shaft bearing of the motors depend on the use hours.

If some motor is used for long duration runs, it might require frequent servicing, while for a motor that is not used regularly the maintenance and service are scheduled less frequently. The accumulated operating time of a motor together with the appropriate settings for warning can be utilized to trigger the condition based maintenance of the motor.

The operating time counter combined with the subsequent reset of the operating-time count can be used to monitor the motor's run time for a single run.

Both the long term accumulated operating time and the short term single run duration provide valuable information about the condition of the machine and device. The information can be co-related to other process data to provide diagnoses for the process where the machine or device is applied.

6.7 Motor start counter MSCPMRI

6.7.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Motor start counter	MSCPMRI	n<	66

6.7.2 Function block

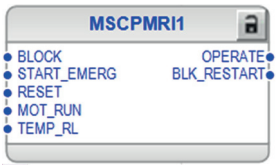

Figure 673: Function block

6.7.3 Functionality

The motor start counter function MSCPMRI counts the number of motor starts and distinguishes between cold and warm starts. The allowed number is generally provided by the motor manufacturer. The motor starting `MOT_START` output of the motor start-up supervision function is used to count the starts. The motor thermal level

TEMP_RL calculated by the thermal overload protection is used to distinguish between a cold and warm start.

The function contains a blocking functionality. It is possible to block the function outputs or the function itself.

6.7.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of MSCPMRI can be described with a module diagram. All the modules in the diagram are explained in the next sections.

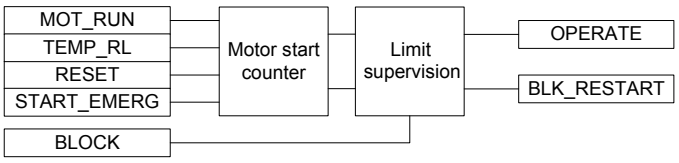

Figure 674: Functional module diagram

Motor start counter

This module counts the number of motor starts. The value of the cold count COLD_COUNT and warm count WARM_COUNT is available in the Monitored data view. On the rising edge of MOT_RUN, the module increments the cold start counter. If the thermal content available at the TEMP_RL input is above the set *Warm start level* when the rising edge of the MOT_RUN input is received, both cold and warm start counter values are incremented.

If *Operation* of the thermal overload protection for motors function MPTTR is set as "Off", the TEMP_RL value is not available. In this case, the warm start counter does not increase.

The counter decrease timer also starts at the first increment of the cold start counter (that is the first time when the counter increases from zero). When *Cnt decrease time* elapses, both cold and warm start counters decrease by one and the counter decrease timer restarts. This is repeated until both cold and warm counters are zero.

When the motor is not in operation, that is, the motor is in stop condition, it takes more time to cool. During such condition *Cnt decrease time* is multiplied by a *Cnt Dec timer Mult* setting.

The motor start detection is available at the MOT_START output of the motor start-up supervision function STTPMSU. The MOT_START output of STTPMSU must be connected to the MOT_RUN input of this function in Application Configuration in

PCM600. Similarly, the TEMP_RL output of MPTTR must be connected to the TEMP_RL input of this function in Application Configuration in PCM600.

When the emergency start signal START_EMERG is set high and if the value of the cold or warm counter is above its start value setting, the value of the counter is set one count less than the respective maximum number of start value setting. This disables BLK_RESTART and OPERATE which makes the restart of motor possible.

The values can be reset by activating the RESET binary input. The activation of the RESET input also resets the counter decrease timer. The counter value can also be reset on the Clear menu.

Limit supervision

This module compares the motor cold and warm count to the set *Max Num cold start* and *Max Num warm start*, respectively. The BLK_RESTART output is activated when either the cold or the warm start counter reaches the set *Max Num cold start* or *Max Num warm start*, respectively. The OPERATE output is activated when either the cold or the warm start counter exceeds the set *Max Num cold start* or *Max Num warm start*, respectively.

When the BLK_RESTART output is active, T_RST_ENA shows the possible time for the next restart. The value of T_RST_ENA is calculated as the time left for both counters to decrease below their maximum number of starts.

Activation of the BLOCK input blocks both OPERATE and BLK_RESTART outputs.

6.7.5 Application

Repeated motor starts increase the temperature to a high value in the stator or rotor windings, or both, unless enough time is allowed for the heat to dissipate. To ensure a safe operation, it is necessary to provide a fixed-time interval between starts or limit the number of starts within a period of time. This is why the motor manufacturers have restrictions on how many starts are allowed in a defined time interval.

This function counts the number of cold and warm starts and provides a block restart signal when the number of starts reaches the permitted limit. The customer can use this signal for blocking a new start operation. An operate signal is also available which can be used to disconnect the motor when the number of starts exceeds the limit.

6.7.6 Signals

Table 1171: MSCPMRI Input signals

Name	Type	Default	Description
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode

6.8 Three-phase remanent undervoltage supervision MSVPR

6.8.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-phase remanent undervoltage supervision	MSVPR	3U<R	27R

6.8.2 Function block

Figure 675: Function block

6.8.3 Functionality

The three-phase remanent undervoltage supervision function MSVPR is used to supervise the remanent voltage of the motor. The rotor with high inertia load may continue to rotate after the primary supply voltage is switched off. Re-energizing the motor immediately can result in catastrophic failure.

MSVPR gives permissive output when the remanent voltage of the motor reaches a safe level to re-energize. Supervision can be selected for one-phase or for three-phase operation. MSVPR can also adapt to a frequency range of 10...70 Hz.

The function contains a blocking functionality. It is possible to block the function output, timer or the function itself.

6.8.4 Analog channel configuration

MSVPR has one analog group input which must be properly configured.

Table 1177: Analog inputs

Input	Description
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1178: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with one voltage channel connected when *Phase supervision* is set to "A or AB", "B or BC" or "C or CA".
	The function requires that all three voltage channels are connected if *Phase supervision* is set to "A&B&C or AB&BC&CA".

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

6.8.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of MSVPR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

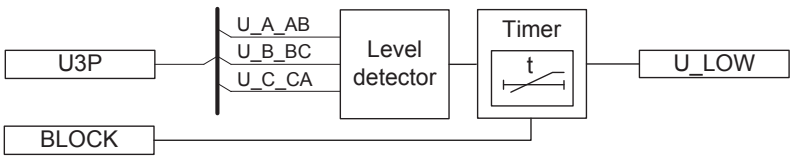

Figure 676: Functional module diagram

Level detector

The *Voltage selection* setting is used for selecting the phase-to-earth or phase-to-phase voltages for supervision.

The voltage measurement can adapt the frequency to a range of 10...70 Hz.

Level detector supports one- or three-phase operation. Selection can be made with setting *Phase supervision*.

Table 1179: Functionality depending on Phase supervision

Value of *Phase supervision*	Functionality
1 = A or AB 2 = B or BC 4 = C or CA	This selection implements single-phase voltage supervision on the selected phase. If the measured voltage of the supervised phase is lower than the set value of the *Start value* setting, Level detector enables the Timer module.
7 = A&B&C or AB&BC&CA	This selection implements three-phase voltage supervision. The measured voltage of three supervised phases is compared against the *Start value* setting. If the number of phases where the voltage is below the setting matches the *Num of phases* setting, Level detector enables the Timer module.

Timer

Once activated, Timer runs until the value of *Operate delay time* has elapsed. The time characteristic is according to DT. When the operation timer has reached the value of *Operate delay time*, the U_LOW output is activated.

In a drop-off case, the remanent voltage returns to a value higher than the set value of *Start value* before *Operate delay time* is exceeded. Also, the timer reset state is activated. The reset timer runs until the *Reset delay time* value is exceeded. If the duration of the voltage drop-off exceeds the set *Reset delay time*, the operate timer is reset and the U_LOW output is deactivated.

The BLOCK input can be controlled with a binary input, a horizontal communication input or an internal signal of the relay program. The activation of the BLOCK input resets Timer and prevents the U_LOW output from being activated.

6.8.6 Application

Systems with critical motor applications provide a backup power source that can be switched in when the primary power source becomes faulty. When the power to a motor is suddenly lost, the motor terminal voltage does not immediately fall to zero because the rotating motor now acts as a generator producing its own voltage. Remanent voltage decays as the motor comes to a stop at a rate depending on the motor and load. Connecting the backup power source while the remanent voltage is at a high level can result in damage to the motor shaft and windings.

MSVPR is used to monitor the motor remanent voltage over a decaying frequency after power supply is lost, before allowing connection of backup power. It provides a permissive signal indicating when the backup power can be safely connected.

This application example describes the re-energization process. MSVPR is used to supervise the Bus1 remanent voltage. Control logic is used to detect the loss of primary power source and initiate the transfer to backup power. Normally, bus tie breaker CB5 is open and motor voltage power is supplied by incoming Feeder1 (see Figure 677).

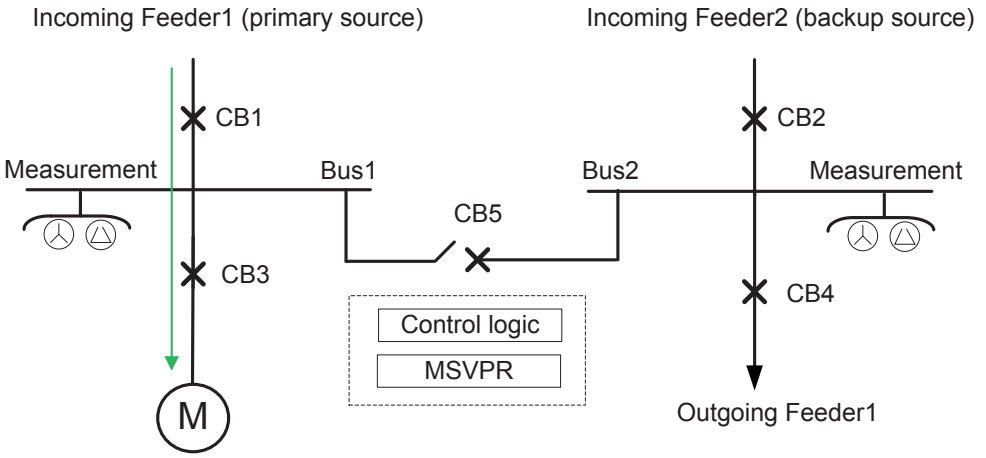

Figure 677: Example of remanent voltage supervision before fault

CB1 is tripped when a fault occurs on incoming Feeder1. MSVPR gives permission to control logic when the remanent voltage of the motor reaches a safe level on Bus1. Control logic closes the tie breaker CB5 if closing conditions are met. Finally, the motor is re-energized by incoming Feeder2 (see Figure 678).

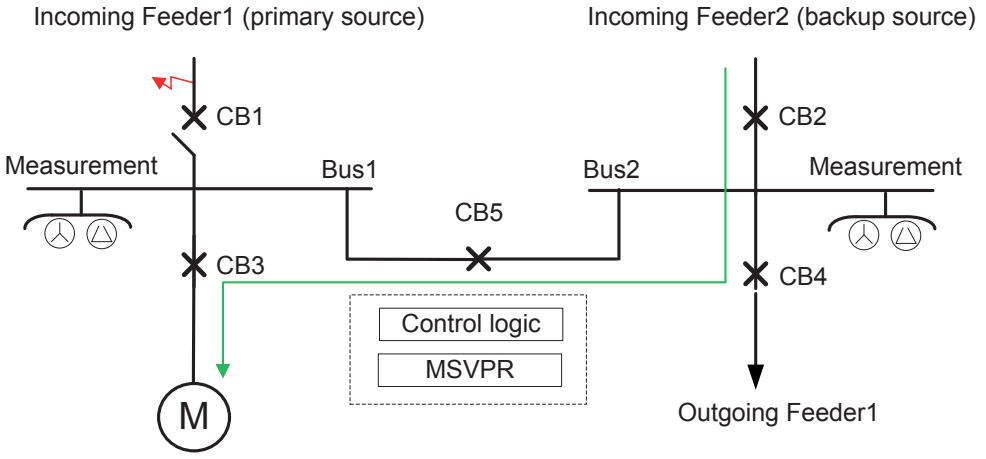

Figure 678: Example of remanent voltage supervision after fault

MSVPR runs in the range of 10...70 Hz. If the frequency is lower than 10 Hz, the motor terminal voltage is very low. The remanent voltage setting is typically set to 20...30 percent of the rated voltage.

6.9 Current circuit supervision for transformers CTSRCTF

6.9.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Current circuit supervision for transformers	CTSRCTF	MCS 3I,I2	CCM 3I,I2

6.9.2 Function block

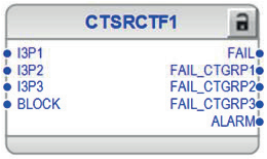

Figure 679: Function block

6.9.3 Functionality

The current circuit supervision for transformers function CTSRCTF is used for monitoring the current transformer secondary circuit where a separate reference current transformer input for comparison is not available or where a separate voltage channel for calculating or measuring the zero-sequence voltage is not available. CTSRCTF can be used for detecting the single-phase failure on the current transformer secondary for protection application involving two or three sets of the three-phase current transformers.

CTSRCTF detects a fault in the measurement circuit and issues an alarm which can be used for blocking the protection functions, for example, differential protection, to avoid unwanted tripping.

CTSRCTF is internally blocked in case of a transformer under no-load condition or if a current in any one phase exceeds the set maximum limit.

6.9.4 Analog channel configuration

CTSRCTF has three analog group inputs which must be properly configured.

Table 1186: Analog inputs

Input	Description
I3P1	Three-phase currents
I3P2	Three-phase currents
I3P3[1)]	Three-phase currents

1) Can be connected to GRPOFF

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

6.9.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of CTSRCTF can be described with a module diagram. All the modules in the diagram are explained in the next sections.

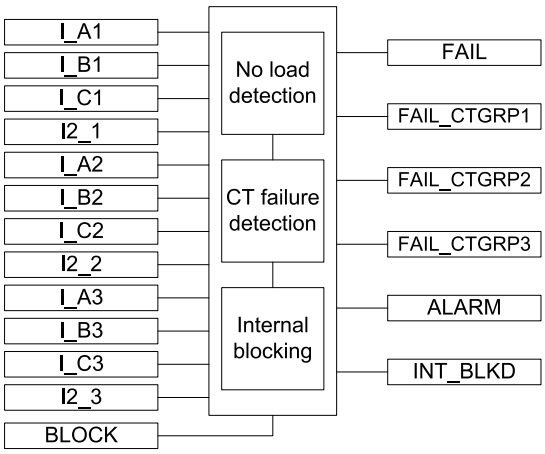

Figure 680: Functional module diagram

No-load detection

No-load detection module detects the loading condition. If all the three-phase currents of any two sets of current transformer are zero, the protected equipment is considered to be in the no-load condition and the function is internally blocked by activating the `INT_BLKD` output.

To avoid any false operation, the function is also internally blocked if any two-phase currents of any set of current transformers are below *Min operate current*. This activates `INT_BLKD`. The value of the *Min operate current* setting depends on the type of equipment to be protected. For example, in case of transformer protection, *Min operate current* depends on the no-load current rating. Typically, it can be set equal to the transformer no-load current rating.

CT failure detection

This module detects the CT secondary failure in any sets of current transformers. The module continuously scans the value of all the three-phase currents in all groups of current transformers to detect any sudden drop in the current value to zero. The detection of a zero current should not be the only criterion for considering a fault in the current transformer secondary. Two other criteria are evaluated to confirm the CT failure:

- A zero current due to the CT failure does not result in a negative-sequence current on healthy CT sets.

  On the detection of a zero current in any phase on either group of CT, the negative-sequence current I_2 is further evaluated. For a genuine CT secondary failure, the magnitude of I_2 changes only on the side where zero current has been detected. The change in the magnitude of I_2 (ΔI_2) on the other sets of the current transformer (other than where zero current is detected) is calculated. If the change is detected on the healthy sets of CT, it is an indication of system failure.

- A zero current due to the CT failure does not result in a phase angle difference between the healthy phases.

  If a system faults happens on the phase A, it results in a change in the phase angle difference between phase B and phase C. This change in the phase angle difference between the healthy phases is evaluated in all three sets of current transformer, and if the change is detected in any set of CT, it is an indication of the system failure.

If both conditions are satisfied at zero current, the FAIL output is activated immediately. The ALARM output is activated after a fixed 200 ms delay. FAIL needs to be active during the delay. The outputs FAIL, CTGRP1, FAIL_CTGRP2 and FAIL_CTGRP3 are activated according to the CT group where the secondary failure is detected.

Activation of the BLOCK input deactivates the FAIL and ALARM outputs.

It is not possible to detect the CT secondary failure happening simultaneously with the system faults or failures or two simultaneous failures in the secondary circuit. The function resets if the zero current does not exist longer than 200 ms.

Internal blocking

This module blocks the function internally under specific condition to avoid any false operation during a system fault situation. When any of the following condition is satisfied, the function is internally blocked and the FAIL output is deactivated immediately.

- Magnitude of any phase current for any group of current transformers exceeds the *Max operate current* setting. The magnitude of phase current is calculated from the peak-to-peak value.
- Magnitude of the negative-sequence current I_2 on the healthy set of current transformer exceeds the *Max Nq Seq current* setting.

The INT_BLKD output is activated when FAIL is deactivated if any of the above conditions is satisfied. The ALARM output is also deactivated after a fixed three-second delay after the FAIL output is deactivated.

6.9.6 Application

Open or short-circuited current transformer secondary can cause unwanted operation in many protection functions, such as earth-fault current and differential. The simplest method for detecting the current transformer secondary failure is by comparing currents from two independent three-phase sets of CTs or the CT cores measuring the same primary currents. Another widely used method is the detection of a zero-sequence current and zero-sequence voltage. The detection of a zero-sequence current

in the absence of a zero-sequence voltage is an indication of the current transformer secondary failure. However, both methods have disadvantages as they require an additional set of current transformer, or a voltage channel is needed for detecting a zero-sequence voltage.

The methods may not be applicable where additional current channels or voltage channels are not available. This CT secondary circuit supervision presents an algorithm that can be used as an example for detecting the CT secondary failure used for the unit protection of a two-winding or three-winding transformer. However, the function has a limitation that it cannot detect failure in case of equipment under protection in no-load condition or when two simultaneous secondary CT failures occur.

The detection of a zero current in any one phase is a partial indication of failure in the current transformer secondary. Furthermore, if this current zero is due to the failure in the current transformer secondary, it results in a change in the magnitude of the negative-sequence current in the group only where current zero has been detected. However, changes in the negative-sequence current in other groups of three-phase current transformers at the instance of zero-current detection is an indication of a system problem. Also, it may happen that after the detection of a failure in the current transformer secondary, a fault may occur in the system. During such condition, functions are internally blocked.

Phase discontinuity

A zero current detected due to the phase discontinuity results in an asymmetry in all the sets of the current transformer, which then results in a change in the negative-sequence current (ΔI_2) in the healthy set. This change in the negative-sequence current on the healthy sides, that is, other than where a zero current has been detected, blocks the function.

In case of a lightly loaded transformer (up to 30%) the change in the negative-sequence current may be very negligible. However, a phase discontinuity results in a change in the phase angle difference between two healthy phases in the set of CTs where a zero current has been detected as well as on the primary side of the transformer. This change in the value of the angle blocks the function internally.

Overload / System short circuit condition

It is required that any overload or short circuit conditions after a CT failure should block the function. During overload or short circuit condition, the phase current increases beyond its rated value; if any phase current on any set of current transformer exceeds the set limit, the function is blocked internally. Also in case of an unsymmetrical fault, the negative-sequence current increases. If the negative-sequence current increases beyond the set limit, the function is blocked internally. The overcurrent and negative-sequence current setting both can be set equal to the overcurrent and negative-sequence protection function start value.

The internal blocking is thus useful for avoiding false operation during a fault situation.

6.9.7 Signals

Table 1187: CTSRCTF Input signals

Name	Type	Default	Description

Circuit-breaker condition monitoring	SSCBR	CBCM	52CM

7.1.2 Function block

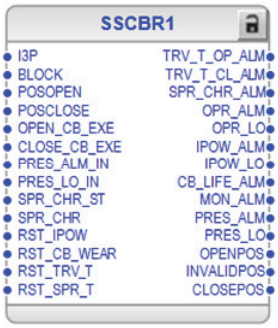

Figure 681: Function block

7.1.3 Functionality

The circuit-breaker condition monitoring function SSCBR is used to monitor different parameters of the circuit breaker. The breaker requires maintenance when the number of operations has reached a predefined value. The energy is calculated from the measured input currents as a sum of $I^y t$ values. Alarms are generated when the calculated values exceed the threshold settings.

The function contains a blocking functionality which can be used to block the function outputs.

7.1.4 Analog input configuration

SSCBR has one analog group input which must be properly configured.

Table 1192: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

7.1.5 Operation principle

The circuit breaker condition monitoring function includes different metering and monitoring sub-functions. The functions can be enabled and disabled with the *Operation* setting. The corresponding parameter values are “On” and “Off”. The operation counters are cleared when *Operation* is set to “Off”.

The operation of SSCBR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

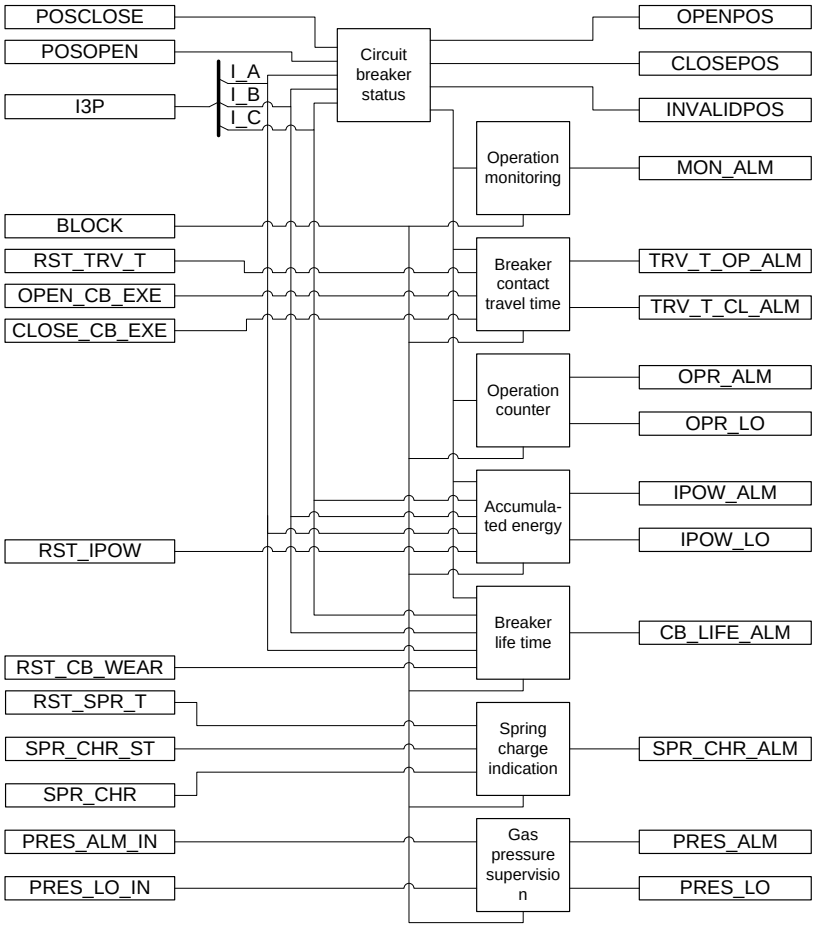

Figure 682: Functional module diagram

7.1.5.1 Circuit breaker status

The Circuit breaker status sub-function monitors the position of the circuit breaker, that is, whether the breaker is in open, closed or invalid position. The operation of the

breaker status monitoring can be described by using a module diagram. All the modules in the diagram are explained in the next sections.

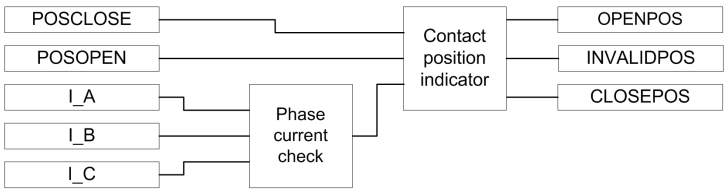

Figure 683: Functional module diagram for monitoring circuit breaker status

Phase current check

This module compares the three phase currents to the setting *Acc stop current*. If the current in a phase exceeds the set level, information about the phase is reported to the contact position indicator module.

Contact position indicator

The OPENPOS output is activated when the auxiliary input contact POSCLOSE is FALSE, the POSOPEN input is TRUE and all the phase currents are below the setting *Acc stop current*.

The CLOSEPOS output is activated when the auxiliary POSOPEN input is FALSE and the POSCLOSE input is TRUE.

The INVALIDPOS output is activated when both the auxiliary contacts have the same value, that is, both are in the same logical level, or if the auxiliary input contact POSCLOSE is FALSE and the POSOPEN input is TRUE and any of the phase currents exceed the setting Acc stop current.

The status of the breaker is indicated by the binary outputs OPENPOS, INVALIDPOS and CLOSEPOS for open, invalid and closed position respectively.

7.1.5.2 Circuit breaker operation monitoring

The purpose of the circuit breaker operation monitoring subfunction is to indicate if the circuit breaker has not been operated for a long time.

The operation of the circuit breaker operation monitoring can be described with a module diagram. All the modules in the diagram are explained in the next sections.

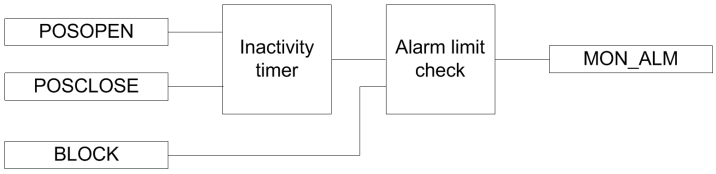

Figure 684: Functional module diagram for calculating inactive days and alarm for circuit breaker operation monitoring

Inactivity timer

The module calculates the number of days the circuit breaker has remained inactive, that is, has stayed in the same open or closed state. The calculation is done by monitoring the states of the POSOPEN and POSCLOSE auxiliary contacts.

The inactive days INA_DAYS is available in the monitored data view. It is also possible to set the initial inactive days with the *Ini inactive days* parameter.

Alarm limit check

When the inactive days exceed the limit value defined with the *Inactive Alm days* setting, the MON_ALM alarm is initiated. The time in hours at which this alarm is activated can be set with the *Inactive Alm hours* parameter as coordinates of UTC. The alarm signal MON_ALM can be blocked by activating the binary input BLOCK.

7.1.5.3 Breaker contact travel time

The Breaker contact travel time module calculates the breaker contact travel time for the closing and opening operation. The operation of the breaker contact travel time measurement can be described with a module diagram. All the modules in the diagram are explained in the next sections.

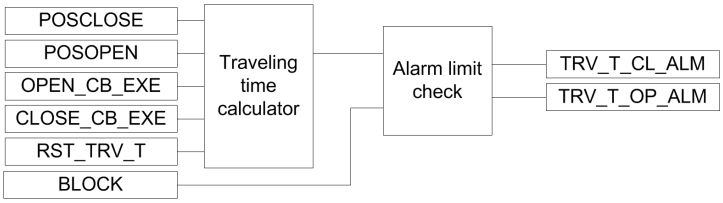

Figure 685: Functional module diagram for breaker contact travel time

Traveling time calculator

The travel time can be calculated using two different methods based on the setting *Travel time Clc mode*.

When the setting *Travel time Clc mode* is “From Pos to Pos”, the contact travel time of the breaker is calculated from the time between auxiliary contacts' state change. The opening travel time is measured between the opening of the POSCLOSE auxiliary

contact and the closing of the POSOPEN auxiliary contact. The travel time is also measured between the opening of the POSOPEN auxiliary contact and the closing of the POSCLOSE auxiliary contact.

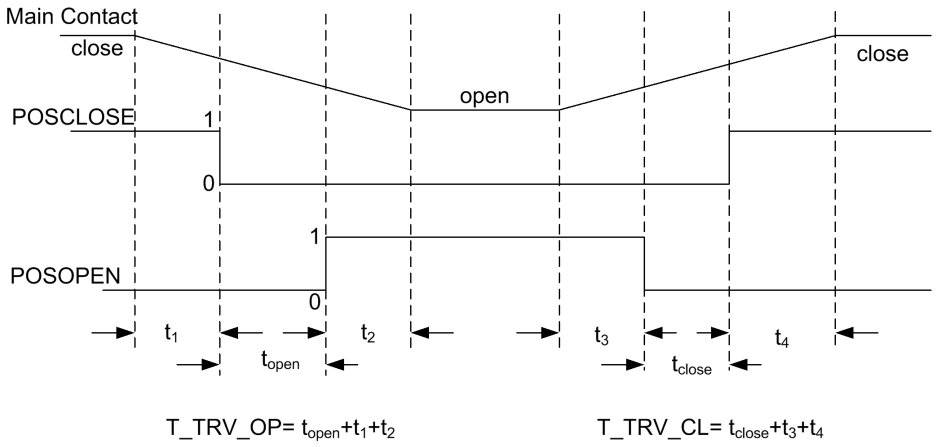

Figure 686: Travel time calculation when Travel time Clc mode is "From Pos to Pos"

There is a time difference t_1 between the start of the main contact opening and the opening of the POSCLOSE auxiliary contact. Similarly, there is a time gap t_2 between the time when the POSOPEN auxiliary contact opens and the main contact is completely open. To incorporate the time $t_1 + t_2$, a correction factor needs to be added with t_{open} to get the actual opening time. This factor is added with the *Opening time Cor* ($= t_1 + t_2$) setting. The closing time is calculated by adding the value set with the *Closing time Cor* ($t_3 + t_4$) setting to the measured closing time.

When the setting *Travel time Clc mode* is "From Cmd to Pos", the contact travel time of the breaker is calculated from the time between the circuit breaker opening or closing command and the auxiliary contacts' state change. The opening travel time is measured between the rising edge of the OPEN_CB_EXE command and the POSOPEN auxiliary contact. The closing travel time is measured between the rising edge of the CLOSE_CB_EXEC command and the POSCLOSE auxiliary contact.

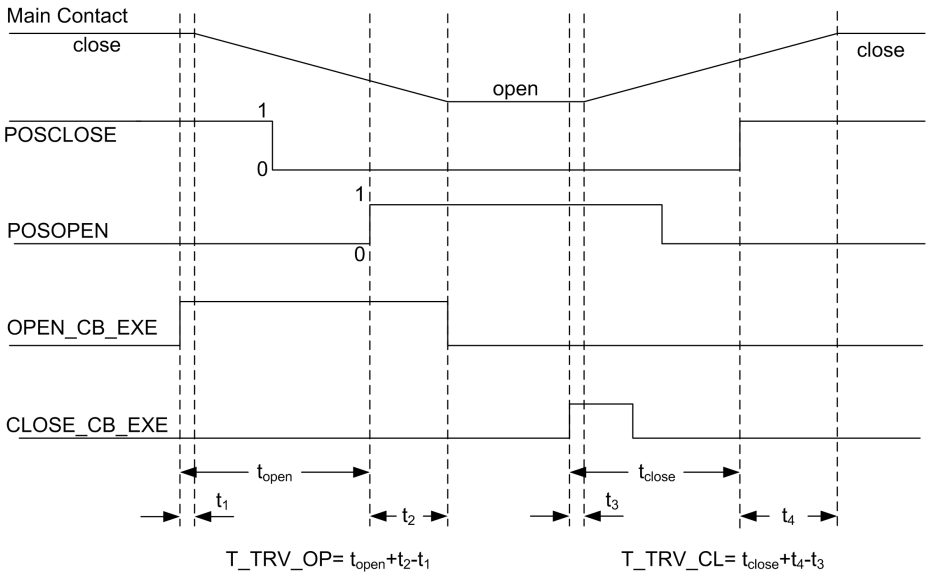

Figure 687: Travel time calculation when Travel time Clc mode is "From Cmd to Pos"

There is a time difference t_1 between the start of the main contact opening and the OPEN_CB_EXE command. Similarly, there is a time gap t_2 between the time when the POSOPEN auxiliary contact opens and the main contact is completely open. Therefore, to incorporate the times t_1 and t_2, a correction factor needs to be added with t_{open} to get the actual opening time. This factor is added with the *Opening time Cor* (= t_2 - t_1) setting. The closing time is calculated by adding the value set with the *Closing time Cor* (t_4 - t_3) setting to the measured closing time.

The last measured opening travel time T_TRV_OP and the closing travel time T_TRV_CL are available in the monitored data view on the LHMI or through tools via communications.

Alarm limit check

When the measured opening travel time is longer than the value set with the *Open alarm time* setting, the TRV_T_OP_ALM output is activated. Respectively, when the measured closing travel time is longer than the value set with the *Close alarm time* setting, the TRV_T_CL_ALM output is activated.

It is also possible to block the TRV_T_CL_ALM and TRV_T_OP_ALM alarm signals by activating the BLOCK input.

7.1.5.4 Operation counter

The operation counter subfunction calculates the number of breaker operation cycles. The opening and closing operations are both included in one operation cycle. The operation counter value is updated after each opening operation.

The operation of the subfunction can be described with a module diagram. All the modules in the diagram are explained in the next sections.

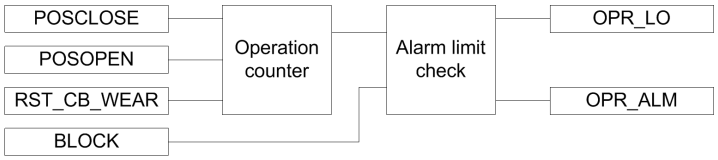

Figure 688: Functional module diagram for counting circuit breaker operations

Operation counter

The operation counter counts the number of operations based on the state change of the binary auxiliary contacts inputs POSCLOSE and POSOPEN.

The number of operations NO_OPR is available in the monitored data view on the LHMI or through tools via communications. The old circuit breaker operation counter value can be taken into use by writing the value to the *Counter initial Val* parameter and by setting the parameter *CB wear values* in the clear menu from WHMI or LHMI.

Alarm limit check

The OPR_ALM operation alarm is generated when the number of operations exceeds the value set with the *Alarm Op number* threshold setting. However, if the number of operations increases further and exceeds the limit value set with the *Lockout Op number* setting, the OPR_LO output is activated.

The binary outputs OPR_LO and OPR_ALM are deactivated when the BLOCK input is activated.

7.1.5.5 Accumulation of I^yt

Accumulation of the I^yt module calculates the accumulated energy.

The operation of the module can be described with a module diagram. All the modules in the diagram are explained in the next sections.

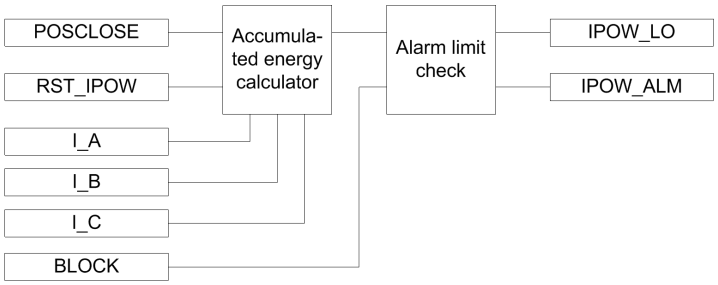

Figure 689: Functional module diagram for calculating accumulative energy and alarm

Accumulated energy calculator

This module calculates the accumulated energy I^yt [$(kA)^y s$]. The factor y is set with the *Current exponent* setting.

The calculation is initiated with the POSCLOSE input opening events. It ends when the RMS current becomes lower than the *Acc stop current* setting value.

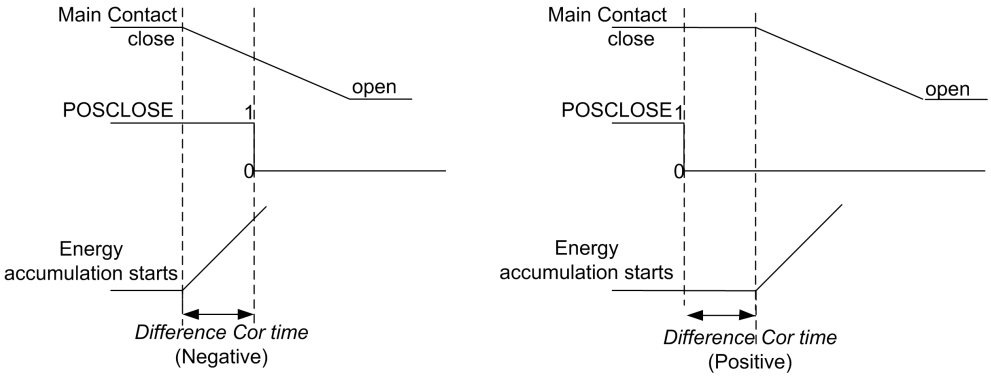

Figure 690: Significance of the Difference Cor time setting

The *Difference Cor time* setting is used instead of the auxiliary contact to accumulate the energy from the time the main contact opens. If the setting is positive, the calculation of energy starts after the auxiliary contact has opened and when the delay is equal to the value set with the *Difference Cor time* setting. When the setting is negative, the calculation starts in advance by the correction time before the auxiliary contact opens.

The accumulated energy outputs IPOW_A (_B, _C) are available in the monitored data view on the LHMI or through tools via communications. The values can be reset by setting the parameter *CB accum. currents power* setting to true in the clear menu from WHMI or LHMI.

Alarm limit check

The IPOW_ALM alarm is activated when the accumulated energy exceeds the value set with the *Alm Acc currents Pwr* threshold setting. However, when the energy exceeds the limit value set with the *LO Acc currents Pwr* threshold setting, the IPOW_LO output is activated.

The IPOW_ALM and IPOW_LO outputs can be blocked by activating the binary input BLOCK.

7.1.5.6 Remaining life of circuit breaker

Every time the breaker operates, the life of the circuit breaker reduces due to wearing. The wearing in the breaker depends on the tripping current, and the remaining life of the breaker is estimated from the circuit breaker trip curve provided by the

manufacturer. The remaining life is decremented at least with one when the circuit breaker is opened.

The operation of the remaining life of the circuit breaker subfunction can be described with a module diagram. All the modules in the diagram are explained in the next sections.

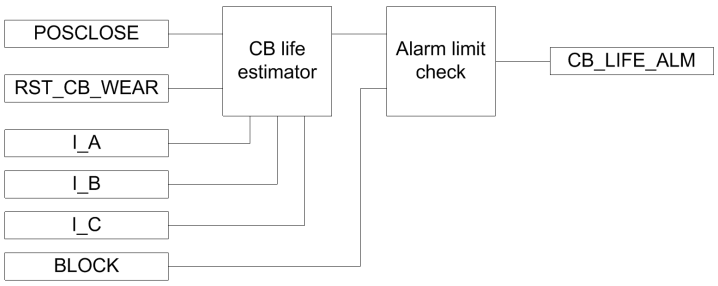

Figure 691: Functional module diagram for estimating the life of the circuit breaker

Circuit breaker life estimator

The circuit breaker life estimator module calculates the remaining life of the circuit breaker. If the tripping current is less than the rated operating current set with the *Rated Op current* setting, the remaining operation of the breaker reduces by one operation. If the tripping current is more than the rated fault current set with the *Rated fault current* setting, the possible operations are zero. The remaining life of the tripping current in between these two values is calculated based on the trip curve given by the manufacturer. The *Op number rated* and *Op number fault* parameters set the number of operations the breaker can perform at the rated current and at the rated fault current, respectively.

The remaining life is calculated separately for all three phases and it is available as a monitored data value `CB_LIFE_A (_B,_C)`. The values can be cleared by setting the parameter *CB wear values* in the clear menu from WHMI or LHMI.

Clearing *CB wear values* also resets the operation counter.

Alarm limit check

When the remaining life of any phase drops below the *Life alarm level* threshold setting, the corresponding circuit breaker life alarm `CB_LIFE_ALM` is activated.

It is possible to deactivate the `CB_LIFE_ALM` alarm signal by activating the binary input `BLOCK`. The old circuit breaker operation counter value can be taken into use by writing the value to the *Initial CB Rmn life* parameter and resetting the value via the clear menu from WHMI or LHMI.

7.1.5.7 Circuit breaker spring-charged indication

The circuit breaker spring-charged indication subfunction calculates the spring charging time.

The operation of the subfunction can be described with a module diagram. All the modules in the diagram are explained in the next sections.

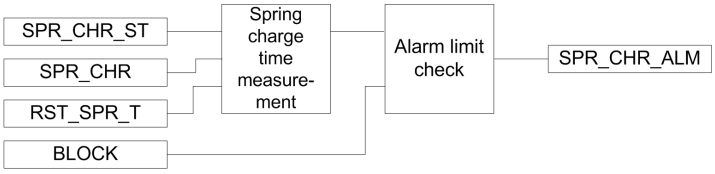

Figure 692: Functional module diagram for circuit breaker spring-charged indication and alarm

Spring charge time measurement

Two binary inputs, SPR_CHR_ST and SPR_CHR, indicate spring charging started and spring charged, respectively. The spring-charging time is calculated from the difference of these two signal timings.

The spring charging time T_SPR_CHR is available in the monitored data view on the LHMI or through tools via communications.

Alarm limit check

If the time taken by the spring to charge is more than the value set with the *Spring charge time* setting, the subfunction generates the SPR_CHR_ALM alarm.

It is possible to block the SPR_CHR_ALM alarm signal by activating the BLOCK binary input.

7.1.5.8 Gas pressure supervision

The gas pressure supervision subfunction monitors the gas pressure inside the arc chamber.

The operation of the subfunction can be described with a module diagram. All the modules in the diagram are explained in the next sections.

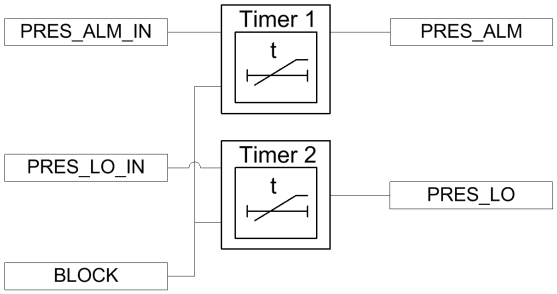

Figure 693: Functional module diagram for circuit breaker gas pressure alarm

The gas pressure is monitored through the binary input signals PRES_LO_IN and PRES_ALM_IN.

Timer 1

When the PRES_ALM_IN binary input is activated, the PRES_ALM alarm is activated after a time delay set with the *Pressure alarm time* setting. The PRES_ALM alarm can be blocked by activating the BLOCK input.

Timer 2

If the pressure drops further to a very low level, the PRES_LO_IN binary input becomes high, activating the lockout alarm PRES_LO after a time delay set with the *Pres lockout time* setting. The PRES_LO alarm can be blocked by activating the BLOCK input.

7.1.6 Application

SSCBR includes different metering and monitoring subfunctions.

Circuit breaker status

Circuit breaker status monitors the position of the circuit breaker, that is, whether the breaker is in an open, closed or intermediate position.

Circuit breaker operation monitoring

The purpose of the circuit breaker operation monitoring is to indicate that the circuit breaker has not been operated for a long time. The function calculates the number of days the circuit breaker has remained inactive, that is, has stayed in the same open or closed state. There is also the possibility to set an initial inactive day.

Breaker contact travel time

High traveling times indicate the need for the maintenance of the circuit breaker mechanism. Therefore, detecting excessive traveling time is needed. During the opening cycle operation, the main contact starts opening. The auxiliary contact A opens, the auxiliary contact B closes and the main contact reaches its opening position. During the closing cycle, the first main contact starts closing. The auxiliary contact B

opens, the auxiliary contact A closes and the main contact reaches its closed position. The travel times are calculated based on the state changes of the auxiliary contacts and the adding correction factor to consider the time difference of the main contact's and the auxiliary contact's position change.

Operation counter

Routine maintenance of the breaker, such as lubricating breaker mechanism, is generally based on a number of operations. A suitable threshold setting to raise an alarm when the number of operation cycle exceeds the set limit helps preventive maintenance. This can also be used to indicate the requirement for oil sampling for dielectric testing in case of an oil circuit breaker.

The change of state can be detected from the binary input of the auxiliary contact. There is a possibility to set an initial value for the counter which can be used to initialize this functionality after a period of operation or in case of refurbished primary equipment.

Accumulation of I^yt

Accumulation of I^yt calculates the accumulated energy ΣI^yt, where the factor y is known as the current exponent. The factor y depends on the type of the circuit breaker. For oil circuit breakers, the factor y is normally 2. In case of a high-voltage system, the factor y can be 1.4...1.5.

Remaining life of the breaker

Every time the breaker operates, the life of the circuit breaker reduces due to wearing. The wearing in the breaker depends on the tripping current, and the remaining life of the breaker is estimated from the circuit breaker trip curve provided by the manufacturer.

Example for estimating the remaining life of a circuit breaker

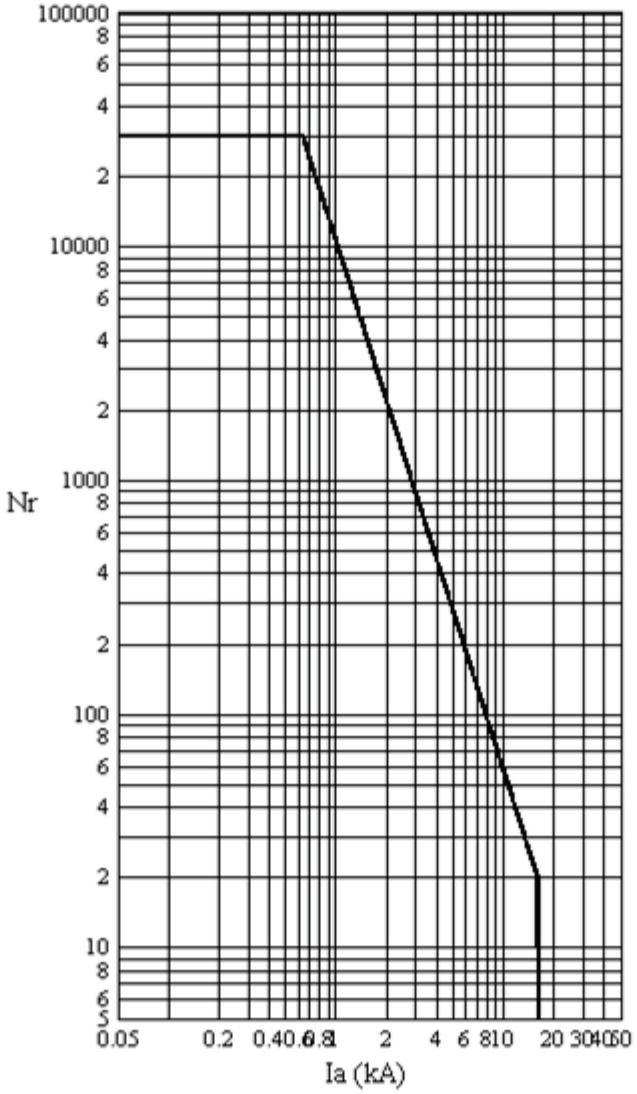

Figure 694: Trip Curves for a typical 12 kV, 630 A, 16 kA vacuum interrupter

Nr	the number of closing-opening operations allowed for the circuit breaker
Ia	the current at the time of tripping of the circuit breaker

Calculation of Directional Coef

The directional coefficient is calculated according to the formula:

$$Directional\,Coef = \frac{\log\left(\frac{B}{A}\right)}{\log\left(\frac{I_f}{I_r}\right)} = -2.2609$$

(Equation 284)

I_r Rated operating current = 630 A

I_f Rated fault current = 16 kA

A Op number rated = 30000

B Op number fault = 20

Calculation for estimating the remaining life

Figure 694 shows that there are 30,000 possible operations at the rated operating current of 630 A and 20 operations at the rated fault current 16 kA. Therefore, if the tripping current is 10 kA, one operation at 10 kA is equivalent to 30,000/60=500 operations at the rated current. It is also assumed that prior to this tripping, the remaining life of the circuit breaker is 15,000 operations. Therefore, after one operation of 10 kA, the remaining life of the circuit breaker is 15,000-500=14,500 at the rated operating current.

$$Remaining\ \ life\ \ reduction = \left(\frac{I}{I_r}\right)^{-Directional\ Coef}$$

(Equation 285)

Spring-charged indication

For normal operation of the circuit breaker, the circuit breaker spring should be charged within a specified time. Therefore, detecting long spring-charging time indicates that it is time for the circuit breaker maintenance. The last value of the spring-charging time can be used as a service value.

Gas pressure supervision

The gas pressure supervision monitors the gas pressure inside the arc chamber. When the pressure becomes too low compared to the required value, the circuit breaker operations are locked. A binary input is available based on the pressure levels in the function, and alarms are generated based on these inputs.

7.1.7 Signals

Table 1193: SSCBR Input signals

Name	Type	Default	Description
I3P	SIGNAL	-	Three-phase currents
BLOCK	BOOLEAN	0=False	Block input status
POSOPEN	BOOLEAN	0=False	Signal for open position of apparatus from I/O

Table continues on next page

Name	Type	Default	Description
POSCLOSE	BOOLEAN	0=False	Signal for closeposition of apparatus from I/O
OPEN_CB_EXE	BOOLEAN	0=False	Signal for open command to coil
CLOSE_CB_EXE	BOOLEAN	0=False	Signal for close command to coil
PRES_ALM_IN	BOOLEAN	0=False	Binary pressure alarm input
PRES_LO_IN	BOOLEAN	0=False	Binary pressure input for lockout indication
SPR_CHR_ST	BOOLEAN	0=False	CB spring charging started input
SPR_CHR	BOOLEAN	0=False	CB spring charged input
RST_IPOW	BOOLEAN	0=False	Reset accumulation energy
RST_CB_WEAR	BOOLEAN	0=False	Reset input for CB remaining life and operation counter
RST_TRV_T	BOOLEAN	0=False	Reset input for CB closing and opening travel times
RST_SPR_T	BOOLEAN	0=False	Reset input for the charging time of the CB spring

Table 1194: SSCBR Output signals

Name	Type	Description
TRV_T_OP_ALM	BOOLEAN	CB open travel time exceeded set value
TRV_T_CL_ALM	BOOLEAN	CB close travel time exceeded set value
SPR_CHR_ALM	BOOLEAN	Spring charging time has crossed the set value
OPR_ALM	BOOLEAN	Number of CB operations exceeds alarm limit
OPR_LO	BOOLEAN	Number of CB operations exceeds lockout limit
IPOW_ALM	BOOLEAN	Accumulated currents power (Iyt),exceeded alarm limit
IPOW_LO	BOOLEAN	Accumulated currents power (Iyt),exceeded lockout limit
CB_LIFE_ALM	BOOLEAN	Remaining life of CB exceeded alarm limit
MON_ALM	BOOLEAN	CB 'not operated for long time' alarm
PRES_ALM	BOOLEAN	Pressure below alarm level
PRES_LO	BOOLEAN	Pressure below lockout level
OPENPOS	BOOLEAN	CB is in open position
INVALIDPOS	BOOLEAN	CB is in invalid position (not positively open or closed)
CLOSEPOS	BOOLEAN	CB is in closed position

7.1.8 Settings

Table 1195: SSCBR Non group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Operation	1=on 5=off			1=on	Operation Off / On

Hot-spot and insulation ageing rate monitoring for transformers	HSARSPTR	3Ihp>T	26/49HS

7.2.2 Function block

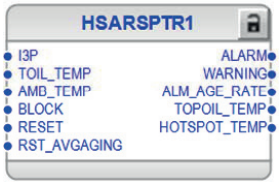

Figure 695: Function block

7.2.3 Functionality

The hot-spot and insulation ageing rate monitoring for transformers function HSARSPTR is used for online monitoring of transformers. The function monitors the hot-spot temperature of the transformer winding and the ageing rate of the insulation caused by thermal stress. The function can be applied for new transformers as well as for transformers already in service.

The hot-spot temperature and loss of life of transformer are calculated for one winding of the transformer from three phase currents and RTD inputs for top oil temperature and ambient temperature.

The hot-spot temperature and the momentary ageing rate are calculated based on the IEC 60076-7 or the IEEE C57.91-2011 standard, depending upon a user defined setting. The total ageing and loss of transformer insulation life is calculated in years.

The function generates WARNING and ALARM signals if the calculated hot-spot temperature exceeds the set value.

7.2.4 Analog channel configuration

HSARSPTR has one analog group input which must be properly configured.

Table 1199: Analog signals

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

7.2.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of HSARSPTR can be described with a module diagram. All modules in the diagram are explained in the next sections.

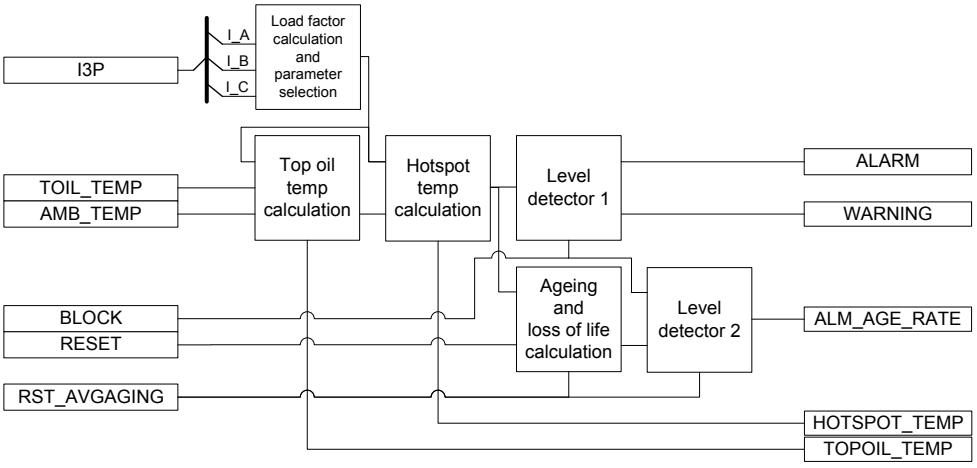

Figure 696: Functional module diagram

Load factor calculation and parameter selection

The transformer top oil and hot-spot temperatures are dependent on the load factor, the winding conductor properties and the cooling oil properties of the transformer. This module calculates the load factor based on the measured phase currents and selects the transformer parameters based on user defined settings.

Load factor calculation

Load factor is a ratio of the load current to the rated current. Since the thermal content of all the three phase currents influence the temperature inside the transformer, the load factor is calculated as a ratio of the root of sum of squared phase currents to three times the rated current.

$$K = \sqrt{\frac{I_A^2 + I_B^2 + I_C^2}{3 \cdot I_{rated}^2}}$$

(Equation 286)

Where

K	Load factor
I_A, I_B and I_C	RMS value of input phase currents (Amperes)
I_{rated}	Rated current (Amperes)

If *Transformer type* is set to “Single phase”, the denominator consists only of I^2_{rated} instead of $3 \times I^2_{rated}$.

Equation 286 assumes that voltage is constant and tap changer position is not considered.

For a star-delta transformer, it is recommended to use the function on the star winding, since the circulating zero sequence currents (in case of unbalance) cannot be measured on the delta winding of the transformer.

Transformer parameter selection

The transformer parameters are selected based on the *Parameter Sel method*, *Cooling mode*, *Transformer type*, and *Transformer rating* settings.

If the *Parameter Sel method* setting is set to "IEC", the transformer parameters' values are automatically selected as per the IEC 60076-7 guidelines based on Table 1200.

Table 1200: Constants based IEC guidelines

	Distribution Transformers	Medium and Large power transformers			
Cooling mode	**ONAN**	**ONAN**	**ONAF**	**OFAF**	**ODAF**
Oil Exponent (x)	0.8	0.8	0.8	1.0	1.0
Winding Exponent (y)	1.6	1.3	1.3	1.3	2.0
Constant K11 (k_{11})	1.00	0.50	0.50	1.00	1.00
Constant K21 (k_{21})	1.00	2.00	2.00	1.30	1.00
Constant K22 (k_{22})	2.00	2.00	2.00	1.00	1.00
Oil Time Constant (τ_0) [minutes]	180	210	150	90	90
Winding Tm Constant (τ_w) [minutes]	4	10	7	7	7

If *Parameter Sel method* is set to "IEEE", the constants are selected as per the IEEE C57.91™-2011 standard based on Table 1201.

Table 1201: Constants based on IEEE guidelines

	Distribution Transformers	Medium and Large power transformers			
Cooling mode	**ONAN**	**ONAN**	**ONAF**	**OFAF**	**ODAF**
Oil Exponent (x)	0.8	0.8	0.8	0.8	1.0
Winding Exponent (y)	0.8	0.8	0.9	0.9	1.0
Constant K11 (k_{11})	1.00	1.00	1.00	1.00	1.00
Constant K21 (k_{21})	1.00	1.00	1.00	1.00	1.00
Constant K22 (k_{22})	1.00	1.00	1.00	1.00	1.00
Oil Time Constant (τ_0) [minutes]	180	210	150	90	90
Winding Tm Constant (τ_w) [minutes]	4	10	7	7	7

A transformer is a distribution transformer if the *Transformer rating* setting < 2.5 MVA and *Transformer type* is set to "Three phase" or if the *Transformer rating* setting < 0.833 MVA and *Transformer type* is set to "Single phase".

Transformer parameters vary with the material used for winding and insulating oil. The *Parameter Sel method* setting can be set to "Manual" and the constants can be set individually through the *Oil exponent*, *Winding exponent*, *Constant K11*, *Constant K21*, *Constant K22*, *Oil time constant* and *Winding Tm constant* settings.

If *Parameter Sel method* is set to "Manual", the *Cooling mode* setting has no effect on the transformer parameters.

Since there is no direct *Cooling mode* based time constants' selection mentioned in the IEEE Std C57.91™- 2011 standard, the oil time constant (τ_0) and winding time constant (τ_w) in the Table 1201 are kept same as in the Table 1200.
For more accuracy, the values of the constants can be entered manually by setting *Parameter Sel method* to "Manual".

Top oil temp calculation

The function receives two sensor inputs for measuring top oil temperature and ambient temperature.

The top oil temperature of the tank is obtained through a sensor placed at the upper inner turn of the winding. If the top oil temperature sensor status `TOIL_SNSFLT` is FALSE, the top oil temperature is directly obtained from the `TOIL_TEMP` input.

If the status of `TOIL_SNSFLT` is TRUE, indicating that the sensor is faulty, the top oil temperature is calculated with the help of measured ambient temperature.

The status of the ambient temperature sensor is obtained through the `AMB_SNSFLT` binary input. If `AMB_SNSFLT` is FALSE, indicating the healthy status of the sensor, the ambient temperature is directly measured through the `AMB_TEMP` input. Else, if `AMB_SNSFLT` is TRUE, the ambient temperature is taken from the *Average ambient Tmp* setting.

The formula for calculating the top oil temperature from the measured or set ambient temperature is shown in Equation 287.

$$D\theta_{0(n)} = \frac{Dt}{(k_{11} \cdot \tau_o)} \cdot \left(\left[\frac{1 + (K^2 \cdot R)}{1 + R} \right]^x \cdot \Delta\theta_{or} - \left[\theta_{0(n-1)} - \theta_a \right] \right)$$

(Equation 287)

Where

$\theta_{0(n)}$	Top oil temperature in the tank at n^{th} time step
θ_a	Ambient temperature [°C]
$\Delta\theta_{or}$	Top oil temperature rise over ambient temperature at rated load, given by the setting *Top oil Tmp rise*
R	Ratio of losses at rated current to no load losses, given by the setting *Ratio of losses*

k_{11}, τ_0, K and x are as defined in the Parameter selection module in Figure 696.

The D operator implies a difference in the associated variable that corresponds to each time step Dt. At each time step, the n^{th} value of $D\theta_{0(n)}$ is calculated from the $(n-1)^{th}$ value.

The initial conditions are calculated by setting the time derivative equal to zero in $D\theta_{0(n)}$ equation, resulting in the following equations.

$$\theta_{0(0)} = \left[\frac{1+\left(K^2 \cdot R\right)}{1+R}\right]^x \cdot \Delta\theta_{or} + \theta_a$$

(Equation 288)

The top oil temperature at the n^{th} time step is calculated as shown below.

$$TOPOIL_TEMP = \theta_{0(n-1)} + D\theta_{0(n)}$$

(Equation 289)

The measured/calculated top oil temperature TOPOIL_TEMP is available in the Monitored data view.

If the top oil temperature sensor is valid, the TOPOIL_TEMP output is equal to the measured top oil temperature TOIL_TEMP input.

Hot-spot temp calculation

Winding hot-spot temperature depends on the winding temperature rise due to the load factor and oil flow. These two factors act complimentary to each other in the influence of temperature rise.

The differential equations for hot-spot temperature rise above top oil temperature is solved as the sum of two differential equations.

$$\Delta\theta_{h(n)} = \Delta\theta_{h1(n)} - \Delta\theta_{h2(n)}$$

(Equation 290)

The two differential equations are shown in the Equation 291 and Equation 292.

$$D\Delta\theta_{h1(n)} = \frac{Dt}{(k_{22} \cdot \tau_w)} \cdot \left(k_{21} \cdot \Delta\theta_{hr} \cdot K^y - \Delta\theta_{h1(n-1)}\right)$$

(Equation 291)

$$D\Delta\theta_{h2(n)} = \frac{Dt}{\left(\left(\frac{1}{k_{22}}\right) \cdot \tau_o\right)} \cdot \left((k_{21} - 1) \cdot \Delta\theta_{hr} \cdot K^y - \Delta\theta_{h2(n-1)}\right)$$

(Equation 292)

Where

$\Delta\theta_{hr}$	Hot-spot-to-top-oil gradient at rated current [°C]

The constants τ_w, k_{21}, k_{22} and y are varying according to the *Cooling mode* setting and are obtained from the Load factor calculation and parameter selection module.

The rated hot-spot to top oil gradient, HS_TOIL_GRA ($\Delta\theta_{hr}$), is calculated using the formula as shown in the Equation 293.

$$\Delta\theta_{hr} = \frac{Hotspot\ \ Tmp\ rise - Top\ oil\ \ Tmp\ rise}{\left(\frac{Current\ type\ test}{I_{rated}}\right)^y}$$

(Equation 293)

Where

I_{rated}	Rated current of the transformer
Hotspot Tmp rise	Hot-spot temperature rise over ambient at rated load
Top oil Tmp rise	Top oil temperature rise over ambient at rated load
Current type test	Current applied in type testing to reach rated hot-spot temperature

At each time step, the n^{th} value of $D\Delta\theta_{h1(n)}$ and $D\Delta\theta_{h2(n)}$ are calculated from the (n-1) value; the solutions of which are combined in accordance with the hot-spot temperature rise equation.

$$\Delta\theta_{h1(n)} = \Delta\theta_{h1(n-1)} + D\Delta\theta_{h1(n)}$$

(Equation 294)

$$\Delta\theta_{h2(n)} = \Delta\theta_{h2(n-1)} + D\Delta\theta_{h2(n)}$$

(Equation 295)

The initial conditions are calculated by setting the time derivative equal to zero in $D\Delta\theta_{h1(n)}$ and $D\Delta\theta_{h2(n)}$ equations, resulting in the following equations.

$$\Delta\theta_{h1(0)} = k_{21} \cdot \Delta\theta_{hr} \cdot K^{y}$$

(Equation 296)

$$\Delta\theta_{h2(0)} = (k_{21} - 1) \cdot \Delta\theta_{hr} \cdot K^{y}$$

(Equation 297)

The final hot-spot temperature is calculated as the sum of top oil temperature and the rise of hot-spot temperature over the top oil temperature.

The hot-spot temperature at the nth time step is calculated as shown in the Equation 298.

$$HOTSPOT_TEMP = \theta_{o(n)} + \Delta\theta_{h(n)}$$

(Equation 298)

The calculated hot-spot temperature HOTSPOT_TEMP and rated hot-spot to top oil gradient, HS_TOIL_GRA are available in the Monitored data view.

Level detector 1

This module compares the calculated hot-spot temperature, HOTSPOT_TEMP value with the *Alarm level* and *Warning level* settings.

If HOTSPOT_TEMP is greater than the *Warning level*, the module activates the WARNING output after a settable *Warning delay time*.

If HOTSPOT_TEMP is greater than the *Alarm level*, the module activates the ALARM output after a settable *Alarm delay time*.

Assuming existing conditions, as long as the alarm/warning conditions are not reached, the module calculates the available load reserve in percentage to reach the alarm condition LD_RSV_ALM_PCT and to reach the warning condition, LD_RSV_WRN_PCT. These outputs can be obtained from the Monitored data view.

If the warning condition is reached, the LD_RSV_WRN_PCT output is forced to zero and if the alarm condition is reached, LD_RSV_ALM_PCT is forced to zero.

The load reserve outputs are only indicative and are calculated based on rated current, assuming the same ambient temperature and cooling modes.
If, for any reason, the load reserve calculation is not feasible, the load reserve outputs are shown as zero.

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates WARNING and ALARM outputs and resets the internal timers.

Ageing and loss of life calculation

This module calculates the rate at which transformer insulation ageing is accelerating compared with the ageing rate at rated hot-spot temperature and equivalent ageing over a time period.

If transformer insulation paper is not upgraded, that is, if setting *Insul paper type* is set to "Normal", the setting *Ageing rate method* selects between the IEC and IEEE methods of calculation. If *Ageing rate method* is set to "IEC", the relative ageing rate is calculated as shown in the Equation 299.

$$V_{IEC} = 2^{\frac{(\theta_h - 98)}{6}}$$

(Equation 299)

If the setting *Ageing rate method* is set to "IEEE", the ageing rate is calculated as shown in the Equation 300.

$$V_{IEEE} = e^{\frac{15000}{110+273} - \frac{15000}{\theta_h + 273}}$$

(Equation 300)

Where

V_{IEC}	Momentary ageing rate as per IEC method
V_{IEEE}	Momentary ageing rate as per IEEE method
θ_h	The calculated hot-spot temperature

If the setting *Insul paper type* is set to "Upgraded", the IEEE method is used for calculating the ageing rate irrespective of the value of *Ageing rate method* setting.

The calculated value of the relative ageing rate, AGEING_RATE is given as an output in the Monitored data view.

The module also calculates the average ageing rate, AVG_AGE_RATE, over a specified time period given by the *Avg Age rate period* setting. The setting *Avg Age rate period* can be set to "DAY", "WEEK", "MONTH" or "YEAR".

For example, if the *Avg Age rate period* is set to "MONTH", the output AVG_AGE_RATE is updated every day with the average ageing rate since the day the calculation started. Once a month is completed, the AVG_AGE_RATE is calculated over the previous 30 days. That is, after the 31st day, the average ageing rate is calculated from day 2 to day 31 and so on.

If the *Avg Age rate period* is set to "DAY", "WEEK" or "MONTH", the calculated AVG_AGE_RATE is refreshed every day at 12:00 hours, but if it is set to "YEAR", the AVG_AGE_RATE is refreshed once in 30 days.

The calculated AVG_AGE_RATE is given as an output in the Monitored data view.

The function considers month as 30 days and correspondingly a year as 12 months or 360 days.

Loss of life calculation

The momentary loss of life can be calculated as the product of the momentary ageing rate and the time step over which the momentary ageing is calculated.

$$DL_n = V_n \cdot Dt$$

(Equation 301)

The total loss of life is the sum of the momentary loss of life and the total loss of life until time, n-1.

$$L_n = L_{n-1} + DL_n$$

(Equation 302)

The initial loss of life L_0, is taken from the setting *Initial loss of life*.

For new transformer installations, the *Initial loss of life* setting should be “0”. For previously installed transformers, the *Initial loss of life* can be set to the consumed transformer life in months.

The calculated value of the loss of life in years, LOSS_OF_LIFE, is given as an output in the Monitored data view.

The calculated value of LOSS_OF_LIFE can be reset through the input RESET.

Level detector 2

This module compares the ALM_AGE_RATE output with the setting *Alarm level Age Rte*.

If the calculated AVG_AGE_RATE over the *Avg Age rate period* setting is greater than *Alarm level Age Rte*, the module activates the binary output ALM_AGE_RATE.

The binary input RST_AVGAGING can be used to reset the output ALM_AGE_RATE and also the calculated value of AVG_AGE_RATE.

Once the RST_AVGAGING input is active, the average ageing rate values stored over the *Avg Age rate period* setting is erased and the calculation of AVG_AGE_RATE is restarted.

If the *Avg Age rate period* is set to "YEAR", the output AVG_AGE_RATE is refreshed once in 30 days starting from the time the relay is installed or since the last activation of binary input RST_AVGAGING.

The activation of the BLOCK input deactivates the ALM_AGE_RATE output.

7.2.6 Application

The insulation used in transformer windings is paper oil insulation that can degrade over a period of time. The deterioration of insulation is a time function of temperature, moisture and oxygen content. With modern oil preservation systems, the moisture and oxygen contributions to insulation deterioration can be minimized, leaving insulation temperature as the controlling parameter.

Since, in most of the transformers the temperature distribution is not uniform, the part that is operating at the highest (hot-spot) temperature normally undergoes the greatest deterioration. Hot-spot temperature of winding needs to be monitored continuously in order to not exceed the flashover value of transformer insulation oil. The first step in monitoring the insulation age is the calculation of hot-spot temperature of the transformer.

A simplified representation of the variation of temperature inside the transformer is shown in the Figure 697 (IEC 60076-7).

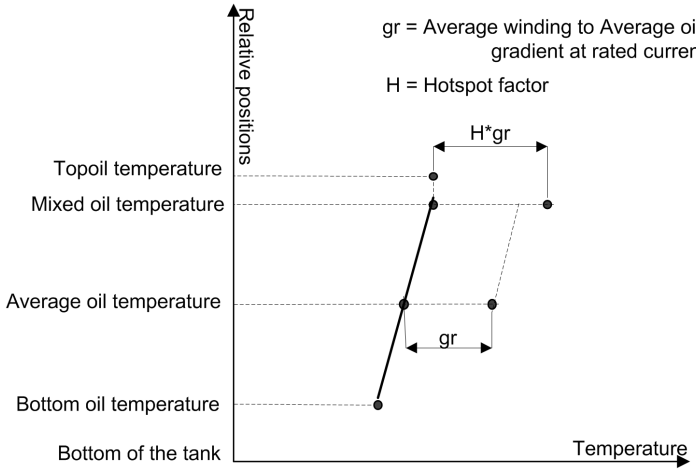

Figure 697: Transformer thermal diagram

The winding hot-spot temperature depends on the load losses, type of cooling and ambient temperature. Usually the conductors near the top of the winding experience the maximum leakage field and the highest surrounding oil temperature (due to convection effect). It is natural to consider that the top conductors contain the hottest spot. Measurements have shown that the hottest spot can also be moved to lower conductors.

Direct measurement of hot-spot temperature with fiber optic probes became available in mid 1980s. Experience has shown that there might be gradients of more than 10 °C between different locations at the top of a transformer winding. It is unlikely that the insertion of one to three sensors detect the real hot-spot. Direct measurement of hot-spot temperature is difficult and it is calculated using the empirical formulae.

The hot-spot temperature calculation is dependent upon the thermal properties of the winding material, cooling oil and the cooling mode of the transformer. The thermal

model may also differ from IEC and IEEE markets, though the underlying principle of temperature calculation remains the same. The transformer constants are decided based on a user defined setting to select the preferred type of thermal model (IEC, IEEE or Manual).

For most transformers in service, the top oil temperature inside a winding is difficult to measure. On the other hand, the top oil temperature at the top of the tank is well known, either by measurement or by calculation. The winding hot-spot temperature rise above the top oil temperature is calculated. By adding this value to the measured or calculated top oil temperature, the winding hot-spot temperature is obtained. A pictorial representation of the location of top oil temperature sensor is shown in the Figure 698.

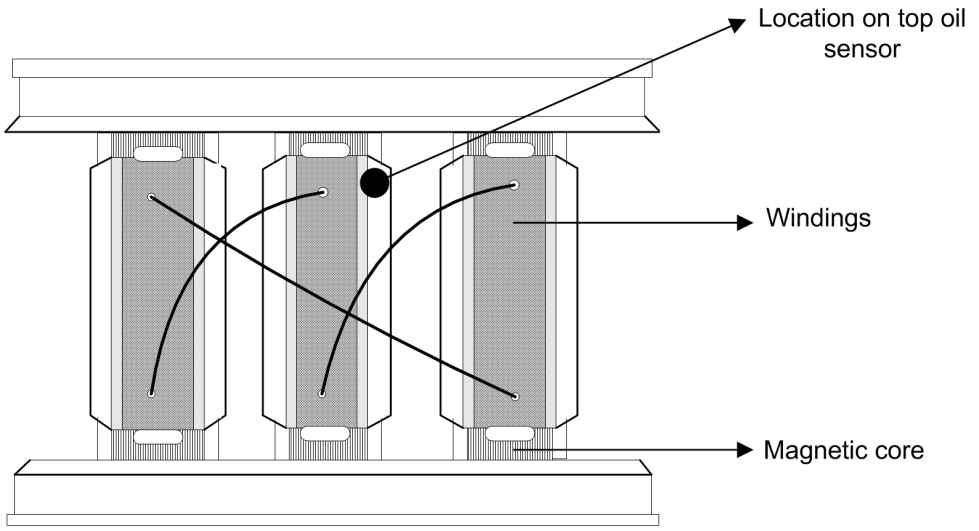

Figure 698: Location of top oil sensor

WARNING and ALARM signals are provided for the operator to take corrective actions to reduce the temperature inside the transformer. Corrective actions include switching on coolers, reducing the load on the transformers and so on.

Normally, warning level is set to indicate if the temperature is nearing the limiting value and alarm is generated when the limiting condition has reached. Hence, alarm level is set at a higher value than the warning level.

The function only calculates hot-spot temperature based on the load factor of the winding. This function does not calculate the rise in actual hot-spot temperature, which occurs due to oil flow blockage or malfunction of cooler groups. That said, the set oil and winding properties can be updated manually to indicate this change.

Based on the calculated hot-spot temperature, the function calculates the relative ageing, that is, the accelerated or decelerated ageing of the insulation at current load compared to its ageing at rated load. The variation of ageing acceleration factor with

respect to the hot-spot temperature for a sample transformer is plotted in Figure 699. Here, 110 °C is taken as the rated hot-spot temperature at which point an ageing acceleration factor of 1.0 is achieved.

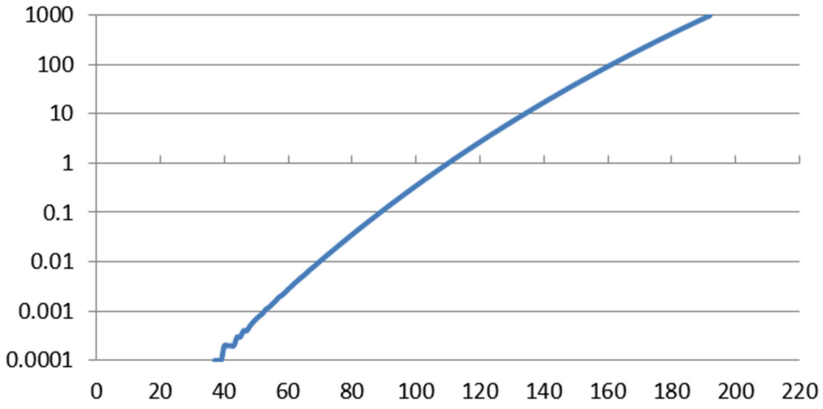

Figure 699: Variation of insulation ageing factor with hot-spot temperature (Graph produced using values from Table 11 of IEEE Std. C57.91-1995)

The variation of insulation life with respect to the hot-spot temperature depends upon the type of insulation paper used. Thermally upgraded insulation paper neutralizes the production of acids caused by the hydrolysis of the material over the lifetime of the transformer and slows down insulation ageing when compared to the normal insulation paper (IEC 60076-7). The proper selection of insulation paper type is needed for better accuracy of loss of life calculation.

In certain cases, it is necessary to monitor the loading of the transformer over a defined time period. For example, during a planned overloading of a transformer for a period of one month. In such cases it is important to know the ageing rate during that period of overload rather than the overall loss of life transformer. Hence, an additional output on average ageing rate over a settable average ageing period is provided in the function.

The function can be applied for new transformers and also for transformers already in service using the *Initial loss of life* setting.

7.2.7 Signals

Table 1202: HSARSPTR Input signals

Name	Type	Default	Description
I3P	SIGNAL	-	Three-phase currents
TOIL_TEMP	FLOAT32	0	Measured top oil temperature
AMB_TEMP	FLOAT32	0	Measured ambient temperature
BLOCK	BOOLEAN	0=False	Block signal for activating the blocking mode
RESET	BOOLEAN	0=False	Reset loss of life calculation
RST_AVGAGING	BOOLEAN	0=False	Reset average ageing rate calculation

Table 1203: HSARSPTR Output signals

Name	Type	Description
ALARM	BOOLEAN	Alarm signal
WARNING	BOOLEAN	Warning signal
ALM_AGE_RATE	BOOLEAN	Alarm signal for Avg ageing rate over set time period
TOPOIL_TEMP	FLOAT32	Calculated value of top oil temperature
HOTSPOT_TEMP	FLOAT32	Calculated value of hot spot temperature

7.2.8 Settings

Table 1204: HSARSPTR Group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Cooling mode	1=ONAN 2=ONAF 3=OFAF 4=ODAF			1=ONAN	Transformer cooling method
Alarm level	50.0...350.0	°C	0.1	120.0	Alarm level for hotspot temperature
Warning level	50.0...350.0	°C	0.1	100.0	Warning level for hotspot temperature
Alarm delay time	0...3600000	ms	10	10000	Time delay for hotspot temperature alarm
Warning delay time	0...3600000	ms	10	10000	Time delay for hotspot temperature warning
Average ambient Tmp	-20.00...70.00	°C	0.01	20.00	Average ambient temperature

Table 1205: HSARSPTR Non group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Operation	1=on 5=off			1=on	Operation Off / On
Transformer type	1=Single phase 2=Three phase			2=Three phase	Number of phases of the transformer
Parameter Sel method	1=IEC 2=IEEE 3=Manual			1=IEC	Transformer parameter selection method
Ageing rate method	1=IEC 2=IEEE			1=IEC	Ageing rate calculation method
Insul paper type	1=Normal 2=Upgraded			1=Normal	Type of transformer paper insulation
Transformer rating	1.00...500.00	MVA	0.01	2.50	Rating of the transformer
Initial loss of life	0...1000		1	0	Initial value for winding insulation loss of life in months
Hotspot Tmp rise	50.0...350.0	°C	0.1	80.0	Hotspot temperature rise over ambient at rated load
Top oil Tmp rise	50.0...350.0	°C	0.1	65.0	Top oil temperature rise over ambient at rated load

Table continues on next page

Parameter	Values (Range)	Unit	Step	Default	Description
Current type test	0.01...2.00	xIn	0.01	1.00	Current applied in type testing to reach rated hotspot Temp
Ratio of losses	0.1...500000.0		0.1	25.0	Ratio of load losses at rated load to no-load losses
CT ratio correction	0.200...5.000		0.001	0.200	Current transformer ratio correction factor
Oil exponent	0.10...10.00		0.01	0.10	User defined value for oil exponent
Winding exponent	0.10...10.00		0.01	0.10	User defined value for winding exponent
Constant K11	0.01...10.00		0.01	1.00	User defined value of thermal model constant K11
Constant K21	0.01...10.00		0.01	1.00	User defined value of thermal model constant K21
Constant K22	0.01...10.00		0.01	2.00	User defined value of thermal model constant K22
Oil time constant	1...20000	s	1	10800	Oil time constant in seconds
Winding Tm constant	1...20000	s	1	240	Winding time constant in seconds
Alarm level Age Rte	0.00...100.00		1	1.00	Alarm level for average ageing rate over set time period

Section 8 Measurement functions

8.1 Basic measurements

8.1.1 Functions

The three-phase current measurement function CMMXU is used for monitoring and metering the phase currents of the power system.

The three-phase voltage measurement function VMMXU is used for monitoring and metering the phase-to-phase voltages of the power system. The phase-to-earth voltages are also available in VMMXU.

Single-phase voltage measurement function VAMMXU is used for monitoring and metering the single-phase voltage of the power system.

The residual current measurement function RESCMMXU is used for monitoring and metering the residual current of the power system.

The residual voltage measurement function RESVMMXU is used for monitoring and metering the residual voltage of the power system.

The frequency measurement function FMMXU is used for monitoring and metering the frequency of the power system.

The sequence current measurement CSMSQI is used for monitoring and metering the phase sequence currents.

The sequence voltage measurement VSMSQI is used for monitoring and metering the phase sequence voltages.

The frequency measurement FMMXU is used for monitoring and metering the power system frequency.

The three-phase power and energy measurement PEMMXU is used for monitoring and metering active power (P), reactive power (Q), apparent power (S) and power factor (PF) and for calculating the accumulated energy separately as forward active, reversed active, forward reactive and reversed reactive. PEMMXU calculates these quantities using the fundamental frequency phasors, that is, the DFT values of the measured phase current and phase voltage signals.

The information of the measured quantity is available for the operator both locally in LHMI or WHMI and remotely to a network control center with communication.

If the measured data in LHMI or WHMI is within parentheses, there are some problems to express the data.

8.1.2 Measurement functionality

The functions can be enabled or disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

Some of the measurement functions operate on two alternative measurement modes: "DFT" and "RMS". The measurement mode is selected with the *X Measurement mode* setting. Depending on the measuring function if the measurement mode cannot be selected, the measuring mode is "DFT".

Demand value calculation

The demand values are calculated separately for each measurement function and per phase when applicable. The available measurement modes are "Linear" and "Logarithmic". The "Logarithmic" measurement mode is only effective for phase current and residual current demand value calculations. The demand value calculation mode is selected with the setting parameter **Configuration/Measurements/A demand Av mode**. The time interval for all demand value calculations is selected with the setting parameter **Configuration/Measurements/Demand interval**.

If the *Demand interval* setting is set to "15 minutes", for example, the demand values are updated every quarter of an hour. The demand time interval is synchronized to the real-time clock of the protection relay. When the demand time interval or calculation mode is changed, it initializes the demand value calculation. For the very first demand value calculation interval, the values are stated as invalid until the first refresh is available.

The "Linear" calculation mode uses the periodic sliding average calculation of the measured signal over the demand time interval. A new demand value is obtained once in a minute, indicating the analog signal demand over the demand time interval proceeding the update time. The actual rolling demand values are stored in the memory until the value is updated at the end of the next time interval.

The "Logarithmic" calculation mode uses the periodic calculation using a log10 function over the demand time interval to replicate thermal demand ammeters. The logarithmic demand calculates a snapshot of the analog signal every 1/15 x demand time interval.

Each measurement function has its own recorded data values. In protection relay, these are found in **Monitoring/Recorded data/Measurements**. In the technical manual these are listed in the monitored data section of each measurement function. These values are periodically updated with the maximum and minimum demand values. The time stamps are provided for both values.

Reset of Recorded data initializes a present demand value to the minimum and maximum demand values.

Value reporting

The measurement functions are capable of reporting new values for network control center (SCADA system) based on various functions.

- Zero-point clamping
- Deadband supervision
- Limit value supervision

In the three-phase voltage measurement function VMMXU the supervision functions are based on the phase-to-phase voltages. However, the phase-to-earth voltage values are also reported with the phase-to-phase voltages.

GOOSE is an event based protocol service. Analog GOOSE uses the same event generation functions as vertical SCADA communication for updating the measurement values. Update interval of 500 ms is used for data that do not have zero-point clamping, deadband supervision or limit value supervision.

Zero-point clamping

A measured value under the zero-point clamping limit is forced to zero. This allows the noise in the input signal to be ignored. The active clamping function forces both the actual measurement value and the angle value of the measured signal to zero. In the three-phase or sequence measuring functions, each phase or sequence component has a separate zero-point clamping function. The zero-value detection operates so that once the measured value exceeds or falls below the value of the zero-clamping limit, new values are reported.

Table 1209: Zero-point clamping limits

Function	Zero-clamping limit
Three-phase current measurement (CMMXU)	1% of nominal (In)
Three-phase voltage measurement (VMMXU)	1% of nominal (Un)
Residual current measurement (RESCMMXU)	1% of nominal (In)
Residual voltage measurement (RESVMMXU)	1% of nominal (Un)
Phase sequence current measurement (CSMSQI)	1% of the nominal (In)
Phase sequence voltage measurement (VSMSQI)	1% of the nominal (Un)
Three-phase power and energy measurement (PEMMXU)	1.5% of the nominal (Sn)

When the frequency measurement function FMMXU is unable to measure the network frequency in the undervoltage situation, the

measured values are set to the nominal and also the quality information of the data set accordingly. The undervoltage limit is fixed to 10 percent of the nominal for the frequency measurement.

Limit value supervision

The limit value supervision function indicates whether the measured value of X_INST exceeds or falls below the set limits. The measured value has the corresponding range information X_RANGE and has a value in the range of 0 to 4:

- 0: "normal"
- 1: "high"
- 2: "low"
- 3: "high-high"
- 4: "low-low"

The range information changes and the new values are reported.

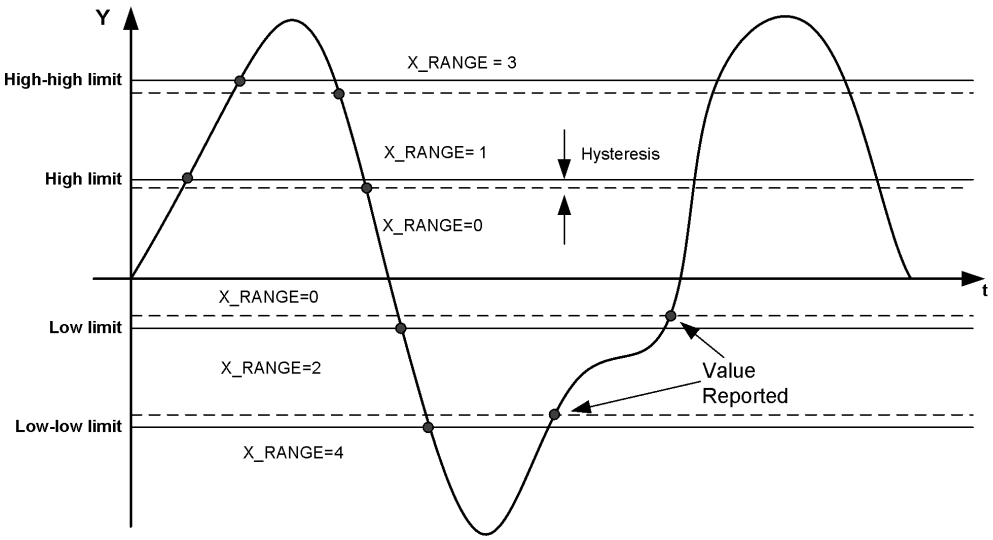

Figure 700: Presentation of operating limits

The range information can also be decoded into boolean output signals on some of the measuring functions and the number of phases required to exceed or undershoot the limit before activating the outputs and can be set with the *Num of phases* setting in the three-phase measurement functions CMMXU and VMMXU. The limit supervision boolean alarm and warning outputs can be blocked.

Table 1210: Settings for limit value supervision

Function	Settings for limit value supervision	
Three-phase current measurement (CMMXU)	High limit	A high limit
	Low limit	A low limit

	Low limit	-
	High-high limit	-
	Low-low limit	-

Deadband supervision

The deadband supervision function reports the measured value according to integrated changes over a time period. In Figure 701 the values are reported at points Y1, Y2, Y3 and Y4. There is no value report at the end of |A3 + A4 + A5 + A6 + A7| because the positive and negative areas counteract each other. The integrated changes, |A3 + A4 + A5 + A6 + A7|, equal approximately zero.

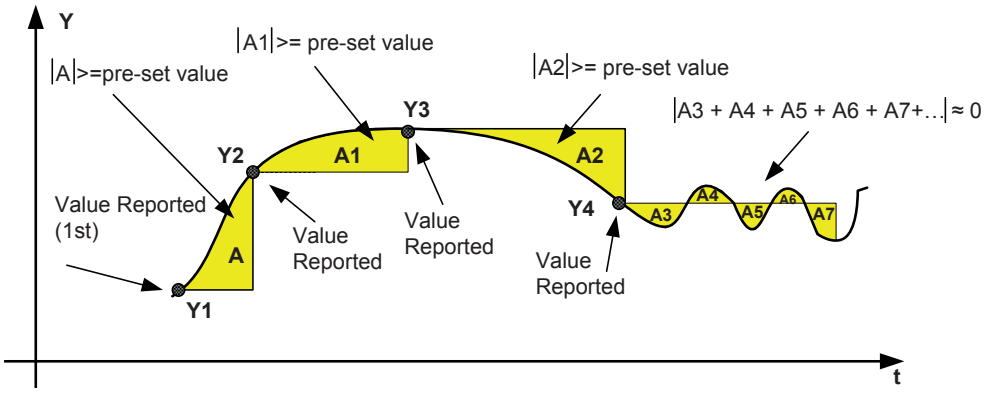

Figure 701: Integral deadband supervision

The deadband value used in the integral calculation is configured with the *X deadband* setting. The value represents the percentage of the difference between the maximum and minimum limit in the units of 0.001 percent x seconds.

The reporting delay of the integral algorithms in seconds is calculated with the formula:

$$t(s) = \frac{(\max - \min) \times deadband / 1000}{|\Delta Y| \times 100\%}$$

(Equation 303)

Example for CMMXU:

A deadband = 2500 (2.5% of the total measuring range of 40)

I_INST_A = I_DB_A = 0.30

If I_INST_A changes to 0.40, the reporting delay is:

$$t(s) = \frac{(40-0)\times 2500/1000}{|0.40-0.30|\times 100\%} = 10s$$

Table 1211: Parameters for deadband calculation

Function	Settings	Maximum/minimum (=range)
Three-phase current measurement (CMMXU)	A deadband	40/0 (=40xIn)
Three-phase voltage measurement (VMMXU)	V Deadband	4/0 (=4xUn)
Single-phase voltage measurement (VAMMXU)	V Deadband	4/0 (=4xUn)
Residual current measurement (RESCMMXU)	A deadband res	40/0 (=40xIn)
Residual voltage measurement (RESVMMXU)	V deadband res	4/0 (=4xUn)
Frequency measurement (FMMXU)	F deadband	75/35 (=40 Hz)
Phase sequence current measurement (CSMSQI)	Ps Seq A deadband, Ng Seq A deadband, Zro A deadband	40/0 (=40xIn)
Phase sequence voltage measurement (VSMSQI)	Ps Seq V deadband, Ng Seq V deadband, Zro V deadband	4/0 (=4xUn)
Three-phase power and energy measurement (PEMMXU)	-	

In the three-phase power and energy measurement function PEMMXU, the deadband supervision is done separately for the apparent power S, and the power factor PF. These deadbands are fixed and linear in the following way:

- A change of 10% x Sn is reported in one second.
- An absolute change of 0.1 in the PF value (-1..0..+1) is reported in one second.

All the power measurement-related values (P, Q, S and PF) are reported simultaneously each time either S or PF causes a reporting.

Power and energy calculation

The three-phase power is calculated from the selected voltage and current measurements as described in Table 1212. The setting *Measurement mode* determines which voltage and current measurements are used.

It is also possible to use positive-sequence components for calculating the apparent power, which makes the determination of power insensitive to any asymmetry in currents or voltages.

Table 1212: Measured apparent power

Measurement mode setting values	Power calculation
PhsA, PhsB, PhsC	$\overline{S} = \overline{U_A} \cdot \overline{I_A}^* + \overline{U_B} \cdot \overline{I_B}^* + \overline{U_C} \cdot \overline{I_C}^*$ (Equation 304)
Arone	$\overline{S} = \overline{U_{AB}} \cdot \overline{I_A}^* - \overline{U_{BC}} \cdot \overline{I_C}^*$ (Equation 305)
Pos Seq	$\overline{S} = 3 \cdot \overline{U_1} \cdot \overline{I_1}^*$ (Equation 306)
PhsAB	$\overline{S} = \overline{U_{AB}} \cdot \left(\overline{I_A}^* - \overline{I_B}^* \right)$ (Equation 307)
PhsBC	$\overline{S} = \overline{U_{BC}} \cdot \left(\overline{I_B}^* - \overline{I_C}^* \right)$ (Equation 308)
PhsCA	$\overline{S} = \overline{U_{CA}} \cdot \left(\overline{I_C}^* - \overline{I_A}^* \right)$ (Equation 309)
PhsA	$\overline{S} = 3 \cdot \overline{U_A} \cdot \overline{I_A}^*$ (Equation 310)
PhsB	$\overline{S} = 3 \cdot \overline{U_B} \cdot \overline{I_B}^*$ (Equation 311)
PhsC	$\overline{S} = 3 \cdot \overline{U_C} \cdot \overline{I_C}^*$ (Equation 312)

Depending upon the set *Measurement mode*, the Power and energy calculation module calculates active power, reactive power and apparent power values from the available set of measurements.

$$P = \mathrm{Re}(\overline{S})$$

(Equation 313)

$$Q = \mathrm{Im}(\overline{S})$$

(Equation 314)

$$S = \left|\overline{S}\right| = \sqrt{P^2 + Q^2}$$

(Equation 315)

$$Cos\varphi = \frac{P}{S}$$

(Equation 316)

The calculated powers are available as function outputs S_INST, P_INST, Q_INST and the power factor angle as PF_INST.

Depending on the unit multiplier selected with *Power unit Mult*, the calculated power values in the monitored data and measurement view are presented in units of kVA/kW/kVAr or in units of MVA/MW/MVAr.

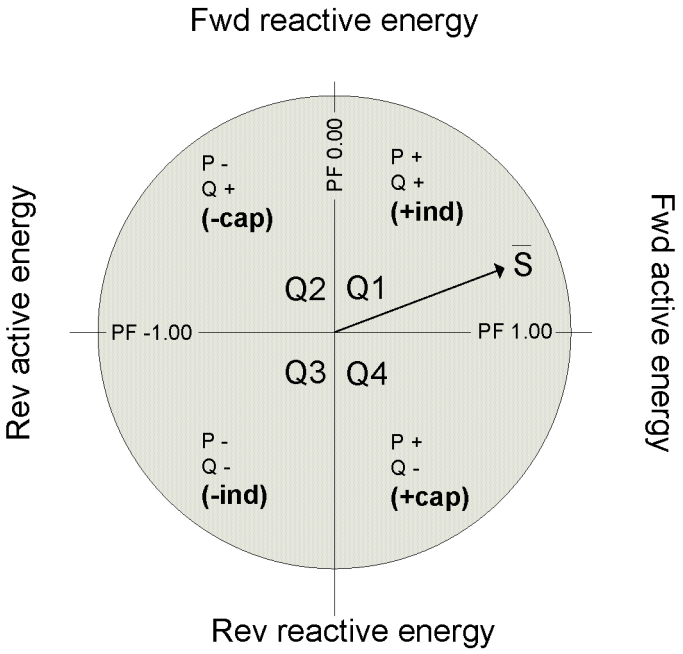

Figure 702: Complex power and power quadrants

Table 1213: Power quadrants

Quadrant	Current	P	Q	PF	Power
Q1	Lagging	+	+	0…+1.00	+ind
Q2	Lagging	-	+	0…-1.00	-cap
Q3	Leading	-	-	0…-1.00	-ind
Q4	Leading	+	-	0…+1.00	+cap

The active power P direction can be selected between forward and reverse with *Active power Dir* and correspondingly the reactive power Q direction can be selected with *Reactive power Dir*. This affects also the accumulated energy directions.

The accumulated energy is calculated separately as forward active (EA_FWD_ACM), reverse active (EA_RV_ACM), forward reactive (ER_FWD_ACM) and reverse reactive (ER_RV_ACM). Depending on the value of the unit multiplier selected with *Energy unit Mult*, the calculated power values are presented in units of kWh/kVArh or in units of MWh/MVArh.

When the energy counter reaches its defined maximum value, the counter value is reset and restarted from zero. Changing the value of the *Energy unit Mult* setting resets the accumulated energy values to the initial values, that is, EA_FWD_ACM to *Forward Wh Initial*, EA_RV_ACM to *Reverse Wh Initial*, ER_FWD_ACM to *Forward VArh Initial* and ER_RV_ACM to *Reverse VArh Initial*. It is also possible to reset the accumulated energy to initial values through a parameter or with the RSTACM input.

Sequence components

The phase-sequence components are calculated using the phase currents and phase voltages. More information on calculating the phase-sequence components can be found in Calculated measurements in this manual.

8.1.3 Measurement function applications

The measurement functions are used for power system measurement, supervision and reporting to LHMI, a monitoring tool within PCM600, or to the station level, for example, with IEC 61850. The possibility to continuously monitor the measured values of active power, reactive power, currents, voltages, power factors and so on, is vital for efficient production, transmission, and distribution of electrical energy. It provides a fast and easy overview of the present status of the power system to the system operator. Additionally, it can be used during testing and commissioning of protection and control protection relays to verify the proper operation and connection of instrument transformers, that is, the current transformers (CTs) and voltage transformers (VTs). The proper operation of the protection relay analog measurement chain can be verified during normal service by a periodic comparison of the measured value from the protection relay to other independent meters.

When the zero signal is measured, the noise in the input signal can still produce small measurement values. The zero point clamping function can be used to ignore the noise in the input signal and, hence, prevent the noise to be shown in the user display. The zero clamping is done for the measured analog signals and angle values.

The demand values are used to neglect sudden changes in the measured analog signals when monitoring long time values for the input signal. The demand values are linear average values of the measured signal over a settable demand interval. The demand values are calculated for the measured analog three-phase current signals.

The limit supervision indicates, if the measured signal exceeds or goes below the set limits. Depending on the measured signal type, up to two high limits and up to two low limits can be set for the limit supervision.

The deadband supervision reports a new measurement value if the input signal has gone out of the deadband state. The deadband supervision can be used in value reporting between the measurement point and operation control. When the deadband supervision is properly configured, it helps to keep the communication load to a minimum and yet measurement values are reported frequently enough.

The instantaneous measurement values of several measurement functions are available as primary values for further use in Application Configuration. The current values are in amperes while voltage values are in kilovolts and power values in kilovolt-amperes, watts or volt-amperes reactive.

8.1.4.2 Function block

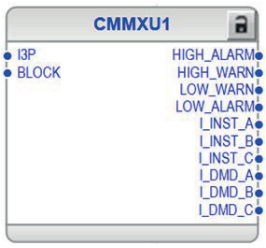

Figure 703: Function block

8.1.4.3 Functionality

The three-phase current measurement function CMMXU provides limit value supervision output (`HIGH_ALARM`, `HIGH_WARN`, `LOW_WARN`, `LOW_ALARM`). The delay of the activation and deactivation of these outputs can be controlled with setting parameters *On delay time* and *Off delay time*.

Instantaneous phase currents (`I_INST_A`, `I_INST_B` and `I_INST_C`) are provided as outputs in amperes. These can be used in the application configuration.

Phase current demand values (`I_DMD_A`, `I_DMD_B` and `I_DMD_C`) are provided as outputs in amperes. These outputs are dedicated for Load profile recorder (LDPRLRC).

8.1.4.4 Analog channel configuration

CMMXU has one analog group input which must be properly configured.

Table 1214: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

8.1.4.5 Signals

Table 1215: CMMXU Input signals

Characteristic	Value
Operation accuracy	Depending on the frequency of the measured current: f_n ±2 Hz
	±0.5% or ±0.002 × I_n (at currents in the range of 0.01...4.00 × I_n)
Suppression of harmonics	DFT: -50 dB at f = n × f_n, where n = 2, 3, 4, 5,… RMS: No suppression

8.1.5 Three-phase voltage measurement VMMXU

8.1.5.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-phase voltage measurement	VMMXU	3U	VA, VB, VC

8.1.5.2 Function block

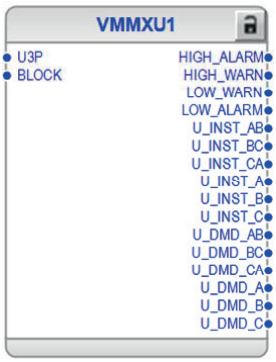

Figure 704: Function block

8.1.5.3 Functionality

The three-phase voltage measurement function VMMXU provides limit value supervision output (`HIGH_ALARM`, `HIGH_WARN`, `LOW_WARN`, `LOW_ALARM`). Setting parameters *On delay time* and *Off delay time* are used for controlling the activation and the deactivation of alarm and warning outputs.

Instantaneous phase-to-phase and phase-to-earth voltages in volts are available for application configurations through outputs `U_INST_AB`, `U_INST_BC` and `U_INST_CA` and `U_INST_A`, `U_INST_B` and `U_INST_C`, respectively.

Phase current demand values in volts are for connecting to Load profile recorder (LDPRLRC) through outputs `I_DMD_A`, `I_DMD_B` and `I_DMD_C`.

8.1.5.4 Analog channel configuration

VMMXU has one analog group input which must be properly configured.

Table 1221: Analog inputs

Input	Description
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1222: Special conditions

Condition	Description
U3P connected to real measurements	The function requires that at least one voltage channel is connected if *Num of start phases* is set to "1 out of 3".
	The function requires that at least two voltage channels are connected if *Num of start phases* is set to "2 out of 3".
	The function requires that all three voltage channels are connected if *Num of start phases* is set to "3 out of 3".

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

Table 1228: VMMXU Technical data

Characteristic	Value
Operation accuracy	Depending on the frequency of the voltage measured: f_n ±2 Hz At voltages in range 0.01…1.15 × U_n
	±0.5% or ±0.002 × U_n
Suppression of harmonics	DFT: -50 dB at f = n × f_n, where n = 2, 3, 4, 5,… RMS: No suppression

8.1.6 Single-phase voltage measurement VAMMXU

8.1.6.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Single-phase voltage measurement	VAMMXU	U_A	V_A

8.1.6.2 Function block

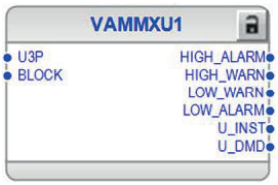

Figure 705: Function block symbol

8.1.6.3 Functionality

The single-phase voltage measurement function VAMMXU provides limit value supervision output (`HIGH_ALARM`, `HIGH_WARN`, `LOW_WARN`, `LOW_ALARM`).

Instantaneous single-phase voltage in volt is available for application configurations through output `U_INST`. Phase voltage demand value in volt is for connecting to Load profile recorder (LDPRLRC) through output `U_DMD`.

8.1.6.4 Analog channel configuration

VAMMXU has one analog group input which must be properly configured.

Table 1229: Analog inputs

Input	Description
U3P	Voltage group signal

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1230: Special conditions

Condition	Description
U3P connected to real measurements	The function requires that the first phase voltage U_A or U_AB is connected.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

Time min demand Io	Timestamp			Time of minimum demand residual current

8.1.7.8 Technical data

Table 1243: RESCMMXU Technical data

Characteristic	Value
Operation accuracy	At the frequency f = f_n
	±0.5% or ±0.002 × I_n (at currents in the range of 0.01...4.00 × I_n)
Suppression of harmonics	DFT: -50 dB at f = n × f_n, where n = 2, 3, 4, 5,… RMS: No suppression

8.1.8 Residual voltage measurement RESVMMXU

8.1.8.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Residual voltage measurement	RESVMMXU	Uo	VG/VN

8.1.8.2 Function block

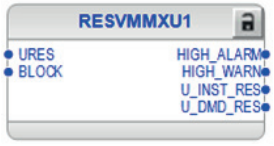

Figure 707: Function block

8.1.8.3 Functionality

The residual voltage measurement function RESVMMXU provides limit value supervision output (`HIGH_ALARM`, `HIGH_WARN`). Setting parameters *On delay time* and *Off delay time* are used for controlling the activation and, respectively, the deactivation of alarm and warning outputs.

Instantaneous residual voltage in volt is available for application configurations through output `U_INST_RES`. The residual voltage demand value in volt is for connecting to Load profile recorder (LDPRLRC) through output `U_DMD_RES`.

8.1.8.4 Analog channel configuration

RESVMMXU has one analog group input which must be properly configured.

Table 1244: Analog inputs

Input	Description
URES	Residual voltage (measured or calculated)

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1245: Special conditions

Condition	Description
URES calculated	The function requires that all three voltage channels are connected to calculate residual voltage. Setting *VT connection* must be "Wye" in that particular UTVTR.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

8.1.8.5 Signals

8.1.9 Frequency measurement FMMXU

8.1.9.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Frequency measurement	FMMXU	f	f

8.1.9.2 Function block

Figure 708: Function block

8.1.9.3 Functionality

The frequency measurement range is 35...75 Hz. The measured frequencies outside the measurement range are considered to be out of range and the minimum and maximum values are then shown in parentheses.

There is an extended range of 10...75 Hz in a 50 Hz network and 12...75 Hz in a 60 Hz network. The measured frequencies outside 35...75 Hz are shown in parentheses.

When the frequencies cannot be measured, for example, due to too low voltage amplitude, the default value for frequency measurement can be selected with the *Def frequency Sel* setting parameter. In the “Nominal” mode the frequency is set to 50 Hz (or 60 Hz) and in “Zero” mode the frequency is set to zero and shown in parentheses.

FMMXU provides instantaneous frequency in hertz which is available for application configurations through output `F_INST`.

Sequence voltage measurement	VSMSQI	U1, U2, U0	V1, V2, V0

8.1.11.2 Function block

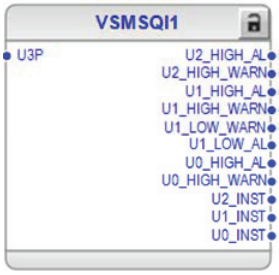

Figure 710: Function block

8.1.11.3 Functionality

The sequence voltage measurement function VSMSQI provides limit value supervision outputs (U2_HIGH_AL, U2_HIGH_WARN, U1_HIGH_AL, U1_HIGH_WARN, U1_LOW_WRN, U1_LOW_AL, U0_HIGH_AL, U0_HIGH_WARN). Setting parameters *Ps Seq V on delay time*, *Ps Seq V off delay time*, *Ng Seq V on delay time*, *Ng Seq V off delay time*, *Zro Seq V on delay time*, *Zro Seq V off delay time* are used for controlling the activation and the deactivation of alarm and warning outputs.

Instantaneous sequence voltages in volt are available for application configurations through outputs U2_INST, U1_INST and U0_INST.

8.1.11.4 Analog channel configuration

VSMSQI has one analog group input which must be properly configured.

Table 1265: Analog inputs

Input	Description
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1266: Special conditions

Condition	Description
U3P connected to real measurements	The function requires that any two voltage channels are connected.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-phase power and energy measurement	PEMMXU	P, E	P, E

8.1.12.2 Function block

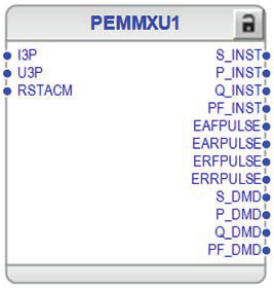

Figure 711: Function block

8.1.12.3 Functionality

The three-phase power and energy measurement function PEMMXU calculates energy and power from the available current and voltage inputs. The function stores the accumulated values of the real and reactive energy in both directions, and presents these values as numerical and pulse outputs.

PEMMXU provides pulse outputs EAFPULSE, EARPULSE, ERFPULSE and ERRPULSE which are activated based on the calculated values of forward and reverse, active and reactive accumulated energy. The activation of the pulse depends on the *Pulse quantity* setting. For example, if *Pulse quantity* is set as "10000" Wh, EAFPULSE is activated every time accumulated energy EA_FWD_ACM increases

by 10000 Wh. The pulse-on and -off time duration can be set using the *Pulse on time* and *Pulse off time* settings.

Instantaneous three-phase power and power factor measurements are available for application configurations through output S_INST, P_INST, Q_INST and PF_INST.

Three-phase power and power factor demand values (S_DMD, P_DMD, Q_DMD and PF_DMD) are provided as outputs. These outputs are dedicated for Load profile recorder (LDPRLRC).

8.1.12.4 Analog channel configuration

PEMMXU has two analog group inputs which all must be properly configured.

Table 1273: Analog inputs

Input	Description
I3P	Three-phase currents
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1274: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with the corresponding one voltage channel connected if *Measurement mode* is set to "PhsAB", "PhsBC" or "PhsCA".
	The function can work with the corresponding two voltage channels connected if *Measurement mode* is set to "PhsA", "PhsB" or "PhsC".
	The function requires that all three voltage channels are connected for the other measurement modes.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

2) |PF| <0.86 which equals |sinφ| >0.5

8.2 Disturbance recorder, common functionality RDRE

8.2.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Disturbance recorder, common functionality	RDRE	DR	DFR

8.2.2 Function block

Figure 712: Function block

8.2.3 Functionality

The protection relay is provided with a disturbance recorder featuring up to 24 analog and 64 binary signal channels. The analog channels can be set to record either the waveform or the trend of the currents and voltages measured and they can trigger the recording function when the measured value falls below or exceeds the set values.

The binary signal channels can be set to start a recording either on the rising or the falling edge of the binary signal or on both. By default, the binary channels are set to record external or internal relay signals, for example, the start or trip signals of the relay stages, or external blocking or control signals. Binary relay signals, such as protection start and trip signals, or an external relay control signal via a binary input

can be set to trigger the recording. Recorded information is stored in a nonvolatile memory and can be uploaded for subsequent fault analysis.

8.2.3.1 Recorded analog and binary inputs

The relay's analog and binary signals for disturbance recorder can be configured with Application Configuration in PCM600. In addition, each channel of the disturbance recorder can be enabled or disabled by setting the *Operation* parameter of the corresponding channel to "on" or "off".

All channels of the disturbance recorder that are enabled and have a valid signal connected are included in the recording.

8.2.3.2 Triggering alternatives

The recording can be triggered by any of the following alternatives.

- Triggering according to the state change of any of the binary channels of the disturbance recorder. The level sensitivity can be set with the *Level trigger mode* parameter of the corresponding binary channel.
- Triggering on limit violations of the analog channels of the disturbance recorder (high and low limit)
- Manual triggering via the *Trig recording* parameter (LHMI or communication)
- Periodic triggering

Regardless of the triggering type, each recording generates the Recording started and Recording made events. The Recording made event indicates that the recording has been stored to the nonvolatile memory. In addition, every analog channel and binary channel of the disturbance recorder has its own *Channel triggered* parameter. Manual trigger has the *Manual triggering* parameter and periodic trigger has the *Periodic triggering* parameter.

Triggering by binary channels

The input signals for the binary channels of the disturbance recorder can be formed from any of the digital signals that can be dynamically mapped. A change in the status of a monitored signal triggers the recorder according to the configuration and settings. Triggering on the rising edge of a digital input signal means that the recording sequence starts when the input signal is activated. Correspondingly, triggering on the falling edge means that the recording sequence starts when the active input signal resets. It is also possible to trigger from both edges. In addition, the monitored signal can be non-triggering. The trigger setting can be set individually for each binary channel of the disturbance recorder with the *Level trigger mode* parameter of the corresponding binary channel.

Triggering by analog channels

The trigger level can be set for triggering in a limit violation situation. The limit values can be set with the *High trigger level* and *Low trigger level* parameters of the

corresponding analog channel. Both high-level and low-level violation triggering can be active simultaneously for the same analog channel. If the duration of the limit violation condition exceeds the filter time of approximately 50 ms, the recorder triggers. In case of a low-level limit violation, if the measured value falls below approximately 0.05 during the filter time, the situation is considered to be a circuit breaker operation and therefore, the recorder does not trigger. This is useful especially in undervoltage situations. The filter time of approximately 50 ms is common to all the analog channel triggers of the disturbance recorder. The value used for triggering is the calculated peak-to-peak value. Either high or low analog channel trigger can be disabled by setting the corresponding trigger level parameter to zero.

Frequency cannot be used as a trigger to disturbance recorder.

Manual triggering

The recorder can be triggered manually via the LHMI or via communication by setting the *Trig recording* parameter to "Trig".

Periodic triggering

Periodic triggering means that the recorder automatically makes a recording at certain time intervals. The interval can be adjusted with the *Periodic trig time* parameter. If the value of the parameter is changed, the new setting takes effect when the next periodic triggering occurs. Setting the parameter to zero disables the triggering alternative and the setting becomes valid immediately. If a new non-zero setting needs to be valid immediately, the *Periodic trig time* parameter should first be set to zero and then to the new value. The time remaining to the next triggering can be monitored with the Time to trigger monitored data which counts downwards.

8.2.3.3 Length of recordings

The recording length can be defined with the *Record length* parameter. The length is given as the number of fundamental cycles.

According to the memory available and the number of analog channels used, the disturbance recorder automatically calculates the remaining number of recordings that fit into the available recording memory. This information can be seen with the Rem. amount of rec. monitored data. The fixed memory size allocated to the recorder can fit in two recordings that are ten seconds long. The recordings contain data from all analog and binary channels of the disturbance recorder, at the sample rate of 32 samples per fundamental cycle.

The number of recordings in the memory can be viewed with the Number of recordings monitored data. The used memory space can be viewed with the Rec. memory used monitored data. It is shown as a percentage value.

The maximum number of recordings is 100.

8.2.3.4 Sampling frequencies

The sampling frequency of the disturbance recorder analog channels depends on the set rated frequency. One fundamental cycle always contains the number of samples set with the *Storage rate* parameter. Since the states of the binary channels are sampled once per task execution of the disturbance recorder, the sampling frequency of binary channels is 400 Hz at the rated frequency of 50 Hz and 480 Hz at the rated frequency of 60 Hz.

Table 1281: Sampling frequencies of the disturbance recorder analog and binary channels

Storage rate (samples per fundamental cycle)	Recording length	Rated frequency = 50 Hz		Rated frequency = 60 Hz	
		Sampling frequency of analog channels	Sampling frequency of binary channels	Sampling frequency of analog channels	Sampling frequency of binary channels
32	1 · Record length	1600 Hz	400 Hz	1920 Hz	480 Hz
16	2 · Record length	800 Hz	400 Hz	960 Hz	480 Hz
8	4 · Record length	400 Hz	400 Hz	480 Hz	480 Hz

8.2.3.5 Uploading of recordings

The protection relay stores COMTRADE files to the `C:\COMTRADE` folder. The files can be uploaded with PCM600 or any appropriate computer software that can access the `C:\COMTRADE` folder.

One complete disturbance recording consists of two COMTRADE file types: the configuration file and the data file. The file name is the same for both file types. The configuration file has .CFG and the data file .DAT as the file extension.

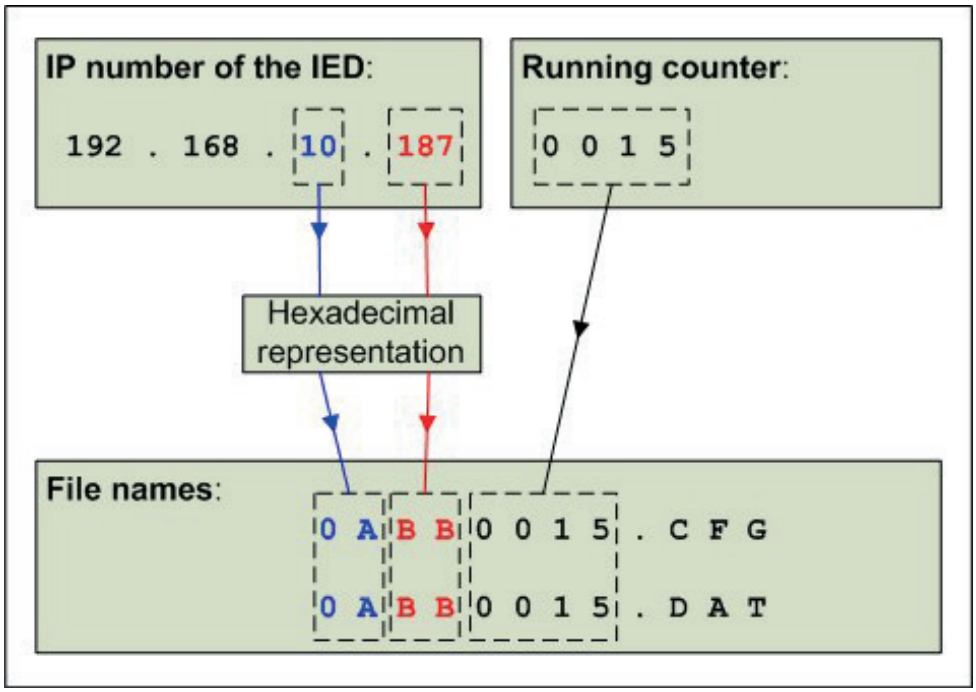

Figure 713: Disturbance recorder file naming

The naming convention of 8+3 characters is used in COMTRADE file naming. The file name is composed of the last two octets of the protection relay's IP number and a running counter, which has a range of 1...9999. A hexadecimal representation is used for the IP number octets. The appropriate file extension is added to the end of the file name.

8.2.3.6 Deletion of recordings

The recordings can be deleted individually or all at once.

Individual disturbance recordings can be deleted with PCM600 or any appropriate computer software, which can access the protection relay's `C:\COMTRADE` folder. The disturbance recording is not removed from the protection relay's memory until both of the corresponding COMTRADE files, .CFG and .DAT, are deleted. Both file types may need to be deleted separately, depending on the software used.

Deleting all disturbance recordings at once is done either with PCM600 or any appropriate computer software, or from the LHMI via the **Clear/Disturbance records** menu. Deleting all disturbance recordings at once also clears the pre-trigger recording in progress.

8.2.3.7 Storage mode

The disturbance recorder can capture data in two modes: waveform and trend mode. The storage mode can be set individually for each trigger source with the *Storage mode* parameter of the corresponding analog channel or binary channel, the *Stor*.

mode manual parameter for manual trigger and the *Stor. mode periodic* parameter for periodic trigger.

In the waveform mode, the samples are captured according to the *Storage rate* and *Pre-trg length* parameters.

In the trend mode, one value is recorded for each enabled analog channel, once per fundamental cycle. The recorded values are RMS values, which are scaled to peak level. The binary channels of the disturbance recorder are also recorded once per fundamental cycle in the trend mode.

Only post-trigger data is captured in trend mode.

The trend mode enables recording times of 32 · *Record length*.

8.2.3.8 Pre-trigger and post-trigger data

The waveforms of the disturbance recorder analog channels and the states of the disturbance recorder binary channels are constantly recorded into the history memory of the recorder. The percentage of the data duration preceding the triggering, that is, the pre-trigger time, can be adjusted with the *Pre-trg length* parameter. The duration of the data following the triggering, that is, the post-trigger time, is the difference between the recording length and the pre-trigger time. Changing the pre-trigger time resets the history data and the current recording under collection.

8.2.3.9 Operation modes

The disturbance recorder has two operation modes: saturation and overwrite mode. The operation mode of the disturbance recorder can be changed with the *Operation mode* parameter.

Saturation mode

In saturation mode, the captured recordings cannot be overwritten with new recordings. Capturing the data is stopped when the recording memory is full, that is, when the maximum number of recordings is reached. In this case, the event is sent via the state change (TRUE) of the *Memory full* parameter. When there is memory available again, another event is generated via the state change (FALSE) of the *Memory full* parameter.

Overwrite mode

In the overwrite mode, if the recording memory is full, the oldest recording is overwritten with the pre-trigger data collected for the next recording. Each time a recording is overwritten, the event is generated via the state change of the *Overwrite of rec.* parameter.

The overwrite mode is recommended if it is important to have the latest recordings in the memory. The saturation mode is preferred when the oldest recordings are more important.

New triggerings are blocked in both modes until the previous recording is completed, but a new triggering can be accepted before all pre-trigger samples are collected for the new recording. In such a case, the recording is as much shorter as there are pre-trigger samples lacking.

8.2.3.10 Exclusion mode

Exclusion mode is on when the value of the *Exclusion time* parameter is higher than zero. During the exclusion mode, new triggerings are ignored if the triggering reason is the same as in the previous recording. The *Exclusion time* parameter controls how long the exclusion of triggerings of same type is active after a triggering. The exclusion mode applies only to the analog and binary channel triggerings, not to periodic and manual triggerings.

When the value set with the *Exclusion time* parameter is zero, the exclusion mode is disabled and there are no restrictions on the triggering types of the successive recordings.

The exclusion time setting is global for all inputs, but there is an individual counter for each analog and binary channel of the disturbance recorder, counting the remaining exclusion time. The remaining exclusion time can be monitored with the *Exclusion time rem* parameter (only visible via communication, IEC 61850 data ExclTmRmn) of the corresponding analog or binary channel. The *Exclusion time rem* parameter counts downwards.

8.2.4 Configuration

The disturbance recorder can be configured with PCM600 or any tool supporting the IEC 61850 standard.

RDRE1 should always be included in Application Configuration when the disturbance recorder is used.

The disturbance recorder can be enabled or disabled with the *Operation* parameter under **Configuration/Disturbance recorder/General**.

One analog signal type of the protection relay can be mapped to each of the analog channels of the disturbance recorder. The mapping is done in Application Configuration in PCM600. The name of the analog channel is user-configurable. It can be modified by writing the new name to the *Channel id text* parameter of the corresponding analog channel.

Any external or internal digital signal of the protection relay which can be dynamically mapped can be connected to the binary channels of the disturbance

recorder. These signals can be, for example, the start and trip signals from protection function blocks or the external binary inputs of the protection relay. The connection is made with dynamic mapping to the binary channel of the disturbance recorder using, for example, Signal Matrix of PCM600. It is also possible to connect several digital signals to one binary channel of the disturbance recorder. In that case, the signals can be combined with logical functions, for example AND and OR. The name of the binary channel can be configured and modified by writing the new name to the *Channel id text* parameter of the corresponding binary channel.

The *Channel id text* parameter is used in COMTRADE configuration files as a channel identifier.

The recording always contains all binary channels of the disturbance recorder. If one of the binary channels is disabled, the recorded state of the channel is continuously FALSE and the state changes of the corresponding channel are not recorded. The corresponding channel name for disabled binary channels in the COMTRADE configuration file is Unused BI.

To enable or disable an analog or a binary channel of the disturbance recorder, the *Operation* parameter of the corresponding analog or binary channel is set to "on" or "off".

The states of manual triggering and periodic triggering are not included in the recording, but they create a state change to the *Periodic triggering* and *Manual triggering* status parameters, which in turn create events.

The `TRIGGERED` output can be used to control the indication LEDs of the protection relay. The triggering of the disturbance recorder sets the `TRIGGERED` output to TRUE. The output remains in this state until all the data for the corresponding recording has been recorded.

The IP number of the protection relay and the value of the *Bay name* parameter are both included in the COMTRADE configuration file for identification purposes.

8.2.5 Application

The disturbance recorder is used for post-fault analysis and for verifying the correct operation of protection relays and circuit breakers. It can record both analog and binary signal information. The analog inputs are recorded as instantaneous values and converted to primary peak value units when the protection relay converts the recordings to the COMTRADE format.

COMTRADE is the general standard format used for storing disturbance recordings.

The binary channels are sampled once per task execution of the disturbance recorder. The task execution interval for the disturbance recorder is the same as for the protection functions. During the COMTRADE conversion, the digital status values are repeated so that the sampling frequencies of the analog and binary channels correspond to each other. This is required by the COMTRADE standard.

The disturbance recorder follows the 1999 version of the COMTRADE standard and uses the binary data file format.

Tap changer position indication	TPOSYLTC	TPOSM	84T

8.5.2 Function block

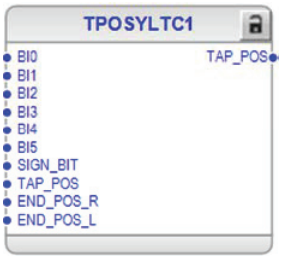

Figure 716: Function block

8.5.3 Functionality

The tap changer position indication function TPOSYLTC is used for transformer tap position supervision. The binary inputs can be used for converting a binary-coded tap changer position to a tap position status indication. The RTD module, available as an option, provides the RTD sensor information to be used and the versatile analog inputs enabling the tap position supervision through mA.

There are three user-selectable conversion modes available for the 7-bit binary inputs where MSB is used as the SIGN bit: the natural binary-coded boolean input to the signed integer output, binary coded decimal BCD input to the signed integer output and binary reflected GRAY coded input to the signed integer output.

8.5.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off". When the function is disabled, the tap position quality information is changed accordingly. When the tap position information is not available, it is recommended to disable this function with the *Operation* setting.

The operation of TPOSYLTC can be described using a module diagram. All the modules in the diagram are explained in the next sections.

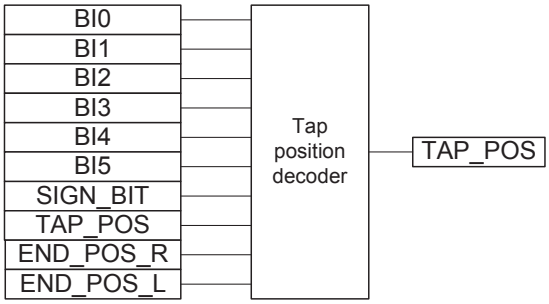

Figure 717: Functional module diagram

Tap position decoder

When there is a wired connection to the TAP_POS input connector, the corresponding tap changer position is decoded from the mA or RTD input. When there is no wired connection to the TAP_POS connector, the binary inputs are expected to be used for the tap changer position information. The tap changer position value and quality are internally shared to other functions. The value is available in the Monitored data view or as a TAP_POS output signal.

The function has three alternative user selectable operation modes: "NAT2INT", "BCD2INT" and "GRAY2INT". The operation mode is selected with the *Operation mode* setting. Each operation mode can be used to convert a maximum of 6–bit coded input to an 8–bit signed short integer output. For less than 6–bit input, for example 19 positions with 5 bits when the BCD coding is used, the rest of the bits can be set to FALSE (0).

The operation mode "NAT2INT" is selected when the natural binary coding is used for showing the position of the transformer tap changer. The basic principle of the natural binary coding is to calculate the sum of the bits set to TRUE (1). The LSB has the factor 1. Each following bit has the previous factor multiplied by 2. This is also called dual coding.

The operation mode "BCD2INT" is selected when the binary-coded decimal coding is used for showing the position of the transformer tap changer. The basic principle with the binary-coded decimal coding is to calculate the sum of the bits set to TRUE (1). The four bits nibble (BI3...BI0) have a typical factor to the natural binary coding. The sum of the values should not be more than 9. If the nibble sum is greater than 9, the tap position output validity is regarded as bad.

The operation mode “GRAY2INT” is selected when the binary-reflected Gray coding is used for showing the position of the transformer tap changer. The basic principle of the Gray coding is that only one actual bit changes value with consecutive positions. This function is based on the common binary-reflected Gray code which is used with some tap changers. Changing the bit closest to the right side bit gives a new pattern.

An additional separate input, SIGN_BIT, can be used for negative values. If the values are positive, the input is set to FALSE (0). If the SIGN_BIT is set to TRUE (1)

making the number negative, the remaining bits are identical to those of the coded positive number.

The tap position validity is set to good in all valid cases. The quality is set to bad in invalid combinations in the binary inputs. For example, when the “BCD2INT” mode is selected and the input binary combination is “0001101”, the quality is set to bad. For negative values, when the SIGN_BIT is set to TRUE (1) and the input binary combination is “1011011”, the quality is set to bad.

If the tap changer has auxiliary contacts for indicating the extreme positions of the tap changer, their status can be connected to END_POS_R and END_POS_L inputs. The END_POS_R (End position raise or highest allowed tap position reached) status refers to the extreme position that results in the highest number of the taps in the tap changer. Similarly, END_POS_L (End position lower or lowest allowed tap position reached) status refers to the extreme position that results in the lowest number of the taps in the tap changer. TAP_POS output is dedicated for transferring the validated tap position for the functions that need tap position information, for example OLATCC and TRxPTDF. It includes both the actual position information and the status of reached end positions, assuming that inputs END_POS_R and END_POS_L are connected.

8.5.5 Application

TPOSYLTC provides tap position information for other functions as a signed integer value that can be fed to the tap position input.

The position information of the tap changer can be coded in various methods for many applications, for example, the differential protection algorithms. In this function, the binary inputs in the transformer terminal connector are used as inputs to the function. The coding method can be chosen by setting the mode parameter. The available coding methods are BCD, Gray and Natural binary coding. Since the number of binary inputs are limited to seven, the coding functions are limited to seven bits including the sign bit and thus the six bits are used in the coding functions. The position limits for the tap positions at BCD, Gray and Natural binary coding are ±39, ±63 and ±63 respectively.

In this example, the transformer tap changer position indication is wired as a mA signal from the corresponding measuring transducer. The position indication is connected to input 1 (`AI_VAL1`) of the (RTD) module. The tap changer operating range from the minimum to maximum turns of the tap and a corresponding mA signal

for the tap position are set in the RTD module. Since the values of the RTD module outputs are floating point numbers, the float to integer (T_R_TO_I8) conversion is needed before the tap position information can be fed to TPOSYLTC. When there is a wired connection to the TAP_POS connector, the validated tap changer position is presented in the TAP_POS output that is connected to other functions, for example, OLATCC1. When there is no wired connection to the TAP_POS connector, the binary inputs are expected to be used for the tap changer position information.

Earthing switch control	ESXSWI	I<->O ESC	29GS

9.1.2 Function block

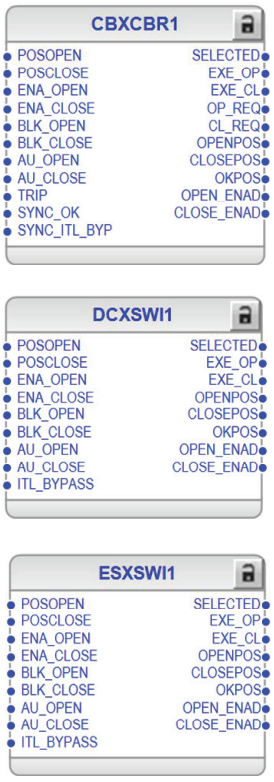

Figure 719: Function block

9.1.3 Functionality

CBXCBR, DCXSWI and ESXSWI are intended for circuit breaker, disconnector and earthing switch control and status information purposes. These functions execute commands and evaluate block conditions and different time supervision conditions. The functions perform an execution command only if all conditions indicate that a switch operation is allowed. If erroneous conditions occur, the functions indicate an appropriate cause value. The functions are designed according to the IEC 61850-7-4 standard with logical nodes CILO, CSWI and XSWI/XCBR.

The circuit breaker, disconnector and earthing switch control functions have an operation counter for closing and opening cycles. The counter value can be read and written remotely from the place of operation or via LHMI.

9.1.4 Operation principle

Status indication and validity check

The object state is defined by two digital inputs, POSOPEN and POSCLOSE, which are also available as outputs OPENPOS and CLOSEPOS together with the OKPOS according to Table 1299. The debouncing and short disturbances in an input are eliminated by filtering. The binary input filtering time can be adjusted separately for each digital input used by the function block. The validity of the digital inputs that indicate the object state is used as additional information in indications and event logging. The reporting of faulty or intermediate position of the apparatus occurs after the *Event delay* setting, assuming that the circuit breaker is still in a corresponding state.

Table 1299: Status indication

Input		Status	Output		
POSOPEN	**POSCLOSE**	**POSITION (Monitored data)**	**OKPOS**	**OPENPOS**	**CLOSEPOS**
1=True	0=False	1=Open	1=True	1=True	0=False
0=False	1=True	2=Closed	1=True	0=False	1=True
1=True	1=True	3=Faulty/Bad (11)	0=False	0=False	0=False
0=False	0=False	0=Intermediate (00)	0=False	0=False	0=False

Enabling and blocking

CBXCBR, DCXSWI and ESXSWI have an enabling and blocking functionality for interlocking and synchrocheck purposes.

Circuit breaker control CBXCBR

Normally, the CB closing is enabled (that is, CLOSE_ENAD signal is TRUE) by activating both ENA_CLOSE and SYNC_OK inputs. Typically, the ENA_CLOSE

comes from the interlocking, and SYNC_OK comes from the synchronism and energizing check. The input SYNC_ITL_BYP can be used for bypassing this control. The SYNC_ITL_BYP input can be used to activate CLOSE_ENAD discarding the ENA_CLOSE and SYNC_OK input states. However, the BLK_CLOSE input always blocks the CLOSE_ENAD output.

The CB opening (OPEN_ENAD) logic is the same as CB closing logic, except that SYNC_OK is used only in closing. The SYNC_ITL_BYP input is used in both CLOSE_ENAD and OPEN_ENAD logics.

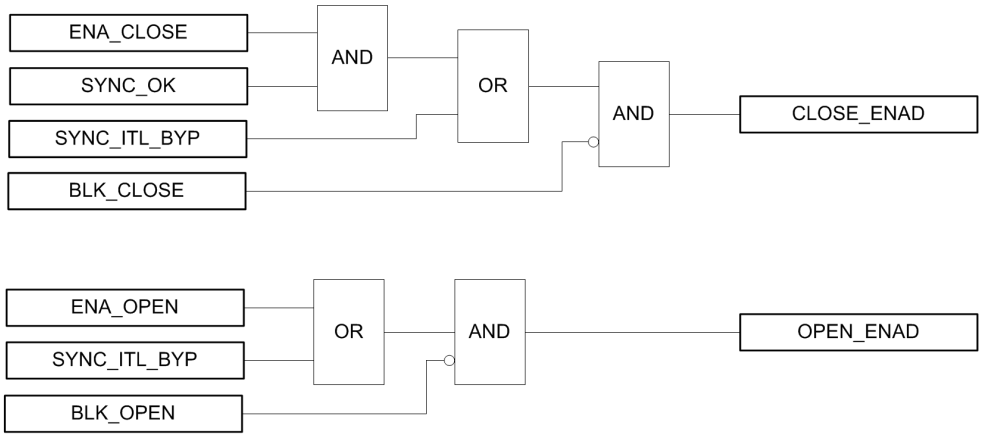

Figure 720: Enabling and blocking logic for CLOSE_ENAD and OPEN_ENAD signals

Disconnector control DCXSWI and earthing switch control ESXSWI

Normally, the switch closing is enabled (that is, the CLOSE_ENAD signal is TRUE) by activating the ENA_CLOSE input. The input ITL_BYPASS can be used for bypassing this control. The ITL_BYPASS input can be used to activate the CLOSE_ENAD discarding the ENA_CLOSE input state. However, the BLK_CLOSE input always blocks the CLOSE_ENAD output.

The CB opening (OPEN_ENAD) logic is identical to CB closing logic. The ITL_BYPASS input is used in both CLOSE_ENAD and OPEN_ENAD logics.

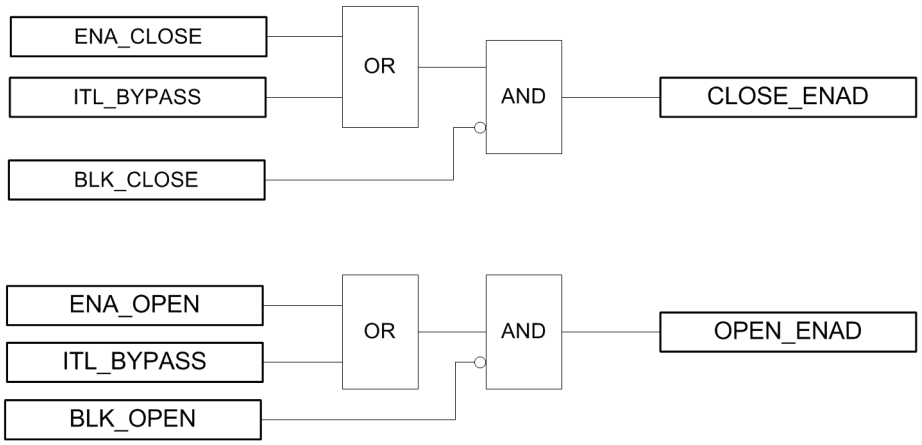

Figure 721: Enabling and blocking logic for CLOSE_ENAD and OPEN_ENAD signals

Opening and closing operations

The opening and closing operations are available via communication, binary inputs or LHMI commands. As a prerequisite for control commands, there are enabling and blocking functionalities for both opening and closing commands (CLOSE_ENAD and OPEN_ENAD signals). If the control command is executed against the blocking or if the enabling of the corresponding command is not valid, CBXCBR, DCXSWI and ESXSWI generate an error message.

When close command is given from communication, via LHMI or activating the AU_CLOSE input, it is carried out (the EXE_CL output) only if CLOSE_ENAD is TRUE.

If the SECRSYN function is used in “Command” mode, the CL_REQ output can be used in CBXCBR. Initially, the SYNC_OK input is FALSE. When the close command given, it activates the CL_REQ output, which should be routed to SECRSYN. The close command is then processed only after SYNC_OK is received from SECRSYN.

When using SECRSYN in the “Command” mode, the CBXCBR setting *Operation timeout* should be set longer than SECRSYN setting *Maximum Syn time*.

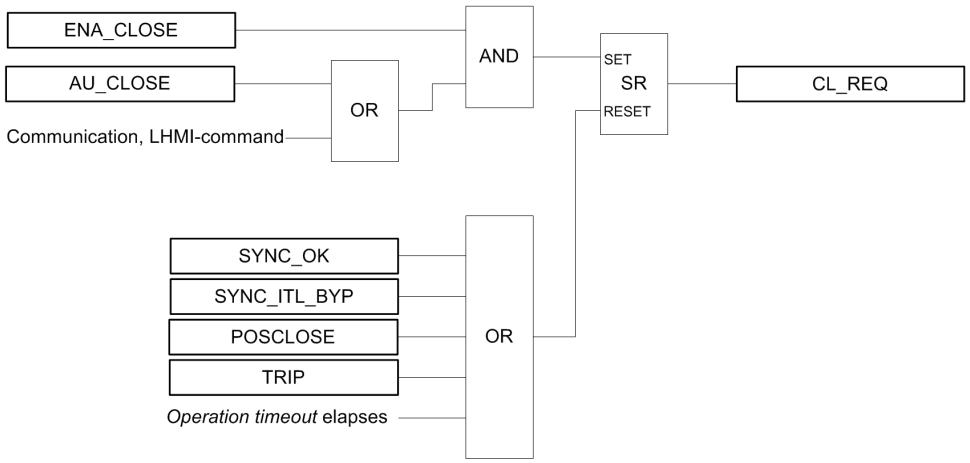

Figure 722: Condition for enabling the close request (CL_REQ) for CBXCBR

When the open command is given from communication, via LHMI or activating the AU_OPEN input, it is processed only if OPEN_ENAD is TRUE. OP_REQ output is also available.

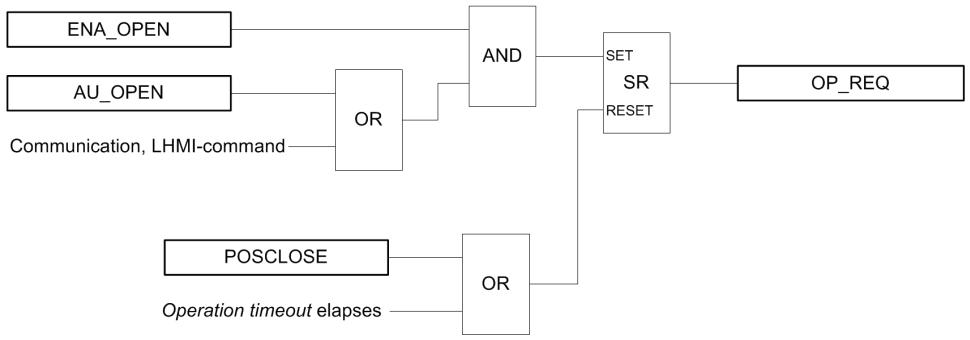

Figure 723: Condition for enabling the open request (OP_REQ) for CBXCBR

OPEN and CLOSE outputs

The EXE_OP output is activated when the open command is given (AU_OPEN, via communication or from LHMI) and OPEN_ENAD signal is TRUE. In addition, the protection trip commands can be routed through the CBXCBR function by using the TRIP input. When the TRIP input is TRUE, the EXE_OP output is activated immediately and bypassing all enabling or blocking conditions.

The EXE_CL output is activated when the close command is given (AU_CLOSE, via communication or from LHMI) and CLOSE_ENAD signal is TRUE. When the TRIP input is “TRUE”, CB closing is not allowed.

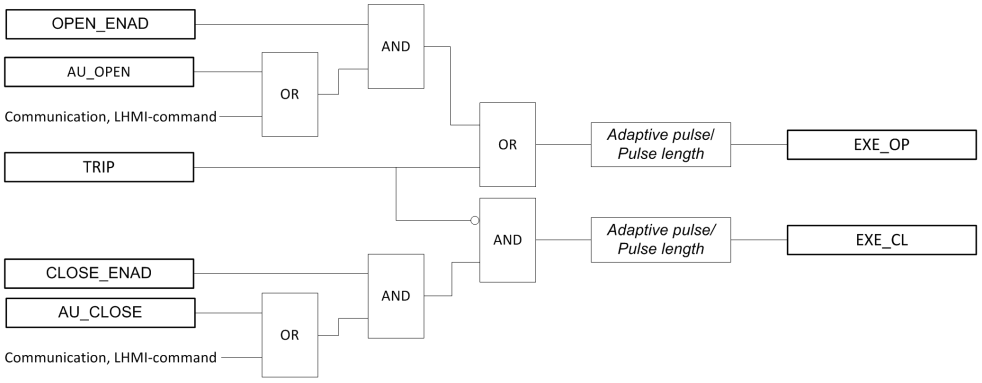

Figure 724: OPEN and CLOSE outputs logic for CBXCBR

Opening and closing pulse widths

The pulse width type can be defined with the *Adaptive pulse* setting. The function provides two modes to characterize the opening and closing pulse widths. When the *Adaptive pulse* is set to “TRUE”, it causes a variable pulse width, which means that the output pulse is deactivated when the object state shows that the apparatus has entered the correct state. If apparatus fails to enter the correct state, the output pulse is deactivated after the set *Operation timeout* setting, and an error message is displayed. When the *Adaptive pulse* is set to “FALSE”, the functions always use the maximum pulse width, defined by the user-configurable *Pulse length* setting. The *Pulse length* setting is the same for both the opening and closing commands. When the apparatus already is in the right position, the maximum pulse length is given.

The *Pulse length* setting does not affect the length of the trip pulse.

Control methods

The command execution mode can be set with the *Control model* setting. The alternatives for command execution are direct control and secured object control, which can be used to secure controlling.

The secured object control SBO is an important feature of the communication protocols that support horizontal communication, because the command reservation and interlocking signals can be transferred with a bus. All secured control operations require two-step commands: a selection step and an execution step. The secured object control is responsible for the several tasks.

- Command authority: ensures that the command source is authorized to operate the object
- Mutual exclusion: ensures that only one command source at a time can control the object
- Interlocking: allows only safe commands
- Execution: supervises the command execution
- Command canceling: cancels the controlling of a selected object.

In direct operation, a single message is used to initiate the control action of a physical device. The direct operation method uses less communication network capacity and bandwidth than the SBO method, because the procedure needs fewer messages for accurate operation.

The “status-only” mode means that control is not possible (non-controllable) via communication or from LHMI. However, it is possible to control a disconnector (DCXSWI) from AU_OPEN and AU_CLOSE inputs.

AU_OPEN and AU_CLOSE control the object directly regardless of the set *Control model*. These inputs can be used when control is wanted to be implemented purely based on ACT logic and no additional exception handling is needed. However, in case of simultaneous open and close control, the open control is always prioritized.

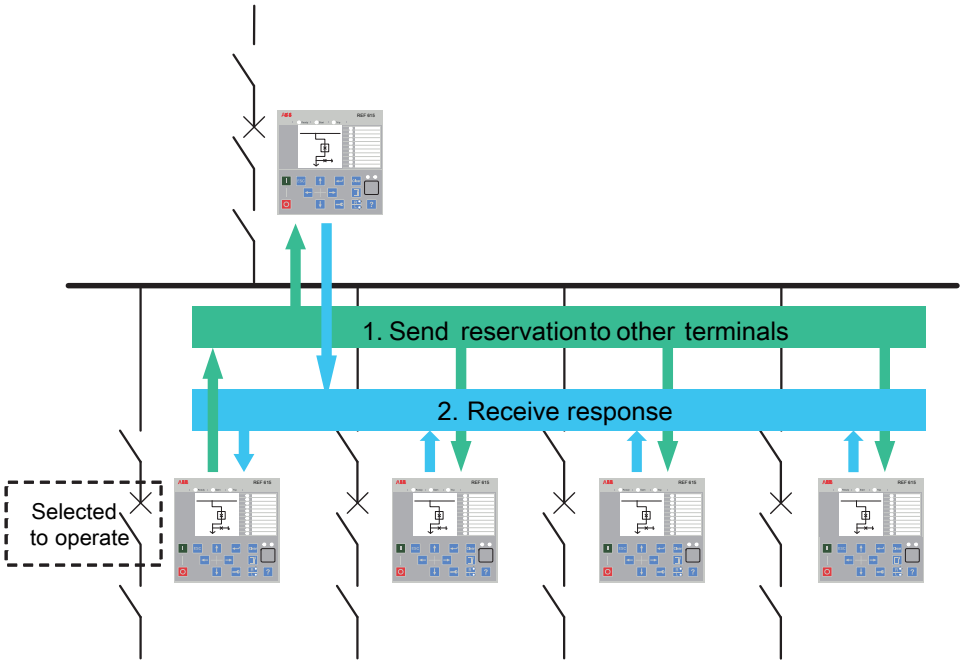

Figure 725: Control procedure in the SBO method

Local/Remote operations

The local/remote selection affects the CBXCBR, DCXSWI and ESXSWI.

- Local: the opening and closing via communication is disabled.
- Remote: the opening and closing via LHMI is disabled.
- AU_OPEN and AU_CLOSE inputs function regardless of the local/remote selection.

9.1.5 Application

In the field of distribution and sub-transmission automation, reliable control and status indication of primary switching components both locally and remotely is in a significant role. They are needed especially in modern remotely controlled substations.

Control and status indication facilities are implemented in the same package with CBXCBR, DCXSWI and ESXSWI. When primary components are controlled in the energizing phase, for example, the correct execution sequence of the control commands must be ensured. This can be achieved, for example, with interlocking based on the status indication of the related primary components. The interlocking on the substation level can be applied using the IEC61850 GOOSE messages between feeders.

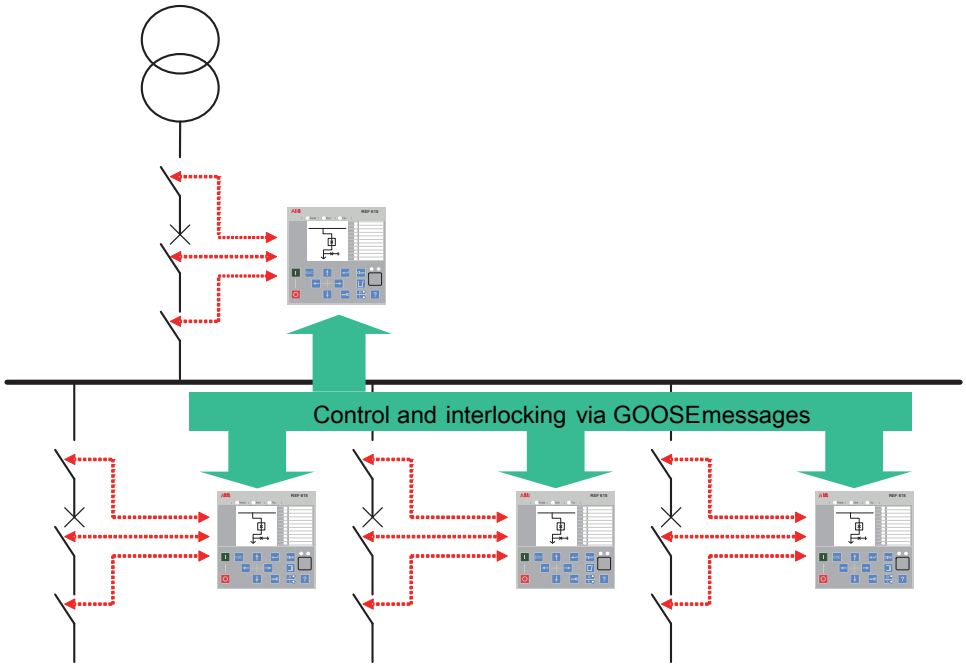

Figure 726: Status indication-based interlocking via the GOOSE messaging

9.1.6 Signals

Table 1300: CBXCBR Input signals

Name	Type	Default	Description
POSOPEN	BOOLEAN	0=False	Signal for open position of apparatus from I/O
POSCLOSE	BOOLEAN	0=False	Signal for close position of apparatus from I/O

9.2 Three-state disconnector control P3SXSWI

9.2.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-state disconnector control	P3SXSWI	I<->O P3S	29DS/GS

9.2.2 Function block

Figure 727: Function block

9.2.3 Functionality

The three-state disconnector control function P3SXSWI is used to control a three-state switch (disconnector closed, both open, earthing switch closed) and to provide status information on the MV air-insulated switchgear (AIS) and gas-insulated switchgear (GIS). P3SXSWI executes commands to RIO600 SCM or directly drives the switchgear motor by direct control of the protection relay's H-bridge (if available). The function evaluates blocking conditions and different supervision conditions and it performs an execution command only if all conditions are fulfilled. If erroneous conditions occur, the function indicates an appropriate cause value. The function is designed according to the IEC 61850-7-4 standard including logical nodes CILO, CSWI and XSWI.

P3SXSWI has operation counters for disconnector operation and earthing switch operation. The counter values can be read and written remotely from the place of operation or via LHMI.

The function can also be configured to handle only two-position switches (earthing switch or disconnector).

9.2.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The switch type is determined depending on the connected inputs in Application Configuration.

- If inputs `DCPOSOPEN`, `DCPOSCLOSE`, `ESPOSOPEN` and `ESPOSCLOSE` are connected, the switch type is three-position switch.
- When only inputs `DCPOSOPEN` and `DCPOSCLOSE` are connected, the switch type is disconnector.
- When only inputs `ESPOSOPEN` and `ESPOSCLOSE` are connected, the switch type is earthing switch.

Any other connection leads to a configuration error.

The motor control application of the three-position switch can be selected with parameter setting *Control mode*. If "With RIO600 SCM" is selected, the motor control is handled externally by the RIO600 SCM module; the protection relay only supervises the switch position and interlocking but provides commands to RIO600. If "Direct control" is selected, the motor control is handled by the protection relay's H-bridge and no external RIO600 SCM device is needed.

Position indication and validity check

Depending on the switch type connection, a three-position switch, disconnector or earthing switch can be configured.

Be aware of the physical switch type and corresponding connections in Application Configuration, both for P3SXSWI and in RIO600 SCM, if used. A wrong connection according to the physical switch type can cause misleading position indication.

In certain three-position switches an additional reed contact is available to indicate safe earthing. The contact is TRUE only when the earthing switch is in closed position. The reed contact is given a short time window to confirm closed earthing switch position, in case of vibrations. If the earthing switch has closed but the reed contact does not close within the time window, faulty position is reported.

Table 1315: Reed contact detection

Control mode	Reed contact detection
Direct control	The availability of the reed contact needs to be set through the *Reed contact* setting by setting it as "Available". The reed contact signal is connected at input REED.
With RIO600 SCM	Reed detection is handled externally by the module. The input ESPOSCLOSE is not indicated TRUE by RIO600 if reed contact closing is not detected. Therefore, unsecure earthing is reported to input REED_ERR so that P3SXSWI can indicate faulty position in this control mode.

The state of the switch is indicated at outputs DCCLOSE_POS, DCOPEN_POS, ESCLOSE_POS and ESOPEN_POS together with the OKPOS information.

Debouncing and short disturbances in an input are eliminated by filtering. The binary input filtering timer can be adjusted separately for each digital input used by the function block. The reporting of faulty or intermediate position of the apparatus occurs after the *Event delay* setting.

Table 1316: Status indication for a three-position switch with auxiliary contacts in direct control mode

Status	Inputs					Outputs				
POSITION	DCPOSCLOSE	DCPOSOPEN	ESPOSCLOSE	ESPOSOPEN	REED	DCCLOSE_POS	DCOPEN_POS	ESCLOSE_POS	ESOPEN_POS	OKPOS
Disconnector closed	1	0	0	1	x	1	0	0	1	1
Disconnector intermediate	0	0	0	1	x	0	0	0	1	0
Both open	0	1	0	1	x	0	1	0	1	1
Earthing switch intermediate	0	1	0	0	x	0	1	0	0	0
Earthing switch closed	0	1	1	0	1[1)]	0	1	1	0	1
Faulty	0	1	1	0	0[2)]	0	1	0	0	0
Faulty	0	1	1	1	x	0	1	0	0	0
Faulty	1	1	0	1	x	0	0	0	1	0
Faulty	1	x	1	x	x	0	0	0	0	0
Faulty	x	0	x	0	x	0	0	0	0	0
x = no difference										

1) REED input has been detected as closed within time-out and earthing switch is indicated as closed.
2) REED input has not been detected as closed within time-out and faulty position is indicated.

The REED input is only supervised during a short time window when earthing switch has closed and if *Reed contact* setting is set as "Available" in direct control mode.

When a two-position switch type is used, the opponent switch outputs are disabled. For example, if the switch type is disconnector, the status of the two-position switch is based only on the connected inputs DCPOSOPEN and DCPOSCLOSE. Furthermore, the outputs ESOPEN_POS and ESCLOSE_POS are disabled.

Common three-position status is indicated at variable POSITION, regardless of the switch type. For example, if only a disconnector is available, and the disconnector is in open state, the open indication equals “both open”.

Table 1317: Position indication values based on switch type

Status	Switch type		
POSITION	Three-position switch	Disconnector	Earthing switch
Earthing switch closed	Earthing switch closed and disconnector open	N/A	Earthing switch closed
Earthing switch intermediate	Earthing switch intermediate and disconnector open	N/A	Earthing switch intermediate
Both open	Earthing switch open and disconnector open	Disconnector open	Earthing switch open
Disconnector intermediate	Earthing switch open and disconnector intermediate	Disconnector intermediate	N/A
Disconnector closed	Earthing switch open and disconnector closed	Disconnector closed	N/A
Faulty	Earthing switch faulty or disconnector faulty (or incorrect combination)	Faulty	Faulty

When controlling P3SXSWI with RIO600 SCM, the switch's position information should be made available to the function in the protection relay via GOOSE or binary inputs from RIO600 to reflect correct position and status information.

Control of a three-position switch

There are three possible end positions in a three-position switch: earthing switch closed, both open, and disconnector closed. Additionally, there are two intermediate states: earthing switch intermediate and disconnector intermediate. The function follows the command order in cyclic order as shown in Figure 728. For example, at disconnector close state only disconnector open command can be executed. Similarly, when the state is both open, both disconnector close and earth close commands can be executed. When the switch indicates earthing switch or disconnector intermediate position (for example, the motor has stopped due to timeout), a specified open command is allowed only.

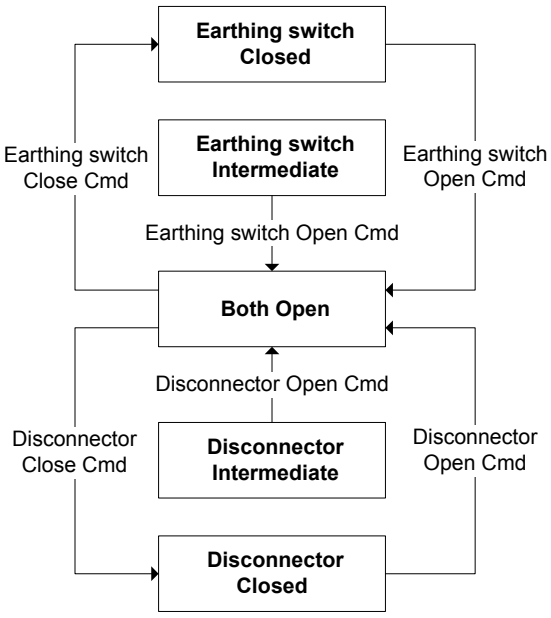

Figure 728: Control of a three-position switch by commands

Blocking

The function has a blocking functionality to prevent human errors that can cause injuries to the operator and damages to the system components.

The control operations are allowed if the interlocking signals for the operations are TRUE. These signals are ENA_DCOPEN, ENA_DCCLOSE, ENA_ESOPEN and ENA_ESCLOSE.

In addition, the function provides a general interlocking bypass input ITL_BYPASS. When ITL_BYPASS is TRUE, the apparatus can be controlled by discarding the ENA_DCOPEN, ENA_DCCLOSE, ENA_ESOPEN and ENA_ESCLOSE input states.

However, the BLK_DCOPEN, BLK_DCCLOSE, BLK_ESOPEN and BLK_ESCLOSE input signals are not bypassed with the interlocking bypass functionality since they always have higher priority.

In Table 1318 the interlocking condition is switch-specific by row.

Table 1318: Interlocking conditions for enabling the closing/opening command

Inputs			Outputs
ITL_BYPASS	ENA_DCCLOSE	BLK_DCCLOSE	DCCLOSE_ENAD
	ENA_DCOPEN	BLK_DCOPEN	DCOPEN_ENAD
	ENA_ESCLOSE	BLK_ESCLOSE	ESCLOSE_ENAD
	ENA_ESOPEN	BLK_ESOPEN	ESOPEN_ENAD
0 = False	0 = False	0 = False	0 = False
0 = False	0 = False	1 = True	0 = False
0 = False	1 = True	0 = False	1 = True

Table continues on next page

Inputs			Outputs
ITL_BYPASS	ENA_DCCLOSE	BLK_DCCLOSE	DCCLOSE_ENAD
	ENA_DCOPEN	BLK_DCOPEN	DCOPEN_ENAD
	ENA_ESCLOSE	BLK_ESCLOSE	ESCLOSE_ENAD
	ENA_ESOPEN	BLK_ESOPEN	ESOPEN_ENAD
0 = False	1 = True	1 = True	0 = False
1 = True	0 = False	0 = False	1 = True
1 = True	0 = False	1 = True	0 = False
1 = True	1 = True	0 = False	1 = True
1 = True	1 = True	1 = True	0 = False

However, the enabled outputs also depend on the actual position of the switch, according to Figure 728 and if any motor operation is ongoing. Internal blocking based on switch position or motor in progress always overrides the enabled output regardless of the status of enable, block and interlock bypass inputs.

For two-position switches, the enabling outputs of the opposite switch type are disabled regardless of the input status. For example, if the switch type is earthing switch, DCCLOSE_ENAD and DCOPEN_ENAD are forced to FALSE.

Operation of the three-position switch is permitted only when the circuit breaker is in open position. The closed circuit breaker information can be connected to the BLK inputs in Application Configuration.

Various operations

The required operation command is available via communication, binary inputs or LHMI. As a prerequisite for control commands, there are enabling and blocking functionalities for all the operations. If the control command is executed against the blocking or if the enabling of the corresponding command is not valid, the function generates an error message. The command operations are requested through binary inputs AU_DCOPEN, AU_DCCLOSE, AU_ESOPEN and AU_ESCLOSE. The requested operation is possible provided the apparatus is not blocked by the interlocking logic and no other previous request is active.

When the function block is selected for performing any of the operations locally from the HMI, the output SELECTED is activated. Once the function is selected, the command for execution of operation should be issued before *Select timeout* time lapses.

The function contains two operation counters: disconnector counter *Operation counter DC* and earthing switch counter *Operation counter ES*. The first one indicates each disconnector opening state and the latter one indicates each earthing switch opening state. The counter values are resettable and writable and stored in a nonvolatile memory.

Output INPRO indicates any active motor operation, including braking and pause operation.

9.2.4.1 Control of three-position switch using RIO600 smart control module

When using RIO600 smart control module (SCM) for controlling a three-position switch, the setting *Control mode* should be set as "With RIO600 SCM".

SCM is available with RIO600 to be able to drive a three-position switch. The motor of the three-position switch is directly driven by the RIO600 SCM. RIO600 sends the status information to the protection relay by GOOSE communication, and the switch position is indicated on the HMI on the protection relay. When a three-position switch operation is requested and enabled by the protection relay, it generates commands via EXE_DCOPEN, EXE_DCCLOSE, EXE_ESOPEN or EXE_ESCLOSE, which are transmitted to RIO600 over GOOSE communication. Though the command handling is pre-checked by P3SXSWI, RIO600 SCM further checks for command priority and if the requested command is allowed. The commands are always checked on rising edge by the RIO600 SCM.

In RIO600 SCM control mode, the operation timeouts in P3SXSWI are not available due to external motor handling by the SCM module. Status feedback from the module is returned to the protection relay via GOOSE. The inputs for P3SXSWI shown in Figure 729 must be connected by GOOSE status signals from SCM. Input REED remains unconnected in this control mode.

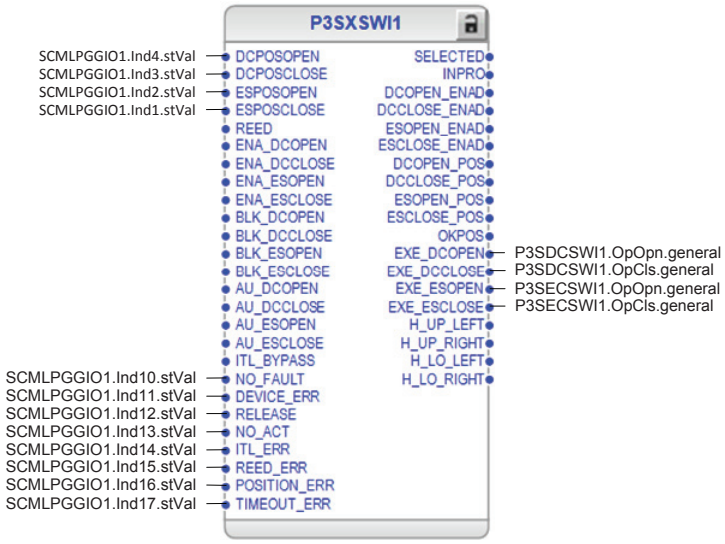

Figure 729: Connections in P3SXSWI when using RIO600 SCM for a three-position switch

See the RIO600 and SCM manual when using RIO600 SCM for three-position switch motor control. All the signals from RIO600 must be connected to the P3SXSWI function block as in Figure 3.

9.2.4.2 Control of three-position switch using H-bridge with static outputs of the protection relay

When using the protection relay for direct motor control of the three-position switch, the setting *Control mode* must be set as "Direct control".

If the protection relay is equipped with static outputs, the three-position switchgear motor can be controlled with an H-bridge. The function has four outputs for motor control.

- H-bridge upper-left: `H_UP_LEFT`
- H-bridge upper-right: `H_UP_RIGHT`
- H-bridge lower-left: `H_LO_LEFT`
- H-bridge lower-right: `H_LO_RIGHT`

These outputs must be connected to the static outputs of the protection relay. With the H-bridge functionality it is possible to drive the motor to left or to right, and brake the motor. The auxiliary voltage (U_{aux}) connected to the H-bridge has to match the voltage of the motor.

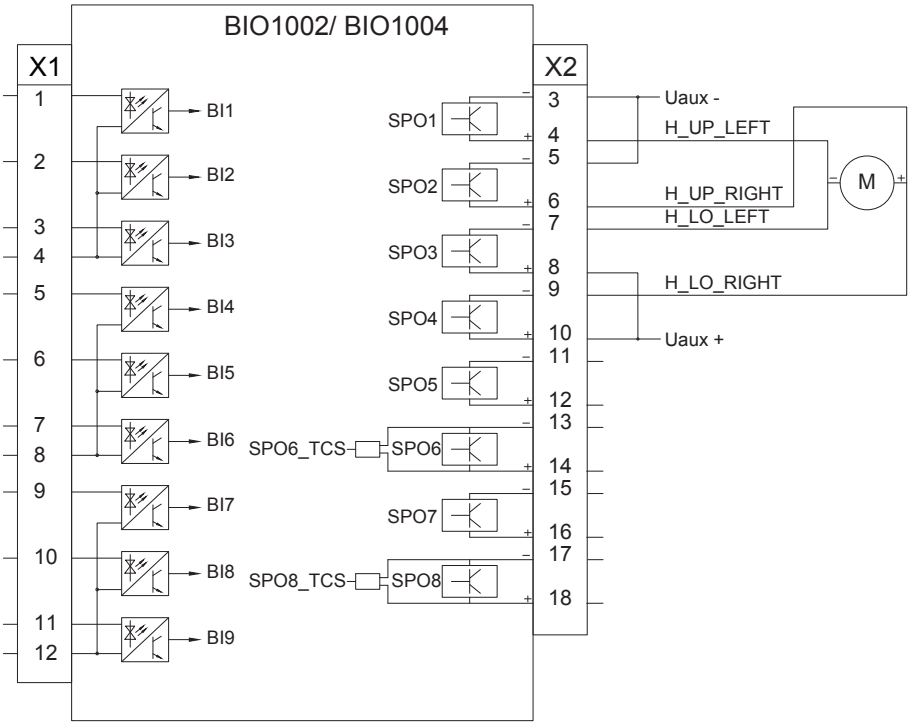

Figure 730: H-bridge motor control for a protection relay equipped with BIO1002 module

Table 1319: H-bridge motor operation depending on active outputs

Motor direction	Static outputs			
	H_UP_LEFT	H_UP_RIGHT	H_LO_LEFT	H_LO_RIGHT
Motor right	1	0	0	1
Motor left	0	1	1	0
Motor brake	1	1	0	0
Motor brake	0	0	1	1
Motor free	0	0	0	0

Be aware of the motor polarity so that a correct connection between the motor and the H-bridge is established. The H-bridge needs to be properly connected to the static outputs of the protection relay in Application Configuration. Wrong connections affect the motor functionality and may cause personal injury or damage to the equipment.

Motor logic and parameters

To prevent damage to the motor, the motor is protected by several settable timeouts. With setting parameter *Motor start timeout*, the maximum start time for the motor to recognize a position indication change is defined. If a position indication change is not recognized during this time, the motor is stopped. If *Motor start timeout* is set to zero, the motor start timeout is disabled.

With timeout *Operation timeout DC*, the maximum time for the disconnector to go from one state to another is defined.

With timeout *Operation timeout ES*, the maximum time for the earthing switch to go from one state to another is defined. If a state change is not fulfilled within this time, the motor is stopped.

If an unexpected position is detected based on the requested command, in other words the motor is running in the wrong direction, or if faulty position of the switch is detected, the motor is immediately stopped. Additionally, an activated block input that corresponds to the active command stops the running motor immediately.

