1 INTRODUCTION

1.1 PROJECT OVERVIEW

Crosswind, a Shell and Eneco joint venture, was awarded the tender to develop the offshore Hollandse Kust Noord (HKN) wind farm, located 18.5km off the coast of Netherlands near the town of Egmond aan Zee. The consortium plans to have HKN operational in 2023 with an installed capacity of 759MW generating at least 3.3TWh per year. This is sufficient renewable power to supply more than 1 million Dutch households with green electricity.

Offshore wind farms produce intermittent electricity and balancing these dips and peaks and integrating this electricity into the national energy system requires new technologies. For this reason, the offshore wind farm will include several new technologies that could be implemented at full-scale in the future. The new technologies being explored include a floating solar park, a short-duration battery storage as well as long-term storage via green hydrogen produced by water electrolysis and subsequently consumed in a fuel cell. The combination of these individual measures, herein referred to as the Base Load Power Hub (BLPH) will ensure a continuous power supply regardless of the wind situation.

1.1.1 Project Location

The Hollandse Kust Noord (HKN) wind farm is located 18.5km off the coast of the Netherlands near the town of Egmond aan Zee.

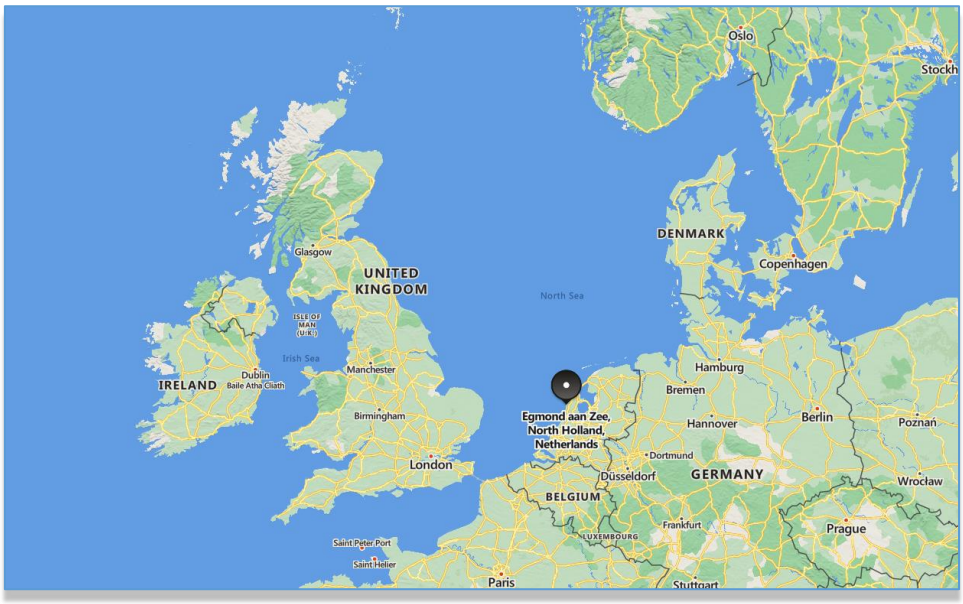

Figure 1 HOLLANDSE KUST NOORD WIND PARK Location Map

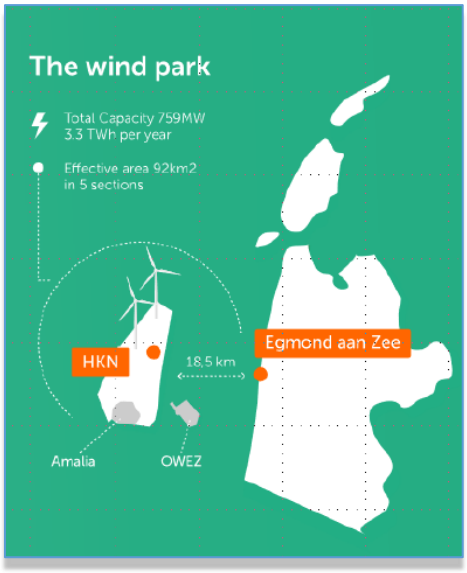

Figure 2 - Wind Park Details

The wind farm will consist of No. 69 x 11.5MW wind turbine generators each to be installed on a dedicated monopile structure. A 70th monopile located on coordinates E 590719.1, N 5841602.3 is reserved for installing the platform accommodating the BLPH. The monopile structure was designed and installed by Van Oord Offshore Wind (VooW) and therefore not part of the BLPH scope.

1.1.2 Project Concept

All components included in the BLPH will be integrated onshore on a topsides and installed in an offshore location within the boundaries of the HKN wind farm. At its simplest, the BLPH will store energy during periods of high electricity generation from renewable sources (a wind turbine generator and the floating solar PV farm) and release it during periods of low generation. In practice. It is expected that the energy stored will supplement generation from renewable sources to ensure that at least 1.0MW of power is exported to the electrical grid regardless of wind/solar availability.

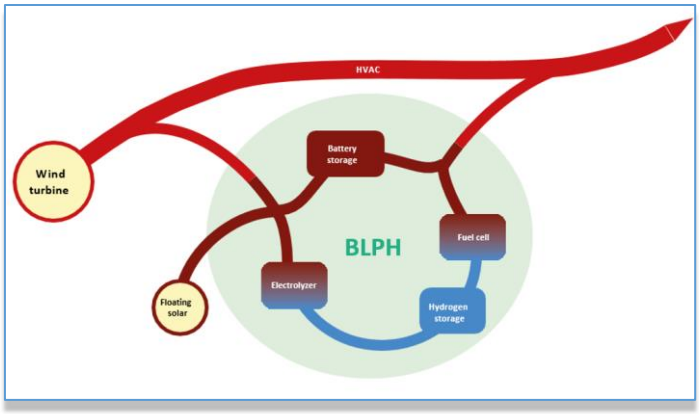

Figure 3 – BLPH Concept

Electricity in the BLPH will be stored in the form of electrons in a battery energy storage system (BESS) as well as converted into green hydrogen via water electrolysis. When the power output from the connecting wind turbine drops to below 1 MWe, the BLPH will return its stored energy to supplement the remaining power output. This will be by discharging the BESS, while stored hydrogen will be converted back into electricity using a fuel cell to extend the discharge duration.

The purpose of the BLPH s to function as a testbed for the integration of energy storage technologies with renewable generation. It is expected that equipment installed on the BLPH will operate as Normally Unmanned Installation for at least two (2) years with no or minimal maintenance and it will have its own independent control room with the ability to communicate with Crosswind's control room.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

2 DOCUMENT SCOPE

The purpose of this document is to provide essential Instructions for Operation and Maintenance (IOM) of Yokogawa PCS based on Centum VP and CI Server which will be used as operation and Monitoring of BLPH - Hollandse Kust Noor Wind Park Project.

The following subjects are covered under this document:

- Instructions for operations
- Instructions for maintenance
- Instructions for proof testing
- Instructions for troubleshooting

Note that this document is not meant to supplant the actual Operations and Maintenance Procedure of the facility. It serves only as a guideline to highlight the salient points to be considered in the development of the Operations and Maintenance Procedure which falls under the authority of the Employer

3 GENERAL INSTRUCTIONS

This section describes the general instructions for operation and maintenance of the Process Control System supplied for the HOLLANDSE KUST NOORD WIND PART Project (BLPH).

- "Operations" involve guidelines for the user to evolve procedures for normal operations of the plant and systems. This includes Operation and Monitoring. Refer Sec.4 of this document for more information.
- The "Maintenance" activities can be classified as Preventive Maintenance and Corrective Maintenance.
  - Within Preventive Maintenance, one can distinguish the actions that can be done without disturbing the process (without restrictions), so called "First line Maintenance" and maintenance that will certainly disturb the process or bear a great risk to do so, called "Shutdown Maintenance". Refer Sec.5 of this document for more information.
  - Corrective Maintenance implies the replacement of the defective part, which failed and/or caused a nuisance trip. Due to the unpredictable nature of this type of maintenance this document does not cover this in great depth, but to aid with corrective maintenance a section Troubleshooting has been introduced.
- It is the responsibility of the Customer to ensure that the plant Operations and Maintenance Procedure is kept up to date to reflect the actual status of the PCS for all "Modifications" implemented at any given time post-handover.

3.1 SYSTEMS INVOLVED

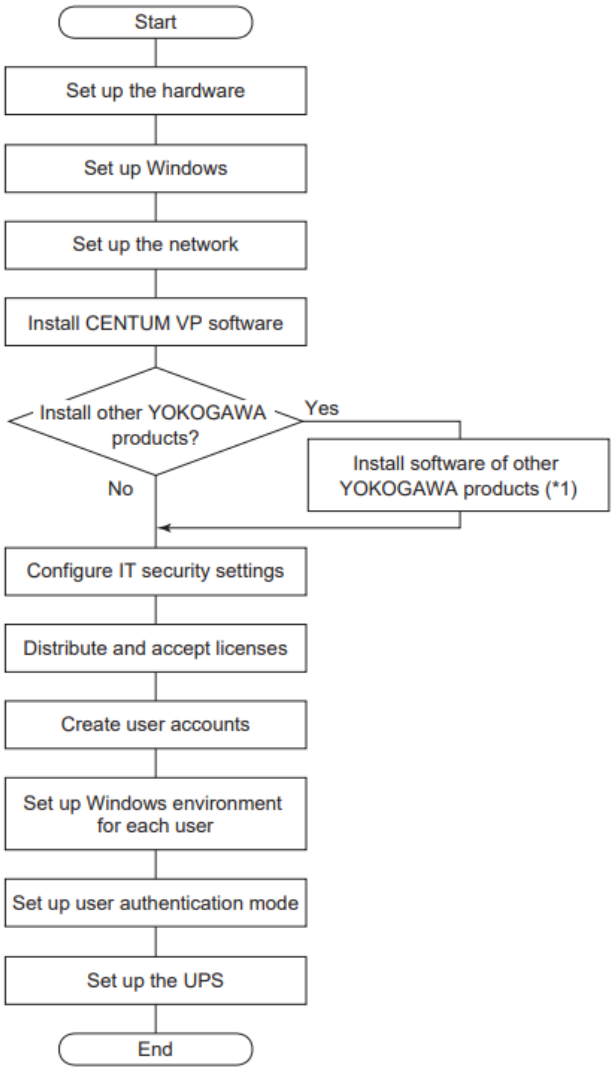
System comprises of the following equipment:

- CentumVP System cabinet
- Associated FIO cabinets
- CentumVP Engineering Workstation (EWS)
- CI Servers
- IAMS

3.2 PREREQUISITES

- It is to be noted that the responsibility to set up the necessary procedures for operation and maintenance rests with the end user.
- The personnel responsible for the operation and maintenance activities must be competent with the system and project documentation.

- It is the responsibility of the maintenance personnel to refer to the appropriate sections in the manual and to read and understand the requirements before performing the actual maintenance activities.
- During maintenance, put up wrist strap for PCS (Electrostatic Discharge) measures (If applicable).



This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

4 INSTALLATION

4.1 CENTUMVP

In order to use CENTUM VP software packages, it is necessary to install the CENTUM VP software on a computer and then grant licenses to the computer to enable the use of the software packages

The following figure shows the setup procedure for a computer installed with only system builders.

*1: You may install other products later. If you install later, you need to configure IT security settings again.

Figure 4 – CentumVP Installation flow chart

Refer IM 33J01C10-01EN CENTUM VP Installation, section B for applicable hardware and software applicable as per BOM

For Hardware Component installation please refer TI33J01J10-01EN CENTUM VP Installation Guidance.

4.2 PROSAFE-RS

In order to use ProSafe-RS software packages, it is necessary to install the ProSafe-RS software on a computer and then grant licenses to the computer to enable the use of the software packages.

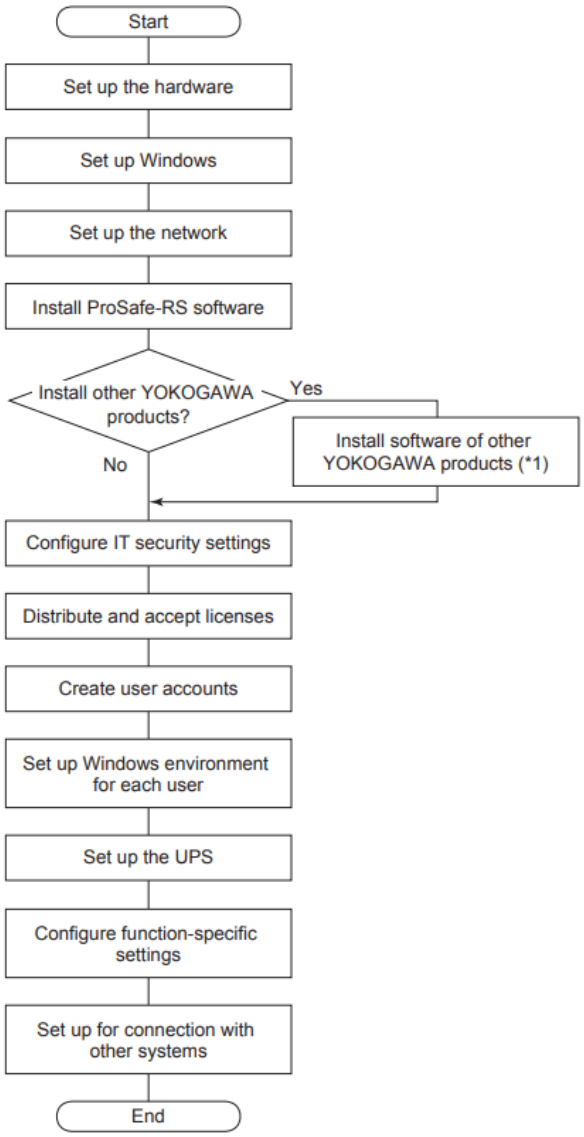


Figure 5 – ProSafe-RS Installation flow chart

Refer IM 32P01C50-01EN Installation Guide, section B for applicable hardware and software applicable as per BOM. CENTUM VP coexists with ProSafe-RS so the name of the PSF_MAINTENANCE group you have created will change to PSF_MAINTENANCE_LCL and add the user to the CTM_MAINTENANCE group.

4.3 IAMS (PLANT RESOURCE MANAGER- PRM)

following media for installing IAMS hereinafter referred to as PRM:

• PRM R4 Software Media (hereinafter referred to as PRM installation media)

There are two discs. Disc 1 contains the following software installers:

- PRM software
- License Manager software
- DeviceViewer for HIS
- Control bus driver
- Vnet/IP open communication driver
- Electronic instruction manuals

Disc 2 contains the InsightSuiteAE Starter Edition installer.

• Device Files Media (hereinafter referred to as Device Files medium) This medium contains YOKOGAWA device DTMs and device files from other manufacturers

PRM R4 License Media (hereinafter referred to as PRM license medium) This medium contains the ordered licenses for PRM software packages, in the form of license key files.

• PLUG-IN Application Media for PRM (hereinafter referred to as PLUG-IN application medium) This medium contains optional PLUG-IN applications.

A PRM station is a computer on which PRM software is installed. The station type determines the PRM packages that can be installed on a computer. Select one of the following PRM station types to install depending on your system requirement:

• PRM Server

• PRM Client

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

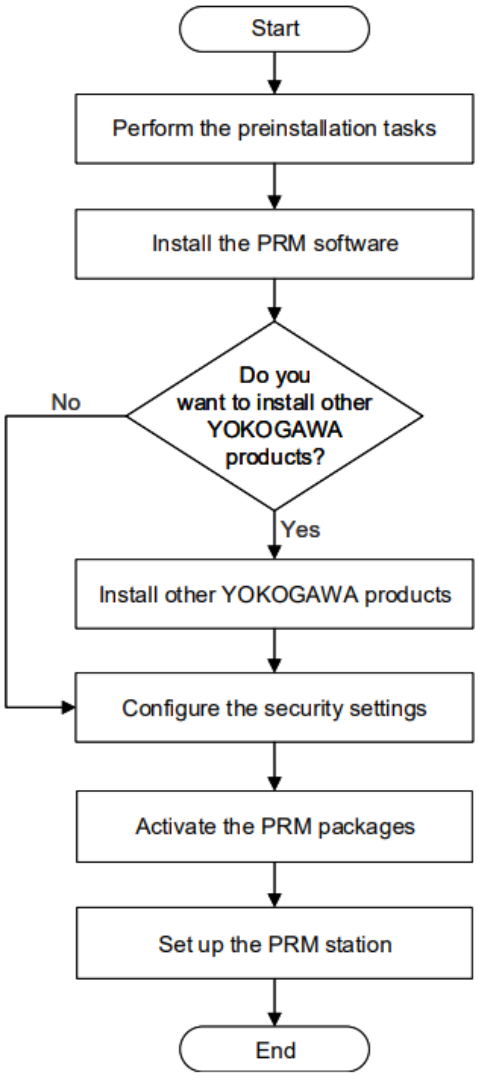

Figure 6 – IAMS(PRM) Installation flow chart

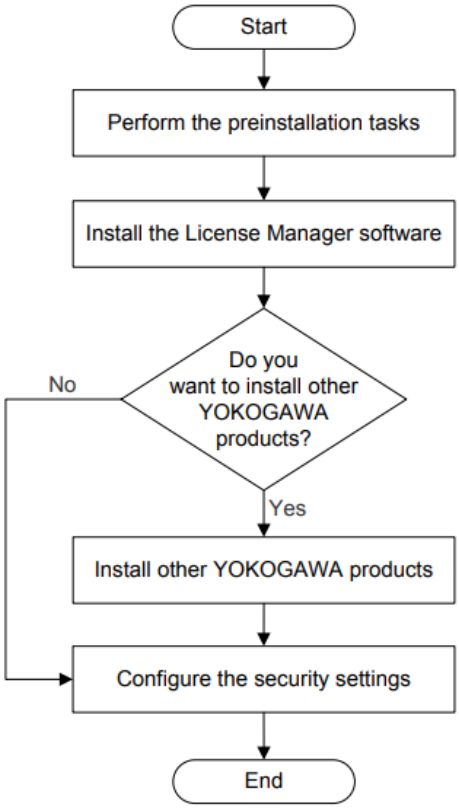

Figure 7 – IAMS License Manager Installation flow chart

Refer IM 30B05A20-01EN Plant Resource Manager Installation, section 6 for applicable hardware and software applicable as per BOM.

4.4 CI CORE/ PORTAL /VIEW

Have the following items at hand before you set up CI Server.

- CI Server software medium
- Activated License File (there is one for each server computer)

The installation is performed by running setup from the CI Server DVD. In setup, all CI Server functions are installed regardless of the type of CI Server package. However, by applying the appropriate license for the CI Server package(Core/Portal), it becomes the configuration suitable for that package.

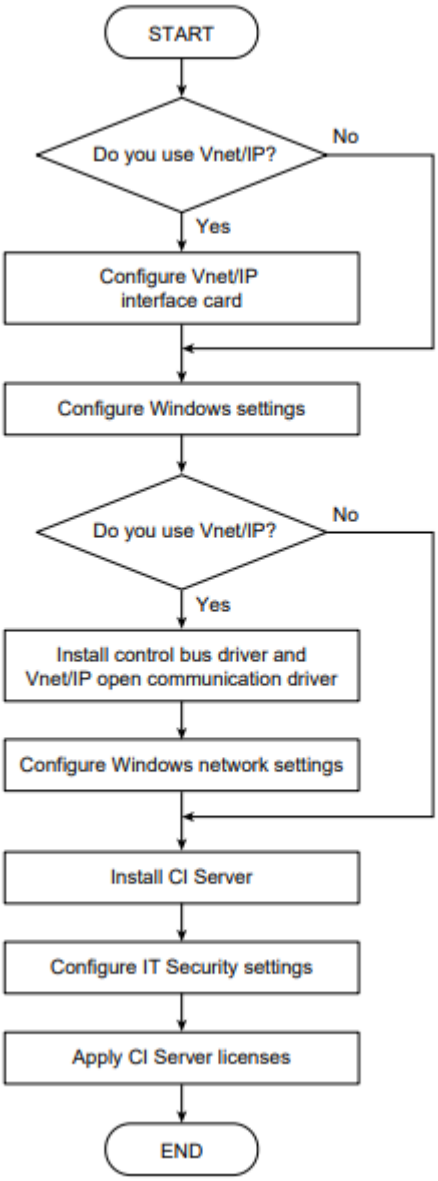

Figure 8 – CI Core/Portal Installation flow chart

Refer IM 36K01C10-01EN CI Server Setup, section 2 for applicable hardware and software applicable as per BOM.

CI View

On CI View (computer prepared as CI View), software called Remote Connect can be used to perform operator interface, edit module, and engineering module as Java applications. To download Remote Connect, open a browser and browse by adding the port number after the IP address of the node running CI Portal (or CI Core and CI Portal) connected to CI View.

Example: http://192.168.1.100:8080/

Thus, even if 8080 is used in the browser, the communication between CI View and CI Portal (server or data gateway) will be secure communication using 8443 port by default.

It can be started by typing:

https://192.168.1.100:8443

Refer IM 36K10R10-01EN CI Portal Setup, section 2.2 for CI view setup.

5 OPERATIONS

Operational requirements are defined by the End-user. Normally this will be included in the overall plant operation procedures and manuals. The following paragraphs will provide brief details on the operating procedures of the PCS. The main functions that are executed by the operator are:

- Power up
- Operator interfaces and system monitoring
- Forcing Analog Values

CentumVP installation guidance (TI 33J01J10-01EN) for the Environmental conditions of supplied products.

5.1 POWER UP

The power supplies that must be available for the system are:

System power supplies:

- PCS : 230 VAC UPS (UPS-1 & UPS-2) with autonomy of 30 min

Utility power supply:

- One 230 VAC 50Hz

The utility power supply will be used to feed the following equipment per cabinet

- Cabinet fans
- Utility sockets
- Cabinet lighting

The starting point for system power up is:

- All power cables connected.
- All field cables connected (If available during the system start-up).
- All grounding cables connected.
- All interface cables to other systems connected (If available during the system start-up).
- All main switches and circuit breakers switched OFF.

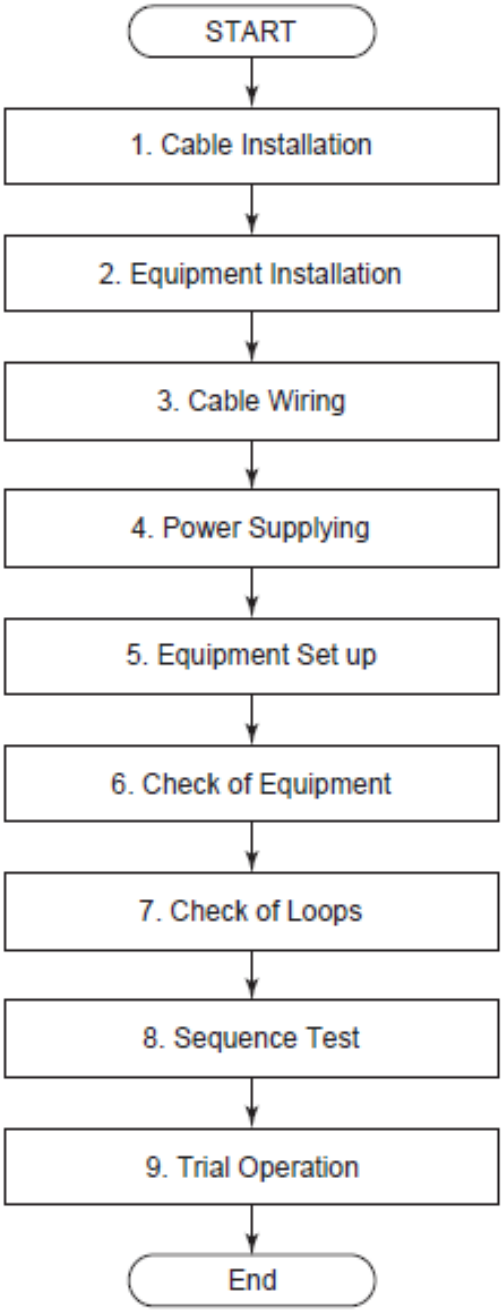

Figure 9 – Start-up

5.2 INTERFACES AND SYSTEM MONITORING

The system provides the following interfaces:

- Critical Action Panel (CAP)
- System status on EWS
- System status on OWS
- LED indications on modules
- IAMS Client
- EWS0164

5.2.1 Critical Action Panel (CAP)

A Critical Action Panel (CAP) shall be software-based control located at CCR for PCS and SIS, FGS. A dedicated tower type PC and screen with installed CI view/License software shall be used to control the action push buttons and monitor the trip status information.

5.2.2 System Status on OWS

NMS (Network Management System) shall be accessible from OWS to monitor all Computers and network switches and firewall status.

CI Core Server, CI portal Server redundancy Status can be monitored from OWS.

For More details refer PCS and SAFETY SISTEMS Software Functional Design Specification (FDS-SW).

5.2.3 System Status on EWS

The FCS Status Overview window displays a list of FCSs assigned to the given CentumVP project. In addition to the current operating conditions of FCSs, it also displays if there is any diagnostic information message from any of the FCS diagnostic functions; it is easy to know which FCS has errors.

If there is an error, the erroneous area is shown using a different colour. It also displays whether there are any messages that have not been acknowledged.

The System Status Overview window display the operating mode, scans period and security level along with the operating status and connection status of CPU and I/O modules.

The System Alarm window displays a list of diagnostic information messages that notify hardware, software, and communication errors in the system as system alarm messages.

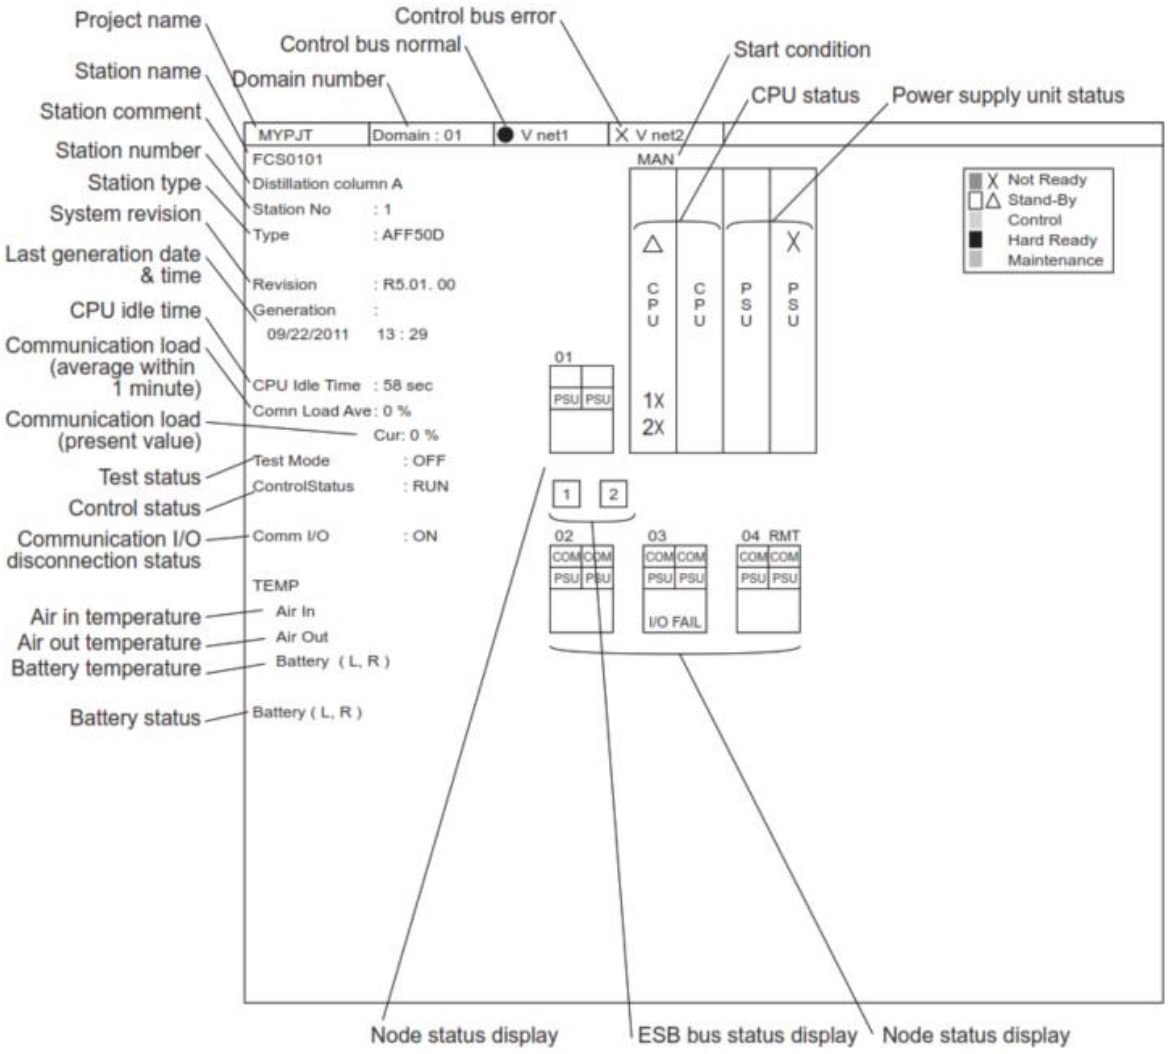

Figure 10 – System Status on OWS

5.2.4 LED Indication on modules

For health status of module, the following LEDs will be lit:

- Node Power Supplies – SYS and FLD

SYS- Power supply module +5V

FLD- Power supply module +24V

- Active Controller – SYNC, HRDY, RDY, COPY, RCV1,2 , SND1,2 and CTRL

SYNC- Synchronizing with external clock.

HRDY- Hardware normal

RDY- Both hardware and software are normal.

COPY- Copying normal

RCV1,2- Receiving frames from Vnet/IP

SND1,2- Sending frames from Vnet/IP

CTRL- Module is operating normally

- Standby Controller – SYNC, HRDY and RDY
- Active I/O Module – STATUS, ACT and DX

STATUS- This LED turns on when the module is operating normally

ACT- This LED turns on when the module is in the controlling status

DX- This LED turns on when the module is in the dual-redundant configuration

- Standby I/O Module – STATUS and DX

5.3 SYSTEM ACCESS

This chapter gives an overview of Authorisation levels, how to log in and how to log out.

Authorisation levels

The following authorisation groups are defined and used within the system:

- View
- Operator
- Supervisor
- Administrator

Each user can be assigned to one of these groups. Table 3 shows the privileges within each authorisation group:

System function	Authorisation levels			
	View	Operator	Supervisor	Administrator
Display variables	X	X	X	X
Change setpoints	-	X	X	X
Acknowledge alarms	-	X	X	X
Modify tuning panel settings (e.g. alarm limits)	-	-	X	X
Modify database (e.g. passwords)	-	-	-	X
Modify/add displays	-	-	-	X

Table 3 – Authorisation levels

5.3.1 Log in / log out

Access to the SCADA system is granted manually. After the workstation is started, the user needs to logon into the Windows Domain environment.

This section describes the procedure to open the Operator Interface from an Operator WorkStation (OWS).

Double click the "Operator Interface" icon located on the desktop.

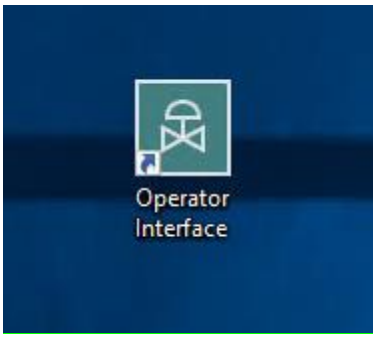

Figure 11 – Operator Interface icon

The login screen of CI SERVER will pop up as indicated in Figure 12 – Operator Interface Login Window

The username and password should be entered here to open the "Operator Interface" which provides access to the process displays.

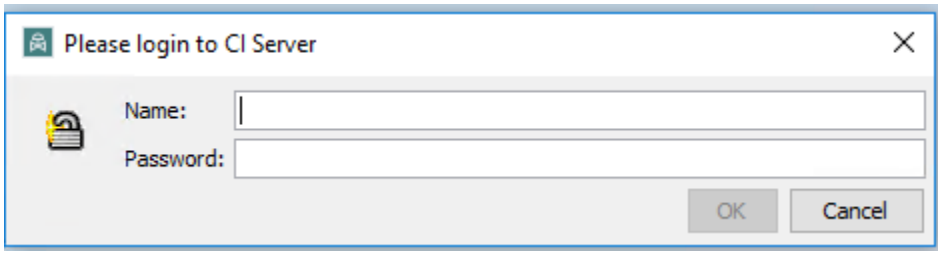

Figure 12 – Operator Interface Login Window

To exit, Select from the File menu, Exit in the Operator Interface.

Active Directory shall be used for login/logout user configurations. The AD integration function of CI Server has priority over the logon method (Login method) configured for each application using the following Authentication and authorization setup file (dssana.sup).

5.3.2 Operator interface

This chapter gives information on the Operator Interface, displays, navigation, menu, etc.

Operator Interface Layout

This section describes the layout and the functionality of the Operator Interface.

Figure 13 – Operator Interface Layout

Windows heading

This is the default windows heading area which allows the operator to minimise or relocate the Operator Interface.

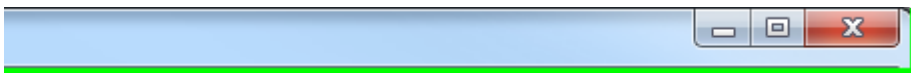

Figure 14 – Windows heading

Menu area

The menu area gives a number of options to the operator, like printing, zoom functions etc. Table 4 describes the available menu options.

Menu item	Sub menu item	Description
File		
	Select Print Area	Select a frame to print
	Print	Print the selected frames
	Page Setup	Page setup for printing
	Print Preview	Print preview
	Login	Log on as temporary user
	Logout	Log off as temporary user
	Exit	Exit the Operator Interface
View		
	Reload	Refresh the current mimic
	Reload All	Refresh all mimics
	Toolbars	Turn the toolbar on or off
	Status Line	Turn the status line on or off
Zoom		
	Zoom In	Zoom in to the mimic
	Zoom Out	Zoom out of the mimic
	Reset	Reset to original mimic size
	Fit	Fit the mimic in the frame
Go		
	Back	Previous Page
	Forward	Page Forward
	Up	The parent page of a mimic (if defined in the mimic)
	Home	Main Page
Playback		
	Record	Start recording the display actions
	Open viewer	Open the recorded item

Table 4 – Menu area

Figure 15 – Menu area

Mouse operation

This chapter describes the operation of the mouse for the operator workstation.

Mouse buttons

Mouse button 1: Select/action
Mouse button 2: Call special information pop-up

Scroll Wheel usage

CTRL + scroll Up: zoom in (only available for Process Area Display)
CTRL + scroll Down: zoom out (only available for Process Area Display)

Toolbar area

The Toolbar area provides shortcuts to a number of functionalities. Table 5 describes the available functionalities.

Figure 16 – Toolbar Area

Item	Description
1	Go to current alarm list
2	Go to shelves alarm list
3	Go to historical alarm list
4	Go to system alarm list
5	Back to display
6	Forward to display
7	Go to parent display
8	Go to home screen
9	Reload display
10	Display name
11	Zoom in
12	Zoom out
13	Reset to actual size
14	Fit the size of display to process display area
15	User login
16	Go to trending
17	Print

Table 5 – Toolbar area

Navigation area

The navigation area provides shortcuts to process displays. The display navigation is explained in Figure 22.

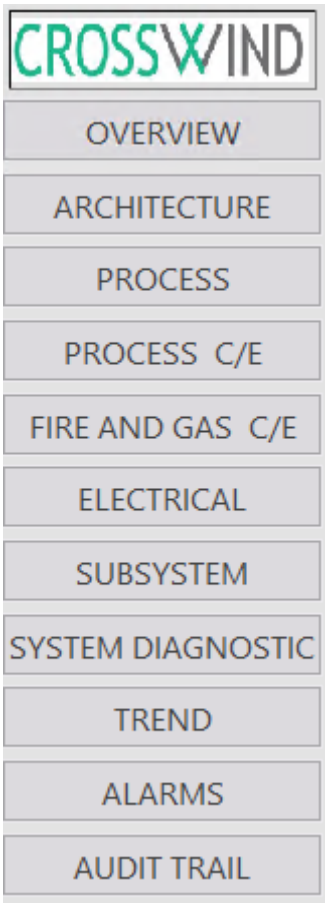

Figure 17 – Navigation area

Process display area

In this area all the process mimics are displayed. Displays can be selected from both toolbar area and navigation area, and are opened in this frame.

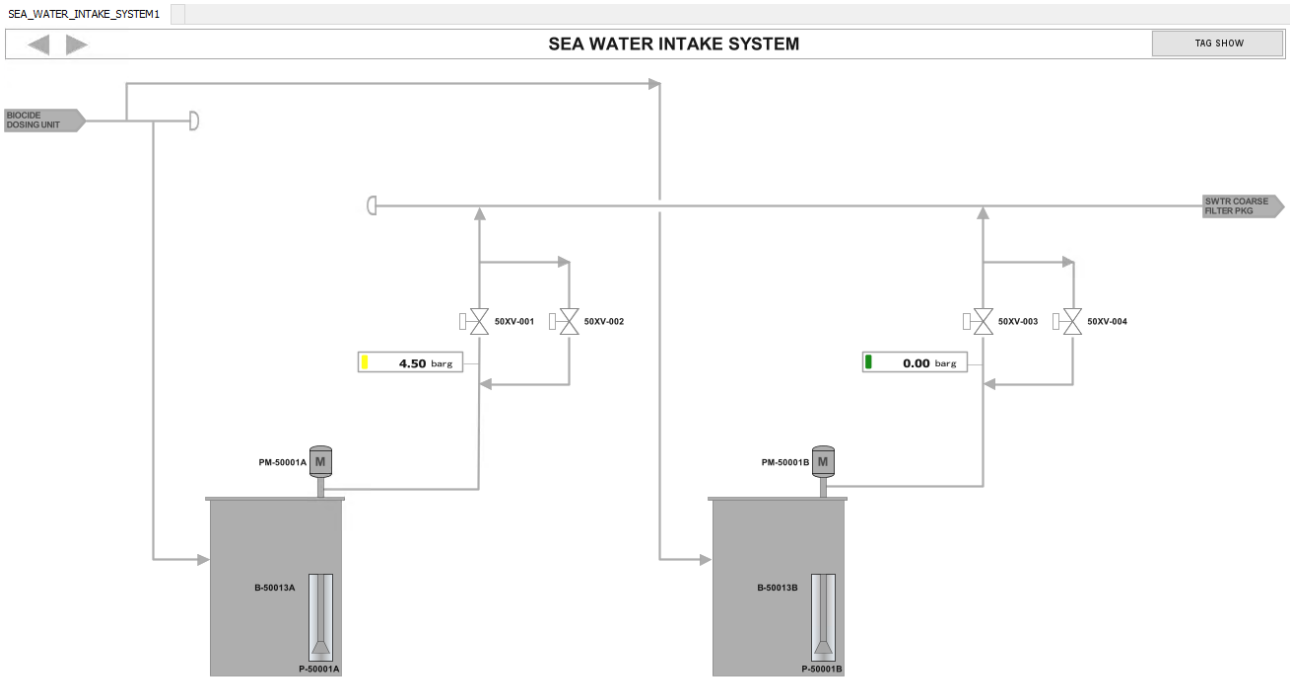

Figure 18 –Process display area

A display is opened in a tab. By clicking in the area besides the most right tab and then selecting a display to open, it will open in a new tab. Maximum 5 tabs are available.

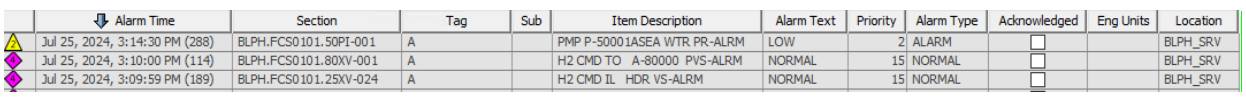

Figure 19 – Opening multiple displays by using tabs

Alarm banner

The alarm banner is located below the Process display area, it is non-removable. The newest outstanding alarms are sorted on the top of this alarm page to highlight the alarms to the operator. Once an alarm is noted, the operator can decide to navigate to the full-scale current alarm page as described in section 5.3.3 Current Alarm overview.

Alarm Time	Section	Tag	Sub	Item Description	Alarm Text	Priority	Alarm Type	Acknowledged	Eng Units	Location
Jul 25, 2024, 3:14:30 PM (288)	BLPH.FCS0101.50PI-001	A		PMP P-50001ASEA WTR PR-ALRM	LOW	2	ALARM			BLPH_SRV
Jul 25, 2024, 3:10:00 PM (114)	BLPH.FCS0101.80XV-001	A		H2 CMD TO A-80000 PVS-ALRM	NORMAL	15	NORMAL			BLPH_SRV
Jul 25, 2024, 3:09:59 PM (189)	BLPH.FCS0101.25XV-024	A		H2 CMD IL HDR VS-ALRM	NORMAL	15	NORMAL			BLPH_SRV

Figure 20 – Alarm banner

Status line

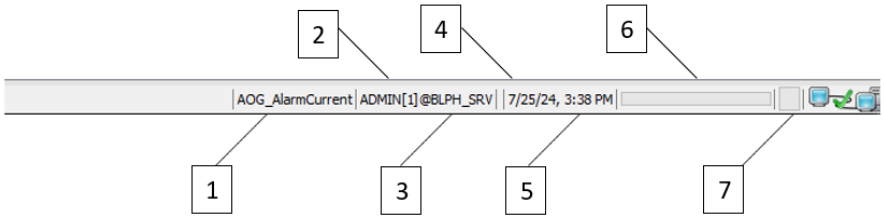

Figure 21 – Status line

Item	Description
1	File Name of the current display presented in the process display area
2	Username of the current loge in user
3	Node number of the licensed station
4	Date (layout depending on regional settings)
5	Time (layout depending on regional settings)
6	Graphics Queue Level
7	Connection State between the Workstation and the main server

Table 6 – Status line

Display navigation

The navigation of the process graphics is arranged hierarchically in a top-down structure. Once a detailed graphic is opened, it is always possible to navigate to a parent display or, if applicable, to a more detailed graphic. Figure 22 displays the navigation philosophy of the process graphics.

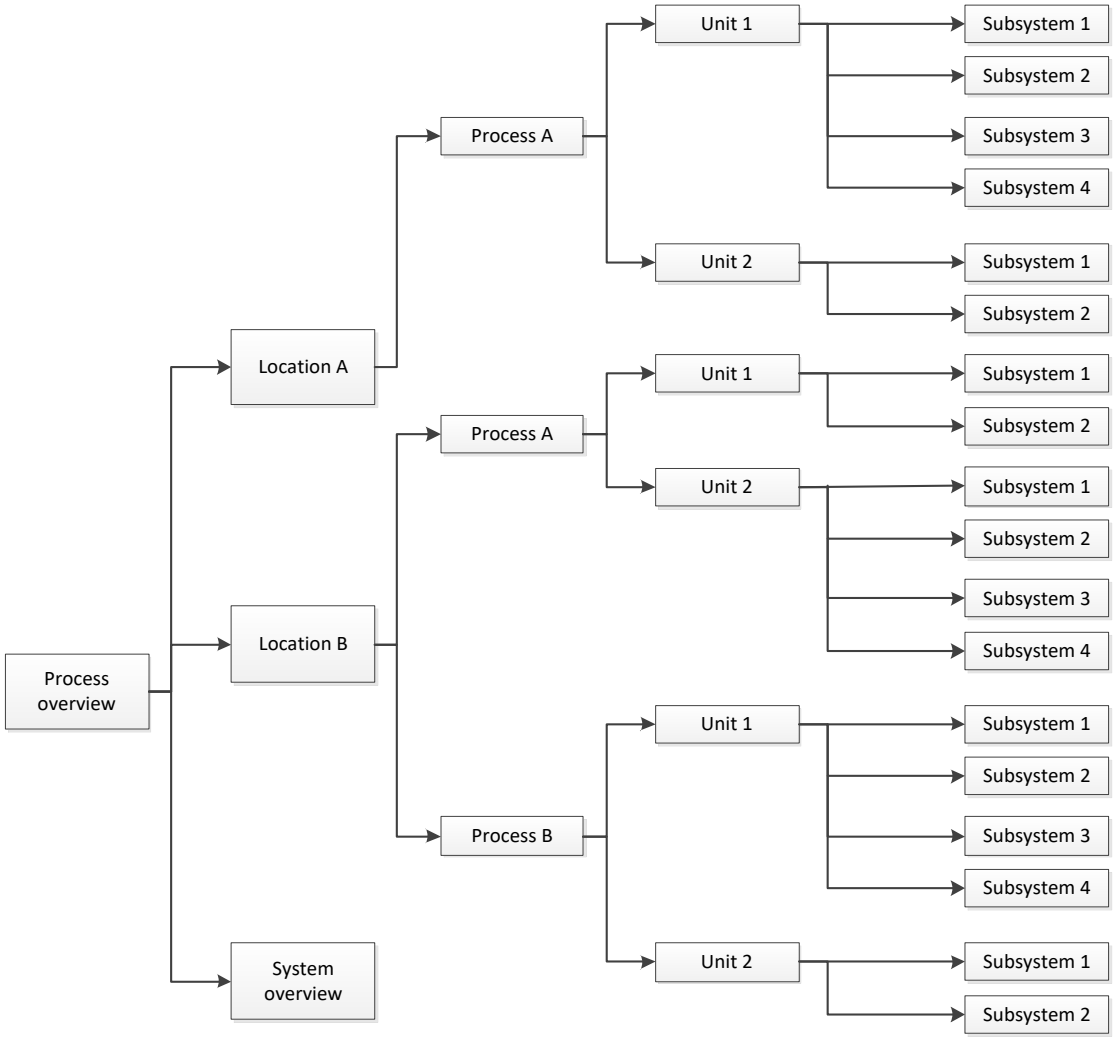

Figure 22 – Display navigation Philosophy

5.3.3 Key displays

Current Alarm overview

The current alarm overview displays the outstanding alarms.

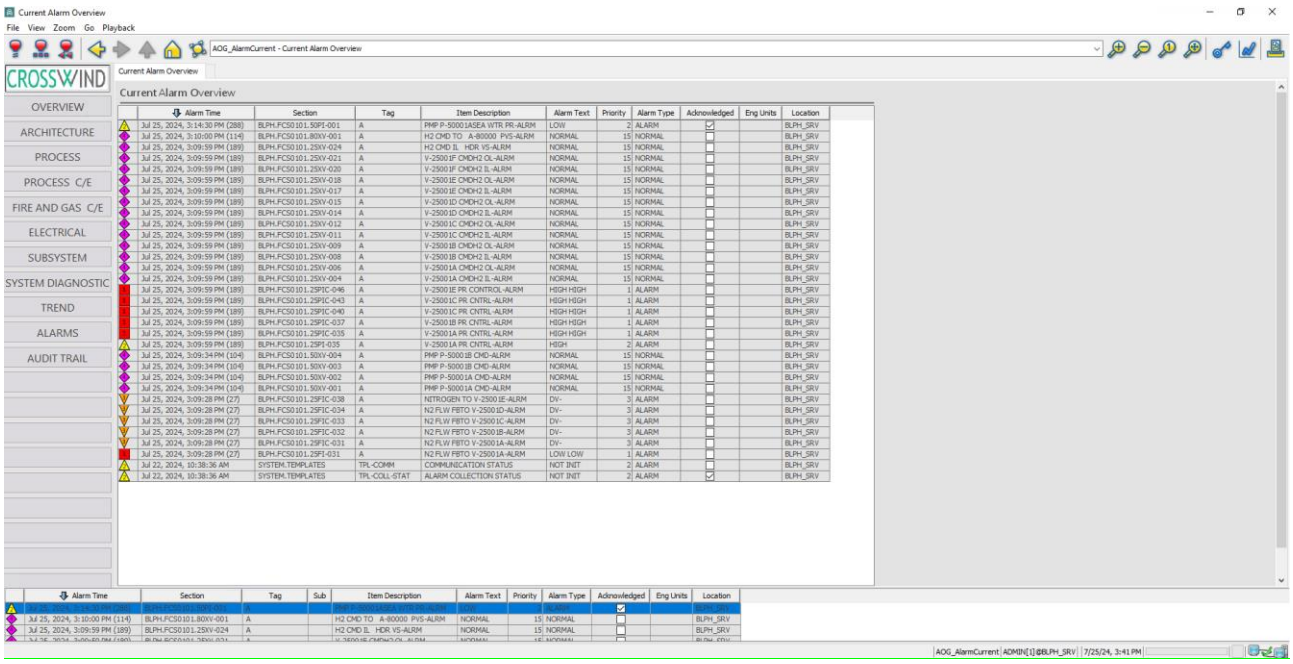

Figure 23 – Current alarm overview

Acknowledgement

Whenever an acknowledgment is required, the alarm message will be displayed on the screen blinking.

Some alarms are automatically acknowledged by the system. E.g. when a tag has an acknowledged High-High alarm and falls down to the High alarm status, it is automatically acknowledged and no (new) operator interference is required.

Alarm filters

This section describes the available filter functions for an operator.

By default there is no filter activated for the alarm displays and alarms are listed in the alarm display. However the operator has the possibility to filter out specific alarms using the filter options in the right bottom area of the alarm page.

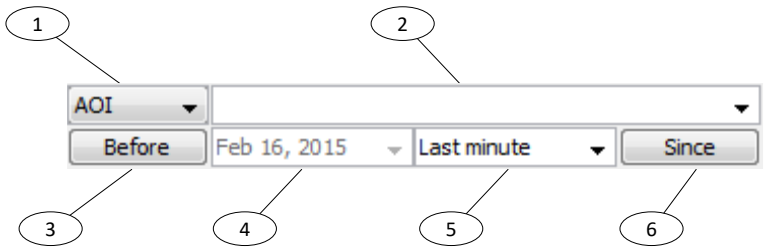

Figure 24 – Alarm filters

Table 7 Description of the alarm filter

Menu item	Available options	Description
1: type of filter		
	None	No filter is selected, default
	AOI	Filter on Area of Interest
	ASA	Filter on Alarm Selection Area
	Installation	Filter on installation name of tags
	Unit	Filter on unit name of tags
	Section	Filter on section name of the tags
	Tag	Filter on a specific tag
2: filter options		
	Dropdown menu	Based on type of filter the available options can be chosen by a dropdown menu.
	Text entry	Text can be entered for a matching filter
3: fetch data before chosen date		
	Single mouse click	Will fetch data before the chosen date and time
4: date picker		

Menu item	Available options	Description
	Single mouse click	Will activate a date picker to select the date
5: time picker		
	Single mouse click	Will activate a time picker to select the time
6: fetch data since chosen date		
	Single mouse click	Will fetch data after the chosen date and time

Table 7 – Alarm filters

Further note that column filtering is available on each column in the alarm overview.

Available Mouse Actions in Alarm grid

With the mouse, a number of actions can be executed on an individual alarm line. With a left mouse button click an individual alarm can be acknowledged. With a right mouse button click an Example of context menu appears as shown below.

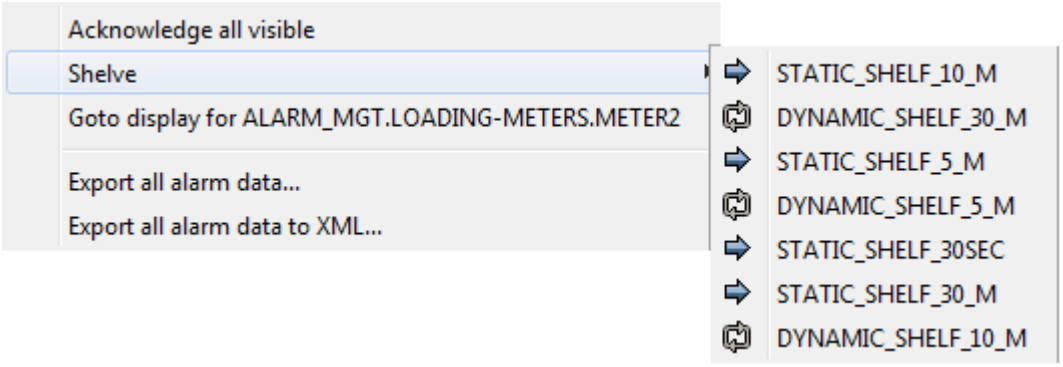

Figure 25 – Right mouse button activated (example)context menu actions

The function of each is explained below.

Action	Object	Result
Left mouse click		
	Individual alarm line	Acknowledge alarm
Right mouse click		
Acknowledge all visible	Current alarm page	Acknowledge all visible alarms
Shelve Static	Individual alarm line	Place alarm on static shelf

Action	Object	Result
Shelve Dynamic	Individual alarm line	Place alarm on dynamic shelf
Goto display for …	Individual alarm line	Go to display which has this alarm
Export all alarm data…	Current alarm page	Export alarms to csv file
Export all alarm data to XML	Current alarm page	Export alarms to XML file

Table 8 – Actions

For alarm shelving two types exist, dynamic and static shelving. For each a number of different time periods have been predefined. When an operator selects to shelve an alarm, the alarm is removed from this alarm overview. However, the alarm is still active and can be viewed from the Shelved alarm overview. For more on alarm shelving, please refer to section on Shelved alarm overview.

Historical alarm overview

The historical alarm overview shows all past occurred alarms. Functionality wise it is very similar to the Current alarm overview. However, there are 2 differences:

- Alarms cannot be acknowledged in the historical alarm overview
- Alarms cannot be shelved in the historical alarm overview.

Shelved alarm overview

In some cases, the number of alarms might be high, and a number of these alarms might not be important to monitor for the time being. For example, a particular plant area is in maintenance, causing many alarms, which are irrelevant as it is currently not in operation. In such a case these alarms can be placed on a 'shelve'. This will remove them from the current alarm overview. The alarms can be viewed from the Shelved alarm overview instead.

There are two types of shelving:

- Static: In this case the operator shelves an alarm. If the status of the alarm changes, it is automatically placed back in the Current alarm overview. If the same state happens again while the time period has not yet expired the alarm is not shelved automatically again.
- Dynamic: In this case the operator shelves an alarm. If the status of the alarm changes, it is automatically placed back in the Current alarm overview. If the same state happens again while the time period has not yet expired the alarm is shelved automatically again.

Shelving is always for a predefined time period. The time period is selected when shelving an alarm.

For Filtering and Exporting functions, please refer to previous paragraphs.

5.3.4 Critical system alarms

The following alarms shall be categorised as critical System alarms.

- Alarm indicating unavailability of emergency systems e.g. firewater pumps.
- Alarm indicating loss of temporary refuge pressurisation.
- Alarm indicating control or protective systems running on batteries.
- Alarm indicating low instrument air pressure to a site or unit.
- Alarm indicating dangerous SIF failure e.g. partial stroke test failure, SIF instrument failure diagnostic.
- Alarm indicating unavailability or failure of F&G detector e.g. beam block alarm on line-of-sight gas detector.
- Alarm indicating bad PV on BPCS layer of protection.
- Alarm indicating degraded redundancy in an SIS or F&G logic solver.
- Others as deemed appropriate by alarm class owners.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

5.3.5 Trending

The Trend is a utility which renders historical and real time values for one up to 20 items, in a single graph. Following interfaces is available for viewing trends:

- From the Operator Interface, by pressing trend button which opens a display with the trend module, here the module is integrated on a graphic page.

Adding an item to trend

In the pen-panel (the area at the bottom of the application main frame), click on the 3 dotted buttons as shown in the picture below. If the pen panel is not shown at start-up, click on the small fountain pen icon in the top menu bar.

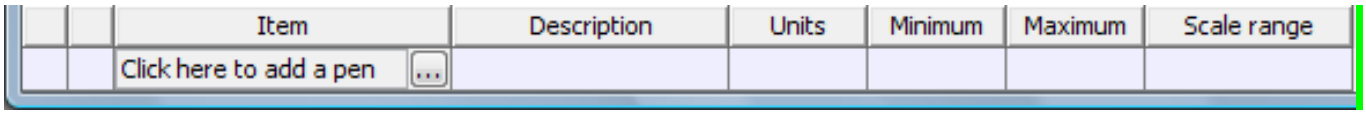

Figure 26 – Pen Panel

Now you will be able to select and add the data points (items) you want to see in the trend.

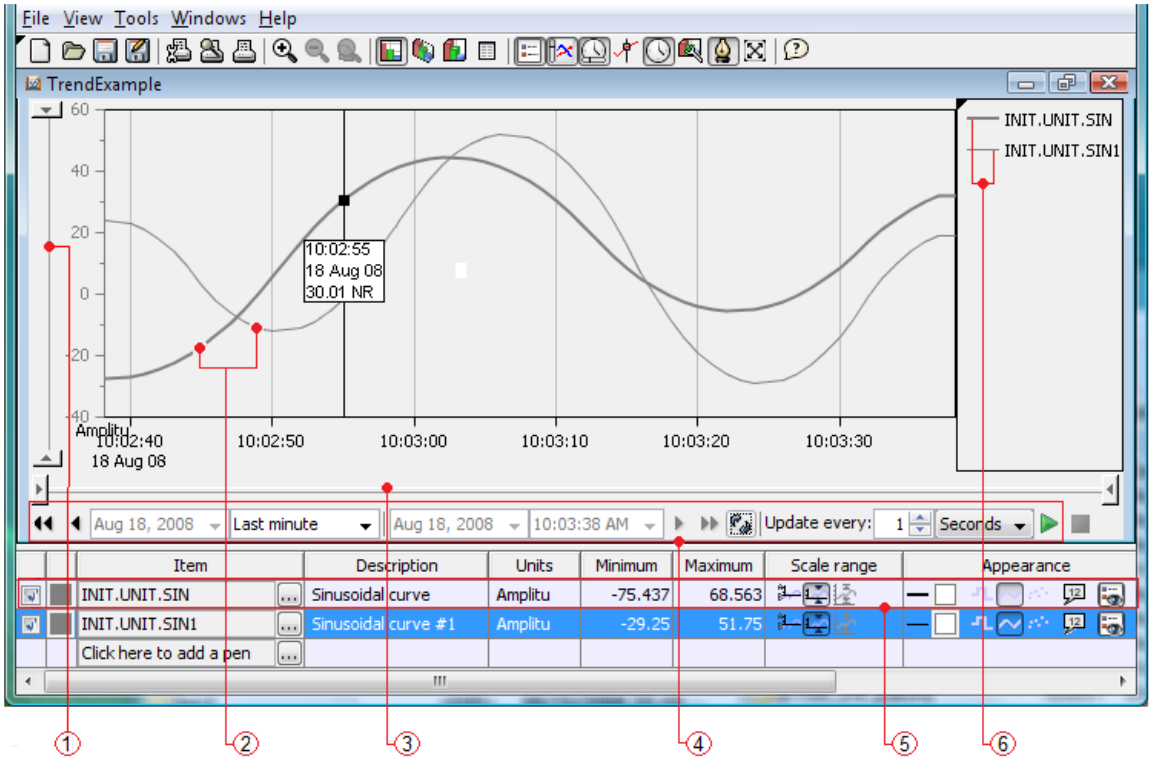

Figure 27 – Introduction to trend application

Legend:
1) Value slider
2) Plots
3) Time slider
4) Time control
5) Pen settings
6) Trend legend

The information shown for an item is not limited to the value attribute of an item. It is also possible to show various other item attributes, these are:

- High High limit
- High limit
- Low limit
- Low Low limit
- Deadband

The toolbar provides quick access to common functions.

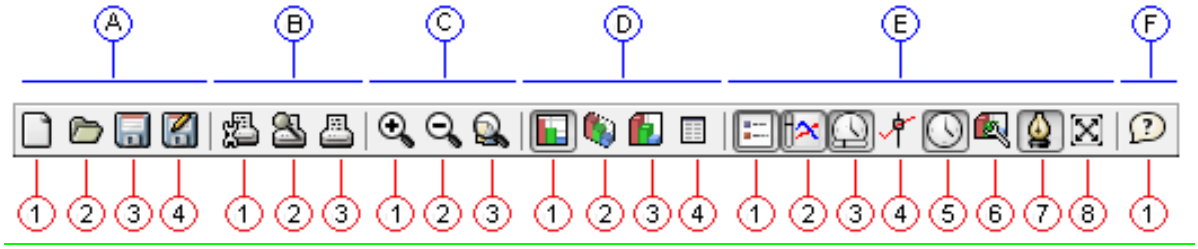

Figure 28 – Trend Toolbar

A: *Create* and *save trends*
- 1 Create a new trend
- 2 Open a trend
- 3 Save a trend
- 4 Save a trend as

B: *Print*
- 1 Print page setup
- 2 Print preview
- 3 Print

C: *Zoom*
- 1 Zoom in
- 2 Zoom out
- 3 Fit to show complete trend contents

D: *Rendering*
- 1 Switch to 2d rendering
- 2 Switch to 3d orographic rendering
- 3 Switch to 3d oblique rendering
- 4 Switch to table rendering

E: *Properties*

- 4 Show / Hide Hairline
- 5 Show / Hide time control
- 6 Show / Hide 3d control panel
- 7 Show / Hide pen selection panel
- 8 Maximize current trend

F: *Help*
- 1 Help

More functions are available by right clicking on the trend itself. A context menu will appear.

5.3.6 Reports

Reports in CI SERVER are managed by a reporting utility in Engineering Module. The reporting module can be used for generating various types of predefined reports, e.g. production reports, alarm reports, device status reports, etc. It is possible to have user defined reports which require user input, e.g. a start and end time. Reports can be generated time scheduled based, event-based (e.g. the change of an item value) or ad-hoc based.

Report definitions are created from the Engineering Module (by Engineer), defined reports can be generated and viewed both in Engineering Module and Operator Interface.

Generate a report from Engineering Module

The Engineering module, under Reporting => Reports, lists all predefined reports. To generate a report, select a report and left click on it, from the context menu, select Generate. The generate form will show.

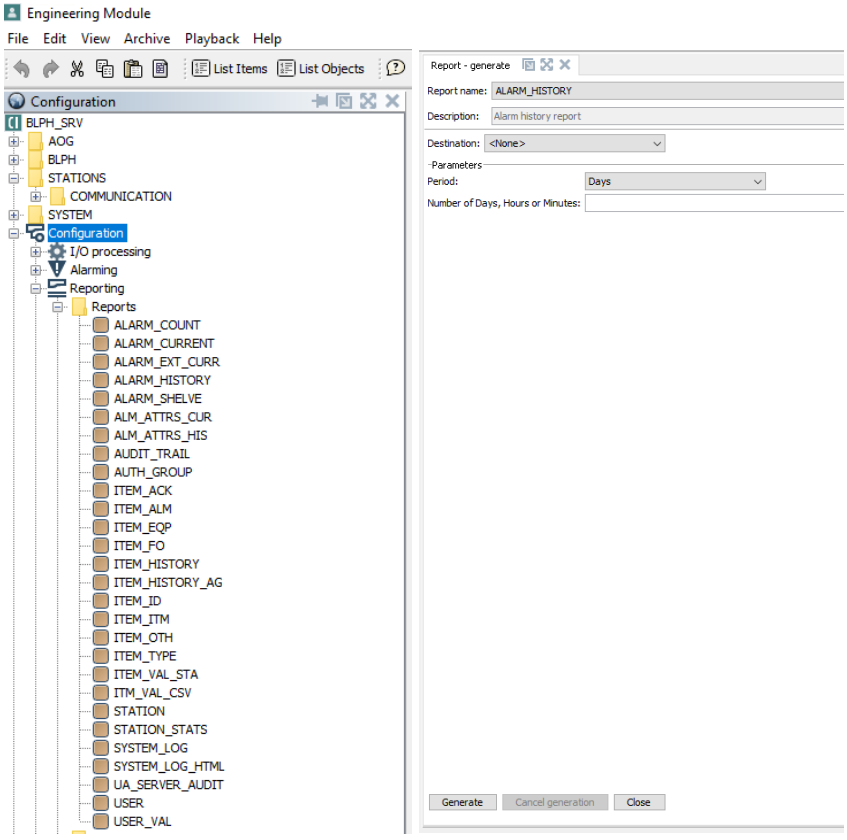

Figure 29 – Manually generating a report

Some reports require user input (under Parameters), after filling these parameters click Generate and in the project tree under the report name a new file will show up, this is the report. The report can be viewed by right mouse click and selecting View option.

Printing report

A generated report is saved in CI SERVER database with a predefined lifetime. However, it is also possible to print a report. This is possible at the time of generating the report by selecting a predefined destination.

Available Reports

The following reports are available:

Report	Description
ALARM_COUNT	Reports the alarm count
ALARM_CURRENT	Reports the current alarms
ALARM_EXT_CURR	Reports the current external alarms
ALARM_HISTORY	Reports the alarm history
ALARM_SHELVE	Reports the alarm shelving status
ALM_ATTS_CUR	Reports the current alarms with alarm attributes
ALM_ATRS_HIS	Reports the historical alarms with alarm attributes
AUDIT_TRAIL	Reports the user operations, and histories of item/object/class changes.
AUTH_GROUP	Reports the authorization group definition information
ITEM_ACK	Reports items and their acknowledgment type definition information
ITEM_ALM	Reports items and their alarm information
ITEM_EQP	Reports items and their equipment information
ITEM_FO	Reports items and their first-out group definition information
ITEM_HISTORY	Reports history data of item
ITEM_HISTORY_AG	Reports historical data of item aggregation values
ITEM_ID	Reports items and their item ID definition information
ITEM_ITM	Reports items and their item table information
ITEM_OTH	Reports items and other related information
ITEM_TYPE	Reports items by item type
ITEM_VAL_STA	Reports item values and their status
ITM_VAL_CSV	Exports CI Server data in CSV format
STATION	Reports station definition information
STATION_STATS	Reports statistics information of station
SYSTEM_LOG	Report of system log
SYSTEM_LOG_HTML	Reports system logs in HTML format
UA_SERVER_AUDIT	Reports the audit trail of OPC UA activity
USER	Reports the user definition information
USER_VAL	Reports the user value overview

Table 9 – Actions

Generate a report from the Report display

Navigate to the Report display. The Report display contains the report viewer component (see Figure 30 – Report viewer). On the left top side all available report definitions are listed (Select a report area). Select a report by left mouse click. If reports have been generated before, they are listed in the area below this list (Select a generated report). To view a previously generated report, select one via left mouse click. Next make sure the View tab is selected. The generated report is displayed here.

In case of generating a report manually, select a report definition first, as explained above. Next select the Generate tab. If printing of the report is required, select a printer from the Destination dialog. Some reports require user input; if this is required additional fields will show up in the Parameters area. The report can be generated by pressing the Generate button. This button will be greyed out until the report generation is finished. For viewing this report follow the procedure explained above.

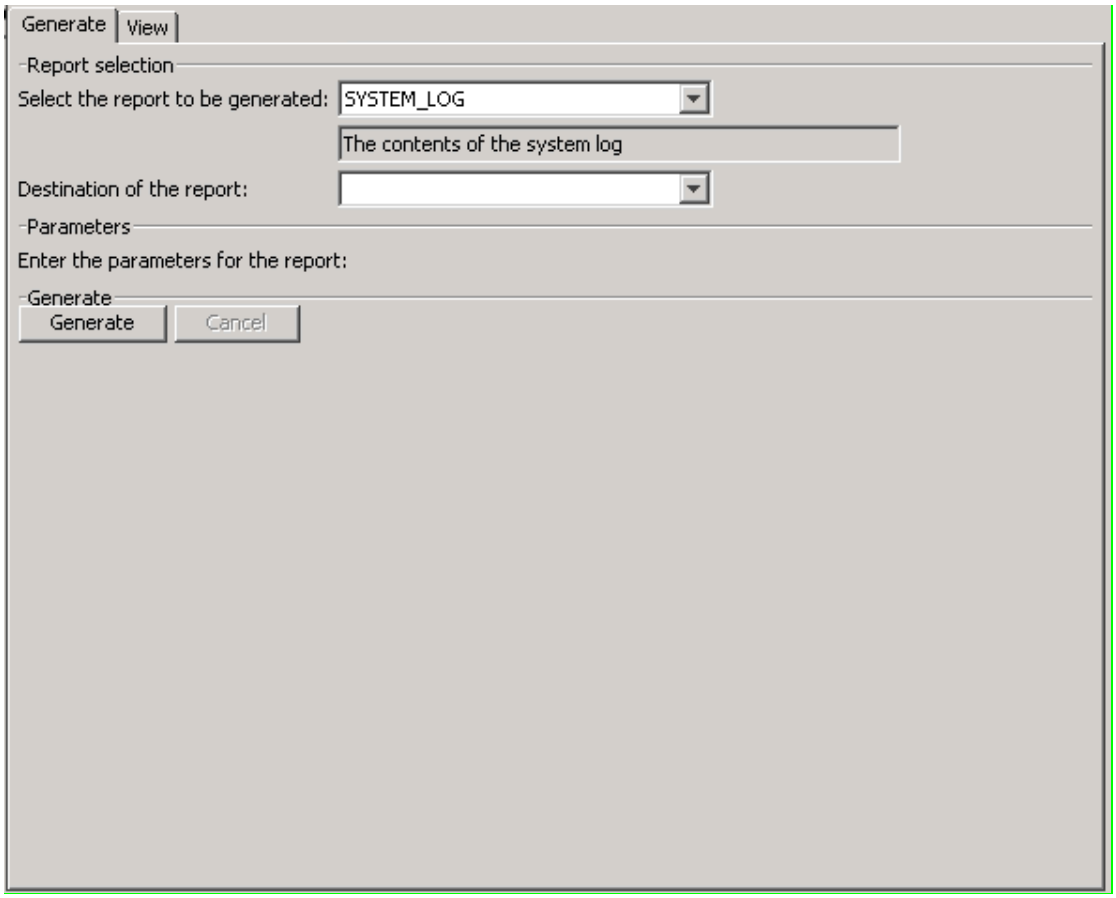

Figure 30 – Report viewer

5.3.7 Project-specific displays

As listed in section 5.3.10 Display navigation, are generically used throughout the project, for the list of displays refer to HMI display screen Document 1724000594-IN-DD-00028.

5.3.8 Typical overview

Typical Overview shall have navigation touch targets to various area i.e. BESS, Electrolyser, fuel cell, Electrical etc.

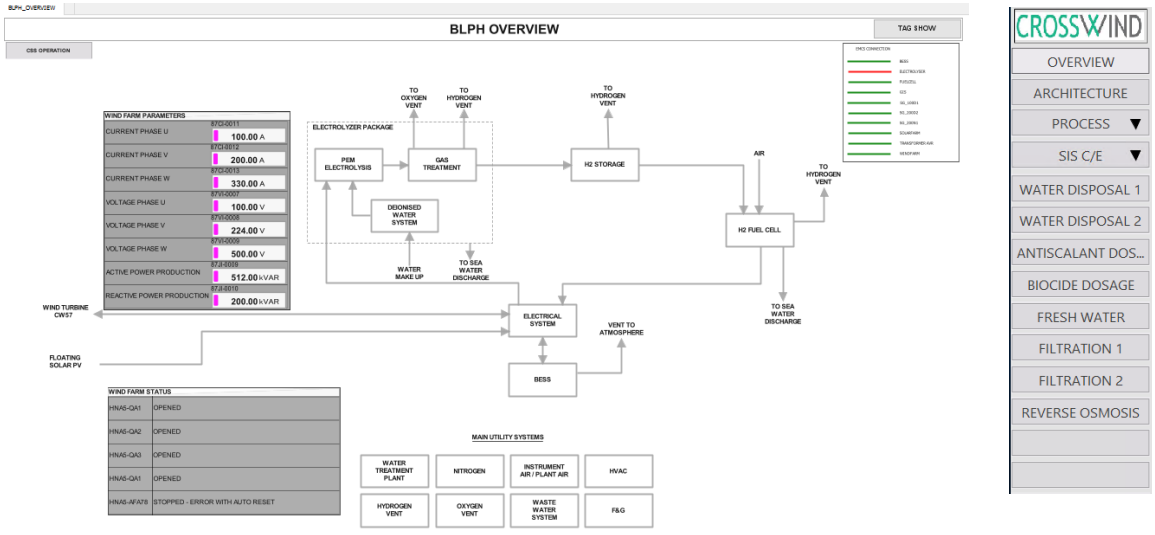

Figure 31 – Overview

Typical introduction

Process displays consist out of symbols with supportive graphic elements (e.g. line, text comment, etc) which together represent the dynamic behaviour of actual field process. And it provides the means for an operator to control the process (e.g. changing a set point or controlling a valve).
The symbols are mapped to the so called CI Server function block library in the PCS,SIS and FGS controller. These symbols together with the CI SERVER logic behind it which makes interacting with PCS,SIS and FGS Function block library possible, defines the so called typical.

Typicals will guarantee the repeatability of the behaviour of a certain type of device (e.g. valves, pumps, indicators, etc.).

A typical symbol has three main user interface components as indicated in Figure 32 – . Symbol, faceplate and Tuning Panel. A left mouse click on the symbol will activate the faceplate. From the faceplate, the Tuning Panel can be activated.

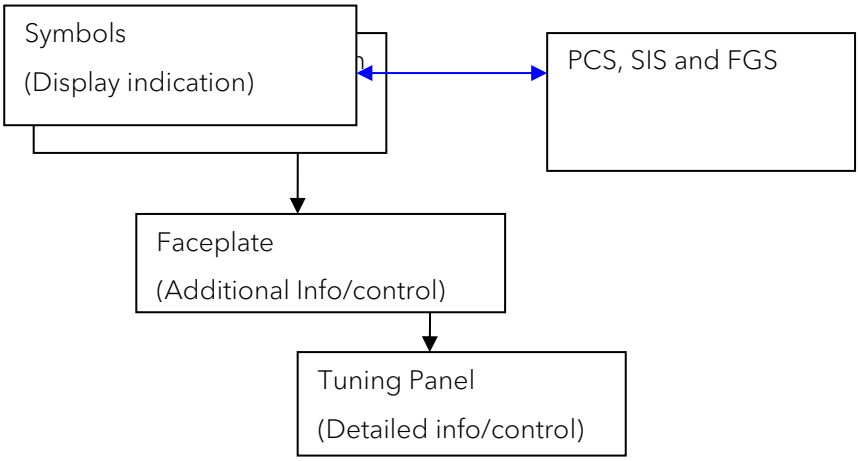

Figure 32 – Typical Display Hierarchy

The *general* behaviour of these typical like faceplates, tuning panel and alarming are described in this section.

Based on the general behaviour of the CI Server Library, the more detailed typical description is described in the following chapters. See Table 10.

Symbol	Description	CI Server Typical	Paragraph
Process value indicator	Analogue input indicator PVI	DCS_PVI	5.3.9
Analogue output indicator Choke valve	Analogue output indicator MLD/MLD-SW	DCS_MLD	5.3.9
PID Controller	PID	DCS_PID	5.3.9
Analog Sept point	DSET	DCS_DSET	5.3.9
Pump, Compressor, Generator, Alarm indicator, MOS indicator, ESD indicator, Valve	SO_1, SIO_11, SIO_12, MC-2/MC-2E *Digital input, output or input/output indicator	Digital switch instruments SIO*	5.3.9

Table 10 – Typical definitions

5.3.9 Faceplate

This paragraph will describe the general layout of the faceplates.

General Characteristics

A Faceplate display is activated by left mouse click on an indicator.
Figure 33 – shows the graphical elements of the faceplate. The faceplate uses standard window decoration. It can be moved across the user screen. It can be closed by using the normal close (X) button but cannot be minimized or resized.
The SCADA faceplate library has a uniform look and feel. However, the configurable elements of the faceplate will differ according to the characteristics of the associated function block, e.g. a Selector function block will have buttons on the Faceplate, while an indicator Faceplate will show a vertical indication bar.
The standard faceplate is drawn to 136 x 600 in pixels.

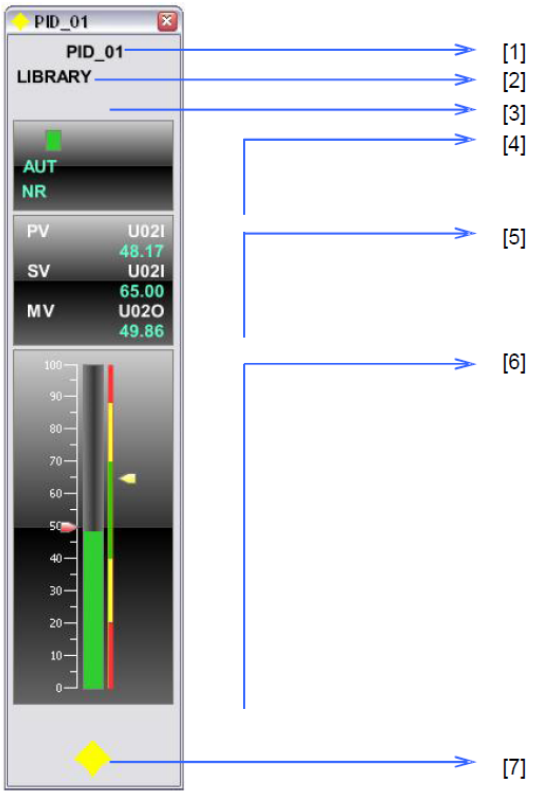

Figure 33 – Faceplate Overview

Item	Description
1	Tag Name
2	Description line – 1
3	Description line – 2 [Can be Blank]
4	Status Area-Alarm Indication, Mode Control and Indication
5	Value Area-shows the variables value with Engineering Unit
6	Vertical Bar –Graphical representation of the value of Key item of the block. The graph is scaled between High and Low Limits of the Display variable.
7	Tuning Panel-Access Point-Left Mouse click to activate the Tuning Panel of the Block.

Table 11: Faceplate definition

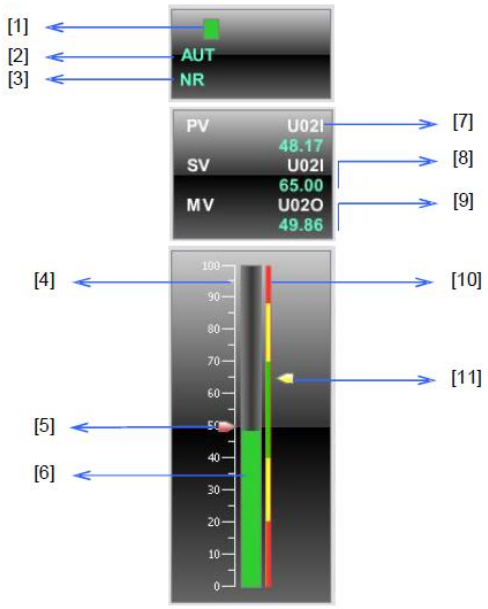

Figure 34 – Detailed faceplate overview

Item	Description
1	Alarm Indicator
2	Control Mode
3	Alarm Text
4	Vertical Linear Scale
5	MV Arrow Indicator
6	Vertical Bar

Item	Description
7	Engineering Unit
8	Set Value
9	Manipulated Value
10	Vertical Limit Bar-Graphical Representation of High-High, High, Low, Low-Low Values.
11	SV Arrow Indicator

Table 12 – Detailed faceplate definition

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

The Vertical Bar component indicates the alarm trip ranges. These ranges are configurable through the tuning panel for each typical and are stored in the PCS,SIS and FGS controller. If the limits are changed in the controller the scale and limit settings are automatically updated on the faceplate.

The example in Figure 35 – shows a HH limit of 80, H limit of 60, L limit of 40, LL limit of 20. In this example the value is below the Low Low alarm limit, consequently the alarming state is Low-Low, and this is reflected by the color of the indicator bar which is red for this case.

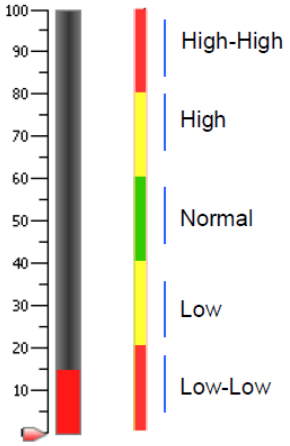

Figure 35 – Vertical Scale & High-Low Alarm Indicator

Varied Configurations

Faceplates are built up from standard graphic components. For example, the vertical bar shown in previous section is both used for the DCS_PVI and DCS_PID control block.

Mode Control

Block mode indicates the control state and the output state of a control block. In general there are 9 kinds of basic block mode. See Table 13 for an overview.
A transition of block mode can be initiated by a mode change command in the faceplate, or it may take place automatically when a mode transition condition is established inside the controller.

Mode	Mode	Description
OOS	Out of Service	All functions of PCS, SIS and FGS logic are currently stopped.
IMAN	Initialisation Manual	Calculation processing and output processing are currently stopped.
TRK	Tracking	Calculation processing is currently stopped and the specified value is forced as output.
MAN	Manual	Calculation processing is currently stopped and the manipulated value MV, which is set manually, is used as output.
AUT	Automatic	Calculation processing is being executed, the set value SV is used for calculation, and the calculation result is used as output.
CAS	Cascade	Calculation processing is being executed, the set value CASV which comes from the cascade connected upstream block is used for calculation, and the calculation result is used as output.
PRD	Primary Direct	Calculation processing is currently stopped, the set value CASV which comes from the cascade connected upstream block is outputted directly.
RCAS	Remote Cascade	Control and calculation processing are being executed using the remote set point value RSV which is set remotely from a supervisory system, and the calculation result is used as output.
ROUT	Remote Output	Calculation processing is currently stopped and the remote manipulated value RMV, which is set remotely from a supervisory system, is used as output.

Table 13 – PCS, SIS and FGS Block Modes

Left click on the Mode text for changing the block mode of the function block. A pop-up Menu is shown for selecting required mode settings. If the operator selects an invalid mode, the controller returns to the previous running mode prior to mode change.

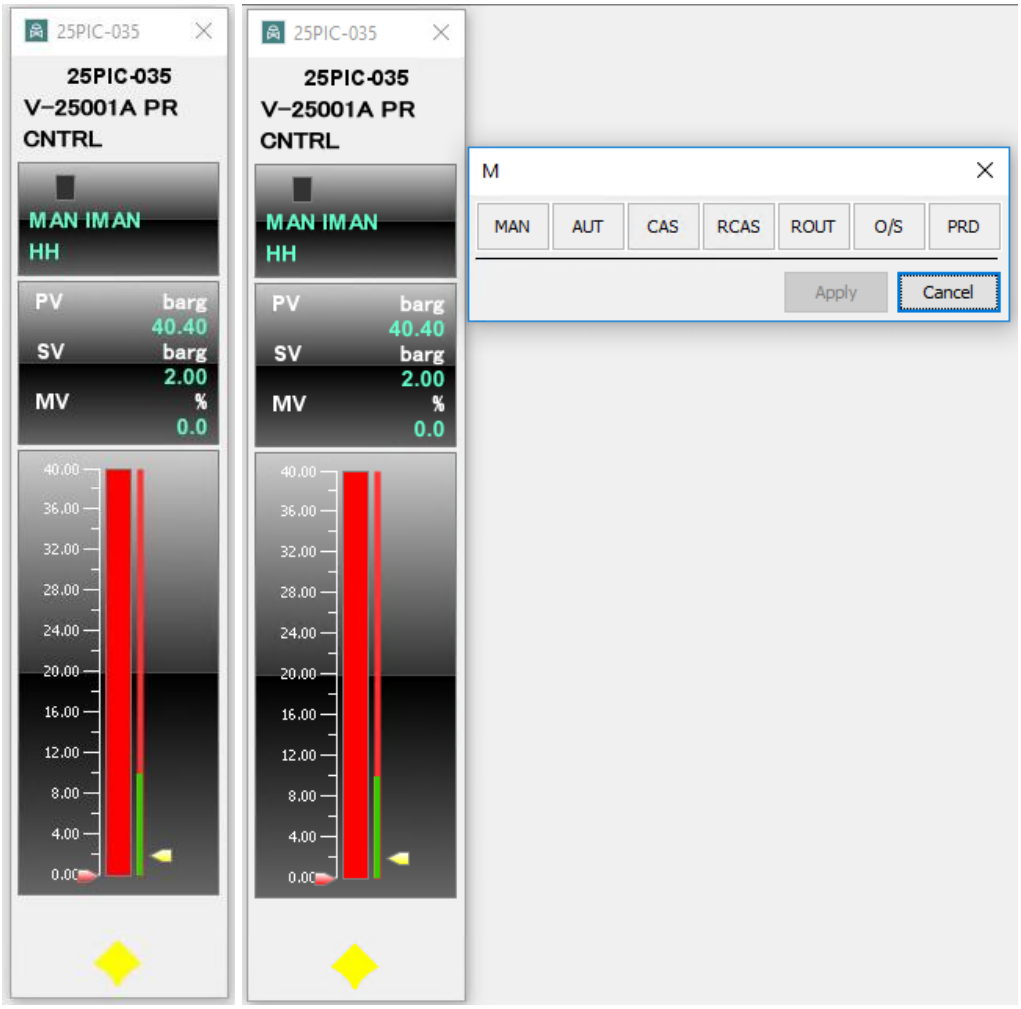

Figure 36 –Mode Command

PCS, SIS and FGS Block	OOS	IMAN	TRK	MAN	AUT	CAS	PRD	RCAS	ROUT
PVI	✓				✓				
PID	✓	✓	✓	✓	✓	✓	✓	✓	✓

SIO_21	✓	✓	✓	✓	✓	✓			✓
SIO_22	✓	✓	✓	✓	✓	✓			✓

Table 14 – Block mode availability

Tag Item Access

The Value area of the faceplate has built in pop-up displays which allow the user to change the values depending on the operational mode of the function blocks and the authorisation level.

To change a value, left click on the item which has to be modified and a dialog is displayed for entering the value. The selected tag has a green border around the symbol to indicate the item is selected. The selected item is also LOCKED by the user, so any item update by a different user is not allowed until the user closes the dialog. The border disappears when the pop-up dialog is acknowledged or cancelled.
The Dialogs pop-up displays are always "on top" and locking other displays.
The pop-up has to be confirmed or cancelled before returning to any other display.

Figure 37 – Tag Locking

Tuning Panel

The Tuning Panel display provides the operator with extended parameter options related to the particular PCS, SIS and FGS function block. The size of standard CI Server Tuning panel display is 900 x 600 (pixels). The Display consists of the following components.

1. Tuning Parameter Area
2. Faceplate Component
3. Trending Area
4. Alarm / Status Bar

Figure 38 – Tuning panel

Tuning Parameter area (1)

This area displays the detailed parameters of the function block and gives access to advanced controls of the function block and tuning parameters.

For instance, in a PID block the key tuning parameters like Proportional gain, Integral and Derivative time units can be adjusted. The values can be changed by clicking on the required parameter, which enables the operator to enter the new value and confirm the change. The parameters which are editable can be identified by equal (=) sign. Entries with a colon (:) sign are read only and cannot be modified by the user.

Figure 39 – Tuning Area

Faceplate Component: (2)

The Faceplate component is always similar to the Faceplate from which the Tuning panel was opened from. This is to give the operator an additional view of the block dynamics like the vertical bar.

Trending Area: [3]

The Trending area shows the trend of the preconfigured variables called Pen Items against time. The configured variables are specific for each typical. The trend component has extensive options for render, view, zoom and export trend data to external applications. To access the trend menu right click anywhere on the plot area to display the trend options.

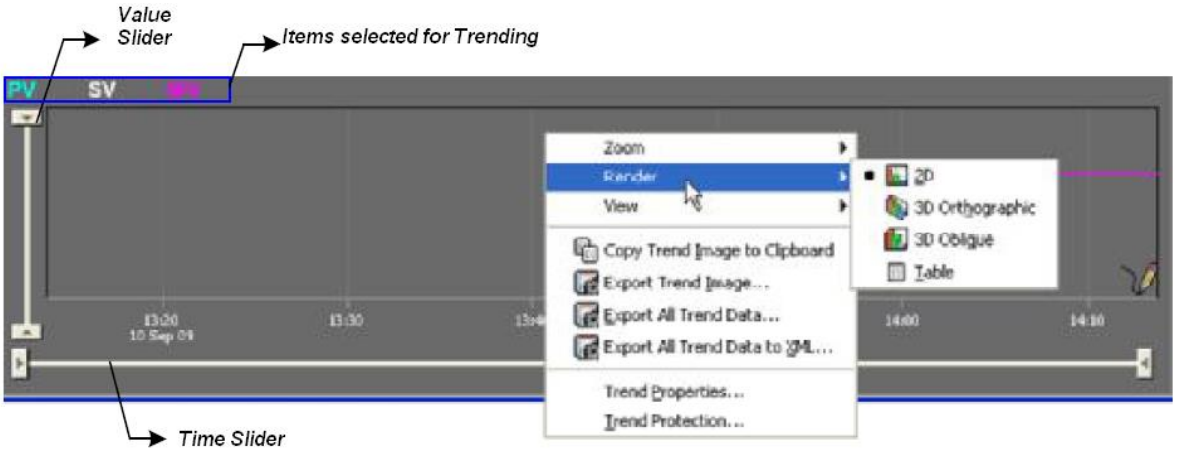

Figure 40 – Tuning Panel Trending Area

Alarm Processing

The PCS, SIS and FGS alarm processing consists of the following two functions:

- Alarm detection function for detection of any abnormality within the process
- Alarm notification function to further process the detected alarms.

The following figure represents the function structure of alarm processing in PCS, SIS and FGS.

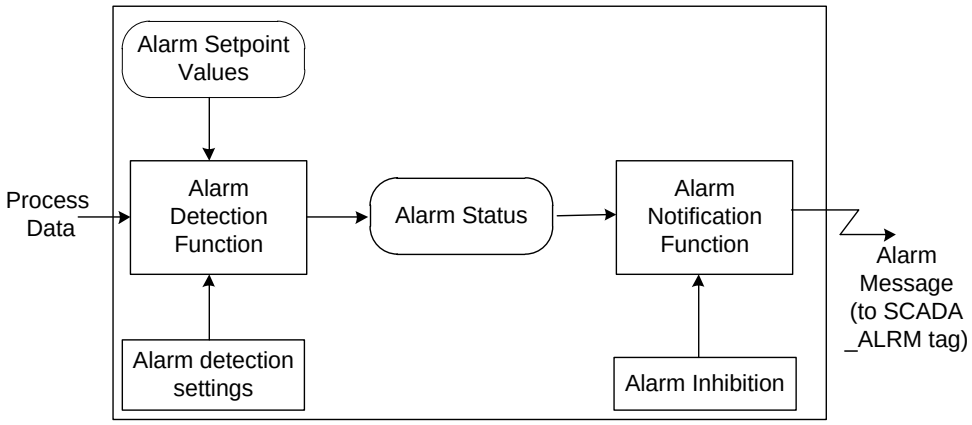

Figure 41 – PCS, SIS and FGS Alarm Processing

The following alarm checks are done under the Alarm Detection Functions. For alarm status text abbreviations and description refer to section 5.3.3.

- Input open alarm check
- Input error alarm check
- Input high-high and low-low limit alarm check
- Input high and low limit alarm check
- Input velocity alarm check
- Deviation alarm check
- Output open alarm check
- Output failure alarm check
- Output high and low limit alarm check
- Connection failure alarm check

Alarm Availability for PCS,SIS and FGS Library

Table 15 and Table 16 list the available alarm checks used for the PCS,SIS and FGS library.

	Process alarms															
	NR	OOP	IOP+	IOP-	HH	LL	HI	LO	DV+	DV-	VEL+	VEL-	MHI	MLO	CNF

Table 16 – PCS, SIS and FGS Sequence control

Alarm Status and Priority

An alarm status is information that represents the alarm state of a process which was detected by the PCS, SIS and FGS logic. The alarm statuses are depending of the type of the PCS, SIS and FGS logic which is used. The alarm status for the operation and monitoring function is displayed in the access parameter ALRM.

Status Text	Alarm Name	Description
NR	Normal	Indicates a state in which no alarm has occurred.
OOP	Output Open Alarm	Indicates a state in which the output data status has become output failure (PTPF) as a result of the failure or disconnection of an operation terminal or process I/O device or the abnormality of output destination data. Normally, the output function is stopped.
IOP IOP+	High Input Open Alarm	Indicates a state in which the input data status has become bad value (BAD) as a result of the failure or disconnection of a detection terminal or process I/O device or the abnormality of input destination data. Normally, any processing that uses input signals is stopped. If the input signal has been overshot due to disconnection, etc., this alarm indicates a state in which input is overshot to the high-limit direction.
IOP–	Low Input Open Alarm	Indicates a state in which the input signal has been overshot to the low-limit direction due to disconnection, etc. The input data status becomes bad value (BAD). Normally, any processing that uses input signals is stopped.
HH	High–HighAlarm	Indicates a state in which the process variable exceeds the high high-limit alarm setpoint
LL	LowLow Alarm	Indicates a state in which the process variable falls below the low low-limit alarm setpoint.
HI	High Alarm	Indicates a state in which the process variable exceeds the high-limit alarm setpoint.
LO	Low Alarm	Indicates a state in which the process variable falls below the low-limit alarm setpoint.
DV+	Deviation Alarm +	Indicates a state in which the deviation between the process variable and the setpoint value exceeds the deviation alarm setpoint in the positive direction.
DV–	Deviation Alarm –	Indicates a state in which the deviation between the process variable and the setpoint value exceeds the deviation alarm setpoint in the negative direction.
VEL+	Velocity Alarm +	Indicates a state in which the change amount of the input signal within a specified time exceeds the velocity limit alarm setpoint in the positive direction.
VEL–	Velocity Alarm –	Indicates a state in which the change amount of the input signal within a specified time exceeds the velocity limit alarm setpoint in the negative direction.

Status Text	Alarm Name	Description
MHI	Output High Alarm	Indicate a state in which the output signal almost exceeded the output high-limit value. The actual output is limited to the output high-limit value.
MLO	Output Low Alarm	It indicates a state in which the output signal almost fell below the output low-limit value. The actual output is limited to the output low-limit value.
CNF	Connection Failure Alarm	Indicates a state in which a block mode of the NPAS logic in the I/O connection destination is in the out of service (OOS) mode. This alarm controls a temporary out of service state due to maintenance, and indicates a PCS, SIS AND FGS block which is still in operation. Normally, IOP or OOP occurs simultaneously.
PERR	Computation Error – Answerback Undefined Alarm	Indicates a state in which an illegal input pattern has occurred, such as when the full-open and full-close signals are inputted simultaneously. (Position Error)
ANS+	Answer back Error +	Indicates a state in which answerback check is being performed and the manipulated output value (MV) of ON operation and the answer backed process variable (PV) do not agree.
ANS–	Answer back Error –	Indicates a state in which answerback check is being performed and the manipulated output value (MV) of OFF operation and the answer backed process variable (PV) do not agree.

Table 17: Alarm status

When multiple alarms are occurring, the alarm status with the highest alarm display priority will be displayed. In Table 18 the priorities are listed from high to low:

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

Regulatory Control	OOP > IOP+ > IOP- > HH > LL > HI > LO > DV+ > DV- > VEL+ > VEL > MHI > MLO > CNF
Sequence	OOP > IOP+ > PERR > ANS+ >ANS- > CNF
Calculation	IOP+ > IOP- > HH > LL > HI > LO > VEL+ > VEL- > CNF

Table 18 – Alarm priority

Refer to PCS and SAFETY SYSTEMS Software Functional 1724000594-IN-SP-00018 Appendix-1HMI Graphic Symbols

5.3.11 Typical Faceplate Library

Refer to PCS and SAFETY SYSTEMS Software Functional 1724000594-IN-SP-00018 Appendix-1HMI Graphic Symbols

6 MAINTENANCE

Maintenance is required to:

- Ensure the lifetime of the system.
- Maintain and detect dormant.
- Correct failures
- Keep the system up to date by updating system software and system documentation.

For the maintenance activities in general, a distinction is made between Preventive and Corrective Maintenance. (Most actions are covered when a Yokogawa maintenance contract is applicable)

6.1 PREREQUISITES

Test equipment, required for maintenance:

{This list of equipment contains the tools needed for the maintenance of the System cabinet. The tools needed for the maintenance of the valves / solenoids and the pressure transmitters should be listed in their respective documentation. If not, these tools should be added to the list here (for example pressure generator with indication}

- Clamp-on current probe
- Multimeter
- Hand tools
- Oscilloscope
- HART Handheld terminal

Note: All measurements must be performed with calibrated tools.

6.2 OWNER ACTIONS

A system custodian must be appointed on site to coordinate all activities and gather all facts and reports with respect to the system. All system anomalies must be logged into a system logbook. This logbook must be stored in the vicinity of the system for quick access.

A maintenance planning is required ahead of the maintenance activities. Since some of the activities are likely to disturb the process, these should be scheduled together with the scheduled shutdown of the process. The logbook must be reviewed before the maintenance activities are taken up for any follow-up actions.

The system documentation must be stored in the vicinity of the system for quick access. Care must be taken that every modification to the system is marked up in the site master copy of the system documentation.

Sufficient maintenance spares must be stored on site.

6.3 SECURITY OF THE INSTALLATION

In all work on the system it is important that the system is in a secure mode after work has been finished. This prevents uncontrolled configuration changes.

6.4 SAFETY PRECAUTIONS

In all activities regarding the system, extreme care must be taken because of sensitive electronics involved. Extreme care must be taken while handling AC supply. Negligence on part of personnel could be lethal.

Circuit must be disconnected at the surge protection devices provided with disconnect feature in the marshalling cabinets before performing any maintenance activity on field devices which are connected to system.

6.5 CENTUMVP BACKUP

6.5.1 Backup Tool

There is the Backup Tool to back up the project data in CENTUM VP. The backup tool can be started from System View.

The following flowchart shows the flow of the project backup.

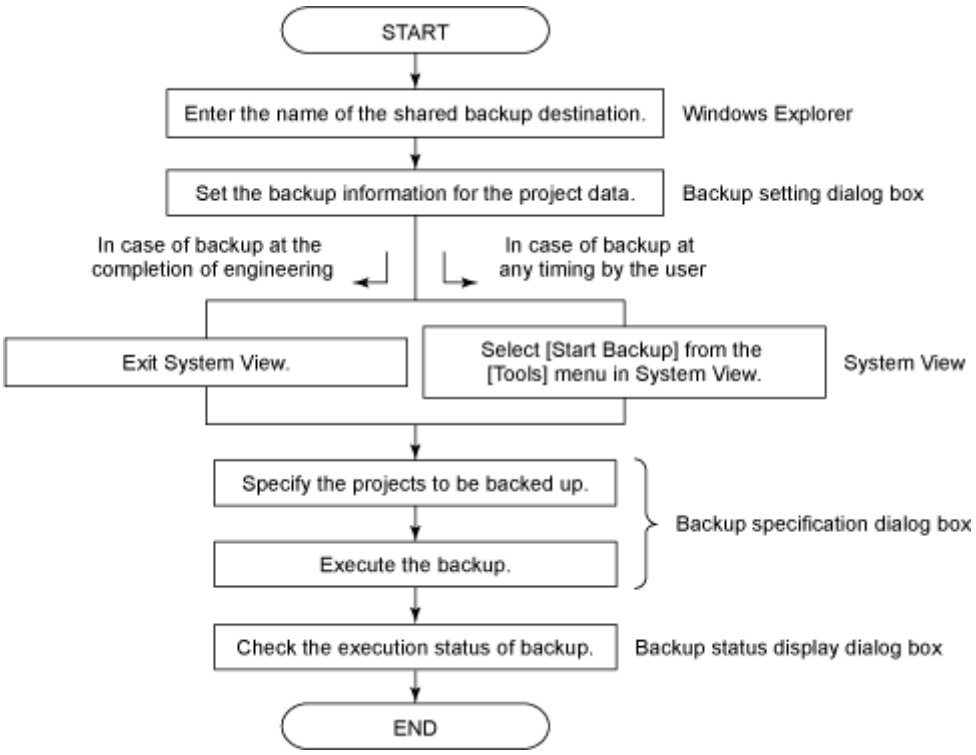

Figure 42 – Project Backup

6.5.2 Setting Backup Information for Projects

Set backup information for projects that are to be backed up. Project databases for which no backup information is set are excluded from the backup targets.

Set the backup information in the Backup setting dialog box.

Select [Set Backup] from the [Tools] menu.

The Backup setting dialog box is displayed.

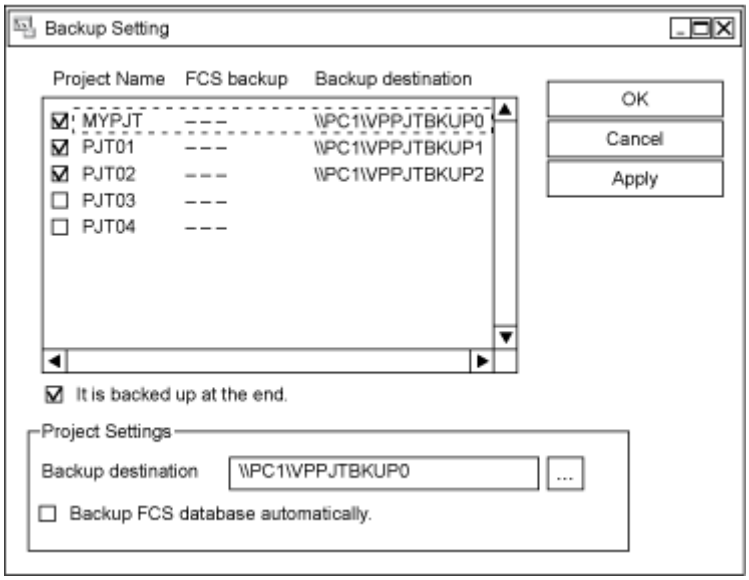

Figure 43 – Project Backup Setting dialog box

6.5.3 Execution of Backup

The execute backup, exit System View or select [Start Backup] from the [Tools] menu.

The Backup specification dialog is displayed. A list of the projects whose backup information is set in the Backup setting dialog box among the projects opened in System View is displayed in the Backup specification dialog box.

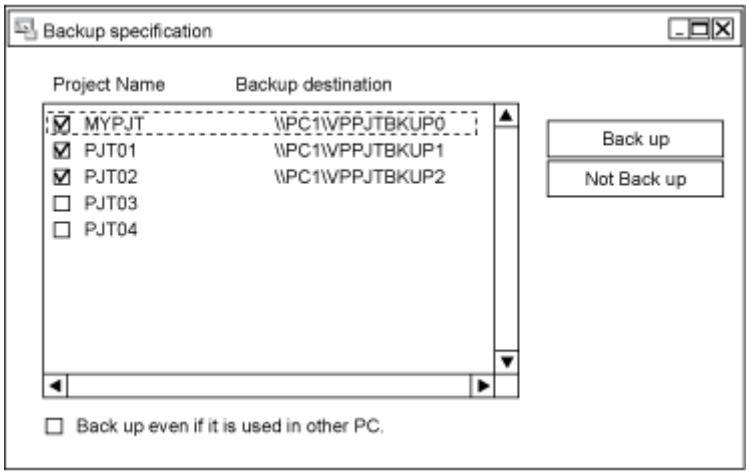

Figure 44 – Process Backup Execution

In the Backup specification dialog box, set the following items for each project listed.

6.5.4 Checking the Progress of Backup

When a backup is being executed, the Backup status display dialog box is displayed.

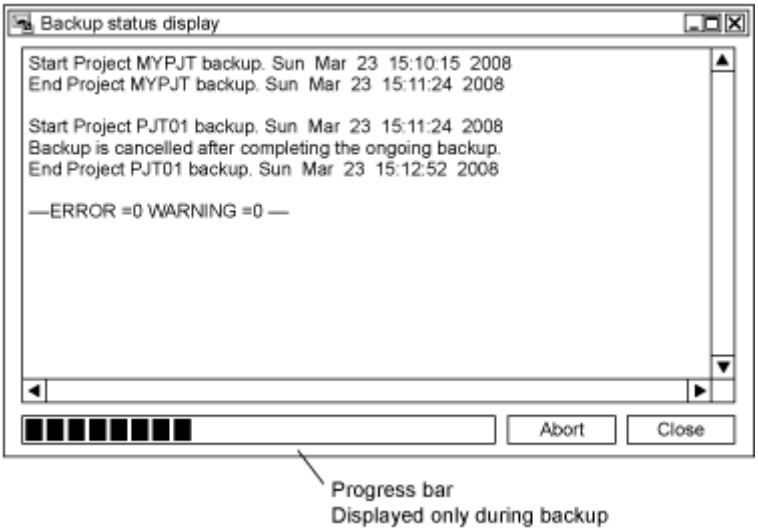

Figure 45 – Project Backup Progress

The progress of the backup is displayed for each project in the Backup status display dialog box.

The user can stop a backup at the end of each project backup by clicking the [Abort] button. The backup is aborted at the point where the backup currently in progress is completed. In this case, any project set to be backed up after the aborted project will not be backed up.

Click the [Close] button to close the Backup status display dialog. This button cannot be operated while a backup is in progress.

6.6 PCS PREVENTIVE MAINTENANCE

6.6.1 General

In general, the Preventative Maintenance of the system involves a routine check of the status of the system. The purpose of PM is to detect system defects which are not detected during normal operation. They might have a degrading effect on the system leading to an increase in nuisance failures.

6.6.2 Schedule

Preventive Maintenance must be carried out on a regular basis. The following is recommended intervals for the PM to ensure an operational system:

Preventative Maintenance Schedule:

System Cabinet	Once per year
Network switches, KVM interfaces	As per product manual
Power supply units and diode modules	As per product manual
Terminal boards, barriers, relays	As per product manual
Cabinet accessories	As per product manual

Peripherals such as printers, HIS do need some regular attention to ensure their lifetime and prevent failures. Refer to their respective manuals for details.

6.6.3 Timing/planning

One can distinguish the actions that may be done without disturbing the process and the actions that will certainly disturb the process or bear a great risk to do so. In order to perform the latter it is essential to start the preparations for these actions timely, in advance of a scheduled shutdown.

6.7 PCS OFFLINE (SHUTDOWN) PREVENTIVE MAINTENANCE

6.7.1 Cleaning

Cleaning may be done with a soft brush to remove dust etc. air filters must be cleaned to ensure required air flow through the cabinet.

6.7.2 Online Preventive Maintenance

The following necessary actions will not disturb the process:

Temperatures

All cabinets are provided with a thermostat to detect the high temperature. It is wired to PCS system as part of common cabinet alarm. Measure the temperature for all cabinets with the door closed. The value should be less than 30 degrees Celsius at normal conditions.

Vnet/IP Network

The healthiness of the Vnet/IP network must be checked at frequent intervals. Network health can be viewed at system overview window in HIS.

I/O Module Handling:

Handling of I/O modules and its connections during maintenance shall be performed cautiously in a simplex configuration to avoid 'spurious' trip.

Online Replacement of Modules:

When system is in operation, if it is necessary to install or remove the modules, cables, connectors, refer sec.1.4.3 of this document, which explain how to remove or install the common modules of the Field Control Unit -Hardware User's Guide - IM 33J01C10-01EN Sec.C.6.1.

The dual-redundantly configured modules (such as PSU, CPU, N-ESB Modules) can be removed and installed one by one without turning off the power supply to the safety control unit. The detailed procedures for the following modules are explained therein:

- Power Supply Module
- Processor Module
- ESB Bus Coupler Module

Refer 'PCS and SAFETY SISTEMS Software Functional Design Specification (FDS-SW) 1724000594-IN-SP-00018 for detailed information.

6.7.3 Visual Inspection

System healthiness must be checked and any alarms, faults or failures must be investigated and rectified.

- Check the system status on the HIS and confirm all components are healthy.
- Check the system alarm window on the HIS and confirm there are no system alarms.
- Check the LEDs on controller, power supply, communication, and I/O modules and confirm all are healthy.
- Check the LEDs on terminal boards and confirm availability of redundant power.
- Check fused terminals and confirm there is no fuse blown indication.

6.7.4 Mechanical Inspection

All physical connections and mechanical elements must be inspected.

- Check network cables connectors are not damaged.
- Check system cables are firmly screwed to their sockets.
- Check for loose connections at termination points inside the cabinets.
- Check proper working of cabinet lights and cabinet fans (as applicable).
- Check proper working of thermostat and air flow switches.
- Check door hinges and door locks.
- Check for mechanical damage in general.

6.7.5 Power supplies

All cabinets have 240VAC Non-UPS supply and most of the cabinets have 110VAC UPS supply to power components. Marshalling cabinets have 24VDC power supplies mounted inside.

Measure the voltage on 110VAC incoming feeders. The value should be within 110VAC +/- 10%.

Measure the voltage on 240VAC incoming feeders. The value should be within 240VAC +/- 10%.

Measure the voltage on the 24VDC power supply distribution terminals. The value should be within 24VDC +/- 1%.

6.7.6 System spares

System spares must be inspected on a yearly basis on their status. Inspection must cover the following:

- Packing of available parts is undamaged.
- Available spare parts.
- Update inventory records, if any.

6.7.7 Hardware replacement

Replacement of the hardware must be carried out during the shutdown. However, if one of the hardware of the dual redundant set has failed, then online replacement is possible.

6.8 PCS CORRECTIVE MAINTENANCE

In general, the Corrective Maintenance of the system involves a finding defective part in the system. The operator will be warned of any fault occurring in the system by an alarm on the HIS under the alarm window.

6.8.1 Troubleshooting facilities

The system provides the following tools to find the defective part in the system:

- System status/alarm window on the HIS
- LED indications on modules
- Test/disconnect terminals

6.8.2 System Status/Alarm window

PCS status is shown on the system overview window. Also diagnostic information are displayed in system and process alarm window.

LED indication on modules

All modules are provided with LEDs to indicate module status and digital and communication modules are also provided with LEDs to indicate status of individual channels.

6.8.3 Test/disconnect terminals

Surge protection devices are provided with disconnect feature to disconnect loops, to allow field loop testing.

6.9 IAMS

IAMS is equipped with other useful functions in device management such as inspection scheduler, inspection record manager, spare parts manager, and document register.

IAMS processes various diagnoses and integrates those diagnostic results that are related to the plant equipments. The diagnostic types are divided into two categories as shown below.

(1) Diagnosis carried out by devices or equipment

(2) Diagnosis carried out by acquiring data from devices or equipment

The diagnosis results carried out by the devices or equipments are stored in IAMS as device related data via fieldbus and displayed on the status display icon. Loop or equipment diagnoses are performed based on the data acquired from the devices and equipments. IAMS also displays the diagnostic results obtained via other companies' diagnostic solutions through an open interface. By utilizing the data accumulated in IAMS, diagnostic algorithms can be developed. In these manners, IAMS can be applied as the platform of diagnostic functions, and the accumulation of the diagnostic data enables to shift the current breakdown maintenance (BM) into preventive maintenance, or even into the predictive maintenance.

6.9.1 Database Maintenance Tool

Using the Database Maintenance Tool, you can manage and maintain the volume of data stored in the PRM Server and the Device Diagnosis Data Historian Server.

The Database Maintenance Tool enables you to archive, retrieve, and delete PRM data. It also enables you to clean up unwanted data from the PRM and Historian databases.

The main functions of the tool are:

- Archiving, retrieving, and deleting data

Free up space in the PRM and Historian databases by either archiving or deleting data that exceeds a certain age. Archived data can be retrieved back into the databases.

- Cleaning up the PRM database

When a device is deleted in a PRM Client, it no longer appears in the PRM Client, but its data remains in the database. Obsolete data can be removed, including the e-EDDL persistent data of the device, by cleaning up the PRM database.

- Cleaning up the Historian database

Free up space in the Historian database by manually removing obsolete data related to deleted devices in the Historian database. In addition, archive, retrieve, and clean-up operations can be set to run automatically at regular intervals, based on a predefined schedule.

However, when you set the clean-up to run automatically, it runs on the first day of every month by default. You cannot change this default setting. You can also use the tool to archive, retrieve, and delete data manually.

In Device Viewer, Custom View This explorer-like tree view can be freely configured to display and manage user-defined information by the maintenance schedule, or by persons in charge.

6.9.2 IAMS Backup

PRM Backup Tool to back up the PRM system or PRM databases, or both. The PRM Backup Tool provides the following backup modes:

- System Backup Mode

This mode enables you to back up the PRM system, along with all PRM databases, and any folders, or files on the computer.

- Database Backup Mode

This mode enables you to back up the PRM Server depending on the packages that are activated on your compute

Refer PCS and SAFETY SYSTEMS Software Functional Design Specification (FDS-SW) for more details

6.10 CI SERVER

All CI Clients are not scheduled for automatic back-up. For these stations a back-up can be initiated on demand.

6.10.1 Restore

Whenever a system needs to be restored it must be booted with the Back-up Exec recovery CD. From the recovery utility one can select the image to restore. After the image has been restored, the machine must be rebooted. After reboot the system is up and running again.

6.10.2 Restore individual files

The backup software as described in the previous section provides the possibility to retrieve individual files and/or folders from a system back-up.

Note: When a CI server folder structure is retrieved, the CI server software on that particular machine must be stopped beforehand.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

7 NETWORK MANAGEMENT AND SECURITY PRODUCTS

NMS, Backup Recovery, EMCS, Antivirus, WSUS and Domain Controller are either Vendor Supplied or MS Windows configurations. PCS and SAFETY SISTEMS Software Functional Design Specification (FDS-SW) document shall have the configuration settings.

7.1 NETWORK MANAGEMENT SYSTEM (WHATSUP GOLD)

7.1.1 Installation

1. Launch the WhatsUp Gold installation program.
2. When prompted, select the language in which you want the WhatsUp Gold installer to run, then click **OK**.
3. Read the Welcome screen and indicate if you want to configure WhatsUp Gold using either **Standard installation** or **Advanced installation** mode.
    a. If you select **Standard installation**, WhatsUp Gold will be installed with a dedicated instance of SQL Server Express 2022. Additionally, if your license includes Log Management features, a dedicated instance of Elasticsearch will also be installed. If you want to use an existing instance of SQL Server or Elasticsearch, choose the **Advanced installation** option and provide your connection information when prompted during the installation process.
    b. If you select Advanced installation you can install WhatsUp Gold using more user-defined settings including specifying a dedicated Windows account for IIS and, depending on your license, enabling Failover and/or Distributed features, and pointing to an existing instance of SQL Server and/or Elasticsearch. Click Next to proceed.
4. If you are presented with results of a system configuration check, please review the results prior to continuing the installation process. If any prerequisite checks did not pass, please resolve them, then click Revalidate to perform the system configuration check again. Click Next to proceed.
5. Enter your WhatsUp Gold Activation Key, then click **Next** to proceed.
6. Configure your SQL Server instance as follows:
    a. If you chose **Standard installation**, enter and confirm a password for the SQL Server Administrator account to use to access the database instance, then click **Next**.
    b. If you chose **Advanced installation** and would like to use the local SQL Server 2022 Express instance included with WhatsUp Gold:

- Select Yes, install a local copy of Microsoft SQL Server 2022 Express named WHATSUP, then click Next.
- Enter and confirm a password for the SQL Server Administrator account to use to access the database instance, then click Next.
- Select the destination folders for the SQL Server Express application and data files, then click Next.

- Enter names for the WhatsUp and NetFlow databases, then click Next.

Important: We recommend using the default names provided for your databases. If you choose to use non-standard database names, please do so during WhatsUp Gold installation as modifying them after installation is complete could cause potential issues with network monitoring.

- Enter and confirm a password for the new SQL Server Login WhatsUp Gold will use to access the databases, then click Next.
- Select the destination folder for the WhatsUp Gold installation, then click Next.
- Select the binding protocol(s) WhatsUp Gold will use for the IIS website. You may select HTTPS, HTTP, or both depending on your specific security needs. If you are using an existing binding, select it from the applicable drop-down menu, then click Next. If your are adding a new binding, specify the desired port number(s) to use if you do not want to use the default port number(s) populated by the installer. If you chose to use HTTPS and a new binding will be added, specify the source of the certificate required for binding. You may select a certificate from a certificate store, navigate to and select a certificate file on your local machine, or generate a self-signed certificate. Then, click Next to proceed.
- Enter a password for the new Windows account created for dedicated WhatsUp Gold use, then click Next.

Note: You will only be presented with the Windows account dialog if you are updating the application from a version prior to WhatsUp Gold 2024 and the existing IIS configuration references the Windows account and that configuration has been modified from what was configured by the initial WhatsUp Gold installation prior to upgrade.

c. Select the language or languages you would like to install for use with the application, then click Next.

d. If you choose Advanced installation and would like to use an existing SQL Server instance:

- Select No, I want to select an existing local or remote installation of Microsoft SQL Server for use with WhatsUp Gold, then click Next.
- Enter the SQL Server name or IP address (followed by the database instance if you are connecting to a non-default database instance, e.g., ip address\database name) along with the SQL Server Administrator Login name and password for WhatsUp Gold to use to access the existing instance, then click Next.
- Enter names for the WhatsUp, and NetFlow databases, then click Next.
- Enter and confirm a password for the new SQL Server Login WhatsUp Gold will use to access the databases, then click Next.
- Select the destination folder for the WhatsUp Gold installation, then click Next.
- Select the binding protocol(s) WhatsUp Gold will use for the IIS website. You may select HTTPS, HTTP, or both depending on your specific security needs. If you are using an existing binding, select it from the applicable drop-down menu, then click Next. If your are adding a new binding, specify the desired port number(s) to use if you do not want to use

the default port number(s) populated by the installer. If you chose to use HTTPS and a new binding will be added, specify the source of the certificate required for binding. You may select a certificate from a certificate store, navigate to and select a certificate file on your local machine, or generate a self-signed certificate. Then, click Next to proceed.

- Enter a password for the new Windows account created for dedicated WhatsUp Gold use, then click Next.

Note: You will only be presented with the Windows account dialog if you are updating the application from a version prior to WhatsUp Gold 2024 and the existing IIS configuration references the Windows account and that configuration has been modified from what was configured by the initial WhatsUp Gold installation prior to upgrade.

- Select the language or languages you would like to install for use with the application, then click Next.

7. Select the binding protocol(s) WhatsUp Gold will use for the IIS website. You may select HTTPS, HTTP, or both depending on your specific security needs. If you are using an existing binding, select it from the applicable drop-down menu, then click Next. If your are adding a new binding, specify the desired port number(s) to use if you do not want to use the default port number(s) populated by the installer.

Note: If you are using the Advanced installation workflow and have already configured your HTTP/HTTPS binding options, please proceed to the next step.

8. Click Proceed. The WhatsUp Gold install program begins the installation. When the installation program completes, the InstallShield Wizard Complete dialog appears.
9. Click Finish. The setup program closes.

7.1.2 Operations

- Device Discovery: WhatsUp Gold provides you the capability called Device Discovery that allows you to discover devices connected to your network.
- Manually adding a device to a device group: When you manually add a device, you are prompted to enter the IP address or host name. WhatsUp Gold attempts to resolve the IP address or hostname, then scans the device for Active Monitors. When the scan is complete, you can further configure the device as needed.
- Organizing Devices, Device Groups, and Maps with drag-and-drop: In the Device and Map views, you can quickly and easily organize your devices and device groups by dragging the device you want in a particular group to the device group folder.
- Polling: Polling is the active watching, or monitoring, of your network by WhatsUp Gold. This is done in a variety of ways, depending on the service monitors you have configured on your devices. The default polling method is done through Internet Control Message Protocol (ICMP). The default polling interval for WhatsUp Gold is 60 seconds.

- Active monitoring: Active monitors query network services installed on a device, then wait on the response. If a response is not received or if the response does not match what is expected, the service is considered down, and a state change occurs on the device.

- Actions: When a device or monitor state change occurs, WhatsUp Gold can perform an action to try to correct the problem, notify someone of the state change, or launch an external application.

- Passive monitoring: Unlike active monitors or performance monitors, which actively poll a device to check its status or to gather statistical data, passive monitors passively listen for events on devices. Passive monitors are also useful because some devices on a network may not provide a clear up or down status when queried.

- Performance monitoring: Performance Monitors in WhatsUp Gold gather important information about the devices running on your network, then use that data to create reports trending the utilization and availability of different aspects of those devices. Through WhatsUp Gold, you can gather statistics on the following areas:
  - CPU utilization
  - Memory utilization
  - Interface utilization (bandwidth)
  - Ping availability
  - Disk utilization

- Report generation: Device reports display information relating to a specific device. For example, when choosing to view the CPU Utilization report for a specific device, only CPU utilization information is listed for the specific device you choose for the report.

7.1.3 Maintenance

Maintenance mode:

This feature lets you place devices in Maintenance mode, where they will not be polled by the engine. Any device placed in maintenance mode is not polled, and actions are not fired for it, but it remains in the device list and historical data is preserved. By default, the maintenance state is represented by an orange color in both the device list view and the map view.

The mode can be set in two ways:

- Force this device into maintenance mode now. Set this device options manually by selecting Device Properties > Polling.
- Scheduled maintenance times. Schedule maintenance times for the device.
- Click Add to schedule a new maintenance time for the device.
- Select an existing entry, then click Edit to change a scheduled time.
- Select an existing entry, then click Remove to delete a scheduled time from the list.

Troubleshooting Tools:

WhatsUp Gold includes several network tools. These troubleshooting tools allow you to take a closer look at the status of your network devices.

The following tools help you check the connectivity of networked devices:

- Ping Tool

- Trace Route Tool
- Lookup Tool
- Telnet Tool

The following tools help you identify information about MIB objects that network devices support:

- SNMP MIB Walker Tool
- SNMP MIB File Explorer Tool

The following tools help you identify problems with network devices so you can take corrective action to resolve issues:

- MAC Address Tool
- Diagnostic Tool
- Using WhatsUp Gold v12
- Web Performance Monitor
- Web Task Manager

Refer https://docs.ipswitch.com/NM/WhatsUpGold2022/02_Guides/Install/index.html for more details

7.2 BACKUP & RECOVERY SYSTEM

For system / image backup of Yokogawa solutions and applications, a centralized backup and recovery management system will be deployed. Veeam Backup & Replication will be installed in the BRS server. The Backup Recovery System (BRS) will be placed in the Level 3 of the Purdue Model.

7.2.1 Installation

Installing Veeam Backup & Replication
Before you install Veeam Backup & Replication, check prerequisites. Then use the Veeam Backup & Replication setup wizard to install the product.

1. Start the setup wizard.
2. Select the component to install.
3. Read and accept the license agreement.
4. Provide a license file.
5. Install missing software.
6. Review the default installation settings.
7. Specify service account settings.
8. Specify the database engine and instance.
9. Perform the configuration check.
10. Specify data locations.
11. Specify service ports.
12. Begin installation.

To install Veeam Agent for Microsoft Windows and all the required components, do the following:

Upload Veeam Agent setup files on the computer you want to protect. Then navigate to the folder where you have saved setup files.

Keep in mind that you must use Veeam Agent setup files that are generated by Veeam Backup & Replication after the protection group for pre-installed Veeam Agents is created.

To install the .NET Framework 4.5.2, double-click the NDP452-KB2901907-x86-x64-AllOS-ENU.exe file located in the <path_to_setup_files>/Windows/6.0.0.960 folder.

If a later version of the .NET Framework is already installed on the computer, you can skip this step.

To install Windows Universal C Runtime (CRT), find and double-click the file depending on your computer OS architecture and version:

OS Architecture	OS Version	File Location	File Name
32-bit	Windows 7 or Windows Server 2008R2	<path_to_setup_files>/Windows/6.0.0.960/VAW/x86/CRT	Windows6.1-KB2999226x86.msu

	Windows 8 or Windows Server 2012		Windows6.1 - KB2999226x64.msu
	Windows 8.1 or Windows Server 2012 R2		Windows8-RTKB2999226x86.msu
64-bit	Windows 7 or Windows Server 2008 R2	<path_to_setup_files>/Windows/6.0.0.960/VAW/x6 4/CRT	Windows8-RTKB2999226x64.msu
	Windows 8 or Window8.1		Windows8.1-KB2999226x86.msu
	Windows Server 2012		
	Window s 8.1 or Windows Server 2012 R2		Windows8.1 – KB2999226x64.msu

To install Veeam Agent for Microsoft Windows, use one of the following files depending on the architecture of your computer OS:

For 32-bit Windows

Double-click the `Veeam_B&R_Endpoint_x86.msi` file located in the `<path_to_setup_files>/Windows/6.0.0.960/VAW` folder

For 64-bit Windows

Double-click the `Veeam_B&R_Endpoint_x64.msi` file located in the `<path_to_setup_files>/Windows/6.0.0.960/VAW` folder

To install the Veeam Installer Service, double-click the `VeeamInstallerSvc` file located in the `<path_to_setup_files>/Windows/6.0.0.960` folder.

7.2.2 Configuration

To configure Veeam Agent for Microsoft Windows, you must apply connection settings from the configuration file. You obtained this file together with other setup files when the protection group for pre-installed Veeam Agents was created. To do configure Veeam Agent, execute the following command from the folder where Veeam Agent setup files are located:

```
"C:\Program Files\Veeam\Endpoint Backup\Veeam.Agent.Configurator.exe" -
setVBRse ttings /p:"<protection_group_name>.xml"
```

where `<protection_group_name>` is a name of the protection group for pre-installed Veeam Agents. Alternatively, you can specify the full path to the configuration file passed with the `/p` option.

Mind that the connection between Veeam Backup & Replication and Veeam Agent is not persistent. Veeam Agent synchronizes with Veeam Backup & Replication every 6 hours. After you apply new backup policy settings in the Veeam Backup & Replication console, Veeam Agent will get these settings during the next synchronization.

To synchronize Veeam Agent immediately, run the following command on the Veeam Agent computer:

```
"C:\Program Files\Veeam\Endpoint Backup\Veeam.Agent.Configurator.exe" -
syncnow
```

7.2.3 Operations

Main functionality of Veeam Backup & Replication includes:

- **Backup:** creating image-level backups of virtual, physical, cloud machines and backups of file shares and object storage repositories.
- **Restore:** performing restore from backup files to the original or a new location. Veeam Backup & Replication offers a number of recovery options for various disaster recovery scenarios, including Instant Recovery, image-level restore, file-level restore, restore of application items and so on.
- **Replication:** creating an exact copy of a VM and maintaining the copy in sync with the original VM.
- **Backup Copy:** copying backup files to a secondary repository.
- **Recovery Verification**: testing VM backups and replicas before recovery.
- **Scale-Out Backup Repositories**: a repository system that allows you to distribute data between performance, capacity and archive tiers.

Refer Veeam-BRS- Document for more details

7.3 ANTIVIRUS MANAGEMENT

7.3.1 Installation

Configuring SQL Server

- Launch the SQL Server installer.
- Click "New installation or add features to an existing installation."
- Click "I accept the license terms". Uncheck"Send feature usage data to Microsoft" and click "Next"
- In Microsoft Update, uncheck the recommended option and click "Next"
- Click "Next" to skip update checking.
- After the wizard is done with its checks, click "Next"
- In Feature Selection, select "Database Engine Services" only.
  Note: Instance root directory and other directories may be changed to a different drive other than the OS partition
- In Instance Configuration, specify Named Instance for Trellix ePO server as "EPOSERVER", same with the Instance ID. Click "Next".
- Proceed with the default values for the Account Name and Startup Type and click "Next".
- In Database Engine Configuration, Select "Windows authentication mode" and leave default selection for SQL administrators. Click "Next"
- A warning to restart the computer may or may not appear. Click "OK" in case it appears.
- If no error has been encountered, click "Close" to end the installation process.
- Open SQL Server Configuration Manager in Apps.
- Expand SQL Server Network Configuration and click on Protocols for EPOSERVER. Right click on TCP/IP and click on "Enable".
- Right click on "TCP/IP" and click on "Properties".
- Scroll down the TCP/IP Properties and expand "IPAll". Under TCP Port enter "1434" and click OK.
- Restart SQL Service by Selecting SQL Server Services on the left pane. Select SQL Server (EPOSERVER) on the right pane. Click Action and Restart.

Installation of ePolicy Orchestrator

- Double click "SETUP.exe" to start installation.
- Click "OK" on the warning regarding RAM recommendation.
- In the InstallShield Wizard, Click "Next" to start installation.
- Additional software will be installed together with ePO. Click Next to proceed.
- Change destination folder to the partition other than the OS partition.
- Specify Database Server by Computer Name and SQL Instance Name (Created upon installing the SQL Server Express). In Database Server credentials, select "Windows Authentication" and specify Domain, Username and Password fields. Windows credential should be the same as specified during SQL Server Database Engine Configuration. Click on "Next".
- Click "OK" on the pop up window regarding access to UDP Port. In SQL server TCP port manually enter "1434"
- In HTTP Port Information, under Agent-server communication port, manually enter "8080". Verify the information before clicking "Next" to proceed.
- In Administrator Information, enter the credentials that will be used for ePO management web console.
- In Type License Key, enter the license key as indicated otherwise, click Evaluation and click Next to proceed. Click OK to acknowledge expiration of Evaluation license.

- In Trellix Licensing, accept the license agreement by clicking on the corresponding button. Click "OK" to proceed. Click "Install" to start the installation.
- Click "Finish" to end ePO installation.

IIS / FTP Installation

- At the Server Manager, click "Add Roles and Features".
- "Add Role and Features" Wizard will open, Click Next. Under "Installation Types", choose "Role based…" and click on "Next".
- Under "Server Selection", choose "Select a server from…" then click on "Next".
- Under Server Roles, select Web Server IIS and ensure FTP Server is also selected then click "Next"
- Under Select Features, click "Next" to proceed.
- Select "Restart the destination server automatically if required" and click "Install" to start installation process.
- Installation progress will be shown. Wait until the installation process is complete.
- Once installation succeeds, click "Close"

FTP Site configuration

- At the Server Manager, click "Tools" and choose Internet Information Services (IIS) Manager.
- On the Connections Pane on the left, click on "Sites" then on the Actions Pane on the right click "Add FTP Site…
- Enter FTP Site Name, and physical content for the site information.
- Enter IP address of ePO Server, and use port 21. Under SSL, select "No SSL". Click Next.
- Under Authentication window, Select Anonymous as authentication and put a Read Only Permission. Click Finish to create the FTP Site.
- After Creation of Site, newly created FTP Site will be shown under "Sites". On the Actions Pane on the right, click "Restart".
- To check if the FTP is up, open a browser and type the FTP address.

Extensions Installation

- Extensions contains files, components, and information necessary to manage a product.
- Open ePO, Click Menu, under Software, choose Extensions
- Under Extensions window, Click Install Extension.
- Browse the location of the extension file to be added. Click Ok to continue.
- Check the package and click Ok to install the extension.
- Under Extension, click VirusScan Enterprise and view the installed extension.

Check-in Package

- Once logged on to the ePO console, click Menu button. Under Software, click Master Repository.
- In Master Repository, click "Check in Package button"
- Browse and add the needed package(s). For VSE8.8, Click "Next" to proceed
- Choose on which repository branch the packaged will be checked in then click "Save".
- Notice that the added VirusScan Enterprise package is now listed in the Master Repository.
- Browse and add the needed package(s). For DAT file, select the package and Click "Next" to proceed.
- Choose on which repository branch the packaged will be checked in then click "Save".
- Notice that the added DAT package is now listed in the Master Repository.

Source Site Configuration

- The source site provides all updates for your master repository. The default source site is the Trellix Http update site, but you can change the source site or create multiple source sites if required.
- For the ePO server in DMZ, Source Site can be either from Internet or ePO server in the office domain, depending on the system architecture. In Crosswind-BLPH source site is from the ePO server in office domain.
- The Source Site for ePO server on DMZ is from the ePO server in office Domain.
- Click Menu, under Configuration click on Server Settings.
- Under Server Settings, in Settings Category select Source Site.
  Click Edit button (lower right corner) to configure Source Site.
- Click Add source Site to add Source Site
- Enter Repository Name. Select Type as "FTP". Click Next.
- Select IPv4. Enter the address of the FTP Server with port number as port 21. Click Next.
- Select IPv4. Enter the address of the FTP Server with port number as port 21. Click Next.
- Summary of all the details will be shown. Click Save.
- The new Source Site will be shown in the site list. Click Save.

Repository Pull

- Repositories house software packages and updates for distribution to managed systems.
- In ePO menu, under Software, Click on Master Repository.
- Master Repository window will open, Click Pull now to trigger pull action from source site
- Select Source site for the Pull action. All source Site configured in the ePO will be shown. Click Next
- Select required packages for the Pull action. Click Next to continue.
- Summary page will be shown review pull action summary and click Start Pull to trigger pull action.
- Server Task Log will open to show the status.
- Once the pull is complete, click Close.
- Master Repository will now reflect the pulled packages.

System Tree - Creating Groups

- Groups are used to segregate the systems so that common tasks and policies can be applied to them independently.
- Open ePO and Select System Tree from the Tab. Click New Subgroups
- Enter the Group Name, then click OK.
- The new created Group will be shown under My Organization in the System Tree.

System Tree - Adding new system to ePO

- Open ePO and select System Tree from the Tabs.
- The client machines can be added by selecting the "New System" Option from the System Tree Tab.
- Under How to add systems, choose "Add systems to the current group (current selected group in System Tree), but do not push agents".
- Under the target systems, add the IP address of the target computer
- Click "OK".
- System tree will display the added system in Unmanaged State.
- Click Actions > Agent > Deploy Agents to change the state to Managed.
- In Deploy Trellix Agent window, enter the required credentials for agent installation (local administrator on the unmanaged system). Click "OK" to proceed.
- Server Task Log will display the progress of the deployment. Click on the task to view more details.

- Once the task is completed click Close to go back to System Tree.
- In System Tree, the system will now be displayed as Managed.

Client Task Catalog

- Open ePO, Click Menu, under Policy choose Client Task Catalog.
- In Client Task Catalog window, choose Product Deployment. Click New Task
- In New Task, choose Product Deployment under Task Types.
- Enter the Task Name and Description. Under Products and components, choose VirusScan Enterprise , Install from Branch Current. Click Save
- The newly created Task will be shown under Product Deployment.
  Under Actions column, Click on Assign to assign the task to a node in the System Tree.
- Assign Client Task to My Organization (or the node where it is applicable)
  Click OK.
- In the Client Task Assignment Builder, ensure that all parameters are correct.
  Schedule can also be set in this window. Once done, click Save.
- The Client Task Catalog should display the product deployment task created with its corresponding assignment.
- To deploy VirusScan Enterprise, select the system that will be deployed with the product.
  Go to Actions menu by clicking Actions. Select Agent > "Run Client Task Now"
- In the Run Client Task Now window, select the Client Task created for product deployment.
  Click "Run Task Now".
- Once deployment task is complete, click Close.
- Check the deployment in the system by logging in to the system
- From ePO menu, open Client Task Catalog, select Product Update. Click New Task to create a new task
- In Task Type, select Product Update and click OK.
- In Client Task Catalog, enter the necessary details. Click Save.
- Once completed, the created task should appear in Client Task Catalog.
- Under Actions Pane, click Assign to assign the task to a node in the System Tree.
- Select the node in the System Tree to assign the created task and click OK.
- In the Client Task Assignment Builder, ensure that all parameters are correct.
  Schedule can also be set in this window. Once done, click Save.
- In System Tree, select the system to update. Go to Actions menu by clicking Actions.
  Select Agent > "Run Client Task Now"
- In the Run Client Task Now window, select the Client Task created for product update.
  Click "Run Task Now".
- Once product update task is complete, click Close.

Policy Catalog

- Policies ensure that the managed security software products are configured and perform accordingly
- From the ePO menu, select Policy Catalog under Policy.
- In Policy Catalog window, under Product select VirusScan Enterprise. Under Category select General Options Polices Click New Policy.
- Provide the necessary details and click OK.
- Open the created policy by clicking on the name.
- Under Display Options tab, select "Display managed tasks in the client console"
- Do the same settings for "Server"

- Click "Password Option Tab", click Password protection for all selected items.
- Do the same settings for "Server". Click save.
- In the System Tree go to Assigned Polices tab and under Category select General Options Policies and click Edit Assignment
- In the Policy Assignment window, under assigned policy, select the created task and Click Save.
- In the System select the client and click Wake Up Agents
- In client VirusScan Console, the view should be updated according to the policy assigned.
- To unlock VirusScan console, go to Tools and click Unlock User Interface. You must know the administrator password that was set from the ePO server.
- Enter the needed credentials to unlock interface.

7.3.2 Implementation and configuration

7.3.1.1 Trellix ePolicy Orchestrator Server (ePO 5.10)

The target Trellix ePO Server must meet the specific system and hardware requirements to run the Trellix ePolicy Orchestrator (ePO). Assess the requirements before installing the Trellix ePO software to guarantee a successful installation.

The following table provides the settings that are required to be configured on the Trellix ePO server of PIN and DMZ.

Description	Trellix ePO Server (DMZ)	Trellix ePO Server (PCN)
Disable the Product Improvement Program	Required	Required
Disable Global Update	Required	Required
FTP Server Configuration	Required	Not Applicable
FTP Distributed Repository	Required	Not Applicable
FTP Source Site	Not Applicable	Required
Export of Security Keys	Required	Not Applicable
Import of Security Keys	Not Applicable	Required
ENS Platform Check-In	Required	Required
ENS Threat Prevention Check-In	Required	Required
ENS AMCore Check-In	Required	Required
Trellix Agent Check-In	Required	Required

Delete Unmanaged Products	Required	Required
Trellix Agent Extension	Optional	Required
Endpoint Security Extension	Optional	Required
Threat Prevention Extension	Optional	Required
Disable Master Repository Update	Required	Required
Disable Download Software Product List	Required	Required
Disable Download and Schedule Deployment of Software Product Updates	Required	Required
Creating Groups	Optional	Required
Trellix Agent Deployment	Optional	Required
Import Yokogawa Advanced Policy	Optional	Required
Import Yokogawa Advanced Task	Optional	Required
Adding the Yokogawa AMCore Update Task	Optional	Required
Adding the Yokogawa Standard AV (ENS) Deployment Task	Optional	Required
Adding the Yokogawa Standard AV (ENS) Uninstallation Task	Optional	Required
Adding the Trellix Agent Update Task	Optional	Required
Optional – Required when there is a client to be managed in the DMZ Trellix ePO Server		

Table 19- Trellix ePO Server Matrix Table

Refer Cyber Security Settings Document for more details

7.4 OS PATCH MANAGEMENT

The Windows Server Update Services (WSUS) is a Microsoft solution that provides a platform for managing and distributing the latest Microsoft product updates to computers on the network. Implementing this solution and following the recommended configuration gives the plant asset administrator the capability to control the patches that would be installed on the plant asset.

7.4.1 Component and Functions

Windows Server Update Service (WSUS) Server

The WSUS server provides a management console to centrally manage and enforce updates to the client. The WSUS stores all the applicable updates and ensures availability to the clients upon patch approval. The WSUS console provides detailed client updates information and reports through the dashboard. In the Yokogawa OS Patch implementation, the WSUS server must be able to connect to the Microsoft Update to get the latest available update information. This server shall have a secure connection to the Microsoft website.

Windows Update Clients

Embedded in each installation of the Microsoft Windows operating system is the Windows Update. This is a built-in service provided by Microsoft for a routine check and installation of updates to the operating system. By default, Windows Update is configured to connect to the Microsoft Update site via the internet, however, this configuration is changed to connect to an onsite WSUS server.

7.4.2 Configuration and Settings

Update Source

The update source is the location from which the WSUS server gets its updates and update metadata. In the Yokogawa implementation, the WSUS server is configured to download updates directly from the Microsoft Update. By design, the initial synchronization will download all the updates that are specified on the WSUS server. Subsequent synchronization shall download only new updates from the update source, as well as revisions in metadata for existing updates, and expirations to updates.

Update Files and Languages

- Storing Updates
  The update files are stored in the WSUS server based on the configured update files settings. In the Yokogawa implementation, the WSUS server is configured to store all selected classification and product updates locally. This will ensure that the required updates during the approval of updates are already available on the WSUS server.
- Selected Languages
  The update files are downloaded based on the languages that are selected on the WSUS server. It is possible to synchronize updates in all the languages in which they are available, or you can specify a subset of languages. In the Yokogawa implementation, only the required language shall be selected on the WSUS server during the configuration.

Supported Products and Classification

The WSUS downloads updates based on the products and classifications that are configured on the server. By default, the WSUS is configured to download all the critical and security updates of all the Windows products.

Computer Groups

The computer node refers to a central access point in the WSUS administrative console for managing computers. The clients can be organized into logical groups/subgroups based on their machine type, topological/ geographical locations, or their functionality boundaries. Creating groups/subgroups for systems with similar properties or requirements allows the administrator to target updates to a group of client computers, so you can ensure that target computers always get the right updates.

The default computer group includes the All Computers and the Unassigned Computers group.

- All Computers – computer clients are always assigned or part of the All Computers Group
- Unassigned Computers – computer clients are part of the Unassigned Computer Group until it is assigned to another computer group.

Schedule

The scheduled configuration on a WSUS depends on the component type. Each component type has its own recommended behavior when it comes to downloading updates.

- WSUS Server Schedule

  During a scheduled synchronization, the WSUS server downloads updates (update metadata and files) from an update source. The frequency of the synchronization depends on the configured timing on the WSUS server. In the Yokogawa implementation, the WSUS server is configured to synchronize every day to the Microsoft Website.

- WSUS Client Schedule

  During a Windows Update, the WSUS clients download the approved updates from the WSUS server. The frequency of the synchronization depends on the configured timing of the WSUS client policy. In the Yokogawa implementation, the WSUS client has no automated schedule on when to download the approved updates. The Windows updates are triggered manually on the client during the approved maintenance schedule.

WSUS with Secure Sockets Layer (SSL)

WSUS with SSL ensures integrity between the WSUS clients and the WSUS server. In the Yokogawa implementation, the Active Directory Certificate Services (AD CS) role is used to manage the digital certificates in implementing the certificate-based authentication of WSUS.

WSUS Permission Groups

In order to use all the features of the WSUS console, the user shall be added as part of the Administrator group or the WSUS Administrator group. It is recommended to provide only the necessary permission based on user job responsibility. For the Windows Domain user management implementation, refer to the reference document.

By default, the two security groups are created on the WSUS server upon setup.

- WSUS Administrator – members of this group can fully manage the distribution of updates to computers on the network and administer the WSUS role
- WSUS Reporter – a member of this group can generate reports but cannot approve updates or configure the WSUS role

Application Pool Configuration

The WSUS application pool private memory threshold is set to 1843200(KB) which at times is too small. When the private memory threshold limit is reached due to heavy load, the WSUS application pools are automatically recycled and clear the WSUS Metadata cache.

7.4.3 WSUS Installation Setps

WSUS Role Installation Procedure

- Open Server Manager and select Add roles and features. This will start the Add Roles and Features Wizard.

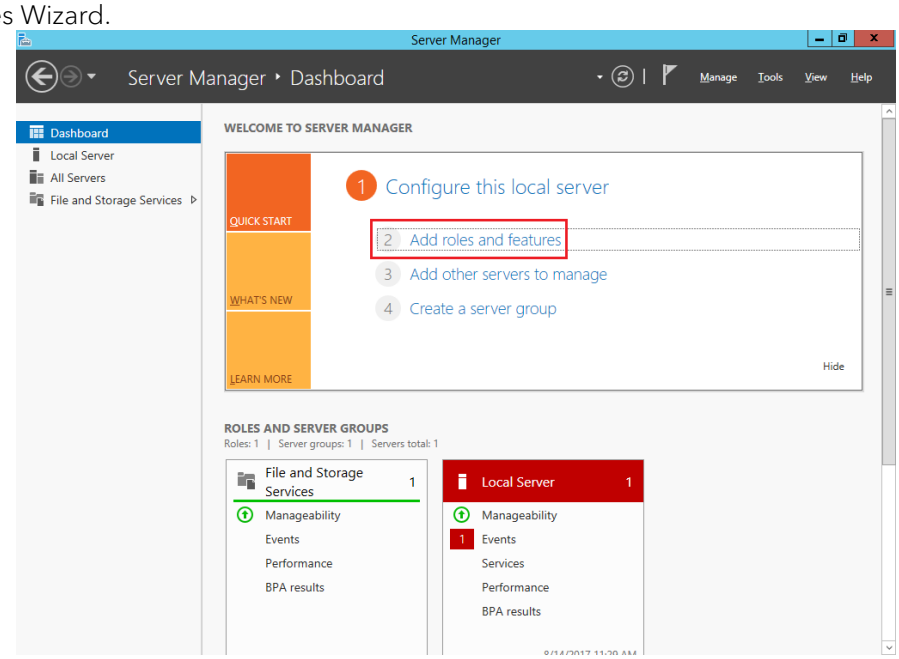

Figure 46 – Server Manager Console

- Once the Wizard opens, click on the "Next" button on the Before You Begin task.

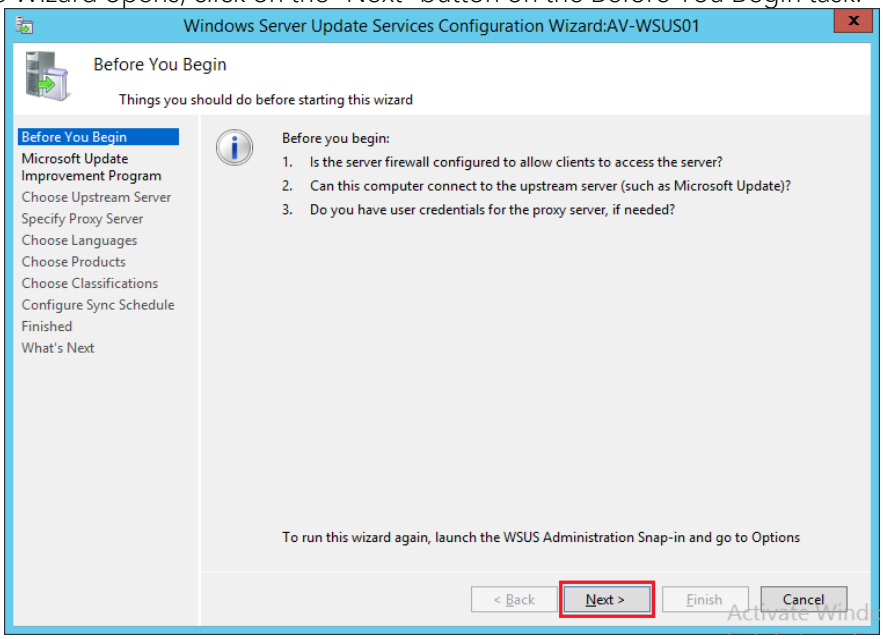

Figure 47 – Prerequisites for WSUS Configuration

- Make sure to select Role-based or feature-based installation before clicking on Next button.

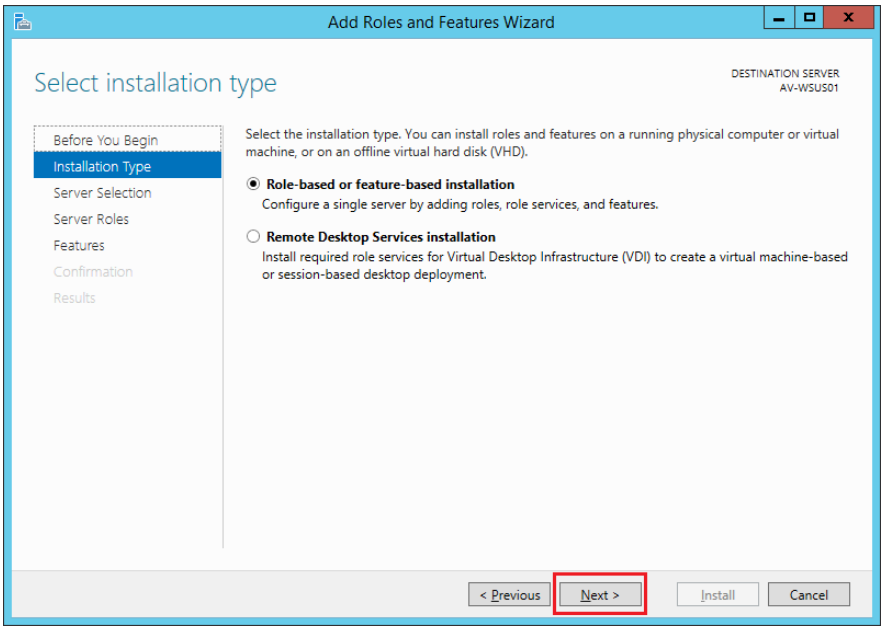

Figure 48 – Roles and Features Wizard to select type of Installation

- Click on Select a server from the server pool and make sure to select the WSUS server on the Server Pool List. Click Next.

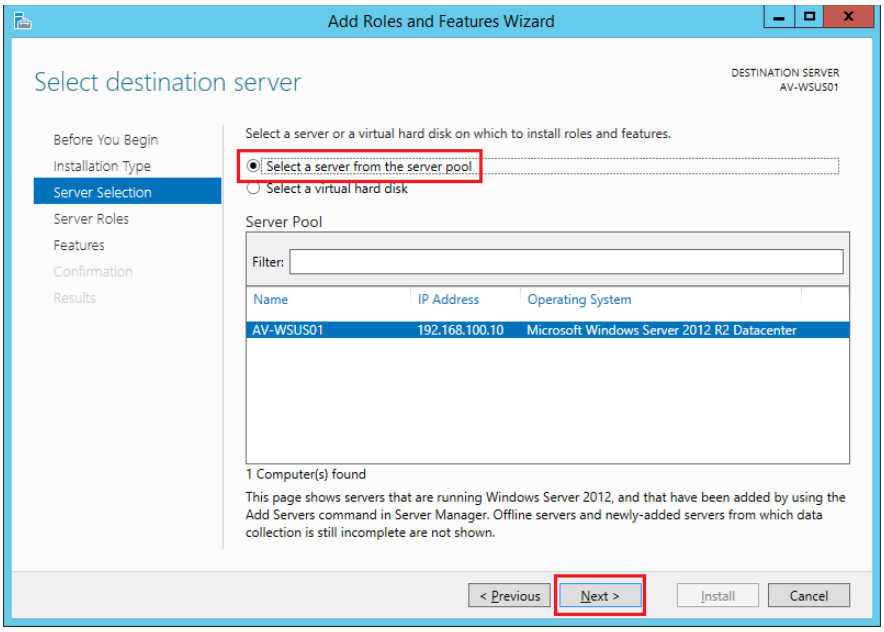

Figure 49 – Roles and Features Wizard to select destination server

- Select Windows Server Update Services and click Next

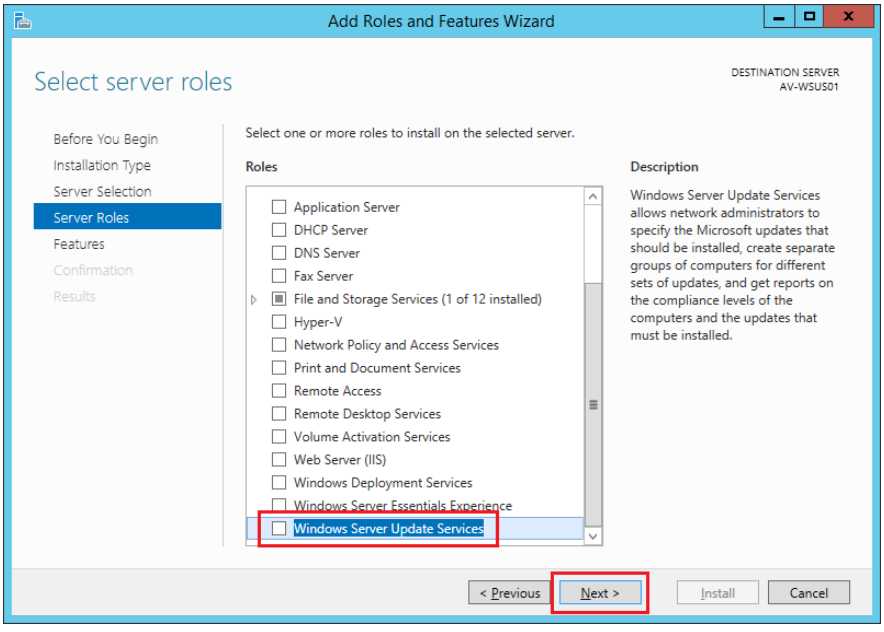

Figure 50 – Roles and Features Wizard to select server roles

- Required role services and features will be automatically selected. Ensure Include management tools (if applicable) is selected. Click Add Features

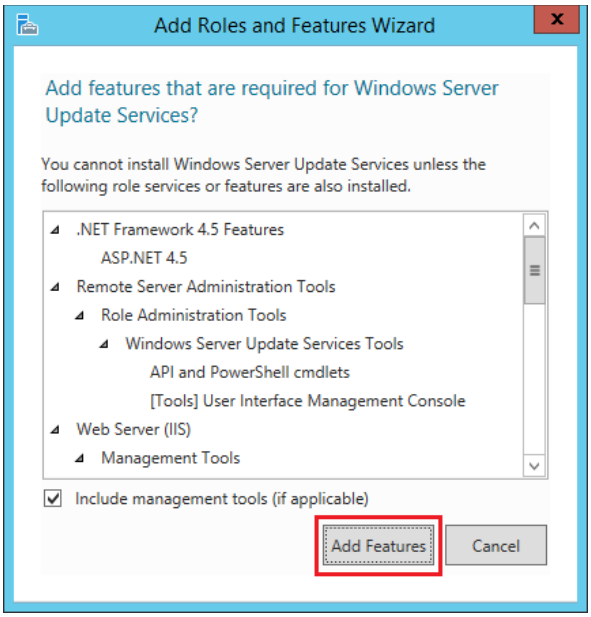

Figure 51 – Roles and Features to include for WSUS setup

- Same as step 5, click Next

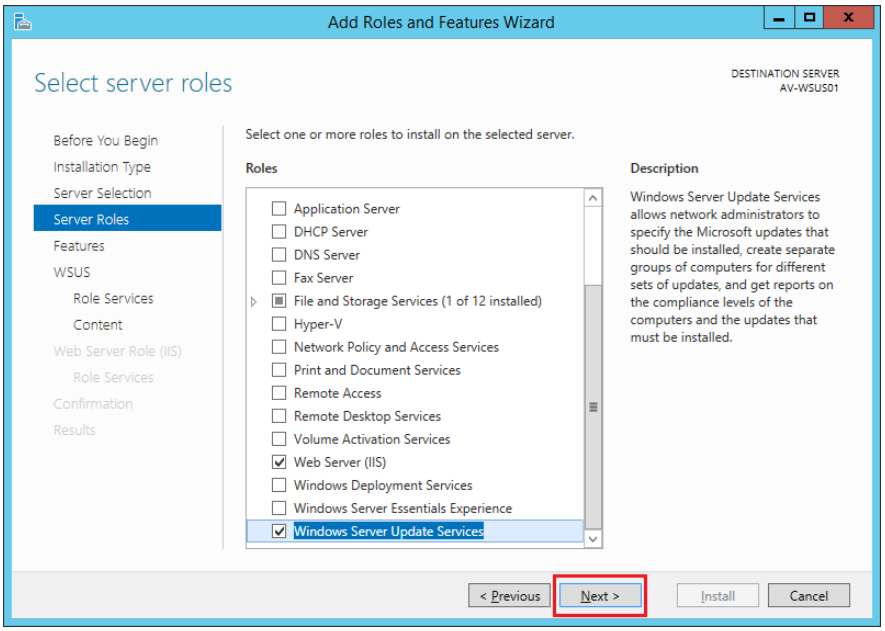

Figure 52 – Roles and Features wizard to select server roles(WSUS,IIS)

- Other required role services and features will be automatically selected. Select .NET Framework 3.5 Features. Click Next.

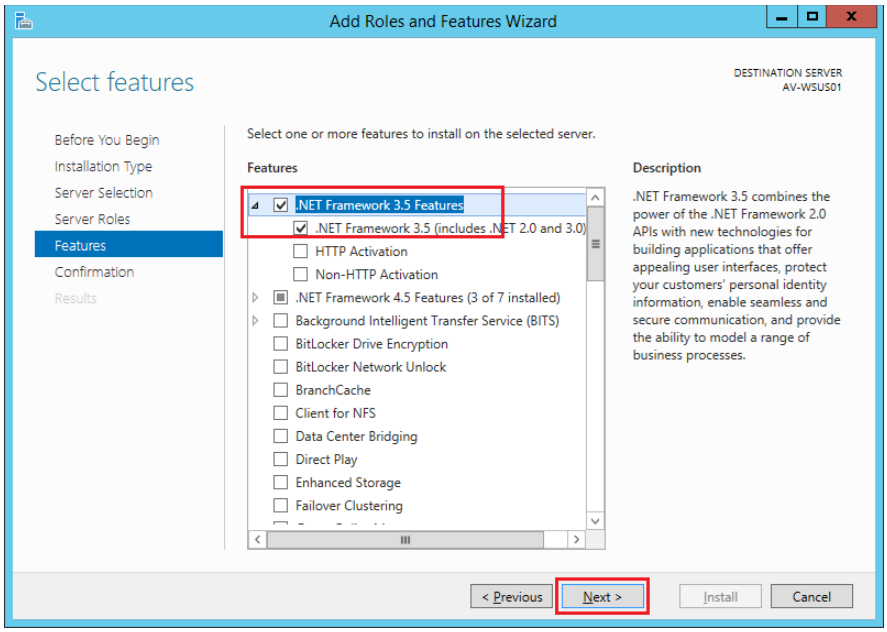

Figure 53 – Roles and Features wizard to include .NET framework

- Click Next.

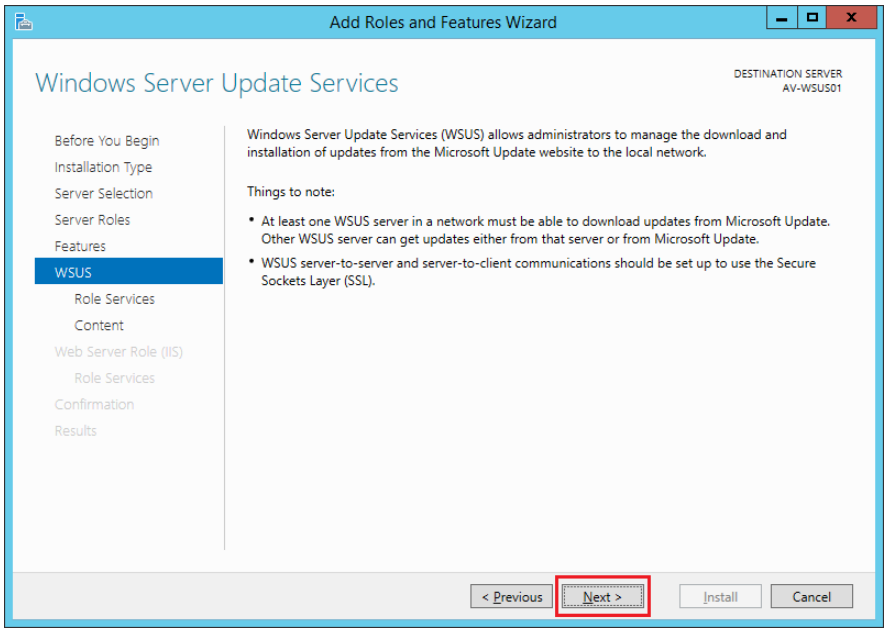

Figure 54 – WSUS Configuration

- Ensure that WID Database and WSUS Services are selected and click Next.

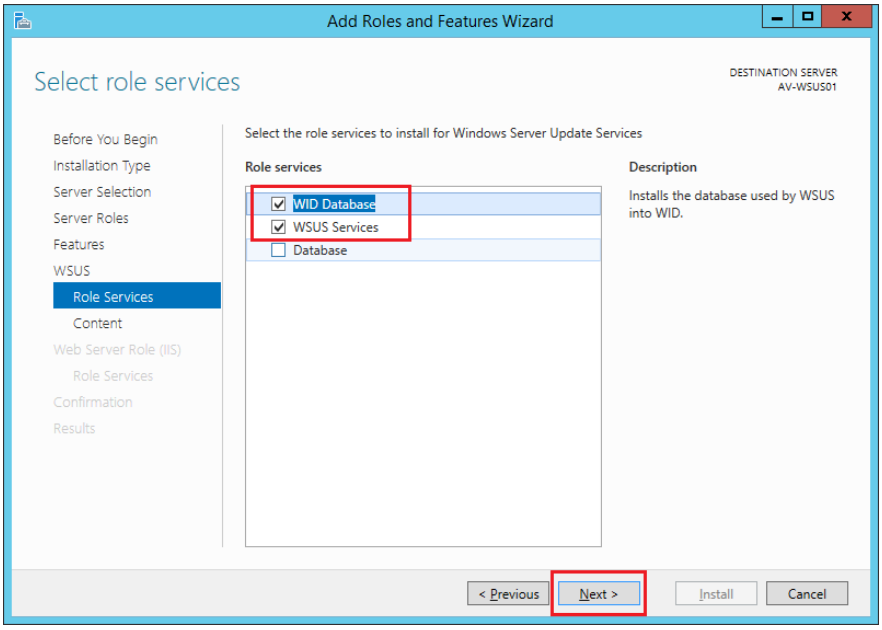

Figure 55 – Installation of database to WID

- Specify the path where the updates will be stored. In this case E:\WSUS\. Click Next.

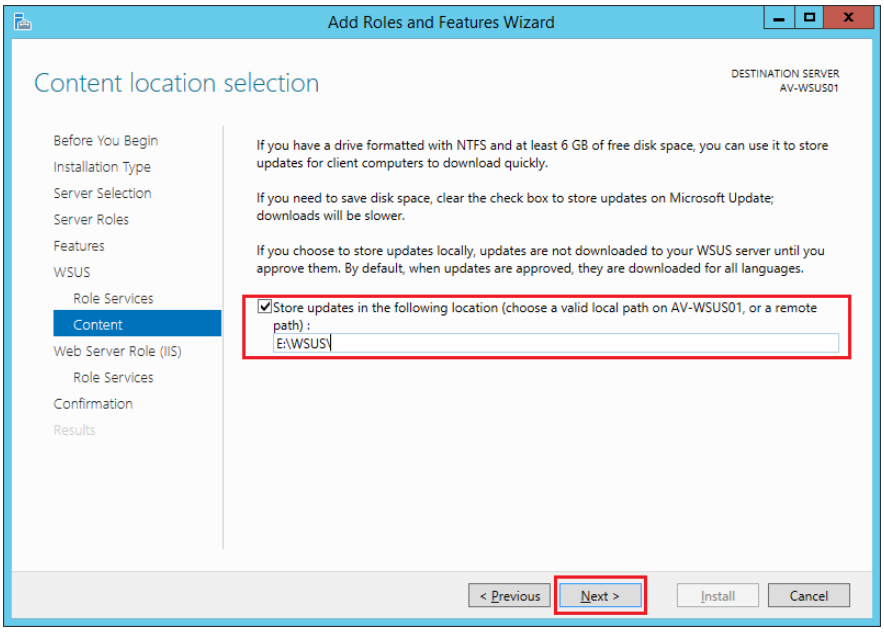

Figure 56 – Roles and features wizard to select the content location

- Under Web Server Role (IIS) Click Next

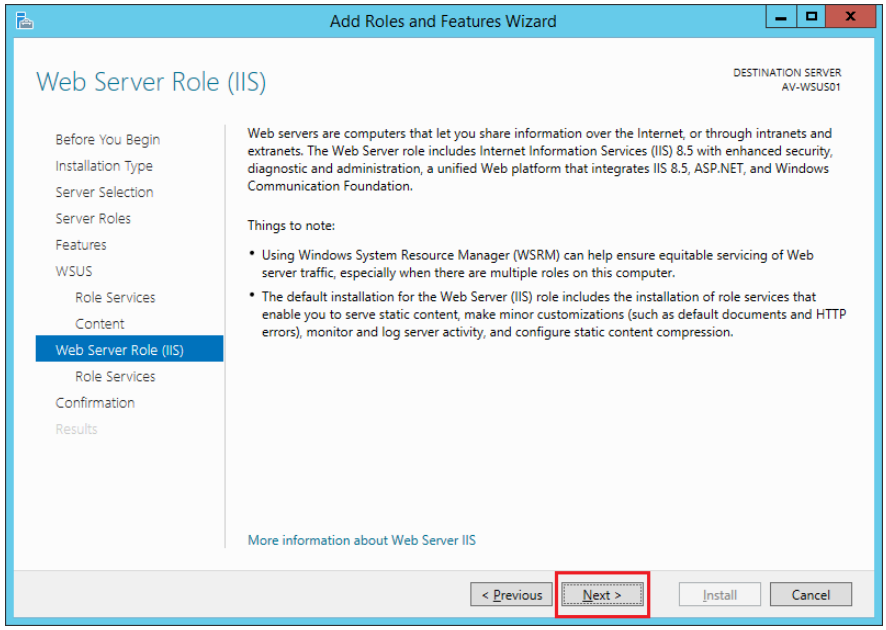

Figure 57 – Web Server role wizard

- Under Role Services for IIS, default requirements are automatically selected, click Next.

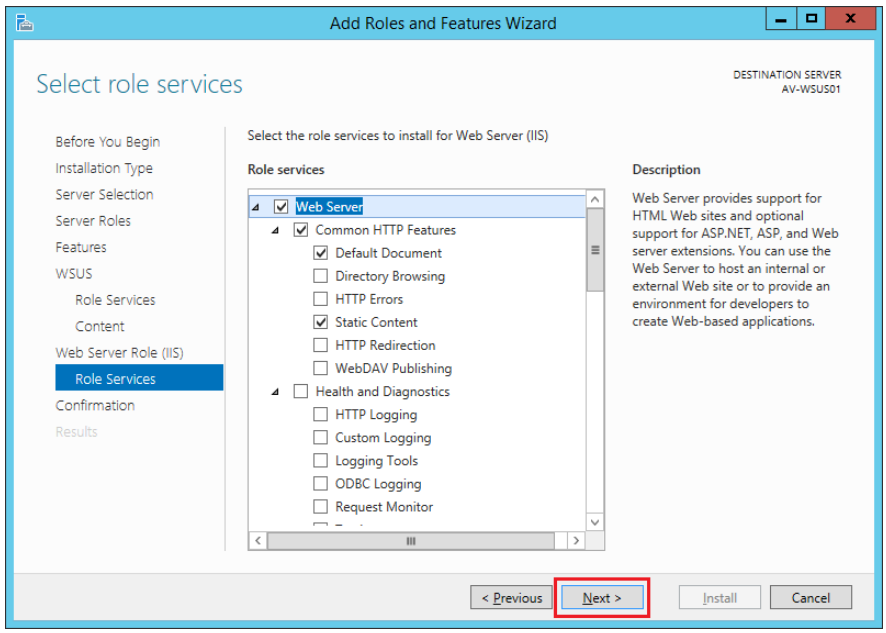

Figure 58 – Roles and features wizard to install services for IIS

- Confirm the installation details. Select Restart the destination server automatically if required. Click Install.

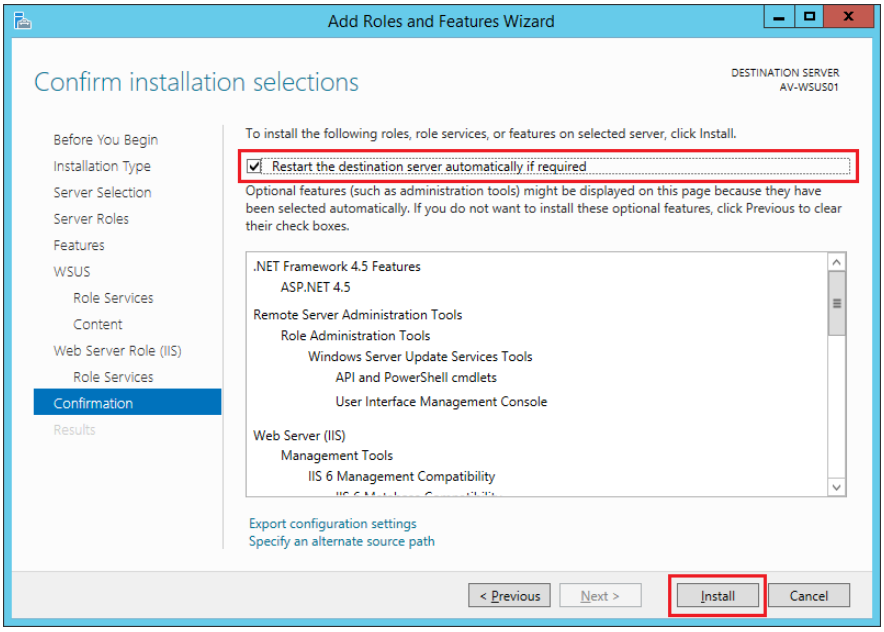

Figure 59 – WSUS Installation wizard

- Wait until the feature installation is done. Click Close.

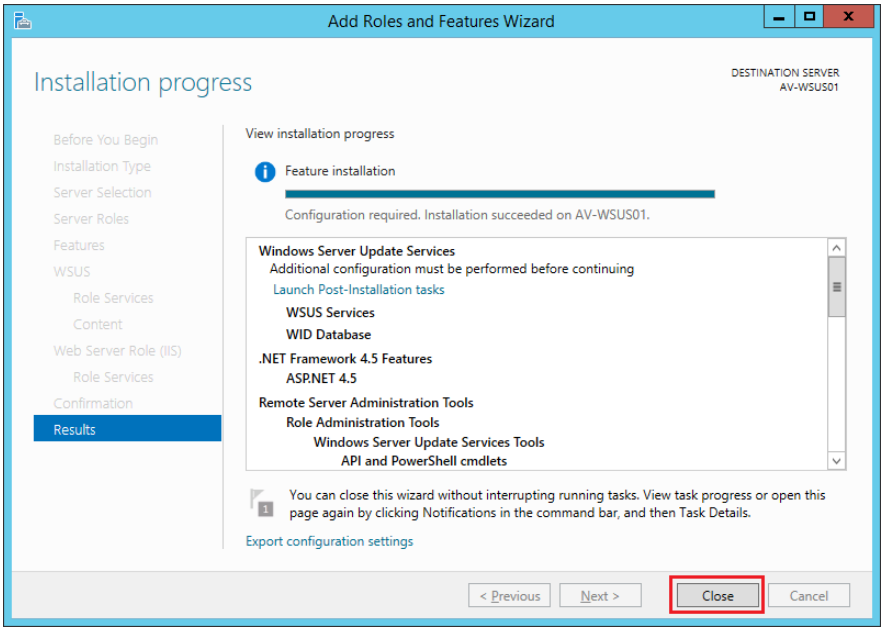

Figure 60 – WSUS Installation Completion wizard

Post Installation Task

- In Server Manager click on the Notifications icon, and click on Launch Post-Installation tasks

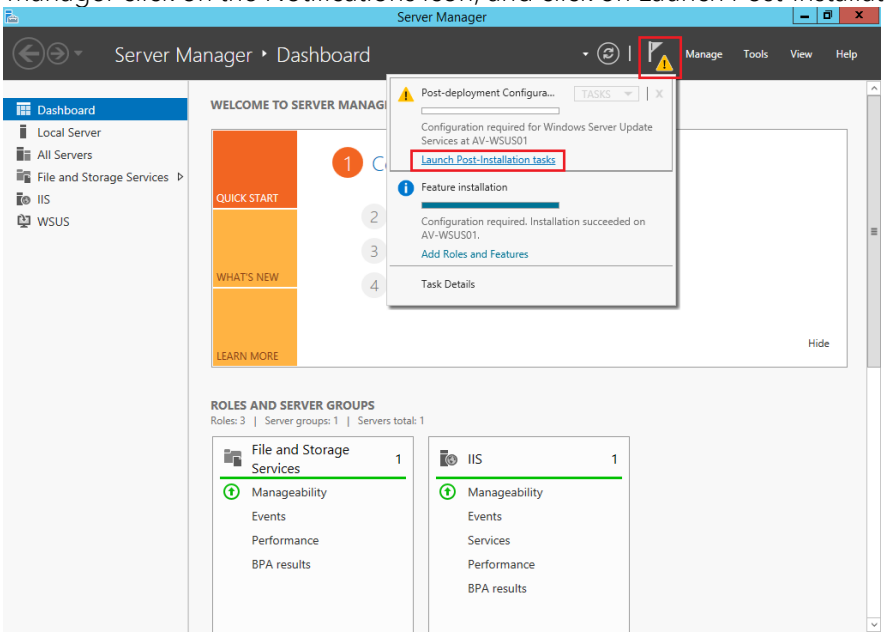

Figure 61 – Server manager console for post deployment configuration

Configuration Wizard

- To open WSUS Management Console. In Server Manager, click on Tools > Windows Server Update Services

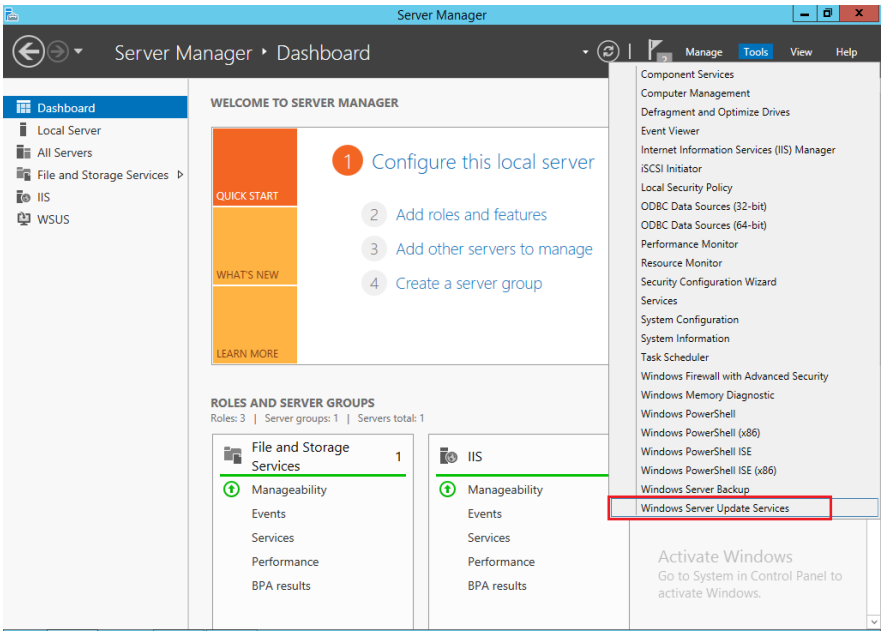

Figure 62 – Server manager dashboard to select WSUS

- Once the configuration wizard launched, click on Next.

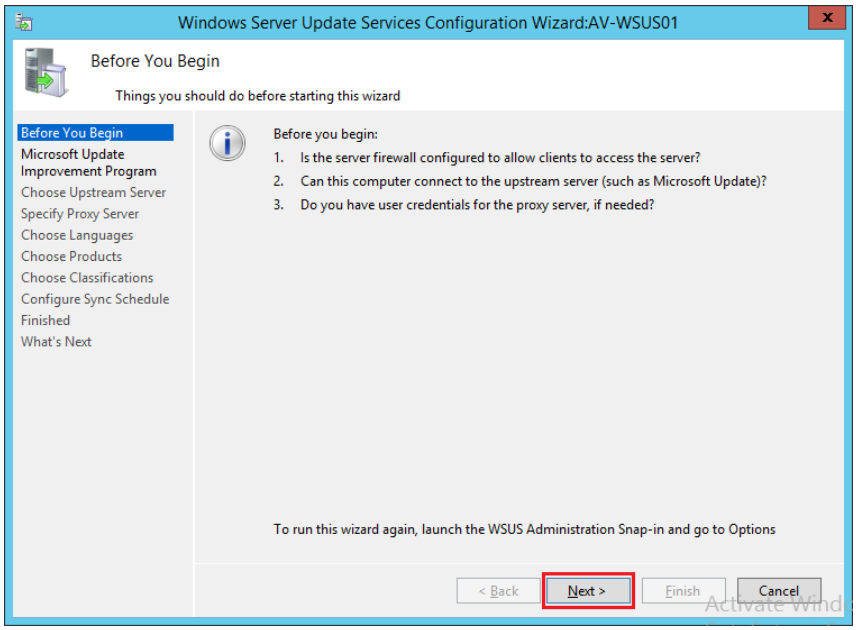

Figure 63 – Windows Server Update Services Configuration Wizard

- Under Microsoft Update Improvement Program, make sure NOT to select Yes, I would like to join the Microsoft Update Improvement Program.

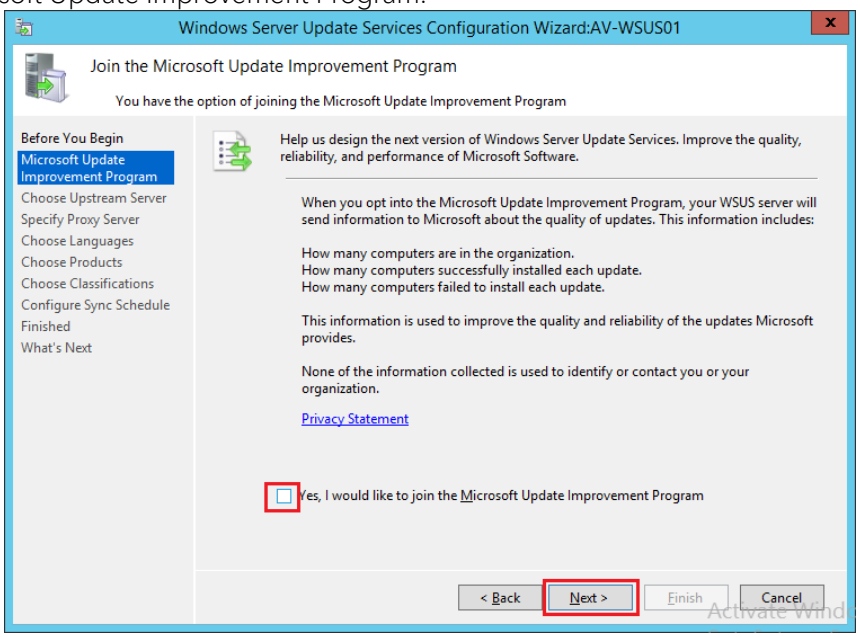

Figure 64 – Windows Update Improvement Program Wizard

- When choosing the upstream server for DMZ WSUS select Synchronize from Microsoft Update.

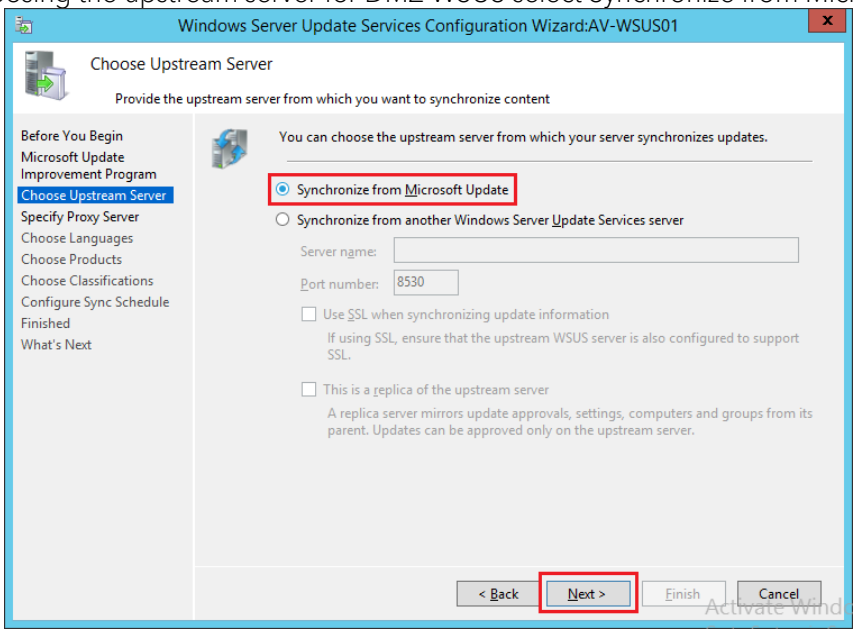

Figure 65 – WSUS wizard to configure the synchronization

- When choosing the upstream server for DMZ PCN select Synchronize from another Windows Server Update Services server and key in the IP Address Ex:192.168.100.10 and port number on the corresponding fields. Click Next.

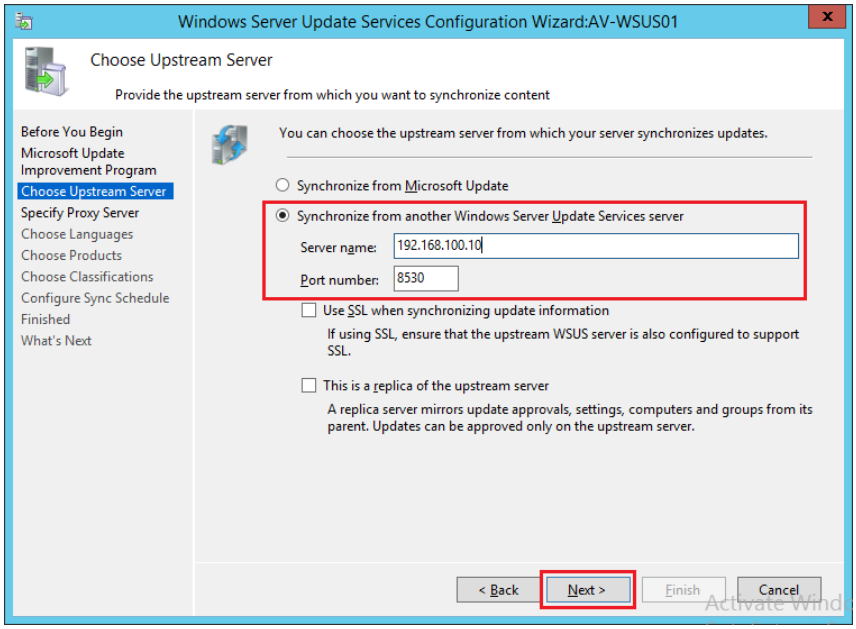

Figure 66 – WSUS wizard to configure the server name & port number of upstream server

- Specify the Proxy server if any and if required. Click Next

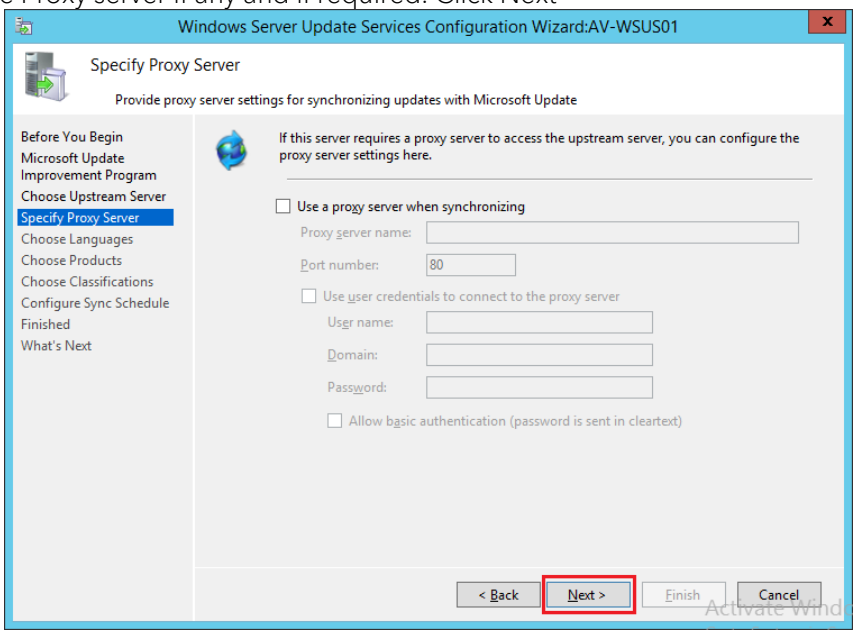

Figure 67 – WSUS wizard to configure the proxy server

- Click Start Connecting to test the connection to the specified Upstream Server.

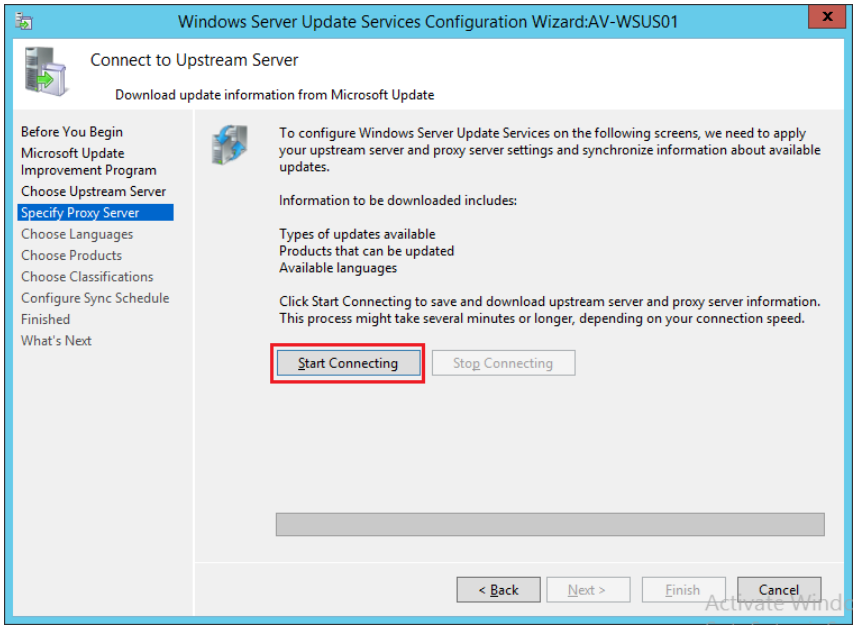

Figure 68 – WSUS wizard to download the update information

- It may take a while to connect, but once done, click Next.

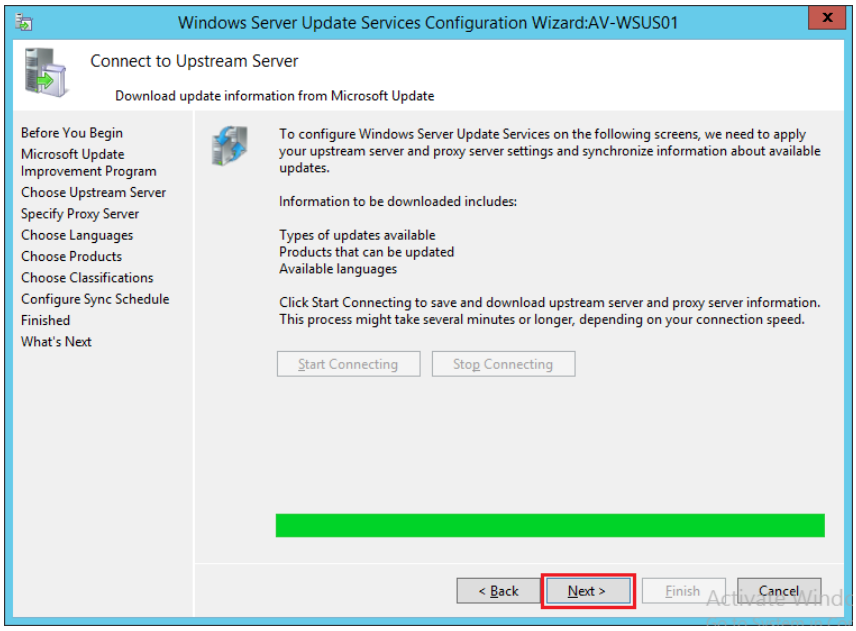

Figure 69 – WSUS wizard showing the completion of downloading the Updates

- Select Download updates only in these languages and select English. Click Next.

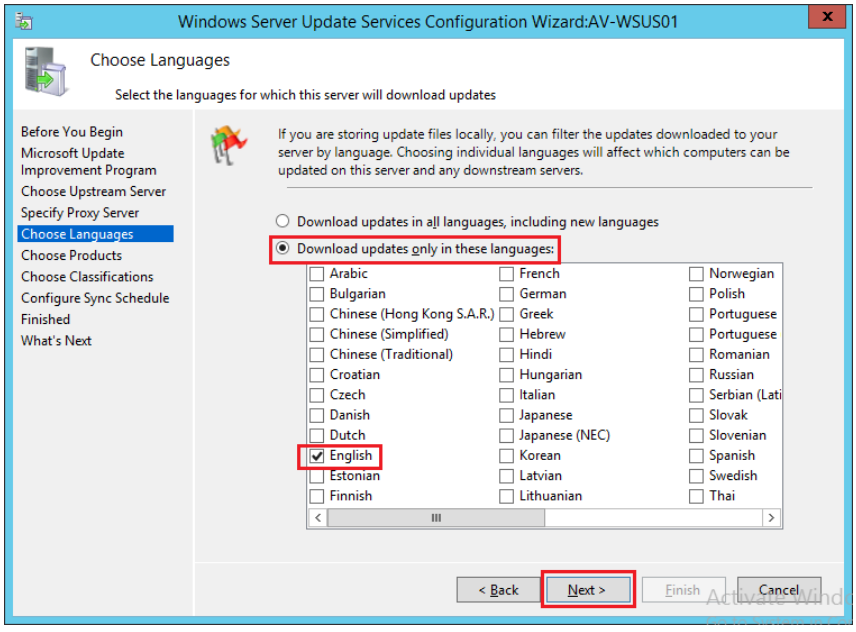

Figure 70 – WSUS wizard for selecting the languages

- Select the supported products that needs to be updated. Click Next.

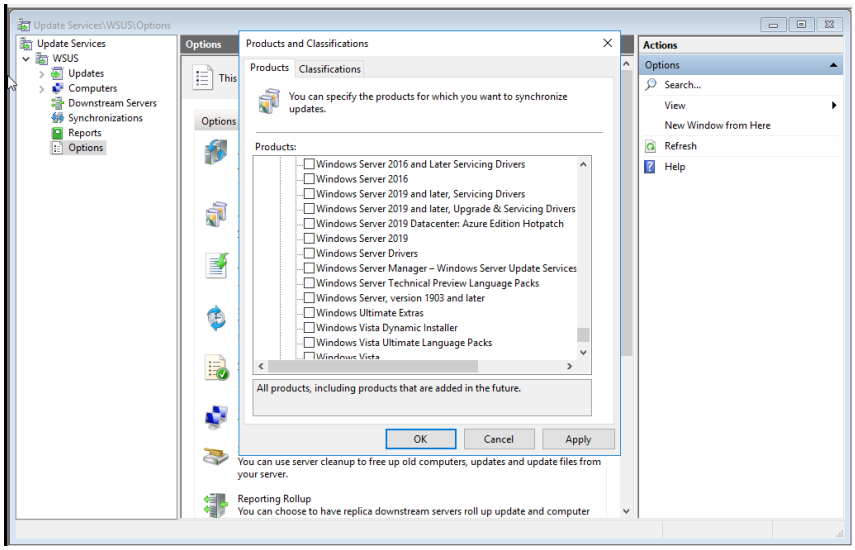

Figure 71 – WSUS wizard for selecting the supported products

- Under Classifications, select Security Updates only. Click Next.

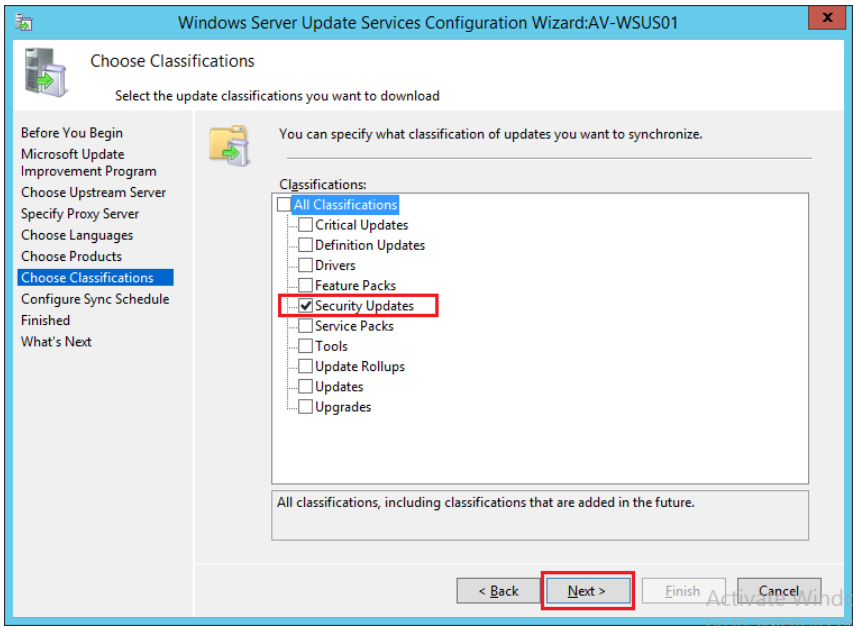

Figure 72 – WSUS wizard for selecting the Updates

- To configure Sync Schedule, select Synchronize automatically and set the time of First Synchronization and frequency of synchronization. Click Next.

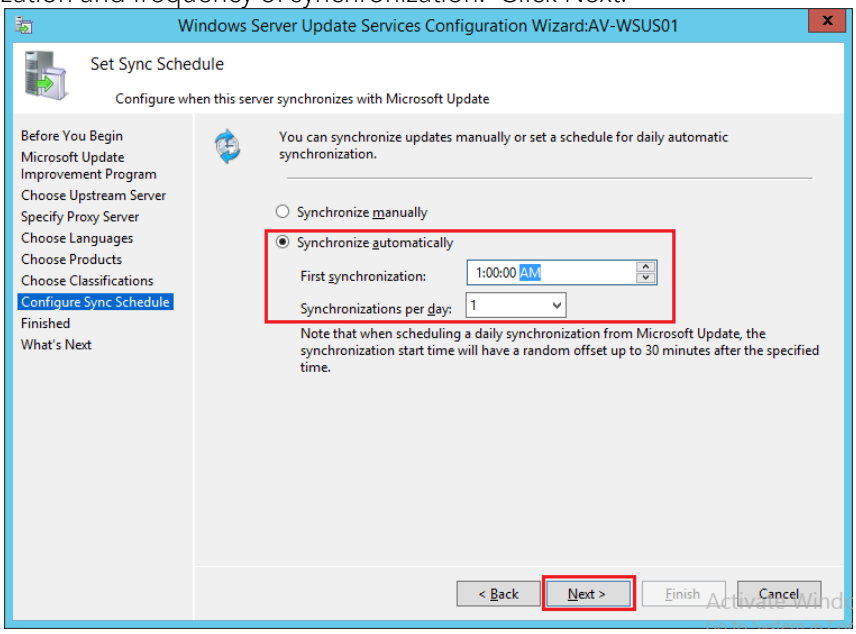

Figure 73 – WSUS wizard for configuring the server synchronization

- Select Begin initial synchronization. Click Next.

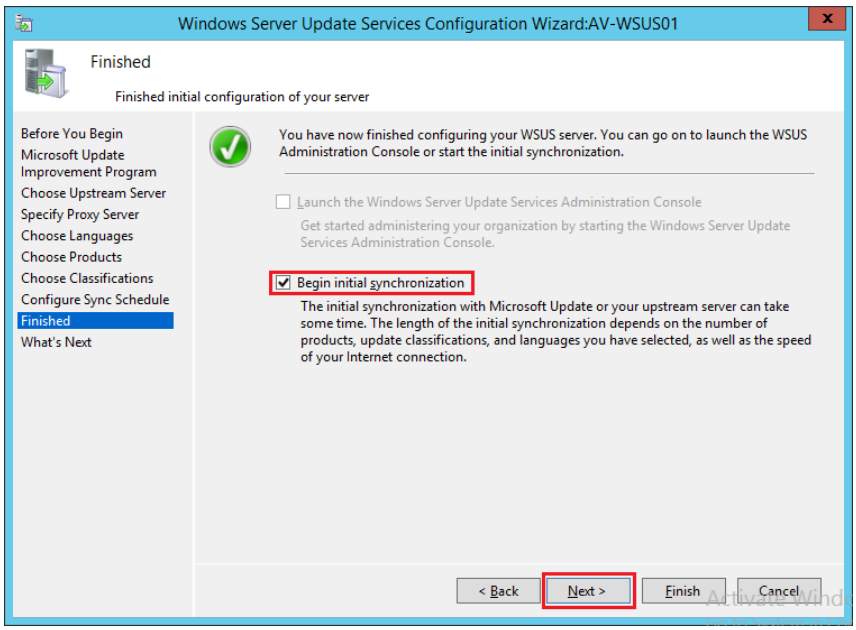

Figure 74 – WSUS Configuration Wizard showing the initial synchronization

- Click Finish. A manual synchronization should appear under Synchronizations.

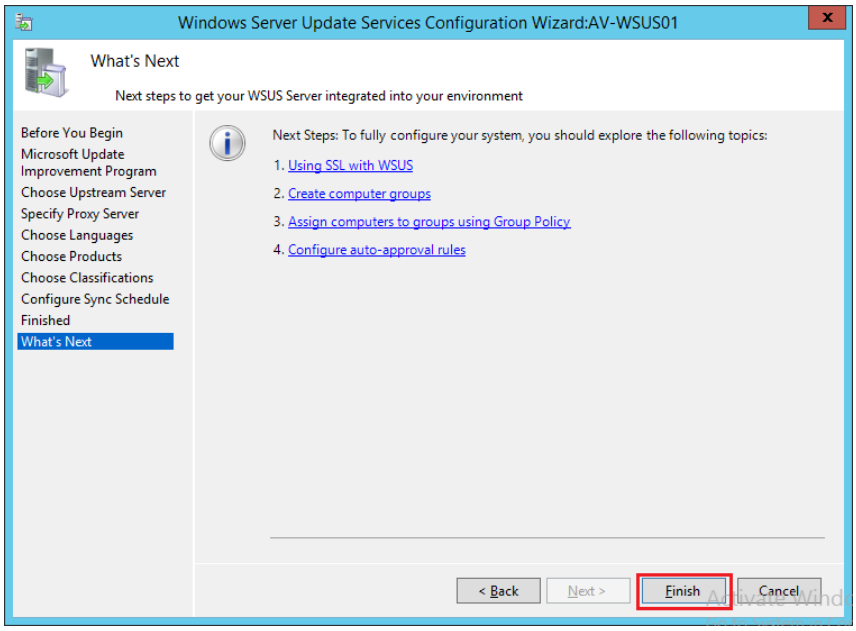

Figure 75 – WSUS Configuration wizard

Synchronization

- To execute a manual synchronization, go to Synchronizations, click Synchronize Now on the Actions Pane on the right

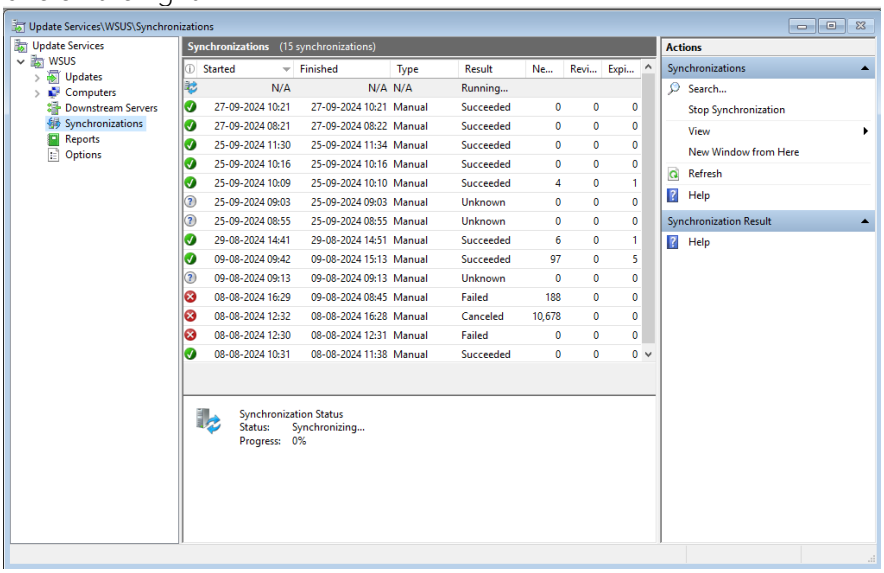

Figure 76 – Initial synchronization status

- A summary of the synchronization will appear on the same window.

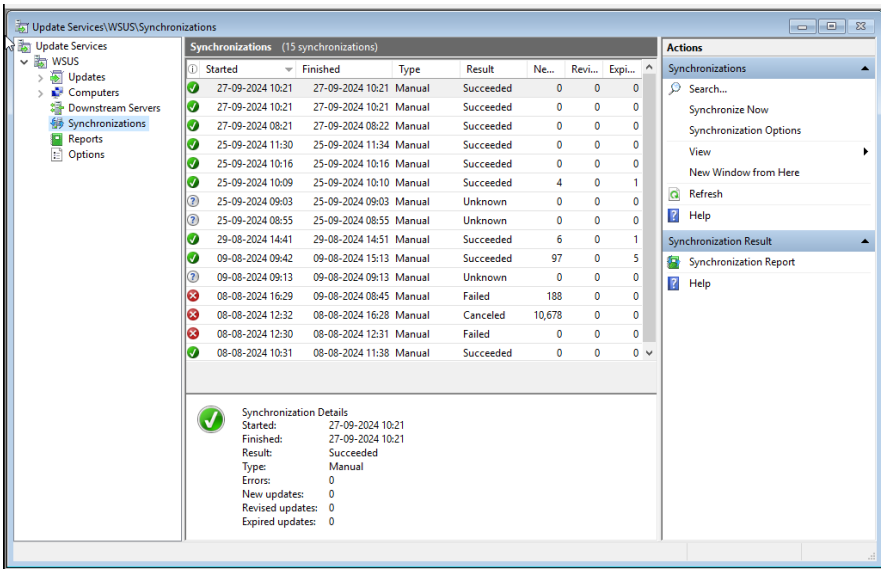

Figure 77 – Synchronization Summary

- Under Updates, a dashboard type of overview of updates is shown.

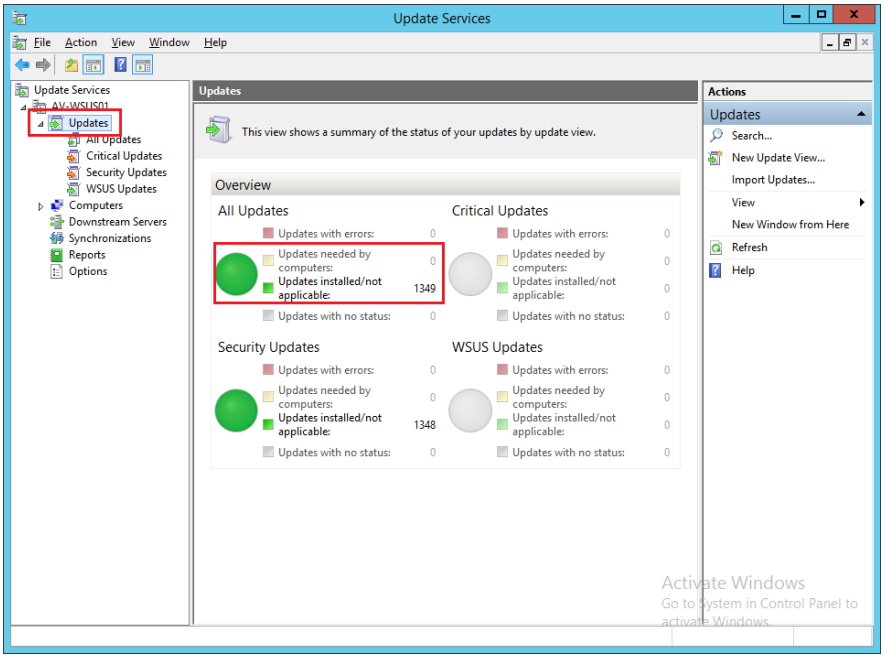

Figure 78 – Summary of the status of updates

Groups and Membership Creation

- To create a group, go to All Computers and click on Add Computer Group on the Actions Pane on the right.

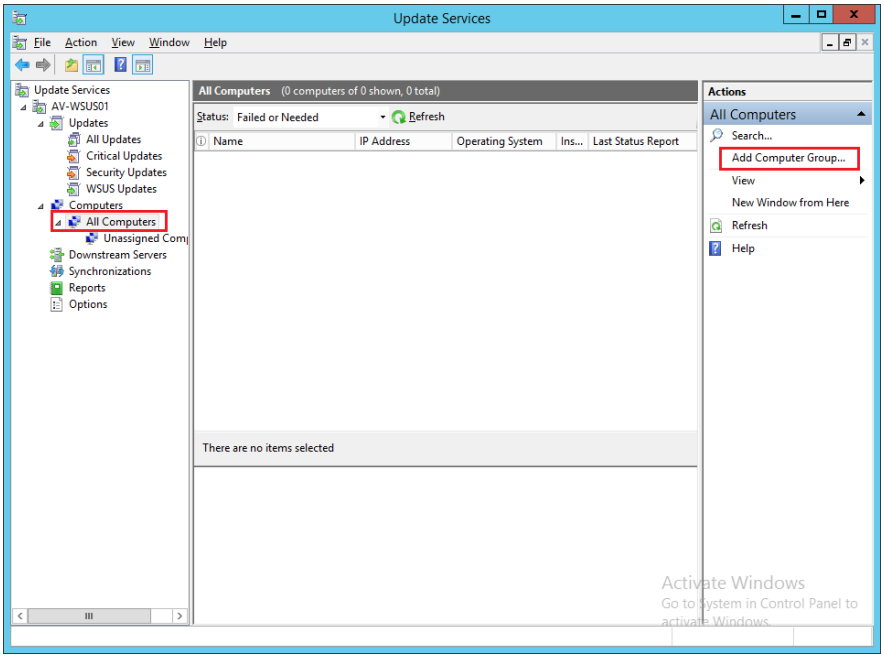

Figure 79 – Creation of group and computers

- Type in the desired group name on the field Name and click Add

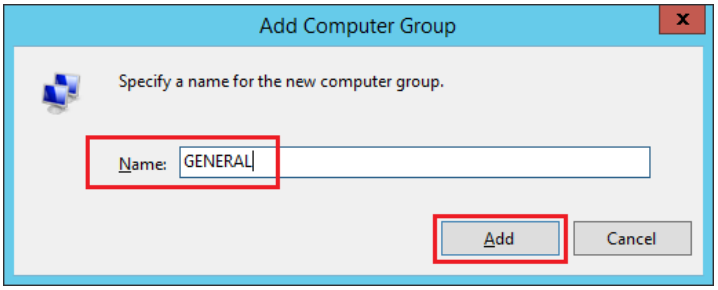

Figure 80 – Specifying Name to a group

Refer Cyber Security Settings Document for more details

8 EMCS INSTALLATION, OPERATION AND MAINTENANCE

8.1 INTRODUCTION

The core of EMCS is built with industrial computers and IO modules:

- 2 SEL-RTAC 3555: redundant computers where the main control logic is executed.
- 2 SEL-Axion 2240: redundant computers mainly used to acquire hardwired signals and to communicate with IE 61850 devices. The Axion is provided with a set of DI/DO modules.

For the position of these computers inside the BLPH network infrastructure, please refer to the System Architecture document (1724000594-IN-DD-00015).

8.1.1 SEL-RTAC 3555

The SEL-3555 Real-Time Automation Controller (RTAC) is a high-performance industrial automation device designed by Schweitzer Engineering Laboratories (SEL). It serves as a powerful programmable logic controller (PLC) and substation automation platform, integrating protection, control, and communication functions for power systems and industrial applications.

Key Features:

- High-Speed Processing: Advanced multi-core processing for fast and reliable control logic execution.
- Secure Communications: Supports multiple protocols (IEC 61850, DNP3, Modbus, etc.) with encryption and authentication for cybersecurity.
- Flexible I/O and Expansion: Interfaces with a wide range of field devices, sensors, and relays.
- SCADA and HMI Integration: Acts as a data concentrator, supporting real-time monitoring and automation.
- Industrial-Grade Reliability: Designed for harsh environments, with ruggedized hardware and redundant power supply options.
- Programming and Configuration: Uses ACSELERATOR RTAC® SEL-5033 software for easy setup, logic development, and maintenance.

The SEL-3555 RTAC is ideal for applications such as substation automation, microgrid control, renewable energy integration, and industrial process automation.

For detailed information about the RTAC 3555, please refer to the manufacturer documentations:

- 3555_IS-GettingStarted_20180727.pdf
- 3555_RTAC_PF00343.pdf
- 3555-2_DS_20241218.pdf

8.1.2 SEL-Axion 2240

The SEL-2240 is a combination of compact RTAC (SEL-RTAC 2241) and IO Module used in industrial and utility automation applications. It serves as a remote I/O module that seamlessly integrates with SEL's RTAC family, including the SEL-3555, to expand I/O capabilities in power system automation and control systems.

Key Features:

- Distributed I/O Expansion: Provides additional digital and analog I/O for RTAC-based automation systems.
- Secure Communication: Supports IEC 61850, DNP3, Modbus over Ethernet or serial connections.
- Rugged Design: Built for harsh environments, with high immunity to electrical transients and extreme temperatures.
- Flexible Mounting Options: DIN rail or panel mounting for easy installation in substations, industrial plants, and renewable energy systems.
- Seamless Integration: Works as an extension of SEL-3555 or other RTAC controllers, enabling scalable automation solutions.

The SEL-2241 RTAC is ideal for substation automation, distributed energy resource (DER) control, and industrial process monitoring, where additional remote I/O is needed for real-time data acquisition and control.

For detailed information about the RTAC 3555, please refer to the manufacturer documentations:

- 2240_IM_20241217_20241217.pdf
- 2240_DS_20241025.pdf
- 2240_PF00274.pdf

For a full list of the document please visit https://selinc.com/products/2240/docs/.

The picture below shows the composability of the IO modules and how they are connected to the RTAC 2241 using a backplane.

Figure 81- RTAC 2241 and IO Modules

8.2 INSTALLATION

This chapter provides detailed guidelines for the proper installation of the SEL-3555 Real-Time Automation Controller (RTAC) and the SEL-2240 Axion. Following these instructions ensures optimal performance, safety, and longevity of the system.

8.2.1 Pre-Installation Requirements

Before proceeding with the installation, ensure the following:

Site Requirements

- Environmental Conditions:
  - Operating temperature: **−40°C to +75°C**
  - Humidity: **0–95% non-condensing**
  - Protection against **dust, moisture, and electromagnetic interference (EMI)**
- Mounting Location:
  - Securely fasten on a **control panel**, **relay rack**, or **DIN rail**
  - Ensure proper **ventilation** to prevent overheating
- Power Supply:

- Input voltage range: 125/250 VDC or 120/240 VAC
- Adequate grounding and protection against power surges

Required Tools & Equipment

- Screwdrivers (flathead and Phillips)
- Multimeter (for voltage and continuity checks)
- Crimping tools (for cable termination)
- Shielded twisted-pair cables (for communication connections)
- Ethernet cables (for network setup)
- Personal protective equipment (PPE)

Safety Precautions

- Disconnect power before installation.
- Follow lockout/tagout (LOTO) procedures.
- Ensure proper electrostatic discharge (ESD) protection.

8.2.2 SEL-3555 RTAC Installation

The SEL-3555 RTAC can be installed using either panel mounting or DIN rail mounting.

Panel Mounting

1. Align the SEL-3555 with the designated mounting holes.
2. Secure the unit using M4 or #8 screws.
3. Verify the unit is firmly attached to prevent vibration damage.

DIN Rail Mounting

1. Attach the DIN rail clips to the RTAC's backplate.
2. Clip the unit onto the 35mm DIN rail.
3. Ensure the RTAC is securely fastened and does not move.

Power Supply Connections

- Use appropriately rated cables and connect to the power terminals.
- Verify polarity when using DC power:
  - + Terminal → Positive
  - − Terminal → Negative
- For AC power, ensure proper phase and neutral connections.
- Connect the protective earth (PE) to a proper grounding point.

Communication Interfaces

The SEL-3555 RTAC supports multiple communication protocols, including:

- Ethernet (RJ-45)
- Serial (RS-232, RS-485)

Ethernet Connection

1. Connect CAT5e or CAT6 cables to the RJ-45 Ethernet ports.
2. Ensure proper IP configuration via ACSELERATOR RTAC® SEL-5033.

Serial Connection

1. Connect RS-232 or RS-485 cables to the DB-9 or terminal block.
2. Set the correct baud rate and parity settings.

8.2.3 SEL-2240 Axion Installation

The Axion system consists of a backplane chassis, power supply module, RTAC processor module, and I/O modules. It can be installed using a panel mounting:

1. Position the Axion chassis on the mounting surface.
2. Secure the unit using M6 or #10 screws through the mounting holes.
3. Ensure the chassis is firmly attached to prevent vibration-related failures.

Power Supply Connections

The SEL-2240 Axion supports multiple power supply options:

- 24–48 VDC
- 110–250 VDC / 120–240 VAC

Steps for Power Connection:

1. Connect the positive (+) and negative (−) terminals of the DC power source.
2. For AC power, connect L (Line) and N (Neutral) terminals correctly.
3. Securely fasten the protective earth (PE) ground connection.
4. Verify power input voltage and polarity using a multimeter before energizing.

Communication Interfaces

The Axion RTAC module provides multiple communication ports:

- Ethernet Ports (for SCADA, RTU, or RTAC integration)
- Serial Ports (RS-232, RS-485) for legacy device communication

Ethernet Connection (RJ-45 Ports)

1. Use CAT5e or CAT6 cables for Ethernet connectivity.
2. Connect the Ethernet cable to the LAN/WAN ports on the RTAC module.
3. Configure IP settings via ACSELERATOR RTAC SEL-5033 software.

Serial Connection (RS-232/RS-485 Ports)

1. Connect the serial cable to the DB-9 or terminal block.
2. Set the correct baud rate, parity, and stop bits.
3. Use RS-485 termination resistors if required.

I/O Module Wiring

The SEL-2240 Axion supports modular I/O expansion, with digital and analog I/O modules.

Digital I/O Wiring (DI/DO Modules)

- Use shielded cables to minimize electrical noise.
- Connect dry contact inputs or relay outputs as per system requirements.
- Verify voltage levels (12V, 24V, 125V DC/AC) before connection.

Analog I/O Wiring (AI/AO Modules)

- Use twisted-pair cables for 4-20mA or 0-10V signals.
- Ensure proper calibration before connecting to field devices.

This document undergoes an issuance cycle within EDMS Fusionlive". Its distribution is electronically controlled. Once printed shall be considered as "NOT CONTROLLED" copy

8.3 OPERATION

This chapter describes the operation, functionality, and management of the SEL-3555 Real-Time Automation Controller (RTAC) and the SEL-2240 Axion, including system startup, user interface navigation, communication setup, control logic execution, and troubleshooting.

8.3.1 Powering Up the System

1. Ensure all power supply connections are secure.
2. Apply power to the RTAC and Axion modules.
3. Observe the LED indicators to confirm normal operation.

LED Indicator	Status	Meaning
Power LED	Solid Green	Normal operation
Status LED	Flashing Green	Device booting up
Status LED	Solid Red	System error (check logs)
Ethernet LED	Blinking Green	Active network communication

4. If error LEDs are illuminated, refer to troubleshooting (Section 5.7).
5. Verify network connectivity via ping test or ACSELERATOR RTAC software.

8.3.2 Web User Interface Navigation

The SEL-3555 RTAC and Axion RTAC module provide a web-based user interface for configuration and monitoring.

Steps to Access Web Interface:

1. Open a web browser (Chrome, Edge, or Firefox).
2. Enter the RTAC's URL address (https://<IP-Address>).
3. Log in using administrator credentials.
4. Navigate through the menus:
    - Status Dashboard: Displays real-time system status.
    - Network Interfaces: To configure the ethernet interfaces
    - Network Utilities: To test network connectivity toward field devices (Ping, TCP Port Check)
    - Communication Diagnostics: Monitor Ethernet and serial connections.
    - Security Settings: Configure user access control and encryption.

8.3.3 ACSELERATOR RTAC Software

For advanced configuration and logic development, use ACSELERATOR RTAC SEL-5033:

1. Open ACSELERATOR RTAC on a PC.
2. Connect via USB, serial, or Ethernet.
3. Import or create a project file.
4. Use the Logic Editor to develop control logic.
5. Upload and validate the configuration.

For details about the AcSELelerator RTAC Software please refer to the **SEL-5033 Manual.pdf** manufacturer document.

8.3.4 Troubleshooting

Issue	Possible Cause	Solution
No Power	Faulty power supply	Check voltage, replace power source
No Network Communication	IP conflict, firewall block	Verify IP settings, disable firewall
RTAC Not Responding	Overloaded CPU/memory	Restart device, check CPU usage
I/O Module Not Detecting Inputs	Loose wiring, incorrect addressing	Recheck wiring, verify I/O configuration
Serial Port Not Communicating	Incorrect baud rate, bad cable	Adjust baud rate, replace cable

8.3.5 Redundancy

The system is configured in a Master/Slave redundancy mode at both the RTAC 3555 and Axion levels, ensuring fault tolerance even if one RTAC 3555 and one Axion module fail (or are powered down) simultaneously.

8.3.6 System Shutdown & Restart

8.3.6.1 Safe Shutdown Procedure

1. Save all configuration changes.
2. Disable network connections if necessary.
3. Power down Axion I/O modules first.
4. Power down the **RTAC last**.

8.3.6.2 Restart Procedure

1. Power on the **RTAC first**.
2. Power on Axion **I/O modules** sequentially.
3. Verify all **LED indicators** for proper startup.
4. Test communication and system performance.

8.4 MAINTENANCE

Regular maintenance ensures reliable operation, longevity, and optimal performance of the SEL-3555 RTAC and SEL-2240 Axion. This chapter provides guidelines for preventive maintenance, firmware updates, diagnostics, troubleshooting, and corrective actions.

8.4.1 General Maintenance Guidelines

To maintain the RTAC 3555 and Axion 2240 in optimal condition:

- Schedule routine inspections every 3 to 6 months.
- Keep firmware and software updated to ensure security and performance enhancements.
- Monitor system logs for early detection of issues.
- Maintain proper ventilation to prevent overheating.
- Regularly verify communication links and I/O module integrity.
- Follow cybersecurity best practices to prevent unauthorized access.

8.4.2 Preventive Maintenance

8.4.2.1 Visual Inspection

Regularly inspect both the RTAC 3555 and Axion 2240 for:

- Loose cables and connectors
- Signs of overheating, corrosion, or dust accumulation
- LED status indicators to detect warnings or errors
- Proper grounding to avoid electrical faults

Action Steps:

- ☐ Tighten any loose connections.
- ☐ Clean the ventilation openings to ensure proper airflow.
- ☐ Replace any damaged cables immediately.

8.4.2.2 Cleaning and Environmental Maintenance

- Dust and debris can cause overheating and affect device performance.
- Use compressed air or a soft brush to clean around the vents and ports.
- Ensure the ambient temperature remains within the operational range:
  - RTAC 3555: −40°C to +75°C
  - Axion 2240: −40°C to +75°C
- Verify that humidity levels do not exceed 95% (non-condensing).

Warning: Do **not** use liquid cleaners or solvents directly on the devices.

8.4.3 Firmware and Software Updates

Keeping the firmware and software up to date is crucial for security, performance, and compatibility with new features.

8.4.3.1 Checking Firmware Version

1. Access the RTAC/Axion Web Interface.
2. Navigate to System > Device Information.
3. Note the current firmware version and compare it with the latest version from Schweitzer Engineering Laboratories (SEL).

8.4.3.2 Updating Firmware

1. Download the latest firmware from SEL's official website.
2. Open ACSELERATOR RTAC SEL-5033 and connect to the device.
3. Navigate to Firmware Update in the settings menu.
4. Upload the new firmware file and initiate the update process.
5. Restart the device after the update completes.

Important: Always back up configuration settings before updating firmware.

8.4.4 System Diagnostics and Health Monitoring

Regular system diagnostics help detect potential failures before they lead to major disruptions.

8.4.4.1 Monitoring System Performance

Use the RTAC Web Interface or ACSELERATOR RTAC to monitor:

- ☐ CPU usage and memory utilization
- ☐ Network traffic and latency
- ☐ Error logs and event history

8.4.4.2 Checking I/O Module Status

1. Open the RTAC Web Interface.
2. Go to I/O Monitoring.
3. Check for non-responsive modules or unexpected input/output states.
4. If a module is unresponsive, reseat it and verify connections.

8.4.5 Troubleshooting and Corrective Actions

8.4.5.1 Common Issues and Solutions

Issue	Possible Cause	Solution
RTAC not powering on	Power supply failure	Check input voltage and replace power source if needed
Intermittent communication loss	Loose cables or network congestion	Reconnect cables and check network load
I/O module not responding	Faulty module or incorrect wiring	Verify wiring, reseat module, or replace if necessary
Slow system performance	High CPU load or memory usage	Restart device, optimize logic execution
Unexpected relay operations	Incorrect logic configuration	Review and correct control logic

8.4.5.2 Resetting the System

If troubleshooting steps do not resolve the issue, a system reset may be necessary.

Soft Reset (Recommended First Step)

1. Open ACSELERATOR RTAC or the Web Interface.
2. Navigate to System > Restart.
3. Confirm the reset.

Hard Reset (If Necessary)

1. Power off the device.
2. Disconnect it from the power source for 30 seconds.
3. Reconnect and power on the device.

Caution: A **hard reset** may clear some configurations. Always back up settings before performing this action.

8.4.6 Backup and Restore Procedures

8.4.6.1 Backing Up Configurations

1. Open **ACSELERATOR RTAC** with a normal PC.
2. Press the Read button.
3. Connect to the RTAC (3555 or 2241). The current online project is stored in the local database
4. Select the saved project, press the right mouse button and select the **Export** item.
5. Save the exported project folder in a secure location.

8.4.6.2 Restoring Configurations

1. Open **ACSELERATOR RTAC**.
2. Load the project folder inside the local database
3. Open the project
4. Push the project by pressing the **Go Online** button
5. Connect to the RTAC (3555 or 2241). The project is uploaded to the PLC.
6. The device restarts automatically with the new loaded project.

Introduction

The CENTUM VP is a distributed control system (abbreviated as DCS) for small to large plants.

This manual describes the requirements for installation (control room size and power supply requirements), storage and transportation, and wiring.

Chapter 1 System Installation Requirements

This chapter describes engineering specifications covering control room design/environment, power supply system, grounding and noise prevention. For power consumption specifications and list of consumable parts, see Chapter 4.

Chapter 2 Transportation, Storage and Installation

This chapter describes precautions in transit, unpacking and storage, such as humidity, temperature change, and how to install devices.

Chapter 3 Cabling

This chapter describes how to connect power, ground, signal and bus cables to the installed devices, and how to connect optical fiber cables.

Chapter 4 Installation Specifications

This chapter covers power consumption and power dissipation, in-rush current, fuse and breaker ratings, and parts that need replacement within 10 years. Read this section when deciding power supply capacity.

Chapter 5 Post-installation Inspection and Environmental Preservation

This chapter describes items that must be checked before applying power and the precautions to be taken to safeguard the environment after installing the system.

Drawing Conventions

Some drawings may be partially emphasized, simplified, or omitted, for the convenience of description.

Safety Precautions

Safety, Protection, and Modification of the Product

- In order to protect the system controlled by the product and the product itself and ensure safe operation, observe the safety precautions described in this Technical Information. We assume no liability for safety if users fail to observe these instructions when operating the product.
- If this product is used in a manner not specified in this Technical Information, the protection provided by this product may be impaired.
- If any protection or safety circuit is required for the system controlled by the product or for the product itself, prepare it separately.
- Be sure to use the spare parts approved by Yokogawa Electric Corporation (hereafter simply referred to as YOKOGAWA) when replacing parts or consumables.
- Do not use the accessories (Power supply cord set, etc.) that came with the product for any other products.
- Modification of the product is strictly prohibited.
- The following symbols are used in the product and instruction manual to indicate that there are precautions for safety:

⚠	Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to this Technical Information and the User's Manuals for necessary actions. In this Technical Information and the User's Manuals, this symbol is used together with a word "CAUTION" or "WARNING" at the locations where precautions for avoiding dangers are described.
	Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.
⏚	Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.
⏚	Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.
~	Indicates an AC supply.
⎓	Indicates a DC supply.
I	Indicates the ON state. The state of a power on/off switch and others is indicated.
○	Indicates the OFF state. The state of a power on/off switch and others is indicated.

Symbol Marks of Installation Guidance

Throughout this Technical Information, you will find several different types of symbols are used to identify different sections of text. This section describes these icons.

WARNING

Identifies important information required to understand operations or functions.

CAUTION

Identifies instructions that must be observed in order to avoid physical injury and electric shock or death to the operator.

IMPORTANT

Identifies important information required to understand operations or functions.

TIP

Identifies additional information.

SEE ALSO

Identifies a source to be referred to.

Cautions for Safely Applying the Device

Wiring Power Cable

WARNING

Connect the power cables according to the procedure in this document.
Power cables must conform to the safety standards of the country where the device is installed.

SEE ALSO For Wiring Power Cable, refer to 3.2, “Connecting Power.”

Earth Wiring

WARNING

This equipment requires a protective grounding defined by the safety standard.
Ground the device following the procedure in this document to prevent from electric shock and to minimize the noise.

SEE ALSO For Earth Wiring, refer to 3.3, “Connecting Ground Cable.”

Tightening Torque of Screws

IMPORTANT

The tightening torque that the Product recommends is showed in the following table. However, if the tightening torque of the screw is specified in the User’s Manuals, follow the instructions described in the User’s Manuals.

Table Table of Recommended Tightening Torque

Nominal diameter of a screw	M2.6	M3	M3.5	M4	M5	M6	M8	M10
Recommended tightening torque (N•m)	0.35	0.6	0.8	1.2	2.8	3.0	12.0	24.0

Battery

CAUTION

- Must use Yokogawa designated batteries.
- Mounting and changing batteries must follow the procedure in the hardware instruction manual for each device.
- When changing batteries while the power supply is not shutdown, do not put hands inside of the device since it is danger of electric shock.

Air Filter

CAUTION

Wash the air filters periodically (such as every three months). Use water and the neutral detergent to clean the filter then reuse it after drying.

- Follow the procedure in the hardware instruction manual for each device to exchange the air filter at the specified period.

SEE ALSO For Air Filter, refer to 4, “Installation Specification Parts Durability.”

Fan Unit

CAUTION

When changing fan unit while the power supply is not shutdown, be careful not to touch other parts so as to avoid electric shock.

SEE ALSO For Fan Unit, refer to 4, “Installation Specification Parts Durability.”

Wiring I/O Cables

CAUTION

Wiring I/O cables must follow the procedure in this document.

SEE ALSO For Wiring I/O Cables, refer to 3.5, “Connecting Signal Cable.”

Connecting Devices

IMPORTANT

To ensure this system compliance with the CSA safety standards, all devices connected to this system shall be CSA certified devices.

Power Distribution Board

WARNING

Exchanging the fuses must follow the procedure in the hardware instruction manual for each device since it has danger of electric shock.

- The fuses for exchange must be the Yokogawa designated fuses.
- Exchanging relay must follow the procedure in the hardware instruction manual for each device so as to avoid electric shock.

SEE ALSO For Power Distribution Board, refer to 3.4, “Power and Ground Cable.”

Exchanging Relay

CAUTION

Exchanging relay must follow the procedure in the hardware instruction manual for each device so as to avoid electric shock.

Exchanging Fuse

WARNING

- The fuses for exchange must be the Yokogawa designated fuses.
- Switch off the power supply before exchanging the fuses.