If any of the cases above occur, the specific event is displayed on the HMI or reported via communication.

When the motor operates and reaches the final destination, the motor brakes if the *Motor braking* setting is selected as "True". The braking time of the motor is selectable with the *Motor brake time* parameter. After the motor has braked and stopped, the motor is in a free state, meaning that the switch is mechanically operable by hand-crank. A successful operation is also displayed on the HMI or reported via communication.

After each operation the motor is paused for one second before any new control command can pass through.

9.2.4.3 Control methods

The command execution mode can be set with the *Control model* setting. The alternatives for command execution are direct control and secured object control, which can be used to secure controlling.

The secured object control SBO is an important feature of the communication protocols that support horizontal communication, because the command reservation and interlocking signals can be transferred with a bus. All secured control operations require two-step commands: a selection step and an execution step. The secured object control is responsible for several tasks.

- Command authority: ensures that the command source is authorized to operate the object
- Mutual exclusion: ensures that only one command source at a time can control the object
- Interlocking: allows only safe commands
- Execution: supervises the command execution
- Command canceling: cancels the controlling of a selected object

In direct operation, a single message is used to initiate the control action of a physical device. The direct operation method uses less communication network capacity and bandwidth than the SBO method, because the procedure needs fewer messages for accurate operation.

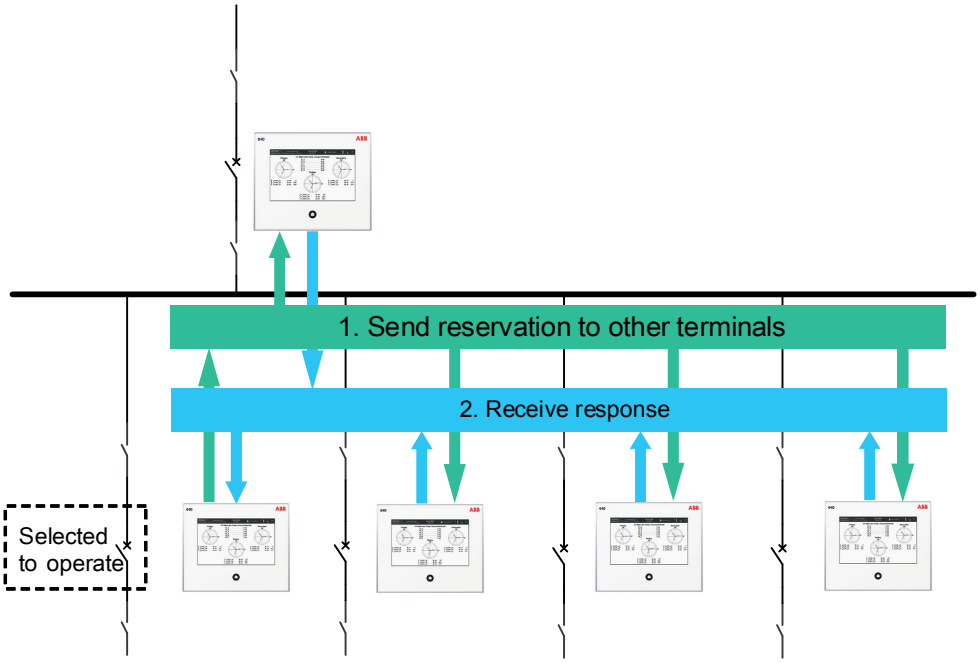

Figure 731: Control procedure in the SBO method

9.2.5 Application

In the field of distribution and sub-transmission, automatic, reliable control and status indication of primary switching components, both locally and remotely, are of significant importance. They are needed especially in modern remotely controlled substations.

P3SXSWI is designed to be used for the control of two- (open, closed) and three-state (earthing switch closed, disconnector closed and both open) switches. The function also handles user-defined interlocking logics and provides commands.

Control and status indication facilities are implemented in the same package with P3SXSWI. When primary components are controlled in the energizing phase, for example, the correct execution sequence of the control command must be ensured. This can be achieved, for example, with interlocking based on the status indication of the related primary components.

The interlocking on the substation level can be applied using the IEC 61850 GOOSE message between feeders.

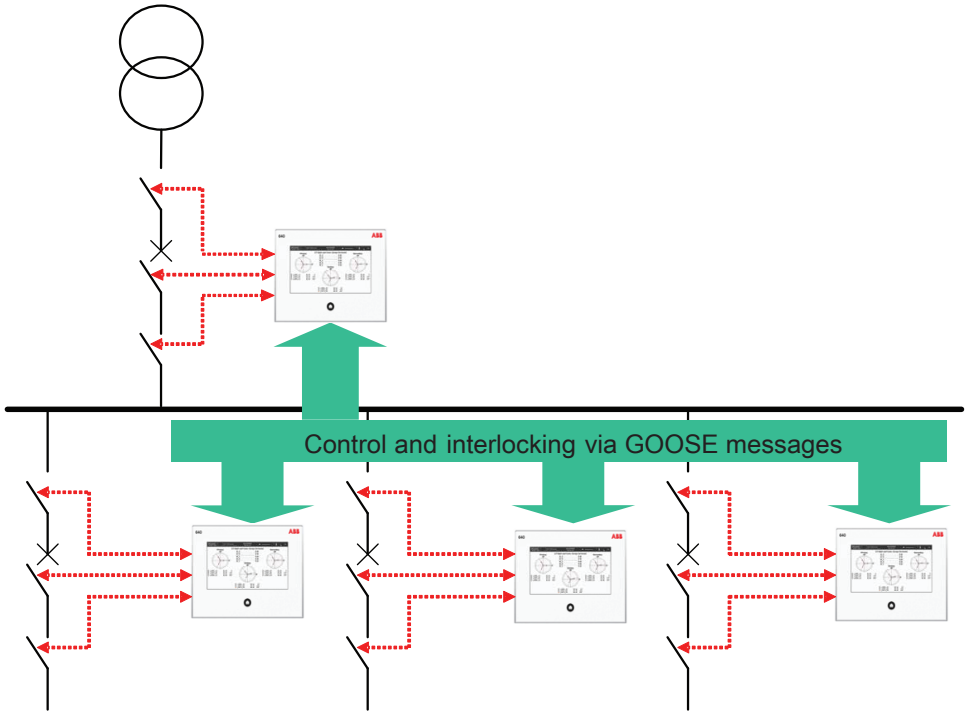

Figure 732: Status indication-based interlocking via the GOOSE messaging

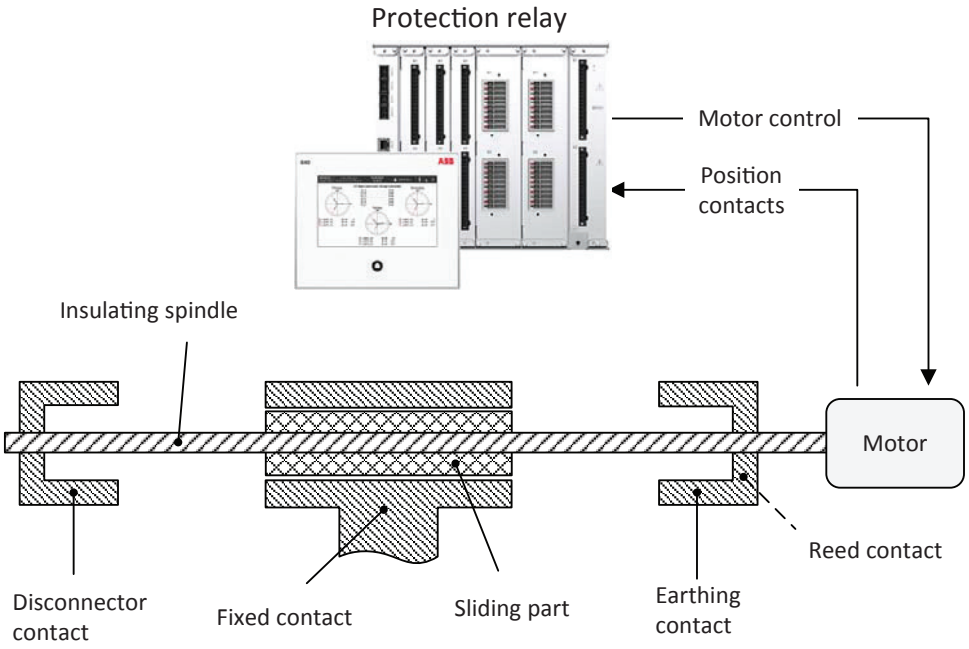

Figure 733: Connection diagram for direct control of a three-position switchgear motor

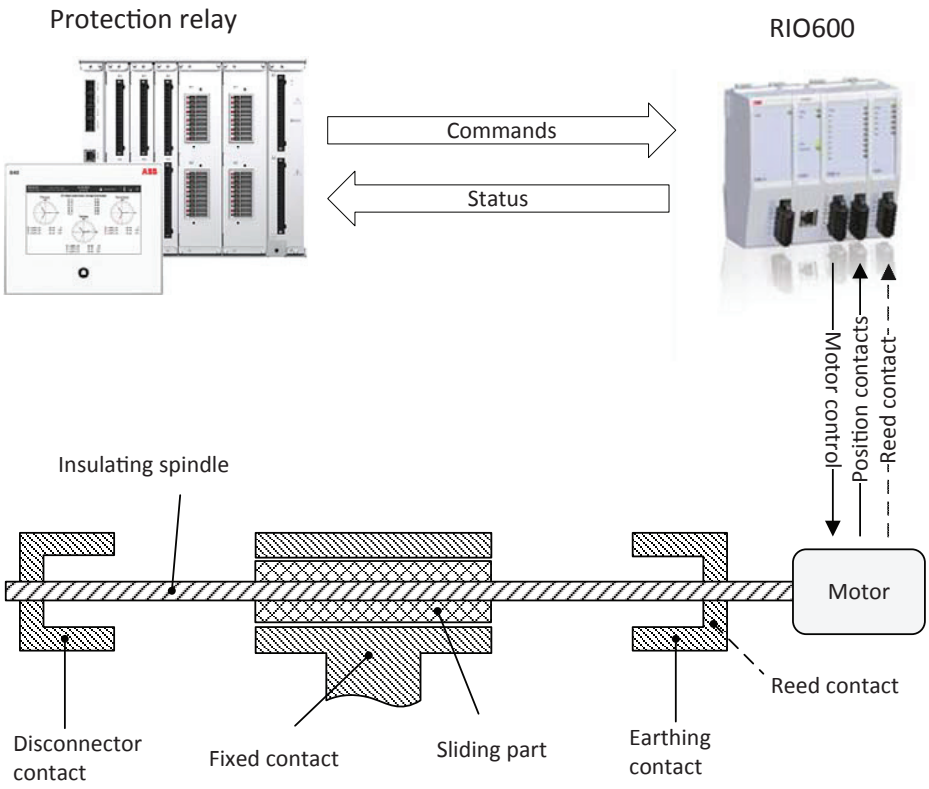

Figure 734: Connection diagram for RIO600 control of a three-position switchgear motor

When the RIO600 SCM module is selected as control mode, outputs EXE_DCCLOSE, EXE_DCOPEN, EXE_ESCLOSE and EXE_ESOPEN are connected in Application Configuration. When direct motor control is selected as control mode, static outputs H_UP_LEFT, H_UP_RIGHT, H_LO_LEFT and H_LO_RIGHT are connected in Application Configuration.

9.2.6 Signals

Table 1320: P3SXSWI Input signals

Name	Type	Default	Description
DCPOSOPEN	BOOLEAN	0=False	Signal for open position of disconnector
DCPOSCLOSE	BOOLEAN	0=False	Signal for close position of disconnector
ESPOSOPEN	BOOLEAN	0=False	Signal for open position of earthing switch
ESPOSCLOSE	BOOLEAN	0=False	Signal for close position of earthing switch
REED	BOOLEAN	0=False	Signal for close position of reed contact
Table continues on next page			

Name	Type	Default	Description
ENA_DCOPEN	BOOLEAN	1=True	Enables opening command for disconnector

9.3 Three-state disconnector position indication P3SSXSWI

9.3.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Three-state disconnector position indication	P3SSXSWI	I<->O P3SS	29DS/GS

9.3.2 Function block

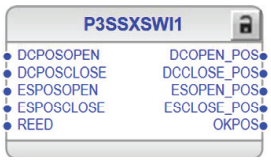

Figure 735: Function block

9.3.3 Functionality

The three-state disconnector position indication function P3SSXSWI provides status information on three-state switches: MV air-insulated switchgear (AIS) and gas-insulated switchgear (GIS). The function is designed according to the IEC 61850-7-4 standard including logical nodes CSWI and XSWI.

9.3.4 Operation principle

Position indication

In certain three-position switches an additional reed contact is available to indicate safe earthing. The contact is TRUE only when the earthing switch is in closed position. The reed contact is given a short time window to confirm closed earthing switch position, in case of vibrations. If the earthing switch has closed but the reed contact does not close within the time window, faulty position is reported. The availability of the reed contact needs to be set through *Reed contact* setting by setting it as "Available". The reed contact signal is connected at input REED in this control mode.

The state of the switch is indicated at outputs DCCLOSE_POS, DCOPEN_POS, ESCLOSE_POS and ESOPEN_POS together with the OKPOS information.

Debouncing and short disturbances in an input are eliminated by filtering. The binary input filtering timer can be adjusted separately for each digital input used by the function block. The reporting of faulty or intermediate position of the apparatus occurs after the *Event delay* setting. A common three-position status is indicated at variable POSITION.

Table 1325: Status indication for a three-position switch based on auxiliary contacts

Status	Inputs					Outputs				
POSITION	DCPOSCLOSE	DCPOSOPEN	ESPOSCLOSE	ESPOSOPEN	REED	DCCLOSE_POS	DCOPEN_POS	ESCLOSE_POS	ESOPEN_POS	OKPOS
Disconnector closed	1	0	0	1	x	1	0	0	1	1
Disconnector intermediate	0	0	0	1	x	0	0	0	1	0
Both open	0	1	0	1	x	0	1	0	1	1
Earthing switch intermediate	0	1	0	0	x	0	1	0	0	0

Table continues on next page

Status	Inputs					Outputs				
POSITION	DCPOSCLOSE	DCPOSOPEN	ESPOSCLOSE	ESPOSOPEN	REED	DCCLOSE_POS	DCOPEN_POS	ESCLOSE_POS	ESOPEN_POS	OKPOS
Earthing switch closed	0	1	1	0	1[1)]	0	1	1	0	1
Faulty	0	1	1	0	0[2)]	0	1	0	0	0
Faulty	0	1	1	1	x	0	1	0	0	0
Faulty	1	1	0	1	x	0	0	0	1	0
Faulty	1	x	1	x	x	0	0	0	0	0
Faulty	x	0	x	0	x	0	0	0	0	0
x = no difference										

1) REED input has been detected as closed within timeout and earthing switch is indicated as closed.
2) REED input has not been detected as closed within timeout and faulty position is indicated.

The REED input is only supervised during a short time window when earthing switch has closed and if *Reed contact* setting is set as "Available".

9.3.5 Application

In the field of distribution and sub-transmission automatic, reliable control and status indication of primary switching components both locally and remotely is of significant importance. They are needed especially in modern remotely controlled substations.

P3SSXSWI is designed to be used for status indication of a three-state (earthing switch closed, disconnector closed and both open) switch.

Earthing switch position indication	ESSXSWI	I<->O ES	29GS

9.4.2 Function block

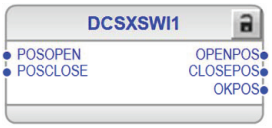

Figure 736: Function block

Figure 737: Function block

9.4.3 Functionality

The functions DCSXSWI and ESSXSWI indicate remotely and locally the open, close and undefined states of the disconnector and earthing switch. The functionality of both is identical, but each one is allocated for a specific purpose visible in the function names. For example, the status indication of disconnectors or circuit breaker truck can be monitored with the DCSXSWI function.

The functions are designed according to the IEC 61850-7-4 standard with the logical node XSWI.

9.4.4 Operation principle

Status indication and validity check

The object state is defined by the two digital inputs POSOPEN and POSCLOSE, which are also available as outputs OPENPOS and CLOSEPOS together with the OKPOS according to Table 1331. The debounces and short disturbances in an input are

eliminated by filtering. The binary input filtering time can be adjusted separately for each digital input used by the function block. The validity of digital inputs that indicate the object state is used as additional information in indications and event logging.

Table 1331: Status indication

Input		Status	Output		
POSOPEN	**POSCLOSE**	**POSITION (Monitored data)**	**OKPOS**	**OPENPOS**	**CLOSEPOS**
1=True	0=False	1=Open	1=True	1=True	0=False
0=False	1=True	2=Closed	1=True	0=False	1=True
1=True	1=True	3=Faulty/Bad (11)	0=False	0=False	0=False
0=False	0=False	0=Intermediate (00)	0=False	0=False	0=False

9.4.5 Application

In the field of distribution and sub-transmission automation, the reliable control and status indication of primary switching components both locally and remotely is in a significant role. These features are needed especially in modern remote controlled substations. The application area of DCSXSWI and ESSXSWI functions covers remote and local status indication of, for example, disconnectors, air-break switches and earthing switches, which represent the lowest level of power switching devices without short-circuit breaking capability.

9.5 Synchronism and energizing check SECRSYN

9.5.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Synchronism and energizing check	SECRSYN	SYNC	25

9.5.2 Function block

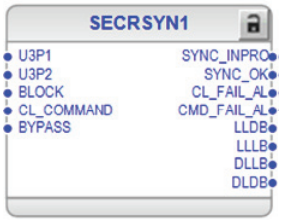

Figure 738: Function block

9.5.3 Functionality

The synchronism and energizing check function SECRSYN checks the condition across the circuit breaker from separate power system parts and gives the permission to close the circuit breaker. SECRSYN includes the functionality of synchrocheck and energizing check.

Asynchronous operation mode is provided for asynchronously running systems. The main purpose of the asynchronous operation mode is to provide a controlled closing of circuit breakers when two asynchronous systems are connected.

The synchrocheck operation mode checks that the voltages on both sides of the circuit breaker are perfectly synchronized. It is used to perform a controlled reconnection of two systems which are divided after islanding and it is also used to perform a controlled reconnection of the system after reclosing.

The energizing check function checks that at least one side is dead to ensure that closing can be done safely.

The function contains a blocking functionality. It is possible to block function outputs and timers.

9.5.4 Analog channel configuration

SECRSYN has two analog group inputs which must be properly configured.

Table 1342: Analog inputs

Input	Description
U3P1	Three-phase voltages (bus side)
U3P2	Three-phase voltages (line side)

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1343: Special conditions

Condition	Description
U3P1 connected to real measurements	The function requires that any two voltage channels from the bus side are connected.
U3P2 connected to real measurements	The function requires that one voltage channel from the line side is connected to channel 1 or any two voltage channels from the line side.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

9.5.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

SECRSYN has two parallel functionalities, the synchro check and energizing check functionality. The operation of SECRSYN can be described using a module diagram. All the modules in the diagram are explained in the next sections.

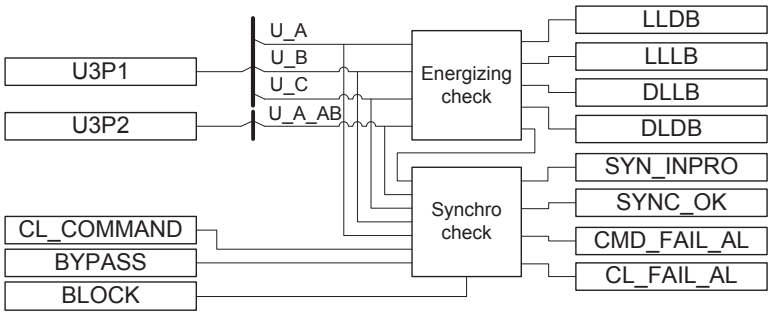

Figure 739: Functional module diagram

If Energizing check is passed, no further conditions need to be fulfilled to permit closing. Otherwise, Synchro check function can operate either with the U_AB or U_A voltages. The selection of used voltages is defined with the *VT connection* setting of the line voltage general parameters.

By default, voltages U_BUS and U_LINE are connected as presented in Figure 748. If necessary, connections can be switched by setting *Voltage source switch* to “True”.

Energizing check

The Energizing check function checks the energizing direction. Energizing is defined as a situation where a dead network part is connected to an energized section of the network. The conditions of the network sections to be controlled by the circuit breaker, that is, which side has to be live and which side dead, are determined by the setting. A situation where both sides are dead is possible as well. The actual value for defining the dead line or bus is given with the *Dead bus value* and *Dead line value* settings. Similarly, the actual values of live line or bus are defined with the *Live bus value* and *Live line value* settings.

Table 1344: Live dead mode of operation under which switching can be carried out

Live dead mode	Description
Both Dead	Both line and bus de-energized
Live L, Dead B	Bus de-energized and line energized
Dead L, Live B	Line de-energized and bus energized
Dead Bus, L Any	Both line and bus de-energized or bus de-energized and line energized
Dead L, Bus Any	Both line and bus de-energized or line de-energized and bus energized
One Live, Dead	Bus de-energized and line energized or line de-energized and bus energized
Not Both Live	Both line and bus de-energized or bus de-energized and line energized or line de-energized and bus energized

When the energizing direction corresponds to the settings, the situation has to be constant for a time set with the *Energizing time* setting before the circuit breaker closing is permitted. The purpose of this time delay is to ensure that the dead side remains de-energized and also that the situation is not caused by a temporary interference. If the conditions do not persist for a specified operation time, the timer is reset and the procedure is restarted when the conditions allow. The circuit breaker closing is not permitted if the measured voltage on the live side is greater than the set value of *Max energizing V*.

The measured energized state is available as a monitored data value ENERG_STATE and as four function outputs `LLDB` (live line / dead bus), `LLLB` (live line / live bus), `DLLB` (dead line / live bus) and `DLDB` (dead line / dead bus), of which only one can be active at a time. It is also possible that the measured energized state indicates “Unknown” if at least one of the measured voltages is between the limits set with the dead and live setting parameters.

Synchro check

The Synchro check function measures the difference between the line voltage and bus voltage. The function permits the closing of the circuit breaker when certain conditions are simultaneously fulfilled.

- The measured line and bus voltages are higher than the set values of *Live bus value* and *Live line value* (ENERG_STATE equals to "Both Live").
- The measured bus and line frequency are both within the range of 95 to 105 percent of the value of f_n.
- The measured voltages for the line and bus are less than the set value of *Max energizing V*.

In case *Syncro check mode* is set to "Syncronous", the additional conditions must be fulfilled.

- In the synchronous mode, the closing is attempted so that the phase difference at closing is close to zero.
- The synchronous mode is only possible when the frequency slip is below 0.1 percent of the value of f_n.
- The voltage difference must not exceed the 1 percent of the value of U_n.

In case *Syncro check mode* is set to “Asyncronous”, the additional conditions must be fulfilled.

- The measured difference of the voltages is less than the set value of *Difference voltage*.
- The measured difference of the phase angles is less than the set value of *Difference angle*.
- The measured difference in frequency is less than the set value of *Frequency difference*.
- The estimated breaker closing angle is decided to be less than the set value of *Difference angle*.

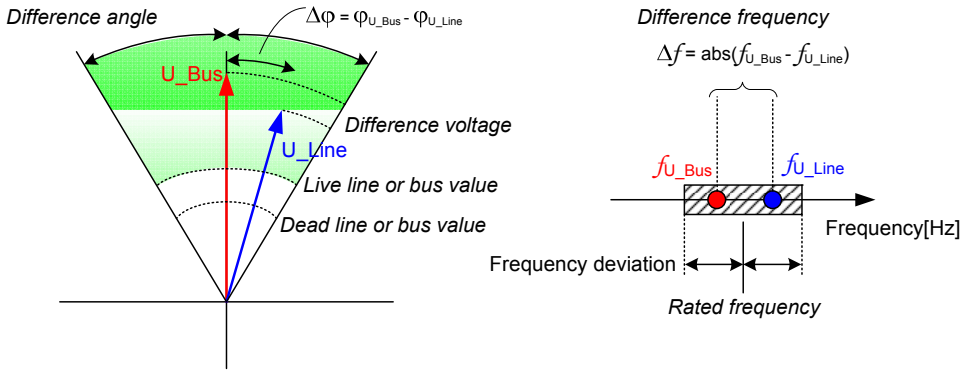

Figure 740: Conditions to be fulfilled when detecting synchronism between systems

When the frequency, phase angle and voltage conditions are fulfilled, the duration of the synchronism conditions is checked so as to ensure that they are still met when the condition is determined on the basis of the measured frequency and phase difference. Depending on the circuit breaker and the closing system, the delay from the moment the closing signal is given until the circuit breaker finally closes is about 50...250 ms. The selected *Closing time of CB* informs the function how long the conditions have to persist. The Synchro check function compensates for the measured slip frequency and the circuit breaker closing delay. The phase angle advance is calculated continuously with the formula.

$$Closing\ angle = \left|\left(\angle U_{Bus} - \angle U_{Line}\right)° + \left(\left(f_{Bus} - f_{line}\right)\cdot\left(T_{CB} + T_{PL}\right)\cdot 360°\right)\right|$$

(Equation 317)

$\angle U_{Bus}$ Measured bus voltage phase angle

$\angle U_{Line}$ Measured line voltage phase angle

f_{Bus} Measured bus frequency

f_{line} Measured line frequency

T_{CB} Total circuit breaker closing delay, including the delay of the protection relay output contacts defined with the *Closing time of CB* setting parameter value

T_{PL} Output type dependent delay according to Table 1345

Table 1345: Typical delays for different output types

Output type	Recommended value for T_{PL}
Semiconductor output (HSO, SPO)	0 ms
Mechanical relay output (POSP, PODP, PO)	6 ms

The closing angle is the estimated angle difference after the breaker closing delay.

The *Minimum Syn time* setting time can be set, if required, to demand the minimum time within which conditions must be simultaneously fulfilled before the SYNC_OK output is activated.

The measured voltage, frequency and phase angle difference values between the two sides of the circuit breaker are available as monitored data values U_DIFF_MEAS, FR_DIFF_MEAS and PH_DIFF_MEAS. Also, the indications of the conditions that are not fulfilled and thus preventing the breaker closing permission are available as monitored data values U_DIFF_SYNC, PH_DIF_SYNC and FR_DIFF_SYNC. These monitored data values are updated only when the Synchro check is enabled with the *Synchro check mode* setting and the measured ENERG_STATE is "Both Live".

Continuous mode

The continuous mode is activated by setting the parameter *Control mode* to "Continuous". In the continuous control mode, Synchro check is continuously checking the synchronism. When synchronism is detected (according to the settings), the SYNC_OK output is set to TRUE (logic '1') and it stays TRUE as long as the conditions are fulfilled. The command input is ignored in the continuous control mode. The mode is used for situations where Synchro check only gives the permission to the control block that executes the CB closing.

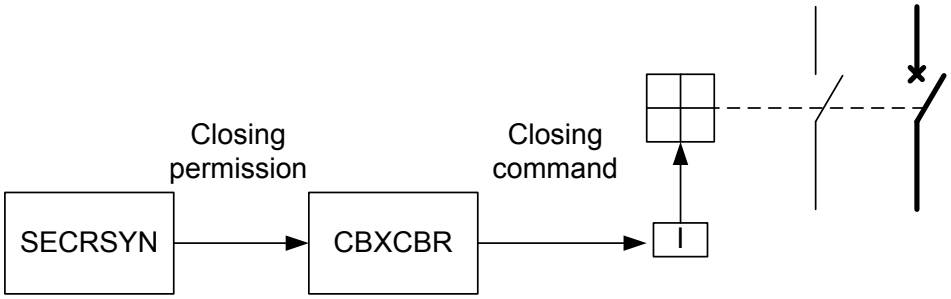

Figure 741: A simplified block diagram of the Synchro check function in the continuous mode operation

Command mode

If *Control mode* is set to "Command", the purpose of the Synchro check functionality in the command mode is to find the instant when the voltages on both sides of the circuit breaker are in synchronism. The conditions for synchronism are met when the voltages on both sides of the circuit breaker have the same frequency and are in phase with a magnitude that makes the concerned busbars or lines such that they can be regarded as live.

In the command mode operation, an external command signal CL_COMMAND, besides the normal closing conditions, is needed for delivering the closing signal. In the command control mode operation, the Synchro check function itself closes the breaker via the SYNC_OK output when the conditions are fulfilled. In this case, the control function block delivers the command signal to close the Synchro check

function for the releasing of a closing-signal pulse to the circuit breaker. If the closing conditions are fulfilled during a permitted check time set with *Maximum Syn time*, the Synchro check function delivers a closing signal to the circuit breaker after the command signal is delivered for closing.

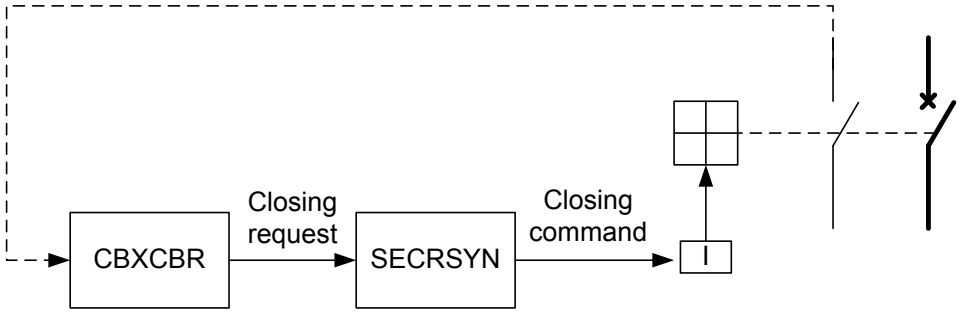

Figure 742: A simplified block diagram of SECRSYN in the command mode operation

The closing signal is delivered only once for each activated external closing command signal. The pulse length of the delivered closing is set with the *Close pulse* setting.

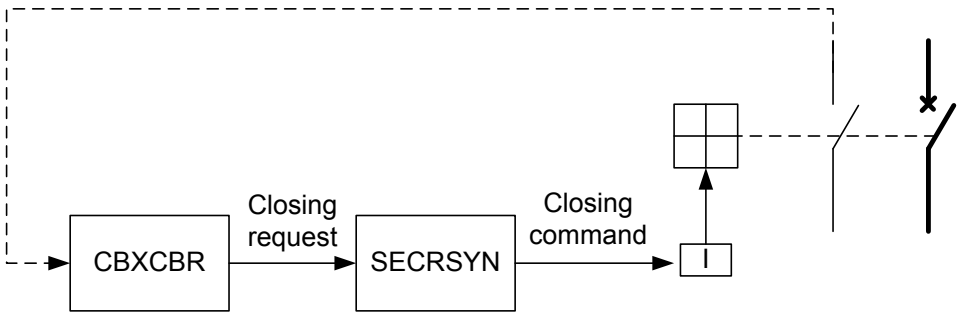

Figure 743: Determination of the pulse length of the closing signal

In the command control mode operation, there are alarms for a failed closing attempt (CL_FAIL_AL) and for a command signal that remains active too long (CMD_FAIL_AL).

If the conditions for closing are not fulfilled within the set time of *Maximum Syn time*, a failed closing attempt alarm is given. The CL_FAIL_AL alarm output signal is pulse-shaped and the pulse length is 500 ms. If the external command signal is removed too early, that is, before conditions are fulfilled and the closing pulse is given, the alarm timer is reset.

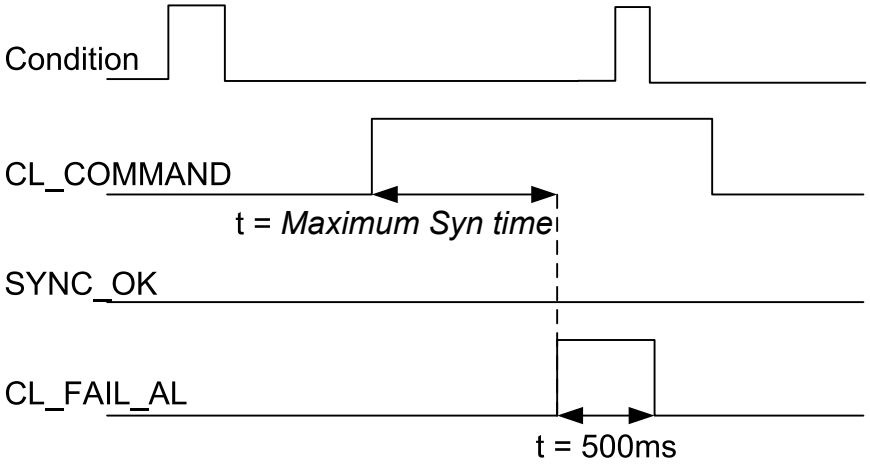

Figure 744: Determination of the checking time for closing

The control module receives information about the circuit breaker status and thus is able to adjust the command signal to be delivered to the Synchro check function. If the external command signal CL_COMMAND is kept active longer than necessary, the CMD_FAIL_AL alarm output is activated. The alarm indicates that the control module has not removed the external command signal after the closing operation. To avoid unnecessary alarms, the duration of the command signal should be set in such a way that the maximum length of the signal is always below *Maximum Syn time* + 5s.

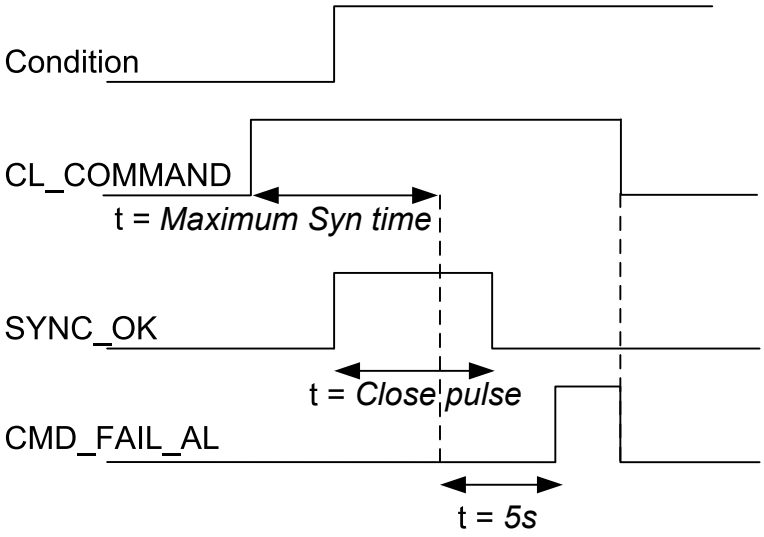

Figure 745: Determination of the alarm limit for a still-active command signal

Closing is permitted during *Maximum Syn time*, starting from the moment the external command signal CL_COMMAND is activated. The CL_COMMAND input must be kept active for the whole time that the closing conditions are waited to be fulfilled. Otherwise, the procedure is cancelled. If the closing-command conditions are fulfilled during *Maximum Syn time*, a closing pulse is delivered to the circuit breaker. If the closing conditions are not fulfilled during the checking time, the alarm CL_FAIL_AL

is activated as an indication of a failed closing attempt. The closing pulse is not delivered if the closing conditions become valid after *Maximum Syn time* has elapsed. The closing pulse is delivered only once for each activated external command signal, and a new closing-command sequence cannot be started until the external command signal is reset and reactivated. The SYNC_INPRO output is active when the closing-command sequence is in progress and it is reset when the CL_COMMAND input is reset or *Maximum Syn time* has elapsed.

Bypass mode

SECRSYN can be set to the bypass mode by setting the parameters *Synchrocheck mode* and *Live dead mode* to "Off" or alternatively by activating the BYPASS input.

In the bypass mode, the closing conditions are always considered to be fulfilled by SECRSYN. Otherwise, the operation is similar to the normal mode.

Voltage angle difference adjustment

In application where the power transformer is located between the voltage measurement and the vector group connection gives phase difference to the voltages between the high- and low-voltage sides, the angle adjustment can be used to meet synchronism.

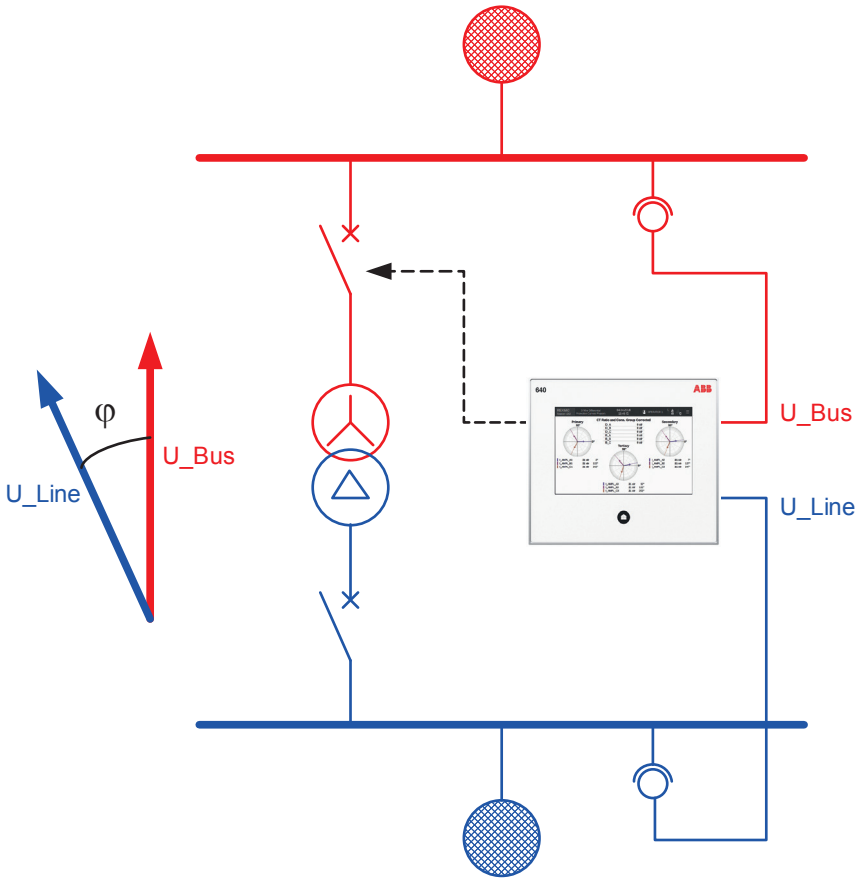

Figure 746: Angle difference when power transformer is in sychrocheck zone

The vector group of the power transformer is defined with clock numbers, where the value of the hour pointer defines the low-voltage-side phasor and the high-voltage-side phasor is always fixed to the clock number 12, which is same as zero. The angle between clock numbers is 30 degrees. When comparing phase angles, the U_BUS input is always the reference. This means that when the Yd11 power transformer is used, the low-voltage-side voltage phasor leads by 30 degrees or lags by 330 degrees the high-voltage-side phasor. The rotation of the phasors is counterclockwise.

The generic rule is that a low-voltage-side phasor lags the high-voltage-side phasor by clock number * 30º. This is called angle difference adjustment and can be set for SECRSYN with the *Phase shift* setting.

9.5.6 Application

The main purpose of the synchrocheck function is to provide control over the closing of the circuit breakers in power networks to prevent the closing if the conditions for synchronism are not detected. This function is also used to prevent the reconnection of two systems which are divided after islanding and a three-pole reclosing.

The Synchro check function block includes both the synchronism check function and the energizing function to allow closing when one side of the breaker is dead.

Network and the generator running in parallel with the network are connected through the line AB. When a fault occurs between A and B, the protection relay protection opens the circuit breakers A and B, thus isolating the faulty section from the network and making the arc that caused the fault extinguish. The first attempt to recover is a delayed autoreclosure made a few seconds later. Then, the autoreclose function DARREC gives a command signal to the synchrocheck function to close the circuit breaker A. SECRSYN performs an energizing check, as the line AB is de-energized (U_BUS> *Live bus value*, U_LINE< *Dead line value*). After verifying the line AB is dead and the energizing direction is correct, the protection relay energizes the line (U_BUS -> U_LINE) by closing the circuit breaker A. The PLC of the power plant discovers that the line has been energized and sends a signal to the other synchrocheck function to close the circuit breaker B. Since both sides of the circuit breaker B are live (U_BUS > *Live bus value*, U_LINE > *Live bus value*), the synchrocheck function controlling the circuit breaker B performs a synchrocheck and, if the network and the generator are in synchronism, closes the circuit breaker.

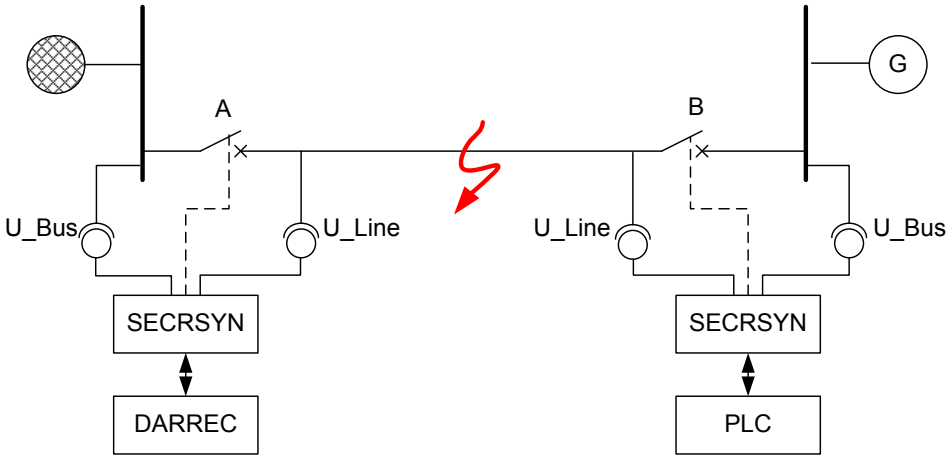

Figure 747: Synchrocheck function SECRSYN checking energizing conditions and synchronism

Connections

A special attention is paid to the connection of the protection relay. Furthermore it is checked that the primary side wiring is correct.

A faulty wiring of the voltage inputs of the protection relay causes a malfunction in the synchrocheck function. If the wires of an energizing input have changed places, the polarity of the input voltage is reversed (180°). In this case, the protection relay permits the circuit breaker closing in a situation where the voltages are in opposite phases. This can damage the electrical devices in the primary circuit. Therefore, it is extremely important that the wiring from the voltage transformers to the terminals on the rear of the protection relay is consistent regarding the energizing inputs `U_BUS` (bus voltage) and `U_LINE` (line voltage).

The wiring should be verified by checking the reading of the phase difference measured between the `U_BUS` and `U_LINE` voltages. The phase difference measured by the protection relay has to be close to zero within the permitted accuracy tolerances. The measured phase differences are indicated in the LHMI. At the same time, it is recommended to check the voltage difference and the frequency differences presented in the monitored data view. These values should be within the permitted tolerances, that is, close to zero.

Figure 748 shows an example where the synchrocheck is used for the circuit breaker closing between a busbar and a line. The phase-to-phase voltages are measured from the busbar and also one phase-to-phase voltage from the line is measured.

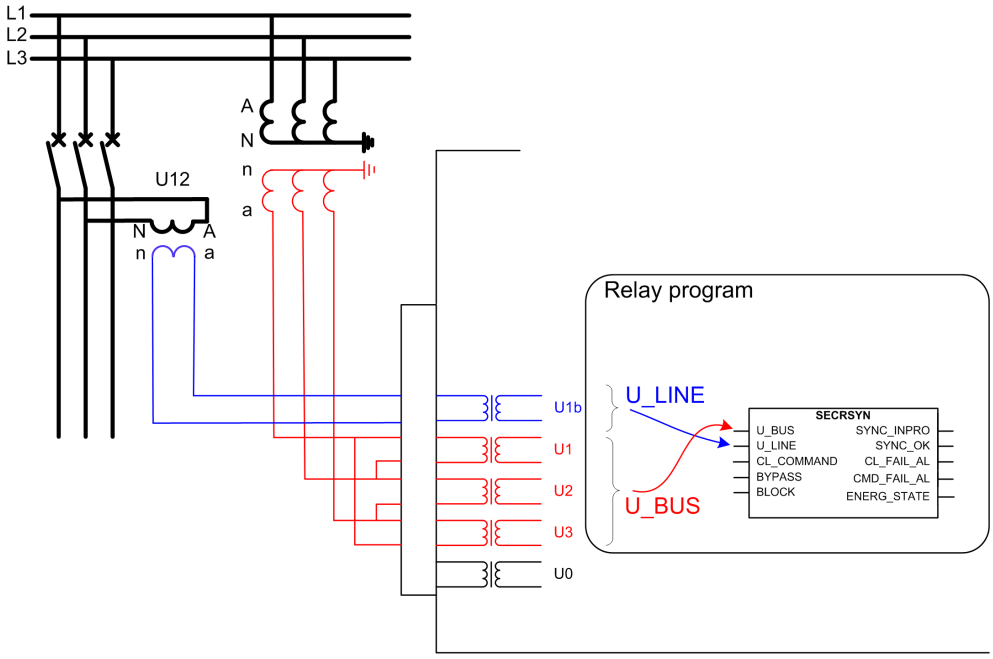

Figure 748: Connection of voltages for the protection relay and signals used in synchrocheck

9.5.7 Signals

Table 1346: SECRSYN Input signals

Name	Type	Default	Description
U3P1	SIGNAL	-	Three-phase voltages 1
U3P2	SIGNAL	-	Three-phase voltages 2
BLOCK	BOOLEAN	0=False	Blocking signal of the synchro check and voltage check function
CL_COMMAND	BOOLEAN	0=False	External closing request
BYPASS	BOOLEAN	0=False	Request to bypass synchronism check and voltage check

Table 1347: SECRSYN Output signals

Name	Type	Description
SYNC_INPRO	BOOLEAN	Synchronizing in progress
SYNC_OK	BOOLEAN	Systems in synchronism
CL_FAIL_AL	BOOLEAN	CB closing failed
CMD_FAIL_AL	BOOLEAN	CB closing request failed
LLDB	BOOLEAN	Live Line, Dead Bus
LLLB	BOOLEAN	Live Line, Live Bus
DLLB	BOOLEAN	Dead Line, Live Bus
DLDB	BOOLEAN	Dead Line, Dead Bus

9.5.8 Settings

Table 1348: SECRSYN Group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Live dead mode	-1=Off 1=Both Dead 2=Live L, Dead B 3=Dead L, Live B 4=Dead Bus, L Any 5=Dead L, Bus Any 6=One Live, Dead 7=Not Both Live			1=Both Dead	Energizing check mode
Difference voltage	0.01...0.50	xUn	0.01	0.05	Maximum voltage difference limit
Difference frequency	0.0002...0.1000	xFn	0.0001	0.0010	Maximum frequency difference limit
Difference angle	5...90	deg	1	5	Maximum angle difference limit

Table 1349: SECRSYN Non group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Operation	1=on 5=off			1=on	Operation Off / On
Synchro check mode	1=Off 2=Synchronous 3=Asynchronous			3=Asynchronous	Synchro check operation mode
Dead line value	0.1...0.8	xUn	0.1	0.2	Voltage low limit line for energizing check
Live line value	0.2...1.0	xUn	0.1	0.8	Voltage high limit line for energizing check
Dead bus value	0.1...0.8	xUn	0.1	0.2	Voltage low limit bus for energizing check
Live bus value	0.2...1.0	xUn	0.1	0.5	Voltage high limit bus for energizing check
Max energizing V	0.50...1.15	xUn	0.01	1.05	Maximum voltage for energizing

Table 1350: SECRSYN Non group settings (Advanced)

Parameter	Values (Range)	Unit	Step	Default	Description
Control mode	1=Continuous 2=Command			1=Continuous	Selection of synchro check command or Continuous control mode
Close pulse	200...60000	ms	10	200	Breaker closing pulse duration
Phase shift	-180...180	deg	1	0	Correction of phase difference between measured U_BUS and U_LINE
Minimum Syn time	0...60000	ms	10	0	Minimum time to accept synchronizing
Maximum Syn time	100...6000000	ms	10	2000	Maximum time to accept synchronizing
Energizing time	100...60000	ms	10	100	Time delay for energizing check
Closing time of CB	40...250	ms	10	60	Closing time of the breaker
Voltage source switch	0=False 1=True			0=False	Voltage source switch

9.5.9 Monitored data

Table 1351: SECRSYN Monitored data

Name	Type	Values (Range)	Unit	Description
ENERG_STATE	Enum	0=Unknown 1=Both Live 2=Live L, Dead B 3=Dead L, Live B 4=Both Dead		Energization state of Line and Bus
U_DIFF_MEAS	FLOAT32	-3.00...3.00	xUn	Calculated voltage amplitude difference
FR_DIFF_MEAS	FLOAT32	-1.500...1.500	xFn	Calculated voltage frequency difference
PH_DIFF_MEAS	FLOAT32	-180.00...180.00	deg	Calculated voltage phase angle difference
U_DIFF_SYNC	BOOLEAN	0=False 1=True		Voltage difference out of limit for synchronizing
PH_DIF_SYNC	BOOLEAN	0=False 1=True		Phase angle difference out of limit for synchronizing
FR_DIFF_SYNC	BOOLEAN	0=False 1=True		Frequency difference out of limit for synchronizing
SECRSYN	Enum	1=on 2=blocked 3=test 4=test/blocked 5=off		Status

9.5.10 Technical data

Table 1352: SECRSYN Technical data

Characteristic	Value
Operation accuracy	Depending on the frequency of the voltage measured: f_n ±1 Hz
	Voltage: ±3.0% of the set value or ±0.01 × U_n Frequency: ±10 mHz Phase angle: ±3°
Reset time	<50 ms
Reset ratio	Typically 0.96
Operate time accuracy in definite time mode	±1.0% of the set value or ±20 ms

9.6 Autosynchronizer for generator breaker ASGCSYN

9.6.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Autosynchronizer for generator breaker	ASGCSYN	AUTOSYNCG	25AUTOSYNCG

9.6.2 Function block

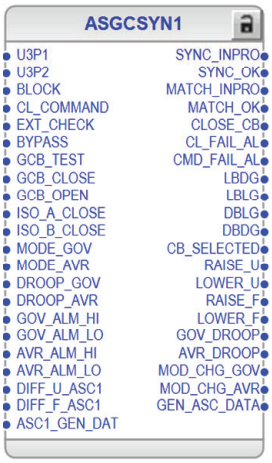

Figure 749: Function block

9.6.3 Functionality

The autosynchronizer for generator breaker function ASGCSYN checks the conditions across the circuit breaker from generator and bus side and issues the pulse commands to the automatic voltage regulator (AVR) and prime mover governor to match the voltage and frequency conditions if required. Once the synchronization check and close CB conditions are fulfilled, the function gives permission to close the circuit breaker. ASGCSYN includes the functionality of energizing check, synchronization check and voltage and frequency matching.

The energizing check function checks that bus side is dead to ensure that breaker closing can be done safely. The synchronization check function checks that the voltages and frequency on both sides of the circuit breaker are within the predefined setting. It is used to perform a controlled reconnection of two systems.

In the auto synchronization control mode, the function's automatic, semi-automatic and manual operation modes decide the operation of voltage and frequency matching and the auto synchronization process.

The voltage and frequency matching function issues raise or lower pulse commands to AVR and the governor to match the voltage and frequency, based on the calculated voltage and frequency difference across the circuit breaker to be synchronized. ASGCSYN also participates in voltage and frequency matching for network breaker synchronization.

9.6.4 Analog channel configuration

ASGCSYN has two analog group inputs which must be properly configured.

Table 1353: Analog inputs

Input	Description
U3P1	Three-phase voltages (generator side)
U3P2	Three-phase voltages (bus side)

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1354: Special conditions

Condition	Description
U3P1 and U3P2 connected to real measurements	When one voltage channel from the generator side is connected to channel 1 of U3P1 and one voltage channel from the bus side is connected to channel 1 of U3P2, the function can only work if UTVTR's *VT connection* settings on the generator and bus sides are similar.
	The function can work if one voltage channel from the generator side is connected to channel 1 of U3P1 and three voltage channels from the bus side are connected to U3P2.
	The function can work if one voltage channel from the generator side is connected to channel 1 of U3P1 and two voltage channels along with the residual voltage from the bus side are connected to U3P2.
	The function can work if three voltage channels from the generator side are connected to U3P1 and one voltage channel from the bus side is connected to channel 1 of U3P2.
	The function can work if two voltage channels and the residual voltage from the generator side are connected to U3P1 and one voltage channel from the bus side is connected to channel 1 of U3P2.
Dissimilar VT connection settings for UTVTR on the generator and bus sides	The function requires that all three voltage channels or two voltage channels and the residual voltage are connected to either U3P1 or U3P2.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

9.6.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of ASGCSYN can be described with a module diagram. All the modules in the diagram are explained in the next sections.

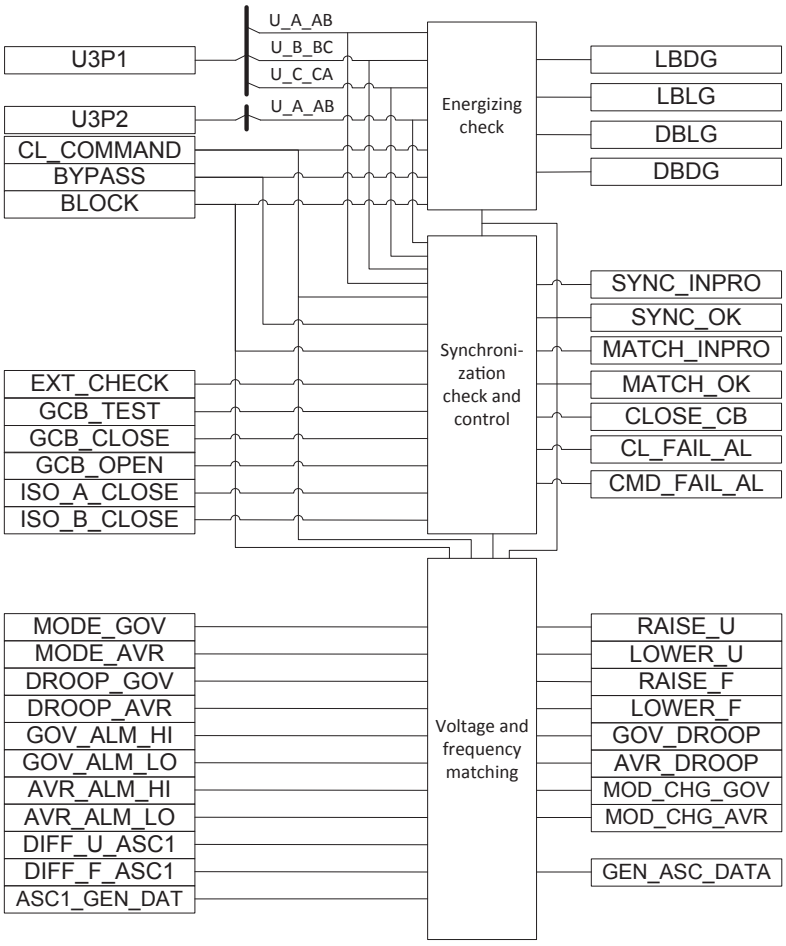

Figure 750: Functional module diagram

ASGCSYN can operate either with the U_AB or U_A voltages. The selection of used voltages is defined with the *VT connection* setting of the voltage measurement parameters.

Energizing check

The Energizing check module checks the energizing direction. Energizing is the situation where a dead network part is connected to an energized section of the network. The conditions of the network sections to be controlled by the circuit breaker, that is, which side has to be live and which side dead, are determined by the setting *Live dead mode*.

Live dead mode can be set in two ways: either through settings or through the command control.

If the *Live dead mode* parameter under the Setting menu is set as "Command", then *Live dead mode Ctl* parameter under the Control menu can be used to select the values in Table 1355. Otherwise, the *Live dead mode* parameter under the Setting menu is used to select the values in Table 1355.

Table 1355: Live dead mode of operation when switching can be carried out

Live dead mode	Description
Off	Live dead mode setting is in off status
Both Dead	Both bus and generator de-energized
Live G, Dead B	Bus de-energized and generator energized
Dead B, G Any	Bus de-energized and generator energized or de-energized

The actual value for defining the dead bus or generator is given with the *Dead voltage value* setting. Similarly, the actual values of live bus or generator are defined with the *Live voltage value* setting.

When the energizing direction corresponds to the settings, the situation has to be constant for a time set with the *Energizing time* setting before the circuit breaker closing is permitted. This time delay ensures that the dead side remains de-energized and that the situation is not caused by a temporary interference. If the conditions do not persist for a specified operate time, the timer is reset and the procedure is restarted when the conditions allow it. The circuit breaker does not close if the measured voltage on the live side is greater than the set value of *Maximum voltage*.

The measured energized state is available as a monitored data value ENERG_STATE and as four function outputs `LBLG` (“Both Live”), `LBDG` (“Live B, Dead G”), `DBLG` (“Dead B, Live G”) and `DBDG` (“Both Dead”), of which only one can be active at a time. The measured energized state indicates “Unknown” if at least one of the measured voltages is between the limits set with the dead and live setting parameters.

Synchronization check and control

The operation of Synchronization check and control can be described with a module diagram. All the modules in the diagram are explained in the next sections.

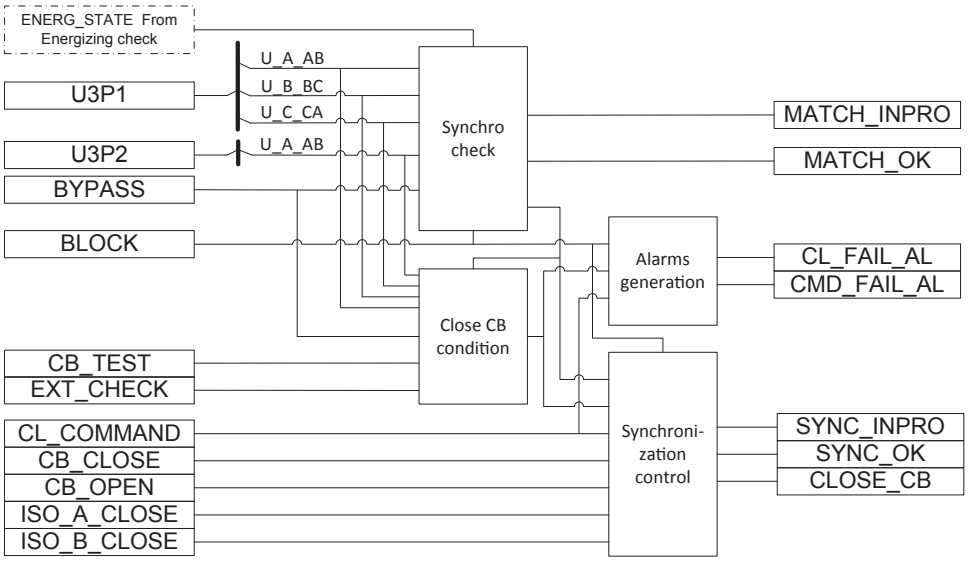

Figure 751: Module diagram for Synchronization check and control

Synchro check

The function measures the voltage difference U_DIFF_MEAS, frequency difference FR_DIFF_MEAS and phase angle difference PH_DIFF_MEAS between the bus voltage and generator voltage. In the calculation of PH_DIFF_MEAS, setting *Phase shift* is used to compensate the angle shift caused if a power transformer is located between the voltage measurements. Offset correction due to different channel measurements (for voltage and frequency values) can be done using *Voltage offset* and *Frequency offset*. The user can select the direction of generator synchronization using the setting *Synchronization Dir*.

$$U_DIFF_MEAS = U_{Gen} - U_{Bus} - Voltage\ offset$$

(Equation 318)

U_{Bus}	Measured bus side voltage
U_{Gen}	Measured generator side voltage
Voltage offset	Setting *Voltage offset*

$$FR_DIFF_MEAS = f_{Gen} - f_{Bus} - Frequency\ offset$$

(Equation 319)

f_{Bus}	Measured bus side frequency
f_{Gen}	Measured generator side frequency
Frequency offset	Setting *Frequency offset*

$$PH_DIFF_MEAS = \angle U_{Gen} - \angle U_{Bus} - Phase\ shift$$

(Equation 320)

$\angle U_{Bus}$	Measured bus side voltage phase angle
$\angle U_{Gen}$	Measured generator side voltage phase angle
Phase shift	Setting *Phase shift*

The synchronism conditions are checked according to several criteria.

- The measured bus and generator voltages are higher than the set value of *Live voltage value* (ENERG_STATE equals “Both Live”).
- The measured bus and generator frequencies are both within the range of 95...105 percent of the nominal frequency (f_n).
- The measured bus and generator voltages are lower than the set value of *Maximum voltage*.

If the *Synchrocheck mode* parameter under the Setting menu is set as "Command", then the *SynchroChk Mod Ctl* parameter under the Control menu is used to set values "OFF/Asynchronous". Otherwise, the *Synchrocheck mode* parameter under the Setting menu is used to set the values "Off/Asynchronous".

Some additional conditions must also be fulfilled as per the set *Synchrocheck mode*.

Table 1356: Additional conditions for the synchro check

Measurements	Synchrocheck mode “Asynchronous”
U_DIFF_MEAS	< Voltage Diff Ov Ex and > -Voltage Diff Un Ex
PH_DIFF_MEAS	< Angle Diff positive and > - Angle Diff negative
FR_DIFF_MEAS	< Freq Diff OV Synch and > -Freq Diff sub Synch
Closing angle	< Angle Diff positive and >- Angle Diff negative

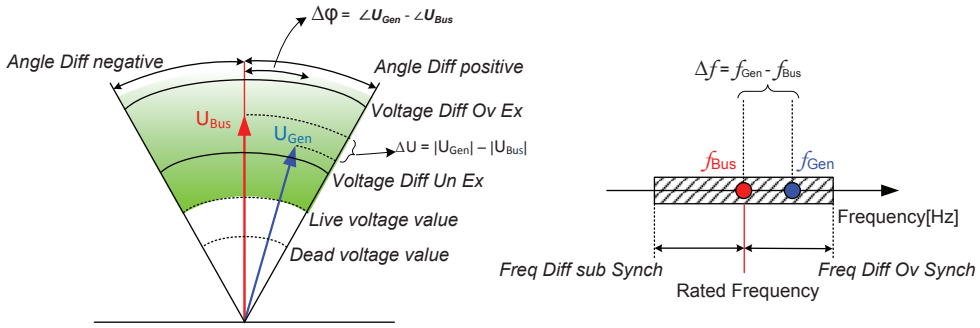

Figure 752: Conditions to be fulfilled when detecting synchronism between systems

When the measured differences in voltage and frequency are within the synchro check limits, the output MATCH_OK is activated. The output MATCH_INPRO is active while the voltage and frequency matching is in progress.

When the frequency, phase angle and voltage conditions are fulfilled, the duration of the synchronism conditions is checked to ensure that they are still met when the condition is determined on the basis of the measured frequency and phase difference. Depending on the circuit breaker and the closing system, the delay between the closing signal and the circuit breaker closing is about 50...250 ms. The selected *Closing time of CB* informs the function how long the conditions have to persist. The value covers both circuit breaker closing delay and output type dependent delay. The synchro check function compensates for the measured slip frequency and the circuit breaker closing delay. The closing angle advance is calculated continuously:

$$Closing\ angle = \left| \left(\angle U_{Gen} - \angle U_{Bus} \right)° + \left(\left(f_{Gen} - f_{Bus} \right) \cdot \left(\frac{TCB}{1000} \right) \cdot 360° \right) \right|$$

(Equation 321)

$\angle U_{Gen}$ Measured generator voltage phase angle

$\angle U_{Bus}$ Measured bus voltage phase angle

TCB Parameter *Closing time of CB* to be set as in Equation 322

$$TCB = t_{CB} + T_{PL} + x$$

(Equation 322)

t_{CB} Circuit breaker closing delay in ms

T_{PL} Output type dependent delay in ms (see Table 1357)

x Hardware delays between the protection relay and CB in ms; delays due to, for example, auxiliary relays and contactors, if used

Table 1357: Typical delays for different output types

Output type	Recommended value for T_{PL}	
	Generator voltage measurement: Non-Adaptive Bus voltage measurement: Non-Adaptive	Generator voltage measurement: Adaptive Bus voltage measurement: Non-Adaptive
Semiconductor output (SPO)	16 ms	7 ms
Mechanical relay output (POSP, PODP)	23 ms	13 ms

The *Minimum Syn time* setting defines the minimum time for which synchro check conditions must be simultaneously fulfilled.

ASGCSYN can be set to the bypass mode by setting the parameters *Synchrocheck mode* and *Live dead mode* to "Off" or, alternatively, by activating the BYPASS input. In the bypass mode, the synchro check conditions are always fulfilled. Otherwise, the operation is similar to the normal mode.

The frequency slip acceleration (ds/dt) FR_SLIP_ACCL is the average value of frequency slip difference (Δs) calculated over a time period of 0.5 s.

$$Frequency\ slip(s) = \frac{(f_{Gen} - f_{Bus})}{f_{Bus}}$$

(Equation 323)

The measured bus voltage (U_{Bus}), bus frequency (f_{Bus}), generator voltage (U_{Gen}), generator frequency(f_{Gen}) and phase angle difference values between the two sides of the circuit breaker are available as monitored data values U_BUS_MEAS, FR_BUS_MEAS, U_GEN_MEAS, FR_GEN_MEAS, U_DIFF_MEAS, FR_DIFF_MEAS and PH_DIFF_MEAS. The calculated frequency slip acceleration (ds/dt) is available as monitored data value FR_SLIP_ACCL. Also, the indications of the conditions that are not fulfilled and thus preventing the breaker closing permission are available as monitored data values U_DIFF_SYNC, PH_DIF_SYNC and FR_DIFF_SYNC. These monitored data values are updated only when the setting *Synchrocheck mode* is set to "Asynchronous" and the measured ENERG_STATE is "Both Live".

The measured voltage, frequency are updated in the monitored data irrespective of any condition.

Close CB condition

When *Synchrocheck mode* is set to "Asynchronous", the close CB condition is generated as explained below.

From the frequency slip s, the acceleration ds/dt, the bus frequency FR_BUS_MEAS (f_{Bus}) and the set *Closing time of CB*, the function calculates the necessary lead angle

(α_{Lead}) by which the close CB command is shifted forward in time so that the main contacts close on phase coincidence.

$$\alpha_{Lead} = \left(360 \cdot f_{Bus} \cdot \left(s + \frac{\frac{TCB}{2} \cdot \frac{ds}{dt}}{1000} \right) \cdot \frac{TCB}{1000} \right)$$

(Equation 324)

f_{Bus}	Bus side frequency
s	Frequency slip
ds/dt	Frequency slip acceleration
TCB	Setting *Closing time of CB*

ASGCSYN can be set to the bypass mode by setting the parameters *Synchrocheck mode* and *Live dead mode* to "Off" or, alternatively, by activating the BYPASS input. In the bypass mode, the close CB conditions are always fulfilled. Otherwise, the operation is similar to the normal mode.

The monitored data CB_CL_BLKD depends on the inputs GCB_TEST and EXT_CHECK, and also on IED test mode as described in Table 1358. CB_CL_BLKD is available in the Monitored data view.

Table 1358: Monitored data CB_CL_BLKD activation based on the inputs

IED test mode	Inputs		Monitored data
	GCB_TEST	EXT_CHECK	CB_CL_BLKD
TRUE	TRUE	TRUE	1(“Unblocked”)
FALSE	FALSE		
TRUE	TRUE	FALSE	2(“Ext Check Fail”)
FALSE	FALSE		
TRUE	FALSE	N/A	3(“IED Test CB Service”)
FALSE	TRUE	N/A	4(“IED Service CB Test”)

The close CB condition is blocked if the CB_CL_BLKD status is 2(“Ext Check Fail”), 3(“IED Test CB Service”) or 4(“IED Service CB Test”).

In case for BYPASS input activation,

- If GCB_TEST is activated, CLOSE_CB is activated.
- If GCB_TEST is deactivated, and the bus and generator terminal voltages are both live or one side live, CLOSE_CB is not activated.

Synchronization control

The general bus bar arrangement for a generator bus is shown in Figure 753. The bus to which the generator is connected is determined based on the circuit breaker and isolator position inputs (GCB_OPEN, GCB_CLOSE, ISO_A_CLOSE and ISO_B_CLOSE). The generator's bus connection status is shared with the autosynchronizer co-ordinator function ASCGAPC as part of the GEN_ASC_DATA output.

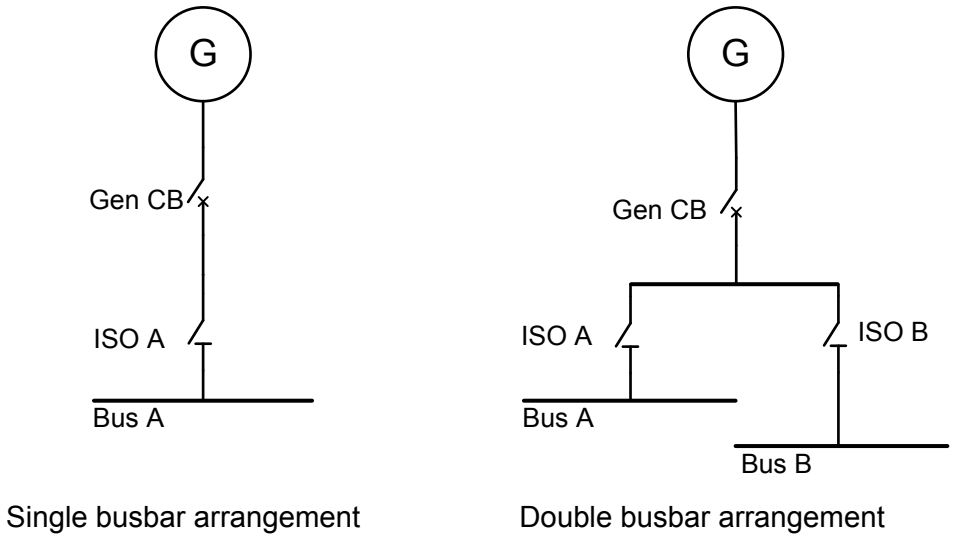

Figure 753: Different bus bar arrangements for a generator bus

Auto synchronization mode

In this mode, the closing signal is delivered if either the command *Synchronize CB* or the input CL_COMMAND is set to TRUE. The relay should be in the local mode if synchronization is initiated with the Synchronize CB command.

If the setting *Auto Syn mode* is set as "Manual mode" or "Semi-automatic synchronising mode", the additional command Manual CB release should be active for the closing signal CLOSE_CB to be activated. If the setting *Auto Syn mode* is set as "Automatic synchronising mode", no additional command is required to activate the closing signal CLOSE_CB.

In this auto synchronization mode, once all the closing conditions are satisfied within the set *Maximum Syn time*, the outputs SYNC_OK and CLOSE_CB become TRUE and remain active as long as the closing conditions are fulfilled. If *Multiple command* is set to "Off", then only CLOSE_CB outputs are delivered once for each activated input signal as shown in Figure 754. If *Multiple command* is set to "On", then CLOSE_CB outputs are delivered each time the conditions are satisfied as shown in Figure 755.

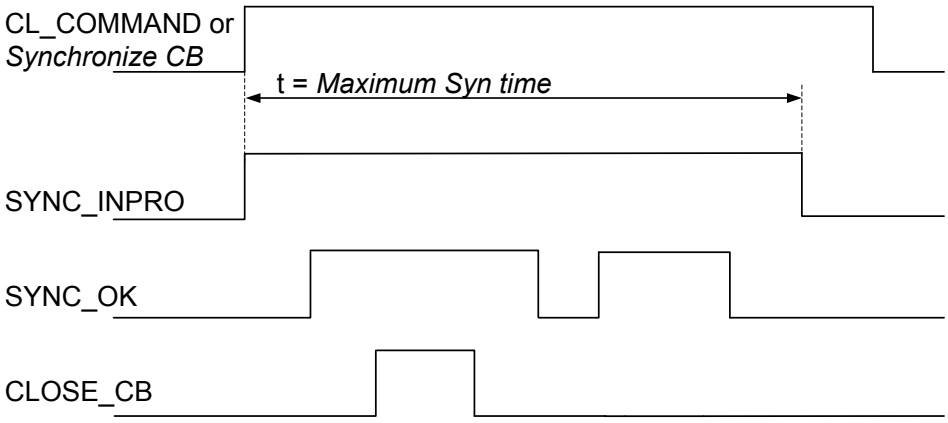

Figure 754: Determination of closing signal CLOSE_CB when Multiple command is set to "Off"

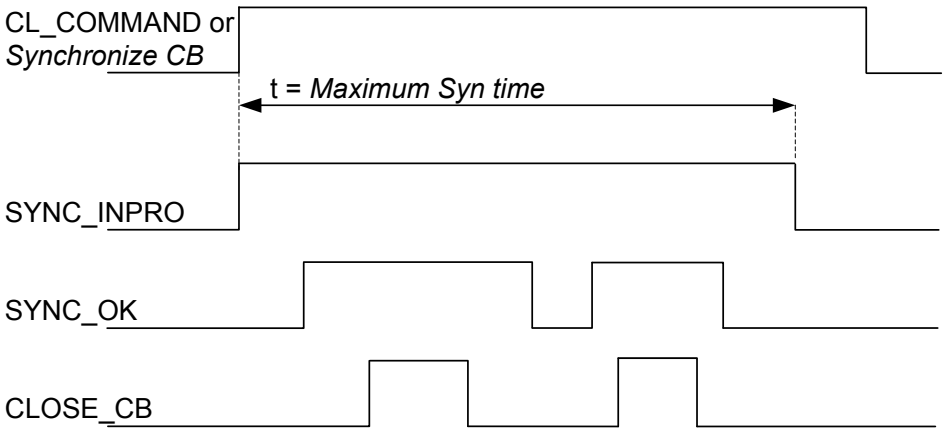

Figure 755: Determination of closing signal CLOSE_CB when Multiple command is set to "On"

The SYNC_INPRO output is active when the close command (CL_COMMAND or *Synchronize CB*) is in progress and it is reset when the close command is reset or *Maximum Syn time* has elapsed.

If the closing conditions are fulfilled during a permitted check time set with *Maximum Syn time*, ASGCSYN gives synchro check permission to the breaker control function block after the closing command signal is delivered. The simplified configuration block diagram of ASGCSYN with CLOSE_CB to the breaker control function block is shown in Figure 756.

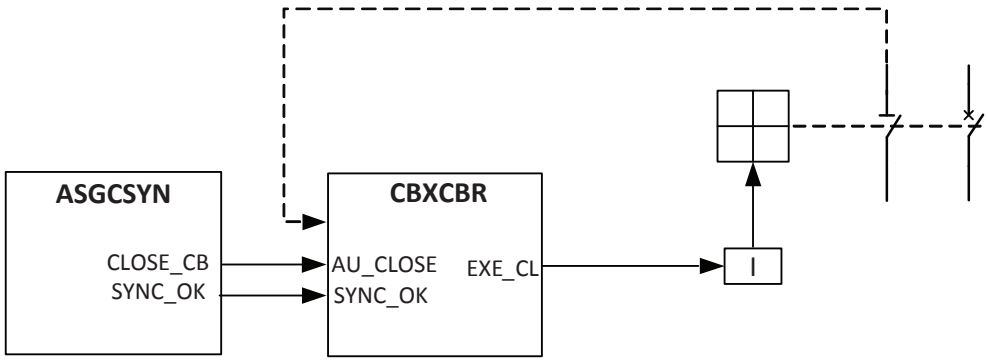

Figure 756: Simplified configuration block diagram of ASGCSYN in auto synchronization mode operation

Alarms generation

In the synchro check command and auto synchronization control mode operation, there are alarms for failed closing attempt (CL_FAIL_AL) and for a command signal that remains active too long (CMD_FAIL_AL).

In the auto synchronization control mode, the closing command generation is activated either by the command input CL_COMMAND or by the command parameter *Synchronize CB*.

From the closing command activation, if the conditions for closing CB are not fulfilled within the set time of *Maximum Syn time*, a failed closing attempt alarm is given. The CL_FAIL_AL alarm output signal is pulse-shaped and the pulse length is 500 ms.

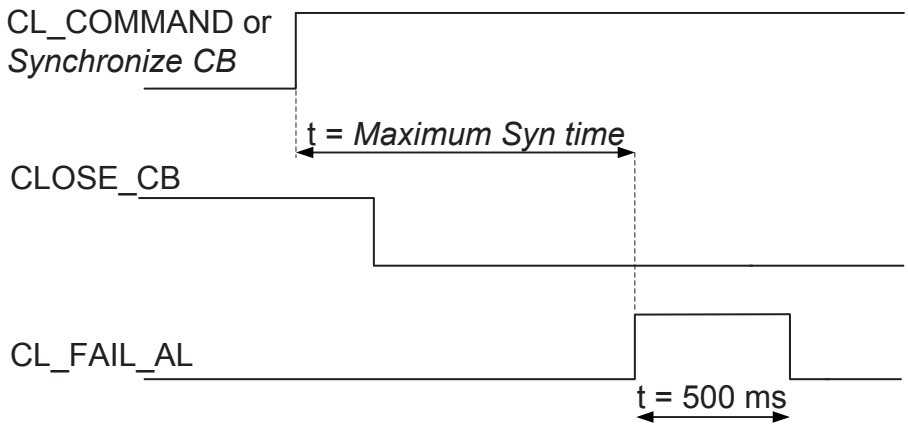

Figure 757: Determination of checking time for closing

CB closing is permitted during *Maximum Syn time*, starting from the moment the close command is activated. The close command must be active while the closing conditions are fulfilled, otherwise the procedure is cancelled. If the closing conditions are fulfilled during *Maximum Syn time*, a closing pulse output is delivered to the

circuit breaker. If the closing conditions are not fulfilled during the checking time, the alarm CL_FAIL_AL is activated as an indication of a failed closing attempt. The closing pulse is not delivered if the closing conditions become valid after *Maximum Syn time* has elapsed. The closing pulse is delivered only once for each activated close command, and a new closing command sequence cannot be started until the close command is reset and reactivated.

The circuit breaker control function block receives information about the circuit breaker status and thus is able to adjust the command signal to be delivered to ASGCSYN. If the closing command is active longer than necessary, the CMD_FAIL_AL alarm output is activated. To avoid unnecessary alarms, the maximum length of the closing command signal should be below *Maximum Syn time* + 5 s.

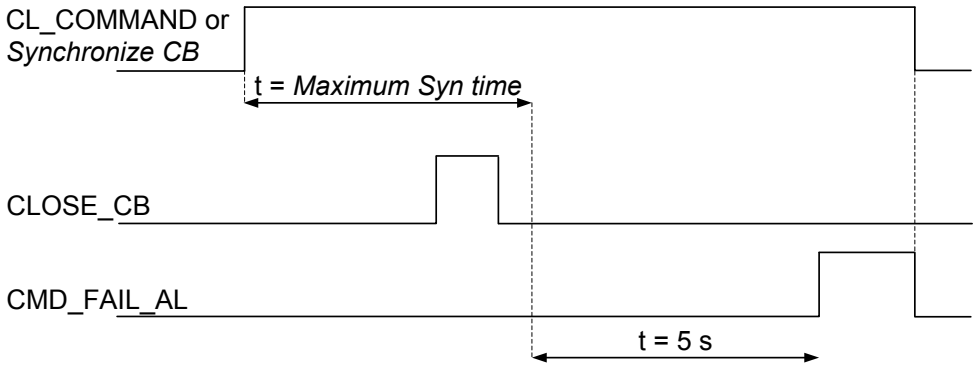

Figure 758: Determination of the alarm limit for a still-active command signal

Voltage and frequency matching

The operation of the Voltage and frequency matching module can be described with a module diagram. All the modules in the diagram are explained in the next sections.

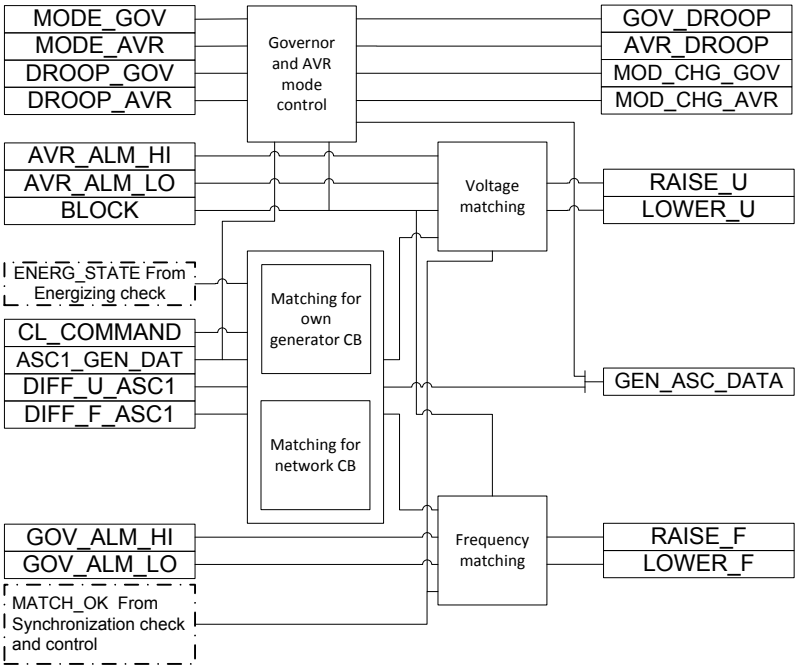

Figure 759: Module diagram for Voltage and frequency matching

The voltage and frequency matching is activated automatically during the “Autosynchronization” mode.

Governor and AVR mode control

If the setting *Central PMS present* is set to "Yes", then the governor and AVR mode is decided based on the inputs MODE_GOV and MODE_AVR, respectively. If the setting *Central PMS present* is set to "No", then the governor and AVR mode is decided based on the inputs DROOP_GOV and DROOP_AVR, respectively.

For the matching of frequency and voltage, the governor or AVR mode must be 1(“Droop”) or 2(“Fixed MW’). Otherwise, the MOD_CHG_GOV or MOD_CHG_AVR output is used for the mode change request.

When the setting *Central PMS present* is set to "Yes" and the Governor or AVR mode is not 1(“Droop”) or 2(“Fixed MW’), then the function sets MOD_CHG_GOV or MOD_CHG_AVR output to (“Droop”) or (“Fixed MW’). Otherwise, the function sets MOD_CHG_GOV or MOD_CHG_AVR output to “No change”.

When the setting *Central PMS present* is set to "No" and the Governor or AVR mode is not Droop mode, then the function activates the binary output GOV_DROOP or AVR_DROOP by using the input DROOP_GOV or DROOP_AVR.

The governor and AVR modes can also be changed through the command parameters *Gov mode change* and *AVR mode change*, respectively. If the command parameter *Gov mode change* is set to "Droop" or "Fixed MW", the function activates the binary output GOV_DROOP and sets integer output MOD_CHG_GOV to 1(“Droop”) or

2(“Fixed MW’), respectively. If the command parameter *AVR mode change* is set to "Droop" or "Fixed MVAr", the function activates the binary output AVR_DROOP and sets integer output MOD_CHG_AVR to 9(“Droop”) or 11(“Fixed MVAr”), respectively.

Matching for own generator CB

If the command ‘Synchronize CB’ is set to “TRUE” or input CL_COMMAND is TRUE, the generator CB is selected for synchronizing. For the voltage and frequency matching to start, the generator CB should be in open position and *Synchrocheck mode* should be set to "Asynchronous".

The measured voltage difference U_DIFF_MEAS is used for generating AVR raise or lower pulses to match the voltages across the CB. The measured frequency difference FR_DIFF_MEAS is used for generating governor raise or lower pulses to match the frequencies across the CB. The voltage and frequency matching starts only when the ENERG_STATE is “Both Live”.

Voltage difference (ΔU) = U_DIFF_MEAS

Frequency difference (ΔF) = FR_DIFF_MEAS

Matching for network CB

The generator is ready for network CB matching only when the generator CB is closed, the protection relay is in remote mode and the generator is requested for matching from non-source function.

After receiving the acknowledgement from ASGCSYN, the autosynchronizer co-ordinator function ASCGAPC gives permission to participate in the voltage and frequency matching across the CB to be synchronized in the network. ASCGAPC also shares the information about how many generators participate in the voltage matching (NgV) and frequency matching (NgF). Depending on the number of participating generators, the voltage and frequency difference is divided among the generators.

The voltage and frequency difference calculated for generating raise or lower pulses for AVR and governor are

Voltage difference (ΔU) = DIFF_U_ASC1 / NgV

Frequency difference (ΔF) = DIFF_F_ASC1 / NgF

The sign bit for voltage difference and frequency difference is decided based on the data received from ASCGAPC. The calculated voltage difference and frequency difference are available in the Monitored data view U_DIFF_NTW and FR_DIFF_NTW, respectively.

Voltage matching

Working range of the voltage matcher

If the bus voltage U_BUS is between settings *Minimum voltage* and *Maximum voltage* and the generator voltage U_GEN is greater than the setting *Dead voltage value*, the adjusting commands are released. The direction of the adjusting commands depends on the polarity of ΔU. As an additional condition, both frequencies must be in the range f_n ±5 Hz.

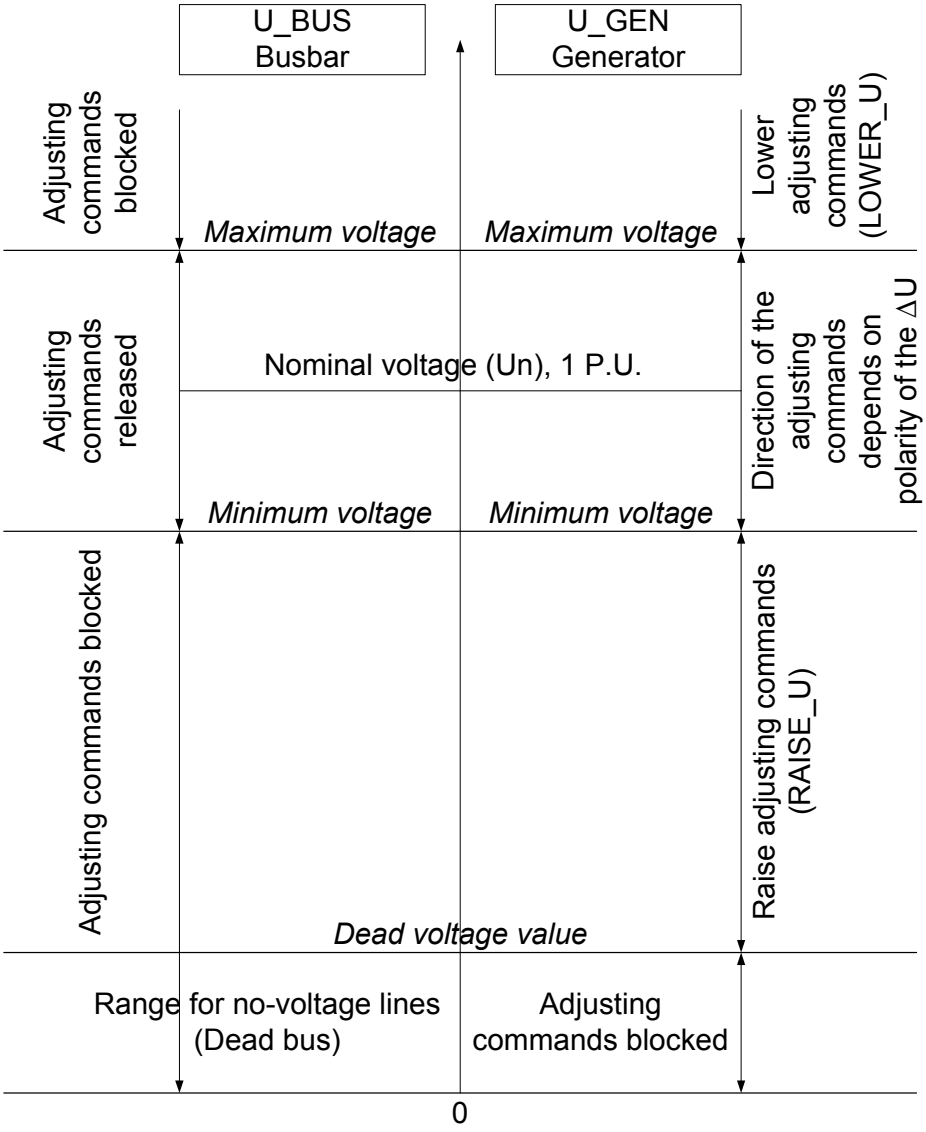

Figure 760: Working range of the voltage matcher

If *Auto Syn mode* is set to either "Semi-automatic synchronizing mode" or "Automatic synchronizing mode", the voltage raise or lower command pulses are generated from the function based on the voltage difference across the breaker and AVR response characteristics. If the voltage difference (ΔU) is negative, it means the reference side voltage is greater than the running side voltage. So the voltage matching generates the voltage raise command pulse `RAISE_U`. If the voltage difference (ΔU) is positive, it

means the reference side voltage is lower than the running side voltage. So the voltage matching generates the voltage lower command pulse LOWER_U.

The length of the voltage raise and lower command pulse (tpU) and the pulse off interval (tsU) are calculated based on the setting *Voltage match mode*.

Voltage matching in manual mode

If *Auto Syn mode* is set to "Manual mode", the voltage raise or lower command pulses are generated manually from the function's user commands.

If the command *AVR voltage raise* is set to "RAISE", the function activates the voltage raise command pulse RAISE_U. If the command *AVR voltage lower* is set to "LOWER", the function activates the voltage lower command pulse LOWER_U.

The lengths of these generated pulses tpU and pulse off interval tsU are based on the settings as: tpU = *Volt pulse Min Dur*; tsU = *Volt pulse off Intv*.

Voltage matching with variable command pulse lengths

When the setting *Voltage match mode* is set to "Variable Pulse", the voltage matching is done with variable command pulse lengths.

The voltage matcher issues a command with a length proportional to the voltage difference. The proportionality factor setting *Volt rate of change* (dU/dt) can be adapted to the voltage regulator. The voltage matcher aims at a value in the middle of the set tolerance band.

The adjusting voltage command pulse length tpU is calculated as

$$tpU = \frac{\Delta U - \left(\frac{+\Delta U\max - \left| -\Delta U\max \right|}{2} \right)}{\frac{dU}{dt}}$$

(Equation 325)

ΔU	Measured voltage difference across the CB to be synchronized
+ΔUmax	Setting *Voltage Diff Ov Ex*
-ΔUmax	Setting *Voltage Diff Un Ex*
dU/dt	Setting *Volt rate of change*

The adjusting pulse is discontinued as soon as the voltage difference exceeds the target value. The command length does not fall below a settable minimum value *Volt pulse Min Dur*. After an adjusting command, the system waits for the set *Volt pulse off Intv* (tsU) so that the actual values can stabilize to the new set point.

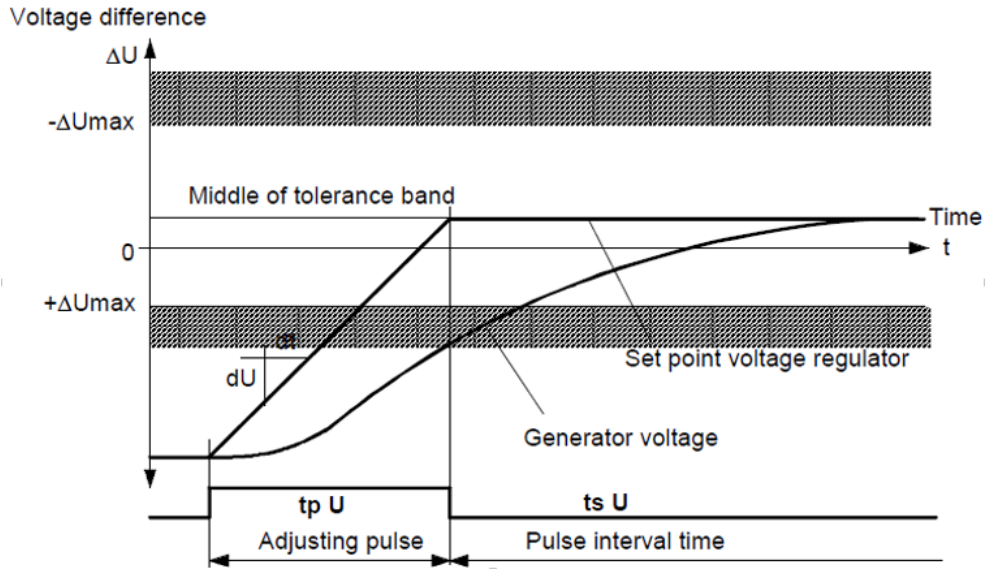

Figure 761: Voltage matching pulse generation with variable command pulse length

Voltage matching with variable command pulse off intervals

When the setting *Voltage match mode* is set to "Variable Interval", the voltage matching is done with variable command pulse off intervals.

The voltage match command pulses are now the same length, but the intervals are inversely proportional to the voltage difference.

Pulse length (tpU): adjustable with the setting *Volt pulse Min Dur* (tpUmin)

Pulse off interval (tsU): adjustable with the setting *Volt pulse off Intv*, and also dependent on settings *Voltage Diff Ov Ex* and *Voltage Diff Un Ex* as per Equation 326.

$$tsU = Volt\ pulse\ off\ Intv \cdot \left(1 - 0.325 \cdot \left(\Delta U - \frac{\left(+\Delta U\max + \left| -\Delta U\max \right| \right)}{2} \right) \right) \geq 0$$

(Equation 326)

ΔU	Measured voltage difference across the CB to be synchronized
+ΔUmax	Setting *Voltage Diff Ov Ex*
-ΔUmax	Setting *Voltage Diff Un Ex*

Reset of voltage raise and lower command pulses

The generated voltage raise and lower command pulses `RAISE_U` and `LOWER_U` are immediately reset if any of the following conditions is met.

- During matching of its own CB synchronization

- If AVR lower limit alarm AVR_ALM_LO is TRUE, it resets the voltage lower command LOWER_U. If AVR high limit alarm AVR_ALM_HI is TRUE, it resets the voltage raise command RAISE_U.
- If the output MATCH_OK is TRUE, the raise and lower commands are reset.
- If the voltage difference reaches the target value with a hysteresis band that is in the middle of the tolerance band specified by the settings *Voltage Diff Ov Ex* and *Voltage Diff Un Ex*, the raise and lower commands are reset.

- During matching of network CB synchronization
  - If either of the AVR limit alarms AVR_ALM_LO and AVR_ALM_HI is TRUE, it resets the voltage raise and lower commands.
  - When the generator is selected for fine tuning, if the voltage difference is within the limits of tolerance band specified by the settings *Voltage Diff Ov Ex* and *Voltage Diff Un Ex*, the raise and lower commands are reset.
  - When the generator is selected for coarse tuning, if the voltage difference reaches within the limits of *Coarse Volt Diff Ov* and *Coarse Volt Diff Un*, the raise and lower commands are reset.

Voltage rate of change tuning

When the control command parameter *Tune V and F match* is set to "Volt match rate", the function calculates the generator voltage matching rate (dU/dt). The calculated voltage matching rate is stored to the nonvolatile memory output VOLT_CHG_RTE and is available in the Monitored data view. Once stored, the value from the output VOLT_CHG_RTE can be used to set the setting *Volt rate of change*.

This tuned voltage matching rate proceeds as follows:

1. The generator voltage is adjusted until it lies in the range of 95...97% of the line voltage, then the adjusting pulse is discontinued.
2. Ten seconds after the first adjusting pulse, the voltage difference ΔU0 is measured, then a voltage raise command RAISE_U lasting 5 s is given. Ten seconds after the end of the pulse, the voltage difference ΔU is measured and dU/dt calculated according to the following formula:

$$\frac{dU}{dt} = \frac{\Delta U - \Delta U_0}{5}$$

(Equation 327)

3. With this dU/dt value, the generator voltage is brought back to approximately 96%.

Ten seconds later, the generator voltage is brought to approximately 100 % with the same dU/dt value. After ten seconds, dU/dt is calculated again and shown as monitored data output VOLT_CHG_RTE.

Frequency matching

Working range of the frequency matcher

No adjustment takes place between 1/3 and 2/3 of smax. The adjusting pulse is discontinued as soon as the slip passes through zero. The command length does not fall below a settable *Freq pulse Min Dur*. After an adjusting command, the system waits for the set *Freq pulse off Intv* so that the actual values can stabilize to the new set point.

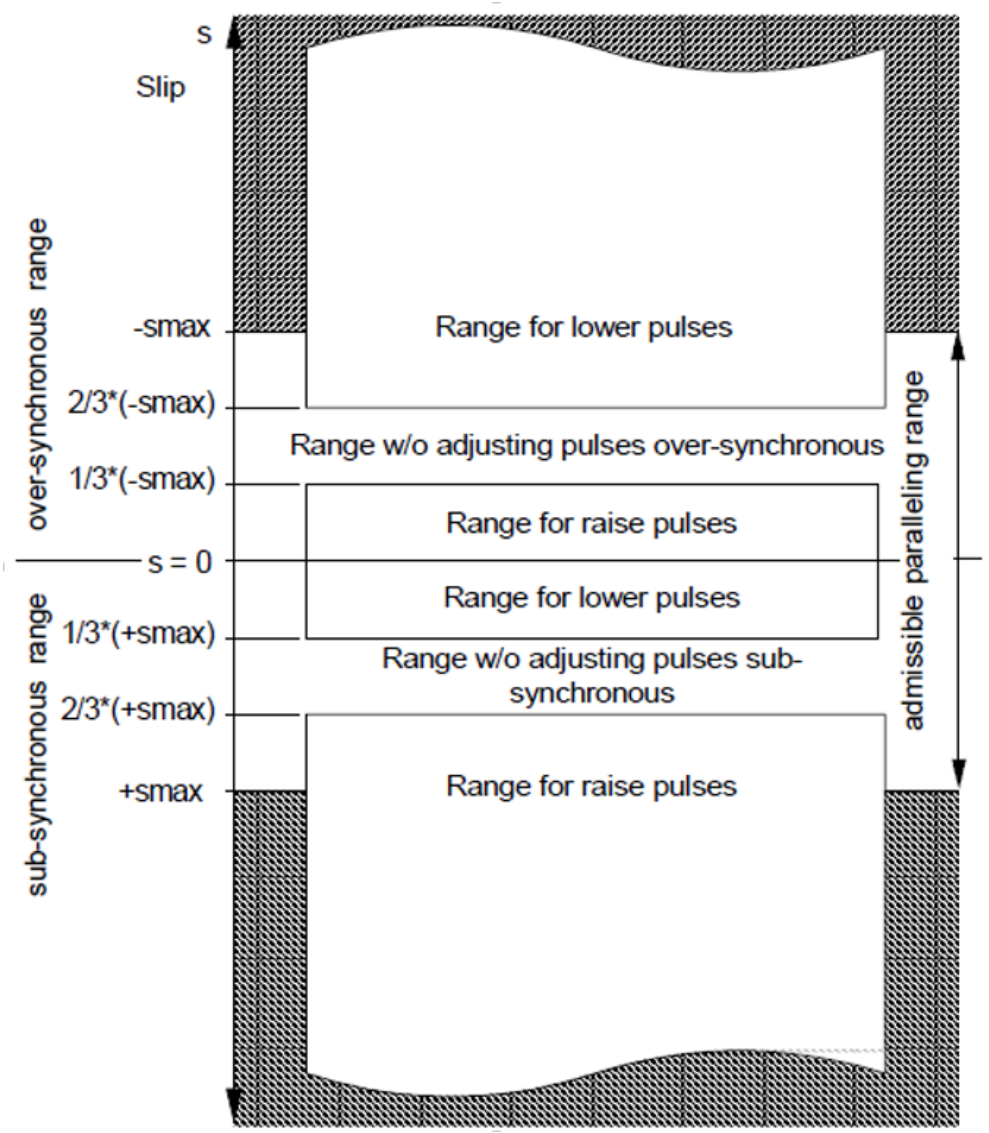

Figure 762: Working range of the frequency matcher

If *Auto Syn mode* is set to either "Semi-automatic synchronizing mode" or "Automatic synchronizing mode", the frequency raise or lower command pulses are generated from the function based on the frequency difference across the CB and governor response characteristics.

If the frequency difference (DF) is negative, the reference side frequency is greater than the running side frequency. So the frequency matching generates frequency raise command pulse `RAISE_F`.

If the frequency difference (DF) is positive, it means the reference side frequency is lower than the running side frequency. So the frequency matching generates frequency lower command pulse LOWER_F.

The length of the frequency raise and lower command pulses (tpf) and pulse off interval (tsf) are calculated based on the setting *Frequency match mode*.

Frequency matching in manual mode

If *Auto Syn mode* is set to "Manual mode", the frequency raise or lower command pulses are generated manually from the function's user commands.

If the command Gov frequency raise is set to “RAISE”, the function activates the frequency raise command pulse RAISE_F. If the command Gov frequency lower is set to “LOWER”, the function activates the frequency lower command pulse LOWER_F.

The length of these generated pulses tpf and pulse off interval tsf are based on the settings as: tpf = *Freq pulse Min Dur*; tsf = *Freq pulse off Intv*.

Frequency matching with variable command pulse lengths

When the setting *Frequency match mode* is set to "Variable Pulse", the frequency matching is done with variable command pulse lengths.

The frequency matcher issues a command with a length proportional to the current slip. The proportionality factor df/dt can be adapted to the governor. The frequency matcher aims at a value midway between the nearer slip limit and zero.

The adjusting frequency command pulse length tpf is calculated as

$$tpf = \frac{|\pm s| - \frac{|\pm s\max|}{2}}{\frac{df}{dt}}$$

(Equation 328)

s	Measured frequency difference across the CB to be synchronized
+smax	Setting *Freq Diff Ov Synch*
-smax	Setting *Freq Diff sub Synch*
df/dt	Setting *Freq rate of change*

The command length does not fall below a settable minimum value *Freq pulse Min Dur*. After an adjusting command, the system waits for the set *Freq pulse off Intv* (tsf) so that the actual values can stabilize to the new set point.

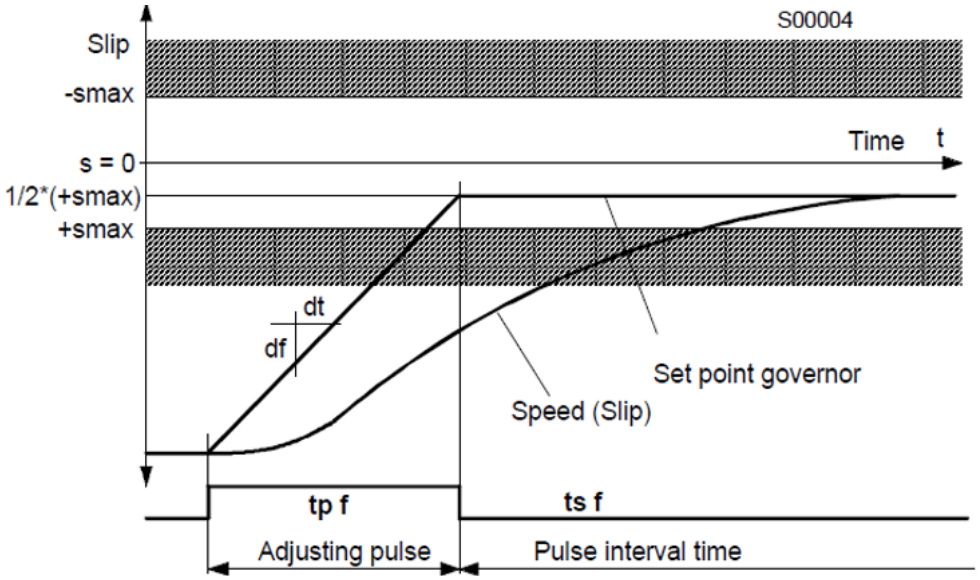

Figure 763: Frequency matching pulses generation with variable command pulse length

Frequency matching with variable command pulse off intervals

When the setting *Frequency match mode* is set to "Variable Interval", the frequency matching is done with variable command pulse off intervals.

The voltage match command pulses are now the same length, but the intervals are inversely proportional to the frequency slip.

Pulse length (tpf): adjustable with the setting *Freq pulse Min Dur* (tpfmin)

Pulse off interval (tsf): calculated as

$$tsf = \frac{1}{f_{Gen} - f_{Bus}} = \frac{1}{f_{Gen}|s|} \leq 30\ [Sec]$$

(Equation 329)

s Measured frequency slip across the CB to be synchronized

f_{Gen} Measured generator side frequency

f_{Bus} Measured bus side frequency

Reset of frequency raise and lower command pulses

The generated frequency raise and lower command pulses RAISE_F and LOWER_F are immediately reset if any of the following conditions is met.

- During matching of its own CB synchronization

- If governor lower limit alarm GOV_ALM_LO is TRUE, it resets the frequency lower command LOWER_F. If governor high limit alarm GOV_ALM_HI is TRUE, it resets the frequency raise command RAISE_F.
- If the output MATCH_OK is TRUE, the raise and lower commands are reset.
- If the frequency difference reaches the target value "± Smax/2" with the hysteresis band specified by the settings *Freq Diff Ov Synch* and *Freq Diff sub Synch*, the raise and lower commands are reset.

- During matching of network CB synchronization
  - If any of the governor limit alarms GOV_ALM_HI or GOV_ALM_LO is TRUE, the raise and lower commands are reset.
  - When the generator is selected for fine tuning, if the frequency difference reaches to target value "± Smax/2" with the hysteresis band specified by the settings *Freq Diff Ov Synch* and *Freq Diff sub Synch*, the raise and lower commands are reset.
  - When the generator is selected for coarse tuning, if the frequency difference reaches within the limits of *Coarse Freq Diff Ov* and *Coarse Freq Diff sub*, the raise and lower commands are reset.

When the matching is done for its own CB synchronization, the output MATCH_OK is activated if the measured voltage and frequency differences are within the set synchro check limits. The MATCH_INPRO output is active while the matching is in progress.

When the matching is done for network CB synchronization, the monitored data NTWMATCH_OK is activated if the network breaker voltage and frequency differences are within the set match limits. NTWMATCH_PRO is active while the matching is in progress. NTWMATCH_OK and NTWMATCH_PRO are available in the Monitored data view.

Frequency rate of change tuning

When the control command parameter *Tune V and F match* is set to "Freq match rate", the function calculates the generator frequency matching rate (dF/dt). The calculated frequency matching rate is stored to the nonvolatile memory output FREQ_CHG_RTE and is available in the Monitored data view. Once stored, the value from FREQ_CHG_RTE can be used to set the setting *Freq rate of change*.

This tune frequency matching rate proceeds as follows:

1. The slip is adjusted until this lies in the range of +1...+3%, then the adjusting pulse is discontinued.
2. Ten seconds after the first adjusting pulse, the slip s0 is measured, then a frequency raise command RAISE_F lasting 3 s is given. Ten seconds after the end of the pulse, the slip s is measured and df/dt is calculated according to the formula

$$\frac{df}{dt} = \frac{s - s0}{3}$$

(Equation 330)

3. With this df/dt value, the slip is brought back to approximately +2%.

Ten seconds later, the slip is brought to 0% with the same df/dt value. After ten seconds, df/dt is calculated again and shown as monitored data output FREQ_CHG_RTE.

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates all binary outputs, binary monitored data and resets the internal timers.

9.6.6 Application

A circuit breaker is used to connect two different power networks. It is essential to ensure that these power networks are synchronized before closing the circuit breaker, otherwise it may lead to disturbances in the power system, causing stress and damage to the connected equipment.

ASGCSYN controls the closing of the generator circuit breakers in power networks; it enables the closing after matching the voltage and frequency conditions to achieve synchronism. ASGCSYN also participates in matching voltage and frequency conditions for the network breaker synchronization.

ASGCSYN includes both the synchronization check function and the energizing function to allow closing when one side of the breaker is dead.

The participation of ASGCSYN in matching of voltage and frequency conditions for the network breaker synchronization is described via one of the typical application example as shown in Figure 764.

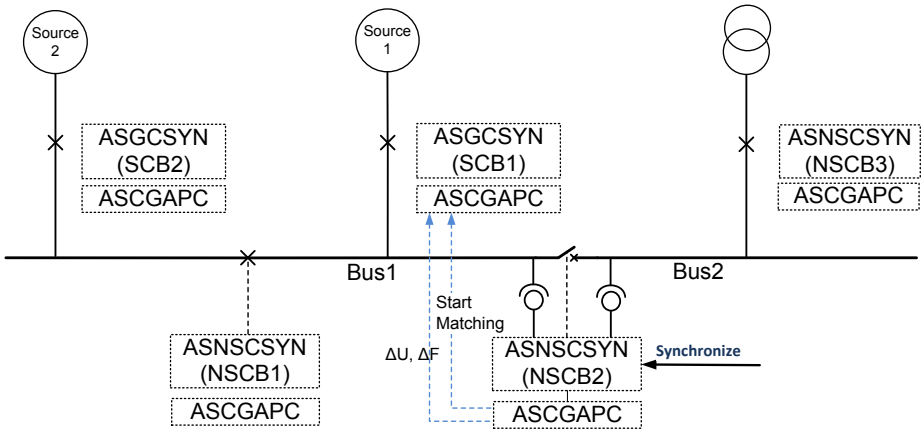

Figure 764: ASGCSYN participation in matching of V, F during network breaker synchronization

In this application example, breaker NSCB2 must be closed, so the synchronizing conditions between the Bus1 and Bus2 power systems are checked by the autosynchronizer for network breaker function ASNSCSYN. If the synchro check conditions are not met, then ASNSCSYN sends the auto synchronization request and voltage and frequency difference (ΔU, ΔF) between Bus1 and Bus2 to the autosynchronizer co-ordinator function ASCGAPC.

ASCGAPC transfers the voltage and frequency difference sent by ASNSCSYN to the ASCGAPC of the generator1 ASGCSYN function. It also sends permission to the generator to start matching the voltage and frequency. The generator's ASGCSYN function gives the raise or lower pulses to AVR and governor to raise or lower their voltage and frequency on Bus2. The matching process is carried out so that the voltage and frequency difference between Bus1 and Bus2 measured by ASNSCSYN reduces and comes within the synchro check limits. This satisfies the synchro check conditions for breaker NSCB2 which can then be synchronized by ASNSCSYN.

Voltage angle difference adjustment

In applications where the power transformer is located between the voltage measurement and the generator circuit breaker, the vector group connection gives phase difference to the voltages between the high- and low-voltage sides. The angle adjustment can be used to meet synchronism.

The vector group of the power transformer is defined with clock numbers, where the value of the hour pointer defines the low-voltage side phasor and the high-voltage side phasor is always fixed to the clock number 12, which is the same as zero. The angle between clock numbers is 30º. When comparing phase angles, the `U_BUS` input is always the reference. This means that when the Yd11 power transformer is used, the low-voltage side voltage phasor leads the high-voltage side phasor by 30º or lags by 330º. The rotation of the phasors is counterclockwise.

The generic rule is that a low-voltage side phasor lags the high-voltage side phasor by clock number · 30º. This is called angle difference adjustment and can be set for ASGCSYN with the *Phase shift* setting.

9.6.7 Signals

Table 1359: ASGCSYN Input signals

Name	Type	Default	Description
U3P1	SIGNAL	-	Three-phase voltages (generator side)
U3P2	SIGNAL	-	Three-phase voltages (bus side)
BLOCK	BOOLEAN	0=False	Blocking signal of the auto synchronization function
CL_COMMAND	BOOLEAN	0=False	External closing request
EXT_CHECK	BOOLEAN	0=False	External permissive check for CB close
BYPASS	BOOLEAN	0=False	Request to bypass synchronism check and voltage check
GCB_TEST	BOOLEAN	0=False	Circuit breaker test position status
Table continues on next page			

Name	Type	Default	Description
GCB_CLOSE	BOOLEAN	0=False	Circuit breaker close status
GCB_OPEN	BOOLEAN	0=False	Circuit breaker open status
ISO_A_CLOSE	BOOLEAN	0=False	Isolator A close status
ISO_B_CLOSE	BOOLEAN	0=False	Isolator B close status
MODE_GOV	Enum	1=Droop	Governor working mode
MODE_AVR	Enum	9=Droop	AVR working mode
DROOP_GOV	BOOLEAN	0=False	Governor droop mode status
DROOP_AVR	BOOLEAN	0=False	AVR droop mode status
GOV_ALM_HI	BOOLEAN	0=False	Governor alarm due to high limits
GOV_ALM_LO	BOOLEAN	0=False	Governor alarm due to low limits
AVR_ALM_HI	BOOLEAN	0=False	AVR alarm due to high limits
AVR_ALM_LO	BOOLEAN	0=False	AVR alarm due to low limits
DIFF_U_ASC1	FLOAT32	0.00	Network breaker voltage difference from ASCGAPC1
DIFF_F_ASC1	FLOAT32	0.000	Network breaker frequency difference from ASCGAPC1
ASC1_GEN_DAT	INT32	0	Integer weighted input data from ASCGAPC1

Table 1360: ASGCSYN Output signals

Name	Type	Description
SYNC_INPRO	BOOLEAN	Auto synchronization in progress
SYNC_OK	BOOLEAN	Systems in synchronism
MATCH_INPRO	BOOLEAN	Voltage and frequency matching in progress
MATCH_OK	BOOLEAN	Voltage and frequency of the systems matched
CLOSE_CB	BOOLEAN	CB close signal
CL_FAIL_AL	BOOLEAN	CB closing failed
CMD_FAIL_AL	BOOLEAN	CB closing request failed
LBDG	BOOLEAN	Live bus, dead generator
LBLG	BOOLEAN	Live bus, live generator
DBLG	BOOLEAN	Dead bus, live generator
DBDG	BOOLEAN	Dead bus, dead generator
CB_SELECTED	BOOLEAN	CB selected for synchronization
RAISE_U	BOOLEAN	Raise voltage pulse
LOWER_U	BOOLEAN	Lower voltage pulse
RAISE_F	BOOLEAN	Raise frequency pulse
LOWER_F	BOOLEAN	Lower frequency pulse
GOV_DROOP	BOOLEAN	Command for governor mode change to droop
AVR_DROOP	BOOLEAN	Command for AVR mode change to droop

Autosynchronizer for network breaker	ASNSCSYN	AUTOSYNCBT/T	25AUTOSYNCBT/T

9.7.2 Function block

Figure 765: Function block

9.7.3 Functionality

The autosynchronizer for network breaker function ASNSCSYN can be used for the controlled closing of a bus coupler or tie feeder circuit breaker (CB). ASNSCSYN includes the functionality of synchrocheck, energizing check and autosynchronization.

ASNSCSYN checks the power system conditions between both networks across the circuit breaker. The energizing check is used to check that at least one side is dead to ensure that closing can be done safely.

In case of a synchronous system, the closing command is issued after considering the function modes, essential checks, CB closing time and the paralleling conditions. In case of asynchronous systems, the function initiates the matching of voltage and frequency with the help of available generators through Autosynchronizer co-ordinator ASCGAPC.

The function contains a blocking functionality. It is possible to block function outputs.

9.7.4 Analog input configuration

ASNSCSYN has two analog group inputs which must be properly configured.

Table 1367: Analog inputs

Input	Description
U3P1	Three-phase voltages (Bus B side)
U3P2	Three-phase voltages (Bus A side)

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1368: Special conditions

Condition	Description
U3P1 and U3P2 connected to real measurements	When one voltage channel from the Bus B side is connected to channel 1 of U3P1 and one voltage channel from the Bus A side is connected to channel 1 of U3P2, the function can only work if UTVTR's VT connection settings on the Bus A and Bus B sides are similar.
	The function can work if one voltage channel from the Bus B side is connected to channel 1 of U3P1 and three voltage channels from the Bus A side are connected to U3P2.
	The function can work if one voltage channel from the Bus B side is connected to channel 1 of U3P1 and two voltage channels along with the residual voltage from the Bus A side are connected to U3P2.
	The function can work if three voltage channels from the Bus B side are connected to U3P1 and one voltage channel from the Bus A side is connected to channel 1 of U3P2.
	The function can work if two voltage channels along with the residual voltage from the Bus B side are connected to U3P1 and one voltage channel from the Bus A side is connected to channel 1 of U3P2.
Dissimilar VT connection settings for UTVTR on the Bus A and Bus B sides	The function requires that all three voltage channels or two voltage channels along with the residual voltage are connected to either U3P1 or U3P2.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

9.7.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of ASNSCSYN can be described with a module diagram. All the modules in the diagram are explained in the next sections.

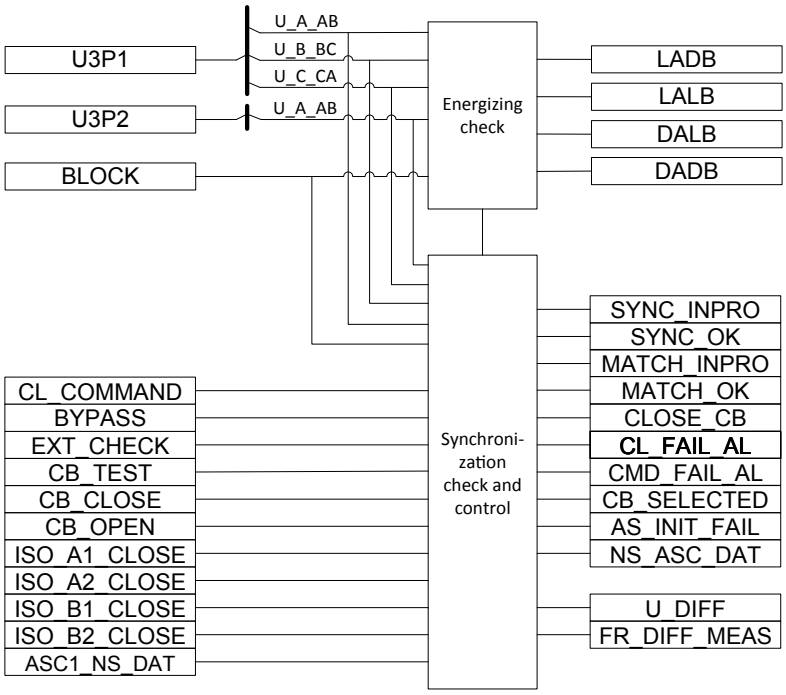

Figure 766: Functional module diagram

This function can operate either with the U_AB or U_A voltages. The selection of used voltages is defined with the *VT connection* setting of the line voltage general parameters.

Energizing check

The Energizing check module checks the energizing direction. Energizing is the situation where a dead network part is connected to an energized section of the network. The *Live dead mode* setting is used to set the energized condition of the bus section across the CB, that is, whether the bus section across the CB is live or dead.

When the *Live dead mode* setting parameter is set to "Command", then the energized condition (see Table 1369) of bus sections across the CB can be set using the *Live dead mode Ctl* control command only. If the *Live dead mode* setting parameter is not set to "Command", then the *Live dead mode* setting parameter is used to set the energized condition (see Table 1369) of the bus section across the CB.

Table 1369: Live dead mode of operation when switching can be carried out

Live dead mode	Description
Command	The *Live dead mode* setting uses *Live dead mode Ctl* control command.
Off	*Live dead mode* is set to "Off".
Both Dead	Both Bus A and Bus B de-energized
Live B, Dead A	Bus B energized and Bus A de-energized
Dead B, Live A	Bus B de-energized and Bus A energized
Dead A , B Any	Bus A de-energized and Bus B energized or de-energized
Dead B, A Any	Bus B de-energized and Bus A energized or de-energized
One Live, Dead	Bus A de-energized and Bus B energized or Bus B de-energized and Bus A energized
Not Both Live	Both Bus A and B de-energized or Bus A de-energized and Bus B energized or Bus B de-energized and Bus A energized

When the energizing direction corresponds to the settings, the situation has to be constant for a time set with the *Energizing time* setting before the CB closing is permitted. This time delay ensures that the dead side remains de-energized and that the situation is not caused by a temporary interference. If the conditions do not persist for a specified operation time, the timer is reset and the procedure is restarted when the conditions allow it. The CB does not close if the measured voltage on the live side is greater than the set value of *Max energizing V*.

The measured energized state is available as a monitored data value ENERG_STATE and as four function outputs `LADB` (live bus A and dead bus B), `LALB` (live bus A and live bus B), `DALB` (dead bus A and live bus B) and `DADB` (dead bus A and dead bus B), of which only one can be active at a time. The measured energized state indicates “Unknown” if at least one of the measured voltages is between the limits set with the dead and live setting parameters.

Synchronization check and control

The operation of Synchronization check and control modes can be described with a module diagram.

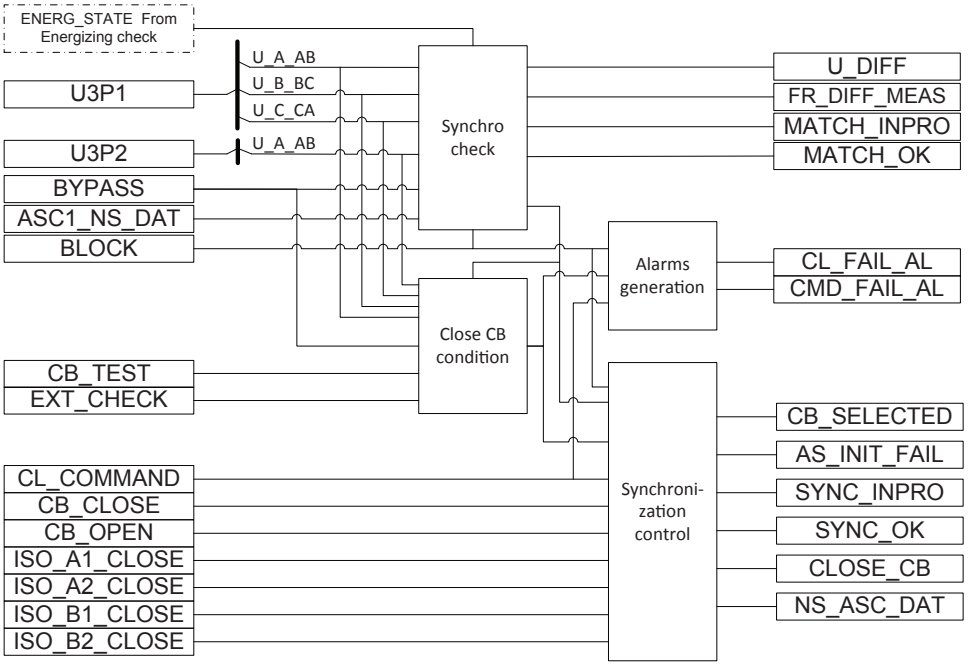

Figure 767: Module diagram for Synchronization check and control

Synchro check

The function measures the voltage difference U_DIFF_MEAS, frequency difference FR_DIFF_MEAS and phase angle difference PH_DIFF_MEAS between the two bus sides.

$$U_DIFF_MEAS = U_{BusA} - U_{BusB} + Voltage\ offset$$

(Equation 331)

U_{BusA}	Measured bus A side voltage
U_{BusB}	Measured bus B side voltage
Voltage offset	Setting *Voltage offset*

$$FR_DIFF_MEAS = f_{BusA} - f_{BusB} + Frequency\ offset$$

(Equation 332)

f_{BusA}	Measured bus A side frequency
f_{BusB}	Measured bus B side frequency
Frequency offset	Setting *Frequency offset*

$$PH_DIFF_MEAS = \angle U_{BusA} - \angle U_{BusB} + Phase\ shift$$

(Equation 333)

$\angle U_{BusA}$	Measured bus A side voltage phase angle
$\angle U_{BusB}$	Measured bus B side voltage phase angle
Phase shift	Setting *Phase shift*

The calculated voltage and phase angle difference values between these voltages are available as monitored data U_DIFF_MEAS and PH_DIFF_MEAS. The setting *Phase shift* is used to compensate the angle shift caused if a power transformer is located between the voltage measurements.

The synchronism condition and CB closing instance are checked according to several criteria.

- The measured bus A and bus B voltages are higher than the set value of *Live bus voltage* (ENERG_STATE equals “Both Live”).
- The measured bus A and bus B frequencies are both within the range of 95...105 % of the value of the nominal frequency (f_n).
- The measured bus A and bus B voltages are lower than the set value of *Max energizing V*.

When the *Synchrocheck mode* setting parameter is set to "Command", then the “Synchronous”, “Asynchronous” or “Off” condition of the network across the CB can be set using the *SynchroChk Mod Ctl* control command only. If the *Synchrocheck mode* setting parameter is not set to "Command", then the *Synchrocheck mode* setting parameter is used to set the “Synchronous”, “Asynchronous” or “Off” condition of the network across the CB.

Some additional conditions must be fulfilled according to the set *Synchrocheck mode*.

Table 1370: Additional conditions for the Synchro check

Measurements	*Synchrocheck mode*	
	“Synchronous”	“Asynchronous”
U_DIFF_MEAS	< 0.01 x Nominal voltage (U_n)	< Difference voltage
PH_DIFF_MEAS	< 5 degree	< Difference angle
FR_DIFF_MEAS	< 0.001 x Nominal frequency (f_n)	< Frequency difference
Estimated closing angle	N/A	< Difference angle

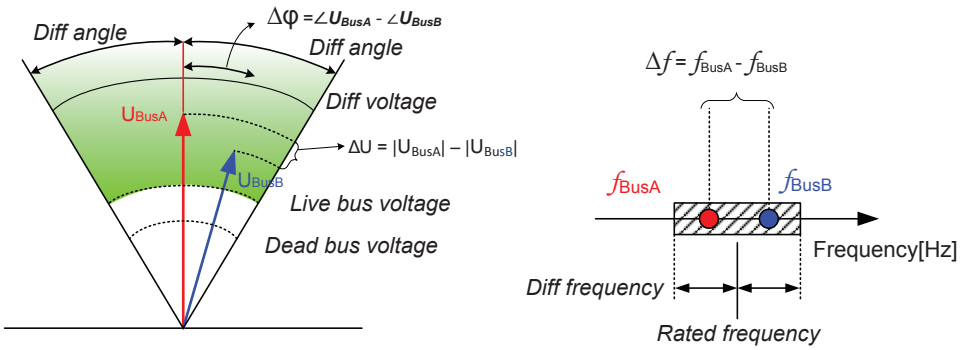

Figure 768: Conditions to be fulfilled when detecting synchronism between systems

When the measured difference of voltages (U_DIFF_MEAS) and measured difference in frequency (FR_DIFF_MEAS) are within the synchro check limits given in Table 1370, the output MATCH_OK is activated. The output MATCH_INPRO is activated when the voltage and frequency matching is in progress. The matching status input is received via ASC1_NS_DAT signal from ASCGAPC.

When the frequency, phase angle and voltage conditions are fulfilled, the duration of the synchronism conditions is checked to ensure that they are still met when the condition is determined on the basis of the measured frequency and phase difference. Depending on the CB and the closing system, the delay between the closing signal and the CB closing is about 50...250 ms. The selected *Closing time of CB* informs the function how long the conditions have to persist. The value covers both the CB closing delay and the output type dependent delay. The synchro check function compensates for the measured slip frequency and the CB closing delay.

The closing angle advance is calculated continuously:

$$Closing\ angle = \left| (\angle U_{BusA} - \angle U_{BusB})° + \left((f_{BusA} - f_{BusB}) \cdot \left(\frac{TCB}{1000} \right) \cdot 360° \right) \right|$$

(Equation 334)

$\angle U_{BusA}$ Measured bus A voltage phase angle

$\angle U_{BusB}$ Measured bus B voltage phase angle

TCB Parameter *Closing time of CB* to be set as in Equation 335

$$TCB = t_{CB} + T_{PL} + x$$

(Equation 335)

t_{CB} CB closing delay in ms

T_{PL} Output type dependent delay in ms (see Table 1371)

x Hardware delays between the protection relay and CB in ms; delays due to, for example, auxiliary relays and contactors, if used

Table 1371: Typical delays for different output types

Output type	Recommended value for T_{PL}	
	Both Bus side voltage measurements: Non-Adaptive or Both Bus side voltage measurements: Adaptive.	Any one of the Bus side voltage measurement: Adaptive, The other Bus side voltage measurement: Non Adaptive
Semiconductor output (SPO)	16 ms	7 ms
Mechanical relay output (POSP, PODP)	23 ms	13 ms

The *Minimum Syn time* setting defines the minimum time for which synchro check conditions must be simultaneously fulfilled.

The frequency slip acceleration (ds/dt) SLIP_ACCL is the average value of frequency slip difference (Δs) calculated over a time period of 0.5 s.

$$Frequency\ slip(s) = \frac{(f_{BusA} - f_{BusB})}{f_{BusA}}$$

(Equation 336)

The measured bus A voltage (U_{BusA}), bus A frequency (f_{BusA}), measured bus B voltage (U_{BusB}), bus B frequency (f_{BusB}), and phase angle difference (PH_DIFF_MEAS) values between the two sides of the CB are available as monitored data values.

If the measured U_DIFF_MEAS does not fulfill the condition given in Table 1370 and thus synchronism is prevented, the monitored data U_DIFF_SYNC is activated. Similarly PH_DIF_SYNC and FR_DIFF_SYNC are activated based on the measurements PH_DIFF_MEAS and FR_DIFF_MEAS, respectively. These monitored data values are updated only when the setting *Synchrocheck mode* is set to either "Synchronous" or "Asynchronous" and the measured ENERG_STATE is "Both Live". The outputs `U_DIFF` and `FR_DIFF_MEAS` give the calculated phase-to-phase voltage difference and the frequency difference values, respectively. These `U_DIFF` and `FR_DIFF_MEAS` outputs are sent to ASCGAPC.

The monitored data ACT_ASC_CB indicates the ASCGAPC CB number. The CB number of the protection relay's ASCGAPC is received via `ASC1_NS_DAT` signal.

Close CB condition

If *Synchrocheck mode* is set to "Asynchronous", the CB close command is generated as explained below.

From the frequency slip s, the acceleration ds/dt, the bus frequency FR_BUS_MEAS (f_{Bus}) and the set *Closing time of CB*, the function calculates the necessary lead angle (α_{Lead}) by which the close CB command is shifted forward in time so that the main contacts close on phase coincidence.

$$\alpha_{Lead} = \left(360 \cdot f_{BusA} \cdot \left(s + \frac{\frac{TCB}{2} \cdot \frac{ds}{dt}}{1000} \right) \cdot \frac{TCB}{1000} \right)$$

(Equation 337)

f_{BusA} Bus A side frequency

s Frequency slip

ds/dt Frequency slip acceleration

TCB Setting *Closing time of CB*

The breaker closes only when the measured phase-angle difference across the breaker (PH_DIFF_MEAS) equals the calculated lead angle (α_{Lead}) and all synchronization check conditions are fulfilled.

If *Synchrocheck mode* is set to "Synchronous", a zero-passage of the phase-angle difference is not necessary and CB closing is permitted as soon as all the synchrocheck conditions are fulfilled. Similarly for dead bus synchronization, CB closing is possible when the energizing check permits.

The CB closing signal can be blocked based on the inputs CB_TEST and EXT_CHECK and IED test mode as described in Table 1372. This blocking status is available in the monitored data CB_CL_BLKD.

Table 1372: CB_CL_BLKD status based on the inputs

IED test mode	Inputs		Monitored data
	CB_TEST	EXT_CHECK	CB_CL_BLKD
TRUE	TRUE	TRUE	1(“Unblocked”)
FALSE	FALSE		
TRUE	TRUE	FALSE	2(“Ext check fail”)
FALSE	FALSE		
TRUE	FALSE	N/A	3(“IED Test, CB Service”)
FALSE	TRUE	N/A	4(“IED Service, CB Test”)

ASNSCSYN can be set to the bypass mode by setting the parameters *Synchrocheck mode* and *Live dead mode* to "Off" or, alternatively, by activating the BYPASS input. In the bypass mode, the closing conditions are always considered to be fulfilled by ASNSCSYN.

Synchronization control

The general bus bar arrangement for a non-source CB bus is shown in Figure 769. The bus to which the generator is connected is determined based on the CB and isolator position inputs (CB_OPEN, CB_CLOSE, ISO_A1_CLOSE, ISO_A2_CLOSE, ISO_B1_CLOSE and ISO_B2_CLOSE). The generator's bus connection status is shared with ASCGAPCs as part of the NS_ASC_DAT output.

The equipment which is capable of voltage and frequency adjustment, that is, the generator, is referred to as source and the rest as non-source. Hence the generator's CB is referred to as source CB and the bus coupler or tie feeder CB as non-source CB.

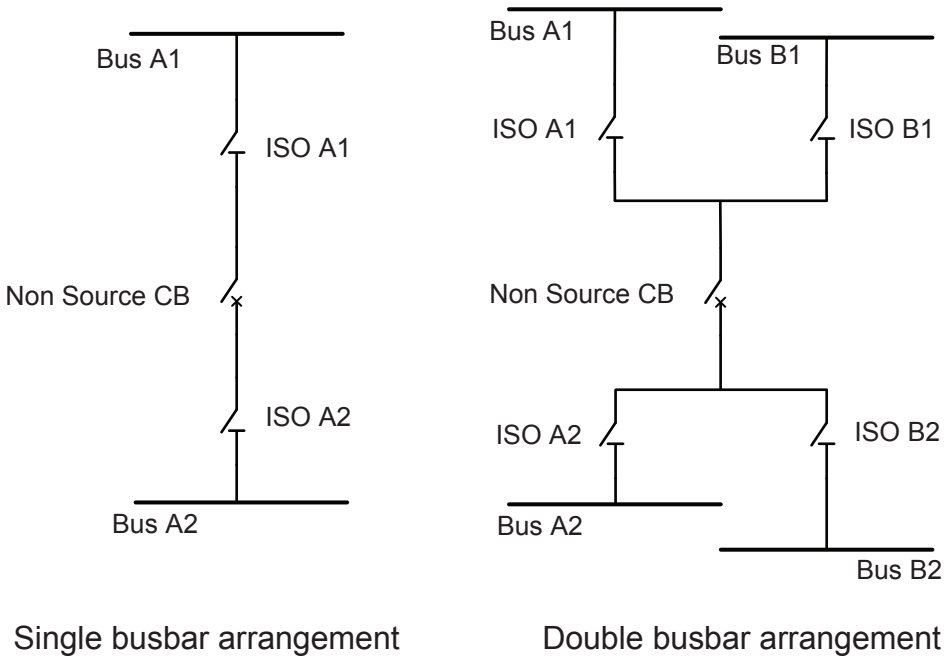

Figure 769: Different busbar arrangement for a non-source CB

Auto synchronization mode

In this mode, the closing signal is delivered if either the command *Synchronize CB* or the input CL_COMMAND is set to TRUE. The device should be in local mode if initiation *Synchronize CB* is given for synchronization.

If the setting *Auto Syn mode* is set as "Manual mode" or "Semi-automatic synchronising mode", the additional command Manual CB release should be active for the closing signal CLOSE_CB to be activated. If the setting *Auto Syn mode* is set as "Automatic synchronising mode", no additional command is required to activate the closing signal CLOSE_CB.

In this auto synchronization mode, once all the closing conditions are satisfied within the set *Maximum Syn time*, the outputs SYNC_OK and CLOSE_CB become TRUE and

remain active as long as the closing conditions are fulfilled. If *Multiple command* is set to "Off", then only CLOSE_CB outputs are delivered once for each activated input signal as shown in Figure 770. If *Multiple command* is set to "On", then CLOSE_CB outputs are delivered each time the conditions are satisfied as shown in Figure 771. In this auto synchronization mode, once all the closing conditions are satisfied within the set *Maximum Syn time*, the outputs SYNC_OK and CLOSE_CB become TRUE. These outputs remain active as long as the respective conditions are fulfilled. If *Multiple command* is set to "Off", then only CLOSE_CB outputs are delivered only once for each activated input signal as shown in Figure 770. If *Multiple command* is set to "On", then CLOSE_CB outputs are delivered each time the conditions are satisfied as shown in Figure 771.

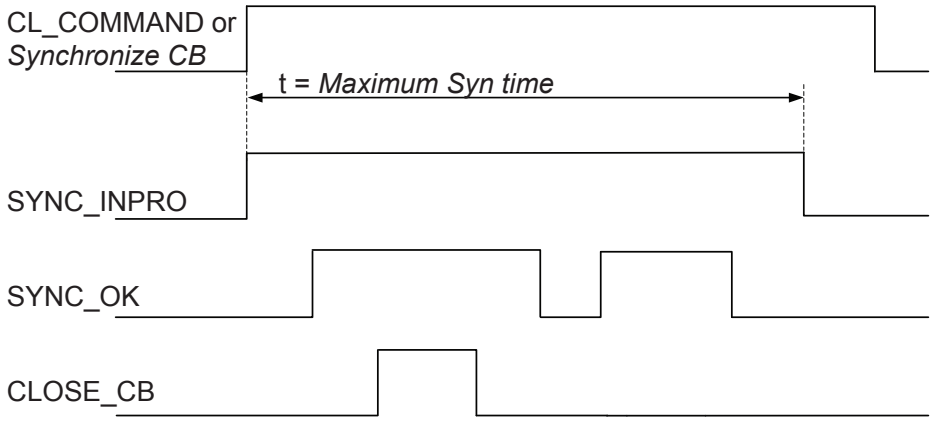

Figure 770: Determination of closing signal CLOSE_CB when Multiple command is set to "Off"

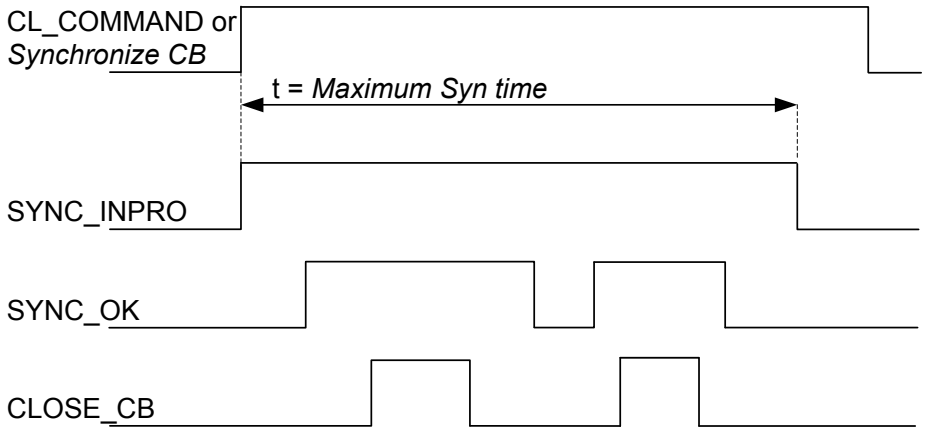

Figure 771: Determination of closing signal CLOSE_CB when Multiple command is set to "On"

The SYNC_INPRO output is active when the close command (CL_COMMAND or *Synchronize CB*) is in progress and it is reset when the close command is reset or

Maximum Syn time has elapsed. In this automatic mode the closing signal CLOSE_CB is activated automatically once all the closing conditions are satisfied.

If the closing conditions are fulfilled during a permitted check time set with *Maximum Syn time*, ASNSCSYN gives synchro check permission to Circuit-breaker control CBXCBR after the closing command signal is delivered. The simplified configuration block diagram of ASNSCSYN with CLOSE_CB to CBXCBR is as shown in Figure 772.

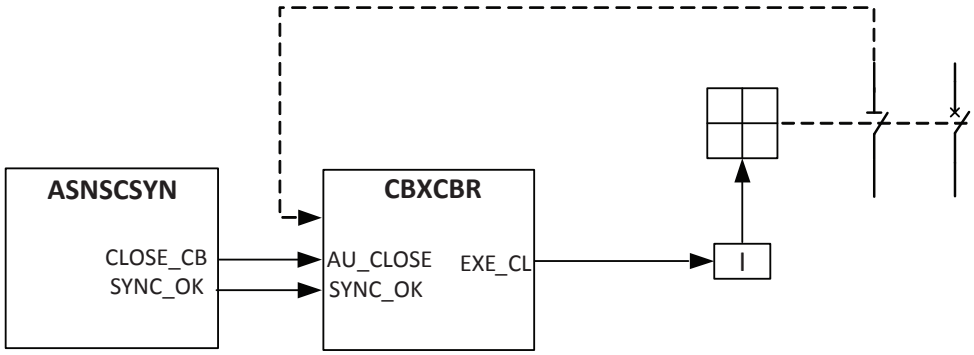

Figure 772: Simplified configuration block diagram of ASNSCSYN in auto synchronization mode operation

Alarms generation

In auto synchronization control mode, the closing command generation is activated by either command input CL_COMMAND or by command parameter *Synchronize CB*.

After the closing command activation, if the conditions for closing CB are not fulfilled within the set time of *Maximum Syn time*, a failed closing attempt alarm is given. The CL_FAIL_AL alarm output signal is pulse-shaped and the pulse length is 500 ms.

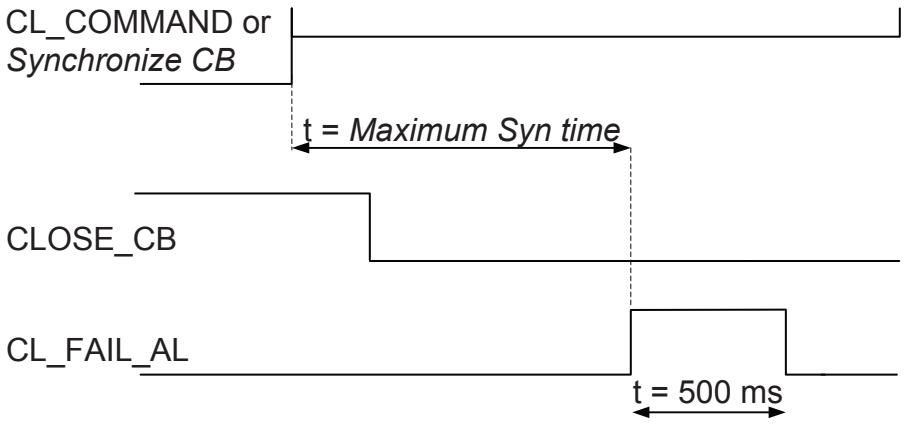

Figure 773: Determination of checking time for closing

CB closing is permitted during *Maximum Syn time*, starting from the moment the close command is activated. The close command must be active while the closing conditions are fulfilled, otherwise the procedure is cancelled. If the closing conditions are fulfilled during *Maximum Syn time*, a closing pulse output is delivered to the CB. If the closing conditions are not fulfilled during the checking time, the alarm CL_FAIL_AL is activated as an indication of a failed closing attempt. The closing pulse is not delivered if the closing conditions become valid after *Maximum Syn time* has elapsed. The closing pulse is delivered only once for each activated close command, and a new closing command sequence cannot be started until the close command is reset and reactivated.

CBXCBR receives information about the CB status and thus is able to adjust the command signal to be delivered to ASNSCSYN. If the closing command is active longer than necessary, the CMD_FAIL_AL alarm output is activated. To avoid unnecessary alarms, the maximum length of the closing command signal should be below *Maximum Syn time* + 5 s.

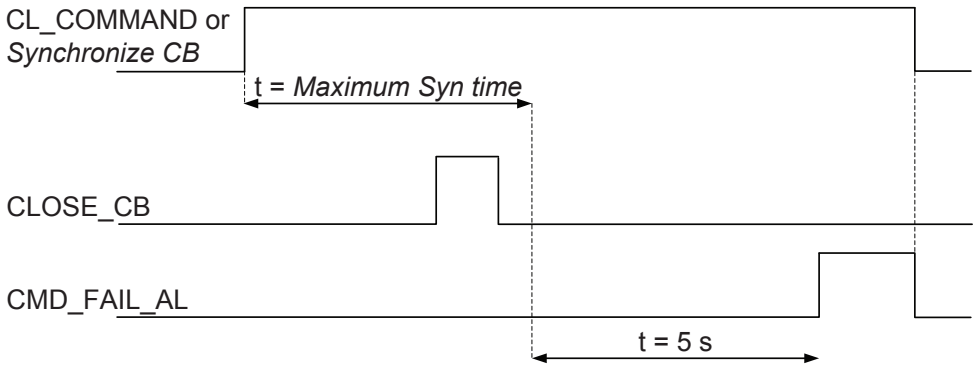

Figure 774: Determination of the alarm limit for a still-active command signal

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates all binary outputs and resets the internal timers.

9.7.6 Application

A circuit breaker is used to connect two different power networks. It is essential to ensure that these power networks are synchronized before closing the CB, otherwise it may lead to disturbances in the power system, causing stress and damage to the connected equipment.

ASNSCSYN can be used for the synchronization of any bus coupler or tie feeder CB. It checks for the synchronization conditions across the CB and releases the CB closing command. If these conditions are not fulfilled, the sources in the power network connected across this bus coupler or tie feeder CB have to change their operating points to meet the requirements. This is achieved with Autosynchronizer co-ordinator ASCGAPC available with the source (ASGCSYN) function and non-source (ASNSCSYN) function.

ASCGAPC assists in the participating sources selection based on the network topology and interacts with the sources to initiate the voltage and frequency matching for the bus coupler or tie feeder CB to be synchronized. When any non-source circuit breaker (NSCB) is selected for synchronization, a synchronization procedure is started. ASCGAPC located in the NSCB relay starts communicating with ASCGAPCs of possible source circuit breaker (SCB) relays for matching the voltage and frequency difference. Both ASCGAPCs pass the required information to the participating sources. A non-source CB synchronization is described with one typical example in Figure 775.

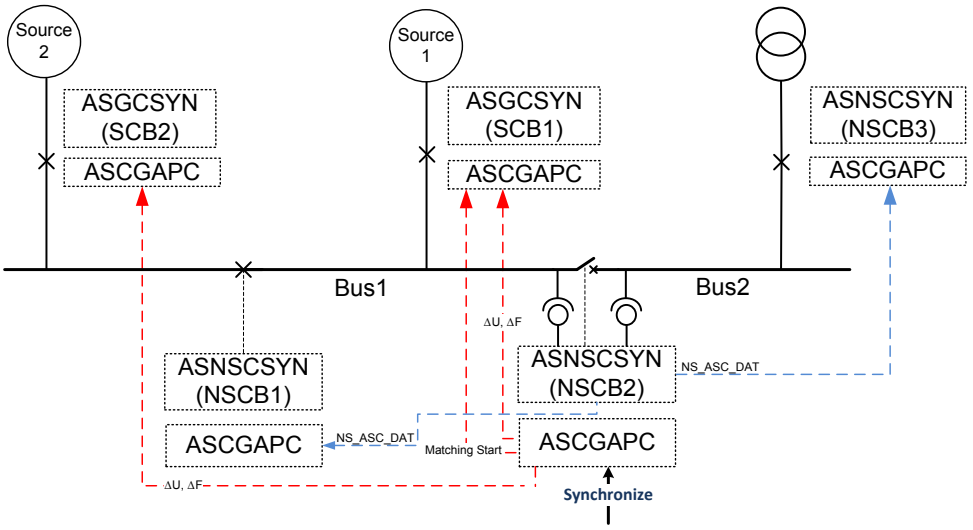

Figure 775: NSCB2 synchronization

In this application example, breaker NSCB2 must be closed. So the synchronizing conditions between Bus1 and Bus2 are checked by ASNSCSYN. ASNSCSYN sends the auto synchronization request and the voltage and frequency difference (ΔU, ΔF) between Bus1 and Bus2 to ASCGAPC.

ASCGAPC transfers the voltage and frequency difference sent by ASNSCSYN to the selected ASCGAPC function of source 1 ASGCSYN function. It also sends the permission to the source to start matching the voltage and frequency. The matching process is carried out so that the voltage and frequency difference between Bus1 and Bus2 measured by ASNSCSYN reduces and comes within the synchro check limits. This satisfies the synchro check conditions for breaker NSCB2 which can then be synchronized by ASNSCSYN. Similarly, the synchronization of NSCB1 and NSCB3 having ASCGAPC is done as shown in Figure 776 and Figure 777.

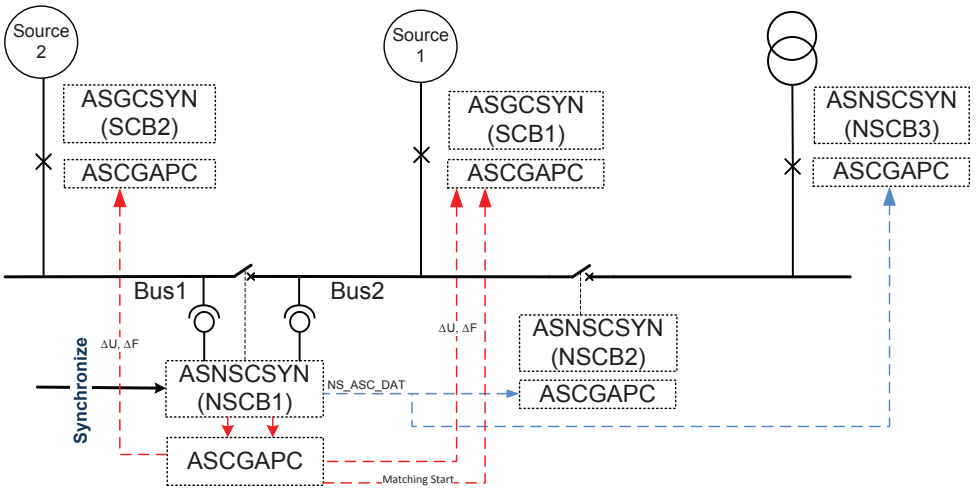

Figure 776: NSCB1 synchronization

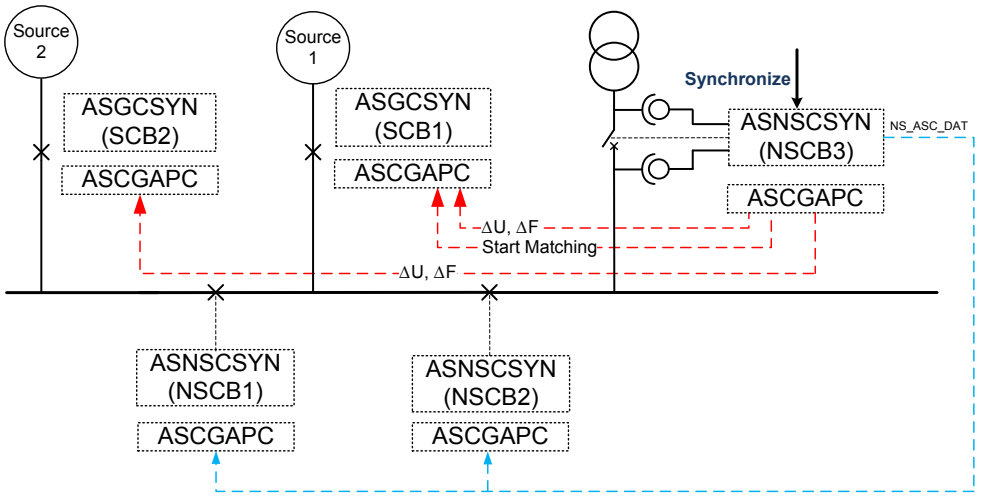

Figure 777: NSCB3 synchronization

This function supports manual, semi-automatic and automatic synchronizing, which adds flexibility in the user operation. In the manual synchronization, the matching is done manually and the closing command is released from the function on user request. In the semi-automatic synchronization, the matching is done automatically with coordination from ASCGAPC and the closing command is released from the function on user request. In the automatic synchronization, the matching is done automatically with coordination from ASCGAPC and the subsequent closing command is released from the function without user intervention.

This function output can be used to block the other functions in the power network to ensure that only one CB is synchronized at a time. This logic has to be developed outside the function block.

Voltage angle difference adjustment

In applications where the power transformer is located between the voltage measurement and the CB, the vector group connection gives phase difference to the voltages between the high- and low-voltage sides. The angle adjustment can be used to meet synchronism.

The vector group of the power transformer is defined with clock numbers, where the value of the hour pointer defines the low-voltage-side phasor and the high-voltage-side phasor is always fixed to the clock number 12, which is the same as zero. The angle between clock numbers is 30°. When comparing phase angles, the U_BUS_A input is always the reference. This means that when the Yd11 power transformer is used, the low-voltage-side voltage phasor leads the high-voltage-side phasor by 30º or lags by 330º. The rotation of the phasors is counterclockwise.

The generic rule is that a low-voltage-side phasor lags the high-voltage-side phasor by clock number · 30º. This is called angle difference adjustment and can be set for ASNSCSYN with the *Phase shift* setting.

9.7.7 Signals

Table 1373: ASNSCSYN Input signals

Name	Type	Default	Description
U3P1	SIGNAL	-	Three-phase voltages (Bus B side)
U3P2	SIGNAL	-	Three-phase voltages (Bus A side)
BLOCK	BOOLEAN	0=False	Blocking signal of the auto synchronization function
BYPASS	BOOLEAN	0=False	Bypass for synchronization and closing conditions check
CL_COMMAND	BOOLEAN	0=False	External closing request
EXT_CHECK	BOOLEAN	0=False	External permissive check for CB close
CB_TEST	BOOLEAN	0=False	Circuit breaker test position status
CB_OPEN	BOOLEAN	0=False	Circuit breaker open status
CB_CLOSE	BOOLEAN	0=False	Circuit breaker close status
ISO_A1_CLOSE	BOOLEAN	0=False	Isolator A1 close status
ISO_B1_CLOSE	BOOLEAN	0=False	Isolator B1 close status
ISO_A2_CLOSE	BOOLEAN	0=False	Isolator A2 close status
ISO_B2_CLOSE	BOOLEAN	0=False	Isolator B2 close status
ASC1_NS_DAT	INT32	0	Coded integer data from ASCGAPC1

Table 1374: ASNSCSYN Output signals

Name	Type	Description
CL_FAIL_AL	BOOLEAN	CB closing failed
CMD_FAIL_AL	BOOLEAN	CB closing request failed
AS_INIT_FAIL	BOOLEAN	Synchronization not initiated

Table continues on next page

Name	Type	Description
CLOSE_CB	BOOLEAN	CB close signal
SYNC_OK	BOOLEAN	Systems in synchronism
MATCH_OK	BOOLEAN	Voltage and frequency of the systems matched
MATCH_INPRO	BOOLEAN	Voltage and frequency matching in progress
SYNC_INPRO	BOOLEAN	Synchronization in progress
LADB	BOOLEAN	Live bus A, dead bus B
LALB	BOOLEAN	Live bus A, live bus B
DALB	BOOLEAN	Dead bus A, live bus B
DADB	BOOLEAN	Dead bus A, dead bus B
U_DIFF	FLOAT32	Line voltage difference across synchronizing CB
FR_DIFF_MEAS	FLOAT32	Calculated voltage frequency difference
CB_SELECTED	BOOLEAN	CB selected for synchronization
NS_ASC_DAT	INT32	Integer weighted output data to ASCGAPC

9.7.8 Settings

Table 1375: ASNSCSYN Group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Live dead mode	-2=Command -1=Off 1=Both Dead 2=Live B, Dead A 3=Dead B, Live A 4=Dead A, B Any 5=Dead B, A Any 6=One Live, Dead 7=Not Both Live			1=Both Dead	Live dead mode

Autosynchronizer co-ordinator	ASCGAPC	AUTOSYNC	25AUTOSYNC

9.8.2 Function block

Figure 778: Function block

9.8.3 Functionality

The autosynchronizer co-ordinator function ASCGAPC can be used as a coordinator for the synchronization of any bus coupler or grid transformer incomer breakers in the power network. ASCGAPC must be present on the relay configuration together with the bus coupler or grid transformer autosynchronization functions (ASNSCSYN) as well as in generator autosynchronization functions (ASGCSYN).

ASCGAPC performs the network topology determination to identify the subnetworks within the whole network. It routes the voltage and frequency difference values from the synchronizing CB to all the generator sources. It also identifies the sources which are eligible to participate in matching the voltage and frequency difference. ASCGAPC allows to select sources for synchronization and gives permission for matching to the selected sources after essential checks.

ASCGAPC allows autosynchronization of only one non-source circuit breaker at a time. It also provides the voltage and frequency matching status for the synchronization in progress.

9.8.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of ASCGAPC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

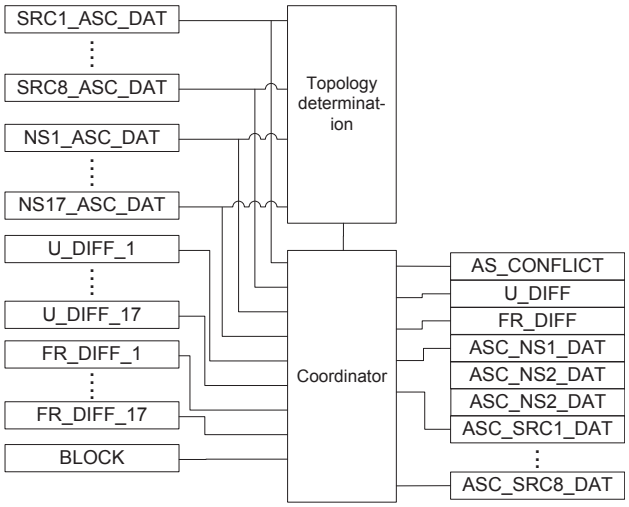

Figure 779: Functional module diagram

Topology determination

This module identifies the group of busbars, power sources and network circuit breakers electrically connected together and calculates the subnetwork number for each group. It also identifies the sources and buses which are electrically connected to the external network. The maximum network configuration considered is 8 sources, 8 source CBs (SCB), 15 busbars and 17 non-source CBs (NSCB).

The equipment which is capable of voltage and frequency adjustment, that is, the generator, is referred to as source and the rest as non-source. Hence the generator CB is referred to as source CB and the bus

coupler or tie feeder CB as non-source CB. Also, any bus or system, external to this network is referred to as grid.

The general busbar arrangement across any NSCB is shown in Figure 780. For each NSCB, the numbers for Bus A1, Bus A2, Bus B1 and Bus B2 must be set. These bus numbers for non-source CB 1 are set in *NonSrc1 bus A1 Num*, *NonSrc1 bus A2 Num*, *NonSrc1 bus B1 Num* and *NonSrc1 bus B2 Num*, respectively. Each of these settings can be set to values "Bus 1"..."Bus 15" or to "Not Configured".

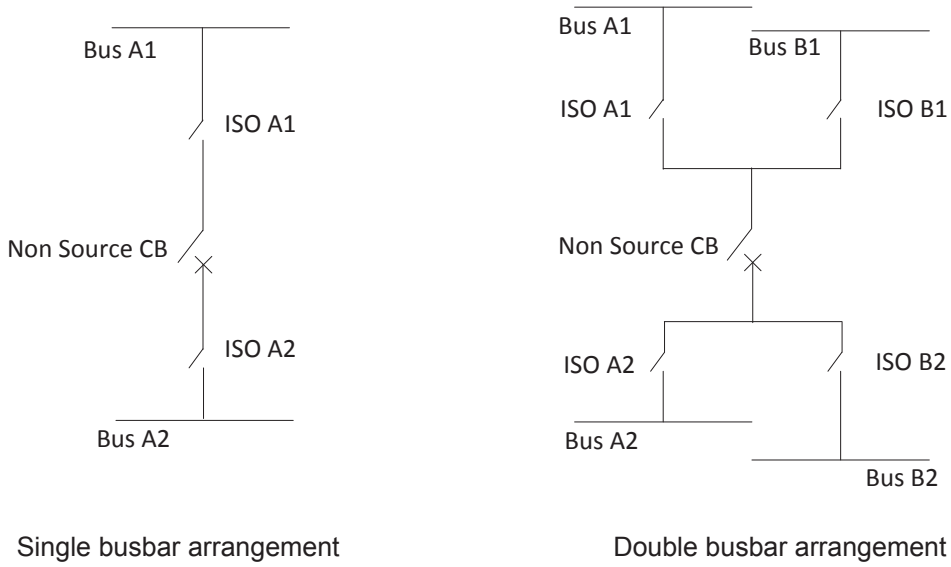

Figure 780: Different busbar arrangement across any non-source CB

The general busbar arrangement across any SCB is shown in Figure 781. For each source CB, the Bus A and Bus B numbers are to be set. These bus numbers for source CB 1 are set in *Src1 bus A Num* and *Src1 bus B Num*, respectively. Each of these settings can be set to values "Bus 1"..."Bus 15" or to "Not Configured".

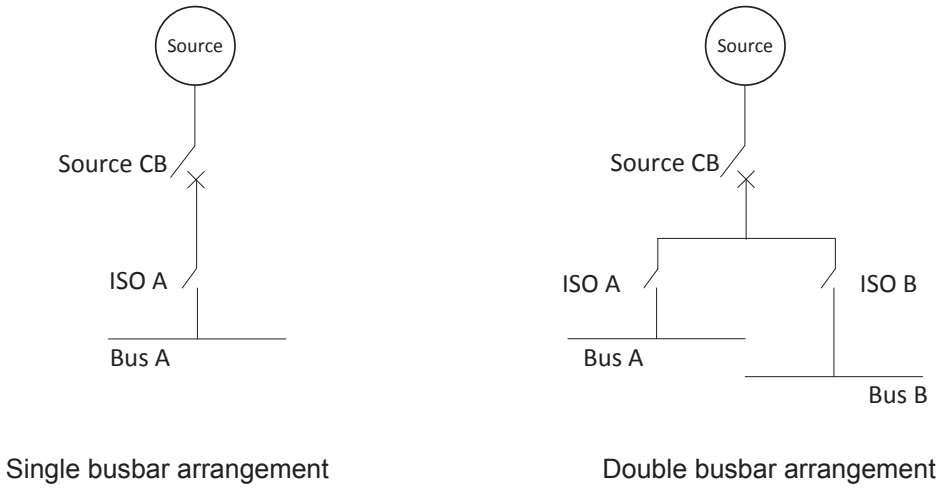

Figure 781: Different busbar arrangement for any source CB

The subnetwork group identification is based on the set busbar arrangement across each CB and the connection status input received from the corresponding ASGCSYN via SRC1_ASC_DAT...SRC8_ASC_DAT or from the corresponding ASNSCSYN via signals NS1_ASC_DAT...NS17_ASC_DAT.

An example of the subnetwork group identification is shown in Figure 782. Since NSCB 2 connects bus bar 1 and bus bar 2, then setting *NonSrc2 bus A1 Num* is set to "Bus 1" and *NonSrc2 bus A2 Num* is set as "Bus 2". Based on the bus connection status received via the input NS2_ASC_DAT, this module determines that Bus 1, Bus 2 and NSCB 2 are electrically connected. Similarly for SCB 2, *Src2 bus A Num* is set as "Bus 2" and the source CB closed status input is received via SRC1_ASC_DAT. So SCB 2 is electrically connected to Bus 2. Hence it is determined that SCB 2, Bus 2, Bus 1 and NSCB 2 are electrically connected to each other.

Two subnetworks are identified in Figure 782. The first comprises Bus 1, Bus 2, NSCB 1, NSCB 2, SCB 2 and source 2. The second comprises Bus 3, Bus 4, NSCB 4, SCB 3 and source 3. Each network group is assigned a subnetwork number which is the lowest bus bar number in the subgroup. Hence the first group is assigned subnetwork number 1 and the second group is assigned subnetwork number 3.

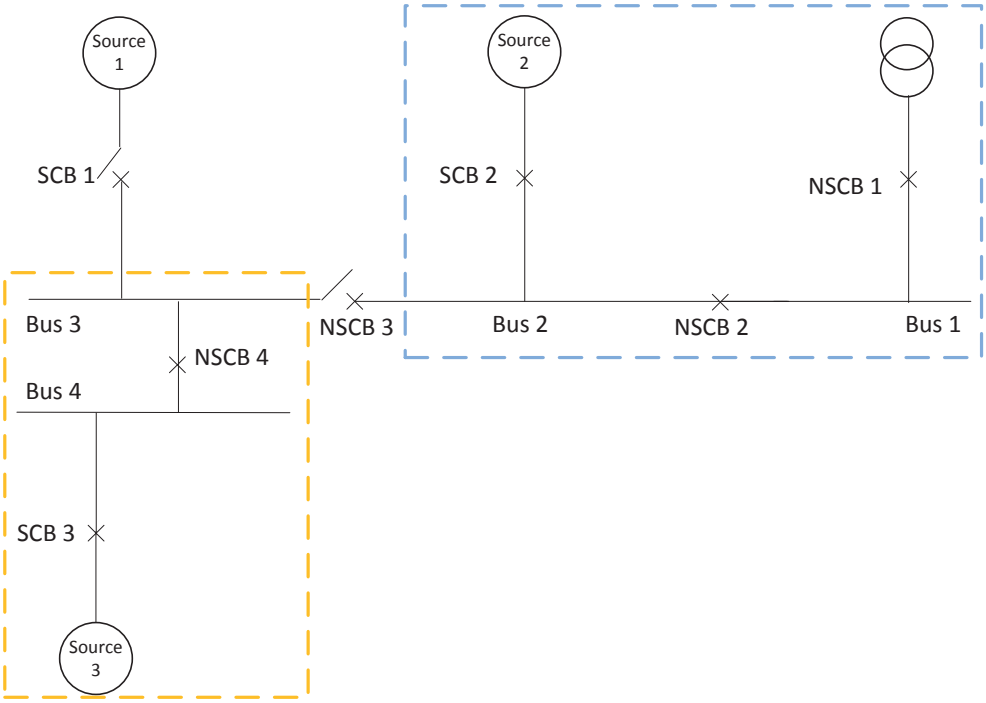

Figure 782: An example of subnetwork group identification

Table 1381: ASCGAPC settings of NSCB1 for given example

Settings	Suggested values	Description
ASC CB Num1	Non source CB 1	ASC1 host circuit breaker number 1
Number of sources	3	Total number of sources present in the system
Number of NonSrc CB	4	Number of bus coupler or grid transformer CB in the system
Src1 bus A Num	Bus 3	Source1 CB connected bus A number
Src2 bus A Num	Bus 2	Source1 CB connected bus A number
Src3 bus A Num	Bus 4	Source1 CB connected bus A number
NonSrc1 bus A1 Num	Bus 1	Non-source CB1 connected bus A1 number
NonSrc1 bus A2 Num	Grid	Non-source CB1 connected bus A2 number
NonSrc2 bus A1 Num	Bus 1	Non-source CB2 connected bus A1 number
NonSrc2 bus A2 Num	Bus 2	Non-source CB2 connected bus A2 number
NonSrc3 bus A1 Num	Bus 2	Non-source CB3 connected bus A1 number

Table 1382: Settings of ASCGAPC of NSCB2 for given example

Settings	Suggested values	Description
ASC CB Num1	Non source CB 2	ASC1 host circuit breaker number 2
Number of sources	3	Total number of sources present in system
Number of NonSrc CB	4	Number of bus coupler or grid transformer CB in the system
Src1 bus A Num	Bus 3	Source1 CB connected bus A number

Table 1387: Settings of ASCGAPC of SCB3 for given example

Settings	Suggested values	Description
ASC CB Num1	Source CB 3	ASC1 host circuit breaker number 3
Number of sources	3	Total number of sources present in system
Number of NonSrc CB	4	Number of bus coupler or grid transformer CB in the system

The subnetwork numbers of eight power sources are available in monitored data SBNW_SRC1...SBNW_SRC8. The subnetwork numbers of NSCBs are available in monitored data SBNW_NSCB1...SBNW_NSCB17. The subnetwork numbers of busbars are available in monitored data SBNW_BB1...SBNW_BB15.