Maintenance

CAUTION

- The maintenance work for the devices described in this manual should be performed only by the educated experts.
- When the device becomes dusty, use a vacuum cleaner or a soft cloth to clean it.
- During maintenance, put up wrist strap, and take other ESD (Electrostatic Discharge) measures.
- If the existing caution label is dirty and illegible, prepare a new label (part number:T9029BX) to replace it.

SEE ALSO For Maintenance, refer to 1.5.2, “Countermeasures against Static Electricity.”

Revision Information i

1. System Installation Requirements

This section describes installation requirements such as environmental conditions, required space and layout considerations, power consumption, cabling and grounding.

1.1 Control Room Design

The control room, in which the system control equipment is to be installed, should be designed in accordance with the following conditions:

General

In designing a control room, ensure adequate floor strength and air conditioning including dust, and moisture-proofing.

SEE ALSO

- 1.1 Control Room Design — Air Conditioner
- 1.2 Control Room Environment — Air Purity
- Installation Environment Specifications

Floor Strength and Space

The floor should have adequate strength, and you should design the layout in accordance with the weight and size of equipment to be installed.

SEE ALSO

- For the maintenance space required, refer to 2.4, “Servicing Area.”
- For the weight and dimensions of standard equipment, refer to “General Specification” (GS).

Floor Structure

To prevent damage to cables by operators and maintenance equipment, do not lay cables on the floor.

Lay cables under the floor as follows:

- Provide an “accessible” floor which also facilitates maintenance work.
- Make cable pits under the floor if it is concrete.

Flooding- & Dust-proof Floor

To protect equipment and cables, design a flooding-proof floor.

After the cabling is completed, seal all cable conduits using putty to prevent intrusion of dust, moisture, rats, and insects into the equipment.

Clearance From The Wall and The Floor Surface

There are ventilation holes on the front and rear doors of the cabinets (AFV40S/AFV40D, ACB51, and A2CAB1). To ensure good air ventilation and easy maintenance, provide a clearance of at least 1000 mm (including the service areas) from the wall to the front and rear doors of the cabinets. Also make sure the height of the ceiling is at least 2400 mm from the floor.

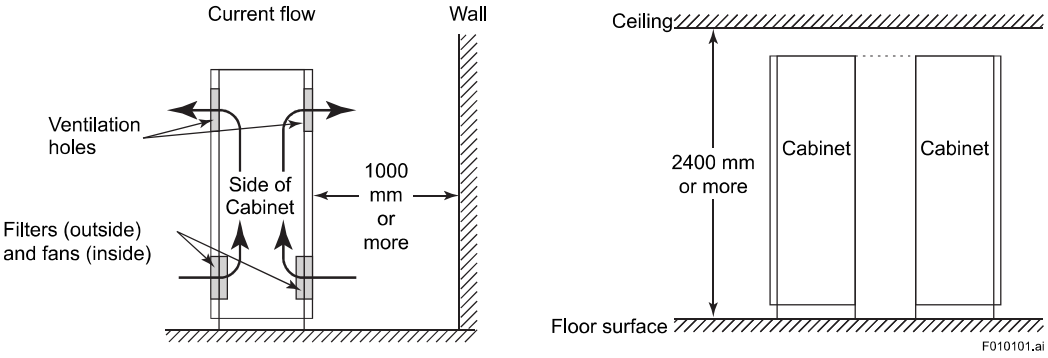

Figure Wall Clearance and Ceiling Height

Illumination

The illumination level around a display unit should be 700 to 1500 lux (target illumination level: 1000 lux). The illumination level inside the control room should be reasonably uniform. Select proper light fixtures and install them in positions where they don't cause glare on the LCDs.

TIP

REFERENCE (Illumination standards):

For ultra-precision work:	1500 to 3000 lux (illumination level: 2000)
For precision work:	700 to 1500 lux (illumination level: 1000)
For ordinary work:	300 to 700 lux (illumination level: 500)
For non-detail work:	150 to 300 lux (illumination level: 200)
Passages, warehouses:	30 to 150 lux (illumination level: 50 to 100)

(Source: JIS Z9110)

Outlets for Maintenance

Outlets (approx. 1.5 kVA) for measurement devices should be provided near the installed equipment for maintenance.

Telephone

Telephones should be installed for communications with related stations.

Air Conditioner

The air conditioner should be operated following the conditions below to prevent dew condensing on the installed equipment:

- Keep the change of temperatures within ±10 °C/h.
- Install air conditioner away from equipment.
- Install substitute air conditioners to prevent dew condensing as a result of temperature rise or fall if an air conditioner fails.

Windows

Close the windows of the control room. If a draft comes in around the windows, seal around the windows.

Opening the window while air conditioning is running may result in condensation forming, or let in dust or corrosive gas, adversely affecting the installed equipment. Windows on the sea side must be closed to keep out salt air.

Install blinds, if necessary, to prevent sunlight reflecting from LCDs.

Side-by-Side Cabinet Installation

When cabinets are placed side by side, make sure of their ventilation system.

For cabinet ventilation system, we have air-cooling without blower and with blower. Moreover, either blast fan pressurization (door fan) or exhaust fan (ceiling fan) is used for air-cooling with blower.

As cabinets with the same ventilation system can be placed side by side, group them according to ventilation system and place them in the same group side by side with side board.

CENTUM VP, CENTUM CS 3000 and CENTUM CS cabinets get air from the bottom front and rear of the cabinet doors, and emit air from the top front and rear of the doors, using a “fan pressurization” system. On the other hand, CENTUM-XL cabinets get air from rear of the doors, and emit air from the top of the cabinets, using an “exhaust fan” system.

When cabinets with different ventilation systems are placed side by side, a special partition board (ETBP) must be placed between cabinets. For the board, please contact Yokogawa.

1.2 Control Room Environment

This section describes environmental conditions of the control room to operate the system safely, and stably over a long period of time.

It is recommended that user have the control room environment assessment. Consult Yokogawa for the assessment if necessary.

Temperatures and Humidity

When equipment is brought from the place out of operational temperature range to the place in operational temperature range, bring it without a package, keep it within temperature change rate and avoid condensation. Keep ambient temperature within operational temperature range and leave it for more than three hours before starting operation.

Under normal operation, the rate of change of ambient temperatures should be within 10 °C/h. All the equipment should be kept out of direct sunlight.

SEE ALSO See “Table of Equipment Installation Specifications” in this section, for the temperatures and humidity limits for operating and storing this equipment.

Condensation

Prevent condensation. If condensation occurs, or its trace is found on the control room equipment, contact Yokogawa.

SEE ALSO See “Section 2.3 Storage” for more information.

Vibration

Vibration in the control room should be limited as follows:

- For vibration frequency up to 14 Hz: Limit displacement amplitude to 0.25 mm or less.
- For vibration frequency over 14 Hz: Limit acceleration to 2 m/s^2 or less.

The following is the relationship of the vibration frequency, displacement amplitude, and acceleration:

Acceleration (m/s^2) = $4\pi^2 \times A \times F^2 \times 10^{-3}$

A: Displacement amplitude (mm)
F: Frequency (Hz)

F010201.ai

The allowable range of displacement amplitude is shown below. Consult Yokogawa if complex vibrations are involved.

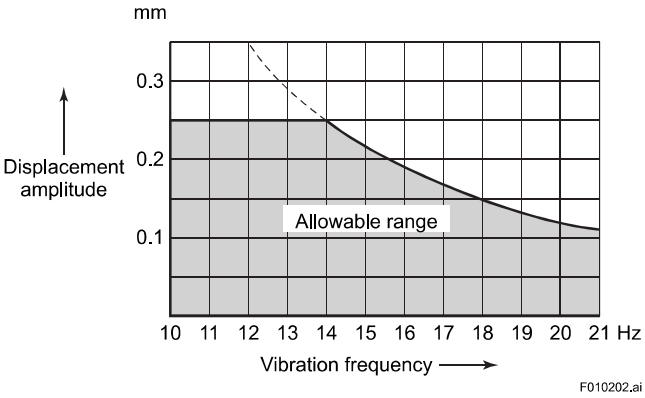

Figure Range of Allowable Displacement Amplitude

Air Purity

The dust in the control room should be kept below 0.3 mg/m^3. Avoid corrosive gas such as hydrogen sulfide (H_2S), sulfur dioxide (SO_2), chlorine, and conductive dust such as iron powder and carbon.

The allowable content of H_2S, SO_2, or any other corrosive gas varies with temperatures, humidity, or existence of other corrosive gas. Consult Yokogawa if corrosive gas exists.

Magnetic Field

Do not install a magnetic disk, or the like near cables with large current flowing or in the magnetic field of a power supply. If installed in such locations, the storage medium data may be corrupted by the magnetic fields.

Electric field strength (Electric wave condition)

To ensure stable operation of the system equipment, use it with the door closed. Consider keeping the electric field strength at the installation location of the system equipment below the values listed below.

For N-IO nodes (excluding equipment for RIO system upgrades) (*1):

10 V/m or less (80 MHz to 1.0 GHz)
3 V/m or less (1.4 to 2.0 GHz)
1 V/m or less (2.0 to 2.7 GHz)

Other than above;

3 V/m or less (26 MHz to 1.0 GHz)
3 V/m or less (1.4 to 2.0 GHz)
1 V/m or less (2.0 to 2.7 GHz)

*1: For specifications of RIO system upgrades, please refer to GS 33J64E10-01EN.

Furthermore, the relationship between the transmission output of the wireless device, the distance from the system device, and the electric field strength is expressed by the following formula.

However, the value derived by this formula is a theoretical value under ideal conditions, so it may be worse under actual usage conditions. Also, this formula does not hold true when the device is close to the equipment, resulting in even worse electric field conditions, so please consider this value as a reference value only.

$$E=\frac{k\sqrt{P}}{d}$$

E: Electric field strength (V/m)
k: Electromagnetic wave propagation characteristic coefficient (7.0) (*1)
d: Distance (m)
P: Radiated power (W)

*1: Using the coefficient values from Annex E of IEC 61000-4-3:2020.

When using wireless devices with the door open for maintenance of system equipment, please be aware of the following points, as the system equipment may be affected by radio frequency interference from the wireless devices, potentially impacting its operation:

- Do not use wireless devices with a transmission power exceeding 1W, such as transceivers, in the vicinity of this equipment.
- When using wireless devices with a transmission output of 1W or less, such as mobile phone terminals, in the vicinity of this equipment, ensure a distance of at least 50cm from this equipment. If it is not possible to maintain a distance of 50cm or more, turn off the power of the wireless devices.

The following are guidelines for the transmission output of wireless devices. For other cases, please consult the manufacturer of the wireless device.

[Reference]

Generation of Communication Method	Maximum Transmission Output
5th Generation (5G)	200 mW
4th Generation (4G)	200 mW
3rd Generation (3G)	250 mW
2nd Generation (2G) (*1)	GSM 1800/1900MHz Band: 2 W GSM 850/900MHz Band: 1 W PDC: 800 mW iDEN/MIRS: 600 mW cdmaOne (IS-95): 200 mW

*1: The maximum transmission output varies depending on the communication method.

Installation Specification

Installation height: N-IO node (*1) (*2): Altitude of up to 3000 m (*3)
Other than N-IO node: Altitude of up to 2000 m

Installation category based on IEC 61010-1 (*4)

Category I

- For YOKOGAWA products, category I applies to the device that receives the electric power not more than 30 V AC, 60 V DC.

Category II

- For YOKOGAWA products, category II applies to the device that receives the electric power exceeding 30 V AC or 60 V DC.

Pollution degree based on IEC 61010-1: 2 (*5)

*1: For more information about specifications of device, refer to General Specification (GS).
*2: Except for equipment for RIO System Upgrade. For specification of RIO System Upgrade, refer to the GS 33J64E10-01EN.
*3: Up to 2000 m for A2BN4D and A2BN5D.
*4: The installation category, also referred to as an overvoltage category, defines the standard for impulse voltage. The category number from I to IV applies the devices to determine the clearance required by this standard.
Category I applies to the device intended to be connected to a power supply with impulse voltage reduced to the safe level.
Category II applies to the device intended to be supplied from the building wiring.
*5: Pollution degree indicates the adhesion level of foreign matter in a solid, liquid, or gaseous state that can reduce dielectric strength. Degree 2 refers to a pollution level equivalent to the general indoor environment.

SEE ALSO See “Installation Environment Specifications” at the end of this chapter.

Measurement Categories

Regarding the measurement inputs, the following requirements must be satisfied to meet the specifications for the device:

The category of the equipment applies to O (Other) in the following table.

The rated transient overvoltage is 1500 V.

Note: Do not use the equipment for measurements within measurement categories II, III and IV.

Table Measurement category

No.	Applicable Standard EN IEC 61010-2-030 CAN/CSA-C22.2 No.61010-2-030	Description
No.1	O (Other) (*1)	Measuring circuits without a MEASUREMENT CATEGORY.
No.2	Measurement category II	For measurements performed on circuits directly connected to the low voltage installation.
No.3	Measurement category III	For measurements performed in the building installation.
No.4	Measurement category IV	For measurements performed at the source of the low-voltage installation.

*1: Measurement category I defined in IEC/EN 61010-1 and CAN/CSA-C22.2 No.61010-1 has been changed to “O (Other)” in EN IEC 61010-2-030 and CAN/CSA-C22.2 No.61010-2-030.

Applied Standards

The CENTUM VP system complies with the standards shown below.

IMPORTANT

Different standards are applied according to the types of equipment. For details, refer to Integrated Production Control System CENTUM VP System Overview (GS 33J01A10-01EN).

*1: The ground suitable for the power distribution system in the country or region has to be used for protective grounding system.
*2: For the rack mountable devices, DIN rail mountable devices, and wall mountable devices to meet the Safety Standards and EMC Standards, the devices must be installed in a lockable metal cabinet. The cabinet must conform to IEC/EN/CSA 61010-2-201 or provide degrees of protection IP3X or above and IK09 or above.
*3: CENTUM measurement input corresponds to the measurement category O (Other) based on EN IEC 61010-2-030 and CAN/CSA-C 22.2 No. 61010-2-030. The measurement category I defined in IEC/EN 61010-1 and CAN/CSA-C 22.2 No. 61010-1 has been changed to O (Other).

*1: FIO Node Unit and Optical ESB Bus Repeater Unit mean ANB10□, ANB11□, ANT10U, and units constructed with Base Plate A2BE2D.
*2: Except for equipment for RIO System Upgrade. For specification of RIO System Upgrade, refer to the GS 33J64E10-01EN.
*3: When an AAP149, AAP849, ADV161, ADV561, ADV859, ADV159, ADV559, ADV869, ADV169, ADV569, ALR111, ALR121-□□0, ALR121-□□1, ALE111-□□0, ALE111-□□1, ALF111, ALP121, A2LP131, and A2LP141 is installed, the ambient temperature should range from 0 to 50°C.
*4: When use at -20 to 70°C, the installation environment must be within the temperature specification range of the communication module and power supply module to be incorporated.
*5: For A2BN4D, use within the range of -20 to 60°C.
For A2BN5D, the maximum ambient temperature specifications depend on style code and compliance criteria.
For details, refer to GS 33J01A10-01EN "Integrated Production Control System CENTUM VP System Overview".
*6: To use A2BN4D or A2BN5D at -20 to 0°C, specify the temperature environment support option for the I/O modules to be mounted. The environment in which A2BN4D or A2BN5D is used depends on the specifications of the barrier mounting to A2BN4D or A2BN5D.
To use A2BN3D with the temperature environment support option (at -40 to 70°C), specify the temperature environment option for the I/O modules and I/O adaptor as well. For the cable connector connection of Base plate for analog digital I/O (A2BN3D-□9), the normal operation temperature is -20 to 70°C depend on the temperature specification of the dedicated cable.
To maintain A2NN30D with the temperature environment support option (at -40 to 70°C), specify the temperature environment support option for the power supply units and N-ESB bus modules as well.
*7: For A2BN3D, 24 V DC ±10%. For A2BN4D and A2BN5D, 24 V DC −14% +10%.

1.3 Power Supply System

To stable system operation, the following conditions should be met:

- **Voltage and frequency fluctuations are within the limits specified for each system component.**
- **Relationship between the waveform's effective values and peak value is within the specified range.**
- **High-frequency noise is not at a level that affects system operation.**
- **Use an UPS (uninterruptible power supply) if necessary.**

AC Power Specification

AC power used for the system must satisfied rated voltage and the peak value must be greater than the minimum specified (see below). DC power must satisfied 24 V DC at the power supply terminals.

IMPORTANT

If the power unit has high output impedance or high wiring impedance, the resulting voltage drop flattens the input voltage wave, forming a distorted waveform with a low peak value ("B" in the chart below).

Even if the effective value of the distorted input voltage wave is the same as that specified for a non-distorted input voltage wave, the voltage across the terminals of the smoothing capacitor in the power circuit may be so low that the system detects power failure. If input voltage waves A and B shown below, have the same effective value of 100 V AC, wave B will have a lower smoothing capacitor terminal voltage.

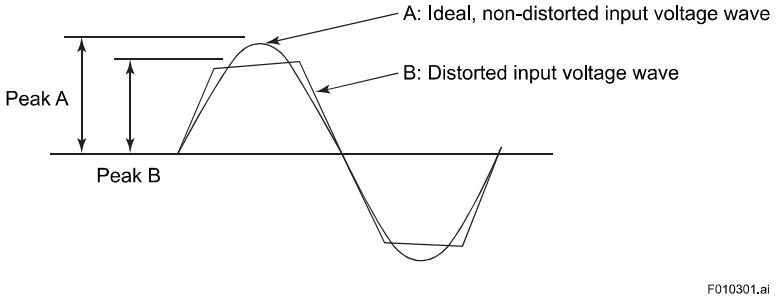

Figure Distorted Input Voltage Waveform

The system operating voltage range is shown below based on the relationship between effective and peak values at the power input terminal of each system. Apply AC power within these ranges to operate the system.

TIP

Average rectified measuring meters such as testers cannot measure effective values accurately. Use Yokogawa's WT series power meter or an meter, which enables effective values, peak values, and waveform distortion to be measured with one unit.

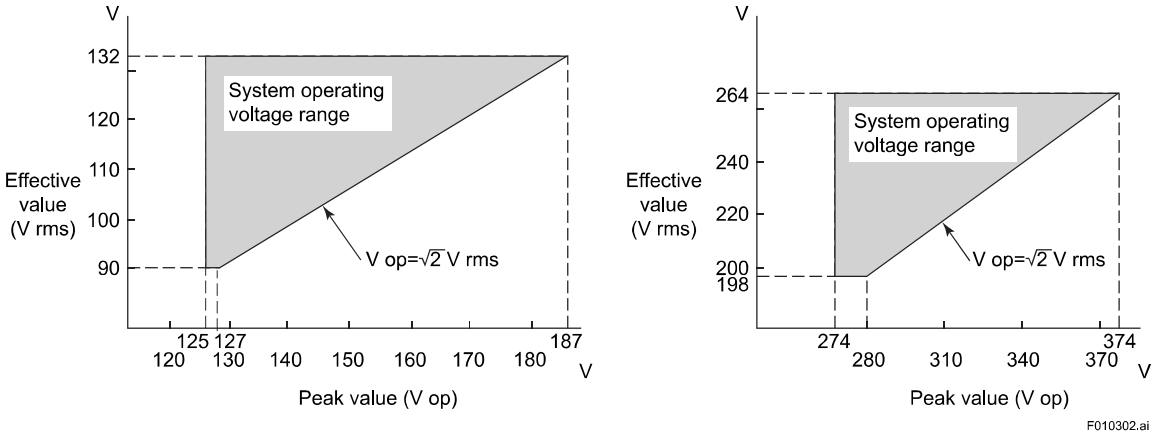

Figure System Operating Voltage Range

The DC stabilized power supply used by Field Control Unit of the CENTUM VP uses a compact and efficient switching regulator circuit. In this circuit, output voltage cannot be maintained if the energy (terminal potential) of the smoothing capacitor falls below a predetermined value. The circuit monitors the capacitor terminal voltage and regards it as power failure if the voltage falls in the danger zone, causing the system to enter power fail mode (non-detected momentary power failure: up to 20 ms).

Current flows to the capacitor in this circuit when AC input voltage is higher than the capacitor terminal voltage. Since the capacitor is charged by the peak value of the input waveform, it is required that both the effective voltage value and the peak value conform to specifications.

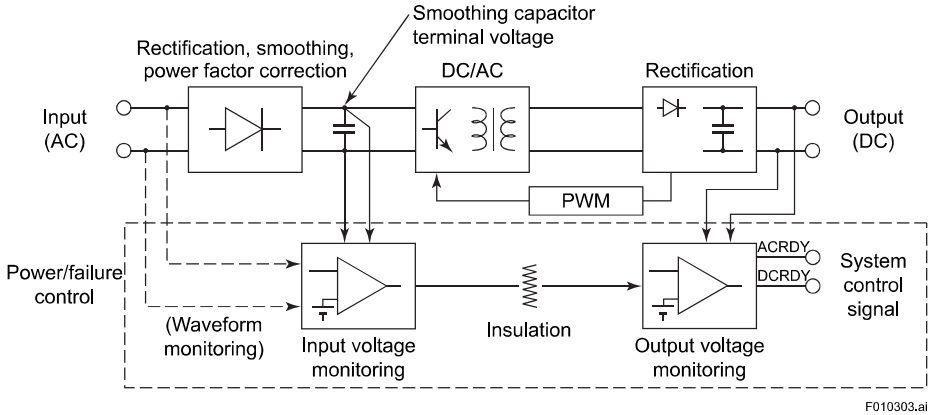

Figure FCU Power Circuit Diagram

Selecting a Power System

The CENTUM VP system requires a power supply that satisfies power requirements in accordance with EMC regulations. It is recommended that an external power supply unit is employed in order to prevent disruptions due to momentary or extended power failure, line noise, or lightening surges, as well as to suppress harmonic current from various devices. For selection of the power supply unit, consult with a power unit manufacturer taking the following points into consideration.

Source Output Capacity

Take the following items into consideration when consulting with a power unit manufacturer to determine the output capacity.

Power consumption:	Both volt-ampere and watt data should be studied (refer to Chapter 4).
Device crest factor:	Ratio of the peak value to the effective value of the device input current.
Device in-rush current:	See Chapter 4 Table “In-rush Current.” The method of turning on the power should also be studied.
Backup ready time after failure:	Time period required to backup the devices when power fails.
Reserve capacity:	An extra power capacity should be determined as reserve to meet any device additions.

Crest factor

The crest factor is the ratio of the peak value to the effective value of the device input current.

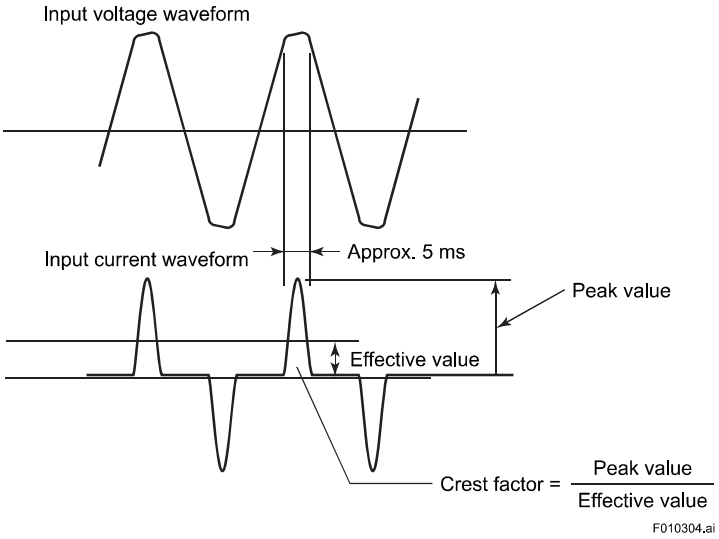

Figure Input Voltage and Input Current Waveforms

Crest factor = Peak value of device input current/Effective value of device input current

The crest factor must be considered for the input current supplied to every device connected to the system when estimating the power output capacity in selecting the power unit. Approximate device crest factors should be as follows:

100-120 V supply voltage: Crest factor About 3.

220-240 V supply voltage: Crest factor About 6.

Common Method to Determine Power Unit Capacity

The following shows the commonly used method used to determine the power unit capacity taking the crest factor into consideration - the final determination should be made in consultation with a power unit manufacturer:

- If the specification of power unit crest factor (the peak current value allowable for the effective current value) is larger than the above device crest factor, the power unit can be used for up to full rated capacity. However, in-rush current, backup time, reserve capacity, etc., must be separately taken into consideration.
- If the power unit crest factor is smaller than the device crest factor, the power unit capacity needs to be calculated in the expression shown below. In-rush current, backup time, reserve capacity, etc., must be separately taken into consideration.

Power unit output capacity = Total device power consumption x Capacity coefficient

Capacity coefficient = Device crest factor / Power unit crest factor specification

In-Rush Current

When the equipment is turned on, a large in-rush current flows as the capacitor is instantaneously charged and the transformer is excited. When any equipment is turned on, this should not cause any voltage fluctuation that could adversely affect other equipment. Do not turn on all equipment at the same time. Start equipment one by one.
Power may be switched to backup or AC line power if in-rush current activates the overload protection circuit on power-up. After such an overload, select an uninterruptible power unit, with automatic-recovery.

Suppressing Harmonic Current

In order to suppress harmonic current supplied to a low-voltage distribution system, it is necessary to install a power unit or an active harmonic suppressor, such as indicated below, between a device and the distribution system:

- Power unit equipped with the harmonic suppression function (a high power-factor inverter-type uninterruptible power unit, etc.)
- Active harmonic suppressor

In Europe, a power unit should be selected so that harmonic current emissions are within the limits specified by EMC regulations.

The capacity of the harmonic suppression unit should be determined in consultation with a power unit manufacturer in the same manner as the selection of power unit's output capacity previously discussed.

Notes for the field power supply unit of N-IO

As described in GS 33J62F40-01EN “Models A2BN3D, A2BN4D, A2BN5D Base Plates (for N-IO)”, field power supply (24 V DC) is required for “Base plate for adaptor” (Model A2BN3D).

When using the node interface unit A2NN30D-□4□□□□□□□ (24 V DC power input type) in combination with A2BN3D and the power supply unit as shown on the left side of the figure below, it is recommended to separate the power supply as shown in right.

This is because the rapid change of the field output load of A2BN3D may causes an influence on 24 V power line, it is worried that the input voltage rating of A2NN30D will not be satisfied.

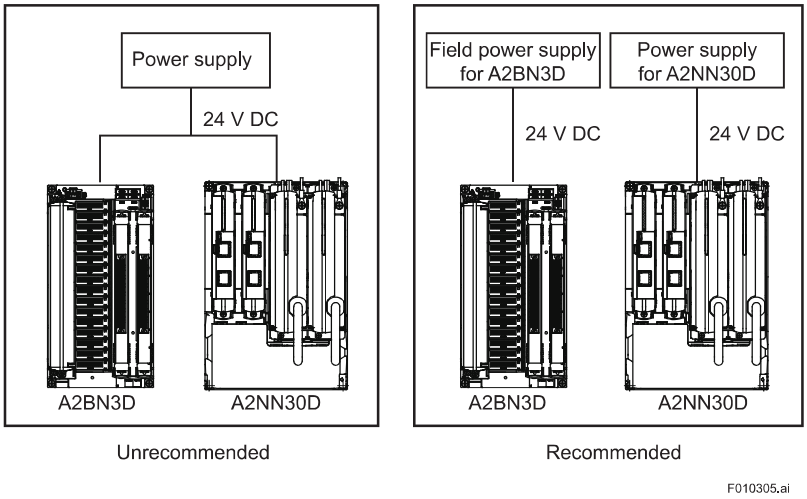

Figure Connection of the field power supply of A2BN3D

Cabling

Observe the following when cabling the power unit to the CENTUM VP system equipment:

- Protect signal cables from induced noise.
- Protect signal cables from induction from high-voltage power lines.
- Separate the CENTUM VP system power supply from other equipment power supplies-use a separate power distribution board.
- Provide a dedicated breaker for each power supply. Install breakers and devices they control in the same room.
- Label the breakers with the name of the connected equipment.
- Install the breakers where they can be easily operated.
- The breaker, must not interrupt connection by wiring to protective grounding system.
- Install power supply cables and high-voltage power lines in metallic conduits as much as possible.
- Use shielded cables if metallic conduits cannot be provided.

1.4 Grounding

To avoid electric shocks and minimize the influences of external noise, the installed devices must be grounded to the protective grounding system which complies with the safety standards, the electrical installations standard, and the power distribution system of the country or the region.

In the CENTUM VP cabinets, grounding bars are provided.

As for the protective grounding systems, the meshed grounding systems described in IEC 60364, IEC 62305 and IEC 61000-5-2 can be applied

A protective device is to be installed in compliance with the rules and regulations, in order to prevent electric shocks caused by a ground fault.

A plug type power cable has to be connected to the receptacle connected to the protective grounding system.

A functional grounding terminal of the equipment has to be connected to the grounding bar for protective grounding in a cabinet in accordance with the instructions in this document. A grounding bar for functional grounding connects to a grounding bar for protective grounding in a cabinet. A functional grounding terminal is electrically connected with a protective grounding system. In order to minimize the influence of noise a grounding cable for other system's cabinets must be connected individually to ground bus inlet.

Grounding

Cabinet

- In the AFV40S/AFV40D, ACB51, and A2CAB1 the channel base is isolated from the cabinet by a Bakelite sheet (t=5 mm) to allow one point grounding.
- The grounding bar (1) to connect a grounding cable is located at the bottom of the cabinet near the front panel and it is electrically connected to the cabinet.
- The grounding bar (2) for shielding the inside of the cabinet is on the bottom of the cabinet near the back panel, which is isolated from the cabinet. Another grounding bar (3) for shielding the inside of the cabinet is on the bottom of the cabinet near the front panel.
- The grounding bars (2) and (3) are connected to the grounding bar (1) by a cable of 5.5 mm^2 (This is used for grounding shields of input/output cables).
- When the grounding bars must be grounded separately depending on the purpose (for shielding and for connecting a grounding cable), disconnect the cable between the grounding bar (1) and (3) or (1) and (2), then ground separately.

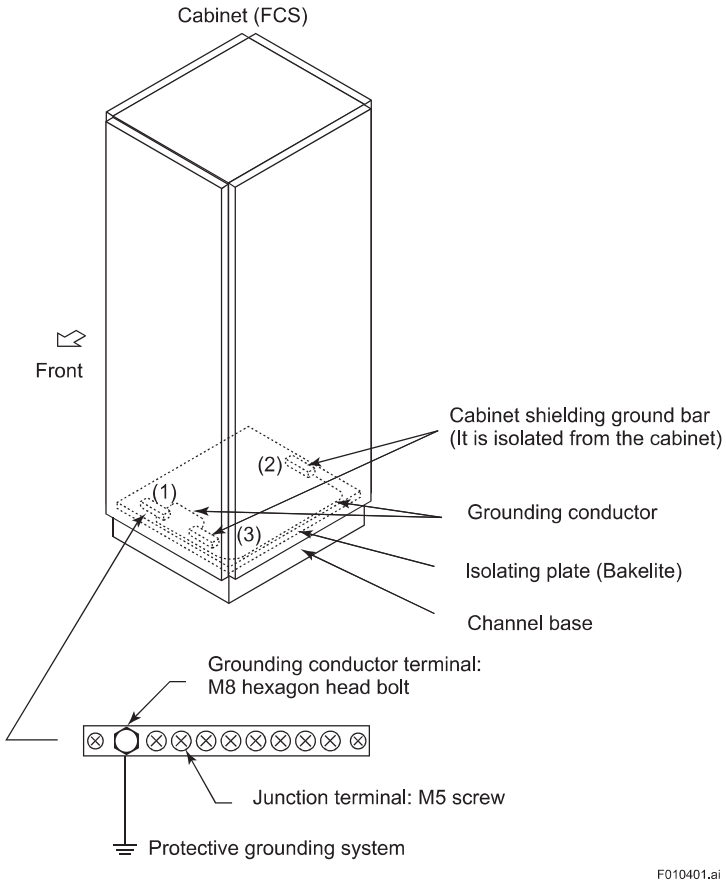

Figure Grounding Bars

Grounding Circuit

A cabinet must be grounded according to the grounding network topology of the building or plant for installation.

In order to connect a cabinet with a protective grounding system, the grounding topology shown in the figures “Grounding connected to single grounding bus inlet” or “Grounding connected to each grounding bus inlet” can be used.

When providing lightning arresters on power and signal lines, those arresters need to be grounded to the same bus. For details, see Section 1.5, “Noise Countermeasures.”

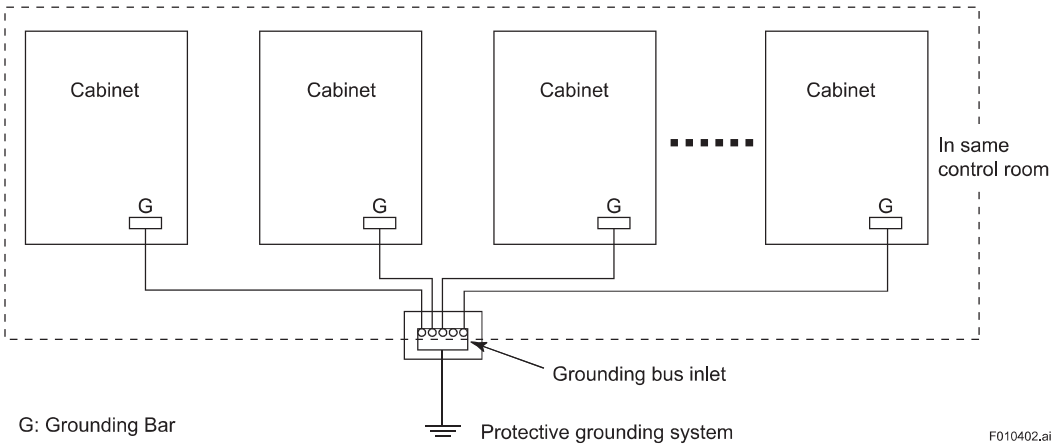

Figure Grounding connected to a single grounding bus inlet

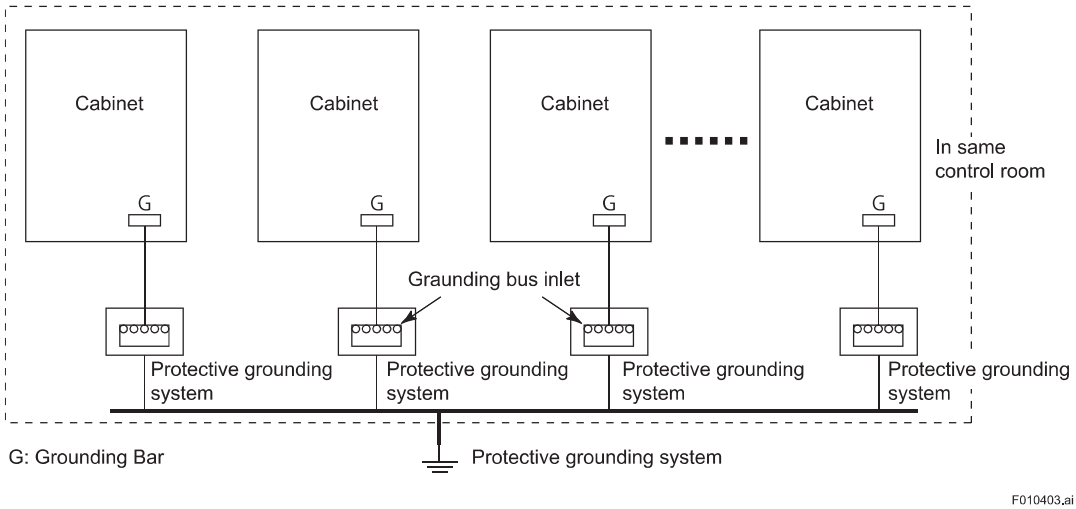

Figure Grounding connected to each grounding bus inlet

Grounding when joining CENTUM VP side by side with other system

Do not connect CENTUM VP's cabinet with other cabinets electrically using bolts or other connection mechanism in order to avoid unexpected electrical connection or interference.

When CENTUM VP is joining side by side with other cabinets, ensure to insert insulating sheets.

The cabinets other than CENTUM VP must be insulated from a floor and connect it to a protective grounding system using a different grounding cable.

The CENTUM VP system in this page can also be read as cabinet of CENTUM CS 3000, CENTUM CS, or ProSafe-RS.

CAUTION

Do not install the following systems side-by-side with CENTUM VP:

- Systems using power supply voltages over 300 V AC.
- Systems with current consumption over 50 A.
- System containing high frequency sources.

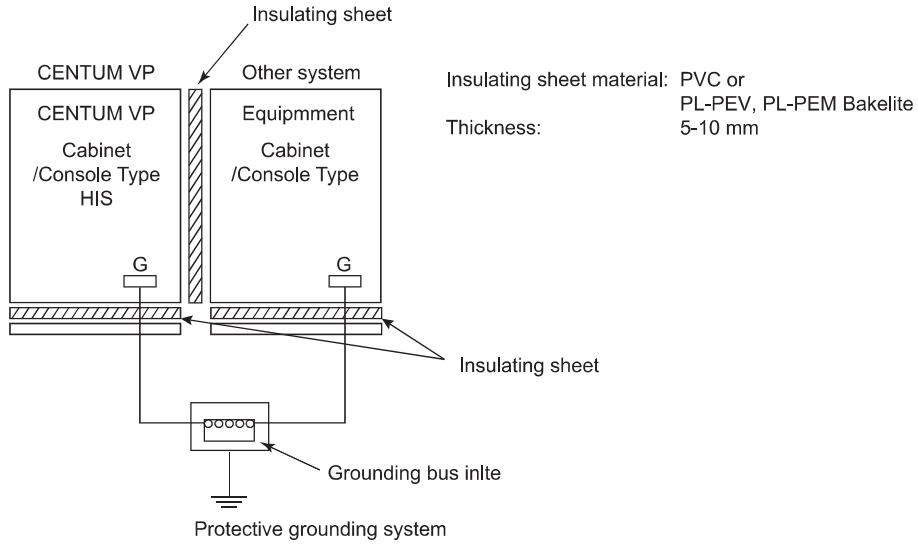

Figure Grounding Using Insulating Sheets

TIP

The CENTUM VP cabinets (e.g. AFV40S/AFV40D, and ACB51) are insulated from the floor by the insulating sheet.
When other cabinets and consoles are used with CENTUM VP, insulate them from the floor using the insulating sheets.

1.5 Noise Countermeasures

Noise may be induced by electromagnetic induction, electrostatic induction, or from radio waves, lightning, inductive loads, static electricity and ground potential differences. It can be picked up by power, signal and ground cables, and devices. With computerized control systems, noise-induced errors in A/D conversion or in an instruction word may lead to malfunction.

To prevent noise and electrostatic buildup, take the measures described in this section in deciding cable type, cable routing, and grounding.

1.5.1 Noise Sources and Noise Countermeasures

It is not easy to identify the cause of any noise-triggered errors or failures due to their lack of reproducibility.

If noise problems occur, take the following countermeasures.

The following table lists typical noise sources, symptoms of noise problems, and preventive countermeasures:

Table Noise Sources & Countermeasures

Noise sources	Effects	Countermeasures
Electromagnetic induction (magnetic field)	• Destroys magnetic disk data.	• Maintain separation from magnetic-field source. • Shield power cables with metallic conduits. • Shield magnetic field using ferromagnetic substance (e.g. Permalloy). • Use twisted-pair cables.
Electrostatic induction	• Equipment maloperation. • Interference with signals.	• Use shielded signal cables. • Electrically separate power and signal cables using metallic conduits and separators. • Lay power and signal cables which intersect at right angles.
Lightning	• Interference with signals. • Equipment maloperation. • Component damage.	• Lay cables underground. • Use optical fiber cables. • Lay cables as close to ground as possible if the cables cannot be laid underground. • Install and ground arresters on field and system.
Electrostatic discharge	• Equipment maloperation. • Electronic component deterioration, damage. • Paper jam.	• Discharge static electricity from operators. • Provide proper humidity. • Ground equipment properly. • Use antistatic floor material and clothing.
Inductive load open/close	• Spike noise interference to power andsignal lines.	• Add protection circuit for noise caused by inductive load. • Separate laying of cables.
Radio (electric field)	• Equipment maloperation. • Interference with signals.	• Use devices (transceivers, mobile phones, smartphones, etc.) that transmit radio waves away from the system so as not to exceed the electric field specifications.
Ground potential difference	• Equipment Maloperation (noise imposed on signal lines)	• Avoid multipoint grounding of signal cable.

Grounding with Lightning Arresters

Connect the protective grounding terminals of arresters and CENTUM VP equipment to the grounding pole as shown in the diagram below.

The grounding method must comply with the grounding system defined by rules and standards of the conuntry or the region.

Concatenation grounding a lightning arrester and other equipment may cause high-tension in each equipment by the product of lightning current from arrester and grounding resistance. To prevent from electrification, overall connection should be equipotential including the floor and the case of other equipment.

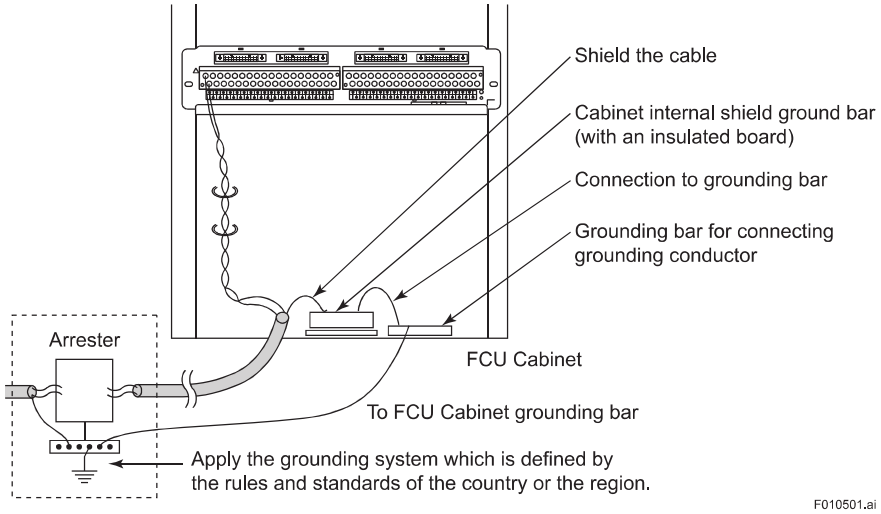

Figure Grounding with Lightning Arresters

Examples of Arrester

The following shows how to install an arrester as a countermeasure against lightning-induced noise :

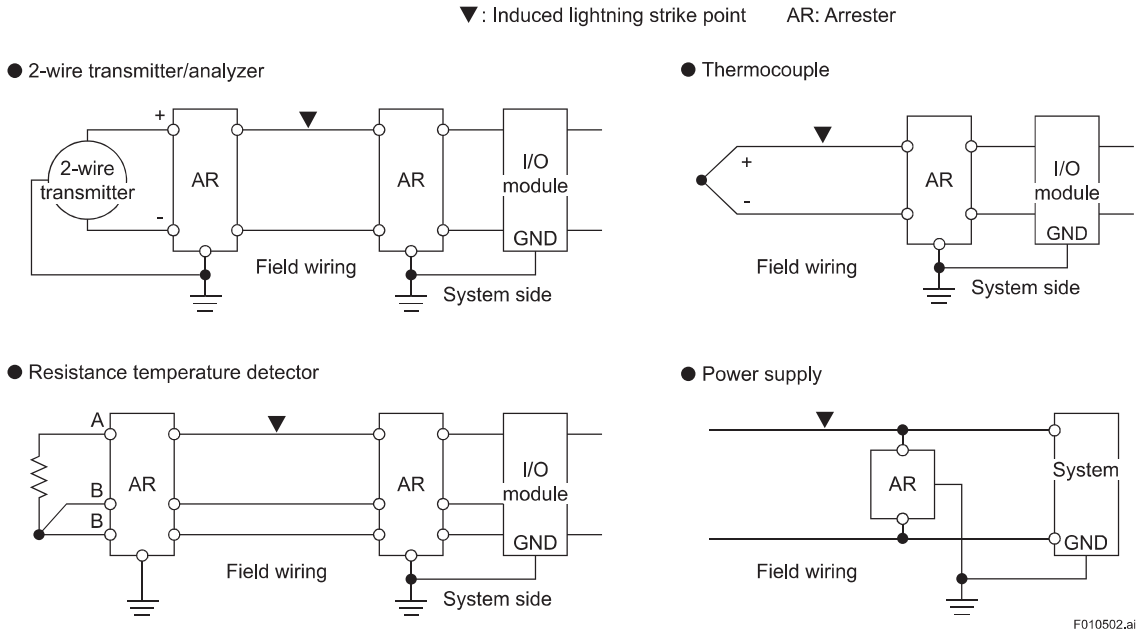

Figure Examples of Arrester Installation

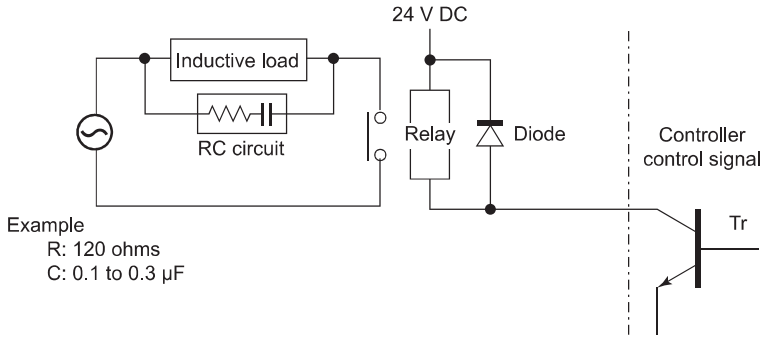

Examples of installing protection circuit for noise caused by inductive load

The following shows how to install a RC circuit and a diode as a countermeasure against noise caused by inductive load:

● Relay contact

The diode protects the output transistor from noise occurring during on-to-off transitions of the relay.

The RC circuit protects the output relay contact.

● Power supply

The RC circuit prevents noise-caused equipment failure when a fluorescent lamp or fan is turned on or off.

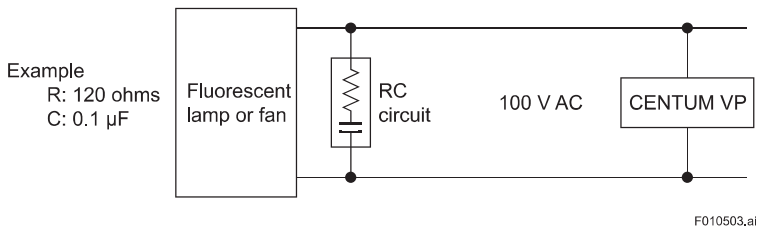

Figure Examples of installing protection circuit for noise caused by inductive load

1.5.2 Countermeasures against Static Electricity

Take countermeasures against electrostatic damage when handling cards with semi-conductor IC components, for maintenance or to change settings.

Observe the following to prevent electrostatic damage:

- When storing or carrying maintenance parts, be sure to enclose them in an antistatic bag. (For shipment these parts are enclosed in an antistatic bag labeled with precautions against electrostatic charge.)
- During maintenance work use a wrist strap with a ground wire via a grounding resistance of 1 M ohm. Be sure to ground the wrist strap.
- When performing maintenance work on a desk or a table, place a conductivity sheet grounded via a grounding resistance of 1 M ohm. The maintenance person must wear a wrist strap while performing maintenance work. Take any plastic and other materials that can easily be charged away from the work area.
- Exercise caution so as not to touch any of the maintenance parts while the wrist strap and a conductivity sheet are not being used.

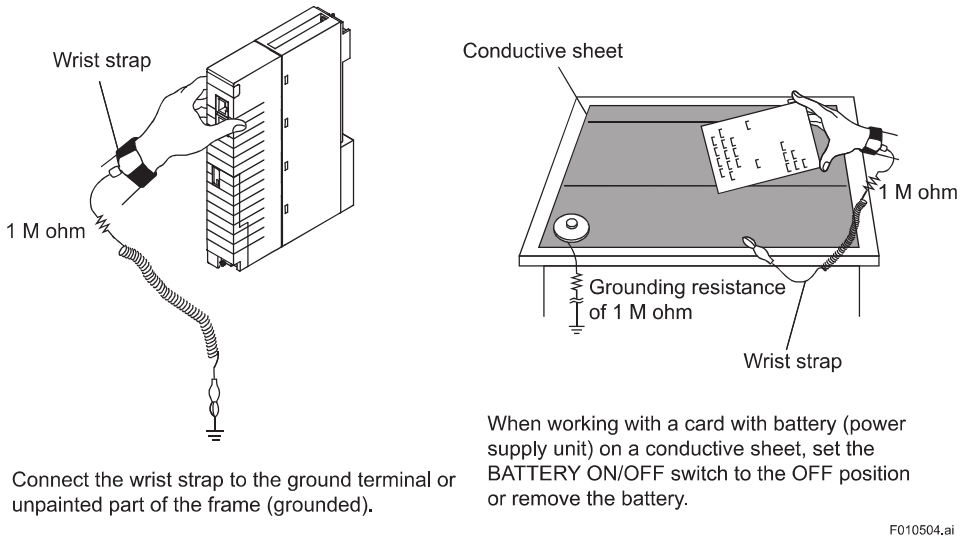

Figure Example of Using a Wrist Strap and Conductive Sheet

1.6 Cabling Requirements

The following requirements must be fulfilled when laying power and signal cables (These are shielded cables unless specified).

Any signal cable used for high-voltage, high-frequency signals (inductive load ON/ OFF) must be separated from other signal cables.

Separator

Provide a separator between power and signal cables as illustrated below:

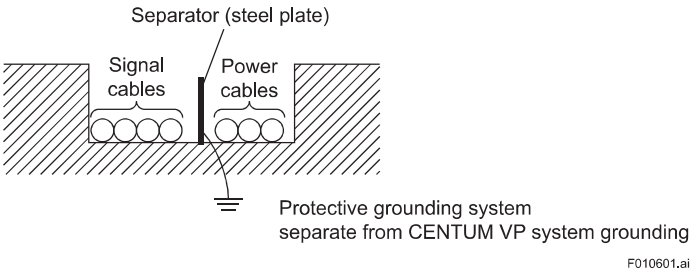

Figure Separator Used in Duct/Pit

Distance between Cables

If a separator cannot be used, keep a distance between signal cables and power cables.

The distances between cables due to operating voltages and currents are shown below.

Table Required Distance between Power & Shielded Signal Cables

Operating voltage	Operating current	Distance
240 V AC max.	10 A max.	150 mm min.
240 V AC max.	10 A min.	600 mm min.
240 V AC min.	10 A max.	600 mm min.
240 V AC min.	10 A min.	Cannot be laid together.

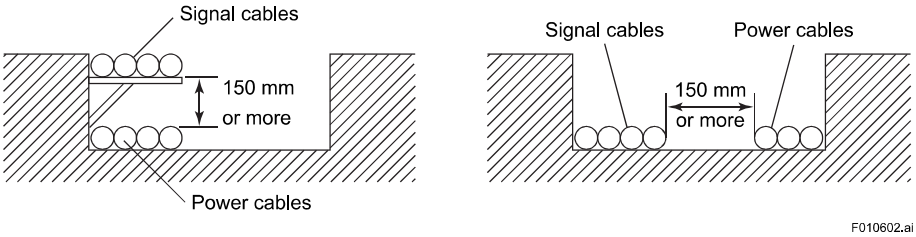

Figure Distance between Cables under Pit/Free-access Floor

Intersecting Cables

With unshielded power cables, place a grounded steel plate with a thickness of at least 1.6 mm over the cables where they intersect with signal cables.

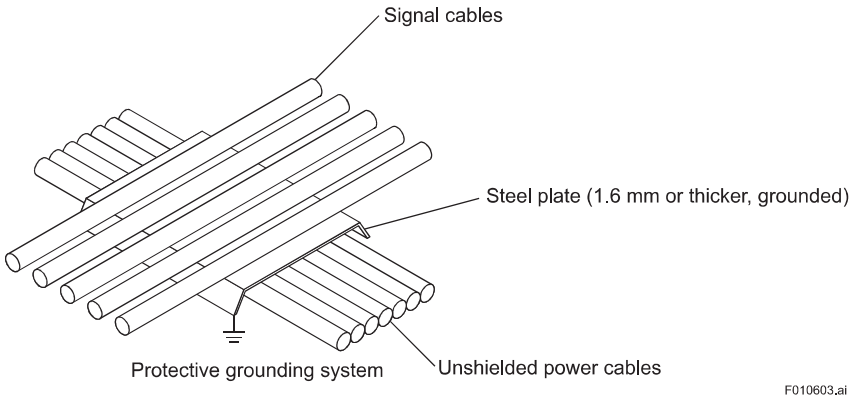

Figure Intersecting Cables under Pit/Free-access Floor

Ambient Temperature

The ambient temperature where signal and bus cables are laid must be within the range -10 to 60 °C.

When using FIO Node Unit, Optical ESB Bus Repeater Unit to conform to the temperature specification, the ambient temperature where the cables are laid must be within the range -20 to 70 °C.

When using N-IO Node (A2NN30D, A2BN3D) to conform to the temperature specification, the ambient temperature where the cables are laid must be within the range -40 to 70 °C.

When using BasePlate Barrier A2BN4D, the ambient temperature where the cables are laid must be within the range -20 to 60 °C.

When using BasePlate Barrier A2BN5D, the maximum ambient temperature specifications for A2BN5D depend on compliance criteria.

For details, refer to GS 33J01A10-01EN “Integrated Production Control System CENTUM VP System Overview”.

When connecting the field signal to the base plate (A2BN3D) via a dedicated cable and terminal board (A2BM4), the ambient temperature where the cables are laid must be within the range -20 to 70 °C.

Measures against EMI

As a rule, avoid laying the cables on the floor. However, lay them on the floor when there are no ducts and no pits. In that case, it is required to cover them with shield plates or take other measures to suit the EMC Directive.

1.7 Corrosive-gas Environment Compatibility

The CENTUM VP system employs Node units, I/O modules, and cables which meet the ANSI/ISA G3 environment requirements and are compatible with the corrosive gas-susceptible environment.

G3 Environment-compatible Products

Table G3 Environment-compatible Products (1/3)

No.	Product	Model	Description
1	Field control unit	AFV30□- □□□□6□ □□□□F□	Field Control Unit (for Vnet/IP and FIO, Rack Mountable type)
		A2FV50□-□□□□1□	Field control unit (for N-IO, 19-inch Rack Mountable)
		A2FV70□-□□□□1□	Field control unit (for RIO System Upgrade, 19-inch Rack Mountable)
2	Node unit	ANB10□ -□□6 -□□7 -□□F -□□G	Node Unit for ESB Bus
		ANB11□ -□□6 -□□F	Optical ESB Bus Node Unit
3	Unit	ANT10U -□□6 -□□F	Unit for Optical ESB Bus Repeater Module
4	Bus Interface Module	A2EN402 -□□□□1	N-ESB Bus Coupler Module (2-Port)
		A2EN404 -□□□□1	N-ESB Bus Coupler Module (4-Port)
		A2EN501 -□□□□1□ -□□□□3□	N-ESB Bus Module
		EC401-□1	ESB Bus Coupler Module
		EC402-□1	ESB Bus Coupler Module
		ANT401-□3	Optical ESB Bus Repeater Master Module 5 km
		ANT411-□3	Optical ESB Bus Repeater Master Module 5 - 50 km
		ANT502-□3	Optical ESB Bus Repeater Slave Module 5 km
		ANT512-□3	Optical ESB Bus Repeater Slave Module 5 - 50 km
		SB401-□3	ESB Bus Interface Slave Module
		A2EE1A	ESB Bus Adapter (for SB401)
		A2EE2A	ESB Bus Adapter (for ANT4□1)
		A2EE3A	ESB Bus Adapter (for ANT5□2)
5	Analog I/O modules	A2MMM843-□□□□1□ -□□□□3□	Analog Digital I/O Module
		AAI141-□□3	Analog input module (4 to 20 mA, 16-channel, non-isolated)
		AAV141-□□3	Analog input module (1 to 5 V, 16-channel, non-isolated)
		AAB141-□□3	Analog input module (1 to 5 V / 4 to 20 mA, 16-channel, non-isolated)
		AAI841-□□3	Analog I/O module (4 to 20 mA input, 4 to 20 mA output, 8-channel/8-channel, non-isolated)
		AAB841-□□3	Analog I/O module (1 to 5 V input, 4 to 20 mA output, 8-channel/8-channel, non-isolated)
		AAB842-□□3	Analog I/O module (1 to 5 V / 4 to 20 mA input, 4 to 20 mA output, 8-channel input / 8-channel output, non-isolated)
		AAI143-□□3	Analog Input Module (4 to 20 mA, 16-Channel, Isolated)
		AAI543 -□□1 -□□3	Analog Output Module (4 to 20 mA, 16-Channel, Isolated)
		AAV144-□□3	Analog input module (–10 to +10 V, 16-channel, isolated)
		AAV544-□□3	Analog output module (–10 to +10 V, 16-channel, isolated)

Table G3 Environment-compatible Products (2/3)

No.	Product	Model	Description
5	Analog I/O modules	AAI135-□□3	Analog input module (4 to 20 mA, 8-channel, isolated channels)
		AAI835-□□3	Analog I/O module (4 to 20 mA, 4-channel/4-channel, isolated channels)
		AAT145-□□3	Thermocouple/mV input module (16-channel, isolated channels)
		AAR145-□□3	Resistance temperature detector/potentiometer input module (16-channel, isolated channels)
		AAP135-□□3	Pulse input module (8-channel, 0 to 10 kHz, isolated channels)
		AAP149-□□1	Pulse input module for compatible PM1 (16-channel, pulse count, 0 to 6 kHz, non-isolated)
		AAP849-□□1	Pulse input/Analog output module for compatible PAC (Pulse count input, 4 to 20mA output, 8-channel/8-channel, non-isolated)
6	Digital I/O modules	A2MDV843-□□□□1□ -□□□□3□	Digital IO module (16-channel, isolated)
		ADV151-□□3	Digital input module (32-channel, 24 V DC, isolated)
		ADV551-□□3	Digital output module (32-channel, 24 V DC, isolated)
		ADV161-□□1	Digital input module (64-channel, 24 V DC, isolated)
		ADV561-□□1	Digital output module (64-channel, isolated)
		ADV859-□□1	Digital I/O module for compatible ST2 (16-channel input/16-channel output, isolated channels)
		ADV159-□□1	Digital input module for compatible ST3 (32-channel, isolated channels)
		ADV559-□□1	Digital output module for compatible ST4 (32-channel, isolated channels)
		ADV869-□□1	Digital I/O module for compatible ST5 (32-channel input/32-channel output, isolated, common minus side every 16-channel)
		ADV169-□□1	Digital input module for compatible ST6 (64-channel, isolated, common minus side every 16-channel)
		ADV569-□□1	Digital output module for compatible ST7 (64-channel, isolated, common minus side every 16-channel)
7	Communication modules	ALR111-□□1	RS-232C Communication Module (2-Port, 1200 bps to 115.2 kbps)
		ALR121-□□1 -□□3	RS-422/RS-485 Communication Module (2-Port, 1200 bps to 115.2 kbps)
		ALE111-□□1 -□□3	Ethernet Communication Module (1-Port, 10 Mbps)
		ALF111-□□1	Foundation Fieldbus (FF-H1) Communication Module (4-Port, 31.25 kbps)
		ALP121-□□1	PROFIBUS-DP Communication Module (1-Port, 9600 bps to 12 Mbps)
		A2LP131-□□1	PROFINET Communication Module (1-Port, 100 Mbps)
		A2LP141-□□1	PROFINET Communication Module (1-Port, 100 Mbps)
8	Router	AVR10D-□□□□1	Duplexed V net Router
		AW810D-□□□□□6	Wide Area Communication Router
9	Turbomachinery I/O Modules	AGS813-□□1	Servo Module (Isolated)
		AGP813-□□1	High Speed Protection Module (Isolated)
10	Node Interface Unit	A2NN10D -□□□□□□□□1	Node Interface Unit (for RIO System Upgrade)
		A2NN20D -□□□□□□□□1	Node Interface Unit (for RIO System Upgrade, Cabinet Installation Type)
		A2NN30D -□□□□□□□□1 -□□□□□□□□3	Node Interface Unit
11	Base Plate	A2BN3D -□□□□1□ -□□□□3□	Base Plate for Adaptor
		A2BN4D	Base Plate for Barrier (MTL)
		A2BN5D	Base Plate for Barrier (P+F)
		A2BE1D-□□1□	Base Plate (for FCU)
		A2BE2D-□□1□	Base Plate (for FIO)

Table G3 Environment-compatible Products (3/3)

No.	Product	Model	Description
12	Nest	A2BA3D-□□□1□	Nest for I/O Adaptor (for RIO System Upgrade)
13	Power Supply Unit	A2PW503 -□□□□1□ -□□□□3□	24 V DC Power Supply Unit (120 W, 100 to 240 V AC Input)
		A2PW504 -□□□□1□ -□□□□3□	24 V DC Power Supply Unit (120 W, 24 V DC Input)
		PW481-□1	100 - 120V AC Input Power Supply Module
		PW482-□1	220 - 240V AC Input Power Supply Module
		PW484-□1	24 V DC Input Power Supply Module
14	Adaptor	A2SAP105 -□□1□ -□□3□	Pulse Input Signal Adaptor
		A2EXR001 -□□□□□3□	Shunt Resistor Unit (for A2SAP105)
		A2SDV105 -□□1□ -□□3□	Digital Input Adaptor
		A2SDV505 -□□1□ -□□3□	Digital Output Adaptor
		A2SDV506 -□□1□ -□□3□	Relay Output Adaptor
		A2SMX801 -□□1□ -□□3□	Pass-through I/O Signal Adaptor
		A2SMX802 -□□1□ -□□3□	Pass-through I/O Signal Adaptor (With field power output)
		A2SAM105 -□□1□	Current Input/Voltage Input Adaptor
		A2SAM505 -□□1□	Current Output/Voltage Output Adaptor
		A2SAT105 -□□1□	mV/TC/RTD Input Adaptor
15	Terminal board	AEA3D -□6 -□F	Terminal Board for Analog (single and dual-redundant, 8-channel)
		AEA4D -□6 -□F	Terminal Board for Analog (single and dual-redundant, 16-channel)
		AET4D -□6 -□F	Terminal Board for Thermocouple (single and dual-redundant, 16-channel)
		AED5D -□6 -□F	Terminal Board for Digital (single and dual-redundant, 32-channel)
		AER4D -□6 -□F	Terminal Board for resistance temperature detectors (single and dual-redundant, 16-channel)
		AEF9D -□6 -□F	Terminal Board for Fieldbus (single and dual-redundant)
		A1BA4D -□6 -□F	Terminal Board for Analog (single and dual-redundant, 16-channel x 1 or 8-channel x 1, DIN rail mount type)
		A1BT4D -□6 -□F	Terminal Board for Thermocouple (single and dual-redundant, 16-channel x 1, DIN rail mount type)
		A1BR4D -□6 -□F	Terminal Board for RTD input (single and dual-redundant, 16-channel x 1, DIN rail mount type)
		A1BD5D -□6 -□F	Terminal Board for Digital (single and dual-redundant, 32-channel x 1, DIN rail mount type)
		A2BM4 -□1□ -□3□	Terminal board for analog digital I/O
16	Interface unit (for FCU)	A2FU1-1□	HKU interface unit
		A2FU2-□□1□	Primary power distribution unit (for FCU)
17	Processor Module	CP471-□1	Processor Module

Outline of G3 Environment Compatibility

The classification of the environment in which the process control equipment is installed is determined by the ANSI/ISA S71.04-1985 “Environmental Conditions for Process Control Systems” standard. The environment having an atmosphere which contains steams and mists (liquids, coded L), dusts (solids, coded S), or corrosive gases (gases, coded G) is classified into four categories according the levels of these substances determined.

The four categories of the corrosive gas environment are defined as follows:

G1 (Mild): A well-controlled environment in which corrosive gas is not the major cause adversely affecting the reliability of plant equipment. The corrosion level on the copper test piece is below 0.03 µm (see note below).

G2 (Moderate): An environment in which corrosive gas can be detected and it could be determined that the gas is the major cause adversely affecting the reliability of plant equipment. The corrosion level on the copper test piece is below 0.1 µm (see note below).

G3 (Harsh): An environment in which corrosive gas is frequently generated to cause corrosion and that it is necessary to provide special measures or employ specially designed or packaged plant equipment. The corrosion level on the copper test piece is below 0.2 µm (see note below).

GX (Severe): A corrosive gas-polluted environment that demands special protective chassis for the plant equipment, specifications of which should be seriously determined by the user and a power unit manufacturer. The corrosion level on the copper test piece is 0.2 µm or more (see note below).

Note: Copper test pieces are used to determine the level of corrosion for the classification of the plant environment. The test piece is an oxygen-free copper sheet, which is 15 cm^2 in area, 0.635 mm in thickness, 1/2 to 3/4 H in hardness. The test piece is placed in the plant site for one month and checked for any change before and after the test to determine the degree of corrosion (see table below). If the test period is shorter than one month, the result is calculated to obtain equivalent data using a expression defined by the standard.

Table Classification of Corrosive-gas Corrosion Levels

Environment category		G1 (Mild)	G2 (Moderate)	G3 (Harsh)	GX (Severe)	
Copper corrosion level		< 300 (< 0.03)	< 1000 (< 0.1)	< 2000 (< 0.2)	≥ 2000 (≥ 0.2)	[Å] ([µm])
Group A	H_2S	< 3	< 10	< 50	≥ 50	[mm^3/m^3]
	SO_2, SO_3	< 10	< 100	< 300	≥ 300	
	Cl_2	< 1	< 2	< 10	≥ 10	
	NOx	< 50	< 125	< 1250	≥ 1250	
Group B	HF	< 1	< 2	< 10	≥ 10	
	NH_3	< 500	< 10000	< 25000	≥ 25000	
	O_3	< 2	< 25	< 100	≥ 100	

Note: The gas density data indicated in the table are for reference only, with the relative humidity of 50 %RH or less. The category goes up one rank higher every time the humidity increases 10 % exceeding the 50 %RH or over 6 % per hour.

The Group-A gases shown in the table may coexist and cause inter-reaction. Inter-reaction factors are not known for the Group-B gases.

1.8 Compliance with Marine Standards

The CENTUM VP comply with the following marine standards, and installation methods.

- **ABS (American Bureau of Shipping)**
- **BV (Bureau Veritas)**
- **LR (Lloyd's Register), ENV2**
- **DNV**

Precaution on Selecting System Components

When building a system, use components which have already obtained type approval of marine standards. For the HISs, also use generic computers (including monitors, keyboards, mice, and other peripheral devices) which are accredited by the required marine standards.

Marine Standard-compliant CENTUM VP (Vnet/IP) Components

The CENTUM VP (Vnet/IP) components which comply with the marine standards, refer to the GS 33J01A10-01EN "Integrated Production Control System CENTUM VP System Overview".

When using the systems components not listed there, compliances to the marine standards and installation methods need to be confirmed individually in advance.

Precaution on Installing Components

In order to comply with the marine standards, the specific installation methods must be followed. Please contact "Process Automation PMK Dept., IA Systems Business Division, IA Platform Business Headquarters" for more details.

2. Transportation, Storage and Installation

This chapter describes the precautions in transporting, storing, and installing the CENTUM VP system equipment.

SEE ALSO See “Section 1.2 Control Room Environment” for the environmental requirement for each piece of equipment.

2.1 Precautions for Transportation

This section describes the precautions required to prevent accidents and damage when transporting CENTUM VP system equipment. These precautions apply when the equipment is contained in our original packing.

Transportation

SEE ALSO See "Table Equipment Installation Specifications" in Section 1.2 Control Room Environment for ambient temperature, humidity, vibration and impact.

Loading

- Do not load crates on top of others or turn them on their sides.
- Keep all crates upright.
- Secure loaded crates using ropes, and cover them completely with waterproof coverings.
- Do not load crates outdoors when it is raining.

Don't Stack Outdoors

Be sure to store cargoes inside a warehouse if they must be stored for some time.

Transportation

Cargoes contain precision instruments. Select a company specializing in the transportation of computers and precision instruments.

Keep all products upright during air transport, freightage, or truck transport. When transporting by track, drive at low speed to avoid vibration and impact. Also, slow down to the limit on a bad road.

Others

Do not transport equipment through areas where there may be corrosive gas, intense electric or magnetic fields.

Unloading

Prepare special equipment for unloading. Avoid unloading outdoor in case of rain.

Location for Unloading

To select a location for safe unloading, check that:

- There is ample space for crane and forklift maneuvering.
- Ground is solid.
- The handrails of scaffold can be removed.
- There is enough working space for unpacking (at least 2500 mm by 4000 mm). Provide a platform if necessary.
- There is a height of at least 3000 mm under the roof.
- Outdoor-indoor temperature difference should be less than 10 °C to avoid condensation.

Keep Upright

Keep crates upright when unloading.

Avoid Physical Shock

Avoid physical shock. Be careful not to lose balance or swing when lifting or placing cargoes on the ground or platform. Also check scaffold strength.

CAUTION

- When lifting Hardware with a crane, do not unpack it, but attach lifting bolts or wire ropes to the baseboard positions shown to lift it. Keep the distance between the crane hook and the cargo to be lifted at a minimum.
- If it is difficult to do this, tie four belts together at a point close to the cargo to keep it from falling.
- Unpacked items are more likely to lose their balance and fall.

Craning the cabinet

When lifting a cabinet by a crane, please follow the instructions below.

- Use two of the eyebolts in diagonal positions, or all four of the eyebolts to lift the cabinet.
- Keep the wire lifting angle of the cabinet less than 90 degrees.
- Use a wire pair each eyebolt.

When craning the cabinet, the wire or the crane must have enough strength against the cabinet weights.

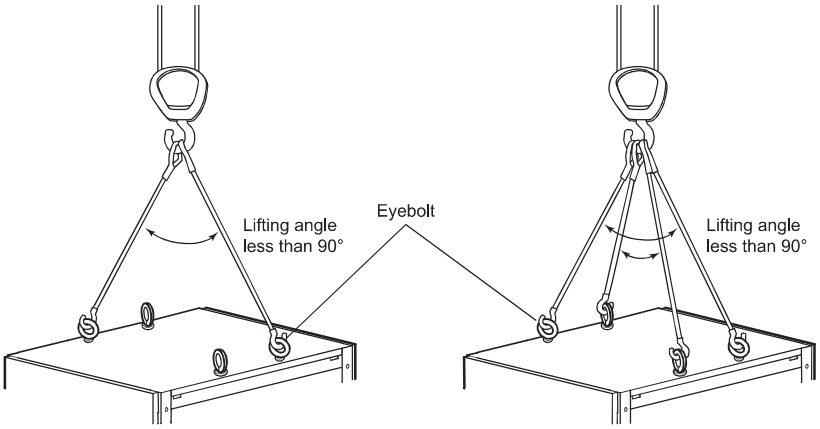

Figure How to lift of a cabinet

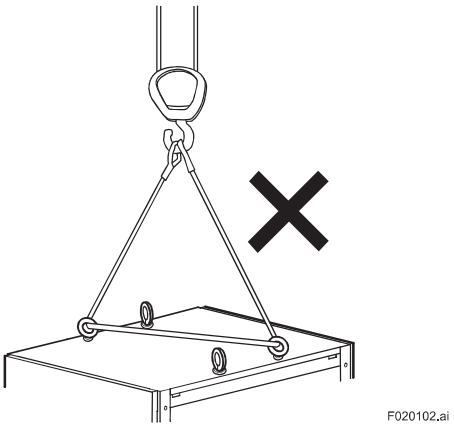

Figure Wrong way of lifting

Carrying

This section describes how to carry cabinets.

Carrying Space

Carry cabinets into the location of installation without unpacking.

To carry them in on the second floor or upper floors using a crane, a scaffold of about 2500 by 4000 mm is required for placing as well as unpacking.

Table Required Entrance and Elevator Size

	Cabinet
Width	800 mm
Height	2400 mm
Depth	1000 mm
Max. loading capacity	400 kg

Passage

The passage must be wide enough as shown below. It must also be strong enough to withstand the weight of the cabinet. Determine the passage according to the cabinet's and carrier's size and weight.

- Carrying cabinet in

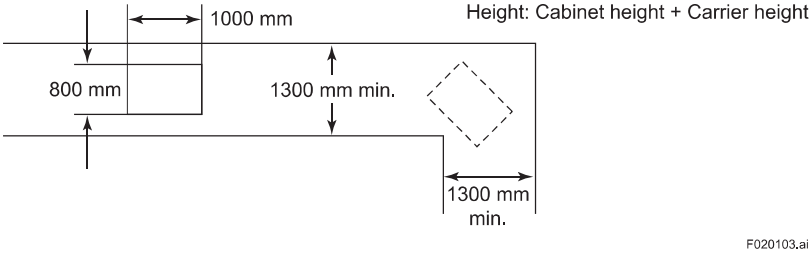

Figure Passage Requirements

Carrying when Headroom is Low

The cabinet should be carried upright. If this is impossible due to low headroom,

- Remove the side boards.
- Turn the cabinet's right or left side (viewed from its front) down.
- Gently carry the cabinet with the side down.
- Turn the cabinet to its upright position as soon as the cabinet passes through a place with low headroom. Attach the side boards to the cabinet.

Using Rollers

The cabinet should be carried in to or near the installation location without unpacking. Do not use rollers if possible. When using them, take the following precautions:

- Use wooden rollers which are long enough so that more than 200 mm remains outside of the cabinet on each side.
- Make sure that two or more rollers are always under the cabinet.
- Do not use a hammer to correct roller positions on the move.

2.2 Unpacking

In unpacking the received cargoes and equipment, inspect them according to inspection list below. It is recommended to unpack by Yokogawa engineers or in their presence.

Table Inspection List

	Inspection Items	Result		Measures Required
Exterior	• Environment of unpacking location (temperature, humidity, dust)	Suitable	Unsuitable	If unsuitable, select proper location according to specified environmental requirements.
	• Rapid temperature fluctuation (should be within ±10 °C/h)	No	Yes	If yes, do not unpack and wait until the fluctuation remains within ±10 °C/h.
	• Damage to equipment exterior	No	Yes	If damaged badly, inform Yokogawa.
	• Condensation or its trace on equipment exterior. (*1)	No	Yes	If yes, inform Yokogawa.
Interior	• Loose parts inside equipment.	No	Yes	If yes, remove them and check the surrounding.
	• Damage to equipment interior.	No	Yes	If damaged badly, inform Yokogawa.
	• Condensation or its trace on equipment interior. (*1)	No	Yes	If yes, inform Yokogawa.

*1: Condensation symptoms are as follows:
- Dew patterns on PCBs.
- Printed circuit copper trace is floating off the board.
- Label characters on PCBs are smudged.
- Connectors on PCBs are smudged.
- Dew patterns or traces of droplets are found on cabinet panels.

CAUTION

Condensation may cause a fatal system failure in the CENTUM VP system. Be sure to unpack the equipment indoor under the specified environmental conditions. Strictly observe the allowable temperature fluctuation range of ±10 °C/h. Do not bring the equipment into a heated room straight from the outside in winter. Our warranty does not cover any damage caused by condensation.

CAUTION

Be careful not to let the products fall when you handle them.

When they are hit hard, the interior of them can be damaged, although there is no damage in the exterior.

If you accidentally drop an product, stop using it immediately and report it to Yokogawa.

2.3 Storage

The delivery date should be determined in accordance with your installation schedule. Avoid storing products more than three months. If long-term storage more than three months cannot be avoided, consult Yokogawa in advance because it is necessary to provide waterproofing, condensation prevention, and dustproofing measures as well as periodical inspections.

Storage Condition

Store products without unpacking. Be sure to confirm that the crate is not damaged. To store them after unpacking, be sure to take the precautions described below.

Location of Storage

Store products in a warehouse or indoor facilities - never in an open-air location.

Storage Environment

- Ambient Temperature for storage: 5 to 40 °C
- Avoid direct sunlight.
- Prevent condensation.
- Do not store products where corrosive gas or salty air may be present.

SEE ALSO See “Section 1.2 Control Room Environment” for permissible temperature, humidity and temperature fluctuation of storage area.

Storage of Packed Equipment

- Place squared pieces of lumber with a height of 100 mm or higher on the floor. The lumber should be long enough so that more than 100 mm remain outside of the crate on every side.
- Securely place unopened crates on the lumber platform.
- Do not stack crates in piles.
- Make sure to provide good air circulation in the storage area and periodically inspect the crates to keep them under proper conditions.

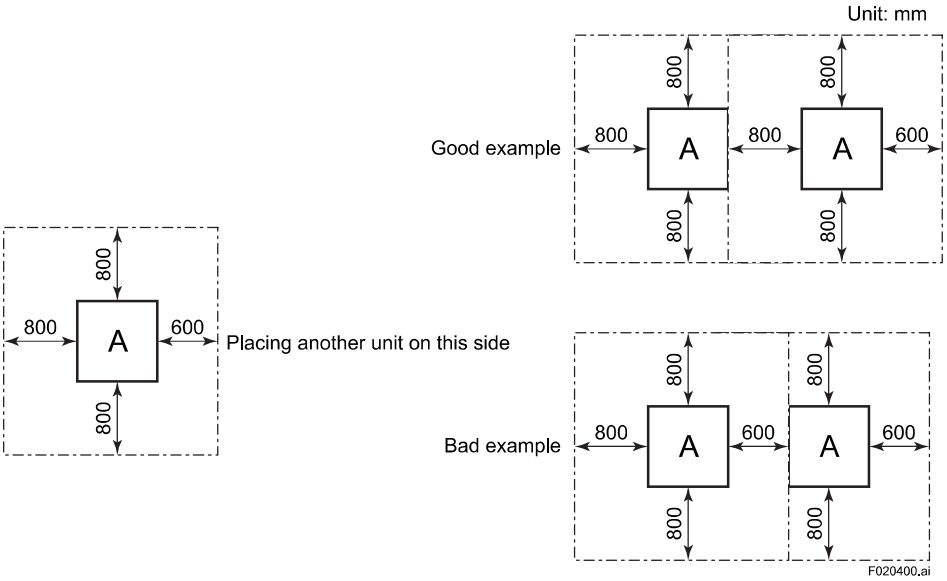
Storage of Unpacked Equipment

To store unpacked products without power connection, follow the specified environmental requirements. If stored in a non-air-conditioned room, cover them with polyethylene or other sheets for protection against dust and moisture. For moisture-proofing, place a sufficient amount of Silica gel or other desiccating agent inside the covering and inspect replace from time to time. When using desiccating agent or corrosion inhibitor etc., please select the appropriate one. Also, please make sure that it does not affect the function and performance of the product before actually using it.

2.4 Servicing Area

Take enough space around equipment for its operation and maintenance service. This servicing area is indicated for each equipment.

The servicing area should be considered in determining the size of installation location. When installing a number of equipment side by side, take the largest service-area between them if different dimensions are indicated for different side of equipment (see below).



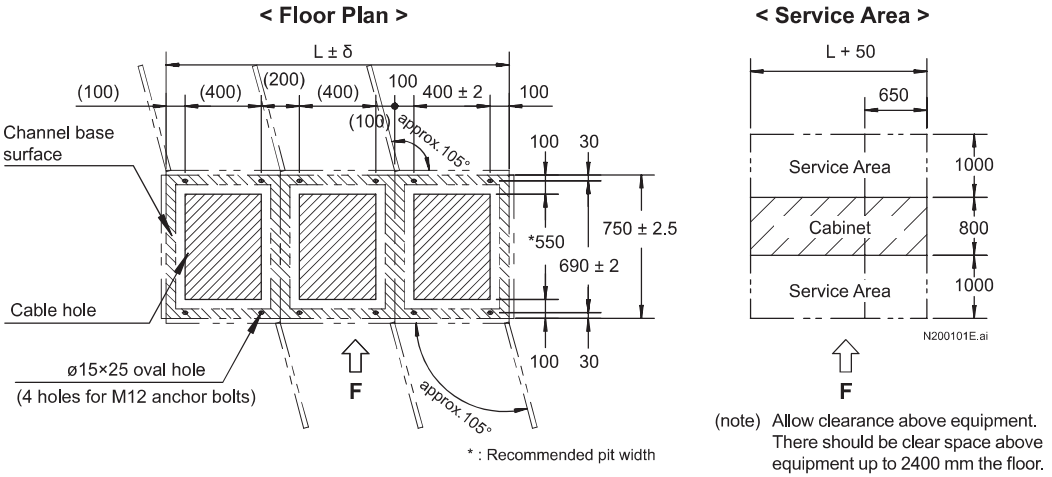


Figure Servicing Area when Installing Units Side-by-side

	Outside dimension							
Number of cabinets	1	2	3	4	5	6	7	8
L	600	1200	1800	2400	3000	3600	4200	4800
± δ	2	4	6	8	10	12	14	16

Nominal Tolerances :

When the reference dimension is over 0.5 mm and equal or less than 120 mm, its nominal tolerance shall be ± 0.8 mm, while its combination of nominal tolerance is ± 1.5 mm.

When the reference dimension is over 120 mm, its nominal tolerance shall be in accordance with JEM 1459.

F020401.ai

Figure Servicing Area when Installing AFV40S/AFV40D/ACB51/A2CAB1

2.5 Installation

Before installation, be sure that anchor bolts, pedestals, and cable holes are provided according to the customer's system configuration plans. Check that the positions of holes on the floor fit the anchor bolt holes in the channel base of each piece of equipment.

2.5.1 Installation on Floor

The installation method varies with the type of the floor and building.

- After unpacked, be careful not to put any impact until it is fixed to the floor to prevent from tip-over.
- Install devices as specified in the plans.
  Check the position of front and back panels of the cabinet.
  Avoid physical shock. Never use hammers.
- Fix each equipment to the floor. The explanation below shows how to fix devices on different types of floors.

Concrete Floor

Clamp the equipment to the floor using anchor bolts. It is recommended to use M12 bolts and 3,200 N•cm tightening torque.

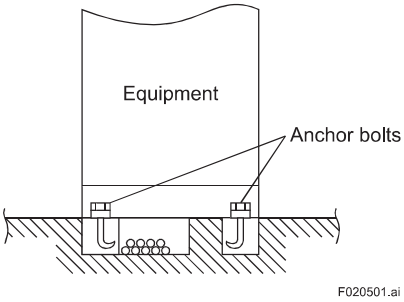

Figure Using Anchor Bolts

Steel Floor

Clamp the equipment to the floor using clamp bolts.

After cabling through the riser duct, fill the duct with rubber sponges and seal the top with putty.

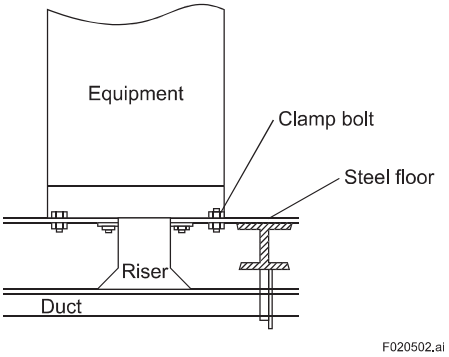

Figure Using Clamp Bolts

"Free-access" Floor

Clamp the equipment to pedestals which are anchored to the base floor.

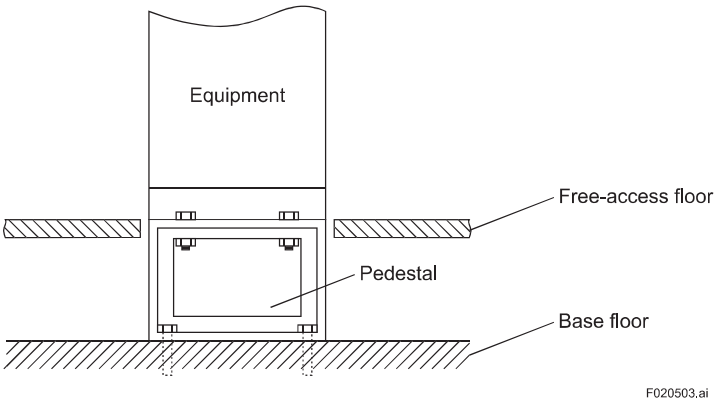

Figure Using Pedestal

In the "free-access" floor, make holes for riser cables to connect to each piece of equipment as follows:

- If one floor tile is removed, be sure to reinforce the opening with an angle frame for floor stability.

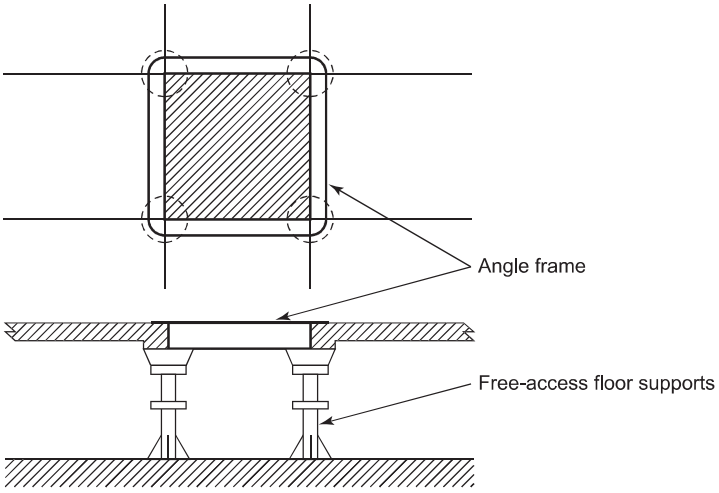

Figure Removing One Floor Tile

- Do not make a holes near the floor supports.
- Do not cut away more than 1/3 of a floor tile.

IMPORTANT

If a number of neighboring floor tiles are removed, be sure to provide angle frames or pedestals for reinforcement.

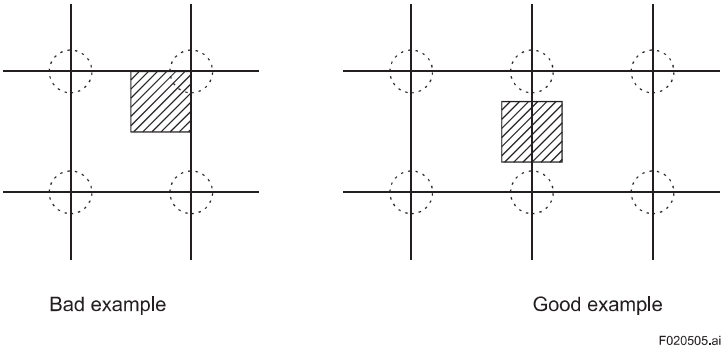

Figure Partially Cutting Floor Tile

Size of Cabling Holes in Floor

For ease of cabling, and for separating power cables from signal cables, it is recommended that you create holes in the floor for cabling that are the maximum size indicated in the floor plans.

SEE ALSO Refer to “General Specification” (GS) for the weight and dimensions.

Refer to "2.4 Service Area" for the floor plan about AFV40☐, ACB51, A2CAB1.

If the specified maximum size hole cannot be provided due to the floor construction or pit dimensions, the size may be smaller within the range indicated in the plans. If you use the specified minimum size of hole, use flexible cables that can bend inside the channel base.

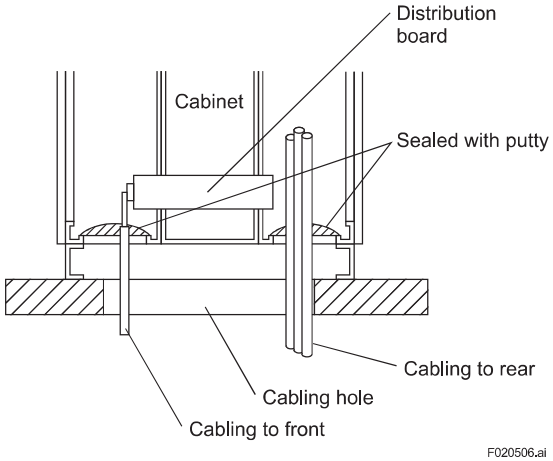

Figure Cabling through Maximum Size Hole

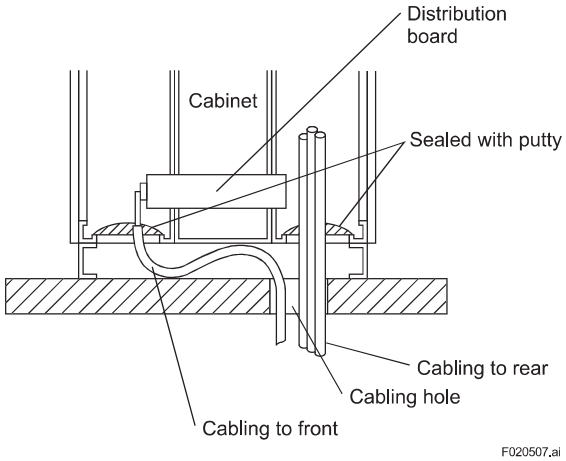

Figure Cabling through Minimum Size Hole

2.5.2 Installing Cabinets in a Side-by-Side Arrangement

Install two or more cabinets (AFV40S/AFV40D, ACB51, and A2CAB1) in a side-by-side arrangement as described below.

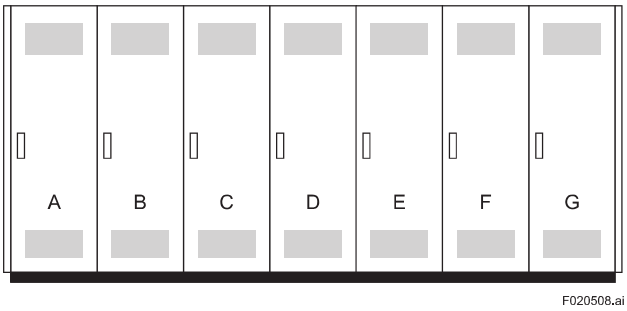

Figure Example of Installing Cabinets in a Side-by-Side Arrangement

Installation

(a) Level the floor surface on which cabinets are to be installed.

(b) To install two or more cabinets in a line, install the central one first (D in Figure), and next ones on both sides (C→B→A, E→F→G).

(c) With bottom plate (a) (see Figure on next page) off, install the cabinet in position, making sure that the anchor bolt position and channel base hole align with each other.

(d) Tighten anchor bolt nut [A] (see Figure on next page) when the installation is complete. When linking many cabinets in a row, tighten the nuts only finger-tight first, fully tightening them when the cabinet interconnection is complete.

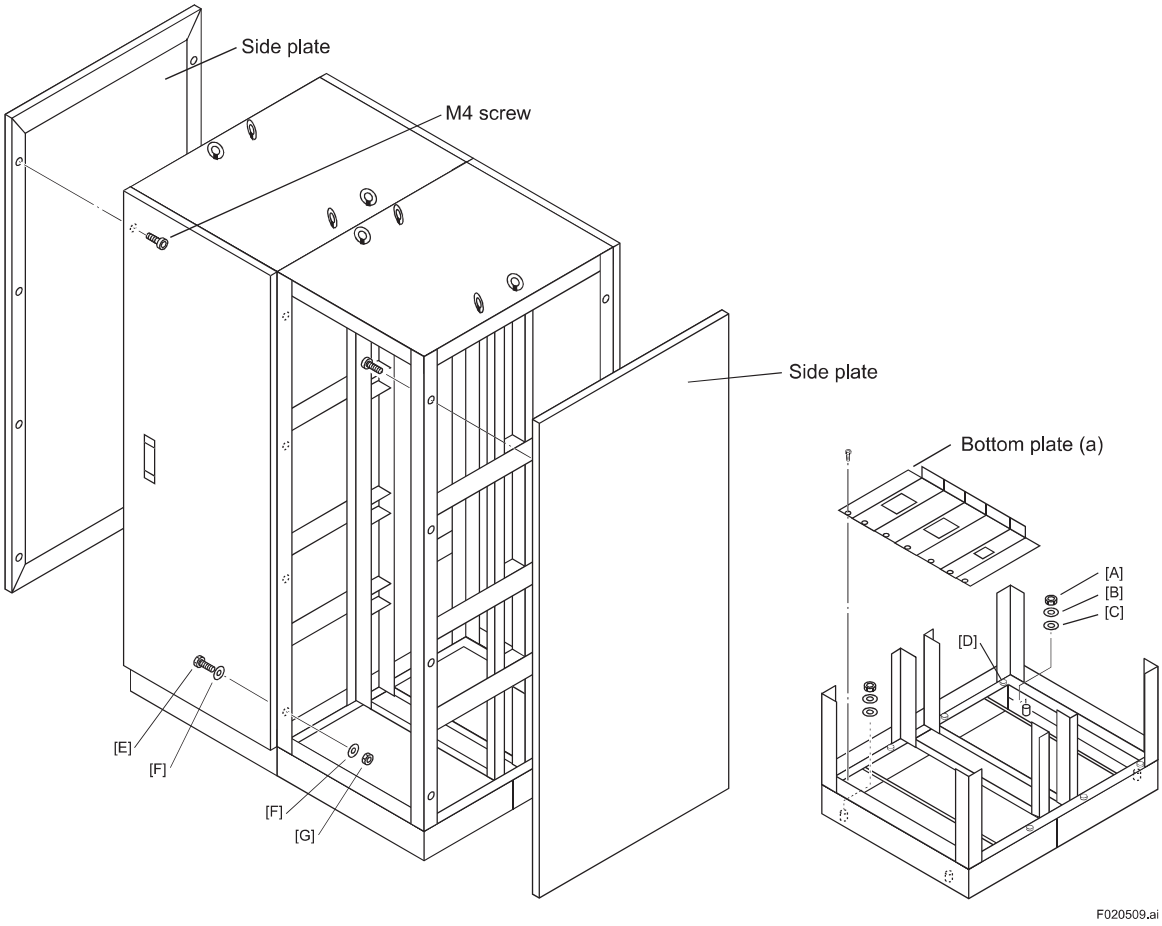

Figure Installing Cabinets Side by Side

Interconnecting cabinets

(a) Using a hexagon wrench, loosen hexagonal socket head bolts [D] (eight bolts) securing the main body and the channel base to each other.

(b) With the front and rear doors open, clamp bolt screw [E], toothed washer [F] and nut [G] using a wrench (at eight positions on the front and rear in total).

(c) After verifying that the cabinet is level in all orientations, clamp hexagonal socket head bolts [D] (eight bolts) securing the main body and the channel base to each other using a hexagonal wrench. If there is a gap between the main body and channel base when the hexagonal socket head bolts are clamped, insert liners into the gap for adjustment.

(d) Replace all bottom plates that have been removed in their original position.

SEE ALSO For details on the related tools and parts for joining cabinet's side-by-side, refer to "Tools and Parts Required for Joining Cabinets."

Tools and Parts Required for Joining Cabinets

Connecting kit to install cabinets side by side. Table lists those parts needed to connect two cabinets together.

- AKT211: Connection kit for Cabinet

Table Joining Parts and Tools (required per additional station)

No.	Names	Part numbers	Quantity
a	Nut or bolt (M12) (*1)	–	4
b	Spring washer (M12) (*1)	–	4
c	Flat washer (M12) (*1)	–	4
d	Hex hole bolt (M10)	– (Cabinet accessory)	8
e	Bolt (M8)	Y9820NS	8
f	Toothed (serrated) washer (M8)	Y9801WL	16
g	Nut (M8)	Y9801BS	8
h	L-shaped hex wrench	S9103PB	2

*1: Parts “a” “b” and “c” need to be provided by the user.

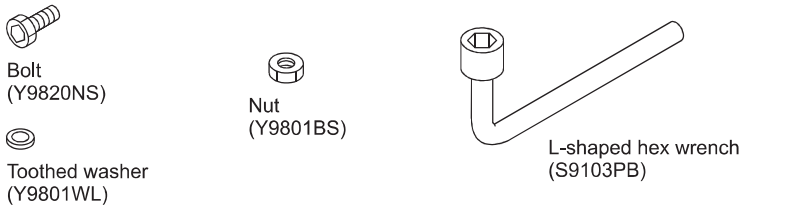

Figure Cabinet Connecting Parts

2.5.3 19-inch Rack Mount Devices

Before use, mount the following devices in a rack. AFV30S/AFV30D, A2FV50S/A2FV50D, A2FV70S/A2FV70D, ANB10S/ANB10D, ANB11S/ANB11D, ANT10U, A2BE1D and A2BE2D Unit for FIO and AVR10D Duplexed V net Router and AW810D Wide Area Communication Router and A2NN10D Node Interface Unit.

CAUTION

- To meet the Safety Standards and EMC Standards, the devices must be installed in a lockable metal cabinet. The cabinet must conform to IEC/EN/CSA 61010-2-201 or provide degrees of protection IP3X or above and IK09 or above.
- Do not install the 19-inch rack mountable devices close to each other. When installing an 19-inch rack mount devices on the same rack, maintain a 3-unit spacing (*1) (1 unit: 44.45 mm) between devices.

*1: Space between devices can be smaller than 3 unit to the extent it does not interfere with device mounting and maintenance, only if Cabinet Utility Kit (ACUKT1) is used or the cabinet interior has been provided with a thermal design and the ambient temperature is within the product specifications.

Notes on Installation

CAUTION

For installation, secure ample working space and work in a team for safety.

Be sure to observe the following when installing in the rack or on an instrumentation panel:

Providing Space for Heat Radiation

Leave space at the top and bottom of rack-mount equipment to permit heat radiation.

- Separate the top of the instrumentation board at least 100 mm away from the ceiling, and cut a ventilation hole of 200 cm^2 or larger in the ceiling or install a ventilation fan.
- Keep at least 50 mm between the back of the equipment and the instrumentation panel or wall.
- When installing an 19-inch rack mount devices on the same rack, maintain a 3-unit spacing (1 unit: 44.45 mm) between devices.
  Do not use any space between equipments for cable wiring or anything.
- Do not block ventilation openings in top and bottom face of equipment.

Providing Area for Servicing

When mounting devices in the 19-inch rack, the mounting plate cut out of instrumentation panel, and so on, leave an area for servicing.

Leave an area for servicing.

- All the work to connect cables to 19-inch rack mountable devices and I/O modules will be performed from the front.
- The work to confirm indicator lamps, configure card settings, and remove/insert cards will be performed from the front.
- The front is the area for wiring and servicing. Leave at least 1000 mm of space at the front.

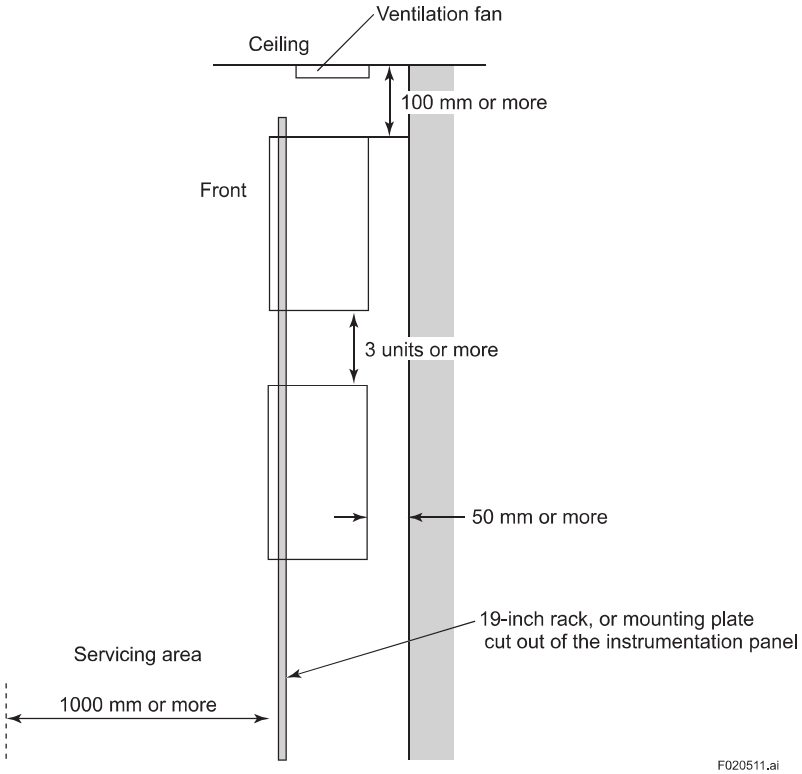

Figure Space Required for Rack-mount Equipment

Isolation from Rack

Isolate the rack mountable devices from the rack by attaching insulating bushings. Fasten a pair of insulating bushings together to each of the screw holes on the plate or the bracket on the devices to prevent the devices from touching the rack. And then screw the devices to the rack. After screwing the devices to the rack, confirm that the devices is electrically isolated. insulating bushings are supplied with the rack mountable devices.

CAUTION

When you install the 'devices with insulating bushings attached' on a rack or an instrument panel, do not keep the devices hung on loose screws in an unstable status. Too much force may apply to the insulating bushings and cause damaged or broken insulating bushings.

Installation Procedure

1. Fasten a pair of insulating bushings together to each of the screw holes on the plate or the bracket on the device. The tapering end of the insulating bushings must come to the front side where a screw enters.

2. Using eight M5 screws to fix the device onto the rack or the panel.

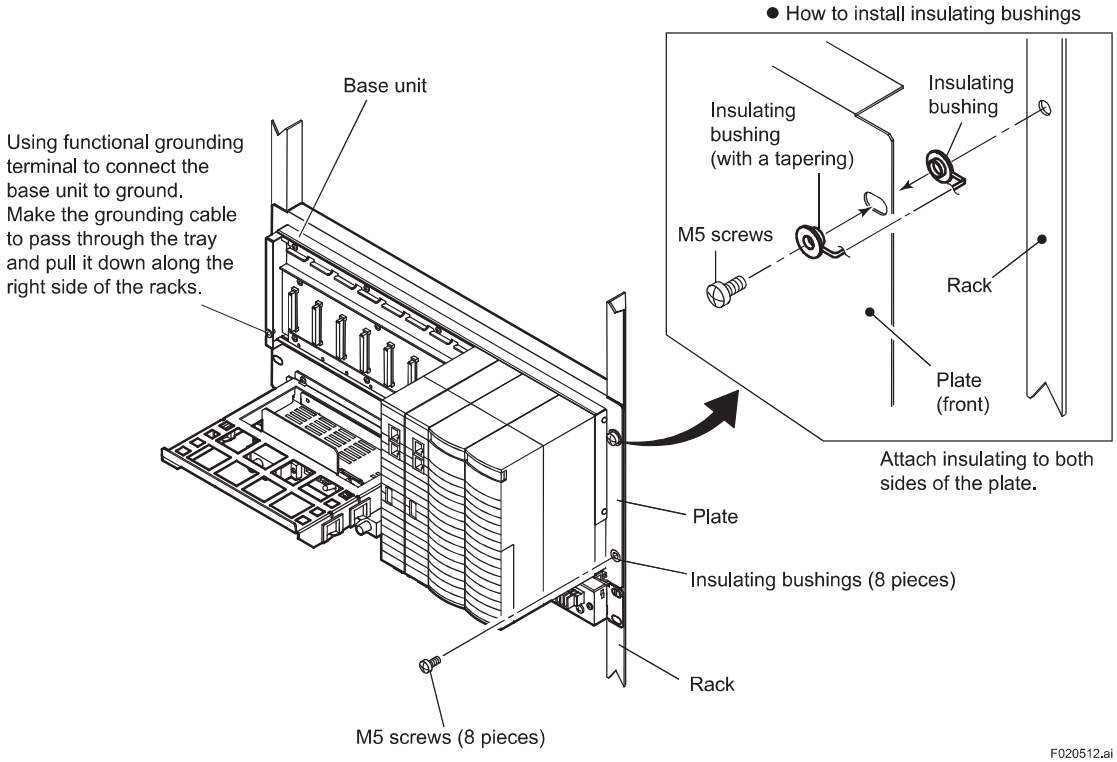

Figure Example of Mounting FCU on a Rack

Isolation Bush

In the front of the I/O expansion cabinet (ACB51) (*1): for cabinet installation type node and the rear: for 19-inch rack mount type, the cabinet installation type node is installed in the front. For this node, the independent grounding plays an important role in the circuit systems.
Therefore, in order that the rear 19-inch rack mount devices do not pass the grounding current which is important to the node, it and devices manufactured by other companies, must be insulated with an insulation brush. As devices manufactured by Yokogawa also do not have the guarantee that it will share a common power supply or grounding with the Model ACB51 itself, make sure to insulate with an isolation bush.

TIP

The isolation bush of Yokogawa devices can be eliminated if both I/O expansion cabinet types are installing Yokogawa devices and shares a common power supply and grounding with Model ACB51 and only when other company devices are insulated with an isolation bush.

*1: The same operation is applied to I/O expansion cabinet constructed with Standard Cabinet (A2CAB1) and Cabinet Utility Kit (A2CUKT4).

Installation Orientation

Install the device in the rack with the screws in the vertically correct orientation.

When installing the unit in the rack, confirm the direction according to the front view shown on General Specifications (GS).

TIP

When the device is supplied with power even if it is temporary, the device must be installed on the rack.
Placing the device on a desk etc. and laying it on its side should be avoided.
The device may become malfunction if the heat radiated from the device cannot be cooled smoothly.

2.5.4 DIN Rail Mountable Devices

The following devices can be mounted to a DIN rail.

Node interface unit:	A2NN30D-□□□0□□□□□
Adaptor base plate:	A2BN3D-0□□□□
Barrier base plate:	A2BN4D-2□□□□
	A2BN5D-2□□□□
Power supply unit:	A2PW503/DN, A2PW504/DN
Terminal board:	A1BA4D, A1BT4D, A1BR4D, A1BD5D, A2BM4
Relay board:	ARS15M, ARS55M

IMPORTANT

Install a DIN rail mountable device inside a metal cabinet.

Installation inside a metal cabinet with a lock is required to comply with standards; in particular, safety standards and EMC conformity standards.

Notes on Installation

CAUTION

For installation, secure ample working space and work in a team for safety.

Provide Space for Mounting

A2NN30D, A2BN3D, and A2BN5D need to be slide when they are mounted on the DIN rail. For that reason, provide a space shown in the following figure. Refer to the General Specifications (GS) for the external dimensions.

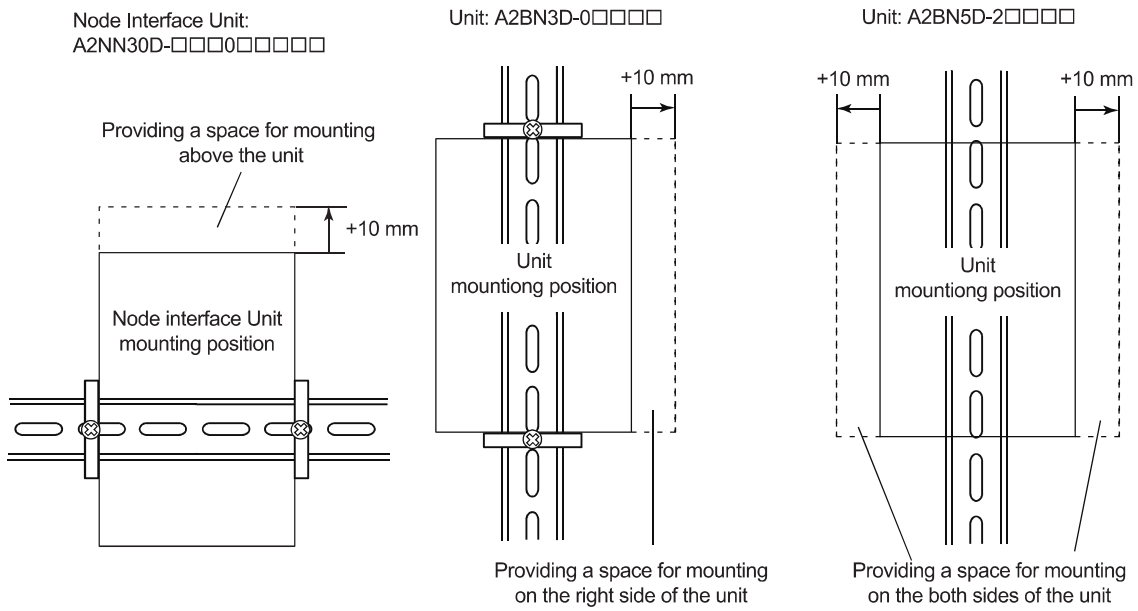

Figure Providing a Space for Mounting (Front View)

Mounting

- When mounting the I/O Units (A2BN3D, A2BN4D) spaced apart from each other on the DIN rail, install the stoppers in both the top and bottom ends of each unit.

When mounting the units close to each other on the DIN rail, install the stoppers in the bottom end of each unit and in the top end of the unit in the highest position.

- When mounting the I/O Units (A2BN5D), fix the both the top and bottom ends to the DIN rail with the built-in stoppers.
- When mounting the Node Interface Unit (A2NN30D), install the stoppers in both the right and left ends of the unit.
- When mounting the Power Supply Unit (A2PW503/DN, A2PW504/DN), fix the both ends to the DIN rail with the built-in stoppers.

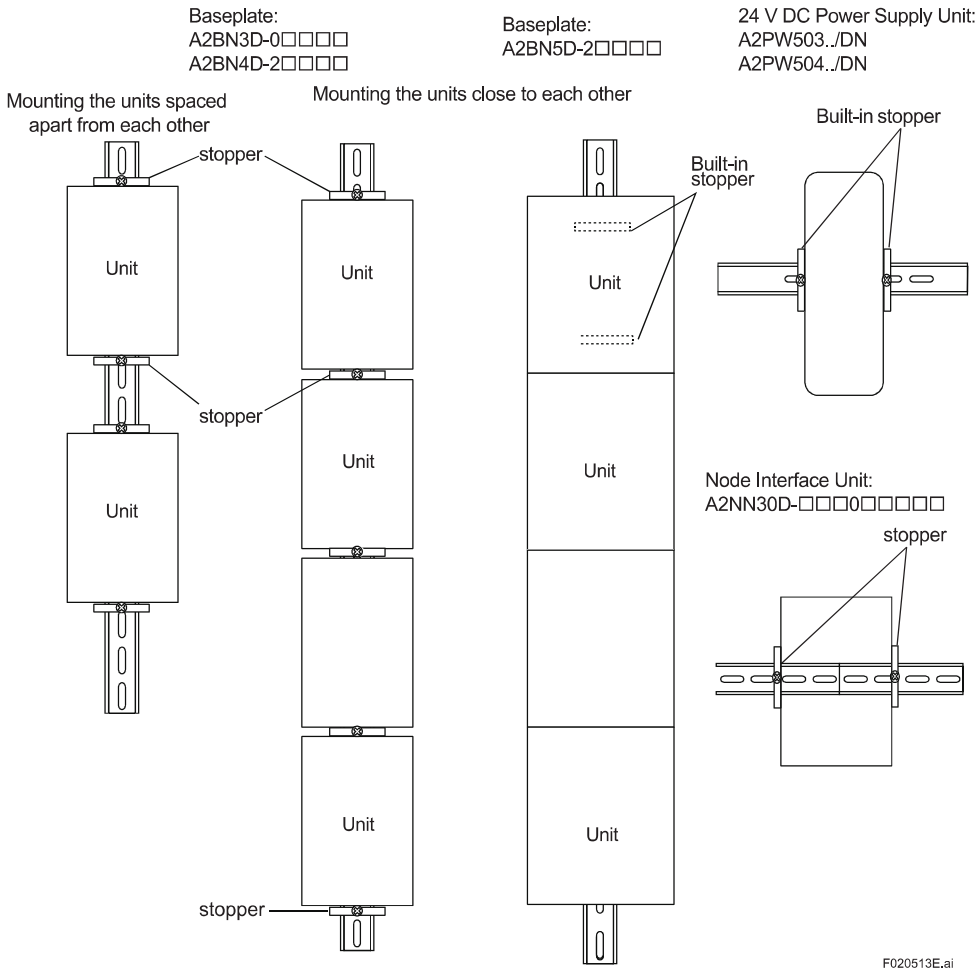

Figure Mounting stopper to the DIN rail

Providing Space for Heat Dissipation

Leave space at the top and bottom of the device to permit heat dissipation.

- Separate the top of the instrumentation board at least 100 mm away from the ceiling, and cut a ventilation hole of 200 cm^2 or larger in the ceiling or install a ventilation fan.
- Do not block the openings (ventilation holes) in the top and bottom surfaces of the device.
- A 1-unit (44.45 mm) or more space shall be provided between the Node Interface Unit and other base plates.

Providing Area for Servicing

Leave an area for servicing.

- All the work to connect cables to DIN rail mountable devices and I/O modules will be performed from the front.
- The work to confirm indicator lamps, configure card settings, and remove/insert cards will be performed from the front.
- The front is the area for wiring and servicing. Leave at least 1000 mm of space at the front.

Compatible DIN Rail

Table Compatible DIN Rail Symbols (DIN 60715, JIS C 2812, IEC 60715, EN50022)

Cross section shapeType symbol	Width - height symbols	Material (chemical symbol)
TH	35-7.5	Fe or Al

Installation of DIN Rail

- Install a DIN rail in a metal mounting plate with screws at 120-mm or less intervals.
- When mounting a DIN rail mountable device to a DIN rail, confirm that the device is securely fixed after the mounting.
- Be sure to bring a DIN rail into contact with a mounting plate in order that the heat generated from the DIN rail mountable device can be radiated to the mounting plate via the DIN rail.

Grounding

Be sure to ground the equipment using the functional grounding terminal of the base plate. Even if there is electrical conduction between the base plate and wall surface via the mounting mechanism, the equipment must be grounded using the functional grounding terminal.

Installation Orientation for base plate, node interface unit, and power unit

Mount the device to the DIN rail in the vertically correct orientation. Check the installation orientation in General Specifications (GS).

Installation Orientation for terminal board

Mount a terminal board in the orientations as shown in the below figure. Refer to the General Specifications (GS) for the external dimensions.

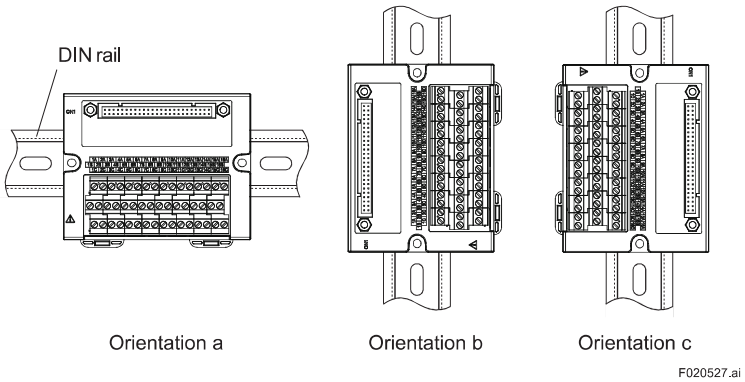

Figure Installation Orientation for terminal board

Remarks for Mounting on a DIN Rail

On the back of DIN rail mountable terminal board, there are two bumps (projections) for fixing screws on the wall. Be sure not to let mechanical interference happen between these bumps and screw tops from the DIN rail. The height of the shaded areas in the below figures must be kept as 2.5 mm or shorter than the DIN rail surface.

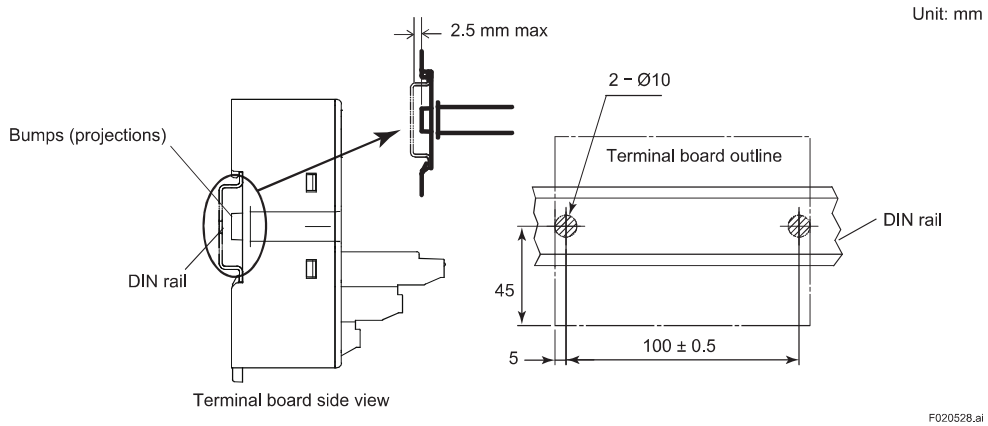

Figure Remarks for Mounting on a DIN Rail

2.5.5 Wall Mountable Devices

The following devices can be mounted to a wall with screws.

Node interface unit:	A2NN10D, A2NN30D-□□□□1□□□□
Adaptor base plate	A2BN3D-1□□□□
Barrier base plate:	A2BN4D-2□□□□
	A2BN5D-2□□□□
Terminal board:	A2BM4

IMPORTANT

Install a wall mountable device inside a metal cabinet.
Installation inside a metal cabinet with a lock is required to comply with standards; in particular, safety standards and EMC conformity standards.

Notes on Installation

Providing Space for Mounting

A2BN4D need to be slide when this is mounted to a wall. For this reason, provide a space shown in the following figure. Refer to the General Specifications (GS 33J62F40-01EN) for the external dimensions.

Unit: A2BN4D-1□□□□

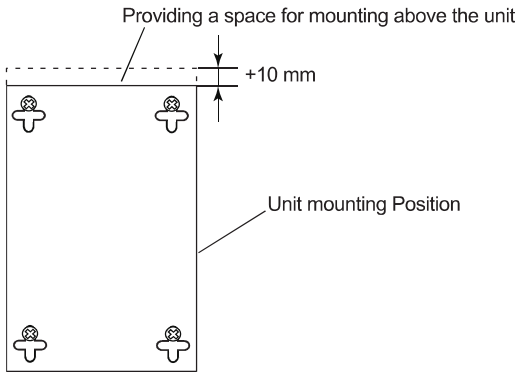

Figure Providing a Space for Mounting (Front View)

Providing Space for Heat Dissipation

Leave space to permit heat dissipation just as for a DIN rail mountable device.

Providing Area for Servicing

Leave an area for servicing just as for a DIN rail mountable device.

Gounding

Be sure to ground the equipment using the functional grounding terminal provided on the base plate.

Mounting of Base plate

- Mount a wall mountable device to a metal mounting plate using screws.
- Be sure to bring a device into contact with a mounting plate in order that the heat generated from the device can be radiated to the mounting plate.

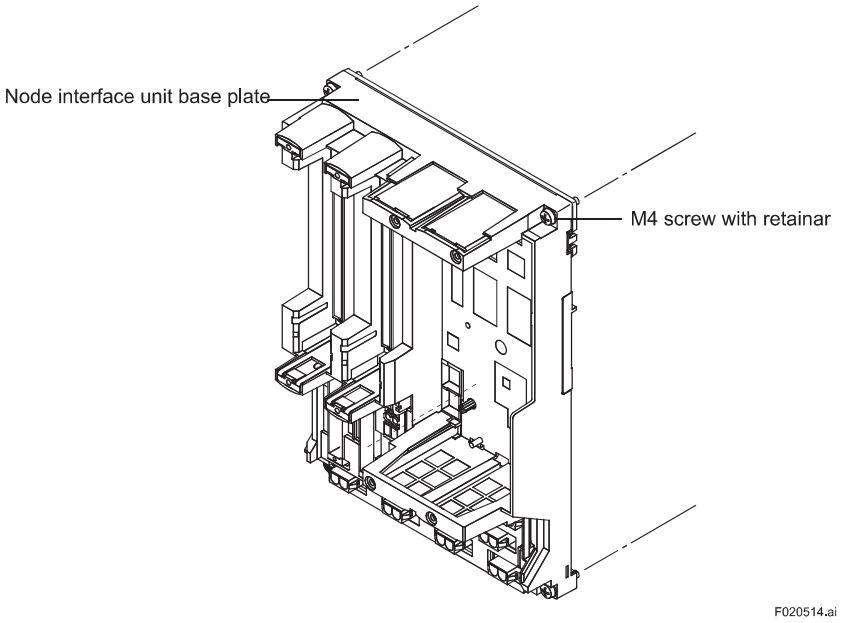

Figure Example of Mounting Node Interface Unit to Wall

Table Tighening Torque for Wall Mountable Devices

Model	Torque (N·m)
A2NN30D	0.8~1.0
A2BN3D	0.8~1.0
A2BN4D	1.2
A2BN5D	1.2

Remarks for Mounting terminal board on a Wall Surface

The following figure shows the screw installation dimensions for a wall mountable terminal board. Installation screws for the terminal board are not supplied and should be purchased separately. You need two installation screws. If you are using binding heads, use M4 screws with a length of at least 10 mm. If you are using screws with washers, use M4 screws with a length of at least 12 mm. The screw tightening torque is approximately 0.8 N·m.

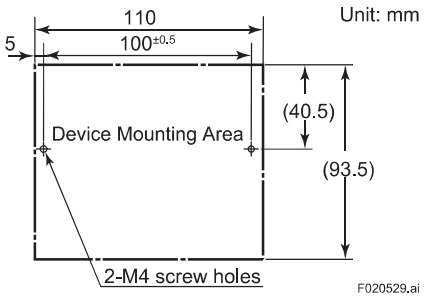

Figure Screw Installation Dimensions for A2BM4

SEE ALSO For the screw mounting dimensions for wall mounting, refer to the General Specifications (GS) for the corresponding device.

Grounding

Ground the equipment using the functional grounding terminal provided on the base plate. Even if there is electrical conduction between the base plate and wall surface via the mounting screws, the equipment must be grounded using the functional grounding terminal.

Insulation from a wall (Node Interface Unit A2NN10D)

To prevent noise from coming into the device through the wall, attach insulating bushings to the brackets on the 19-inch rack mountable node interface unit so that the unit does not directly touch the wall. Insulating bushings are supplied as accessories.

Installation Orientation

Mount the device to the DIN rail with the screws in the vertically correct orientation. Check the installation orientation in General Specifications (GS).

2.5.6 Example of Mounting to General Purpose Cabinet / Junction Box

This section describes examples of the maximum number of devices mounted in a general-purpose cabinet or a junction box. When mounting more devices than the number shown in the examples, or when changing the conditions explained later, please carry out thermal design for each device, and make sure it meets the temperature specifications for each device.

Cabinet for FIO System

Mounting to Cabinet Using ACUKT1, A2CUKT4

The following describes how to mount the field control unit and node units to a Rettal TS8 cabinet using the Cabinet Utility Kit (ACUKT1, A2CUKT4).

Cabinet Specification

Cabinet Utility Kit (ACUKT1) can be used for mounting to a Rettal TS8 cabinet with the dimensions of 800 mm (W) x 800 mm (D) x 2,000 mm (+100 mm) (*1) (H).

*1: 100 mm is the height of the channel base.

Operating Temperature

- The ambient temperature of the cabinet should be 50°C or less.
- The field control unit and node units should meet the temperature range specified in the General Specifications (GS).

Mounting Conditions

- Maximum number of mounted units
  Field Control Unit (for FIO):
  One unit can be mounted either at the front or rear of the cabinet (max. one unit).

  Node unit:
  Up to 7 units can be mounted each at the front and rear of the cabinet. However, up to 6 units can be mounted on the side where the field control unit is mounted.
- Use the door fan that is included in ACUKT1, A2CUKT4.
- Do not mount a heat dissipating device (e.g., power supply) in the cabinet, with the exception of the field control unit and node units.
- Provide space for one unit between the higher-level node fan unit and the node unit beneath it.
- Mount the appropriate number of node fan units in accordance with the number of units mounted. For details, refer to GS 33J60K20-01EN.

IMPORTANT

The restrictions on the I/O modules installed in the FIO node units are described in the document of “FIO System Overview” (GS 33J60F10-01EN).

Mounting Position of Devices

- Field Control Unit (for FIO with HKU I/F): Location 38 to 42
- Node Unit : Location 4 to 34

Mounting Position of cabinet Utility Kit (ACUKT1, A2CUKT4)

- Node fan Unit (ANFAN): Location 34, 36
- PDB: Location 1 to 3
- Door fan unit (ADFAN): To the door
- Power Supply Bus Unit, Vertical type (AEPV7D)

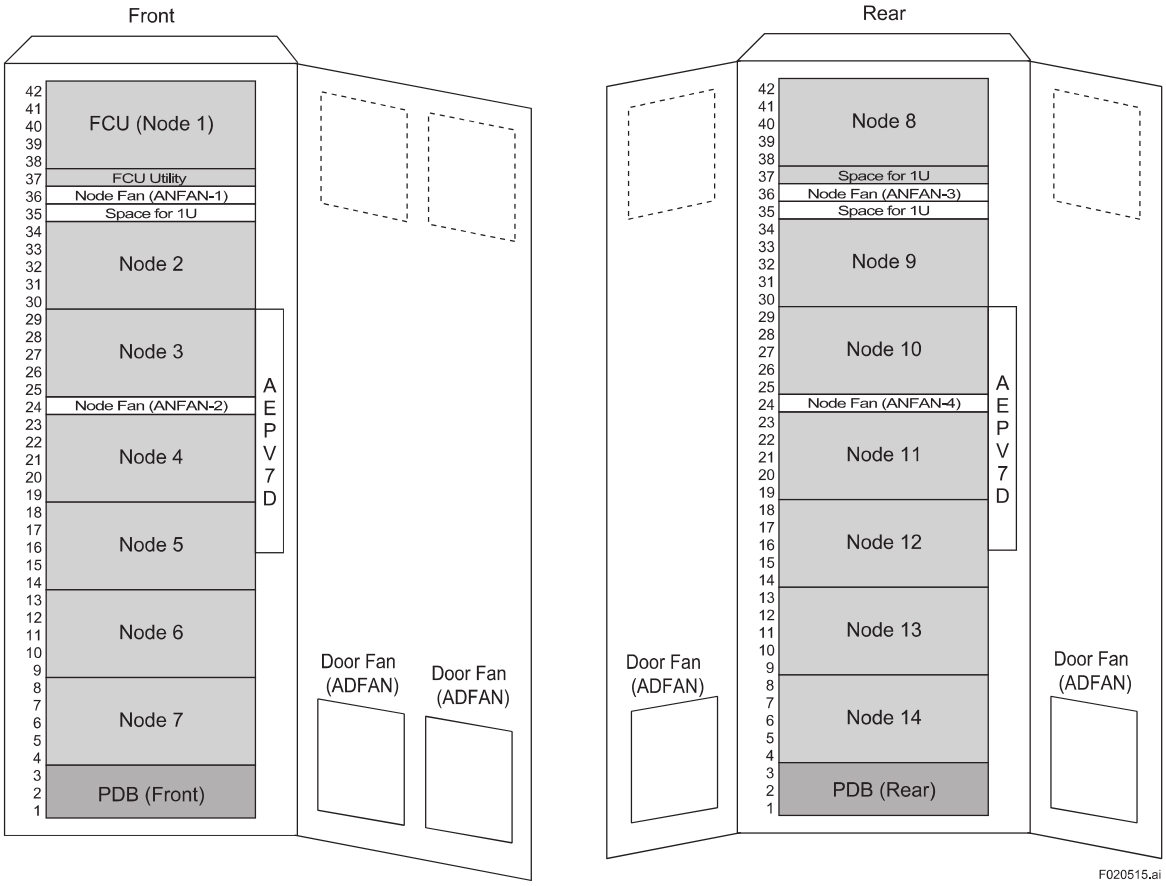

Figure Example of Closely-installed FIO Node Units (A single door is mounted at the front, A double door is mounted at the rear)

Mounting of Door Fan

Mount the door fan unit using the chassis of Rittal's standard door fan unit.

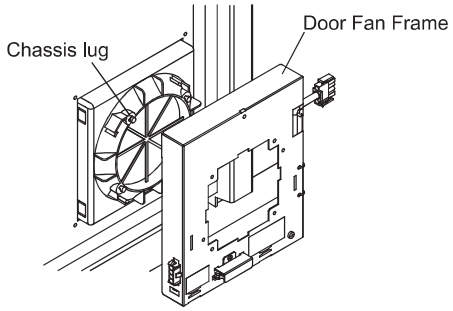

Figure Mounting of Door Fan frame

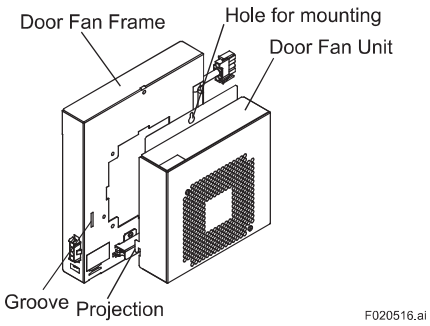

Figure Mounting of Door Fan Unit

Mounting to General Purpose Cabinet without ACUKT1, A2CUKT4

The following describes how to mount the field control unit and node units to a Rittal or other general purpose cabinet without using the Cabinet Utility Kit (ACUKT1, A2CUKT4).

Cabinet Specification Example

- Cabinet dimensions: 800 mm (W) x 800 mm (D) x 2,000 mm (+100 mm) (*1) (H).

  *1: 100 mm is the height of the channel base.
- Door fans must be mounted on both front- and rear-door panels. (Both fans' air flow rate should be equal or greater than 230 m^3/h.)

Temperature Condition

The ambient cabinet outside a cabinet must be below 40 degree Celsius.

The ambient temperature inside a cabinet where the Field Control Unit and the FIO Node Units are installed must satisfy the conditions specified in GS (General Specification)documents of the Field Control Unit and the FIO Node Units.

Installation Condition

- Maximum Number of Devices
  Field Control Unit: One each can be installed in front part and rear part of a cabinet.
  Node Unit: Four each can be installed in front part and rear part of a cabinet.

  If Field Control Unit is not installed in the part of the cabinet, up to five FIO node units can be installed.
- Any heat generating device other than Field Control Unit and FIO node unit (such as a power supply) should not be installed in the cabinet.
- A three unit mounting space (one unit mounting space equals to 44.45 mm) should be kept between the highest position of the mounting frame and the highest Field Control Unit or FIO node unit in the cabinet.
- One unit mounting space (one unit mounting space equals to 44.45 mm) should be kept between an Field Control Unit and an FIO node unit.
- Up to two FIO node units can be installed close to each other in the same cabinet.

If three FIO node units need to be installed close to each other, a circulation fan unit (with 300 m^3/h or more airflow capability) should be placed at the top of the three FIO node units.

IMPORTANT

The restrictions on the I/O modules installed in the FIO node units are described in the document of "FIO System Overview" (GS 33J60A10-01EN).

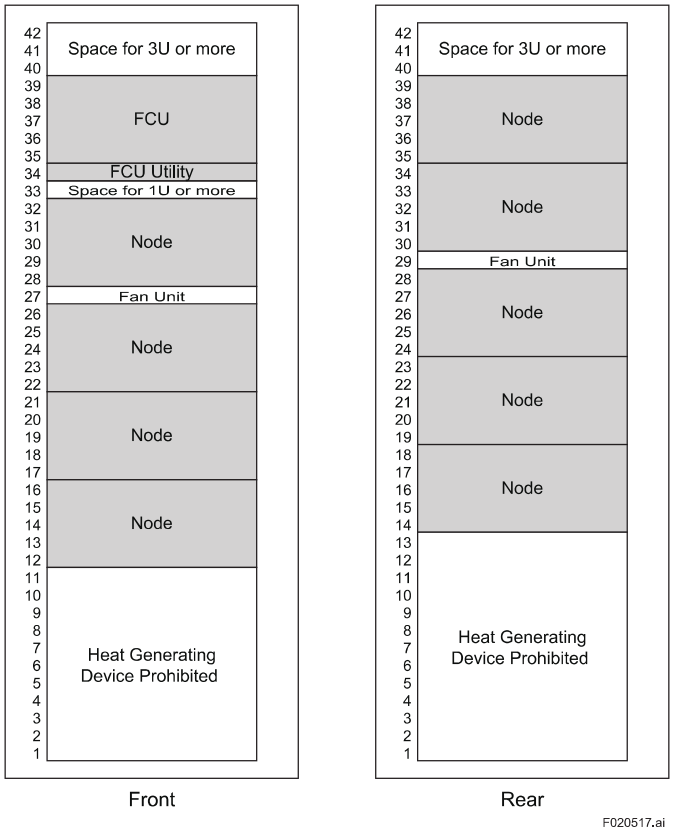

Figure Mounting Example Using General Purpose Cabinet (Without Using ACUKT1, A2CUKT4)

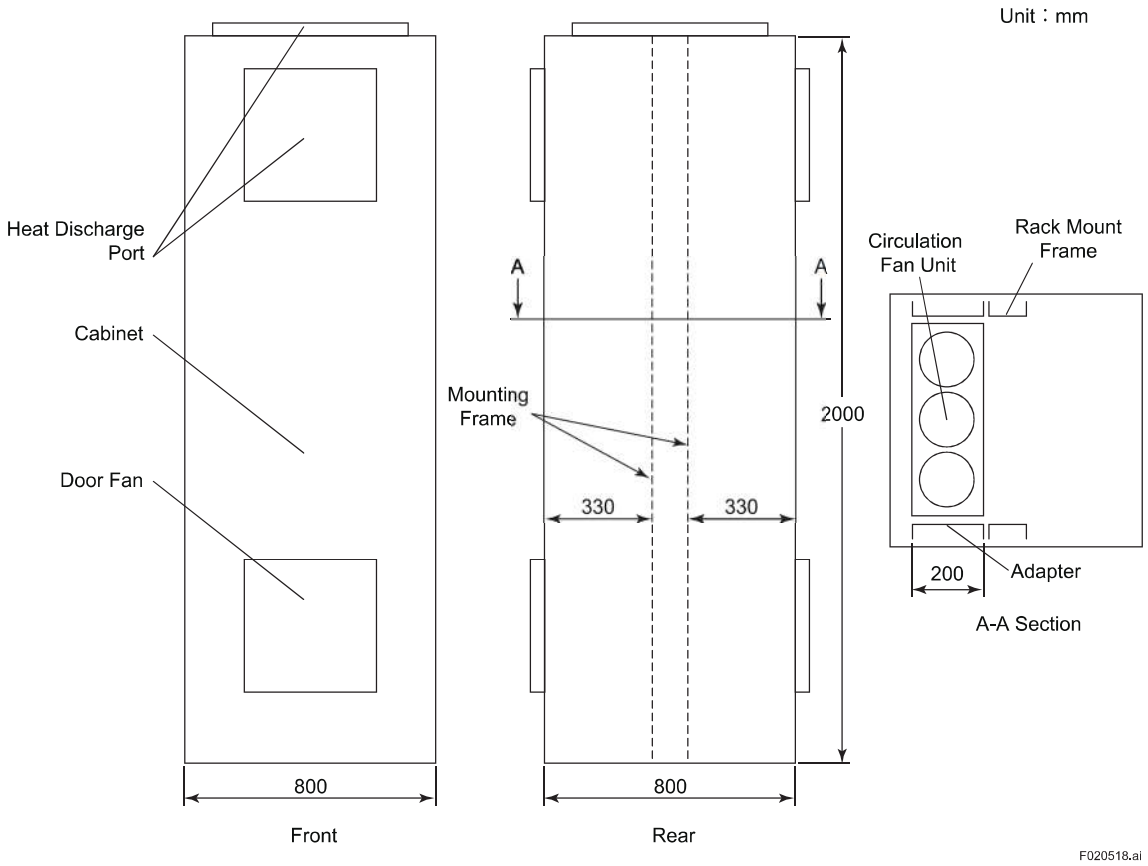

Figure An Example of Installation in Rittal Cabinet

Cabinet for N-IO System

This section describes examples of the maximum number of N-IO system equipment (except for equipment for RIO System Upgrade) installed in general-purpose cabinets.

The following shows the common specifications to the examples of cabinets for N-IO system that are explained later.

Cabinet Specifications

The following cabinet is assumed to be used.

Table Cabinet Dimensions

W	D	H	Product example
800 mm	800 mm	2000 mm (+100 mm) (*1)	Rittal TS8808 series

*1: 100 mm is the height of the channel base.

Table Specifications of a cabinet ambient temperature and an air supply / air exhaust port (In case N-IO FCU is included in a cabinet.)

Cabinet ambient temperature	Air supply port	Air flow	Area of an air supply/ air exhaust port (Panel cut of a cabinet)	Product example	Remarks
40 ºC or less	Fan	Door fan 230 m^3/h or more Circulation fan 230 m^3/h or more	Air supply port 60000 mm^2 or more Air exhaust port 60000 mm^2 or more	Rittal SK3239 series (Fan)	• Be sure to mount two push-fit door fans on each side in case of a failure. • The air flow and the area in the left show the total value on each side.

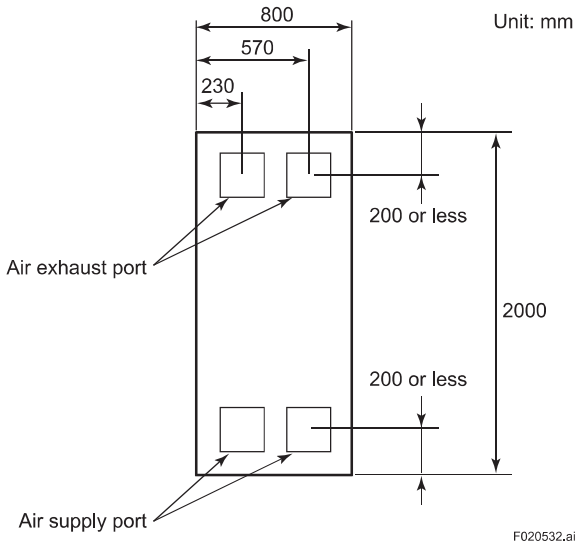
Table Specifications of a cabinet ambient temperature and an air supply / air exhaust port (In case only N-IO nodes (Non-Intrinsic Safety Barrier) are included in a cabinet.)

Cabinet ambient temperature	Air supply port	Air flow	Area of an air supply/ air exhaust port (Panel cut of a cabinet)	Product example	Remarks
50 ºC or less	Fan	Door fan 40 m^3/h or more	Air supply port 16000 mm^2 or more Air exhaust port 60000 mm^2 or more	Rittal SK3237 series (Fan)	• It is recommended to mount two push-fit door fans on each side in case of a failure. • The air flow and the area in the left show the total value on each side.
40 ºC or less	Outlet filter	— (*1)	Air supply port 60000 mm^2 or more Air exhaust port 60000 mm^2 or more	Rittal SK3239.200 (Outlet filter)	• Be sure to mount two outlet filters on each side in case of a failure such as filter clogging.

*1: When not mounting a fan, be sure to secure a ventilation path in the cabinet.

Table Specifications of a cabinet ambient temperature and an air supply / air exhaust port (In case only N-IO nodes (Intrinsic Safety Barrier) are included in a cabinet.)

Cabinet ambient temperature	Air supply port	Air flow	Area of an air supply/ air exhaust port (Panel cut of a cabinet)	Product example	Remarks
50 °C or less	Fan	Door fan 230 m^3/h or more	Air supply port 60000 mm^2 or more Air exhaust port 60000 mm^2 or more	Rittal SK3239 series (Fan)	• Be sure to mount two or more push-fit door fans on each side in case of a failure. • The air flow and the area in the left show the total value on each side.



Notes

The following shows the common notes to the examples.

- The ventilation for each system shall not be blocked.
- The mounting plate for mounting the IOBP and IOBP_IS shall be made of metal, regardless of whether DIN rail or panel mounting.
- A DIN rail shall be made of metal.
- For mounting restrictions other than the above, refer to the General Specifications (GS).

Position of an air supply / air exhaust port

In this mounting example, arrange an air supply / air exhaust port as follows.

Note: This is the dimension from the end face of the cabinet. (Not the dimension from the end face of the cabinet door.)

Figure Position of an air supply/ air exhaust port

Conventions

The following shows the common abbreviations used and their explanations.

Abbreviations	Explanations
FCU	Field Control Unit
NIU	Node Interface Unit (for N-IO)
IOBP	I/O Base Plate
IOBP_IS	I/O Base Plate for Intrinsic Safety explosion protection
NIO node	Consists of NIU and IOBP/IOBP_IS.
Unit	Unit of 19 inch rack. 1 Unit = 44.45 mm
Side	One of the front and the back of a cabinet. (e.g., side, one side)

Example of Mounting Multiple FCUs for N-IO in a Cabinet

Temperature conditions

In this example, the ambient temperature is assumed to be the following.

Cabinet ambient temperature	40 °C or less

Maximum numbers of units that can be mounted

Type	Model	Number of units that can be mounted per side
FCU	A2FV50D A2FV50S A2BE1D	Up to 4

Heat-generating devices other than the above shall not be mounted in the cabinet.

Mounting conditions

- FCU shall be mounted with a 3-unit or more space from the top-shelf mounting position of the cabinet.
- A 2-unit or more space shall be provided between the circulation fan unit and the FCU on the bottom shelf.
- Devices that block the convective air flow from the circulation fan unit or door fans to each module shall not be mounted.

The following shows how to mount multiple FCUs for N-IO in a cabinet:

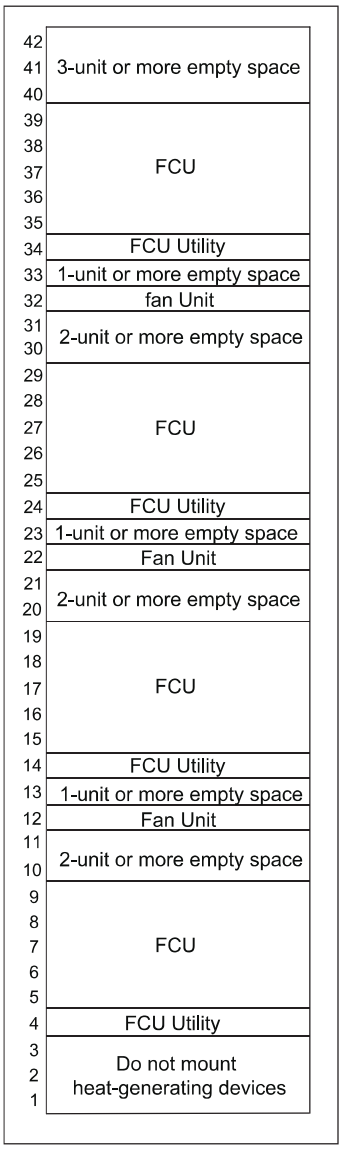


Figure Example of Mounting Multiple FCUs for N-IO in a Cabinet

Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet

Temperature conditions

In this example, the ambient temperature is assumed to be the following.

Cabinet ambient temperature	40 °C or less

Maximum numbers of units that can be mounted in case of this example

Type	Model	Number of units that can be mounted per side
FCU	A2FV50D/A2FV50S/ A2BE1D	Up to 1
NIU	A2NN30D	Up to 1
IOBP	A2BN3D	Up to 6 (2 rows × 3 shelves)

Heat-generating devices other than the above shall not be mounted in the cabinet.

Exception to mounting heat-generating devices

Shunt Resistor Unit : A2EXR001 for the Pulse Input Signal Adaptor (A2SAP105) can be mounted in the same cabinet under the following conditions:

- A2EXR001 shall be mounted on the side of the cabinet or under IOBP with a distance of 200 mm from NIU.
- When 5 or more A2EXR001units are mounted on a cabinet, the number of IOBP on the cabinet shall be reduced in accordance with the following table.

Table Example of Number of A2EXR001 Mounted and Mounting Conditions

Number of A2EXR001 mounted	Mounting condition
1 to 4	Can be mounted in the same cabinet
5 to 12	Can be mounted in the same cabinet by reducing one IOBPs
13 to 20	Can be mounted in the same cabinet by reducing two IOBPs

- Further reduce one IOBP on the cabinet per 8 A2EXR001 units when 21 or more A2EXR001 units are mounted on a cabinet.

Mounting conditions

- The FCU on the top shelf shall be mounted with a 100-mm or more space from the cabinet ceiling.
- A 1-unit (=44.45 mm) or more space shall be provided between NIU and IOBP.
- A circulation fan unit shall be mounted on the shelf below the FCU with a 1-unit space. A 1-unit or more space shall be provided under the circulation fan unit.
- Suitable length of signal cables and power cables should be used.

The following shows how to mount an FCU for N-IO and N-IO nodes in a cabinet:

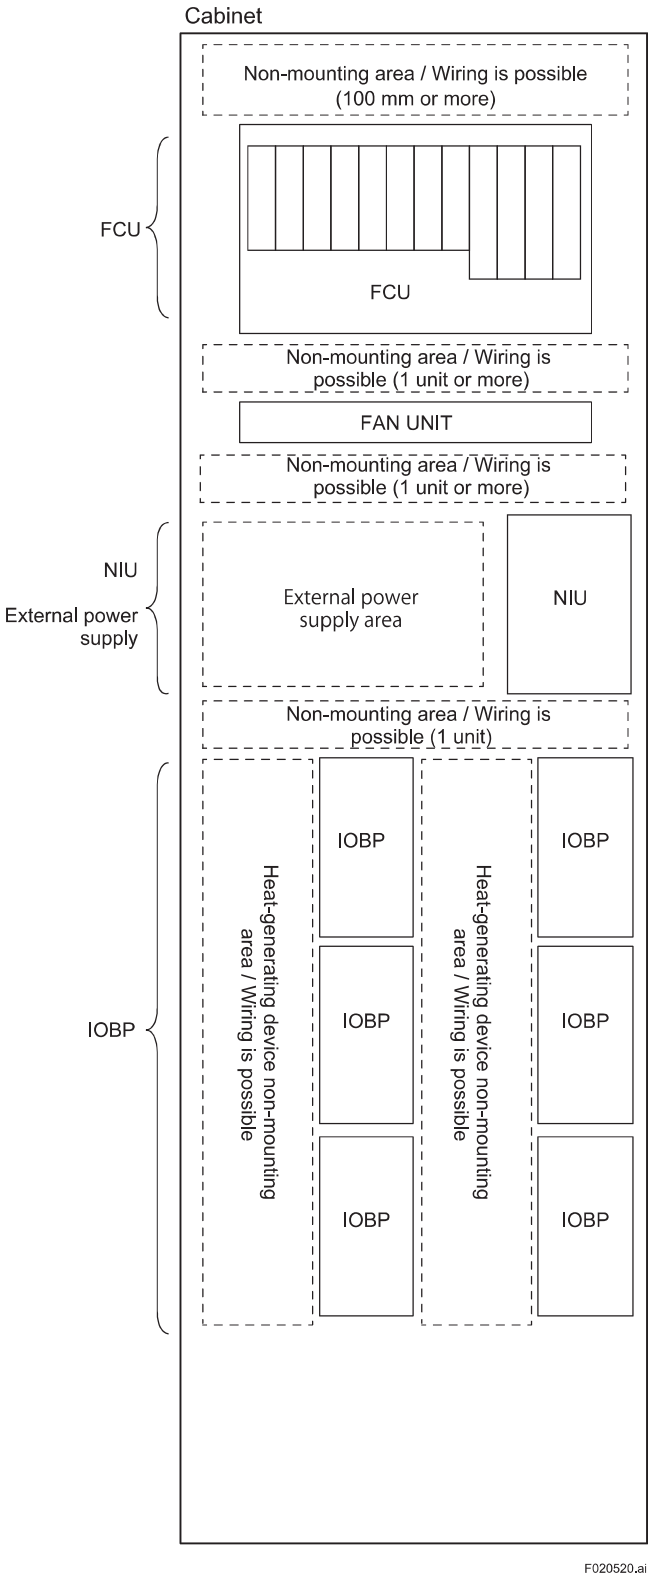

Figure Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet

Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet (For field wiring via terminal board)

Temperature conditions

In this example, the ambient temperature is assumed to be the followings.

Cabinet ambient temperature	40 °C or less

Maximum numbers of units that can be mounted in case of this example

Type	Model	Number of units that can be mounted per side
FCU	A2FV50S/A2FV50D/ A2BE1D	Up to 1
NIU	A2NN30D	Up to 2
IOBP	A2BN3D	Up to 12 (3 rows × 4 shelves)

Heat-generating devices other than the above shall not be mounted in the cabinet.

Mounting conditions

- The FCU on the top shelf shall be mounted with a 100-mm or more space from the cabinet ceiling.
- A 1-unit (= 44.45 mm) or more space shall be provided between NIU and IOBP.
- A circulation fan unit shall be mounted on the shelf below the FCU with a 1-unit space.

  A 1-unit or more space shall be provided under the circulation fan unit.
- Suitable length of signal cables and power cables should be used.

The following shows how to mount an FCU for N-IO and N-IO nodes in a cabinet (IOBP×3 columns mounted).

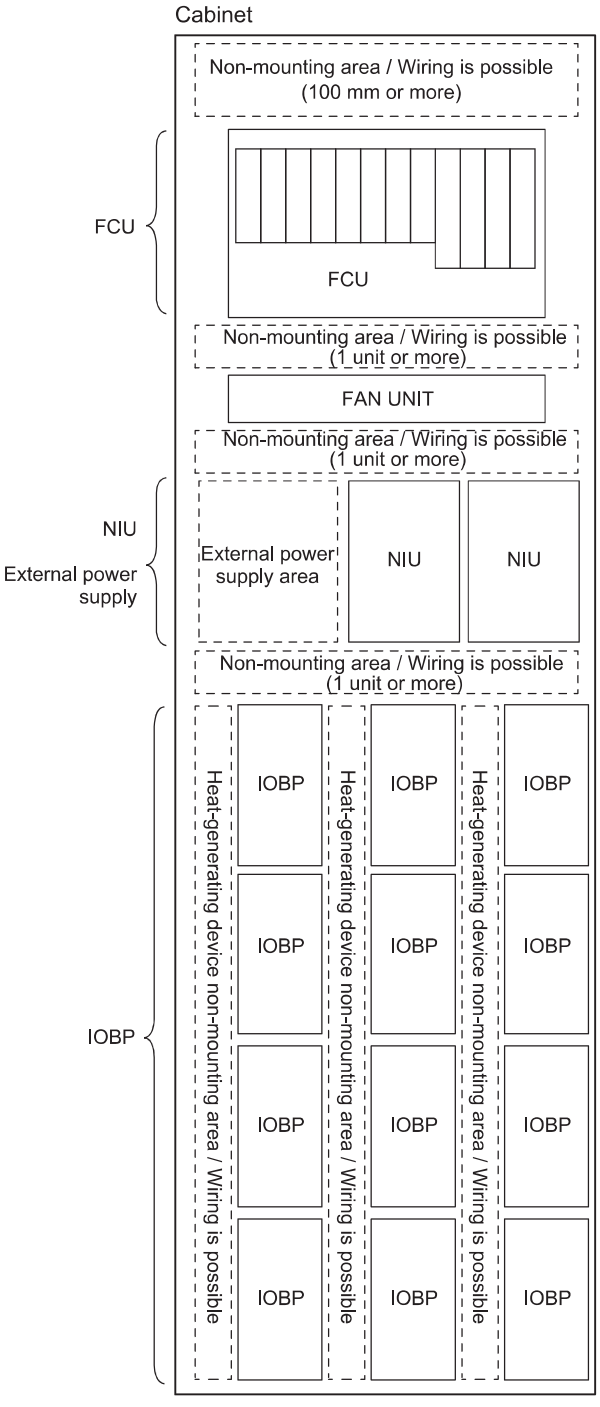

Figure Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet (IOBP×3 columns mounted)

Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Cabinet

Temperature conditions (For direct field wiring to IOBP)

In this example, the ambient temperature is assumed to be the followings.

Cabinet ambient temperature	50 °C or less (*1)

*1: The cabinet ambient temperature is 40 °C or less, when the temperature option (-40 to 70 °C) of NIU and IOBP is not specified.

Maximum numbers of units that can be mounted in case of this example

Type	Model	Number of units that can be mounted per side
NIU	A2NN30D (*1)	Up to 2
IOBP	A2BN3D (*1)	Up to 10 (2 rows × 5 shelves)

*1: Specify the temperature environment option (-40 to 70 °C).

Heat-generating devices other than the above shall not be mounted in the cabinet.

Exception to mounting heat-generating devices

Shunt Resistor Unit: A2EXR001 for the Pulse Input Signal Adaptor (A2SAP105) can be mounted in the same cabinet under the following conditions:

- A2EXR001 shall be mounted on the side of the cabinet or under IOBP with a distance of 200 mm from NIU.
- When 5 or more A2EXR001units are mounted on a cabinet, the number of IOBP on the cabinet shall be reduced in accordance with the following table.

Table Number of Shunt Resistors Mounted and Mounting Conditions

Number of shunt resistors mounted	Mounting condition
1 to 4	Can be mounted in the same cabinet
5 to 12	Can be mounted in the same cabinet by reducing one IOBPs
13 to 20	Can be mounted in the same cabinet by reducing two IOBPs

- Further reduce one IOBP on the cabinet per 8 A2EXR001 units when 21 or more A2EXR001 units are mounted on a cabinet.

Mounting conditions

- The NIU shall be mounted with a 100-mm or more space from the cabinet ceiling.
- A 1-unit (=44.45 mm) or more space shall be provided between NIU and IOBP.
- Suitable length of signal cables and power cables should be used.

The following shows how to mount N-IO nodes (Non-Intrinsic Safety barrier) in a cabinet:

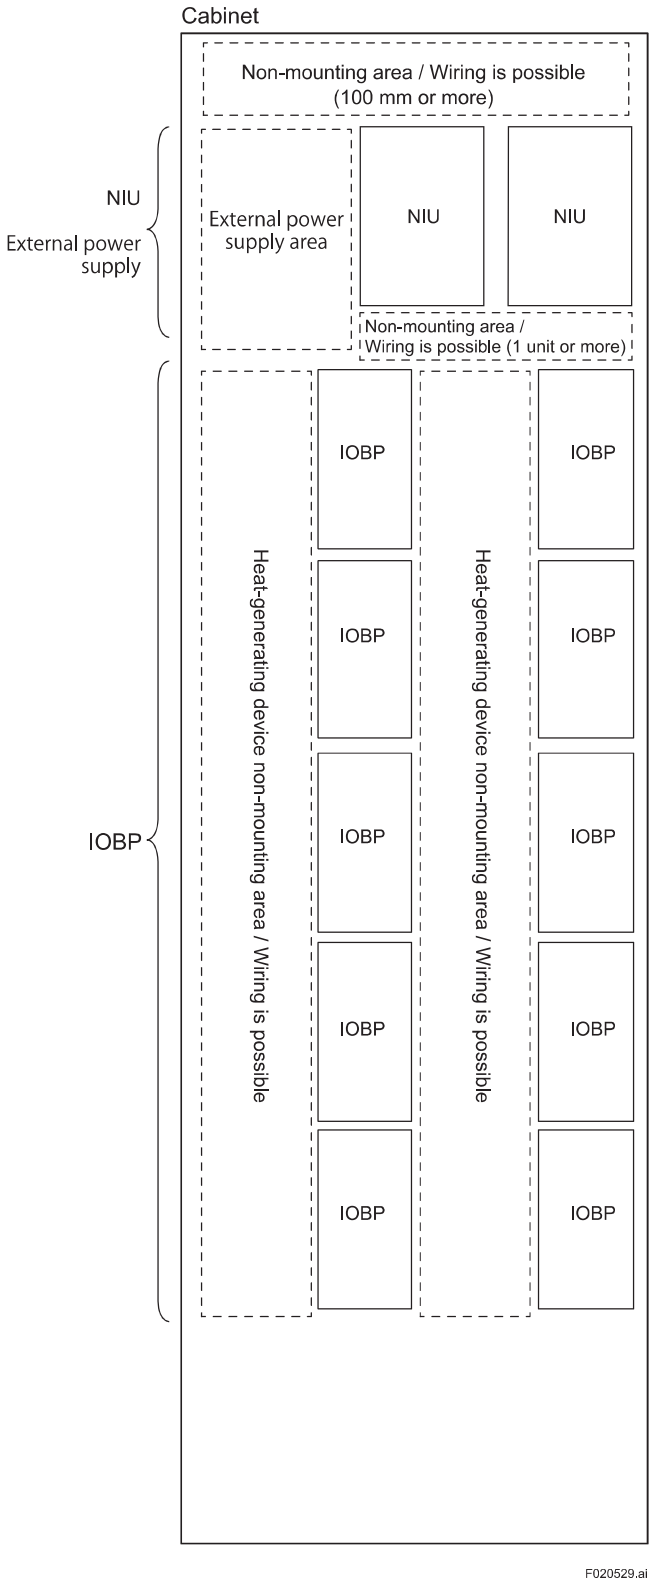

Figure Example of Mounting N-IO Nodes (Non-Intrinsic Safety barrier) in a Cabinet

Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Cabinet (For field wiring via terminal board)

Temperature conditions

In this example, the ambient temperature is assumed to be the followings.

Cabinet ambient temperature	50 °C or less (*1)

*1: The cabinet ambient temperature is 40 °C or less, when the temperature option (-40 to 70 °C) of NIU and IOBP is not specified.

Maximum numbers of units that can be mounted in case of this example

Heat-generating devices other than the above shall not be mounted in the cabinet.

Mounting surface of cabinet	Type	Model	Number of units that can be mounted per side (*2)
Mounting surface of external power supply	NIU	A2NN30D (*1)	Up to 3
	IOBP	A2BN3D (*1)	Up to 15 (3 rows x 5 shelves)
Non-mounting surface of external power supply	NIU	A2NN30D (*1)	Up to 3
	IOBP	A2BN3D (*1)	Up to 18 (3 rows x 6 shelves)

*1: Specify the temperature environment option (-40 to 70 °C).
*2: It is subject to use of wall-mount type IOBP.

Mounting conditions

- The NIU shall be mounted with a 100-mm or more space from the cabinet ceiling.
- A 1-unit (=44.45 mm) or more space shall be provided between NIU and IOBP.
- When using a DIN rail, be sure to install a DIN rail on the mounting plate. Fixing at the both ends of a DIN rail and not fixing at the middle.
- Suitable length of signal cables and power cables should be used.

The following shows how to mount N-IO nodes (Non-Intrinsic Safety barrier) in a cabinet:

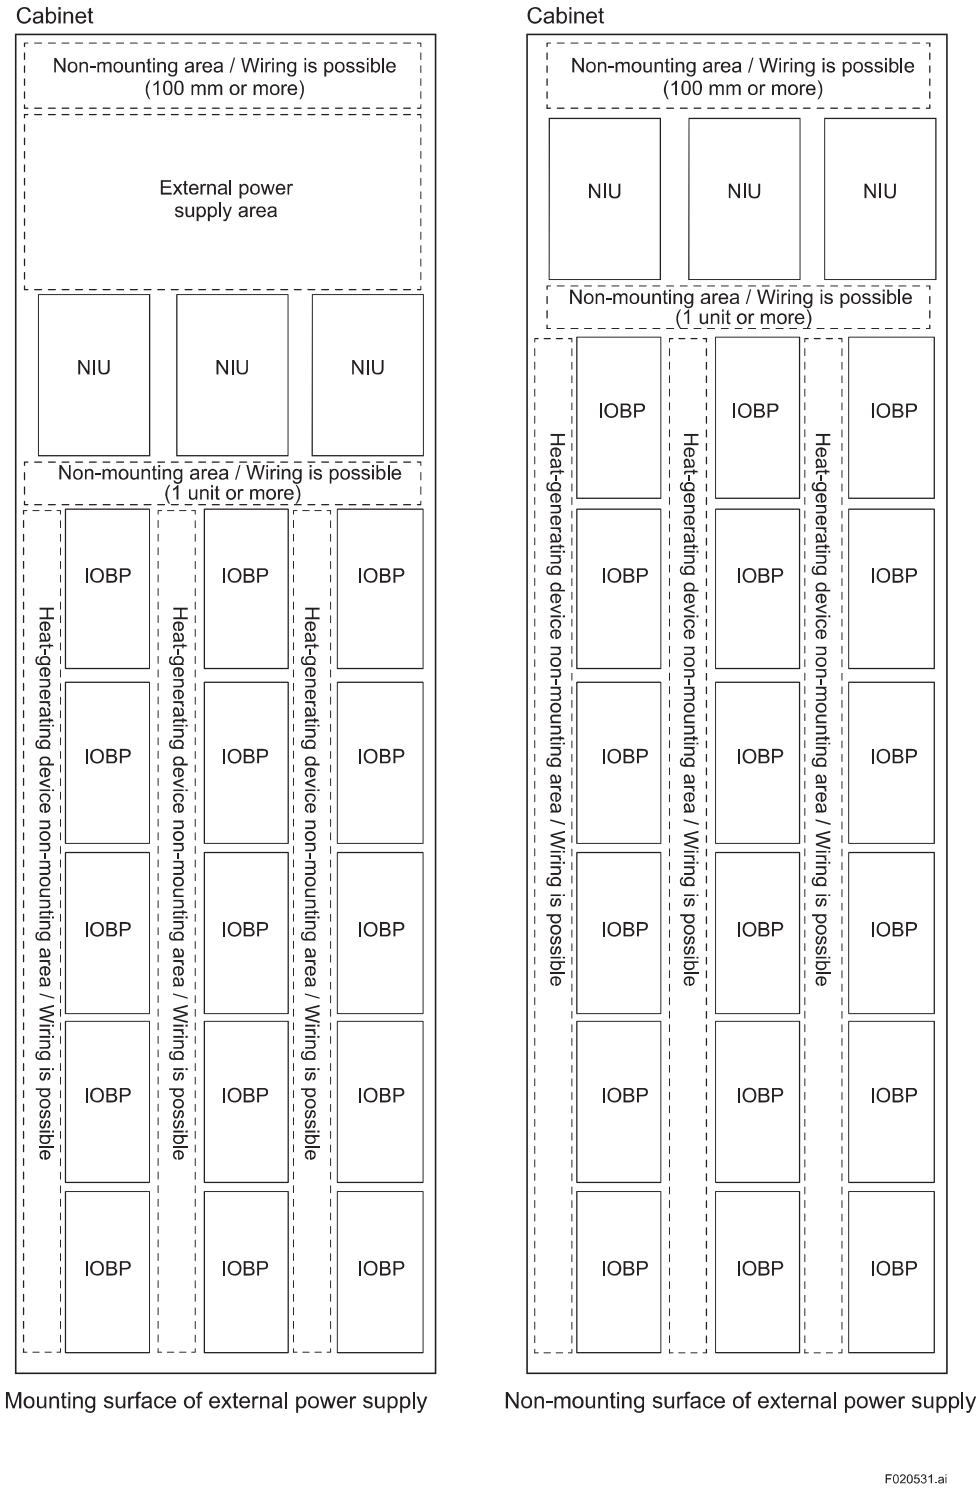

Figure Example of Mounting N-IO Nodes (Non-Intrinsic Safety barrier) in a Cabinet

Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Cabinet

Temperature conditions (For direct field wiring to IOBP)

In this example, the ambient temperature is assumed to be the followings.

Cabinet ambient temperature	50 °C or less

Maximum numbers of units that can be mounted in case of this example

Type	Model	Number of units that can be mounted per side
NIU	A2NN30D (*1)	Up to 2
IOBP_IS	A2BN4D	8 (2 rows × 4 shelves)
	A2BN5D	10 (2 rows × 5 shelves)

*1: Specify the temperature environment option (-40 to 70 °C).

Heat-generating devices other than the above shall not be mounted in the cabinet.

IOBP cannot be mounted.

Mounting conditions

- The NIU shall be mounted with a 100-mm or more space from the cabinet ceiling.
- A 1-unit (=44.45 mm) or more space shall be provided between NIU and IOBP_IS.
- Suitable length of signal cables and power cables should be used.
- Mounting the devices in the cabinet should be in line according to the intrinsic safety standard.

The following shows how to mount N-IO nodes (Intrinsic Safety barrier) in a cabinet:

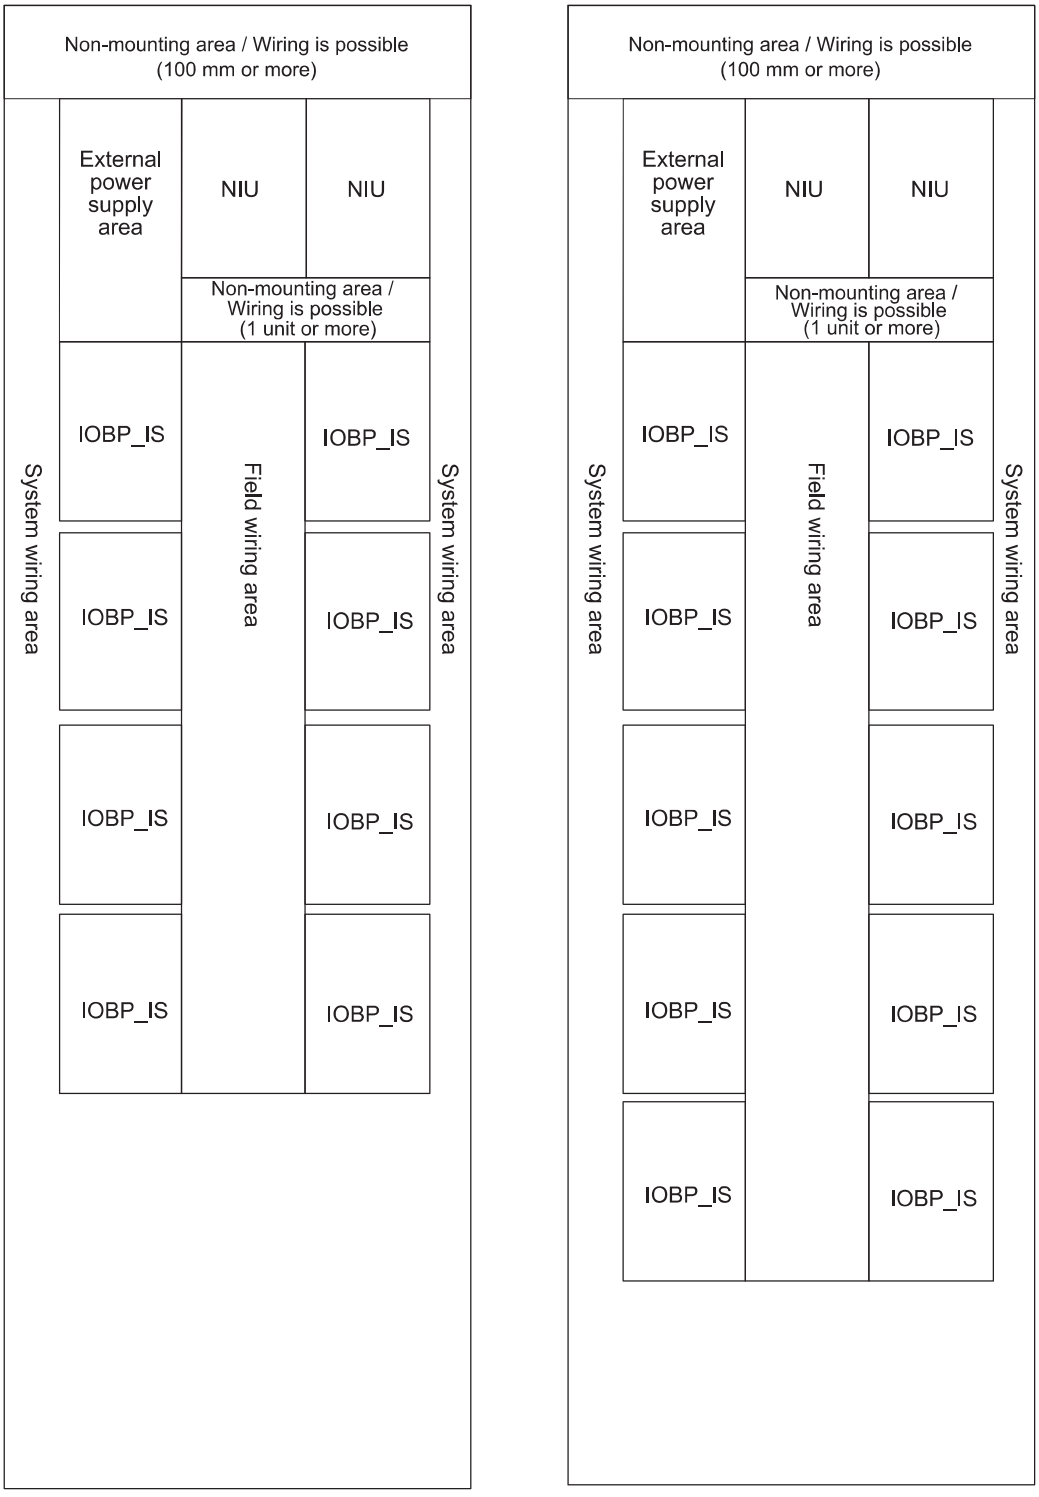

Figure Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Cabinet

Junction Box for N-IO System

This section describes examples of the maximum number of N-IO system equipment (except for equipment for RIO System Upgrade) installed in general-purpose junction boxes.

The following shows the common specifications to the examples of junction boxes for N-IO system that are explained later.

Junction Box Specifications

The following junction box is assumed to be used.

Table Junction Box Dimensions

W	D	H
800 mm	300 mm	1000 mm

Product examples

Table Product examples

	Manufacturer	Model
Junction Box	Rittal	1180 series

Notes

The following shows the common notes to the examples.

- The ventilation for each system shall not be blocked.
- The mounting plate for mounting the IOBP and IOBP_IS shall be made of metal, regardless of whether DIN rail or panel mounting.
- A DIN rail shall be made of metal.
- For mounting restrictions other than the above, refer to the General Specifications (GS).

Conventions

The following shows the common abbreviations used and their explanations.

Abbreviations	Explanations
NIU	Node Interface Unit or Base Plate for Node Interface Unit
IOBP	Base Plate
IOBP_IS	Base Plate Intrinsic Safety explosion protection
Unit	Unit of 19 inch rack. 1 Unit = 44.45 mm

Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Junction Box

Temperature conditions

In this example, the ambient temperature is assumed to be the followings.

Junction Box ambient temperature	50 °C or less

Maximum numbers of units that can be mounted

	Type	Model	Number of units that can be mounted per side
Per junction box	NIU	A2NN30D (*1)	Up to 1
	IOBP	A2BN3D (*1)	Up to 4 (2 rows × 2 shelves)
	Other	Heat-generating device (*2)	heat generation: 40 W or less

*1: Specify the temperature environment option (-40 to 70 °C).
*2: The device to be mounted shall be selected from those that have the ambient temperature range of +15 °C or more.

Heat-generating devices other than the above shall not be mounted in the junction box.

In this example, IOBP_IS cannot be mounted.

Mounting conditions

- Do not mount the IOBP so that its heat-generating part (adaptor or I/O) is located immediately under the N-ESB Bus module (A2EN501). The IOBP may be mounted immediately under the power supply of the NIU (A2PW50x).
- The NIU shall be mounted with a 2-unit or more space from the ceiling of the junction box.
- A 1-unit or more space shall be provided between the NIU and IOBP.
- To mount heat-generating devices other than NIU and IOBP shall be mounted with 30-mm intervals on the right of the NIU on the top shelf. The specifications of the devices shall be observed.

The following shows how to mount N-IO nodes (Non-Intrinsic Safety barrier) in a junction box:

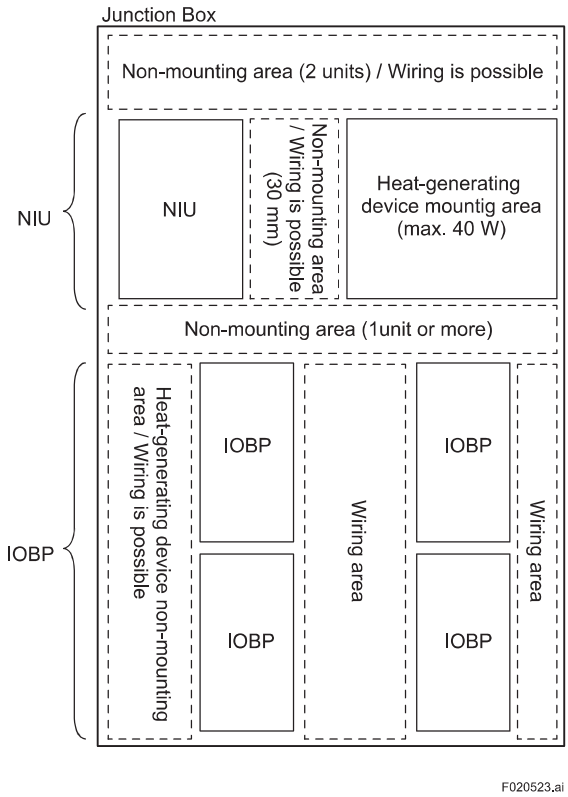

Figure Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Junction Box

Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Junction Box

Temperature conditions

In this example, the ambient temperature is assumed to be the following.

Junction Box ambient temperature	50 °C or less

Maximum numbers of units that can be mounted

	Type	Model	Number of units that can be mounted per side
Per junction box	NIU	A2NN30D (*1)	Up to 1
	IOBP_IS	A2BN4D or A2BN5D	Up to 2 (2 rows × 1 shelf)
	Other	Heat-generating device (*2)	heat generation: 20 W or less

*1: Specify the temperature environment option (-40 to 70 °C).
*2: The device to be mounted shall be selected from those that have the ambient temperature range of +15 °C or more.

Heat-generating devices other than the above shall not be mounted in the junction box.
In this example, IOBP cannot be mounted.

Mounting conditions

- Do not mount the IOBP_IS so that its heat-generating part (Barrier or I/O) is located immediately under the N-ESB Bus module (A2EN501). The IOBP_IS may be mounted immediately under the power supply of the NIU (A2PW50x).
- The NIU shall be mounted with a 2-unit or more space from the ceiling of the junction box.
- A 1-unit or more space shall be provided between the NIU and IOBP_IS.
- To mount heat-generating devices other than NIU and IOBP_IS shall be mounted with 30-mm intervals on the right of the NIU on the top shelf. The specifications of the devices shall be observed.

The following shows how to mount N-IO nodes (Intrinsic Safety barrier) in a junction box:

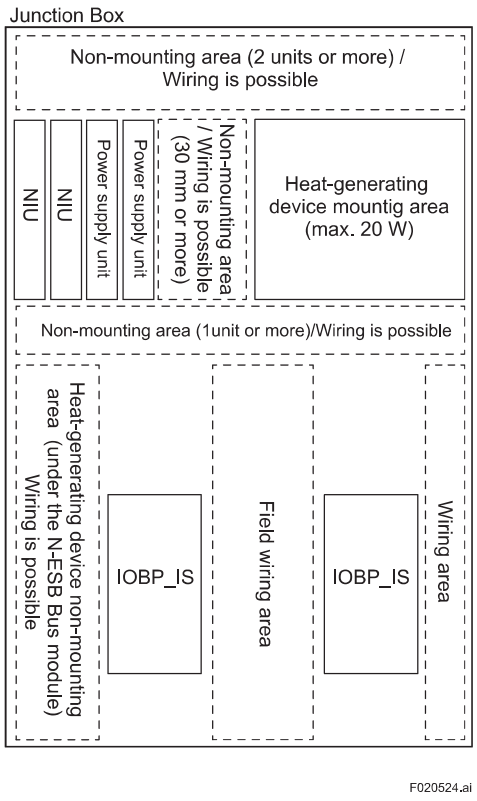

Figure Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Junction Box

CAUTION

The wiring that will be intrinsic safety circuits must be installed so that they are electrically separated from the wiring of non-intrinsic safety circuits, including the in-cabinet wiring. Install the wiring according to the IEC 60079-14 standards or the requirements for explosion-proof wiring of the country where the system is used.

Example of Mounting N-IO Nodes (Mixture of Intrinsic Safety Barrier and Non-Intrinsic Safety Barrier) in a Junction Box

Temperature conditions

In this example, the ambient temperature is assumed to be the following.

Junction Box ambient temperature	50 °C or less

Maximum numbers of units that can be mounted

	Type	Model	Number of units that can be mounted per side
Per junction box	NIU	A2NN30D (*1)	Up to 1
	IOBP	A2BN3D (*1)	Up to 2 (1 row × 2 shelves)
	IOBP_IS	A2BN4D or A2BN5D	Up to 1 (1 row × 1 shelf)
	Other	Heat-generating device (*2)	heat generation: 20 W or less

*1: Specify the temperature environment option (40 to 70 °C).
*2: The device to be mounted shall be selected from those that have the ambient temperature range of +15 °C or more.

Heat-generating devices other than the above shall not be mounted in the junction box.

Mounting conditions

- Do not mount the IOBP/IOBP_IS so that its heat-generating part (Barrier or I/O) is located immediately under the N-ESB Bus module (A2EN501). The IOBP/IOBP_IS may be mounted immediately under the power supply of the NIU (A2PW50x).
- The NIU shall be mounted with a 2-unit or more space from the ceiling of the junction box.
- A 1-unit or more space shall be provided between the NIU and IOBP/IOBP_IS.
- To mount heat-generating devices other than NIU and IOBP/IOBP_IS shall be mounted with 30-mm intervals on the right of the NIU on the top shelf. The specifications of the devices shall be observed.

The following shows how to mount N-IO nodes (mixture of Intrinsic Safety barrier and Non-Intrinsic Safety barrier) in a junction box:

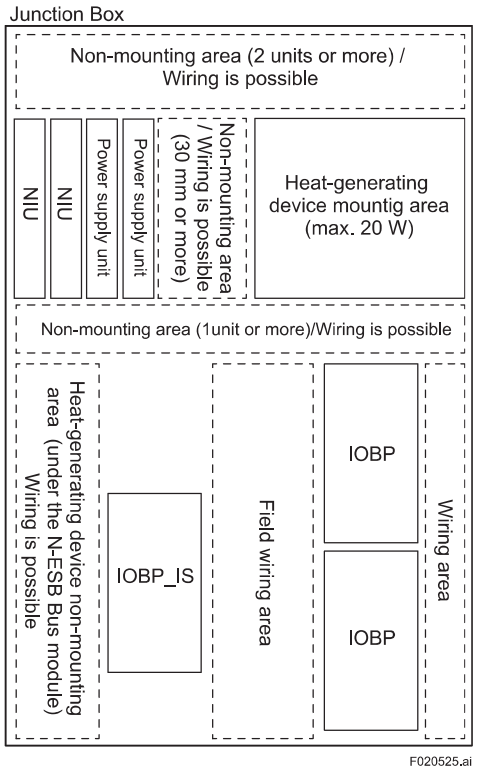

Figure Example of Mounting N-IO Nodes (Mixture of Intrinsic Safety Barrier and Non-Intrinsic Safety Barrier) in a Junction Box

CAUTION

The wiring that will be intrinsic safety circuits must be installed so that they are electrically separated from the wiring of non-intrinsic safety circuits, including the in-cabinet wiring. Install the wiring according to the IEC 60079-14 standards or the requirements for explosion-proof wiring of the country where the system is used.

2.5.7 Desktop Equipment

There are PCs, printers, etc. as the devices used on the desks.

When installing any devices on the desks, take care the followings:

- It should provide a level horizontal surface for the PC or the printer.
- A work space should be preserved to connect the cables.
- Support rising cables to prevent their weight from being applied to connectors directly. Keep a space of 100 mm radius or more around the connectors.
- Do not place the desk such as to expose the PC to direct sunlight or high humidity.

2.5.8 Installing Control Bus Interface Card

This section describes how to install VI702 Control Bus interface card. The card is installed in the PCI Express slot of a IBM PC/AT compatible PC to connect it to the Control Bus. The card permits you to use CENTUM VP system operation and monitoring functions on the PC when used with the dedicated software.

SEE ALSO

- The steps described below are based on a common IBM PC/AT compatible machine. Refer to the manual of the PC to be used for precise instructions.
- For station address setting, refer to “Peripherals Manual (A4. Control Bus Interface Card)” (IM 33J50B10-01EN).

Card Installation Procedure

1. Set a station address for the Control Bus interface card.
2. Turn off the computer and unplug the power cord to ensure safety.
3. Remove the PC cover.
4. Remove the slot cover.
5. Insert the Control Bus interface card in the slot. Make certain that the card is properly set in the slot.
6. Attach the PC cover.
7. Write the station address on a seal (sticker) and attach it to the front of the PC or a similar highly-visible place.

SEE ALSO For electrostatic protection, refer to Item 1.5.2, “Countermeasures against Static Electricity.”

3. Cabling

This section describes how to cable the installed system equipment.

Connecting terminals for power, grounding, and signal cables are shown in figures.

The figures also show how to connect the HIS-connected Control Bus interface card to Field Control Units, and an optical fiber cable to the optical ESB bus.

3.1 Cables and Terminals

It is recommended that you use flexible, thin, easy-to-bend, twisted-pair cables to connect the terminals of the system equipment. Use solderless (crimp-on) terminals with insulating cover, which have low contact resistance little aging.

Rigid cables make cabling work difficult and exert unnecessary force on the terminals, which may result in system failures.

Cables with the temperature rating of an ambient temperature plus 10 °C or more must be used.

As for the following models, cables with the temperature rating as shown in the below Table must be used.

Table Rating temperature of Cables

Models	Cables	Temperature rating of Cables
ARS15M, ARS55M	Signal Cables	An ambient temperature plus 20 °C or more
AEP7D (100-120 / 220-240 V AC)	Input Power Cables	An ambient temperature plus 30 °C or more
AEP7D (24 VDC)	Input Power Cables	An ambient temperature plus 50 °C or more
AEPV7D (100-120 / 220-240 V AC)	Input Power Cables	An ambient temperature plus 30 °C or more
AEPV7D (24 VDC)	Input Power Cables	An ambient temperature plus 40 °C or more
AEP9D	Input Power Cables	An ambient temperature plus 60 °C or more
A2PW50□ (When /NCBL)	Input/PE Cables	An ambient temperature plus 30 °C or more
A2BN3D	Field Power/ Grounding Cables	An ambient temperature plus 30 °C or more
A2BN3D	I/O Cables	An ambient temperature plus 20 °C or more
A2BN4D	I/O Cables	An ambient temperature plus 20 °C or more
A2BN5D	I/O Cables/ Barrier Power Cables/ Grounding Cables	An ambient temperature plus 20 °C or more
A2BM4	Terminal board	An ambient temperature plus 20 °C or more
N-IO field enclosure (A2NN70D, A2CB60)	I/O Cables	Enclosure ambient temperature plus 35 ºC or more

Signal Cables

Nominal conductor cross-sectional area:
For FIO Node 0.75 to 2.00 mm^2
For N-IO Node 0.5 to 2.50 mm^2 (AWG20 to 14)

Example of Suitable Cables:
600 V vinyl isolated cable (IV); JIS C 3307/IEC60227-3
Vinyl isolated wire (KIV); JIS C 3316/IEC60227-3
600 V vinyl isolated cable type 2 (HIV); JIS C 3317/IEC60227-3
Heat-proof vinyl isolated wire (UL1015/UL1007)
Vinyl isolated sheath cable for control loop (CVV); JIS C 3401

Alarm and Control Circuit Cables

Nominal conductor cross-sectional area:
Node Inerface Unit External Alarm input terminal:
0.13 to 2.5 mm^2
Other than above: 0.5 to 1.25 mm^2

Example of Suitable Cables:
600 V vinyl isolated cable (IV); JIS C 3307/IEC60227-3
Vinyl isolated wire (KIV); JIS C 3316/IEC60227-3
Heat-proof vinyl-insulated wire (UL1007)

Power Cables

Nominal conductor cross-sectional area
For rack-mounted AC 100-120/220-240 V-driven equipment: 1.25 to 2.0 mm^2
For rack-mounted DC 24 V-driven equipment: Minimum 2.0 mm^2
For N-IO I/O Base plates (Field Power Supply terminal): 0.5 to 1.5 mm^2
For N-IO Barrier Base plates (Barrier Power Supply terminal): 0.5 to 1.5 mm^2
For cabinets AC 100-120/220-240 V-driven: Minimum 8.0 mm^2
For cabinets DC 24 V-driven equipment: Minimum 14.0 mm^2
For Power Unit (A2PW50☐/NCBL):
1.25 mm^2 (AWG16) Double insulation structure

Example of suitable cables:
600 V vinyl isolated cable (IV); JIS C 3307/IEC60227-3
Vinyl isolated wire (KIV); JIS C 3316/IEC60227-3

Note: Use cables capable of supplying current required by respective pieces of equipment with low voltage drop.

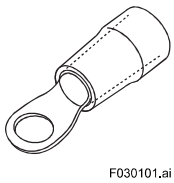
Grounding Cables

SEE ALSO See Section 1.4, “Grounding,” for wiring of grounding cables connecting grounding bars of different cabinets and/or panels to each other.

Nominal conductor cross-sectional area
For rack-mounted equipment: Minimum 2.0 mm^2
For Power Supply Unit (A2PW50☐/NCBL):
1.25 mm^2 (AWG16) or 2.00 mm^2 (AWG14)
For Node Interface Unit: Minimum 2.0 mm^2 (AWG14)
For N-IO I/O Base plates: Minimum 2.0 mm^2 (AWG14)
For N-IO Barrier Base plates: Minimum 2.0 mm^2 (AWG14)
Grounding cables connecting cabinets AC 100-120/220-240/V-driven
to protective grounding system: Minimum 5.5 mm^2
Grounding cables connecting cabinets DC 24 V-driven to protective grounding system:
Minimum 8.0 mm^2

Example of suitable cables:
600 V vinyl isolated cable (IV); JIS C 3307/IEC60227-3
Vinyl insulated wire (KIV); JIS C 3316/IEC60227-3

Note: Use the cable that is defind in the rules/standards of the country or the region.



Cable Terminals

Use the specified solderless terminals and sleeves for pressure clamp terminal on the end of terminal-connected cables, providing low contact resistance, high durability, and low aging.

Solderless Lug

CAUTION

- Be sure to use solderless terminals with insulating sheath.
- Use solderless terminals and crimp tools from the same maker.
- Use different crimp tools according to cable size.

F030101.ai

Figure Solderless Terminal with Insulating Sheath

Sleeve for pressure clamp terminal and spring clamp terminal

When connecting the process I/O signal to the pressure clamp terminal of FIO and N-IO, strip the cable coating (without a sleeve) or attach a sleeve to the cable.

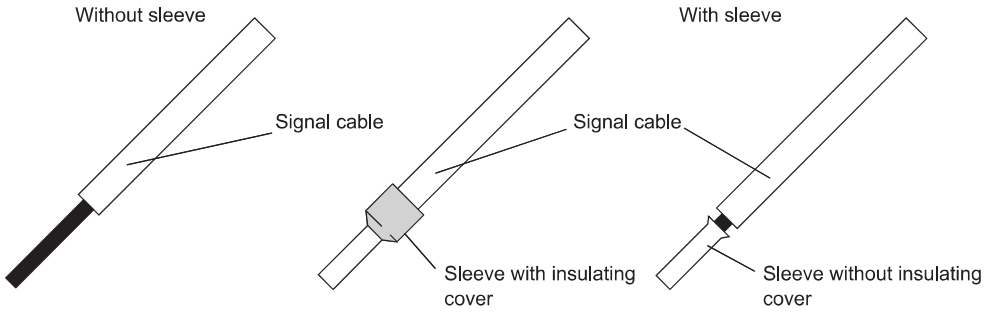


Figure Sleeve for Pressure Clamp Terminal

CAUTION

- Use a sleeve and a clamp tool from the same manufacturer.
- Use a sleeve and a clamp tool which suit the cable thickness.
- Use a sleeve which meet the following DIN standards.
  Sleeve without insulating cover (DIN 46 228/1)
  Sleeve with insulating cover (DIN 46 228/4)

Bending radius of the cable

When connecting a cable to a system instrument, ensure to secure the minimum bending radius of the cable.
The minimum bending radius is either the value shown in the cable manufacturer's specifications or six-fold of the cable conductor diameter, whichever is bigger should be applied.

3.2 Connecting Power

Power is connected either by using a grounding-type bipolar (three-pin) plug or by wiring to terminals.

When piece of CENTUM VP equipment has a power switch, it is recommended that you install a breaker for each piece of equipment in the same room, for maintenance and safety considerations.

Power Cable Termination

Solderless (crimp-on) Lug Terminal Processing

Use solderless lugs for power cables (see Figure).

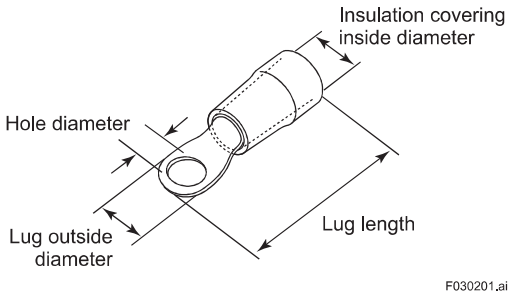

Figure Solderless (crimp-on) Lug

Solderless (crimp-on) Lug Specifications

The solderless lug to use must have the dimensions given in table according to the nominal cross sectional area of the power cable for which the lug is to be used.

Table Solderless Lug Dimensions

Nominal cross sectional area (mm^2)	Screw used (mm)	Hole diameter (mm)	Lug outside diameter (mm)	Lug length (mm)	Insulation covering inside diameter (mm)
1.25	4	4.3 or more	8.2 or less	approx.21	3.6 or more
2.0	4	4.3 or more	8.7 or less	approx.21	4.3 or more
5.5	5	5.3 or more	9.7 or less	approx.29	5.9 or more
8.0	6	6.3 or more	12.2 or less	approx.41	7.0 or more
22.0	8 (hexagon head bolt)	8.3 or more	16.8 or less	approx.50	11.0 or more

CAUTION

- Always use solderless lugs with insulating covering.
- Always use solderless lugs and crimp-on tool manufactured by the same manufacturer.
- The crimp-on tool must be matched to the wire thickness.

Sleeve Terminal Processing

Perform the following terminal processing for the primary power supply input with pressure clamp terminal.

Use a sleeve with insulating cover which meet the DIN 46 228/4.

CAUTION

- Use sleeves and a tool that are from the same manufacturer.
- Use sleeves and a tool that are suitable for the cable thickness.
- Connect the cable properly by inserting the wires all the way into the pressure clamp terminals.

Strip the cable coating at the end of the cable and then attach a sleeve. The sleeve specifications differ depending on the cable thickness. The sleeve specifications are shown in the following table.

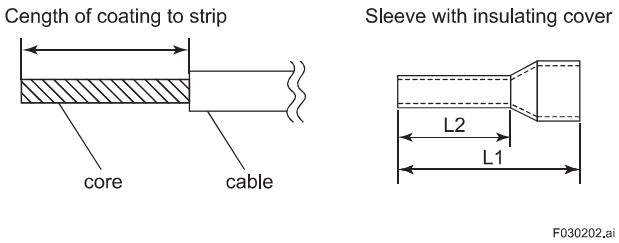

Figure Terminal Processing

Table Cable termination example of Sleeve with Insulating Cover

Nominal cross sectional area (mm^2)	Length to strip (mm)	Sleeve dimensions (mm)	
		L1	L2
1.25 (AWG16)	10	14	8

CAUTION

- Power cables must be laid 1 cm or further away from signal cables.
- Power and grounding cable are use power and ground cables which are in conformance with the safety standard of each country.

Type and Maximum Length of Power Cables

Formulas are given below for determining the type and the maximum length (m) of branch cables from an indoor low-voltage main line.

- The standard type of cable used (nominal cross sectional area) is equivalent to JIS C 3312.
- Calculate the maximum power cable length from the following conditions in Figure. However, the power cable must meet the conditions described in Section “1.3 Power Supply System”, “AC Power Specification”.

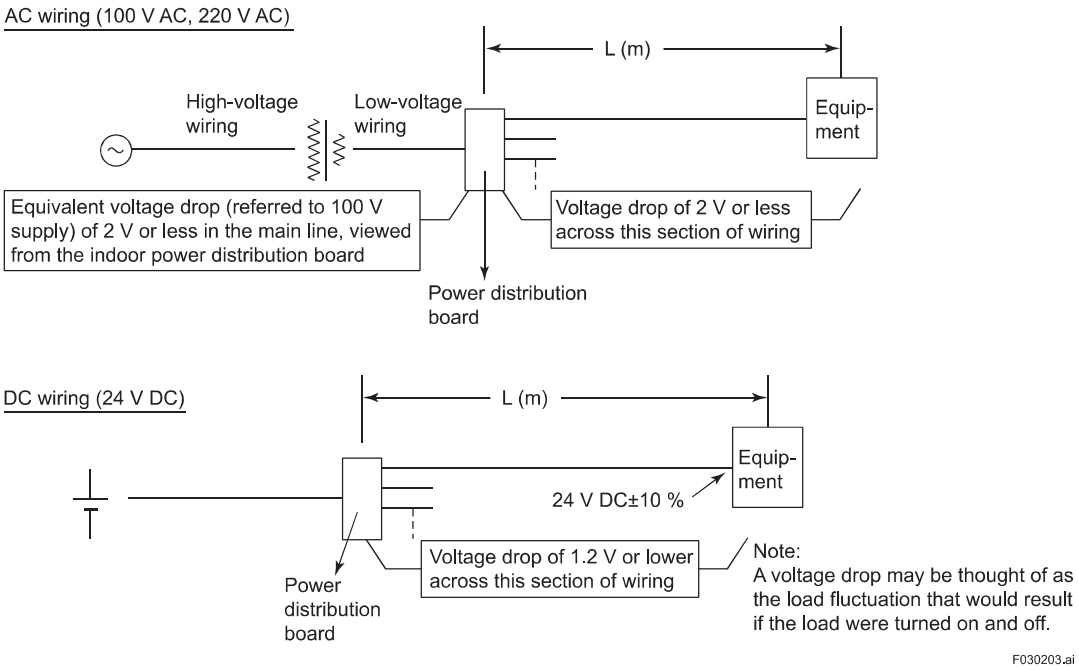

Figure Maximum Cable Length Calculation Conditions

[Maximum power cable length calculation conditions]

Use the following formula to calculate the maximum power cable length:

(a) 100 V AC and 220 V AC supply voltages

$$L\,(m) = \frac{\text{Voltage drop across wiring}}{\text{Conductor resistance (ohm/km)} \times \text{(Number of cores)} \times \text{Equipment current consumption}} \times 1000$$

F030204.ai

(b) 24 V DC supply voltage

$$L\,(m) = \frac{\text{Voltage drop across wiring}}{\text{Conductor resistance (ohm/km)} \times \text{(Number of cores)} \times \text{Equipment current consumption}} \times 1000$$

F030205.ai

Note: In the formulas above, the voltage drop across wiring is assumed to be 2 V for AC power supplies and 1.2 V for DC power supplies; the number of cores is two; and the conductor resistance is as specified in the table below.

Table Wire Nominal Cross Sectional Areas and Resistances

Wire nominal cross sectional area	5.5 mm^2	8 mm^2	14 mm^2	22 mm^2
Wire conductor resistance	3.37 ohm/km	2.39 ohm/km	1.36 ohm/km	0.82 ohm/km

Power Distribution Boards

Power distribution boards are normally provided by the customer. Figures show examples of AC and DC power distribution boards.

AC Power Distribution Board

The power cables is branched to each unit by way of a circuit breaker.

Each power system uses three terminals (AC and ground: ISO M4 to M6 screws).

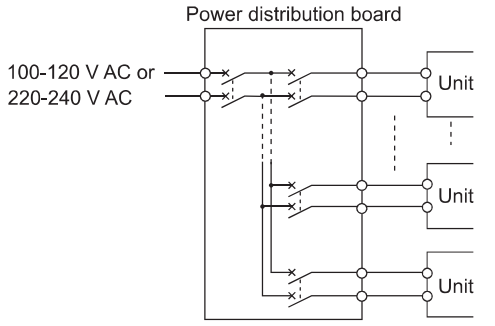

Figure AC Power Distribution Board

24 V DC Power Distribution Board

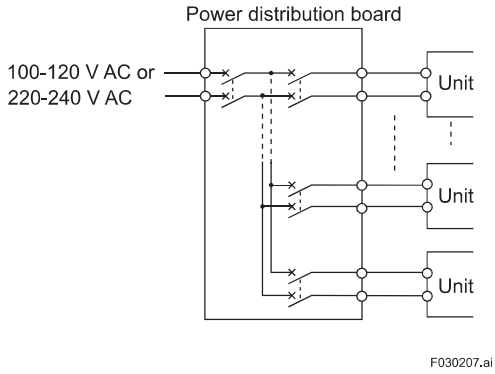

Figure 24 V DC Power Distribution Board

Terminal Connection

The power supply terminals and the grounding terminals of each equipment are as follows.

Table The power supply terminals and the grounding terminals of each equipment (1/2)

Category	Model		Power supply Type	Power supply terminal	Grounding terminal	Grounding Type
Field Control Unit	AFV30S/AFV30D		Power Supply Input	M4 Screw (A cable with dedicated connector is connected to a terminal by default.)	M4 Screw (A cable with dedicated connector is connected to a terminal by default.)	Functional grounding

Conduit Power-cabling

Conduit cabling using cable glands is recommended to lay a power cable for the cabinet and instrumentation boards. It prevents the power cable from contacting metallic plates and putting its weight on power connection terminal.

The console type HIS, or cabinet, has a conduit hole in the bottom plate directly below the terminal box, and the hole can be exposed by removing the blank plate screwed to the bottom. See figures below for conduit cabling:

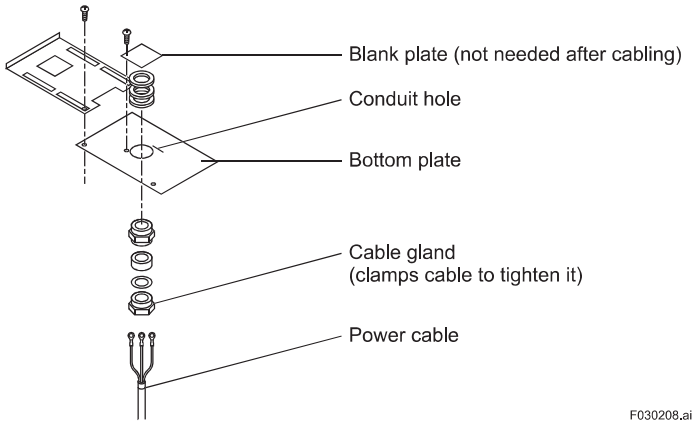

Figure Conduit Hole & Cable Gland

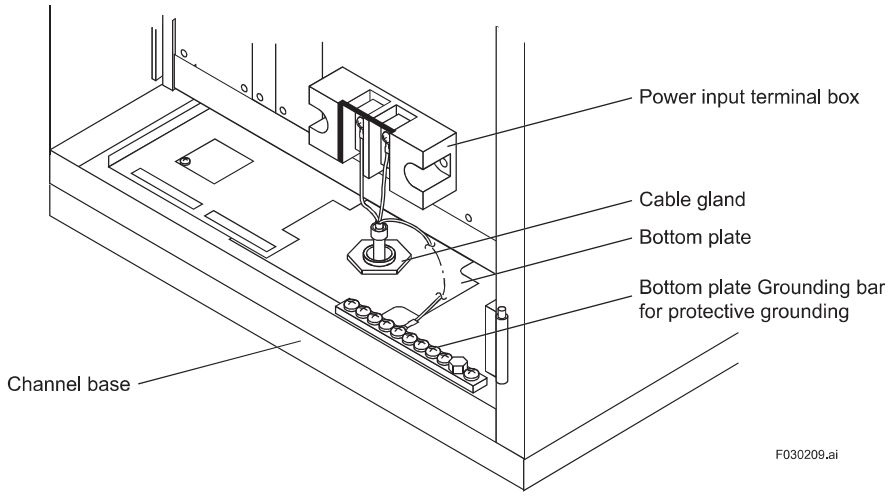

Figure Conduit Cabling

Conduit cabling is also recommended for the 19-inch rack-mount equipment, laying a power cable through a conduit hole where the cable enters the metallic cabinet.

3.3 Connecting Ground Cable

Connect ground cables as follows:

CAUTION

- Connect the terminal connection type device to the protective conductor terminal.
- Connect AFV40S/AFV40D, ACB51, and A2CAB1 to the relay terminal of the ground bar for protective grounding for connecting a ground cable with M5 screws.
- Connect a power cable of the plug-in device to a grounded socket. The cabinet is grounded when the power cable is plugged in.

3.4 Power and Ground Cabling

The following figures illustrate how to connect a power and grounding cable with each system equipment.

A2BN4D Base Plate for Barrier (MTL)

A2BN5D Base Plate for Barrier (P+F)

CAUTION

To avoid the influences of external noise, the cable length outside the cabinet connected to Barrier power supply input connector shall be less than 3 m.

Connecting Power Supply with Node Interface Unit and I/O Units

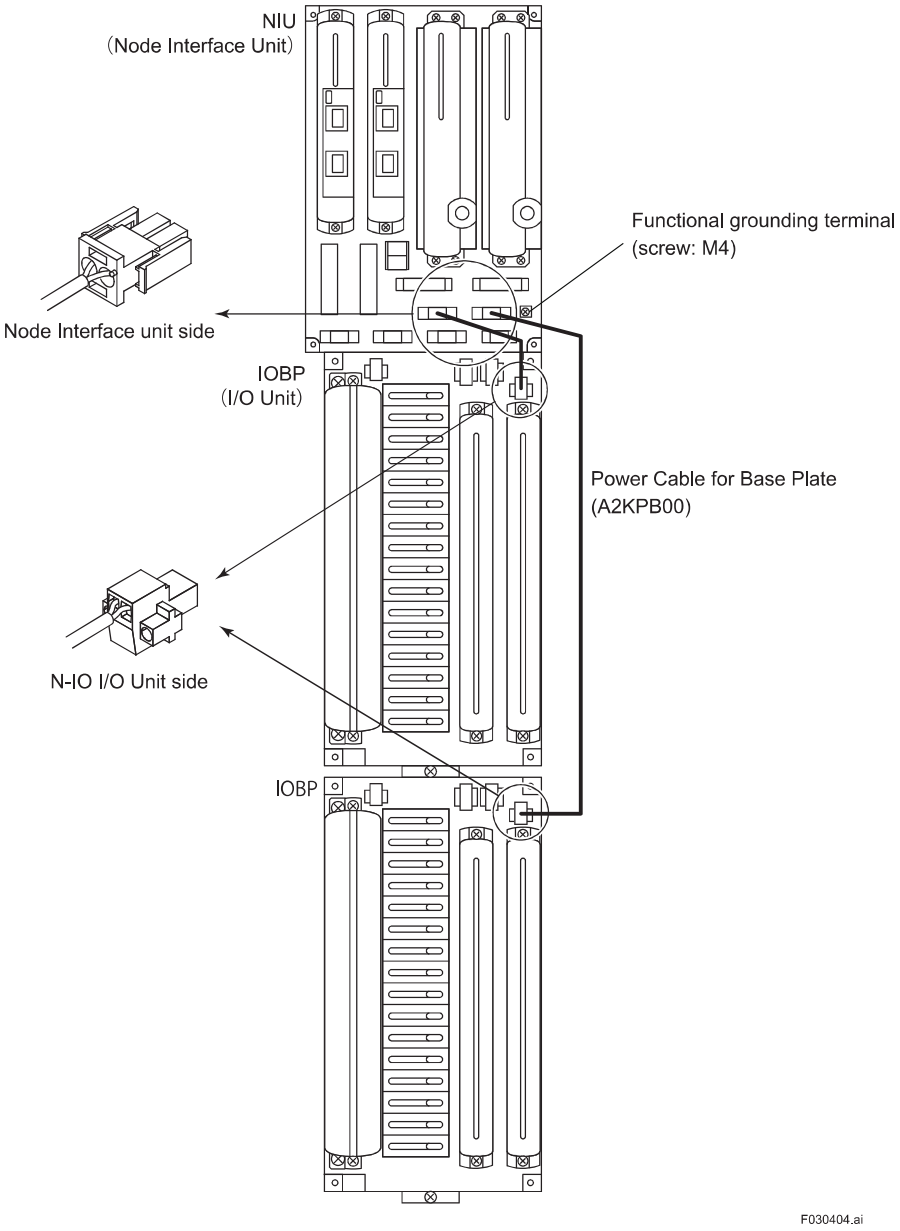

Figure Connecting Power Supply with Node Interface Unit and I/O Units

CAUTION

When connecting a Power Cable for Base Plate to a N-IO node, ensure to keep the minimum bending radius of the cable.

The minimum bending radius of the Power Cable is six-fold of the diameter of the cable.

Example of System Cabinet Installation and Grounding Wiring

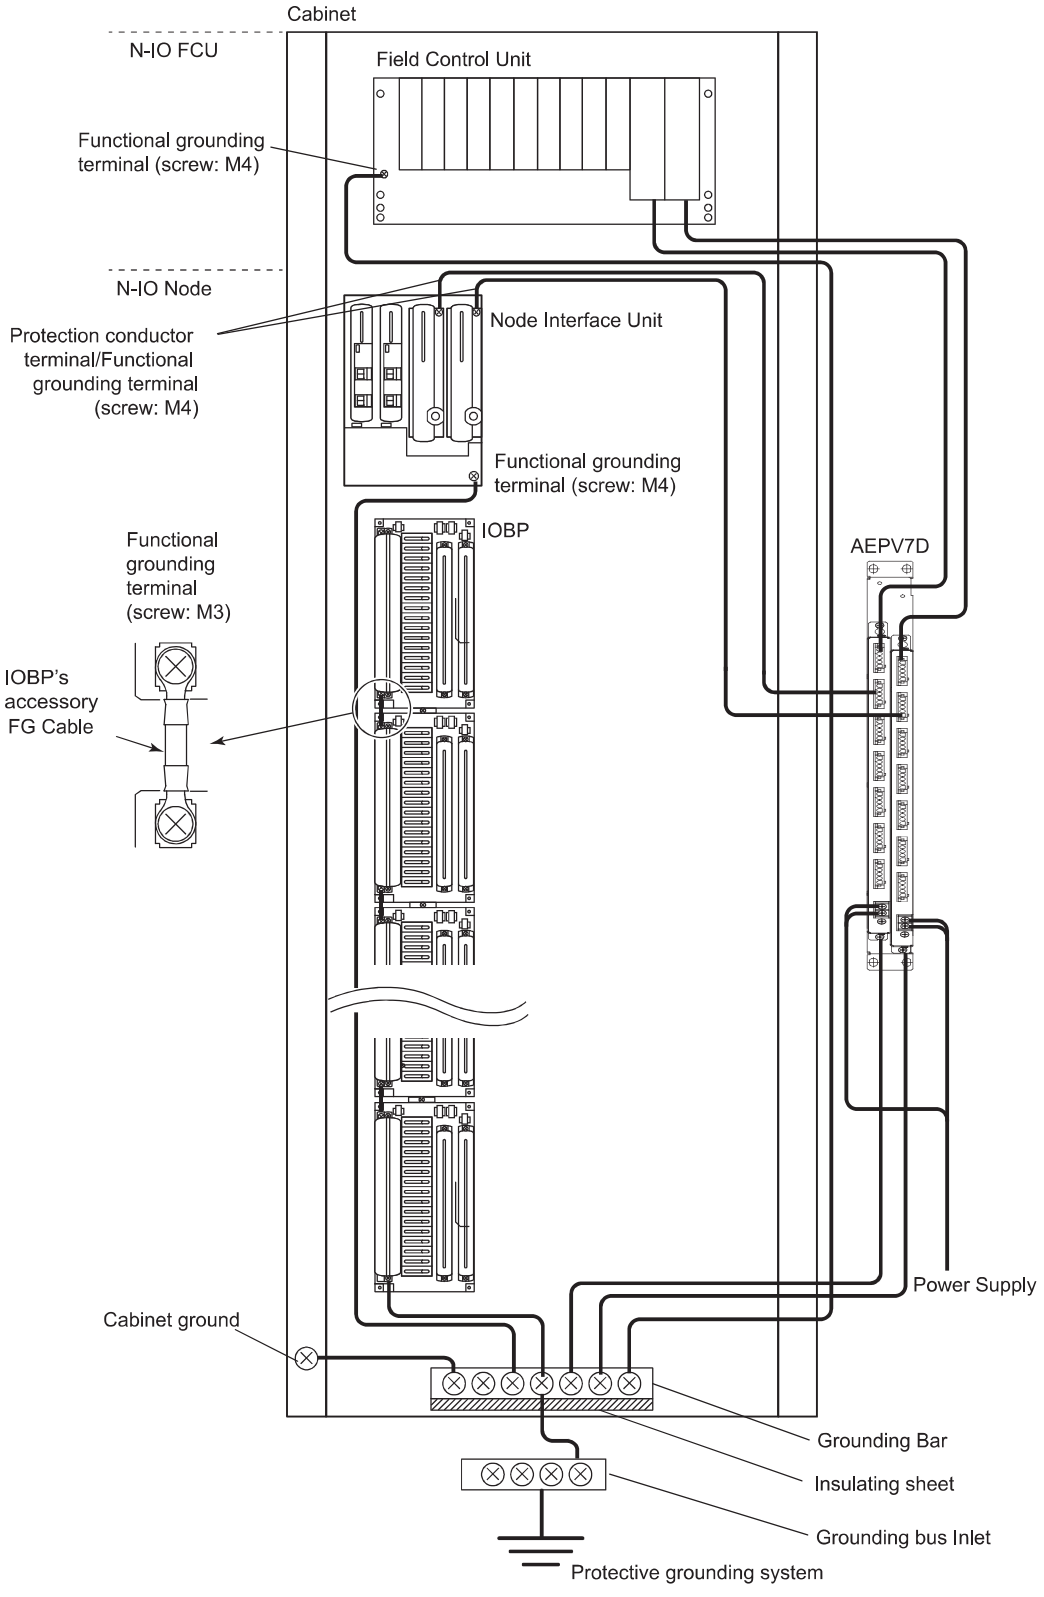

Figure N-IO system devices installation and grounding wiring (Cabinet)

WARNING

The wiring that will be intrinsic safety circuits must be installed so that they are electrically separated from the wiring of non-intrinsic safety circuits, including the in-cabinet wiring. Install the wiring according to the IEC 60079-14 standards or the requirements for explosion-proof wiring of the country where the system is used.

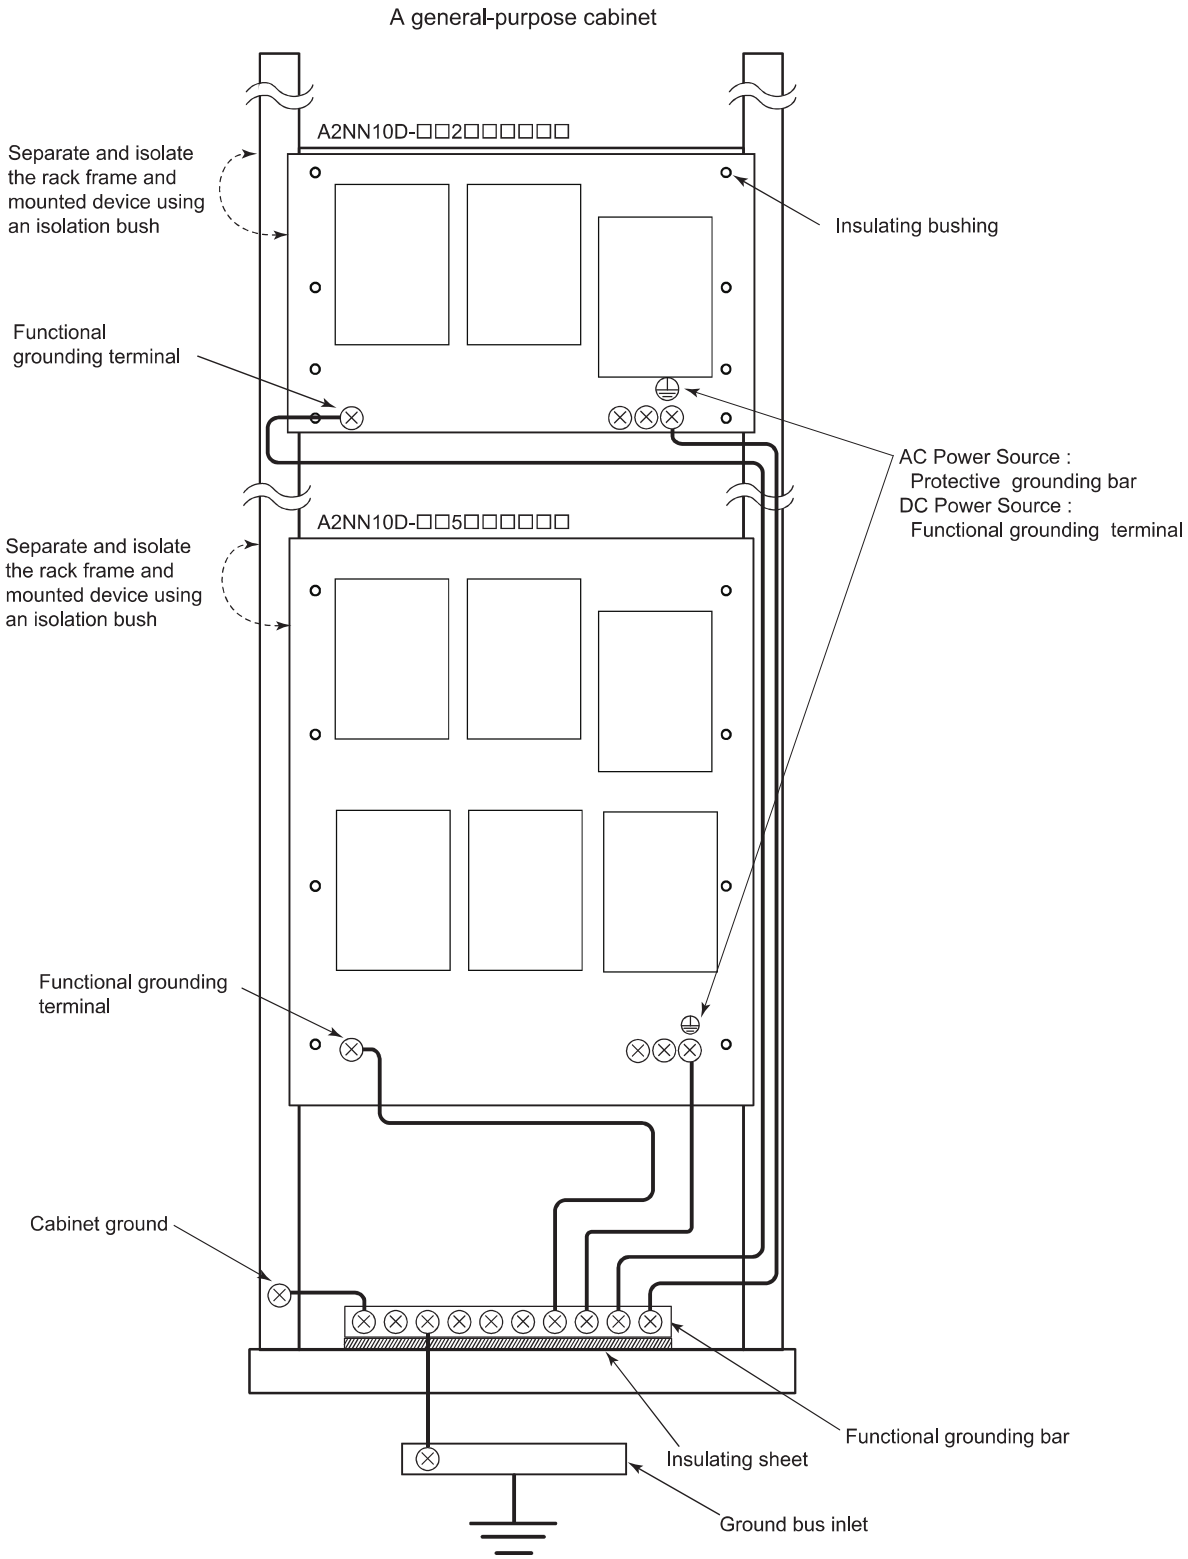
19-inch Rack-mount Devices and Wiring (For FIO System)



An example of wiring when AFV30□, A2FV50□, A2FV70□, ANB10□ or ANB11□ is mounted to a general-purpose cabinet in the following:

*1: Keep a space of 3 units or more for heat radiation.

Figure 19-inch Rack-mount Devices and Wiring

An example of wiring when A2NN10D is mounted to a general-purp cabinet in the following:

Mounting and Wiring Example of Cabinet Utility Kit (ACUKT1)

The following shows a mounting and wiring example of ACUKT1.

In this example, a single door is mounted at the front and a double door at the rear.

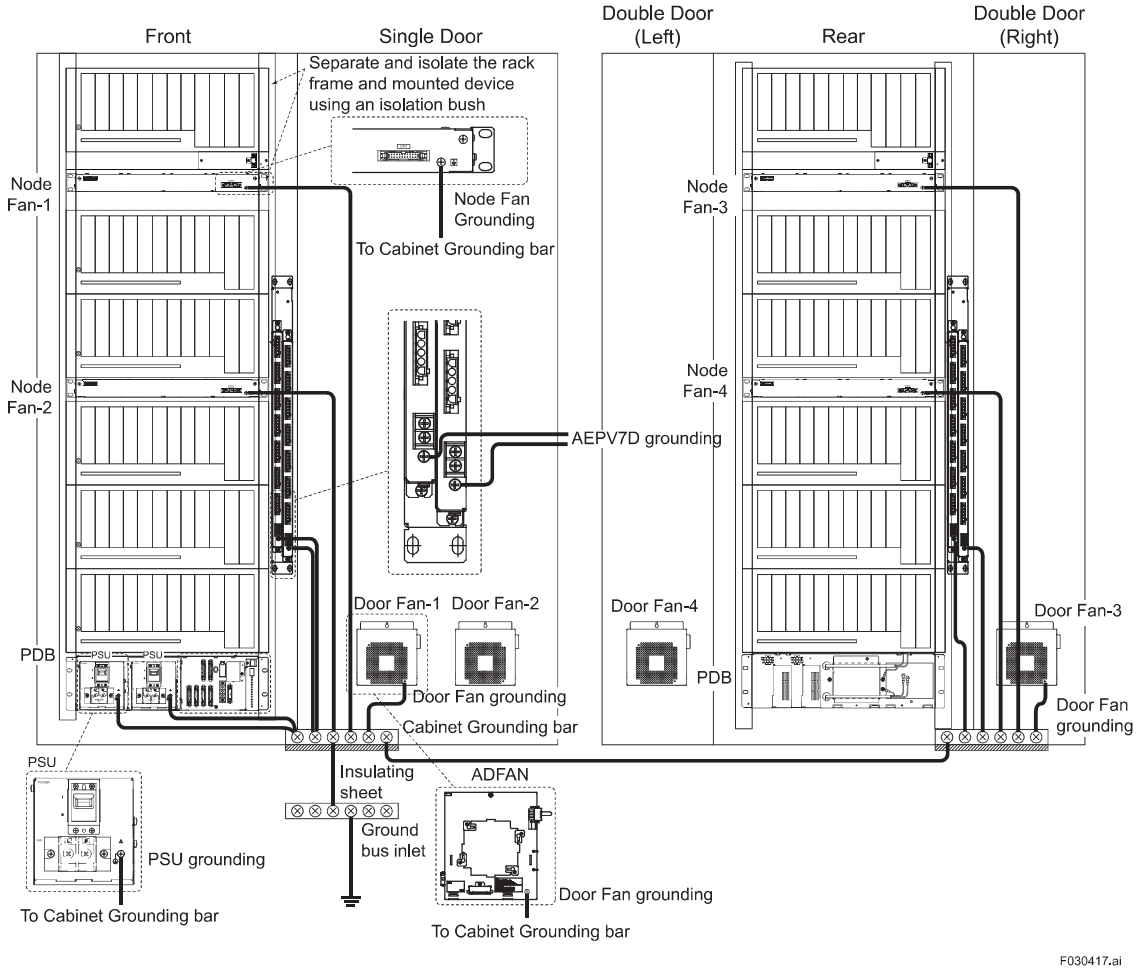


Figure Example of ground wiring

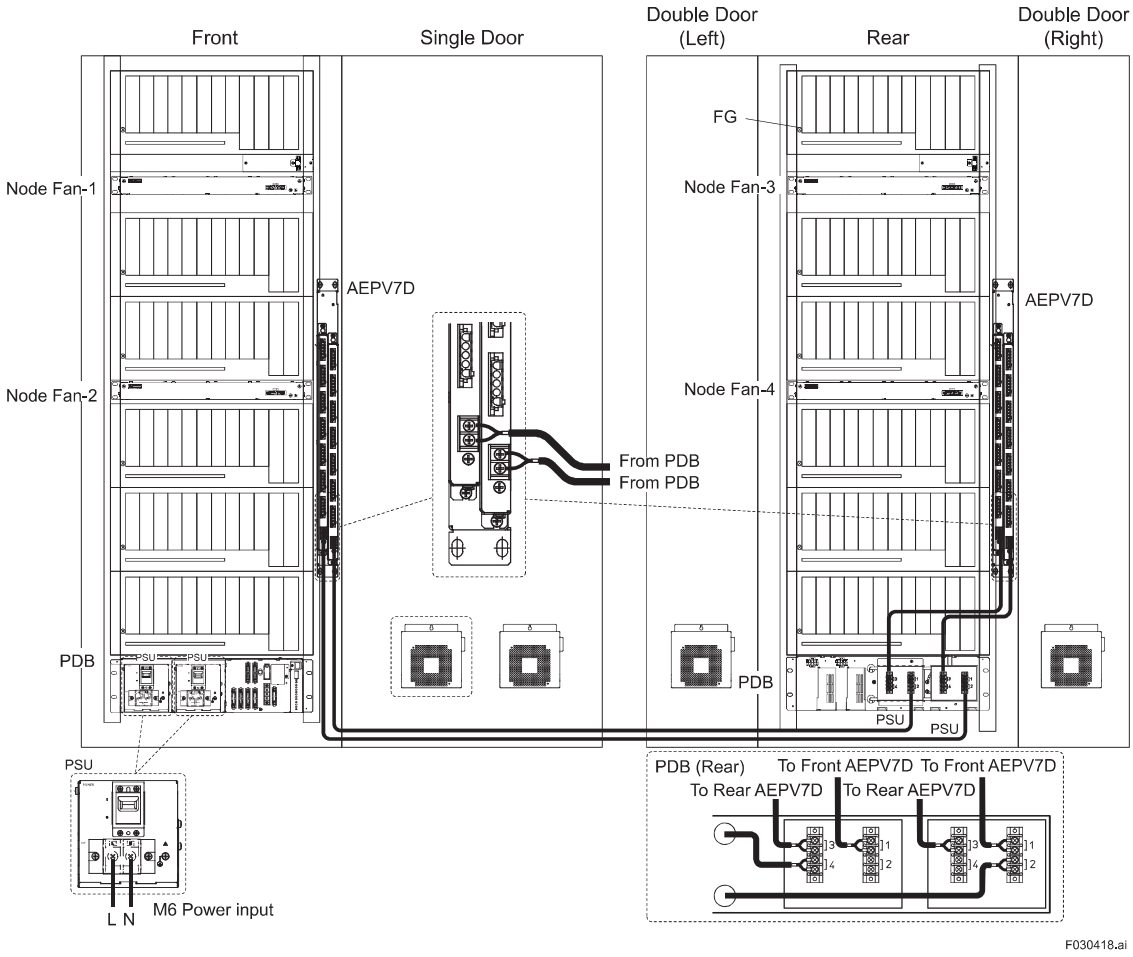

Figure Example of Dual AC Power Supply

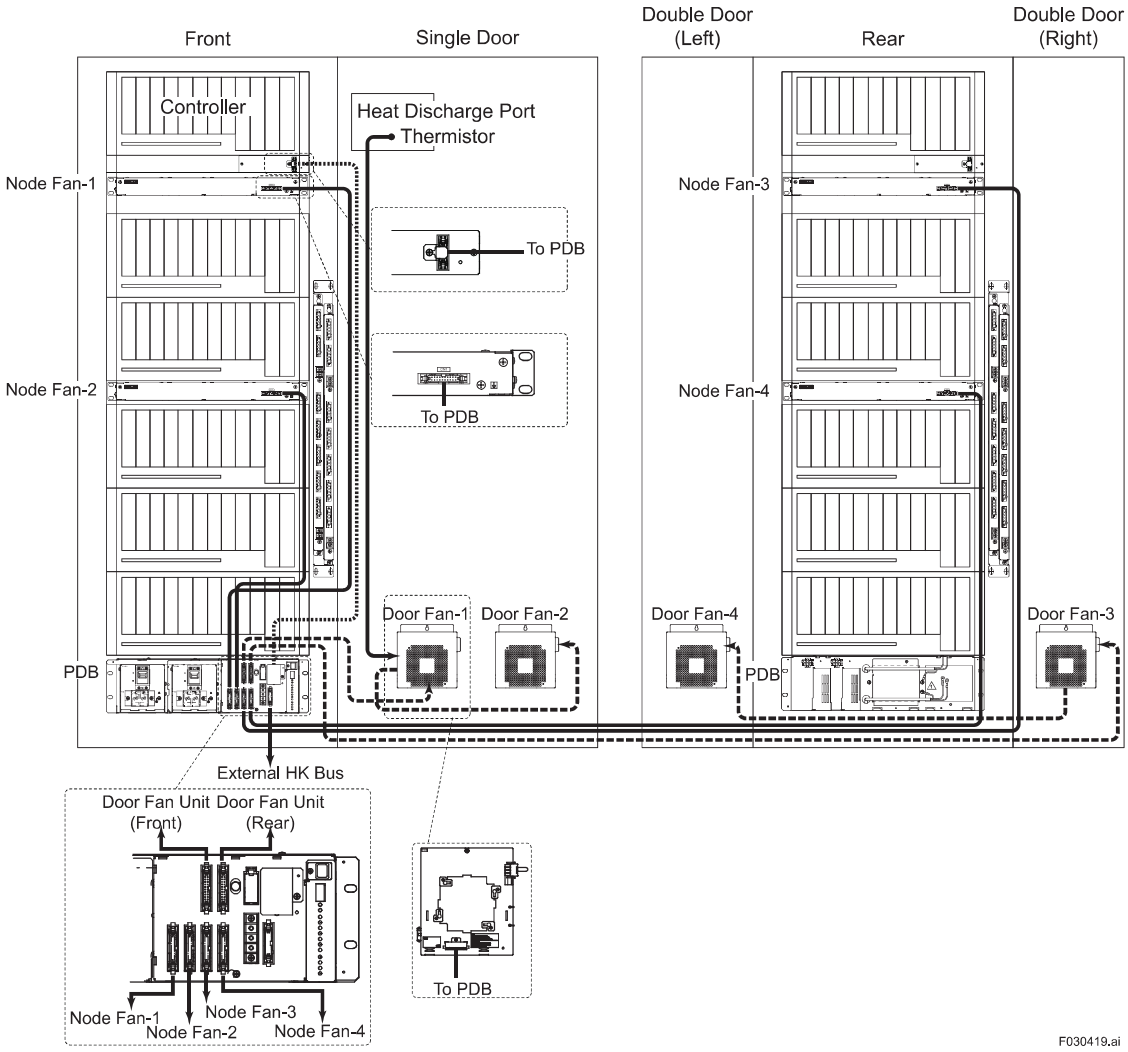

Figure Example of signal wiring

3.5 Connecting Signal Cable

The terminal blocks or connectors of I/O modules are the interface of the field signals. When connecting the field signals to I/O modules via a dedicated cable and a terminal board, the terminal board becomes the interface of the field signals.