The monitored data SRC1_GRI_CON...SRC8_GRI_CON give the grid connection status of source 1...source 8. In Figure 782, source 2 is electrically connected to the grid, so the monitored data SRC2_GRID_NW is TRUE. Also, zero subnetwork number is assigned to all the open CBs. Hence SCB 1 and NSCB3 are assigned zero as subnetwork number.

The CB status is assumed uncertain in abnormal conditions (communication failure, bad quality of the data received from any ASGCSYN or ASNSCSYN) or when the CB status inhibit input is received via `SRC1_ASC_DAT...SRC8_ASC_DAT` or `NS1_ASC_DAT...NS17_ASC_DAT` signal. When the status of the CB is uncertain, the group including this CB or the groups connected across this CB are assigned zero as the subnetwork number. For example, if the SCB1 status is uncertain, then source 1, source 3, SCB1, SCB3, NSCB4, Bus 3 and Bus 4 are assigned zero as subnetwork number.

All subnetwork numbers are displayed as zero when *ASC CB Num1* = "Sourcex", x= 1...8.

Coordinator

Three instances of ASNSCSYN can be configured for the synchronization of three NSCBs. The CB number can be set using settings *ASC CB Num1*, *ASC CB Num2* and *ASC CB Num3*. The function allows only NSCBs to be synchronized at a time. If synchronization is initiated for one of the three breakers, Coordinator sends the synchronized status to all the sources via `ASC_SRC1_DAT...ASC_SRC8_DAT` signal and to all the non-sources via `ASC_NS_DAT` signal. The rest of the operation is explained in Figure 783.

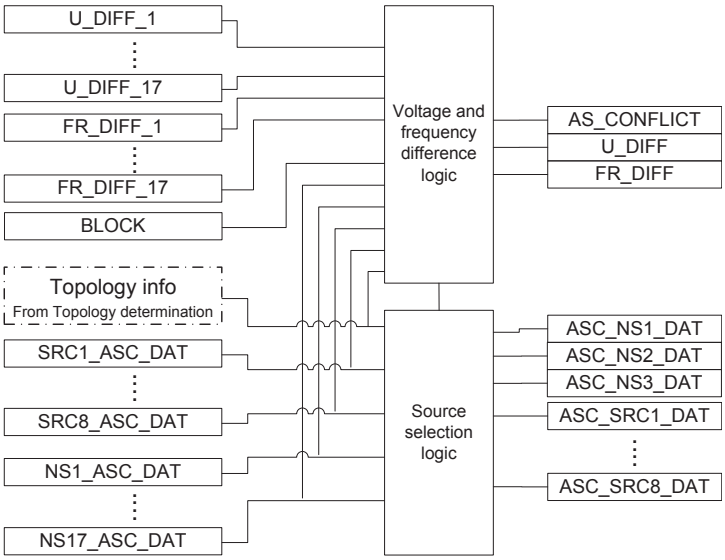

Figure 783: Module diagram of Coordinator

Voltage and frequency difference logic

This module sends the voltage and frequency difference values received from the NSCB to be synchronized to all the sources with appropriate sign according to the topology.

Of the two busbars connected across any NSCB, the voltage transformer (VT) from the lower-number busbar should be connected to bus A voltage channel (U_BUS_A) and the other to bus B voltage channel (U_BUS_B).

If these VT connections are interchanged physically, then the correction can be done in function using *NonSrc1 VT Conn...NonSrc17 VT Conn* for NSCB 1...NSCB 17. When the coordinator is active and NSCB 1 is selected for synchronization, the corresponding voltage and frequency difference inputs `U_DIFF_1` and `FR_DIFF_1` are available as outputs `U_DIFF` and `FR_DIFF`, respectively, with their sign adjusted according to the setting *NonSrc1 VT Conn*. If set as "No Change", the sign of `U_DIFF` and `FR_DIFF` remains the same. If set as "Reverse", the sign is reversed. Similarly, when any of the NSCB 2...NSCB 17 is selected for synchronization, the corresponding inputs `U_DIFF_2...U_DIFF_17` and `FR_DIFF_2...FR_DIFF_17` are passed as the outputs `U_DIFF` and `FR_DIFF`, respectively.

The output `AS_CONFLICT` is active in any of the following conditions:

- If more than one NSCB are selected for synchronization at the same time.
- If a NSCB is selected for synchronization while source synchronization is in progress.
- If more than one source are in synchronization.

When AS_CONFLICT is TRUE, then the Coordinator module stops the ongoing coordination activities till a new synchronization request is received from any NSCB. This conflict status is available in the monitored data CONFL_STATUS as given in Table 1388.

Table 1388: States of CONFL_STATUS

Monitored data	Value
CONFL_STATUS	1(“No conflict”)
	2(“Multiple NSCB sync”)
	3(“Multiple SCB sync”)
	4(“NSCB and SCB sync”)

Source Selection Logic

Source selection logic is responsible for the selection and coordination of the sources for the voltage and frequency matching. It is enabled only when the autosynchronization function of the selected NSCB is in “Semiautomatic” or “Automatic” mode.

A source is available for participation in the voltage and frequency matching if the corresponding autosynchronization function is in “Semi-automatic” or “Automatic” mode and the host protection relay is in remote mode. This information is received from the corresponding source via input signals SRC1_ASC_DAT...SRC8_ASC_DAT.

All the sources in the network can be divided into nine participation groups based on topology and their availability for participation.

Table 1389: Groups for source participation (monitored data SRC1_PTC_GRP...SRC8_PTC_GRP)

Source participation group	Description
Group 1	All the sources which are unavailable for participation, are electrically connected to the grid or are not part of either subnetwork which must be synchronized by the selected CB
Group 2	The sources which do not belong to Group 1 and are part of the subnetwork which includes the lower-number busbar of the two busbars connected across the selected CB
Group 3	The sources which do not belong to Group 1 and are part of the other subnetwork, which includes the higher-number busbar.
Group 4	The sources in Group 2 which are not ready for participation in matching
Group 5	The sources which are part of Group 3, but not ready for participation in matching.

Table continues on next page

Source participation group	Description
Group 6	The sources which are part of Group 2 or Group 3, but the network is internally connected and setting *Synchrocheck mode* in ASNSCSYN is "Synchronous"
Group 7	The sources which are part of Group 2 or Group 3, but the network is internally connected and the setting *Synchrocheck mode* in ASNSCSYN is "Asynchronous"
Group 8	The sources which are part of Group 2 or Group 3, but the network is internally asynchronous and setting *Synchrocheck mode* in ASNSCSYN is "Synchronous"
Group 9	The sources which are part of Group 2 or Group 3, but setting *Synchrocheck mode* in ASNSCSYN is "Off"

The participation group number for source 1...source 9 is available in the monitored output SRC1_PTC_GRP...SRC8_PTC_GRP.

Any source can be nominated for participation in voltage and frequency matching from the command parameter *Source1 selected*...*Source8 selected*. This selection is confirmed from the command parameter *Confirm source Sel*. The selected participation group information is available in monitored data SELECTED_GRP.

ASCGAPC allows multiple sources to participate in the voltage and frequency matching simultaneously, but all the sources nominated for matching should belong to either participation Group 2 or participation Group 3.

One of the participating sources (set with *Tuning source*) is used for the fine tuning of voltage and frequency. This information is sent to the corresponding source via the respective output signal ASC_SRC1_DAT...ASC_SRC8_DAT.

Table 1390: States of MATCH STATUS

Value	Description
1(“No request”)	No NSCB is selected for synchronization.
2(“Request received”)	Synchronization request is received.
3(“No source selection”)	The request is received and the command parameter *Confirm source Sel* is "FALSE".
4(“Correct Src selection”)	The synchronization request is received, the command parameter *Confirm source Sel* is "TRUE", and the nominated sources belong to either Group 2 or Group 3.
5(“Wrong source selection”)	The synchronization request is received, the command parameter *Confirm source Sel* is "FALSE", and the nominated sources do not belong to Group 2 or all belong to Group 3.
6(“Wrong tuning Src Sel”)	The source selected for fine tuning is not among the nominated sources.

Table continues on next page

Value	Description
8(“Source ready”)	Any of the selected sources are ready for matching.
9(“GOV-AVR modes not OK”)	Any source is selected for matching and the governor and AVR of all the participating sources are not in droop mode and non-participating sources are not in “Fixed MW” and “Fixed MVAr” mode. The governor and Automatic Voltage Regulator (AVR) modes corresponding to each source are received via the corresponding input signal SRC1_ASC_DAT...SRC8_ASC_DAT. If modes are different, then mode change request is sent to the sources via the corresponding output signal ASC_SRC1_DAT...ASC_SRC8_DAT.
10(“GOV-AVR modes OK”)	Any source is selected for matching, and its governor and AVR are in droop mode and non-participating sources are in “Fixed MW” and “Fixed MVAr” mode.
11(“Matching in progress”)	All the selected sources are issued the permission for matching.
12(“Matching done”)	Matching is complete according to the NSCB under synchronization.
13(“Matching not done”)	Matching is not done within the set *Max matching time*.
14(“Int Connect,set Sync”)	The network is internally connected and setting *Synchrocheck mode* in ASNSCSYN is "Synchronous".
15(“Int Connect,set Async”)	The network is internally connected and setting *Synchrocheck mode* in ASNSCSYN is "Asynchronous".
16(“Externally connected”)	The network is externally connected.
17(“Int Async,set Sync”)	The network is internally asynchronous and setting *Synchrocheck mode* in ASNSCSYN is "Synchronous".

Internally connected

A network where Bus1 is connected to Bus3, Bus2 is connected to Bus4 and CB1 is closed is seen as an internally connected network by CB2.

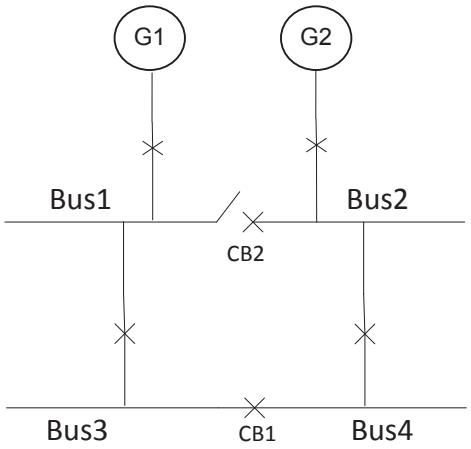

Figure 784: Example of an internally connected network

Externally connected

A network where both Bus3 and Bus4 are connected to the grid across CB1 is considered an externally connected network.

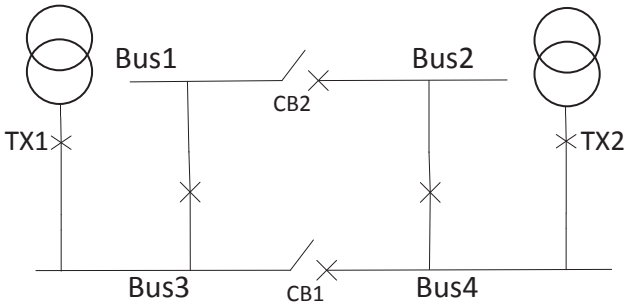

Figure 785: Example of an externally connected network

The number of sources active in the voltage and frequency matching is shared to sources via the corresponding output signal ASC_SRC1_DAT...ASC_SRC8_DAT.

The binary input BLOCK can be used to block the function. The activation of the BLOCK input deactivates all binary outputs and resets the internal timers.

9.8.5 Application

A circuit breaker is used to connect two different power networks. It is essential to ensure that these power networks are synchronized before closing the CB, otherwise it may lead to disturbances in the power system, causing stress and damage to the connected equipment.

The synchronization of any bus coupler or tie feeder is not feasible if the voltage and frequency differences across the circuit breaker are not within the allowed limits. In this case, the sources which are part of the power network connected across this bus

coupler or tie feeder CB have to adjust their voltage and frequency. ASCGAPC can be used as coordinator for selection and coordination with the sources, during the synchronization of any bus coupler or tie feeder circuit breaker. The function allows the synchronization of only one circuit breaker at a time. In case of any conflict, the synchronization process is stopped.

As a coordinator the function assists in the participating sources selection based on the network topology and interacts with the sources to initiate the voltage and frequency matching for the bus coupler or tie feeder CB to be synchronized.

When selected for synchronization, any NSCB communicates with ASCGAPC for matching of voltage and frequency difference. ASCGAPC passes the required information to the participating sources along with their active status. An NSCB synchronization is described with one typical example in Figure 786.

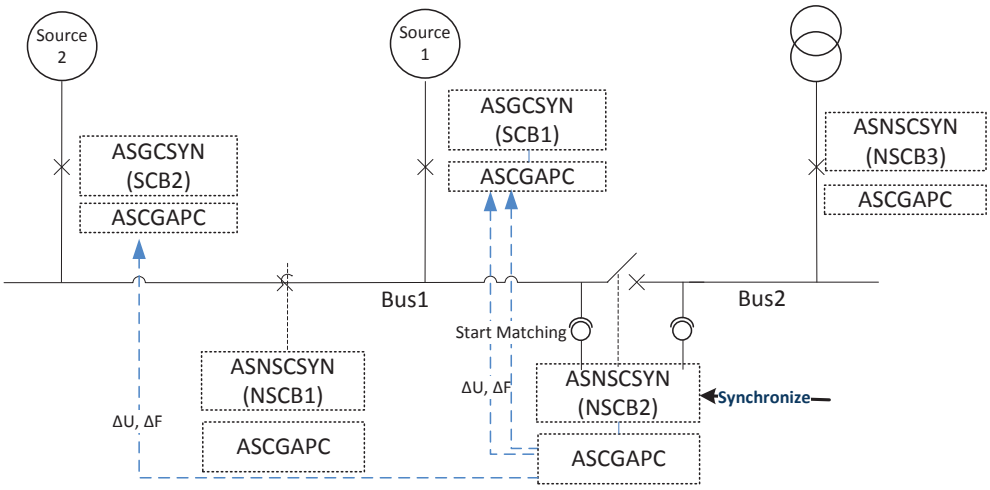

Figure 786: NSCB2 synchronization

In this application example, breaker NSCB2 must be closed so the synchronizing conditions between Bus1 and Bus2 are checked by ASNSCSYN. ASNSCSYN sends the autosynchronization request and voltage and frequency difference (ΔU, ΔF) between the Bus1 and Bus2 to the Autosynchronization coordinator functions ASCGAPC.

ASCGAPC transfers the voltage and frequency difference sent by ASNSCSYN to the ASCGAPC of source 1 ASGCSYN function as well as to the ASCGAPC of source 2 ASGCSYN function. It also sends the permission to the source to start matching the voltage and frequency. The matching process is carried out so that the voltage and frequency difference between Bus1 and Bus2 measured by ASNSCSYN reduces and comes within the synchrocheck limits. This satisfies the synchrocheck conditions for breaker NSCB2 which can then be synchronized by ASNSCSYN.

9.8.6 Signals

Table 1391: ASCGAPC Input signals

Name	Type	Default	Description
BLOCK	BOOLEAN	0=False	Blocking output signal of the function
SRC1_ASC_DAT	INT32	0	Input data from source number 1

9.9 Autoreclosing DARREC

9.9.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Autoreclosing	DARREC	O -> I	79

9.9.2 Function block

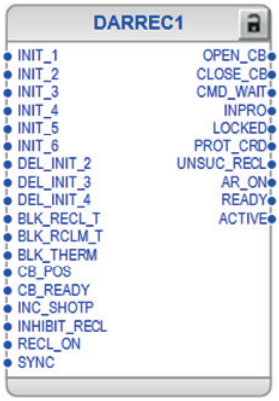

Figure 787: Function block

9.9.3 Functionality

About 80 to 85 percent of faults in the MV overhead lines are transient and automatically cleared with a momentary de-energization of the line. The rest of the faults, 15 to 20 percent, can be cleared by longer interruptions. The de-energization of the fault location for a selected time period is implemented through automatic reclosing, during which most of the faults can be cleared.

In case of a permanent fault, the automatic reclosing is followed by final tripping. A permanent fault must be located and cleared before the fault location can be re-energized.

The autoreclosing function DARREC can be used with any circuit breaker suitable for autoreclosing. The function provides five programmable autoreclosing shots which can perform one to five successive autoreclosings of desired type and duration, for instance one high-speed and one delayed autoreclosing.

When the reclosing is initiated with starting of the protection function, the autoreclosing function can execute the final trip of the circuit breaker in a short operate time, provided that the fault still persists when the last selected reclosing has been carried out.

9.9.3.1 Protection signal definition

The *Control line* setting defines which of the initiation signals are protection start and trip signals and which are not. With this setting, the user can distinguish the blocking signals from the protection signals. The *Control line* setting is a bit mask, that is, the lowest bit controls the `INIT_1` line and the highest bit the `INIT_6` line. Some example combinations of the *Control line* setting are as follows:

Table 1398: Control line setting definition

Control line setting	INIT_1	INIT_2 DEL_INIT_2	INIT_3 DEL_INIT_3	INIT_4 DEL_INIT_4	INIT_5	INIT_6
0	other	other	other	other	other	other
1	prot	other	other	other	other	other
2	other	prot	other	other	other	other
3	prot	prot	other	other	other	other
4	other	other	prot	other	other	other
5	prot	other	prot	other	other	other
...63	prot	prot	prot	prot	prot	prot

prot = protection signal

other = non-protection signal

When the corresponding bit or bits in both the *Control line* setting and the INIT_X line are TRUE:

- The CLOSE_CB output is blocked until the protection is reset
- If the INIT_X line defined as the protection signal is activated during the discrimination time, the AR function goes to lockout
- If the INIT_X line defined as the protection signal stays active longer than the time set by the *Max trip time* setting, the AR function goes to lockout (long trip)
- The UNSUC_RECL output is activated after a pre-defined two minutes (alarming earth-fault).

9.9.3.2 Zone coordination

Zone coordination is used in the zone sequence between local protection units and downstream devices. At the falling edge of the INC_SHOTP line, the value of the shot pointer is increased by one, unless a shot is in progress or the shot pointer already has the maximum value.

The falling edge of the INC_SHOTP line is not accepted if any of the shots are in progress.

9.9.3.3 Master and slave scheme

With the cooperation between the AR units in the same protection relay or between protection relays, sequential reclosings of two breakers at a line end in a 1½-breaker, double breaker or ring-bus arrangement can be achieved. One unit is defined as a master and it executes the reclosing first. If the reclosing is successful and no trip takes place, the second unit, that is the slave, is released to complete the reclose shot. With persistent faults, the breaker reclosing is limited to the first breaker.

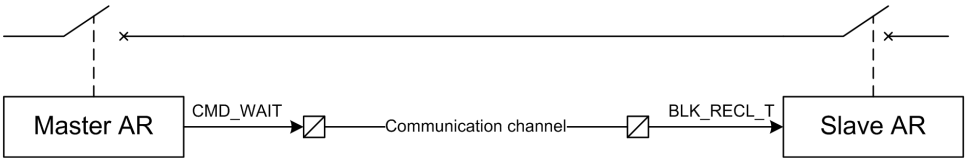

Figure 788: Master and slave scheme

If the AR unit is defined as a master by setting its terminal priority to high:

- The unit activates the CMD_WAIT output to the low priority slave unit whenever a shot is in progress, a reclosing is unsuccessful or the BLK_RCLM_T input is active
- The CMD_WAIT output is reset one second after the reclose command is given or if the sequence is unsuccessful when the reclaim time elapses.

If the AR unit is defined as a slave by setting its terminal priority to low:

- The unit waits until the master releases the BLK_RECL_T input (the CMD_WAIT output in the master). Only after this signal has been deactivated, the reclose time for the slave unit can be started.
- The slave unit is set to a lockout state if the BLK_RECL_T input is not released within the time defined by the *Max wait time* setting , which follows the initiation of an autoreclosing shot.

If the terminal priority of the AR unit is set to "none", the AR unit skips all these actions.

9.9.3.4 Thermal overload blocking

An alarm or start signal from the thermal overload protection (T1PTTR) can be routed to the input BLK_THERM to block and hold the reclose sequence. The BLK_THERM signal does not affect the starting of the sequence. When the reclose time has elapsed and the BLK_THERM input is active, the shot is not ready until the BLK_THERM input deactivates. Should the BLK_THERM input remain active longer than the time set by the setting *Max Thm block time*, the AR function goes to lockout.

If the BLK_THERM input is activated when the auto wait timer is running, the auto wait timer is reset and the timer restarted when the BLK_THERM input deactivates.

9.9.4 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off". Setting *Operation* to "off" resets non-volatile counters.

The reclosing operation can be enabled and disabled with the *Reclosing operation* setting. This setting does not disable the function, only the reclosing functionality. The

setting has three parameter values: “On”, “External Ctl” and ”Off”. The setting value “On” enables the reclosing operation and “Off” disables it. When the setting value “External Ctl” is selected, the reclosing operation is controlled with the RECL_ON input. AR_ON is activated when reclosing operation is enabled.

The operation of DARREC can be described using a module diagram. All the modules in the diagram are explained in the next sections.

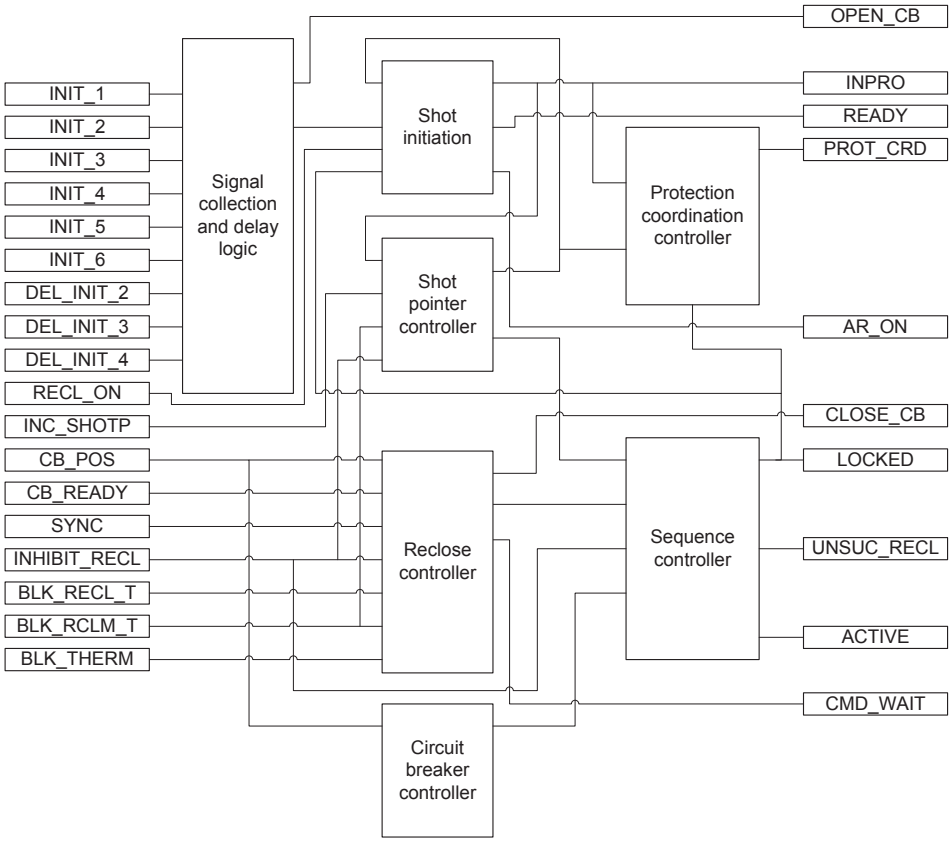

Figure 789: Functional module diagram

Signal collection and delay logic

When the protection trips, the initiation of autoreclosing shots is in most applications executed with the INIT_1...6 inputs. The DEL_INIT2...4 inputs are not used. In some countries, starting the protection stage is also used for the shot initiation. This is the only time when the DEL_INIT inputs are used.

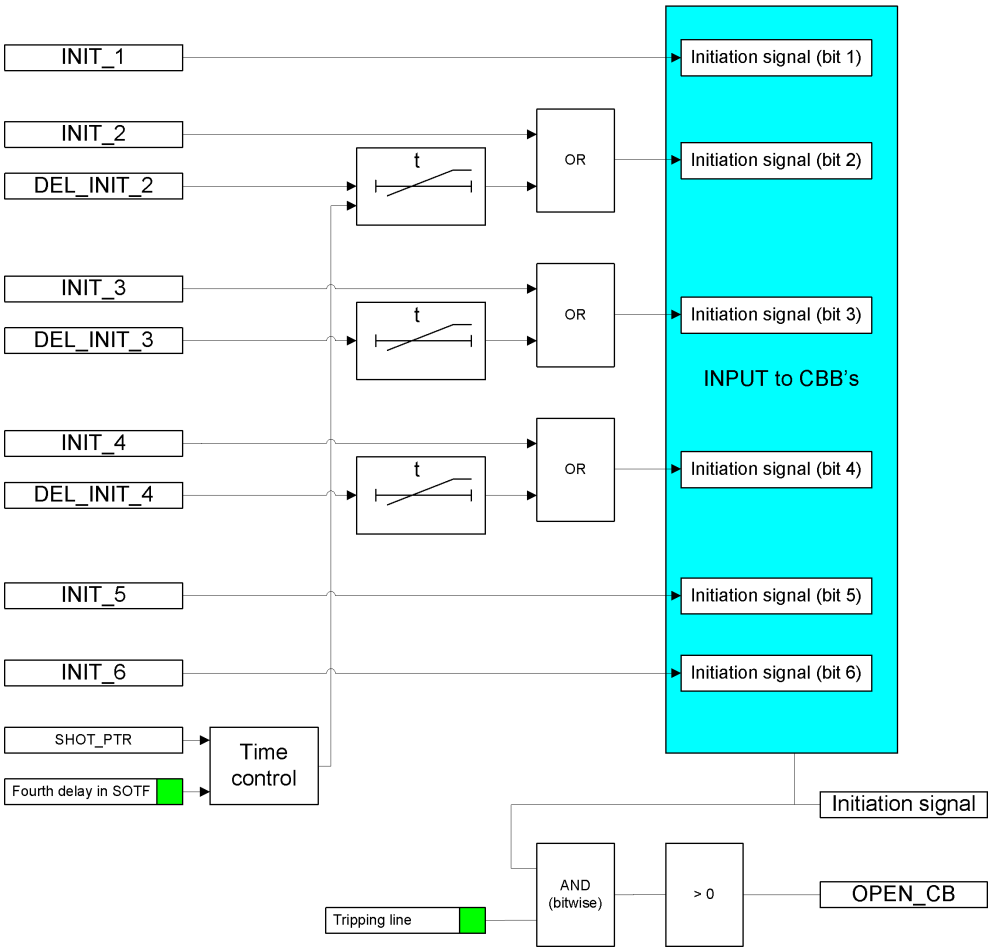

Figure 790: Schematic diagram of delayed initiation input signals

In total, the AR function contains six separate initiation lines used for the initiation or blocking of the autoreclosing shots. These lines are divided into two types of channels. In three of these channels, the signal to the AR function can be delayed, whereas the other three channels do not have any delaying capability.

Each channel that is capable of delaying a start signal has four time delays. The time delay is selected based on the shot pointer in the AR function. For the first reclose attempt, the first time delay is selected; for the second attempt, the second time delay and so on. For the fourth and fifth attempts, the time delays are the same.

Time delay settings for the `DEL_INIT_2` signal

- *Str 2 delay shot 1*
- *Str 2 delay shot 2*
- *Str 2 delay shot 3*
- *Str 2 delay shot 4*

Time delay settings for the `DEL_INIT_3` signal

- *Str 3 delay shot 1*
- *Str 3 delay shot 2*
- *Str 3 delay shot 3*
- *Str 3 delay shot 4*

Time delay settings for the DEL_INIT_4 signal

- *Str 4 delay shot 1*
- *Str 4 delay shot 2*
- *Str 4 delay shot 3*
- *Str 4 delay shot 4*

Normally, only two or three reclosing attempts are made. The third and fourth attempts are used to provide the so-called fast final trip to lockout.

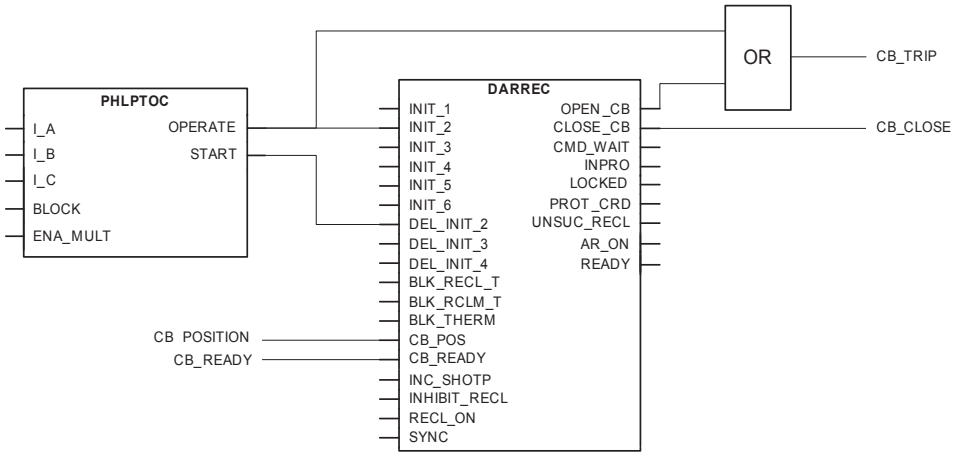

Figure 791: Autoreclosing configuration example

Delayed DEL_INIT_2...4 signals are used only when the autoreclosing shot is initiated with the start signal of a protection stage. After a start delay, the AR function opens the circuit breaker and an autoreclosing shot is initiated. When the shot is initiated with the trip signal of the protection, the protection function trips the circuit breaker and simultaneously initiates the autoreclosing shot.

If the circuit breaker is manually closed against the fault, that is, if SOTF is used, the fourth time delay can automatically be taken into use. This is controlled with the internal logic of the AR function and the *Fourth delay in SOTF* parameter.

A typical autoreclose situation is where one autoreclosing shot has been performed after the fault was detected. There are two types of such cases: operation initiated with protection start signal and operation initiated with protection trip signal. In both cases, the autoreclosing sequence is successful: the reclaim time elapses and no new sequence is started.

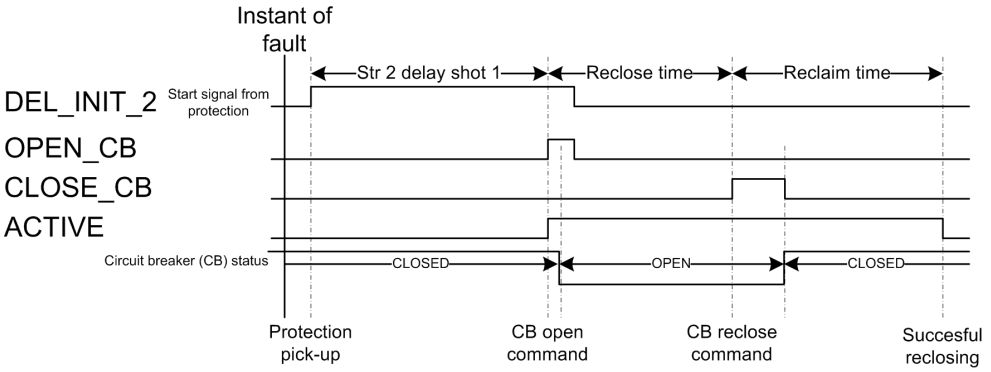

Figure 792: Signal scheme of autoreclosing operation initiated with protection start signal

The autoreclosing shot is initiated with a start signal of the protection function after the start delay time has elapsed. The autoreclosing starts when the *Str 2 delay shot 1* setting elapses.

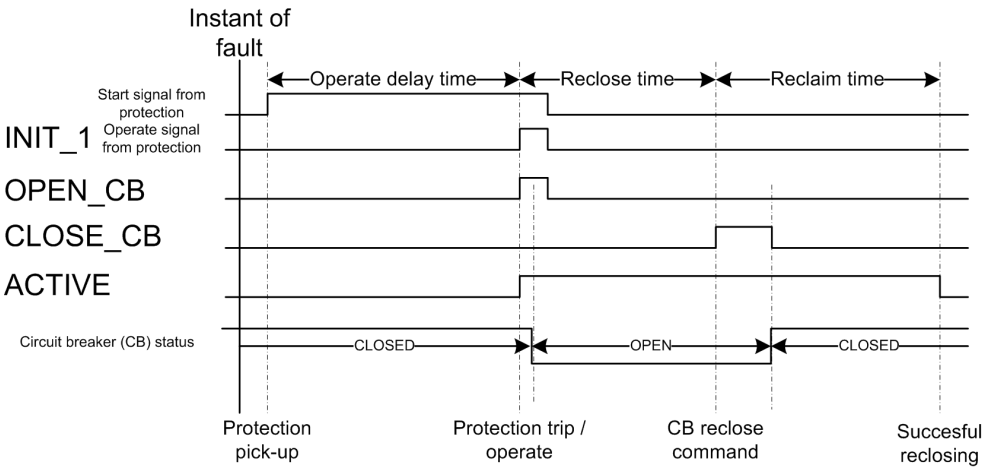

Figure 793: Signal scheme of autoreclosing operation initiated with protection operate signal

The autoreclosing shot is initiated with a trip signal of the protection function. The autoreclosing starts when the protection operate delay time elapses.

Normally, all trip and start signals are used to initiate an autoreclosing shot and trip the circuit breaker. `ACTIVE` output indicates reclosing sequence in progress. If any of the input signals `INIT_X` or `DEL_INIT_X` are used for blocking, the corresponding bit in the *Tripping line* setting must be FALSE. This is to ensure that the circuit breaker does not trip from that signal, that is, the signal does not activate the `OPEN_CB` output. The default value for the setting is "63", which means that all initiation signals activate the `OPEN_CB` output. The lowest bit in the *Tripping line* setting corresponds to the `INIT_1` input, the highest bit to the `INIT_6` line.

Shot initiation

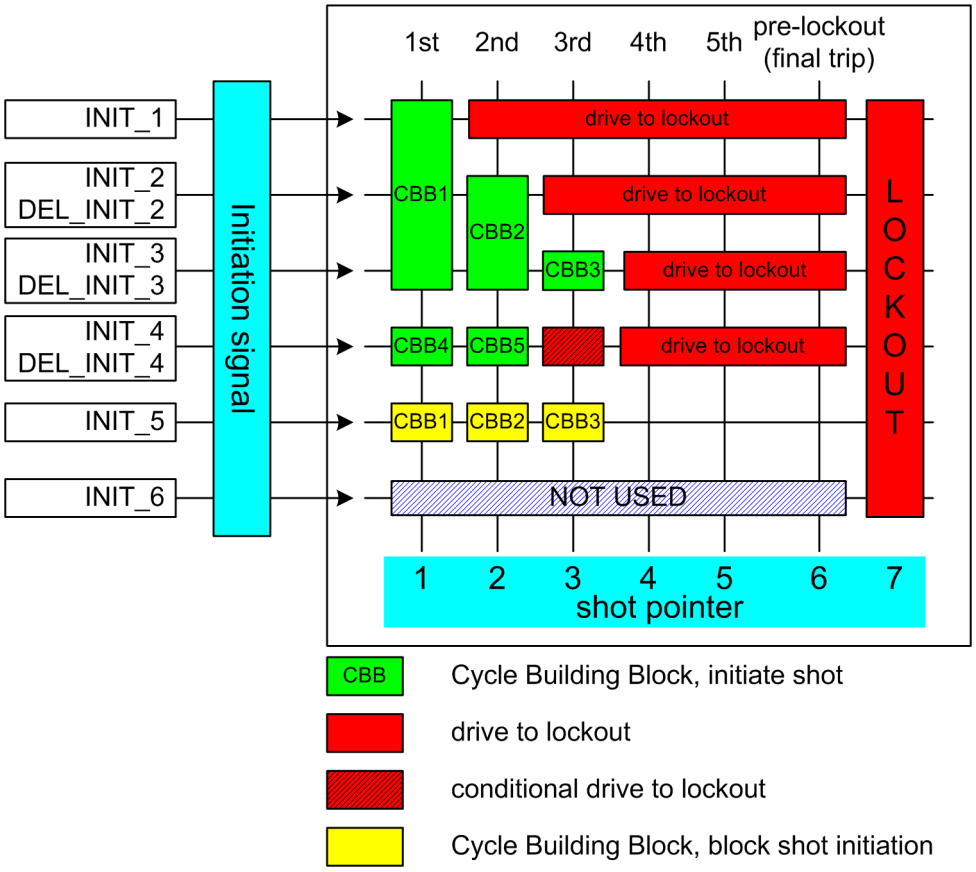

Figure 794: Example of an autoreclosing program with a reclose scheme matrix

In the AR function, each shot can be programmed to locate anywhere in the reclose scheme matrix. The shots are like building blocks used to design the reclose program. The building blocks are called CBBs. All blocks are alike and have settings which give the attempt number (columns in the matrix), the initiation or blocking signals (rows in the matrix) and the reclose time of the shot.

The settings related to CBB configuration are:

- *First...Seventh reclose time*
- *Init signals CBB1...CBB7*
- *Blk signals CBB1...CBB7*
- *Shot number CBB1...CBB7*

The reclose time defines the open and dead times, that is, the time between the `OPEN_CB` and the `CLOSE_CB` commands. The *Init signals CBBx* setting defines the initiation signals. The *Blk signals CBBx* setting defines the blocking signals that are related to the CBB (rows in the matrix). The *Shot number CBB1...CBB7* setting defines which shot is related to the CBB (columns in the matrix). For example, CBB1 settings are:

- *First reclose time* = 1.0s
- *Init signals CBB1* = 7 (three lowest bits: 111000 = 7)
- *Blk signals CBB1* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB1* = 1

CBB2 settings are:

- *Second reclose time* = 10s
- *Init signals CBB2* = 6 (the second and third bits: 011000 = 6)
- *Blk signals CBB2* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB2* = 2

CBB3 settings are:

- *Third reclose time* = 30s
- *Init signals CBB3* = 4 (the third bit: 001000 = 4)
- *Blk signals CBB3* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB3* = 3

CBB4 settings are:

- *Fourth reclose time* = 0.5s
- *Init signals CBB4* = 8 (the fourth bit: 000100 = 8)
- *Blk signals CBB4* = 0 (no blocking signals related to this CBB)
- *Shot number CBB4* = 1

If a shot is initiated from the INIT_1 line, only one shot is allowed before lockout. If a shot is initiated from the INIT_3 line, three shots are allowed before lockout.

A sequence initiation from the INIT_4 line leads to a lockout after two shots. In a situation where the initiation is made from both the INIT_3 and INIT_4 lines, a third shot is allowed, that is, CBB3 is allowed to start. This is called conditional lockout. If the initiation is made from the INIT_2 and INIT_3 lines, an immediate lockout occurs.

The INIT_5 line is used for blocking purposes. If the INIT_5 line is active during a sequence start, the reclose attempt is blocked and the AR function goes to lockout.

If more than one CBBs are started with the shot pointer, the CBB with the smallest individual number is always selected. For example, if the INIT_2 and INIT_4 lines are active for the second shot, that is, the shot pointer is 2, CBB2 is started instead of CBB5.

Even if the initiation signals are not received from the protection functions, the AR function can be set to continue from the second to the fifth reclose shot. The AR function can, for example, be requested to automatically continue with the sequence when the circuit breaker fails to close when requested. In such a case, the AR function

issues a CLOSE_CB command. When the wait close time elapses, that is, the closing of the circuit breaker fails, the next shot is automatically started. Another example is the embedded generation on the power line, which can make the synchronism check fail and prevent the reclosing. If the auto-reclose sequence is continued to the second shot, a successful synchronous reclosing is more likely than with the first shot, since the second shot lasts longer than the first one.

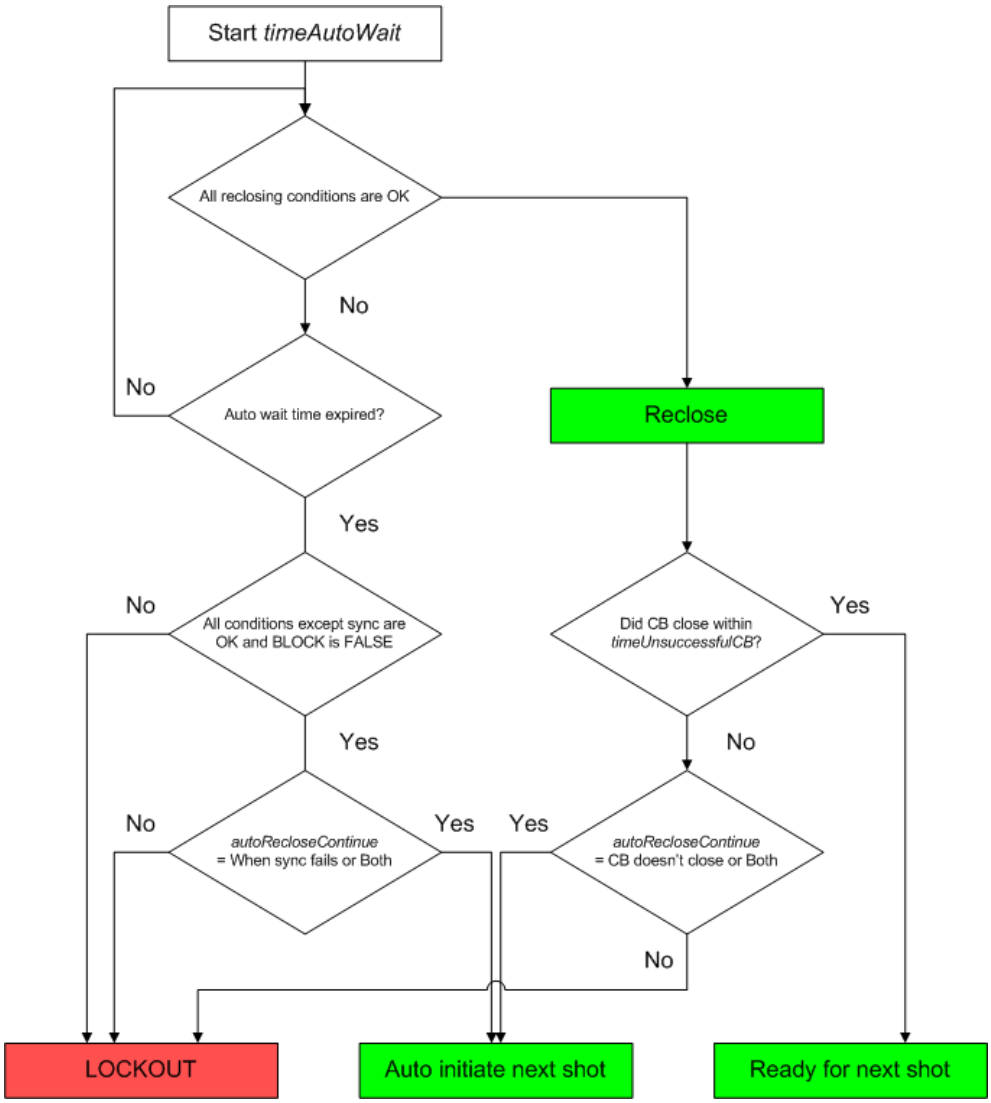

Figure 795: Logic diagram of auto-initiation sequence detection

Automatic initiation can be selected with the *Auto initiation Cnd* setting to be the following:

- Not allowed: no automatic initiation is allowed
- When the synchronization fails, the automatic initiation is carried out when the auto wait time elapses and the reclosing is prevented due to a failure during the synchronism check
- When the circuit breaker does not close, the automatic initiation is carried out if the circuit breaker does not close within the wait close time after issuing the reclose command
- Both: the automatic initiation is allowed when synchronization fails or the circuit breaker does not close.

The *Auto init* parameter defines which INIT_X lines are activated in the auto-initiation. The default value for this parameter is "0", which means that no auto-initiation is selected.

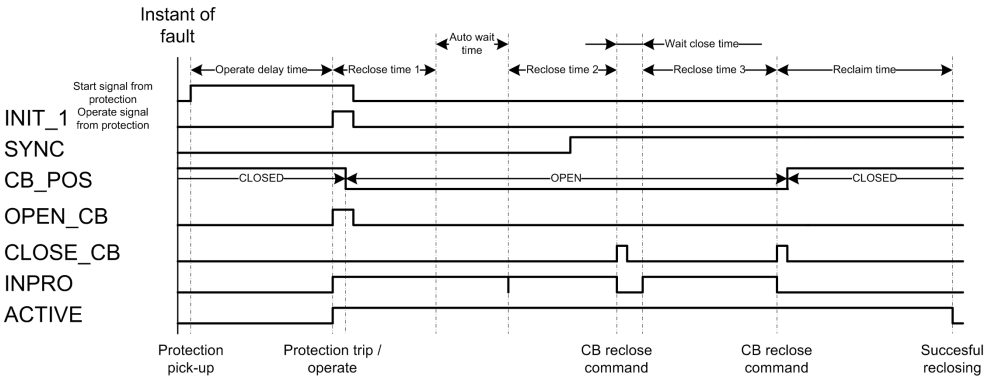

Figure 796: Example of an auto-initiation sequence with synchronization failure in the first shot and circuit breaker closing failure in the second shot

In the first shot, the synchronization condition is not fulfilled (SYNC is FALSE). When the auto wait timer elapses, the sequence continues to the second shot. During the second reclosing, the synchronization condition is fulfilled and the close command is given to the circuit breaker after the second reclose time has elapsed.

After the second shot, the circuit breaker fails to close when the wait close time has elapsed. The third shot is started and a new close command is given after the third reclose time has elapsed. The circuit breaker closes normally and the reclaim time starts. When the reclaim time has elapsed, the sequence is concluded successful.

Shot pointer controller

The execution of a reclose sequence is controlled by a shot pointer. It can be adjusted with the SHOT_PTR monitored data.

The shot pointer starts from an initial value "1" and determines according to the settings whether or not a certain shot is allowed to be initiated. After every shot, the shot pointer value increases. This is carried out until a successful reclosing or lockout takes place after a complete shot sequence containing a total of five shots.

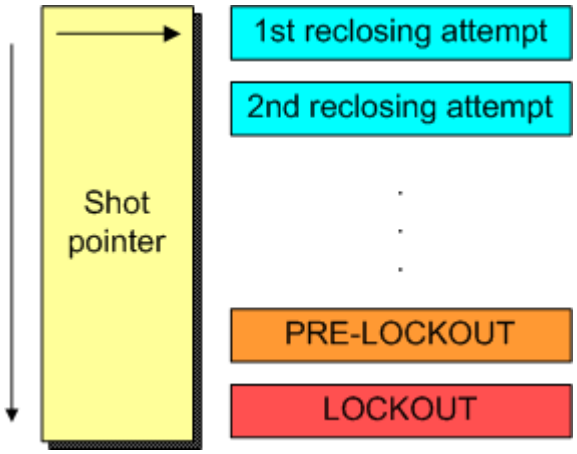

Figure 797: Shot pointer function

Every time the shot pointer increases, the reclaim time starts. When the reclaim time ends, the shot pointer sets to its initial value, unless no new shot is initiated. The shot pointer increases when the reclose time elapses or at the falling edge of the INC_SHOTP signal.

When SHOT_PTR has the value six, the AR function is in a so called pre-lockout state. If a new initiation occurs during the pre-lockout state, the AR function goes to lockout. Therefore, a new sequence initiation during the pre-lockout state is not possible.

The AR function goes to the pre-lockout state in the following cases:

- During SOTF
- When the AR function is active, it stays in a pre-lockout state for the time defined by the reclaim time
- When all five shots have been executed
- When the frequent operation counter limit is reached. A new sequence initiation forces the AR function to lockout.

Reclose controller

The reclose controller calculates the reclose, discrimination and reclaim times. The reclose time is started when the INPRO signal is activated, that is, when the sequence starts and the activated CBB defines the reclose time.

When the reclose time has elapsed, the CLOSE_CB output is not activated until the following conditions are fulfilled:

- The SYNC input must be TRUE if the particular CBB requires information about the synchronism
- All AR initiation inputs that are defined protection lines (using the *Control line* setting) are inactive
- The circuit breaker is open
- The circuit breaker is ready for the close command, that is, the CB_READY input is TRUE. This is indicated by active READY output.

If at least one of the conditions is not fulfilled within the time set with the *Auto wait time* parameter, the auto-reclose sequence is locked.

The synchronism requirement for the CBBs can be defined with the *Synchronisation set* setting, which is a bit mask. The lowest bit in the *Synchronisation set* setting is related to CBB1 and the highest bit to CBB7. For example, if the setting is set to "1", only CBB1 requires synchronism. If the setting is it set to "7", CBB1, CBB2 and CBB3 require the SYNC input to be TRUE before the reclosing command can be given.

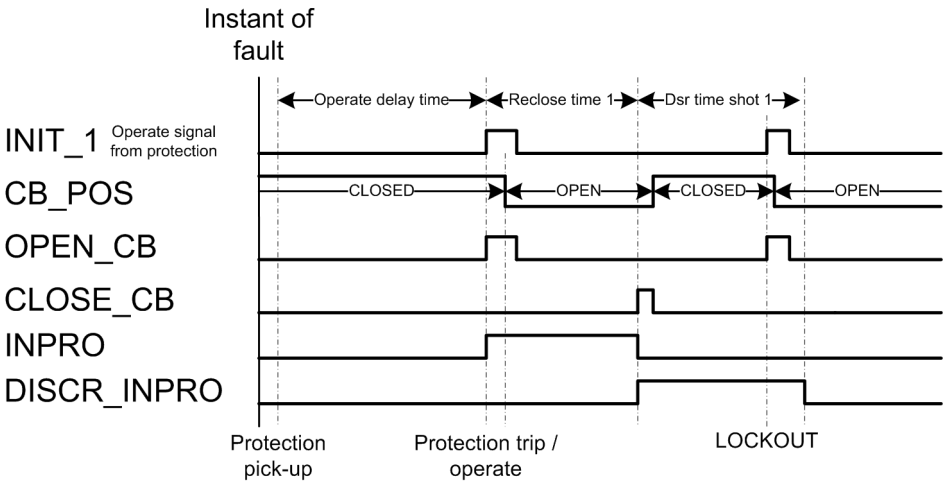

Figure 798: Initiation during discrimination time - AR function goes to lockout

The discrimination time starts when the close command CLOSE_CB has been given. If a start input is activated before the discrimination time has elapsed, the AR function goes to lockout. The default value for each discrimination time is zero. The discrimination time can be adjusted with the *Dsr time shot 1...4* parameter.

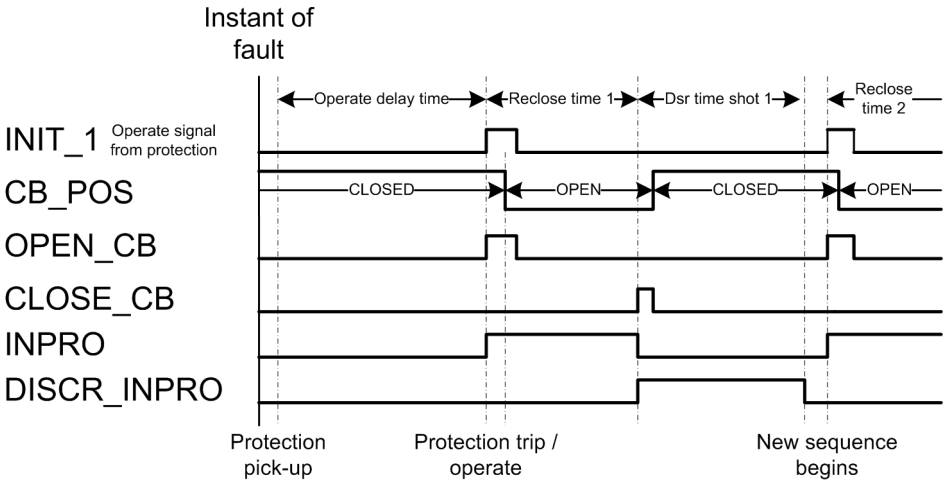

Figure 799: Initiation after elapsed discrimination time - new shot begins

Sequence controller

When the LOCKED output is active, the AR function is in lockout. This means that new sequences cannot be initialized, because AR is insensitive to initiation commands. It can be released from the lockout state in the following ways.

- The function is reset through communication with the *RecRs* parameter. The same functionality can also be found in the Clear menu (DARREC1 reset).
- The lockout is automatically reset after the reclaim time, if the *Auto lockout reset* setting is in use.

If the *Auto lockout reset* setting is not in use, the lockout can be released only with the *RecRs* parameter.

The AR function can go to lockout for many reasons.

- The INHIBIT_RECL input is active.
- All shots have been executed and a new initiation is made (final trip).
- The time set with the *Auto wait time* parameter expires and the automatic sequence initiation is not allowed because of a synchronization failure.
- The time set with the *Wait close time* parameter expires, that is, the circuit breaker does not close or the automatic sequence initiation is not allowed due to a closing failure of the circuit breaker.
- A new shot is initiated during the discrimination time.
- The time set with the *Max wait time* parameter expires, that is, the master unit does not release the slave unit.
- The frequent operation counter limit is reached and new sequence is initiated. The lockout is released when the recovery timer elapses.
- The protection trip signal has been active longer than the time set with the *Max wait time* parameter since the shot initiation.
- The circuit breaker is closed manually during an autoreclosing sequence and the manual close mode is FALSE.

Protection coordination controller

The PROT_CRD output is used for controlling the protection functions. In several applications, such as fuse-saving applications involving down-stream fuses, tripping and initiation of shot 1 should be fast (instantaneous or short-time delayed). The tripping and initiation of shots 2, 3 and definite tripping time should be delayed.

In this example, two overcurrent elements PHLPTOC and PHIPTOC are used. PHIPTOC is given an instantaneous characteristic and PHLPTOC is given a time delay.

The PROT_CRD output is activated, if the SHOT_PTR value is the same or higher than the value defined with the *Protection crd limit* setting and all initialization signals have been reset. The PROT_CRD output is reset under the following conditions:

- If the cut-out time elapses
- If the reclaim time elapses and the AR function is ready for a new sequence
- If the AR function is in lockout or disabled, that is, if the value of the *Protection crd mode* setting is "AR inoperative" or "AR inop, CB man".

The PROT_CRD output can also be controlled with the *Protection crd mode* setting. The setting has the following modes:

- "no condition": the PROT_CRD output is controlled only with the *Protection crd limit* setting
- "AR inoperative": the PROT_CRD output is active, if the AR function is disabled or in the lockout state, or if the INHIBIT_RECL input is active
- "CB close manual": the PROT_CRD output is active for the reclaim time if the circuit breaker has been manually closed, that is, the AR function has not issued a close command
- "AR inop, CB man": both the modes "AR inoperative" and "CB close manual" are effective
- "always": the PROT_CRD output is constantly active

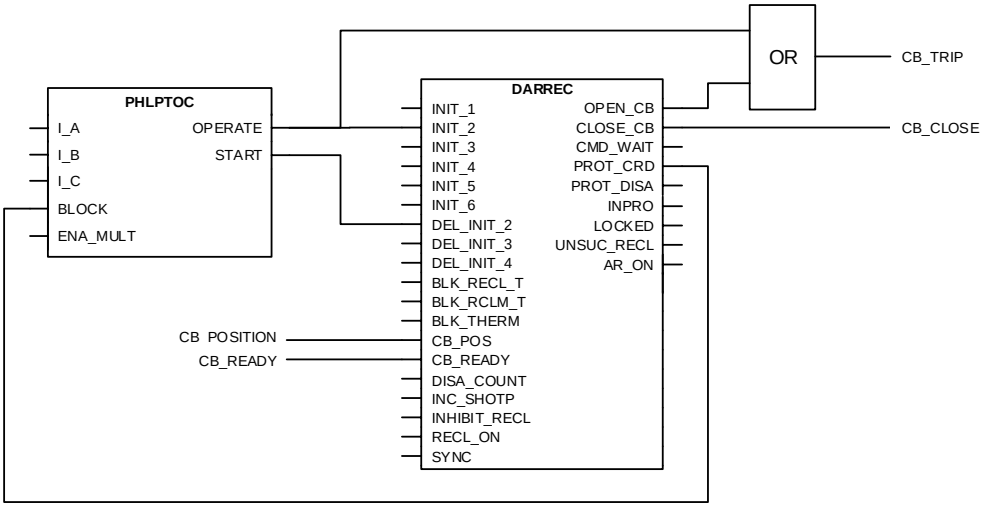

Figure 800: Configuration example of using the PROT_CRD output for protection blocking

If the *Protection crd limit* setting has the value "1", the instantaneous three-phase overcurrent protection function PHIPTOC is disabled or blocked after the first shot.

Circuit breaker controller

Circuit breaker controller contains two features: SOTF and frequent-operation counter. SOTF protects the AR function in permanent faults.

The circuit breaker position information is controlled with the *CB closed Pos status* setting. The setting value "TRUE" means that when the circuit breaker is closed, the CB_POS input is TRUE. When the setting value is "FALSE", the CB_POS input is

FALSE, provided that the circuit breaker is closed. The reclose command pulse time can be controlled with the *Close pulse time* setting: the CLOSE_CB output is active for the time set with the *Close pulse time* setting. The CLOSE_CB output is deactivated also when the circuit breaker is detected to be closed, that is, when the CB_POS input changes from open state to closed state. The *Wait close time* setting defines the time after the CLOSE_CB command activation, during which the circuit breaker should be closed. If the closing of circuit breaker does not happen during this time, the autoreclosing function is driven to lockout or, if allowed, an auto-initiation is activated.

The main motivation for autoreclosing to begin with is the assumption that the fault is temporary by nature, and that a momentary de-energizing of the power line and an automatic reclosing restores the power supply. However, when the power line is manually energized and an immediate protection trip is detected, it is very likely that the fault is of a permanent type. A permanent fault is, for example, energizing a power line into a forgotten earthing after a maintenance work along the power line. In such cases, SOTF is activated, but only for the reclaim time after energizing the power line and only when the circuit breaker is closed manually and not by the AR function.

SOTF disables any initiation of an autoreclosing shot. The energizing of the power line is detected from the CB_POS information.

SOTF is activated when the AR function is enabled or when the AR function is started and the SOTF should remain active for the reclaim time.

When SOTF is detected, the parameter *SOTF* is active.

If the *Manual close mode* setting is set to FALSE and the circuit breaker has been manually closed during an autoreclosing shot, the AR unit goes to an immediate lockout.

If the *Manual close mode* setting is set to TRUE and the circuit breaker has been manually closed during an autoreclosing shot (the INPRO is active), the shot is considered as completed.

When SOTF starts, reclaim time is restarted, provided that it is running.

The frequent-operation counter is intended for blocking the autoreclosing function in cases where the fault causes repetitive autoreclosing sequences during a short period of time. For instance, if a tree causes a short circuit and, as a result, there are autoreclosing shots within a few minutes interval during a stormy night. These types of faults can easily damage the circuit breaker if the AR function is not locked by a frequent-operation counter.

The frequent-operation counter has three settings:

- *Frq Op counter limit*
- *Frq Op counter time*
- *Frq Op recovery time*

The *Frq Op counter limit* setting defines the number of reclose attempts that are allowed during the time defined with the *Frq Op counter time* setting. If the set value is reached within a pre-defined period defined with the *Frq Op counter time* setting, the AR function goes to lockout when a new shot begins, provided that the counter is still above the set limit. The lockout is released after the recovery time has elapsed. The recovery time can be defined with the *Frq Op recovery time* setting .

If the circuit breaker is manually closed during the recovery time, the reclaim time is activated after the recovery timer has elapsed.

9.9.5 Counters

The AR function contains six counters. Their values are stored in a semi-retain memory. The counters are increased at the rising edge of the reclosing command. The counters count the following situations.

- `COUNTER`: counts every reclosing command activation
- `CNT_SHOT1`: counts reclosing commands that are executed from shot 1
- `CNT_SHOT2`: counts reclosing commands that are executed from shot 2
- `CNT_SHOT3`: counts reclosing commands that are executed from shot 3
- `CNT_SHOT4`: counts reclosing commands that are executed from shot 4
- `CNT_SHOT5`: counts reclosing commands that are executed from shot 5

The counters are disabled through communication with the *DsaCnt* parameter. When the counters are disabled, the values are not updated.

The counters are reset through communication with the *CntRs* parameter. The same functionality can also be found in the clear menu (DARREC1 counters).

9.9.6 Application

Modern electric power systems can deliver energy to users very reliably. However, different kind of faults can occur. Protection relays play an important role in detecting failures or abnormalities in the system. They detect faults and give commands for corresponding circuit breakers to isolate the defective element before excessive damage or a possible power system collapse occurs. A fast isolation also limits the disturbances caused for the healthy parts of the power system.

The faults can be transient, semi-transient or permanent. Permanent fault, for example in power cables, means that there is a physical damage in the fault location that must first be located and repaired before the network voltage can be restored.

In overhead lines, the insulating material between phase conductors is air. The majority of the faults are flash-over arcing faults caused by lightning, for example.

Only a short interruption is needed for extinguishing the arc. These faults are transient by nature.

A semi-transient fault can be caused for example by a bird or a tree branch falling on the overhead line. The fault disappears on its own if the fault current burns the branch or the wind blows it away.

Transient and semi-transient faults can be cleared by momentarily de-energizing the power line. Using the auto-reclose function minimizes interruptions in the power system service and brings the power back on-line quickly and effortlessly.

The basic idea of the auto-reclose function is simple. In overhead lines, where the possibility of self-clearing faults is high, the auto-reclose function tries to restore the power by reclosing the breaker. This is a method to get the power system back into normal operation by removing the transient or semi-transient faults. Several trials, that is, auto-reclose shots are allowed. If none of the trials is successful and the fault persists, definite final tripping follows.

The auto-reclose function can be used with every circuit breaker that has the ability for a reclosing sequence. In DARREC auto-reclose function the implementing method of auto-reclose sequences is patented by ABB

Table 1399: Important definitions related to autoreclosing

Autoreclose shot	An operation where after a preset time the breaker is closed from the breaker tripping caused by protection
Autoreclose sequence	A predefined method to do reclose attempts (shots) to restore the power system
SOTF	If the protection detects a fault immediately after an open circuit breaker has been closed, it indicates that the fault was already there. It can be, for example, a forgotten earthing after maintenance work. Such closing of the circuit breaker is known as switch on to fault. Autoreclosing in such conditions is prohibited.
Final trip	Occurs in case of a permanent fault, when the circuit breaker is opened for the last time after all programmed auto-reclose operations. Since no auto-reclosing follows, the circuit breaker remains open. This is called final trip or definite trip.

9.9.6.1 Shot initiation

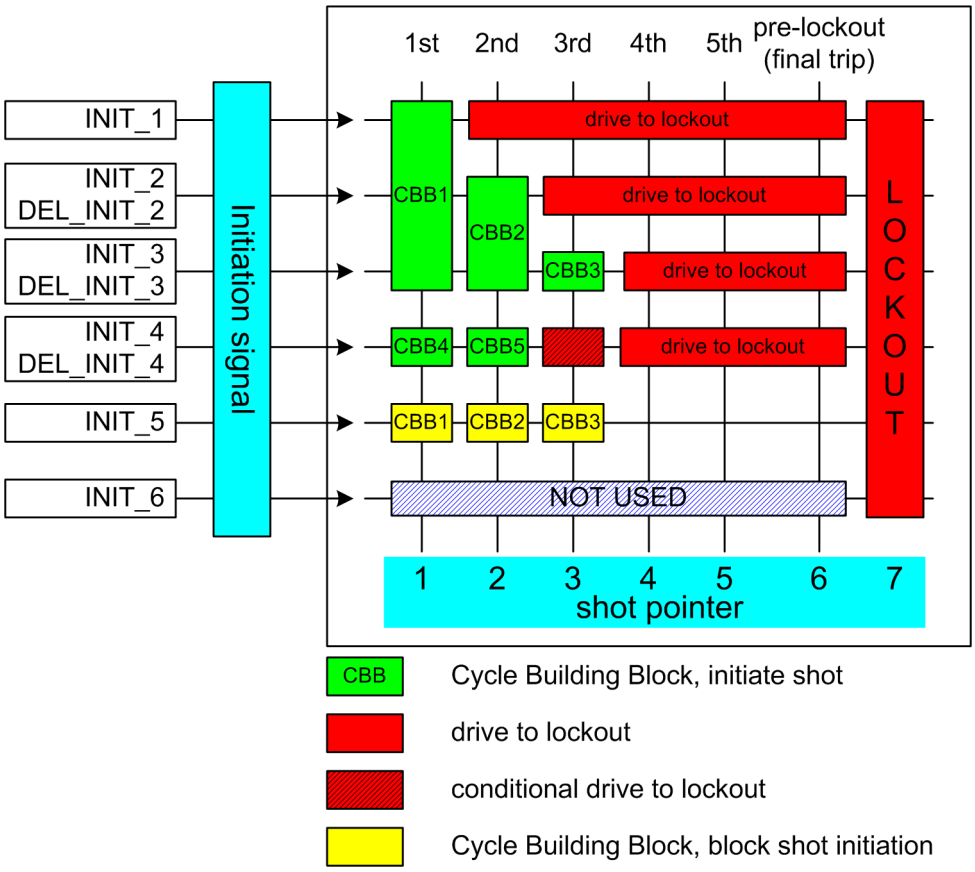

Figure 801: Example of an autoreclosing program with a reclose scheme matrix

In the AR function, each shot can be programmed to locate anywhere in the reclose scheme matrix. The shots are like building blocks used to design the reclose program. The building blocks are called CBBs. All blocks are alike and have settings which give the attempt number (columns in the matrix), the initiation or blocking signals (rows in the matrix) and the reclose time of the shot.

The settings related to CBB configuration are:

- *First...Seventh reclose time*
- *Init signals CBB1...CBB7*
- *Blk signals CBB1...CBB7*
- *Shot number CBB1...CBB7*

The reclose time defines the open and dead times, that is, the time between the `OPEN_CB` and the `CLOSE_CB` commands. The *Init signals CBBx* setting defines the initiation signals. The *Blk signals CBBx* setting defines the blocking signals that are related to the CBB (rows in the matrix). The *Shot number CBB1...CBB7* setting defines which shot is related to the CBB (columns in the matrix). For example, CBB1 settings are:

- *First reclose time* = 1.0s
- *Init signals CBB1* = 7 (three lowest bits: 111000 = 7)
- *Blk signals CBB1* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB1* = 1

CBB2 settings are:

- *Second reclose time* = 10s
- *Init signals CBB2* = 6 (the second and third bits: 011000 = 6)
- *Blk signals CBB2* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB2* = 2

CBB3 settings are:

- *Third reclose time* = 30s
- *Init signals CBB3* = 4 (the third bit: 001000 = 4)
- *Blk signals CBB3* = 16 (the fifth bit: 000010 = 16)
- *Shot number CBB3* = 3

CBB4 settings are:

- *Fourth reclose time* = 0.5s
- *Init signals CBB4* = 8 (the fourth bit: 000100 = 8)
- *Blk signals CBB4* = 0 (no blocking signals related to this CBB)
- *Shot number CBB4* = 1

If a shot is initiated from the INIT_1 line, only one shot is allowed before lockout. If a shot is initiated from the INIT_3 line, three shots are allowed before lockout.

A sequence initiation from the INIT_4 line leads to a lockout after two shots. In a situation where the initiation is made from both the INIT_3 and INIT_4 lines, a third shot is allowed, that is, CBB3 is allowed to start. This is called conditional lockout. If the initiation is made from the INIT_2 and INIT_3 lines, an immediate lockout occurs.

The INIT_5 line is used for blocking purposes. If the INIT_5 line is active during a sequence start, the reclose attempt is blocked and the AR function goes to lockout.

If more than one CBBs are started with the shot pointer, the CBB with the smallest individual number is always selected. For example, if the INIT_2 and INIT_4 lines are active for the second shot, that is, the shot pointer is 2, CBB2 is started instead of CBB5.

Even if the initiation signals are not received from the protection functions, the AR function can be set to continue from the second to the fifth reclose shot. The AR function can, for example, be requested to automatically continue with the sequence when the circuit breaker fails to close when requested. In such a case, the AR function

issues a CLOSE_CB command. When the wait close time elapses, that is, the closing of the circuit breaker fails, the next shot is automatically started. Another example is the embedded generation on the power line, which can make the synchronism check fail and prevent the reclosing. If the auto-reclose sequence is continued to the second shot, a successful synchronous reclosing is more likely than with the first shot, since the second shot lasts longer than the first one.

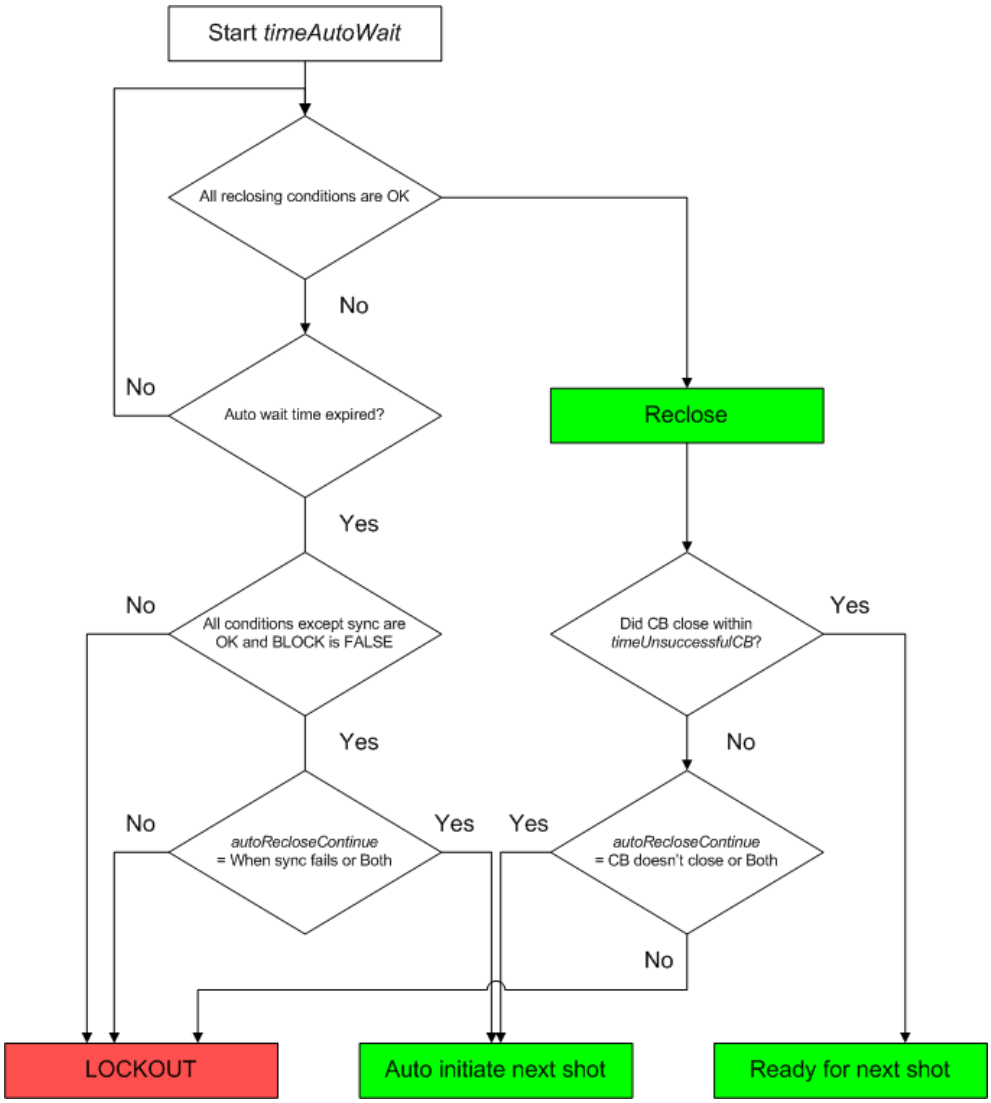

Figure 802: Logic diagram of auto-initiation sequence detection

Automatic initiation can be selected with the *Auto initiation Cnd* setting to be the following:

- Not allowed: no automatic initiation is allowed
- When the synchronization fails, the automatic initiation is carried out when the auto wait time elapses and the reclosing is prevented due to a failure during the synchronism check
- When the circuit breaker does not close, the automatic initiation is carried out if the circuit breaker does not close within the wait close time after issuing the reclose command
- Both: the automatic initiation is allowed when synchronization fails or the circuit breaker does not close.

The *Auto init* parameter defines which INIT_X lines are activated in the auto-initiation. The default value for this parameter is "0", which means that no auto-initiation is selected.

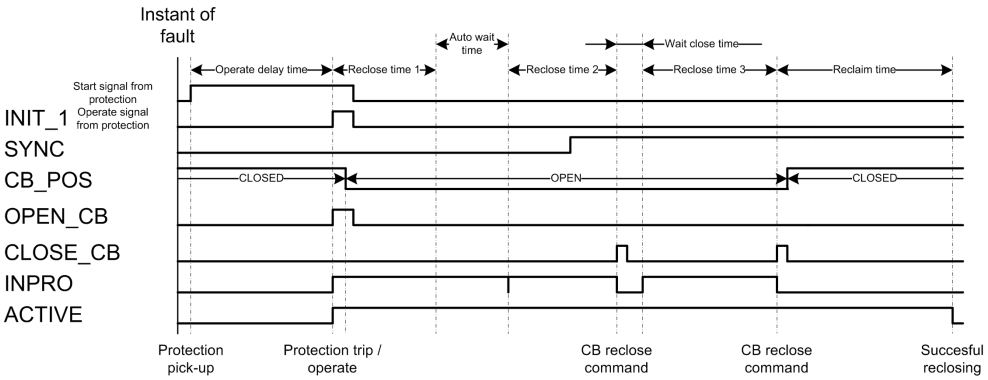

Figure 803: Example of an auto-initiation sequence with synchronization failure in the first shot and circuit breaker closing failure in the second shot

In the first shot, the synchronization condition is not fulfilled (SYNC is FALSE). When the auto wait timer elapses, the sequence continues to the second shot. During the second reclosing, the synchronization condition is fulfilled and the close command is given to the circuit breaker after the second reclose time has elapsed.

After the second shot, the circuit breaker fails to close when the wait close time has elapsed. The third shot is started and a new close command is given after the third reclose time has elapsed. The circuit breaker closes normally and the reclaim time starts. When the reclaim time has elapsed, the sequence is concluded successful.

9.9.6.2 Sequence

The auto reclose sequence is implemented by using CBBs. The highest possible amount of CBBs is seven. If the user wants to have, for example, a sequence of three shots, only the first three CBBs are needed. Using building blocks instead of fixed shots gives enhanced flexibility, allowing multiple and adaptive sequences.

Each CBB is identical. The *Shot number CBB_* setting defines at which point in the auto-reclose sequence the CBB should be performed, that is, whether the particular CBB is going to be the first, second, third, fourth or fifth shot.

During the initiation of a CBB, the conditions of initiation and blocking are checked. This is done for all CBBs simultaneously. Each CBB that fulfils the initiation conditions requests an execution.

The function also keeps track of shots already performed, that is, at which point the auto-reclose sequence is from shot 1 to lockout. For example, if shots 1 and 2 have already been performed, only shots 3 to 5 are allowed.

Additionally, the *Enable shot jump* setting gives two possibilities:

- Only such CBBs that are set for the next shot in the sequence can be accepted for execution. For example, if the next shot in the sequence should be shot 2, a request from CBB set for shot 3 is rejected.
- Any CBB that is set for the next shot or any of the following shots can be accepted for execution. For example, if the next shot in the sequence should be shot 2, also CBBs that are set for shots 3, 4 and 5 are accepted. In other words, shot 2 can be ignored.

In case there are multiple CBBs allowed for execution, the CBB with the smallest number is chosen. For example, if CBB2 and CBB4 request an execution, CBB2 is allowed to execute the shot.

The auto-reclose function can perform up to five auto-reclose shots or cycles.

9.9.6.3 Configuration examples

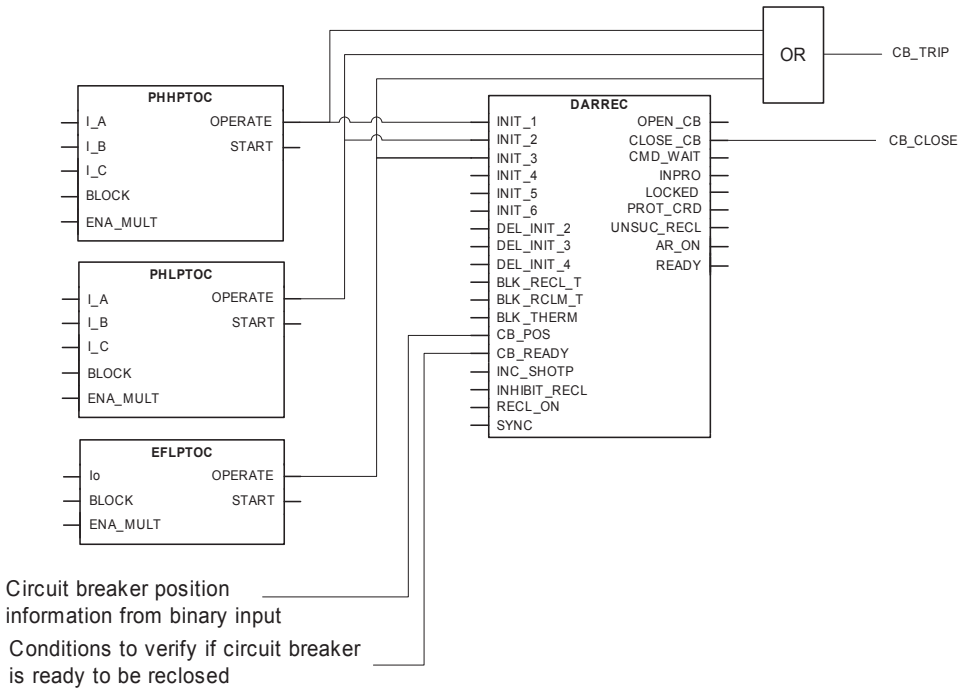

Figure 804: Example connection between protection and autoreclosing functions in protection relay configuration

It is possible to create several sequences for a configuration.

Autoreclose sequences for overcurrent and non-directional earth-fault protection applications where high speed and delayed autoreclosings are needed can be as follows:

Example 1

The sequence is implemented by two shots which have the same reclosing time for all protection functions, namely I>>, I> and Io>. The initiation of the shots is done by activating the operating signals of the protection functions.

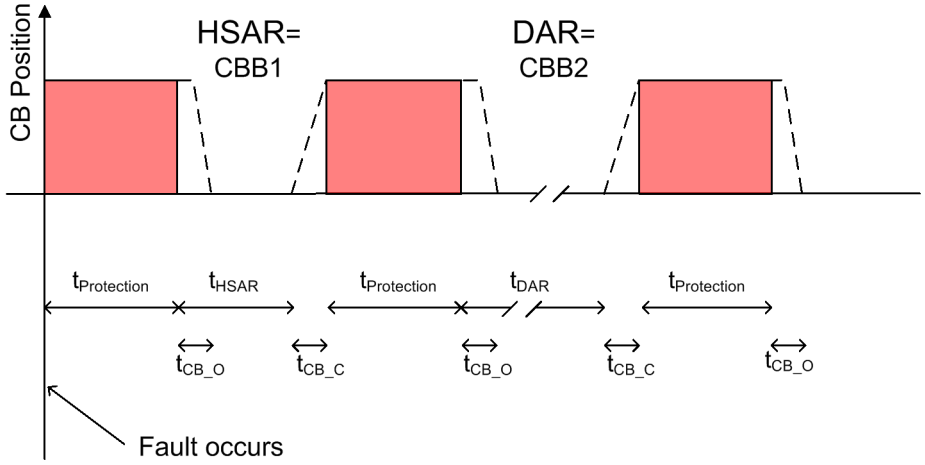

Figure 805: Autoreclosing sequence with two shots

t_{HSAR}	Time delay of high-speed autoreclosing, here: *First reclose time*
t_{DAR}	Time delay of delayed autoreclosing, here: *Second reclose time*
$t_{Protection}$	Operating time for the protection stage to clear the fault
t_{CB_O}	Operating time for opening the circuit breaker
t_{CB_C}	Operating time for closing the circuit breaker

In this case, the sequence needs two CBBs. The reclosing times for shot 1 and shot 2 are different, but each protection function initiates the same sequence. The CBB sequence is described in Table 1400 as follows:

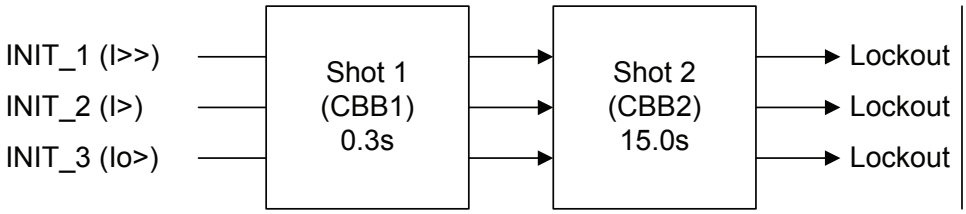

Figure 806: Two shots with three initiation lines

Table 1400: Settings for configuration example 1

Setting name	Setting value
Shot number CBB1	1
Init signals CBB1	7 (lines 1, 2 and 3 = 1+2+4 = 7)
First reclose time	0.3 s (an example)
Table continues on next page	

Setting name	Setting value
Shot number CBB2	2
Init signals CBB2	7 (lines 1, 2 and 3 = 1+2+4 = 7)
Second reclose time	15.0 s (an example)

Example 2

There are two separate sequences implemented with three shots. Shot 1 is implemented by CBB1 and it is initiated with the high stage of the overcurrent protection (I>>). Shot 1 is set as a high-speed autoreclosing with a short time delay. Shot 2 is implemented with CBB2 and meant to be the first shot of the autoreclose sequence initiated by the low stage of the overcurrent protection (I>) and the low stage of the non-directional earth-fault protection (Io>). It has the same reclosing time in both situations. It is set as a high-speed autoreclosing for corresponding faults. The third shot, which is the second shot in the autoreclose sequence initiated by I> or Io>, is set as a delayed autoreclosing and executed after an unsuccessful high-speed autoreclosing of a corresponding sequence.

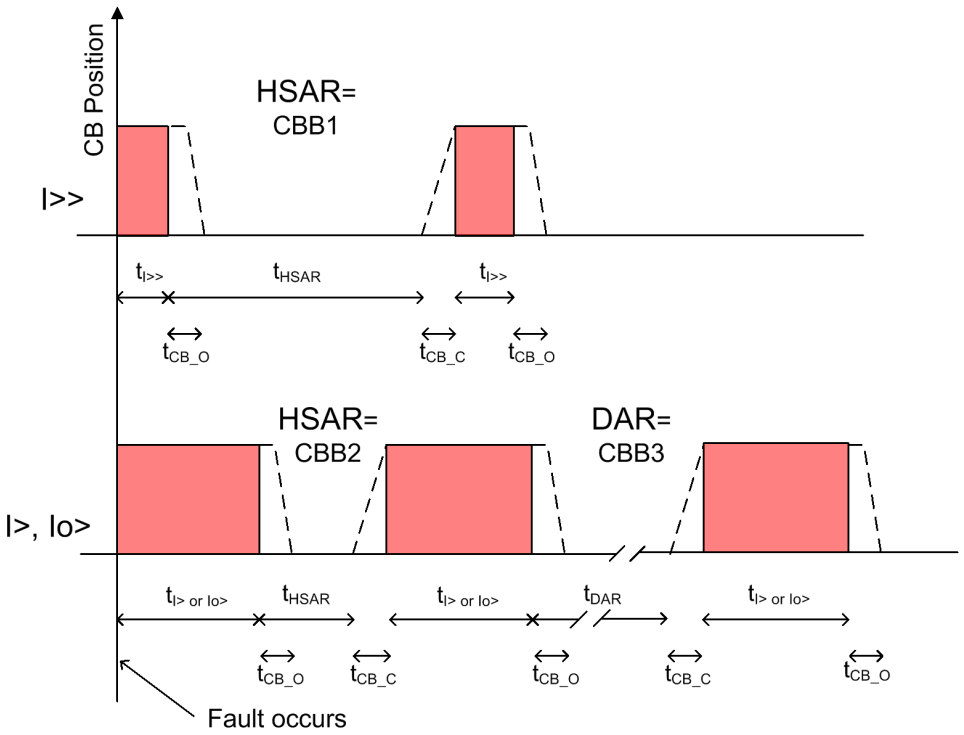

Figure 807: Autoreclosing sequence with two shots with different shot settings according to initiation signal

t_{HSAR}	Time delay of high-speed autoreclosing, here: *First reclose time*
t_{DAR}	Time delay of delayed autoreclosing, here: *Second reclose time*
$t_{I>>}$	Operating time for the I>> protection stage to clear the fault

$t_{I>}$ or $_{Io>}$	Operating time for the I> or Io> protection stage to clear the fault
t_{CB_O}	Operating time for opening the circuit breaker
t_{CB_C}	Operating time for closing the circuit breaker

In this case, the number of needed CBBs is three, that is, the first shot's reclosing time depends on the initiation signal.

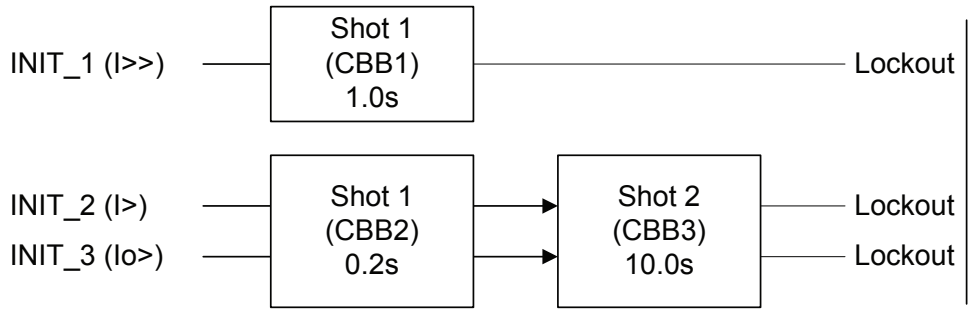

Figure 808: Three shots with three initiation lines

If the sequence is initiated from the `INIT_1` line, that is, the overcurrent protection high stage, the sequence is one shot long. If the sequence is initiated from the `INIT_2` or `INIT_3` lines, the sequence is two shots long.

Table 1401: Settings for configuration example 2

Setting name	Setting value
Shot number CBB1	1
Init signals CBB1	1 (line 1)
First reclose time	0.0 s (an example)
Shot number CBB2	1
Init signals CBB2	6 (lines 2 and 3 = 2+4 = 6)
Second reclose time	0.2 s (an example)
Shot number CBB3	2
Init signals CBB3	6 (lines 2 and 3 = 2+4 = 6)
Third reclose time	10.0 s

9.9.6.4 Delayed initiation lines

The autoreclose function consists of six individual autoreclose initiation lines `INIT_1...INIT 6` and three delayed initiation lines:

- `DEL_INIT_2`
- `DEL_INIT_3`
- `DEL_INIT_4`

DEL_INIT_2 and INIT_2 are connected together with an OR-gate, as are inputs 3 and 4. Inputs 1, 5 and 6 do not have any delayed input. From the autoreclosing point of view, it does not matter whether INIT_x or DEL_INIT_x line is used for shot initiation or blocking.

The autoreclose function can also open the circuit breaker from any of the initiation lines. It is selected with the *Tripping line* setting. As a default, all initiation lines activate the OPEN_CB output.

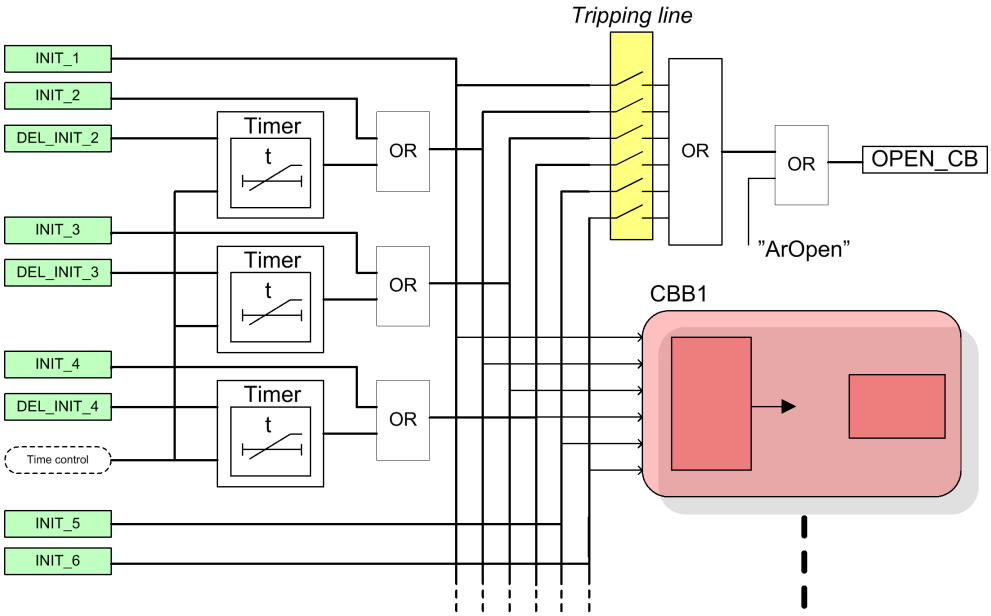

Figure 809: Simplified logic diagram of initiation lines

Each delayed initiation line has four different time settings:

Table 1402: Settings for delayed initiation lines

Setting name	Description and purpose
Str x delay shot 1	Time delay for the DEL_INIT_x line, where x is the number of the line 2, 3 or 4. Used for shot 1.
Str x delay shot 2	Time delay for the DEL_INIT_x line, used for shot 2.
Str x delay shot 3	Time delay for the DEL_INIT_x line, used for shot 3.
Str x delay shot 4	Time delay for the DEL_INIT_x line, used for shots 4 and 5. Optionally, can also be used with SOTF.

9.9.6.5 Shot initiation from protection start signal

In it simplest, all auto-reclose shots are initiated by protection trips. As a result, all trip times in the sequence are the same. This is why using protection trips may not be the

optimal solution. Using protection start signals instead of protection trips for initiating shots shortens the trip times.

Example 1

When a two-shot-sequence is used, the start information from the protection function is routed to the DEL_INIT 2 input and the operate information to the INIT_2 input. The following conditions have to apply:

- protection operate time = 0.5s
- *Str 2 delay shot 1* = 0.05s
- *Str 2 delay shot 2* = 60s
- *Str 2 delay shot 3* = 60s

Operation in a permanent fault:

1. Protection starts and activates the DEL_INIT 2 input.
2. After 0.05 seconds, the first autoreclose shot is initiated. The function opens the circuit breaker: the OPEN_CB output activates. The total trip time is the protection start delay + 0.05 seconds + the time it takes to open the circuit breaker.
3. After the first shot, the circuit breaker is reclosed and the protection starts again.
4. Because the delay of the second shot is 60 seconds, the protection is faster and trips after the set operation time, activating the INIT 2 input. The second shot is initiated.
5. After the second shot, the circuit breaker is reclosed and the protection starts again.
6. Because the delay of the second shot is 60 seconds, the protection is faster and trips after the set operation time. No further shots are programmed after the final trip. The function is in lockout and the sequence is considered unsuccessful.

Example 2

The delays can be used also for fast final trip. The conditions are the same as in Example 1, with the exception of *Str 2 delay shot 3* = 0.10 seconds.

The operation in a permanent fault is the same as in Example 1, except that after the second shot when the protection starts again, *Str 2 delay shot 3* elapses before the protection operate time and the final trip follows. The total trip time is the protection start delay + 0.10 seconds + the time it takes to open the circuit breaker.

9.9.6.6 Fast trip in Switch on to fault

The *Str _ delay shot 4* parameter delays can also be used to achieve a fast and accelerated trip with SOTF. This is done by setting the *Fourth delay in SOTF* parameter to "1" and connecting the protection start information to the corresponding DEL_INIT_ input.

When the function detects a closing of the circuit breaker, that is, any other closing except the reclosing done by the function itself, it always prohibits shot initiation for

the time set with the *Reclaim time* parameter. Furthermore, if the *Fourth delay in SOTF* parameter is "1", the *Str _ delay shot 4* parameter delays are also activated.

Example 1

The protection operation time is 0.5 seconds, the *Fourth delay in SOTF* parameter is set to "1" and the *Str 2 delay shot 4* parameter is 0.05 seconds. The protection start signal is connected to the `DEL_INIT_2` input.

If the protection starts after the circuit breaker closes, the fast trip follows after the set 0.05 seconds. The total trip time is the protection start delay + 0.05 seconds + the time it takes to open the circuit breaker.

9.9.7 Signals

Table 1403: DARREC Input signals

Name	Type	Default	Description
INIT_1	BOOLEAN	0=False	AR initialization / blocking signal 1
INIT_2	BOOLEAN	0=False	AR initialization / blocking signal 2
INIT_3	BOOLEAN	0=False	AR initialization / blocking signal 3
INIT_4	BOOLEAN	0=False	AR initialization / blocking signal 4
INIT_5	BOOLEAN	0=False	AR initialization / blocking signal 5
INIT_6	BOOLEAN	0=False	AR initialization / blocking signal 6
DEL_INIT_2	BOOLEAN	0=False	Delayed AR initialization / blocking signal 2
DEL_INIT_3	BOOLEAN	0=False	Delayed AR initialization / blocking signal 3
DEL_INIT_4	BOOLEAN	0=False	Delayed AR initialization / blocking signal 4
BLK_RECL_T	BOOLEAN	0=False	Blocks and resets reclose time
BLK_RCLM_T	BOOLEAN	0=False	Blocks and resets reclaim time
BLK_THERM	BOOLEAN	0=False	Blocks and holds the reclose shot from the thermal overload
CB_POS	BOOLEAN	0=False	Circuit breaker position input
CB_READY	BOOLEAN	1=True	Circuit breaker status signal
INC_SHOTP	BOOLEAN	0=False	A zone sequence coordination signal
INHIBIT_RECL	BOOLEAN	0=False	Interrupts and inhibits reclosing sequence
RECL_ON	BOOLEAN	0=False	Level sensitive signal for allowing (high) / not allowing (low) reclosing
SYNC	BOOLEAN	0=False	Synchronizing check fulfilled

Table 1404: DARREC Output signals

Name	Type	Description
OPEN_CB	BOOLEAN	Open command for circuit breaker
CLOSE_CB	BOOLEAN	Close (reclose) command for circuit breaker
CMD_WAIT	BOOLEAN	Wait for master command

Table continues on next page

Name	Type	Description
INPRO	BOOLEAN	Reclosing shot in progress, activated during dead time
LOCKED	BOOLEAN	Signal indicating that AR is locked out
PROT_CRD	BOOLEAN	A signal for coordination between the AR and the protection
UNSUC_RECL	BOOLEAN	Indicates an unsuccessful reclosing sequence
AR_ON	BOOLEAN	Autoreclosing allowed
READY	BOOLEAN	Indicates that the AR is ready for a new sequence, i.e. the CB_READY input equals TRUE
ACTIVE	BOOLEAN	Reclosing sequence is in progress

9.9.8 Settings

Table 1405: DARREC Non group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Operation	1=on 5=off			1=on	Operation Off/On
Reclosing operation	1=Off 2=External Ctl 3=On			1=Off	Reclosing operation (Off, External Ctl / On)
Close pulse time	10...10000	ms	10	200	CB close pulse time
Reclaim time	100...1800000	ms	100	10000	Reclaim time
Terminal priority	1=None 2=Low (follower) 3=High (master)			1=None	Terminal priority
Synchronisation set	0...127		1	0	Selection for synchronizing requirement for reclosing
Auto initiation cnd	1=Not allowed 2=When sync fails 3=CB doesn't close 4=Both			2=When sync fails	Auto initiation condition
Tripping line	0...63		1	0	Tripping line, defines INIT inputs which cause OPEN_CB activation
Fourth delay in SOTF	0=False 1=True			0=False	Sets 4th delay into use for all DEL_INIT signals during SOTF
First reclose time	0...300000	ms	10	5000	Dead time for CBB1
Second reclose time	0...300000	ms	10	5000	Dead time for CBB2
Third reclose time	0...300000	ms	10	5000	Dead time for CBB3
Fourth reclose time	0...300000	ms	10	5000	Dead time for CBB4
Fifth reclose time	0...300000	ms	10	5000	Dead time for CBB5
Sixth reclose time	0...300000	ms	10	5000	Dead time for CBB6
Seventh reclose time	0...300000	ms	10	5000	Dead time for CBB7
Init signals CBB1	0...63		1	0	Initiation lines for CBB1

Tap changer control with voltage regulator	OL5ATCC	COLTC	90V

9.10.2 Function block

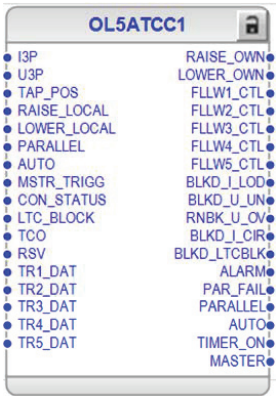

Figure 810: Function block

9.10.3 Functionality

The tap changer control with voltage regulator function OL5ATCC (on-load tap changer controller) is designed for regulating the voltage of power transformers with on-load tap changers in distribution substations. OL5ATCC provides a manual or automatic voltage control of the power transformer by using the raising or lowering signals to the on-load tap changer.

The automatic voltage regulation can be used in single or parallel transformer applications. The parallel operation can be based on the Master/Follower principle (M/F), Negative Reactance Principle (NRP) or Minimizing Circulating Current (MCC).

OL5ATCC includes the line drop compensation (LDC) functionality, and the load decrease is possible with a dynamic voltage reduction.

Either definite time characteristic (DT) or inverse time characteristic (IDMT) is selectable for delays between the raising and lowering operations.

The function contains a blocking functionality. It is possible to block the voltage control operations with an external signal or with the supervision functionality of the function.

9.10.4 Analog channel configuration

OL5ATCC has two analog group inputs which must be properly configured.

Table 1409: Analog inputs

Input	Description
I3P	Three-phase currents
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1410: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with one voltage connected to channel 1, two voltages connected to channels 2 and 3, or all three voltage channels connected.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks

in this document. The configuration can be written to the protection relay once the mismatch is corrected.

9.10.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of OL5ATCC can be described with a module diagram. All the modules in the diagram are explained in the next sections.

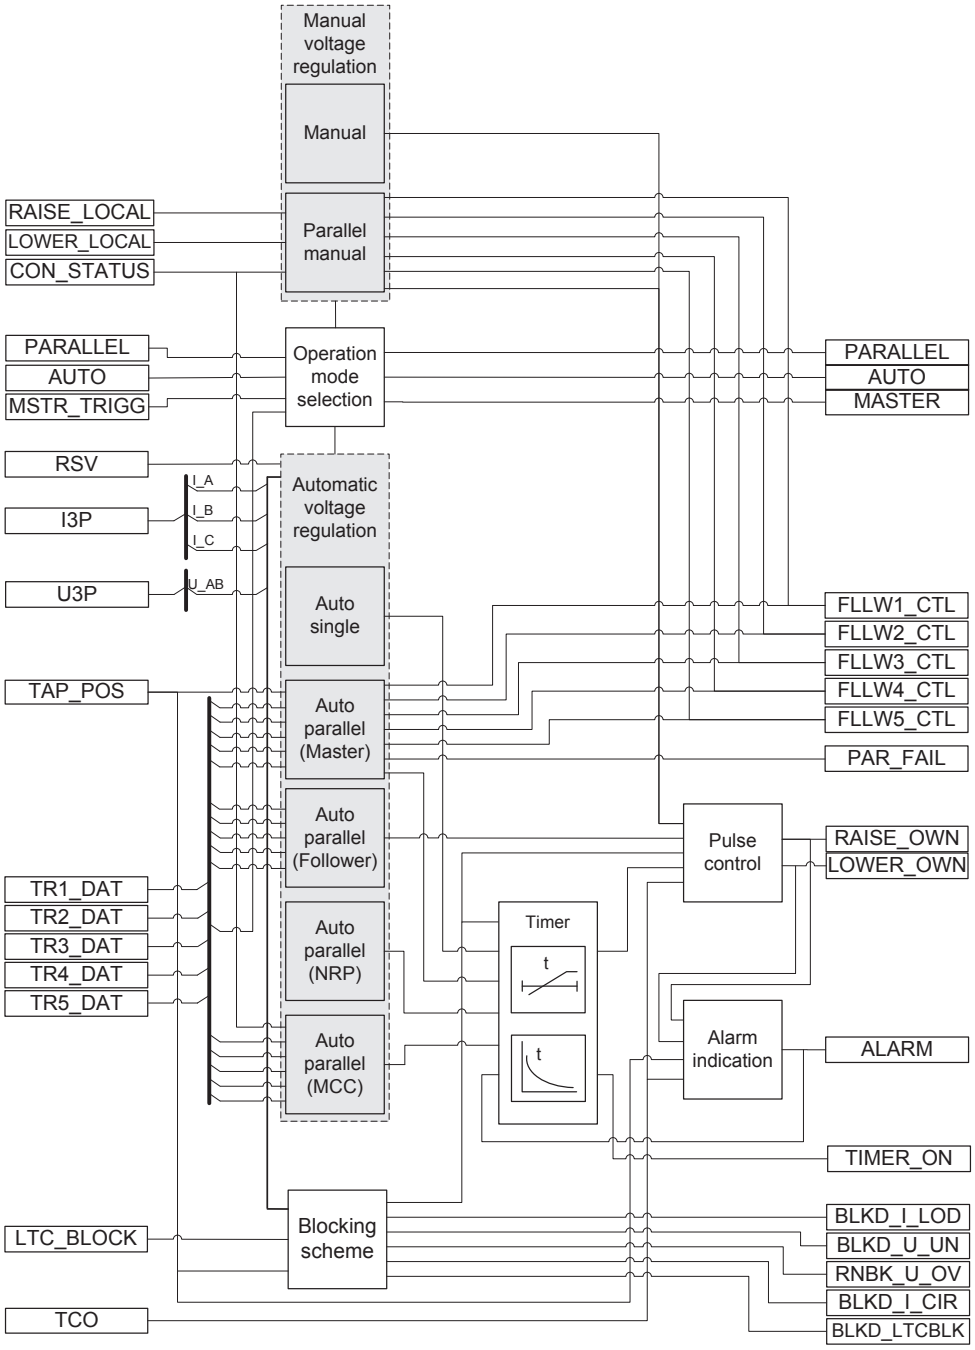

Figure 811: Functional module diagram

9.10.5.1 Voltage and current measurements

The measured voltage must be a phase-to-phase voltage from the regulated side. Typically, it is the phase-to-phase voltage U_AB from the secondary side of the power

transformer. If the phase voltages are measured, the voltage U_AB is calculated internally in the protection relay.

The currents from the secondary side of the power transformer (I_x, where x is A, B or C) have several uses.

- The highest phase current value is used for overcurrent blocking.
- The currents from the secondary side of the power transformer are used for LDC (average of the connected inputs).
- The currents from the secondary side of the power transformer are used for calculating the circulating current in the NRP and MCC operation modes.

Both voltage U_AB and the phase currents from the secondary side are always measured using the value of the filtered fundamental frequency component (DFT). Hence, the harmonics are always suppressed. Moreover, the measured voltage value is continuously average-filtered with the eight-value-long sliding window. The phase-compensated voltage U_A is always used in calculations, although it is not connected. This averaged value, the parameter U_m in Equation 345, is used for control, and its magnitude can be read from the monitored data U_MEAS.

Similarly, the magnitude of the phase current of the own transformer, I_x, and the phase angle difference between the internally phase-compensated voltage U_A and phase current I_x are also average-filtered by the same fixed-length window. The phase angle value can be read from the monitored data ANGL_UA_IA. These currents and phase angle differences are used solely in circulating current calculations.

The angle difference is used in Equation 341 and Equation 343.

There are minimum limits for the voltage and current magnitudes, so the magnitude and phase angle difference values diverge from zero. The voltage magnitude must exceed three percent of U_n and the current I_A must exceed two percent of I_n.

9.10.5.2 Tap changer position inputs

The position value of the tap changer can be brought to OL5ATCC as a resistance value, an mA signal or a binary-coded signal. More information on how the resistance value, the mA signal or a binary-coded interface are implemented can be found in TPOSYLTC in this manual.

The indicated tap changer position of the own transformer is internally connected to the `TAP_POS` input, and the tap changer positions of the parallel transformers are fed to inputs `TRx_DAT` via data combiner function blocks OLGAPC. This also defines the connection identity so that follower 1 is connected to `TR1_DAT`, follower 2 is connected to `TR2_DAT` and follower 3 is connected to `TR3_DAT`. The own transformer position can be read from the input `TAP_POS`. The follower tap changer positions can be read from the input data `TR_TAP_POS` of OLGAPCx.

The tap changer position value is given in parentheses. For example, (0) indicates that there is no tap changer position connected or the quality of the tap changer position value is bad. Typically, if no tap changer position is connected, all the TPOSYLTC binary inputs are FALSE by default and the value shown is (0). A value other than zero indicates bad quality. OL5ATCC treats a bad-quality tap changer position as unconnected tap position information.

9.10.5.3 Operation mode selection

OL5ATCC has the *Operation mode* and *Parallel mode* settings for selecting the desired operation mode. The *Operation mode* setting can have any of the following values: "Manual", "Auto single", "Parallel manual", "Auto parallel", "Input control" and "Command". If the *Operation mode* setting is set to "Input control", the active operation mode is determined by the inputs PARALLEL and AUTO.

The PARALLEL input defines if the transformer (voltage regulator) is in parallel or single mode. The AUTO input defines if the operation is in auto or manual mode. The PARALLEL and AUTO outputs represent acting “Parallel or single operation” and “Auto/Manual indication”, respectively.

When the *Operation mode* setting is set to "Command", the active operation mode is determined by the IEC 61850 command data points Auto and ParOp.

Furthermore, if the operation mode has been set to any parallel mode, that is "Parallel manual" or "Auto parallel" via the *Operation mode* setting, binary inputs or commands, the parallel mode is selected by the setting *Parallel mode*.

The *Parallel mode* setting can have any of following values: "Master", "Follower", "NRP", "MCC", "Input control" or "Command".

If the *Parallel mode* setting is set to "Input control", the active operation mode is determined by the input MSTR_TRIGG.

When the *Parallel mode* setting is set to "Command", the active operation mode is determined by the IEC 61850 command data point MstrOp.

MSTR_TRIGG is a rising edge input, that is, the master role is kept even though the MSTR_TRIGG input changes from “true” to “false”. This functionality is used because another parallel transformer must be able to assume the master role even though the MSTR_TRIGG input has remained in “true” state. Switching between operation mode states resets the internal master set. However, switching between Auto master mode and Parallel manual mode keeps the master role.

Table 1411: Active operation mode when Operation mode setting is "Manual", "Auto single", "Parallel manual" or "Auto parallel"

Operation mode	Parallel mode	MSTR_TRIGG	OPR_MODE_STS
Manual	-	-	Manual
Auto single	-	-	Auto single
Parallel manual	Master	-	Parallel manual

Table continues on next page

Operation mode	Parallel mode	MSTR_TRIGG	OPR_MODE_STS
Parallel manual	Input control Command	0[1)]	Manual
Parallel manual	Input control Command	1[1)]	Parallel manual
Auto parallel	Master	-	Auto master
Auto parallel	Follower	-	Auto follower
Auto parallel	MCC	-	MCC
Auto parallel	NRP	-	NRP
Auto parallel	Input control Command	0[1)]	Auto follower
Auto parallel	Input control Command	1[1)]	Auto master

1) The master role is set on rising edge and internally kept until another parallel transformer assumes the master role, or the operation mode is changed.

Table 1412: Active operation mode when Operation mode setting is "Input control" or "Command"

PARALLEL	AUTO	Parallel mode	MSTR_TRIGG	OPR_MODE_STS
0	0	-	-	Manual
0	1	-	-	Auto single
1	0	Master	-	Parallel manual
1	0	Follower	-	Manual
1	0	MCC	-	Manual
1	0	NRP	-	Manual
1	0	Input control Command	0[1)]	Manual
1	0	Input control Command	1[1)]	Parallel manual
1	1	Master	-	Auto master
1	1	Follower	-	Auto follower
1	1	MCC	-	MCC
1	1	NRP	-	NRP
1	1	Input control Command	0[1)]	Auto follower
1	1	Input control Command	1[1)]	Auto master

1) Master role is set on rising edge and internally kept until another parallel transformer overtakes master role, or if operation mode is changed.

The active operation mode can be read from the monitored data OPR_MODE_STS.

Command exclusion

An active operation mode change using three inputs (PARALLEL, AUTO, MSTR_TRIGG and setting group change either by input or via menu) is needed when

the active operation mode must be changed automatically, that is, there is a logic which drives these three inputs based on the status information from the circuit breakers.

The common Local/Remote (L/R) exclusion concerns the manual raise and lower commands of OL5ATCC, that is, it internally provides the exclusion mechanism to prevent remote commands (from SCADA) when the protection relay is in local mode and vice versa.

9.10.5.4 Manual voltage regulation

The manual raising and lowering commands can be given via the configuration inputs LOWER_LOCAL and RAISE_LOCAL, via the HMI of the protection relay or via remote commands. The active operation mode of OL5ATCC must be set to "Manual" or "Parallel manual" and the Local/Remote control LR state monitored data of the protection relay has to be "Local" to execute the control commands manually from HMI or via configuration inputs. If OL5ATCC is set to "Manual" or "Parallel manual" but the LR state is set to "OFF" or "Remote", no manual control commands can be given.

For remote commands, the active operation mode of OL5ATCC must also be set to "Manual" or "Parallel manual" and the LR state monitored data has to be "Remote".

The manual raising or lowering commands can be given locally either via the *Manual control* parameter ("Cancel"/"Lower"/"Raise") located in the HMI menu **Control/ OL5ATCC1** or via the configuration inputs LOWER_LOCAL or RAISE_LOCAL.

A raising command is given by selecting the enumeration value "Raise" and the lowering command is given by selecting the enumeration value "Lower". An accepted manual raising or lowering command activates the corresponding output RAISE_OWN or LOWER_OWN to control the voltage of the own transformer.

Parallel manual voltage regulation

While in single manual mode the voltage regulator acts independently, in parallel manual mode the voltage regulator set to "Parallel manual" acts as master and the others follow.

The parallel manual mode is intended for maintenance work and has no permanent settings. When the mode is set again to automatic, the voltage is stepped back to the set value.

Followers not responding to parallel manual command are indicated at output PAR_FAIL and the number of failed followers at monitored data FAIL_FLLW.

In parallel manual mode, the TR_STATUS monitored data indicates "Master" status to the other parallel transformers.

Voltage control vs. tap changer moving direction

OL5ATCC has the control settings *Lower block tap* and *Raise block tap* which give the tap changer position that results in the lowest and highest controlled voltage value (usually at the LV side of the transformer). *Raise block tap* can be set higher than *Lower block tap* and *Lower block tap* can be set higher than *Raise block tap*.

When the value of *Raise block tap* exceeds the *Lower block tap* value, the raise control activates the RAISE_OWN output. This results in raising the tap changer position, and the measured voltage rises. Furthermore, the RAISE_OWN output value is TRUE. If the own tap changer position is connected (that is, the own tap changer's quality is good), the tap changer alarm is activated if the tap changer does not move upwards within *Cmd error delay time* after the pulse activation. As a result, ALARM_REAS in the monitored data contains a command error value. The default value of the *Cmd error delay time* setting is 20 seconds.

The lowering control works in a similar way, as shown in Figure 812. In the output data, the LOWER_OWN output value is TRUE. An alarm is generated if the tap changer does not move downwards in *Cmd error delay time* after the pulse activation, assuming that the own tap changer position is connected.

In the second case, the parameters are set so that the value of *Lower block tap* exceeds the value of *Raise block tap*. The raising control activates the RAISE_OWN output. The result should be that the tap changer lowers its position and the measured voltage rises. Furthermore, the RAISE_OWN output value is TRUE in the output data. If the own tap changer position is connected, the tap changer alarm is activated if the tap changer does not move downwards in *Cmd error delay time* after the pulse activation, resulting that ALARM_REAS in the monitored data contains a command error value.

The lowering control works in a similar way, as shown in Figure 812. In the output data, the LOWER_OWN output value is TRUE. An alarm is generated if the tap changer does not move upwards in *Cmd error delay time* after the pulse activation, assuming that the own tap changer position is connected.

9.10.5.5 Automatic voltage regulation of single transformers (Auto single)

OL5ATCC is intended to control the power transformers with a motor-driven on-load tap changer. The function regulates the voltage at the secondary side of the power transformer. The control method is based on a step-by-step principle, which means that one control pulse at a time is issued to the tap changer mechanism to move it exactly one position upwards or downwards. However, when intermediate steps are not indicated for the tap changer, it does not cause alarm if more than one step change is met.

The purpose of the regulator is to maintain a stable secondary voltage of the power transformer. The basis for this operation is the *Band center voltage* setting. By increasing or decreasing various compensation factors, the regulator calculates a control voltage from the band center voltage as shown in Equation 338. Hence, the control voltage is the desired transformer secondary voltage to be maintained by the

regulator. The control voltage is compared to the measured voltage and the difference between the two forms the regulating process error.

Since the tap changer changes the voltage in steps, a certain error has to be allowed. The error, called *Band width voltage*, is also set by the user. A recommended setting for *Band width voltage* is close to twice the step voltage of the transformer ΔU_{step} and never below it as a minimum. For example, *Band width voltage* is twice the value of ΔU_{step} in Figure 812.

If the measured voltage fluctuates within the control voltage ± half the *Band width voltage* setting, the regulator is inactive. If the measured voltage is outside the half-bandwidth voltage limits, an adjustable delay T1 (*Control delay time 1*) starts, as shown in Figure 812, where the lowering function is an example. The delay T1 remains active as long as the measured voltage is outside the hysteresis limits of half the value of *Band width voltage*. The factory setting for the hysteresis is 10 percent of the set *Band width voltage*.

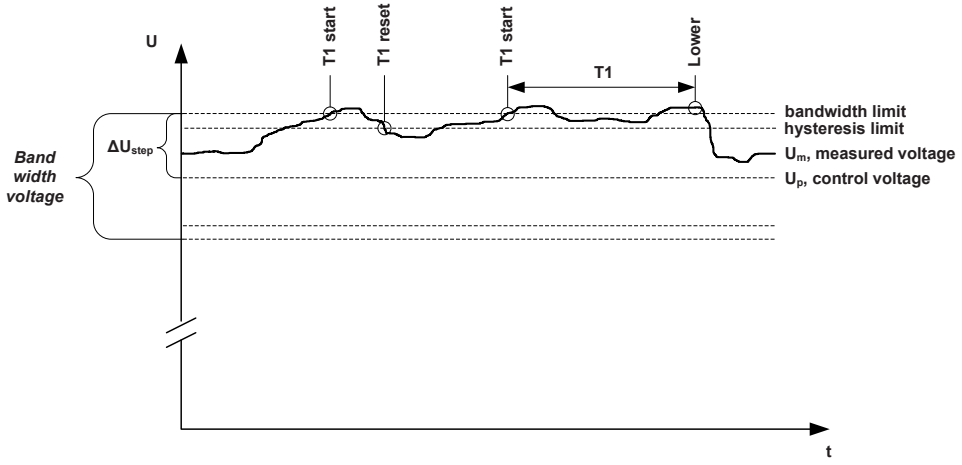

Figure 812: Voltage-regulating function. A control pulse to lower the voltage is issued after the elapsed T1.

If the measured voltage is outside the hysteresis when the delay counter T1 reaches its setting value, the raising or lowering output relay is activated. This activates either output pulse `RAISE_OWN` or `LOWER_OWN`, and the motor drive of the tap changer operates. The status of these outputs can be read from the output data `RAISE_OWN` or `LOWER_OWN`.

If the measured voltage falls or rises within the hysteresis limits during the operating time, the delay counter is reset.

The pulse length can be defined with the *LTC pulse time* setting. The default value is 1.5 seconds.

A short delay, same as the typical tap changer operating time, is active before the start of the next operating timer. For OL5ATCC, the delay is set to 6 seconds. If one tap changer operation is not enough to regulate the transformer voltage within the

hysteresis limits, a second adjustable delay T2 (*Control delay time 2*), usually with a shorter time setting than T1, starts. This delay is used for the control commands within the same sequence until the recovery of voltage occurs. The delays T1 and T2 can be selected either with definite or inverse time characteristics. In the inverse time mode, the operate time depends on the difference between the control voltage and the measured voltage as shown in Equation 345. The bigger the difference in the voltage, the shorter the operating time. More information on the inverse time operation can be found in the Timer characteristics chapter.

Regulation equation

The simple regulating principle is often complemented by additional features to take the voltage drop of lines into account (line drop compensation), coordinate the regulation of parallel transformers and change the voltage level according to the loading state of the network. The control voltage U_p is calculated according to the equation

$$U_p = U_s + U_z + U_{ci} - U_{rsv}$$

(Equation 338)

U_p	Control voltage
U_s	Set voltage level (*Band center voltage*)
U_z	Line drop compensation term
U_{ci}	Circulating current compensation term
U_{rsv}	Voltage reduction parameter

U_p can be directly read in the monitored data U_CTL.

The circulating current compensation term is calculated only in the parallel active operation modes "NRP" and "MCC".

Line drop compensation (LDC)

The LDC feature is used to compensate the voltage drop along a line or network fed by the transformer. The compensation setting parameters can be either calculated if the resistance and reactance of the line are known or measured from the line drop.

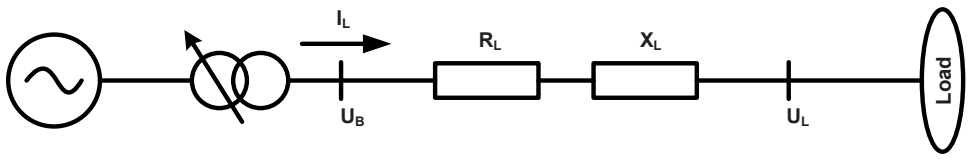

Figure 813: Equivalent electrical circuit for calculating the LDC term

The compensation parameters *Line drop V Ris* (U_r) and *Line drop V React* (U_x) are percentage values of U_n according to the equations

$$Line\ drop\ V\ Ris = U_r[\%] = \frac{\sqrt{3} \cdot I_{CT_n1} \cdot R}{U_{VT_n1}} \cdot 100 \quad [\%U_n]$$

$$Line\ drop\ V\ React = U_x[\%] = \frac{\sqrt{3} \cdot I_{CT_n1} \cdot X}{U_{VT_n1}} \cdot 100 \quad [\%U_n]$$

(Equation 339)

I_{CT_n1}	Nominal primary current of the CT
U_{VT_n1}	Nominal primary voltage of the VT (phase-to-phase voltage)
R	Resistance of the line, Ω/phase
X	Reactance of the line, Ω/phase

The general LDC equation can be calculated.

$$U_z = \frac{I_L}{I_{CT_n1}} \cdot \frac{\left(U_r[\%]\cos\varphi + U_x[\%]\sin\varphi\right)}{100} \quad [xU_n]$$

(Equation 340)

I_L	Average of the currents I_A, I_B and I_C
I_{CT_n1}	Nominal primary current of the CT
U_r	Setting *Line drop V Ris*
U_x	Setting *Line drop V React*
φ	Phase angle between U_A and I_A (ANGL_UA_IA)

By default, LDC is not active, but it can be activated by setting *LDC enable* to "True". To keep the LDC term within acceptable limits in all situations, OL5ATCC has a setting parameter *LDC limit*, which has a default value of 0.10 xU_n. This gives the maximum value for U_z in Equation 338.

If more than one line is connected to the LV busbar, the equivalent impedance is calculated and given as a parameter setting as shown in Figure 813 for the equivalent electrical circuit for calculating LDC. For example, if there are N number of identical lines with identical loads in the substation, the R and X values needed for the settings *Line drop V React* and *Line drop V Ris* are obtained by dividing the resistance and the reactance of one line by N. Because the voltage drop is different in lines with different impedances and load currents, it is necessary to make a compromise when setting the *Line drop V React* and *Line drop V Ris* settings. Raising the voltage in the point of the lowest voltage must not lead to overvoltage elsewhere.

By default, LDC is effective only on the normal active power flow direction. If the active power flow in the transformer turns opposite, that is, from the regulated side towards the system in the upper level, the LDC term is ignored, that is, it is set to zero. In such a case, it is assumed that the feeding units at the regulated side of the transformers maintain proper voltage levels. This can cause a conflict if the transformer tries to reduce the voltage at the substation. Additionally, it is difficult to

predict the actual voltage levels in the feeder lines in such a case, and lowering the voltage at the substation can have harmful effects in the far end of the network. However, the *Rv Pwr flow allowed* setting allows also negative LDC terms to be taken into equation.

The topology changes in the network can cause changes to the equivalent impedance value of the network. If the change is substantial, the setting groups can be used to switch between different setting values for *Line drop V React* and *Line drop V Ris*. In practice this means that the boolean-type information from the topology change is connected to the active setting group change.

The use of the LDC equation in the case of parallel transformers is described in the Automatic voltage regulation of parallel transformers (Auto parallel) chapter.

Reduce Set Voltage (RSV) input

The system frequency decreases when the active power production in the network is smaller than its consumption. Either the power supply has to be increased or some loads have to be shed to restore the power balance.

The simplest way to decrease the load is to reduce the voltage level by giving a lower band center voltage value to the regulators. For this purpose, OL5ATCC has the setting group parameter *Band reduction*. The `RSV` input activation results in reduction. If this input is set to TRUE, a set target voltage value is decreased by *Band reduction*. If more than one `RSV` reduction steps are desired, the setting group change has to be used where different *Band reduction* values are supported. The decreased value is kept as a target value as long as the `RSV` input is TRUE.

Because the decrease of frequency indicates a need to reduce the load, it is practical to connect the start signal of an underfrequency function block to the `RSV` digital input.

It depends on the load characteristics how much the load is reduced when the voltage drops. For instance, purely resistive loads are proportional to the square of the voltage, whereas motor drives based on frequency controllers may draw constant power despite small voltage changes.

The status of the `RSV` input can be read from the `RSV` input data.

9.10.5.6 Automatic voltage regulation of parallel transformers (Auto parallel)

A circulating current may occur between transformers if two or more transformers with slightly different ratios are energized in parallel. This is due to the unbalanced short circuit impedances of the parallel transformers. To avoid such currents, the tap changers of the transformers should be adjusted to achieve equilibrium. If the transformers are assumed identical, the tap (voltage) steps and tap positions should also match. In this case, the Master/Follower principle can be used. However, unequally rated transformers with different tap steps can be connected in parallel and these configurations can also be managed by OL5ATCC. For these configurations, the Minimizing Circulating Current (MCC) or Negative Reactance Principle (NRP)

should be used. The MCC and NRP principles are also suitable for identical transformers.

The circulating current, which is almost purely inductive, is defined as negative if it flows towards the transformer. U_{ci} in Equation 338 is positive and the control voltage U_p rises as a result of the RAISE_OWN output signal activation if the circulating current level is sufficient (Equation 342 and Equation 344) and the other parameters remain the same. As a result, the voltage rise should diminish the circulating current.

LDC equation and parallel connection

The additional challenge in the parallel connection regarding LDC is to know the total current which flows through the parallel transformers.

In the Master/Follower mode, it is easier to know the total current than in other parallel modes since the transformers are assumed to have identical ratings, that is, the total current (I_L in Equation 340) is obtained by multiplying the measured load current (the average of the secondary currents I_A, I_B and I_C of the connected own transformer) with the number of parallel transformers. OL5ATCC can internally determine the number of parallel transformers from the connected tap changer position inputs. However, if there is no position information from the other parallel transformers, the correct number of parallel transformers, excluding the own transformer, needs to be set with the *Parallel trafos* setting.

In the MCC mode, the horizontal communication transfers the information from the measured load currents between the regulators so that the total current needed in LDC can be summed accurately. Here, I_L is defined to be the phasor sum of all the parallel transformers' secondary-side currents. The currents from other transformers must be fed via the TR_I_AMPL and TR_I_ANGL inputs of the OLGAPC function.

In the NRP mode, the parallel transformers have different ratings and there is no communication between the regulators. Therefore, when setting *Line drop V React* and *Line drop V Ris*, the I_{CT_n1} used in the equation should be the sum of the rated currents of all the transformers operating in parallel. Here, I_L is also defined as the average of the connected secondary currents (I_A, I_B and I_C). The calculated LDC value can be read from the monitored data LDC.

Master/Follower principle M/F

The M/F operation principle is suitable for power transformers with identical ratings and step voltages. One voltage regulator (master) measures and controls and the other regulators (followers) follow the master, that is, all the tap changers connected in parallel are synchronized. This parallel operation is obtained by connecting the FLLWx_CTL output of the master to the corresponding OLGAPC function input TR_TAP_FLLW of the followers via horizontal GOOSE communication.

The values for the FLLWx_CTL command are 1=Lower follower x and 2=Raise follower x. Consequently, the values for OLGAPC function TR_TAP_FLLW command are 1=Lower and 2=Raise.

If several regulators act as masters (one at a time), their outputs also have to be routed to the inputs of the other regulators. To start the parallel operation, the master regulator is set to the "Auto master" mode and the followers to the "Auto follower" mode. In input control or command mode, a regulator acting as a follower, can be set to master by activating the MSTR_TRIGG input if the *Master input enabled* setting is activated. The regulator indicates its master status (“Independent”, “Master” or “Follower”) by the TR_STATUS output. A parallel regulator, previously acting as master, receives this signal via the TR_STATUS input of OLGAPC and changes its status to follower.

Connect the TR_STATUS input to the OLGAPC of the parallel transformer and route the TR_DAT output from OLGAPC to OL5ATCC TRx_DAT for proper M/F functionality. If TR_STATUS is left unconnected, that particular parallel transformer is assumed to not be participating even though receiving valid tap position information.

To keep all the tap changers in the same position, the master needs to know the tap positions of the followers. This way, the circulating current is kept at its minimum. The position values of the followers can be brought to the master either via horizontal GOOSE communication or TPOSYLTC.

If it is not possible to use horizontal communication between the protection relays and the position information cannot be wired from the parallel transformers, the M/F principle can still be used to regulate two or an unlimited number of transformers in parallel. Since the master cannot detect the tap positions of parallel transformers, it just activates the lowering and raising outputs for all the followers when it controls its own tap changer. This is called blind control. In this case, a number of parallel transformers are regulated as one unit.

The combined data inputs TRx_DAT must be left unconnected for the master to know that the tap positions of the followers are unknown. The time delay between successive commands can be set by the *Follower delay time* setting. The default value is 6 seconds.

When a disconnected transformer is taken into use and the tap position is unknown, the follower should be manually controlled to the same position as the master. This can also take place in the M/F mode. First, the master gives its own transformer a control command which is echoed to the followers (the follower's tap positions have to be connected). Thereafter, successive control commands to the followers take place until the master and followers have the same tap positions.

Out-of-step function

The out-of-step function is usually used in the M/F mode only. The out-of-step function means that the master is able to detect the position values of the followers and control them to the same position as the master's. In this case, the master assumes that the followers also have either *Raise block tap* higher than *Lower block tap* or *Lower block tap* higher than *Raise block tap* because this defines what is the given command pulse for a follower. If the master has *Raise block tap* higher than *Lower block tap* and

the follower has *Lower block tap* higher than *Raise block tap*, the corresponding tap changer follow included control signals should be connected crosswise. This requires extra logic where dual point command bits have to be converted, that is, 0=>0, [01]=1=>[10]=2 and [10]=2=>[01]=1.

M/F is the only parallel mode which has an out-of-step functionality. In the MCC and NRP operation modes, the circulating current is minimized, which often means different tap positions in the parallel transformers. Moreover, these modes allow different ratings and step voltages for the parallel transformers. Therefore, it is reasonable to apply the out-of-step function only to the M/F operation mode.

The out-of-step function is triggered when the master detects a difference of at least one step between the tap changer positions in the follower and in the master. The master then sends special raise or lower commands to the diverging follower. If two consecutive commands fail to change the position of the follower to the right direction, the master activates the PAR_FAIL output, that is, PAR_FAIL is set to TRUE, and stops the special recovery efforts. However, every time the master controls its own tap changer later, it sends a controlling pulse to the diverging follower too. Furthermore, if the master notices a correct position change after a sent pulse, it restarts the attempts to drive the follower to the same position and deactivates the PAR_FAIL output, that is, PAR_FAIL is set to FALSE. However, if there still are diverging followers, the reset is not indicated. It is indicated only when no diverging followers exist. Monitoring, and hence the indication of a paralleling failure, is not possible in blind control.

The followers with a parallel failure can be read from the monitored data FAIL_FLLW. For example, if only follower 3 is in the parallel failure state, FAIL_FLLW has the value "T3". If both followers 1 and 2 are in the parallel failure state, FAIL_FLLW has the value "T1+T2". By default, when no failed followers exist, the value is "No failed followers".

Negative Reactance Principle NRP

This parallel control scheme is suitable for power transformers with different ratings and step voltages. Since no communication between the regulators is needed, this principle can be applied even when the parallel transformers are located at different substations. To start the parallel operation, the active operation mode has to be set to "NRP" for all the regulators of the connection. The active operation mode can be changed via function block inputs or by setting it either locally or remotely.

When applying this principle, each regulator has a phase angle setting φ_{Load} (setting parameter *Load phase angle*) towards which it tries to regulate the current. The setting value is chosen according to the expected power factor of the load (positive setting value equals inductive load). When the actual phase angle of the load current is the same as the setting and the transformers and their tap changer positions are identical, the currents of the transformers are in the same phase as the total load current. If the tap changer positions are different, the circulating current flows and the currents of different transformers either lag or lead the load current. Figure 814 shows that the circulating current is the reactive component which separates the measured current vector from the expected angle value.

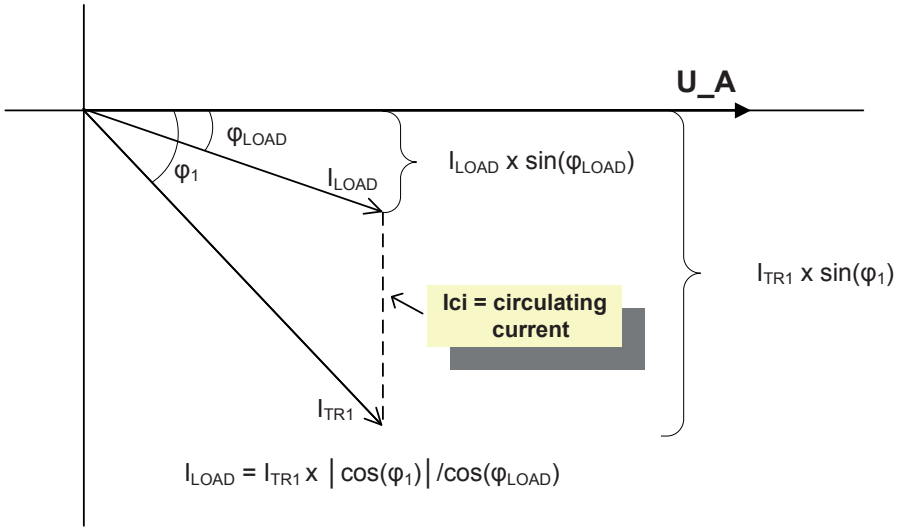

Figure 814: The expected phase angle of the load supplied by the transformers operating in parallel is entered as a setting value φ_{Load}

The regulators calculate the circulating current with the equation

$$I_{ci} = (\sin\varphi_1 - \tan\varphi_{Load} \cdot |\cos\varphi_1|) \cdot I_{TR1}$$

(Equation 341)

I_{TR1}	Average of the currents I_A, I_B and I_C
φ_1	Phase angle between U_A and I_A
φ_{Load}	Set *Load phase angle* of the load current

In the negative reactance method, the circulating current is minimized by changing the control voltage according to the measured circulating current. The regulator calculates the circulating current compensation term U_{ci} (Equation 338) as in the MCC

$$U_{ci} = \frac{-I_{ci}}{I_n} \cdot \frac{Stability\ factor}{100} \cdot U_n$$

(Equation 342)

I_{ci}	Circulating current
Stability factor	Stability setting (the recommended value depends on the loop impedance)

If the transformers operating in parallel have different rated currents, the value of the *Stability factor* setting of the regulator should be proportional to the rated currents, that is, the higher the rated current, the higher the *Stability factor* setting value.

It is possible to find out if the circulating current has been minimized by comparing the reactive components of the currents measured by the different regulators. The circulating current is minimized when the reactive components are equal.

The negative reactance method gives satisfactory results only if the phase angle of the load current is known relatively accurately. If the actual phase angle deviates from the phase angle setting, a regulating error occurs. However, if there is an occasional stepwise change in the phase angle of the load, the regulating error can be suppressed with the logic. This kind of stepwise change can occur, for example, when a capacitor bank is switched on to compensate a reactive power flow. Another possibility is to use an automatic setting group change between setting groups in different loading situations. The setting groups then have different set values for the load phase angle.

Minimizing Circulating Current MCC

The MCC principle is an optimal solution for controlling parallel transformers of different ratings or step voltages in substations with varying reactive loads. Since this control scheme allows the exchange of data between regulators, the circulating current can be calculated more accurately than with other schemes. However, a maximum of six regulators can be connected in parallel. To start the parallel operation, the active operation mode parameter has to be set to "MCC" for all the regulators of the connection. Furthermore, the signal CON_STATUS must indicate that the transformers are connected to the network. A unit that minimizes the circulating current must have the active operation mode set to "MCC". Units that have the active operation mode set to "Manual" do not perform any circulating current minimization operations themselves.

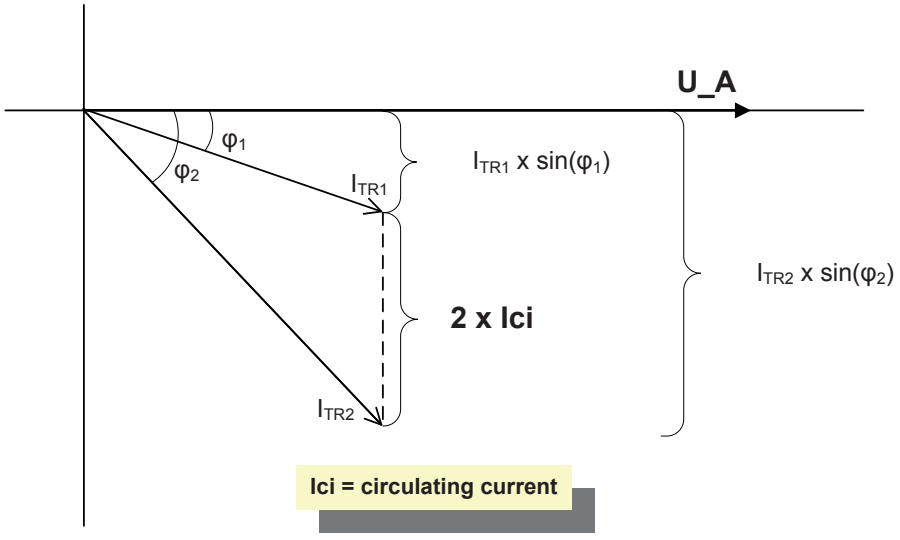

Figure 815: The circulating current between two parallel transformers

In this case, the circulating current can be calculated with the equation

$$I_{ci} = \frac{(\sin\phi_1 \cdot I_{TR1} - \sin\phi_2 \cdot I_{TR2})}{2}$$

(Equation 343)

I_{TR1} Current magnitude of regulator 1

I_{TR2} Current magnitude of regulator 2

φ_1 Phase angle between U_A and I_A in regulator 1

φ_2 Phase angle between U_A and I_A in regulator 2

The circulating current can be read from the monitored data I_CIR.

Using the circulating current, the compensation term U_{ci} can be calculated with the equation

$$U_{ci} = \frac{-I_{ci}}{I_{CT_n1}} \cdot \frac{Stability\ factor}{100} \cdot U_n$$

(Equation 344)

I_{ci} Circulating current

I_{CT_n1} Nominal primary current of the CT

Stability factor Stability setting (the recommended value depends on the loop impedance)

The value of U_{ci}, which can be positive or negative, is added to the *Band center voltage* U_s (Equation 338). According to Figure 815 and Equation 343, the phasor information from the other protection relays is needed.

Parallel unit detection and the MCC mode

The network connection status information is essential for the MCC operation mode. The status FALSE needs to be connected to the CON_STATUS input to ensure a proper operation of the MCC calculation if the transformer is disconnected but OL5ATCC remains in the MCC mode. This way the disconnected transformer is excluded from the circulating current calculations.

The CON_STATUS input is used to identify if a transformer controller can send the current information to other transformer controllers for circulating current minimization purposes. As a result, this input has effect only in the MCC or Manual active operation modes. In these modes, if CON_STATUS is TRUE, the information transmission is started. The circulating current information receiving is allowed only in the MCC active operation mode when CON_STATUS is TRUE. PAR_UNIT_MCC can be seen in the Monitored data view.

Communication and the MCC mode

The phasor information from the other parallel protection relays is needed for the circulating current calculation. Therefore, horizontal GOOSE communication is needed between protection relays when the MCC principle is used.

The transferred current phasor information contains a primary value of the measured current. The magnitude and angle of the current phasor can be read from the OLGAPC function input data TR_I_AMPL and TR_I_ANGL, respectively.

The sent phasor information always represents the difference between the voltage phasor *U_A* and current phasor *I_A*. The information about the current phasor can be read from the monitored data TR0_I_AMPL and TR0_I_ANGL. The allowed active operation modes for sending data are MCC or Manual, both with the input CON_STATUS activated. The communication is active when the sent and received phasor magnitude is not clamped to zero. The communication phasor magnitude is zero due to a rejected active operation mode or too low signal magnitudes (see Voltage and current measurements chapter). Active CON_STATUS indicates that the corresponding transformer is connected to the network and its current affects the circular current of other transformers even when it is in the manual operating mode.

9.10.5.7 Timer characteristics

Operation timer functionality

The delay times can be set to follow either the definite time characteristic or the inverse time characteristic with the *Delay characteristic* setting. By default, the "Definite time" mode is selected. The timer mode cannot be changed between cycles T1 and T2, but only either before T1 has started or after T2 has elapsed.

Table 1413: Different timer mode delays

Timer mode	Setting	Description
T1	*Control delay time 1*	First delay when the measured voltage exceeds or falls below the limit value
T2	*Control delay time 2*	Second delay when the first control did not bring the measured voltage to a desired level

The delay after the command pulse activation and the restart of the timer is six seconds. The delay is assumed to be the tap changer operating delay. The timer status can also be read from the monitoring data TIMER_STS, where T1 active gives a value "Lower timer1 on" or "Raise timer1 on" while T2 active gives a value "Lower timer2 on" or "Raise timer2 on". Furthermore, the "Fast lower T on" value indicates that the fast lower control functionality is active (Blocking scheme chapter).

Activation of operation timer also activates the TIMER_ON output.

IDMT type operation

The IDMT timer can be selected by setting *Delay characteristic* to "Inverse time". The minimum time at the inverse time characteristic is limited to 1.0 second. However, the minimum recommended setting of the control delay times T1 and T2 is 10 seconds when the definite time delay is used and 25 seconds when the inverse time delay is used.

The inverse time function is defined by the equations:

$$B = \frac{U_d}{\frac{U_{BW}}{2}}$$

(Equation 345)

U_d $|U_m - U_p|$, differential voltage

U_{BW} Setting parameter *Band width voltage*

$$t = \frac{T}{2^{(B-1)}}$$

(Equation 346)

T T1 or T2

The monitored data UD_CTL shows the differential voltage value $U_m - U_p$. If the value exceeds half of the *Band width voltage* setting and has a negative sign, a raising pulse is issued. The UD_CTL monitored data can also be seen in the DT timer mode.

The hysteresis approach is presented in Figure 812.

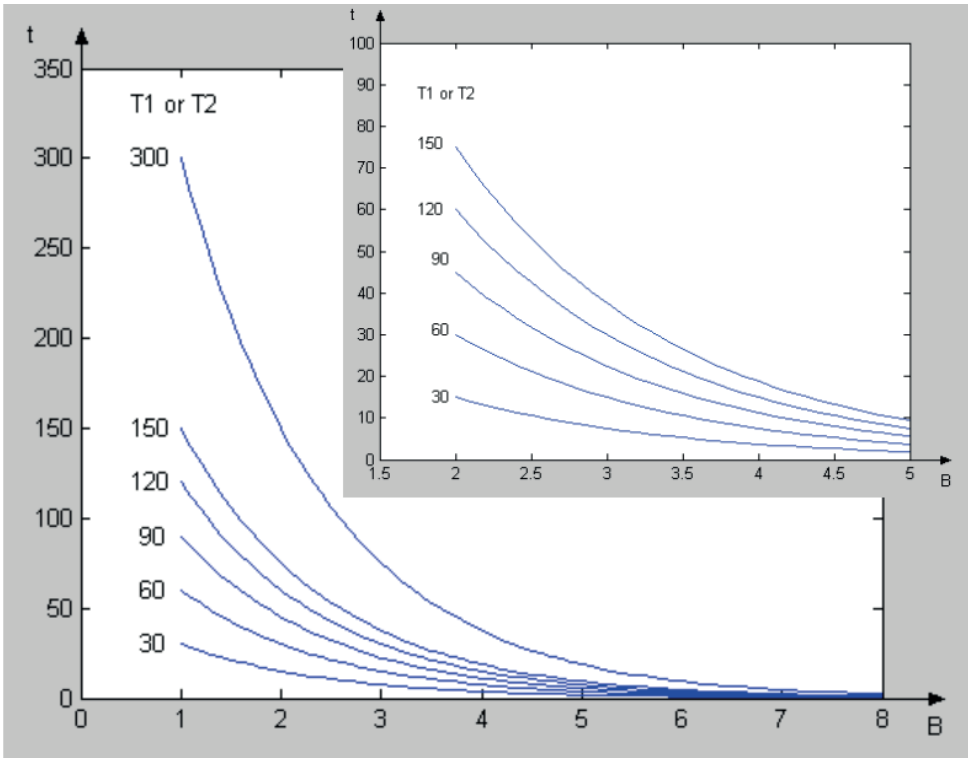

Figure 816: Inverse time characteristic for different values of T1 or T2 (The smaller figure is a zoom-in of the larger one)

9.10.5.8 Pulse control

The tap changer generates an active operating signal when the tap-changing process is active. This signal is used for alarming purposes and must be connected to the TCO input. If the signal is active (=TRUE) for more than 15 seconds after the control pulse has been deactivated, an alarm is generated (Alarm indication chapter). If the TCO input is not connected, no alarm is generated.

The control operation is disabled when the TCO input signal is active, unless no stuck tap changer is detected (Alarm indication chapter). Thus, the controller cannot send new pulses to the tap changer when this is already operating because tap changers are typically immune to new pulses when they operate. Furthermore, because the pulses are omitted, the tap changer pulse counter of the controller is not incremented.

The commands are not tolerated during an active pulse. Therefore the command pulse length (setting *LTC pulse time*) has to be carefully selected, although an active TCO input is used internally to prevent new commands from reaching the tap changer.

To be more certain that no new pulses are sent when the tap changer is in operation, the tap changer operating signal can be connected to the LTC_BLOCK input. In this case, external blocking is achieved when an automatic pulse is sent to the operating tap

changer. By default, the external LTC_BLOCK has no effect when the active operation mode is set to "Manual" or "Parallel manual".

The status of the TCO input can be read from the TCO input data.

9.10.5.9 Blocking scheme

The operation of the voltage regulator can be blocked for several reasons. The purpose of blocking is to prevent the tap changer from operating under conditions that can damage the tap changer or exceed other power system limits. The BLK_STATUS monitored data does not imply actual blocking but reveals if the coming command pulse is issued or not. The blocking itself happens when the corresponding bit in the signal BLK_STATUS is active and the command pulse is started due to a timer elapse or a local command. This is to avoid unnecessary event sending.

The BLK_STATUS monitored data is also packed. It contains information about the blocking status as bit-coded output. The block status output does not indicate the actual blocking but indicates if the coming command is successful. The actual blocking is indicated by the corresponding output (BLKD_I_LOD, BLKD_U_UN, RNBK_U_OV, BLKD_LTCBLK and BLKD_I_CIR) values. Table 1414 illustrates the meaning of different monitored data values. For example, block status value 9 indicates that there are conditional circulating current and load current blockings (8 + 1 = 9) indicated. By default, the status is “0”.

Table 1414: Bit-coded block status and the meaning of different bits

Bit	Active value	Blocking reason
6 (msb)	64	Lowest position reached
5	32	Highest position reached
4	16	External LTC_BLOCK
3	8	High circuit current
2	4	Overvoltage - Runback raise voltage
1	2	Undervoltage - Block lower voltage
0 (lsb)	1	Overcurrent - Load current

The cross (X) in the table defines when the operation is blocked (if the corresponding bit is active in BLK_STATUS). For example, an overvoltage (runback raising voltage) results in blocking only when the active operation mode is "Manual" and the manual raising command is given.

Table 1415: Default blocking schema in OL5ATCC

Active operation mode	Command	Load current	Block lower voltage	Runback raise voltage	High circulating current	External block	Extreme positions
Manual, Parallel manual	Raise	X		X			X
	Lower	X					X
Auto follower	Raise	X	X			X	X
	Lower	X	X			X	X
Auto single, Auto master, NRP, MCC	Raise	X	X		X[1)]	X	X[2)]
	Lower	X	X		X[1)]	X	X[2)]

1) Because the circulating current is calculated only in the NRP and MCC modes, it can have a blocking effect only in these modes.
2) In these cases the automatic operation notices that the extreme position has already been reached and there is no need to activate the signal for data set event sending. The automatic follower case can here be compared to a manual case and an event can be sent, that is, the corresponding output is activated.

In addition to the default blocking, the *Custom Man blocking* setting has been added due to different operation practices of the manual command blocking. The setting can be used to adapt blockings considering the manual overcurrent, undervoltage or external blocking. (The blockings are in Table 1415 in columns Load current, Block lower voltage and External block for the manual operating mode.) The default value for the parameter is "OC". This means that the default blocking schema explained in Table 1415 operates as such. However, there are other alternatives that cause different operations.

Table 1416: Customized manual blocking schema

Manual blocking	Enumeration	Description
1	Custom disabled	No load current, block lower (under) voltage, external blocking has no effect in the manual operation modes
2	OC	Load current blocking has an effect in the manual operation modes
3	UV	Block lowering (under) voltage blocking has an effect in the manual operation modes
4	OC, UV	Conditions 2 and 3 together: Load current and block lowering (under) voltage blocking have effect in the manual operation modes
5	EXT	External blocking has effect in the manual operation modes
6	OC, EXT	Conditions 2 and 5 together: Load current and external blocking have effect in the manual operation modes
7	UV, EXT	Conditions 3 and 5 together: Block lowering (under) voltage and external blocking have effect in the manual operation modes
8	OC, UV, EXT	All conditions 2, 3 and 5 together: Load current, block lowering (under) voltage and external blocking have effect in the manual operation modes

If the *Custom Man blocking* setting is "Custom disabled", the blocking schema regarding the active operation mode "Manual" or “Parallel manual” is given in Table 1417. Other operation modes follow the default schema.

Table 1417: Blocking schema for selection "Custom disabled"

Active operation mode	Command	Load current	Block lower voltage	Runback raise voltage	High circulating current	External block	Extreme positions
Manual, Parallel manual	Raise			x			x
	Lower						x

Table 1418: Blocking schema for selection "OC, UV, EXT"

Active operation mode	Command	Load current	Block lower voltage	Runback raise voltage	High circulating current	External block	Extreme positions
Manual, Parallel manual	Raise	x	x	x		x	x
	Lower	x	x			x	x

Table 1419: Blocking schema for selection "UV, EXT"

Active operation mode	Command	Load current	Block lower voltage	Runback raise voltage	High circulating current	External block	Extreme positions
Manual, Parallel manual	Raise		x	x		x	x
	Lower		x			x	x

Load current

The load current blocking is mainly used for preventing the tap changer from operating in an overcurrent situation. For example, if the current is not high enough to activate the protection relay of the substation, it can still be fatal for the diverter switch of the tap changer. This operation can be adjusted with the setting parameter *Load current limit*. The maximum of measurements from the secondary-side current phases is used for blocking. By default, both the automatic operation and the manual operation are blocked (Table 1415) when the set limit is exceeded.

The blocking status can be read from the output `BLKD_I_LOD`.

Block lowering voltage

The block lowering voltage feature blocks both raise and lower voltage commands if the measured voltage is too low to be corrected by operating the tap changer. Such a situation can occur due to a faulty measuring circuit, an earth fault or an overcurrent situation. By default, only the automatic (also automatic follower) operation is blocked when the undervoltage condition is met (Table 1415). This operation can be adjusted with the setting parameter *Block lower voltage*.

The blocking status can be read from the output BLKD_U_UN.

However, there is no minimum limit for the undervoltage blocking. The blocking is allowed even if the measured voltage is not connected or it temporarily has a very low value. There is a minimum limit for the phase angle calculation based on the voltage phasor magnitude.

Runback raising voltage

The manual raising command is blocked if the overvoltage limit is exceeded (Table 1415). However, in the automatic operation mode, the overvoltage situation triggers the fast lowering feature. More information can be found in the Manual voltage regulation chapter. This operation can be adjusted with the setting parameter *Runback raise V*.

The blocking status can be read from the output RNBK_U_OV.

High circulating current

The circulating current value is calculated in the operation modes Negative Reactance Principle (NRP) and Minimizing Circulating Current (MCC). Only the automatic operation in these modes is blocked when the high circulating current is measured (Table 1415). This operation can be adjusted with the setting parameter *Cir current limit*.

The blocking status can be read from the output BLKD_I_CIR.

LTC_BLOCK – external block input

With the PCM600 tool configuration possibilities, a blocking condition can be built by connecting an outcome to this input. The blocking status can be read from the output BLKD_LTCBLK. When activated, this input blocks only the automatic operation of the regulator by default (Table 1415). For the fully automatic modes, the signal activation resets the timer, and the output BLKD_LTCBLK is not activated.

Extreme positions

This blocking function supervises the extreme positions of the tap changer. These extreme positions can be adjusted with the setting parameters *Raise block tap* and *Lower block tap*. When the tap changer reaches one of these two positions, the commands in the corresponding direction are blocked (Table 1415). It depends on the comparison between the *Raise block tap* and *Lower block tap* settings, which direction is blocked (Voltage control vs. tap changer moving direction section). This blocking affects both the automatic and manual operation modes.

However, as shown in Table 1415, no blocking indication is generated in the fully automatic modes. Here "Auto follower" is not a fully automatic mode. The unconnected position information does not cause the total block of OL5ATCC; only the extreme position blocking does not work.

The blocking status can be seen in the generated events.

Fast lowering control

OL5ATCC provides the fast lowering control in the automatic operation modes. When the set *Runback raise V* is exceeded, the regulator gives fast lowering control pulses until the voltage drops below the specified limit. This fast lowering control can be seen with the monitoring data TIMER_STS, where the value "Fast lower T on" indicates this functionality to be active.

To allow the fast lowering operation, *Runback raise V* has to be set always to a value higher than the control voltage (U_CTL) plus half of *Band width voltage*.

Typically, blockings are reset when the corresponding limit with the hysteresis is undershoot or exceeded. Although blocking is reset after undershooting the above-mentioned limit, the fast lowering control operation continues until the measured voltage signal difference undershoots half the *Band width voltage* hysteresis limit (Figure 812). As a result, the normal automatic operation mode is not possible before this happens.

Fast lowering control causes successive `LOWER_OWN` pulses to be activated. The time between consecutive pulses is the pulse length plus 1.5 seconds.

- There is no tap changer operating delay (otherwise 6 seconds) taken into account in this cycle meaning that some command pulses are ineffective due to tap changer operation, as described in the Pulse control chapter.
- Timer mode set by *Delay characteristic* has no effect here (always the DT timer mode). Because the minimum pulse length (the *LTC pulse time* setting) is 0.5 seconds, the shortest interval between successive pulses can be 2 seconds.

In the automatic follower mode, the fast lowering is not triggered. In this way, the awkward dispersion of position values in different units can be avoided. The master always decides on the fast lowering on behalf of the follower units. Moreover, master and follower should measure an equal voltage level and have similar setting values for the overvoltage blocking limit.

9.10.5.10 Alarm indication

Tap changer monitoring

OL5ATCC supervises the operation of the tap changer and generates alarms if the alarm condition is detected. An alarm activation means that the `ALARM` output is activated and the alarm reason can be read from the monitored data ALARM_REAS. Alarms are in use by default but they can be set not to be in use by setting *Alarms enabled* to "False". Three different alarm conditions and their combinations can be detected by OL5ATCC.

Command error

OL5ATCC supervises the tap changer position information of the own transformer when a control pulse is given. If the correct position change (direction depends on the comparison of the settings *Raise block tap* and *Lower block tap*) is not seen by OL5ATCC in *Cmd error delay time* after the pulse start, the alarm is issued.

If the position information is not connected, no alarm is generated. The alarm is reset when the correct change in position value is detected after a given pulse or if a new command pulse is given.

The monitored data ALARM_REAS is set during an alarm. This means that if the alarm reason is active, ALARM_REAS has the value "Cmd error".

TCO signal fails

If the tap changer operating signal TCO stays active for more than 15 seconds after the output pulse deactivation, OL5ATCC sees this as an abnormal condition and assumes that the tap changer is stuck. The alarm is reset when the TCO input signal deactivates. The monitored data ALARM_REAS is set during the alarm. This means that only if alarm reason is active, ALARM_REAS has the value "TCO error".

If the TCO input signal is not connected (indicated by bad quality), this type of alarm is not possible.

Regulator pumping

Faulty settings may cause the regulator to give control pulses too frequently. For example, too low a setting for the *Band width voltage* (Figure 812) can result in a pumping condition where the regulator has problems to bring the regulated voltage to a desired level. To detect this, OL5ATCC has a setting *Max operations in 1h*, which defines the allowed number of lowering and raising commands during a one-hour sliding time window. The detection is active both in the manual and automatic operation modes. The alarm is reset after the number of operations during the one-hour time window is less than the set value. The number of executed operations of the last one hour can be read from the monitored data OP_TM_NUM_H. However, this parameter is updated only in three-minute intervals. The monitored data ALARM_REAS is set during an alarm. This means that only if alarm reason is active, ALARM_REAS has the value "Pump error".

The operation of OL5ATCC is not blocked during an alarm situation, but all the alarms mentioned above cause the automatic operation to be delayed, which means that the set delay times T1 and T2 are doubled.

In addition to the alarm detections, OL5ATCC provides a nonvolatile operation counter parameter (monitored data OPR_CNT) for determining the service intervals of the tap changer. The counter gives the total number of raising and lowering commands given in the manual and automatic modes. All commands, even those that are omitted by the tap changer due to its operation sequence, are calculated in a cumulative counter. This data parameter can be reset via the parameter *OL5ATCC counter* on the Clear menu.

9.10.6 Application

See the application manual for more information.

9.10.7 Signals

Table 1420: OL5ATCC Input signals

Name	Type	Default	Description
I3P	SIGNAL	-	Three-phase currents
U3P	SIGNAL	-	Three-phase voltages
TAP_POS	INT8	0	Integer value representing tap changer position of own transformer
RAISE_LOCAL	BOOLEAN	0=False	Raise command input from configuration
LOWER_LOCAL	BOOLEAN	0=False	Lower command input from configuration
CON_STATUS	BOOLEAN	0=False	Network connection status of the (own) transformer
LTC_BLOCK	BOOLEAN	0=False	External signal for blocking
TCO	BOOLEAN	0=False	Tap changer operating input
RSV	BOOLEAN	0=False	Reduce set voltage active
PARALLEL	BOOLEAN	0=False	Parallel or single operation
AUTO	BOOLEAN	0=False	Auto/Manual indication
MSTR_TRIGG	BOOLEAN	0=False	Master trigger
TR1_DAT	INTEGER	0	Combined data from transformer 1
TR2_DAT	INTEGER	0	Combined data from transformer 2
TR3_DAT	INTEGER	0	Combined data from transformer 3
TR4_DAT	INTEGER	0	Combined data from transformer 4
TR5_DAT	INTEGER	0	Combined data from transformer 5

Table 1421: OL5ATCC Output signals

Name	Type	Description
RAISE_OWN	BOOLEAN	Raise command for own transformer
LOWER_OWN	BOOLEAN	Lower command for own transformer
FLLW1_CTL	INT32	Lower/Raise command for follower transformer 1 in the Master/Follower operation mode
FLLW2_CTL	INT32	Lower/Raise command for follower transformer 2 in the Master/Follower operation mode
FLLW3_CTL	INT32	Lower/Raise command for follower transformer 3 in the Master/Follower operation mode
FLLW4_CTL	INT32	Lower/Raise command for follower transformer 4 in the Master/Follower operation mode
FLLW5_CTL	INT32	Lower/Raise command for follower transformer 5 in the Master/Follower operation mode
BLKD_I_LOD	BOOLEAN	Indication of over current blocking
BLKD_U_UN	BOOLEAN	Indication of under voltage blocking

Table continues on next page

Name	Type	Description
RNBK_U_OV	BOOLEAN	Indication of raise voltage runback
BLKD_I_CIR	BOOLEAN	Indication of high circulating current blocking
BLKD_LTCBLK	BOOLEAN	Indication of external blocking
ALARM	BOOLEAN	Alarm status
PAR_FAIL	BOOLEAN	Parallel failure detected
PARALLEL	BOOLEAN	Parallel or single operation
AUTO	BOOLEAN	Auto/Manual indication
TIMER_ON	BOOLEAN	Timer on
MASTER	BOOLEAN	Master indication

9.10.8 Settings

Table 1422: OL5ATCC Group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
LDC limit	0.00...2.00	xUn	0.01	0.10	Maximum limit for line drop compensation term
Lower block tap	-36...36		1	0	Tap changer limit position which gives lowest voltage on the regulated side
Raise block tap	-36...36		1	17	Tap changer limit position which gives highest voltage on the regulated side
LDC enable	0=False 1=True			1=True	Selection for line drop compensation
Parallel mode	2=Master 3=Follower 5=NRP 7=MCC -1=Input control -2=Command			2=Master	Parallel mode selection
Band center voltage	0.000...2.000	xUn	0.001	1.000	Band center voltage Us
Line drop V Ris	0.0...25.0	%	0.1	0.0	Resistive line-drop compensation factor
Line drop V React	0.0...25.0	%	0.1	0.0	Reactive line-drop compensation factor
Band reduction	0.00...9.00	%Un	0.01	0.00	Step size for reduce set voltage (RSV)
Stability factor	0.0...70.0	%	0.1	0.0	Stability factor in parallel operation
Load phase angle	-89...89	deg	1	0	Load phase-shift, used only with the negative reactance principle
Control delay time 1	1000...300000	ms	100	60000	Control delay time for the first control pulse
Control delay time 2	1000...300000	ms	100	30000	Control delay time for the following control pulses

Table 1423: OL5ATCC Group settings (Advanced)

Parameter	Values (Range)	Unit	Step	Default	Description
Rv Pwr flow allowed	0=False 1=True			0=False	Reverse power flow allowed

Table 1424: OL5ATCC Non group settings (Basic)

2) Voltage before deviation = set *Band center voltage*

9.11 Petersen coil controller PASANCR

9.11.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Petersen coil controller	PASANCR	ANCR	90

9.11.2 Function block

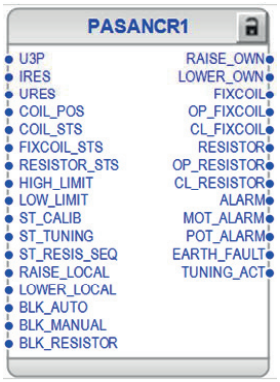

Figure 817: Function block

9.11.3 Functionality

The Petersen coil controller function PASANCR is a numerical automatic controller for the continuously adjustable arc suppression coil (ASC or Petersen coil) and the parallel resistor of the coil. It can be applied to compensated networks where an earth-fault current raising resistor is optionally connected in parallel with the arc suppression coil.

PASANCR is intended for controlling arc suppression coils in networks with natural asymmetry, for example, mixed overhead line and cable networks. The main features of the function are:

- Operation based on forced change in zero-sequence voltage
- Arc suppression coil tuning to the desired position
- Network parameter calculation and displaying of the resonance curve and the fault current estimate curve of the network
- Control of the parallel resistor
- Clear numerical value of the resonance point steady-state zero-sequence voltage, for example, for earth-fault protection purposes

9.11.4 Analog channel configuration

PASANCR has three analog group inputs which must be properly configured.

Table 1428: Analog inputs

Input	Description
U3P	Three-phase voltages
IRES[1)]	Residual current (measured or calculated)
URES	Residual voltage (measured)

1) IRES must always be connected irrespective of the setting value of *Position Meas mode*. The possible options are measured IRES from the coil/main transformer neutral point or calculated IRES from the phase CTs of earthing transformer.

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

9.11.5 Controller connections

Voltages

PASANCR supports zero-sequence voltage measurement from busbar or from coil. Busbar measurement is, for example, an open-delta connection of phase-to-earth voltage transformers. Coil measurement uses the coil's own secondary measurement winding. *Voltage measurement* setting is used to select the active measurement. Available options are "Busbar" and "Coil".

Phase-to-phase voltage AB must be connected to the controller. If only the phase voltages are measured, the voltage U_AB is calculated internally in the protection relay.

Coil position

The controller supports two possibilities for the coil position measurement. *Position Meas mode* setting is used to select the active coil position measurement. Available options are:

- "Pos. indication": Using only the RTD input module to measure the resistance value from the arc suppression coil potentiometer with `COIL_POS` input and to convert it into corresponding coil position according to the linearization table.
- "Pos. ind. and meas.": Using both `COIL_POS` and `IRES` signals. `IRES` is arc suppression coil current measurement using conventional CTs or sensors. Special attention should be paid to the accuracy of the current signals at low amplitudes. Additionally, high accuracy can be ensured by applying measurement class CTs and sensors. Current measurement improves controller speed and accuracy. The recommendation for the CT is a primary current equivalent to the coil's maximum current and accuracy class 0.5S or better. The `IRES` signal is not sufficient for the controller as it does not allow manual control of the coil if it is disconnected from the network.

All voltage and current signals are measured using the value of the filtered fundamental frequency component (DFT). Hence, the harmonics are always suppressed.

Status information

The connection status (`COIL_STS`) information from the adjustable arc suppression coil disconnector or circuit breaker should be wired to the controller. Also, fixed parallel coil status (`FIXCOIL_STS`) and the parallel resistor status (`RESISTOR_STS`) should be wired to the controller if they are present in the system. Inactive status information signal means that the device is not connected and active status information signal means that the device is connected.

Outputs

The following outputs should be considered in order to ensure correct operation of the controller if a fixed parallel coil or parallel resistor is installed in the network:

- FIXCOIL, OP_FIXCOIL and CL_FIXCOIL: Status signal and corresponding open and close command signals for controlling the circuit breaker or disconnector of the fixed parallel coil. These signals are applied if a fixed parallel coil is installed in the system.
- RESISTOR, OP_RESISTOR and CL_RESISTOR: Status signal and corresponding open and close command signals for controlling the contactor, circuit breaker or disconnector of the parallel resistor. These signals are applied if a parallel resistor is installed in the system.

An example configuration of the connections is shown in Figure 818. Controller inputs are indicated with red lines and outputs with green lines. This example shows a simple, one-controller setup without the parallel resistor of the coil.

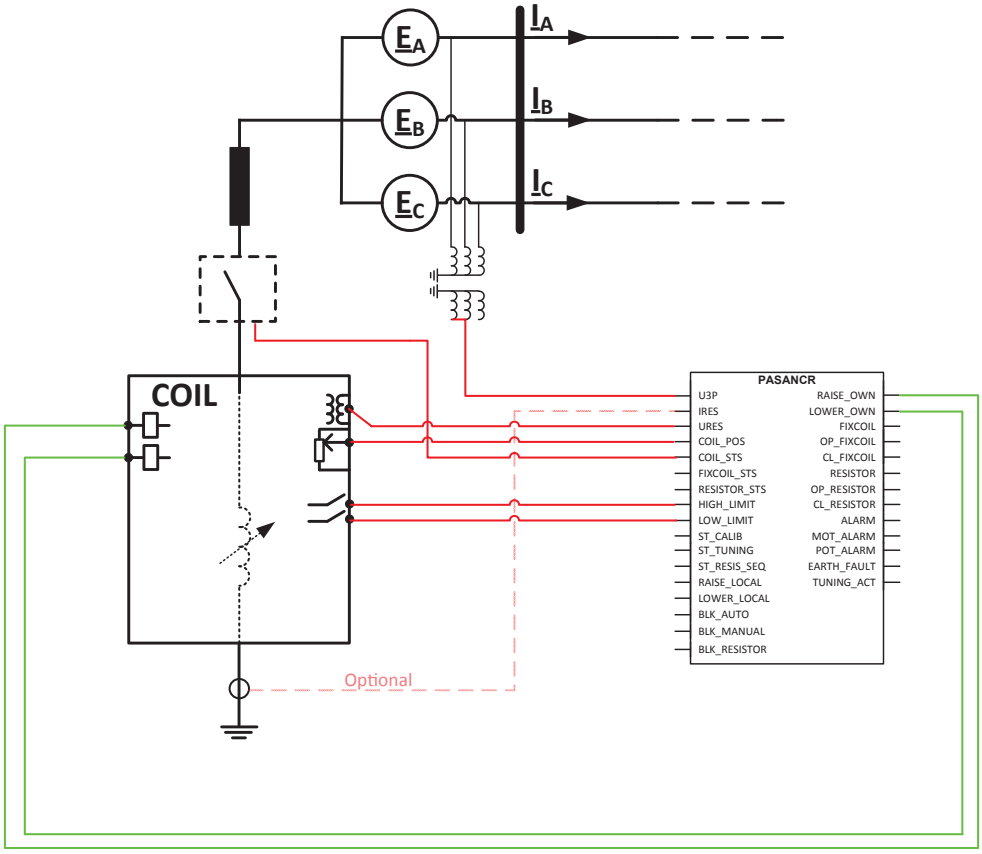

Figure 818: Example configuration of the controller connections

9.11.6 Operation principle

The *Operation* setting is used to enable or disable the function. The corresponding parameter values are "on" and "off".

The operation of PASANCR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

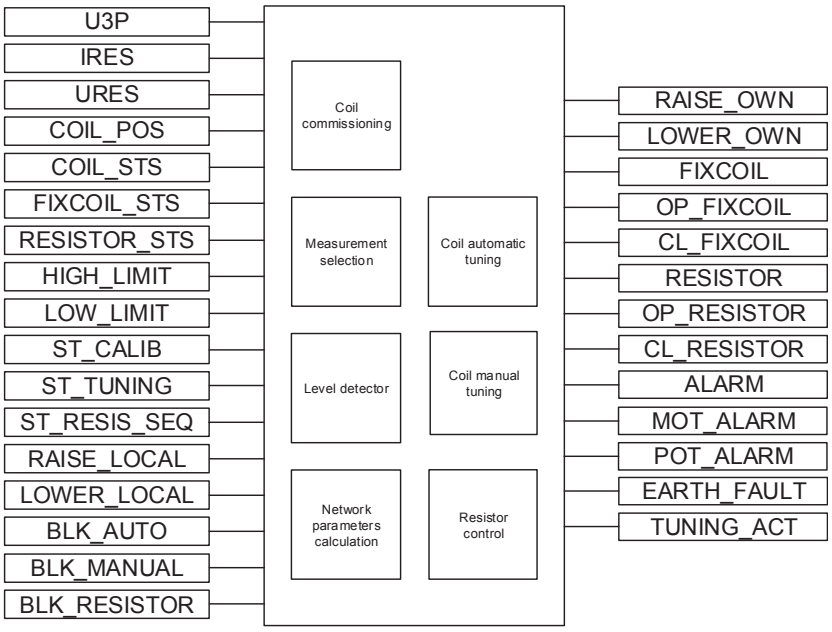

Figure 819: Functional module diagram

Measurement selection

PASANCR supports two possibilities for zero-sequence voltage and coil position measurement.

Voltage measurement setting is used to define the location of voltage measurement: from busbar or from coil. Busbar measurement is usually an open-delta connection of phase-to-earth voltage transformers. Coil measurement is available from the arc suppression coil's measurement winding.

Position Meas mode setting is used to select the measurement between coil position indication and coil position indication with a CT or sensor. "Pos. indication" option uses the potentiometer-based `COIL_POS` information only. If "Pos. ind. and meas." option is selected, the measured `IRES` is used for the control algorithm. In this case, the `COIL_POS` signal works as a backup and is switched automatically into use if the coil is disconnected from the network.

Level detector

Level detector op setting is used to enable or disable the Level detector module. "Enable" means that the Level detector module is enabled and can be used to start the tuning procedure.

When "Disable" is selected, the automatic coil tuning procedure can be started with input `ST_TUNING`.

Level detector's main task is to release the coil automatic tuning procedure in case of network switching operation. After every successful tuning procedure, the measured

zero-sequence voltage is stored as a new reference voltage U_{ref}. Also, the calculated network admittances are stored as new reference admittances Y_{symm_ref} and Y_{asymm_ref} (for more information, see Network parameter calculation in this chapter).

If the change in the measured zero-sequence voltage exceeds the setting *V Res change level* with respect to U_{ref}, then a new coil tuning procedure is released. The measured zero-sequence voltage must exceed the threshold at least by the time defined with *Tuning delay* setting, otherwise the start of the tuning procedure is canceled.

Zero-sequence voltage change can be determined considering the voltage amplitude only or a phasor value. Setting *V Res Meas mode* is used to select between these two modes. The available options are "Amplitude" and "Phasor". The phasor triggering mode is explained in Figure 820. Monitored data output TUNING_TRIGG indicates the relation between present zero-sequence voltage and the reference voltage. When TUNING_TRIGG value is below 100%, the controller is at stand-by. When TUNING_TRIGG value is above 100%, that is, Uo vector in Figure 820 enters the red area, the tuning delay is started.

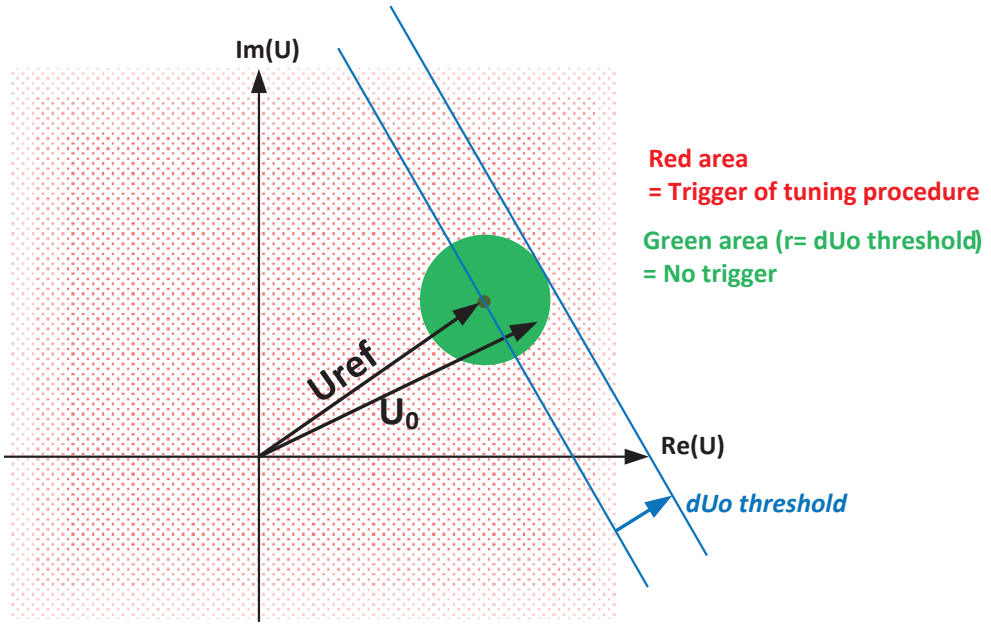

Figure 820: Phasor triggering mode

Level detector also includes a threshold-based earth-fault detection functionality. The detection is based on *V Res EF level* voltage threshold setting. If the measured zero-sequence voltage exceeds the threshold at least by the time defined in *Transient time EF* setting, the earth fault is indicated by activating the EARTH_FAULT output and the controller proceeds as described in Operation during earth faults in this chapter.

The delay defined in *Tuning delay* can be bypassed by activating ST_TUNING input, for example, via HMI application. When the rising edge of the signal is detected, the controller skips the tuning delay and proceeds immediately with the coil automatic tuning procedure. The automatic tuning procedure can be started with ST_TUNING

input even without the zero-sequence voltage trigger. The automatic tuning procedure is also released when the controller mode is switched from “manual” to “auto”.

PASANCR has an adaptive U_{ref} feature. The *V Ref adaptive mode* setting is used to enable or disable the functionality. The functionality allows slow changes in measured zero-sequence voltage and therefore reduces unnecessary tuning operations. If the measured zero-sequence voltage does not exceed the *V Res change level* setting during the time defined in *V Ref adaptive delay* setting, the existing measured zero-sequence voltage is stored as a new reference voltage U_{ref} at the end of the adaptive period. The operation principle of the adaptive U_{ref} feature is explained in Figure 821.

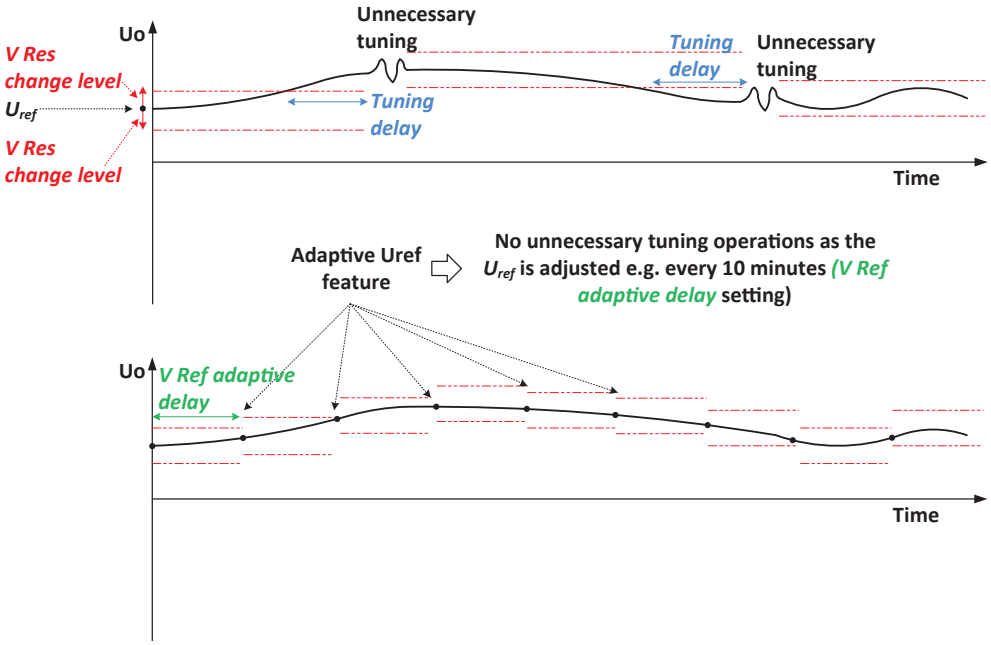

Figure 821: Example of Uo fluctuation with and without adaptive U_{ref} feature (amplitude triggering mode)

Network parameter calculation

To explain the controller, the simplified equivalent circuit of a three-phase distribution network illustrated in Figure 822 is used. The controller assumes that:

- The real network is presented with its shunt admittances neglecting line series impedances as their values are very small compared with the shunt admittances.
- The individual phase admittances of the network are presented with symmetrical phase admittances whose sum equals

$$\underline{Y}_{symm} = G_{symm} + j \cdot B_{symm}$$

(Equation 347)

(one third connected in each phase)

- The natural asymmetry in a real network is due to differences in individual phase admittances and it is presented with an asymmetry admittance concentrated into phase A and presented with admittance

$$\underline{Y}_{asymm} = G_{asymm} + j \cdot B_{asymm}$$

(Equation 348)

(only connected in phase A)

- The single-phase earth fault in the network is presented with admittance $\underline{Y}_f = G_f + j \cdot B_f$. Fault impedance can be assumed to be purely resistive (fault resistance R_f) which is connected between phase A, B or C and earth depending on the faulted phase.
- The zero-sequence impedance of the earthing (or main) transformer with the neutral point connected to the coil is represented with impedance $\underline{Z}_{oTr}$ (in the three-phase equivalent scheme one third must be applied).

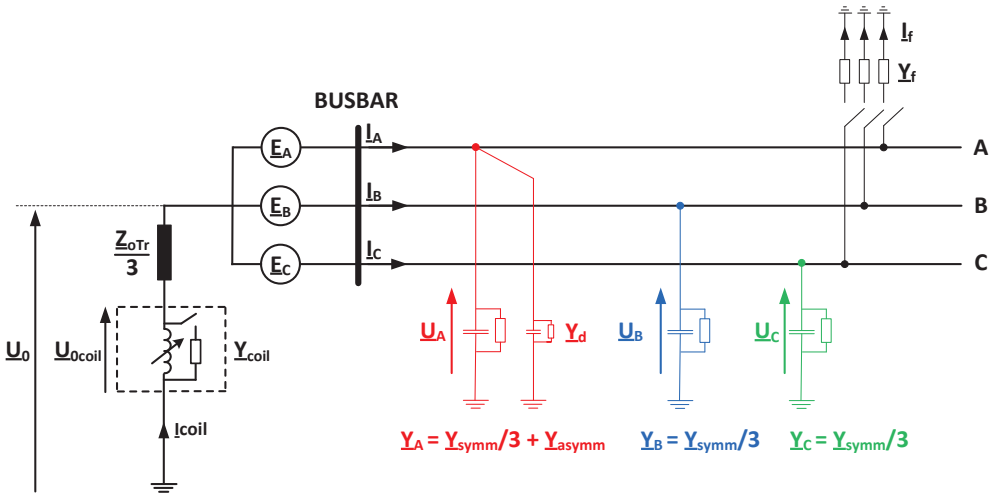

Figure 822: Simplified three-phase equivalent circuit of a compensated distribution network

$\underline{E}_A$	Phase A to earth voltage of the source
$\underline{E}_B$	Phase B to earth voltage of the source
$\underline{E}_C$	Phase C to earth voltage of the source
$\underline{U}_A$	Phase A to earth voltage at busbar (=$\underline{E}_A$ + $\underline{U}_o$)
$\underline{U}_B$	Phase B to earth voltage at busbar (=$\underline{E}_B$ + $\underline{U}_o$)
$\underline{U}_C$	Phase C to earth voltage at busbar (=$\underline{E}_C$ + $\underline{U}_o$)
$\underline{U}_0$	Zero-sequence voltage = ($\underline{U}_A$ + $\underline{U}_B$ +$\underline{U}_C$)/3
$\underline{U}_{0coil}$	Zero-sequence voltage measured at coil
$\underline{I}_A$	Phase A current at the source
$\underline{I}_B$	Phase B current at the source
$\underline{I}_C$	Phase C current at the source
$\underline{I}_{coil}$	Current through the central compensation coil
$\underline{Y}_A$	Phase A to earth admittance of the network
$\underline{Y}_B$	Phase B to earth admittance of the network
$\underline{Y}_C$	Phase C to earth admittance of the network
$\underline{Y}_{coil}$	Admittance of central compensation coil including the parallel resistor
$\underline{Z}_{oTr}$	Zero-sequence impedance of the earthing transformer or the main transformer through which the coil is connected to the network. Settings *R0Transformer* and *X0Transformer* are used to input the zero-sequence impedance of the earthing / main transformer. If the settings are applied, the controller can consider the transformer when calculating network parameters.

Using this network model, the controller determines network parameters G_{symm}, B_{symm}, G_{asymm}, B_{asymm}, G_{coil} and B_{coil}.

G_{symm}	Real part of symmetrical part of the total network admittance. The sign is positive and it represents the shunt losses of the network (excluding the losses of the central coil and the parallel resistor). If there are distributed compensation coils in the network, their shunt losses are included in this value.
B_{symm}	Imaginary part of symmetrical part of the total network admittance. The sign is positive (capacitive) and it represents the capacitive uncompensated earth-fault current of the network. If there are distributed compensation coils in the network, their effect is included in this value.
G_{asymm}	Real part of asymmetry admittance. The sign may be positive or negative depending on the actual level of asymmetry.
B_{asymm}	Imaginary part of asymmetry admittance. The sign may be positive or negative depending on the actual level of asymmetry.
G_{coil}	Real part of the coil admittance. The sign is positive and it represents the resistive losses of the central coil including the parallel resistor.
B_{coil}	Imaginary part of the coil admittance. The sign is negative and it represents the inductive current of the central coil, which defines the compensation degree of the network.

All previous admittance terms can be easily converted into equivalent current values by multiplying them by the system nominal phase-to-earth voltage U_n.

$I_{ef_network} = (B_{symm} + B_{asymm}) \cdot U_n$	Uncompensated earth-fault current
$I_{loss_network} = (G_{symm} + G_{asymm}) \cdot U_n$	Network shunt losses
$I_{coil} = B_{coil} \cdot U_n$	Coil inductive current
$I_{loss_coil} = G_{coil} \cdot U_n$	Coil loss current

Network parameter calculation is based on the forced change in network zero-sequence voltage. This is achieved by changing the coil position or by changing the connection state of the parallel resistor of the coil.

Coil automatic tuning

Coil automatic tuning mode is enabled with setting *Controller mode* = "Automatic". In this mode, the TUNING_ACT binary output is activated. The coil automatic tuning procedure consists of two parts. First, sufficient zero-sequence voltage variation is obtained using coil movement or resistor switching. Secondly, network parameters are calculated.

The automatic tuning procedure requires a sufficient change to be detected in the measured zero-sequence voltage. This can be achieved by coil movement or switching the parallel resistor of the coil. The mode is selected with *Tuning mode* setting. The available options are "Coil movement" and "Resistor switching".

In the coil movement mode, the controller first moves the coil a little towards the coil's default position and determines the direction of raising Uo voltage. Then the controller moves the coil preferably to the direction of raising zero-sequence voltage until the measured zero-sequence voltage is changed by the amount defined with *V Res variation* setting. *V Res maximum* setting defines the maximum zero-sequence voltage that the controller does not exceed when obtaining the required Uo variation. If the zero-sequence voltage reaches the value defined in *V Res maximum* setting, the

controller seeks the required Uo variation from the direction of decreasing zero-sequence voltage.

The measured zero-sequence voltage level must exceed setting *V Res minimum* during the whole tuning process. If the measured zero-sequence voltage is initially below the *V Res minimum* setting, the controller extends the search range in order to achieve this minimum level. If the minimum required level of zero-sequence voltage cannot be reached, the controller cancels the tuning. If the required zero-sequence voltage variation cannot be reached, the controller moves the coil to *Error position*.

The most accurate tuning is possible when *Pass resonance* setting is enabled: the controller moves the coil over the network resonance point and collects additional measurement points resulting in the most accurate estimate of the network parameters. Particularly passing the resonance point improves the estimate of network losses. Setting *V Res maximum* can deny the resonance point passing functionality.

V Res EF level setting should be set to a higher value than *V Res maximum*.

If the coil is equipped with a parallel resistor, the resistor switching mode offers a fast alternative to obtain the change in measured zero-sequence voltage. In the resistor switching mode, the controller switches the connection status of the parallel resistor for three seconds and then switches the resistor back to its original connection status. If the change in the measured zero-sequence voltage exceeds the *V Res variation* setting, the controller can proceed immediately to network parameters calculation. If the change defined in *V Res variation* setting cannot be obtained using resistor switching, the controller automatically uses the coil movement method.

In the case of resistor switching, the setting *V Res maximum* is ineffective.

After sufficient change in the measured zero-sequence voltage is obtained using coil movement or resistor switching, the controller calculates new network parameters and compares them to the reference values. If the network's capacitive earth-fault current has changed, the controller moves the coil to maintain the set compensation level. The active compensation mode is selected with *Compensation mode* setting. The available options are "Absolute" (tuning level selected with *Detuning level* setting) and "Relative" (tuning level selected with *Detuning level Rl* setting). The controller monitors the actual coil current while moving it to the desired tuning position. Taking into account the after-running of the coil motor, it is stopped just before reaching the desired tuning point. If the zero-sequence voltage reaches the voltage level set with *V Res maximum* setting, the controller stops the coil movement.

If the parallel resistor is installed in the system (setting *Parallel resistor* = "True"), PASANCR includes a feature to temporarily connect the parallel resistor into the system while moving the coil to the desired tuning position if the resistor is initially disconnected. The temporary connection of the parallel resistor should lower the zero-sequence voltage and therefore the movement of the coil to the desired tuning position

could be possible. The feature can be enabled with *Temporary damping* setting. The available options are "True" and "False".

An example of the feature is shown in Figure 823 where the initial coil position is at 60 A, the parallel resistor is disconnected and the target position is at 110 A. Before the controller starts moving the coil, it estimates if the zero-sequence voltage at target position is below the *V Res maximum* setting and if the movement is allowed. If the conditions allow, the controller starts moving the coil towards the higher current. While the movement stops at *V Res maximum* (set to 3.5 percent of the system's nominal phase-to-earth voltage in this example), the controller automatically connects the parallel resistor and moves the coil to the desired inductive current position (that is, 110 A). After the coil has reached the target position, the controller automatically disconnects the resistor, that is, returns it to its original connection state while simultaneously obtaining the target position of 110 A with the parallel resistor disconnected.

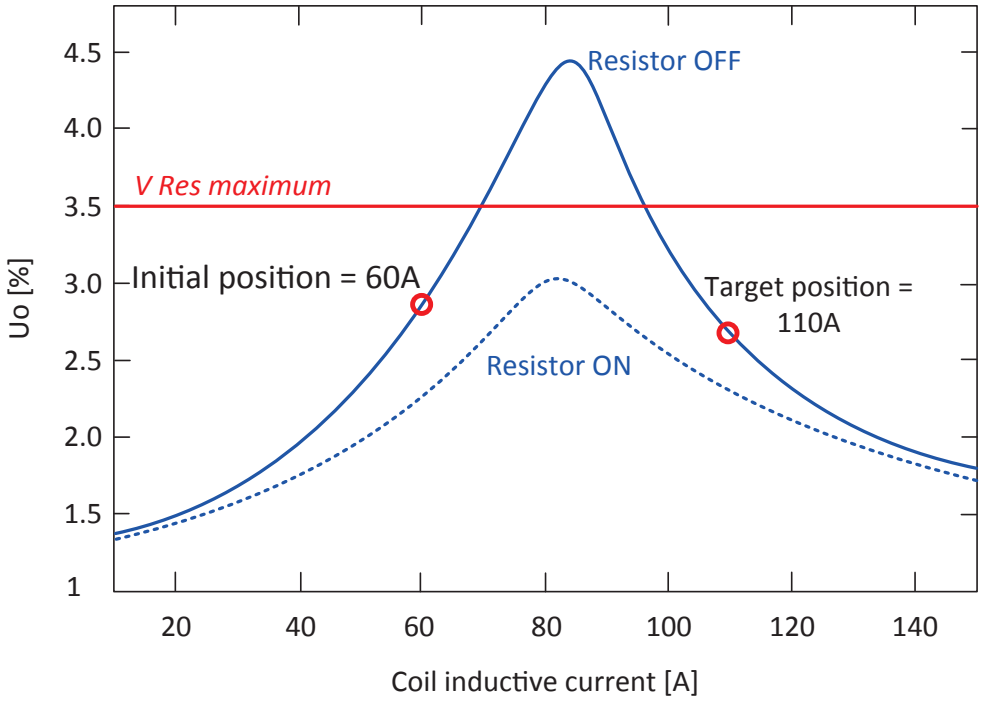

Figure 823: Damping of the resonance curve by using the parallel resistor

The number of maximum tuning cycles can be limited with *Tuning cycles* setting. The delay between consecutive tuning cycles is controllable by setting *Tuning cycle delay*. After the maximum number of tuning cycles is reached, the tuning procedure can be started by activating the ST_TUNING input, for example, via HMI application. The counter for maximum tuning cycles is reset after a successful tuning operation.

The ALARM output is a general problem indication during the tuning process. Usually, it is an indication of not obtaining a required minimum level or change of zero-sequence voltage during the coil movement. The reason for this might be, for example, a very symmetrical network. Other reasons for the ALARM indication are coil

movement into wrong direction, maximum number of tuning sequences exceeded or simultaneous indication from both end switches of the coil. There is a dedicated MOT_ALARM output indicating no detected coil movement after activating RAISE_OWN or LOWER_OWN outputs.

After ALARM indication with ALARM_STS “Umin not reached” or “Cannot obtain minimum Uo variation” the coil is moved to a position which is defined with *Error position* setting. The same procedure is executed after CLC_SEQ_WRN indication. The options are to move the coil to the position from where the tuning procedure was started, leave it to its present position or to move the coil to the default position which is settable by the user.

The active tuning range of the arc suppression coil can be limited with *Minimum current* and *Maximum current* settings. Once the operating limits are activated, the controller does not leave the selected range during the tuning procedure. If the operating limits are applied, the limited range of the coil is indicated on the HMI resonance curve view.

Operation during earth faults

The controller supports three modes for operation during earth fault. The active mode can be selected with *EF mode* setting. The available modes are "Blocked during EF", "Resonance" and "Tuning during EF".

- Blocked during EF: No coil movement when the earth fault is detected
- Resonance: Coil is moved to the resonance point which is determined during the healthy-state operation of the network.
- Tuning during EF: The controller determines the network parameters during a sustained earth fault and maintains the set compensation level. The controller can also detect network switching operations and tune the ASC correspondingly (for example, disconnecting feeders to isolate the earth fault). Tuning during EF can be performed when the measured zero-sequence voltage is below 80 percent of the system's nominal phase-to-earth voltage. If the measured zero-sequence voltage is over 80 percent of the system's nominal phase-to-earth voltage, the “Blocked during EF” mode is automatically switched into use.

Fixed parallel coil control

PASANCR supports the control of the fixed parallel coil. The ampere value and the nominal voltage of the coil can be set with *Fix coil value* and *Fix coil V Nom* settings. The treatment of the fixed parallel coil is selected with *Fix coil type* setting. By applying “OFF” or “ON”, the controller cannot automatically switch the connection status of the fixed parallel coil. If “Automatic” is selected, the controller can change the connection status of the fixed parallel coil to reach the desired compensation level. During the automatic operation, the controller tunes the adjustable ASC first. If the desired compensation level cannot be reached, the fixed parallel coil can be switched on or off. The presence of the fixed parallel coil in the system has effect on correct tuning when the compensation mode is relative.

Absolute detuning current can be calculated:

$$I_v = I_{coil} + I_{fix} - I_{reson}$$

(Equation 349)

The corresponding relative detuning is calculated as:

$$v = \frac{I_{coil} + I_{fix} - I_{reson}}{I_{reson}} \cdot 100\%$$

(Equation 350)

I_{coil} Current of the adjustable ASC

I_{fix} Value of the fixed parallel coil

I_{reson} Current at resonance point

If a fixed parallel coil is introduced in the network (“ON” or “Automatic”), the x axis title of the resonance curve displayed on the HMI can be selected with the *Resonance curve Cur* setting. Available options are:

- Icoil: Only the current of adjustable ASC
- Icoil + Ifix: Total current of adjustable ASC and fixed parallel coil

Statistics

The controller supports displaying resettable statistics. The statistics can be reset via settings menu using *Clear counters* command.

Table 1429: Displayed statistics

Type	Statistics	Description
General	Operation time	Controller time in operation
	Tuning procedures	Number of started tuning procedures
	Tuned	Number of successful tuning operations
	Canceled tunings	Number of the canceled tuning procedures, that is, *Tuning delay* has not elapsed
	Tuned at Uo max	Number of tuning cases when coil movement has stopped to *V Res maximum* position
	Tuned at low limit	Number of cases when coil final position is limited either by low end position indication of the coil or the limited operating range *Minimum current*
	Tuned at high limit	Number of cases when coil final position is limited either by high end position indication of the coil or the limited operating range *Maximum current*
Earth faults	Transient earth-faults	Number of transient earth faults (that is, fault time shorter than time defined in *Transient time EF* setting)
	Permanent earth-faults	Number of permanent earth faults (that is, fault time longer than time defined in *Transient time EF* setting)

Table continues on next page

Type	Statistics	Description
Resistor control	Switch parallel resistor (auto)	Number of parallel resistor switch operations. For example, if the resistor is initially off, then it is switched on and after a defined delay, it is again switched off, this increases the counter by two.
	Switch parallel resistor (manual)	Number of manual switch operations for parallel resistor
Other	Motor running time	Sum time of RAISE_OWN and LOWER_OWN outputs activated

Coil manual tuning

PASANCR supports manual coil tuning when *Controller mode* setting is "Manual". Manual control is achieved by activating RAISE_LOCAL and LOWER_LOCAL inputs which activate the corresponding RAISE_OWN and LOWER_OWN outputs. The manual mode and the corresponding inputs can be activated, for example, via HMI application. Moreover, the manual control of the coil can be achieved via communication by using the *Coil Target Pos* setting. Once the setting is committed, the controller moves to the desired position. Also the activated operating limits can restrict the coil movement. The MOT_ALARM output is activated during manual control if the coil position is not changed due to activated RAISE_OWN and LOWER_OWN commands. The ALARM output is activated when the movement of the coil is in wrong direction or both end switches indicate simultaneously enabled signaling.

Coil manual movement is possible only after calibration.

During the manual control mode the network resonance curve is not updated automatically. The previous automatically detected resonance curve is displayed on the HMI view.

It is possible to manually control the connection status of the fixed parallel coil with *Fix coil type* setting by selecting "ON" or "OFF". The setting can be changed via the settings menu or HMI application.

Resistor control

Zero-sequence currents in compensated networks are usually very low, making it difficult to select the faulty line. To avoid sensitivity problems, the parallel resistor of the ASC is often used to increase the zero-sequence current allowing a simple earth-fault protection to locate the faulty line. PASANCR contains a functionality to switch the resistor on and off automatically or on user input.

First, the resistor installation status is set with *Parallel resistor* setting. The available options are "True" and "False". If the parallel resistor is installed in the system, the value is selected with *Resistor Nom value* setting. Second, the nominal voltage level of the power auxiliary winding is selected with *Auxiliary Wnd V Nom* setting.

The *Resistor control* setting is used to enable the automatic control sequence or to connect or disconnect the resistor. The automatic control sequence is released if the

functionality is enabled (*Resistor control* = "Automatic") and the EARTH_FAULT output is active. The resistor control sequence after the earth-fault indication depends on the resistor connection status during the healthy state. The healthy-state status is selected with the *Resistor healthy St* setting. The available options are "On" and "Off". The settings affecting the control sequence are explained in Figure 824.

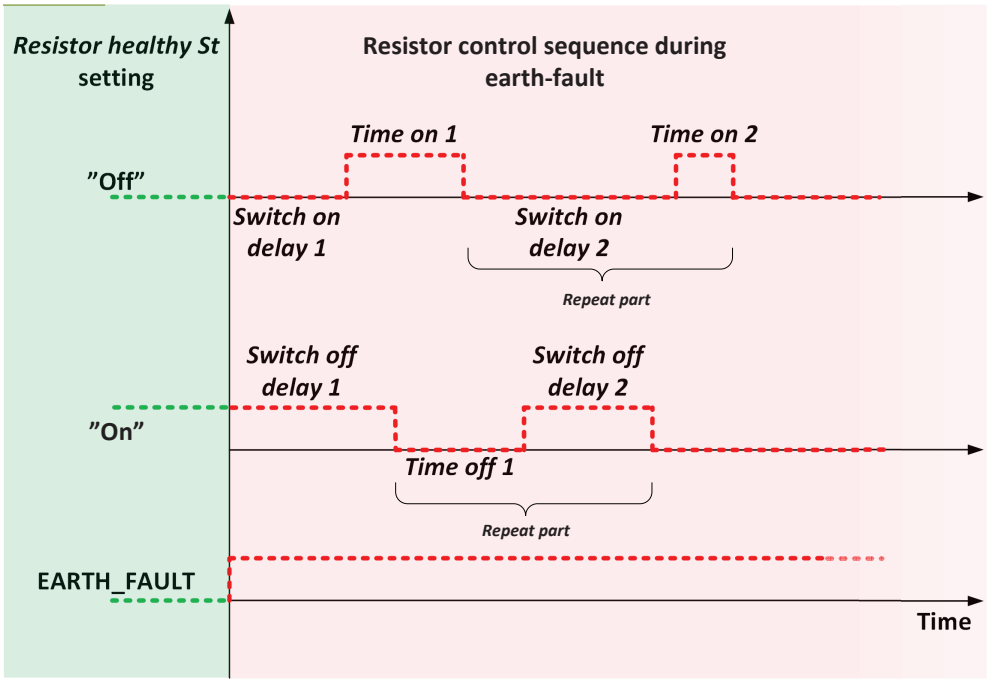

Figure 824: Resistor control sequence

When the earth-fault indication becomes inactive, both the single sequence and the repeat sequences are finished and the resistor is switched back to its initial state.

The resistor control sequence contains a repeat part which can be repeated after the whole sequence is executed once. The number of repetitions can be selected with *Resistor repeats* setting. Additionally, the pause between the consecutive repeats can be selected with *Resistor pause* setting. After the sequences are completed, the initial resistor healthy state is restored within 1 s if the *Resistor healthy St* = "On". If the healthy state is "Off", the resistor is already in its healthy-state position after the sequence is completed.

It is also possible to manually trigger the resistor control sequence with ST_RESIS_SEQ binary input.

Blocking

The BLK_AUTO input blocks the automatic operation of the function. PASANCR's automatic operation is blocked internally if the ASC is disconnected at the substation, that is, COIL_STS signal is low. The BLK_MANUAL input blocks the manual control of the coil. The BLK_RESISTOR input disconnects the parallel resistor and blocks its switching on, for example, due to resistor overheating.

9.11.7 Application

PASANCR is a numerical automatic controller for arc suppression coil (Petersen coil) and the parallel resistor. It can be applied to compensated networks where a switched parallel resistor is optionally connected in parallel with the arc-suppression coil. An efficient protecting method against earth faults occurring in a medium-voltage compensated network is the earth-fault compensation. It is carried out by inserting an inductive coil (arc suppression coil or Petersen coil) between the transformer's star point and the earth in order to compensate the zero-sequence capacitive current of the network. It increases the probability of the arc extinction in case of a temporary earth fault. The arc extinction coil is effective only if its value is tuned to the zero-sequence capacity of the network so they are in resonance state and as a consequence the earth-fault current is very low.

9.11.8 Commissioning

During the coil setup process, it is not yet needed to connect the ASC to the network. The coil setup consists of two parts:

- Calibration of coil
- Evaluation of coil linearity

The coil calibration procedure is started by activating `ST_CALIB` input which can be done via local HMI application. Before starting the procedure, it must be checked that coil end switches (`HIGH_LIMIT` and `LOW_LIMIT`) are connected to the controller. If end switches are not available, end positions are detected during the calibration process if there was no coil movement for more than 20 s.

First, in the coil calibration procedure the coil is moved automatically from the lower-end switch to the upper-end switch. In both locations, the corresponding potentiometer values are recorded for further use. Also, the coil movement speed is determined during the calibration procedure. Secondly, the coil is moved to its middle position and the after-running and mechanical play of the coil are determined. Finally, the potentiometer gaps are determined. All results from coil calibration (running speed, after running, mechanical play and potentiometer gap locations) are visible in the Monitored data view.

After the calibration, the coil linearity is evaluated. The automatic coil calibration determined the potentiometer ohmic end-switch values. These values are displayed on the HMI and can be entered into the linearization table. The corresponding coil position values (that is, inductive current of the coil) might be entered, for example, from the coil routine test report delivered by the coil manufacturer. The values are entered at coil nominal voltage level which is defined with *Coil V Nom* setting. Moreover, if the potentiometer/coil position relationship is nonlinear, additional eight interpolation points, or part of them, might be applied. This is done by entering the potentiometer and corresponding coil position values into the linearization table. Values which are left to default value of 0.0 are discarded from the actual linearization curve. Both end values of the linearization table are displayed on the HMI view of the

resonance curve. An example of the linearization table is given in Table 1430 and the corresponding linearization curve is plotted in Figure 825.

The values put in ascending order are automatically adjusted so they are in the neighboring positions of the array, irrespective of the position in the linearization table.

Table 1430: Example of a linearization table

Potentiometer value (setting Pot value x, x = 1…10)	Coil position (setting Coil current x, x = 1…10)
100	10
150	20
200	30
250	37
300	43
350	48
400	53
450	57
600	68
1000	90

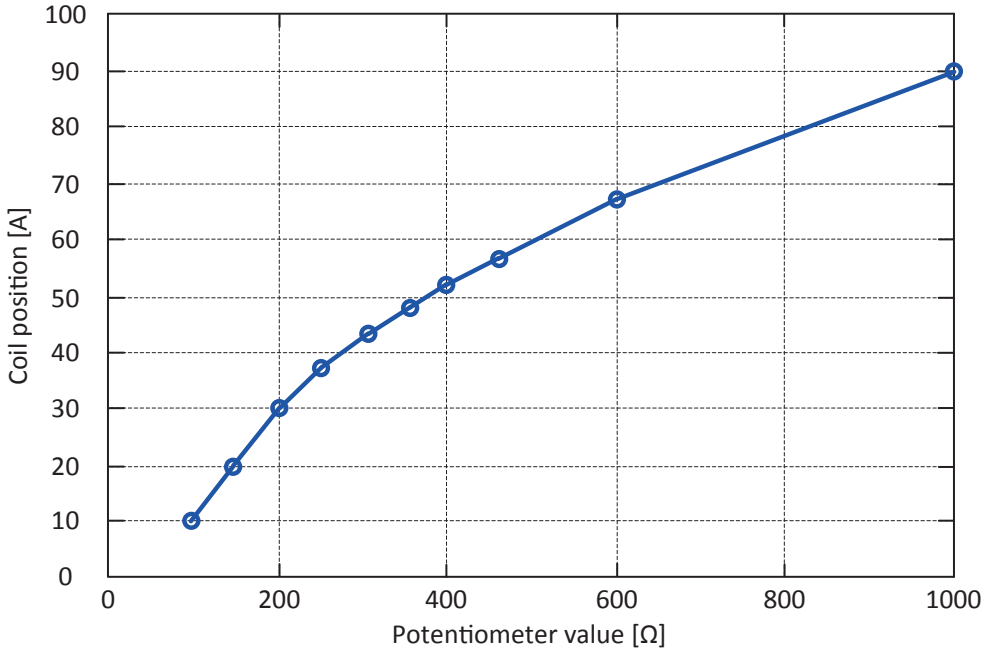

Figure 825: Example of a linearization curve

Aged ASCs can suffer from wearing of the position-indicating potentiometer. The potentiometer gaps are identified during the calibration and the number of the gaps is displayed on the HMI after the calibration. Actual gap locations GAP_LO_VAL_x and GAP_HI_VAL_x (x = 1…5, which corresponds to the gap identification number)

are visible in the Monitored data view. If the maximum number of five gap locations is exceeded, the first pair is overwritten.

The coil position should be known and the controller operation should be guaranteed even if no new calibration is done. When potentiometer gaps are present in either both ends or in the middle of the potentiometer range, the potentiometer should be replaced. These are the three critical points of the calibration where ohmic measurements must be precise.

The maximum percentage length of the potentiometer gap can be set with setting *Pot Max gap*. The controller determines a gap length by measuring the distance between both ends of a gap in ohms. A gap is indicated when the ohmic position exceeds 2000 Ω.

If the coil potentiometer enters a gap during the normal operation, the controller estimates the coil position based on its previous known position and coil movement speed. If the actual gap length exceeds the setting *Pot Max gap* or a new gap appears during daily operation, `POT_ALARM` output is activated. Moreover, TUNING_STS monitored data indicates the reason of alarm. High values of the *Pot Max gap* setting introduce inaccuracy to the coil movement as the coil position is based on a calculated estimate. The purpose of the gap detection functionality is to enable the controller operation even if the potentiometer is worn out during the normal operation. The potentiometer should be replaced during the next service break in order to guarantee accurate operation of the controller. The gap detection functionality can be disabled by setting the *Pot Max gap* value to 0. Potentiometer gaps are illustrated in Figure 826.

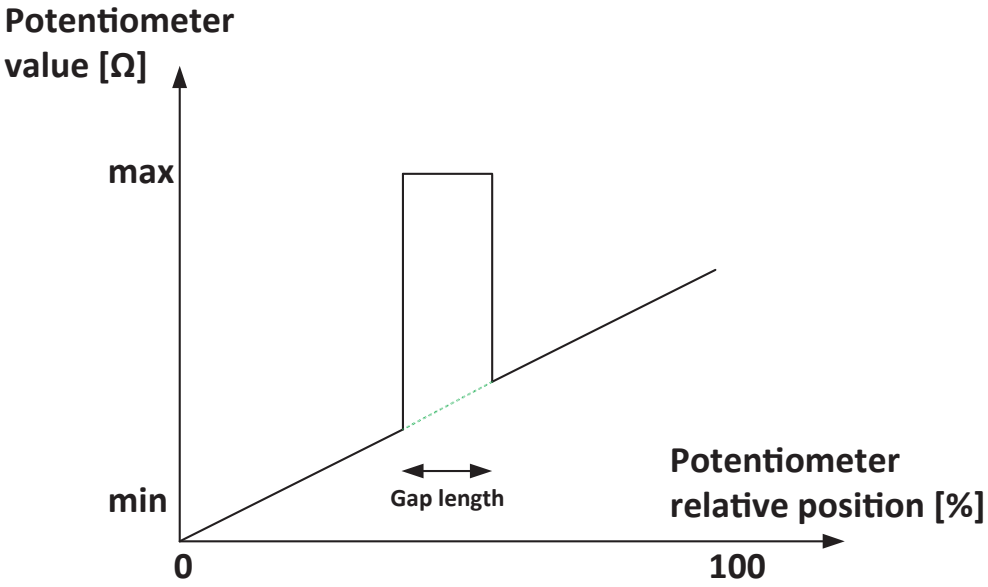

Figure 826: Potentiometer gaps

9.11.9 Signals

Table 1431: PASANCR Input signals

Name	Type	Default	Description
U3P	SIGNAL	-	Three-phase voltages
IRES	SIGNAL	-	Residual current
URES	SIGNAL	-	Residual voltage
COIL_POS	FLOAT32	0	Coil position derived from the potentiometer reading
COIL_STS	BOOLEAN	0=False	Connection status of the variable arc suppression coil
FIXCOIL_STS	BOOLEAN	0=False	Connection status of the fixed coil
RESISTOR_STS	BOOLEAN	0=False	Connection status of the parallel current raising resistor
HIGH_LIMIT	BOOLEAN	0=False	High end position reached
LOW_LIMIT	BOOLEAN	0=False	Low end position reached
ST_CALIB	BOOLEAN	0=False	Rising edge of this signal triggers the calibration procedure of the coil
ST_TUNING	BOOLEAN	0=False	Rising edge of this signal triggers the automatic tuning procedure
ST_RESIS_SEQ	BOOLEAN	0=False	Rising edge of this signal triggers the resistor control sequence
RAISE_LOCAL	BOOLEAN	0=False	Increase arc suppression coil current
LOWER_LOCAL	BOOLEAN	0=False	Decrease arc suppression coil current
PARALLEL	BOOLEAN	0=False	Parallel controller has coil movement in progress
BLK_AUTO	BOOLEAN	0=False	Blocking the coil automatic tuning
BLK_MANUAL	BOOLEAN	0=False	Blocking the coil manual operation
BLK_RESISTOR	BOOLEAN	0=False	Disconnect and block switching on the parallel resistor

Table 1432: PASANCR Output signals

Name	Type	Description
RAISE_OWN	BOOLEAN	Increase coil current
LOWER_OWN	BOOLEAN	Decrease coil current
FIXCOIL	BOOLEAN	Status information to control fixed coil on/off
OP_FIXCOIL	BOOLEAN	Command to disconnect fix coil
CL_FIXCOIL	BOOLEAN	Command to connect fix coil
RESISTOR	BOOLEAN	Status information to control parallel current rising resistor on/off
OP_RESISTOR	BOOLEAN	Command to disconnect parallel current rising resistor
CL_RESISTOR	BOOLEAN	Command to connect parallel current rising resistor
ALARM	BOOLEAN	General alarm indication

Table continues on next page

Name	Type	Description
MOT_ALARM	BOOLEAN	Motor alarm: no detected coil movement
POT_ALARM	BOOLEAN	Potentiometer alarm
EARTH_FAULT	BOOLEAN	Earth-fault indication
TUNING_ACT	BOOLEAN	Automatic tuning procedure ongoing

9.11.10 Settings

Table 1433: PASANCR Group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Compensation mode	1=Absolute 2=Relative			1=Absolute	Compensation degree in absolute amperes or relative to the resonance point
Detuning level	-100...100	A	1	0	Detuning level in amperes
Detuning level Rl	-100.0...100.0	%	0.1	0.0	Detuning level in percents
V Res change level	0.0...1000.0	%Uref	0.1	10.0	Zero-sequence voltage change threshold as percent of reference voltage
V Res Meas mode	1=Amplitude 2=Phasor			2=Phasor	Uo trigger based on amplitude or phasor measurement
Tuning delay	0...3600	s	1	60	Zero-sequence voltage trigger delay to start control procedure
V Res variation	0.1...100.0	%Un	0.1	2.0	Req. change in Uo that calc. of net. param. can be executed
Tuning mode	1=Coil movement 2=Resistor switching			1=Coil movement	Method for obtaining Uo variation
V Ref adaptive mode	0=Disable 1=Enable			1=Enable	Uref adaptive mode
V Ref adaptive delay	0...1000	min	1	20	Uref adaptive delay
V Res EF level	0.00...100.00	%Un	0.01	15.00	Uo level for detection of earth fault in the network
Default position	0...1000	A	1	50	Coil default position
V Res minimum	0.00...20.00	%Un	0.01	0.10	Minimum level for zero-sequence voltage to allow coil automatic tuning
V Res maximum	0.00...150.00	%Un	0.01	10.00	Maximum level for zero-sequence voltage allowed during automatic tuning process
Temporary damping	0=False 1=True			0=False	Resistor switching on/off allowed during the automatic tuning procedure
Minimum current	0...100	A	1	0	Minimum current of arc-suppression coil (low operating limit)
Maximum current	0...10000	A	1	10000	Maximum current of arc-suppression coil (high operating limit)
Error position	1=Current 2=Previous 3=Default			2=Previous	Coil position in the case error occured during the automatic tuning process
Pass resonance	0=False 1=True			0=False	Pass resonance enabled / disabled
Transient time EF	0...1000000	ms	1	5	Transient earth-fault duration threshold

Table continues on next page

Parameter	Values (Range)	Unit	Step	Default	Description
EF mode	1=Blocked during EF 2=Resonance 3=Tuning during EF			1=Blocked during EF	Operation mode during earth-fault (alarming earth-fault)
Resistor healthy St	0=Off 1=On			0=Off	Resistor connection status during healthy state operation
Resistor repeats	0...100		1	0	Number of resistor control sequence repeats
Resistor pause	0...100000000	ms	1	5	Time between consecutive resistor control sequence repeats
Resonance curve Cur	1=Icoil 2=Icoil + Ifix			2=Icoil + Ifix	Resonance curve x-axis title on HMI
Switch on delay 1	0...300000	ms	1	1000	Resistor switch-on delay time
Time on 1	0...300000	ms	1	1000	Resistor switch on time

Characteristic	Value
Measuring accuracy	Resistance: ±2% or ±1 Ω
Operation accuracy[1)]	I_RESONANCE: Typically ±2 A
	I_DAMPING: Typically ±2 A

1) Network resonance point voltage must be at least 0.01 × U_n, where U_n = nominal phase-to-earth voltage

Section 10 Power quality measurement functions

10.1 Current total demand, harmonic distortion, DC component (TDD, THD, DC) and individual harmonics CHMHAI

10.1.1 Identification

Function description	IEC 61850 identification	IEC 60617 identification	ANSI/IEEE C37.2 device number
Current total demand, harmonic distortion, DC component (TDD, THD, DC) and individual harmonics	CHMHAI	PQM3IH	PQM ITHD,IDC

10.1.2 Function block

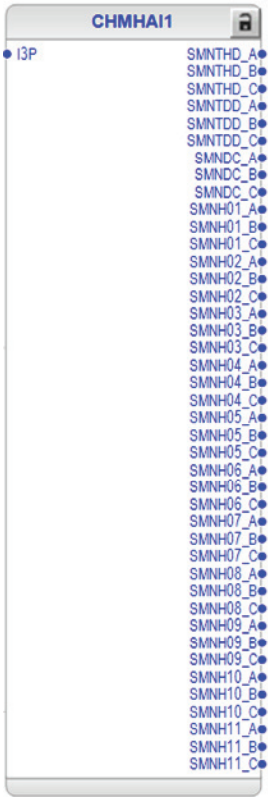

Figure 827: Function block

10.1.3 Functionality

Harmonic current values are available as measurements for each harmonic, THD and TDD. There are also direct current component and fundamental frequency values. The values of three phases are calculated separately.

There are short-time sliding measurement mean values (3 seconds, 1 minute or 5 minutes). In the configuration tool these values can be connected to other logics. Blocks can be used as limiters, timers and multipurpose analog protection, and alarms can be created when needed.

Non-sliding 10-minute measured mean values are available via communication to substation monitoring products such as COM600S. Only the main function part with an analog signal input must be connected in relay configuration. Data can be collected and stored with the substation monitoring system to the historian database.

These mean values can also be found in the LHMI menus of the protection relay and WHMI.

The applicable power quality standards include EN 50160:2010, IEEE 519-2014, IEC 61000-4-7:2002+A1:2008 and IEC 61000-4-30:2015.

10.1.4 Analog channel configuration

CHMHAI has one analog group input which must be properly configured.

Table 1438: Analog inputs

Input	Description
I3P	Three-phase currents

See the preprocessing function blocks in this document for the possible signal sources.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

10.1.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off". Changes will result to reset the function internal data.

The operation of CHMHAI can be described with a module diagram. All the modules in the diagram are explained in the next sections.

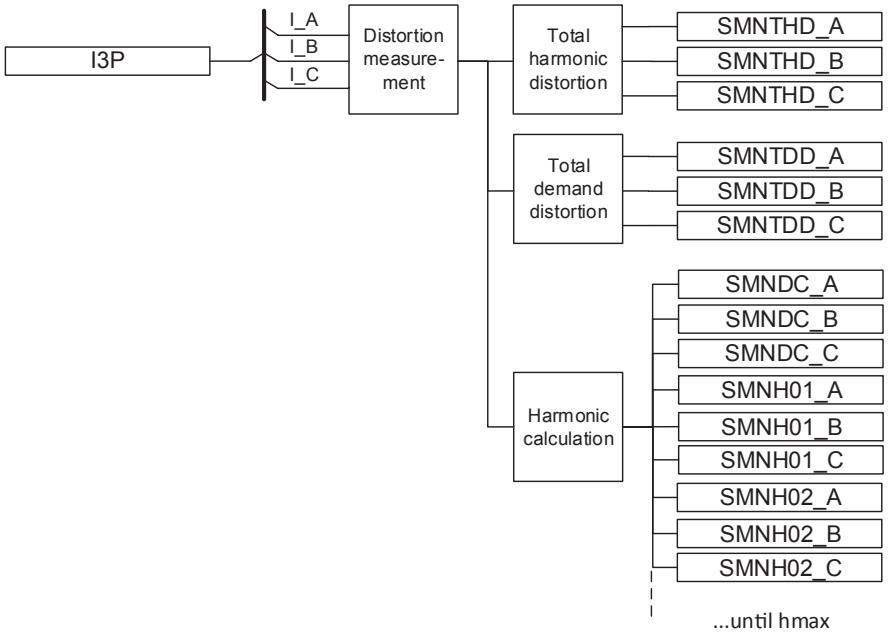

Figure 828: Functional module diagram

Distortion measurement

The Distortion measurement module measures harmonics up to the 11th harmonic.

The filter used for harmonics includes a spectrum of frequencies near each harmonic frequency. FFT for one period is used. The resulting frequency spectrum is wider than in a harmonic subgroup. An anti-aliasing filter is used.

Total harmonic distortion

The total harmonic distortion THD is calculated from the measured harmonic components with the formula

$$THD = \sqrt{\sum_{h=2}^{n}\left(\frac{I_h}{I_1}\right)^2}$$

(Equation 351)

I_h hth harmonic component

I_1 Fundamental frequency current (1st harmonic)

n Number of harmonics

THD sliding mean value outputs are SMNTHD_A, SMNTHD_B and SMNTHD_C. Non-sliding 10-minute mean values LMNTHD_A, LMNTHD_B and LMNTHD_C are seen in the monitored data. These values are always shown as percentage of the fundamental frequency current mean value. The 10-minute mean values follow 10 min ticks. See also Figure 829 and the description for sliding values.

Total demand distortion

The total demand distortion TDD is calculated from the measured harmonic components with the formula

$$TDD = \sqrt{\sum_{h=2}^{n}\left(\frac{I_h}{I_L}\right)^2}$$

(Equation 352)

I_h h^{th} harmonic component

I_L Maximum demand load current set with *Demand current* setting

n Number of harmonics

The used reference current is the absolute value of the *Demand current* setting. It is typically set according to the maximum load current of the feeder. The TDD value is calculated separately for each phase.

TDD sliding mean value outputs are SMNTDD_A, SMNTDD_B and SMNTDD_C. Non-sliding 10-minute mean values LMNTDD_A, LMNTDD_B and LMNTDD_C are seen in the monitored data. These values are always shown as percentage of the setting *Demand current*. The 10-minute mean values follow 10 min ticks. See also Figure 829 and the description for sliding values.

Harmonic calculation

Harmonic mean values are calculated for each phase. Also, the mean values of the nominal frequency (fundamental) and direct current component are calculated. The fundamental frequency mean values are shown as percentage of the nominal phase current.

The actual harmonic mean values are shown as percentage of the reference current. By default, the fundamental frequency current is used as reference. This can be selected by setting *Reference Cur Sel* to "fundamental". When amplitude of fundamental frequency current is very low, below 0.02 xIn, calculation is blocked internally. As a result, value zero is used in the mean value calculation. Extremely high harmonic values are limited to 2.0 xIn. This is also used for fundamental mean value, but not for reference.

The value of *Demand current* setting can be used as reference by setting *Reference Cur Sel* to "absolute". Typically, it is set according to the maximum demand load current. That is more typically used when TDD is preferred, but might also be found useful when THD is monitored.

Settings *Reference Cur Sel* and *Demand current* have no effect in THD calculation, but setting *Demand current* is used in TDD calculation.

The calculation window length is set with the *Sliding interval* setting. It has three window lengths ("3 seconds", "1 minute" or "5 minutes") for sliding mean value outputs. Output values can also be seen in monitoring.

The window type used for configuration tool output values is always sliding. Output values are updated once every 0.1 seconds.

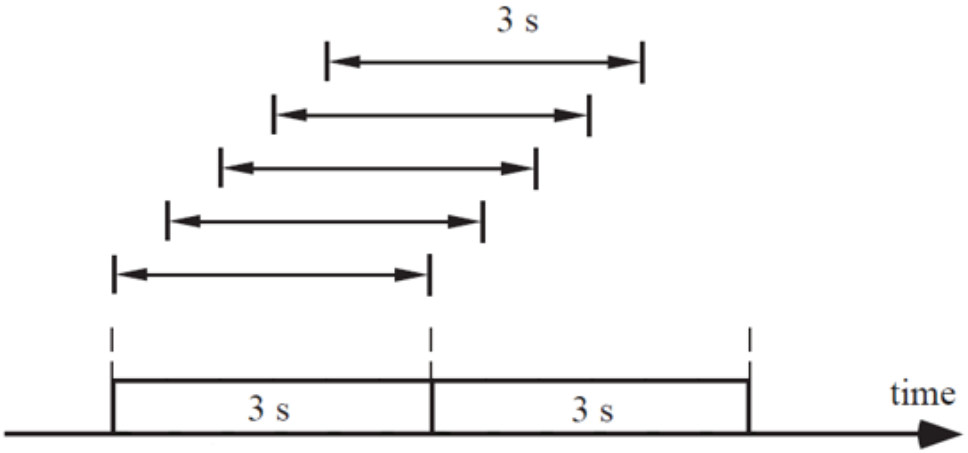

Figure 829: Sliding 3 seconds value calculation in principle

The sliding mean values of the fundamental of each phase are SMNH01_A, SMNH01_B and SMNH01_C. Actual harmonics are seen with their number, for example, phase A for second harmonic is SMNH02_A and phase C for 9th harmonic is SMNH09_C. Direct current component outputs are SMNDC_A, SMNDC_B and SMNDC_C.

Intervals that are longer than 3 seconds are calculated using free running 3-second mean values.

The longer 10-minute mean values of the fundamental of each phase are seen in monitored data as LMNH01_A, LMNH01_B and LMNH01_C. Actual harmonics are seen with their number. Direct current components are LMNDC_A, LMNDC_B and LMNDC_C.

Time stamps for ready 10-minute mean value calculation can be seen in the monitored data L time stamp.

The window type used for the 10-minute mean value calculation is always non-sliding. The 10-minute value calculation begins based on the protection relay's internal clock 10 minutes time (for example,11:00, 11:10, 11:20, 11:30, 11:40, 11:50, 12:00…). This is called 10 min tick.

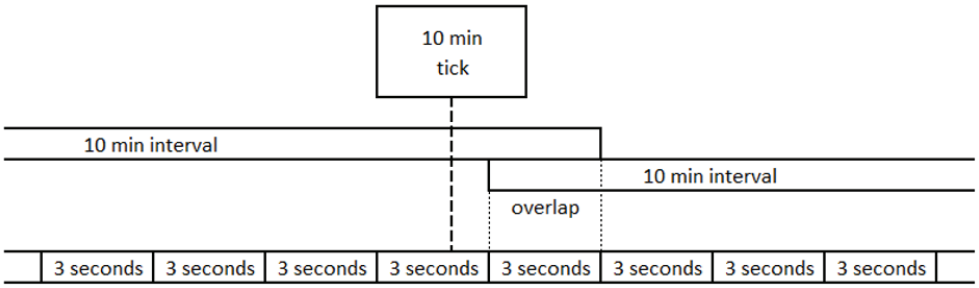

Figure 830: The 10-minute interval with time synchronization and free running 3 seconds

The 10-minute mean value is shown in the monitored data until the next 10-minute mean value has been cumulated. Another 10-minute calculation might be started when time synchronization is used to change the protection relay's internal clock. The first calculation continues for 10 minutes and is then seen in the monitored data with a time stamp. An event is sent every time a 10-minute value calculation is ready in the monitored data.

See the Time synchronization chapter in this document.

When the protection relay is powered on, the shown value is zero until the first 10-minute mean value has been cumulated. During this time, the 10-minute output quality is marked questionable in the IEC 61850 data.

When the settings *Reference Cur Sel* or *Demand current* are changed, older data is not cleared. Although older data is calculated based on different setting values, those can still be used as they are used to calculate mean values. The influence might be seen in mean values. These are considered as minor adjustments to the reference current, similar to varying fundamental current.

Changing setting *Sliding interval* has influence on the seen mean values. Sliding values change slowly towards the input value during the time interval. When mean values have not been calculated for a full interval, quality is marked questionable in the IEC 61850 data. Questionable quality is also indicated for a full interval if the protection relay is reset.

10.1.6 Application

Typically, the measured short-time 3-second mean values are used with a suitable logic to give alarms. If a more stabilized value is needed, a 1-minute or 5-minute mean value should be selected.

One example of using short-time mean values is to compare the level of THD or TDD and some harmonics, for example, 5^{th} and 7^{th}. The values to be compared to the same limit can be combined with MAX3R and MAPGAPC can be used to test if the settable

limit value is exceeded. Outputs of MAPGAPC can be connected to the needed logic and, for example, an event can be sent with MVGAPC.

The 10-minute mean values can be collected to an external substation monitoring system. Collected data can be used in weekly reporting. If longer mean values are needed, the collected 10-minute mean values can be used to calculate, for example, two-hour mean values.

Typically, 10-minute THD or TDD mean values are collected from all three phases. Individual harmonics and the fundamental frequency component can also be collected.

10.1.7 Signals

Table 1439: CHMHAI Input signals

Name	Type	Default	Description

10.2.2 Function block

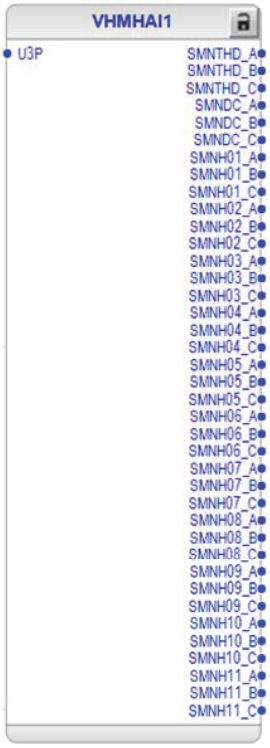

Figure 831: Function block

10.2.3 Functionality

Harmonic voltage values are available as measurements for each harmonic and THD. There are also direct current component and fundamental frequency values. The values of three phases are calculated separately.

There are short-time sliding measurement mean values (3 seconds, 1 minute or 5 minutes) which can be connected to other logics in the configuration tool. Blocks, such as limiters, timers and multipurpose analog protection, can be used and alarms can be created when needed.

Non-sliding 10-minute measured mean values are available via communication to substation monitoring products such as COM600S. Only the main function part with an analog signal input must be connected in relay configuration. Data can be collected and stored with the substation monitoring system to the historian database.

These mean values can also be found in the LHMI menus of the protection relay and WHMI.

The applicable power quality standards include EN 50160:2010, IEEE 519-2014, IEC 61000-4-7:2002+A1:2008 and IEC 61000-4-30:2015.

10.2.4 Analog channel configuration

VHMHAI has one analog group input which must be properly configured.

Table 1445: Analog inputs

Input	Description
U3P	Three-phase voltages for voltage harmonic measurement function VHMHAI

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1446: Special conditions

Condition	Description
U3P connected to real measurements	The function requires that all three voltage channels are connected.

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

10.2.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off". Changes will result to reset the function internal data.

The operation of VHMHAI can be described with a module diagram. All the modules in the diagram are explained in the next sections.

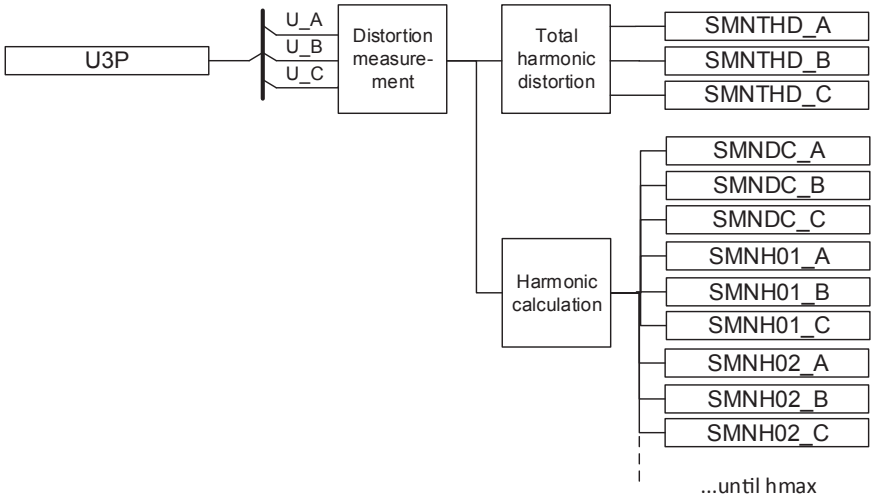

Figure 832: Functional module diagram

Distortion measurement

The Distortion measurement module measures harmonics up to the 11th harmonic.

The filter used for harmonics includes a spectrum of frequencies near each harmonic frequency. FFT for one period is used. The resulting frequency spectrum is wider than in a harmonic subgroup. An anti-aliasing filter is used.

Total harmonic distortion

The total harmonic distortion THD is calculated from the measured harmonic components with the formula

$$THD = \sqrt{\sum_{h=2}^{n}\left(\frac{U_h}{U_1}\right)^2}$$

(Equation 353)

U_h hth harmonic component

U_1 Fundamental voltage (1st harmonic)

n Number of harmonics

THD shorter mean value outputs are SMNTHD_A, SMNTHD_B and SMNTHD_C. These and also the 10-minute mean values LMNTHD_A, LMNTHD_B and LMNTHD_C are seen in the monitored data. These values are always shown as percentage of the fundamental frequency's phase-to-earth voltage 3-second mean value. The 10-minute mean values also follow 10 min ticks. See also Figure 833 and the description for sliding values.

Harmonic calculation

Harmonic mean values are calculated for each phase. Also, the mean values of the nominal frequency (fundamental) and direct current component are calculated. The fundamental frequency mean values are shown as percentage of the nominal phase-to-earth voltage.

The actual harmonic mean values are shown as percentage of the fundamental voltage. When the reference voltage (the fundamental voltage) is extremely low (below 0.02 xUn), the calculation is blocked internally. As a result, value zero is used in the mean value calculation of individual harmonics. Extremely high harmonic values are limited to 2.0 xUn.

The calculation window length is set with the *Sliding interval* setting. It has three window lengths ("3 seconds", "1 minute" or "5 minutes") for shorter mean value outputs. Output values can also be seen in the monitored data.

The window type used for configuration tool output values is always sliding. Output values are updated once every 0.1 seconds.

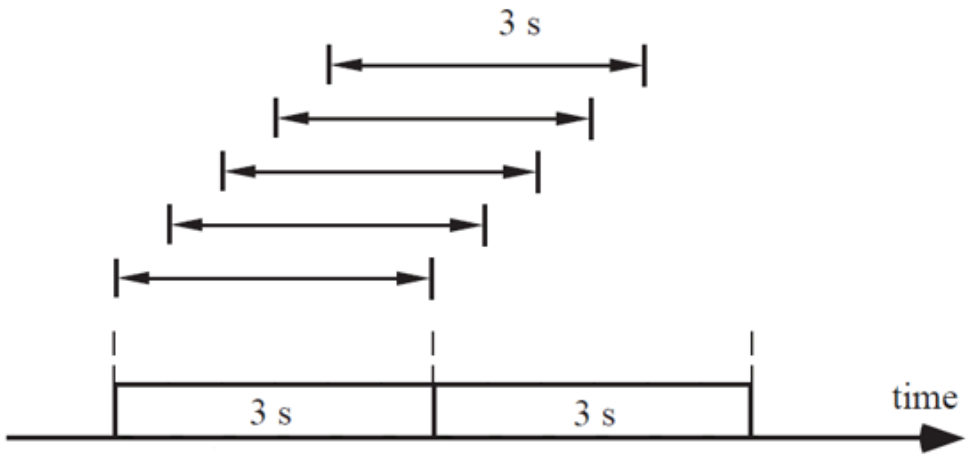

Figure 833: Sliding 3 seconds value calculation in principle

The shorter mean values of the fundamental of each phase are `SMNH01_A`, `SMNH01_B` and `SMNH01_C`. Actual harmonics are seen with their number, for example, phase A for second harmonic is `SMNH02_A` and phase C for 9th harmonic is `SMNH09_C`. Direct current component outputs are `SMNDC_A`, `SMNDC_B` and `SMNDC_C`.

Intervals that are longer than 3 seconds are calculated using free running 3-second mean values.

The longer 10-minute mean values of the fundamental of each phase are seen in monitored data as LMNH01_A, LMNH01_B and LMNH01_C. Actual harmonics are seen with their number. Direct current components are LMNDC_A, LMNDC_B and LMNDC_C.

The time stamp for the ready 10-minute mean value calculation can be seen in monitored data L time stamp.

The window type used for the 10-minute mean value calculation is always non-sliding. The 10-minute value calculation begins based on the protection relay's internal clock 10 minutes time (for example, 11:00, 11:10, 11:20, 11:30, 11:40, 11:50, 12:00…). This is called 10 min tick.

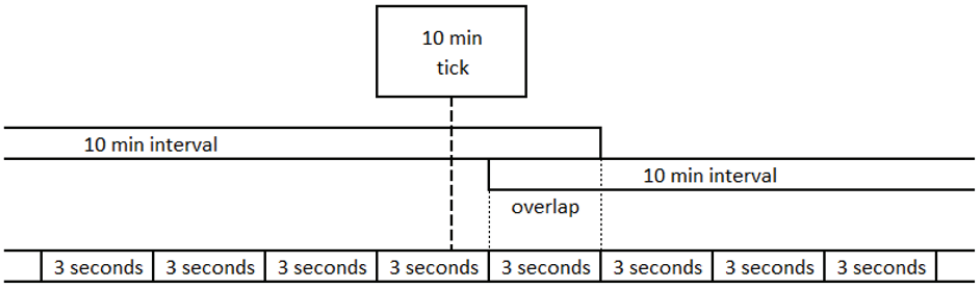

Figure 834: The 10-minute interval with time synchronization and free running 3 seconds

The 10-minute mean value is shown in monitored data until the next 10-minute mean value has been cumulated. Another 10-minute calculation can be started when time synchronization is used to change the protection relay's internal clock. The first calculation continues for 10 minutes and is then seen in the monitored data with a time stamp. An event is sent every time a 10-minute value calculation is ready in the monitored data.

See also the Time synchronization chapter in this document.

When the protection relay is powered on, the shown value is zero until the first 10-minute mean value has been cumulated. During this time, the 10-minute output quality is marked as bad in the IEC 61850 data.

Changing setting *Sliding interval* has influence on the seen mean values. Sliding values change slowly towards the input value during the time interval. When mean values have not been calculated for a full interval, quality is marked as bad in the IEC 61850 data. Bad quality is also indicated after the protection relay has been reset.

10.2.6 Application

Typically, the measured short-time 3-second mean values are used with a suitable logic to give alarms. If a more stabilized value is needed, a 1-minute or 5-minute mean value should be selected.

One example of using short-time mean values can be to compare the level of THD and some harmonics, for example, 5^{th} and 7^{th}. The values to be compared to the same limit can be combined with MAX3R, and MAPGAPC can be used to test if the settable limit

value is exceeded. Outputs of MAPGAPC can be connected to the needed logic and, for example, an event can be sent with MVGAPC.

The 10-minute mean values can be collected to an external substation monitoring system. Collected data can be used in weekly reporting. If longer mean values are needed, the collected 10-minute mean values can be used to calculate, for example, two-hour mean values.

Typically, 10-minute THD or TDD mean values are collected from all three phases. Individual harmonics and the fundamental frequency component can also be collected.

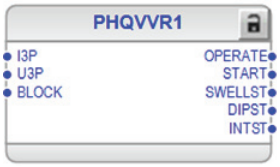

Figure 835: Function block

10.3.3 Functionality

The voltage variation function PHQVVR is used for measuring the short-duration voltage variations in distribution networks.

Power quality in the voltage waveform is evaluated by measuring voltage swells, dips and interruptions. PHQVVR includes single-phase and three-phase voltage variation modes.

Typically, short-duration voltage variations are defined to last more than half of the nominal frequency period and less than one minute. The maximum magnitude (in the case of a voltage swell) or depth (in the case of a voltage dip or interruption) and the duration of the variation can be obtained by measuring the RMS value of the voltage for each phase. International standard 61000-4-30 defines the voltage variation to be implemented using the RMS value of the voltage. IEEE standard 1159-1995 provides recommendations for monitoring the electric power quality of the single-phase and polyphase ac power systems.

PHQVVR contains a blocking functionality. It is possible to block a set of function outputs or the function itself.

10.3.4 Analog channel configuration

PHQVVR has two analog group inputs which must be properly configured.

Table 1452: Analog inputs

Input	Description
I3P[1)]	Three-phase currents
U3P	Three-phase voltages

1) Can be connected to GRPOFF

See the preprocessing function blocks in this document for the possible signal sources. The GRPOFF signal is available in the function block called Protection.

There are a few special conditions which must be noted with the configuration.

Table 1453: Special conditions

Condition	Description
U3P connected real measurements	The function can work with one voltage channel connected (A, B or C depending on the *Phase supervision* setting "Ph A", "Ph B" or "Ph C") if *Phase mode* is set to "Single Phase".
	The function can work with two voltage channel connected (A-B, B-C or C-A depending on the *Phase supervision* setting "Ph A+B", "Ph B+C" or "Ph A+C") if *Phase mode* is set to "Three Phase".
	The function requires that all three voltage channels are connected if *Phase supervision* is set to "Ph A+B+C" and *Phase mode* setting is set to "Three Phase".

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

10.3.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "On" and "Off".

The operation of PHQVVR can be described with a module diagram. All the modules in the diagram are explained in the next sections.

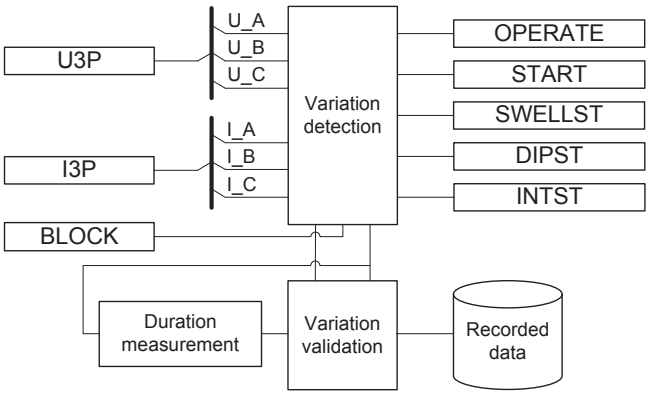

Figure 836: Functional module diagram

10.3.5.1 Phase mode setting

PHQVVR is designed for both single-phase and polyphase ac power systems, and selection can be made with the *Phase mode* setting, which can be set either to the "Single Phase" or "Three Phase" mode. The default setting is "Single Phase".

The basic difference between these alternatives depends on how many phases are needed to have the voltage variation activated. When the *Phase mode* setting is "Single Phase", the activation is straightforward. There is no dependence between the phases for variation start. The START output and the corresponding phase start are activated when the limit is exceeded or undershot. The corresponding phase start deactivation takes place when the limit (includes small hysteresis) is undershot or exceeded. The START output is deactivated when there are no more active phases.

However, when *Phase mode* is "Three Phase", all the monitored phase signal magnitudes, defined with *Phase supervision*, have to fall below or rise above the limit setting to activate the START output and the corresponding phase output, that is, all the monitored phases have to be activated. Accordingly, the deactivation occurs when the activation requirement is not fulfilled, that is, one or more monitored phase signal magnitudes return beyond their limits. Phases do not need to be activated by the same variation type to activate the START output. Another consequence is that if only one or two phases are monitored, it is sufficient that these monitored phases activate the START output.

10.3.5.2 Variation detection

The module compares the measured voltage against the limit settings. If there is a permanent undervoltage or overvoltage, the *Reference voltage* setting can be set to this voltage level to avoid the undesired voltage dip or swell indications. This is accomplished by converting the variation limits with the *Reference voltage* setting in the variation detection module, that is, when there is a voltage different from the nominal voltage, the *Reference voltage* setting is set to this voltage.

The *Variation enable* setting is used for enabling or disabling the variation types. By default, the setting value is "Swell+dip+Int" and all the alternative variation types are indicated. For example, for setting "Swell+dip", the interruption detection is not active and only swell or dip events are indicated.

In a case where *Phase mode* is "Single Phase" and the dip functionality is available, the output DIPST is activated when the measured TRMS value drops below the *Voltage dip set 3* setting in one phase and also remains above the *Voltage Int set* setting. If the voltage drops below the *Voltage Int set* setting, the output INTST is activated. INTST is deactivated when the voltage value rises above the setting *Voltage Int set*. When the same measured TRMS magnitude rises above the setting *Voltage swell set 3*, the SWELLST output is activated.

There are three setting value limits for dip (*Voltage dip set 1..3*) and swell activation (*Voltage swell set 1..3*) and one setting value limit for interruption.

If *Phase mode* is "Three Phase", the DIPST and INTST outputs are activated when the voltage levels of all monitored phases, defined with the parameter *Phase supervision*, drop below the *Voltage Int set* setting value. An example for the detection principle of voltage interruption for "Three Phase" when *Phase supervision* is "Ph A + B + C", and also the corresponding start signals when *Phase mode* is "Single Phase", are as shown in the example for the detection of a three-phase interruption.

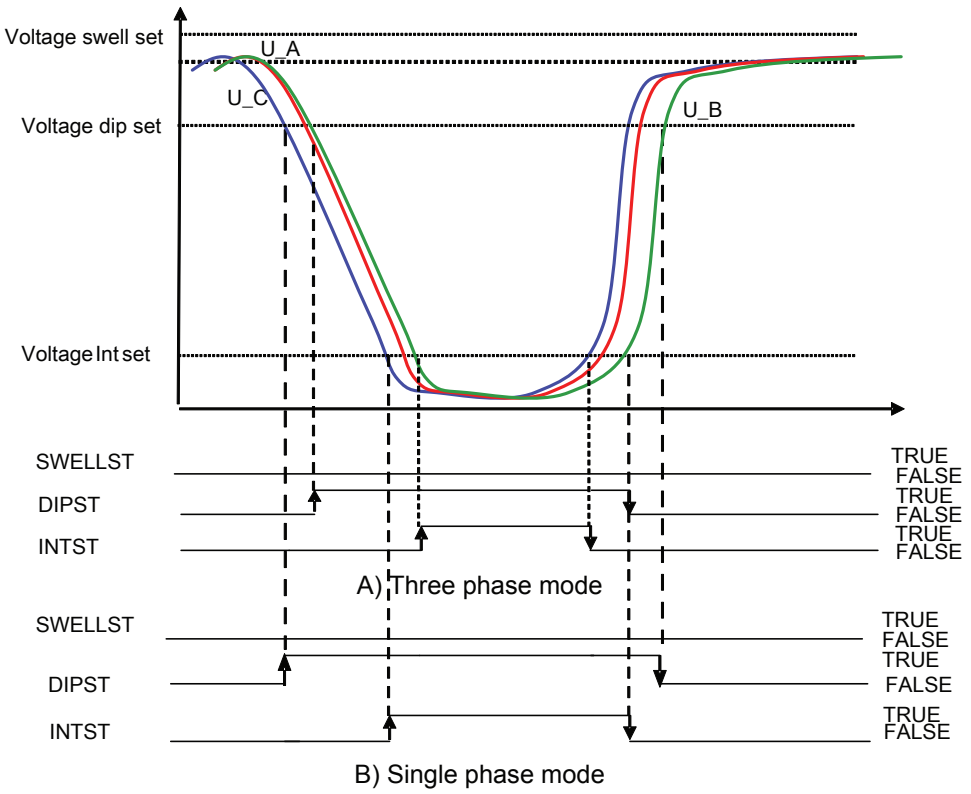

Figure 837: Detection of three-phase voltage interruption

The module measures voltage variation magnitude on each phase separately, that is, there are phase-segregated outputs ST_A, ST_B and ST_C for voltage variation indication. The configuration parameter *Phase supervision* defines which voltage phase or phases are monitored. If a voltage phase is selected to be monitored, the function assumes it to be connected to a voltage measurement channel. In other words, if an unconnected phase is monitored, the function falsely detects a voltage interruption in that phase.

The maximum magnitude and depth are defined as percentage values calculated from the difference between the reference and the measured voltage. For example, a dip to 70 percent means that the minimum voltage dip magnitude variation is 70 percent of the reference voltage amplitude.

The activation of the BLOCK input resets the function and outputs.

10.3.5.3 Variation validation

The validation criterion for voltage variation is that the measured total variation duration is between the set minimum and maximum durations (Either one of *VVa dip time 1*, *VVa swell time 1* or *VVa Int time 1*, depending on the variation type, and *VVa Dur Max*). The maximum variation duration setting is the same for all variation types.

Figure 838 shows voltage dip operational regions. In Figure 837, only one voltage dip/swell/Int set is drawn, whereas in this figure there are three sub-limits for the dip operation. When *Voltage dip set 3* is undershot, the corresponding ST_x and also the DIPST outputs are activated. When the TRMS voltage magnitude remains between *Voltage dip set 2* and *Voltage dip set 1* for a period longer than *VVa dip time 2* (shorter time than *VVa dip time 3*), a momentary dip event is detected. Furthermore, if the signal magnitude stays between the limits longer than *VVa dip time 3* (shorter time than *VVa Dur max*), a temporary dip event is detected. If the voltage remains below *Voltage dip set 1* for a period longer than *VVa dip time 1* but a shorter time than *VVa dip time 2*, an instantaneous dip event is detected.

For an event detection, the OPERATE output is always activated for one task cycle. The corresponding counter and only one of them (INSTDIPCNT, MOMDIPCNT or TEMPDIPCNT) is increased by one. If the dip limit undershooting duration is shorter than *VVa dip time 1*, *VVa swell time 1* or *VVa Int time 1*, the event is not detected at all, and if the duration is longer than *VVa Dur Max*, MAXDURDIPCNT is increased by one but no event detection resulting in the activation of the OPERATE output and recording data update takes place. These counters are available through the monitored data view on the LHMI or through tools via communications. There are no phase-segregated counters but all the variation detections are registered to a common time/magnitude-classified counter type. Consequently, a simultaneous multiphase event, that is, the variation-type event detection time moment is exactly the same for two or more phases, is counted only once also for single-phase power systems.

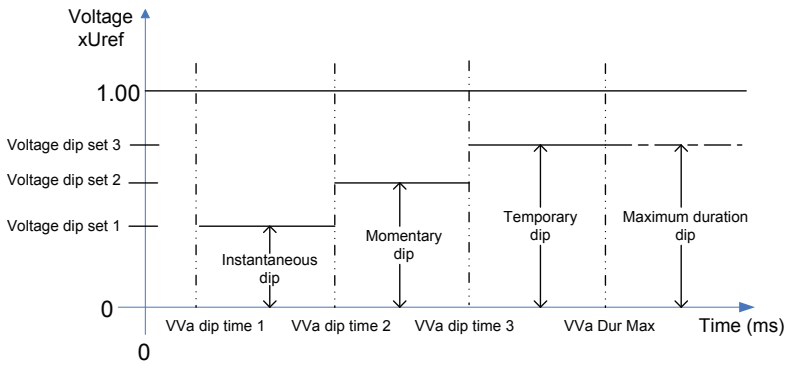

Figure 838: Voltage dip operational regions

In Figure 839, the corresponding limits regarding the swell operation are provided with the inherent magnitude limit order difference. The swell functionality principle

is the same as for dips, but the different limits for the signal magnitude and times and the inherent operating zone change (here, *Voltage swell set x* > 1.0 xUn) are applied.

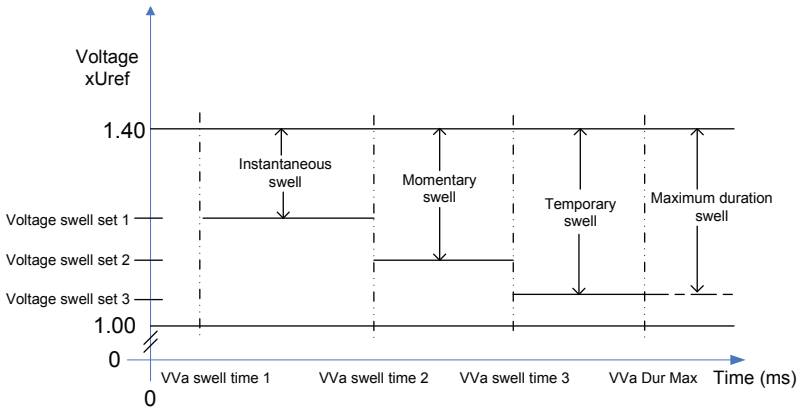

Figure 839: Voltage swell operational regions

For interruption, as shown in Figure 840, there is only one magnitude limit but four duration limits for interruption classification. Now the event and counter type depends only on variation duration time.

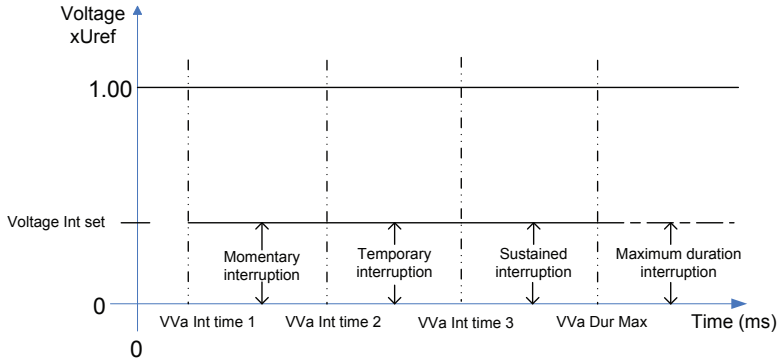

Figure 840: Interruption operating regions

Generally, no event detection is done if both the magnitude and duration requirements are not fulfilled. For example, the dip event does not indicate if the TRMS voltage magnitude remains between *Voltage dip set 3* and *Voltage dip set 2* for a period shorter than *VVa dip time 3* before rising back above *Voltage dip set 3*.

The event indication ends and possible detection is done when the TRMS voltage returns above (for dip and interruption) or below (for swell) the activation-starting limit. For example, after an instantaneous dip, the event indication when the voltage magnitude exceeds *Voltage dip set 1* is not detected (and recorded) immediately but only if no longer dip indication for the same dip variation takes place and maximum duration time for dip variation does not exceed before the signal magnitude rises above *Voltage dip set 3*. There is a small hysteresis for all these limits to avoid the oscillation of the output activation. No drop-off approach is applied here due to the hysteresis.

Consequently, only one event detection and recording of the same variation type can take place for one voltage variation, so the longest indicated variation of each variation type is detected. Furthermore, it is possible that another instantaneous dip event replaces the one already indicated if the magnitude again undershoots *Voltage dip set 1* for the set time after the first detection and the signal magnitude or time requirement is again fulfilled. Another possibility is that if the time condition is not fulfilled for an instantaneous dip detection but the signal rises above *Voltage dip set 1*, the already elapsed time is included in the momentary dip timer. Especially the interruption time is included in the dip time. If the signal does not exceed *Voltage dip set 2* before the timer *VVa dip time 2* has elapsed when the momentary dip timer is also started after the magnitude undershooting *Voltage dip set 2*, the momentary dip event instead is detected. Consequently, the same dip occurrence with a changing variation depth can result in several dip event indications but only one detection. For example, if the magnitude has undershot *Voltage dip set 1* but remained above *Voltage Intr set* for a shorter time than the value of *VVa dip time 1* but the signal rises between *Voltage dip set 1* and *Voltage dip set 2* so that the total duration of the dip activation is longer than *VVa dip time 2* and the maximum time is not overshot, this is detected as a momentary dip even though a short instantaneous dip period has been included. In text, the terms "deeper" and "higher" are used for referring to dip or interruption.

Although examples are given for dip events, the same rules can be applied to the swell and interruption functionality too. For swell indication, "deeper" means that the signal rises even more and "higher" means that the signal magnitude becomes lower respectively.

The adjustable voltage thresholds adhere to the relationships:

VVa dip time 1 ≤ *VVa dip time 2* ≤ *VVa dip time 3*.

VVa swell time 1 ≤ *VVa swell time 2* ≤ *VVa swell time 3*.

VVa Int time 1 ≤ *VVa Int time 2* ≤ *VVa Int time 3*.

There is a validation functionality built-in function that checks the relationship adherence so that if *VVa x time 1* is set higher than *VVa x time 2* or *VVa x time 3*, *VVa x time 2* and *VVa x time 3* are set equal to the new *VVa x time 1*. If *VVa x time 2* is set higher than *VVa x time 3*, *VVa x time 3* is set to the new *VVa x time 2*. If *VVa x time 2* is set lower than *VVa x time 1*, the entered *VVa x time 2* is rejected. If *VVa x time 3* is set lower than *VVa x time 2*, the entered *VVa x time 3* is rejected.

10.3.5.4 Duration measurement

The duration of each voltage phase corresponds to the period during which the measured TRMS values remain above (swell) or below (dip, interruption) the corresponding limit.

Besides the three limit settings for the variation types dip and swell, there is also a specific duration setting for each limit setting. For interruption, there is only one limit setting common for the three duration settings. The maximum duration setting is common for all variation types.

The duration measurement module measures the voltage variation duration of each phase voltage separately when the *Phase mode* setting is "Single Phase". The phase variation durations are independent. However, when the *Phase mode* setting is "Three Phase", voltage variation may start only when all the monitored phases are active. An example of variation duration when *Phase mode* is "Single Phase" can be seen in Figure 841. The voltage variation in the example is detected as an interruption for the phase B and a dip for the phase A, and also the variation durations are interpreted as independent U_B and U_A durations. In case of single-phase interruption, the DIPST output is active when either ST_A or ST_B is active. The measured variation durations are the times measured between the activation of the ST_A or ST_B outputs and deactivation of the ST_A or ST_B outputs. When the *Phase mode* setting is "Three Phase", the example case does not result in any activation.

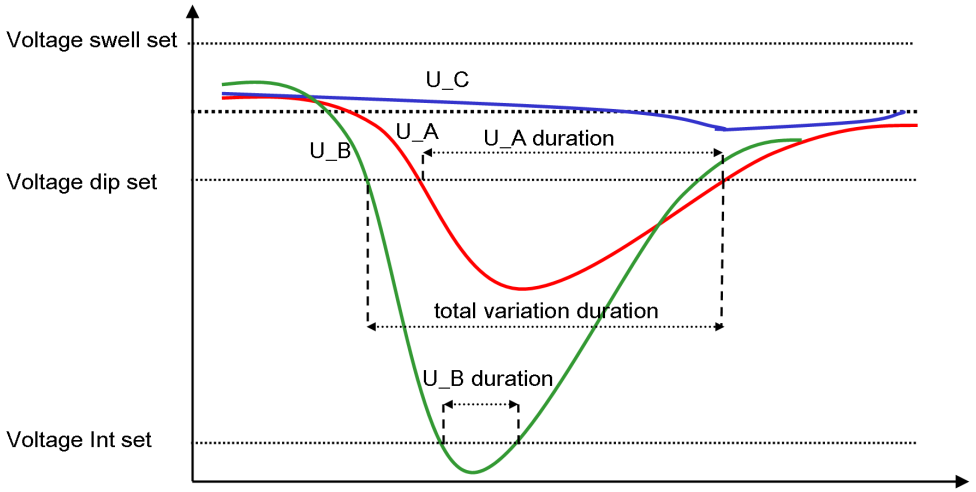

Figure 841: Single-phase interruption for the Phase mode value "Single Phase"

10.3.5.5 Three/single-phase selection variation examples

The provided rules always apply for single-phase (*Phase mode* is "Single Phase") power systems. However, for three-phase power systems (where *Phase mode* is "Three Phase"), it is required that all the phases have to be activated before the activation of the START output. Interruption event indication requires all three phases to undershoot *Voltage Int set* simultaneously, as shown in Figure 837. When the requirement for interruption for "Three Phase" is no longer fulfilled, variation is indicated as a dip as long as all phases are active.

In case of a single-phase interruption of Figure 841, when there is a dip indicated in another phase but the third phase is not active, there is no variation indication start when *Phase mode* is "Three Phase". In this case, only the *Phase mode* value "Single Phase" results in the ST_B interruption and the ST_A dip.

It is also possible that there are simultaneously a dip in one phase and a swell in other phases. The functionality of the corresponding event indication with one inactive phase is shown in Figure 842. Here, the "Swell + dip" variation type of *Phase mode* is

"Single Phase". For the selection "Three Phase" of *Phase mode*, no event indication or any activation takes place due to a non-active phase.

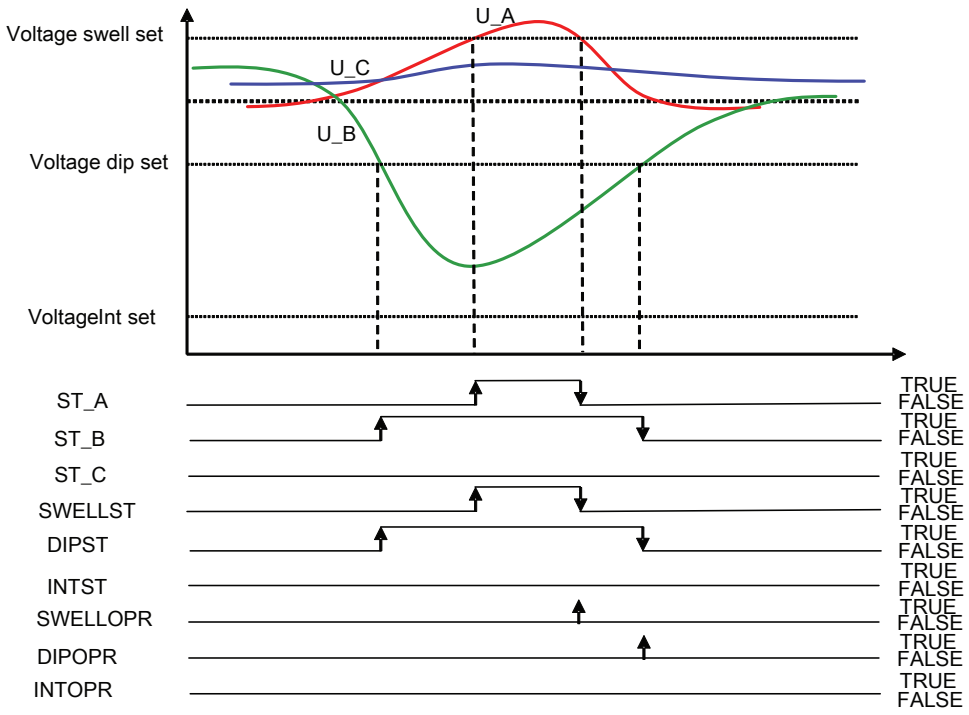

Figure 842: Concurrent dip and swell when Phase mode is "Single Phase"

In Figure 843, one phase is in dip and two phases have a swell indication. For the *Phase mode* value "Three Phase", the activation occurs only when all the phases are active. Furthermore, both swell and dip variation event detections take place simultaneously. In case of a concurrent voltage dip and voltage swell, both SWELLCNT and DIPCNT are incremented by one.

Also Figure 843 shows that for the *Phase mode* value "Single Phase", two different time moment variation event swell detections take place and, consequently, DIPCNT is incremented by one but SWELLCNT is totally incremented by two. In bothFigure 842 and Figure 843 it is assumed that variation durations are sufficient for detections to take place.

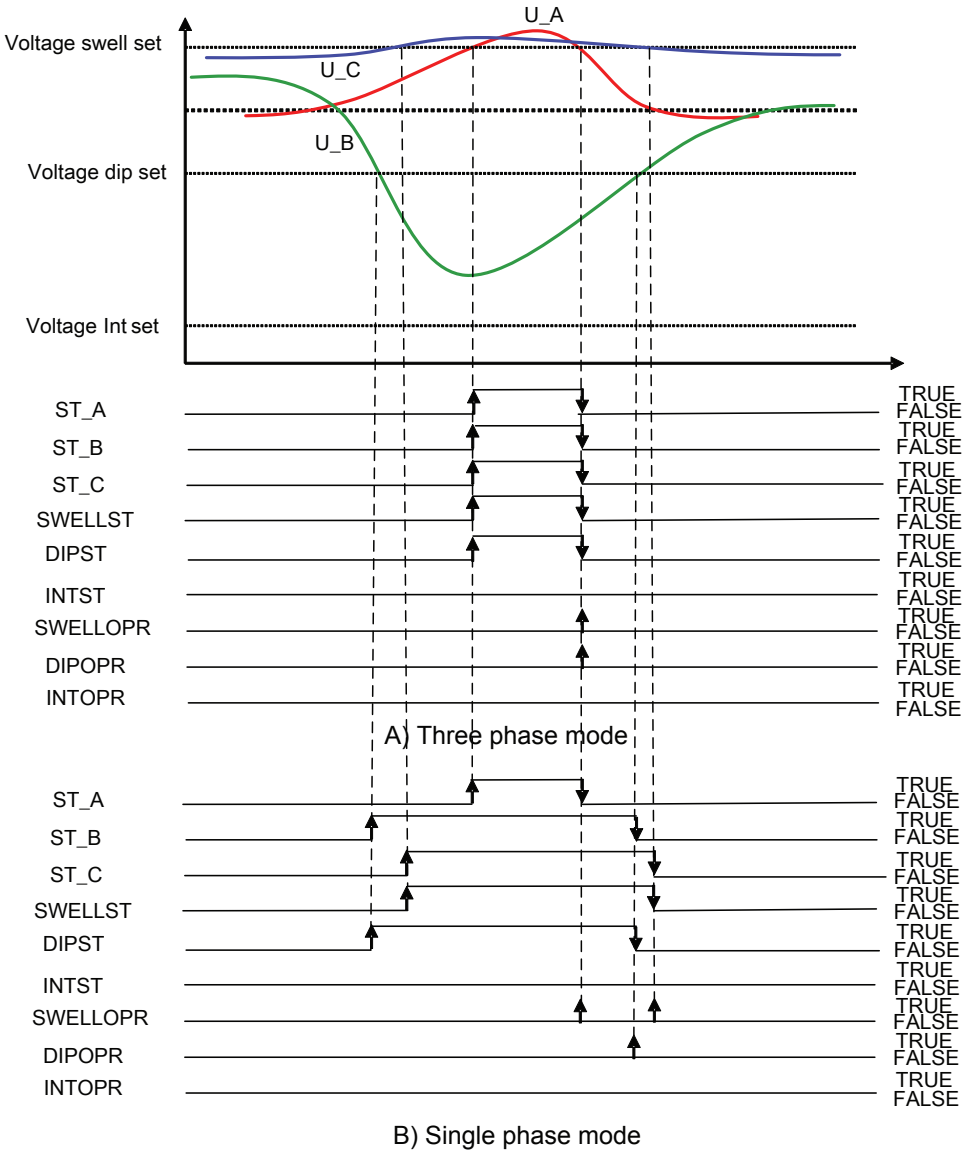

Figure 843: Concurrent dip and two-phase swell

10.3.6 Recorded data

Besides counter increments, the information required for a later fault analysis is stored after a valid voltage variation is detected.

Recorded data information

When voltage variation starts, the phase current magnitudes preceding the activation moment are stored. Also, the initial voltage magnitudes are temporarily stored at the variation starting moment. If the variation is, for example, a two-phase voltage dip, the voltage magnitude of the non-active phase is stored from this same moment, as shown in Figure 844. The function tracks each variation-active voltage phase, and the

minimum or maximum magnitude corresponding to swell or dip/interruption during variation is temporarily stored. If the minimum or maximum is found in tracking and a new magnitude is stored, also the inactive phase voltages are stored at the same moment, that is, the inactive phases are not magnitude-tracked. The time instant (time stamp) at which the minimum or maximum magnitude is measured is also temporarily stored for each voltage phase where variation is active. Finally, variation detection triggers the recorded data update when the variation activation ends and the maximum duration time is not exceeded.

The data objects to be recorded for PHQVVR are given in Table 1454. There are totally three data banks, and the information given in the table refers to one data bank content.

The three sets of recorded data available are saved in data banks 1-3. The data bank 1 holds always the most recent recorded data, and the older data sets are moved to the next banks (1→2 and 2→3) when a valid voltage variation is detected. When all three banks have data and a new variation is detected, the newest data are placed into bank 1 and the data in bank 3 are overwritten by the data from bank 2.

Figure 844 shows a valid recorded voltage interruption and two dips for the *Phase mode* value "Single Phase". The first dip event duration is based on the U_A duration, while the second dip is based on the time difference between the dip stop and start times. The first detected event is an interruption based on the U_B duration given in Figure 844. It is shown also with dotted arrows how voltage time stamps are taken before the final time stamp for recording, which is shown as a solid arrow. Here, the U_B timestamp is not taken when the U_A activation starts.

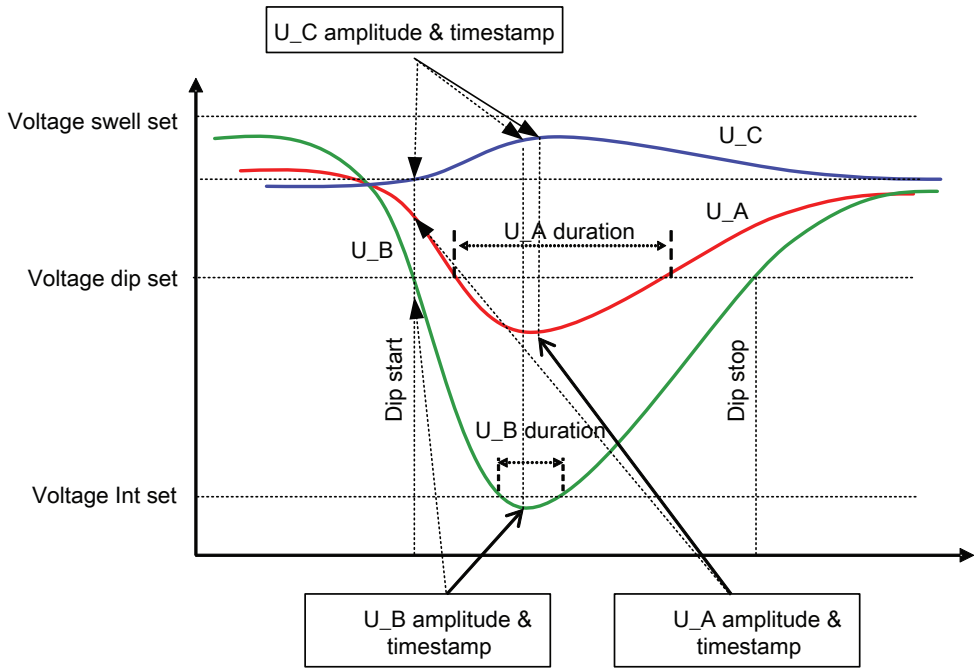

Figure 844: Valid recorded voltage interruption and two dips

10.3.7 Application

Voltage variations are the most typical power quality variations on the public electric network. Typically, short-duration voltage variations are defined to last more than

half of the nominal frequency period and less than one minute (European Standard EN 50160 and IEEE Std 1159-1995).

These short-duration voltage variations are almost always caused by a fault condition. Depending on where the fault is located, it can cause either a temporary voltage rise (swell) or voltage drop (dip). A special case of voltage drop is the complete loss of voltage (interruption).

PHQVVR is used for measuring short-duration voltage variations in distribution networks. The power quality is evaluated in the voltage waveform by measuring the voltage swells, dips and interruptions.

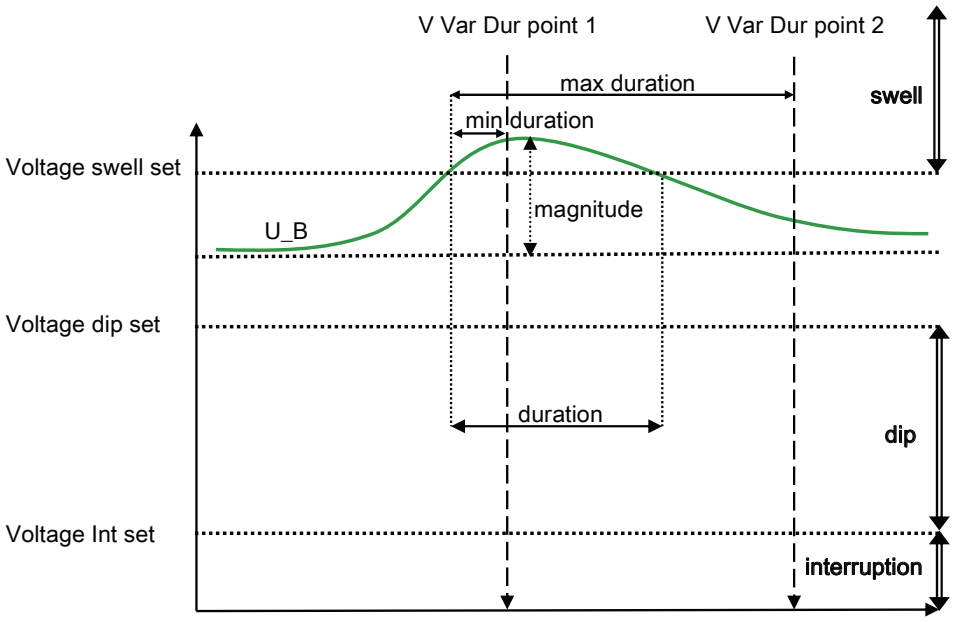

Figure 845: Duration and voltage magnitude limits for swell, dip and interruption measurement

Voltage dips disturb the sensitive equipment such as computers connected to the power system and may result in the failure of the equipment. Voltage dips are typically caused by faults occurring in the power distribution system. Typical reasons for the faults are lightning strikes and tree contacts. In addition to fault situations, the switching of heavy loads and starting of large motors also cause dips.

Voltage swells cause extra stress for the network components and the devices connected to the power system. Voltage swells are typically caused by the earth faults that occur in the power distribution system.

Voltage interruptions are typically associated with the switchgear operation related to the occurrence and termination of short circuits. The operation of a circuit breaker disconnects a part of the system from the source of energy. In the case of overhead networks, automatic reclosing sequences are often applied to the circuit breakers that

interrupt fault currents. All these actions result in a sudden reduction of voltages on all voltage phases.

Due to the nature of voltage variations, the power quality standards do not specify any acceptance limits. There are only indicative values for, for example, voltage dips in the European standard EN 50160. However, the power quality standards like the international standard IEC 61000-4-30 specify that the voltage variation event is characterized by its duration and magnitude. Furthermore, IEEE Std 1159-1995 gives the recommended practice for monitoring the electric power quality.

Voltage variation measurement can be done to the phase-to-earth and phase-to-phase voltages. The power quality standards do not specify whether the measurement should be done to phase or phase-to-phase voltages. However, in some cases it is preferable to use phase-to-earth voltages for measurement. The measurement mode is always TRMS.

Voltage unbalance	VSQVUB	PQUUB	PQMV UB

10.4.2 Function block

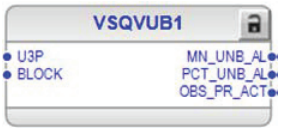

Figure 846: Function block

10.4.3 Functionality

The voltage unbalance function VSQVUB monitors voltage unbalance conditions in power transmission and distribution networks. It can be applied to identify a network and load unbalance that can cause sustained voltage unbalance. VSQVUB is also used to monitor the commitment of the power supply utility of providing a high-quality, that is, a balanced voltage supply on a continuous basis.

VSQVUB uses five different methods for calculating voltage unbalance. The methods are negative-sequence voltage magnitude, zero-sequence voltage magnitude, ratio of the negative-sequence voltage magnitude to the positive-sequence voltage magnitude, ratio of the zero-sequence voltage magnitude to the positive-sequence voltage magnitude and ratio of maximum phase voltage magnitude deviation from the mean voltage magnitude to the mean of the phase voltage magnitude.

VSQVUB provides statistics which can be used to verify the compliance of the power quality with the European standard EN 50160 (2000). The statistics over selected period include a freely selectable percentile for unbalance. VSQVUB also includes an alarm functionality providing a maximum unbalance value and the date and time of occurrence.

VSQVUB contains a blocking functionality. It is possible to block a set of function outputs or the function itself.

10.4.4 Analog channel configuration

VSQVUB has one analog group input which must be properly configured.

Table 1463: Analog inputs

Input	Description
U3P	Three-phase voltages

See the preprocessing function blocks in this document for the possible signal sources.

There are a few special conditions which must be noted with the configuration.

Table 1464: Special conditions

Condition	Description
U3P connected to real measurements	The function can work with any two voltage channels connected but it is recommended to connect all three voltage channels.
	Further, if *VT connection* is "Delta" in that particular UTVTR, the *Unb detection method* cannot be set to "Zero Seq" or "Zero to Pos Seq".

Improper analog channel configuration causes a validation error if the analog channels are not completely configured or they do not match with certain settings. For troubleshooting, check the contents of this chapter and also the preprocessing blocks in this document. The configuration can be written to the protection relay once the mismatch is corrected.

10.4.5 Operation principle

The function can be enabled and disabled with the *Operation* setting. The corresponding parameter values are "on" and "off".

The operation of VSQVUB can be described with a module diagram. All the modules in the diagram are explained in the next sections.

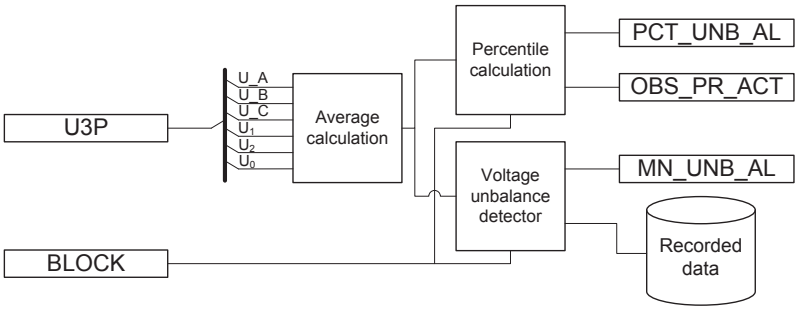

Figure 847: Functional module diagram

Average calculation

VSQVUB calculates two sets of measured voltage unbalance values, a three-second and a ten-minute non-sliding average value. The three-second average value is used for continuous monitoring. The ten-minute average is used for percentile calculation for a longer period.

The Average calculation module uses five different methods for the average calculation. The required method can be selected with the *Unb detection method* parameter.

When the "Neg Seq" mode is selected with *Unb detection method*, the voltage unbalance is calculated based on the negative-sequence voltage magnitude. Similarly, when the "Zero Seq" mode is selected, the voltage unbalance is calculated based on the zero-sequence voltage magnitude. When the "Neg to Pos Seq" mode is selected, the voltage unbalance is calculated based on the ratio of the negative-sequence voltage magnitude to the positive-sequence magnitude. When the "Zero to Pos Seq" mode is selected, the voltage unbalance is calculated based on the ratio of the zero-sequence voltage magnitude to the positive-sequence magnitude. When the "Ph vectors Comp" mode is selected, the ratio of the maximum phase voltage magnitude deviation from the mean voltage magnitude to the mean of the phase voltage magnitude is used for voltage unbalance calculation.

The calculated three-second value and ten-minute value are available in the Monitored data view through the outputs 3S_MN_UNB and 10MIN_MN_UNB.

3S_MN_UNB values are updated every three seconds and 10MIN_MN_UNB is updated every minute.

For VT connection = "Delta", the calculated zero-sequence voltage is always zero, hence, the setting *Unb detection method* = "Zero Seq" is not applicable in this VT configuration.

Voltage unbalance detector

The three-second average value is calculated and compared to the set value *Unbalance start val*. If the voltage unbalance exceeds this limit, the MN_UNB_AL output is activated.

The activation of the BLOCK input blocks MN_UNB_AL output.

Percentile calculation

The Percentile calculation module performs the statistics calculation for the level of voltage unbalance value for a settable duration. The operation of the Percentile calculation module can be described with a module diagram.

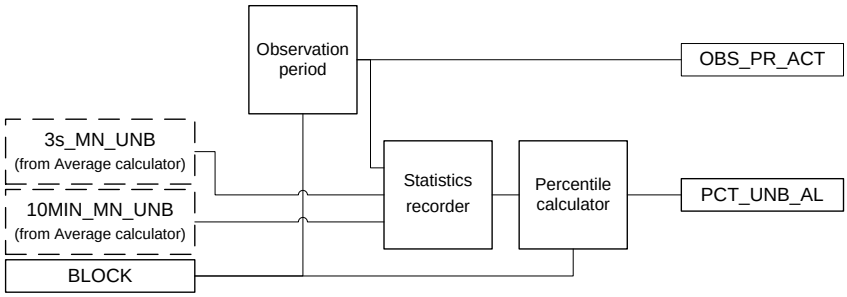

Figure 848: Percentile calculation

Observation period

The Observation period module calculates the length of the observation time for the Statistics recorder sub-module as well as determines the possible start of a new one. A new period can be started by timed activation using calendar time settings *Obs period Str year*, *Obs period Str month*, *Obs period Str day* and *Obs period Str hour*.

The observation period start time settings *Obs period Str year*, *Obs period Str month*, *Obs period Str day* and *Obs period Str hour* are used to set the calendar time in UTC. These settings have to be adjusted according to the local time and local daylight saving time.

A preferable way of continuous statistics recordings can be selected over a longer period (months, years). With the *Trigger mode* setting, the way the next possible observation time is activated after the former one has finished can be selected.

Table 1465: Trigger mode observation times

Trigger mode	Observation time
Single	Only one period of observation time is activated.
Periodic	The time gap between the two trigger signals is seven days.
Continuous	The next period starts right after the previous observation period is completed.

The length of the period is determined by the settings *Obs period selection* and *User Def Obs period*. The `OBS_PR_ACT` output is an indication signal which exhibits rising edge (TRUE) when the observation period starts and falling edge (FALSE) when the observation period ends.

If the *Percentile unbalance*, *Trigger mode* or *Obs period duration* settings change when `OBS_PR_ACT` is active, `OBS_PR_ACT` deactivates immediately.

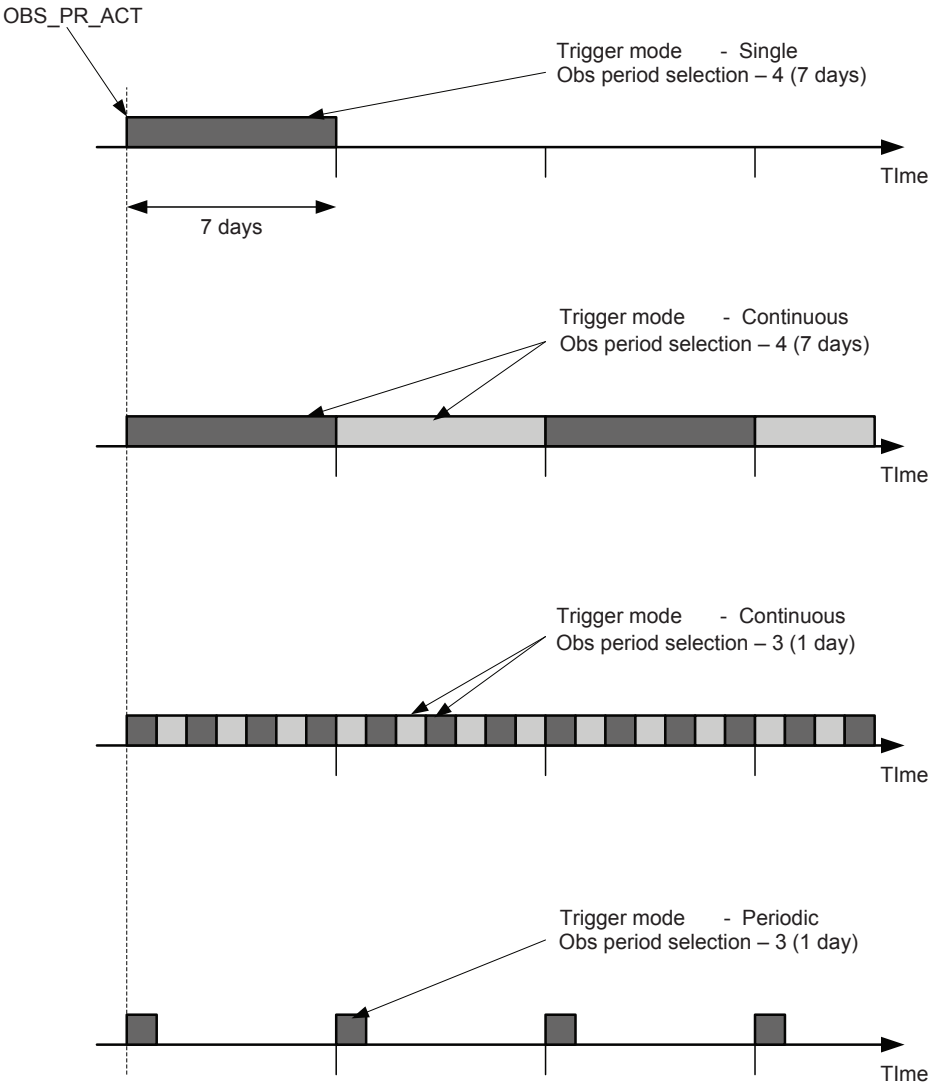

Figure 849: Periods for statistics recorder with different trigger modes and period settings

The BLOCK input blocks the OBS_PR_ACT output, which then disables the maximum value calculation of the Statistics recorder module. If the trigger mode is selected "Periodic" or "Continuous" and the blocking is deactivated before the next observation period is due to start, the scheduled period starts normally.

Statistics recorder

The Statistics recorder module provides readily calculated three-second or ten-minute values of the selected phase to the percentile calculator module based on the length of the active observation period. If the observation period is less than one day, the three-second average values are used. If the observation period is one day or longer, the ten-minute average values are used.

The maximum three-second or ten-minute mean voltage unbalance is recorded during the active observation period. The observation period start time PR_STR_TIME, observation period end time PR_END_TIME, maximum voltage unbalance value during observation period active, MAX_UNB_VAL and time of occurrence MAX_UNB_TIME are available through the Monitored data view. These outputs are updated once OBS_PR_ACT deactivates.

Percentile calculator

The purpose of the Percentile calculator module is to find the voltage unbalance level so that during the observation time 95 percent (default value of the *Percentile unbalance* setting) of all the measured voltage unbalance amplitudes are less than or equal to the calculated percentile.

The computed output value PCT_UNB_VAL, below which the percentile of the values lies, is available in the Monitored data view. The PCT_UNB_VAL output value is updated at the end of the observation period.

If the output PCT_UNB_VAL is higher than the defined setting *Unbalance start Val* at the end of the observation period, an alarm output PCT_UNB_AL is activated. The PCT_UNB_AL output remains active for the whole period before the next period completes.

The BLOCK input blocks the output PCT_UNB_VAL.

Recorded data

The information required for a later fault analysis is stored when the Recorded data module is triggered. This happens when a voltage unbalance is detected by the Voltage unbalance detector module.

Three sets of recorded data are available in total. The sets are saved in data banks 1...3. The data bank 1 holds the most recent recorded data. Older data are moved to the subsequent banks (1 to 2 and 2 to 3) when a voltage unbalance is detected. When all three banks have data and a new variation is detected, the latest data set is placed into bank 1 and the data in bank 3 is overwritten by the data from bank 2.

The recorded data can be reset with the RESET binary input signal by navigating to the HMI reset (**Main menu/Clear/Reset recorded data/VSQVUBx**) or through tools via communications.

When a voltage unbalance is detected in the system, VSQVUB responds with the MN_UNB_AL alarm signal. During the alarm situation, VSQVUB stores the maximum magnitude and the time of occurrence and the duration of alarm MN_UNB_AL. The recorded data is stored when MN_UNB_AL is deactivated.

Table 1466: Recorded data

Parameter	Description
Alarm high mean Dur	Time duration for alarm high mean unbalance
Max unbalance Volt	Maximum three-second voltage
Time Max Unb Volt	Time stamp of voltage unbalance

10.4.6 Application

Voltage unbalance is one of the basic power quality parameters.

Ideally, in a three-phase or multiphase power system, the frequency and voltage magnitude of all the phases are equal and the phase displacement between any two consecutive phases is also equal. This is called a balanced source. Apart from the balanced source, usually the power system network and loads are also balanced, implying that network impedance and load impedance in each phase are equal. In some cases, the condition of a balance network and load is not met completely, which leads to a current and voltage unbalance in the system. Providing unbalanced supply voltage has a detrimental effect on load operation. For example, a small magnitude of a negative-sequence voltage applied to an induction motor results in a significant heating of the motor.

A balanced supply, balanced network and balanced load lead to a better power quality. When one of these conditions is disturbed, the power quality is deteriorated. VSQVUB monitors voltage unbalance conditions in power transmission and distribution networks. VSQVUB calculates two sets of measured values, a three-second and a ten-minute non-sliding average value. The three-second average value is used for continuous monitoring while the ten-minute average value is used for percentile calculation for a longer period of time. It can be applied to identify the network and load unbalance that may cause sustained voltage unbalance. A single-phase or phase-to-phase fault in the network or load side can create voltage unbalance but, as faults are usually isolated in a short period of time, the voltage unbalance is not a sustained one. Therefore, the voltage unbalance may not be covered by VSQVUB.

Another major application is the long-term power quality monitoring. This can be used to confirm a compliance to the standard power supply quality norms. The function provides a voltage unbalance level which corresponds to the 95^{th} percentile of the ten minutes' average values of voltage unbalance recorded over a period of up to one week. It means that for 95 percent of time during the observation period the voltage unbalance was less than or equal to the calculated percentile. An alarm can be obtained if this value exceeds the value that can be set.

The function uses five different methods for calculating voltage unbalance.

- Negative-sequence voltage magnitude
- Zero-sequence voltage magnitude
- Ratio of negative-sequence to positive-sequence voltage magnitude
- Ratio of zero-sequence to positive-sequence voltage magnitude
- Ratio of maximum phase voltage magnitude deviation from the mean voltage magnitude to the mean of phase voltage magnitude.

Usually, the ratio of the negative-sequence voltage magnitude to the positive-sequence voltage magnitude is selected for monitoring the voltage unbalance. However, other methods may also be used if required.

10.4.7 Signals

Table 1467: VSQVUB Input signals

Name	Type	Default	Description
U3P	SIGNAL	-	Three-phase voltages
BLOCK	BOOLEAN	0=False	Block all outputs except measured values

Table 1468: VSQVUB Output signals

Name	Type	Description
MN_UNB_AL	BOOLEAN	Alarm active when 3 sec voltage unbalance exceeds the limit
PCT_UNB_AL	BOOLEAN	Alarm active when percentile unbalance exceeds the limit
OBS_PR_ACT	BOOLEAN	Observation period is active

10.4.8 Settings

Table 1469: VSQVUB Non group settings (Basic)

Parameter	Values (Range)	Unit	Step	Default	Description
Operation	1=on 5=off			1=on	Operation On/Off
Unb detection method	1=Neg Seq 2=Zero Seq 3=Neg to Pos Seq 4=Zero to Pos Seq 5=Ph vectors Comp			3=Neg to Pos Seq	Set the operation mode for voltage unbalance calculation
Unbalance start Val	1...100	%	1	1	Voltage unbalance start value
Trigger mode	1=Single 2=Periodic 3=Continuous			3=Continuous	Specifies the observation period triggering mode
Percentile unbalance	1...100	%	1	95	The percent to which percentile value PCT_UNB_VAL is calculated
Obs period selection	1=1 Hour 2=12 Hours 3=1 Day 4=7 Days 5=User defined			5=User defined	Observation period for unbalance calculation
User Def Obs period	1...168	h	1	168	User define observation period for statistic calculation
Obs period Str year	2008...2076			2011	Calendar time for observation period start year in YYYY

Section 11 General function block features

11.1 Definite time characteristics

11.1.1 Definite time operation

The DT mode is enabled when the *Operating curve type* setting is selected either as "ANSI Def. Time" or "IEC Def. Time". In the DT mode, the `OPERATE` output of the function is activated when the time calculation exceeds the set *Operate delay time*.

The user can determine the reset in the DT mode with the *Reset delay time* setting, which provides the delayed reset property when needed.

The *Type of reset curve* setting has no effect on the reset method when the DT mode is selected, but the reset is determined solely with the *Reset delay time* setting.

The purpose of the delayed reset is to enable fast clearance of intermittent faults, for example self-sealing insulation faults, and severe faults which may produce high asymmetrical fault currents that partially saturate the current transformers. It is typical for an intermittent fault that the fault current contains so called drop-off periods, during which the fault current falls below the set start current, including hysteresis. Without the delayed reset function, the operate timer would reset when the current drops off. In the same way, an apparent drop-off period of the secondary current of the saturated current transformer can also reset the operate timer.

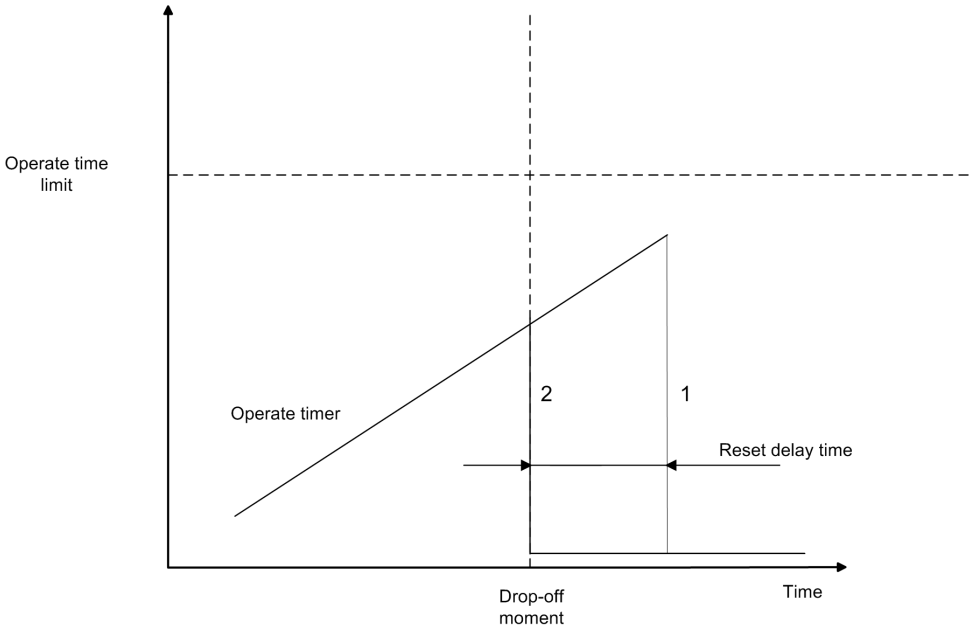

Figure 850: Operation of the counter in drop-off

In case 1, the reset is delayed with the *Reset delay time* setting and in case 2, the counter is reset immediately, because the *Reset delay time* setting is set to zero.

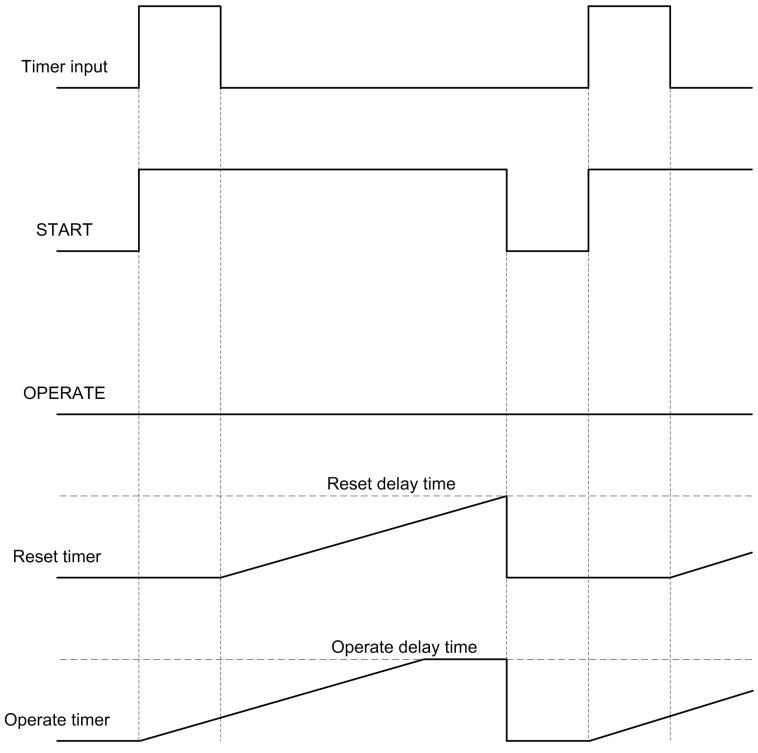

Figure 851: Drop-off period is longer than the set Reset delay time

When the drop-off period is longer than the set *Reset delay time*, as described in Figure 851, the input signal for the definite timer (here: timer input) is active, provided that the current is above the set *Start value*. The input signal is inactive when the current is below the set *Start value* and the set hysteresis region. The timer input rises when a fault current is detected. The definite timer activates the START output and the operate timer starts elapsing. The reset (drop-off) timer starts when the timer input falls, that is, the fault disappears. When the reset (drop-off) timer elapses, the operate timer is reset. Since this happens before another start occurs, the OPERATE output is not activated.

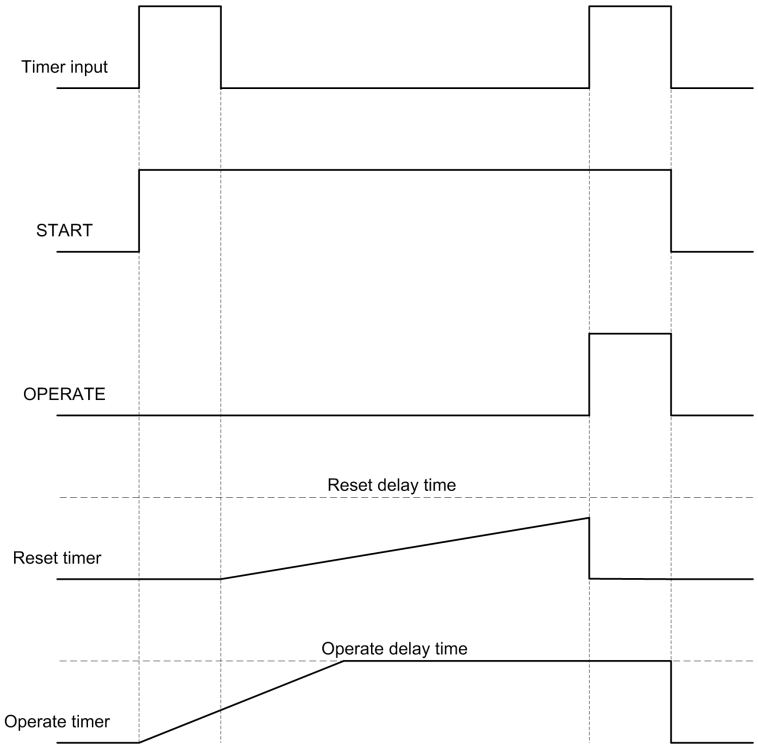

Figure 852: Drop-off period is shorter than the set Reset delay time

When the drop-off period is shorter than the set *Reset delay time*, as described in Figure 852, the input signal for the definite timer (here: timer input) is active, provided that the current is above the set *Start value*. The input signal is inactive when the current is below the set *Start value* and the set hysteresis region. The timer input rises when a fault current is detected. The definite timer activates the START output and the operate timer starts elapsing. The Reset (drop-off) timer starts when the timer input falls, that is, the fault disappears. Another fault situation occurs before the reset (drop-off) timer has elapsed. This causes the activation of the OPERATE output, since the operate timer already has elapsed.

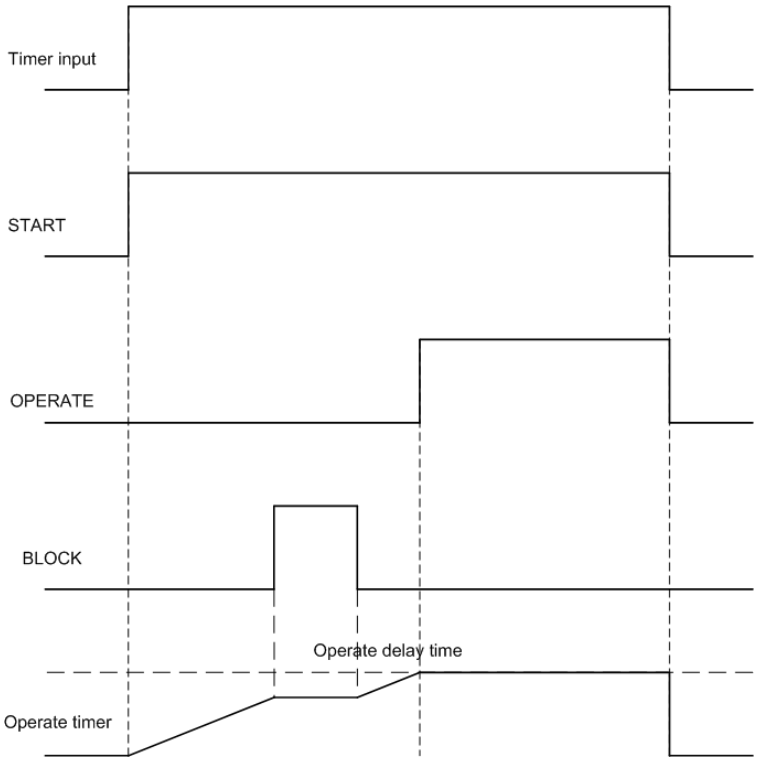

Figure 853: Operating effect of the BLOCK input when the selected blocking mode is "Freeze timer"

If the BLOCK input is activated when the operate timer is running, as described in Figure 853, the timer is frozen during the time BLOCK remains active. If the timer input is not active longer than specified by the *Reset delay time* setting, the operate timer is reset in the same way as described in Figure 851, regardless of the BLOCK input .

The selected blocking mode is "Freeze timer".

11.2 Current based inverse definite minimum time characteristics

11.2.1 IDMT curves for overcurrent protection

In inverse-time modes, the operation time depends on the momentary value of the current: the higher the current, the faster the operation time. The operation time calculation or integration starts immediately when the current exceeds the set *Start value* and the START output is activated.

The OPERATE output of the component is activated when the cumulative sum of the integrator calculating the overcurrent situation exceeds the value set by the inverse-time mode. The set value depends on the selected curve type and the setting values used. The curve scaling is determined with the *Time multiplier* setting.

There are two methods to level out the inverse-time characteristic.

- The *Minimum operate time* setting defines the minimum operating time for the IDMT curve, that is, the operation time is always at least the *Minimum operate time* setting.
- Alternatively, the *IDMT Sat point* is used for giving the leveling-out point as a multiple of the *Start value* setting. (Global setting: **Configuration/System/*IDMT Sat point***). The default parameter value is 50. This setting affects only the overcurrent and earth-fault IDMT timers.

IDMT operation time at currents over 50 x In is not guaranteed.

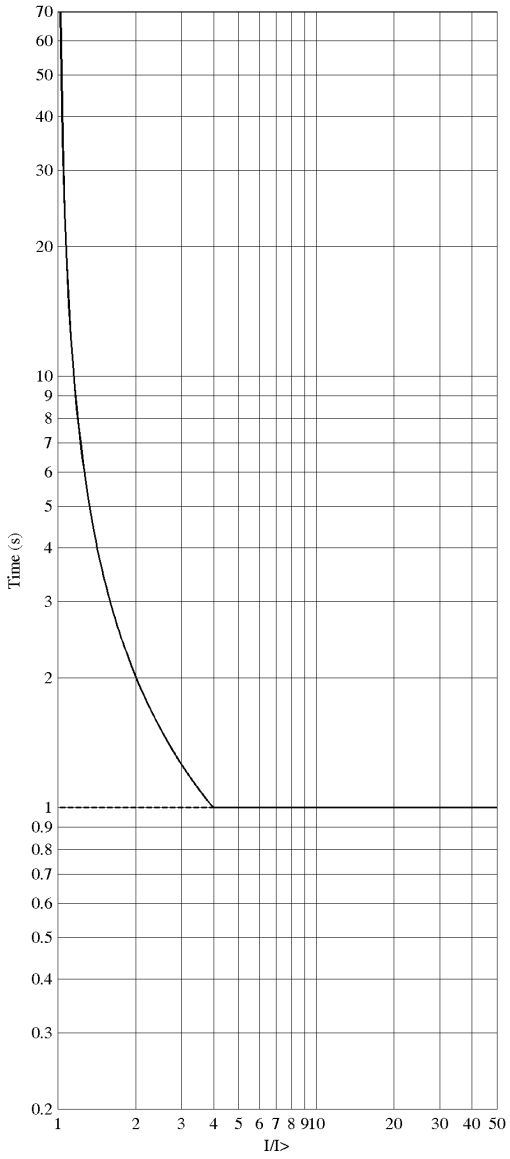

Figure 854: Operation time curve based on the IDMT characteristic leveled out with the Minimum operate time setting is set to 1000 milliseconds (the IDMT Sat point setting is set to maximum).

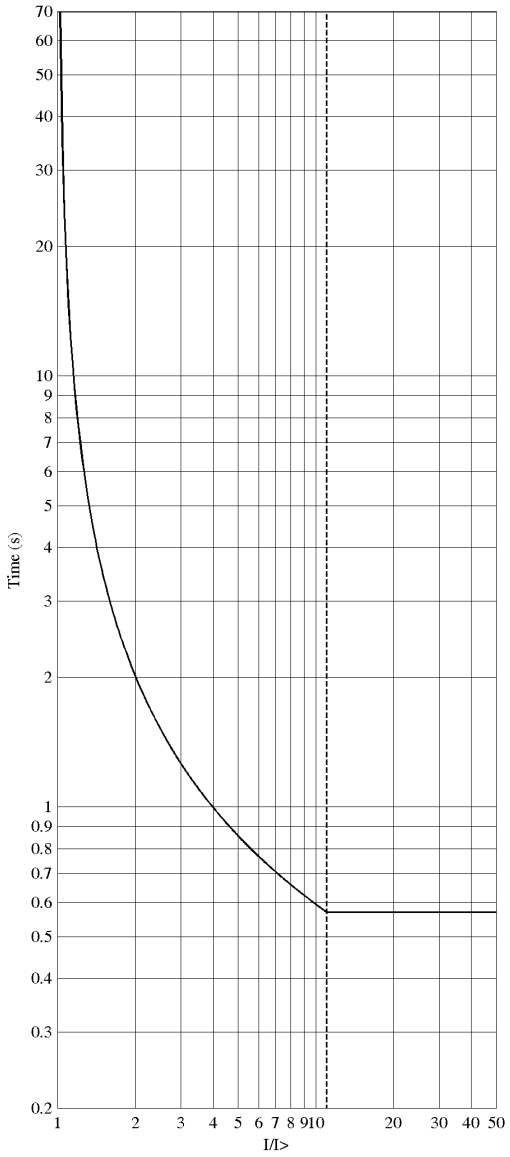

Figure 855: Operation time curve based on the IDMT characteristic leveled out with IDMT Sat point setting value “11” (the Minimum operate time setting is set to minimum).

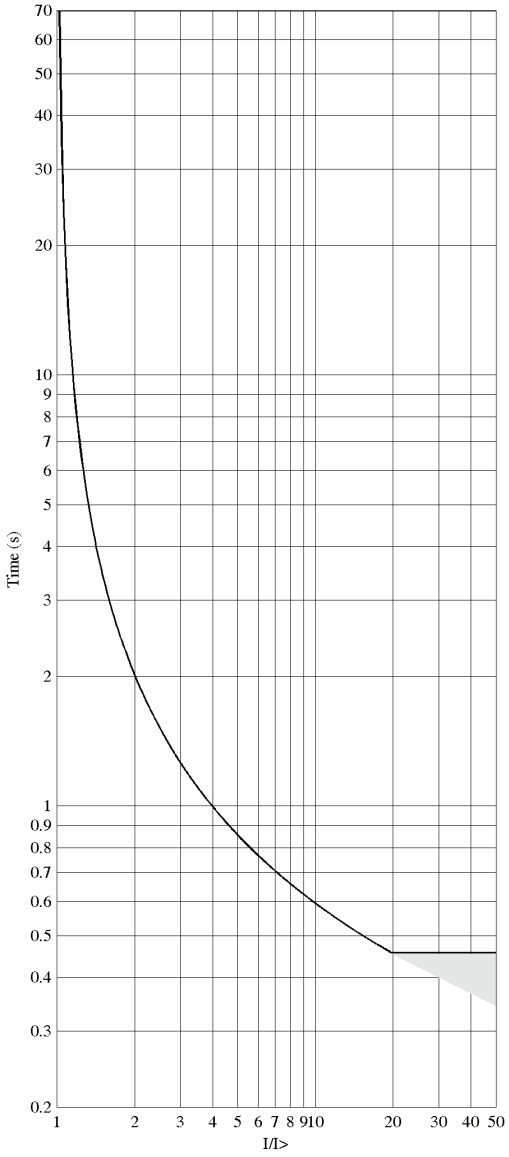

Figure 856: Example of how the inverse time characteristic is leveled out with currents over 50 x In and the Setting Start value setting "2.5 x In". (the IDMT Sat point setting is set to maximum and the Minimum operate time setting is set to minimum).

The grey zone in Figure 856 shows the behavior of the curve in case the measured current is outside the guaranteed measuring range. Also, the maximum measured current of 50 x In gives the leveling-out point 50/2.5 = 20 x I/I>.

11.2.1.1 Standard inverse-time characteristics

For inverse-time operation, both IEC and ANSI/IEEE standardized inverse-time characteristics are supported.

The operate times for the ANSI and IEC IDMT curves are defined with the coefficients A, B and C.

The values of the coefficients can be calculated according to the formula:

$$t[s] = \left(\frac{A}{\left(\frac{I}{I>} \right)^{c} - 1} + B \right) \cdot k$$

(Equation 354)

t[s] Operate time in seconds

I Measured current

I> Set *Start value*

k Set *Time multiplier*

Table 1472: Curve parameters for ANSI and IEC IDMT curves

Curve name	A	B	C
(1) ANSI Extremely Inverse	28.2	0.1217	2.0
(2) ANSI Very Inverse	19.61	0.491	2.0
(3) ANSI Normal Inverse	0.0086	0.0185	0.02
(4) ANSI Moderately Inverse	0.0515	0.1140	0.02

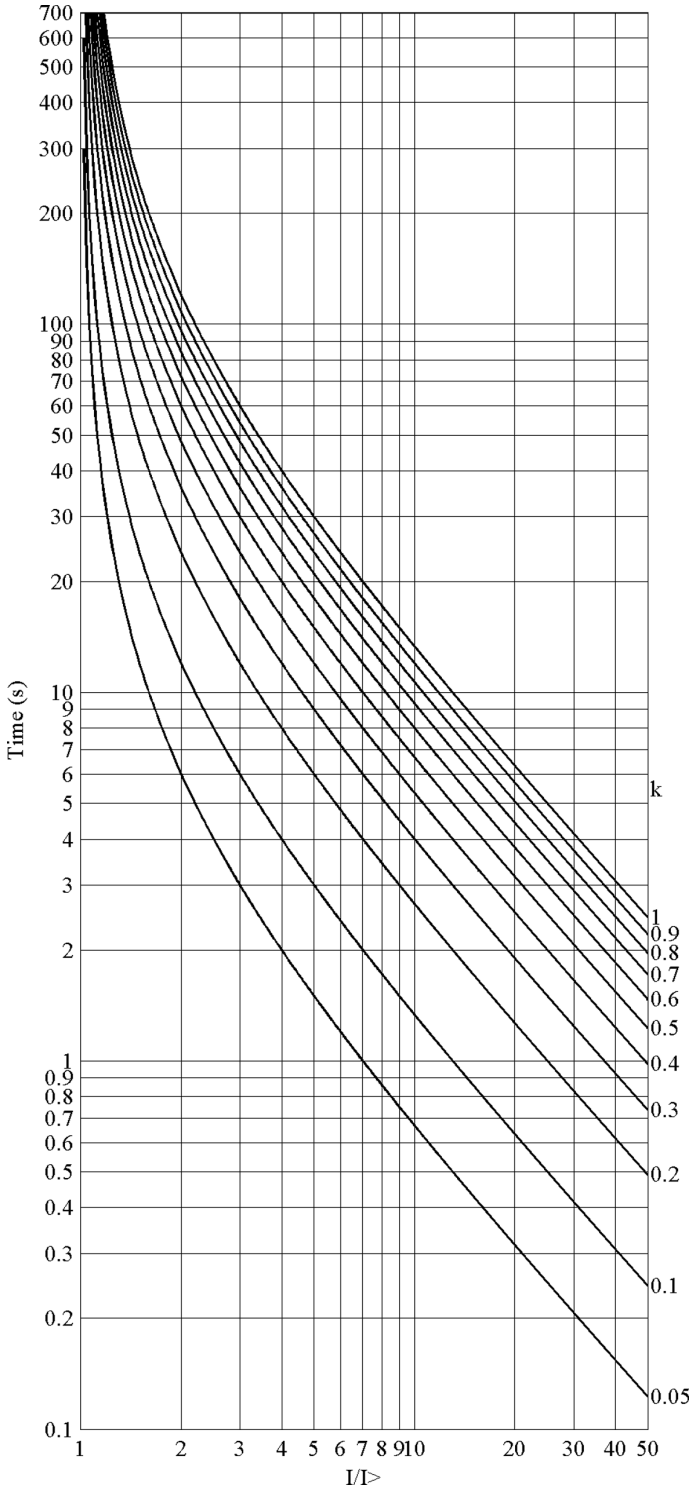

Figure 869: IEC long-time inverse-time characteristics

11.2.1.2 User-programmable inverse-time characteristics

The user can define curves by entering parameters into the following standard formula:

$$t[s] = \left(\frac{A}{\left(\frac{I}{I>} \right)^{c} - E} + B \right) \cdot k$$

(Equation 355)

t[s] Operate time (in seconds)
A Set *Curve parameter A*
B Set *Curve parameter B*
C Set *Curve parameter C*
E Set *Curve parameter E*
I Measured current
I> Set *Start value*
k Set *Time multiplier*

11.2.1.3 RI and RD-type inverse-time characteristics

The RI-type simulates the behavior of electromechanical relays. The RD-type is an earth-fault specific characteristic.

The RI-type is calculated using the formula

$$t[s] = \left(\frac{k}{0.339 - 0.236 \cdot \frac{I>}{I}} \right)$$

(Equation 356)

The RD-type is calculated using the formula

$$t[s] = 5.8 - 1.35 \cdot ln\left(\frac{I}{k \cdot I>} \right)$$

(Equation 357)

t[s] Operate time (in seconds)

k Set *Time multiplier*

I Measured current

I> Set *Start value*

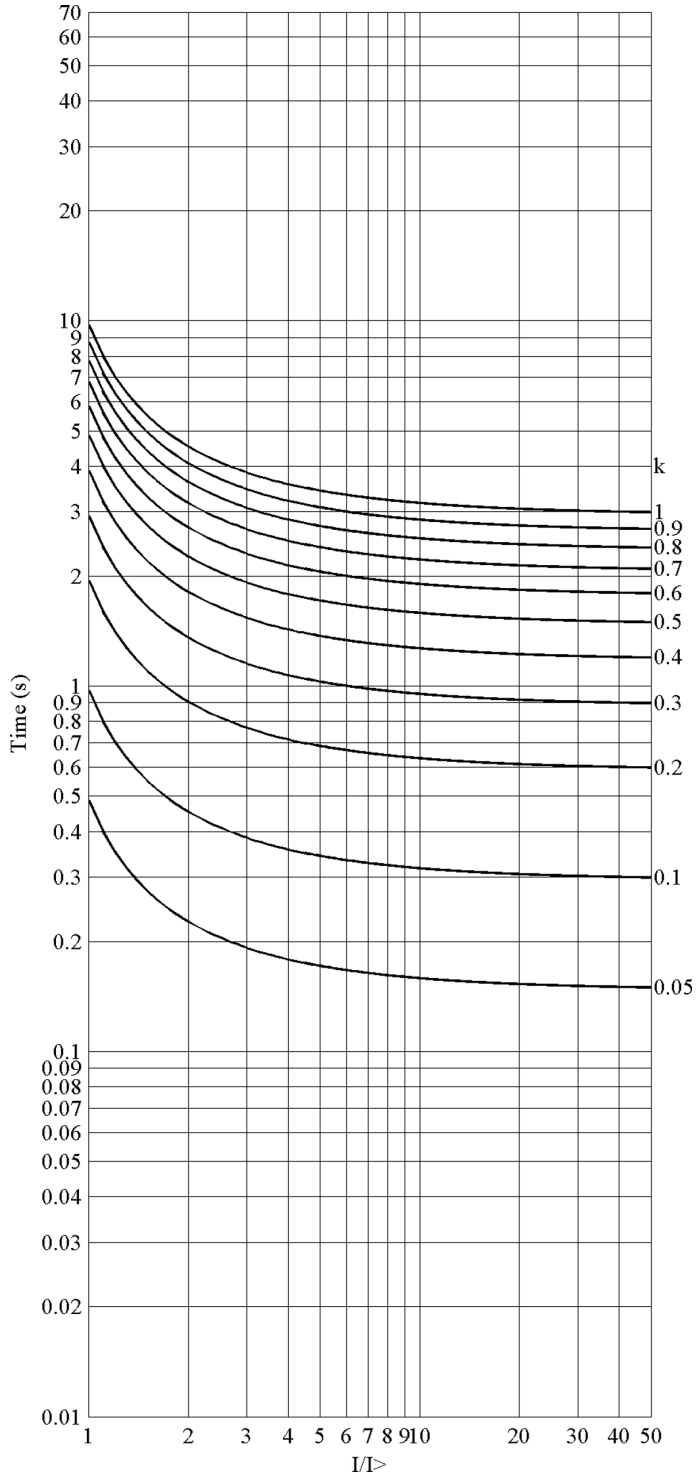

Figure 870: RI-type inverse-time characteristics

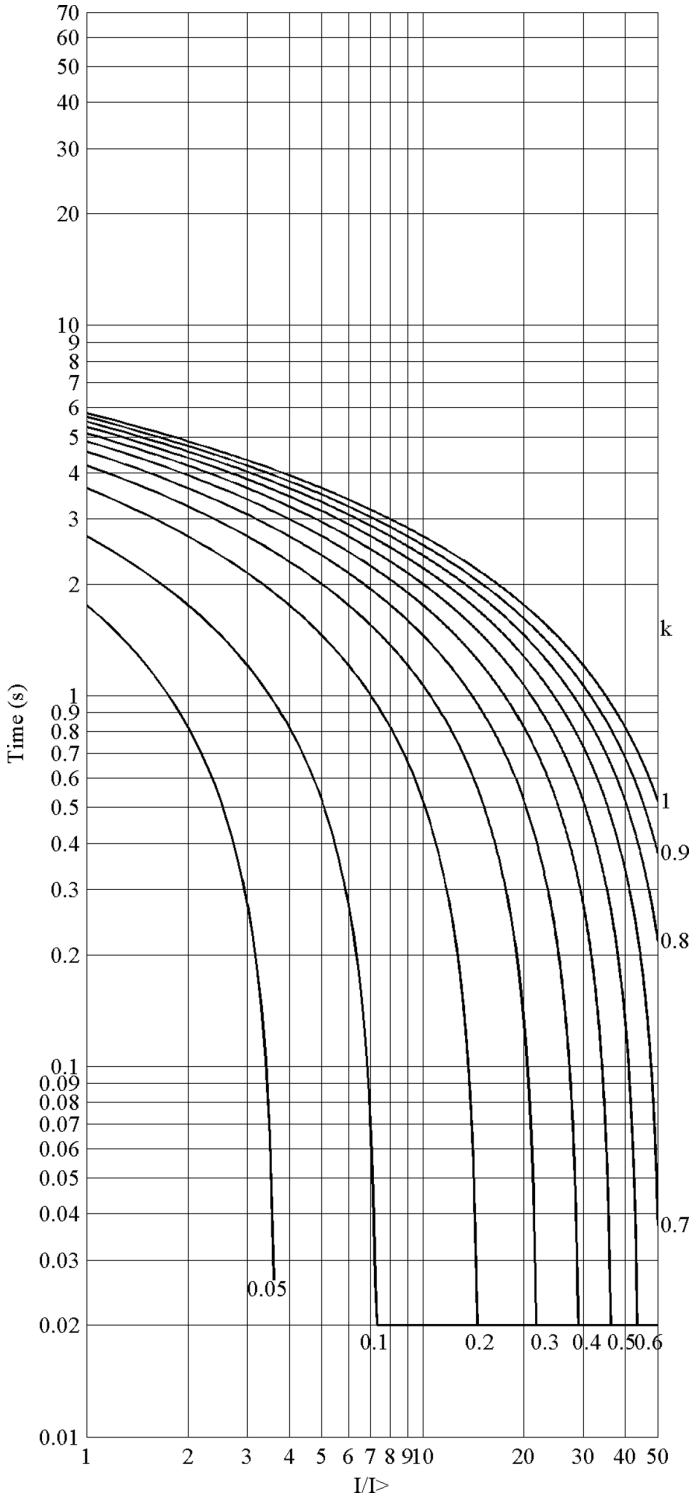

Figure 871: RD-type inverse-time characteristics

11.2.1.4 UK rectifier inverse-time characteristic

The UK rectifier type simulates the rectifier bridge.

The operate times are defined with the coefficients A, B and C.

The values of the coefficients can be calculated according to the formula

$$t[s] = \left(\frac{A}{\left(\frac{I}{I>} \right)^{c} - 1} + B \right) \cdot k$$

(Equation 358)

Operating curve type	A	B	C
(20) UK rectifier	45900	0	5.6

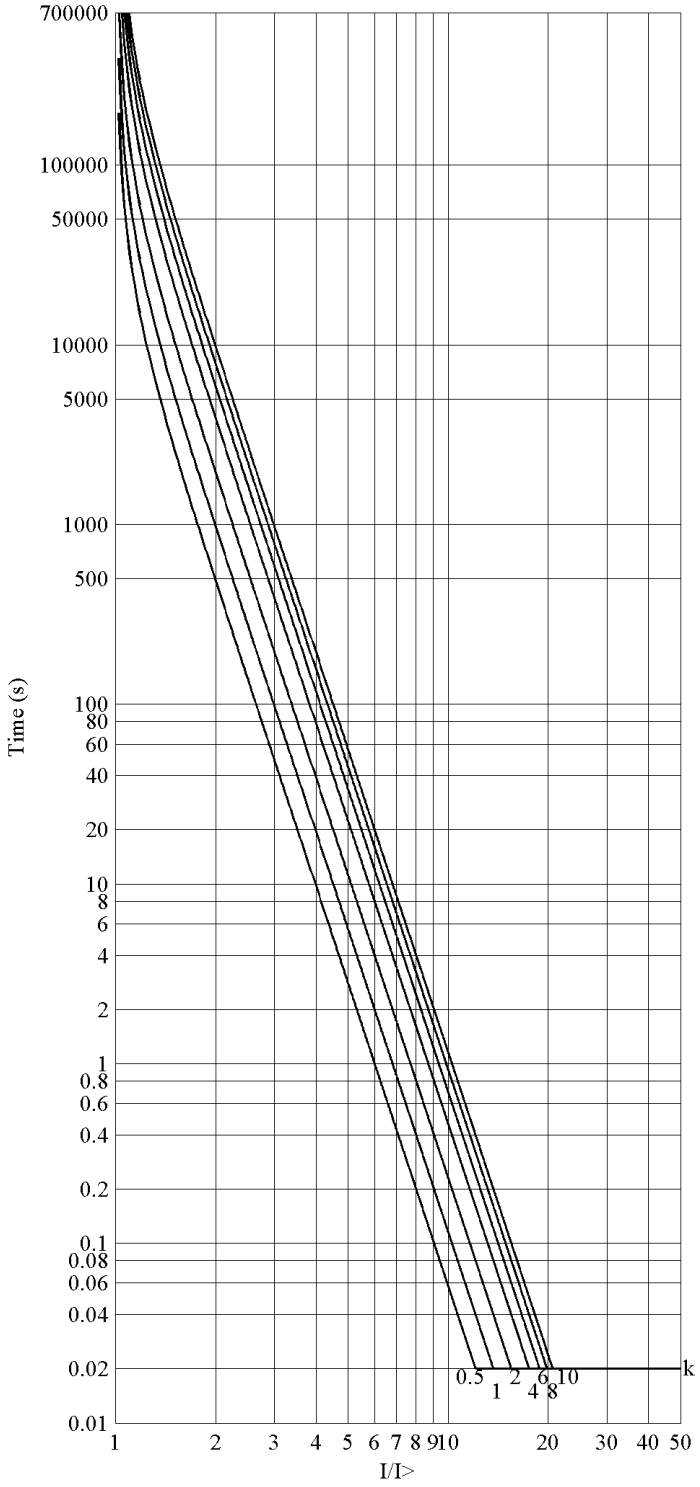

Figure 872: UK rectifier inverse-time characteristic

11.2.2 Reset in inverse-time modes

The user can select the reset characteristics by using the *Type of reset curve* setting.

Table 1474: Values for reset mode

Setting name	Possible values
Type of reset curve	1=Immediate 2=Def time reset 3=Inverse reset

Immediate reset

If the *Type of reset curve* setting in a drop-off case is selected as "Immediate", the inverse timer resets immediately.

Definite time reset

The definite type of reset in the inverse-time mode can be achieved by setting the *Type of reset curve* parameter to “Def time reset”. As a result, the operate inverse-time counter is frozen for the time determined with the *Reset delay time* setting after the current drops below the set *Start value*, including hysteresis.The integral sum of the inverse-time counter is reset, if another start does not occur during the reset delay.

If the *Type of reset curve* setting is selected as “Def time reset”, the current level has no influence on the reset characteristic.

Inverse reset

Inverse reset curves are available only for ANSI and user-programmable curves. If you use other curve types, immediate reset occurs.

Standard delayed inverse reset

The reset characteristic required in ANSI (IEEE) inverse-time modes is provided by setting the *Type of reset curve* parameter to “Inverse reset”. In this mode, the time delay for reset is given with the following formula using the coefficient D, which has its values defined in the table below.

$$t[s] = \left(\frac{D}{\left(\frac{I}{I>} \right)^2 - 1} \right) \cdot k$$

(Equation 359)

t[s] Reset time (in seconds)

k Set *Time multiplier*

I Measured current

I> Set *Start value*

Table 1475: Coefficients for ANSI delayed inverse reset curves

Curve name	D
(1) ANSI Extremely Inverse	29.1
(2) ANSI Very Inverse	21.6
(3) ANSI Normal Inverse	0.46
(4) ANSI Moderately Inverse	4.85
(6) Long Time Extremely Inverse	30
(7) Long Time Very Inverse	13.46
(8) Long Time Inverse	4.6

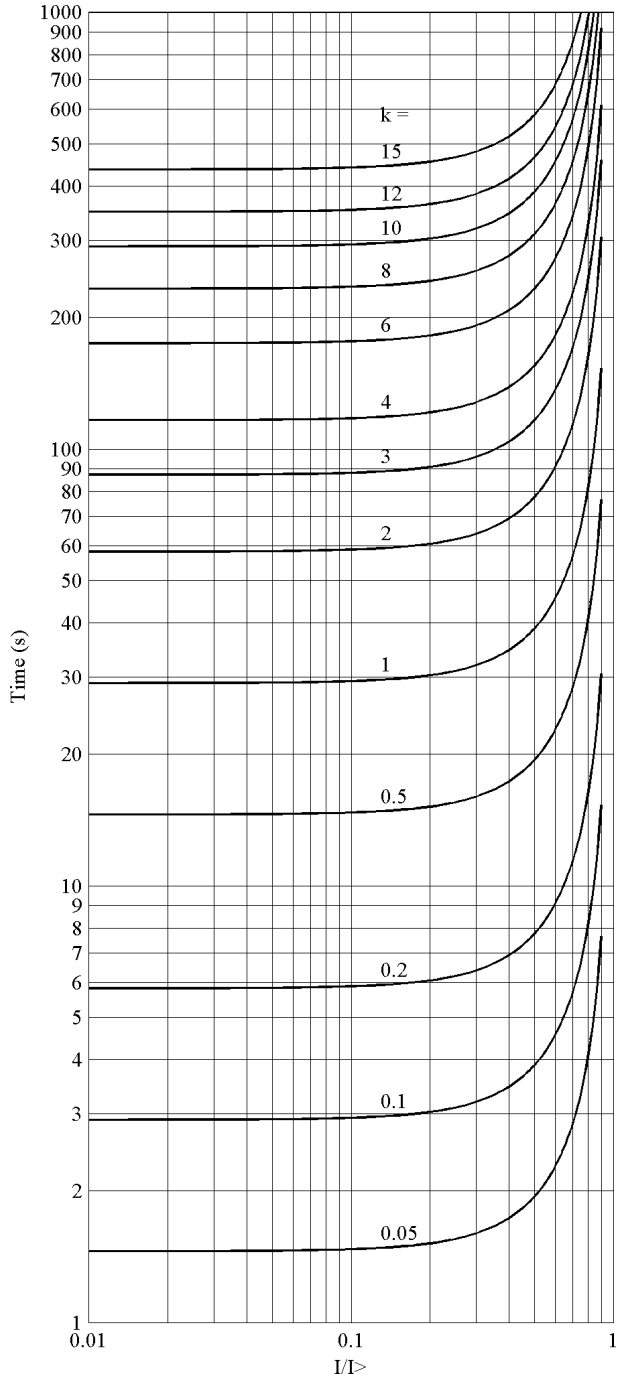

Figure 873: ANSI extremely inverse reset time characteristics

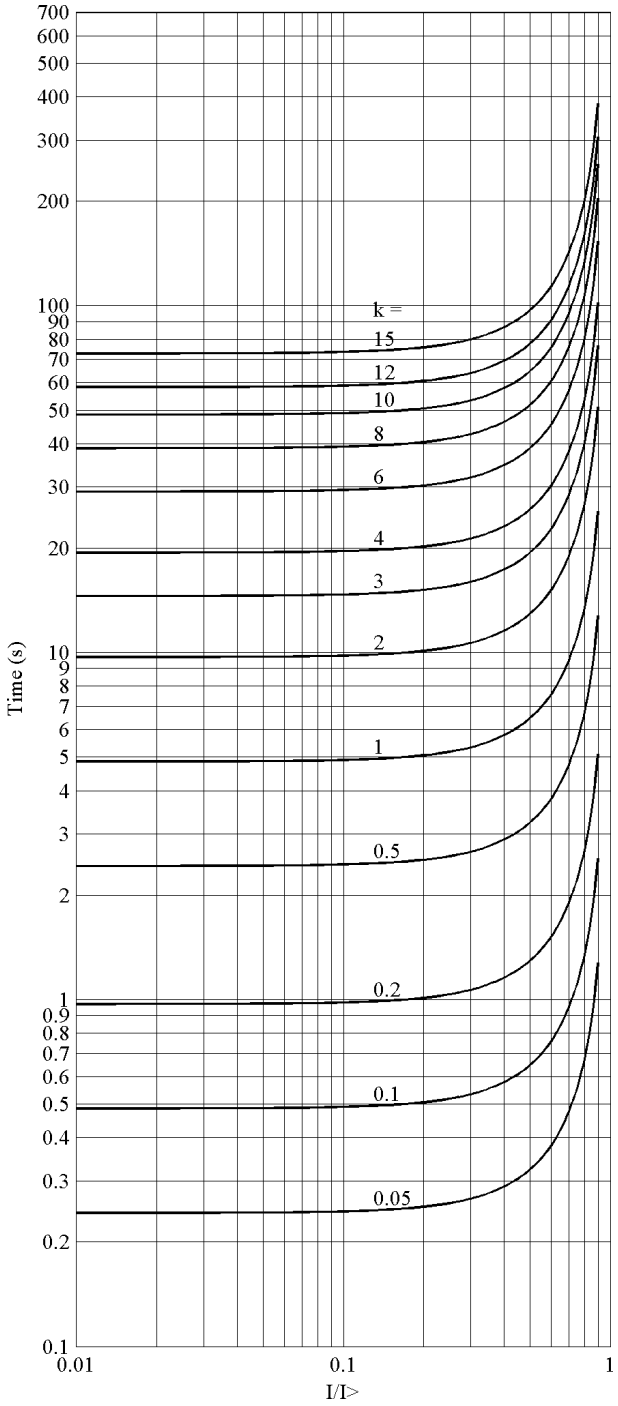

Figure 876: ANSI moderately inverse reset time characteristics

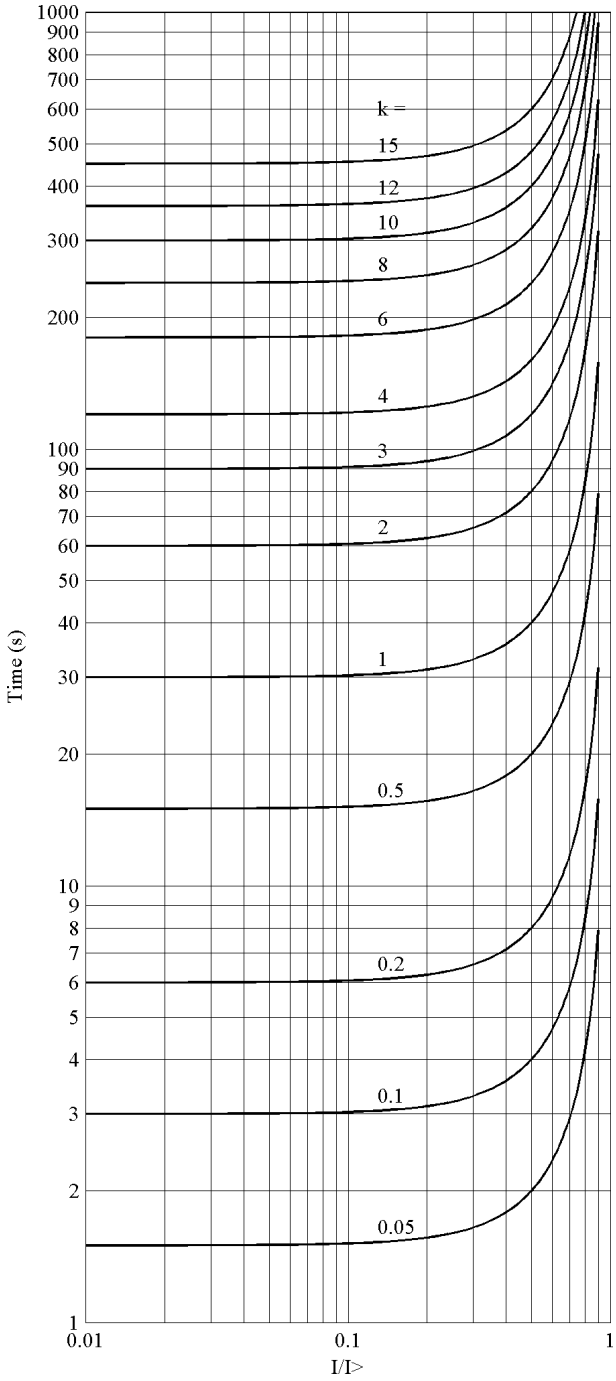

Figure 877: ANSI long-time extremely inverse reset time characteristics

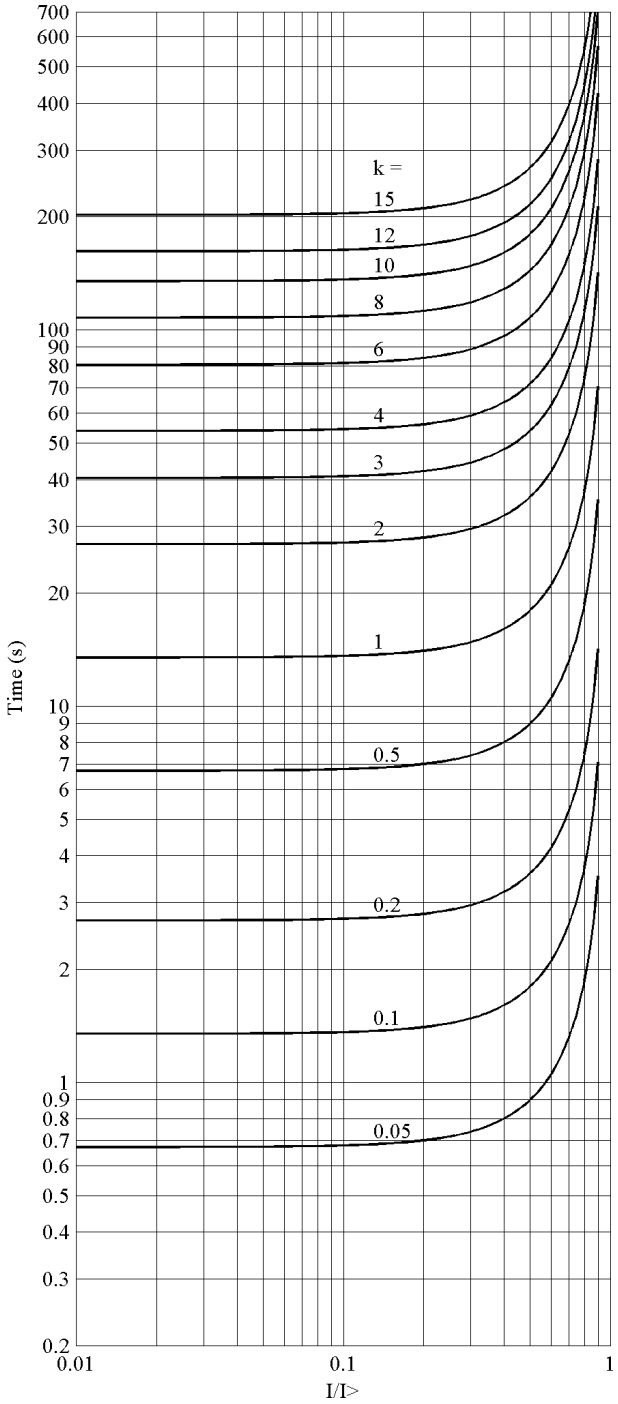

Figure 878: ANSI long-time very inverse reset time characteristics

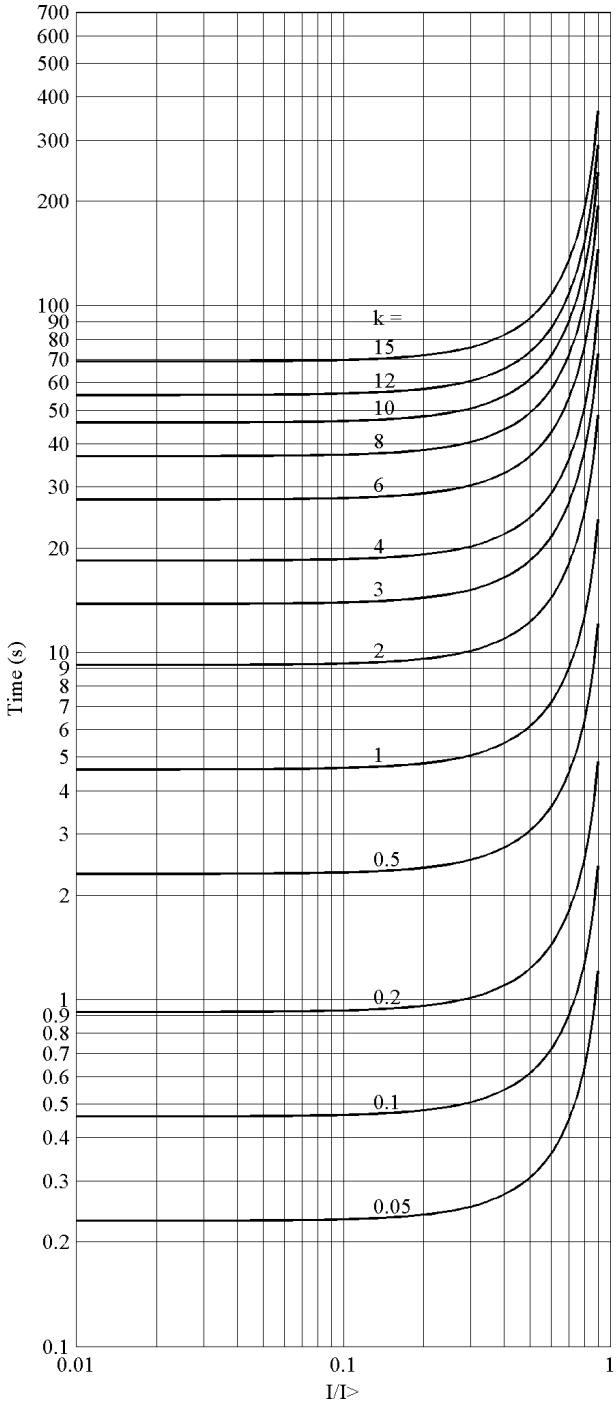

Figure 879: ANSI long-time inverse reset time characteristics

The delayed inverse-time reset is not available for IEC-type inverse time curves.