Process I/O Signal Connection

- Power, Control Bus, and signal cables must be separately laid. Avoid laying them in parallel.
- The use of group-shielded twisted-pair cables is recommended for analog signal input specifically in order to prevent induction noise. A twisted-pair cable pitch of 50 mm or less should be used and the shielded cables must be grounded.
- The use of twisted-pair cables is also recommended for digital signals.
- The twisted-pair cable has the following advantages over a solid wire:
  - More flexible for easy curving and cabling in limited spaces.
  - With good contact and durable in using a solderless contact.
- Signal cables must be clamped so that their weight does not affect terminals.
- Use solderless lug or pressure clamp terminal contact when process I/O signals are connected with terminals.

Solderless Lug

CAUTION

- The CENTUM VP system uses screw terminals for signal connections.
- Use the solderless contact with an insulation covering.
- Use the solderless contact and crimp tools of the same make.
- Use correct-size crimp tools according to cable sizes.
- When the door is attached or detached for cable connection, be sure to then OFF the power of the main unit before connecting or disconnecting a cable.

Pressure Clamp Terminal

CAUTION

- The CENTUM VP uses a pressure clamp terminal for signal connection of FIO and N-IO.
- For cable connection with a sleeve attached, use a sleeve and a clamp tool from the same manufacturer.
- Use a clamp tool which suits the cable thickness.
- When the door is attached or detached for cable connection, be sure to then OFF the power of the main unit before connecting or disconnecting a cable.

Push-in terminal

CAUTION

- The N-IO field enclosure also uses a push-in terminal for signal connection.
- For cable connection with a sleeve attached, use a sleeve and a clamp tool from the same manufacturer.
- Use a clamp tool which suits the cable thickness.

Spring Clamp Terminal

CAUTION

- The CENTUM VP uses a spring clamp terminal for signal connection of N-IO.
- For cable connection with a sleeve attached, use a sleeve and a clamp tool from the same manufacturer.
- Use a clamp tool which suits the cable thickness.
- When the door is attached or detached for cable connection, be sure to then OFF the power of the main unit before connecting or disconnecting a cable.

Signal Cable Termination

Use the specified sleeves for pressure clamp terminal on the end of terminal - connected cables.

Pressure Clamp Terminal (for FIO Module Pressure Clamp Terminal Block)

- Terminal processing
  When connecting the process I/O signal to the pressure clamp terminal of FIO I/O Modules or N-IO, strip the cable coating (without a sleeve) or attach a sleeve to the cable. The following shows the length of the coating stripped for cases when a sleeve is not used and when it is used.

ATA4S, ATD5S, ATI3S, ATB5S, ATF9S, A1BT4D,ATA4D, ATD5D, ATI3D, and ATB5D

Table Without a sleeve

Cable thickness (mm^2)	Length of coating stripped (mm)	Remarks
0.5 to 2 (AWG20 to 14)	11	—

It is recommended to use any one of the following sleeves.

Sleeve without insulating cover (DIN 46 228/1)
Sleeve with insulating cover (DIN 46 228/4)

Table With a sleeve

Nominal cross sectional area (mm^2)	When using a sleeve with an isolation cover			When using a sleeve without an isolation cover	
	Length of coating stripped (mm)	Sleeve size		Length of coating stripped (mm)	Sleeve size
		Total length (mm)	Contact section length (mm)		Total length (mm)
0.5	12	16	10	10	10
0.75	12	16	10	10	10
1	12	16	10	10	10
1.25 to 1.5	12	16	10	10	10

Pressure Clamp Terminal (for ARS□□M)

For both signal line and power line of the Solid State Relay Board ARS□□M, pressure clamp terminals are used.

- Terminal processing
  When connecting the signal and power line to the pressure clamp terminal, strip the cable coating (without a sleeve) or attach a sleeve to the cable. The following shows the length of the coating stripped for cases when a sleeve is not used and when it is used.

Table Terminal treatment for pressure clamp terminal signal line

	Cable thickness (mm^2)	Length of coating stripped (mm)	Inserting length of sleeve (mm)
Without sleeve	0.5 to 2 (AWG20 to 14)	8	–
With sleeve	0.5 to 2 (AWG20 to 14)	8	8

Table Terminal treatment for pressure clamp terminal power line

	Cable thickness (mm^2)	Length of coating stripped (mm)	Inserting length of sleeve (mm)
Without sleeve	0.5 to 2 (AWG20 to 14)	9	–
With sleeve	0.5 to 1.5 (AWG20 to 16)	9	8

Pressure Clamp Terminal, Spring Clamp Terminal (for N-IO), Push-in terminal (for N-IO field enclosure)

At the end of the signal cables to the following applicable interface, provide the following cable termination:

Table Applicable Interface

Products	Models	Interface	Sleeve Normal cross sectional area (mm^2)
Node Interface Unit	A2NN30D	External alarm input terminal	0.5 ~ 2.5
I/O Unit	A2BN3D	I/O signal terminal (Pressure clamp terminal)	0.5 ~ 2.5
		I/O signal terminal (Spring clamp terminal)	0.5 ~ 1.5
		Field power supply input terminal	0.5 ~ 1.5
	A2BN5D	I/O signal terminal	0.5 ~ 1.5
		Barrier power supply input terminal	0.5 ~ 1.5
Terminal board	A2BM4	I/O signal terminal	0.5 ~ 2.5
Shunt resistor unit (For A2SAP105)	A2EXR001	Input terminal	0.5 ~ 2.5
N-IO field enclosure	A2NN70D, A2CB60	I/O signal terminal (Push-in terminal)	0.5 ~ 2.5

- When using a sleeve
  At the cable end, peel off the coating and attach a sleeve. The specifications of the sleeve differ, depending on the cable thickness. Provide cable termination according to the following figure and tables:

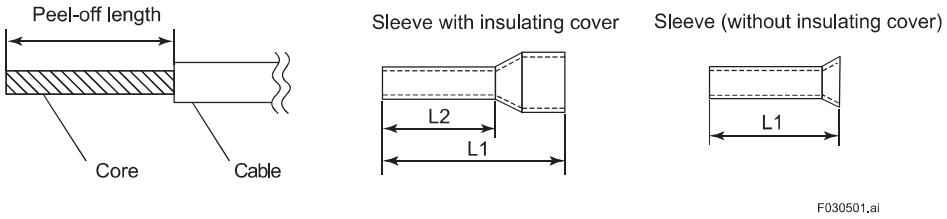

Figure Cable termination (for pressure clamp terminals)

It is recommended to use any one of the following sleeves.

Sleeve without insulating cover (DIN 46 228/1)
Sleeve with insulating cover (DIN 46 228/4)

Table When sleeves with insulating cover are used

Nominal cross sectional area (mm^2)	Peel-off length (mm)	Sleeve dimensions (mm)	
		L1	L2
0.5	10	14	8
0.75	10	14	8
1.0	10	14	8
1.5	10	14	8
2.5	10	14	8

Table When sleeves without insulating cover are used

Nominal cross sectional area (mm^2)	Peel-off length (mm)	Sleeve dimensions (mm)
		L1
0.5	6	6
0.75	6	6
1.0	6	6
1.5	7	7
2.5	7	7

- When not using a sleeve
  The peel-off length should be 7 mm. (*1)
- For I/O Unit Model A2BN4D
  The pressure clamp terminal is on the MTL I.S. barrier. A cable must be prepared separately. Cable specification of field signal depends on the requirements specification of MTL's I.S. barriers. Refer to the instruction manual of I.S. barriers provided by the vendor.

*1: In case of A2EXR001, the peel-off length should be 8 mm for pressure clamp terminals and 7 mm for spring clamp terminals.

Solderless Lug

- Solderless lug specifications

  The specifications of the solderless lug to use are determined by the nominal cross sectional area of the power cable for which the lug is to be used, the lug screw, dimensions and so on.

Table Solderless Lug Dimensions

Nominal cross sectional area (mm^2)	Screw used (mm)	Hole diameter (mm)	Lug outside diameter (mm)	Lug length (mm)	Insulation covering inside diameter (mm)	Dimension "C" (mm)
0.75 ~ 1.25	4 (*1)	4.3 or more	8.2 or less	Approx.21	3.6 or more	7.0 or more
2.0	4 (*1)	4.3 or more	8.7 or less	Approx.21	4.3 or more	7.1 or more

*1: Recommended tightening torque is 1.2 N•m.

CAUTION

- For CENTUM VP, spring lugs are used for connecting signals for equipment for RIO System Upgrade.
- Always use solderless lugs with insulated covering.
- Always use solderless lugs and crimp-on tool manufactured by the same manufacturer.
- The crimp-on tool must be matched to the wire thickness.

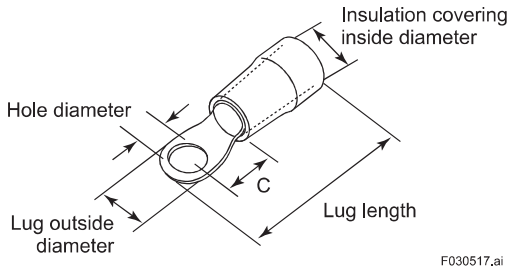

Figure Solderless Lug

Connecting Signal Cables to Terminals (for FIO)

Connecting to Pressure-clamp Terminal

1. Loosen the cable connecting terminal screw.
2. Strip the cable coating (without a sleeve) or attach a sleeve to the cable, then insert the tip of the cable into the connecting section of the pressure clamp terminal.
3. Fasten the screw using the special tool (a screw driver conforming to the DIN 5264B standard with a tip width of 0.6 mm and a shaft diameter of 3.5 mm) with a fastening torque of 0.5 N•m.

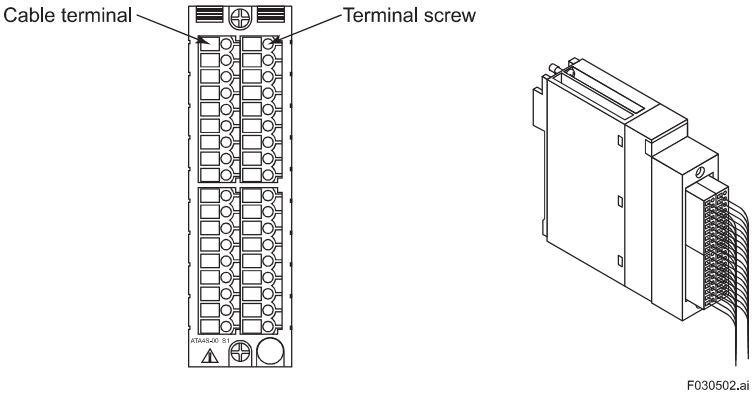

Figure Connecting Signal Cable to Terminal (for FIO)

CAUTION

Do not use non-standard signal cable or sleeve; using them could cause improper connection. Be sure to remove the cable sheath just as much as specified, fit the sleeve, and clamp the cable firmly to the terminal.

Routing Signal Cables (for FIO)

Areas for Signal Cables from Field

Signal cables from the field enter the FCS at the bottom and connect to individual node units in the routes shown in Figure below.

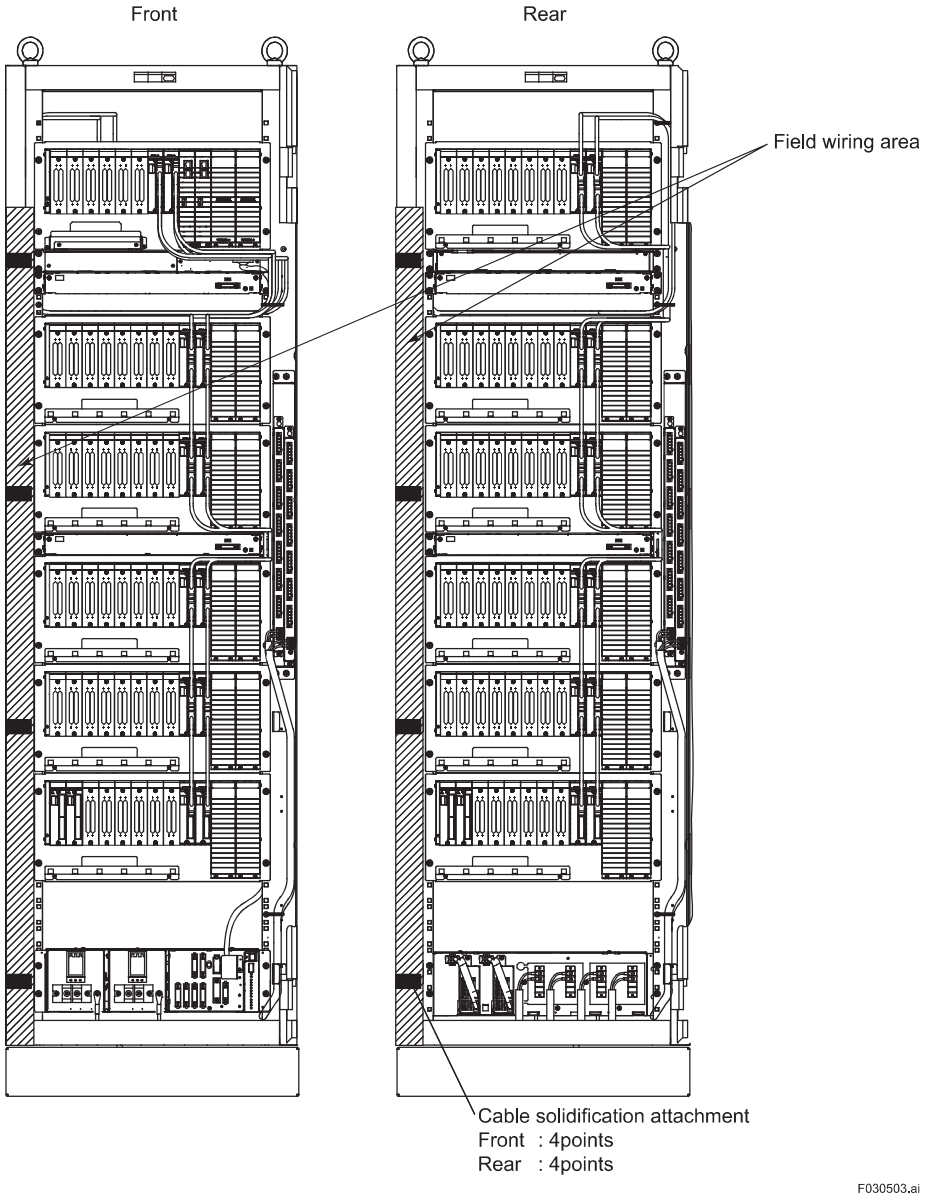

Figure Areas for Signal Cables from Field

FIO Node Unit Wiring in FCU with Cabinet

Model: AFV40S/AFV40D, the cabinet constructed with A2CAB1 and A2CUKT4

The figure shows a dual-redundant ESB bus example.

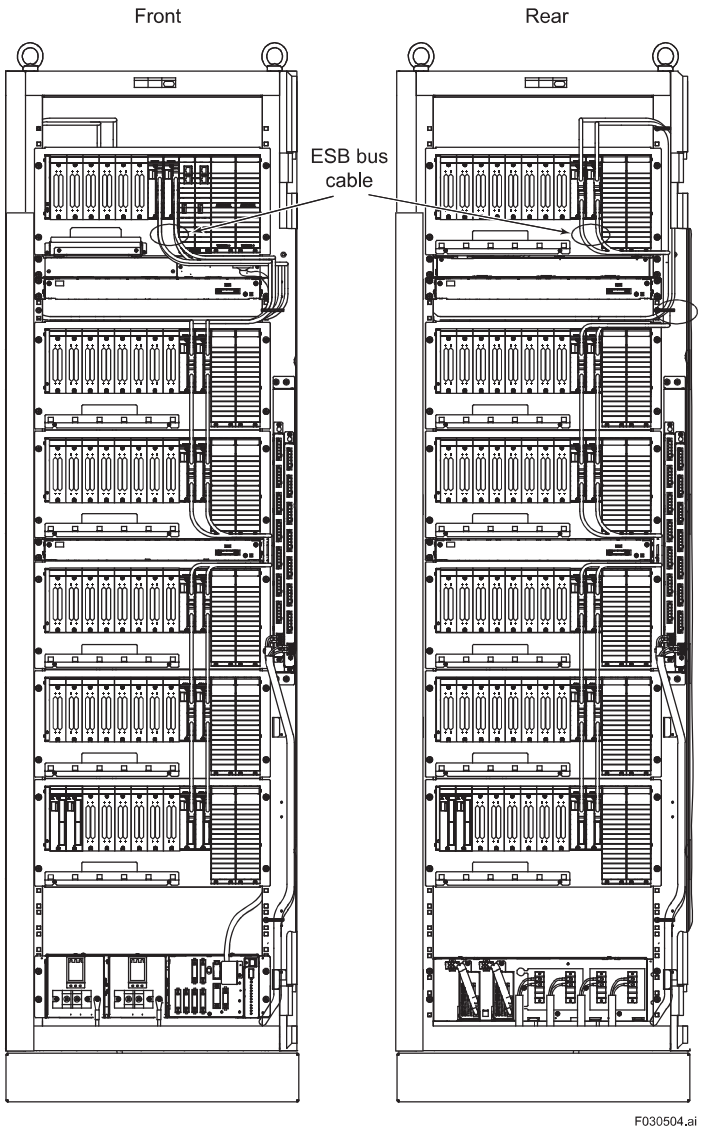

Figure FIO Node Unit Wiring in FCU with Cabinet

FIO Node Unit Wiring in I/O Expansion Cabinet

Model: ACB51, the cabinet constructed with A2CAB1 and A2CUKT4

The figure shows a dual-redundant ESB bus example, the ESB bus node units installed in the front of the cabinet and the terminal boards in the rear.

Avoid using ESB bus cable with other cables and also avoid wiring its cable in parallel with others.

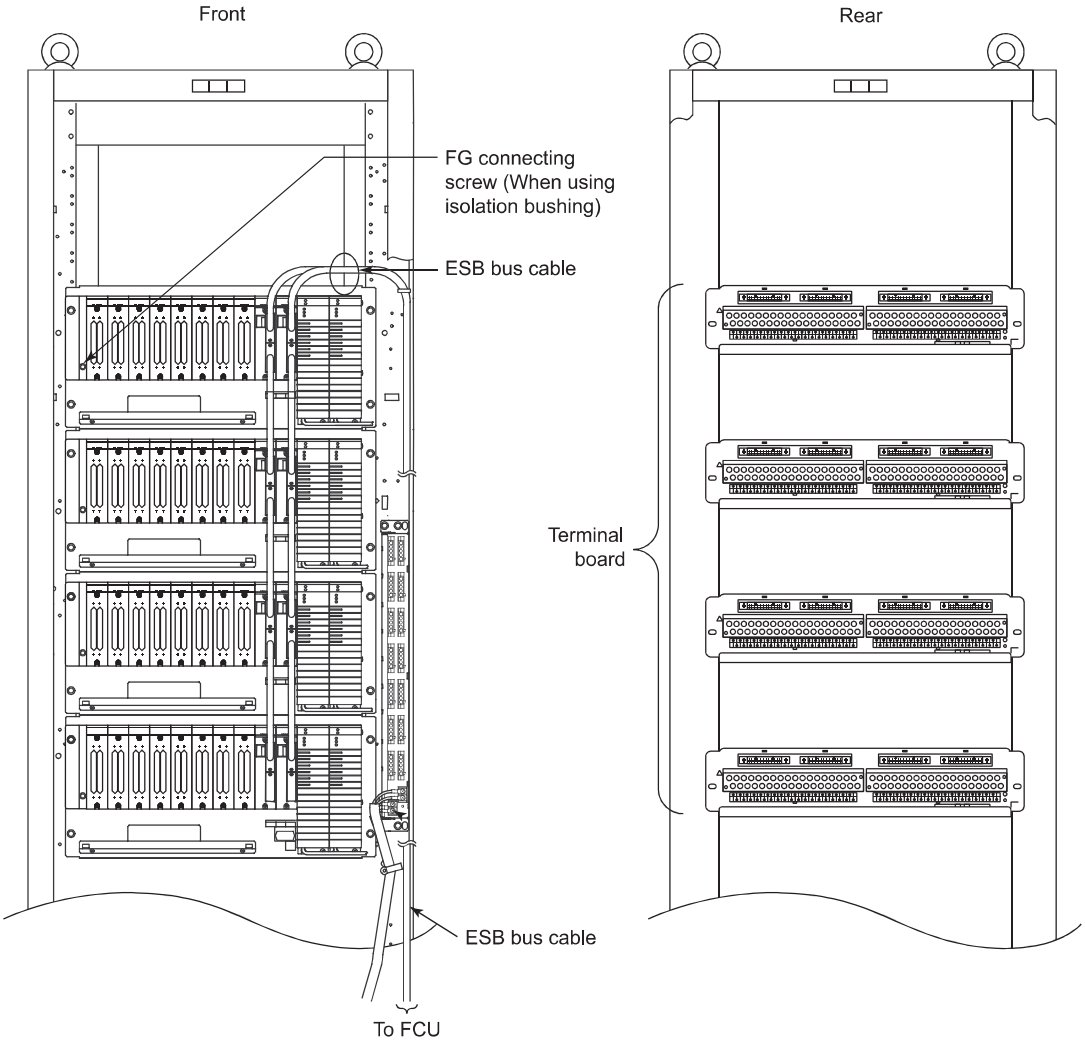

Figure FIO Node Unit Wiring in I/O Expansion Cabinet

FCU (for FIO), ESB Bus Node Unit

CAUTION

To reserve the ventilation for I/O module, the signal cable should not exceed the separator at the center of cable tray.

The following shows a dual-redundant ESB bus example.

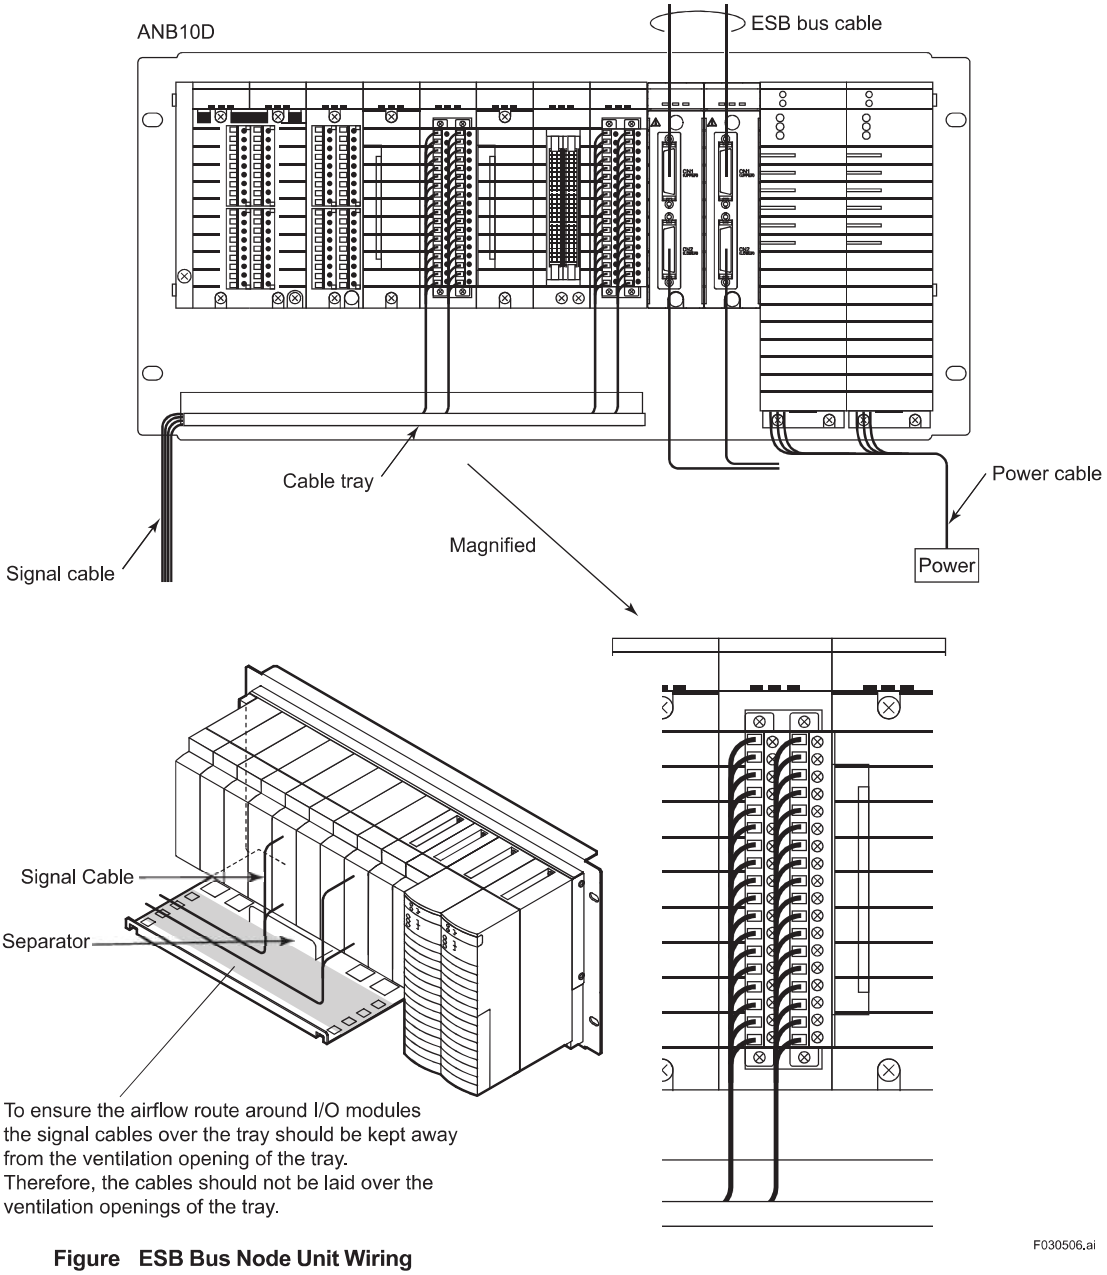

Figure ESB Bus Node Unit Wiring

FIO Signal Cabling

IMPORTANT

The signal cable for the top node unit must be wired at the innermost part in the field control area as the figure shows.
When fixing cables to a clamp, allow enough space so that the cards can be maintained.
Bind the bottom cables to the clamp bar on the channel base.

Push in the signal cables for the top node unit as far as they will go.

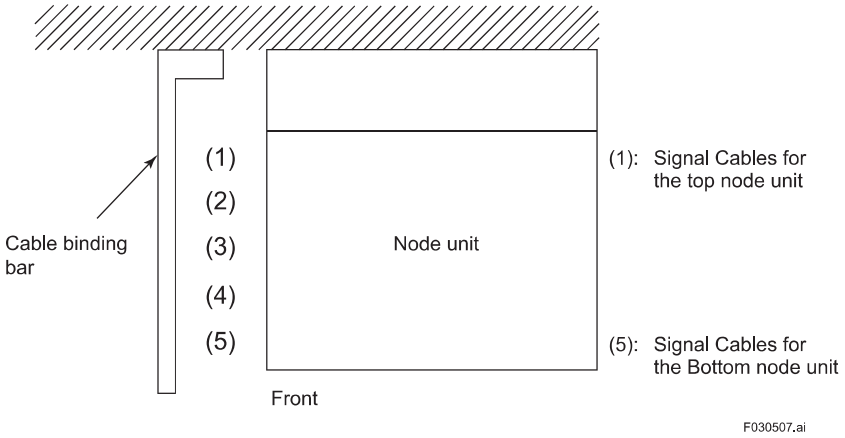

Figure Signal Cabling

FIO with KS Cable Interface Adaptor Cabling

When connecting a dedicated cable to an FIO module, ensure to keep the minimum bending radius of the cable.
Place the cable in front of the separator on the cable tray for ventilation.

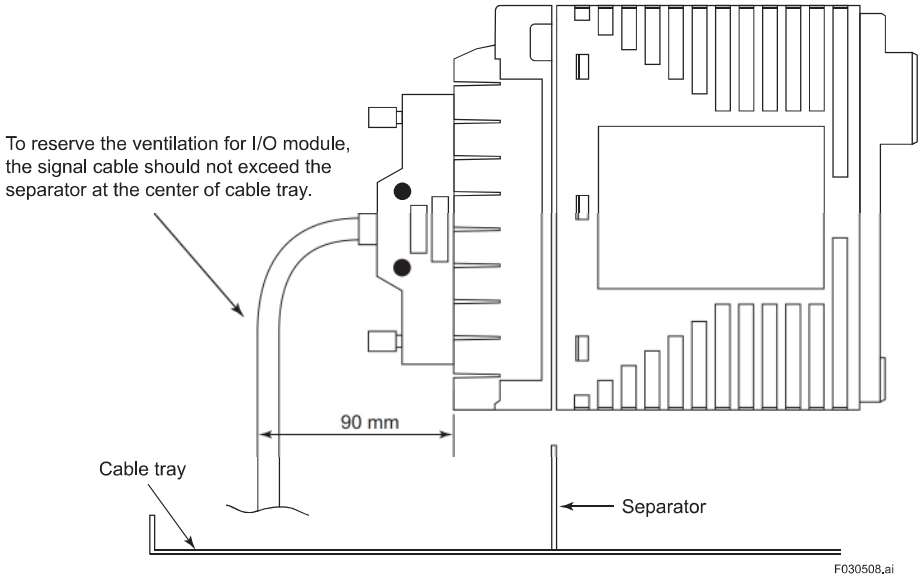

Figure FIO with KS Cable Interface Adaptor Cabling

Modifying the Cabinet Bottom Plates for Cable Wiring

Cables are passed through the holes in the bottom plates of the cabinet.
The diameters of these holes can be changed to match the diameter of the cables. There are four bottom plates two each for AFV40☐/ACB51/A2CAB1 specifically for signal cable wiring.

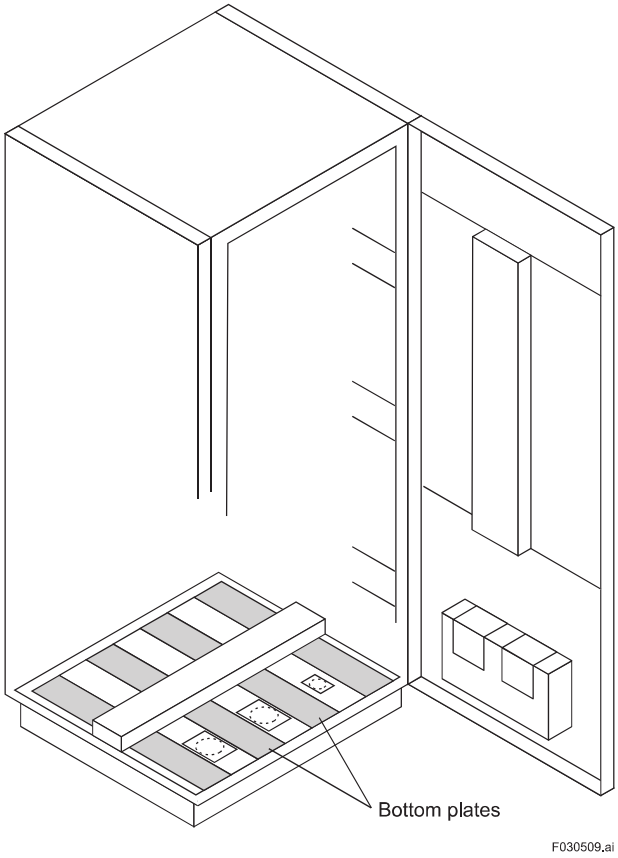

Figure Bottom Plates of AF☐20☐/ACB21/A2CAB1

To modify the bottom plates, follow these steps.

1. Remove the bottom plate to be modified.

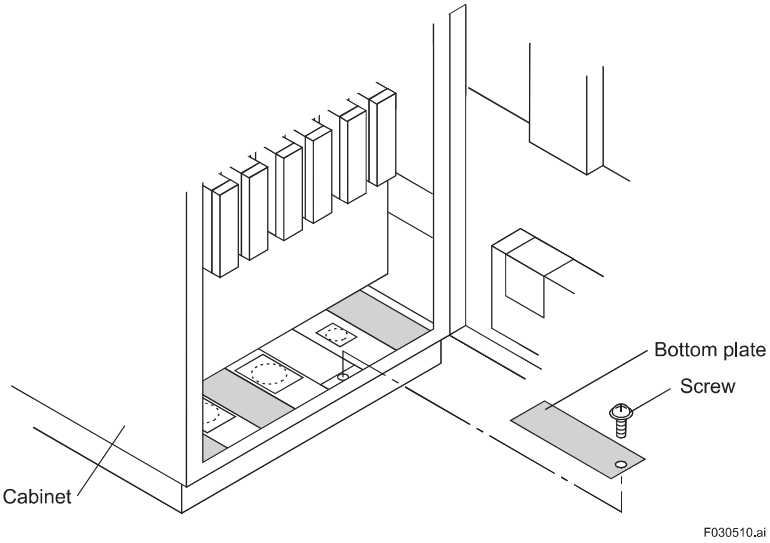

Figure Removing the Bottom Plate

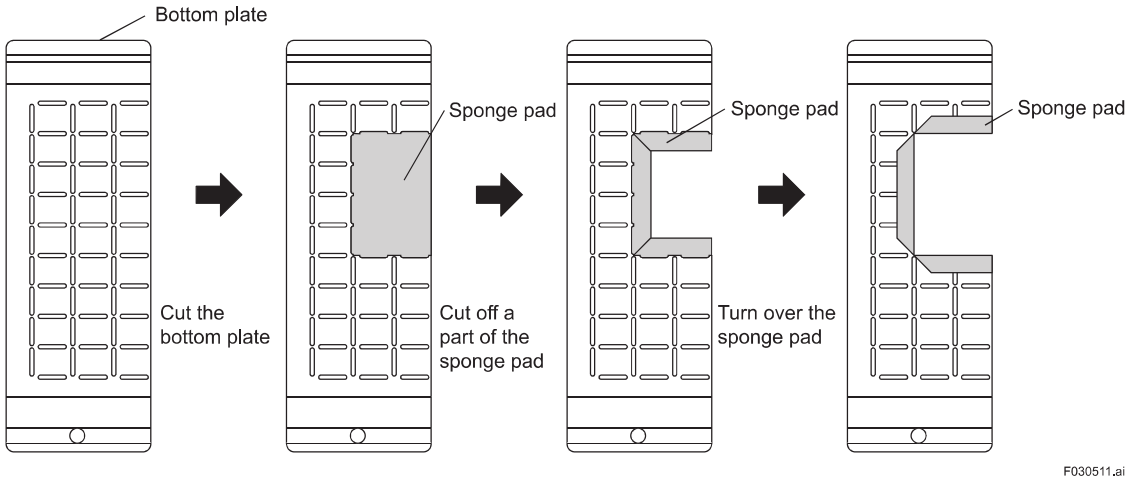
2. Turn the bottom plate upside down so that the bottom faces upwards.
3. Use a wire cutter or another appropriate tool to remove sections of the bottom plate so that a hole large enough for the cable to pass through is made. Do not cut the sponge pad on the reverse side of the plate.
4. Cut and remove the area protective padding approximately 20 mm inside the opening made in the preceding step.
5. Turn the rim of the protective padding (width: 320 mm) inside out. This will protect the cable from the rough edges of the plate. The sponge pad has an adhesive surface. Peel the paper from the surface and stick the sponge pad to the plate.



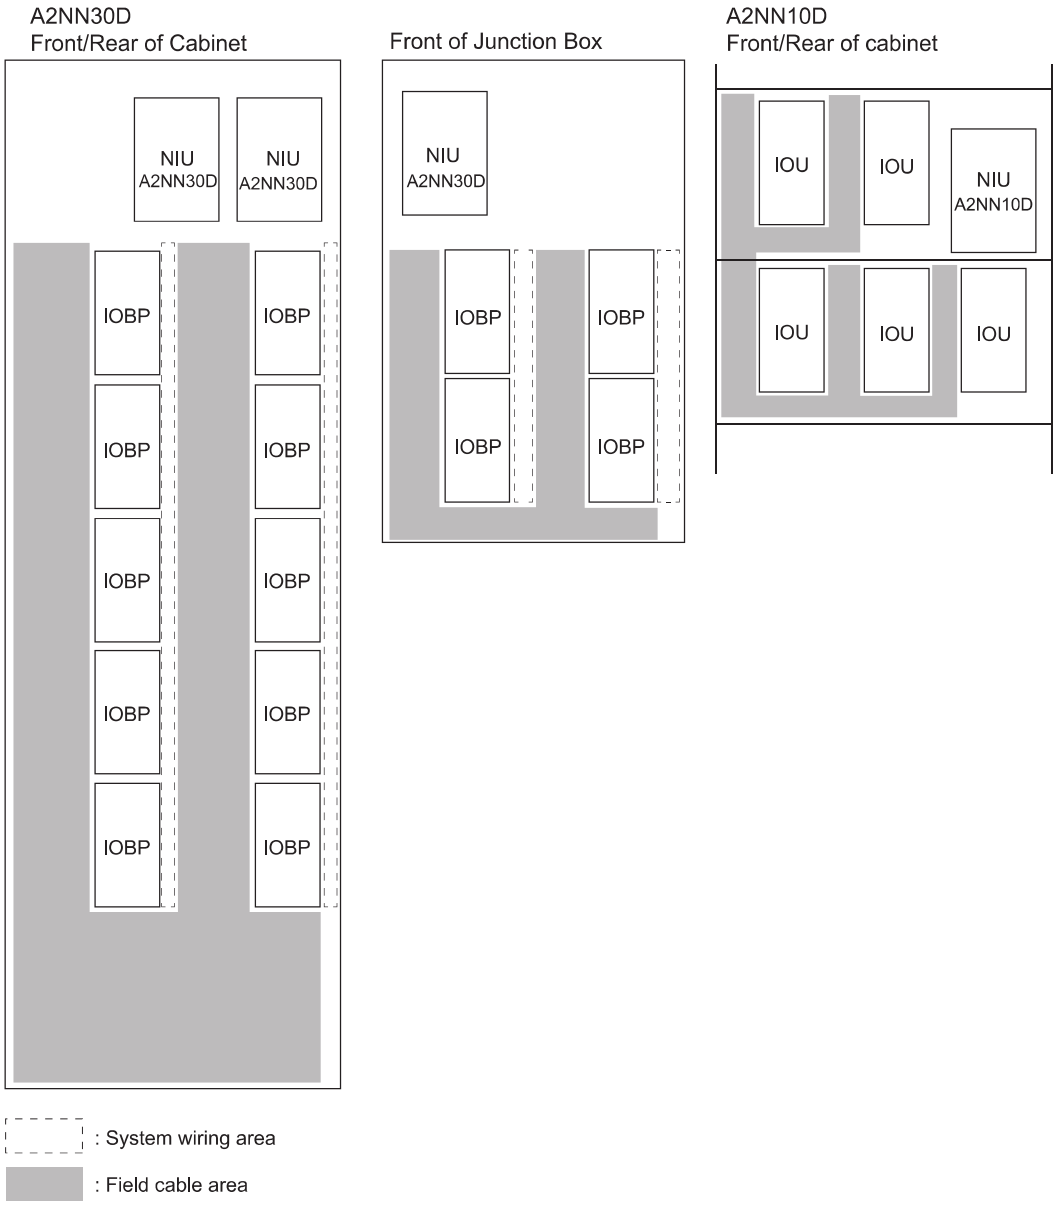


Figure Modifying the Bottom Plate

6. Replace the bottom plate.

Routing Signal Cables (for N-IO)

Field Cable Area

Signal cables from the field enter the Cabinet at the bottom and connected to individual IOBP units in the routes shown in Figure below.

NIU: Node Interface Unit
IOBP: N-IO I/O Base Plate
IOU: I/O Unit (for RIO System Upgrade)

Figure Area for Signal Cable from Field

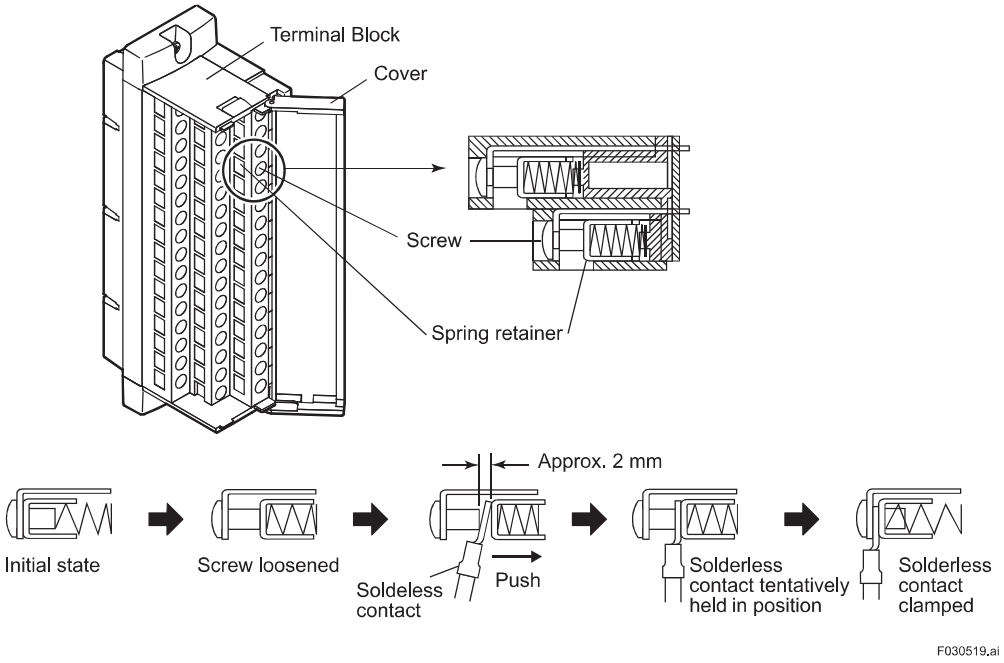
Connecting Signal Cables to Terminals (for N-IO)

Connecting cables to pressure clamp terminals (A2BN3D-□1□□□)

Follow these steps to connect cables to pressure clamp terminals:

1. Open the cover of the terminal block of the base plate for N-IO I/O.
2. Confirming the cable polarity, insert the cable to the pressure clamp terminal and tighten the screw. The tightening torque of the screws should be 0.5 to 0.6 N·m.
3. Pull the cable gently to check that it is fixed securely.
4. Close the cover of the terminal block of the base plate for N-IO I/O.

Connecting cables to spring clamp terminals (A2BN3D-□2□□□)



Follow these steps to connect cables to spring clamp terminals:

1. Open the cover of the terminal block of the base plate for N-IO I/O.
2. Pressingly expand the spring clamp terminal with a flat-blade screwdriver.
3. Insert a cable without pulling out the screwdriver.
4. Pull out the flat-blade screwdriver.
5. Pull the cable gently to check that it is fixed securely.
6. Close the cover of the terminal block of the base plate for N-IO I/O.

Connecting Signal Cables to Terminals (for RIO System Upgrade)

Follow these steps to connect cables to terminanl Block for RIO System Upgrade:

1. Open the terminal block cover.
2. Loosen the terminal screws.
3. Insert the tip of the cable's solderless contact between the screw and the spring retainer, and press the retainer to make a gap of about 2 mm between them.
4. Insert the solderless contact further in the gap until the screw enters in the hole of the solderless contact.
5. Tighten the terminal screw.
6. Close the terminal block cover.

IMPORTANT

- When connecting solderless lug, be sure to clamp its ring only.
- Using non-standard solderless lug may crush its sleeve, causing a connection failure.

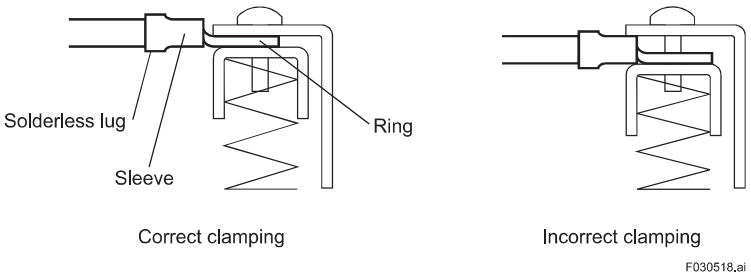


Figure Connect Clamping of Solderless Lug

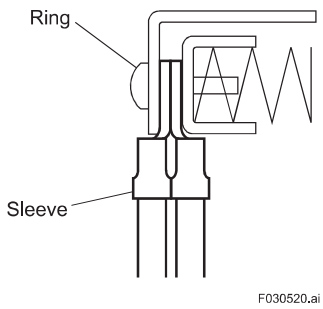

Figure Connecting two cables with single terminal

N-IO Signal Cabling

IMPORTANT

The signal cable for the top IOBP must be wired at the innermost part in the field control area as the figure shows.
When fixing cables to a clamp, allow enough space so that the cards can be maintained.
Bind the bottom cables to the clamp bar on the channel base.

Push in the signal cables for the top IOBP as far as they will go.

NIU: Node Interface Unit (A2NN30D)
IOBP: N-IO I/O Unit

Figure Example of Node Interface Unit and I/O Unit

WARNING

The wiring that will be intrinsic safety circuits must be installed so that they are electrically separated from the wiring of non-intrinsic safety circuits, including the in-cabinet wiring. Install the wiring according to the IEC 60079-14 standards or the requirements for explosion-proof wiring of the country where the system is used.

Connecting external alarm input terminal with Node Interface Unit

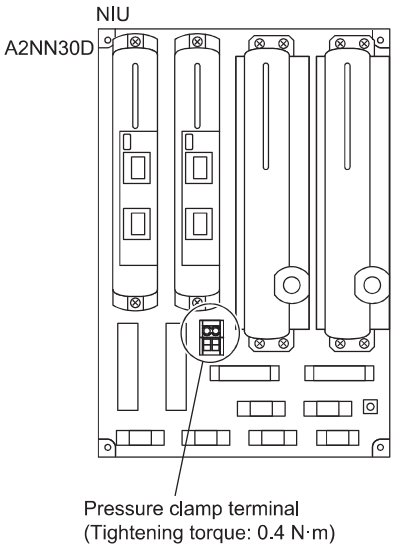

Figure Connecting external alarm input terminal with Node Interface Unit

3.6 Connecting Signal Cables with Fieldnetwork I/O (FIO)

This section describes the signal connections with FIO.

3.6.1 Combination of Fieldnetwork I/O (FIO) and Terminal Blocks

A pressure clamp terminal block or KS cable (also called a “Yokogawa-specific cable”) interface adaptor is available for field-wiring, or an MIL cable provided by the user may be used.

SEE ALSO For the terminal arrangement of the pressure clamp terminals and terminal board, and the pin arrangement of the MIL connector, refer to “Field Connection Specifications (for FIO)” (GS 33J60A20-01EN).

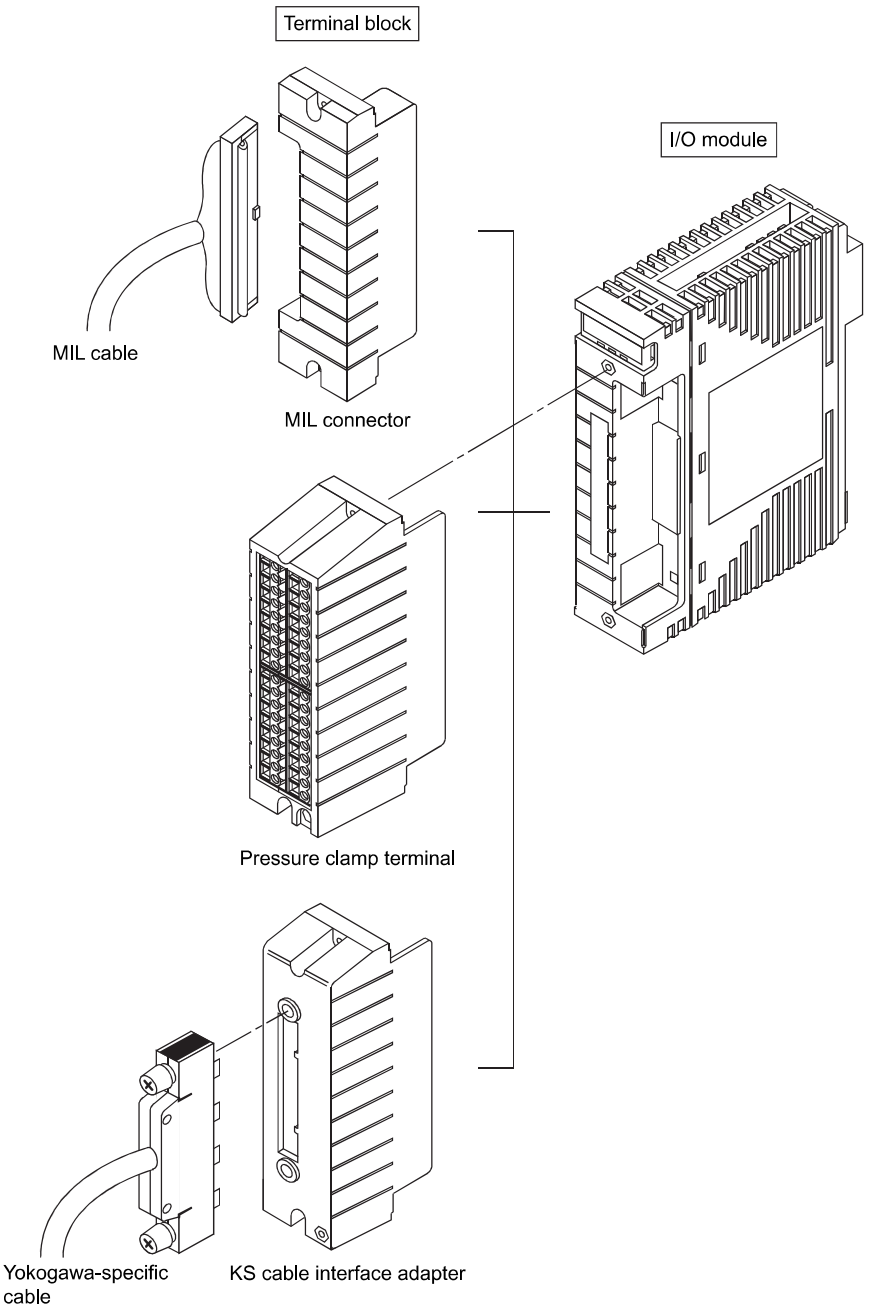

Figure FIO Terminals

3.6.2 List of Signal Cables for Connection with FIO

The following table shows the list of signal cables connections with FIO.

Table Signal Cables for Connection with FIO (1/2)

Module	Name	I/O channels per Module	Connection Signal		
			Pressure Clamp Terminal	Yokogawa-specific Cable (*1)	MIL Cable
Analog I/O Modules					
AAI141	Analog Input Module (4 to 20 mA, Non-Isolated)	16	x	x	x
AAV141	Analog Input Module (1 to 5 V, Non-Isolated)	16	x	x	x
AAB141	Analog Input Module (1 to 5 V / 4 to 20 mA, Non-Isolated)	16	–	x	–
AAI841	Analog I/O Module (4 to 20 mA Input, 4 to 20 mA Output, Non-Isolated)	8 input/8 output	x	x	x
AAB841	Analog I/O Module (1 to 5 V Input, 4 to 20 mA Output, Non-Isolated)	8 input/8 output	x	x	x
AAB842	Analog I/O Module (1 to 5 V / 4 to 20 mA Input, 4 to 20 mA Output, Non-Isolated)	8 input/8 output	–	x	–
AAI143	Analog Input Module (4 to 20 mA, Isolated)	16	x	x	x
AAI543	Analog Output Module (4 to 20 mA, Isolated)	16	x	x	x
AAV144	Analog Input Module (-10 to +10 V, Non-Isolated)	16	x	x	x
AAV544	Analog Output Module (-10 to +10 V, Non-Isolated)	16	x	x	x
AAI135	Analog Input Module (4 to 20 mA, Isolated Channels)	8	x	x	x
AAI835	Analog I/O Module (4 to 20 mA, Isolated Channels)	4 input/4 output	x	x	x
AAT145	TC/mV Input Module (TC: R, J, K, E, T, B, S, N /mV: -100 to 150 mV, Isolated Channels)	16	–	x (*2)	–
AAR145	RTD/POT Input Module (RTD: Pt100 Ω / POT: 0 to 10 kΩ, Isolated Channels)	16	–	x (*2)	–
AAP135	Pulse Input Module (Pulse Count, 0 to 10 kHz, Isolated Channels)	8	x	x	x
AAP149	Pulse Input Module for compatible PM1 (Pulse Count, 0 to 6 kHz, Non-Isolated)	16	–	x	–
AAP849	Pulse Input/Analog Output module for compatible PAC (Pulse Count input, 4 to 20 mA output, Non-Isolated)	8 input/8 output	–	x	–

x : Can be connected.
– : Cannot be connected.
*1: Yokogawa-specific cable for connecting I/O Module and a terminal board, etc.
*2: Can be connected directly with a Yokogawa-specific cable, without a terminal block.

Table Signal Cables for Connection with FIO (2/2)

Module	Name	I/O channels per Module	Connection Signal		
			Pressure Clamp Terminal	Yokogawa-specific Cable (*1)	MIL Cable
Digital I/O Modules					
ADV151	Digital Input Module (24 V DC, 4.1 mA)	32	x	x	x
ADV551	Digital Output Module (24 V DC, 100 mA)	32	x	x	x
ADV161	Digital Input Module (24 V DC, 2.5 mA)	64	–	x (*2)	x
ADV561	Digital Output Module (24 V DC, 100 mA)	64	–	x (*2)	x

A2LP141	PROFINET Communication Module (for N-IO/FIO)	1 port	–	X (RJ-45) (*2)	–
Turbomachinery I/O Modules					
AGS813	Servo Module (Isolated)	12	–	x (*3)	–
AGP813	High Speed Protection Module (Isolated)	26	–	x (*3)	–

x : Can be connected.
– : Cannot be connected.
*1: Yokogawa-specific cable for connecting I/O Module and a terminal board, etc.
*2: Can be connected directly with a Yokogawa-specific cable, without a terminal block.
*3: Available cables are AKB337-M005, M007 and M010.

CAUTION

When connecting a Yokogawa-specific cable to an FIO module, ensure to keep the minimum bending radius of the cable. The minimum bending radius of the Yokogawa specific cable is six-fold of the diameter of the cable.

3.6.3 Connecting Signal Cables with FIO

Pressure Clamp Terminal

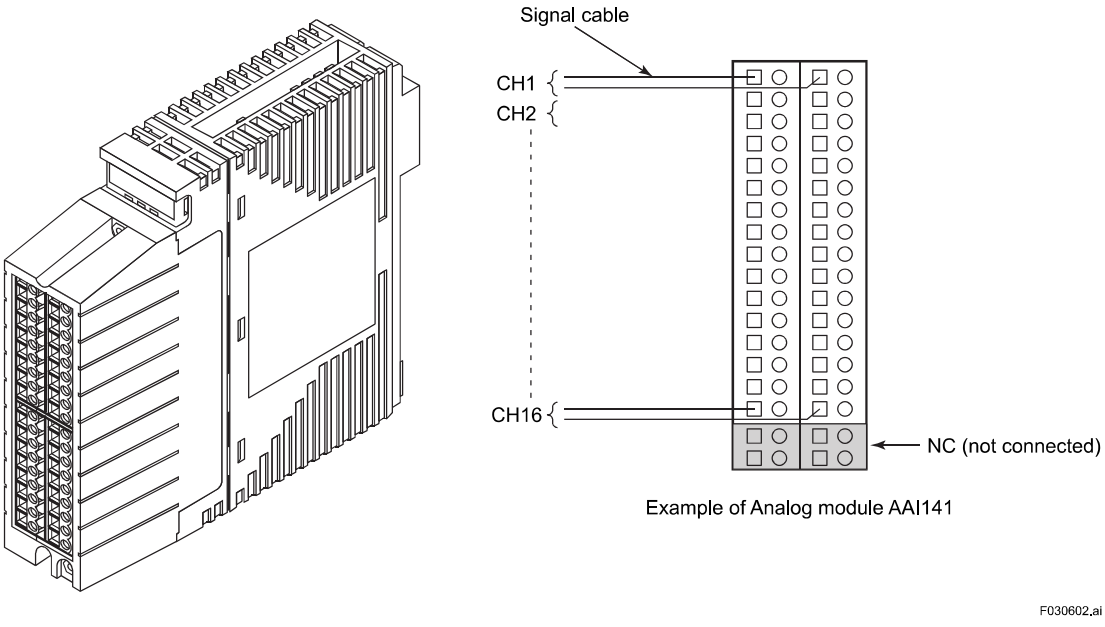

Figure I/O Module with Pressure Clamp Terminal

Dual-redundant Pressure Clamp Terminal

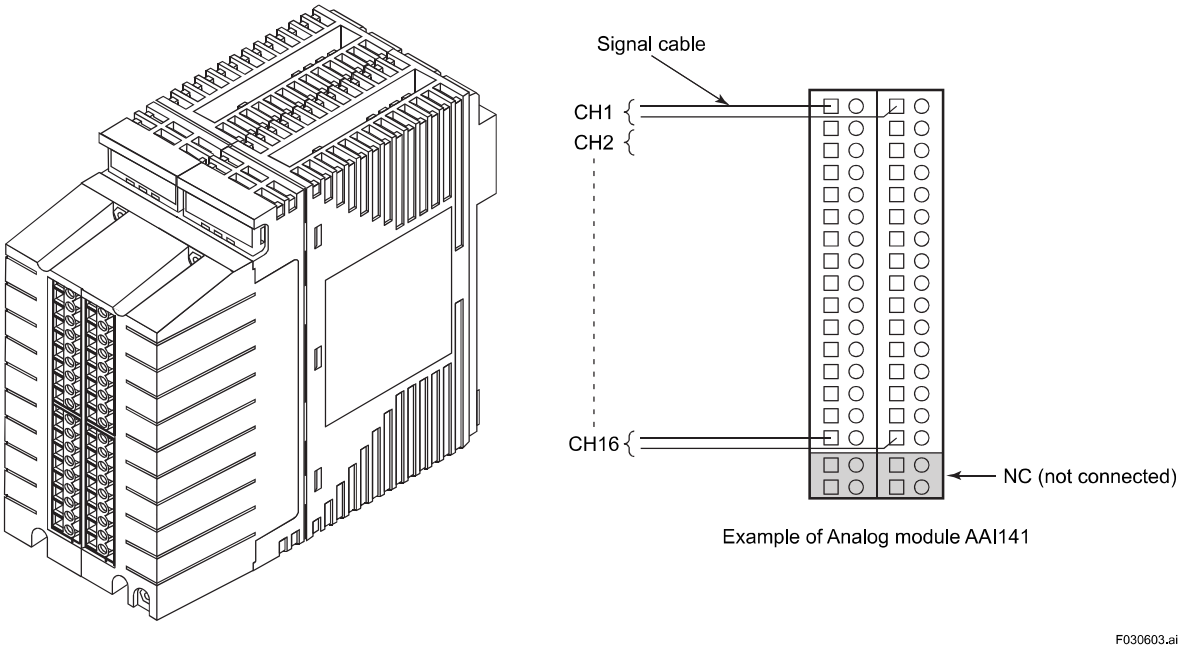

Figure I/O Module with Dual-redundant Pressure Clamp Terminal

KS Cable Interface Adaptor

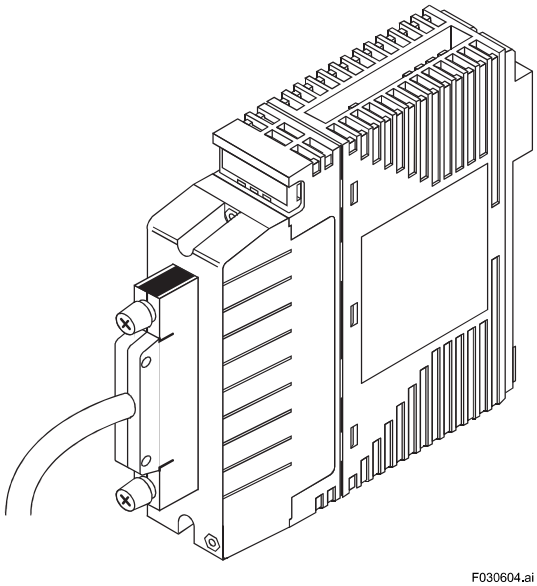

Figure I/O Module with KS Cable Interface Adaptor

The I/O modules are arranged in a dual-redundant configuration on the terminal board.

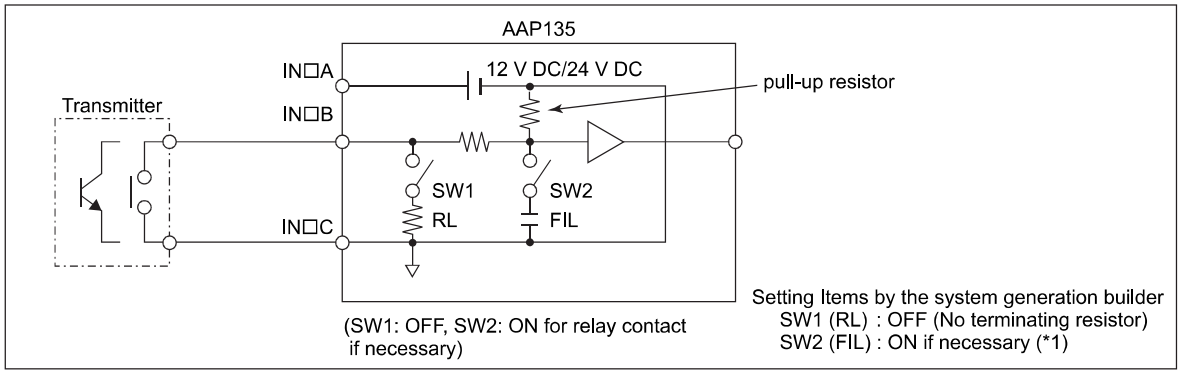
Connecting Signal Cables with Analog I/O Module

Signal cables are connected to different terminals according to the devices to be connected as listed below:

Table Signal Names and I/O Signals of Analog I/O Module

Model Name	Single Name	I/O Signal		
AAI141 AAI841 AAI143	IN☐A	2-wire transmitter input +	Current input -	–
	IN☐B	2-wire transmitter input -	Current input +	
AAI135 AAI835 (*1)	IN☐A	2-wire transmitter input +	–	–
	IN☐B	2-wire transmitter input -	Current input +	
	IN☐C	–	Current input -	
AAR145 (*2)	IN☐A	Resistance temperature detector input A	Potentiometer input, 100%	–
	IN☐B	Resistance temperature detector input B	Potentiometer input, 0%	
	IN☐C	Resistance temperature detector input B	Potentiometer input, variable	
AAP135	IN☐A	2-wire power supply source	–	3-wire power supply source
	IN☐B	2-wire power supply signal	2-wire voltage, contact +	3-wire power supply +
	IN☐C	–	2-wire voltage, contact -	3-wire power supply -

☐ is channel number.
*1: If the power to models AAI141, AAI841, AAI135 and AAI835 is off or abnormal, the current input loop is in the open state. Do not use current signals with other receiving devices. When in use, also use an external receiver resistance in the voltage mode (Shunt resistor module part no. A1080RZ 250 ohm).
*2: Wiring resistance for the signal cables of IN☐A and IN☐B must be identical.



Connecting Signal Cables with Pulse Input Module AAP135

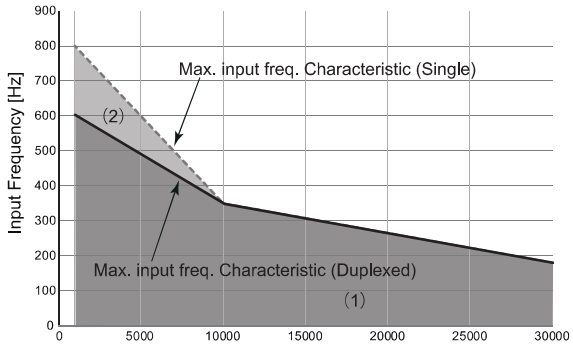
The AAP135 receives contact ON/OFF, voltage pulse and current pulse. Refer to the figures below for details on how to connect signal cables since the items to be set by the system generation builder depend on the input pulse types.

When Receiving No-Voltage Contact Signals (1)

For the relay contacts or transistor contacts, connect as follows.

Pulse input frequency should be 0 to 800 Hz. Max. frequency differs due to the wiring effect, etc.

F030605.ai



*1: When there is a chattering noise at a mechanical relay, set the SW2 to ON to eliminate the noise.

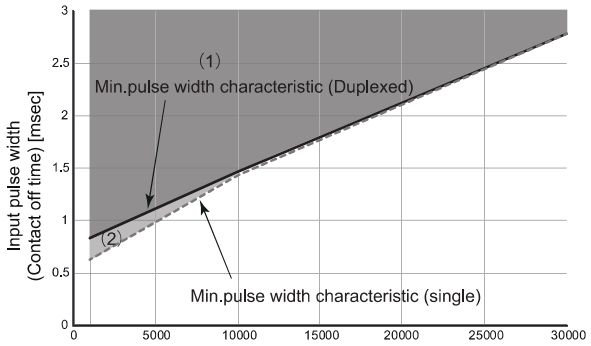


Figure No-Voltage contact Input (1)

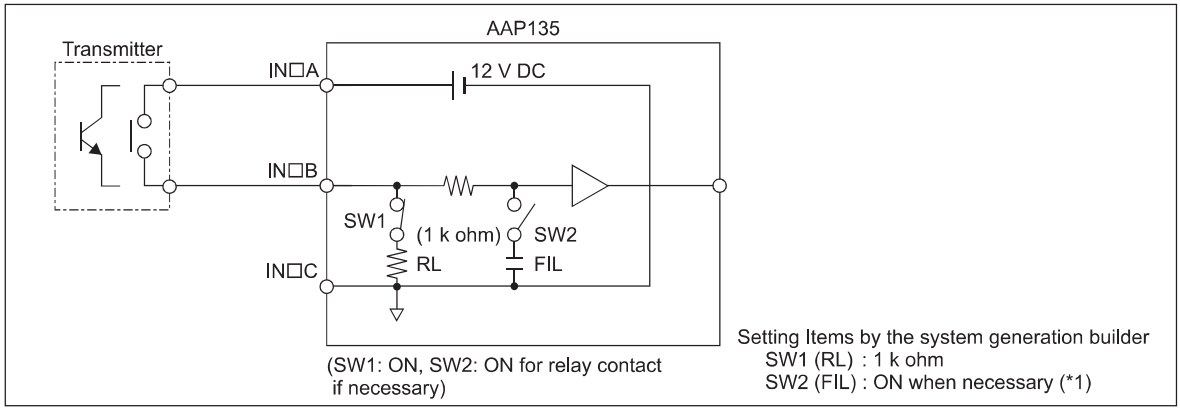
A receivable maximum frequency and minimum pulse width of AAP135 depend on redundancy configuration of AAP135.

Table Receivable minimum pulse width (when synthetic capacity of connected wiring and transmitter is less or equal than 1000 pF)

I/O module redundancy	Input frequency	Minimum input pulse width (Contact off time)
Single	0 to 800 Hz	625 µs
Duplexed	0 to 600 Hz	833 µs

	I/O module redundancy	
Area	Single	Duplexed
(1)	Receivable	Receivable
(2)	Receivable	Not receivable



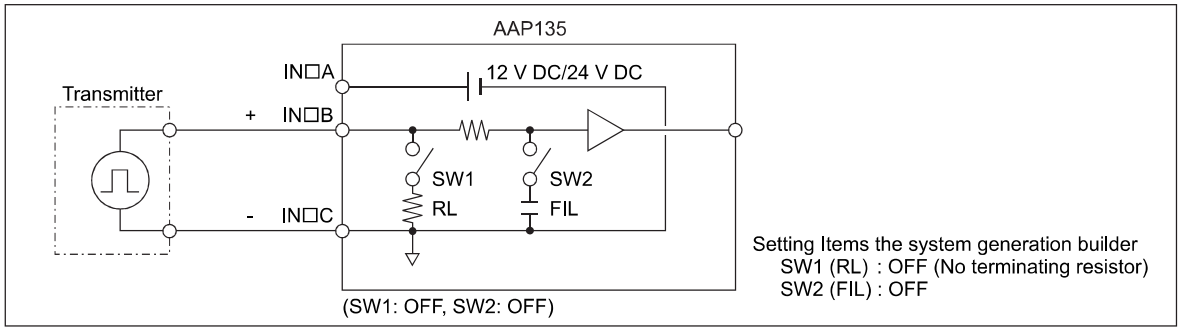
F030617.ai

Figure Receivable minimum pulse width (when synthetic capacity of connected wiring and transmitter is more than 1000pF)

When Receiving No-Voltage Contact Signals (2)

Carry out connection as follows if a current is needed to flow to the relay contacts or transistor contacts.

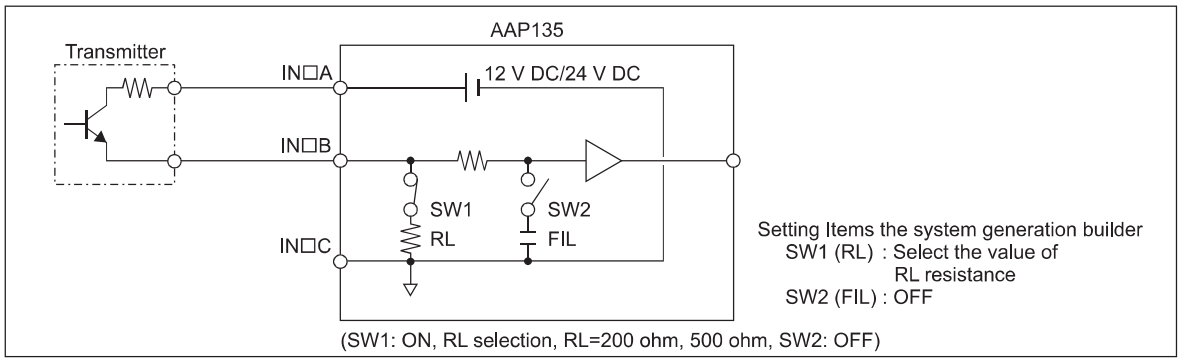
When receiving transistor contact signal of more than 800 Hz frequency, connect as follows.



F030606.ai

*1: When there is a chattering noise at a mechanical relay, set the SW2 to ON to eliminate the noise.

Figure No-Voltage contact Input (2)



When Receiving Voltage Pulse Signals

F030607.ai

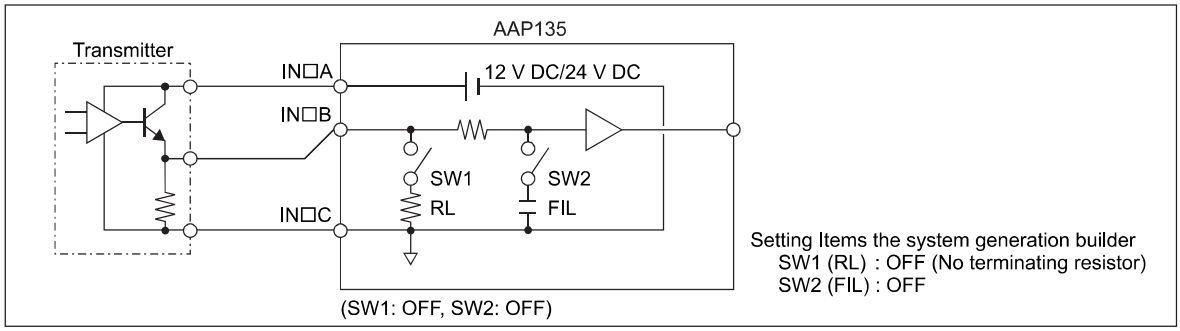
When Receiving Current Pulse By Using the Internal Power to Drive the Transmitter (2-wire power supply type)



F030608.ai

Figure 2-Wire Power Supply Type

This method supplies power to the transmitter, and receives the transmitter output signals as the current pulse signals. By using the input load resistance (select from None, 200 ohm, 500 ohm), the current signal is converted to the voltage level pulse and receives it.

When Receiving Voltage Pulse By Using the Internal Power to Drive the Transmitter (3-wire power supply type)

F030609.ai

Figure 3-Wire Power Supply Type

Connecting Terminal Board with FIO

The I/O module equipped with a KS cable interface adaptor can be connected to the terminal board using a Yokogawa-specific cable. Field signals are connected using the terminal board.

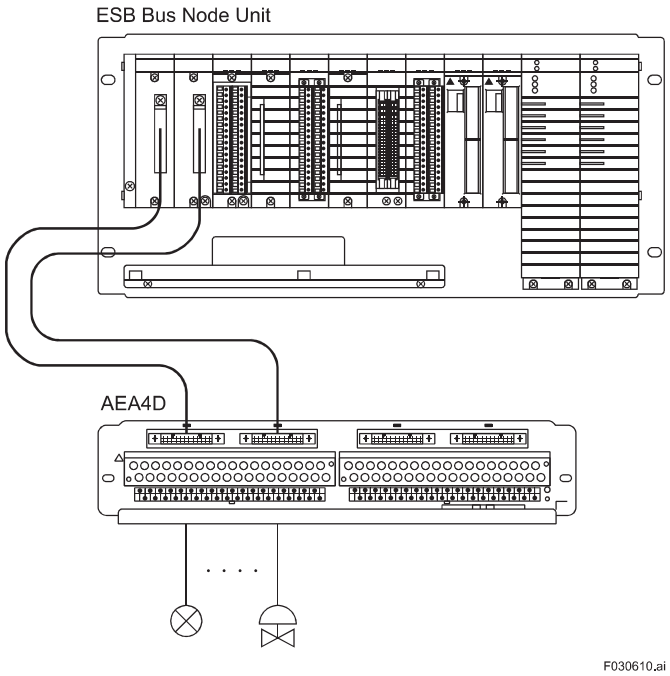


Figure Example of Terminal Board Connection with Dual-redundant I/O Module

SEE ALSO For details of the KS cable interface adaptor model and the cable model, refer to “Field Connection Specifications (for FIO)” (GS 33M50H10-40E).

Connecting Relay Board with Digital I/O Module

An example of the connection of the mechanical relay board ARM55D with the Digital I/O Module ADV551 is shown below.

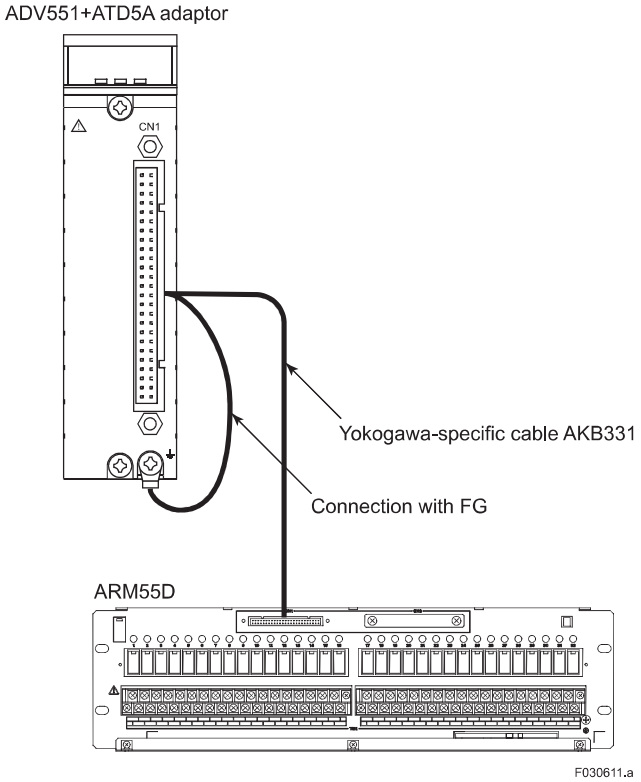

Figure Example of Relay Board Connection with Digital I/O Module

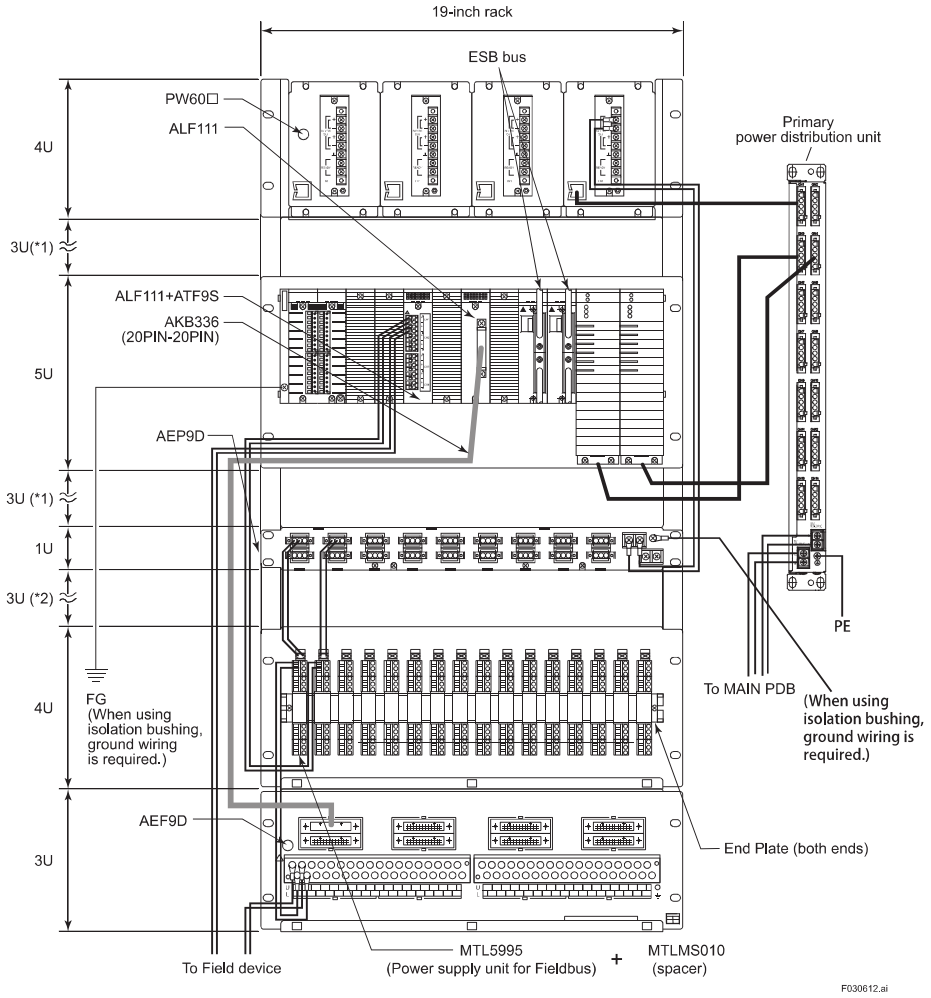
3.6.4 Implementation and Cable Connection of Fieldbus Communication Module ALF111

This section describes the implementation and cable connection of the Foundation Fieldbus Communication Module ALF111.



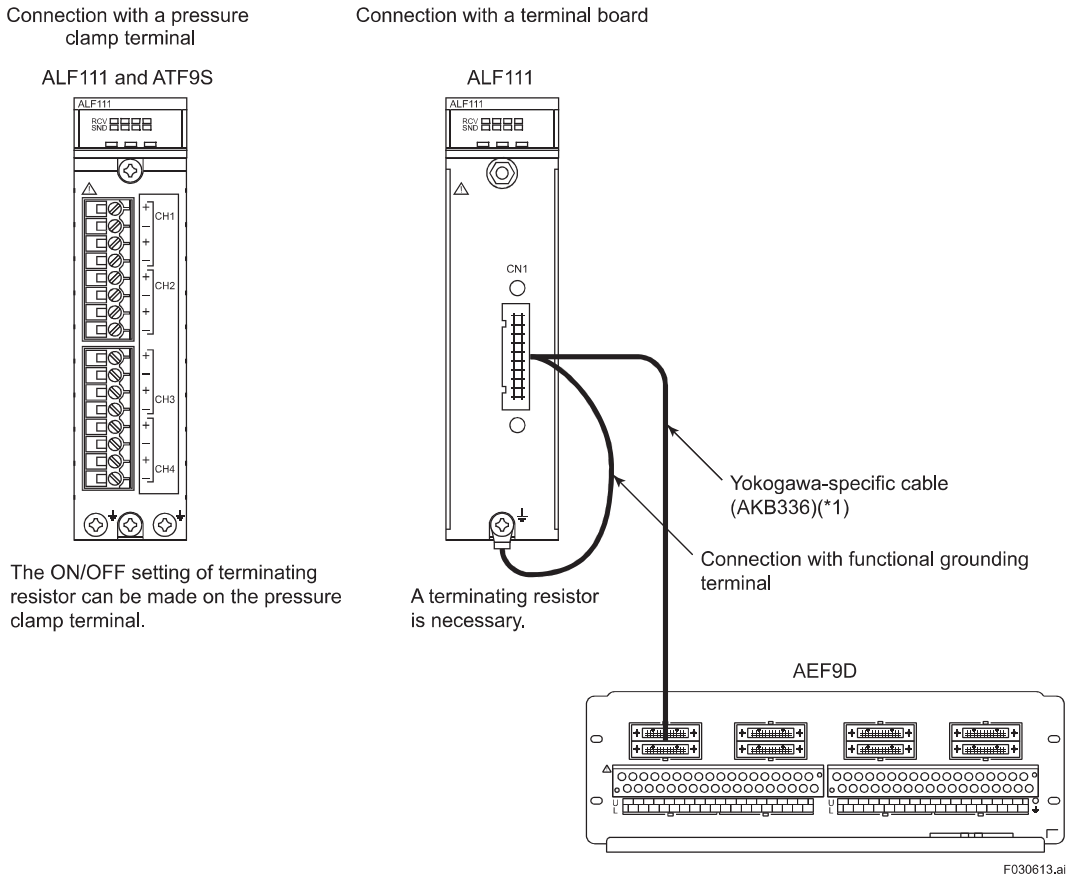
Foundation fieldbus H1 (Low Speed Voltage Mode) is called Foundation fieldbus, Fieldbus, H1 Fieldbus, FF, or FF-H1 in this manual.

Example of Implementation of Fieldbus Communication Module ALF111

To connect Fieldbus using the ALF111, the power supply unit for the Fieldbus must be prepared as shown below.

The example of the implementation and the wiring of the ALF111 is shown below.

For the implementation of the ALF111 and the relevant devices, follow the implementation conditions for the devices. 1 U (unit) = 44.45 mm.



*1: Reserve a space of 3U for heat radiation.
*2: Reserve a space of 3U for heat radiation and wiring.

Figure Example of ALF111 Implementation

Connection of Fieldbus Communication Module ALF111

The Fieldbus can be connected by attaching a pressure clamp terminal block or by using a Yokogawa-specific cable for connection to the terminal board (M4 screw).

*1: If Type A cables are used for Fieldbus wiring, double the length of the AKB336 cable and include its length in with the total length of the branch cables. Keep the trunk cable length (trunk line cable length) within 1900 m (total branch length).

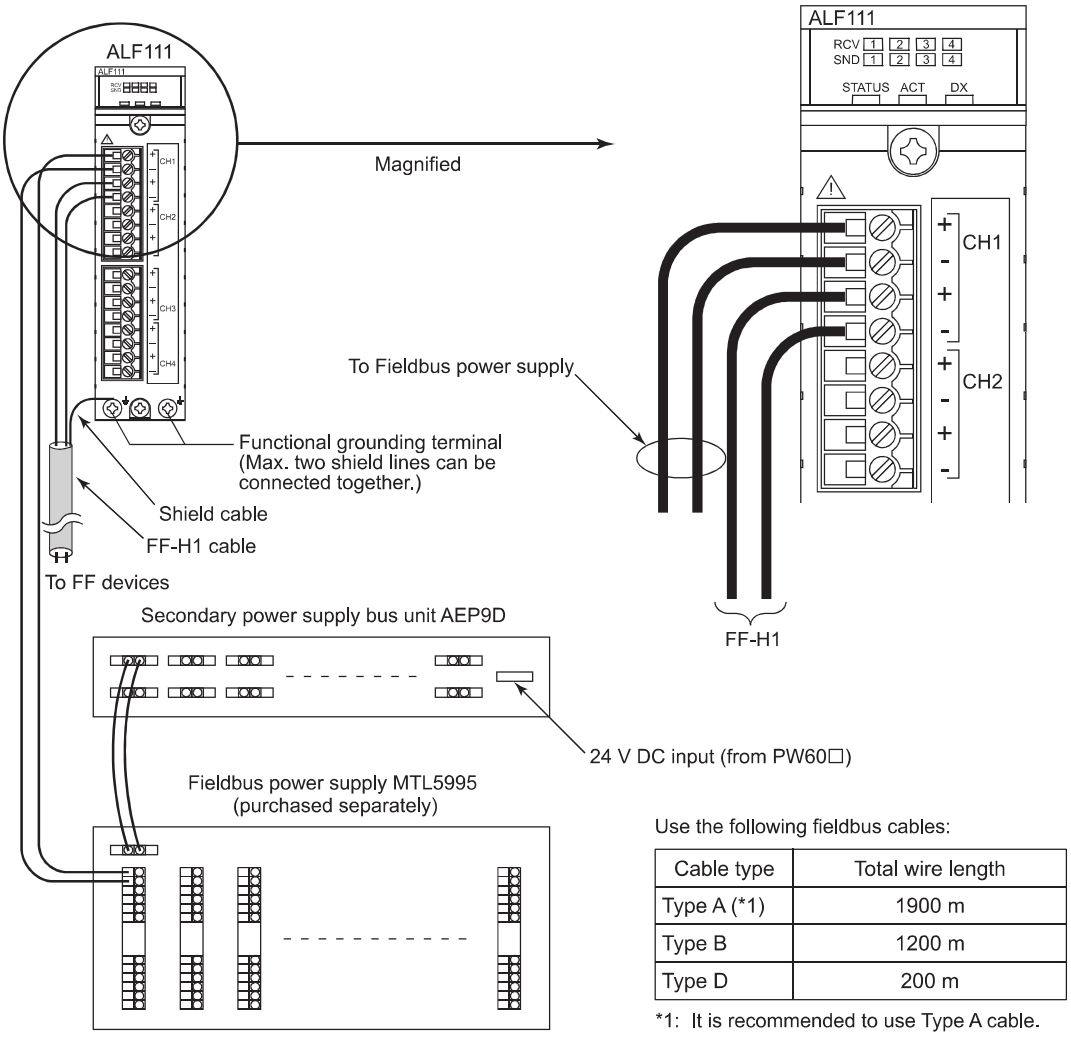
Figure Fieldbus Wiring for ALF111

SEE ALSO For details of the Fieldbus connection and wiring work, refer to “Fieldbus Technical Information” (TI 38K03A01-01E).

Fieldbus Wiring for ALF111 with Pressure Clamp Terminal Block

The signal cables from the field device should be connected to the + and - terminals of the pressure clamp terminal block (ATF9S). (*1)

*1: Tightening torque: 0.4 (N•m)



Do not connect anything to the terminals of channels that are not used.

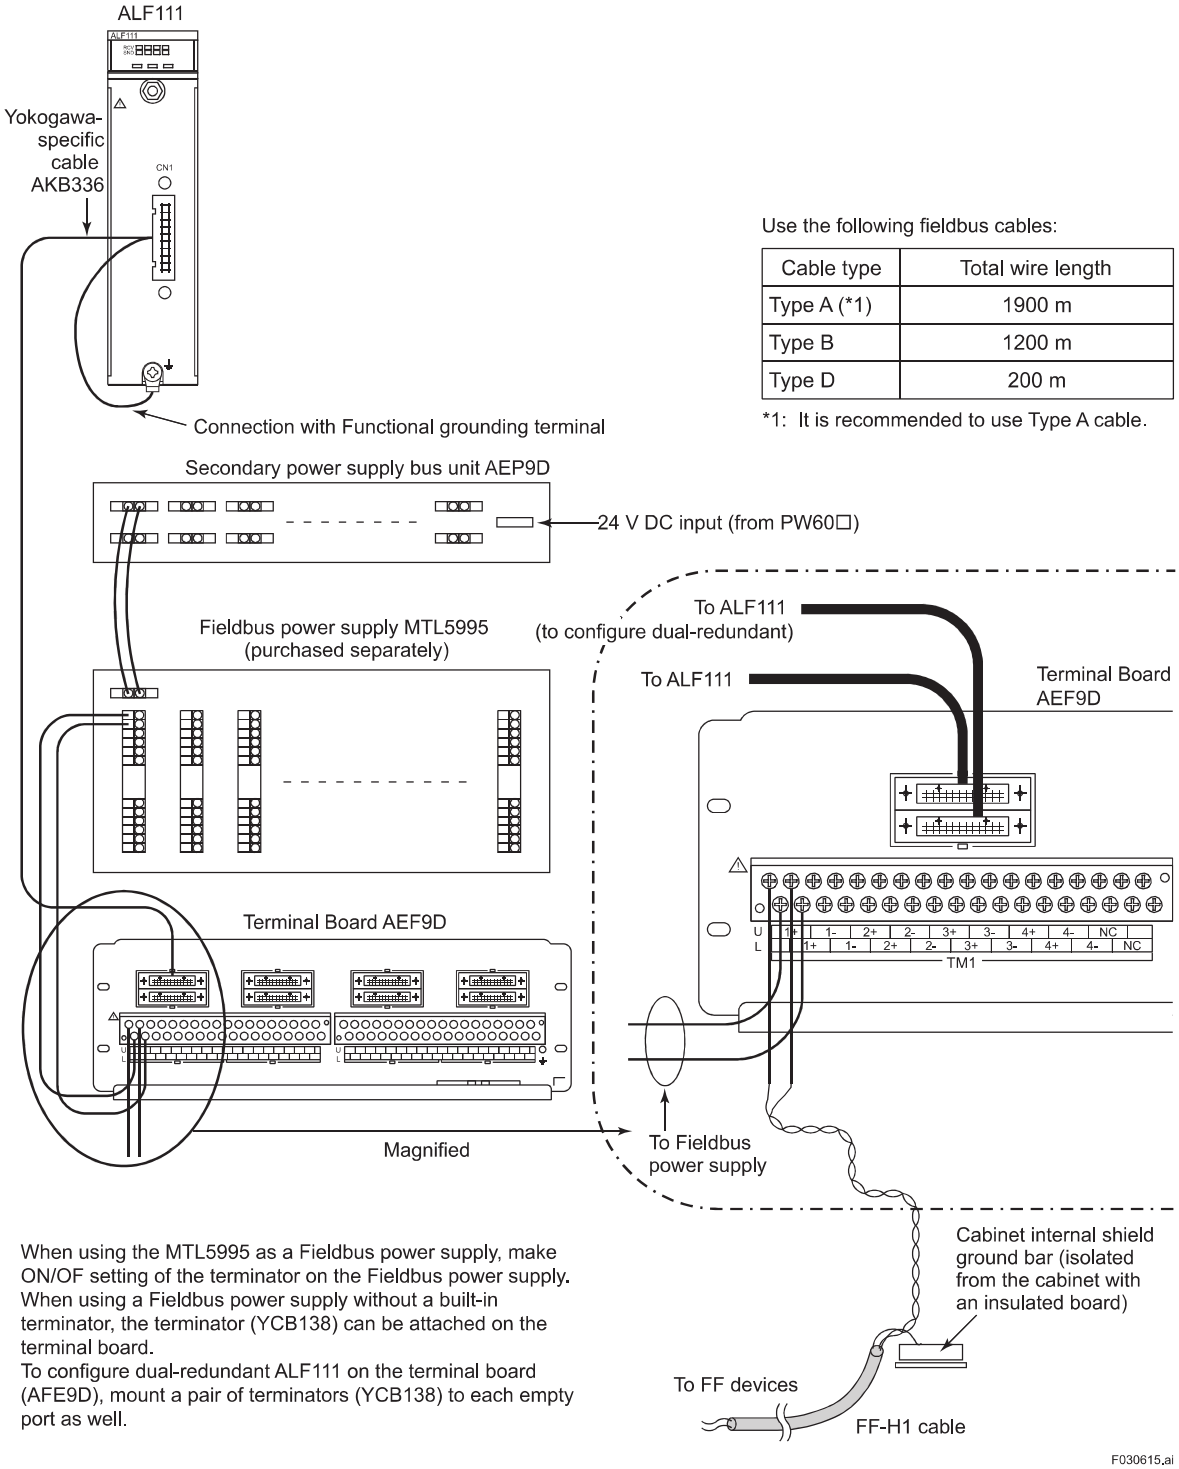
When installing the node unit mounted with the ALF111 on the 19-inch rack, connect the shield lines of Fieldbus cables from the field devices to the Functional grounding terminal of the ATF9S. If two or more channels are used, no more than two shield lines can be connected to one Functional grounding terminal.

When installing the node unit mounted with the ALF111 in the control station cabinet, connect the shield lines of Fieldbus cables to the shield ground bar within the cabinet (insulated from the cabinet itself), not to the Functional grounding terminal of the ATF9S.

The length of the connection cable between the power supply unit and the ALF111 should be less than one meter. Use a type A cable and connect the cable shield to the same potential as the Functional grounding terminal of the node if the cable length exceeds one meter.

Note that, when installing wiring within the cabinet, the shield line should be connected to the shield ground bar within the cabinet as well. For details about example of wiring, see section 3.7.11.

Use the following fieldbus cables:



Cable type	Total wire length
Type A (*1)	1900 m
Type B	1200 m
Type D	200 m

*1: It is recommended to use Type A cable.

F030614.ai

Figure Fieldbus Wiring for ALF111 with Pressure Clamp Terminal

Fieldbus Wiring for ALF111 with Terminal Board

Use the following fieldbus cables:

Cable type	Total wire length
Type A (*1)	1900 m
Type B	1200 m
Type D	200 m

*1: It is recommended to use Type A cable.

When using the MTL5995 as a Fieldbus power supply, make ON/OF setting of the terminator on the Fieldbus power supply. When using a Fieldbus power supply without a built-in terminator, the terminator (YCB138) can be attached on the terminal board.
To configure dual-redundant ALF111 on the terminal board (AFE9D), mount a pair of terminators (YCB138) to each empty port as well.

Figure Fieldbus Wiring for ALF111 with Terminal Board

Installation of Terminator to Terminal Board AEF9D

Make sure to install a terminator (YCB138) if the ALF111 (terminal board AEF9D) terminates the network, in other words, if the network is not terminated by a terminator in the power supply unit.

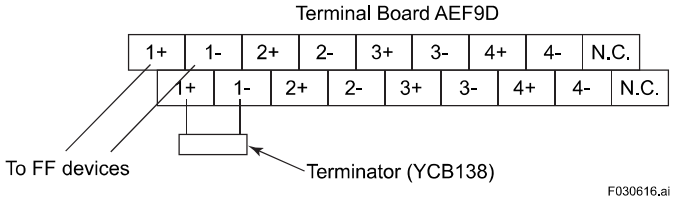


Figure Installation of Terminator to Terminal Board AEF9D

IMPORTANT

In the following condition, the vacant port should be terminated with a pair of terminators: The AEF9D terminal board is used, the ALF111 is in a dual-redundant configuration, and any of the four ports is vacant.

3.7 Signal Connections of N-IO I/O Unit

This section describes connecting to the N-IO I/O unit.

3.7.1 N-IO I/O Unit Types

I/O Modules that can be used with Base Plate

The following table shows I/O Modules installable with Base Plate.

Table I/O Modules Installable with Base Plate

Base plate model	Description	I/O module model
A2BN3D	Base Plate for Adaptor	A2MMM843 Analog Digital I/O Module
A2BN4D	Base Plate for Barrier (MTL)	
A2BN5D	Base Plate for Barrier (P+F)	
A2BN3D	Base Plate for Adaptor	A2MDV843 Digital I/O Module
A2BN4D	Base Plate for Barrier (MTL)	
A2BN5D	Base Plate for Barrier (P+F)	

3.7.2 Base Plate for Adaptor

Adaptors Installable with Base Plate for Adaptor

The following table shows adaptors installable with A2BN3D Base Plate for Adaptor.

Table Adaptors Installable with A2BN3D Base Plate for Adaptor

Base plate model	Compatible adaptor models
A2BN3D (Base Plate for Adaptor)	A2SAP105 Pulse Input Signal Adaptor
	A2SDV105 Digital Input Adaptor
	A2SDV505 Digital Output Adaptor
	A2SDV506 Relay Output Adaptor
	A2SMX801 Pass-through I/O signal Adaptor
	A2SAM105 Current Input/Voltage Input Adaptor
	A2SAM505 Current Output/Voltage Output Adaptor
	A2SAT105 mV/TC/RTD input Adaptor
	A2SMX802 Pass-through I/O Signal Adaptor

Terminal type that can be select with Base Plate for Adaptor

The following table shows terminal types can be select with A2BN3D Base Plate for Adaptor.

Table Terminal type Compatible with A2BN3D Base Plate for Adaptor

Base plate model	Suffix code	Terminal type
A2BN3D (Base Plate for Adaptor)	-□1□□□	Pressure clamp terminal
	-□2□□□	Spring clamp terminal

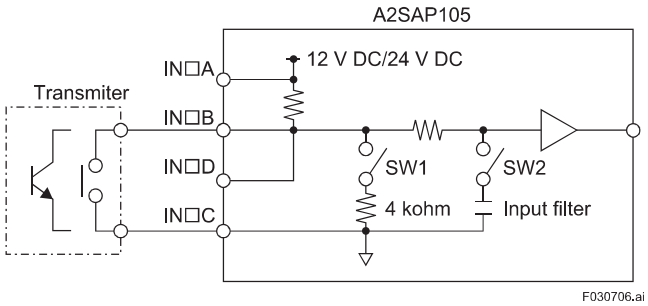
*1: □ = 1 to 16
Terminal-A, B, C, and D are for A2BN3D-□1□□□,-□2□□□.
Terminal-A, B, and C are for A2BN3D-□9□□□. (Terminal-D is unused for A2BN3D-□9□□□.)
*2: "—" denotes that the terminal is not used. Do not connect any signal because the terminal is connected to internal circuits.
*3: This adaptor can be used in combination with the A2MMM843 only.
*4: When the power supply is turned off or overcurrent is detected, the current input loop enters a high impedance state.
*5: Used when the input frequency is 0 to 5 kHz.
*6: Used when the input frequency is 0 to 10 kHz.
*7: Used when the input frequency is 0 to 800 Hz.
*8: The resistance values of the connecting cables must match.
*9: Connect the field power supply to the base plate.
*10: Normal state, the status output is OFF.
*11: The signal type is set by software.
*12: In the internal circuit, terminals B and D have a common potential.
*13: A2SAT105 is available for A2BN3D-□1□□□,-□2□□□. (Unavailable for A2BN3D-□9□□□)

IMPORTANT

The pass-through I/O signals adaptor A2SMX802 is not isolated from the pass-through I/O signal adaptor A2SMX801,digital output adaptor that are mounted on the same base plate for adaptor.



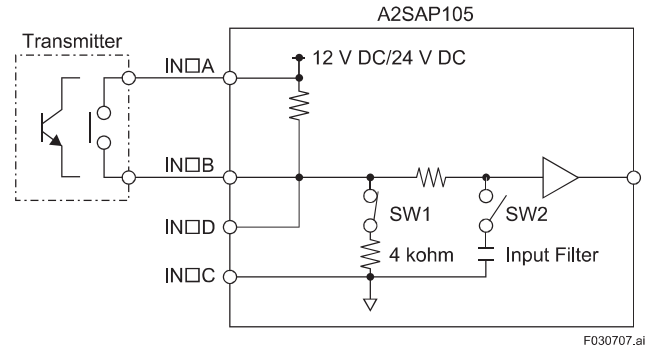
3.7.3 Adaptors (for A2BN3D)

A2SAP105 Pulse Input Signal Adaptor

When the pulse input signal adaptor is used, signal connections to the base plate and shunt resistor usage depend on the type of the pulse signal that is input. When receiving dry contact signals, you can remove mechanical chattering noise by selecting the pulse input filtering option in the IOM builder. However, the input filter passes a limited range of frequencies.
When connecting the field signal via the terminal board (A2BM4), the terminal-A, B, and C can be used for the following circuit diagrams but the terminal-D cannot be used.

When receiving dry contact signals (Input frequency: 0 to 800 Hz)

Select “Without Shunt Resistor” (SW1: OFF) in the IOM builder.
The following figure shows the circuit diagram.

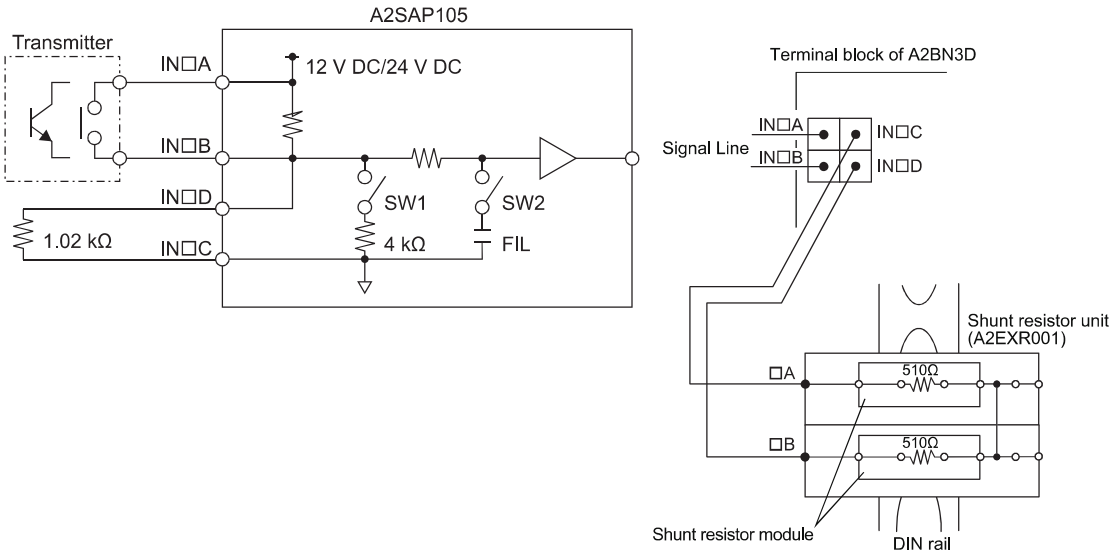


□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 800 Hz)

When receiving dry contact signals (Input frequency: 0 to 5 kHz)

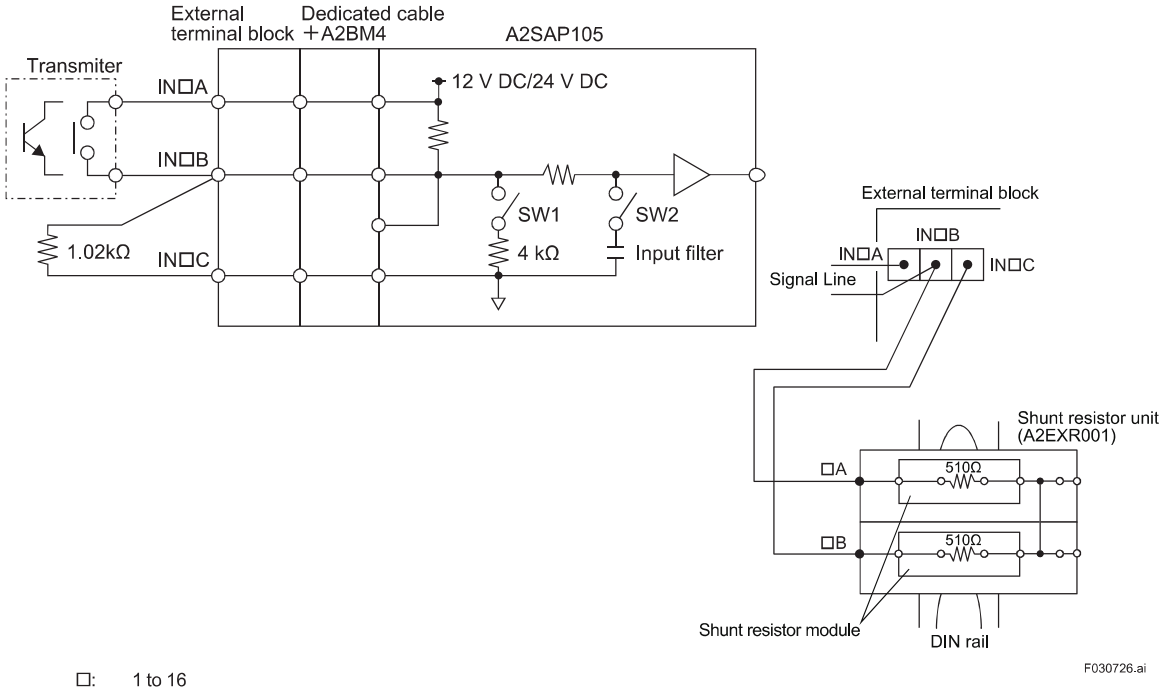
Select “Shunt Resistor 4000 ohm” (SW1: ON) in the IOM builder.
The following figure shows the circuit diagram.



□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 5 kHz)

When receiving dry contact signals (Input frequency: 0 to 10 kHz)



Select “Without Shunt Resistor” (SW1: OFF) in the IOM builder. Also install two 510 Ω shunt resistor modules on the shunt resistor unit (Model:A2EXR001). The total resistance value will be 1.02 kΩ.
When connecting the field signal via the terminal board (A2BM4), it can be substituted by connecting a shunt resistor unit between terminal-B and C of the external terminal block.
The following figure shows the circuit diagram.

Direct field wiring to base plate

□: 1 to 16

Field wiring via terminal board

□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 10 kHz)

• Shunt Resistor Unit (A2EXR001)

SEE ALSO For more information about the specifications of A2EXR001, refer to :I/O Adaptors (for N-IO) (GS 33J62F30-01EN)

The shunt resistor unit (Model: A2EXR001) converts the current signals of the internal circuit of the pulse input signal adaptor into voltage signals and is capable of converting four points of signals. It is used when receiving dry contact signal inputs with 0 to 10 kHz input frequencies or current pulse signal inputs.

Structure and parts of the shunt resistor unit

The shunt resistor unit has terminal blocks with either pressure clamp terminals or spring clamp terminals.

The following figure shows the structure and parts of the shunt resistor unit, using an example of the model with pressure clamp terminal-type terminal blocks.

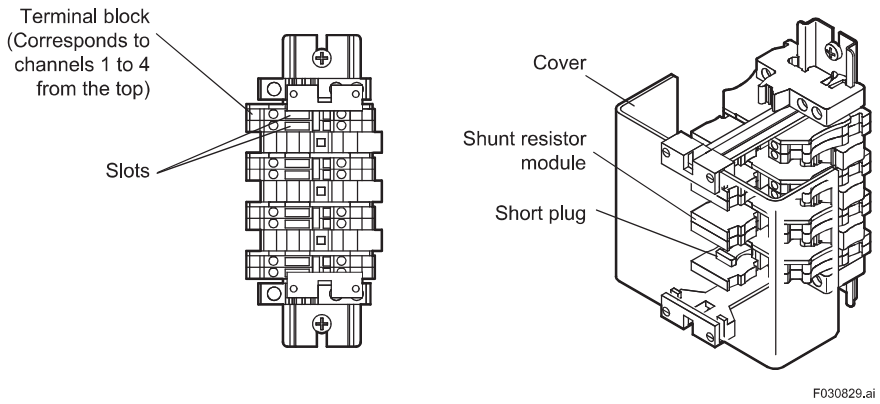


Figure Shunt resistor unit

The shunt resistor unit has terminal blocks for channel numbers 1 to 4. Each terminal block is provided with two slots that are used to install a shunt resistor module or a short plug. Short plugs are installed on these slots when the unit is shipped from the factory. The shunt resistor modules are accessories.

Installation and wiring for the shunt resistor unit

Install A2EXR001 at least 200 mm away from edge of the IOBP.
A2EXR001 should be installed with the distance of 30mm or more from other heat source.

CAUTION

Handle an shunt resistor module in A2EXR001 with care as it may become high in temperature. Use a cover to prevent from touching the resistor directly to avoid being burned.

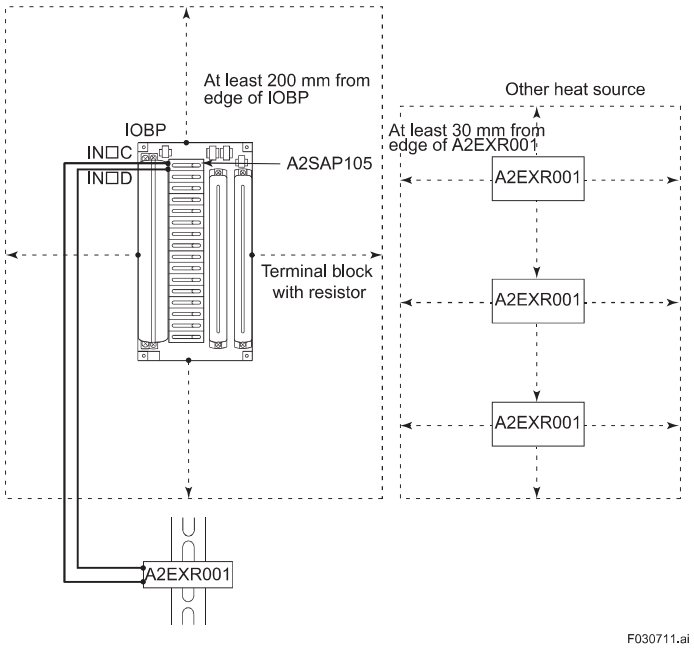

Figure Distance to Separate A2EXR001 and IOBP

Installing the shunt resistor unit

The following figure shows how to install the shunt resistor unit on the inner wall surface of the cabinet.

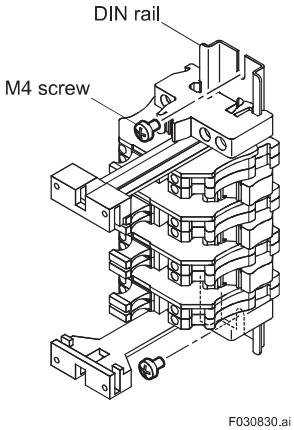

Figure Installing the shunt resistor unit on the wall

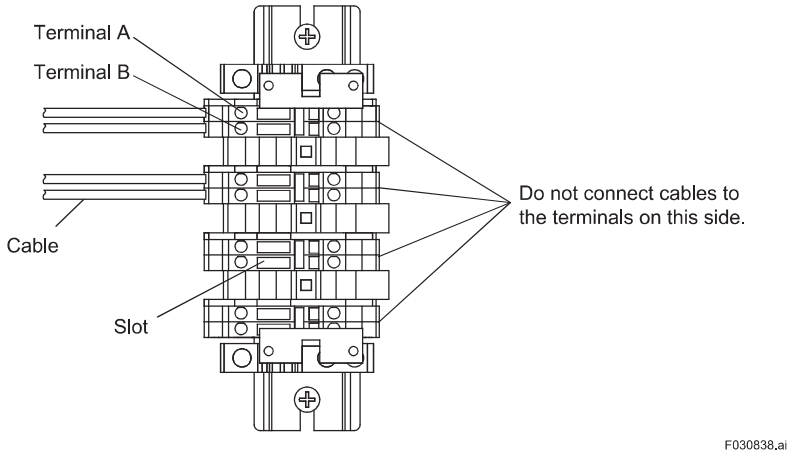
Using two M4 screws, fix the DIN rail of the shunt resistor unit on the wall.
The M4 screws are accessories.

Wiring for the shunt resistor unit

Connect the signal cables to the shunt resistor unit for the required number of signals.
The following figure shows the cable connections to the shunt resistor unit.



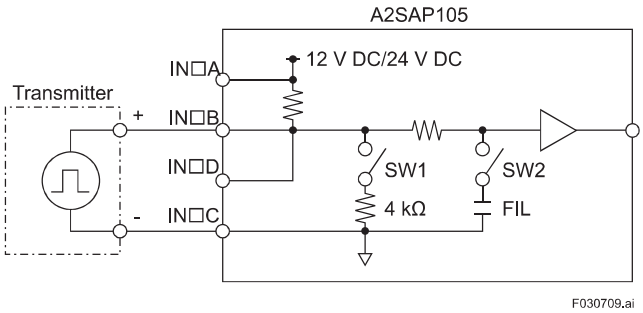


Figure Cable connections to the shunt resistor unit

When receiving voltage pulse signals

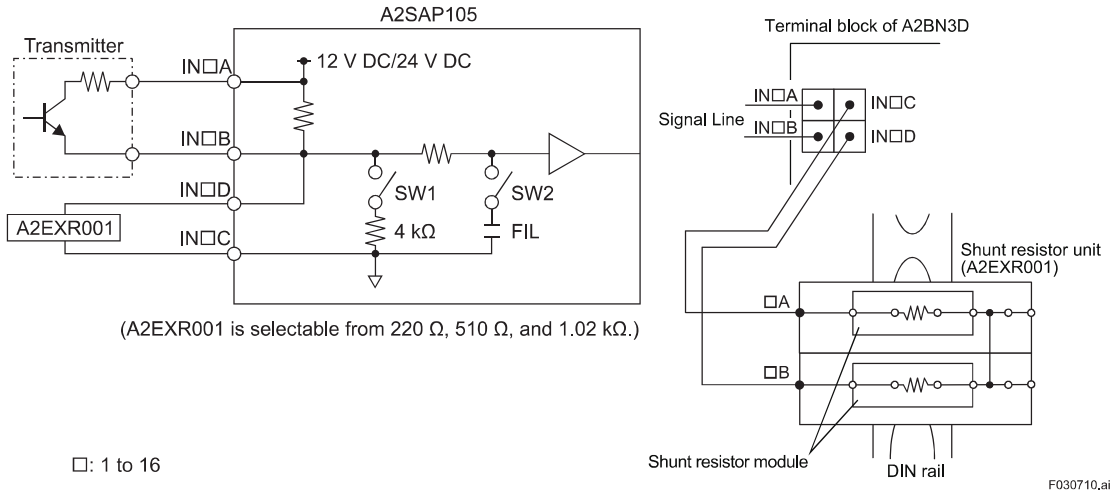
In the IOM builder, select “Without Shunt Resistor” (SW1: OFF) and clear the “Input Filtering” (SW2: OFF) option.

The following figure shows the circuit diagram.

□: 1 to 16

Figure When Receiving Voltage Pulse Signals

When receiving current pulse signals (2-wire power supply type)



According to the input signal level, connect the shunt resistor unit (A2EXR001) of which resistor value is selected by the combination of the shunt resistor module and short plug. The resistor value of A2EXR001 can be selected to the following values.

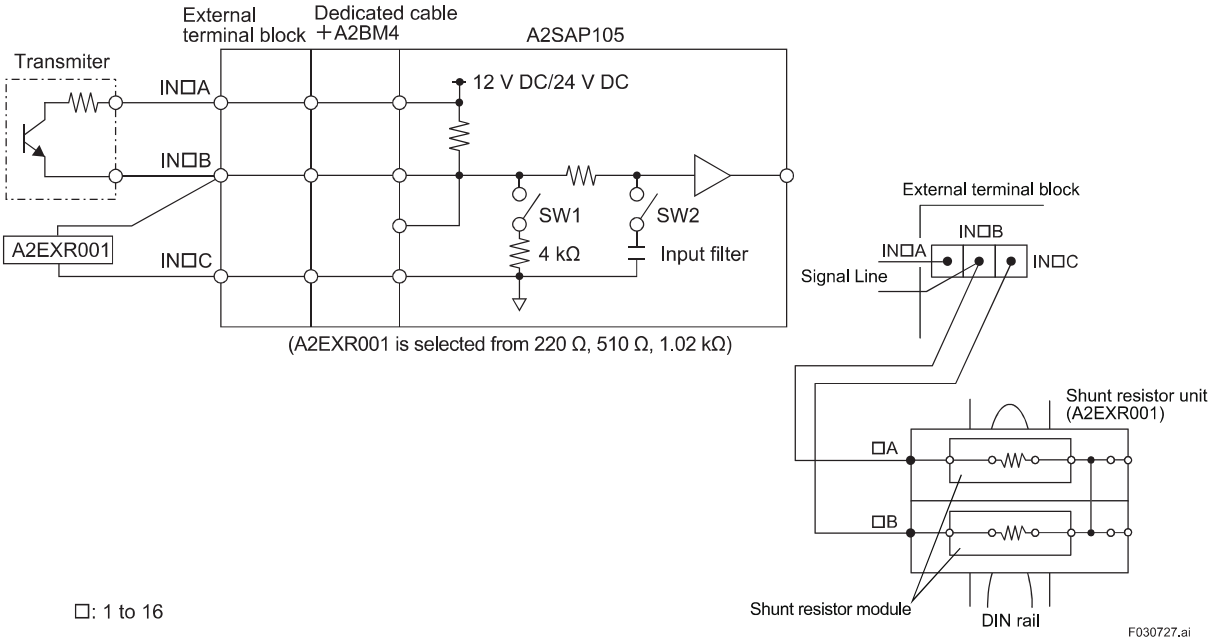
- 220 Ω
- 510 Ω
- 1.02 kΩ

In the IOM builder, select "Without Shunt Resistor" (SW1: OFF) and clear the "Input Filtering" (SW2: OFF) option.When connecting the field via the terminal board (A2BM4), it can be substituted by connecting a shunt resistor unit between terminal-B and C on the external terminal block.

The following figure shows the circuit diagram.

Direct field wiring to base plate

Field wiring via terminal board



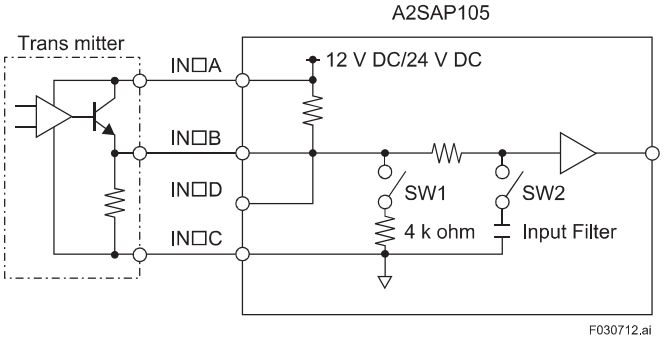


Figure When receiving current pulse signals (2-wire power supply type)

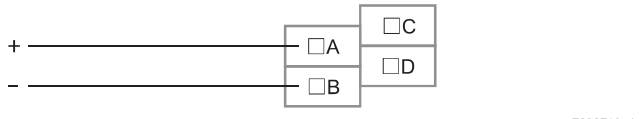
When receiving voltage pulse signals by using the internal power to drive the transmitter (3-wire power supply type)

In the IOM builder, select “Without Shunt Resistor” (SW1: OFF) and clear the “Input Filtering” (SW2: OFF) option.

The following figure shows the circuit diagram.



□: 1 to 16

Figure When receiving voltage pulse signals by using the internal power to drive the transmitter (3-wire power supply type)

A2SAM105 Current input/voltage input adaptor

□: 1 to 16

Figure when using the current input/voltage input adaptor

A2SAT105 mV/TC/RTD input adaptor

The following figure shows the signal wiring when using the mV/TC/RTD input adaptor A2SAT105 is unavailable for A2BN3D-□9□□□.

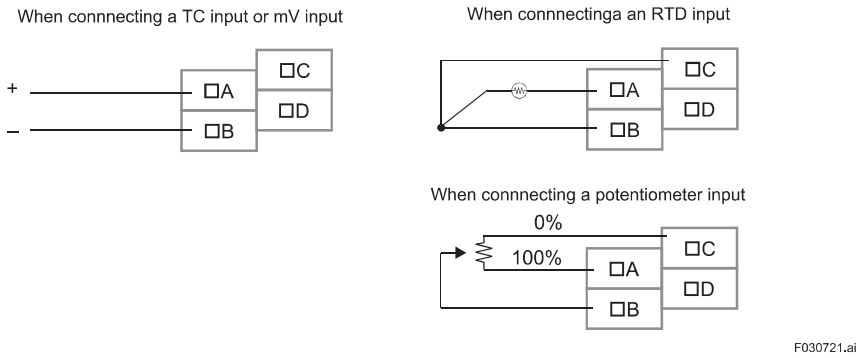

Figure When using the mv/TC/RTD input adaptor

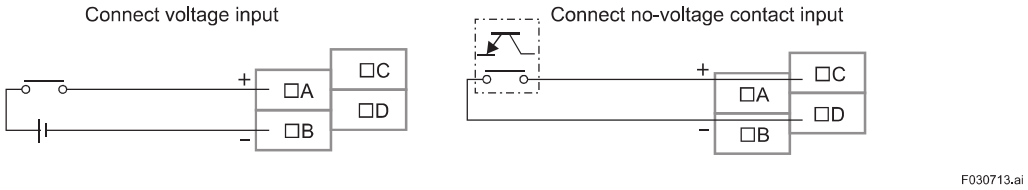


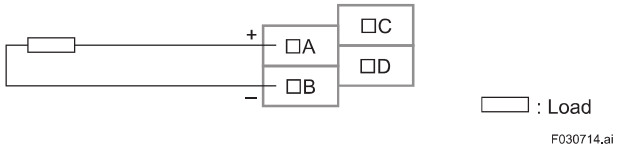
For thermocouple signalinput,mountthemV/TC/RTD input adaptor on the base plate for adaptor with RJC.

SEE ALSO For more information about the types of TC and RTD that can be connected to the mV/TC/RTD input adaptor and the standards they must conform to, refer to:
"I/O Adaptors (for N-IO)" (GS 33J62F30-01EN).

A2SDV105 Digital input adaptor

The following figure shows the signal wiring for the base plate when you use the digital input adaptor. The dry contact input is not supported for A2BN3D-□9□□□. For the dry contact input, it is necessary to change the adaptor to A2SMX801 and set the DI mode by software for the connection between terminal-A and B. In that case, it becomes non-isolated from an I/O module.

If you connect a dry contact input, connect the field power supply to the base plate.



□: 1 to 16

Figure When Using the digital Input Adaptor

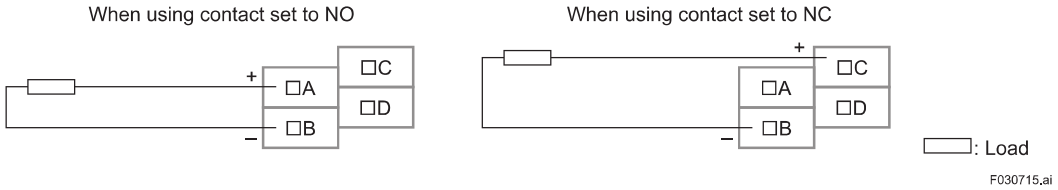
A2SDV505 Digital output adaptor

The following figure shows the signal wiring to the base plate when you use the digital output adaptor.

When you use the digital output adaptor, connect the field power supply to the base plate.

□: 1 to 16

Figure When Using the digital output adaptor



IMPORTANT

When you connect an inductive load, connect a diode in parallel with the load.

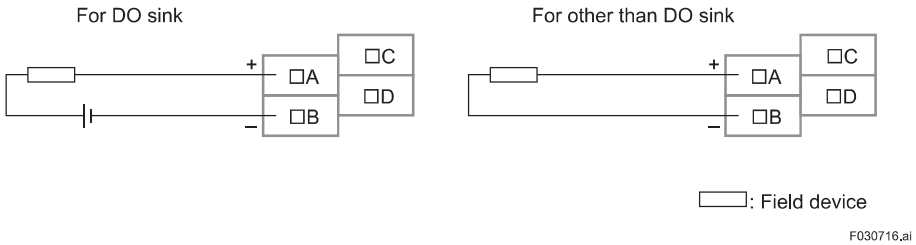
A2SDV506 Relay output adaptor

When you use the relay output adaptor, signal connections to the base plate differ, depending on whether the contact output is NC or NO.

The following figure shows the signal connection to the base plate.

□: 1 to 16

Figure When using the relay output adaptor



IMPORTANT

When you connect an inductive load, connect a diode in parallel with the load.

A2SMX801 Pass-through I/O signal adaptor

When you use the pass-through I/O signal adaptor, you need to set the signal type by software.

The following figure shows the signal wiring to the base plate.

□: 1 to 16

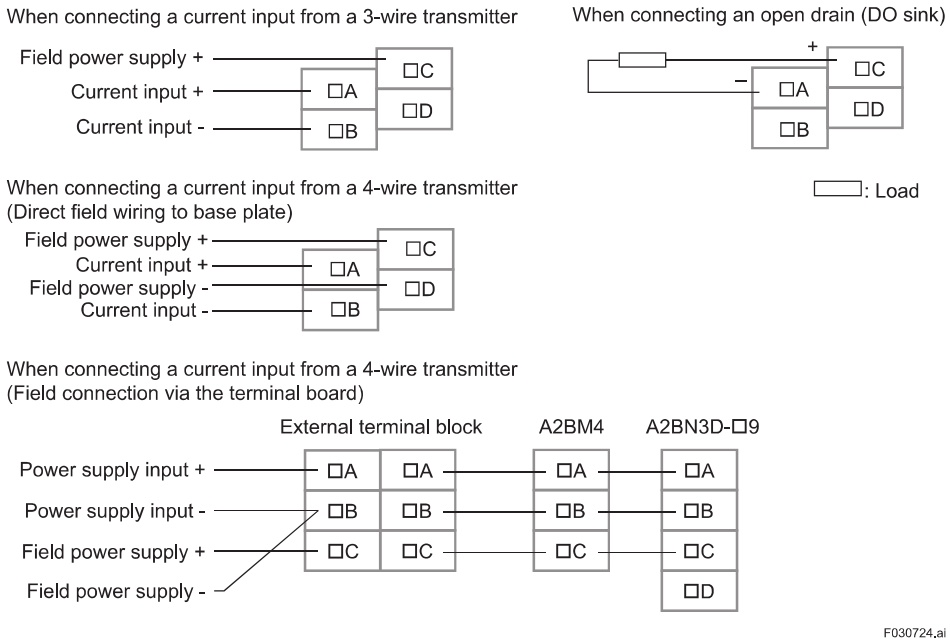


Figure When using the pass-through I/O signal adaptor

A2SMX802 Pass-through I/O signal adaptor

CAUTION

When you connect an inductive load, connect a diode in parallel with the load.

For current input from a 4-wire transmitter, when connecting the field signals via the terminal board, it is necessary to connect the field power supply - to the terminal-B on the external terminal block.
The following figure shows the signal wiring to the base plate when you use the pass-through I/O signal adaptor

☐: 1 to 16

Figure When using the pass -through i/o signal adaptor A2SMX 802

TIP

When using A2SMX802, connect the field power supply to the base plate.
When mounting A2SMX802 to the base plate, each channel between A2SDV105, A2SDV505, and A2SMX801 is not insulated.
For details of the Fieldbus connection and wiring work, refer to “Fieldbus Technical Information” (TI 38K03A01-01E).

3.7.4 Base Plate for Barrier

Base Plate for Barrier Types and Terminal Types

The following table shows relation between Base Plate for Barrier Types and Terminal Types.

Table Base Plate for Barrier Types and Terminal Types

Signal connection of the terminal block of the nest for I/O adaptor A2BA3D

The signal cables of the field devices to the terminal block that is mounted on the nest for I/O adaptor must be connected to different terminals depending on the types of signals. To prevent damage to the devices, connect signal cables to the appropriate terminals according to the type of signals.

The following table shows the relationship between signal types and terminal numbers of channels.

Table Terminal numbers and signal types

Adaptor (model)	Terminal number (*1)	Signal type (*2)				
		Case 1	Case 2	Case 3	Case 4	Case 5

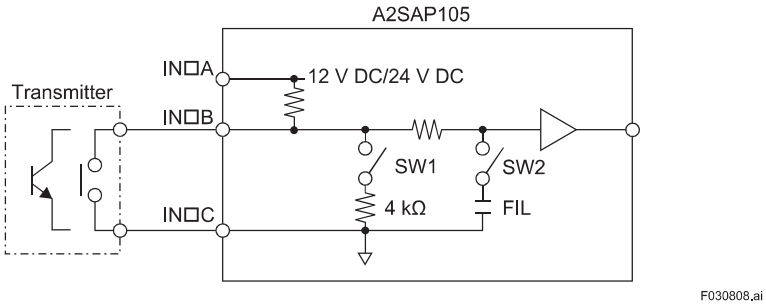
*1: ☐: 1 to 16
*2: "—" denotes that the terminal is not used. Do not connect any signal because the terminal is connected to internal circuits.
*3: When the power supply is turned off or overcurrent is detected, the current input loop enters a high impedance state. Do not share the current signal with other receiving devices. If the signals are shared, you must convert the signals into voltage signals by using an external shunt resistor or shunt resistor module (Part:A1080RZ) to receive the signals.
*4: Power for transmitter is supplied from the A terminal. If an overcurrent is detected, the A terminal enters an open state.
*5: The resistance values of the connecting cables must match.
*6: When the power supply is turned off or overcurrent is detected, the transmitter power supply terminal enters an open state.
*7: Used when the input frequency is 0 to 5 kHz.
*8: Used when the input frequency is 0 to 10 kHz.
*9: Used when the input frequency is 0 to 800 Hz.

3.8.3 Adaptors (for A2BA3D)

A2SAP105 Pulse input signal adaptor



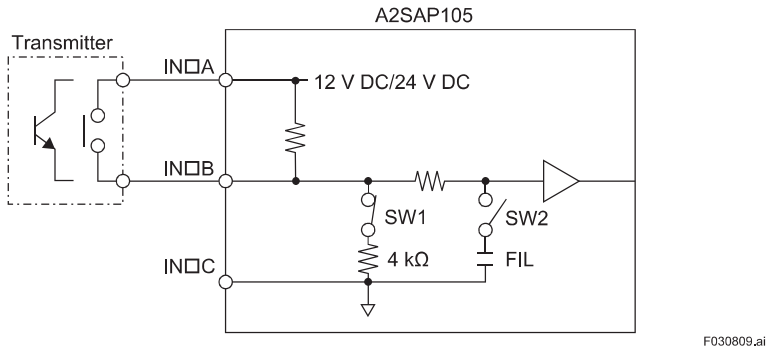
When the pulse input signal adaptor (Model: A2SAP105) is used, signal connections and shunt resistor usage depend on the type of the pulse signal that is input.

When receiving dry contact signals, you can remove mechanical chattering noise by selecting the pulse input filtering option in the IOM builder. However, the input filter passes a limited range of frequencies.

SEE ALSO For more information about removing the mechanical chattering noise, refer to:
N-IO Node (for RIO System Upgrade) (GS 33J64F10-01EN)

When receiving dry contact signals (Input frequency: 0 to 800 Hz)

Select "Without Shunt Resistor" (SW1: OFF) in the IOM builder.
The following figure shows the circuit diagram.

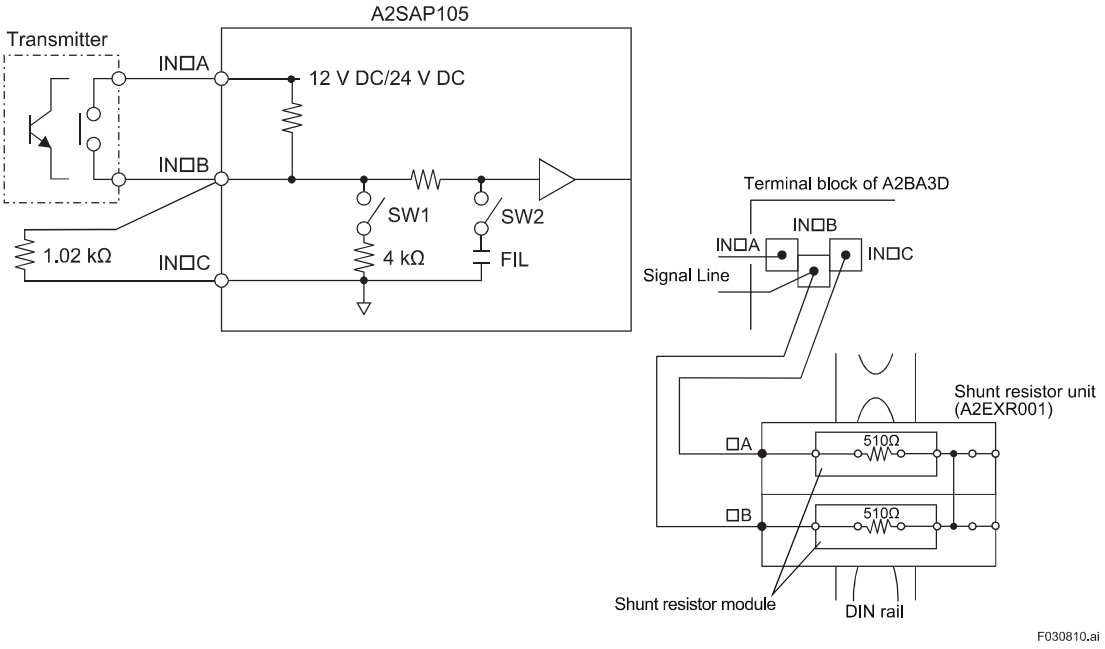


□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 800 Hz)

When receiving dry contact signals (Input frequency: 0 to 5 kHz)

Select "Shunt Resistor 4000 ohm" (SW1: ON) in the IOM builder.
The following figure shows the circuit diagram.



□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 5 kHz)

When receiving dry contact signals (Input frequency: 0 to 10 kHz)

Select "Without Shunt Resistor" (SW1: OFF) in the IOM builder. Also install two 510 Ω shunt resistor modules on the shunt resistor unit. The total resistance value will be 1.02 kΩ.
The following figure shows the circuit diagram.

□: 1 to 16

Figure When receiving dry contact signals (Input frequency: 0 to 10 kHz)

• Shunt Resistor Unit (A2EXR001)

SEE ALSO For the General specifications of A2EXR001, refer to N-IO Node (For RIO System Upgrade) (GS 33J64F10-01EN)

The shunt resistor unit (Model: A2EXR001-S000030/KFR) converts the current signals of the internal circuit of the pulse input signal adaptor into voltage signals and is capable of converting four points of signals. It is used when receiving dry contact signal inputs with 0 to 10 kHz input frequencies or current pulse signal inputs.

Elements of the shunt resistor unit

The following figure shows the elements of the shunt resistor unit.

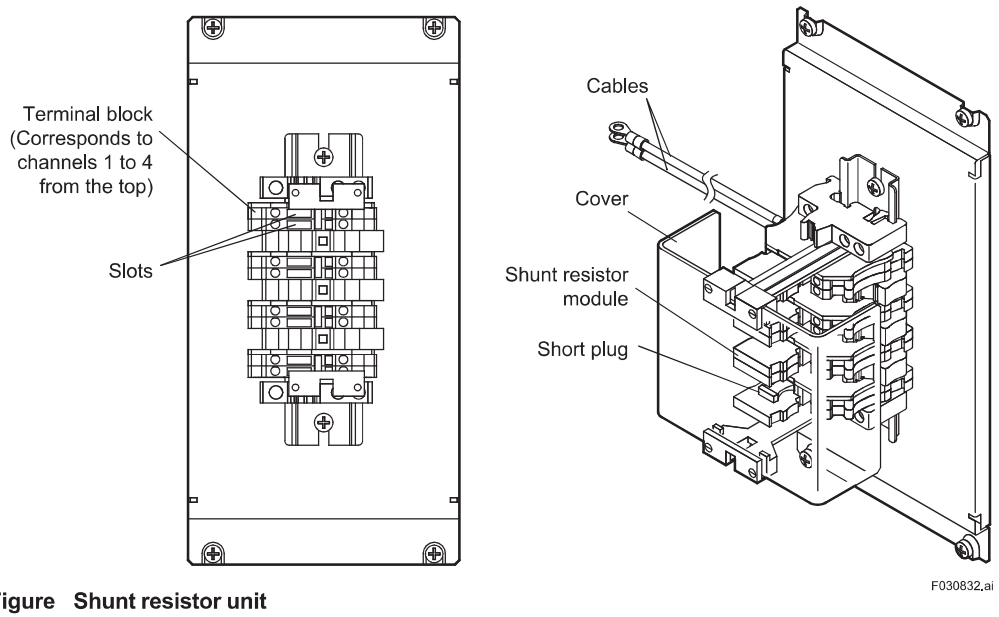


Figure Shunt resistor unit

The shunt resistor unit has terminal blocks for channel numbers 1 to 4. Each terminal block is provided with two slots that are used to install a shunt resistor module or a short plug. Short plugs are installed on these slots when the unit is shipped from the factory. The shunt resistor unit comes with shunt resistor modules and cables for connecting the shunt resistor unit and the nest for I/O adaptor as accessories.

Installation and wiring for the shunt resistor unit

CAUTION

Handle shunt resistor module in A2EXR001 with care as it may become high in temperature. Use a cover to prevent from touching the resistor directly to avoid being burned.

Installing the shunt resistor unit

The following figure shows how to install the shunt resistor unit.

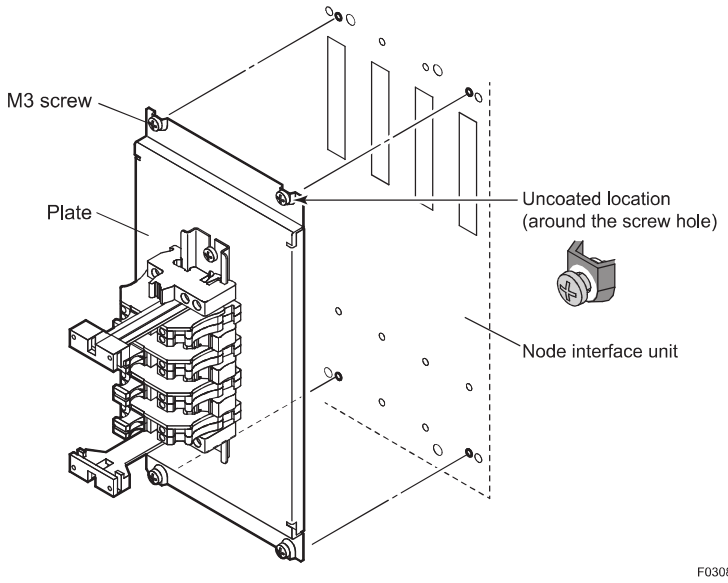

Figure Installing the shunt resistor unit

Install the shunt resistor unit onto the node interface unit securely by tightening the four M3 screws.

When there is no empty space in the node interface unit and the shunt resistor unit (Model: A2EXR001) cannot be mounted, Multiple shunt resistor units can be installed in the empty space on the back of the FCU (Model: A2FV70☐) or Base Plate (Model: A2BE1D) by using shunt resistor unit fixing plate. For details of the Shunt resistor unit fixing plate, Refer to the figure below.

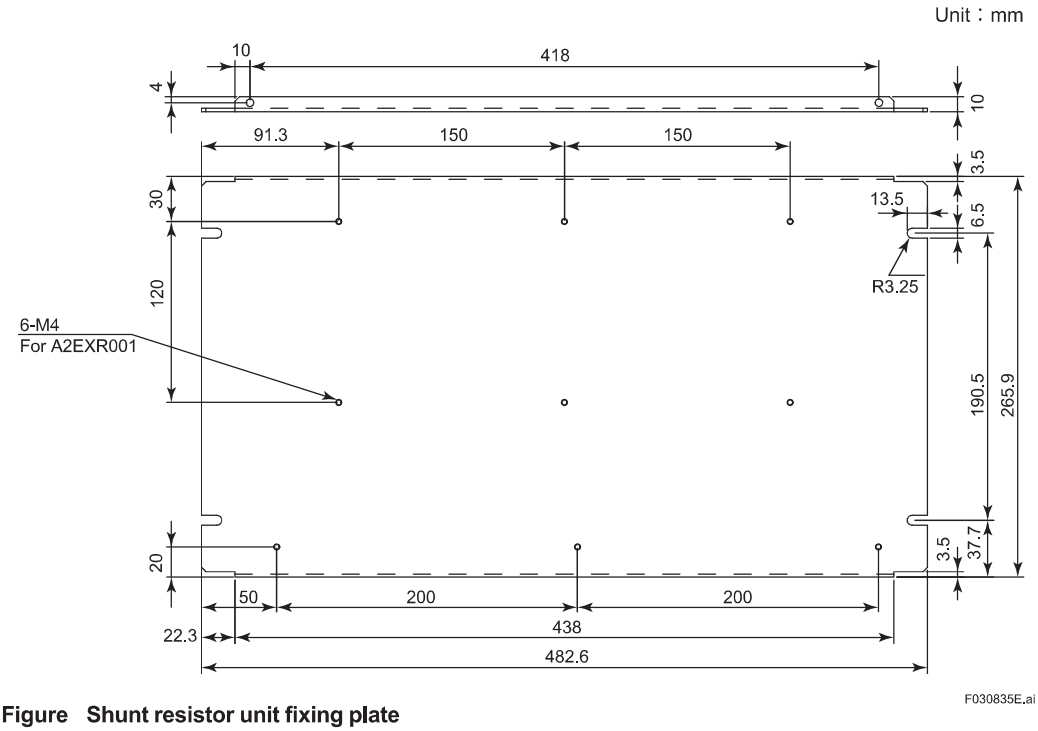

Figure Shunt resistor unit fixing plate

The shunt resistor unit fixing plate can be mounted on the upper rear of the RIO system upgrade application cabinet.

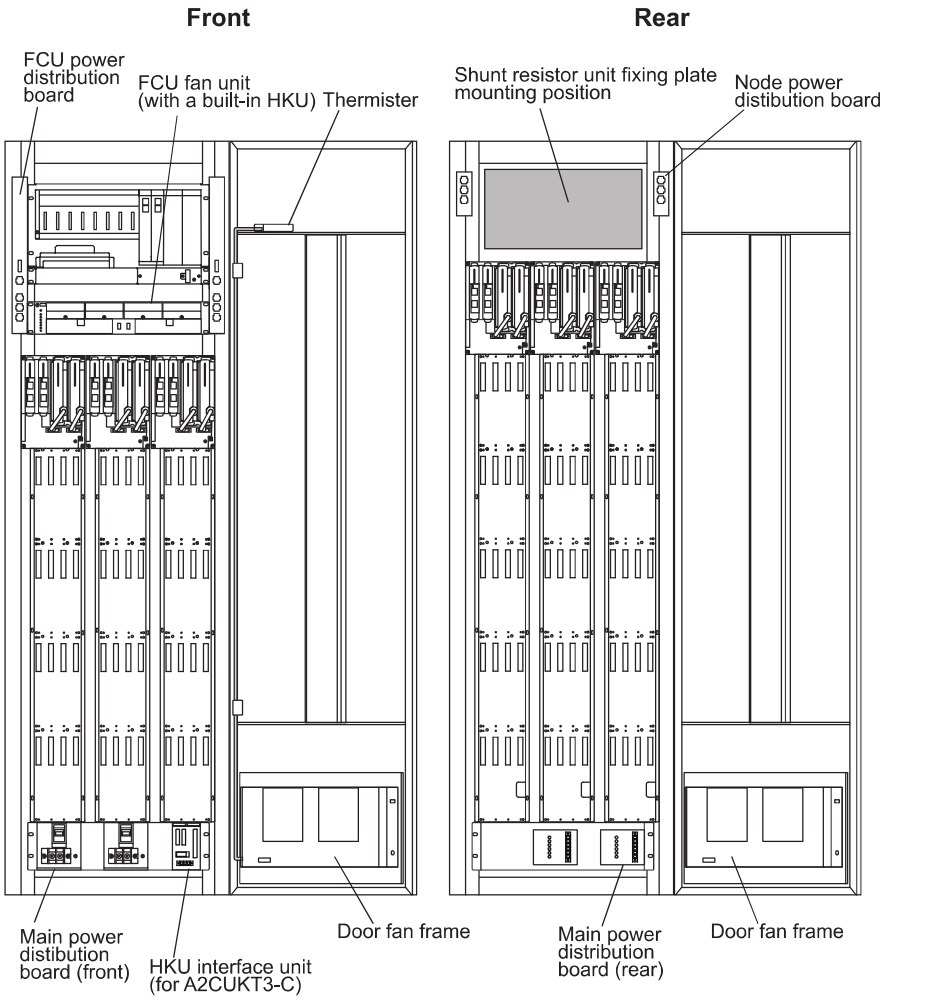

Figure Shunt resistor unit fixing plate mounting position

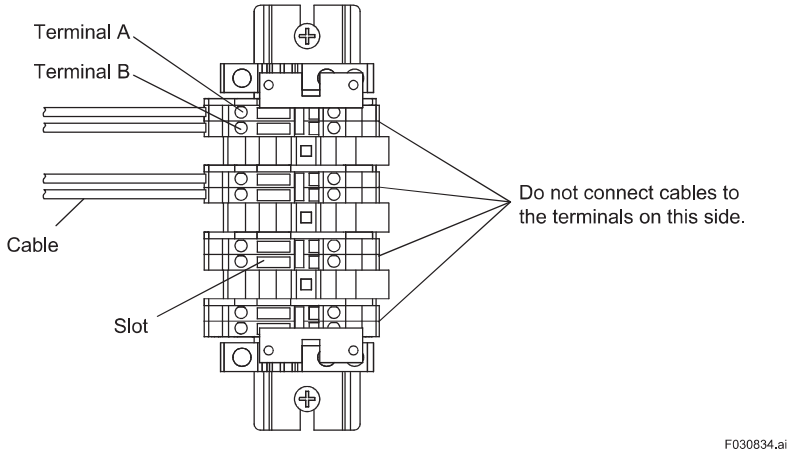
Wiring for the shunt resistor unit

For the wiring between the shunt resistor unit and the nest for I/O adaptor, use the cables that are provided as accessories of the shunt resistor unit. The cables have a sleeve at one and for connection to the shunt resistor unit and a ring terminal for M4 screw at the other and for connection to the nest for I/O adaptor.
Connect the cables to the shunt resistor unit for the required number of signals.
The following figure shows the cable connections to the shunt resistor unit.



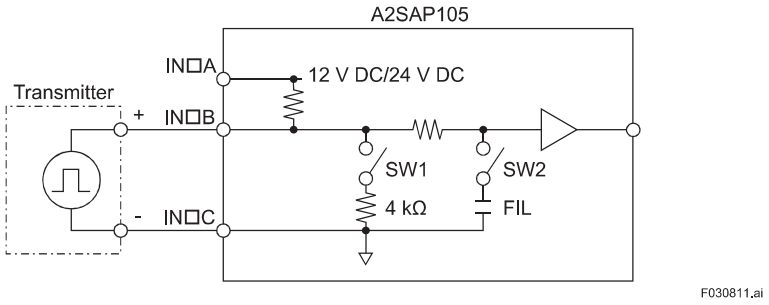


Figure Cable connections to the shunt resistor unit

When receiving voltage pulse signals

In the IOM builder, select "Without Shunt Resistor" (SW1: OFF) and clear the "Input Filtering" (SW2: OFF) option.
The following figure shows the circuit diagram.

□: 1 to 16

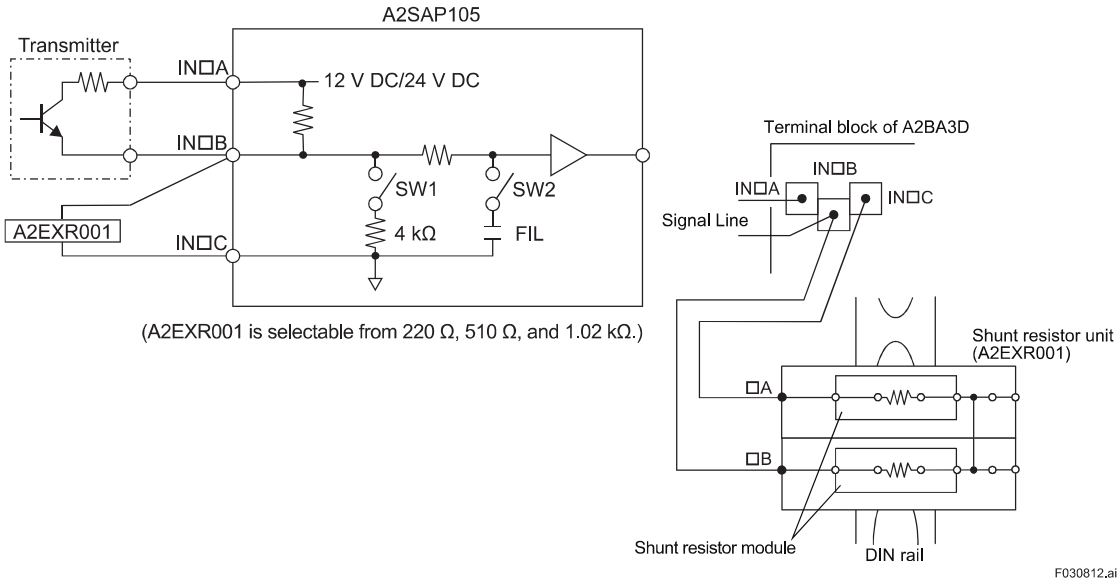

Figure When receiving voltage pulse signals

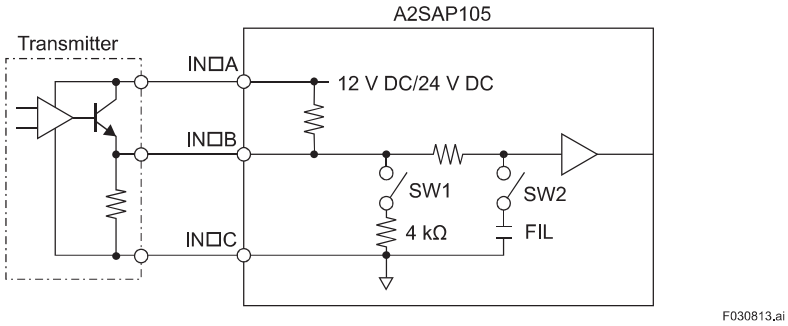
When receiving current pulse signals (2-wire power supply type)

According to the input signal level, install the shunt resistor module and short plug onto the shunt resistor unit so that the total resistance value becomes one of the following values:

- 220 Ω
- 510 Ω
- 1.02 kΩ

In the IOM builder, select "Without Shunt Resistor" (SW1: OFF) and clear the "Input Filtering" (SW2: OFF) option.
The following figure shows the circuit diagram.



□: 1 to 16

Figure When receiving current pulse signals (2-wire power supply type)

When receiving voltage pulse signals by using the internal power to drive the transmitter (3-wire power supply type)

In the IOM builder, select "Without Shunt Resistor" (SW1: OFF) and clear the "Input Filtering" (SW2: OFF) option.
The following figure shows the circuit diagram.

□: 1 to 16

Figure When receiving voltage pulse signals by using the internal power to drive the transmitter (3-wire power supply type)

When attaching a shunt resistor to the M4 screw terminal block of A2BA3D

If there is no empty space in the node interface unit and it is difficult to install the shunt resistor unit (Model: A2EXR001) in the cabinet, it is possible to prepare the shunt resistor separately and attach it to the M4 screw terminal block of the nest for I/O adaptor (Model: A2BA3D). However, the following (1) to (4) implementation conditions must be met.

(1) Cabinet ambient Temperature Conditions

Check the cabinet ambient temperature considering the temperature rise in the cabinet caused by the shunt resistor. Check that the cabinet is installed in an air-conditioned control room and that the operating cabinet ambient temperature is 30 °C or less.

(2) Protection from the heat generated by the shunt resistor

Select a shunt resistor from 220 Ω, 510 Ω, 1.0 kΩ (accuracy ± 5 %, rated 2 W) according to the type of signal, and install it between the B and C terminals of the M4 screw terminal block. At this time, terminal B is tightened together with the input signal. The shunt resistor generates heat depending on the operating conditions, so protect it with a heat resistant tube etc. and use it. The following figure shows the connection diagram and example of the shunt resistor assembly.

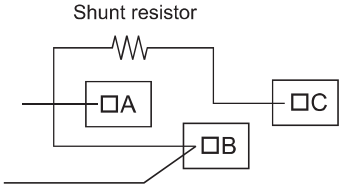


Figure Shunt resistor connection diagram

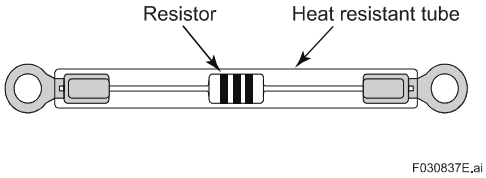

Figure Example of shunt resistor assembly

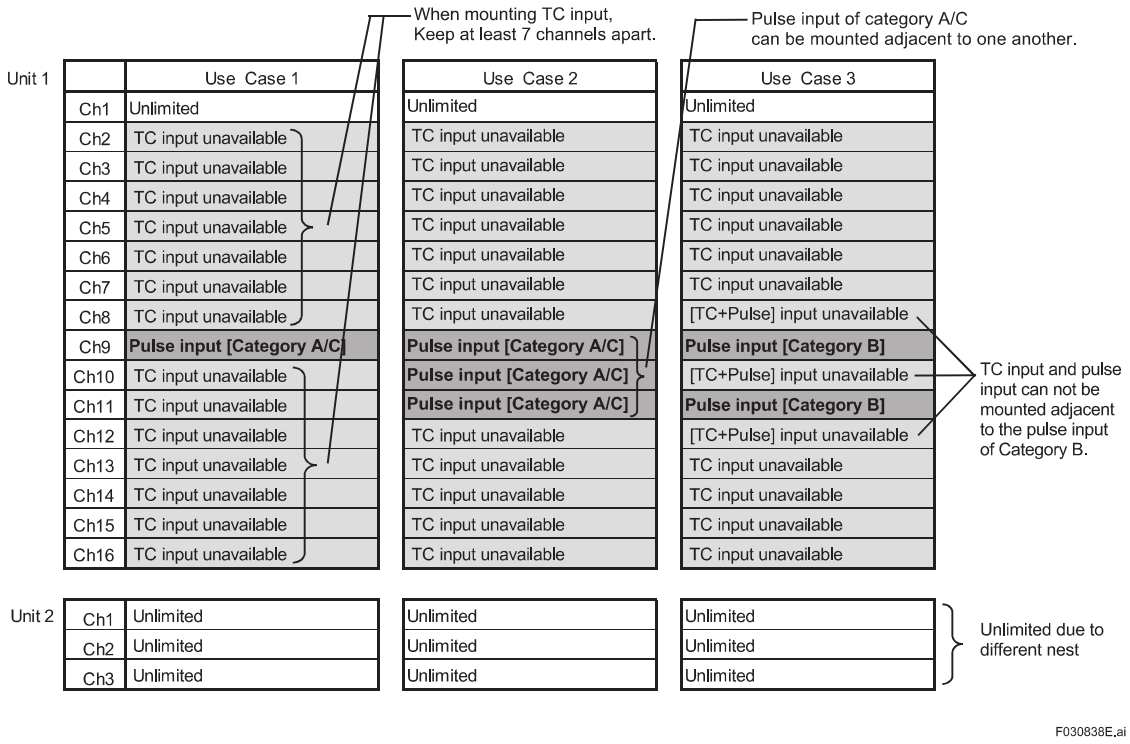
(3) Signal cable temperature rating conditions



The heat generated by the shunt resistor affects to the insulation performance of the signal cable coating. Especially when operating under conditions of large heat generation (Category B and Category C in the table below), please check the temperature rating of the signal cable. If the temperature rating of the signal cable is less than 75 °C (Category B in the table below), avoid using it on adjacent channels to prevent the heat generated by the shunt resister.
Keep one or more channels apart from the channels where resistors are installed. If an adjacent installation is unavoidable, add 1m of signal cables with a temperature rating of 75 °C or higher to the existing signal cables before connecting them (Category C in the table below).

Table Signal cable temperature rating classification

		Transmitter power supply	Shunt resistor value	Signal cable temperature rating	Installation on adjacent channel
Category A	Current pulse	12 V or 24 V	220 Ω	60 °C or less	available
			510 Ω		
	Dry contact pulse	12 V	510 Ω		
			1.0 KΩ		
Category B	Current pulse	24 V	1.0 KΩ	Less than 75 °C	not available (At least one channel away)
	Dry contact pulse				
Category C	Current pulse	24 V	1.0 KΩ	75 °C or higher	available
	Dry contact pulse				

(4) A2SAT105 (TC input) mounting conditions

The heat generated by the shunt resistor affects the TC input measurement accuracy of the mV/TC/RTD input adaptor (Model: A2SAT105). When attaching a shunt resistor to an M4 screw terminal block, do not mix it with the TC input in “Nest for I/O adaptor” (Model: A2BA3D). If mixing is happened, mount the TC input channel more than 7 channels away from the pulse input channel connected with the shunt resistor. Other input signals such as mV input and RTD input can be used in the adjacent channel of pulse input.

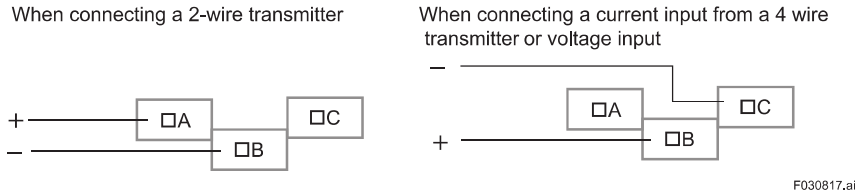

Figure I/O Adaptor Implementation Example 2

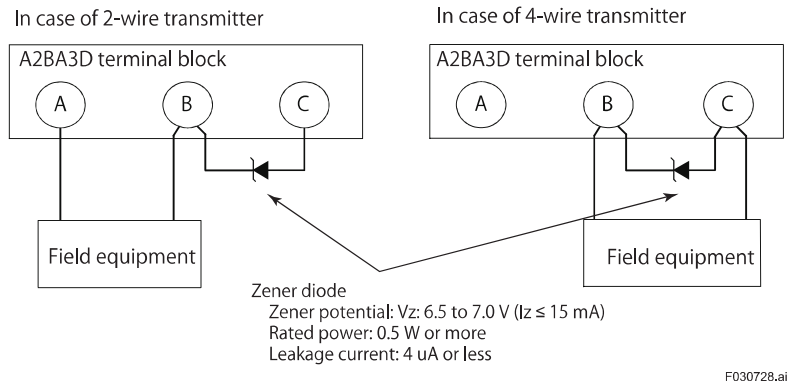
A2SAM105 Current input/voltage input adaptor

IMPORTANT

Do not share the current signal with other receiving devices. If the signals are shared, you must convert the signals into voltage signals by using an external shunt resistor or shunt resistor module to receive the signals.

The following figure shows the signal wiring when using the current input/voltage input adaptor (Model: A2SAM105).



□: 1 to 16

Figure When using the current input/voltage input adaptor

When the input current value exceeds 25 m A

When the input current exceeds 25 mA due to the inrush current of the connected equipment etc. (eg, NOHKEN ultrasonic level meter, etc.), the inrush current exceeds the allowable input current of the adapter, so startup failure of the connected equipment may occurs. As a measure, by connecting a zener diode for bypassing the inrush current to the B - C terminal of the A2BA3D, the input current value can be used from 25 to 40 m A.

Connection example

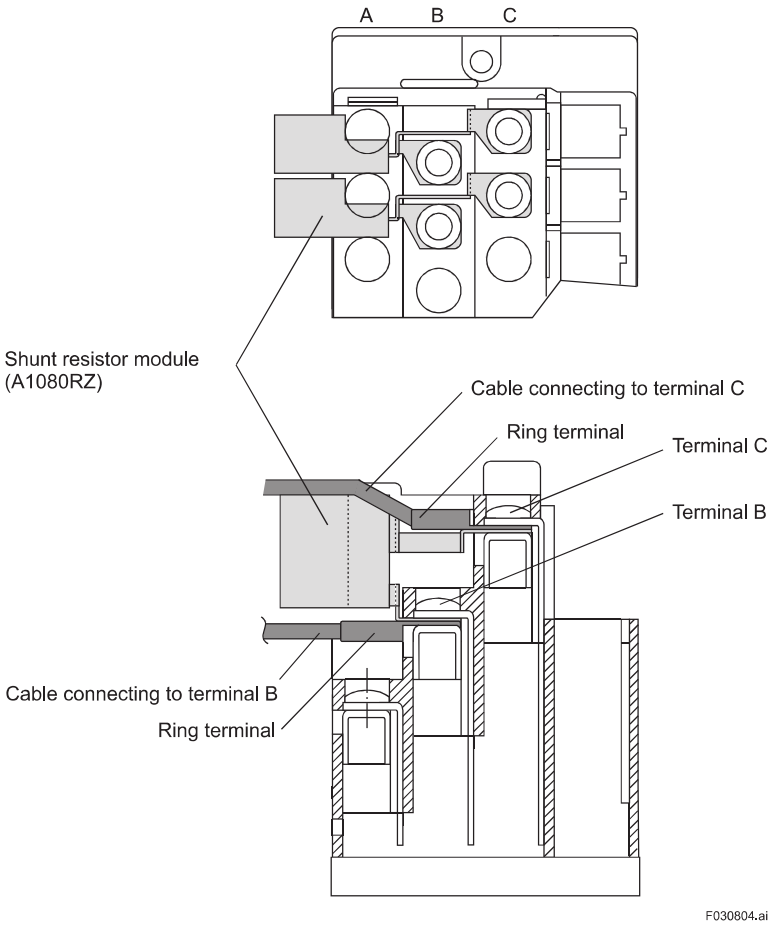
When sharing the current signal with another receiving device

When receiving 4-20 mA current signals from the four-wire transmitter by converting them into 1-5 V DC voltage signals, you must install the shunt resistor module (Part: A1080RZ, 250 Ω) on the receiving terminals of the terminal block.

IMPORTANT

Do not share the current signal with other receiving devices. If the signals are shared, you must convert the signals into voltage signals by using an external shunt resistor or shunt resistor module to receive the signals.

The following figure shows how to install the shunt resistor module.



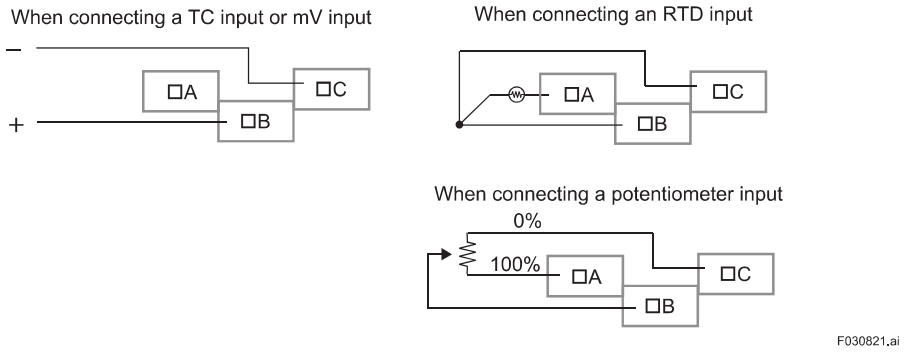


Figure Installing the shunt resistor module

Follow these steps to install the shunt resistor module on the terminal block:

1. Open the cover of the terminal block.
2. Loosen the M4 screws of terminals B and C.
3. Insert the ring of the ring terminal of the cable that connects to terminal B into the gap. Be sure to insert it with the convex side of the crimping part of the ring terminal being oriented to the terminal block side.
4. Orient the shunt resistor module as shown in the figure and insert it into each gap of terminals B and C.
   The screw goes into the screw hole of the ring terminal and is secured temporarily.
5. Insert the ring of the ring terminal of the cable that connects to terminal C into the gap. Be sure to insert it with the convex side of the crimping part of the ring terminal being oriented in the opposite orientation of the shunt resistor module.
6. Tighten the M4 screws on terminals B and C.
7. Close the cover of the terminal block.

A2SAT105 mV/TC/RTD input adaptor

The following figure shows the signal wiring when using the mV/TC/RTD input adaptor (Model: A2SAT105).

□: 1 to 16

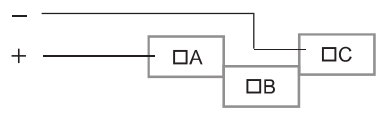

Figure When using the mV/TC/RTD input adaptor

For thermocouple signal input, mount the reference junction compensation module (Part number: S9393UK) on the terminal block.

SEE ALSO For more information about the types of TC and RTD that can be connected to the mV/TC/RTD input adaptor and the standards they must conform to, refer to:
"N-IO Node (for RIO System Upgrade)" (GS 33J64F10-01EN)

A2SAM505 Current output/voltage output adaptor

The following figure shows the signal wiring when using the current output/voltage output adaptor (Model: A2SAM505).

□: 1 to 16

Figure When using the current output/voltage output adaptor

Dual-redundant current output

For current signal output, adaptors can be configured for redundancy. Mount the adaptors in the slots that are vertically next to one another, and set the signal setting of the adaptors in the odd-numbered slot and the even-numbered slot to dual-redundant.

To also match the output, connect terminal A to terminal A, and terminal C to terminal C on the terminal blocks by using short-bars (Part number: A1534JT).

The following figure shows how to attach short-bars by using an example of a dual-redundant configuration of adaptors in slots 3 and 4.

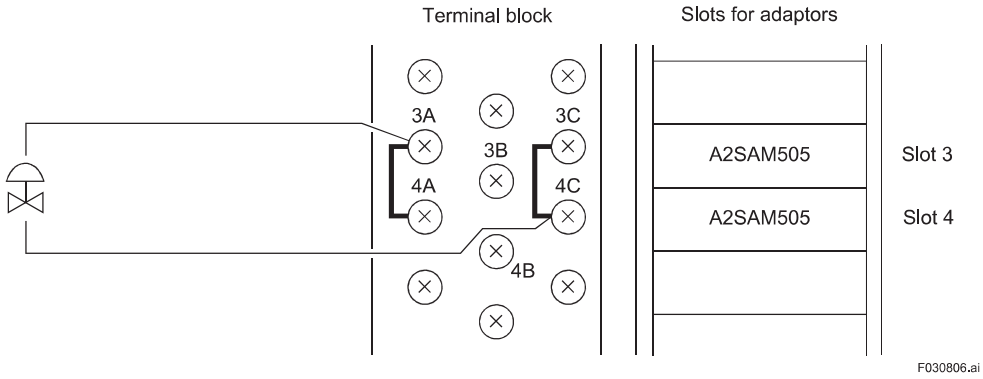

Figure Example of attaching short-bars

TIP

When using the ELCO connector, short the pins that correspond to terminal A on a terminal block, and the pins that correspond to terminal C.

SEE ALSO

For more information about the ELCO connector pin assignment, refer to:
"N-IO Node (for RIO System Upgrade)" (GS 33J64F10-01EN)

Signal connection of a terminal block for the multichannel I/O module

The signal cables of the field devices to the terminal blocks for the multi-channel I/O module must be connected to different terminals depending on the types of signals. To prevent damage to devices, connect signal cables to the appropriate terminals according to the type of signals. The following table shows the relationship between signal types and terminal numbers of channels.

Table Terminal numbers and signal types - Analog I/O module

I/O modules		Terminal number (*1)	Signal types
Device	Model and suffix code		
Analog input module	AAI143-HM☐	☐A	Current input +

*2: "—" denotes that the terminal is not used. Do not connect any signal to it.

Connect the signal cables to the terminal blocks.

Analog I/O

This section describes the signal wiring when the following signals are received or sent:

- Voltage signals are received on AAV144-SM☐.
- Thermocouple or mV signals are received on AAT145-SM☐.
- Signals from the 2-wire transmitter are received on AAI143-HM☐.
- Current signals are sent by AAI543-HM☐.

The following figure shows the signal wiring for the preceding signals.

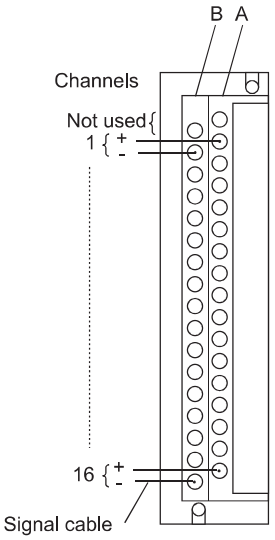

Figure For voltage input, thermocouple input, mV input, 2-wire transmitter input, or current output

IMPORTANT

When using I/O module AAI143-HM☐, do not share the current signals with other receiving devices.

RTD input

The following figure shows the signal wiring when receiving RTD signal input on AAR145- SM☐.

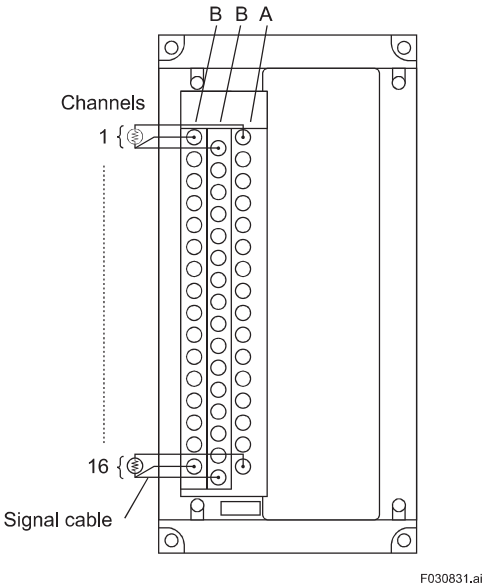

Figure For RTD Input

SEE ALSO For more information about the types of RTD that can be connected to AAR145-SM☐ and the standards the RTD must conform to, refer to:
"N-IO Node (for RIO System Upgrade)" (GS 33J64F10-01EN)

Contact input or output of isolated channels

This section describes the signal wiring when the following signals are received or sent:

- When receiving contact signals on ADV159-PM□
- When sending contact signals by ADV559-PM□

The following figure shows the wiring for the preceding cases.

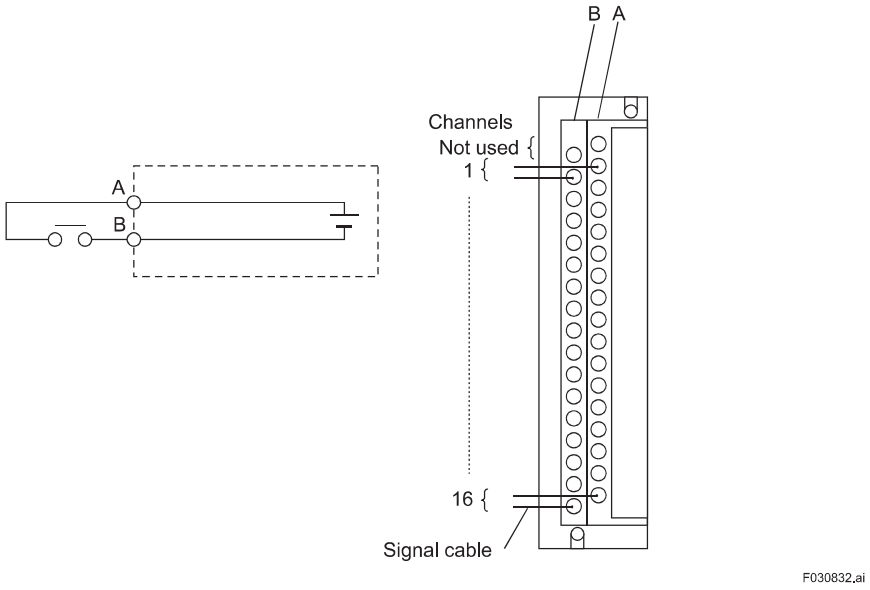

Figure For contact input or output of isolated channels

Isolated contact input or output

This section describes the signal wiring when the following signals are received or sent:

- When receiving contact signals on ADV169-PM☐
- When sending contact signals by ADV569-PM☐

The following figure shows the signal wiring for the preceding signals.

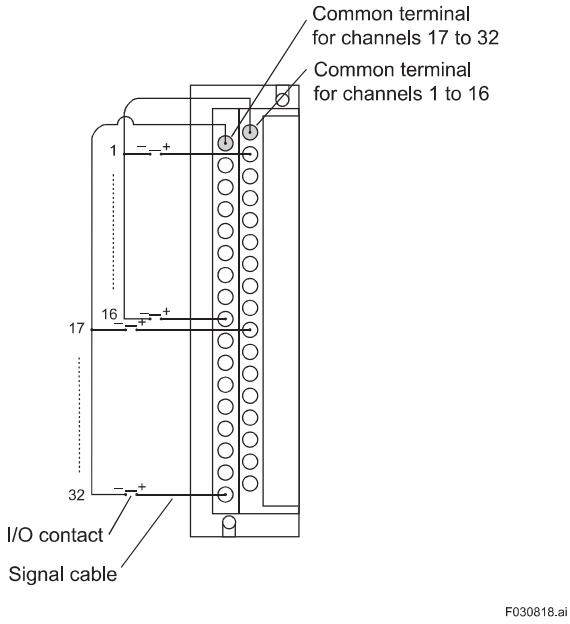

Figure For isolated contact input or output

Relay input

The following figure shows the signal wiring when receiving relay signal input on ADV159-PY☐.

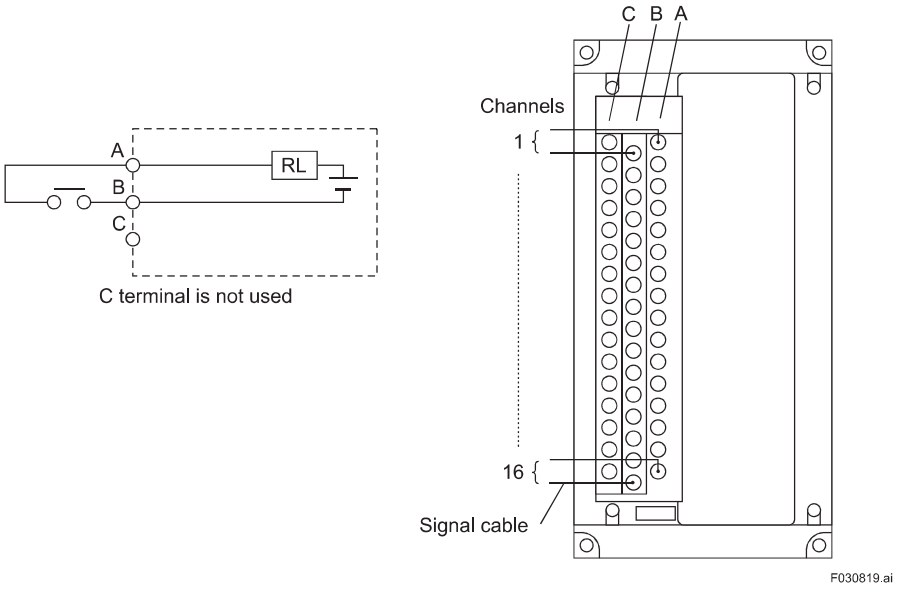

Figure For relay input

Relay output

The following figure shows the signal wiring when sending relay signal output by ADV559-PY☐.

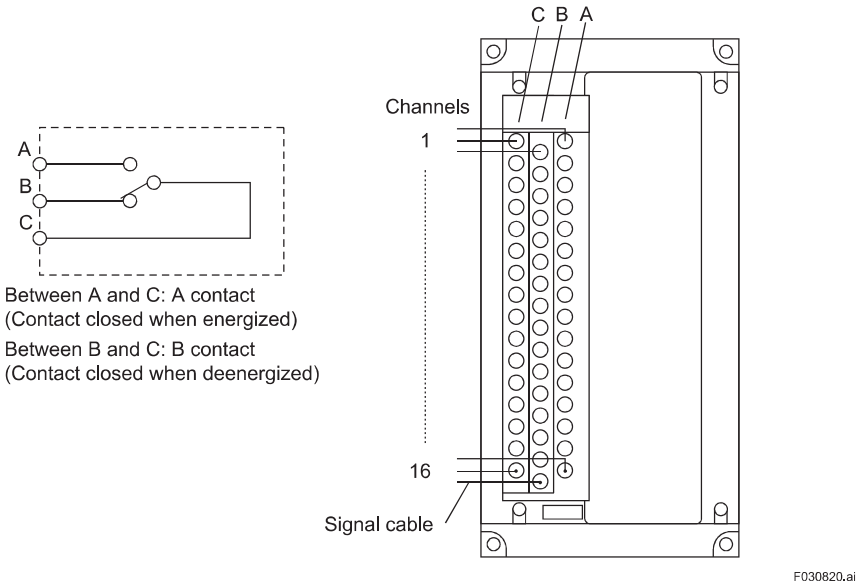

Figure For relay output

CAUTION

High voltage signals can be connected to ADV559-PY☐.
To prevent electrical shock, shut off the power to the field devices before you install wiring for ADV559-PY☐.

SEE ALSO

For more information about the output rating of ADV559-PY☐, refer to:
"N-IO Node (for RIO System Upgrade)" (GS 33J64F10-01EN)

3.9 Connecting Bus Cable

Control Bus (Vnet/IP)

Information on Vnet/IP interface connection and an example of Human Interface Station (HIS) and AFV30D connection are shown below:

Vnet/IP Interface

- Topology : tree connection
- Configuration : dual redundancy only
- Connector : RJ45 connector
- Intra-domain connection : Layer 2 switch (L2SW) used
- Inter-domain connection : Layer 3 switch (L3SW) used
- Recommended cable : UTP cable of CAT5e or above (optical cable for outdoor use)

HIS and FCU Connection

Differentiation between BUS 1 and BUS 2 (WAN 1 and WAN 2)

Use different colors, etc., to differentiate between BUS 1 and BUS 2 (WAN 1 and WAN 2).

Destination Display

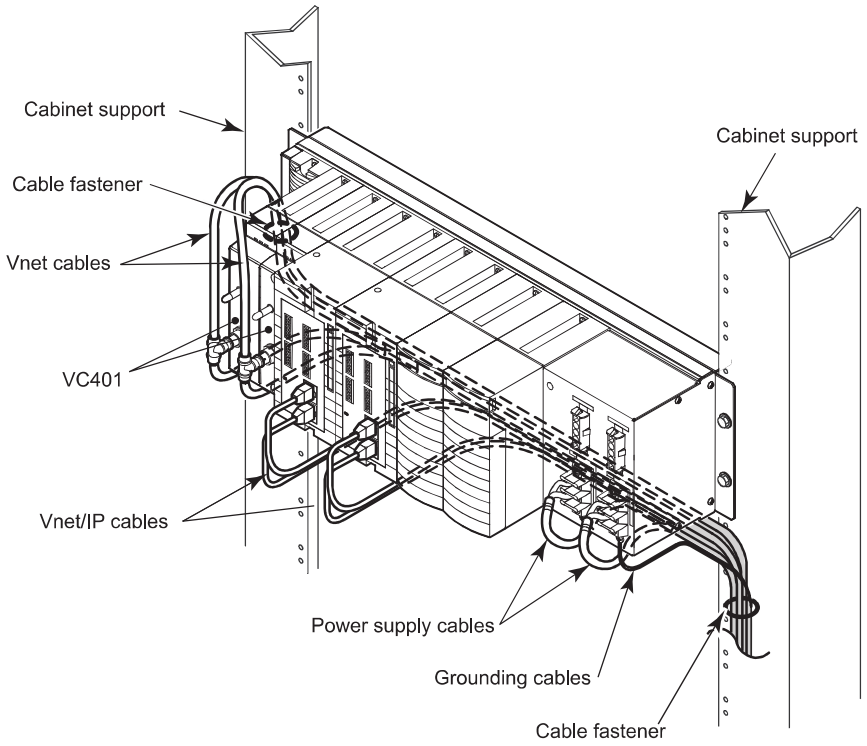
Attach a display tag at the tip of cables to indicate the station number, switch number, and port number of the destination.

Cable Fixing

Fix cables securely so that their connectors are not exposed to undue stress.

Handling of Vnet/IP Cables Connected to the Processor Module (CP461 or CP471)

- Turn the power on after connecting the cables to the CP4☐1.
- When removing the CP4☐1 on-line, remove it with the cable connected to it.
- Before installing the CP4☐1 on-line, connect a cable to it.

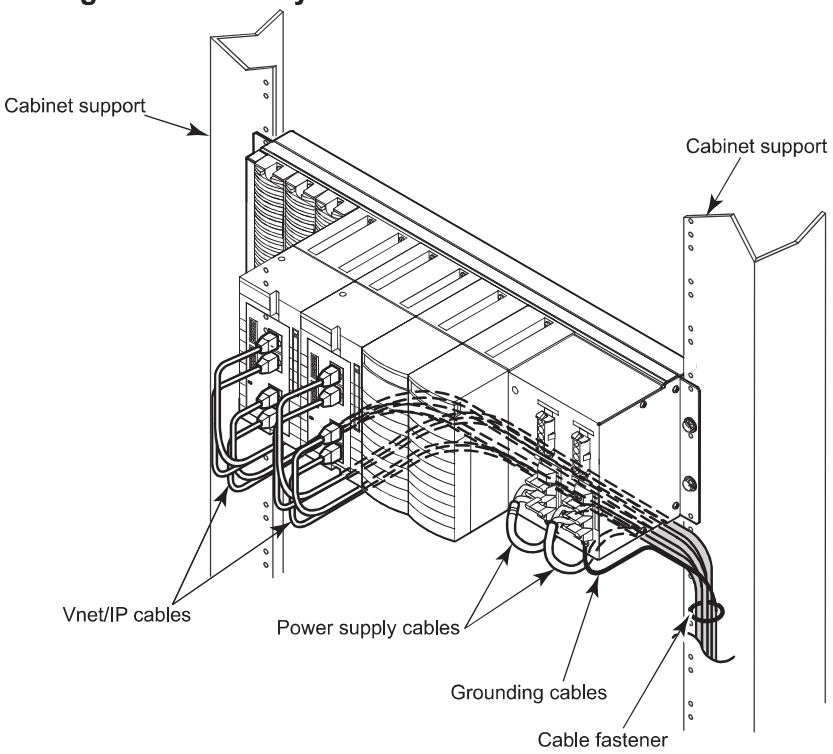


Handling of Cables Connected to the AVR10D/AW810D

- The power supply should not be turned on unless the cables are connected.
- When online removing the module, the module should be removed together with the connected cables.
- When online installing the module, the cable should be connected to the module first.

Handling of Cables Connected to the VI702

- The power of the PC should not be turned on until the cables are connected.
- When disconnecting the cables, the power of the PC must be turned off.



Cabling for AVR10D System

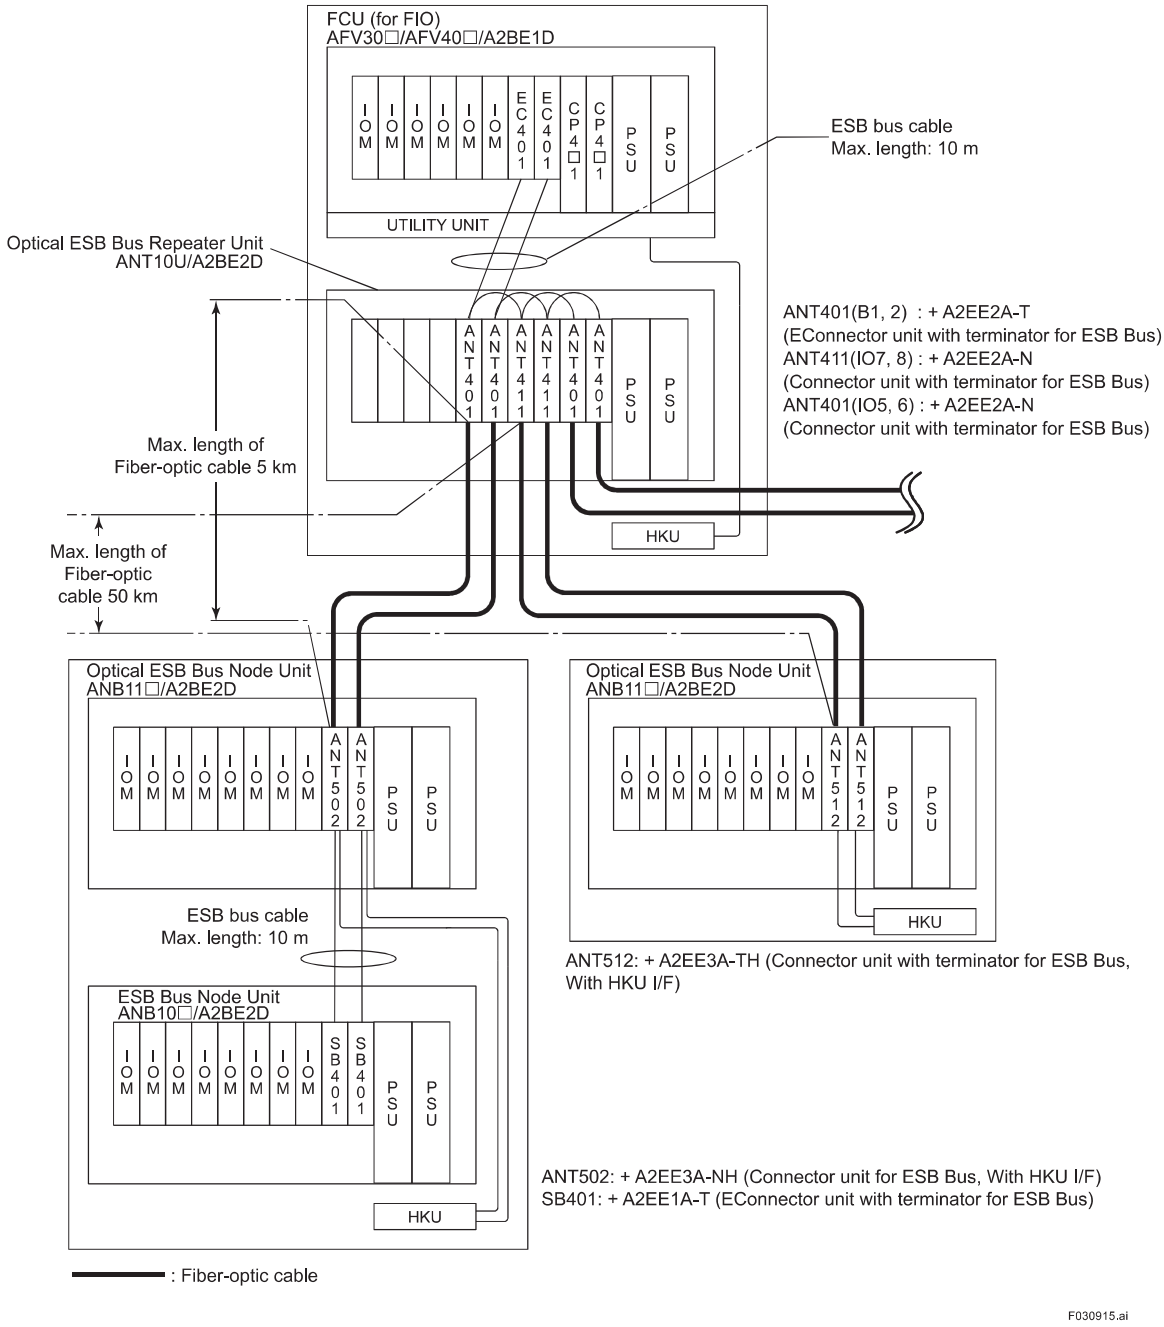

Figure Example of Optical ESB Bus Star Connection Using HK Function

Specifications of Fiber-optic Cables Used in Optical ESB Bus Repeater Modules

The table below shows the specifications of the fiber-optic cables used in optical ESB bus repeater modules.

Table Specifications of Fiber-optic Cables Used in Optical ESB Bus Repeater Modules

Item	Specification
Connector	Type LC connector (IEC 61754-20-compliant product)
Cable	Silica-based single-mode fibers (JIS C6835 SSMA-9.3/125, IEC 60793-2-50B1.1)
Number of cores used	Two

Note: If light attenuation between ANT411 and ANT512 is less than 3 dB, increase attenuation by 3 dB using an attenuator.

The fiber-optic cables should be selected what the rating temperature is the ambient temperature plus 20 °C or more.

Lay fiber-optic cables according to the manufacturer's cable handling precautions such as allowable bending radius.

Secure and wire the fiber-optic cables so as not to put extra stress on the cable trays in the units listed below:

- Field control unit
- Node Unit
- Unit for optical bus repeater module

F-SB Bus (for N-IO Node)

The following figure shows a conne

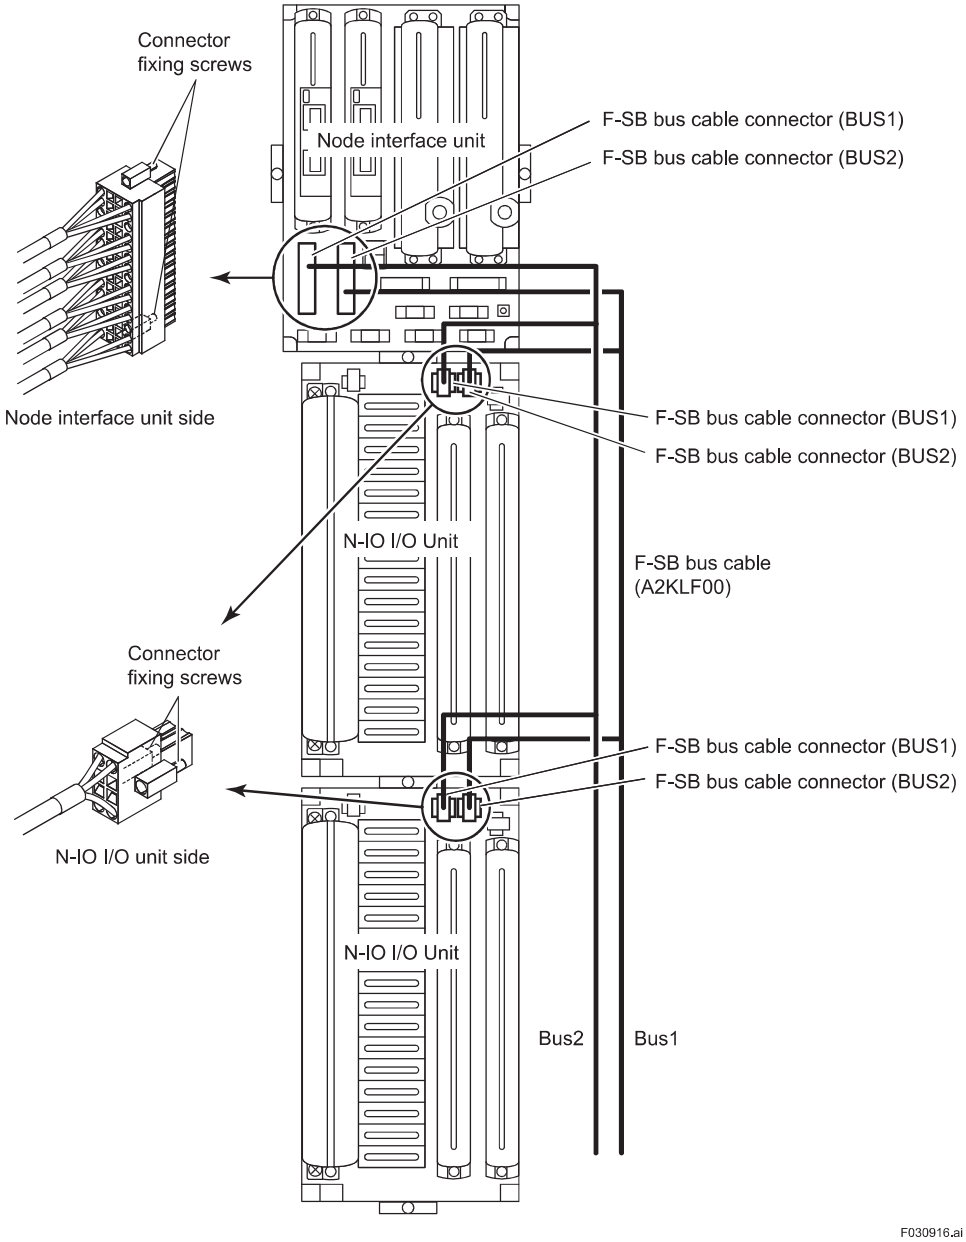

Figure F-SB Bus Connection

IMPORTANT

When connecting a F-SB bus cable to N-IO node, ensure to keep the minimum bending radius of the cable.

The minimum bending radius of the F-SB bus cable is six-fold of the diameter of the cable.

ACUKT1 (without AFV30□)	Fan, fan power supply or cabinet temperature fault	
A2FU2	Power and processor failure	30 V DC, 0.3A
A2CUKT4-C□□□□	Power and processor failure	250 V AC/30 V DC, 2A, 125 VA
A2CUKT4-L□□□□/A2CUKT4-R□□□□	Fan, fan power supply or cabinet temperature fault	250 V AC/30 V DC, 2A, 125 VA

Use of Lamps

When you want to turn on lamps using contacts, use the following lamps:

- The rated voltage of lamp does not exceed the rated contact voltage.
- When using incandescent lamps, their rush current does not exceed the rated contact current. It is considered to be 10 to 15 times the rated current. If the rush current exceed the rated contact current, use a dim lamp resister or a rush current preventing resistor. It is recommended to use a dim lamp resistor using 40 to 50 % of the lamp current rating, or a rush current preventing resistor using 80 to 90 % of the lamp current rating. A dim lamp resistor permits detection of lamp failure.

Be sure to test the lamp before installation.

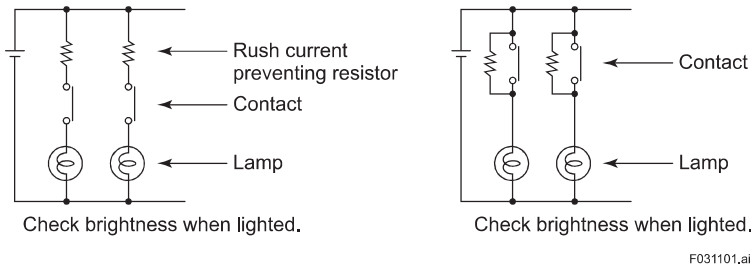

Figure Examples of Using Lamps

Use of Relays

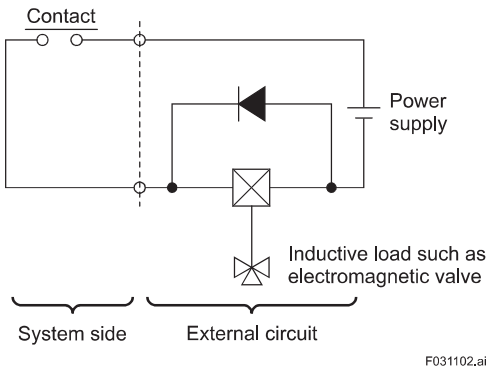
Contact protection and surge absorption can be provided in various manners. When using contacts output to drive relays and solenoids, the following precautions should be taken:

- Install a diode in parallel to induction load for noise prevention and contact protection.
- Use a relay circuit with voltage rating as low as possible for increased reliability.
- Select a diode having a reverse withstand voltage which is 10 times or larger than a circuit voltage and a forward current which exceeds a load current.

IMPORTANT

Relays and solenoids cause reverse electromotive voltages at both coil ends due to inductive load. This phenomenon causes contact damage or noise, leading to device errors and adversely affecting the entire system.

When a DC Power Supply Is Used



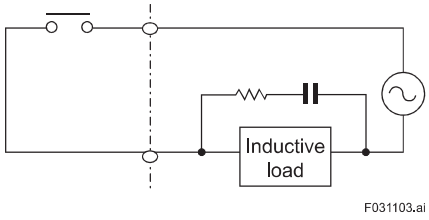


Figure Example of Using Diode for Contact Protection

When a AC (or DC) Power Supply Is Used

- Shunt the load with a resistor (R) and a capacitor (C).
- The recovery time increases when using relays or solenoid valves.

Note: Avoid direct AC voltage input to the contact output terminal on 19-inch rack mountable type.

Figure Example of Capacitor/Resistor-protected Circuit

3.12 Connecting input devices such as operation keyboard

When connecting the input devices such as an operation keyboard, a mouse, or a keyboard, please note the following instructions for wiring.

- Keep signal cables of the input devices and power cables of PCs or LCD monitors physically segregated (do not bundle cables together).
- Do not pull the unlocked type connector with excess strength, or it may get loose.
- When the connector is pulled off for cleaning or something, put it back in to the same port.
- Pulling off an USB connector while it is powered on for replacing the operation keyboard, please note that the system operation and monitoring functions may be interrupted.

4. Installation Specifications

This section summarizes power consumption, in-rush current, breaker ratings, parts durability and other data for the installation of CENTUM VP system.

Electrical Specifications

Power consumption (current) and other electrical data are shown below:

Table Electrical Specifications (1/3)

Equipment	Input-voltage range		Max. power consumption (VA, A, W) (*1)	Heating value J/h (*2)
	Voltage (V AC)	Frequency (Hz)		
AFV30S Field Control Unit	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
AFV30D Duplexed Field Control Unit	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
AFV40S Field Control Unit (at maximum installation of FIO)	100-120	50/60±3	2500 VA	5400×10^3 (1500 W)
	220-240		2860 VA	
	24 V DC		71 A	
AFV40D Duplexed Field Control Unit (at maximum installation of FIO)	100-120	50/60±3	2500 VA	5400×10^3 (1500 W)
	220-240		2860 VA	
	24 V DC		71 A	
A2FV50S 19-inch Rack Mountable Type Field Control Unit for FIO (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2FV50D 19-inch Rack Mountable Type Duplexed Field Control Unit for FIO (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2FV70S Field Control Unit (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2FV70D Field Control Unit (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
ANB10S ESB Bus Node Unit (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
ANB10D Duplexed ESB Bus Node Unit (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
ANB11S Node Unit for Single ESB Bus with Optical Repeater (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	

*1: Power consumption in steady operation is indicated in VA (AC), A (DC) or W (DC). When power consumption varies according to the installed number of equipment, power consumption by the maximum number of units installed is listed.

*2: Heating value in steady operation is indicated in Joule/hour. When heating value varies according to the installed number of equipment, heating value by the maximum number of units installed is listed.

Table Electrical Specifications (2/3)

Equipment	Input-voltage range		Max. power consumption (VA, A, W) (*1)	Heating value J/h (*2)
	Voltage (V AC)	Frequency (Hz)		
ANB11D Node Unit for Dual-Redundant ESB Bus with Optical Repeater (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
ANT10U Unit for Optical ESB Bus Repeater Module (at maximum installation of FIO)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
ACB51 I/O Expansion Cabinet (at maximum installation of FIO)	100-120	50/60±3	2500 VA	5400×10^3 (1500 W)
	220-240		2860 VA	
	24 V DC		71 A	
AVR10D Duplexed Vnet Router	100-120	50/60±3	80 VA	158×10^3 (44 W)
	220-240		110 VA	
	24 V DC		1.7 A	
ACUKT1 Cabinet Utility Kit (at maximum installation of FIO)	100-120	50/60±3	2900 VA	6264×10^3 (1740 W)
	220-240		3320 VA	
	24 V DC		82 A	
ACUKT1 Cabinet Utility Kit (excluding node)	100-120	50/60±3	100 VA	216×10^3 (60 W)
	220-240		100 VA	
	24 V DC		5 A	
AW810D Wide Area Communication Router	100-120	50/60±3	80 VA	158×10^3 (44 W)
	220-240		110 VA	
	24 V DC		1.7 A	
A2NN10D Node Interface Unit	100-240	50/60±3	320 VA	540×10^3 (150 W)
	24 V DC		180 W	
A2NN30D Node Interface Unit	100-240	50/60±3	190 VA	98×10^3 (150 W)
	24 V DC		150 W	
A2BE1D (Installing CP471, PW48☐ and FIO) Field Control Unit (at maximum installation of module)	24 V DC		28.8 W	58×10^3 (16 W)
A2BE2D (Installing PW48☐ and FIO) FIO Node Unit (at maximum installation of module)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2BE2D (Installing PW48☐ and Optical ESB Bus repeater module) Optical ESB Bus Repeater Unit (at maximum installation of module)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2BE2D (Installing PW48☐ and Optical ESB Bus repeater module) Optical ESB Bus Repeater Unit (at maximum installation of module)	100-120	50/60±3	200 VA	432×10^3 (120 W)
	220-240		230 VA	
	24 V DC		5.5 A	
A2CUKT4-☐3☐☐☐ Cabinet Utility Kit (at maximum installation of module, for Standard Cabinet A2CAB1)	100-120	50/60±3	2500 VA	5400×10^3 (1500 W)
	220-240		2860 VA	
	24 V DC		71 A	

*1: Power consumption in steady operation is indicated in VA (AC), A (DC) or W (DC). When power consumption varies according to the installed number of equipment, power consumption by the maximum number of units installed is listed.

*2: Heating value in steady operation is indicated in Joule/hour. When heating value varies according to the installed number of equipment, heating value by the maximum number of units installed is listed.

Table Electrical Specifications (3/3)

Equipment	Input-voltage range		Max. power consumption (VA, A, W) (*1)	Heating value J/h (*2)
	Voltage (V AC)	Frequency (Hz)		
A2CUKT4-□1□□□, A2CUKT4-□2□□□ Cabinet Utility Kit (at maximum installation of module, for Rittal Cabinet)	100-120	50/60±3	2900 VA	6264×10^3 (1740 W)
	220-240		3320 VA	
	24 V DC		82 A	
A2CUKT4 Cabinet Utility Kit (excluding node)	100-120	50/60±3	100 VA	216×10^3 (60 W)
	220-240		100 VA	
	24 V DC		5 A	

*1: Power consumption in steady operation is indicated in VA (AC), A (DC) or W (DC). When power consumption varies according to the installed number of equipment, power consumption by the maximum number of units installed is listed.

*2: Heating value in steady operation is indicated in Joule/hour. When heating value varies according to the installed number of equipment, heating value by the maximum number of units installed is listed.

Actual Power-On In-Rush Current of Each Component

Actual in-rush current data measured for each component is listed below:

Table System Equipment Power-On In-Rush Current

Model		In-Rush current (A)		In-Rush current (A)		In-Rush current (A)	
		100 V AC		220 V AC		24 V DC	
		Primary	Secondary	Primary	Secondary	Primary	Secondary
AFV30S	FCU (rack mountable type)	62	5	124	5	30	23
AFV30D	Duplexed FCU (rack mountable type)	62	5	124	5	30	23
AFV40S	FCU with Cabinet (with Maximum no. of node units installed)	344	180	540	132	120	170
AFV40D	FCU with Cabinet (with Maximum no. of node units installed)	344	180	540	132	120	170
A2FV50S	FCU (19-inch rack mountable type)	62	5	124	5	30	23
A2FV50D	Duplexed FCU (19-inch rack mountable type)	62	5	124	5	30	23
A2FV70S/D	FCU (rack mountable type)	62	5	124	5	30	23
AVR10D	Duplexed V net router	47	1	48	0.5	10	2
ACB51	I/O Expansion Cabinet (With maximum no. of node units installed)	344	180	540	132	120	170
ANB10S/D	Node Unit for ESB Bus	62	5	124	5	30	23
ANB11S/D	Optical ESB Bus Node Unit	62	5	124	5	30	23
AVR10D	Duplexed V net Router	47	1	48	0.5	10	2
AW810D	Wide Area Communication Router	47	1	48	0.5	10	2
A2NN10D	Node Interface Unit	40	—	80	—	60	—
A2NN30D	Node Interface Unit	40	—	80	—	60	—
A2PW503	Power Supply Unit (100-240 V AC)	20	—	40	—	—	—
A2PW504	Power Supply Unit (24 V DC)	—	—	—	—	30	—
A2BE1D	Field Control Unit (Installing CP471, PW48□ and FIO)	62	5	124	5	30	23
A2BE2D	FIO Node Unit (Installing PW48□ and FIO)	62	5	124	5	30	23
A2BE2D	Optical ESB Bus Repeater Unit (Installing PW48□ and Optical ESB Bus repeater module)	62	5	124	5	30	23

—: There are no specifications.

Input current peak values and waveforms, influenced by input impedance, varies with system configurations, line sharing with other systems, and other factors. The rush current data shown above were measured under predetermined conditions (see below). Please note that the values are subject to change.

The power input circuit, with an in-rush current limiting circuit, restrains primary in-rush current, turning any current exceeding the limit to secondary and successive rush current.

Measurement Conditions

Input voltage: 132/264 V AC, 50 Hz, and 24 V DC

Power line impedance: Approx. 0.4 ohms (external line and internal impedance)

Turn-on timing: At 50 Hz, 90° or 5 ms after the AC zero-crossing point

(60 Hz data are almost identical to the 50 Hz data shown above.)

Measurement: The primary peak and secondary peak are measured after turn-on.

Note

- The timing of the maximum primary/secondary in-rush current varies with devices.
- The restart in-rush current after a momentary power failure exceeds the above data and its timing is also different.
- For a system composed of multiple pieces of equipment, the in-rush current is normally smaller than the total of the in-rush currents by individual pieces of equipment.

Maximum Power Consumption of FIO

Table Maximum Power Consumption of FIO (1/3)

Model name	Name	Max. current consumption 5 V DC (mA)	Max. current consumption 24 V DC (mA)
Bus Interface Module (FIO system) (N-IO system)			
EC401	ESB Bus Coupler Module	500	–
EC402	ESB Bus Coupler Module (for AFV30☐/AFV40☐, 2-Port)	500	–
A2EN402	N-ESB Bus Coupler Module (for N-IO, 2-Port)	500	–
A2EN404	N-ESB Bus Coupler Module (for N-IO, 4-Port)	500	–
ANT401	Optical ESB Bus Repeater Master Module 5 km (for AFV30☐/AFV40☐)	500	–
ANT411	Optical ESB Bus Repeater Master Module 5 - 50 km (for AFV30☐/AFV40☐)	500	–
ANT502	Optical ESB Bus Repeater Slave Module 5 km (for AFV30☐/AFV40☐)	500	–
ANT512	Optical ESB Bus Repeater Slave Module 5 - 50 km (for AFV30☐/AFV40☐)	500	–
Analog I/O Modules (FIO system) (*1)			
AAI141	Analog Input Module (4 to 20 mA, 16-channel, Non-Isolated)	310	450
AAV141	Analog Input Module (1 to 5 V, 16-channel, Non-Isolated)	350	–
AAB141	Analog Input Module (1 to 5 V / 4 to 20 mA, 16-channel, Non-Isolated)	480	120
AAI841	Analog I/O Module (4 to 20 mA, 8-channel Input / 8-channel Output, Non-Isolated)	310	500
AAB841	Analog I/O Module (1 to 5 V Input, 4 to 20 mA Output, 8-channel Input / 8-channel Output, Non-Isolated)	310	250
AAB842	Analog I/O Module (1 to 5 V / 4 to 20 mA Input, 4 to 20 mA Output, 8-channel Input / 8-channel Output, Non-Isolated)	410	290
AAI143	Analog Input Module (4 to 20 mA, 16-channel, Isolated)	230	540
AAI543	Analog Output Module (4 to 20 mA, 16-channel, Isolated)	230	540
AAV144	Analog Input Module (-10 to +10 V, 16-channel, Isolated)	500	–
AAV544	Analog Output Module (-10 to +10 V, 16-channel, Isolated)	860	–
AAI135	Analog Input Module (4 to 20 mA, 8-channel, Isolated Channels)	360	450
AAI835	Analog I/O Module (4 to 20 mA, 4-channel Input/4-channel Output, Isolated Channels)	360	450
AAT145	TC/mV Input Module (TC: R, J, K, E, T, B, S, N/mV: -100 to 150 mV, 16-channel, Isolated Channels)	350	–
AAR145	RTD/POT Input Module (RTD: Pt100 ohm/POT: 0 to 10 kohm, 16-channel, Isolated Channels)	350	–
AAP135	Pulse Input Module (8-channel, Pulse Count, 0 to 10 kHz, Isolated Channels)	300	400
AAP149	Pulse Input Module for Compatible PM1 (16-channel, Pulse Count, 0 to 6 kHz, Non-Isolated)	400	–
AAP849	Pulse Input/Analog Output Module for compatible PAC (Pulse count Input, 4 to 20mA Output, 8-channel Input/8-channel Output, Non-Isolated)	310	250

*1: Except for suffix code of -☐K☐, and -☐M☐.

Table Maximum Power Consumption of FIO (2/3)

Model name	Name	Max. current consumption 5 V DC (mA)	Max. current consumption 24 V DC (mA)
Digital I/O Modules (FIO system) (*1)			
ADV151	Digital Input Module (32-channel, 24 V DC)	500	–
ADV551	Digital Output Module (32-channel, 24 V DC)	700	–
ADV161	Digital Input Module (64-channel, 24 V DC)	550	–
ADV561	Digital Output Module (64-channel, 24 V DC)	780	–
ADV859	Digital I/O Module for Compatible ST2 (16-channel Input/16-channel Output, Isolated Channels)	450	–
ADV159	Digital Input Module for Compatible ST3 (32-channel Input, Isolated Channels)	330	–
ADV559	Digital Output Module for Compatible ST4 (32-channel Output, Isolated Channels)	570	–
ADV869	Digital I/O Module for Compatible ST5 (32-channel Input/32-channel Output, Common Minus Side Every 16-channel)	800	–
ADV169	Digital Input Module for Compatible ST6 (64-channel Input, Common Minus Side Every 16-channel)	800	–
ADV569	Digital Output Module for Compatible ST7 (64-channel Output, Common Minus Side Every 16-channel)	800	–
Communication Modules (FIO system) (N-IO system)			
ALR111	RS-232C Communication Module (2-Port, 1200 bps to 115.2 kbps)	500	–
ALR121	RS-422/RS-485 Communication Module (2-Port, 1200 bps to 115.2 kbps)	500	–
ALE111	Ethernet Communication Module (1-Port, 10 Mbps)	500	–
ALF111	Foundation Fieldbus (FF-H1) Communication Module (4-Ports, 31.25 kbps)	500	–
ALP121	PROFIBUS-DP Communication Module (1-Port, 9600 bps to 12 Mbps)	700	–
A2LP131	PROFINET Communication Module (1-Port, 100 Mbps)	800	–
A2LP141	PROFINET Communication Module (1-Port, 100 Mbps)	800	–
Turbomachinery I/O Modules			
AGS813	Servo Module (Isolated)	500	–
AGP813	High Speed Protection Module (Isolated)	900	–

*1: Except for suffix code of -□K□, -□M□, and -□Y□.

Table Maximum Power Consumption of FIO (3/3)

Model name		Name	Max. current consumption 5 V DC (mA)	Max. current consumption 24 V DC (mA)
Analog I/O Modules (for RIO System Upgrade)				
AAB841	-☐K☐	Analog I/O Module (1 to 5 V Input, 4 to 20 mA Output, 8-channel Input / 8-channel Output, Non-Isolated)	–	330
AAI143	-☐M☐	Analog Input Module (4 to 20 mA, 16-channel, Isolated)	–	600
AAI543	-☐M☐	Analog Output Module (4 to 20 mA, 16-channel, Isolated)	–	680
AAV144	-☐K☐ -☐M☐	Analog Input Module (-10 to +10 V, 16-channel, Isolated)	–	130
AAT145	-☐K☐ -☐M☐	Analog Input Module (-10 to +10 V, 16-channel, Isolated)	–	130
AAR145	-☐K☐ -☐M☐	RTD/POT Input Module (RTD: Pt100 ohm/POT: 0 to 10 kohm, 16-channel, Isolated Channels)	–	120
Digital I/O Modules (for RIO System Upgrade)				
ADV159	-☐K☐ -☐M☐	Digital Input Module for Compatible ST3 (16-channel Input, Isolated Channels)	–	120
	-☐Y☐		–	300
ADV559	-☐K☐ -☐M☐	Digital Output Module for Compatible ST4 (32-channel Output, Isolated Channels)	–	130
	-☐Y☐		–	410
ADV169	-☐K☐ -☐M☐	Digital Input Module for Compatible ST6 (32-channel Input, Common Minus Side Every 16-channel)	–	170
ADV569	-☐K☐ -☐M☐	Digital Output Module for Compatible ST7 (64-channel Output, Common Minus Side Every 16-channel)	–	190

Maximum Power Consumption of N-IO

Mode	Name	Max current cosumption 24 V DC (A)
A2BN3D	Base Plate for Adaptor (Field Power Supply)	8 A
A2BN4D	Base Plate for Barrier (Barrier Power Supply)	1.6 A
A2BN5D	Base Plate for Barrier (Barrier Power Supply)	1.2 A

Breaker Specifications

Breaker ratings are listed below:

Table Breaker Ratings (1/2)

Equipment	Built-in breaker rating (A/V)	External breaker rating (Recommend) (A/V) (*1)
A2FV50S/A2FV50D field control unit (100 V AC, 220 V AC)	6.3/250 (fuse)	15/250
A2FV50S/A2FV50D field control unit (24 V DC)	10/250 (fuse)	20/250
A2FV70S/A2FV70D field control unit (100 V AC, 220 V AC)	6.3/250 (fuse)	15/250
A2FV70S/A2FV70D field control unit (24 V DC)	10/250 (fuse)	20/250
ANB10S/10D ESB bus node unit (100 V,220 V AC)	6.3/250 (fuse)	15/250
ANB10S/10D ESB bus node unit (24 V DC)	10/250 (fuse)	20/250
AFV30S/D field control unit (100 V AC system)	6.3/250 (fuse)	15/250
AFV30S/D field control unit (220 V AC system)	6.3/250 (fuse)	15/250
AFV30S/D field control unit (24 V DC)	10/250 (fuse)	20/250
AFV40S/D field control unit (100 V AC system)	20/250 (two)	50/250
AFV40S/D field control unit (220 V AC system)	20/250 (two)	50/250

Table Breaker Ratings (2/2)

Equipment	Built-in breaker rating (A/V)	External breaker rating (Recommend) (A/V) (*1)
AFV40S/D field control unit (24 V DC)	30/24 (three)	100/24
ACB51 I/O expansion cabinet (100 V AC system)	20/250 (two)	50/250
ACB51 I/O expansion cabinet (220 V AC system)	20/250 (two)	50/250
ACB51 I/O expansion cabinet (24 V DC)	30/24 (three)	100/24
ANB11S/D Optical ESB bus node unit (100 V AC system)	6.3/250 (fuse)	15/250
ANB11S/D Optical ESB bus node unit (220 V AC system)	6.3/250 (fuse)	15/250
ANB11S/D Optical ESB bus node unit (24 V DC)	10/250 (fuse)	20/250
ANT10U Unit for optical ESB bus repeater module (100 V AC system)	6.3/250 (fuse)	15/250
ANT10U Unit for optical ESB bus repeater module (220 V AC system)	6.3/250 (fuse)	15/250
ANT10U Unit for optical ESB bus repeater module (24 V DC)	10/250 (fuse)	20/250
ACUKT1 Cabinet utility kit (100 V AC system)	20/250 (fuse)	50/250
ACUKT1 Cabinet utility kit (220 V AC system)	20/250 (fuse)	50/250
ACUKT1 Cabinet utility kit (24 V DC)	30/24 (three)	100/24
AVR10D Duplexed V net router (100 V AC system)	3.15/250 (fuse)	10/250
AVR10D Duplexed V net router (220 V AC system)	3.15/250 (fuse)	10/250
AVR10D Duplexed V net router (24 V DC)	6.3/250 (fuse)	15/250
AW810D Wide Area Communication Router (100 V AC system)	3.15/250 (fuse)	10/250
AW810D Wide Area Communication Router (220 V AC system)	3.15/250 (fuse)	10/250
AW810D Wide Area Communication Router (24 V DC)	6.3/250 (fuse)	15/250
A2NN10D Node Interface Unit (100-240 V AC system)	5/250 (fuse)	15/250

Durability of Parts

Some hardware components require periodical replacement. As a guideline to the intervals between preventive maintenance checks, the following table lists components with life span of less than 10 years.

Users can replace parts indicated by “Yes” in the “user replacement”. For other components, users should not attempt to replace them; contact Yokogawa for replacement.

There can be some parts having defined life spans in resale material mounted to a console kit. If that is the case, replace the parts according to a manual of resale material.

The average ambient temperature shown in the table is the average temperature surrounding the corresponding parts.

When the parts are installed in a cabinet of Yokogawa product, though varies with actual installations, in general, the temperature inside of the cabinet is about 10 °C higher than the temperature outside the cabinet.

Note: Random failures within the recommended replacement intervals may occur in some parts.

IMPORTANT

The reliability and life span of electronic equipment greatly depend on the operating environment. It is essential for ensuring reliable operation and prolonged life span that the equipment is used not only within the range of environment resistance standards but also in a more satisfactory environment. For instance, if a piece of equipment is always used at 35 °C when its operating temperature ranges from 5 to 40 °C, generally its resulting in a reduced life span compared with operation at 25 °C.

If corrosive gas is present in the environment, the corrosion of the equipment’s contacts and printed circuit boards is accelerated more than in a cleaner environment, resulting in a reduced life span. Moreover, if dust can be easily generated in the environment, filters must be cleaned and replaced more often.

AIP830, AIP831

Part names	Part numbers	Recommended replacement cycle	Replacement by user	Remarks
AIP830	AIP830	–	Yes	Depends on frequency of use.
AIP831	AIP831	–	Yes	Depends on frequency of use.

Channel base	Spring Black (3.3PB2.5/0.5)	LPCKIT, YPCKIT, AFV40S/AFV40D, YAX801, AFS20S/AFS20D, AFS40S/AFS40D, AFG20S/AFG20D, AFG40S/AFG40D

5. Post-installation Inspection and Environmental Preservation

Post-installation Inspection

Upon the completion of installation of instrumentation, before turning on the power inspect the following items in the list below to avoid system contamination by dust and moisture dust and condensation.

Table Inspection before Power On

	Inspection items (daily inspection/maintenance items)
Environment	☐ No water intrusion from cable ducts. ☐ No wind/rain blow-in ☐ Air-conditioned ☐ Cable ducts and cabinet bottoms covered to prevent entry of wind, dust, moisture ☐ Cabinets and surroundings cleaned ☐ No dust entering from air vents ☐ Free of salty, ferrous, corrosive gas ☐ No direct sunlight on equipment
Equipment	☐ No condensation or traces on cabinet interior/exterior ☐ No discoloration or rust on cabinet interior/exterior ☐ No condensation or traces on cards (disconnect cards on the upper, middle, and lower stands, and left and right sides of the cabinet to check that there is no condensation on the cards or defects anywhere in the cabinet.) ☐ No dust remaining inside cabinet

It is recommended that you turn on the power in the presence of Yokogawa when turning it on first.

Post-installation Environment Preservation

The following precautions should be taken to preserve the proper operating environment after the system has been installed:

- Seal the pits if they are shared by equipment in other rooms, preventing entry of dust and moisture from the other rooms.
- Seal all cable ducts of equipment and building with putty upon completion of cabling.
- Always turn on air conditioner. Turning it on/off may cause condensation inside equipment. If you turn on the power of an air conditioner after a long stop, turn on the air conditioner first and the system. Otherwise condensation may occur.
- Monitor and record ambient temperature and humidity. To maintain the reliability of the equipment be sure to remove the cause if they fluctuate violently.
- Note that leaving exits and entrances open during installation, or leaving open cable ducts whiles pulling cables, may result in condensation.

Revision Information

- Title : CENTUM VP Installation Guidance
- Manual No. : TI 33J01J10-01EN

Apr. 2024/26th Edition
1.2 ■ Electric field strength (Electric wave condition) [completely revised]
1.2 Table Equipment Installation Specifications (1/2) [remark *3 was revised]
1.7 Table G3 Environment-compatible Products (2/3) [A2LP141 was added]
3.6.2 Table Signal Cables for Connection with FIO (2/2) [A2LP141 was added]
4. Table Maximum Power Consumption of FIO (2/3) [A2LP141 was added]

Dec. 2023/25th Edition
1.5.1 Noise Sources and Noise Countermeasures
Table Noise Sources & Countermeasures [Spark Killer Terminology was corrected.]
■ Examples ofinstalling protection circuit for noise caused by inductive load [Title and content were corrected.]

Nov. 2023/24th Edition
1.2 Control Room Environment
Table Measurement category [Applicable Standard was revised.]
3.1 Cables and Terminals
Table Rating temperature of Cables [N-IO field enclosure was added.]
3.5 Connecting Signal Cable
■ Process I/O Signal Connection [● Push-in terminal was added.]
■ Signal Cable Termination [● Push-in terminal was added.]

Aug. 2023/23rd Edition
1.2 Control Room Environment
■ Measurement Categories [Applicable standard was changed. Correction of errors.]
■ Applied Standards [Applicable standard was changed.]
4. Installation specifications
■ Durability of Parts [The recommended replacement cycle for ANT401, ANT411, ANT502, ANT512, and A2EN501are changed.]

Apr. 2023/22nd Edition
1.2 Control Room Environment
■ Conformity Standards
● Standard for Hazardous (Classified) Locations [Notation review and revision]
■ Installation Environment Specifications
Table Equipment Installation Specifications (1/2) [Correction of clerical error]

June 2022/21st Edition
3.6.2 List of Signal Cables for Connection with FIO [I/O Modules with Built-in Barrier (for FIO) are deleted.]
4. Installation Specifications [I/O Modules with Built-in Barrier (for FIO) are deleted.]

Apr. 2022/20th Edition
1.2 Control Room Environment
■ Applied Standards
[Notes of CENTUM manufacturer and official representative in EEA related to CE marking was deleted.]
■ Installation Ebvironment Specifications [Corrected Note]
1.6 Cabling Requirements
■ Ambient Temperature [Changed description]
2.5.6 Example of Mounting to General Purpose Cabinet/Junction Box
● Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Cabinet
Table Maximum numbers of units that can be mounted in case of this example [Note was revised]
● Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Junction Box
Table Maximum numbers of units that can be mounted [Note was revised]
● Example of Mounting N-IO Nodes (Mixture of Intrinsic Safety Barrier and Non-Intrinsic Safety

Barrier) in a Junction Box
Table Maximum numbers of units that can be mounted [Note was revised]

Dec. 2021/19th Edition
1.1 Control Room Design
■ Floor Strength and Space [Change reference documents to GS from SD]
1.2 Control Room Environment
■ Applied Standards [Added Ex "ec"] [Added UKCA Marking] [Changed CSA number] [Change "DNV GL" to "DNV"]
1.8 Compliance with Marine Standards [Change "DNV GL" to "DNV"]
2.4 Servicing Area[Add the figure of servicing area] [Deleted External Dimensions (SD)]
2.5.1 Installation on Floor
■ Size of Cabling Holes in Floor [Deleted External Dimensions (SD)]
2.5.3 19-inch Rack Mount Devices
■ Notes on Installation [Deleted External Dimensions (SD)]
3.2 Connecting Power
■ Terminal Connection [Add AEP7D and AEP9D]
3.6.4 Implementation and Cable Connection of Fieldbus Communication Module ALF111
■ Fieldbus Wiring for ALF111 with Pressure Clamp Terminal Block[Add an annotation]

May 2021/18th Edition
1.2 Control Room Environment
■ Installation Specification[The voltage of Category I and Category II was changed.]
■ Applied Standards[CE Marking Low Voltage Directive Number was changed. The describe about the breakers was delete.]

Jan. 2021/17th Edition
Summary: Correspondence to CENTUM VP R6.08
All Chapter
Added the configurations with Base Plate (for FCU) A2BE1D, HKU Interface Unit A2FU1, Primary Power Distribution Unit (for FCU) A2FU2, Base Plate (for FIO) A2BE2D, , ESB Bus Adapter (for SB401) A2EE1A, ESB Bus Adapter (for ANT4□1) A2EE2A, ESB Bus Adapter (for ANT5□2) A2EE3A, Cabinet Utility Kit A2CUKT4, and Standard Cabinet A2CAB1.

Mar. 2020 /16th Edition
3.2 Connecting Power
● Sleeve Terminal Processing [Table for sleeves was revised.]
3.5 Connecting Signal Cable
● Pressure Clamp Terminal (for FIO Module Pressure Clamp Terminal Block) [Table for sleeves was revised.]
● Pressure Clamp Terminal, Spring Clamp Terminal (for N-IO) [Table for sleeves was revised. Description for A2BN4D was added.]