User-programmable delayed inverse reset

The user can define the delayed inverse reset time characteristics with the following formula using the set *Curve parameter D*.

$$t[s] = \left(\frac{D}{\left(\frac{I}{I>} \right)^2 - 1} \right) \cdot k$$

(Equation 360)

t[s] Reset time (in seconds)
k Set *Time multiplier*
D Set *Curve parameter D*
I Measured current
I> Set *Start value*

11.2.3 Inverse-timer freezing

When the BLOCK input is active, the internal value of the time counter is frozen at the value of the moment just before the freezing. Freezing of the counter value is chosen when the user does not wish the counter value to count upwards or to be reset. This may be the case, for example, when the inverse-time function of a protection relay needs to be blocked to enable the definite-time operation of another protection relay for selectivity reasons, especially if different relaying techniques (old and modern relays) are applied.

The selected blocking mode is "Freeze timer".

The activation of the BLOCK input also lengthens the minimum delay value of the timer.

Activating the BLOCK input alone does not affect the operation of the START output. It still becomes active when the current exceeds the set *Start value*, and inactive when the current falls below the set *Start value* and the set *Reset delay time* has expired.

11.3 Voltage based inverse definite minimum time characteristics

11.3.1 IDMT curves for overvoltage protection

In inverse-time modes, the operate time depends on the momentary value of the voltage, the higher the voltage, the faster the operate time. The operate time calculation or integration starts immediately when the voltage exceeds the set value of the *Start value* setting and the START output is activated.

The OPERATE output of the component is activated when the cumulative sum of the integrator calculating the overvoltage situation exceeds the value set by the inverse time mode. The set value depends on the selected curve type and the setting values used. The user determines the curve scaling with the *Time multiplier* setting.

The *Minimum operate time* setting defines the minimum operate time for the IDMT mode, that is, it is possible to limit the IDMT based operate time for not becoming too short. For example:

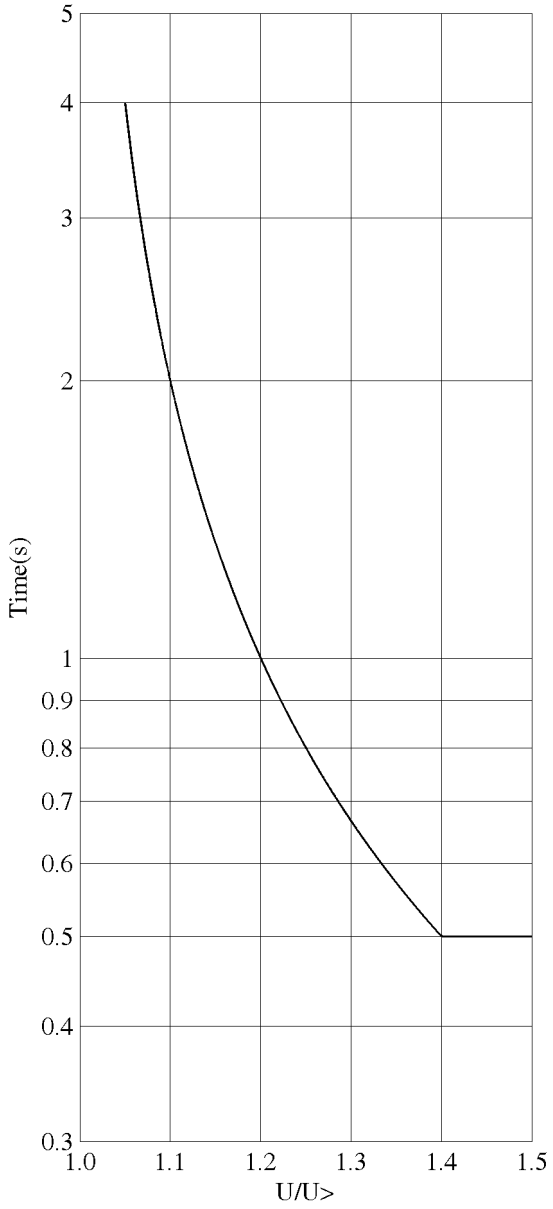

Figure 880: Operate time curve based on IDMT characteristic with Minimum operate time set to 0.5 second

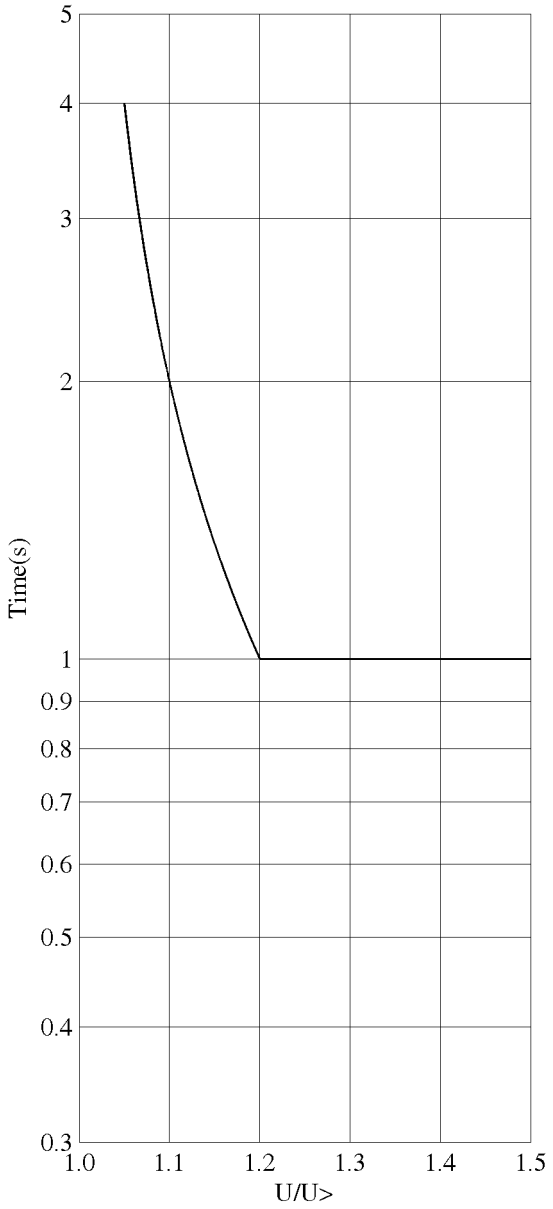

Figure 881: Operate time curve based on IDMT characteristic with Minimum operate time set to 1 second

11.3.1.1 Standard inverse-time characteristics for overvoltage protection

The operate times for the standard overvoltage IDMT curves are defined with the coefficients A, B, C, D and E.

The inverse operate time can be calculated with the formula:

$$t[s] = \frac{k \cdot A}{\left(B \cdot \frac{U - U>}{U>} - C\right)^{E}} + D$$

(Equation 361)

t [s] Operate time in seconds

U Measured voltage

U> Set value of *Start value*

k Set value of *Time multiplier*

Curve name	A	B	C	D	E
(17) Inverse Curve A	1	1	0	0	1
(18) Inverse Curve B	480	32	0.5	0.035	2
(19) Inverse Curve C	480	32	0.5	0.035	3

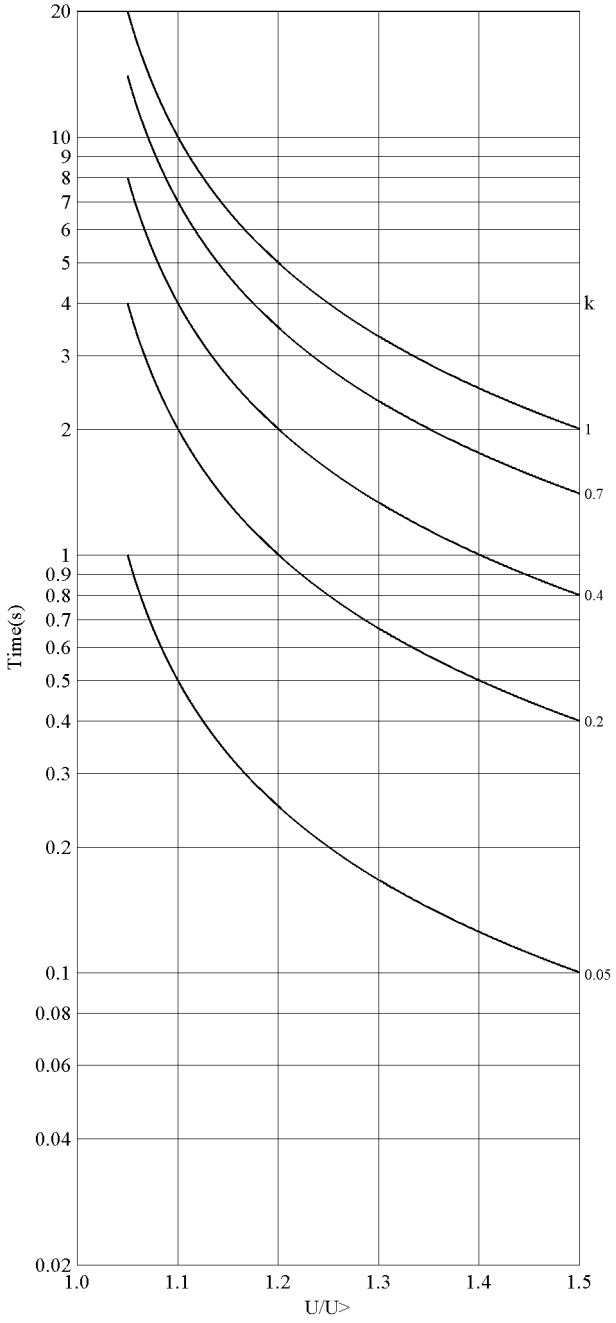

Figure 882: Inverse curve A characteristic of overvoltage protection

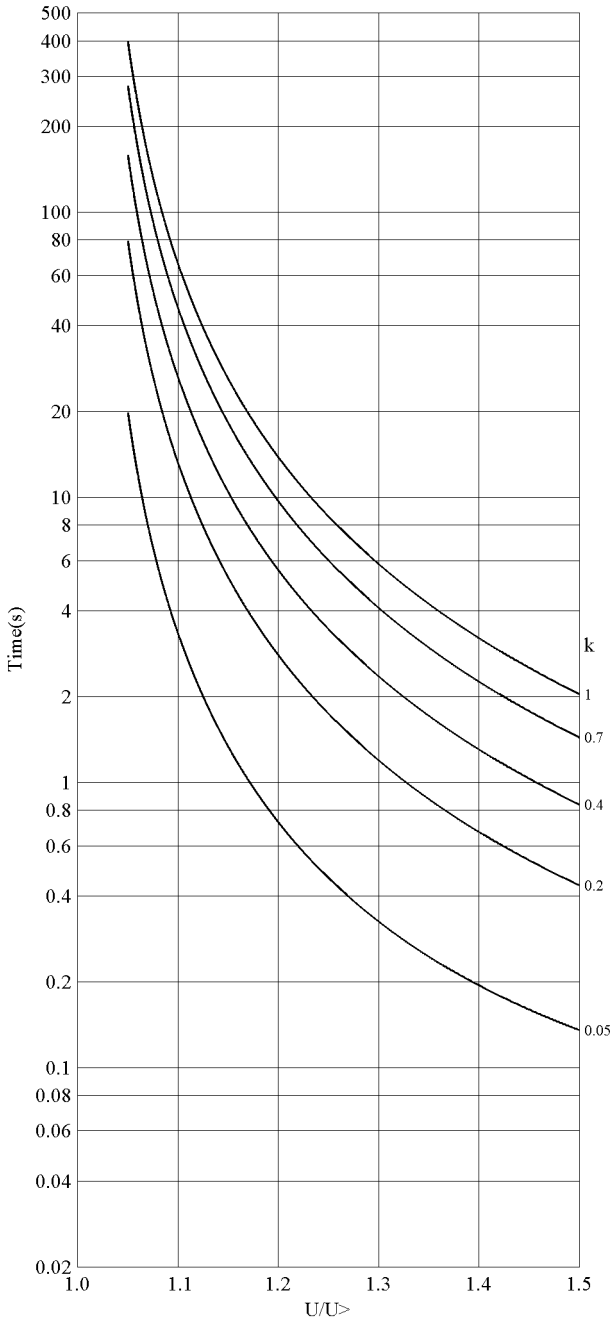

Figure 883: Inverse curve B characteristic of overvoltage protection

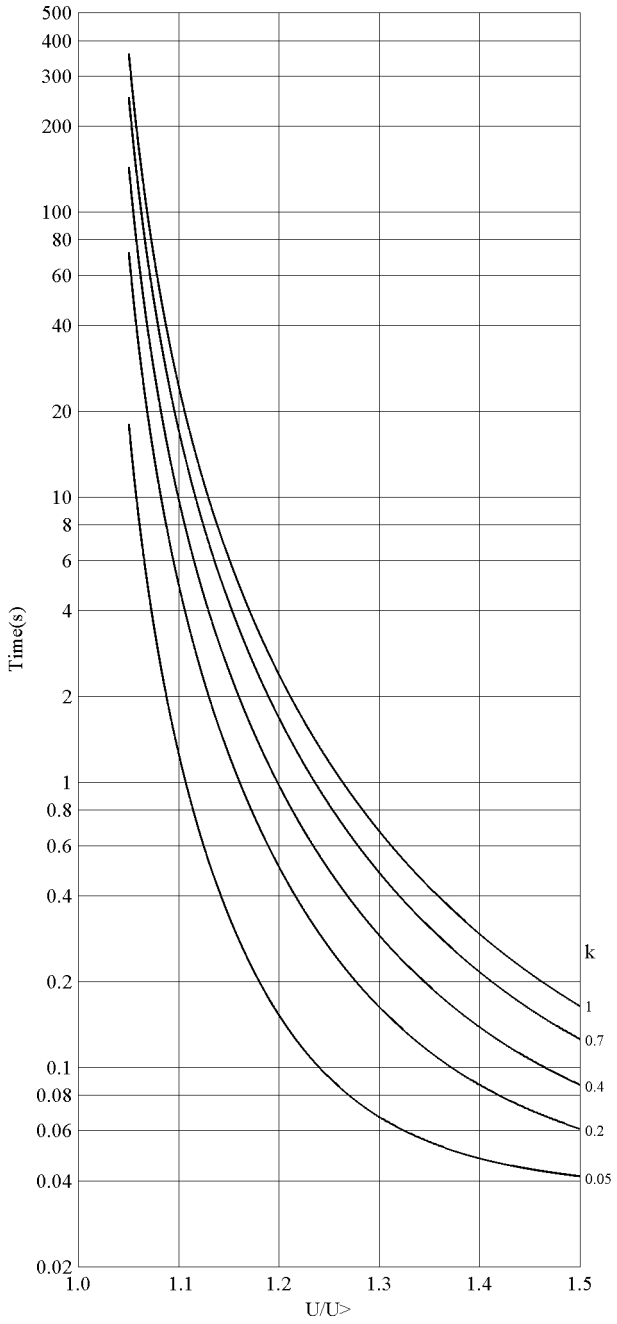

Figure 884: Inverse curve C characteristic of overvoltage protection

11.3.1.2 User programmable inverse-time characteristics for overvoltage protection

The user can define the curves by entering the parameters using the standard formula:

$$t[s] = \frac{k \cdot A}{\left(B \cdot \frac{U - U>}{U>} - C\right)^{E}} + D$$

(Equation 362)

t[s] Operate time in seconds
A Set value of *Curve parameter A*
B Set value of *Curve parameter B*
C Set value of *Curve parameter C*
D Set value of *Curve parameter D*
E Set value of *Curve parameter E*
U Measured voltage
U> Set value of *Start value*
k Set value of *Time multiplier*

11.3.1.3 IDMT curve saturation of overvoltage protection

For the overvoltage IDMT mode of operation, the integration of the operate time does not start until the voltage exceeds the value of *Start value*. To cope with discontinuity characteristics of the curve, a specific parameter for saturating the equation to a fixed value is created. The *Curve Sat Relative* setting is the parameter and it is given in percents compared to *Start value*. For example, due to the curve equation B and C, the characteristics equation output is saturated in such a way that when the input voltages are in the range of *Start value* to *Curve Sat Relative* in percent over *Start value*, the equation uses *Start value* * (1.0 + *Curve Sat Relative* / 100) for the measured voltage. Although, the curve A has no discontinuities when the ratio U/U> exceeds the unity, *Curve Sat Relative* is also set for it. The *Curve Sat Relative* setting for curves A, B and C is 2.0 percent. However, it should be noted that the user must carefully calculate the curve characteristics concerning the discontinuities in the curve when the programmable curve equation is used. Thus, the *Curve Sat Relative* parameter gives another degree of freedom to move the inverse curve on the voltage ratio axis and it effectively sets the maximum operate time for the IDMT curve because for the voltage ratio values affecting by this setting, the operation time is fixed, that is, the definite time, depending on the parameters but no longer the voltage.

11.3.2 IDMT curves for undervoltage protection

In the inverse-time modes, the operate time depends on the momentary value of the voltage, the lower the voltage, the faster the operate time. The operate time calculation or integration starts immediately when the voltage goes below the set value of the *Start value* setting and the START output is activated.

The OPERATE output of the component is activated when the cumulative sum of the integrator calculating the undervoltage situation exceeds the value set by the inverse-

time mode. The set value depends on the selected curve type and the setting values used. The user determines the curve scaling with the *Time multiplier* setting.

The *Minimum operate time* setting defines the minimum operate time possible for the IDMT mode. For setting a value for this parameter, the user should carefully study the particular IDMT curve.

11.3.2.1 Standard inverse-time characteristics for undervoltage protection

The operate times for the standard undervoltage IDMT curves are defined with the coefficients A, B, C, D and E.

The inverse operate time can be calculated with the formula:

$$t[s] = \frac{k \cdot A}{\left(B \cdot \frac{U< - U}{U<} - C \right)^{E}} + D$$

(Equation 363)

t [s]	Operate time in seconds
U	Measured voltage
U<	Set value of the *Start value* setting
k	Set value of the *Time multiplier* setting

Table 1477: Curve coefficients for standard undervoltage IDMT curves

Curve name	A	B	C	D	E
(21) Inverse Curve A	1	1	0	0	1
(22) Inverse Curve B	480	32	0.5	0.055	2

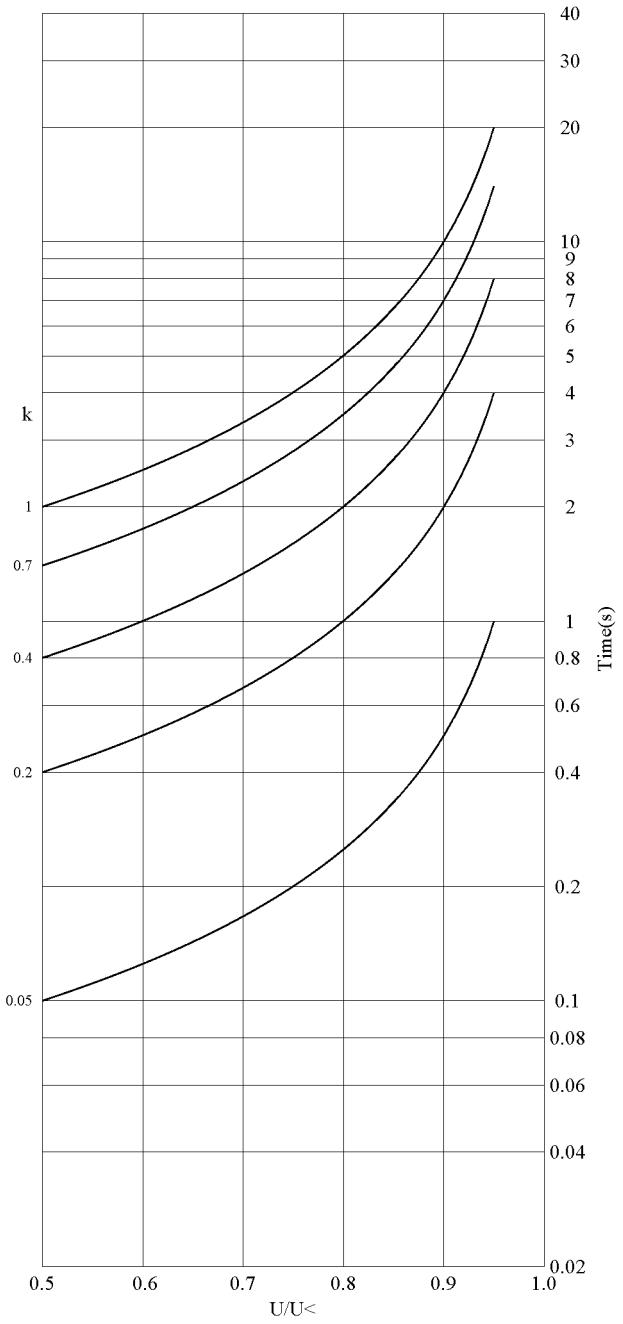

Figure 885: Inverse curve A characteristic of undervoltage protection

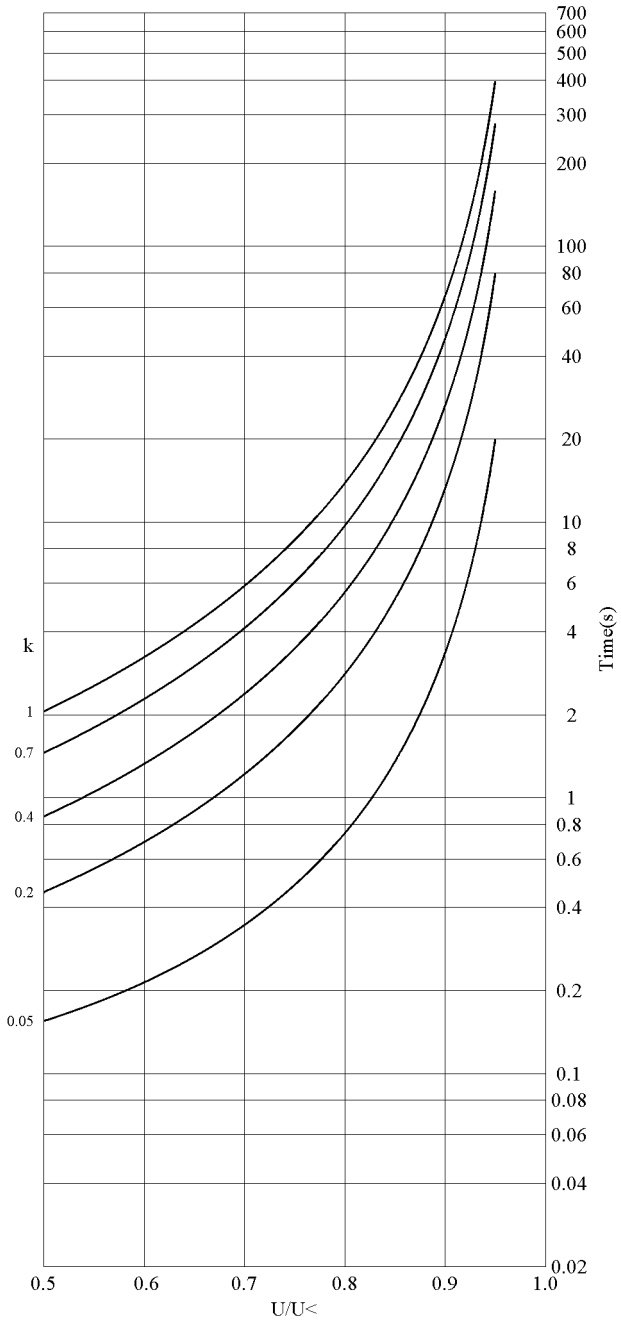

Figure 886: Inverse curve B characteristic of undervoltage protection

11.3.2.2 User-programmable inverse-time characteristics for undervoltage protection

The user can define curves by entering parameters into the standard formula:

$$t[s] = \frac{k \cdot A}{\left(B \cdot \frac{U<-U}{U<} - C\right)^{E}} + D$$

(Equation 364)

t[s] Operate time in seconds
A Set value of *Curve parameter A*
B Set value of *Curve parameter B*
C Set value of *Curve parameter C*
D Set value of *Curve parameter D*
E Set value of *Curve parameter E*
U Measured voltage
U< Set value of *Start value*
k Set value of *Time multiplier*

11.3.2.3 IDMT curve saturation of undervoltage protection

For the undervoltage IDMT mode of operation, the integration of the operate time does not start until the voltage falls below the value of *Start value*. To cope with discontinuity characteristics of the curve, a specific parameter for saturating the equation to a fixed value is created. The *Curve Sat Relative* setting is the parameter and it is given in percents compared with *Start value*. For example, due to the curve equation B, the characteristics equation output is saturated in such a way that when input voltages are in the range from *Start value* to *Curve Sat Relative* in percents under *Start value*, the equation uses *Start value* * (1.0 - *Curve Sat Relative* / 100) for the measured voltage. Although, the curve A has no discontinuities when the ratio U/U> exceeds the unity, *Curve Sat Relative* is set for it as well. The *Curve Sat Relative* setting for curves A, B and C is 2.0 percent. However, it should be noted that the user must carefully calculate the curve characteristics concerning also discontinuities in the curve when the programmable curve equation is used. Thus, the *Curve Sat Relative* parameter gives another degree of freedom to move the inverse curve on the voltage ratio axis and it effectively sets the maximum operate time for the IDMT curve because for the voltage ratio values affecting by this setting, the operation time is fixed, that is, the definite time, depending on the parameters but no longer the voltage.

11.4 Frequency measurement and protection

All the function blocks that use frequency quantity as their input signal share the common features related to the frequency measurement algorithm. The frequency estimation is done from one phase (phase-to-phase or phase voltage) or from the positive phase sequence (PPS). The voltage groups with three-phase inputs use PPS as the source. The frequency measurement range is 0.2...1.5 × F_n. The df/dt measurement range always starts from 0.6 × F_n. When the frequency exceeds these limits, it is regarded as out of range and a minimum or maximum value is held as the measured

value respectively with appropriate quality information. The frequency estimation requires 160 ms to stabilize after a bad quality signal. Therefore, a delay of 160 ms is added to the transition from the bad quality. The bad quality of the signal can be due to restrictions like:

- The source voltage is below $0.02 \times U_n$ at F_n.
- The source voltage waveform is discontinuous.
- The source voltage frequency rate of change exceeds 15 Hz/s (including stepwise frequency changes).

When the bad signal quality is obtained, the nominal or zero (depending on the *Def frequency Sel* setting) frequency value is shown with appropriate quality information in the measurement view. The frequency protection functions are blocked when the quality is bad, thus the timers and the function outputs are reset. When the frequency is out of the function block's setting range but within the measurement range, the protection blocks are running. However, the `OPERATE` outputs are blocked until the frequency restores to a valid range.

11.5 Frequency adaptivity and generator start-up protection

Frequency adaptivity enables sensitive and selective protection during the start-up and shutdown phase of the generator when low frequency and low voltage amplitude exist at the same time. Sensitive protection is necessary because, for example, the fault current level in generator internal fault during start-up or shutdown (when field excitation is not present) may not exceed even the nominal current level.

Frequency adaptivity can be enabled by setting *Frequency adaptivity* and setting one UTVTR *Frequency adaptivity* to "Main frequency source". One additional UTVTR or ILTCTR can be set to "Backup frequency source". For main or backup frequency source, all three-phases must be connected. Each TxTR block that is set to Frequency adaptivity mode enable outputs measurements adapted to either main or backup source frequency depending on their availability.

See the Preprocessing blocks chapter for more information.

The frequency adaptivity uses the positive-sequence voltage in the frequency tracking and adapts the DFT, RMS, peak-to-peak and peak measurement accuracies of the current and voltage inputs by using the tracked frequency in the operation range of 0.2...1.5 xFn. Frequency adaptation starts when the generator terminal positive-sequence voltage level exceeds 0.04 xUn (minimum level). If frequency adaptivity backup source is currents their positive sequence must exceed 0.07 xIn to be usable as backup source. Backup source threshold limit is valid at nominal frequency and threshold increases when frequency deviates from nominal (up to 0.35 xIn or 0.2 xUn

at 0.2 xFn or 0.11 xIn or 0.06 xUn at 1.5 xFn). As the Synchronism and energizing check (SECRSYN) bus voltage U12b voltage input always expects *Rated frequency*, the frequency adaptivity does not apply for this input.

If the generator terminal positive-sequence voltage is below the minimum level, the relay is not able to maintain frequency adaptation. The non-adaptive situation is indicated by function Protection output `FRQ_ADP_FAIL`. When frequency adaptivity uses backup frequency source, the `FRQ_ADP_BU` output is activated. The tracked frequency is retained for 3 seconds until the `FRQ_ADP_FAIL` output is activated and *Rated frequency* is expected. Outputs `FRQ_ADP_FAIL`, `FRQ_ADP_BU` and `FRQ_ADP_WARN` can be used in the application configuration, if necessary.

See function block Protection for more information.

The operation accuracy of the protection functions in the range of 0.2...1.5 xFn can be assumed to be according to the technical data given separately for each function. Slight deviations in operation accuracy are possible outside the frequency range specified in technical data. Operate time accuracy and reset times given in technical data are only valid in the frequency range specified for each function.

The specified operate times are expected to increase at lower frequency due to longer network cycles.

Frequency adaptivity depends on the availability of voltages or currents. The generator start-up protection can be also extended by using wide peak-to-peak measurement mode (operational from 2 Hz upward) with designated start-up overcurrent protection function (PHLPTOC). Before the generator is connected with the rest of the network by closing the circuit breaker, the designated start-up overcurrent function should be either blocked or its start value increased, as the *Start value* setting is typically lower than the nominal current.

11.6 Measurement modes

In many current or voltage dependent function blocks, there are various alternative measuring principles.

- RMS
- DFT which is a numerically calculated fundamental component of the signal
- Peak-to-peak
- Peak-to-peak with peak backup
- Wide peak-to-peak

Consequently, the measurement mode can be selected according to the application.

In extreme cases, for example with high overcurrent or harmonic content, the measurement modes function in a slightly different way. The operation accuracy is defined with the frequency range of f/fn=0.95...1.05. In peak-to-peak and RMS measurement modes, the harmonics of the phase currents are not suppressed, whereas in the fundamental frequency measurement the suppression of harmonics is at least -50 dB at the frequency range of f= n · fn, where n = 2, 3, 4, 5,...

RMS

The RMS measurement principle is selected with the *Measurement mode* setting using the value "RMS". RMS consists of both AC and DC components. The AC component is the effective mean value of the positive and negative peak values. RMS is used in applications where the effect of the DC component must be taken into account.

RMS is calculated according to the formula:

$$I_{RMS} = \sqrt{\frac{1}{n}\sum_{i=1}^{n} I_i^2}$$

(Equation 365)

n Number of samples in a calculation cycle

I_i Current sample value

DFT

The DFT measurement principle is selected with the *Measurement mode* setting using the value "DFT". In the DFT mode, the fundamental frequency component of the measured signal is numerically calculated from the samples. In some applications, for example, it can be difficult to accomplish sufficiently sensitive settings and accurate operation of the low stage, which may be due to a considerable amount of harmonics on the primary side currents. In such a case, the operation can be based solely on the fundamental frequency component of the current. In addition, the DFT mode has slightly higher CT requirements than the peak-to-peak mode, if used with high and instantaneous stages.

Peak-to-peak

The peak-to-peak measurement principle is selected with the *Measurement mode* setting using the value "Peak-to-Peak". It is the fastest measurement mode, in which the measurement quantity is made by calculating the average from the positive and negative peak values. The DC component is not included. The retardation time is short. The damping of the harmonics is quite low and practically determined by the characteristics of the anti-aliasing filter of the protection relay inputs. Consequently, this mode is usually used in conjunction with high and instantaneous stages, where the suppression of harmonics is not so important. In addition, the peak-to-peak mode allows considerable CT saturation without impairing the performance of the operation.

Peak-to-peak with peak backup

The peak-to-peak with peak backup measurement principle is selected with the *Measurement mode* setting using the value "P-to-P+backup". It is similar to the peak-to-peak mode, with the exception that it has been enhanced with the peak backup. In the peak-to-peak with peak backup mode, the function starts with two conditions: the peak-to-peak value is above the set start current or the peak value is above two times the set *Start value*. The peak backup is enabled only when the function is used in the DT mode in high and instantaneous stages for faster operation.

Wide peak-to-peak

The wide peak-to-peak measurement principle is available in products where it is necessary for overcurrent protection to operate already starting from as low frequency as 2 Hz during the generator start-up or shutdown phase. The wide peak-to-peak measurement principle is selected with the *Measurement mode* setting "Wide P-to-P".

The measurement mode calculates the average from the positive and negative peak values over the 500 ms wide measurement window, independently of the *Frequency adaptivity* setting value. Retardation and reset times are longer due to the length of the measurement window. The frequency of the fault current affects the operate time. The damping of the harmonics is quite low and practically determined by the characteristics of the anti-aliasing filter of the protection relay current inputs.

When using measurement mode “Wide P-to-P”, the protection relay accepts only *Operate delay time* setting value 800 ms or longer and *Operating curve type* 5=”ANSI Def. Time” or 15=”IEC Def. Time”. These settings should be used for all six setting groups. If the settings are applied only in the active setting group, the validation is not satisfied and the setting commit fails.

Operation accuracy in the frequency range 2...85 Hz is ±1.5% or ±0.003 xI_n. Operate time accuracy in definite time mode is ±1.0% of the set value or ±60 ms when $I_{Fault} = 2 \cdot$ set *Start value* and the fault current frequency is 10...85 Hz.

11.7 Calculated measurements

Calculated residual current and voltage

The residual current is calculated from the phase currents according to equation:

$$\overline{Io} = -(\bar{I}_A + \bar{I}_B + \bar{I}_C)$$

(Equation 366)

The residual voltage is calculated from the phase-to-earth voltages when the VT connection is selected as “Wye” with the equation:

$$\overline{Uo} = \frac{(\overline{U}_A + \overline{U}_B + \overline{U}_C)}{3}$$

(Equation 367)

Sequence components

The phase-sequence current components are calculated from the phase currents according to:

$$\bar{I}_0 = \frac{(\bar{I}_A + \bar{I}_B + \bar{I}_C)}{3}$$

(Equation 368)

$$\bar{I}_1 = \frac{(\bar{I}_A + a \cdot \bar{I}_B + a^2 \cdot \bar{I}_C)}{3}$$

(Equation 369)

$$\bar{I}_2 = \frac{(\bar{I}_A + a^2 \cdot \bar{I}_B + a \cdot \bar{I}_C)}{3}$$

(Equation 370)

The phase-sequence voltage components are calculated from the phase-to-earth voltages when *VT connection* is selected as “Wye” with the equations:

$$\overline{U}_0 = \frac{(\overline{U}_A + \overline{U}_B + \overline{U}_C)}{3}$$

(Equation 371)

$$\overline{U}_1 = \frac{(\overline{U}_A + a \cdot \overline{U}_B + a^2 \cdot \overline{U}_C)}{3}$$

(Equation 372)

$$\overline{U}_2 = \frac{(\overline{U}_A + a^2 \cdot \overline{U}_B + a \cdot \overline{U}_C)}{3}$$

(Equation 373)

When *VT connection* is selected as “Delta”, the positive and negative phase sequence voltage components are calculated from the phase-to-phase voltages according to the equations:

$$\overline{U}_1 = \frac{(\overline{U}_{AB} - a^2 \cdot \overline{U}_{BC})}{3}$$

(Equation 374)

$$\overline{U}_2 = \frac{(\overline{U}_{AB} - a \cdot \overline{U}_{BC})}{3}$$

(Equation 375)

The phase-to-earth voltages are calculated from the phase-to-phase voltages when *VT connection* is selected as "Delta" according to the equations.

$$\overline{U}_A = \overline{U}_0 + \frac{\left(\overline{U}_{AB} - \overline{U}_{CA}\right)}{3}$$

(Equation 376)

$$\overline{U}_B = \overline{U}_0 + \frac{\left(\overline{U}_{BC} - \overline{U}_{AB}\right)}{3}$$

(Equation 377)

$$\overline{U}_C = \overline{U}_0 + \frac{\left(\overline{U}_{CA} - \overline{U}_{BC}\right)}{3}$$

(Equation 378)

If the $\overline{U}_0$ channel is not valid, it is assumed to be zero.

The phase-to-phase voltages are calculated from the phase-to-earth voltages when *VT connection* is selected as "Wye" according to the equations.

$$\overline{U}_{AB} = \overline{U}_A - \overline{U}_B$$

(Equation 379)

$$\overline{U}_{BC} = \overline{U}_B - \overline{U}_C$$

(Equation 380)

$$\overline{U}_{CA} = \overline{U}_C - \overline{U}_A$$

(Equation 381)

11.8 Test mode

11.8.1 Functionality

The mode of all the logical nodes in the relay's IEC 61850 data model can be set with *Test mode*. *Test mode* activation method can be changed via parameter **Tests/IED test/Test mode selection**. Available activation methods are "Local", "Local+remote, maintenance", "Local+Remote, all levels" and "Binary input". By default, *Test mode* activation method is "Local" which means the test mode can be activated only via LHMI through parameter **Tests/IED test/Test mode**. The remote activation method via binary input or via IEC 61850 communication is possible (LD0.LLN0.Mod). When the binary input is selected as the test mode activation method, the behavior can be configured with the application configuration.

Table 1478: Test mode

Test mode	Description	Protection BEH_BLK	Protection BEH_TST
Normal mode	Normal operation	FALSE	FALSE
IED blocked	Protection works as in “Normal mode” but the ACT configuration can be used to block physical outputs to process. Control function commands are blocked.	TRUE	FALSE
IED test	Protection works as in “Normal mode” but protection functions work in parallel with test parameters	FALSE	TRUE
IED test and blocked	Protection works as in “Normal mode” but protection functions work in parallel with the test parameter. The ACT configuration can be used to block physical outputs to process. The control function command is blocked.	TRUE	TRUE

See function block Protection for more details.

The behavior data objects in all logical nodes follow LD0.LLN0.Mod value. If "Normal mode" is selected, the behavior data objects follow the mode (.Mod) data object of the corresponding logical device.

Vertical and horizontal communication is not blocked by the “IED blocked” or “IED test and blocked” modes.

11.8.2 Application configuration and Test mode

The physical outputs from control commands to process are blocked with ”IED blocked” and “IED test and blocked” modes. If physical outputs need to be blocked from the protection, the application configuration must be used to block these signals. The blocking scheme needs to use `BEH_BLK` output of PROTECTION function block.

11.8.3 Control mode

The mode of all logical nodes located under CTRL logical device can be set with *Control mode*. The *Control mode* parameter is available via the HMI or PCM600 path **Configuration/Control/General**. By default, *Control mode* can only be set locally through LHMI. *Control mode* inherits its value from *Test mode* but *Control mode*

values "On", "Blocked" and "Off" can also be set independently. *Control mode* is also available via IEC 61850 communication (CTRL.LLN0.Mod).

Table 1479: Control mode

Control mode	Description	Control BEH_BLK
On	Normal operation	FALSE
Blocked	Control function commands blocked	TRUE
Off	Control functions disabled	FALSE

See function block Control for more details.

The behavior data objects under CTRL logical device follow CTRL.LLN0.Mod value. If "On" is selected, the behavior data objects follow the mode of the corresponding logical device.

11.8.4 Application configuration and Control mode

The physical outputs from commands to process are blocked with “Blocked“ mode. If physical outputs need to be blocked totally, meaning also commands from the binary inputs, the application configuration must be used to block these signals. The blocking scheme uses `BEH_BLK` output of CONTROL function block.

11.8.5 Authorization

By default, *Test mode* and *Control mode* can only be changed from LHMI. It is possible to write test mode by remote client if it is needed in configuration. This is done via LHMI by setting parameter *Test mode selection* via **Tests/IED test/Test mode**. Remote operation is possible only when the relay's control position is in remote position. Local and remote control can be selected with R/L button or via Control function block in application configuration

When using the Signal Monitoring tool to force online values, the following conditions need to be met.

- *Remote force* is set to "All levels".
- *Test mode* is enabled.
- The relay's control position is in remote position.

Table 1480: Test mode selection

Test mode selection	LHMI	61850-8-1-MMS	WHMI	Binary input
Local	Yes	No access	No access	No access
Local+Remote, Maintenance	Yes	Command originator category maintenance	No access	No access
Local+Remote, All levels	Yes	All originator categories	Yes	No access
Binary input	No access	No access	No access	Yes

11.8.6 LHMI indications

The yellow Start LED flashes when the relay is in “IED blocked” or “IED test and blocked” mode. The green Ready LED flashes to indicate that the “IED test and blocked” mode or "IED test" mode is activated.

Section 12 Requirements for measurement transformers

12.1 Current transformers

12.1.1 Current transformer requirements for overcurrent protection

For reliable and correct operation of the overcurrent protection, the CT has to be chosen carefully. The distortion of the secondary current of a saturated CT may endanger the operation, selectivity, and co-ordination of protection. However, when the CT is correctly selected, a fast and reliable short circuit protection can be enabled.

The selection of a CT depends not only on the CT specifications but also on the network fault current magnitude, desired protection objectives, and the actual CT burden. The protection settings of the protection relay should be defined in accordance with the CT performance as well as other factors.

12.1.1.1 Current transformer accuracy class and accuracy limit factor

The rated accuracy limit factor (F_n) is the ratio of the rated accuracy limit primary current to the rated primary current. For example, a protective current transformer of type 5P10 has the accuracy class 5P and the accuracy limit factor 10. For protective current transformers, the accuracy class is designed by the highest permissible percentage composite error at the rated accuracy limit primary current prescribed for the accuracy class concerned, followed by the letter "P" (meaning protection).

Table 1481: Limits of errors according to IEC 60044-1 for protective current transformers

Accuracy class	Current error at rated primary current (%)	Phase displacement at rated primary current		Composite error at rated accuracy limit primary current (%)
		minutes	centiradians	
5P	±1	±60	±1.8	5
10P	±3	-	-	10

The accuracy classes 5P and 10P are both suitable for non-directional overcurrent protection. The 5P class provides a better accuracy. This should be noted also if there are accuracy requirements for the metering functions (current metering, power metering, and so on) of the protection relay.

The CT accuracy primary limit current describes the highest fault current magnitude at which the CT fulfils the specified accuracy. Beyond this level, the secondary current

of the CT is distorted and it might have severe effects on the performance of the protection relay.

In practise, the actual accuracy limit factor (F_a) differs from the rated accuracy limit factor (F_n) and is proportional to the ratio of the rated CT burden and the actual CT burden.

The actual accuracy limit factor is calculated using the formula:

$$F_a \approx F_n \cdot \frac{|S_{in} + S_n|}{|S_{in} + S|}$$

(Equation 382)

F_n	the accuracy limit factor with the nominal external burden S_n
S_{in}	the internal secondary burden of the CT
S	the actual external burden

12.1.1.2 Non-directional overcurrent protection

Current transformer selection

Non-directional overcurrent protection does not set high requirements on the accuracy class or on the actual accuracy limit factor (F_a) of the CTs. It is, however, recommended to select a CT with F_a of at least 20.

The nominal primary current I_{1n} should be chosen in such a way that the thermal and dynamic strength of the current measuring input of the protection relay is not exceeded. This is always fulfilled when

$I_{1n} > I_{kmax} / 100$,

I_{kmax} is the highest fault current.

The saturation of the CT protects the measuring circuit and the current input of the protection relay. For that reason, in practice, even a few times smaller nominal primary current can be used than given by the formula.

Recommended start current settings

If I_{kmin} is the lowest primary current at which the highest set overcurrent stage is to operate, the start current should be set using the formula:

Current start value < $0.7 \times (I_{kmin} / I_{1n})$

I_{1n} is the nominal primary current of the CT.

The factor 0.7 takes into account the protection relay inaccuracy, current transformer errors, and imperfections of the short circuit calculations.

The adequate performance of the CT should be checked when the setting of the high set stage overcurrent protection is defined. The operate time delay caused by the CT saturation is typically small enough when the overcurrent setting is noticeably lower than F_a.

When defining the setting values for the low set stages, the saturation of the CT does not need to be taken into account and the start current setting is simply according to the formula.

Delay in operation caused by saturation of current transformers

The saturation of CT may cause a delayed protection relay operation. To ensure the time selectivity, the delay must be taken into account when setting the operate times of successive protection relays.

With definite time mode of operation, the saturation of CT may cause a delay that is as long as the time constant of the DC component of the fault current, when the current is only slightly higher than the starting current. This depends on the accuracy limit factor of the CT, on the remanence flux of the core of the CT, and on the operate time setting.

With inverse time mode of operation, the delay should always be considered as being as long as the time constant of the DC component.

With inverse time mode of operation and when the high-set stages are not used, the AC component of the fault current should not saturate the CT less than 20 times the starting current. Otherwise, the inverse operation time can be further prolonged. Therefore, the accuracy limit factor F_a should be chosen using the formula:

$F_a > 20 \cdot$ *Current start value* / I_{1n}

The *Current start value* is the primary start current setting of the protection relay.

12.1.1.3 Example for non-directional overcurrent protection

The following figure describes a typical medium voltage feeder. The protection is implemented as three-stage definite time non-directional overcurrent protection.

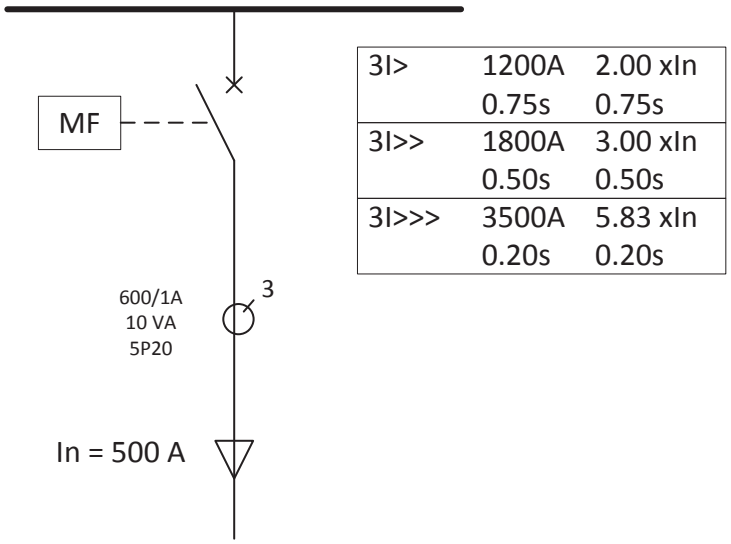

Figure 887: Example of three-stage overcurrent protection

The maximum three-phase fault current is 41.7 kA and the minimum three-phase short circuit current is 22.8 kA. The actual accuracy limit factor of the CT is calculated to be 59.

The start current setting for low-set stage (3I>) is selected to be about twice the nominal current of the cable. The operate time is selected so that it is selective with the next protection relay (not visible in Figure 887). The settings for the high-set stage and instantaneous stage are defined also so that grading is ensured with the downstream protection. In addition, the start current settings have to be defined so that the protection relay operates with the minimum fault current and it does not operate with the maximum load current. The settings for all three stages are as in Figure 887.

For the application point of view, the suitable setting for instantaneous stage (I>>>) in this example is 3 500 A (5.83 × I_n). I_n is the 1.2 multiple with nominal primary current of the CT. For the CT characteristics point of view, the criteria given by the current transformer selection formula is fulfilled and also the protection relay setting is considerably below the F_a. In this application, the CT rated burden could have been selected much lower than 10 VA for economical reasons.

12.1.2 Current transformer requirements for transformer differential protection

The more important the object to be protected, the more attention has to be paid to the current transformers. It is not normally possible to dimension the current transformer so that they repeat the currents with high DC components without saturating when the residual flux of the current transformer is high. TR2PTDF and TR3PTDF operate reliably even though the current transformers are partially saturated.

The accuracy class recommended for current transformers to be used with TR2PTDF and TR3PTDF is 5P, in which the limit of the current error at the rated primary current

is 1 percent and the limit of the phase displacement is 60 minutes. The limit of the composite error at the rated accuracy limit primary current is 5 percent.

The approximate value of the accuracy limit factor F_a corresponding to the actual current transformer burden can be calculated on the basis of the rated accuracy limit factor F_n at the rated burden, the rated burden S_n, the internal burden $S_{in}$and the actual burden S_a of the current transformer.

$$F_a = F_n \cdot \frac{S_{in} + S_n}{S_{in} + S_a}$$

(Equation 383)

F_a The approximate value of the accuracy limit factor (ALF) corresponding to the actual CT burden

F_n The rated accuracy limit factor at the rated burden of the current transformer

S_n The rated burden of the current transformer

S_{in} The internal burden of the current transformer

S_a The actual burden of the current transformer

Example 1

The rated burden S_n of the current transformer 5P20 is 10 VA, the secondary rated current is 5A, the internal resistance R_{in}= 0.07 Ω and the accuracy limit factor F_n corresponding to the rated burden is 20 (5P20). Thus the internal burden of the current transformer is S_{in}= $(5A)^2$ * 0.07 Ω = 1.75 VA. The input impedance of the protection relay at a rated current of 5A is < 20 mΩ. If the measurement conductors have a resistance of 0.113 Ω, the actual burden of the current transformer is S_a=$(5A)^2$ * (0.113 + 0.020) Ω = 3.33 VA. Thus the accuracy limit factor F_a corresponding to the actual burden is approximately 46.

The CT burden can grow considerably at the rated current 5A. The actual burden of the current transformer decreases at the rated current of 1A while the repeatability simultaneously improves.

At faults occurring in the protected area, the currents may be very high compared to the rated currents of the current transformers. Due to the instantaneous stage of the differential function block, it is sufficient that the current transformers are capable of repeating the current required for instantaneous tripping during the first cycle.

Thus the current transformers usually are able to reproduce the asymmetric fault current without saturating within the next 10 ms after the occurrence of the fault to secure that the operate times of the protection relay comply with the retardation time.

The accuracy limit factors corresponding to the actual burden of the phase current transformer to be used in differential protection fulfill the requirement.

$$F_a > K_r \times Ik_{\max} \times (T_{dc} \times \omega \times (1 - e^{-T_m/T_{dc}}) + 1)$$

(Equation 384)

Ik_{max}	The maximum through-going fault current (in I_r) at which the protection is not allowed to operate
T_{dc}	The primary DC time constant related to Ik_{max}
ω	The angular frequency, that is, 2*π*fn
T_m	The time-to-saturate, that is, the duration of the saturation free transformation
K_r	The remanence factor 1/(1-r), where r is the maximum remanence flux in p.u. from saturation flux

The accuracy limit factors corresponding to the actual burden of the phase current transformer is used in differential protection.

The parameter *r* is the maximum remanence flux density in the CT core in p.u. from saturation flux density. The value of the parameter *r* depends on the magnetic material used and on the construction of the CT. For instance, if the value of *r* = 0.4, the remanence flux density can be 40 percent of the saturation flux density. The manufacturer of the CT has to be contacted when an accurate value for the parameter *r* is needed. The value *r* = 0.4 is recommended to be used when an accurate value is not available.

The required minimum time-to-saturate T_m in TR2PTDF and TR3PTDF is half fundamental cycle period (10 ms when fn = 50Hz).

Two typical cases are considered for the determination of the sufficient accuracy limit factor (F_a):

1. A fault occurring at the substation bus:
   The protection must be stable at a fault arising during a normal operating situation. Re-energizing the transformer against a bus fault leads to very high fault currents and thermal stress and therefore re-energizing is not preferred in this case. Thus, the remanence can be neglected.
   The maximum through-going fault current Ik_{max} is typically 10 I_r for a substation main transformer. At a short circuit fault close to the supply transformer, the DC time constant (T_{dc}) of the fault current is almost the same as that of the transformer, the typical value being 100 ms.

Ik_{max}	10 I_r
T_{dc}	100 ms
ω	100π Hz
T_m	10 ms
K_r	1

   When the values are substituted in Equation 384, the result is:

$$F_a > K_r \times Ik_{\max} \times (T_{dc} \times \omega \times (1 - e^{-T_m / T_{dc}}) + 1) \approx 40$$

2. Re-energizing against a fault occurring further down in the network:
The protection must be stable also during re-energization against a fault on the line. In this case, the existence of remanence is very probable. It is assumed to be 40 percent here.
On the other hand, the fault current is now smaller and since the ratio of the resistance and reactance is greater in this location, having a full DC offset is not possible. Furthermore, the DC time constant (T_{dc}) of the fault current is now smaller, assumed to be 50 ms here.
Assuming a maximum fault current being 30 percent lower than in the bus fault and a DC offset 90 percent of the maximum.

Ik_{max}	0.7* 10 = 7 (I_r)
T_{dc}	50 ms
ω	100π Hz
T_m	10 ms
K_r	1/(1-0.4) = 1.6667

When the values are substituted in the equation, the result is:

$$F_a > K_r \times Ik_{\max} \times 0.9 \times (T_{dc} \times \omega \times (1 - e^{-T_m / T_{dc}}) + 1) \approx 40$$

If the actual burden of the current transformer (S_a) in Equation 383 cannot be reduced low enough to provide a sufficient value for F_a, there are two alternatives to deal with the situation:

- a CT with a higher rated burden S_n can be chosen (which also means a higher rated accuracy limit F_n)
- a CT with a higher nominal primary current I_{1n} (but the same rated burden) can be chosen

Example 2

Assuming that the actions according to alternative two above are taken in order to improve the actual accuracy limit factor:

$$F_a = \frac{IrCT}{IrTR} \times F_n$$

(Equation 385)

IrTR	1000 A (rated secondary side current of the power transformer)
IrCT	1500 A (rated primary current of the CT on the transformer secondary side)
F_n	30 (rated accuracy limit factor of the CT)

F_a (IrCT / IrTR) * Fn (actual accuracy limit factor due to oversizing the CT) = (1500/1000) * 30 = 45

In TR2PTDF and TR3PTDF, it is important that the accuracy limit factors F_a of the phase current transformers at both sides correspond with each other, that is, the burdens of the current transformers on both sides are to be as equal as possible. If high inrush or start currents with high DC components pass through the protected object when it is connected to the network, special attention is required for the performance and the burdens of the current transformers and for the settings of the function block.

13.2 Communication modules

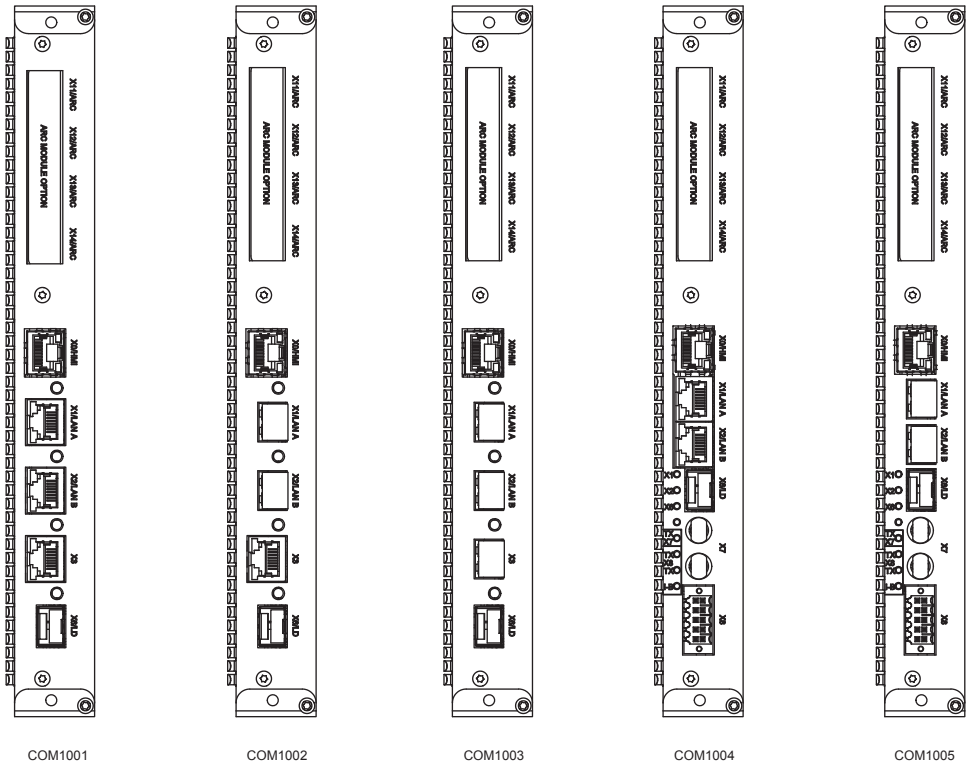

Figure 896: Communication module options

The Ethernet ports marked with LAN A and LAN B are used with redundant Ethernet protocols HSR and PRP. The third station bus Ethernet port without the LAN A or LAN B label is an interlink port which is used to connect a device to the common redundant Ethernet channel.

Table 1482: Ports in communication modules

Port	Type	Description
X0	RJ-45	HMI
X1	RJ-45 or LC	Ethernet (LAN A)
X2	RJ-45 or LC	Ethernet (LAN B)
X3	RJ-45 or LC	Ethernet (Interlink)
X6	SFP - LC	Protection communication
X7	FO - ST	Serial communication
X8	TP[1)]	Serial communication/IRIG-B

1) 2- or 4-wire twisted pair

Table 1483: Station bus communication interfaces included in communication modules

Module ID	RJ-45	LC	EIA_485	ST
COM1001	3	-	-	-
COM1002	1	2	-	-
COM1003	-	3	-	-
COM1004	2	-	1	1
COM1005	-	2	1	1

13.3 Arc sensor interface

Light sensor input connections for the arc protection are available on the optional hardware module in Slot A1. The module supports connection of up to four sensors. The sensors can be lens or loop types or a free mixture.

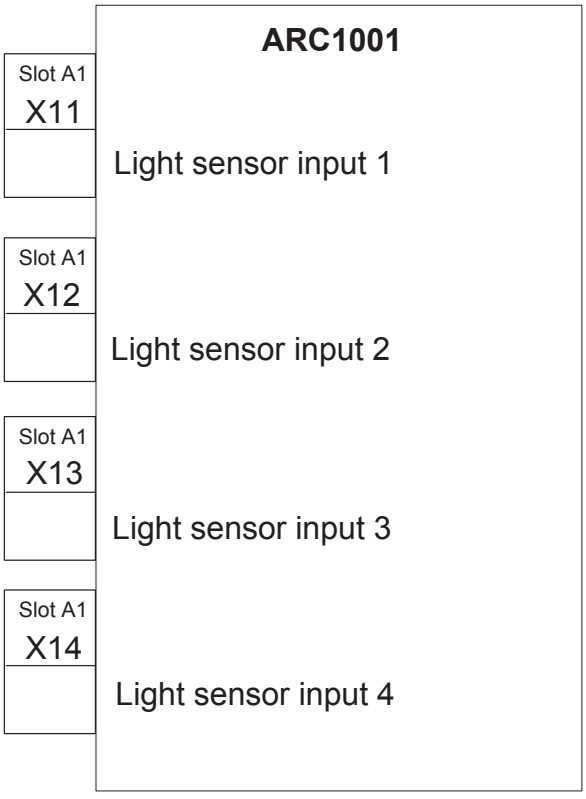

Figure 897: ARC module

The ARCSARC function must be instantiated in the application configuration to enable the sensor inputs.

Table 1484: ARCSARC instances and arc sensor inputs

Instance	Sensor input activation
ARCSARC1	Light sensor input 1
ARCSARC2	Light sensor input 2
ARCSARC3	Light sensor input 3
ARCSARC4	Light sensor input 4

Section 14 Technical data

Table 1485: Dimensions of the relay

Description		Value
Width		304.0 mm
Height		264.8 mm
Depth	With compression type CT/VT connectors	242.2 mm
	With ring lug type CT/VT connectors	254.1 mm
	With grounding bar	274.0 mm
Weight box		6.9...8.8 kg

Table 1486: Dimensions of the LHMI

Description	Value
Width	212.5 mm
Height	177.5 mm
Depth	57.6 mm
Weight	1.6 kg

Table 1487: Power supply for the relay

Description	PSM1001	PSM1002	PSM1003
Nominal auxiliary voltage U_n	24, 30, 48, 60 V DC	100, 110, 120, 220, 240 V AC, 50 and 60 Hz	110, 125 V DC
		48, 60, 110, 125, 220, 250 V DC	
Maximum interruption time in the auxiliary DC voltage without resetting the relay	50 ms at U_n		
Auxiliary voltage variation	50...120% of U_n (12...72 V DC)	38...110% of U_n (38...264 V AC)	70...120% of U_n (77...150 V DC)
		80...120% of U_n (38.4...300 V DC)	
Start-up threshold	16 V DC (24 V DC × 67%)		77 V DC (110 V DC × 70%)

Table continues on next page

Description	PSM1001	PSM1002	PSM1003
Burden of auxiliary voltage supply under quiescent (P_q)/ operating condition	DC <18.0 W (nominal)/ <25.0 W (max.)	DC <20.0 W (nominal)/ <25.0 W (max.) AC <20.0 W (nominal)/ <25.0 W (max.)	DC <17.0 W (nominal)/ <25.0 W (max.)
Ripple in the DC auxiliary voltage	Max 15% of the DC value (at frequency of 100 Hz)		
Fuse type	T8A/250 V	T4A/250 V	

Table 1488: Power supply for the LHMI

Description	Value
Nominal auxiliary voltage U_n	100, 110, 120, 220, 240 V AC, 50 and 60 Hz
	24, 48, 60, 110, 125, 220, 250 V DC
Auxiliary voltage variation	38...110% of U_n (38...264 V AC)
	80...120% of U_n (19.2...300 V DC)
Start-up threshold	19.2 V DC (24 V DC × 80%)
Burden of auxiliary voltage supply under quiescent (P_q)/operating condition	DC <6.0 W (nominal)/<14.0 W (max.) AC <7.0 W (nominal)/<12.0 W (max.)
Ripple in the DC auxiliary voltage	Max 15% of the DC value (at frequency of 100 Hz)
Fuse type	T3.15A/250V

Table 1489: Energizing inputs

Description		Value	
Rated frequency		50/60 Hz	
Current inputs	Rated current, I_n	0.2/1 A	1/5 A[1)]
	Thermal withstand capability: • Continuously • For 1 s	 4 A 100 A	 20 A 500 A
	Dynamic current withstand: • Half-wave value	 250 A	 1250 A
	Input impedance	<100 mΩ	<20 mΩ
Voltage inputs	Rated voltage	57...240 V AC	
	Voltage withstand: • Continuous • For 10 s	 288 V AC 360 V AC	
	Burden at rated voltage	<0.05 VA	

1) Residual current and/or phase current

Table 1490: Energizing inputs (sensors)

Description		Value
Current sensor input	Rated current voltage (in secondary side)	75 mV...9000 mV[1)]
	Continuous voltage withstand	125 V
	Input impedance at 50/60 Hz	4 MΩ
Voltage sensor input	Rated primary voltage	6 kV...40.5 kV[2)]
	Continuous voltage withstand	50 V
	Input impedance at 50/60 Hz	8 MΩ

1) Equals the current range of 40...4000 A with a 80 A, 3 mV/Hz Rogowski
2) This range is covered (up to 2*rated) with sensor division ratio of 10 000:1

Table 1491: Binary inputs

Description	Value
Operating range	±20% of the rated voltage
Rated voltage	24...250 V DC
Current drain	1.6...1.9 mA
Power consumption	31.0...570.0 mW
Threshold voltage	16...176 V DC
Ripple in the DC auxiliary voltage	Max 15% of the DC value (at frequency of 100 Hz)

Adjust the binary input threshold voltage correctly. It is recommended to set the threshold voltage to 70% of the nominal auxiliary voltage. The factory default is 16 V to ensure the binary inputs' operation regardless of the auxiliary voltage used (24, 48, 60, 110, 125, 220 or 250 V DC). However, the default value is not optimal for the higher auxiliary voltages. The binary input threshold voltage should be set as high as possible to prevent any inadvertent activation of the binary inputs due to possible external disturbances. At the same time, the threshold should be set so that the correct operation is not jeopardized in case of undervoltage of the auxiliary voltage.

Table 1492: RTD/mA inputs and mA outputs

Description		Value	
RTD inputs	Supported RTD sensors	100 Ω platinum 250 Ω platinum 100 Ω nickel 120 Ω nickel 250 Ω nickel	TCR 0.00385 (DIN 43760) TCR 0.00385 TCR 0.00618 (DIN 43760) TCR 0.00618 TCR 0.00618
	Supported resistance range	0...4 kΩ	
	Maximum lead resistance (three-wire measurement)	100 Ω per lead	
	Isolation	2 kV (inputs to protective earth)	
	Response time	<1 s	
	RTD/resistance sensing current	<1 mA rms	
	Operation accuracy	Resistance	Temperature
		± 2.0% or ±1 Ω	±1°C
mA inputs	Supported current range	±0…20 mA	
	Current input impedance	44 Ω ±0.1%	
	Operation accuracy	±0.5% or ±0.01 mA	
mA outputs	Supported current range	±0…20 mA	
	Maximum loop impedance	700 Ω	
	Operation accuracy	±0.1 mA	

Table 1493: Signal outputs and IRF output

Description	Value
Rated voltage	250 V AC/DC
Maximum continuous burden (resistive load, AC)	1250 VA
Continuous contact carry	5 A
Make and carry for 3.0 s	10 A
Make and carry 0.5 s	15 A
Breaking capacity when the control-circuit time constant L/R<40 ms, at 48/110/220 V DC	1 A/0.25 A/0.15 A
Minimum contact load	10 mA at 5 V AC/DC

Table 1494: Single-pole power output relays

Description	Value
Rated voltage	250 V AC/DC
Maximum continuous burden (resistive load, AC)	2000 VA
Continuous contact carry	8 A
Make and carry for 3.0 s	15 A
Make and carry for 0.5 s	30 A
Breaking capacity when the control-circuit time constant L/R<40 ms, at 48/110/220 V DC	5 A/3 A/1 A
Minimum contact load	100 mA at 24 V AC/DC

Table 1495: Static signal output (SSO) relays

Description	Value
Rated voltage	250 V AC/DC
Maximum continuous burden (resistive load, AC)	250 VA
Continuous contact carry	1 A
Make and carry for 3.0 s	5 A
Breaking capacity when the control-circuit time constant L/R<40 ms, at 110 V DC	>0.25 A
Minimum load current	1 mA
Maximum operation frequency at 50% duty cycle	10 Hz

Table 1496: Double-pole power output relays with TCS function

Description	Value
Rated voltage	250 V AC/DC
Maximum continuous burden (resistive load, AC)	2000 VA
Continuous contact carry	8 A
Make and carry for 3.0 s	15 A
Make and carry for 0.5 s	30 A
Breaking capacity when the control-circuit time constant L/R<40 ms, at 48/110/220 V DC (two contacts connected in series)	5 A/3 A/1 A
Minimum contact load	100 mA at 24 V AC/DC
Trip-circuit supervision (TCS): • Control voltage range • Current drain through the supervision circuit • Minimum voltage over the TCS contact	 20...250 V AC/DC ~1.5 mA 20 V AC/DC (15...20 V)

Table 1497: Static power output (SPO) relays

Description	Value
Rated voltage	250 V DC
Maximum continuous burden (resistive load, DC)	2000 VA
Continuous contact carry	5 A (one output at a time) 1 A (multiple outputs simultaneously active)
Make and carry for 0.2 s	30 A
Breaking capacity when the control-circuit time constant L/R<40 ms, at 48/110/220 V DC two contacts connected in series	16 A/6 A/3 A
Minimum load current	1 mA
Trip-circuit supervision (TCS) SP06 and SP08:	
• Control voltage range	20...250 V DC
• Current drain through the supervision circuit	~1.5 mA
• Minimum voltage over the TCS contact	20 V DC
SP05 and SP07:	
• Current drain through the circuit	~3 mA

Table 1498: Serial rear interface

Type	Counter connector
Serial port X8	10-pin 2-row counter connector
Serial port X7	Optical ST-connector

Table 1499: USB interface, LHMI

Type	Description
USB	Hi-Speed USB Type A

Table 1500: Ethernet interfaces

Connector	Media	Reach	Rate	Wavelength	Permitted path attenuation
RJ-45	CAT 6 S/FTP	100 m	100 mbits/s	-	–
LC	MM 62.5/125 or 50/125 µm glass fiber core	2 km[1)]	100 mbits/s	1300 nm	<8 dB[2)]

1) Maximum length depends on the cable attenuation and quality, the amount of splices and connectors in the path
2) Maximum allowed attenuation caused by connectors and cable togethe

Table 1501: Protection communication link

Connector	Part number	Fiber type	Wave Length	Max. length	Permitted path attenuation
SFP	2RCA045621	MM 62.5/125 or 50/125 µm	1310 nm	2 km	<8 dB
SFP	2RCA045622	SM 9/125 µm	1310 nm	20 km	<13 dB
SFP	2RCA045623	SM 9/125 µm	1310 nm	50 km	<26 dB

Table 1502: IRIG-B (connector X8)

Description	Value
IRIG time code format	B004, B005[1)]
Isolation	500V 1 min
Modulation	Unmodulated
Logic level	5 V TTL
Current consumption	<1.0 mA
Power consumption	<0.5 W

1) According to the 200-04 IRIG standard

Table 1503: Lens sensor and optical fiber for arc protection

Description	Value
Fiber optic cable including lens	1.5 m, 3.0 m or 5.0 m
Normal service temperature range of the lens	-40...+100°C
Maximum service temperature range of the lens, max 1 h	+140°C
Minimum permissible bending radius of the connection fiber	100 mm

Table 1504: Degree of protection of flush-mounted protection relay

Description	Value
Front/connector side	IP 20
Top and bottom	IP 30
Rear	IP 40

Table 1505: Degree of protection of the LHMI

Description	Value
Front	IP 54
Other sides	IP 20

Table 1506: Environmental conditions

Description	Value
Operating temperature range	-25...+55ºC (continuous)
Short-time service temperature range	-40...+85ºC (<16 h)[1)2)]
Relative humidity	<93%, non-condensing
Atmospheric pressure	86...106 kPa
Altitude	Up to 2000 m
Transport and storage temperature range	-40...+85ºC

1) Degradation in MTBF and HMI performance outside the temperature range of -25...+55 ºC
2) For relays with an LC communication interface the maximum operating temperature is +70 ºC

Section 17 Glossary

100BASE-FX	A physical medium defined in the IEEE 802.3 Ethernet standard for local area networks (LANs) that uses fiber optic cabling
100BASE-TX	A physical medium defined in the IEEE 802.3 Ethernet standard for local area networks (LANs) that uses twisted-pair cabling category 5 or higher with RJ-45 connectors
ACT	1. Application Configuration tool in PCM600 2. Trip status in IEC 61850
AD	Active directory
AIM	Analog input module
AIS	Air-insulated switchgear
AR	Autoreclosing
ASC	Arc suppression coil
AVR	Automatic voltage regulator
BCD	Binary coded decimal
CAM	Centralized account management
CAT 6	Cable standard for gigabit Ethernet and other network protocols that is backward compatible with CAT 5/5e and CAT 3 cable standards
CB	Circuit breaker
CBB	Cycle building block
CBCT	Core balance current transformer
CBFP	Circuit breaker failure protection
COM600S	Substation Management Unit. An all-in-one communication gateway, automation platform and user interface solution for utility and industrial distribution substations.
COMTRADE	Common format for transient data exchange for power systems. Defined by the IEEE Standard.
CR	Carrier receive signal
CS	Carrier send signal
CT	Current transformer

DAN	Doubly attached node
DC	1. Direct current 2. Disconnector 3. Double command
DCB	Directional comparison blocking scheme
DCUB	Directional comparison unblocking scheme
DFT	Discrete Fourier transform
DG	Distributed generation
DIP switch	A set of on-off switches arranged in a standard dual in-line package
DNP3	A distributed network protocol originally developed by Westronic. The DNP3 Users Group has the ownership of the protocol and assumes responsibility for its evolution.
DT	Definite time
DUTT	Direct underreach transfer trip
EEPROM	Electrically erasable programmable read-only memory
EMC	Electromagnetic compatibility
Ethernet	A standard for connecting a family of frame-based computer networking technologies into a LAN
FLC	Full load current
FPGA	Field-programmable gate array
FTP	File transfer protocol
FTPS	FTP Secure
GFC	General fault criteria
GIS	Gas-insulated switchgear
GND	Ground/earth
GOOSE	Generic Object-Oriented Substation Event
GPS	Global Positioning System
HF	High frequency
HMI	Human-machine interface
HSR	High-availability seamless redundancy
HTTPS	Hypertext Transfer Protocol Secure
HV	High voltage
IDMT	Inverse definite minimum time
IEC	International Electrotechnical Commission

IEC 60870-5-103	1. Communication standard for protective equipment 2. A serial master/slave protocol for point-to-point communication
IEC 61850	International standard for substation communication and modeling
IEC 61850-8-1	A communication protocol based on the IEC 61850 standard series
IEC 61850-9-2	A communication protocol based on the IEC 61850 standard series
IEC 61850-9-2 LE	Lite Edition of IEC 61850-9-2 offering process bus interface
IED	Intelligent electronic device
IRF	1. Internal fault 2. Internal relay fault
IRIG-B	Inter-Range Instrumentation Group's time code format B
L/R	Local/Remote
LAN	Local area network
LC	Connector type for glass fiber cable, IEC 61754-20
LDC	Line drop compensation
LE	Light Edition
LED	Light-emitting diode
LF	Low frequency
LHMI	Local human-machine interface
LOG	Loss of grid
LOM	Loss of mains
LV	Low voltage
M/F	Master/Follower
MAC	Media access control
MCB	Miniature circuit breaker
MCC	Minimizing circulating current
MM	1. Multimode 2. Multimode optical fiber
MMS	1. Manufacturing message specification 2. Metering management system

Modbus	A serial communication protocol developed by the Modicon company in 1979. Originally used for communication in PLCs and RTU devices.
Modbus ASCII	Link mode using 7-bit ASCII characters
Modbus RTU	Link mode using 8-bit binary characters
MSB	Most significant bit
MV	Medium voltage
NC	Normally closed
NPS	Negative phase sequence
NRP	Negative reactance principle
NSCB	Non-source circuit breaker
OSB	Out of step blocking
P2P	peer-to-peer
PC	1. Personal computer 2. Polycarbonate
PCL	Product connectivity level
PCM600	Protection and Control IED Manager
Peak-to-peak	1. The amplitude of a waveform between its maximum positive value and its maximum negative value 2. A measurement principle where the measurement quantity is made by calculating the average from the positive and negative peak values without including the DC component. The peak-to-peak mode allows considerable CT saturation without impairing the performance of the operation.
Peak-to-peak with peak backup	A measurement principle similar to the peak-to-peak mode but with the function starting on two conditions: the peak-to-peak value is above the set start current or the peak value is above two times the set start value
PGU	Power generating unit
PLC	Programmable logic controller
PO	Power output
PODP	Power output, double pole
POSP	Power output, single pole
POTT	Permissive overreach transfer trip
PPS	Pulse per second
PRP	Parallel redundancy protocol
PTP	Precision Time Protocol

PUTT	Permissive underreach transfer trip
RAM	Random access memory
RCA	Also known as MTA or base angle. Characteristic angle.
RIO600	Remote I/O unit
RJ-45	Galvanic connector type
RMS	Root-mean-square (value)
ROM	Read-only memory
RS-485	Serial link according to EIA standard RS485
RSTP	Rapid spanning tree protocol
RTC	Real-time clock
RTD	Resistance temperature detector
Rx	Receive/Received
SAN	Single attached node
SBO	Select-before-operate
SCADA	Supervision, control and data acquisition
SCB	1. Shunt capacitor bank 2. Source circuit breaker
SCL	XML-based substation description configuration language defined by IEC 61850
SCM	Smart control module
SDM600	A software solution for automatic management of service and cyber security relevant data across substations
SIM	Subscriber identity module
SM	1. Single mode 2. Single-mode optical fiber
SMT	Signal Matrix tool in PCM600
SMV	Sampled measured values
SNTP	Simple Network Time Protocol
SOTF	Switch onto fault
SPO	Static power output
SSO	Static signal output
ST	Connector type for glass fiber cable
TCP/IP	Transmission Control Protocol/Internet Protocol
TCS	Trip-circuit supervision

TLV	Type length value
TP	Disturbance data recorded with or without trip bit
Tx	Transmit/Transmitted
UART	Universal asynchronous receiver-transmitter
UDP	User datagram protocol
USB	Universal serial bus
UTC	Coordinated universal time
VDR	Voltage-depended resistor
VT	Voltage transformer
WAN	Wide area network
WEI	Weak-end infeed logic
WHMI	Web human-machine interface

Exertherm® Alarm Relay Module XL
ARM XL
Installation & Setup Manual

MA-131-5-EN

There are 3 hardware connection options for use with the ARM XL.

Instructions detailed in Sections 3 to 8 are generic and applicable to all, and therefore must be adhered to for all hardware selections.

Following this please refer to the relevant Section for your selected hardware connection:

- **8ch Datacard Only Section 9**
- **MMA Only Section 10**
- **Both 8ch Datacard & MMA Section 11**

2. OWNERSHIP, NOTES AND CRITICAL DISCLAIMERS

NO PART OF THIS MANUAL MAY BE COPIED OR REPRODUCED VIA ANY MEANS WITHOUT THE PRIOR WRITTEN CONSENT OF EXERTHERM. THIS MANUAL & IT'S CONTENTS ARE SUBJECT TO CHANGE WITHOUT NOTICE.

This document, including all the descriptions within it, assumes that the user is conversant with the operation and uses of basic control and monitoring systems.

In addition, this document does not include any specific documentation concerning the systems with which integration takes place. The user should seek additional information from the supplier's documentation for each of the connected systems.

Where devices such as display panels and personal computers are used, we have assumed that the user will either be familiar with the operation of the devices or will be able to familiarise themselves with the information supplied with the equipment.

The utility, configuration, terminal or stream modes of the connected systems enable all control parameters to be changed. Qualified persons only should carry this out, and it is strongly recommended that any changes made be recorded at the time of the changes. Note that if a change is to be made, a backup of the systems concerned should be made before this where possible.

2.1 NOTICES:

The information, products and specifications, configurations, and other technical information regarding the products and data contained in this document are subject to change without notice. All the statements, technical information, and recommendations contained in this document are believed to be accurate and reliable but are presented without warranty of any kind, and users must take full responsibility for the application of any products or data specified in this document.

IN NO EVENT SHALL EXERTHERM, OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO EQUIPMENT OR DATA OF ANY KIND WHATSOEVER ARISING OUT OF THE USE OR INABILITY TO USE THIS DOCUMENT, EVEN IF EXERTHERM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

THIS LIMITATION OF LIABILITY WILL PREVAIL OVER ANY OTHER TERMS & CONDITIONS RELATING TO THE SUPPLY OF EXERTHERM PRODUCTS / SERVICES.

2.2 INTELLECTUAL PROPERTY, PATENTS, TRADE MARKS AND REGISTERED DESIGNS

Exertherm is a registered trademark. The Exertherm suite of products contain proprietary information and intellectual property of Exertherm. Exertherm will vigorously protect itself in the event of any misuse of any or all such intellectual property.

All other products or services referred to in this document are the trademarks, service marks, or product names of their respective holders.

2.3 STANDARDS AND APPROVALS

Exertherm ARM XL, MMA, MMD, 8ch Modbus Datacard & IR + Cable Sensors are all CE certified & UL Listed.

Exertherm declare that all our components are produced in accordance with EU Directive 2011/65/EU requirement for RoHS Compliance.

2.4 PERSONNEL QUALIFICATION AND TRAINING

It is assumed that the Exertherm ARM XL Product will only be installed in accordance with the instruction contained within this Manual.

Personal responsibilities, competence and supervision must be clearly defined by the commissioner / installer. If the personnel in question are not already in possession of the requisite knowledge, then appropriate training and instruction must be provided.

2.5 WARRANTY

Exertherm ARM XL Return/Warranty Policy

Exertherm offers a one year warranty on ARM XL Product from date of sale. We warrant that product will be free of defects in material and workmanship and will repair or replace the returned product at no charge during that one year period. The warranties are void if the product is misused, mishandled or installed incorrectly (not in accordance with the methods and procedures outlined in this document).

Repairs to Exertherm ARM XL Product can only be undertaken by Exertherm. Any repairs or attempted repairs by others will void product warranties.

The warranty is conditional upon the above caveats and strictly limited to the replacement cost of ARM XL Product. Labour costs associated with removal of ARML XL Product and/or re-installation are excluded, as is any consequential loss resulting from the ARM XL Product failure.

Exertherm reserves the right to examine and test any returned products to determine the cause of failure. No returned products will be accepted prior to issue of a Return Material Authorization (RMA) number by Exertherm.

Please contact Exertherm if you have any questions – support@Exertherm.com, current telephone numbers can be found at www.Exertherm.com .

2.6 LIVE WORKING

DO NOT PERFORM ANY ACTIVITY ON A PIECE OF LIVE SWITCHGEAR. FAILURE TO COMPLY WITH THESE AND OTHER NATIONAL, REGIONAL OR LOCAL HEALTH AND SAFETY REGULATIONS/GUIDELINES COULD RESULT IN PERMANENT INJURY OR DEATH.

Prior to undertaking any work the operator MUST ensure that all busbars, connections and sources of energy are totally isolated and checked prior to any works taking place which should be completed by a competent and suitably qualified person.

All energy sources onto the panel must be isolated, removed and locked out to prevent the panel being re-energised while any works are taking place. If the panel being tested is part of an existing installation then all connections should be bonded to earth.

5. WHAT'S IN THE BOX?

Part Number & description of box contents below:

Exertherm Part No. 900451

1) Exertherm Alarm Relay Module (ARM XL)
2) ARM XL Install & Setup Manual
3) 2 x mounting screws & 1 x power connector
4) Panel cut out Template
5) Comms Cable

Replacement Parts:

The following replacement parts can be ordered, part numbers + description below:

1) Comms Cable is – PN 800455
2) 2 x mounting screws & 1 x power connector – PN 800456

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

6. MOUNTING INSTRUCTIONS

6.1 UNIT SIZE

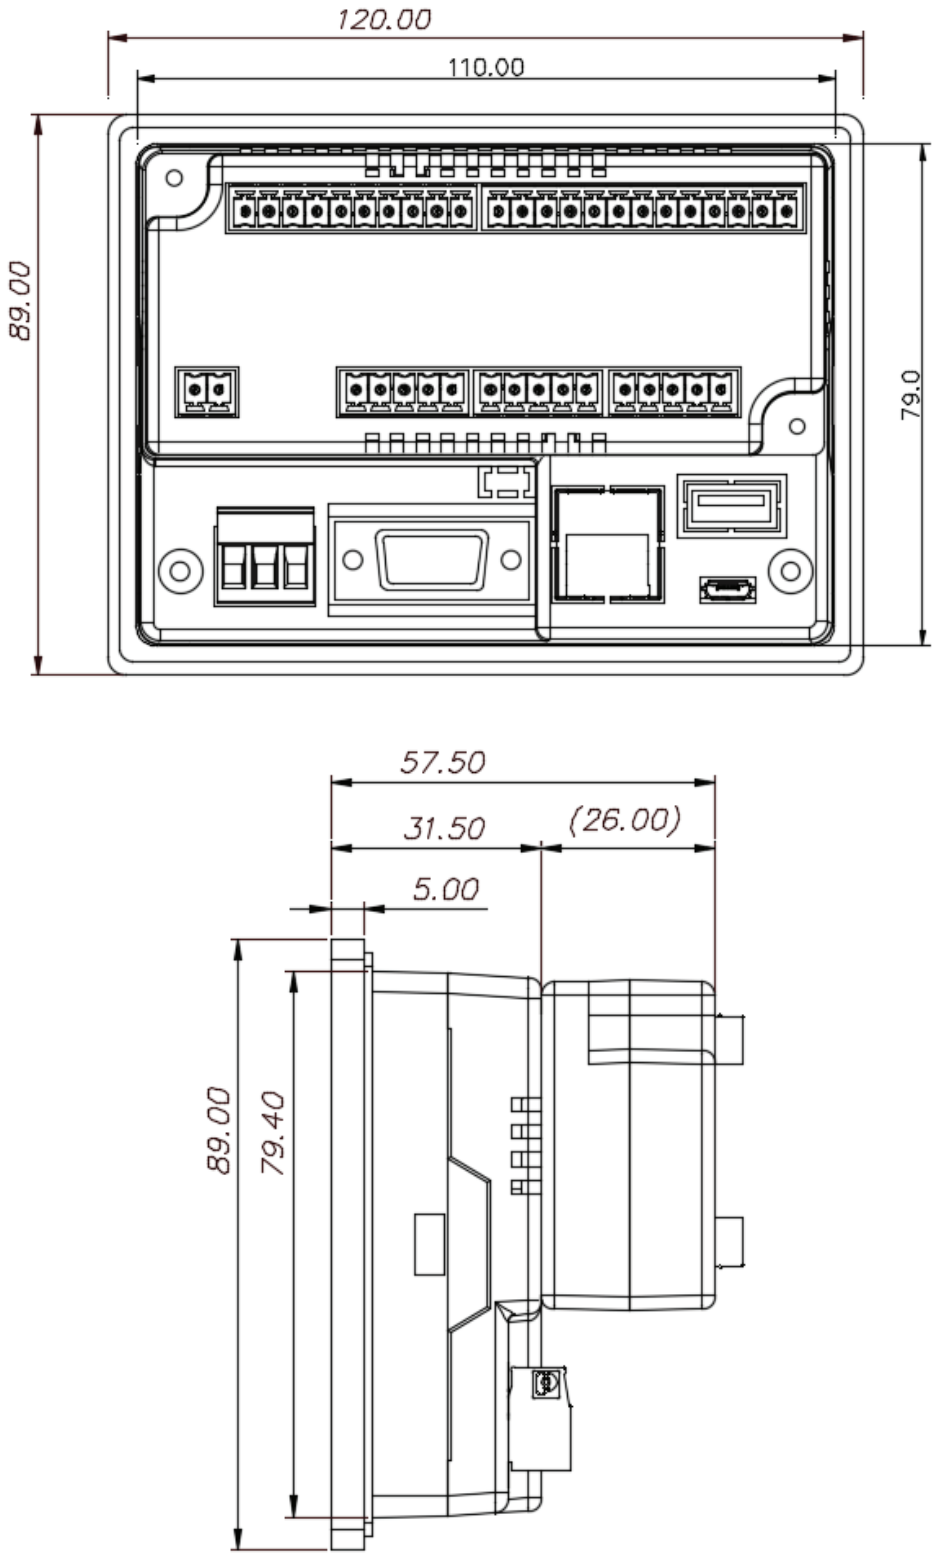

Figure 4 ARM XL Unit Dimensions

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

6.2 PANEL CUTOUT

The panel which the ARM XL is to mounted in must not be greater than 5 mm (0.2 “) thick.

1. Make a panel cut-out measuring 111.0 x 80.0mm (4.4” x 3.1”)

Please use the self-adhesive template provided in ARM XL box or create your own template using the measurements above

2. Slide the ARM XL into the cut-out.
3. Push the mounting brackets into their slots on the side of the unit.
4. Tighten the bracket screws against the panel. Hold the bracket securely against the unit while tightening the screw.
5. When properly mounted, the ARM XL is squarely situated in the panel cut-out.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

7. CONNECTIONS

7.1 CAUTION

Do not touch live wires.

Install an external circuit breaker. Guard against short-circuiting in external wiring.

Use appropriate circuit protection devices.

Unused pins should not be connected. Ignoring this directive may damage the ARM XL.

Double-check all wiring before turning on the power supply.

To avoid damaging the wire, do not exceed a maximum torque of 0.5 N·m (5 kgf·cm).

Do not use tin, solder, or any substance on stripped wire that might cause the wire strand to break.

Install at maximum distance from high-voltage cables and power equipment.

7.2 POWER SUPPLY

- The ARM XL requires a 24VDC power supply ±15% (20.4 to 27.6) 300mA max
- The power supply must include double insulation. Outputs must be rated as SELV/PELV/Class 2/Limited Power.
- Use separate wires to connect the functional earth line (pin 3) to the system earth ground.
- Do not connect either the 'Neutral' or 'Line' signal of a 110/220 VAC source to the ARM XL
- In the event of voltage fluctuations or non-conformity to power supply voltage specifications, connect the ARM XL to a regulated power supply.

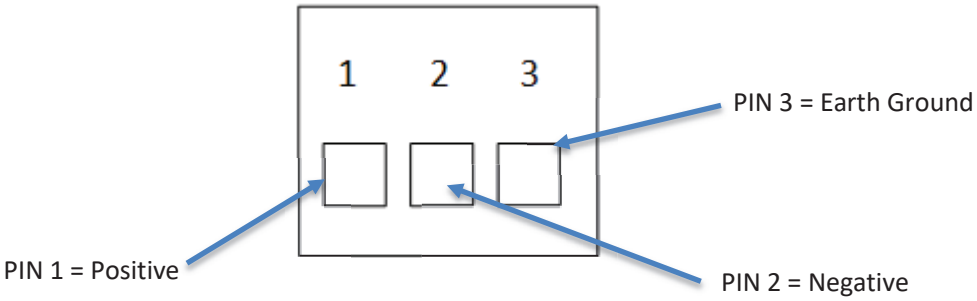

Figure 5 Power Supply Connections

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

7.3 RELAY OUTPUTS

The ARM XL has 2 sets of relay outputs. These are located on the lower set of terminals on the expansion module on the rear of the ARM XL. Set 1 on terminals Y2, Y3, Y4, Y5 and set 2 on terminals Y6, Y7, Y8, Y9.

Terminals COM1 & COM2 are common inputs for these relays. See Figure 6 Relay Outputs below.

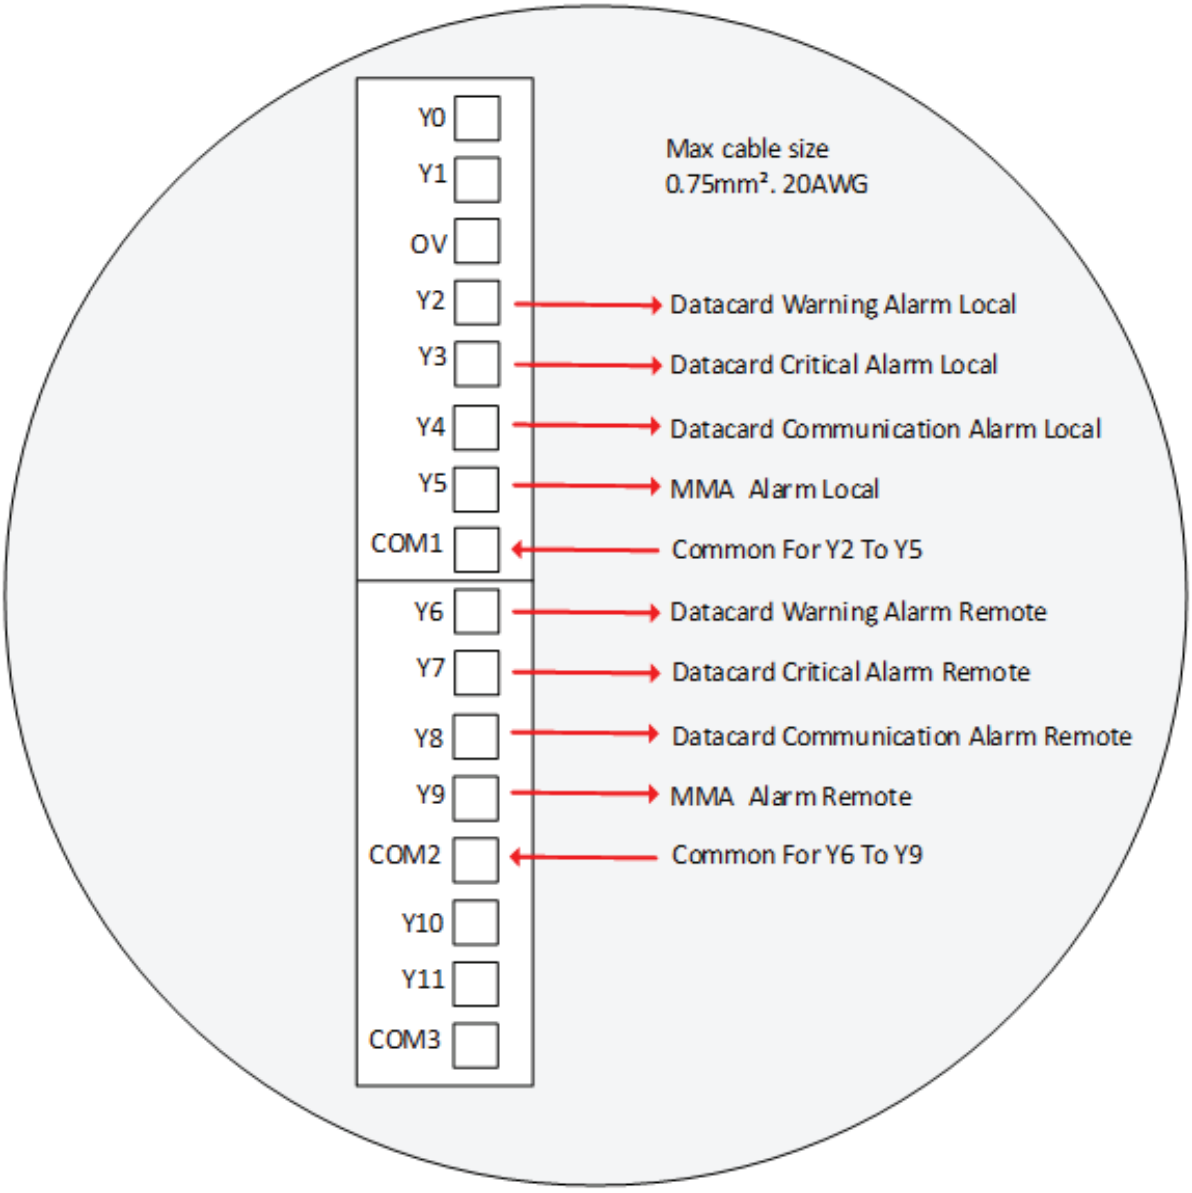

Figure 6 Relay Outputs

These relays are **all** rated to 2Amp at 230v ac.

These 2 sets of relays allow for both local and remote indication of alarms i.e. 1 set for local e.g. klaxon / flashing beacon, and the second for contact inputs to BMS or SCADA systems.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

7.4 COMMUNICATION / CONNECTIVITY WITH EXERTHERM DEVICES

The ARM XL allows for the connection of:

- 8ch Datacards - up to a maximum of 10 (80 Exertherm IR or Cable Sensors), and/or
- up to 60 MCC drawer/bucket MMDs via up to 5 MMAs (12 MMDs per MMA).

Both the 8ch Datacard & the MMA connect to the ARM XL via a pre-manufactured cable (part no. 800455) which is supplied as part of the ARM XL.

This cable has a maximum length of 3metres (10 feet) and should not be cut or extended.

This cable has 2 connectors, 1 is an RJ45 for connecting to the port on the 8ch Datacard or MMA labelled 'X0' and the second is a DB9 male for connecting to the ARM XL's port labelled 'COM1' as shown below in Figure 7.

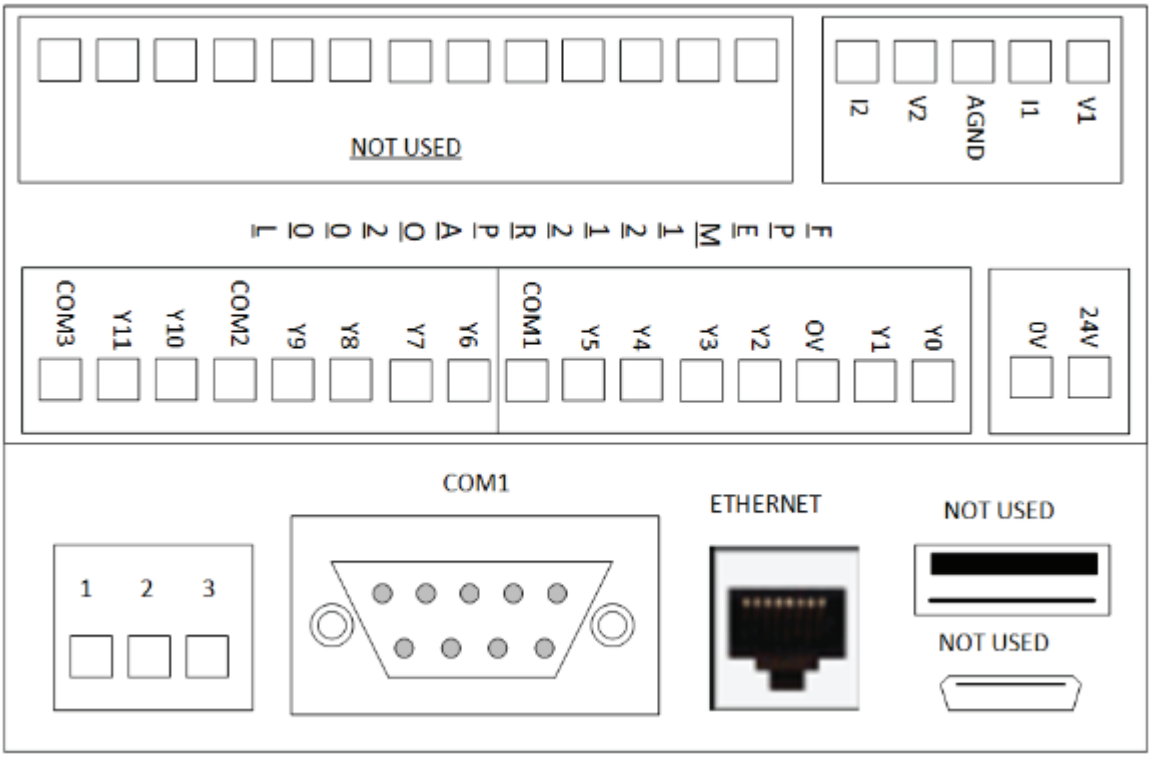

Figure 7 Communication to Exertherm Devices – RJ45 to COM1

All communication is set to operate at 9600 (9k6) baudrate only and cannot be adjusted.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

7.4.1 EXERTHERM DEVICE NUMBERING

8ch Datacards MUST only be numbered from 10 through to 19, MUST be sequential and always start at 10.

MMAs MUST be numbered from 20 through to 24, MUST be sequential and always start at 20.

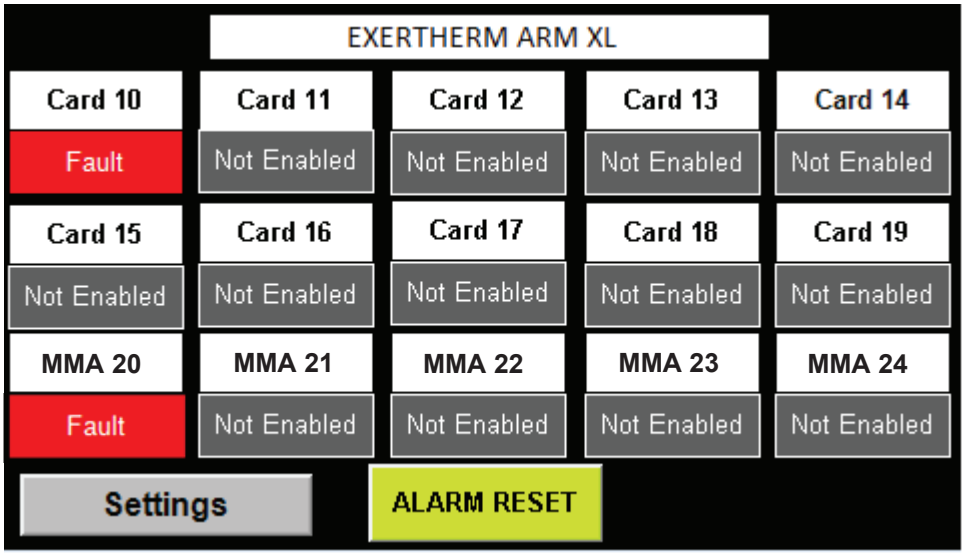
- There can be a maximum of 12 MMDs connected to any single MMA. The 12 MMDs can only be numbered 1 through to 12 and must be sequential and always start at 1.

There can be no gaps in the numbering.

E.g. if we have 4 of the 8ch Datacards in the setup we must use sequential numbering 10, 11, 12, 13

If 8ch Datacard numbers are not sequential, e.g. 10, 11, 13, 14 this will cause communication alarms on 8ch Datacards 13 & 14 (from where the numbering sequence is broken).

E.g. if we have 3 MMAs in the setup we must use sequential numbering 20,21,22



If MMA numbers are not sequential, e.g. 20,21,23 this will cause communication alarms on the MMAs 23,24 (from where the numbering sequence is broken).

7.4.2 COMMUNICATION ALARMS

The ARM XL constantly monitors the communication to each 8ch Datacard / MMA and if lost, will recheck this 3 times before reporting a failure.

Once a failure of communication to any of the devices connected is detected, the relevant relays will energise and the Home View screen will identify which devices are in Comms alarm and the yellow 'Alarm Reset' button will appear at the bottom of the screen – e.g. the screen below shows a system with both 8ch Datacards & MMAs in fault, see Figure 8.

This is reporting a communication fault on Card 10 and MMA 20.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

Figure 8 Communication Alarm

Reason for Comms alarm:

Network broken:

- A broken network will affect the 8ch Datacards / MMAs at the breakpoint and all subsequent enabled devices in the numbered addressing sequence.
    - e.g. if Datacards 10, 11 & 12 and MMA 20 are enabled, and the network was broken at Datacard 11, the system would report a Comms Fault at the network break point Datacard 11.
    - It will then issue a Comms alarm for any enabled 8ch Datacards / MMAs past the break point following on in the numbered addressing sequence e.g. Card 12 & MMA 20 (see Figure 9 below).

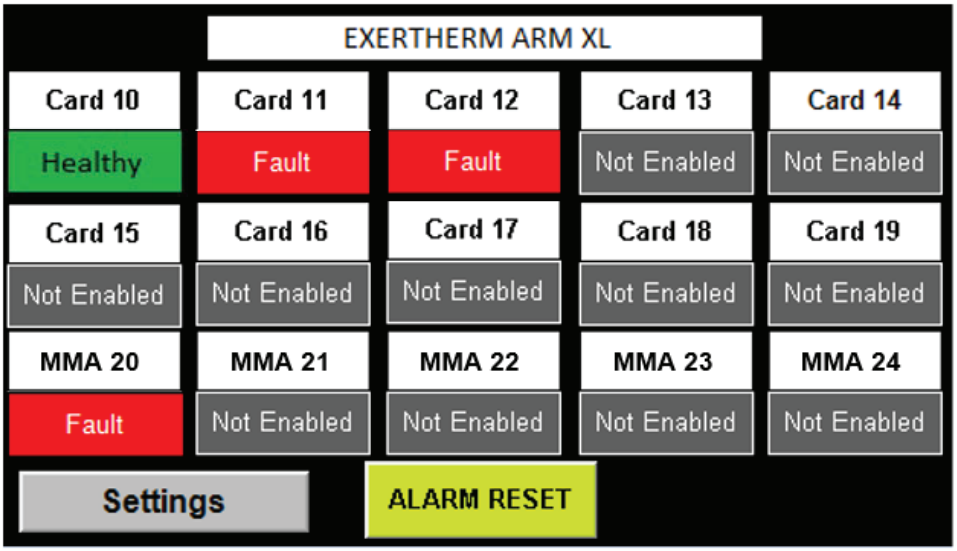


Figure 9 Comms alarm - Network Broken

Power Failure:

- Lost power or power failure will only affect the 8ch Datacard / MMA that has power issues.
- Following example in Figure 9, e.g. if Datacard 11 lost power or failed and Datacard 12 was powered and connected, then only Datacard 11 would return a Comms Fault and Datacard 12 & MMA 20 would operate as normal.

Each scan of the program will attempt to regain communication to any failed 8ch Datacards / MMAs until they are either repaired or disabled, at this point the Comms alarm can be reset by pressing the yellow 'Alarm Reset' button, the relays will then de-energise and clear.

If an 8ch Datacard / MMA is enabled that does not exist, this will generate a Comms alarm.

To reset, disable the 8ch Datacard / MMA:

- For 8ch Datacard see Section 8.1.1

- For MMA see Section 8.1.2

- For both 8ch & MMA see Section 8.1.3

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

8. CONFIGURATION AND SETUP

The ARM XL is pre-configured with no programming tools or PLC knowledge required. There is a set of basic screen views which are described as follows:

8.1 INITIAL SETUP / CONFIGURATION

On initial setup/configuration you do NOT need to be logged in to select the choice of hardware or to enable/disable devices.

For first power up, the initial setup/configuration screen will appear.

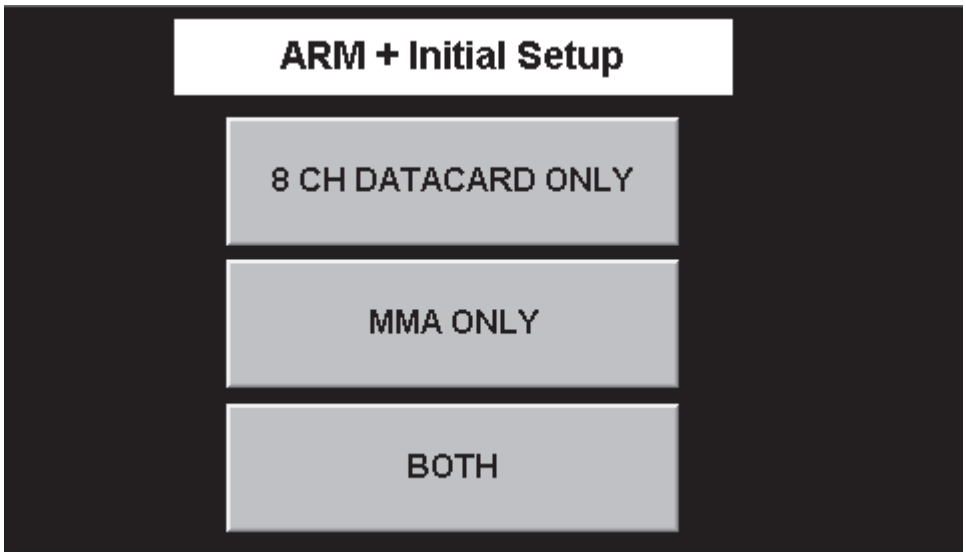

Figure 10 ARM XL Initial Setup/ Configuration

This screen provides the user with the ability to select which hardware they wish the ARM XL to communicate with.

There are 3 options to choose from:

- 8ch Datacard only (this is the correct selection for Exertherm IR & Cable Sensors)
- MMA only (this is the correct selection for MCC drawer/bucket solution - MMDs)
- Both

Pressing the selected hardware button from the 3 options above will take you to the relevant hardware Enabling / Disabling screen. Follow the relevant hardware enabling/disabling device instructions:

- For 8ch Datacard see Section 8.1.1
- For MMA see Section 8.1.2
- For Both see Section 8.1.3

This main configuration screen also has a 'Beep disable/enable' button which mutes the touch screen sound.

NOTE: As default, sound is disabled.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

NOTE:

It is strongly recommended that prior to the ARM XL set up process, the physical location of each 8ch Datacard & Sensor and/or MMA & MMD is recorded as part of the configuration process.

For 8ch Datacard - See Section 9.5

For MMA – See Section 10.4.2

Only enable 8ch Datacards / MMAs which have already been configured as part of the system commissioning process, and which are connected to the ARM XL.

Do not enable 8ch Datacards or MMAs that are not connected, as this will cause false communication alarms.

8.1.1 ENABLING / DISABLING 8CH DATACARDS ONLY

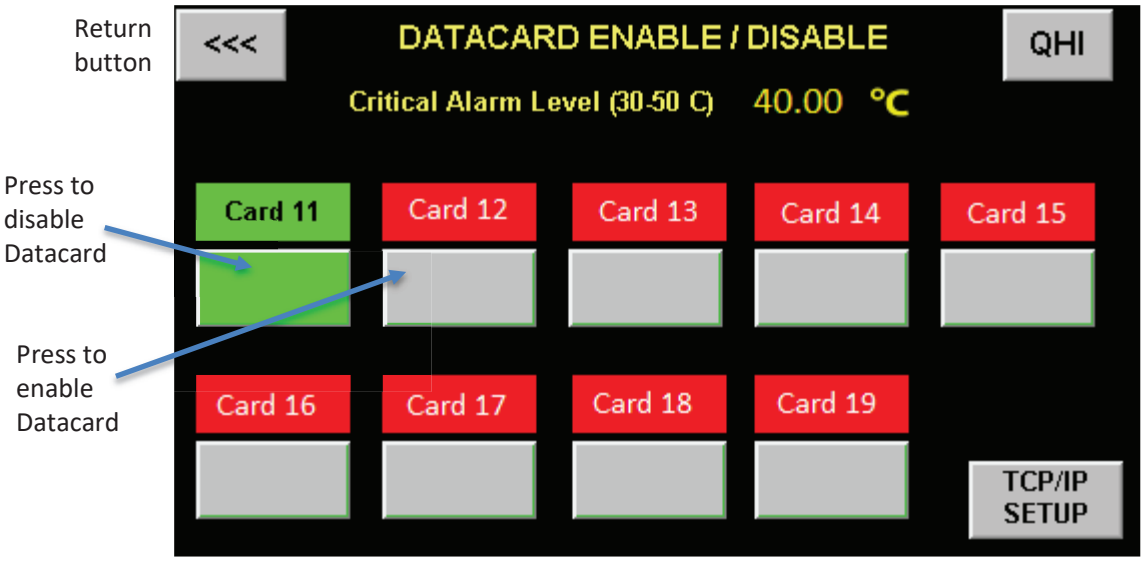

Figure 11 Initial Setup / Config - Enabling/Disabling 8ch Datacards only

On this screen, disabled 8ch Datacards will show with the Card number in a red button, and the button below in grey.

To Enable communication from a 8ch Datacard to the ARM XL, press the grey button under the relevant Card number and both buttons will turn green as shown on Card 11 in Figure 11.

To Disable communication from a 8ch Datacard to the ARM XL, press the green button under the relevant Card number. The Card number button will then turn red, and the button below will be grey.

Once all required 8ch Datacards are enabled continue to the 'Home / 8ch Datacard view' screen by pressing the Return button in the top left corner of the screen.

IMPORTANT:

To operate the system, it is essential one 8ch Datacard is enabled.

As 8ch Datacards must be enabled & addressed sequentially, it follows that 'Card 10' must always be enabled.

Therefore, it is not shown on the above screen in Figure 11 so that it cannot be disabled.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

However, 'Card 10' will still show on the 'Home / 8ch Datacard View' screen so that Comms / Temperature alarms remain visible.

8.1.2 ENABLING / DISABLING MMA'S ONLY

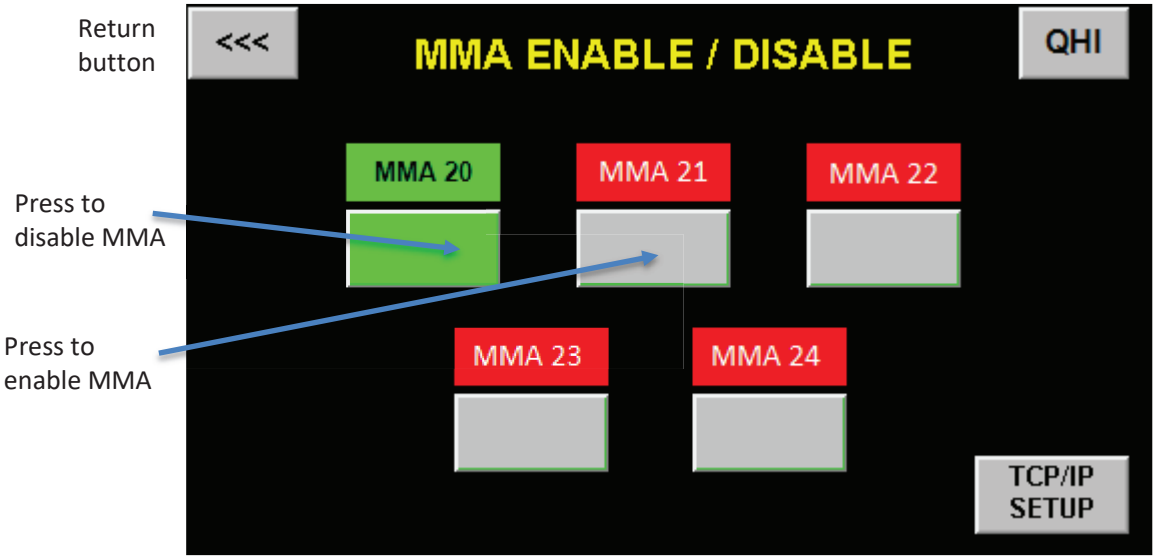

Figure 12 Enabling / Disabling MMA only

On this screen, disabled MMAs will show with the MMA number in a red button, and the button below in grey.

To Enable communication from an MMA to the ARM XL, press the grey button under the relevant MMA number and both buttons will turn green as shown on MMA 20 in Figure 12 above.

To Disable communication from a MMA to the ARM XL, press the green button under the relevant MMA number. The MMA number button will then turn red, and the button below will be grey.

Once all required MMAs are enabled continue to the 'Home / MMA view' screen by pressing the Return button in the top left corner of the screen.

IMPORTANT:

All MMAs must be enabled & addressed sequentially, MMAs can only be numbered from 20 through to 24, and always start at 20.

There can be a maximum of 12 MMDs connected to any single MMA. The 12 MMDs can only be numbered 1 through to 12 and must be sequential and always start at 1.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

8.1.3 ENABLING / DISABLING BOTH 8CH DATACARDS & MMA'S

On this screen, there is a choice of both 8ch Datacards & MMAs.

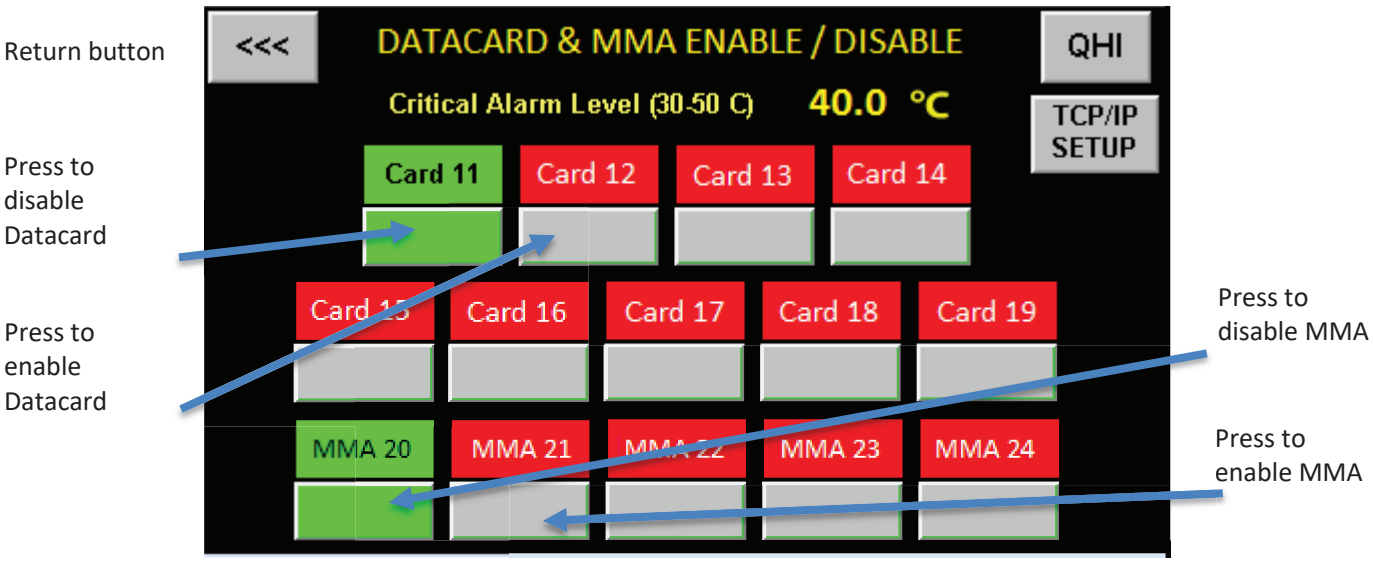

Figure 13 Enabling / Disabling both 8ch Datacards & MMAs

8ch Datacards

To Enable communication from a 8ch Datacard to the ARM XL, press the grey button under the relevant Card number and both buttons will turn green as shown on Card 11 in Figure 13.

To Disable communication from a Datacard to the ARM XL, press the green button under the relevant Card number. The Card number button will then turn red, and the button below will be grey.

Once all required 8ch Datacards are enabled continue to the 'Home / 8ch Datacard & MMA view' screen by pressing the Return button in the top left corner of the screen.

IMPORTANT - DATACARD:

To operate the system, it is essential one 8ch Datacard is enabled.

As 8ch Datacards must be enabled & addressed sequentially, it follows that 'Card 10' must always be enabled.

Therefore, it is not shown on the above screen in Figure 13 so that it cannot be disabled.

However, 'Card 10' will still show on the 'Home / 8ch Datacard & MMA view' screen so that Comms / Temperature alarms remain visible.

MMAs

To Enable communication from an MMA to the ARM XL, press the grey button under the relevant MMA number and both buttons will turn green as shown on MMA 20 in Figure 13.

To Disable communication from a MMA to the ARM XL, press the green button under the relevant MMA number. The MMA number button will then turn red, and the button below will be grey.

Once all required MMAs are enabled continue to the 'Home / 8ch Datacard & MMA view' screen by pressing the Return button in the top left corner of the screen.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

IMPORTANT - MMA:

All MMAs must be enabled & addressed sequentially, MMAs can only be numbered from 20 through to 24, and always start at 20.

There can be a maximum of 12 MMDs connected to any single MMA. The 12 MMDs can only be numbered 1 through to 12 and must be sequential and always start at 1.

8.2 CHANGING HARDWARE SELECTION

If you wish to change and/or add to the main hardware selection:

- a mistake has been made and you wish to change the hardware selection e.g. 8ch Datacard has been selected, when actually MMA should have been selected.
  OR
- you wish to add another hardware option to the existing hardware selected on the system e.g. existing system is 8ch Datacards only, and in addition you wish to add MMAs.

8.2.1 CHANGING HARDWARE SELECTION PROCEDURE

To make changes / additions to the hardware selection you must be logged in as a high-level user by following the below steps:

1. From the relevant hardware 'Home' screen, pressing the 'Settings' button in the lower left-hand corner of the screen will take you to the below screen, Figure 14.

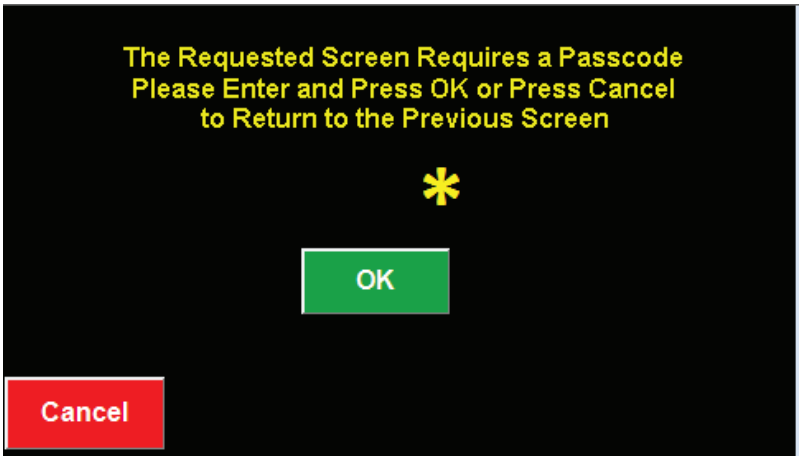

Figure 14 Settings - Initial Password Screen

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

2. From the screen shown in Figure 14 above, press the yellow star, a keypad will then appear

3. Using the numeric buttons on the keypad type in the password: 61123.
4. Then press the 'ENT' key – the following screen will appear

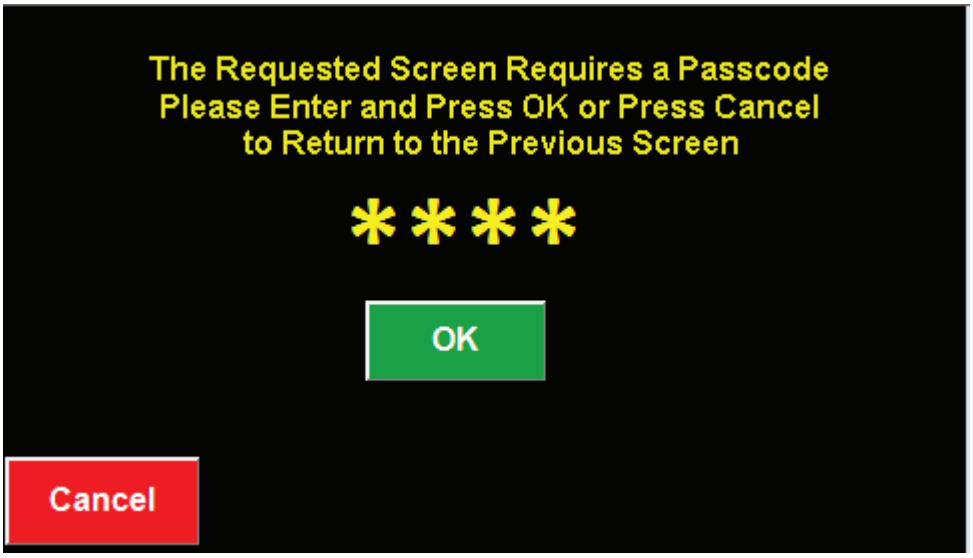

Figure 15 Settings - Password Accepted Screen

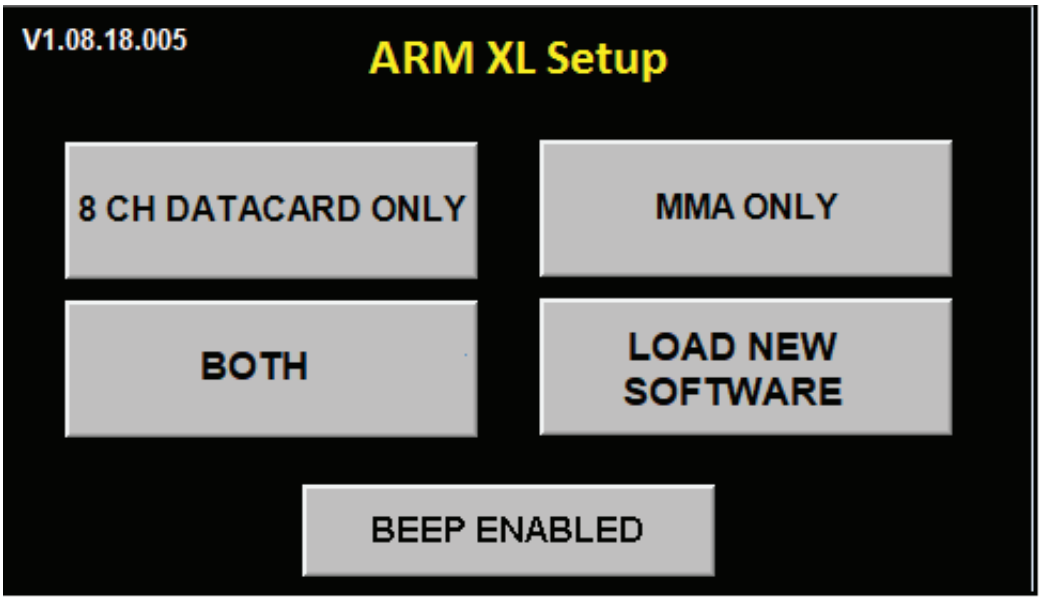

5. Then press the green 'OK' button in Figure 15 above
6. You are now logged in as a high-level user. This will then show you the re-configuration version of the 'Enable / Disable' screen for the hardware originally selected
7. Press the 'QHI' button in the top right corner

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

8. This will then return you to the initial Setup/Configuration screen shown below where you can re-select the choice of hardware from the 3 options.

9. Then follow the relevant hardware enabling/disabling device instructions.
    - For 8ch Datacard see Section 8.1.1
    - For MMA see Section 8.1.2
    - For Both see Section 8.1.3

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

ONCE INITIAL SETUP / CONFIGURATION IS COMPLETE, PLEASE NOW CONTINUE TO THE RELEVANT SECTION TO FOLLOW VIEWING & USING INSTRUCTIONS FOR YOUR SELECTED HARDWARE

USER GUIDE FOR 8CH DATACARD ONLY – PLEASE GO TO SECTION 9

USER GUIDE FOR MMA ONLY – PLEASE GO TO SECTION 10

USER GUIDE FOR BOTH 8CH DATACARD & MMA – PLEASE GO TO SECTION 11

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9. USER GUIDE– ARM XL & 8CH DATACARD ONLY

9.1 HOME / 8CH DATACARD VIEW SCREEN

Once the system has been configured & required 8ch Datacards enabled, Figure 16 below will be the main user viewing screen. This screen will then appear whenever the ARM XL is powered up.

The Home/ 8ch Datacard view screen shows the status of each 8ch Datacard, including alarms for temperature or communication for each 8ch Datacard enabled on the system.

8ch Datacards not enabled, will show as below e.g. Card 12.

8ch Datacards with no alarms will be displayed as 'Healthy' with a green button as shown below e.g. Card 10 & Card 11.

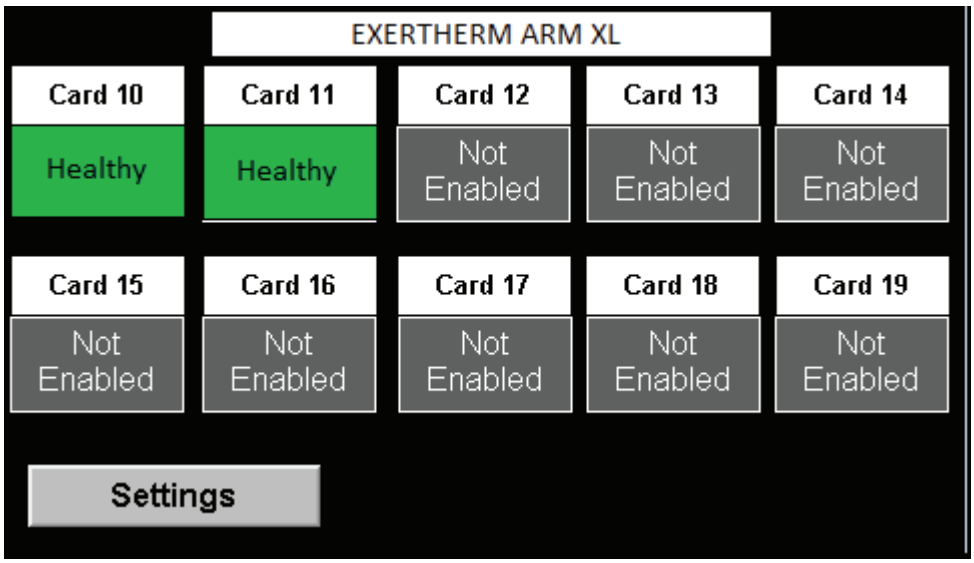

Figure 16 Home / 8ch Datacard View Screen

The 'Alarm Reset' button re-sets the alarm contacts when an alarm condition has been resolved.

The 'Alarm Reset' button only appears when there is an active alarm condition. This button will be displayed centrally at the bottom of the screen.

The 'Settings' button takes you to 8ch Datacard Enable / Disable screen (for more detail please see Section 8.1.1).

The 'Home / 8ch Datacard View' screen also provides access to each enabled 8ch Datacard with real-time sensor values and warning alarms.

From the Home / 8ch Datacard view screen, press the button for the 8ch Datacard you wish to view e.g. Card 10.
The screen as shown in Figure 17 will appear.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9.1.1 SENSOR VIEW & WARNING ALARMS

Sensor view: Down the left side are the sensor channels, which are numbered 1 through 8. The next column indicates the real-time ΔT temperature values for each Sensor in °C.

Sensor names e.g. Sensor 1, can be edited:

- This is done by pressing on the Sensor name e.g. Sensor 1
- A keypad will then appear (see Figure 18 below)
- Enter the unique Sensor name
    - Sensor names can include letters, numbers and symbols but can only be a maximum of 8 characters long e.g. CB2/A/L1
- Once you have keyed in the new name, press 'ENT' to confirm name

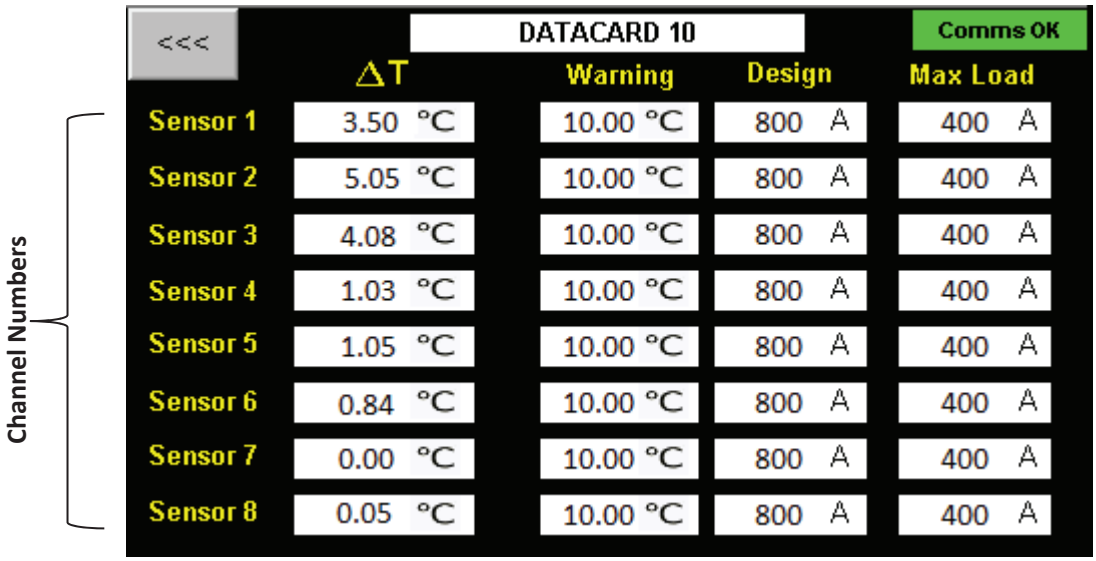

Figure 17 Sensor View & Warning Alarms

Figure 18 8ch Datacard - Sensor name change keypad

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

To change the Design and Maximum load values, you must be logged in as detailed in Section 9.2.

Once logged in, return to the Datacard Home screen, and then select the Datacard which values are to be altered.

Design and Max load values can be edited by:

- Pressing on the white box for the relevant Sensor number for either Design or Max Load
- A keypad will then appear

- Enter the required value
- Once you have keyed in the new value, press 'ENT' to confirm

The column 'Warning' is the load related calculated ΔT alarm threshold from the LoadMap® algorithms. This field is not user adjustable but utilises the Design A & Max Load data to calculate this value.

- Design A – is the design load (Amps) of the circuit on which the joint being monitored resides and should be entered by clicking on the relevant box and entering the appropriate value in Amps.
- Max Load – is the maximum load at which the circuit being monitored is expected to operate at, and should be entered by clicking on the relevant box and entering the appropriate value in Amps.

The Design A & Max Load values must be entered for each Sensor

NOTE: If Load data for any sensor is unknown then a generic alarm threshold of ΔT 22°C can be set by entering in the Design A column a value of 800A and in the Max Load column a value of 600A.

Press the 'Return' button in the top left corner of the screen to go back to the Home / 8ch Datacard View screen.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9.1.2 VIEWING WARNING ALARMS

If a Sensor value exceeds the warning alarm threshold the Home / 8ch Datacard View screen view will change as in Figure 19 below.

The status indicator below the Card number will change to show 'Fault' on a Red background.

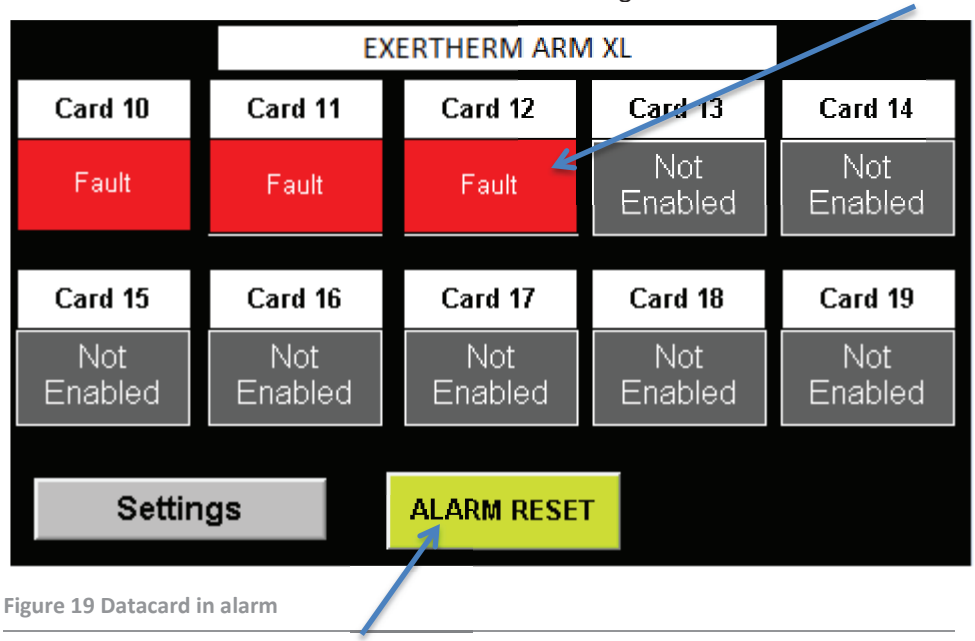

Figure 19 Datacard in alarm

At the same time the 'Alarm Reset' button will appear at the bottom of the screen in Yellow with the word 'Alarm Reset' and the relevant relays will activate.

All alarms are set with a 1 minute time delay to stop the system from 'chattering' and causing false alarms. A Sensor must be in an alarm state for over 1 minute for the relays to operate.

To view the Sensor in alarm – press the red 'Fault' button below the Card number button which is in alarm.
The Sensor View screen will appear as below in Figure 20. A yellow warning indicator box will be shown next to the Sensor in alarm.

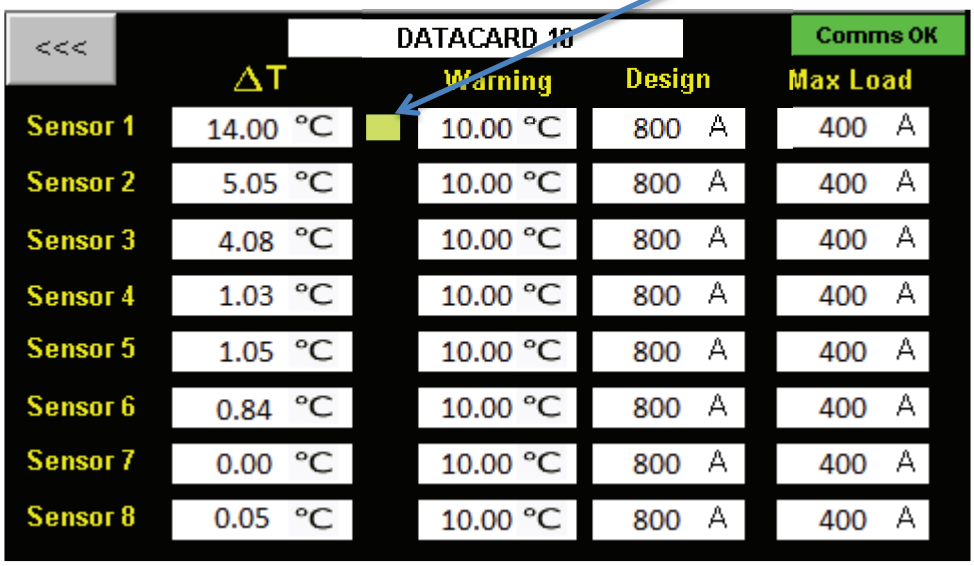

Figure 20 Sensor view - Sensor showing warning alarm

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

When the alarm clears and the 8ch Datacard status returns to green & 'Healthy' both the output relays will remain energised until they are reset by pressing the yellow 'Alarm Reset' button on the Home / 8ch Datacard View screen as shown below in Figure 21.

This will reset the relays and the 'Alarm Reset' button will disappear.

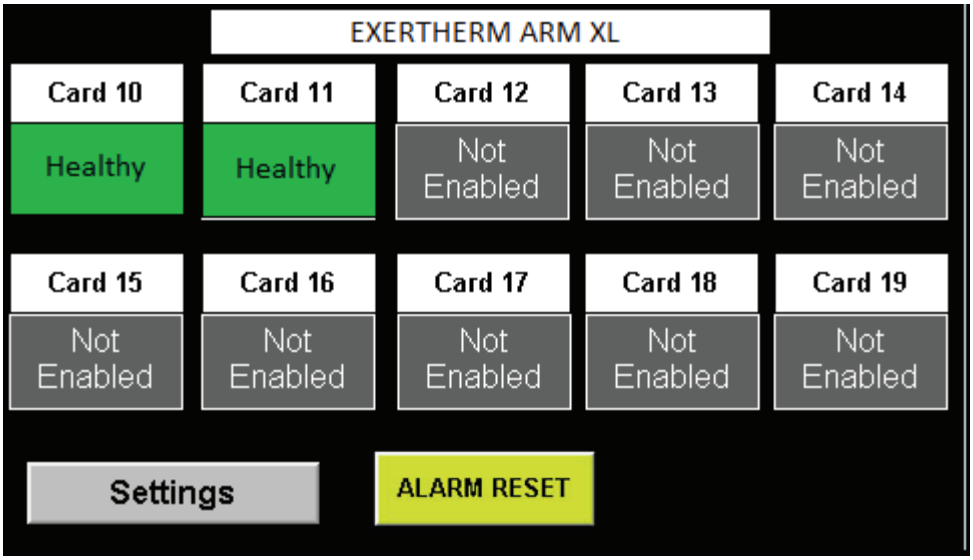

Figure 21 Warning Alarm Reset

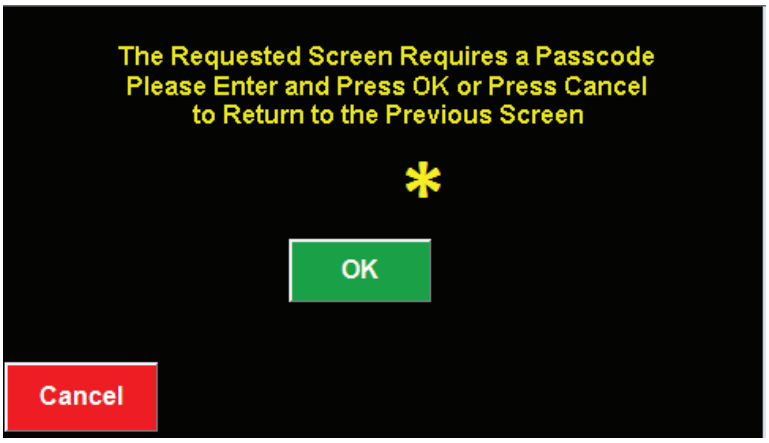
©Exertherm 2021

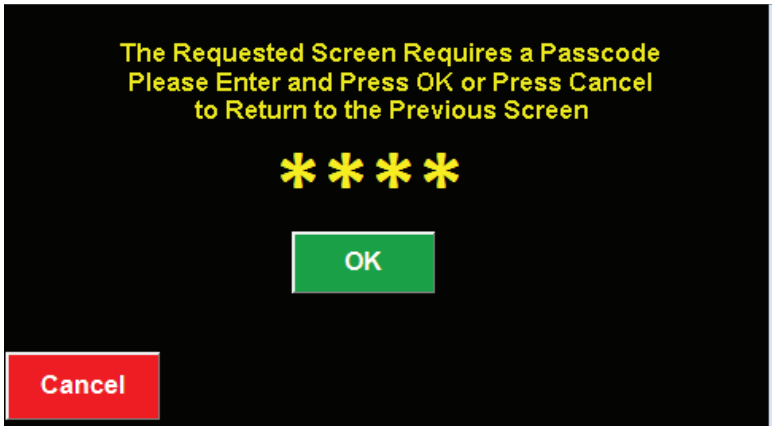


Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9.2 SYSTEM SETTINGS

To access system settings you will need to login.
This will allow you to access the following functions:

- **Enable / Disable 8ch Datacards**
- **Set critical alarm level**
- **Set TCP/IP settings**



1. From the 'Home / 8ch Datacard view' screen, pressing the 'Settings' button in the lower left-hand corner will take you to the below screen.

2. From the screen shown above press the yellow star, a keypad will then appear

3. Using the numeric buttons on the keypad type in the password: 1582.
4. Then press the 'ENT' key – the following screen will appear

5. Then press the green 'OK' button

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

6. You are now logged in as a standard user. This will then show you the Settings version of the '8ch Datacard Enable / Disable' screen as shown in Figure 22 in Section 9.2.1.

9.2.1 ENABLE / DISABLE 8CH DATACARDS

First login as detailed in Section 9.2.

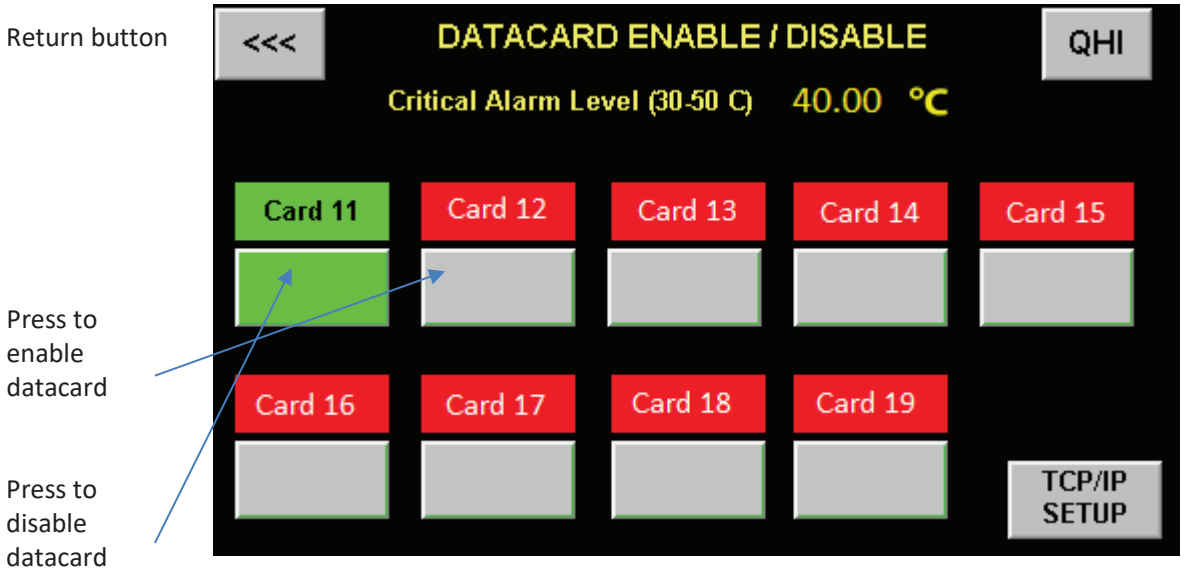


Figure 22 System Settings - Enabling/Disabling 8ch Datacards only

On this screen, disabled 8ch Datacards will show with the Card number in a red button, and the button below in grey.

To Enable communication from a 8ch Datacard to the ARM XL, press the grey button under the relevant Card number and both buttons will turn green as shown on Card 11 in Figure 22.

To Disable communication from a 8ch Datacard to the ARM XL, press the green button under the relevant Card number. The Card number button will then turn red, and the button below will be grey.

Once all required 8ch Datacards are enabled continue to the 'Home / 8ch Datacard view' screen by pressing the Return button in the top left corner of the screen.

IMPORTANT:

To operate the system, it is essential one 8ch Datacard is enabled.

As 8ch Datacards must be enabled & addressed sequentially, it follows that 'Card 10' must always be enabled.

Therefore, it is not shown on the above screen in Figure 22 so that it cannot be disabled.

However, 'Card 10' will still show on the 'Home / 8ch Datacard View' screen so that Comms / Temperature alarms remain visible.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9.2.2 SET CRITICAL ALARM LEVEL

First login as detailed in Section 9.2.

The Critical alarm has a default threshold of Delta T (ΔT) 40°C which applies to **ALL** sensors.

It is user-configurable between ΔT 30-50°C.

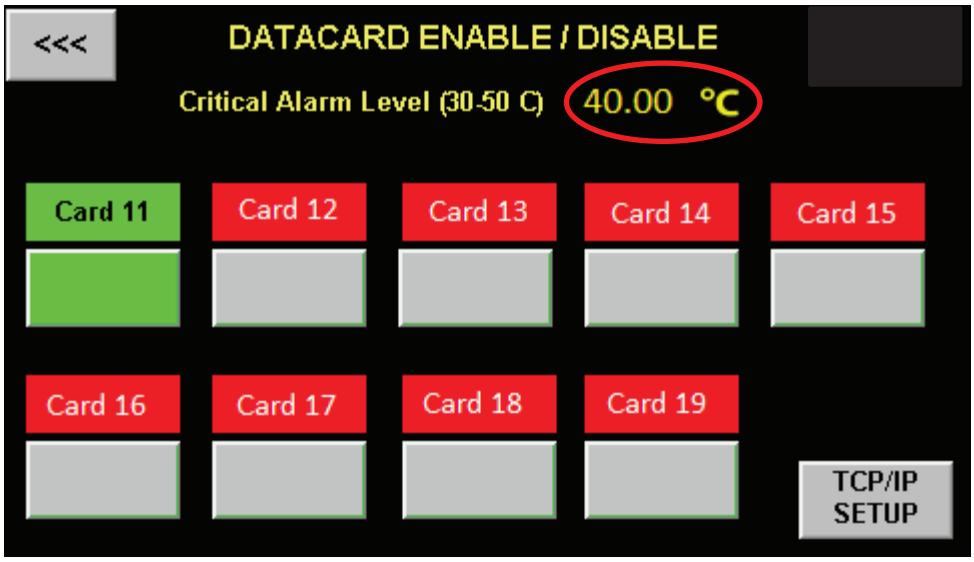

Figure 23 Setting Critical Alarm Level

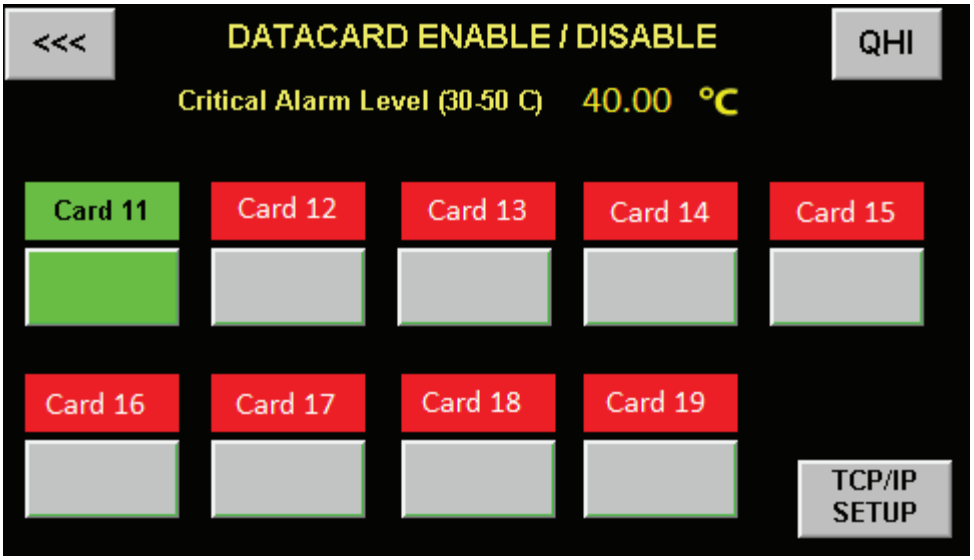
IMPORTANT: ALL temperature values are Delta T (ΔT) °C e.g. rise of target temperature above the local ambient

To edit the critical alarm level, press the alarm threshold value as circled above. The keypad as shown below will then appear:

- Insert the new critical alarm threshold value required e.g. 30.00
- and press the 'ENT' button
- you will then be returned to the '8ch Datacard Enable / Disable' screen
- the new critical alarm threshold will now be applied to all Sensors connected to the ARM XL



©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

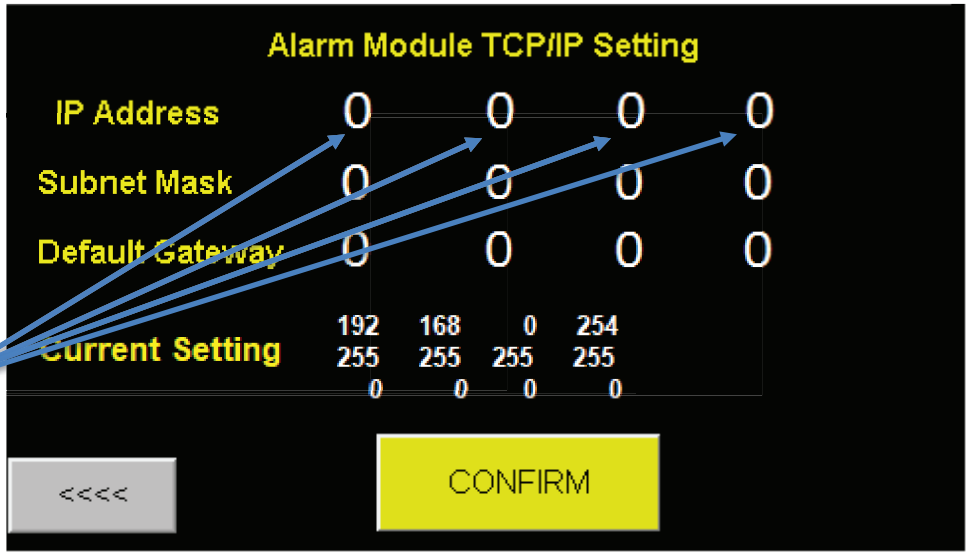
9.2.3 8CH DATACARD - SET TCP / IP SETTINGS

First login as detailed in Section 9.2.

1. From the '8ch Datacard Enable / Disable' screen press the 'TCP/IP Setup' button

2. The following address screen will appear (see Figure 24 below), the IP address is split into 4 separate segments.

By touching the relevant segment of the IP address, the keypad will pop up and you can then enter the relevant portion of the IP address individually



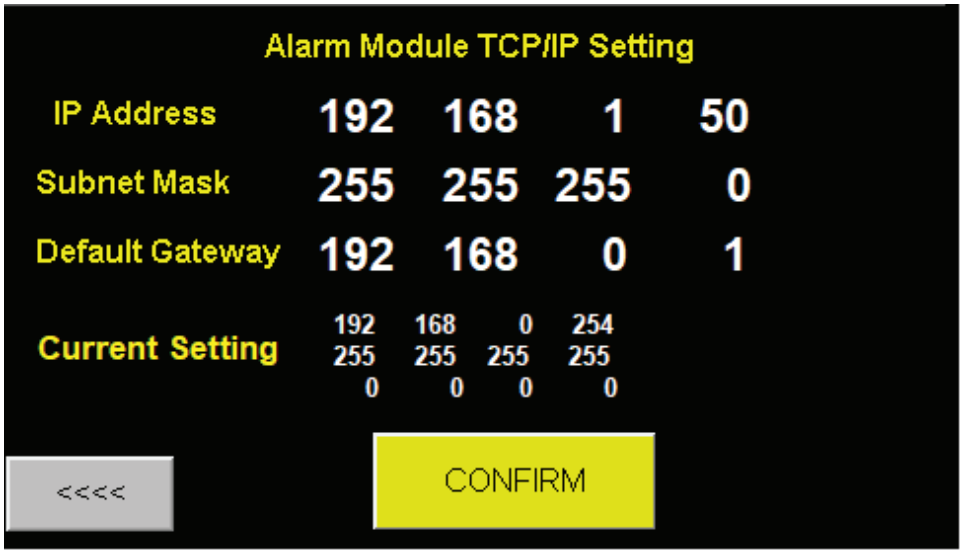


Figure 24 ARM XL TCP/IP Setting

3. Enter the Modbus TCP/IP address by first touching the relevant segment and then enter the relevant portion of the IP address. Existing settings are shown under heading 'Current Setting' as above.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

4. As in the IP address below, an example address has been entered – 192.168.1.50
5. Repeat the same process for the Subnet Mask and IP Gateway.
6. The screen will then show as below (example addresses have also been entered for Subnet Mask & Default Gateway)

7. Once this information has been entered press the yellow 'CONFIRM' button that will then enter the information into system.
8. Then press the 'return' button in the bottom left hand corner to take you back to the '8ch Datacard Enable / Disable' screen.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9.3 OBTAINING RAW DATA FROM THE ARM XL

Raw data in Modbus TCP/IP protocol can be obtained from the ARM XL via the following actions:

1. Ensure TCP/IP settings have been entered as per instruction in 9.2.3
2. Then connect an Ethernet cable into the Port circled in red below on the rear of the ARM XL, as shown in Figure 25 .
3. Then connect the other end of the cable to a suitable host system connection point.

The Modbus TCP uses standard Port 502 for communication and the ARM XL is set as device 1

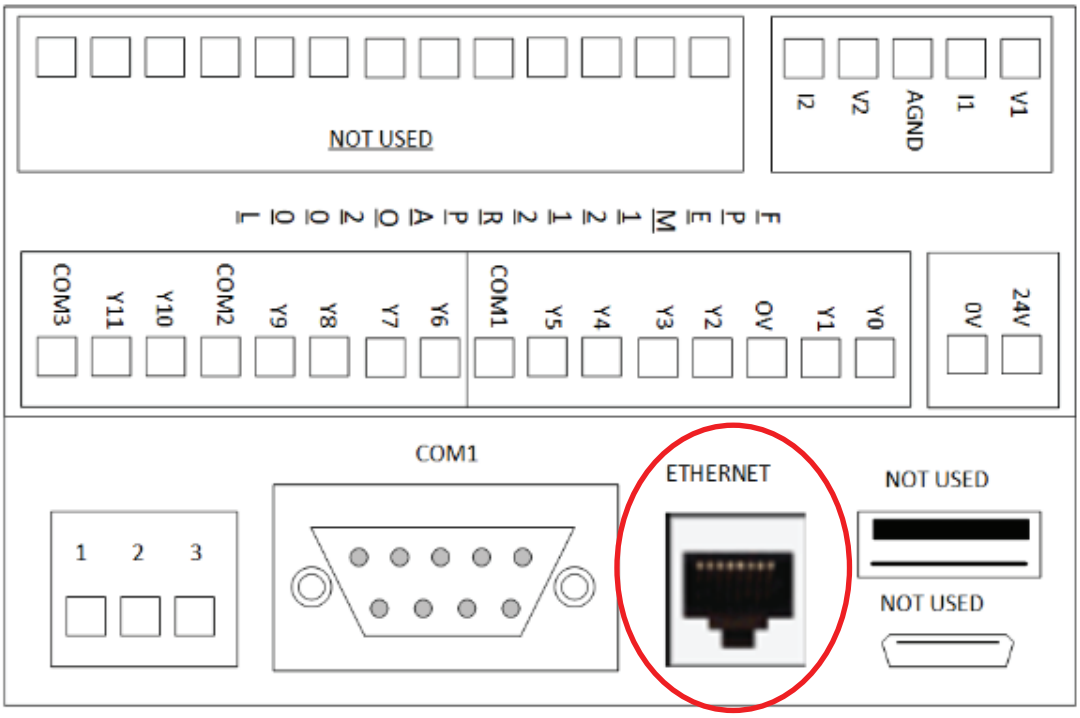

Figure 25 ARM XL Ethernet Port

To read the Sensor registers please refer to Table 1 in Section 9.4 which shows the Modbus holding registers. The registers require a 0.1 multiplier to read the correct value, e.g. if the register reads a raw data value of 150, then use 150 * 0.1 to read the correct register value of 15°C ΔT.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

10. USER GUIDE – ARM XL & MMA ONLY

10.1 HOME / MMA VIEW SCREEN

Once the system has been configured & required MMA's enabled, Figure 26 below will be the main user viewing screen. This screen will then appear whenever the ARM XL is powered up.

The Home/MMA view screen shows the status of each MMA, including alarms for temperature or communication for each MMA enabled on the system.

MMAs not enabled, will show as below e.g. MMA 21.

MMAs with no alarms will be displayed as 'Healthy' with a green button as shown below e.g. MMA 20.

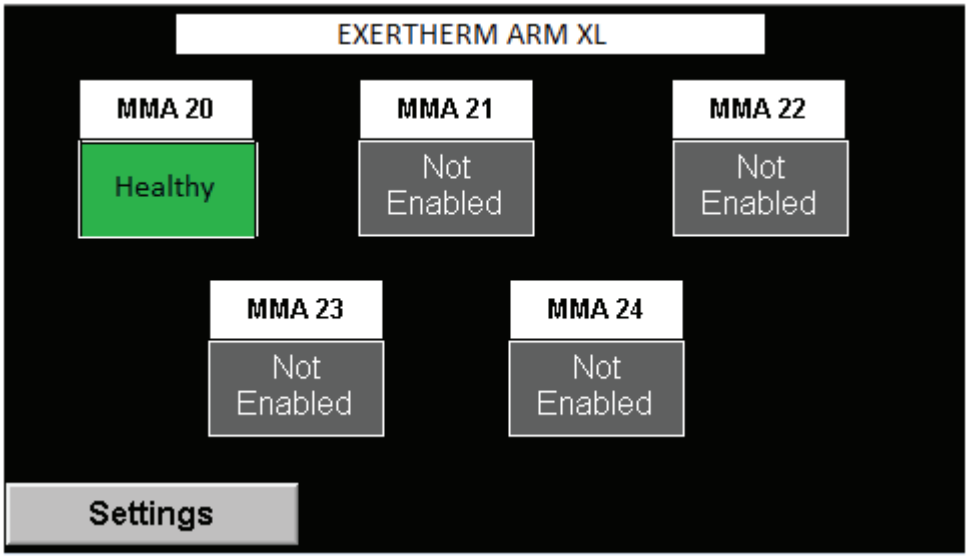

Figure 26 Home / MMA View Screen

The 'Settings' button takes you to MMA Enable / Disable screen. For more detail please see Section 8.1.2.

The Home / MMA view screen also provides access to the status of each MMD on the system, this screen is accessed by pressing on the button below the card number for the relevant enabled MMA.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

10.1.1 MMD STATUS SCREEN

Once you have pressed the button of the MMA you wish to view, the following screen will appear – see below Figure 27.

Only MMDs installed on the system will show with a green ‘healthy’ button as shown in MMDs 1-4 below.

Any MMDs in alarm will show with a red ‘Fault’ button, as show in MMD 3 below.

From the MMD View Screen press the ‘Healthy’ button for the MMD you wish to view e.g. MMD 1 which will take you to Figure 28 on the next page.

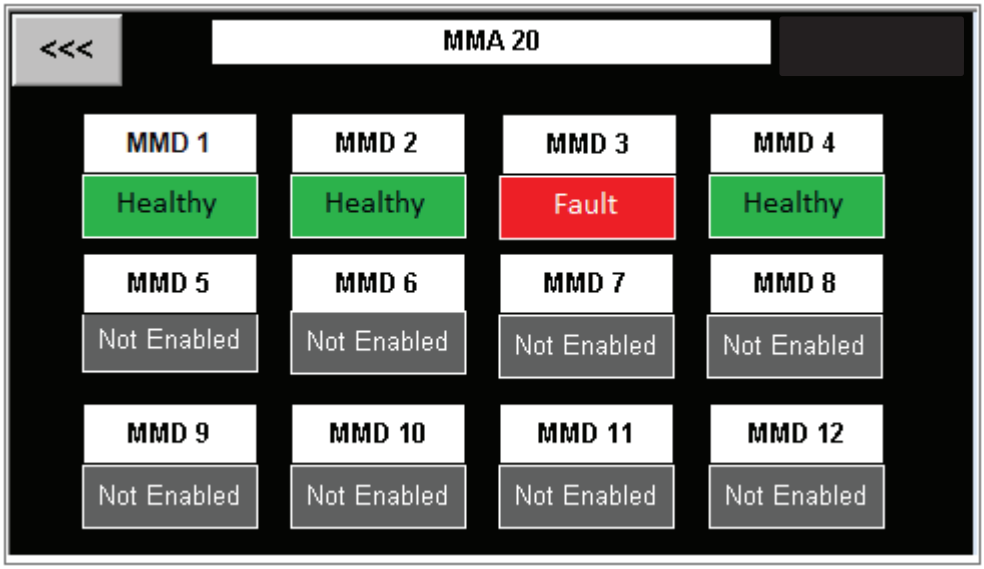

Figure 27 MMD View Screen

Pressing the ‘Fault’ button of the MMD in alarm will take you to Figure 29 (Section 10.1.2), which will signify which sensor is in alarm and in addition, identify the type of alarm.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

10.1.2 MMD SENSOR VIEW & ALARMS

Once you have pressed for the button of the MMD you wish to view as in Figure 27, the following screen will appear – see below Figure 28.

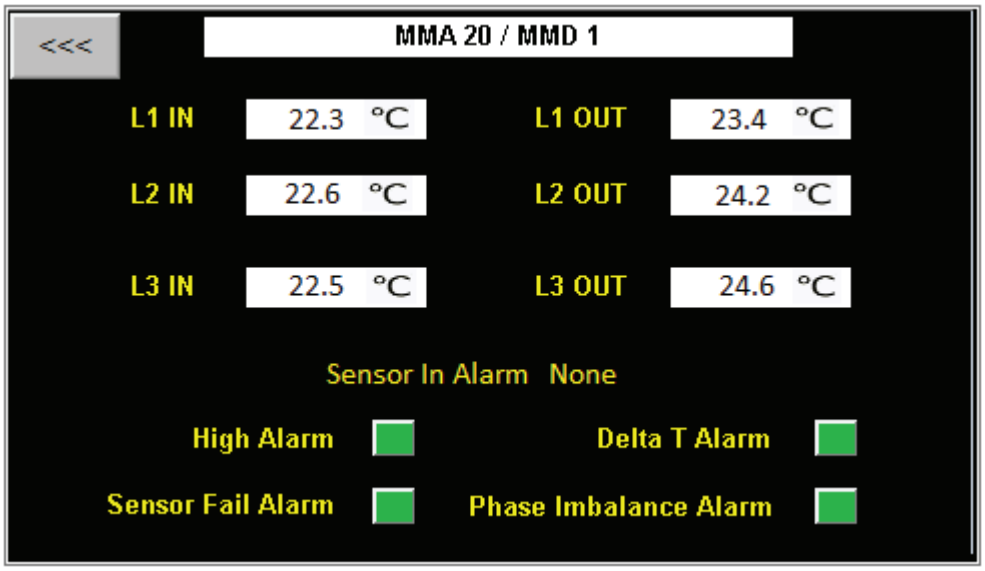

Figure 28 MMD Sensor View & Alarms - Healthy

Sensors are labelled:

- L1 IN, L2 IN, L3 IN
- L1 OUT, L2 OUT, L3 OUT

The white boxes next to the sensor labels indicate the real-time temperature values for each sensor in °C.

NOTE: These values are absolute temperature values

At the bottom of the screen, it shows the four alarm types:

- High Alarm
- Sensor Fail Alarm
- Delta T Alarm
- Phase imbalance Alarm

The small box next to each alarm type signifies the status e.g.

- green = no alarm
- red = active alarm

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

This screen also indicates which sensor is in alarm, the name of the sensor will appear as circled in yellow in Figure 29.
The type of alarm will be specified by the small box next to it turning red to indicate the active alarm e.g. as shown in Figure 29.

NOTE: The location of which sensor is in alarm only shows for High alarm and Delta T Alarm.

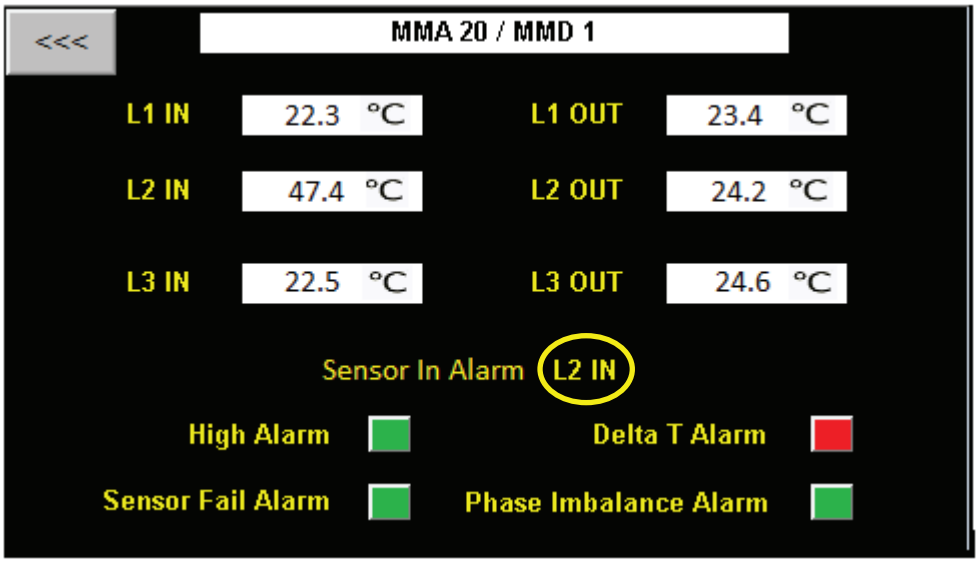

Figure 29 MMD Sensor View & Alarms - Active Alarm

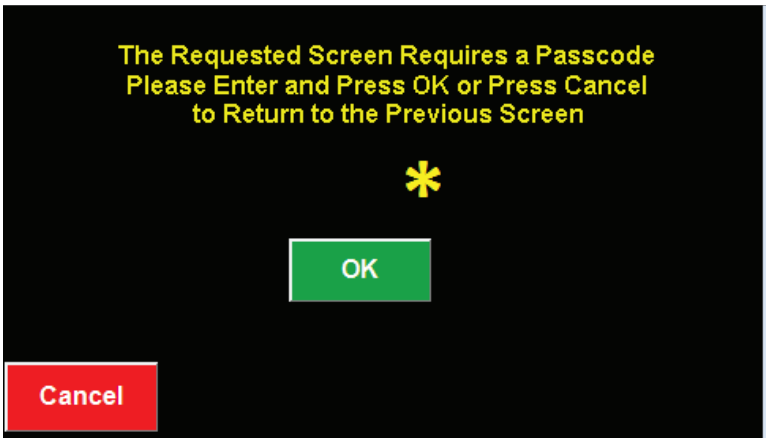
Alarms will only clear when they are re-set on the MMD itself.

NOTE: No re-set for any MMD alarms can be carried out on the ARM XL.

For instructions on how to re-set on the MMD, please see Section 9.4 of the MMS & MMA Installation Setup Manual.

Press the 'Return' button in the top left corner of the screen to go back to the MMD status view (Figure 27 – Section 10.1.1).

©Exertherm 2021

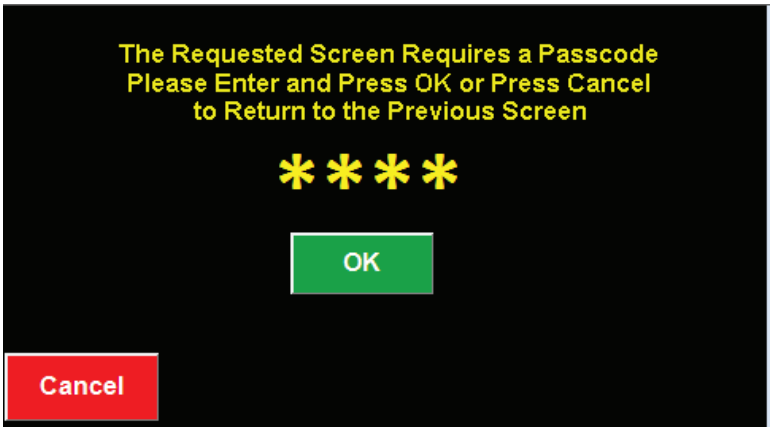


Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

10.2 SYSTEM SETTINGS

To access system settings you will need to login.
This will allow you to access the following functions:

- **Disable / Enable MMAs**
- **Set TCP/IP settings**



7. From the 'Home / MMA view' screen, pressing the 'Settings' button in the lower left-hand corner will take you to the below screen.

8. From the screen shown above press the yellow star, a keypad will then appear

9. Using the numeric buttons on the keypad type in the password: 1582.
10. Then press the 'ENT' key – the following screen will appear

11. Then press the green 'OK' button
12. You are now logged in as a standard user. This will then show you the Settings version of the 'MMA Enable / Disable' screen as shown in Figure 30 Section 10.2.1 on the following page.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

10.2.1 ENABLE / DISABLE MMA

First login as detailed in Section 10.2.

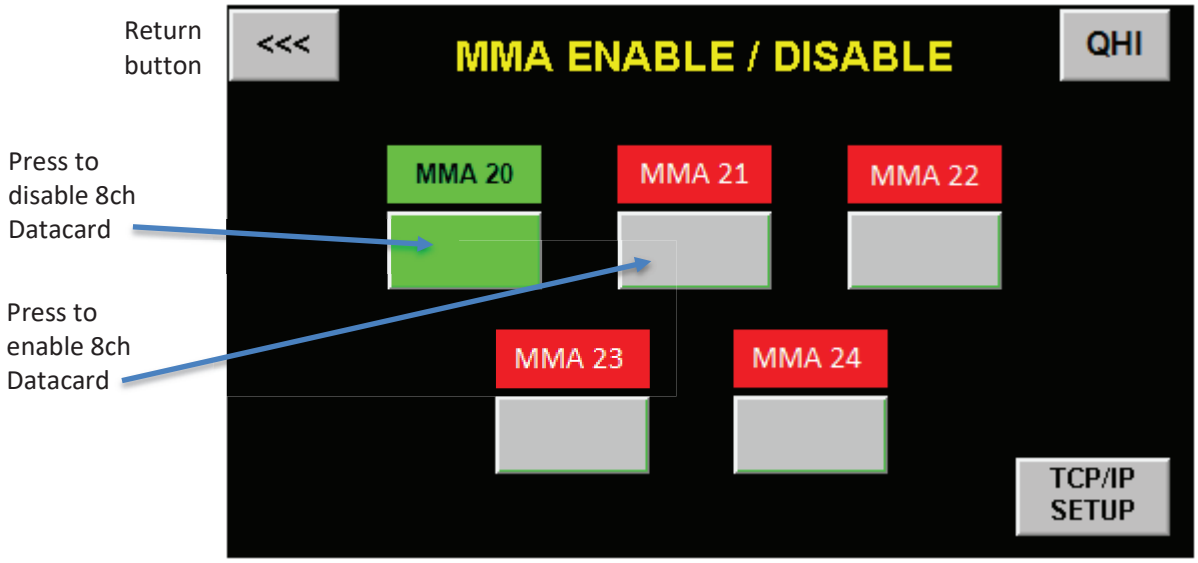


Figure 30 System Settings - Enabling/Disabling MMA only

On this screen, disabled MMAs will show with the MMA number in a red button, and the button below in grey.

To Enable communication from an MMA to the ARM XL, press the grey button under the relevant MMA number and both buttons will turn green as shown on MMA 20 in Figure 30 above.

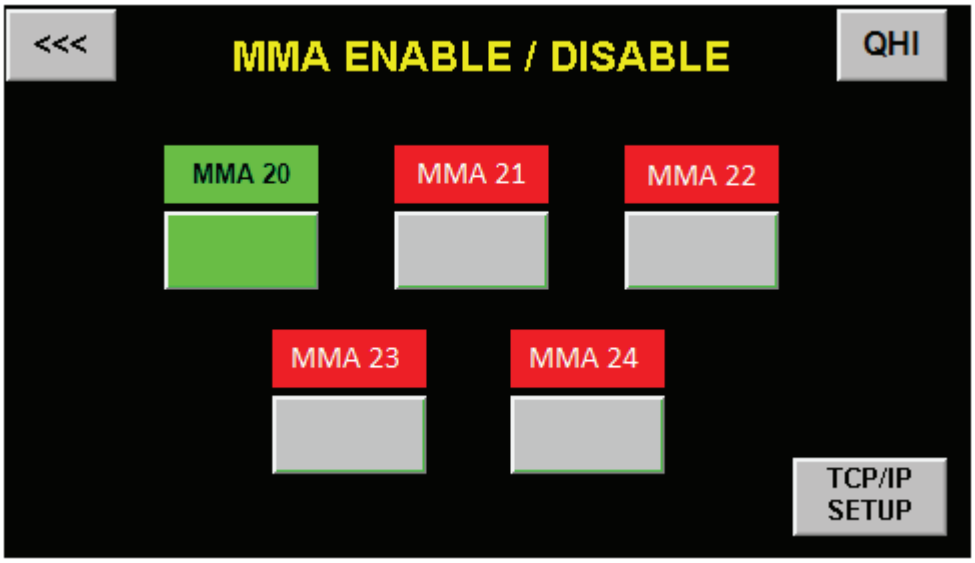
To Disable communication from a MMA to the ARM XL, press the green button under the relevant MMA number. The MMA number button will then turn red, and the button below will be grey.

Once all required MMAs are enabled continue to the 'Home / MMA view' screen by pressing the Return button in the top left corner of the screen.

IMPORTANT:

All MMAs must be enabled & addressed sequentially, MMAs can only be numbered from 20 through to 24, and always start at 20.

There can be a maximum of 12 MMDs connected to any single MMA. The 12 MMDs can only be numbered 1 through to 12 and must be sequential and always start at 1.



©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

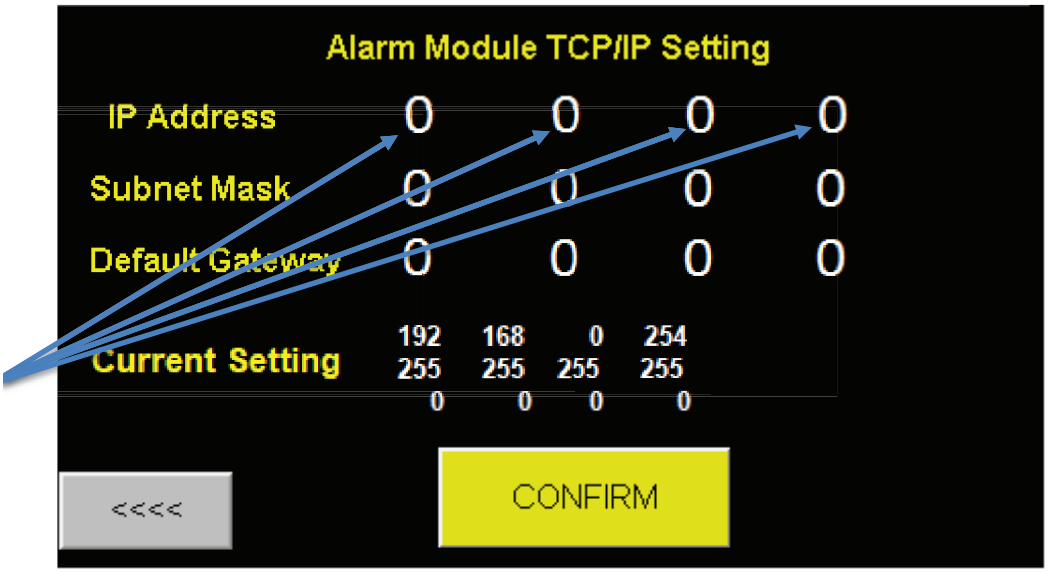
10.2.2 MMA – SET TCP / IP SETTINGS

First login as detailed in Section 10.2

9. From the 'MMA Enable / Disable' screen press the 'TCP/IP Setup' button

10. The following address screen will appear (see Figure 31Figure 24 below), the IP address is split into 4 separate segments.

By touching the relevant segment of the IP address, the keypad will pop up and you can then enter the relevant portion of the IP address individually



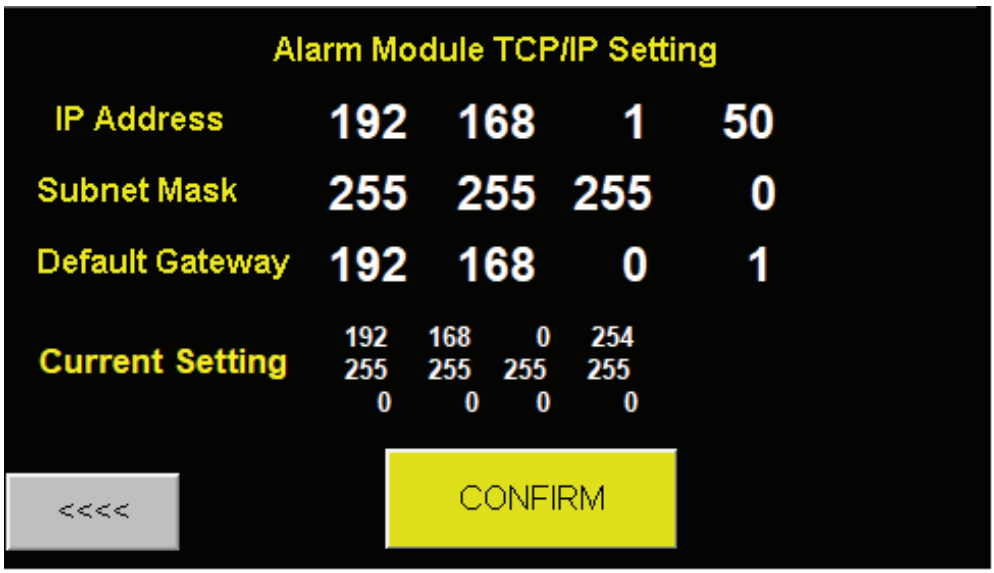


Figure 31 ARM XL TCP/IP Setting

11. Enter the Modbus TCP/IP address by first touching the relevant segment and then enter the relevant portion of the IP address. Existing settings are shown under heading 'Current Setting' as above.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

12. As in the IP address below, an example address has been entered – 192.168.1.50
13. Repeat the same process for the Subnet Mask and IP Gateway.
14. The screen will then show as below (example addresses have also been entered for Subnet Mask & Default Gateway)

15. Once this information has been entered press the yellow 'CONFIRM' button that will then enter the information into system.
16. Then press the 'return' button in the bottom left hand corner to take you back to the 'MMA Enable / Disable' screen.

©Exertherm 2021

10.3 OBTAINING RAW DATA FROM THE ARM XL

Raw data in Modbus TCP/IP protocol can be obtained from the ARM XL via the following actions:

1. Ensure TCP/IP settings have been entered as per instruction in 10.2.2
2. Then connect an Ethernet cable into the Port circled in red below on the rear of the ARM XL, as shown in Figure 32 below.
3. Then connect the other end of the cable to a suitable host system connection point.

The Modbus TCP uses standard Port 502 for communication and the ARM XL is set as device 1

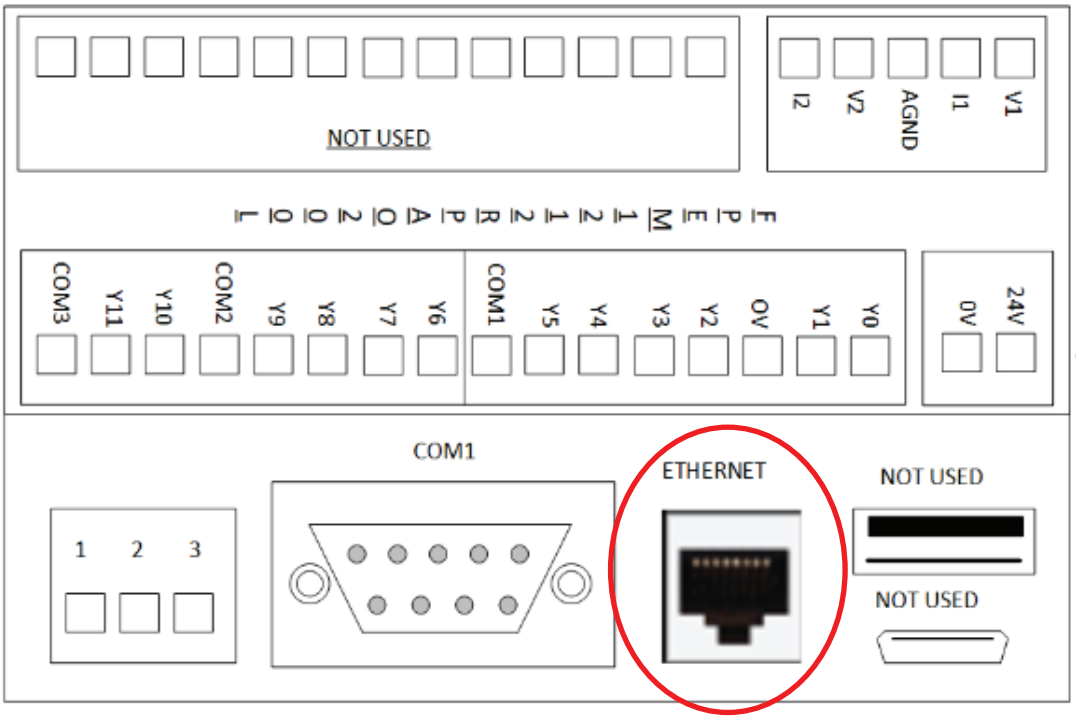

Figure 32 ARM XL TCP/IP Port

To read the Sensor registers please refer to the relevant tables within Section 10.4 on the following page which shows the Modbus holding registers. The registers require a 0.1 multiplier to read the correct value, e.g. if the register reads a raw data value of 150, then use 150 * 0.1 to read the correct register value of 15°C absolute temperature.

11. USER GUIDE – ARM XL WITH BOTH 8CH DATACARD + MMA

11.1 HOME / 8CH DATACARD & MMA VIEW SCREEN

Once the system has been configured & required 8ch Datacards & MMAs have been enabled, Figure 33 below will be the main user viewing screen. This screen will then appear whenever the ARML XL is powered up.

The Home / 8ch Datacard & MMA view screen shows the status of each enabled device, including alarms for temperature or communication.

8ch Datacards:

- 8ch Datacards not enabled, will show was below e.g. Card 12
- 8ch Datacards with no alarms will be displayed as 'Healthy' with a green button as shown below e.g. Card 10.
- 8ch Datacards with alarms with be displayed as 'Fault' with a red button as shown below e.g. Card 11

MMAs:

- MMAs not enabled, will show was below e.g. MMA 22
- MMAs with no alarms will be displayed as 'Healthy' with a green button as shown below e.g. MMA 20.
- MMAs with alarms with be displayed as 'Fault' with a red button as shown below e.g. MMA 21

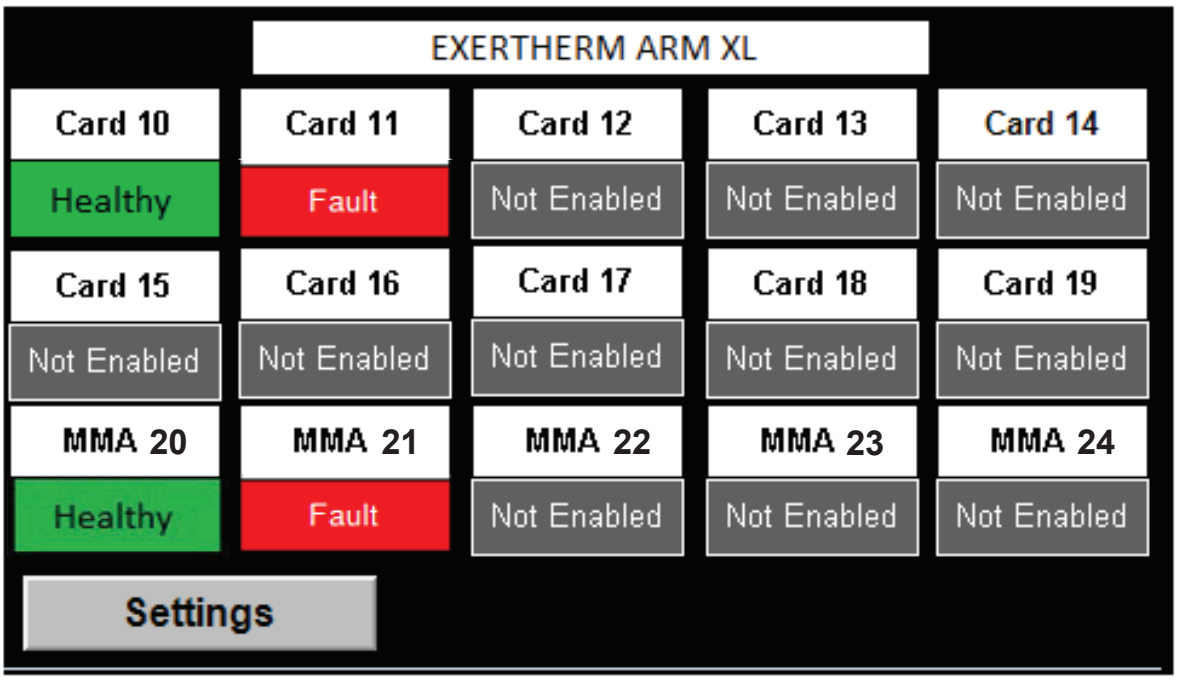

Figure 33 Home / 8ch Datacard & MMA View Screen

The 'Settings' button takes you to the 8ch Datacard & MMA Enable/Disable screen. For more detail please see Section 8.1.3.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

11.1.1 8CH DATACARD & MMA STATUS SCREEN

The Home / 8ch Datacard & MMA view screen also provides access to each enabled device with real-time sensor values and warning alarms.

Datacards

From the Home / 8ch Datacard & MMA view screen, press the button for the 8ch Datacard you wish to view e.g. Card 10.

For further instructions please refer to Section 9 User Guide– ARM XL & 8ch Datacard Only.

PLEASE NOTE:

Although the screen on the ARM XL

Although screens shown in Section 9 only show 8ch Datacards, the screens will show both 8ch Datacards & MMAs – the functionality and instructions remain exactly the same.

MMAs

From the Home / 8ch Datacard & MMA view screen, press the button for the MMA you wish to view e.g. MMA 20.

For further instructions please refer to Section 10 User Guide – ARM XL & MMA Only.

PLEASE NOTE:

Although screens shown in Section 9 only show MMAs, the screens you see will show both 8ch Datacards & MMAs – the functionality and instructions remain exactly the same.

12. UPGRADING ARM XL SOFTWARE

12.1 GETTING STARTED

To begin upgrading the ARM XL Software, you will need a USB memory stick loaded with the latest version of the Software.

Software will be supplied by Exertherm, memory stick must be 4gb or less.

1. Please follow Login instructions detailed in Section 8.2.1
2. When you are then on the relevant hardware's Enable / Disable screen, press the QHI button in the top right hand corner
3. The screen as below will then appear as in Figure 34
4. This screen also shows the current version of the Software in the top left hand corner e.g. V1.08.18.005

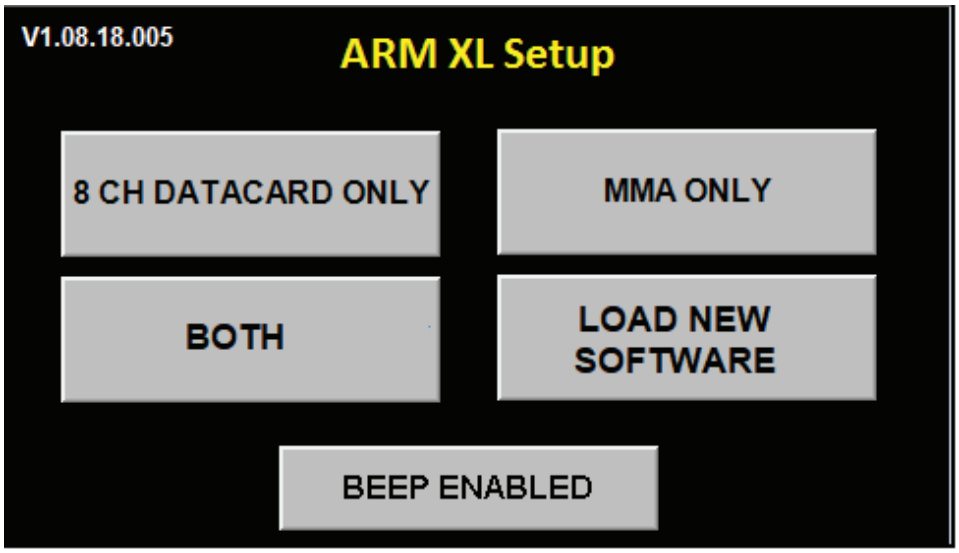

Figure 34 Software Upgrade - ARM XL Setup Screen

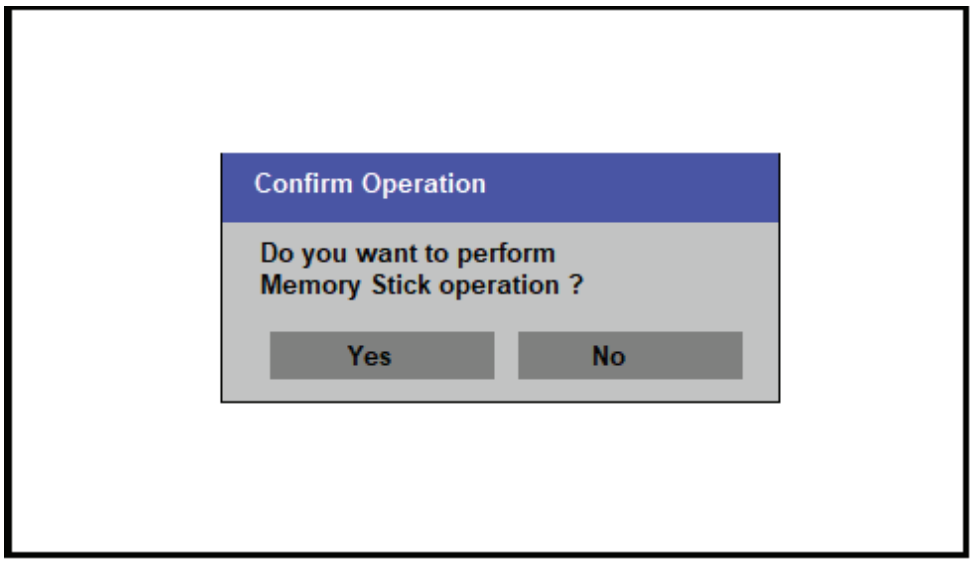
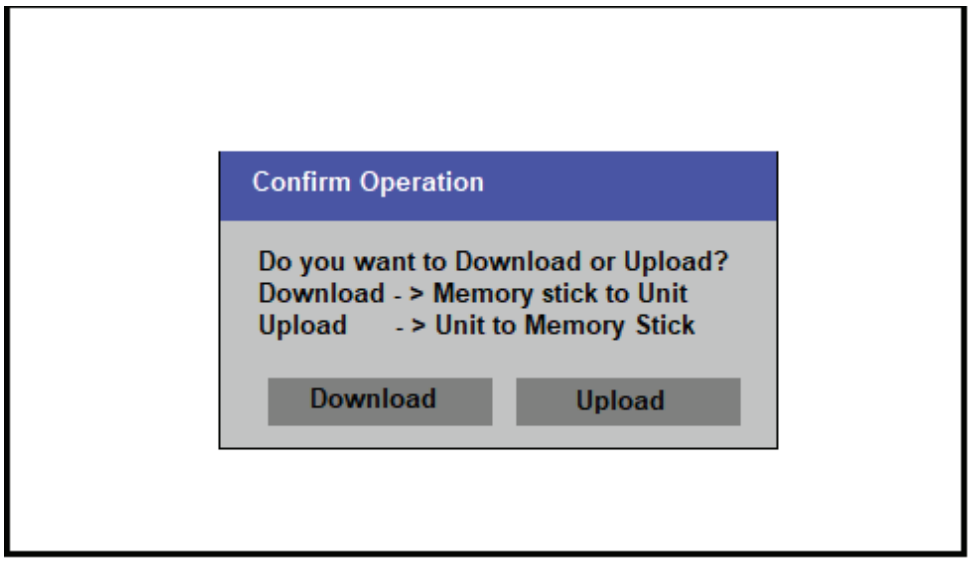
©Exertherm 2021



Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

12.2 ARM XL UPGRADE PROCESS

1. Please insert the USB memory stick into the 'Host' port on the reverse of the ARM XL
2. Press the 'Load New Software' button as shown on Figure 39 above.
3. You will then see the following screen – press 'Yes'

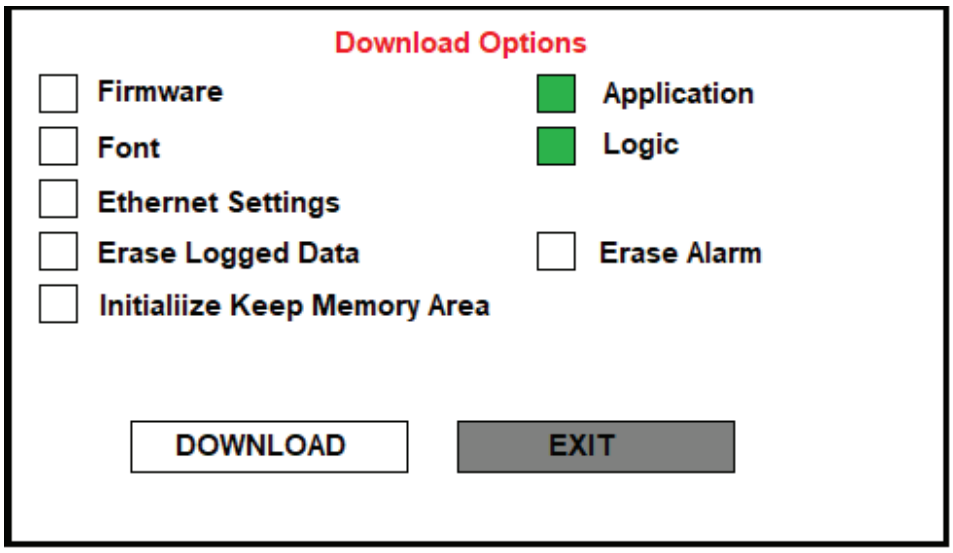


If you do not press anything the ARM XL will time out and re-start.

If you press 'No' the ARM XL will automatically re-start.

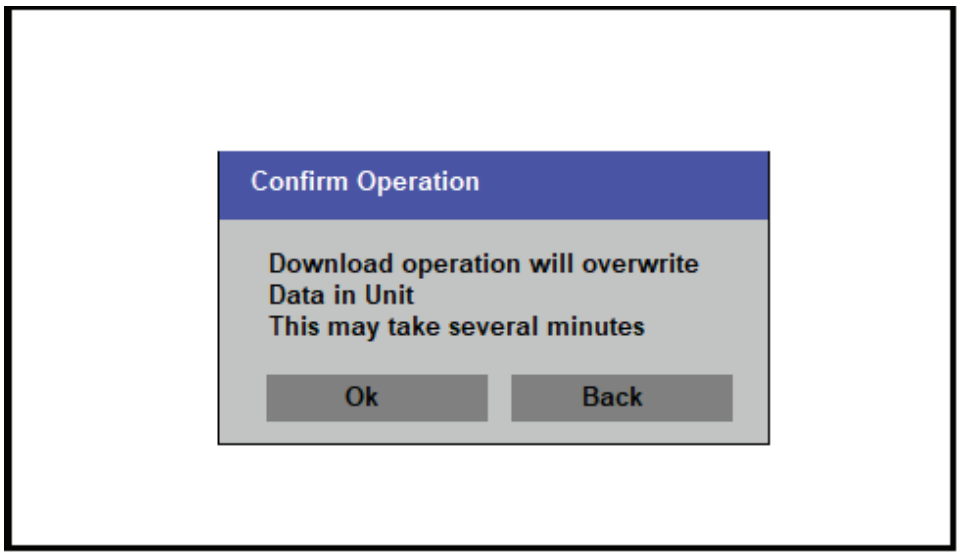
4. Once you have pressed 'Yes' the below screen will appear. Press the 'Download' button.

IMPORTANT:
DO NOT PRESS THE 'UPLOAD' BUTTON OR THE USB MEMORY STICK WILL BE OVERWRITTEN



©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

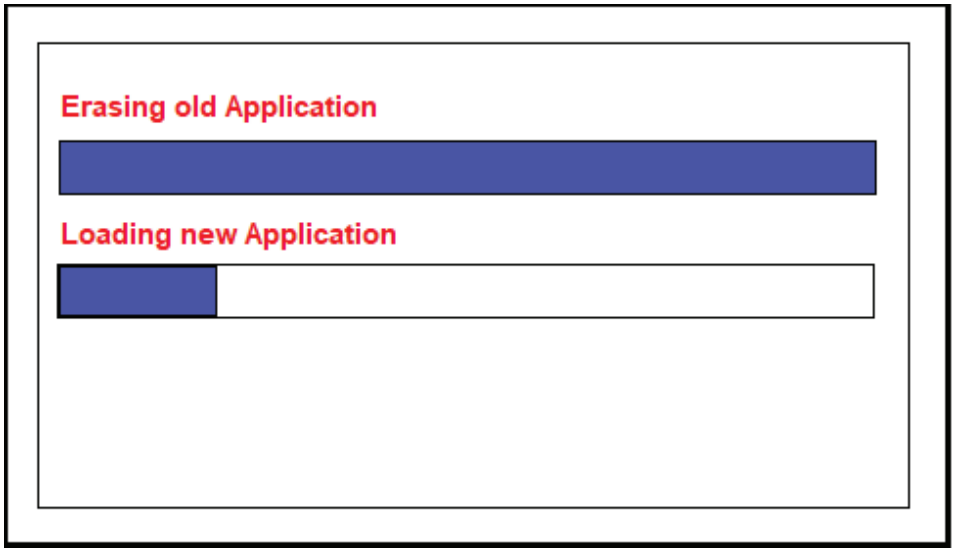


5. The below screen will then appear, you must then select the 'Application' and 'Logic' boxes only – once selected the boxes will turn green as shown below. Then press the 'Download' button.

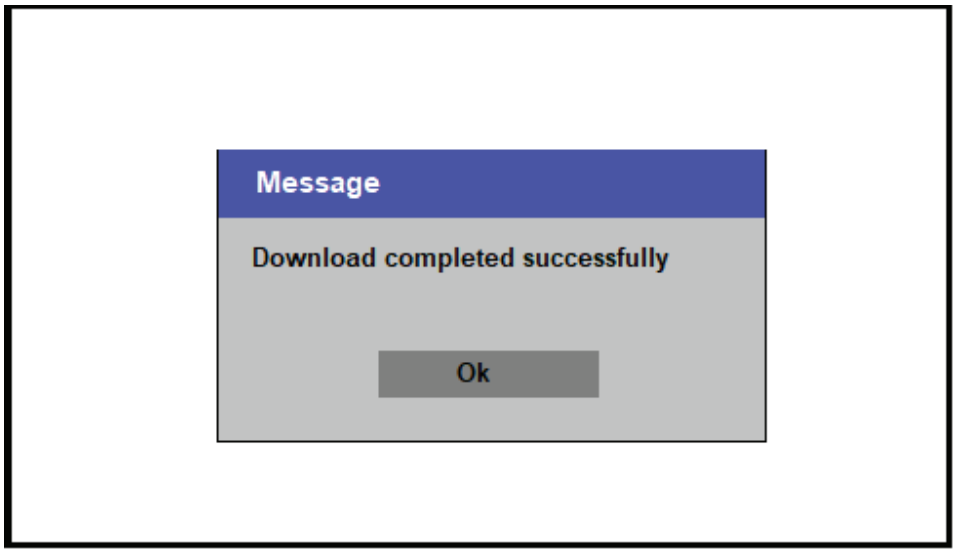
IMPORTANT:

Do NOT select any other options

6. This will take you to the following screen, press 'OK'.



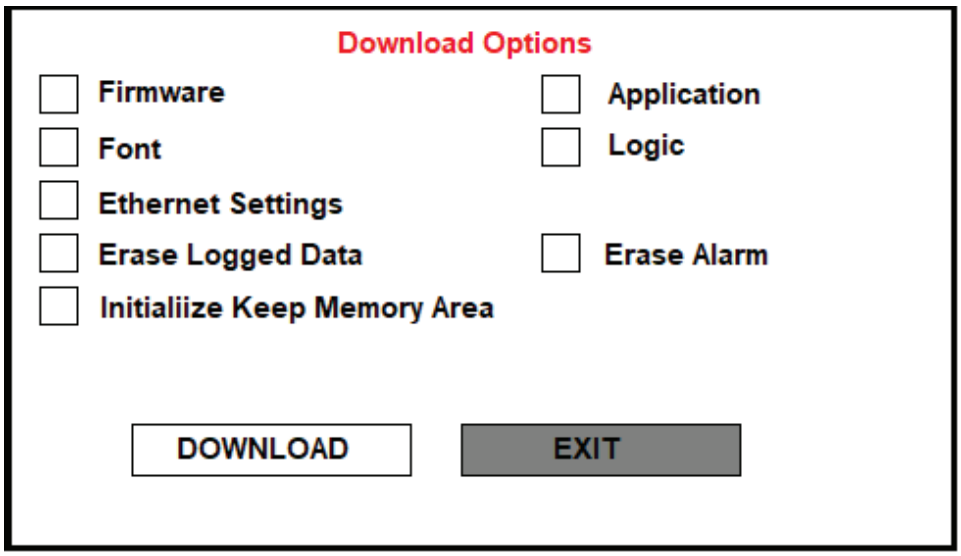
©Exertherm 2021



Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

7. While the Software is downloading you will see the below progress bar screen.

IMPORTANT:
Do NOT unplug the memory stick and do not unplug the ARM XL at any time during the upgrade process.



8. The following screen will then appear when the download has completed successfully. Then press 'OK'.

©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

9. The below screen will then appear. Now remove the USB memory stick and then press ‘Exit’.

10. The ARM XL will then automatically re-start with the new version of Software.

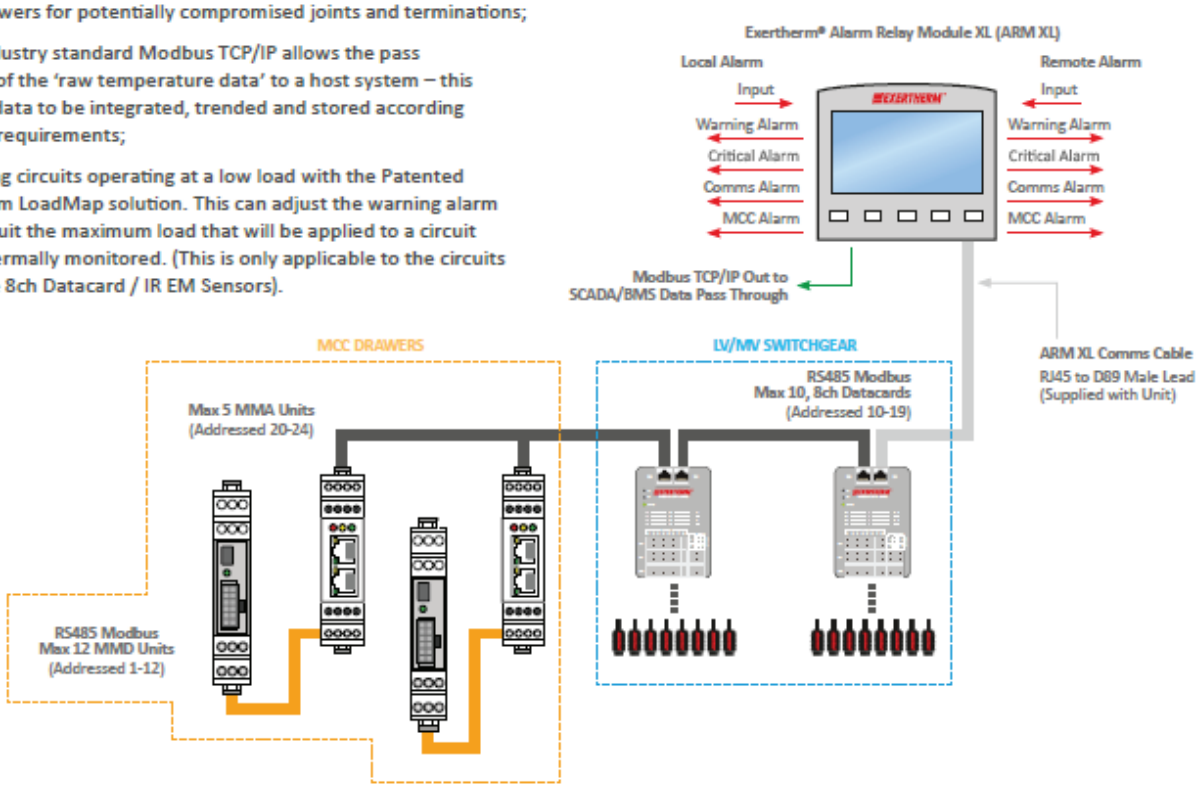
©Exertherm 2021

Global: +44 (0)1582 461123 USA: +1 646 512 5727 E: Sales@Exertherm.com

13. ARM XL DATASHEET

The Exertherm Alarm Relay Module XL (ARM XL) device is ideal for those who wish to continuously thermally monitor critical electrical circuits, 100% of operational time, rather than rely on one day per year thermal inspections. It is designed for busy engineers who require a simple monitoring system to just inform when and where a fault is detected, without yet another suite of software.

The Exertherm ARM XL device is designed to provide a complete integral monitoring solution per switchboard, and is suitable for both new build or retro-fit, while being entirely vendor neutral (e.g. can be fitted to any manufacturer's equipment).



The key benefits of the ARM XL:

- Monitoring 24x7 up to 80 Exertherm Sensors and / or up to 60 MCC Drawers for potentially compromised joints and terminations;
- Using industry standard Modbus TCP/IP allows the pass through of the 'raw temperature data' to a host system – this enables data to be integrated, trended and stored according to client requirements;
- Protecting circuits operating at a low load with the Patented Exertherm LoadMap solution. This can adjust the warning alarm level to suit the maximum load that will be applied to a circuit being thermally monitored. (This is only applicable to the circuits using the 8ch Datacard / IR EM Sensors).

This simple to use, plug and play device, which has 2 sets dry contact relays for connection to a local alarm output and also to a BMS or SCADA system. These relays are a dry contact type.

The ARM XL device connects up to a maximum of 10 Exertherm 8-channel Modbus Datacards (80 Exertherm IR or Cable Sensors) and 5 Exertherm MMA units each of which can connect 12 MMD units (60 MCC Drawers). The ARM XL is supplied with a Comms cable for connection to the 8ch Datacard and MMA.

A simple set up, using the pre-configured screens, provides an easy to use graphical interface to indicate the status of all Sensors, as well as providing both local and remote alarms.

4.3" Touchscreen Display

Features

- Panel Mounted HMI
- Plug & Play Solution
- Pre-configured screens allow simple set-up
- 2 sets of Relay Alarm Outputs (Local & Remote)
- Patented LoadMap for load related Warning Alarm threshold (on Exertherm IR Sensors only)
- Transfer of raw temperature data to host system using Modbus TCP/IP
- 4 Different Alarms:
  - Warning Alarm
  - Critical Alarm
  - Communication Failure
  - MCC Alarm

Specification

Power Supply	
Input voltage:	24VDC
Permissible range:	20.4VDC to 27.6VDC with less than 10% ripple
Maximum current consumption:	300mA @ 24VDC

Digital Outputs	
Number of outputs:	8 relay (in 2 groups)
Output type:	SPST-NO (Form A)
Isolation:	By relay
Output current (resistive load):	5A maximum per output
Minimum load:	10mA, 5VDC
Life expectancy:	50k operations at maximum load
Response time:	10ms (typical)

Modbus TCP/IP Output	
TCP / IP Port:	Standard port 502
IP Settings:	User adjustable, IP address, Subnet and Gateway
Register type:	Signed Integer
Register format:	16 bit
Register Linearisation:	Requires a 0.1 Multiplier on raw value

Graphic Display Screen	
LCD type:	WQVGA Colour TFT, LCD display
Illumination backlight:	White LED, software-controlled
Display resolution:	480x272 pixels
Viewing area:	4.3"
Colours:	65,536 (16 bit)
Touchscreen:	Resistive, analog
Virtual keypad:	Displays virtual keyboard when the application requires data entry

Miscellaneous	
Battery back-up:	Via Super-Cap, for RTC and system data, including variable data
Battery replacement:	Not Required

Dimensions	
Size:	120 x 89 x 57.5mm (4.72 x 3.5 x 2.26")
Mounting cut out:	111 x 80mm (4.37 x 3.14")
Weight:	333g (11.75 oz.)

Environment	
Operational temperature:	0 to 60°C (32 to 140°F) 0 to 50C (32 to 122°F for UL
Storage temperature:	-20 to 85°C (-4 to 185°F)
Relative Humidity (RH):	10% to 90% (non-condensing)
Mounting method:	Panel mounted (IP65) using supplied seal
Certifications:	CE & cUL Listed. Class 1 Div2 Group A,B,C,D Industrial Control Equipment for use in Hazardous Locations

Ordering Information

QHI Part No.	**Product Description**
900451	Exertherm ARM XL, HMI 4.3" Touchscreen Display, 8-ch Datacard + MCC input, Relay & Modbus TCP/IP output (supplied with Comms cable & 2 x Mounting screws + 1 x Power Connector)
Replacement Parts:	
800445	Comms cable from Exertherm Alarm Module XL (ARM XL) 8ch Datacard / MMA
800456	2 x Mounting screws & 1 x Power Connector for Exertherm Alarm Module XL (ARM XL)
Optional Parts:	
800457	Exertherm Humidity Sensor for ARM XL

MTI Line

RELAYbility

AMRA®
CHAUVIN ARNOUX GROUP

RMB

SERIES

INSTANTANEOUS BISTABLE (LATCHING) RELAYS
7 TO 20 CONTACTS

RMBE13

APPLICATIONS

Shipbuilding | Petroleum industry | Heavy industry | Power generation | Power distribution | Railway equipment

OVERVIEW

- Plug-in instantaneous bistable relay
- Solid and rugged construction for heavy or intensive duty
- Very high electrical life expectancy and exceptional endurance
- Pulsed or permanent power supply, AC or DC
- Self-cleaning knurled contacts
- Fitted with mechanical optical contact status indicator as standard
- Lever for manual operation (optional)
- Wide variety of configurations and customizations
- Transparent cover, fixing/pulling screws
- Label holder in cover for customer's use
- Positive mechanical keying for relay and socket

DESCRIPTION

RMB relays are multipole bistable types sharing the same basic mechanical design as those of the RGB series, and offering the same specifications and performance.

Available in versions with from 7 to 20 change-over contacts, these highly reliable products provide top performance and are suitable for applications in particularly harsh and unsettled environments, such as high voltage electricity distribution stations and medium voltage substations.

An automatic coil de-energization system ensures that power consumption of the relay reduces to zero once the operating cycle has been completed. Versatility in manufacture allows the production of relays with any voltage from 12 to 250VDC / 440VAC, and with a variety of operating ranges adaptable to different application requirements.

The contacts used are of a type designed to give notable levels of performance both with high and strongly inductive loads, and with particularly low loads; knurled contacts ensure not only better self-cleaning characteristics, but also lower ohmic resistance thanks to multiple points of electrical connection, thereby extending the electrical life expectancy of the component.

All models offer the facility of manual operation, so that tests can be performed even in the absence of electrical power.

To ensure that the relay remains firmly anchored to the sockets, these are equipped with fixing screws, so that there is no need for the use of retaining clips.

A product of proven reliability, as demonstrated by its use for over 40 years in electrical energy transport and distribution systems, and fixed equipment used in the railway sector.

Like all AMRA relays, models of the RMB series are assembled as part of a controlled manufacturing process in which every step of production is verified by the next step in succession. In effect, each relay is calibrated and tested individually, by hand, in such a way as to guarantee top reliability.

Drop-out (NC contact closing)		≤ 56 - ≤ 65	≤ 40 - ≤ 60	≤ 50 - ≤ 60	≤ 36 - ≤ 57	≤ 43 - ≤ 53	≤ 43 - ≤ 58

(1) On all contacts simultaneously, reduction of 30%

(2) Maximum peak and pulse currents are those currents that can be handled, for a specified time, by the contact. They do not refer to steady or interrupted currents

(3) For other examples, see electrical life expectancy curves

(4) Values referred to a new product, measured in laboratory. The ability to maintain this performance over the time depends on the environmental conditions and the contact' frequency use The use of gold plated contacts is recommended in the case of very low loads. For a correct contact use, refer to the chapter "Installation, operation and maintenance".

(5) A gold contact, if subjected to high loads, degrades superficially. In this case, the characteristics of the standard contact must be considered. This does not affect the operation of the relay

(6) Unless specified otherwise, operating times are understood as comprising stabilization of the contact (inclusive of bounces)

INSULATION	
Insulation resistance (at 500Vdc)	
between electrically independent circuits and between these circuits and ground	> 10,000 MΩ

Fire behaviour	V0

STANDARDS AND REFERENCE VALUES	
EN 61810-1, EN 61810-2, EN 61810-7	Electromechanical elementary relays
EN 60695-2-10	Fire behaviour
EN 60529	Degree of protection provided by enclosures

Unless otherwise specified, the products are designed and manufactured according to the requirements of the above-mentioned European and International standards.

In accordance with EN 61810-1, all technical data are referred to ambient temperature of 23°C, atmospheric pressure of 96kPa and 50% humidity.

Tolerance for coil resistance and nominal power is ±7%.

CONFIGURATIONS - OPTIONS	
TROPICALIZATION	Surface treatment of the coil with protective coating for use with RH 95%.
GOLD PLATING	Surface treatment of the contacts, with gold-cobalt alloy ≥ 5µ (since 2023, May). This treatment ensures long-term ability of the contact to conduct lower currents.
FLYBACK DIODE	Component connected in parallel to the coil designed to dampen overvoltages generated by the coil when de-energized.
LEVER FOR MANUAL OPERATION	Allows manual operation of the relay, with the cover closed, using a screwdriver.

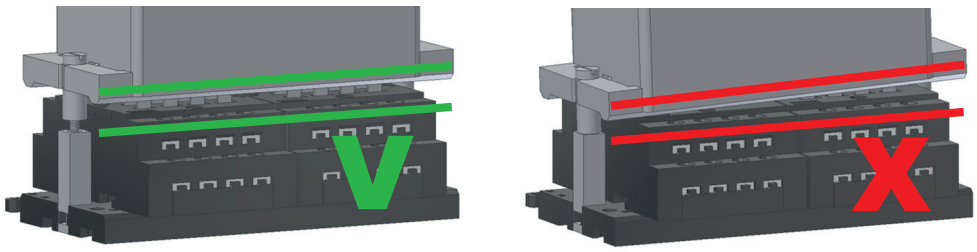
	Screw	PRVM321	PRVM481	PRVM801

INSTALLATION, OPERATION AND MAINTENANCE

Installation

Before installing the relay on a wired socket, disconnect the power supply.

The preferential mounting position is on the wall, with the relay positioned horizontally in the “reading orienting” of marking so that the label is readable in the correct sense.



Spacing: these relays can be mounted without distance between one relay and the next.

Mounting of the relay on the socket:

the relays are equipped at their ends with 2 screws that allow to obtain the correct insertion in the socket and to hold the relay in the correct mounting position.

Place the relay against the socket, making a slight pressure to center the relay terminals over the socket terminals. Screw the two screws progressively and alternately, moving the relay evenly towards the socket.

Avoid screwing/unscrewing completely one screw and then the other one.

Operation

Before use: if relay is not used, for example after long storage periods, contact resistance may increase due to a natural and slight oxidation or polluting deposits.

In order to restore the optimal conductivity and for standard contacts (NOT gold plated) it is recommended to switch several time a load of at least 110Vdc - 100mA or 24Vdc - 2A. The contacts will be "cleaned" thanks to the electric arc generated during the current interruption and the mechanical self-cleaning action.

The common contact rubs against the fixed poles (NO and NC contacts) both when opening and when closing, which ensures a self-cleaning action.

An increase in contacts' resistance, in most cases, does not represent a problem. Many factors contribute to the correct use of contact and consequently to the relay' long-term reliability:

- **Load:** the current switching generates an electric arc with cleaning effects. For proper electrical cleaning and performance keeping we recommend:
  - o Standard contacts: Minimum current = 20mA (20V)
  - o Gold plated contacts: Minimum current = 10mA (20V)
- **Operating frequency:** relays are components that can operate with a wide range of switching frequency. High frequency operation also allows a continuous cleaning effect by "sliding" (mechanical cleaning). In case of low frequency operation (for example few time a day), we advise:
  - o Use of contact with currents twice compared to those indicated.
  - o For currents lower than 10mA, use gold plated contacts and connect 2 contacts in parallel, in order to reduce the equivalent contact resistance
- **Pollution:** the presence of pollution can cause impurities on contact surface. Electric charges attract organic molecules and impurities that are deposited on the contact surface. Electrical and mechanical cleaning, respectively, burn and remove such impurities. In pollution presence, the minimum recommended currents must be respected. In extreme cases, provide double the cleaning current.

While a contact open high loads, impurities develop inside the relay due to the formation and interruption of the electric arc. These impurities are greater the higher the load and the more frequent the switching operation. These impurities could deposit on the adiacent contacts and alter the initial conductivity characteristics. If all contacts are used with similar loads, this is not a problem.

Please, contact AMRA for further informations.

Condensation is possible inside the relay when energized and the outside ambient temperature is cold; this is quite normal and does not affect the operation of the relay. Plastic materials of relay do not possess hygroscopic properties.

Maintenance

No maintenance is required.

In case of normal relay wear (reaching the end of electrical or mechanical life), the relay cannot be restored and must be replaced.

Unmounting of the relay from the socket:

as for the installation, it is necessary to unscrew the relay on the 2 anchor screws of the product in a progressive and alternating way, extracting the relay evenly from the socket.

Avoid screwing/unscrewing completely one screw and then the other one.

Often the malfunctions are caused by power supply with inverted polarity, by external events or by use with loads exceeding the contact performance.

In case of suspected malfunction, energize relay and observe if mechanical operation of contacts / relay mechanism is performed. Pay attention to the power supply polarity, if relay is equipped with polarized components (example: diode, led).

- In case of expected operation, clean the contacts (see paragraph “OPERATION”) and check if the circuit load ranges within the contact performance. If necessary, replace with relays with gold contacts. Note: the electrical continuity of contacts must be checked with adequate current.
- If it does not work, we recommend to use a relay of the same model and configuration.

If an investigation by AMRA is required, pull-out the relay from the socket, don’t remove the cap, avoid any other manipulation and contact us. You will be asked for the following data: environmental conditions, power supply, switching frequency, contact load, number of operations performed.

The fault can be described through the “TECHNICAL SUPPORT” section of the website www.amra-chauvin-arnoux.it.

In any case, the relay cannot be repaired by the user.

Storage

Storage conditions must guarantee the environmental conditions (temperature, humidity and pollution) required for the product conservation, in order to avoid deterioration.

The product must be stored in an environment sheltered from atmospheric agents and not polluted, with an ambient temperature between -25 and +70°C with max 75% RH. Humidity can reach peaks of 95%. In any case, there must be no condensation. Before use, please read carefully “OPERATION” section.

ST-GB-666 Ed.04/24 - Non-contractual document - Specifications are to be confirmed at time of ordering and subject to change without notice.

DISTRIBUTION SOLUTIONS

Medium-voltage fuses
3 kV – 40.5 kV, 0.4 A – 315 A

- Continuous protection and reliable operation
- Proven design and compliance with newest fuses standards
- Compatibility with other ABB products

ABB presents the most effective protective devices – fuses. Our MV fuses are continuously being developed and delivered for more than 90 years.
Nowadays, produced in fully automatic process and with greatest care of highest quality and reliable operation fuses are delivered to customers around the world. Millions of ABB MV fuses are now in operation protecting electrical equipment in countless applications.

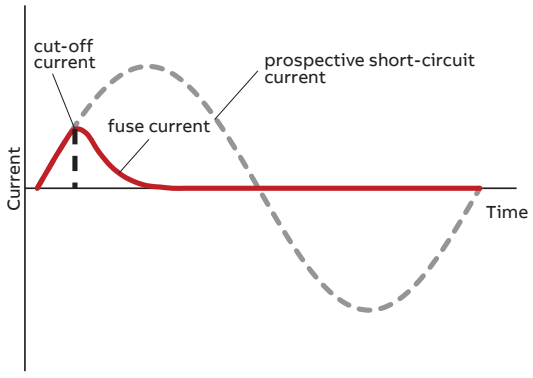
01
Limitation of short--circuit current

The main function of current limiting fuses is to protect electrical apparatus, such as distribution transformers, motors and capacitor banks against overload currents. Fuses can operate as sole devices or can be combined with air/SF6 insulated switch disconnectors. The choice depends on each application requirements and specific network conditions. One of the most critical factors for optimum protection is proper fuse selection. This can be done based on theoretical calculations but in many cases practical knowledge obtained from actual test results could make it easier and even more reliable. ABB, with its extensive apparatus product portfolio, has years of experience in this field. Our current limiting fuses have been designed to ensure safe operation in open air and for limited heat dissipation in installations such as gas insulated switchgears.
Fuse selection principles for the most common situations are presented in the following pages together with common definitions. Moreover we offer our support for each specific case where presented criteria are not sufficient.



Definitions
Current limiting fuses

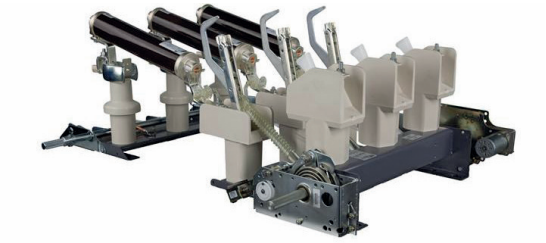
Current limiting fuse family is generally composed of three different fuse groups:
- back-up fuses
- general-purpose fuses
- full-range fuses

All of them limit the value of prospective short-circuit currents during the interruption process, thereby extending the life time of nearby installed electrical equipment. The main difference is in the minimum breaking current that characterizes the lowest fault current that the fuses are capable of interrupting. This value is generally highest for back-up fuses, slightly smaller for general-purpose fuses and smallest, with the value close to the minimum melting current, for full-range fuses. But reaction time is critical for the protection function. That is why back-up fuses, with an interruption time for the minimum breaking current in the range of a few seconds down to a few tens of milliseconds, are the most commonly used. The total clearing time in cases of high short-circuit currents is even shorter i.e. only a few milliseconds. That is why back-up fuses can be used as typical overload protection elements. General-purpose and full-range fuses capable of interrupting even the smallest values of currents can only be considered as over current devices since the interruption time is greater than one hour. Therefore, these types are used rarely and are usually recognized as a separate element of protection, without any linkage to the opening function of load break switch. ABB current limiting fuses have low minimum breaking currents, i.e. close to three times the rated current I_r.

Current limitation
All ABB fuse-links presented are current limiting ones. A large short-circuit current will therefore not reach its full value. The cut-off characteristics show the relationship between the prospective short-circuit current and the peak value of the cut-off current. Substantial current limitation results in a considerable reduction in thermal and mechanical stress in a high-voltage installation.

—
01

Back-up fuses
All presented in catalog fuse-links are back-up class. That means the operating range in which the fuse-links are able to clear all fault currents is from the minimum breaking current I_3 to maximum breaking current I_1.



—
02
NALF – switch-fuse combination

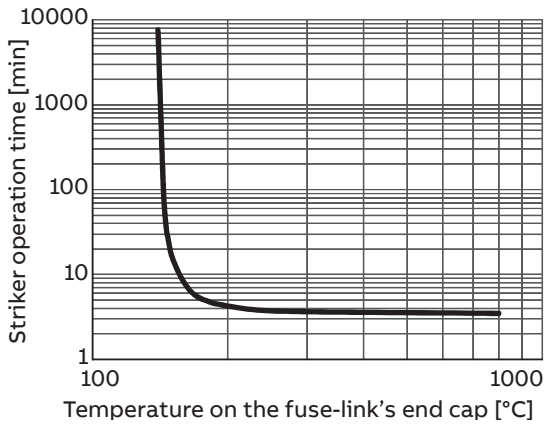
—
03
TCU operation diagram

Switch-fuse combination

Back-up fuses are commonly used in switch-fuse combinations, both in open air and in gas insulated panels. When a switch-fuse combination operated as a protective device by tripping a system, the fuse assumes two different functions depending on the interrupted current value. When the fault current is greater than the transfer current, the fuse simply extends the breaking capability of the switch ending the interruption operation faster than the incorporated switch. This happens when the fuse clearing time is shorter than the total opening time of the Load Break Switch (LBS). By the time the striker pin pops up, the fuse has already cleared the fault current and the switch opens in almost no load conditions. If the fault currents are less than the nominal transfer current, the fuse then uses the striker pin to activate the switch, which in turn causes the system to trip. In other words, the interruption process is completed by the switch to prevent overloading of the fuses in situations where the fault current is low. Fuses used in switch-fuse combinations have to fulfill conditions specified in IEC 62271-105 (former IEC 60420 and IEC 420). Back-up fuses are specially designed for such application. The use of general-purpose or full-range fuses in switch-fuse combinations are not reasonable due to coordination principles.

—
02

Temperature Control Unit – TCU



The Temperature Control Unit is tripping device which is integrated with the striker of high-voltage (HV) fuses. It is activated when the allowable temperature in the switchgear is exceeded. When the temperature is too high the TCU activates the striker by releasing the switch disconnector, which in turn opens the electric circuit and avoids further temperature increases. The high temperatures inside the switchgear interior may be caused by external conditions or by a high current passing through the fuse-link. List of possible reasons of too high temperatures inside fuse compartment:

- reduced heat transfer inside the switchgear
- over-heating of degraded conducting contacts
- long-term fuse overloads
- improper selection of the fuse rating
- local melting of fuse elements caused by transformer inrush currents, starting currents of motors etc.

Safety is significantly increased when fuses are equipped with a TCU. This is especially true in devices where fuses are located inside closed fuse compartments, as is the case of SF6 switchgear. In gas insulated switchgear fuse canisters or in narrow panels of air switchgear the risk of overheating is high because cooling is limited. High temperatures in switchgears cause degradation and oxidation of the metal contacts, degradation of switchgear equipment or enclosures, and insulator ageing. Unfavorable effects, i.e. temperature rise inside the switchgear, leads to internal short-circuit and further temperature increases. In case of reaching too high temperature, TCU will be activated, releasing a striker and opening associated switch, thus eliminating the threat. The ABB CEF, CEF-S, CMF and CEF-VT (with striker) are equipped with a TCU as standard design.
Temperature Control Unit features:

- Operation according to diagram presented on Fig. 3
- Operation after approximately one hour at temperature of 150°C on the fuse end-cap
- Withstanding temperatures up to 125°C on the fuse end-cap – without operation
- Withstanding currents not exceeding 110% of fuse rated current – without operation
- Operation time tolerance is ±10% (referred to the temperature)

General principles for fuse-links selection

Choice of rated voltage U_r:
The rated voltage of the fuse-links must be equal to, or higher than the operating line voltage.
By choosing the fuse-link rated voltage considerably higher than the line voltage, the maximum arc voltage must not exceed the insulation level of the network.

Choice of rated current I_r:
To obtain the best possible current limitation and thereby protection, the rated current of fuse-link must be as low as possible compared to the rated current of the object to be protected. However, the following limitations must be taking into consideration:

- the largest load current must not exceed rated current
- cooling conditions (e.g. in compact switchgear)
- inrush current of off load transformers
- starting currents of motor circuits (details in chapter: Fuse-links for motor circuits protection)

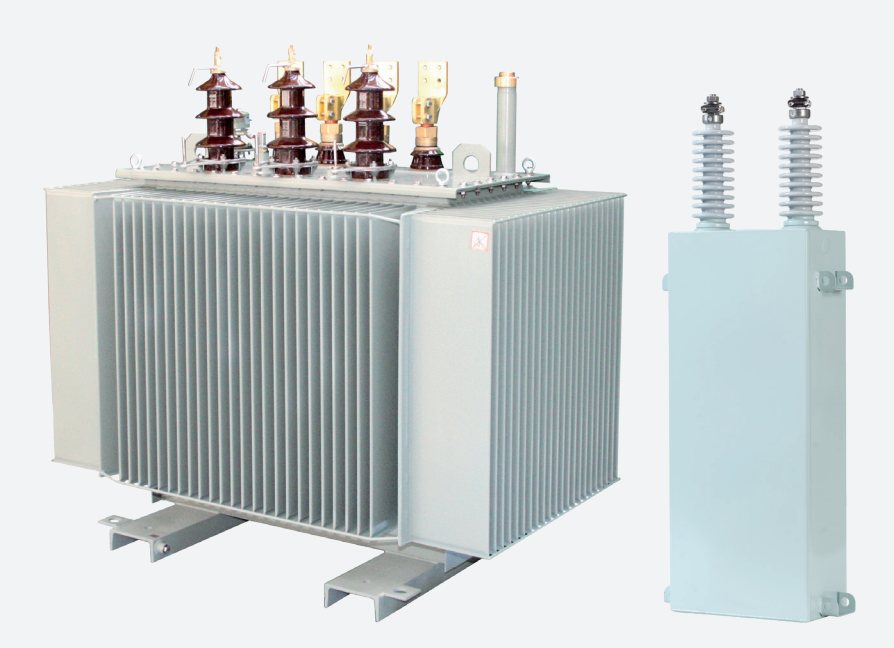
Protection of capacitor banks
ABB fuses are normally connected in series with capacitor units or banks. They are activated when these units become faulty under normal operating voltages, including the transient voltage as the capacitor are being energized. That is why the chosen fuse-link rated voltage should not be less than 1.1 times that of the rated voltage of the capacitor unit. As recommended in IEC 60549, the rated current of the fuse should be at least 1.43 times that of the capacitor's rated current. In practice it can be distinguished two general cases:

- Only one capacitor bank connected:
  selected rated current (I_r) for the fuses should be at least twice the rated current (I_{rc}) of the capacitor bank. The rated voltage of fuse-link (U_r) should also be at least twice the reated voltage of capacitor (U_{rc}).
  $I_r \geq 2 x I_{rc}$
  $U_r \geq 2 x U_{rc}$
  Example: 315 kvar capacitor bank with 10 kV U_{rc}.
  I_{rc} = 315 / (10 * √3) = 18.2 A
  Selected fuses: I_r = 40 A; U_r = 24 kV

- More than one capacitor connected in parallel: when there is a possibility of reloading i.e. transmitting from a load capacitor bank to the unloaded condition, very high transient currents may occur. The rated current (I_r) of the fuses should be selected so that it is more than three times the rated current of capacitor bank (I_{rc}). Because a wide variation in transient currents may occur, ABB recommends that the calculation be discussed with the supplier of the capacitors.

Application in limited heat dissipation conditions
The setup of interaction between fuses and switch disconnectors in limited heat dissipation conditions can be obtained mainly from practical tests performed under different loading conditions. The maximum allowable power losses should be defined for the fuse so the temperature rise limits are not exceeded according to the referred standard. Therefore, the rated current of fuses with power losses above this limit are de-rated to a safe level. This procedure should be verified by temperature rise and breaking tests of the set.
Above procedure is valid for fuses operating in fuse compartment of switchgears or contactors.

Replacement of melted fuse-links
HV fuse-links cannot be regenerated. According to IEC Publication 60282-1, in a three phase system all three fuse-links should be replaced even if only one of them melts. Exceptions are allowed when it can be verified that the fuse-link (s) have not experienced any over current.



Fuse selection – detailed procedure
This catalog is divided into few chapters of various applications of fuse-links. Each of these chapter contains a list of suitable fuses and detailed selection procedure.

* for fuses with rated current marked with RC (i.e. 125RC110A), maximum application continuous current should not exceed RC value indicated in subscript

Fuse-links for transformer and capacitor protection

010 – 018 **CEF** – Essential fuse-links for distribution transformers and capacitor protection

019 – 025 **CEF-S** – Fast-acting fuse-links for protection of distribution transformers

CEF

Essential fuse-links for distribution transformers and capacitor protection

Class, type	Back-up, current limiting fuse-link
Rated voltages	3/7.2 kV – 20/36 kV
Rated currents	6.3 A – 200 A
Rated frequency	50 Hz
Applicable standard	IEC 60282-1, VDE 0670-T4 and VDE 0670-T402
Application	Indoor/outdoor
Striker	80 N (medium), with integrated TCU

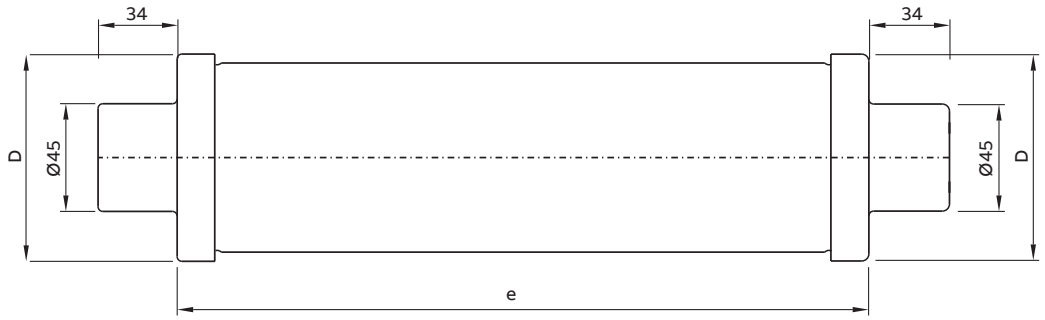
Lower power losses by average level of 20 % comparing to previous design, generating additional savings during product life-cycle

Continuous protection and reliable operation guaranteed by robust design and compliance with newest IEC standards

Compatibility with other ABB products provides fast and accurate product selection

Outdoor sealing included in standard version, designed and tested for harsh conditions

Fuse-links type CEF are designed to protect distribution transformers, cables, overhead lines and other apparatus against thermal and dynamic effects of short-circuit currents.



Key features:

- Rated voltages 3/7.2 kV – 20/36 kV with rated currents of 6.3 A – 200 A
- For indoor and outdoor applications
- Designed and type tested acc. to IEC 602821, VDE 0670-T4 and VDE 0670-T402
- Top level fault current limitation and interruption performance up to 63kA RMS
- Striker 80 N (medium type)
- Equipped with Temperature Control Unit enabling the additional protection against thermal stresses in small enclosures

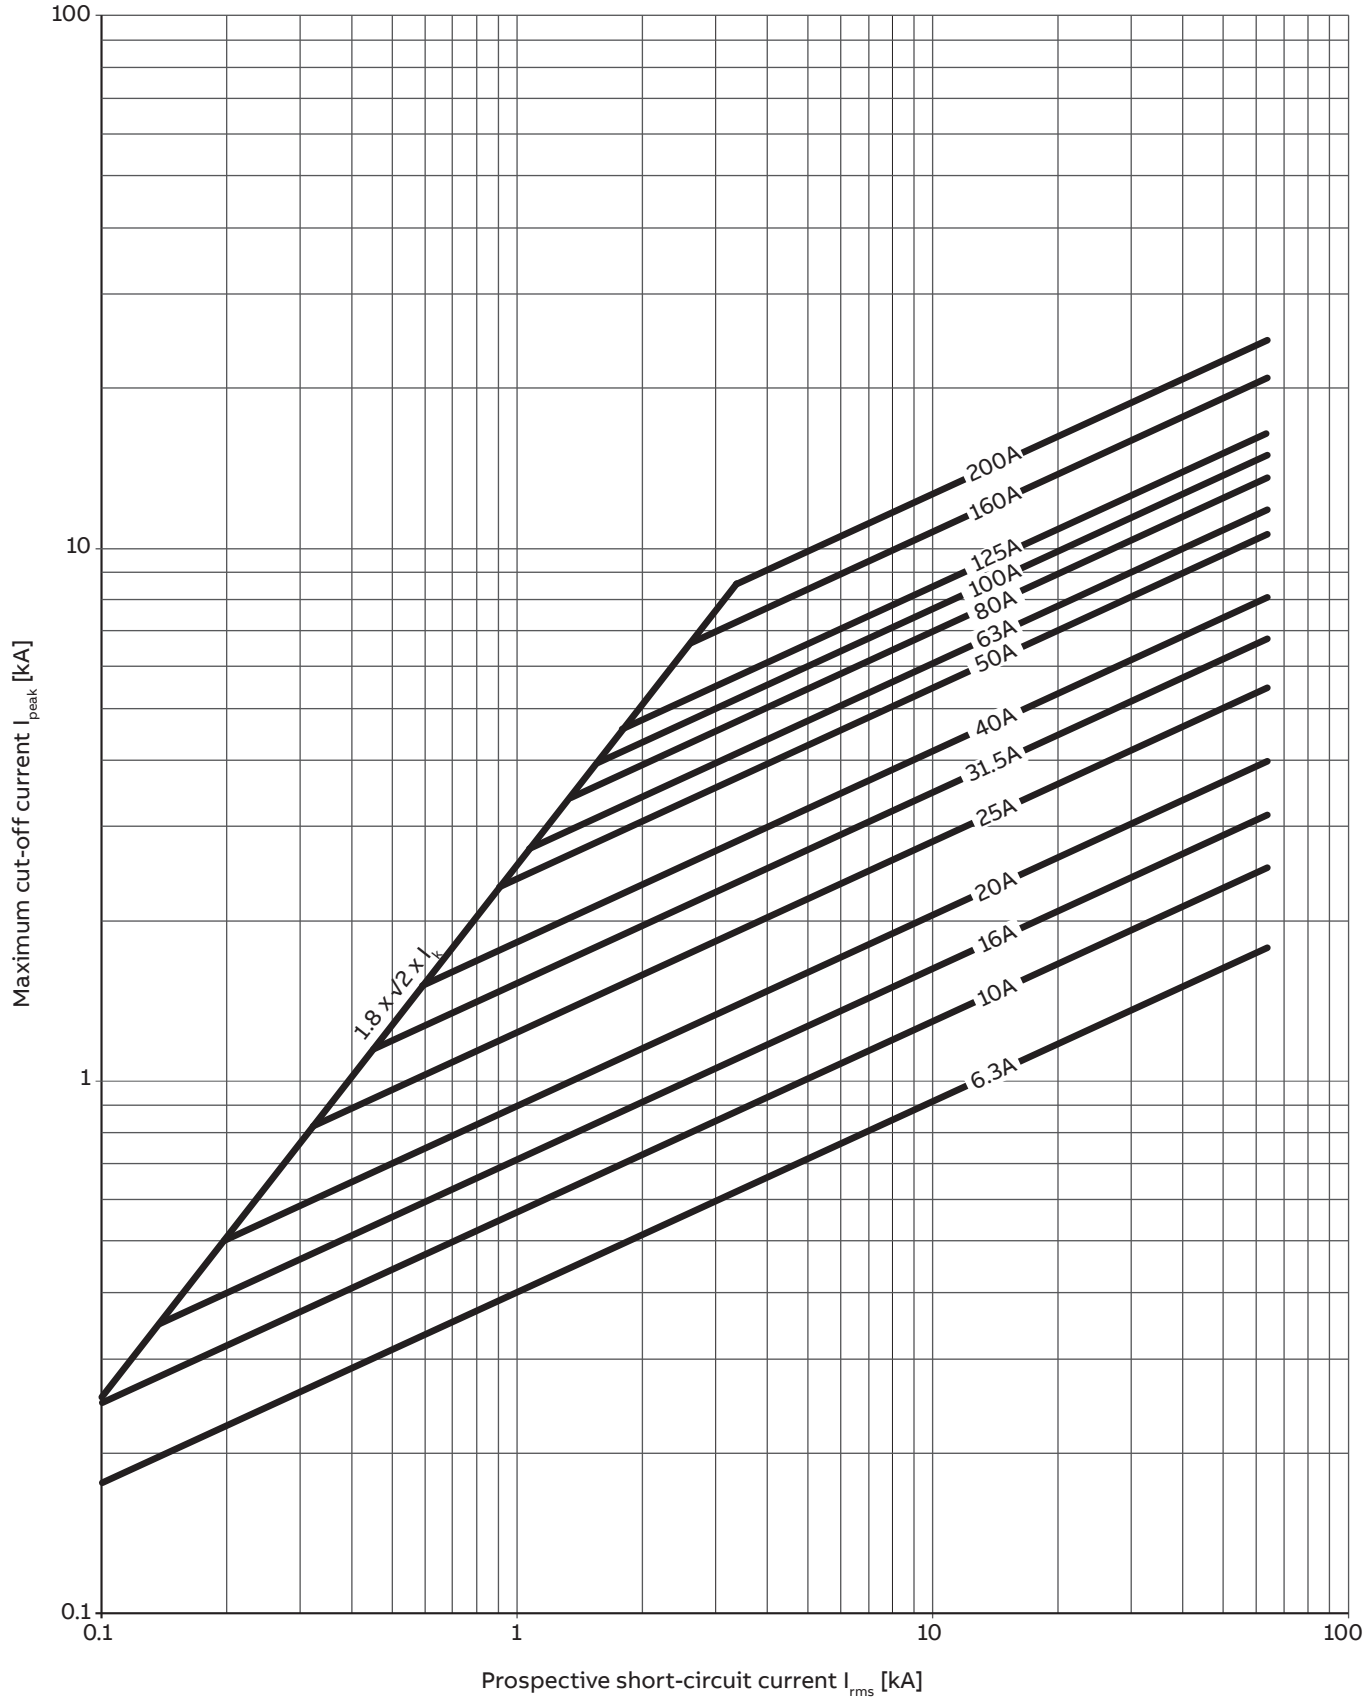
[1] – fuse is not able to clear independently transformer's secondary side terminals short-circuit current; [2] – fuse type CEF-VT; [3] – fuse type CMF

Recommended fuse rating is on the crossing of transformer rating and line voltage. For different line voltage level, please use closest smaller value from the table. The table was calculated according to standards IEC 60787 and IEC 62271-105 with following assumptions:

- Maximum long lasting transformer current overload – 120%
- Magnetizing transformer inrush current – 12 x I_r during 100ms (up to 800 kVA) or 10 x I_r during 100ms (800 kVA and above)
- Transformer short-circuit voltage according to IEC 60076-5
- No fuse derating due to small enclosures assumed

For different working conditions fuse selection has to be recalculated.

—
07



Characteristics show the average melting time as a function of the prospective current and are recorded from cold condition of fuse-link.

The tolerance is ± 10% referred to the current. Characteristics are valid for frequency 50 Hz.

CEF-S

Fast-acting fuse-link for protection of distribution transformers

Class, type	Back-up, current limiting fuse-link
Rated voltages	6/12 kV – 30/40.5 kV
Rated currents	6.3 A – 63 A
Rated frequency	50 Hz
Applicable standard	IEC 60282-1
Application	Indoor/outdoor
Striker	80 N (medium), with integrated TCU

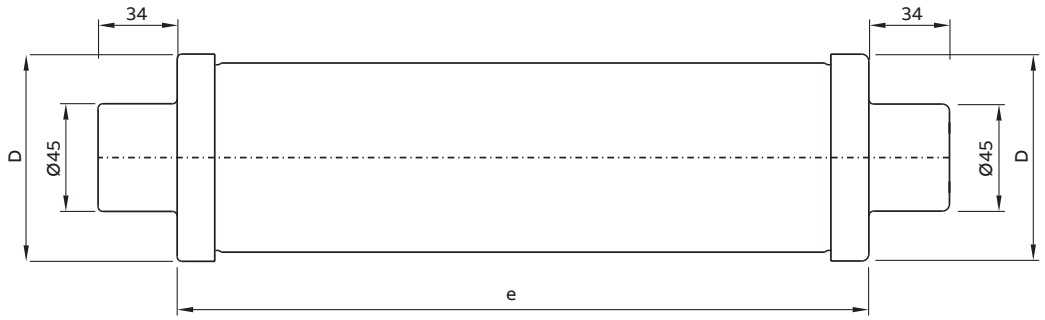
Superior performance versus standard fuses ensuring up to 40% faster protection in case of low fault currents

Continuous protection and reliable operation guaranteed by robust design and compliance with newest IEC standards

Compatibility with other ABB products provides fast and accurate product selection

Outdoor sealing included in standard version, designed and tested for harsh conditions

Fuse-links type CEF-S are designed for fast--acting protection of distribution transformers, increasing safety on low voltage side of the transformer



Key features:

- Rated voltages 6/12 kV – 30/40.5 kV with rated currents of 6.3 A – 63 A
- For indoor and outdoor applications
- Designed and type tested acc. to IEC 60282-1
- Top level fault current limitation and interruption performance up to 63kA RMS
- Striker 80 N (medium type)
- Equipped with Temperature Control Unit enabling the additional protection against thermal stresses in small enclosure

Recommended fuse rating is on the crossing of transformer rating and line voltage. For different line voltage level, please use closest smaller value from the table. The table was calculated according to standards IEC 60787 and IEC 62271-105 with following assumptions:

- Maximum long lasting transformer current overload – 120%
- Magnetizing transformer inrush current – 12 x I_r during 100ms (up to 800 kVA) or 10 x I_r during 100ms (800 kVA and above)
- Transformer short-circuit voltage according to IEC 60076-5
- No fuse derating due to small enclosures assumed
- For ratings marked with “*” fuse is not able to clear independently transformer’s secondary side terminals short-circuit current

For different working conditions fuse selection has to be recalculated.
The CEF-S fuse-links can be selected in reference to § 17 STEV-FS requirements that ensure very good protection and prevents many faults in low voltage switchgears. The selection table according to that is available on request.

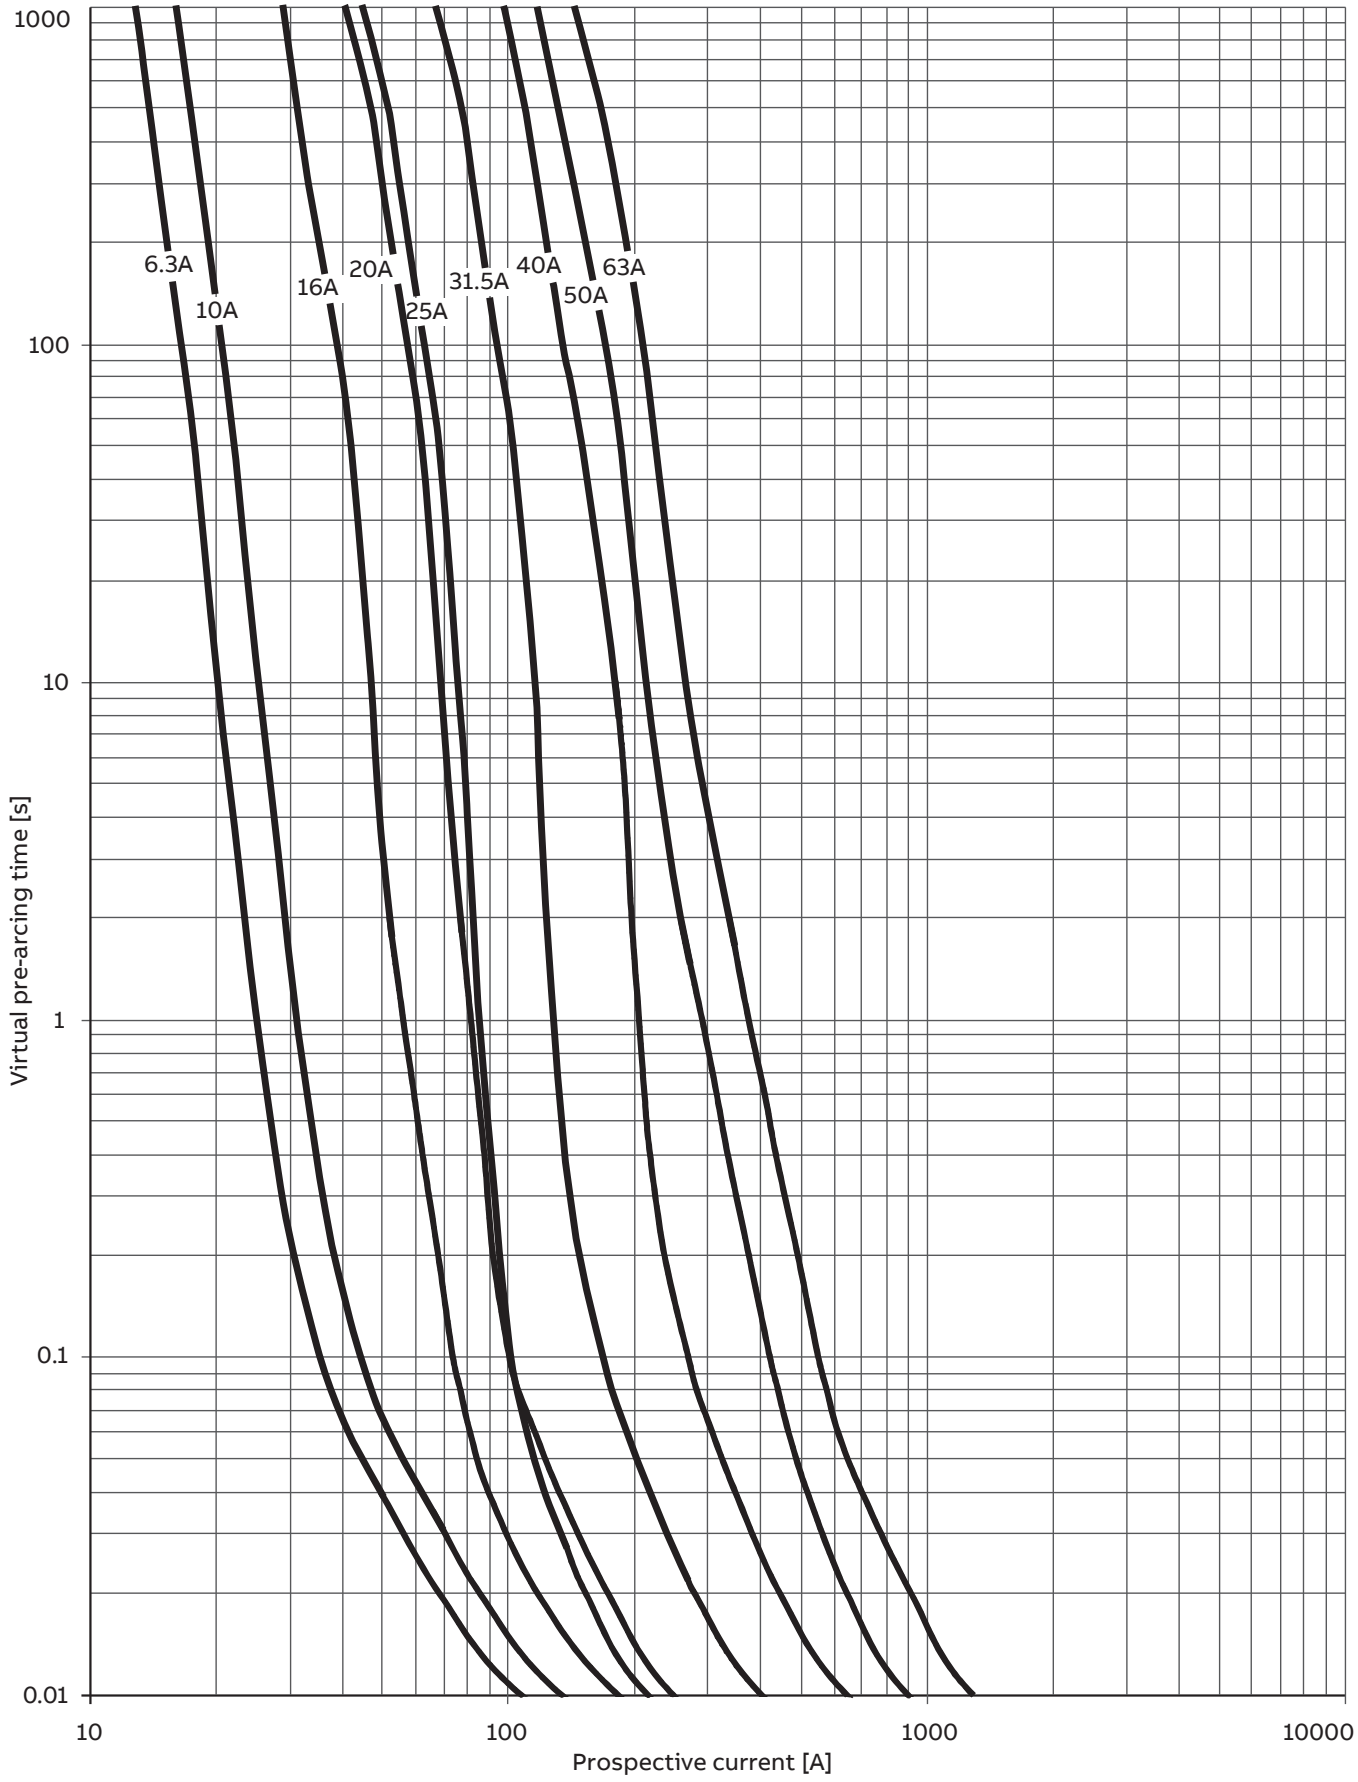
CEF-S 6/12, 10/24 kV fuses time-current characteristic

Characteristics show the average melting time as a function of the prospective current and are recorded from cold condition of fuse-link.

The tolerance is ± 10% referred to the current. Characteristics are valid for frequency 50 Hz.



—
14

—
14
CEF-S 6/12 kV, 10/24 kV cut-off current characteristics

Characteristics show the cut-off current corresponding to a prospective short-circuit current. Characteristics are valid for frequency 50Hz.

Fuse-links for motor circuits protection

028 – 035 **CMF** – Essential fuse-links for motor circuit protection

036 – 039 **CMF-BS** – Fuse-links with tags for motor circuit protection

CMF

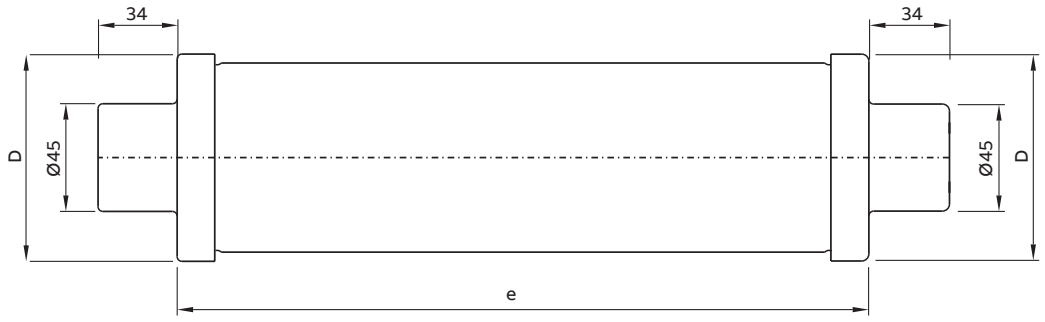
Essential fuse-links for motor circuit protection

Class, type	Back-up, current limiting fuse-link
Rated voltages	3.6 kV, 7.2 kV, 12 kV
Rated currents	63 A – 315 A
Rated frequency	50 Hz
Applicable standard	IEC 60282-1
Application	Indoor/outdoor
Striker	80 N (medium), with integrated TCU

Special design of fuse-links resistant to cyclical load typical for motor applications

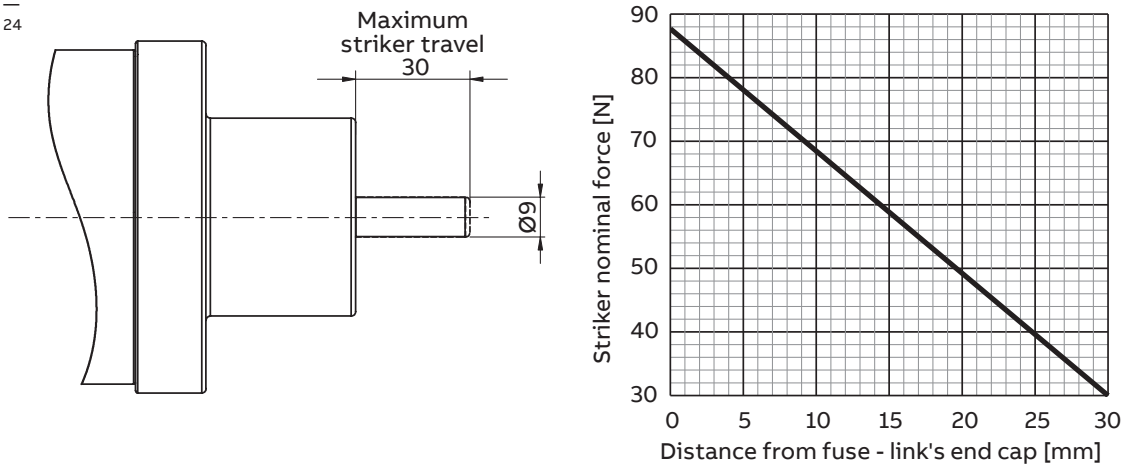
Continuous protection and reliable operation guaranteed by robust design and compliance with newest IEC standards

Compatibility with other ABB products provides fast and accurate product selection



Outdoor sealing included in standard version, designed and tested for harsh conditions

Fuse-links type CMF are designed to protect motor circuits against thermal and dynamic effects of short-circuit currents



Key features:

- Rated voltages up to 12 kV with rated currents of 63 A – 315 A
- For indoor and outdoor applications
- Designed and type tested acc. to IEC 60282-1
- Striker 80 N (medium type)
- Equipped with Temperature Control Unit enabling the additional protection against thermal stresses in small enclosures

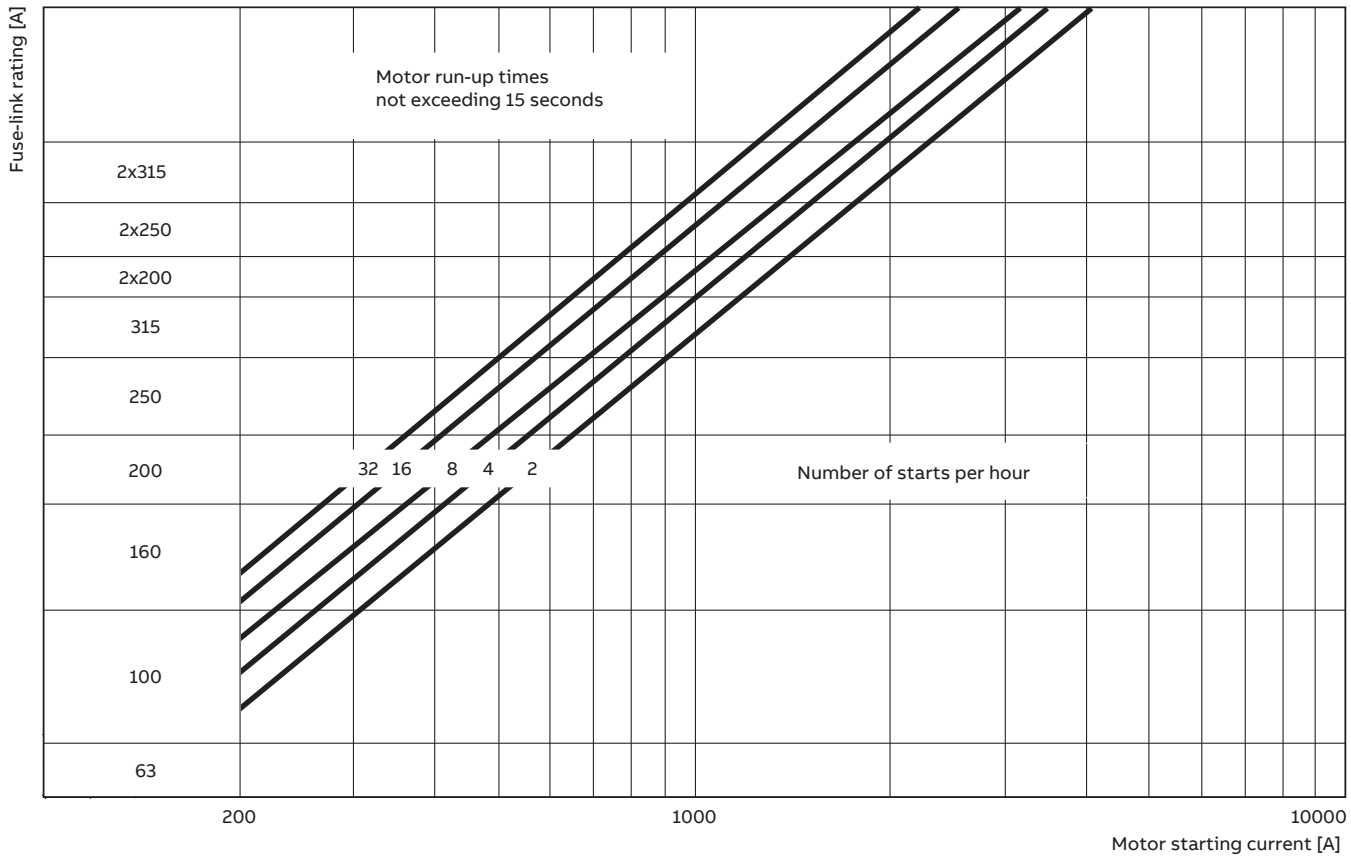
Choice of fuse-links for motor protection:
The minimum permissible current rating of the fuse-links for motor protection may be determined from the selection charts. These three charts are for run-up times of 6, 15 and 60 seconds respectively. Each chart contains different characteristics, depending on the number of starts per hour. With reference to the number of starts per hour, the first two are in immediate succession while the rest are evenly spaced at intervals of one hour. The number of starts per hour indicates the time interval between separated starts. For example, four starts in 15 minutes are represented by 16 starts per hour. The horizontal axis of the selection chart indicates the motor starting current, while the current rating of the fuse-link is found along the vertical axis.



Selection procedure:
- Select the chart which is appropriate for the run-up time of the motor
- Select the starting current along the horizontal axis
- Depending on the number of starts per hour, select the correct characteristic (2, 4, 8, 16, 32)
- Read the correct fuse-link rating on the vertical axis.

Example	A	B
Starting current of the motor	850 A	250 A
Run-up time	6 seconds	15 seconds
Number of starts per hour	2	16
Chart number	3	2
Rated current of fuse link	250 A	160 A

Choice of fuse-links for motor protection – the same selection procedure applies as for CMF fuse-links, see page 34.

Time-current and cut-off current characteristic – the same characteristics apply as for the CMF fuse-links, presented on pages 36-39.

Fuse-links for voltage transformer protection

042 – 047 **CEF-VT** – Essential fuse-links for voltage transformer protection

048 – 054 **WBP** – Compact fuse-links for voltage transformer protection

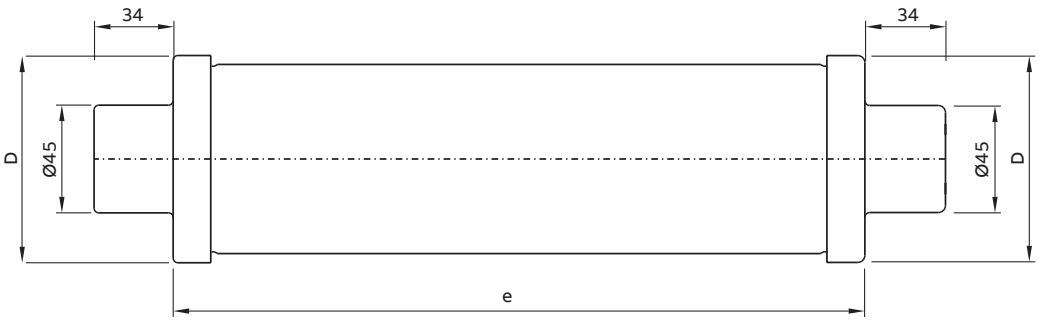
CEF-VT

Essential fuse-links for voltage transformer protection

Class, type	Back-up, current limiting fuse-link
Rated voltages	3/7.2 kV - 10/24 kV
Rated currents	0.5 A – 6.3 A
Rated frequency	50 Hz
Applicable standard	IEC 60282-1
Application	Indoor/outdoor
Striker	Without / 80 N (medium), with integrated TCU

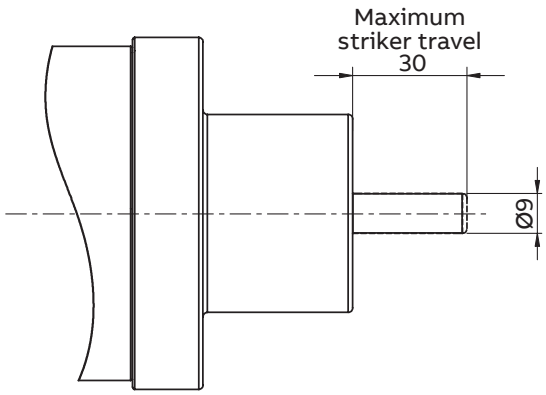
Efficient protection of voltage transformer circuits

Extending the lifetime of installed electrical equipment thanks to the limitation of the short-circuit current

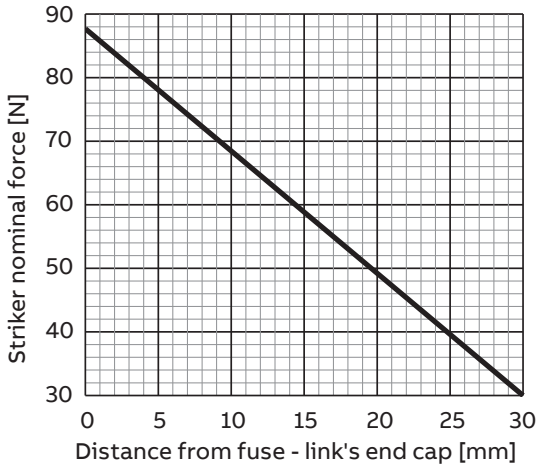


Outdoor sealing included in standard version, designed and tested for harsh conditions

CEF-VT fuses are designed for protection against faults in voltage transformer installation



Key features:



- Designed and type tested acc. to IEC 60282-1
- Low power losses, generating additional savings during product life-cycle
- Top level fault current limitation and interruption performance up to 63kA RMS
- Outdoor sealing included in standard version, designed and tested for harsh conditions
- Welded current path
- Contacts made from silver coated copper
- Striker 80N (medium type) / without striker
- Equipped with Temperature Control Unit enabling the additional protection against thermal stresses in small enclosures

Choice of fuse-links for voltage transformer protection:
Rated voltage U_r – should be equal to or higher than the maximum operating system voltage.

Rated current I_r – should be higher than the maximum continuous current of the voltage transformer.

The following points should be observed:
- Initial starting current of voltage transformer, energizing and operations of installed switching apparatus should not cause fuse tripping under normal working conditions
- Rated breaking capacity of the fuse-links should be higher than the prospective value of the short-circuit in its place of installation
- The ability of the electrical system (switchgear) to withstand impulses should exceed the switching overvoltages generated by the fuse-links

35

—
35
CEF-VT 3/7.2 kV; 6/12 kV; 10/17.5 kV; 10/24 kV time-current characteristics

Characteristic show the average melting time as a function of the prospective current and are recorded from cold condition of fuse-link. The tolerance is ± 20% referred to the current for single fuses. Characteristics are valid for frequency 50 Hz

—
36

—
36
CEF-VT 3/7.2 kV; 6/12kV; 10/17.5 kV; 10/24 kV cut-off current characteristics

Characteristics show the upper limit of the cut-off current corresponding to a prospective short--circuit current.

Characteristics are valid for frequency 50Hz.

WBP

Compact fuse-links for voltage transformer protection

Class, type	Back-up, current limiting fuse-link
Rated voltages	3 kV - 40.5 kV
Rated currents	0.4 A - 4 A
Rated frequency	50 Hz
Applicable standard	IEC 60282-1
Application	Indoor
Striker	Without

Safe operation of electrical circuit with voltage transformers

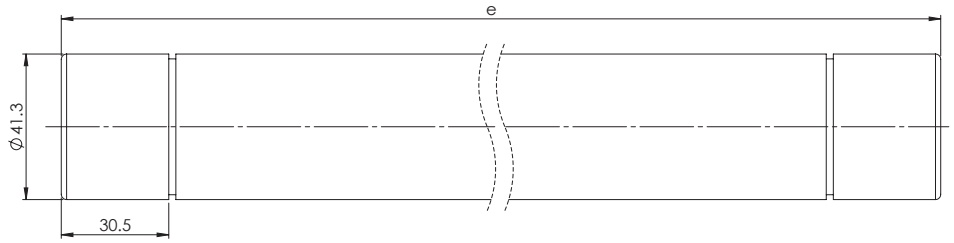
Reduce cost of service due to extended lifetime of related electrical equipment by effective limitation of short-circuit currents

Easier handling thanks to a more durable design comparing to previous generation

Fuse-links type WBP are designed for efficient protection of the circuit from faults in voltage transformers (potential transformers)

Key features:

- Designed and type tested acc. to IEC 60282-1
- Low power losses, generating additional savings during product life-cycle
- Designed for indoor applications
- Compact dimensions
- More durable design comparing to previous generation, with the use of porcelain tube
- Top level fault current limitation and interruption performance up to 63kA RMS
- Welded current path
- Contacts made from silver coated copper
- Compatible with ABB voltage transformers type TJC, TDC and other types with suitable fuse holders



37
Dimensional drawing of fuse-link type WBP 7.2 kV – 36 kV

37

38
Dimensional drawing of fuse-link type WBP 40.5 kV

38

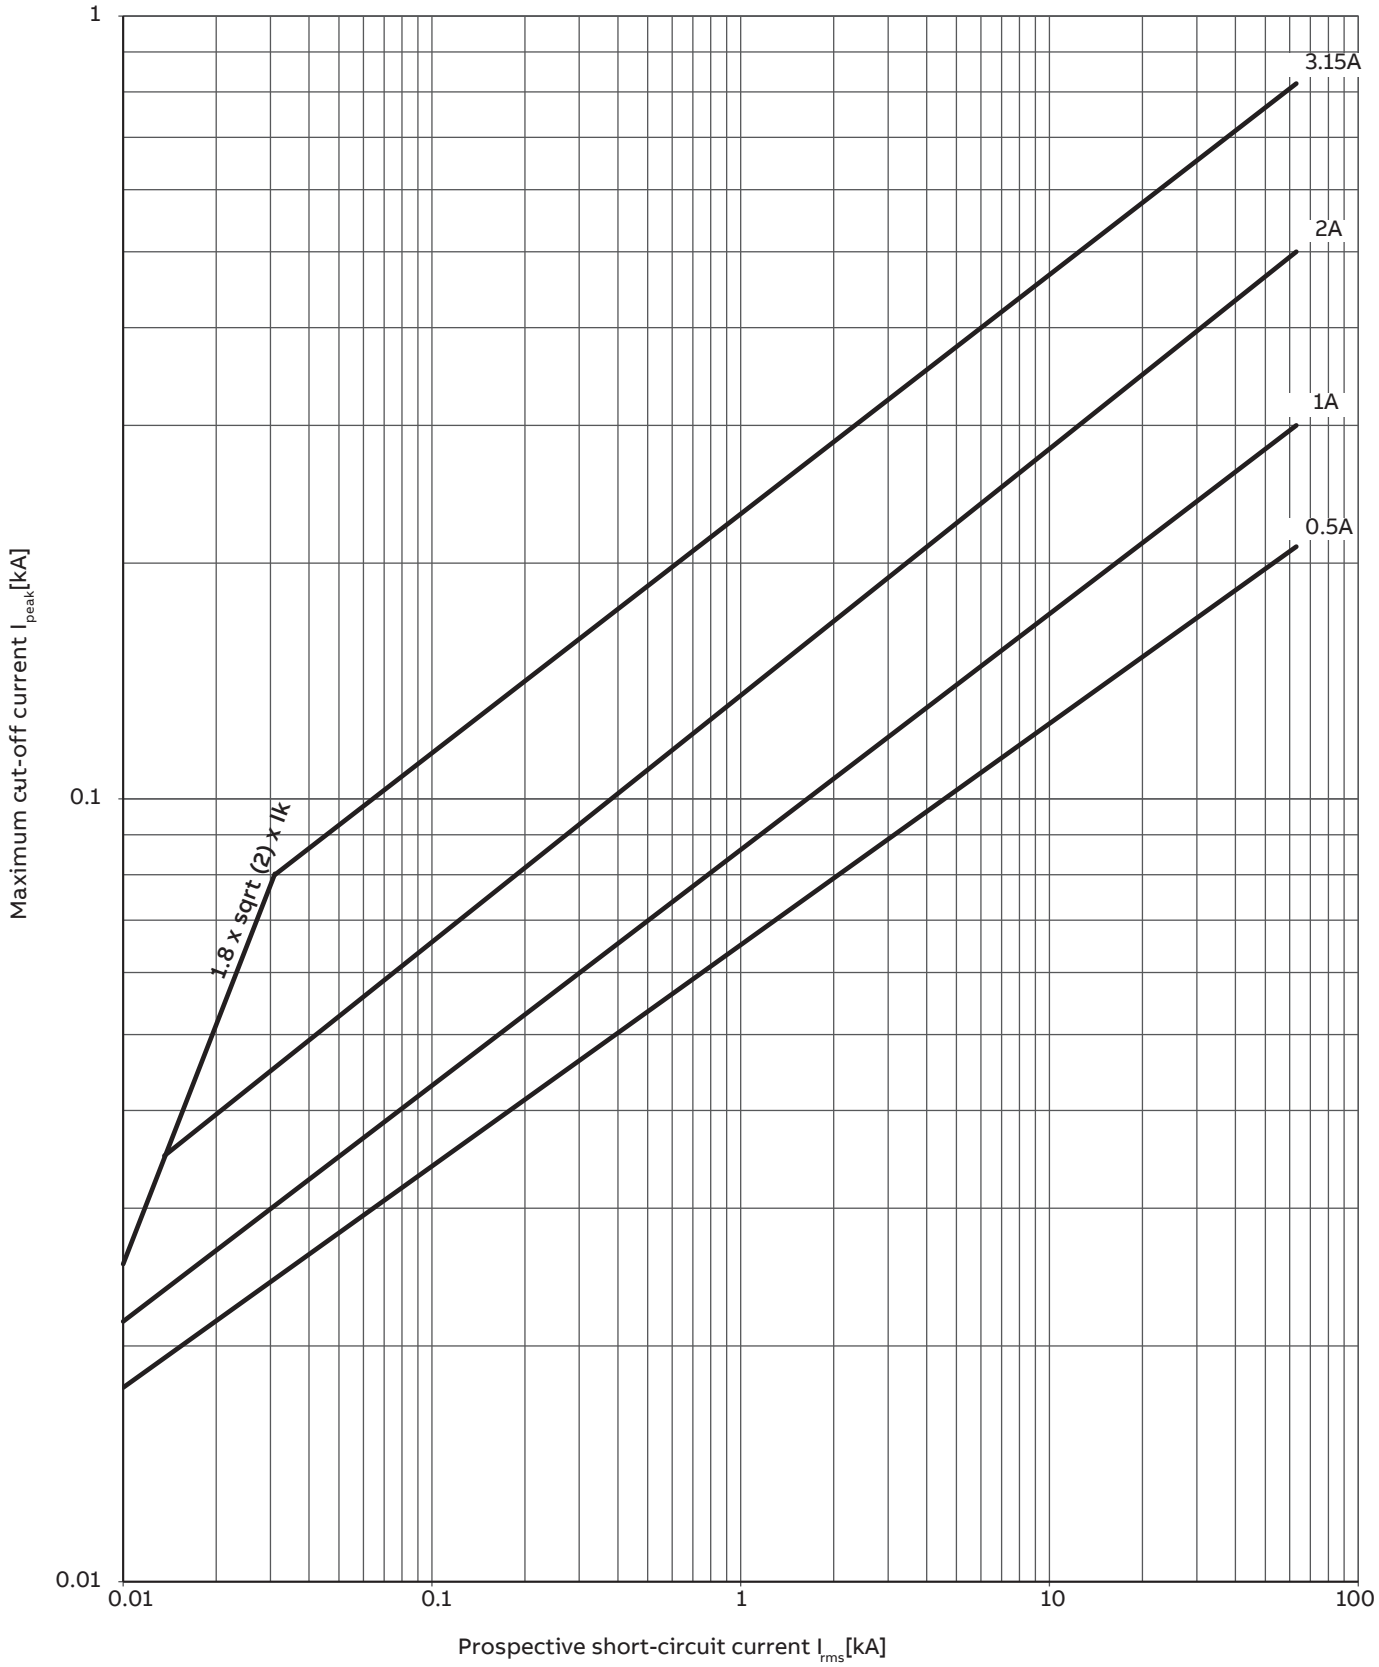
Choice of fuse-links for voltage transformer protection:

Rated voltage U_r - should be equal to or higher than the maximum operating system voltage
Rated current I_r - should be higher than the maximum continuous current of the voltage transformer

The following points should be observed:

- Initial starting current of voltage transformer, energizing and operations of installed switching apparatus should not cause fuse tripping under normal working conditions
- Rated breaking capacity of the fuse-links should be higher than the prospective value of the short-circuit in its place of installation
- The ability of the electrical system (switchgear) to withstand impulses should exceed the switching overvoltages generated by the fuse-links

—
39

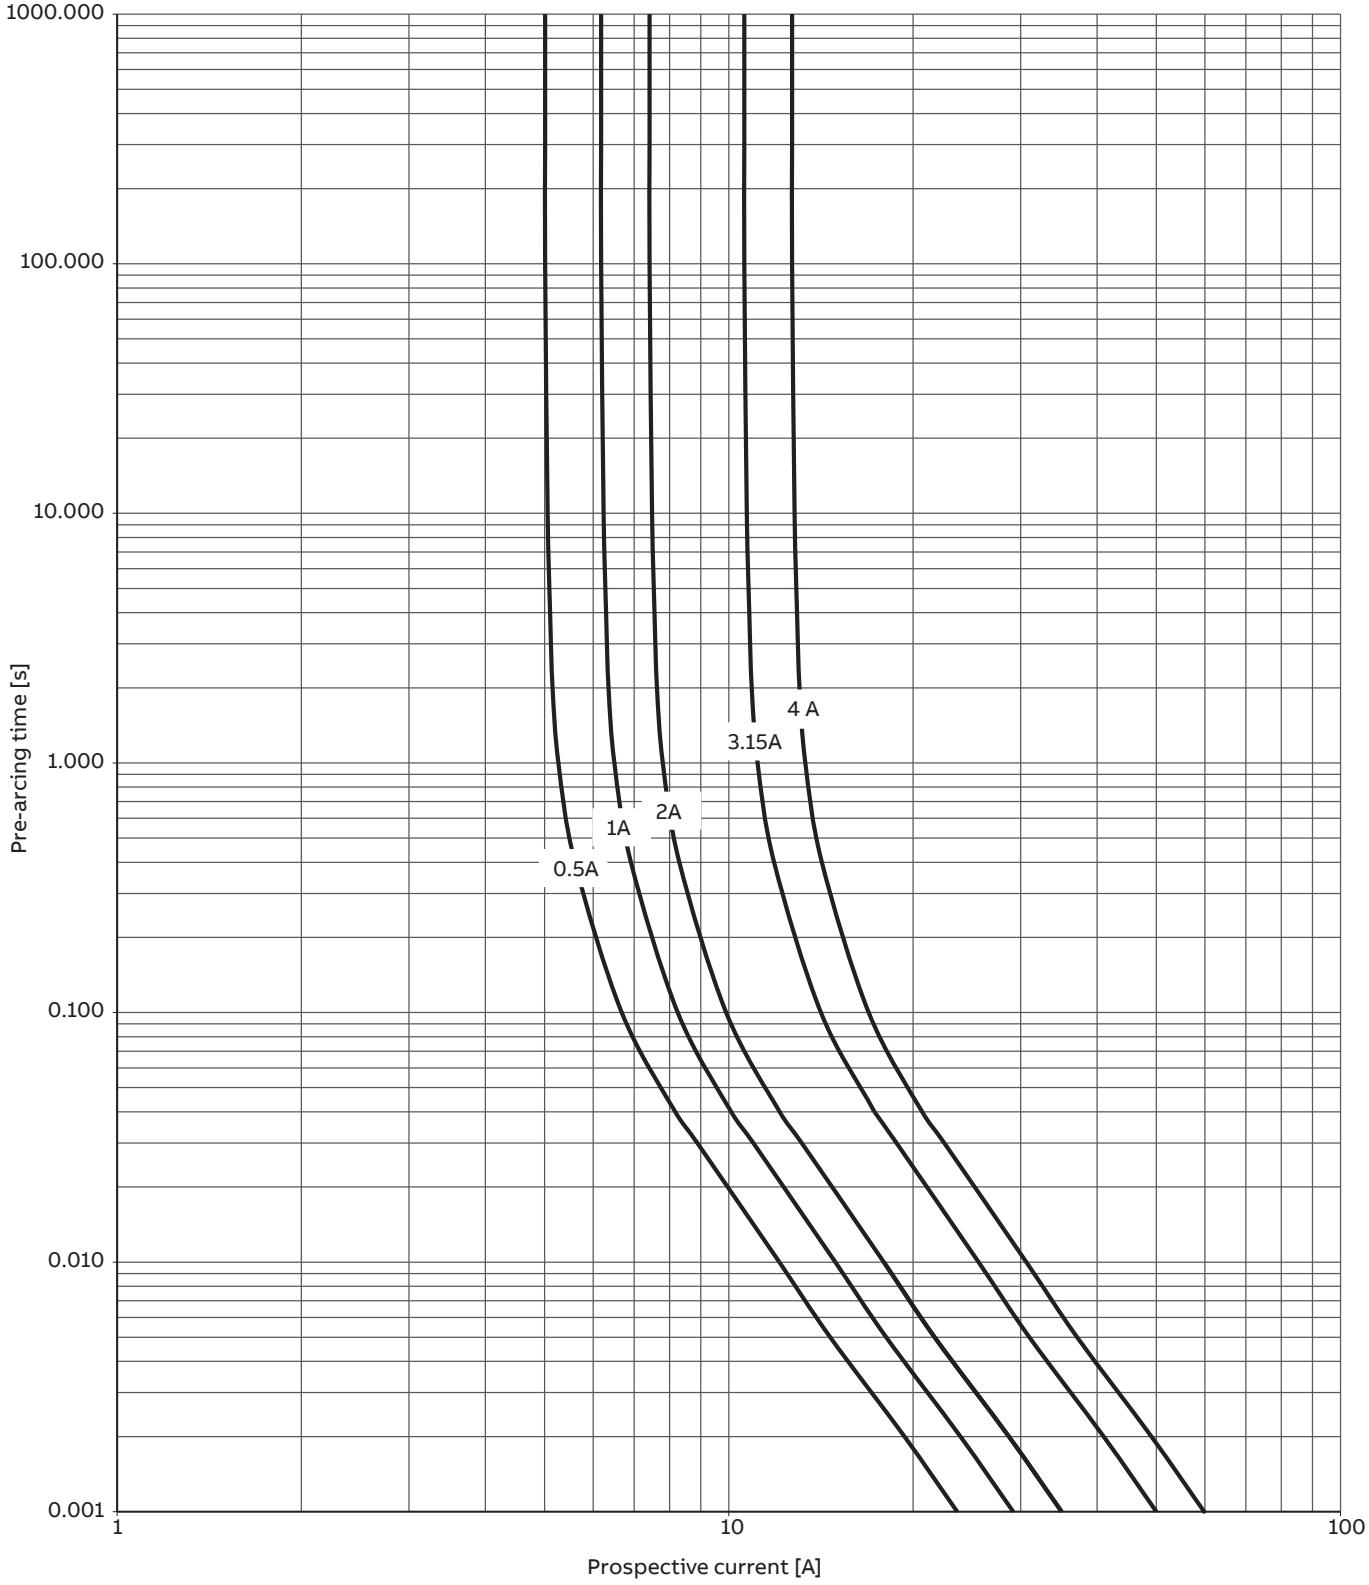


Characteristic show the average melting time as a function of the prospective current and are recorded from cold condition of fuse-link.

The tolerance is ± 20% referred to the current for single fuses. Characteristics are valid for frequency 50 Hz

—
39
WBP 7.2 kV, 12 kV, 24 kV fuses time-current characteristics

—
40



Characteristics show the cut-off current corresponding to a prospective short-circuit current.

Characteristics are valid for frequency 50Hz.

Fuse-bases and accessories

058 – 060 **UCE-NI** – Indoor fuse-bases for CEF, CEF-S, CEF-VT, CMF fuse-links

061 – 063 **PBPM** – Indoor fuse-bases for WBP fuse-links

064 – 068 **Accessories** – Accessories for fuse-links and fuse-bases

UCE-NI

Indoor fuse-bases for CEF, CEF-S, CEF-VT, CMF fuse-links

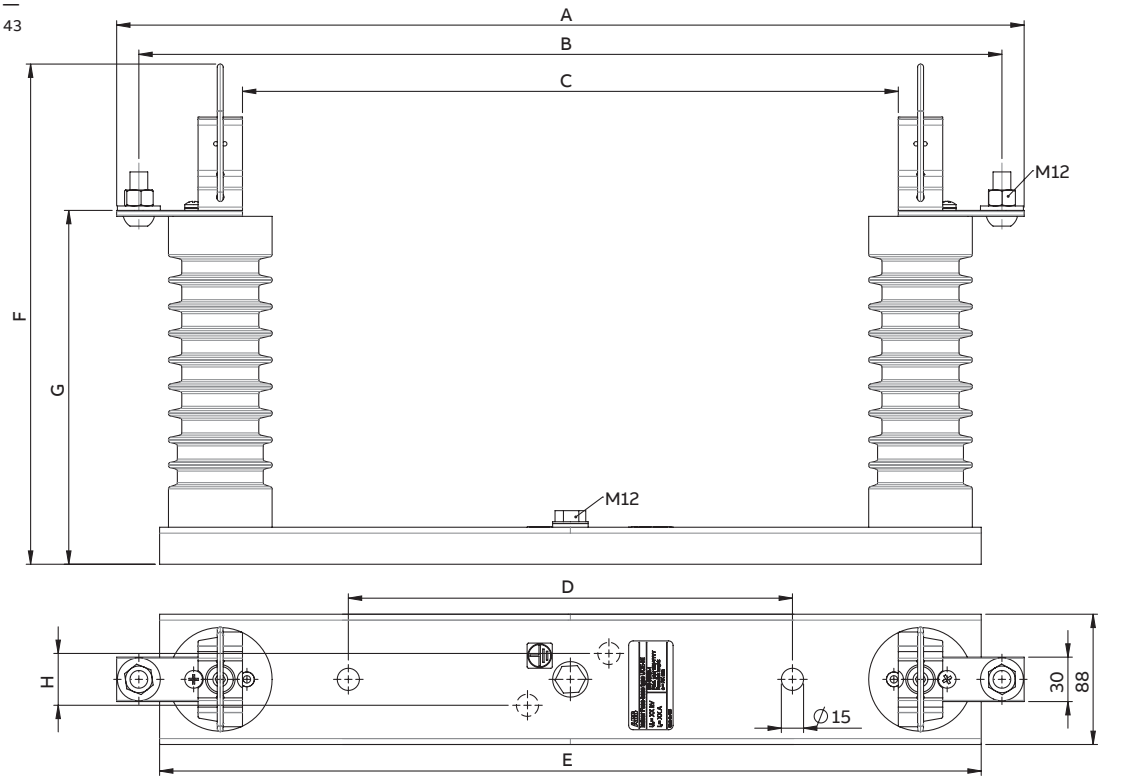
Application	Indoor fuse-base
Rated voltages	12 kV – 36 kV
Rated currents	200 A, 315 A
Rated frequency	50 Hz – 60 Hz
Compatible fuse-links	CEF, CEF-S, CEF-VT, CMF

Suitable for all types of DIN-size fuse-links

Reliable operation guaranteed by proven design

Firm connection with fuse-link secured by locks, allowing any mounting position

Fuse-bases type UCE-NI are designed for securing fuse-links in indoor application



Key features:

- Rated voltage 12 kV – 36 kV
- Rated current up to 315 A
- Type tested acc. to IEC 60282-1
- Silver coated contacts

PBPM

Indoor fuse-bases for WBP fuse-links

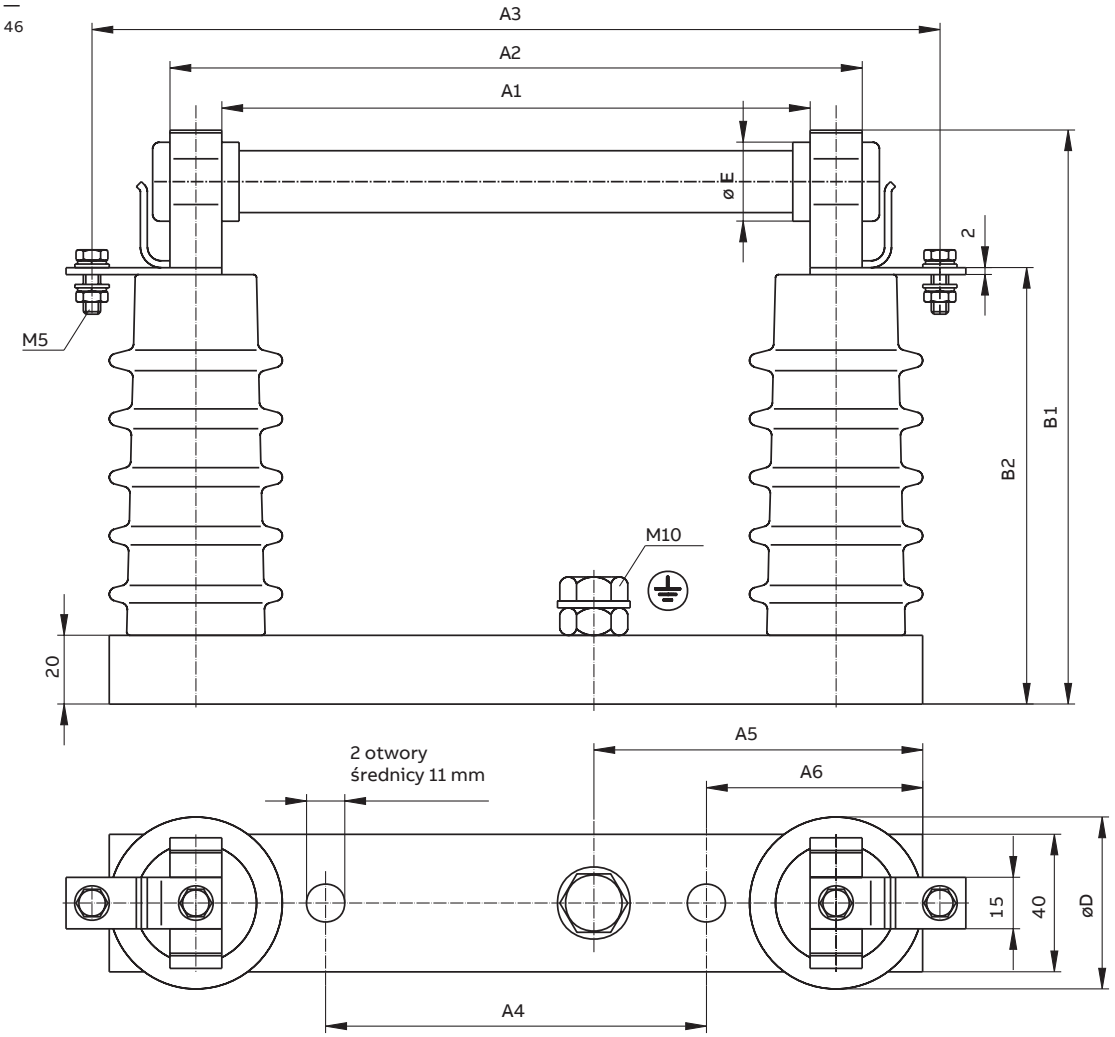
Application	Indoor fuse-base
Rated voltages	7.2 kV – 36 kV
Rated currents	3.15 A
Rated frequency	50 Hz – 60 Hz
Compatible fuse-links	WBP

Reliable operation guaranteed by proven design

Flexibility in mounting position

Small dimensions support both application and storage

Fuse-bases type PBPM are designed for securing WBP fuse-links in indoor application



Key features:

- Rated voltage 7.2 kV – 36 kV
- Rated current 0.4 A – 3.15 A
- Designed for indoor conditions

DMI 9 10 1 L (990 003)

Figure without obligation

Dimension drawing DMI 9 10 1 L

Type Part No.	DMI 9 10 1 L 990 003
Nominal discharge current (8/20 µs) (I_n)	10 kA
High current impulse (4/10 µs)	100 kA
Overload capacity	20 kA
Line discharge class (1)	1 (2.8 kJ/kV $_{Ur}$)
Long-duration current impulse (1)	250 A / 2000 µs
Rated voltage (a.c.) (U_r)	9 kV
Continuous operating voltage (a.c.) (MCOV) (U_c)	7.2 kV
Temporary overvoltage (TOV) at 1 sec. (U_{1s})	10.4 kV
Temporary overvoltage (TOV) at 10 sec. (U_{10s})	9.8 kV
Residual voltage at 10 kA (1/2 µs) ($\hat{u}_{res}$)	28.9 kV
Residual voltage at 5 kA (8/20 µs) ($\hat{u}_{res}$)	25.1 kV
Residual voltage at 10 kA (8/20 µs) ($\hat{u}_{res}$)	27.0 kV
Residual voltage at 20 kA (8/20 µs) ($\hat{u}_{res}$)	30.0 kV
Residual voltage at 40 kA (8/20 µs) ($\hat{u}_{res}$)	33.8 kV
Residual voltage at 125 A (40/100 µs) ($\hat{u}_{res}$)	19.7 kV
Residual voltage at 250 A (40/100 µs) ($\hat{u}_{res}$)	20.3 kV
Residual voltage at 500 A (40/100 µs) ($\hat{u}_{res}$)	21.1 kV
Residual voltage at 1000 A (40/100 µs) ($\hat{u}_{res}$)	21.9 kV
Residual voltage at 2000 A (40/100 µs) ($\hat{u}_{res}$)	23.0 kV
Insulation of arrester housing / nominal power frequency withstand voltage (dry) (U_{PFWL})	40 kV
Insulation of arrester housing / nominal lightning withstand voltage (U_{LIWL})	58 kV
Height (h)	132 mm
Creepage distance (+/- 5%)	108 mm
Torsional strength	78 Nm
Maximum permissible dynamic service load (MPDSL)	230 Nm
Tensile strength	1400 N
Ambient temperature (T_A)	-40 °C ... +55 °C
Altitude	up to 1000 m above sea level
Power frequency (f_N)	16-62 Hz
Housing material	HTV silicone housing
Colour	auburn, RAL 3013
Fittings	terminals, screws and nuts of stainless steel
Conductor clamp	up to Ø16 mm
Test standards	IEC 60099-4
Weight	1 kg
Customs tariff number (Comb. Nomenclature EU)	85354000
GTIN	4013364102606
PU	1 pc(s)

We reserve the right to introduce changes in performance, configuration and technology, dimensions, weights and materials in the course of technical progress. The figures are shown without obligation.

For your safety!

- Make sure that the installation room (spaces, divisions and ambient) is suitable for the electrical apparatus.
- Check that all the installation, putting into service and maintenance operations are carried out by qualified personnel with suitable knowledge of the apparatus.
- Make sure that the standard and legal prescriptions are complied with during installation, operation and maintenance, so that installations according to the rules of good working practice and safety in the work place are constructed.
- Strictly follow the information given in this instruction manual.
- Check that the rated performance of the apparatus is not exceeded during service.
- Check that the personnel operating the apparatus have this instruction manual to hand as well as the necessary information for correct intervention.
- Pay special attention to the danger notes indicated in the manual by the following symbol:

Responsible behaviour safeguards your own and others' safety!

For any requests, please contact the ABB Assistance Service.

I. Introduction

The instructions in this manual refer to the fixed and withdrawable versions of the VSC series of contactors. For correct use of the product, please read it carefully.

For the electrical and construction characteristics and the overall dimensions of the V-Contact VSC contactors, please also see technical catalogue 1VCP000165.

Like all the apparatus we manufacture, the V-Contact vacuum contactors are designed for different installation configurations. Furthermore, this apparatus allows further technical and construction modifications (at the customer's request) to adapt to special installation requirements. Consequently, this manual may not provide information concerning special configurations of the apparatus.

Apart from this manual, it is therefore always necessary to consult the latest technical documentation (circuit and wiring diagrams, assembly and installation drawings, any protection coordination studies, etc.), especially regarding any variants requested in relation to the standardised configurations.

Only use original spare parts for maintenance operations. The use of non-original spare parts can cause hazardous malfunctions and the apparatus warranty will no longer be valid.

Please refer to the technical sheets of the Kits for correct assembly of the accessories and/or spare parts. For further information, also see the 1VCP000165 technical catalogue of the contactor and the spare parts catalogue.

This manual and all the enclosed drawings must be considered an integral part of the apparatus. They must be easily to hand at all times for revision and reference.

These instructions do not intend to cover all the details, configurations or variants of the apparatus, storage or installation. For this reason, the information given below may sometimes not contain the instructions regarding special configurations. This does not relieve the user from their responsibility for using good technical working practices in application, installation, service and maintenance of the apparatus purchased. Should further information be required, please contact ABB.

WARNING

Dangerous voltages. Risk of death, serious injury to people, damage to the apparatus or other objects.

Before carrying out any maintenance operations, turn the power supply off and earth the apparatus.

Read and understand this instruction manual before installation, service or maintenance of the apparatus.

Maintenance must only be carried out by skilled personnel.

The use of unauthorized spare parts for repairs to the apparatus, modification of the apparatus itself, or tampering by unskilled personnel creates hazardous conditions which may cause death or serious injury to people, or damage to the apparatus or other objects. Carefully follow all the safety instructions given in this manual.

II. Environmental protection programme

The V-Contact VSC vacuum contactors are manufactured in accordance with the ISO 14000 Standards (Guidelines for environmental management). The production processes are carried out in compliance with the Standards for environmental protection in terms of reduction in energy consumption as well as in raw materials and production of waste materials.
All this is thanks to the medium voltage apparatus manufacturing facility environmental management system.

III. Application of the X-ray emission Standards

One of the physical properties of vacuum insulation is the possibility of X-ray emission when the interrupter contacts are open. The tests carried out at the PTB laboratories (Physikalisch-Technische Bundesanstalt, in Brunswick - Germany) show that local emission at a distance of 10 cm from the interrupter or pole surface, does not exceed 1 µSv/h. It follows that:

– at the rated service voltage the use of vacuum interrupters is absolutely safe;
– application of the withstand voltage at power frequency, according to the IEC 62271-1 Standard, is safe;
– application of a voltage higher than the withstand voltage at power frequency or of a direct current test voltage, specified in the IEC Standard, cannot be used;
– limitation of the above-mentioned local phenomena, on interrupters with open contacts, depends on keeping the specified distance between the contacts. This condition is intrinsically guaranteed by correct operation of the drive and by transmission system adjustments.

IV. Safety information

All the installation, putting into service, running and maintenance operations must be carried out by suitably qualified personnel with in-depth knowledge of the apparatus. Make sure that the personnel working on the apparatus have this manual to hand and all the information required for correct intervention.
Strictly follow the information given in this instruction manual. Make sure that during the installation, service and maintenance stages the standard and legal requirements for constructing the installations in accordance with the regulations for safety in the workplace are respected.
Check that the rated performance of the apparatus is not exceeded during service.

V. Qualified personnel

For the purposes of this manual and the product rating plates, a qualified person is intended as a person who:

1) carefully reads the instruction manual all the way through.
2) has in-depth knowledge of the installation, construction and service of the apparatus and knows about the risks connected with any interventions.
3) is qualified and authorised to energise, de-energise, earth and identify the circuits according to the safety procedures and the local regulations in force.
4) is qualified and authorised to put this apparatus into service, and to carry out maintenance and repair operations on it.
5) is trained in correct use of protective equipment, such as rubber gloves, hard hats, protective goggles, face shields, flameproof clothing, etc. according to the safety procedures and the local regulations in force.
6) is trained in first-aid procedures.

VI. Interventions in the field

ABB can provide competent and well-trained personnel for assistance in the field to give technical guidance and consultancy regarding installation, full servicing, repair and maintenance of apparatus.

1. Description

The medium voltage V-Contact VSC contactors are pieces of apparatus suitable for operating in alternating current and are normally used to control users requiring a high number of hourly operations.

The basic contactors consist of:

- moulded polyester resin monobloc containing the vacuum interrupters
- bistable electromagnet actuator
- multi-voltage feeders
- auxiliary contacts
- mechanical status indicator (open/closed)
- manual emergency opening device.

Apart from what is specified for the fixed contactors, the withdrawable contactors also consist of:

- fuseholders preset for DIN or BS fuses (according to the customer's requirements)
- automatic opening device for intervention of even a single fuse
- truck
- lock which prevents closing during the racking-in/out operation.

The V-Contact VSC contactor introduces the drive with permanent magnets - already widely used, experimented and appreciated in medium voltage circuit-breakers - into the worldwide panorama of medium voltage contactors.
The experience acquired by ABB in the field of medium voltage circuit-breakers fitted with drives with "MABS" permanent magnets, has made it possible to develop an optimised version of the actuator (Bistable MAC drive) for medium voltage contactors.

The drive is operated by means of an electronic feeder able to cover all the power supply voltages required by the major international Standards.

1.1. "MAC" magnetic drive

Based on the experience gained in the field of circuit-breakers with magnetic drive, ABB has implemented this technology in the field of contactors.

The magnetic drive adapts perfectly to this type of apparatus thanks to its precise and linear travel.

This means that a simple and direct axial transmission of the movement to the moving contacts of the vacuum interrupter can be realised, with both electrical and mechanical benefits.

The drive, which is of bistable type, is fitted with an opening and a closing coil.

The two coils - individually energised - allow the drive core to be moved from one of the two stable positions to the other.

The drive shaft is solid with an iron core which is immersed and held in position in a field generated by two permanent magnets (fig. A).

Energising the coil opposite to the magnetic latching position (fig. A) of the core, the magnetic field (fig. B) is generated, which attracts and moves the core into the opposite position (fig. C).

Every opening and closing operation creates a magnetic field concordant with the one generated by the permanent magnets, with the advantage, during service, of keeping the intensity of the field itself constant as the number of operations carried out increases.

The energy needed for operation is not supplied directly by the auxiliary power supply, but is always "stored" in the capacitor which acts as an energy accumulator, and therefore operation always takes place with constant speeds and times, regardless of the divergence of the power supply voltage from the rated value.

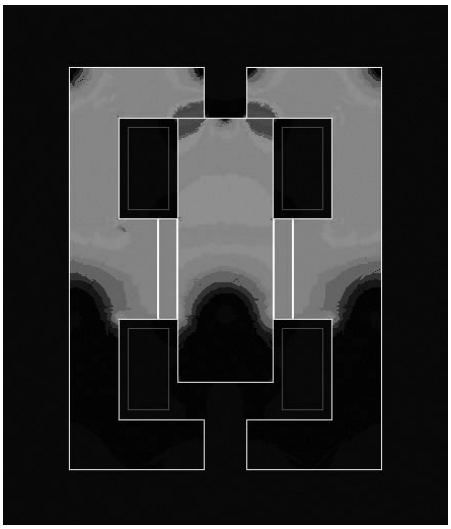

Fig. A
Magnetic circuit in the closed position.

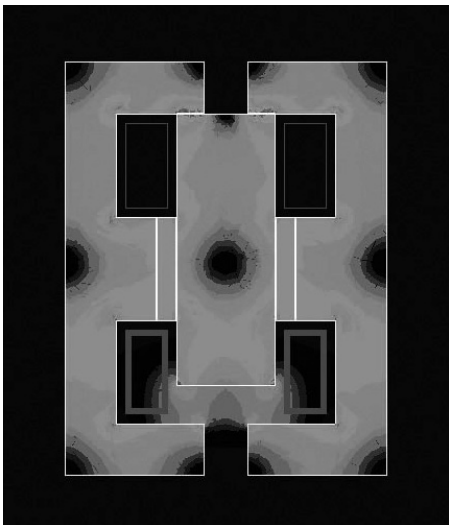

Fig. B
Magnetic circuit with opening coil supplied.

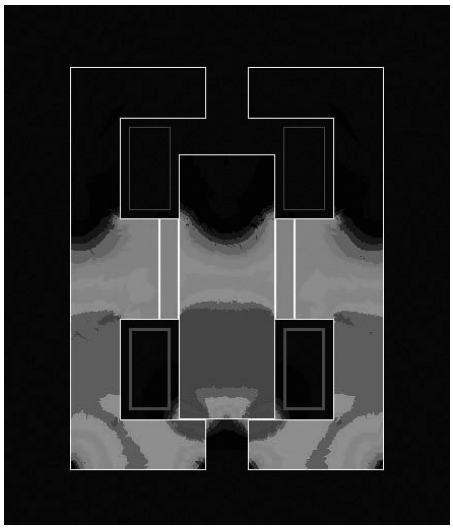

Fig. C
Magnetic circuit in the open position.

The auxiliary power supply only has the aim of keeping the capacitor charged.
Consumption is therefore minimal.

The power required by the electronic device is indicated in the table below:

Power supply voltage	Starting (1)		After closing	After opening	Continuous power consumption
	Inrush for 2 ms	Inrush for 6 sec	Inrush for 1.2 sec	Inrush for 1.2 sec	
24...60 V DC 110...250 V DC 110...250 V AC	42 A (2)	35 W	25 W	30 W	5 W

(1) This value refers to a discharged capacitor.
(2) The value drops to 8 A for voltage values between 24...30V

Supply from voltage transformer or from UPS (Uninterrupted Power System) not available.
Use the ABB S282UC-C3 thermal-magnetic circuit-breaker or an equivalent type to protect the secondary circuits.
After powering, the electronic board takes 15 seconds to perform self-diagnosis and then prepares for normal operation, depending on the configuration. Do not operate the contactor during this phase. Contact DO1 will remain open, signal “not ready” and will only close after self-diagnosis has terminated (“ready” state).

Careful selection of the components and a precise design make the electronic multi-voltage feeder extremely reliable, unaffected by electromagnetic interference generated by the surrounding environment and free of any emissions which may affect other apparatus placed in the vicinity.

These characteristics have made it possible for the V-Contact VSC contactors to pass the electromagnetic compatibility tests (EMC).

1.2. Versions available

The V-Contact VSC are available in:
– fixed version without fuseholder
– fixed versions with fuseholder: VSC/F e VSC/FN.
– four withdrawable versions with fuseholder:
  - VSC/P (IEC) and VSC/PG or VSC-S/PG (IEC/GB-DL) withdrawable versions for UniGear, PowerCube, CBE and PowerBloc with manual or motorized truck
  - VSC/PN (IEC) and VSC/PG or VSC-S/PNG (IEC/GB-DL) both versions withdrawable for UniGear MCC with manual truck.

1.6. Contactor auxiliary circuits

10 auxiliary contacts (5 normally open and 5 normally closed) are available on the contactor for the customer's use, with the following characteristics.

Auxiliary contacts characteristics		
Rated voltage	24 … 660	V
Rated normal current	10	A
Rated short time current (30 ms, 20 times)	100	A
Rated frequency (for AC only)	50	Hz
Rated insulation voltage (DC)	800	V
Rated insulation voltage (AC)	660	V
Insulation test voltage	2500	V
Number of contacts	5	-
Stroke	6 … 7	mm
Maximum contact resistance	10	mΩ
Storage temperature range	-20 … +120	°C
Operating temperature range	-20 … +70	°C
Emperature rise of contacts	30	K
Breaking capacity (single contact τ = 20 ms, 250 V dc)	250	W
Breaking capacity (single contact τ = 20 ms, 110 V dc)	440	W
Breaking capacity (two contacts in series τ = 20 ms, 250 V dc)	440	W

Characteristics of the contacts of the “Coil Continuity Control” and “Capacity Survey” devices	
Technology	Relay with air-insulated contacts
Breaking characteristics:	
Maximum breaking power	1200 VA (on resistive load)
Maximum breaking voltage	277 V AC, 30 V DC
Maximum breaking current	3 A
Rated current	5 A @ 4 s
Contact characteristics:	
Maximum resistance with contact open	150 mohm (measure of voltage drop 6 V DC 1)
Maximum capacity	1.5 pF
Trip times:	
During closing	5.0 ms
During release	2.0 ms
Insulation:	
Between contacts and coil	3000 V rms (50 Hz / 1 min.)
Between open contacts	750 V rms (50 Hz / 1 min.)
Resistance with contacts open	Min. 103 Mohm at 500 V DC

1.7. Compliance with Standards

V-Contact contactors comply with the Standards of the major industrialised countries and in particular with the following Standards:

– IEC 62271-106 (2011);
– IEC 62271-1 (2007);
– GB/T 14808-2001;
– DL/T 593-2006;
– IEC 60278 replaced by IEC 62271-200;
– IEC 60694 (2002) replaced by IEC 62271-1;
– IEC 60056 (4.104) replaced by IEC 62271-100;
– IEC 60470 replaced by IEC 62271-106.

1.8. Protection against short-circuit

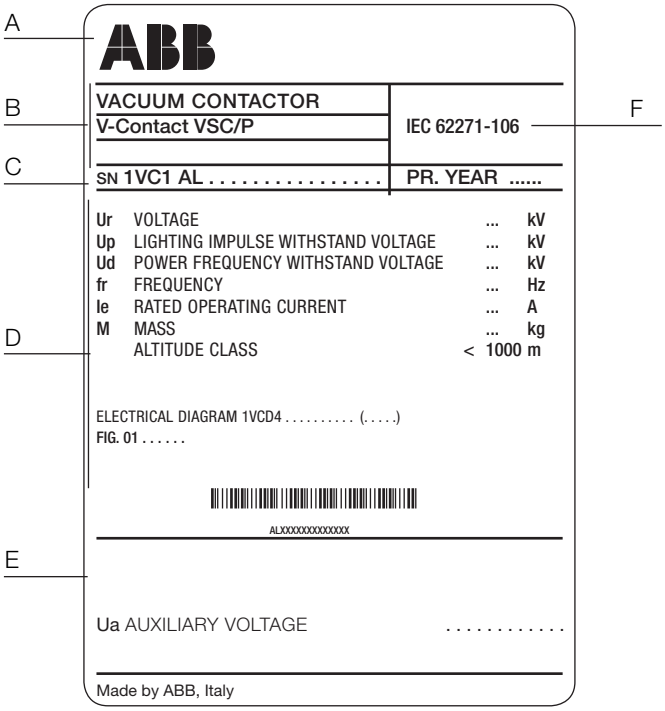
The value of the installation short-circuit current could exceed the breaking capacity of the contactor. The contactor must therefore have adequate protection against short-circuit.

Fuse replacement must only be carried out by qualified personnel.

2. Checking on receipt

During handling, take great care not to stress the insulating parts of the apparatus and the terminals of the contactor.

Any operation carried out on the contactor must be done without the presence of voltage and with the main protection device open: danger of electrocution and/or severe burns.



Make sure that operations are carried out with the main and auxiliary power off.

On receipt, immediately check integrity of the packing and the colour of the “SHOCKWATCH” indicator (Fig. 1) placed on it.
If the “SHOCKWATCH” impact indicator is WHITE, it means that the packing has not received any notable shocks during transport. Open the packing, remove the contactor as indicated below, and check the state of the apparatus and its correspondence with the nameplate data (see fig. 2) with what is specified in the accompanying shipping note and in the order confirmation sent by ABB.
If the “SHOCKWATCH” impact indicator is RED, follow the instructions indicated on the plate.
Opening the packing does not damage its components and it can therefore be re-instated using the original material.
The contactor is shipped in special packing, in the open position.
Each piece of apparatus is protected by a plastic cover to prevent any infiltration of water during the loading and unloading stages and to keep the dust off during storage.
To remove the contactor from the packing, proceed as follows:
– open the plastic bag
– remove the contactor, avoiding any stress to the functional insulating parts and the terminals of the apparatus.
– use the special lifting plates for the withdrawable version
– check the rating plate characteristics to make sure that the performances are suitable for the destined application and that they are those indicated in the order confirmation.

Should any damage or irregularity be noted in the supply on unpacking, notify ABB (directly or through the agent or supplier) as soon as possible and in any case within five days of receipt.
The apparatus is only supplied with the accessories specified at the time of ordering and validated in the order confirmation sent by ABB.
The accompanying documents inserted in the shipping packing are:
– instruction manual (this document)
– test certification
– identification label
– fiscal copy of the shipping advice note
– electric wiring diagram.

Fig. 1

A Trademark
B Type of apparatus
C Serial number
D Characteristics of the apparatus
E Characteristics of the control auxiliaries
F Reference standards

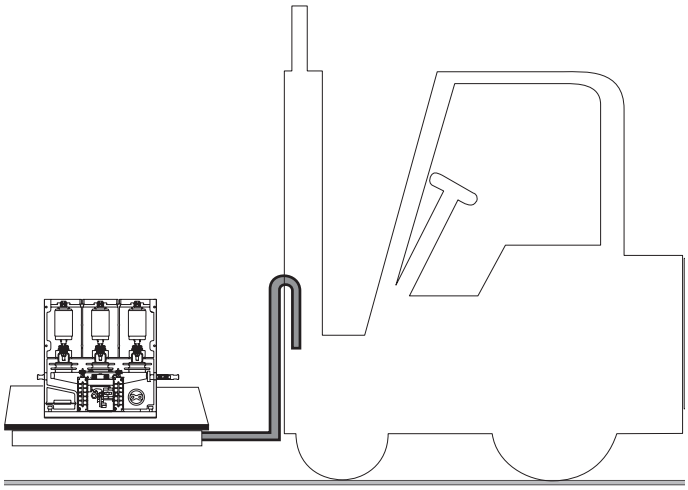
Fig. 2

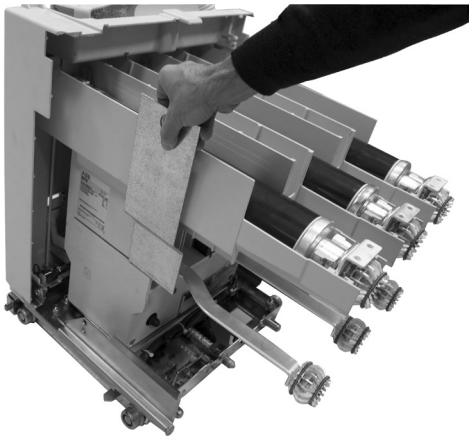
Other documents which are sent prior to shipment of the apparatus are:
– order confirmation
– original shipping advice note
– any drawings or documents referring to special configurations/conditions.

3. Handling

The contactor can be lifted using a lifting truck or a fork-lift truck.
The following precautions must be taken during contactor handling:

1. Keep the contactor in the upright position.
2. Make sure that the load is balanced on the truck or on the transport plate/pallet.
3. Interpose protective material between the contactor and the truck to avoid any damage or scratches.
4. Fix the contactor onto the truck or onto the transport plate/pallet to prevent it moving or tilting over.
5. Avoid excessive speed, sudden starts and stops or sharp changes in direction during contactor handling.
6. Only lift the contactor enough to avoid any obstacles on the floor.
7. Take care to avoid any impacts with structures, other apparatus or with personnel when handling the contactor.
8. Never lift a contactor over an area where there are people.
9. During handling of the apparatus, do not stress the insulating parts and the contactor terminals.





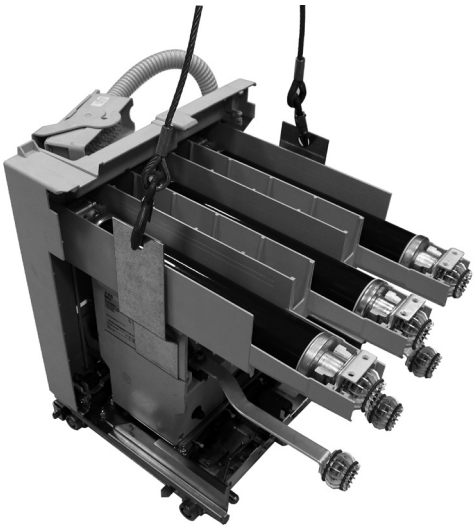


Fig. 3a - Handling using a lifting or fork-lift truck.

3.1. Handling and lifting using a crane

– Insert the lifting plates
– Lift
– After the unpacking and lifting operations, remove the lifting accessories.
  Warning: with lifting tools, it is mandatory to move the contactors not by pulling them, but by pushing them from the screen

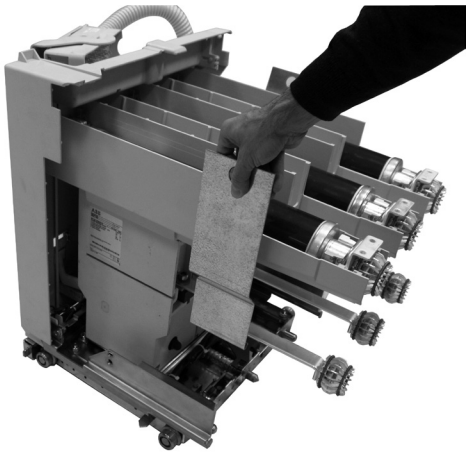

Fig. 3b - Removal of the contactor from the packing and dismantling the lifting tools.

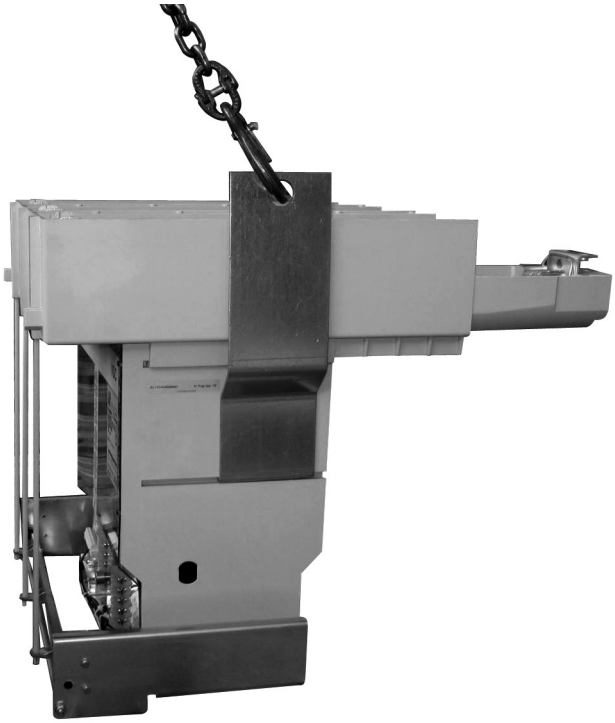

Fig. 3c - Fixed contactor with fuses

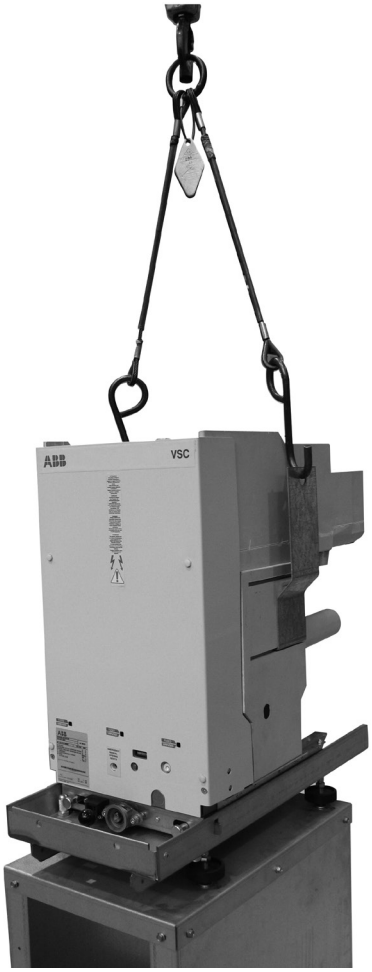

Fig. 3d - Withdrawable contactor

4. Storage

When a period of storage is foreseen, the original packing must be put back. Store the contactor in a dry dust-free area. It must not be left outside or in adverse micro-climatic conditions: if it is left without protection, rust and deterioration of the insulation can occur.
Insert special hygroscopic packets inside the packing, with at least one standard packet per piece of apparatus. Replace the packets approximately every 6 months.

Should the original packing no longer be available and immediate installation is not possible, store in a covered, well-ventilated, dry, dust-free, non-corrosive ambient, with a dry atmosphere, away from any flammable materials and at a temperature between – 5 °C and + 40 °C.
In any case, avoid any accidental impacts or positioning which stresses the structure of the apparatus.

5. Installation

5.1. General

Correct installation is of primary importance. The manufacturer's instructions must be carefully studied and followed. It is good practice to use gloves for handling the pieces during installation.

The areas involved in the passage of power conductors or conductors of auxiliary circuits must be protected against access of any animals which might cause damage or disservices.

The contactor enclosure must be installed in a clean, dry and heated place with good ventilation. It must be easily accessible for cleaning and inspection, and must be levelled, placed on the supporting foundations and securely fixed into position.
When the contactor is connected to a capacitive load, make sure that there is a heating element to keep the humidity down and of suitable size for the compartment where the contactor is installed. The contactor must always be installed associated with a suitable protection device (e.g.: fuses).

The fixed version of the V-Contact VSC contactors must be installed by the customer so as to guarantee a minimum degree of protection of IP2X.

5.2. Installation and operating conditions

The following Standards must be taken into particular consideration during installation and service:
- IEC62271-1/DIN VDE 0101
- VDE 0105: Operation of electrical plants
- DIN VDE 0141: Earthing systems for electrical installations with rated voltage higher than 1 kV
- All the accident prevention regulations in force in the relative countries.

5.3. Normal conditions

Follow the recommendations in the IEC 62271-1 and 62271-106 Standards. In more detail:

Ambient temperature	
Maximum	+ 40 °C
Average maximum over 24 hours	+ 35 °C
Minimum (according to class – 5), apparatus for indoor installation	– 5 °C

Humidity

The average value of the relative humidity, measured for a period longer than 24 hours, must not exceed 95%.
The average value of the water vapour pressure, measured for a period longer than 24 hours, must not exceed 2.2 kPa.
The average value of the relative humidity, measured for a period longer than 1 month, must not exceed 90%.
The average value of the water vapour pressure, measured for a period longer than 1 month, must not exceed 1.8 kPa

Altitude

< 1000 m above sea level.

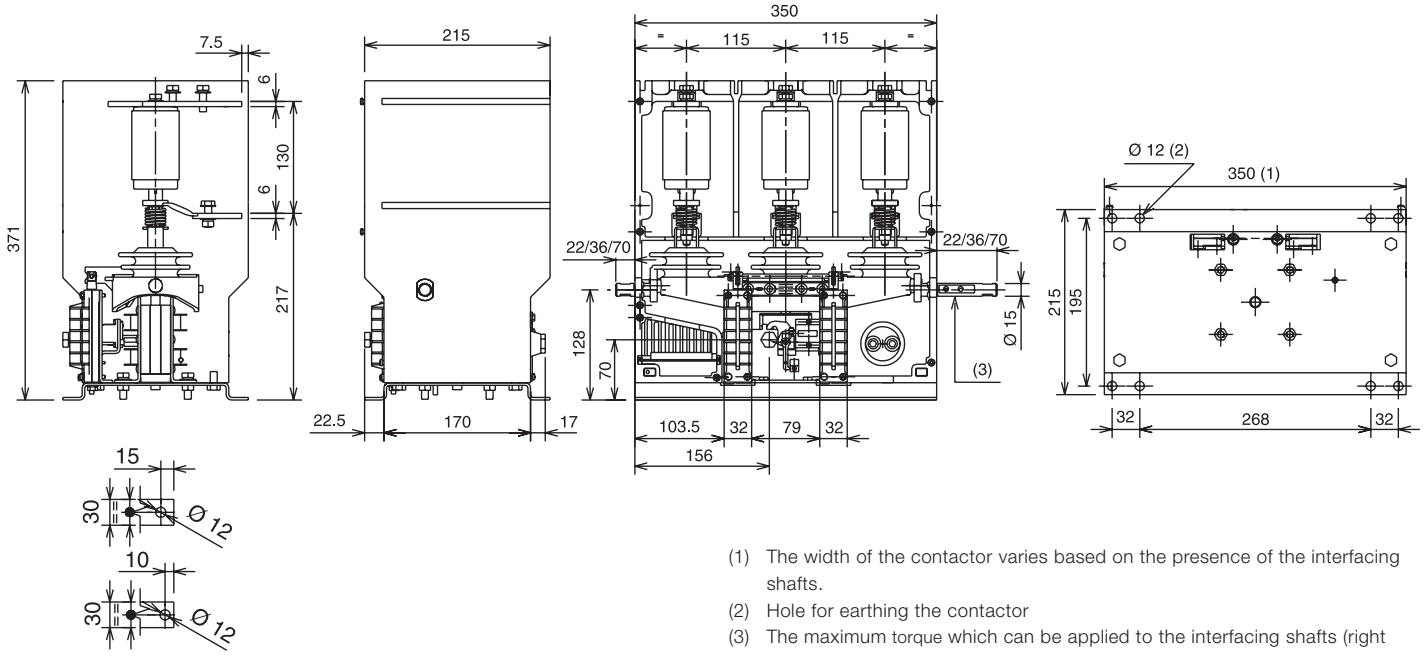
5.4. Special conditions

Installations above 1000 m a.s.l.

Possible within the limits allowed by reduction of the dielectric resistance of air.
For altitudes over 2000 m ask ABB.