Jan. 2020 /15th Edition
Introduction Updated descriptions of trademark.
1.2 Control Room Environment
■ Applied Standards[Added $C_{\mathfrak{P}}$ Marking]

Aug. 2019 /14th Edition
1.7 Corrosive-gas Environment Compatibility
Table G3 Environment-compatible Products [Added A2MDV843, A2NN20D, A2SMX802]
3.4 Power and Ground Cabling
■ A2BN5D Base Plate for Barrier (P+F) [Added CAUTION]
3.8.3 Adaptors (for A2BA3D) [Added shunt resistor unit fixing plate mounting specifications]
● When attaching a shunt resistor to the M4 screw terminal block of A2BA3D [Added newly]

July 2019 /13th Edition
1.2 Table Equipment Installation Specifications (1/2) [remark *2 was revised]
1.7 Table G3 Environment-compatible Products (2/3) [ALP111 was deleted, A2LP131 was added]
3.4 Power and Ground Cabling
■ A2BN4D Base Plate for Barrier (MTL) [CAUTION was deleted]
■ A2BN5D Base Plate for Barrier (P+F) [CAUTION was deleted]

3.6.2 Table Signal Cables for Connection with FIO (2/3) [ALP111 was deleted, A2LP131 was added]
4. Table Maximum Power Consumption of FIO (2/3) [ALP111 was deleted, A2LP131 was added]
Installation Specifications ■ Parts Durability [Revised the description of IMPORTANT]

Mar. 2019 /12th Edition
1.2 ■ Measurement Categories [Updated the description of safety standard.]
■ Applied Standards [Updated the description of safety standard.]
2.5.6 ■ Cabinet for N-IO System [Updated the specification for cabinet.]
4. Table Breaker Ratings [Correction of clerical error]

Jan. 2019 /11th Edition
1.1 Control Room Design
■ Side-by-Side Cabinet Installation [Contact information was changed]
1.2 Control Room Environment [Contact information was changed]
■ Vibration [Contact information was changed]
1.5.2 Countermeasures against Static Electricity [Arrangement Information of wrist straps and conductive sheets were deleted]
2.2 Unpacking
Caution [Contact information for Condensation was deleted]
Caution [Contact information at product fall was changed]
2.3 Storage [Contact information was changed]

Oct. 2018 /10th Edition
Front page Changed logo mark
Safety Precautions Changed symbol mark description
1.2 ■ Applied Standards [Corrected the target GS]
Table Equipment Installation Specifications [Added the note of temperature specification]
1.4 Grounding Table [Corrected the target grounding]
1.6 ■ Measures against EMI [Added the note for ambient temperature]
1.7 ■ Table G3 Environment-compatible Products [Added terminal boards]
2.3 ■ Storage of Unpacked Equipment [Added the note for desiccating agent or corrosion inhibitor]
2.5.4 DIN Rail Mountable Devices [Added A2BM4]
■ Notes on Installation [Revised the terms, Added notes for A2BM4]
2.5.5 Wall Mountable Devices [Added the notes for mounting A2BM4]
2.5.6 Example of Mounting to General Purpose Cabinet / Junction Box
Table Cabinet Dimensions [Changed the dimension]
[Added “Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet (For field wiring via terminal board)”]
[Added the notes of cabinet ambient temperature for mounting N-IO nodes]
[Added “Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Cabinet (For field wiring via terminal board)”]
3.1 Table Rating temperature of Cables [Added A2BM4]
3.4 ■ A2BN3D Base Plate for Adaptor [Added figure of power and ground cabling for A2BN3D]
■ Example of System Cabinet Installation and Grounding Wiring [Clerical corrections]
3.5 Connecting Signal Cable [Revised the description]
Table Applicable Interface [Added A2BM4]
■ Connecting Signal Cables to Terminals (for N-IO) [Added supplementary information]
3.7.2 Table Terminal type Compatible with A2BN3D Base Plate for Adaptor [Added new suffix code and note]
[Added “■ Terminal board for analog digital I/O (Pressure Clamp Terminals)”]
■ Connecting Signal Cables with A2BN3D [Added description]
Table Terminal Numbers and Signal Types (A2BN3D) [Added notes]
3.7.3 ■ A2SAP105 Pulse Input Signal Adaptor [Added description for connecting field signals to A2BM4]
[Added the figure for connecting field signals to A2SAP105 via A2BM4]
● When receiving dry contact signals (Input frequency: 0 to 10 kHz) [Figure were added]
■ A2EXR001 Shunt Resistor Unit [Changing position described]
■ A2SAT105 mV/TC/RTD input adaptor [Added notes for using A2SAT105]
■ A2SDV105 Digital input adaptor [Added description for A2SDV105]
■ A2SMX802 Pass-through I/O signal adaptor [Added description for A2SMX802]
3.8.2 Table Terminal numbers and signal types [revised]
3.8.3 ● When receiving dry contact signals (Input frequency: 0 to 10 kHz) [Figure were added]
■ A2EXR001 Shunt Resistor Unit [Changing position described]
■ A2SAM105 Current input/voltage input adaptor [Revised description for installing the shunt resistor

module]
● When the input current value exceeds 25 m A [Added]
● When sharing the current signal with another receiving device. [Title added]

June 2018 /9th Edition
3.1 Cables and Terminals
Table Rating temperature of Cables [Revised A2BN5D cable requirements]
3.7.1 N-IO I/O Unit Types
■ I/O Modules that can be used with Base Plate
Table I/O Modules Installable with Base Plate [Correction of clerical error]
3.7.3 Table Terminal Numbers and Signal Types (A2BN5D) [P+F I.S. barrier models are deleted]

Mar. 2018 /8th Edition
1.3 Notes for the field power supply unit of N-IO is added.
1.5.1 Examples of Spark-Killer and Diode Installation [Title is changed.]
2.5.4 Figure Mounting stopper to the DIN rail is revised.
2.5.6 Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet
[Mounting conditions are corrected.]
Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Cabinet
[Mounting conditions are corrected.]
Example of Mounting N-IO Nodes (Intrinsic Safety Barrier) in a Cabinet
[Mounting conditions are corrected.]
3.5 Figure Area for Signal Cable from Field is revised.
Figure Example of Node Interface Unit and I/O Unit Cable Wiring (Cabinet) is revised.
Figure Example of Node Interface Unit and I/O Unit Cable Wiring (Junction Box) is revised
3.7.3 ■ A2SDV505, ■ A2SDV506, ■ A2SMX802, [Errors in writing are corrected]

Jan. 2018 /7th Edition
- N-IO product A2EXR001 was added.
1. System Installation Requirements
1.7 Corrosive-gas Environment Compatibility [A2EXR001 was added]
2. Transportation, Storage and Installation
2.5 Installation
2.5.6 Example of Mounting to General Purpose Cabinet/Junction Box
Example of Mounting an FCU for N-IO and N-IO Nodes in a Cabinet [A2EXR001 was added]
Example of Mounting N-IO Nodes (Non-Intrinsic Safety Barrier) in a Cabinet [A2EXR001 was added]

Veeam Backup & Replication

Deployment

To start working with Veeam Backup & Replication, you must configure a backup server — install Veeam Backup & Replication on a machine that meets the system requirements. To do this, you can use the setup wizard or install the product in the unattended mode.

When you install Veeam Backup & Replication, the Veeam Backup & Replication console is automatically installed on the backup server. If you want to access Veeam Backup & Replication remotely, you can install the Veeam Backup & Replication console on a dedicated machine.

Installing Veeam Backup & Replication

Before you install Veeam Backup & Replication, check prerequisites. Then use the Veeam Backup & Replication setup wizard to install the product.

Before You Begin

Before you install Veeam Backup & Replication, check the following prerequisites:

- A machine on which you plan to install Veeam Backup & Replication must meet the system requirements. For more information, see System Requirements.
- A user account that you plan to use for installation must have sufficient permissions. For more information, see Permissions.
- Backup infrastructure components communicate with each other over specific ports. These ports must be open. For more information, see Ports.
- You must remove Veeam Backup & Replication components of versions that are not supported by the upgrade procedure from the target machine. You may also need to remove earlier versions of other Veeam products and components.
- Before deploying Veeam Backup & Replication, define where the Veeam Backup & Replication server will be located. Depending on what kind of protection are you planning to use, the
  Veeam Backup & Replication server should be located on the source site or the Disaster Recovery site.
  - When replication or CDP is used: If you plan to use replication or Continuous Data Protection (CDP), the Veeam Backup & Replication server should be deployed in the disaster recovery site. In this case, if the production host crashes, Veeam Backup & Replication will automatically fail over to the replica without any manual operations. The source backup infrastructure still can be managed with the same Veeam Backup & Replication server with the help of backup proxies deployed in the source site.
  - When only backup features are used: If you plan to use Veeam Backup & Replication for backup jobs only, the backup server should be placed in the production site.

Configuration Database

Before deploying Veeam Backup & Replication, decide which database engine and version you need to use:

- If you do not prepare a database engine in advance, Veeam Backup & Replication will automatically install PostgreSQL 15.1 locally on the backup server.
- Decide if you need the database engine installed on the same server as Veeam Backup & Replication or on a remote server. Veeam Backup & Replication requires a database engine deployed either locally on the backup server or remotely.

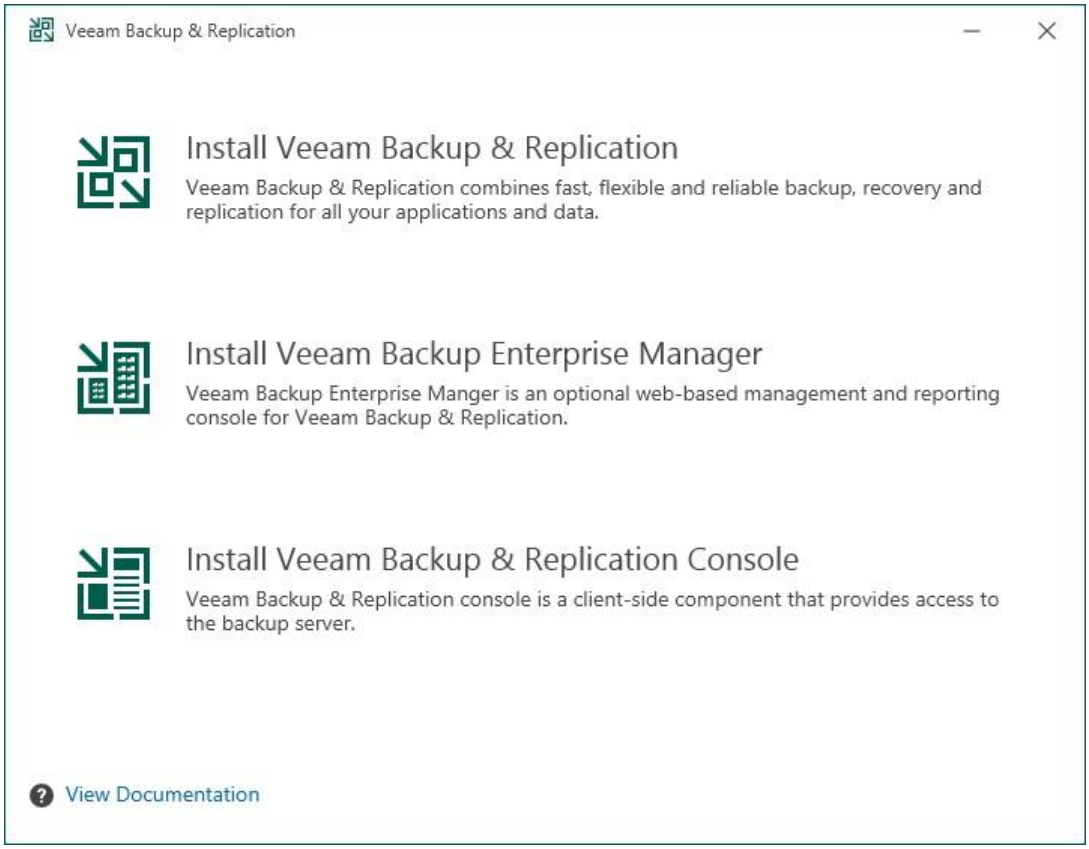
  It is recommended to run the database engine instance locally to eliminate latency issues. However, in some scenarios a remote instance can be the better choice:
  - High Availability. SQL Clustering and Always On Availability Group on external SQL Servers can be used for high availability of the configuration database. To learn about the configuration details, see this Veeam KB article.
  - Licensing. Some enterprises have dedicated virtual clusters for SQL Servers due to licensing constraints. In such cases, you can place the Veeam configuration database on an existing instance to lower the total cost of ownership.
- If you prefer to use an Express Edition of Microsoft SQL Server as your database engine, note that its usage is limited by 10 GB of configuration database. The Express Edition is enough for evaluation purposes and not very large environments (<500 VMs). If your infrastructure is large (more than 500 VMs), you may consider to install a Microsoft SQL Server in advance.
- If Microsoft SQL Server is installed by the previous product version, Veeam Backup & Replication will connect to the existing configuration database, upgrade it (if necessary) and use it for work.

Step 1. Start Setup Wizard

To start the setup wizard:

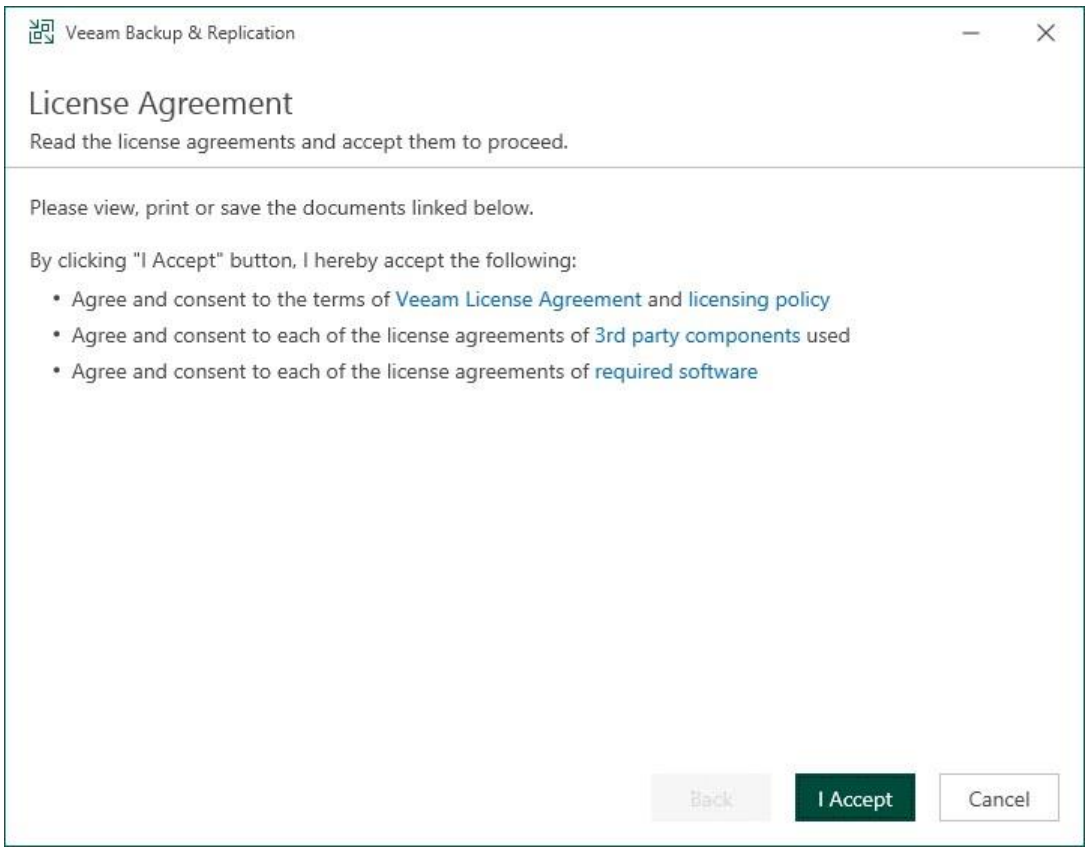
1. Download the latest version of the Veeam Backup & Replication installation image from the Download Veeam Products page.
2. Mount the installation image to the machine on which you plan to install Veeam Backup & Replication or burn the image file to a flash drive or other removable storage device. If you plan to install Veeam Backup & Replication on a VM, use built-in tools of the virtualization management software to mount the installation image to the VM.

   To extract the content of the ISO, you can also use the latest versions of utilities that can properly extract data from ISOs of large size and can properly work with long file paths.
3. After you mount the image or insert the disk, Autorun will open a splash screen. If Autorun is not available or disabled, run the `Setup.exe` file from the image or disk.
4. In the splash screen, click Install.



> IMPORTANT
>
> It is strongly recommended that you install Veeam Backup & Replication using Autorun or the Setup.exe file. If you run other installation files from the ISO folders, you may miss some components that need to be installed, and Veeam Backup & Replication may not work as expected.

Step 2. Select Component



At the Select Veeam Backup & Replication Component step of the wizard, select Install Veeam Backup & Replication.

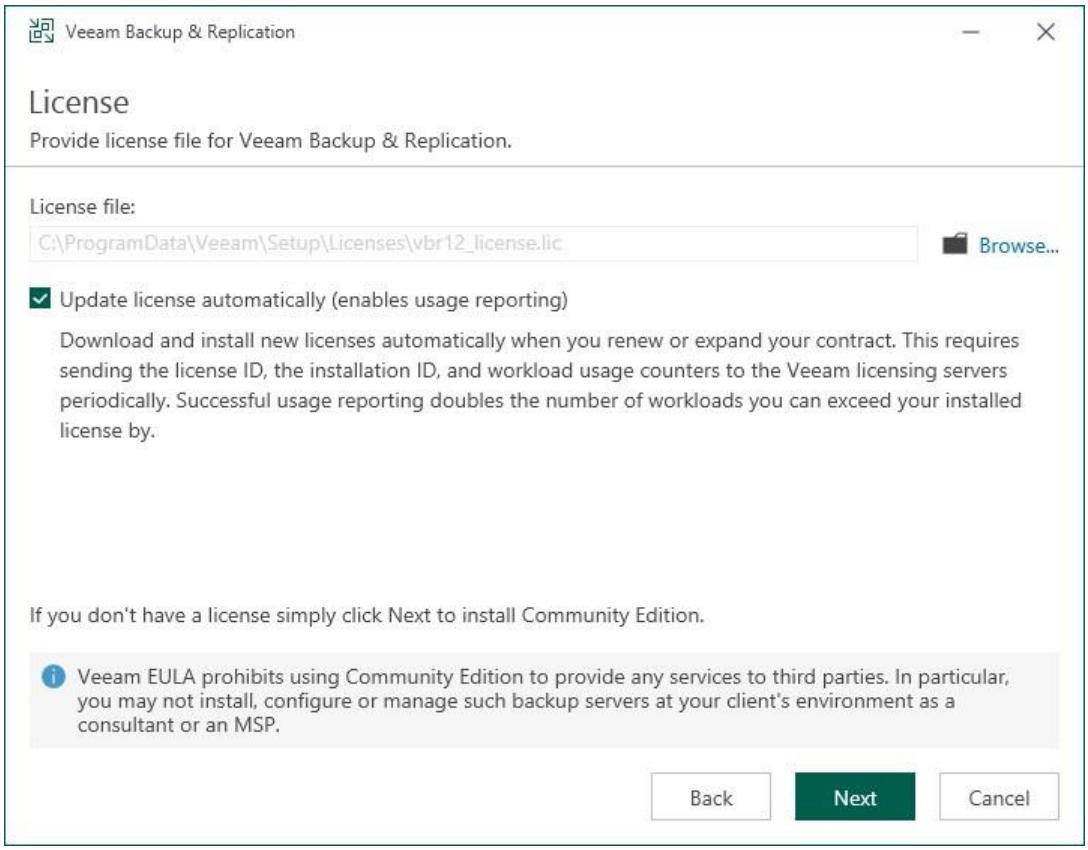
To open Veeam Help Center from the setup wizard, click View Documentation.

Veeam Backup & Replication
Install Veeam Backup & Replication
Veeam Backup & Replication combines fast, flexible and reliable backup, recovery and replication for all your applications and data.
Install Veeam Backup Enterprise Manager
Veeam Backup Enterprise Manger is an optional web-based management and reporting console for Veeam Backup & Replication.
Install Veeam Backup & Replication Console
Veeam Backup & Replication console is a client-side component that provides access to the backup server.
View Documentation

Step 3. Read and Accept License Agreement

At the License Agreement step of the wizard, read Veeam License Agreement and licensing policy as well as license agreements of 3rd party components that Veeam incorporates and license agreements of required software. To accept the license agreements and continue installing Veeam Backup & Replication, click I Accept.

Step 4. Provide License File



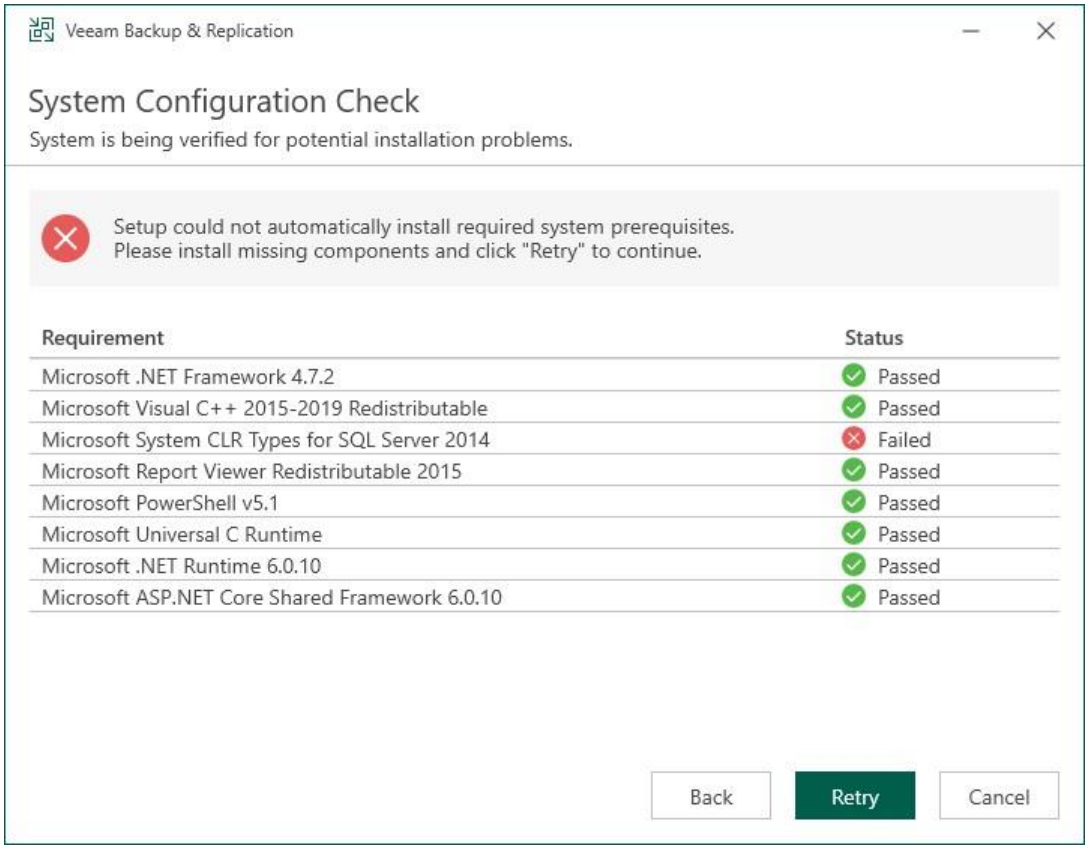
At the Provide License step of the wizard, specify what license you want to install for Veeam Backup & Replication. For more information, see Licensing.

If a valid license is already installed on the machine, the setup wizard will inform you about it. In this case, you can skip the Provide License step and move to the next step of the wizard.

If you do not install a license, the product will operate in the Veeam Backup & Replication Community (free) Edition. For more information, see Veeam Backup & Replication Community Edition.

To install a license:

1. Next to the License file field, click Browse.
2. Select a valid license file for Veeam Backup & Replication.
3. To install new licenses automatically when you renew or expand your contract, select the Update license automatically check box. If you enable the automatic license update, and therefore enable usage reporting, you will double the number of workloads by which you can exceed your installed license. For more information, see Exceeding License Limit.



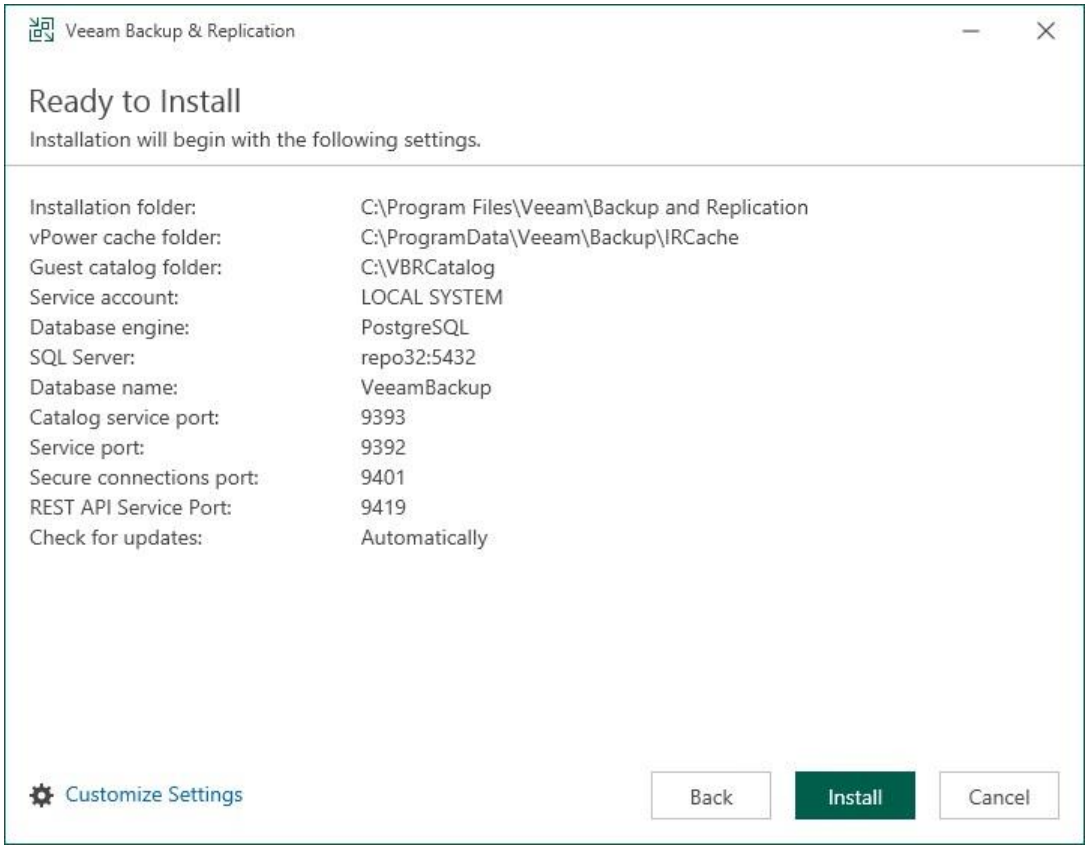
Step 5. Install Missing Software

At the System Configuration Check step of the wizard, the setup wizard checks if the required software is installed on the machine. If some of the required components are missing, the setup will try to install them automatically. After the components are successfully installed, reboot is required. To reboot the machine, click Reboot.

If the setup wizard cannot install some of the required software components automatically, install them manually and click Retry.

> NOTE
>
> If all required software is already installed on the machine, the System Configuration Check step will be skipped. For more information on the necessary software, see System Requirements.

Step 6. Review Default Installation Settings



At the Ready to Install step of the wizard, you can select to install Veeam Backup & Replication with default installation settings or specify custom installation settings.

- To use the default installation settings, click Install.
- To use custom installation settings, click Customize Settings. The setup wizard will include additional steps that will let you configure installation settings.

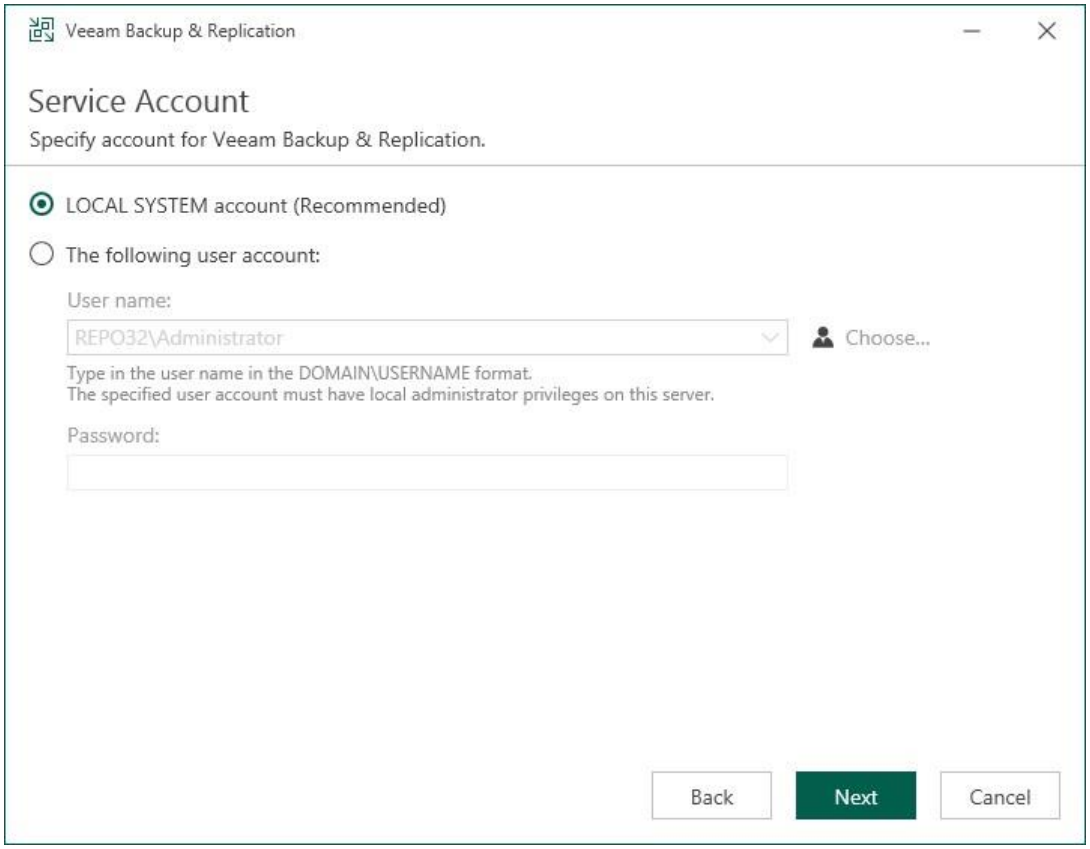
The table below lists the default installation settings.

Setting	Default Value	Description
Installation folder	C:\Program Files\Veeam\Backup and Replication	Folder where Veeam Backup & Replication will be installed.
vPower cache folder	C:\ProgramData\Veeam\Backup\IRCache	The `IRCache` folder on a volume with the maximum amount of free space. The IR cache folder stores the write cache for machines that are started from backups during recovery verification or restore operations. Make sure that you have at least 10 GB of free disk space to store the write cache.
Guest catalog folder	C:\VBRCatalog	The `VBRCatalog` folder on a volume with the maximum amount of free space. The guest catalog folder stores indexing data for VM guest OS files. Indexing data is required for browsing and searching for VM guest OS files inside backups and performing 1-click restore.
Service account	LOCAL SYSTEM	Account under which the Veeam Backup Service runs.
Database engine	PostgreSQL	The setup wizard installs PostgreSQL 15.1 as a database engine locally on the Veeam Backup & Replication server.
SQL server	<host_name>:5432	The local host name and port number to be used by SQL server.

Database name	VeeamBackup	The setup deploys the Veeam Backup & Replication configuration database on the locally installed instance of PostgreSQL.
Catalog service port	9393	The catalog service port is used by the Veeam Guest Catalog Service to replicate catalog data from backup servers to Veeam Backup Enterprise Manager.
Service port	9392	The service port is used by Veeam Backup Enterprise Manager to collect data from backup servers. In addition to it, the Veeam Backup & Replication console uses this service port to connect to the backup server.
Secure connections port	9401	The secure connections port is used by the mount server to communicate with the backup server.
REST API service port	9419	This service port is used to access the Veeam Backup & Replication REST API.
Check for updates	Automatically	Veeam Backup & Replication will check for product updates weekly. When a new product build is published on the Veeam update server, a notification is displayed in the Windows Action Center.

Veeam Backup & Replication
Ready to Install
Installation will begin with the following settings.
Installation folder: C:\Program Files\Veeam\Backup and Replication
vPower cache folder: C:\ProgramData\Veeam\Backup\IRCache
Guest catalog folder: C:\VBRCatalog
Service account: LOCAL SYSTEM
Database engine: PostgreSQL
SQL Server: repo32:5432
Database name: VeeamBackup
Catalog service port: 9393
Service port: 9392
Secure connections port: 9401
REST API Service Port: 9419
Check for updates: Automatically
Customize Settings
Back
Install
Cancel

Step 7. Specify Service Account Settings



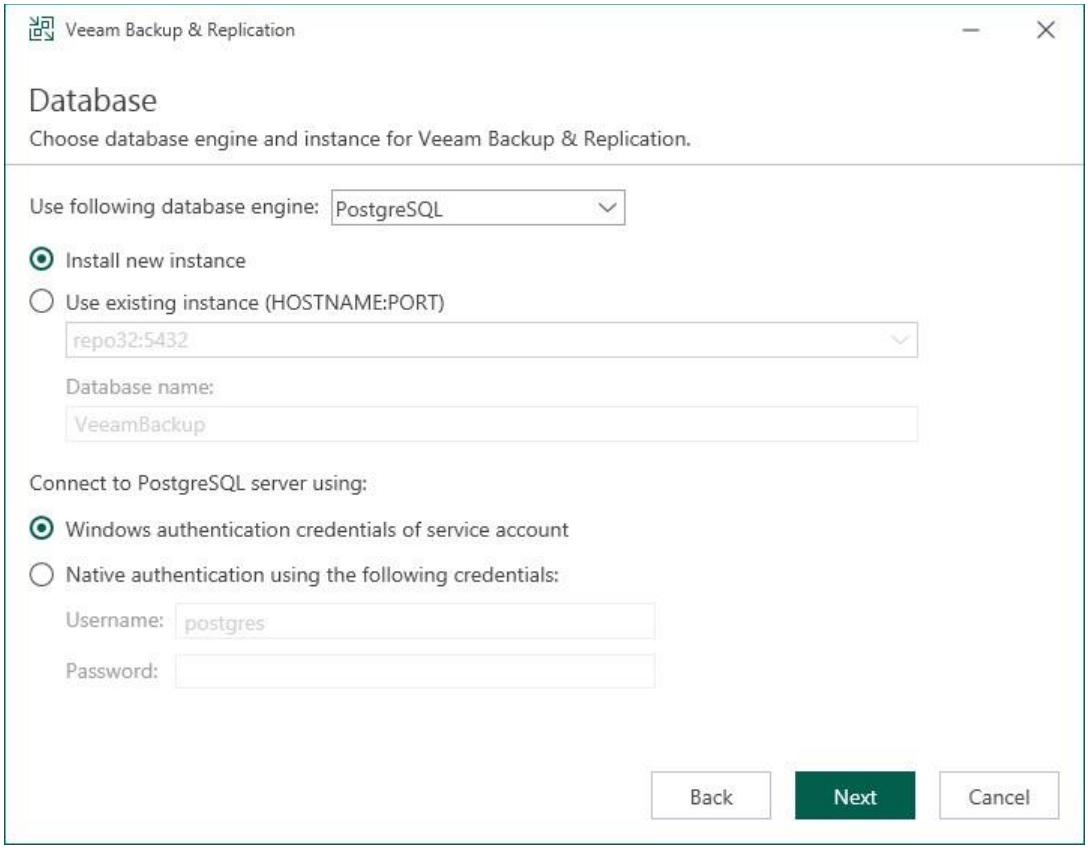
The Service Account step of the wizard is available if you have selected to configure installation settings manually.

You can select an account under which you want to run the Veeam Backup Service:

- LOCAL SYSTEM account (recommended, used by default)
- Another user account

The user name of the custom account must be specified in the DOMAIN\USERNAME format.

> NOTE
>
> The user account must have the following rights and permissions:
>
> - The account must be a member of the Administrators group on the machine where Veeam Backup & Replication is installed.
> - The account must have db_owner rights for the configuration database.
>
> Veeam Backup & Replication automatically grants the Logonasservice right to the specified user account.

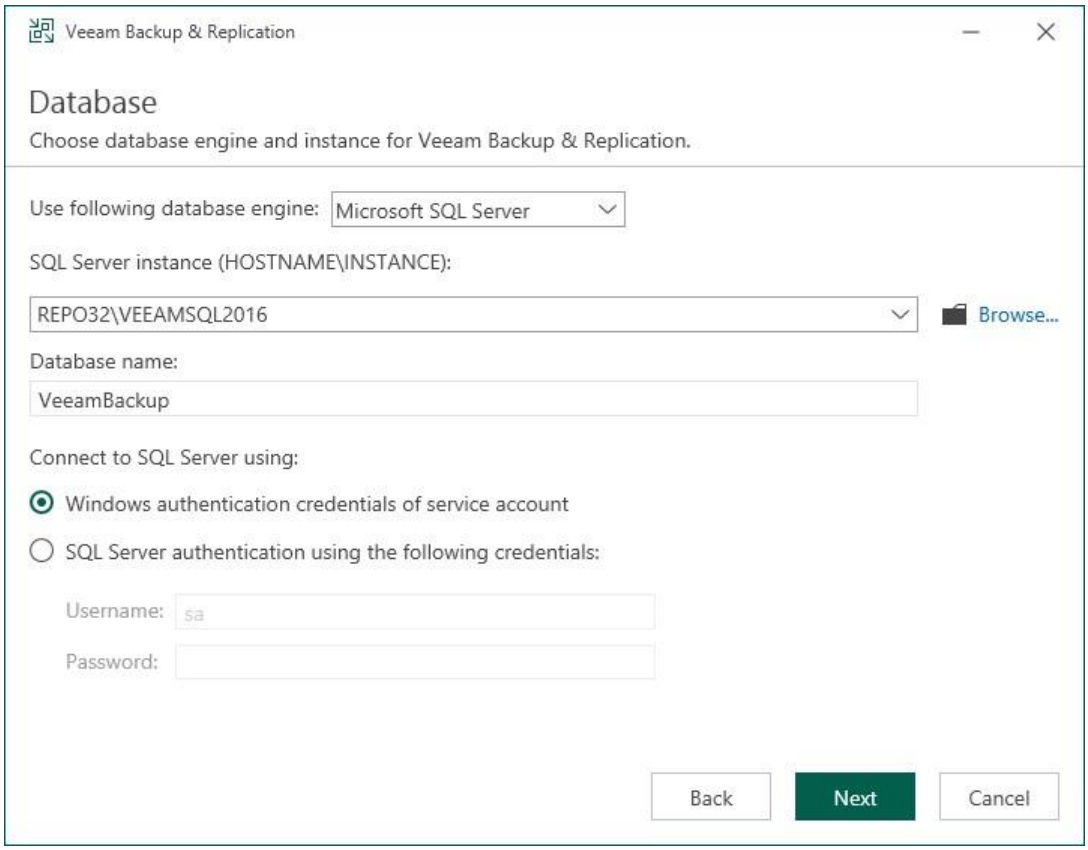


Step 8. Specify Database Engine and Instance

The Database step of the wizard is available if you have selected to configure installation settings manually.

At this step of the wizard, you can choose a database engine (PostgreSQL or Microsoft SQL Server) for the Veeam Backup & Replication configuration database, specify a new or existing instance where you want to deploy the configuration database, and specify the authentication mode.

1. Select one of the following database engines that you want to use for the configuration database:
   - PostgreSQL
   - Microsoft SQL Server
2. Specify instance settings:
   - [For PostgreSQL] You can use an already installed PostgreSQL instance or install a new one.
     - ✦ To install a new PostgreSQL instance, select the Install a new instance option. The setup will install PostgreSQL 15.1 on the Veeam Backup & Replication server and create a database with the VeeamBackup name.
     - ✦ To use an already installed PostgreSQL instance, select the Use the existing instance option. Enter the instance name in the HOSTNAME:PORT format. In the Database name field, specify a name for the Veeam Backup & Replication configuration database.



> IMPORTANT
>
> If you use the already installed PostgreSQL instance or make any changes in the machine hardware, perform the additional configuration of the PostgreSQL instance. To do that:
>
> 1. Run the Set-VBRPSQLDatabaseServerLimits cmdlet in the automatic mode.
> 2. Restart the PostgreSQL service.

   - [For Microsoft SQL Server] You can use an already installed Microsoft SQL Server database only.

i. In the SQL Server instance field, enter the instance name in the HOSTNAME\INSTANCE format or select an instance from the drop-down list. You can also click Browse to choose a Microsoft SQL Server on a remote machine.

ii. In the Database name field, specify a name for the Veeam Backup & Replication configuration database.

3. Select an authentication mode to connect to the database server instance: Microsoft Windows authentication or native database server authentication. If you select the native authentication, enter credentials of the database account.

If a configuration database with the specified name already exists (for example, it was created by a previous installation of Veeam Backup & Replication), the setup wizard will notify about it. To connect to the detected database, click Yes. If necessary, Veeam Backup Enterprise Manager will automatically upgrade the database to the latest version.

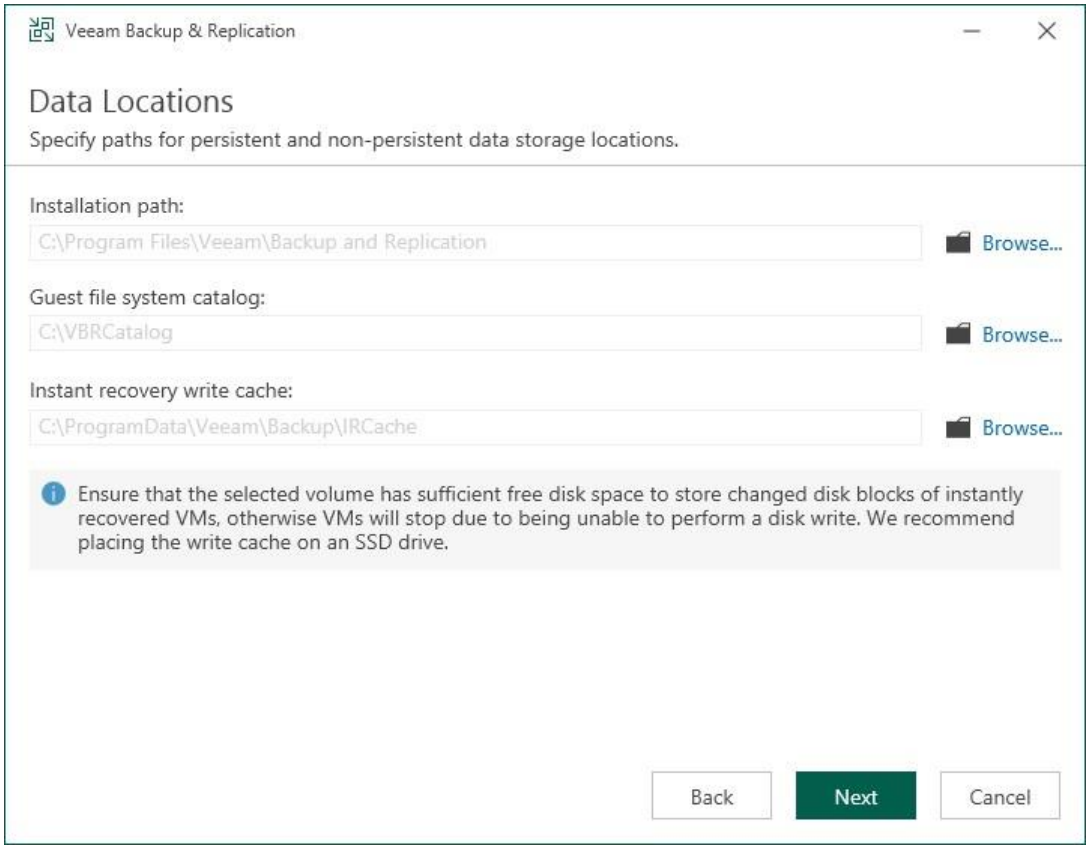
Step 9. Specify Data Locations

The Data Locations step is available if you have selected to configure installation settings manually and to install a new instance of the database server.

At this step of the wizard, you can specify the installation folder and where the write cache and indexing data must be stored.

1. To change the default installation folder, click Browse next to the Installation path field.

   By default, the setup wizard uses the following installation folder: `C:\Program Files\Veeam\Backup and Replication`.



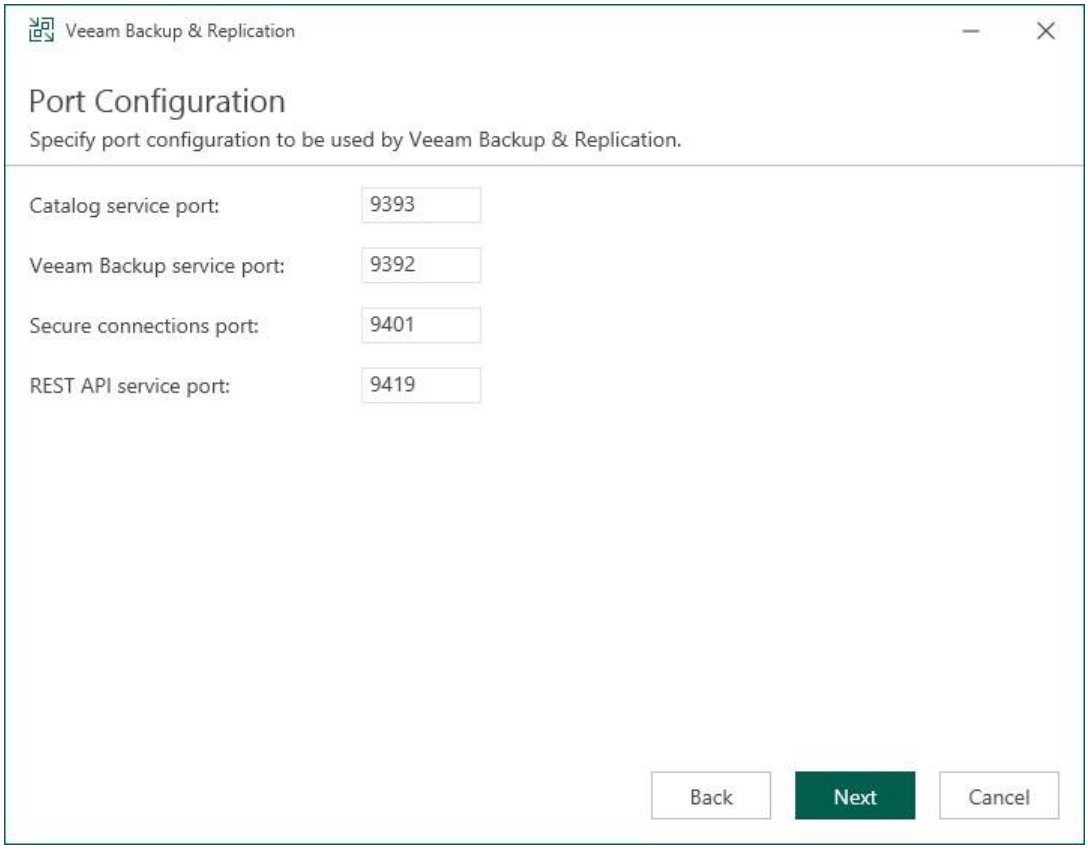
2. To change the path to the folder where index files will be stored, click Browse next to the Guest file system catalog field.

   By default, the setup wizard creates the VBRCatalog folder on a volume with the maximum amount of free space, for example: `C:\VBRCatalog`.

3. [For VMware environments] The instant recovery cache folder stores the write cache for machines that are started from backups during recovery verification or restore operations. To change the path to the IR cache folder, click Browse next to the Instant recovery write cache field. Make sure that you have at least 10 GB of free disk space to store the write cache.

   By default, the setup wizard creates the IR cache folder on a volume with the maximum amount of free space, for example: `C:\ProgramData\Veeam\Backup\IRCache`.

   You do not need to configure this data location for Microsoft Hyper-V environments.



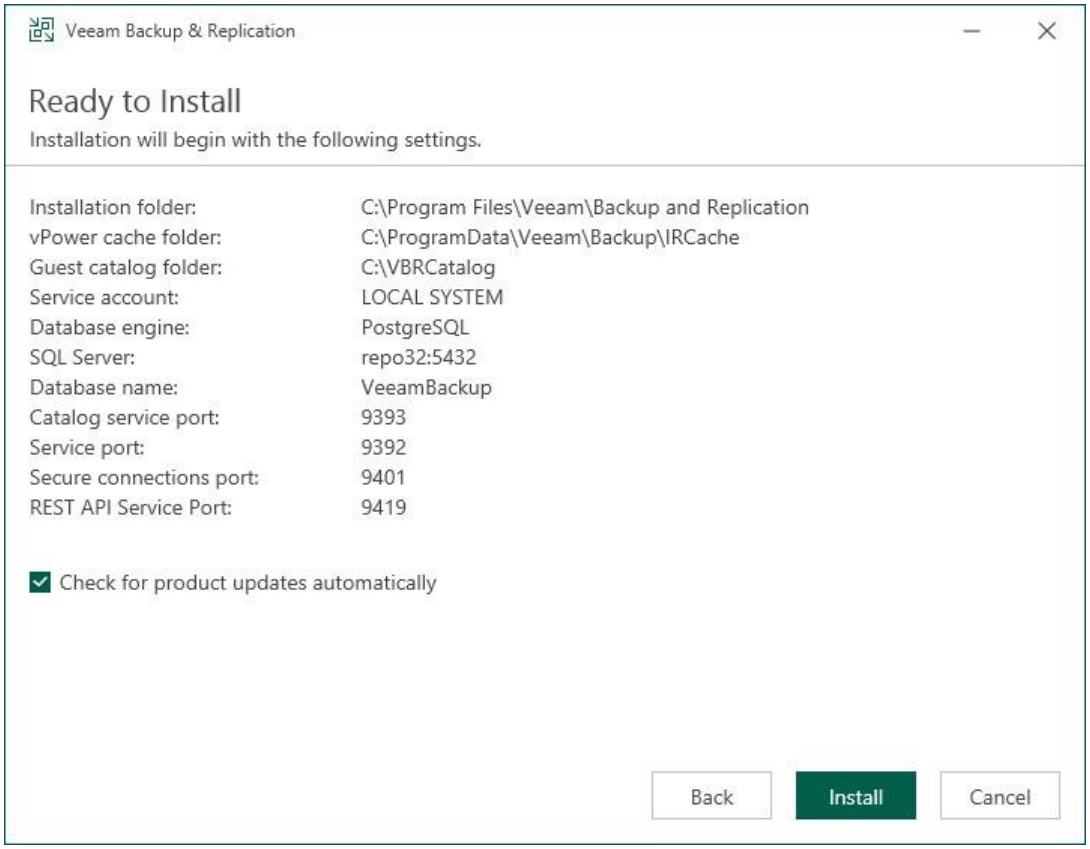
Step 10. Specify Service Ports

The Port Configuration step of the wizard is available if you have selected to configure installation settings manually.

At this step of the wizard, you can customize port number values that will be used for communication between backup infrastructure components. For more information about Veeam Backup & Replication ports, see Ports.

- Catalog service port. This port is used by the Veeam Guest Catalog Service to replicate catalog data from backup servers to Veeam Backup Enterprise Manager. By default, port 9393 is used.

- Veeam Backup service port. This port is used by Veeam Backup Enterprise Manager to collect data from backup servers. In addition to it, the Veeam Backup & Replication console uses this service port to connect to the backup server. By default, port 9392 is used.
- Secure connections port. This port is used by the mount server to communicate with the backup server. By default, port 9401 is used.
- REST API service port. This port is used to communicate with the Veeam Backup & Replication REST API. By default, port 9419 is used.



Step 11. Begin Installation

The Ready to Install step of the wizard is available if you have selected to configure installation settings manually.

At this step of the wizard, you can review the Veeam Backup & Replication installation settings and start the installation process:

1. If you want Veeam Backup & Replication to check for product updates weekly, select the Check for product updates automatically check box. When a new product build is published on the Veeam update server, a notification will be displayed in the Windows Action Center.
2. Click Install to begin the installation.
3. Wait for the installation process to complete and click Finish to exit the setup wizard.

Backup Infrastructure

Veeam Backup & Replication is a modular solution that lets you build a scalable backup infrastructure for environments of different sizes and configuration. The installation package of Veeam Backup & Replication includes a set of components that you can use to configure the backup infrastructure. Some components are mandatory and provide core functionality; some components are optional and can be installed to provide additional functionality for your business and deployment needs. You can co-install Veeam Backup & Replication components on the same machine, physical or virtual, or you can set them up separately for a more scalable approach.

Backup Infrastructure Components

The Veeam backup infrastructure comprises a set of components. Some components can be deployed with the help of the setup file. Other components can be deployed using the Veeam Backup & Replication console.

Backup Server

The backup server is a Windows-based physical or virtual machine on which Veeam Backup & Replication is installed. It is the core component in the backup infrastructure that fills the role of the "configuration and control center". The backup server performs all types of administrative activities:

- Coordinates backup, replication, recovery verification and restore tasks
- Controls job scheduling and resource allocation
- Is used to set up and manage backup infrastructure components as well as specify global settings for the backup infrastructure

In addition to its primary functions, a newly deployed backup server also performs the roles of the default VMware backup proxy and the backup repository (it manages data handling and data storing tasks).

Backup Server Services and Components

The backup server uses the following services and components:

- Veeam Backup Service is a Windows service that coordinates all operations performed by Veeam Backup & Replication such as backup, replication, recovery verification and restore tasks. The Veeam Backup Service runs under the LocalSystem account or account that has the local Administrator permissions on the backup server.
- Veeam Broker Service interacts with the virtual infrastructure to collect and cache the virtual infrastructure topology. Jobs and tasks query information about the virtual infrastructure topology from the broker service, which accelerates job and task performance.
- Veeam Guest Catalog Service manages guest OS file system indexing for VMs and replicates system index data files to enable search through guest OS files. Index data is stored in the Veeam Backup Catalog — a folder on the backup server. The Veeam Guest Catalog Service running on the backup server works in conjunction with search components installed on Veeam Backup Enterprise Manager and (optionally) a dedicated Microsoft Search Server.
- Mount Service mounts backups and replicas for file-level access, browsing the VM guest file system and restoring VM guest OS files and application items to the original location.
- VMware Backup Proxy Services In addition to dedicated services, the backup server runs a set of Veeam Data Movers. For details, see VMware Backup Proxy.
- Veeam CDP Coordinator Service communicates with vCenter, assigns continuous data protection (CDP) tasks and manages the infrastructure components involved in CDP. For more information on CDP, see Continuous Data Protection (CDP).
- Veeam Backup & Replication Configuration Database stores data about the backup infrastructure, jobs, sessions and other configuration data. The database instance can be located on a SQL Server installed either locally (on the same machine where the backup server is running) or remotely. For more information, see the following guidelines: Veeam Backup & Replication Best Practices.

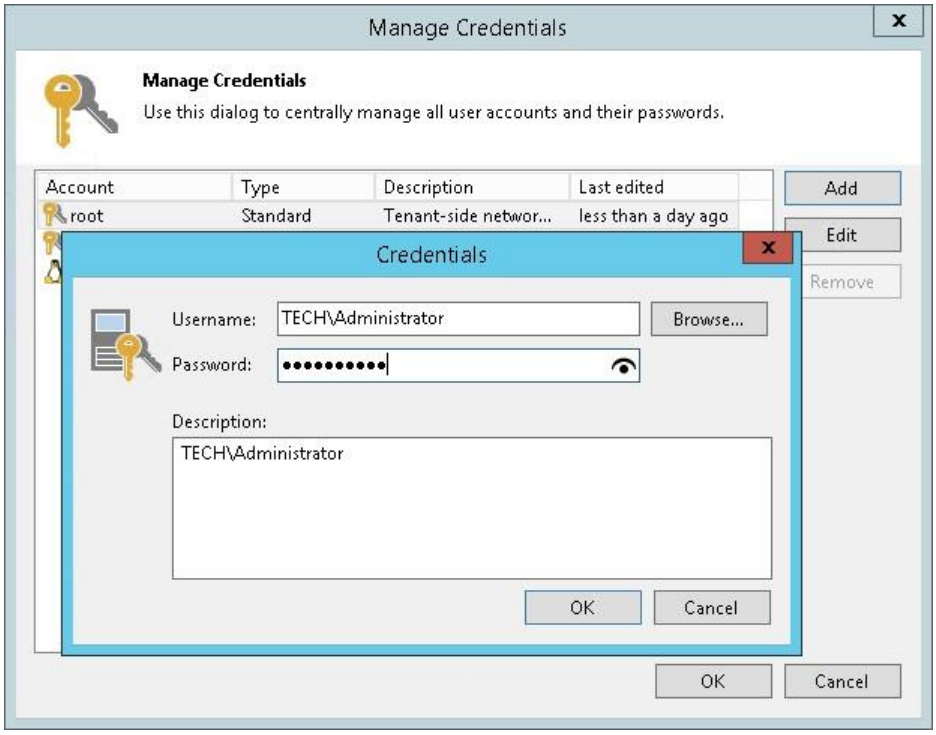
  Veeam Backup & Replication maintains the configuration database. Veeam Backup & Replication runs the DatabaseMaintenance system job once a week and when the Veeam Backup Service is restarted. The job updates the database internal statistics, defragments indexes and clears unused data. For details, see the `Job.DatabaseMaintenance` log file in the `%ProgramData%\Veeam\Backup` folder.
- Veeam Backup & Replication Console provides the application user interface and allows user access to the application functionality.
- Veeam Backup PowerShell Module is an extension for Microsoft Windows PowerShell that adds a set of cmdlets to allow users to perform backup, replication and recovery tasks through the command-line interface of PowerShell or run

custom scripts to fully automate operation of Veeam Backup & Replication. For more information on the Microsoft Windows PowerShell module, see the Getting Started section of Veeam PowerShell Reference.

Credentials Manager

You can use the Credentials Manager to create and maintain a list of credentials records that you plan to use to connect to components in the backup infrastructure.

The Credentials Manager lets you create the following types of credentials records:



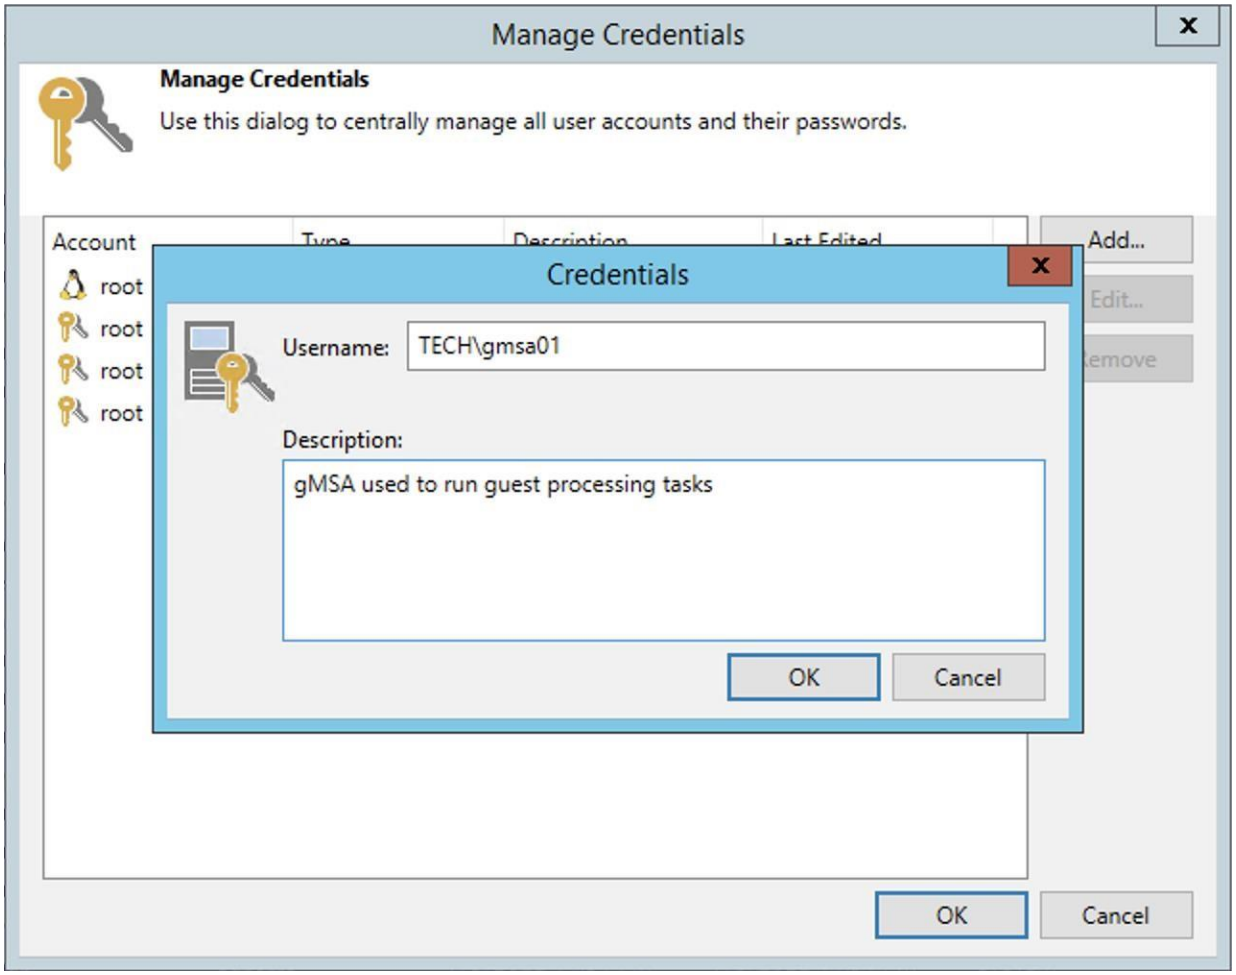
- Standard account
- Group Managed Service Accounts
- Linux account (user name and password)
- Linux private key (Identity/Pubkey)

Standard Accounts

You can create a credentials record for an account that you plan to use to connect to a Microsoft Windows server, a VM running Microsoft Windows OS or a storage system.

To create a new standard credentials record:

1. From the main menu, select Credentials and Passwords > Datacenter Credentials.
2. Click Add > Standard account.
3. In the Username field, enter a user name for the account that you want to add. You can also click Browse to select an existing user account.
4. In the Password field, enter a password for the account that you want to add. To view the entered password, click and hold the eye icon on the right of the field.
5. In the Description field, enter a description for the created credentials record. As there can be a number of similar account names, for example, Administrator, it is recommended that you provide a meaningful unique description for the credentials record so that you can distinguish it in the list. The description is shown in brackets, following the user name.



Group Managed Service Accounts

You can add a credentials record for a Group Managed Service Account (gMSA) that you plan to use to run guest processing tasks. Note that before you add a record you should check requirements and limitations and perform actions described in the Using Group Managed Service Accounts section.

To add a new credentials record with the gMSA:

1. From the main menu, select Credentials and Passwords > Datacenter Credentials.
2. Click Add > Managed service account.
3. In the Username field, enter a gMSA that you want to add. Note that the name of the account must be specified in the following format: DOMAIN\User or user@domain.xxx.
4. In the Description field, enter a description for the created credentials record. As there can be a number of similar account names, for example, gmsa01, it is recommended that you provide a meaningful unique description for the credentials record so that you can distinguish it in the list. The description is shown in brackets, following the user name.

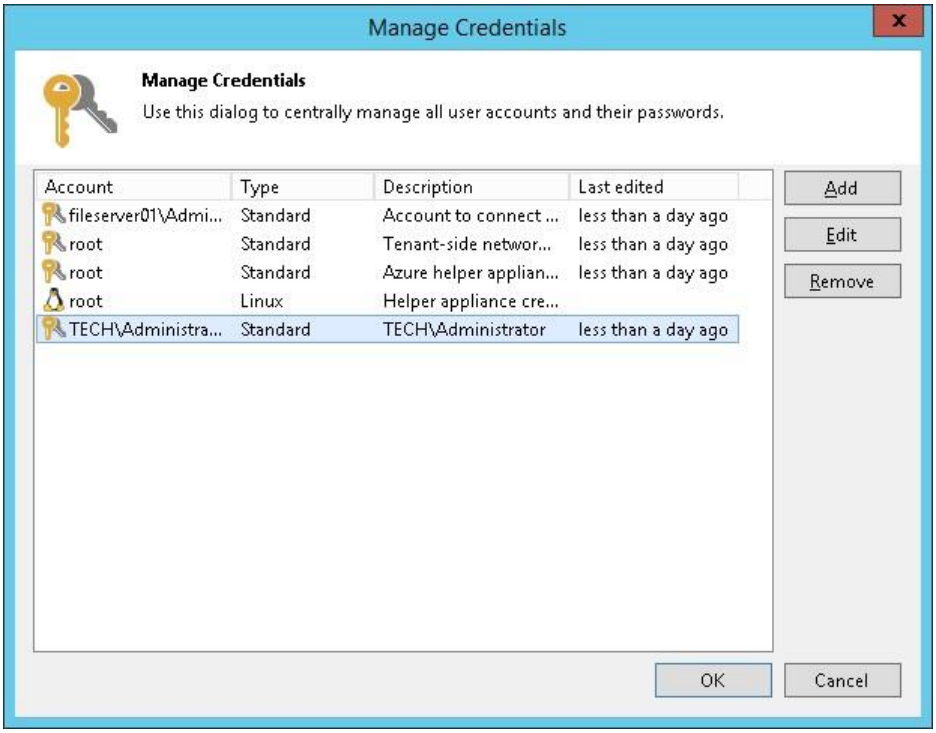
Editing and Deleting Credentials Records

You can edit or delete credentials records that you have created.

To edit a credentials record:

1. From the main menu, select Credentials and Passwords > Datacenter Credentials.
2. Select the credentials record in the list and click Edit.
3. If the credentials record is already used for any component in the backup infrastructure, Veeam Backup & Replication will display a warning. Click Yes to confirm your intention.
4. Edit settings of the credentials record as required.

To delete a credentials record:



1. From the main menu, select Credentials and Passwords > Datacenter Credentials.
2. Select the credentials record in the list and click Remove. You cannot delete a record that is already used for any component in the backup infrastructure.

NOTE

The Credentials Manager contains 3system credentials records:

- A credentials record for the Veeam FLR appliance
- A credentials record for the tenant-side network extension appliance
- A credentials record for Microsoft Azure restore proxy appliance (former Azure proxy).

You cannot delete these credentials records. However, you can edit them: change a password and record description.

Backup Proxies & Agents

Veeam Agent for Microsoft Windows

To deploy Veeam Agent for Microsoft Windows using setup files generated by Veeam Backup & Replication, perform the following operations:

- Installation
- Configuration

> TIP
>
> You can also find detailed instructions on the Veeam Agent deployment in the `readme.txt` file that is available among the setup files generated by Veeam Backup & Replication.

Configuration

To configure Veeam Agent for Microsoft Windows, you must apply connection settings from the configuration file. You obtained this file together with other setup files when the protection group for pre-installed Veeam Agents was created. To do configure Veeam Agent, execute the following command from the folder where Veeam Agent setup files are located:

```
"C:\Program Files\Veeam\Endpoint Backup\Veeam.Agent.Configurator.exe" -setVBRse
ttings /p:"<protection_group_name>.xml"
```

where `<protection_group_name>` is a name of the protection group for pre-installed Veeam Agents. Alternatively, you can specify the full path to the configuration file passed with the `/p` option.

Mind that the connection between Veeam Backup & Replication and Veeam Agent is not persistent. Veeam Agent synchronizes with Veeam Backup & Replication every 6 hours. After you apply new backup policy settings in the Veeam Backup & Replication console, Veeam Agent will get these settings during the next synchronization.

To synchronize Veeam Agent immediately, run the following command on the Veeam Agent computer:

```
"C:\Program Files\Veeam\Endpoint Backup\Veeam.Agent.Configurator.exe" -syncnow
```

Backup Jobs

Microsoft Windows – Host Server Backup

To back up data of a computer protected with Veeam Agent for Microsoft Windows, you must configure a Veeam Agent backup job in Veeam Backup & Replication.

Before You Begin

Before you create a Veeam Agent backup job in the Veeam Backup & Replication console, check the following prerequisites:

- The Veeam Backup & Replication license must have a sufficient number of instances to process servers and/or workstations that you plan to add to the Veeam Agent backup job.
- The target location where you plan to store backup files must have enough free space.
- Protection groups that you want to add to the job must be configured in advance.
- [For backup jobs targeted at the cloud repository] The Veeam Cloud Connect service provider must be added in the Veeam backup console.

Veeam Agent backup jobs have the following limitations:

- For Veeam Agent backup job managed by backup server, you can create Veeam Agent backups in a Veeam backup repository and Veeam Cloud Connect repository. If you want to save backups in other target locations, you must configure a Veeam Agent backup job managed by Veeam Agent (backup policy). To learn more, see Veeam Agent Backup Jobs and Policies.
- [For Veeam Agent backup job managed by Veeam Agent] You cannot save the backup of entire computer on the local computer disk. Use an external hard drive or USB drive, network shared folder or backup repository as a target location.
- Veeam Agent for Microsoft Windows does not support file-level backup for backup jobs that include failover clusters.
- Veeam Agent for Microsoft Windows does not back up data to which symbolic links are targeted. It only backs up the path information that the symbolic links contain. After restore, identical symbolic links are created in the restore destination.
- After you start managing a Veeam Agent computer with Veeam Backup & Replication, data backup for this computer is performed by a backup job configured in Veeam Backup & Replication. Veeam Agent running on the computer starts a new backup chain in a target location specified in the backup job settings. You cannot continue the existing backup chain that was created by Veeam Agent operating in the standalone mode.
- You cannot map a Veeam Agent backup job configured in Veeam Backup & Replication to a Veeam Agent backup chain created by a standalone Veeam Agent in a backup repository.
- The backup cache is supported only for Veeam Agent backup jobs managed by Veeam Agent.
- Veeam Agent does not support creating transaction log backups in a cloud repository. You cannot enable transaction log backup options in the properties of the backup job targeted at a cloud repository.

Step 1. Launch New Agent Backup Job Wizard

You can create a Veeam Agent backup job for protected computers that run a Microsoft Windows OS in one of the following ways:

- Create a new backup job — in this case, Veeam Backup & Replication will launch the New Agent Backup Job wizard. You will be able to specify protection groups, individual Active Directory objects and/or Veeam Agent computers to which the backup job settings must apply at the Computers step of the wizard.
- Add a protection group to a new backup job — in this case, Veeam Backup & Replication will launch the New Agent Backup Job wizard and add the selected protection group to the backup job. You will also be able to change the list of Veeam Agent computers to which the backup job settings must apply at the Computers step of the wizard.
- Add individual computers to a new backup job — in this case, Veeam Backup & Replication will launch the New Agent Backup Job wizard and add the selected computers to the backup job. You will also be able to change the list of Veeam Agent computers to which the backup job settings must apply at the Computers step of the wizard.

Launching Backup Job Wizard

To launch the New Agent Backup Job wizard, do either of the following:

On the Home tab, click Backup Job > Windows computer.

Open the Home view. Select the Jobs node and click Backup Job > Windows computer on the ribbon.

Open the Home view. Right-click the Jobs node and select Backup > Windows computer.

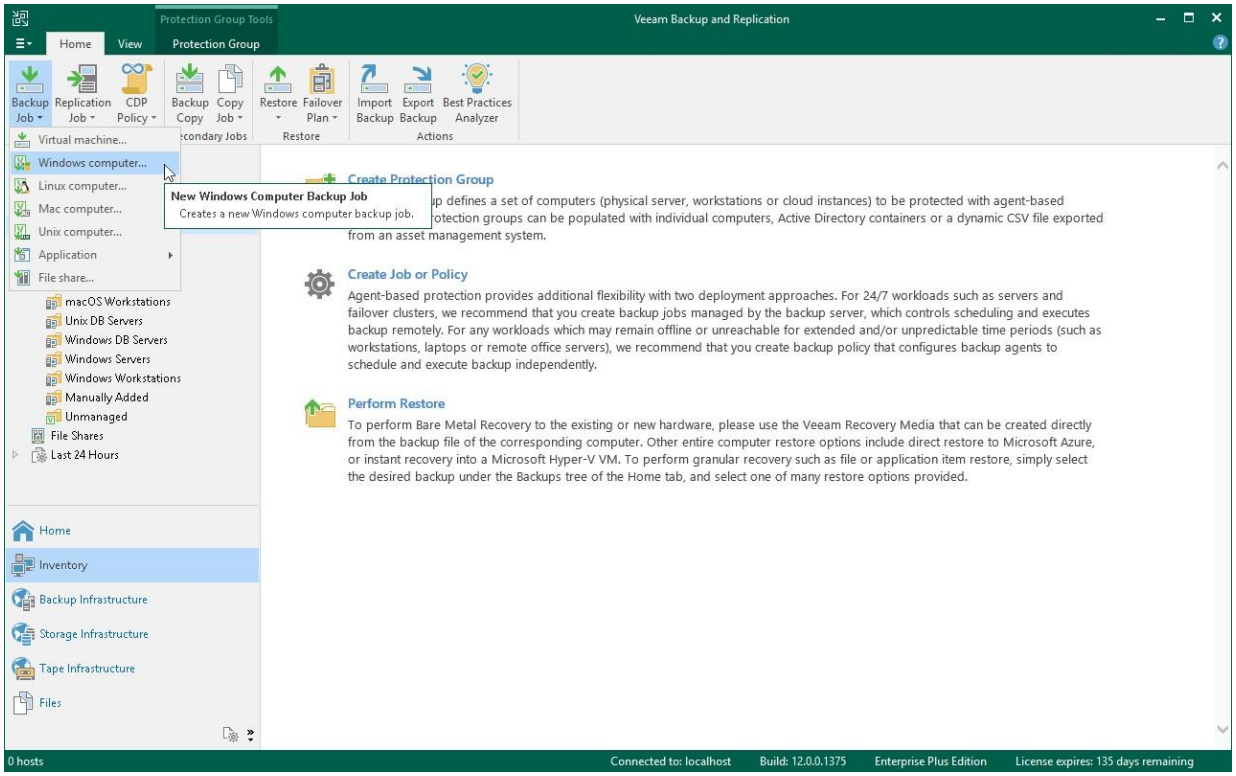
Adding Protection Group to New Backup Job

To add a protection group to a new Veeam Agent backup job, do either of the following:

- Open the Inventory view. In the Physical Infrastructure node, right-click the protection group that you want to add to the backup job and select Add to backup job > Windows > New job.
- Open the Inventory view. In the Physical Infrastructure node, select the protection group that you want to add to the backup job and click Add to Backup > Windows > New job on the ribbon.

Veeam Backup & Replication will start the New Agent Backup Job wizard and add the protection group to the job. You can add other protection groups and (or) individual computers to the job later on, when you pass through the wizard steps.

Adding Computers to New Backup Job



To add specific computers to a new Veeam Agent backup job, do either of the following:

Open the Inventory view. In the Physical Infrastructure node, click the protection group whose computers you want to add to the backup job. In the working area, select one or more computers that you want to add to the job, right-click the selected computer and select Add to backup job > New job.

Open the Inventory view. In the Physical Infrastructure node, click the protection group whose computers you want to add to the backup job. In the working area, select one or more computers that you want to add to the job and click Add to Backup > New job on the ribbon.

Veeam Backup & Replication will start the New Agent Backup Job wizard and add the selected computers to the job. You can add other computers and (or) protection groups to the job later on, when you pass through the wizard steps.

> TIP
>
> Consider the following:
>
> - You can press and hold [CTRL] to select multiple computers at once.
> - You can add an individual computer or protection group to a Veeam Agent backup job that is already configured in Veeam Backup & Replication. To learn more, see Adding Computers to Backup Job and Adding Protection Group to Backup Job.

Step 2. Select Job Mode

At the Job Mode step of the wizard, specify protection settings for the backup job:

Select the type of protected computers whose data you want to back up with Veeam Agents.

If you choose to back up data pertaining to servers, select the job mode.

The job mode defines the type of the created Veeam Agent backup job: the backup job (backup job managed by the backup server) or backup policy (backup job managed by Veeam Agent).

Selecting Protected Computer Type

At the Job Mode step of the wizard, in the Type field, select the type of protected computers whose data you want to back up with Veeam Agents. The selected type defines what modes will be available for the configured backup job and what job settings will be available at subsequent steps of the wizard. You can select one of the following computer types:

Workstation — select this option if you want to back up data pertaining to workstations or laptops. This option is suitable for computers that reside in a remote location and may have limited connection to the backup server.

For backup jobs that process workstations, Veeam Backup & Replication offers settings similar to the settings of the backup job available in the Workstation edition of Veeam Agent for Microsoft Windows. To learn more, see Veeam Agent for Microsoft Windows User Guide.

With this option selected, the backup job will be managed by Veeam Agent installed on the protected computer — you do not need to select the job mode.

Server — select this option if you want to back up data pertaining to standalone servers. This option is suitable for computers that have permanent connection to the backup server.

For backup jobs that process servers, Veeam Backup & Replication offers settings similar to the settings of the backup job available in the Server edition of Veeam Agent for Microsoft Windows. To learn more, see Veeam Agent for Microsoft Windows User Guide.

With this option selected, you can also select the job mode. To learn more, see Selecting Job Mode.

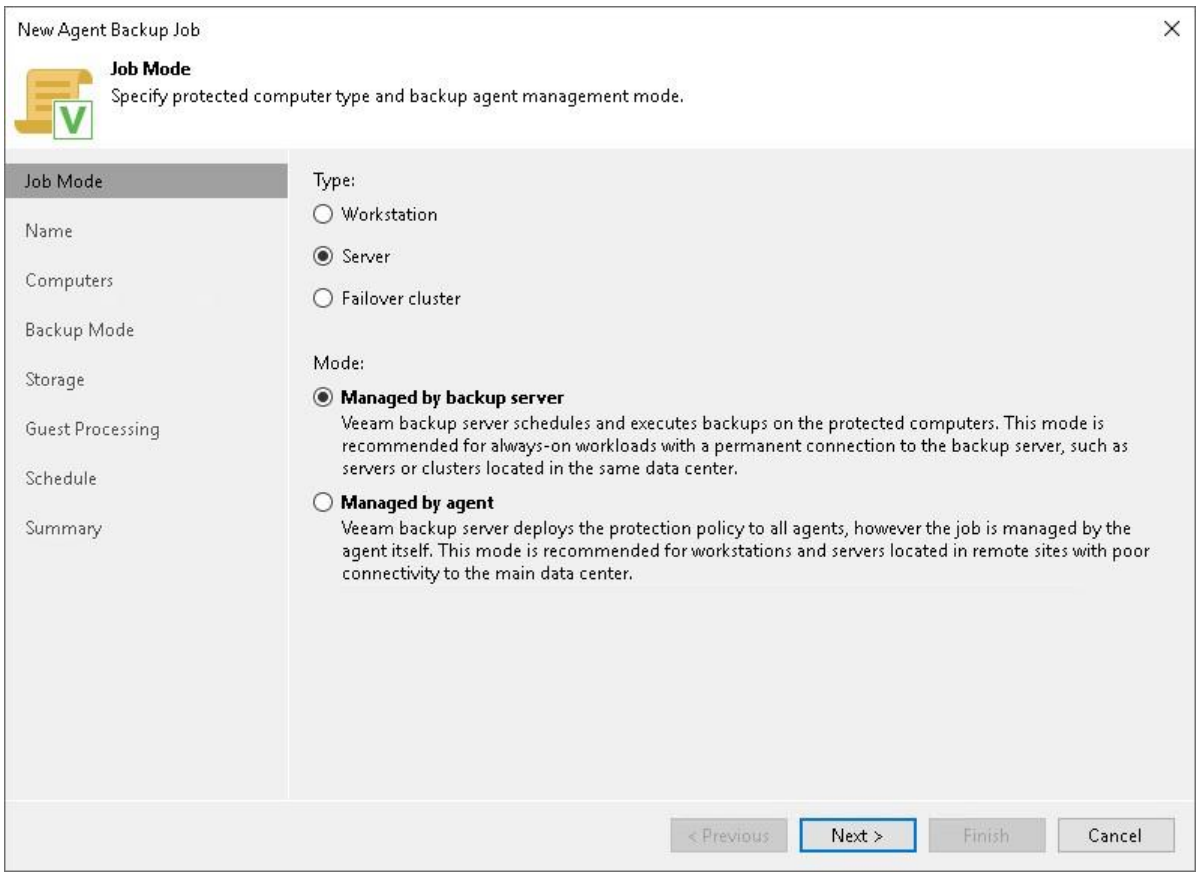
Failover cluster — select this option if you want to back up data pertaining to a failover cluster.

For backup jobs that process failover clusters, Veeam Backup & Replication offers practically the same backup job settings as for servers.

With this option selected, the backup job will be managed by the Veeam backup server — you do not need to select the job mode.

Selecting Job Mode

If you selected the Server computer type in the Type field, in the Mode field, select the job mode. You can select one of the following modes:



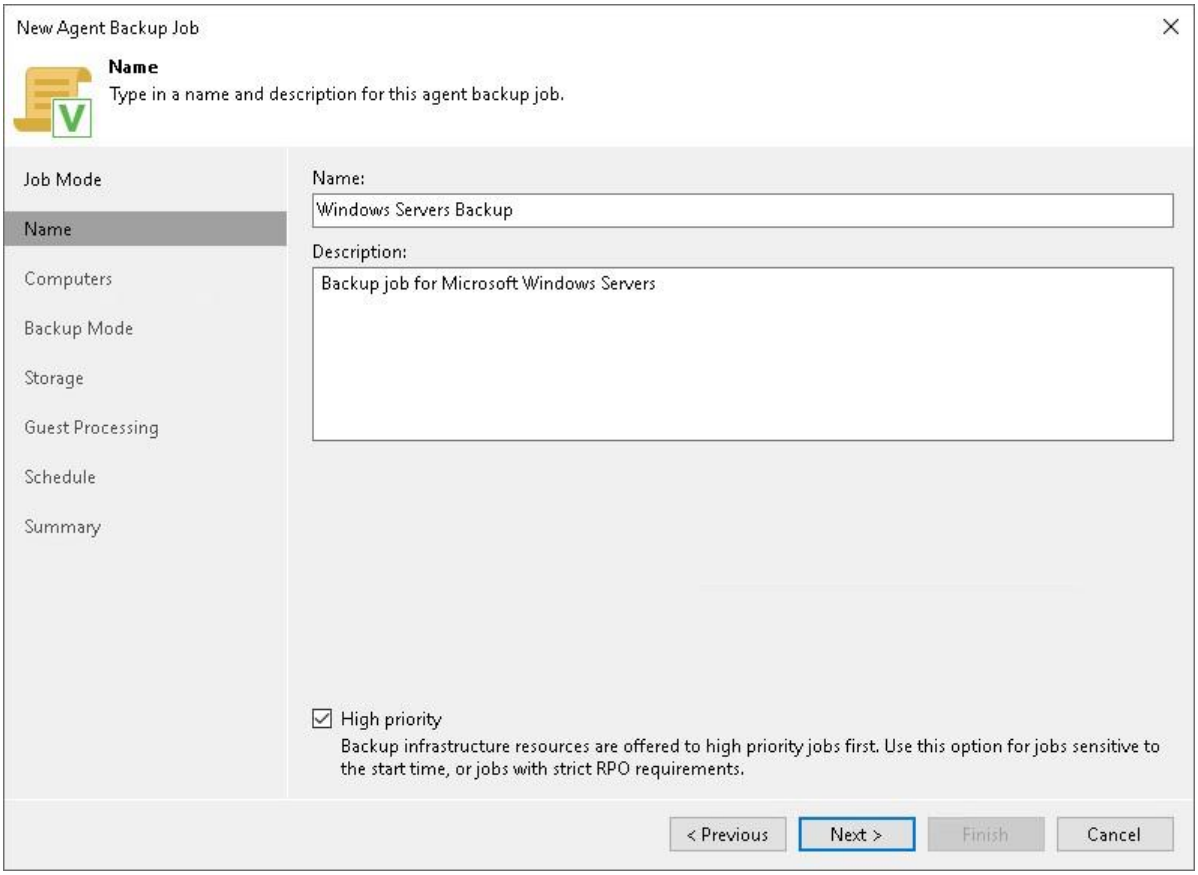
Managed by backup server — select this option if you want to configure the Veeam Agent backup job. With this option selected, you will be able to add one or more individual computers and/or protection groups to the job and instruct Veeam Backup & Replication to create Veeam Agent backups in a Veeam backup repository or Veeam Cloud Connect repository. The Veeam Agent backup job will run on the backup server in the similar way as a regular job for VM data backup. To learn more, see Backup Job.

> NOTE
>
> The Managed by backup server option is available for the Server and Failover cluster computer types. For Failover cluster, this is the only available option. This option is not available for the Workstation computer type.
>
> You must select the Managed by backup server option if you want to use the backup job to protect cloud machines. To learn more, see Select Protection Group Type.

Managed by agent — select this option if you want to configure the backup policy. The backup policy describes configuration of individual Veeam Agent backup jobs that run on protected computers, and acts as a saved template. With this option selected, you will be able to add one or more individual computers and/or protection groups to the backup policy, and instruct Veeam Agent to create backups on a local disk of a protected computer, in a network shared folder, in a Veeam backup repository or in a Veeam Cloud Connect repository. To learn more, see Backup Policy.

NOTE

- The Managed by agent option is available for the Workstation and Server computer types. For Workstation, this is the only available option. This option is not available for the Failover cluster computer type.
- You must select the Managed by agent option if you want to use the backup job to protect computers with pre-installed Veeam Agents. To learn more, see Select Protection Group Type.



Step 3. Specify Job Name and Description

At the Name step of the wizard, specify a name and description for the backup job.

In the Name field, enter a name for the backup job.

In the Description field, provide a description for future reference. The default description contains information about the user who created the job, date and time when the job was created.

[For backup job managed by backup server] Select the High priority check box if you want the resource scheduler of Veeam Backup & Replication to prioritize this job higher than other similar jobs and to allocate resources to it in the first place. To learn more, see the Job Priorities section in the Veeam Backup & Replication User Guide.

Step 4. Select Computers to Back Up

At the Computers step of the wizard, select protection groups and/or individual computers whose data you want to back up.

You can add to the Veeam Agent backup job one or more protection groups and/or individual computers added to inventory in the Veeam Backup & Replication console. You can also add to the job computers that are not added to inventory yet. Veeam Backup & Replication will add such computers to the job and also add them to the Manually Added protection group.

Jobs with protection groups are dynamic in their nature. If Veeam Backup & Replication discovers a new computer in a protection group after the Veeam Agent backup job is created, Veeam Backup & Replication will automatically update the job settings to include the added computer.

NOTE

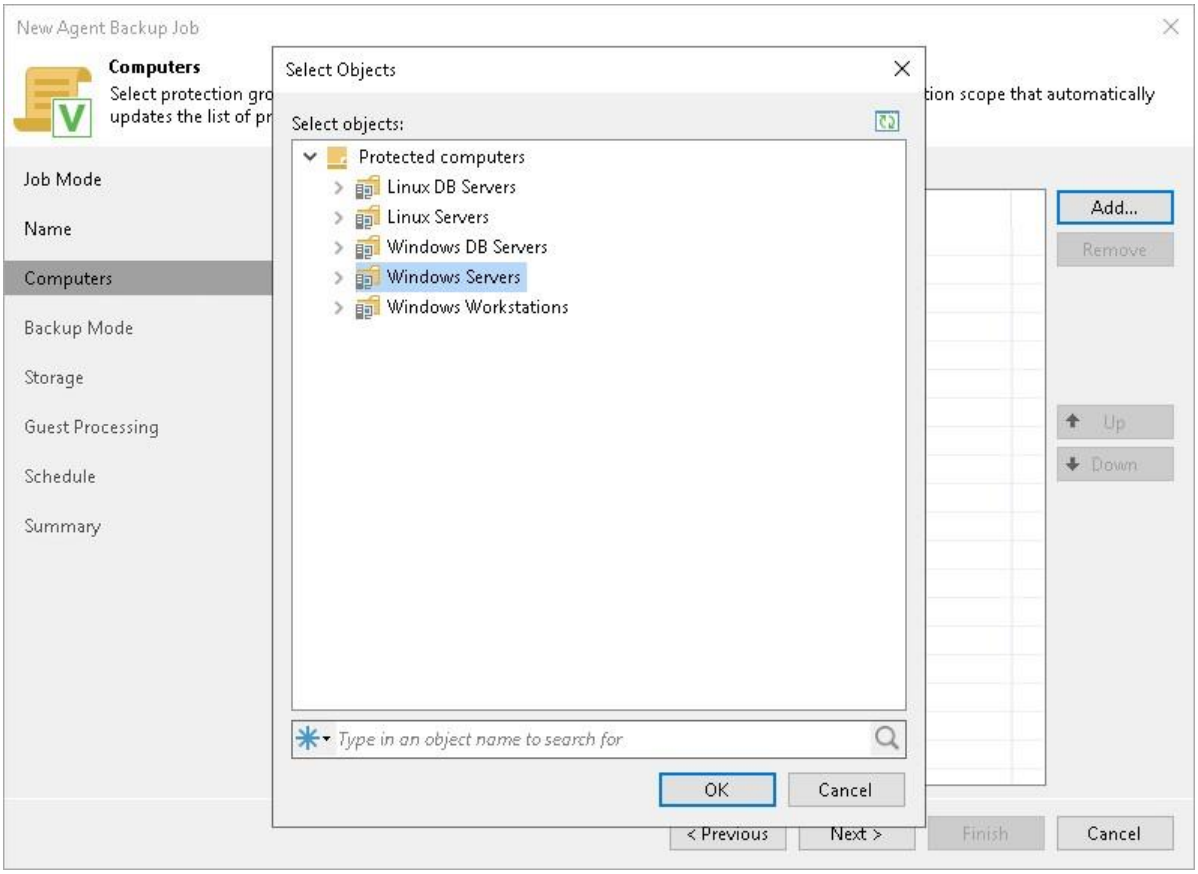
If you used the Add to backup job > Windows > New job option to launch the New Agent Backup Job wizard, the Protected computers list will already contain computers that you have selected to add to the job. You can remove some computers from the job or add new computers to the job, if necessary.

Veeam Backup & Replication displays protection groups for pre-installed Veeam Agents and their members only if you selected the Managed by agent option at the Job Mode step of the wizard. You cannot add protection groups for pre-installed Veeam Agents to backup jobs managed by backup server. To learn more, see Selecting Job Mode.

Veeam Backup & Replication displays protection groups for cloud machines and their members only if you selected the Managed by backup server option at the Job Mode step of the wizard. You cannot add protection groups for cloud machines to backup policies (backup jobs managed by backup Veeam Agent). To learn more, see Selecting Job Mode.

Adding Protection Groups and Computers from Inventory

To add protection groups and/or individual computers to the Veeam Agent backup job:



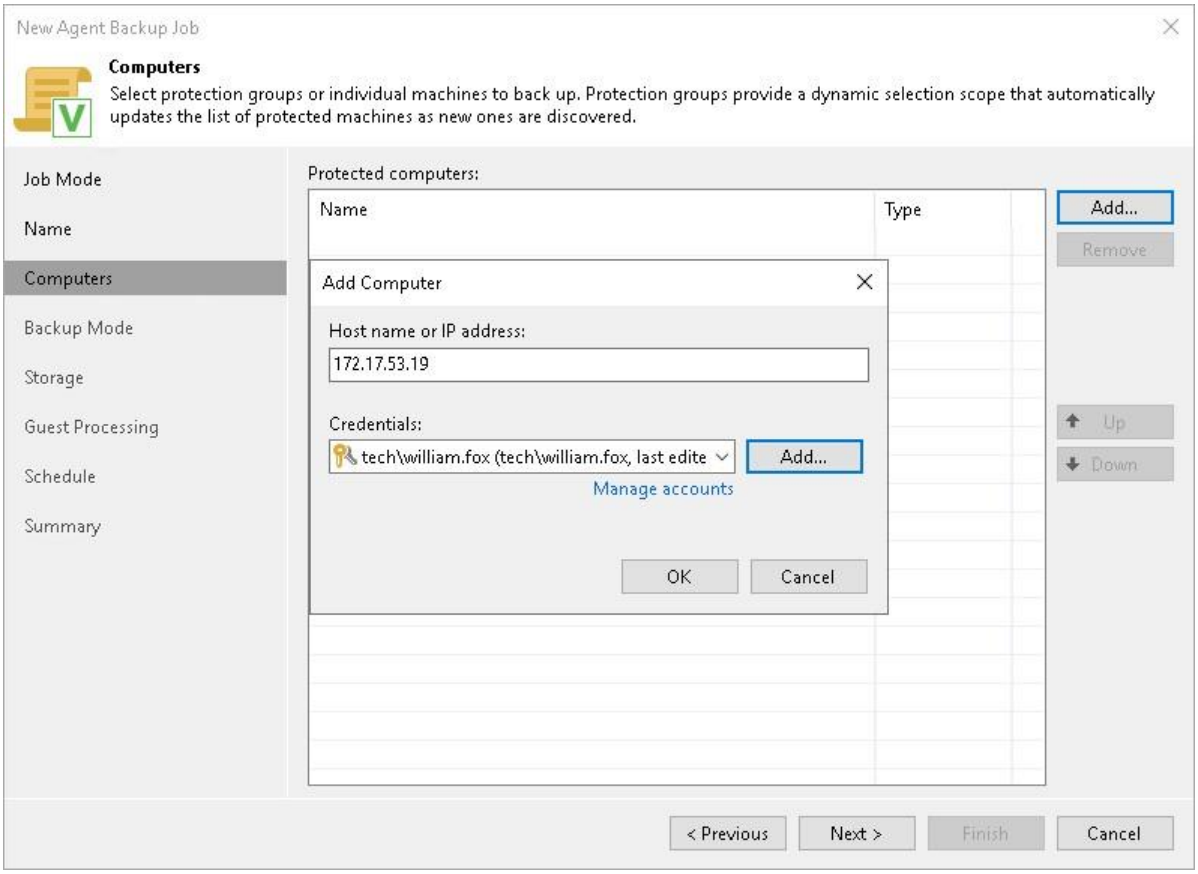
Click Add > Protection group.

In the Select Objects window, select one or more protection groups and/or computers in the list and click OK. You can press and hold [CTRL] to select multiple objects at once.

To quickly find the necessary object, use the search field at the bottom of the Select Objects window.

Enter the object name or a part of it in the search field.

Click the Start search button on the right or press [ENTER].



Adding New Computers

To add to the Veeam Agent backup job new computers that do not exist in the inventory:

Click Add > Individual computer.

In the Add Computer window, in the Host name or IP address field, enter a full DNS name or IP address of the computer that you want to add to the job.

From the Credentials list, select a user account that has administrative permissions on the computer that you want to add to the job. If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials. For more information, see the Credentials Manager section in the Veeam Backup & Replication User Guide.

Step 5. Select Backup Mode

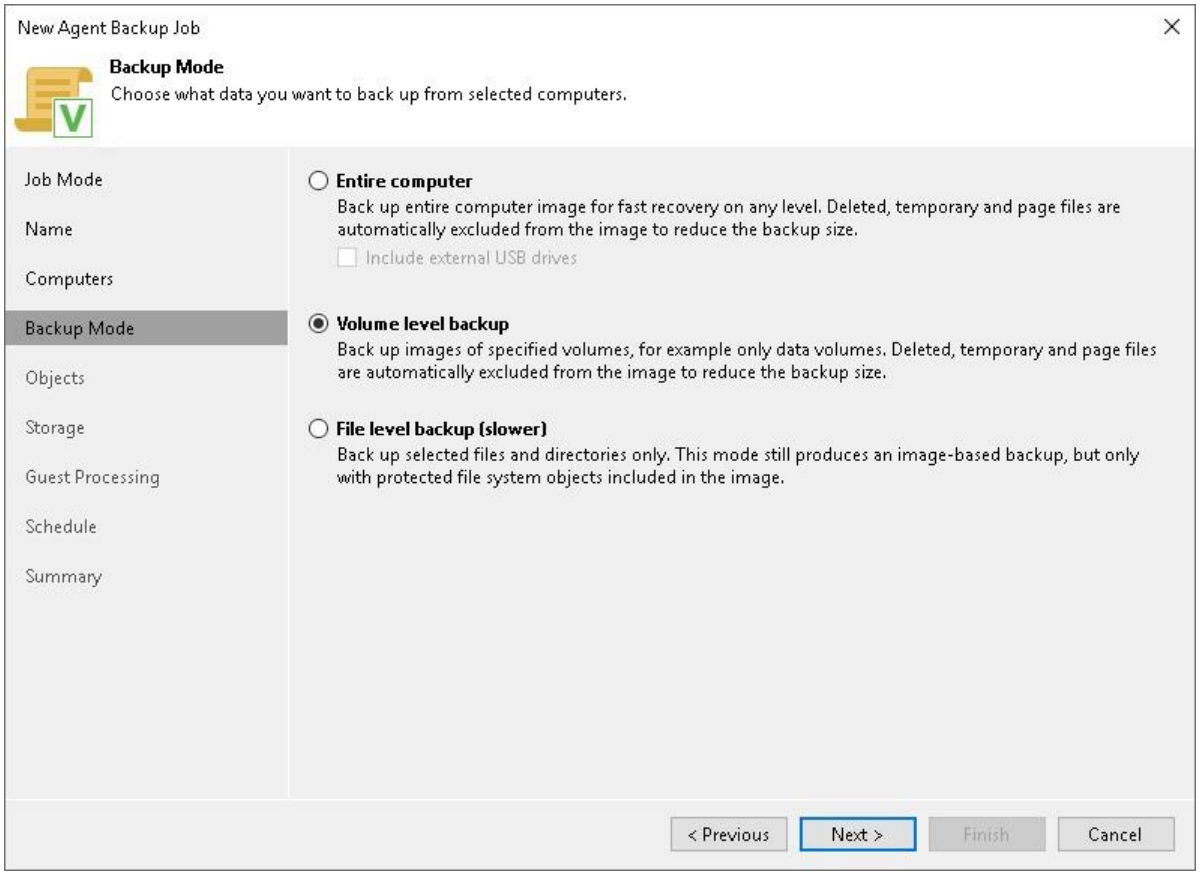
At the Backup Mode step of the wizard, select the mode in which you want to create a backup.

In the Backup mode section, select the backup mode. You can select one of the following options:

Entire computer — select this option if you want to create a backup of the entire computer image. When you restore data from such backup, you will be able to recover the entire computer image as well as data on specific computer volumes: files, folders, application data and so on. With this option selected, you will pass to one of the following steps of the wizard:

Storage — if you have selected the Managed by backup server option at the Job Mode step of the wizard.

Destination — if you have selected the Managed by agent option at the Job Mode step of the wizard.



Volume level backup — select this option if you want to create a backup of specific computer volumes, for example, all volumes except the system one. When you restore data from such backup, you will be able to recover data on these volumes only: files, folders, application data and so on. With this option selected, you will pass to the Objects step of the wizard.

File level backup — select this option if you want to create a backup of individual folders on your computer. With this option selected, you will pass to the Objects step of the wizard.

[For entire computer backup] If you want to include in the backup one or more external USB drives, select the Include external USB drives check box. With this option selected, Veeam Agent will include in the backup all external USB drives that are connected to the Veeam Agent computer at the time when the backup job starts. To learn more, see the Backup of External Drives section in the Veeam Agent for Microsoft Windows User Guide.

NOTE

- The File level backup option is not available if you have selected theFailover cluster option at the Job Mode step of the wizard.
- File-level backup is typically slower than volume-level backup. Depending on the performance capabilities of your computer and backup environment, the difference between file-level and volume-level backup job performance may increase significantly. If you plan to back up all folders with files on a specific volume or back up large amount of data, it is recommended that you configure volume-level backup instead of file-level backup.

Step 6. Specify Backup Scope Settings

The Objects step of the wizard is available if you chose to create volume-level or file-level Veeam Agent backups. Specify backup scope for the Veeam Agent backup job:

Specify volumes to back up — if you have selected the Volume level backup option at the Backup Mode step of the wizard.

Specify folders to back up — if you have selected the File level backup option at the Backup Mode step of the wizard.

Specifying Volumes to Back Up

The Objects step of the wizard is available if you have selected the Volume level backup option at the Backup Mode step of the wizard.

At this step of the wizard, you must specify the backup scope — define what volumes you want to include in the backup. The specified backup scope settings will apply to all computers that are added to the backup job. If a specified volume does not exist on one or more computers in the job, the job will skip such volume on those computers and back up only existing ones.

To specify the backup scope, you can select the Backup the following volumes only option and add necessary objects.

Alternatively, you can back up the whole Veeam Agent computer. To do this, select the Backup all volumes except the following option. With this option selected, you can exclude objects that you do not need from the backup scope.

You can include or exclude the following objects:

- OS volume — data pertaining to the OS installed on a protected computer. This object includes the Microsoft Windows system partition and boot partition of your computer. For GPT disks on Microsoft Windows 8.1, 10, 11, 2012, 2012 R2, 2016, 2019, and 2022, the object additionally includes the recovery partition. To learn more, see the System State Data Backup section in the Veeam Agent for Microsoft Windows User Guide.

  To include or exclude the OS volume, in the necessary wizard section, click Add and select the OS volume option.

- Individual volumes.

  To include or exclude individual volumes:

  a. In the necessary wizard section, click Add and select the Volume name option.

  b. In the Add Object window, type the drive letter of a volume that you want to back up, for example, `C:\`, and click OK.

  c. Repeat steps a–b for all volumes that you want to back up.

- Individual mount points.

  To include or exclude individual mount points:

  a. In the necessary wizard section, click Add and select the Volume name option.

  b. In the Add Object window, type the path to a folder that is an entry point to the mounted volume you want to back up, for example, `C:\Data`, and click OK.

  c. Repeat steps a–b for all mount points that you want to back up.

NOTE

Mind the following:

- If you include a system volume in the volume-level backup, Veeam Agent for Microsoft Windows automatically includes the System Reserved/UEFI or other system partitions in the backup too.
- You cannot include volumes located on virtual hard disks (VHD or VHDX) in the volume-level backup.
- Veeam Agent for Microsoft Windows automatically adds to the list of exclusions the following Microsoft Windows objects for all computer users: temporary files folder, Recycle Bin, Microsoft Windows pagefile, hibernate file and VSS snapshot files from the System Volume Information folder.

Specifying Folders to Back Up

The Objects step of the wizard is available if you have selected the File level backup option at the Backup Mode step of the wizard.

In the file-level backup mode, you can create two types of backups:

File-level backup that includes individual folders on your computer.

Hybrid backup that contains individual folders and specific volumes of your computer.

At this step of the wizard, you must specify the backup scope — define what folders with files or entire volumes you want to include in the backup. The specified backup scope settings will apply to all computers that are added to the backup job. If a specified object does not exist on one or more computers in the job, the job will skip such object on those computers and back up existing ones.

To specify the backup scope, in the Objects to backup list, select check boxes next to necessary objects. You can include the following data in the backup:

Operating system — data related to the OS installed on a protected computer. To learn more, see the System State Data Backup section in the Veeam Agent for Microsoft Windows User Guide.

Personal files — data related to user profiles. With this option enabled, Veeam Backup & Replication will include in the backup scope settings and data related to Veeam Agent computer user profiles. To learn more, see the Personal Data Backup section in the Veeam Agent for Microsoft Windows User Guide.

Individual file system objects — folders, mount points, and volumes of a protected computer.

To specify individual folders to back up:

Select the The following file system objects check box and click Add.

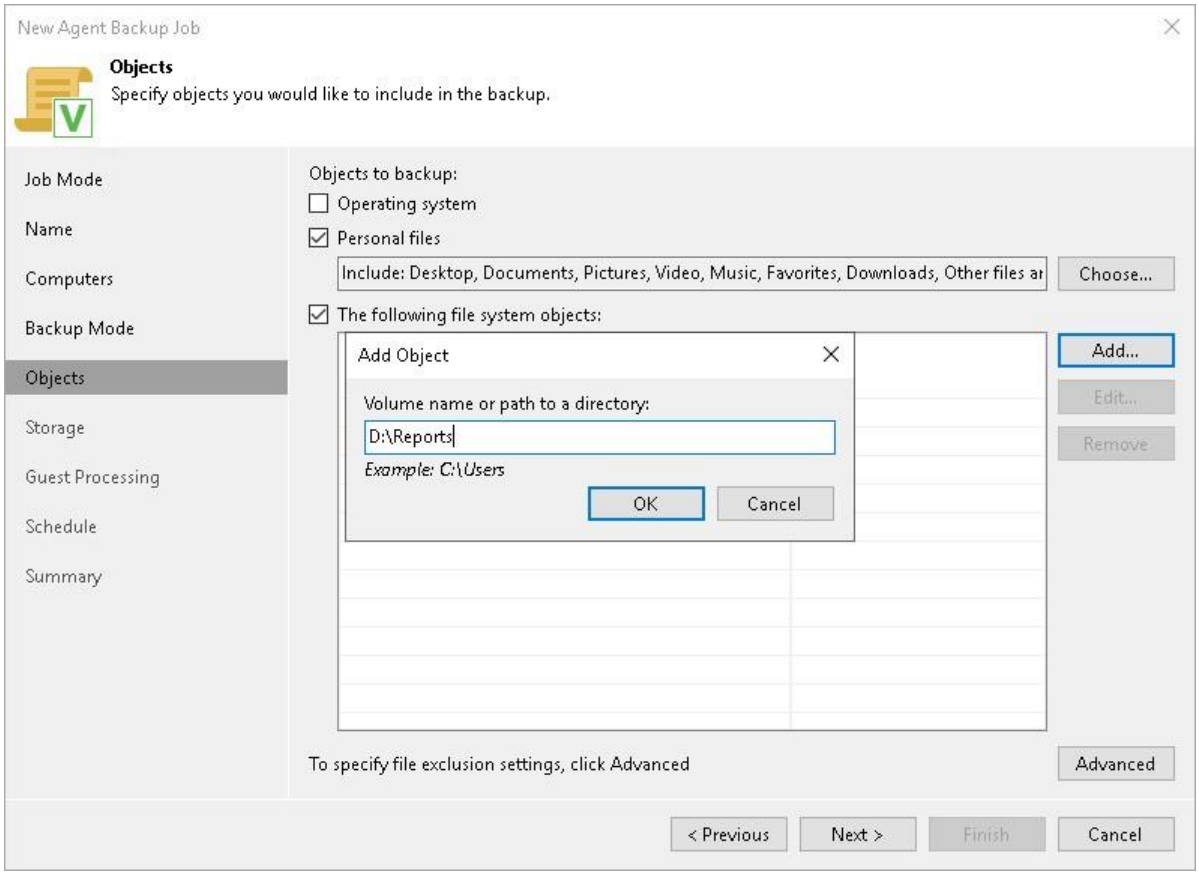
In the Add Object window, type the path to a folder, mount point folder, or volume that you want to back up, for example, `D:\Reports` or `D:\`, and click OK.

To specify the backup scope, you can use system environment variables such as %ProgramFiles% or %WinDir%. This may be useful, for example, in case computers added to the backup job run different versions of Microsoft Windows OSes, and actual paths to directories that contain data of the same type differ on these computers.

Consider the following:

You can use only system environment variables — variables defined for the Local System account on computers added to the backup job. User-dependent environment variables are not supported.

Environment variables that contain multiple values (such as the %PATH% variable) are not supported.



Environment variables that contain other environment variables are not supported.

Repeat steps 1–2 for all items that you want to back up.

NOTE

Mind the following:

- If you include a system volume in the file-level backup, Veeam Agent does not automatically include the System Reserved/UEFI or other system partitions in the backup. These volumes are automatically included in the backup only if you select the Entire computer option to specify the backup scope.
- Veeam Agent automatically adds to the list of exclusions the following Microsoft Windows objects for all computer users: temporary files folder, Recycle Bin, Microsoft Windows pagefile, hibernate file and VSS snapshot files from the System Volume Information folder.
- You can exclude Microsoft OneDrive folders from the backup scope in the File Filters window.

Configuring Filters

To include or exclude folders and files of a specific type in/from the file-level backup, you can configure filters.

> NOTE
>
> Consider the following:
>
> If you include a specific folder in the file-level backup, Veeam Agent applies filters to files in specific folders that you include in the backup. Filters are not applied to computer volumes, mount points, and folders selected for backup. If you plan to create a hybrid backup that will contain volumes, mount points, and folders, filters will be applied to files in folders only.
> If you include a whole volume in the file-level backup, you cannot apply filters to include or exclude files of a specific type in/from the backup. You can only exclude specific folders that reside on the volume.
> You cannot apply filters to files and folders that reside on the mount point.

To configure a filter:

1. At the Objects step of the wizard, click Advanced.
2. Specify what files you want to back up:
   - If you include a specific folder in the file-level backup, in the Include masks field, specify file names and/or masks for file types that you want to back up, for example, `MyReport.pdf`, `*filename*`, `*.docx`. The resulting Veeam Agent backup will contain only selected files. Other files will not be backed up.

     You cannot specify include masks if you add an entire volume in the backup.
   - In the Exclude masks field, specify files that you do not want to back up in the following ways:

     If you include an entire volume in the file-level backup, in the Exclude masks field, specify paths to folders that contain files that you do not want to back up. The resulting Veeam Agent backup will contain all folders that reside on the backed-up volume except the files in the specified folders.

     For example, you include the `D:\` volume in the backup and specify the `D:\Reports\OldReports` folder in the Exclude masks field. The resulting backup will contain all folders and files that reside on the volume except files that reside in the `D:\Reports\OldReports` folder.

     If you include a specific folder in the file-level backup, in the Exclude masks field, specify file names and/or masks for file types that you do not want to back up, for example, `OldReports.rar`, `*.temp`, `*.tmp`, `*.back`. The resulting Veeam Agent backup will contain all files except files whose names match the specified names or masks.

     Keep in mind that depending on the backup type, Veeam Agent excludes files and folders from the backup scope differently:

     For the volume-level backup, content of folders you do not want to back up is excluded from the VSS snapshot with the FilesNotToSnapshot registry key.

     For the file-level backup, folders and files are excluded by Veeam Agent after the VSS snapshot is created.

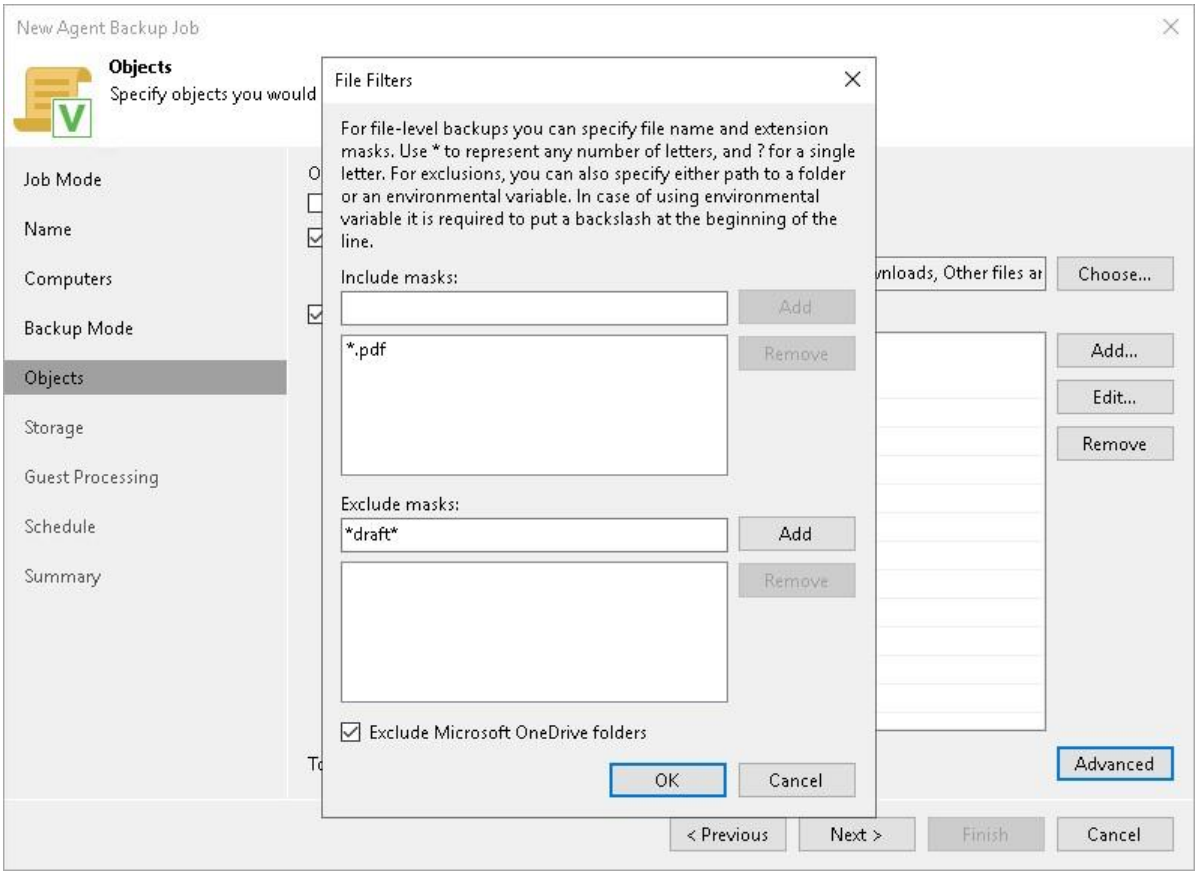
     As a result, some objects may be excluded or not excluded from the backup scope depending on the type of the created backup. For example, if you configure a volume-level backup, the objects that you excluded may stay in the backup scope due to the FilesNotToSnapshot registry key limitations. To learn more, see this Microsoft article.
3. Click Add.
4. Repeat steps 2–3 for each mask that you want to add.

> TIP
>
> You can also use system environment variables to specify include and exclude masks. In this case, you must type the back slash (\) symbol in the beginning of the mask. For example: \%appdata%.
>
> Consider the following:
>
> To specify include and exclude masks, you can use only system environment variables — variables defined for the Local System account on computers added to the backup job, and cannot use user environment variables. For example, if you specify the \%appdata% exclude mask, Veeam Agent
> will exclude the `C:\Windows\system32\config\systemprofile\AppData\Roaming` folder from the backup. Application data directories for other user accounts (for example,
> `C:\Users\Administrator\AppData\Roaming`) will not be excluded from the backup.
> You cannot use environment variables that contain multiple values or other environment variables to specify include and exclude masks.

You can use a combination of include and exclude masks. Note that exclude masks have a higher priority than include masks. For example, you can specify masks in the following way:

Include mask: `*.pdf`

Exclude mask: `*draft*`



The resulting Veeam Agent backup will contain all files of the PDF format that do not contain draft in their names.

Additionally, you can specify how Veeam Agent for Microsoft Windows will process Microsoft OneDrive folders. Select the Exclude Microsoft OneDrive folders option to exclude Microsoft OneDrive folders and their content from the backup scope.

Consider the following limitation:

Veeam Agent excludes Microsoft OneDrive folders only in file-level backups. If you include an entire volume in the backup, Veeam Agent will not exclude Microsoft Onedrive folders from this volume.

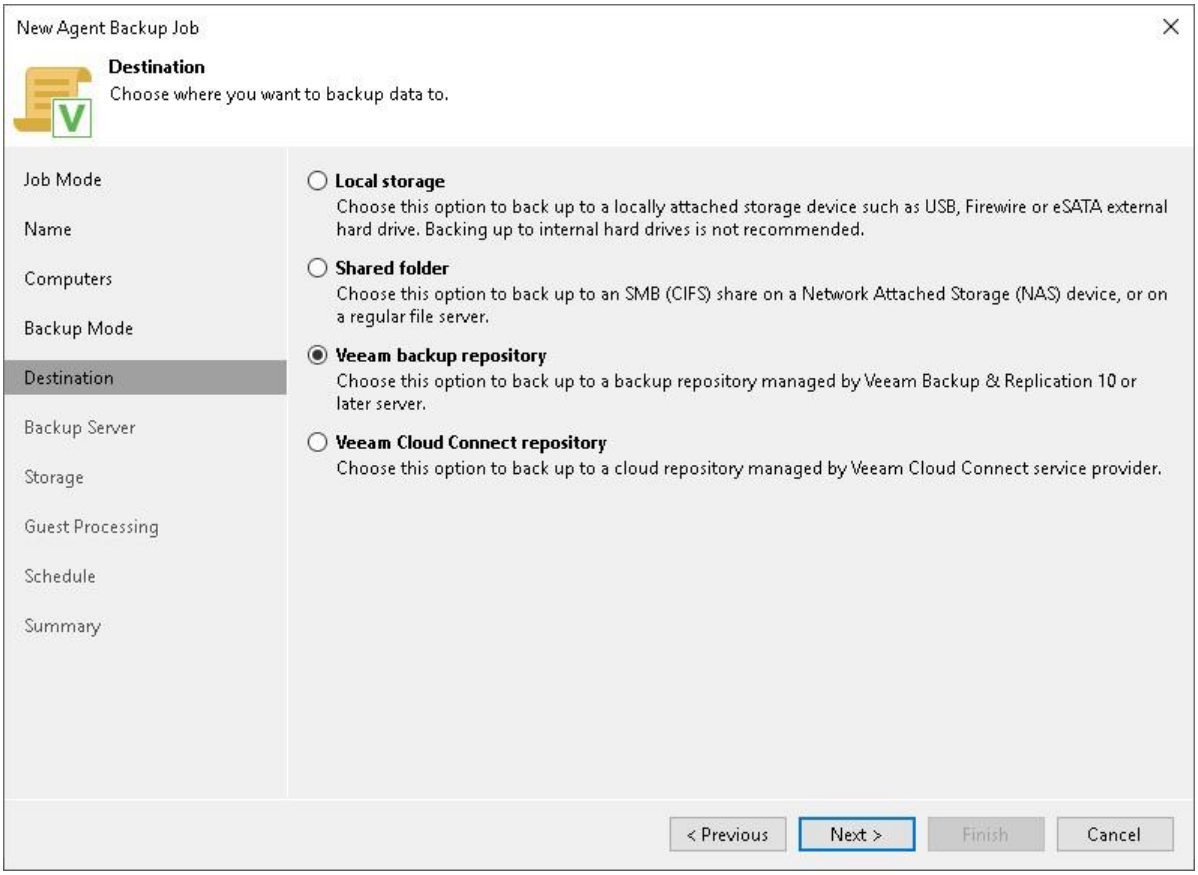
Due to the OS limitations, the Exclude Microsoft OneDrive folders option behaves properly only on Veeam Agent computers running Microsoft Windows 10. If your Veeam Agent computers run other OS versions, we recommend to exclude Microsoft OneDrive folders manually.

Step 7. Select Backup Destination

The Destination step of the wizard is available if you have selected the Managed by agent option at the Job Mode step of the wizard.

At this step of the wizard, select a target location for backups created by Veeam Agents installed on protected computers.

You can store backup files in one of the following locations:



Local storage — select this option if you want to save a backup on a removable storage device attached to a protected computer or on a local drive of a protected computer. With this option selected, you will pass to the Local Storage step of the wizard.

> IMPORTANT
>
> Consider the following:
>
> It is strongly recommended that you store backups in the external location like USB storage device or shared network folder. You can also keep your backup files on the separate non-system local drive.
>
> If you select to store the backup in a local folder included in the backup scope, Veeam Agent for Microsoft Windows will automatically exclude this folder from the backup.

Shared folder — select this option if you want to save a backup in a network shared folder. With this option selected, you will pass to the Shared folder step of the wizard.

Veeam backup repository — select this option if you want to save a backup in a backup repository managed by the Veeam backup server of which the Veeam Agent backup job is configured. With this option selected, you will pass to the Backup Server step of the wizard.

Veeam Cloud Connect repository — select this option if you want to save a backup in a cloud repository exposed to you by the Veeam Cloud Connect service provider. With this option selected, you will pass to the Storage step of the wizard.

Step 8. Specify Backup Storage Settings

Specify backup storage settings for the backup job:

If you have selected the Managed by backup server mode at the Job Mode step of the wizard, you can create Veeam Agent backups only in a backup repository managed by this Veeam backup server or in a cloud repository exposed to you by a Veeam Cloud Connect service provider. Specify backup repository settings at the Storage of the wizard.

If you have selected the Managed by agent mode at the Job Mode step of the wizard, specify backup storage settings at one of the following steps of the wizard:

- Local storage settings — if you have selected the Local storage option at the Destination step of the wizard.
- Shared folder settings — if you have selected the Shared folder option at the Destination step of the wizard.
- Veeam backup repository settings — if you have selected the Veeam backup repository option at the Destination step of the wizard.
- Cloud repository settings — if you have selected the Veeam Cloud Connect repository option at the Destination step of the wizard.

Backup Storage Settings

The Storage step of the wizard is available if you have selected the Managed by backup server mode at the Job Mode step of the wizard.

Specify settings for the target backup repository:

From the Backup repository list, select a backup repository where you want to store Veeam Agent backups. You can select from the following types of backup repositories: ○ Veeam backup repository configured on the backup server that will manage the created backup job. ○ Cloud repository allocated to your tenant account by a Veeam Cloud Connect service provider.

When you select a backup repository, Veeam Backup & Replication automatically checks how much free space is available on the backup repository.

> NOTE
>
> Keep in mind when you work with cloud machines, Veeam Backup & Replication displays only AWS or Azure object storage repositories depending on the type of cloud machine you selected to back up.

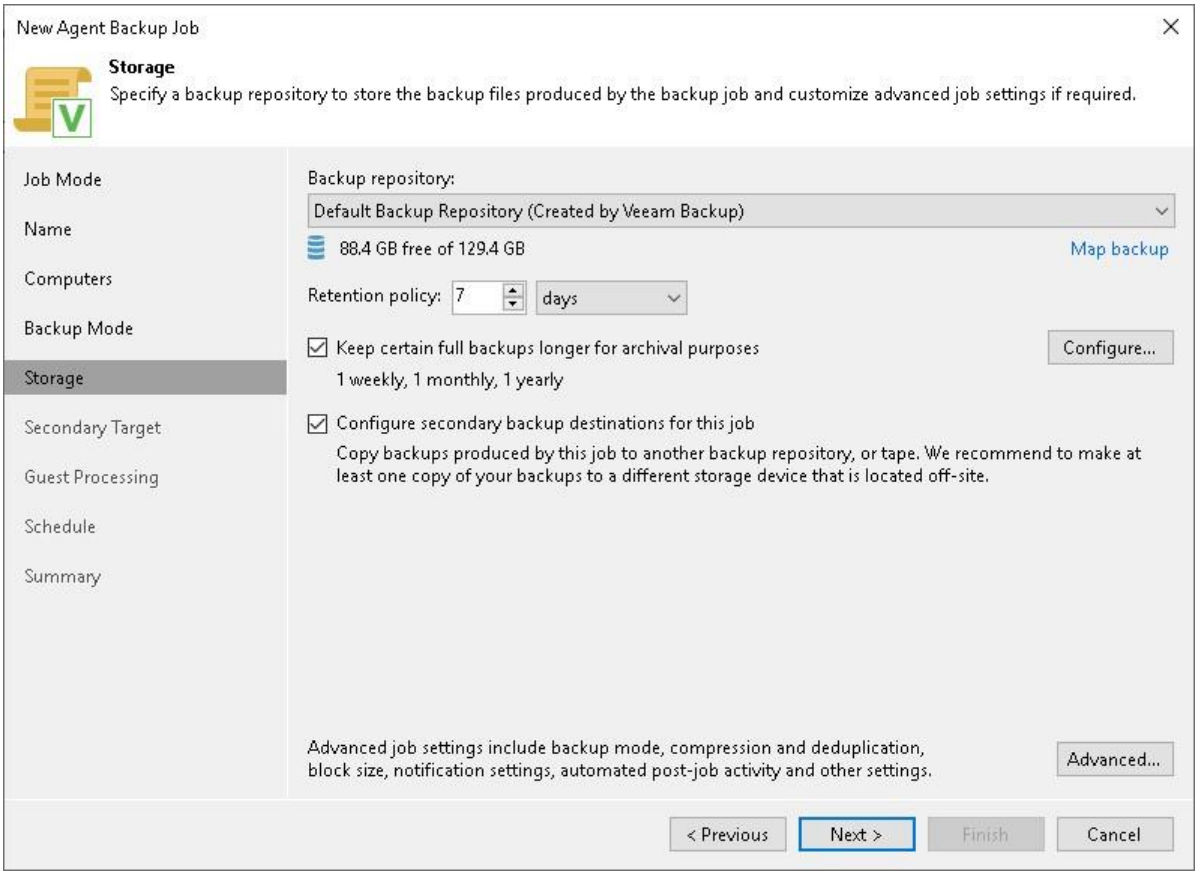
You can map the job to a specific backup stored in the backup repository. Backup job mapping can be helpful if you have moved backup files to a new backup repository and want to point the job to existing backups in this new backup repository. You can also use backup job mapping if the configuration database got corrupted and you need to reconfigure backup jobs.

To map the job to a backup, click the Map backup link and select the backup in the backup repository. Backups can be easily identified by job names. To find the backup, you can also use the search field at the bottom of the window.

> NOTE
>
> Mind the following:
>
> The Map backup link is available only for a Veeam Agent backup job managed by the backup server. If you want to map a backup job managed by Veeam Agent, see Backup Job Mapping.
> You cannot map a Veeam Agent backup job configured in Veeam Backup & Replication to a backup chain that was created by Veeam Agent operating in the standalone mode.

Specify short-term backup retention policy settings in one of the following ways:

From the Retention policy list, select restore points and specify the number of restore points for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files created for 7 latest restore points. After this number is exceeded, Veeam Backup & Replication will remove the earliest restore points from the backup chain.



From the Retention policy list, select days and specify the number of days for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files for 7 days. After this period is over, Veeam Backup & Replication will remove the earliest restore points from the backup chain.

To use the GFS (Grandfather-Father-Son) retention scheme, select the Keep certain full backups longer for archival purposes check box and click Configure. In the Configure GFS window, specify how weekly, monthly and yearly full backups must be retained. To learn more, see the Long-Term Retention Policy (GFS) section in the Veeam Backup & Replication User Guide.

If you want to archive backup files created with the backup job to a secondary destination (backup repository or tape), select the Configure secondary destinations for this job check box. With this option enabled, the New Agent Backup Job wizard will include an additional step — Secondary Target. At the Secondary Target step of the wizard, you can link the backup job to the backup copy job or backup to tape backup job.

You can enable this option only if a backup copy job or backup to tape job is already configured on the backup server.

Click Advanced to specify advanced settings for the backup job. To learn more, see Specify Advanced Backup Settings.

Local Storage Settings

The Local Storage step of the wizard is available if you have selected the Managed by agent mode at the Job Mode step of the wizard and chosen to save the backup on a local drive of your computer.

Specify local storage settings:

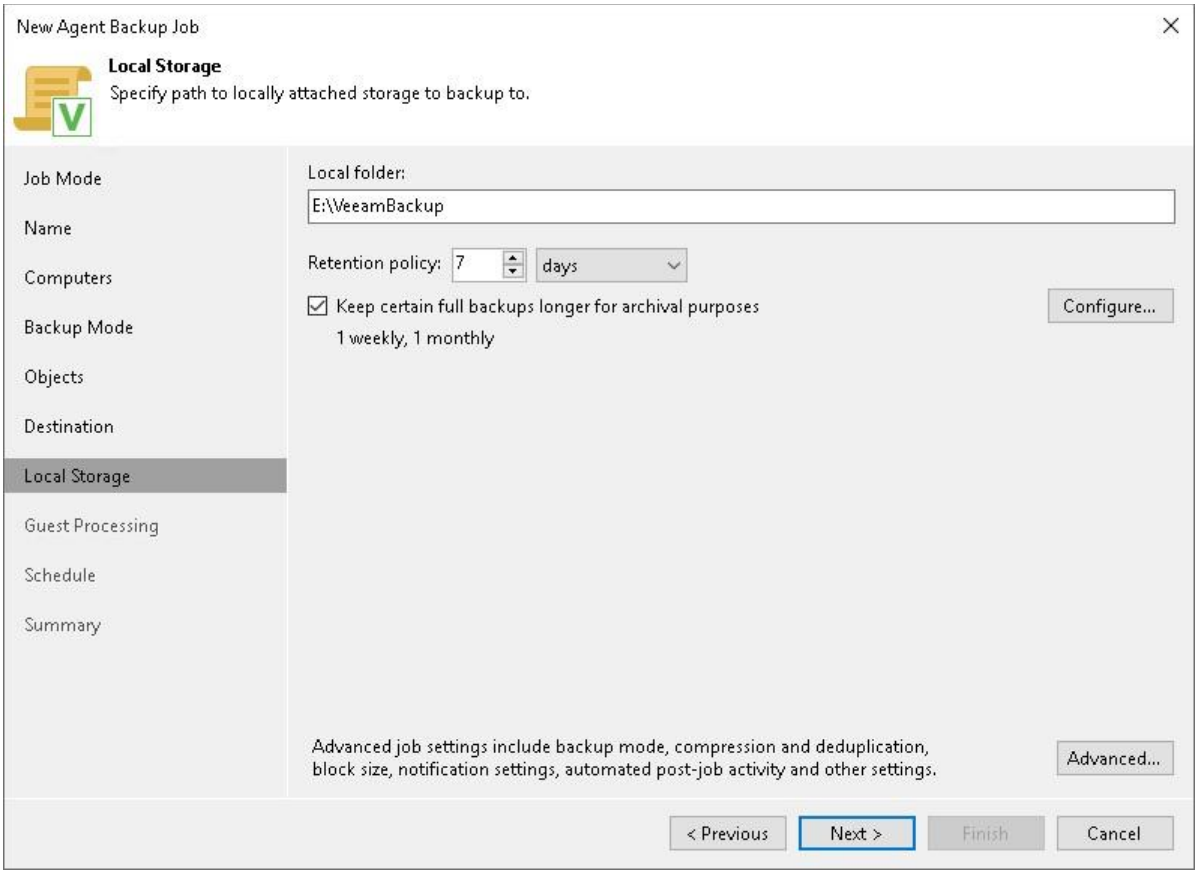
In the Local folder field, type a path to a folder on a protected computer where backup files must be saved. If the specified folder does not exist in the file system of a protected computer, Veeam Agent for Microsoft Windows will create this folder and save the resulting backup file to this folder. If the volume on which the specified folder must reside does not exist on a protected computer, Veeam Backup & Replication will not apply the backup job settings to this computer.

> IMPORTANT
>
> USB storage devices formatted as FAT32 do not allow storing files larger than 4 GB in size. For this reason, it is recommended that you do not use such USB storage devices as a backup target.
>
> We do not recommend targeting a backup job at the storage device with the exFAT file system. If the protected computer runs Microsoft Windows 10 or Microsoft Windows Server 2019 and later, this configuration may lead to the backup data corruption caused by the exFAT file system issue.

Specify short-term backup retention policy settings in one of the following ways:

From the Retention policy list, select restore points and specify the number of restore points for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files created for 7 latest restore points. After this number is exceeded, Veeam Backup & Replication will remove the earliest restore points from the backup chain.

From the Retention policy list, select days and specify the number of days for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files for 7 days. After this period is over, Veeam Backup & Replication will remove the earliest restore points from the backup chain.



Keep in mind that if you have selected the Workstation type at the Job Mode step of the wizard, you can specify retention policy only in days.

> NOTE
> The short-term retention policies for backups of workstations and servers are the same as in Veeam Agent for Microsoft Windows operating in the standalone mode. To learn more about retention policies, see the following sections in the Veeam Agent for Microsoft Windows User Guide:
>
> - The Retention Policy in Free and Workstation Editions section about retention policy using that Veeam Agent retains restore points for a certain number of days.
> - The Retention Policy in Server Edition section about retention policy using that Veeam Agent retains restore points for a certain number of days or retains the number of latest restore points.

To use the GFS (Grandfather-Father-Son) retention scheme, select the Keep certain full backups longer for archival purposes check box and click Configure. In the Configure GFS window, specify how weekly, monthly and yearly full backups must be retained. To learn more, see the Long-Term Retention Policy (GFS) section in the Veeam Backup & Replication User Guide.

Keep in mind that to use the GFS retention policy, you must set Veeam Agent to create full backups. To learn more, see Backup Settings.

Click Advanced to specify advanced settings for the backup job. To learn more, see Specify Advanced Backup Settings.

Shared Folder Settings

The Shared Folder step of the wizard is available if you have selected the Managed by agent mode at the Job Mode step of the wizard and chosen to save the backup in a network shared folder.

Specify shared folder settings:

In the Shared folder field, type a UNC name of the network shared folder in which you want to store backup files. Keep in mind that the UNC name always starts with two back slashes (\\).

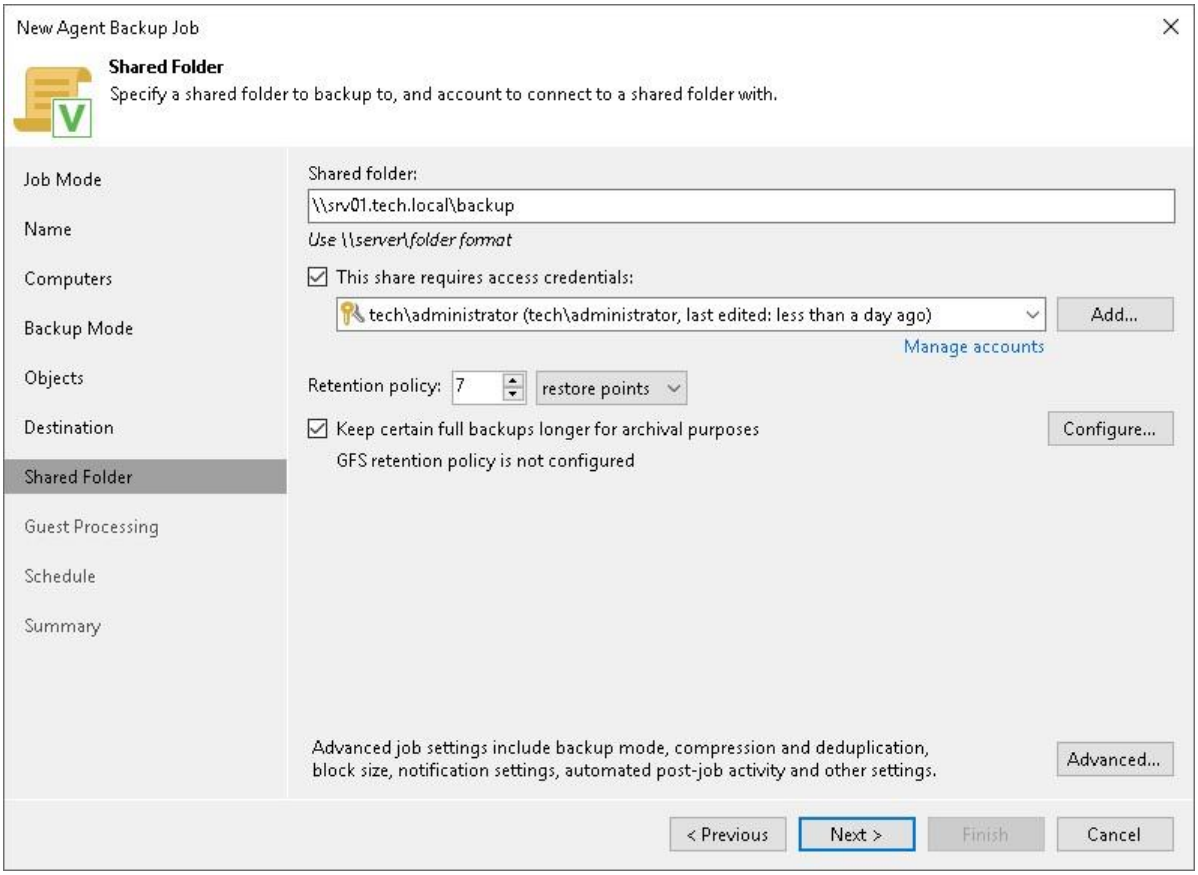
If the network shared folder requires authentication, select the This share requires access credentials check box and select from the list a user account that has access permissions on this shared folder. If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials. The user name must be specified in the DOMAIN\USERNAME format.

If you do not select the This share requires access credentials check box, Veeam Agent for Microsoft Windows will connect to the shared folder using the NT AUTHORITY\SYSTEM account of the computer where the product is installed. You can use this scenario if the Veeam Agent computer is joined to the Active Directory domain. In this case, you can simply grant Full Control access on the shared folder and underlying file system to the computer account (DOMAIN\COMPUTERNAME$).

Specify short-term backup retention policy settings in one of the following ways:

From the Retention policy list, select restore points and specify the number of restore points for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files created for 7 latest restore points. After this number is exceeded, Veeam Backup & Replication will remove the earliest restore points from the backup chain.

From the Retention policy list, select days and specify the number of days for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files for 7 days. After this period is over, Veeam Backup & Replication will remove the earliest restore points from the backup chain.



Keep in mind that if you have selected the Workstation type at the Job Mode step of the wizard, you can specify retention policy only in days.

> NOTE
>
> The short-term retention policies for backups of workstations and servers are the same as in Veeam Agent for Microsoft Windows operating in the standalone mode. To learn more about retention policies, see the following sections in the Veeam Agent for Microsoft Windows User Guide:
>
> - The Retention Policy in Free and Workstation Editions section about retention policy using that Veeam Agent retains restore points for a certain number of days.
> - The Retention Policy in Server Edition section about retention policy using that Veeam Agent retains restore points for a certain number of days or retains the number of latest restore points.

To use the GFS (Grandfather-Father-Son) retention scheme, select the Keep certain full backups longer for archival purposes check box and click Configure. In the Configure GFS window, specify how weekly, monthly and yearly full backups must be retained. To learn more, see the Long-Term Retention Policy (GFS) section in the Veeam Backup & Replication User Guide.

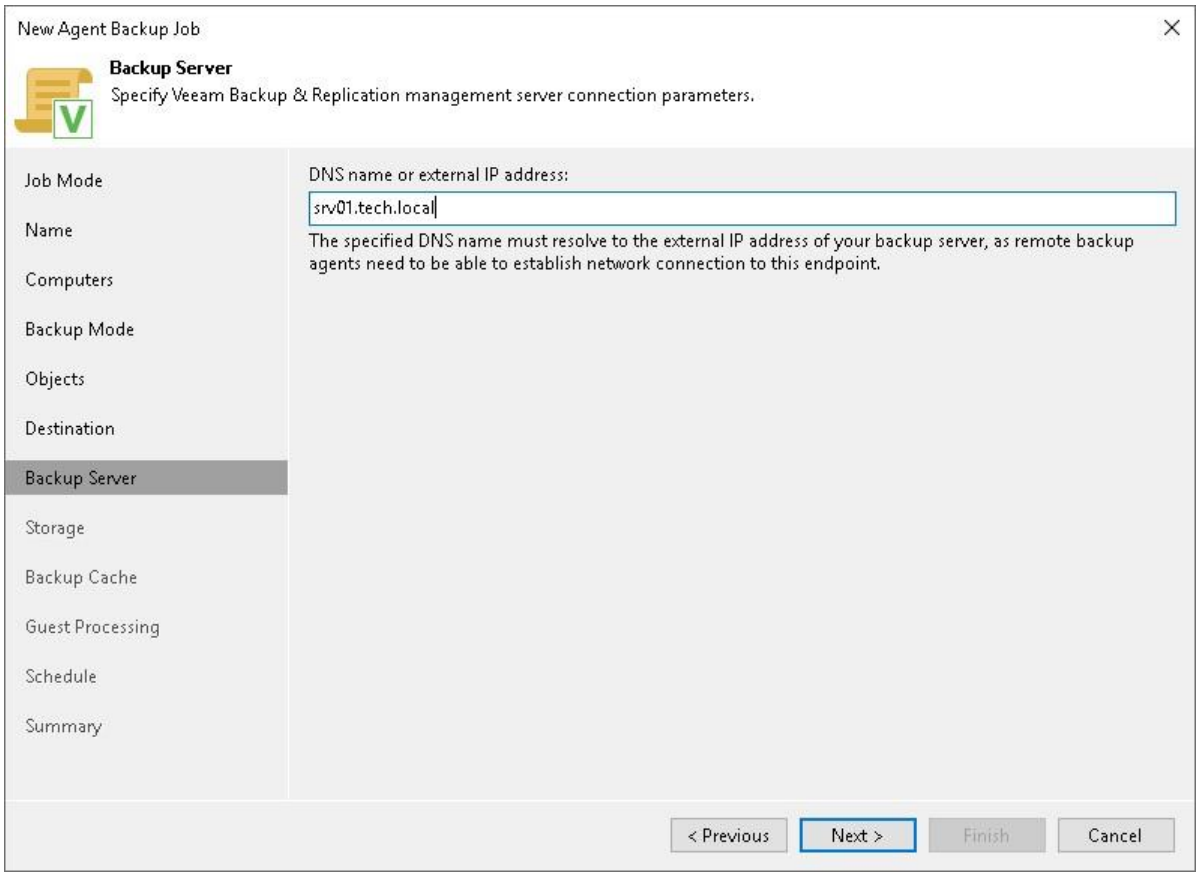
Keep in mind that to use the GFS retention policy, you must set Veeam Agent to create full backups. To learn more, see Backup Settings.

Click Advanced to specify advanced settings for the backup job. To learn more, see Specify Advanced Backup Settings.

Veeam Backup Repository Settings

If you have selected the Managed by agent mode for the backup job and chosen to store backup files in a Veeam backup repository, specify settings to connect to the backup repository:

At the Backup Server step of the wizard, specify backup server settings.



At the Storage step of the wizard, select the Veeam backup repository.

Specifying Backup Server Settings

The Backup Server step of the wizard is available if you have selected the Managed by agent mode at the Job Mode step of the wizard and chosen to store backup files in a Veeam backup repository.

In the DNS name or external IP address field, review and change if necessary the name or IP address of the Veeam backup server on which you configure the Veeam Agent backup job. The specified DNS name or IP address must be accessible from Veeam Agent computers.

> NOTE
>
> Veeam Backup & Replication does not automatically update information about the backup server in the backup policy settings after migration of the configuration database. After you migrate configuration data to a new location, you must specify the name or IP address of the new backup server in the properties of all backup policies configured in Veeam Backup & Replication.

Selecting Backup Repository

The Storage step of the wizard is available if you have selected the Managed by agent mode at the Job Mode step of the wizard and chosen to save backup files in a Veeam backup repository.

Specify settings for the target backup repository:

From the Backup repository list, select a backup repository where you want to store created backups. When you select a backup repository, Veeam Backup & Replication automatically checks how much free space is available on the backup repository.

Specify short-term backup retention policy settings in one of the following ways:

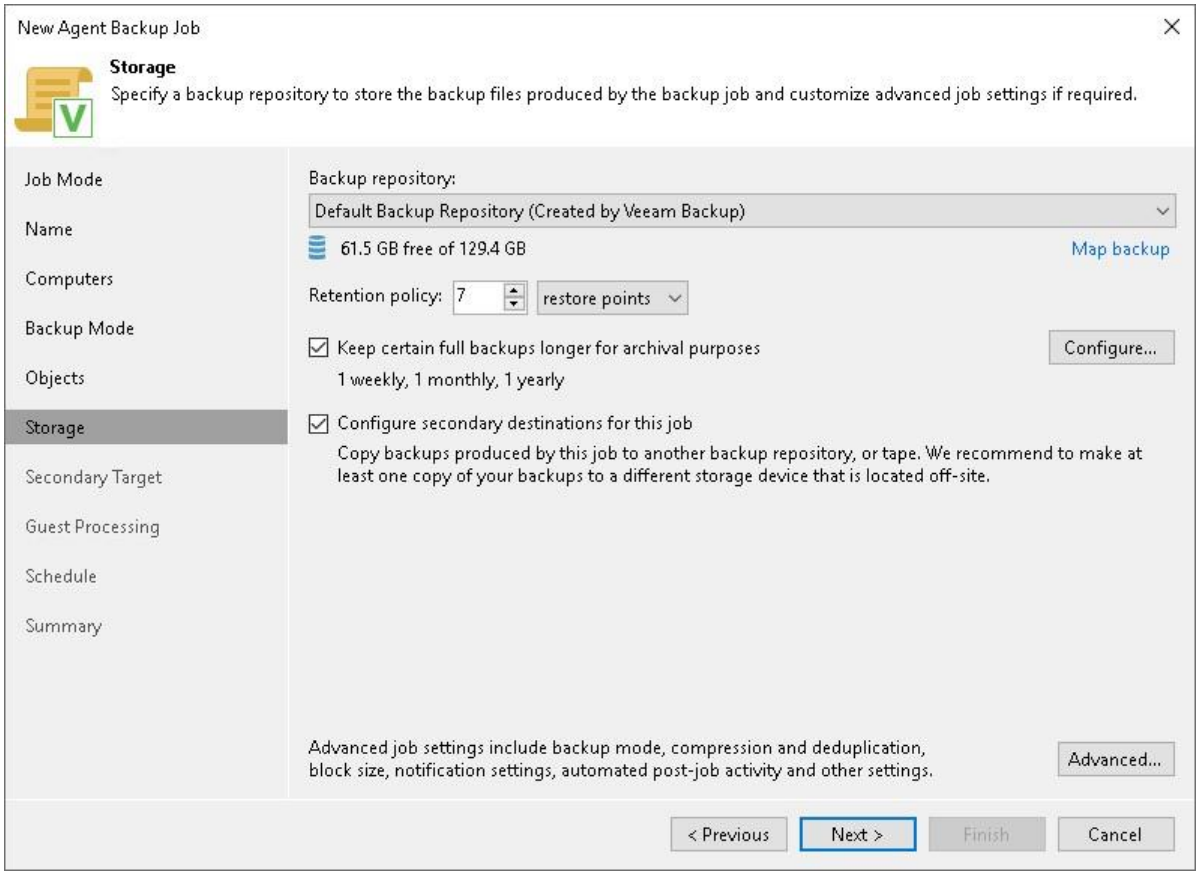
From the Retention policy list, select restore points and specify the number of restore points for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files created for 7 latest restore points. After this number is exceeded, Veeam Backup & Replication will remove the earliest restore points from the backup chain.

From the Retention policy list, select days and specify the number of days for which you want to store backup files in the target location. By default, Veeam Backup & Replication keeps backup files for 7 days. After this period is over, Veeam Backup & Replication will remove the earliest restore points from the backup chain.

Keep in mind that if you have selected the Workstation type at the Job Mode step of the wizard, you can specify retention policy only in days.

> NOTE
> The short-term retention policies for backups of workstations and servers are the same as in Veeam Agent for Microsoft Windows operating in the standalone mode. To learn more about retention policies, see the following sections in the Veeam Agent for Microsoft Windows User Guide:
>
> - The Retention Policy in Free and Workstation Editions section about retention policy using that Veeam Agent retains restore points for a certain number of days.
> - The Retention Policy in Server Edition section about retention policy using that Veeam Agent restore points for a certain number of days or retains the number of latest restore points.

To use the GFS (Grandfather-Father-Son) retention scheme, select the Keep certain full backups longer for archival purposes check box and click Configure. In the Configure GFS window, specify how weekly, monthly and yearly full backups must be retained. To learn more, see the Long-Term Retention Policy (GFS) section in the Veeam Backup & Replication User Guide.



If you want to archive backup files created with the backup job to a secondary destination (backup repository or tape), select the Configure secondary destinations for this job check box. With this option enabled, the New Agent Backup Job wizard will include an additional step — Secondary Target. At the Secondary Target step of the wizard, you can link the backup job to the backup copy job or backup to tape backup job.

You can enable this option only if a backup copy job or backup to tape job is already configured on the backup server.

Click Advanced to specify advanced settings for the backup job. To learn more, see Specify Advanced Backup Settings.

TIP

You can map the job to a specific backup stored in the Veeam backup repository. Backup job mapping can be helpful if you have moved backup files to a new backup repository and want to point the job to existing backups in this new backup repository. To learn more, see Backup Job Mapping.

Step 9. Specify Advanced Backup Settings

In the Advanced Settings window, specify advanced settings for the Veeam Agent backup job:

Backup settings

Maintenance settings

Storage settings

Notification settings

[For Veeam Agent jobs managed by the backup server] Integration settings

[For Veeam Agent jobs managed by the backup server] Script settings

TIP

After you specify necessary settings for the Veeam Agent backup job, you can save them as default settings. To do this, click Save as Default at the bottom left corner of the Advanced Settings window. When you create a new backup job, Veeam Backup & Replication will automatically apply the default settings to the new job.

Backup Settings

To specify settings for a backup chain created with the backup job:

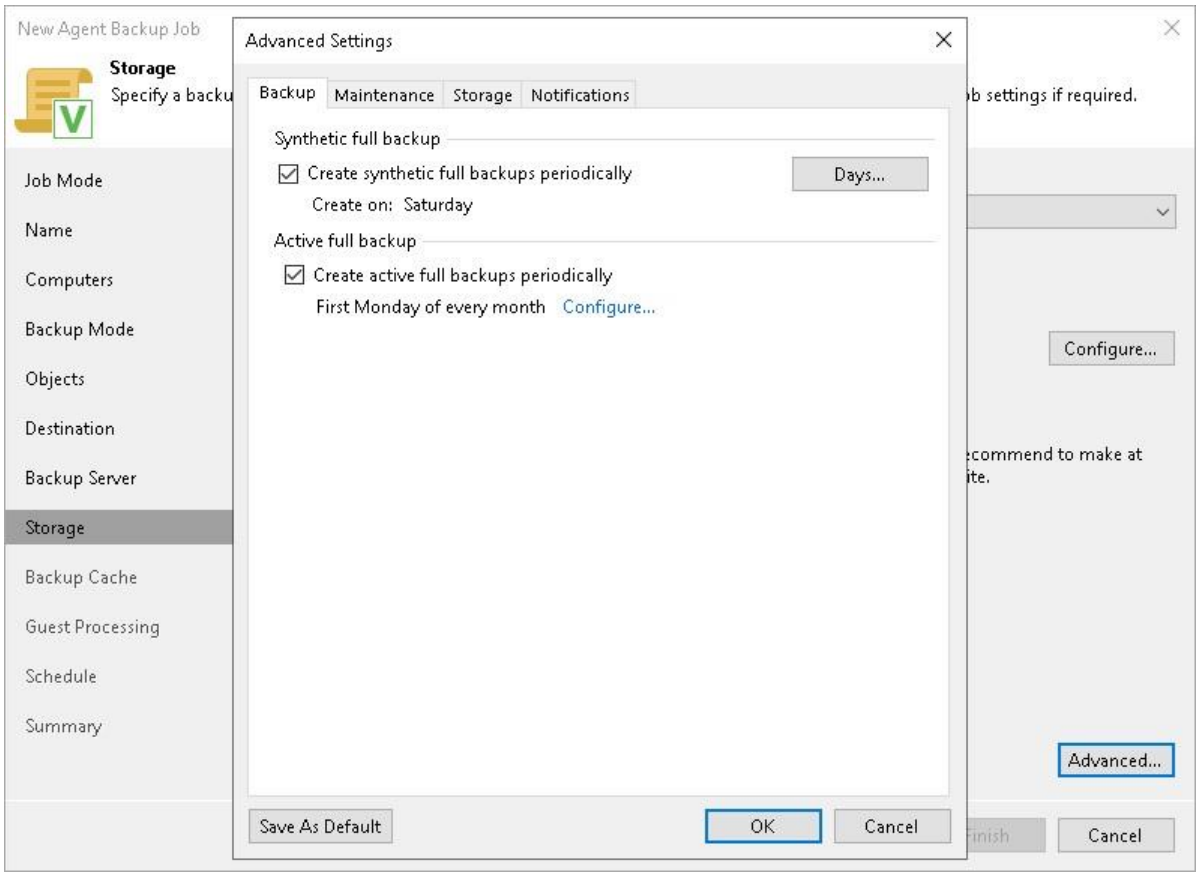
Click Advanced at one of the following steps of the wizard:

Storage — if you have selected to save backup files in a Veeam backup repository or cloud repository.

Local Storage — if you have selected to save backup files in a local storage of a Veeam Agent computer.

Shared Folder — if you have selected to save backup files in a network shared folder.

If you want to periodically create synthetic full backups, on the Backup tab, select the Create synthetic full backups periodically check box and click Days to schedule synthetic full backups on the necessary week days.



> NOTE
>
> Synthetic full backup is not available for backup jobs targeted at an object storage repository.

If you want to periodically create active full backups, select the Create active full backups periodically check box. To define scheduling settings, click Configure.

NOTE

Consider the following:

- Before scheduling periodic full backups, you must make sure that you have enough free space on the target location. For more information about periodic full backups, see the Active Full Backup and Synthetic Full Backup sections in the Veeam Agent for Microsoft Windows User Guide.
- If you schedule the active full backup and synthetic full backup on the same day, Veeam Agent for Microsoft Windows will perform only active full backup. Synthetic full backup will be skipped.

Maintenance Settings

You can specify maintenance settings for a backup chain created with the Veeam Agent backup job. Maintenance operations help make sure that the backup chain remains valid and consistent.

Maintenance settings are available for the following types of Veeam Agent backup jobs that process Microsoft Windows computers:

Backup job managed by the backup server.

Backup job managed by Veeam Agent (backup policy).

To specify maintenance settings for the backup job:

Click Advanced at one of the following steps of the wizard:

Storage — if you have selected to save backup files in a Veeam backup repository or cloud repository.

Local Storage — if you have selected to save backup files in a local storage of a Veeam Agent computer.

Shared Folder — if you have selected to save backup files in a network shared folder.

In the Advanced Settings window, click the Maintenance tab.

To periodically perform a health check for the latest restore point in the backup chain, in the Storage-level corruption guard section, select the Perform backup files health check check box. To specify the schedule for the health check, click Configure.

An automatic health check can help you avoid a situation where a restore point gets corrupted, making all dependent restore points corrupted, too. If during the health check Veeam Agent for Microsoft Windows or Veeam Backup & Replication detect corrupted data blocks in the latest restore point in the backup chain (or the restore point before the latest one if the latest restore point is incomplete), it will start the health check retry and transport valid data blocks from the Veeam Agent computer to the target location. The transported data blocks are stored to a new backup file or the latest backup file in the backup chain, depending on the data corruption scenario.

For Veeam Agent backup jobs managed by the backup server, the health check process is similar to the one for backup jobs that process VMs. For more information, see the Health Check for Backup Files section in the Veeam Backup & Replication User Guide.

For Veeam Agent backup jobs managed by Veeam Agent, the health check process is the same as for Veeam Agent backup jobs configured directly on a Veeam Agent computer. For more information, see the Health Check for Backup Files section in the Veeam Agent for Microsoft Windows User Guide.

> NOTE
>
> For object storage, Veeam Agent offers a special health check mechanism as default. To run the health check for object storage, enable the Perform backup files health check option in the Storagelevel corruption guard section and specify the health check schedule.
>
> You can also switch from the health check for object storage to the standard health check. To do so, select the Verify content of each object in backup check box in the backup job settings. Keep in mind that enabling this setting may result in additional charges from your object storage provider.

[For backup jobs and policies targeted at a Veeam backup repository or cloud repository] Select the Remove deleted items data after check box and specify the number of days for which you want to keep the backup created with the backup job in the target location.

For backup jobs managed by the backup server, deleted items retention policy is similar to retention policy for deleted VMs. After you remove a protection group or individual computer from a Veeam Agent backup job, Veeam Backup & Replication will keep its data on the backup repository for the period that you have specified. When this period is over, backup data of this computer will be removed from the backup repository. For more information, see the Retention Policy for Deleted VMs section in the Veeam Backup & Replication User Guide.

For backup jobs managed by Veeam Agent, if Veeam Agent does not create new restore points for the backup, the backup will remain in the target location for the period that you have specified. When this period is over, the backup will be removed from the target location. For more information, see the Retention Policy for Outdated Backups section in the Veeam Agent for Microsoft Windows User Guide.

By default, the deleted items data retention period is 30 days. Do not set the deleted items retention period to 1 day or a similar short interval. In the opposite case, the backup job may work not as expected and remove data that you still require.

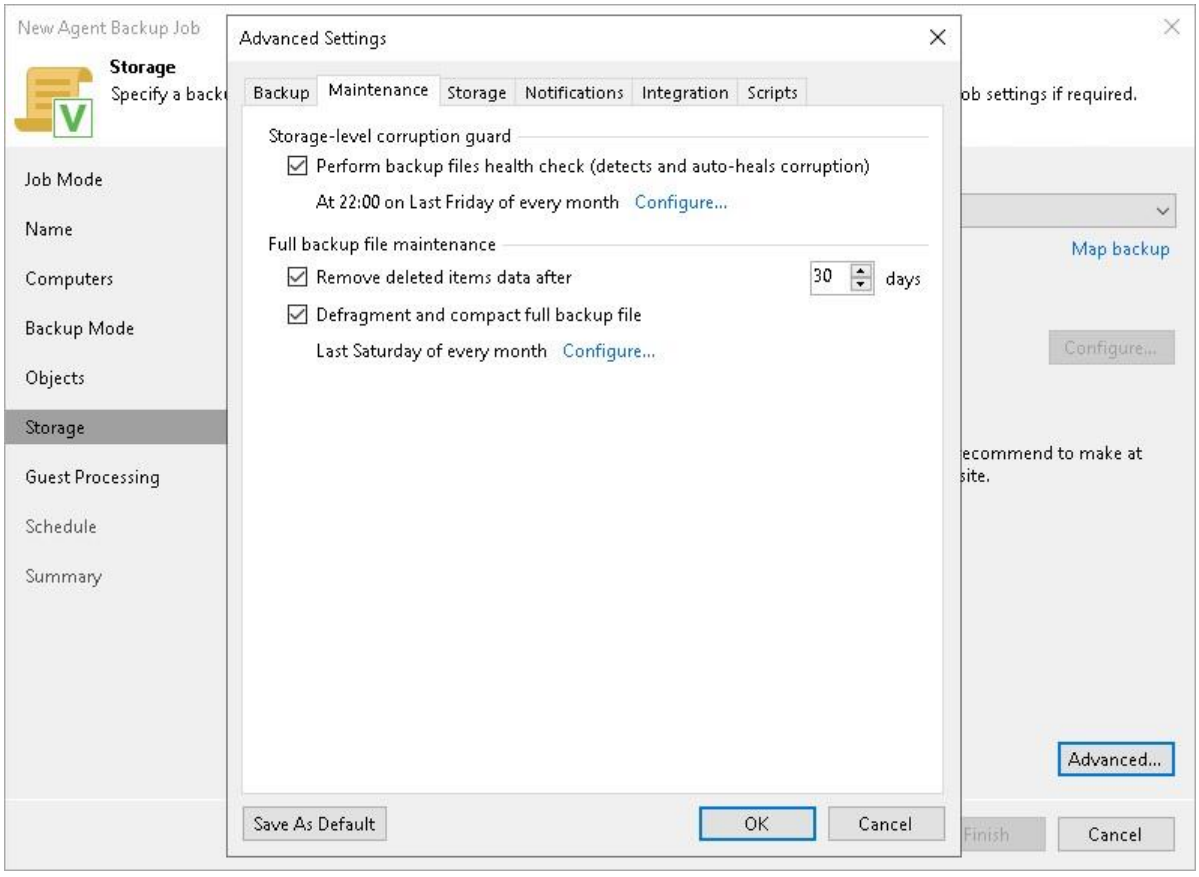
> NOTE
>
> The Remove deleted items data after option is not available if you configure a backup job managed by Veeam Agent (backup policy) and have selected the Local storage or Shared folder option at the Destination step of the wizard.

To periodically compact a full backup, select the Defragment and compact full backup file check box. To specify the schedule for the compact operation, click Configure. During the compact operation, data blocks from the full backup file are copied to a new empty file. As a result, the full backup file gets defragmented, and the speed of reading from and writing to the backup file increases.

NOTE

The Defragment and compact full backup file option is not available for backup jobs targeted at object storage.

The compact operation differs depending on the type of the backup job.



For Veeam Agent backup jobs managed by the backup server, the compact operation is similar to the compact operation performed for VM backup jobs. If the full backup file contains data blocks for deleted items (protection groups or individual computers that were removed from the backup job), Veeam Backup & Replication will remove these data blocks. For more information, see the Compact of Full Backup File section in the Veeam Backup & Replication User Guide.

For Veeam Agent backup jobs managed by Veeam Agent, if the full backup file contains data blocks for deleted drives, Veeam Agent for Microsoft Windows will remove these data blocks. For more information, see the Compact of Full Backup File section in the Veeam Agent for Microsoft Windows User Guide.

NOTE

Consider the following:

- If you want to periodically compact a full backup, you must make sure that you have enough free space in the target location. For the compact operation, the amount of free space must be equal to or more that the size of the full backup file.
- In contrast to the compact operation for a VM backup, during compact of a full Veeam Agent backup file, Veeam Backup & Replication does not perform the data take out operation. If the full backup file contains data for a computer that has only one restore point and this restore point is older than 7 days, Veeam Backup & Replication will not extract data for this computer to a separate full backup file.

Storage Settings

To specify storage settings for the backup job:

Click Advanced at one of the following steps of the wizard:

- Storage — if you have selected to save backup files in a Veeam backup repository or cloud repository.
- Local Storage — if you have selected to save backup files in a local storage of a Veeam Agent computer.
- Shared Folder — if you have selected to save backup files in a network shared folder.

Click the Storage tab.

[For a failover cluster backup job] By default, Veeam Backup & Replication deduplicates failover cluster data before storing it in the backup repository. Data deduplication provides a smaller size of the backup file but may reduce the backup job performance. You can disable data deduplication if necessary, for example, if you use a deduplication storage appliance as a backup repository. To disable data deduplication, clear the Enable inline data deduplication check box.

> NOTE
>
> The Enable inline data deduplication option is unavailable if you selected the Workstation or Server option at the Job Mode step of the wizard.

From the Compression level list, select a compression level for the backup: None, Dedupe-friendly, Optimal, High or Extreme.

In the Storage optimization section, select what size of data blocks you plan to use: 4 MB, 1 MB, 512 KB, 256 KB. Veeam Agent for Microsoft Windows will use data blocks of the chosen size to optimize the size of backup files and job performance.

To encrypt the content of backup files, select the Enable backup file encryption check box. In the Password field, select a password that you want to use for encryption. If you have not created the password beforehand, click Add or use the Manage passwords link to specify a new password. For more information, see the Password Manager section in the Veeam Backup & Replication User Guide.

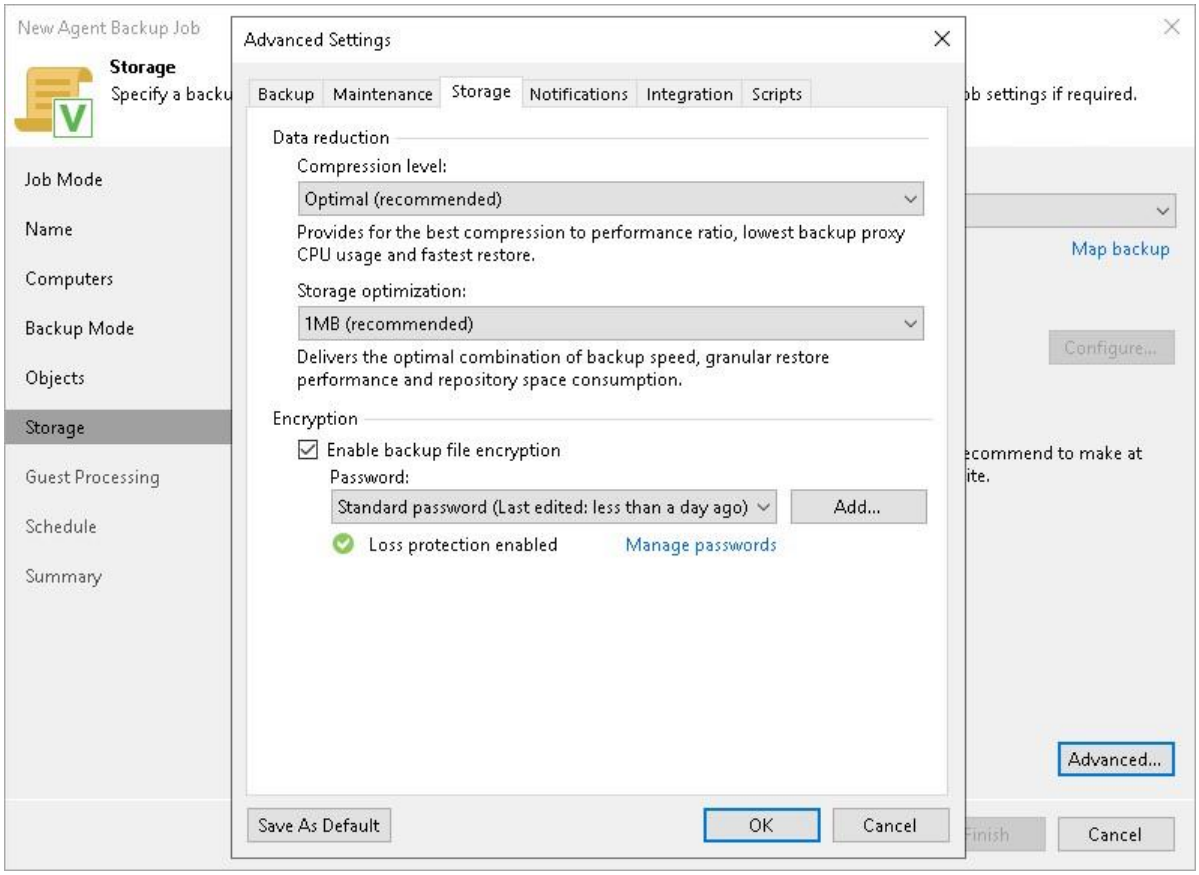
If the backup server is not connected to Veeam Backup Enterprise Manager, you will not be able to restore data from encrypted backups in case you lose the password. Veeam Backup & Replication will display a warning about it. For more information, see the Decrypting Data Without Password section in the Veeam Backup & Replication User Guide.

NOTE

Consider the following:

Data encryption settings for Veeam Agent backup jobs and backup policies configured in Veeam Backup & Replication are stored to the Veeam Backup & Replication database. For backup jobs and policies targeted at a Veeam backup repository, all data encryption operations are performed in Veeam Backup & Replication, too. Encryption settings are passed to a Veeam Agent computer only in case this computer is added to a backup policy targeted at a local drive of a protected computer, at a network shared folder, or at a cloud repository. Veeam Backup & Replication performs this operation when applying the backup policy to a protected computer.

If you change a password for data encryption for an existing backup policy targeted at a Veeam backup repository without changing other backup policy settings, the process of applying the backup policy to a protected computer completes with a notification informing that the backup policy was not modified. This happens because data encryption settings for managed Veeam Agents are saved to the Veeam Backup & Replication database and are not passed to a Veeam Agent computer.



If you enable encryption for an existing Veeam Agent backup, during the next job session Veeam Agent for Microsoft Windows will create a full backup file. The created full backup file and subsequent incremental backup files in the backup chain will be encrypted with the specified password.

Encryption is not retroactive. If you enable encryption for an existing backup job, Veeam Agent for Microsoft Windows will encrypt the backup chain starting from the next restore point created with this job.

[For backup policies targeted at a local drive, network shared folder or cloud repository] When you enable data encryption for a backup policy, Veeam Backup & Replication uses the specified password to encrypt backups of all Veeam Agent computers added to the backup policy. A Veeam Agent computer user can restore data from the backup of this computer without providing a password to decrypt backup. To restore data from a backup of another computer in this backup policy, a user must provide a password specified in the backup policy settings.

This scenario differs from the same scenario in earlier versions of Veeam Backup & Replication where all backups created for Veeam Agent computers in the backup policy could be accessed from any computer in the backup policy without providing a password.

To learn more about data encryption in Veeam Backup & Replication, see the Data Encryption section in the Veeam Backup & Replication User Guide.

Notification Settings

You can specify notification settings for Veeam Agent backup jobs configured in Veeam Backup & Replication. Notification options differ depending on the job mode that you have selected at the Job Mode step of the wizard:

- Managed by backup server. To learn more, see Notification Settings for Veeam Agent Backup Job.
- Managed by agent. To learn more, see Notification Settings for Backup Policy.

Notification Settings for Veeam Agent Backup Job

To specify notification settings for the backup job:

At the Storage step of the wizard, click Advanced.

Click the Notifications tab.

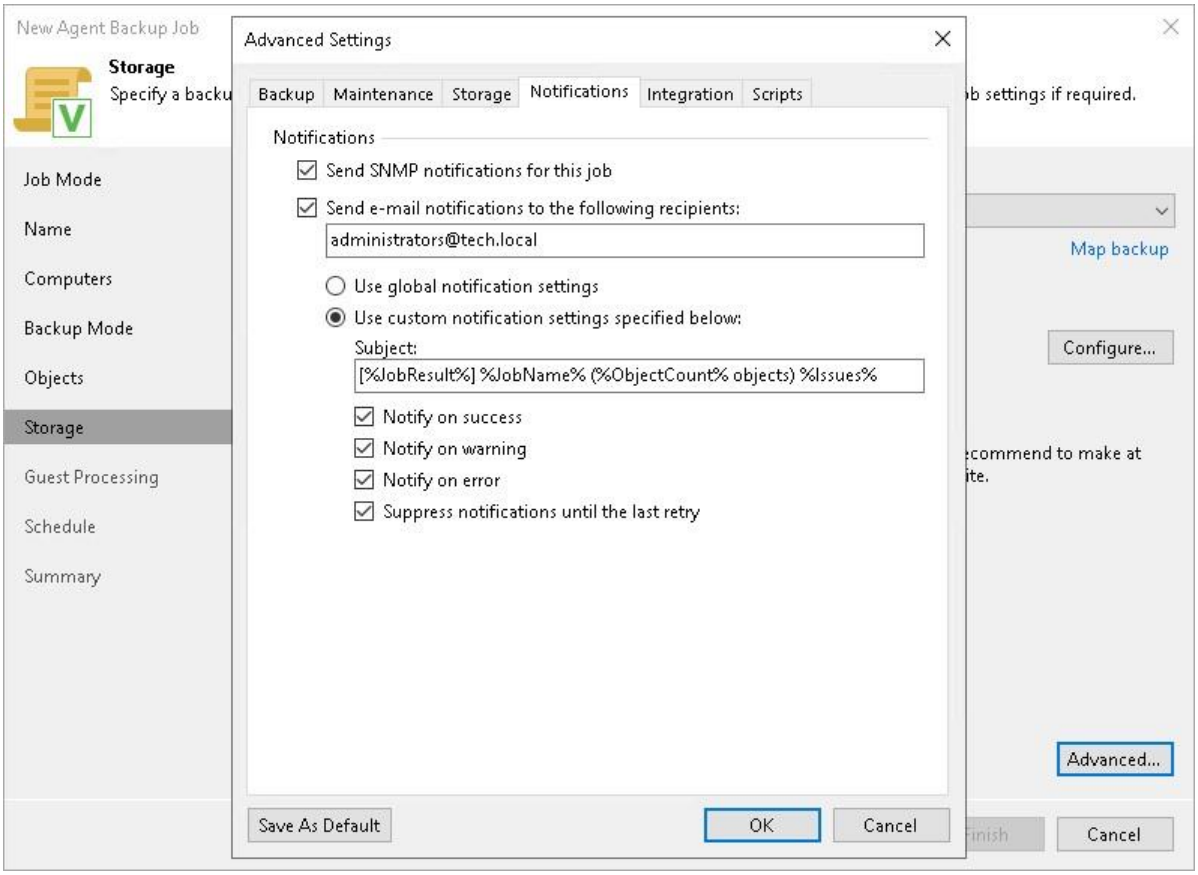
Select the Send SNMP notifications for this job check box if you want to receive SNMP traps when the job completes successfully.

SNMP traps will be sent if you specify global SNMP settings in Veeam Backup & Replication and configure software on recipient's machine to receive SNMP traps. For more information, see the Specifying SNMP Settings section in the Veeam Backup & Replication User Guide.

Select the Send e-mail notifications to the following recipients check box if you want to receive notifications about the job completion status by email. In the field below, specify a recipient's email address. You can enter several addresses separated by a semicolon.

Email notifications will be sent if you configure global email notification settings in Veeam Backup & Replication. For more information, see the Configuring Global Email Notification Settings section in Veeam Backup & Replication User Guide.

You can choose to use global notification settings or specify custom notification settings.



To receive a typical notification for the job, select Use global notification settings. In this case, Veeam Backup & Replication will apply to the job global email notification settings specified for the backup server.

To configure a custom notification for the job, select Use custom notification settings specified below. You can specify the following notification settings:

In the Subject field, specify a notification subject. You can use the following variables in the subject: %Time% (completion time), %JobName%, %JobResult%, %ObjectCount% (number of machines in the job) and %Issues% (number of machines in the job that have been processed with the Warning or Failed status).

Select the Notify on success, Notify on warning or Notify on error check boxes to receive email notification if the job completes successfully, completes with a warning or fails.

Select the Suppress notifications until the last retry check box to receive a notification about the final job status. If you do not enable this option, Veeam Backup & Replication will send one notification per every job retry.

Notification Settings for Backup Policy

You can specify email notification settings for the backup policy. If you enable notification settings, Veeam Backup & Replication will send a daily email report with backup policy statistics to a specified email address. The report contains cumulative statistics for backup job sessions performed for the last 24-hour period on computers to which the backup policy is applied.

> NOTE
>
> Email reports with backup policy statistics will be sent if you configure global email notification settings in Veeam Backup & Replication. For more information, see the Configuring Global Email Notification Settings section in the Veeam Backup & Replication User Guide.
>
> After you enable notification settings for the backup policy, Veeam Backup & Replication will send reports with the backup policy statistics to email addresses specified in global email notification settings and email addresses specified in the backup policy settings.

To specify notification settings for the backup policy:

1. Click Advanced at one of the following steps of the wizard:
   - Storage — if you have selected to save backup files in a Veeam backup repository or cloud repository.
   - Local Storage — if you have selected to save backup files in a local storage of a Veeam Agent computer.
   - Shared Folder — if you have selected to save backup files in a network shared folder.
2. Click the Notifications tab.
3. Select the Send daily e-mail report to the following recipients check box and specify a recipient's email address in the field below. You can enter several addresses separated by a semicolon.
4. In the Send daily summary at field, specify the time when Veeam Backup & Replication must send the email notification for the backup policy. Veeam Backup & Replication will send the report daily at the specified time.
5. You can choose to use global notification settings or specify custom notification settings.
   - To receive a typical notification for the backup policy, select Use global notification settings. In this case, Veeam Backup & Replication will apply to the backup policy global email notification settings specified for the backup server.
   - To configure a custom notification for the backup policy, select Use custom notification settings specified below. You can specify the following notification settings:
     - In the Subject field, specify a notification subject. You can use the following variables in the subject: %Time% (completion time), %JobName%, %JobResult%, %ObjectCount% (number of machines in the backup policy) and %Issues% (number of machines in the backup policy that have been processed with the Warning or Failed status).
     - Select the Notify on success, Notify on warning or Notify on error check boxes to receive email notification if the job completes successfully, completes with a warning or fails.
6. In the Backup monitoring section, select the Warn me if no backups were created in the last N days check box and specify a number of days. In this case, Veeam Backup & Replication will display a warning message in a backup policy session statistics in case successful backups are not created for a specified number of days.

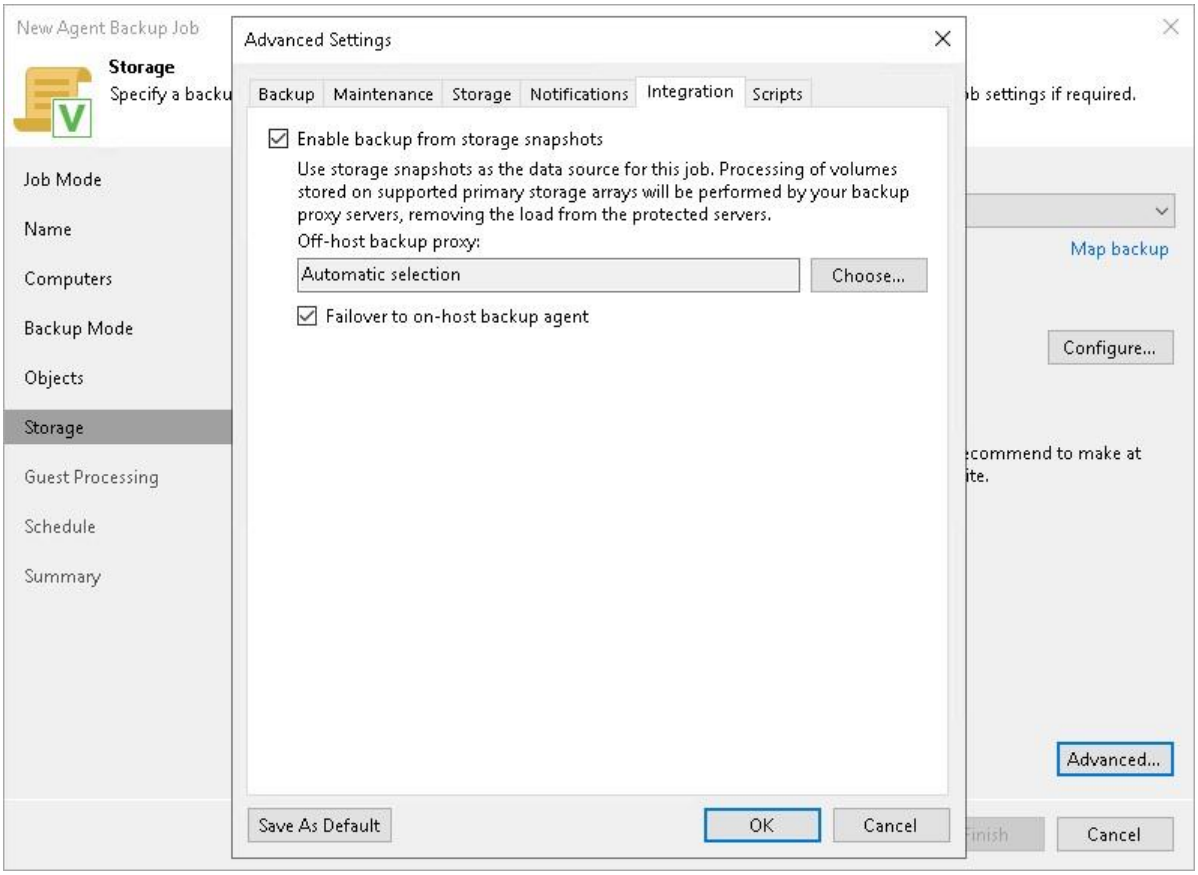
Integration Settings

You can specify storage integration settings for the job if you have selected the Managed by backup server mode at the Job Mode step of the wizard.

Keep in mind that storage integration settings are unavailable if you work with protection group for cloud machines.

To specify storage integration settings for the backup job:

At the Storage step of the wizard, click Advanced.



Click the Integration tab.

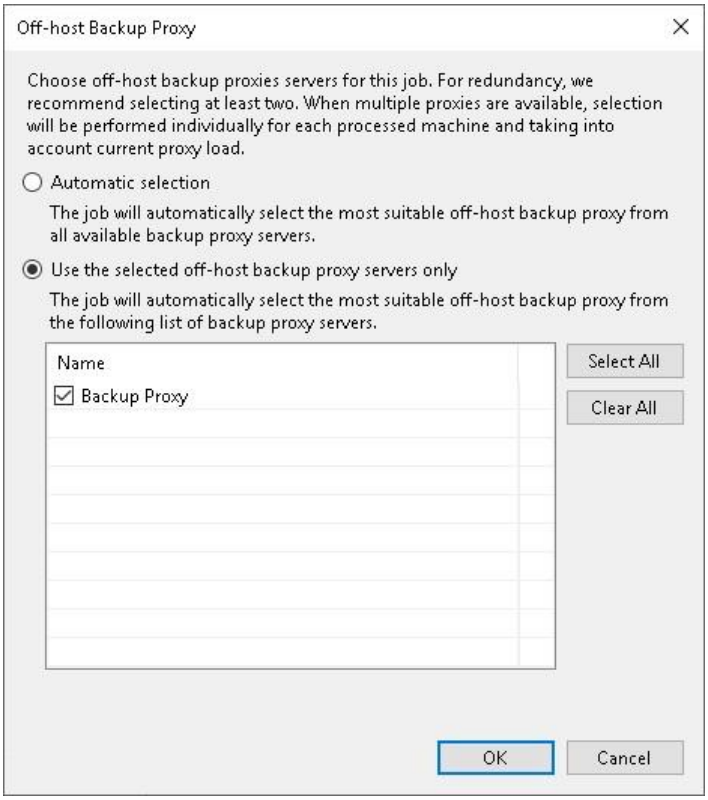
If you select the Enable backup from storage snapshots check box, Veeam Backup & Replication will use native storage snapshots to create Veeam Agent backups. To learn more about storage snapshots support, see Storage Snapshots Support.

To transfer a snapshot from storage to the target repository, Veeam Backup & Replication uses off-host backup proxies. You can allow Veeam Backup & Replication to use any suitable backup proxies or you can select specific backup proxies. To learn more, see Selecting Off-Host Backup Proxy.

If Veeam Backup & Replication fails to create a storage snapshot or backup proxy is unavailable, you can fail over to the regular backup scenario that uses the software VSS provider. To do this, select the Failover to on-host backup agent check box.

To learn more about regular backup scenario, see the How Backup Works section in the Veeam Agent for Microsoft Windows User Guide.

Selecting Off-Host Backup Proxy



To specify what backup proxies Veeam Backup & Replication will use during the backup process, click Choose and select one of the following options in the Off-host Backup Proxy window:

If you want Veeam Backup & Replication to use any suitable backup proxies, select the Automatic selection option. In this case, the number of backup proxies that Veeam Backup & Replication uses for data transfer depends on the backup scope.

> IMPORTANT
>
> If you use the NetApp Element storage system and you have 4 or more backup proxies set in your Veeam Backup & Replication infrastructure, you cannot use automatic selection. You must manually select up to 3 backup proxies.

If you want to select backup proxies manually, select the Use the selected off-host backup proxy servers only option and select check boxes near backup proxies you plan to use.

Keep in mind that Veeam Backup & Replication displays only those backup proxies that run Microsoft Windows Server OS. For more information about backup proxy requirements, see Storage Snapshots Support.

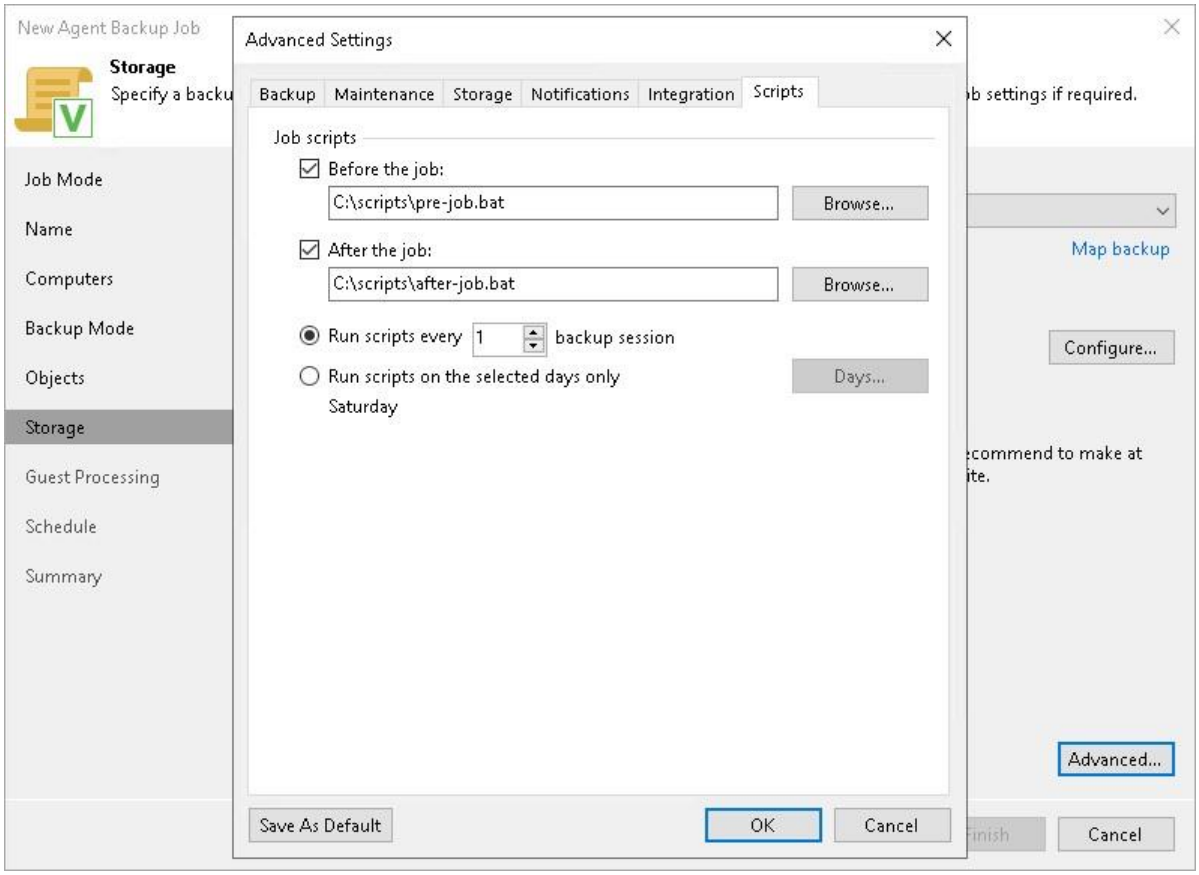
Script Settings

You can specify script settings for the job if you have selected the Managed by backup server mode at the Job Mode step of the wizard.

To specify script settings for the backup job:

At the Storage step of the wizard, click Advanced.

Click the Scripts tab.



If you want to execute custom scripts before or after the backup job, select the Before the job or After the job check boxes and click Browse to choose executable files from a local folder on the backup server. The scripts are executed on the backup server.

You can select to execute pre- and post-backup actions after a number of backup sessions or on specific week days.

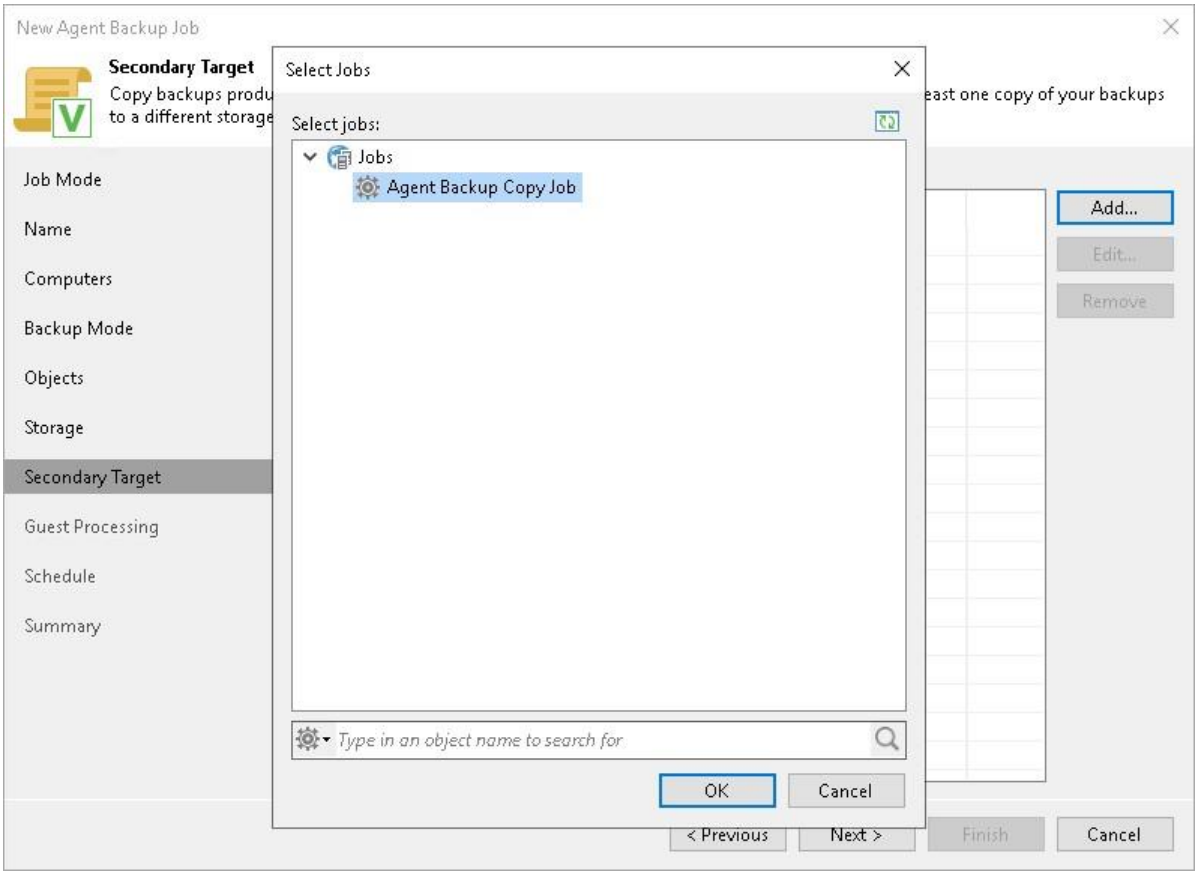
If you select the Run scripts every <N> backup session option, specify the number of the backup job sessions after which the scripts must be executed.

If you select the Run scripts on the selected days only option, click Days and specify week days on which the scripts must be executed.

> NOTE
>
> Custom scripts that you define in the advanced job settings relate to the backup job itself, not the OS quiescence process on protected computers. To add pre-freeze and post-thaw scripts for Veeam Agent computer OS quiescence, use the Guest Processing step of the wizard.

Step 10. Specify Secondary Target

The Secondary Target step of the wizard is available if you have enabled the Configure secondary destinations for this job option at the Storage step of the wizard.



At the Secondary Target step of the wizard, you can link the Veeam Agent backup job to a backup to tape or backup copy job. As a result, the backup job will be added as a source to the backup to tape or backup copy job. Backup files created with the backup job will be archived to tape or copied to the secondary backup repository according to the secondary jobs schedule. For more information, see the Linking Backup Jobs to Backup Copy Jobs and Linking Backup Jobs to Backup to Tape Jobs sections in the Veeam Backup & Replication User Guide.

The backup to tape job or backup copy job must be configured beforehand. You can create these jobs with an empty source. When you link the Veeam Agent backup job to these jobs, Veeam Backup & Replication will automatically update the linked jobs to define the Veeam Agent backup job as a source for these jobs.

To link jobs:

Click Add.

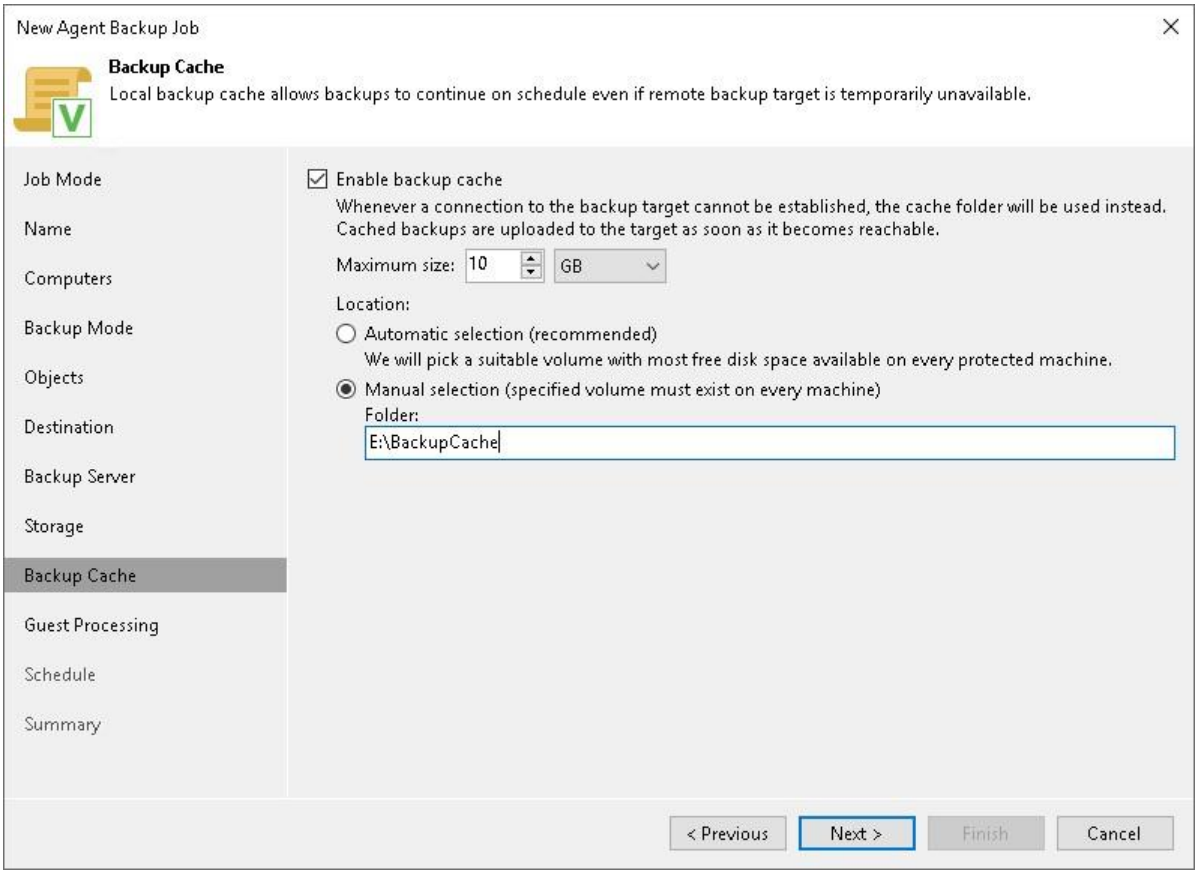
From the jobs list, select a backup to tape or backup copy job that must be linked to the Veeam Agent backup job. You can link several jobs to the backup job, for example, one backup to tape job and one backup copy job. To quickly find the job, use the search field at the bottom of the wizard.

Step 11. Specify Backup Cache Settings

The Backup Cache step of the wizard is available if you selected the following options at the previous steps of the wizard:

- Selected the Managed by agent mode at the Job Mode step of the wizard.
- Selected the Veeam backup repository or Veeam Cloud Connect repository option at the Destination step of the wizard.

To specify backup cache settings:



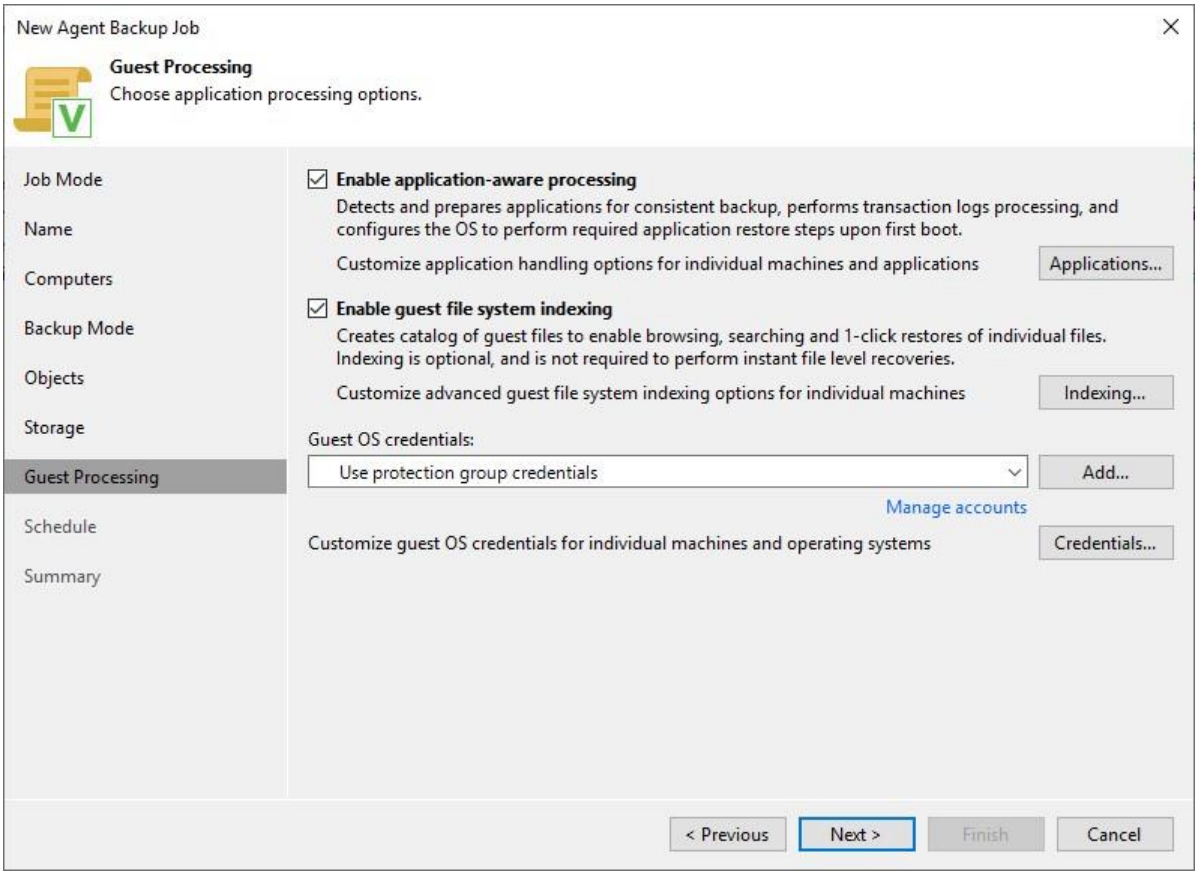
1. Select the Enable backup cache check box.
2. In the Maximum size field, specify the size for the backup cache.

   When defining the size of the backup cache, assume the following:

   - Each full backup file may consume about 50% of the backed-up data size.
   - Each incremental backup file may consume about 10% of the backed-up data size.
3. In the Location section, specify where Veeam Agent for Microsoft Windows will create the backup cache. You can select from the following options:

   - Automatic selection — select this option if you want to let Veeam Agent pick a location for the backup cache automatically. On every computer added to the backup policy, Veeam Agent will detect a volume with the largest amount of free disk space and create the backup cache in the Veeam Backup Cache folder on this volume. To learn more, see Backup Cache.

Manual selection — select this option if you want to specify a location for the backup cache manually. If you select this option, in the Folder field, specify a path to the folder on a protected computer in which backup files must be stored.



Step 12. Specify Guest Processing Settings

The Guest Processing step of the wizard is available if you have selected the Server or Failover cluster option at the Job Mode step of the wizard.

For a Veeam Agent backup job that includes Windows-based computers, you can enable the following guest OS processing settings:

- Application-aware processing
- Transaction log handling for Microsoft SQL Server
- Archived log handling for Oracle databases
- SharePoint account settings
- Use of pre-freeze and post-thaw scripts
- File indexing

Application-Aware Processing

If your computer runs VSS-aware applications, you can enable application-aware processing to create a transactionally consistent backup. The transactionally consistent backup guarantees proper recovery of applications without data loss.

To enable application-aware processing:

At the Guest Processing step of the wizard, make sure that the Enable application-aware processing check box is selected.

Click Applications.

In the displayed list, select a protection group or individual computer and click Edit.

To define custom settings for a computer added as a part of a protection group, you must include the computer to the list as a standalone object. To do this, click Add and choose the computer whose settings you want to customize. Then select the computer in the list and define the necessary settings.

On the General tab, in the Applications section, make sure that the Enable application-aware processing check box is selected.

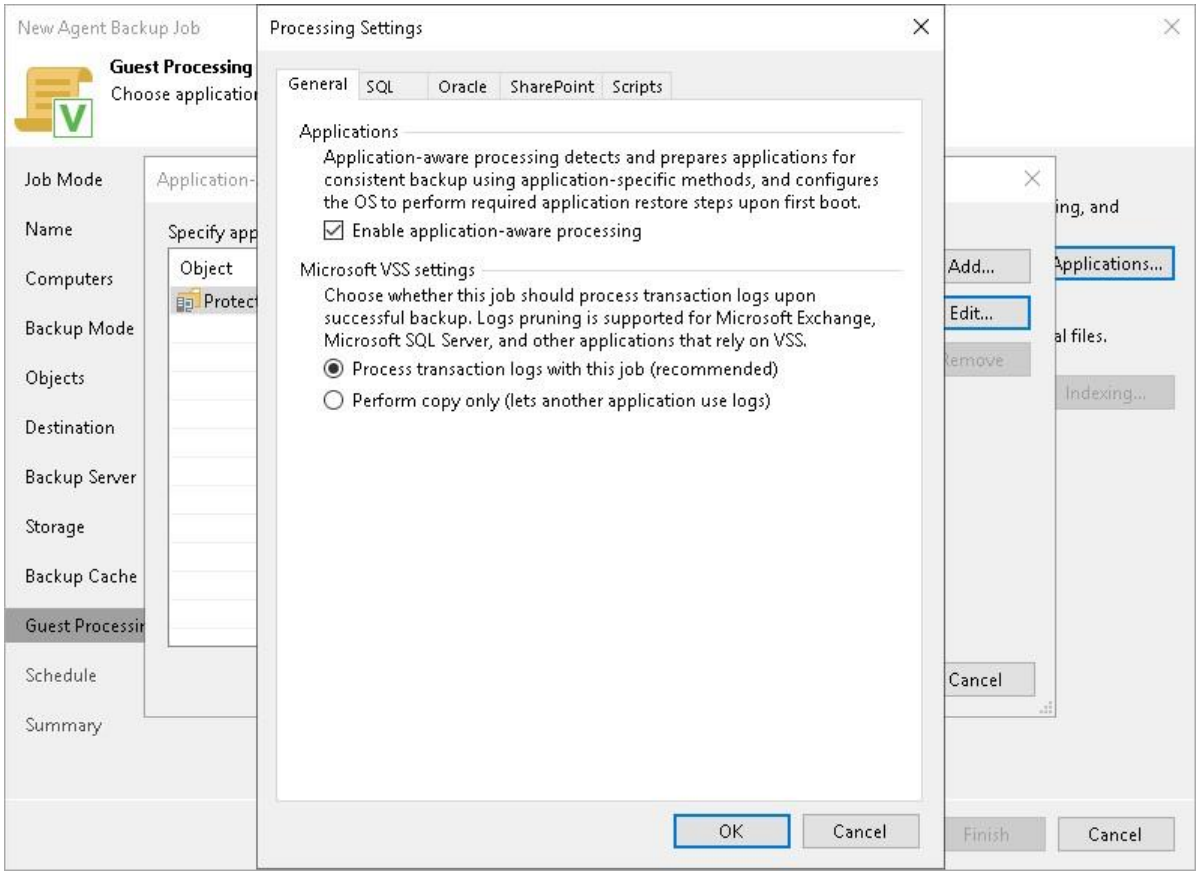
You can clear this check box, for example, if you want to disable application-aware processing for a specific computer added to the backup job as a part of a protection group.

[For Microsoft SQL Server] If you disable application-aware processing, Veeam Agent will not include information about databases in the backup. However, you can use Veeam Explorer for Microsoft SQL to locate a database file in the backup and restore the database.

[For Microsoft Exchange, Microsoft SQL Server and other applications that rely on VSS] In the Microsoft VSS settings section, specify if Veeam Agent for Microsoft Windows running on a protected computer must process transaction logs or copy-only backups must be created.

Select Process transaction logs with this job if you want Veeam Agent for Microsoft Windows to process transaction logs.

[For Microsoft Exchange] With this option selected, Veeam Agent for Microsoft Windows will wait for backup to complete successfully, and then trigger truncation of transaction logs. If the backup job fails, the logs will remain untouched until the next backup job session.



[For Microsoft SQL Server and Oracle] You will have to specify settings for database log handling on the SQL and Oracle tabs of the Processing Settings window. For more information, see Microsoft SQL Server Transaction Log Settings and Oracle Archived Log Settings.

Select Perform copy only if you use another tool to maintain consistency of the database state. Veeam Agent for Microsoft Windows will create a copy-only backup. The copy-only backup preserves the chain of full/differential backup files and transaction logs. After a copy-only backup, Veeam Agent does not trigger truncation of transaction logs. For more information, see this Microsoft article.

IMPORTANT

Consider the following:

- [For Microsoft Exchange] Veeam Agent for Microsoft Windows performs truncation of Microsoft Exchange transaction logs only if all disks that contain the Microsoft Exchange database are included in a volume-level backup job.
- [For Microsoft SQL Server and Oracle] If both Microsoft SQL Server and Oracle Server are installed on one guest OS, and log backup is enabled for both applications, Veeam Agent for Microsoft Windows will back up only Oracle transaction logs. Microsoft SQL Server transaction logs will not be processed.

check

Microsoft SQL Server Transaction Log Settings

If you back up Microsoft SQL Server, you can specify how Veeam Agent for Microsoft Windows must process database transaction logs:

At the Guest Processing step of the wizard, make sure that the Enable application-aware processing box is selected.

Click Applications.

In the displayed list, select a protection group or individual computer and click Edit.

In the Microsoft VSS settings section, select Process transaction logs with this job.

In the Processing Settings window, click the SQL tab.

To specify a user account that Veeam Agent will use to connect to the Microsoft SQL Server, select from the Specify Windows account with sysadmin role on SQL Server list a user account that has access permissions on the database. This account must be a Microsoft Windows user account with roles and permissions as specified in the Performing Guest Processing section of the Veeam Backup & Replication User Guide. Keep in mind that you cannot use Microsoft SQL Server accounts (for example, the SA account) to connect to the database.

By default, the Use guest credentials option is selected in the list. With this option selected, Veeam Agent will connect to the Microsoft SQL Server under the account that you have specified for the protected computer in the protection group settings.

If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials.

Specify how transaction logs must be processed. You can select one of the following options:

Select Truncate logs to truncate transaction logs after successful backup. Veeam Agent will wait for the backup to complete successfully and then truncate transaction logs. If the backup job fails, the logs will remain untouched until the next backup job session.

Select Do not truncate logs to preserve transaction logs. When the backup job completes, Veeam Agent will not truncate transaction logs.

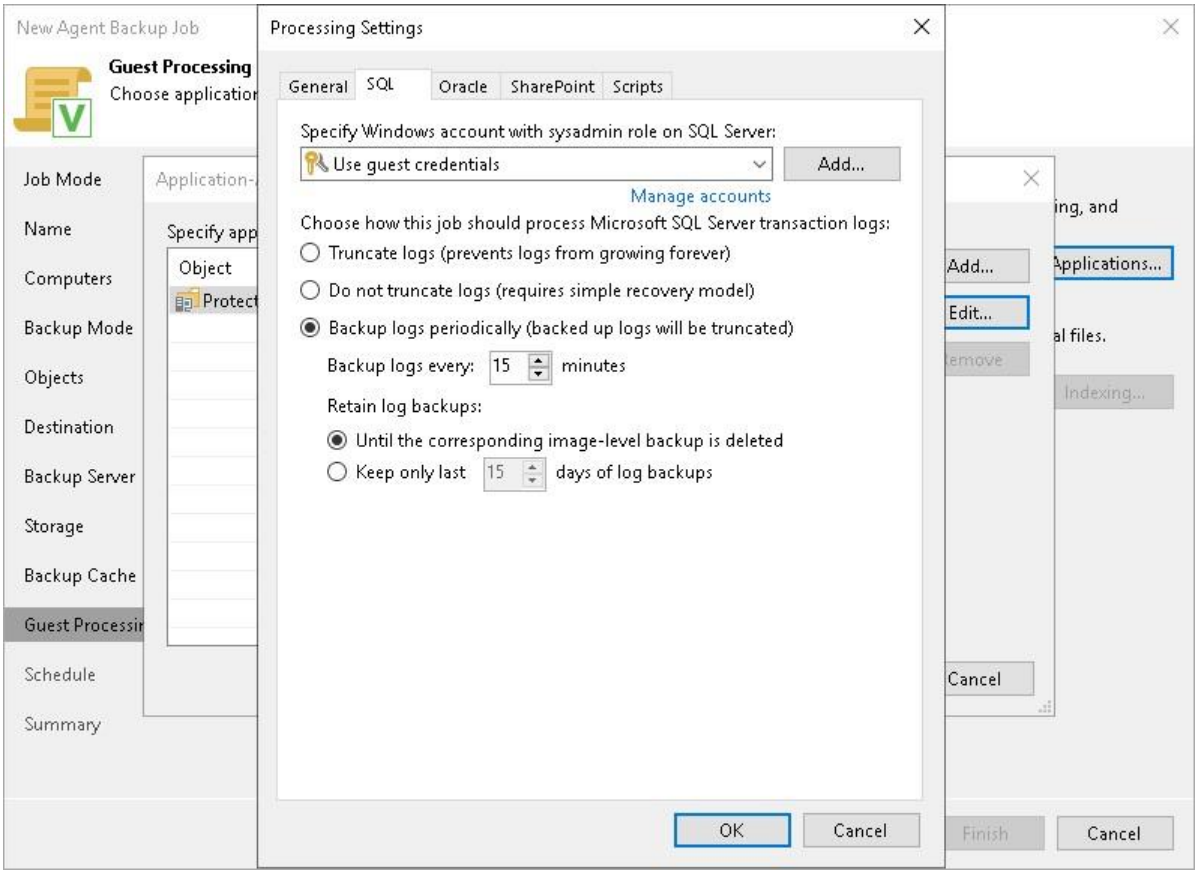
It is recommended that you enable this option for databases that use the Simple recovery model. If you enable this option for databases that use the Full or Bulk-logged recovery model, transaction logs may grow large and consume all disk space. In this case, the database administrator must take care of transaction logs him-/herself.

Select Backup logs periodically to back up transaction logs with Veeam Agent. Veeam Agent will periodically copy transaction logs to the backup location and store them together with the imagelevel backup. During the backup job session, transaction logs will be truncated.

For more information, see the Microsoft SQL Server and Oracle Logs Backup section in the Veeam Agent User Guide.

If you have selected to back up transaction logs with Veeam Agent for Microsoft Windows, you must specify settings for transaction logs backup:

In the Backup logs every <N> minutes field, specify the frequency for transaction logs backup. By default, transaction logs are backed up every 15 minutes. The maximum log backup interval is 480 minutes.



In the Retain log backups section, specify retention policy for transaction logs stored in the backup location.

check

Select Until the corresponding image-level backup is deleted to apply the same retention policy for image-level backups and transaction log backups.

Select Keep only last <N> days of log backups to keep transaction logs for a specific number of days. By default, transaction logs are kept for 15 days. If you select this option, you must make sure that retention for transaction logs is not greater than retention for the image-level backup. For more information, see the Retention for Database Log Backups section in the Veeam Agent for Microsoft Windows User Guide.

> IMPORTANT
>
> Veeam Agent for Microsoft Windows automatically excludes its configuration database from application-aware processing during backup. Transaction logs for the configuration database are not backed up.

Oracle Archived Log Settings

If you back up an Oracle database, you can specify how Veeam Agent for Microsoft Windows must process archived logs:

At the Guest Processing step of the wizard, make sure that the Enable application-aware processing box is selected.

Click Applications.

In the displayed list, select a protection group or individual computer and click Edit.

In the Microsoft VSS settings section, select Process transaction logs with this job.

check

In the Processing Settings window, click the Oracle tab.

To specify a user account that Veeam Agent for Microsoft Windows will use to connect to the Oracle database, select from theSpecify Oracle account with SYSDBA privileges list a user account that has SYSDBA rights on the database. If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials.

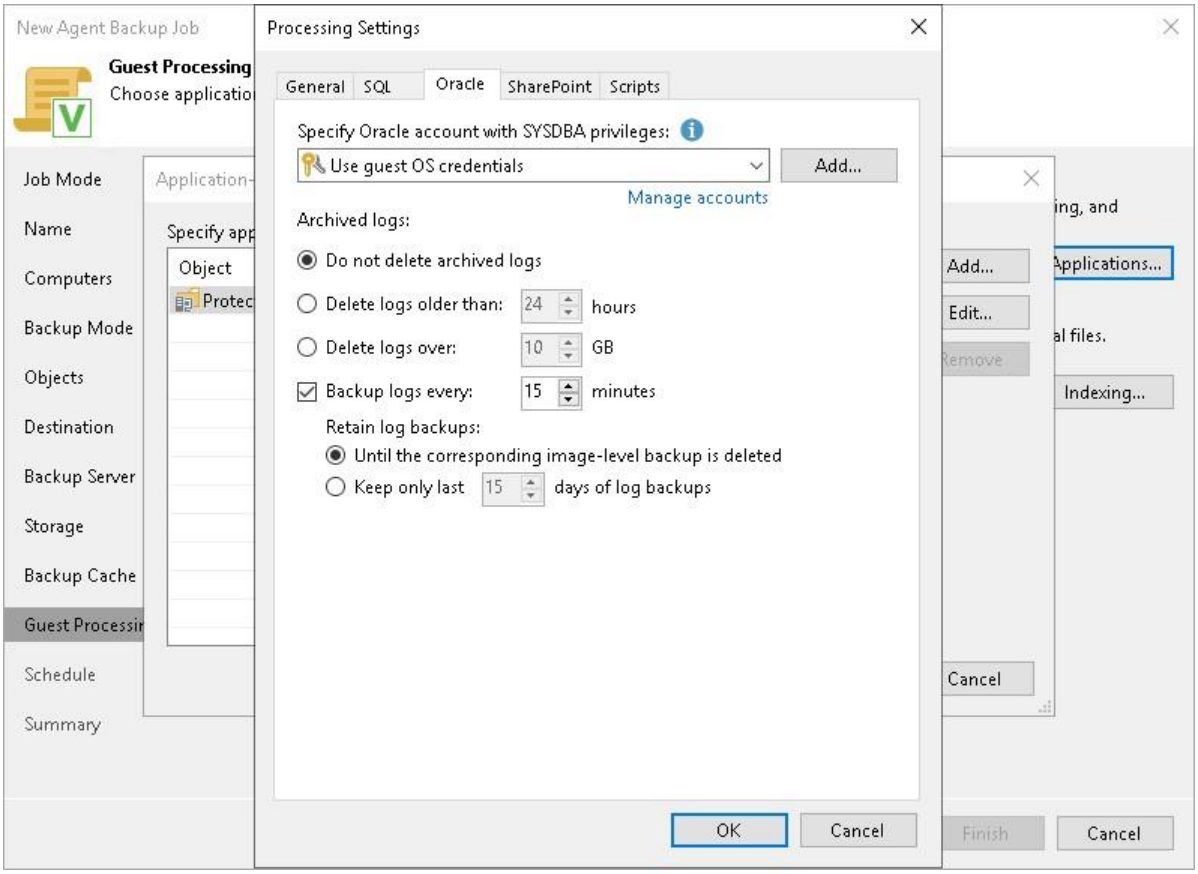
By default, the Use guest OS credentials option is selected in the list. With this option selected, Veeam Agent for Microsoft Windows will connect to the Oracle database under the account that you have specified for the protected computer in the protection group settings.

In the Archived logs section, specify if Veeam Agent for Microsoft Windows must delete archived logs on the Oracle database:

Select Do not delete archived logs if you want Veeam Agent for Microsoft Windows to preserve archived logs. When the backup job completes, Veeam Agent for Microsoft Windows will not delete archived logs.

It is recommended that you select this option for databases for which the ARCHIVELOG mode is turned off. If the ARCHIVELOG mode is turned on, archived logs may grow large and consume all disk space. In this case, the database administrator must take care of archived logs him-/herself.

Select Delete logs older than <N> hours or Delete logs over <N> GB if you want Veeam Agent for Microsoft Windows to delete archived logs that are older than <N> hours or larger than <N> GB. Veeam Agent for Microsoft Windows will wait for the backup to complete successfully and then trigger archived logs truncation via Oracle Call Interface (OCI). If the backup job fails, the logs will remain untouched until the next successful backup job session.



To back up Oracle archived logs with Veeam Agent for Microsoft Windows, select the Backup logs every <N> minutes check box and specify the frequency for archived logs backup. By default, archived logs are backed up every 15 minutes. The minimum log backup interval is 5 minutes. The maximum log backup interval is 480 minutes.

In the Retain log backups section, specify retention policy for archived logs stored in the backup location:

Select Until the corresponding image-level backup is deleted to apply the same retention policy for Veeam Agent backups and archived log backups.

Select Keep only last <n> days of log backups to keep archived logs for a specific number of days. By default, archived logs are kept for 15 days. If you select this option, you must make sure that retention for archived logs is not greater than retention for the Veeam Agent backups. For more information, see the Retention for Database Log Backups section in the Veeam Agent for Microsoft Windows User Guide.

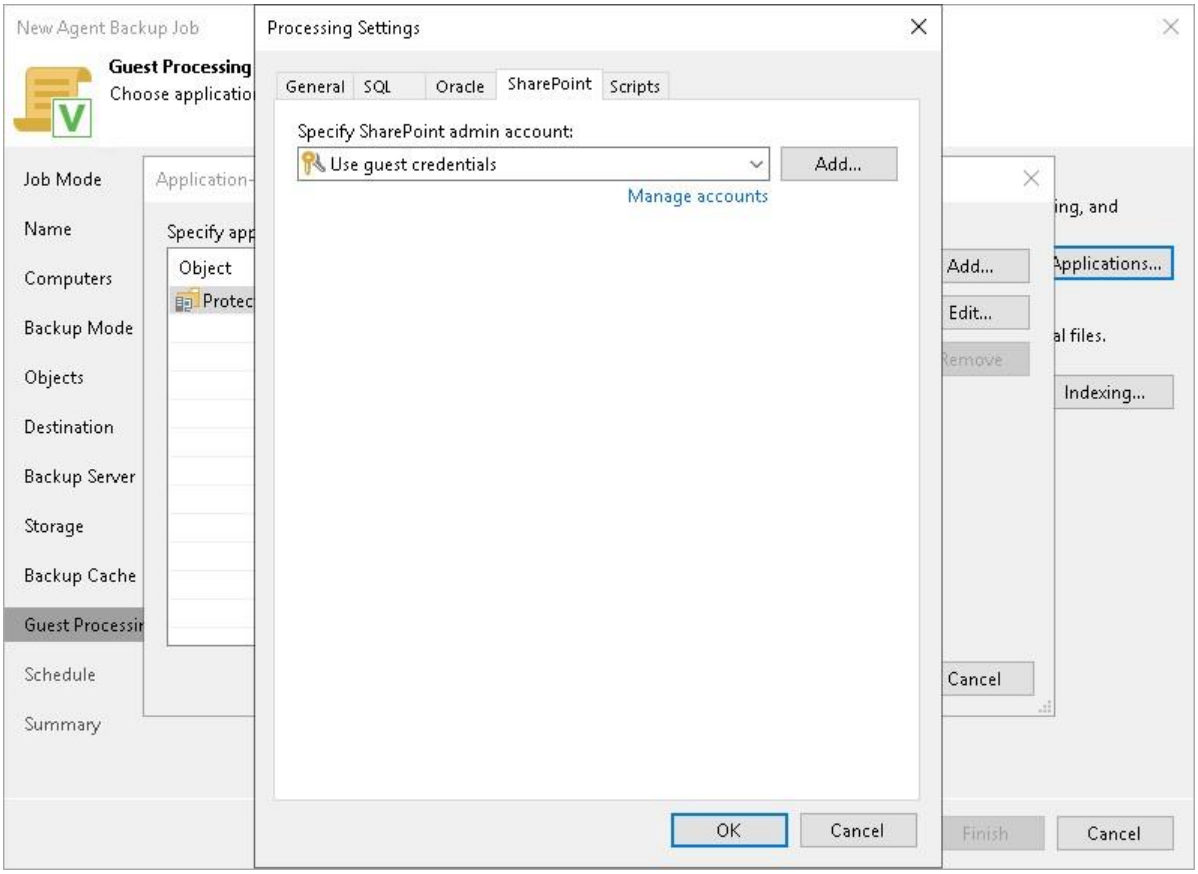
check

Microsoft SharePoint Account Settings

If you back up Microsoft SharePoint, you must specify a user account that has enough permissions on the application:

At the Guest Processing step of the wizard, make sure that the Enable application-aware processing box is selected.

Click Applications.



In the displayed list, select a protection group or individual computer and click Edit.

In the Processing Settings window, click the SharePoint tab.

From the Specify SharePoint admin account list, select a user account that Veeam Agent for Microsoft Windows will use to connect to the SharePoint application. If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials.

By default, the Use guest credentials option is selected in the list. With this option selected, Veeam Agent for Microsoft Windows will connect to the SharePoint application under the account that you have specified for the protected computer in the protection group settings.

check

Pre-Freeze and Post-Thaw Scripts

If you plan to back up data of applications that do not support VSS, you can specify what scripts Veeam Agent for Microsoft Windows must use to quiesce the OS on the protected computer. The pre-freeze script quiesces the file system and application data to bring the OS to a consistent state before Veeam Agent for Microsoft Windows creates a VSS snapshot. After the VSS snapshot is created, the post-thaw script brings the file system and applications to their initial state.

To specify pre-freeze and post-thaw scripts for the job:

At the Guest Processing step, make sure that the Enable application-aware processing check box is selected.

Click Applications.

In the displayed list, select a protection group or individual computer and click Edit.

In the Processing Settings window, click the Scripts tab.

From the Specify admin account for script execution list, select a user account that Veeam Agent for Microsoft Windows will use to run pre-freeze and post-thaw scripts. If you have not set up credentials beforehand, click the Manage accounts link or click Add on the right to add credentials.

By default, the Use guest credentials option is selected in the list. With this option selected, Veeam Agent for Microsoft Windows will run pre-freeze and post-thaw scripts under the account that you have specified for the protected computer in the protection group settings.

In the Script processing mode section, specify the scenario for scripts execution:

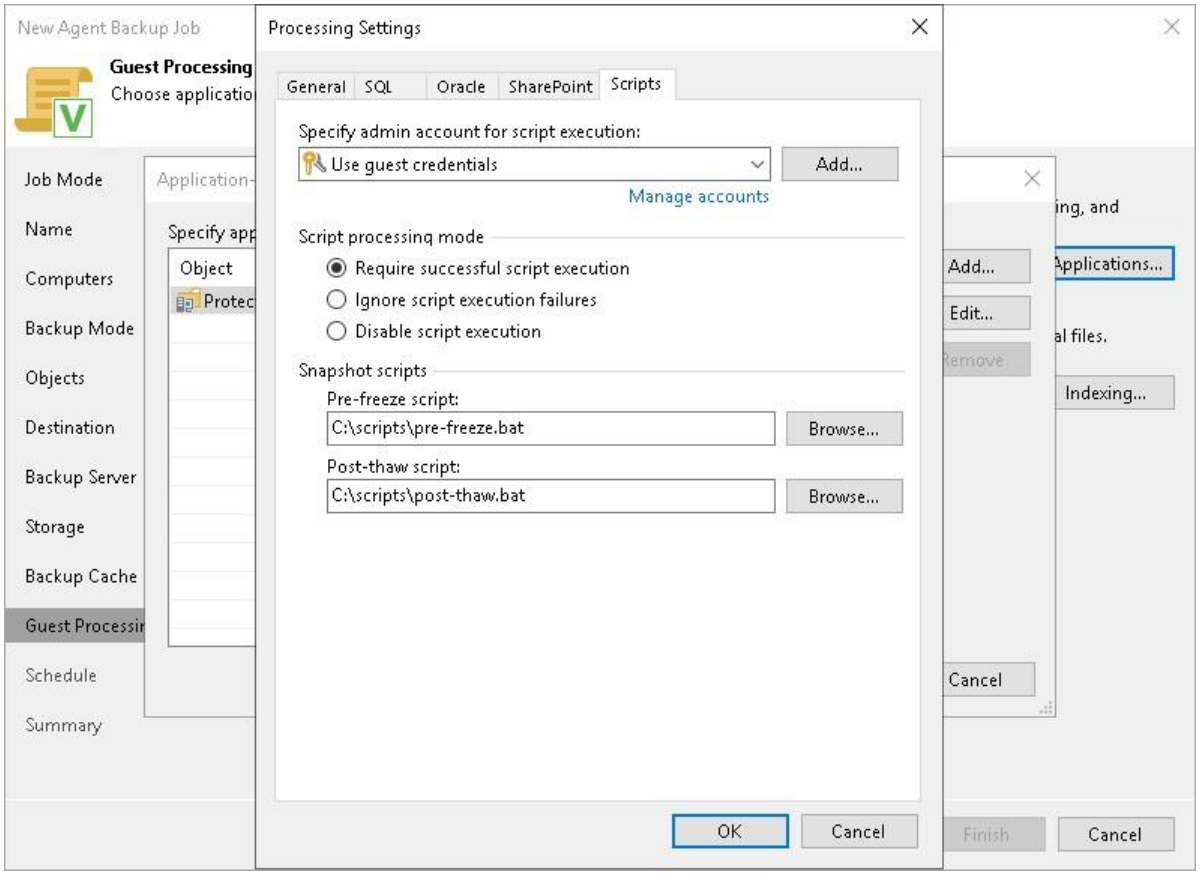
check

Select Require successful script execution if you want Veeam Agent for Microsoft Windows to stop the backup process if the script fails.

Select Ignore script execution failures if you want to continue the backup process even if script errors occur.

Select Disable script execution if you do not want to run scripts.

3. In the working area, right-click a VM and select



In the Snapshot scripts section, in the Pre-freeze script and Post-thaw script fields, click Browse to choose executable files from a local folder on the backup server. During the backup job session, Veeam Backup & Replication will upload the scripts to Veeam Agent computers added to the job and execute them on these computers.

Veeam Agent for Microsoft Windows supports the following types of scripts: ○

Program files in the EXE, BAT and CMD format ○ Windows script files in the JS, VBS

and WSF format ○ PowerShell script files in the PS1 format

You can use scripts of other formats as well, but we cannot guarantee correct processing of such scripts.

File Indexing

You can instruct the backup job to create an index of files and folders on the protected computer OS during backup. If you enable the file indexing option, you will be able to search for individual files inside Veeam Agent backups and perform 1-click restore in Veeam Backup Enterprise Manager.

> NOTE
>
> File system indexing is optional. If you do not enable this option in the backup job settings, you will still be able to perform 1-click restore from the backup created with such backup job. For more information, see the Preparing for File Browsing and Restore section in the Veeam Backup Enterprise Manager User Guide.

To specify file indexing options:

At the Guest Processing step of the wizard, select the Enable guest file system indexing check box.

Click Indexing.

In the displayed list, select a protection group or individual computer and click Edit.

In the Windows indexing settings window, specify the indexing scope:

- Select Index everything if you want to index all files within the backup scope that you have specified at the Backup mode step of the wizard. Veeam Agent for Microsoft Windows will index all files that reside:

  On the protected computer OS (for entire computer backup)

  On the volumes that you have specified for backup (for volume-level backup)

  In the folders that you have specified for backup (for file-level backup)

Select Index everything except if you want to index all files on the protected computer OS except those defined in the list. By default, system folders are excluded from indexing. You can add or delete folders using the Add and Remove buttons on the right. You can also use system environment variables to form the list, for example: %windir%, %Program Files% and %Temp%.

To reset the list of folders to its initial state, click Default.

Select Index only following folders to define folders that you want to index. You can add or delete folders to index using the Add and Remove buttons on the right. You can also use system environment variables to form the list, for example: %windir%, %Program Files% and %Temp%.

Step 13. Specify Backup Schedule

At the Schedule step of the wizard, specify the schedule according to which you want to perform backup. Backup job scheduling options differ depending on the platform and job mode that you have selected at the Job Mode step of the wizard:

- Scheduling Settings for Workstations
- Scheduling Settings for Servers and Failover Clusters

> NOTE
>
> If you configure a backup policy, after you click Apply at the Schedule step of the wizard, Veeam Backup & Replication will immediately apply the backup policy to protected computers.

Scheduling Settings for Workstations

At the Schedule step of the wizard, specify the schedule according to which you want to perform backup.

To specify the job schedule:

Select the Daily at check box and use the fields on the right to specify time and days when the backup job must start: ○

Everyday — select this option to start the job at specific time daily. ○ On week-days — select this option to start the job at specific time on week-days.

○ On these days — select this option to start the job at specific time on selected days.

You can leave the Daily at check box unchecked to configure the backup job without daily schedule. In this case, you will be able to use the backup job to perform backup automatically at specific events.

If you have selected the On these days option, click the Days button and clear check boxes for the days when the job must not start.

Select the action that Veeam Agent for Microsoft Windows must perform in case the protected computer is powered off at the time when the scheduled backup job must start.

Backup once powered on — select this option if you want Veeam Agent for Microsoft Windows to start the scheduled backup job when the protected computer is powered on.

Skip backup — select this option if you want Veeam Agent for Microsoft Windows not to start the scheduled backup job when the computer is powered on. Veeam Agent for Microsoft Windows will perform backup at the next scheduled time.

If you want Veeam Agent for Microsoft Windows to perform a finalizing action after the backup job completes successfully, select the necessary action: ○ Keep running — select this option if the computer must keep on working.

Sleep — select this option if you want Veeam Agent for Microsoft Windows to bring the computer to the standby mode.

Shutdown — select this option if you want Veeam Agent for Microsoft Windows to shut down the computer.

Hibernate — select this option if you want Veeam Agent for Microsoft Windows to bring the computer to the hibernate mode. This option is available if the hibernate mode is enabled on the protected computer. To learn more, see this Microsoft KB article.

When the backup job completes, Veeam Agent for Microsoft Windows will prompt a dialog with a countdown to the selected post-job action. You can select to proceed to the action immediately or to cancel the action. To learn more, see the Controlling Backup Post-Job Action section in the Veeam Agent for Microsoft Windows User Guide.

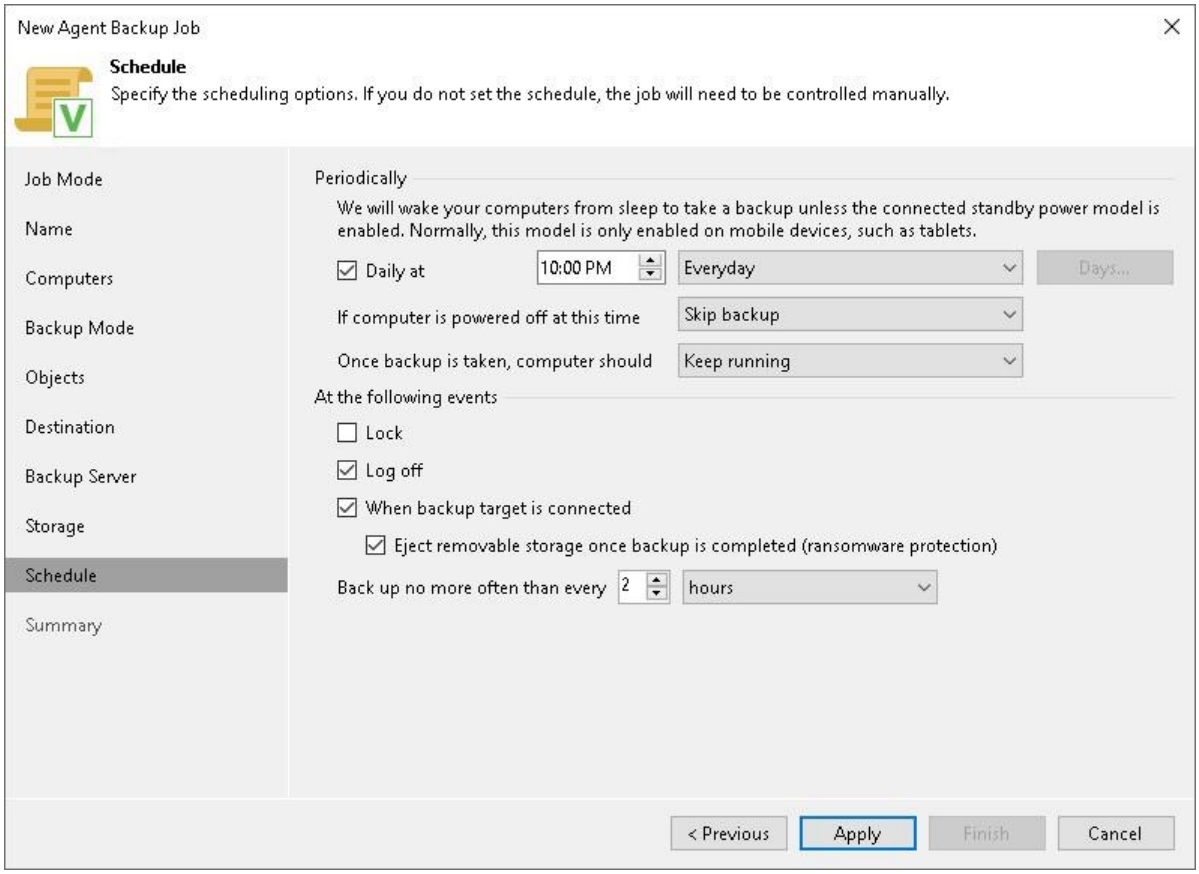
In the At the following events section, specify settings for events that trigger the backup job launch:

Select the Lock check box if you want to start the backup job when the user locks the Veeam Agent computer.

Select the Log off check box if you want to start the backup job when the user working with the computer performs a logout operation.

Select the When backup target is connected check box if you want to start the backup job when the backup storage becomes available (for example, when the computer connects to a local network and the target shared folder is accessible).

Select the Eject removable storage once backup is completed check box if you want Veeam Agent for Microsoft Windows to unmount the storage device after the backup job completes successfully. With this option selected, backup files on the removable storage will be protected from encrypting ransomware, such as CryptoLocker.



Veeam Agent applies this setting only to backup jobs triggered by the When backup target is connected event. In case of backup jobs triggered by other computer events or started periodically at specific time, Veeam Agent will ignore this setting, and the storage device will not be unmounted after the backup job completes successfully.

> IMPORTANT
>
> The Eject removable storage once backup is completed option does not guarantee a bulletproof protection against ransomware. To ensure your backups are safe, keep the OS up to date and regularly scan your backup repository for virus threats using modern antivirus software.

Use the Back up no more often than every <N> <time units> field to restrict the frequency of backup job sessions. Specify a minutely, hourly or daily interval between the backup job sessions.

The Back up no more often than every <N> <time units> option is applied only to job sessions started at specific events. Daily backups are performed according to defined schedule regardless of the time interval specified for this setting.

> IMPORTANT
>
> If the power scheme on the Veeam Agent computer does not allow using wake up timers, Veeam Agent for Microsoft Windows will not be able to wake your computer from sleep for backup. You can manually change the power scheme settings on the Veeam Agent computer. To do this, navigate to Control Panel > All Control Panel Items > Power Options > Edit Plan Settings.

Scheduling Settings for Servers and Failover Clusters

At the Schedule step of the wizard, specify the schedule according to which you want to perform backup.

To specify the job schedule:

Select the Run the job automatically check box. If this check box is not selected, you will have to start the backup job manually to create backup.

Define scheduling settings for the job:

To run the job at specific time daily, on defined week days or with specific periodicity, select Daily at this time. Use the fields on the right to configure the necessary schedule.

To run the job once a month on specific days, select Monthly at this time. Use the fields on the right to configure the necessary schedule.

To run the job repeatedly throughout a day with a specific time interval, select Periodically every. In the field on the right, select the necessary time unit: Hours or Minutes. Click Schedule and use the time table to define the permitted time window for the job. In the Start time within an hour field, specify the exact time when the job must start.

A repeatedly run job is started by the following rules:

The defined interval always starts at 12:00 AM. For example, if you configure to run a job with a 4-hour interval, the job will start at 12:00 AM, 4:00 AM, 8:00 AM, 12:00 PM, 4:00 PM and so on.

If you define permitted hours for the job, after the denied interval is over, the job will start immediately and then run by the defined schedule.

For example, you have configured a job to run with a 2-hour interval and defined permitted hours from 9:00 AM to 5:00 PM. According to the rules above, the job will first run at 9:00 AM, when the denied period is over. After that, the job will run at 10:00 AM, 12:00 PM, 2:00 PM and 4:00 PM.

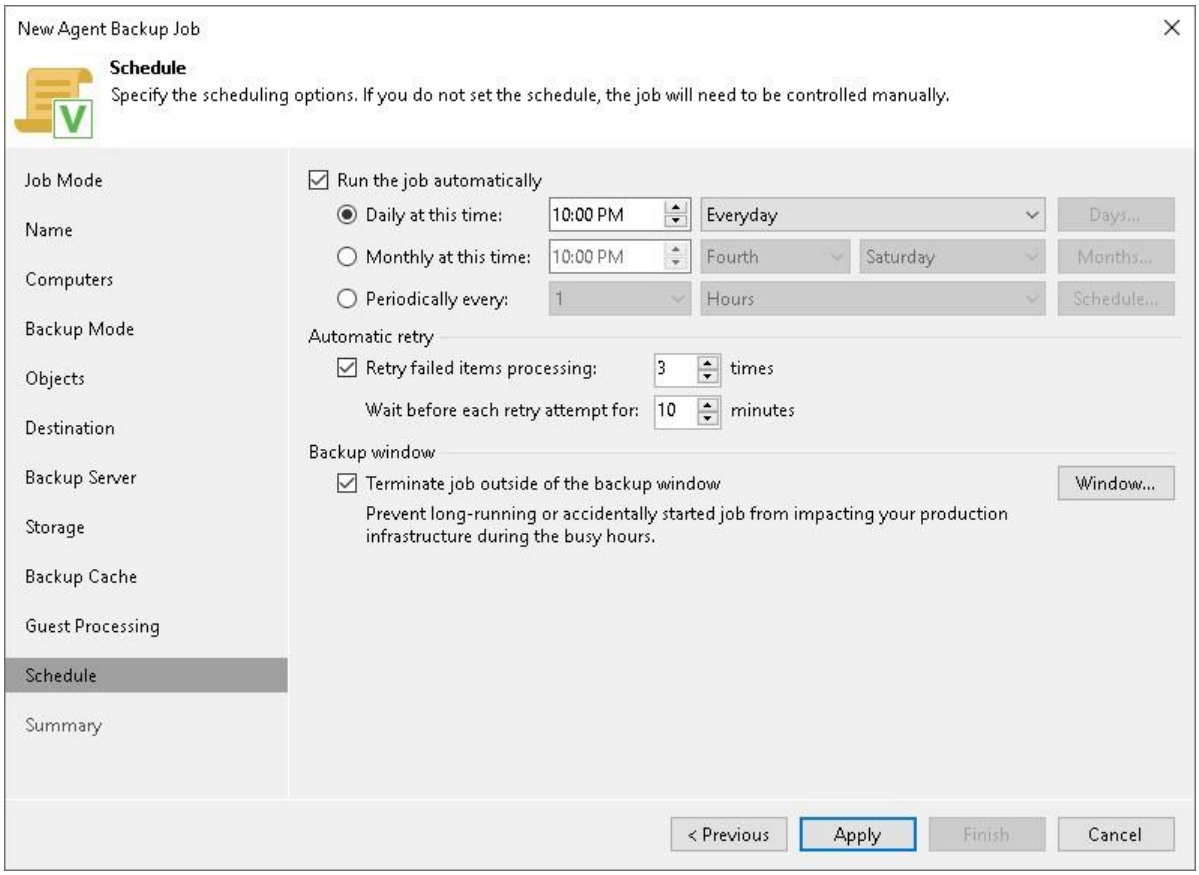
To run the job continuously, select the Periodically every option and choose Continuously from the list on the right. A new backup job session will start as soon as the previous backup job session finishes.

[For Managed by backup server mode only] To chain jobs, use the After this job field. In the common practice, jobs start one after another: when job A finishes, job B starts and so on. If you want to create a chain of jobs, you must define the time schedule for the first job in the chain. For the rest of the jobs in the chain, select the After this job option and choose the preceding job from the list.

> NOTE
>
> Mind the following:
>
> The After this job option is not available if you have selected the Managed by agent option at the Job Mode step of the wizard.
> The After this job function will automatically start a job if the first job in the chain is started automatically by schedule. If you start the first job manually, Veeam Backup & Replication will display a notification. You will be able to choose whether Veeam Backup & Replication must start the chained job as well.

In the Automatic retry section, define whether Veeam Backup & Replication or Veeam Agent for Microsoft Windows (depending on the selected job mode) must attempt to run the backup job again if the job fails for some reason. Enter the number of attempts to run the job and define time intervals between them. If you select continuous backup, Veeam Backup & Replication or Veeam Agent for Microsoft Windows retries the job for the defined number of times without any time intervals between the job runs.

[For Managed by agent mode only] If a backup policy fails and Veeam Agent retries the session, Veeam Agent does not transfer all the data again. Instead, Veeam Agent continues data transfer that was started before the backup policy fail. To do so, Veeam Agent compares hash values for data blocks on source and target. After the hash comparison, Veeam Agent also transfers only those data blocks that were not transferred before the policy fail. If data blocks on source were changed before the retry, Veeam Agent transfers these data blocks as well.



In the Backup window section, define the time interval within which the backup job must complete. The backup window prevents the job from overlapping with production hours and ensures that the job does not impact performance of your server. To set up a backup window for the job:

Select the Terminate job if it exceeds allowed backup window check box and click Window.

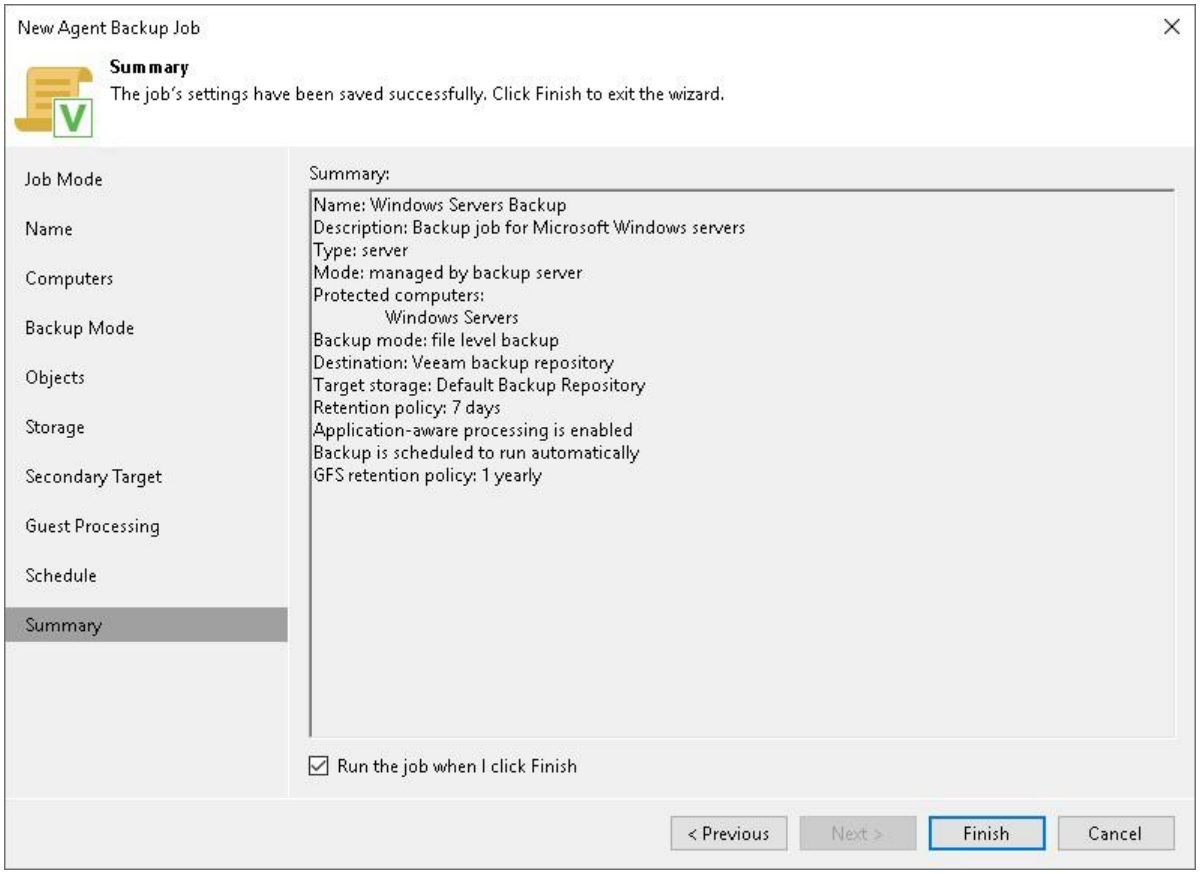
In the Time Periods window, define the allowed hours and prohibited hours for backup.

If the job exceeds the allowed window, it will be automatically terminated. In this case, data transport and backup chain transformation processes are stopped. Keep in mind that this behavior differs from a VM backup job where backup window affects data transport process and health check operations only.

> IMPORTANT
>
> [For backup policy] The backup window does not affect the process of uploading backup files from the backup cache to the target storage. If Veeam Agent creates one or more backup files in the backup cache, and then the backup target becomes available, Veeam Agent uploads backup files to the target location immediately, regardless of the specified backup window.

Step 14. Review Backup Job Settings

At the Summary step of the wizard, complete the backup job configuration process.



Review settings of the configured Veeam Agent backup job.

[For backup job managed by backup server] Select the Run the job when I click Finish check box if you want to start the job right after you finish working with the wizard.

Click Finish to close the wizard.

[For backup job managed by Veeam Agent] Keep in mind that Veeam Backup & Replication does not immediately apply backup policy to computers included in protection groups for pre-installed Veeam Agents. Veeam Agents installed on computers that are included in these groups connect to Veeam Backup & Replication every 6 hours and get updated backup policy settings. If you targeted a backup policy at the Veeam backup server and scheduled earlier than the next connection to Veeam Backup & Replication, this backup policy will get updated backup policy settings at the next backup policy session start. To learn more about protection groups for pre-installed Veeam Agents, see Protection Group Types.

If you want to apply backup policy immediately, you must synchronize Veeam Agent with Veeam Backup & Replication from the Veeam Agent computer side manually. To learn more, see Veeam Agent for Microsoft Windows Configuration.

Recovery Jobs

Windows Server Restoration

You can use Veeam Backup & Replication to restore a specific computer volume or all volumes from a volume level backup created with Veeam Agent for Microsoft Windows.

If data on a computer volume gets corrupted, you can restore this volume from the backup. For volume-level restore, you can use backups that were created at the volume level. File-level backups cannot be used for volume restore.

When you perform volume-level restore, Veeam Backup & Replication restores the entire content of the volume. It retrieves from the backup data blocks pertaining to a specific volume and copies them to the necessary location. Keep in mind that you cannot browse the volume in the backup and select individual application items, files and folders for restore. For granular file-level restore, you can use the Restore guest files option.

A volume can be restored to its original location or a new location. If you restore the volume to its original location, Veeam Backup & Replication overwrites data on the original volume. If you restore the volume to a new location, and the target disk contains any data, Veeam Backup & Replication overwrites data in the target location with data retrieved from the backup.

A volume can be restored to a new location that has greater or less space than the size of the volume in the backup. Depending on the amount of free disk space on target location, you can select either to shrink or to extend the volume during restore. To learn more, see the Volume Resize section in the Veeam Agent for Microsoft Windows User Guide.

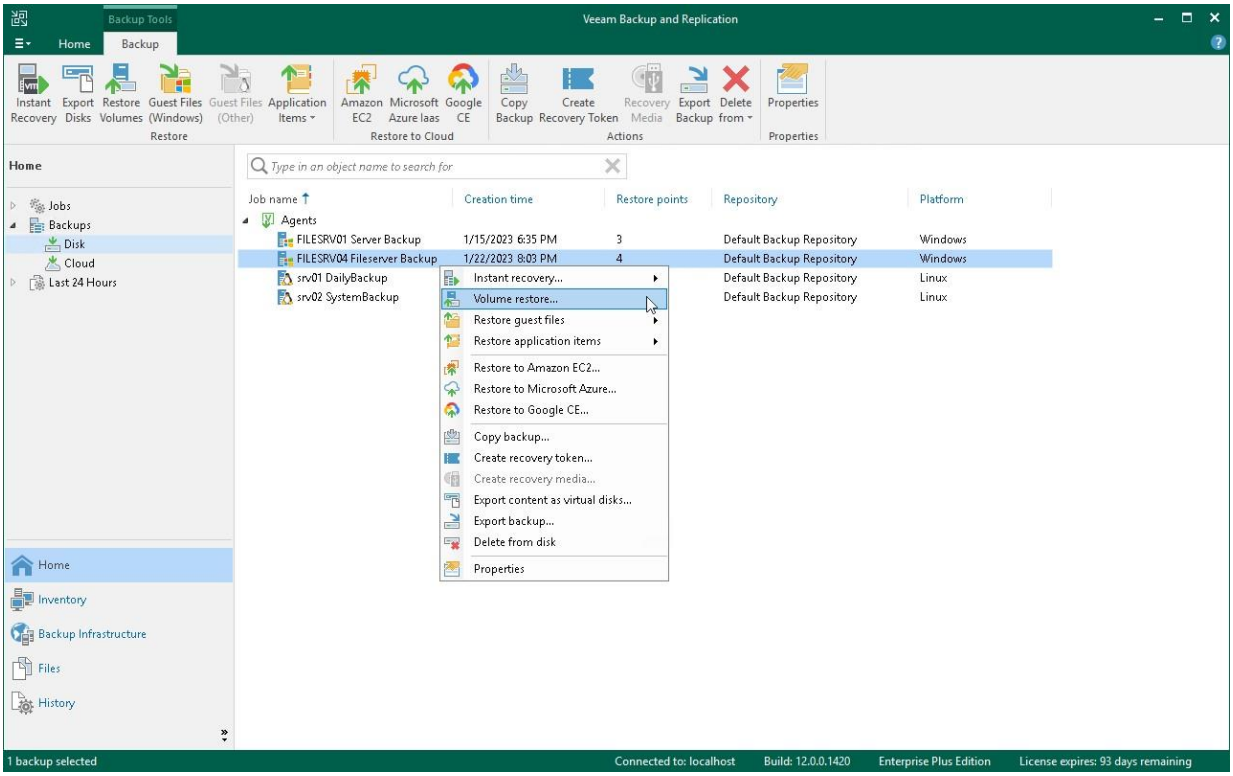
Before You Begin

Before you begin the volume-level restore process, check the following prerequisites:

- The volume-level backup from which you plan to restore data must be successfully created at least once.
- A computer on which you want to restore a volume must be added to the Veeam Backup & Replication inventory and run Veeam Agent for Microsoft Windows operating in the managed mode.

Volume-level restore has the following limitations:

- You can restore volumes only from backups created with Veeam Agent for Microsoft Windows.
- You cannot restore a system volume to a system volume of the original Veeam Agent computer or another computer with the running OS. To perform such restore, you need to boot the OS from the recovery image. For details, see Restoring Data with Veeam Recovery Media. You can also restore a system volume to a non-system volume that has enough free space.
- You cannot restore a volume to a volume on which the Microsoft Windows swap file is hosted.



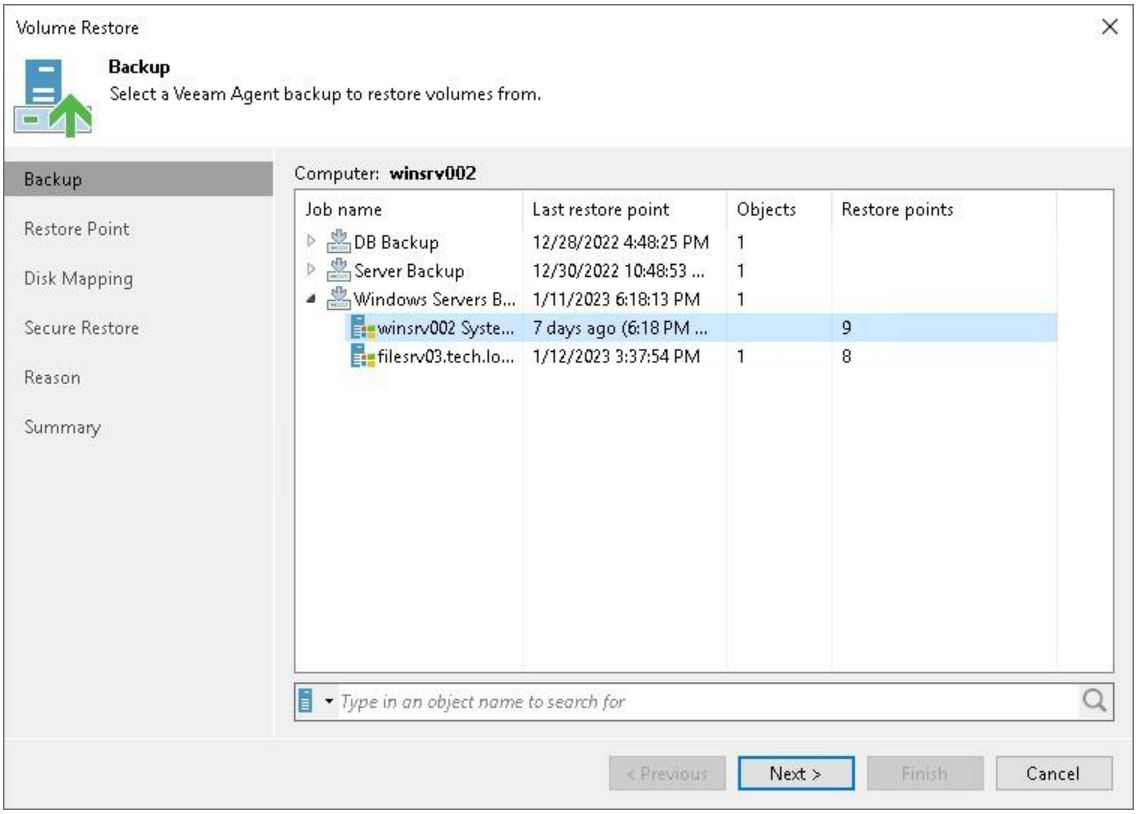
Step 1. Launch Volume Level Restore Wizard

To launch the Volume Level Restore wizard, do either of the following:

Open the Home tab and click Restore > Agent > Disk restore > Volume restore. In this case, you will be able to select a backup of the necessary Veeam Agent computer at the Backup step of the wizard.

Open the Home view. In the inventory pane, click the Backups node. In the working area, expand the necessary Veeam Agent backup, select the necessary computer in the backup and click Restore Volumes on the ribbon or right-click the computer and select Volume restore.

In this case, you will proceed immediately to the Restore Point step of the wizard.

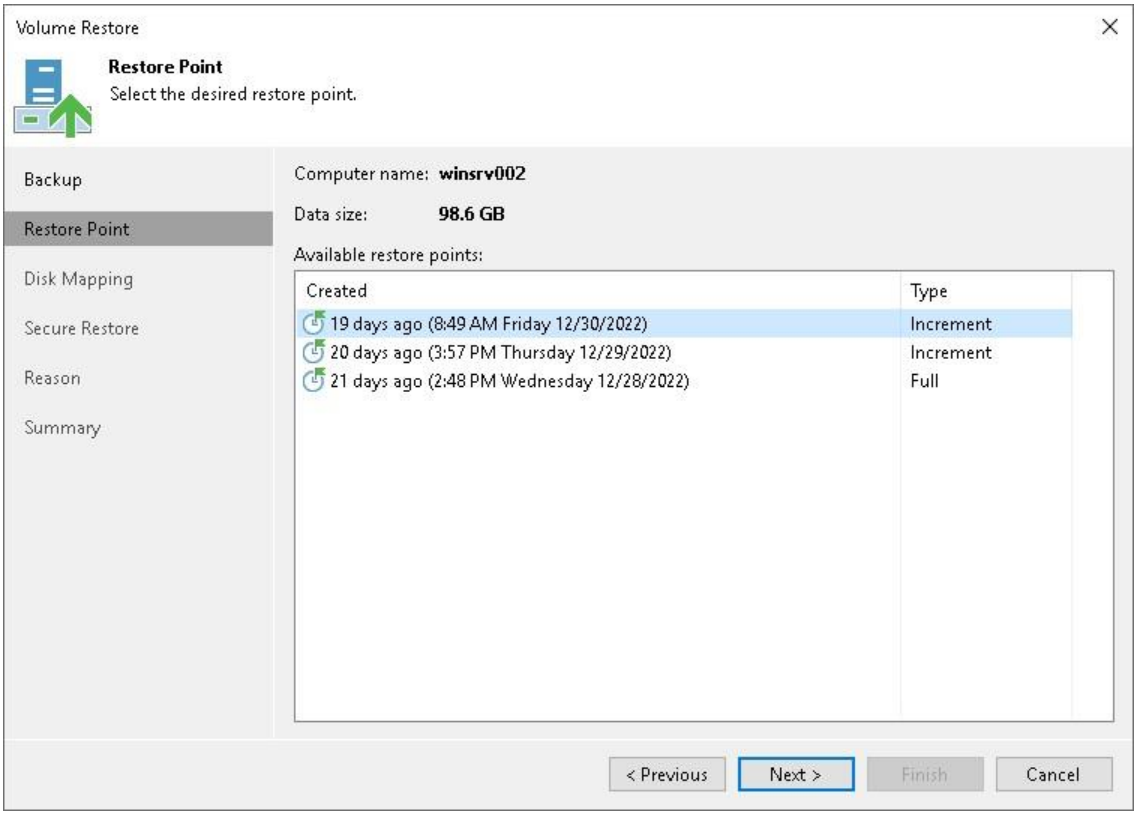


Step 2. Select Backup

At the Backup step of the wizard, select a backup from which you want to recover data.

To quickly find the necessary backup, use the search field at the bottom of the window: enter a backup name or a part of it in the search field and click the Start search button on the right or press [ENTER].

In the list of backups, Veeam Backup & Replication displays only volume-level backups created with Veeam Agent for Microsoft Windows. File-level backups and backups created with Veeam Agent for Linux are not displayed.



Step 3. Select Restore Point

At the Restore Point step of the wizard, select a restore point from which you want to recover data.

By default, Veeam Backup & Replication uses the latest restore point. However, you can select any valid restore point to recover volumes to a specific point in time.

Veeam Backup & Replication displays restore points for volume-level backups only. For example, if you have run 3 job sessions to create a backup of all computer volumes and then changed the backup scope to file-level backup, Veeam Backup & Replication will display only 3 restore points in the list.

Step 4. Map Restored Disks

At the Disk Mapping step of the wizard, select what volumes you want to restore and map volumes from the backup to volumes on the target computer.

> IMPORTANT
>
> It is strongly recommended that you change disk mapping settings only if you have experience in working with Microsoft Windows disks and partitions. If you make a mistake, your computer data may get corrupted.

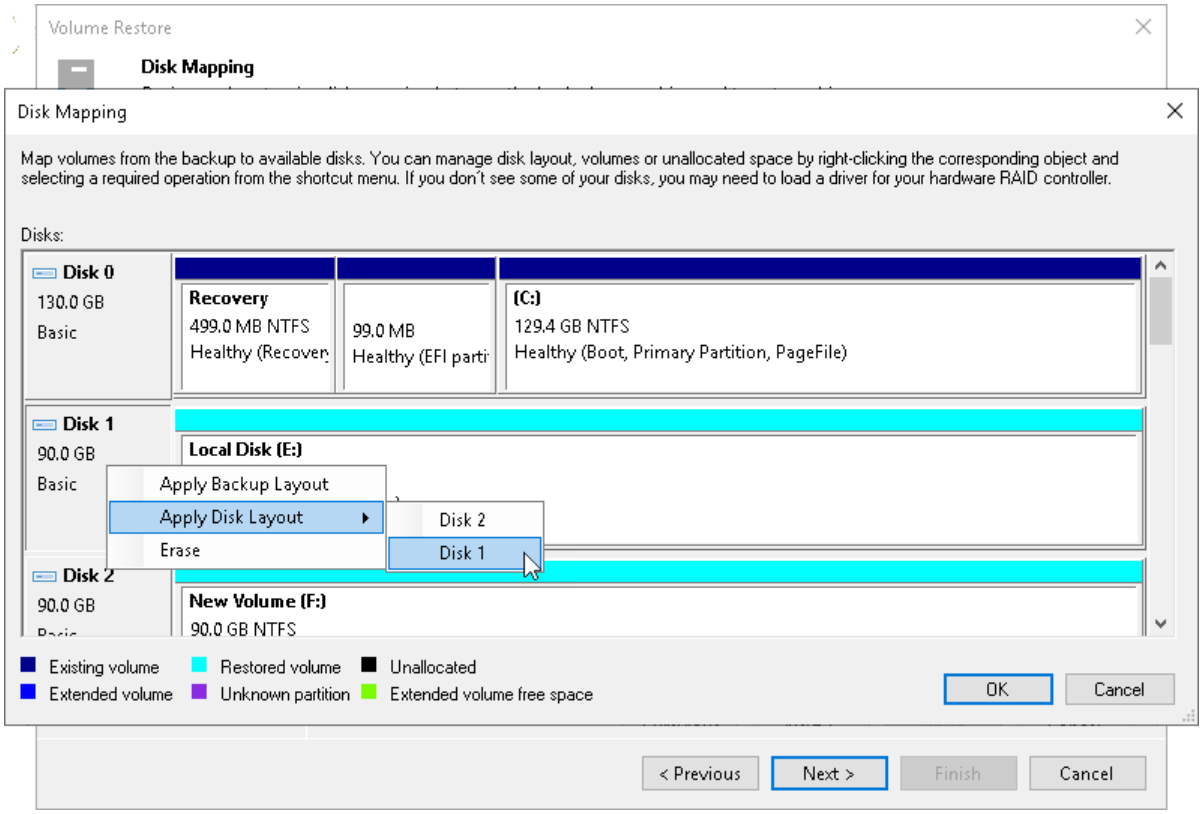
To select volumes for restore:

In the Destination host field, specify the target computer where you want to restore volumes. By default, Veeam Backup & Replication restores volumes to their original location. If you want to restore volumes from the backup to another computer, click Choose and select the necessary computer. You can restore volumes only to computers that are added to the Veeam Backup & Replication inventory and run Veeam Agent for Microsoft Windows.

If you select a computer included in a protection group for pre-installed Veeam Agents, you must provide credentials of the account that has administrator permissions on the target computer. Keep in mind that Veeam Backup & Replication will keep these credentials only during the restore process and delete them after the restore process completion. To learn more about protection groups for pre-installed Veeam Agents, see Protection Group Types.

In the Disk mapping section, select check boxes next to volumes that you want to restore from the backup. By default, Veeam Backup & Replication restores volumes to their initial location and maps the restored volumes automatically. If the initial location is unavailable, a volume is restored to a disk of the same or larger size. If you want to map the restored volume to another computer disk, at the bottom of the wizard click Customize disk mapping.

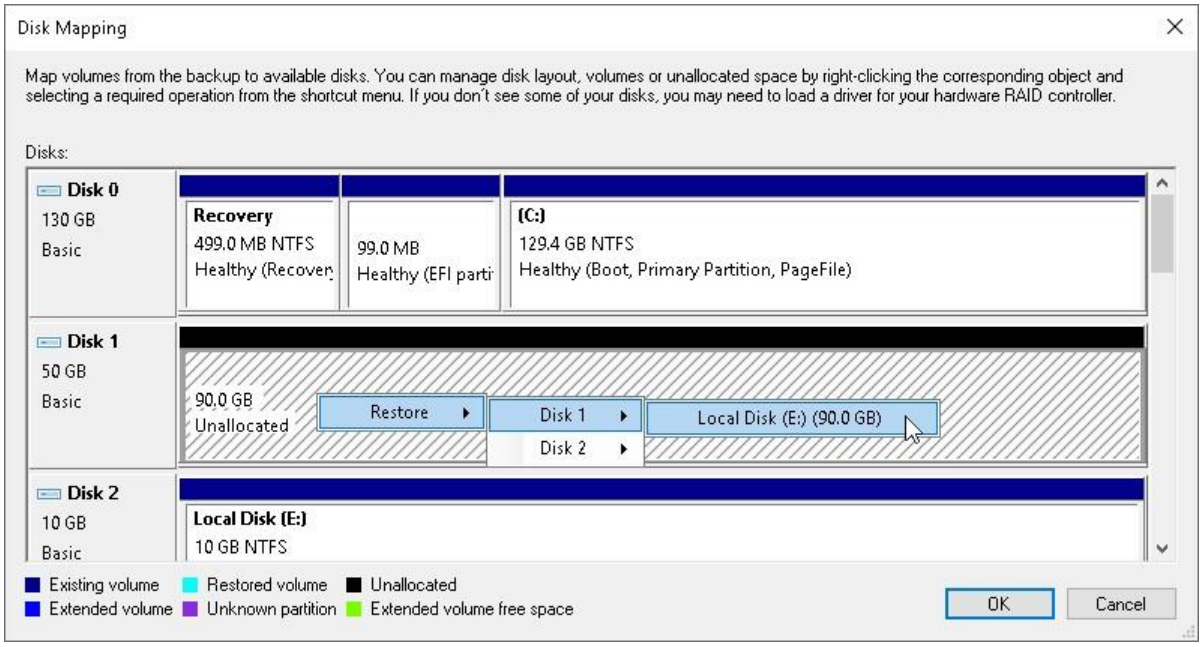
> NOTE
>
> If Veeam Backup & Replication cannot map a volume automatically, Veeam Backup & Replication will prompt you to perform disk mapping manually. To proceed to the Disk Mapping window, click Yes.



In the Disk Mapping window, specify how volumes must be restored:

Right-click the target disk on the left and select the necessary disk layout:

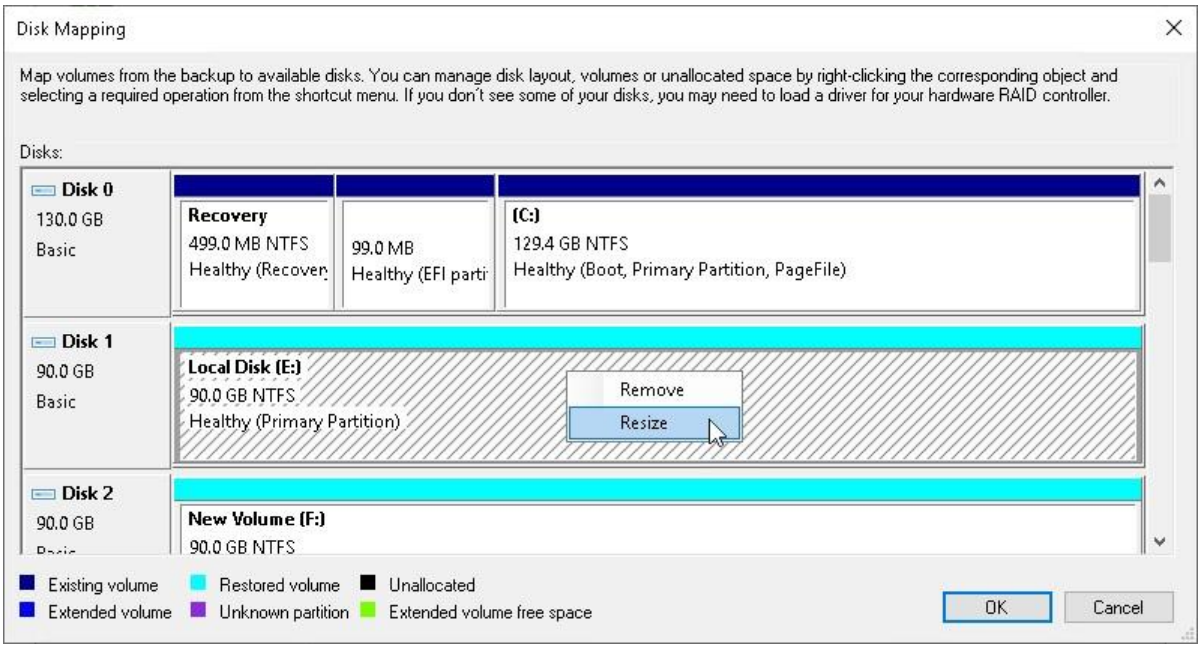
Apply Backup Layout — select this option if you want to apply to disk the settings that were used on your computer at the moment when you performed backup.



Apply Disk Layout — select this option if you want to apply to the current disk settings of another disk.

Erase — select this option if you want to discard the current disk settings.

Right-click unallocated disk space in the disk area on the right and select what volume from the backup you want to place on this computer disk.



If you want to change disk layout configured by Veeam Backup & Replication, right-click an automatically mapped volume and select Remove. You will be able to use the released space for mapping volumes in your own order.

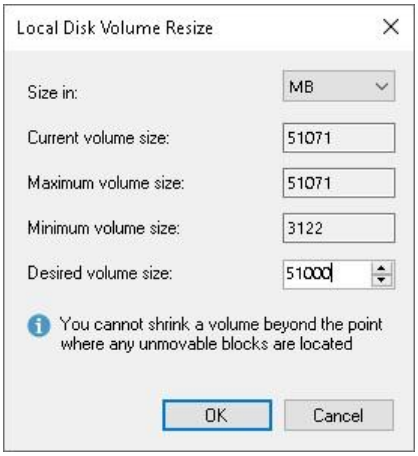
[For restore with volume resize] You can resize a volume mapped by Veeam Backup & Replication to a target computer disk. To resize a volume, right-click it in the Disk Mapping window and select Resize. With this option selected, you will pass to the Volume Resize window.

NOTE

If you map a backup volume that is larger than the amount of available space on the target disk, Veeam Backup & Replication will prompt you to shrink the restored volume. After you agree and click OK, Veeam Backup & Replication will prepare to shrink the volume to the size of available disk space.

Step 5. Resize Restored Volumes

At the Disk Mapping step of the wizard you can set the necessary size for the restored volumes. A volume will be shrunk or extended to the specified size during the process of data restore.



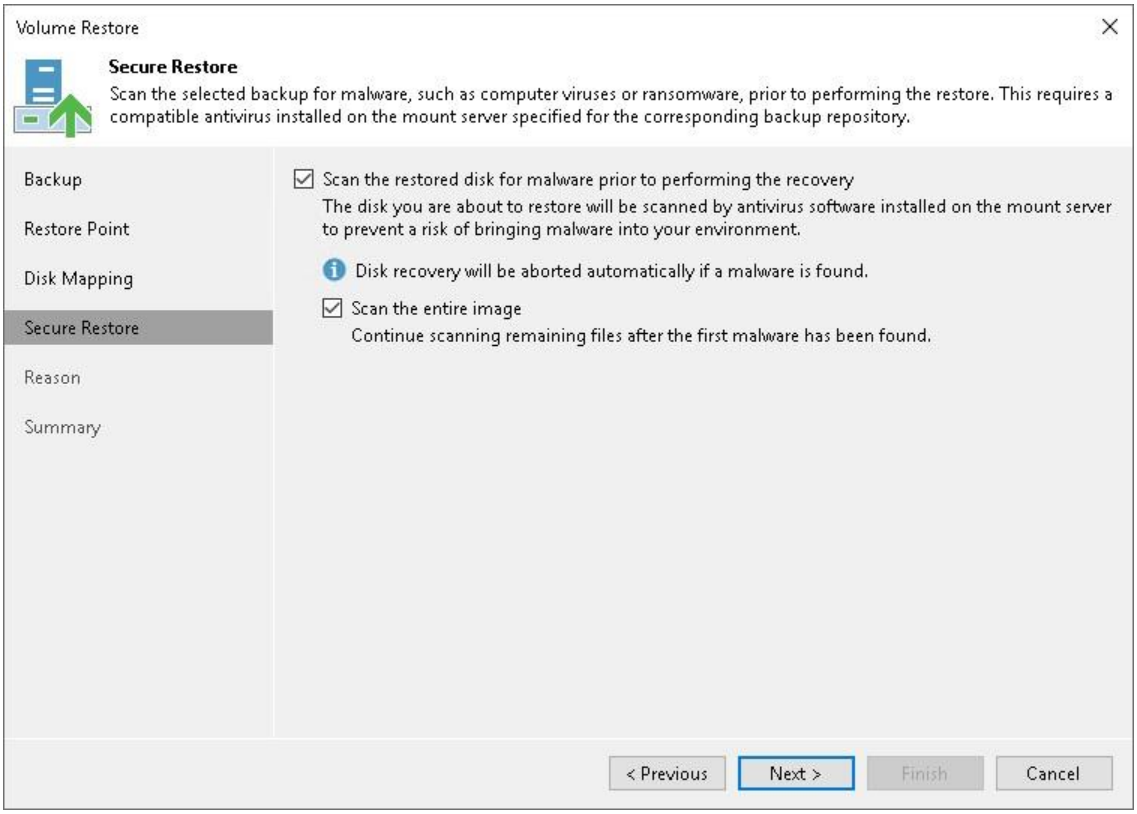
> NOTE
>
> By default, Veeam Agent for Microsoft Windows displays volume size in megabytes (MB). This allows you to specify the desired size for the volume precisely. You can also choose to display volume size in gigabytes (GB). This may be helpful when you need to resize volumes on larger computer disks and want to simplify disk size calculations.
>
> When you use GB as a volume size unit, you can specify volume size with integral numbers, for example, 1 GB, 60 GB or 200 GB, but not 0,8 GB, 60,5 GB or 200,7 GB. However, if the maximum volume size is in fact greater than the displayed value for less than 1 GB, Veeam Agent for Microsoft Windows will automatically add the exceeding amount of disk space to the extended volume. For example, if the maximum volume size is 60,2 GB, Veeam Agent for Microsoft Windows will display this size as 60 GB. When you specify 60 GB as a desired volume size, Veeam Agent for Microsoft Windows will extend the volume to 60,2 GB.

To resize a volume:

Specify a volume you want to resize:

- Right-click a restored volume mapped to a target disk and select Resize.
- [For volume shrink] Right-click unallocated disk space and select what volume from the backup you want to place on the computer disk. If the selected volume is larger than the amount of unallocated disk space, Veeam Backup & Replication will prompt you to shrink the restored volume.

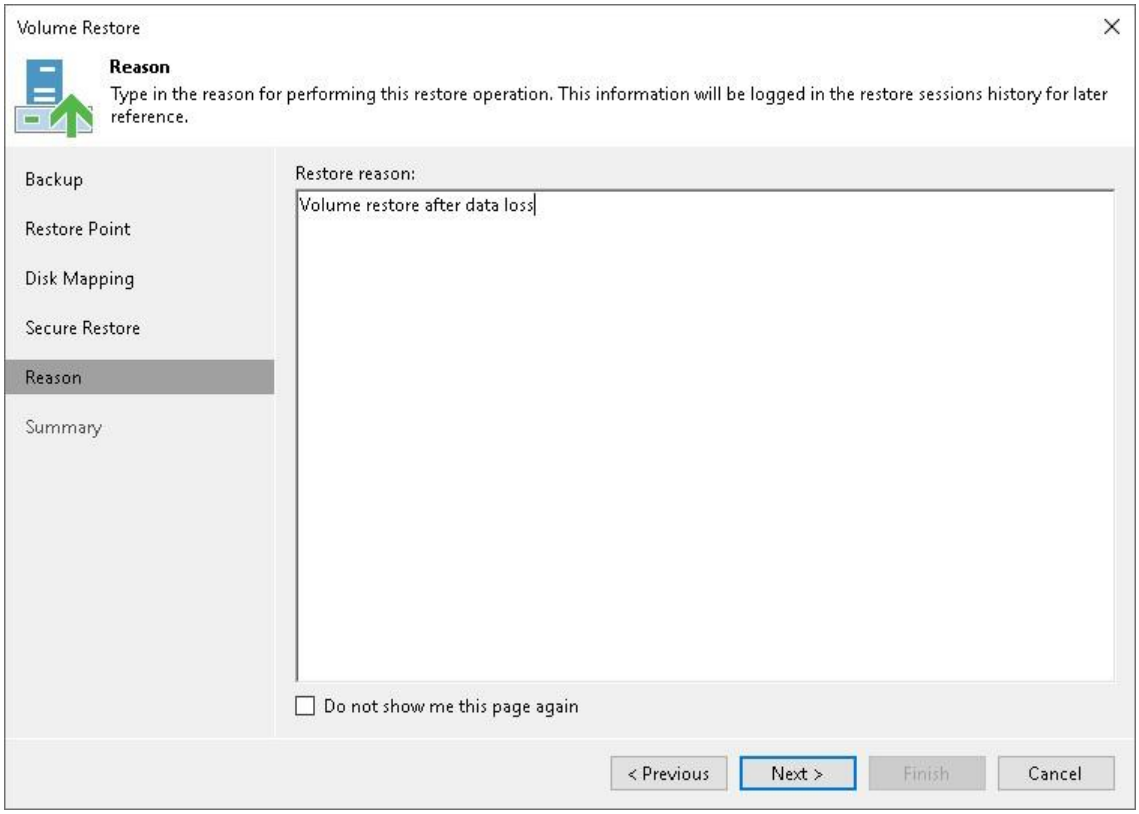
In the Volume Resize window, select the volume size unit and specify the desired size for the restored volume.



Step 6. Specify Secure Restore Settings

At the Secure Restore step of the wizard, you can instruct Veeam Backup & Replication to perform secure restore — scan restored volume data with antivirus software before restoring the volume. To learn more about secure restore, see the Secure Restore section in the Veeam Backup & Replication User Guide.

To specify secure restore settings:

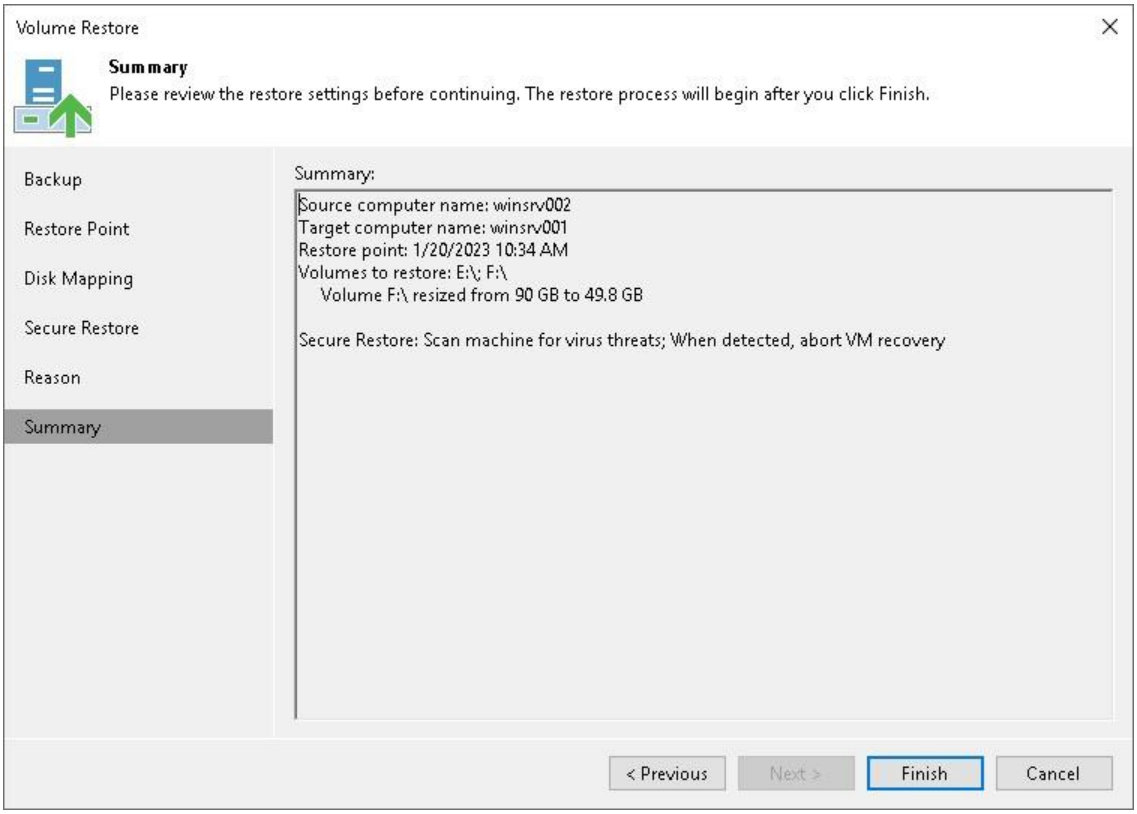


- At the Secure Restore step of the wizard, select the Scan the restored disk for malware prior to performing the recovery check box.
- Select the Scan the entire image check box if you want the antivirus software to continue volume scan after the first malware threat is found. For information on how to view results of the antivirus scan, see the Viewing Antivirus Scan Results section in the Veeam Backup & Replication User Guide.

Step 7. Specify Restore Reason

At the Reason step of the wizard, enter a reason for restoring the computer volume.

> TIP
>
> If you do not want to display theRestore Reason step of the wizard in future, select theDo not show me this page again check box.



Step 8. Complete Restore Process

At the Summary step of the wizard, complete the procedure of volume-level restore.

Review settings of the restore process.

Click Finish to start the recovery process. Veeam Backup & Replication will perform partition re-allocation operations if necessary, restore the necessary volume data from the backup and overwrite volume data on the target computer with the restored data.

APPENDIX

Creating Veeam Recovery Media

You can use the backup console to create a Veeam Recovery Media for a Veeam Agent computer that you manage in Veeam Backup & Replication. The process of creating a Veeam Recovery Media in Veeam Backup & Replication practically does not differ from the same procedure performed on a Veeam Agent computer. To learn more about the Veeam Recovery Media, see the Veeam Recovery Media section in the Veeam Agent for Microsoft Windows User Guide.

Keep in mind that you can create Veeam Recovery Media in Veeam Backup & Replication only for computers that are protected with Veeam Agent for Microsoft Windows.

Before You Begin

You can create a Veeam Recovery Media for a protected computer in Veeam Backup & Replication if the following conditions are met:

- A protected computer runs a Microsoft Windows OS.
- A full backup file of one of the following backup types was created for the protected computer on the target location by a Veeam Agent backup job:
  - Entire computer backup
  - Volume-level backup of the computer OS data (created with the Operating system option selected in the backup job settings) or computer system volume
  - File-level backup of the computer OS data created with the Operating system option selected in the backup job settings

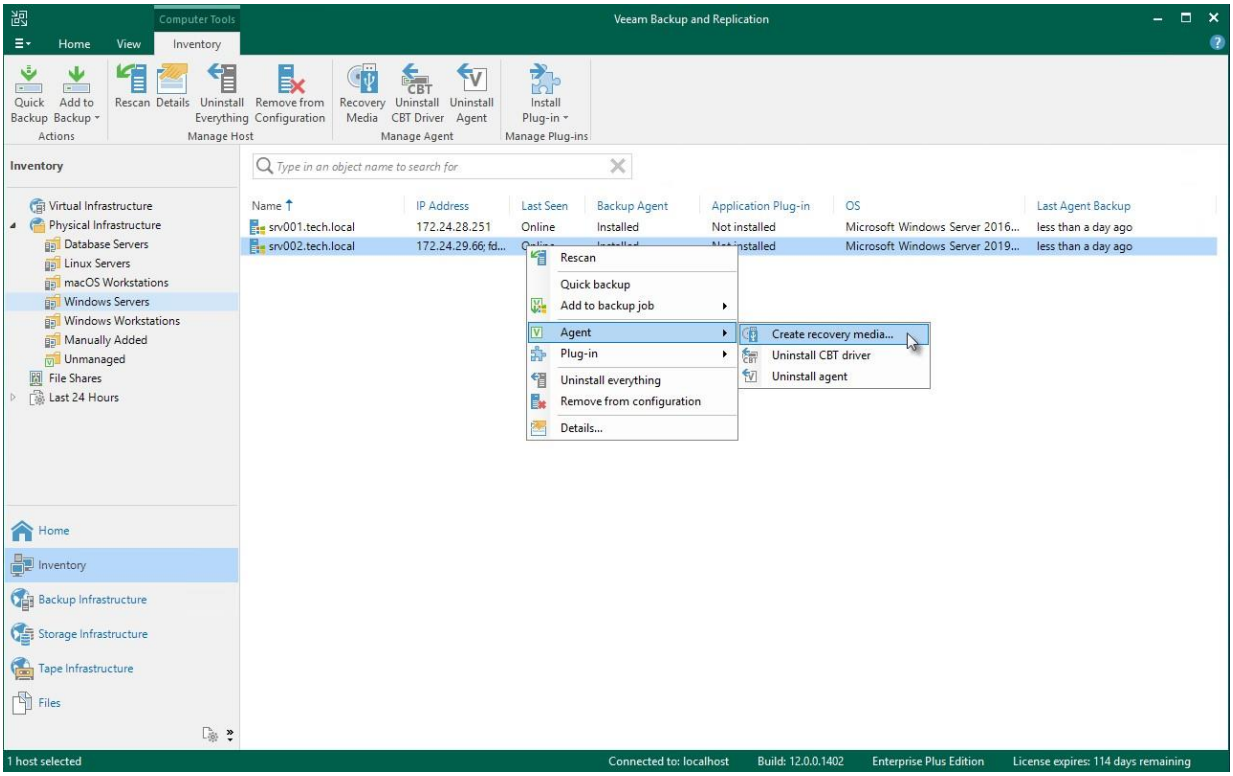
> NOTE
>
> You can create a Veeam Recovery Media for a protected computer using a copy of a full backup file that meets all the conditions. The copy must be created by a backup copy job. To learn more, see the Backup Copy section in the Veeam Backup & Replication User Guide.
>
> By default, you cannot create a Veeam Recovery Media for a failover cluster with Cluster Shared Volumes (CSV). You can enable creation of a Veeam Recovery Media for such failover clusters with a registry value. For more information, contact Veeam Customer Support.

Removable Storage Device Scenario (USB, SD Card and Other)

- The removable storage device must be inserted into a corresponding slot on the computer or connected to the computer.
- The removable storage device must have enough capacity to store the created recovery image. On average, the size of the created recovery image without manually loaded drivers is 500 MB.
- During the recovery image creation, Veeam Agent for Microsoft Windows formats the removable storage device. If you have important information on the device, create a copy of this data in some other location.

CD/DVD/BD Scenario

- An empty or re-writable CD/DVD/BD must be inserted into a CD/DVD/BD drive on the computer.
- The CD/DVD/BD must have enough capacity to store the created recovery image. On average, the size of the created recovery image without manually loaded drivers is 500 MB.
- [For RW CD/DVD/BD] During the recovery image creation, Veeam Agent for Microsoft Windows erases information on the CD/DVD/BD. If you have important information on the CD/DVD/BD, create a copy of this data in some other location.



Step 1. Launch Create Recovery Media Wizard

To launch the Create Recovery Media wizard:

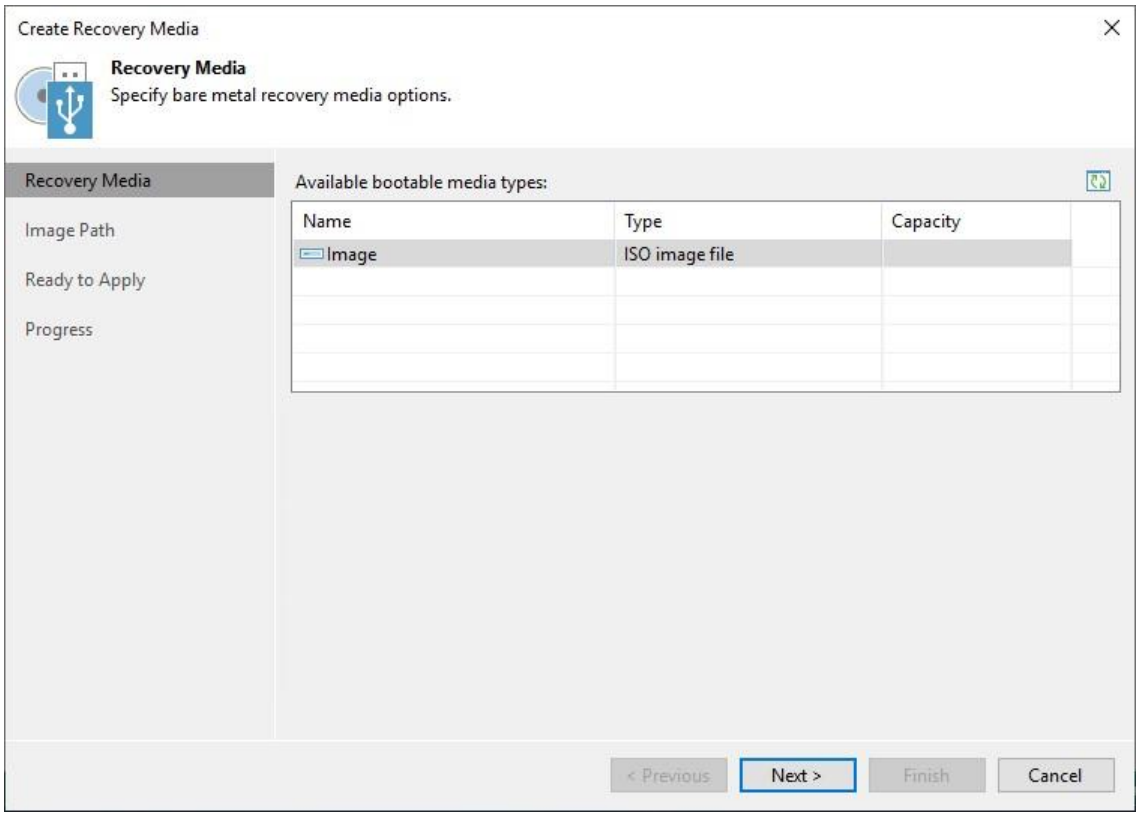
- Open the Inventory view.
- In the inventory pane, expand the Physical Infrastructure node and select a protection group that contains the necessary protected computer.
- In the working area, select the computer and click Recovery Media on the ribbon or right-click the computer and select Agent > Create recovery media.

TIP

You can also launch the Create Recovery Media wizard from the Backups node in the Home view of the Veeam backup console. To learn more, see Creating Recovery Media from Backup.

Step 2. Specify Recovery Media Options

At the Recovery Media step of the wizard, in the Available bootable media types list, specify on which type of media you want to create a recovery image. You can create the following types of recovery images:

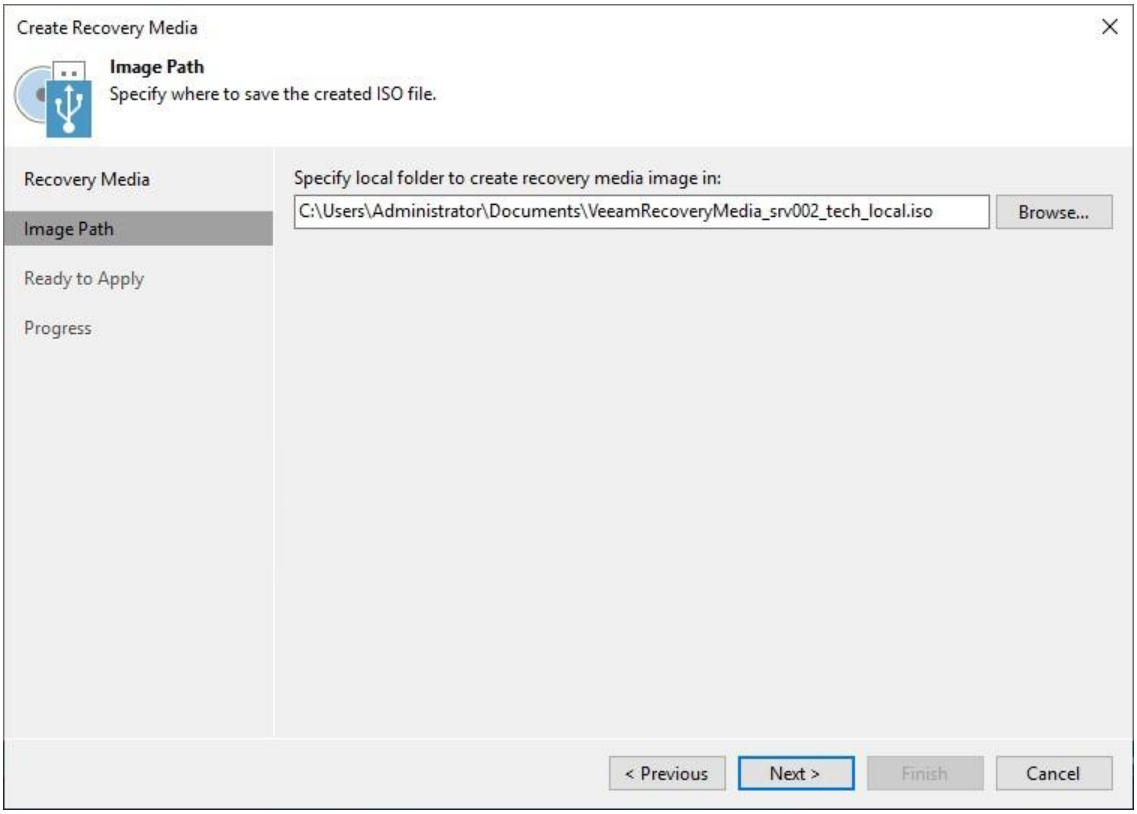


Recovery image on a removable storage device. You can create a recovery image on a USB drive, SD card and so on. Veeam Backup & Replication displays all removable storage devices currently attached to the backup server. Select the necessary one in the list.

Recovery image on an optical disk. You can create a recovery image on a CD, DVD or BD. Veeam Backup & Replication displays all CD, DVD and BD drives available on the backup server. Select the necessary one in the list.

ISO file with the recovery image. You can create a recovery image in the ISO file format and save the resulting file locally on the backup server.

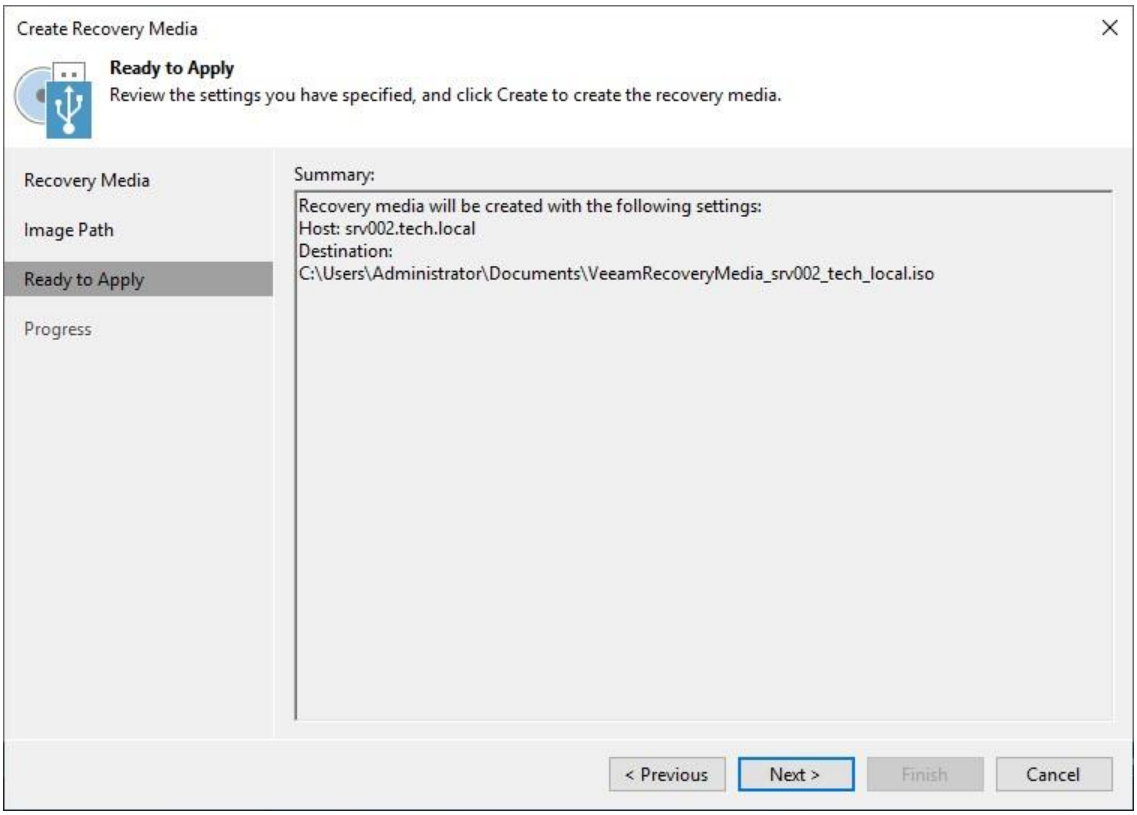
NOTE



When you create a recovery image from the Veeam backup console, you cannot specify additional recovery media options in the same way as when you create a recovery image on the Veeam Agent computer. In this scenario, the recovery image is created with default settings: Veeam Backup & Replication includes network connection settings and hardware drivers installed on the Veeam Agent computer in the recovery image.

Step 3. Specify Path to ISO

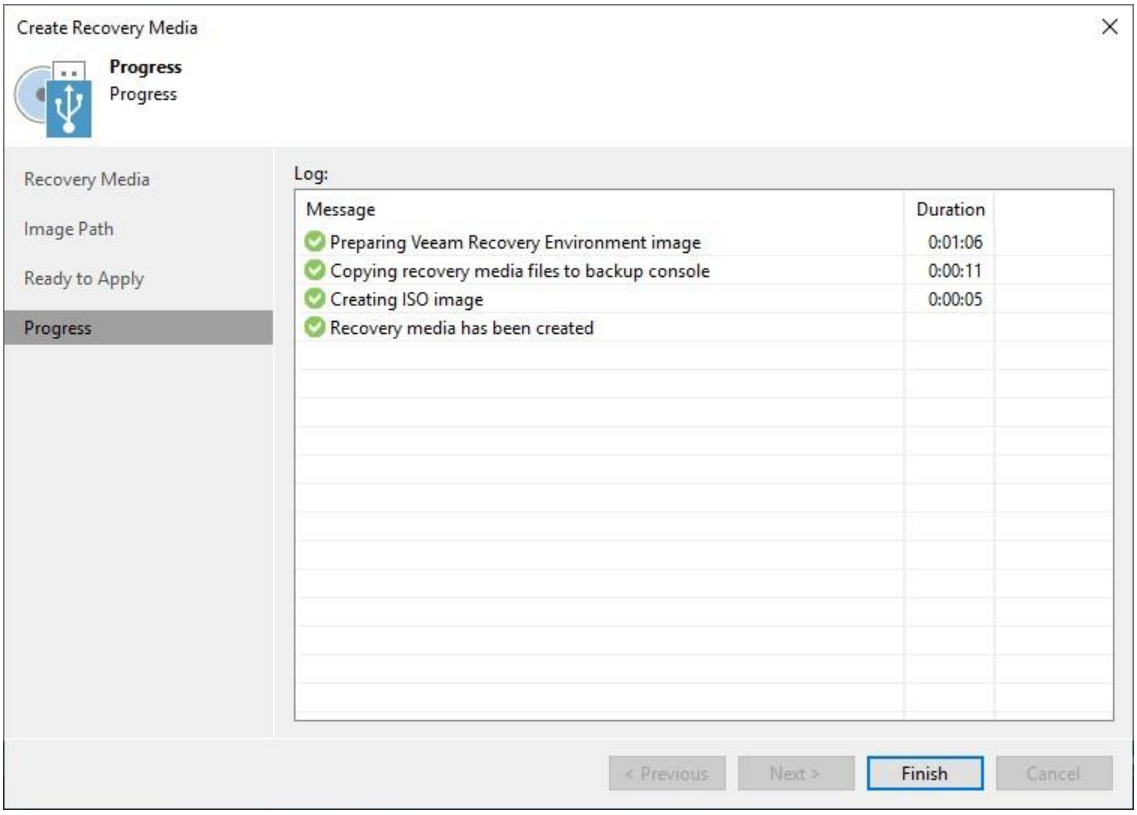
The Image Path step of the wizard is available if you have selected to create an ISO file with the recovery image.



In the Specify folder to create recovery media image in field, specify a real path to the folder where you want to save the created recovery image, and the ISO file name. When you create Veeam Recovery Media using the Veeam Backup & Replication console, you can save the ISO file on the local drive of the Veeam backup server only. Thus, the recovery image will always be available should Veeam Agent computer volumes get corrupted or the computer fail to start.

Step 4. Review Recovery Image Settings

At the Ready to Apply step of the wizard, review settings of the recovery image that you plan to create and click Create.

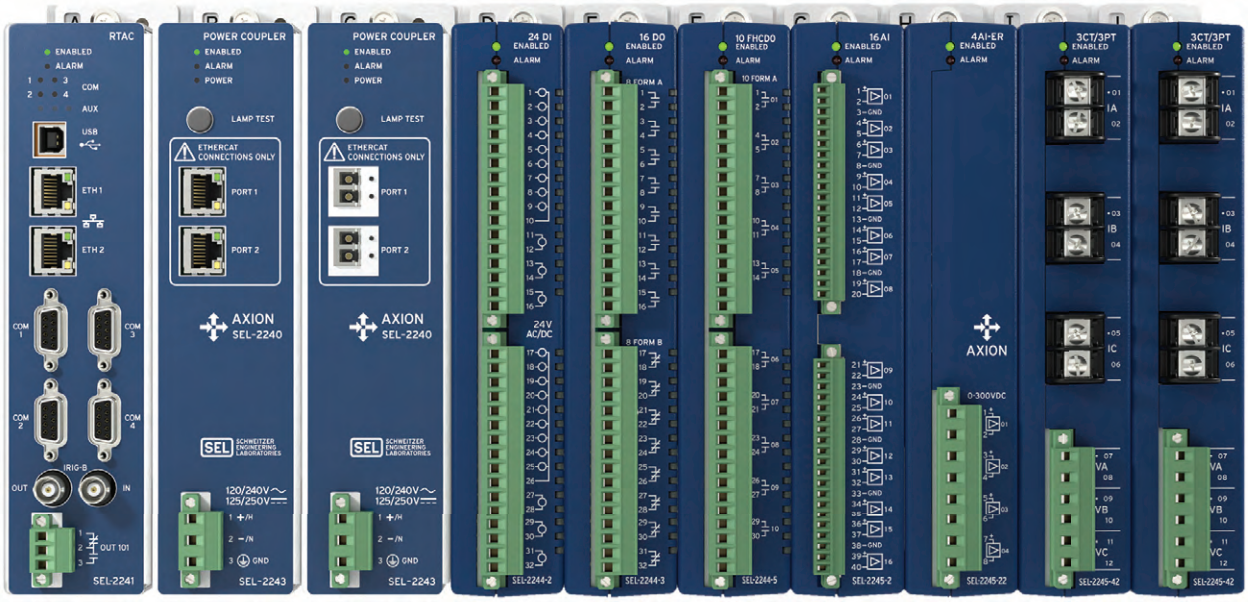


Veeam Backup & Replication will collect data necessary for recovery image creation and write the resulting recovery image to the specified target.

Step 5. Finish Working with Wizard

The process of recovery image creation may take some time. Wait for the process to complete and click Finish to exit the wizard.

If you want to interrupt the process of recovery image creation, click Cancel or close the wizard window.



What You Do Next

[For ISO file] After the recovery image is created, you can burn the created ISO file to a CD/DVD/BD. To do this, you can use native Microsoft Windows tools or third-party software.

SEL-2240 Axion

Rugged Digital I/O, Analog I/O, Current and Voltage Measurements, and Control for Your Toughest Applications

The SEL Axion® is a fully integrated modular digital I/O, analog I/O, current and voltage measurement, and control solution suitable for many utility and industrial applications. It combines the communications, built-in security, and IEC 61131 logic engine of the SEL Real-Time Automation Controller (RTAC) family with a durable suite of I/O modules that provide high-speed, deterministic, control performance over an EtherCAT® backplane.

Major Features and Benefits

- **High-Speed and High-Accuracy DC Analog Control.** Use the Axion DC Analog Output module to provide high-accuracy current and voltage control signals for low-level self-wetted (sourcing) control applications.
- **Proportional Integral Derivative (PID) Control.** Use the PID function block to provide advanced closed-loop control for analog set points commonly used in generator and process control.
- **Synchronized Current and Voltage Measurements.** Retrieve high-accuracy current and voltage measurements with the advantage of synchronized measurements. Multiple CT/PT modules in an Axion system sample all measurements at the same time to ensure a common reference for all voltages and currents. This enables many time-deterministic control applications without performing additional processing to align the measurements to a reference. Use this capability to accomplish complex control schemes including load shedding, microgrid control, and autosynchronization.
- **Top of Second Synchronized Measurements.** When connected to IRIG, synchronize the measurement of all CT/PT modules to the top of the second. This enables Axions in geographically dispersed locations to run algorithms on voltage and current measurements and provide time-aligned data from all the Axion modules. This expands time-deterministic control capability to wide-area applications because the CT/PT measurements from multiple Axion systems are all synchronized.

- **Protection Against Malware and Other Cybersecurity Threats.** Protect your RTAC system with exe-GUARD®, which uses advanced cryptographic algorithms to authorize the execution of any program or service on the system. Any tasks not approved by the whitelist are blocked from operation.
- **RTU and PLC in a Single System.** Employ the Axion's I/O, SCADA communications, and control logic support in many industrial and utility applications.
- **Simple Setup With ACSELERATOR RTAC® SEL-5033 Software.** Use standard device templates to build a system, including I/O modules, quickly.
- **Flexible I/O Selections.** Choose a custom mix of digital and analog I/O modules that suit the application. Include hundreds of points in a single panel, all connected to a deterministic EtherCAT backplane.
- **Advanced User Authentication and System Security.** Enforce LDAP user accounts to maintain security perimeter integrity. Apply corporate logging and port control policies to comply with NERC/CIP requirements.
- **Integrated Web-Based Human-Machine Interface (HMI).** Integrate the SEL-2241 RTAC module directly into the Axion system. The RTAC, via the embedded web server, includes a flexible graphical HMI system.
- **Deterministic I/O Performance.** Update connected I/O at a deterministic frequency; all inputs provide 1 ms Sequential Events Recorder (SER) time stamps.
- **More than SCADA.** Go beyond SCADA by using the Axion industry-standard communications protocols to enable multiple SCADA connections, as well as distributed control networks, among many stations.
- **Networking Options.** Implement I/O networks that use optional fiber-optic cables to provide outstanding signal isolation and flexibility in module placement.
- **Standard IEC 61131-3 Logic Design.** Create innovative logic solutions directly in ACSELERATOR RTAC by using editor tools such as Ladder Diagram, Tag Processor, Structured Text, or Continuous Function Chart.
- **Redundant Power Supplies.** Install optional dual SEL-2243 power couplers for applications needing redundant power sources.

Product Overview

Functional Diagram

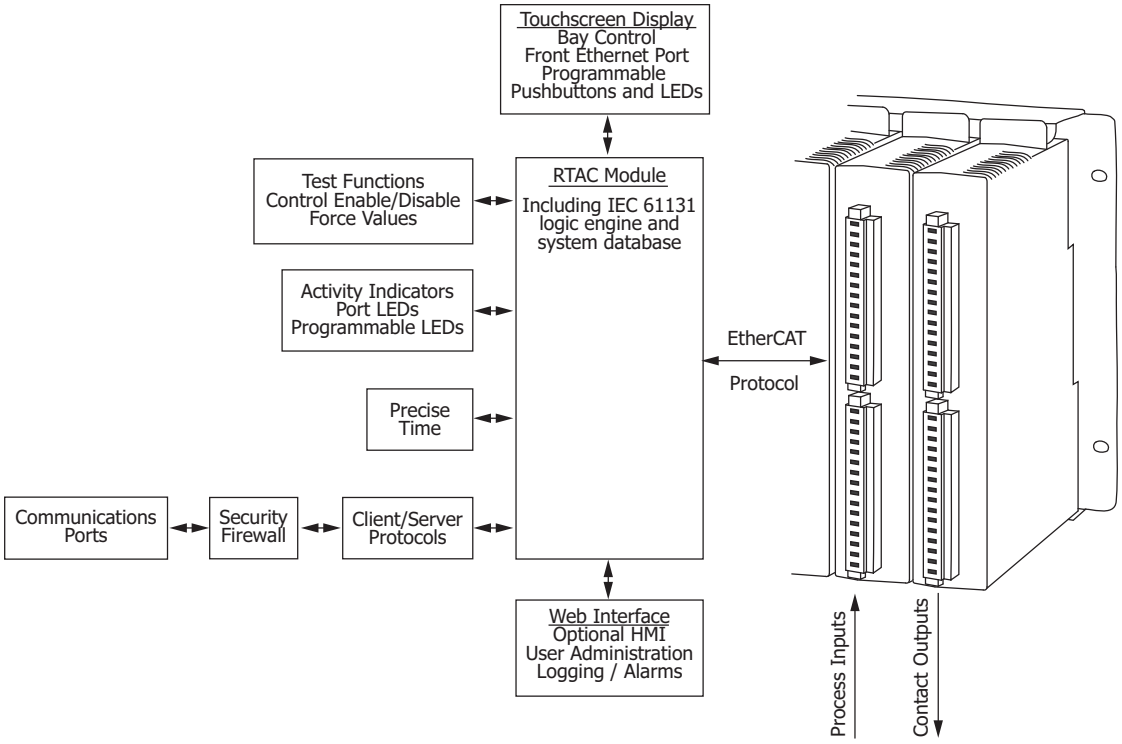


Figure 1 Functional Diagram

Flexible System Architecture

Today's monitoring and control applications need flexible system architectures and integrated security. The Axion meets these needs by using SEL RTAC as the system CPU. Two configurations are possible. There can be an SEL-2241 RTAC module installed directly in the Axion node, or the node can be connected to a standalone RTAC. A standalone SEL RTAC (e.g., SEL-3350) RTAC connects via Ethernet to an SEL-2240 node.

NOTE: The SEL-2242 backplane with 7-inch touchscreen display is only compatible with the SEL-2241 RTAC module in Slot A. See the SEL-2240 Axion Bay Controller data sheet for more details.

SEL designs all Axion hardware to published standards (see *Specifications* on page 25) and performs tests to verify that each component exceeds standards by adequate margins. The Power Coupler module (model SEL-2243) is a highly reliable device that uses the same power supply technology presently in use in SEL protective relays. Configure the SEL Axion to include single or redundant power couplers for critical applications. In redundant configurations, the pair of SEL-2243 modules actively share loads to supply power for the entire node. If one module should become unavailable, the remaining power coupler can accommodate the entire node with no loss of system capability. Employ dual power couplers for installations where you have dual power sources, one that is ac and one that is dc.

Figure 2 Modules Installed in Chassis/Backplane

Each Axion node is mounted in a chassis/backplane (model SEL-2242) that provides a means for each node to include a custom arrangement of modules. A single node can contain as many as nine modules. Use any combination, quantity, and sequence of modules that suits the application.

The node does not need to be entirely full to function properly. Leave empty slots for future expansion as necessary. Many RTU and control systems need more I/O points than will fit in a single Axion node. In those cases, use the EtherCAT protocol to connect multiple nodes together via a real-time Ethernet network. Through use of an Axion system EtherCAT network, you can use as many as 60 modules in a single network with no loss of speed or determinism. *Applications* on page 5 explores several possible network configurations. In each implementation, a single RTAC module provides logic functions and data concentration for the entire network.

RTU and PLC Functionality

The Axion is both a remote terminal unit (RTU) and ultra-rugged programmable logic controller (PLC). All the modules are rated from –40°C to +85°C and can optionally include conformal coating. The system is designed to be flexible; use the right combination of modules and nodes, in almost any arrangement, to suit the job. The SEL-2244 Digital Output Module has trip-rated contacts (30 A make, 6 A carry) to limit the need for interposing relays.

The SEL-2241, SEL-3530, and SEL-3530-4 RTACs all interface seamlessly with the I/O modules and provide easy integration with other serial and Ethernet devices via preinstalled communications protocols. The RTACs also support multiple SCADA/HMI channels. For high-speed communication, use EtherCAT fieldbus connections to I/O modules or optional IEC 61850 GOOSE messaging with station IEDs. Poll data sets and reports from other IEDs with optional IEC 61850 MMS client.

With the Axion, you need no optional hardware or software to have the programmable logic engine required for many applications. Each RTAC includes an IEC 61131 logic engine that ships preconfigured to provide access for all system tags, intelligent electronic device (IED) and I/O data, diagnostics, alarms, security events, and communications statistics. The RTAC provides unified tag mapping between protocols and programmable logic that simplifies developing applications. You simply use any necessary IED and I/O data, calculated values, and system tags in deterministic logic for the control of critical applications.

Management of the task processing sequence and solve rate in the RTAC is similar to that for traditional PACs. Optimize processor use by setting the processing rate no faster than necessary for your application.

Task processing in the logic engine includes protocols, I/O, system management, and any custom logic programs you create using Structured Text (ST), Ladder Logic Diagrams (LD), or Continuous Function Charts (CFC). CFC programs are type of IEC 61131-3 Function Block Diagram (FBD) that provide more programming flexibility than standard FBDs. The ACSELERATOR RTAC software, free of charge with purchase of an SEL RTAC, includes the IEC 61131-3 and Tag Processor editors you will use to manage any protocol information and custom logic necessary for your system.

Secure Operation

You can use the built-in web interface to manage user accounts and system alarms remotely. Each user account has a unique username, password, and assigned role that defines system permissions. You can also configure the system to use LDAP central authentication for user account management. There are webpages for monitoring user logs and maintaining network policies.

By enabling Ethernet and serial ports independently, you can minimize any security threat from unused but enabled ports. Employ SSH encryption for remote engineering access to further protect the system. Combine the Axion with other SEL security solutions to simply deploy a solution that meets your needs for maintaining a secure electronic perimeter for the control system.

Seamless System Configuration

ACSELERATOR RTAC is a Microsoft Windows-compatible configuration software for offline and online use with the SEL-2241, SEL-3530, and SEL-3530-4 RTACs. A project in ACSELERATOR RTAC contains the complete configuration, settings, and logic for an individual RTAC device. Preconfigured device and I/O module templates are available for you to quickly create all device and master connections for the project.

Once you create the settings for a specific device connection, improve engineering efficiency by saving a custom device template for later use with similar projects. Share custom templates via email or network for even greater savings. The application also includes complete project templates for some common project types.

The Tag Processor view facilitates the mapping of operational data between IEDs and SCADA. ACSELERATOR RTAC is compatible with Microsoft Excel and other programs, so you can save time and increase accuracy by copying SCADA maps from the source document.

There is no need to install or learn more than one software interface. Use the included Structured Text, Ladder Diagram, or Continuous Function Chart editors to develop custom IEC 61131 logic.

Enable remote monitoring and control functions by using the optional web-based HMI for any of the RTAC devices. *Figure 3* shows an example of a screen displaying operational data and secure controls from connected I/O and other devices. Every tag in the database is available for use in HMI screens.

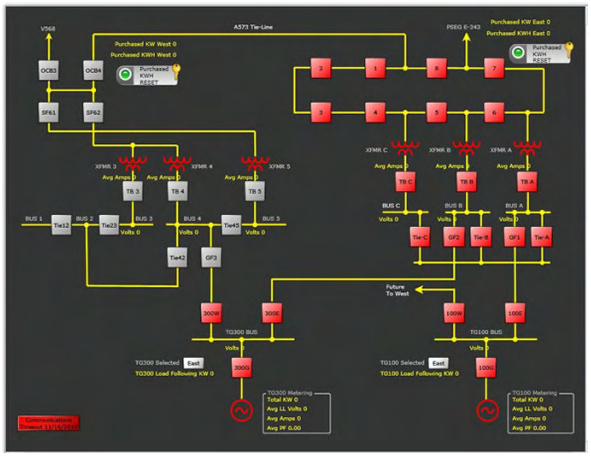

Figure 3 Powerful Monitoring Functions Using the Web-Based HMI

Deterministic System Performance

If your application includes distributed control strategies, sequential logic, or SER reports, the deterministic performance of EtherCAT will meet your needs. The software updates all I/O and time-stamps inputs with 1 ms accuracy. Log any tag values and system events to provide a system-wide SOE report that you can view online. You can also use an ODBC connection to transfer the logs to a central database.

Applications

Load Shedding for Industrial Applications

The Axion system eliminates the need for separate input, output, and control devices for industrial and microgrid load-shedding schemes. Combining system frequency and power measurements with the ability to add hundreds of binary inputs and outputs, the Axion combines the measurement, logic engine, and mitigation equipment into a single unit. Employing the CT/PT module's frequency and power elements, the powerful logic engine in the Axion incorporates system variables into fast-acting control logic for underfrequency or demand control load shedding. Complete with the HMI, the Axion is a standalone control system for many remedial action schemes.

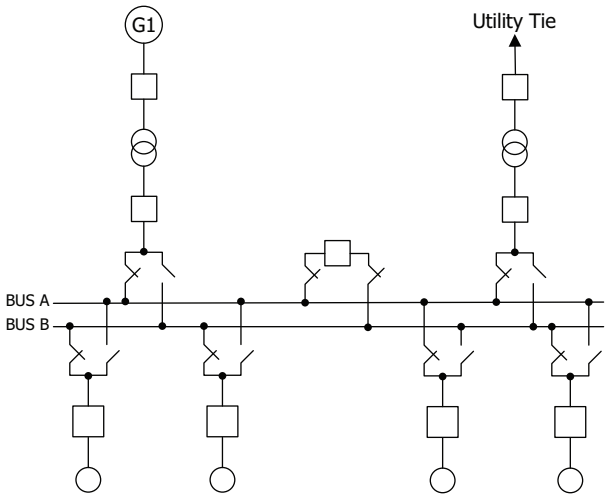

Figure 4 Load-Shedding Topology

Microgrid Control Applications

The SEL-2245-4 adds dozens of voltage and current channels to the hundreds of input, output, and analog channels already available in a single Axion system. With the capability of linking Axion backplanes as far as five kilometers away, the Axion is well suited to monitor and control across distances consistent with many microgrid applications. In an Axion system, all CT/PT modules sample at precisely the same time, ensuring a common reference for all voltages and currents entering the RTAC logic engine. This synchronized sampling enables many unique microgrid applications, including islanding detection, generation restoration, and dispatch algorithms.

Figure 5 Offshore Microgrid

Autosynchronization Systems

Use multiple CT/PT and I/O modules to create advanced and highly scalable autosynchronization systems. Automatically adjust the governor exciter controls as necessary to provide safe, secure, and unattended synchronization of generation onto the power system. With synchronized sampling from multiple CT/PT modules, the control algorithm for multiple governor exciters all have access to all necessary PT measurements in the same Axion system. Additionally, the measurements are already time-aligned, eliminating the need to adjust to a common reference. An added bonus is that the CT/PT modules can be located remotely across the system and provide the synchronized measurements through the Axion's deterministic EtherCAT network.

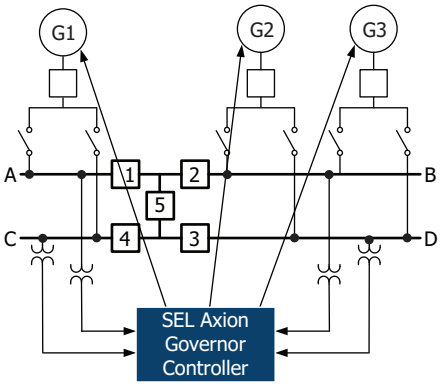

Figure 6 SEL Axion Autosynchronization System

Remote Terminal Unit (RTU)

Remote terminal units gather digital and analog signals at remote sites and supply these data over a variety of industry-standard protocols (DNP3, Modbus®, LG 8979, or IEC 61850) to a central supervisory control and data acquisition (SCADA) center or HMI. A master controller in the SCADA center can perform all logic or distribute logic to the RTU. The SEL-2244 I/O modules are available in a variety of types to gather many types of I/O at RTU locations. The SEL-2241 RTAC module has a variety of industry-standard protocols by which it can integrate seamlessly with any SCADA system. Additionally, the versatile IEC 61131 logic engine in the RTAC can meet the majority of logic requirements for small to large automation projects. The modular design of the Axion provides it the ability to perform as an RTU in two ways: as a centralized master RTU or as distributed logic in each substation.

Systems using distributed logic at the RTU use an SEL-2241 RTAC in each Axion node, thus providing all automation capabilities of the RTAC in each RTU. This architecture allows each RTU to function autonomously even if the central SCADA system is offline. Each RTAC can communicate with the SCADA master over DNP3, Modbus, LG 8979, IEC 61850, or SEL Fast Message. The following diagram illustrates use of the Axion as a distributed RTU communicating over DNP3 to a SCADA master.

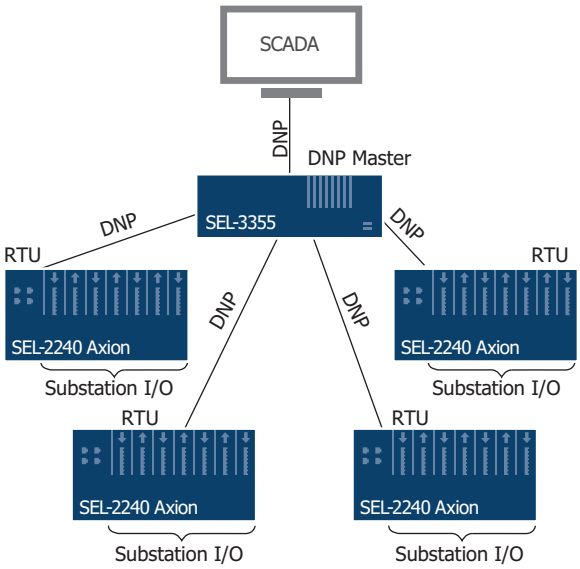

Figure 7 RTACs Distributed With RTUs

Systems that do not need autonomous operation at each RTU can use a central SEL-2241 and communicate to the remote nodes through the SEL-2243 Power Couplers. This architecture offers an economical solution to distributed I/O over EtherCAT at an extremely fast acquisition rate. The master SEL-2241 can host all data from remote nodes over DNP3 and interface directly with the SCADA system. The master Axion in *Figure 7* illustrates this functionality.

EtherCAT Network Topologies

The SEL-2243 Power Couplers provide not only hot-pluggable power supplies, but also fast EtherCAT connections to remote SEL-2240 nodes. The power couplers create EtherCAT links in star network topology, sequential network topology, or a combination of both. Star-configured topologies still use the sequential message format inherent to EtherCAT design and offer greater flexibility than wired sequential network topologies in creating a network to match your physical system. Refer to *Appendix C* in the *ACSELERATOR RTAC SEL-5033 Software Instruction Manual* for detailed information on EtherCAT.

Apply single or dual power couplers in each Axion node based on connection or redundancy requirements. *Figure 8* illustrates a star topology for four remote SEL-2240 nodes with single power couplers in the remote nodes and dual couplers in the RTAC master.

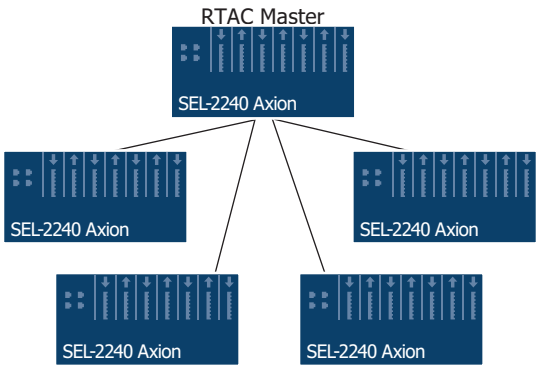

Figure 8 EtherCAT Star Network Topology

Figure 9 illustrates connections for an EtherCAT sequential topology with six Axion nodes. Each node uses a single SEL-2243 Power Coupler to provide connections to the previous and next node in the EtherCAT network.

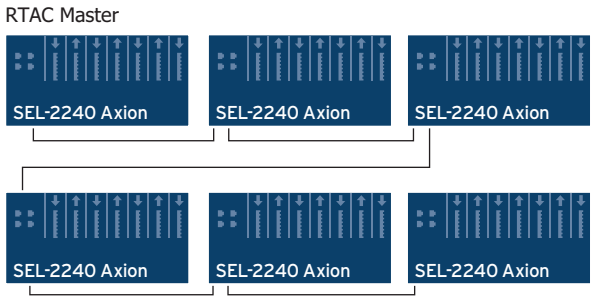

Figure 9 EtherCAT Sequential Network Topology

Figure 10 illustrates a combination of star and sequential connections with six Axion nodes.

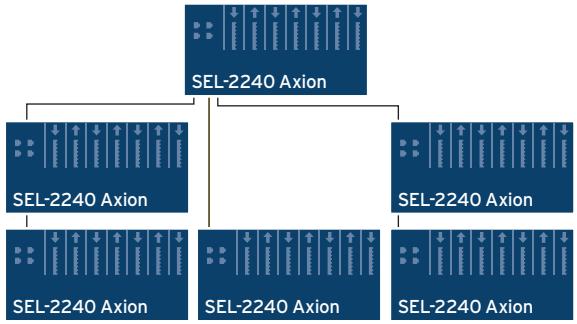

Figure 10 EtherCAT Hybrid Network Topology

Remote I/O

When you use single or dual power couplers, the Axion serves as a low-cost remote I/O module. As many as 60 modules or six nodes can connect to one resident SEL-2241 RTAC or to a separate SEL-3530 RTAC. The Axion is an excellent teleprotection device that provides through EtherCAT a simple means for expanding the number of I/O points available in an automation system at rapid data acquisition rates.

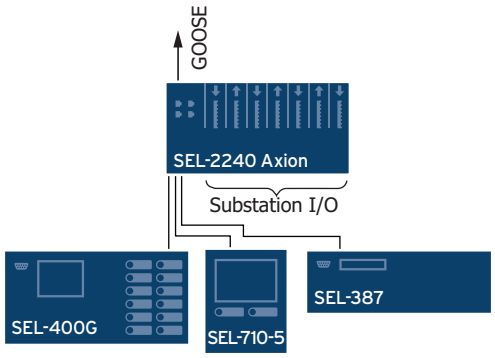

Figure 11 IEC 61850 GOOSE Concentrator

IEC 61850 GOOSE Concentrator

Gather a variety of substation I/O with the SEL-2244 modules and share the data with IEC 61850 Generic Object-Oriented Substation Event (GOOSE) messages. Use the protocol flexibility of the RTAC to concentrate data from non-IEC 61850 relays and convert these data to GOOSE messages.

Synchrophasor Concentrator

Use standard protocols, such as DNP3, to move synchrophasor data to SCADA operation centers. Include time stamps and time quality in the SCADA message to allow for system-wide usage of synchrophasor data. Within the RTAC logic engine, you can perform complex math and logic calculations on synchrophasor data you collect from SEL relays and other IEEE C37.118-compliant devices.

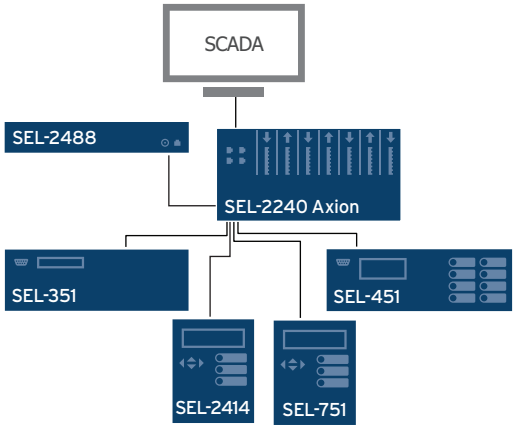

Figure 12 Synchrophasor Concentrator

SCADA Data Concentrator

Use the RTAC with your protective relays and other IEDs as the substation SCADA data concentrator. You can configure the RTAC to collect and view station-wide SER and event reports. Use MIRRORED BITS® protocol to ensure compatibility with any SEL device. Retrieve asset optimization data from SEL or other IEDs to maintain

the best possible system reliability. Take advantage of multiprotocol support to collect SCADA information, process control commands, and obtain SNTP/NTP time synchronization through a single communications link to each Ethernet device. Scale values and calculate logic in a familiar IEC 61131 configuration environment. Enjoy secure, encrypted communications to any device on the substation network or serial channel.

Remotely access the RTAC through the Ethernet connection, and use any web browser to manage users, view diagnostics, and access logs. Establish a remote connection with any IED connected to the RTAC through engineering access communications channels. Use the SEL Fast Message protocol to maintain SCADA control and metering updates throughout the engineering access connection. Use ACSELERATOR QuickSet® SEL-5030 Software to remotely manage protection and control settings in attached relays.

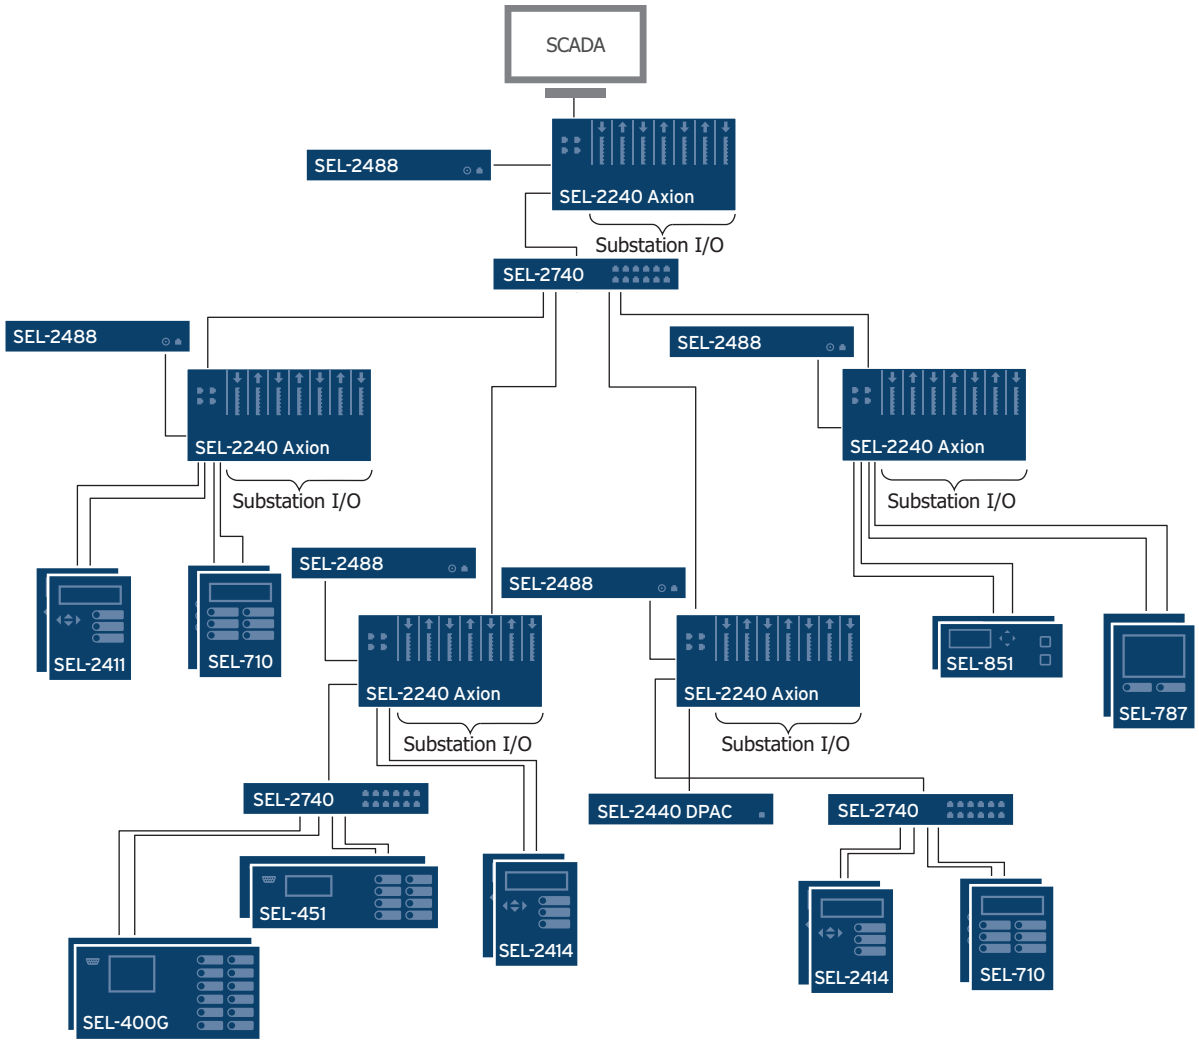

Figure 13 SCADA Data Concentrator and HMI

Human-Machine Interface

Use the built-in web HMI in the RTAC for viewing and controlling any tags you configured in the RTAC. Use ACSELERATOR Diagram Builder to develop custom HMI screens and load them into the RTAC. You can include one-line diagrams, annunciators, and graphical representations that contain control buttons, and you can then display any data in the RTAC. Once you have loaded the screens into the RTAC, you can view the screens in the RTAC web interface. Because the HMI application is web-based, multiple users can view the HMI screens simultaneously.

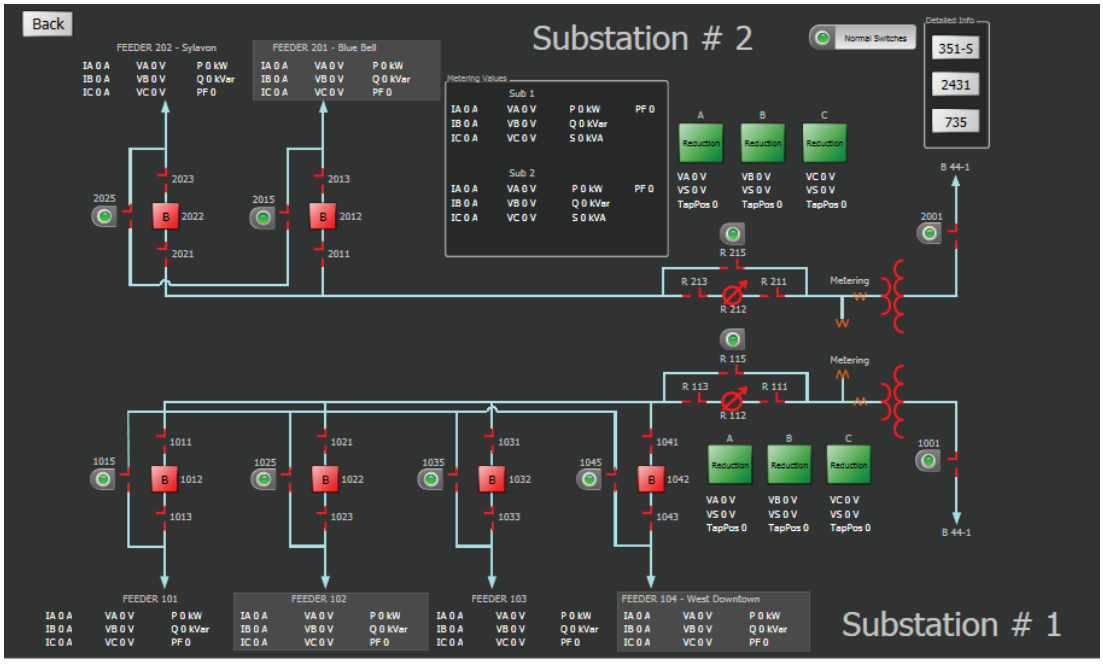

Figure 14 HMI One-Line Diagram

The logging system in the RTAC provides comprehensive logging for all variables in the RTAC, including those that connected IEDs provide. The logging system compensates for time-stamp differential among data from different IEDS, so all data are in sequence and on the same time-stamp reference. The RTAC can log data for changes in the state of Boolean values, changes in string values, and changes in Boolean, analog, or string time stamps. The RTAC can also alarm for analog values that cross defined thresholds. Assign variables for logging in the Tag Processor, or use one of the logger function blocks in IEC 61131 custom programs.

There are two user interfaces for viewing logged data. These include a secure HTML interface and an open database connectivity (ODBC) connection. Access the HTML interface through a web browser connection. Use the ODBC connection for standard data transfer between the logged data and database or spreadsheet software.

Programmable Logic/Automation Controller

Use the Axion as a programmable logic/automation controller (PLC/PAC) to automate your real-time tasks based on a variety of input conditions and diagnostic information. Use the powerful IEC 61131 logic engine to write programs in Structured Text, Function Block, or Ladder Logic. Schedule periodic tasks, or drive event-driven tasks with multiple preconditions. Create function blocks of complex tasks for simple configuration. Easily replace aging PLCs implemented in Ladder Logic by replicating the same logic or by using a conversion tool to translate logic to Structured Text.

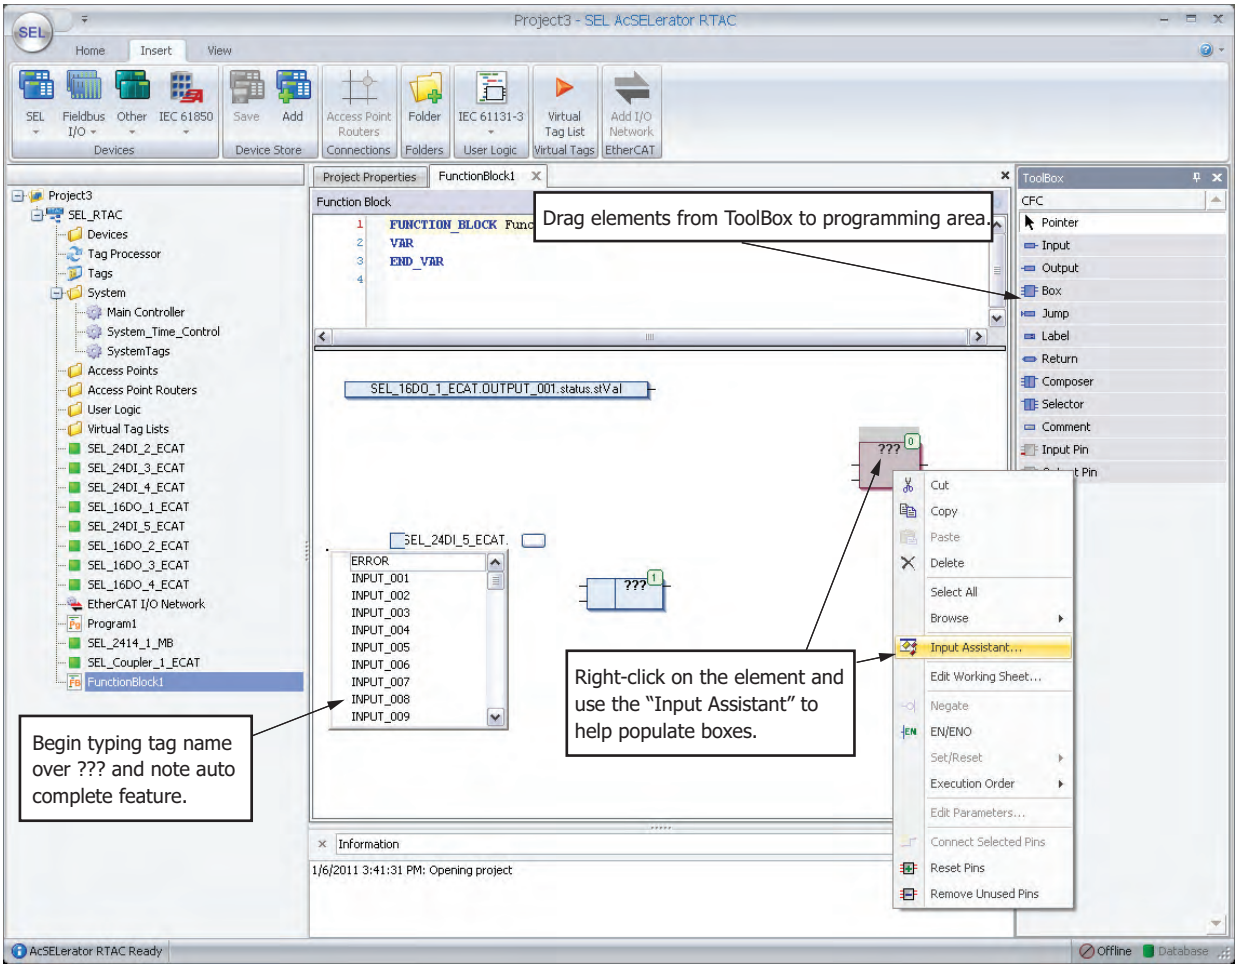

Figure 15 IEC 61131 Logic Example

Intelligent Port Switch

Flexible communications parameters make the RTAC a great choice for almost any port-switching application. Although RTAC multitasking/multiuser and data handling capabilities make it a very powerful remote automation platform, it is still an economical choice for port-switching applications. The time-synchronization capabilities of the RTAC add to its value in this application.

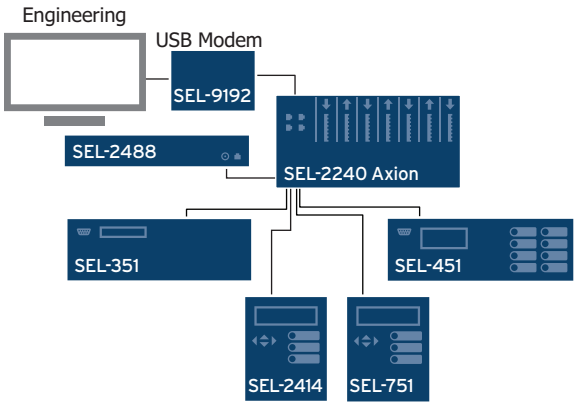

Figure 16 Intelligent Port Switch

Network Gateway

The SEL-2241 RTAC has two Ethernet ports through which it can make serially connected devices available to high-speed networks. The RTAC supports virtual terminal connections through the Ethernet ports. For example, Ethernet users can establish secure Telnet sessions and communicate with an IED connected to the RTAC.

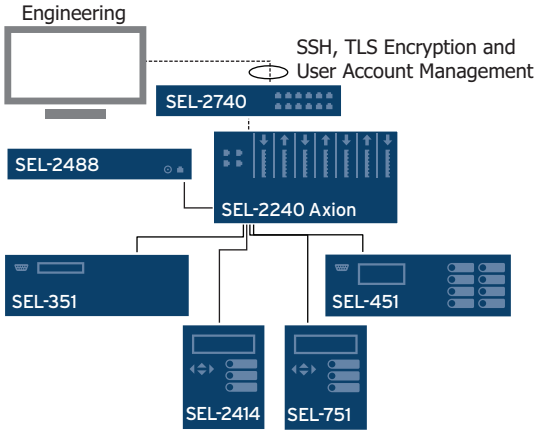

Figure 17 Network Gateway

Protocol Gateway

Collect downstream data with client protocols. Then send these data to your upstream HMI, RTU, or SCADA master with server protocols, converting the data from one protocol to another in the process. RTAC multitasking/multiuser and data handling capabilities make it a great choice for data concentration.

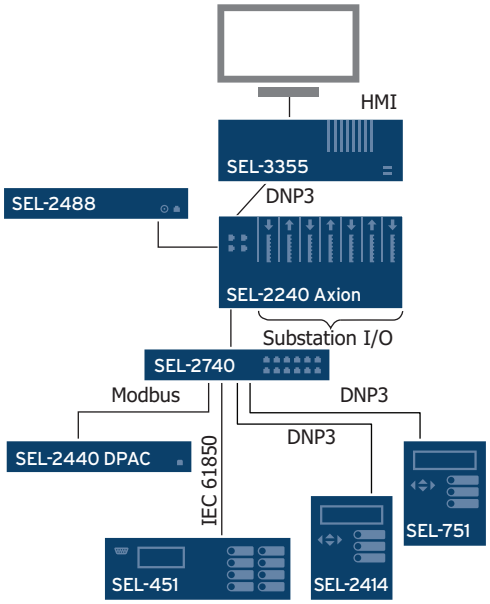

Figure 18 Protocol Converter

Time-Synchronization Source

Synchronize the time clocks in attached devices that accept a demodulated IRIG-B time signal. The SEL-2241 RTAC regenerates the demodulated IRIG-B signal from an external modulated or demodulated source, such as a GPS satellite clock receiver, SNTP/NTP source, or serial or Ethernet protocol such as DNP3. If an external clock source is unavailable, the RTAC generates an IRIG-B signal from its internal clock, providing device synchronization to a common clock for improved SER data analysis.

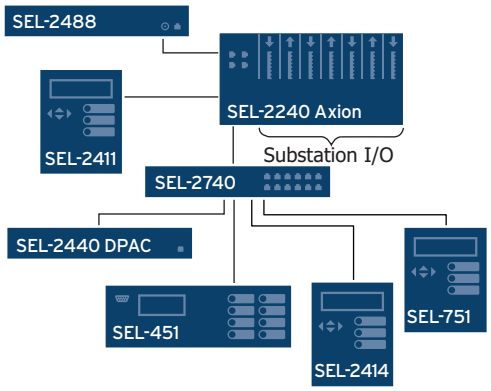

Figure 19 Time Synchronization

Security Gateway

Secure the automation network with the Axion. Enable encryption for any engineering access channel or SCADA link. Implement system security auditing, logging, and password restrictions to enforce NERC standards. Comply with role-based requirements by implementing per-user security profiles. Optionally, incorporate serial and wireless encrypting devices to further secure communications to any device

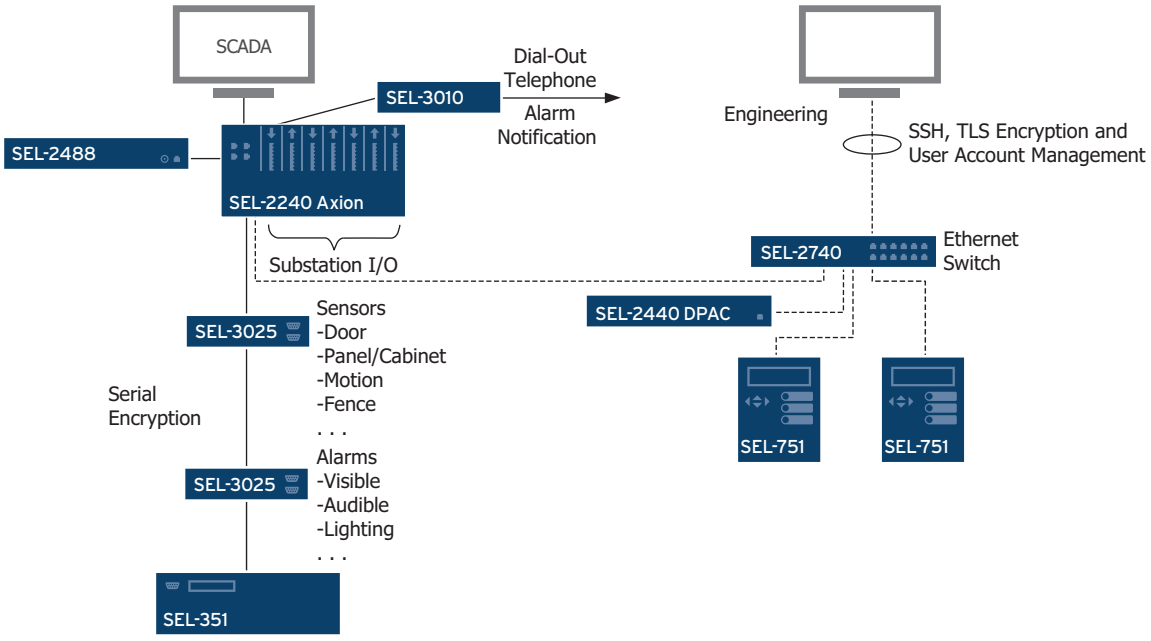

Figure 20 Security Gateway

Ordering Options

Table 1 SEL-2241 RTAC Module

Ethernet Communication	Two Ethernet ports: 10/100BASE-T copper (standard) 100BASE-FX fiber-optic (optional) 100BASE-LX single-mode fiber-optic (optional)
Web-Based HMI	Basic runtime license and Diagram Builder software
Peer-to-Peer Protocols	IEC 61850 GOOSE
Client Protocols	IEC 61850 MMS
Server Protocols	IEC 61850 MMS
Environment	Conformal coating for chemically harsh and high-moisture environments

Table 2 SEL-2242 Chassis/Backplane

Slot Configuration	10-Slot, 4-Slot, or Dual 4-Slot
Mounting	Horizontal Surface Mount, 5U[a] Horizontal Rack Mount, 5U Horizontal Panel Mount, 5U (10-Slot or Dual 4-Slot)
Environment	Conformal coating for chemically harsh and high-moisture environments

[a] For applications compliant with IEC 60255-27, surface-mount units must be installed in IP4X enclosures.

Table 3 SEL-2243 Power Coupler

Voltage Range	24/48 Vdc or 120/250 Vac/Vdc
EtherCAT Communication	Two ports: RJ45 Ethernet (standard) LC fiber-optic multimode or single-mode (optional)
Environment	Conformal coating for chemically harsh and high-moisture environments

Specifications

Compliance

Designed and manufactured under an ISO 9001 certified quality management system

SEL Axion operates at the specified limits on power up as soon as the device enables. Refer to the individual SEL Axion module datasheets for compliance and type test specifications.

UKCA Mark

Enclosure Protection

IP4X Front
IP2X Product Without SEL-2245-4, SEL-2245-411, and SEL-2245-42
IP1X Product With SEL-2245-4, SEL-2245-411, or SEL-2245-42
Note: If rear terminals are accessible during normal use, the product must be mounted in a locked enclosure or restricted area accessible by trained maintenance or operation personnel only.

Product Standards

IEC 60255-26:2013 - Relays and Protection Equipment: EMC
IEC 60255-27:2014 - Relays and Protection Equipment: Safety
IEC 60825-2:2004 +A1:2007 +A2:2010 for fiber-optic communications
IEC 61850-3:2013 - Comm Systems for Power Utility Automation

General

Operating System

SEL Linux® Yellowstone running Linux kernel 3.x with real-time preemption patches

Operating and Storage Temperature Range

–40° to +85°C (–40° to +185°F)
Units should be stored and transported in their original packaging.

Note: Operating temperature evaluated for UL ambient 0° to 40°C.
Note: The optional front-panel LCD is impaired for temperatures below –20°C and above +70°C.

Operating Environment

Pollution Degree:	2
Overvoltage Category:	II
Insulation Class:	1
Relative Humidity:	5%–95%, noncondensing
Maximum Altitude:	2000 m
Vibration, Earth Tremors:	Class 1

Dimensions

Refer to *Section 2: Installation* for dimensions.

Weight

SEL-2241 RTAC:	0.670 kg (1.47 lb)
SEL-2242 19 in Backplane:	3.24 kg (7.13 lb)
Panel Mount Bezel:	0.283 kg (0.625 lb)
SEL-2242 10-Slot (19 in Rack Width) With 7 in Touchscreen Display:	3.999 kg (8.80 lb)
SEL-2243-1 HV Coupler:	0.85 kg (1.87 lb)
SEL-2243-2 LV Coupler:	0.89 kg (1.97 lb)

SEL-2244-2 24 DI:	0.45 kg (1.00 lb)
SEL-2244-3 16 DO:	0.59 kg (1.30 lb)
SEL-2244-5 10 FHCDO:	0.57 kg (1.26 lb)
SEL-2245-2 16 AI:	0.51 kg (1.12 lb)
SEL-2245-22 4 AI-ER:	0.42 kg (0.92 lb)
SEL-2245-221 4 LEA:	0.42 kg (0.92 lb)
SEL-2245-3 8 AO:	0.46 kg (1.01 lb)
SEL-2245-4 4 CT/4 PT:	0.54 kg (1.18 lb)
SEL-2245-411 4 CT/4 LEA:	0.54 kg (1.18 lb)
SEL-2245-42 3 CT/3 PT:	0.73 kg (1.60 lb)

Module Burden

Table 14 Maximum Burden Per Module for Each Node

Module	Maximum Added Burden (W)[a]
SEL-2241 RTAC (Copper Ethernet)	12.5
SEL-2241 RTAC (Fiber Ethernet)	15
SEL-2242R Standard Rack-Mount Backplanes	1
SEL-2242 With Touchscreen Display	4
SEL-2243 Power Coupler (Fiber Ethernet)	5[b]
SEL-2243 Power Coupler (Copper Ethernet)	2.5[b]
SEL-2244-2 24 DI	2
SEL-2244-3 16 DO	8[c]
SEL-2244-5 10 FHCDO	6[c]
SEL-2245-2 16 AI	3
SEL-2245-22 4 AI-ER	2
SEL-2245-221 4 LEA	2
SEL-2245-3 8 AO	13
SEL-2245-4 4 CT/4 PT	3
SEL-2245-411 4 CT/4 LEA	3
SEL-2245-42 3 CT/3 PT	6
Feature Selections	**Typical Burden (W)**
No use of SEL-2241 Serial Port +5 Vdc	–3
Each DO port not energized (SEL-2241, SEL-2244-3, or SEL-2244-5 relay coil)	–0.3
Each AO port not energized (SEL-2245-2)	–0.7

[a] Values include worst-case real power consumption and do not include worst-case ac power factor correction (0.4). If the unit will not be used in wide temperature extremes, reduce power by up to 6%.

[b] Each SEL-2243 will draw a minimum of 11 W (quiescent) when the total burden of all other modules in the node is less than 11 W.

[c] All DO relay coils may be energized simultaneously and still meet specifications.

CPU Processing and Memory

Processor Speed:	533 MHz
Memory:	1024 MB DDR2 ECC RAM
Storage:	4 GB (2 GB reserved)

Security Features

Account Management:	User Accounts User Roles LDAP Central Authentication RADIUS Central Authentication Strong Passwords Inactive Account Logouts
Intrusion Detection:	Access/Audit Logs Alarm LED Alarm Contact
Encrypted Communication:	SSL/TLS, SSH, HTTPS

Automation Features (Protocols)

Client:	DNP3 Serial, DNP3 LAN/WAN, Modbus RTU, Modbus TCP, SEL ASCII, SEL Fast Messaging, LG 8979, IEEE C37.118, IEC 61850 MMS, CP2179, IEC 60870-5-101/104, SNMP, SES-92, CDC Type II, Courier, IEC 60870-5-103, Ethernet/IP Explicit Message Client
Server:	DNP3 Serial, DNP3 LAN/WAN, Modbus RTU, Modbus TCP, SEL Fast Messaging, LG 8979, SES-92, IEEE C37.118, IEC 61850 MMS, IEC 60870-5-101/104, FTP, SFTP, CDC Type II, Ethernet/IP Implicit Message Adapter
Peer-to-Peer:	SEL MIRRORED BITS Communications, IEC 61850 GOOSE, Network Global Variables (NGVL), Parallel Redundancy Protocol
Fieldbus:	EtherCAT Client (in RTAC), EtherCAT Server (I/O modules)
Engineering Access	
Modes:	SEL Interleaved, Direct
Port Server:	Map Serial Ports to IP Ports
Secure Web Server:	Diagnostic and Communications Data

Time-Code Input (Modulated IRIG-B)

Input Impedance:	2 kΩ
Accuracy:	500 µs

Time-Code Input (Demodulated IRIG-B)

On (1) State:	$V_{ih} > 2.2$ V
Off (0) State:	$V_{il} < 0.8$ V
Input Impedance:	2 kΩ
Accuracy:	500 ns

Time-Code Output (IRIG-B)

On (1) State:	$V_{oh} > 2.4$ V
Off (0) State:	$V_{ol} < 0.8$ V
Load:	50 Ω

Network Time Protocol (NTP) Modes

NTP Client:	As many as three configurable servers
NTP Server	

Simple Network Time Protocol (SNTP) Accuracy

±1 ms:	This does not take into account external factors such as network switches and topologies

Precise Time Protocol (PTP)

PTP Client:	Peer delay request and end-to-end path delay supported

Communications Ports (SEL-2241 RTAC)

Ethernet Ports (To Backplane)

Ports:	1
Data Rate:	Automatic
Protocols:	Dedicated EtherCAT port

Ethernet Ports (Terminal Side)

Ports:	2
Data Rate:	10 or 100 Mbps
Connector:	RJ45 Female or LC Fiber (Multimode or Single-Mode 100 Mbps only)

Fiber-Optic Ports (Class 1 LASER/LED)

Wavelength

1300 nm

Optical Connector Type

LC

Multimode Option

Link Budget:	11 dB
Min. TX Power:	–20 dBm
Min. RX Sensitivity:	–31 dBm
Fiber Size:	50–200 µm
Approximate Range:	2 km
Data Rate:	100 Mbps
Typical Fiber Attenuation:	–2 dB/km

Single-Mode Option

Link Budget:	10 dB
Min. TX Power:	–15 dBm
Min. RX Sensitivity:	–25 dBm
Fiber Size:	9 µm
Approximate Range:	15 km
Data Rate:	100 Mbps
Typical Fiber Attenuation:	–0.4 dB/km

Serial Ports

Ports:	4
Types:	EIA-232/EIA-485 (software selectable)
Data Rate:	300 to 115,200 bps
Connector:	DB-9 Female
Time Synchronization:	IRIG-B
Power:	+5 Vdc power on Pin 1 (500 mA maximum per SEL-2241)

USB Device Ports

1 Type B

Output (SEL-2241 RTAC)

Mechanical Durability

10 M no-load operations

DC Output Ratings

Rated Operational Voltage:	250 Vdc
Rated Voltage Range:	19.2–275 Vdc
Rated Insulation Voltage:	300 Vdc
Make:	30 A @ 250 Vdc per IEEE C37.90
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C
Thermal:	50 A for 1 s
Contact Protection:	360 Vdc, 40 J MOV

Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time ≤8 ms typical		
Breaking Capacity (10,000 Operations) Per IEC 60255-0-20:1974:	24 Vdc 48 Vdc 125 Vdc 250 Vdc	0.75 A 0.50 A 0.30 A 0.20 A	L/R = 40 ms L/R = 40 ms L/R = 40 ms L/R = 40 ms
Cyclic Capacity (2.5 Cycles/Second) Per IEC 60255-0-20:1974:	24 Vdc 48 Vdc 125 Vdc 250 Vdc	0.75 A 0.50 A 0.30 A 0.20 A	L/R = 40 ms L/R = 40 ms L/R = 40 ms L/R = 40 ms

AC Output Ratings

Rated Operational Voltage:	240 Vac
Rated Insulation Voltage:	300 Vac
Utilization Category:	AC-15 (control of electromagnetic loads > 72 VA)
Contact Rating Designation:	B300 (B = 5 A, 300 = rated insulation voltage)
Contact Protection:	270 Vac, 40 J
Continuous Carry:	3 A @ 120 Vac 1.5 A @ 240 Vac
Conventional Enclosed Thermal Current (I_{the}) Rating:	5 A
Rated Frequency:	50/60 ± 5 Hz
Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time <8 ms typical
Electrical Durability Make VA Rating:	3600 VA, cosø = 0.3
Electrical Durability Break VA Rating:	360 VA, cosø = 0.3

Backplane (SEL-2242)

Ethernet Port

Port:	1
Data Rate:	10/100 Mbps
Connector:	RJ45 Female
Protocol:	Engineering Access

Note: SEL-2242 Ethernet port is included with the optional touchscreen, 10-slot model only.

Fuse Rating

Non-Serviceable:	2.5 A, 125 V, time lag T

Power Coupler (SEL-2243)

EtherCAT Ports

Ports:	2
Data Rate:	Automatic
Connector:	RJ45 Female or LC Fiber
Protocols:	Dedicated EtherCAT

RJ45 Ports

Cable Length:	<3 m

Fiber-Optic Ports (Class 1 LASER/LED)

Wavelength

1300 nm

Optical Connector Type

LC

Multimode Option

Link Budget:	11 dB
Min. TX Power:	–20 dBm
Min. RX Sensitivity:	–31 dBm

Fiber Size:	50–200 µm
Approximate Range:	2 km
Data Rate:	100 Mbps
Typical Fiber Attenuation:	–2 dB/km

Single-Mode Option

Link Budget:	10 dB
Min. TX Power:	–15 dBm
Min. RX Sensitivity:	–25 dBm
Fiber Size:	9 µm
Approximate Range:	15 km
Data Rate:	100 Mbps
Typical Fiber Attenuation:	–0.4 dB/km

Power Supply

AC Input Voltage (High-Voltage Model)

Note: Single phase.

Nominal Supply Voltage:	120–240 Vac, 50–60 Hz
Operational Voltage Range:	85–264 Vac, 40–70 Hz

DC Input Voltage (High-Voltage Model)

Nominal Supply Voltage:	125–250 Vdc
Operational Voltage Range:	85–300 Vdc

DC Input Voltage (Low-Voltage Model)

Nominal Supply Voltage:	24–48 Vdc
Operational Voltage Range:	19.1–57.6 Vdc polarity-dependent

Note: UL operational voltage range is equal to the nominal voltage range ±10 percent.

Fuse Rating

High-Voltage Model, F1:	3.15 A, high breaking capacity, time lag T, 250 V (5x20 mm, T3.15AH 250 V)
High-Voltage Model, F2 (Non-Serviceable):	8 A, high breaking capacity, time lag T, 60 Vdc (2.7x6.1 mm, T8A 60 Vdc)
Low-Voltage Model:	6.30 A, high breaking capacity, time lag T, 250 V (5x20 mm, T6.3AH 250 V)

Power Consumption: See *Table 14* for power per module.

Maximum AC Burden:	160 VA
Maximum DC Burden:	75 W
Interruptions:	30 ms @ 24 Vdc 130 ms @ 48 Vdc 50 ms @ 125 Vac/Vdc 100 ms @ 250 Vac/Vdc

The following exceptions for the IEC 61850-3 acceptance criteria for normal equipment functioning regarding ac power dips and interruptions and dc voltage dips are applicable (refer to IEC 61850-3 subclause 7.5.5, Equipment functioning, and 7.5.6, Exceptions).

Power Supply	Requirement	Exception[a]
125 Vac	5 cycles (83,33 ms @ 60 Hz, 100 ms @ 50 Hz)	50 ms
	50 cycles	Not applicable[b]

[a] Voltage interruptions that are longer than the specified interruption duration result in a device restart.

[b] Equipment is not intended to be connected to power supply ports that are directly connected to a public low-voltage power supply network.

Max Inrush:	17 A
Isolation:	3100 Vdc
Redundant Installation:	Each node may have one or two SEL-2243 modules installed. When two are used, they operate in load-sharing mode.

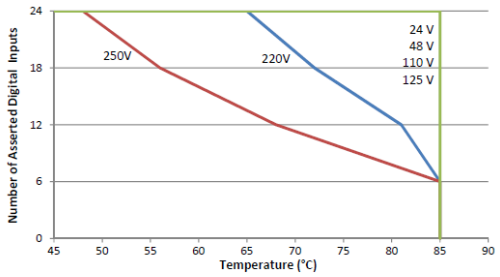
Recommended External Overcurrent Protection

Breaker Type:	Standard
Breaker Rating:	15 A or 20 A at 250 Vdc
Current Breaking Capacity:	10 kA
Grounded Neutral System:	Device in series with the HOT or energized conductor
DC and Isolated Systems:	Device in series with both conductors

Optoisolated Control Inputs (SEL-2244-2)

When Used With DC Control Signals:

250 Vdc	ON for 200–275 Vdc	OFF below 150 Vdc
220 Vdc	ON for 176–242 Vdc	OFF below 132 Vdc
125 Vdc	ON for 100–135.5 Vdc	OFF below 75 Vdc
110 Vdc	ON for 88–121 Vdc	OFF below 66 Vdc
48 Vdc	ON for 38.4–52.8 Vdc	OFF below 28.8 Vdc
24 Vdc	ON for 15–30 Vdc	OFF for < 10 Vdc



When Used With AC Control Signals:

250 Vdc	ON for 170.6–300 Vac	OFF below 106 Vac
220 Vdc	ON for 150.3–264 Vac	OFF below 93.2 Vac
125 Vdc	ON for 85–150 Vac	OFF below 53 Vac
110 Vdc	ON for 75.1–132 Vac	OFF below 46.6 Vac
48 Vdc	ON for 32.8–60 Vac	OFF below 20.3 Vac
24 Vdc	ON for 14–27 Vac	OFF for < 5 Vac

Burden/Current Draw at Nominal DC Voltage:	2–6 mA (Except for 24 V, 8 mA)
Rated Insulation Voltage:	300 Vac
Rated Impulse Withstand Voltage (U_{imp}):	4000 V

Input Thermal Derating

SEL-2244-2 Digital Input Derating Curve

Control Outputs (SEL-2244-3 Standard Contacts)

Mechanical Durability

10 M no-load operations

DC Output Ratings

Rated Operational Voltage:	250 Vdc
Rated Voltage Range:	19.2–275 Vdc
Rated Insulation Voltage:	300 Vdc
Make:	30 A @ 250 Vdc per IEEE C37.90
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A 60 to 70°C
Thermal:	50 A for 1 s

Contact Protection:	350 Vdc, 145 J MOV protection across open contacts		
Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time ≤ 8 ms typical		
Breaking Capacity (10,000 Operations) Per IEC 60255-0-20:1974:	24 Vdc	0.75 A	L/R = 40 ms
	48 Vdc	0.50 A	L/R = 40 ms
	125 Vdc	0.30 A	L/R = 40 ms
	250 Vdc	0.20 A	L/R = 40 ms
Cyclic Capacity (2.5 Cycles/Second) Per IEC 60255-0-20:1974:	24 Vdc	0.75 A	L/R = 40 ms
	48 Vdc	0.50 A	L/R = 40 ms
	125 Vdc	0.30 A	L/R = 40 ms
	250 Vdc	0.20 A	L/R = 40 ms

AC Output Ratings

Rated Operational Voltage:	240 Vac
Rated Insulation Voltage (Excluding EN 61010-1):	300 Vac
Utilization Category:	AC-15 (control of electromagnetic loads > 72 VA)
Contact Rating Designation:	B300 (B = 5 A, 300 = rated insulation voltage)
Contact Protection:	250 Vac, 145 J
Continuous Carry:	3 A @ 120 Vac 1.5 A @ 240 Vac
Conventional Enclosed Thermal Current (I_{the}) Rating:	5 A
Rated Frequency:	50/60 ±5 Hz
Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time <8 ms typical
Electrical Durability Make VA Rating:	3600 VA, cosø = 0.3
Electrical Durability Break VA Rating:	360 VA, cosø = 0.3

Control Outputs (SEL-2244-5 Fast High-Current Contacts)

Mechanical Durability

10 M no-load operations

DC Output Ratings

Rated Operational Voltage:	250 Vdc
Rated Voltage Range:	19.2–275 Vdc
Rated Insulation Voltage:	300 Vdc
Make:	30 A @ 250 Vdc per IEEE C37.90
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A 60 to 70°C
Thermal:	50 A for 1 s
Contact Protection:	330 Vdc, 145 J MOV protection across open contacts
Operating Time (Coil Energization to Contact Closure, Resistive Load)	
Pickup Time:	≤12 µs at 250 Vdc, 16 µs at 125 Vdc, 65 µs at 19.2 Vdc typical (results with 100 kΩ resistive load)
Dropout Time:	≤8 ms typical

Inductive Breaking Capacity (10,000 Operations) Per IEC 60255-0-20:1974:	24 Vdc	10 A	L/R = 40 ms
	48 Vdc	10 A	L/R = 40 ms
	125 Vdc	10 A	L/R = 40 ms
	250 Vdc	10 A	L/R = 20 ms
Cyclic Capacity (4 Cycles/Second Followed by 2 Min Idle Thermal Dissipation) Per IEC 60255-0-20:1974:	24 Vdc	10 A	L/R = 40 ms
	48 Vdc	10 A	L/R = 40 ms
	125 Vdc	10 A	L/R = 40 ms
	250 Vdc	10 A	L/R = 20 ms

AC Output Ratings

Rated Operational Voltage:	110/120/220/240 Vac
Voltage Range:	19.2–250 Vac
Rated Insulation Voltage:	250 Vac
Make:	30 A @ 240 Vac
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A @ 60° to 70°C
Thermal:	50 A for 1 s
Contact Protection:	250 Vac, 145 J MOV protection across open contacts
Operating Time (Coil Energization to Contact Closure, Resistive Load)	
Pickup Time:	≤12 µs at 250 Vac, 16 µs at 125 Vac, 65 µs at 19.2 Vac typical (results with 100 kΩ resistive load)
Dropout Time:	≤8 ms typical

Note: Per IEC 60255-23:1994, using the simplified method of assessment.
Note: Make rating per IEEE C37.90-1989.

Fuse Rating	
Non-Serviceable:	4 A, 450 V, medium time lag M

DC Transducer (Analog) Inputs (SEL-2245-2)

Input Impedance

Current Mode:	200 Ω for ±20 mA 5000 Ω for ±2 mA
Voltage Mode:	10 MΩ

Input Range (Maximum)

±20 mA (transducers: 4–20 mA or 0–20 mA typical)
±2 mA (transducers: 0–1 mA or 0–2 mA typical)
±10 V (transducers: 0–5 V or 0–10 V typical)

Sampling Rate

1 ksps

Anti-Alias Filter

Corner Frequency:	330 Hz
Rolloff:	20 dBV per decade

Digital Filter

Corner Frequency:	Filter A: 16 Hz Filter B: 10 Hz Filter C: 0.2 Hz
50 Hz Rejection:	Filter A: > 30 dB Filter B: > 50 dB Filter C: > 70 dB
60 Hz Rejection:	Filter A: > 60 dB Filter B: > 70 dB Filter C: > 70 dB

Step Response

No Filter:	3 ms (10%–90% response)
Filter A:	23 ms (10%–90% response)
Filter B:	35 ms (10%–90% response)
Filter C:	700 ms (10%–90% response)

Common Mode Range

±35 Vdc between separate inputs
±250 Vdc all inputs to chassis

Isolation

500 Vac between inputs
2000 Vac all inputs to chassis

Accuracy at 25°C

ADC:	16 bit
Voltage Inputs (±10 V):	0.25% of full-scale typical 0.05% with field calibration 2% of full-scale maximum
High Current Inputs (±20 mA):	0.5% of full-scale typical 0.1% with field calibration 2% of full-scale maximum
Low Current Inputs (±2 mA):	0.5% of full-scale typical 0.1% with field calibration 4% of full-scale maximum

Accuracy Variation With Temperature

Inputs:	±0.015% per °C of full scale (±20 mA, ±2 mA, or ±10 V)
ADC:	±0.004% per °C

Triggered Waveform Recording

Sampling Rate:	1 kHz
Record Duration:	0.1 second increments from 0.5 s to 144 s
Record Pre-Trigger:	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

DC Analog Inputs Extended Range (SEL-2245-22 in DC Mode)

Input Impedance

>7 MΩ

Input Range (Maximum)

0–300 V

Sampling Rate

24 ksps

Anti-Alias Filter

Corner Frequency:	5 kHz
Rolloff:	20 dB per decade

Digital Filter

Corner Frequency:	Filter A: 16 Hz Filter B: 10 Hz Filter C: 0.2 Hz
50 Hz Rejection:	Filter A: > 30 dB Filter B: > 50 dB Filter C: > 70 dB
60 Hz Rejection:	Filter A: > 60 dB Filter B: > 70 dB Filter C: > 70 dB

Step Response

Group Delay (Pre-Filter):	5.3 ms
No Filter:	3 ms (10%–90% response)
Filter A:	23 ms (10%–90% response)
Filter B:	35 ms (10%–90% response)
Filter C:	700 ms (10%–90% response)

Common Mode Range

±250 Vdc between separate inputs
±250 Vac all inputs to chassis

Isolation

2500 Vrms between separate inputs
2500 Vrms all inputs to chassis

Accuracy at 25°C

ADC:	16 bit
Inputs:	0.25% of full scale typical 3% of full scale worst case

Accuracy Variation With Temperature (Inputs)

±0.015% per °C of full scale

Triggered Waveform Recording

Sampling Rate:	1, 2, 4, 8, 24 kHz
Record Duration:	0.1 second increments from 0.5 s to 144 s
Record Pre-Trigger:	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

DC Analog Outputs (SEL-2245-3)

Current Mode

Output Range:	–20.48 to +20.48 mA
Load Impedance:	0–750 Ω @ 20 mA, 100 µH

Voltage Mode

Output Range:	–10.24 to +10.24 volts
Load Impedance:	>2000 Ω, 1 µF

Step Response

1 ms (10%–90% response typical)

Isolation

2000 Vdc between outputs or ground

Accuracy at 25°C (Outputs)

Current Mode:	±0.3% of full-scale typical ±3% of full-scale worst case (average during an EMI event over a 1-second period)
Voltage Mode:	±0.2% of full-scale typical ±2% of full-scale worst case (average during an EMI event over a 1-second period)

Accuracy Variation With Temperature (Outputs)

±0.01% of full-scale/°K (current or voltage mode)

AC Metering Inputs (SEL-2245-4, SEL-2245-411, SEL-2245-221, and SEL-2245-22 Voltage Inputs in AC Mode)

Frequency:	50/60 Hz
Range:	45–65 Hz
Typical Accuracy	
SEL-2245-4 and SEL-2245-22:	±0.005 Hz above 20 V
SEL-2245-411 and SEL-2245-221:	±0.005 Hz above 500 mV
Worst-Case Accuracy	
SEL-2245-4 and SEL-2245-22:	±0.01 Hz above 20 V
SEL-2245-411 and SEL-2245-221:	±0.01 Hz above 500 mV
Phase Rotation:	ABC, ACB
Input Configuration:	3-Wire Delta, 4-Wire Wye
Update Interval	
Fundamental Metering:	200 Hz
RMS Metering:	5 Hz

Current Inputs Phase and Neutral

I_{NOM}:	1 A or 5 A (no setting required)
Measurement Range:	0.050–22 A Continuous 22–100 A Symmetrical for 25 s
Thermal Withstand Limit:	500 A for 1 s
Typical Accuracy:	±0.1% Fundamental @ f_{NOM} and > 0.6 A ±0.1% RMS @ f_{NOM} and > 0.6 A
Worst-Case Accuracy:	±2% ± 0.005 A Fundamental ±1% ± 0.005 A RMS
Angle	
Range:	±180°
Typical Accuracy:	±0.1° Fundamental @ f_{NOM} and > 0.6 A
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA @ I_{NOM}

Voltage Inputs (SEL-2245-4 and SEL-2245-22 in AC Mode)

V_{NOM}:	300 V
Measurement Range:	5–400 L-N, 9–693 L-L Vac Fundamental/RMS 5–300 L-N, 9–520 L-L Vac Fundamental/RMS (UL)
Maximum:	600 L-N, 1039 L-L Vac Fundamental/RMS for 10 s
Typical Accuracy:	±0.1% Fundamental @ f_{NOM} and > 20 V ±0.1% RMS@ f_{NOM}
Worst-Case Accuracy:	±2% Fundamental @ f_{NOM} ±1% RMS plus ±0.05 V
Angle	
Range:	±180°
Typical Accuracy:	±0.1° @ f_{NOM} and >20 V
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA

LEA Voltage Inputs (SEL-2245-411 and SEL-2245-221)

V_{NOM}:	1.5 V
Measurement Range:	30 Vac peak 0.05–22 Vac RMS
Maximum:	300 V_{L-N} RMS for 10 s (surge)
Typical Accuracy:	±0.1% RMS@ f_{NOM} and >50 mV ±0.1% Fundamental @ f_{NOM} and >50 mV
Worst-Case Accuracy:	±3% ±1 mV @ f_{NOM} Fundamental/RMS
Angle	
Range:	±180°
Typical Accuracy:	±0.1° @ f_{NOM} and > 50 mV
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA

Sequence Components (SEL-2245-4)

Values:	I0, I1, I2, V0, V1, V2
Typical Accuracy	
Magnitude:	±0.2% @ f_{NOM} and V > 6.7 V, I > 0.6 A
Angle:	±0.2° @ f_{NOM} and V > 6.7 V, I > 0.6 A
Worst-Case Accuracy	
Magnitude:	±3% @ f_{NOM} and V > 6.7 V, I > 0.6 A
Angle:	±0.2° @ f_{NOM} and V > 6.7 V, I > 0.6 A

Power and Power Factor Per Phase and Three-Phase (SEL-2245-4)

PA, PB, PC, 3P	
Typical Accuracy:	0.1% @ PF > 0.1
Worst-Case Accuracy:	2%
QA, QB, QC, 3Q	
Typical Accuracy:	0.1% @ PF < 0.9
Worst-Case Accuracy:	2%
SA, SB, SC, 3S	
Typical Accuracy:	0.1%
Worst-Case Accuracy:	2%
PFA, PFB, PFC, 3PF	
Typical Accuracy:	0.1% @ PF > 0.1
Worst-Case Accuracy:	2%

Power and Power Factor Per Phase and Three-Phase (SEL-2245-411)

PA, PB, PC, 3P	
Typical Accuracy:	0.1% @ PF ≥ 0.5
Worst-Case Accuracy:	2%
QA, QB, QC, 3Q	
Typical Accuracy:	0.1% @ PF ≤ 0.98
Worst-Case Accuracy:	2%
SA, SB, SC, 3S	
Typical Accuracy:	0.1%
Worst-Case Accuracy:	2%
PFA, PFB, PFC, 3PF	
Typical Accuracy:	0.1% @ Unity PF
Worst-Case Accuracy:	2%

Synchrophasor

Conformance:	IEEE C37.118.1-2011 as amended by IEEE C37.118.1a-2014 IEEE C37.118.2-2011
Accuracy:	Level 1 as specified by IEEE C37.118
Measurements:	Software selectable (P or M class)
Voltage:	VA, VB, VC, VS
Current:	IA, IB, IC, IN
Positive-Sequence:	V1, I1
Periodic:	Frequency and df/dt
Processing Rate:	120 Hz
Frequency Resolution:	±1.25 mHz*
Calculated Power Resolution:	±0.1%*

* Resolution values tested on SEL-2245-4 with 69 V voltage inputs, 0.6 A to 1 A current inputs, and 49.5 to 50.5 Hz frequency range.

Message Rates (60 Hz nominal):	1, 2, 4, 5, 10, 12, 15, 20, 30, 60, and 120* (messages/second)
Message Rates (50 Hz nominal):	1, 2, 5, 10, 25, 50, and 100* (messages/second)

* This message rate is only supported on the SEL-2245-4 and SEL-2245-411 Axion modules. Message rates are supported on the SEL-3350, SEL-3555, and SEL-3560.

Triggered Waveform Recording (SEL-2245-4, SEL-2245-411, SEL-2245-22, and SEL-2245-221)

Sampling Rates:	1, 2, 4, 8, 24 kHz software selectable
Record Duration:	0.1 second increments from 0.5 s to specified maximum for each sample rate.
Maximum Record Duration:	6 s @ 24 kHz 18 s @ 8 kHz 36 s @ 4 kHz 72 s @ 2 kHz 144 s @ 1 kHz
Record Pre-Trigger:	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

AC Protection Inputs (SEL-2245-42)

Frequency

Rated:	50/60 Hz
Range:	40–90 Hz
Typical Accuracy:	±0.005 Hz above 20 V
Worst-Case Accuracy:	±0.01 Hz above 20 V (±0.1 Hz for < 2.5 cycles during transients)

Phase Rotation

ABC, ACB

Input Configuration

3-Wire Delta, 4-Wire Wye

Update Interval

Fundamental Metering:	250 Hz
RMS Metering:	250 Hz
RMS Window Size:	1 cycle

AC Current Channels

Nominal Current:	1 A_{RMS} or 5 A_{RMS} (no setting required)
Current Range Rating (With DC Offset at X/R = 10, 1.5 Cycles):	0.1–91 A
Operational Range:	0.1–300 A_{RMS}
Measurement Range:	0.1–20 A_{RMS}
Thermal Withstand Limit:	15 A_{RMS} continuous 500 A_{RMS} for one second

Fundamental Measurement Accuracy

Magnitude:	±0.1%, typical, ±0.001 A ±2%, worst case, ±0.001 A
Phase:	±0.1°, typical at f_{NOM} and current > 0.4 A ±1°, over full rated temperature range ±2°, worst case

RMS Measurement Accuracy

Magnitude:	±0.1%, typical, ±0.001 A ±2%, worst case, ±0.001 A
Burden:	<0.1 VA

AC Voltage Channels

Rated Range:	67–240 V_{L-N}

Note: Rated Range refers to the IEEE C37.118 rating system.

Operational Range:	0–300 V_{L-N}
Accuracy Range:	6.7–300 V_{L-N}
Rated Insulation Voltage:	300 V_{L-N} continuous 600 V_{L-N} for ten seconds

Isolation (Galvanic Isolated Channels)

Channel-to-Ground:	2.5 kV_{RMS} for one minute
Channel-to-Channel:	2.5 kV_{RMS} for one minute

Fundamental Measurement Accuracy

Magnitude:	±0.1%, typical, plus ±0.05 V ±3%, worst case, plus ±0.05 V
Phase:	±0.1° @ f_{NOM}, typical ±1° @ f_{NOM}, over full rated temperature range ±2° @ f_{NOM}, worst case

RMS Measurement Accuracy

Magnitude:	±0.1%, typical, plus ±0.05 V ±3%, worst case, plus ±0.05 V
Burden:	<0.01 VA @ 67 V Impedance >500 kΩ

Sequence Components

Values:	I0, I1, I2, V0, V1, V2

Note: Sequence components are of the fundamental frequency.

Accuracy

Magnitude:	±1%, typical
Angle:	±0.5°, typical

Power and Power Factor (Per-Phase and Three-Phase)

Values:	PA, PB, PC, PAB, PBC, PCA QA, QB, QC, QAB, QAC, QCA SA, SB, SC, SAB, SBC, SCA PFA, PFB, PFC, P3, Q3, S3, PF3
Accuracy:	±1%, typical

THD and Noise (Accuracy)

±5% of measurement plus ±0.25%

Synchrophasors

Conformance:	IEEE C37.118.1-2011 as amended by IEEE C37.118.1a-2014 IEEE C37.118.2-2011
Accuracy:	Level 1 as specified by IEEE C37.118
Measurements:	Software selectable (P or M Class)
Voltage:	VA, VB, VC
Current:	IA, IB, IC
Positive-Sequence:	V1, I1
Periodic:	Frequency and df/dt
Processing Rate:	120 Hz
Frequency Resolution:	±1.25 mHz*
Calculated Power Resolution:	±0.1%*

* Resolution values tested with 69 V voltage inputs, 0.6 A to 1 A current inputs, and 49.5 to 50.5 Hz frequency range.

Message Rates (60 Hz nominal):	1, 2, 4, 5, 10, 12, 15, 20, 30, 60, and 120* (messages/second)
Message Rates (50 Hz nominal):	1, 2, 5, 10, 25, 50, and 100* (messages/second)

* Message rates are supported on the SEL-3350, SEL-3555, and SEL-3560.

Triggered Waveform Recording

Sampling Rates:	1, 2, 4, 8, 24 kHz software selectable

Transient Fault Record Length

Individual Records as Long as:	24 s for 24 kHz 72 s for 8 kHz 144 s for 4 kHz 288 s for 2 kHz 576 s for 1 kHz
Pre-Fault Time:	0.05 s to (max. event length – 0.05 s)
Data Format:	IEEE C37.111-2013 COMTRADE
File Naming:	IEEE C37.232 COMNAME

Fuse Rating

Non-Serviceable:	2.5 A, 125 V, time lag T

Technical Support

We appreciate your interest in SEL products and services. If you have questions or comments, please contact us at:

Preface

Safety Information

⚠CAUTION
To ensure proper safety and operation, the equipment ratings, installation instructions, and operating instructions must be checked before commissioning or maintenance of the equipment. The integrity of any protective conductor connection must be checked before carrying out any other actions. It is the responsibility of the user to ensure that the equipment is installed, operated, and used for its intended function in the manner specified in this manual. If misused, any safety protection provided by the equipment may be impaired.

Dangers, Warnings, and Cautions

This manual uses three kinds of hazard statements, defined as follows:

⚠DANGER
Indicates a potentially hazardous situation that, if not avoided, **will** result in death or serious injury.

⚠WARNING
Indicates a potentially hazardous situation that, if not avoided, **could** result in death or serious injury.

⚠CAUTION
Indicates a potentially hazardous situation that, if not avoided, **may** result in minor or moderate injury or equipment damage.

Safety Symbols

The following symbols are often marked on SEL products.

	**⚠CAUTION** Refer to accompanying documents.	**⚠ATTENTION** Se reporter à la documentation.
	Earth (ground)	Terre
	Protective earth (ground)	Terre de protection
	Direct current	Courant continu
	Alternating current	Courant alternatif

	Both direct and alternating current	Courant continu et alternatif
	Instruction manual	Manuel d'instructions

Safety Marks

The following statements apply to this device.

Table 1 General Safety Marks

⚠CAUTION There is danger of explosion if the battery is incorrectly replaced. Replace only with Rayovac no. BR1632 or equivalent recommended by manufacturer. See Owner's Manual for safety instructions. The battery used in this device may present a fire or chemical burn hazard if mistreated. Do not recharge, disassemble, heat above 100°C or incinerate. Dispose of used batteries according to the manufacturer's instructions. Keep battery out of reach of children.	**⚠ATTENTION** Une pile remplacée incorrectement pose des risques d'explosion. Remplacez seulement avec un Rayovac no BR1632 ou un produit équivalent recommandé par le fabricant. Voir le guide d'utilisateur pour les instructions de sécurité. La pile utilisée dans cet appareil peut présenter un risque d'incendie ou de brûlure chimique si vous en faites mauvais usage. Ne pas recharger, démonter, chauffer à plus de 100°C ou incinérer. Éliminez les vieilles piles suivant les instructions du fabricant. Gardez la pile hors de la portée des enfants.
⚠CAUTION Use supply wires suitable for 60°C (140°F) above ambient.	**⚠ATTENTION** Utilisez des fils d'alimentation appropriés pour 60°C (140°F) au-dessus ambiante.
For use in Pollution Degree 2 environment.	Pour l'utilisation dans un environnement de Degré de Pollution 2.
Ambient air temperature shall not exceed 40°C (104°F).	La température de l'air ambiant ne doit pas dépasser 40°C (104°F).
Terminal Ratings Tightening Torque I/O and Power Terminal Blocks: 0.6 to 0.8 Nm (5 to 7 in-lb) Serial Ports: 0.6 to 0.8 Nm (5 to 7 in-lb) CT Terminal Blocks: 1.0 to 2.0 Nm (9 to 18 in-lb) Wire Type: Copper or Aluminum	Spécifications des bornes Couple de serrage Borniers d'entrée/sortie et de puissance: 0,6 à 0,8 Nm (5 à 7 livres-pouce) Ports série: 0,6 à 0,8 Nm (5 à 7 livres-pouce) CT borniers: 1,0 à 2,0 Nm (9 à 18 livres-pouce) Type de fil : cuivre ou aluminium

Table 2 Other Safety Marks

⚠DANGER Contact with instrument terminals can cause electrical shock that can result in injury or death.	**⚠DANGER** Tout contact avec les bornes de l'appareil peut causer un choc électrique pouvant entraîner des blessures ou la mort.
⚠DANGER Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.	**⚠DANGER** Débrancher tous les raccordements externes avant d'ouvrir cet appareil. Tout contact avec des tensions ou courants internes à l'appareil peut causer un choc électrique pouvant entraîner des blessures ou la mort.
⚠WARNING Use of this equipment in a manner other than specified in this manual can impair operator safety safeguards provided by this equipment.	**⚠AVERTISSEMENT** L'utilisation de cet appareil suivant des procédures différentes de celles indiquées dans ce manuel peut désarmer les dispositifs de protection d'opérateur normalement actifs sur cet équipement.

⚠ WARNING Have only qualified personnel service this equipment. If you are not qualified to service this equipment, you can injure yourself or others, or cause equipment damage.	**⚠ AVERTISSEMENT** Seules des personnes qualifiées peuvent travailler sur cet appareil. Si vous n'êtes pas qualifiés pour ce travail, vous pourriez vous blesser avec d'autres personnes ou endommager l'équipement.
⚠ WARNING Segregation between Class 1 (field, factory wiring, terminal, and uninsulated live parts) and Class 2 and Class 3 (wiring and uninsulated live parts) must be provided in the installation. Segregate by 1) using any combination of clamping, routing, or equivalent wire management method with a minimum of 6.0 mm of separation, 2) using insulation rated for the highest voltage on both wires and cables, or 3) adding an additional sleeving rated for the highest voltage on the Class 2 or Class 3 wiring (completely covering the wiring, end to end). Wiring class is defined per NFPA 70.	**⚠ AVERTISSEMENT** La ségrégation entre la classe 1 (sur site, câblage d'usine, borne et pièces sous tension non isolées) et les classes 2 et 3 (câblage et pièces sous tension non isolées) doit être fournie avec l'installation. Séparer par 1) en utilisant toute combinaison de méthode de serrage, d'achemi-nement ou de gestion des câbles équivalente avec un minimum de 6,0 mm de séparation, 2) en utilisant une isolation évaluée pour la ten-sion la plus élevée sur les fils et les câbles, ou 3) en ajoutant une gaine supplémentaire évaluée pour la tension la plus élevée sur le câblage de classe 2 ou de classe 3 (couvrant complètement le câblage, bout à bout). La classe de câblage est définie par NFPA 70.
⚠ CAUTION Equipment components are sensitive to electrostatic discharge (ESD). Undetectable permanent damage can result if you do not use proper ESD procedures. Ground yourself, your work surface, and this equipment before removing any cover from this equipment. If your facility is not equipped to work with these components, contact SEL about returning this device and related SEL equipment for service.	**⚠ ATTENTION** Les composants de cet équipement sont sensibles aux décharges électrostatiques (DES). Des dommages permanents non-décelables peuvent résulter de l'absence de précautions contre les DES. Raccordez-vous correctement à la terre, ainsi que la surface de travail et l'appareil avant d'en retirer un panneau. Si vous n'êtes pas équipés pour travailler avec ce type de composants, contacter SEL afin de retourner l'appareil pour un service en usine.
⚠ CAUTION The relay contains devices sensitive to Electrostatic Discharge (ESD). When working on the relay with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.	**⚠ ATTENTION** Le relais contient des pièces sensibles aux décharges électrostatiques. Quand on travaille sur le relais avec les panneaux avant ou du dessus enlevés, toutes les surfaces et le personnel doivent être mis à la terre convenablement pour éviter les dommages à l'équipement.
⚠ CAUTION Looking into optical connections, fiber ends, or bulkhead connections can result in hazardous radiation exposure.	**⚠ ATTENTION** Regarder vers les connecteurs optiques, les extrémités des fibres oules connecteurs de cloison peut entraîner une exposition à des rayonnements dangereux.
⚠ CAUTION Use extreme caution when changing POU settings. Contact an SEL representative for assistance.	**⚠ ATTENTION** Veuillez faire preuve d'une extrême prudence quand vous changez les réglages POU. Contactez un représentant de SEL pour de l'aide.

General Information

Environmental Conditions and Voltage Information

The following table lists important environmental and voltage information.

Condition	Range/Description
Indoor/outdoor use	Indoor
Altitude	As high as 2000 m
Relative humidity	5% to 95%

Condition	Range/Description
Overvoltage	Category II
Pollution	Degree 2
Vibration, earth tremors	Class 1
Atmospheric pressure	80 to 110 kPa

NOTE
For applications compliant with IEC-60255-27, surface-mount units must be installed in IP4X enclosures.

Laser/LED Emitter

The SEL-2240 is a Class 1 LED Product and complies with IEC 60825-1:1993 + A1:1997 + A2:2001.

The following table shows LED information specific to the SEL-2240 for **ETH 1** and **ETH 2**, the ports that optionally use LED transmitters.

Table 3 SEL-2241 and SEL-2243 LED Information

Item	Detail
Mode	Multimode (62.5 µm fiber)
Wavelength	1300 nm
Source	LED
Connector type	LC
Output power	–14 to –19 dBm

Safety Warnings and Precautions

⚠CAUTION
Use of controls or adjustments, or performance of procedures other than those specified herein, may result in hazardous radiation exposure.

- Do not look into the end of an optical cable connected to an optical output.
- Do not look into the fiber ports/connectors.
- Do not perform any procedures or adjustments that are not described in this manual.
- During installation, maintenance, or testing of the optical ports only use test equipment classified as Class 1 laser products.
- Incorporated components such as transceivers and laser/LED emitters are not user serviceable. Units must be returned to SEL for repair or replacement.

Instructions for Cleaning and Decontamination

Use care when cleaning the SEL-2240. Use a mild soap or detergent solution and a damp cloth to clean the chassis. Clean the touchscreen display gently with a moist cotton cloth. Do not use abrasive materials, polishing compounds, or harsh chemical solvents (such as xylene or acetone) on any surface.

SECTION 1

Introduction and Specifications

Overview

The SEL-2240 Axion® is a fully integrated modular input and output (I/O) and control solution suitable for many utility and industrial applications. It combines the communications, built-in security, and IEC 61131 logic engine of the SEL Real-Time Automation Controller (RTAC) family with a durable suite of I/O modules that provide high-speed, deterministic, control performance over an Ethernet network. An Axion node consists of a 10-slot, 4-slot, or dual 4-slot chassis configurable to contain a CPU, one or two power supplies (called SEL-2243 Power Couplers), and as many as nine I/O modules. Power couplers operate in a fully redundant, load-sharing fashion. A single coupler module can accommodate the entire node for those applications that do not need redundant supplies.

Figure 1.1 Rear and Front Panels

For bay control applications, the optional 7-inch color touchscreen display (available on the 10-slot backplane only) provides a one-line diagram mimic display for comprehensive bay control and monitoring. Use this interface to operate breakers or switches and access Sequence of Events (SOE) logs, device information, module statuses, and more.

The SEL-2240 is designed to be easily scalable for larger projects. You can expand the system by connecting multiple nodes via Ethernet. EtherCAT® protocol creates a virtual Ethernet backplane between the I/O nodes without any loss of speed or determinism. Only a single central processing unit (CPU) module is necessary, even for a multinode network. Optionally, employ fiberoptic Ethernet cables between nodes to ensure excellent electrical isolation and enable greater distances between nodes. The CPU within the RTAC includes secure communications and user administration, advanced data concentration, high-speed logic processing, flexible engineering access, and protocol conversion capabilities between multiple built-in client/server protocols. The Axion gives an integrator the necessary tools to easily integrate and concentrate information from a wide variety of local I/O, remote I/O, and microprocessor-based devices in today's substations and plants. With the intuitive software in the device, you can quickly configure large automated systems.

Functional Concept

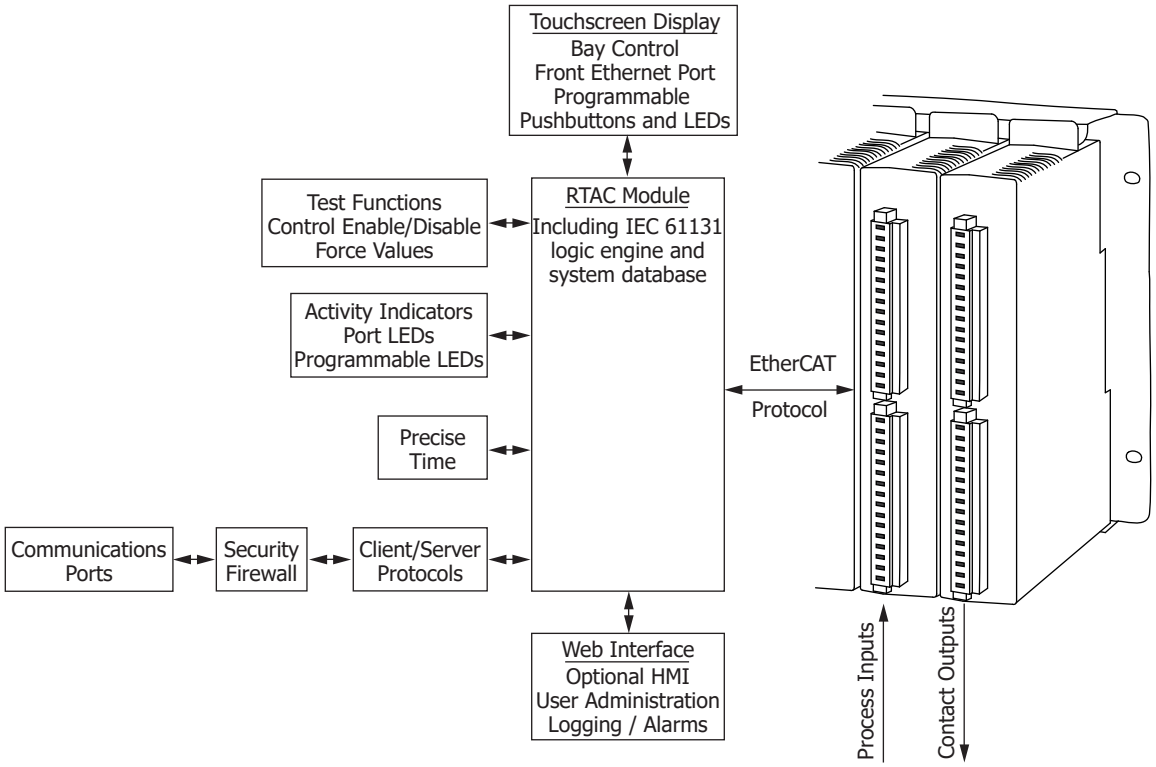

Figure 1.2 Functional Design Concept

Key Attributes

Today's monitoring and control applications need flexible system architectures and integrated security. The Axion meets these needs by using SEL RTAC modules as the system CPU. Two configurations are possible. There can be an SEL-2241 RTAC module installed directly in the Axion node, or there can be a standalone SEL-3530 or SEL-3555 RTAC installed separately from the node.

SEL designs all SEL-2240 hardware to published standards (see *Specifications on page 40*) and performs tests to verify that each component exceeds standards by adequate margins. The Power Coupler module (model SEL-2243) is a highly reliable device that uses the same power supply technology presently in use in SEL protective relays. You can also configure any node with redundant power couplers for critical applications needing redundant supplies. In such configurations, the SEL-2243 modules actively share loads to supply power needs for the entire node. If one module should become unavailable, the remaining power coupler can accommodate the entire node with no loss of system capability.

Each SEL-2240 node is mounted in a chassis/backplane (model SEL-2242) that provides a means for each node to include a custom configuration of I/O modules. A single node can contain as many as nine I/O modules. Within a node, use any combination, quantity, and sequence of I/O modules that suits the application. The node does not need to be entirely full to function properly. Leave empty slots for future expansion as necessary.

Many RTU and control installation systems need more I/O points than will fit in a single node. In those cases, connect multiple nodes together via a real-time Ethernet network by using the EtherCAT protocol (see *Section 2: Communications* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual*). Through use of the Axion EtherCAT implementation, you can connect as many as 60 modules in a single network with no loss of speed or determinism. A single RTAC module provides logic functions and data concentration for the entire network.

Features

Physical

Table 1.1 Module Features

SEL-2240 Including Modules	
Height	5 rack units (22.15 cm (8.72 in))
Width	48.26 cm (19 in)
Depth	17.53 cm (6.9 in)
Weight	7.26 kg (16 lb)
Mounting	Surface mounting for control panels Rack mounting for relay panel or swing panels Panel mounting (10-slot and dual 4-slot)
SEL-2241 RTAC Module	
Ethernet	2 RJ45 ports (LC fiber multimode or single-mode option)
Host USB	1
EIA-232/EIA-422/EIA-485 Serial	4 (DB-9) ports
IRIG-B Input	1 (BNC) for modulated or demodulated IRIG-B
IRIG-B Output	1 (BNC) for demodulated IRIG-B
Digital Outputs	1 electromechanical, Form C

SEL-2242 Backplane	
The SEL-2242 backplane with touchscreen display is only compatible with SEL-2241 RTACs that ship with R149 firmware or later.	
Front Panel	Standard: **LAMP TEST** button and module status LEDs, includes standard overlay Bay Control: 7-inch touchscreen display, 6 programmable pushbuttons, and 19 LEDs (optional add-on, available with 10-slot, rack-mount model)
Ethernet	One RJ45 port for Engineering Access (included with touchscreen display)
SEL-2243 Power Coupler Module	
Ethernet	2 RJ45 ports (LC fiber multimode or single-mode option)
Incoming Power (High-Voltage Model)	120/240 Vac, 50/60 Hz, 125/250 Vdc
Incoming Power (Low-Voltage Model)	24/48 Vdc
SEL-2244-2 Digital Input Module	
Inputs	6 independent, eighteen common-return
Input Voltage (AC or DC)	24 V, 48 V, 110 V, 125 V, 220 V, 250 V
SEL-2244-3 Digital Output Module	
Outputs	16
Type	Form A or Form B
SEL-2244-5 Fast High-Current Digital Output Module	
Outputs	10
Type	Form A or Form B
SEL-2245-2 DC Analog Input Module	
Inputs	16
Input Range (DC)	±20 mA, ±2 mA, ±10 V
SEL-2245-22 DC Analog Input Extended Range Module	
Inputs	4
Input Range (DC)	0–300 V
SEL-2245-3 DC Analog Output Module	
Outputs	8
Output Range (DC)	±20 mA, ±10 V
SEL-2245-4 AC Metering Module	
Inputs	4 CT/4 PT
Input Range	0–22 A / 5–400 Vac: 45–65 Hz

SEL-2245-411 Standard Current and Low-Voltage (LEA) Monitoring Module	
Inputs	4 CT/4 LEA
Input Range	0–22 A / 0.05–30 Vac: 45–65 Hz
SEL-2245-221 Low-Voltage (LEA) Monitoring Module	
Inputs	4 LEA
Input Range	0.05–30 Vac: 45–65 Hz
SEL-2245-42 AC Protection Module	
Inputs	3 CT/3 PT
Input Range	0–20 A / 0–300 Vac: 40–70 Hz

Processing System

These features will be present for use of the SEL-2241 RTAC Module, SEL-3530 RTAC, or SEL-3555 RTAC.

Embedded Real-Time Operating System
The embedded SEL Linux® operating system provides exceptional speed, flexibility, and functionality along with increased security.
Watchdog Timer
A separate watchdog microcontroller system provides an extra level of computer system reliability. The microcontroller will activate an alarm and halt all input/output activity if there is a problem with the IEC 61131 logic engine.
Diagnostics and Logging
Manage users, view logs, and check report diagnostics via the built-in web server. Access the historical database for diagnostics and logging. Use open database connectivity (ODBC) to view security and diagnostics logs in off-the-shelf ODBC-compliant programs.

HMI

Use ACSELERATOR Diagram Builder SEL-5035 Software to build HMI diagrams and load the pages into the RTAC for the optional web-based HMI. Use the HMI pages for annunciation, one-line diagrams, trending, and controls. Because the HMI is web-based, no software is needed besides a web browser. View the HMI through a web browser on a remote computer.

The RTAC detects which web browser is being used for viewing the HMI and renders the images by using either HTML5 or Microsoft Silverlight technology, which is a browser plug-in used for graphical web content display. See *Table 1.2* for further requirements for viewing the HMI on a remote PC.

Table 1.2 HMI Browser Requirements

Requirement	HTML5	Silverlight
Operating System	Windows 7 SP1 Ubuntu 14.04+	Windows 7 SP1
Processor	Intel Core Duo 2 GHz or higher processor	Intel Core Duo 2 GHz or higher processor

Requirement	HTML5	Silverlight
RAM	2 GB or greater	2 GB or greater
Web Browser	Google Chrome 40+ Opera 27+	Internet Explorer 8, 9, 11[a] Google Chrome 34+ Mozilla Firefox 35+

[a] Required Silverlight plug-in version is 5.1.30514.0.

Automation and Control

These features will be present for use of the SEL-2241 RTAC Module, SEL-3530 RTAC, or SEL-3555 RTAC.

Industry Standard (IEC 61131) Logic Processing

The RTAC includes the IEC 61131 programming environment with standard, custom, and Ethernet libraries for logic processing and scaling of collected data. Two configurable processing cycles give flexibility to run high-speed automation tasks at speeds as fast as one millisecond while SCADA and other lower-speed tasks can run at a slower rate.

Data Concentration and Protocol Conversion

Collect I/O and IED data from attached devices and store these data locally. Integrate with SCADA, HMI, and other SEL-2240 systems via popular industry-standard and SEL protocols, such as MIRRORED BITS communications, Modbus RTU, Modbus TCP, IEC 61850 GOOSE, IEC 61850 MMS client/server, LG 8979 client/server, SES-92 server, IEC 60870-5 101/104 client/server, EtherCAT fieldbus, DNP3 Level 3 Serial client/server, DNP3 LAN/WAN client/server, IEEE C37.118 client/server, CP2179 client, and SNMP client.

System Configuration and Maintenance

Configure the RTAC network interface, user account, and security settings over the network via the web interface. Configure I/O networks and protocol communications, program IEC 61131 logic, and send project settings with ACSELERATOR RTAC SEL-5033 Software. After sending project settings, view and force data values to test user logic and data-mapping schemes. Create as many as 25 custom bay screen and modify settings for the 7-inch, color touchscreen display by using the embedded Bay Screen Builder application in ACSELERATOR RTAC.

System Security

These features will be present for use of the SEL-2241 RTAC Module, SEL-3530 RTAC, or SEL-3555 RTAC.

Malware Protection

exe-GUARD® anti-malware technology protects the RTAC in two ways:

1. Only authorized tasks are allowed to run on the system.
2. Mandatory Access Control restricts privileges of programs and services to the absolute minimum required to function on the system.

There is no need for virus definition files because only whitelisted or preapproved tasks are allowed to run on the RTAC. SEL Whitelist operates at the core of the RTAC operating system, where it intercepts every program before it is executed. Using advanced cryptographic algorithms, Whitelist inspects a program's binary image before it is allowed to execute, verifying its legitimacy and integrity against a known digital signature. As defined by user configuration, unauthorized changes to the system result in either an alarm indication or device reset to factory defaults. Similarly, any modification or replacement of an existing firmware binary is also revealed by the digital signature verification process and results in the same denial of execution and security response.
Mandatory Access Control fine-tunes the system security policy so that programs and services are constrained to the absolute minimum access privileges required to function. Defining this minimal privilege set at design time ensures firmware processes can be locked to their minimal scope of influence in the system.

User Account Management

Each user account has a unique username, password, and assigned permissions. You can configure accounts to use LDAP central authentication for user account management.

Logging and Auditing

Logged tag values and system events provide a system-wide Sequential Events Recorder report. View the logs online or use ODBC connectivity to download them to a central database.

Time Synchronization

These features will be present for use of the SEL-2241 RTAC Module, SEL-3530 RTAC, or SEL-3555 RTAC.

Time Synchronization for Connected Devices

The RTAC provides a modulated or demodulated coaxial IRIG-B output signal. The RTAC also provides a demodulated IRIG-B output signal to connected intelligent electronic devices (IEDs) via all EIA-232/EIA-422/EIA-485 ports. The RTAC also includes an NTP and SNTP server function for compatible Ethernet devices.

IRIG-B Generation

In the absence of an external IRIG-B signal, the RTAC generates a demodulated IRIG-B signal. If necessary, you can synchronize the system clock with a network time server (via SNTP, NTP, or PTP).

Communications Protocols

These features will be present for use of the SEL-2241 RTAC Module, SEL-3530 RTAC, or SEL-3555 RTAC.

Table 1.3 Communications Protocols

SEL Protocols	Connection	Serial	Ethernet
Encrypted Engineering Access	Pass-Through	Yes[a]	Yes
Transparent Connections	Pass-Through	Yes	Yes
SEL Fast Meter	Client	Yes	Tunneled Serial
SEL Fast Message	Client/Server	Yes	Tunneled Serial
SEL Compressed ASCII	Client	Yes	Tunneled Serial
SEL MIRRORED BITScommunications	Peer-to-Peer	Yes	

SEL Protocols	Connection	Serial	Ethernet
Industry Protocols	Connection	Serial	Ethernet
DNP3	Client/Server	Yes	Yes
Telnet	Server		Yes
FTP	Client		Yes
Modbus	Client/Server	Yes (RTU)	Yes
IEEE C37.118 Synchrophasors	Client/Server	Yes	Yes
IEC 61850 GOOSE	Peer-to-Peer		Yes
IEC 61850 MMS	Client/Server		Yes
EtherCAT	Client		Yes (Non-routable)
LG 8979	Client/Server		Tunneled Serial
SES-92	Server	Yes	Tunneled Serial
CP2179	Client	Yes	Tunneled Serial
IEC 60870-5-101 Server	Client/Server	Yes	Tunneled Serial
IEC 60870-5-104 Server	Client/Server		Yes
SNMP	Client		Yes
File Transfer Protocol	Server		Yes

[a] Using an accessory SEL encrypting transceiver module.

Models, Options, and Accessories

Models

This manual does not provide complete ordering information. For complete information, see the latest model option tables (MOT) at selinc.com/products/2240, and select Online Product Configuration under Ordering Information. The following modules comprise an SEL-2240 system.

Table 1.4 SEL-2240 Models

Part Number	Description
SEL-2241	Real-Time Automation Controller (RTAC)
SEL-2242	Chassis/Backplane
SEL-2243	Power Coupler
SEL-2244	Digital Input and Output Modules
SEL-2245	Analog Input and Output Modules

See *Section 2: Communications* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for options for each module.

Options

The 10-slot SEL-2242 Chassis/Backplane includes three slots (Slot **A**, Slot **B**, and Slot **C**) that are wider than the rest, to accommodate the SEL-2241 RTAC and SEL-2243 Power Coupler. Slots **B** and **C** can also accommodate an SEL-2244 module. Slots **D**–**J** will only accept SEL-2244 modules (See *Section 2: Communications* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual*). You can configure the 10-slot SEL-2242 with an optional LCD touchscreen for certain applications. When configured with an LCD, only rack-mount configurations are supported, and an SEL-2241 must be installed in Slot **A** for proper operation. The 4-slot SEL-2242 Chassis/Backplane contains only wider slots to accept any of the SEL-2240 modules. This allows redundant power coupler and redundant RTAC configurations or smaller I/O configurations. There is no requirement that you install a predefined sequence or number of I/O modules in a node. You can, for instance, install modules to group together all inputs and outputs associated with a certain apparatus. Another method would be to install modules so that all inputs of a given voltage are together. Install modules in each node consecutively, starting in Slot **A**. All empty slots must be to the right of the last module in the node. Refer to *Table 1.5* through *Table 1.9* for a summary of ordering options available for Axion modules.

Table 1.5 Slot Allocation Guidelines

Slot	Description
A	SEL-2241 RTAC (required for 10-slot SEL-2242 with optional touchscreen) SEL-2243 Power Coupler (when using standalone RTAC or multinode system)
B	SEL-2243 Power Coupler SEL-2244 I/O Modules SEL-2245 I/O Modules
C	SEL-2243 Power Coupler SEL-2244 I/O Modules SEL-2245 I/O Modules
D–J	SEL-2244 I/O Modules SEL-2245 I/O Modules

Table 1.6 SEL-2241 RTAC

Communications Options (Ethernet)
2 Ethernet ports, 10/100BASE-T copper Ethernet ports (standard)
2 Ethernet ports, 100BASE-FX or 100BASE-LX fiber-optic Ethernet ports
Applications and Protocols

DC Analog Inputs
16 dc analog inputs. Range options:
±20 mA
±2 mA
±10 V

DC Analog Inputs Extended Range
4 dc analog inputs. Range options:
0–300 V
AC Analog Inputs
4 CT/4 PT ac metering inputs. Range Options:
PT inputs 5–400 V CT inputs 0–22 A
4 CT/4 LEA standard current and low-voltage (LEA) inputs. Range Options:
LEA inputs 0.05–30 V peak CT inputs 0–22 A
3 CT/3 PT ac protection inputs. Range Options:
PT inputs 0–300 V CT inputs 0–20 A
Outputs
DC Analog Outputs
8 dc analog outputs. Range options:
±20 mA
±10 V
Environment
Conformal coating for chemically harsh and high-moisture environments

Accessories

For all SEL-2240 mounting and other accessories, visit selinc.com/products/accessories. Contact your Technical Service Center or the SEL factory for additional details and ordering information for all other accessories.

Table 1.11 Optional Accessories

Product	Description
SEL-2401	Precise Timing Source—Satellite-Synchronized Clock
SEL-3610	Expansion Serial Ports—Port Server
SEL-3620	Secure Communications—Ethernet Security Gateway
SEL-3010	Automatic Voice Notification—Event Messenger
SEL-3025	Secure Communications—Serial Shield
SEL-2925	BLUETOOTH Serial Adapter
SEL-3031	Radio Communications—Serial Radio Transceiver
SEL-2810	200 µm Fiber-Optic Transceiver With IRIG-B
SEL-2812	Multimode Fiber-Optic Transceiver With IRIG-B
SEL-2814	Multimode Fiber-Optic Transceiver With Hardware Handshaking
SEL-2815	Multimode Fiber-Optic Transceiver—15 km
SEL-2829	Single-Mode Fiber-Optic Transceiver—23 km
SEL-2830	Single-Mode Fiber-Optic Transceiver—80 km

Product	Description
SEL-2831	Single-Mode Fiber-Optic Transceiver—110 km
915900240	SEL-2244 Wetting Voltage Jumper Kit, 24 4-Prong Jumpers, 2 Jumpers per DI Module, Four per DO Module
915900241	Wetting Voltage Jumpers Bulk, 100 pack 4-Prong Jumpers
91590185	32 conductor panel wiring harness (16 AWG/1.3 mm^2) with pre-terminated SEL-2244 connectors on one end and partially stripped wires on the other—8 ft
91590186	32 conductor panel wiring harness (16 AWG/1.3 mm^2) with pre-terminated SEL-2244 connectors on one end and partially stripped wires on the other—12 ft
91590187	32 conductor panel wiring harness (16 AWG/1.3 mm^2) with pre-terminated SEL-2244 connectors on one end and partially stripped wires on the other—20 ft

Applications

The SEL-2240 Axion provides a robust automation platform capable of using IEC 61131 programming to perform a vast range of automated tasks. Implement programs in Structured Text, Function Block, or Ladder Logic to meet any logic requirements. Use the backplane I/O modules to acquire data or gather information securely from virtually any intelligent electronic device (IED) with the wide variety of protocols built into the RTAC. Use the optional web-based human-machine interface (HMI) on the RTAC to combine traditional remote terminal units (RTUs) and HMIs in the same platform.

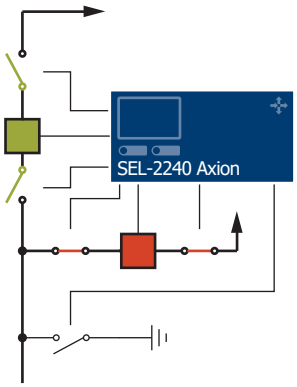
SEL-2240 Applications

- Bay Control
- Remote Terminal Unit (RTU)
- SCADA Data Concentrator
- Human-Machine Interface (HMI)
- Remote I/O
- Programmable Logic/Automation Controller (PLC/PAC)
- GOOSE Integration
- Synchrophasor Processor
- Intelligent Port Switch
- Network Gateway
- Protocol Gateway
- Time-Synchronization Source
- Security Gateway

Bay Control

The SEL-2240 Axion Bay Controller combines modular I/O cards, advanced automation, a powerful logic engine, current and voltage measurement, a flexible color touchscreen HMI, and advanced communications protocols to provide comprehensive monitoring and reliable control for your bay control application. Choose from a variety of digital and analog modules to fit your application requirements. The advanced automation capability, combined with the diversity and flexibility of I/O modules, allows you to implement any blocking or interlocking scheme required by the switching devices in your substation. Use the Axion Controller as an economical yet powerful alternative for monitoring and controlling one or more substation bays at the transmission or distribution level. Configure custom screens by using the Bay Screen Builder application in ACSELERATOR RTAC (see *Section 6: Bay Screen and Touchscreen Display* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual*).

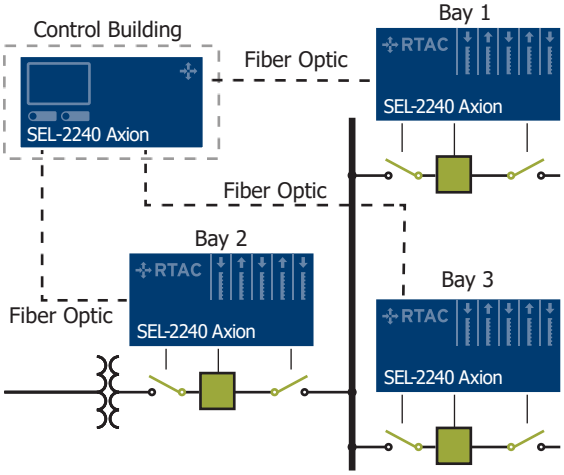
- **Switch Position Monitoring.** Monitor as many as four position states (open, close, alarm, and in-progress) of two-position switches, and as many as eight position states of three-position switches. Monitor as many switches as your application requires. Measure switch position directly by using digital input signals or indirectly by using other devices via communications protocols (e.g., IEC 61850).
- **Interlocking Control Logic.** Use the powerful IEC 61131-3 logic to program complex automation functions, interlocking schemes, or bypass logic. Create innovative logic solutions directly in *ACSELERATOR* RTAC by using any of the following editor tools: Tag Processor, Structured Text, Ladder Logic, or Continuous Function Chart.
- **Monitor and Control of Substation Equipment in Local or Remote Mode.** Perform local and remote control and monitoring of circuit breakers, disconnect switches, shunt reactors, and capacitor banks. The local touchscreen display makes the local control quick and efficient. Perform remote control and monitoring by using a variety of industry-standard protocols, such as IEC 61850, DNP3, Modbus, Mirrored Bits communications, and IEC 60870-101/103/104.



- **Synchronism Check.** Use the SynchronismCheck function block to verify that the voltages on both sides of the breaker are within allowed phase and magnitude. The SynchronismCheck function block compensates for circuit breaker close time. Use selectable voltage sources as inputs for the synchronism check on each breaker.
- **Design Custom Screens to Meet Your System Needs.** Design bay screens, monitor screens, or meter screens by launching ACSELERATOR Bay Screen Builder SEL-5036 Software for Axion Bay Controller. Display the bay configuration as a single-line diagram (SLD) on the touchscreen. Use ANSI and IEC symbols, along with analog and digital labels, for the SLD to indicate the status of breaker and disconnect switches, bus voltages, and power flow through the breaker. In addition to SLDs, design custom screens to show the status of any digital or analog tag of the RTAC logic. Design these custom screens with the help of ACSELERATOR Bay Screen Builder in conjunction with ACSELERATOR RTAC. You can create as many as 25 custom screens.
- **Programmable Pushbuttons and LED Status Indication.** Program six pushbuttons to quickly perform custom control commands. Each pushbutton (located on the Axion Bay Controller front panel) includes two programmable tricolor LEDs. Seven general-purpose tricolor LEDs are available for alarms or any other local indication. Use IEC 61131-3 logic to program custom operator control and LED status functions.
- **Control Multiple Bays.** Control and monitor circuit breakers, disconnect switches, and earthing switches for multiple bays with a single SEL-2240 Axion Bay Controller system.
- **Flexible I/O Selections for Your Application.** Include hundreds of digital and analog I/O points in a single panel.
- **Distributed I/O.** Improve safety and reduce copper conductor and installation time by installing the remote Axion ac analog input modules and digital I/O modules in the substation yard, near the circuit breaker, and control the breakers and monitor current, voltages, and status of contact points from the substation control building.
- **Deterministic I/O Performance.** Update connected I/O at a deterministic processing interval; all inputs provide 1 ms SER time stamps.
- **Redundant Power Supplies for Maximum Availability.** Apply redundant power support with two load-sharing SEL-2243 power couplers for applications requiring two independent power sources.
- **Synchronized Current and Voltage Measurements.** Retrieve high-accuracy current and voltage measurements with the advantage of synchronized measurements. Multiple AC Analog Input modules in an Axion system sample all measurements at the same time to ensure a common reference for all voltages and currents. This enables many time-deterministic control applications without performing additional processing to align the measurements to a reference. Use this capability to accomplish complex control schemes including load shedding, microgrid control, and synchronism check.
- **Create Historic Data Logs.** Leverage the Dynamic Disturbance Recording (DDR) library to continuously record fundamental, rms, synchrophasor quantities, or I/O status data.

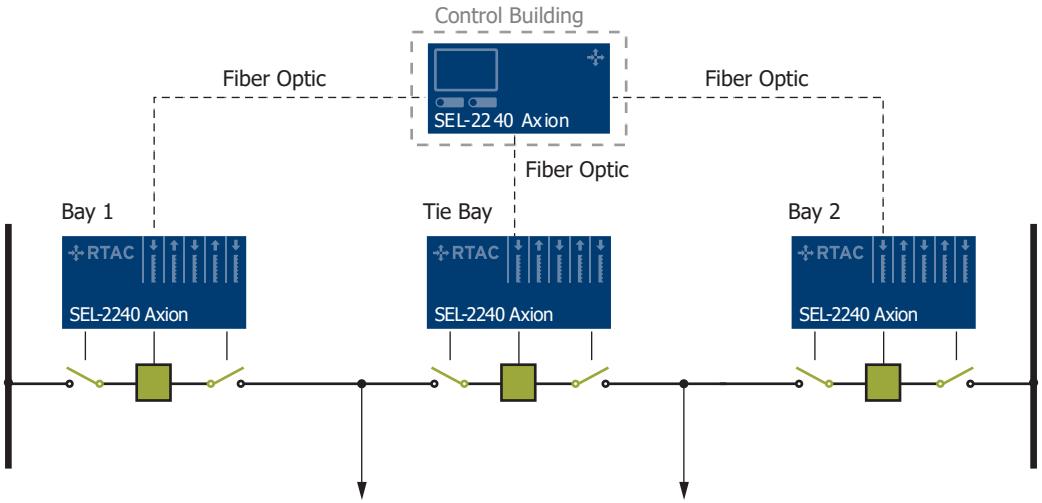
- **Sensor Integration.** Use the SEL-2245-22 DC Analog Input modules to integrate gas pressure, oil level, tap position sensor, or any other voltage (–10 to +10 Vdc) or current (–20 mA to +20 mA) sensor. Use the SEL-2600 Resistance Temperature Detector (RTD) Module to integrate RTD sensors. Sensors can also be integrated via communications protocols.
- **Low-Energy Analog (LEA) Inputs.** Eliminate outage costs by using the SEL-2245-221 Low Voltage Monitoring Input module to connect external split-core current transformers.
- **Secure Operation.** Manage user accounts and permissions to only allow access to the touchscreen to approved users.

Applications



Control a Bay With Single or Dual Breaker

Use a single SEL-2240 Axion Bay Control node to control a substation bay with as many as 3 breakers and 20 disconnect switches.



Use Distributed I/O to Control Multiple Bays

Use high-speed and deterministic fiber-optic communications from the control house in place of high-energy copper cables. Install ac measurement modules and digital I/O modules near assets in the substation yard and perform bay control and monitoring from within the control house.

Control Breaker-and-a-Half Diameter

Monitor and control breakers and switches in a breaker-and-a-half scheme. Ensure safe connections by using synchronism check and automate control operations with the powerful logic engine in the RTAC.

Remote Terminal Unit (RTU)

Remote terminal units gather digital and analog signals at remote sites and supply these data over a variety of industry-standard protocols (DNP, Modbus, or IEC 61850) to a central supervisory control and data acquisition (SCADA) center or HMI. A master controller in the SCADA center can perform all logic or distribute logic to the RTU. The SEL-2244 I/O modules are available in a variety of types to gather many types of I/O at RTU locations. The SEL-2241 RTAC module has a variety of industry-standard protocols by which it can integrate seamlessly with any SCADA system. Additionally, the versatile IEC 61131 logic engine in the RTAC can meet the majority of logic requirements for small to large automation projects. The modular design of the SEL-2240 provides it the ability to perform as an RTU in two ways: as a centralized master RTU or distributed in each substation.

Systems using distributed logic at the RTU use an SEL-2241 RTAC in each Axion node, thus providing all automation capabilities of the RTAC in each RTU.

This architecture allows each RTU to function autonomously even if the central SCADA system is offline. Each RTAC module can communicate with the SCADA master over DNP, Modbus, IEC 61850 GOOSE, or SEL Fast Message. *Figure 1.3* illustrates use of the Axion as a distributed RTU communicating over DNP to a SCADA master.

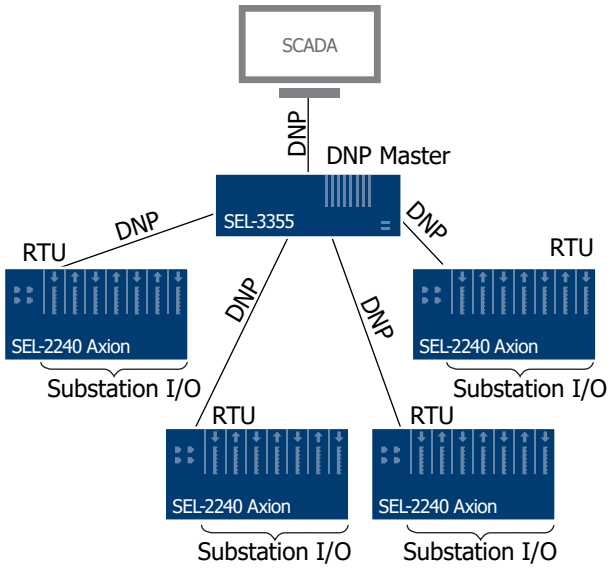


Figure 1.3 RTACs Distributed With RTUs

Systems that do not need autonomous operation at each RTU can use a central SEL-2241 and communicate to the remote nodes through the SEL-2243 Power Couplers. This architecture offers an economical solution to distributed I/O over EtherCAT at an extremely fast acquisition rate. The master SEL-2241 can host all data from remote nodes over DNP and interface directly with the SCADA system. The master Axion in *Figure 1.4* illustrates this functionality.

EtherCAT Network Topologies

The SEL-2243 Power Couplers provide not only hot-pluggable power supplies, but also fast EtherCAT connections to remote SEL-2240 nodes. The power couplers create EtherCAT links in star network topology, sequential network topology, or a combination of both. Star-configured topologies still use the sequential message format inherent to EtherCAT message design and offer greater flexibility than wired sequential network topologies in creating a network to match your physical system. Refer to *Section 2: Communications* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for detailed information on EtherCAT.

Apply single or dual power couplers in each Axion node based on connection or redundancy requirements. *Figure 1.4* illustrates a star topology for four remote SEL-2240 nodes with single power couplers in the remote nodes and dual couplers in the RTAC master. Each remote node on the star has a corresponding slot on the EtherCAT message train.

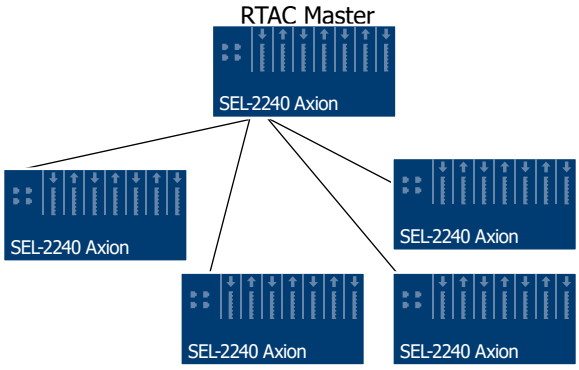

Figure 1.4 EtherCAT Star Network Topology

Figure 1.5 illustrates connections for an EtherCAT sequential topology with six Axion nodes. Each node uses a single SEL-2243 Power Coupler to provide connections to the previous and next node in the EtherCAT train.

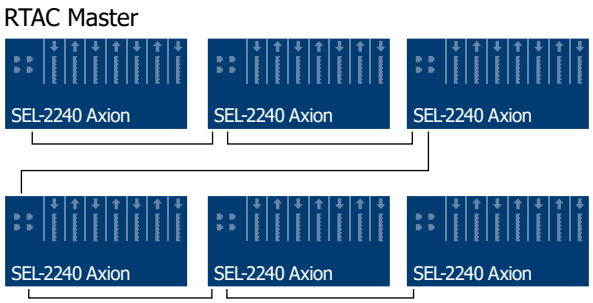

Figure 1.5 EtherCAT Sequential Network Topology

Figure 1.6 illustrates a combination of star and sequential connections with six Axion nodes.

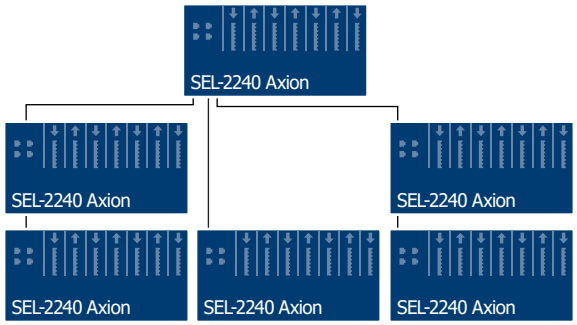

Figure 1.6 EtherCAT Combination Network Topology

SCADA Data Concentrator

Use the RTAC with your protective relays and other IEDs as the substation SCADA data concentrator. You can configure the RTAC to collect and view station-wide Sequential Events Recorder (SER) and event reports. Use MIRRORED BITS protocol to ensure compatibility with any SEL device. Retrieve asset optimization data from SEL or other IEDs to maintain the best possible system reliability. Take advantage of multiprotocol support to collect SCADA information, process control commands, and obtain SNTP/NTP

time synchronization through a single communications link to each Ethernet device. Scale values and calculate logic in a familiar IEC 61131 configuration environment. Enjoy secure, encrypted communications to any device on the substation network or serial channel.

Remotely access the RTAC through the Ethernet connection, and use any web browser to manage users, view diagnostics, and access logs. Establish a remote connection with any IED connected to the RTAC through engineering access communications channels. Use the SEL Fast Message protocol to maintain SCADA control and metering updates throughout the engineering access connection. Use ACSELERATOR QuickSet SEL-5030 Software to remotely manage protection and control settings in attached relays. See *Figure 1.7* for an example of this application.

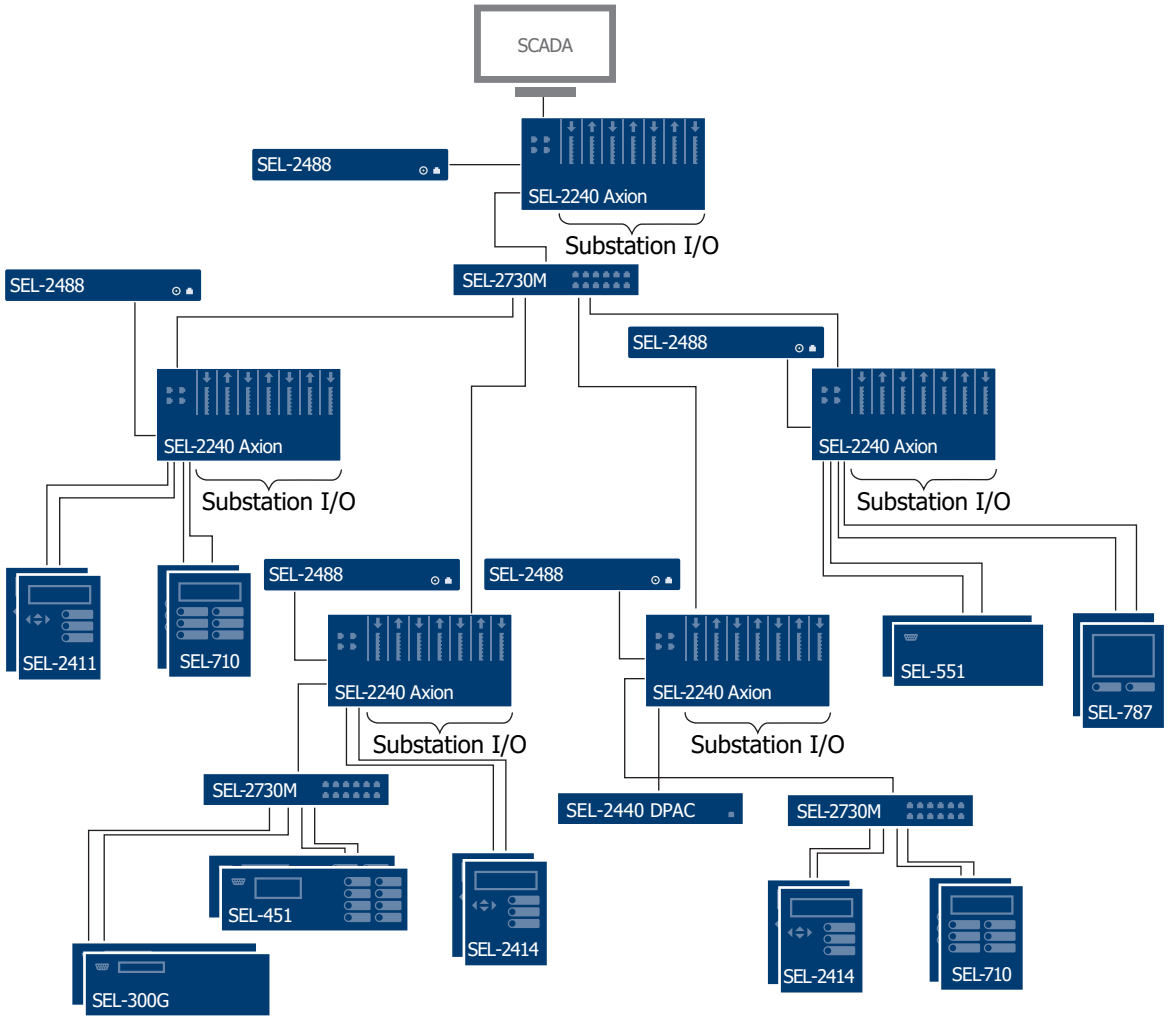

Figure 1.7 SCADA Data Concentrator and HMI

Human-Machine Interface (HMI)

Use the built-in web HMI in the RTAC for viewing and controlling any tags you configured in the RTAC. Use ACSELERATOR Diagram Builder to build custom HMI screens and load them into the RTAC. You can build one-line diagrams, annunciators, and graphical representations that contain control buttons, and

you can then display any data in the RTAC, as shown in *Figure 1.8*. Once you have loaded the screens you built into the RTAC, you can view the screens in the RTAC web interface. The RTAC has a web-based HMI, so multiple users can view the HMI screens simultaneously.

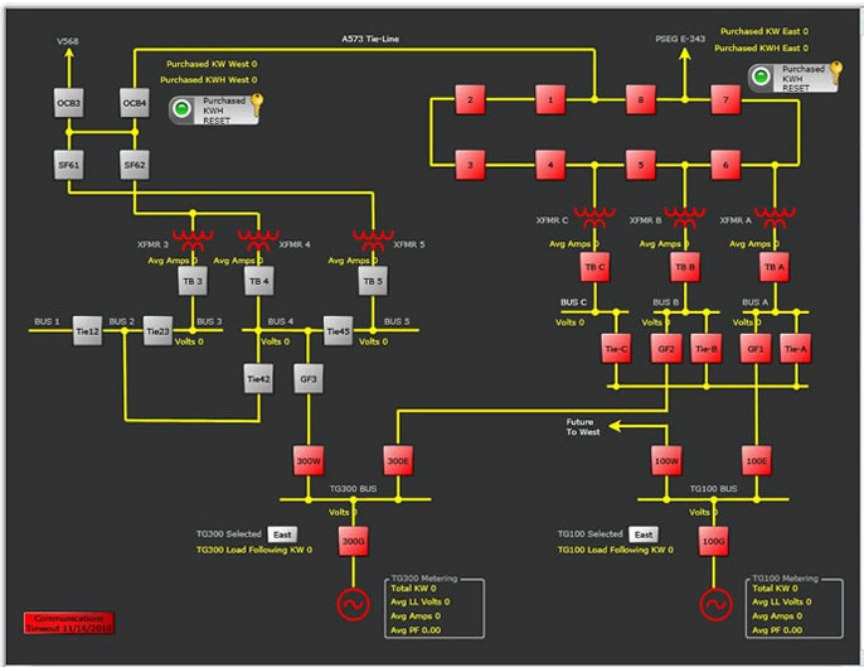

Figure 1.8 HMI One-Line Diagram

The logging system in the RTAC provides comprehensive logging for all variables in the RTAC, including those that connected IEDs provide. The logging system compensates for time-stamp differential among data from different IEDS, so all data are in sequence and on the same time-stamp reference. The RTAC can log data for changes in the state of Boolean values, changes in string values, and changes in Boolean, analog, or string time stamps. The RTAC can also alarm for analog values that cross defined thresholds. Assign variables for logging in the Tag Processor, or use one of the logger function blocks in IEC 61131 custom programs.

There are two user interfaces for viewing logged data. These include a secure HTML interface and an open database connectivity (ODBC) connection. Access the HTML interface through a web browser connection. Use the ODBC connection for standard data transfer between the logged data and database or spreadsheet software.

Remote I/O

When you use single or dual power couplers, the Axion serves as a low-cost remote I/O module. As many as 60 modules or six nodes can connect to one resident SEL-2241 RTAC or to a separate SEL-3530 or SEL-3555 RTAC. The Axion is an excellent teleprotection device that provides, through EtherCAT, a simple means for expanding the number of I/O points available in an automation system at rapid data acquisition rates.

Programmable Logic/Automation Controller (PLC/PAC)

Use the Axion as a programmable logic controller to automate your real-time tasks based on a variety of input conditions and diagnostic information. Use the powerful IEC 61131 logic engine to write programs in Structured Text, Function Block, or Ladder Logic. Schedule periodic tasks or configure event-driven tasks with multiple preconditions. Create function blocks of complex tasks for simple configuration. Easily replace aging PLCs implemented in Ladder Logic by replicating the same logic or by using a conversion tool to translate logic to Structured Text. See *Figure 1.9* for an example of this application.

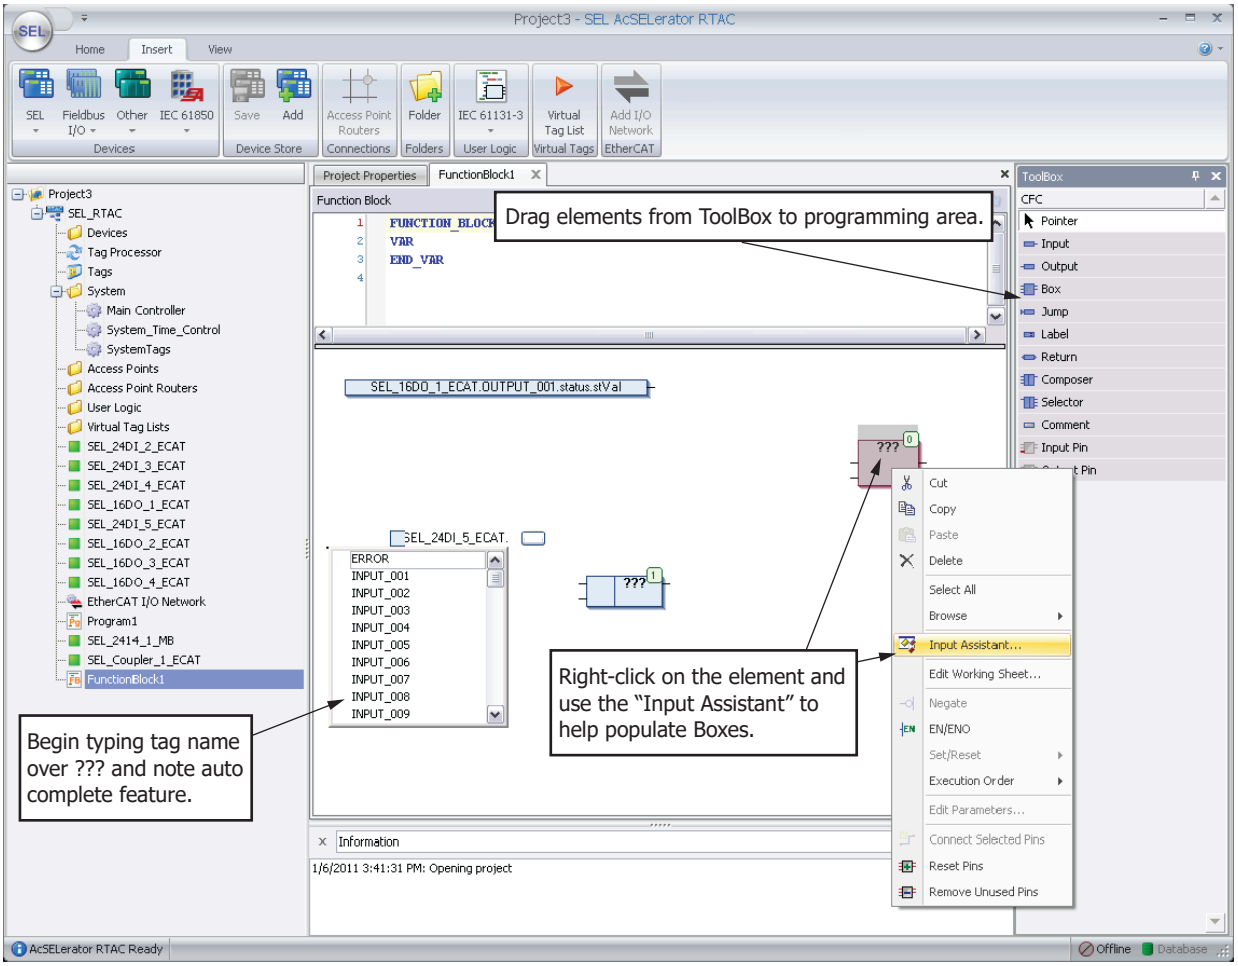

Figure 1.9 IEC 61131 Logic Example

IEC 61850 GOOSE Concentrator

Gather a variety of substation I/O with the SEL-2244 modules and share the data with IEC 61850 Generic Object-Oriented Substation Event (GOOSE) messages. Use the protocol flexibility of the RTAC to concentrate data from non-IEC 61850 relays and convert these data to GOOSE messages. See *Figure 1.10* for an example of this application.

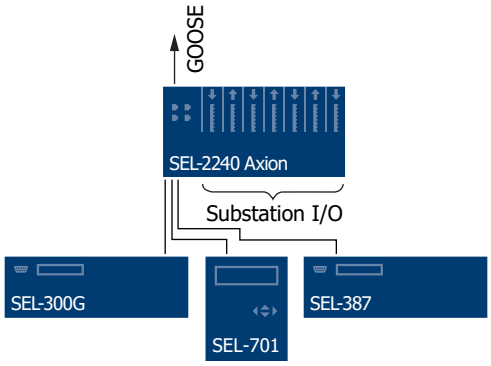

Figure 1.10 IEC 61850 GOOSE Concentrator

Synchrophasor Concentrator

Use standard protocols, such as DNP3, to move synchrophasor data to SCADA operation centers. Include time stamps and time quality in the SCADA message to allow for system-wide usage of synchrophasor data. Within the RTAC logic engine, you can perform complex math and logic calculations on synchrophasor data you collect from SEL relays and other IEEE C37.118-compliant devices. See *Figure 1.11* for an example of this application.

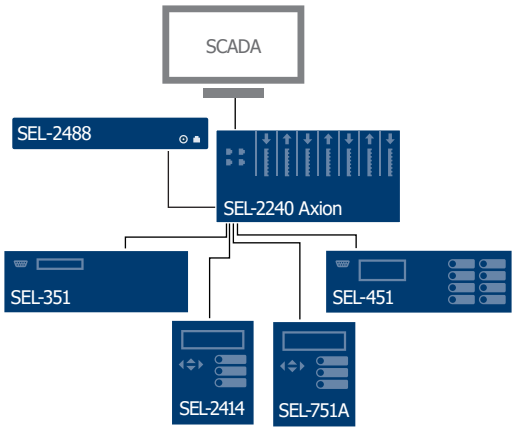

Figure 1.11 Synchrophasor Concentrator

Intelligent Port Switch

Flexible communications parameters make the RTAC a great choice for almost any port-switching application. Although RTAC multitasking/multiuser and data handling capabilities make it a very powerful remote automation platform, it is still an economical choice for port-switching applications. The time-synchronization capabilities of the RTAC add to its value in this application. See *Figure 1.12* for an example of this application.

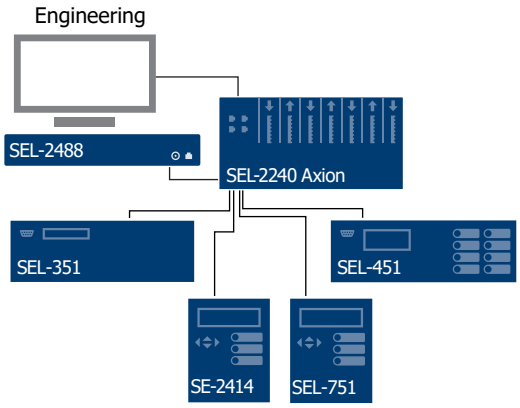

Figure 1.12 Intelligent Port Switch

Network Gateway

The SEL-2241 RTAC has two Ethernet ports through which it can make serially connected devices available to high-speed networks. The RTAC supports virtual terminal connections through the Ethernet ports. For example, Ethernet users can establish secure Telnet sessions and communicate with an IED connected to the RTAC. See *Figure 1.13* for an example of this application.

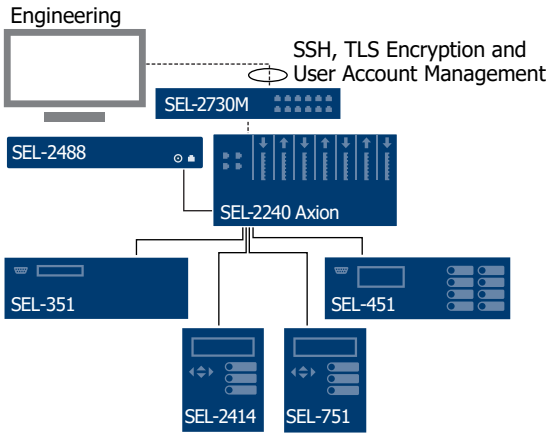

Figure 1.13 Network Gateway

Protocol Gateway

Collect downstream data with client or peer-to-peer protocols. Then send these data to your upstream HMI, RTU, or SCADA master with server protocols, converting the data from one protocol to another in the process. RTAC multitasking/multiuser and data handling capabilities make it a great choice for data concentration. See *Figure 1.14* for an example of this application.

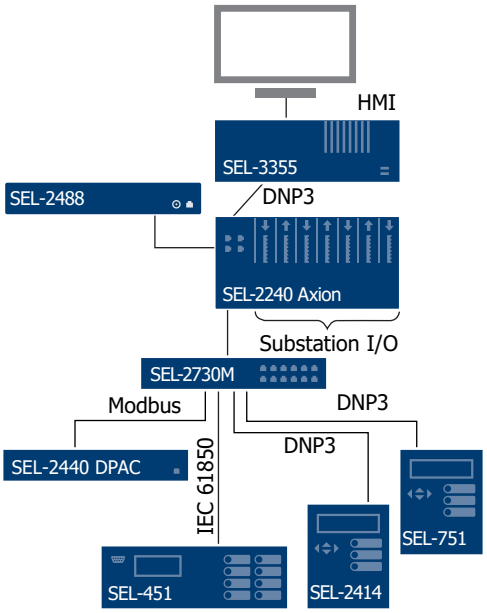

Figure 1.14 Protocol Converter

Time-Synchronization Source

Synchronize the time clocks in attached devices that accept a demodulated IRIG-B time signal. The RTAC regenerates the demodulated IRIG-B signal from an external modulated or demodulated source, such as a GPS satellite clock receiver, SNTP/NTP/PTP source, or serial or Ethernet protocol such as DNP3. If an external clock source is unavailable, the RTAC generates an IRIG-B signal from its internal clock, providing device synchronization to a common clock for improved SER data analysis. See *Figure 1.15* for an example of this application.

To determine how many devices an IRIG-B output is able to synchronize, a parallel resistance calculation is required because the input resistance of connected devices significantly affects this number. The Specifications section of each RTAC product provides the output drive capability. If the RTAC output resistance is greater than or equal to the parallel resistance calculation of connected devices, all devices can be synchronized by the RTAC.

For example, most SEL relays (excluding SEL-100 and SEL-200 Series Relays) have an IRIG-B input resistance of approximately 2500 ohms. For a BNC demodulated IRIG-B output that supports a drive capacity of 25 ohms, this allows approximately 20 SEL relays to be connected in parallel and be time-synchronized. For most serial port IRIG-B outputs, the drive resistance capability is approximately 500 ohms. This allows 5 SEL relays with IRIG-B input resistance of approximately 2500 ohms to be connected in parallel.

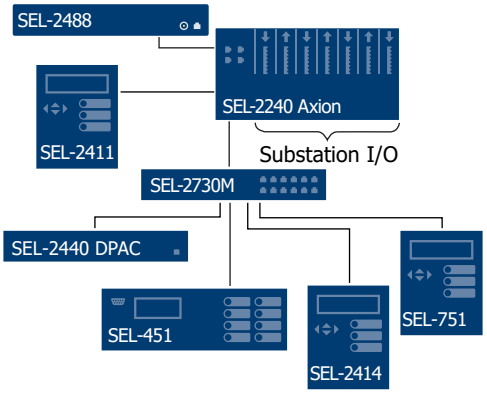

Figure 1.15 Time Synchronization

Security Gateway

Secure the automation network with the RTAC. Enable encryption for any engineering access channel or SCADA link. Implement system security auditing, logging, and password restrictions to enforce NERC standards. Comply with role-based requirements by implementing per-user security profiles. Optionally incorporate serial and wireless encrypting devices to further secure communications to any device. See *Figure 1.16* for an example of this application.

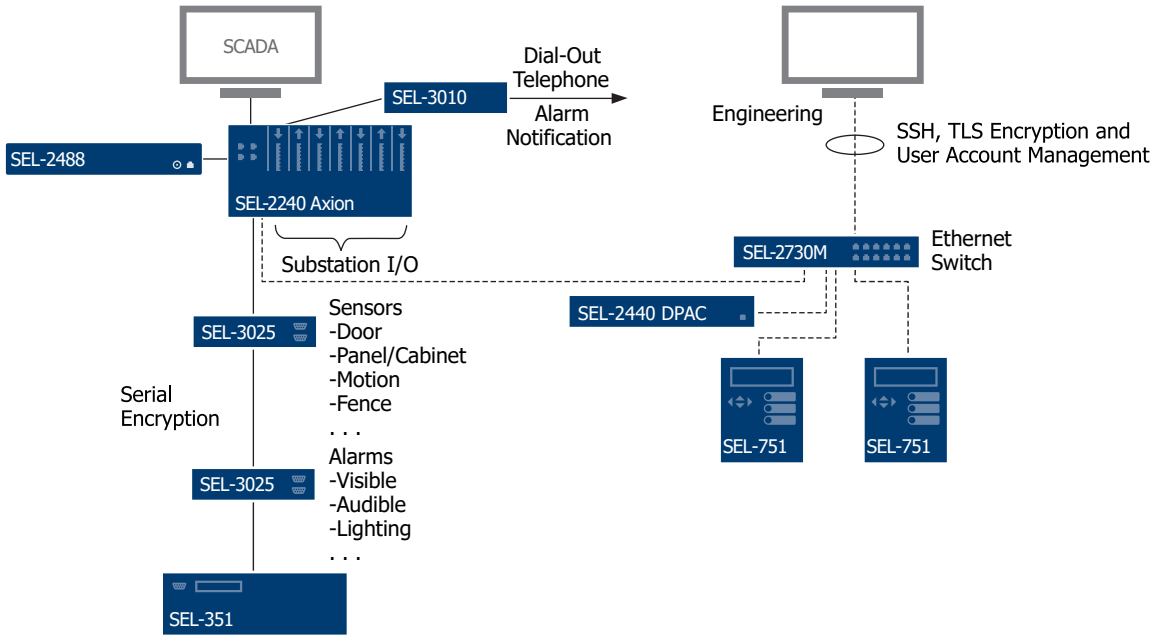

Figure 1.16 Security Gateway

Specifications

Compliance

Designed and manufactured under an ISO 9001 certified quality management system
SEL Axion operates at the specified limits on power up as soon as the device enables. Refer to the individual SEL Axion module datasheets for compliance and type test specifications.
UKCA Mark

Enclosure Protection

IP4X Front
IP2X Product Without SEL-2245-4, SEL-2245-411, and SEL-2245-42
IP1X Product With SEL-2245-4, SEL-2245-411, or SEL-2245-42

NOTE
If rear terminals are accessible during normal use, the product must be mounted in a locked enclosure or restricted area accessible by trained maintenance or operation personnel only.

Product Standards

IEC 60255-26:2013 - Relays and Protection Equipment: EMC
IEC 60255-27:2014 - Relays and Protection Equipment: Safety
IEC 60825-2:2004 +A1:2007 +A2:2010 for fiber-optic communications
IEC 61850-3:2013 - Comm Systems for Power Utility Automation

General

Operating System

SEL Linux® Yellowstone running Linux kernel 3.x with real-time preemption patches

Operating and Storage Temperature Range

–40° to +85°C (–40° to +185°F)
Units should be stored and transported in their original packaging.

NOTE
Operating temperature evaluated for UL ambient 0° to 40°C.

NOTE
The optional front-panel LCD is impaired for temperatures below –20°C and above +70°C.

Operating Environment

Pollution Degree:	2
Overvoltage Category:	II
Insulation Class:	1
Relative Humidity:	5%–95%, noncondensing
Maximum Altitude:	2000 m
Vibration, Earth Tremors:	Class 1

Dimensions

Refer to *Section 2: Installation* for dimensions.

Weight

SEL-2241 RTAC:	0.67 kg (1.47 lb)
SEL-2242 19 inch Backplane:	3.24 kg (7.13 lb)
Panel Mount Bezel:	0.283 kg (0.625 lb)

SEL-2242 10-Slot (19 in Rack Width) With 7 in Touchscreen Display:	3.999 kg (8.80 lb)
SEL-2243-1 HV Coupler:	0.85 kg (1.87 lb)
SEL-2243-2 LV Coupler:	0.89 kg (1.97 lb)
SEL-2244-2 24 DI:	0.45 kg (1.00 lb)
SEL-2244-3 16 DO:	0.59 kg (1.30 lb)
SEL-2244-5 10 FHCDO:	0.57 kg (1.26 lb)
SEL-2245-2 16 AI:	0.51 kg (1.12 lb)
SEL-2245-22 4 AI-ER:	0.42 kg (0.92 lb)
SEL-2245-221 4 LEA:	0.42 kg (0.92 lb)
SEL-2245-3 8 AO:	0.46 kg (1.01 lb)
SEL-2245-4 4 CT/4 PT:	0.54 kg (1.18 lb)
SEL-2245-411 4 CT/4 LEA:	0.54 kg (1.18 lb)
SEL-2245-42 3 CT/3 PT:	0.73 kg (1.60 lb)

Module Burden per Module for Each Node

Module	Maximum Added Burden (W)[a]
SEL-2241 RTAC (Copper Ethernet)	12.5
SEL-2241 RTAC (Fiber Ethernet)	15
SEL-2242R Standard Rack-Mount Backplanes	1
SEL-2242 With Touchscreen Display	4
SEL-2243 Power Coupler (Fiber Ethernet)	5[b]
SEL-2243 Power Coupler (Copper Ethernet)	2.5[b]
SEL-2244-2 24 DI	2
SEL-2244-3 16 DO	8[c]
SEL-2244-5 10 FHCDO	6[c]
SEL-2245-2 16 AI	3
SEL-2245-22 4 AI-ER	2
SEL-2245-221 4 LEA	2
SEL-2245-3 8 AO	13
SEL-2245-4 4 CT/4 PT	3
SEL-2245-411 4 CT/4 LEA	3
SEL-2245-42 3 CT/3 PT	6
Feature Selections	**Typical Burden (W)**
No use of SEL-2241 Serial Port +5 Vdc	–3
Each DO port not energized (SEL-2241, SEL-2244-3, or SEL-2244-5 relay coil)	–0.3
Each AO port not energized (SEL-2245-2)	–0.7

[a] Values include worst-case real power consumption and do not include worst-case ac power factor correction (0.4). If the unit will not be used in wide temperature extremes, reduce power by up to 6%.
[b] Each SEL-2243 will draw a minimum of 11 W (quiescent) when the total burden of all other modules in the node is less than 11 W.
[c] All DO relay coils may be energized simultaneously and still meet specifications.

CPU Processing and Memory

Processor Speed:	533 MHz
Memory:	1024 MB DDR2 ECC RAM
Storage:	4 GB (2 GB reserved)

Security Features

Account Management:	User Accounts User Roles LDAP Central Authentication RADIUS Central Authentication Strong Passwords Inactive Account Logouts
Intrusion Detection:	Access/Audit Logs Alarm LED Alarm Contact
Encrypted Communication:	SSL/TLS, SSH, HTTPS

Automation Features (Protocols)

Client:	DNP3 Serial, DNP3 LAN/WAN, Modbus RTU, Modbus TCP, SEL ASCII, SEL Fast Messaging, LG 8979, IEEE C37.118, IEC 61850 MMS, CP2179, IEC 60870-5-101/104, SNMP, SES-92, CDC Type II, Courier, IEC 60870-5-103, Ethernet/IP Explicit Message Client
Server:	DNP3 Serial, DNP3 LAN/WAN, Modbus RTU, Modbus TCP, SEL Fast Messaging, LG 8979, SES-92, IEEE C37.118, IEC 61850 MMS, IEC 60870-5-101/104, FTP, SFTP, CDC Type II, Ethernet/IP Implicit Message Adapter
Peer-to-Peer:	SEL MIRRORED BITS Communications, IEC 61850 GOOSE, Network Global Variables (NGVL), Parallel Redundancy Protocol
Fieldbus:	EtherCAT Client (in RTAC), EtherCAT Server (I/O modules)

Power Supply

AC Input Voltage (High-Voltage Model)

NOTE
Single phase.