Climate - Increase in temperature

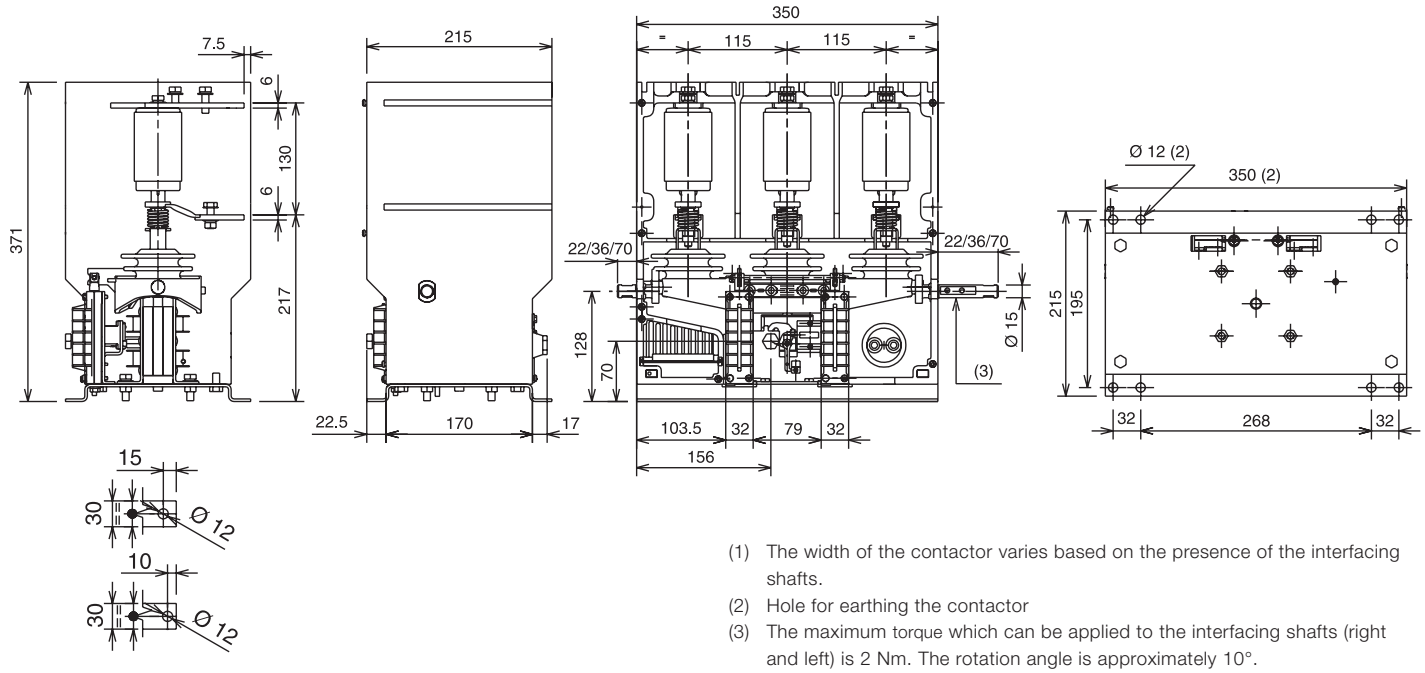
In order to avoid the risk of corrosion or other damage in areas with high humidity and/or rapid large fluctuations in temperature, take appropriate measures (for example, using suitable electric heaters) to prevent any condensation phenomena.



For special installation requirements or other operating conditions, please contact ABB.

5.5. Overall dimensions

5.5.1. VSC fixed contactor



For the overall dimensions and distances between fixing holes, refer to figure 4a.
In any case, avoid stressing the supporting structure of the contactor: if necessary, arrange slots in the fixing area to facilitate correct positioning of the apparatus.
The assembly positions can be selected between the two shown in figure 4b.

VSC7

(1) The width of the contactor varies based on the presence of the interfacing shafts.
(2) Hole for earthing the contactor
(3) The maximum torque which can be applied to the interfacing shafts (right and left) is 2 Nm. The rotation angle is approximately 10°.

VSC12

(1) The width of the contactor varies based on the presence of the interfacing shafts.
(2) Hole for earthing the contactor
(3) The maximum torque which can be applied to the interfacing shafts (right and left) is 2 Nm. The rotation angle is approximately 10°.

Fig. 4a

Installation of fixed contactors

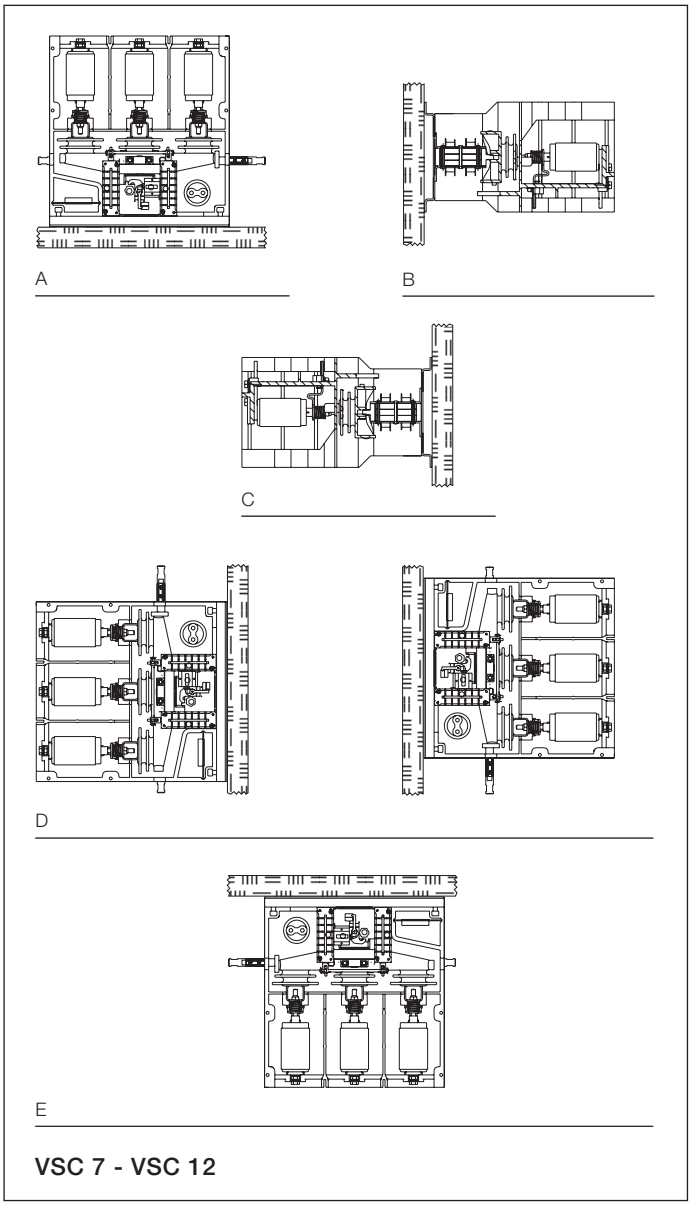
The performance of the contactor remains unaltered in the installation positions indicated below:

VSC 7 - VSC 12

A) Floor-mounted with moving contacts at the bottom.
B) Wall-mounted with horizontal moving contacts and terminals at the bottom.
C) Wall-mounted with horizontal moving contacts and terminals at the top.
D) Wall-mounted with horizontal moving contacts with interrupters on the front (or rear) with vertical terminals.
E) Ceiling-mounted with moving contacts at the top.

VSC 7/F - VSC 12/F - VSC 7/FN

A) Floor-mounted with moving contacts at the bottom.



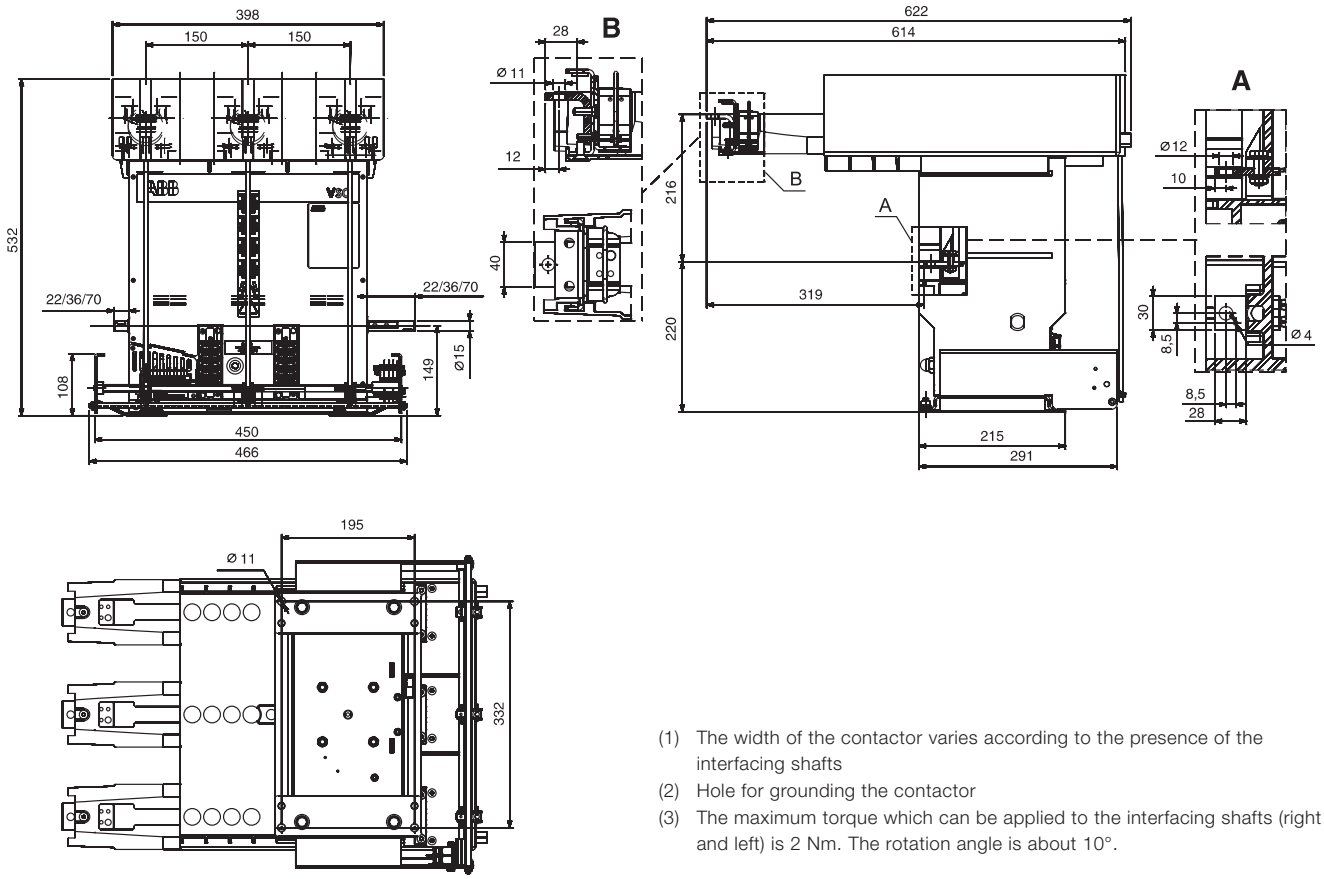


Fig. 4b

5.5.2. VSC/F contactor in fixed version with fuses

Please refer to figures 5a - 5b for the overall dimensions and the distances between the fixing holes.
In any case, avoid stressing the supporting structure of the contactor: if necessary, prepare slots in the fixing area to facilitate correct positioning of the apparatus.
The contactor must be installed on the floor with moving contacts at the bottom (figure 5c).

VSC7/F

(1) The width of the contactor varies according to the presence of the interfacing shafts
(2) Hole for grounding the contactor
(3) The maximum torque which can be applied to the interfacing shafts (right and left) is 2 Nm. The rotation angle is about 10°.

5.6. Assembly and making the connections

5.6.1. Fixed contactors

WARNING

Dangerous voltages. Risk of death, serious injury to people, damage to the apparatus or other objects.

Remove the power supply, ground and put all the power and control voltage sources under safe conditions before starting the work on this or any other electrical apparauts.
Installation must only be carried out by qualified personnel.

Introduction

Before carrying out any installation operations:

- Test all the power terminals to check that they are not supplied with voltage. Only use high voltage testing equipment approved for checking the voltage on the power terminals. **Do not attempt to measure the high voltage (above 600 volt) with a volt-ohm/meter.**
- Check all the control and secondary circuit terminals with a voltmeter to ensure that all the control and secondary input voltage sources have been turned off.
- Connect the safety earthing to the power terminals after having turned the power supply to the system off and before working on the apparatus.
- Carry out all the operations for turning off the voltage and earthing according to the established safety procedures.

Power circuit

General precautions

– Check that the connections of the fixed contactor or the isolating contacts of the withdrawable contactor are clean and free of any deformation caused by shocks received during transport or storage in the warehouse.
– Select the cross-section of the conductors according to the service current and the short-circuit current of the installation.
– Prepare special pole insulators, near the terminals of the contactor, sized according to the electrodynamic forces deriving from the short-circuit current of the installation and avoid stressing the connections laterally.

Surface treatment of the connections

The connections can either be made of bare copper or bare aluminium. In any case, it is always advisable to silver-plate the contact surfaces. The surface treatment must have a constant and even thickness.

Assembly procedures for fixed contactors

– Check that the contact surfaces of the connections are flat, and are free of any burrs, traces of oxidation or deformation caused by drilling or impacts received.
– Carry out the operations indicated on the contact surface of the conductor (silver-plated copper):
  - clean with a rough dry cloth
  - only in the case of obstinate traces of oxidation, clean with a very fine grain emery cloth taking care not to remove the surface layer
  - if necessary, restore the surface treatment (consult ABB)
  - put the connections in contact with the contactor terminals, taking care to avoid mechanical stresses produced, for example, by the conductor busbars on the terminals themselves.
– Interpose a spring and a flat washer between the head of the bolt and the connection.
– The use of bolts according to DIN class 8.8 Standards is recommended, also referring to what is indicated in the table.
– In the case of cable connections, strictly follow the manufacturer's instructions for making the terminals.

Bolt	Recommended tightening torque (1) Without lubricant
M6	10.5 Nm
M8	23 Nm
M10	50 Nm
M12	86 Nm

(1) The nominal tightening torque is based on a friction coefficient of the thread of 0.14 (distributed value the thread is subjected to which, in some cases, is not negligible). Take into account the deviations from the general Standards table (for example, for contact systems or terminals) as foreseen in the specific technical documentation. The thread and surfaces in contact with the heads of bolts must be slightly oiled or greased, so as to obtain a correct nominal tightening torque.
The tightening torques indicated can only be applied to metal parts.

Earthing and cabling procedures

VSC conforms to level 3 of the IEC 61000-4-x EMC Standards. With regard to medium voltage switchgear, the plants where the VSC contactors are to be installed must conform to the IEC 60694:2002-01 and IEC 62271-1 ed. 1.0 Standards, to ensure adequate electromagnetic immunity. Pay great attention during earthing and cabling operations of the auxiliary circuits. Follow the procedures indicated. For further advice, please contact the ABB Service office.

Grounding

A good connection to earth guarantees correct operation of all the apparatus installed. However, even earthing carried out correctly is not a sufficient measure to ensure a good connection between the VSC control module and earth. In fact, since the control module of the contactor is connected to the metallic base of the VSC by means of a copper connection (Fig. 7), it is always necessary to check that the connection is intact.
Furthermore, earthing must always be carried out between the VSC frame and the main earthing system of the plant.
Use cables with a suitable cross-section and of the minimum length needed.

Connection of metallic structures to exposed conductive parts

In the case of painted parts of the supporting structure, the various parts must always be scraped to eliminate the paint and connected with busbars or copper braids so as to guarantee low inductance connections.
To make a low inductance earthing connection, use cables or busbars with an appropriate cross-section, preferably rectangular. Scrape away the paint of the metallic parts over a sufficiently large area, tighten the fixing screws and cover the connected parts with Vaseline grease.
The length of the earthing cables must be as short as possible. Connection to earth of the parts must guarantee the same electric potential and low impedance.

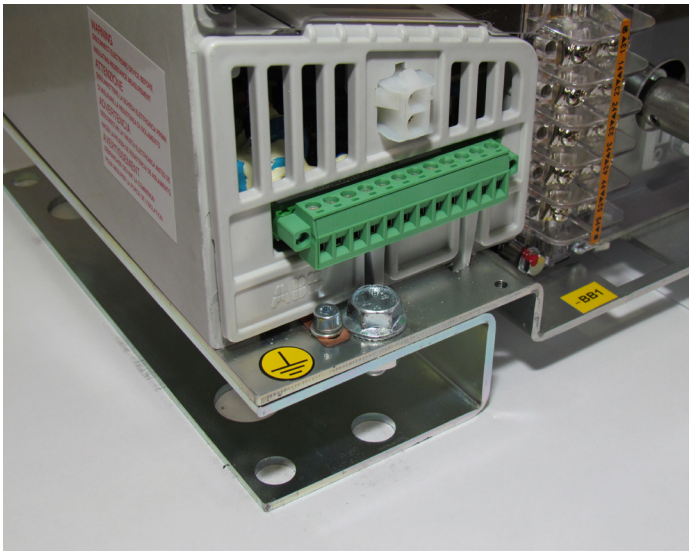

Fig. 7 - Grounding

Figs. 8a - 8b show a grounding operation carried out correctly.

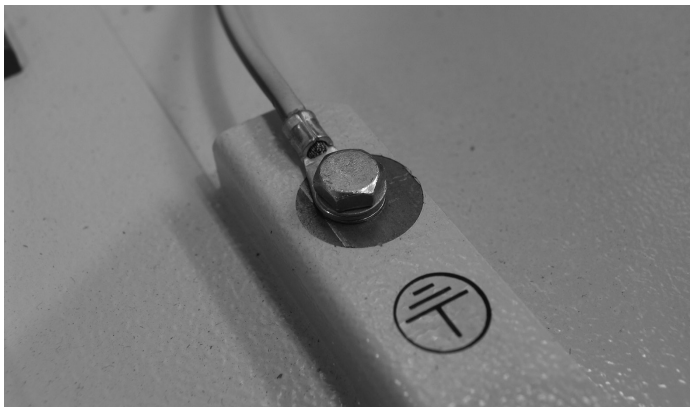

Fig. 8a

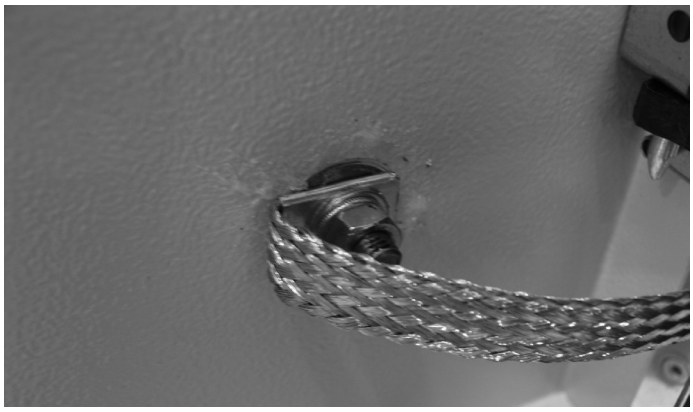

Fig. 8b

Figs. 8c - 8d show a grounding operation not carried out correctly and which, apart from being dangerous, does not guarantee correct operation of the VSC.

Fig. 8c

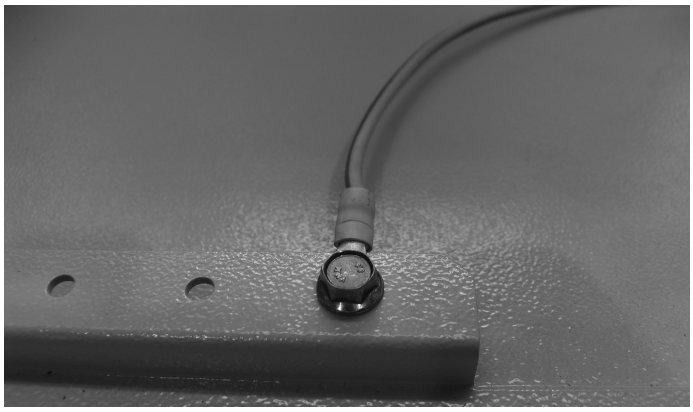

Fig. 8d

Cabling

Make short connections (maximum 1 metre) inside the medium voltage units and avoid positioning them close to the medium voltage busbars.
All long connections must follow paths as close as possible to the metallic frame. The connections must also be fitted with ferrite rings to suppress high frequency interference.
It is good practice to run the cables inside metallic pipes or ducts (earthed at several points) when they are subject to or may be a cause of interference.
Cabling and earthing procedures according to IEC 61000-5-2 Standards: “Technical report: Installation and mitigation guidelines”.

Where possible, the power supply and auxiliary circuit cables must be braided. Their length must be calculated appropriately to prevent any surplus and the maximum length must be:

- 135 m for 24 to 130 V auxiliary voltage
- 400 m for 220 to 250 V auxiliary voltage

Longer lengths require an additional filter for every operating input used (consult ABB).
In any case, any surplus parts of cables must be wound separately and taken into the low voltage apparatus compartment. Always avoid placing them in the vicinity of the medium voltage cables or close to cables which may generate interference or disturbances, such as current or voltage transformer cables or power supply cables.

Connection of the auxiliary circuits

The cables to be used for connection of the auxiliary circuits must have a rated voltage Uo/U of 450/750 V and be insulated for 3 kV test.
Note: before carrying out the test, disconnect the earthing connection of the electronic feeder.
Also remember that the auxiliary circuits must be checked at the maximum voltage of 2 kV for 1 second in accordance with what is prescribed in the Standards.

The cross-section of the connection cables must not be less than 1.5 mm^2.
Connection of the contactor auxiliary circuits must be made by means of the socket with terminal box mounted on the front of the electronic card.
Outside, the wires must run through metallic pipes or ducts suitably earthed.

Connection to be made by the customer (*)

Pins XDB10-1 and XDB10-2 must always be supplied, both in the SCO and DCO version (also see par. 5.8.). The polarity is not important since the internal circuits take both AC or DC signals. For further details, consult the electric circuit diagram enclosed with the apparatus.

N. of pin	Connections	Abbr. of binary outputs/inputs	Meaning of each pin (*)	
			Basic version	"Full option" version
-XDB10-1	Auxiliary power supply	–	Auxiliary power supply AC or DC (pole 1)	Auxiliary power supply AC or DC (pole 1)

-XDB10-12	Binary input n° 3		Undervoltage (pole 2)	Undervoltage (pole 2)

(*) For availability, ask ABB.

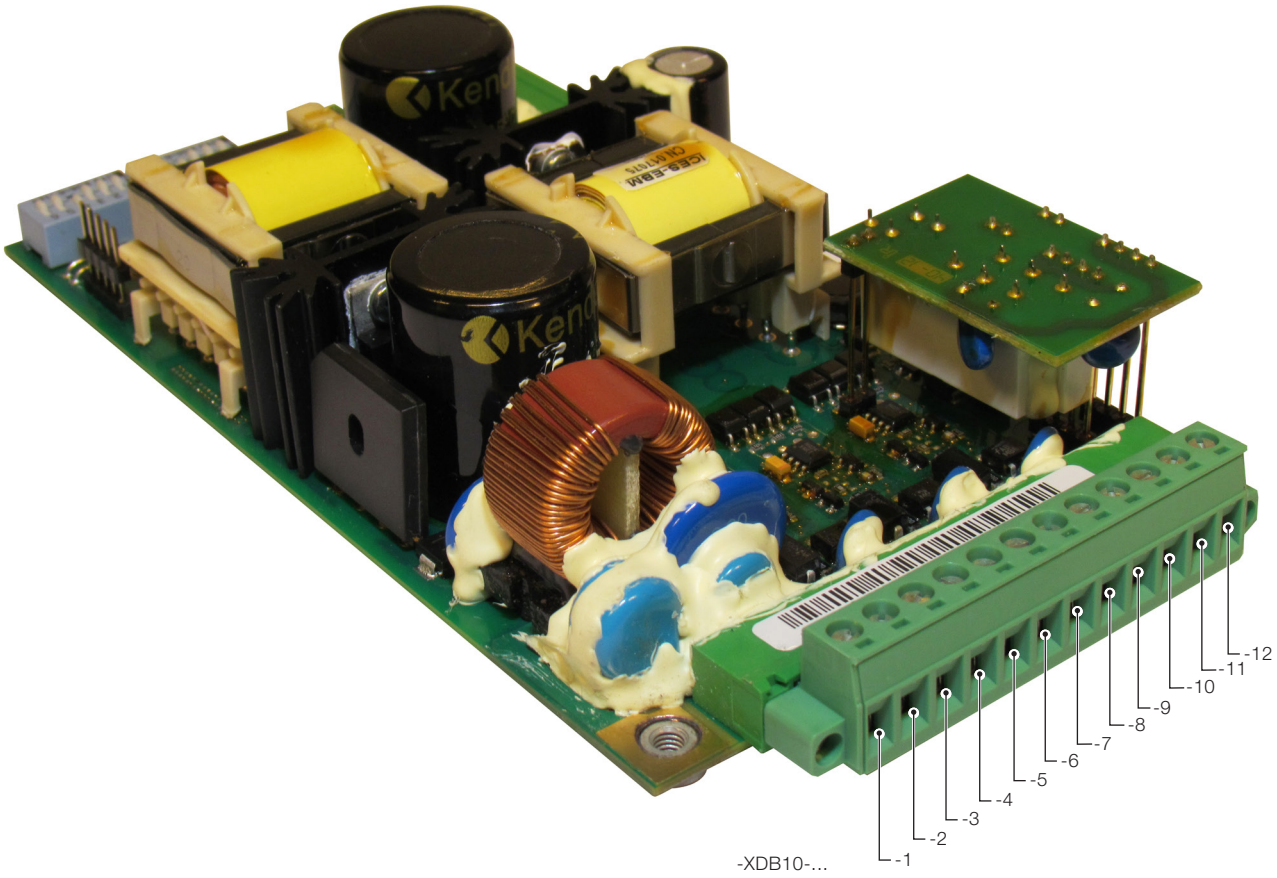

Fig. 9

Checks

After the above-mentioned operations, carry out the following checks:

– check that the connections do not exert any force on the terminals
– check tightness of the connections.

Fig. 10

5.6.2. Withdrawable contactors and enclosures

The withdrawable contactors are used in the UniGear ZS1 type switchgear and in the PowerCube modules. Appropriately fixed together in the configurations defined by the customer, the enclosures build up medium voltage switchgear consisting of various units.

Rules for designing the switchgear

Arc proofing

The ABB enclosures are supplied with a reinforced door, suitable for making arc proof switchgear.

- **The reinforced enclosure alone cannot guarantee arc proofing of the switchgear designed by the customer. To guarantee this, some representative configurations, selected by the customer, must be subjected to the tests according to the prescriptions indicated in the IEC 62271-200 Standards.**
- **For UniGear ZS1 type switchgear, all the door knurls must be tightened to guarantee arc proofing.**

Degree of protection

Limited to the front part, the ABB enclosures guarantee the following degree of protection:
- IP30 on the external housing;
- IP20 inside the switchgear with the door open.

Special versions up to IP41.

The enclosure alone supplied by ABB cannot guarantee the degree of protection of the switchgear designed by the customer. It must undergo the tests according to the prescription indicated in the IEC62271-200 Standards.

Heating

Refer to technical catalogue 1VCP000165 for the rated capacity of the contactors, bearing in mind that apparatus heating is affected by the following variables:
- layout of the enclosures in the switchgear designed by the customer;
- degree of protection (ventilation slats);
- current density of the power supply busbars (busbar duct - branches);
- ambient temperature.

For any needs, please contact ABB Service.

5.6.2.1. Withdrawable VSC/P contactors

The contactors are used for rated voltages from 7.2 to 12 kV, rated normal currents up to 400 A and fault levels up to 1000 MVA (with suitable protection fuses in series with the contactor).
The VSC/P contactor is made up of:
– a three-pole contactor with SCO or DCO function
– mechanical signalling of open/closed
– two pairs of auxiliary contacts signalling open/closed
– feeder able to operate in DC and AC
– a truck on which the supporting structure of the contactor is fixed, consisting of two supports, closed at the front by the protection with characteristics nameplate.
In the top part of the protection there are strikers 30a and 30b (fig. 11) for actuating the enclosure contacts to signal the connected/isolated position.

The pin (34) for locking contactor racking-in with the earthing switch closed on the enclosure, comes out on the right side of the truck.

The crosspiece for hooking up the contactor to the enclosure for operation of the truck is mounted on the front of the truck (3);
– two supports (102) house the slide for actuation of the segregation shutters of the fixed medium voltage contacts of the enclosure and the locking slide of operation of the switch itself with the contactor in the connected position or during the isolation stage;
– when it is not inserted in the socket located on the enclosure, the plug connector for the auxiliary circuits of the contactor must be hooked up to the pin (101);
– mechanical signalling of open/closed (103);
– fuseholder complete with connections for fuses (104);
– input and output tulip isolating contacts (105);
– locks as per par. 5.6.2.2.;
– three current-limiting fuses (supplied on request) with high breaking capacity connected in series to the contactor, with dimensions according to:
  - DIN 43625 Standard with maximum cartridge length e = 442 mm;
  - BS 2692 Standard with maximum centre fixing distance L = 553 mm;
– an impulse counter (supplied on request) which indicates the number of operations carried out by the contactor (106);
– manual emergency opening device (107)
– device for opening when a fuse blows.

5.6.2.2. Description of the locks for withdrawable VSC/P contactors

- Electric lock which prevents the contactor being closed when the truck is not in the racked-in and isolated positions.
- Mechanical lock which prevents the contactor being racked-in and out when it is closed and closing of the contactor when the truck is not in the racked-in and isolated positions.
- Electric lock which prevents closing of the contactor when a fuse is missing or blown.
- Lock which prevents putting a contactor into service in an enclosure preset for a circuit-breaker (*).
- Locking electromagnet on the contactor truck which when there is no voltage, prevents racking-in or racking-out (-RL2).
- Mechanical lock which prevents contactor racking-in if the enclosure door is not closed (requires the same interlock in the fixed part) (108).
- Mechanical interlock with earthing switch placed on the enclosure - with earthing switch closed the contactor cannot be racked-in and with the contactor racked-in or in intermediate positions between racked-in and isolated, it is not possible to close the earthing switch (34).
- Mechanical lock of the shutters when the contactor is racked-out.

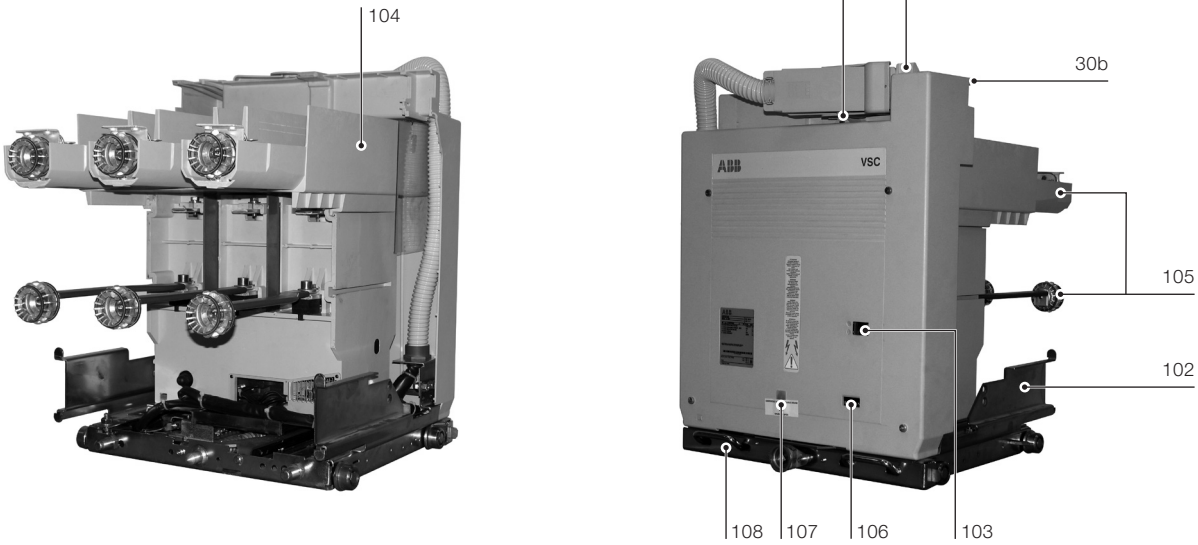

Fig. 11a

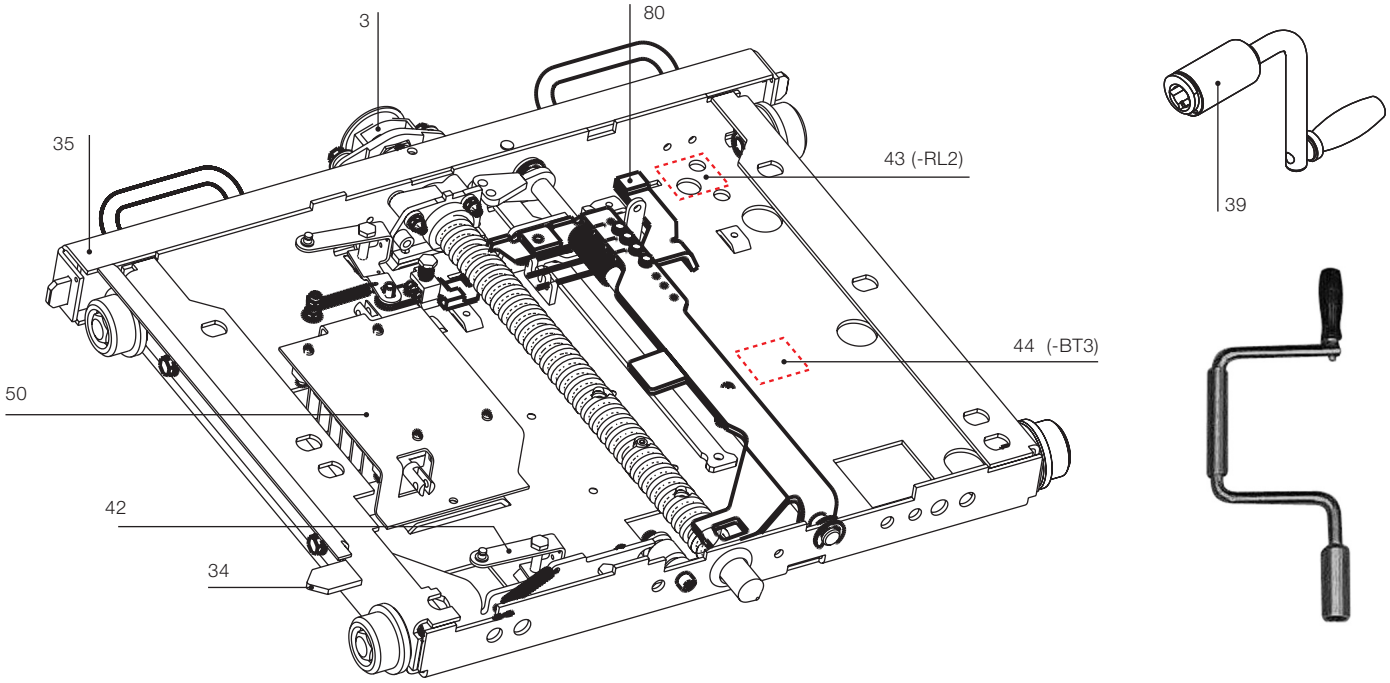

Fig. 11b - Locking devices on the racking-out truck

– Key lock on contactor racking-in - it is only possible to activate the lock and free the key preventing contactor racking-in with the contactor in the isolated position.
– Key lock with earthing switch open - this can only be activated with the earthing switch open. The key can only be removed with the electric lock activated.
– Key lock with earthing switch closed - this can only be activated with the contactor in the isolated position and with the earthing switch closed. The key can only be removed with the lock activated.
– Preset for independent padlocks on the shutters and in the closed and/or open position.
– Electric lock on racking-in and racking-out with the door open (microswitch on the door) of the enclosure connected in series with the locking electromagnet on the contactor truck.
– Key lock on earthing truck racking-in - with the lock activated all the operations with the contactor are possible, but positioning the earthing truck in the isolated position starting from the racked-out position is not allowed.
– Mechanical lock which prevents racking-out of the connector of the auxiliaries when the contactor is racked-in and during racking-in and racking-out.
– Electro-mechanical lock on de-energisation for the earthing switch, which when there is no voltage prevents the earthing switch operations.
– Electro-mechanical lock on the compartment door.

5.6.2.3. VSC/PN and VSC/PNG withdrawable contactors

The VSC/PN contactors are used for rated voltages from 7.2 to 12 kV, rated thermal currents up to 400 A and fault levels up to 1000 MVA (with suitable protection fuses in series with the contactor). In the same way, the VSC/PNG contactor is used for 7.2 kV rated voltage and 400 A rated thermal current.
Both the VSC/PN and the VSC/PNG versions of contactors consist of:
– a three-pole contactor with SCO or DCO operation
– a fuseholder complete with terminals for fuses (121). In the upper part there are strikers 1a, 1b and 1c (fig. 12 - page 29) for activating the enclosure contacts for signalling the connected/test/isolated position
– a mechanical open/closed signalling device (120)
– two pairs of auxiliary contacts signalling open/closed
– feeder able to operate in d.c. and a.c.
– a truck on which the base plate of the contactor is fixed and the front protective screen by means of two supports. At the rear, two pins are positioned on the side walls of the truck for locking contactor racking-in with the earthing switch open on the enclosure, whereas the 45° slides operate the segregation shutters of the medium voltage fixed contacts of the enclosure. The crosspiece for hooking the contactor onto the enclosure for truck operation is mounted on the front of the truck
– the jaw-type input and output isolating contacts (122)
– the locks as per par. 5.6.2.4.
– three current-limiting fuses (supplied on request) with high breaking capacity connected in series with the contactor, with dimensions according to:
  • DIN 43625 Standard with maximum cartridge length e = 442 mm (single cartridge)
  • BS 2692 Standard with maximum fixing distance L = 553 mm (single and/or double cartridge)
– a mechanical operation counter which indicates the number of operations carried out by the contactor (122)
– a manual emergency opening device even when energised with medium voltage (125)
– a device for opening when a fuse blows, with relative fuse blown indication.

5.6.2.4. Description of the locks for VSC/PN and VSC/PNG withdrawable contactors

– Electric lock which prevents the contactor being closed when the truck is not in the “racked-in” (200 mm), “test” (47.5 mm) and “racked-out” (0 mm) positions (-BGT3) (fig. 12a).
– Mechanical lock which prevents the contactor being racked-in and out when it is closed, and contactor closing when the truck is not in the “racked-in”, “test” and “racked-out” positions (1) (fig. 12a).
– Electric lock which prevents contactor closing when a fuse is missing or blown.
– Locking electromagnet on the contactor truck which, when there is no voltage, prevents racking-in or racking-out (-RL2) (fig. 12a).
– Mechanical lock which prevents contactor racking-in if the enclosure door is not closed (requires a reciprocal interlock in the fixed part) (126).
– Mechanical lock for the “test” position (2) (fig. 12a).
– Lock for different currents (5) (fig. 12a).

(*) This lock consists of some pins assembled in the plugs of the auxiliary circuits which, with a suitable code, prevent connection of the plug in the enclosure socket. The lock also foresees compulsory application of the locking magnet in the truck.

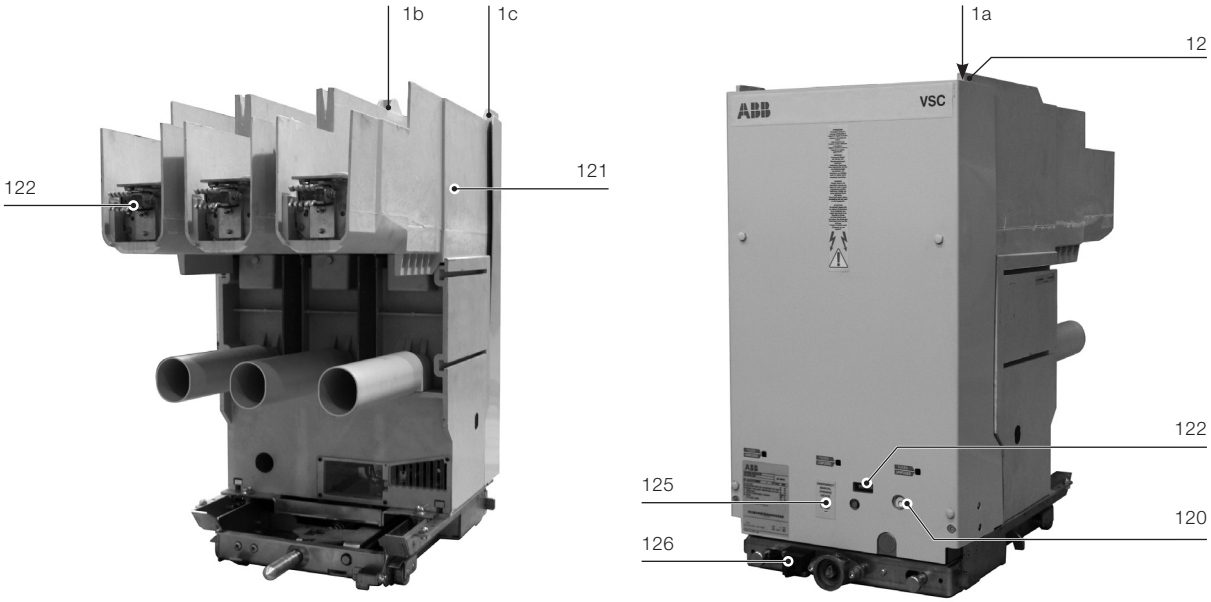

Fig. 12

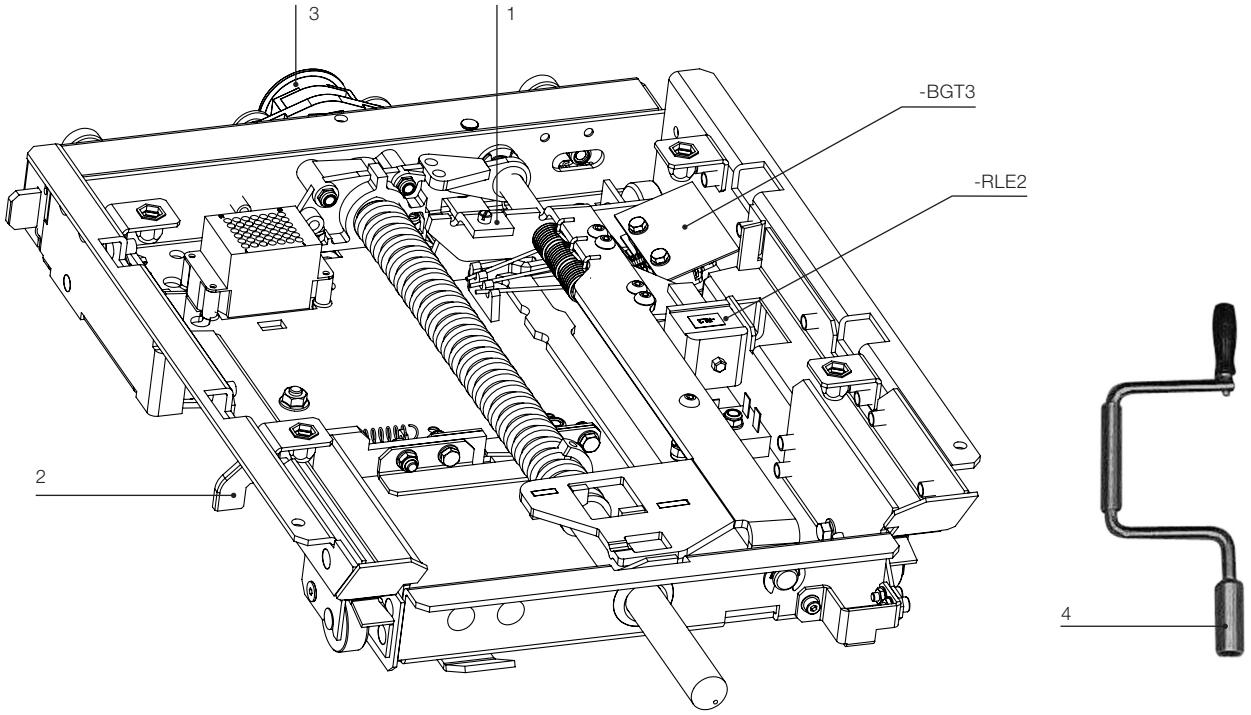

Fig. 12a - Locking devices on withdrawable truck.

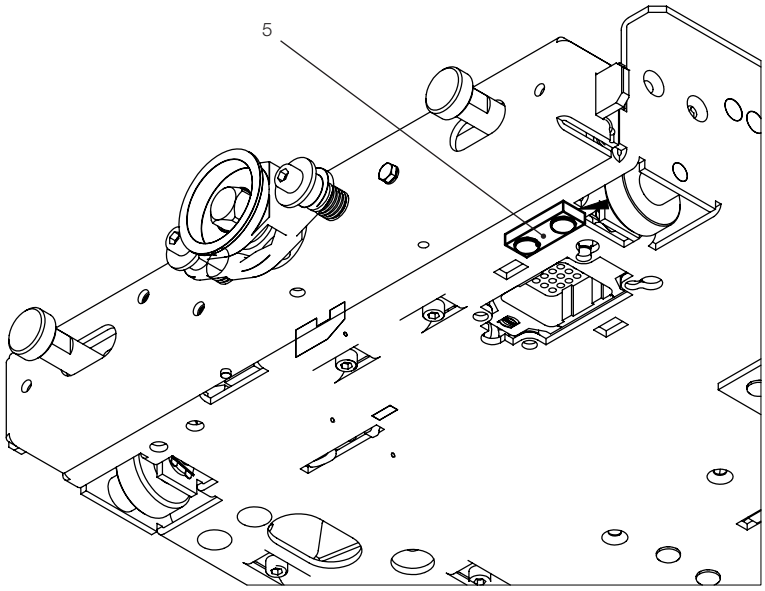

Fig. 12b - Interlocking devices on withdrawable truck.

5.7. Description of the closing and opening operations

The contactor drive operates in two different ways as shown in Table 1.

For the DCO version, further personalisation of the apparatus can be made. In fact – the first of its kind – the V-Contact VSC contactor is fitted (on request) with an undervoltage function (UV) with delays which can be set according to the requirements of the installation.

For a more detailed description of the behaviour of the apparatus according to the version, see table 2.

Supply the contactor with auxiliary voltage and operate it several times electrically. The contactor must carry out the opening and closing operations correctly in accordance with the threshold values defined in the IEC 62271-106 Standards.

TABLE 1

Version	Description	Inputs		
		Closing -XDB10-7, -XDB10-8	Opening -XDB10-9, -XDB10-10	Undervoltage -XDB10-11, -XDB10-12
SCO (Single Command Operated)	This version operates according to the state of the command signal at terminals -XDB10-11 and -XDB10-12. Contactor closing takes place when the voltage applied to terminals -XDB10-11 and -XDB10-12 corresponds with the values indicated in Table 2a	Not used	Not used	Used
DCO (1) (Double Command Operated)	This version operates by means of two independent signals for closing and opening applied to terminals -XDB10-7 and -XDB10-8 for opening and -XDB10-9 and -XDB10-10 for closing. The values of the signals are indicated in Table 2b. Furthermore, on request, automatic delayed opening of the contactor is available in the case of a drop or lack of voltage at terminals -XDB10-11 and -XDB10-12 (configurable delay filter). See Table 2b.	Used	Used	If the undervoltage function is required (2)

(1) The contactor is restarted if the supply voltage of the board drops below 18V for more than 300ms.
(2) The undervoltage with time-delay function is guaranteed with 18V minimum residual voltage.

TABLE 2a

SCO (Single Command Operated) version
Terminals -XDB10-1 and -XDB10-2 must always be supplied at the rated voltage (tolerance: 85% ... 110%)

Closing operation		Power supply, in continuous mode, to the UV input
Opening operation (3)	Release voltage (drop out)	A voltage drop occurs at terminals -XDB10-11 and -XDB10-12 for power supply voltage values between 75% and 10% of the rated voltage.

TABLE 2b

DCO (Double Command Operated) version
Terminals -XDB10-1 and -XDB10-2 must always be supplied at the rated voltage (tolerance: 85% ... 110%)

Closing operation		Supply terminals -XDB10-7 and -XDB10-8 with power. An impulse lasting at least 100 ms is recommended. Note: an impulse lasting a shorter time may also cause contactor closing.
Opening operation	Opening operation (switching)	Supply terminals -XDB10-9 and -XDB10-10 with power. An impulse lasting at least 100 ms is recommended. Note: an impulse lasting a shorter time may also cause contactor closing. In the case of simultaneous power supply of terminals -XDB10-7 and -XDB10-8 and terminals -XDB10-9 and -XDB10-10, the opening command prevails.
	Release voltage (undervoltage)	– Function available on request (UV = Undervoltage). – Opening takes place for voltage values applied to terminals -XDB10-11 and -XDB10-12, between 70% and 35% of the rated voltage (4)

(3) The opening operation is only instantaneous.
(4) The opening operation can be instantaneous or delayed (adjusting the daily by means of the special selectors) a 0.3 - 1 - 2 - 3 - 4 - 5 s. It is set to 0 s by default.

Setting for DCO

UV time (s)	S1-3	S1-4	S1-5
Instantaneous (1)	0	0	0
0.3s	0	0	1
1s	0	1	0
2s	0	1	1
3s	1	0	0
4s	1	0	1
5s	1	1	1

S1-6 → Reserved – (1) See opening time par. 1.3.

5.7.1. Diagnostics

Two types of electronic cards are available, “Basic board” and “Full option”, differing from each other in the diagnostic functions they have available.
Both have:
– coil continuity control connected to the card
– capacitor voltage level control.
The “Full option” card also makes the following available:
– control of the state of capacitor efficiency, which is fundamental for correctly carrying out the opening and closing operations
– checking and indicating the temperature inside the contactor.
The alarms corresponding to the above functions are made available to the user by means of two contacts (3-4 and 5-6) of the -XDB10 terminal box.
The cards periodically carry out the controls without preventing the opening and closing operations.
The table below indicates the functions available.

5.7.3. Coil continuity control (CCC) and temperature monitoring

The unit checks actuator connection continuity so as to reduce the risk of failure to operate following disconnection. It also monitors the temperature of the board to reduce the risk of operating beyond the board’s design limits.
This function is provided for both the basic MAC R2 board and the “full option” version.
The test is performed:
– Every 2 minutes (irrespective of whether the apparatus is in the open or closed condition)
– 15 seconds after starting
– After each operation
The test is not performed:
If the voltage of the external capacitance is less than 75 V (“not ready” signal already given)
If the ambient temperature is less than -30° (“not ready” signal already given)
An alarm signal is given by opening contact DO1 if errors occur.

Basic board - Full option board				
Ready DO1 -XDB10 (3-4)	Continuity control	Capacitor voltage level and VSC internal temperature	Anomaly	No anomaly
	– After each operation – Start-up – Every 12 hours	Continuously	DO1 open	DO1 closed

Full option only				
CBC DO2 -XDB10 (5-6)	Control of state of capacitor efficiency	–	Anomaly	No anomaly
	– Start-up – Every 12 hours	–	DO2 open	DO2 closed

5.7.2. Contactor power supply

The contactor has been tested for all the auxiliary operating voltages foreseen and indicated in the table:

Feeder 1-2 V DC	Feeder 3-4 V DC / V AC (50/60 Hz)	
24	110	220
30	120	230
48	125	240
60	127	250
	130	

The contactor is, however, set with the operating voltage defined in the order confirmation. The power supply voltage is indicated on the contactor rating label.

The tolerances over the voltage values conform to what is defined in the IEC 62271-106 Standard.

5.7.4. Capacitor ageing control (CBC)

The unit supervises bulk capacitor discharging so as to check capacitor life.
The unit supervises main capacitor discharging so as to check capacitor life.
This function is only available for the MAC R2 “full option” version.
The test is performed:
– Every 12 hours when the apparatus is in the open condition.
– 15 seconds after starting.
– Two seconds after each opening operation if the contactor has remained closed for 12 hours.
The test is not performed:
– If the voltage of the external capacitance is less than 75 V (“not ready” signal already given).
– If the ambient temperature is less than -5° (“not ready” signal already given).
The “not ready” state is signalled when the CBC function is being performed and the function has priority over the closing operation.
An alarm signal is given by opening contact DO2 if errors occur.

5.7.2.1 Changing the supply voltage of the contactor (within the reference range)

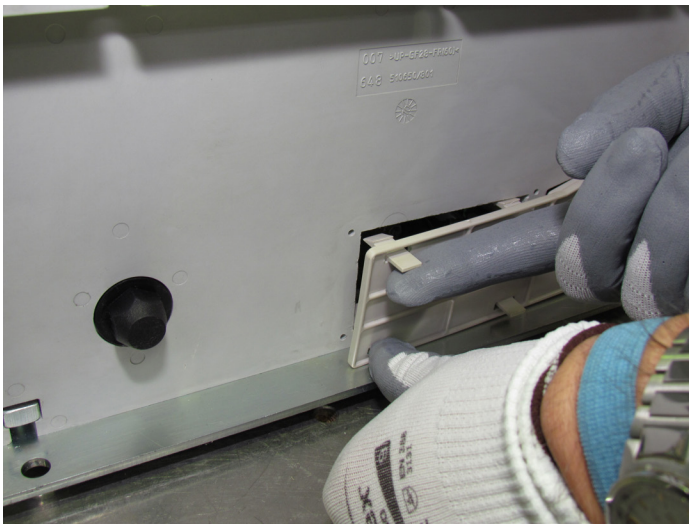

Fig. 13a

Fig. 13b

Fig. 13c

- This operation must be carried out by ABB personnel or by suitably qualified customer personnel with in-depth knowledge of the apparatus (IEC 62271-1, par. 10.4.2.).
- Always check that the apparatus is in the open position before carrying out any activities.
  Check that the medium voltage and auxiliary power supplies have been removed.
  Maintenance of the apparatus must only be carried out with the contactor de-energized, racked-out of the compartment of the enclosure and with the capacitor of the auxiliary circuit discharged. To discharge the capacitor, remove power from the -XDB10 terminal box and connect the mobile two-pole -XDB50 connector to the ABB type CFD device (fig. 13c). Completion of discharging is signalled by the red light going completely off.
- The auxiliary circuit can be configured for all the direct and alternating current voltages within the reference range. To change the voltage value defined during the ordering stage, proceed as follows: 1) remove the rear plastic protection (fig. 13a); 2) access the MAC R2 electronic card (fig. 13b); 3) prepare the dip-switches according to the indications given on the last page of the electric circuit diagram.
- After having set the desired value, the label with the new voltage value must be overlayed the front rating plate of the contactor.

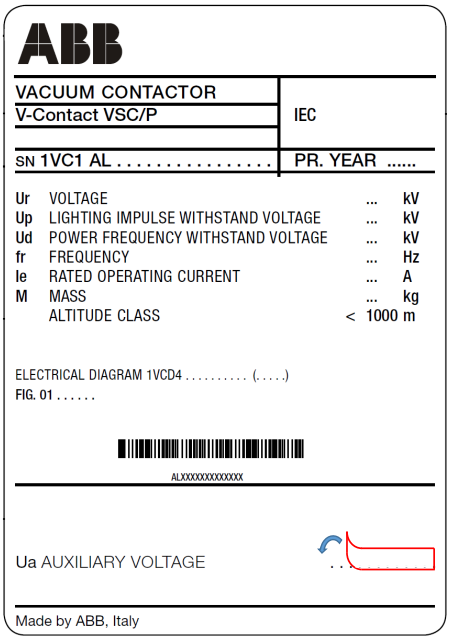

Fig. 13d

- The small plate with the correct voltage value is in the document envelope accompanying the product, along with the electric circuit diagram and this manual.
- Contactor functional check is mandatory after the new voltage setting; the qualified customer's personnel should carry out this check, responsibility for the interventions lies with the customer.

5.8. Emergency opening operation

The contactor is fitted with manual emergency operation which must be carried out by suitably qualified personnel with in-depth knowledge of the apparatus.

The following Standards must be taken into particular consideration during installation and service:

- **IEC 62271-1/DIN VDE 0101**
- **VDE 0105: Operation of electrical plants**
- **DIN VDE 0141: Earthing systems for electrical installations with rated voltage higher than 1 kV**
- **All the accident prevention regulations, in force in the relative countries.**

To manually open the contactor, it is necessary to work on operating part A, consisting of a 8 mm hexagonal-head bolt, working clockwise with a torque of about 20 Nm and at an angle of about 60° (see fig. 14a).
If the contactor (in the fixed version) is placed inside the switchgear, it is necessary to use a transmission made of insulating material of suitable length, which allows safe operation. The transmission device is to be provided by the customer.

For the withdrawable VSC/P contactors placed in UniGear ZS1 switchgear or PowerCube modules and for the withdrawable VSC/PN and VSC/PNG contactors in UniGear MCC switchgear, carry out the emergency operation with the compartment door closed. To carry out the operation, work towards the opening on the compartment door using the special tool provided, fitted on the end with an 8 mm hexagonal spanner. Apply a torque of 20 Nm with an operating angle of about 60° clockwise. The point to operate in is shown by the special plate located on the contactor shield (see detail 1 - fig. 14b and 14c).

For fixed contactors, if the operations are carried out with the medium voltage protection “B” removed, pay great attention to the moving parts.

For withdrawable contactors, do not remove the front shield to carry out the emergency opening operation.

In any case, if auxiliary voltage is present, take special care not to remove the protective shield of the stored energy capacitor and not to touch the capacitor itself in any way.

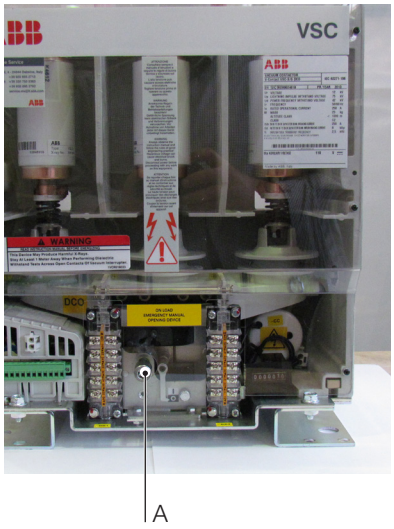

Fig. 14a

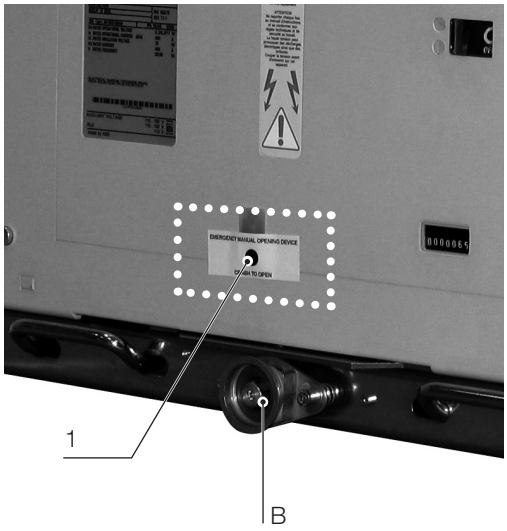

Fig. 14b

Fig. 14c

6. Putting into service

6.1. General procedures

All the operations regarding putting into service must be carried out by ABB personnel or by suitably qualified customer personnel with in-depth knowledge of the apparatus and of the installation.

Before putting the apparatus into service, carry out the following operations as well as those indicated in the table:
- check that the voltage and current applied are within the specified rated values
- check tightness of the power connections of the fixed contactors and integrity of the isolating contacts of the withdrawable contactors
- carefully clean the sheets and insulating parts with brushes and clean dry cloths. Avoid using jets of compressed air
- check the earthing connection of the fixed contactors
- check that no foreign bodies, such as bits of packing, have got into the moving parts
- check that the value of the power supply voltage of the circuits is between 85% and 110% of the rated auxiliary voltage of the apparatus
- check that the contactor vacuum interrupter has not been damaged due to accidental impacts. In case of doubt, carry out the check indicated in paragraph 7.3. Table 4.
- make sure that all the barriers and protective shields are correctly installed
- carry out the inspections indicated in table 3.

On completion of the operations indicated, check that everything is put back in its original position.

The check can only be considered as passed if all the tests indicated have had a positive outcome.
In the case of a negative check, do not put the apparatus into service and, if necessary, contact ABB Service.

TAB. 3

Item inspected	Procedure	Positive check
1 Insulation resistance	Medium voltage circuit With a 2500 V megger, measure the insulation resistance between the phases and the exposed conductive part of the circuit.	The insulation resistance should be at least 50 Mohm.
2 Drive. Open/closed indicator, operation counter (if provided)	Carry out a few closing and opening operations of the contactor.	Operations and signals normal.
3 Auxiliary circuits	Check that the connections to the control circuits are correct: proceed with the relative power supply.	Operations and signals normal.
	With the contactor open, check that the thickness between the body of the contact and the stem is 0.5 mm.	Tighten the fixing screws.
		

6.2. Racking the VSC/P contactor in and out

- **Should operations be carried out with the contactor racked-out of the switchgear, pay great attention to the moving parts.**
- **The contactor must only be racked into the unit in the open position. Racking-in and racking-out must be gradual to avoid shocks which might deform the mechanical interlocks.**

6.2.1. Contactor with manual truck

For the racking-in and racking-out operations of the manual contactor, refer to the following manuals:
– PowerCube PBF fixed part – code: 1VCD600530
– PowerCube PBE and PBM module - code: 647652001
– UniGear ZS1 switchgear – code: 1VLM000363.

6.2.2. VSC/P contactors with motorised withdrawable truck

Carry out the racking-in/out test of the motorised truck in the same way as for a manual truck, following the instructions below:
– Rack the contactor into the switchgear in the open position. Motor power supply circuit de-energized.
– Supply the truck motor circuit with power.
– Activate the command for the electrical racking-in operation. When racking-in has been done, check correct changeover of the relative auxiliary contact.
– Afterwards, activate the command for the electrical racking-out operation. When racking-out has been done, check correct changeover of the relative auxiliary contact.
– In the case of a fault in the motor during a racking-in or racking-out operation, the truck can be taken to the run end manually in an emergency, first cutting off the voltage to the motor power supply circuit and then using the manual lever (Fig. 15) to operate in the same way as for the manual truck.
– Insert the manual racking-in lever (Fig. 15) in the special coupling (B - Fig. 14b).
The torque needed to carry out truck handling is < 25 Nm.
Checks:
a) clockwise rotation of the motor during circuit-breaker racking-in.
b) anti-clockwise rotation of the motor during circuit-breaker racking-out.
– Remove the manual crank.

Note

By means of the chain transmission, truck handling carried out with the manual lever causes rotation of the truck motor rotor which, behaving like a generator, can cause reversal of voltage at the connection terminals. This can damage the permanent magnet of the motor, therefore all the truck racking-in and racking-out operations carried out with the manual lever must be done with the motor circuit de-energized.

Fig. 15

7. Maintenance

Maintenance operations are aimed at ensuring trouble-free operation of the apparatus for the longest possible time.
The following operations must be carried out in accordance with the IEC 61208/DIN 31051 Standards:

Inspection: Assessment of the actual conditions
Servicing: Measures to be taken to maintain the specified conditions
Repairs: Measures to be taken to restore the specified conditions.

Notes

The following rules must be respected for all maintenance operations:

– the relative specifications indicated in the “Standards and specifications” chapter;
– the regulations for safety in the workplace indicated in the “Putting into service and running” chapter;
– the regulations and specifications in the country of installation.

7.1. General

It is good practice to keep a maintenance card and a service book where all the operations carried out can be noted down in detail, together with the date, description of the anomaly and the references of data needed to identify the apparatus, etc. (see chapter 2).
Experience gained in use of the apparatus will allow the optimal time intervals for interventions to be established. In any case, inspection of the apparatus not more than one year after it has been put into service is recommended.
In case of need and for further details, please refer to what is prescribed in article 10.4.2 of the Standard (IEC 62271-1).
In any case, for any problems, please do not hesitate to contact us.

7.2. Handling the MAC-R2 electronic card

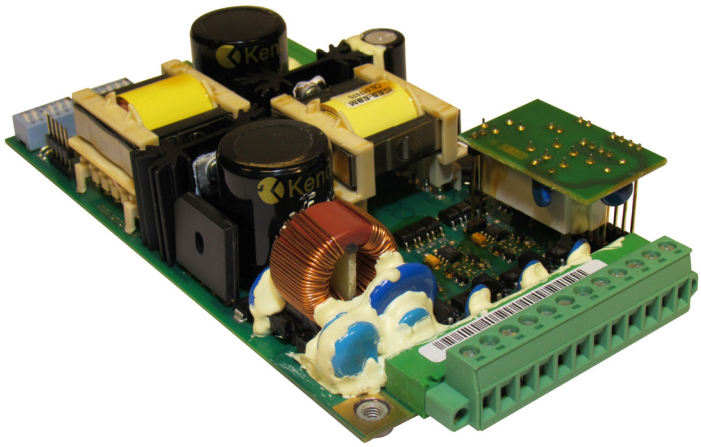
Management of sensitive devices outside protected areas is considered to be “field work” and normally includes product packing, unpacking, installation and maintenance.
In all these cases, handling the devices must be carried out taking care to keep the potential of your hands and that of the work surface earthed, with an equipotential connection to the main grounding branch point.
It is advisable for the operator to wear conductive shoes and overalls and to wear earthed conductive arm bands.
Fig. 13a-13b shows a maintenance kit consisting of an arm band and ground connection, both fitted with a 1 MW integrated resistance.
Using suitable protective means to protect the electronic devices is an indispensable task requiring diligence and attention. Inserting these procedures in the normal service activities allows optimization of resources and underlines their importance.

The main activities which allow an efficient protection system to be maintained are:

- making personnel aware of the problems regarding protection against electrostatic discharges, with reference to the IEC 61340-5-1 Standards (these problems are often unknown or underrated)
- training personnel in correct use of protection equipment and on its perfect working order
- selecting protection materials suitable for the effective production requirements and using them
- marking the protected area and highlighting the presence of sensitive devices so as to attract the attention of operators on correct use of the protection devices
- technicians must always set an example by respecting the rules and using protection devices appropriately

Observe the following basic rules:

- avoid using tools which are unsuitable for removing the electronic cards (e.g. screwdrivers, etc.)
- handling the electronic card during maintenance or replacement operations must be limited to the minimum time possible
- always hold the electronic card at the edges
- avoid touching the components mounted on the card
- pay attention when cables or connectors have to be connected or disconnected
- avoid bending the card while inserting it in its seat or during connector cabling
- avoid damaging the connectors, aligning the pins before connecting the cable



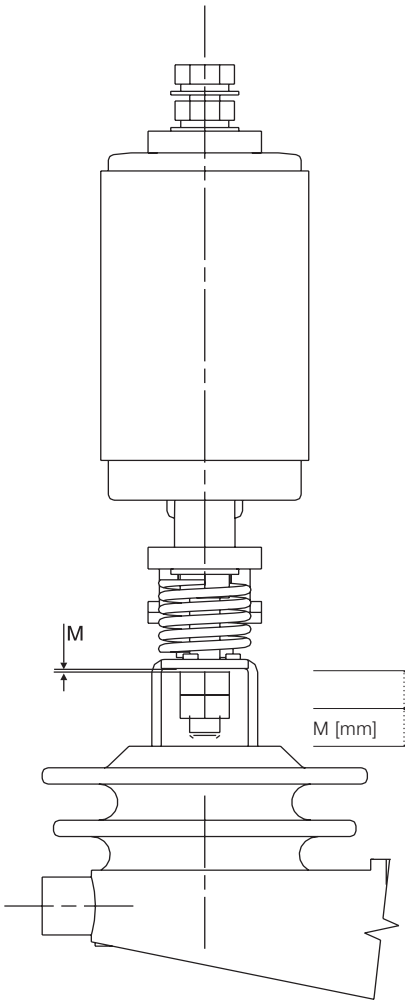


Fig. 16

7.3. Inspection

– Carry out regular inspections to check that the interruption devices are in good condition.
– The checks must include a visual inspection to find any contamination, traces of corrosion or electrical discharge phenomena (according to what is prescribed in table 4.
– When there are unusual service conditions (including adverse climatic conditions) and/or in the case of environmental pollution (e.g. heavy contamination or an atmosphere with aggressive agents), the frequency of inspections must be increased.
– Visual examination of the main contacts. The contact areas must be cleaned if there are signs of overheating (discoloured surface) (also see the paragraph on “Repairs”).

If any anomalous conditions are found, appropriate maintenance measures must be taken (see the “Servicing” paragraph).

	VSC 7	VSC 12 / VSC-S
M [mm]	1.5...2	1.3...1.7

Fig. 17

TABLE 4

Item to be inspected	Interval	Operation to be carried out
1 Insulating parts.	1 year or 50,000 operations.	Visual inspection of the insulating parts. The insulating parts must be free of any accumulation of dust, humidity, dirt (clean), cracks, traces of surface discharges or damage.
2 Structure..	1 year or 50,000 operations.	Visual inspection of the structure and mechanisms. The components must be free of any deformation, accumulation of dust, dirt or damage. The screws, nuts and bolts must be correctly tightened. Avoid touching the ceramic surface.
3 Interrupter.	1 year or 50,000 operations.	Check that the interrupter is free of accumulation of dust, dirt (clean), cracks (replace), traces of surface discharges or damage.
	In case of accidental impacts.	Carry out a voltage test with the contacts open at 15 kV - 50 Hz for one minute. If there is a discharge during the test, the interrupter must be replaced because this type of phenomenon corresponds to deterioration in the degree of vacuum. In case of need, contact ABB Service.
4 Interrupter contacts.	1 year or 50,000 interruptions at the rated current.	Refer to fig. 17. The contact material vaporises from the surfaces during each interruption and condenses elsewhere inside the vacuum interrupter. This is a normal process, and is foreseen by the overrun, or by the wear tolerance. As the contacts wear, the overrun distance “M” decreases. When distance “M”, of any pole, goes below 0.5 mm with the contactor in the closed position, all the sub-assemblies must be replaced. Use a fork-shaped gauge 0.5 mm thick to carry out this measurement. **Caution! Never attempt to adjust the nuts of the vacuum interrupters for any reason whatsoever.** The overrun distance must be checked, but not adjusted.
5 Auxiliary contacts.	1 year or 50,000 operations.	Check correct operation and the signals. Check that there are no burnt or worn contacts (replace).
6 Auxiliary circuit conductors.	1 year or 50,000 operations.	Check whether any cabling straps are loose or broken and check connection tightness. Examine all the wire or cable connections to make sure that none of them are loose and that there is no overheating.
7 Visual inspection of the isolating contacts (withdrawable contactors)	5 years.	The isolating contacts must be free of any deformation or erosion. Lubricate the contact elements with 5RX Moly type grease.

7.4. Servicing

Carry out the checks described below.

Item to be serviced		Interval	Operation to be carried out
1	Contactor.	2 years or 100,000 operations.	Carry out five mechanical closing and opening operations. The contactor must operate regularly without stopping in intermediate positions.
2	Contactor springs.	2 years or 100,000 operations.	Check integrity of the springs.
3	Power connections.	2 years or 100,000 operations.	Check tightness: M8 bolt = 23 Nm; M10 bolt = 33 Nm. Check there are no traces of overheating or oxidation.
4	Earthing contact (fixed contactors)	2 years or 100,000 operations.	Check tightness of the connections.
5	Insulation resistance.	2 years or 100,000 operations.	See par. 6.1.
6	Racked-in/isolated auxiliary contacts in the truck.	2 years or 100,000 operations.	Check that the signals are correct.
	Furthermore provide:	– replacement of the auxiliary contacts after 250,000 operations.	

7.5. Servicing following a short-circuit or overload

General

It is foreseen that the VSC contactor be protected by power fuses and/or by a circuit-breaker. In any case, the value of a short-circuit can exceed the threshold of damage to the vacuum bottles.

After interruption of a short-circuit at the maximum rated MVA of the contactor, put the cause of the fault right, inspect all the apparatus and carry out the repairs or replacements necessary before putting the apparatus back into service.

Make sure that all the spare parts (when required) are suitable for the application.

In case of any doubts, please contact ABB.

Have a complete check of the contactor carried out by ABB personnel after 1,000,000 operations or 10 years of operation.

Contact ABB Service Assistance.

Vacuum interrupters

A dielectric test by itself cannot be confirmation that the interrupters have to be put back into service after a fault. However, if there is no physical sign of stress and if the distance M exceeds a minimum of 0.5 mm, the interrupters can be tested dielectrically as mentioned in point 3 of table 4. Should this test also be positive, it is reasonable to put the interrupters back into service following a fault.

Enclosures

External evidence of deformation of the enclosure is usually indicative of damage inside it. Extensive damage will require replacement of the enclosure parts and of the apparatus contained in it.

Terminals and internal conductors

Replace the damaged parts which show discolouration, melting or damage caused by electric arcs.
Pay special attention to the moving parts.
Carry out the “Checking” procedures indicated in par. 6. of this manual before putting the apparatus back into service.

7.6. Repairs

Replacement with spare parts and accessories must only be carried out by ABB personnel or by suitably qualified personnel with appropriate training.
All the power supply sources must be turned off and the capacitor must be discharged.
Always work with the contactor open, with the work area insulated and made safe.

Should maintenance be carried out by the customer’s personnel, responsibility for the interventions lies with the customer.

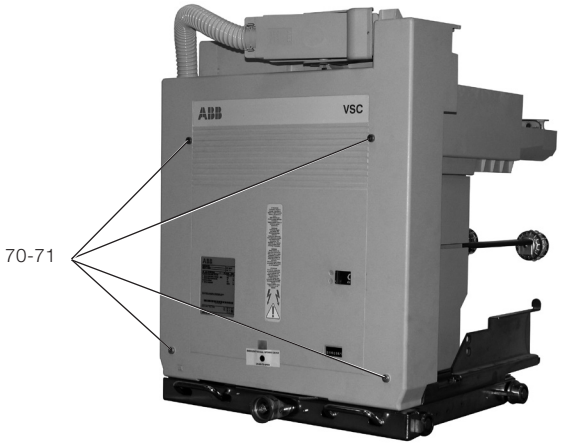

Fig. 18a

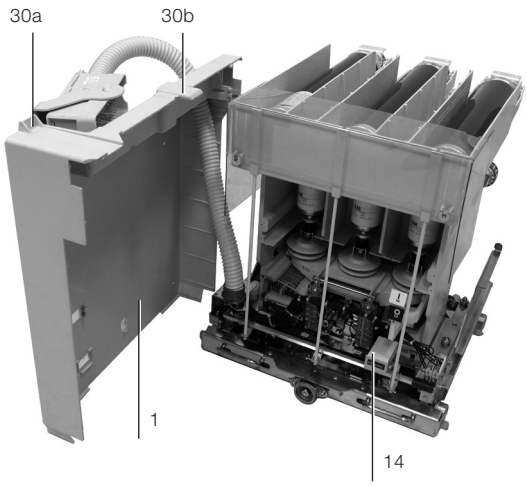

Fig. 18b

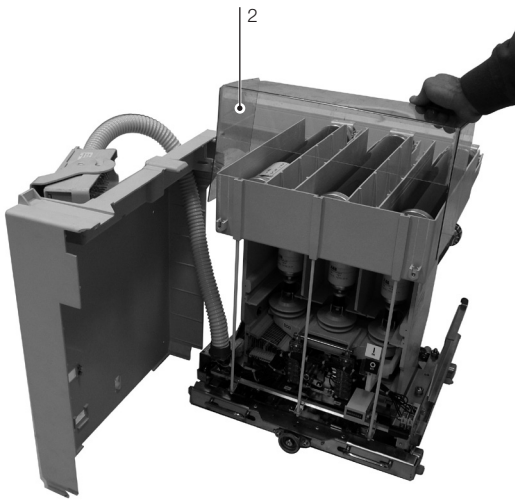

Fig. 18c

7.7. Instructions for dismantling and replacing fuses

7.7.1. General

- **All the operations described below must be carried out by suitably qualified personnel with in-depth knowledge of the apparatus.**
- **Do not rack the contactor out unless the enclosure is securely fixed in the switchgear or to a stable base.**
- **Check that the contactor is open before proceeding with isolation and its racking-out from the enclosure.**
- **Check that the contactor is open before proceeding with replacement of the fuses.**
- **The contactor is preset to house ABB CMF/BS and ABB CEF/BS fuses.**

The fuseholder is preset for installation of fuses with the dimensions and average type of striker according to DIN 43625 (1983) and BS 2692 (1975) Standards and with electrical characteristics according to IEC 282-1 (1974) Standards.
The fuseholder is always fitted with an automatic opening device for a fuse blowing. This device prevents contactor closing when even a single fuse is missing.

7.7.2. Preliminary operations for fuse replacement

a) VSC/P

The contactor must be racked out of the enclosure for replacement of the fuses.
The instructions for the racking-out operations are given in the switchgear/enclosure manuals.
With the contactor racked out of the switchgear, unscrew the four fixing screws of the shield and relative DIN washers (fig. 18a) and position it as in fig. 18b. For 12 kV contactors, remove protection (2) and (fig. 18c) proceed to replace the fuses according to the instructions given in par. 7.8.

b) VSC/PN and VSC/PNG

To replace the fuses it is necessary to rack the contactor out of the enclosure. The instructions for the racking-out operations are given in the switchgear/enclosure manuals, then proceed to replace the fuses according to the instructions given in par. 7.8.

7.8. Replacement of the contactor fuses

Check that the rated normal current of the fuses to be installed corresponds with the value indicated on the nameplate on the rear of the fuseholder.

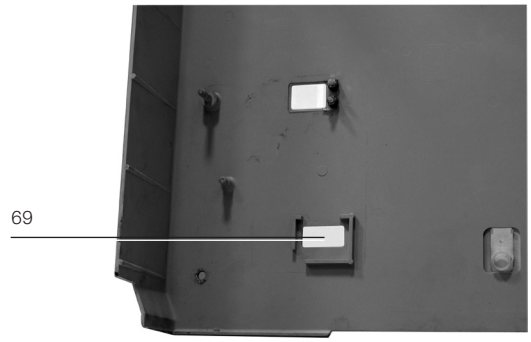

Fig. 18d

Fuses according to DIN Standards

a) Mounting the adapters (fig. 19a)

The fuseholder is designed to take fuses with a length of 442 mm. For smaller sizes, two adapters are required:
– Adapter (45) for fuses with a length of 192 mm (A)
– Adapter (46) for fuses with a length of 292 mm (B).
Select the type of adapter in relation to the type of fuse to be used, and insert it fully over the fuse contact, opposite to the one of the striker.
Tighten the steel band (47) and fully tighten the screw (48).
To dismantle, proceed in reverse order.
The same instructions are given in the Kit sheet put in the adapter packing.

Fig. 18e

b) Dismantling the fuses (fig. 19b)

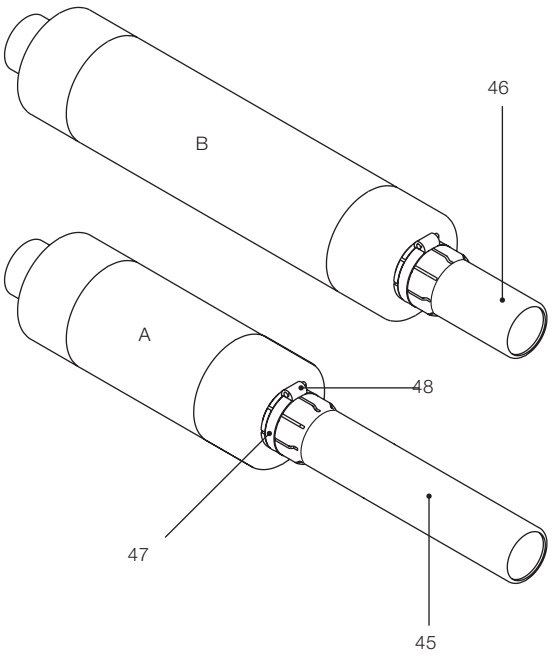
Open the locking rings (49) (fig. 19b) moving them in the direction shown by the arrows using the tool (50), and remove the fuse using the special tool (50).

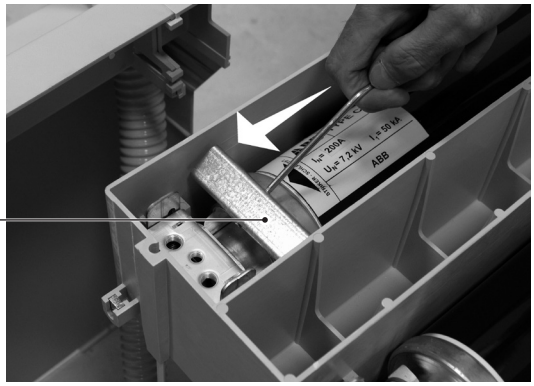
c) Mounting the fuses (fig. 19c)

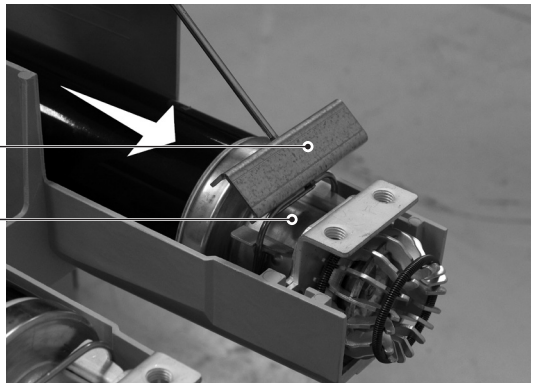
Open the locking rings (49) moving them in the direction shown by the arrows using the tool (50) (fig. 19b), fully insert the fuses with the contacts fitted with striker on the opposite side to the isolating contacts of the contactor. Close the locking rings again, moving them in the opposite direction to the opening one.

Fuses according to BS Standards.

- **Check that the rated normal current of the fuses to be installed corresponds with the value indicated on the nameplate on the rear of the fuseholder.**
- **When tightening the screws, do not force the connections (25 Nm maximum tightening torque).**
- **Fuse mounting and dismantling must only be done with the adapter (if required) already mounted on it.**
- **Only use the material specified, provided by ABB, for assembly.**







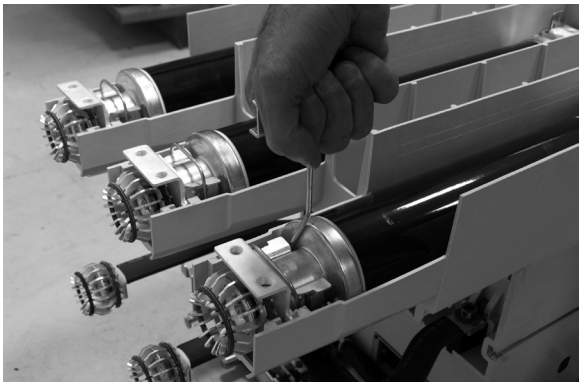


Fig. 19a

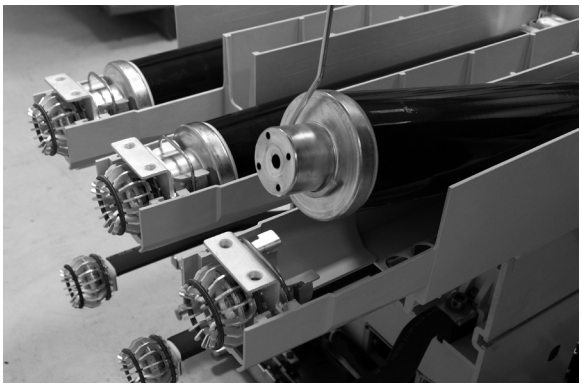

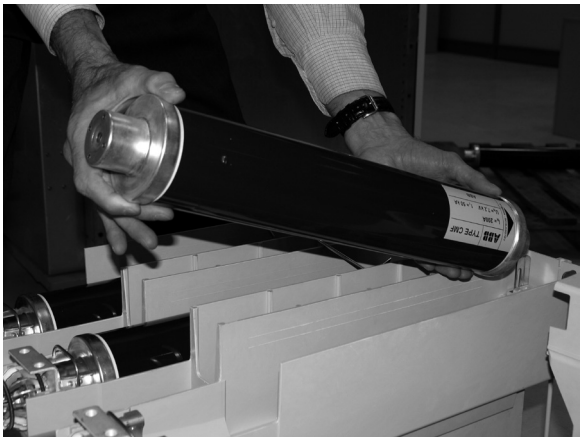

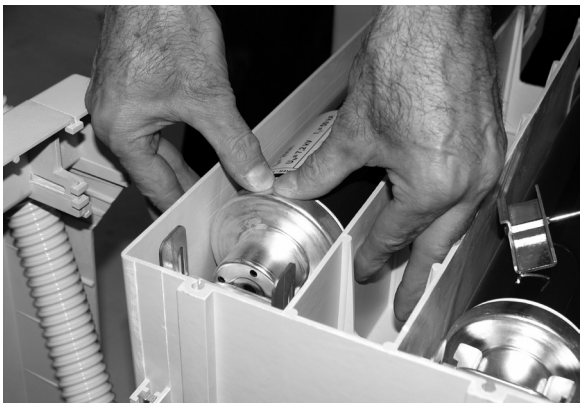

Fig. 19b

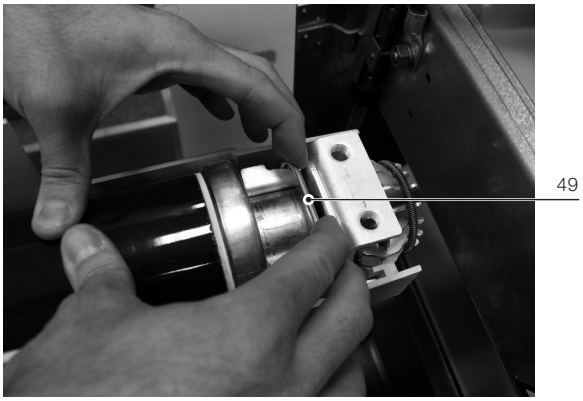

Fig. 19c

a) Mounting the adapters (fig. 20a)

The fuseholder (32) (fig. 20b) is preset to take fuses with fixing centre distance of 553 mm. For smaller sizes, three adapters are needed, as indicated below:

– adapter (51) for fuses with fixing centre distance
  l = 235 mm
– adapter (52) for fuses with fixing centre distance
  l = 305 mm
– adapter (53) for fuses with fixing centre distance
  l = 454 mm.

Select the type of adapter, fix it onto the fuse on the striker side by means of the grub screws (54), the cup springs (55) and the short nuts (58). Mount the adapter with the extension, with the cap facing the striker.

The same instructions are given in the Kit sheet put in the adapter packing.

Only position the grub screws (54) as shown in the drawing.

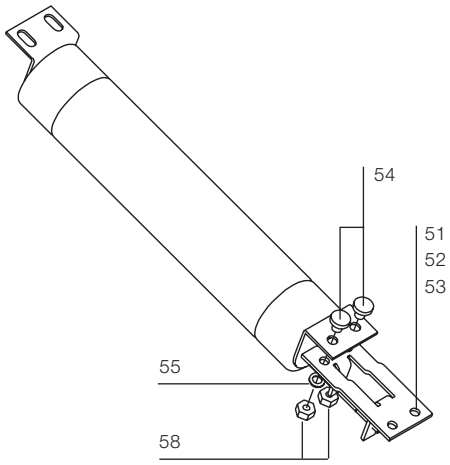

Fig. 20a

b) Mounting the fuses (fig. 20b)

Mount the fuses or the adapter (preassembled as indicated in par. a) with the striker, (indicated by the arrow) facing the opposite side to the one of the contactor tulips and fix them by means of the screws (56) and the spring washers (57).

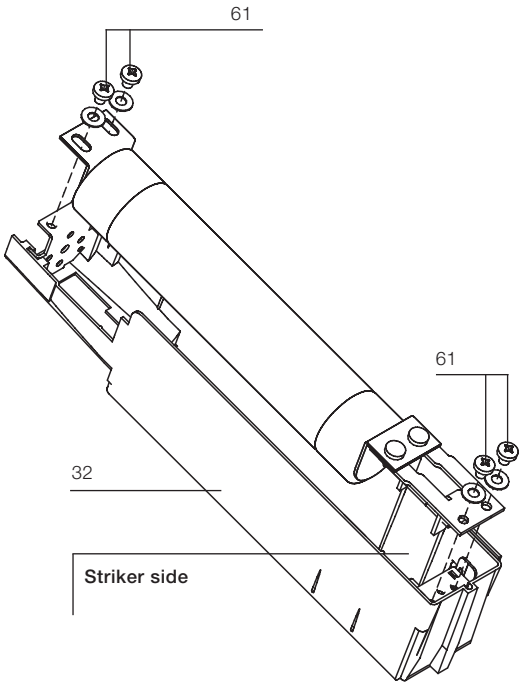

Fig. 20b

c) Dismantling the fuses

To dismantle the fuses and relative adapters, proceed in reverse order to par. b) and a).

d) Assembling and dismantling the VSC/PN and VSC/PNG contactor fuses

It is also possible to use BS fuses with double cartridge connected in parallel in the VSC/PN and VSC/PNG contactors (fig. 20c) and therefore in series with the contactor. The assembly and dismantling operations are the same as what is described in sections a) , b) and c) above, with the only difference being to handle a pair of fuses per phase at the same time (fig. 20c) connected by means of a suitable adapter.

Fig. 20c

7.9. Mounting and dismantling the short-circuit busbar

a) Mounting (fig. 21)

Mount the busbar with the feeler pin (60) on the opposite side to that of the tulips and fix it with the screws (61).

b) Dismantling (fig. 21)

To dismantle, proceed in reverse order.

The same instructions are given in the Kit sheet put in the short-circuit busbar packing.

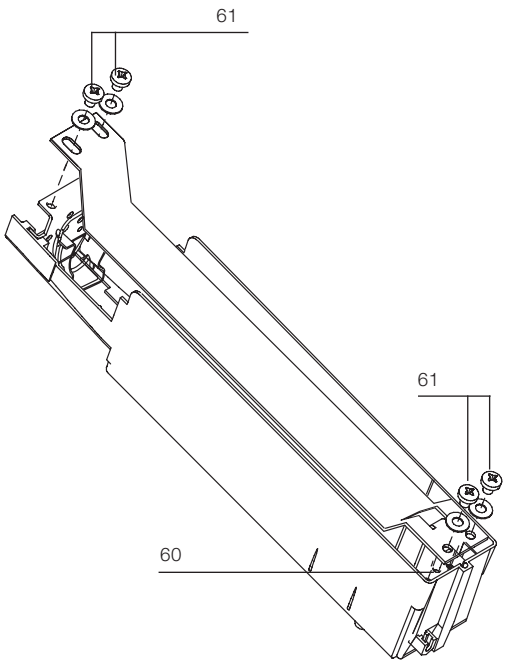

Fig. 21

7.10. Putting the contactor back into service

7.10.1. Mounting the shield and insulating guard (fig. 18)

Reposition the protection (1) (fig. 18b), repeating the operations indicated in par. 7.7.2. in reverse order.
Remount the shield. Check that the impulse counter (14) (fig. 18c) inserts itself into the special seat (69) (fig. 18d) and fix the shield with the screws (70) and DIN washers (71) (fig. 18a).

7.10.2. Checking apparatus functions

Rack the contactor into the enclosure, working as indicated in par. 6.
In the “isolated for test” position, check the correctness and functionality of the contactor “open/closed” signalling by carrying out a few operations.

7.11. Checking the degree of vacuum of the interrupter

This test is not required for normal maintenance. Should it become necessary for extraordinary maintenance, carry out the test on the interrupter without dismantling it from the contactor and use the VIDAR tester, of the Programma Electric GmbH, Bad Homberg v.d.H. company, for the vacuum test.
To check the vacuum air tightness of the interrupter, prepare the following VIDAR tester test values:

Contactor rated voltage	DC test voltage
7.2 kV	16 kV
12 kV	22.5 kV

The test must always be carried out with the contactor open, with the contacts at the nominal distance.
Procedure for testing the vacuum of the interrupter of the contactor poles:

- turn off the power and make the working area safe according to the safety regulations of the IEC/DIN VDE standards;
- open the contactor;
- ground a terminal of each contactor pole;
- connect the ground terminal of the VIDAR tester to the structure of the contactor (grounding point of the contactor);
- connect the high voltage terminal of the VIDAR tester to the terminal not connected to ground of the contactor pole (phase L1) and carry out the test. Repeat the test for phases L2 and L3.

The tester connection cables can produce an indication due to capacitive effect. In this case, the cables must not be removed.

8. Spare parts and accessories

To order contactor spare parts/accessories, refer to technical catalogue 1VCP000165 and always state the following:
– type of contactor
– rated voltage of the contactor
– rated normal current of the contactor
– serial number of the contactor
– rated voltage and frequency of any electrical spare parts.

For availability and to order spare parts, please contact ABB Service.

8.1. List of spare parts

– Vacuum interrupter assembly (replacement to be carried out by ABB)
– MAC-R2 electronic card
– Auxiliary contacts (5 normally open and/or 5 normally closed)
– Capacitor
– Interfacing shaft (only fixed contactors)
– 12 kV insulation partitions (only fixed contactors)
– Actuator assembly (replacement to be carried out by ABB).
– Operation counter
– Fuses
– Adapters for fuses
– Fuseholders (replacement to be carried out by ABB)
– Tulip and jaw-type isolating contacts
– Locking magnet in the truck
– Microswitches.

9. Product quality and environmental protection

The pieces of apparatus are produced in compliance with the requirements of the international standards regarding quality and environmental management systems. In these fields, the excellent level is proved by availability of the ISO 9001 and ISO 14001 certificates.

End of product life

ABB is committed to respecting the requirements and laws for protection of the environment laid down according to the ISO 14001 Standard.

ABB offers its competency and collaboration in facilitating recycling and disposal of the products at the end of their life. It is always necessary to act in compliance with the local regulations in force for disposal of the products.

Methods of disposal

Disposal can either be carried out with thermal treatment in an incineration plant or by storage in special areas

Material	Recommended method of disposal
Metals (Fe, Cu, Al, Ag, Zn, W, others)	Separation and recycling
Thermoplasts	Recycling or disposal
Epoxy resin	Separation of metal parts and disposal of resin parts
Rubber	Disposal
Dielectric oil (oil for transformers)	Recovery and recycling or disposal
Wood for packing	Recycling or disposal
Aluminium foil for packing	Recycling or disposal

1VCD600943-V8185 - Rev. D, en - Instruction Manual - 2020.11 (V-Contact VSC-F-P-PN-PNG) (gs)

Medium Voltage Product

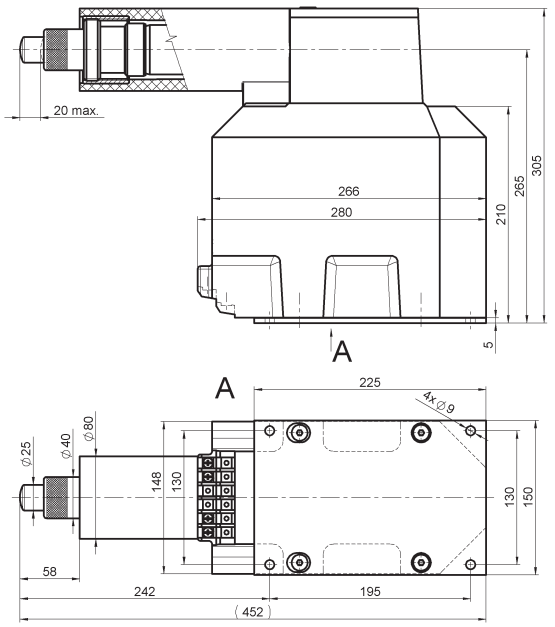
TJP 4.3, TJP 5.3, TJP 6.3
Indoor voltage transformers

Highest voltage for equipment	[kV]	3.6 - 24(25)
Power frequency test voltage, 1 min.	[kV]	10 - 50
Lightning impulse test voltage	[kV]	40 - 125
SesuF	[A]	2 or 6,3 (IEC)
Max. rated burden, classes	[VA/cl]	25/0.2 - 50/0.5 - 100/1
Residual winding	[VA/cl]	50 - 200/6P

Description

TJP 4.3, TJP 5.3 , TJP 6.3 epoxy insulated voltage transformers are cast in epoxy resin and designed mostly for insulation voltages of
- 3.6 kV to 12 kV....TJP 4.3 type
- 17,5 kV..... TJP 5.3 type
- 24 (25)kV.....TJP 6.3 type

Trasformers are suitable for ABB UNISAFE panel or PowerCube type PB.
If no a different value is required, the transformers are manufactured with a overvoltage factor of 1.9 x Un/8 hrs.
One outlet of the primary winding, including the respective terminal is insulated from the earth to a level which corresponds to the rated insulation value.
Other outlet of primary winding with its terminal is earthed during the operation.
Most of the transformers are equipped with two secondary windings, the first one for either measuring or protection purposes, other for being connected into an open-delta connection in a three-phase system. One terminal of each secondary winding and one of the open delta connected terminals have to be earthed during the transformer operation.
The secondary windings are lead out into a cast-type secondary terminal board. The transformer can be mounted in any position.
Transformer body is fixed by four screws, the bolted M8 earthing clamp is located on the transformer base plate.



The TJP 4.3, TJP 5.3 , TJP 6.3 transformers are equipped with a fuses conformably to IEC standard.

Rated primary voltages ... 3/V3 kV; 3,3/V3 kV; 6/V3 kV; 6,6/V3 kV; 10/V3 kV; 11/V3 kV, 13,8/V3 kV, 15/V3 kV; 20/V3 kV, 22/V3 kV
Other primary voltages can also be supplied upon request.
Rated secondary voltages... 100/V3 V; 110/V3 V – accuracy classes 0.2; 0.5; 1 (measuring winding) or 3P; 6P (protection winding).
Other secondary voltages can also be supplied upon request.
Rated voltages for open-delta connection: ... 100/3 V; 110/3 V- class 6P. Other voltages for open-delta connection can also be supplied based on customer requirement.
Rated frequency ... 50 Hz; 60 Hz
Based on a discussion with the manufacturer the transformer can also be provided with primary winding designed for two different primary voltages (with secondary side changeover).
Transformers are manufactured conformably to the requirements and recommendations of the following standards and regulations: IEC, VDE, ANSI, BS, GOST, CSN.

Disclaimer

The data, examples and diagrams in this manual are included solely for the concept or product description and are not a statement of guaranteed properties. All persons responsible for applying the equipment described in this manual must ensure that each intended application is suitable and acceptable, and that all applicable safety or other operational requirements are complied with. In particular, all risks in applications where a system failure and/or product failure would create a risk of harm to property or persons (including but not limited to personal injuries or death) shall be the sole responsibility of the person or entity who/that applies the equipment, and such parties are hereby requested to ensure that all measures are taken to exclude or mitigate such risks.

This document has been carefully checked by ABB but discrepancies cannot be completely ruled out. If discrepancies are detected, the reader is kindly requested to notify the manufacturer. With the exception of explicit contractual commitments, in no event shall ABB be responsible or liable for any loss or damage resulting from use of this manual or application of the equipment.

Conformity

The products listed in the document comply with the directive of the Council of the European Communities implemented by the laws of the Member States relating to electromagnetic compatibility (EMC Directive 2004/108/EC) and concerning electrical equipment for use within specified voltage limits (Low-voltage directive 2006/95/EC). Such conformity is the result of tests conducted by ABB in accordance with product standards EN50263 and EN60255-26 for the MEC directive and with product standards EN 60255-1 and EN 60255-27 for the low voltage directive.

Safety Information

Dangerous voltages can occur on the connectors, even when the auxiliary voltage has been disconnected.

Non-observance can result in death, personal injury or substantial property damage.

Only a competent electrician must be allowed to perform the electrical installation tasks.

National and local electrical safety regulations must always be followed.

SWICOM must be earthed

1. Introduction

The installation manual contains instructions on how to install PDCOM. The manual describes procedures for mechanical and electrical installation. The chapters are set out in the order in which the device should be installed and connected to the circuit breaker.

1.1 Intended recipients

This manual is for use by the personnel responsible for installing the product hardware.
The installation personnel must possess basic knowledge about handling electronic equipment.

1.2 Product documentation

The Installation manual contains instructions on how to install PDCOM. The manual describes procedures for mechanical and electrical installation. The chapters are set out in the order in which the device should be installed and connected to the switchgear.

1.3 Revision history

Document revision/date	Product series version	History
2020-09-13	2.1	First release

Download the latest documents from the ABB web site

1.4 Related documentation

Product series- and product specific manuals can be downloaded from the ABB web site.

1.5 Symbols

The electrical warning icon indicates the presence of a hazard which could result in electrical shock.

The warning icon indicates the presence of a hazard which could result in personal injury

The caution icon indicates important information or warnings related to the subject discussed in the text. It might indicate the presence of a hazard which could result in damage to software, equipment or property.

The information icon alerts the reader of important facts and conditions.

The tip icon indicates advice on, for example, how to design your project or use a certain function.

Although warning hazards are related to personal injury, it is necessary to understand that under certain operational conditions, operation of damaged equipment may result in degraded process performance leading to personal injury or death. Therefore, comply fully with all warning and caution notices.

2 Environmental aspects

2.1 Sustainable development

Sustainability was taken into account from the time product design began and included the pro-environmental manufacturing process, long life, operation reliability and disposal of PDCOM.
The choice of materials and the suppliers was made in accordance with the EU RoHS directive 2011/65/EU of the European Parliament and of the council of 8 June 2011 on the Restriction of Hazardous Substances in electrical and electronic equipment (RoHS Directive).
PDCOM complies with the maximum values for lead (Pb), mercury, hexavalent chromium, polybrominated biphenyls (PBB), polybrominated diphenyl ethers (PBDE) and cadmium.
Pursuant to EU-regulation REACH that came into force on 1 June 2007, the products are solely non-chemical. Moreover, the products supplied will not release any substances under normal and reasonably foreseeable application circumstances.

2.2 Disposing of the product

Definitions and regulations concerning hazardous materials are country-specific and change as knowledge of materials increases. The materials used in this product are typical for electric and electronic devices.
All parts used in this product are recyclable. When disposing of PDCOM or its parts contact a local waste handler who is authorized and specialized in disposing of electronic waste. These handlers can sort the material by using dedicated sorting processes and dispose of the product in accordance with local requirements.

Table 1: Product composition

PDCOM	Parts	Material
Case	Parts and screws	Steel
	Case	Metal
	Electronic modules	Various
Package	Box	Cardboard
Attached material	Manuals	Paper

2.3 Applicable directives, standards and compliance

The following directives, standards and compliances are applicable to PDCOM:

- Electrostatic Discharges Immunity test
- Radiated Electromagnetic RF- Field immunity test
- Conducted Low Frequency Immunity test
- EFT Immunity test: EN61000-4-4
- Surge immunity: EN61000-4-5
- Common Mode Conducted RF-Immunity test: EN61000-4-6
- Power frequency magnetic field Immunity test: EN61000-4-8
- Slow Damped Oscillatory Wave Immunity test
- DC Voltage Dips, Interruptions and Variations
- AC component (Ripple) in DC
- Pulse Magnetic Field Immunity test
- Low Frequency conducted disturbances Immunity test
- Conducted Field emission test: CISPR 11
- Radiated Field Emission test

For VPIS systems supported:

- IEC 62271-206: Voltage presence indicating systems for rated voltages above 1 kV and up to and including 52 kV
- IEC 61243-5:1997: Live working - Voltage detectors - Part 5: Voltage detecting systems (VDS)

3 Unpacking, inspection and storage

3.1 Removal of transport packaging

PDCOM requires careful handling.

1. Examine the delivered products to ensure that they have not been damaged during transport.
2. Remove the transport packing carefully without force.

The cardboard packaging material is 100% recyclable.

3.2 Product identification

The identification label of PDCOM is behind the PDCOM. The label gives the following information: part number, serial number and product code.

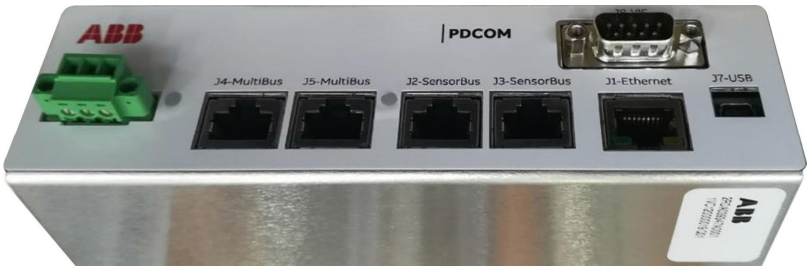

Figure 1: Identification label on backplate

The Serial Number is an important traceability tool for the user and for manufacturer.

3.3 Checking delivery items

Check that the items received comply with those listed in the delivery documents.

3.4 Inspecting the device

PDCOM requires careful handling before installation on site.

- Check the device to see if any damage occurred during transportation

If the device has been damaged during transportation, lodge a claim with the transport contractor, and notify the local ABB representative.

3.5 Returning devices damaged in transit

If damage has occurred during transport, appropriate actions must be taken against the final carrier. Please inform the nearest ABB office or representative. ABB should be notified immediately if there are any discrepancies in relation to the delivery documents.

3.6 Storage

If PDCOM is stored before installation, it must be kept in its original transport packaging in a dry and dust free place. Comply with the environmental requirements given in the technical manual.

4 Precondition for PDCOM installation

- VPIS/VDS tested

The following table shows which VPIS (also called as VIS) and VDS has been tested.

ABB ID number	Coupling capacitance (pF)	Nominal Voltage (kV)
3WDA020579P0001	10:40	3:24
3WDA038144P0001	10:40	3:24

In case VPIS/VDS used is not present in the table it has to follow the minimum Capacitance Range requirement reported below:

- Capacitive coupler requirements
  15:250 (pF) - above 50(pF) is preferable

- SWG shutdown
  Note on safety at work
  All relative work and operating procedures must be carefully carried out by trained specialists familiar with the installation, taking into account all the relative safety regulations according to the IEC and other relevant professional bodies, as well as any local and work regulations and instructions.

- Ground busbars
  Earthing the switchgear
  Connect main earthing bar with connections provided in every panel. Ensure protection for the wiring connection of the floor frame or the erected raised false floor. Connect the earthing conductor from the earth electrode, preferably via a removable bolted connection for testing purposes, to the main earthing bar of the switchgear.

- Case 1: Identification of VPIS/VDS

- Case 2: identification of coupler placement
  (in case VPIS/VDS is not present and a dedicated coupler is required)

4.1 Checking environmental conditions and installation space

The mechanical and electrical environmental conditions at the installation site must be within the limits described in the technical manual.

- Avoid installation in dusty, damp places
  Avoid places susceptible to rapid temperature variations, powerful vibrations and shocks, surge voltages of high amplitude and fast rise time, strong induced magnetic fields or similar extreme conditions.

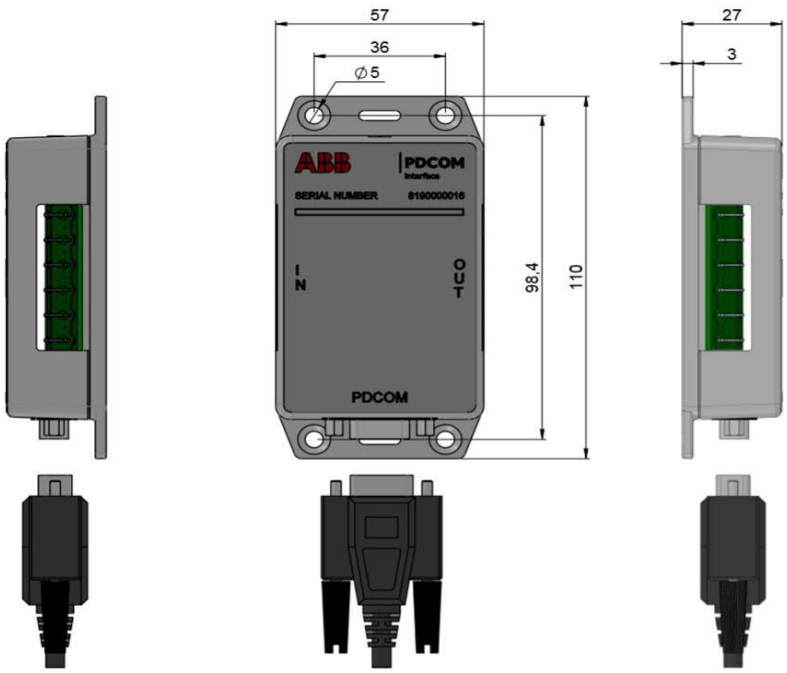
- Installation
  The protection class of the device is IP54 from the front side and IP20 from the backside. It is therefore suitable for outdoor installation. The unit is designed to be installed on the front door of the panel, however it can be integrated in an enclosed cabinet too, protected from excessive heat, humidity and dust. The unit can function in any other position.

- Check that sufficient space is available
  Sufficient space is needed on top and in front to allow access to wires and to enable maintenance and future modifications.

- Environmental conditions
  The equipment will operate within the specified tolerances only if the following environmental conditions are respected:
  Ambient temperature range: -20 °C to +55 °C
  Storage temperature range: -30 °C to +70 °C
  Ambient humidity: 0 – 95% non-condensing

- Grounding the device
  Unwanted transients must be eliminated (lightning protection). Comply with EMC requirements.

5 PDCOM interface Mounting (with VPIS/VDS)



Hardware interfaces (PDCOM interface)
The following interfaces are located on the backplate of the device:

- 1 connector for PDCOM (J10)
  - The connector is standard DB9 straight-through
- 1 connector for VPIS/VDS (J12) (Phoenix connector)
- 1 connector for CAP divider (J11)

Figure 2: PDCOM interface: connection to PDCOM, Dsub9 connector and PDCOM interface: connection to VIS, Phoenix connector

The dimensions of PDCOM interface are the following (mm):

5 PDCOM interface Mounting (with VPIS/VDS)

Commercial code: 1VCF681000S0104

If the device is installed inside an enclosed cabinet, please check that there is enough space all round so that the connectors and cables can be fitted.
In case the device is installed in the front door of the panel (low voltage area) the following procedure must be used. It is made by following steps:

- Step 1: Identify the VPIS/VPIS

Figure 3: VIS

•Step 2: VPIS/VDS Wires connection options

- Option 1: choose a VIS interface with the same connector of your VPIS/VDS, so you can connect the wires to the VIS interface and the to the VPIS/VDS with very short wires or if not possible shielded wires.

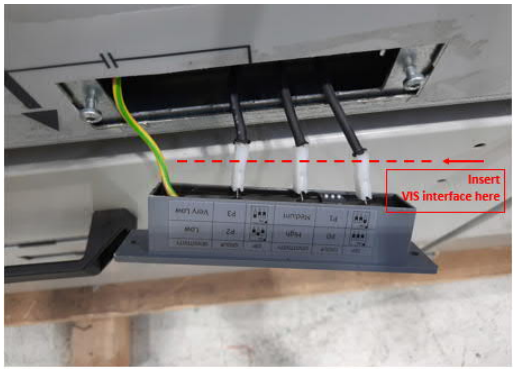


Figure 4: VIS interface connection

- Option 2: if VIS interface connectors are different from your VPIS/VDS connectors you can make 3 adapter cables. These cables should be very short (3 centimeters maximum).

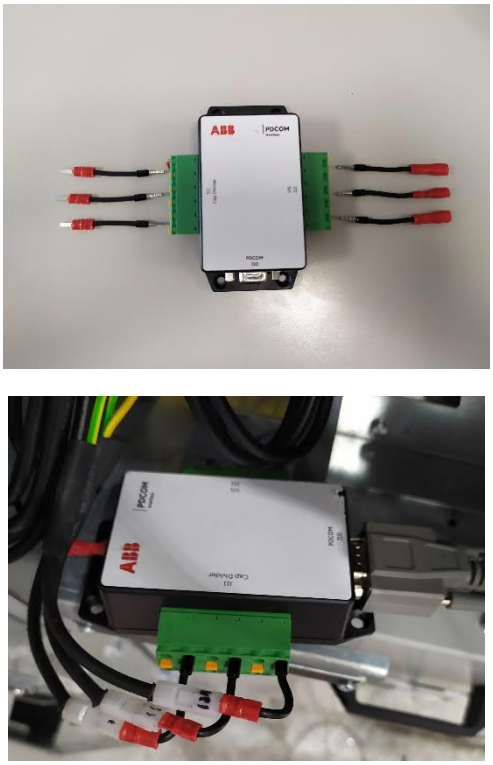

Figure 5: Adapter cables

- Case 3: if adapter cables need to be longer than 3 centimeters a shielded wire must be used and the shield must be connected to the VPIS/VDS cables earth (see Figure 8 and Figure 10 for hearth connection).

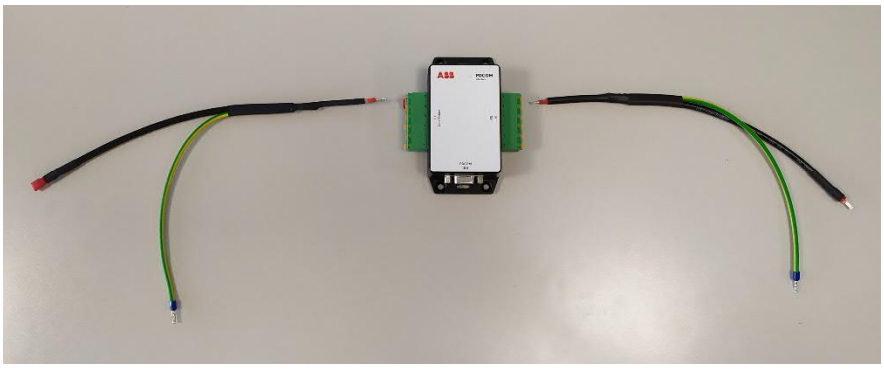

Figure 6: Shielded adapter cables

- Step 3: install the VIS interface:
  - Connect the 3 phases (see connector J11 in Figure 18). The VPIS/VDS should be connected in series, between the capacitor divider (4.1a) and the VPIS/VDS (4.1b).

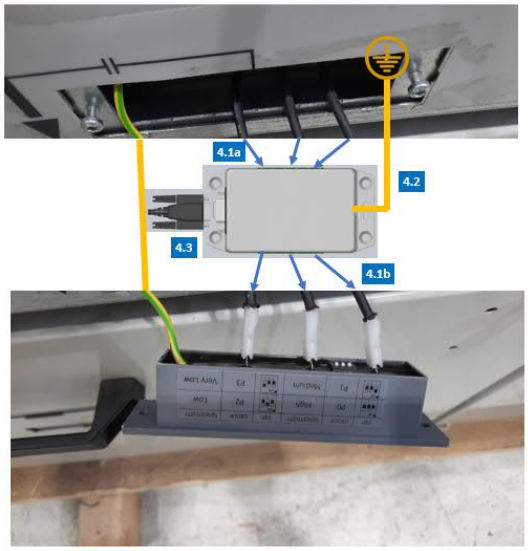

Figure 7: VIS interface connection with VPIS/VDS

What is key with the grounding in general is to avoid ground loops. For this reason, the shield of the cable connecting the capacitive coupler to the installation kit should be grounded on one side only. We strongly advise to connect the shield to the installation kit.

Option 1: connect wires shields and VIS interface ground to the same hearth

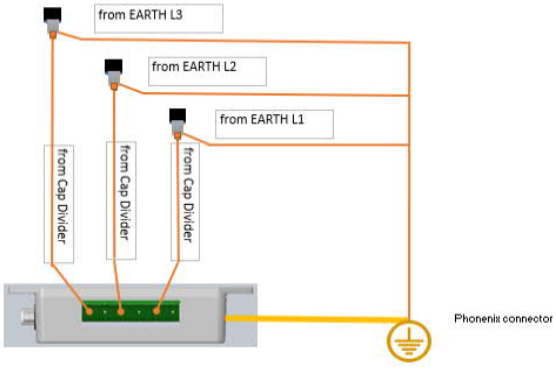

Figure 8: Common hearth

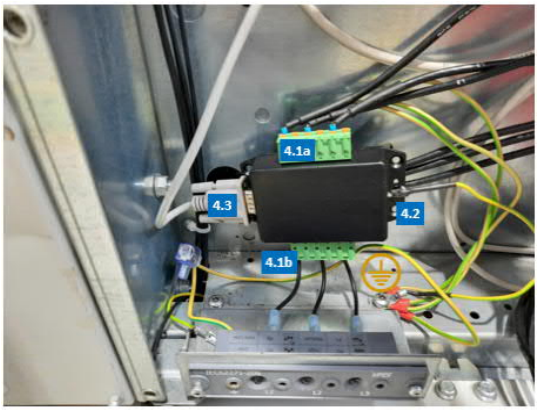

Figure 9: VIS installation with grounding option 1

Option 2: connect wires shields to VIS interface grounds and then the VIS interface to the SWG hearth. In this case be sure to use a wire with an adequate section to ground the VIS interface (it's recommended use cables with section 2,5 mm^2).

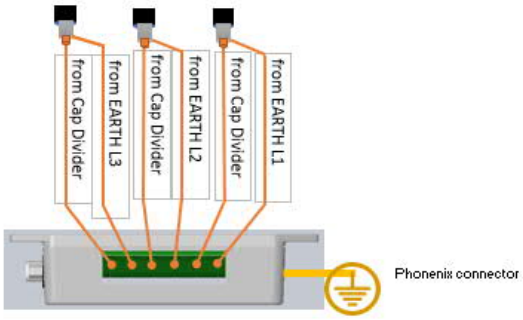

Figure 10: Shields hearth to VIS interface

- Step 4: Install the PCDOM in the LV cabinet, closest to VIS interface and connect the cable between the VIS interface and the PDCOM (5.2).

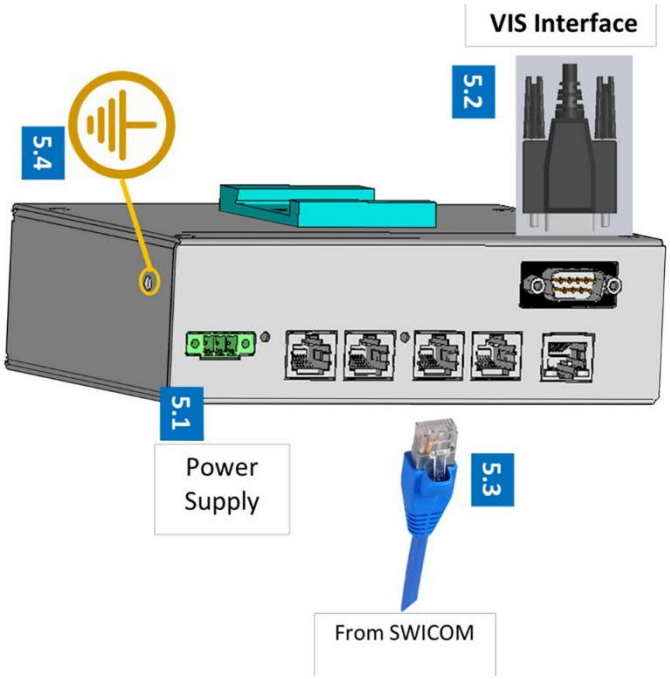

Figure 11: PDCOM connections

- Connect the ethernet cable 5.3 to the SWICOM or to the previous PDCOM if more than one is installed.

- As a general note, the ground connection between the PDCOM, VIS interface and shielded cables should always be as short as possible.

6 PDCOM interface Mounting (without VPIS/VDS)

Commercial code: 1VCF681000S0105

- Step 1: Refer to Capacitive divider installation
- Step 2: Install the VIS interface:
  - connect the 3 phases. The VIS Interface should be connected to the capacitor divider (4.1a). The connector J12 of the VIS Interface (see Figure *19*: PDCOM electrical scheme without VISFigure 19) should have a dedicated connector with capacitors (4.1b), electrical scheme 1VCD400305.

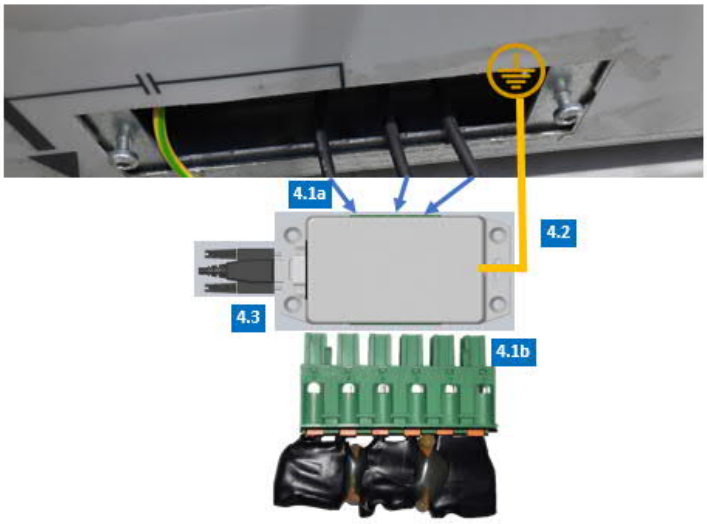

Figure 12: PDCOM connections without VIS

What is key with the grounding in general is to avoid ground loops. For this reason, the shield of the cable connecting the capacitive coupler to the installation kit should be grounded on one side only. We strongly advise to connect the shield to the installation kit.

Option 1: connect wires shields and VIS interface ground to the same hearth

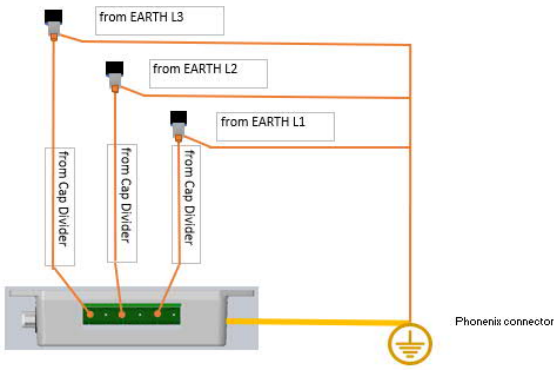

Figure 13: Common hearth

Option 2: connect wires shields to VIS interface grounds and then the VIS interface to the SWG hearth. In this case be sure to use a wire with an adequate section to ground the VIS interface.

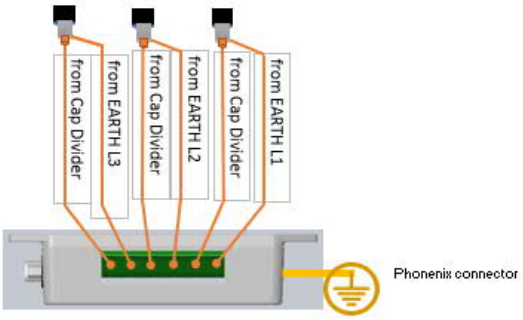

Figure 14: Shields hearth to VIS interface

- Step 3: Install the PCDOM in the LV cabinet, closest to VIS interface and connect the cable between the VIS interface and the PDCOM (5.2).

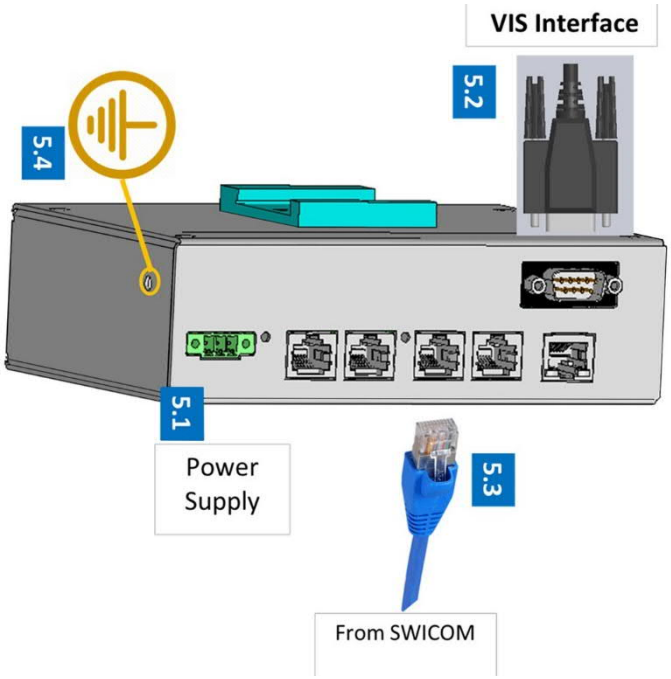

Figure 15: PDCOM connections

- Connect the ethernet cable 5.3 to the SWICOM or to the previous PDCOM if more than one is installed.
- The VIS interface must be the one dedicated with capacitor mounted

7 PDCOM Mounting

- Mechanical installation
- Wirings and connections

7.1 Checking environmental conditions and installation space

The mechanical and electrical environmental conditions at the installation site must be within the limits described in the technical manual.

- Avoid installation in dusty, damp places.
  Avoid places susceptible to rapid temperature variations, powerful vibrations and shocks, surge voltages of high amplitude and fast rise time, strong induced magnetic fields or similar extreme conditions.
- Installation
  The protection class of the device is IP2X
- Check that sufficient space is available.
  Sufficient space is needed on top and in front to allow access to wires and to enable maintenance and future modifications.
  The dimensions of PDCOM are the following:

- Environmental conditions
  The equipment will operate within the specified tolerances only if the following environmental conditions are respected:
  Ambient temperature range: -20°C to +55°C
  Storage temperature range: -30°C to +70°C
  Ambient humidity: 0 – 95% non-condensing

- Grounding the device
  Unwanted transients must be eliminated (lightning protection). Comply with EMC requirements.

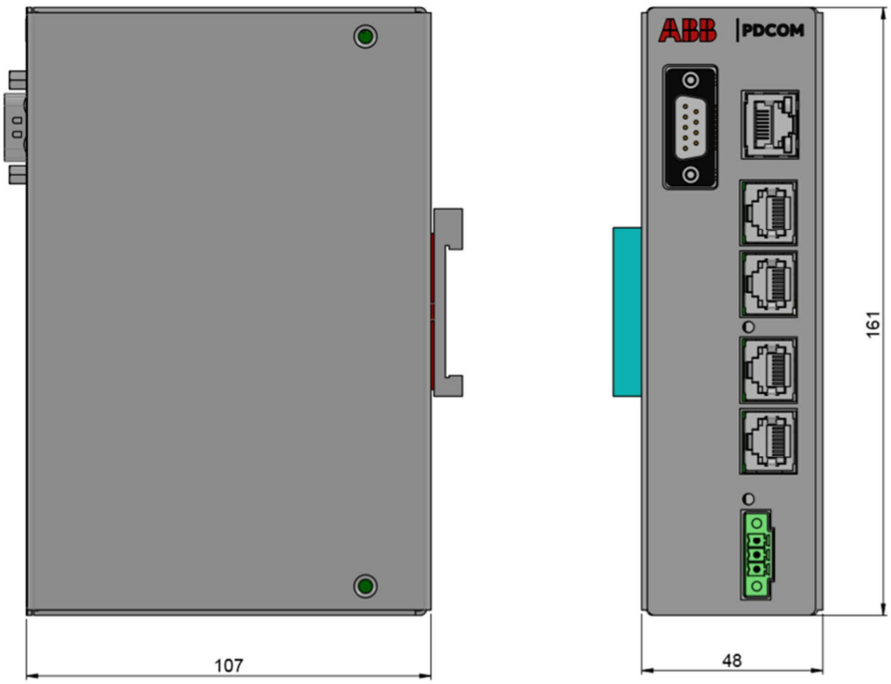

Figure 16: PDCOM dimensions

7.2 Hardware interfaces

The following interfaces are located on the backplate of the device:

- 1 connector for multibus (J4 or J5)
- 1 connector for sensor bus (J2) to connect to SWICOM, J3 to connect to other PDCOM with in/out connection
  - The connector is standard RJ45 cable straight-through category 5 or 6
- 1 connector for ethernet (J1)
- 1 connector to PDCOM interface (J8)
  - The connector is standard DB9 straight-through
- 1 connector for USB interface (J7)
- 1 connector for auxiliary power supply (J6)

Refer to electrical scheme (“1VCD400305”).

Figure 17: PDCOM connectors

7.3 Electrical Diagrams for connections, 1VCD400305

The following scheme is when VIS is available:

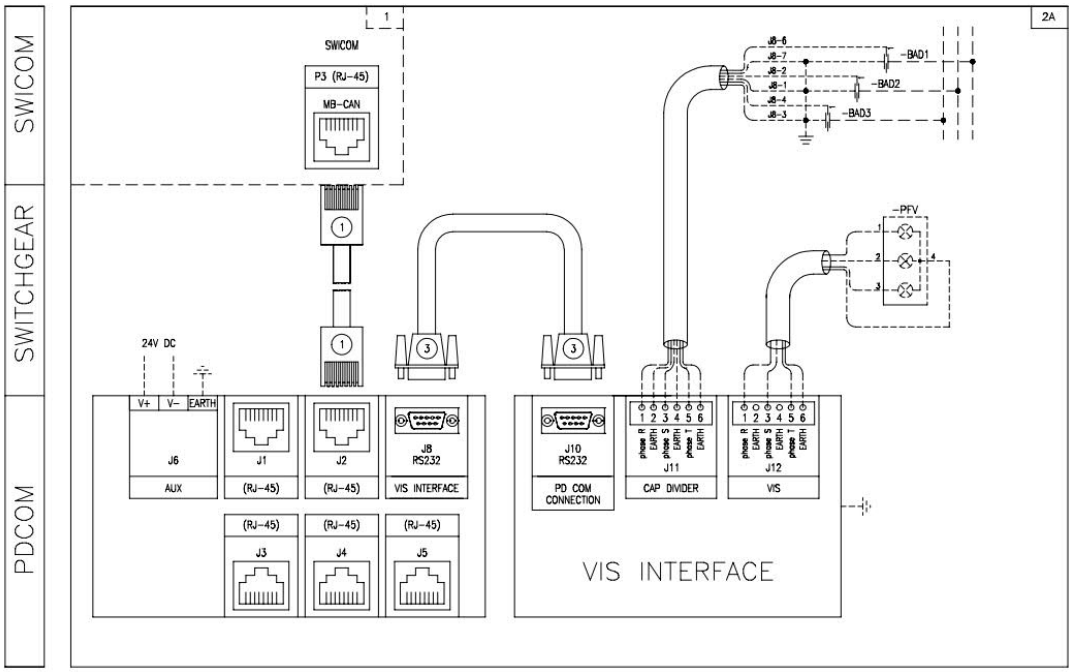

Figure 18: PDCOM electrical scheme with VIS

The following scheme is when VIS is not available:

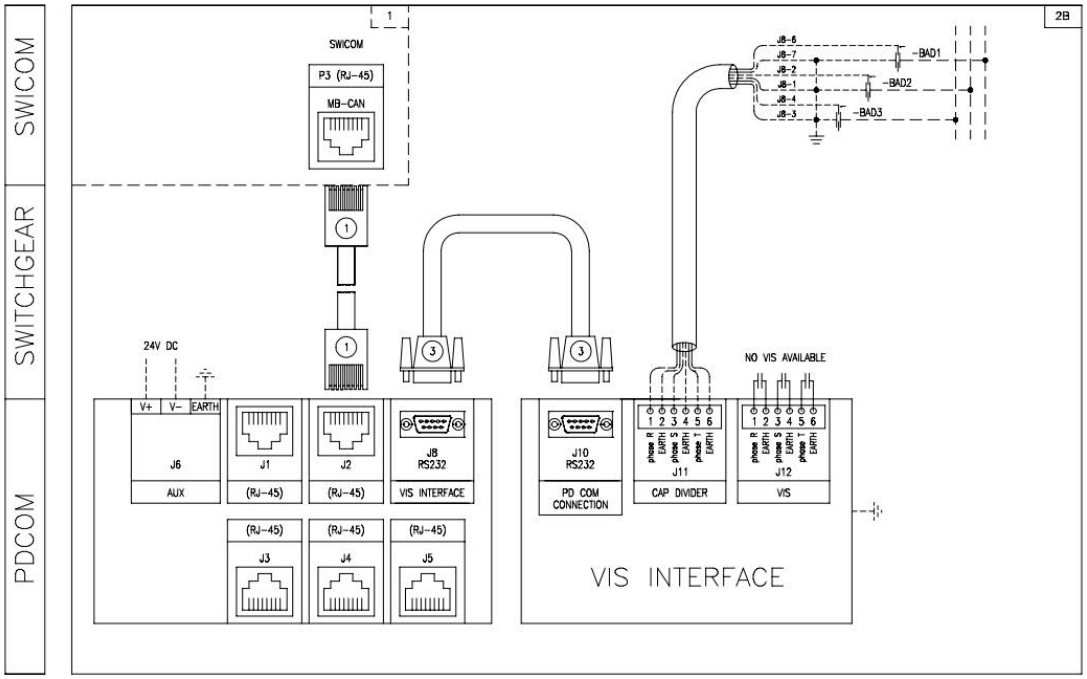

Figure 19: PDCOM electrical scheme without VIS

If the device is installed inside an enclosed cabinet, please check that there is enough space all round so that the connectors and cables can be fitted.

PDCOM installation procedure in the LV cabinet (closest to PDCOM interface):

Step 1: Install the Power Supply (24Vdc) (5.1)
Step 2: Connect the cable coming from PDCOM interface (5.2)
Step 3: Connect the RJ45 form the SWICOM (to the P3 port of SWICOM)
Step 4: Connect the PDCOM to SWG ground
The connect should as short as possible and done by a grounding braid

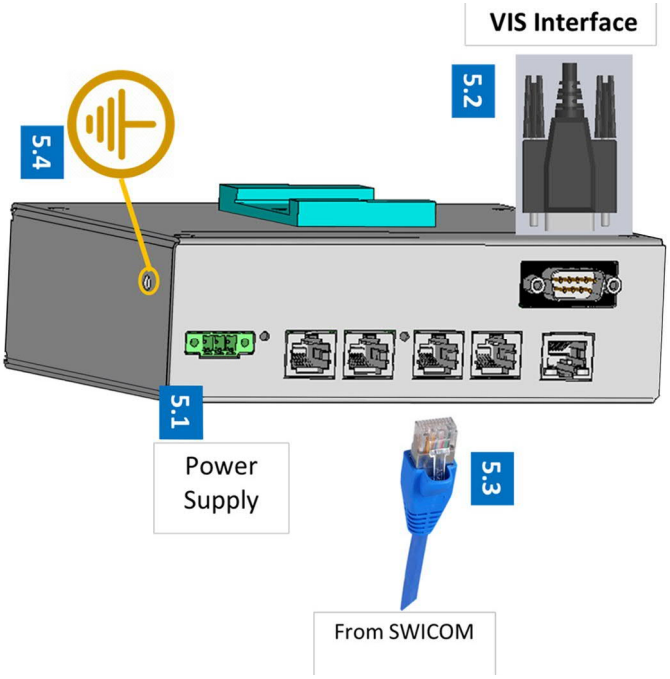

Figure 20: PDCOM connections

Then remove the switchgear ground connection

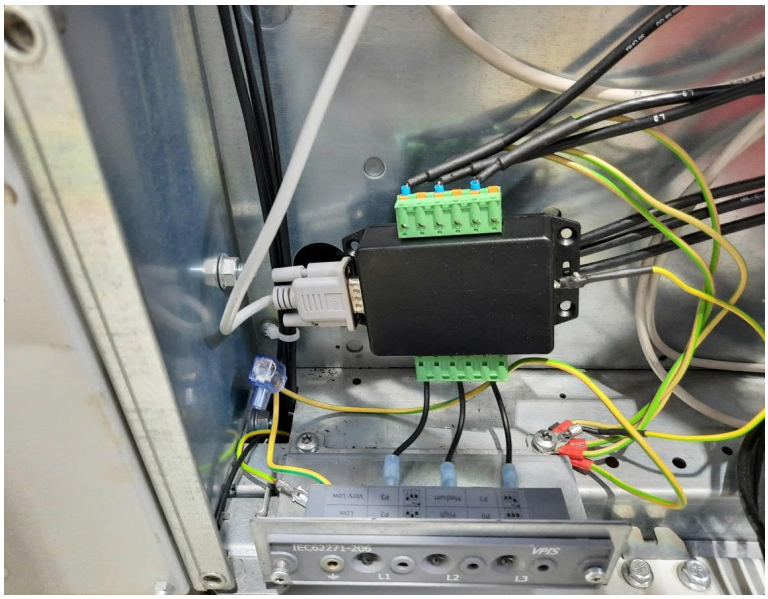

Figure 21: PDCOM installation completed

8 Connection

8.1 Required tools

The following tools are required:

- A flat tip screwdriver for power supply
- A spanner or wrench for ground nut

8.2 Connecting wires

All wire connections are made to the power supply, which is on the backplate. No soldering is needed. Terminals can be connected with 0.5 ... 2.5 mm^2 wires.

Use the pre-made cables and connectors for the communication part. Otherwise, use only 0.5 ... 1mm^2 twisted and shielded wires.

8.3 Protective earth connection

The earthing tape or wire must be at least 6.0 mm^2. Increase the cross section of the tape or wire if the earth lead is very long.
Connect the earthing wire from one screw of PDCOM to the earthing point of the switchgear.

8.4 Power supply connection

The external power supply is intended to provide to PDCOM the required 12-24V starting from the switchgear auxiliary voltage.

Please check the Technical Manual carefully

Table 2: Power supply

Description	Voltage
Vout	12-24VDC
Vout variation	-15% ... +15%
Power consumption	35.0 W
Ripple	Max 12% of the DC value (f =100kHz)
Maximum interruption time	50 ms
Conductor material (Mandatory for UL certification)	Copper [(60 -75) °C]
Conductor wire size (Mandatory for UL certification)	28-16 AWG (stranded or solid)
Terminal tightening torque (Mandatory for UL certification)	0.22 Nm
Ambient Temperature (Mandatory for UL certification)	> 50 °C

Ground the unit with the earth screw at the top. This is essential to ensure safety and electro-magnetic compatibility (EMC) of the device.

8.5 Serial communication connection

PDCOM use the SWICOM sensor bus that provides the interface for the sensors placed on the switchgear.
PDCOM J2 connector shall have to be connected to the SWICOM P3 through a standard RJ45 cable straight-through category 5 or 6.

9 Removal, repair and replacement

9.1 Product lifecycle

During the product lifecycle, the time will come when PDCOM must be upgraded to a next generation. Although this will not be required until some 10 years after installation, it is wise to already consider the product lifecycle when investing on the original product.
Specific options are given in the specific Service & Support sheet of the ABB Product Guide.

9.2 Device info

The device information includes details about the device, such as version and serial number. PDCOM information is available using the corresponding software tools (Monitoring or Configuration tools). See the Operation Manual for further details.

9.3 Removal of the device

1. Turn off the power
2. Detach the power connector
3. Disconnect sensor cables, serial cables and power supply plugs, unscrew the earthing strip.
4. Remove the device from the front door.

9.4 Repairs

Contact the nearest ABB or representative for consultation and instructions if the product develops faults.

9.5 Replacement of the device

To replace PDCOM with another identical unit, first remove the device itself and then install the new one. The configuration can be copied from the old one. Use the configuration tool as explained in the Engineering Manual.

10 Installation Kit

The PDCOM unit can be installed in at least two different places:

- In front of the low voltage compartment (following the procedure in chapter 4)
- In a metal-enclosed box (usually when the low voltage comportment door is already full)

11 Accessories and ordering data

Table 3: Device and sensors

Item	Order number
PDCOM HV	1VCF681000S0103
PDCOM HV with VIS	1VCF681000S0104
PDCOM HV without VIS	1VCF681000S0105

MEDIUM VOLTAGE INSTRUMENT TRANSFORMERS

OUTDOOR / INDOOR

GLOBAL ORGANIZATION

Arteche is a global organization that has manufacturing, technical and trade facilities worldwide, and has **products installed in more than 175 countries** around the world.

This **worldwide presence** allows us to directly meet the local needs of the generation, transmission, and distribution sectors, understanding the local demands and complexities.

In short, we are a global, strong, and stable brand with over 75 years of experience, prepared to respond to any market changes through our main purpose: to respond to energy challenges with agility and responsibility, true to our commitment to people, society and the planet. Always MOVING TOGETHER. Always ADDING ENERGIES.

To this end, **we have the best source of energy on the planet**: **our people**. People have made Arteche the company it is today thanks to their professionalism, knowledge, and commitment to this common project. Our international team has experience and commitment, allowing us to work based on continuous innovation, adapting our answers to the needs of our clients.

Arteche is a project that is shared with our people, and clients, and suppliers, and the whole of the society in which we develop our activity.

Sustainability, ethics, honesty, solidarity, and transparency are the principles that make up our philosophy and which all of us at Arteche follow, always seeking excellence in quality and service. Our commitment to society is strong, and all of us at Arteche want to participate actively to contribute to social development, and to generate value for our clients and for society as a whole.

In July 2021 **ESITAS company** has been added to Arteche`s project, a company with **over 35 years' experience** in the sector and in the instrumentation and measuring market.

With this acquisition, Arteche reinforces its leadership as it looks to the future challenges around the transformation of the energy sector. We also strengthen our commitment to continue to add energies to move into the future.

WE ARE SUPPLYING INSTRUMENT TRANSFORMERS TO ALL OVER THE WORLD

M.V. CURRENT TRANSFORMERS

arteche

General Definitions

General definitions have been given according to International Standarts IEC 61869

Instrument Transformer

A transformer intended to supply measuring instruments meters, protection relays and other similiar apparatus.

Applicable Standards

Our transformers comply with applicable national and international standards.

Current Transformers

An instrument transformer in which the secondary current, in normal conditions of use, is substantially proportional to the primary current and differs in phase from it by angle which is approximately zero for an appropriate direction of the connections. It isolates the instrument and protection circuit from the primary side and protect the devices against overload according to the overcurrent characteristics of the transformer. Current transformers can have several secondary windings with cores of identical of different characteristics completely isolated from each other.

Measuring Current Transformer

A current transformer intended to supply indicating instruments, integrating meters and similiar apparatus.

Protective Current Transformer

A current transformer intended to supply protective relays.

Primary Winding

The winding through which flows the current to be transformed.

Secondary Winding

The winding, which supplies the current circuits of measuring instruments, meters, relays or similiar devices.

Secondary Circuit

The external circuit supplied by the secondary winding of a transformer.

Rated Primary Current

The value of the primary current on which the performance of the transformer is based.

Rated Secondary Current

The value of the secondary current on which the performance of the transformer is based.

Rated Transformation Ratio

The ratio of rated primary current to the rated secondary current (I1N/I2N-i.e. 100/5A)

Current Error (Ratio Error)

The error which a transformer introduces into the measurement of a current and which arises from the fact that the actual transformation ratio is not equal to the rated transformation ratio.
The current error expressed in per cent is given by formula:

$$\text{Current Error}\% = \frac{Kn\ Is - Ip}{Ip} \times 100$$

Where

Kn is the rated transformation ratio;
Ip is the actual primary current
Is is the actual secondary current when Ip is flowing, under the conditions of measurements.

Accuracy Class

A designation assigned to a current transformer errors of which remain within specified limits under prescribed conditions of use.

Burden

The impedance of the secondary circuit in ohms and power-factor. The burden is usually expressed as the apparent power in voltamperes absorbed at a specified power-factor and at the rated secondary current.

Rated Burden

The value of the burden on which the accuracy requirements are based on.

Rated Output

The value of the apparent power (in voltamperes at a specified power-factor) which the transformer is intended to supply to the secondary circuit at the rated secondary current and with rated burden connected to it.

Rated Insulation Level

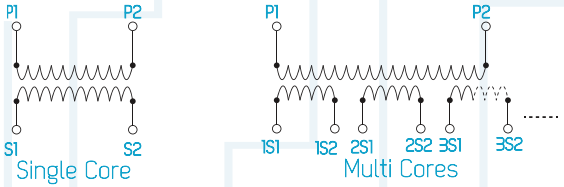
The combination of voltage values which characterizes the insulation of a transformer with regard to its capability to whitstand dielectric stresses.

Rated Frequency

This is the frequency for which the transformer is designed and given in Hz on the rating plate.

Rated Short-Time Thermal Current (Ith)

The r.m.s. value of the primary current which a transformer will withstand for one second without suffering harmful effects, the secondary winding being short-circuited.



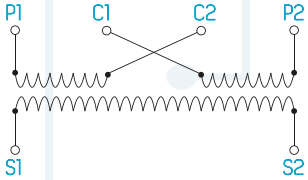
Rated Dynamic Current (Idyn)

The peak value of the primary current which a transformer will withstand, without being damaged electrically or mechanically by the resulting electromagnetic forces, the secondary winding being short-circuited.

Rated Continuous Thermal Current

The value of the current which can be permitted to flow continuously in the primary winding, the secondary winding being connected to the rated burden, without temperature rise exceeding the values specified.

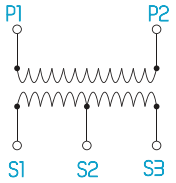
CONNECTION DIAGRAMS
Single Ratio Current Transformers



Reconnection of Current Transformer

In case of changeable ratios, it is possible to design the transformer with primary reconnection or secondary tapping;

Primary Reconnection

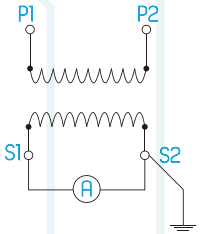


Changeover will be done at the primary side by using joint bars.
Can be used only for primary currents up to 2 x 600A

C1 -C2 short circuited: low rated current
P1 - C1 and P2 - C2 short circuited: high rated current

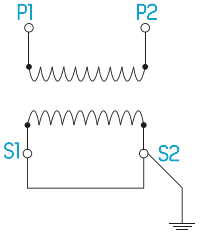
Secondary Tapping

Changeover will be done at the secondary side.



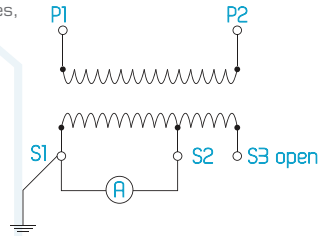
S1 -S2 low rated current
S1 - S3 high rated current

Safety Operation Conditions for Current Transformers



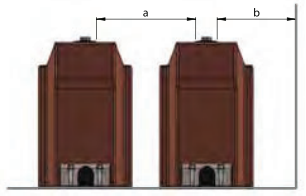
- When the secondary terminals are connected to the measuring or protection devices, one of the terminals should be earthed for safety, as seen in Diagram-1.

Diagram-1



- The secondary circuit of a current transformer must not be operated with an open - circuit.
- The secondary winding of a current transformer which will not be used must be short - circuited and earthed as seen in Diagram-2

Diagram-2



- For the transformer with reconnectable and - or tapped secondaries, unused terminals must be left open as seen in Diagram-3.

Diagram-3

- The current transformers which have capacitive divider tap (Ck) must be connected to the indicator, if the tap will not be used then it must be earthed.

RING TYPE CURRENT TRANSFORMERS

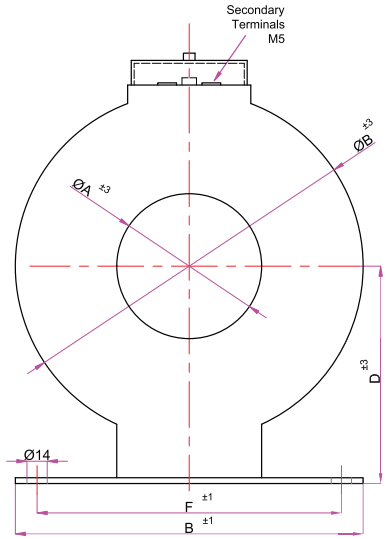
(Um=0,72kV)

INDOOR RING TYPES

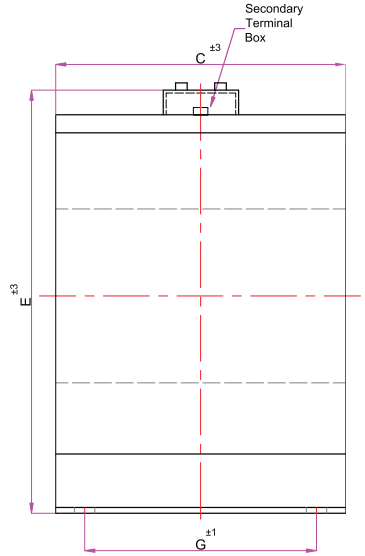
OUTDOOR RING TYPES

- Cable type.
- Insulated by cast resin.
- Applicable for measurement and protection purposes.

BUSHING TYPES



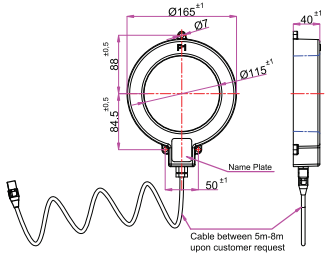
- For power transformers.
- Suitable for operation under oil continuous 130°C.
- Insulated by Insulation paper or Polyester tape.
- Applicable for measurement and protection purposes.



- Dimensions : According to the customer requirements.
- Standards : According to the customer requirements.
- Please contact with ARTECHE for feasibility of required transformer's which have different ratio, class, burden and dimensions.

C.T.'S TECHNICAL DRAWING

** All dimensions are in mm.*



INDOOR TYPE LPCT
(Low Power Current Transformer) (Cable Type)

(Um=0, 72kV)

Types:
LPCT-115

- LPCT-115 is defining low power current transformer with voltage output in compliance with IEC 60044-8.
- It is designed for measuring nominal currents of 5A to 1250 A with ratio 100A / 22,5mV. Thus it should be used with a digital relay which have 100A / 22,5mV input with LPCT.
- Esitas LPCT Set is composed of three LPCT and one digital relay. In case of preffered set without relay, Esitas has to be informed about the relay that will be used.
- The sensor is delivered with cable which is between 5m - 8m upon customer request.

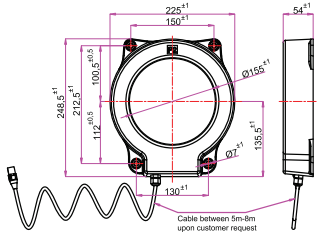
Advantages :
-Same transformer is usable for nominal currents of 5A to 1250A.
- Accurracy warranty throughout the range :
  • Protection : 5A-40kA ; class 5P
  • Measuring: 100A-1250A; class 0,5 (class 0,75 for 20A, class 1,5 for 5A).

Simple Assembly :
- Ready for connection secondary cables.
- Simple connection with insulated cable for all types cubicles.

Safety Operation :
- Openable secondary circuit under load.

Technical Data

Types	LPCT - 115
Standard	IEC 60044-8
Minimum primary curent (A)	5
Rated primary current (A)	100
Rated secondary voltage (mV)	22,5
Rated maximum primary current (A)	1250
Class of protection	0,5 (100A - 1250A), 0,75 (20A), 1,5 (5A)
Class of measuring	5P
Accuracy limit factor (Kalf)	150
Rated short - time current (kA / 1s)	40
Insulation level (kV)	0,72 / 3 / -
Frequency (Hz)	50 - 60
Burden (Rbr) (kΩ)	2



INDOOR TYPE LPCT
(Low Power Current Transformer) (Cable Type)

(Um=0, 72kV)

Types:
LPCT-160

- LPCT-160 is defining low power current transformer with voltage output in compliance with IEC 60044-8.
- It is designed for measuring nominal currents of 5A to 2000 A with ratio 100A / 22,5mV. Thus it should be used with a digital relay which have 100A / 22,5mV input with LPCT.
- Esitas LPCT Set is composed of three LPCT and one digital relay. In case of preffered set without relay, Esitas has to be informed about the relay that will be used.
- The sensor is delivered with cable which is between 5m - 8m upon customer request.

Advantages :
-Same transformer is usable for nominal currents of 5A to 2000A.
- Accurracy warranty throughout the range :
  • Protection : 5A-40kA ; class 5P
  • Measuring: 100A-2000A; class 0,5 (class 0,75 for 20A, class 1,5 for 5A).

Simple Assembly :
- Ready for connection secondary cables.
- Simple connection with insulated cable for all types cubicles.

Safety Operation :
- Openable secondary circuit under load.

Technical Data

Types	LPCT - 160
Standard	60044-8
Minimum primary curent (A)	5
Rated primary current (A)	100
Rated secondary voltage (mV)	22,5
Rated maximum primary current (A)	2000
Class of protection	0,5 (100A - 2000A), 0,75 (20A), 1,5 (5A)
Class of measuring	5P
Accuracy limit factor (Kalf)	400
Rated short - time current (kA / 1s)	40
Insulation level (kV)	0,72 / 3 / -
Frequency (Hz)	50 - 60
Burden (Rbr) (kΩ)	2

M.V. VOLTAGE TRANSFORMERS

arteche

M.V. VOLTAGE TRANSFORMERS

Voltage Transformers

An instrument transformer in which the secondary voltage, in normal conditions of use, is substantially proportional to the primary voltage and differs in phase from it by an angle which is approximately zero for an appropriate direction of the connections.

It isolates the primary side rated voltage from the connected instruments and protection circuits and convert the primary voltage into a measurable secondary voltage, which is true in magnitude and phase.

Primary Winding

The winding to which the voltage to be transformed is applied.

Secondary Winding

The winding, which supplies the voltage circuits of measuring instruments, meters, relays or similar apparatus.

Rated Primary Voltage

The value of the primary voltage, which appears in the designation of the transformer and on which its performance is based.

Rated Secondary Voltage

The value of the secondary voltage, which appears in the designation of the transformer and on which its performance is based.

Rated Transformation Ratio

The ratio of the rated primary to the rated secondary voltage.

Voltage Error (Ratio Error)

The error which a transformer introduces into the measurement of a voltage and which arises when the actual transformation ratio is not equal to the transformation ratio.
The voltage error, expressed in per cent, is given by the formula:

$$\text{Voltage Error}\,\% = \frac{Kn\,Us - Up}{Up} \times 100$$

Where
Kn is the rated transformation ratio;
Up is the actual primary voltage;
Us is the actual secondary voltage when Up is applied under the conditions of measurement.

Accuracy Class

A designation assigned to a voltage transformer, the errors of which remain within specified limits under prescribed conditions of use.

Burden

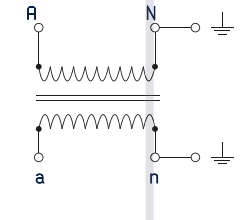
The admittance of the secondary circuit expressed in siemens and power factor (lagging or leading)

Rated Burden

The value of the burden on which the accuracy requirements are based on.

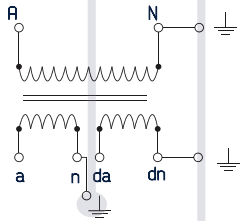
Rated Output

The value of apparent power (in voltamperes at a specified power - factor), which the transformer is intended to supply to the secondary circuit at the rated secondary voltage and with rated burden, connected to it.



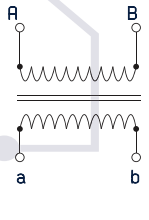
Rated Insulation Level

The combination of voltage values which characterizes the isolation of a transformer with regard to its capability to withstand dielectric stresses.



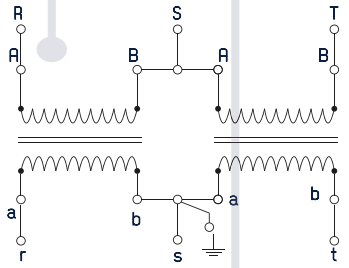
Rated Voltage Factor

The multiplying factor to be applied to the rated primary voltage to determine the maximum voltage at which a transformer must comply with the relevant thermal requirements for a specified time and with the relevant accuracy requirements.



CONNECTION DIAGRAMS

Single Pole insulated
voltage transformer
(e.g. 11000/√3: 100/√3V)



Single Pole insulated
voltage transformer
with an open delta winding
(e.g. 11000/√3: 100/√3V - 100/3V)

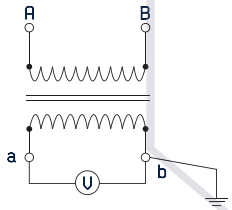
Double pole insulated
voltage transformer
(e.g. 11000: 100V)

It can be required for multi secondary winding and changeable ratios.

V-Connection of Two Double Pole Insulated Voltage Transformers

Safety Operation Conditions for Voltage Transformers

-When the Secondary terminals are connected to the measuring or protection devices, one of the terminals should be earthed for safety as seen in Diagram-1.hh



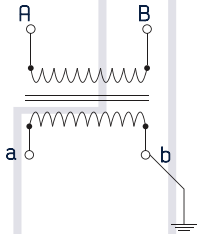


Diagram-1

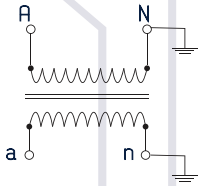

- The base plate must be earthed
- The secondary circuits must not be short-circuited during operation. Otherwise the voltage transformers will be thermally destroyed.
- If any of the secondary windings of a voltage transformer will not be used, then it must be left open with one of the terminals connected to the earth as seen in Diagram-2.

Diagram-2

- For the single phase transformers, the neutral terminal of the primary "N" must be earthed in the earthed (neutral) systems as seen in Diagram-3.

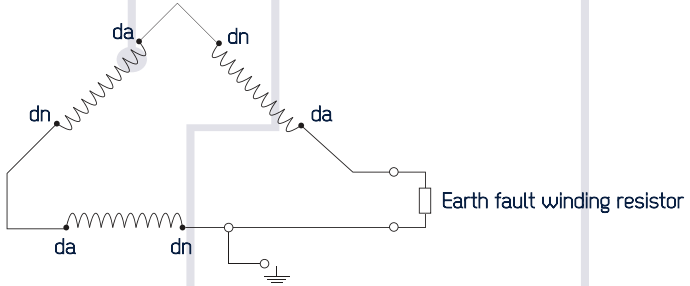

Diagram-3

Other Important Points and Notes

When using single pole insulated inductive voltage transformers it is very important to understand that, when a circuit is being closed or during the decaying period of an earth fault ferroresonance may occur. Ferroresonance can lead to the overheating and thermal destruction of the voltage transformer or high levels of voltages may be induced. In general, ferroresonance can be eliminated by the use of an appropriate resistor placed as a burden in open-delta circuit formed by three voltage transformers open-delta windings. The open-delta circuit must always be earthed only at one point as seen in Diagram-4. The open-delta connection can also be used for earth-fault monitoring with appropriate devices.

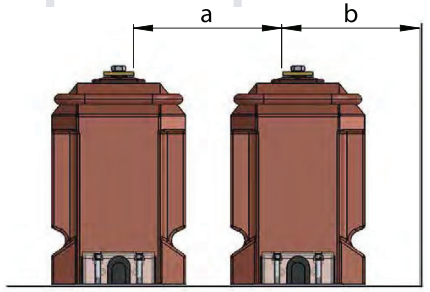

Diagram-4

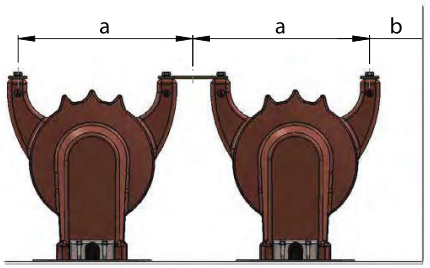
As the number of cable systems is increasing in the energy distribution systems, the protection of voltage transformers have become very important for the uninterrupted operation of the system without any failure and/or down time. For that reason, ARTECHE is always recommending the use of open-delta windings in single phase inductive voltage transformers.



M.V. VOLTAGE TRANSFORMERS CONNECTION CLEARENCES

SINGLE PHASE VOLTAGE TRANSFORMERS

INSULATION LEVEL	a minimum	b minimum
12kV	100mm	110mm
24kV	190mm	210mm

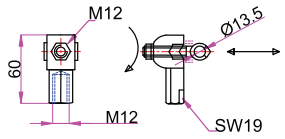
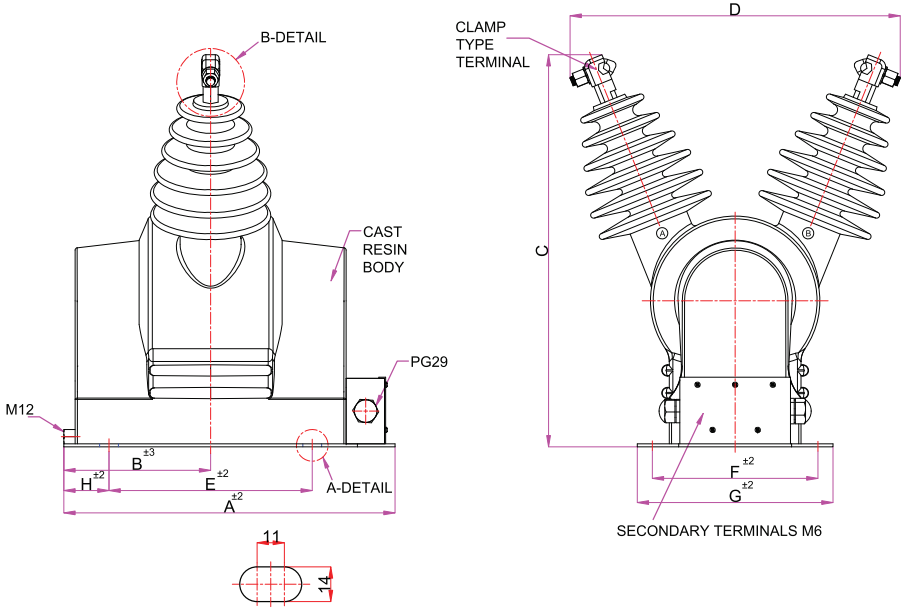
OUTDOOR DRY TYPE PHASE TO PHASE CAST RESIN INSULATED VOLTAGE TRANSFORMERS

(Um=3,6kV.....36kV)

Types:
2VTH 20
2VTH 30



Clamp type terminal
for high voltage connection.



Technical Data						Produced only in Indonesia Factory
Types	2VTH 20					2VTH 30
Operating voltage, Um (kV)	3,6	7,2	12	17,5	24	36
Rated power-frequency withstand voltage (1 minute) (kV)	10	20	28	38	50	70
Rated impulse test voltage (1.2/50 µs) full wave (kV)	40	60	75	95	125	170
Rated frequency (Hz)	50-60					
Rated primary voltage (max.) (kV)	24					36
Secondary voltage (V)	100, 110, 120 & suitable for 220V winding.					
Rated burden (max.) in class 0,2 (VA)	30					40
Rated burden (max.) in class 0,5 (VA)	100					120
Rated burden (max.) in class 1 (VA)	200					200
Rated burden for 220V winding (VA)	800					
Rated voltage factor (30sec. or 8h) (Un)	1,2					
Short time load (mechanical) (N)	3750					
Min. creepage distance (mm)	820					1220
Altitude (m)	According to the customer requirements					
Standard	According to the customer requirements					
Weight (approx.) (kg)	60					70

INSULATORS

arteche

INSULATORS

Insulators are insulating and supporting components of the power transmission lines and busbars (distribution centers, switchgears) where they are fixed.

Insulators are intended to be used for 2 reason:
-Separating conductors from the earth in regards to electricity
-Supporting the weight of conductors and additional loads

Arteche Insulators are epoxy cast resin insulated with internal metal fittings.

The insulators are particularly suitable to be used as single support or voltage control.

Arteche MV Insulators are designed for indoor-indoor and outdoor-indoor applications (from 3,6kV to 36kV):

- Bushing Insulators
- Post Insulators
- Capacitive Insulators(voltage divider)

Post insulators for indoor installation

General characteristics
Epoxy resin post insulators, for indoor application, with internal metal fitting.
These insulators are particularly suitable to be used as single supports for conductors, for fuses and for other equipment (as switchgears).

Application
For indoor installation with working condition at T° max. 85 °C.

Service voltage
Up to 36 kV (40,5 kV available on request)

Routine Tests
Visual inspection
Testing of conductive connection of fixing inserts for post insulators
Dry power-frequency withstand voltage
Partial discharge extinction voltage test

Standards
IEC 60273 (CEI 36/12) - CENELEC HD 578 S1
IEC 60660

General characteristics
Epoxy resin post insulators with capacitive divider for the reading of the voltage.
Manufactured with internal metal fitting, they can be equipped with couplings and low voltage light signal box.
These insulators are mainly suitable to be used as insulated supports of equipment, bus bar or fuses.

Application
Max working temperature of 85 °C.

Routine Tests
Visual inspection
Testing of conductive connection of fixing inserts for post insulators
Dry power-frequency withstand voltage
Partial discharge extinction voltage test (connected to the voltage indicator)

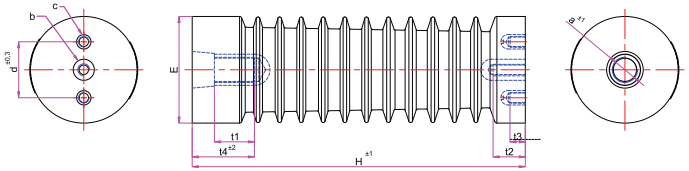
Service voltage
Up to 36 kV (40,5 available on request)

Standards
IEC 60660

Bushing Insulators for indoor-indoor / outdoor-indoor

General characteristics
12 - 36 kV epoxy resin bushing insulators. The insulators can be fitted with copper bars designed from 250 up to 1250 A.
They are equipped with internal metal fittings for installation on the relevant frame and with brass nuts and washers for fastening of phase connectors.

Application
Indoor/outdoor installation at max working temperature of 85 ºC.



Service voltage
Up to 36 kV.

Routine Tests
Visual inspection
Dry power-frequency withstand voltage
Measurement of partial discharge quantity

Standards
IEC 60137

INDOOR POST INSULATORS UP TO 36kV

1 APPLICABILITY AND RESPONSIBILITY

These Job Instructions describe the testing procedures applicable to 6.6 kV Main Electric Switchboard manufactured by IMESA, in accordance with Regulations **IEC 62271-200**.

The Head of Quality Control (CQ) or his collaborators (see list of IMESA qualified testers) are responsible for ensuring the proper implementation of the following Job Instructions.

The tests described on this document will be executed at IMESA factory.

2 GENERAL INFORMATION

The switchboard will be placed in a separated area to which access is allowed only to authorised personnel; it should not be possible to isolate the switchboard, the area will be marked off by means of barriers, notices, visible and flashing barriers.

The tester will use the following standards, drawings (switchboard front, overall dimensions, schematic diagrams, etc.) and specifications, as reference:

Applicable standards:

- IEC 62271-200 HV Switchboard
- IEC 62271-100 Circuit breaker
- IEC 62271-102 Earthing switch
- IEC 61869-2 CTs
- IEC 61869-3 VTs
- IEC 60529 Degree of protection

Reference Contractor Documents:

- 123A90-DDL-EL-SP-20019 / Technical Specification, IDS and DDS for 6.6kV Switchgear
- 123A90-DDL-EL-DS-20020/ Technical Data Sheet (TDS) for 6.6kV Switchgear

Applicable IMESA Documents:

3 DESIGN, VISUAL AND MECHANICAL CHECK

3.1 Design, Visual and mechanical check

1. Check the structural dimensions with respect to those shown by the assembly drawings of the different units.
2. Check that there are no bends and that the sheet plate is perfectly flat
3. Check that assembly has been carried out correctly and that the doors are earthed.
4. Check that ducts have been provided for the auxiliary cables as shown by the foundation drawings.
5. Check the coating or plating If the bus-bars are plated (silver plating, resin coating etc).
6. Check that the Main Equipment has been positioned correctly as per the Mimic Diagrams and Switchboard Front View drawing.
7. Check that the equipment is securely fixed.
8. Check that the equipment is properly earthed, wherever appropriate.
9. Check the equipment for eventual damage caused during assembly.
10. Equipment characteristic and rated data checking
11. Check that the paint colour complies with that indicated on the assembly list and that is has not been damaged during assembly.
12. Check the thickness of the paint by an appropriate instrument insuring that the thickness corresponds to one in specification.
13. Check the required internal form of segregation
14. Equipment accessibility and removability checking
15. Check of nameplate and label legend
16. Bus bar creepage and clearance distances check (phase-earth min 60mm / phase-phase min 90mm)
17. Checking of steel thickness (20/10), steel structure work, welding (if any), sheet metal, lifting tool.