Nominal Supply Voltage:	120–240 Vac, 50–60 Hz
Operational Voltage Range:	85–264 Vac, 40–70 Hz

DC Input Voltage (High-Voltage Model)

Nominal Supply Voltage:	125–250 Vdc
Operational Voltage Range:	85–300 Vdc

DC Input Voltage (Low-Voltage Model)

Nominal Supply Voltage:	24–48 Vdc
Operational Voltage Range:	19.1–57.6 Vdc polarity-dependent

NOTE
UL operational voltage range is equal to the nominal voltage range ±10 percent.

Fuse Rating

High-Voltage Model, F1:	3.15 A, high breaking capacity, time lag T, 250 V (5x20 mm, T3.15AH 250 V)
High-Voltage Model, F2 (Non-Serviceable):	8 A, high breaking capacity, time lag T, 60 Vdc (2.7x6.1 mm, T8A 60 Vdc)
Low-Voltage Model:	6.30 A, high breaking capacity, time lag T, 250 V (5x20 mm, T6.3AH 250 V)

Power Consumption: See *Module Burden per Module for Each Node on page 41* for power per module.

Maximum AC Burden:	160 VA
Maximum DC Burden:	75 W
Interruptions:	30 ms @ 24 Vdc 130 ms @ 48 Vdc 50 ms @ 125 Vac/Vdc 100 ms @ 250 Vac/Vdc

The following exceptions for the IEC 61850-3 acceptance criteria for normal equipment functioning regarding ac power dips and interruptions and dc voltage dips are applicable (refer to IEC 61850-3 subclause 7.5.5, Equipment functioning, and 7.5.6, Exceptions).

Power Supply	Requirement	Exception[a]
125 Vac	5 cycles (83,33 ms @ 60 Hz, 100 ms @ 50 Hz)	50 ms
	50 cycles	Not applicable[b]

[a] Voltage interruptions that are longer than the specified interruption duration result in a device restart.
[b] Equipment is not intended to be connected to power supply ports that are directly connected to a public low-voltage power supply network.

Max Inrush:	17 A
Isolation:	3100 Vdc
Redundant Installation:	Each node may have one or two SEL-2243 modules installed. When two are used, they operate in load-sharing mode.

Recommended External Overcurrent Protection

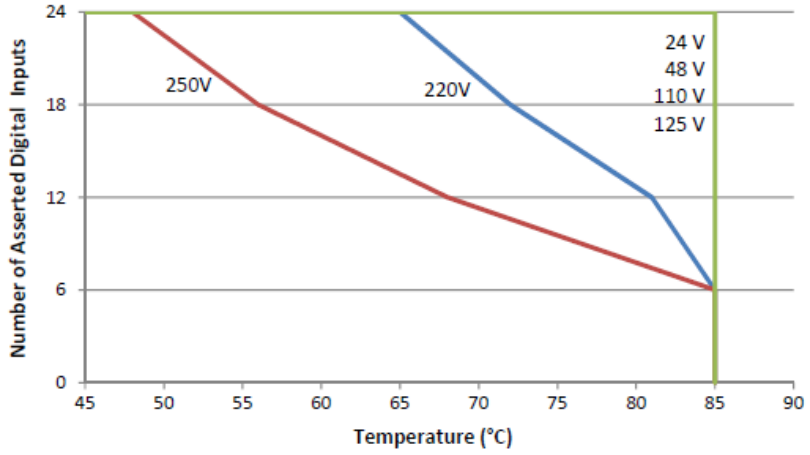
Breaker Type:	Standard
Breaker Rating:	15 A or 20 A at 250 Vdc

Current Breaking Capacity:	10 kA
Grounded Neutral System:	Device in series with the HOT or energized conductor
DC and Isolated Systems:	Device in series with both conductors

Optoisolated Control Inputs (SEL-2244-2)

When Used With DC Control Signals:

250 Vdc	ON for 200–275 Vdc	OFF below 150 Vdc
220 Vdc	ON for 176–242 Vdc	OFF below 132 Vdc
125 Vdc	ON for 100–135.5 Vdc	OFF below 75 Vdc
110 Vdc	ON for 88–121 Vdc	OFF below 66 Vdc
48 Vdc	ON for 38.4–52.8 Vdc	OFF below 28.8 Vdc
24 Vdc	ON for 15–30 Vdc	OFF for < 10 Vdc



When Used With AC Control Signals:

250 Vdc	ON for 170.6–300 Vac	OFF below 106 Vac
220 Vdc	ON for 150.3–264 Vac	OFF below 93.2 Vac
125 Vdc	ON for 85–150 Vac	OFF below 53 Vac
110 Vdc	ON for 75.1–132 Vac	OFF below 46.6 Vac
48 Vdc	ON for 32.8–60 Vac	OFF below 20.3 Vac
24 Vdc	ON for 14–27 Vac	OFF for < 5 Vac

Burden/Current Draw at Nominal DC Voltage:	2–6 mA (Except for 24 V, 8 mA)
Rated Insulation Voltage:	300 Vac
Rated Impulse Withstand Voltage (U_{imp}):	4000 V

10 M no-load operations

DC Output Ratings

Rated Operational Voltage:	250 Vdc		
Rated Voltage Range:	19.2–275 Vdc		
Rated Insulation Voltage:	300 Vdc		
Make:	30 A @ 250 Vdc per IEEE C37.90		
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C		
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A 60 to 70°C		
Thermal:	50 A for 1 s		
Contact Protection:	350 Vdc, 145 J MOV protection across open contacts		
Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time ≤ 8 ms typical		
Breaking Capacity (10,000 Operations) Per IEC 60255-0-20:1974:	24 Vdc	0.75 A	L/R = 40 ms
	48 Vdc	0.50 A	L/R = 40 ms
	125 Vdc	0.30 A	L/R = 40 ms
	250 Vdc	0.20 A	L/R = 40 ms
Cyclic Capacity (2.5 Cycles/Second) Per IEC 60255-0-20:1974:	24 Vdc	0.75 A	L/R = 40 ms
	48 Vdc	0.50 A	L/R = 40 ms
	125 Vdc	0.30 A	L/R = 40 ms
	250 Vdc	0.20 A	L/R = 40 ms

AC Output Ratings

Rated Operational Voltage:	240 Vac
Rated Insulation Voltage (Excluding EN 61010-1):	300 Vac
Utilization Category:	AC-15 (control of electromagnetic loads > 72 VA)
Contact Rating Designation:	B300 (B = 5 A, 300 = rated insulation voltage)
Contact Protection:	250 Vac, 145 J
Continuous Carry:	3 A @ 120 Vac 1.5 A @ 240 Vac
Conventional Enclosed Thermal Current (I_{the}) Rating:	5 A
Rated Frequency:	50/60 ±5 Hz
Operating Time (Coil Energization to Contact Closure, Resistive Load):	Pickup/Dropout time ≤ 8 ms typical
Electrical Durability Make VA Rating:	3600 VA, cosø = 0.3
Electrical Durability Break VA Rating:	360 VA, cosø = 0.3

Control Outputs (SEL-2244-5 Fast High-Current Contacts)

Mechanical Durability

10 M no-load operations

DC Output Ratings

Rated Operational Voltage:	250 Vdc
Rated Voltage Range:	19.2–275 Vdc

Rated Insulation Voltage:	300 Vdc		
Make:	30 A @ 250 Vdc per IEEE C37.90		
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C		
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A 60 to 70°C		
Thermal:	50 A for 1 s		
Contact Protection:	330 Vdc, 145 J MOV protection across open contacts		
Operating Time (Coil Energization to Contact Closure, Resistive Load)			
Pickup Time:	≤12 µs at 250 Vdc, 16 µs at 125 Vdc, 65 µs at 19.2 Vdc typical (results with 100 kΩ resistive load)		
Dropout Time:	≤8 ms typical		
Inductive Breaking Capacity (10,000 Operations) per IEC 60255-0-20:1974:	24 Vdc	10 A	L/R = 40 ms
	48 Vdc	10 A	L/R = 40 ms
	125 Vdc	10 A	L/R = 40 ms
	250 Vdc	10 A	L/R = 20 ms
Cyclic Capacity (4 Cycles/Second Followed by 2 Min Idle Thermal Dissipation) Per IEC 60255-0-20:1974:	24 Vdc	10 A	L/R = 40 ms
	48 Vdc	10 A	L/R = 40 ms
	125 Vdc	10 A	L/R = 40 ms
	250 Vdc	10 A	L/R = 20 ms

AC Output Ratings

Rated Operational Voltage:	110/120/220/240 Vac
Voltage Range:	19.2–250 Vac
Rated Insulation Voltage:	250 Vac
Make:	30 A @ 240 Vac
Continuous Carry:	6 A @ 70°C; 4 A @ 85°C
Continuous Carry (UL/CSA Derating With All Outputs Asserted):	5 A @ < 60°C; 2.5 A @ 60° to 70°C
Thermal:	50 A for 1 s
Contact Protection:	250 Vac, 145 J MOV protection across open contacts
Operating Time (Coil Energization to Contact Closure, Resistive Load)	
Pickup Time:	≤12 µs at 250 Vac, 16 µs at 125 Vac, 65 µs at 19.2 Vac typical (results with 100 kΩ resistive load)
Dropout Time:	≤8 ms typical

NOTE
Per IEC 60255-23:1994, using the simplified method of assessment.

NOTE
Make rating per IEEE C37.90-1989.

Fuse Rating	
Non-Serviceable:	4 A, 450 V, medium time lag M

DC Transducer (Analog) Inputs (SEL-2245-2)

Input Impedance

Current Mode:	200 Ω for ±20 mA 5000 Ω for ±2 mA
Voltage Mode:	10 MΩ

Input Range (Maximum)

±20 mA (transducers: 4–20 mA or 0–20 mA typical)
±2 mA (transducers: 0–1 mA or 0–2 mA typical)
±10 V (transducers: 0–5 V or 0–10 V typical)

Sampling Rate

1 ksps

Anti-Alias Filter

Corner Frequency:	330 Hz
Rolloff:	20 dBV per decade

Digital Filter

Corner Frequency:	Filter A: 16 Hz Filter B: 10 Hz Filter C: 0.2 Hz
50 Hz Rejection:	Filter A: > 30 dB Filter B: > 50 dB Filter C: > 70 dB
60 Hz Rejection:	Filter A: > 60 dB Filter B: > 70 dB Filter C: > 70 dB

Step Response

No Filter:	3 ms (10%–90% response)
Filter A:	23 ms (10%–90% response)
Filter B:	35 ms (10%–90% response)
Filter C:	700 ms (10%–90% response)

Common Mode Range

±35 Vdc between separate inputs
±250 Vdc all inputs to chassis

Isolation

500 Vac between separate inputs
2000 Vac all inputs to chassis

Accuracy at 25°C

ADC:	16 bit
Voltage Inputs (±10 V):	0.25% of full scale typical 0.05% with field calibration 2% of full-scale maximum
High Current Inputs (±20 mA):	0.5% of full scale typical 0.1% with field calibration 2% of full-scale maximum
Low Current Inputs (±2 mA):	0.5% of full scale typical 0.1% with field calibration 4% of full-scale maximum

Accuracy Variation With Temperature

Inputs:	±0.015% per °C of full scale (±20 mA, ±2 mA, or ±10 V)
ADC:	±0.004% per °C

Triggered Waveform Recording

Sampling Rate:	1 kHz
Record Duration:	0.1 second increments from 0.5 s to 144 s
Record Pre-Trigger:	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

DC Analog Inputs Extended Range (SEL-2245-22 in DC Mode)

Input Impedance

>7 MΩ

Input Range (Maximum)

0–300 V

Sampling Rate

24 ksps

Anti-Alias Filter

Corner Frequency:	5 kHz
Rolloff:	20 dB per decade

Digital Filter

Corner Frequency:	Filter A: 16 Hz Filter B: 10 Hz Filter C: 0.2 Hz
50 Hz Rejection:	Filter A: > 30 dB Filter B: > 50 dB Filter C: > 70 dB
60 Hz Rejection:	Filter A: > 60 dB Filter B: > 70 dB Filter C: > 70 dB

Step Response

Group Delay (Pre-Filter):	5.3 ms
No Filter:	3 ms (10%–90% response)
Filter A:	23 ms (10%–90% response)
Filter B:	35 ms (10%–90% response)
Filter C:	700 ms (10%–90% response)

Common Mode Range

±250 Vdc between separate inputs
±250 Vac all inputs to chassis

Isolation

2500 Vrms between separate inputs
2500 Vrms all inputs to chassis

Accuracy at 25°C

ADC:	16 bit
Inputs:	0.25% of full scale typical 3% of full scale worst case

Accuracy Variation With Temperature

±0.015% per °C of full scale

Triggered Waveform Recording

Sampling Rate:	1, 2, 4, 8, 24 kHz
Record Duration:	0.1 second increments from 0.5 s to 144 s
Record Pre-Trigger	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

DC Analog Outputs (SEL-2245-3)

Current Mode

Output Range:	–20.48 to +20.48 mA
Load Impedance:	0–750 Ω @ 20 mA, 100 µH

Voltage Mode

Output Range:	–10.24 to + 10.24 volts
Load Impedance:	>2000 Ω, 1 µF

Step Response

1 ms (10%–90% response typical)

Isolation

2000 Vdc between outputs or ground

Accuracy at 25°C (Outputs)

Current Mode:	±0.3% of full scale typical ±3% of full-scale worst case (average during an EMI event over a 1-second period)
Voltage Mode:	0.2% of full scale typical ±2% of full-scale worst case (average during an EMI event over a 1-second period)

Accuracy Variation With Temperature (Outputs)

±0.01% of full-scale/°K (current or voltage mode)

AC Metering Inputs (SEL-2245-4, SEL-2245-411, SEL-2245-221, and SEL-2245-22 Voltage Inputs in AC Mode)

Frequency:	50/60 Hz
Range:	45–65 Hz
Typical Accuracy	
SEL-2245-4 and SEL-2245-22:	±0.005 Hz above 20 V
SEL-2245-411 and SEL-2245-221:	±0.005 Hz above 500 mV
Worst-Case Accuracy	
SEL-2245-4 and SEL-2245-22:	±0.01 Hz above 20 V
SEL-2245-411 and SEL-2245-221:	±0.01 Hz above 500 mV
Phase Rotation:	ABC, ACB
Input Configuration:	3-Wire Delta, 4-Wire Wye
Update Interval	
Fundamental Metering:	200 Hz
RMS Metering:	5 Hz

Current Inputs Phase and Neutral

I_{NOM}:	1 A or 5 A (no setting required)
Measurement Range:	0.050–22 A Continuous 22–100 A Symmetrical for 25 s
Thermal Withstand Limit:	500 A for 1 s
Typical Accuracy:	±0.1% Fundamental @ f_{NOM} and > 0.6 A ±0.1% RMS @ f_{NOM} and > 0.6 A
Worst-Case Accuracy:	±2% ± 0.005 A Fundamental ±1% ± 0.005 A RMS
Angle	
Range:	±180°
Typical Accuracy:	±0.1° fundamental @ f_{NOM} and > 0.6 A
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA @ I_{NOM}

Voltage Inputs (SEL-2245-4 and SEL-2245-22 in AC Mode)

V_{NOM}:	300 V
Measurement Range:	5–400 L-N, 9–693 L-L Vac Fundamental/RMS 5–300 L-N, 9–520 L-L Vac Fundamental/RMS (UL)
Maximum:	600 L-N, 1039 L-L Vac Fundamental/RMS for 10 s
Typical Accuracy:	±0.1% Fundamental @ f_{NOM} and > 20 V ±0.1% RMS @ f_{NOM}
Worst-Case Accuracy:	±2% Fundamental @ f_{NOM} ±1% RMS ± 0.05 V
Angle	
Range:	±180°
Typical Accuracy:	±0.1° @ f_{NOM} and > 20 V
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA

LEA Voltage Inputs (SEL-2245-411 and SEL-2245-221)

V_{NOM}:	1.5 V
Measurement Range:	30 Vac peak 0.05–22 Vac RMS
Maximum:	300 V_{L-N} RMS for 10 s (surge)
Typical Accuracy:	±0.1% RMS @ f_{NOM} and >50 mV ±0.1% fundamental @ f_{NOM} and >50 mV
Worst-Case Accuracy:	±3% ±1 mV @ f_{NOM} Fundamental/RMS
Angle	
Range:	±180°
Typical Accuracy:	±0.1° @ f_{NOM} and > 50 mV
Worst-Case Accuracy:	±2° @ f_{NOM}
Burden:	<0.1 VA

Sequence Components (SEL-2245-4)

Values:	I0, I1, I2, V0, V1, V2
Typical Accuracy	

Magnitude:	±0.2% @ f_{NOM} and V > 6.7 V, I > 0.6 A
Angle:	±0.2° @ f_{NOM} and V > 6.7 V, I > 0.6 A
Worst-Case Accuracy	
Magnitude:	±3% @ f_{NOM} and V > 6.7 V, I > 0.6 A
Angle:	±0.2° @ f_{NOM} and V > 6.7 V, I > 0.6 A

Power and Power Factor Per Phase and Three-Phase (SEL-2245-4)

PA, PB, PC, 3P	
Typical Accuracy:	0.1% @ PF > 0.1
Worst-Case Accuracy:	2%
QA, QB, QC, 3Q	
Typical Accuracy:	0.1% @ PF < 0.9
Worst-Case Accuracy:	2%
SA, SB, SC, 3S	
Typical Accuracy:	0.1%
Worst-Case Accuracy:	2%
PFA, PFB, PFC, 3PF	
Typical Accuracy:	0.1% @ PF > 0.1
Worst-Case Accuracy:	2%

Power and Power Factor Per Phase and Three-Phase (SEL-2245-411)

PA, PB, PC, 3P	
Typical Accuracy:	0.1% @ PF ≥ 0.5
Worst-Case Accuracy:	2%
QA, QB, QC, 3Q	
Typical Accuracy:	0.1% @ PF ≤ 0.98
Worst-Case Accuracy:	2%
SA, SB, SC, 3S	
Typical Accuracy:	0.1%
Worst-Case Accuracy:	2%
PFA, PFB, PFC, 3PF	
Typical Accuracy:	0.1% @ Unity PF
Worst-Case Accuracy:	2%

Synchrophasor

Conformance:	IEEE C37.118.1-2011 as amended by IEEE C37.118.1a-2014 IEEE C37.118.2-2011
Accuracy:	Level 1 as specified by IEEE C37.118
Measurements:	Software selectable (P or M class)
Voltage:	VA, VB, VC, VS
Current:	IA, IB, IC, IN
Positive-Sequence:	V1, I1
Periodic:	Frequency and df/dt
Processing Rate:	120 Hz

Frequency Resolution:	±1.25 mHz*
Calculated Power Resolution:	±0.1%*

* Resolution values tested on SEL-2245-4 with 69 V voltage inputs, 0.6 A to 1 A current inputs, and 49.5 to 50.5 Hz frequency range.

Message Rates (60 Hz nominal):	1, 2, 4, 5, 10, 12, 15, 20, 30, 60, and 120 (messages/second)
Message Rates (50 Hz nominal):	1, 2, 5, 10, 25, 50, and 100* (messages/second)

* This message rate is only supported on the SEL-2245-4 and SEL-2245-411 Axion modules. Message rates are supported on the SEL-3350, SEL-3555, and SEL-3560.

Triggered Waveform Recording (SEL-2245-4, SEL-2245-411, SEL-2245-22, and SEL-2245-221)

Sampling Rates:	1, 2, 4, 8, 24 kHz software selectable
Record Duration:	0.1 second increments from 0.5 s to specified maximum for each sample rate.
Maximum Record Duration:	6 s at 24 kHz 18 s at 8 kHz 36 s at 4 kHz 72 s at 2 kHz 144 s at 1 kHz
Record Pre-Trigger:	0.05 s minimum to a maximum of (record length minus 0.05 s)
Waveform File Format:	COMTRADE (IEEE C37.111-1999 compliant)

AC Protection Inputs (SEL-2245-42)

Frequency

Rated:	50/60 Hz
Range:	40–90 Hz
Typical Accuracy:	±0.005 Hz above 20 V
Worst-Case Accuracy:	±0.01 Hz above 20 V (±0.1 Hz for < 2.5 cycles during transients)

Phase Rotation

ABC, ACB

Input Configuration

3-Wire Delta, 4-Wire Wye

Update Interval

Fundamental Metering:	250 Hz
RMS Metering:	250 Hz
RMS Window Size:	1 cycle

AC Current Channels

Nominal Current:	1 A_{RMS} or 5 A_{RMS} (no setting required)
Current Range Rating (With DC Offset at X/R = 10, 1.5 Cycles):	0.1–91 A
Operational Range:	0.1–300 A_{RMS}
Measurement Range:	0.1–20 A_{RMS}
Thermal Withstand Limit:	15 A_{RMS} continuous 500 A_{RMS} for one second

Fundamental Measurement Accuracy

Magnitude:	±0.1%, typical, ±0.001 A ±2%, worst case, ±0.001 A
Phase:	±0.1°, typical at f_{NOM} and current > 0.4 A ±1°, over full rated temperature range ±2°, worst case

RMS Measurement Accuracy

Magnitude:	±0.1%, typical, ±0.001 A ±2%, worst case, ±0.001 A
Burden:	<0.1 VA

AC Voltage Channels

Rated Range: 67–240 $V_{L–N}$

NOTE
Rated Range refers to the IEEE C37.118 rating system.

Operational Range:	0–300 $V_{L–N}$
Accuracy Range:	6.7–300 $V_{L–N}$
Rated Insulation Voltage:	300 $V_{L–N}$ continuous 600 $V_{L–N}$ for ten seconds

Isolation (Galvanic Isolated Channels)

Channel-to-Ground:	2.5 kV_{RMS} for one minute
Channel-to-Channel:	2.5 kV_{RMS} for one minute

Fundamental Measurement Accuracy

Magnitude:	±0.1%, typical, plus ±0.05 V ±3%, worst case, plus ±0.05 V
Phase:	±0.1° @ f_{NOM}, typical ±1° @ f_{NOM}, over full rated temperature range ±2° @ f_{NOM}, worst case

RMS Measurement Accuracy

Magnitude:	±0.1%, typical, plus ±0.05 V ±3%, worst case, plus ±0.05 V
Burden:	<0.01 VA @ 67 V Impedance >500 kΩ

Sequence Components

Values: I0, I1, I2, V0, V1, V2

NOTE
Sequence components are of the fundamental frequency.

Accuracy

Magnitude:	±1%, typical
Angle:	±0.5°, typical

SECTION 2

Installation

Overview

The first steps in applying the SEL Axion are mounting the chassis, installing modules into the chassis, and connecting the system. This section describes common installation features and requirements. To install and connect the Axion safely and effectively, you must be familiar with configuration features and options. You should carefully plan the placement, cable connections, and communication. Use the following drawings and information as a starting point for planning your particular application.

Device Placement

NOTE
For applications compliant with IEC 60255-26, surface-mount units must be installed in IP4X enclosures.

You can mount the Axion in a sheltered indoor environment (a building or an enclosed cabinet) that does not exceed the temperature and humidity ratings for the modules. Equipment must be installed in an enclosure that protects against shock and fire to meet UL requirements. Configurations with an SEL-2245-42 as the right-most module in a backplane should have the backplane installed in a metal enclosure to meet Radiated RF Immunity Type Test requirements.

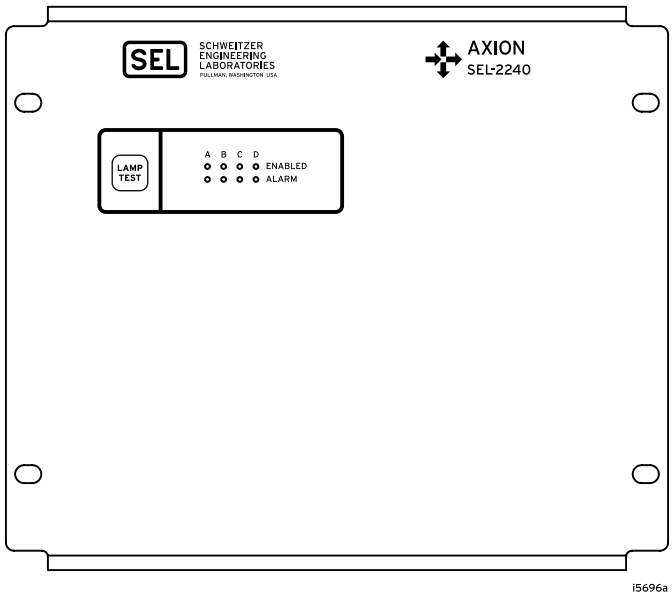

Figure 2.12 SEL-2240 4-Slot Front Panel

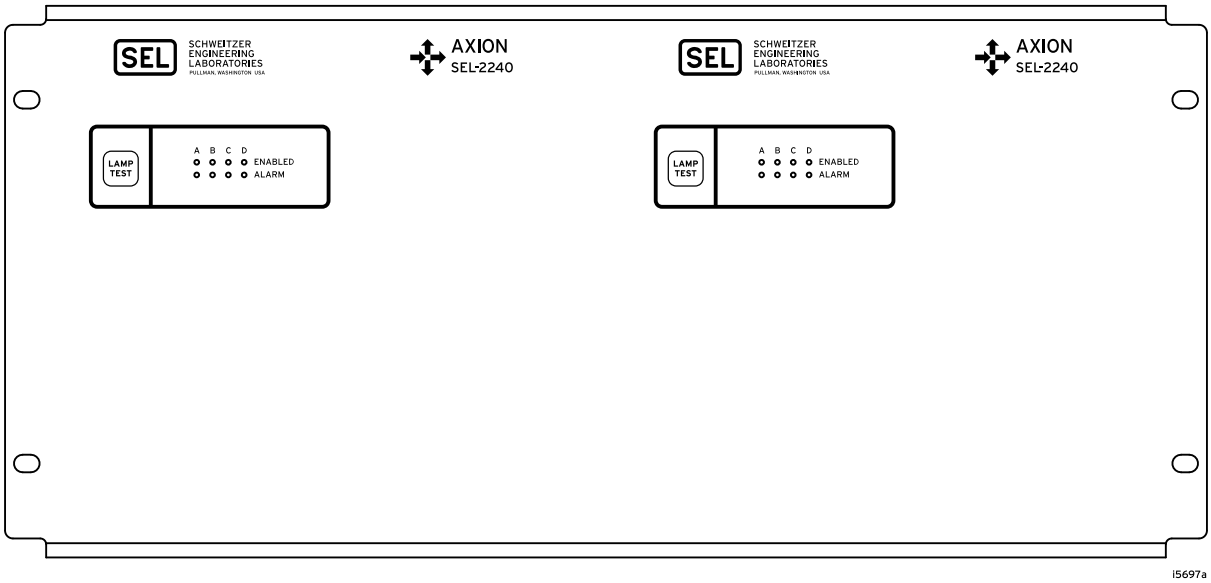

Figure 2.13 SEL-2240 Dual 4-Slot Front Panel (Rack Mount)

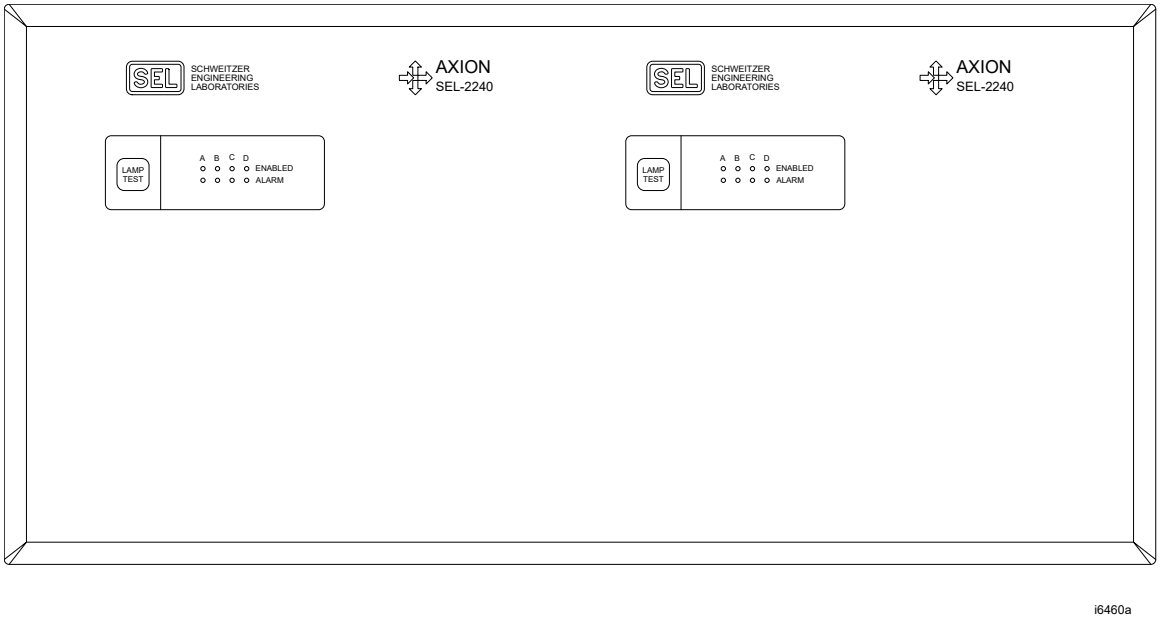

Figure 2.14 SEL-2240 Dual 4-Slot Front Panel (Panel Mount)

Protective Connector Covers

The SEL-2242 is shipped with protective covers installed in each backplane connector. Prior to installing any Axion modules, grasp either side of the connector cover and pull it straight out of the connector. We suggest that you leave the covers inserted in any unused slots to provide dust and mechanical protection.

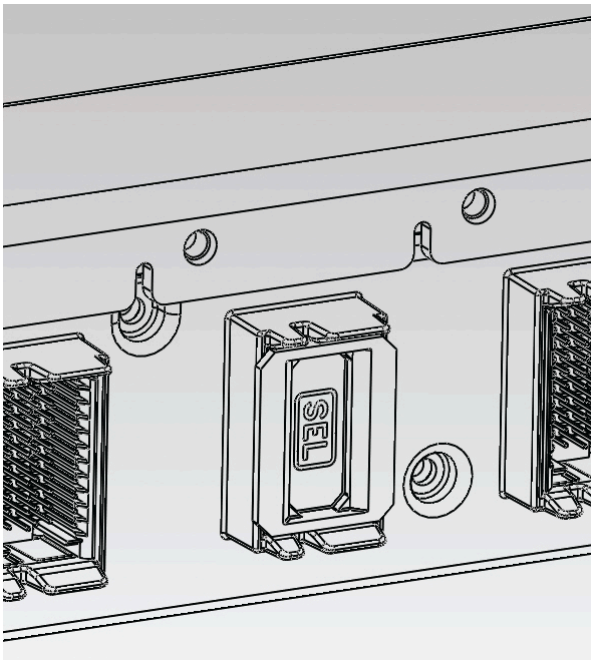

Figure 2.15 Protective Connector Cover

SEL-2241 Real-Time Automation Controller (RTAC)

For each Axion system, you have the option of using an external RTAC (SEL-3530 or SEL-3530-4) as the system controller or using the integrated SEL-2241 RTAC module. The SEL-2241 has all of the capabilities of the external RTAC units, but it receives power from the Axion backplane.

The SEL-2242 backplane chassis with touchscreen display requires an SEL-2241 RTAC in Slot **A**. The touchscreen is only compatible with SEL-2241 RTACs that ship with R149 firmware or later.

Front Panel

Figure 2.16 shows the RTAC status LEDs that aid system troubleshooting and the connectors for communications and wiring.

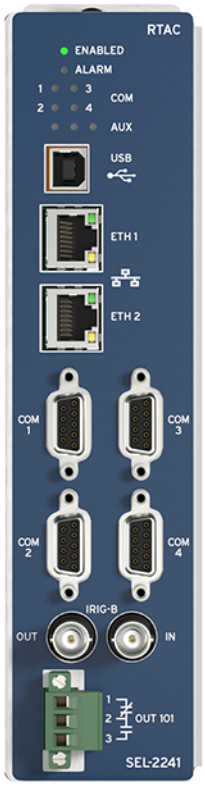

Figure 2.16 SEL-2241 RTAC Front Panel, Copper Ethernet

Mechanical Installation

Each SEL-2242 chassis/backplane has four or ten slots, labeled **A** through **J**. Only Slot **A** supports the SEL-2241 RTAC module.

To install the RTAC, tip the top of the module away from the chassis, align the notch on the bottom of the module with Slot **A** of the chassis, and place the module on the bottom lip of the chassis as *Figure 2.17* illustrates. The module is aligned properly when it rests entirely on the lip of the chassis.

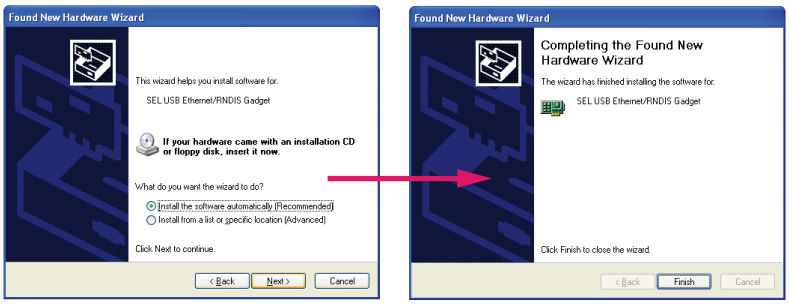
Figure 2.17 Proper Module Placement

Carefully rotate the module into the chassis, making sure that the alignment pin fits into the corresponding slot at the top of the chassis (see *Figure 2.18*). Finally, press the module firmly into the chassis and tighten the chassis retaining screw.

Figure 2.18 Final Module Alignment

Connections

Communications Ports



NOTE
Never connect two RTACs via USB to one PC.

All web access, settings changes and ODBC connections use either the RTAC Ethernet ports or the front USB Type B port. Until you have configured the Ethernet interfaces on the RTAC, you will need to use the supplied USB Type B cable to access the RTAC web interface. The ACSELERATOR RTAC installation will place the required USB driver on your PC. Once Microsoft Windows detects the USB connection, the driver will be installed automatically. Plug the USB cable into the RTAC and into your PC. If you receive a prompt to connect to Windows Update, select **No, not at this time** and press **Next**. Then use the Windows Device Installation Wizard and follow the automatic install prompts to install the SEL USB driver.

NOTE
USB ports are intended for programming only, not continuous use.

NOTE
Do not use USB cables longer than three meters.

After completing this step, you can use IP address 172.29.131.1 to access the RTAC web interface through the USB cable. See *Section 7: Security and Account Management* in the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for RTAC web password setup.

The SEL-2241 has four nonisolated serial ports. You can select all RTAC serial ports through software to be either EIA-232 or EIA-485/EIA-422. You can configure any serial protocol on the RTAC to use any of these serial ports. See *Table 2.1* for the pinout of the RTAC serial ports.

Table 2.1 Nonisolated Female DB-9 Ports

EIA-232	EIA-485/EIA-422
Pin 1: N/C or +5 Vdc (also DCD input on COM 1 if +5 Vdc is disabled)	Pin 1: N/C or +5 Vdc (also DCD input on COM 1 if +5 Vdc is disabled)
Pin 2: RXD	Pin 2: –RXD

Port	Port Interface	Cables
USB-B	USB Type B to USB Type A	SEL-C664 (no longer than three meters)
ETH 1 and **ETH 2**	10/100BASE-T (RJ45 for Copper)	SEL-C627F (double shielded with a ferrite clamp)
COM 1–**COM 4** (serial)	EIA-232 (Nonisolated)	SEL-C234A, SEL-C273A, and SEL-C387 are popular selections
IRIG-B INput	Female BNC	SEL-C953
IRIG-B OUTput	Female BNC	SEL-C953

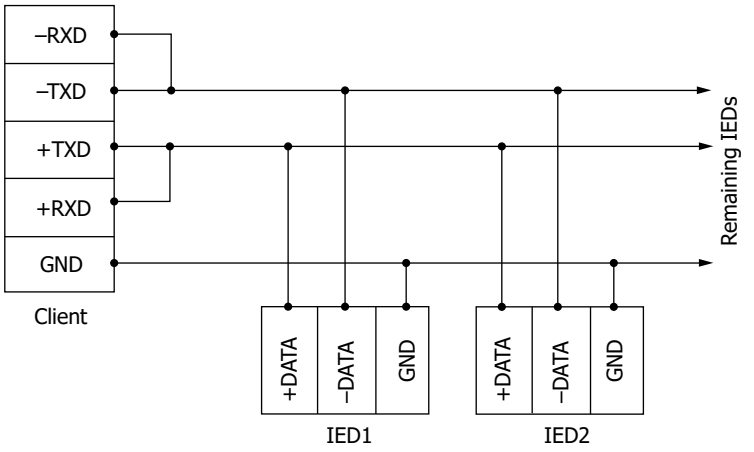

Figure 2.19 EIA-485 Typical Two-Wire Connection

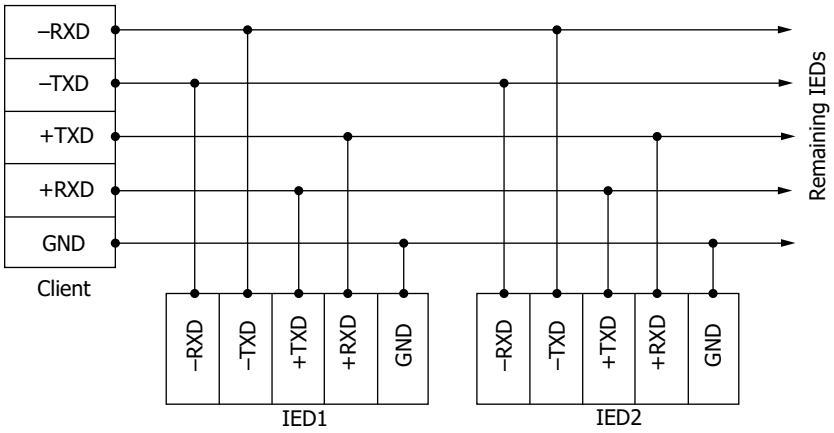

Figure 2.20 EIA-485 Typical Four-Wire Connection

Outputs

Refer to *Section 1: Introduction and Specifications* for output contact ratings and *Figure 2.16* for terminal assignments. Configure the contact output under SystemTags (Contact Outputs Tab) in ACSELERATOR RTAC. You can change the name of the point, create an alias tag name, and initialize status values. The RTAC will use the initialized value until run time, when it uses the actual value.

Figure 2.21 shows that a trip coil has a resistive and inductive component. After a trip output has been closed for a long time, the current settles to a steady-state value. When the trip output opens, it tries to interrupt the inductive current that wants to continue to flow (V = L di/dt). This attempted interruption of current causes a large voltage spike that can turn into an arc. When the contacts bounce during the arc, they often weld closed. SEL has designed, tested, and specified the outputs for this application to prevent any such welding (see *Breaking Capacity (10,000 Operations) on page 44*).

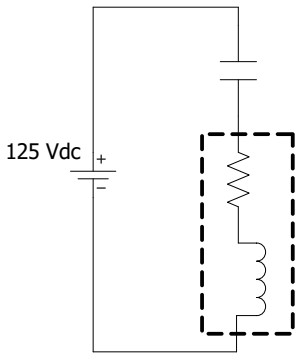

Figure 2.21 Inductive Interrupt of a Trip Output

LED Indicators

In addition to LEDs representing module status and communications activity, the SEL-2241 has three user-programmable bi-color LEDs. Configure these LEDs under SystemTags (LEDs Tab) in ACSELERATOR RTAC.

Field Serviceability

You can upgrade RTAC firmware and custom programming in the field or remotely over Ethernet. Self-tests provide status indication of errant conditions that can occur in the RTAC. You can map one or a combination of these or other status indications to the alarm contact to create a diagnostic alarm.

The real-time clock battery and power coupler fuses are the only field-serviceable parts. Return all modules to SEL for any other servicing or maintenance.

The battery and fuses are only serviceable on units that are fully disconnected from any hazardous live voltage (such as connections to input power or OUT101).

Module Replacement

To replace the SEL-2241 RTAC, perform the following steps:

Step 1. Back up all RTAC settings. See *Section 1: Getting Started* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for instructions on how to back up and restore RTAC projects.

Step 2. De-energize any power source connected to the power coupler(s) in the Axion node.

Step 3. Loosen retaining screws and remove the terminal strip for the alarm contact. Disconnect all communications cables.

Step 4. Loosen the chassis retaining screw at the top of the module.

Step 5. Tip the top of the module away from the chassis and lift it from the bottom lip.

Step 6. Install the new module according to the applicable mechanical installation instructions in this section.

Step 7. Make all necessary connections to the module according to the applicable connection instructions in this section.

Step 8. Apply power to the Axion node.

Step 9. Use IP address 172.29.131.1 to access the RTAC web interface through the supplied USB cable. See *Section 7: Security and Account Management* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for RTAC web password setup. Also enable all necessary communications ports.

Step 10. Download the settings project from ACSELERATOR RTAC.

Real-Time Clock Battery Replacement

⚠ DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

⚠ CAUTION
The device contains devices sensitive to Electrostatic Discharge (ESD). When working on the device with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

⚠ CAUTION
There is danger of explosion if the battery is incorrectly replaced. Replace only with Rayovac no. BR1632 or equivalent recommended by manufacturer. See Owner's Manual for safety instructions. The battery used in this device may present a fire or chemical burn hazard if mistreated. Do not recharge, disassemble, heat above 100°C or incinerate. Dispose of used batteries according to the manufacturer's instructions. Keep battery out of reach of children.

The real-time clock battery is a field-replaceable component and cannot be recharged. A lithium battery powers the clock (date and time) during loss or removal of the external power source. The battery is a 3 V lithium coin cell, Rayovac BR1632 or equivalent. At room temperature (25°C), the battery will operate nominally for ten years. When the device receives power from an external source, the battery experiences a low self-discharge rate. Thus, battery life can extend well beyond ten years.

To replace the real-time clock battery, perform the following steps:

Step 1. Follow the instructions in *SEL-2241 Disassembly on page 77* to expose the circuit board.

Step 2. Locate the battery clip (holder) on the board.

Step 3. Carefully remove the battery from beneath the clip. Properly dispose of the old battery.

Step 4. Install the new battery with the positive (+) side facing up.

Step 5. Follow the instructions in *SEL-2241 Reassembly on page 77*.

Step 6. Set the device date and time.

Power Supply Fuse Replacement

⚠ DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

⚠ WARNING

Have only qualified personnel service this equipment. If you are not qualified to service this equipment, you can injure yourself or others, or cause equipment damage.

⚠ CAUTION

Equipment components are sensitive to electrostatic discharge (ESD). Undetectable permanent damage can result if you do not use proper ESD procedures. Ground yourself, your work surface, and this equipment before removing any cover from this equipment. If your facility is not equipped to work with these components, contact SEL about returning this device and related SEL equipment for service.

You can replace a bad primary fuse in a power coupler, or you can return the power coupler to SEL for fuse replacement. If you decide to replace the fuse, perform the following steps:

Step 1. Follow your company standard to remove the whole Axion node from service.

Step 2. Disconnect power from all power couplers in the backplane.

Step 3. Remove all connections to the failed power coupler and remove it from the backplane.

Step 4. Ground the equipment to an ESD mat.

Step 5. Remove the six screws holding the lid on the chassis and remove the lid.

Step 6. While properly grounded to the ESD mat, remove the six screws holding the PCB in the chassis and remove the PCB from the chassis.

Step 7. Locate fuse **F1** near the power supply input header.

Step 8. Examine the power supply for blackened marks or damage. If there is obvious damage, reassemble the power coupler and contact SEL to arrange for return of the module for repair.

Step 9. Remove the plastic fuse protector and remove the spent fuse from the fuse clips.

Step 10. Replace the fuse with an exact replacement (see *Power Coupler (SEL-2243) on page 45* for fuse ratings).

Step 11. Reinstall the PCB in the chassis and secure it with the six pan head screws.

Step 12. Replace the lid and secure it with the six flat head screws.

Step 13. Reinstall the power coupler in the unpowered backplane and reconnect all cables removed in the disassembly process.

Step 14. Follow your company standard procedure to return the Axion node to service.

Step 15. If the fuse opens while restoring service, return the power coupler to SEL for module replacement.

Jumpers

Table 2.3 shows the configurable jumper positions.

Table 2.3 Configurable Jumper Positions

Jumper	Position
JMP1	OPEN[a]
JMP2	OPEN[a]
JMP3	OPEN[a]
JMP4	1–2[a] Routes IRIG-B+ to COM 1 Pin 4 3–4 Routes DTR signal to COM 1 Pin 4 5–6[a] Routes IRIG-B ground to COM 1 Pin 6 7–8 Routes DSR signal to COM 1 Pin 6

[a] Factory-default position.

SEL-2241 Disassembly

⚠ DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

⚠ CAUTION
The device contains devices sensitive to Electrostatic Discharge (ESD). When working on the device with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

To disassemble the SEL-2241 RTAC, perform the following steps:

Step 1. Disconnect any hazardous live voltage (such as connections to OUT101).

Step 2. Follow the instructions in *Module Replacement on page 74*.

Step 3. Remove the six retaining screws (two top, two rear, two bottom).

Step 4. Place the module on its side and lift the cover to expose the circuit board.

SEL-2241 Reassembly

⚠ DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

⚠ CAUTION
The device contains devices sensitive to Electrostatic Discharge (ESD). When working on the device with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

To reassemble the SEL-2241 RTAC, perform the following steps:

Step 1. Gently close the cover until the retaining screw holes are aligned.

Step 2. Replace the six retaining screws.

Step 3. Follow the instructions in *Mechanical Installation on page 70*.

SEL-2243 Power Coupler

Every Axion node requires at least one SEL-2243 Power Coupler module. The SEL-2243 serves two purposes in an Axion system:

1. It is the power supply for all modules installed in the node, and;
2. It provides two dedicated EtherCAT® ports so that multiple Axion nodes can operate together.

Front Panel

Figure 2.22 SEL-2243 Front Panel, Copper and Fiber Connectors

Power Supply Operation

One SEL-2243 has sufficient power capacity to accommodate an entire Axion node. The terminal strip at the bottom of the unit, as seen in *Figure 2.22*, is the connection point for incoming power. All Axion modules have a 55-position IEC C-style connector that provides a communications and power interface to the backplane. The SEL-2243 provides power to the node via the backplane connector.

The power coupler module uses the same power supply design that you would find in SEL protective relays. The Axion provides test-proven superior performance and availability, while also allowing for redundant power couplers in a node for applications that need these. If you install two power couplers in a node, both modules actively share load and provide the necessary power for node functions. If one SEL-2243 becomes unavailable, there is zero switching delay or power loss to the node.

EtherCAT Operation

Each SEL-2243 provides two dedicated ports for EtherCAT networks. The ports will either be standard 10/100BASE-T or optional 100BASE-FX Ethernet ports. EtherCAT is a real-time fieldbus protocol (See *Appendix E* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual*) that we can use to connect an RTAC to I/O modules in an Axion system. If the installation has only one node, then the backplane transmits EtherCAT messages. Alternatively, if you use an SEL-3530 RTAC, or if you need more I/O than will fit in a node, then the ports on a power coupler module provide a mechanism for extending the EtherCAT network through the use of dedicated Ethernet wiring. Refer to *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* to learn more about configuring a network.

⚠CAUTION
Always ensure that power couplers are not connected to any Ethernet switches or other Ethernet devices, including RJ45-to-fiber-optic converters. The power coupler EtherCAT ports are only for direct connections between power couplers of the same type or to an RTAC EtherCAT port. Connecting a power coupler to any other Ethernet device can cause the EtherCAT network to stop communicating completely or behave unpredictably.

If an Axion node contains two SEL-2243 modules, then the EtherCAT ports in both power couplers will operate normally even if one power supply becomes unavailable. The remaining power supply will serve as the source for all I/O modules and communications needs.

Mechanical Installation

Slots **A**, **B**, and **C** support the SEL-2243 Power Coupler module. See *Mechanical Installation on page 70* for SEL-2243 module installation instructions.

NOTE
For applications compliant with IEC-60255-27, surface-mount units must be installed in IP4X enclosures.

Connections

General

Terminals are not intended for use with bare conductors. Solid or stranded wire can be used with ferrule or spade terminals. The customer is responsible for verifying that wire insulation and temperature ratings are sufficient for their application.

Power

The power terminals on the high-voltage power coupler (1 (**+/H**) and 2 (**–/N**)) must connect to 120–240 Vac with the proper polarity or to 125/250 Vdc. The power terminals on the low-voltage power coupler (1 (**+/H**) and 2 (**–/N**)) must connect to 24/48 Vdc. The power terminals are isolated from the chassis ground. Use 14 AWG (2.1 mm^2) wire with an external 15 A branch circuit protection device or 12 AWG (3.3 mm^2) wire with an external 20 A branch circuit protection device.

⚠DANGER
Contact with instrument terminals can cause electric shock that can result in injury or death.

⚠CAUTION
Damage may occur from connecting a high-voltage source to a low-voltage power coupler.

Grounding (Earthing)

Connect the ground terminal labeled ⏚ **GND(3)** on the power coupler to a rack frame or switchgear ground for proper safety and performance. Connect the ground terminal on the backplane behind the module in slot A to a rack frame or switchgear ground for proper safety and performance. Use less than 2 m (6.6 feet) of 14 AWG (2.1 mm^2) wire of sufficient current capacity and insulation voltage ratings for the ground connection. Protective earth connections should not be removed when the equipment is energized.

EtherCAT Ports

The SEL-2243 includes two 10/100BASE-T or 100BASE-FX Ethernet ports dedicated for EtherCAT protocol. Use a standard RJ45 connector for a copper port and an LC connector for a fiber-optic port to connect **PORT 1** or **PORT 2** of the module. Make each connection by using a direct cable to the next device. Use SEL cable SEL-C627F (double shielded with a ferrite cable clamp) on copper ports to shield against RF noise. Copper cables for EtherCAT connections should be less than 3 m (10 ft) in length.

⚠CAUTION
Do not connect the SEL-2243 Power Coupler to an Ethernet switch.

Buttons and LEDs

Each power coupler includes a **LAMP TEST** button useful for system testing. When depressed, all module LEDs on the terminal side and front panel (rack mount only) will illuminate.

The green LED labeled **POWER** on the SEL-2243 will illuminate if incoming power is present and the power supply is operating normally. The LEDs labeled **ENABLED** and **ALARM** are related to EtherCAT network operation. The green **ENABLED** LED will illuminate when the module is operating normally on the network. The **ALARM** LED will illuminate during network initialization or when there is a problem with the network.

Module Replacement

Steps for replacing an Axion module will differ based on whether the module has failed or if you want different system functionality. The following steps apply to the SEL-2243 Power Coupler and SEL-2244 Digital I/O Modules for an Axion system that is configured and in operation. Refer to *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* if you are configuring a new system.

Replacing a Module to Change System Functionality

The flexible design of the Axion allows you to modify system features by adding or replacing a module. For instance, you can replace a digital output module with a digital input module.

Step 1. Open the ACSELERATOR RTAC project for the Axion system you want to modify. In the **Home** ribbon, select the **Go Online** button. Follow the software prompts to enter online mode.

Step 2. Select **EtherCAT I/O Network** from the project view pane. The EtherCAT I/O Network editor will display in the editing pane.

Step 3. Navigate to the **Connections** tab within the editor. As *Figure 2.23* shows, right-click on the module you want to replace and select **Decommission**. Decommissioning removes all network settings from the module so that you can use it as a spare for another system at a later date.

> **NOTE**
> Failure to decommission a module can cause network configuration errors if the subject module is placed in another Axion system at a later date.

Step 4. (Only applies if you are replacing an SEL-2243 Power Coupler.) De-energize any power source connected to the power coupler. Remove the incoming power plug-in connector and all network cables. If the Axion node has only one power coupler, the entire node will shut down and connected nodes will lose network connectivity.

Step 5. (Only applies if you are replacing an SEL-2244 Digital I/O Module.) Loosen terminal strip retaining screws and remove I/O terminal strips.

Step 6. Loosen the chassis retaining screw at the top of the module.

> **NOTE**
> Do not decommission any modules in an Axion system while network errors exist on the system. The decommission function depends on a fully functioning network to complete properly.

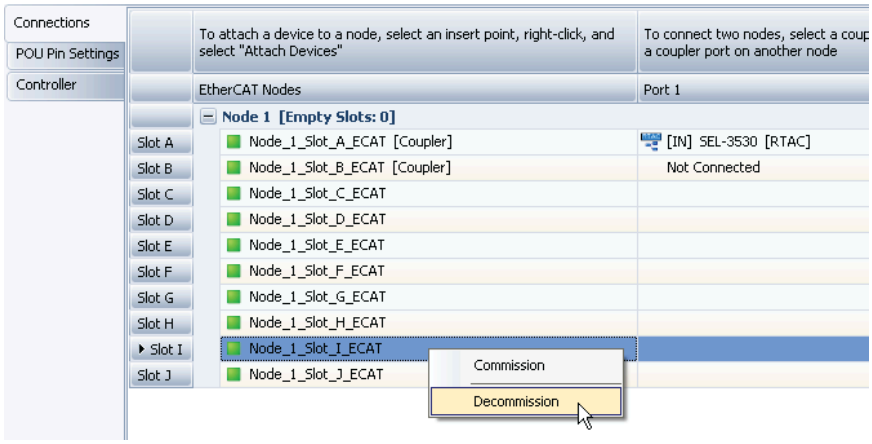

Figure 2.23 Decommissioning a Module

Step 7. Tip the top of the module away from the chassis and lift it from the bottom lip. By default, the RTAC asserts an EtherCAT network error and stops all EtherCAT messages. All output modules will deassert. See *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* to learn how to use a POU pin setting to disable this behavior.

Step 8. Install the new module according to the applicable mechanical installation instructions in this section.

Step 9. Make all needed connections to the module according to the applicable connection instructions in this section.

Step 10. You are installing a different module type, so you will need an updated settings project to take advantage of the new module. Select **Go Offline** and edit the ACSELERATOR RTAC project to include the new module. Use the downloading instructions in *Section 1: Getting Started* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* to save and download the new project. The EtherCAT network will automatically configure and enable once you have installed the new project.

Replacing a Failed Module

⚠CAUTION
Use extreme caution when changing POU settings. Contact an SEL representative for assistance.

The default behavior of the Axion will be to disable the EtherCAT network if there are any module errors. In case of an error, such as a hardware fault, the RTAC will identify the network error and shut down all network traffic. For such an occurrence, all output modules will deassert. If you alter the EtherCAT POU setting "Disable_On_Network_Error" to a value of FALSE, then the network will continue to operate with the remaining modules even if an error occurs (see *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* to learn about EtherCAT POU settings).

Replacing a Failed Module With Disabled Network (Disable_On_Network_Error = TRUE)

If you have determined that an Axion module has failed and the EtherCAT network is disabled, use the following steps to install a replacement.

Step 1. (Only applies if you are replacing an SEL-2243 Power Coupler.) De-energize any power source connected to the power coupler. Remove the incoming power plug-in connector and all network cables. If the Axion node has only one power coupler, the entire node will shut down.

Step 2. (Only applies if you are replacing an SEL-2244 Digital I/O Module.) Loosen terminal strip retaining screws and remove I/O terminal strips.

Step 3. Loosen the chassis retaining screw at the top of the module.

Step 4. Tip the top of the module away from the chassis and lift it from the bottom lip.

Step 5. Install the new module according to the applicable mechanical installation instructions in this section.

Step 6. Make all needed connections to the module according to the applicable connection instructions in this section.

Step 7. Open the ACSELERATOR RTAC project for the Axion system. In the **Home** ribbon, select the **Go Online** button. Follow the software prompts to enter online mode.

Step 8. Select **EtherCAT I/O Network** from the project view pane. The EtherCAT I/O Network editor will display in the editing pane.

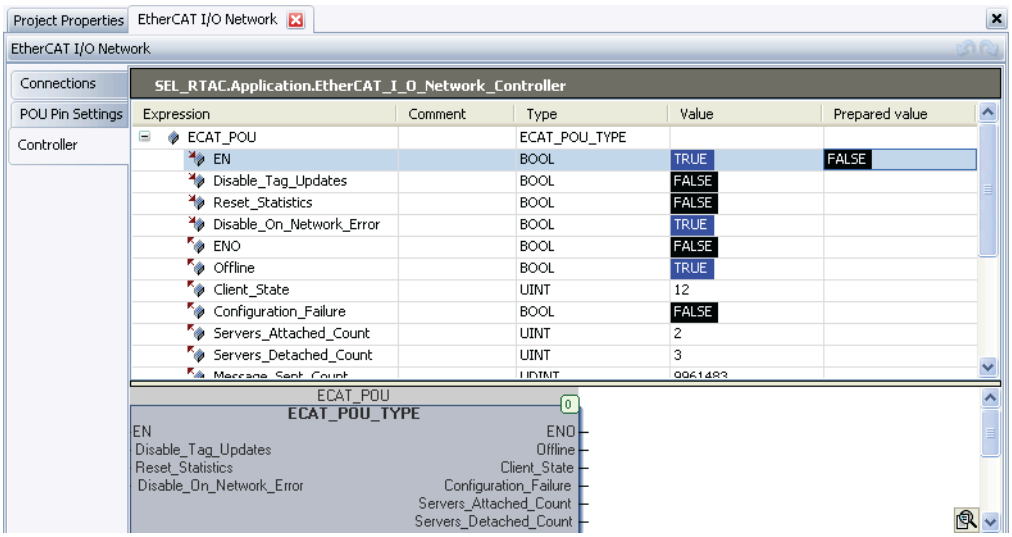

Figure 2.24 Manually Enabling the EtherCAT Network

Step 9. Navigate to the **Controller** tab within the editor. As *Figure 2.24* shows, enter a **Prepared value** of **FALSE** for the **EN** (enable) pin for the EtherCAT POU. In the **Home** ribbon, select **Tools** and select **Force Values** (press **<F6>** on your keyboard as a shortcut).

Step 10. Select **Tools** and select **Unforce and Restore Values** (press **<Shift+F6>** on your keyboard as a shortcut) to release the forced value and restart the EtherCAT network.

Replacing a Failed Module With Enabled Network (Disable_On_Network_Error = FALSE)

If you have determined that an Axion module has failed and that the EtherCAT network is still enabled, use the following steps to install a replacement.

Step 1. (Only applies if you are replacing an SEL-2243 Power Coupler.) De-energize any power source connected to the power coupler. Remove the incoming power plug-in connector and all network cables. If the Axion node has only one power coupler, the entire node will shut down.

Step 2. (Only applies if you are replacing an SEL-2244 Digital I/O Module.) Loosen terminal strip retaining screws and remove I/O terminal strips.

Step 3. Loosen the chassis retaining screw at the top of the module.

Step 4. Tip the top of the module away from the chassis and lift it from the bottom lip.

Step 5. Install the new module according to the applicable mechanical installation instructions in this section. *Do not tighten the chassis retaining screw*.

Step 6. Make all necessary connections to the module according to the applicable connection instructions in this section.

Step 7. Open the ACSELERATOR RTAC project for Axion system. In the **Home** ribbon, select the **Go Online** button. Follow the software prompts to enter online mode.

Step 8. The EtherCAT network is still enabled; you need to commission the replacement module so that it will join the network. During the commissioning process, the RTAC will download all of the necessary settings to the new module. Select **EtherCAT I/O Network** from the project view pane. The EtherCAT I/O Network editor will display in the editing pane.

Step 9. Navigate to the **Connections** tab within the editor. As *Figure 2.25* shows, right-click on the entry for the new module and select **Commission**.

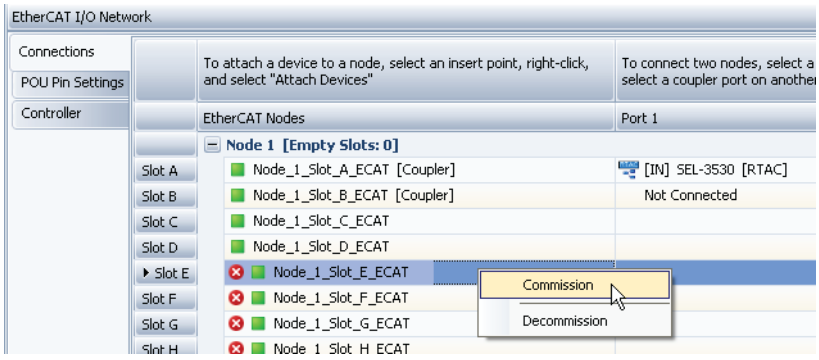

Figure 2.25 Commissioning a Module

Step 10. ACSELERATOR RTAC will display a dialog box instructing you to cycle power to the new module. This is necessary for the new settings to take effect. Tip the top of the module away from the chassis far enough that all LEDs on the module extinguish. Press the module back into place and tighten the chassis retaining screw. The module will join the network automatically.

SEL-2244 Digital Input/Output Module

The SEL-2244 provides contact input and outputs for the Axion. Within an Axion node, install any combination of SEL-2244 modules you want.

Front Panel

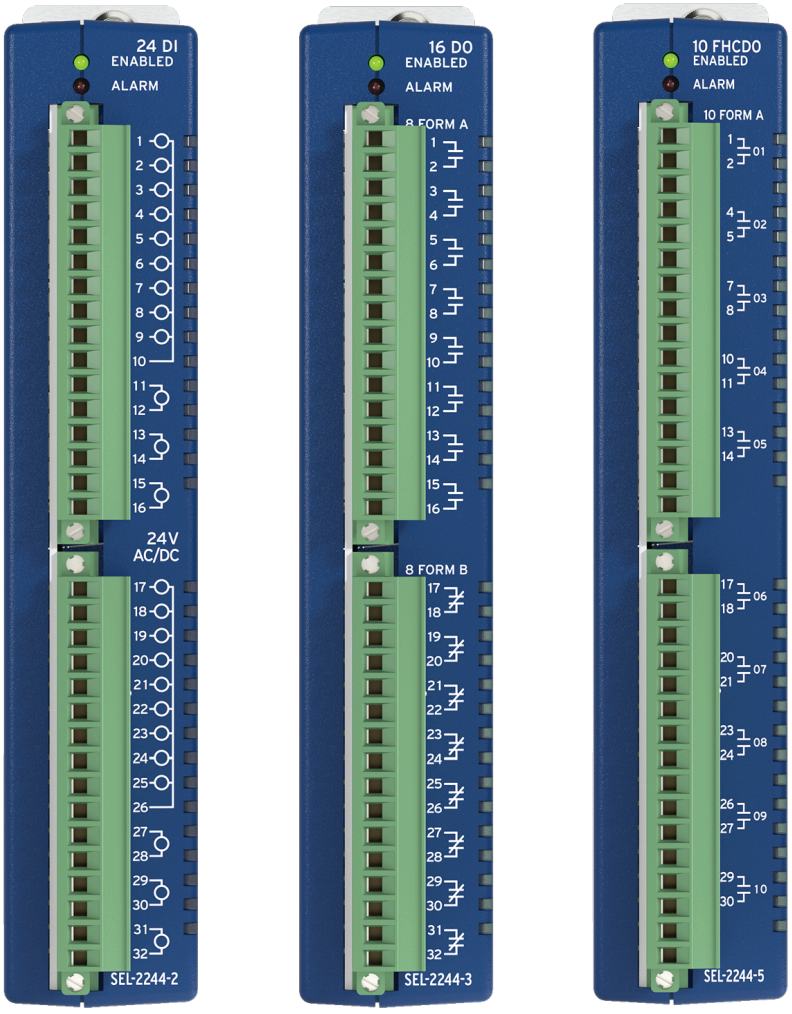

Figure 2.26 SEL-2244 Digital Input and Output Modules

Mechanical Installation

Each SEL-2242 chassis/backplane has four or ten slots, labeled **A** through **J**. Slots **B**–**J** support the SEL-2244 Digital Input and Digital Output modules.

To install an SEL-2244 module, tip the top of the module away from the chassis, align the notch on the bottom of the module with the slot you want on the chassis, and place the module on the bottom lip of the chassis as *Figure 2.27* illustrates. The module is aligned properly when it rests entirely on the lip of the chassis.

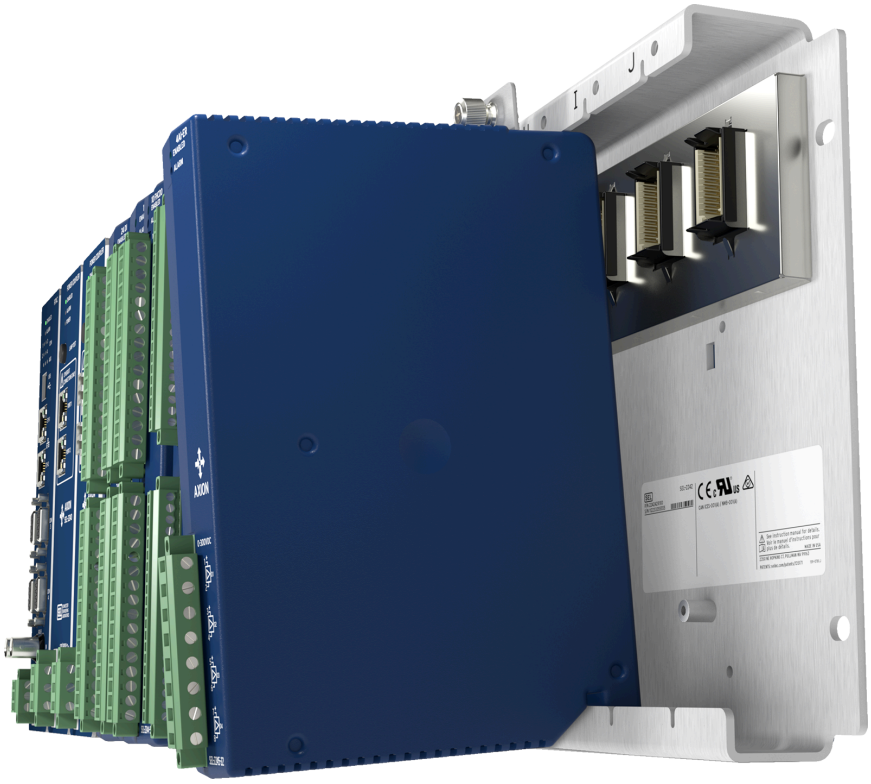

Figure 2.27 Proper Module Placement

Next, carefully rotate the module into the chassis, making sure that the alignment tab fits into the corresponding slot at the top of the chassis (refer to *Figure 2.28*). Finally, press the module firmly into the chassis and tighten the chassis retaining screw.

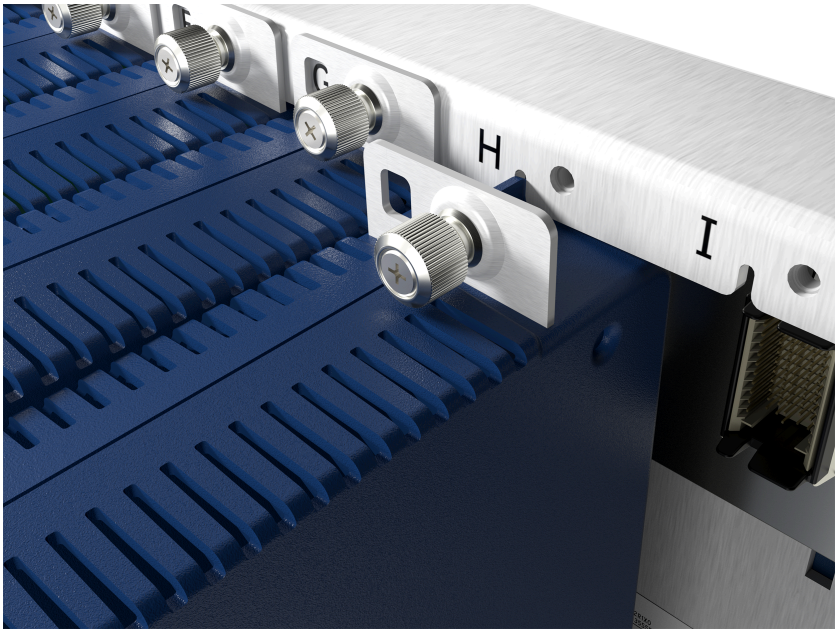

Figure 2.28 Final Module Alignment

Connections

Digital Inputs

The SEL-2244 optoisolated inputs are not polarity-dependent. Refer to *Section 1: Introduction and Specifications* for optoisolated input ratings and *Figure 2.26* for terminal assignments. You can configure inputs to respond to ac or dc control signals. Configure contact inputs by adding a Fieldbus I/O connection for each module in ACSELERATOR RTAC. See the EtherCAT portion of *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the digital input terminals for your application.

NOTE

Ensure that when you are applying ac power to inputs with common returns that ac neutral is connected to the common terminal.

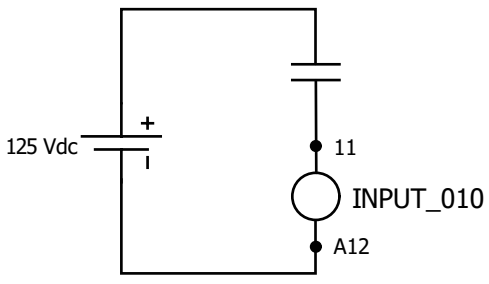

Figure 2.29 Digital Inputs

Digital Outputs

Refer to *Section 1: Introduction and Specifications* for output contact ratings and *Figure 2.26* for terminal assignments. Depending on which module type you ordered, the module will have all Form A, all Form B, or some of each contact type. Configure contact outputs by adding a Fieldbus I/O connection for each module in ACSELERATOR RTAC. See the EtherCAT portion of *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the digital output terminals for your application.

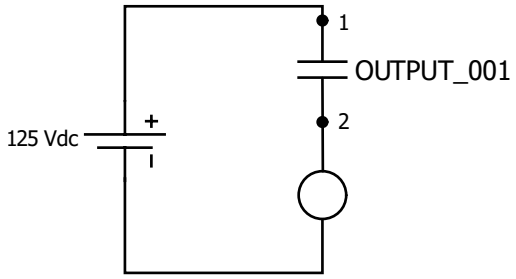

Figure 2.30 Digital Outputs

LED Indicators

Each input and output is associated with a red LED on the right edge of the module. The LED will be illuminated when you assert the point or depress the lamp test button.

The LEDs labeled **ENABLED** and **ALARM** are related to EtherCAT network operation. The green **ENABLED** LED will illuminate when the module is operating normally on the network. The **ALARM** LED will illuminate during network initialization or when there is a problem with the network.

Replacing Modules

Refer to *Module Replacement on page 74* for the SEL-2243.

SEL-2245 Analog Input/Output Modules

The SEL-2245 provides analog inputs and outputs for the Axion. Install as many as 16 modules of each type of analog module in an Axion system. Only three dc analog output modules can be installed in a standard backplane. Furthermore, only two dc analog output modules can be installed in a backplane with the 7-inch color touchscreen display.

Front Panels

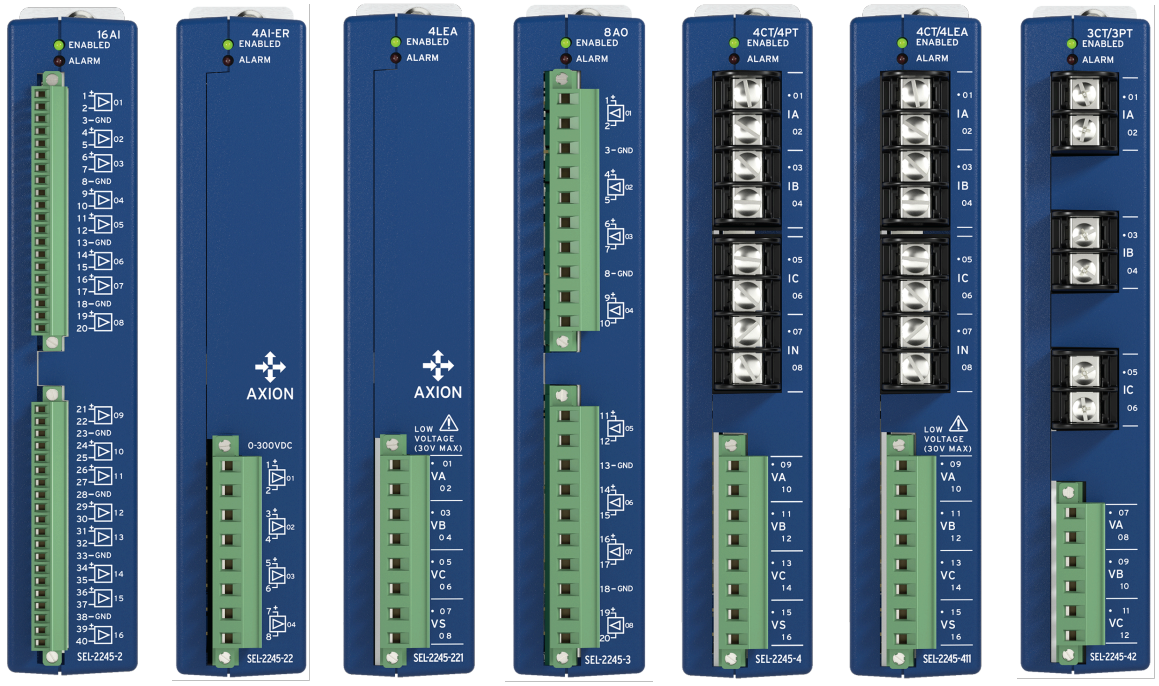

Figure 2.31 SEL-2245 Modules

Mechanical Installation

Slots **B**–**J** support the SEL-2245 Analog Input and Output modules. See *Mechanical Installation on page 85* for SEL-2245 module installation instructions.

DC Analog Inputs

The SEL-2245-2 dc analog inputs include a plus sign to indicate the positive convention. Refer to *Section 1: Introduction and Specifications* for analog input ratings and *Figure 2.32* for terminal assignments. You can configure inputs to measure ±20 mA, ±2 mA, or ±10 V signals. Configure inputs by adding a Fieldbus I/O connection for each module in ACSELERATOR RTAC. See EtherCAT in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 28–16 AWG (0.1–1.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog input terminals for your application.

The return terminal for all inputs, including unused inputs, must be connected together in order to ensure measurement errors stay within the maximum limits during transient events. This is required when using the SEL-2245-2 in a command and control system. The inputs may be isolated from each other for measurement only applications. Accuracy returns to typical values within 100 ms of the end of a transient when using Filter A. Filter B and Filter C extend recovery time, but reduce the magnitude of erroneous readings during transient events.

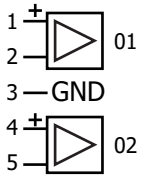

Figure 2.32 DC Analog Inputs

DC Analog Inputs Extended Range

The SEL-2245-22 extended range dc analog inputs include a plus sign to indicate the positive convention. Refer to *Section 1: Introduction and Specifications* for analog input ratings and *Figure 2.33* for terminal assignments. Extended range inputs are for measuring 0–300 Vdc signals. Configure inputs by adding a Fieldbus I/O connection for each module in ACSELERATOR RTAC. See *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog input terminals for your application.

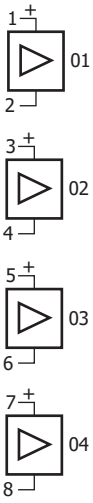

Figure 2.33 DC Analog Inputs Extended Range

DC Analog Outputs

The SEL-2245-3 dc analog outputs include a plus sign to indicate the positive convention. Refer to *Section 1: Introduction and Specifications* for analog output ratings and *Figure 2.34* for terminal assignments. You can configure outputs to produce ±20 mA or ±10 V signals. Configure outputs by adding a Fieldbus I/O connection for each module in ACSELERATOR RTAC. See *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog output terminals for your application.

NOTE
You cannot install more than two dc analog outputs on the same node if the device is configured with an LCD touchscreen. Otherwise, you cannot install more than three outputs on the same node.

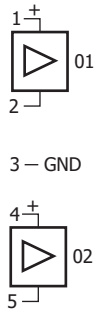

Figure 2.34 DC Analog Outputs

AC Metering Inputs

The SEL-2245-4 inputs use a dot by the terminal numbers to indicate the polarity connection of the CTs and PTs. Refer to *Section 1: Introduction and Specifications* for CT/PT analog input ratings and *Figure 2.35* for terminal assignments. Configure inputs by adding a Field-bus I/O connection for each module in ACSELERATOR RTAC. See *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog input terminals for your application. Use #8 ring or spade terminals for CT connections.

⚠CAUTION
If CT inputs are connected to external CTs, ensure that the external CTs are shorted prior to removing CT connections.

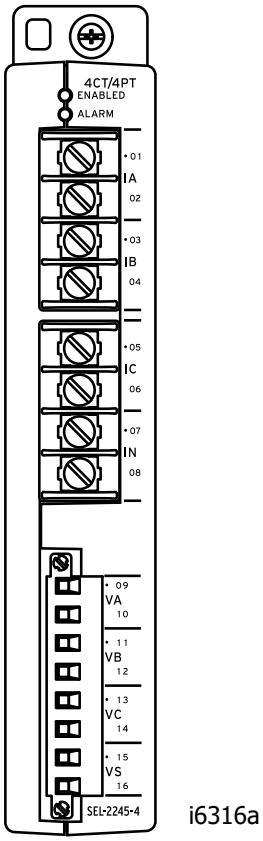

Figure 2.35 AC Metering Inputs

Low-Voltage (LEA) Monitoring Inputs

The SEL-2245-411 and SEL-2245-221 inputs use a dot by the terminal numbers to indicate the polarity connection of the CTs and low-voltage (LEA) inputs. Refer to *Section 1: Introduction and Specifications* for CT/LEA analog input ratings and *Figure 2.36* for terminal assignments. Configure inputs by adding a field-bus I/O connection for each module in ACSELERATOR RTAC. See *EtherCAT* in *Section 2: Communications* of the ACSELERATOR RTAC SEL-5033 Instruction Manual for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog input terminals for your application. Use #8 ring or spade terminals for CT connections.

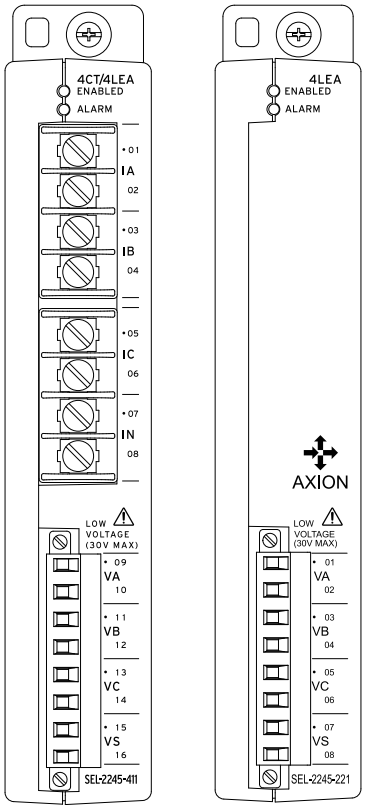

Figure 2.36 Low-Voltage (LEA) Monitoring Inputs

AC Protection Inputs

The SEL-2245-42 inputs use a dot by the terminal numbers to indicate the polarity connection of the CTs and PTs. Refer to *Section 1: Introduction and Specifications* for CT/PT analog input ratings and *Figure 2.37* for terminal assignments. Configure inputs by adding a Field-bus I/O connection for each module in ACSELERATOR RTAC. See *EtherCAT* in *Section 2: Communications* of the *ACSELERATOR RTAC SEL-5033 Instruction Manual* for details. Use 24–12 AWG (0.2–3.3 mm^2) wire of sufficient current capacity and insulation voltage ratings to connect to the analog input terminals for your application. Use #8 ring or spade terminals for CT connections.

⚠CAUTION
If CT inputs are connected to external CTs, ensure that the external CTs are shorted prior to removing CT connections.

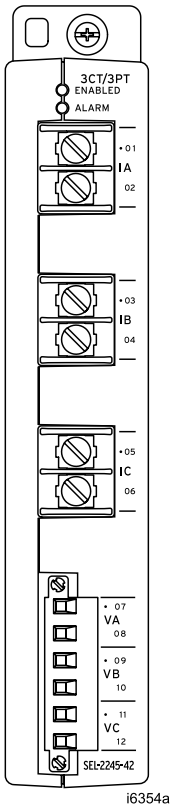

Figure 2.37 AC Protection Inputs

Wye-Connected Voltage Inputs

To connect wye-configuration voltage inputs on the SEL-2245-4 or SEL-2245-42 voltage inputs, directly connect each input (i.e., phase VA is connected to input VA on the module) as shown in *Figure 2.38*.

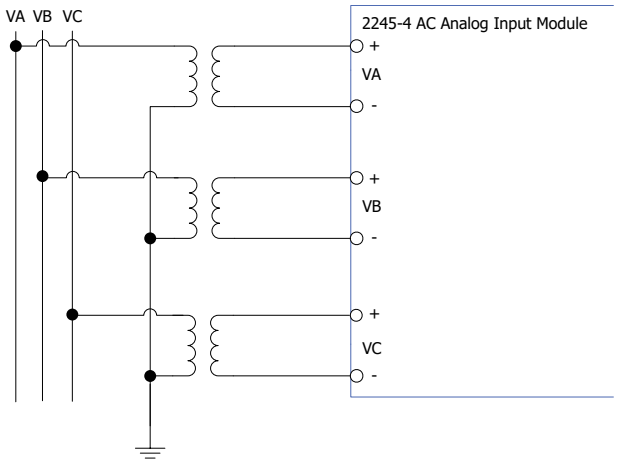

Figure 2.38 PT Wye-Connected Voltage Inputs

With wye voltages, the following tag assignments provide the individual voltages:

- VA = VA phase voltage
- VB = VB phase voltage
- VC = VC phase voltage

Delta-Connected Voltage Inputs

To connect delta voltage inputs on the SEL-2245-4 or SEL-2245-42, connect the open-delta inputs as shown in *Figure 2.39*.

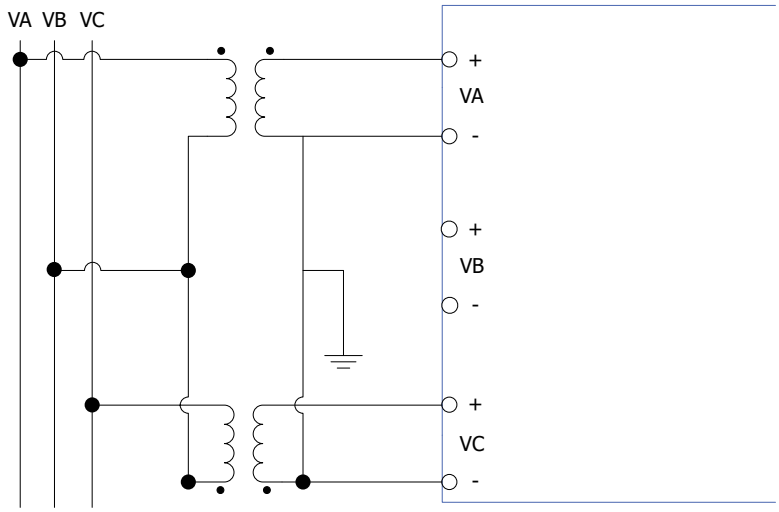

Figure 2.39 Open-Delta Voltage Inputs

With delta voltages, the following tag assignments provide the individual voltages:

- VAB = VA
- VBC = –VC
- VCA = VC – VA

LED Indicators

The LEDs labeled **ENABLED** and **ALARM** are related to EtherCAT network operation. The green **ENABLED** LED will illuminate when the module is operating normally on the network. The **ALARM** LED will illuminate during network initialization or when there is a problem with the network.

Replacing Modules

Refer to *Module Replacement on page 74* for the SEL-2243.

This page intentionally left blank

SECTION 3

Factory Reset

Override Login

The RTAC has a jumper that allows you to override the requirement to use a user password. SEL recommends using this jumper only when necessary to restore a unit when the administrative password is forgotten. For security reasons, you should not operate the RTAC without a password.

NOTE
ODBC and other tools may still prompt you for a password when the RTAC password override is enabled. You can enter any text for a password in those situations.

The following pages include information about changing specific jumper positions on the RTAC circuit board. Referring to *Figure 3.1*, you will notice that each jumper has one corner with wider silkscreen than the remaining portions of the jumper. This will indicate the location of Pin **1** and Position **A** of the jumper.

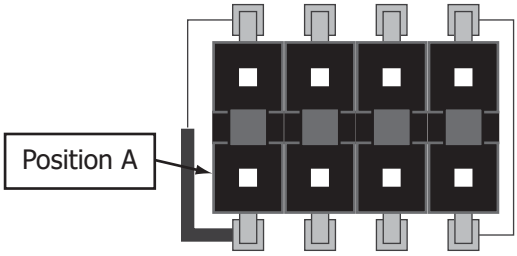

Figure 3.1 Connections Status for an Individual Module Failure

⚠DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

To override log in username/password verification, perform the following steps:

Step 1. Follow *SEL-2241 Disassembly on page 77* to expose the main circuit board.

⚠CAUTION
The device contains devices sensitive to Electrostatic Discharge (ESD). When working on the device with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

Step 2. Locate the reset jumper:

SEL-3530: **JMP6**

SEL-3530-4: **JMP4**

SEL-2241: **JMP3**

Step 3. Place a jumper across the **C** position in the jumper block.

Step 4. (Only applies to the SEL-2241.) Follow *SEL-2241 Reassembly on page 77*, and reinstall all connectors.

Step 5. Apply power to the unit. Wait until the **ENABLED** LED is on.

Step 6. Log in to the RTAC via the web interface with username **Edison** and no password. Edison is an administrative account that is only active when a jumper is in the **C** position. Previously configured user accounts will remain intact.

Step 7. Make any user account changes you need to make.

Step 8. Turn off the RTAC and remove the jumper.

Step 9. Follow *SEL-2241 Reassembly on page 77*, reinstall all connectors, and energize the unit.

Reset to Factory Settings

You can reset the RTAC to factory-default settings via the web interface or by using a hardware jumper. All programming, user accounts, logs, etc., will be lost and the procedure is not reversible.

Perform the following steps to reset the RTAC to factory-default settings via the web interface.

Step 1. Log in to the web interface.

Step 2. Select **Device Reset**.

Step 3. Check **Reset To Factory Default Settings** (see *Figure 3.2*).

Step 4. Select **Submit**.

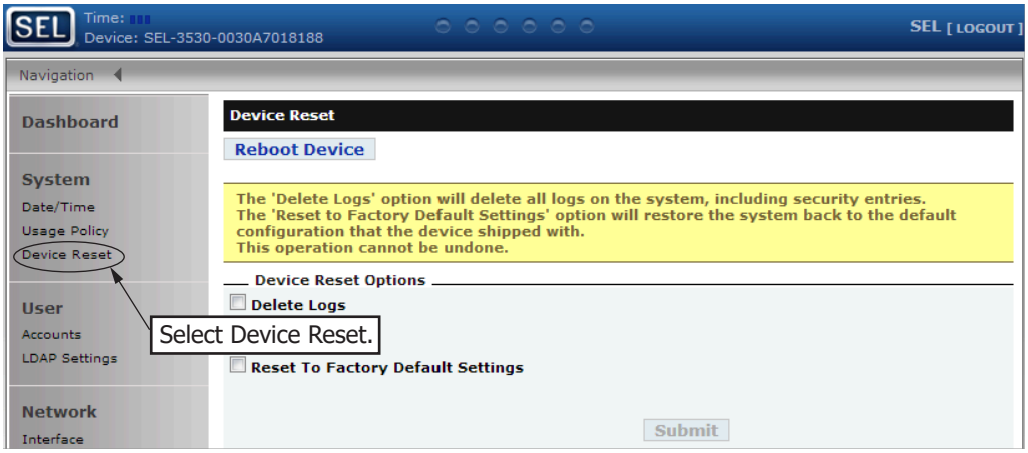

Figure 3.2 Factory Reset Via Web Interface

⚠DANGER
Disconnect or de-energize all external connections before opening this device. Contact with hazardous voltages and currents inside this device can cause electrical shock resulting in injury or death.

Perform the following steps to reset the RTAC to factory defaults by using the internal jumper only as a last attempt to recover from a failed state.

Step 1. Follow *SEL-2241 Disassembly on page 77* to expose the main circuit board.

⚠CAUTION
The device contains devices sensitive to Electrostatic Discharge (ESD). When working on the device with the front panel removed, work surfaces and personnel must be properly grounded or equipment damage may result.

Step 2. Locate the reset jumper:

SEL-3530: **JMP6**

SEL-3530-4: **JMP4**

SEL-2241: **JMP3**

Step 3. Place a jumper across the **A** position in the jumper block.

NOTE
Do not perform a firmware upgrade while the factory reset jumper is set.

Step 4. (Only applies to the SEL-2241.) Follow *SEL-2241 Reassembly on page 77*, reinstall all connectors.

Step 5. Apply power to the unit. Wait until the **ENABLED** LED is on before proceeding to the next step.

Step 6. Turn off the RTAC and remove the jumper.

Step 7. Follow *SEL-2241 Reassembly on page 77*, reinstall all connectors, and energize the unit.

APPENDIX A

Firmware and Manual Versions

Firmware

Determining the Firmware Version in Your Device

Appendix A in the *ACSELERATOR RTAC SEL-5033 Software Instruction Manual* lists the firmware versions, a description of modifications, and the instruction manual date code that corresponds to firmware versions.

Instruction Manual

The date code at the bottom of each page of this manual reflects the creation or revision date.

Table A.1 lists the instruction manual release dates and a description of modifications. The most recent instruction manual revisions are listed at the top.

Table A.1 Manual Revision History

Date Code	Summary of Revisions
20241217	**General** ➤ Removed the part number.
20241025	**Section 1** ➤ Updated *Specifications*.
20240716	**Section 2** ➤ Updated *Figure 2.16: SEL-2241 RTAC Front Panel, Copper Ethernet*, *Figure 2.18: Final Module Alignment*, *Figure 2.22: SEL-2243 Front Panel, Copper and Fiber Connectors*, *Figure 2.26: SEL-2244 Digital Input and Output Modules*, *Figure 2.27: Proper Module Placement*, *Figure 2.28: Final Module Alignment*, and *Figure 2.31: SEL-2245 Modules*.
20240419	**Section 1** ➤ Updated Message Rates in *Specifications*.
20240320	**Section 1** ➤ Updated *Specifications*.
20230712	**Section 1** ➤ Updated *Table 1.1: Module Features* and *Table 1.7: SEL-2242 Chassis/Backplane*. ➤ Updated *Specifications*. **Section 2** ➤ Added *Figure 2.2: SEL-2240 Dimensions for 10-Slot Panel Mount*, *Figure 2.3: SEL-2240 Dimensions for 10-Slot Rack With 7-Inch, Color Touchscreen Display (Rack Mount)*, *Figure 2.4: SEL-2240 Dimensions for 10-Slot Rack With 7-Inch, Color Touchscreen Display (Panel Mount)*, *Figure 2.7: SEL-2240 Dimensions for Dual 4-Slot Panel Mount*, *Figure 2.9: SEL-2240 10-Slot Front Panel (Panel Mount)*, *Figure 2.11: SEL-2240 10-Slot Front Panel 7-Inch Touchscreen Display (Panel Mount)*, and *Figure 2.14: SEL-2240 Dual 4-Slot Front Panel (Panel Mount)*.

Date Code	Summary of Revisions
20230119	**Section 1** ➤ Updated *Accuracy at 25°C* in *Specifications*. ➤ Updated *Synchrophasor* in *Specifications*. ➤ Updated *Synchrophasor* under *AC Protection Inputs (SEL-2245-42)* in *Specifications*. **Section 2** ➤ Added note under *Device Placement*. ➤ Updated *DC Analog Inputs in SEL-2245 Analog Input/Output Modules*.
20221221	**Section 1** ➤ Added UKCA Mark to *Specifications*.
20220902	**Section 1** ➤ Updated *Burden/Current Draw at Nominal DC Voltage* under *Optoisolated Control Inputs (SEL-2244-2)* in *Specifications*.
20220729	**Section 1** ➤ Added *Simple Network Time Protocol (SNTP) Accuracy* under *General* in *Specifications*.
20220225	**Section 1** ➤ Updated *Specifications* to include additional details. **Section 2** ➤ Updated *Field Serviceability*.
20211105	**Section 1** ➤ Updated product photos. **Section 2** ➤ Updated product and module photos.
20210921	**Preface** ➤ Updated *Safety Marks* and *Instructions for Cleaning and Decontamination*. **Section 1** ➤ Updated *Overview*. ➤ Updated *Figure 1.1: Functional Design Concept*. ➤ Updated *Table 1.1: Module Features*. ➤ Added *Bay Control*. ➤ Updated *Automation and Control*, *Options*, and *Specifications*. **Section 2** ➤ Updated *Figure 2.1: SEL-2240 10-Slot Rack- and Surface-Mount Dimensions*. ➤ Added *Figure 2.5: SEL-2242 10-Slot Front Panel With LCD Panel*. ➤ Updated *Figure 2.16: SEL-2241 RTAC Front Panel, Copper Ethernet*.
20210219	**Section 1** ➤ Updated *Specifications*. **Section 2** ➤ Updated *Power*. ➤ Updated *Grounding (Earthing)*. ➤ Updated *EtherCAT Ports*. ➤ Updated *Field Serviceability*. ➤ Added *Power Supply Fuse Replacement*.
20200224	**Section 1** ➤ Updated *Specifications*.
20190216	**Section 1** ➤ Updated *Specifications*. **Section 2** ➤ Updated *Figure 2.4: SEL-2242 10-Slot Front Panel, Rack-Mount*.

Date Code	Summary of Revisions
20181207	**Section 1** ➤ Added *SEL-2245-221 Low-Voltage (LEA) Monitoring Module*. ➤ Updated *Specifications*. **Section 2** ➤ Added *SEL-2245-221 Low-Voltage (LEA) Monitoring Module*.
20180629	**Section 1** ➤ Updated *Time-Synchronization Source* to include additional PTP configuration information. ➤ Updated *Specifications*. **Section 2** ➤ Added *Low-Voltage (LEA) Monitoring Inputs*.
20180330	**Section 1** ➤ Updated *Specifications*.
20171107	**Section 1** ➤ Updated *Specifications*.
20170728	**Preface** ➤ Updated *Copyrighted Software*. **Section 2** ➤ Updated *Figure 2.28: SEL-2245 Modules*.
20170505	**Section 1** ➤ Updated *Specifications*. **Section 2** ➤ Updated *Figure 2.28: SEL-2245 Modules*. ➤ Added *AC Protection Inputs*. **Appendix B** ➤ Added *RTAC Web Upgrade Procedure*.
20170109	**Section 1** ➤ Updated *Automation and Control*. ➤ Updated *Communications Protocols*. ➤ Updated *Specifications*.
20160624	**Section 1** ➤ Updated *Features* and *Applications* for client/server and PTP information. **Appendix B** ➤ Added point-release information.
20160325	**Preface** ➤ Updated *Safety Information*. **Section 1** ➤ Updated *Specifications*.
20151029	**Section 2** ➤ Added recommended wire size and connection details.
20150904	**Section 1** ➤ Revised for the addition of IEC 61850 MMS server.
20150807	**Preface** ➤ Updated *General Safety Marks* in *Safety Marks*. **Section 1** ➤ Updated *Specifications*. **Section 2** ➤ Updated *Figure 2.37: Open-Delta Voltage Inputs*.

Date Code	Summary of Revisions
20150417	**Section 1** ➤ Added a reference to exe-GUARD® security feature. ➤ Updated *Features* and added subsection, *Human-Machine Interface*. ➤ Added figure references in *Applications*. ➤ Updated *Specifications*. **Section 2** ➤ Added *Wye-Connected Voltage Inputs and Delta-Connected Voltage Inputs*. **Section 3** ➤ Removed note from *User Sessions* and updated *Table 3.1: Self-Test System Tags*. ➤ Updated *Self-Test* and added subsection, *Power Source Scale*. ➤ Updated *Using Online Debug*, added subsection, *Tag Cross References* and *Figure 3.5: Create a Watch Window*. ➤ Updated *Watchdog*. **Appendix B** ➤ Added Chrome™ to the browsers in *Step 11* of *Upgrade Procedure*.
20150123	**Preface** ➤ Updated Tightening Torque values in *Safety Marks*. **Section 1** ➤ Updated *Table 1.7: Optional Accessories*.
20141230	**Preface** ➤ Changed *Safety and General Information* to *Safety Information*. ➤ Updated *Safety Information*. ➤ Added *General Information* subsection.
20141006	**Section 1** ➤ Revised *Physical Features* for addition of SEL-2245-22 4AI-ER module. ➤ Updated *Table 1.6: SEL-2245 Analog I/O Module*. ➤ Revised *Specifications* for addition of SEL-2245-22 4AI-ER module. **Section 2** ➤ Added DC Analog Inputs Extended Range to *SEL-2245 Analog Input/Output Module*. ➤ Added *Figure 2.33: DC Analog Inputs Extended Range*.
20140714	**Section 1** ➤ Updated *Specifications*. **Section 2** ➤ Added notes about correct usage of power coupler EtherCAT ports. ➤ Added notes about correct usage of USB ports. ➤ Clarified number of dc analog output modules that can be installed in a node.
20140428	**Section 1** ➤ Revised *Physical Features* for addition of SEL-2245-3 AO module. ➤ Updated *Table 1.6: SEL-2245 Analog I/O Module*. ➤ Revised *Specifications* for addition of SEL-2245-3 AO module. **Section 2** ➤ Updated *Figure 2.1: SEL-2240 10-Slot Rack- and Surface-Mount Dimensions*, *Figure 2.2: SEL-2240 4-Slot Rack- and Surface-Mount Dimensions*, and *Figure 2.3: SEL-2240 Dimensions for Dual 4-Slot Rack- and Surface-Mount*. ➤ Added *DC Analog Outputs* to *SEL-2245 Analog Input/Output Module*. ➤ Added *Figure 2.33: DC Analog Outputs*.
20130827	**Section 1** ➤ Added SES-92, IEC 60870-5-101, and -104 Server to *Communications Protocols*. ➤ Revised *Specifications* for addition of SEL-2245-4 CT/PT Module. **Section 2** ➤ Added *AC Analog Inputs* to *Installation*. **Section 3** ➤ Updated *Table 3.1: Self-Test System Tags*.

Date Code	Summary of Revisions
20130531	**Section 1** ➤ Added protocol to *Data Concentration and Protocol Conversion* in *Automation and Control* in *Features*. ➤ Updated *Communications Protocols* table in *Features*. ➤ Updated *Table 1.7: Optional Accessories*; *Figure 1.6: SCADA Data Concentrator and HMI*; *Figure 1.12: Intelligent Port Switch*; *Figure 1.13: Network Gateway*; *Figure 1.14: Protocol Converter*; *Figure 1.15: Time Synchronization*; and *Figure 1.16: Security Gateway*. ➤ Updated *Specifications*. **Section 3** ➤ Added note in *Force Tags* in *Using Online Debug*. ➤ Added watchdog task in *Watchdog*. ➤ Updated *Troubleshooting* table. ➤ Updated *Figure 3.8: Factory Reset via Web Interface*.
20121121	**General** ➤ Updated manual throughout for greater clarity in text and figures.
20120713	**Section 1** ➤ Revised *Specifications* for FHC digital output release.
20120427	**Section 1** ➤ Revised for addition of 16 analog inputs and 10 FHC digital output modules. **Section 2** ➤ Revised for addition of 16 analog inputs and 10 FHC digital output modules. **Appendix B** ➤ Revised for addition of module firmware upgrades.
20120208	**Section 1** ➤ Revised for addition of IEC 61850 MMS Client.
20111125	**Section 2** ➤ Revised for addition of low-voltage power coupler, 4-slot backplane, and dual 4-slot backplane.
20110721	➤ Initial version.

SECTION 1

Getting Started

Overview and Features

The ACSELERATOR RTAC SEL-5033 Software is an intuitive, easy-to-use application designed to configure the SEL Real-Time Automation Controller (RTAC) family of products, including the SEL-2240 Axion®. The main principles behind using the software involve the following:

- Creating a project for each RTAC or SEL-2240 system. An SEL-2240 system can encompass more than one node. You will need one ACSELERATOR RTAC project for each SEL-2241 RTAC module you use.
- Inserting and configuring various protocols for devices that connect to IP and serial communications ports on an RTAC or I/O modules for the SEL-2240. Each device name is user configurable with a maximum of 100 characters.
- Mapping tags (data) from intelligent electronic devices (IEDs) or other data sources to data recipients (remote clients) via the Tag Processor. A tag is a 100 maximum character limit name that specifies a data structure (such as a binary input) or piece of data within that structure (such as the Boolean value).
- Writing logic and math statements that create outputs based on tag value inputs. An example would be ORing several binary inputs to create one binary value.
- Writing logic programs/functions in the following IEC 61131 languages:
  - Structured Text
  - Continuous Function Block
  - Ladder Logic Diagram
- Creating a device configuration to use as a template for other similarly configured devices.

NOTE

The ACSELERATOR RTAC SEL-5033 Software configures all devices that are included in the RTAC family, including the following:

SEL-3505	SEL-3505-3	SEL-3530	SEL-3530-4
SEL-3532	SEL-3555	SEL-2240 Axion	SEL-3350

Throughout this manual, RTAC refers to all devices in the RTAC family. Any unique instructions for a particular model will be clarified.

Minimum and Recommended System Specifications

ACSELERATOR RTAC requires a 64-bit version of Windows 10, Windows 11, or Windows Server 2016, 2019, or 2022. ACSELERATOR RTAC performance will scale depending on the size of the projects being created (number of tags, devices, etc.). The minimum system specifications for basic projects (25 devices and less than 5,000 tags) are:

- 1.5 Ghz multi-core Intel i5/i7, seventh generation or later
- 8 GB RAM
- 8 GB of HDD storage

Larger, more advanced projects (more than 100 devices and 10,000 tags) require the following system specifications:

- 2.8 Ghz multi-core Intel i7, tenth generation or later
- 16 GB RAM
- 32 GB of solid-state disk storage

Logging in to the ACSELERATOR RTAC Database

After launching ACSELERATOR RTAC, provide the login and database information necessary to access the default ACSELERATOR RTAC database and begin configuring your RTAC project. The login and database fields identify which ACSELERATOR RTAC database you are using. The software saves this set of information as a connection record with a unique connection name (in the following example, this name is RTAC Default Connection). Initially, you can leave all the fields in the login screen at their default values.

The ACSELERATOR RTAC software can use alternative connection records to access different project databases. To access another database, create a unique name in the **Connection Name** field and then fill out the **Server**, **Port**, **Database**, **User Name**, and **Password** fields. If the ACSELERATOR RTAC software finds the database, and if the username and password are correct for that database connection, it will create a new connection record automatically. This login connection name will be the default connection the next time you start ACSELERATOR RTAC. Select any previously used connection records by using the drop-down list in the **Connection Name** field. Once you have chosen a connection record name, the software will populate all the other fields automatically in the login screen, except for the Password field. Enter the password necessary to log in to the connection you have selected.

Initially, two user accounts exist for the default database. One user account has a username of admin and a password of TAIL. The second user account has a username of engineer and a password of OTTER. The admin account has full access to all software features, including adding and deleting user accounts and unlocking projects that are locked for editing by another user. The engineer account can change their own password but cannot unlock locked projects. SEL recommends that you change the default account usernames and passwords immediately to secure your application. Until you secure the application, the software will display a warning indicating that the database is not secure. For more information regarding the updating of accounts, see *Section 7: Security and Account Management*.

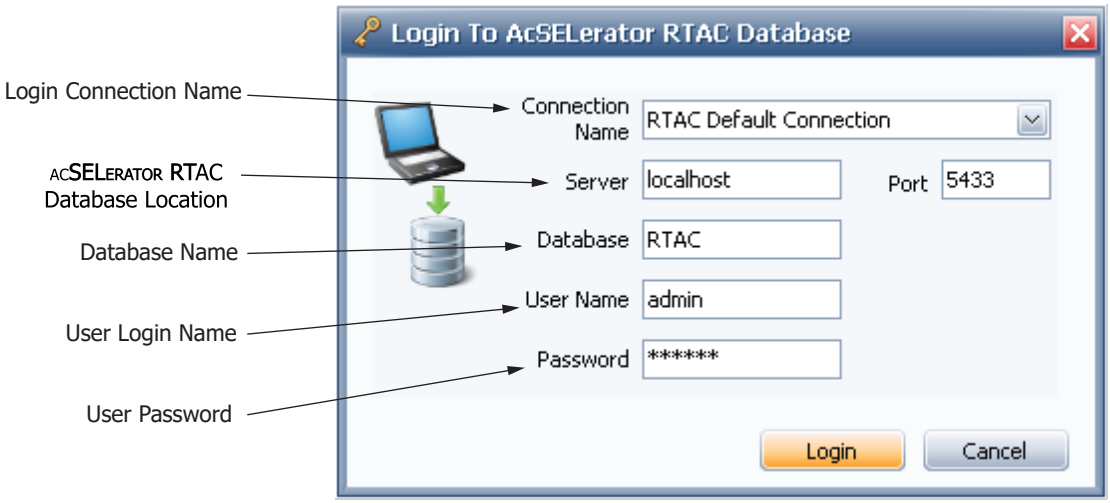

Figure 1.1 ACSELERATOR RTAC Login Screen

Use the start page that appears after you log in to the ACSELERATOR RTAC database to view existing projects or create new ones.

Start Page

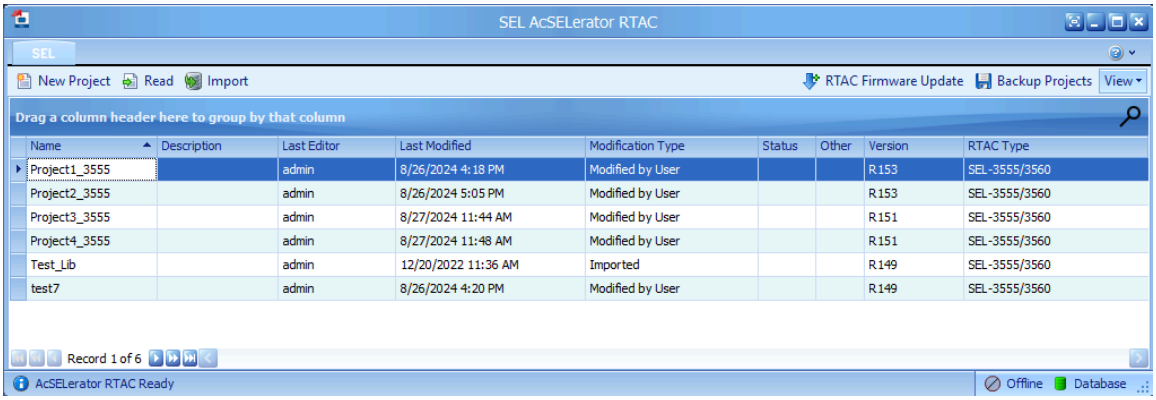

Figure 1.2 ACSELERATOR RTAC Start Page

Start Page Buttons

Several common-function toolbar buttons are available in the ACSELERATOR RTAC start page. The functions of these buttons are described in this section.

Select **New Project** to create a new ACSELERATOR RTAC project.

Select **Read** to read a project from a previously configured RTAC into a new project in your database. You must be connected to an RTAC to read its project. See *Save, Send a Project, and Go Online on page 144* for more information.

Select **Import** to import a project that was previously exported to an EXP file.

Select **RTAC Firmware Update** to update the firmware of the RTAC.

Select **Backup Projects** to export all projects in your database to EXP files and create a ZIP file containing all of the exported files.

Select **View** to configure a Grid or Tree view for the projects list. The Grid view is the default format and contains all projects in a flat list. The Tree view allows for projects to be organized into folders.

Projects List

View the list of existing projects in the current database. Open an existing project by double-clicking on the project.

The Projects List has several columns displayed for each project, including the following:

- Name: The name of the project.
- Description: The first line of the Project Description from the Project Properties.
- Last Editor: The user account that most recently made changes to the project.
- Last Modified: The time stamp corresponding to when changes were most recently made to a project.
- Modification Type: The most recent operation that happened in the project, such as the following:
  - Read from Device
  - Created
  - Converted
  - Imported
  - Modified by User
- Status: Indicates if a project is locked or unlocked.
- Other: Displays any advanced read-in project components embedded in the project, such as Ethernet Settings or User Accounts, when you hover your mouse over a cell.
- Version: The version of the project.
- RTAC Type: The type of RTAC (e.g., SEL-3350 or SEL-3555/3560).

Right-click on a project to perform the following actions:

- Open the project.
- Unlock the project.
- Clean the project. This deletes the embedded user logic image from the project and requires a resend to go back online with an RTAC. This action is not typically required.
- Rename the project.
- Delete the project.
- Import a project from an EXP file.
- Export a project to an EXP file.
- Back up all projects to a ZIP file.
- Restore all projects from a ZIP file.
- Convert the project to a newer firmware version or to a different RTAC type.

- Compare two or more projects. This action requires that multiple projects using the same firmware version be selected at once by using **<Ctrl +click>** or **<Shift+click>**. See *Compare ACSELERATOR RTAC Projects on page 153* for more information.
- Set the password security for a project.
- Disable the password security for a project.

Creating a New Project

A project contains communications settings, tags, and logic for a particular RTAC configuration. You can create a new project or use a project you saved previously as a starting point for a new project.

Click the **New SEL RTAC Project** icon in the start page or select **New** from the menu in the SEL application button to access the project creation dialog box.

To quickly create a new default project for the latest RTAC version, select the **Create** button shown in *Figure 1.3* to open the project view. The **RTAC Firmware Version** pane provides a method to create projects for earlier RTAC versions. ACSELERATOR RTAC selects the latest firmware version by default. If you select a previous version, ACSELERATOR RTAC will remember that selection the next time you create a new project.

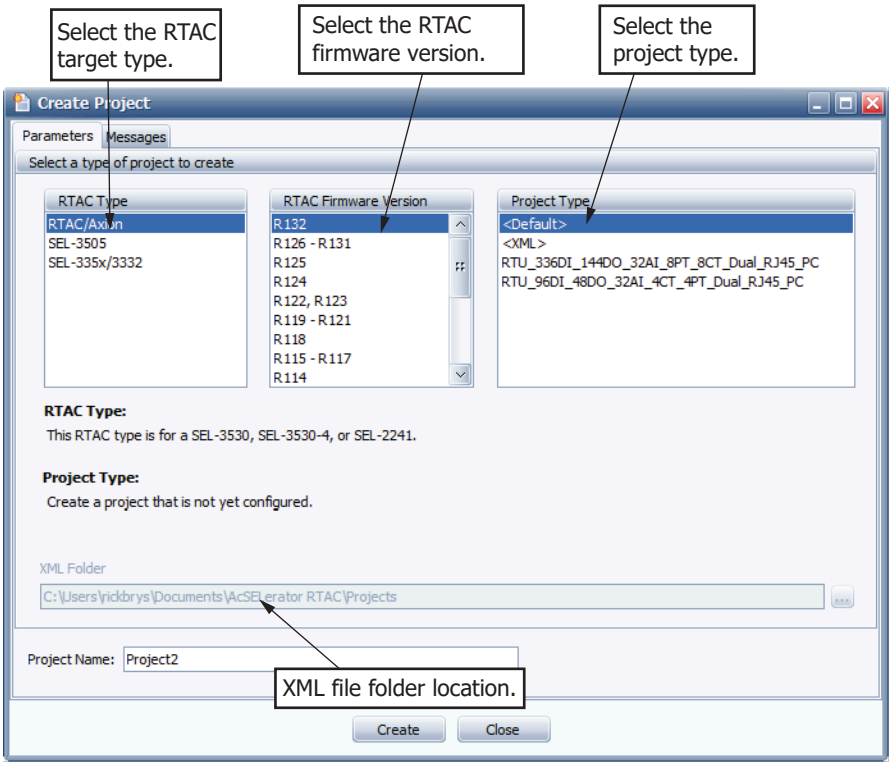

Figure 1.3 ACSELERATOR RTAC Project Creation Interface

The default ACSELERATOR RTAC project template includes an RTAC (system tags and diagnostics), but no pre-configured client or server protocol connections. Select the default project category and default project template to create and open a default project. If necessary, enter a custom project name. If you have previously exported items from an RTAC project in XML format, you can select **XML** under **Project Type** to create a new project using those XML files.

ACSELERATOR RTAC also provides some Axion example projects in the Project Type column that include common settings for certain types of applications. Click on an RTU project type name from the list to see a project description. Provide a custom project name, if necessary, and select Create to open the example in the project view for editing. Refer to *RTU Project Examples on page 421* for more information.

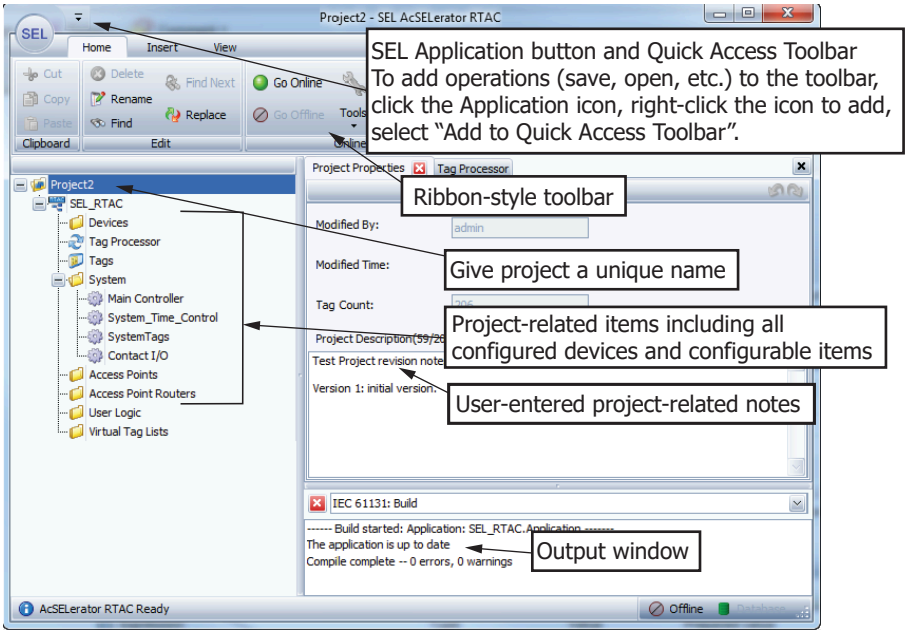

Figure 1.4 Project View

Navigate this screen by using the ribbon menu and the configurable **Quick Access Toolbar** at the top. The ribbon menu has four tabs:

- **Home**: Perform standard editing functions such as copy, paste, find, replace, etc. Also contains online tools including online/offline buttons, communications monitoring (Comm Monitor), and the Tools menu for user logic debugging options.
- **Insert**: Add a new intelligent electronic device (IED) or remote polling device, add new SEL-2240 I/O modules, save or retrieve a custom device configuration, add an access point router, or create custom IEC 61131-3 user logic.
- **View**: Open/close window panes, view reports, return all docked windows, and change skins for personal preference.
- **Tag Processor**: Append, insert, and delete lines in the Tag Processor as well as copy, paste, and delete items. This menu is only visible when the Tag Processor window is in focus.

The following descriptions are for items in the project tree, located in the left window pane of *Figure 1.4*. Right-click the project name to rename it. Right-click on **SEL_RTAC** to add any of the following features. You can also add folders in the project tree by using the right-click menu. Organize devices and connections by dragging and dropping them into the custom folders as needed. To re-order folders on the same level of the project tree hierarchy, hold the <Shift> key while moving the folder to prevent it from being relocated as a sub-folder.

- **Project2**: The configurable name of the current project. This must be a unique name in a given database.
- **SEL_RTAC**: The name of the device in the project.
- **Devices**: A blank folder where you can place devices configured for this project (IEDs, remote client connections, etc.).
- **Tag Processor**: Tag mapping tool used to map data from IEDs to polling client devices.
- **Tags**: View of all alias tags. When online, view of task timers, task controller blocks, and program organizational unit (POU) pins.
- **System**:
  - **Main Controller**: Set cycle time, watchdog time, and execution order of tasks or program organizational units (POUs). For example, alter the execution order to ensure that all defined protocols collect data before a custom logic program uses the data.
  - **System_Time_Control**: Configure device time-source information such as IRIG-B, PTP, and NTP. Configure UTC time and Daylight-Saving Time settings.
  - **SystemTags**: Configure and view all system (non-device or user logic) tags here. Open **SystemTags** when online to view and/or force present values of all system tags. Also configure the C37.118 Data_Rate or rate of data transmission. *IEEE C37.118 Synchrophasors on page 258* explains this further.
- **Contact I/O**: Configure RTAC contact inputs and outputs, including tag names, pickup and dropout delays, and default values.
- **EtherCAT I/O Network**: Visible once you have inserted an Axion node from the insert menu. Configure and view SEL-2240 nodes and modules. View network messages in Online mode.
- **Access Points**: A blank folder where you can place names of access point configurations, which are used with access point routers in creating transparent connections.
- **Access Point Routers**: A blank folder where you can place names of transparent connection configurations.
- **User Logic**: A blank folder where you can place user-defined logic blocks. This includes IEC 61131-3 programs, functions, function blocks, user-defined global variable lists (GVLs), and data types.
- **Virtual Tags**: A blank folder where you can place virtual tag lists. Virtual tags are global variables that you can use anywhere in an RTAC project. You can create as many as 30 virtual tag lists in a single project (100 virtual tag lists in SEL-3555 and SEL-3350 projects).

Task Cycle Time

The RTAC executes all tasks each task cycle time interval to which they are assigned. Configured task cycle times that are evenly divisible into one second are synchronized to execute at the top of each second of the system time. For example, if the processing cycle is configured as 100 ms, the first task cycle will be at the top of the second. Subsequent task cycles are executed at 100 ms intervals until the top of the next second, at which time the next processing cycle is executed. Configured task cycle times that are not evenly divisible into one second are not executed at the top of the second but are still locked to system time. By default, all tasks run in the main task cycle interval.

Perform the following steps to assign certain tasks to the automation task cycle so that they can run independently and at a faster interval than the main tasks.

Step 1. From the **Main Controller** tab, click the task in the task order list.

Step 2. Click the **Move To** button to move the task from the main task cycle to the automation task cycle.

Step 3. Click the **Automation** tab to configure the automation task cycle parameters.

With the present software, you cannot directly map tags from a task that is in the automation task cycle to a task that is in the main task cycle. Each tag value, control, and logical operation cannot update faster than the task cycle time. While online with the RTAC, you can view various task timers, as well as an overall task timer, in ACSELERATOR RTAC by clicking on **Tags** under the device tree. The task timers indicate how long, in microseconds, the tasks are taking to run. You should configure the main task cycle time to be at least 140 percent of the overall task timer. This provides enough time for the tasks to run, with added time for the RTAC web interface and HMI access. If you configure the RTAC main task cycle time less than what is actually required to run all the defined tasks, the RTAC will run over the task cycle time. For example, if you configure the RTAC to run every 20 milliseconds, but the total task timer indicates the RTAC tasks are using 50 milliseconds to complete, the RTAC will not drop tasks, but will use time from subsequent task cycles to ensure each task runs to completion. The RTAC will therefore not complete every task in the configured 20 milliseconds, and web access performance will be degraded.

The automation task timers are not contained in the **Tags** tab. To view the task times for tasks that are located in the automation task, click **Tools** on the **Home** ribbon while online. Select **Watch Values** and open a watch window. In the watch window, type the following:

SEL_RTAC.Application.Automation_SystemTotal_task_timer

This contains the automation task timers. Use this information to adjust the automation processing cycle. The information regarding adjusting the main task cycle for optimal performance applies to adjusting the automation task cycle as well.

NOTE

If an SEL-2245-4 or SEL-2245-42 CT/PT module is the source of any C37.118 data, the task cycle time will lock to the configured Nominal Frequency. The task cycle time will be 20 ms for 50 Hz and an average of 16.667 ms for 60 Hz. The 16.667 ms average is achieved by running the task cycle time at 17 ms for two cycles and then 16 ms for one cycle.

A rising edge change triggers control operations in the RTAC per cycle interval. This implies a control value that is high must drop low and become high again for a second control operation. Because the RTAC only updates values each cycle-time interval, the control state change must occur each interval. For example, a change in control state from high to low to high during one cycle-time interval will not trigger a new control value because only the last value (high) will be stored. It is possible, therefore, to configure the cycle-time interval in such a way to cause the RTAC to miss rapid control changes. As a rule, set the cycle-time interval such that control operations are not executed at a rate greater than half the cycle-time interval.

Startup Time

The initial startup time of the RTAC varies depending on the version of the RTAC used. The initial startup time includes initializing all of the operating system, exe-GUARD®, and initialization of communication links among other system tasks. This corresponds to when the RTAC **ENABLED** LED turns green and does not include the time to establish communication to downstream devices. Fully establishing communication with downstream devices requires additional time based on the configured communications parameters and can be adversely impacted if the RTAC is configured with a high burden. *Table 1.1* shows expected initialization times for each RTAC type.

Table 1.1 Typical RTAC Startup Time

RTAC Type	Time to Enable
SEL-3530, SEL-3530-4, SEL-2241	~2.5 minutes
SEL-3555	~45 seconds

Application Button

Click the **SEL Application** button to execute file and database functions.

Add frequently used functions by clicking on the **SEL Application** button, right-clicking on the function you want added, and selecting **Add to Quick Access Toolbar** from the pop-up menu.

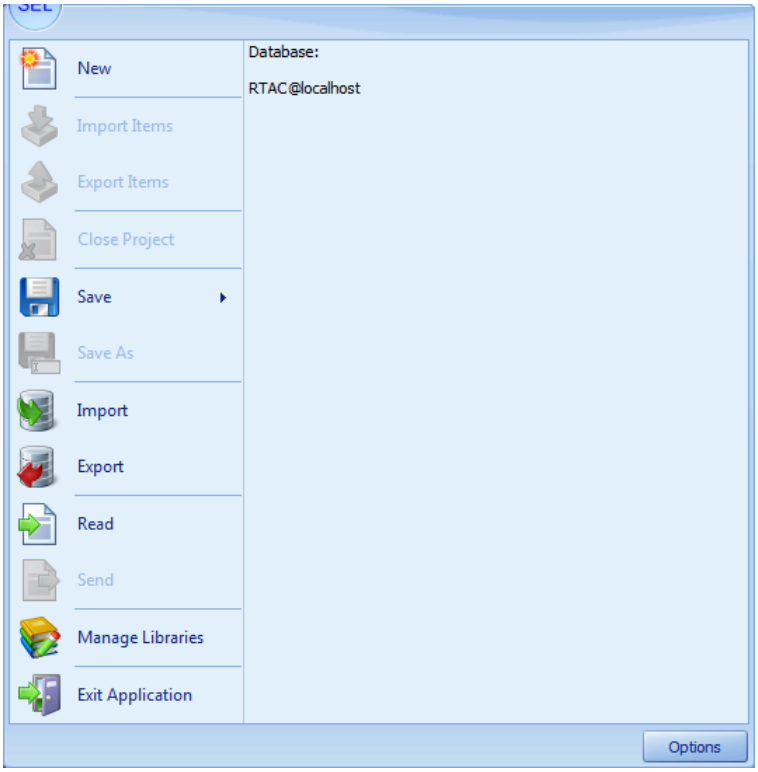

Figure 1.5 Application Button and Quick Access Toolbar

NOTE

User-created names must conform to IEC 61131-3 standards: only use letters, numbers, and underscore; always alert with a letter; and never have two consecutive underscores. If a name is invalid, a ⊗ will appear beside it.

- **New**: Create a new project for an RTAC.
- **Import Items**: Import individual project items from previously exported XML files. This is only available while a project is open.
- **Export Items**: Save selected project items as XML files. This is only available while a project is open.
- **Close Project**: Close current project. This will not close ACSELERATOR RTAC.
- **Save/Save As**: Save current project.
- **Import**: View or edit projects that you exported previously. This is only available from the start page.
- **Export**: For the selected configuration, generate a configuration file that can be imported into any ACSELERATOR RTAC database. This is only available from the start page.
- **Read**: Read an existing configuration from a connected RTAC. This is only available from the start page.
- **Send**: Send a compiled project to a connected RTAC.
- **Manage Libraries**: Install previously created libraries for use in ACSELERATOR RTAC projects.
- **Exit Application**: Close ACSELERATOR RTAC. Be certain that you save and close projects before exiting.

Docking Windows

From the Project View, you can open configuration windows by clicking devices in the device tree. Most of these windows can be undocked from ACSELERATOR RTAC and placed anywhere on your computer workspace. To do this, click the top bar, which bears the name of the window in focus, and drag it anywhere on your workspace. See *Figure 1.6*.

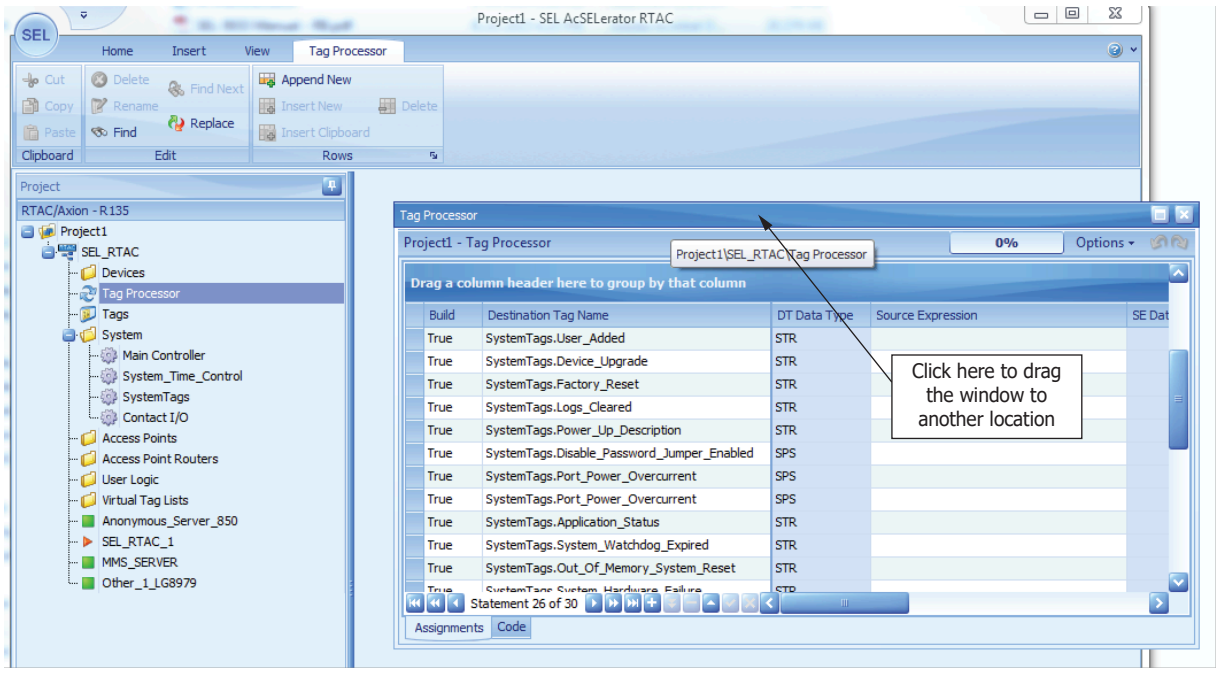

Figure 1.6 Docking Windows

Each window will retain the project and window names. To return the window, close the window by selecting the **X** in the upper right-hand corner or click **View > Reset Window Layout** to restore all windows to your project. See *Figure 1.7*.

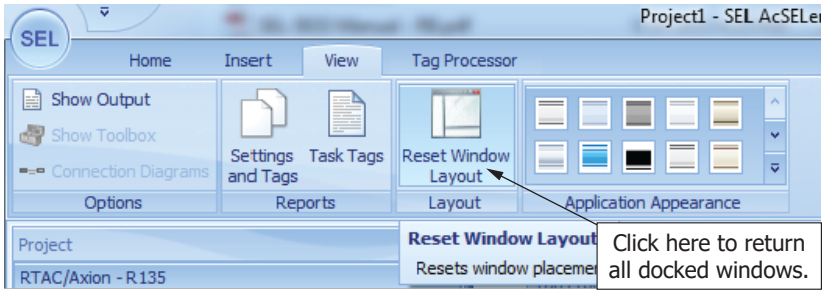

Figure 1.7 Reset Docked Windows

Key Shortcuts

As with most Microsoft Windows-based programs, there are a number of keystroke shortcuts you can use to copy, paste, find, and perform other operations. From the **Home** ribbon, or within the SEL action button, hover your mouse over the operation to display a tooltip window that describes the operation and the keystroke shortcuts.

Use **<Ctrl+Alt+click>** in structured text programs to highlight, copy, paste, and delete columns of text. Anything you type in a highlighted column will be replicated in every row of that column.

Open/Edit an Existing Project

You can open and edit an existing project by double-clicking on the project name in the ACSELERATOR RTAC start page. You can also open and edit projects not in the database that are presently in an RTAC, or projects that have been previously exported.

Use the **Read SEL RTAC Project** button on the start page to retrieve an existing project from a working RTAC.

Step 1. Ensure proper physical connection with either Ethernet or USB to the RTAC. See the installation instructions for your RTAC module for physical connection requirements.

Step 2. Click the **Read SEL RTAC Project** button. The login screen will appear.

Step 3. Enter correct RTAC login information and press **Next**.

Step 4. If required, enter a unique project name.

Step 5. Click **Next**.

Step 6. The settings read will commence. Read time will vary depending on the project size.

Step 7. Press **Finish** when done. The read operation is now complete, and you can view or edit the project.

> **NOTE**
> RTAC projects created in newer versions of ACSELERATOR RTAC and sent to an RTAC are not guaranteed to be compatible when read out with prior versions of ACSELERATOR RTAC.

Use the import/export functions to save/retrieve an existing project.

Step 1. After you have created and saved a project, click the **Export** icon from the **SEL Application** button. Note that all projects must be closed before you can use the export/import functions.

Step 2. Create a unique name and press **Save**. The software will save the selected project as a file with extension .EXP. You can use email, USB memory stick, etc. to send this file to any PC running the same version of ACSELERATOR RTAC software and import the file to make further edits or send the settings to an RTAC.

> **NOTE**
> EXP files created in newer versions of ACSELERATOR RTAC are not guaranteed to be compatible when imported into prior versions of ACSELERATOR RTAC.

Step 3. To open an exported file, select the **Import** icon from the **SEL Application** button.

Step 4. Browse and select the correct file name with extension .EXP and click **Open**. The software imports the project information in the .EXP file into the ACSELERATOR RTAC configuration database in the local machine.

Tag Selector

During configuration of project settings, many operations require that project tag names be entered in to various fields for mapping operations, such as those described in *Section 3: Tag Processor* and *Section 10: Extensions*. The Tag Selector is a tool that allows for drag-and-drop operations of one or more tags into tag entry fields in the project. Launch the tool by selecting **Tag Selector** from the Home ribbon. The Tag Selector will open, docked in the same position as the left project tree. Toggle back and forth between the project tree and Tag Selector by using the tabs at the bottom of the docked window. Close the Tag Selector by selecting the **X** in the upper right corner when tag mapping operations are complete.

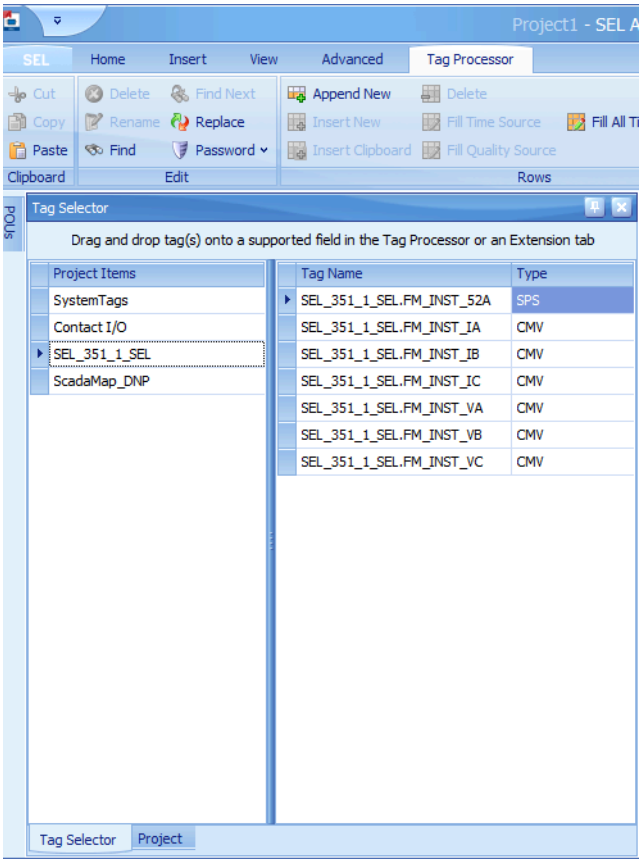

Figure 1.8 Tag Selector

The following project items are displayed in the left side of the Tag Selector as sources for tags:

- Devices
- Shared Tag Maps (e.g., DNP server shared maps)
- Virtual Tag Lists

- System Tags
- Contact I/O

Selecting a different project item in the left side of the Tag Selector will update the right side with the available tags from that item. Apply filters to the list of tags by using the Type column to reduce the list to only display specific tag types (e.g., SPS or MV).

You can drag-and-drop information from the Tag Selector to the following settings fields in an RTAC project:

- Tag Processor **Destination Tag Name** and **Source Expression** fields
- Settings fields where the tags are entered in extensions such as the **Monitored Data** tab in the Dynamic Disturbance Recorder extension and the client-to-server mapping tabs in the **Generated_Map** subitem of the Simple Tag Mapper extension

Select one or more tags from the Tag Selector using **<Ctrl+click>** or **<Shift +click>** and drag the tag(s) to an empty cell in the Tag Processor or extension. If multiple tags were selected and not enough rows exist on the destination object to accept them, new rows are automatically added to accommodate all of the tags.

Save, Send a Project, and Go Online

After completing the RTAC configuration, save and send the project into the RTAC. Before sending the project, you must first set up a user account on your RTAC through the web interface. See *Section 7: Security and Account Management* for details.

Step 1. Ensure proper physical connection with either Ethernet or USB to the RTAC. See *Section 2: Installation* in the *SEL-2240 Instruction Manual* for physical connection requirements.

Step 2. Click the **Save** icon, accessible either from the **Quick Access Toolbar** or by clicking the **SEL Application** button, to save and compile the project. Alternatively, you can press **<Ctrl+S>** to save the project.

> **NOTE**
> The save operation first checks the project for syntactic errors before storing the project in the database. The normal save operation does not, however, check for tags that are referenced in the automation and main task. This is referred to as cross-task checking and is done only when you select the save with cross-task checking option, or when you send the project to the target.

Step 3. Check the output window for compile errors or warnings. Resolve errors before continuing. Double-click on the error line in the output window to have the program direct you to the item causing the error.

Step 4. Click the Send icon  to send the new configuration and logic to the RTAC.

Step 5. Enter the RTAC IP address in the RTAC Address field, username, and password then press **Next**. Note that the **RTE Port** and **Port** fields are exposed to allow connections to RTACs located behind firewalls or routers that may map the default connection ports of 1217 and 5432 to custom ports.

You can use the same default connection name for each time you connect to an RTAC. Alternatively, you can create a unique connection name for each unique IP address of each RTAC residing on the network. To create a new connection, type a unique connection name and IP address, enter the username and password, then press **Login**. The connection information is stored in the ACSELERATOR RTAC database. The next time you attempt to go online with a project, the most recently used connection information is displayed. You can also select other previously used connections from the **Connection Name** drop-down menu.

Note that the RTAC and ACSELERATOR RTAC software usernames and passwords are not necessarily the same. The RTAC web interface maintains the RTAC username and password information. See *Section 7: Security and Account Management* for more information on password management.

Step 6. Optional: Click the **Options** tab and indicate if you want to send the complete project or only IEC 61131 logic changes.

> **NOTE**
> If a protocol is disabled during a settings send through custom logic or a direct transparent connection, it will not re-enable until after the RTAC restarts with the newly received settings.

You can do quick iterative testing of IEC 61131 logic by selecting **Send only custom IEC 61131 logic**. This option does not reset the RTAC and thus allows a form of online editing of your custom logic. Other settings, such as those in protocol configurations, are not sent to the RTAC when this is selected, so it is important to resend the entire project when you are finished testing IEC 61131 logic changes.

When you are satisfied with the IEC 61131 logic, always select **Send Complete Project** and resend the entire project. This puts the RTAC into service and allows you to read the entire project out of the RTAC at a later date if necessary.

Step 7. When the the settings send operation is complete, click **Finish**. Upon completion of RTAC programming, the RTAC automatically enters online mode.

Step 8. (This step only applies to projects that include SEL Axion I/O modules and EtherCAT protocol.)

After settings are completely sent and the project starts running, the RTAC will automatically configure and start the EtherCAT network. No user selections will be required during the configuration process. All other protocols and user logic in the RTAC will begin to run as soon as the project send operation is complete.

Monitor the configuration status by watching the messages in the software status bar (bottom of software window). Configuration will take 10–15 seconds per power coupler and I/O module on the network. A network with 60 modules can take 12 minutes to fully configure. Configuration times will be longest during the initial project sending sequence. Subsequent project changes will configure more quickly.

The sequence of configuration messages are as follows:

- "Beginning EtherCAT boot sequence..."
- "Reading EtherCAT settings..."
- "Addressing EtherCAT network..."
- "Verifying EtherCAT network..."

Step 9. While online, you can view data, force values, and perform other online functions, as necessary.

Step 10. After you finish viewing data, etc., press to go offline. Note that all logic and configuration will continue to run and that the RTAC application is now in service.

If any tag values remain forced when you attempt to go offline, a dialog box will ask if you want to unforce them. If you go offline because of inactivity, the values are automatically unforced and returned to their original state.

Go online anytime by selecting the icon. Upon selecting the go online icon and entering your user credentials for authentication, the RTAC software compares the currently open project with that in the RTAC. If these projects are the same, the RTAC will go online immediately. If the projects differ, ACSELERATOR RTAC will prompt you to send the currently open project to the RTAC.

If you are online with an RTAC running firmware version R151-V0 or later, the device icons in the project tree will display the communication status of that device. Green indicates an online device, red indicates an offline device, and grey indicates a disabled device.

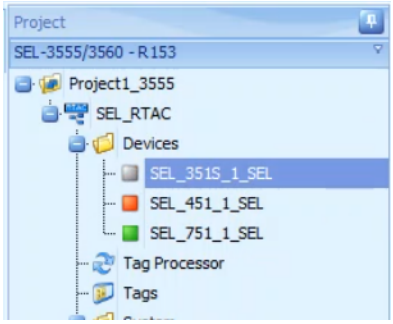

Figure 1.9 Project Tree Device Communication Status

For more information about online options such as forcing data values, creating tag watch windows, and changing the tag display modes, refer to *Section 11: Testing and Troubleshooting*.

Creating and Augmenting Projects With XML

Exporting Programs to XML

You can export individual POUs such as custom function blocks, client and server POUs, and tag processors to an Extensible Markup Language (XML) format. You can later import these individual XML files into existing projects or group them together to generate a new project.

NOTE
Manually editing the exported XML files can create settings that are not valid in an RTAC project. Be careful not to place invalid combinations of XML files in the same directory. For example, copying and pasting a program XML file would create an invalid condition because the program name is the same in both XML files even though the file names differ. The RTAC software ensures that all configured POUs have unique names.

To export your POUs to XML, perform the following:

Step 1. In an open project, select **Export Items** from the **SEL Application** button or right-click the desired POU and select **Export Items**.

Step 2. Select the items you want to export from the resulting pop-up window.

Step 3. Click the ... button choose a directory in which to store the exported features.

Step 4. Press **Export**.

The software exports each selected item into individual XML files and places the files in the export location directory you selected.

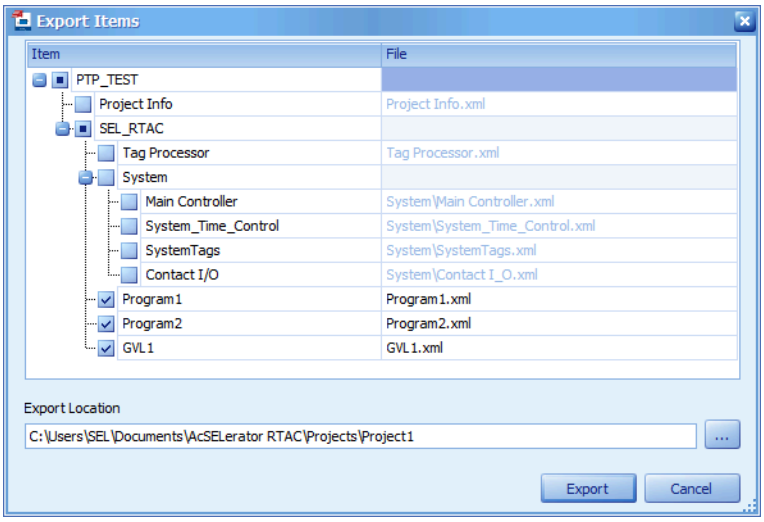

Figure 1.10 Export to XML Window

Alternatively, you can select one or more POUs from the project list, right-click, and select **Export Items**. The resulting pop-up window indicates with check marks all POUs you selected.

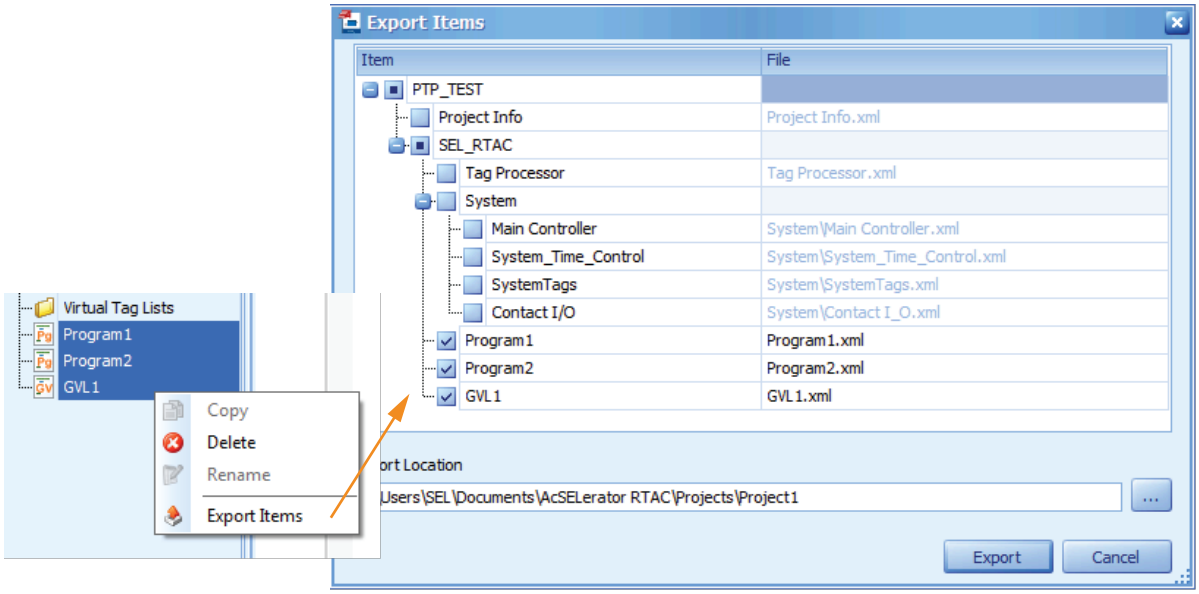

Figure 1.11 Export Selection to XML

Using Windows Explorer, you can create custom folders and place combinations of these XML files as necessary for future projects. You do not need to have every object from a project in the folder. Use only the objects you want. For example, in *Figure 1.11*, Project1 contains two custom IEC 61131 programs and a Global Variable List (GVL1) to use in multiple future projects. You can export each of the items you selected into a folder for use as a base for future projects that need those items.

To use the exported XML, you can either add individual XML files to an existing project or create a new project from exported XML files.

> **NOTE**
> Exported XML content created in newer versions of ACSELERATOR RTAC is not guaranteed to be compatible when used with prior versions of ACSELERATOR RTAC.

Modify Existing Projects With XML

ACSELERATOR RTAC software allows you to import existing XML projects. Perform the following steps to import XML POUs directly to an existing project.

Step 1. From an open project, select **Import Items** from the **SEL Application** button.

Step 2. Choose the folder that contains the XML file you want. See *Exporting Programs to XML on page 147* for instructions on generating the necessary XML files.

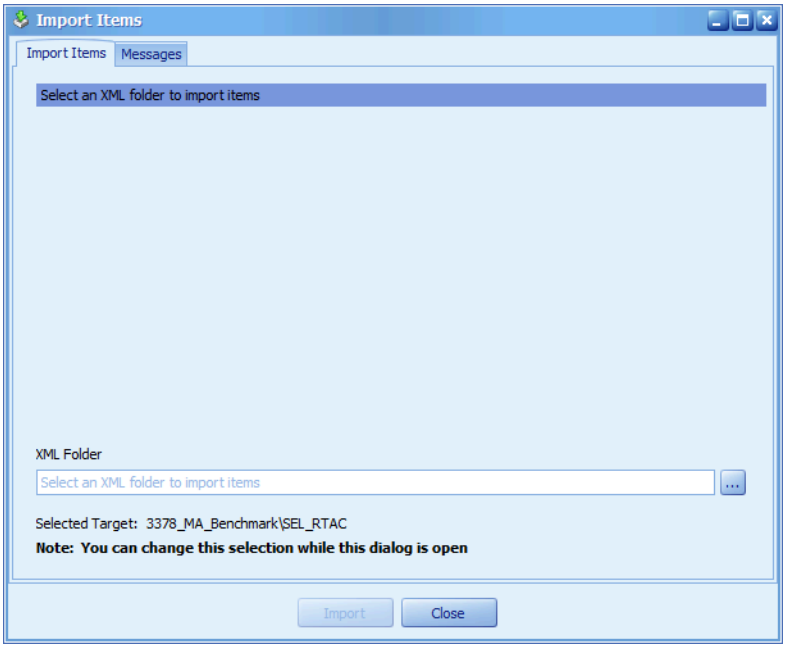

Figure 1.12 Import XML Window

Once you select the folder, the software displays all XML files available for importing.

Step 3. Select one or more of the available XML files and click **Import**.

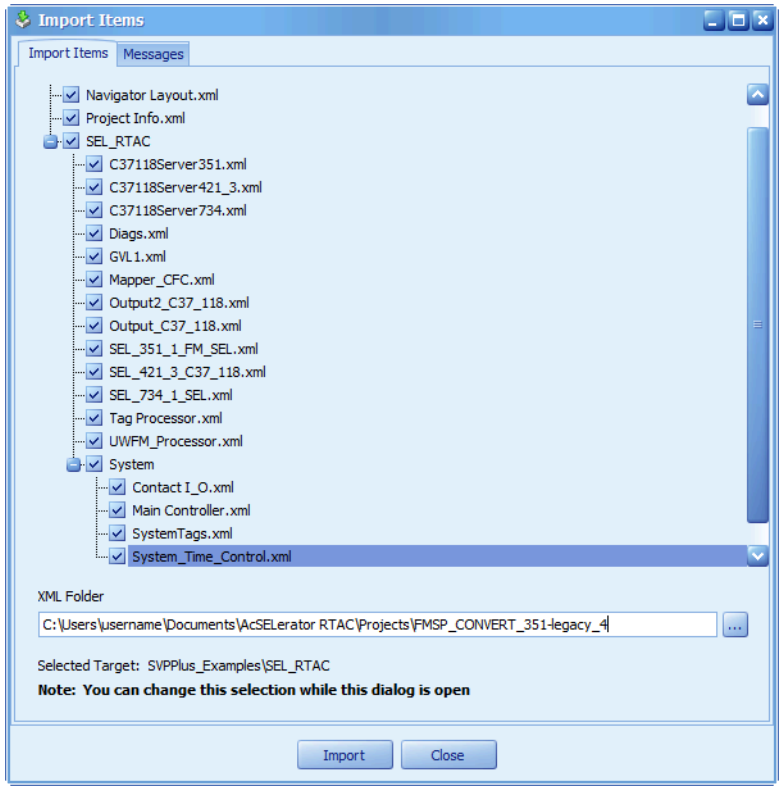

Figure 1.13 Import XML Items

Configuration parameters on certain project items require project uniqueness in an ACSELERATOR RTAC project file (for example, the **Virtual Port Number** value assigned to all SEL Client protocol devices). If there are collisions between these values encountered while importing XML content into an existing project, the values in the incoming XML template are forced to a new unique value in order to enforce the uniqueness rules. If these values are changed during the import process, a notification message is posted to the import window, as shown in *Figure 1.14*.

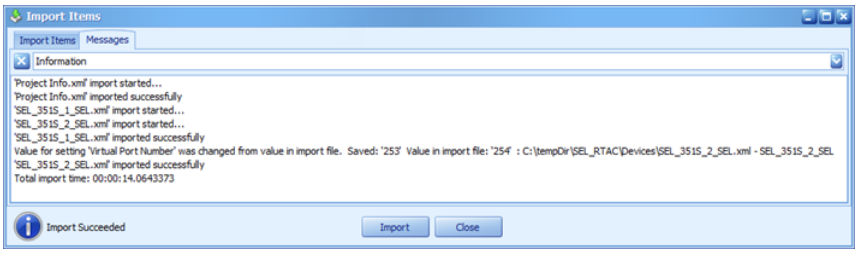

Figure 1.14 Import XML Items—Setting Value Changed

The following items from exported XML content cannot be imported into an existing project:

- Main Controller
- Navigator Layout
- POUs tab content from developer mode projects

Creating a New Project From XML

To use the exported XML files to generate a new project, select the **New SEL RTAC Project** icon while on the start page or select **New** in **SEL Application**. Select **XML** under **Project Type**, browse to the folder you previously created with the XML files, and select **Create**. The software uses all settings within the XML files in your selected folder to create a new project.

Backup/Restore Projects

The Backup Projects feature allows you to create a zipped file of all projects presently in your RTAC database.

Step 1. From the ACSELERATOR RTAC start page, right-click anywhere in the **Projects** area.

Step 2. Select **Backup Projects**.

Step 3. Navigate to the location in which you want to save the archive.

Step 4. Name the file and press **Save**.

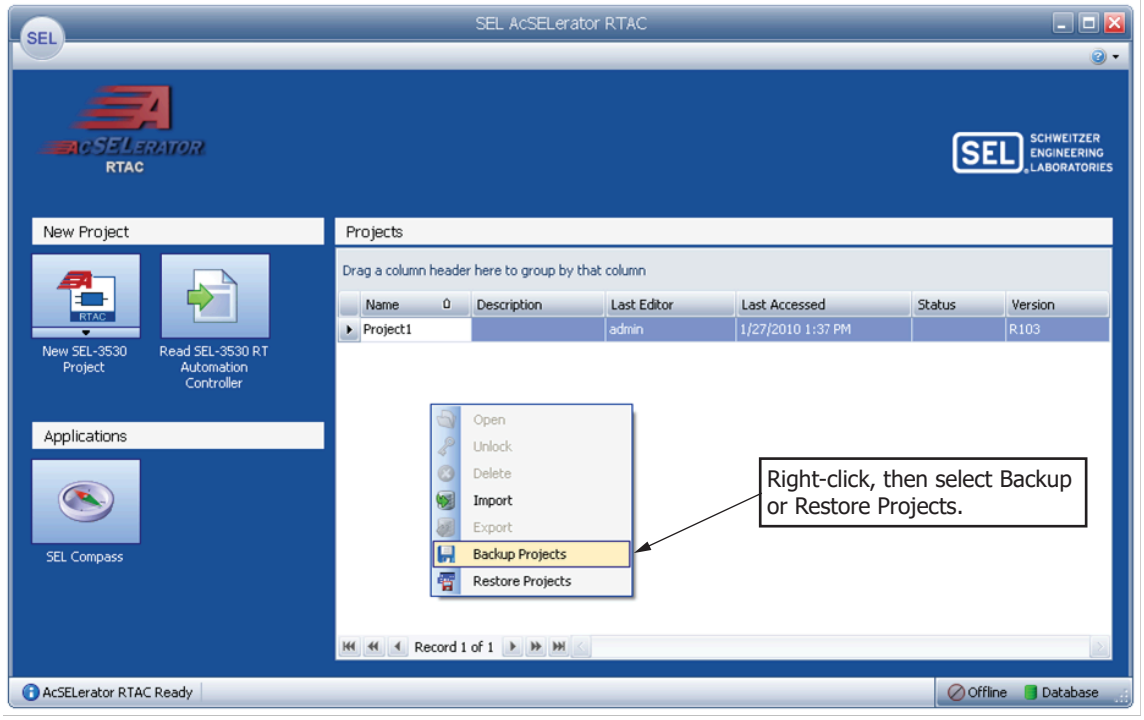

Figure 1.15 Project Backup and Restore

ACSELERATOR RTAC will create a zipped file of all projects. You can email this zipped file, store it on external media, etc. To restore the projects, use the same version of ACSELERATOR RTAC that you used to create the projects:

Step 1. From the ACSELERATOR RTAC start page, right-click in the **Projects** area.

Step 2. Select **Restore Projects**.

Step 3. Navigate to the location of the archive .zip file.

Step 4. Select the .zip file and click **Open**.

ACSELERATOR RTAC restores all projects that are part of the archive, without overwriting existing projects. The restore process will resolve any name conflicts by appending a .0, .1, etc. to the end of the restored project names. For example, restore a project named MyProject when there is already a project with that name in the ACSELERATOR RTAC database. The software renames the restored project to MyProject.0. Restoring the project again will retain the two existing projects and create a newly restored project with the name MyProject.1.

Converting Projects

Use the project backup utility before updating ACSELERATOR RTAC to a newer version. Once the update is complete, restore projects, as necessary. You can use the projects as they are, or you can upgrade the database of the older projects to the latest version to be compatible with the latest RTAC firmware. The new project version can contain extra settings fields in existing protocols that allow

the use of new features, new protocols, or additional data tags in database definition files (DDF) associated with templated devices. Project conversion can also be used to convert existing projects between the different available RTAC types:

- RTAC/Axion
- SEL-3505
- SEL-3350
- SEL-3354/3351/3332/1102
- SEL-3555/3560

To convert an older project, follow these steps:

Step 1. Enter the **Convert SEL RTAC Project Settings** tool by doing either of the following:

- Right-click a project from the list of projects on the start page, then select **Convert Projects > By Project Type** or **By Project Version**.
- From the **SEL** button, select **Options > Convert Project Settings > OK**.

Step 2. Check the tab at the top of the conversion tool (by version or by type) to ensure use of the correct conversion mode.

Step 3. Select the project to convert.

Step 4. Change the **Convert?** field from **No** to **Yes**.

Step 5. If converting by type, change the **Converted Type** to the type of RTAC to which you want to convert.

Step 6. Click **Convert**.

The project will now have the new features from the latest database schema or, if converted to another type, those that can be loaded into the RTAC type to which it is converted. Open the converted project and ensure that the new schema settings are the values you need.

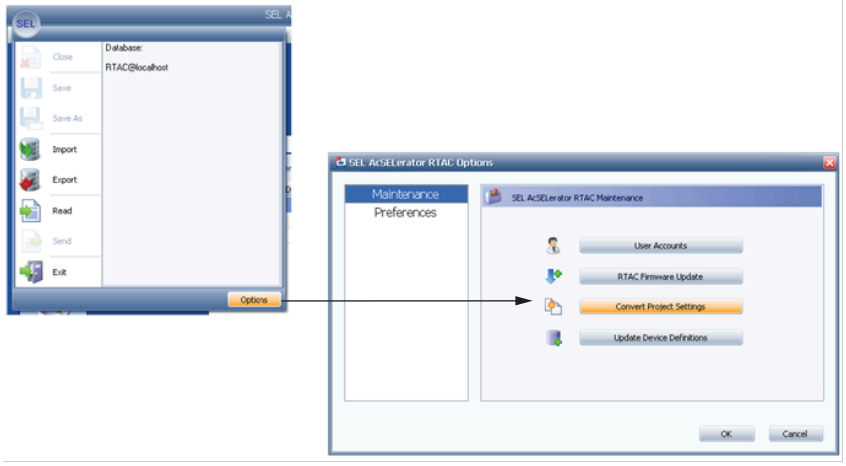

Figure 1.16 Convert a Project

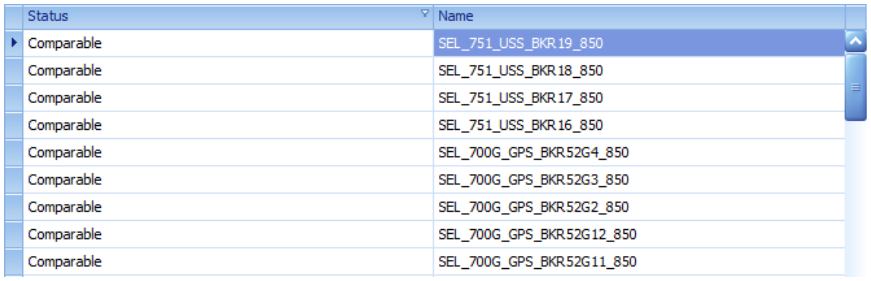

Compare ACSELERATOR RTAC Projects

To compare two projects in ACSELERATOR RTAC, from the main menu, hold **<Control>** and select the desired projects to compare, and then right-click and select **Compare**.

When the comparison is done, a window appears showing the POUs that registered a difference. In the top portion of the window, the **Baseline** project can be changed. This changes the detection of additional missing POU classifications in the list below. There is also an option to show all POUs in the configuration regardless of whether differences are detected.

The bottom portion of the window shows the list of POUs that have detected differences (if the **Show only differences** check box is selected). For items that are listed as Comparable, double-click or right-click an entry to see a more detailed comparison screen.

Status	Name
Comparable	SEL_751_USS_BKR19_850
Comparable	SEL_751_USS_BKR18_850
Comparable	SEL_751_USS_BKR17_850
Comparable	SEL_751_USS_BKR16_850
Comparable	SEL_700G_GPS_BKR52G4_850
Comparable	SEL_700G_GPS_BKR52G3_850
Comparable	SEL_700G_GPS_BKR52G2_850
Comparable	SEL_700G_GPS_BKR52G12_850
Comparable	SEL_700G_GPS_BKR52G11_850

Table 1.2 Status Values

Status Name	Description
Comparable	Differences were detected (double-click for a detailed view).
Added	The baseline configuration contains a POU that the **Compare To** project did not.
Removed	The baseline configuration does not contain a POU that the **Compare To** project did.
Over threshold percentage	This designation indicates that although the POU name is the same, there are so many differences detected that it is likely that the POU is *not* the same type in both configurations. This is designated by a percent difference detected, which is configurable under **SEL > Options > Preferences**.

Compare Window Layout

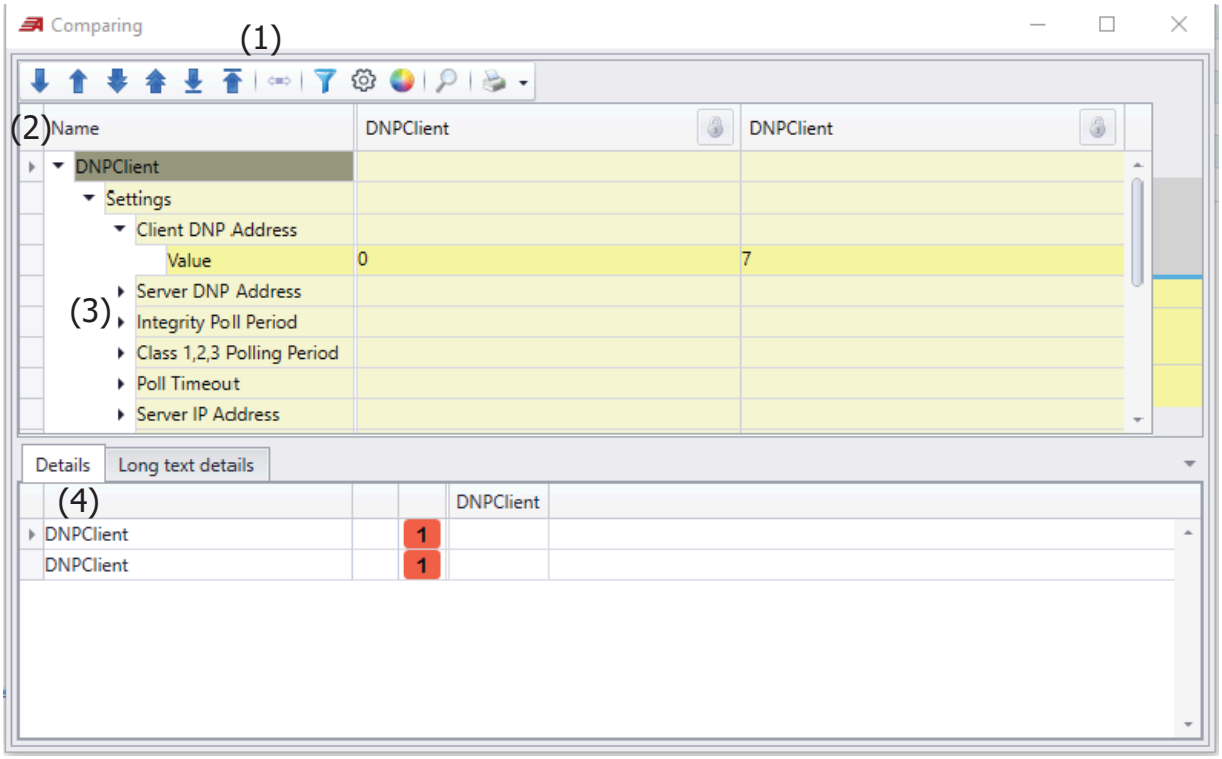

Figure 1.17 Compare Window Components

① **Navigation and Filter Options**: This section includes the navigation and filter options for the Compare Results window.
② **Compare Node Names**: This section displays the names of selected nodes and enables the Save icon for those nodes that have changes.
③ **Compare Results Window**: This section displays the node information and attached settings and highlights the differences.
④ **Difference Output**: This section displays the values for and differences, if any, from the selected row in the Compare Results window.

Filter Options

Hide Similar Values

This option filters out any similar values across the rows of settings being compared so that only rows with differences appear.

Hide Inactive (Hidden) Rows

This option filters out device node rows rendered inactive and unchangeable because of either a part number or settings rule.

Reset to Default

This option resets the filters to original ACSELERATOR RTAC default values.

Comparison Options

Ignore Case Differences

When the **Ignore case differences** option is enabled, Device Manager treats values that differ only in their use of uppercase or lowercase letters as if they are identical.

For example, "ABC" and "abc" compare identically when **Ignore case differences** is enabled.

Ignore White Spaces Differences

When the **Ignore white spaces** option is enabled, Device Manager ignores white space characters when performing comparisons of individual items between entities.

For example, "ABC" and "A B C" compare identically when **Ignore white spaces** enabled.

Ignore Missing Values

When the **Ignore missing values** option is enabled, missing entity items are ignored.

Compare as Text

When the **Compare as text** option is enabled, all entity items are compared alphanumerically regardless of item data type.

For example, Numeric items "01.1" and "1.10" do not compare equally when **Compare as text** is enabled; otherwise, they are considered equal.

Ignore Differences in Setting Comments

When the **Ignore differences in setting comments** option is enabled, any differences in comments included in the attached settings of the nodes being compared are ignored.

Comparison Window

Best Fit

Adjusts the width of a selected column to fit all text in that column's values.

Best Fit (All Columns)

Adjusts the width of each column to fit the text in those column's values.

Freeze Column

Fixes a column at the left so that it does not scroll with the other columns.

Select Reference Column

Selects the column used to generate difference values.

Connection Directory

In software version 1.31.147.xxxx and later, the connection directory will be preserved when a software upgrade occurs. The connection directory is saved in the following folder location:

\Users\<your user name>\Local\SEL AcSELerator\RTAC\Connections

There are two files in this directory that save connections:

- SEL3530.csv: This file contains IP addresses to which RTAC projects can be sent. This list is accessible when sending RTAC projects.
- RTAC.csv: This file contains IP addresses of remote RTAC databases to access with ACSELERATOR RTAC. This list is accessible when logging into the RTAC database.

Connections can be added through ACSELERATOR RTAC or by directly editing the CSV files. These CSV files can be copied and moved between installations of ACSELERATOR RTAC.

RTAC Database on a Shared Server

In the standard configuration, the ACSELERATOR RTAC program installs and accesses the RTAC database on the local computer. As an alternative, you can configure one computer on a local area network (LAN) as a shared RTAC database server. In this configuration, each PC on the LAN can access RTAC projects from a common database that resides on the common server.

Perform the following steps to create and use a common RTAC project database on a shared server:

Step 1. Ensure the server machine and all computers that will access this machine are all visible on the same LAN. You can verify this by using the Ping command from the command prompt on one of the computers to ping each of the computers on the network. Also ensure that no firewall rules exist that block outgoing TCP port 5433 on any client PCs or incoming TCP port 5433 on the server.

Step 2. Install ACSELERATOR RTAC on the PC that is designated as the server. You must install ACSELERATOR RTAC software to install the RTAC database on that machine.

Step 3. Use Notepad or a similar text editing software to open the file postgresql.conf with Administrative rights. This file is located at C:\ProgramData\SEL\AcSELerator\RTAC\Database\data.

Step 4. On approximately line 59, change the following (note the removal of the "#" from the beginning of the line):

```
#listen_addresses = localhost # what IP address(es) to listen on;
```

to:

```
listen_addresses = '*' # what IP address(es) to listen on;
```

Step 5. Save the postgresql.conf file.

Step 6. From within the same directory, open the file pg_hba.conf.

Step 7. Search for and copy this line:

```
host RTAC all 127.0.0.1/32 md5
```

Step 8. Paste the copied line directly after the line you just copied and make the following change:

```
host RTAC all 10.202.13.0/24 md5
```

Note that the address 10.202.13.0/24 is a placeholder representing a subnet of client addresses that are allowed to connect to this server instance. In place of 10.202.13.0/24, enter the address and CIDR subnet to match the address of the ACSELERATOR RTAC client PCs. Alternatively, a single client IP address can be specified using a /32 mask (e.g., 10.202.13.101/32)

Step 9. Save the pg_hba.conf file.

Step 10. Restart the server computer or restart the RTAC Database service.

Step 11. On each client machine, install ACSELERATOR RTAC software.

Step 12. On a client computer, start ACSELERATOR RTAC software.

Step 13. In the login dialog, you can optionally change the Connection Name to something that reflects a server connection. Typing a new Connection Name creates a connection record, as this section described previously, and will store the Server information for that connection.

Step 14. Change the Server field to be the IP address or hostname of the server computer but leave the Port field = 5433 and the Database field = RTAC. See *Figure 1.18*.

Step 15. Log in as normal. Note that the username and password login credentials you use in ACSELERATOR RTAC to access the server are stored on the server machine.

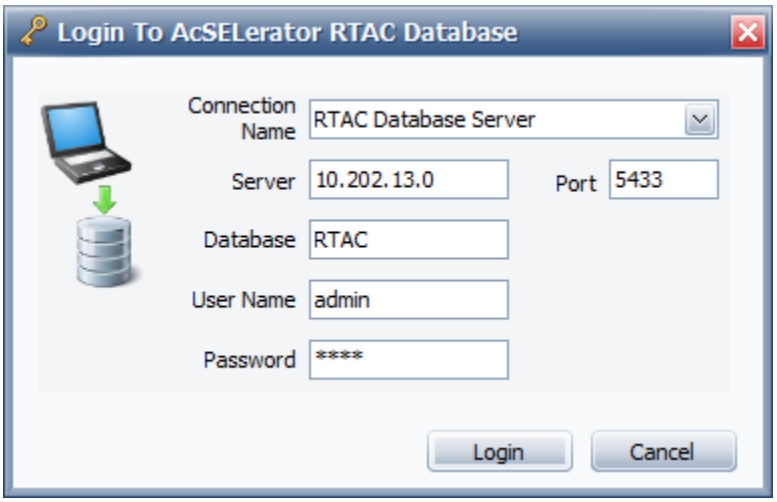

Figure 1.18 Logging In to Database Server

Startup Switches

You can modify the shortcut to ACSELERATOR RTAC to include various startup runtime switches. These switches provide features not available in the software in normal run mode. To modify the shortcut, right-click the **AcSELerator RTAC** shortcut and select **Properties**. Modify the line labeled **Target** to include the needed switch by adding */switchname* to the right of the quoted path name. Save the shortcut and run it to start ACSELERATOR RTAC using the new switch.

Change File Storage Location

ACSELERATOR RTAC uses the current user's **Documents** folder in Windows for program-related file storage (project exports, communication monitor captures, log files, etc.). If the Documents folder is located on a network drive instead of your local computer, modify the ACSELERATOR RTAC shortcut to include the startup switch */documents*, as shown in the following example:

```
"C:\Program Files\SEL\AcSELerator\RTAC\RTAC.exe"  /documents
I:\documents\location\MyDocuments
```

where *I:\documents\location\MyDocuments* is the location of the **My Documents** folder.

Modification of the */documents* path may also be required when your Documents folder is on a network path and ACSELERATOR RTAC is used in offline mode while disconnected from the network.

Disable User Logic Cross-Task Compilation Checks

Typically, ACSELERATOR RTAC produces a compilation error when attempting to go online if any tags from GVLs or devices in the automation task are referenced for reading or writing in the logic of the main task. A compilation error is also produced when attempting to go online if any tags from GVLs or devices in the main task are referenced for reading or writing in the logic of the automation task. This is to prevent the user logic from being in a problematic state where the automation task could interrupt the main task and update the tag values, causing the main task to have an incorrect or out-of-date collection of tag values, such as in the following scenario:

1. The main task reads tag values owned by the automation task and performs a calculation based on those values.
2. Before the main task can read the complete set tag values, the automation task interrupts the main task and updates the tags with new values.
3. The main task resumes and completes reading the tag values, but because the tag values were updated, the data for the calculation being performed is now incorrect or out-of-date.

This scenario is commonly referred to as a race condition. The CrossTaskData library included with ACSELERATOR RTAC helps to avoid this condition (see the *SEL RTAC Programming Reference Manual* for more details), but for the purposes of testing, a startup switch can be used to disable cross-task checking. To run ACSELERATOR RTAC in this mode, use the */unchecked_user_logic* switch as follows:

```
"C:\Program Files\SEL\AcSELerator\RTAC
\RTAC.exe" /unchecked_user_logic
```

Software Install, Uninstall, and Backup

Silent Installation

It is possible to install ACSELERATOR RTAC silently (i.e., without any of the installation wizard graphical prompts). To do this, use the command prompt to navigate to where your RTACSetup.exe file is located on your PC and run the following command:

```
.\RTACSetup.exe /S
```

Clean Install and Uninstall

The clean switch when moved will remove ACSELERATOR RTAC from the PC that it is currently installed on. It will search the following locations on the PC and remove all relevant ACSELERATOR RTAC files and registry entries.

NOTE
The locations shown are for Windows 10 64-bit. Other Windows versions will have similarly named folders, registry locations, and registry services.

- Folders
  - C:\Program Files\SEL\AcSELerator\RTAC
  - C:\Program Files\SEL\AcSELerator\RTAC Database
  - C:\Program Files\SEL\AcSELerator\RTAC USB Driver
  - C:\ProgramData\SEL\AcSELerator\RTAC
  - C:\ProgramData\SELFramework
  - C:\Users\YOURUSERNAME\AppData\Local\SEL\AcSELerator \RTAC
  - C:\Users\YOURUSERNAME\AppData\Local\SEL\RTAC.exe_Url_*
  - C:\Users\YOURUSERNAME\Documents\AcSELerator RTAC
- Registry Locations
  - HKEY_LOCAL_MACHINE\SOFTWARE\SEL\SEL-5033
  - HKEY_LOCAL_MACHINE\SOFTWARE\SEL\SEL-5033 DB
  - HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\SEL \SEL-5033
  - HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\SEL \SEL-5033 DB
- Registry Services
  - RTAC Database (RTACDB)

Unlike the Documents switch, the clean functionality is not included with the shortcut for the ACSELERATOR RTAC software but rather with the actual setup or uninstall file. When run with the setup file, the clean functionality will remove all parts of the software from the PC before installing the new version of software.

Clean Install

Open the command prompt and navigate to the folder where the RTACSetup.exe file is. Run the following command to have the software completely remove any remnants of ACSELERATOR RTAC before beginning to install the software. This will remove any projects that were automatically backed up in the C:\ProgramData\SEL\AcSELerator\RTAC folder.

```
.\RTACSetup.exe /Clean
```

Clean Uninstall

Open the command prompt and navigate to the folder where the uninstall.exe file is. Run the following command to have the software completely remove any remnants of ACSELERATOR RTAC. This will remove any projects that were automatically backed up in the C:\ProgramData\SEL\AcSELerator\RTAC folder.

```
.\uninstall.exe /Clean
```

NOTE
The uninstall file typically exists in C:\Program Files\SEL\AcSELerator\RTAC\Installation. If you received the uninstall file from an SEL representative, you may have saved it in a different location. Navigate to that location before running this command.

Automatic RTAC Project Backup

When ACSELERATOR RTAC is updated from a previous version all RTAC projects from the previous version are automatically backed up and saved on the local disk in the following location. These projects can be imported into ACSELERATOR RTAC or zipped and have all projects brought back into the software with the restore option.

- C:\ProgramData\SEL\AcSELerator\RTAC\backup_exp

Database Maintenance

Software versions 1.28.xxx and later include a database maintenance option found under **SEL > Options > Maintenance**. Performing maintenance cleans up the database and improves software performance, especially after the software has imported, exported, converted, or deleted numerous projects. You can choose between standard or advanced maintenance; a detailed description is provided for each option, and SEL-5033 provides a recommendation of which type to use (if any).

SECTION 2

Communications

Overview

A core feature of the SEL Real-Time Automation Controller (RTAC) family of products is the ability to provide communications protocol conversion and data concentration among intelligent electronic devices (data sources) and SCADA or other upstream polling devices (data destinations). Use the following steps from within ACSELERATOR RTAC SEL-5033 Software to configure RTAC communications.

Step 1. Insert a device into your project.

Step 2. Specify the protocol you want to use in communicating with the device.

Step 3. Specify whether the connection is a client or a server.

Client and server are synonymous with master and slave in legacy protocols.

- A client connection is one in which the RTAC will be a client that polls the connected device for data.
- A server connection is one in which the RTAC serves data to SCADA or some other remote client polling for data.

Data Tags

Data within the RTAC are referenced by database points called tags that may be associated with client or server protocols, system values, global variables (including virtual tags), or values created in user-defined logic.

Tags are generally either global (visible to every RTAC process) or local (limited to a particular function and unavailable elsewhere in the RTAC software). Most tags, such as system tags, device tags, virtual tags, and tags defined in global variable lists (GVLs) in the IEC 61131-3 user logic are global. Other tags declared in user-defined functions are local to those functions. The maximum number of supported tags varies by RTAC hardware type as follows:

Table 2.1 Maximum Tag Counts Per RTAC Hardware Model

Maximum Tag Count	RTAC Hardware Models
5000	➤ SEL-3505 ➤ SEL-3505-3
25,000	➤ SEL-3530 ➤ SEL-3530-4 ➤ SEL-2241 ➤ SEL-1102 ➤ SEL-3332 ➤ SEL-3351 ➤ SEL-3354

Maximum Tag Count	RTAC Hardware Models
50,000	➤ SEL-3350
100,000	➤ SEL-3555 ➤ SEL-3560

See *Section 9: Custom Logic* for more information on tag declaration.

Data flows within the RTAC from source tags to destination tags via Tag Processor mapping. Source data are typically from client device (IED) tags. Destination data tags typically are from server devices (HMIs, remote polling clients).

NOTE
Remember that RTAC updates tag values, including controls, once during each cycle-time interval.

Step 1. Use the **Insert** ribbon to build source tags in the RTAC by inserting IED devices as client connections.

Configure tags with the data type tabs for corresponding devices. These tags are global and are available for use anywhere in the RTAC. Reference these tags by using their corresponding assigned tag names.

Step 2. Use the **Insert** ribbon to build destination tags in the RTAC by inserting devices as server connections.

Configure tags with the data type tabs for corresponding devices. These tags are global and are available for use anywhere in the RTAC. Source tags typically provide the data values for destination tags.

Step 3. Use the Tag Processor to map source tags to destination tags. Data from the source tag transfers to the destination tag at each RTAC processing cycle. See *Section 3: Tag Processor* for additional details.

If you need global tags that are of the same types as those contained in protocol tasks, insert a virtual tag list. Use GVLs to create standard data type global tags under the IEC 61131-3 ribbon (see *Section 9: Custom Logic*).

Data Structures

The RTAC data points each have a data structure similar to the IEC 61850 standard. This structure provides much more information for each point, including such other attributes as instantaneous value, time stamp, data quality, and dead-banded values. See *Appendix B: IEC 61131-3 Programming Reference* for an in-depth break down of each data type.

You can use data structure attributes for each tag in logic or map these attributes within the Tag Processor. To access each attribute within the structure, enter the tag name followed by a period (.) and the next structure level. ACSELERATOR RTAC concatenates the device name (Relay1) with the protocol (DNP) and the actual variable name (AI_0000). A period (.) after the tag name joins the tag name with the specific attribute (i.e., instMag). In this way, the point value is self-describing. Instead of typing only the point name (AI_0000) in the Tag Processor or other RTAC field to access the instantaneous value of AI_0000, type the fully qualified tag name (Relay1_DNP.AI_0000.instMag).

Example 2.1 Tag Data Structure Breakdown

This example illustrates the structure of an analog input tag name. We are assuming for this example that the RTAC is configured to poll one analog point from an IED named Relay1 using the DNP3 protocol. The default analog input tag name will be:

Relay1_DNP.AI_0000

The instantaneous value for that analog input will be:

Relay1_DNP.AI_0000.instMag

The following figure illustrates all the attributes in this tag's data structure.

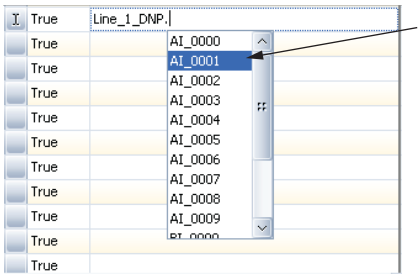
AI_0000	MV
instMag	REAL
mag	REAL
range	RANGE_T
q	quality_t
validity	VALIDITY_T
detailQual	detailQual_t
source	SOURCE_T
test	BOOL
operatorBlocked	BOOL
t	timeStamp_t
value	dateTime_t
quality	timeQuality_t
daylight_savings_time	DST_t
UTC_Offset	INT
source	timeSource
db	REAL
zeroDb	REAL
rangeC	rangeConfigReal_t
hhLim	REAL
hLim	REAL
lLim	REAL
llLim	REAL
minVal	REAL
maxVal	REAL

Data structure description:

- **Relay1_DNP** is the device name. This is also the global name for this device. All tags associated with this device will begin with this name.
- **AI_0000** is the IEC 61131-3 variable name.
- **instMag** is the instantaneous value.
- **mag** is the value snapshot after instMag exceeds the dead-band value. It changes each time instMag exceeds the dead band (db). In event-driven protocols such as DNP3, this is the time-stamped dead-banded event value.
- **range** is the result of testing instMag against the rangeC values.
- **q** is a quality structure that contains data quality flags for this point.
- **t** is a time structure that contains the data time stamp as well as time quality information for this point.

- **db** is the dead-band value applied to the analog value instMag.
- **zeroDb** is a zero cutoff dead band. If mag is < zeroDb, mag will be set to 0.
- **rangeC** is a structure that contains user-configurable high and low limits. The range limits include high-high, high, low, low-low alarm limits. You can configure the RTAC to generate an alarm when the mag value exceeds the rangeC limit. The software logs this alarm, and it can then be viewed on the webpage. The type of alarm (high-high, etc.) is stored in the range field.

The following illustrates how to access some of the elements from the data point AI_0000.



Dead-Banded Value of AI_0000	
Relay1_DNP.AI_0000.mag	Analog event value after the instantaneous value exceeds the dead band.
Time Stamp of AI_0000	
Relay1_DNP.AI_0000.t.value.dateTime	The date/time of the last dead band excursion for this point.
Data Quality of AI_0000	
Relay1_DNP.AI_0000.q.detailQual.outOfRange	A Boolean value that, if true, indicates that the value is presently out of range.

See *Data Types on page 1127* for more detail on individual data type structures. Following is an example of various data values in a DNP IED called Relay_1.

Binary Input	
Relay1_BI_0000.stVal	Instantaneous value
Analog Input	
Relay1_AI_0000.instMag Relay1_AI_0000.mag	Instantaneous value Value when the dead band was exceeded
Counter	
Relay1_CNT_0000.actVal Relay1_CNT_0000.frVal	Instantaneous value Present frozen value
Analog Output	
Relay1_AO_0000.oper.setMag	Instantaneous value
DNP Binary Output	
Various DNP control methods for this point Relay1_BO_0000.operPulse.ctlVal Relay1_BO_0000.operLatchOn.ctlVal Relay1_BO_0000.operLatchOff.ctlVal Relay1_BO_0000.operTrip.ctlVal Relay1_BO_0000.operClose.ctlVal	

Autocomplete

The RTAC has an autocomplete tag entry mechanism. As you type a tag, this feature will automatically complete the tag name and the components of the tag structure. The RTAC software finds tag names that closely match what you type. Choose the name or structure element from the resulting list by selecting it with the mouse or arrow keys and pressing **<Enter>**. Next press the period **<.>** to see a list of the next data structure elements.

Create a Client Device Connection

A client device connection defines the protocol, port number, port settings, and a tag list of all data that the RTAC will poll from an IED.

The following steps illustrate, generally, how to configure a client connection to poll data from an IED. Sections that contain protocol-specific configuration information are described later in *Section 2: Communications*.

Step 1. Click the **Insert** ribbon or right-click **SEL_RTAC** in the device tree.

Step 2. Select the type of device (**SEL**, **Fieldbus I/O**, **Other**) from the ribbon menu.

Step 3. Select the device/protocol from the drop-down list within the device type.

For example, to poll a non-SEL IED that uses DNP master protocol, select **Other** for the device type, then **DNP** for the protocol.

Step 4. Select the type of client connection (serial, Ethernet, etc.).

Scroll through the list to see the graphic change with each connection type to show the relationship of communications between the RTAC and the device.

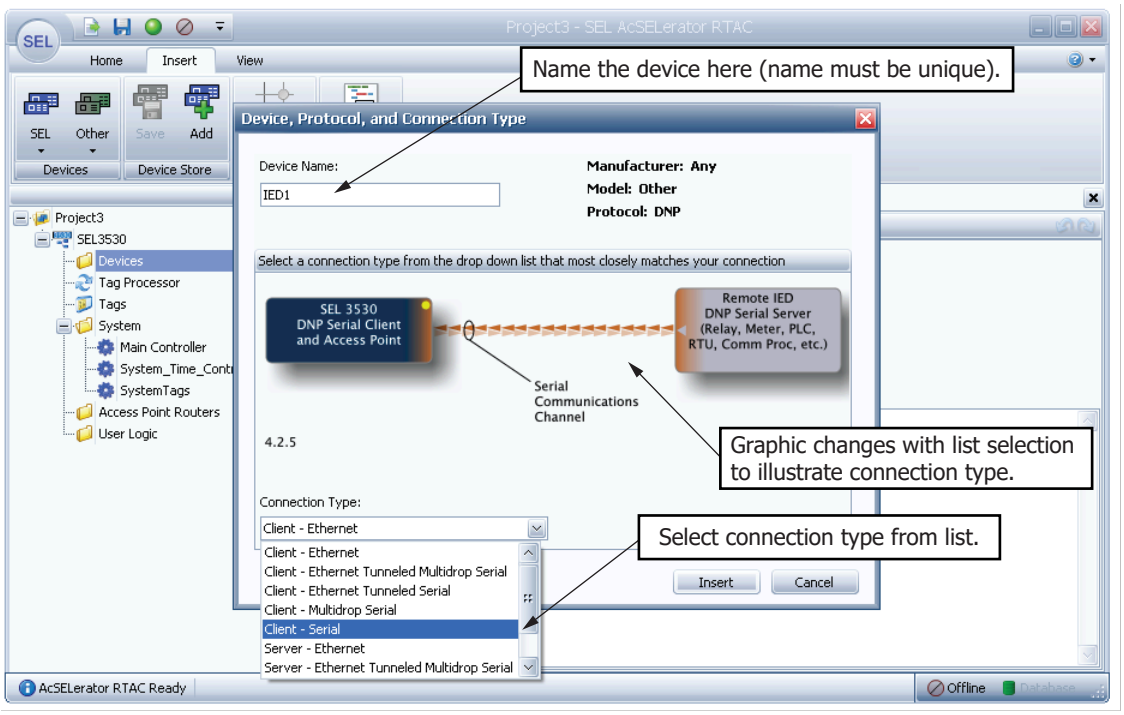


Figure 2.1 Select Serial or IP Client Connection

Step 5. Configure the communications parameters of the connection in the grid view. See *Figure 2.2* as an example.

This view displays automatically. Descriptions of each parameter are on the right of the screen. All configurable communications parameters are listed in this view and may include the following:

a. Port number.

The software assigns the next contiguous port number automatically, or you can choose to assign this number yourself.

b. Data rate, communication time-outs, etc.

c. Protocol-specific IDs, time-synchronization information, etc.

d. **Advanced Settings** check box.

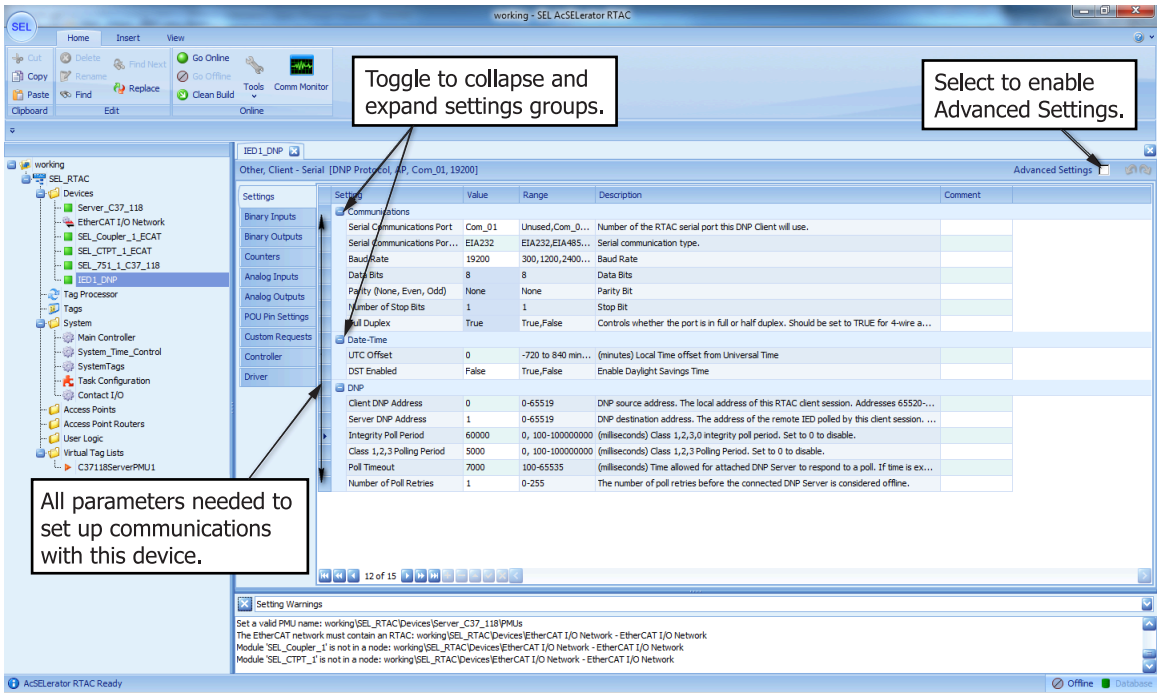

Figure 2.2 Example Serial Client Settings

Step 6. Unless data points are preconfigured, click on each device tag type tab to add the number of data tags (binary, analog, etc.) you want to use on this port.

Client Connection Types

Client—Serial: Use this setting to communicate in a point-to-point, radio, fiber, or other configuration where an EIA-232/EIA-422 connection is necessary. Insert one of these types of connections for each unique EIA-232/EIA-422 communications port on the RTAC that connects to an IED via EIA-232/ EIA-422.

Client—Ethernet: Use this setting to communicate over Ethernet to an IED. Insert a new device connection for each device. The combination of the IEDs IP address and the IEDs port must be unique (i.e., two IEDs can have the same IP port number only if those two IEDs have different IP addresses).

Client—Multidrop Serial: Use this setting to enable polling of multiple IEDs on one serial port. Set the port to EIA-485 or EIA-232. If the port is configured as EIA-485, connect all IEDs on an EIA-485 loop to the RTAC on the specified serial port. Configure the port as EIA-232 if you are using multidrop communications equipment (EIA-232/EIA-485 transceiver, fiber modem, radio, etc.) that has an EIA-232 interface. Insert one multidrop direct serial client for each IED connected to that port. Configure each new device with a corresponding unique remote server address, if applicable. Configure each new device on this multidrop chain with the same serial communications port number. This configuration will cause the software to direct all traffic for the configured IEDs through a single configured serial port.

Client—Ethernet Tunneled Multidrop Serial: Use this setting to enable an Ethernet tunnel through a serial port server (SPS). Connect an IED to each port on a serial port server via EIA-232 serial cables. Connect the serial port server to the RTAC LAN. Insert one SPS multidrop Ethernet Tunneled Multidrop Serial connection for each IED connected to the SPS. Configure each of the SPS multidrop clients for the corresponding unique address of each IED and the unique IP port number configured on the SPS. Configure each SPS multidrop client for the same IP address of the SPS. Each poll will go first to the SPS and then to the appropriate port according to your configuration.

Client—Ethernet Tunneled Serial: Use this setting as in the previous configuration to enable Ethernet tunnel through an SPS, but for a point-to-point type connection.

The following steps detail adding client device data:

Step 1. Click the device tag type tab to add and configure points (tags).

Step 2. Click + to add tags (10,000 tag limit or 5000 for SEL-3505, per device tag type).

> **NOTE**
> Use Copy **<Ctrl+C>** and Paste **<Ctrl+V>** to populate the columns of Tag names and to duplicate devices.

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

Repeat these steps to configure all IED devices. When finished, configure one or more servers to deliver the data to remote client devices.

> **NOTE**
> Save the configuration by clicking the Save icon or **<Ctrl+S>**.

Create a Server Device Connection

A server device connection defines the protocol, port number, port settings, and a tag list of all data that a remote client device, communications processor, RTU, etc. will poll from the RTAC.

The following steps illustrate, generally, how to configure a server connection to send data to a polling device. Sections that contain protocol-specific configuration information are described later in *Section 2: Communications*.

Step 1. Select the type of device (**SEL**, **Other**) from the ribbon menu or right-click **SEL_RTAC** in the device tree.

Step 2. Select the protocol.

In the case of an SEL IED, select the device from the drop-down list within the device type ribbon and then select the protocol. For example, select **SEL > 3500 Series > RTAC > DNP**.

Step 3. Select the type of server connection (serial, Ethernet, etc.).

Step 4. Scroll through the list to see the graphic change with each connection type to show the relationship of communications between the RTAC and the device.

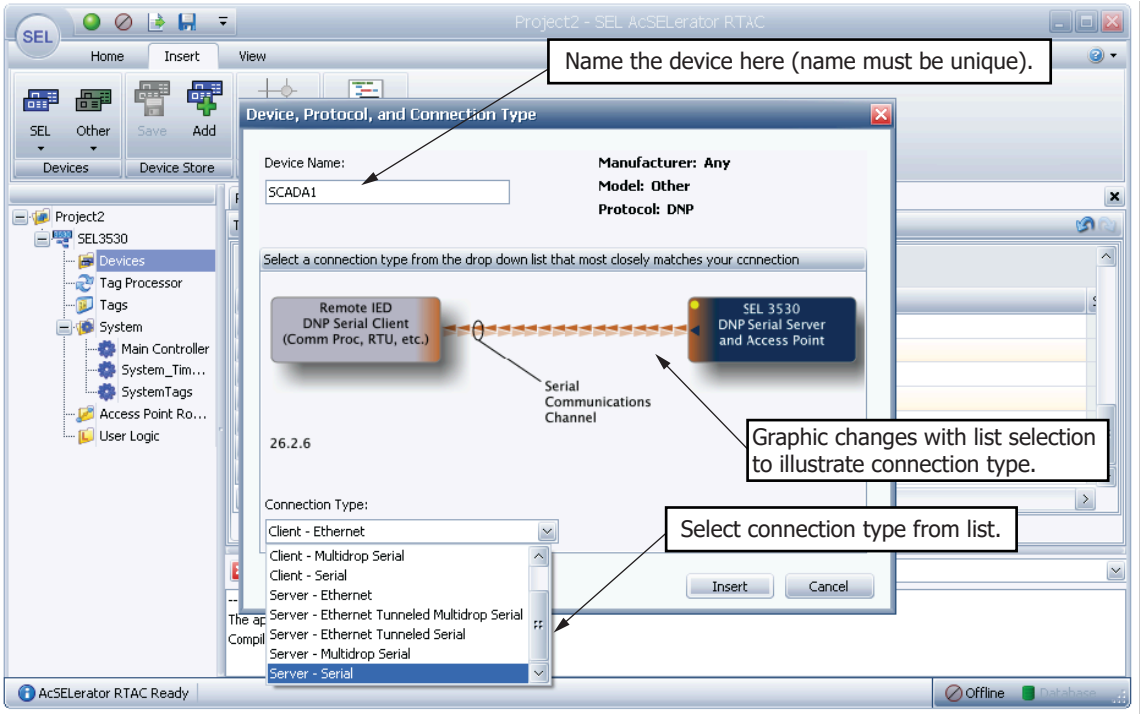

Figure 2.3 Select Serial or IP Server Connection

Step 5. Configure the communications parameters of the connection in the grid view. This view displays automatically.

Descriptions of each parameter are on the right of the screen. All configurable communications parameters are listed in this view and include the following:

a. Port number.

   The software assigns the next contiguous port number automatically, or you can choose to assign this number yourself.

b. Data rate, communication time-outs, etc.

c. Protocol-specific IDs, time-synchronization information, etc.

d. **Advanced Settings** check box.

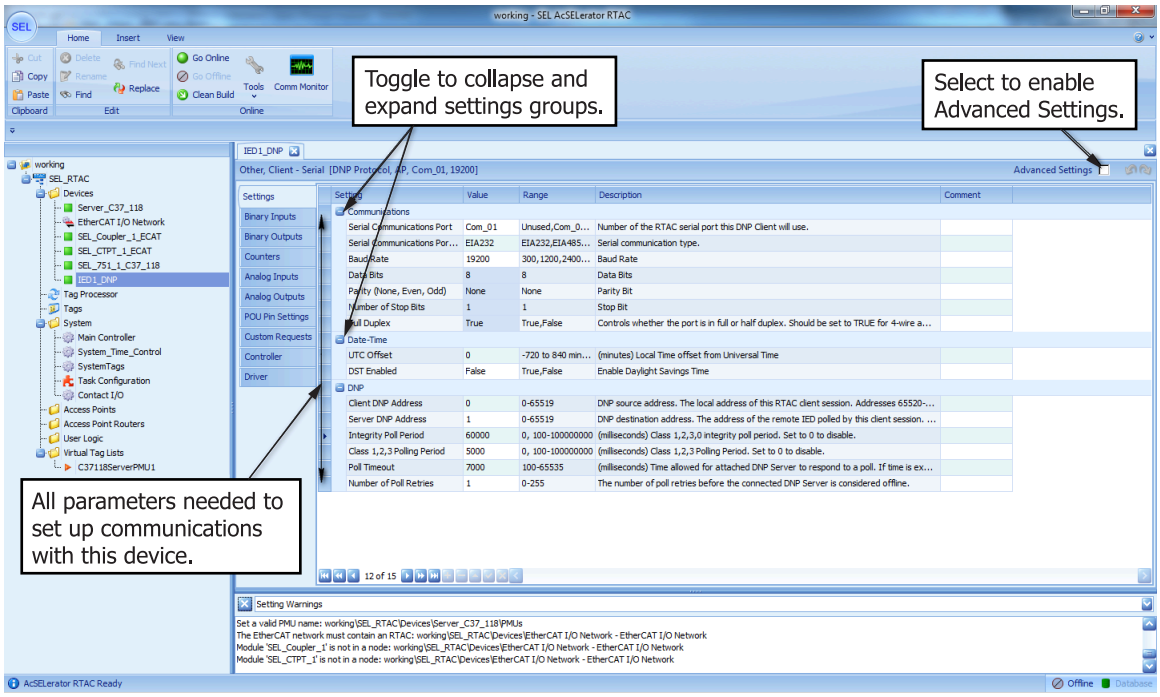

Figure 2.4 Example Serial Server Settings

Server Connection Types

Server—Serial: Use this setting to communicate in a point-to-point, radio, fiber, or other configuration where an EIA-232/EIA-422 connection is necessary to connect to a polling client (master). Insert one of these types of connections for each unique EIA-232/EIA-422 communications port on the RTAC that connects to a master via EIA-232/EIA-422.

Server—Ethernet: Use this setting to communicate over Ethernet to a client polling device. Insert a new server device connection for each remote client device. Configure each server connection with a unique server IP address and port if you set Allow Anonymous DNP IP Clients to False. The combination of the clients IP address and the servers local port must be unique (i.e., two server connections can have the same IP port number only if the two corresponding clients have different IP addresses).

Server—Multidrop Serial: Use this setting to configure the serial port as EIA-485 to allow the RTAC to reside on a multidrop EIA-485 polling loop. Each device on the loop must have a unique ID.

Server—Ethernet Tunneled Multidrop Serial: Use this setting to enable an Ethernet tunnel through a serial port server (SPS) to multiple polling clients. Connect one or more polling client to a serial port server via EIA-232 serial cables. Connect the serial port server to the RTAC LAN. Insert an Ethernet Tunneled Multidrop Serial server connection for each client connected to the SPS. Configure each of the SPS multidrop server connections for the appropriate address of each polling clients and the unique port number they are connected to on the SPS. Configure each SPS multidrop server for the same IP address of the SPS. Each poll reply will go first to the SPS and then to the appropriate port as configured.

Server—Ethernet Tunneled Serial: Use this setting to enable an Ethernet tunnel through a SPS as previously described, except that this is designed for a single-port SPS or point-to-point type connection.

The following steps detail adding server device data:

Step 1. Click the device tag type tab to add and configure points (tags).

Step 2. Click + to add tags (10,000 tag limit or 5,000 for SEL-3505, per device tag type).

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

Repeat these steps to configure all server connections. When finished, configure the Tag Processor to populate these server connection tags with actual values.

Using Copy/Paste Shortcuts

Copy a Column of Tag Names

If you have a list of tag names available in a column format (spreadsheet, IED documentation, etc.), you can save time by copying and pasting the entire column.

Step 1. From within ACSELERATOR RTAC, create the number of tags you want from each device tag type, as the client section, server section, and *Section 3: Tag Processor* describe.

Step 2. Highlight and copy the column of names from the source (Microsoft Excel spreadsheet, column from another RTAC device configuration, etc.).

Step 3. Click the first point from *Step 1* that you want to replace. You must highlight the entire tag name cell.

Step 4. Paste the new column onto the highlighted tag name cell. The pasted column of names will replace the default tag names one-for-one.

Step 5. See *Section 3: Tag Processor* for instructions on how you can use a SCADA tag name spreadsheet to also populate source and destination tag names.

Copy/Paste a Device

Use copy/paste to duplicate a configured device. An example would be a duplicate master station port used for testing that must be exactly the same as the main SCADA port.

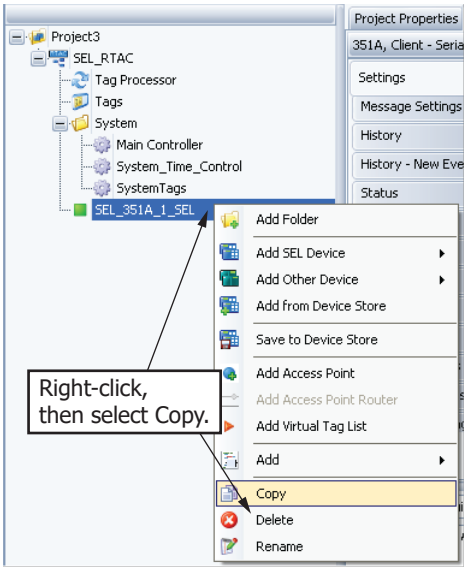
Use this operation as well for a new device that is similar to or exactly the same as a configured device. In such a case, create a copy of the configured device and use this as a starting point for the new device. This operation will copy names and settings that you can then change in the new device.

To make a copy of a configured device:

Step 1. Right-click the device name.

Step 2. Select **Copy** or press **<Ctrl+C>**.

Step 3. Right-click the **Devices** label and select **Paste** or press **<Ctrl+V>**.



Step 4. Rename the new device to a unique name.

All tag names of the new device will reflect the new device name and the port number of the connection increments automatically for the new device. Custom logic written for that device will not be copied.

Example 2.2 SEL_351A_1 Device Copied to Make SEL_351A_1copy

The following figure illustrates making an exact copy of an SEL_351A device. Notice the duplicated device has the word copy appended to the name to avoid duplicate names.

To avoid confusion, rename SEL_351A_1copy to something unique, such as SEL_351A_2. Right-click, then select **Copy**.

Custom XML Templates

Use XML Export functionality to save a configured device template onto your PC. For example, you can store a large IED that you have configured and use frequently and insert this IED later into new projects as necessary. All configuration, points, etc. will remain intact as originally configured except for custom logic.

To create an XML template file:

Step 1. Configure a device according to the instructions previously in this section.

Step 2. Save your project by pressing **<Ctrl+S>** or by selecting the save (💾) icon.

Step 3. Ensure there are no errors in the output window after the save operation.

Step 4. Select **Export Items** under the **XML Template** ribbon or right-click the device configuration you want to save and choose **Export Items**.

Step 5. In the pop-up dialog box, ensure the device(s) for which you wish to save a template has a checkmark beside it to generate an XML file.

Step 6. Verify that the default **Export Location** folder (shown at the bottom of the window) is where you want to save the XML template.

Step 7. Select **Export**.

To use an XML template file:

Step 1. With a project open, select **Import Items** under the **XML Template** ribbon or right-click the project tree in a user folder location and choose **Import Items**.

Step 2. In the pop-up dialog box, choose the **XML Folder** in which you stored your XML templates and select the check box next to the XML template you wish to import to your project.

Step 3. Select **Import**.

Step 4. The software will add the device, completely configured as before, into your project.

As with copy/paste, the software will copy names and settings, but you can change these later after creating the copy.

POU Pin Settings (Advanced Usage)

The **POU Pin Settings** tab provides the names, types, and default values of various components of each task for advanced usage. Each pin name has a Visible flag with a configurable value of True or False. Items marked as True will display on the controller logic block. Input pins control task operation, including polling functionality and data collection into the database. Output pins contain real-time task values used by the protocol. You can configure the default value for most input pins. You can use real-time pin values in logic you write in the RTAC.

NOTE
Use caution when making any programming modifications to the Controller Block or to the POU Pin settings. For more information on using the Controller CFC and POU Pin settings, please contact an SEL application engineer.

NOTE
Copying and pasting a device will not copy custom logic in the Controller Block or POU Pin settings.

Controller (Advanced Usage)

The **Controller** tab contains the Continuous Function Chart (CFC) function block for the task. POU Pin Settings that have their Visible tags set to True in the **POU Pin Settings** tab become visible in the Controller. The Controller block provides advanced users the ability to alter the standard functionality of the protocol task. The task function block contains input POU pins on the left side of the CFC block and output POU pins on the right side of the block. You can add CFC logic such as input blocks, output blocks, functions and function blocks to the controller work space as standalone logic or to interface to the controller task function block.

Tags (Overview)

The **Tags** tab for each device is a view of all the tags you have configured for this device connection.

While offline, use the **Tags** tab to view, select, copy, and paste large groups of data points from this server connection to the Tag Processor or spreadsheet. Right-click on the column heading to display options, including a filter, that you can use to restrict information display to only the data you want to see.

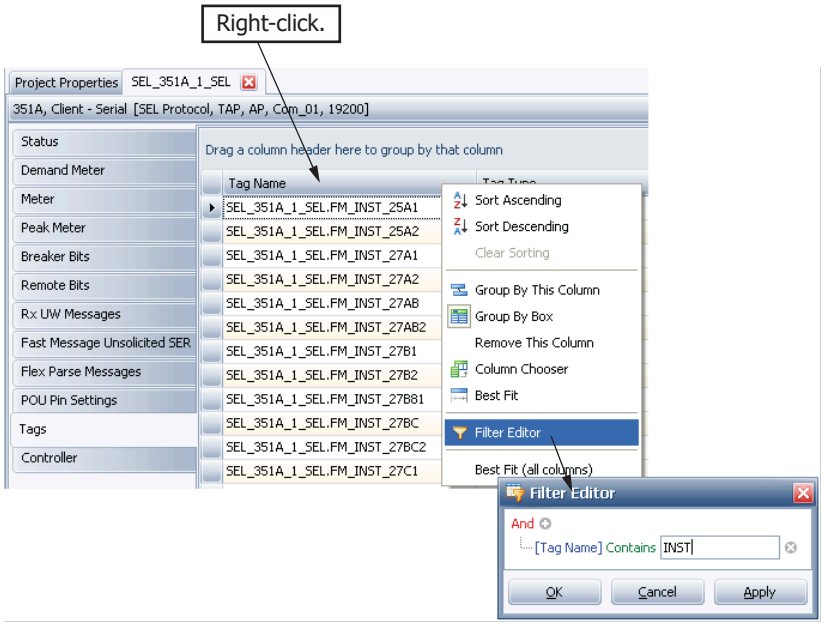


Figure 2.5 Using a Tag Filter

While online, use the **Tags** tab to see the present values of all tags you have defined for this device except for those tags for which you have assigned alias tag names. Alias tag names are part of a different global variable list and are located under the main **Tags** tab in the left-hand side of the ACSELERATOR RTAC menu tab. Expand each tag structure to view all embedded elements such as present value, time, quality, etc. See *Appendix B: IEC 61131-3 Programming Reference* for data type descriptions.

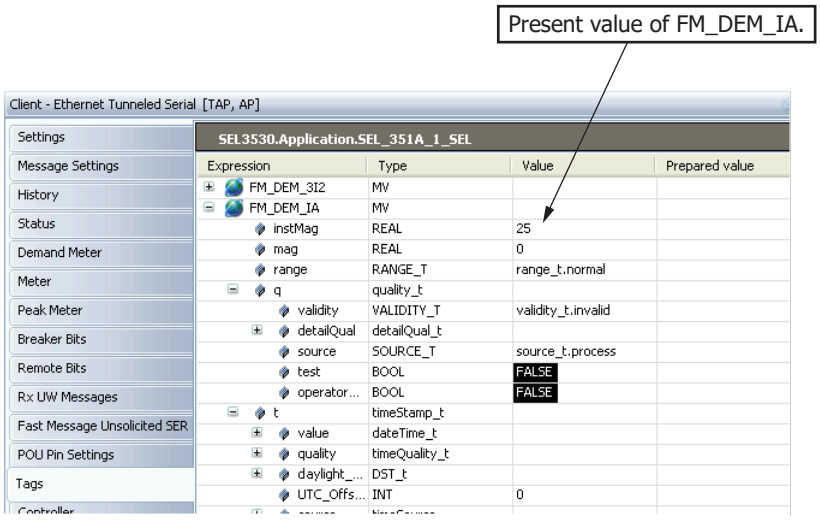

Figure 2.6 View Tags Online

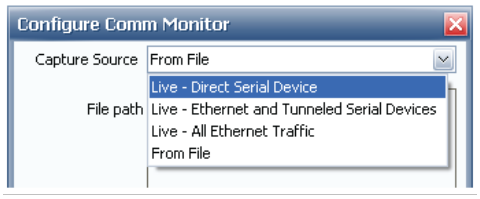
Comm Monitor

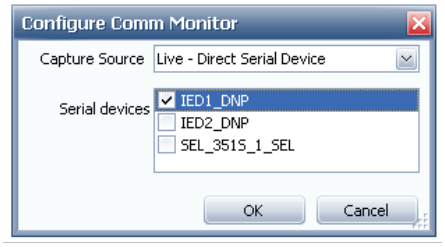
Overview

You can use the communication monitor (Comm Monitor) to view data traffic in real time for all serial and Ethernet communications. The Comm Monitor displays communications events, such as data transmission and reception, and UART control signal transitions. The Comm Monitor shows the time of the event, the present state of the UART (when capturing serial communications) and data associated with the event. Data are displayed in raw hexadecimal and ASCII character format.



Configure Comm Monitor

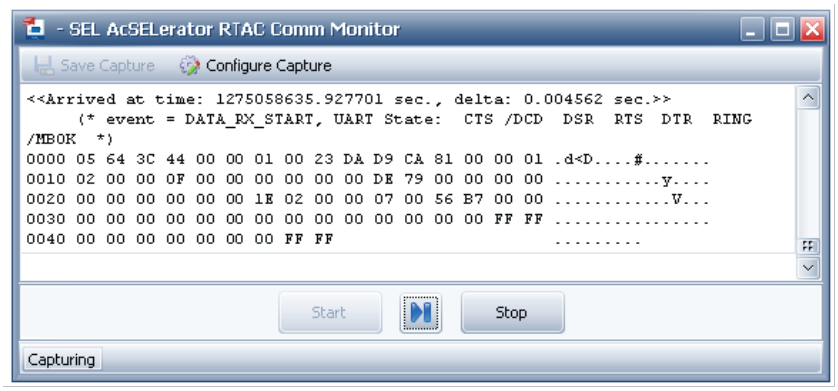
From the **Insert** ribbon, add and configure a DNP, Modbus, SEL, or other device to communicate with the RTAC. Once you have completed the configurations, send the project to the RTAC and leave ACSELERATOR RTAC online with the RTAC. Perform the following steps to configure and use as many as 60 instances of the Comm Monitor:



Step 1. Verify that you are online with the RTAC by observing the Online indicator at the bottom right corner of ACSELERATOR RTAC.

Step 2. From the **Home** ribbon menu, click **Comm Monitor**.

Step 3. From the drop-down menu under **Capture Source**, select the type of communications to monitor. Note that choosing the **Live - All Ethernet Traffic** option will capture all Ethernet traffic sent and received by the RTAC, minus a select list of internal system ports (79–83, 443, 1217, 5432–5435, and 15453).



Step 4. ACSELERATOR RTAC will present all available devices of the communications type you selected. Select the check boxes of the devices you want to monitor and select **OK**.

Step 5. The monitor screen will appear. Click the controls to start, pause, stop, save, and configure the capture.

- **Start**: Comm Monitor clears the display, connects to the configured device, and captures data.
- **Pause**: Stops display scrolling. Press **Resume** to continue displaying present communications.
- **Stop**: Stops data capture. After stopping, you can save the capture. Press **Start** again to clear the display and begin a new capture.
- **Save Capture**: After stopping the capture, you can save the present file in WireShark format.
- **Configure Capture**: Reconfigure the capture session to view data traffic on another device.
- **Open Capture in Wireshark**: After stopping, the capture can be directly opened in Wireshark (if it is installed) without saving.

Step 6. Once you have captured all the needed data, click **Stop** and then **Save Capture**.

Step 7. Provide a file name and press **Save**.

You can load the saved file into Comm Monitor at any time while on- or offline by selecting **From File** as the Capture Source.

NOTE

You can also view the saved Comm Monitor files with Wireshark. Download WireShark software from WireShark.org.

Comm Monitor Components

The Comm Monitor provides detailed information to help you not only see what the protocols are sending "on the wire" but also to provide timing information to help troubleshoot communications problems. For example, the RTAC sends a correct poll to an IED but is configured to time out too quickly because the IED reply is delayed. If the IED does not respond in a timely fashion, the RTAC will transmit a retry and may appear to be sending incorrect polls. The Comm Monitor delta time will show how much time has transpired between each communication event displayed and reveal that adding a slight increase to the time out value in the RTAC configuration resolves the issue.

Figure 2.7 shows an example communication capture of SEL IED traffic. Note the ASCII messages displayed in hexadecimal and in human-readable character form. For example:

Hexadecimal characters:	46	49	44	3D	53	45	4C
ASCII character equivalent:	F	I	D	=	S	E	L

See *Table 2.2* for an explanation of Comm Monitor display field names. *Table 2.3* describes the data field portions of the Comm Monitor.

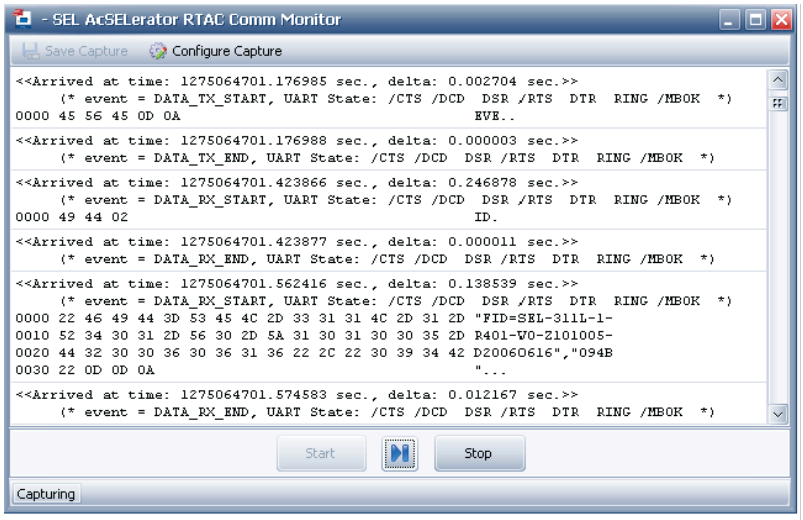


Figure 2.7 Comm Monitor Display Fields

Table 2.2 Comm Monitor Display Fields

Name	Meaning
Arrived at time	The time the communications event occurs in seconds. This does not indicate direction of data flow.
delta	The time difference in seconds between the present communications event and the one immediately preceding it.
event	A description of the type of event. For example, DATA_TX_START is when the UART begins transmitting data. See *Table 2.4*.
UART State	Shown for serial data capture, indicates the present state of the UART signals, e.g., CTS, DCD, DSR, etc. Deasserted state indicated by a / beside the state name. See *Table 2.5*.

Table 2.3 Comm Monitor Data Fields

Byte Count (Hexadecimal)	Hex Representation	ASCII Representation
0000 0010 0020 0030	22 46 49 44 3D 53 45 4C 2D 33 31 31 4C 2D 31 2D 52 34 30 31 2D 56 30 2D 5A 31 30 31 30 30 35 2D 44 32 30 30 36 30 36 31 36 22 2C 22 30 39 34 42 22 0D 0D 0A	"FID=SEL-311L-1- R401-V0-Z101005- D20060616","094B " ...

Table 2.4 UART Event Types

Code	Name	Meaning
0x00	STATUS_CHANGE	Change to the state of any of the UART signals (RTS, CTS, etc.).
0x01	DATA_TX_START	The UART has begun transmitting data.
0x02	DATA_RX_START	The UART has begun receiving data.
0x03	DATA_TX_END	The UART has completed transmitting data.
0x04	DATA_RX_END	The UART has completed receiving data.
0x05	CAPTURE_DATA_LOST	The UART has reported a possible loss of capture data, usually as a result of an EIA-485 communications error.
0x06	CAPTURE_COMPLETE	--
0x07	FRAMING_ERROR	The UART encountered a data framing error, possibly due to actual data corruption on the wire or a misconfigured number of data bits, parity bits, or stop bits between the sending and receiving device.
0x08	PARITY_ERROR	The UART encountered a parity error, possibly due to actual data corruption on the wire or a misconfigured number of data bits, parity bits, or stop bits between the sending and receiving device.
0x09	SERIAL_BREAK_EVENT	The UART receiver detected a serial break event. This can indicate that the remote sender forced the data line to a particular state for a longer than expected amount of time, or a general data communications error.
0x0A	SERIAL_OVERFLOW_EVENT	The UART encountered a serial overflow event. This can occur when the UART receives data that it does not have room to buffer, so they are discarded.

Table 2.5 UART Signals

Name	Meaning
CTS	Clear to send hardware flow control signal.
DCD	Data carrier detected.
DSR	Data set ready.
RTS	Request to send hardware flow control signal.
DTR	Data terminal ready.
RING	Valid only when using a modem. Indicates modem has sent RING to the RTAC.
MBOK	Valid only on MIRRORED BITS communications. Indicates MIRRORED BITS channel receive OK is asserted.

RTAC Serial Line Captures in Wireshark

Communications captures of EIA-232 or EIA-485 serial traffic created by the Comm Monitor can be opened in Wireshark, which includes support for dissection of standardized and supported serial protocols. When opening a pcap file containing RTAC serial traffic in Wireshark, the packets will first only be labeled as a Protocol of 'RTAC Serial' and no dissection of any data payload is attempted. In order to configure the protocol dissector for Wireshark to use, right-click on one of the packets and choose **Decode As**. In the **Decode As** dialog, configure the **Current** field associated with the RTAC Serial Data Subdissector with the appropriate protocol.

Protocols supported for RTAC serial line dissection in Wireshark include the following:

- CP 2179
- DNP 3.0
- IEC 60870-5-101
- IEC 60870-5-103
- IEEE C37.118 Synchrophasors
- L&G 8979
- Modbus RTU
- SEL Protocol

NOTE
RTAC Serial Line dissection in Wireshark does not support any form of payload reassembly between multiple packets. Thus, if protocol data contained in DATA_START_RX or DATA_START_TX packets are split across multiple entries (perhaps separated by a STATUS_CHANGE entry generated by an UART control line change), Wireshark will be unable to dissect the complete protocol message. This can manifest itself in packets that are described by Wireshark as "Malformed." Note that this error is limited to Wireshark's ability to dissect the data and the actual protocol message itself is likely not malformed in any way.

Network Event Capture (Trigger-Based Communication Captures)

SEL-3555, SEL-3560, and SEL-3350 hardware with firmware version R153 or later supports a licensed feature called **Network Event Capture** that creates trigger-based PCAP records. When the feature is active, a running buffer of all Ethernet communications traffic is maintained. Upon activation of a user-logic based trigger, a configurable pre- and post-trigger duration of Ethernet traffic is written to a PCAP file in the RTAC file manager. This is useful for capturing network conditions during unpredictable scenarios, such as a device going temporarily offline or GOOSE messages containing trip signals being received.

When a Network Event Capture is configured, the pre-trigger duration can be assigned a value from 1 to 60 seconds and the post-trigger duration can be assigned a value from 0 to 60 seconds. PCAP files are written to a **NetworkEventCaptures** directory in the RTAC file manager. PCAP files are named in time-stamped COMNAME format, with the Station Name, Device GUID, and Company Name elements extracted from the matching RTAC SystemTags values configured in the project.

More details on configuring the IEC 61131-3 user logic to perform a Network Event operation can be found in *Network Event Capture on page 1094*.

SCADA Protocol Redundancy

SCADA protocol redundancy is available on the DNP server and IEC 60870-5-101/104 server.

Protocol event synchronization between two separate RTAC units is available in RTAC firmware version R136 and later. If two separate RTAC units are configured in a failover scheme and are serving the same data to a single client, you can configure the two units to synchronize which events the client has already confirmed. When the client confirms the reception of an event from a server, that server transmits a UDP message to the other RTAC serving the event information. The second, or failover, RTAC then uses that information to identify which event the client on the first RTAC acknowledged and to acknowledge the same event in its own system.

In this configuration, if a single IED sends the same binary point change with time stamp to two separate RTACs and a client acknowledges the event on Server A, there will be no reporting of that same event to the client when the client begins communicating with Server B. This prevents transmission of duplicate events to the same client. This feature is ideal in a redundancy configuration where multiple RTACs collect the same data from IEDs. The client can then switch communications between the two RTACs without receiving duplicate events.

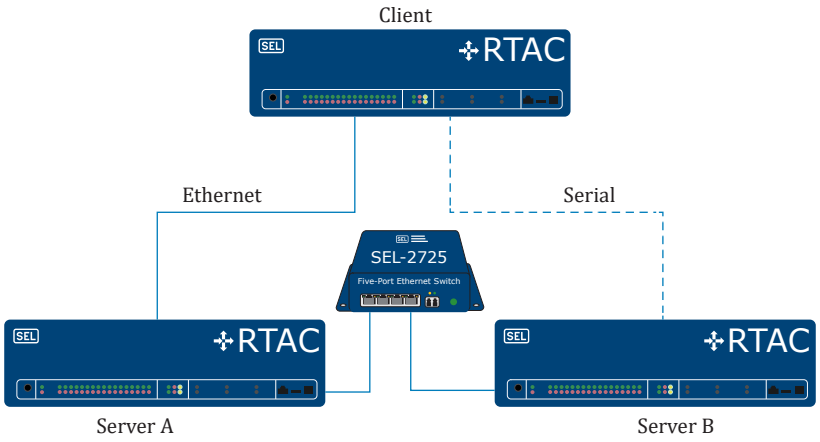

Figure 2.8 SCADA Synchronization

To synchronize two servers, use the Event Synch IP Address and Event Synch IP Port settings. An Ethernet connection between the two RTACs must be available. This can be the same physical Ethernet port that the client and server connection uses, or it can be any other Ethernet interface on the RTAC. The two synchronized RTACs can use any configurable connection method with the SCADA client, including a combination of serial and Ethernet connections. The two synchronized RTACs must be time synchronized and be configured with the same UTC and DST offset settings.

NOTE
In an application with SCADA protocol redundancy enabled, each server tracks the time stamp of the last event for each unique object group (e.g., Binary Input Change) and point index. If a subsequent change in the value of the point located at that index is detected but the time stamp is not newer than the previously stored time stamp, the change is ignored and will not generate a DNP event on the wire. This means that changes without an updated time stamp, such as performing commissioning checks by forcing values of the same index multiple times, will not generate DNP events from the server.

Communication Protocol Device Count Support

The maximum number of communication protocol devices that can be inserted into a single RTAC project will vary by hardware. The table below shows the number of supported protocol devices that can be inserted into a project of that particular hardware type.

Protocol Type	SEL-3530, SEL-3530-4, SEL-2241	SEL-3505, SEL-3505-3	SEL-1102, SEL-3332, SEL-3351, SEL-3354	SEL-3350	SEL-3555, SEL-3560
DNP	200 Clients/Servers (Combination of both)	200 Clients/Servers (Combination of both)	200 Clients/Servers (Combination of both)	200 Clients/Servers (Combination of both)	500 Clients/Servers (Combination of both, as of R148)[a]
Modbus	120 Clients/Servers (Combination of both)	120 Clients/Servers (Combination of both)	120 Clients/Servers (Combination of both)	200 Clients/Servers (Combination of both, as of R152)[b]	256 Clients/Servers (Combination of both)
SEL Protocol	64 Clients/Servers (Combination of both)	64 Clients/Servers (Combination of both)	64 Clients/Servers (Combination of both)	100 Clients/Servers (Combination of both)	254 Clients/Servers (Combination of both)
MIRRORED BITS	Limited by number of serial ports	Limited by number of serial ports	Not supported	Limited by number of serial ports	Limited by number of SEL-3390S8 serial ports
IEEE C37.118 Synchrophasor	100 Clients, 100 Servers	100 Clients, 100 Servers	100 Clients, 100 Servers	100 Clients, 100 Servers	100 Clients, 100 Servers
IEC 61850 MMS	256 Clients[c], 10 Servers	Clients not supported, 10 Servers	256 Clients, 10 Servers	256 Clients, 10 Servers	256 Clients, 10 Servers
IEC 61850 GOOSE	150 receive, 150 transmit	150 receive, 150 transmit	150 receive, 150 transmit	150 receive, 150 transmit	150 receive, 150 transmit
LG 8979	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)
CP2179	100 Clients	100 Clients	100 Clients	100 Clients	100 Clients
SES-92	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)	10 Clients, 10 Servers (simultaneous)
Courier	100 Clients	100 Clients	100 Clients	100 Clients	100 Clients
IEC 60870-5-101/104	100 Clients/Servers (combination of both)	100 Clients/Servers (combination of both)	100 Clients/Servers (combination of both)	100 Clients/Servers (combination of both)	256 Clients/Servers (combination of both)
IEC 60870-5-103	50 Clients	50 Clients	50 Clients	50 Clients	50 Clients

Protocol Type	SEL-3530, SEL-3530-4, SEL-2241	SEL-3505, SEL-3505-3	SEL-1102, SEL-3332, SEL-3351, SEL-3354	SEL-3350	SEL-3555, SEL-3560
CDC Type 2	Clients limited by number of serial ports, 10 servers	Clients limited by number of serial ports, 10 servers	Clients limited by number of serial ports, 10 servers	Clients limited by number of serial ports, 10 servers	Clients limited by number of SEL-3390S8 serial ports, 10 servers
SNMP	100 Clients/Managers, 10 Servers/Agents	100 Clients/Managers, 10 Servers/Agents	100 Clients/ Managers, 10 Servers/Agents	100 Clients/ Managers, 10 Servers/Agents	100 Clients/ Managers, 10 Servers/Agents
(S)FTP Server	1 server, 10 simultaneous connections	1 server, 10 simultaneous connections	1 server, 10 simultaneous connections	1 server, 10 simultaneous connections	1 server, 10 simultaneous connections
Ethernet/ IP Explicit Message Client	100 CIP messages, 100 PCCC messages	100 CIP messages, 100 PCCC messages	100 CIP messages, 100 PCCC messages	100 CIP messages, 100 PCCC messages	100 CIP messages, 100 PCCC messages
Ethernet/IP Implicit/Explicit Server/Adapter	128 simultaneous connections	128 simultaneous connections	128 simultaneous connections	128 simultaneous connections	128 simultaneous connections
OPC UA	Not supported	Not supported	Not supported	10 clients, 1 server (10 simultaneous connections)	10 clients, 1 server (10 simultaneous connections)

[a] In firmware versions prior to R148, the SEL-3555 and SEL-3560 both support 256 DNP clients/servers (combination of both).
[b] in firmware versions prior to R152, the SEL-3350 supports 120 Modbus clients/servers (combination of both).
[c] Depending on the SCD configuration size.