3.2 Mechanical structural tests

1. Check that the circuit-breakers can be plugged in and drawn out correctly and possible mechanical interlocking.
2. Check that mechanical locks to prevent the insertion into the unit of similar circuit breakers with rated current inferior to that of the compartment, have been fitted on the mobile section of the circuit breaker and on the fixed section of the unit.
3. Wherever appropriate, check the operating efficiency of the limit switches for racked-in and isolated circuit breaker. To carry out the check, electrically test the switching of the auxiliary contacts both with the circuit-breaker drawn out and the circuit breaker plugged in.
4. Check the operating efficiency of the signalling auxiliary contacts of the open – closed circuit breaker. The check consists of electrically testing the switching of the auxiliary contact both with the circuit breaker in open and closed position.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

5. Check the operating efficiency of the mechanical lock that prevents the manual or electrical closing of the circuit breaker when it is positioned between the plugged in and drawn out positions with the door open. To carry out the check, attempt to close the circuit breaker rack manually and electrically when the circuit breaker is more or less in the plugged in position (or in the case of a HV switchboard, with the door of the box is slightly open).
6. Check the operating efficiency of the key locks and ring the keys if necessary.
7. Check the operating efficiency of all the mechanical interlocks between the circuit-breakers, disconnecting switches and earthing switches.
8. Carry out a number of starting up and stopping sequences as indicated by the table referring to the cell.
9. Check the functional efficiency of the key locks and perform the key ringing when required
10. Check the operating efficiency of all mechanical interlocks between the circuit-breakers, disconnecting switches and earthing switches.
11. Carry out a number of starting up and stopping sequences as indicated by the table referring to the cell.
12. Connections resistor measurement by Voltage Drop Test

3.3 Checking the degree of protection

Check that the degree of protection of the Electrical Switchboards complies with the Order Specifications of the Customer and CEI EN 60529 regulation (Classifications of degrees of protection provided by enclosures for electrical equipment).

3.4 Checking the cabling

1. Check that the information shown on the switchgear nameplates complies with the project data.
2. Check that the cables and equipment have been correctly marked and tagged whit what is reported on the functional diagrams.
3. Check the section of the bars/cables, as provided by project for the power of switch/utilities.
4. Check that the connections on the main circuits are securely tightened (ensuring that the signs on the bolts are correctly marked, where applicable).

Bus bar tightness check

The table below shows the torque wrench settings to use for the nuts and screws for fixing and connecting the compartments and the busbar. (Tolerance 0 % + 20 %)

Screws	M6	M8	MI0	M12	M14	M16
Wrench setting (Nm) -Min	8	19	40	68	100	160
Wrench setting (Nm) -Nominmal	9	22	45	75	115	185
Wrench setting (Nm) -Max	10	25	50	83	130	200

Current Transformers tightness check:

Screw	Max. torque [Nm]	Min. torque [Nm]
M5	3.5	2.8
M6	4	3
M8	20	16
M10	20	16
M12	70	56

5. Check that the cables and wires comply with requirements (marine cable SH-W, etc.) and the nominal voltage U_0/U.
6. Check that all the wires are installed in suitable ducts or have been grouped in bunches placed so that they do not interfere with moving components or cut the insulating sheath.
7. Carry out sample checks on the cable terminations to ensure that they are properly crimped and marked as shown by the relevant diagram.
8. Check that the terminal boards have been correctly positioned and marked and that the terminal is suited to the required function.
9. Check the terminal board connection to the adjacent units ensuring that it has been marked as shown by the Functional Diagrams and that the terminals and jumpers comply with the schematics.
10. Carry out all the checks indicated by point 4 on terminal boards supplied by the Customer and check that all the contacts requested by the Customer have been cabled (e.g. auxiliary relay contacts, protection relay contacts etc.).

4 Electrical and Functional Test

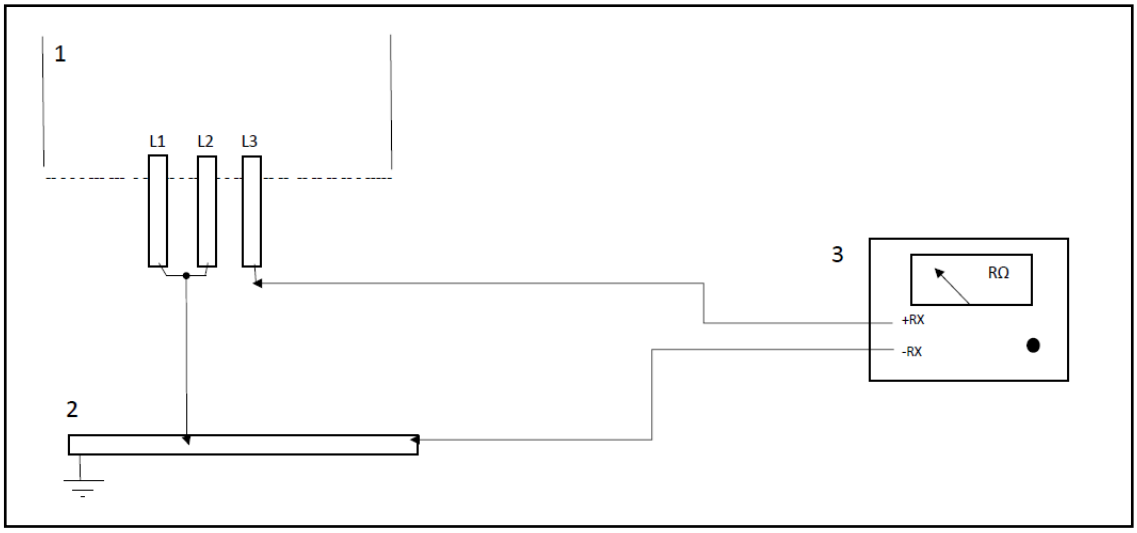
4.1 Functional Test

These tests consist of checking the operating efficiency of all the electric and electromechanical circuits, as shown by the diagrams, by simulating as far as possible different operating conditions. In the case of the **HV** switchboards, the cells must be placed in service position.

1. Check the supply and closing circuit of the spring charging geared motor as follows: set the supply voltage of the circuit to Vn and check the operating efficiency of the spring charging geared motor. With the supply voltage on Vn, place the unit on local operating mode and check compliance of the remote control and lock circuits with the Operating Diagram of the unit. The remote control function must also be simulated by activating on the output terminal boards.
2. Check the opening circuit as follows: set the supply voltage of the circuit on Vn and check the opening circuit of the circuit breaker in the following conditions:

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

- **Local**: the circuit breaker must open when the relevant pushbutton or controller is pressed or activated.
- **Remote**: simulate remote operation by activating the relevant output terminal boards.



3. Check the closing circuit as follows: set the supply voltage of the circuit on Vn and check the opening circuit of the circuit breaker in the following conditions:
   - **Local**: the circuit breaker must close when the relevant pushbutton or controller is pressed or activated.
   - **Remote**: simulate remote operation by activating the relevant output terminal boards.
4. Check the signalling circuits as follows:
   - check the operating efficiency of the optical signals on the unit and ensure that they comply with the Operating Diagram;
   - check that the remote signalling circuits on the output terminal boards are suitable.
5. Check that all the logics shown by the diagrams have been complied with and are efficient both in local and remote by simulating electrical commands or locks from the exterior (it depends on the operating philosophy shown on functional and logic diagrams)
   - Check the closing and opening commands in local and remote.
   - Check the intertrip and interlock signals operating.
   - Check the HW remote alarm operating.
   - Check the operating of auxiliary devices.
   - Electrical functional tests on typical single unit including I/O.

   For the above Tests, please take as reference the Functional and Logis schematic diagrams
6. Measurement of the resistance on the main circuits.
   (100% verification already done my IMESA before FAT. IMESA report can be provided.

   The test is carried out by applying a voltage of 5000 Vdc for 10" between the power circuits (in sequence L1, L2, L3) and ground.
   This Test is carried out to detect the Insulation resistance before and after the test described at item 4.3 (Hi-Pot Test)

   Acceptance Criteria:
   The insulation resistance (based on the cubicles tested) is greater than 10MΩ and the megger does not give an earth fault.

   Resistance Insulation Test on Power Circuit - HV Switchboard Lay-Out
   HV Switchboard Busbar
   Ground Reference
   Megger (-Rx shall be connected with the ground)

Test lay-out for L1 phase Example

Carrying out the test
Reading of the insulation resistance with a “MEGGER” on the following points:
between phase L1 and the phases L2 and L3 connected to earth (-Rx of instrument);
between phase L2 and the phases L1 and L3 connected to earth (-Rx of instrument);
between phase L3 and the phases L1 and L2 connected to earth (-Rx of instrument).

7. Check the amperometric circuits as follows: apply a primary or secondary current and check the operating efficiency of the current transformers, ammeter, protection relays.
   (100% verification already done my IMESA before FAT. IMESA report can be provided.)
8. Check the voltmeter circuits as follows: applying primary power, check the operating efficiency of the voltmetrical transformers and the protection relays.
9. Check CT Polarity, physical marking of P1, P2 and S1, S2. Through the galvanometer, with the connection cables, connected to primary and secondary terminals of the current transformer, the instrument will indicate if the polarity is "according to" "or" discording "
   (100% verification already done my IMESA before FAT)
10. Check of anti-condensation resistance by means power supply. Check the operating efficiency of thermostat and anti-condensation resistance.
11. Check of the protection relay by means of secondary current/voltage injection to verify some trip functions

These tests consist of checking the operating efficiency of the electrical protective relays, by means of secondary current injection and secondary voltage supply, in terms of:

measurements delivered by the in-built instruments,

tripping of the relevant protection functions, in accordance with the settings defined in the Selectivity Analysis, proper activation of digital output contacts and optical signals (LED).

4.2 VOID

4.3 Power Frequency Test and measurement of Insulation resistance

The dielectric tests are carried out to check the insulation distances, the soundness of the insulating materials and that the connections have been made correctly.

Remember to disconnect all current absorbing equipment which would be damaged by the application of voltage (coils, metering instruments, differential circuit breakers etc). A voltage generator at industrial frequency is used to carry out this test.

On agreement between builder and user, operating frequency voltage test, it can be repeated after installation on site; in this case the test voltage shall be equal to 80% the value shown in the table below (CEI EN 62271-200):

Rated Voltage Efficacy Value (kV)	Test Voltage Efficacy Value (kV)
3,6	10
7,2	20
12	28
17,5	38
24	50
36	70

Voltage is applied for 60” for each configuration.

In the presence of CTs, they must be short-circuited and the switches closed.

During this time one operator check the activation of voltage indicator of relevant phase

Main busbars will be fully installed, and all MV circuit breakers will be closed and connected.

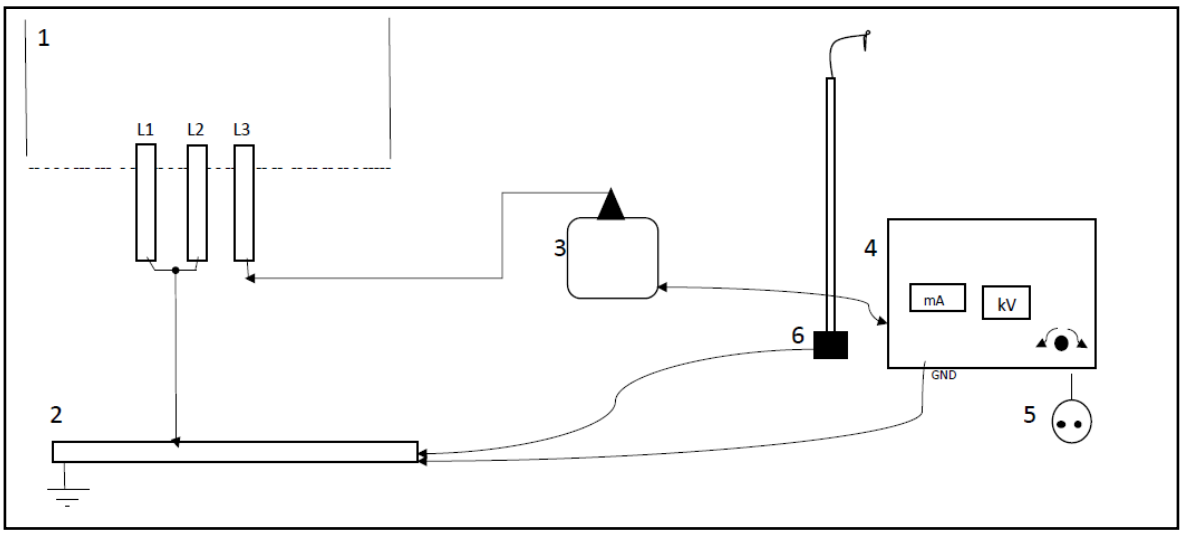
Carrying out the test

To run the test proceed as described:

- Connect to ground the control desk, the VT truck, the foil, the equipment under test;
- Limit the test patch with appropriate barriers;

- Connect the HV pole of VT to the object or to a phase of the electrical panel in test, with the other two phases grounded.
- Connect from table with special cables the lights flashing, the TV and the power plug of the same.
- The operator, before starting the test, must ensure that nobody is within the hurdles.
- Close the main switch of the instrument and work slowly on the rheostat knob until you reach the test voltage read on the voltmeter. (**N.B.** if the rheostat knob is in position zero, the circuit in not closed)

Acceptance Criteria:



The test is passed if for a minute there is no shock.

Imesa consider valid the test if the control desk doesn't detect any fault, this shall consider valid also in case if some discharge can be hearded during the test

- After the test or if there has been a download, return to zero the rheostat, unload with the foil, the pole of VT. In these conditions you can approach the device under test.
- Apply to the other two phases the voltage required by repeating the steps described above for each phase.
- All voltage indicator lamps working properly

HI-Pot Test Lay-Out

1) HV Switchboard Busbar
2) Ground Reference
3) Step-up Transformer
4) Hi-Pot Tester
5) Power supply
6) Ground stick

Test lay-out for L1 phase Example

Carrying out the test

- between phase L1 and the phases L2 and L3 connected to earth;
- between phase L2 and the phases L1 and L3 connected to earth;
- between phase L3 and the phases L1 and L2 connected to earth.

During the Test a Tester has to check that the indication voltage presence of the main circuit is light on

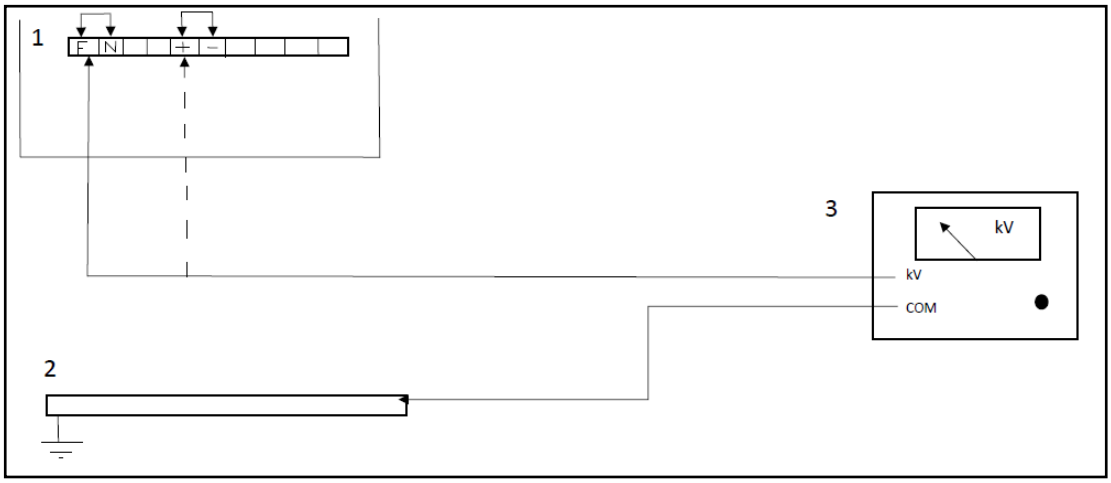
Between to adjust the circuit for a new test it is necessary to discharge to system by Ground Stick

After the dielectric Test on each phase, item 6 has been repeated the value detected will be mentioned on the FAT Report.

4.4 Dielectric test on auxiliary circuit and Insulation resistance measurement

Testing of voltage applied between the auxiliary and control circuits and mass, 1.5kV for 1 min according to RINA rules.

Insulation resistance through Megger device to be checked before and after the here below dielectric Test.



The values detected before and after will be reported in the Test Report.

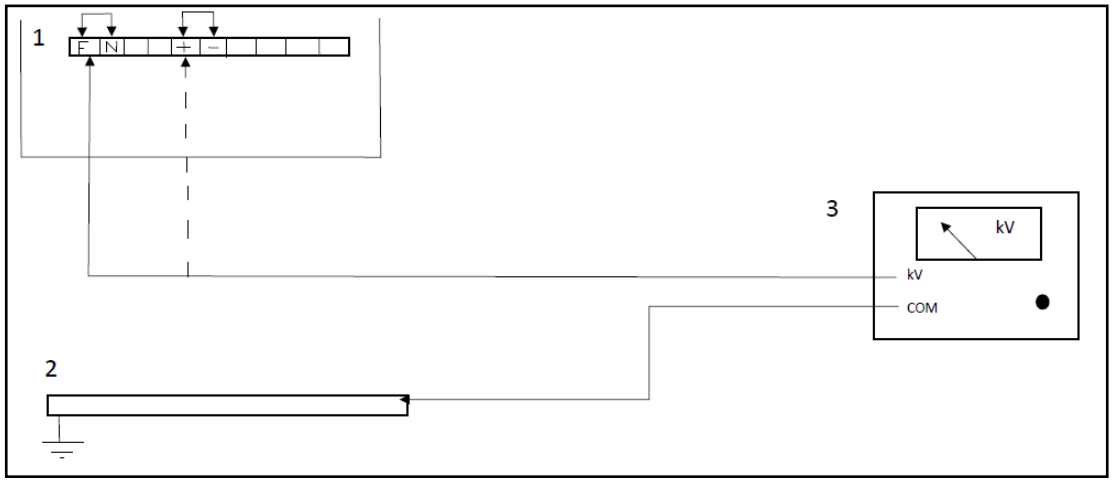
Acceptance Criteria:

The test is passed if for a minute there is no shock detected by the Test Banch.

Resistance Insulation Test on Aux Circuit HV Switchboard Lay-Out

1) HV Switchboard Busbar
2) Ground Reference
3) Megger (-Rx shall be connected with the ground)

4.4 Applied voltage test on the auxiliary and control circuits



Testing of voltage applied between the auxiliary and control circuits and mass, applying a voltage of 2 kV for 60 seconds (CEI EN 62271-1)

Acceptance Criteria:

The test is passed if for a minute there is no shock detected by the Test Banch.

Resistance Insulation Test on Aux Circuit HV Switchboard Lay-Out

1) HV Switchboard Busbar
2) Ground Reference
3) Megger (-Rx shall be connected with the ground)

Test lay-out for L1 phase Example

After the dielectric Test on each phase, item 4.4 has been repeated the value detected will be mentioned on the FAT Report.

4.5 Checking the continuity of the protection circuit

The purpose of this check is to ensure that the protection circuit has been installed correctly and is carried out with both a visual examination (check that rough contact washers have been fitted) and an electrical test (resistor less than 0,1Ω).
With the multitest instrument we use a measure system with no.4 wires. Switchboard is split into no.2 parts and the measure of the continuity of the protection circuit is carried out as follows:
RPE connectors red and reference black are connected to the earth main busbar in the rear section of the switchboard. To close the circuit others RPE red and reference black connectors are connected to the earthing strap on the auxiliary front door on the opposite side of the first red connector on main earth busbar.
An injection of 25A ac is carried out for 3 sec, and the resistance of the circuit is measured.
Test is considered accepted if the resistance is less than 0,1Ω.

4.6 Drop voltage on main busbar

The drop voltage is performed to check the busbar connections, and is carried out with nr. 2 tests.

First test is carried out as follows:
A current generator 100A dc is connected between the vertical busbar near the upper pole of the circuit breaker and cable connection with main circuit breaker closed and connected. The test is carried out for each phase.
With a digital multimeter the value of the drop voltage is measured in mV.
Consequently it is calculated the value of the contact resistance in microΩ.
Acceptance criteria:
The test is considered accepted if the value of the contact resistance does not deviate each other more than 30%.

Second test is carried out as follows:
A current generator 100A dc is connected between the begin and the end of horizontal main busbar. The test is carried out for each phase.
With a digital multimeter the value of the drop voltage is measured in mV.
Consequently it is calculated the value of the contact resistance in microΩ.
Acceptance criteria:
The test is considered accepted if the value of the contact resistance does not deviate each other more than 30%.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

4.7 External Auxiliary Power Supply

Redundancy Test of Incoming supply Lines (110Vdc)

Since there are n.2 incoming line for 110Vdc, the test consists of disconnecting one line at a time verifying that all units continue to be supplied without any unexpected switchgear malfunction.

4.8 Check electric arc

Electric arc on busbar compartment, switch compartment and cable compartment

Trial set:

- Connect the test bench with amperometric terminal blocks for secondary current injection.
- Check flash setting (maximum output)

Test procedure:

- Turn on and close the switches of the users involved.
- Carry out the flash test in the absence of power, in the compartment concerned, checking the correct opening of the "light only" trip switches according to the project specifications.
- Close the switches of the users involved.
- Inject the current onto an amperometric input of the protection relay, with a value higher than the threshold limits and check that the relays acquire this value.
- Carry out the flash test in the compartment concerned, checking the correct opening of the "light and power" trip switches according to the project specifications.
- Repeat the tests alternating the amperometric inputs of the three-phase protection relay.

Acceptance Criteria:

• The incoming and bus-tie circuit breakers must open and the blocking relay must be activated, depending on the design specifications.

4.9 Integrate Test with EMS

(This test will not be held with HV switchgear FAT since it is not in charge of IMESA)

5 Final checks

Once all the tests have been carried out on the different units, before sending the switchboard to the packaging department, the following checks must be carried out:

1. Check that all the jumpers used for the electrical tests of the different circuits have been removed from the terminal boards and the equipment.
2. Clean all the equipment in the unit.
3. Touch up the paintwork if necessary.
4. Check that the foundation bars comply precisely with the drawings.
5. Compile the "Mod. CAR/CAB 04 bill of material for shipment" with an indication of the material to be shipped loose, including material required for installation of the units.
6. Make out the list of missing materials (this list should include materials which are missing because found to be faulty during testing and the equipment to be installed by the Customer).
7. Check that the Manufacturer's data plate showing the characteristics of the switchboard has been fitted.
8. Insert the maintenance manual of the framework
9. CQ deals with the issue the test report and sees to its storage.
10. Check the commissioning spare parts, if any.

N.B In case of acceptance by the customer, it's up to present PM inform RP which involves the planning of production and make it aware of CAB and CQ; PM also defines the exact date that he agreed with the customer and informs the affected functions.

At the end of the test, customer must sign the test report.

6 TEST EQUIPMENT

The following test equipment will be used to carry out the above tests:

- Universal power supply for the auxiliary circuits,

- Amperometric power supply for the primary and secondary currents,

- Instrument for the applied voltage test at industrial frequency of the main circuit,

- Instrument for the applied voltage test of the auxiliary and control circuits,

- Digital thickness gauge

7 CARRYING OUT THE TESTING ACTIVITIES

The testing activities must be carried out in compliance with the safety requirements of the current regulation by restricting the test area with the special hurdles.

The testing activities must be carried out exclusively by personnel who have received training under the CEI 11-27 anyway the operators must always be at least two.

If testing is manned by customer (or by those third parties designated by it), this is absolutely not permitted to carry out maneuvers on the switch and are not allowed to stay alone at the IMESA plant.

All electrical parts must be banned from all contact and the area should be well lit and free from hindrances and obstacles.

Operators must be equipment with suitable DPI and certified equipment under current regulations.

During testing must always be at least one first aid worker who has received its education.

When testing the dielectric properties (applied voltage test), remember to wear insulated gloves and shoes with retractable toe caps as well as suitable protection clothing covering body and arms. If the test is suspended even temporarily, the test instrument must be disconnected from the mains.

1 APPLICABILITY AND RESPONSIBILITY

These Job Instructions describe the testing procedures applicable to LV Electric Switchboards manufactured by IMESA, in accordance with Regulation **IEC 61439-1**
The Head of Quality Control (QC), the Head of CAB and the team leader that perform testing are responsible for ensuring the proper implementation of the following Job Instruction.
The tests described on this document will be executed at IMESA factory.

2 GENERAL INFORMATION

The switchboards which are ready for tested should be placed in a separated area to which access should be allowed only to authorised personnel; should it not be possible to isolate the switchboard, the area should be marked off by means of barriers, notices, visible and flashing barriers.

The tester must use the diagrams (SLD, Functional, etc) and the drawings (switchboard front, overall dimensions etc.) and eventual special specifications, as reference.

A list of all the checks and tests carried out on both types of switchboards, namely LV Electric Switchboards (unless otherwise indicated) manufactured by IMESA, is provided (see Annex 1).

When testing the dielectric properties (applied voltage test), insulated gloves and shoes with retractable toe caps, as well as suitable protection clothing covering body and arms, to be worn. If the test is suspended even temporarily, the test instrument must be disconnected from the mains.

Applicable standards:

IEC 61439-1:2020 – Low-voltage switchgear and controlgear assemblies – Part 1: General rules.
IEC 61439-2:2020 – Low-voltage switchgear and controlgear assemblies – Part 2: Power switchgear and controlgear assemblies.
IEC 60947-2:2016 with Amendment 1:2019 – Low-voltage switchgear and controlgear – Part 2: Circuit-breakers.
IEC 61869-2:2012 – Instrument transformers – Part 2: Additional requirements for current transformers.
IEC 61869-3:2011 – Instrument transformers – Part 3: Additional requirements for voltage transformers.

IEC 60529:1989 with Amendments 1:1999 and 2:2013 – Degrees of protection provided by enclosures (IP Code).

3 DESIGN, VISUAL AND MECHANICAL CHECKS

3.1 Visual and dimensional check

1. Check of nameplate and label legend
2. Bus bar creepage and clearance distances check
3. Checking of steel thickness, steel structure work, welding, sheet metal, lifting beams (thickness of roofing sheets, plinths, uprights, 3mm; door sheets, segregations, shelves, 2mm)
4. Equipment characteristic and rated data checking
5. Equipment accessibility and removability checking
6. Check the structural dimensions with respect to those shown by the assembly drawings of the different units.
7. Check that there are no bends and that the sheet plate is perfectly flat
8. Check that assembly has been carried out correctly and that the doors are earthed.
9. Check that ducts have been provided for the auxiliary cables as shown by the foundation drawings.
10. Check the coating or plating If the bus-bars are plated (silver plating, resin coating etc).
11. Check that the Main Equipment has been positioned correctly as per the Mimic Diagrams and Switchboard Front View drawing.
12. Check that the equipment is securely fixed.
13. Check that the equipment is properly earthed, wherever appropriate.
14. Check the equipment for eventual damage caused during assembly.
15. Check that the paint colour complies with that indicated on the assembly list and that is has not been damaged during assembly.
16. Check the thickness of the paint by an appropriate instrument insuring that the thickness corresponds to one in specification.
17. Check the required internal form of segregation

3.2 Mechanical structural tests

1. Check that the circuit-breakers can be plugged in and drawn out correctly and possible mechanical interlocking.
2. Check that mechanical locks to prevent the insertion into the unit of similar circuit breakers with rated current inferior to that of the compartment, have been fitted on the mobile section of the circuit breaker and on the fixed section of the unit.
3. Wherever appropriate, check the operating efficiency of the limit switches for racked-in and isolated circuit breaker. To carry out the check, electrically test the switching of the auxiliary contacts both with the circuit-breaker drawn out and the circuit breaker plugged in.
4. Check the operating efficiency of the signalling auxiliary contacts of the open – closed circuit breaker. The check consists of electrically testing the switching of the auxiliary contact both with the circuit breaker in open and closed position.

5. Check the operating efficiency of the mechanical lock that prevents the manual or electrical closing of the circuit breaker when it is positioned between the plugged in and drawn out positions with the door open. To carry out the check, attempt to close the circuit breaker rack manually and electrically when the circuit breaker is more or less in the plugged in position (or in the case of a MV switchboard, with the door of the box is slightly open).
6. Check the operating efficiency of the key locks and ring the keys if necessary.
7. Check the operating efficiency of all the mechanical interlocks between the circuit-breakers, disconnecting switches and earthing switches.
8. Carry out a number of starting up and stopping sequences as indicated by the table referring to the cell.
9. Check the functional efficiency of the key locks and perform the key ringing when required
10. Check the operating efficiency of all mechanical interlocks between the circuit-breakers, disconnecting switches.
11. Carry out a number of starting up and stopping sequences as indicated by the table referring to the cell.

3.3 Checking the degree of protection

Check that the degree of protection of the Electrical Switchboards complies with the Order Specifications of the Customer and CEI EN 60529 regulation (Classifications of degrees of protection provided by enclosures for electrical equipment).

3.4 Checking the wiring

1. Check that the information shown on the data plates complies with the data shown by the mimic Diagram and apply the setting of caps (when are known).
2. Check that the cables and equipment have been correctly marked and tagged whit what is reported on the operation diagram.
3. Check that the wording on the data plates and positioning of the same comply with the Data Plate and Mimic Diagram List.
4. Check the section of the bars/cables, as provided by project for the power of switch/utilities.
5. Check that the connections on the main circuits are securely tightened (ensuring that the signs on the bolts are correctly marked).
6. Check that the cables and wires comply with requirements (flameproof SH-W) and the nominal voltage U_0/U.
7. Check that all the wires are installed in suitable ducts or have been grouped in bunches placed so that they do not interfere with moving components or cut the insulating sheath.
8. Carry out sample checks on the cable terminations to ensure that they are properly crimped and marked as shown by the relevant diagram.
9. Check that the terminal boards have been correctly positioned and marked and that the terminal is suited to the required function.

10. Check the terminal board connection to the adjacent units ensuring that it has been marked as shown by the Operating Diagram and that the terminals and jumpers comply with the Operating Diagram.
11. Carry out all the checks indicated by point 4 on terminal boards supplied by the Customer and check that all the contacts requested by the Customer have been cabled (e.g. auxiliary relay contacts, protection relay contacts etc.).
12. Verification of thightening of internal circuits and connections / bar connections. * Acceptance criteria as per following table: (see Imesa document TAB 11)

Type of screw	Tightening torque (Nm)	Tolerance
M5	5	5%
M6	9	5%
M8	22	5%
M10	45	5%
M12	75	5%
M14	115	5%
M16	185	5%

*** for tightening torques regarding insulators, CT's-VT's, refer to the values provided by the manufacturer**

4 ELECTRICAL AND FUNCTIONAL TESTS

4.1 Functional Test

These tests consist of checking the operating efficiency of all the electric and electromechanical circuits, as shown by the diagrams, by simulating as far as possible different operating conditions.

In particular:

1. Check the supply and closing circuit of the spring charging geared motor as follows: set the supply voltage of the circuit to Vn and check the operating efficiency of the spring charging geared motor. With the supply voltage on Vn, place the unit on local operating mode and check compliance of the remote control and lock circuits with the Operating Diagram of the unit. The remote control function must also be simulated by activating on the output terminal boards.
2. Check the opening circuit as follows: set the supply voltage of the circuit on Vn and check the opening circuit of the circuit breaker in the following conditions:
   - Local: the circuit breaker must open when the relevant pushbutton or controller is pressed or activated.
   - Remote: simulate remote operation by activating the relevant output terminal boards.
3. Check the closing circuit as follows: set the supply voltage of the circuit on Vn and check the closing circuit of the circuit breaker in the following conditions:

- Local: the circuit breaker must close when the relevant pushbutton or controller is pressed or activated.
- Remote: simulate remote operation by activating the relevant output terminal boards.

4. Check the signalling circuits as follows:
   - check the operating efficiency of the optical and acoustic signals on the unit and ensure that they comply with the Operating Diagram;
   - check that the remote signalling circuits on the output terminal boards are suitable.
5. Check the amperometric circuits as follows: apply a primary or secondary current and check the operating efficiency of the current transformers, amperometers, amperometric relays and protection relays.
6. Check the voltmeter circuits as follows: applying primary power, check the operating efficiency of the voltmetric relays and the protection relays.
7. Check that all the logics shown by the diagrams have been complied with and are efficient both in automatic and manual by simulating electrical commands or locks from the exterior (it depends on the operating philosophy)
8. Automatic and Manual transfer operating: please refer to the electric tests that will be performed with the helps of relevant approved Schematic Diagrams
9. Intertrip and interlock signals operating: please refer to the electric tests that will be performed witn the helps of relevant approved Schematic Diagrams
10. HW remote alarm operating: please refer to the electric tests that will be performed with the help of relevant approved Schematic Diagrams
11. Check CT Polarity, physical marking of P1, P2 and S1, S2. Through the galvanometer, with the connection cables, connected to primary and secondary terminals of the current transformer, the instrument will indicate if the polarity is "according to" "or" discording " (100% verification).
12. Check of the Protection Relays by means of secondary current / voltage injection to verify some trip functions

Note: The above tests are carried out on typical feeders only. Hardware and software modification which come out during the FAT can be implemented, if possible, during the FAT on the tested typical units for a prompt verification. After the FAT the software will be prepared for all units including the IED protections settings (out of IMESA scope), however the download and testing of all units will be carried out during the Commissioning activities. Electrical and functional tests will be performed for 100% of the switchgear during fabrication. Relative test reports will be made available during the FAT for Contractor review.

4.2 Tests of auxiliary devices

The check of the auxiliary equipment is double. The first, is to check the supplier and other "general" characteristics with the help of SLD & Schematics, the second is to check their "functionality" by the electrical tests that will be performed (please note that all equipment are - in any case - tested during the internal checks before FAT).

4.3 Power Frequency voltage test and measurement of insulation resistance

The dielectric tests are carried out to check the insulation distances, the soundness of the insulating materials and that the connections have been made correctly.

Remember to disconnect all current absorbing equipment which would be damaged by the application of voltage (coils, metering instruments, differential circuit breakers etc). A voltage generator at industrial frequency is used to carry out this test.

Carry out the applied voltage test at industrial frequency on the main circuit between each conductor and the other conductors to earth. The test voltage must comply with that shown by the following table (Table 8 CEI EN 61439-1 pos. 10.9.2.2 + Rina rules) for 1 minute

Rated insulation voltage Ui	Dielectric test voltage in a.c. (efficacy)
Ui ≤ 60	1500
60 < Ui ≤ 300	1500
300 < Ui ≤ 690	1890
690 < Ui ≤ 800	2000
800 < Ui ≤ 1000	2200

Carrying out the test :

To carry out the test, use an insulation reader at a voltage of at least 500V. (as reported by RINA rules PT C – ch2-sec.8 – point 3.4.1)
Measure the insulation resistance of the main circuits.
Read the insulation resistance with a “MEGGER” on the following points:

- between phase L1 and the phases L2 and L3 connected to earth (valid for both tests);
- between phase L2 and the phases L1 and L3 connected to earth (valid for both tests);
- between phase L3 and the phases L1 and L2 connected to earth (valid for both tests).

Acceptance Criteria:

Relevant the insulation test, this is considered successful if, for each circuit tested, the insulation resistance is above 1 MΩ as described in the RINA rules (as reported by RINA rules PT C – ch2-sec.8 – point 3.4.2)

Relevant the industrial frequency test, this is considered successful, if no discharges or perforation occur during the test.

4.4 Dielectric test on auxiliary circuit and insulation resistance measurement

Testing of voltage applied between the auxiliary and control circuits and mass, applying a voltage as indicated in the table below, for a period of 1 minute (CEI EN 61439-1+ Rina rules)

Rated insulated voltage Ui	Dielectric test voltage in a.c. (efficacy)
Ui ≤ 12	250
12 < Ui ≤ 60	500
Ui > 60	2 Ui + 1000 with at least 1500

Carrying out the test:

To carry out the applied voltage test between the auxiliary and control circuits and earth, apply the voltage highlighted in the above table (checking the insulation between the two short-circuited lines and earth)

Acceptance Criteria:

Relevant the insulation test, this is considered successful if, for each circuit tested, the insulation resistance is above 1 MΩ as described in the RINA rules (as reported by RINA rules PT C – ch2-sec.8 – point 3.4.2)

Relevant the auxiliary voltage tests, this is considered to be successful, if no discharges or perforation occur during the test.

4.5 Checking the continuity of the protection circuit

The purpose of this check is to ensure that the protection circuit has been installed correctly and is carried out with both a visual examination (check that rough contact washers have been fitted) and an electrical test (resistor less than 0,1Ω).

4.6 Integrate Test with EMS

(This test will not be held with HV switchgear FAT since it is not in charge of IMESA)

5 Final checks

Once all the tests have been carried out on the different units, before sending the switchboard to the packaging department, the following checks must be carried out:

1. Check that all the jumpers used for the electrical tests of the different circuits have been removed from the terminal boards and the equipment.
2. Clean all the equipment in the unit.
3. Touch up the paintwork if necessary.
4. Check that the foundation bars comply precisely with the drawings.
5. Compile the "Mod. CAR/CAB 04 bill of material for shipment" with an indication of the material to be shipped loose, including material required for installation of the units.
6. Make out the list of missing materials (this list should include materials which are missing because found to be faulty during testing and the equipment to be installed by the Customer).
7. Check that the Manufacturer's data plate showing the characteristics of the switchboard has been fitted.
8. Insert the maintenance manual of the framework
9. CQ deals with the issue the test report and sees to its storage.

N.B In case of acceptance by the customer, it's up to present REC inform RP which involves the planning of production and make it aware of CAB and CQ; REC also defines the exact date that he agreed with the customer and informs the affected functions. At the end of the test, the customer must sign the test report.

6 TEST EQUIPMENT

The following test equipment will be used to carry out the above tests:

- Universal power supply for the auxiliary circuits,
- Amperometric power supply for the primary and secondary currents,
- Instrument for the applied voltage test at industrial frequency of the main circuit,
- Instrument for the applied voltage test of the auxiliary and control circuits,
- Digital thickness gauge

7 CARRYING OUT THE TESTING ACTIVITIES

The testing activities must be carried out in compliance with the safety requirements of the current regulation by restricting the test area with the special hurdles. The testing activities must be carried out

exclusively by personnel who have received proper training, anyway the operators must always be at least two.

If testing is manned by customer (or by those third parties designated by it), this is absolutely not permitted to carry out maneuvers on the switch and are not allowed to stay alone at the IMESA plant.

All electrical parts must be banned from all contact and the area should be well lit and free from hindrances and obstacles.

Operators must be equipment with suitable DPI and certified equipment under current regulations.

During testing must always be at least one first aid worker who has received its education.

When testing the dielectric properties (applied voltage test), remember to wear insulated gloves and shoes with retractable toe caps as well as suitable protection clothing covering body and arms. If the test is suspended even temporarily, the test instrument must be disconnected from the mains.

1. INTRODUCTION

1.1. PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.
Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1. Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

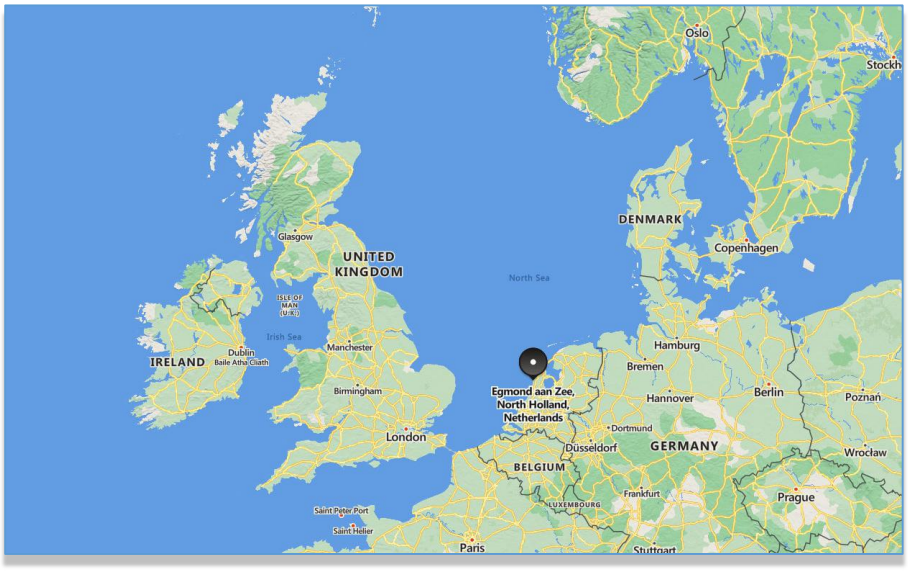

Figure 1 HOLLANDSE KUST NOORD WIND PARK Location Map

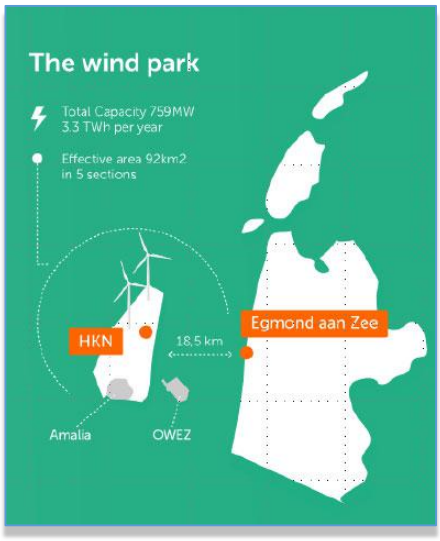

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed by Van Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2. Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

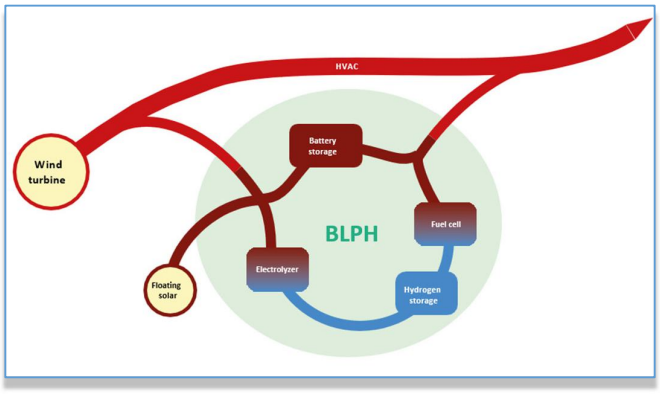

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.
The purpose of the BLPH s to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

2. SCOPE AND APPLICABILITY

This document provides the commissioning and start-up methods, as well as the testing procedures at site, applicable to H.V. Electrical Switchboards, manufactured by IMESA in compliance to Standard IEC 62271-200 and designated as Miniver-C type.

The procedure is applicable to the following switchgear tag: SG-100D1

3. APPLICABLE STANDARDS AND DOCUMENTS

The tester will make reference to Standards IEC 62271-200 and IEC 62271-1 and to the engineering documents listed here below.

Hard copy of the a.m. IMESA documents, properly stamped and signed as "AS BUILT", will be available for the needed testing activities and verifications.

4. SAFETY RECOMMENDATIONS

WARNING

- **All the operations of electric maintenance and installation must be performed by qualified technicians**
- **All the standard electric safety procedures must be respected**
- **Never touch inside the switchboard; only after making sure it is out of voltage and grounded**
- **Always wear personal protective equipments (insulating shoes in rubber, protective glasses, safety helmet, etc...)**
- **Never work alone**
- **Never remove safety screens**
- **Always pay maximum attention when handling components or performing measurements inside the panel**
- **It shall be taken in mind that this test procedure is only for the equipment and is to be used together (not instead of) all safety procedures specified by local Laws, rules, regulations and Standards**

People attending the commissioning and testing activities must wear:

SHOES: Workers, staff of the Customer, the End User or its representatives (inspectors) present during the tests shall wear safety shoes, ever. The staff of the Customer, the End User or its representatives (inspectors) present during the tests must arrive already equipped with their own shoes. The staff of the Customer, the End User or its representatives (inspectors), present during the tests and not wearing safety shoes, may still access the Safe Area, but not the test area. They will therefore only observe the test from Safe Area and conducting the review of the results in test reports.

GLASSES: Workers must wear safety glasses when performing risky for their eyes.

HELMET: Workers must wear protective helmets when performing lifting and handling, or when there is a suspended load. When there are suspended loads or handling and lifting the staff of the Customer, the End User or its representatives (inspectors) present during the tests must remain in the Safe Area.

GLOVES: Workers must wear gloves when performing risky for the hands or vibrations.

DRESS: All workers must wear appropriate safety clothing, forever. Helmet, gloves, glasses, safety clothing are not required to staff of the Customer, the end Customer or his representatives (inspectors) present during the tests.

When testing the dielectric properties (applied voltage test), **insulated gloves** and **shoes with retractable toe caps**, as well as suitable **protection clothing covering body and arms**, to be worn.
If the test is suspended even temporarily, the test instrument must be disconnected from the mains.

Before to start any activity, to thoroughly check that the following points are confirmed:

- the lighting system in the area is suitable and in operation
- phone or radio communication system is available, even temporarily for the present activities
- the fire-fighting system is in operation and provided with valid certification (portable fire extinguishers may be also suitable for purpose)
- earthing plant in the area and earthing connections of the subsystems to be energized have been completed and tested

5. GENERAL DESCRIPTION

5.1. PURPOSE OF SAT

The purpose of the SAT (Site Acceptance Test) is to inspect the switchboard, after installation at site, to ensure that it is ready for energization and start-up and also that its performance requirements will be met.
Prior to performing any Site Acceptance Testing, all Punch list items have to be rectified and closed.

5.2. TESTING TASKS

After completion of the installation phase of the switchboard and in order to prepare it for SAT, pre-commissioning and commissioning are to be first carried out, as further detailed in the next paragraphs.

The overall test activities will be performed by means of the specific test equipment, under the control and responsibility of the test executor, along with some assistants.

The main steps that will be performed are the following:

- Verification of the test procedures and of the related documentation availability.
- Preparation of the test setup
- Execution of the tests according to the Test Procedure and release of the SAT Test Report
- Signing of the SAT Test Report by the test executor and the attending people.

Estimated lead time to carry out all these tests is 3/4 weeks (it depends on site activities conditions, actually).

For additional tests not included in its own scope of work, IMESA will provide technical support, as agreed in advance.

List of the tests

Item	Activity	Tool	Support Requested	Type of Test
a.	Mechanical check	Torque Wrench	Mech. Engineer Inspection/Quality Officer	Mandatory
b.	Testing contact resistance at busbars, CBs & Fused Contactors	Current generator and digital multimeter	Electrical Engineer Inspection/Quality Officer	Mandatory
c.	Primary Injection on current transformers	Injection current bench	Electrical Engineer Inspection/Quality Officer	Suggested (to verify that CT is not damaged)
d.	Primary Injection on voltage transformers	Apply low voltage to check the functionality of VT (400V)	Electrical Engineer Inspection/Quality Officer	Suggested (to verify that VT is not damaged)
e.	Testing of protection relays by secondary injection	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory

Item	Activity	Tool	Support Requested	Type of Test
f.	Functional test of IEDs, and interlocks.	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory
g.	High voltage test	Hi pot equipment	Electrical Engineer Inspection/Quality Officer	Mandatory
h.	Infrared sensors tests	Non-contact temperature measuring tool	Electrical Engineer (Temperature sensors specialist) Inspection/Quality Officer	Suggested (to verify correct settings)
i.	Arc flash detecting system test	Camera Flash Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory
j.	Network Goose Messaging system test	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory
k.	ENMC system communication test	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer ENMC test is intended in charge to PMS vendor (IMESA to only provide assistance, where requested and agreed)	Mandatory
l.	Partial discharge detecting system test	Calibration tools	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Suggested (to verify correct settings)

5.3. TEST EQUIPMENT

- Megger (e.g. : Chauvin Arnoux ca 6547)
- Tester / Multimeter
- Testing bench for primary injection (e.g. : Omicron CPC 100)
- Relay Testing System (through current / voltage secondary injection - (e.g. : Omicron CMC 353)
- Torque Wrench (e.g. Dina Beta NM 20÷100)
- Voltage drop test equipment (e.g. : Multimeter + TEIB PP77 100A DC)
- Hi-pot test bench (e.g. : Phenix 650-2P)

NOTES:

- it shall be advised in advance availability of the testing equipment at site or whether those are to be provided by the commissioning engineer himself;
- availability of calibration certificates of the above testing equipment, having valid date, must be ensured.

5.4. TEST PHASE AND PASS/FAIL CRITERIA

For each test a set of pass/fail criteria will be defined (it is also possible that each test has a different criteria) in order to establish an acceptance procedure.
Where acceptance and rejection criteria are not established, they shall be defined according to the best practice, making reference to standards or samples.

The main possibilities are the following:

- All the steps are successfully performed (the test passes)
- Some steps fail but the function under test is verified (the test passes after client approval)
- Some steps fail and the function under test is not verified (the test fails)
- Some steps fail but with a specific corrective action the proper function is recovered (the test must be repeated);

If the test fails, a related NCR will be released.

6. PRE-COMMISSIONING PROCEDURE

6.1. GENERAL INFORMATION

Locking magnets are installed on the HV circuit breaker / HV Fused contactor compartments, to increase general safety of the H.V. Switchboard.

RLE1
Locking magnet on the operating mechanism.
If de-energized, it mechanically prevents circuit breaker / contactor closure.

RLE2
Locking magnet on the truck.
If de-energized, it mechanically prevents circuit breaker / contactor racking-in and racking-out operations.

RLE3 (provided on request)
Locking magnet on the earthing switch.
If de-energized, it mechanically prevents any earthing switch operation (closing and opening, as well).

RLE4
Locking magnet on the circuit breaker compartment door.
If de-energized, it prevents opening and closing of the circuit breaker compartment door.

Circuit Breaker and contactor status (Open / Close / Tripped) is showed on the HMI panel of the protection relays.

For the programmable indication, assigned to the single LED indicator available on the protection relay's HMI panel, please, refer to the relevant table in the schematic diagrams.

IT IS RECOMMENDED TO FORESEE THE ATTENDANCE OF AN IMESA TECHNICIAN DURING THE ABOVE MENTIONED ACTIVITIES

6.2. PRE-COMMISIONING ACTIVITIES

Before to start Pre-Commissioning, please, read carefully the I.O.M. document (Installation, Operation and Maintenance manual).
Then proceed with the following checks and actions.

1. Switchboard's cubicles shall be in good and clean status. Make sure that switchboard is clean, free from dust, traces of humidity, installation material debris, cables pieces, tools, provisional connections, etc. , as well as any foreign object.
2. Visually check the interior and exterior of the switchboard for signs of evident damage
3. Make sure that the switchboard is correctly installed according to the General Arrangement Drawings
4. Maintenance clearances shall be according to the General Arrangement Drawings
5. Make sure that any support or protection used to handle the equipment has been removed
6. Make sure that, after completion of the installation, the switchboard overall protection degree is as per General Arrangement Drawings
7. Visual inspection to check that bolted connections of the HV and earthing circuits (at busbars, CBs poles, CTs, VTs, etc.) are suitably tighten. No disalignment is expected at the marks provided over the bolt, during torque wrench tightening at the factory. In case found, to torque wrench again the connection (see par. 7.1).
8. Cable passages shall be free and unobstructed
9. Couple the auxiliary interpanel connections by the relevant plugs and socket (see schematic diagrams with control voltage distribution loop, panels interconn. wiring and communication network loop)
10. Cabling of control cables from the field in accordance with I/O list / schematics shall be completed
11. Check the incoming / outgoing power cables proper support and earthing screens connections.
12. Make sure that terminals and all the connections have been properly tightened
13. Make sure that all the safety interlock keys (master and copies) have been provided and installed. There are manoeuvres not allowed (forced operations shall be avoided).
14. Remove each H.V. circuit breaker and contactor from its cubicle, by means of the provided lifting / transport trolley, for a visual check of the breaker status and cleaning; including fixed poles of the enclosure and tulip contacts on the removable part.
    Make sure that the breaker is free from dust and traces of humidity and that there are no signs of evident damage.
15. Make sure that all H.V. fuses are correctly installed and that rating is in conformity to the schematic diagrams and parts lists.
16. All necessary warning and caution signs (voltage level indication, warning for live parts, etc.) shall be installed according to the safety standards and procedures.

The results of the a.m. activities shall be recorded on PRE-COMMISSIONING ACTIVITIES REPORT form (see par. 9)

7. COMMISIONING ACTIVITIES

Carry out the following checks and actions.

1. To be verified that all HV circuit breakers and HV fused contactors are in open and racked-out position; with charged closing springs.

   N.B. : it is recommended to manually rewind all the circuit breakers closing springs, before to supply the relevant spring motor chargers, with aux. supply voltage 110 V d.c. , in order to prevent concurrent start-up of many motor gears, which may result in excessive load for the supplying circuit.

   As an alternative, it can be taken care that supply to those motors is provided one by one; by separately closing the relevant MCB, provided within the LV compartment of each feeder unit.
2. Check that all the earthing switches are in closed position.
3. Connect all external aux. supplies and check that are at correct voltage value and phase sequence.
4. Check thoroughly the Operating Sequences and the relevant mechanical safety interlocks, by putting in service and then again out of service all the H.V. units.
5. With CBs / Contactors in test position, close and open the same by local command.
6. Make sure that the phase sequence, at the H.V. circuits, is in accordance to the electrical diagrams and that all incoming breakers are connected with the same phase sequence.
7. Check monitoring loops (hardwired status / alarm signals / visual status indications).
8. Check protection relays loops, concerning IEDs' integrated logic functions.
9. Put the HV CBs / HV Contactors in service (racked-in) position and repeat the test for opening / closing the same from local and remote commands, including control loops from / to the field (commands, status, alarm, etc.)

   N.B. : It is necessary to simulate voltage presence at the bus-bars and at the incomers, to enable CBs closing commands. Voltage presence shall be simulated, at voltage and frequency protection relays, to avoid trip commands for "dead bus-bars" function (see relevant schematic diagrams and protective relays selectivity study).
10. Check HV CBs / HV Contactors tripping, locking-out and alarming functions.

The results of the a.m. activities shall be recorded on the COMMISSIONING ACTIVITIES REPORT form (see par. 9)

8. SAT TESTING PROCEDURE

8.1. MECHANICAL TESTS

1. Bus-bars tightening check

Torque wrench all the bolted joints of the shipping sections, which have been coupled at site, according to the values indicated here below.
After tightening, each bolt is to be marked by red paint to indicated its relative position against the fixed part (as done for the torque wrench tightening provided at the factory).

The table below shows the torque wrench settings to be used for bolted connections fixing the panels and the bus-bars, too.

Screws	M6	M8	MI0	M12	M14	M16
Wrench setting (Nm) -Min	8	19	40	68	100	160
Wrench setting (Nm) - Nominal	9	22	45	75	115	185
Wrench setting (Nm) - Max	10	25	50	83	130	200

2. Tightening at CTs and VTs primary terminals

Primary terminals of the current transformer are made of copper, with threaded screws inserts provided to be used for fastening the primary conductor.

Torque wrench values are to be applied in accordance to the data sheets / to the installation manuals of the Current & Voltage Transformers' manufacturer.

The results of the a.m. activities shall be recorded on SAT REPORT FOR MECHANICAL TEST form (see par. 9)

8.2. MEASUREMENT OF THE RESISTANCE OF THE MAIN CIRCUITS

Measurement of the resistance of the main circuit shall be carried out where joints between shipping sections have been coupled at site. The test is to carried out in accordance to subclause 6.4.1 of Std. IEC 62271-1.
For the routine test, the d.c. voltage drop or resistance of each pole of the main circuit shall be measured under conditions as much as possible similar, with regard to ambient air temperature and point of measurement, to those of the corresponding type test.
The measurement is to be made by volt-ammetrical method with a d.c. current equal to 100 A, across the main circuit of each panel unit phase.

Acceptance criteria:
The measured resistance shall not exceed 1,2 Ru where Ru is equal to the resistance measured before the temperature rise type test.

The results of the a.m. activities shall be recorded on SAT REPORT FOR MEASUREMENT OF THE RESISTANCE OF THE MAIN CIRCUITS form (see par. 9)

8.3. TESTING H.V. CIRCUIT BREAKERS AND H.V. FUSED CONTACTORS

Insulation resistance measurement
When the breaker is closed, measure the insulation resistance, phase to ground, with 5 kV d.c. Megger. The test is to be carried out with the other two phases short-circuited and connected to ground.
Then open the breaker and measure the insulation resistance pole to pole.
The above to be carried out for all the phases.

Minimum value of insulation resistance is to be 50 MΩ.

Contact resistance test
The breaker will be in close position before starting the test.
Then inject d.c. current of 100 A on each pole (from in to out of each phase) and measure the voltage drop across it. The measurement is to be done by multimeter
By applying Ohm's law, the resistance value is then calculated. The obtained value needs to be compared with the value given by the manufacturer. Reference is to be made to the voltage drop value of VD4 Circuit Breakers/VSC Contactors, detailed in the relevant Test Reports.

As an alternative, an apparatus with direct reading (Omicron) can be used.

The results of the a.m. activities shall be recorded on SAT REPORT FOR TESTING H.V. CIRCUIT BREAKERS AND H.V. FUSED CONTACTORS form (see par. 9)

8.4. PRIMARY INJECTION ON CURRENT AND VOLTAGE TRANSFORMERS

1. Testing CTs ratio

   Test the CT for correct ratio with direct current injection to CT primary circuit and reading the measured value from the instruments or protection relays LCD display, provided at the LV compartment front door.

2. Testing VTs ratio

   Test the VT for correct ratio with direct voltage injection to VT primary circuit (low voltage 400 V, for testing purpose) and reading the measured value from the instruments or protection relays LCD display, provided at the LV compartment front door.

   The results of the a.m. activities shall be recorded on SAT REPORT FOR PRIMARY INJECTION TESTING ON CTs AND VTs form (see par. 9)

8.5. SECONDARY INJECTION TESTS ON PROTECTION RELAYS

Refer to the schematic diagrams, for connections and for checking logic functions.
Refer to the selectivity study for the protection relays' setting parameters.
Softwares to be employed for uploading, setting and testing the H.V. Switchgear's protection relays are:

- Interface Software to be used – ABB PCM600 2.9 32 bit / ABB PCM600 2.10 32 bit
- ITT600 Integrated Testing Tool or equivalent

Omicron secondary injection test kit – connection and interface

Example of testing instruments connection

1 – Connection of the test set to the PC (USB Port) for data exchange: output of the data simulation, loading of the binary signal
2 – Connection of the analogue outputs of the test set to the transformer inputs of the test object, to inject the simulated currents and voltages.
3 – Connection of the binary outputs of the test set to the binary inputs of the test object, to send binary input signals to the test object.
4 – Connection of the binary inputs of the test set to the binary outputs of the test object, to receive the binary output signals from the test object.

The recorded tripping values shall be in conformity with the Selectivity study

N.B. : Checks on the Partial Discharge detecting systems calibration are also intended within this testing phase.

The results of the a.m. activities shall be recorded on SAT REPORT FOR PROTECTION FUNCTIONS CHECK form (see par. 9)

8.6. HI-POT TEST

The dielectric tests are carried out to check that the installation and re-connection activities at site have been made correctly and that no damage occurred to the equipment, during shipment and installation.

These tests shall be performed before to install the power and cables.

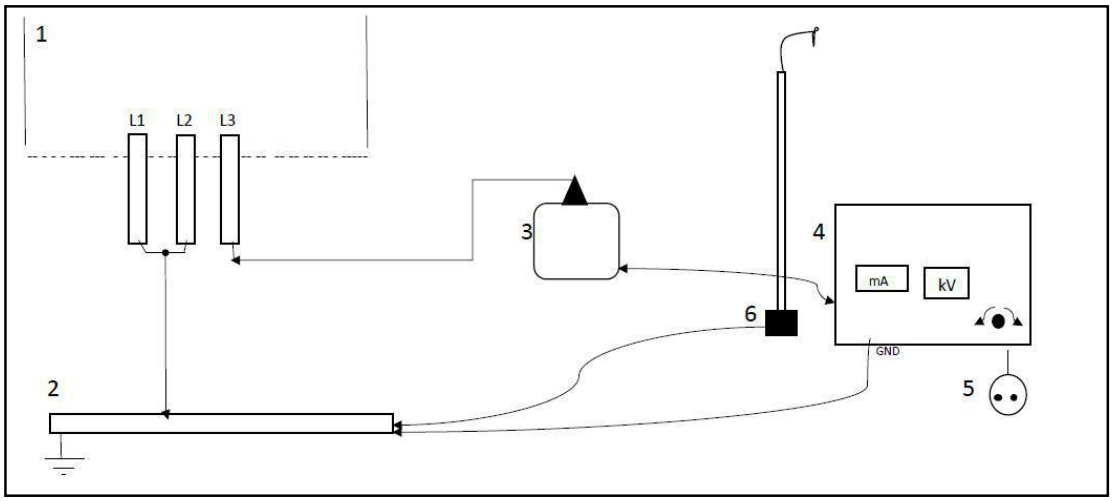
8.6.1. POWER-FREQUENCY WITHSTAND VOLTAGE TEST AND INSULATION RESISTANCE MEASUREMENT

All the VT's, surge arresters, insulation monitoring devices, etc. must be disconnected before the test. A voltage generator, at industrial power frequency voltage, is to be used to carry out the test.

1. Insulation resistance measurement

Before and after the Hi-pot test, insulation resistance measurement is to be carried out, applying 5 kV d.c. by means of Megger device. The measurement is to be carried out at each phase, while the other two are short-circuited and connected to ground.
The values detected before and after the Hi-pot test will be recorded in the SAT Report.

2. Carrying out the test on the power circuits



The test voltage to be applied, referring to the rated voltage of the switchboard is as follows (ref. IEC 62271-1, Table 1):

Rated Voltage kV r.m.s. value)	Test Voltage (kV r.m.s. value) AC (100% during F.A.T.)	Test Voltage (kV r.m.s. value) AC (80% during S.A.T.)	Applicability
7.2	20	16	

N.B. : the above test voltage value is 80% of the rated power-frequency withstand voltage at FAT, as specified in clause 7.105 of Std. IEC 62271-200.

HI-Pot Test Lay-Out

1) HV Switchboard Busbar
2) Ground Reference
3) Step-up Transformer
4) Hi-Pot Tester
5) Power supply
6) Ground stick

Example: test layout for testing at phase L3

- Connect to ground the control desk, the VT truck, the foil, the equipment under test
- Limit the test area by means of appropriate barriers
- Connect the MV pole of the VT to the phase under test of the panel, while the other two phases are connected together and to ground
- Connect the flashing lights barriers, the VT truck and its power plug
- The operator, before starting the test, must ensure that nobody is within the hurdles
- Close the main switch of the testing bench and rotate slowly the rheostat knob, until reached the test voltage value, read on the voltmeter (**N.B.** if the rheostat knob is in zero position, the circuit is not closed)

All the above indication may be slightly different, depending on the VT truck type, available at site.

Check the dielectric strength of the main circuits by applying the test voltage for 1 minute on the following points:

- between phase L1 and the phases L2 and L3 connected to ground
- between phase L2 and the phases L1 and L3 connected to ground
- between phase L3 and the phases L1 and L2 connected to ground

The test is considered successful when no discharge or perforation occur within 1 minute.
If discharge phenomena are perceived, the test is considered anyway valid if the test bench does not detect this phenomenology.

After the test or if there has been a discharge, return to zero the rheostat and discharge any possible capacitive voltage remained on the VT pole, by means of the foil. After that, it will be allowed to access to the test object.

Apply the same test to the other two phases, in turn, by repeating the steps described here above.

The results of the a.m. dielectric tests shall be recorded on SAT REPORT FOR HI-POT TEST form (see par. 9)

8.6.2. DIELECTRIC TEST ON AUXILIARY CIRCUIT AND INSULATION RESISTANCE MEASUREMENT

1. Insulation resistance measurement

Before and after the dielectric test on auxiliary circuits, insulation resistance measurement is to be carried out, applying 500 V d.c. by means of Megger device. The measurement is to be carried out at each pole, while the other one is connected to ground.

The values detected before and after the below test will be recorded in the SAT Report.

2. Carrying out the dielectric test on the auxiliary circuits

The test is to be carried out by applying the voltage test between the single pole of the auxiliary and control circuits and ground (between each conductor and the other conductors connected to ground, in turns).

All current absorbing equipment, which would be damaged by the application of the testing voltage (coils, metering instruments, differential circuit breakers, etc.) must be disconnected before the test.

The voltage value to be applied is 2000 V, with duration of 1 min. (CEI EN 62271-1, pos. 6.2.10 applies).

The test is considered successful, if no discharge or perforation occur during the test (1 minute).

The results of the a.m. dielectric tests shall be recorded on SAT REPORT FOR DIELECTRIC TEST ON AUX. CIRCUITS form (see par. 9)

8.7. INFRARED SENSORS TESTS

It is here detailed the test method to carry out testing on Exertherm devices, based on infrared thermal sensing.

1. All sensor distance from busbar locations must adhere to standards for clearance from bus bars and cables, depending on circuits rated voltage.

2. Testing must be carried out in a location which provides reasonably stable ambient conditions; i.e. avoid rooms where direct sunlight cannot be prevented, or which are subject to frequent ambient variances.

3. Ambient temperature will be measured on the Exertherm Sensors i.e. at the lens end of the IRT/c using any suitably calibrated non-contact temperature measuring instrument, with certified accuracy. Calibration certificate must be available for scrutiny and up to date.

4. The following method of ambient measurement will be adopted.

   Ambient air temperature is to be between 10°C and 40°C

   - Measurement of ambient air temperature: indoor ambient air temperatures shall be determined by taking the average of the readings of three temperature-measuring devices, such as thermometers or thermocouples, placed as follows:

   a) One level with the top of the structure
   b) One 30 cm above the bottom of the structure
   c) One midway between the two positions a) and b).

   - All temperature-measuring devices shall be placed 30 cm from the structure, not in front of ventilators, and in locations unaffected by drafts caused by the structure or appreciable radiation from the equipment. When the ambient air temperature is subject to variations that might result in errors in measuring the temperature rise, the temperature-measuring devices should be immersed in a suitable liquid, such as oil, in a suitable container, or reliably attached to a suitable mass of metal.

NOTE - A convenient form for such a container consists of a metal cylinder with a hole drilled partly through it. This is filled with liquid and the temperature-measuring device is placed therein. The size of the container should be at least 2.5 cm in diameter and 5.0 cm high.

The ambient temperature used when calculating the connection delta temperature will be the local ambient recorded at the Exertherm Sensor location.

5. All Datacard power supplies will be maintained at 24V d.c. ±10%.

6. All equipment test apparatus and Sensors to be used during these tests will be left to acclimatise in the switchgear for a period of a minimum of 1 hour prior to any tests taking place.

7. It is assumed that all Datacards are programmed and commissioned according to the relevant product instructions.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

8.7.1. TEST PROCEDURE – TEST WITH CIRCUITS NOT ENERGISED

1. Ensure all power supplies are set at the correct voltage and within specification i.e. at 110 V d.c. and 24 V d.c. ±10%.

2. Take a reading of room ambient as described in the previous section and note this value on the test check sheet (section Room Ambient)

3. Take a reading of the ambient temperature at the Sensor under test and note this value on the test check sheet (section Ambient Test Reading)

4. Take a reading from the Datacard software on the Sensor under test and note the value on the test check sheet (section Sensor Reading Under Test)

5. Take a reading of absolute temperature from the busbar with a suitably calibrated and certified temperature measurement device and note this reading. This should be an average reading across the connection point and not just one 'spot' temperature and note the value on the test check sheet (section Absolute Reading At Sensor)

6. Subtraction of the ambient temperature (at the sensor) from the connection temperature will result in the Delta T value and note the value on the test check sheet (section Calculated Delta T Reading). This should comply with the IR Sensor reading ±3°C (5.4°F)

7. Note down all these readings for future reference.

Repeat the steps 3 to 7 for all Sensors in the panel.

All these readings should produce a Delta T value of between -3°C (-5.4°F) to +3°C (+5.4°F)

It should be noted that this is not process control and therefore readings will not be exact to the degree. The Exertherm Sensor is 100% repeatable in identical conditions.

8.7.2. TEST PROCEDURE – TEST WITH CIRCUITS ENERGISED

1. With the switchgear energised and set in test conditions, with test currents and loading, allow all temperature, including ambient temperature to become stable.
Leave all equipment to again acclimatise to local conditions for a minimum of 30 minutes.

2. Ensure all power supplies are set at the correct voltage and within specification i.e. at 110 V d.c. and 24 V d.c. ±10%.

3. Take a reading of room ambient temperature as described in the previous section and note this value on the test check sheet (section Room Ambient)

4. Take a reading of the ambient temperature at the Sensor under test and note this value on the test check sheet (section Ambient Test Reading)

5. Take a reading from the Datacard software on the Sensor under test and note the value on the test check sheet (section Sensor Reading Under Test)

6. Take a reading of absolute temperature from the busbar with a suitably calibrated and certified temperature measurement device and note this reading. This should be an average reading across the connection point and not just one 'spot' temperature and note the value on the test check sheet (section Absolute Reading At Sensor)

7. Subtraction of the ambient (at the sensor) from the connection temperature will result in the Delta T value and note the value on the test check sheet OEM Design Validation Test Record (section Calculated Delta T Reading). This should comply with the Exertherm IRT/c sensor reading ±3°C (5.4°F)

8. Note all these readings for future reference.

Repeat these steps 4 to 7 for all Sensors in the panel.

All these readings should produce a Delta T value of between -3°C (-5.4°F) to +3°C (+5.4°F).

The results shall be compared to the relevant data sheet for the Sensor's tolerances in terms of accuracy and repeatability.

The results of the a.m. tests shall be recorded on SAT REPORT FOR INFRARED SENSORS TESTS form (see par. 9)

8.8. NETWORK and GOOSE TESTING

Preliminary checks

1) Ensure that each IED is set with the right parameter of the network below cited
   - Technical key
   - IP address
   - Subnet Mask (in charge to Network vendor engineer)
   - Main NTP address (in charge to Network vendor engineer)
   - Backup NTP address (in charge to Network vendor engineer)
   - Time clock (in charge to Network vendor engineer)
2) Ensure that Ethernet switch is duly set (in charge to Network vendor engineer)
3) Ensure that the IED is switched ON

8.8.1. INTERNAL GOOSE MESSAGING TEST

- Function ANSI 27 block for feeders

Simulate voltage loss from VTs on Busbars metering unit, by opening the distribution MCB, at the secondary circuits of the VTs, or rack-out the VTs trolley, or simulate fuses blown on the VTs' primary circuits.
On different feeder, simulate undervoltage condition with racked-in & closed position of the HV breaker. The HV Circuit Breaker or HV Vacuum Contactor shall remain closed.

- Arc Flash Trip

CABLE COMPARTMENT

Arc Flash detected on power cables compartment shall only open the breaker of its own feeder unit, in case of contemporary detection of arc flash light and current flow reading, through the CTs and protection relay.
At the Incoming units, breaker opening is activated by only detecting arc flash light.

Test execution:
Connect the test bench in order to inject a secondary current, according the setting tables, to the unit's protection relay.
Inject the current and simulate a flash light in the cables compartment, from the rear of the Swbd.
The test can be consider passed if the breaker will be opened.

BUSBARS OR CB COMPARTMENT:

Arc Flash detected on Busbars chamber or on CB compartment shall result in a complete shutdown of the Switchboard, in case of contemporary detection of arc flash light and current flow reading, through the CTs and protection relay.

Test execution:
Connect the test bench in order to inject a secondary current, according the setting tables, to the protection relay of the Incoming unit.
Choose a CB compartment or Busbar section where to simulate the flash light, inject the current and simulate the flash light in the compartment.
The test can be consider passed if the complete shutdown of the busbars section will be verified.

8.8.2. EXTERNAL GOOSE MESSAGING TEST

Scope of these tests is in cooperation with the Network vendor engineer.
The tests can start only if all Ethernet switches have been set from the Network vendor engineer.

- PMS Goose test:

The HVSB receives and transmit goose messages from/to PMS.
For testing purpose of proper communication with PMS, the HVSB vendor can support the PMS vendor or the Network vendor engineer for execution of the following activities:

- opening closing the HV circuit breaker / HV Contactors
- racking-in / racking-out HV circuit breaker / HV Contactors
- opening / closing the earthing switches
- secondary injection tests on the protection relays

This part of the SAT is in charge to the Network Vendor.

8.8.3. INFRARED SENSORS MODBUS NETWORK

Scope of these tests is in cooperation with the Network vendor engineer.
The tests can start only if all Ethernet switches have been set from the Network vendor engineer.

These activities can be performed in parallel to IR sensors tests (see paragraph 7.7). This is possible also if the Network is not connected with the PMS, by connecting directly to the switch installed in the HVSB.

This part of the SAT is in charge to the Network Vendor.

The results of the a.m. Goose messaging tests shall be recorded on SAT REPORT FOR GOOSE MESSAGING TESTS form (see par. 9)

9. PRE-ENERGIZATION REQUIREMENTS

Before to proceed with energization of the HVSB, the following is to be verified.

- Make sure to pull off the short-circuit jumpers fitted on amperometric terminal boards, to avoid running the units with current transformer (-TI..-L..) short-circuited at secondary windings.
- Make sure to have re-closed the disconnecting terminals fitted on voltmetric terminal boards, to avoid running the units with voltage transformer (-TU-L..) not connected at secondary windings.
- Make sure that all the miniature CBs for aux. and measuring circuits are closed
- All system protections, controls, detectors and monitoring devices shall be reset and ready for operation
- All protections and control logics shall be reset and ready for operation
- All recording equipment, where provided, shall be in operation
- No alarm and/or trip signal shall be active
- Earthing switches shall be locked in open position
- Voltage transformers shall be in service position (racked-in), with primary fuses suitably placed
- H.V. circuit breakers and vacuum contactors shall be in service position (racked-in), open and available
- Fuses at the HV vacuum contactors shall be suitably placed
- Mechanical and electrical interlocks are to be suitably in operation
- All removable protections against direct contacts with accessible parts (panels, grids, plates, doors, etc.), shall be correctly placed and fixed
- All the doors shall be closed and fixed panels are to be correctly positioned and bolted

10. PRE-COMMISSIONING, COMMISSIONING AND SAT REPORT TEMPLATES

The following forms are intended for recording the results of Pre-Commissioning, Commissioning and SAT activities.

Forms provided by the customer may also be employed, on request.

PRE-COMMISSIONING ACTIVITIES REPORT

1 INTRODUCTION

1.1 PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.
Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1 Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

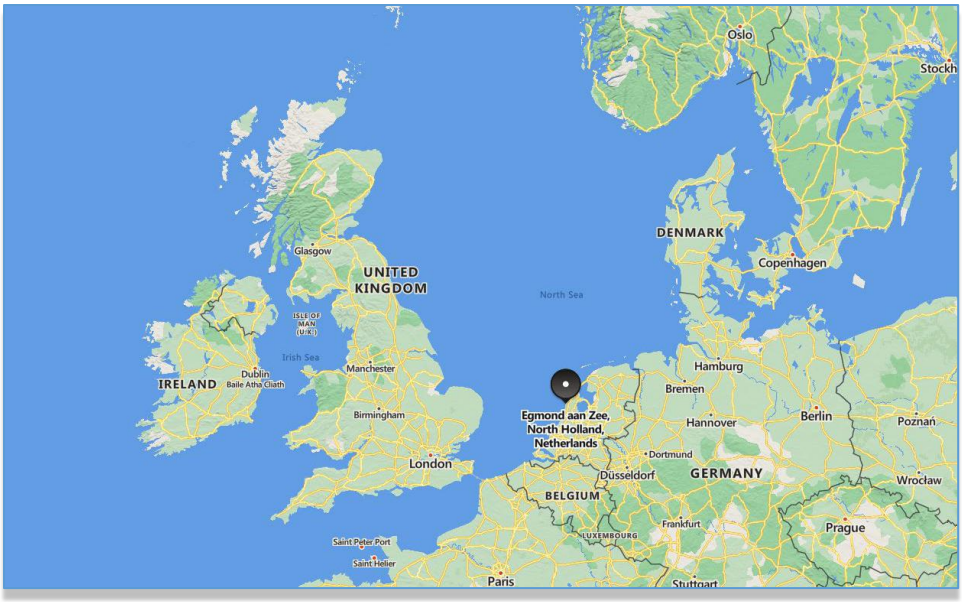

Figure 1 HOLLANDSE KUST NOORD WIND PARK Location Map

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed byVan Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2 Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

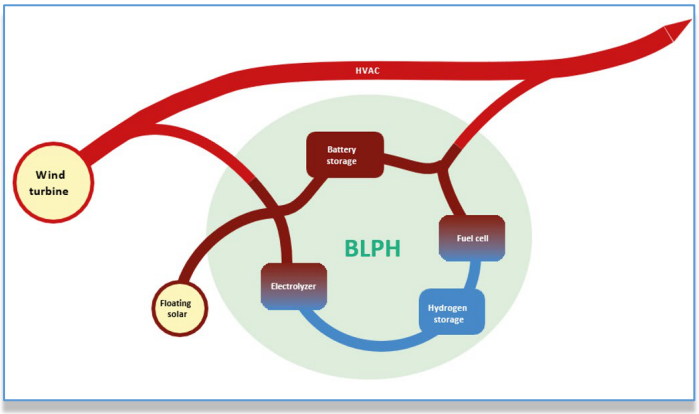

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.
The purpose of the BLPH s to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

2 SCOPE AND APPLICABILITY

This document provides the commissioning and start-up methods, as well as the testing procedures at site, applicable to L.V. Electrical Switchboards, manufactured by IMESA in compliance to Standard IEC 61439-1 and 61439-2.

The procedure is applicable to the following switchgear tag: SG-200N1, SG-200D2, DP-200N1.

3 APPLICABLE STANDARDS AND DOCUMENTS

The tester will make reference to Standards IEC 61439-1 and IEC 61439-2 and to the engineering documents listed here below.

4 SAFETY RECOMMENDATIONS

WARNING

- **All the operations of electric maintenance and installation must be performed by qualified technicians**
- **All the standard electric safety procedures must be respected**
- **Never touch inside the switchboard; only after making sure it is out of voltage and grounded**
- **Always wear personal protective equipment (insulating shoes in rubber, protective glasses, safety helmet, etc...)**
- **Never work alone**
- **Never remove safety screens**
- **Always pay maximum attention when handling components or performing measurements inside the panel**
- **It shall be taken in mind that this test procedure is only for the equipment and is to be used together (not instead of) all safety procedures specified by local Laws, rules, regulations and Standards**

People attending the commissioning and testing activities must wear:

SHOES: Workers, staff of the Customer, the End User or its representatives (inspectors) present during the tests shall wear safety shoes, ever. The staff of the Customer, the End User or its representatives (inspectors) present during the tests must arrive already equipped with their own shoes. The staff of the Customer, the End User or its representatives (inspectors), present during the tests and not wearing safety shoes, may still access the Safe Area, but not the test area. They will therefore only observe the test from Safe Area and conducting the review of the results in test reports.

GLASSES: Workers must wear safety glasses when performing risky for their eyes.

HELMET: Workers must wear protective helmets when performing lifting and handling, or when there is a suspended load. When there are suspended loads or handling and lifting the staff of the Customer, the End User or its representatives (inspectors) present during the tests must remain in the Safe Area.

GLOVES: Workers must wear gloves when performing risky for the hands or vibrations.

DRESS: All workers must wear appropriate safety clothing, forever. Helmet, gloves, glasses, safety clothing are not required to staff of the Customer, the end Customer or his representatives (inspectors) present during the tests.

When testing the dielectric properties (applied voltage test), **insulated gloves** and **shoes with retractable toe caps**, as well as suitable **protection clothing covering body and arms**, to be worn.
If the test is suspended even temporarily, the test instrument must be disconnected from the mains.

Before to start any activity, to thoroughly check that the following points are confirmed:

- the lighting system in the area is suitable and in operation
- phone or radio communication system is available, even temporarily for the present activities
- the fire-fighting system is in operation and provided with valid certification (portable fire extinguishers may be also suitable for purpose)
- earthing plant in the area and earthing connections of the subsystems to be energized have been completed and tested

5 GENERAL DESCRIPTION

5.1 LIST OF ABREVIATIONS

S.A.T.	Site Acceptance Test
VT	Voltage Transformer
CT	Current Transformer
NCR	Non-Conformity Report
IED	Intelligent Electronic Device (like programmable relay)
MCB	Miniature Circuit Breaker
CB	Circuit Braker
MCC	Motor Control Center
LV	Low Voltage (Circuit with voltage under 1000Vac or 1500Vdc)
I.O.M.	Installation, Operation and Maintenance manual
a.m.	above mentioned.

5.2 PURPOSE OF SAT

The purpose of the SAT (Site Acceptance Test) is to inspect the switchboard, after installation at site, to ensure that it is ready for energization and start-up and also that its performance requirements will be met.
Prior to performing any Site Acceptance Testing, all Punch list items have to be rectified and closed.

5.3 TESTING TASKS

After completion of the installation phase of the switchboard and in order to prepare it for SAT, pre-commissioning and commissioning are to be first carried out, as further detailed in the next paragraphs.

The overall test activities will be performed by means of the specific test equipment, under the control and responsibility of the test executor, along with some assistants.

The main steps that will be performed are the following:
- Verification of the test procedures and of the related documentation availability.
- Preparation of the test setup
- Execution of the tests according to the Test Procedure and release of the SAT Test Report
- Signing of the SAT Test Report by the test executor and the attending people.

For additional tests not included in its own scope of work, IMESA will provide technical support, as agreed in advance.

List of the tests

Item	Activity	Tool	Support Requested	Type of Test
a.	Mechanical check	Torque Wrench	Mech. Engineer Inspection/Quality Officer	Mandatory
b.	Primary Injection on current transformers	Injection current bench	Electrical Engineer Inspection/Quality Officer	Suggested (to verify that CT is not damaged)
c.	Primary Injection on voltage transformers	Apply low voltage to check the functionality of VT (400V)	Electrical Engineer Inspection/Quality Officer	Suggested (to verify that VT is not damaged)
d.	Testing of protection relays by secondary injection	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory
e.	Functional test of IEDs, and interlocks.	Secondary injection bench (Omicron)	Electrical Engineer (Relay specialist) Inspection/Quality Officer	Mandatory
f.	Insulating resistance measurement	Megger	Electrical Engineer Inspection/Quality Officer	Mandatory

5.4 TESTING EQUIPMENT

- Megger (e.g. : Chauvin Arnoux ca 6547)
- Tester / Multimeter
- Testing bench for primary injection (e.g. : Omicron CPC 100)
- Relay Testing System (through current / voltage secondary injection – (e.g. : Omicron CMC 353)
- Testing kit for air circuit breakers type Emax ABB (Ekip T&P)
- Torque Wrench (e.g. Dina Beta NM 20÷100)
- Hi-pot test bench (e.g. : Phenix 650-2P)

NOTES:
- it shall be advised in advance availability of the testing equipment at site or whether those are to be provided by the commissioning engineer himself;
- availability of calibration certificates of the above testing equipment, having valid date, must be ensured.

5.5 TEST PHASE AND PASS/FAIL CRITERIA

For each test a set of pass/fail criteria will be defined (it is also possible that each test has a different criteria) in order to establish an acceptance procedure.
Where acceptance and rejection criteria are not established, they shall be defined according to the best practice, making reference to standards or samples.

The main possibilities are the following:

- All the steps are successfully performed (the test passes)
- Some steps fail but the function under test is verified (the test passes after client approval)
- Some steps fail and the function under test is not verified (the test fails)
- Some steps fail but with a specific corrective action the proper function is recovered (the test must be repeated)

If the test fails, a related NCR will be released.

6 PRE-COMMISSIONING ACTIVITIES

Before to start Pre-Commissioning, please, read carefully the I.O.M. document (Installation, Operation and Maintenance manual).
Then proceed with the following checks and actions.

1. Switchboard's cubicles shall be in good and clean status. Make sure that switchboard is clean, free from dust, traces of humidity, installation material debris, cables pieces, tools, provisional connections, etc. , as well as any foreign object.

2. Visually check the interior and exterior of the switchboard for signs of evident damage or shocks. Protective shields, insulating sheaths, etc.. shall be correctly placed and in good order

3. Painting visual check

4. Make sure that the switchboard is correctly installed according to the General Arrangement Drawings and suitably fixed

5. Maintenance clearances shall be according to the General Arrangement Drawings

6. Make sure that any support or protection used to handle the equipment has been removed

7. Make sure that, after completion of the installation, the switchboard overall protection degree is as per General Arrangement Drawings

8. Visual inspection to check that bolted connections of the LV and earthing circuits (at busbars, CBs poles, etc.) are suitably tighten. No disalignment is expected at the marks provided over the bolt, during torque wrench tightening at the factory. In case found, to torque wrench again the connection (see par. 8.1)

9. Cable passages shall be free and unobstructed

10. Couple the auxiliary interpanel connections by the relevant plugs and socket (see schematic diagrams with control voltage distribution loop, panels interconn. wiring and communication network loop)

11. Cabling of control cables from the field in accordance with I/O list / schematics shall be completed

12. Check the incoming / outgoing power cables proper support

13. Make sure that terminals and all the connections have been properly tightened

14. Make sure that all the safety interlock keys (master and copies) have been provided and installed. Where manoeuvres not allowed (forced operations shall be avoided).

15. Remove each L.V. air circuit breaker and MCC drawer from its cubicle, by means of the provided lifting / transport trolley, for a visual check of the breaker status and cleaning; including poles of the fixed part and the terminals on the removable part.
    Make sure that the breaker and the MCC drawer is free from dust and traces of humidity and that there are no signs of evident damage.
    Check that LV withdrawable circuit brakers and MCC drawers can be racked-in and racked out properly

16. Make sure that all fuses are correctly installed
17. All necessary warning and caution signs (voltage level indication, warning for live parts, etc.) shall be installed according to the safety standards and procedures

The results of the a.m. activities shall be recorded on PRE-COMMISSIONING ACTIVITIES REPORT form (see par. 10).

7 COMMISIONIG ACTIVITIES

Carry out the following checks and actions.

1. To be verified that all LV withdrawable circuit breakers and MCC drawers are in open and racked-out position; with charged closing springs (where present).

   N.B.: it is recommended to manually rewind all the circuit breakers closing springs, before to supply the relevant spring motor chargers, with aux. supply voltage, in order to prevent concurrent start-up of many motor gears, which may result in excessive load for the supplying circuit.

   As an alternative, it can be taken care that supply to those motors is provided one by one; by separately closing the relevant MCB, provided within the LV compartment of each feeder unit.
2. Connect all external aux. supplies and check that are at correct voltage value and phase sequence.
3. Check thoroughly the Operating efficiency and the mechanical locks and key safety interlocks.
4. With CBs in test position, close and open the same by local command.
5. Make sure that the phase sequence is in accordance to the electrical diagrams and that all incoming breakers are connected with the same phase sequence.
6. Check monitoring loops (hardwired status / alarm signals / visual status indications).
7. Check protection relays loops, concerning IEDs' integrated logic functions.
8. Put in service (racked-in) position and repeat the test for opening / closing the same from local and remote commands, including control loops from / to the field (commands, status, alarm, etc.)
9. Check CBs tripping, locking-out and alarming functions.

The results of the a.m. activities shall be recorded on the COMMISSIONING ACTIVITIES REPORT form (see par. 10)

8 SAT TESTING PROCEDURE

8.1 MECHANICAL TESTS

1. Bus-bars tightening check

Torque wrench all the bolted joints of the shipping sections, which have been coupled at site, according to the values indicated here below.
After tightening, each bolt is to be marked by red paint to indicated its relative position against the fixed part (as done for the torque wrench tightening provided at the factory).

The table below shows the torque wrench settings to be used for bolted connections fixing the panels and the bus-bars, too.

Type of screw	Tightening torque (Nm)	Tolerance
M5	5	5%
M6	9	5%
M8	22	5%
M10	45	5%
M12	75	5%
M14	115	5%
M16	185	5%

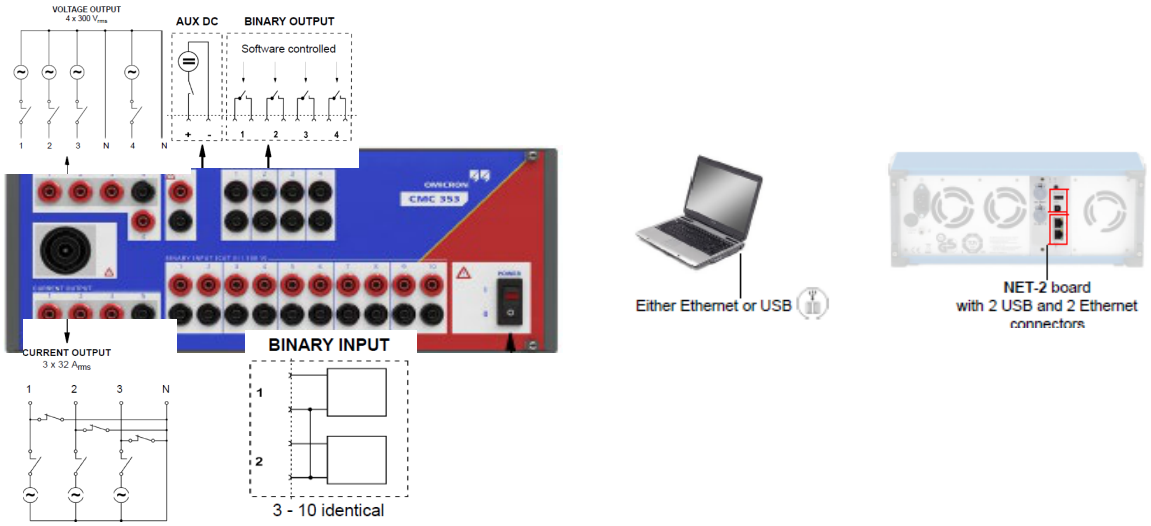
The results of the a.m. activities shall be recorded on SAT REPORT FOR MECHANICAL TEST form (see par. 10)

8.2 PRIMARY INJECTION ON CURRENT AND VOLTAGE TRANSFORMER

1. Testing CTs ratio

Test the CT for correct ratio with direct current injection to CT primary circuit and reading the measured value from the instruments or protection relays LCD display, provided at the LV compartment front door.

2. Testing VTs ratio



Test the VT for correct ratio with direct voltage injection to VT primary circuit (low voltage 400 V, for testing purpose) and reading the measured value from the instruments or protection relays LCD display, provided at the LV compartment front door.

The results of the a.m. activities shall be recorded on SAT REPORT FOR PRIMARY INJECTION TESTING ON CTs AND VTs form (see par. 10)

8.3 SECONDARY INJECTION TESTS ON PROTECTION RELAYS

Refer to the schematic diagrams, for connections and for checking logic functions.
Refer to the selectivity study for the protection relays' setting parameters.

Omicron secondary injection test kit – connection and interface

Example of testing instruments connection

1. Connection of the test set to the PC (USB Port) for data exchange: output of the data simulation, loading of the binary signal
2. Connection of the analogue outputs of the test set to the transformer inputs of the test object, to inject the simulated currents and voltages.
3. Connection of the binary outputs of the test set to the binary inputs of the test object, to send binary input signals to the test object.
4. Connection of the binary inputs of the test set to the binary outputs of the test object, to receive the binary output signals from the test object.

The recorded tripping values shall be in conformity with the Selectivity study

The results of the a.m. activities shall be recorded on SAT REPORT FOR PROTECTION FUNCTIONS CHECK form (see par. 10)

8.4 INSULATION RESISTANCE MEASUREMENT

The measurement of the insulation resistance is carried out to check that the installation and re-connection activities at site have been made correctly and that no damage occurred to the equipment, during shipment and installation.
All the VT's, surge arresters, insulation monitoring devices, etc. must be disconnected before the test.

1. Insulation resistance measurement of the main circuits

   It is to be carried out, applying at least 500V d.c. by means of Megger device. The measurement is to be carried out at each phase, while the other two are short-circuited and connected to ground.

   ACCEPTANCE CRITERIA: The test is considered successful if, for each tested circuit, the insulation resistance is above 1MΩ.

The values detected shall be recorded on SAT REPORT FOR INSULATION RESIST MEASUREMENT MAIN CIRCUITS form (see par. 10)

2. Insulation resistance measurement of the auxiliary circuits

   To carry out insulation resistance measurement on auxiliary circuits applying 500V d.c. by means of Megger device. The measurement is to be carried out at each pole, while the other one is connected to ground.

   ACCEPTANCE CRITERIA: The test is considered successful if, for each tested circuit, the insulation resistance is above 1MΩ.

The results of the a.m. dielectric tests shall be recorded on SAT REPORT FOR INSULATION RESIST MEASUREMENT ON AUX CIRCUITS form (see par. 10)

9 PRE-ENERGIZATION REQUIREMENTS

Before to proceed with energization of the LVSB, the following is to be verified.

- Make sure to pull off the short-circuit jumpers fitted on amperometric terminal boards, to avoid running the units with current transformer (-TA) short-circuited at secondary windings.
- Make sure to have re-closed the disconnecting terminals fitted on voltmetric terminal boards, to avoid running the units with voltage transformer (-TV) not connected at secondary windings.
- Make sure that all the miniature CBs for aux. and measuring circuits are closed.
- All system protections, controls, detectors, and monitoring devices shall be reset and ready for operation.
- All protections and control logics shall be reset and ready for operation.
- All recording equipment, where provided, shall be in operation.
- No alarm and/or trip signal shall be active.
- Voltage transformers shall be with fuses suitably placed.
- Circuit breakers shall be in service position (racked-in), open and available.
- Fuses shall be suitably placed.
- Mechanical and electrical interlocks are to be suitably in operation.
- All removable protections against direct contacts with accessible parts (panels, grids, plates, doors, etc.), shall be correctly placed and fixed.
- All the doors shall be closed and fixed panels are to be correctly positioned and bolted.

10 PRE-COMMISSIONING, COMMISSIONING AND SAT REPORT TEMPLATES

The following forms are intended for recording the results of Pre-Commissioning, Commissioning and SAT activities.

Forms provided by the customer may also be employed, on request.

- PRE-COMMISSIONING ACTIVITIES REPORT
- COMMISSIONING ACTIVITIES REPOR
- SAT REPORT FOR MECHANICAL TEST
- SAT REPORT FOR PRIMARY INJECTION TESTING ON CTs AND VT
- SAT REPORT FOR PROTECTION FUNCTIONS CHECK
- SAT REPORT FOR INSULATION RESISTANCE MEASUREMENT ON MAIN CIRCUITS
- SAT REPORT FOR INSULATION RESISTANCE MEASUREMENT ON AUX. CIRCUITs

1. GENERAL INFORMATION

NORMATIVE REQUIREMENTS

- Standards series UNI EN ISO 12944: 2018
- ISO 6270-1: 2018 (humidistat)
- ISO 8501.1:2012 (surface preparation for painting treatment)
- DIN EN ISO 9227:2023 (saline fog chamber)
- UNI EN ISO 2813:2014 (Gloss)
- ISO 2409:2020-12
- UNI ISO 2178:2016

IMESA takes painting systems for indoor installations with power paint through electrostatic application.

IMESA defines the correct painting system for HV/LV electrical switchboards according on relevant protection against corrosion in the installation environment.

The installation environments are identified in 6 classes of atmospheric corrosion (C1 ÷ C5-M) and 3 classes of durability (low, medium, high) according to ISO 12944:2018.

IMESA guarantees the systems in the below table, where there are also the relative classes of atmospheric corrosion.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

Treatment cycle	**A**
Corrosion - durability class	C3M
Installation environment	Unpolluted urban and industrial areas
Degreasing	X
Phosphatising	X
Wash 1	X
Wash 2	X
Passivation in demineralized product with nanotechnology	
Drying	X
Epoxy polyester powder coating	X
Kiln polymerisation	X

Tables 1

There must be no traces of calamine or soldering slag, lamination etc, on the parts to be painted before the phosphatising treatment, in compliance with Directive ISO 8501.1:2012.

The colours used correspond to the standardised RAL colours.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

2. DESCRIPTION AND CHARACTERISTICS OF SYSTEMS

2.1 CYCLE A

2.1.1 PRETREATMENT

The surfaces to be painted must be prepared in compliance with Directive ISO 8501-1:2012 (rusting and preparation grades of steel surfaces); the part is then chemically prepared according to the following cycle:

HOT DEGREASING (40 ÷ 50°C)

HOT PHOSPHATING (40 ÷ 50°C)

SPRAY WASH

SPRAY RINSE

KILN DRYING (110°C)

The surface must be dry, clean and degreased.

The powder is guaranteed for 24 months since production date whether stored in a temperature not over 30°C and in the original packaging.

2.1.2 PAINTING PROCESS

Electrostatic epoxy polyester powder paint coating,

RAL according to the technical specification,

polymerization at 180°C, 60/70 gloss (*),

smooth or orange peel finish according to the technical specification,

minimum thickness 60 micron (dry film).

In this phase the process parameters are monitored in order to obtain an excellent powder paint coating (See Annex 01 - WI 18 Rev. 09).

(*) The check of gloss is not significant for surface treatment with orange peel finish. Infact the value will be non compliant to what the data sheets because the brilliance depends on the type of surface treatment and the orange peel finish makes impossible a correct evaluation of gloss.

The evaluation of smooth finish is significant

2.1.3 CHARACTERISTICS

Exposure in a saline fog chamber in compliance with ISO DIN EN ISO 9227:2023 with resistance more than 240 hours.

Exposure in a humidistat in compliance with ISO 6270 – 1: 2018 with resistance more than 120 hours.

Adhesion: in compliance with Standard ISO 2409:2020-12 (See Annex 02)

N.B. All the characteristics guaranteed by the paint manufacturer must however be complied with.

3. PAINTING CHECKS

Since some of the checks are destructive tests, we recommend painting sheet plate specimens in sizes suitable for the destructive tests, with the same paintwork cycle used for the lot.

The specific modes of the checks that are performed internally are described in Annex 1 IL CAR.18

3.1 APPEARANCE

The paint on the painted sheet plate must be uniformly coated. There must be no signs of sagging, local thickening or other paintwork defects.

In any case the thickness' must not be under the minimum values requested. Moreover, the undercut and areas which are difficult to reach with normal painting tools, must be retouched by hand.

Boxed areas (e.g. doors, armour - plated switchboards) must be protected against corrosion with suitable protecting means at the discretion of the manufacturer provided the same ensure a lasting protection.

In cases of small defects in the surface it's possible to make retouches with spray paint or with a hand brush on the same RAL of specification; in case of bigger defects, the surface paint must be removed and a new treatment must be done.

3.2 THICKNESS CHECK

This check is carried out by means of magnetic induction readings in compliance with Directive UNI ISO 2178:2016. The readings must be carried out on the diagonal of the part; areas which are difficult to reach during painting, must have at least the minimum values indicated in this specification.

3.3 ADHESION CHECK

Carried out in compliance with Standard ISO 2409:2020-12 (See Annex 02).

3.4 GLOSS CHECK (THIS TEST WILL BE MADE IF REQUIRED IN AN EXTERNAL LABORATORY)

This check is carried out on smooth surfaces in compliance with UNI EN ISO 2813:2014.

3.5 SALINE FOG TEST (THIS TEST WILL BE MADE IF REQUIRED IN A EXTERNAL LABORATORY)

In compliance with ISO 9227:2023 (duration of the test according to the painting system carried out).

3.6 HUMIDISTAT TEST (THIS TEST WILL BE MADE IF REQUIRED IN AN EXTERNAL LABORATORY)

According to ISO 6270-1:2018 (duration of the test according to the painting system carried out).

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

4. INDICATIONS ON THE DRAWINGS

The painting cycle must be indicated on the drawing by the letter of the system and the thickness to be used. Painting cycle and RAL colour is mentioned on following doc:

- 1723002197-EL-DA-00006 / SG-100D1 GA DWG AND FOUNDATION LOAD CALCULATION INCLUDING COG
- 1723002197-EL-DA-00007 / SG-200N1 GA DWG AND FOUNDATION LOAD CALCULATION INCLUDING COG
- 1723002197-EL-DA-00008 / SG-200D2 GA DWG AND FOUNDATION LOAD CALCULATION INCLUDING COG
- 1723002197-EL-DA-00009 / DP-200N1 GA DWG AND FOUNDATION LOAD CALCULATION INCLUDING COG

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

TECHNICAL DATA SHEET

DURPOL EE 9B2870303T000 (EX 9068A6522) GREY ENEL TEXT HG TS X R7030

Composition

Powder based on polyester saturated carboxylated resins hardened in stoichiometrically relation with epoxy resins and formulated with pigments and inert fillers appropriate to guarantee good resistances in places do not exposed to direct weathering agents

Recommended uses

Powder indicated for a wide range of artefacts having excellent aesthetical finishing level and good resistance to yellowing such as: radiators, domestic appliances, tools, metallic furniture, scaffolding, indoor lighting, electric cabinets, office equipment.In order to obtain a good protection, it is necessary to spray an average thickness of 80- 100 micron.

Substrate pre-treatment

Powders adhere to most metal surfaces provided these are dry, clean and degreased. A chemical pre-treatment of the surface is required in order to improve the resistance against the corrosion, based on the kind of metallic support.

Application

This powder is suitable for use with electrostatic spraying equipments whose voltage is between 40 and 90 KV. Where acronym "TS" is present, our products are working also with triboelectical guns.
A difference of thickness of applied coating can generate modification of the appearance of hardened coating.In case of products having special effects, the use of overspray is not advised except for bonded products.

Polymerization conditions

170°C x 25', 180°C x 15', 190°C x 10' (piece temperature)

Characteristics after polymerization (application on steel panel)

Erichsen Drawing:	>=5 mm	ISO 1520
Mandrel Bend Test:	>= 4 mm	ISO 1519
Impact Resistance:	>= 2,5 Nm	ASTM D2794
Buchholz Hardness:	>= 80	ISO 2815
Cross Cut Test:	Gt0	ISO 2409
Gloss 60°:	Not applicable.	ISO 2813

Chemical resistance

The product has good resistance to most 10% acids and to ethylalcohol at room temperature (25°C).
For specific requests we invite you to contact our technical assistance.

Corrosion resistance (application on iron-phosphate bonder)

Humidity Chamber:	After 500 hours no change.	ISO 6270
Kesternich:	After 10 cycles no loss of adhesion.	ISO 22479
Salt Spray:	After 1000 hours < 1 mm penetration.	ISO 9227

Accelerated ageing (QUV-B) (313 nm) with QUV/SE cycle 4 hours, condensation at 40°C/4 h irradiation 50°C (0,75 W/m²/nm. Application on aluminium panel)

Test:	Not applicable.	ISO 16474:3

Storage

The product is guaranteed for 24 months since production date whether stored in a temperature not over 30°C and in the original packaging.

Notes:

* The above data are the results of careful researches and our long experience, nevertheless considering the large number of factors concurring to determine the values in the present technical data sheet, the utilizer will have the duty to effect the best conditions so as to get the best result.
* This product is destined to be used only in industrial plants. The manipulation of the product from the utilizer must be conform to laws concerning the use of powder coatings and to information described in our technical data sheet sent together with the product itself.

ANNEXES:

- ✓ Form VER 01 – Painted parts control board,
- ✓ Form VER 02 – Painting system control board
- ✓ Form MAN 18 – Painting system periodic maintenance registration sheet
- ✓ Sheet 18 – Periodic maintenance of the Painting Plant

APPLICABLE DOCUMENTS:

- ✓ Work order

APPLICABILITY AND LIABILITY

The purpose of this Work Instruction is to describe and define the checks and tests to perform during the powder coating work phase, in order to keep this process under control.

The Body responsible for the correct implementation of the following WI is the CAR/LAV Department

GENERAL INFORMATION

The automatic powder coating system is described in detail in the manuals of the BIV, CAM and WAGNER manufacturers and consists mainly of:

- **Pre-treatment tunnel;**
- **Cabins and equipment for powder application;**
- **Drying and curing ovens;**
- **Overhead conveyor.**

The process is kept under control by measuring the fundamental parameters (listed below) such as to ensure the desired product quality.

ACTIVITY SEQUENCE

1 The department head, according to WO, must communicate to the operators in charge of painting:

- the type of treatment to perform;
- the method of execution of the painting (automatic or manual);
- the pieces to be treated, divided by order/construction;

2 The operator must activate the preheating of the phospho-degreasing tank and ovens, by operating the selectors of the burners and fans, on the control panel.

3 Examine the pieces or the batch to be processed, accompanied by the relative WP and visually verify the absence of defects such as:
- extensive rust or calamine presence;
- unbrushed welds.

4 Check that the colour of the powder in the container is that of the batch to be painted.

5 Operate the overhead conveyor with the appropriate button and start hanging the pieces on the hooks. For each batch, also hang 1 sample of the same material as the first piece .

6 Operate the pumps for phospho-degreasing and the following rinses according to the type of painting cycle when the first piece approaches the entrance of the first tunnel.

7 At the exit of the drying oven, after degreasing, check that the first piece is well cleaned.

If the piece is not clean, stop the conveyor belt and check with the department head the operation of the phospho-degreasing tunnel and the bath titration. After eliminating any inconvenience, repeat the pre-treatment on the pieces made.

8 Activate the suction of the expected painting cabin (automatic or manual) and ensure that the operator is ready on his platform, for painting or only for touch-ups depending on the cabin used.

9 In the case of automatic painting, activate the reciprocators and guns, using the appropriate control panel.

10 As soon as the last piece of each batch has been painted, make a first brief cleaning of the cabin used and move on to the other cabin already prepared for the colour of the second batch of pieces, or clean the manual guns and change the powder with its container.

11 Remove the painted pieces from the hooks and place the WP in the pallet.

12 Store the pieces with their drawings in the dedicated area awaiting collection by the Assembly Department.

13 To turn off the system, deactivate the pretreatment tunnel, turn off the burner of the drying oven just after the last piece has been rinsed; after painting the last piece, turn off the burner of the curing oven and finally stop the conveyor belt.

14 Turn off the air extraction fans 30 minutes after turning off the ovens.

Quality CHECK of painted parts

During the unloading phase, at the end of the cycle, perform the following checks:

A. Visually inspect all painted parts;

B. On the sample, at each colour change, check the adhesion of the paint with the UNI EN ISO 2409 DIN 53151 squaring method as indicated on "Guide 01" and record the check on the form VER 01

C. On all the samples, measure the thickness of the paint and record the value detected on the form VER 01

D. The minimum reference thickness is that indicated in the Work Order, if not indicated, use the standard of **60** mμ for "Cycle A" and **90** mμ for "Cycle B" (see Guide 01). In any case, the maximum thickness must not exceed 200 microns unless expressly requested in writing by the Customer in the work order.

E. On the painted pieces make **6 thickness measurements** (3 front and 3 back), the frequency of the control is indicated at the next point.

F. The frequency of thickness control on the painted pieces is as follows

Take measurements on the first 3/4 pieces; then check **one piece every 15** of the batch.

G. If all thickness measurements indicate a value ≥ to the reference value, the piece is **ACCEPTED**

H. If **2 or +** thickness measurements indicate a value < to the reference value, the part must be considered **DEFECTIVE;** in this case, the matter must be submitted to the Department Head, who decides how to proceed.

CHECKS ON THE SYSTEM

Checks and tests are performed on the system both before and during the special painting process, in the following ways:

1. **Checks on the degreasing tank**

Before each painting cycle, check the PH of the phospho-degreasing bath by viewing it in the monitor of the degreasing product dosing pump.

The value must be within the range established in the technical data sheet of the product used as a degreaser and check that the tank temperature is between 40 and 50°C.

The values detected must be recorded on the VER 02 form "Painting system control sheet"

2. **Oven temperature control**

The correct curing of paint, being the length of the section travelled inside the oven constant, depends on the curing temperature and the speed of the conveyor belt.

Based on the indications provided by the paint manufacturer, the temperature must be between 180 and 210 °C and the speed must be adjusted between 1 m/min and 1.5 m/min.

For this purpose, it must be verified at each cycle that the actual temperature indicated on the control panel corresponds to that set, with a tolerance of ± 10 °C.

The values detected must be recorded on the form VER 02 "Painting system control sheet".

Check that the temperature set for the drying oven is 90°C and that the temperature actually detected does not deviate by more than ± 10°C.

Record the check performed on the form VER 02

3. **Check of hook cleanliness and bias voltage**

For a correct adhesion of the powder to the piece to be painted (electrostatically biased at a voltage between 60-80 kV managed automatically by the WAGNER equipment), it is necessary to periodically clean the hooks used to hang the pieces on the conveyor belt.

At the points of contact between the hook and the workpiece, the thickness of dry paint present must be less than 2÷4 mm. If there are hooks with more paint attached than indiacted above, the operators must collect these hooks and the department head must send them to the external supplier for cleaning.

4. **Other checks**

Checks to be performed **weekly** taking as reference the values and parameters indicated in the manual or set by the manufacturers:

- check the pressure of the pumps (must be between 0.8 and 2 bar);
- check the correct setting of the paint guns according to the manufacturer's parameters

on board of the painting cabin or near **the manual guns**

Record the operations carried out on the form MAN 18 – Periodic maintenance registration of the painting system.

It is implied that if the system remains stationary for the entire week, the check is postponed to the following week.

If powder paint is used that has exceeded the validity period recommended by the supplier, IMESA reserves the right, before painting the batch in production, to perform adhesion and thickness tests on specific samples. Only after verifying the suitability and goodness of the characteristics of the painting process, can the batch be processed.

CHECK TOOLS

- Painting Thickness Gauge (magnetic type).
- Cross Hatch Tester for Adhesion Tests.
- Electrode for checking the pH of the phospho-degreasing liquid.
- Instruments for measuring temperature.

DOCUMENTATION FOR THE VALIDATION OF THE SPECIAL PROCESS

The duly completed forms VER 01 and VER 02 and the storage of the painted samples are the objective evidences that demonstrate the control of the process in question.

The process must be validated by three-year external laboratory tests (See PO 7.17) to verify the salt spray resistance of components made according to the above process parameters and according to the technical data sheets of the products used.

Resistance in salt spray must be at least 100 hours.

QUALIFICATION OF OPERATORS

The qualification of the painting plant operators takes place through education, handover with more experienced operators and training.
These activities are internal to IMESA and for safety aspects the Competent Physician is also called into question.
The training topics are reported in the relevant form and in any case concern the operation and management of the plant, environmental, safety aspects and practical tests on samples that will be made available in the department.
This qualification activity must be performed for each new operator or, for experienced operators, every three years (See PO 7.17).
If the experienced operator is dedicated to another task for more than one year, he/she must repeat the qualification activity.

SYSTEM MAINTENANCE

Given that the preventive maintenance is performed by an external company, for the correct operation of the system it is necessary to carry out the operations provided for in Sheets 18 "Maintenance activities of the painting system" and 19 "Maintenance activities of the tanks" and the related records must be indicated in the Form "MAN 18 – Periodic maintenance record sheet for the painting system."

ENVIRONMENTAL REQUIREMENTS

The cleaning of the painting system must be performed at the end of each working day, in particular the powder paint deposited on the ground must be carefully collected in the appropriate airtight bags, to be subsequently disposed of according to the regulations in force.

In the same way, proceed with separate collection for other types of waste.

The emissions into the atmosphere of the painting plant are sampled annually by competent external companies and the results obtained communicated to the local authorities responsible for controls.

The disposal of the liquids contained in the pretreatment tunnel, when they are "exhausted", is entrusted to authorised companies.

SAFETY REQUIREMENTS

The maintenance operations of the system must always be carried out with the machine stopped and with the power switched off.

During the painting and loading activities of the parts, use the appropriate PPE as indicated in the company Risk Assessment Document.

Do not stand under the conveyor if the pieces are at the top.

elcometer

Elcometer 107 Cross Hatch Cutter

The coating may be continuous and look good, but how well is it connected to the substrate? The Elcometer 107 Cross Hatch Cutter provides an instant assessment of the quality of the bond to the substrate. Due to is rugged construction this gauge is ideal for thin, thick or tough coatings on flat or curved surfaces. An ideal field or laboratory test.

- Low cost
- Robust design
- Easy to change cutters
- Large Non slip grip
- Ideal for thick or hard coatings
- Large selection of cutters, each with four cutting faces
- Can be converted into the Elcometer 141 Paint Inspectors Gauge (P.I.G.)

The Elcometer 107 Cross Hatch Cutter is available in two versions.

- *The Basic Kit comes complete with:*
  Robust handle, the cutter of your choice (see below), Allen Key (wrench), presentation storage case and instructions (together with the Classification of Adhesion Test Results Chart)
- *The Full Kit includes all that is supplied in the Basic Kit, and also includes:*
  An eye glass, brush, and adhesive tape (either ASTM or ISO tape), all in a plastic ABS carrying case.

Adhesion

From the largest man-made structures to the smallest household appliances, most manufactured products have a protective or cosmetic coating. Premature failure of this coating can, at the very least, result in costly penalties or rework.

Adhesion testing during the coating process will quantify the strength of the bond between substrate and coating, or between different coating layers or the cohesive strength of some substrates. Routine testing is also used as part of inspection and maintenance procedures to help detect potential coating failures.

Elcometer offer a highly comprehensive range of Adhesion Gauges designed specifically to meet your requirements. These gauges can be split into three categories:

Cross Hatch / Cross Cut Method
The coating is cut into small squares, thereby reducing lateral bonding, and the adhesion assessed against ISO, ASTM or Corporate Standards

Pull Off Adhesion Method
Tensile Dollies (or stubs) are glued to the coating and, once the adhesive has cured, the force required to pull the dolly off the surface is measured.

Push Off Adhesion Method
Similar to the Pull Off Adhesion Test, a dolly is glued to the coating, once the adhesive has cured, however, the dolly is pushed off the surface by the adhesion gauge.

HOW TO SELECT THE CORRECT ADHESION GAUGE

Cross Hatch Cutters

Advantages:
A fast, low cost, comparison method

Possible Limitations:
A subjective test for flat surfaces for a limited thickness range.

Applications:
Paint and powder coating adhesion up to a thickness of 125µm (5 mils).

Pull Off Adhesion Testers

Advantages:
Simple to use, quantitative range – giving you a definitive adhesion value

Possible Limitations:
Time required for adhesive to cure

Applications:
Ideal gauge for the laboratory or field – flat or curved substrate applications

Push Off Adhesion Testers

Advantages:
Fast cure time adhesives can be used, ideal for curved surfaces

Possible Limitations:
High forces exerted by gauge may cause thin substrates to deform

Applications:
Pipelines and metal spray coatings.

EDUCATION COURSE/TRAINING ACTIVITY REPORT

Location of the course/training	**IMESA S.p.A. – Via G. Di Vittorio, 14, Zona Industriale JESI (AN), 60035**
Date / Period	**10/16/2023 2023**
Duration in "h"	**15 hours – TRAINING**
Title of the course/training	**Education/training in the use of POWDER COATING SYSTEM**
Name of Speaker/Trainer	**Cristiano Stefano Chiappa**
Signature Speaker/Trainer	
Main topics covered	**Correct use of the system – Environmental and safety regulations – Creation of samples and tests**
Illustration of procedures for the safe use of the system (Reference Work Instructions – Risks evaluation document - Risk assessment sheets)	
Information on the risks associated with the use of the system and correct use of the PPE/CPE associated with it (Reference Work Instructions - Risks evaluation document - Risk Assessment Sheets)	
Examination of the main accident prevention regulations and extracts of specific risks from the company risks evaluation document (Reference Work Instructions - Risks evaluation document - Risk assessment sheets)	
Illustration of the Use and maintenance manual (System use and maintenance manual)	
Analysis of foreseeable abnormal situations, safety and alarm systems (System use and maintenance manual)	
Environmental regulations and methods of disposing of waste products (Reference Work Instructions)	
Process control parameters and their recording - Spill test (System use and maintenance manual - paint and chemical products technical data sheets)	
Product control parameters and their recording (paint and chemical products technical data sheets)	
Technical and safety data sheets of the products used	
Training through practical test – see images

LEARNING TEST

For each question, tick only one answer		
1.	What is the reference instruction for painting?	1. WI CAR.17
		2. WI CAR.18
		3. WI CAB.06
2.	Are exposed surfaces of the component permitted after painting?	1. Yes
		2. No
		3. Only for a surface area less than 3 cm2
3.	Which instrument is used for thickness measurement?	1. Gauge
		2. Cross hatch
		3. Thickness gauge
4.	Which instrument is used for adhesion measurement?	1. Gauge
		2. Cross hatch
		3. Thickness gauge
5.	What is the optimal thickness range for an A cycle?	1. 60-200 microns
		2. 30-60 microns
		3. 200 – 400 microns
6.	What is the optimal speed of the painting system chain?	1. 0.5m/s
		2. 1.2m/s
		3. 3 m/s
7.	What temperature should the cooking oven be set at?	1. 60°C
		2. 400°C
		3. 190°C

OUTCOME OF EDUCATION AND TRAINING

TRAINER SIGNATURE

Gardobond® A 4818

Amorphous iron phosphate pre-treatment

Scope

Gardobond A 4818 is a liquid concentrate, combined cleaner and amorphous iron phosphate solution designed to simultaneously degrease and pre-treat metal ferrous substrates.

The surfaces of parts made of aluminium and zinc materials can be cleaned and slightly tarnished by this process.

Gardobond A 4818 is applied by spray.

Physical properties

Appearance:	colourless to bright yellow liquid
Density (20ºC):	approx. 1.2 g/cm³
pH value (10 g/l, 20ºC):	approx. 3.0
Flash point (DIN 51755 / 53213):	non-flammable

Process sequence

Combined cleaning and phosphating

Cleaning / phosphating – rinsing – demin rinsing / post rinsing – drying and painting.

Separate cleaning and phosphating

Cleaning – rinsing – phosphating – rinsing – demin rinsing / post rinsing – drying and painting.

Chemicals required

Gardobond A 4818 (make-up and replenishment solution)

Gardobond-Additive H 7143 (to reduce pH), either ***Gardobond-Additive H 7141*** (to increase pH)

The above data have been compiled to the best of our knowledge on the basis of thorough tests and with regard to the current state of our long practical experience. No liabilities or guarantee deriving from or in connection with this leaflet can be imputed to us. - Reproduction, in whole or in part, only with our express permission.

Bath make-up

Add per 1.000 litres of working solution:

10 – 30 kg of ***Gardobond A 4818***

Mix and heat to operating temperature. This may be varied dependant on the degree and type of soiling to be removed.

Bath operation

Spray time:	1 - 3 minutes
Spray pressure:	1 - 2 bar
Bath temperature:	40 - 60 °C
Bath concentration:	1.0 - 3.0 % ***Gardobond A 4818***
pH value:	4,5 – 5,3

These operating limits are for guidance only. Plant conditions will vary and your Chemetall Field Support Engineer may recommend operation close to or even outside the limits quoted under certain circumstances.

Bath control

Testing chemicals required

Test Indicator 2 (phenolphthalein)
Testg Solution 1 (0.1 M sodium hydroxide)

Total acid pointage

Take a 10 ml sample of the working solution, dilute with approx. 50 ml of distilled water add 5 drops of Test Indicator 2 and titrate with Test Solution 1 until the colour changes from colourless to pink. The number of mls of Test Solution 1 required is known as the Total Acid Pointage of the solution.

Gardobond A 4818 is normally used in the range of 3.0 to 9.0 Total Acid Points.

Bath replenishment

An addition of 3.3 kg (2.8 litres)of ***Gardobond A 4818*** per 1000 litres of working solution will raise the Total Acid Pointage by one.

Pre-treatment

Separate cleaning and degreasing

Alkali cleaners are well suited for cleaning and degreasing.
Alkali cleaners are supplied by Chemetall under the designation ***Gardoclean***.

Cleaning additives

In general, the built-in cleaning properties of ***Gardobond A 4818*** will be sufficient for most requirements. Slightly more difficult cleaning jobs can usually be handled by a slight increase in the ***Gardobond A 4818*** pointage.

If, however, difficult cleaning tasks are encountered, use may be made of a Gardobond-Additive surfactant additive. This additive is used to increase the cleaning and degreasing performance of the process without generating excessive amounts of foam.

Gardobond-Additive should be added in increments of 0.5 litres per 1000 litres of working solution, until the cleaning performance is satisfactory.

Equipment materials

Tank and Heating element

General-purpose constructional steels to DIN EN 10025, with acid-resistant rubber lining. Chromium nickel steel, material no. 1.4541

Labour and environmental protection

For transport, storage, use and waste treatment of chemicals in concentrated or diluted form as well as bath solutions, the appropriate local legislation must be followed.

Further specific information on the products can to be obtained from the EC Safety Data Sheets. For the used solutions the hazard code on the label should be followed.

Waste disposal

All effluent discharge must be treated in accordance with national legislation and local regulations prior to discharge to the sewer.

9. PRESERVATION OF SWITCHBOARD AFTER INSTALLATION……..17

1 INTRODUCTION

Check that during installation, operation and maintenance, prescriptions relating to technical and safety rules at workplace are complied.

Follow meticulously the indications of this manual.

The switchboards manufactured by IMESA, are designed for different standardized system configurations. Additional technical – structural variations may however be requested by the Customer for particular system requirements.

Remember that you should always refer, not only to this manual, but also to the updated technical documentation forwarded by IMESA (operating diagram, construction drawings etc.); above all, to the instruction manuals of the equipment installed on the switchboard.

2 SHIPPING AND CHECKS ON ARRIVAL

In order to facilitate the transport, the switchboard is divided in sections consisting of one or more upright standard units, generally in lengths of no more than 3000 mm.

Each section is packaged according to the shipping and storage requirements, in compliance with the customer's requests.

In general, the switchboards are shipped complete with the mobile parts (circuit breakers, contactors, VT) inserted in the respective cells, unless otherwise agreed with the Customer. The switchboard has its earthing switches in close position while the circuit breakers in open and disconnected position.

On arrival, the compartments and accessories must be unpacked and checked as indicated in the technical documents forwarded before delivery of the switchboard.
If damage or faults (switchboard and equipment) are discovered when the material is unpacked, please inform our sales offices immediately (either directly or through your agent).
Claims for any defects, even after receipt, must show the construction number and year, which are shown on the data plate affixed to the switchboard.

3 STANDARD PACKING PROCEDURE

Each switchboard unit/section rests on its own base (not fixed on a wooden pallet).

The following steps are adopted by IMESA for a correct standard packing procedure:

1. covering the protruding parts (lamps, devices, etc.) with bubble wrap with large bubbles and securing them with rubberized paper tape.
2. covering the switchboard with bubble wrap starting from the bottom and climbing up to the top, paying attention to covering the front with at least two layers of bubble wrap.
3. fixing the bubble wrap with IMESA adhesive tape.
4. identifying the unit with the shipping mark.

4 LIFTING THE SWITCHBOARD

Each unit rests on its own base (not fixed on a wooden pallet). Since the units contain the apparatus (circuit breaker, contactor, VT service truck) it is compulsory to use proper lifting method, as mentioned in this document.

LIFTING METHOD "A": lifting by using no. 1 spreader bar and no. 2 ropes with hooks (fig. A):

- connect the lifting ropes to the spreader bar coupling points (A).
  The choice of the coupling points must be done in order that the ropes do not compress the switchboard and that lifting occurs in a balanced way.
- connect the other ends of the ropes to the lifting tools in the lower part of switchboard (B)
  Lifting must be carried out according to fig. a – b – c - d

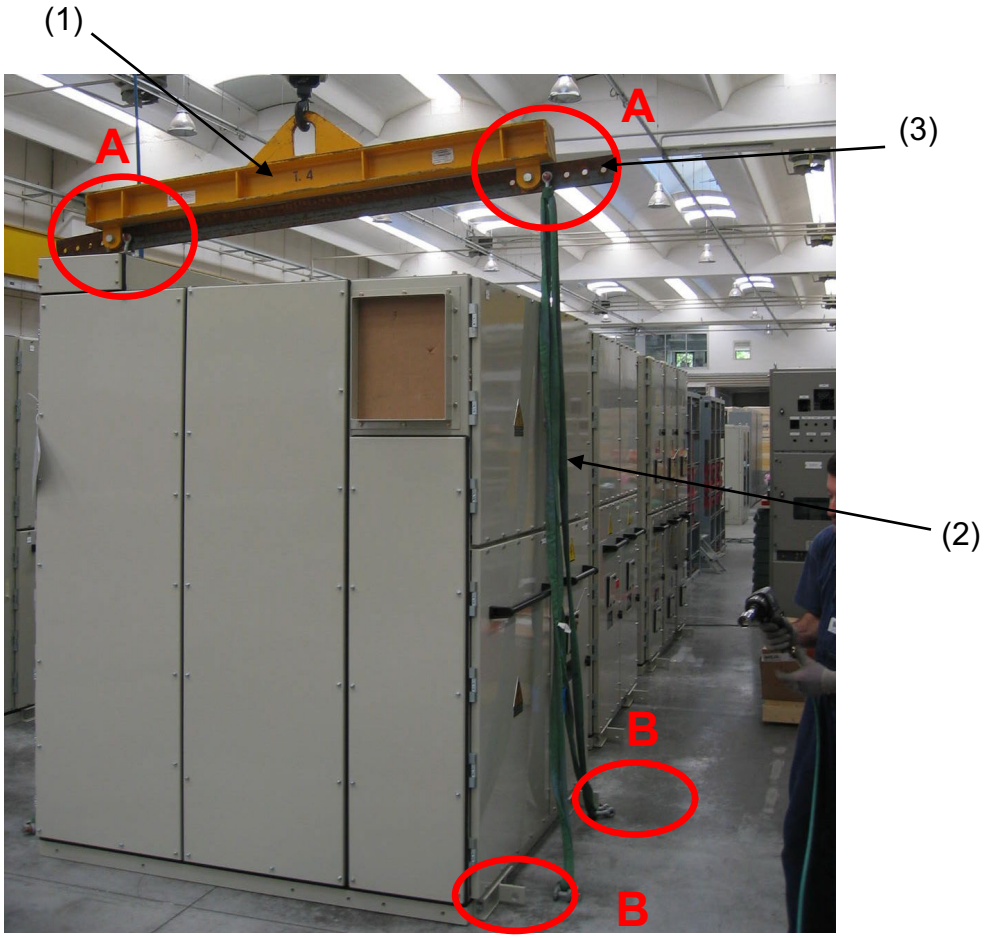

Fig. a

Items out of Swbds scope of supply (can be provided on request):
Spreader bar (1) – lifting ropes (2) – coupling crossbar (3)

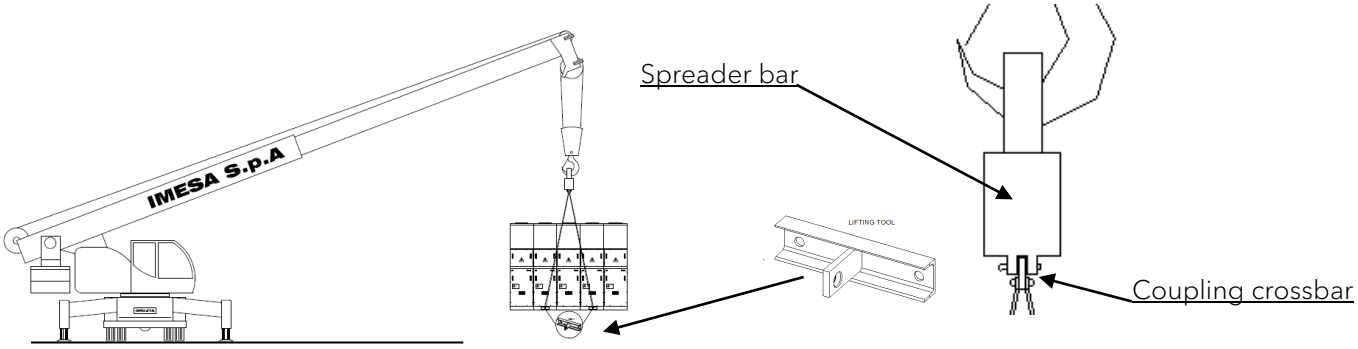

Fig. b

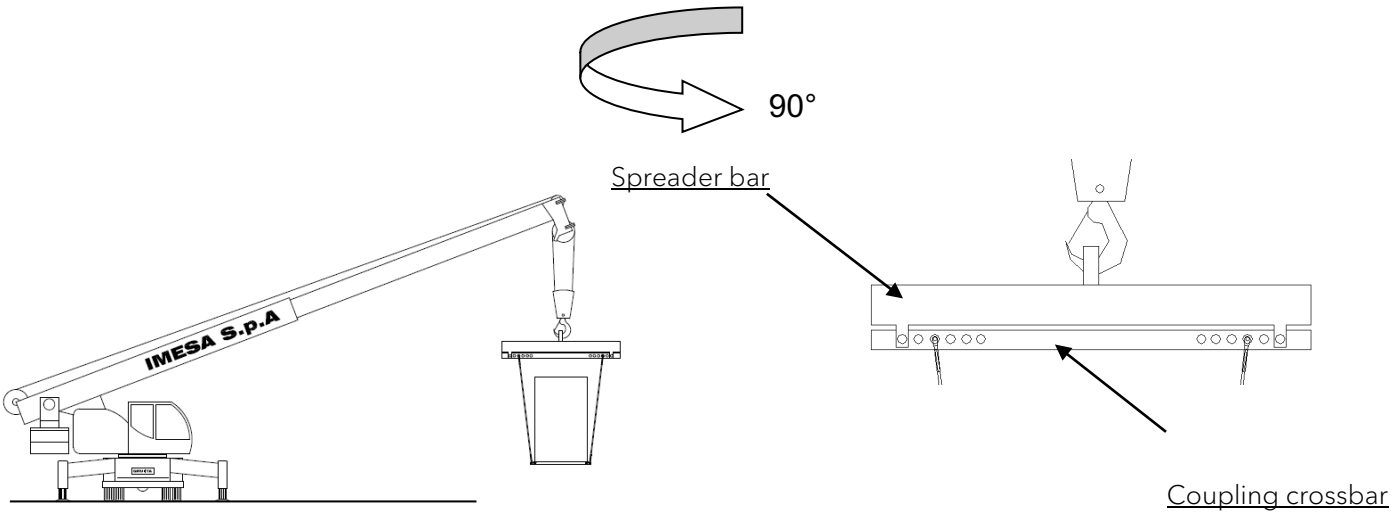

Fig. c

ADJUSTABLE POSITION OF THE COUPLING POINTS (IN CASE THE C.O.G. OF THE SWITCHBOARD IS NOT SYMMETRICAL)

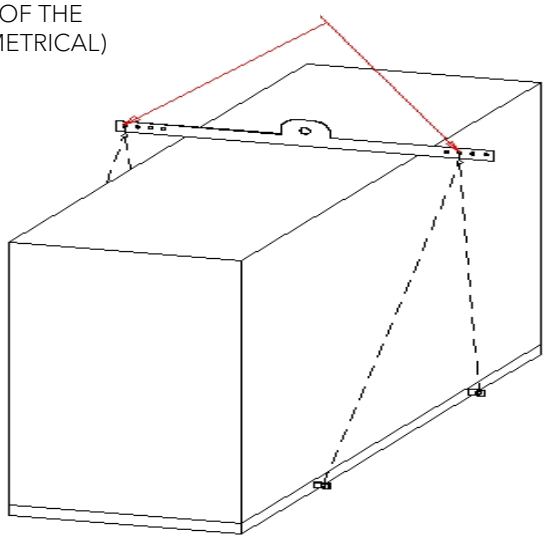

Fig. d

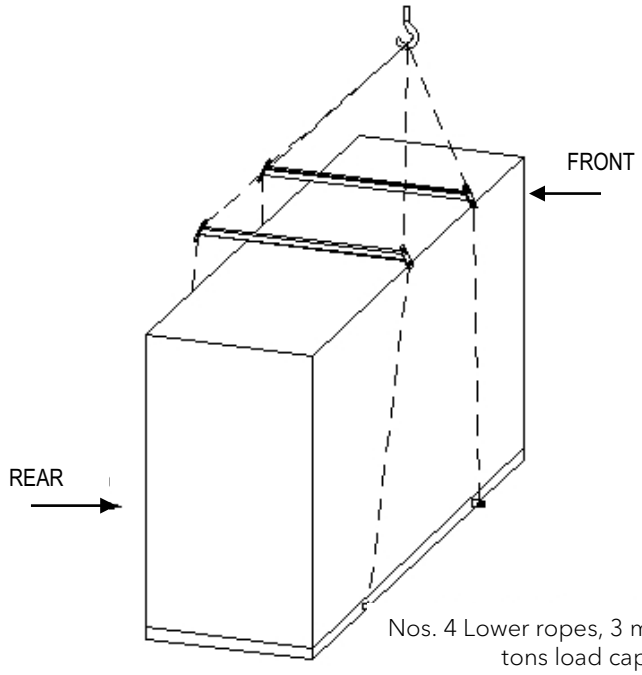
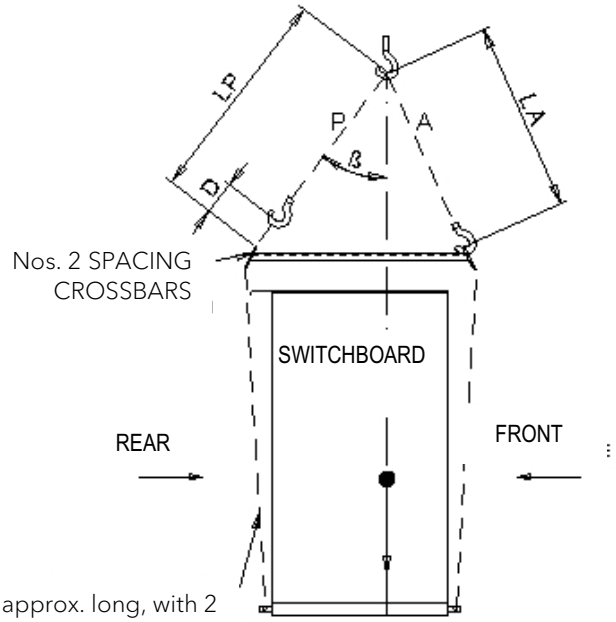
LIFTING METHOD "B": lifting by using no. 2 spacing crossbars bar and no. 8 ropes with hooks (fig. e – f):





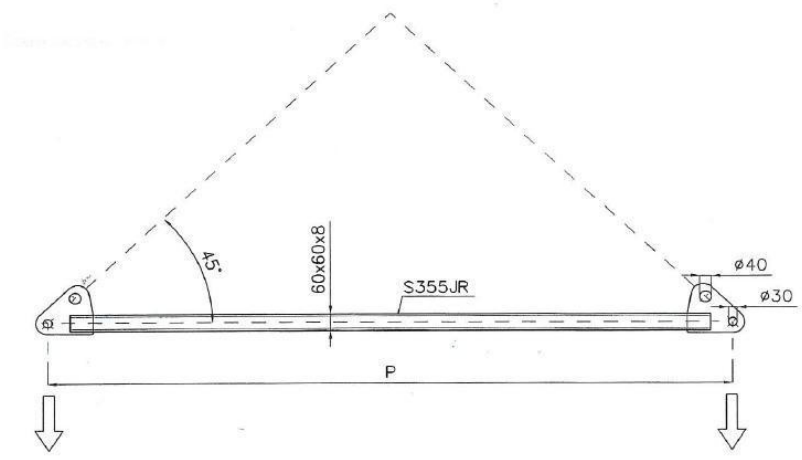


Fig. e

Nos. 4 Lower ropes, 3 m approx. long, with 2 tons load capacity/each
(not included in the Swbds scope of supply)

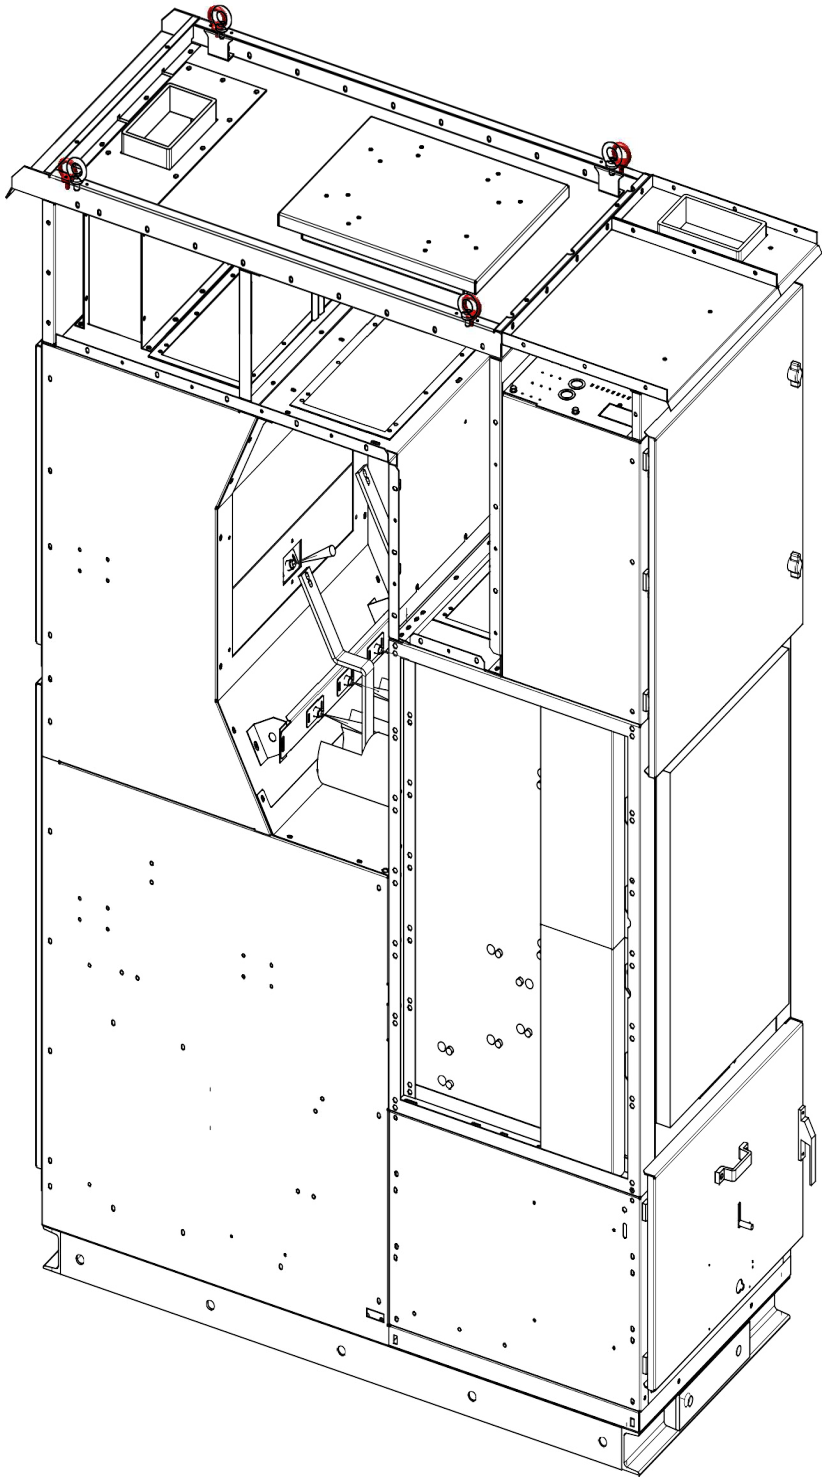
Fig. f

β = 45° max
A = no. 2 front straps or chains, with one or more closing U-hooks. Load capacity 3 tons each (not included in the Swbds scope of supply)
P = no. 2 rear straps or chains, with one or more closing U-hooks. Load capacity 3 tons each (not included in the Swbds scope of supply)
D = difference between LP and LA, to be defined through a lifting test (min. 50 – max 200 mm)

Spacing Crossbar out of scope of supply (can be provided on request)

LIFTING METHOD "C": lifting the unit using eyebolts and ropes with hooks (fig. G):

Connect the lifting ropes to the 4 eyebolts highlighted in red and lift the switchboard by means of equipments suitable to support the switchboard weight.



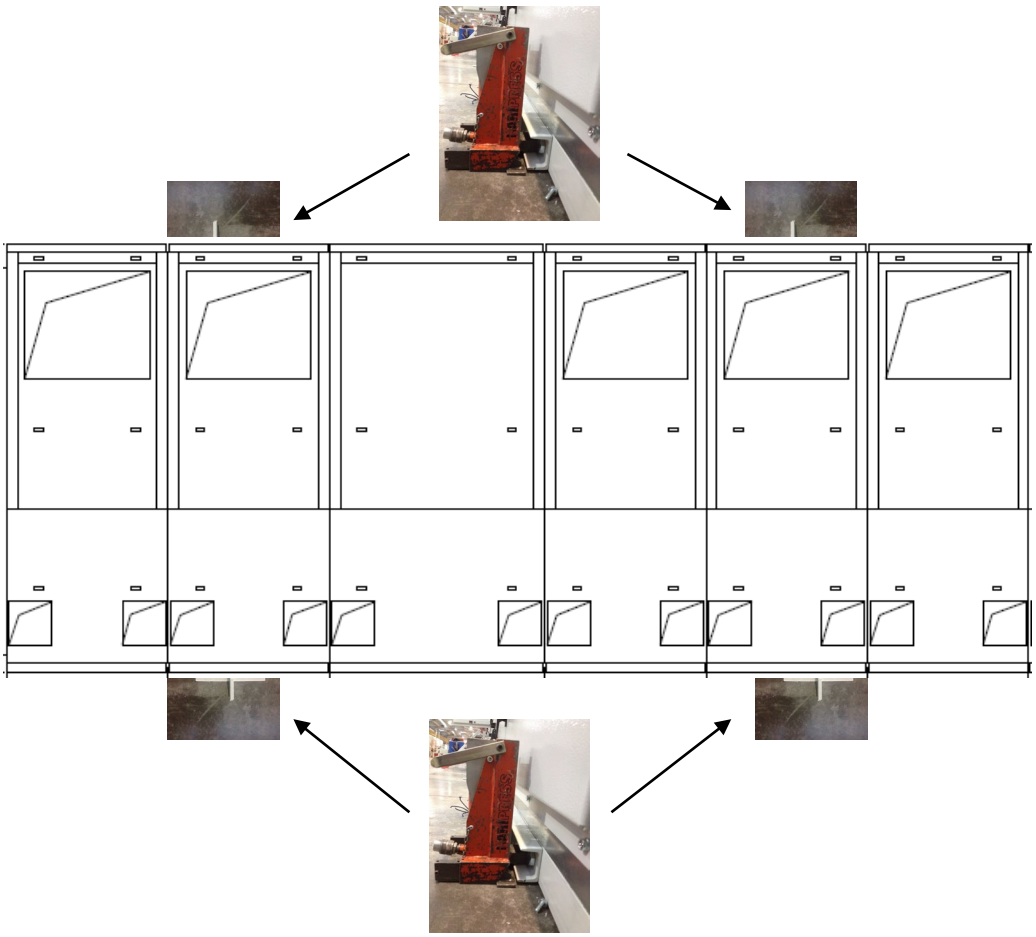


Fig. G

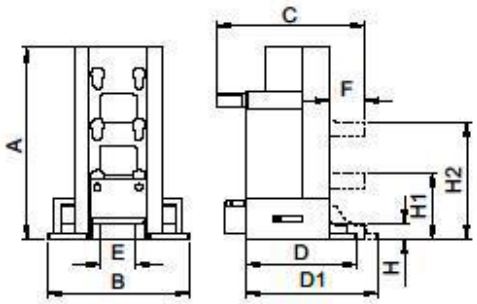
5 HANDLING THE SWITCHBOARD

The floor on which the roller slides or machinery skates move shall be completely levelled.

Place no. 4 hydraulic jacks to lift the unit for placing the rollers or the machinery skates and place the panel at the installation location.

Hydraulic Jack-1/2



Hydraulic Jack-3/4

5.1 Hydraulic Jack (Example)

UJ

EUROJACK HEAD AND TOE LIFTING JACK

- Force 10 - 25 t
- Stroke 150 mm
- Max Working Pressure: 700 bar

HYDRAULIC TOOLS

FEATURES

Power jack with adjustable lifting toe designed to lift large loads from very low positions.
They are provided with extendable bases for maximum stability. The lifting toe can be positioned at three different levels with only 25 mm minimum clearance needed. The head of the jack may also be used to lift vertically, or if the jack is turned onto its side it can be used for pushing.

APPLICATIONS

Particularly suitable for lifting, moving and levelling of machinery and heavy equipment from a very low starting height.

Hand Pump model **PL131** is the recommended pump to operate the power jack **UJ** model.

p. 49

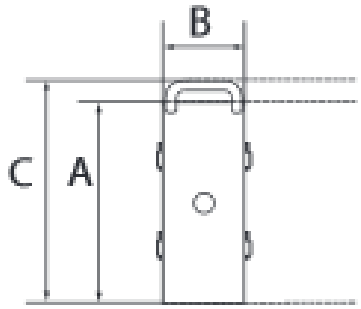
SKATES (PAKROL™)

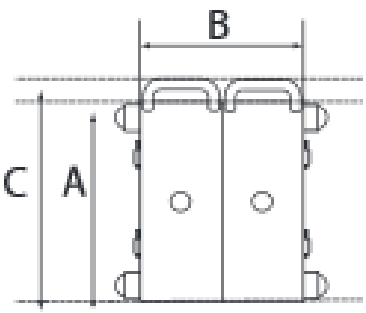
LIFTING & HANDLING EQUIPMENT

1 OVERVIEW

The PAKROL™ range has been designed to handle and move heavy and rigid loads manually on a flat and resistant floor.



2 FEATURES



- Unit Consisting Of Steering Handle and Trolley Combinations from 8 to 20 Tons
- A Modular Line to Steer and Move Loads
- Robust Construction
- Trolley Skates Have Turntables
- Skates Can Be Joined Together To Increase Capacity
- Nylon or PU Rollers with Ball Bearings

	G	840
	H	400 x 220

6 STORAGE OF SWITCHBOARD

6.1 Primary considerations

Proper storage must protect items from moisture, environmental contamination and physical damage. This protection must be achieved with adequate:

A. ventilation
B. heat
C. support stand

Storage temperature and humidity ranges are to be considered as follows:

- Maximum environmental temperature: + 40 °C
- Minimum environmental temperature: - 5 °C
- Relative humidity: 85 % max.

6.2 Ventilation

To avoid condensation of humidity, the air must be free to circulate through and around the switchboard and on any exhaust ducts:

- The switchgear grids must be free for air circulation.
- Protective covers and shipping packaging must be ventilated to allow air to circulate freely from below through the top of the enclosure.
- Where applicable to guarantee proper covering protection, the electrical panels must be covered with heavy duty polyethylene sheets; taking care that ventilation is anyway adequately assured.
- Enclosed storage areas such as buildings, warehouses, sheds, temporary shelters and similar must be well ventilated.

6.3 Heat

To prevent moisture condensation, heating may be required depending upon the warehouse room rate and extremes of temperature change, humidity, etc.
When in doubt, it is recommended to re-heat, by means of the provided space heaters.

Closed storage areas provided with heating system are generally satisfactory, where the temperature of the area is kept at least ten degrees above the outside temperature.

6.4 Supporting stand

To prevent distortions and stresses to the switchboards frame structure, the flooring of the storage area must be true and flat.

6.5 Internal preservation

The electrical panels of the switchboard are packed and protected in accordance to the Packing Procedure.
All packing materials are of the non-hygroscopic type.

During storage, the equipment must be kept dry, free of dust and protected from mechanical shocks.

6.6 Checks on arrival

The switchboard is shipped and delivered with removable parts (HV circuit breakers, HV contactors, VT trolley) racked in, in the respective compartment and with the earthing switches in closed position.

On arrival, the panels must be unpacked and checked, to immediately advise and highlight any possible damage found out.

7 STORAGE OF LOOSE MATERIAL AND EQUIPMENT

7.1 HV Circuit Breakers / HV Contactors

In case immediate installation is not allowed / not foreseen, the equipment is to be stored kept in the original packaging provided by the manufacturer and warehoused as per instructions further detailed at following par. 3, at a range of ambient air temperature between – 5 °C and + 40 °C.

The switching apparatus is to be left in OFF position and with discharged stored-energy spring mechanism (the latter is applicable to circuit breakers only).

It is to be avoided positioning of the items in risky location, in terms of accidental mechanical impacts or stresses to the structure of the apparatus.

7.2 Protection relays

If relays are not to be installed immediately, they shall be stored in a place free from dust and moisture in their original cartons. Where de-humidifier bags have been included in the packing, they should be retained. The action of the de-humidifier crystals will be impaired if the bag has been exposed to ambient conditions and may be restored by gently heating the bag for about an hour, prior to replacing it in the carton.

Dust which collects on a carton may, on subsequent unpacking, find its way into the relay; in damp conditions the carton and packing may become impregnated with moisture and the dehumidifier will lose its efficiency.

Storage temperature: –25°C to +70°C

7.3 Current and Voltage Measuring Transformers

In case measuring transformers are not intended for immediate installation, they shall be stored and protected against direct sunshine and rain.

Storage temperature: –5°C to +40°C

8 PRESCRIPTIONS

The following prescriptions refer to the equipment, material or switchboard panels stored on site before installation.

- To store the items in closed, weather protected, controlled temperature areas; accessible to authorized personnel, only.
- To keep the equipment, the material and the electrical panels in their original packaging.
- To protect the items from extreme temperatures, humidity and dew accumulation.

Remove packing just before the installation.

- To carefully open the package, in order to avoid any damage to the contents.
- To pay particular attention to corrosion and dirt protection requirements of the equipment.
- To check the status of the protective measures of the panels every 12 months (e.g.: paint, grease, covers, etc.) and, in case found it necessary, to renew them.
- Where necessary, to take additional precautions, based on the local site actual conditions, to avoid damage to the equipment.
- Observe load capacity of cases when piling them up (where applicable)

The equipment, material and switchboard panels, stored as per indications in the present document up to 12 months, can be kept in their original packaging without further storage requirements; where storage temperature and humidity level are maintained as per vendor recommendations.

Packing, boxes and wraps containing loose material must be stored in a closed, covered and unheated location (warehouse), after having checked the integrity of the contents and restored the protection provided by the original packaging.

When a long period of storage in the warehouse of the electrical panels is foreseen (beyond 12 months), the following requirements must be applied:

- to keep the electrical panel in its original packaging and periodically check its preservation.
- to lubricate with non-aggressive lube, grease or protective film, all the unprotected metal parts.

  This is required to prevent corrosion.

9 PRESERVATION OF SWITCHBOARD AFTER INSTALLATION

The following prescriptions refer to the switchboard panels preservation, after installation into the electrical room.

- To keep closed/locked all the panels and doors, when the works are not on going.
- To keep thoroughly cleaned the switchboard compartments (e.g. by means of vacuum cleaner), in order to keep the same free from dust and dirt.
- All sensitive items located on the panel doors (e.g.: equipment having glass/plastic panels) shall be mechanically protected by covering with cardboard or polythene sheet and bubble wrap.
- All opening/entries shall be kept closed/sealed to prevent rats or other animals entering within the panels enclosure.

PROVE INDIVIDUALI (secondo lo standard IEC 61439-1)**:**
ROUTINE TESTS (according to standard IEC 61439-1):

■ = **TESTED**

■ **11.1 GENERALITA'**
GENERALITY

■ **CONTROLLO VISIVO E DIMENSIONALE**
VISUAL AND DIMENSIONAL CONTROL *Point 3.1 FAT proc.*

■ **CONTROLLO OSSERVANZA ALLE SPECIFICHE ED ORDINE**
CHECK OF COMPLIANCE TO SPECS AND ORDER *Point 3.1 FAT proc.*

■ **CONTROLLO CARPENTERIA, SBARRE,CONNESSIONI PRIMARIE**
STRUCTURAL WORKS, BUS-BAR CONTROL *Point 3.4 FAT proc.*

■ **CONTROLLO VERNICIATURA (RAL 7035 ≥ 60 µm)**
PAINTING CONTROL *Point 3.1 FAT proc*

■ **11.2 GRADO DI PROTEZIONE DEGLI INVOLUCRI**
PROTECTION DEGREE *Point 3.3 FAT proc.*

■ **11.3 DISTANZE DI ISOLAMENTO IN ARIA E SUPERFICIALI**
CLEARENCE AND CREPAGE DISTANCES *Point 3.1 FAT proc.*

■ **11.4 PROTEZIONE CONTRO LA SCOSSA ELETTRICA ED INTEGRITA' DEI CIRCUITI DI PROTEZIONE**
PROTECTION AGAINST ELECTRIC SHOCK AND INTEGRITY OF PROTECTIVE CIRCUITS *Point 3.4 FAT proc.*

■ **11.5 INSTALLAZIONE DEI COMPONENTI,FISSAGGIO EVENTUALI DANNI IN ASSEMBLAGGIO E COLLEGAMENTI TERRE**
INCORPORATION OF BUILT-IN COMPONENTS , FIXED,EVENTUAL DAMAGE CAUSED BY ASSEMBLING, EARTHED *Point 3.1 FAT proc.*

■ **VERIFICA FONDO SCALA STRUMENTI E DATI NOMINALI APPARECCHIATURE**
CHECK FULL SCALE OF INSTRUMENTS & EQUIPMENT RATED DATA CONTROL *Point 3.1 FAT proc.*

■ **VERIFICA DEL SERRAGGIO E MARCATURA BULLONERIA**
CHECKING THE TIGHTENING AND MARKING OF BOLTS
Point 3.4 FAT proc.

■ **CONTROLLO CABLAGGIO & DATI DI TARGA**
WIRING CHECK & PLATE CHECK *Point 3.4 FAT proc.*

■ **MISURA RESISTENZA D'ISOLAMENTO**
MEASURE OF INSULATION RESISTANCE *Point 4.3-4.4 FAT proc.*

CIRCUITI DI POTENZA **L1= >500 MΩ; L2= >500 MΩ**
POWER CIRCUIT **L3= >500 MΩ; N = / MΩ**
CIRCUITI AUSILIARI
AUXILIARY CIRCUITS 230 Vac= **>500 MΩ**

■ **11.6 CIRCUITI ELETTRICI INTERNI E COLLEGAMENTI**
INTERNAL ELECTRICAL CIRCUITS AND CONNECTIONS
Point 3.4 FAT proc.

■ **11.7 CONTROLLO DEI TERMINALI PER I CONDUTTORI ESTERNI**
CHECK OF TERMINALS FOR EXTERNAL CONDUCTORS
Point 3.4 FAT proc.

■ **11.8 CONTROLLO FUNZIONAMENTO MECCANICO**
MECHANICAL OPERATION TEST
VERIFICA DI FUNZIONAMENTO: FUNZIONAMENTO DEGLI INTERRUTTORI,PORTE,CHIAVI INTERBLOCCHI SEGNALI E LE PARTI MECCANICHE CHE FORMANO IL QUADRO
OPERATION TEST: CHECK OPERATION OF C.B. DOORS, SIGNALLING, EFFICIENCY OF KEY LOCKS AND THE MECHANICS PART THAT FORM THE PANEL,INTERLOCKS BETWEEN C.B, CARRY OUT A NUMBER OF STARTING UP AND STOPPING SEQUENCES *Point 3.2 FAT proc.*

■ **11.9 PROVE DI TENSIONE : f = 50 Hz e t = 1 sec.**
VOLTAGE TEST : f = 50 Hz and t = 1 sec. **(*60 sec)**

CIRCUITI DI POTENZA **2,2** kV
MAIN CIRCUITS *Point 4.3 FAT proc.*
Leakage curr. L1= <1 mA L2= <1 mA L3= <1 mA **N= / mA**

CIRCUITI AUSILIARI ; 230Vac= 1,5 kV
AUXILIARY CIRCUITS *Point 4.4 FAT proc.*
Leakage current: 230Vac= 1 mA

■ **PROVE DI FUNZIONAMENTO ELETTRICO E SEQUENZE, ARC FLASH TEST VANO CAVI, BUSBAR & C.B.**
ELECTRICAL OPERATION & SEQUENCE TESTS, ARC FLASH TEST ON CABLE COMP. BUSBAR & C.B. *Point 4.1FAT proc.*
N.A. not applicable

■ ***FUNZIONAMENTO CORRETTO DELLE LOGICHE*** **DI CONTROLLO**
RIGHT WORKING OF THE LOGICAL CONTROLS
VERIFICA DI FUNZIONAMENTO: CIRCUITI AUSILIARI E DI COMANDO, POLARITA' CIRCUITI VOLTMETRICI/AMPEROM.
CHECKING OF OPERATIONS: AUXILIARY AND CONTROL CIRCUIT, CHECK VOLTMETRIC/AMPEROMETRIC CIRCUIT & POLARITY,INTERTRIP SIGNAL *Point 4.1 FAT proc.*

■ **PROVE SUI DISPOSITIVI AUSILIARI**
TEST OF AUXILIARY DEVICE *Point 4.2 FAT proc.*

■ **CONTROLLO DI CONTINUITA' DEL CIRCUITO DI TERRA**
CHECKING OF ELECTRICAL CONTINUITY EARTH CIRCUIT
Max = ≤0,1Ω (Max Value Measured: 0,003 Ω)
Point 4.5 FAT proc.

RULES :
According to Standard IEC 62271-200

N° Certificato/ Certificate N°:	303	Data / Date:	29/07 ÷ 01/08/2024

■ MISURA RESISTENZA D'ISOLAMENTO
MEASURE OF INSULATION RESISTANCE
IL TEST SI CONSIDERA SUPERATO SE NON AVVENGONO SCARICHE DISRUPTIVE DURANTE LA PROVA
SI PRENDE IL VALORE PIU' BASSO DI RESISTENZA DI ISOLAMENTO DOPO LA PROVA DIELETTRICA
SI APPLICA UNA TENSIONE DI 5000Vdc PER 10" TRA OGNI FASE E TERRA NEL CASO DEI CIRCUITI DI POTENZA
SI APPLICA UNA TENSIONE DI 500 Vdc PER 5" TRA OGNI CIRCUITO AUSILIARIO VERSO TERRA
APPLYING A VOLTAGE OF 5000 Vdc FOR 10" BETWEEN THE POWER CIRCUITS (IN SEQUENCE L1, L2, L3) AND GROUND.
APPLYING A VOLTAGE OF 500 Vdc FOR 5" BETWEEN THE AUX CIRCUITS AND GROUND
THE TEST IS CONSIDERED PASSED IF NO DISRUPTIVE DISCHARGES OCCUR DURING THE TEST
LOWER INSULATION RESISTANCE VALUE TAKEN AFTER THE DIELECTRIC TEST

CIRCUITI DI POTENZA = 19,2 GΩ *point 4.3 FAT Proc*
POWER CIRCUIT

BEFORE TEST	AFTER TEST
L1= 9,43 GΩ	L1= 28,7 GΩ
L2= 17,4 GΩ	L2= 26,8 GΩ
L3= 15,3 GΩ	L3= 19,2 GΩ

CIRCUITI AUSILIARI 24 Vdc= >500 MΩ; 110Vdc = 208 MΩ; 230Vac= >500 MΩ *point 4.4 FAT Proc*
AUXILIARY CIRCUITS

BEFORE TEST	AFTER TEST
24 Vdc= 498 MΩ	24 Vdc= >500 MΩ
110 Vdc= 225 MΩ	110 Vdc= 208 MΩ
230 Vac= >500 MΩ	230 Vac= >500 MΩ

2.5.2.2. Circuit Breakers & Contactors Test Reports

ABB SPA - POWER PRODUCTS DIVISION
Via Vittorio Pisani , 16 - 20124 Milano

CONFIRMATION	1240093780	**ITEM**	13900
CUSTOMER	I.M.E.S.A. SPA		
CUSTOMER ORDER	890	**QUANTITY**	1

VACUUM - CIRCUIT BREAKER

TYPE	VD4/P 12.06.25
SERIAL NUMBER	1VC1CE00021446

RATINGS

Rated Voltage	**Ur**	**12**	**KV**
Rated insulation Voltage	**Us**	**12**	**KV**
Withstand voltage at 50 HZ - 1 min	**Ud**	**28**	**KV**
Impulse Withstand voltage	**Up**	**75**	**KV**
Rated frequency	**Fr**	**50/60**	**Hz**
Rated Normal current (40°C)	**Ir**	**630**	**A**
Rated breaking capacity	**Isc**	**25**	**KA**
Rated short time withstands current (3s)	**Ik**	**25**	**KA**
Making capacity	**Ip**	**63**	**KA**
Operation sequence		**O-0,3S-CO-15S-CO**	

Accessories C.B.

Spring charging geared motor	**(-MAS)**	**110**	**V**	**AC**
Shunt opening release	**(-MBO1)**	**110**	**V**	**DC**
Add shunt opening release	**(-MBO2)**		**V**	
Opening solenoid	**(-MBO3)**		**V**	
Shunt closing release	**(-MBC)**	**110...127**	**V**	**AC/DC**
Undervoltage release	**(-MBU)**	**110...127**	**V**	**AC/DC**
Locking magnet	**(-RLE1)**	**110...127**	**V**	**AC/DC**
Add shunt opening release	**(-MBO4)**		**V**	

Accessories On Truck

Locking magnet	**(-RLE2)**	**110**	**V**	**DC**
Motor moving truck	**(-MAT)**		**V**	

Individual tests according to IEC 62271-100

Design and visual check	**OK**

Mechanical and electrical operating tests				
5 O/C operations at rated supply Voltage	**5 O/C operations at max. supply Voltage**	**5 O/C operations at min. supply Voltage**	**5 O/C operating cycles with -MC energized**	**5 sequences O-t-C**
OK	**OK**	**OK**	**OK**	**OK**

Power frequency voltage withstand test

Main circuits	28	**KV applied for 1 min**
Auxiliary circuits	1	**KV applied for 1 sec**

Voltage drop test with 200A DC

	R	**S**	**T**	
Drop Voltage Measured (mV)	**4.8**	**4.7**	**4.8**	**Max 6,7 mV**

Contact speed measured

Closing speed	1.08	**Range 0,9 - 1,2 m/sec**
Opening speed	1.21	**Range 1 - 1,3 m/sec**
Main contacts simultaneity check	0.20	Max 2 ms
Direct Envelope Comparison	**OK**	**Max +/- 2mm from the standard**

Operating time at rated voltage applied

	Min. Vn	**Vn**	**Max Vn**	**Range Vn**
Closing Time	52	50	48	**35 - 60 ms**
Opening Time	64	37	35	**33 - 60 ms**

The circuit breaker has passed the tests

Department	**Date**	**Quality Result**
OAQ	20240430	**Passed**

DESIGN AND VISUAL CHECKS

THE COMPLIANCE WITH THE ORDER SPECIFICATION AND THE RELEVANT STANDARDS WAS CHECKED.
NO DEFECTS IN MATERIAL, TREATMENT AND WORKMANSHIP WERE VERIFIED.

MECHANICAL WORKING

THE MECHANICAL WORKING OF THE APPARATUS WAS CHECKED BY CARRING OUT SUCCESSIVELY N. 5 INSERTION AND DRAWOUT OPERATIONS OF THE BREAKER.
DURING THESE OPERATIONS,THE INTERLOCKS WERE CHECKED MAKING 5 ATTEMPTS TO PERFORM THE OPERATION INTENDED TO BE PREVENTED.

SERIAL NUMBER
1VC1CE00020058

DESIGN AND VISUAL CHECKS

THE COMPLIANCE WITH THE ORDER SPECIFICATION AND THE RELEVANT STANDARDS WAS CHECKED.
NO DEFECTS IN MATERIAL, TREATMENT AND WORKMANSHIP WERE VERIFIED.

MECHANICAL WORKING

THE MECHANICAL WORKING OF THE APPARATUS WAS CHECKED BY CARRING OUT SUCCESSIVELY N. 5 INSERTION AND DRAWOUT OPERATIONS OF THE BREAKER.
DURING THESE OPERATIONS,THE INTERLOCKS WERE CHECKED MAKING 5 ATTEMPTS TO PERFORM THE OPERATION INTENDED TO BE PREVENTED.

2.5.2.3. Protection Relays Test Reports

ROUTINE TEST REPORT

Product type: REX640
Date tested: 10.05.2024
Serial No: 1VHR81041854
Order No: REX640_1AC2
Rated frequency: 50/60 Hz

This is to certify that the product above has been tested in accordance with the applicable procedures of ABB Oy during production.

The tests performed on the product were:

1. Insulation tests including
   - Dielectric test for binary/analog input module and power supply module at 2,2kV, 50 Hz, 1sec (IEC 60255-5 and IEC 60255-27) — PASSED
   - Dielectric test for communication module at 0,55kV, 50 Hz, 1sec (IEC 60255-5 and IEC 60255-27) — PASSED

2. Final product testing including the relevant tests depending on the hardware composition:
   - Visual inspection — PASSED
   - Current consumption test — PASSED
   - Communication interfaces — PASSED
   - Binary inputs and binary outputs — PASSED
   - Analog inputs — PASSED

3. Product test run
   - Minimum 12h test run in heat cabinet in 55 degree Celsius — PASSED

At the time of shipment the product was in conformance to the specified requirements of the manufacturer.

ROUTINE TEST REPORT

Product type: 2RCA033008A0001V
Date tested: 16.05.2024
Serial No: 1VHR51024466

This is to certify that the product above has been tested in accordance with the applicable procedures of ABB Oy during production.

The tests performed on the product were:

1. Insulation tests including
   Dielectric test for power supply module at 2,2kV, 50 Hz, 1sec (IEC 60255-5 and IEC 60255-27) PASSED

   Dielectric test for communication module at 0,5kV, 50 Hz, 1sec (IEC 60255-5 and IEC 60255-27) PASSED

2. Final product testing including the relevant tests:
   Visual inspection PASSED
   Current consumption test PASSED
   Touch screen PASSED
   HOME-button with LEDs PASSED
   Communication interfaces PASSED

At the time of shipment the product was in conformance to the specified requirements of the manufacturer.