ACSELERATOR RTAC allows for creation of projects of sizes that may begin to burden legacy RTAC hardware models (SEL-2241, SEL-3505, SEL-3505-3, SEL-3530, and SEL-3530-4). The SEL-3505 and SEL-3505-3 should *not* be used for any projects containing more than 20 devices. In addition, the SEL-2241, SEL-3530, and SEL-3530-4 should not be used with projects that contain more than 50 percent of the supported devices for a given protocol or if the device is used simultaneously for multiple purposes (e.g., as a data concentrator with high-speed logic, or with EtherCAT I/O and an RTAC HMI). Legacy RTAC models running projects that approach or meet the maximum number of supported devices for that model may exhibit degraded performance in some of the following processes:

- Settings read or send operations
- Go Online time
- Web interface responsiveness
- RTAC HMI performance
- Device startup time-to-enable all protocol devices
- Main or Automation task cycle execution time

DNP3

Overview

Configure DNP3 protocol on any of the RTAC serial or Ethernet ports to communicate with such other devices and systems as DNP3 IEDs, communications processors, RTUs, and remote client systems. See *Communication Protocol Device Count Support on page 181* for the number of DNP servers and clients supported for each RTAC model.

This section describes the configuration and use of DNP3 protocol with ACSELERATOR RTAC. The DNP3 Device Profile Document is included at the end of this section. For more DNP3 protocol information, go to *www.dnp.org*.

For a detailed description of client and server concepts and other general information on protocol configuration, see *Overview on page 161*.

DNP Client Configuration

Configure a DNP client connection to communicate via serial or Ethernet to IEDs. The RTAC will poll data from these IEDs and store the data it receives in global variables. Use the Tag Processor to map these data to any protocol, logs, user logic, etc.

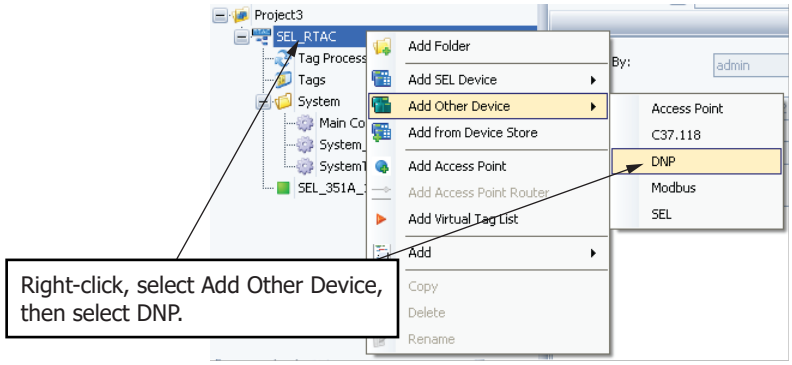

Figure 2.9 Insert DNP Client Device

Give the device connection a unique name and select the connection type, as shown in *Figure 2.1*. Refer to *Client Connection Types on page 167* for a description of each connection type. Note that, in a DNP client connection, the client DNP address setting is the address of the RTAC. The server DNP address setting is the DNP address of the IED being polled.

Settings Tab

The **Settings** tab contains all configurable items necessary for communications. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description. Type any applicable comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Add Client Device Data

The following steps detail adding client device data.

Step 1. Click a device tag type tab to add and configure tags.

Step 2. Click + to add tags (30,000 tag limit or 5000 for SEL-3505, per device tag type).

> **NOTE**
> Use Copy (**<Ctrl+C>**) and Paste (**<Ctrl+V>**) to populate columns of Tag names and to duplicate devices.

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

Repeat these steps to configure all IED devices. When finished, configure one or more servers to deliver the data to remote client devices.

> **NOTE**
> Save the configuration by clicking the **Save** icon or by pressing **<Ctrl+S>**.

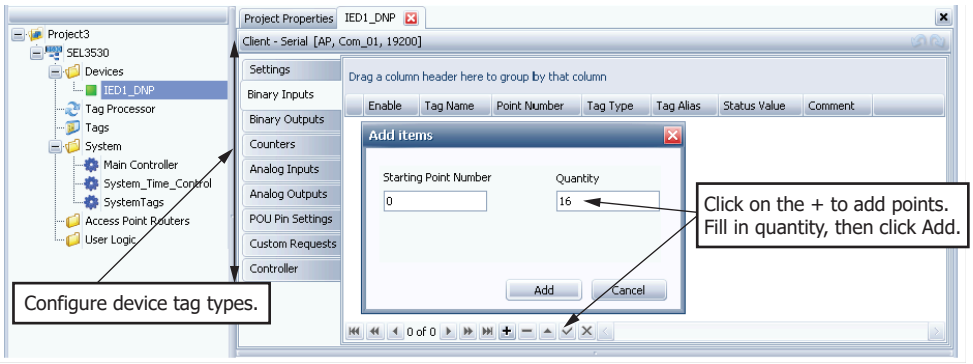

Figure 2.10 Add DNP Client Tags

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation.

Table 2.6 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name and tag type and is numbered 0–*n* tags.

Parameter	Description	Default
Point Number	This is the point number for which the DNP client will poll. If points are not contiguous in the IED, change these point numbers to match the DNP database for the IED.	Contiguous from 0 to the point count.
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	

Table 2.7 Binary Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	SPS
Status Value	The initialized value at startup.	False
Comment	Optional user-entered comment field.	

Table 2.8 Binary Output Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. In DNP, there are five binary output operations and one status.	Control operations is operSPC. Status is SPS.
Status Value	The initialized state at startup.	False
Control Value	The initialized control value at startup.	False
Control Model	Defines if the control is a single pulse or persistent (latch) type control.	Defaults are set according to control type and cannot be changed.
Number of Pulses	Defines the number of pulses the control will issue each time this point is controlled.	1
On Pulse Dur	Defines the duration for an active pulse.	
Off Pulse Dur	Defines the duration for an inactive pulse. Although you can configure the pulse-off duration, the pulse-off command in DNP is not supported in the RTAC. A pulse-off command is treated as a pulse-on command.	
Comment	Optional user-entered comment field.	

Table 2.9 Counter Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	BCR
Actual Value	The initialized running value at startup.	0
Frozen Value	The default frozen value the tag will have before the RTAC initializes the tag upon startup.	
Comment	Optional user-entered comment field.	

Table 2.10 Analog Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	MV
Inst Magnitude	The initialized instantaneous value at startup.	
Magnitude	The initialized dead-banded value at startup.	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion of this dead band will generate a time-stamped DNP event.	

Parameter	Description	Default
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	
Comment	Optional user-entered comment field.	

Table 2.11 Analog Outputs

Parameter	Description	Default
Set Magnitude	The commanded value of the analog output.	0

The other analog output settings are identical to those for analog inputs.

Custom Requests

Create as many as 15 optional custom requests per DNP client session. Add a request by clicking the + icon. Expand the custom request headings to configure the object, poll period, and broadcast request, and to add function codes and all other configurations related to the custom DNP request.

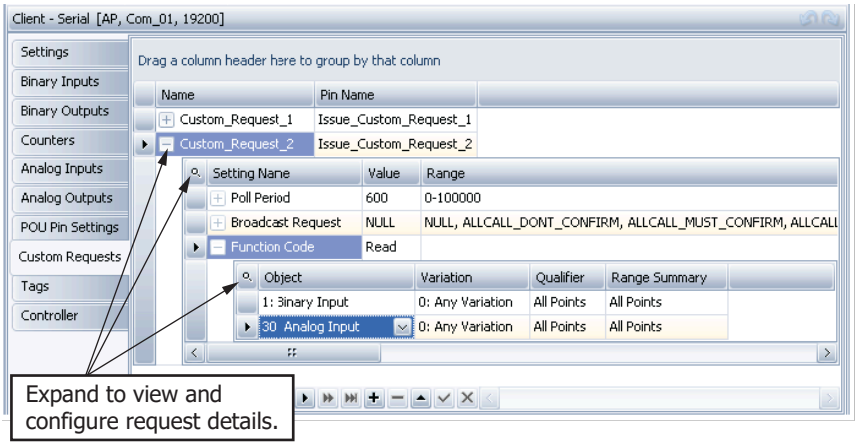

Figure 2.11 DNP Client Custom Requests

DNP Server Configuration

Configure a DNP server connection to communicate via serial or Ethernet to DNP polling clients (HMIs, communications processors, etc.). Create binary input, analog input, and counter tags in a DNP Server Shared Map as placeholders for data that the clients will poll. Configure the DNP server to use the configured shared map. Each DNP server can use a unique map, or can share

the same map. Although two or more DNP servers can share a map, each server will maintain its own event queue. You can create a maximum of 100 shared DNP server maps in a project. Map data to those tags by using the Tag Processor from client IED or other source tags in the RTAC database.

Insert a unique DNP Server connection for each DNP client connected to the RTAC. Although sharing DNP server connections simultaneously with one or more polling clients is not permitted, you can configure various failover scenarios in the RTAC (see *DNP Server Failover on page 187*).

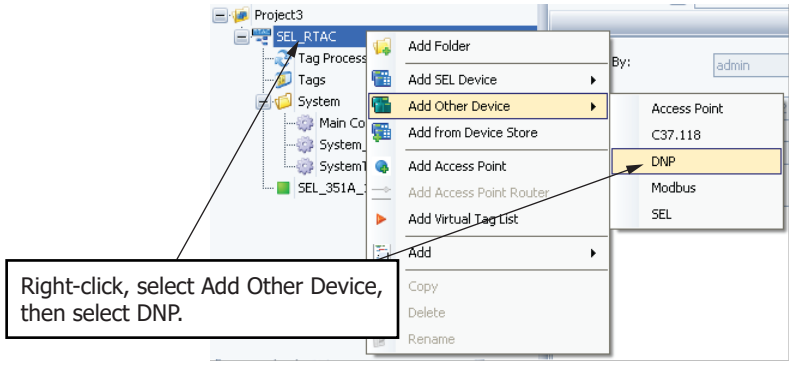

Figure 2.12 Insert DNP Server Device

Give the device connection a unique name and select the type of connection as shown in *Figure 2.3*. Note in DNP server, the Server DNP Address is the DNP address of the RTAC. The Client DNP Address is the address of the device polling the RTAC. You can configure multiple serial DNP servers to use the same serial port to create a virtual multidrop environment within the RTAC. Each server monitors traffic on the one configured serial port and responds to messages that contain the correct DNP address for that server. Each server maintains its own event queue.

The **Settings** tab contains all configurable items for communications. Note that you must enter a DNP Server Shared Map name in the settings. This map contains all of the tags that this DNP server uses. You insert and configure a DNP shared map under Tag Lists in the **Insert** tab. Check the Description column for details on each configuration item. Move the slider or hover your cursor over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

DNP Server Failover

You can configure DNP servers to operate under the following failover scenarios:

DNP/IP: Multiple clients can poll one RTAC server if they are configured in a failover configuration so as to poll the RTAC one at a time. In this configuration, the DNP server maintains one DNP event queue. Events reported to one client are not reported in the next reply, even if the poll comes from a different client. If you set Anonymous DNP IP Clients = TRUE, the RTAC will allow any DNP client that can connect to the RTACs network to poll this DNP server, as long as the DNP IP addresses are correct. If you set Allow Anonymous DNP IP Clients = False, you can configure as many as 20 Client IP Addresses, separated by commas. In this configuration, the RTAC will reply to any client that has one of the configured IP addresses.

DNP Serial and Tunneled Serial: You can configure a DNP server to communicate DNP serial or tunneled serial over Ethernet with a redundant dial-up, leased line, etc., serial port with the following steps. Insert a DNP serial server, select **Advanced Settings**, then scroll down and configure the Failover Type to be another serial port or a tunneled connection. Configure the respective serial port or IP information for the failover port. You can configure as many as 10 TCP addresses, separated by commas. The DNP server monitors both the primary serial port and the failover Ethernet or serial port as redundant communication paths, and responds to polls from the respective interface. Because the DNP task is monitoring and responding to both interfaces, there are no failover delays or risks of missing queued events. The DNP server maintains one event queue regardless of how many failover ports are configured.

DNP Server Event Reporting

You can configure event data storage in the advanced settings for each DNP server. The analog, binary input, and counter data buffers each have separate event queues that are configurable in size from 1–65,535 entries. By default, each event buffer is configured as a one-to-one correlation with the number of defined tags in the DNP server. As such, each buffer entry contains only one event (the most recent) with a time stamp for each configured tag. Configure the binary, analog, and counter buffer sizes to match the number of tags defined for the respective types. Alternatively, you can configure each event buffer type as SOE and configure the size to as many as 65,535 entries. When a buffer type is configured as SOE, the RTAC places all events for a tag type in the respective buffer until the buffer size is exceeded. On a buffer overflow, the oldest events shall be maintained in the buffer and new events discarded. In SOE mode, the buffer may contain many events from a few tags or a few events from many tags.

Each DNP object (binary input, analog input, etc.) is configurable with a per-point **Event Class** that controls the reporting of change events for that point in Class 1, 2, and 3 and Integrity (Class 0) poll responses. By default, binary input changes are reported under Class 1 and analog input changes are reported under Class 2. All other point types are assigned by default to Class 0, which means they do not generate change events and thus are only reported in a response to a Class 0 poll. Each point type can optionally be configured with an Event Class of **None**, which causes them to be excluded in the response to any Class 0 polls.

Unsolicited event reporting can introduce a challenge for half-duplex communications in collision avoidance. If two devices on a multidrop line attempt to talk at the same time, a collision will occur. If they hold off the exact amount of time and then retry, they will experience another collision. You can configure the Transmit Minimum Delay and Transmit Maximum Delay in each RTAC to create a window of random transmit delays for unsolicited reporting. With these parameters configured, the two RTACs will retry at different random times, therefore avoiding the chances of another communication collision.

DNP Server Shared Tag Maps

The following steps detail adding and configuring a DNP server shared tag map. Each map is configured with the required tags for the server (binary inputs, analog inputs, etc.) and can be shared across multiple DNP server devices.

Step 1. From the **Insert** tab, select **Tag Lists** and then **DNP Server Shared Map**.

This inserts a configurable tag list for a DNP server.

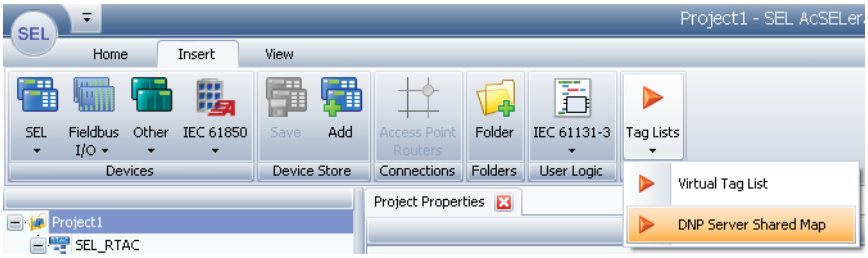

Figure 2.13 Add DNP Server Map

Step 2. Click a device tag type tab to add and configure tags.

Step 3. Click + to add tags (10,000 tag limit or 5000 for SEL-3505, per device tag type).

Creating only the number of necessary tags will help the system run at optimum performance.

Step 4. Change the names of the tags, if necessary.

Step 5. Change other tag-related information as necessary.

Repeat these steps to configure all server tags. When finished, configure the DNP server to use this custom map by selecting the Map Name under settings. Although more than one DNP server can use the same map, each DNP server will manage separate event queues. Configure the Tag Processor to populate these server connection tags with actual values.

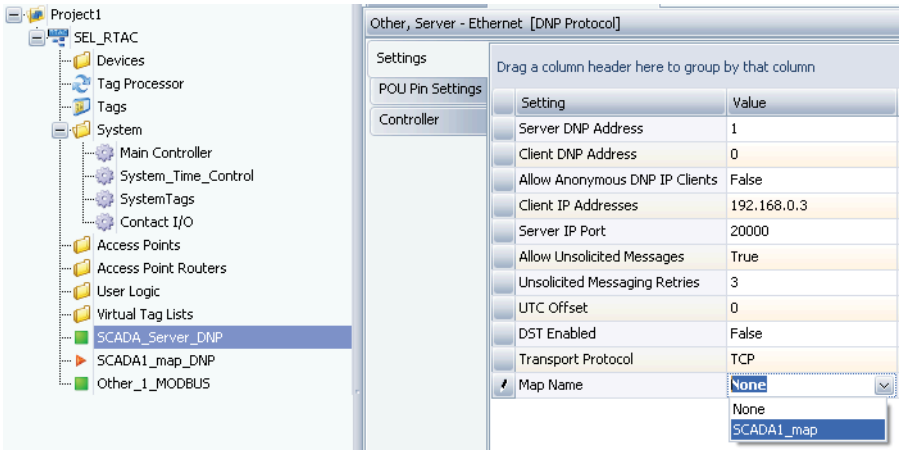

Figure 2.14 Select DNP Shared Map

DNP Tag Type Configuration Parameters

Each DNP tag type has parameters that must be configured correctly to ensure proper system operation. Configuration columns in the DNP Shared Map have the same meaning as in DNP clients (described previously) except for the addition of fields that have special meaning in DNP servers. Use these fields to alter the default object variations returned to a polling DNP client. Analog Input point types allow configuration of a per-point **Deadband** value that should be tuned to provide a point update rate that is frequent enough for event polls, but not so frequent that it could be interpreted as noise or chatter.

DNP Server Dial-Out

You can configure a DNP serial server device to dial out automatically to report unsolicited data. Insert a DNP serial server connection and select **Advanced Settings**. *Figure 2.15* shows these settings that are enabled when Modem Connected = TRUE. Notice the configuration supports an optional second phone number in case the RTAC does not get an answer when using the first phone number.

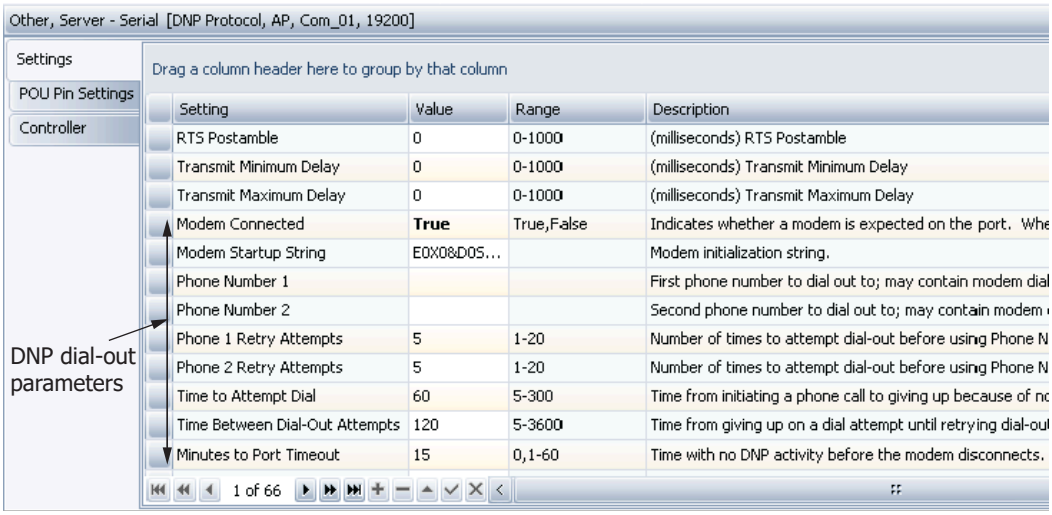

Figure 2.15 DNP Server Dial-Out

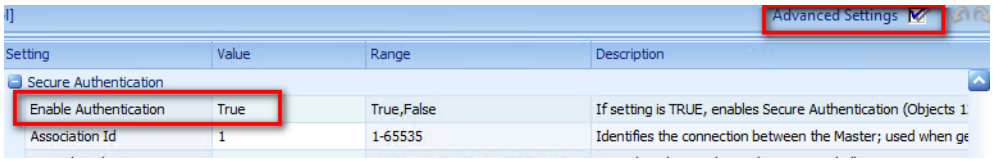

Secure Authentication

In firmware versions R143 and later, the DNP server supports Secure Authentication Version 5. Select the **Advanced Settings** check box in the DNP server to enable this feature. DNP Secure Authentication uses cryptographic hashing techniques for a challenge-and-response infrastructure that serves to authenticate critical commands and services. IEEE 1815 (DNP standard) defines commands and services that are critical and which must be challenged.

When Secure Authentication is enabled, the commands and services that can be challenged are configurable. This will cause the RTAC to issue a challenge any time the RTAC receives one of the configured function codes. By default, read commands do not prompt challenges. This can be configured to your desired configuration list. When Secure Authentication is enabled it will cause additional bandwidth consumption and delays in processing received messages that are challenged.

How to Configure Secure Authentication

Step 1. Under **Advanced Settings**, set **Enable Authentication** to True.

Step 2. Configure the appropriate options for the client connection under **Secure Authentication** in the **Settings** tab. Most values, by default, are configured for interoperability with most connections.

Step 3. When Secure Authentication is enabled, two new tabs appear on the DNP server: **Secure Event/Statistic Parameters** and **User Settings**. The **Secure Event/Statistic Parameters** tab allows for configuration of statistics about the secure authentication connection usage. The **User Settings** tab includes additional configuration parameters.

Step 4. In the **User Settings** tab, the user and update key information is configured. By default, there is a user defined with the role of **singleuser**. The DNP standard defines these roles and the capabilities each connection has with the DNP session. These roles are specific to DNP3 and have no effect on user accounts in the RTAC system or on other functionality outside of the DNP3 protocol. The singleuser default user contains the superset of permissions contained in the various roles. *Table 2.12* shows the permissions of each user role for DNP services.

Table 2.12 DNP Services User Role Permissions

Commands	User Roles							
	VIEWER	OPERATOR	ENGINEER	INSTALLER	SECADM	SECAUD	RBACMNT	SINGLEUSER
CONFIRM	X	X	X	X		X	X	X
READ	X	X	X	X		X	X	X
WRITE		X						X
SELECT		X						X
OPERATE		X						X
DIRECT_OP		X						X
DIRECT_OP_ NOACK		X						X
FRZ		X						X
FRZ_NOACK		X						X
FRZ_CLEAR		X						X
FRZ_ CLEAR_ NOACK		X						X
COLD_ RESTART		X						X

Commands	User Roles							
	VIEWER	OPERATOR	ENGINEER	INSTALLER	SECADM	SECAUD	RBACMNT	SINGLEUSER
WARM_ RESTART		X						X
ENABLE_ UNSOL		X	X					X
DISABLE_ UNSOL		X	X					X
ASSIGN_ CLASS			X					X
DELAY_ MEASURE		X	X					X
RECORD_ CURRENT_ TIME		X	X					X

Step 5. These user types only apply to the DNP session and do not allow for any use with other functionality of the RTAC. The columns Transfer data files, Change config, Change security config, change code, and local login do not have any functional capabilities on the RTAC. For this reason, SEL recommends using either the default USER or VIEWER role for read-only communications sessions and OPERATOR for reading and sending controls. The username must match the username that the client uses in the DNP communications session.

Step 6. Once a user is selected, configure the update key. The update key will be the symmetric key from the user on the DNP client. If there are multiple users, the update key can be the same or different between users. This is primarily dependent upon how the users on the clients are configured.

Step 7. The user public key is optional. The user public key is used to remotely change the update key through use of the asymmetric method for that user. If there is no user public key entered, the update key must be updated through the RTAC configuration software.

Changing the Update Key for DNP Secure Authentication

The DNP protocol offers a mechanism for remotely changing the update key. How often the update key needs to be changed depends on the security practices and policy of the implementers. There are two methods by which to change the update key: manually through the configuration software (The DNP standard does not specify a specific process for this) or by using DNP.

Through the Configuration Software

Once the new public key for the client has been obtained, open the RTAC settings and update the public key. This can be done locally at the unit or remotely if a connection to the RTAC is available.

The RTAC software will validate that the entered text contains a public key and conforms to valid privacy enhanced mail (PEM) format content.

Through DNP

When using DNP, there are two options for changing the update key: symmetric or asymmetric.

- **Symmetric**: In this manner, the RTAC configuration will need to have the Authority Certification Key, which is configured in the **DNP Settings** tab under the enable DNP Secure Authentication option. The RTAC will verify that the Authority Certification Key matches what the client sends when an update key change is attempted through the symmetric process.
- **Asymmetric**: In this manner, the RTAC configuration will need to have the User Public Key that the client uses, and the client will need to have RTAC active x.509 certificate public key. This allows the client and the RTAC to authenticate and change the update key.

NOTE
The outstation name is required as part of an Update Key Change Request. In the RTAC, the device name of the DNP server (for example, **SCADA_DNP**) is used for the outstation name, and the client must be configured to match.

Remote User Management

The DNP standard allows for the protocol to dynamically manage users for secure authentication. An authority can be set up that will authenticate that the client is capable of adding, removing, or changing a user. The client and the authority cannot have the same credentials. In order for the RTAC to accept user management changes via DNP, the RTAC must have the public key of the authority. This public key is added to the CA certificates in the RTAC web interface.

POU Pin Settings

Use POU pin settings to view the present state of the DNP Server operation and to modify some of the behavior of the protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.13* for the settings descriptions.

Table 2.13 DNP Server POU Pin Settings

Pin Name	Pin Type	Description	Default
Disable_Controls	Input BOOL	While True, processing of any controllable tags is blocked. Note: If other DNP server instances are assigned to the same DNP Server Shared Map as this DNP server, asserting Disable_Controls will also disable controls for those other DNP server instances.	False
Disable_Tag_Updates	Input BOOL	The POU will not update or process changes to tags while this input is True. Note: If other DNP server instances are assigned to the same DNP Server Shared Map as this DNP server, asserting Disable_Tag_Updates will also disable updates for those other DNP server instances.	False
EN	Input BOOL	The EN input enables or disables this specific function block instance. Other inputs have no effect while EN is False.	True

Pin Name	Pin Type	Description	Default
Force_Buffer_Overflow_IIN_Bit	Input BOOL	Forces the assertion of the Buffer Overflow International Indication bit (IIN2.3) contained in all response messages generated by this DNP server.	False
Force_Device_Trouble_IIN_Bit	Input BOOL	Forces the assertion of the Device Trouble International Indication bit (IIN1.6) contained in all response messages generated by this DNP server.	False
Reset_Statistics	Input BOOL	On the rising-edge trigger, all counter POU outputs are reset.	False
Application_Confirmation_Timeout_Count	Output UINT	Contains a running count of Application Confirmation timeout conditions.	0
Data_Link_Timeout_Count	Output UINT	Contains a running count of data link failures.	0
Direct_Transparent_Connection	Output BOOL	Indicates that the associated access point is being used in direct transparent mode.	False
ENO	Output BOOL	Indicates that this specific function block instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have successfully been sent or received.	0
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	0
Message_Success_Count	Output UDINT	A running sum of the messages successfully sent or received	0
Offline	Output BOOL	This output is False when protocol communications are in progress. Set to True when the DNP communications channel is offline due to an application confirmation timeout, data link (link status) timeout, or a transmission error, until a subsequent DNP frame is successfully received. For a DNP Server using a serial connection method, this value is also set to True if no communications have been received for the period specified by the Communications Offline Timer. Note: It is possible for Offline to indicate False, but no successful data are exchanged because of settings configuration issues.	False

DNP3 Device Profile Document

The following DNP3 Device Profile displays only selections relevant to the RTAC DNP3 implementation.

Table 2.14 Server (Outstation)

Parameter	Value
Vendor name	Schweitzer Engineering Laboratories
Device name	RTAC
Highest DNP request level	Level 3
Highest DNP response level	Level 3
Device function	Outstation
Notable objects, functions, and/or qualifiers supported	Analog Dead-Band Objects (object 34)
Maximum data link frame size transmitted/ received (octets)	292
Maximum data link retries	Configurable, range 0–15
Requires data link layer confirmation	Configurable by setting
Maximum application fragment size transmitted/received (octets)	2048
Maximum application layer retries	None
Requires application layer confirmation	When reporting event data
Data link confirm time-out	Configurable
Complete application fragment time-out	None
Application confirm time-out	Configurable
Complete application response time-out	None
Executes control WRITE binary outputs A	Always
Executes control SELECT/OPERATE	Always
Executes control DIRECT OPERATE	Always
Executes control DIRECT OPERATE-NO ACK	Always
Executes control count greater than 1	When pulse count > 1
Executes control Pulse On	Always
Executes control Pulse Off	Never
Executes control Latch Off	Always
Executes control Latch On	Always
Executes control Queue	Never
Executes control Clear Queue	Never
Reports binary input change events when no specific variation requested	Only timetagged
Reports time-tagged binary input change events when no specific variation requested	Binary input change with time

Parameter	Value
Sends unsolicited responses	Configurable with unsolicited message enable settings. Increases retry time (configurable) when a maximum retry setting is exceeded.
Sends static data in unsolicited responses	Never
Default counter object/variation	Object 20, Variation 6
Counter rollover	32 bits
Sends multifragment responses	Yes

Although the RTAC is classified as a DNP3 Level 3 client, it will support the items indicated in the previous tables in automated or custom requests. It is the user's responsibility to create custom requests that the connected DNP3 server can parse.

Table 2.17 DNP Secure Authentication Protocol Implementation Extra Information for Testing (PIXIT)

12.1	Master System Configuration	DNP Secure Authentication is not supported for RTAC master station.
12.1.1	How to restart the master	DNP Secure Authentication is not supported for RTAC master station.
12.1.2	How to change addresses of master?	DNP Secure Authentication is not supported for RTAC master station.
12.1.3	How to change addresses of outstation	DNP Secure Authentication is not supported for RTAC master station.
12.1.4	How to change the name of the outstation	DNP Secure Authentication is not supported for RTAC master station.
12.1.5	Number of users supported	DNP Secure Authentication is not supported for RTAC master station.
12.1.6	Names of any pre-configured users	DNP Secure Authentication is not supported for RTAC master station.
12.1.7	How to change which user is performing an operation	DNP Secure Authentication is not supported for RTAC master station.
12.1.8	How to display security statistics	DNP Secure Authentication is not supported for RTAC master station.
12.1.9	How to perform control operations	DNP Secure Authentication is not supported for RTAC master station.
12.1.10	How to configure “no ack” operations	DNP Secure Authentication is not supported for RTAC master station.
12.1.11	How to make responses critical	DNP Secure Authentication is not supported for RTAC master station.
12.1.12	How to read logs	DNP Secure Authentication is not supported for RTAC master station.
12.1.13	Whether time synchronization is performed on start-up	DNP Secure Authentication is not supported for RTAC master station.

12.1.14	Whether polling is performed automatically on start-up	DNP Secure Authentication is not supported for RTAC master station.
12.1.15	How to manually cause an integrity poll	DNP Secure Authentication is not supported for RTAC master station.
12.1.16	How to manually cause an event poll	DNP Secure Authentication is not supported for RTAC master station.
12.1.17	How to manually cause an Update Key Change	DNP Secure Authentication is not supported for RTAC master station.
12.2	**Outstation Configuration**	
12.2.1	How to restart the outstation	1. When online with the ACSELERATOR RTAC SEL-5033 software, toggle the EN pin of the outstation. 2. Power cycle the RTAC. 3. With function codes cold_restart or warm_restart.
12.2.2	How to change addresses of master	Via project configuration with ACSELERATOR RTAC software.
12.2.3	How to change addresses of outstation	Via project configuration with ACSELERATOR RTAC software.
12.2.4	How to change name of outstation	The outstation name matches the DNP server device name (e.g., SCADA_DNP) in the RTAC project configuration.
12.2.5	How to configure the Area of Responsibility	Outstation does not require an area of responsibility; will accept any string from the master's certificate.
12.2.6	Maximum number of users supported	64
12.2.7	How User Numbers are assigned	Via project configuration with ACSELERATOR RTAC software.
12.2.8	How to disable unsolicited responses	Supported, via project configuration with ACSELERATOR RTAC software.
12.2.9	How to make application confirmations critical (if supported)	Via project configuration with ACSELERATOR RTAC software.
12.2.10	How user names and Update Keys are pre-configured	Via project configuration with ACSELERATOR RTAC software.
12.2.11	Which user names and Update Keys are pre-configured	Via project configuration with ACSELERATOR RTAC software.
12.2.12	How to configure multiple masters (if supported)	Via project configuration with ACSELERATOR RTAC software.
12.2.13	How to read logs	Via the system tag DNP_Authentication_Message which can be saved in the RTAC's sequence of events or integrated with any communication or visualization feature supported by the RTAC.
12.2.14	How to display security statistics (if possible)	Security statistics are available via POU output pins located on the controller of the DNP server in IEC 61131-3. The statistics can then be mapped to any supported communication or visualization feature the RTAC platform supports.

12.2.15	How to cause event data to be generated	Map changes via user logic or other communication protocols to the tags DNP server map associated with the DNP outstation.
12.3	**Support for Critical Functions**	
12.3.1	How to Cause a Critical Function to be Sent	Via project configuration with ACSELERATOR RTAC software. Each message is configurable to require a critical challenge between the outstation and master.
12.3.2	How to evaluate if critical functions are successfully performed	The DNP outstation controller tab has statistics about message communications and by monitoring the system tag, SystemTags.DNP_Authentication_Message.
12.3.3	What non-security requirements are placed on critical functions	Dependent upon project configuration of the DNP outstation using the ACSELERATOR RTAC software.
12.3.4	How to evaluate if non-critical functions have been successfully performed	The DNP outstation controller tab has statistics about message communications.
12.4	**How to Modify Security Parameters (Note: None of these parameters are permitted to be changed remotely)**	
12.4.1	How to disable authentication	Via project configuration with ACSELERATOR RTAC software.
12.4.2	How to disable aggressive mode	Via project configuration with ACSELERATOR RTAC software.
12.4.3	How to change the reply timer	Via project configuration with ACSELERATOR RTAC software.
12.4.4	How to change the statistic thresholds	Via project configuration with ACSELERATOR RTAC software.
12.4.5	How to change the Session Key Change Interval and Count (master)	Via project configuration with ACSELERATOR RTAC software.
12.4.6	How to change the Expected Session Key Change Interval and Count (outstation)	Via project configuration with ACSELERATOR RTAC software.
12.4.7	How to change the Maximum Session Key Status Count (outstation)	Via project configuration with ACSELERATOR RTAC software.
12.4.8	How to change the Maximum Error Messages Sent	Via project configuration with ACSELERATOR RTAC software.
12.4.9	How to change the MAC algorithm.	Via project configuration with ACSELERATOR RTAC software.
12.4.10	How to change the Key Wrap or Key Transport algorithm	Via project configuration with ACSELERATOR RTAC software.
12.4.11	How to change the Key Change Method	Via project configuration with ACSELERATOR RTAC software.
12.4.12	How to change the protocol profile	Via project configuration with ACSELERATOR RTAC software(Configuration of TCP, UDP, TLS, or serial).

12.4.13	How to configure security credentials (i.e., Certificates) for using TLS	Certificate management for TLS connections are managed via the RTAC's web interface. New public/private key pairs can by generated by the RTAC and activated for use. The public key is then made available via the X.509 page on the RTAC's web interface.
12.4.14	How to configure TLS operating parameters	Not supported. TLS operating parameters are fixed.
12.4.15	How to revoke a TLS certificate	Not supported.
12.4.16	How to create a certificate	The outstations public/private key pair is generated on the RTAC's web interface. The activated key pair will have the public key via the X.509 page on the RTAC's web interface. This public key will need to be distributed to any DNP client who is communicating with the DNP outstation via secure authentication.
12.4.17	How to configure a version of Secure Authentication	Only Version 5 is supported.
12.5	**How to Change User Status (Authority) (This information is only necessary if the master DUT supports remotely changing User Status; i.e., Update Keys)**	
12.5.1	How to establish communications between authority and master	DNP Secure Authentication is not supported for RTAC master station.
12.5.2	How to inform the master of a user status change	DNP Secure Authentication is not supported for RTAC master station.
12.5.3	How to add a user	DNP Secure Authentication is not supported for RTAC master station.
12.5.4	How to delete a user	DNP Secure Authentication is not supported for RTAC master station.
12.5.5	How to change the user role	DNP Secure Authentication is not supported for RTAC master station.
12.5.6	How to change the user expiry interval	DNP Secure Authentication is not supported for RTAC master station.
12.5.7	How to change the user Update Key	DNP Secure Authentication is not supported for RTAC master station.
12.5.8	How to change the user Public Key	DNP Secure Authentication is not supported for RTAC master station.

Modbus

This section describes the configuration and usage of the Modbus protocol with ACSELERATOR RTAC. The RTAC supports Modbus RTU, Modbus/TCP, and Modbus serial tunneled over Ethernet. Modbus ASCII is not supported at this time. Configure the Modbus protocol clients or servers on any of the RTAC serial or Ethernet ports to communicate with Modbus IEDs, communications processors, RTUs, HMI systems, etc. See *Communication Protocol Device Count Support on page 181* for the number of Modbus servers and clients supported for each RTAC model.

Supported Modbus Function Codes

- Read Coil Status, function code 01h
- Read Discrete Inputs, function code 02h
- Read Holding Registers, function code 03h
- Read Input Registers, function code 04h
- Write Single Coil, function code 05h
- Write Single Holding Register, function code 06h
- Write Multiple Coils, function code 0Fh
- Write Multiple Holding Registers, function code 10h
- Report Client/Server ID, function code 11

Important: Register addresses used with some Modbus devices, such as 30001 or 40001, are used for referencing legacy addressing schemes that designate different regions for the various register types into one address space. For example, register addresses in the 30000 range are for input registers, and addresses in the 40000 range are for holding registers. These addresses are for documentation purposes only and are not actually used in the Modbus protocol. The RTAC does not use these register offsets when setting up Modbus protocol.

NOTE

Register addressing in RTAC Modbus is 0 based. For example, a holding register designated as address 40001 in a third-party device is configured as holding register address 0 in the ACSELERATOR RTAC project. For more details on Modbus addressing and conversion to raw 0-based addressing, see SEL white paper "Modbus Register Addressing and Data Type Variations."

Modbus Client Configuration

Configure multiple concurrent Modbus client connections to communicate via serial or Ethernet to IEDs. The RTAC will poll data from these IEDs and store the data in its database. Use the Tag Processor to map these data to server connections, logs, user logic, etc.

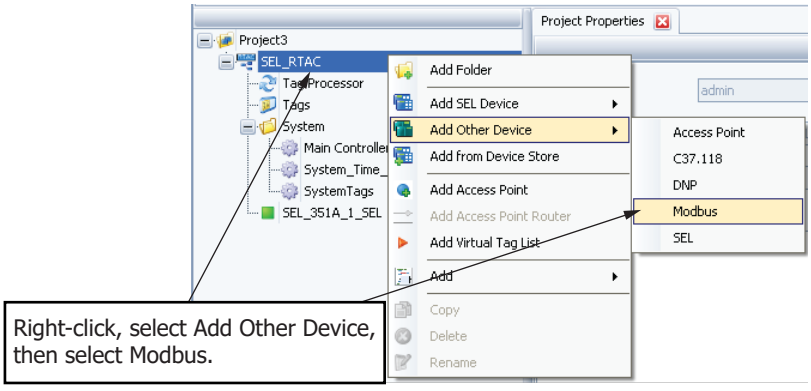

Figure 2.16 Insert Modbus Client

Give the device connection a unique name, and select the type of connection as shown in *Figure 2.1*.

Settings Tab

Upon your selecting the **Settings** tab, the RTAC displays all configurable items for communication. Check the **Description** column for details on each configuration item. Move the slider bar, or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Select the **Advanced Settings** check box to enable configuration of advanced settings.

The **Server Modbus Address** field allows you to configure the address of the remote Modbus server with which this client will communicate. This value is typically in the range of 1–247 (in traditional serial-line communications, addresses 248–255 are reserved); however, a client can be assigned a value of 0 to dedicate that client for broadcast purposes. A broadcast client is used to issue command messages (using the various function codes to write coils and/or holding registers) that are received and processed by all servers listening on a multidrop communications network regardless of their address. In this mode, no configured polls are issued by the client and only write requests are allowable for Coils and/or Holding Register tags. Because Modbus servers receiving a broadcast write message do not issue a response, no retries are performed (the **Poll Timeout** and **Poll Retries** settings are ignored) and the **Intermessage Transmit Delay** setting is expected to force a delay after a write request is issued before any subsequent requests are issued by this client or other clients on a multidrop network. While in broadcast mode, the **Offline** POU pin generally remains False because no responses from the remote servers are expected.

Select device data settings tabs such as **Coils**, **Discrete Inputs**, etc., to add and configure Modbus tags.

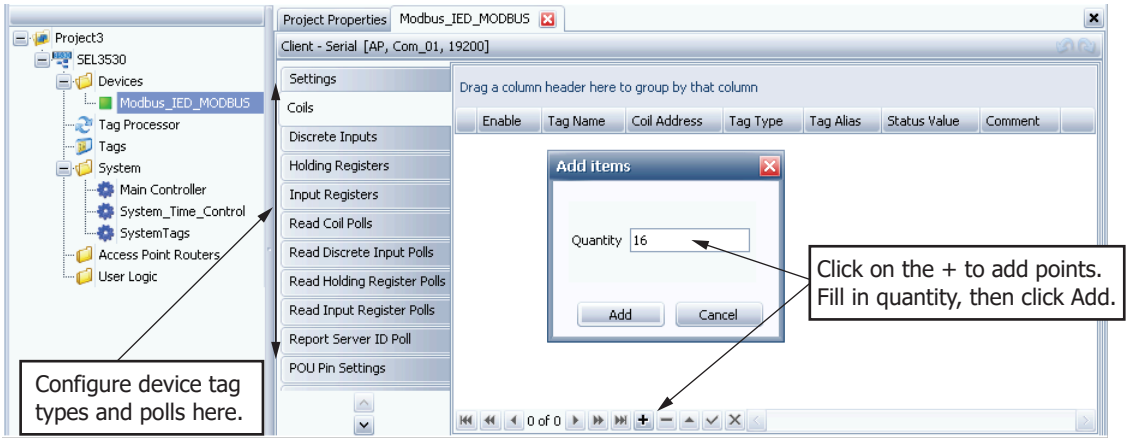

Figure 2.17 Add Modbus Client Tags

Add Client Device Data

The following steps detail adding client device data.

Step 1. Click on a device tag type tab to add and configure tags.

Step 2. Click + to add tags (30,000 tag limit or 5,000 for an SEL-3505, per device tag type).

NOTE
Use Copy (**<Ctrl+C>**) and Paste (**<Ctrl+V>**) to populate columns of Tag names and to duplicate devices.

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

Repeat these steps to configure all IED devices. When finished, configure one or more servers to deliver the data to remote client devices.

Device Tag Type Configuration Parameters

Data and poll types have parameters that you must configure correctly to ensure proper system operation. ACSELERATOR RTAC will gray out configuration fields that do not apply to a specific device tag type. The common input parameters are configurable in all device tag types. The following tables list specific device tag type configuration parameters.

Table 2.18 Common Input Parameters

Parameter	Description	Default
Enable	Tag processing enable. This flag must be True to enable processing of this tag. Setting this flag to False disables processing.	True
Tag Name	Configurable name that contains the device name and point description by default. You can change this name as necessary.	
Tag Type	The data type of this tag. See *Data Types on page 1127* for more details.	
Tag Alias	An optional descriptive tag name. If you use a Tag Alias, reference this alias, instead of the actual tag name, in the RTAC.	
Status Value	The default value for the tag prior to initialization of the tag at startup.	False
Comment	Optional user-entered comment field.	

Configure how many coils the RTAC will poll from the IED.

Table 2.19 Coils

Parameter	Description	Default
Coil Address	The bit address of the coil you want to operate.	Contiguous numbering from 0–*n*, where *n* = number of coils – 1.

Configure how many discrete inputs the RTAC will poll from the IED.

Table 2.20 Discrete Inputs

Parameter	Description	Default
Input Address	The discrete input address.	Contiguous numbering from 0–*n*, where *n* = number of coils – 1.

Configure how many holding registers the RTAC will poll from the IED.

Table 2.21 Holding Registers

Parameter	Description	Default
Register Address Start	The starting address of each holding register in the polled Modbus IED.	Contiguous numbering from 0–*n*, where *n* = number of inputs – 1. If Variation = 32 bits, the consecutive numbering will skip every other register to allow two registers per tag.
Register Address Stop	A noneditable field that indicates the ending register for this tag.	The value of Register Address Start + 0 if Variation = 16 bit. If Variation = 32 bit, the value is Register Address Start + 1.
Variation	Definition of the holding register size, type, sign, and configuration. You can swap the order of high and low bytes or registers by using the variation type. Variation types for single registers are as follows: LSB = least significant byte first; MSB = Most significant byte first; Variation types for multiple registers that are combined into one tag are as follows: LSR=Least significant register first; MSR=Most significant register first.	
Bit Reference	Definition for each bit in a holding register. This parameter is applicable only when holding register type = MDBC.	
Control Value	The initialized control value before the RTAC database is initialized at startup.	
Set Magnitude	The default instantaneous value that the RTAC will write to the IED in a write holding register message.	
Inst Magnitude	The default instantaneous value prior to initialization of the tag at startup.	
Magnitude	The default dead-banded value prior to initialization of the tag at startup.	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion of this dead band will cause the RTAC to generate a time-stamped event. Setting the dead band to 0 causes an event with every instantaneous magnitude the RTAC receives.	
Zero Dead Band	The number of units at or below which the Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point.	

Configure how many input registers the RTAC will poll from the IED.

Table 2.22 Input Registers

Parameter	Description	Default
Register Address Start	The starting address of each holding register in the polled Modbus IED.	Contiguous numbering from 0–*n*, where *n* = number of inputs – 1. If Variation = 32 bits, the consecutive numbering will skip every other register to allow two registers per tag.
Register Address Stop	A noneditable field that indicates the ending register for this tag.	The value of Register Address Start + 0 if Variation = 16 bit. If Variation = 32 bit, the value is Register Address Start + 1.
Variation	Definition of the input register size and configuration. You can swap the order of high and low bytes or registers by using the variation type.	
Bit Reference	Definition for each bit in an input register. Applicable only when input register type = SPS.	
Number of Bytes	The number of bytes to read for this tag. Applicable only when Tag Type = STR.	
Inst Magnitude	The default instantaneous value prior to initialization of the tag at startup.	
Magnitude	The default dead-banded value prior to initialization of the tag at startup.	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion of this dead band will generate a time-stamped event. Setting the dead band to 0 causes an event with every instantaneous magnitude the RTAC receives.	
Zero Dead Band	The number of units at or below which the Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point.	
Inst Angle	For a CMV data type, the default instantaneous angle value prior to initialization of the tag at startup. This is only available in Modbus Server.	
Angle	For a CMV data type, the default dead-banded angle value prior to initialization of the tag at startup. This is only available in Modbus Server.	
String Value	Default string value before the RTAC is initialized on startup. Applicable only when Tag Type = STR.	

Set up the number of read coil polls you want to use. If the coil status addresses you have configured are noncontiguous, you can break up the polling scheme into multiple polls. Each message can poll for a group of contiguous coils. Configure the following fields for each coil status poll.

Table 2.23 Read Coil Polls

Parameter	Description	Default
Poll Number	Consecutive field indicating the poll entry.	Sequential from 1–*n*, where *n* = total number of polls.
Starting Address	Starting coil address for that poll. Remember that the RTAC uses 0 relative addressing.	
Quantity	The number of coil points read for that poll operation.	

Read Discrete Input Polls

The setup for Read Discrete Input Polls is the same as for Read Coil Polls.

Read Holding Register Polls

The setup for Read Holding Register Polls is the same as for Read Coil Polls.

Read Input Register Polls

The setup for Read Input Register Polls is the same as for Read Coil Polls.

Report Server ID Poll

The setup for Report Server ID Poll is similar to that for Holding Registers configuration. This poll will return the following three values:

- Modbus Server ID
- Run Indicator Status as defined by the Modbus IED vendor
- Server ID Data as defined by the Modbus IED vendor

GE Relay Event Collection

Event Collection

The RTAC can automatically collect COMTRADE event records and Sequential Events Recorder (SER) data from connected GE relays by using the Modbus protocol. To collect COMTRADE event records, perform the following steps:

Step 1. Insert a Modbus client and configure communications settings as needed to communicate with the GE relay.

Step 2. Select **POU Pin Settings** and set **Enable_Event_Collection** to True.

Step 3. Under the **Settings** tab, adjust the Polling period between requests to locate new events as needed. The RTAC uses this value to periodically check for new events from the relay.

The RTAC will poll the relay periodically and collect any new events that are present.

SER Logging

You can configure the RTAC to automatically collect SER data from a GE relay connected via Modbus and log that SER data into the RTAC SOE log. For each Modbus client, set the POU pin setting **Enable_ASCII_SER_Logging_Enabled** to True. Set the **ASCII SER Logging Poll Period** under the **Settings** tab to control how often the SER data are polled. To identify which device the SER came from, you can enter a unique device identifier by using the **Device GUID** setting. When the RTAC receives the events, it logs the SERs in the RTAC SOE log with the optional GUID name and a time stamp that is constructed from the response of the GE relay. If needed, convert the SER time stamp to the RTAC time reference with the **Adjust ASCII SER Logging Timestamps** setting.

Modbus Server Configuration

Configure Modbus server or client connections to communicate via direct serial or Modbus TCP to polling masters (SCADA, HMIs, communications processors, etc.). Create tags in a Modbus Server Shared Map as placeholders for data that the RTAC will return to a polling client. Use the Tag Processor or Simple Tag Mapper to map data to these tags from client IED tags or other tags in the RTAC database.

> **NOTE**
> In RTAC firmware versions R152 and earlier, tags were directly configured on each individual Modbus server device. In RTAC firmware versions R153 and later, each Modbus Server references a Modbus Server Shared Map that is potentially shared by multiple Modbus servers. Existing projects of earlier versions that are upgraded to version R153 or later have existing Modbus server devices split out into device and shared map components. The shared map has the same name as the existing Modbus server device and the new Modbus server device referencing that shared map is named <Existing Server Device Name>_Device_MODBUS. Following the upgrade, any pre-existing IEC 61131 user logic that references POU pins from the Modbus server device will need to be manually updated to refer to the new device name.

The **Ethernet** connection type uses Modbus TCP messaging, and the **Ethernet Tunneled Serial** device connection type uses Modbus RTU messaging encapsulated into TCP/IP frames. When using one of the Ethernet-based communication methods, you can configure the server to allow connections from a comma-separated list of as many as 20 client IP addresses. Alternatively, the server can be configured to allow anonymous connections, which means any client on the RTAC network can connect and poll for Modbus data. Note, however, that the Modbus server only allows one client connection at a time and is designed for a "connect and stay connected" type of communications scheme.

Generally, if configured to allow anonymous connections, each Ethernet-based server device must use a uniquely configured **Server IP Port**. Multiple servers can share the same port number if the servers are configured to not allow anonymous connections and are configured with a unique list of allowable clients.

When configuring a server with the **Ethernet** connection type, multiple servers can be configured to allow anonymous connections and listen on the same **Server IP Port** in the following scenarios:

- Each server is configured with a unique **Server MODBUS Address** between 1 and 247. This configuration allows for a collection of Modbus TCP servers that are each queried by a single client in a round-robin polling style over the same TCP/IP channel by using the server's specified address. This emulates a common application performed by port servers that provides Modbus TCP access to multi-drop EIA-485 networks of Modbus RTU devices.
- In projects with firmware version R153 or later, each server is configured with a **Server MODBUS Address** of 255 and uses the same Modbus Server Shared map. This configuration allows for a collection of Modbus TCP servers that each offer an identical register map, listen on an identical TCP port, and communicate to remote clients over unique TCP/IP channels opened by each client. Incoming client connection requests are connected to the next available server in the collection in a first come, first served manner. This configuration is useful when an application demands that a large group of clients need to simultaneously connect to a single Modbus server. Since each RTAC Modbus server device only allows a single connection at a time, this collection of servers is available on a single TCP port and, by using an identical register map, will appear to external clients as a single Modbus server that accepts multiple simultaneous connections. Add as many Modbus servers as you need to support the required number of simultaneous client connections. It is important that each Modbus server in the collection use the same Modbus Server Shared map so that each client connection is presented with a consistent register map.

When configuring a server with the **Ethernet** connection type, the **Server MODBUS Address** value is configurable as 1–247 or 255. 255 is a reserved address assigned to a server to indicate that it will respond to all queries it receives from a client, regardless of the address specified in the query. Prior to firmware version R153, this address was internally fixed as 255 when using this type of Modbus server. In projects with firmware versions R153 and later, the address is configurable.

When configuring a server with the **Ethernet Tunneled Multidrop Serial** connection type, multiple servers can be configured to allow anonymous connections and listen on the same **Server IP Port**. These servers must use a unique **Server MODBUS Address** from 1–247 and communicate individually with a single client connection, similar to the servers configured with an **Ethernet** connection type.

To insert a Modbus Server to your project from the project tree right-click menu, use the **Add Other Device - Modbus Protocol** option or select **Other** from the Insert tool ribbon. Give the device connection a unique name and select the type of connection, as shown in *Figure 2.3*.

The **Settings** tab contains all configurable items for communications. Check the Description column for details on each configuration item. Move the slider, or hover your cursor over the description to see the entire description text. Type any necessary comments in the Comment column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Add Modbus Server Shared Map

All tags associated with a Modbus server are configured on a Modbus Server Shared map. As many as 120 shared maps can be added to a project and shared across multiple servers. Add a Modbus Server Shared Map to your project by right-clicking and pulling up the Project Tree menu. Select **Add Tag List > Modbus Server Shared Map** or select the **Tag Lists** option from the Insert ribbon.

Step 1. Click on a Modbus register type tab to add tags for Discrete Inputs, Coils, Input Registers, and Holding Registers.

Step 2. Click + to add tags (30,000 tag limit or 5,000 for the SEL-3505, per device tag type).

Creating only the number of tags necessary optimizes system performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

Step 5. Revisit the Modbus Server device and assign the shared map to the **Map Name** setting.

Step 6. Repeat these steps to configure all shared maps. When finished, configure the Tag Processor or Simple Tag Mapper to populate these shared maps tags with actual values.

Device Tag Type Configuration Parameters

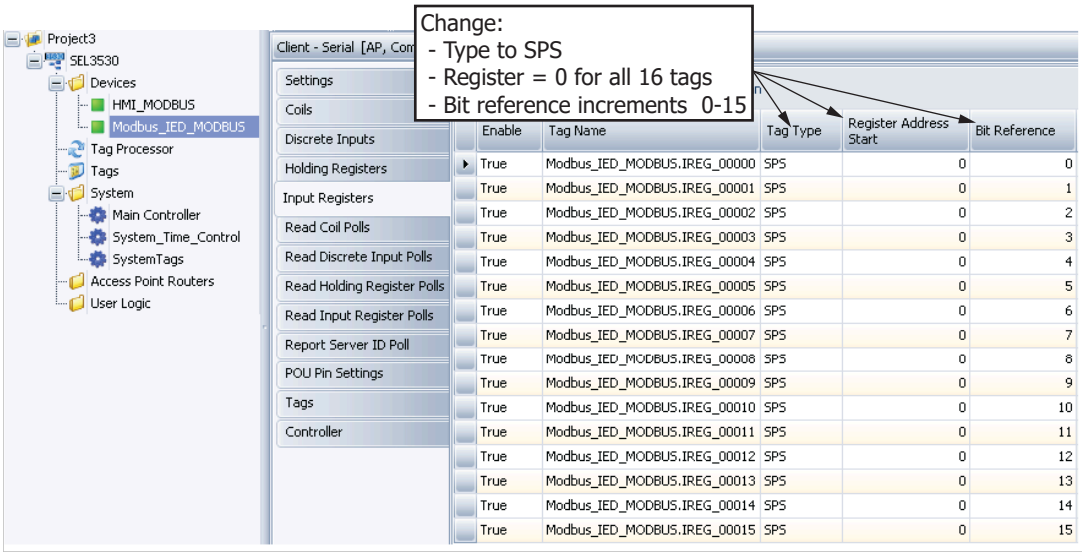
Each device tag type has parameters that you must configure correctly for proper Modbus responses. Configuration columns have the same meaning as in Modbus client configuration (see *Modbus Client Configuration on page 207*) except for the addition of fields that have special meaning in Modbus server configuration. Use these fields to manipulate data returned in Modbus server configuration. For example, you can change the device tag type, value limits, etc.

Bit reference also differs between Modbus server and client configurations. In Modbus client configuration, the bit reference specifies the bit in the data stream that will populate the client tag. In Modbus server configuration, the bit reference specifies the bit in the server tag that returns to a polling client or master. Populate the specified bits in a server tag through values in the Tag Processor.

Example 2.3 Packed Status Bits From an IED Input Register

This example illustrates how to access individual status bits from a 16-bit packed input register. You can access individual bits by using the bit reference either in the protocol point setup or in the Tag Processor. This example uses the Modbus Client protocol tag configuration.

Step 1. On the **Insert** ribbon, select **Other** and then **Modbus**.



Step 2. Configure the device as Client Serial and change the Device Name to **IED1**.

Step 3. On the resulting **Modbus Client** configuration screen, click on the **Input Registers** tab.

Step 4. Add 16 Input Register tags and make the following changes:

- ➤ Change Tag Type to single point status (SPS).
- ➤ Change Register Address Start to 0 for all 16 tags.
- ➤ Press **<Ctrl+S>** to save.
- ➤ Change Bit Reference to increment from 0–15.

The RTAC will take a single bit *n*, where *n* = bit reference, from Register 0 and place it in IED_Modbus_IREG_*n*.

POU Pin Settings

Use POU pin settings and the Controller tab to view the present state of the Modbus server operation and to modify some of the behavior of the Modbus protocol. See *Table 2.24* for the settings descriptions.

Table 2.24 Modbus Server POU Pin Settings

Pin Name	Pin Type	Description	Default
Communications_Offline_Timer	Input TIME	Assigned from the Communications Offline Timer Advanced setting.	T#10000MS
Disable_Controls	Input BOOL	Disables all coil and holding register controls through the server. Note: If other Modbus server instances are assigned to the same Modbus Server Shared Map as this server, asserting Disable_Controls will also disable controls for those other Modbus server instances.	False
Disable_Tag_Updates	Input BOOL	Disables updating of tag values. Note: If other Modbus server instances are assigned to the same Modbus Server Shared Map as this server, asserting Disable_Tag_Updates will also disable updates for those other Modbus server instances.	False
EN	Input BOOL	Enables this Modbus server device.	True
Reset_Statistics	Input BOOL	Resets all communications statistics.	False
Controls_Disabled	Output BOOL	Indicates controls are disabled via the Disable_Controls POU input pin.	False

Pin Name	Pin Type	Description	Default
Direct_Transparent_Connection	Output BOOL	A direct transparent connection is presently established through this Modbus server using an access point.	False
ENO	Output BOOL	Indicates this Modbus server device is running.	False
Illegal_Data_Address	Output BOOL	Asserts when a connected client attempts to read an invalid data address. Stays asserted for at least one processing interval and then clears.	False
Illegal_Data_Value	Output BOOL	Asserts when a connected client attempts to write an invalid data value. Stays asserted for at least one processing interval and then clears.	False
Illegal_Function_Code	Output BOOL	Asserts when a connected client attempts to issue an unsupported function code. Stays asserted for at least one processing interval and then clears.	False
Invalid_Function_Block_Input	Output BOOL	Asserts when a constant or variable is assigned to an input pin and the value is not within an acceptable range.	False
Message_Failure	Output BOOL	Asserts for a single-processing interval following a message failure.	False
Message_Failure_Count	Output UDINT	Increments in value by one each time Message_Failure is asserted.	0
Message_Success_Count	Output UDINT	Tracks the sum of the messages successfully sent or received.	0
Messages_Received_Count	Output UDINT	Counts the number of messages received.	0
Messages_Sent_Count	Output UDINT	Counts the number of messages sent.	0
Offline	Output BOOL	Set to True if a message has not been received for a period of time as defined by the Communications Offline Timer setting. For an Ethernet device type, this can also indicate a loss of the TCP/IP connection.	True

SEL Protocol

You can configure multiple SEL protocol client and server devices to communicate with SEL IEDs and allow engineering access to the RTAC and its connected devices. ACSELERATOR RTAC supports the configuration of SEL protocol on any of the RTAC serial or Ethernet ports. ACSELERATOR RTAC includes preconfigured device definition files (DDFs) that contain the necessary template data map information for communicating with supported SEL relays. Advanced users can also define custom DDFs to communicate with other SEL products. The RTAC SEL client can detect and notify if any polled devices have changes in their configurations. See *Communication Protocol Device Count Support on page 181* for the number of SEL protocol servers and clients supported for each RTAC model.

SEL Client Configuration

The RTAC SEL Client supports the following:

- Auto-configure
- Auto-bps detection
- Compressed ASCII messages (e.g., History, Status)
- Fast Meter messages (e.g., Demand Meter, Meter, Peak Meter)

- Limited Fast Meter for SEL-100 and SEL-200 series relays
- IED configuration change monitor
- Access password management
- Unsolicited write messages
- User-configured flex parse messages
- SER logging to SOE log
- Event filtering and collection
- Remote access and file transfer

User-configured flex parse messages provide the tools to create custom messages and parse data from those messages into tags. See *Flex Parse Protocol on page 519* for more detail. There can be only one client association (a relay, for example) for each client connection. Only one lower-tier communications processor (RTAC, SEL-2032, etc.) is valid per client connection.

The ACSELERATOR RTAC software SEL client provides a DDF for each supported device. Each DDF is a template containing a superset of every point available for each SEL device. Select which points you want to use from the superset by setting Enable = TRUE in the data type tabs. Save the project and upload it into the RTAC. The RTAC will perform an autoconfiguration on each SEL device to which it is connected and compare the results with your configuration. Tags configured in the RTAC project that are not found during the autoconfiguration process will be marked with an invalid quality. Verify the RTAC configuration while offline and make the necessary changes to resolve the unmatched data tags.

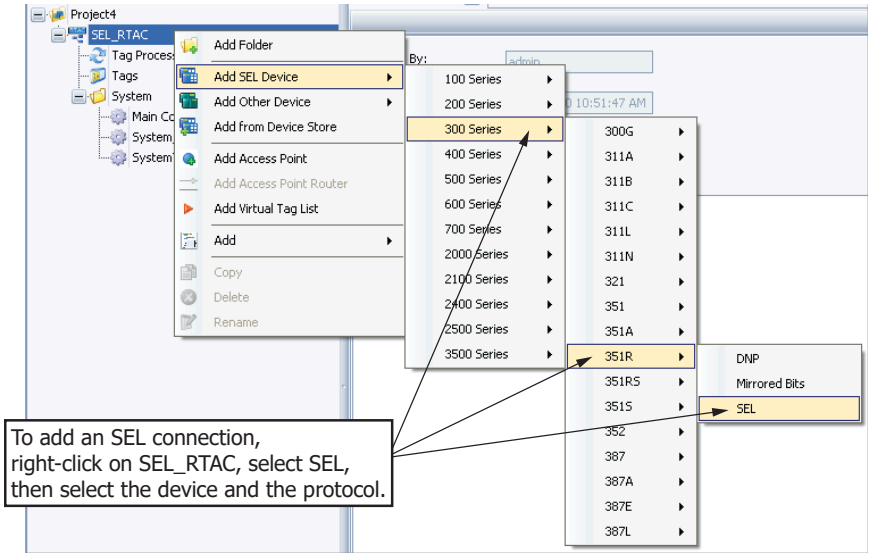


Figure 2.18 Insert SEL Client

To insert an SEL client, choose **SEL** under the Insert ribbon or right-click on **SEL_RTAC**. Select the IED series, the specific device, and then the SEL protocol.

Give the device connection a unique name, and select the connection type as shown in *Figure 2.1*. Because SEL protocol is a point-to-point protocol, multi-drop options are not available for selection.

The **Settings** tab contains communications and time configuration parameters. Check the Description column for details on each configuration item. Move the slider, or hover your cursor over a description to see the entire text of an item description. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Tag Configuration

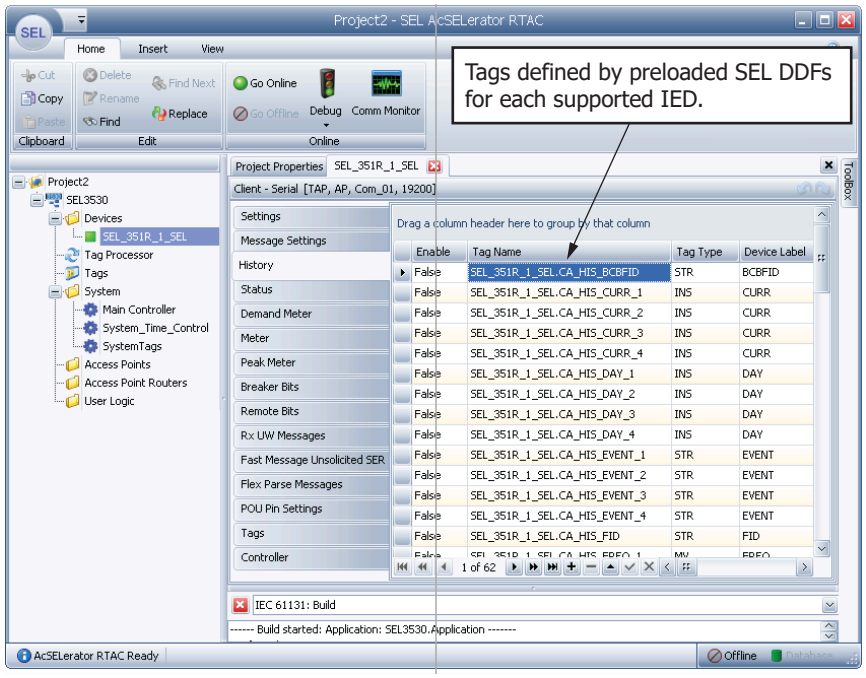

Figure 2.19 Tag Configuration

ACSELERATOR RTAC contains predefined DDFs for each supported SEL IED, so you typically do not have to add data tags. In the majority of applications, the word bit and analog metering values of interest are located in the **Meter** tab. By default, all SEL Client tags are disabled; if you want to use these tags in your project, set the **Enable** field to True. Enabling only the tags that you need helps optimize system performance. After making your modifications, you can use the **Export Items** functionality to create XML templates for each customized IED type. Use the exported XML template in other projects that have the same SEL client configuration requirements.

NOTE

Use Copy (**<Ctrl+C>**) and Paste (**<Ctrl+V>**) to populate columns of Tag names and to duplicate Devices. Save the configuration by selecting **Save** or pressing **<Ctrl+S>**.

Each message in the SEL protocol returns a specific group of data. The Message Names in the **Message Settings** tab define the labels for each data group setting tab. For example, **History**, **Status**, **Demand Meter**, etc., are each data groups from different messages. Configure each tag in each data group by clicking on that configuration tab. The ACSELERATOR RTAC grays out nonapplicable configuration columns.

Table 2.25 SEL Tag Configuration Parameters

Parameter	Description	Default
Enable	The processing enable flag. Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	False for most tags.
Tag Name	The default tag name contains the device name and tag description. You can change this name as necessary.	
Tag Type	The data type of this tag. See *Data Types on page 1127* for more details.	
Device Label	The logical name of a group of data in an SEL protocol message. Typically, but not always, a label is unique in a message.	
Tag Alias	An optional descriptive tag name. Use this tag alias anywhere in the RTAC system in place of the actual tag name.	
Device Label Instance	When a label in a message is not unique, the Device Label Instance identifies the occurrence of the label for the data element you want in the message.	0
Device Label Data Index	Specifies the data element within the data group under a particular label.	
Device Bit Label	The logical name of a group of binary data in an SEL protocol message. Typically, but not always, a Device Bit Label is unique in a message.	
Device Bit Label Instance	When a device bit label in a message is not unique, the Device Bit Label Instance identifies the occurrence of the device bit label for the data element you want in the message.	0
Status Value	The default value for the tag prior to initialization of the tag at startup.	False
Inst Magnitude	The default instantaneous value prior to initialization of the tag at startup.	
Magnitude	The default dead-banded value prior to initialization of the tag at startup.	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion from this dead band causes the RTAC to generate a time-stamped event. Setting the dead band to 0 causes an event for every time the RTAC receives an instantaneous magnitude.	
Zero Dead Band	The number of units at or below which the RTAC forces Magnitude to zero. If | mag| < zeroDB, then mag := 0.	
Max Value	The maximum value the RTAC allows for this point.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
Min Value	The minimum value the RTAC allows for this point.	
Inst Angle	The instantaneous angle value measured in degrees.	
Angle	A snapshot value of Inst Angle at the time of an Inst Magnitude excursion past the dead-band value.	
Actual Value	The default actual value of a BCR type tag before initialization on startup.	
String Value	The default string value the tag will have prior to initialization of the tag at startup.	
Comment	Optional user-entered comment field.	

Configuration Monitor

Use the Check IED Configuration settings to monitor configuration changes in connected SEL devices. Select the **Advanced Settings** check box under the **Settings** tab to expose these settings. The IED configurations are monitored as follows:

Step 1. The RTAC sends each user-defined Command String found under the **Check IED Configuration Commands** tab at the interval, in minutes, defined by the setting **Period between attempts to detect a change in the configuration of the connected IED**. This setting is found under the **Settings** tab.

Step 2. The RTAC calculates a 32-bit CRC on the response for all characters between STX and ETX. In addition to the per-response CRC, in firmware versions R151-V0 and later, a SHA-256 is also calculated across all responses.

Step 3. The response CRC is compared to a CRC stored in the nonvolatile memory that was calculated for the same response previously sent.

Step 4. If a mismatch is detected, or if the response is not received within the **Timeout for a Check IED Configuration request**, the process repeats until one of the following occurs:

a. **Number of retries for a Check IED Configuration request** is met.

b. The calculated CRC matches the stored CRC.

Step 5. If the CRC cannot be validated, the **Check_IED_Configuration_Error** output POU pin is pulsed for one task cycle.

Step 6. If one or more of the CRCs do not match the stored CRCs, the **Check_IED_Configuration_Mismatch** output POU pin is pulsed and the calculated CRCs are stored in nonvolatile memory and used the next time the **Check_IED_Configuration** POU pin is triggered (either manually or via the time period defined in the settings). In firmware versions R151-V0 and later, the calculated SHA-256 is also stored in nonvolatile memory and the **Check_IED_Configuration_Mismatch_Count** POU output pin increments.

If the number of CRCs stored in the nonvolatile memory is not equal to the number of user-defined requests, all stored CRCs are deleted and the **Check_IED_Configuration_Mismatch** output POU pin will pulse the next time the configuration monitor process completes.

In firmware versions R151-V0 and later, Check IED Configuration exceptions are exposed as reports on the RTAC's file system and available via the File Manager in the web interface, SFTP server, and MMS server file transfer. These reports are stored within the **CONFIGURATION_MONITOR** directory in a subdirectory named for the SEL client device. Each report is a text file with a file name in the following format: **<Device Name>_Configuration_Change.txt**. These files are formatted for Compressed ASCII and contain the following items:

- Virtual Port Number of the device
- Name of the device

- Custom GUID of the device
- A two-column table containing a time stamp and SHA-256 representing the last ten configuration mismatch events. Events are listed in descending order.

The following is a sample of how these report files are formatted.

```
"VIRTUAL_PORT_NUMBER","254","076E"
"DEVICE_NAME","SEL_451_1","067D"
"DEVICE_GUID","Custom451GUID","0856"
"DETECTED","SHA256_HASH","061E"
"2022-10-21 00:33:41.000000","6566DDD1F90536B41AAA26849442CB1044169995799C88097E88B5F1F56A8B0A","1414"
"2022-10-21 00:33:14.000000","CA885AA430EEC3B46285F7488CA4481BE5F7F154F84F0316C8E543F53F5EFC1E","1478"
```

Autoconfiguration and transparent connections will interfere with this process. The process will resume once autoconfiguration is complete and all transparent or direct transparent connections are closed.

Access Passwords

You can configure the Level 1 and Level 2 access passwords that the RTAC uses to connect to the relay under the **Settings** tab. You can also, through user logic, modify the Level 1 and Level 2 access passwords in real time by setting the Level_1_Password or Level_2_ Password POU pins and asserting the Write_Level_1_Password or Write_Level_2_Password POU pins. When Write_Level_1_Password or Write_Level_2_Password is asserted, the Level 1 or Level 2 access passwords are updated with the value of Level_1_Password or Level_2_Password, respectively. Through the use of custom logic, it is possible for the RTAC to perform password management and allow controlled engineering access to users without the user knowing the relay passwords. Whenever passwords are modified, it is good practice to log the new POU pin password values, pass the new values to SCADA, or in some other way store the password values as part of a backup contingency plan.

As described in *SEL Server Configuration on page 244*, you can transparently connect to SEL clients through the SEL server connection (available in firmware versions R134-V0 and later). Set **Enable Password Monitor** to True in each SEL client to allow the RTAC to detect when the transparently connected user uses the **PAS** command to change the relay password, capture the password the user enters, and automatically update the passwords in the SEL client in the RTAC project.

⚠ WARNING

Any modifications made to the Level 1 and Level 2 access passwords (via the password pins) while the project is running in the RTAC will be overwritten when new settings are downloaded to the RTAC. Before downloading a project to the RTAC, you should first read the currently running project to retain the current value of the Level 1 and Level 2 access passwords. Failure to do so will result in the inability to access the relays.

Message Settings

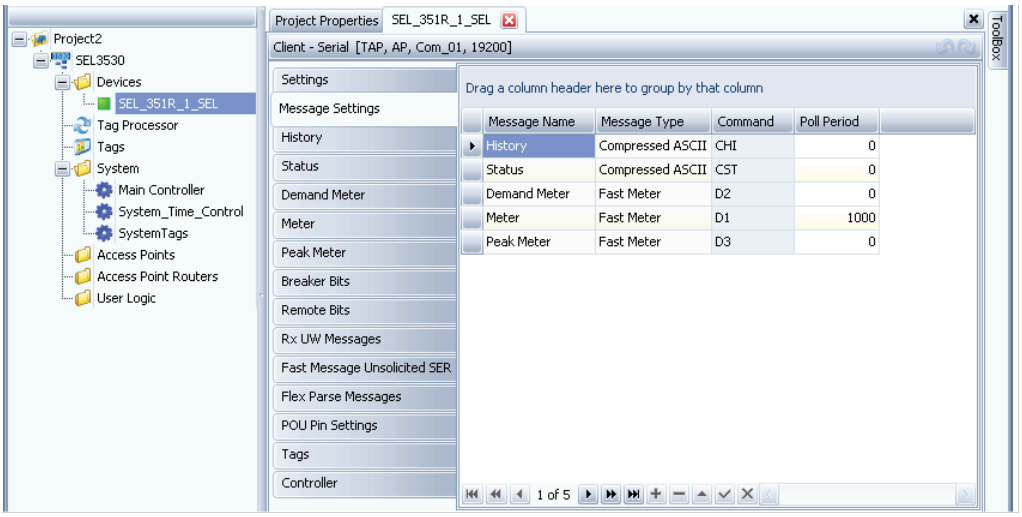

Figure 2.20 Message Settings

As shown in *Figure 2.20*, the **Message Settings** tab defines which messages the RTAC sends to the SEL IED and how often it sends them. You can adjust the default settings to alter the poll period or the commands the messages use.

Column Name	Description
Message Name	User-defined message name
Message Type	Which SEL message type is used to get the data
Command	Which SEL command is sent in the message to get the data
Poll Period	User-defined time in milliseconds between messages. A value of 0 disables the message.

See each relay-specific instruction manual for information on which points to poll and what messages and commands to use to poll each device. The RTAC supports SEL Compressed ASCII (CASCII), SEL Fast Operate, SEL Fast Meter, Unsolicited Write, and SEL Fast SER. The SEL client uses the configuration on each message name tab to parse the data from messages. When the same data are available in CASCII and binary, always use the binary message data. CASCII is compressed, but it is neither as efficient nor as secure as binary messages. Binary messages are also uninterrupted by transparent engineering access, while such access does interrupt CASCII messages.

See the SEL application guide "Configuration and Fast Meter Messages" (AG95-10) for a comprehensive description of SEL binary messages.

Fast Message Unsolicited SER Data

An SEL IED generates time-stamped Sequential Events Recorder (SER) data for any word bits that are located in its configured SER equations. The RTAC can request to receive unsolicited notifications of new SER data through an SEL protocol mechanism known as Unsolicited Fast SER messages. These messages are enabled via the **Enable_Unsolicited_SER_RX** setting located on the **POU Pin Settings** tab (this feature is enabled by default). The RTAC automatically

routes all SER data it receives from SEL client devices to all configured SEL server device connections. No configuration is necessary on SEL client or SEL server device connections to enable this feature. The RTAC can use received unsolicited SER data through two exclusive methods.

With the first method, you can create and configure tags under the **Fast Message Unsolicited SER** tab. The RTAC identifies which tag to populate with received SER data based on either the index or the label. The index identifies sequentially which SER point the SEL IED identifies. For example, the first SER point configured in the IED is Index 1, the second is Index 2, etc. The label identifies the SER point by the label the SEL IED defined. You generally should refer to the SER point by label; the SER point order can change because it is configurable in the IED. The RTAC assigns all unsolicited SER data (states and times) to these tags.

To use the second method in assigning unsolicited SER data in the RTAC, you do not create tags in the **Fast Message Unsolicited SER** tab. Instead, set the enable flag to True for binary tags in the **Meter** tab in the SEL client configuration. As the RTAC receives unsolicited SER data, it searches through the **Meter** tab for a binary tag label that matches the SER data table. When it finds a match, it assigns the time and state to that tag. This allows you to map an SEL binary tag (for example, IN_201) to a DNP binary tag in the Tag Processor and update the DNP tag automatically with unsolicited SER data. Note that this functionality is only available for tags located on the **Meter** tab and does not apply to tags located on other tabs that contain word bits, such as **Targets 2**.

Flex Parse Messages

Use Flex Parse Messages to create custom commands as long as 255 bytes and optionally parse the response messages. You can configure the RTAC to send a Command String to the connected SEL device at a configurable Poll Period interval. You can also configure the Start of Response Parse Expression and other parse expressions to enable the RTAC to determine when a valid response is received and to interpret the returned message and populate user-created tags. You can define parse expressions in SEL type class expressions or Perl 5 regular expressions (regex). It is important to note that the SEL client will not send user-defined flex parse messages to the configured device until after the auto-configuration is complete. For details, including SEL type class expressions, regex, and examples of using flex parse within the SEL client or using flex parse directly with other devices, please refer to *Flex Parse Protocol on page 519* in this instruction manual.

Add a flex parse command by performing the following steps:

Step 1. After adding an SEL device, click on **Flex Parse Messages**.

Step 2. Click on + to add a message, then click on **Add**.

Step 3. Configure the Command String, which is the message that will be sent to the SEL device.

Step 4. Configure the timing parameters to dictate how often the command should be sent and the time allotted for the command to complete.

Step 5. Configure the Start of Response Expression that the RTAC will compare with the incoming message to ensure it is parsing the correct message.

Step 6. Configure individual flex parse tags and parsing messages by using the information in *Flex Parse Protocol on page 519*. The configuration for flex parse messages added to an SEL client and flex parse messages added to a Flex Parse Protocol client is the same.

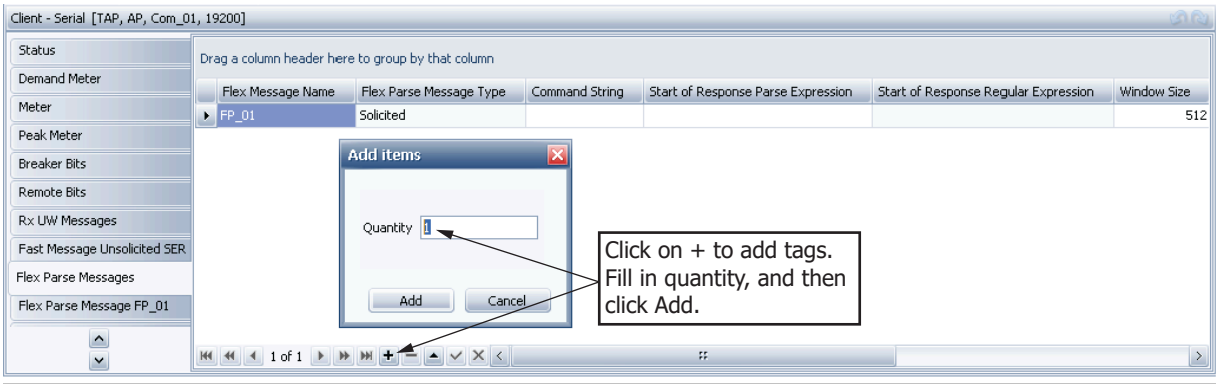

Figure 2.21 Add Flex Parse Message

Flex Parse Capture to File

In firmware versions R147 and later, flex parse messages can be configured to save the IED response to a text file on the RTAC file system. Enable this functionality by toggling the **Capture To File** parameter of a configured flex parse message to True. When the flex parse message response is received, it is stored in the **FLEX_PARSE** directory and in a subdirectory named for the SEL Client device name in the following format: **<SEL Client Name>_<Flex Parse Message Name>.Capture**. New files will overwrite older ones.

Unsolicited Write Messages

Unsolicited write messages can be configured to periodically write to specific memory locations on a remote device. An SEL client or SEL server configuration can receive unsolicited write messages from a remote device and can transmit unsolicited write messages to another device. Unsolicited write messages are typically only used when interfacing with a legacy communication processor (SEL-2020, SEL-2030, SEL-2032) or configuring the RTAC to write data into Remote Analog signals on a compatible IED.

Configure transmit unsolicited write (Tx UW) messages in SEL client or server to create, define, and write tag values into memory locations in a target SEL IED. Configure receive unsolicited write (Rx UW) messages in SEL client or server to create and define tags and memory locations in the RTAC to which another SEL device will write. A remote SEL IED uses UW messages to write data to these memory locations.

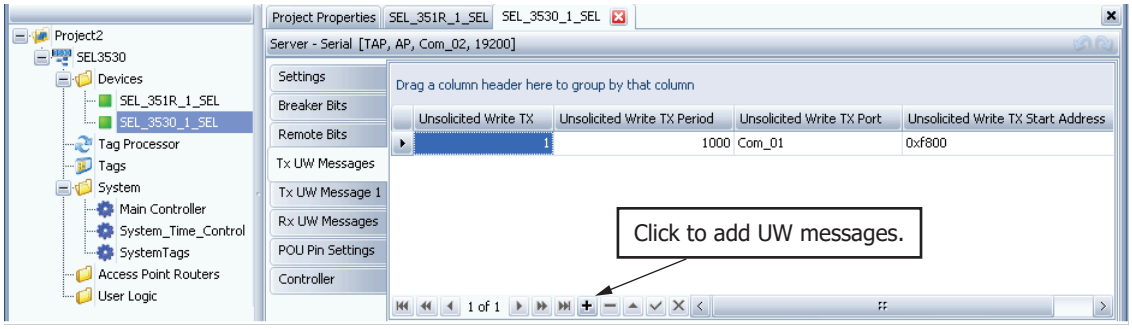

Figure 2.22 Unsolicited Write Messages

Add Tx UW messages to send data to the remote SEL IED. Click + to add a number of Tx UW messages. Configure each message.

Column	Description
Unsolicited Write TX	The order in which the RTAC sends the Tx UW messages.
Unsolicited Write TX Period	The time period in milliseconds between each UW transmission.
Unsolicited Write TX Port	The port the RTAC uses for this UW communication.
Unsolicited Write TX Start Address	The starting address in hexadecimal format on the receiving RTAC to which the transmitting device will be sending data.

Each Tx UW message you add causes ACSELERATOR RTAC to create a **Tx UW Message** tab. Use each **Tx UW Message** tab to add and configure data tags for its respective Tx UW message. The maximum number of registers an unsolicited message can contain is 117, so if you configure each tag in the UW Message tab to use one register, you can configure a maximum of 117 tags. However, you can configure as many as 2000 tags to address as many as 1872 individual bits (16 bits • 117 registers) by using the following configuration:

NOTE
Use Copy and Paste to populate columns of tag names and to duplicate devices.

Tag Type = SPS

Treat As = BOOL

Address Range Start = Use the same register address for each group of 16 tags.

Bit Index = Increment from 0–15 for each group of 16 tags of the same register address.

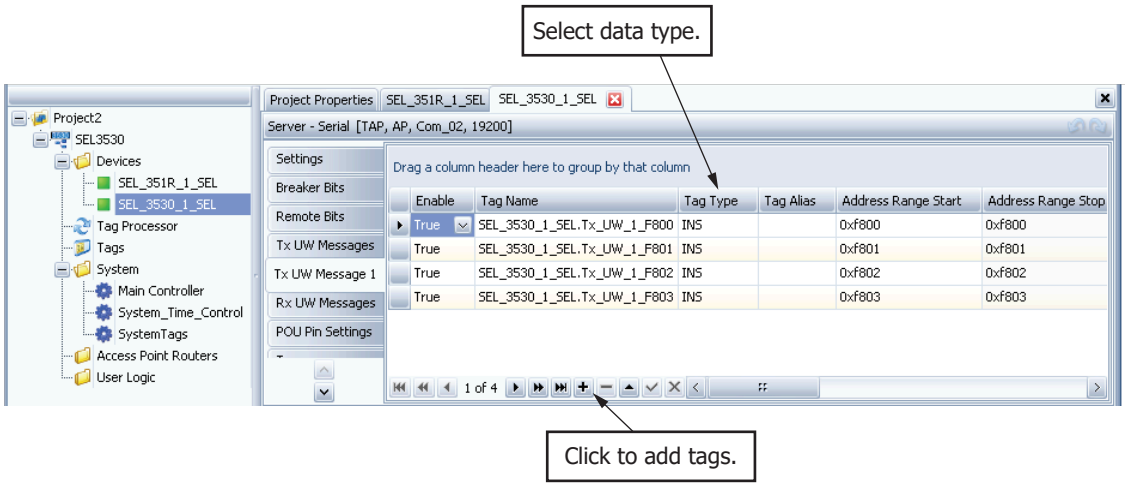

Figure 2.23 SEL Unsolicited Write Tags

To add Tx UW tags:

Step 1. Add an SEL server device.

Step 2. Click on the **Tx UW Message *n*** (where *n* is the Tx UW message number) tab to add and configure tags.

Step 3. Click + to add tags (10,000 tag limit or 5000 for SEL-3505, per device tag type).

Creating and enabling only the number of tags necessary helps optimize system performance.

Step 4. Change tag names, if necessary.

Step 5. Change other tag-related information as necessary.

Configure each Tx UW message group of data tags. The settings for each tab depend upon the Tag Type you have selected for that tag. ACSELERATOR RTAC grays out nonapplicable configuration columns. The configuration settings have the same meaning as those for SEL client configuration, except as the following table describes.

Setting Column	Description
Address Range Start	The beginning address on the target SEL IED to which the RTAC will write the Tx UW tag value.
Address Range Stop	The ending address on the target SEL IED beyond which the RTAC will not write the Tx UW tag.
Treat As	Convert the tag value to this data type when writing to the target. For example, to send two bytes of data per tag, change the Treat As type to INT. Remember to renumber the Address Range Start as needed if you change the Treat As data type.

Configure Rx UW messages and tags in the same way as Tx UW messages and tags. Remember that Rx UW messages define data that are coming from an SEL device. The remote SEL IED will populate the tags you define in the Rx UW messages by writing to the memory locations you have defined for each tag. Use the Tag Processor to map those values to other tags in the RTAC.

Remote Bits and Breaker Bits

Add remote bits (RB) and breaker bits (BB) as necessary. Link RB and BB tags in the Tag Processor to control tags in the RTAC. The RTAC will issue controls to a remote SEL IED through the configured RBs and BBs.

ASCII SER Logging

You can configure the RTAC to automatically collect SER data from an SEL client and log those SER data into the RTAC SOE log. For each SEL client, set the POU pin setting **Enable_ASCII_SER_Logging** to True. Select the **Advanced Settings** check box under the **Settings** tab and locate the applicable settings under the Event section.

The **ASCII SER Logging Collection Period** is the interval at which the RTAC sends the ASCII SER command to the SEL relay to collect the events. To identify which device the SER came from, you can enter a unique device identifier by using the Device GUID setting. When the RTAC receives the events, it notifies each configured SEL server that new SERs have been collected and logs the SERs in the RTAC SOE log. The SER event is logged into the SOE with the optional GUID name and a time stamp that is constructed from the response of the ASCII SER command. If needed, modify the date format with the **ASCII SER Logging Date Format** setting.

The command to collect the ASCII SER data is dependent on the SEL device with the **CSE** command taking precedence over the **SER** command. The **ASCII SER Logging Command Parameter** setting configures the value appended to the ASCII SER command; this determines the count of the SER records returned from the command. Upon a subsequent execution of the ASCII SER command, if the last-known SER record (determined by a word bit name and time stamp) is no longer present in the command output, the ASCII SER collection process will reset its last-known record time reference based on the newest record data available to it. If this reset occurs, an RTAC SOE log entry is created indicating that a **Sequence Restart** has occurred and that SER records may have been lost and will not be retrieved by the RTAC using this collection mechanism. This may occur, for example, if there is a chattering word bit logged to the IED SER that causes events to be generated at a rate greater than that allowed by the SER collection interval and the record count determined by the SEL client settings.

Event Filtering and Collection

You can configure the RTAC to collect events automatically from each configured SEL client if the relay supports the compressed ASCII history (CHI) message. Depending on configuration, the RTAC can store event information (fault current, location, time of event, etc.) for the first event of the most recent fault and/or all event information in the RTAC database. The RTAC stores new event information in tags available to any RTAC protocols and applications from the event tab. Enable this feature by setting the POU pin Enable_New_Event_Filtering = True. The RTAC can also store as many as 576 records of all event information it retrieves from the compressed ASCII event (CEV) message into nonvolatile storage in the RTAC database. Enable this feature by setting the POU pin Enable_Event_Collection = True. Once the

RTAC stores event information in the database, this information is available to SEL server connections configured in the RTAC through special event commands. These two event collection methods are neither exclusive nor dependent upon each other.

Configure New Event Filtering

Step 1. Insert an SEL client for the correct SEL relay type.

Step 2. On the **POU Pin Settings** tab, set **Enable_New_Event_Filtering** to True.

Step 3. Select the **Advanced Settings** check box to enable configuration of advanced settings. You can now edit the settings related to event filtering, collection, and reporting.

The event polling period dictates how often the RTAC sends a **CHI** command to determine whether there are any new events. If the relay replies to one of these solicited polls with new events, or if the relay sends an unsolicited short event report at any time, the RTAC knows at least one event is ready for filtering/collection/reporting. It is important to note that the **History, Compressed ASCII** command in the message settings tab populates tags in the **History** tab; it is not part of this event-collection process.

The RTAC defines the newest event as either a single event or the first in a group of events in which the time stamp is greater (by the configured New Event Lockout Period) than for adjacent events. If Report New Event On Detection = True, then the RTAC uses the new event data to populate the tags in the **History - New Event** tab. If Report New Event On Detection = FALSE or a new event is unavailable, the tags do not update unless the POU pin report_new_event is asserted.

If the POU pin Reset_New_Event is asserted or the period specified by New Event Hold Duration expires, the RTAC replaces the time stamp and quality of the History - New Event tags with the present system time and invalid quality. The New Event Reset Location Value and the New Event Reset Event Value are used to assign values to the NEW_EVENT_FAULT_LOC and NEW_EVENT_EVENT tags respectively. Additionally, if the POU pin Report_New_Event is asserted and the RTAC finds no new event after issuing a **CHI** command, it replaces the data in the History - New Events tags as if the Reset_New_Event pin had been asserted.

Configure CEV Event Collection

Step 1. Insert an SEL client for a particular SEL relay (or use one already configured for event filtering).

Step 2. On the appropriate settings tab, set **Enable Event Collection** to True.

Step 3. Select the **Advanced Settings** check box to enable configuration of advanced settings. The **Event Polling Period** settings works the same as in new event filtering except that it is the period at which the RTAC will issue a compressed ASCII event history (CHI) message to detect new events and follow up with the CEV command to retrieve any uncollected events that are detected. The RTAC will also request a CHI report if it receives a short event report from the relay; on SEL relays, this is typically enabled by setting the AUTO parameter on the RTAC-connected-serial port to 'Y'.

In event collection, all event information is gathered from the CEV reports and stored in nonvolatile RAM in the RTAC. When event collection is first enabled, only the 12 most recent entries are collected from each relay, with a maximum of 576 event records stored in the RTAC's memory. If 576 records already exist in the database, the next record stored will cause the oldest 64 records to be purged before the new record is stored, resulting in a new total of 513 records.

Optionally, use the **Event Collection Parameter** setting on the **Settings** tab to modify the **CEV** command that the RTAC sends to collect the events. For example, an entry in the Event Collection Parameter setting of **S16 L12** will result in the command **CEV *x* S16 L12** to the relay, where *x* is the event number and S16 L12 specifies 16 samples plus 12 cycles. Do not use the TERSE or NSUM parameters; these will result in a compressed event report that the RTAC does not recognize.

When the RTAC collects and stores new CEV event records, it sends a message to each configured SEL server notifying it that there are new events ready for collection. An SEL server can then use this information to issue a notification to an external event aggregator such as ACSELERATOR TEAM® SEL-5045 Software or the SEL Blueframe® Data Management and Automation (DMA) application suite. If the Enable_New_Event_Filtering POU pin is set to TRUE and CEV event collection is left disabled, the RTAC will detect new events but not store event data in the database. Neither will it notify configured SEL servers that there are event data available.

You can download collected CEV events in the RTAC web interface by selecting the **Event Collection** tab. Enter the start and end dates for the events you want to download and select **Download**. CEV events are also available from the RTACs SFTP interface if an SFTP server has been added to the project. They are made available in the **EVENTS/CEV** directory, where a named subdirectory will exist for each separate SEL client.

In project versions R153 and later, the **Generate Comtrade** setting is available. If CEV event collection is enabled and **Generate Comtrade** is set to True, each collected CEV record is automatically converted into an equivalent COMTRADE record. This matching COMTRADE record can be retrieved by using the same web and SFTP interface options previously described.

Configure COMTRADE Event Collection

Step 1. Insert an SEL client for a particular SEL relay (or use one already configured for event filtering).

Step 2. On the appropriate settings tab, set **Enable Comtrade Collection** to True.

Step 3. Select the **Advanced Settings** check box to enable configuration of advanced settings. The **Comtrade Polling Period** is used to define the period at which the RTAC will issue a **FILE DIR** or **FILE DIR EVENTS** command to search for new COMTRADE events.

In addition to collecting CEV-based events with the SEL client, COMTRADE collection is also supported for SEL IEDs that support the COMTRADE event storage format. Most RTACs support storing as many as 1024 COMTRADE events at a single time, however the SEL-3555 and SEL-3560 RTACs support storing 10,000 COMTRADE events. This COMTRADE collection count is shared with COMTRADE events collected through Modbus, MMS, and

EtherCAT CT/PT modules. The COMTRADE event collection queue is separate from the 576 CEV collection count. Also, as with CEV event collection, when COMTRADE event collection is first enabled, only the most recent 12 events are collected from an SEL IED.

Starting in firmware version R147, COMTRADE collection is also available via FTP, if the SEL client is configured to use an Ethernet-tunneled-serial connection. The **Connection to use when performing Comtrade Event Collection** parameter allows the SEL connection to use either the Primary SEL protocol connection (typically a Telnet session) or a separate FTP connection to the SEL relay to collect COMTRADE events. Some SEL relays have large COMTRADE files, which may prevent the files from being collected in a reasonable amount of time via the primary connection. For these files, SEL recommends using the FTP collection method as the transfer will complete much faster and not block the primary connection during the transfer. Once FTP is selected as the connection type, use the **FTP Username for Comtrade Event Collection** and **FTP Password for Comtrade Event Collection** parameters to configure the login for the FTP connection, based on the IEDs FTP settings. The FTP Password can be selected from the stored copy of the IEDs Level_1 or Level_2 password from the RTACs database.

Some SEL relays have multiple types of COMTRADE event reports; for these relays, you can configure the RTAC to collect any desired event types. Use the **List of Event types to be collected** parameter with a comma-separated list of the different event types to configure which specific COMTRADE files to collect. Relay-specific instruction manuals document what types of events each relay supports. Some examples of event types include traveling-wave (TW), high-resolution (HR), and 10 kHz (TDR). Note that the RTAC collects high-resolution COMTRADE event types by default because that is the most common event type across SEL relays. If the RTAC detects multiple copies of the same COMTRADE record ID on an IED, it will prioritize the record that was named with COMNAME format, as these are typically stored in the updated COMTRADE 2011 format.

You can download collected COMTRADE events in the RTAC web interface by selecting the **Event Collection** tab. Enter the start and end dates for the events you want to download and select **Download**. COMTRADE events are also available from the RTAC's SFTP interface if an SFTP server has been added to the project. They are made available in the **EVENTS/COMTRADE** directory, where a named subdirectory exists for each separate SEL client.

Configure Tiered Communication Processor Event Collection

In firmware version R149-V0 and later, it is possible for the RTAC to collect CEV and COMTRADE event records from IEDs that are connected as children to SEL-2020, SEL-2030, or SEL-2032 Communications Processors to which the RTAC is configured to communicate. These child IEDs are configured as unique entries under a single SEL Client device associated with the communications processors. To configure event collection from communication processor child IEDs, perform the following:

Step 1. Insert an SEL client configured as an SEL-2020, SEL-2030, or SEL-2032 Communications Processor.

Step 2. On the **Settings** tab, set **Enable Event Collection** to True.

Step 3. Select the **Advanced Settings** check box to enable configuration of advanced settings. The **Event Polling Period** parameter is used to determine the period at which the RTAC will attempt event collection from child IEDs using the method specified by the **Child IED Event Polling Mode** parameter.

Step 4. The **Pre-Termination Timeout**, **Termination String**, and **Post-Termination Timeout** parameters should be configured with values matching the communication processor parameters **TERTIME1**, **TERSTRING**, and **TERTIME2** on the specific port that is communicating to the RTAC. These values are used by the RTAC to navigate to and from the communications processor-connected Child IEDs.

Step 5. The **Child IED Event Polling Mode** parameter is used to configure how the RTAC will interface with the communications processor to collect child IED events. The two options available for configuration are as follows:

- **Round-Robin Polling**. In this mode, the RTAC will use the **POR *x*** command to transparently connect to each configured child IED, at the interval specified by the Event Polling Period setting. Once a connection to the child IED is established, if CEV collection is configured, the **CHIS** command is used to determine if any new CEV records need to be collected. If COMTRADE collection is configured, a direct transparent connection (**POR *x* D**) is used to establish connectivity to the child IED and the **FILE DIR** command is used to determine if any new COMTRADE records need to be collected.
- **Fault-Register Polling**. In this mode, it is assumed that the communications processor has some Math Move statements programmed in order to populate a 16-bit 'fault register' in which each bit state represents a new event being available on a particular port (bit 0 for port 1, bit 1 for port 2, etc.). The RTAC will periodically use the **VIEW** command to check the state of the fault register configured via the **Fault Register Address** setting (e.g., 16:USER:FAULT). If any bit in the register is set for a particular port, then the **POR** command is used to establish a transparent connection to the child IED on that specific port. Once all events are collected, the RTAC will exit the child IED transparent connection and issue a **TOG** command to clear the appropriate bit in the fault register. Fault-Register polling is considered more efficient than Round-Robin polling, but some programming is required in the communications processor to enable it. More details on the required programming are available in the SEL application guide *Configuring ACSELERATOR TEAM and the SEL-2032 for Event Collection* (AG2015-15), specifically in the section *Configure the SEL-2032*.

Step 6. On the **Child IEDs** tab, use the + button to add a row for each child IED present on the communications processor for which events should be collected. Each child IED row has the following parameters associated with it:

- **IED Name**. The name of the IED associated with the communications processor.
- **IED Virtual Port Number**. The communications processor serial port connected to the child IED. Used as an identifier used to initiate the Transparent connections to the child IED. Must be between ports 1–16.

Each configured row on the **Child IEDs** tab will create a sub-item (named for the child IED Name) that can be accessed in the project tree under the communications processor SEL client. This sub-item will contain configurable parameters for that particular child IED. These parameters include the following:

- **IED GUID**. A unique database identifier to be associated with this IED's events. Used by TEAM and Blueframe DMA in order to uniquely identify events from this particular child IED when configured to collect events from the RTAC using a direct database connection.
- **Level 1 Password**. The child IED Level 1 password. Used to log in to the ACC level of the child IED to perform automatic configuration and event retrieval functions. When a secure engineering access session is established through an SEL server and the parent SEL Protocol device connects to the child device, the stored child IED Level 1 password is automatically issued for an ACC access attempt made by the user (see *SEL Server Commands on page 247* for more details). This password can be updated here or via web API password-vault calls.
- **Level 2 Password**. The child IED Level 2 password. When a secure engineering access session is established through an SEL server and the parent SEL Protocol device connects to the child device, the stored child IED Level 2 password is automatically issued for a 2AC access attempt made by the user (see *SEL Server Commands on page 247* for more details). This password can be updated here or via web API password-vault calls.
- **Fault Register Logic Bit**. The communications processor per-port logic bit used to populate the FAULT register; only used in Fault-Register Polling mode. Following successful collection of events from a child IED, the RTAC exits the transparent connection to the child IED, logs in to the 2AC level of the communications processor, and issues the **TOG <*port*>:C<*bit*>** command, where <*port*> is equal to the child IED virtual port and <*bit*> is equal to the configured logic bit.
- **Format used to define Event filenames**. Selects the format of filenames for collected CEV and COMTRADE events. Configured as either Default or COMNAME; see *Event Collection File Naming on page 235* for more details.

- **List of names used to define event filenames**. When COMNAME event naming is used, this string is appended to the embedded filename time stamp as part of the file name.
- **Event Formats to be Collected**. Select the type of events to collect from a child IED. Select from CEV, COMTRADE, or Both.
- **CEV Event Collection Parameter**. Optional parameter appended to the CEV command when retrieving CEV events.
- **List of Comtrade Event types to be collected**. Comma-delimited list of Comtrade Event types to be collected. Defaults to HR (high- resolution), but others can be configured such as MHR, TW, etc.

CEV and COMTRADE events collected from child IEDs are available for download from the RTAC web interface by selecting the **Event Collection** tab. The events will be associated by name with the child IED Name assigned to the IED on the Child IEDs tab. Any CEV events collected from child IEDs are made available in the SEL Server command-line interface via **CAR** and **SUM** commands; they will be associated with the parent communications processor SEL client. CEV and COMTRADE events are also available from the RTAC's SFTP interface if an SFTP server has been added to the project. They are made available in the **/EVENTS/CEV/** and **/EVENTS/COMTRADE/** directories, where a named subdirectory will exist for each separate unique child IED.

Collecting event records through a communications processor generates a relatively large amount of data traffic that the hardware was not designed to handle on a regular basis. Some configuration choices that should be considered include the following:

- **RTS/CTS Handshaking**. Hardware flow control (also known as RTS/CTS handshaking) should be enabled (**RTS_CTS** = **Y**) on both the SEL IED serial port and the communications processor serial port. It is also important that a serial cable that supports the RTS/CTS lines (such as the SEL-C273A) be used to connect the SEL IED to the communications processor.
- **Connection Type to RTAC**. Options exist to allow the RTAC to communicate to the communications processor either serially or via Ethernet to an SEL-2701 card installed in Port 17 or 18 of the communications processor. The most bandwidth-efficient and high-performance choice for collecting CEV and COMTRADE events from child IEDs connected to a communications processor is with a 19200 baud (or higher) serial connection. Using this connection method requires a dedicated communications processor serial port configured with the **DEVICE** parameter set to **M** (master) and the **PROTOCOL** parameter set to **S** (SEL protocol). This serial connection should use an SEL-C273A cable to connect the communications processor to the RTAC and also enable RTS/CTS handshaking on both ends.
- **SEL-2701 Communications**. If you choose to configure the RTAC to communicate via Ethernet to the communications processor, ensure that the port that has the SEL-2701 card installed (Port 17 or 18) has the **T1RECV** parameter set to Y and the **T1PNUM** set to a known Telnet port, such as 23. Note that the effective bandwidth provided to the SEL-2701 for access to other communications processor serial

ports is 9600 baud. If COMTRADE event collection is desired through a SEL-2701 connection, any SEL IED port from which events are to be collected must *not* be configured for a speed exceeding 9600 baud; otherwise, failed event retrieval or loss of data can occur.

- **Unsolicited SER Data and Writes**. In a tiered event collection application performing COMTRADE record collection, the SEL client connecting to the communications processor should be configured to disable unsolicited SER data reporting. If this is not done, the SEL client may mistakenly interact with the Fast SER buffer of the child IED itself if a direct transparent connection happens to be established when the SEL client issues a periodic Unsolicited SER Enable/Disable message. This feature can be disabled from the **POU Pin Settings** tab by modifying the default value of the **Enable_Unsolicited_SER_RX** Pin Name to FALSE. For the same reasons listed above, the use of **Tx UW Messages and Rx UW Messages** should also be avoided.

Event Collection File Naming

Starting in firmware version R148-V0 and later, the format for how an event is named on the RTAC file system is a configurable option. Events can maintain the standard format, which was used prior to R148, or the event can be named in compliance with the COMNAME standard.

For CEV collected events, the formatting shall be as follows.

If Event_Name_Format is configured as default:

- Format: SEL_event_<sequence # -- 0 - (n-1) events>.cev
- Example: "SEL_event_3.cev"

If Event_Name_Format is configured as COMNAME:

- Format: <Event's Faulted Timestamp -- YYMMDD,hhmmss000000>, <Time Code+t>,<COMNAME_Event_Name_String>,<Event Number -- 0, 10000-65535>.cev
- The time stamp stored with the .cev file (displayed by the Web), shall be the time stamps extracted from the CHI response.
- The value of Time Code (i.e., UTC Offset) shall be derived from interpreting the Event's Trigger time stamp and the SEL Client Date-Time settings.
- The event reference will be derived from the "REF_NUM" value (10000–65535) from the CHI response, if it exists; otherwise, it will be 0.
- Example:
  - 170220,215117461,+2h30t,StationId,DeviceId,Company,10009.cev

For COMTRADE collected events, the formatting shall be as follows.

If Event_Name_Format is configured as default:

- The file name of the zipped COMTRADE event files and ZIP file shall be the base file name of the COMTRADE Event files from the relays file directory response.
- The entire ZIP file name shall be uppercase; the cfg/dat/hdr file names may be mixed-case and the extension shall be lowercase.

- The time stamp stored with the COMTRADE Event files (displayed by the Web), shall be the time stamps extracted from the relay's directory response. If the relay's directory response does not include time stamps for the COMTRADE Event files, the time of retrieval shall be used.
- Example:
  - "170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.CFG/DAT/HDR" becomes:
    - 170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.ZIP
    - 170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.cfg
    - 170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.dat
    - 170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.hdr
  - "StationA,SEL-T401L,SEL-T401L,200313,232558.5775,-1h30t,No.10000,MHR.CFG/DAT/HDR" becomes:
    - STATIONA,SEL-T401L,SEL-T401L,200313,232558.5775,-1H30T,NO.10000,MHR.ZIP
    - StationA,SEL-T401L,SEL-T401L,200313,232558.5775,-1h30t,No.10000,MHR.cfg
    - StationA,SEL-T401L,SEL-T401L,200313,232558.5775,-1h30t,No.10000,MHR.dat
    - StationA,SEL-T401L,SEL-T401L,200313,232558.5775,-1h30t,No.10000,MHR.hdr
  - "HR_10001.CFG/DAT/HDR" becomes:
    - HR_12345.ZIP
    - HR_12345.cfg
    - HR_12345.dat
    - HR_12345.hdr

If Event_Name_Format is configured as COMNAME:

- The name of the zipped COMTRADE event files and ZIP file shall be as follows:
  - Format: <Event's Faulted Timestamp -- YYMMDD,hhmmss000000>,<Time Code+t>,<COMNAME_Event_Name_String>,<Event Type -- e.g., "HR", "TDR", etc.>,<Event Number -- 10000-65535>.CFG/DAT/HDR/ZIP
- The entire ZIP file name shall be uppercase; the cfg/dat/hdr file names may be mixed-case and the extension shall be lowercase.
- Presence and accuracy of milliseconds and microseconds in the Event's file name shall be dependent on the presence and accuracy of the Event's Trigger time stamp.
- The time stamp stored with the COMTRADE Event files (displayed by the Web), shall be the time stamps extracted from the relay's directory response. If the relay's directory response does not include time stamps for the COMTRADE Event files, the time of retrieval shall be used.

- The value of Time Code (i.e., UTC Offset) shall be derived from interpreting the Event's Trigger time stamp and the SEL clients Date-Time settings.
- Example:
  - "170220,215117461,2T,T400L,0L#53,KAY,TDR,10009.CFG/DAT/HDR" becomes:
    - 170220,215117461,2T,STATIONID2,DEVICEID2,COMPANY2,TDR,10009.ZIP
    - 170220,215117461,2t,StationId2,DeviceId2,Company2,TDR,10009.cfg
    - 170220,215117461,2t,StationId2,DeviceId2,Company2,TDR,10009.dat
    - 170220,215117461,2t,StationId2,DeviceId2,Company2,TDR,10009.hdr
  - "StationA,SEL-T401L,SEL-T401L,200313,232558.5775,-1h30t,No.10000,MHR.CFG" becomes:
    - 200313,2325585775,-1H30T,STATIONID3,DEVICEID3,COMPANY3,MHR,10000.ZIP
    - 200313,2325585775,-1h30t,StationId3,DeviceId3,Company3,MHR,10000.cfg
    - 200313,2325585775,-1h30t,StationId3,DeviceId3,Company3,MHR,10000.dat
    - 200313,2325585775,-1h30t,StationId3,DeviceId3,Company3,MHR,10000.hdr
  - "HR\12345.CFG/DAT/HDR" becomes:
    - 200102,030405666,+2H30T,STATIONID1,DEVICEID1,COMPANY1,HR,12345.ZIP
    - 200102,030405666,+2h30t,StationId1,DeviceId1,Company1,HR,12345.cfg
    - 200102,030405666,+2h30t,StationId1,DeviceId1,Company1,HR,12345.dat
    - 200102,030405666,+2h30t,StationId1,DeviceId1,Company1,HR,12345.hdr

Remote Engineering Access and File Transfer Monitor

The SEL client supports remote engineering access to the connected SEL device. There are two methods for configuring engineering access. The first method is to configure a transparent connection by using an access point and access point router (APR). For further information on this method, refer to *Section 4: Engineering Access*. The second method uses the SEL server device type. For more information on this method, refer to *SEL Server Configuration on page 244*.

When a remote engineering access attempt is initiated through an SEL server via the **PORT** command with a serial connection to the IED, access is only available through the primary data polling connection. If an Ethernet-tunneled-serial connection is in use, the RTAC will attempt to open a secondary Ethernet connection to the SEL client device. If the SEL client device receives no response within the time configured in the **Secondary Transparent Connection**

Timeout, and **Allow Transparent on Polling Connection** is set to True, the SEL server establishes an engineering access session on the primary data polling connection. To force the remote engineering access session to always use the primary data polling connection, set the **Secondary Transparent Connection Timeout** value to 0. Note that the **Direct_Transparent_Connection** and **Transparent_Connection** POU pins on an SEL Protocol client only indicate active connections when they are established over the primary data polling connection. If you want to use these POU pins (e.g., to indicate user access) while using a device configured with an Ethernet-tunneled-serial connection, ensure that the **Secondary Transparent Connection Timeout** value is set to 0. To disable remote engineering access for an SEL client, set **Disable Remote Access** in the **Settings** tab to True.

Both engineering access methods support file transfers for reading settings from the connected SEL IED. When engineering access is successfully established through a transparent connection or through an SEL server device, the SEL client monitors the connection for a Ymodem file transfer initiation via the **FILE READ** command. If the SEL client detects a file transfer initiation, the connection switches to a direct transparent connection. If the engineering access connection is on the primary data polling connection, all data polling is suspended until the file transfer succeeds or fails. To disable the file transfer monitor function for a particular SEL client, set **Enable File Transfer Monitor** in the **Settings** tab to False.

POU Pin Settings

Use POU pin settings to view the present state of the SEL client operation and to modify some of the behavior of the protocol. Setting the **Visible** field to TRUE will cause the POU pin to appear in the **Controller** tab. Some pins have their **Default Value** field grayed out and not editable—these pins are controlled by various settings located on the **Settings** tab. See *Table 2.26* for settings descriptions.

Table 2.26 SEL Client POU Pin Settings

Pin Name	Pin Type	Description	Default
Check_For_Comtrade_Event	Input BOOL	A rising-edge trigger that causes the system to check for new COMTRADE files.	FALSE
Check_IED_Configuration	Input BOOL	Initiate an attempt to detect a change in the configuration of the IED.	FALSE
Check_IED_Configuration_Period	Input TIME	Governs the periodic attempts to detect a change in the configuration of the IED.	FALSE
Delete_All_Acked_Event_Collection	Input BOOL	Delete all of the acknowledged stored events that are associated with this SEL client.	FALSE
Delete_All_Event_Collection	Input BOOL	Delete all of the stored events that are associated with this SEL client.	FALSE
Disable_Controls	Input BOOL	While TRUE, processing of any controllable tags is blocked.	FALSE
Disable_Remote_Access	Input BOOL	While TRUE, disallow usage of transparent connections to the IED.	FALSE
Disable_Tag_Updates	Input BOOL	While TRUE, the value of all tags (status/value, quality, and time stamps) shall not change.	FALSE
EN	Input BOOL	Enable this specific SEL client.	TRUE

Pin Name	Pin Type	Description	Default
Enable_ASCII_SER_Logging	Input BOOL	Enable collection of SER via the **CSE** command and logging of new SER events into the RTAC SOE log.	FALSE
Enable_Comtrade_Collection	Input BOOL	Enable Comtrade event collection from the relay.	FALSE
Enable_Event_Collection	Input BOOL	Enable CEV event collection from a relay or relays connected by a Communications Processor.	FALSE
Enable_File_Transfer_Monitor	Input BOOL	Enable X/YMODEM file transfer monitor during transparent connections.	TRUE
Enable_New_Event_Filtering	Input BOOL	Enable event filtering and updates to NEW_EVENT tags.	FALSE
Enable_Unsolicited_SER_RX	Input BOOL	Enable the reception of Unsolicited SER messages via Fast Message.	TRUE
Enable_Unsolicited_Write_RX	Input BOOL	Enable and disable the reception of Unsolicited Write messages via Fast Message.	FALSE
Initiate_Auto_Configuration	Input BOOL	A rising-edge trigger that causes the Autoconfiguration process to be initiated.	FALSE
Level_1_Password	Input STRING(32)	The string used to update the stored IED Level 1 password.	
Level_2_Password	Input STRING(32)	The string used to update the stored IED Level 2 password.	
Poll_XXXXX (Repeat for each polling message: CASCII, Fast Meter, Fast Message)	Input BOOL	A rising-edge trigger that causes a single message poll to be transmitted.	FALSE
Poll_XXXXX_Period (Repeat for each polling message: CASCII, Fast Meter, Fast Message)	Input TIME	Governs the periodic transmission cycle of the polling message.	FALSE
Report_New_Event	Input BOOL	A rising-edge trigger that causes the collection and reporting of the new event data.	FALSE
Reset_New_Event	Input BOOL	A rising-edge trigger that causes the new event data to be reset/expire immediately.	FALSE
Reset_Statistics	Input BOOL	On the rising-edge trigger, all counter POU outputs are reset.	FALSE
Send_Unsolicited_Write_TX_*message* (where *message* represents the message instance)	Input BOOL	A rising-edge trigger that causes a transmission of the Unsolicited Write message.	FALSE
Send_Unsolicited_Write_TX_*message*_Period (where *message* represents the message instance)	Input TIME	Governs the periodic transmission cycle of the Unsolicited Write message.	FALSE
Write_Level_1_Password	Input BOOL	While TRUE, causes the Level_1_Password setting to be updated with the value of Level_1_Password input.	FALSE
Write_Level_2_Password	Input BOOL	While TRUE, causes the Level_2_Password setting to be updated with the value of Level_2_Password input.	FALSE
ASCII_SER_Logging_Enabled	Output BOOL	Asserted when logging of SOE records from data collected via the SER command is enabled via the Enable_ASCII_SER_Logging input pin.	FALSE
ASCII_SER_Logging_Pending	Output BOOL	Asserted while SER records are being actively collected via the **SER** command.	FALSE

Pin Name	Pin Type	Description	Default
ASCII_SER_Logging_Sequence_Restart	Output BOOL	Pulses for one processing interval when the previous logged SOE record cannot be found in the new SER command output, indicating that data loss may have occurred. Typically occurs after a period of rapid SER event generation on the IED, shifting the visibility of the last collected SER record beyond that visible by the number of displayed records specified by the **ASCII SER Logging Command Parameter** setting.	FALSE
ASCII_SER_Logging_Stored	Output BOOL	Pulses for one processing interval upon logging of a new SOE record collected from the **SER** command.	FALSE
ASCII_SER_Logging_Stored_Count	Output UDINT	Increments each time an SOE record, collected from the SER command, is logged.	0
Auto_Configuration_Failure	Output BOOL	Asserts when an Autoconfiguration completes and was not successful; remains asserted until the rising-edge of Auto_Configuration_Pending.	FALSE
Auto_Configuration_Pending	Output BOOL	Asserts at the start of the startup autoconfiguration or re-autoconfiguration process when Initiate_Auto_Configuration is asserted. Remains asserted until the process completes (successfully or terminates because of a failure).	FALSE
Buffer_Overflow	Output BOOL	Asserts for one processing interval after an overflow condition (e.g., the loss of Unsolicited SER events) is detected.	FALSE
CASCII_Failure	Output BOOL	Asserts for at least one processing interval when an error is detected in an ASCII message transaction such as a flex parse response, CEV event collection attempt or ASCII-based SER retrieval.	FALSE
CASCII_Failure_Count	Output UDINT	Running sum of failed ASCII message transactions.	0
CASCII_Success_Count	Output UDINT	Running sum of successful ASCII message transactions.	0
Check_IED_Configuration_Delay	Output BOOL	Asserts when Check_IED_Configuration processing is triggered and the previous triggering of Check_IED_Configuration processing hasn't yet completed.	FALSE
Check_IED_Configuration_DN	Output BOOL	Asserts for one processing interval when IED Check Configuration processing completes.	FALSE
Check_IED_Configuration_Error	Output BOOL	Asserts for one processing interval when the IED Check Configuration processing fails (e.g., a checksum error was encountered in the CASCII output).	FALSE
Check_IED_Configuration_Mismatch	Output BOOL	Asserts for one processing interval when a change in the IED's configuration has been detected.	FALSE
Check_IED_Configuration_Mismatch_Count	Output UDINT	Increments each time a change in the IED's configuration is detected.	0
Comtrade_Collection_Enabled	Output BOOL	Asserts when Comtrade Event Collection is enabled, typically via the **Enable Comtrade Collection** parameter on the Settings tab.	FALSE

Pin Name	Pin Type	Description	Default
Comtrade_Event_Collection_Count	Output UDINT	Running count of the number of COMTRADE event records that have been collected during this session. Resets upon an assert of Reset_Statistics or EN transitioning to TRUE.	0
DDF_Configuration_Mismatch	Output BOOL	Asserts when the autoconfiguration process completes in failure due to a mismatch of the expected IED type contained in the FID string. Commonly encountered when an SEL client is configured for an incorrect type as compared to the actual connected IED.	FALSE
Delete_All_Acked_Event_Collection_DN	Output BOOL	Asserts for a processing interval when event collection deletions have completed after having been requested by the Delete_All_Acked_Event_Collection input pin.	FALSE
Delete_All_Event_Collection_DN	Output BOOL	Asserts for a processing interval when event collection deletions have completed after having been requested by the Delete_All_Event_Collection input pin.	FALSE
Direct_Transparent_Connection	Output BOOL	Indicates TRUE when the port is direct transparently connected (i.e., SEL server or access point) or the port is transparently connected and a file transfer is active. During the transparent connection period, processing of all SEL messaging is blocked. All ASCII and binary traffic passes through the direct transparent link.	FALSE
ENO	Output BOOL	Indicates that this SEL client instance is active.	FALSE
Event_Collection_Count	Output UDINT	Running count of the number of CEV event records that have been collected and stored in nonvolatile memory.	0
Event_Collection_Enabled	Output BOOL	Asserts when Enable_Event_Collection is asserted (typically via the **Enable Event Collection** parameter on the Settings tab) and a successful autoconfiguration has completed, indicating support for CHIS and CEV CASCII messages to allow collection of CEV events. If Enable_Event_Collection is asserted and this output pin does not assert following autoconfiguration, the IED does not support the required CASCII messages for CEV event collection.	FALSE
Event_Collection_Pending	Output BOOL	Asserts when a CEV or COMTRADE event record is being actively collected.	FALSE
Event_Collection_Stored	Output BOOL	Asserts for a single processing interval when a collected CEV or COMTRADE event has been stored in nonvolatile memory.	FALSE
Fast_Message_Failure	Output BOOL	Asserts for at least one processing interval when an error is detected in a Fast Message transaction.	FALSE
Fast_Message_Failure_Count	Output UDINT	Running sum of failed Fast Message transactions.	0
Fast_Message_Read_Success_Count	Output UDINT	Running sum of successful Fast Message transactions.	0
Fast_Message_Success_Count	Output UDINT	Running sum of successful Fast Message transactions.	0

Pin Name	Pin Type	Description	Default
Fast_Meter_Failure	Output BOOL	Asserts for at least one processing interval when an error is detected in a Fast Meter message transaction.	FALSE
Fast_Meter_Failure_Count	Output UDINT	Running sum of failed Fast Meter message transactions.	0
Fast_Meter_Success_Count	Output UDINT	Running sum of successful Fast Meter message transactions.	0
Fast_Operate_TX_Enabled	Output BOOL	Asserts while the transmission of Fast Operate messages is enabled.	FALSE
Fast_Operate_TX_Success_Count	Output UDINT	Running sum of valid Fast Operate messages transmitted.	0
Invalid_Function_Block_Input	Output BOOL	Asserted when the SEL client function block has received an invalid input (e.g., input to Timer is outside of range, invalid User Message command, Invalid Level_#_Password, etc.).	FALSE
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	0
New_Event_Detected	Output BOOL	Asserts for one processing interval after a new event has been detected, either via polling with the CHI command or receipt of an unsolicited message from the IED.	FALSE
New_Event_Filtering_Enabled	Output BOOL	Asserts when new event filtering is enabled.	FALSE
New_Event_Report_Delay	Output BOOL	Asserts if a previous triggering of the message (e.g., Report_New_Event was asserted) is waiting to be processed. Deasserts when the response for the previously triggered message is received.	FALSE
New_Event_Report_DN	Output BOOL	Asserts for one processing interval after a new event has been reported (e.g., the new event tags have been populated).	FALSE
Offline	Output BOOL	If TRUE, indicates the communications channel is offline due to the IED not responding to a data poll request or command that expects a response. If FALSE, indicates the communications channel is online (deasserted when a valid response is received and ENO is asserted).	TRUE
Poll_XXXXX_Delay (Repeat for each polling message: CASCII, Fast Meter, Fast Message)	Output BOOL	Asserts when this message is triggered and the previous triggering of this Poll_XXXXX is not yet complete.	FALSE
Poll_XXXXX_DN (Repeat for each polling message: CASCII, Fast Meter, Fast Message)	Output BOOL	Asserts for one processing interval when the message transaction is complete.	FALSE
Send_Unsolicited_Write_TX_*message*_Delay (where *message* represents the message instance)	Output BOOL	Asserts when this message is triggered and the previous triggering of this Send_Unsolicited_Write_TX_*message* is not yet complete.	FALSE
Send_Unsolicited_Write_TX_*message*_DN (where *message* represents the message instance)	Output BOOL	Asserts for one processing interval when the message transmission is complete.	FALSE

Pin Name	Pin Type	Description	Default
Slow_Poll_Mode_Enabled	Output BOOL	Asserted when Slow Poll mode is enabled due to the IED not responding to a solicited message request and exceeding the number of message retries.	FALSE
Transparent_Connection	Output BOOL	Indicates TRUE when the port is transparently connected to an external source (i.e., SEL server or transparent access point). During the transparent connection period, the SEL client actively performs all binary messaging; ASCII messaging is blocked. When a file transfer is detected, a transparent connection will transition to a direct transparent connection and all binary and ASCII messaging is blocked.	FALSE
Unacked_Event_Collection_Count	Output UDINT	Running count of the number of CEV and COMTRADE event records that have been collected and stored in nonvolatile memory but not acknowledged.	0
Unresolved_Tag_Reference_Count	Output UDINT	Following Autoconfiguration, indicates the number of tags that have been enabled that contain data references that do not exist in the connected IED.	0
Unresolved_Tag_Reference_Error	Output BOOL	Asserts when Autoconfiguration completes and one or more tags that have been enabled on tag tabs (e.g., the Meter tab) contain data references that do not exist in the connected IED. Commonly encountered if a tag is enabled that refers to a Relay Word bit that does not exist on the actual IED (e.g., an input contact on an expansion card that is not present on the actual connected IED).	FALSE
Unsolicited_ASCII_Message_RX	Output BOOL	Asserts for at least one processing interval after an Unsolicited ASCII message has been received from the IED.	FALSE
Unsolicited_SER_RX_Enabled	Output BOOL	Asserts while the reception of Unsolicited SER messages is enabled.	FALSE
Unsolicited_SER_RX_Overflow	Output BOOL	Asserts for one processing interval upon receipt of an SOE Overflow message.	FALSE
Unsolicited_SER_RX_Overflow_Count	Output UDINT	Running sum of received Fast SOE Overflow messages.	0
Unsolicited_SER_RX_Success_Count	Output UDINT	Running sum of valid Fast Unsolicited SER messages received.	0
Unsolicited_Write_RX_Enabled	Output BOOL	Asserts while the reception of Unsolicited Write messages is enabled.	FALSE
Unsolicited_Write_RX_Success_Count	Output UDINT	Running sum of valid Fast Unsolicited Write messages received.	0
Unsolicited_Write_TX_Enabled	Output BOOL	Asserts while the transmission of Unsolicited Write messages is enabled.	FALSE
Unsolicited_Write_TX_Success_Count	Output UDINT	Running sum of valid Fast Unsolicited Write messages transmitted.	0
Write_Level_1_Password_DN	Output BOOL	Asserts for one processing interval when the Level_1_Password setting has been updated.	FALSE
Write_Level_2_Password_DN	Output BOOL	Asserts for one processing interval when the Level_2_Password setting has been updated.	FALSE

SEL Server Configuration

The RTAC supports one primary SEL protocol communications session with one upper-tier SEL device (such as another RTAC) per SEL server connection. Create SEL unsolicited write tags in an SEL server as placeholders that the server will use to exchange data with a polling RTAC. Use the Tag Processor to map those tags to client IED or other source tags in the RTAC database. You can also configure RBs and BBs for control messages. The primary SEL protocol session is associated with all SEL protocol data exchanges mentioned previously as well as unsolicited SER reporting and event notifications.

Each SEL server in the RTAC supports only one primary SEL protocol client connection. If more than one SEL client will connect to this RTAC, create another SEL server for each client connection.

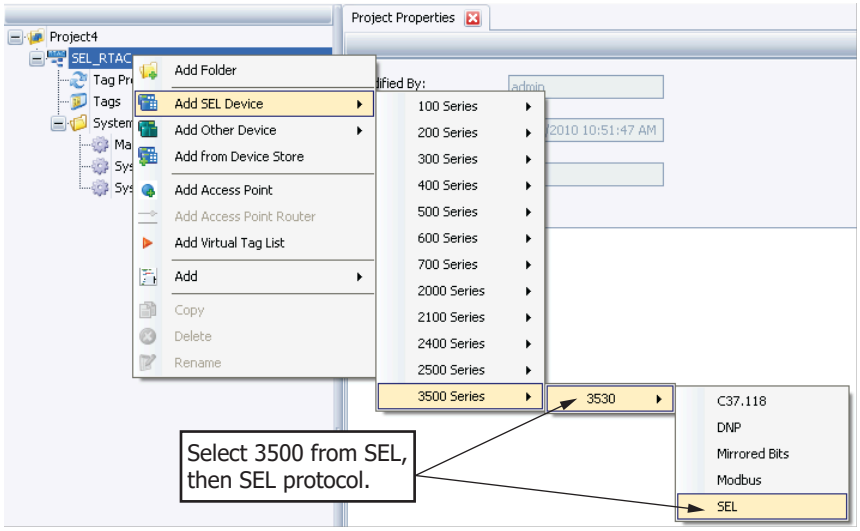

Figure 2.24 SEL Server

For example, insert an RTAC from the SEL ribbon menu under the **Insert** ribbon or from right-clicking on **SEL_RTAC** in the device pane. Select **3500 Series**, then **3530**, then **SEL** protocol.

Give the device a unique name, or accept the default as shown in *Figure 2.3*. Select either **Server – Serial** or **Server – Ethernet Tunneled Serial**.

The **Settings** tab contains all configurable items for communication and time. Check the Description column for details on each configuration item. Move the slider, or hover your cursor over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Multiple Simultaneous Connections Support

The SEL server supports multiple connections. All connections other than the primary connection are secondary connections and will only allow ASCII command line sessions. If **Allow Anonymous SEL IP Clients** is set to True, then all connections are accepted. If **Allow Anonymous SEL IP Client** is set to False, then only the IP addresses configured in the **Client IP Address** and **Engineering Access IP Address** may connect to the SEL server.

Primary SEL Protocol Connection Configuration

The primary SEL protocol connection is associated with sending all unsolicited message notifications (including SER, event report oscillography, SOE, and configuration change notifications) and such other SEL protocol functions as unsolicited writes and remote bit operation. An SEL server device accepts only one primary connection. If **Allow Anonymous SEL IP Clients** is set to False, the Client IP Address and Client IP Port settings determine the primary SEL protocol connection. If **Allow Anonymous SEL IP Clients** is set to True, the primary connection is associated with the first successful connection to the SEL server.

Unsolicited Event, SOE, and Config Change Notifications

You can configure the SEL server to send notifications to other applications when new event report oscillography, SOE data, and IED configuration change events are available for collection. To configure this capability, assign the **Client IP Address** and **Client IP Port** settings to specify the address and listening port on the reporting application. Note that assigning a non-zero **Client IP Port** will force **Allow Anonymous SEL IP Clients** to be False, which will disable the setting and enforce the entry of a valid **Client IP Address**. Following that, navigate to the **POU Pin Settings** tab in the SEL server. To send notifications when the RTAC has new SOE data available, set the default value for **Enable_Unsolicited_ASCII_SER_Notice_TX** to TRUE. To send notifications when new event report oscillography is available, set **Enable_Unsolicited_Event_Report_TX** to TRUE. To send notifications of IED Configuration Change events, set the default value for **Enable_Unsolicited_Config_Change_Notice_TX** to TRUE.

There are two exclusive event report oscillography notifications because there are two different automated methods for collecting event report oscillography from the RTAC. The legacy method uses the commands available in the SEL server to read event reports through an ASCII data session. See *Table 2.27* for the **CAR *archive*** and other SEL server commands. The database collection method uses a direct connection to the RTAC database over a TLS tunnel, which encrypts the data transfer. COMTRADE event collection is supported during use of the database collection method. Select an event collection mechanism in accordance with the security and infrastructure requirements of your organization. To configure which notification the SEL server sends, navigate to the **Settings** tab and configure the **New Event Notification** . For legacy event collection, select **Legacy**, and for the database collection method, select **Encrypted Database**. If you select **Legacy**, the SEL server sends a New Event notification when new CEV events are available for collection. If you select **Encrypted Database**, the SEL server sends a notification when either a new CEV or COMTRADE event is available.

When new SOE data are available, the SEL server sends the NEW SOE message. When new IED configuration change records are available, the NEW IED CONFIGURATION message is sent. In systems where more than a single RTAC may be reporting to a centralized application, an RTAC-specific GUID can be configured under the **SystemTags** configuration using the **Device_GUID** setting. If configured, this GUID value will be included with each unsolicited notification message.

The respective notifications repeat every minute until the notified application collects and subsequently acknowledges receipt of the new event collection, SOE data, or IED configuration change.

Unsolicited Messages

See *SEL Client Configuration on page 217* for a discussion of unsolicited messages.

Remote Bits and Breaker Bits

Add RBs and BBs as necessary. The RTAC will receive controls from a remote SEL client through the use of configured RBs and BBs. Link RB and BB tags in the Tag Processor to control tags in the RTAC.

SEL Server SER Data

As discussed in *SEL Client Configuration on page 217*, the RTAC automatically routes all SER data from all SEL client connections to all configured SEL server connections. The RTAC can also generate local system SER data from any configured RTAC tags. The RTAC automatically routes all local system SER data to all configured SEL server connections.

Step 1. Under **System**, click **SystemTags**, then click on the **SEL Server SER** tab.

Step 2. Click on the + icon to add the number of SER tags necessary.

Step 3. Configure the Tag Name and SEL Label, if needed.

Step 4. Map the new SER tags as Destinations in the Tag Processor.

Step 5. Map Source Expressions in the Tag Processor to populate the SER tags with data.

The RTAC will generate an SER message for each change of state it detects in the defined system SER tags. All configured SER server device connections will transmit these unsolicited SER messages.

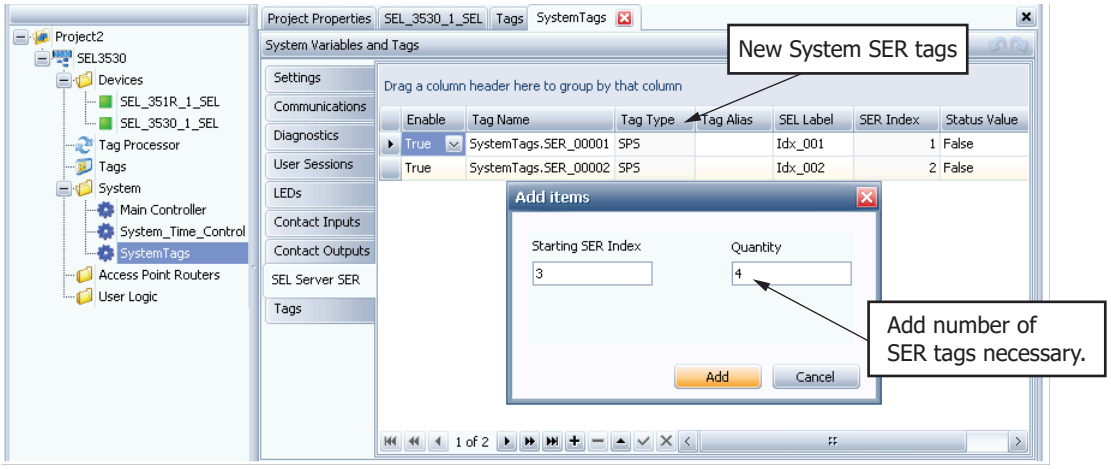

Figure 2.25 System SER Tags

SEL Server Commands

The SEL server for the RTAC is similar to other SEL devices in supporting user authentication and other commands to provide an interactive user session. From the advanced options under the settings tab, set Perform Authentication = True if you want the RTAC to authenticate users before allowing access to other SEL server commands. Login usernames and passwords are those you configure through the RTAC web interface as local accounts or accounts you manage through an LDAP central authentication server. If user authentication is turned on, you can log in to the SEL server through a terminal emulation program as you would any SEL relay or IED. Enter the correct username and password, then enter **ACC** to reach Level 1 access and **2AC** to reach Level 2 access. If user authentication is not enabled, you must enter **ACC** and then use the password OTTER to enter Level 1 access. Enter **2AC** with password TAIL to enter Level 2 access. You can change the default passwords of OTTER and TAIL using the **PAS** command from Level 2. In firmware versions R151-V0 and later, the Level 1 and Level 2 passwords can be changed via the **Level 1 Password** and **Level 2 Password** advanced settings available on the Settings tab. SEL server authentication has three access levels associated with RTAC user account levels:

- Level 0: Attain this level upon successful login. This is also the level you access if client authentication is disabled.
- Level 1: Access Level 1 by entering the **ACC** command. User manager and monitor local system roles can attain Level 1 access.
- Level 2: Access Level 2 by entering the **2AC** command. Administrator and engineer local system roles can attain Level 2 access. From Level 2 you can change the default SEL server ACC and 2AC passwords.

Table 2.27 lists SEL server commands.

Table 2.27 SEL Server Commands (All Commands Access Level 1)

Command	Description
ACC	Gain access to Level 1. Password = OTTER if Perform Authentication = FALSE.
2AC	Gain access to Level 2. Password = TAIL if Perform Authentication = FALSE.
ID	Display RTAC ID information.
CAR SUM	Retrieve event report summary.
CAR SUM ALL	Retrieve event report summary for all ports.
CAR SUM ***port***	Retrieve event report summary for specified *port* number.
CAR READ ***port event***	Retrieve detailed event data for specified *port* number and *event* number. Each event has a unique *event* number.
CAR ACK ALL	Acknowledge all events.
CAR ACK ***port*** **ALL**	Acknowledge all events for specified *port* number.
CAR ACK ***[port] [event]***	Acknowledge all events for specified *port* number and/or *event* number.

Command	Description
PAS	From the 2AC level, change the SEL server default user passwords for either Level 1 or Level 2. To use, enter **PAS *n* <Enter>** (where *n* is either 1 or 2) and follow the prompts to change the default password.
CMO SUM ALL	Output a CASII-formatted report of the latest unacknowledged Configuration Change events for all ports.
CMO SUM *port*	Output a CASCII-formatted report of the latest unacknowledged Configuration Change event for the specified *port* number.
CMO ACK ALL	Acknowledge Configuration Change events for all ports.
CMO ACK *port*	Acknowledge Configuration Change event for the specified *port* number.
POR *n*	Transparently connect to the SEL client configured on Port *n*.
POR *n* DIRECT	Create a direct transparent connection to the SEL client configured on Port *n*.
STA	Show other clients who have active direct/transparent connections.
WHO	List information for configured SEL clients.
FIL SHOW *file_path_and_name*	Outputs content of listed file in ASCII format. SEL server setting **Perform Authentication** must be TRUE. The full file path is required and must be preceded by FILES/ (i.e., FILES/*file_path_and_name*). For example, if the FTP server is enabled, a valid command would be **FIL SHOW FILES/ftplog.txt**.

Engineering Access to SEL Client Devices

The **POR** command provides an immediate direct transparent or transparent connection to the SEL client configured on the indicated port. For example, to transparently connect to an SEL device on Port 1 without using an Access Point Router, follow these steps:

Step 1. Configure an SEL server using an Ethernet tunneled serial connection or serial connection, as desired.

Step 2. Load the project into the RTAC.

Step 3. Connect to the SEL server by using the Ethernet serial tunneled IP port number or directly by using a serial cable, depending on your configuration.

Step 4. If you have configured the **Perform Authentication** setting as True, log in as described previously in this section.

Step 5. Enter the command **POR 1** and press **<Enter>**. You are transparently connected to the SEL device configured on Port 1. Alternatively, enter the command **POR 1 D** and press **<Enter>**. You now have a direct transparent connection to the SEL device configured on Port 1.

Step 6. Press **<Ctrl+D>** to exit the transparent connection and return to the SEL server.

When a single connection is initiated through the SEL server to an SEL client, the server either creates a new connection to the client or uses the primary connection, which provides for binary data transfer. The client connection type and the settings in the client device determine the behavior of the connection. Clients configured for serial connections automatically use the primary connection because serial communications channels only support one connection. Clients configured for Ethernet communication create a secondary connection if configured in the client settings. See *SEL Client Configuration on page 217* for more information.

When engineering access initiates multiple connections to the same SEL client device, the SEL server attempts to create a new connection to the client if the use of secondary connections is configured in the client settings. Many SEL IEDs support multiple concurrent Telnet sessions. For every connection you initiate through the SEL server, the server attempts to create a unique session to the IED until the IED rejects the connection request. At that point, the server may attempt to use the primary connection if the client settings allow it.

If the **Perform Authentication** setting is True, during engineering access sessions made to SEL client devices, the Change Access Level Monitoring feature can be used. This feature is activated when the RTAC user account that originally logged into the SEL server session is assigned a role that contains the **Relay ACCess** and/or **Relay 2ACess** permissions (see *Table 7.6* for more details). By default, the Administrator user role is assigned both of these permissions. When this feature is active, an engineering access session to an SEL client device (or defined child IED there-of) is monitored for the ACC or 2AC command; if these user commands are seen in the engineering access session, the RTAC will automatically issue the stored Level 1 Password and/or Level 2 Password to the device. In a system with password management in use, this allows for authenticated and authorized engineering access to SEL client devices without the end user being aware of the actual SEL IED password. Additional IED access levels such as CAL, BAC, (etc) are not monitored or controlled.

If you change the SEL device password while transparently connected, you will interrupt normal SEL client polling operations. To resolve this, you can either change the password in the SEL client configuration in the RTAC project and resend the project, or you can configure the system to do it automatically. Set the advanced setting **Enable Password Monitor** on each SEL client to True and resend the project. Each time you transparently connect to one of the SEL clients through the SEL server, the RTAC monitors for password changes and automatically updates the configured passwords in each affected SEL client.

⚠IMPORTANT

You must read the project from the RTAC to ensure you have the latest passwords. Resending an older project to the RTAC will erase passwords that have been stored during a transparent connection password monitoring activity. During a project send operation, the **Retain Password Vault** option in the Options tab can be enabled to preserve the passwords present in the RTAC and ignore those from the project being sent.

Command Examples

Example: CAR SUM

The CAR SUM response format is as follows:

```
"NEWEVENT=00000000000..,", "CSUM",
```

Where CSUM is the message checksum, and the zeros following NEWEVENT total 254 characters. Each character in the response corresponds to a virtual port on the RTAC. The first character is for **Port 1**, the second is for **Port 2**, and so on. If there are unacknowledged reports for a given port, the RTAC sets the corresponding character to a value of one in the **CAR SUM** response. If no ports have unacknowledged events, the **CAR SUM** response contains 254 zeros.

Example: CAR SUM ALL

The **CAR SUM ALL** command responds with a summary of all event reports for all ports configured for event collection. The event summary contains a header row followed by zero or more rows of data. Data rows are organized in descending chronological order.

Command:

CAR SUM ALL

Response:

```
"EVENT ID","FID","PORT","MONTH","DAY","YEAR","HOUR","MIN","SEC",
"MSEC","USEC","EVENT","CURR","TARGETS","STATUS","CSUM"

227,"SEL-421-R127-V0-Z012011-D20090218",3,7,6,2010,10,25,21,123,
"OVR",0,"","UNACK","CSUM"

228,"SEL-421-R127-V0-Z012011-D20090218",3,7,6,2010,10,24,21,123,
"TRIG",0,"","UNACK","CSUM"

229,"SEL-421-R127-V0-Z012011-D20090218",3,7,6,2010,10,23,21,123,
"OVR",0,"","UNACK","CSUM"

230,"SEL-421-R127-V0-Z012011-D20090218",3,7,6,2010,10,22,21,123,
"TRIG",0,"","ACK","CSUM"

231,"SEL-351-R225-V0-Z012011-D20080315",4,7,6,2010,10,22,10,123,
"TRIG",0,"","ACK","CSUM"

232,"SEL-351-R225-V0-Z012011-D20080315",4,7,6,2010,9,30,21,123,
"OVR",0,"","UNACK","CSUM"

233,"SEL-734-R325-V0-Z012011-D20060520",2,7,5,2010,6,22,21,673,
"TRIG",0,"","UNACK","CSUM"

234,"SEL-734-R325-V0-Z012011-D20080520",16,7,1,2010,11,43,31,225,
"OVR",0,"","UNACK","CSUM"
```

Example CAR READ

Command:

CAR READ 3 232

Response:

```
"CMD","EVENT ID","FID","CSUM"

"CEV 1 S8","232","SEL-421-R127-V0-Z012011-D20090218","CSUM"
```

```
[Event Report. 232]
```

where [Event Report. 232] is the response to the **CEV 1 S8** command associated with Port 3 on the RTAC. The RTAC transfers the report in CASCII format.

Example: CMO SUM ALL

The **CMO SUM ALL** command responds with a summary of the most recent configuration change events for all ports that have unacknowledged events. The configuration change summary contains a header row followed by zero or more rows of data. The data rows contain the virtual port number, name, and GUID of the device that detected the configuration change event as well as a time stamp and SHA-256 from the event. An example of the response format is as follows:

Command:

CMO SUM ALL

Response:

```
"PORT","DEVICE_NAME","DEVICE_GUID","DETECTED","SHA256_HASH","OF1B"

252,"SEL_751_1","","2022-10-23 23:16:52.000000","48B4628041CD2CACA
66B628F82EB20C33053B1E90019EFE502E80AEEAA06D5AE","1871"

254,"SEL_451_1","Custom451GUID","2022-10-23 23:16:23.000000","6566
DDD1F90536B41AAA26849442CB1044169995799C88097E88B5F1F56A8B0A","1C6E"
```

Password Command and Managing User Accounts

Starting in R145-V0 users are able to manage passwords for local accounts on the RTAC. In order for this functionality to be active the SEL server setting **Perform Authentication** must be true. If this setting is false, the password command will work in the same manner as specified in *Table 2.27*.

Example Password Command (R145-V0 and later):

Command: **PAS**

Response: `User Name: ?`

Command: Enter the account name for which to change the password.

Response: `New Password: ?`

Command: Enter a new desired password for the specified local account.

Response: `Confirm New Password: ?`

Command: Re-enter the password to confirm.

Response: `Password Changed`

POU Pin Settings

See *POU Pin Settings (Advanced Usage) on page 173* for a description of the **POU Pin Settings** tab.

MIRRORED BITS

Overview

MIRRORED BITS communications is a direct relay-to-relay communications protocol that allows IEDs to exchange information quickly, securely, and with minimal expense. The MIRRORED BITS message consists of eight transmit bits (TMBs) and eight receive bits (RMBs). The RTAC sends TMBs to IEDs. IEDs send TMBs to the RTAC, which receives these as RMBs.

The RTAC communicates MIRRORED BITS as would a relay, but it also acts as a data gateway between MIRRORED BITS and other protocols or programs running in the RTAC. For example, you can map MIRRORED BITS RMBs to DNP digital inputs to interface to a SCADA system. You can map control tags from user-defined logic or a remote client to TMBs to issue high-speed controls to an SEL IED through MIRRORED BITS.

When using MIRRORED BITS in user logic, SEL recommends that POU pin Rx_OK_Instantaneous and/or the validity of individual received MIRRORED BITS tags be considered before making assignments to other protocols or contact I/O. This helps prevent undesired actions being taken when communications are lost. In firmware versions R150-V0 and later, in the unlikely scenario where the logic engine detects a hardware issue with the serial port, the following diagnostics occur: POU pin Rx_OK_Instantaneous deasserts; POU pin RX_ID_Error resets to 0; POU pin Rx_Under_Run_Error_Count begins incrementing at every task interval; the validity of all MIRRORED BITS tags are set to invalid; MIRRORED BITS status values follow the setting "Channel Fail State"; and a diagnostic message is written to the System_Hardware_Failure system tag, which is logged by default to the SOE log.

MIRRORED BITS Configuration

Because MIRRORED BITS is a peer-to-peer serial communications protocol, there are no client, server, or Ethernet options. You can configure MIRRORED BITS on an EIA-485/EIA-422 or EIA-232 serial line, but this configuration does not support multi-drop communication. You can configure as many MIRRORED BITS communications channels on one RTAC as there are serial ports not already used for another purpose.

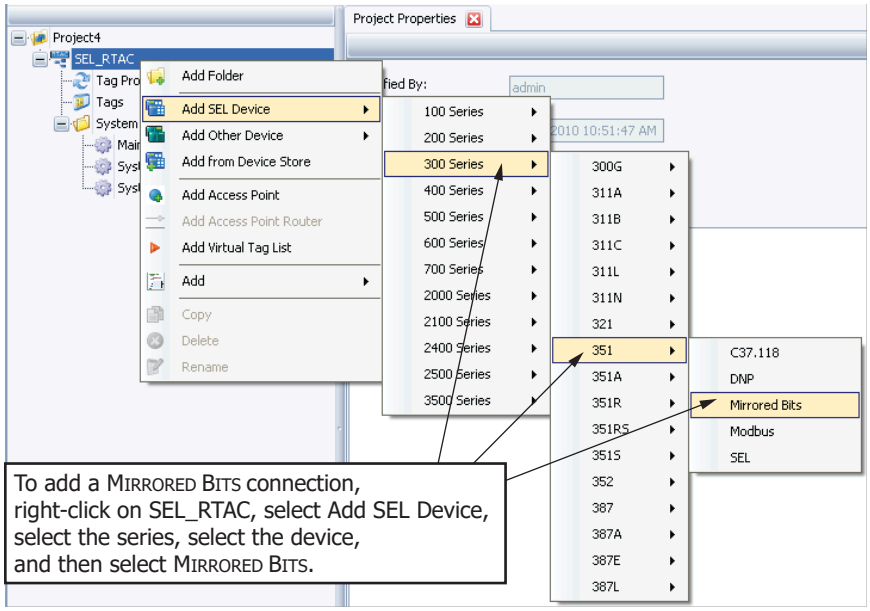

Figure 2.26 Insert MIRRORED BITS Device

Give the device connection a unique name, and select a connection type as shown in *Figure 2.1*. Note that MIRRORED BITS is a point-to-point serial protocol, so the only connection option is serial.

MIRRORED BITS is a peer-to-peer protocol designed for one-to-one high-speed serial communications; it cannot be multidropped. Insert one of these types of connections for each communications port on the RTAC that connects to a MIRRORED BITS IED connection via EIA-232 or EIA-485/EIA-422.

The **Settings** tab contains all configurable items for communications. Check the description column for details on each configuration item. Move the slider, or hover your mouse over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Right-click on the title bar above the column headings or click **Options** to show advanced configuration settings. The following text explains some of the MIRRORED BITS-specific settings.

MIRRORED BITS Message Type	
MB	The standard MIRRORED BITS configuration using six data bits, one parity bit, and one stop bit for data encoding.
MB8	MIRRORED BITS using six data bits, one parity bit, and two stop bits for data encoding.
MBT9600	Provide for use over a Pulsar MBT-9600 modem. Set data rate = 9600 A delay of at least 2 ms shall be inserted after each outgoing message RTS shall be reset (to a negative voltage at the EIA-232 connector)
Accept Receive Identification	
	The incoming MIRRORED BITS message will have an encoded address (historically called RXID). Configure this receive address to match the address in the message. The received message is only valid if its RXID matches the Accept Receive Identification. The MIRRORED BITS protocol driver will reject the message if the receive ID in the message does not match the receive address you configured.

Send Transmit Identification	
	The RTAC will encode the outgoing MIRRORED BITS message with this configurable transmit address (historically called TXID). The receiving device will match this address with its receive address to ensure that it has received a valid message.
Receive MIRRORED BITS Bad Channel Pickup	
	The number of seconds a MIRRORED BITS channel must be without communications before the RTAC considers the channel to be no longer functioning. If the channel drops out for more than this configurable number of seconds, the Rx_Channel_Bad output pin asserts.
PPM MIRRORED BITS Unavailable Channel Pickup	
	Used to detect degraded communication on this MIRRORED BITS channel. Communication is still occurring, but the RTAC is dropping some number of packets. The PPM setting specifies an acceptable bad or dropped packet error rate in parts per million (PPM). If the dropped packet rate exceeds this setting, the output pin Rx_Channel_Unavailable asserts. The present value of this calculation is contained in the POU output pin Rx_Channel_Unavailable_PPM. For example, if the RTAC were to drop half the packets, the PPM error rate would be 500000.
Transmission Mode	
	Paced mode will send MIRRORED BITS at a rate of one message every 3 ms to allow for communications with relays that only communicate every quarter cycle (every 4 ms at 60 Hz). Set Transmission Mode to Normal to communicate to other RTACs and for 400-series relays. Note that this setting is locked out and unavailable for Baud Rates of 9600 or less.
Loopback Timeout	
	Automatically disconnect loopback mode after this time-out. Note that the time-out does not initiate loopback. Initiate loopback by forcing the Loop_Back_Without_Data POU pin. See *Example 2.4* for details of performing a MB loopback test.

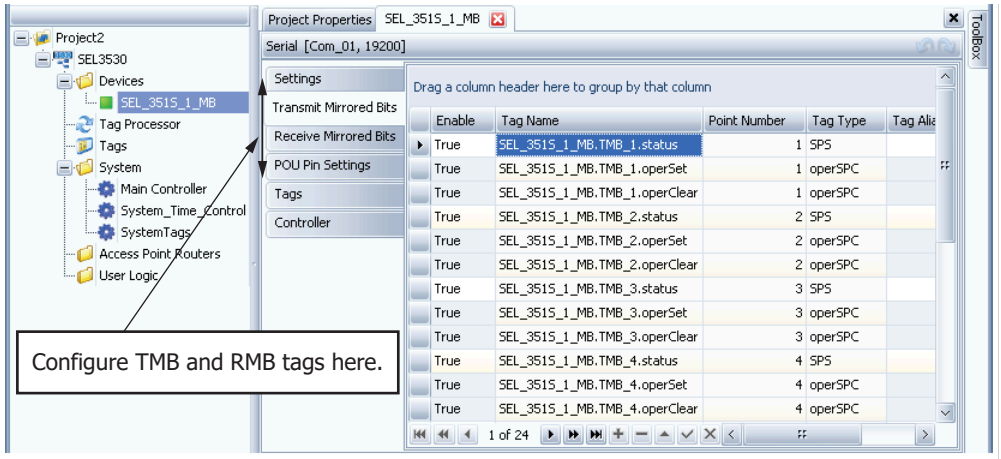

Figure 2.27 Configure MIRRORED BITS Tags

Data Configuration Parameters

Configure default values and other information for transmit and receive MIRRORED BITS. Descriptions of common fields will only be detailed in *Transmit MIRRORED BITS on page 255*.

Step 1. Click on the **Transmit Mirrored Bits** or **Receive Mirrored Bits** tab.

Step 2. Change the names of the tags, as necessary (Receive MIRRORED BITS only).

Step 3. Add alias names, as necessary.

Step 4. Change other point-related information as needed.

Transmit MIRRORED BITS

Transmit MIRRORED BITS populate outgoing messages to IEDs. They have a default value and are set through mapping in the Tag Processor or through custom logic.

Table 2.28 TX MIRRORED BITS Parameters

Parameter	Description	Default
Enable	Set this flag True to enable processing of this point. Set this flag False to disable.	True
Tag Name	The fixed tag name contains the device name and point type (TMB), and it is numbered 1–*n* points.	
Point Number	The point number of these MIRRORED BITS. Note that point numbers are duplicated in sets of three. This is because the attributes, operSet, operClear, and status, belong to the same point.	
Tag Type	See *Data Types on page 1127* for more details.	Each tag has three attributes. Two are controls (operSPC type), and one is a status (SPS type).
Tag Alias	Enter an optional descriptive tag name in this field and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Status Value	The initialized value at startup.	False
Comment	Optional user-entered comment field.	

Receive MIRRORED BITS

Receive MIRRORED BITS are contained in messages that come from another IED.

Table 2.29 RX MIRRORED BITS Parameters

Parameter	Description	Default
Tag Name	The configurable tag name contains the device name and point type (RMB), and it is numbered 1–*n* points.	
Bit Number	The bit in the received MIRRORED BITS message corresponding with this point.	
Channel Fail State	The state to which the RTAC will drive the MIRRORED BITS in the event of channel loss.	True, False, or Previous (last known state)
Pickup Delay	The number of consecutive packets in which an incoming bit must be asserted before the associated receive MIRRORED BITS asserts.	
Dropout Delay	The number of consecutive packets in which an incoming bit must be deasserted before the associated receive MIRRORED BITS deassert.	

MIRRORED BITS Tag

Each MIRRORED BITS point has three main components:

1. **operSet.ctlVal**: A rising-edge change to operSet.ctlVal will set the MIRRORED BITS to a value of 1.
2. **operClear.ctlVal**: A rising-edge change to operClear.ctlVal will set the MIRRORED BITS to a value of 0.
3. **status**: The present state of the MIRRORED BITS.

A rising edge triggers the change, so the values of operSet.ctlVal and operClear.ctlVal must go low before they can trigger another change. For example:

T-0: SEL_351R_1_MB.TMB_1.operSet := TRUE

SEL_351R_1_MB.TMB_1.status becomes TRUE (1)

T+1: SEL_351R_1_MB.TMB_1.operSet := TRUE

No change because operSet is already high

T+2: SEL_351R_1_MB.TMB_1.operClear := TRUE

SEL_351R_1_MB.TMB_1.status becomes FALSE (0)

Figure 2.28 illustrates the relationship of operSet, operClear, and status in the MIRRORED BITS data structure.

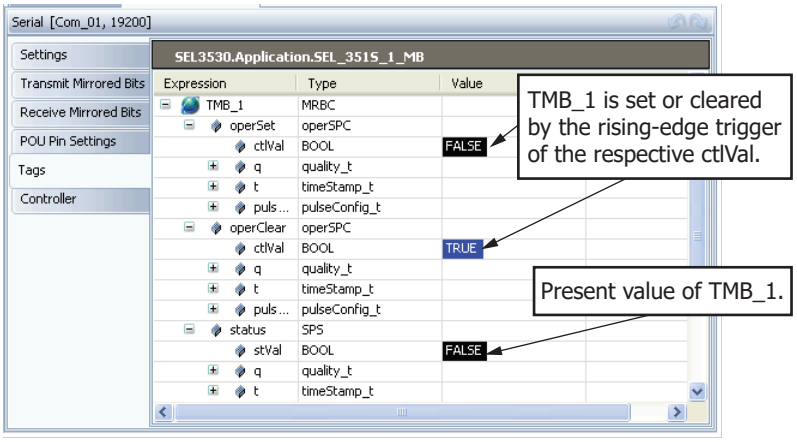

Figure 2.28 Online MIRRORED BITS

Example 2.4 Loopback Test With Controller

This is an example of forcing the Loop_Back_Without_Data POU pin while online to initiate a loopback test. Forcing the pin to TRUE initiates the loopback test. Forcing the pin back to FALSE ends the test.

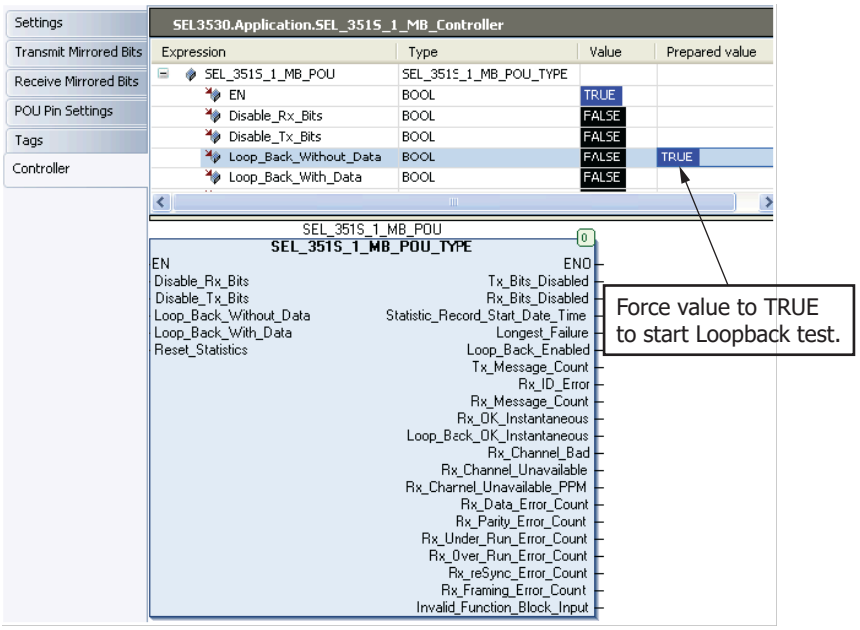
Step 1. Download project to RTAC and stay online.

Step 2. Click on the **Controller** tab.

Step 3. Type **TRUE** in the prepared **Value** column for Loop_Back_Without_Data pin.

> **NOTE**
> The RTAC will only increment the Tx_Message_Count when a transmit bit changes state. It is possible then for the RTAC to transmit many messages without incrementing this counter.

Step 4. Press **<F6>** to force value.



Loopback test begins.

Step 5. Click on **TRUE**, and a dialog box prompts for another forced value.

Step 6. Type **FALSE** in the dialog box, and click **Force**.

Step 7. The value of Loop_Back_Without_Data is False, and the test ends.

Step 8. Enter **<Shift+F6>** to unforce the value.

IEEE C37.118 Synchrophasors

Synchrophasors provide the ability to compare time-stamped power measurements from different devices and physical locations throughout a power system. A device that measures and reports synchrophasors is called a phasor measurement unit (PMU). IEEE C37.118 is the industry standard protocol that defines how to send and receive synchrophasor messages between PMUs and other devices such as the RTAC. A synchrophasor message includes magnitude, angle, and time stamp for each measured quantity. Synchrophasors can provide comparisons of simultaneous measurements from different locations with errors of less than a quarter of an electrical degree.

Configure the IEEE C37.118 client protocol on any of the RTAC serial or Ethernet ports to communicate with any device that supports an IEEE C37.118 server to gather synchrophasor values. You can configure as many as 100 synchrophasor client sessions on the RTAC at any given time. The RTAC also supports 100 synchrophasor server sessions.

Synchrophasor systems often employ phasor data concentrators (PDCs) to collect data from multiple PMUs, align the samples based on a common time stamp, and aggregate the samples into a concentrated data message. These time-aligned data sets can provide a coherent snapshot of wide-area measurements to an end application. A PDC can be a standalone device, supporting data receipt and transmission over a standardized protocol such as IEEE C37.118, or a function within an end-application. The RTAC, as a PDC, supports IEEE C37.118 client and server functionality and applies time alignment to all configured IEEE C37.118 clients. This ensures coherency of the phasor data presented to the SEL-RTAC logic engine as well as any configured IEEE C37.118 servers. The SEL-RTAC IEEE C37.118 client is also capable of reading concentrated data messages from other PDCs, see IEEE C37.118 Client Configuration.

This section describes the configuration and use of the IEEE C37.118 protocol client and server with ACSELERATOR RTAC. For specific information on the IEEE C37.118 protocol, see *IEEE C37.118.2-2011, IEEE Standard for Synchrophasor Data Transfer for Power Systems*.

For a detailed description of client and server concepts and other general information on protocol configuration, see *Overview on page 161*.

IEEE C37.118 System Configuration

Configure the RTAC for basic data concentration and time alignment, as a synchrophasor logic processor and controller, or as a combination of the two. The RTAC provides the option to route synchrophasor data directly between IEEE C37.118 clients or SEL Axion modules and IEEE C37.118 servers, thus bypassing the logic engine. Synchrophasor data channels from IEEE C37.118 clients and Axion modules can optionally be enabled for use as tags in the logic engine. *Figure 2.33* shows the available routing paths for synchrophasor data in the RTAC.

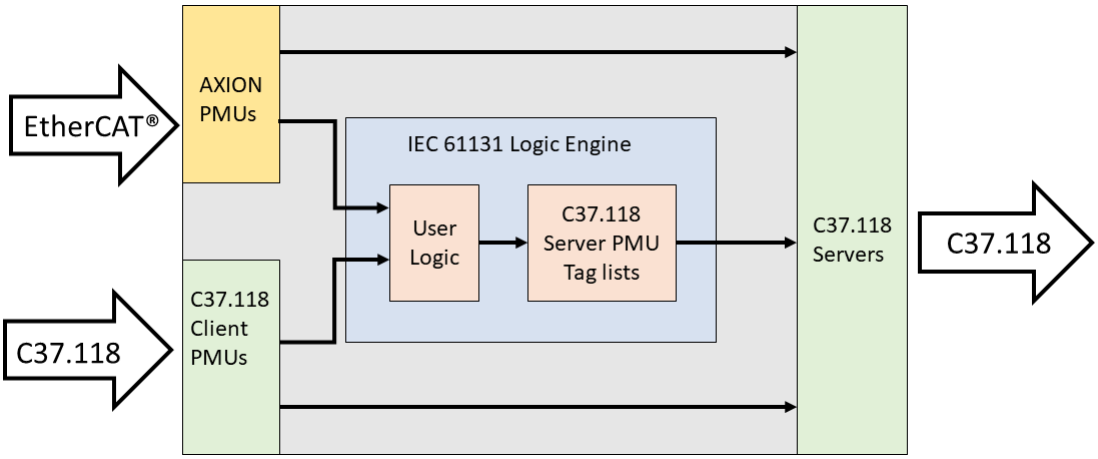


Figure 2.29 SEL RTAC Synchrophasor Data Routing Options

Note that application extensions, such as the Dynamic Disturbance Recorder (DDR) for synchrophasor data archiving, are dependent on the logic engine. Therefore, synchrophasor data channels must be enabled for use as logic engine tags before they can be applied to these extensions.

IEEE C37.118 Client Configuration

Configure an IEEE C37.118 client connection to communicate via serial or Ethernet to PMUs and relays that provide phasor data via the IEEE C37.118 protocol. The RTAC accepts phasor measurement data from these IEDs, makes the PMU data sets directly available to configured IEEE C37.118 servers, and optionally inserts the data into the logic engine.

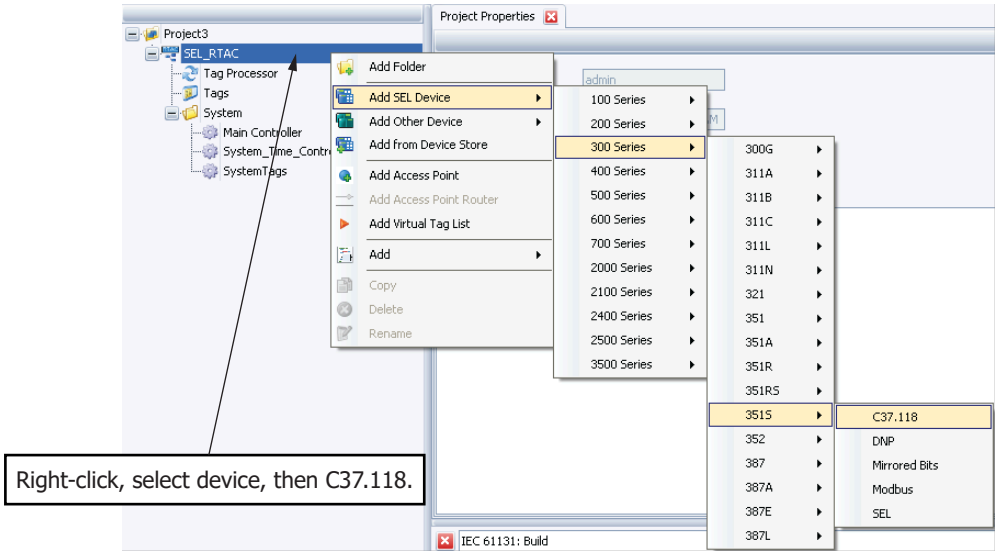

Figure 2.30 Insert IEEE C37.118 Client Device

Insert a non-SEL IEEE C37.118 device by selecting **Other** from the **Insert** ribbon. SEL devices that support IEEE C37.118 (including the SEL-421, SEL-451, SEL-751A, etc.) are preconfigured in ACSELERATOR RTAC. Insert those devices by selecting **SEL** from the **Insert** ribbon.

Give the device connection a unique name and select the connection type as shown in *Figure 2.1*. For Ethernet connections, the combination of the PMUs IP address and the PMUs port must be unique (i.e., two PMUs can have the same IP port number only if those two PMUs have different IP addresses).

By selecting the **Settings** tab, you see all configurable items for communications. Check the **Description** column for details on each configuration item. Move the slider bar or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

PDC Id

Configure the PDC ID for this IEEE C37.118 client. In most configurations where the client is communicating to a single-PMU device, the PDC Id value will match that of the Pmu Id configured on the **PMUs** tab.

Time Variance

The Time Variance setting is an advanced setting on the **Settings** tab of each IEEE C37.118 client. It defines the allowable limit by which an incoming IEEE C37.118 time stamp can be rounded to conform to the expected IEEE C37.118 time stamp.

Add IEEE C37.118 PMUs

Data messages transmitted directly from a PMU generally incorporate a single PMU data set within the data message. Data messages transmitted by a PDC may contain one or more PMU data sets for a given time stamp. Each SEL RTAC IEEE C37.118 client can accept data messages that represent between 1

and 100 individual PMU data sets. Preconfigured SEL IEEE C37.118 clients are preloaded with a single predefined PMU data set when they are added to the project. Non-SEL IEEE C37.118 devices added to the project must be assigned one or more empty PMU data sets that must be configured appropriately. To add a PMU to an IEEE C37.118 client, perform the following:

Step 1. Click on the **PMUs** tab.

Step 2. Click + to add PMUs.

Step 3. Specify the number of PMUs to add to the IEEE C37.118 client and click **Add**.

Step 4. Specify the **Station Name**. The first 16 characters must exactly match the Station Name setting programmed in the IED.

Step 5. Specify the **Pmu Id**. This must match the PMU ID setting programmed in the IED.

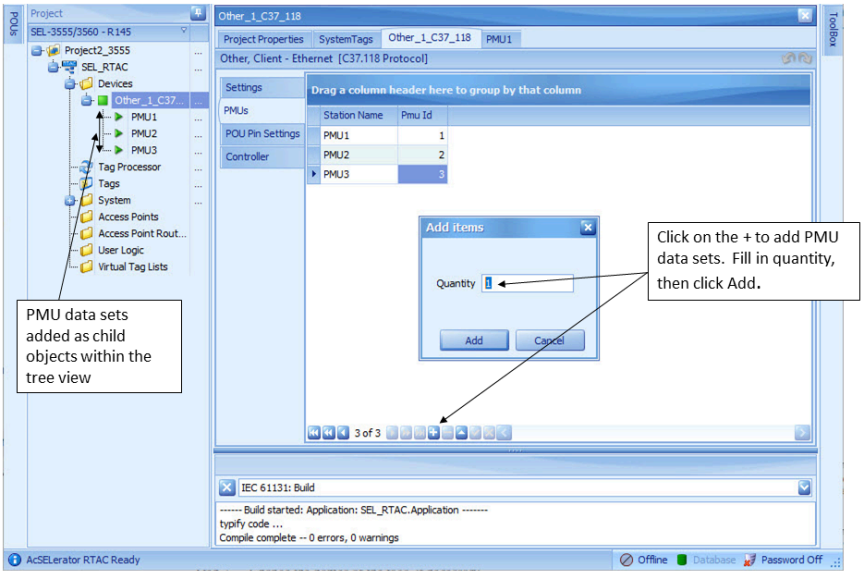

Figure 2.31 Add IEEE C37.118 PMUs

Configure PMU Datasets

Each PMU data set added to an IEEE C37.118 client contains five tabs (Status, Frequency, Phasors, Analogs, and Digitals) that can be configured to represent the full set of measurements and status from a PMU. All channels represented in these tabs use an identical set of parameters.

Table 2.30 Common Settings for PMU Data Set Tags

Parameter	Description
Enable	Enables the channel for direct access by IEEE C37.118 servers
Channel Name	Name as defined in the IED (as many as 16 characters)
Enable Tag	Enable the channel for use in the logic engine (requires Enable = TRUE)
Tag Name	Logic engine tag name for tag enabled channels
Tag Type	IEC 61131 data structures used for tag enabled channels

Channels can be independently enabled and enabled for logic engine use. All enabled channels are directly available to any configured IEEE C37.118 servers. This allows the RTAC to perform basic PDC time alignment and data aggregation without requiring the logic engine for tag mapping between client and server. See *IEEE C37.118 Client Configuration on page 259* for additional information on direct mapping of IEEE C37.118 client PMU data sets to IEEE C37.118 servers.

On each of the Phasors, Analogs, and Digitals tabs, add channels as needed to correspond with the IED data set. Again, SEL IEEE C37.118 clients come preloaded with a single PMU data set with predefined Phasor, Analog, and Digital data channels.

Using IEEE C37.118 Client POU Controller Outputs for Troubleshooting

This section details a subset of useful POU controller output pins. For advanced troubleshooting, set the **Visible** field to True for all tags on the IEEE C37.118 client POU Pin Settings page and observe the **Controller** tab while online with the project.

Unresolved_Tag_Reference_Error and Unresolved_Tag_Reference_Count

These outputs indicate the presence and number of configured data channels that contain a Channel Name setting that does not exactly match any channel name found in the IEEE C37.118 configuration frame received from the connected PMU. The count encompasses all channels amongst all configured PMUs on the IEEE C37.118 client.

Missed_Data_Count

This output is the running count of data messages that have been missed. This number is updated by comparing the most recently received synchrophasor time stamp against the previously received time stamp and comparing the difference to the data rate interval (i.e., 1 / Data_Rate), where Data_Rate is configured on the System Settings page.

Missed data may be a result of network congestion that leads to complete packet loss. It can also result from network latency causing the packet to be received at the RTAC after the synchrophasor time alignment wait period has elapsed, in which case it will be thrown away. You can adjust the duration of the wait period via the Waiting_Period setting on the System Tags page.

Considerations for Logic Engine Enabled Channels

Task Cycle

When channels are optionally enabled for use in the logic engine, consideration needs to be given to the associated Cycle Time setting on the Main Controller settings page. SEL recommends setting Cycle Time to approximately 1 / Data_rate, where Data_Rate is the C37.118 Message Rate setting on the System Tags page.

Mapping From IEEE C37.118 Protocol to Logic Engine Tags

Corresponding logic engine tags will be created for channels that are enabled for use in the logic engine. The IEC tag data structures (e.g., MV, CMV, SPS) will be populated from the IEEE C37.118 data frame.

Status Mapping

Common tag sub-structures, such as timestamp_t and quality_t, will be synchronized across all tags associated with a given PMU data set and mapped as described in tables *Table 2.31* and *Table 2.32*.

Table 2.31 IEEE C37.118 Mapping to timeStamp_t

IEEE C37.118 Field	Manipulations	To Logic Engine Tag
SOC	Convert to local time	.value.dateTime
FRACSEC value	Round via Time Variance setting*	.value.uSec
Fault – Clock Failure		.quality.accuracy = timeAccuracy_t.unspecified
Within 10 s of UTC		.quality.accuracy = timeAccuracy_t.unspecified
Within 1 s of UTC		.quality.accuracy = timeAccuracy_t.unspecified
Within 100 ms of UTC		.quality.accuracy = timeAccuracy_t.unspecified
Within 10 ms of UTC		.quality.accuracy = timeAccuracy_t.T0
Within 1 ms of UTC		.quality.accuracy = timeAccuracy_t.T1
Within 100 µs of UTC		.quality.accuracy = timeAccuracy_t.T2
Within 10 µs of UTC		.quality.accuracy = timeAccuracy_t.T3
Within 1 µs of UTC		.quality.accuracy = timeAccuracy_t.T5
Within 100 ns of UTC		.quality.accuracy = timeAccuracy_t.T5
Within 10 ns of UTC		.quality.accuracy = timeAccuracy_t.T5
Within 1 ns of UTC		.quality.accuracy = timeAccuracy_t.T5
Clock Locked		.quality.accuracy = timeAccuracy_t.T5
STAT bit 13: PMU No Sync = TRUE		.quality.clock_not_synchronized .quality.clock_failure

Table 2.32 IEEE C37.118 Mapping to quality_t

IEEE C37.118 Field	To Logic Engine Tag
STAT bit 15 (Data Invalid) = FALSE STAT bit 14 (PMU Error) = FALSE STAT bit 12 (Sort by arrival) = FALSE	.validity = validity_t.good
STAT bit 15 (Data Invalid) = TRUE STAT bit 14 (PMU Error) = TRUE	.validity = validity_t.invalid
STAT bit 12 (Sort by arrival) = TRUE STAT bit 15 (Data Invalid) = FALSE STAT bit 14 (PMU Error) = FALSE	.validity = validity_t.questionable

Measurement Mapping

Phasor, analog, and Boolean quantities within the PMU data set that are enabled for use in the logic engine will be mapped to respective CMV, MV, and SPS structures as described in *Table 2.33*.

Table 2.33 IEEE C37.118 Measurement Mapping to Logic Engine Tags

IEEE C37.118 Field	Manipulations	To Logic Engine Tag
Phasor	Convert to polar coordinates with angle in degrees	CMV.instCVal.mag CMV.cVal.mag CMV.instCVal.ang CMV.cVal.ang
Analog		MV.instMag MV.mag
Boolean		SPS.stVal

Starting with RTAC firmware version R145-V0, the range and dead-band settings associated with IEEE C37.118 phasors and analogs are no longer included when those data are mapped to CMV and MV tags, respectively. This was done to promote the streaming nature of IEEE C37.118 data. If desired, the range and dead-band settings can be applied to the data in user logic. See the MVRangeAndDeadbandCheck and CMVRangeAndDeadbandCheck functions in *Appendix B: IEC 61131-3 Programming Reference* for more information.

Required System Settings and IEEE C37.118 Client Time Alignment

All PMUs communicating with IEEE C37.118 clients on the RTAC must be configured with the same Nominal_Frequency and Data_Rate as configured in the RTAC system settings.

The RTAC applies time alignment to all IEEE C37.118 clients. The system setting Waiting_ Period specifies how long the RTAC will wait to receive all IEEE C37.118 data messages for a given time stamp amongst all configured IEEE C37.118 clients. The internal counter, to which the Waiting_Period is applied, begins upon the receipt of the first data message with a new time stamp. This relative form of time alignment eliminates the need for RTAC synchronization to a GPS time source. Once the set is received, or the Waiting_Period duration has elapsed, the received samples will be made available to the rest of the system.

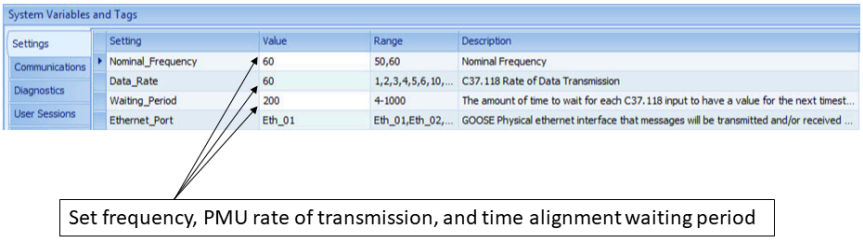

Figure 2.32 System Tags

Ensure configuration of all PMUs to the same frequency and data rate as the RTAC client. The RTAC accepts as valid only PMU messages that match the RTAC settings.

IEEE C37.118 Axion PMU

Each SEL Axion module that provides IEEE C37.118.1-2011-compliant synchrophasor measurements represents an independent PMU with frequency, voltage, and current measurements. The following Axion modules provide such synchrophasor measurements:

- SEL-2245-4 AC Metering Module
- SEL-2245-411 Standard Current and Low-Voltage (LEA) Monitoring Module
- SEL-2245-22 DC Analog Input Extended Range Module
- SEL-2245-221 Low-Voltage (LEA) Monitoring Module
- SEL-2245-42 AC Protection Module

At a minimum, each Axion PMU includes its own PMU ID, station name, frequency measurement, and rate-of-change-of-frequency measurement. Additionally, each Axion PMU provides an optional global PMU ID configuration and a large station name (greater than 16 characters) to support Configuration 3 (CFG3) requests. The Axion automatically synchronizes all modules and their respective synchrophasor measurements to its IRIG-B input time source and requires no additional time alignment from the IEEE C37.118 server.

Settings

An Axion PMU includes the settings shown in *Table 2.34*.

NOTE
Only ac analog input modules that have current input channels (such as the SEL-2245-42 AC Protection module) support the Current Phasor Data Set. Additionally, the SEL-2245-42 AC Protection Module does not support IN or VS.

Table 2.34 Axion PMU Settings

Setting	Range	Description
Station Name	1–255 characters	The station name of the PMU
Current Phasor Data Set	All, Phase, Positive Sequence, None	Enable current phasor channels for the PMU data set

Setting	Range	Description
Voltage Phasor Data Set	All, Phase, Positive Sequence, None	Enable voltage phasor channels for the PMU data set
PMU ID	1–65534	The identifier of the PMU
Global PMU ID	$0–2^{128-1}$	The global identifier (Advanced Setting) of the PMU

Table 2.35 shows the current and voltage channels that the Axion PMU includes for each data set configuration.

Table 2.35 Axion Voltage and Current Settings

Voltage/Current Phasor Data Set	PMU Current Channels	Wye PMU Voltage Channels	Delta PMU Voltage Channel
All	IA, IB, IC, IN, I1, I2, and I0	VA, VB, VC, VS, V1, V2, and V0	VAB, VBC, VCA, V1, and V2
Phase	IA, IB, IC, and IN	VA, VB, VC, and VS	VAB, VBC, and VCA
Positive Sequence	I1	V1	V1
None	No current channels	No voltage channels	No voltage channels

Table 2.36 shows the settings for Axion PMU message rate and message class. All Axion PMUs use the same synchrophasor message rate and message class.

Table 2.36 Axion PMU Rate

Setting	Range	Description
Synchrophasor Message Rate	1, 2, 4, 5, 10, 12, 15, 20, 30, 60, or 120 (Nominal_Frequency = 60) 1, 2, 5, 10, 25, 50, or 100 (Nominal_Frequency = 50)	The synchrophasor messaging rate (messages/second)
Synchrophasor Performance Class	P or M	The synchrophasor performance class

[a] The Synchrophasor Message Rate must match the Data Rate of the IEEE C37.118 server. Message rates of 120 or 100 are only supported on the SEL-3350, SEL-3555, and SEL-3560 hardware with SEL-2245-42, SEL-2245-4, and SEL-2245-411 modules that use a performance class of P (protection).
[b] IEEE C37.118.1-2011 defines two performance classes: P (protection) and M (meter). P-class measurements use less filtering, resulting in faster response times and lower message latency. M-class measurements use more filtering, resulting in slower response times and higher message latency.

Configuration

Configuring an Axion PMU does not require channel mapping or naming. After adding an ac analog input module (see *EtherCAT on page 325*), configure its PMU settings in the **Settings** tab under the PMU grouping, as shown in *Figure 2.33*.

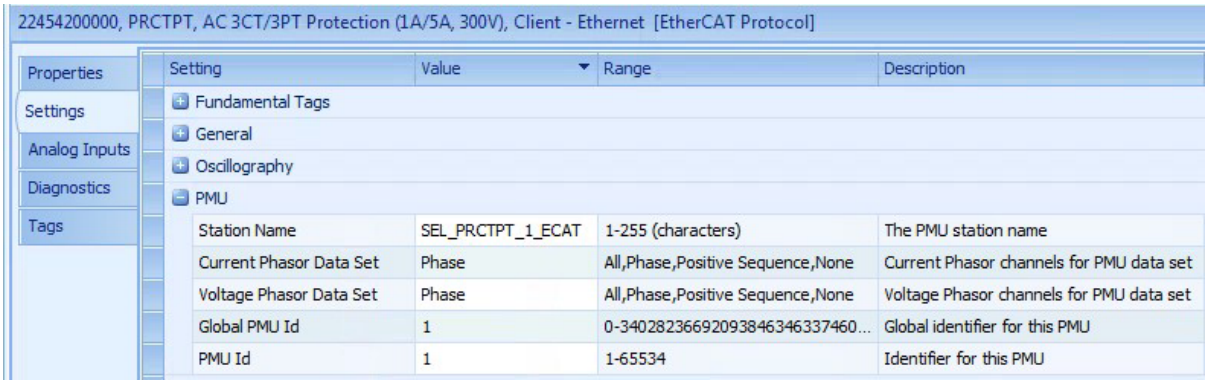

Figure 2.33 Axion PMU Configuration

Add the Axion PMU to an IEEE C37.118 server by selecting the name of the module in the PMU Reference column in the **PMUs** tab of the server, as shown in *Figure 2.34*.

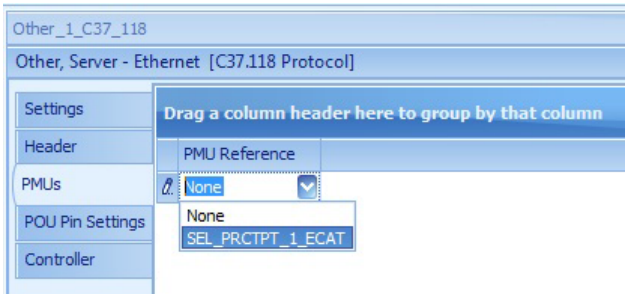

Figure 2.34 Add Axion PMU

Configure the Synchrophasor Messaging Rate and Synchrophasor Performance Class in the **Settings** tab in the EtherCAT I/O Network page. ACSELERATOR RTAC will indicate an error if the Synchrophasor Messaging Rate does not match the data rate of the IEEE C37.118 server.

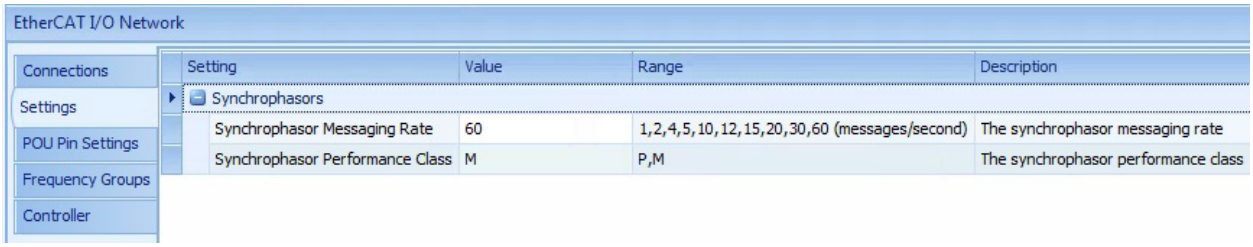

Figure 2.35 Axion PMU Message Rate Settings

IEEE C37.118 Server PMU

A Server PMU is a tag list that defines a custom PMU data set within the RTAC logic engine. Data values, time stamps, and quality status associated with the data set must be specified by the user. This allows for the creation of a virtual PMU within the RTAC logic engine. An IEEE C37.118 server can be configured to transmit any PMU data set defined in the RTAC project, including IEEE C37.118 server PMUs, Axion PMUs *IEEE C37.118 Axion PMU on page 265*, and IEEE C37.118 client PMUs.

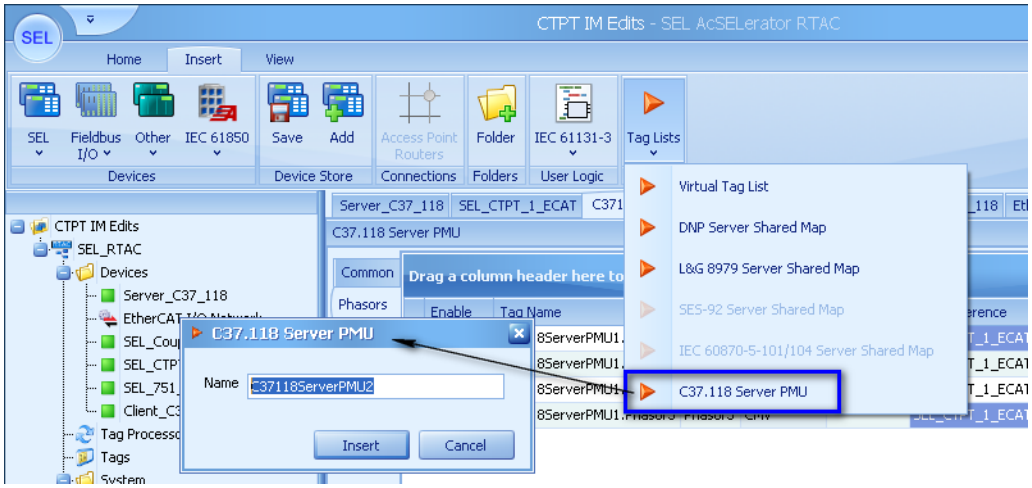

Figure 2.36 Insert IEEE C37.118 Server PMU

Add an IEEE C37.118 server PMU by selecting **Tag Lists** from the **Insert** menu. Give the PMU a unique name.

Server PMU Time Stamps

The IEEE C37.118 server PMU data set is associated with a single time stamp that is derived from either a user-specified time stamp or the system time. The original time stamp is adjusted to conform to the IEEE C37.118-mandated sequence of sub-second values which begin at zero for the top of the second and are evenly divided based on the synchrophasor reporting rate.

Tag Referencing

The IEEE C37.118 server PMU tag list allows the optional specification of a tag reference for all measurements and statuses, as well as a required tag reference for the Time Reference and Quality Reference settings on the **Settings** tab. Creation of a data assignment through use of the tag referencing differs from creation of a data assignment made through the Tag Processor or user logic. Instead of copying the value of the tag from the source tag to the destination tag, the software creates a direct link to the source tag in the memory of the RTAC. Because of this, working with reference tags within RTAC settings differs from use of the Tag Processor or user logic in the following ways:

- No data manipulation (such as scaling, offsetting, or logical math) can be performed on the data prior to assignment.
- Because both the source and destination tag point to the same memory location, a change to the destination tag changes the source tag (the tag reference), and a change to the source tag changes the destination tag.

⚠IMPORTANT
Only tags from communication protocol clients and tag lists are considered valid for tag referencing. This excludes variables declared in custom POUs or GVLs.

Server PMU Configuration

The server PMU contains a tab for general settings as well as tabs for defining measurements and additional status information.

Settings Tab Configuration

The **Settings** tab allows for the definition of global identifiers for the PMU data set as well as settings that can affect how an IEEE C37.118 server handles the data set.

Time Reference

Assign a timestamp_t tag or any tag that contains a timestamp_t structure. This tag is used as the time reference for the PMU data set. This time reference will supersede the timestamp_t substructure on each tag in the data set.

Time Variance (Advanced Setting)

This is the maximum allowable amount that the time reference can be rounded in order to conform to an IEEE C37.118 sequence of sub-second values for the given Data_Rate System Tags setting. If the time reference time stamp deviates by more than the specified time variance, the time stamp assigned to the IEEE C37.118 server PMU will not update. Any IEEE C37.118 servers configured in the RTAC project will observe this as a missing sample. *Table 2.37* shows an example sequence of Time Reference values and the corresponding rounded sub-second time stamps that are assigned to the IEEE C37.118 server PMU data set.

Table 2.37 PMU Time Stamp Rounding Example for System Tags

Time Reference Fraction of Second (in microseconds)	IEEE C37.118 Server PMU Fraction of Second (in microseconds)
1000	0
15000	16667
34000	33333
48500	50000
69000	50000 (No change. Expected 66667 ± 2000)
84000	83333
110000	100000

Streaming (Advanced Setting)

When streaming mode is enabled, the Time Reference and Time Variance settings are disabled. Synchrophasor time stamps for the PMU data set will be derived from the system time. Note that when streaming mode is enabled, the outgoing IEEE C37.118 messages will indicate fault time quality for the entire message and will indicate "PMU Not Synchronized and Unlocked for over 1000 s" for the PMU data set within the message.

Quality Reference

Assign a quality_t tag or any tag that contains a quality_t structure. This tag is used as the quality reference for the PMU data set. This quality reference will supersede the quality_t substructure on each tag in the data set.

Station Name

Assign a station name (1–255 characters) to the PMU data set. An IEEE C37.118 server that includes this data set will apply the station name to the associated STN field of any transmitted configuration frames.

PMU ID

Assign a numerical ID between 1 and 65534 to the PMU data set. An IEEE C37.118 server that includes this data set will apply the ID to the associated IDCODE field of any transmitted configuration frames.

Global PMU ID (Advanced Setting)

Optionally assign a global ID code for the PMU data set. This can be any whole number representable by a 128-bit unsigned integer. An IEEE C37.118 server that includes this data set will apply the global ID to the associated G_PMU_ID field of the CFG3 message, as defined by IEEE C37.118.2-2011. This setting provides support for unique identification in synchrophasor systems with more than 65534 PMUs.

PMU Latitude, Longitude, and Elevation

Optionally assign global coordinates and elevation to the IEEE C37.118 server PMU data set. An IEEE C37.118 server that includes this data set will apply the coordinates and elevation to the corresponding fields in the CFG3 message.

Measurement and Status Configuration

Configure the **Frequency**, **Status**, **Phasors**, **Analogs**, and **Digitals** tabs to fully define the PMU data set that will be made available to one or more IEEE C37.118 servers. Each tab contains a **Tag Reference** column that can be used to map directly from the memory space of an existing tag. If this field is left blank, the **Tag Name** column is enabled. This column specifies the name of the newly created tag which can be populated through user logic in the Tag Processor or a dedicated POU. The **Channel Name** field specifies the data channel name, the first 16 characters of which will appear in the CHNAM field of any outgoing IEEE C37.118 configuration frames transmitted by an IEEE C37.118 server that includes this data set.

Frequency Tab Configuration

The **Frequency** tab allows for the user specification of the frequency and rate-of-change-of-frequency (ROCOF, denoted as DF_DT in settings) quantities to be associated with the IEEE C37.118 server PMU. The inclusion of these quantities is required by the IEEE C37.118 standard. If either tag is disabled, an IEEE C37.118 server that includes this data set will set the invalid data flag (IEEE C37.118 Data Frame STAT bit 15 = TRUE) for the given PMU data set in the outgoing data message.

Status Tab Configuration

The **Status** tab allows for user definition of additional information that is implicit to the IEEE C37.118 protocol.

- **PMTRIG** (PMU trigger) is a Boolean quantity, per PMU data set, in each IEEE C37.118 data message, which allows the PMU to inform an upstream device that a predefined condition has been met. This bit is typically allowed to be driven by user logic in most PMUs and is often used to initiate triggered archiving in upstream PDCs.
- **TREA** (trigger reason) is an integer value that is meant to be set in conjunction with an assertion of the PMTRIG Boolean quantity and is intended to provide additional information about the PMU trigger. The IEEE C37.118 standard specifies predefined interpretations of the trigger reason, as shown in *Table 2.38*.

Table 2.38 Trigger Reason

Bit	Reason
0	Manual
1	Magnitude low
2	Magnitude high
3	Phase angle diff
4	Frequency high or low
5	Df/dt high
6	Reserved
7	Digital
8–15	Available for user definition

Add IEEE C37.118 Data

Step 1. Click on a tag type to add and configure tags.

Step 2. Click + to add tags.

Step 3. Change Channel Names of tags if necessary.

Step 4. Assign a tag reference or populate the Tag Name tag in user logic.

Add as many as 3200 phasor tags, 3200 analog tags, and 4000 digital tags to the IEEE C37.118 server PMU data set by configuring the respective **Phasors**, **Analogs**, and **Digitals** tabs. The first 16 characters of each Channel Name setting, for each channel, will be used as the associated channel name (CHNAM

field) within an outgoing IEEE C37.118 configuration frame that includes this data set. For phasor tags, the Phasor Type will be applied to the phasor type byte within the associated PHUNIT field of an outgoing IEEE C37.118 configuration frame.

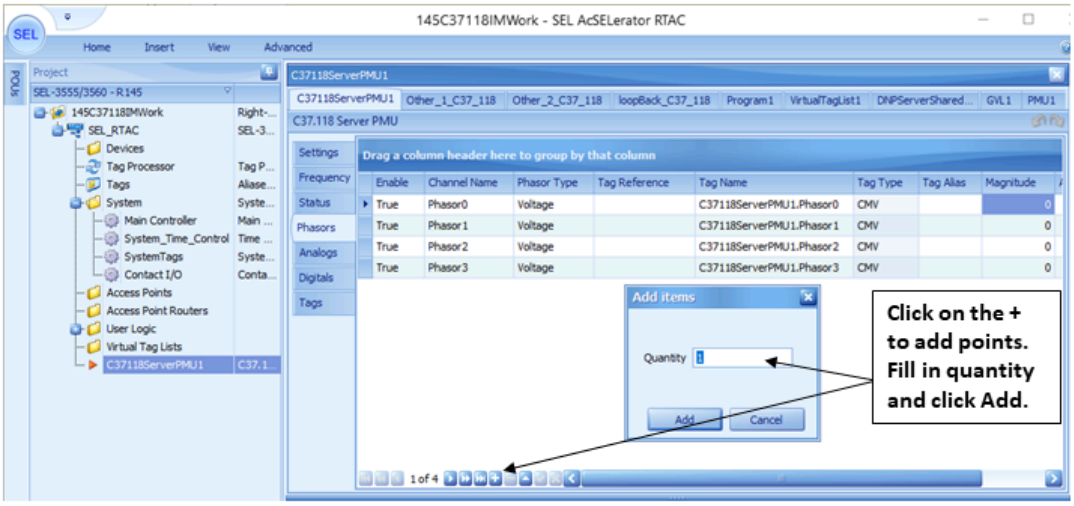

Figure 2.37 Add IEEE C37.118 Tags

Mapping From Logic Engine Tags to IEEE C37.118 Protocol

An IEEE C37.118 server PMU tag list not only allows the specification of a custom PMU data set, but also converts the data, time stamp, and status indicators into an IEEE C37.118-formatted message for consumption by the IEEE C37.118 server. *Table 2.39*, *Table 2.40*, and *Table 2.41* detail the mapping from IEEE C37.118 server PMU tags to the IEEE C37.118 message format.

Table 2.39 timestamp_t Mapping to IEEE C37.118

From Logic Engine Tag	Manipulations	To C37.118 Field
.value.dateTime	Convert to UTC	SOC
.value.uSec	Round subsecond value based on Time Variance setting and System Tags Data_Rate setting.	FRACSEC value
Unlocked Time (Bits 4–5 of STAT field)		
.quality.clock_not_synchronized OR .quality.clock_failure OR .quality.accuracy = IEC_Unspecified		If TRUE: Unlocked for 1000 s or more If FALSE: Locked or unlocked for less than 10 s
FRACSEC Time Quality		
.quality.clock_not_synchronized OR .quality.clock_failure OR .quality.accuracy = IEC_Unspecified		If TRUE: Fault—Clock Failure If FALSE: defer to .quality.accuracy

SPS.stVal		Digital

IEEE C37.118 Server

Add an IEEE C37.118 server to transmit PMU data sets from IEEE C37.118 client PMUs, IEEE C37.118 server PMUs, or Axion PMUs. The IEEE C37.118 server applies time alignment to all PMU data sets added to the **PMUs** tab. See *Required System Settings and IEEE C37.118 Client Time Alignment on page 264* for additional information on synchrophasor time alignment in the RTAC.

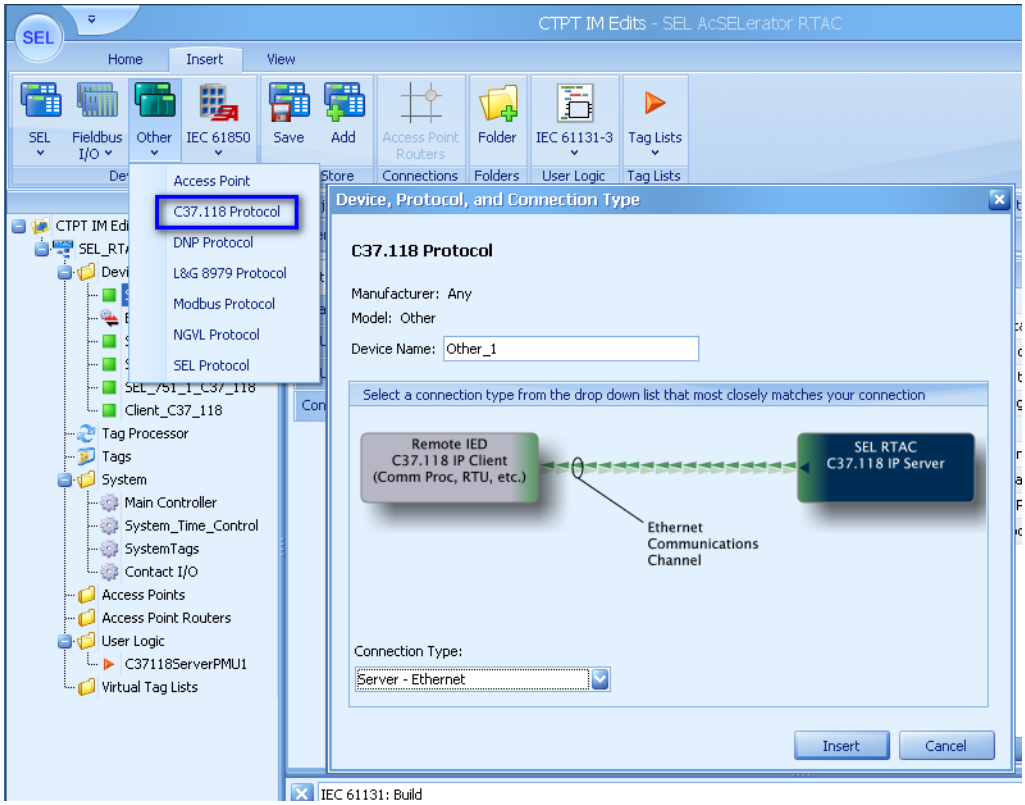

Figure 2.38 Insert IEEE C37.118 Server Device

Insert a non-SEL C37.118 device by selecting **Other** from the **Insert** ribbon. Give the device a unique name and select **Server – Ethernet** under **Connection Type**.

By selecting the **Settings** tab, you see all configurable items for communications. Check the **Description** column for details on each configuration item. Move the scroll bar or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Setting	Value	Range	Description	Comment
Communications				
Transport Scheme	TCP	TCP,UDP,UDP_...	Choose the transport protocols and behavior desired.	
Client IP Address		Valid IPV4 Addr...	The remote IP address where output packets will be sent.	
Auto Client IP Port	True	True,False	Enable automatically inferring the Client IP Port.	
Client IP Port	5712	1-65534	The remote UDP port where output packets will be sent.	
Server IP Port	4712	1024-65534	The local IP port that will accept commands.	
General				
PDC Id	1	1-65534	Phasor data concentrator (PDC) identifier.	
Data Rate	60	1,2,3,4,5,6,10,...	Number of data messages to output per second.	
Waiting Period	200	4-1000 (millisec...	Amount of time to wait for outputs to be available after the first.	

Figure 2.39 IEEE C37.118 Server Device Settings

PDC ID

Assign the global ID for transmitted messages. This will be applied to the IDCODE field in outgoing IEEE C37.118 data messages.

Data Rate

Data rate is the number of data messages transmitted per second. The IEEE C37.118 server does not require that the data rates associated with the incoming PMUs match the Data Rate setting (except for Axion PMUs); however, the incoming data rates and the IEEE C37.118 server Data Rate value must be divisible into each other. For example, an IEEE C37.118 server can use a Data Rate value of 30 messages per second while including PMUs that use data rates of 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, 60, 120, or 240 messages per second. An IEEE C37.118 server cannot, for example, use a Data Rate value of 20 messages per second while including PMUs that use data rates of 3, 6, 12, 15 or 30.

Data rate conversions from higher to lower are accomplished with simple decimation (no filtering applied).

Data rate conversions from low to high are accomplished by the insertion of zero-filled data samples and invalid quality indicators in between valid samples.

The data rate associated with Axion PMUs is required to match the IEEE C37.118 server Data Rate.

Waiting Period

The Waiting Period setting defines the length of time after receiving the first value that the server will wait before determining that data are missing and declaring the message invalid. When this occurs, the value is set to zero and the status of the message is set to invalid in the corresponding IEEE C37.118 server PMU. Additionally, the IEEE C37.118 Controller POU **Missing_Data_Error** pin will assert and the **Missing_Data_Count** will increment.

Communications

Transport Scheme

Transport Scheme configures transport protocols and behavior.

TCP

All messages are sent over a TCP connection. TCP provides a more robust communication path and can recover from some network problems, but adds additional latency.

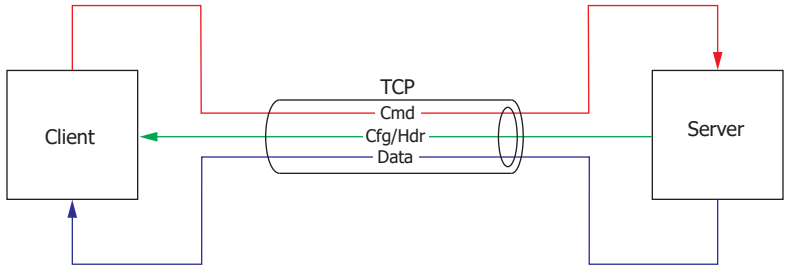

Figure 2.40 TCP Connection

UDP

UDP communicates exclusively over UDP including commands, data, headers, and configuration messages. In this scheme, the client must know the server address and port number. The disadvantage of UDP is that server-to-client communication receives no confirmation, making troubleshooting errors in communication problematic. Because there is no retransmission of data in the event of an error, packets can be permanently lost. In this transport scheme, set **Auto Client IP Port** to **True** to automatically infer the Client IP Port.

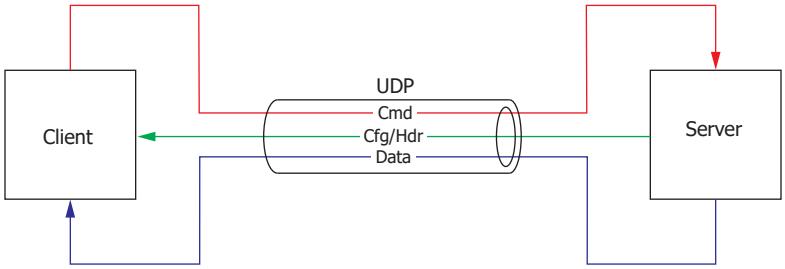

Figure 2.41 UDP Connection

UDP_S

Configuration and data messages are sent from the server to a UDP port on the client machine. No commands are required or accepted by the server. Configuration messages are sent when the IEEE C37.118 server is enabled and once per minute after that. In firmware versions R150-V0 and later, the Spontaneous Configuration setting allows control over the configuration sent once a minute. You can choose to transmit only standard configuration information, only extended configuration information, both types of information, or no configuration information.

UDP_S provides more secure connections because no incoming connections and no additional firewall exceptions are required.

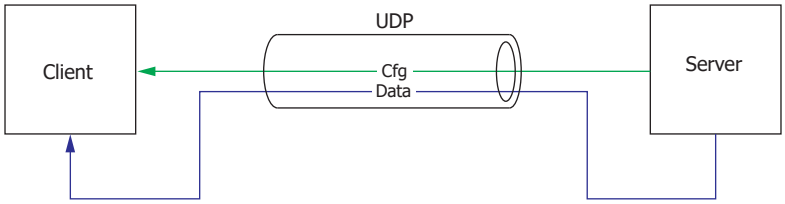

Figure 2.42 UDP_S Connection

UDP_T

Command, configuration, and header messages are transmitted and received over a TCP connection, while the data are transmitted to a separate UDP port on the client machine. This allows the command and configuration messages to have the robust transport of TCP while reducing latency on the data messages through UDP. The TCP connection must be maintained for continued transmission of the data messages.

NOTE

A large Time Variance increases the probability of successfully aggregating the tag, but introduces data to time stamp coherency errors.

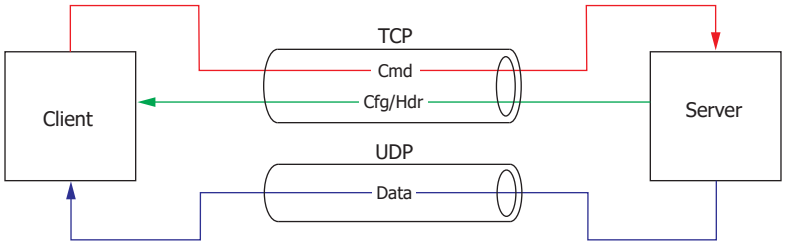

Figure 2.43 UDP_T Connection

UDP_U

Only command messages are transmitted over a TCP connection. The configuration, header, and data messages are transmitted over UDP to the client machine. The TCP connection must be maintained for continued transmission of the data messages.

This is useful in certain firewall situations. Each port is largely unidirectional; the TCP connection is always command messages from the client to the server, and the configuration and data messages are always going to the UDP port on the client.

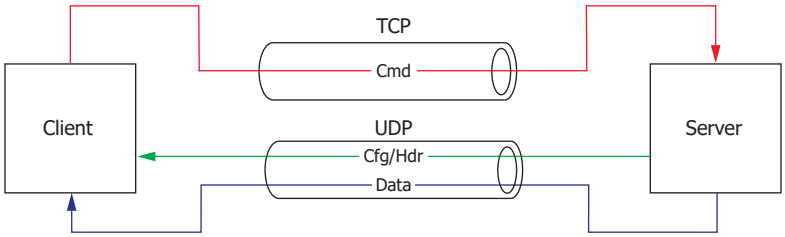

Figure 2.44 UDP_U Connection

Client IP Address

The remote IP address where output packets will be sent when using a connectionless Transport Scheme. Only available when the selected Transport Scheme is UDP, UDP_S, UDP_T, or UDP_U.

Auto Client IP Port

Automatically infer the Client IP Port. Only available in Transport Scheme UDP.

Client IP Port

The remote UDP port where output packets will be sent when using certain connectionless Transport Schemes. Only available when the selected Transport Scheme is UDP_S, UDP_T, or UDP_U.

Server IP Port

Local TCP port that will accept connections.

Enable Multicast

Only available in Transport Scheme UDP_S.

Multicast Group IP Address

The multicast group where output packets are sent.

Ethernet Port

Specify which physical port is used to multicast IEEE C37.118 messages.

Header Tab

The **Header** tab is where the human-readable header is written.

PMU Tab

The **PMU** tab allows PMU data sets to be added to the given IEEE C37.118 server.

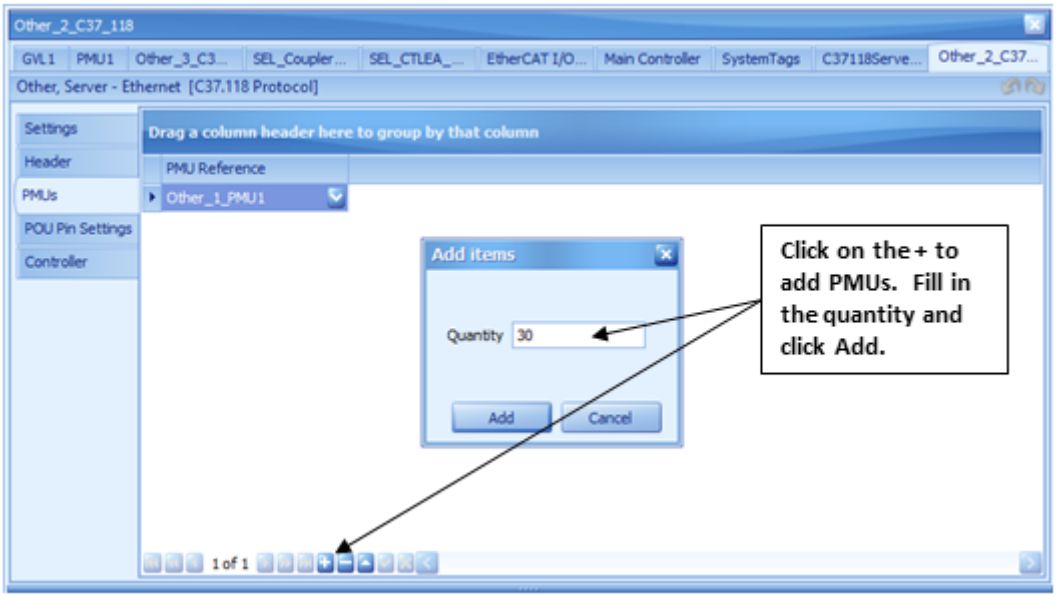

Figure 2.45 Server PMU Reference

Specify a PMU data set from the **PMU Reference** drop-down list. Note that PMU data sets from all configured IEEE C37.118 clients, Axion modules, and IEEE C37.118 server PMU tag lists will be available for inclusion in the IEEE C37.118 server configuration.

Note that the IEEE C37.118 server requires all referenced PMU datasets to use unique station names. Review *IEEE C37.118 Client Configuration on page 259*, *IEEE C37.118 Axion PMU on page 265*, and *IEEE C37.118 Server PMU on page 267* in this manual to identify the location of the associated Station Name settings.

Using IEEE C37.118 Server POU Controller Outputs for Troubleshooting

This section details a subset of useful POU controller output pins. For advanced troubleshooting, set the **Visible** field to TRUE for all tags on the IEEE C37.118 server POU Pin Settings page and observe the **Controller** tab while online with the project.

Missing_Data_Error and Missing_Data_Count

These outputs indicate the presence and quantity of missing data amongst the PMU data sets assigned to the IEEE C37.118 server. The most common cause of this condition is nonsynchronized time references amongst the PMU data sets. The IEEE C37.118 server applies time alignment to the included PMU data sets and will block data when detecting time references that differ more than the **Waiting Period** setting.

IEC 61850

Overview

The RTAC supports the following protocols within the IEC 61850 standard:

- GOOSE Transmit and Receive
- MMS Client
- MMS Server

NOTE
The SEL-3505 currently does not support IEC 61850 MMS client protocol.

Licensing

The RTAC enables GOOSE messaging, MMS client, and MMS server support by verifying the presence of IEC 61850 GOOSE or MMS protocol licensed options. The licensed options are assigned at the factory when you order IEC 61850 GOOSE or MMS on a new RTAC. If you want to add IEC 61850 GOOSE or MMS to an existing RTAC, contact your SEL sales representative. You will receive a firmware update as well as a licensed option upgrade file that you can load into the RTAC through use of the firmware upgrade procedure. The upgrade file will update the RTAC licensed options to enable GOOSE messaging, MMS client, or MMS server support.

Features

The RTAC uses Ethernet and IEC 61850 to support the following features.

MMS Client

Update RTAC tags with data from MMS devices by either polling for DataSets or by receiving reports. You can configure the RTAC for as many as 32 DataSets per IED, with as many as 16 used for polling and as many as 16 used for reporting. Presently most RTACs are limited to communicating with as many as 256 IEDs simultaneously using MMS client protocol. Reporting can be a mixture of buffered and unbuffered reports.

In firmware versions R144-V0 and later, the entryID received with buffered reports is saved to nonvolatile memory every 3 seconds. This maintains a record of which reports in a buffered report have already been processed in case the RTAC loses power, preventing the chance of processing duplicate events from IEDs when power is restored. When a project is downloaded to the RTAC, all entryID values are deleted and the RTAC will process all entryID values from the IED.

In firmware versions R150-V0 and later, the Local_Buffer_OverFlow POU pin indicates when more data have been received than can be processed in a reasonable amount of time. When the MMS client receives multiple data changes for a single point within a single task interval, the subsequent changes for the multiple state changes of that point and all other points received are buffered to be clocked through the logic engine in subsequent processing cycles. The size of this buffer is calculated as the number of configured tags in a single MMS client multiplied by 15. The buffer has a minimum size of 2000 and a maximum size of 5000 state changes. When the buffer becomes full in a single processing cycle, all of the data entries in the buffer are updated to the logic engine. Points with multiple state changes in the buffer only pass on the most recent state change to the logic engine. When this buffer flushing occurs, the Local_Buffer_OverFlow pin asserts for a single processing cycle. This is indicative of a system that may not be optimally configured. Filling this buffer is a symptom of a system where data change in the server faster than the client is able to process for an extended period of time. For example, if a data point in the server changes at a rate of 50 ms and the client task cycle time (the rate at which data are passed into the RTAC's logic engine) is 100 ms, the client will not be able to process all data from the server. In such a case, either the client needs to be configured to process data faster or the server configuration needs to remove the chattering point from the report. The MMS client is capable of processing as many as 60 unsolicited reports between task intervals. SEL recommends that data changes in a server for a single point do not change faster than the configured task cycle interval for more than a duration of 60 seconds.

Functional Naming

In firmware versions R151-V0 and later, working with functionally named data objects is supported for the MMS client and GOOSE receive messages. If a device has data that are functionally named, the tag name in ACSELERATOR RTAC will contain the functional name instead of the product name. To

enable functional naming, set the "supportsLdName" attribute in the SCL to True. This attribute can be found in the client services portion of the services section of the RTAC configuration. For configurations that do not contain the "supportsLdName" attribute, functional named tags will not be created.

```
<Services nameLength="64">
    <FileHandling mms="true" ftp="true" />
    <ClientServices goose="true" maxGOOSE="150" supportsLdName="true"/>
    <SupSubscription maxGo="64"/>
</Services>
```

When this attribute is set when importing an MMS client connection or GOOSE receive message and the IED has an a ldName attribute, ACSELERATOR RTAC will create tags with the functional name instead of product naming. Devices that use both functional naming and product naming will have the corresponding names for tags in the RTAC project.

MMS Server

Configure the MMS server to send data from the RTAC to as many as 10 remote MMS client sessions. Configure logical nodes, tags, and buffered and unbuffered reports by using ACSELERATOR Architect SEL-5032 Software. In firmware versions prior to R147, 25 buffered reports and 25 unbuffered reports are supported. Starting in version R147, 100 buffered reports and 100 unbuffered reports are supported. Map tags in the RTAC to the MMS server shared map tags by using the Tag Processor or IEC 61131 logic. Configure the MMS server to respond to anonymous polls or configure as many as 10 IP addresses for the connected clients.

Peer-to-Peer Real-Time Status and Control

Use GOOSE with as many as 150 incoming (receive) and 150 outgoing (transmit) messages. Map received GOOSE tags to RTAC tags and map any RTAC tags to GOOSE transmit tags.

Configuration

Use Architect to configure the Substation Configuration Description file (.SCD) or SEL Architect Project (selaprj). Import the configuration file into ACSELERATOR RTAC to complete configuration and load the file into the RTAC.

Commissioning and Troubleshooting

Use software such as MMS Object Explorer and AX-S4 MMS from Sisco, Inc., to browse the relay logical nodes and verify functionality.

This section presents the information you need to use the IEC 61850 features of the RTAC:

- *Introduction to IEC 61850 on page 282*
- *IEC 61850 Operation on page 283*
- *MMS Client and GOOSE on page 294*
- *ACSI Conformance Statements on page 318*

Introduction to IEC 61850

In the early 1990s, the Electric Power Research Institute (EPRI) and the Institute of Electrical and Electronics Engineers, Inc. (IEEE) began to define a Utility Communications Architecture (UCA). They initially focused on intercontrol center and substation-to-control center communications and produced the Inter-Control Center Communications Protocol (ICCP) specification. This specification, later adopted by the IEC as 60870-6 TASE.2, became the standard protocol for real-time exchange of data between databases. In 1994, EPRI and IEEE began work on UCA 2.0 for Field Devices (simply referred to as UCA2). In 1997, they combined efforts with Technical Committee 57 of the IEC to create a common international standard. Their joint efforts created the present IEC 61850 standard. The IEC 61850 standard, a superset of UCA2, contains most of the UCA2 specification, plus additional functionality. The standard describes client/server and peer-to-peer communications, substation design and configuration, testing, and project standards. The IEC 61850 standard consists of the parts listed in *Table 2.42*.

Table 2.42 IEC 61850 Document Set

IEC 61850 Sections	Definitions
IEC 61850-1	Introduction and overview
IEC 61850-2	Glossary
IEC 61850-3	General requirements
IEC 61850-4	System and project management
IEC 61850-5	Communication requirements
IEC 61850-6	Configuration description language for substation IEDs
IEC 61850-7-1	Basic communication structure for substations and feeder equipment- principles and models
IEC 61850-7-2	Basic communication structure for substations and feeder equipment- Abstract communication service interface (ACSI)
IEC 61850-7-3	Basic communication structure for substations and feeder equipment- Common data classes
IEC 61850-7-4	Basic communication structure for substations and feeder equipment- Compatible logical node (LN) classes and data classes
IEC 61850-8-1	SCSM-Mapping to Manufacturing Messaging Specification (MMS) (ISO/IEC 9506-1 and ISO/IEC 9506-2 over ISO/ IEC 8802-3)
IEC 61850-9-1	SCSM-Sampled values over serial multidrop point-to-point link
IEC 61850-9-2	SCSM-Sampled values over ISO/IEC 8802-3
IEC 61850-10	Conformance testing

The IEC 61850 document set, available directly from the IEC at *www.iec.ch*, contains information necessary for successful implementation of this protocol. SEL strongly recommends that anyone involved with the design, installation, configuration, or maintenance of IEC 61850 systems be familiar with the appropriate sections of this standard.

IEC 61850 Operation

Object Models

The IEC 61850 standard relies heavily on the Abstract Communication Service Interface (ACSI) models to define a set of services and responses to those services. In terms of network behavior, abstract modeling enables all intelligent electronic devices (IEDs) to act identically. These abstract models are used to create objects (data items) and services that exist independently of any underlying protocols.

These objects are in conformance with the common data class (CDC) specification IEC 61850-7-3, which describes the type and structure of each element within a logical node. CDCs for status, measurements, controllable analogs and statuses, and settings all have unique CDC attributes. Each CDC attribute belongs to a set of functional constraints that groups the attributes into specific categories such as status (ST), description (DC), and substituted value (SV). Functional constraints, CDCs, and CDC attributes serve as building blocks for defining logical nodes.

UCA2 used GOMSFE (Generic Object Models for Substation and Feeder Equipment) to present data from station IEDs as a series of objects called models or bricks. The IEC working group has incorporated GOMSFE concepts into the standard, with some modifications to terminology; one change was the renaming of bricks to logical nodes. Each logical node represents a group of data (controls, status, measurements, etc.) associated with a particular function. For example, the MMXU logical node (polyphase measurement unit) contains measurement data and other points associated with three-phase metering including voltages and currents. Each IED can contain many functions such as protection, metering, and control. Multiple logical nodes represent the functions in multifunction devices.

Logical nodes can be organized into logical devices that are similar to directories on a computer disk. As represented in the IEC 61850 network, each physical device can contain many logical devices and each logical device can contain many logical nodes. Many relays, meters, and other IEC 61850 devices contain one primary logical device where all models are organized.

IEC 61850 devices are capable of self-description. You do not need to refer to the specifications for the logical nodes, measurements, and other components to request data from another IEC 61850 device. IEC 61850 clients can request and display a list and description of the data available in an IEC 61850 server device. This process is similar to the autoconfiguration process SEL communications processors (SEL-2032 and SEL-2030) use. Simply run an MMS browser to query devices on an IEC 61850 network and discover what data are available. Self-description also permits extensions to both standard and custom data models. Instead of having to look up data in a profile stored in its database, an IEC 61850 client can simply query an IEC 61850 device and receive a description of all logical devices, logical nodes, and available data.

Unlike other supervisory control and data acquisition (SCADA) protocols that present data as a list of addresses or indices, IEC 61850 presents data with descriptors in a composite notation made up of components. *Table 2.43* shows how the A-phase current expressed as MMXUAphsA$cVal breaks down into its component parts.

Table 2.43 Example IEC 61850 Descriptor Components

Component Descriptor	Component Type	Description
METMMXU1	Logical Node	Polyphase measurement unit
A	Data Object	Phase-to-ground amperes
phsA	Sub-Data Object	A-phase
cVal	Data Attribute	Complex value

Data Mapping

Device data are mapped to IEC 61850 logical nodes (LN) according to rules defined by SEL. Refer to IEC 61850-5:2003(E) and IEC 61850-7 4:2003(E) for the mandatory content and usage of these LNs. The RTAC logical nodes are grouped under logical devices for organization based on function. See *Table 2.44* for descriptions of the logical devices in an RTAC.

Table 2.44 RTAC Logical Devices

Logical Device	Description
ANN	Annunciator elements-alarms, status values
CFG	Configuration elements-DataSets and report control blocks

MMS

Manufacturing messaging specification (MMS) provides services for the application-layer transfer of real-time data within a substation LAN. MMS was developed as a network-independent data exchange protocol for industrial networks in the 1980s and standardized as ISO 9506. MMS supports complex named objects and flexible services that enable mapping to IEC 61850 in a straightforward manner. This was why the UCA users group used MMS for UCA from the start, and why the IEC chose to keep it for IEC 61850. Because the RTAC uses similar complex named objects, mapping to/from IEC 61850 and other tags in the RTAC is straightforward and easy to do. As an MMS client, the RTAC supports polling for DataSets and reports as defined in ACSELERATOR Architect. As an MMS server, the RTAC can respond to as many as 10 MMS client sessions as well as send reports such as defined in an Architect project.

GOOSE

The Generic Object Oriented Substation Event (GOOSE) object within IEC 61850 is for high-speed control messaging. IEC 61850 GOOSE automatically broadcasts messages containing status, controls, and measured values onto the network for use by other devices. IEC 61850 GOOSE sends the message several times, increasing the likelihood that other devices receive the messages. GOOSE message publication is a persistent function. Once GOOSE is enabled, the IED will continuously publish GOOSE messages, regardless of their contents, until they are disabled. The publication process description indicates when and why the publication rate changes.

IEC 61850 GOOSE objects can quickly and conveniently transfer status, controls, and measured values between peers on an IEC 61850 network. Configure the RTAC to send or receive DataSets with ACSELERATOR Architect. See the Architect instruction manual or online help for more information.

Each IEC 61850 GOOSE sender includes a text identification string (GOOSE Control Block Reference), APP ID field, and an Ethernet multicast group address in each outgoing message. Some devices that receive GOOSE messages use the text identification and multicast group to identify and filter incoming GOOSE messages. The RTAC uses only the APP ID and multicast group to identify and filter incoming GOOSE messages. See *Table 2.42* for details on which logical nodes and attributes the RTAC uses. This information can be useful when searching through device data with MMS browsers.

SCL Files

Substation Configuration Language (SCL) is an XML-based configuration language used to support the exchange of database configuration data between different tools, which may come from different manufacturers. There are four types of SCL files:

- Intelligent Electronic Device (IED) Capability Description file (.ICD)
- System Specification Description (.SSD) file
- Substation Configuration Description file (.SCD)
- Configured IED Description file (.CID)

The ICD file describes the capabilities of an IED, including information on LN and GOOSE support. You can import ICD files from non-SEL IEDs into ACSELERATOR Architect. The SSD file describes the single-line diagram of the substation and the required LNs. The SCD file contains information on all IEDs, communications configuration data, and a substation description. The CID file, of which there may be several, describes a single instantiated IED within the project and includes address information.

DataSets

The RTAC supports publishing and subscribing to DataSets in GOOSE messaging. As an MMS client, the RTAC can also poll IEC 61850 IEDs for MMS DataSets and reports. You can create custom RTAC DataSets in ACSELERATOR Architect. The data tags are placeholders in the DataSet to which you will later map RTAC project data tags in ACSELERATOR RTAC. You can import CID files from other IEDs into Architect to map the IEDs DataSets to GOOSE or MMS messaging.

Within Architect, IEC 61850 DataSets have three main purposes:

- GOOSE: You can use predefined or edited DataSets, or create new DataSets for outgoing GOOSE transmission.
- MMS Client: You can define which data the RTAC will poll via MMS by selecting DataSets and/or reports from other IEDs in the Client Inputs section.
- MMS Server: You can define server sessions with which the RTAC will connect. You can also define the server model, DataSets, and/or reports that the RTAC will send to a polling MMS client.

Supplemental Software

Examine the data structure and values of the supported IEC 61850 LNs with an MMS browser such as MMS Object Explorer and AX-S4 MMS from Sisco, Inc.

Time Stamps and Quality

In addition to the various data values, the two attributes quality and t (time stamp) are available at any time. Creation of a time stamp results upon RTAC detection of a data or quality change.

The time stamp applies to all data and quality attributes (Boolean, Bstrings, Analogs, etc.) in the same fashion when the RTAC detects a data or quality change. Time stamps within GOOSE are in Universal Time (UTC) format but the RTAC database converts these to and from RTAC system time.

The RTAC uses GOOSE quality attributes to indicate the quality of the data in its transmitted GOOSE messages. Under normal conditions, all attributes are zero, indicating good quality data. Internal status indicators provide the information necessary for the device to set these attributes.

GOOSE Processing and Performance

SEL devices support GOOSE processing as defined by IEC 61850-7-1:2003(E), IEC 61850-7-2:2003(E), and IEC 61850-8-1:2004(E).

GOOSE Construction Tips

- Quality bit strings SEL devices publish are not generally useful in determining the quality of associated data because the SEL IEDs suspend publication of GOOSE messages if any quality attribute fails. Therefore, receipt of the message indicates that all quality attributes are normal. Do not include quality bit strings in published GOOSE messages unless some other type of IED requires this.
- Make GOOSE publications as small as possible. Include in the GOOSE publication only the information subscribing relays require.
- Give higher VLAN priority tags to more important GOOSE. This allows the network to preferentially forward those GOOSE to the subscribers, and it also gives a subscribing RTAC an indication that the more important GOOSE should be decoded before lower priority GOOSE.

GOOSE Subscription (Receive) Processing

The RTAC supports as many as 150 GOOSE subscriptions. GOOSE messages that arrive at the relay are subjected to the following processing steps.

NOTE
The Sync_Automation_To_GOOSE_RX System Tag, when True, immediately schedules execution of the automation task upon receipt of a subscribed GOOSE message with a changed stNum value. To enable this setting, the project must contain an EtherCAT I/O network, located in the automation task.

Filter

The RTAC inspects each message for the proper multicast MAC address and GOOSE App ID. If those parameters match values the RTAC expects for one of the GOOSE subscriptions, then the RTAC passes the message on to the next level of processing. Otherwise, the RTAC discards the message. Each message on the LAN must have a unique combination of multicast MAC address and GOOSE App ID.

Buffer

The RTAC retains the most recent arrival for each of as many as 150 subscriptions. If a subsequent GOOSE arrives for a subscription that already has a buffered message, then the RTAC discards the earlier arrival.

Header Decoding

Each message contains a header that indicates the status of the message. The RTAC ignores the remainder of the message if any of four indicators in the message header is true:

Configuration Mismatch

The configuration number of the incoming GOOSE changes.

Needs Commissioning

This Boolean parameter of the incoming GOOSE message is true.

Test Mode

This Boolean parameter of the incoming GOOSE message is true.

State Number

This parameter is the same as the last time the message was decoded. State number increments when the contents of the message change, so if the state number is unchanged, there is no reason to decode the rest of the message.

The RTAC decodes and processes a message for which header decoding indicates message validity.

GOOSE Simulation Mode

In firmware versions R151-V0 and later, simulation mode (as described by the IEC 61850 standard) for GOOSE is available.

Turning Simulation Mode On and Off

Simulation mode is managed via the data object CFG.LPHD.Sim in the RTAC data model. Any other LPHD.Sim data object in the RTAC's data model will not turn simulation mode on or off. If CFG.LPHD.Sim is not included in the data model, Simulation mode is effectively always turned off or disabled.

Simulation mode can be managed either through the MMS server interface or through the logic engine. Access from the logic engine allows for the RTAC's HMI or another protocol connection to pass information into the logic engine to manage the state of Simulation mode. The CFG.LPHD.Sim object can be either an SPC or SPS data type. Configuring the data type of CFG.LPHD.Sim to be of type SPS restricts control of Simulation mode to only the logic engine, although its status can still be read via the MMS server interface. Configuring CFG.LPHD.Sim as an SPC allows control from either the MMS server interface or the logic engine. By default, CFG.LPHD.Sim is configured as an SPC with a control model of direct enhanced security.

Simulation Mode Processing

The RTAC will treat a GOOSE message as simulated when either the simulation bit is set in the GOOSE header or in the GOOSE PDU. Transitioning between simulated and non-simulated messages when CFG.LPHD.Sim is either TRUE or FALSE will cause the POU pin New_Data to assert for a single processing cycle. POU pin Sequence_Error will not assert during a transition between simulated and non-simulated messages. POU pin SimSt reflects whether the GOOSE message is currently processing simulated or non-simulated messages. LGOS (Logical Node for GOOSE Subscription) statistics are updated based upon the current message type that is currently being processed.

When CFG.LPHD.Sim transitions to TRUE, all non-simulated GOOSE message processing will continue unchanged until that GOOSE receive instance receives a simulated GOOSE message. At that point and while CFG.LPHD.Sim remains TRUE, that GOOSE receive instance will only process simulated messages. When CFG.LPHD.Sim transitions to FALSE, all processing of simulated goose messages stops. The descriptions below help provide examples of this behavior in various states of GOOSE message communication status.

When CFG.LPHD.Sim transitions to TRUE, the following processing occurs in the four possible situations that may exist when the transition occurs:

- **Receiving Goose messages simultaneously with and without the simulation bits set.** The POU pins will have the following behavior: the Offline bit will remain deasserted, new_data will assert for a single processing cycle, and SimSt will assert. The logic engine will populate with data from the simulated GOOSE message. If the time to live expires for the simulated GOOSE message, Offline will assert, SimSt will remain asserted, and the non-simulated messages that are being received will not be processed until CFG.LPHD.Sim deasserts.
- **Receiving only non-simulated GOOSE messages.** The POU pins will have the following behavior: both the Offline bit and SimSt will remain deasserted. Logic engine tags will continue to update from the non-simulated GOOSE message data. Normal processing of the GOOSE message will occur (i.e., time to live expiration and receipt of new GOOSE messages will deassert and assert the Offline bit) until a message with a simulation bit is set. After that point, while CFG.LPHD.Sim is TRUE, the GOOSE receive instance will only process simulated GOOSE messages until CFG.LPHD.Sim becomes FALSE.

- **Receiving only simulated GOOSE messages.** The POU pins will have the following behavior: the Offline bit will transition from TRUE to FALSE, new_data will assert for a processing cycle, and SimSt will transition to TRUE. Logic engine tags will update with data from the simulated GOOSE message. While CFG.LPHD.Sim is TRUE, only simulated messages will be processed.
- **Receiving no GOOSE messages.** The POU pins will have the following behavior: the Offline bit will remain TRUE. If non-simulated GOOSE messages are received, they will be processed until a simulated GOOSE message is received. From that time until CFG.LPHD.Sim is FALSE, only simulated GOOSE messages will be processed.

LGOS Statistics

In firmware version R151 and later projects, LGOS logical nodes are automatically added to the MMS server data model in the CFG logical device when the CID class file version is 8 or later when using ACSELERATOR Architect.

GOOSE receive message statistics in the LGOS nodes are updated at the main task cycle rate regardless of whether the GOOSE receive message is processed in the main or automation thread. The data objects in the LGOS logical node are updated with the same information from the POU pins on each GOOSE receive message. See *GOOSE Receive POU Pins on page 289* for additional information on the data objects. POU pins are named similarly to the LGOS data objects.

The validity of all LGOS data objects is driven by the ENO POU pin on the corresponding GOOSE receive message. If ENO is TRUE, validity of the data objects in LGOS will be Good. If ENO is FALSE, validity of the data objects in LGOS will be Invalid.

GOOSE Receive POU Pins

Pin Name	Pin Type	Description	Default
EN	Input BOOL	If FALSE, the GOOSE_RX function block will not perform any GOOSE processing and will not process any changes to other input or output pins. Any received GOOSE messages will be discarded.	TRUE
Disable_Tag_Updates	Input BOOL	When TRUE, tags associated with the GOOSE message will not update with information from received GOOSE messages	FALSE
Reset_Statistics	Input BOOL		FALSE
ENO	Output BOOL	When TRUE, the received GOOSE message is processed. When FALSE, the received GOOSE message is discarded.	FALSE
Offline	Output BOOL	When TRUE, indicates that the time to live has expired without receipt of the configured GOOSE message. When FALSE, indicates the configured GOOSE message is received and processed.	FALSE
gocbRef	Output STRING	The ObjectReference to the GOOSE control box that this GOOSE message is associated with. Populated from the SCL configuration.	Populated from SCL

Pin Name	Pin Type	Description	Default
goID	Output STRING	Displays the received goID in the received GOOSE message	Populated from SCL
datSet	Output STRING	Displays the configured data set in the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
confRev	Output UDINT	Displays the configuration revision from the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
RxConfRevNum	Output UDINT	Displays the confRev value from the received GOOSE message	0
Dest_MAC_Address	Output STRING	Displays the destination MAC address from the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
VLAN_Priority	Output STRING	Displays the VLAN priority from the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
VLAN_ID	Output STRING	Displays the VLAN id from the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
APPID	Output STRING	Displays the APPID from the GOOSE control block. Populated from the SCL configuration.	Populated from SCL
Bad_Configuration	Output BOOL	When TRUE, indicates a configuration or settings problem. Received GOOSE messages will not be decoded when this pin is TRUE.	FALSE
Config_Mismatch	Output BOOL	When TRUE, indicates that the GoID, DatSet, ConfRev, or number of dataset entries does not match between the SCL configuration and the received GOOSE message. Tags associated with the GOOSE message do not update when this pin is TRUE.	FALSE
timeAllowedtoLive_Exceeded-_Count	Output UDINT	Counts the number of times the timeAllowedtoLive timer expired without receipt of a GOOSE message	0
ASN_Decode_Failure	Output BOOL	When TRUE, the last received GOOSE message encountered an ASN.1 decoding error. This pin will remain asserted until a GOOSE message is successfully decoded without error.	FALSE
Sequence_Error	Output BOOL	This pin will be asserted for a single processing cycle when any of the following conditions occur: ➤ The value of stNum incremented more than once. ➤ The value of stNum incremented by one, but sqNum > 0. ➤ The value of stNum is unchanged, but sqNum incremented more than once.	FALSE
New_Data	Output BOOL	Asserts for a single processing cycle when stNum in the received GOOSE message has changed, or when a switch between non-simulated and simulated GOOSE processing has occurred	FALSE
timeAllowedtoLive	Output TIME	The time allowed to live from the last GOOSE message received	T#0s
stNum	Output UDINT	The state number from the last GOOSE message received	0
sqNum	Output UDINT	The sequence number from the last GOOSE message received	0
OosCnt	Output UDINT	The number of messages received where stNum or sqNum was not the expected value. Typically a running count of the number of sequence error pin assertions.	0

Pin Name	Pin Type	Description	Default
MsgLosCnt	Output UDINT	Accumulation of the estimated number of messages lost due to out-of-sequence errors. Increments by the number of missed state number changes plus the number of missed sequence numbers.	0
MaxLosCnt	Output UDINT	Maximum number of estimated Messages lost due to a single out-of-sequence error	0
test	Output UDINT	The status of test/simulation bit from the last received GOOSE message	0
ndsCom	Output BOOL	The Needs Commissioning bit from the last received GOOSE message	FALSE
SubSt	Output BOOL	TRUE if subscription is receiving messages and TTL has not expired; FALSE otherwise	FALSE
SimSt	Output BOOL	Simulation status of the subscription. TRUE when Simulation mode is enabled and a GOOSE message is received with the Simulation bit set; FALSE otherwise.	FALSE
ErrSt	Output ENUM	0: ok 1: device_disabled 2: confrev_mismatch 3: needs_commissioning 4: message_corrupted 5: ttl_expired 6: out_of_sequence	1
DecErrCnt	Output UDINT	Count of messages that were decoded sufficiently enough to be associated with the subscription, but which failed subsequent decoding	0
TotDwnTm	Output REAL	The time for which ErrSt has been greater than a value of 2 (device_disabled). Accuracy of this time is dependent upon configured main task cycle time.	0.0
MaxDwnTm	Output REAL	Maximum number of seconds that the subscription has been in an error state (i.e., the maximum value of TotDwnTm)	0.0

GOOSE Publication (Transmit) Processing

The RTAC supports as many as 150 GOOSE publications. Each publication can contain data from any logical node in the RTAC. The RTAC processes GOOSE at the rate of the task cycle time. GOOSE can run as part of the Automation Task or as part of the Main Task. An RTAC project that contains a mixture of protocols or large configurations may require more processing time for GOOSE processing than a project dedicated to GOOSE messaging.

Transmit Interval

The retransmit interval of GOOSE messages in the RTAC is based on the two settings min time and max time, which you configure in the CID file in the ACSELERATOR Architect project. If these settings are not a multiple of the task cycle time in which GOOSE is assigned, the RTAC will use a multiple of the task cycle time that is closest to the actual min time and max time values from the CID file.

When the RTAC detects a data change of one or more GOOSE tags, it will transmit the change in a GOOSE message. Following an interval of min time, the RTAC retransmits the previous GOOSE message. The sequence number of each retransmitted message is incremented to indicate it is not an original message resulting from a data change. The RTAC then waits double the length of min time (2 • min time), increments the sequence number, and retransmits the same message. The RTAC continues to double the last retransmit interval, increment the sequence number, and retransmit the message. When the transmit interval exceeds max time, the RTAC uses max time as the retransmit interval for subsequent retransmits until the RTAC detects another data change.

Ethernet Port Setting for GOOSE Messages

In RTAC firmware versions R150-V0 and later, the RTAC supports individual GOOSE messages configured on different Ethernet interfaces. The following subsections explain which Ethernet ports in the RTAC support IEC 61850 GOOSE, how to configure GOOSE messages on different Ethernet ports, and how different configurations affect performance.

Supported Ethernet Ports

Table 2.45 lists the RTAC devices and the Ethernet ports that support GOOSE. (Note that IEC 61850 GOOSE is not supported on **ETH F** on any devices that have a front panel Ethernet port).

Table 2.45 GOOSE Ethernet Ports on RTAC Devices

Device	Ethernet Ports That Support GOOSE
SEL-3505, SEL-3505-3	**ETH 1**, **ETH 2**
SEL-2241 (Axion)	**ETH 1**, **ETH 2**
SEL-3530, SEL-3530-4	**ETH 1**, **ETH 2**
SEL-3354	**ETH 1**, **ETH 2**
SEL-3350	**ETH 1**–**ETH 4**
SEL-3555	**ETH 1** and **ETH 2** (standard); **ETH 3**–**ETH 10** available with additional PCI cards
SEL-3560S	**ETH 1**, **ETH 2**
SEL-3560E	**ETH 1** and **ETH 2** (standard); **ETH 3**–**ETH 6** available with additional PCI card

While the RTAC does require a license to publish or subscribe to GOOSE messages, no additional licensing is required to use any available Ethernet ports for GOOSE Transmit or GOOSE Receive messages.

Configuration of GOOSE Messages on Multiple Ethernet Ports

The process of configuring GOOSE on multiple interfaces is performed in ACSELERATOR RTAC. The process of configuring GOOSE messages in ACSELERATOR Architect is the same regardless of whether the user intends to configure GOOSE messages on multiple Ethernet ports. Substation Configuration Language (SCL) allows a GOOSE message to define an

association with a physical port. If the imported Substation Configuration Description (SCD) file contains such information, the GOOSE message will use a specific port as the initial value for the Ethernet port associated with that GOOSE message. Additionally, there are no settings on the RTAC web interface associated with GOOSE messages.

After the IEC 61850 configuration has been set in the RTAC project, the GOOSE Transmit and GOOSE Receive messages each have a setting for **Ethernet Port**, as shown in *Figure 2.46*. The drop-down is populated with the list of Ethernet ports that are available to receive or transmit GOOSE messages. Each GOOSE message Ethernet port setting only supports one Ethernet interface—it is not possible to process the same GOOSE message on multiple Ethernet ports. The port on which the GOOSE message is processed cannot be dynamically changed in IEC 61131 logic. Note that setting the Ethernet port in the ACSELERATOR RTAC project overrides any Ethernet port assignments that were made in the SCL software.

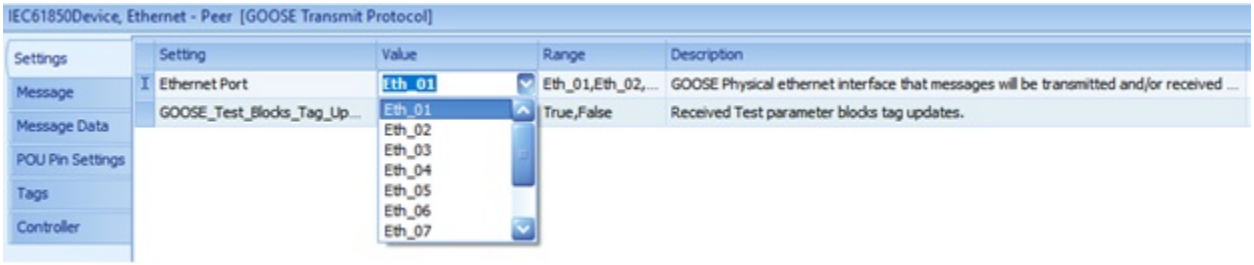

Figure 2.46 GOOSE Message Ethernet Port Setting

There is no limitation on the number of GOOSE messages on an Ethernet interface. Additionally, in ACSELERATOR RTAC projects with firmware versions R150-V0 and later, the Ethernet port setting in systemTags (which previously configured all GOOSE messages) is no longer present (i.e., GOOSE messages are no longer automatically set to the same Ethernet port when saving).

There are no restrictions with any combination of GOOSE messages operating in either the Main task or the Automation task on any Ethernet interface.

Configuring GOOSE messages on different Ethernet interfaces can be done alongside port configuration such as port bonding, bridging, and Parallel Redundancy Protocol (PRP). The port configuration for bridging/bonding/PRP is performed in the RTAC web interface (see *Section 7: Security and Account Management*). When configuring GOOSE on multiple interfaces and changing the port configuration, consider the following:

- **Bridging**: Any GOOSE receive message that is configured on an Ethernet interface which is a part of a bridge can be received and passed to the logic engine on any other Ethernet interfaces in the bridge. Similarly, Any GOOSE transmit message that is configured on a bridged Ethernet port will be published on both bridged ports.
- **Bonding**: GOOSE transmit and receive messages that are configured on any ports associated with a bonded configuration are processed on the active port of the bond.
- **PRP**: Parallel Redundancy Protocol can be enabled on the Ethernet ports of the RTAC from the web interface (detailed in *Section 7: Security and Account Management*). Any GOOSE transmit messages that are configured on Ethernet ports which are part of a PRP configuration

will be published on both Ethernet ports. GOOSE receive messages configured on any interface associated with a PRP configuration can be received and processed on any port that is associated with that PRP configuration.

Performance

When configuring GOOSE transmit and GOOSE receive messages to Ethernet ports, there is no noticeable performance difference in a project that uses a single Ethernet port for all GOOSE messages compared to the same project that spreads the GOOSE messages over multiple Ethernet ports. However, when GOOSE transmit and receive messages are segregated to different Ethernet ports (for example, all transmit messages on Port 1 and all receive messages on Port 2), there may be a reduction in CPU usage and task cycle time. Depending on the configuration and amount of data processed, the average reduction is between 5 and 10 percent.

The maximum size, or GOOSE Capacity, of a configured GOOSE dataset remains the same whether the GOOSE messages are configured on different Ethernet ports or a single Ethernet port.

MMS Client and GOOSE

Overview

Many IEC 61850 settings, including subscriptions to incoming GOOSE messages, are configured with ACSELERATOR Architect.

Architect

Architect enables protection and integration engineers to design and commission IEC 61850 substations containing SEL IEDs.

Engineers can use Architect to do the following:

- Organize and configure all SEL IEDs in a substation project.
- Configure incoming and outgoing GOOSE messages.
- Edit and create DataSets for GOOSE or MMS.
- Edit and create MMS client DataSet and report polling configurations.
- Configure MMS server sessions as anonymous (reply to any MMS client poll) or specific by identifying as many as 10 MMS client IP addresses.
- Configure the MMS server model to include logical devices and logical nodes, which are placeholders for tags that you will later map to actual tags in the RTAC project.
- Read non-SEL IED Capability Description (ICD) and Configured IED Description (CID) files and determine the available IEC 61850 messaging options.
- Use or edit preconfigured DataSets for reports.
- Load IEC 61850 CID files into SEL IEDs.

- Generate SCD or SELPRJ configuration files for import into ACSELERATOR RTAC.
- Generate ICD files that will provide SEL IED descriptions to other manufacturers tools so they can use SEL GOOSE messages and reporting features.

Architect provides a graphical user interface (GUI) for engineers to select, edit, and create IEC 61850 GOOSE messages important for substation protection, coordination, and control schemes. The engineer can also select, edit and create IEC 61850 MMS client polling definitions as well as DataSets and reports for IEC 61850 MMS server for the RTAC. Typically, you first drag icons representing IEDs from the IED Palette to a substation container (in the Project Editor window), then edit the outgoing GOOSE messages or create new ones for each IED. You can also select incoming GOOSE messages for the RTAC to receive from any other IEDs in the domain. Architect has the capability to read other manufacturers ICD and CID files, enabling you to map the data seamlessly into SEL IED logic. See the Architect online help for more information.

NOTE
Some non-SEL ICD and CID files may contain IED definitions where an IED name is configured the same as a logical device name. This is not supported in the RTAC.

MMS Client and GOOSE Configuration

Use Architect to configure all GOOSE transmit and receive messages, as well as to define MMS client inputs for connected devices.

Step 1. Open a new project in Architect by selecting **New Project** in the Project Editor pane.

Step 2. Drag an SEL_RTAC IED icon from the IED Palette onto the Project Editor. This is the RTAC you are configuring for IEC 61850 messaging.

Step 3. Drag the icons for the IEDs that will communicate to the RTAC from the IED Palette onto the Project Editor pane. You can import non-SEL ICD files into the **IED Palette** by right-clicking in the IED Palette pane and selecting **Import ICD**.

Step 4. Create new and edit existing DataSets. Remember that tags in the RTAC DataSets are placeholders for tag types. You can map project tags later in ACSELERATOR RTAC.

Step 5. Configure GOOSE Receive and GOOSE Transmit messages, if applicable.

Step 6. For MMS client configuration, click the **Client Inputs** tab. The Project Editor pane will display all DataSets and reports available from the IEDs. From the **Source** window, select the DataSets and reports you want the RTAC to gather from the IEDs and move these to the **Inputs** window tab. See *Figure 2.47*.

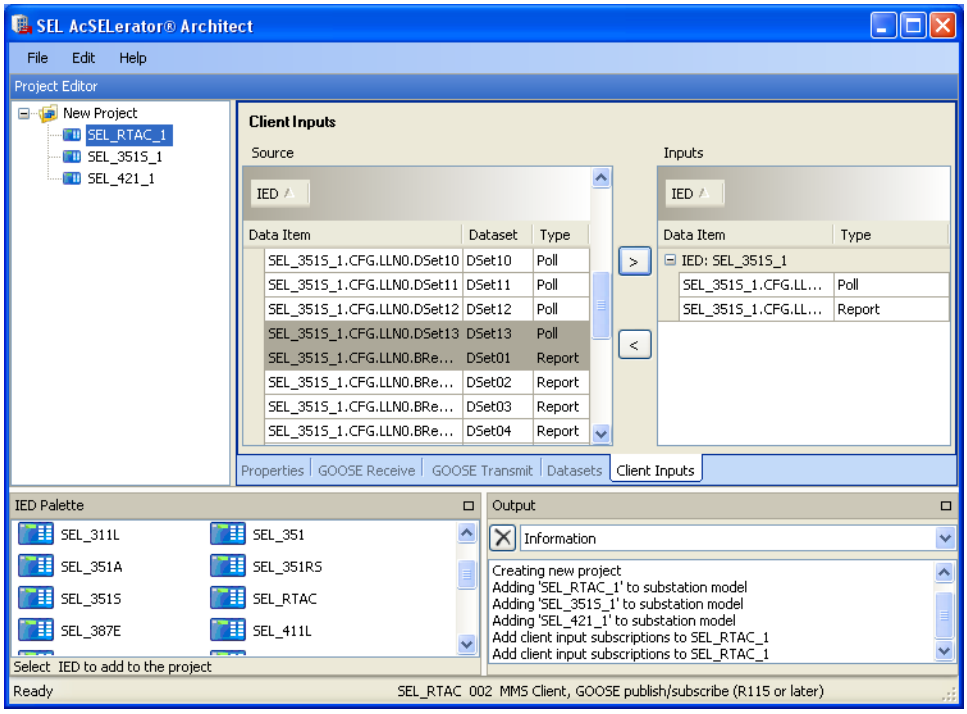

Figure 2.47 Configure IEC 61850 Messages

Step 7. Save the project.

Step 8. In ACSELERATOR RTAC, select **SET IEC 61850 Configuration** from the **Insert** ribbon and browse to the selaprj project file (see *Figure 2.48*).

Step 9. Select the file and click **Open**.

Data tags from the Architect project are now available in the RTAC project for mapping, manipulation, etc.

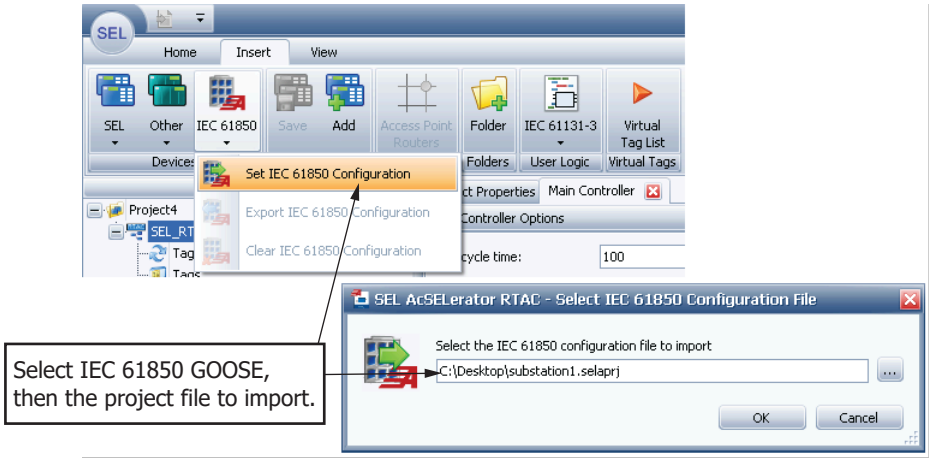

Figure 2.48 Insert GOOSE Configuration

Step 10. Configure which Ethernet interface the RTAC uses for GOOSE messaging by clicking on **SystemTags** under the device tree. Under settings, configure Ethernet_Port to use Eth_01 or Eth_02.

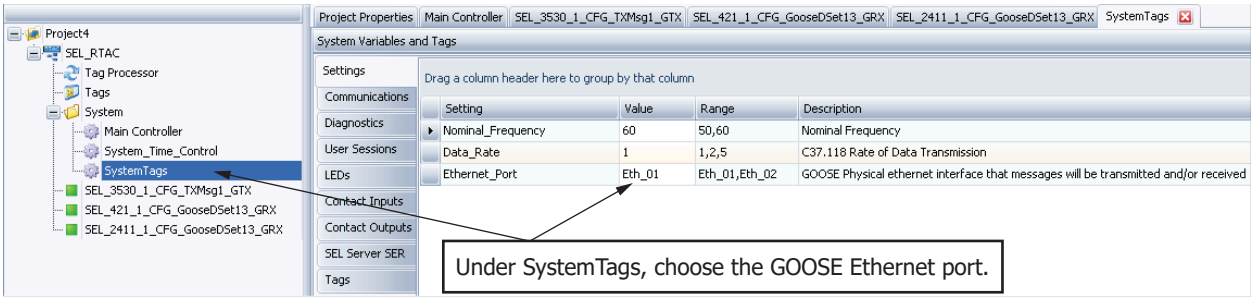

Figure 2.49 Configured GOOSE Ethernet

Because all IEC 61850 message configuration is done in Architect, you cannot make modifications to the message configuration in ACSELERATOR RTAC. *Table 2.46* describes the only configurable IEC 61850-related parameters in ACSELERATOR RTAC. Also, because the IEC 61850 configuration file contains all information necessary for the IEC 61850 communications network, ACSELERATOR RTAC allows only one Architect IEC 61850 configuration file per RTAC project. *Figure 2.50* shows how one IEC 61850 project file contains the configuration for all IEC 61850 devices on this RTAC.

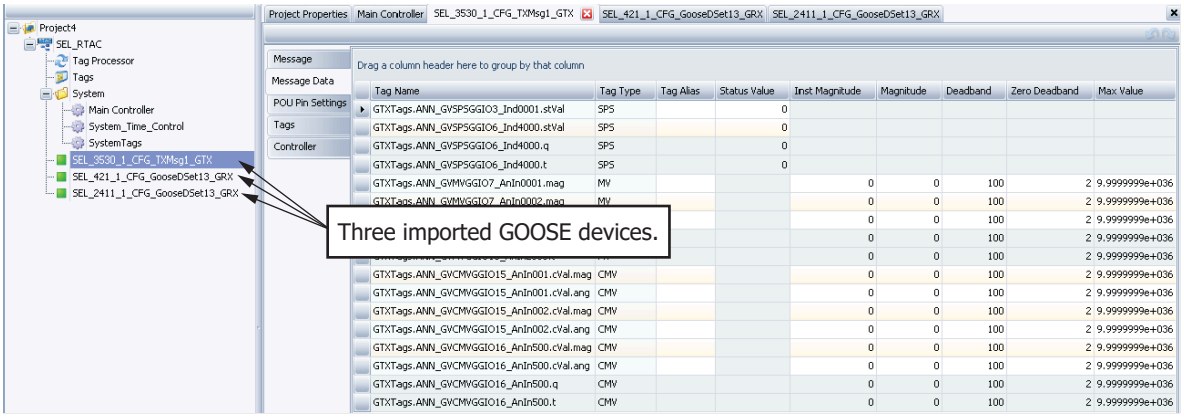

Figure 2.50 Configured GOOSE Devices

Table 2.46 Configurable GOOSE Parameters

Configurable Parameter	Description
Initial Status Value	Initial value for SPS or INS data types
Initial Measure Value	Initial Value for MV or CMV data types
Alias	Alias tag name
Ethernet_Port Under System Tags	Which Ethernet interface RTAC uses for GOOSE messages

Table 2.47 and *Table 2.48* show the maximum number of points possible in a single RX or TX GOOSE message. See *Table 2.49*.

Table 2.47 Simple Typed Global Tags Per RX or TX Message

IEC 61850 Data Type	IEC 61131 Data Type	Maximum Point Count Per Message
BOOLEAN	BOOL	468

MMS Client File Services and Generic File Services

Configuration of MMS Client File collection occurs in ACSELERATOR RTAC on the Settings tab of an MMS Client device. MMS Client Generic file collection is configured in the **Settings** and **Generic File Collections** tab. MMS Client file collection supports collection of COMTRADE files from any IEC 61850 MMS server, edition 1 or edition 2. MMS Client Generic file collection is used to collect files from MMS Server devices that support generic file services.

COMTRADE Collection

When the **MMS Comtrade Enable** setting is set to True, the client will use the timing specified by the **MMS File Services Period** setting to query the MMS server's file system to find any directories named COMTRADE. The RTAC MMS client then collects all COMTRADE event files in that directory. This includes any potential COMTRADE events in directories inside the COMTRADE folder. The RTAC collects the COMTRADE files regardless of whether an event is compressed or separated into individual files on the server. Once the RTAC collects the files from the server, it stores the files on the RTAC file system as a ZIP file regardless of the original storage format of the COMTRADE file(s). All collected events are stored in the following location: /COMTRADE/*[IED name]*/*[directory structure in server's COMTRADE folder]*/*[event name on server]*.zip.

For an example of file naming and location, see the following:

- **IED Name**
  SEL_421
- **Event Location on Server**
  /COMTRADE/DKR_A/EVENT_00021.zip
- **Stored Event Location on RTAC**
  /EVENTS/COMTRADE/SEL_421_1/BKR_A/EVENT_0021.zip

The default behavior of the MMS client is to keep an internal record of the file names and time stamps of all COMTRADE records that it has already collected. The next time the MMS client performs a query of the MMS server's directory listing, the previously collected file name will be listed and will be ignored. If an IED is replaced in the field, or its COMTRADE record content is cleared, it is possible that the file names of new COMTRADE records are duplicates of old records that the MMS client has already retrieved. In this situation, the new records will not be collected. The **MMS File Re-collection** parameter (available on the Settings tab when the Advanced check box is selected) can be set to True to enable additional comparison of the COMTRADE record time stamps that are returned along with the file name when the directory listing is performed. If a duplicate file name is detected but the time stamp is different than the previously collected record, the COMTRADE record will be re-collected. Be cautious of using this value with some non-SEL IEDs as they will update the COMTRADE record time stamps with every directory query; in this scenario, records will constantly be re-collected.

The time necessary to collect event files from a server is dependent on the capability of the server. Edition 2 servers typically support the directory listing "/*", which returns a list of all files on the server in a single response. Using this response, the MMS client efficiently finds the new COMTRADE files to collect. If the server does not support this capability, the RTAC searches the server's file system one directory at a time. This may require many file directory polls to find all possible COMTRADE files and can result in additional time for the MMS client to find and collect all COMTRADE files. An MMS server may also return a directory listing that only lists items in the root directory and no other files in subdirectories. In this case, the MMS client will attempt to open each item listed in the root directory to determine if the listing is a directory that may or may not have been formatted correctly in the return listing. This can cause the appearance of the MMS client attempting to collect files for which it is not configured to do so. In practice, the MMS client is checking all returned listing locations as subdirectories which may contain additional files the client is configured to collect.

Generic File Collection

MMS Generic File Collection provides a way for the RTAC to collect non-COMTRADE files from devices that support MMS file server. There is no restriction on the file types that can be collected. The files that are collected using Generic File Services are stored in the RTAC's file system at /FILES/MMS_Generic_File_Collection/. These files are viewable on the RTAC web interface under the **File Manager** page. The files can also be deleted, downloaded, or renamed from this page. Deleting or renaming the file will do so in the MMS client RTAC file system but not in the file system of the remote MMS server device.

Generic File Collection configuration in the RTAC is done using ACSELERATOR RTAC via an IEC 61850 MMS client imported from ACSELERATOR Architect or some other SCL software. In the Settings tab of the MMS client, the **IP Address** should be set. The **Generic File Collection** tab is used to configure a file path for which the MMS client will query the server and collect files in the designated **Allowed Path**. The Allowed Path setting is case-sensitive. If the path name in the MMS client setting does not exactly match the name in the MMS server file system, including casing, the client will not collect any files. If the

Recurse setting is enabled, the MMS client will collect files in the Allowed Path directory and its subdirectories. The RTAC will match the directory structure and file location on the RTAC's local file system. When Recurse is disabled, only files within the Allowed Path will be collected.

ACSELERATOR RTAC allows for a maximum of 500 file paths per MMS client device that can be configured for file collection. The collection of generic files is done at timed intervals based on the **MMS FileServices Period** setting. When **MMS_Generic_FileServices_Enabled** is set to TRUE, a timer will count up until this period is reached, at which point the files will be initially collected. The MMS client collects files once and records the name and time stamps. The next time the MMS client performs a query of the MMS server's directory listing, the file names that were collected during a previous MMS poll are ignored. By setting the **MMS File Re-collection** parameter (available on the Settings tab when the Advanced check box is selected) to TRUE, the MMS client will compare file names and time stamp values. If a file is collected that has the same name as one previously collected, but a different time stamp, the MMS Client will re-collect the file. The MMS File Re-collection settings parameter also applies to COMTRADE file collection, as detailed in *COMTRADE Collection on page 298*.

For generic files that have been collected by the RTAC, the directory path will have the following structure in the RTAC's file system:

> **FILES/MMS_Generic_File_Collection**/<name of IED as defined in SCL file>/<name of directory where the file is stored in MMS server device>

When accessing these files via the RTAC's web interface, they are found in the File Manager with the following structure:

> **MMS_Generic_File_Collection**/<name of IED as defined in SCL file>/<name of directory where the file is stored in MMS server device>

Generic file collection can occur simultaneously with COMTRADE file collection. The two file collection services share the **MMS FileServices Period** configuration settings and both add to the cumulative total represented in the **MMS_File_Count** statistic. A change in the MMS_File_Count indicates that new files were found on the MMS server device and were collected by the RTAC. If COMTRADE records are found in a path configured for generic file collection, those COMTRADE records are ignored and not retrieved by the generic file collection feature.

Criteria for Collecting Files

The MMS client collects all configured files if the follow criteria are met:

- The MMS protocol standard has a maximum file path of 255 characters; the file path cannot exceed 255 characters.
- The file path contains only printable ASCII characters.
- The file path does not contain "." or ".." as a directory or file name.

When a file is collected and placed on the RTAC file system, the file's time stamp reflects the system time when the RTAC finished collecting the file. If a file name on the server changes case, the MMS client will neither rename nor attempt to again collect the file on the RTAC file system. If the RTAC collects a file from a server and that file is then deleted from the file system through either the web interface or another method, the RTAC will not collect that file again from the server.

The RTAC platform has several hardware variants with different memory capacity. The MMS client continues to collect files from servers until only 512 MB of free space on the RTAC file system remains. At this point, the MMS client ceases collection of additional files until additional free space on the file system is available.

MMS Server

MMS Server Configuration

Use ACSELERATOR Architect to also configure MMS server connections, DataSets, and reports for connected clients.

Step 1. Open a new project in Architect by selecting **New Project** in the **Project Editor** pane.

Step 2. Drag an SEL_RTAC IED icon from the **IED Palette** onto the **Project Editor**. In the resulting **IED Properties** window, pick the entry that includes MMS Server.

Note: You can configure MMS client, GOOSE, and MMS server for this one RTAC IED in the **Project Editor**. Follow the instructions for MMS client and GOOSE messaging, if needed, before proceeding to *Step 3*.

Step 3. Click the **Server Sessions** tab, then **Edit** or **New** to edit the existing default session or create as many as 10 sessions. Each session is a connection to a unique MMS client.

Step 4. In the **Session (Edit)** window, select the **Anonymous connections allowed** check box to permit anonymous sessions, or clear the box and enter as many as 10 IP addresses of the client(s) with which the RTAC will communicate. The **Name** field (with a default of Anonymous_Server) is the name that will appear in the ACSELERATOR RTAC project in the device tree. Click **OK** when finished.

Step 5. Click on the **Server Model** tab, then click **Edit**. In the resulting edit window, you can create and modify MMS logical devices and logical nodes. The default logical device has two logical nodes, specifically **LLN0** and **LPHD0**. These cannot be modified.

Step 6. Create a new logical device by clicking **Logical Devices +**. Notice that all logical devices have two non-editable logical nodes. Click **Logical Nodes +** to create a new editable logical node. You can also hover your cursor in the window for selectable tooltips. See *Figure 2.51*.

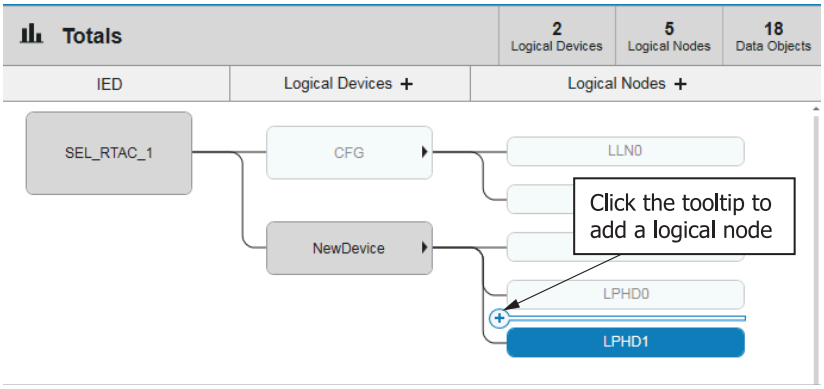

Figure 2.51 Add a New Logical Node

Step 7. Click the **Class** drop-down box to change the class of this logical node. For example, change it to a GGIO type. See *Figure 2.52*.

Hint: You can quickly find the class type by typing what you are looking for in the **Class** drop-down box.

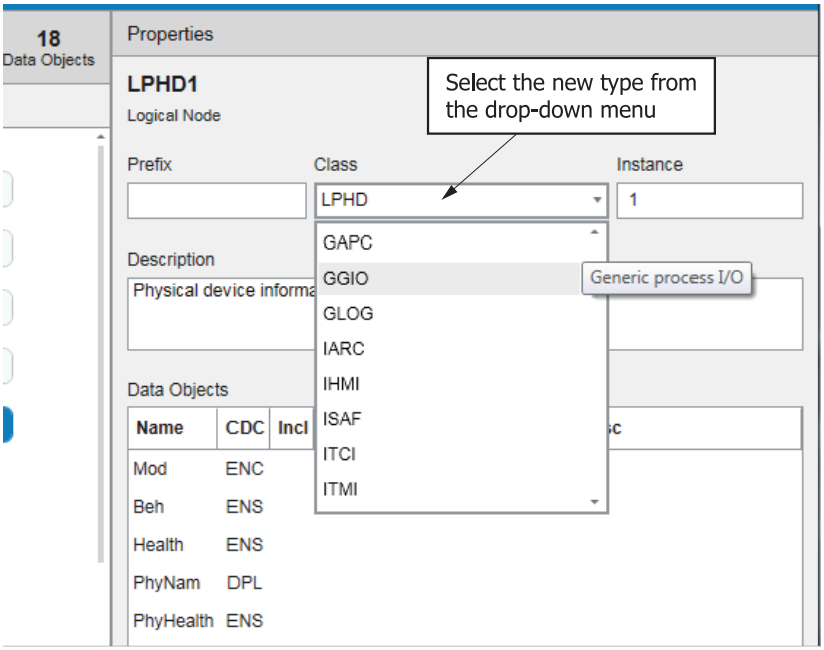

Figure 2.52 Changing the Logical Node Type

Step 8. Create data objects by selecting check boxes or increasing the quantity (Qty) of the objects listed. See *Figure 2.53*. When finished, click **OK**.

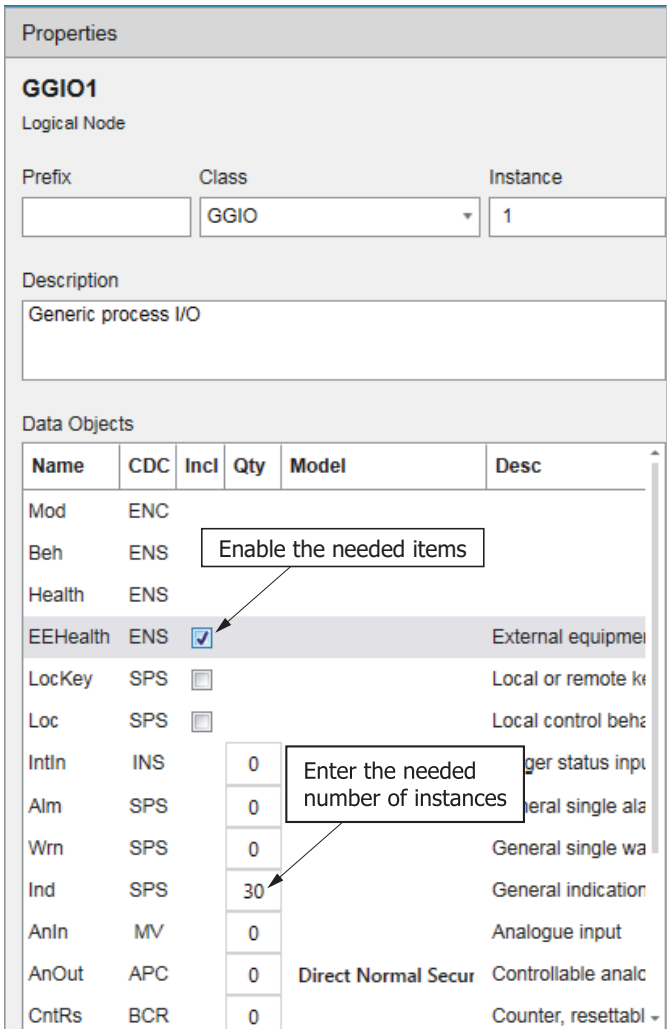

Figure 2.53 Creating Data Objects

Step 9. Click **Datasets** to create a new dataset or edit an existing dataset. Note the new logical device (named **NewDevice** by default) created in *Step 6* is available for mapping into a DataSet. See *Figure 2.54*.

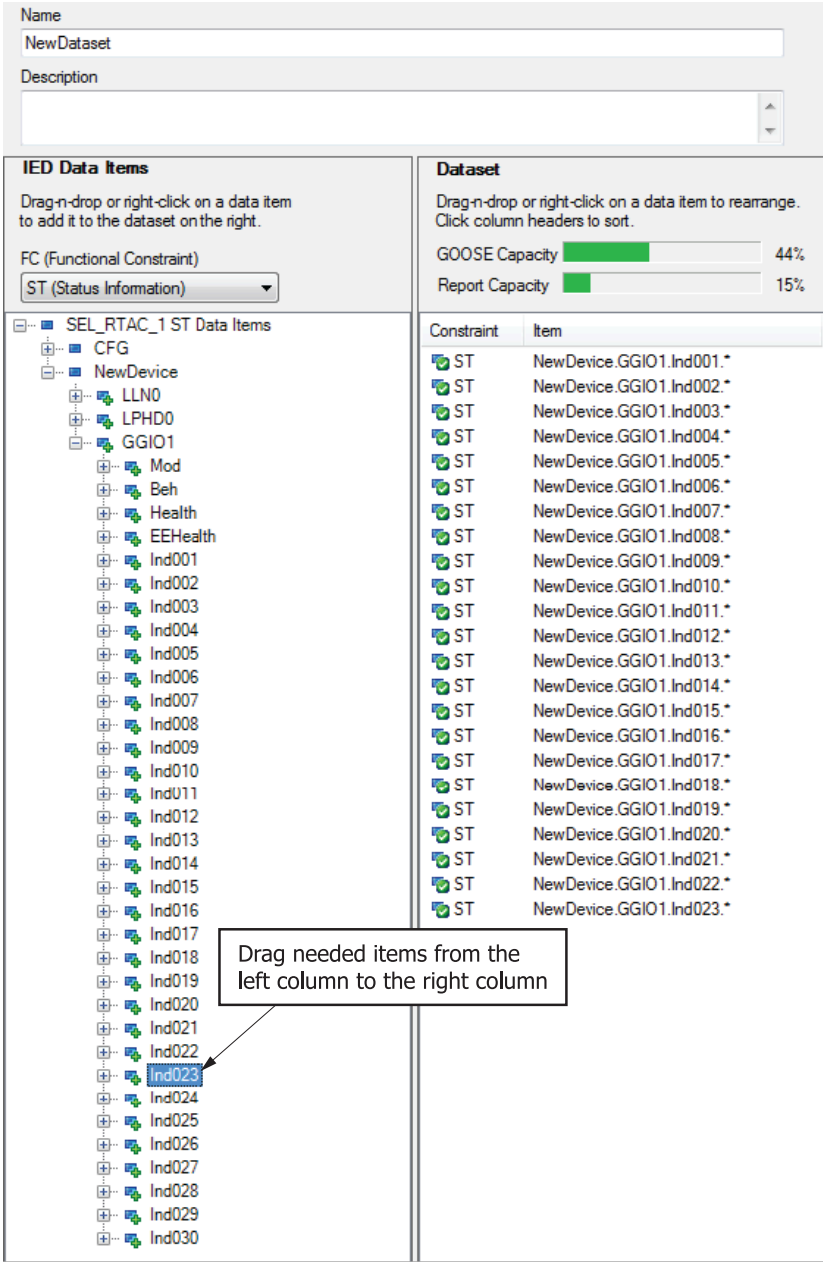

Figure 2.54 Create a Dataset

Step 10. Click on **Reports** and configure as needed. Configuration includes specifying if the report is buffered or unbuffered, which dataset to use, and other configurations related to triggers and buffer times. See *Figure 2.55* for options.

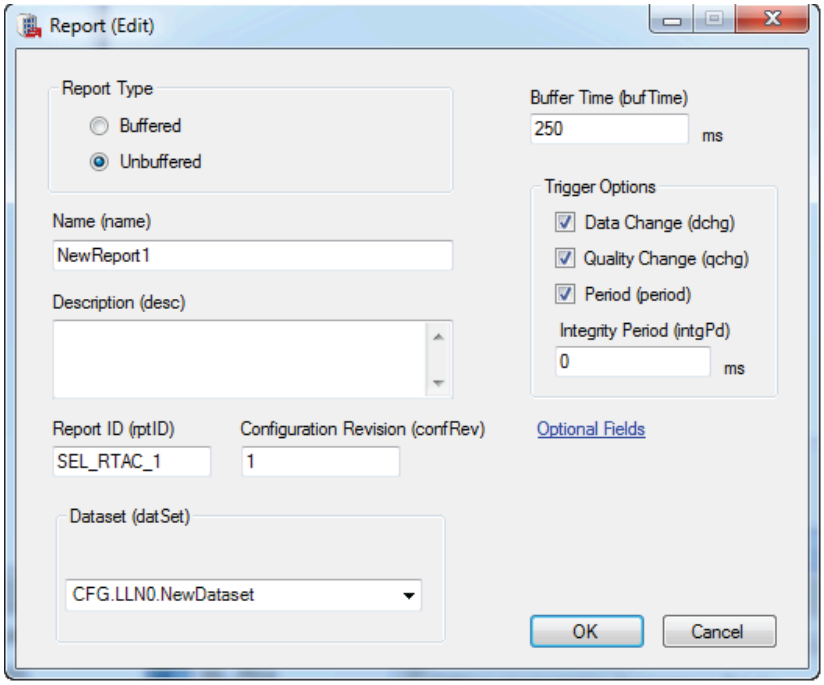

Figure 2.55 Configure Reports

Step 11. Save the project.

Step 12. In ACSELERATOR RTAC, select **SET IEC 61850 Configuration** from the **Insert** ribbon and browse to the **selaprj** project file (see *Figure 2.48*).

Step 13. Select the file and click **Open**.

Data tags from the Architect project are now available in the RTAC project for mapping, manipulation, etc.

Once the IEC 61850 configuration is set, there will be at least three new entries in the Device Tree.

1. **Anonymous_Server_850**: The default name for the server instance created in *Step 3*. There will be one of these for each of the instances created in *Step 3*. The only editable setting is allowance of anonymous connections; the IP addresses of the clients are editable if anonymous is not allowed. The POU pin settings indicate communications statistics for this one MMS server instance.
2. **SEL_RTAC_1**: The MMS server shared map, bearing the name of the IEC 61850 IED created in *Step 2*. SEL_RTAC_1 is the default name but may be changed in the Architect project. This shared map contains all the MMS server tags created in the Architect project. As with any server tags in an RTAC project, you can populate values in these tags by mapping them in the Tag Processor or in IEC 61131 logic.
3. **MMS_Server**: The POU of the actual server. Unlike other server protocols in the RTAC, there is only one actual server for MMS, with sessions for each polling client. There will be, therefore, only one of these entries. The only setting is to enable authentication and define the

authentication string, which actions will apply to all MMS server sessions defined in the RTAC project. The POU pins provide the ability to disable the server, disable the server tag updates, and disable the server controls. All of these actions will apply to all MMS server sessions.

Using MMS Server Tags

Some of the tags in the MMS server shared map are dedicated to use by the MMS server, but you can use the tags you created in Architect anywhere in the RTAC project as you would other IED tags. A unique feature to MMS server tags is that ACSELERATOR RTAC software can automatically move tags to different tasks if needed. To illustrate this feature, follow these steps:

Step 1. Create an MMS server in Architect.

Step 2. Insert that IEC 61850 configuration into an RTAC project and save the project.

Step 3. Create a program in the RTAC project.

Step 4. In that program, assign a value to one of the MMS server tags. For example: **SEL_RTAC_1.NewDevice.GGIO1.Loc.stVal := true;**

Step 5. In the **Main Controller** tab, click the program name, then select **Automation** from the **Move To** drop-down menu. The task will now execute at the speed of the Automation task. Generally you cannot use tags from an Automation task in the Main task, but in this case, the software will move only that one tag from the MMS server shared map into the Automation task. Though it is now native to the Automation task, the MMS server (in the Main task) still can access it.

Note: Once this move has taken place, you can no longer access this tag outside of the Automation task.

To view which tasks have been automatically moved, click the **View** ribbon, then the **Task Tags** icon for a textual report.

MMS Server Mode and Behavior (Firmware Versions R150-V0 and Later)

In firmware versions R150-V0 and later, the MMS server supports the behavior described in the IEC 61850-7-4—Annex A standard for processing data according to the mode and behavior tags associated with a logical node. When a configuration that contains an MMS server is converted to firmware version R150-V0 or later, it will automatically support mode and behavior functionality. Also note that all data objects related to mode and behavior functionality are required to have the following data types: Mod (ENC/ENS), Beh (ENS), and Health (ENS). If any of these data object names are not the correct data types, the configuration will not be imported into the software.

The processing of mode/behavior tags occurs at the logical node level. This means the RTAC will look at the mode data object in a logical node and the mode data object in LLN0 of the logical node's parent logical device to determine the behavior of that specific logical node. If the mode data object does not exist for a logical node, that node is assumed to be in the On state and processing will effectively follow the mode object of the parent logical device.

The value of any mode data object in the RTAC's data model can be managed either from the MMS server protocol interface or through the logic engine. This allows the RTAC's data model behavior to be managed via MMS, physical contact switches, the RTAC's web HMI, or another protocol service. Because processing of mode/behavior tags occurs at the logical node level in the RTAC and not at the IED level, there is no single data object that controls the mode/behavior of the entire device by default. If desired, user logic can be written to tie all logical device modes to a single mode object to create control of mode/behavior at the IED level.

The RTAC supports all modes described by the IEC 61850 standard and the associated behavior functionality with the single exception of the Off mode. In this mode, the RTAC complies with all described behavior in Annex A of IEC 61850-7-4 except the statement of "No process output will be done." When the mode is Off for a logical node, the MMS data model will still update the data objects with corresponding status values in the logic engine. The validity of all data objects in a logical node in the Off mode is forced to invalid excluding Mod, Beh, and Health data objects (if they are part of the data model). If a value outside of the enumerated values 1–5 is assigned to a mode object, the resulting behavior assignment will be set to On. The default value of all Mod objects in the data model is On.

Each Beh data object in the RTAC's data model will be calculated and updated automatically in the logic engine and in the MMS server protocol interface. The MMS Server protocol interface will process request and controls based upon the Beh object for each logical node. The Mod data object in the RTAC's logic engine is of type ENC, which consists of an oper and status structures. The Beh data object, which is of type ENS, is automatically updated by an internal function that takes the status value of the logical node Mod data object and logical device Mod data object to calculate the appropriate Beh value. When the MMS server Mode_Mapping_Disable POU pin is set to False, the status structure of the Mod data object is automatically updated from the oper structure of the Mod data object. When Mode_Mapping_Disable is set to True, the status structure of the Mod data object is no longer automatically updated from the oper structure of the Mod data object. This effectively disables the MMS protocol interface from managing mode tags. This allows for custom IEC 61131-3 logic that manages the Mod's status value to manage the Beh of a logical node. This pin allows for management of the behavior object such as mode lockout managed via a local HMI or physical switch instead of managing the mode of the logical node via an MMS protocol interface.

For the Test and Test/blocked modes, controls that are received with the test bit set will be passed into the logic engine with the test and/or operatorBlocked bits asserted. User logic can make decisions on what to do with controls that have these bits asserted to facilitate application behavior when the IEC 61850 data model is in Test or Test/blocked mode. It is important to note that when a control that has operatorBlocked asserted is mapped to another protocol control or a contact output, that process will not send a control via that protocol or operate the contact if the operatorBlocked bit is asserted. For contact I/O with the test bit asserted in the quality structure, the contact output will not operate when the test or operatorBlocked bit is set.

MMS Server LTIM and LTMS (Firmware Versions R151-V0 and Later)

In firmware versions R151-V0 and later, the MMS server supports the LTIM and LTMS logical nodes described in the IEC 61850-7-4 specification for Time Management and Time Master Supervision, respectively. The configuration of these logical nodes in the RTAC is done in the RTAC CID and will be attributed to the CFG logical device. For this reason, the LTIM and LTMS logical nodes are permanent fixtures of the RTAC's server model and can pass local time and time synchronization functions of the RTAC to MMS client devices.

The LTIM logical node data objects are populated with values from the RTAC's System Time Controller and include daylight-saving time settings and indications of when the RTAC will transition to daylight-saving time or to standard time. The LTMS logical node data objects provide time synchronization information and can provide the remote device with specific details of the RTAC's time source. The LTMS logical node also provides date stamp data for when the RTAC transitions from one time synchronization source to another, which can occur when a higher-priority time source signal is lost or re-established.

MMS Server File Services

Use the **Enable File Transfer** setting on the Settings tab of the MMS server device in your ACSELERATOR RTAC project to enable file services on the MMS server. When this value is True, the MMS server responds to file requests. When this value is False, the MMS server rejects file service requests.

The MMS server has the following files available:

- The CID file from the presently configured RTAC (named "SET_61850.CID")
- All event files collected from SEL clients
- All files collected from MMS Clients
- All files collected from Modbus Clients
- All files generated by Axion I/O modules
- All files created or collected using the IEC 61131 file IO library

Note the following:

- The MMS protocol standard has a maximum file path of 255 characters. Any file on the RTAC file system whose file path name exceeds 255 characters will be unavailable through MMS file transfer.
- The MMS file server is case sensitive. An error message is returned for clients that issue file requests with incorrect casing.
- Any file request the MMS server receives that contains path constructs (e.g., /./, /../, etc.) will generate an error.
- The MMS server supports the following wildcard characters:
  - *—matches any character at its position
  - ?—matches zero or one character at its position
- A wildcard character cannot be the last character in a directory name. The server returns a file name-syntax error for such a situation.

Local and Remote Processing (Firmware R150-V0 and Earlier)

When a Loc object in a logical node is set to TRUE, all controllable objects except for mode in that logical node will be rejected regardless of orcat processing.

Local and Remote Processing (Firmware R151-V0 and Later)

Starting in firmware version R151-V0, the RTAC implements the local/remote concepts as described in the IEC 61850 standard if the RTAC's SCL contains either of the following conditions. (Class file definitions 8 and later will have these conditions by default.)

- The RTAC SCL contains a definition for a logical node to be at process, bay, or station level.
- The RTAC SCL contains an InRef link reference to another logical node with the Loc data object.

If the RTAC SCL does not contain either of these definitions, it will process the Loc data object as it did in firmware versions R150-V0 and earlier; i.e., if Loc.stVal is asserted, all controls except for the data object mode will be rejected.

The RTAC supports local/remote control at the logical device and the logical node. When a logical node or logical device is in local mode, it will consider the orcat value in acceptance of the control. The following table describes supported data objects for local/remote processing.

Data Object	CDC	Description
Loc	SPS	If true, the control behavior is allowed at the level of the logical node and higher-level operations are blocked.
LocKey	SPS	If true, the operation of the whole logical device has been switched (from remote) to local. This changeover is always done locally with a physical key or toggle switch, which may have a set of contacts from which the position can be read.
LocSta	SPC	If true, control authority is at station level and control from remote is disabled; otherwise, control from remote is allowed.
MltLev	SPG	Only valid in the LLN0 logical node and operates for the entire logical device. If the MltLev object is not included in the RTAC data model, it is considered to be true. If true, control authority from multiple levels is allowed; otherwise, no other control level is allowed.

Consideration of the Logical Node Level

Local processing as described by the IEC 61850 standard is affected by the level a logical node is at when considering accepting a control based upon its control authority (i.e., the orcat value in the control message). For example, a logical node at the bay level, when placed in local mode, would reject controls with a control authority of higher levels like station or remote. It would still process controls of bay, process, maintenance, or not-supported. If a logical node

does not contain the optional element to define what level the logical node is processed at, it is assumed to be at bay level. To define the level a logical node is at, add the following private SEL_LnInfo element in the type definition for the logical node:

```
<Private type="SEL_LnInfo">
    <esel:Level level="station|process|bay"/>
</Private>
```

Then select either station, process, or bay as the level. For example, an XCBR logical node type definition appear as follows:

```
<LNodeType id="XCBR1" lnClass="XCBR">
    <DO name="Beh" type="behENS"/>
    <DO name="Loc" type="SPS_O"/>
    <DO name="OpCnt" type="INS_O"/>
    <DO name="Pos" type="DPC_O"/>
    <DO name="BlkOpn" type="SPC_O"/>
    <DO name="BlkCls" type="SPC_O"/>
    <DO name="CBOpCap" type="CBOpCapENS"/>
    <Private type ="SEL_LnInfo">
        <esel:Level level="process"/>
    </Private>
</LNodeType>
```

The following tables show the truth tables for accepting and rejecting controls based upon received orcat values. The Loc object in the following table is the OR operation between Loc and LocKey. Additionally, if the LLN0 logical node contains the Loc or LocSta data object, it is "ORed" together with a Loc or LocSta object inside a logical node.

Processing of a Station-Level Logical Node

MltLev	Loc	LocSta	Remote	Station	Bay	Process	Maintenance	Not-Supported
False	False	False	allow	block	block	allow	allow	allow
False	False	True	block	allow	block	allow	allow	allow
False	True	False	block	allow	block	allow	allow	allow
False	True	True	block	allow	block	allow	allow	allow
True	False	False	allow	allow	allow	allow	allow	allow
True	False	True	block	allow	allow	allow	allow	allow
True	True	False	block	allow	allow	allow	allow	allow
True	True	True	block	allow	allow	allow	allow	allow

Processing of a Bay-Level Logical Node

MltLev	Loc	LocSta	Remote	Station	Bay	Process	Maintenance	Not-Supported
False	False	False	allow	block	block	allow	allow	allow
False	False	True	block	allow	block	allow	allow	allow
False	True	False	block	block	allow	allow	allow	allow

MltLev	Loc	LocSta	Remote	Station	Bay	Process	Maintenance	Not-Supported
False	True	True	block	block	allow	allow	allow	allow
True	False	False	allow	allow	allow	allow	allow	allow
True	False	True	block	allow	allow	allow	allow	allow
True	True	False	block	block	allow	allow	allow	allow
True	True	True	block	block	allow	allow	allow	allow

Processing of Process-Level Logical Node

According to the IEC 61850 standard, processing consideration of the MltLev and LocSta for a logical node at the process level is not considered. In this case, control processing is entirely dependent upon the Loc object.

Loc	Remote	Station	Bay	Process	Maintenance	Not-Supported
False	allow	allow	allow	allow	allow	allow
True	block	block	block	block	block	block

Association of a Logical Node With Another Logical Node

The IEC 61850 standard describes a concept where the local processing of one logical node may impact the processing of controls in another logical node. The most typical use case is a process-level logical node like XCBR, which has no controllable objects, but which accepts control decisions from a CSWI logical node. In this case, the XCBR logical node is linked to the CSWI logical node, and when the XCBR logical node is placed in local mode, the CSWI logical node is prevented from accepting controls from all control authorities due to XCBR being at the process level. When an association between two logical nodes occurs, the linked logical node will "OR" the processing of the source logical node when deciding to accept controls. Therefore, in the previous example, when deciding if a CSWI controllable object would accept a control or not, the truth tables for a process-level LN and the truth table for the bay-level logical node would be "ORed" together, creating the truth table for the linked logical node.

To create a link between two logical nodes, the following data object needs to be included during instantiation of the source logical node in the SCL. The name of the data object must be "InRef" followed by a number (the value of the number does not matter). The setSrcRef value must reference the Loc object of the desired logical node to create a link between the two logical nodes. The following is an example of single data object instantiation.

```
<LN lnType="XCBR1" lnClass="XCBR" inst="1" prefix="BKR1">
    <DOI name="InRef1">
        <DAI name="setSrcRef">
            <Val>PRO/CSWI1.Loc</Val>
        </DAI>
    </DOI>
</LN>
```

The referenced DOType for the ORG definition for the InRef will need to specify a functional constraint set point and a read-only attribute. If these attributes are not a part of the ORG class definition, then the MMS server will not enable.

```
<DOType id="ORG_O" cdc="ORG">
   <DA name="setSrcRef" fc="SP" bType="ObjRef" dchg="true" valKind="RO"/>
</DOType>
```

Interlocking

The MMS server will check for interlocking when processing a control with a common data class of DPC when the logical node that contains the DPC data object has inRef links to EnaOpn and EnaCls data objects. If both links to EnaOpn and EnaCls do not exist the MMS server will not enable. Additionally, EnaOpn and EnaCls must be in the same logical node. If either of the linked data objects are true, the control will be rejected with an add cause of blocked by interlocking.

```
<LN lnType="CSWI1" lnClass="CSWI" inst="1" prefix="BKR1">
    <DOI name="InRef1">
       <DAI name="setSrcRef">
          <Val>PRO/CILO.EnaOpn</Val>
       </DAI>
    </DOI>
    <DOI name="InRef2">
       <DAI name="setSrcRef">
          <Val> PRO/CILO.EnaCls</Val>
       </DAI>
    </DOI>
</LN>
```

The referenced DOType for the ORG definition for the InRef must specify a functional constraint set point and a read-only attribute. If these attributes are not a part of the ORG class definition, the MMS server will not enable.

```
<DOType id="ORG_O" cdc="ORG">
    <DA name="setSrcRef" fc="SP" bType="ObjRef" dchg="true" valKind="RO"/>
</DOType>
```

Protocol Implementation Conformance Statement: RTAC

Table 2.49 and *Table 2.50* are as shown in the IEC 61850 standard, Part 8-1, Section 24. Note that because the standard explicitly dictates which services and functions must be implemented to achieve conformance, only the optional services and functions are listed.

Table 2.49 PICS for A-Profile Support

	Profile	Client	Server	Value/Comment
A1	Client/Server	Y	N	
A2	GOOSE/GSE management	Y	Y	Only GOOSE, not GSSE management
A3	GSSE	N	N	
A4	Time Sync	Y	Y	

Table 2.50 PICS for T-Profile Support

	Profile	Client	Server	Value/Comment
T1	TCP/IP	Y	N	
T2	OSI	N	N	
T3	GOOSE/GSE	Y	Y	Only GOOSE, not GSSE
T4	GSSE	N	N	
T5	Time Sync	Y	Y	

Refer to the ACSI Conformance Statements starting with *Table 2.62* for information on the supported services.

MMS Conformance

The Manufacturing Message Specification (MMS) stack provides the basis for many IEC 61850 protocol services. *Table 2.51* defines the service support requirement and restrictions of the MMS services in the RTAC.

Generally, only those services whose implementation is not mandatory are shown. Refer to the IEC 61850 standard Part 8-1 for more information.

		Time			
T1	Time resolution of internal clock		As many as 20	As many as 20	Nearest negative power of 2 (in seconds)
T2	Time accuracy of internal clock		T0	T0	T0 (10 ms) T1 (1 ms) T2 (100 µs) T3 (25 µs) T4 (4 µs) T5 (1 µs)
T3	Supported TimeStamp resolution		20 (1 µs)	10 (1 ms)	Nearest negative power of 2 (in seconds). The value of the TimeAccuracy attribute depends on the time-source accuracy of and variation of the internal clock relative to the time source.
				T0 or T1	For SNTP and NTP, T0 or T1 is typical. If accuracy is less than 10 ms, it will be set to "Unspecified".

[a] Type of application association (AA): Two Party (TP) or Multicast (MC).

Model Implementation

This model implementation conformance statement is applicable for SEL RTAC, with firmware R136:

The MICS document specifies the modeling extensions compared to IEC 61850 Edition 1. For the exact details on the standardized model please compare the ICD substation configuration file: "03530 006.ICD".

Common data class extensions

2.1 Supported common data classes

The IEC 61850 client and server in the SEL RTAC are capable of mapping the mandatory attributes of the following data classes with a functional constraint of ST or MX:

Common data class specifications for description information

Common data class specifications for status information

- Single point status (SPS)
- Double point status (DPS)
- Integer status (INS)
- Enumerated status (ENS)
- Protection activation information (ACT)
- Directional protection activation information (ACD)
- Binary counter reading (BCR)

Common data class specifications for measurand information

- Measured value (MV)
- Complex measured value (CMV)
- Phase to ground related measured values of a three phase system (WYE)
- Phase to phase related measured values of a three phase system (DEL)
- Sequence (SEQ)

Common data class specifications for controllable status information

- Controllable single point (SPC)
- Controllable double point (DPC)
- Controllable integer status (INC)
- Controllable enumerated status (ENC)
- Binary controlled step position information (BSC)
- Integer controlled step position information (ISC)

Common data class specifications for controllable analog information

- Controllable analog set point information (APC)
- Binary controlled analog process value (BAC)

In addition to directly supporting the mapping of data from the above data classes, the IEC 61850 client and server support the ability to access most attributes within any data class (supported or not), mandatory, optional, or specialized.

2.2 Unsupported common data classes

Common data class specifications for description information

- Device name plate (DPL)
- Logical node name plate (LPL)
- Curve shape description (CSD)

Common data class specifications for status information

- Security violation counting (SEC)

Common data class specifications for measurand information

- Sampled value (SAV)
- Harmonic Value (HMV)
- Harmonic value for WYE (HWYE)
- Harmonic value for DEL (HDEL)

Common data class specifications for status settings

- Single point setting (SPG)
- Integer status setting (ING)
- Enumerated status setting (ENG)
- Object reference settings (ORG)
- Time setting group (TSG)
- Currency setting group (CUG)
- Visible string setting (VSG)

Common data class specifications for analog settings

- Analog setting (ASG)
- Setting curve (CURVE)
- Curve shape settings (CSG)

EtherCAT

This section describes the configuration and use of EtherCAT® protocol with ACSELERATOR RTAC. EtherCAT is unique from other protocols available for the RTAC because connected I/O modules (EtherCAT servers) are automatically configured during network initialization. This means that you will provide configuration information for both EtherCAT servers and the EtherCAT client (SEL RTAC) in the ACSELERATOR RTAC project. You can continue to use all other client, server, and peer-to-peer protocols, such as SEL or DNP3, in an ACSELERATOR RTAC project that includes EtherCAT I/O.

NOTE
The following devices currently do not support the EtherCAT communications protocol: SEL-3505, SEL-3505-3, and SEL-3532.

The primary steps needed to configure an EtherCAT I/O network in ACSELERATOR RTAC are as follows:

- Designate an Ethernet port for EtherCAT (only needed when using the SEL-3350, SEL-3530, SEL-3530-4, or SEL-3555). On the SEL-3555, if the synchrophasor protocol is going to be used and you need a high-accuracy time source, this port must be a PCI expansion Ethernet port with IRIG-B connected to the card.
- Create device connections for each power coupler module, digital input module, analog input module, and digital output module. You can configure as many as 60 I/O modules on a single EtherCAT network.
- Select the physical placement of modules and node network connections.
- Map I/O tags into needed Tag Processor locations or custom logic programs.

NOTE
Always ensure that power couplers are not connected to any Ethernet switches or other Ethernet devices, including RJ45-to-fiber-optic converters. The power coupler EtherCAT ports are only for direct connections between power couplers of the same type or to an RTAC EtherCAT port. Connecting a power coupler to any other Ethernet device can cause the EtherCAT network to stop communicating completely or behave unpredictably.

Designating an Ethernet Port for EtherCAT Use

The designated port will be dedicated for EtherCAT; no other protocol will be available on that port. If you are using the SEL-2241 RTAC module in an SEL-2240 Axion® node, EtherCAT is provided via the backplane connector. You cannot alter this selection or enable EtherCAT via the two front-panel Ethernet ports. Both of the Ethernet ports can be configured for any other available Ethernet protocol.

NOTE

The USB port and **ETH F** are unavailable for use with EtherCAT.

To enable an EtherCAT network by using either the SEL-3530, SEL-3530-4, SEL-3350, or SEL-3555, you must first dedicate an Ethernet port for use by the I/O network. To configure the Ethernet port, use an Internet browser to connect with the RTAC web application (see *Section 5: Web Interface and Reports*) and navigate to the Ethernet Network page, as shown in *Figure 2.56*. Select the **List Ethernet Settings** tab. Click the **Edit** button corresponding to the port you want to use. If you have already selected a port (such as Eth_01 in *Figure 2.56*) to be the default gateway, you cannot use the gateway port for EtherCAT.

NOTE

EtherCAT connections on the SEL-3555 and SEL-3560E are only available on ports of a PCI expansion Ethernet card. IRIG should be connected to the PCI card internally to ensure high-accuracy time is available.

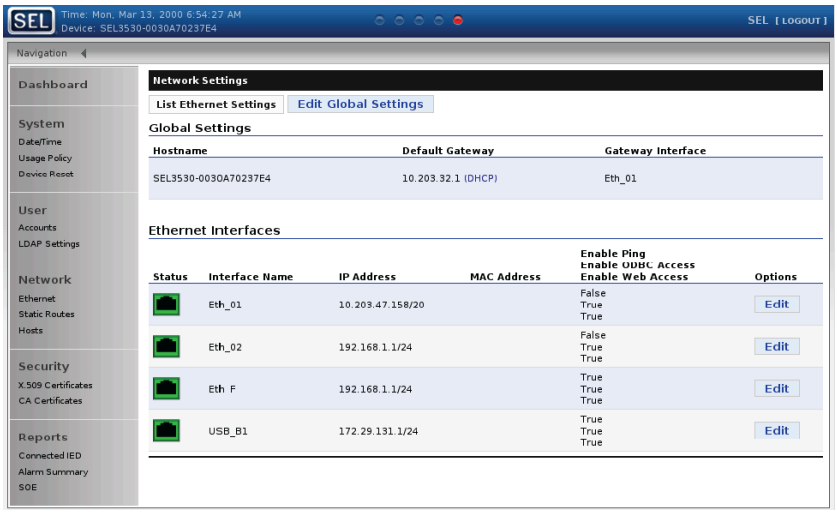

Figure 2.56 RTAC Ethernet Interfaces

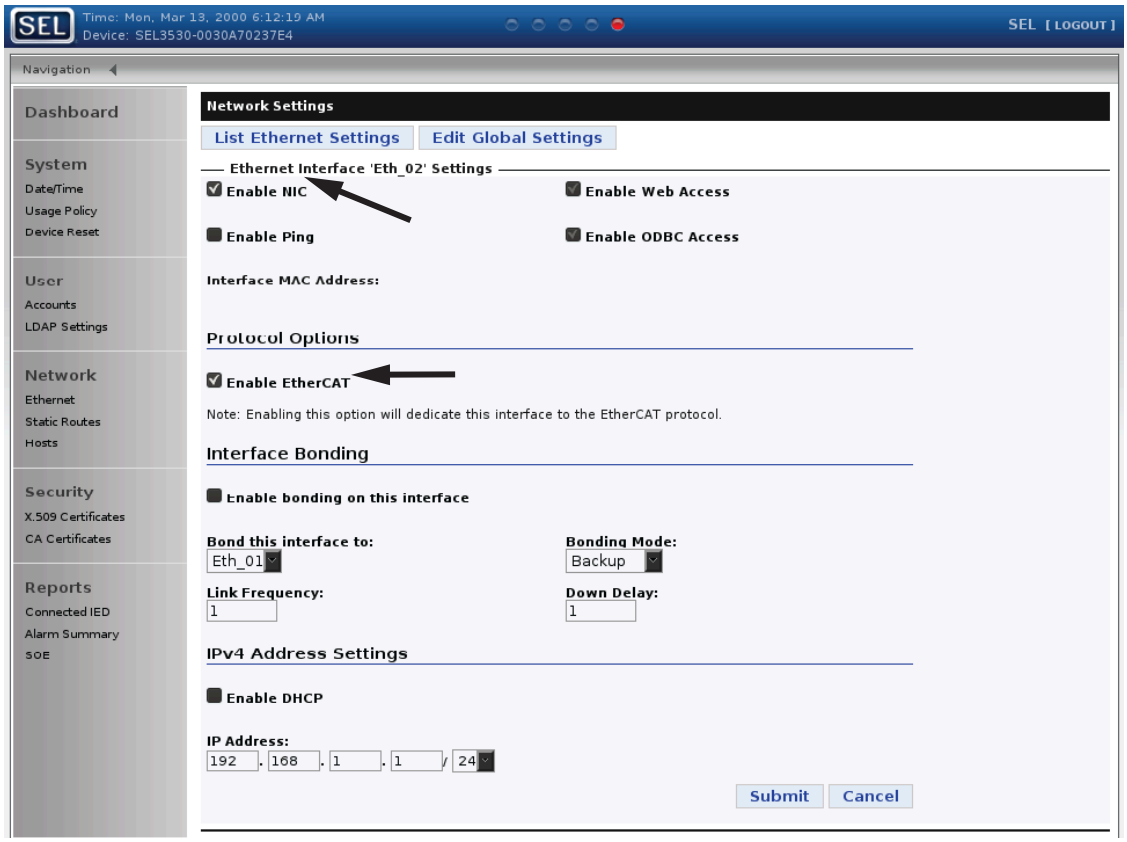

Figure 2.57 Configure a Dedicated EtherCAT Port

Verify that the port you selected is enabled. As shown in *Figure 2.57*, select the check box labeled **Enable NIC** if the port is disabled. Select the **Enable EtherCAT** check box and press **Submit** to complete the selection. The RTAC will automatically turn off other Ethernet interface services, such as web access, for your EtherCAT port. There is no requirement to manually deselect such items. Bonding, DHCP, and PRP are all unavailable on an EtherCAT port.

NOTE

Ethernet port settings will revert to previous values if you disable EtherCAT on a port.

Once you have saved settings, the Ethernet Interfaces page will display again in your browser. Notice that the port you selected for EtherCAT shows "EtherCAT Dedicated," as shown in the upper image of *Figure 2.58*. Only one port at a time can support EtherCAT. Notice the lower image in *Figure 2.58*, which shows the result of attempting to enable a second concurrent EtherCAT port.

NOTE

Do not assign 128.0.0.0 as the IP address on any Ethernet port if you are using an EtherCAT I/O network.

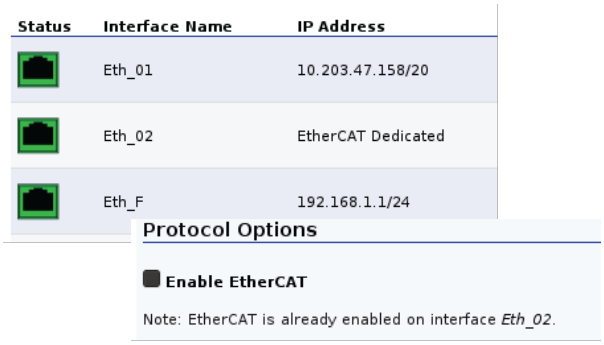

Figure 2.58 Results of EtherCAT Configuration

Once you have set the port, navigate to the **Ethernet Global Settings** tab to verify that the correct port is set to EtherCAT. The IP Address of the selected port will display "EtherCAT Dedicated," as shown in *Figure 2.59*. If you need to change the dedicated EtherCAT port at a later time, you must manually stop the EtherCAT protocol prior to making the setting change. Manually restart EtherCAT once the setting change is complete. Refer to *Replacing a Failed Module With Disabled Network* in the *SEL-2240 Instruction Manual* for the steps necessary to force the EN pin for the EtherCAT POU.

⚠CAUTION
Changing SFP ports while online can cause momentary communication interruptions. In the case of EtherCAT, this can cause the EtherCAT network to disable.

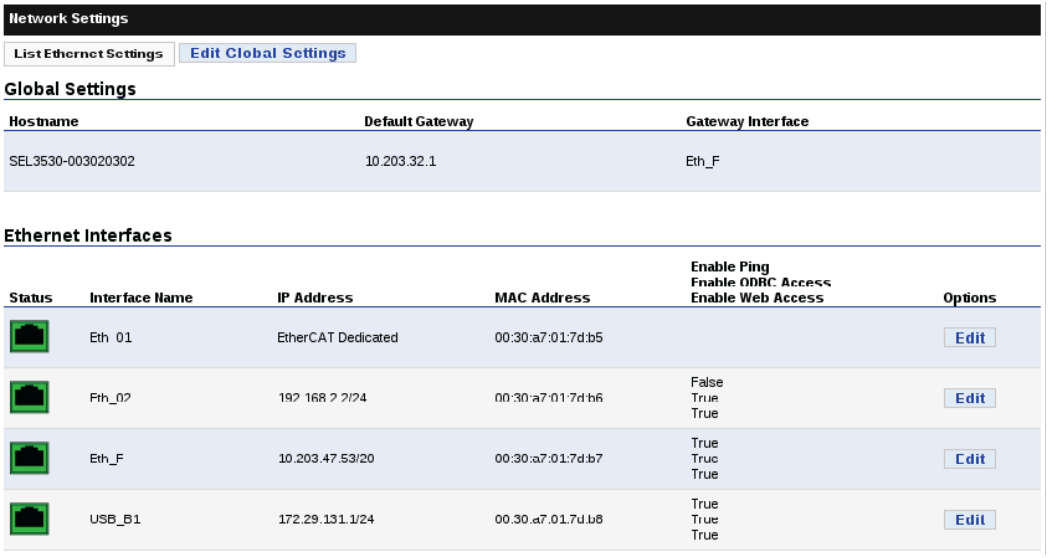

Figure 2.59 EtherCAT Port Unavailable for Other Applications

This configuration is unnecessary for the SEL-2241 RTAC module because the backplane port is permanently configured at the factory for EtherCAT.

Creating Device Connections for New Modules in the Project

The process for adding power couplers and I/O modules to an ACSELERATOR RTAC project is similar to the process for adding IED connections. Place the power couplers and I/O modules into your project by using the following steps. Also refer to *Figure 2.60*.

Step 1. Select **Fieldbus I/O** from the **Insert** ribbon.

Step 2. Hover or click the mouse on the **SEL** entry. Then hover your cursor or click the entry for the type of module you are adding to the project. Finally, click on the specific module type you need.

Step 3. Provide a module name in the dialog box that displays (or use the default name provided). IEC naming conventions are enforced; use an underscore rather than a space in the module name. The system appends the text "_ECAT" to each module name, so you can easily identify which modules in the project use EtherCAT versus other available protocols. The only **Connection Type** available will be **Client - Ethernet**. The I/O module itself is an EtherCAT server; the Connection Type selection refers to the method the RTAC uses to connect with the module.

Step 4. Press the **Insert** button.

Note in the inset photo of *Figure 2.60* that the RTAC places the new module by default at the end of the project view listing. On the other hand, if you select an existing folder prior to inserting a module, then the RTAC places the new module automatically in the folder you select.

There is no requirement that you add the I/O modules to the project in a specific sequence. The system will use the EtherCAT I/O *Node Connections Editor* to organize the modules based on their physical arrangement in a node. The arrangements of modules in the project view and I/O Node Connections Editor view do not need to match.

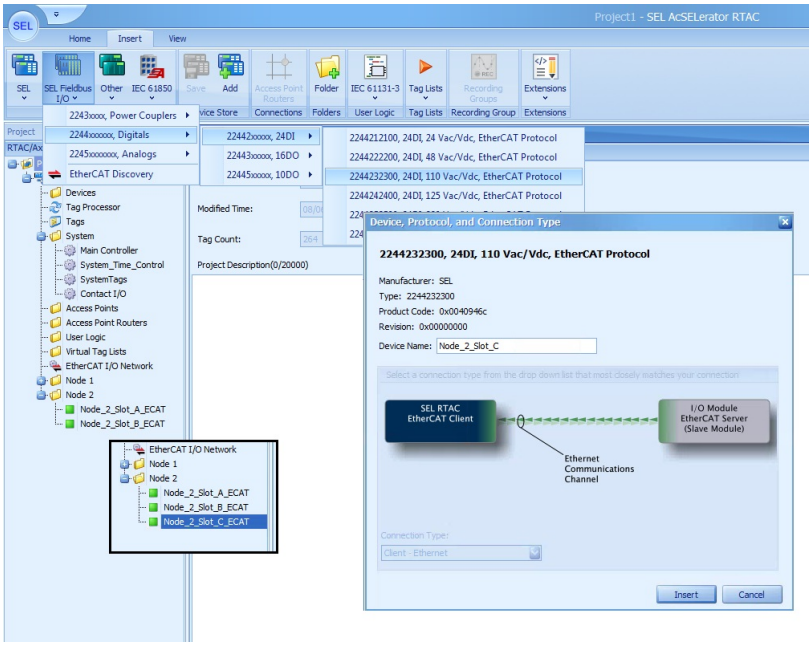

Figure 2.60 Adding SEL-2240 I/O Modules to a Project

Naming Conventions

As you plan a new project with the SEL-2240, carefully consider the node and I/O module naming conventions you will use and how these can help expedite your work during commissioning or troubleshooting.

Especially for the case of a large system with many nodes, consider a naming convention where each module name includes information about the node within which it resides. *Figure 2.60* shows a simple scheme to accomplish this. Each node is named sequentially (Node_1, Node_2). When we added a module to a particular node, we named the module by joining the node name with the physical slot in the node where we intended to place that module (i.e., Node_2_Slot_C_ECAT). If you do not know the intended physical location of a module, you can rename it at any time during the project development process. The module name automatically becomes a prefix for the tag names associated with that module, so this type of naming convention provides an efficient way to identify the physical location of a tag.

If nodes are mounted near the apparatus being monitored and controlled, then consider including a designation for the apparatus in the module naming convention. Many different naming methods will work well.

Organizing an EtherCAT I/O Network in an ACSELERATOR RTAC Project

An Axion system can include one or more I/O nodes that use EtherCAT protocol as a real-time network. When you load a project that includes I/O network information into an SEL-3530 RTAC, SEL-3530-4 RTAC, SEL-3350 RTAC, or SEL-2241 RTAC module, the system will automatically start and scan the EtherCAT network; during such scanning, the system verifies and reports proper operation. A single project can include no more than 60 I/O modules and power couplers. Because an RTAC project can include a large quantity of I/O modules, we highly recommend that you use the available tools in the project view of ACSELERATOR RTAC to organize the list of module connections. The project view has two tools available to help you keep the project organized: you can either add custom folders, similar to a Microsoft Windows operating system folder organization, to collect devices into logical groups; or use drag-and-drop selections to quickly change the sequence of devices in the project view.

To add a custom folder, press the **Folder** button in the **Insert** menu, as shown in *Figure 2.61*. The software will ask for a name for each new folder you create. You can right-click on a folder to use the context menu and rename the folder at any time. Folder names follow no IEC requirements, so you can include spaces in names. ACSELERATOR RTAC also supports nesting of folders. Select the parent folder prior to pressing the **Folder** button in the **Insert** ribbon to create a child folder. Refer to *Figure 2.61* for an example.

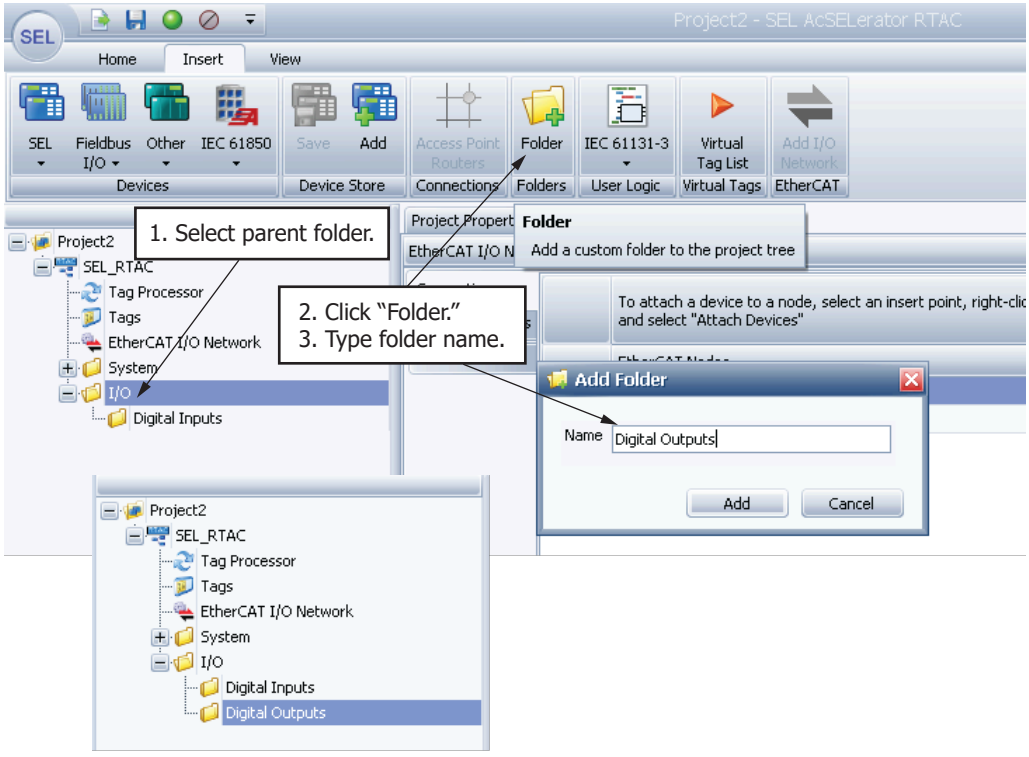

Figure 2.61 Creating Custom Project Folders

Once you add folders or devices to the project tree, organize them to meet your needs by using simple drag-and-drop operations. As a first example, consider a case where a module resides in one folder and we want to move it to a second folder.

To move an I/O module, refer to *Figure 2.62* and perform the following:

Step 1. Click and hold the mouse on the module name in the project view.

Step 2. While holding the mouse button, drag the module onto the desired folder name. Note the yellow arrow that appears to the left of the project view. This arrow points at the folder you have presently selected, and it indicates that the module will become a member of that folder.

Step 3. Release the mouse button.

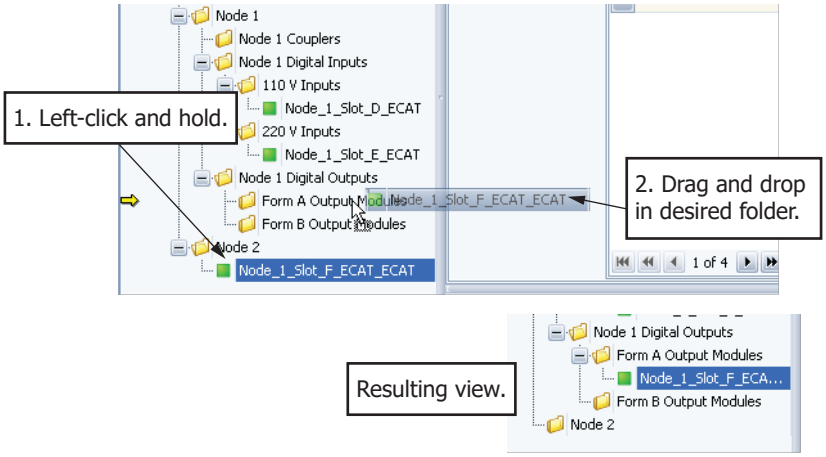

Figure 2.62 Moving an Object Between Folders in Project View

The same process works for folders or modules. If you move a folder, all of the contents (including subfolders) move with it. You cannot select and move multiple independent objects simultaneously.

As a second example, we want to change the sequence of folders within the project view. This operation is similar to the previous example, but we use a hot key in conjunction with the mouse. Please refer to *Figure 2.63*, and perform the following steps.

Step 1. Select the folder you want to move, by clicking and releasing the mouse.

Step 2. Press and hold the **<Shift>** key.

Step 3. Click, hold, and drag the folder to the position you want. Notice the curved blue arrow that appears to the left of the project view. This arrow shows the present mouse position and indicates that you are reordering the objects rather than dropping the objects into a parent folder.

Step 4. Release the mouse button and the **<Shift>** key.

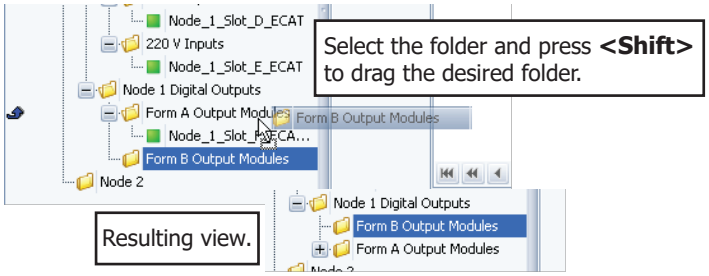

Figure 2.63 Changing Object Sequence in Project View

This procedure works for folders or modules. Perform the same steps if you want to move a folder or module from within a parent folder out to the same hierarchy level as the parent folder.

EtherCAT Discovery

EtherCAT Discovery allows a user to plug in their Axion modules as desired and automatically populate the EtherCAT I/O Network without any manual addition of modules in the software. To discover an Axion network, Select the **EtherCAT Discovery** option as shown in *Figure 2.64* to begin the discovery process for connected Axion modules.

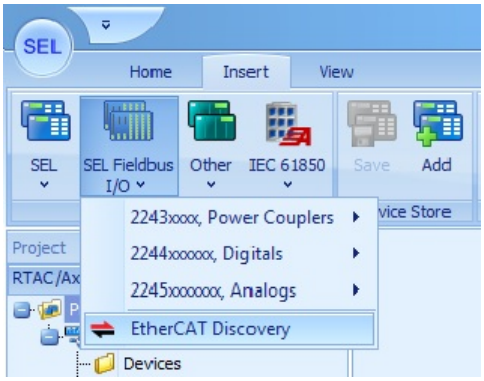

Figure 2.64 EtherCAT Discovery

EtherCAT Discovery requires you to go online with your RTAC to discover the Axion modules you have connected. The modules are subject to the same constraints governing physical placement of modules as the software requires. Log in as shown in *Figure 2.65*.

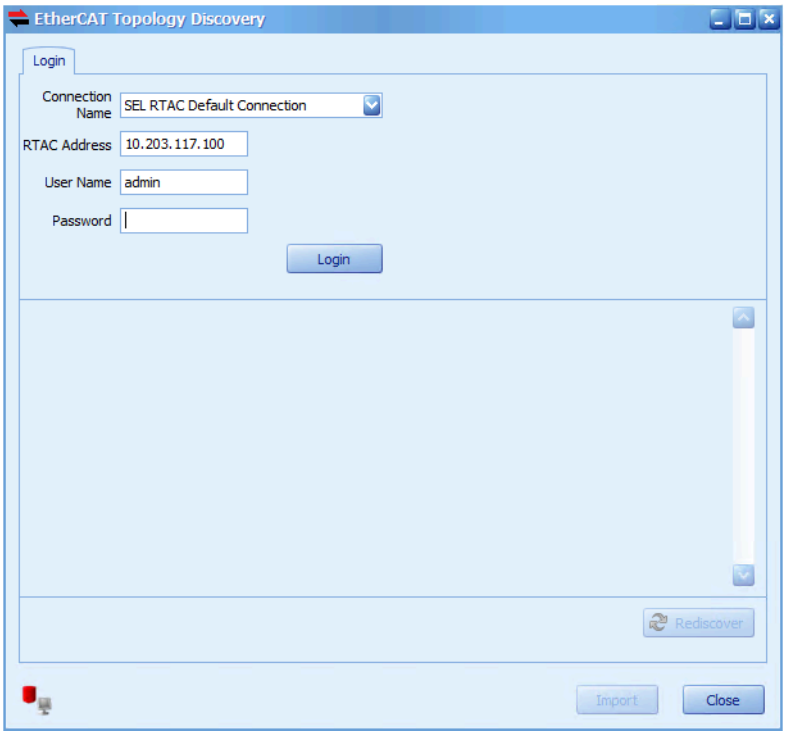

Figure 2.65 EtherCAT Topology Discovery Login

Once the EtherCAT Discovery process completes, click **Import** to accept the discovered network, as shown in *Figure 2.66*.

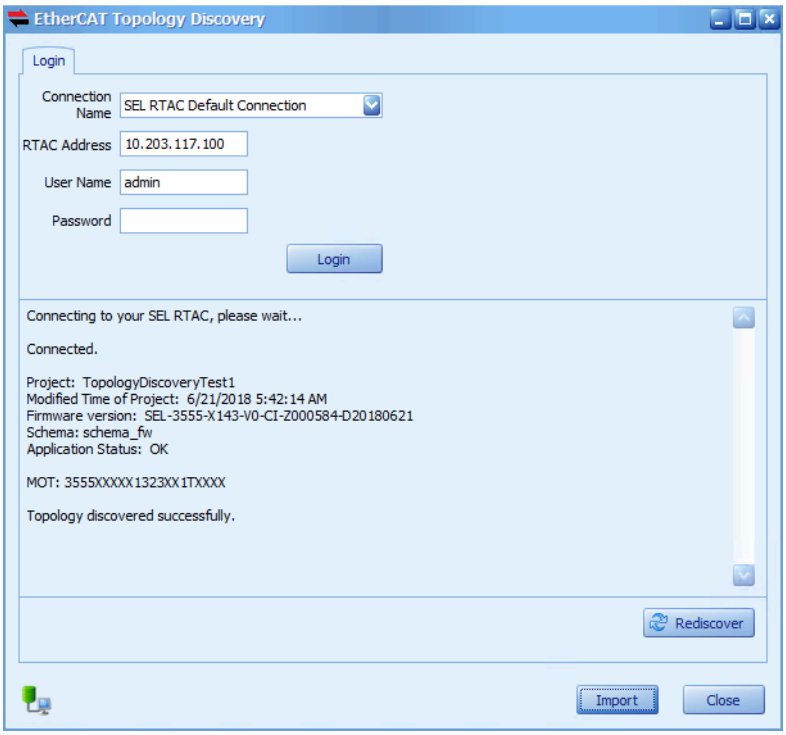

Figure 2.66 EtherCAT Topology Discovered

If an unsupported topology is discovered, the message `Invalid EtherCAT topology` will be displayed. You can correct the module or cable connections and then click **Rediscover** to run the discovery process again.

If your project contains a preconfigured or previously discovered EtherCAT network that you have already set up in this project (as shown in *Figure 2.67*), you may choose to overwrite it. This will overwrite any preconfigured EtherCAT or module settings with default values.

NOTE

Choosing to import settings from EtherCAT Discovery will overwrite any preconfigured EtherCAT network and module settings with default values. If you have existing settings that you have created, SEL recommends saving a copy of your project before overwriting the EtherCAT network.

NOTE

In RTAC firmware version R153 and later, unused power coupler ports and empty backplane slots are disabled when project settings containing an Axion network are loaded. In order to use the EtherCAT Discovery tool in this scenario, go online to the project settings and navigate to the Controller tab of the EtherCAT I/O Network device. Locate the EN input POU pin and write a value of FALSE into the pin to disable the EtherCAT network and re-enable the discovery of new nodes and modules.

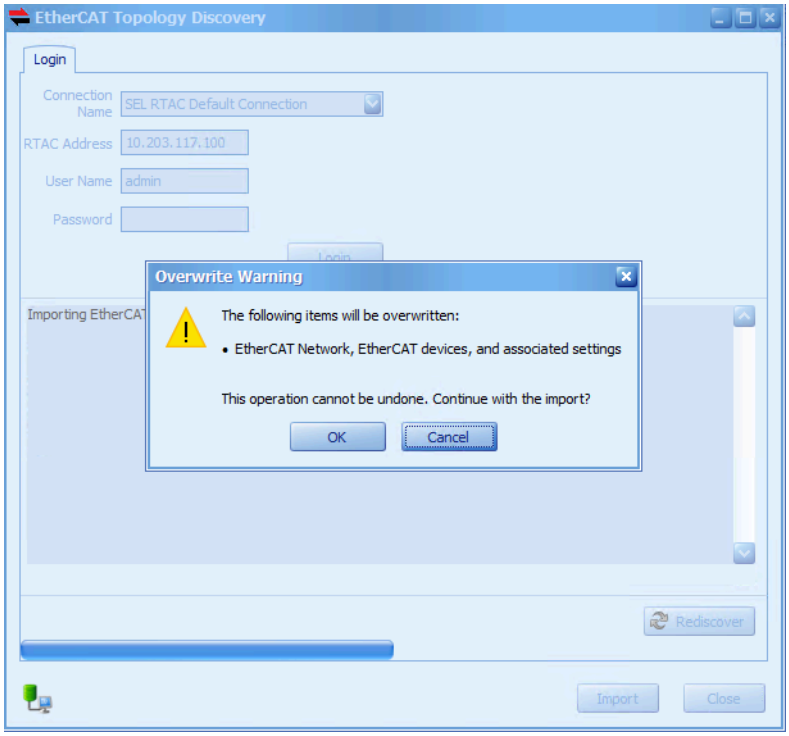

Figure 2.67 Overwrite Existing Network

Reading and Writing I/O Module Tags

Each power coupler or I/O module has a fixed set of inputs or outputs and diagnostic information available. The EtherCAT network updates these data automatically. The RTAC logic engine evaluates the data at the processing rate you set (100 ms default). Use the Tag Processor, as described in *Section 3: Tag Processor*, to apply the information in your custom IEC 61131-3 logic or map it into another protocol session.

Common Diagnostic Tags

Power couplers and I/O modules have a number of EtherCAT diagnostic tags that are common in each device. As shown in *Figure 2.68*, the diagnostic tags reside in the **Diagnostics** tab for each module. *Table 2.65* describes these tags. Diagnostic tags are always enabled and may not be renamed or aliased.

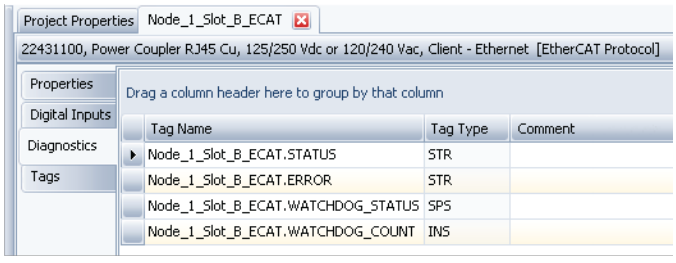

Figure 2.68 Power Coupler and I/O Module Diagnostic Tags

Table 2.65 Module Diagnostic Tag Descriptions

Parameter	Tag Type	Description	Possible Values
STATUS	STR	String representing the present operational status of the module	**Operational**—Normal operation **Non-Operational**—Module is not communicating on the EtherCAT network
ERROR	STR	String representing the network state for a module	**No Error**—Normal operation **Cable Error**—The network configuration has changed and does not match settings. This error could arise either from the movement of a server module or an Ethernet cable change.

Common Module Properties

Each power coupler and I/O module in your project will contain a set of properties that you can view in the **Properties** tab for a module, as shown in the top portion of *Figure 2.69*.

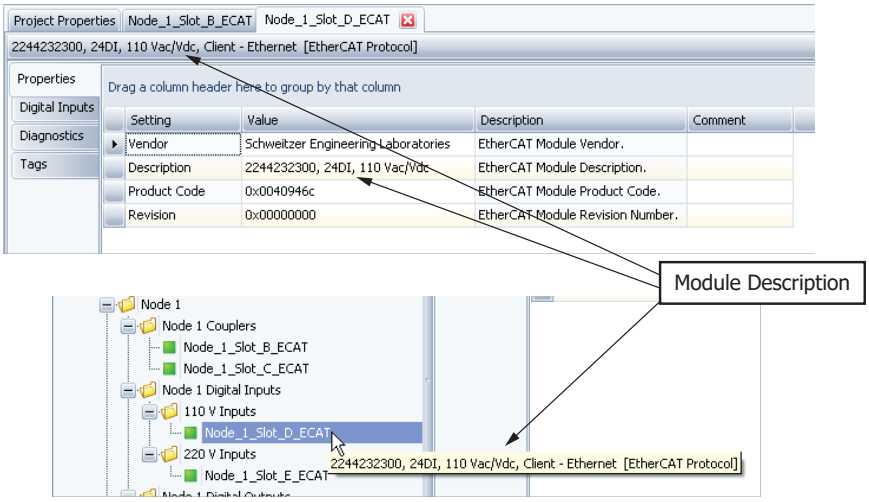

Figure 2.69 Power Coupler and I/O Module Properties

The module description includes detailed information about the function of the module. This information includes a partial model option string, module type (power coupler, digital input, digital output), and other operational information. There are three ways to see the module description. First, hover your cursor over the module name in the project view (see lower portion of *Figure 2.69*); second, hover your cursor over the title bar of an open module, and; third, hover your cursor over the description field of the **Properties** tab. If your module naming convention does not include a reference to the function of a module, use these viewing methods to quickly identify module types in the project.

SEL-2243 Power Coupler

The SEL-2243 Power Coupler provides two functions for an Axion node. First, the power coupler is a power supply with sufficient capacity to accommodate a complete node. Second, the power coupler provides internode EtherCAT network connections. When you add a power coupler to a project, the editor pane will display a tab for it, as shown in *Figure 2.68*. The previous section described module properties and diagnostics.

Power couplers have copper and fiber Ethernet ports available. The fiber ports enable greater isolation and increased physical separation of nodes. When you add a power coupler to an RTAC project, select the type of Ethernet port you are using. *Figure 2.70* illustrates this menu option.

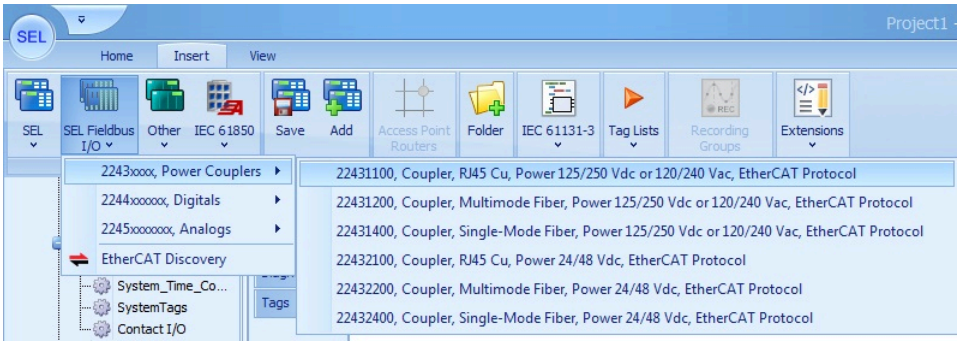

Figure 2.70 Choose Power Coupler Options

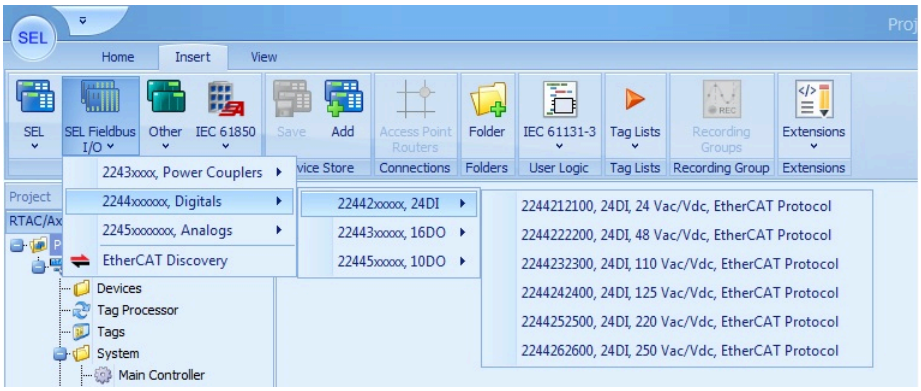
Each power coupler has one digital input that represents the state of the on-board power supply. The input will be of type Single Point Status (SPS) with a default name of <Module_Name>.HW_STATUS_001, which resides in the **Diagnostics** tab for the subject power coupler. All diagnostic and status tags for EtherCAT modules are enabled by default.

SEL-2244 24 Optoisolated Digital Input Module

The SEL-2244 Digital Input Module includes 18 common-return and six independent inputs. All of the inputs are dry contact type inputs. Use the **Insert** ribbon selection, as shown in *Figure 2.71*, to include an instance of this module in your project. Be careful to select the control voltage level you will be using for each module; the voltage is fixed for each module. You can configure an Axion node as necessary to have inputs that use a variety of control voltage types and levels.



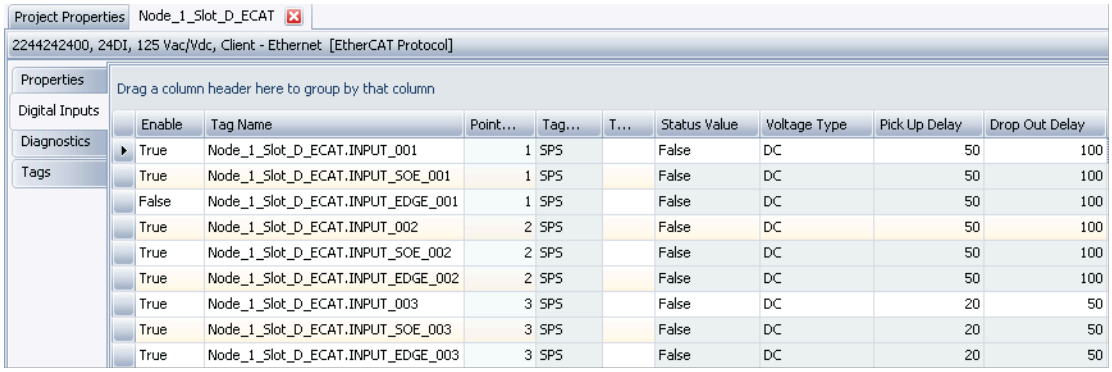


Figure 2.71 Insert an SEL-2244 Digital Input Module

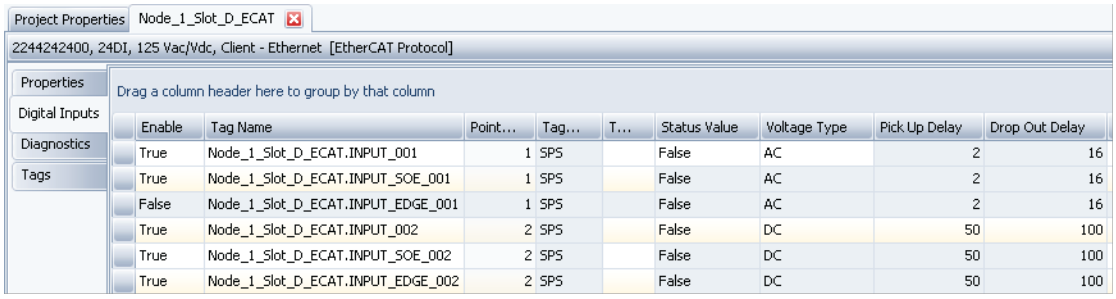
Once you add a digital input module to a project, click the module name in the project view to open the connection editor. The Properties and Diagnostics tabs (see *Figure 2.72*) include the common EtherCAT module data discussed previously. The **Tags** tab lists all available and enabled tags from the module. The **Digital Inputs** tab lists the tags associated with the 24 inputs in the module. Each physical input is represented by three tags of data type SPS named

INPUT_*xxx*, INPUT_SOE_*xxx*, and INPUT_EDGE_*xxx*, where *xxx* refers to the physical input designation within a module. The following discussion describes the signal processing and function of each tag. Each input tag is enabled by default. Disable any unneeded tags to optimize processing resources.



Enable	Tag Name	Point...	Tag...	T...	Status Value	Voltage Type	Pick Up Delay	Drop Out Delay
True	Node_1_Slot_D_ECAT.INPUT_001	1	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_SOE_001	1	SPS		False	DC	50	100
False	Node_1_Slot_D_ECAT.INPUT_EDGE_001	1	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_002	2	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_SOE_002	2	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_EDGE_002	2	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_003	3	SPS		False	DC	20	50
True	Node_1_Slot_D_ECAT.INPUT_SOE_003	3	SPS		False	DC	20	50
True	Node_1_Slot_D_ECAT.INPUT_EDGE_003	3	SPS		False	DC	20	50

Figure 2.72 Digital Inputs Tab for the SEL-2244 Digital Input Module

Digital Input Debounce

To comply with different control voltages, the SEL-2244 Digital Input Module offers dc debounce and ac debounce modes. You can use the voltage type setting in the **Digital Inputs** tab to select these modes on a per-input basis. If you change the setting for a given input from dc to ac and save the project, ACSELERATOR RTAC will configure all three tags associated with that physical input to the new setting. *Figure 2.73* illustrates this functionality after the voltage type setting for Node_1_Slot_D_ECAT.INPUT_001 changed from dc to ac. Changing the value from ac to dc and saving the project will have the reverse effect.

Enable	Tag Name	Point...	Tag...	T...	Status Value	Voltage Type	Pick Up Delay	Drop Out Delay
True	Node_1_Slot_D_ECAT.INPUT_001	1	SPS		False	AC	2	16
True	Node_1_Slot_D_ECAT.INPUT_SOE_001	1	SPS		False	AC	2	16
False	Node_1_Slot_D_ECAT.INPUT_EDGE_001	1	SPS		False	AC	2	16
True	Node_1_Slot_D_ECAT.INPUT_002	2	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_SOE_002	2	SPS		False	DC	50	100
True	Node_1_Slot_D_ECAT.INPUT_EDGE_002	2	SPS		False	DC	50	100

Figure 2.73 Changing Voltage Type Setting for Digital Input Module

If the control input voltage is dc, select **DC** for the voltage type. If the control input voltage is ac, select **AC** for the voltage type. In general, debounce refers to a qualifying time delay before processing the change of state of a digital input. Normally, this delay applies to the processing of the debounced input when used in IEC 61131-3 logic, and to the time-stamping of the tag for logging and SOE. We provide INPUT_*xxx* and INPUT_SOE_*xxx* as separate tags to account for two different processing intervals operating in the RTAC. First, the IEC 61131 logic engine performs logic on a user-settable interval between 4 ms and 1 second. Second, the EtherCAT network updates every 1 ms and buffers the input state and time stamp every millisecond in the INPUT_SOE_*xxx* tag, regardless of the logic engine processing interval. If you need a high-speed record for an input, then use the Tag Processor to log the INPUT_SOE_*xxx*

tag. *Section 5: Web Interface and Reports* provides detailed instructions on this feature. The INPUT_*xxx* tag does not buffer changes of state between logic processing intervals. It is a debounced value and always represents the last recorded state of an input. Use this tag in IEC 61131-3 programmable logic. The time stamp for INPUT_*xxx* will represent the last recorded change of state.

NOTE
AC debounce mode is processor intensive. Using a large number of AC debounced inputs is not recommended.

In some cases, it is also important to record the time of first assertion of an input. To this end, the SEL-2244 Digital Input Module provides the initial assertion time via the INPUT_EDGE_*xxx* tag. The module buffers this tag with a time stamp for each event. Include it in logging along with the INPUT_SOE_*xxx* tag as necessary. The INPUT_EDGE_*xxx* tags are automatically disabled and unavailable when you set the voltage type to ac mode.

DC Mode Processing (DC Control Voltage)

NOTE
In R118 and later, the AC/DC mode selection applies to an entire module rather than individual inputs. Converting from an older project with mixed settings will result in the first selection applying to the whole module.

Figure 2.74 shows the logic for the dc voltage type mode of operation, which we select through use of the voltage type setting shown in *Figure 2.73*. The Input_*xxx*, Input_SOE_*xxx*, and INPUT_EDGE_*xxx* tags share a debounce timer. Set the timer Pick Up Delay and Drop Out Delay for the INPUT_*xxx* tag and save the project; ACSELERATOR RTAC will automatically apply the same timer settings to all three tags. On assertion, INPUT_RAW_*xxx* (internal variable) starts Debounce Timer 1, producing INPUT_*xxx* and INPUT_SOE_*xxx* after the debounce time pickup delay.

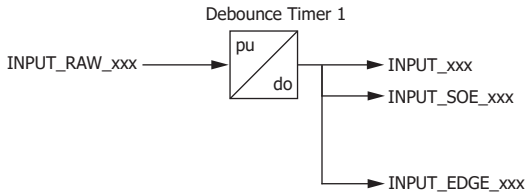


Figure 2.74 DC Mode Processing

Figure 2.75 shows a timing diagram when INPUT_RAW_*xxx* changes from the deasserted state to the asserted state. At the first assertion of INPUT_RAW_*xxx*, the following takes place in regards to the edge detection function:

- INPUT_EDGE_*xxx* asserts
- Debounce Timer 1 starts
- All edge changes are ignored

If you want to record the time of the first assertion of an input, be sure to enable logging for INPUT_EDGE_*xxx* in the Tag Processor. During the time when Debounce Timer 1 runs, the device ignores all edge changes with regards to the INPUT_EDGE_*xxx* tag. At the end of this timing period, the system

evaluates the status of INPUT_RAW_*xxx* (either logical 0 or logical 1), and sets INPUT_EDGE_*xxx* to this value. In *Figure 2.75*, INPUT_RAW_*xxx* has a status of logical 1 at the expiration of the timer, and INPUT_EDGE_*xxx* remains at logical 1.

NOTE
INPUT_EDGE and INPUT_SOE tags are disabled by default in R118 and later, to optimize processing capability.

INPUT_*xxx* and INPUT_SOE_*xxx* assert only if INPUT_RAW_*xxx* remains asserted for the complete Pick Up Delay time of Debounce Timer 1. If INPUT_RAW_*xxx* deasserts at any point while Debounce Timer 1 is running, Debounce Timer 1 resets and starts timing from the beginning of the next rising edge.

The inverse operation applies when the input changes from the asserted state to the deasserted state, as shown in *Figure 2.76*.

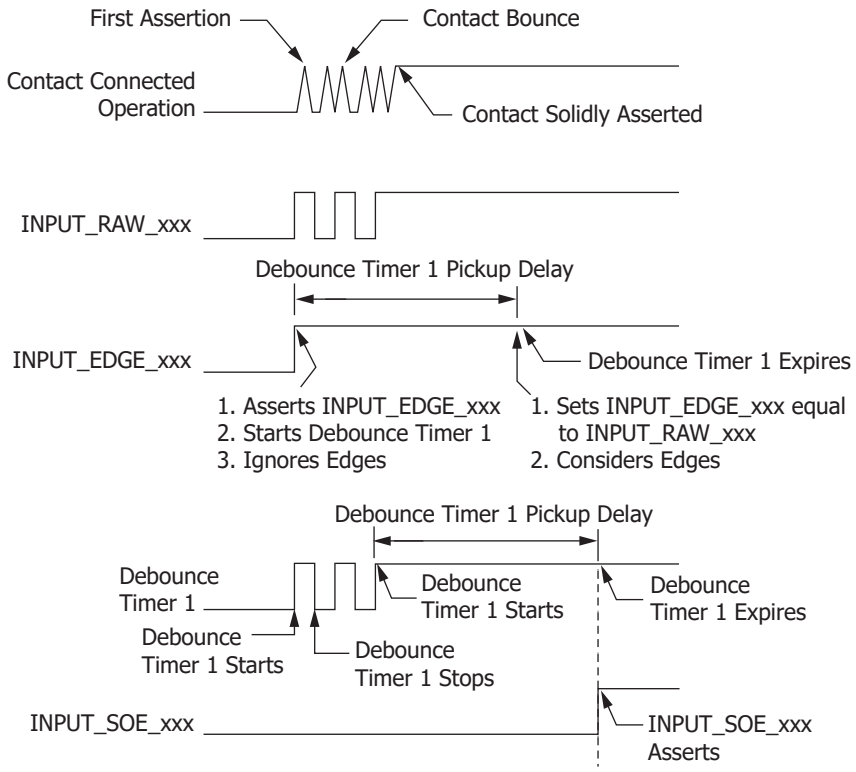

Figure 2.75 Timing Diagram When Input Changes From the Deasserted State to the Asserted State

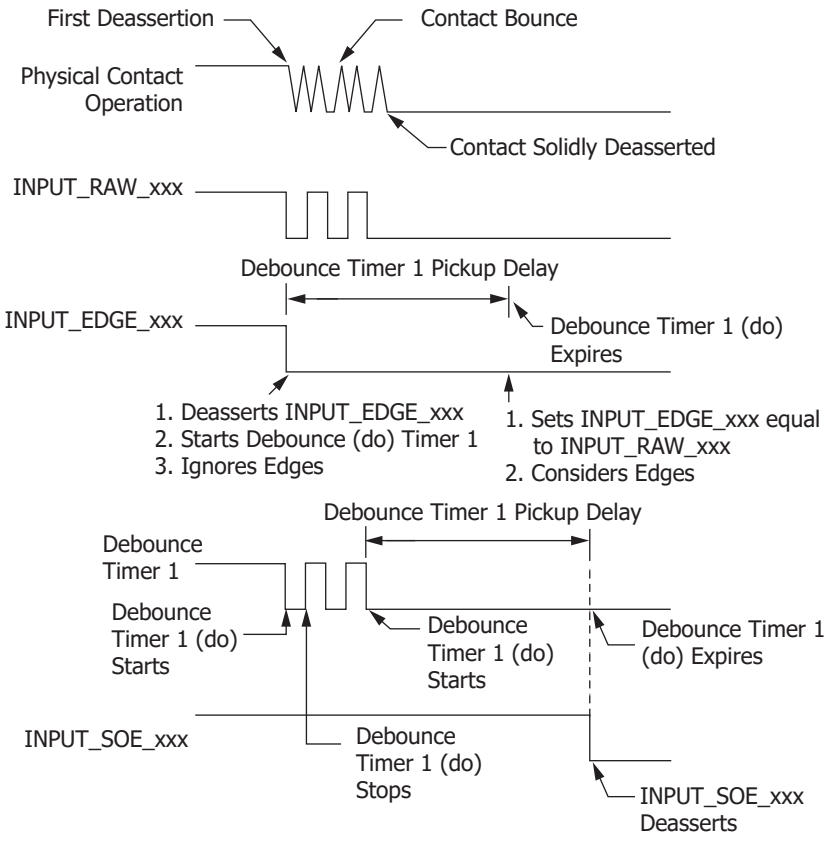

Figure 2.76 Timing Diagram When Input Changes From the Asserted State to the Deasserted State

AC Mode Processing (AC Control Voltage)

NOTE

In R118 and later, the AC/DC mode selection applies to an entire module rather than individual inputs. Converting from an older project with mixed settings will result in the first selection applying to the whole module.

Figure 2.77 shows the logic for the ac voltage type mode of operation, which you select through use of the voltage type setting shown in *Figure 2.73*. The Input_*xxx* and Input_SOE_*xxx* tags share a debounce timer. On assertion, INPUT_RAW_*xxx* (internal variable) starts the debounce timer, producing INPUT_*xxx* and INPUT_SOE_*xxx* after the debounce time delay. The ac mode differs from the dc mode in having only delayed time information available. There are also no adjustable time settings for the debounce timer in the ac mode: the Pick Up Delay is fixed at 2 ms, and the Drop Out Delay is fixed at 16 ms.

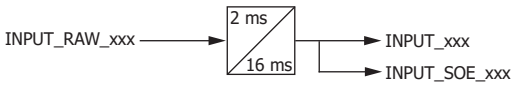

Figure 2.77 AC Mode Processing

Figure 2.78 shows a timing diagram for the ac mode of operation. On the rising edge of INPUT_RAW_*xxx*, the pickup timer starts timing (points marked 1 in *Figure 2.78*). If INPUT_RAW_*xxx* deasserts (points marked 2 in *Figure 2.78*) before expiration of the Pick Up Delay time, INPUT_*xxx* and INPUT_SOE_*xxx* will not assert, and they remain at logical 0. If, however, INPUT_RAW_xxx remains asserted for a period longer than the Pick Up Delay time, then both INPUT_*xxx* and INPUT_SOE_*xxx* assert to a logical 1.

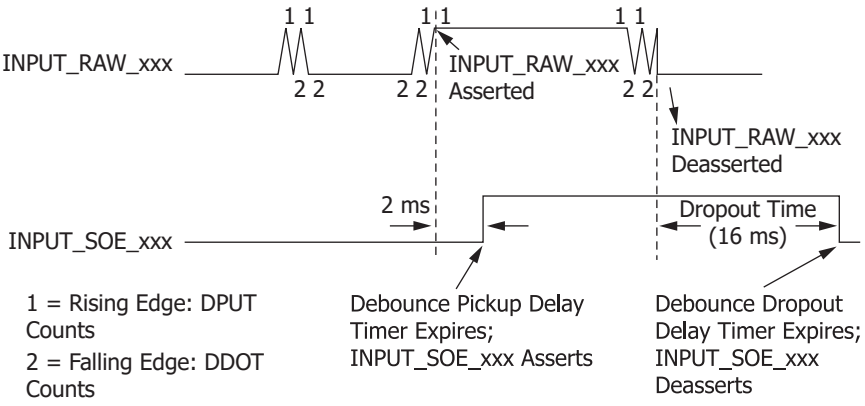

Figure 2.78 Timing Diagram for Debounce Timer Operation When Operating in AC Mode

Deassertion follows the same logic. On the falling edge of INPUT_RAW_*xxx*, the Drop Out Delay timer starts timing. If INPUT_RAW_*xxx* remains deasserted for a period longer than the Drop Out Delay setting, then INPUT_*xxx* and INPUT_SOE_*xxx* deassert to a logical 0.

Be aware that ac mode digital inputs require more processing time in the RTAC than dc mode digital inputs. As a general rule, you should not install more than two nodes full of ac digital inputs in a single Axion system. However, because of processor burden for other protocols and user logic, the best method to validate system performance is to test your project and verify that the EtherCAT message processing task does not regularly exceed 500 microseconds to run. You can check this by going online in ACSELERATOR RTAC, select **EtherCAT I/O Network** from the project tree view, and monitor the tags Client_Max_us and Client_Last_us. As discussed in *Task Cycle Time on page 138*, if you overload a task you will see poor performance in the web HMI or web server application. One way to reduce system burden is to distribute Axion I/O between multiple RTAC modules.

Creating a Counter From a Digital Input

You can use the input tags in any custom logic you want. Refer to the *Section 9: Custom Logic* for examples and *Appendix B: IEC 61131-3 Programming Reference* for IEC 61131-3 programming reference material. As a brief example, we will evaluate how to create a simple accumulator from a digital input. You could use this function to accumulate metering values or store the number of times an apparatus performs a specific sequence of operation. In this example, we used a CFC diagram, as shown in *Figure 2.79*. We use the stVal attribute of digital input INPUT_002 (refer to SPS data type in the IEC 61131-3 Programming Reference) in conjunction with a Rising Edge Trigger and an Incrementing Counter function block to create an output representing

the number of times the input has changed from the deasserted state to the asserted state. Remember that debouncing of INPUT_*xxx* values occurs as we discussed in the previous section. Add automatic or manual counter reset logic as necessary.

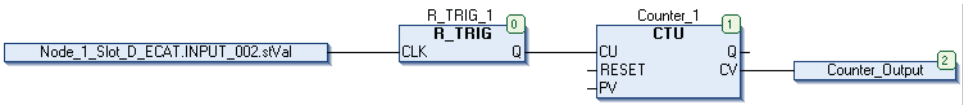

Figure 2.79 Creating a Counter Function From a Digital Input

SEL-2244 16 Digital Output and 10 Fast High-Current Digital Output Modules

The SEL-2244 Digital Output Module includes 16 independent standard contact outputs or 10 independent fast high-current contact outputs. You can order the module to have all Form A or all Form B contacts; they are not software selectable. Also, you can order a module that contains half Form A and half Form B outputs. Use the **Insert** ribbon selection, as shown in *Figure 2.80*, to include an instance of this module in your project. Be careful to select the output type you require for each module. You can configure an Axion node to have output modules with a variety of contact types.

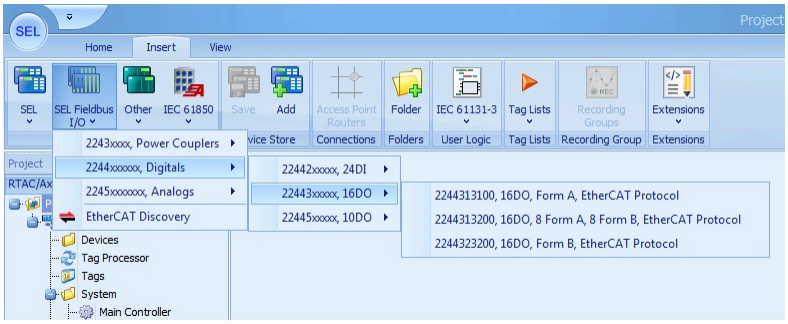

Figure 2.80 Insert an SEL-2244 Digital Output Module

Once you add a digital output module to a project, click the module name in the project view to open the connection editor. The **Properties** and **Diagnostics** tabs (see *Figure 2.72*) include the common EtherCAT module data discussed previously. The **Tags** tab lists all available and enabled tags from the module. Each of the 16 outputs in a module is controlled by an Input/Output Control (IOC) type tag. Refer to the IEC 61131-3 Programming Reference for detailed information on this tag type. Notice in *Figure 2.87* that each output will include a status, operSet, and operClear attribute. The physical output will assert when you set the operSet attribute. The physical output will deassert when you set the operClear attribute. The status attribute displays the latest commanded value for the output. Each output tag is enabled by default. Disable any unneeded tags to optimize processing resources.

Output Contact Pulse

EtherCAT Digital outputs and the optional SEL-3530 digital outputs execute pulse operations without custom logic. Enter pulse configuration data directly from custom programs or map the **TRIP**, **CLOSE**, or **PULSE** command from a DNP Binary Output by using the Tag Processor. When the operPulse.ctlVal is

toggled from FALSE to TRUE, the Output contact asserts for the length defined by operPulse.pulseConfig.OnDur and deasserts for the length of time defined by operPulse.pulseConfig.offDur. The pulse repeats the number of times defined by operPulse.pulseConfig.numPls. Assertions and deassertions occur in multiples of the RTE Cycle. On and Off durations that are not multiples of the RTE cycle time execute on the RTE cycle after the transition occurs. For example, if the RTE cycle is set to 100 ms, the onDur is set to 97 ms, and the offDur is set to 103 ms, the output contact will assert for 100 ms and then deassert for 200 ms (see *Figure 2.81*).

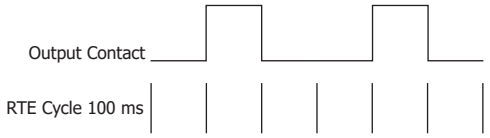

Figure 2.81 Pulse Train Duration

If an output is already asserted and a pulse command is received, the first state transition occurs at a time of onDur after the pulse command is processed (see *Figure 2.82*).

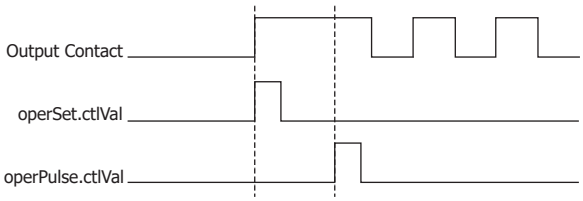

Figure 2.82 Pulsing an Asserted Output

If a pulse operation is in progress and the operClear.ctlVal is set to TRUE, the output deasserts and pulse operation ceases (see *Figure 2.83*).

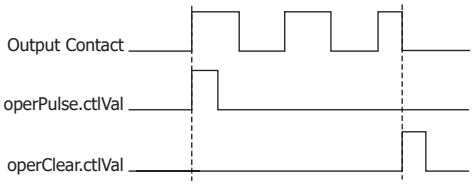

Figure 2.83 Interrupting a Pulse With a Clear Command

If a pulse operation is in progress and a new pulse command is received with a pulseConfig. onDur = 0, the output deasserts and pulse operation ceases (see *Figure 2.84*).

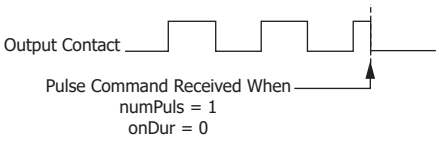

Figure 2.84 New Pulse Config onDur = 0

If a pulse operation is in progress and a new pulse command is received with a pulseConfig. numPls = 0, the asserted output remains asserted until onDur expires and pulse operation ceases. A deasserted output remains deasserted and pulse operation ceases (see *Figure 2.85*).

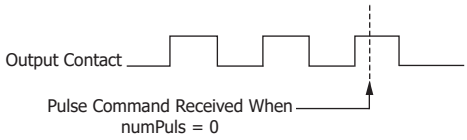

Figure 2.85 New Pulse Config numPls = 0

If a pulse command is received with a pulseConfig.offDur = 0, the output asserts for a time of onDur * numPls (see *Figure 2.86*).

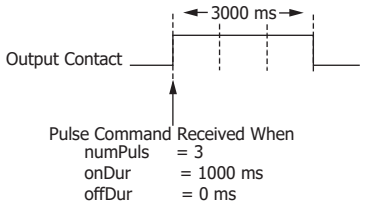

Figure 2.86 New Pulse Config offDur = 0

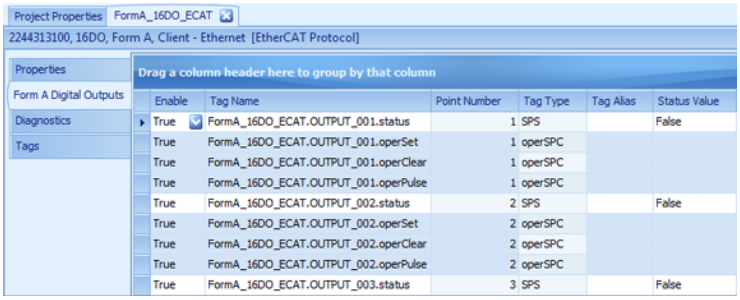

Figure 2.87 Digital Output Module Tag Attributes

Creating Paired Outputs

You can use the output tags in any custom logic you want. Refer to *Section 9: Custom Logic* for examples and *Appendix B: IEC 61131-3 Programming Reference* for IEC 61131-3 programming reference material. As an example, we will evaluate how to combine two physical outputs in an SEL-2244 Digital Output Module into a trip-close pair when used in conjunction with a DNP binary output tag. For this example, the RTAC module is connected to the SEL-2244 Digital Output Module and also operates as a DNP server (slave). This example associates one binary output DNP tag's trip and close attributes with two physical outputs (refer to *Figure 2.88* for the Tag Processor example). Configure the operTrip.pulseConfig and operClose.pulseConfig attributes for the tag SCADA_DNP.BO.00000 the same, setting the onDur := 3000ms, offDur := 1000ms, and numPls := 1. When the RTAC receives a **TRIP** command from the DNP Client, OUTPUT_001 asserts for three seconds. When the RTAC receives a **CLOSE** command from the DNP Client, OUTPUT_002 asserts for three seconds.

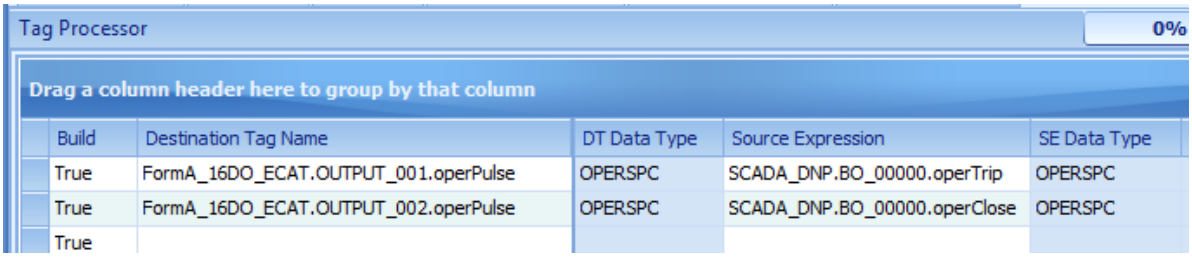

Figure 2.88 Tag Processor for Trip-Close Pair Example

SEL-2245-2 16 DC Analog Input Module

The SEL-2245-2 DC Analog Input Module includes 16 inputs for measuring low-level dc signals. The inputs are user configurable in pairs to measure signals within ±20 mA, ±2 mA, or ±10 V ranges. Use the **Insert** ribbon as shown to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click **Insert**.

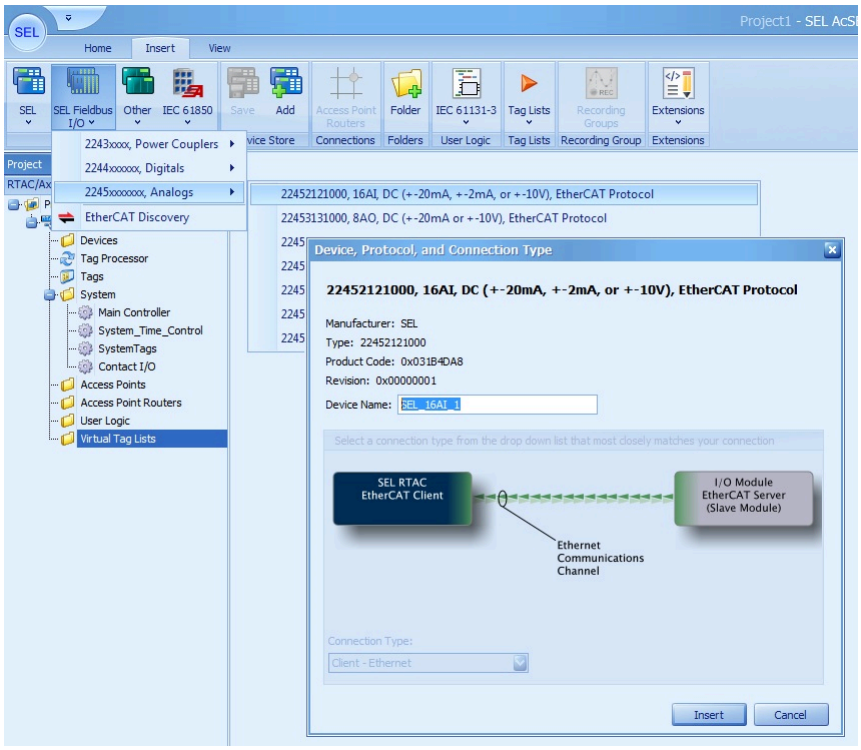

Figure 2.89 Insert an SEL-2245 DC Analog Input Module

Configure the Analog Input Module

In the project tree, select the module to open the module settings dialog window. Go to the **Settings** tab to select the input range of the analog inputs type (High Current, Low Current, and Voltage). See the specifications section for input specifications. Each input range selection is for a pair of inputs.

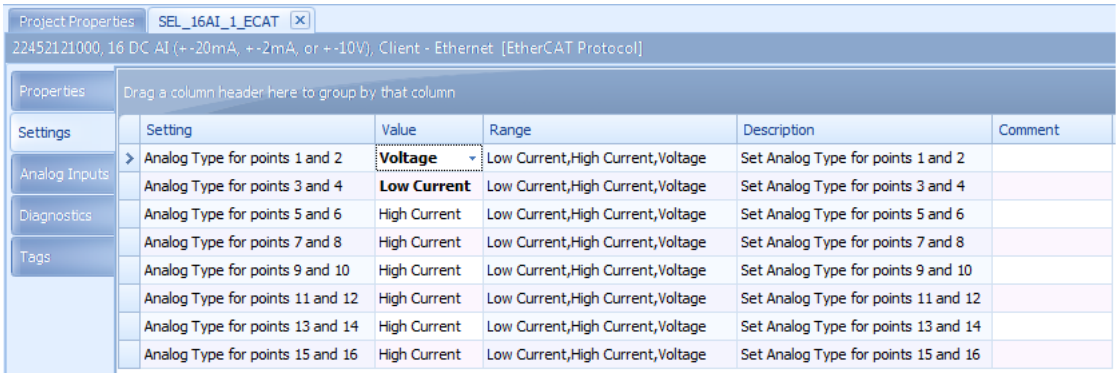

Figure 2.90 Analog Input Range Selection

The **Analog Inputs** tab allows you to configure the range of the inputs, alarm points and sampling parameters.

Enable

When True, this tag will be included when the program is compiled. When False, it will not be included. Disable all tags not in use to optimize processing resources.

Tag Name

Programming designation of a resource.

Tag Alias

Input an alternative name to use in place of the Tag Name while programming (for example, SEL_16AI_1_ECAT.INPUT_VALUE_001 could be replaced by "coolant_temp").

Engineering Units High and Engineering Units Low

The real-world quantities that the analog signal represents: temperature, pressure, etc.

Physical High and Physical Low

The high and low signal levels expected.

Example settings for a –50degC to 150degC 4–20mA transducer would be as follows:
Engineering Units High: 150
Engineering Unit Low: –50
Physical High: 20
Physical Low: 4

The software will then create a scaling factor to relate the current value to a real world temperature; for example 6 mA = –25 degrees C.

There are four set points: **Low Alarm**, **Low Warning**, **High Alarm**, **High Warning**. These fields are of the same type as the Engineering Units: temperature, psi, etc. When the analog value is exceeded the corresponding tag is set.

Example:

Setting **Low Alarm** to 10 would set the SEL_16AI_1_ECAT.INPUT_LOW_ALARM_001 tag when Temp ≤ 10 degrees C

Setting **High Alarm** to 90 would set the SEL_16AI_1_ECAT.INPUT_HIGH_ALARM_001 tag when Temp ≥ 90 degrees C

Deadband
The value is set in engineering units and is the amount that the analog input value must return below or above the high and low alarms, respectively, to clear the alarm condition.

Filter Type	
None	No filters are applied. This will yield the fastest signal response.
Filter A	Slower response than None but has higher noise immunity. (See Specifications.)
Filter B	Medium response and medium immunity. (See Specifications.)
Filter C[a]	Slowest response but has the highest immunity. (See Specifications.)

Rate of Change
The amount the analog value has to change in the time specified (Rate of Change Sample Duration) before the rate of change alarm tag is set. Rate of Change is in engineering units and Rate of Change Sample Duration is in milliseconds.

[a] Filter C is only supported in SEL-2245-2 firmware R102 or later.

Diagnostics

STATUS	String representing the present operational status of the module.
Operational	Normal Operation
Non-Operational	Module is not communicating on the EtherCAT network.
ERROR	**String representing the network state for a module.**
No Error	Normal Operation
Cable Error	The network configuration has changed and does not match settings. This error could arise either from the movement of a server module or an Ethernet cable change.

Tags

INPUT_VALUE_*xxx* is of type MV and the value is of type REAL.[a]

All other tags are of type SPS and the value is of type BOOL

INPUT_HIGH_ALARM_*xxx*

INPUT_HIGH_WARN_*xxx*

INPUT_LOW_ALARM_*xxx*

INPUT_LOW_WARN_*xxx*

INPUT_RATE_CHANGE_ALARM_*xxx*

[a] xxx refers to the physical input designation within a module.

All alarm tags will return to false on the next cycle after an alarm condition is no longer present.

Waveform Recording

NOTE
Waveform reading is only supported in SEL-2245-2 firmware R102 or later.

Waveforms will be recording in COMTRADE format with an accompanying configuration file. File names are stored as follows:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

A maximum of 1024 COMTRADE events can be stored in the RTAC with the oldest record being deleted when a new event is triggered and 1024 is exceeded. The SEL-2245-2 can record two back-to-back events. A new record can be triggered as soon as the current one has finished recording. A trigger condition that occurs before the current recording finishes is ignored. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

Inputs

The following analog inputs are recorded in the COMTRADE files generated by the SEL-2245-2 modules:

AI1–AI16

Downloading Events Via the Web Interface

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **https://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click on **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the **Device Filter**.

Step 7. Select the desired events and click **Download**. You can also delete events by clicking **Delete**.

Table 2.66 Waveform Settings

Setting	Description
VoltageInputConfiguration	Voltage input configuration
FrequencyNominal	Nominal system frequency
OscillographyCaptureRate	Sampling rate: 1 kHz
OscillographyRecordLength	Total record length: 0.5–144 seconds

Setting	Description
OscillographyPreTriggerLength	Pre-trigger record length: 0.05 seconds minimum to a maximum of (record length – 0.05) seconds
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
Module_name.Event_Trigger	Boolean input that triggers waveform recording in the module and only responds to rising edges

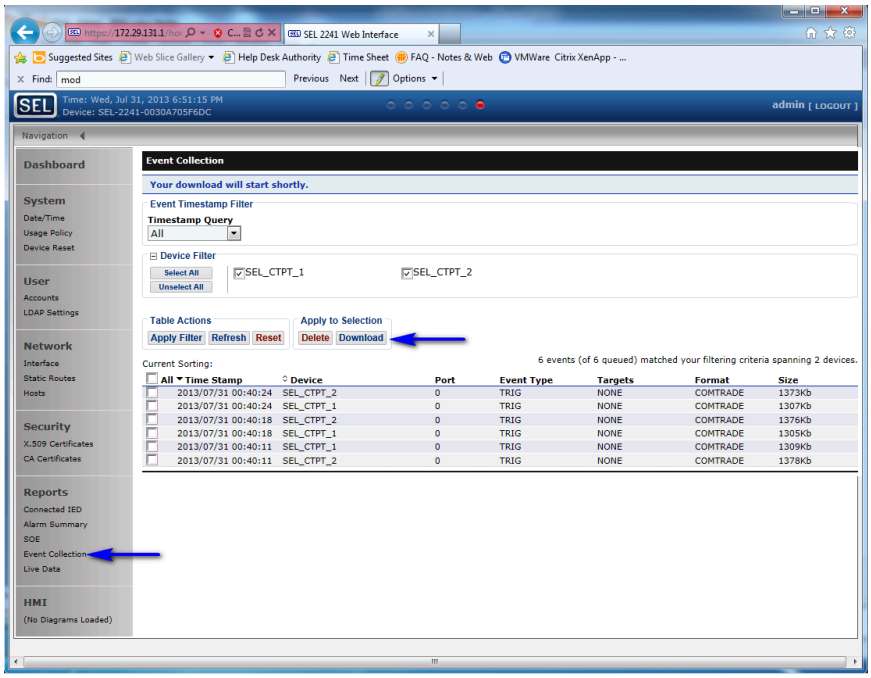

Figure 2.91 Waveform Record Retrieval

Viewing Waveforms and Event Files

Events files created by the SEL-2245-2 are in COMTRADE format. Event viewing software such as SEL-5601-2 SYNCHROWAVE® Event Software is required to open these files.

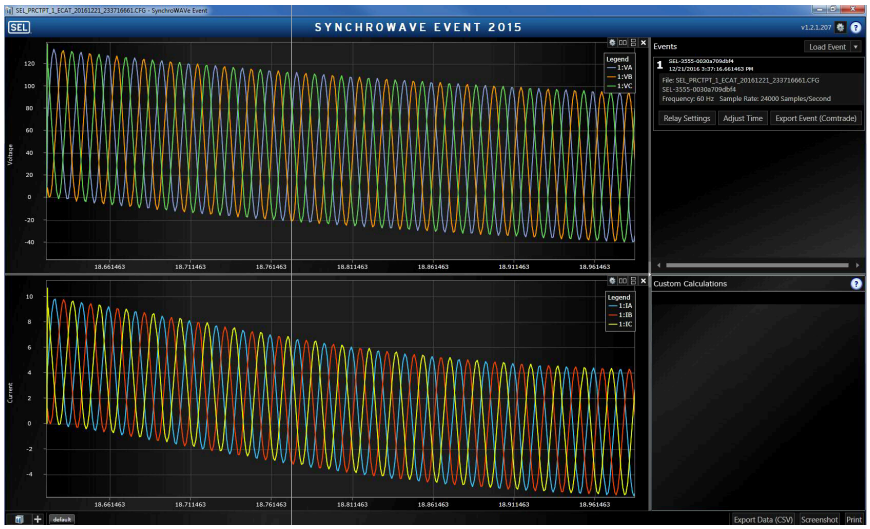

Figure 2.92 SYNCHROWAVE Event Display Waveform

Field Calibration Procedure

Step 1. Turn the Axion with the SEL-2245-2 on and allow it to warm up for a few minutes.

Step 2. Set the analog inputs for each analog channel to the desired range (e.g., 4–20 mA), using the value on the **Settings** tab and **Physical High**, and **Physical Low** on the **Analog Input** tab. Set **Engineering Units High** equal to **Physical High** and **Engineering Units Low** equal to **Physical Low**.

Step 3. Using a calibrated source, drive the signal line from the transducer end to the low value (for example, 4 mA).

Record ten measurements from the analog input value, then calculate the average of the ten measurements by adding the ten values algebraically, and dividing the sum by ten. This is the actual low value (for example, 3.9 mA).

Step 4. Enter this value in **Physical Low**.

Step 5. Drive the line to the high value (for example, 20 mA).

Step 6. Repeat *Step 3*.

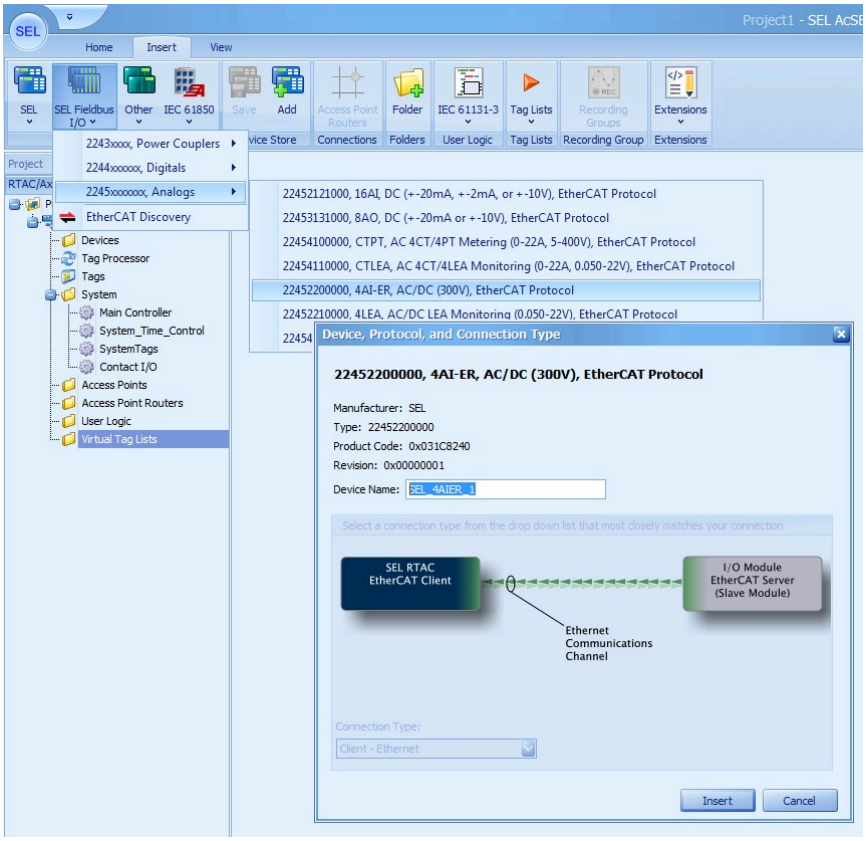
Step 7. This is the actual high value (for example, 20.012 mA). Enter this value in **Physical High**.

Step 8. Set **Engineering Units High** and **Engineering Units Low** to desired values (for example, –50F to +150F).

SEL-2245-22 Four Analog Input Extended Range Module

The SEL-2245-22 Analog Input Extended Range Module includes four inputs for measuring high-level dc or ac signals. Refer to *Specifications in the SEL-2240 Axion Instruction Manual* for details on the input range for DC or AC Mode. Use the **Insert** ribbon as shown to add an instance of this module to your project. The displayed popup will allow you to change the module name if necessary. When finished, click **Insert**.

NOTE
AC metering mode was added to the SEL-2245-22 module firmware in R101 and to the RTAC in R141.



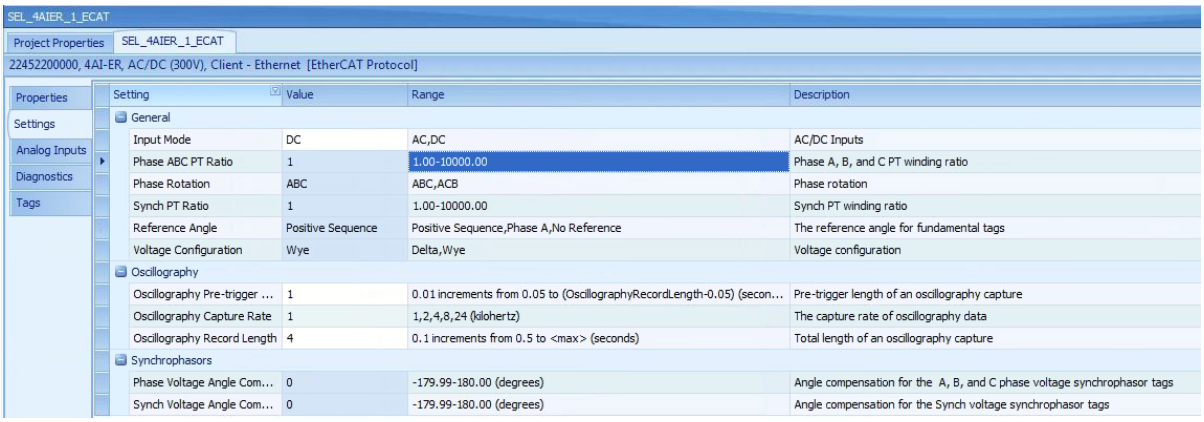


Figure 2.93 Insert an SEL-2245-22 DC Analog Input Extended Range Module

Configuring the Analog Input Module (DC Mode)

In the **Settings** tab, select DC for the Input Mode. This will enable the dc analog measurements and the associated settings.

The **Settings** tab also includes voltage parameter settings for AC Mode as well as Oscillography and Synchrophasor settings.

Setting	Value	Range	Description
General			
Input Mode	DC	AC,DC	AC/DC Inputs
Phase ABC PT Ratio	1	1.00-10000.00	Phase A, B, and C PT winding ratio
Phase Rotation	ABC	ABC,ACB	Phase rotation
Synch PT Ratio	1	1.00-10000.00	Synch PT winding ratio
Reference Angle	Positive Sequence	Positive Sequence,Phase A,No Reference	The reference angle for fundamental tags
Voltage Configuration	Wye	Delta,Wye	Voltage configuration
Oscillography			
Oscillography Pre-trigger ...	1	0.01 increments from 0.05 to (OscillographyRecordLength-0.05) (secon...	Pre-trigger length of an oscillography capture
Oscillography Capture Rate	1	1,2,4,8,24 (kilohertz)	The capture rate of oscillography data
Oscillography Record Length	4	0.1 increments from 0.5 to <max> (seconds)	Total length of an oscillography capture
Synchrophasors			
Phase Voltage Angle Com...	0	-179.99-180.00 (degrees)	Angle compensation for the A, B, and C phase voltage synchrophasor tags
Synch Voltage Angle Com...	0	-179.99-180.00 (degrees)	Angle compensation for the Synch voltage synchrophasor tags

Figure 2.94 SEL-2245-22 Settings Tab (DC Mode)

The **Analog Inputs** tab allows you to configure the range of the inputs, alarm points and sampling parameters. The following table shows the settings of the **Analog Inputs** tab in DC Mode.

Enable
When True, this tag will be included when the program is compiled. When False, it will not be included. Disable all tags not in use to optimize processing resources.
Tag Name
Programming designation of a resource.
Tag Alias
Input an alternative name to use in place of the Tag Name while programming (for example, SEL_4AIER_1_ECAT.INPUT_VALUE_001 could be replaced by "coolant_temp").
Engineering Units High and Engineering Units Low
The real-world quantities that the analog signal represents: temperature, pressure, etc.
Physical High and Physical Low
The high and low signal levels expected. Example settings: Engineering Units: 300 Engineering Units Low: 0 Physical High: 300 Physical Low: 0 The software will then create a scaling factor to relate the current value to a real-world value.

There are four set points: **Low Alarm**, **Low Warning**, **High Alarm**, **High Warning**. These fields are of the same type as the Engineering Units: voltage, temperature, psi, etc. When the analog value is exceeded the corresponding tag is set.

Example:

Setting **Low Alarm** to 100 would set the SEL_4AIER_1_ECAT.INPUT_LOW_ALARM_001 tag when Volts ≥ 100 Vdc

Setting **High Alarm** to 130 would set the SEL_4AIER_1_ECAT.INPUT_HIGH_ALARM_001 tag when Volts ≥ 130 Vdc

Deadband	
The value is set in engineering units and is the amount that the analog input value must return below or above the high and low alarms, respectively, to clear the alarm condition.	
Filter Type	
None	No filters are applied. This will yield the fastest signal response.
Filter A	Slower response than None but has higher noise immunity. (See Specifications.)
Filter B	Medium response and medium immunity. (See Specifications.)
Filter C	Slowest response but has the highest immunity. (See Specifications.)
Rate of Change	
The amount the analog value has to change in the time specified (Rate of Change Sample Duration) before the rate of change alarm tag is set. Rate of Change is in engineering units and Rate of Change Sample Duration is in milliseconds.	

Diagnostics

STATUS	String representing the present operational status of the module.
Operational	Normal Operation
Non-Operational	Module is not communicating on the EtherCAT network.
ERROR	**String representing the network state for a module.**
No Error	Normal Operation
Cable Error	The network configuration has changed and does not match settings. This error could arise either from the movement of a server module or an Ethernet cable change.

Tags

INPUT_VALUE_*xxx* is of type MV and the value is of type REAL.[a]
All other tags are of type SPS and the value is of type BOOL
INPUT_HIGH_ALARM_*xxx*
INPUT_HIGH_WARN_*xxx*
INPUT_LOW_ALARM_*xxx*
INPUT_LOW_WARN_*xxx*
INPUT_RATE_CHANGE_ALARM_*xxx*

[a] xxx refers to the physical input designation with a module.

All alarm tags will return to false on the next cycle after an alarm condition is no longer present.

Configuring the Analog Input Module (AC Mode)

In the **Settings** tab, select AC for the Input Mode. This will enable the ac metering inputs and its associated settings.

The **Settings** tab also includes Voltage parameter settings for DC Mode as well as Oscillography and Synchrophasor settings.

Figure 2.95 SEL-2245-22 Settings Tab (AC Mode)

The **Analog Inputs** tab allows you to configure the range of the inputs, alarm points and sampling parameters. *Table 2.67* shows the settings of the **Analog Inputs** tab in AC Mode.

NOTE

RMS voltage quantities have units of kilovolts and Fundamental voltage quantities are in units of volts.

Table 2.67 Analog Inputs Settings

Setting	Configuration Options
Phase Rotation	ABC or ACB
Voltage Configuration	Configure inputs for three-wire Delta or four-wire Wye
Phase ABC PT ratio	1.00–10000.00
Synch PT Ratio	1.00–10000.00
Reference Angle	Select reference for Fundamental Vector quantities
Oscillography Capture Rate	Capture rate of oscillography data
Oscillography Record Length	Length of oscillography capture. Capture rate affects maximum record length.
Oscillography Pre-Trigger Length	Length of time before trigger to start capture
Station Name	1–255 characters
Voltage Phasor Data Set	All, Phase, Positive Sequence, None
PMU Id	1–65534
Global PMU Id	$0–2^{128 - 1}$

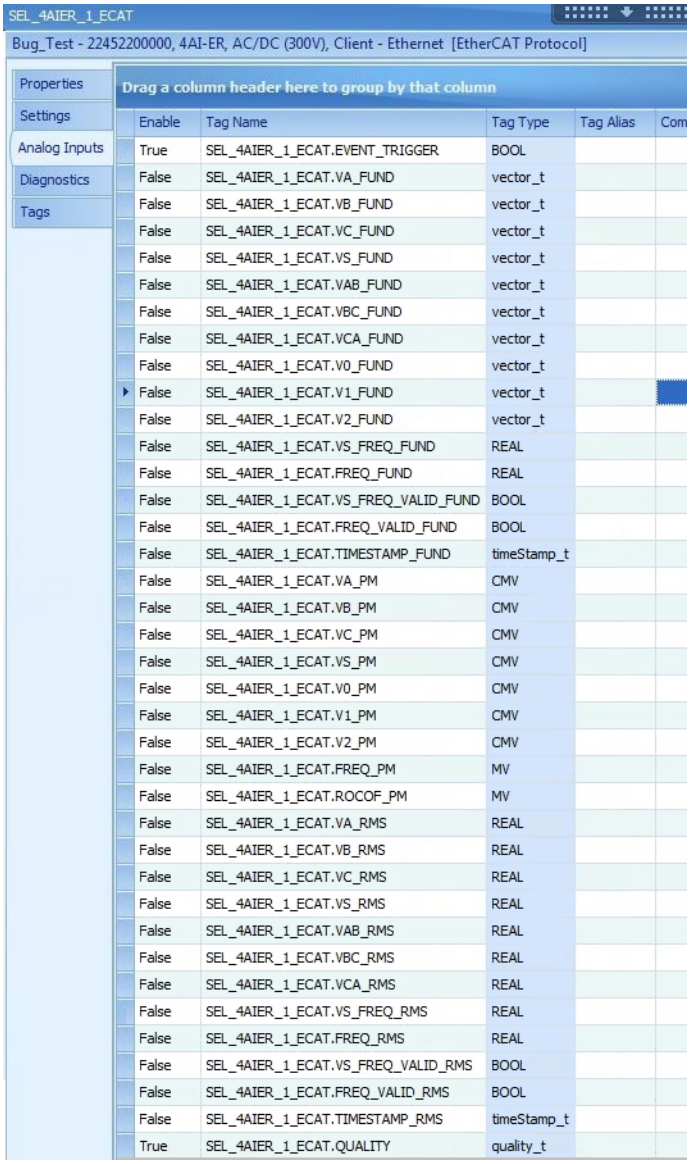

Figure 2.96 AC Mode Tag Settings

Analog Input	Description
Enable	When True, this tag will be included when the program is compiled. When False it will not be included. Disable all tags not in use to optimize processing resources. If there are too many analog data on the EtherCAT backplane, you will receive a message that the bandwidth has been exceeded (shown in *Figure 2.112*).
Tag Name	Programming designation of a resource.
Tag Alias	Input an alternative name to use in place of the Tag Name while programming (for example, SEL_CTPT_1_ECAT.IA_FUND could be replaced by IA_Bus1).

Waveform Recording

Waveforms will be recording in COMTRADE format with an accompanying configuration file. File names are stored as follows:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

A maximum of 1024 COMTRADE events can be stored in the RTAC with the oldest record being deleted when a new event is triggered and 1024 is exceeded. The SEL-2245-22 can record two back-to-back events. A new record can be triggered as soon as the current one has finished recording. A trigger condition that occurs before the current recording finishes is ignored. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

Inputs

The following analog inputs are recorded in the COMTRADE files generated by the SEL-2245-22 modules in DC Mode:

AI1–AI4

The following analog inputs are recorded in the COMTRADE files generated by the SEL-2245-22 modules in AC Mode:

VA, VB, VC, VS (Wye)

VAB, VBC, VCA (Delta)

Downloading Events Via the Web Interface

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **https://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click on **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the **Device Filter**.

Step 7. Select the desired events and click **Download**. You can also delete events by clicking **Delete**.

Table 2.68 Waveform Settings

Setting	Description
VoltageInputConfiguration	Voltage input configuration
FrequencyNominal	Nominal system frequency
OscillographyCaptureRate	Sampling rate: 1, 2, 4, 8, 24 kHz; software-selectable
OscillographyRecordLength	Total record length: 6 seconds at 24 kHz 18 seconds at 8 kHz 36 seconds at 4 kHz 72 seconds at 2 kHz 144 seconds at 1 kHz
OscillographyPreTriggerLength	Pre-trigger record length: 0.05 seconds minimum to a maximum of (record length – 0.05) seconds
PTRatio	Phase A, B, C PT winding ratio
PTRatioS	Synch PT winding ratio
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
module_name.Event_Trigger	Boolean input that triggers waveform recording in the module and only responds to rising edges

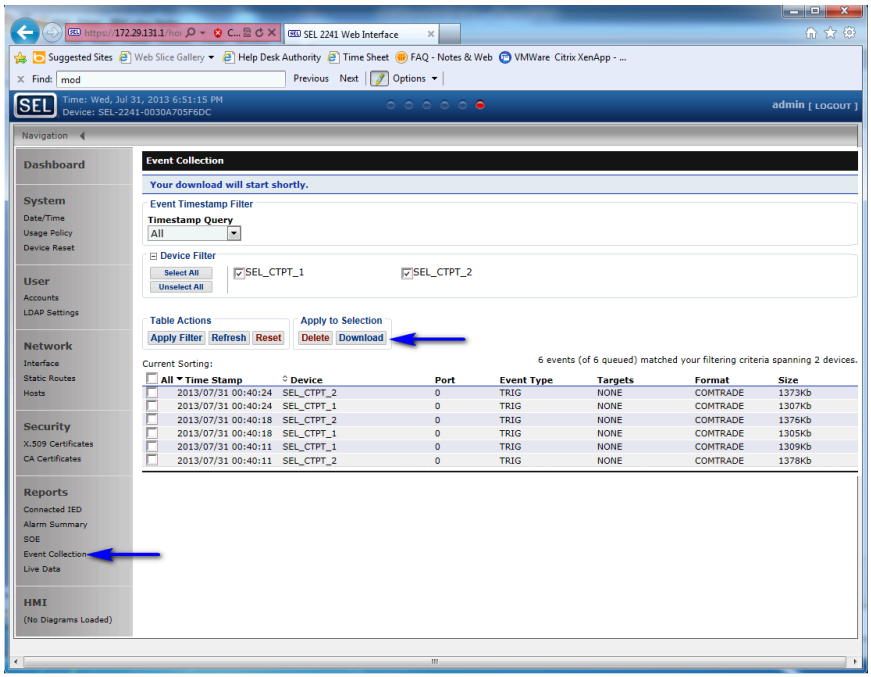

Figure 2.97 Waveform Record Retrieval

Viewing Waveforms and Event Files

Events files created by the SEL-2245-22 are in COMTRADE format. Event viewing software such as SYNCHROWAVE Event is required to open these files.

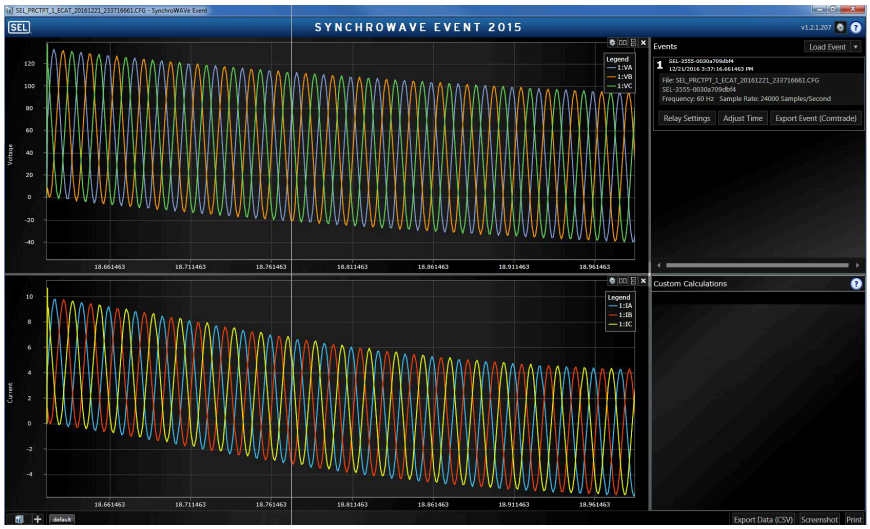

Figure 2.98 SYNCHROWAVE Event Display Waveform

Field Calibration Procedure

Step 1. Turn the Axion with the SEL-2245-22 on and allow it to warm up for a few minutes.

Step 2. Set the analog inputs for each analog channel to the desired range (e.g., 0–300 V), using the value on the **Physical High**, and **Physical Low** on the **Analog Input** tab. Set **Engineering Units High** equal to **Physical High** and **Engineering Units Low** equal to **Physical Low**.

Step 3. Using a calibrated source, drive the signal line from the transducer end to the low value (for example, 0 V).

Step 4. Record ten measurements from the analog input value, then calculate the average of the ten measurements by adding the ten values algebraically, and dividing the sum by ten. This is the actual low value (for example, 0.01 V).

Step 5. Enter this value in **Physical Low**.

Step 6. Drive the line to the high value (for example, 300 V).

Step 7. Repeat *Step 4*.

Step 8. This is the actual high value (for example, 300.1 V). Enter this value in **Physical High**.

Step 9. Set **Engineering Units High** and **Engineering Units Low** to desired values (for example, 0 V to 300 V).

SEL-2245-221 Low-Voltage (LEA) Monitoring Module

The SEL-2245-221 Low-Voltage (LEA) Monitoring Module (4 LEA) includes four low-voltage inputs with isolated returns for measuring ac signals. Refer to *Specifications in the SEL-2240 Axion Instruction Manual* for details on the input range. Use the **Insert** ribbon as shown in *Figure 2.103* to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click **Insert**.

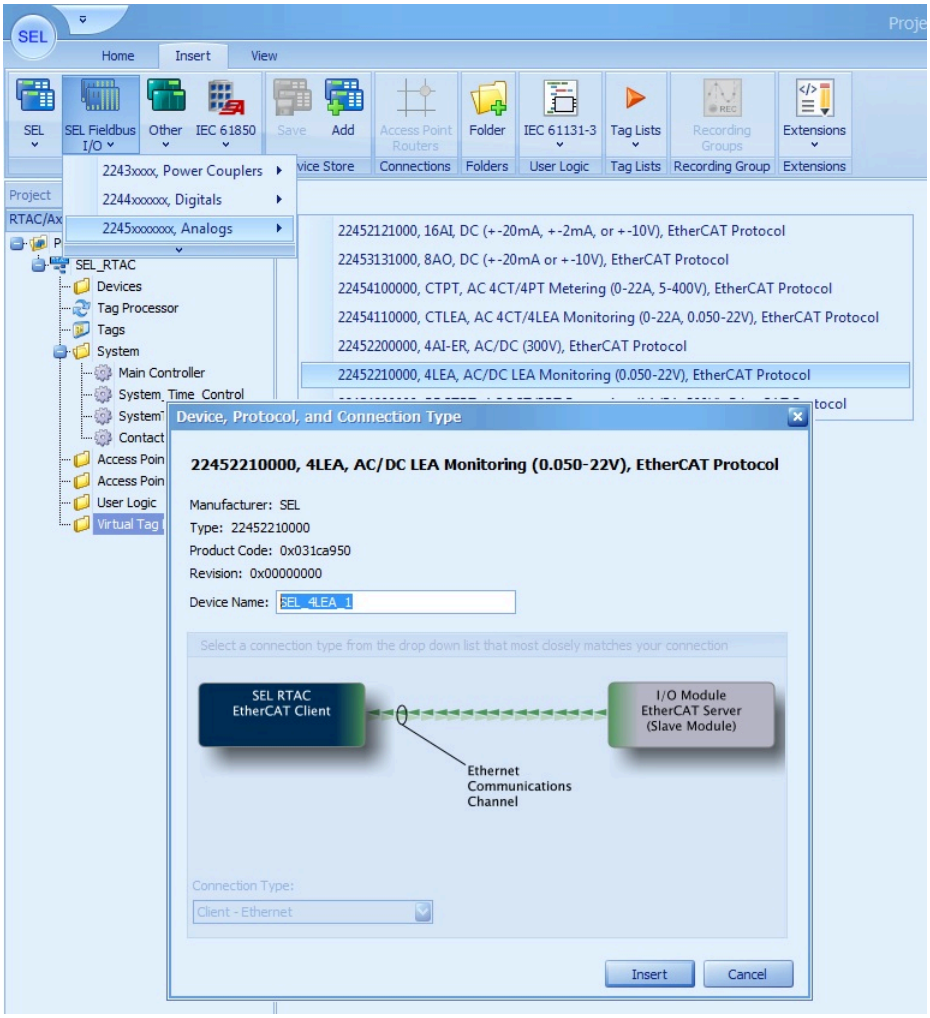

Figure 2.99 Insert an SEL-2245-221 4 LEA Module

Configuring the LEA Monitoring Module

In the project tree, select the module to open the module settings window. Click the **Settings** tab to configure the module.

NOTE

Only individual tags enabled per the LEA Monitoring Module are included in the EtherCAT message frame to reduce bandwidth. This allows for the use of more modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration.

Setting	Value	Range	Description
General			
Input Mode	AC	AC,DC	AC/DC Inputs
Phase Rotation	ABC	ABC,ACB	Phase rotation
Phase ABC PT Ratio	35	1.00-10000.00	Phase A, B, and C PT winding ratio
Synch PT Ratio	35	1.00-10000.00	Synch PT winding ratio
Voltage Configuration	Wye	Delta,Wye	Voltage configuration
Reference Angle	Positive Sequence	Positive Sequen...	The reference angle for fundamental tags
LEA			
VA Voltage Magnitude Com...	1	0.500-50.000	Magnitude Compensation for the VA Voltage Channel
VB Voltage Magnitude Com...	1	0.500-50.000	Magnitude Compensation for the VB Voltage Channel
VC Voltage Magnitude Com...	1	0.500-50.000	Magnitude Compensation for the VC Voltage Channel
VS Voltage Magnitude Com...	1	0.500-50.000	Magnitude Compensation for the VS Voltage Channel
VA Voltage Angle Compens...	0	-10.00-10.00 (d...	Angle Compensation for the VA Voltage channel
VB Voltage Angle Compens...	0	-10.00-10.00 (d...	Angle Compensation for the VB Voltage channel
VC Voltage Angle Compens...	0	-10.00-10.00 (d...	Angle Compensation for the VC Voltage channel
VS Voltage Angle Compens...	0	-10.00-10.00 (d...	Angle Compensation for the VS Voltage channel
Oscillography			
Oscillography Capture Rate	1	1,2,4,8,24 (kilo...	The capture rate of oscillography data
Oscillography Record Length	4	0.1 increments ...	Total length of an oscillography capture
Oscillography Pre-trigger L...	1	0.01 increments...	Pre-trigger length of an oscillography capture
Oscillography Channel Units	Volts	Volts,Amps	Oscillography Channel Units for COMTRADE Configuration File
PMU			
Station Name	SEL_4LEA_1_ECAT	1-255 (characte...	The PMU station name
PMU Id	1	1-65534	Identifier for this PMU
Voltage Phasor Data Set	Phase	All,Phase,Positi...	Voltage Phasor channels for PMU data set
Synchrophasors			
Phase Voltage Angle Comp...	0	-179.99-180.00...	Angle compensation for the A, B, and C phase voltage synchrophasor tags
Synch Voltage Angle Comp...	0	-179.99-180.00...	Angle compensation for the Synch voltage synchrophasor tags

Figure 2.100 LEA Module Settings

Setting	Configuration Options
Phase Rotation	ABC or ACB
Voltage Configuration	Configure inputs for three-wire Delta or four-wireWye
Phase ABC PT Ratio	1.00–10000.00
Synch PT Ratio	1.00–10000.00
Enable RMS Tags	Shows rms quantities in the **Analog Inputs** tab
Enable Fundamental Tags	Shows Fundamental quantities in the **Analog Inputs** tab
Reference Angle	Select reference for Fundamental Vector quantities
Oscillography Capture Rate	Capture rate of oscillography data
Oscillography Record Length	Length of oscillography capture. Capture rate affects maximum record length (see *Specifications* in the *SEL-2240 Instruction Manual*).
Oscillography Pre-Trigger Length	Length of time before trigger to start capture
VA Voltage Magnitude Compensation	0.500 to 1.500
VB Voltage Magnitude Compensation	0.500 to 1.500

Setting	Configuration Options
VC Voltage Magnitude Compensation	0.500 to 1.500
VS Voltage Magnitude Compensation	0.500 to 1.500
VA Voltage Angle Compensation	–10.00 to 10.00
VB Voltage Angle Compensation	–10.00 to 10.00
VC Voltage Angle Compensation	–10.00 to 10.00
VS Voltage Angle Compensation	–10.00 to 10.00
Phase Voltage Angle Compensation	–179.99 to 180.00
Synch Voltage Angle Compensation	–179.99 to 180.00

NOTE

RMS voltage quantities have units of kilovolts and fundamental voltage quantities are in units of volts.

Figure 2.101 LEA Tag Enable Settings

Analog Input	Description
Enable	When True, this tag will be included when the program is compiled. When False, it will not be included. Disable all tags not in use to optimize processing resources. If there are too many analog data on the EtherCAT backplane, you will receive a message that the bandwidth has been exceeded (shown in *Figure 2.102*).
Tag Name	Programming designation of a resource.
Tag Alias	Input an alternative name to use in place of the Tag Name while programming (for example, SEL_CTLEA_1_ECAT.IA_FUND could be replaced by IA_Bus1).

NOTE
If you receive the message "EtherCAT Bandwidth Exceeded," you will need to disable a number of RMS or Fundamental tags on one or more LEA modules to reduce the bandwidth in use.

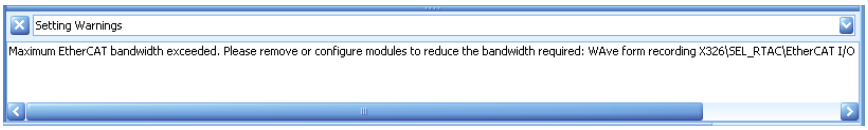

Figure 2.102 EtherCAT Bandwidth Exceeded

LEA Module Simple Tags

The LEA measurements are in a simplified format referred to as "Simple Tags." Complex measured values (CMV) display as the vector_t data subtype containing the angle and magnitude quantities. Measured values (MV) display as the REAL numeric type.

TimeStamp_t and quality_t tags are still available at the module level and automatically insert when mapping a Simple Tag to another tag type in the Tag Processor. Switching to the code view in the Tag Processor allows you to modify the default quality and time source if desired.

Waveform Recording

Waveforms are recorded in COMTRADE format with an accompanying configuration file. File names are stored in the following format:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

A maximum of 1024 COMTRADE events can be stored in the RTAC, with the oldest record being deleted when a new event is triggered and 1024 events are exceeded. The SEL-2245-221 can record two back-to-back events. A new record can be triggered as soon as the present one has finished recording. A trigger condition that occurs before the current recording finishes is ignored. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

Inputs

The following voltage and current inputs are recorded in the COMTRADE files generated by the SEL-2245-221 modules:

- IA, IB, IC, IN
- VA, VB, VC, VS (Wye)
- VAB, VBC, VCA (Delta)

NOTE
Waveform settings are configured in the individual LEA module settings tabs.

NOTE
Oscillography Pre-Trigger Length is relative to when the module receives the trigger through EtherCAT. Two or more processing intervals of the configured RTAC task cycle rate should be added to the desired pre-trigger length to ensure all desired data are captured.

Table 2.69 Waveform Settings

Setting	Description
VoltageInputConfiguration	Voltage input configuration
FrequencyNominal	Nominal system frequency
OscillographyCaptureRate	Sampling rate: 1, 2, 4, 8, 24 kHz; software-selectable
OscillographyRecordLength	Total record length: 6 seconds at 24 kHz 18 seconds at 8 kHz 36 seconds at 4 kHz 72 seconds at 2 kHz 144 seconds at 1 kHz
OscillographyPreTriggerLength	Pre-trigger record length: 0.05 seconds minimum to a maximum of (record length – 0.05) seconds
PTRatio	Phase A, B, C PT winding ratio
PTRatioS	Synch PT winding ratio
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
module_name.Event_Trigger	Boolean input that triggers waveform recording in the module and only responds to rising edges

Downloading Events Via the Web Interface

NOTE
To reduce bandwidth, only individually enabled LEA module tags are included in the EtherCAT message frame. This allows the use of more LEA modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration.

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **HTTPS://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the **Device Filter**.

Step 7. Select the desired events and click **Download**. You can also delete events by clicking **Delete**.

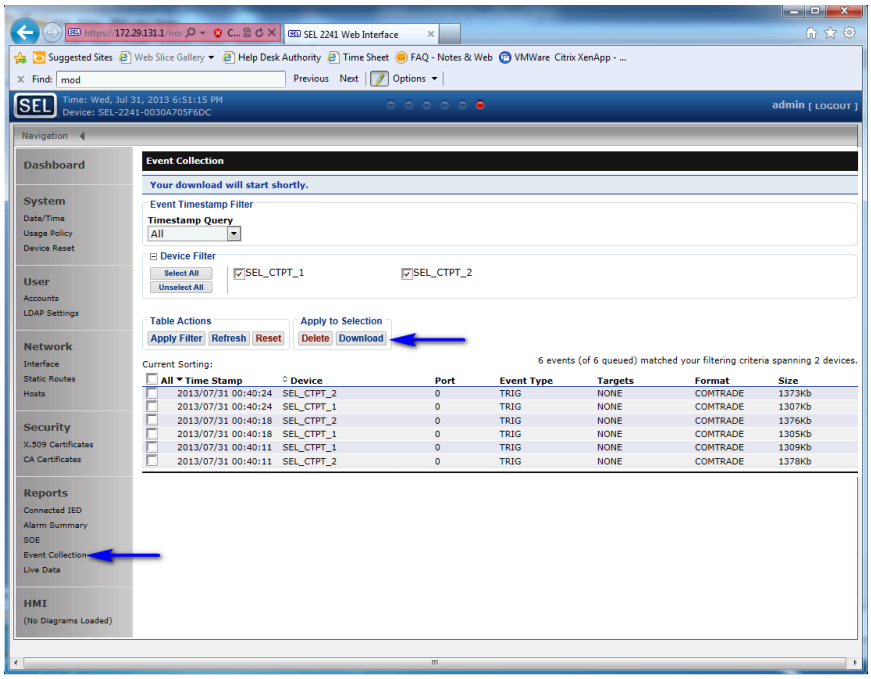

Figure 2.103 Waveform Record Retrieval

Viewing Waveforms and Event Files

Event files created by the SEL-2245-221 are in COMTRADE format. Event viewing software such as SYNCHROWAVE Event is required to open these files.

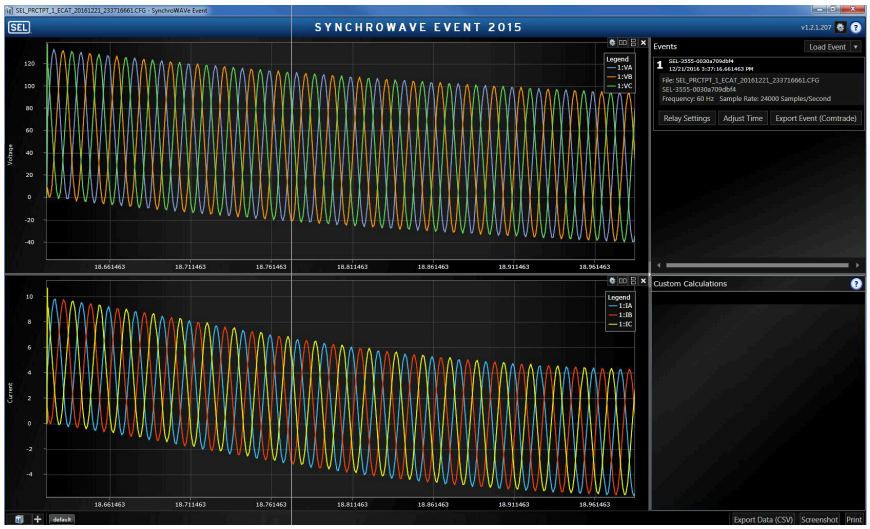

Figure 2.104 SYNCHROWAVE Event Display Waveform

SEL-2245-3 Eight DC Analog Output Module

The SEL-2245-3 DC Analog Output Module has eight sourcing dc outputs. Each output is user-configurable via a software switch between ±20 mA or ±10 Vdc. Use the **Insert** ribbon as shown in *Figure 2.109* to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click **Insert**.

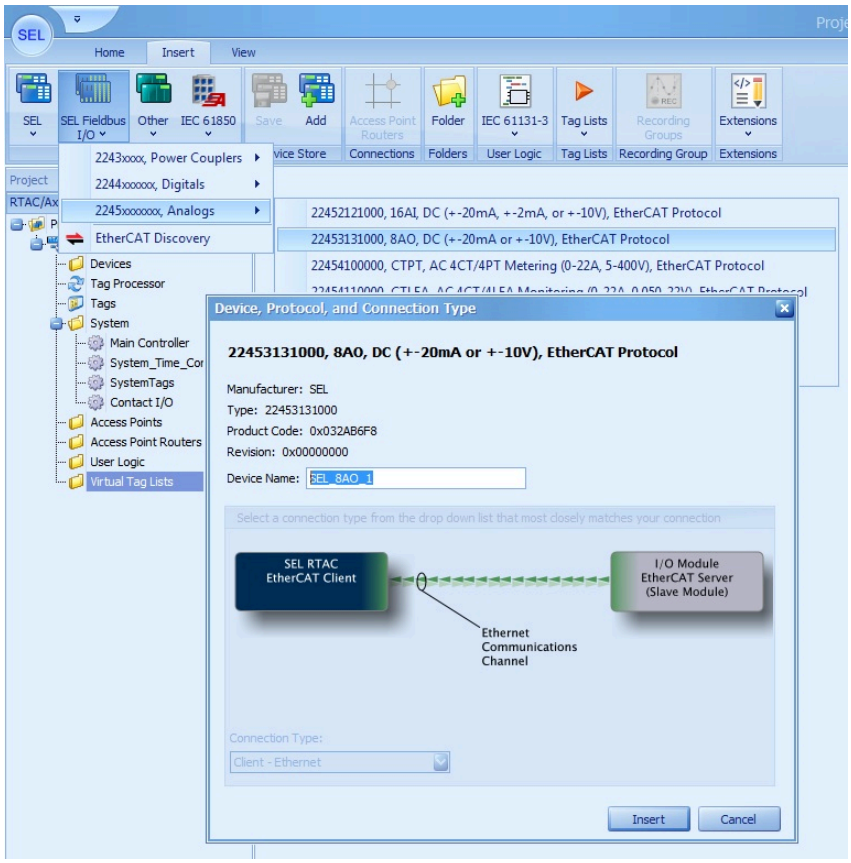

Figure 2.105 Insert an SEL-2245-3 DC Analog Output Module

Configuring the DC Analog Output Module

In the project tree, select the module to open the **Analog Outputs** dialog window. Go to the **Analog Outputs** tab to configure the analog output parameters. See *Specifications* in the *SEL-2240 Instruction Manual* for output specifications.

Enable

When TRUE, this tag will be included when the program is compiled. When FALSE, it will not be included. Disable all tags not in use to optimize processing resources.

Tag Name

Programming designation of a resource.

Tag Alias

Input an alternative name to use in place of the Tag Name while programming (for example, SEL_8AO_1_ECAT.AO_VALUE_001 could be replaced by "Conveyor_Speed").

Analog Type

Software switch for selecting voltage and current output modes.

Engineering Units High and Engineering Units Low

The real-world quantities that the analog signal represents: temperature, pressure, speed, etc.

Physical High and Physical Low

The high and low signal levels produced at the outputs in milliamperes (mA) or volts.

NOTE: The Analog Output is not restricted from driving above or below these values. To limit the output level, see Clamp Enable.

Example: Settings for a Variable Frequency Drive (VFD) connected to a conveyor with a maximum speed of 100 Feet Per Minute (FPM) based upon a 0 to +10 Vdc voltage reference would be as follows:
Engineering Units High: 100
Engineering Unit Low: 0
Physical High: 10
Physical Low: 0

The software will use the Engineering Units and Physical to create a slope equation to relate the real conveyor speed to a voltage for the VFD. In this example, setting AO_Value_*xxx* to 60 FPM will cause Output *xxx* to drive to +6 Vdc. However, if Clamp_ENABLE is FALSE and AO_VALUE_*xxx* is set to –90 FPM, the Analog Output will drive to –9 Vdc.

Safe Output

State applied to output when the module loses communication with the EtherCAT client for 100 ms or more. Options are **Last Value** or **User Defined**.

User Safe Output

Output is driven to this value when Safe Output is User Defined and the module loses EtherCAT communication for 100 ms or more. The output will be driven to this value even if it is outside the optional Clamp High or Clamp Low settings. This value is in engineering units.

Clamp Enable

Enables or disables software limits on output values.

Clamp Low

Lower limit on output when Clamp Enable is True. Value is in engineering units.

Clamp High
Upper limit on output when Clamp Enable is True. Value is in engineering units.
Comment
Editable description field.

Input TAGS	
AO_VALUE_*xxx*	Output value of the analog output in engineering units.
RAMP_ENABLE_*xxx*	Boolean input to enable ramping on an output channel.
RAMP_HOLD_*xxx*	Boolean input to hold the output at the current value during a ramp operation.
RAMP_TARGET_*xxx*	Value for the output to ramp to from AO_VALUE_*xxx* in engineering units.
RAMP_TIME_*xxx*	Number of milliseconds to ramp from VALUE_*xxx* to RAMP_TARGET_ *xxx*.
RAMP_TRIGGER_*xxx*	Boolean rising-edge trigger that latches AO_VALUE_*xxx*, RAMP_TARGET_*xxx*, and RAMP_TIME_*xxx*; begins or restarts ramp operation from VALUE_*xxx*.

Output TAGS	
AO_VALUE_ACTUAL_*xxx*	Actual value being output after ramping and clamping functions are applied. Value is in engineering units.
RAMPING_*xxx*	Boolean output indicating a ramp is in progress but the output has not reached RAMP_TARGET_*xxx*.
OUTPUT_CLAMPING_*xxx*	Boolean output indicating AO_VALUE_*xxx* is outside Clamp High and Clamp Low settings and is being clamped.

Field Calibration Procedure

Step 1. Set the Physical High and Physical Low values to the desired output levels (e.g., +10 V and –10 V).

Step 2. Set Engineering Units High equal to Physical High and Engineering Units Low equal to Physical Low.

Step 3. Force AO_VALUE_*xxx* to the High value (+10 V).

Step 4. Record the value displayed on your calibrated meter. This will be MEAS_high.

Step 5. Force AO_VALUE_*xxx* to the Low value (–10 V).

Step 6. Record the value displayed on your calibrated meter. This will be MEAS_low.

Step 7. Set Physical High value to (Physical High – MEAS_high + Physical High).

Step 8. Set Physical Low to (Physical Low – MEAS_low + Physical Low).

Step 9. Set the Engineering High and Low units to the desired range for your project.

Ramping Functions

If RAMP_ENABLE_*xxx* is TRUE and there is a rising edge on RAMP_TRIGGER_*xxx*, RAMP_TARGET_*xxx*, RAMP_TIME_*xxx*, and AO_VALUE_*xxx* are latched and the ramp process begins.

The output ramps from AO_VALUE_*xxx* to RAMP_TARGET_*xxx* over the time interval of RAMP_TIME_*xxx*.

If RAMP_ENABLE_*xxx* becomes FALSE, the output will return to the AO_VALUE_*xxx* that was latched.

If RAMP_HOLD_*xxx* becomes TRUE, the ramp timer is paused and the output will hold the current value until RAMP_HOLD_*xxx* or RAMP_ENABLE_*xxx* becomes FALSE.

When RAMP_TARGET_*xxx* is reached, the output will remain at that value until RAMP_ENABLE_*xxx* becomes FALSE.

If a rising edge is detected on RAMP_TRIGGER_*xxx* during the ramp process, RAMP_TARGET_*xxx*, RAMP_TIME_*xxx*, and AO_VALUE_*xxx* are latched and the ramp process restarts with the new values.

RAMP_TRIGGER_*xxx* is ignored if RAMP_HOLD_*xxx* is TRUE.

Figure 2.106 is an example of RAMP_HOLD_*xxx* asserting and deasserting during a ramp process.

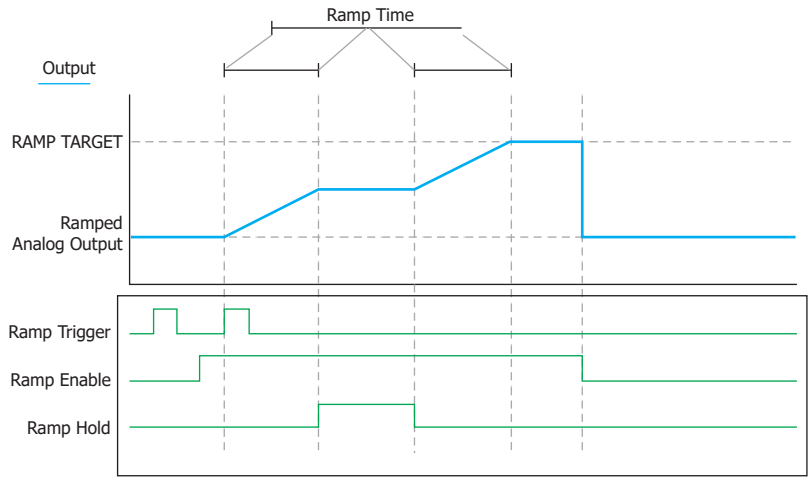

Figure 2.106 Hold During a Ramp Process

Figure 2.107 is an example of retriggering a ramp operation.

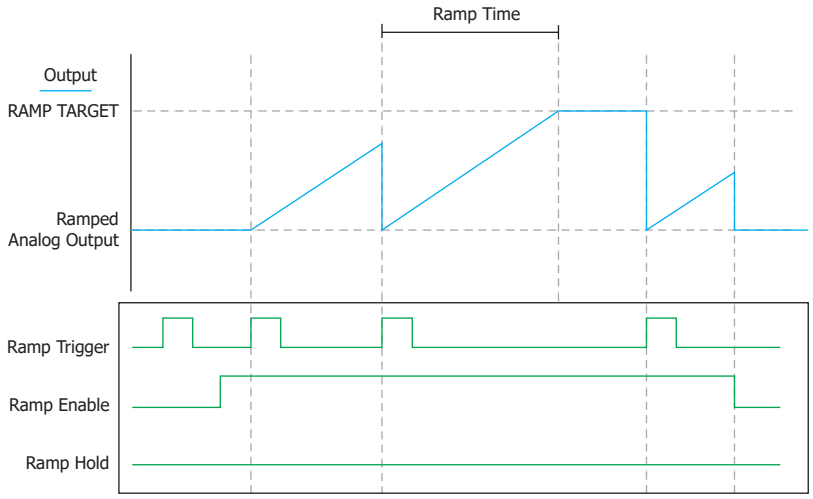

Figure 2.107 Retriggering a Ramp During a Ramp Process

SEL-2245-4 AC Metering Module

The SEL-2245-4 AC Metering Module (CTPT) includes four Potential Transformer inputs and four Current Transformer inputs with isolated returns for measuring ac signals. Refer to *Specifications in the SEL-2240 Axion Instruction Manual* for details on the input range. Use the **Insert** ribbon as shown in *Figure 2.112* to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click on **Insert**.

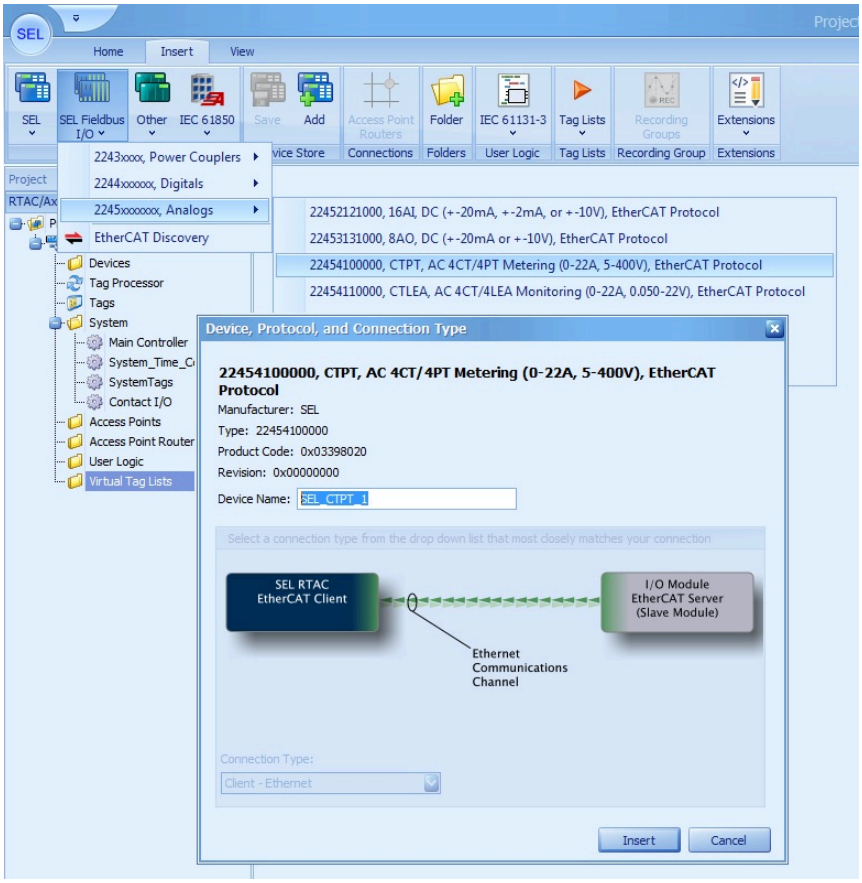

Figure 2.108 Insert an SEL-2245-4 CT/PT Analog Input Module

Configuring the AC Analog Input Module

In the project tree, select the module to open the module settings dialog window. Click on the **Settings** tab to configure the module.

Setting	Value	Range	Description
General			
Phase ABC CT Ratio	250	1.00-50000.00	Phase A, B, and C CT winding ratio
Neutral CT Ratio	250	1.00-50000.00	Neutral CT winding ratio
Voltage Configuration	Wye	Delta,Wye	Voltage configuration
Phase ABC PT Ratio	35	1.00-10000.00	Phase A, B, and C PT winding ratio
Synch PT Ratio	35	1.00-10000.00	Synch PT winding ratio
Phase Rotation	ABC	ABC,ACB	Phase rotation
Enable RMS Tags	True	True,False	Enables the creation of the RMS tags
Enable Fundamental Tags	False	True,False	Enables the creation of the fundamental tags
Enable Synchrophasor Tags	False	True,False	Enables the creation of the synchrophasor tags
Reference Angle	Positive Sequence	Positive Sequen...	The reference angle for fundamental tags
Oscillography			
Oscillography Record Length	1	0.1 increments ...	Total length of an oscillography capture
Oscillography Pre-trigger L...	0.05	0.01 increments...	Pre-trigger length of an oscillography capture
Oscillography Capture Rate	8	1,2,4,8,24 (kilo...	The capture rate of oscillography data
PMU			
Station Name	SEL_CTPT_1_ECAT	1-255 (characte...	The PMU station name
PMU Id	1	1-65534	Identifier for this PMU
Voltage Phasor Data Set	Phase	All,Phase,Positi...	Voltage Phasor channels for PMU data set
Current Phasor Data Set	Phase	All,Phase,Positi...	Current Phasor channels for PMU data set
Synchrophasors			
Phase Voltage Angle Comp...	0	-179.99-180.00...	Angle compensation for the A, B, and C phase voltage synchrophasor tags
Synch Voltage Angle Comp...	0	-179.99-180.00...	Angle compensation for the Synch voltage synchrophasor tags
Phase Current Angle Comp...	0	-179.99-180.00...	Angle compensation for the A, B, and C phase current synchrophasor tags
Neutral Current Angle Com...	0	-179.99-180.00...	Angle compensation for the neutral current synchrophasor tags

Figure 2.109 CT/PT Module Settings

Setting	Configuration Options
Phase Rotation	ABC or ACB
Voltage Configuration	Configure inputs for three-wire Delta or four-wire Wye
Phase ABC CT Ratio	1.00–50000.00
Neutral CT Ratio	1.00–50000.00
Phase ABC PT Ratio	1.00–10000.00
Synch PT Ratio	1.00–10000.00
Enable RMS Tags	Shows rms quantities in the **Analog Inputs** tab
Enable Fundamental Tags	Shows Fundamental quantities in the **Analog Inputs** tab
Enable Synchrophasor Tags	Shows Synchrophasor quantities in the **Analog Inputs** tab
Reference Angle	Select reference for Fundamental Vector quantities
Oscillography Capture Rate	Capture rate of oscillography data
Oscillography Record Length	Length of oscillography capture. Capture rate affects maximum record length (see Specifications).
Oscillography Pre-Trigger Length	Length of time before trigger to start capture

NOTE

In firmware R141 or later, only individual tags enabled per AC Metering Module are included in the EtherCAT message frame to reduce bandwidth. This allows the use of more AC Metering Modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration. Prior to R141, enabling the RMS, Fundamental, or Synchrophasor tag streams added all tags of each stream to the EtherCAT bandwidth.

NOTE

RMS voltage quantities have units of kilovolts and Fundamental voltage quantities are in units of volts.

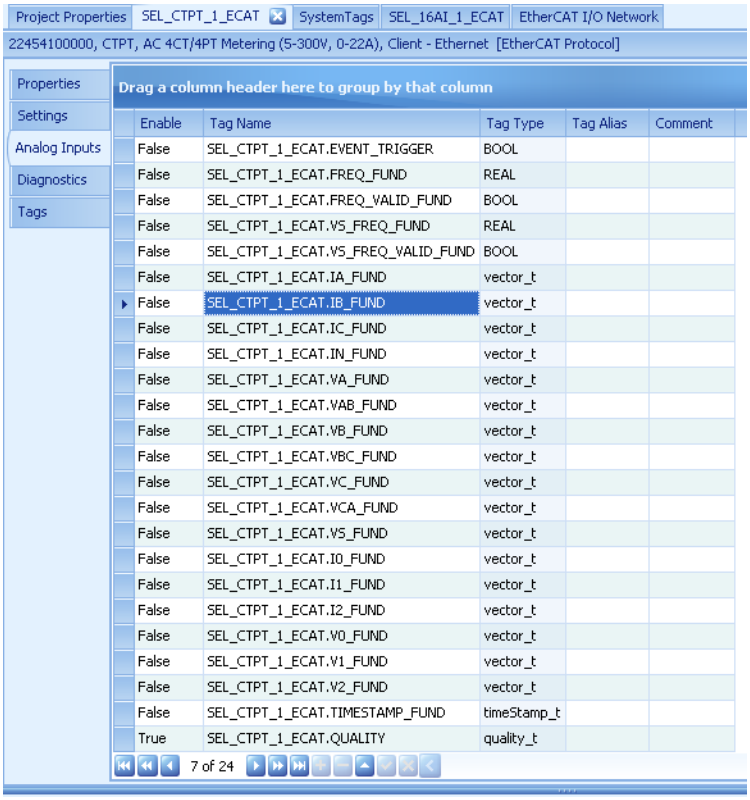

Figure 2.110 CT/PT Tag Enable Settings

Analog Input	Description
Enable	When True, this tag will be included when the program is compiled. When False it will not be included. Disable all tags not in use to optimize processing resources. If there are too many analog data on the EtherCAT backplane, you will receive a message that the bandwidth has been exceeded (shown in *Figure 2.111*).
Tag Name	Programming designation of a resource.
Tag Alias	Input an alternative name to use in place of the Tag Name while programming (for example, SEL_CTPT_1_ECAT.IA_FUND could be replaced by IA_Bus1).

NOTE
If you receive the message "EtherCAT Bandwidth Exceeded," you will need to disable a number of RMS, Fundamental, or Synchrophasor tags on one or more CT/PT modules to reduce the bandwidth in use.

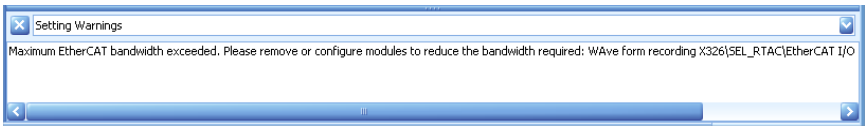

Figure 2.111 EtherCAT Bandwidth Exceeded

AC Module Simple Tags

The CT/PT measurements are in a simplified format referred to as "Simple Tags." Complex measured values (CMV) display as the vector_t data subtype containing the angle and magnitude quantities. Measured values (MV) display as the REAL numeric type.

TimeStamp_t and quality_t tags are still available at the module level and automatically insert when mapping a Simple Tag to another tag type in the Tag Processor. Switching to the code view in the Tag Processor will allow you to modify the default quality and time source if desired.

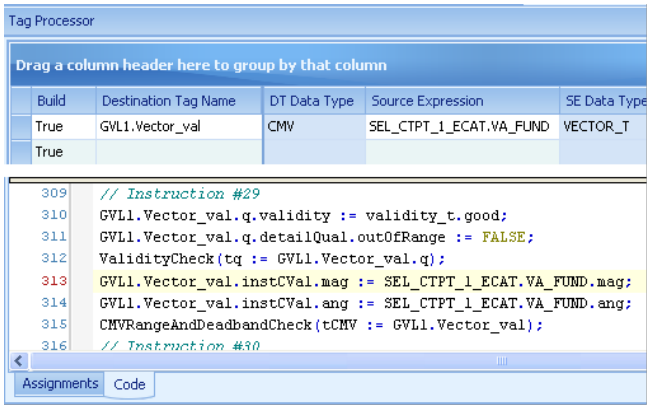

Figure 2.112 CT/PT Simple Tag to Complex Tag Mapping

Waveform Recording

Waveforms will be recording in COMTRADE format with an accompanying configuration file. File names are stored as follows:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

A maximum of 1024 COMTRADE events can be stored in the RTAC with the oldest record being deleted when a new event is triggered and 1024 is exceeded. The SEL-2245-4 can record two back-to-back events. A new record can be triggered as soon as the current one has finished recording. A trigger condition that occurs before the current recording finishes is ignored. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

Inputs

The following voltage and current inputs are recorded in the COMTRADE files generated by the SEL-2245-4 modules:

- IA, IB, IC, IN
- VA, VB, VC, VS (Wye)
- VAB, VBC, VCA (Delta)

NOTE
Waveform settings are configured in the individual CT/PT module settings tabs.

NOTE
Oscillography Pre-Trigger Length is relative to when the module receives the trigger through EtherCAT. Two or more processing intervals of the configured RTAC task cycle rate should be added to the desired pre-trigger length to ensure all desired data are captured.

Table 2.70 Waveform Settings

Setting	Description
VoltageInputConfiguration	Voltage input configuration
FrequencyNominal	Nominal system frequency
OscillographyCaptureRate	Sampling rate: 1, 2, 4, 8, 24 kHz; software-selectable
OscillographyRecordLength	Total record length: 6 seconds at 24 kHz 18 seconds at 8 kHz 36 seconds at 4 kHz 72 seconds at 2 kHz 144 seconds at 1 kHz
OscillographyPreTriggerLength	Pre-trigger record length: 0.05 seconds minimum to a maximum of (record length – 0.05) seconds
CTRatio	A-, B-, and C-phase CT winding ratio
CTRatioN	Neutral CT winding ratio
PTRatio	Phase A, B, C PT winding ratio
PTRatioS	Synch PT winding ratio

Setting	Description
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
module_name.Event_Trigger	This is a Boolean input that triggers waveform recording in the module and only responds to rising edges.

Downloading Events Via the Web Interface

NOTE
In firmware R140 or later, only individual tags enabled per AC Protection Module are included in the EtherCAT message frame to reduce bandwidth. This allows the use of more AC Protection Modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration. Prior to R140, enabling the RMS, Fundamental, or Synchrophasor tag streams added all tags of each stream to the EtherCAT bandwidth.

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **https://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click on **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the **Device Filter**.

Step 7. Select the desired events and click **Download**.

Step 8. You can also delete events by clicking **Delete**.

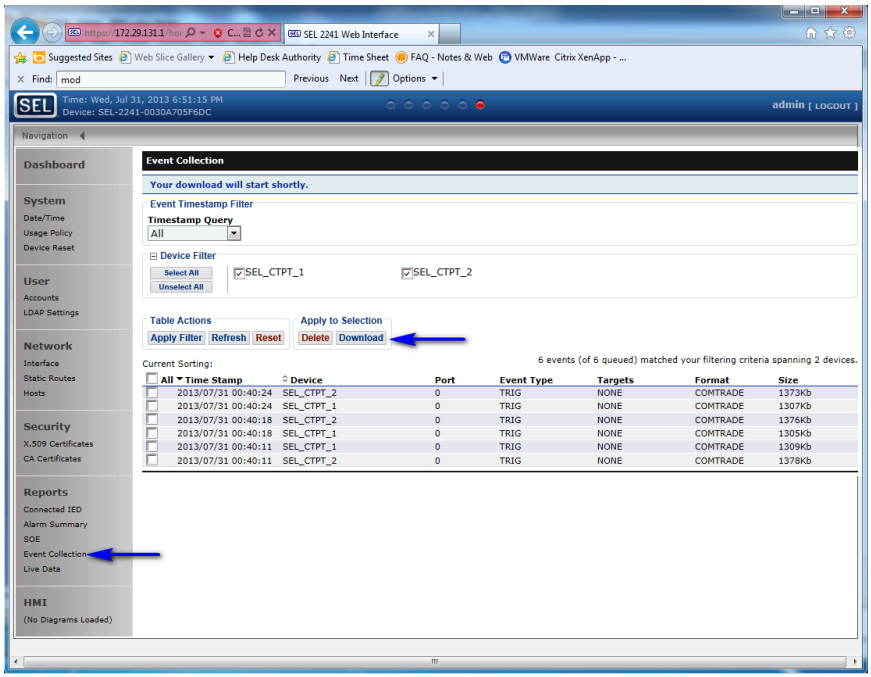

Figure 2.113 Waveform Record Retrieval

Viewing Waveforms and Event Files

Events files created by the SEL-2245-4 are in COMTRADE format. Event viewing software such as SYNCHROWAVE Event is required to open these files.

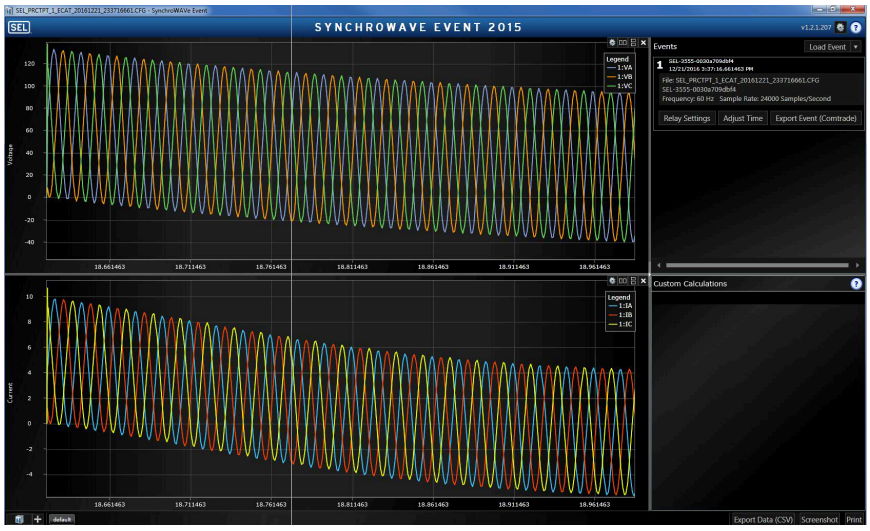

Figure 2.114 SYNCHROWAVE Event Display Waveform

SEL-2245-411 Standard Current and Low-Voltage (LEA) Monitoring Module

The SEL-2245-411 Standard Current and Low-Voltage (LEA) Monitoring Module (4 CT/4 LEA) includes four low-voltage inputs and four current transformer inputs with isolated returns for measuring ac signals. Refer to *Specifications in the SEL-2240 Axion Instruction Manual* for details on the input range. Use the **Insert** ribbon as shown in *Figure 2.115* to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click **Insert**.

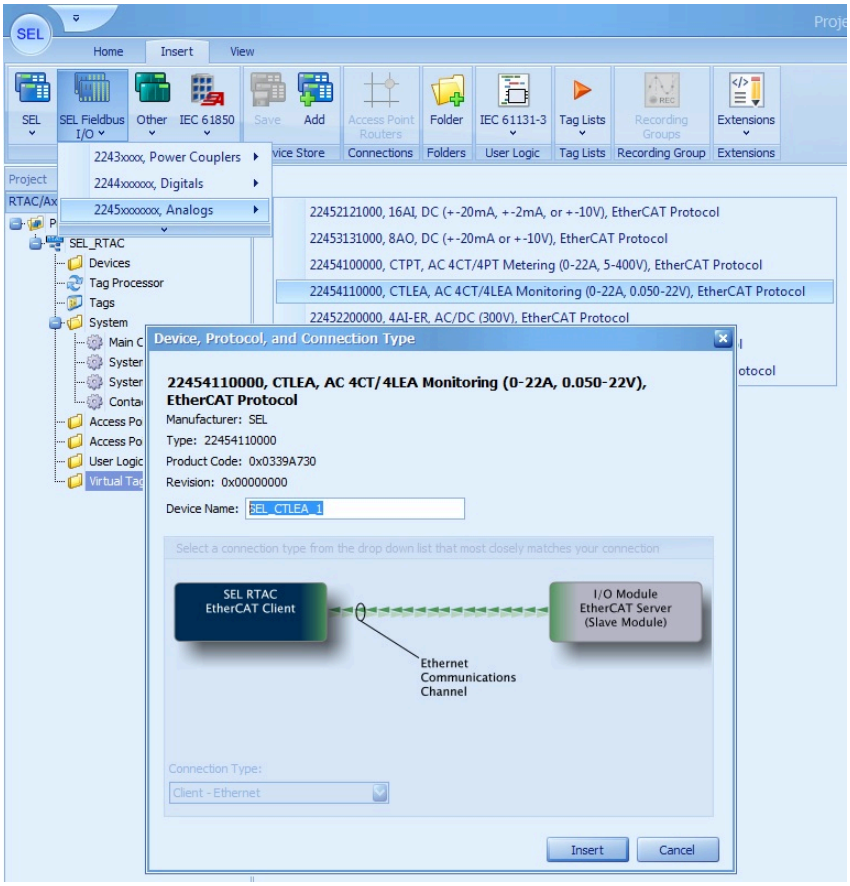

Figure 2.115 Insert an SEL-2245-411 4 CT/4 LEA Module

Configuring the CT/LEA Monitoring Module

In the project tree, select the module to open the module settings window. Click the **Settings** tab to configure the module.

NOTE

Only individual tags enabled per the CT/LEA Monitoring Module are included in the EtherCAT message frame to reduce bandwidth. This allows for the use of more modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration.

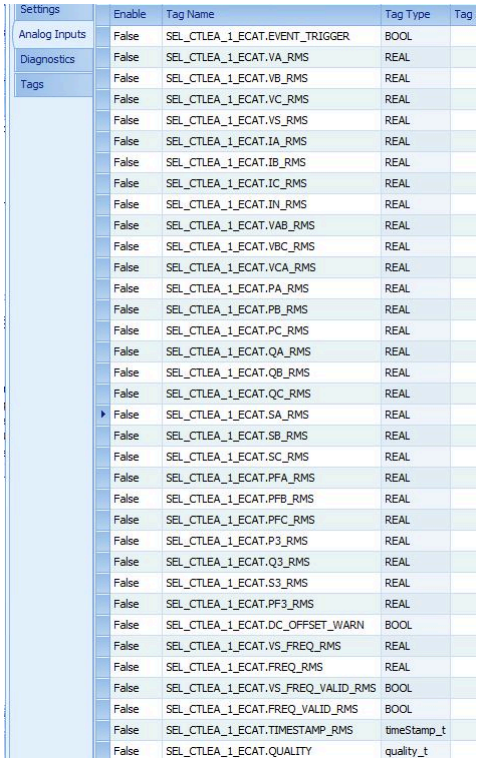

Figure 2.117 CT/LEA Tag Enable Settings

Analog Input	Description
Enable	When True, this tag will be included when the program is compiled. When False, it will not be included. Disable all tags not in use to optimize processing resources. If there are many analog data on the EtherCAT backplane, you will receive a message that the bandwidth has been exceeded (shown in *Figure 2.118*).
Tag Name	Programming designation of a resource.
Tag Alias	Input an alternative name to use in place of the Tag Name while programming (for example, SEL_CTLEA_1_ECAT.IA_FUND could be replaced by IA_Bus1).

NOTE
If you receive the message "EtherCAT Bandwidth Exceeded," you will need to disable a number of RMS or Fundamental tags on one or more CT/LEA modules to reduce the bandwidth in use.

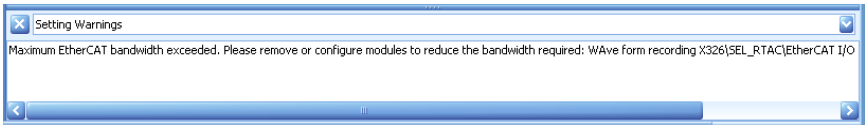

Figure 2.118 EtherCAT Bandwidth Exceeded

CT/LEA Module Simple Tags

The CT/LEA measurements are in a simplified format referred to as "Simple Tags." Complex measured values (CMV) display as the vector_t data subtype containing the angle and magnitude quantities. Measured values (MV) display as the REAL numeric type.

TimeStamp_t and quality_t tags are still available at the module level and automatically insert when mapping a Simple Tag to another tag type in the Tag Processor. Switching to the code view in the Tag Processor will allow you to modify the default quality and time source if desired.

Waveform Recording

Waveforms will be recorded in COMTRADE format with an accompanying configuration file. File names are stored in the following format:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

A maximum of 1024 COMTRADE events can be stored in the RTAC with the oldest record being deleted when a new event is triggered and 1024 events are exceeded. The SEL-2245-411 can record two back-to-back events. A new record can be triggered as soon as the present one has finished recording. A trigger condition that occurs before the current recording finishes is ignored. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

Inputs

The following voltage and current inputs are recorded in the COMTRADE files generated by the SEL-2245-411 modules:

- IA, IB, IC, IN
- VA, VB, VC, VS (Wye)
- VAB, VBC, VCA (Delta)

NOTE
Waveform settings are configured in the individual CT/LEA module settings tabs.

NOTE
Oscillography Pre-Trigger Length is relative to when the module receives the trigger through EtherCAT. Two or more processing intervals of the configured RTAC task cycle rate should be added to the desired pre-trigger length to ensure all desired data are captured.

Table 2.71 Waveform Settings

Setting	Description
VoltageInputConfiguration	Voltage input configuration
FrequencyNominal	Nominal system frequency
OscillographyCaptureRate	Sampling rate: 1, 2, 4, 8, 24 kHz; software-selectable

OscillographyPreTriggerLength	Pre-trigger record length: 0.05 seconds minimum to a maximum of (record length – 0.05) seconds
CTRatio	A-, B-, and C-phase CT winding ratio
CTRatioN	Neutral CT winding ratio
PTRatio	Phase A, B, C PT winding ratio
PTRatioS	Synch PT winding ratio
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
module_name.Event_Trigger	This is a Boolean input that triggers waveform recording in the module and only responds to rising edges

Downloading Events Via the Web Interface

NOTE
Only individually enabled CT/LEA module tags are included in the EtherCAT message frame to reduce bandwidth. This allows the use of more CT/LEA modules if fewer tags are needed. The EtherCAT connection tab shows the amount of bandwidth used by your current configuration.

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **https://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click on **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the **Device Filter**.

Step 7. Select the desired events and click **Download**.

Step 8. You can also delete events by clicking **Delete**.

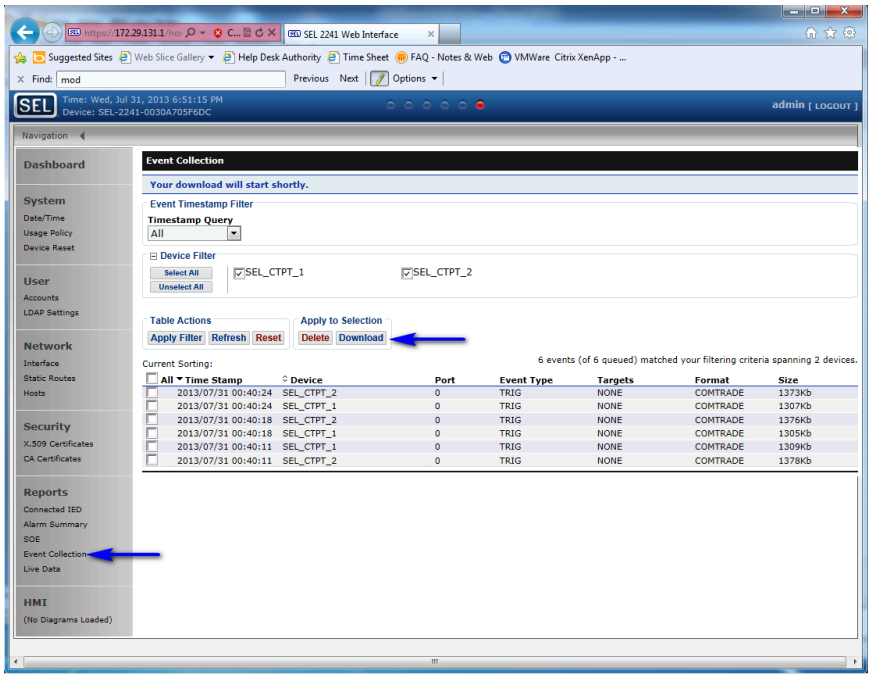

Figure 2.119 Waveform Record Retrieval

Viewing Waveforms and Event Files

Event files created by the SEL-2245-411 are in COMTRADE format. Event viewing software such as SYNCHROWAVE Event is required to open these files.

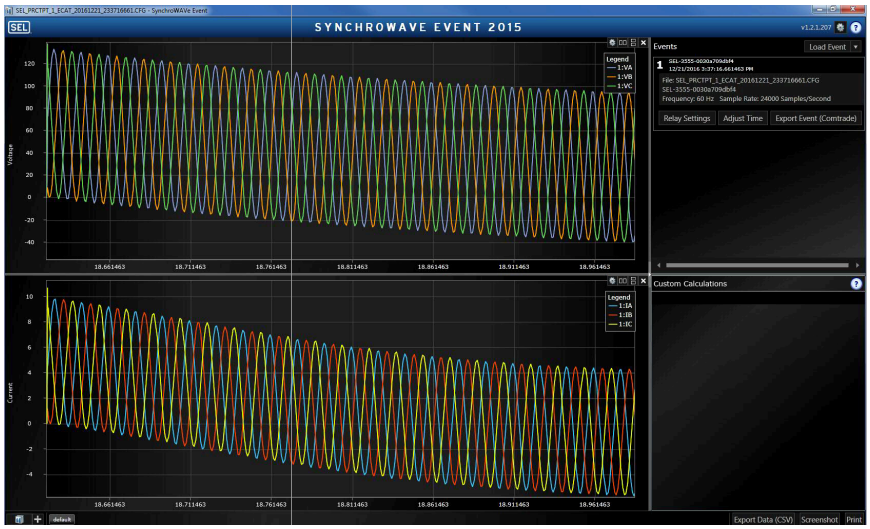

Figure 2.120 SYNCHROWAVE Event Display Waveform

SEL-2245-42 AC Protection Module

The SEL-2245-42 AC Protection Module (PRCTPT) includes three Potential Transformer inputs and three Current Transformer inputs with isolated returns for measuring ac signals. See *Specifications in the SEL-2240 Axion Instruction Manual* for details on the input range. Use the **Insert** ribbon, as shown in *Figure 2.121*, to add an instance of this module to your project. The displayed pop-up will allow you to change the module name if necessary. When finished, click **Insert**.

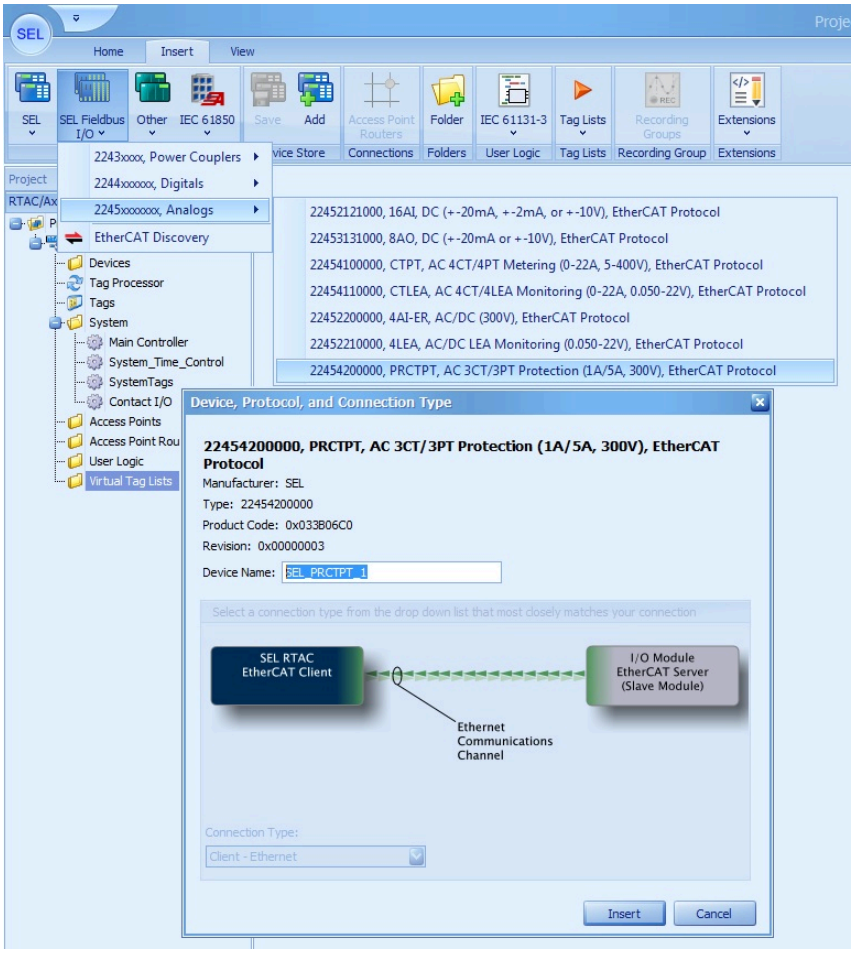

Figure 2.121 Insert an SEL-2245-42 AC Protection Module

Configuring the AC Protection Module

In the project tree, select the module to open the module settings dialog window. Click the **Settings** tab to configure the module.

Figure 2.122 PRCTPT Module Settings

Table 2.72 PRCTPT Module Settings Options

Setting	Configuration Options
Fundamental Tags	
Reference Angle	Positive Sequence, Phase A, No Reference
Fundamental Voltage Scaling Magnitude	kV or V
Enable Fundamental CT and PT Ratios	True, False
General	
Phase CT Ratio	1.00–50000.00
Phase PT Ratio	1.00–6000.00
PT Connection	Delta, Wye
Phase Rotation	ABC or ACB
Frequency Group	Assign the frequency group to use for frequency tracking
Oscillography	
Oscillography Capture Rate	1, 2, 4, 8, 24 kHz
Minimum Oscillography Record Length	0.5–72 seconds in 0.1 increments

Setting	Configuration Options
Maximum Oscillography Record Length	1–72 seconds in 0.1 increments
Oscillography Pre-trigger Length	0.05–0.95 seconds in 0.01 increments
RMS Tags	
RMS Voltage Scaling Magnitude	kV, V
Enable RMS CT and PT Ratios	True, False
Synchrophasors	
Phase Voltage Angle Compensation	–179.99–180.00
Phase Current Angle Compensation	–179.99–180.00
PMU	
Station Name	1–255 characters
Current Phasor Data Set	All, Phase, Positive Sequence, None
Voltage Phasor Data Set	All, Phase, Positive Sequence, None
PMU Id	1–65534

NOTE

To conserve EtherCAT bandwidth, enable only the necessary tags. An error message will appear in the diagnostic window if the EtherCAT bandwidth is exceeded.

Figure 2.123 PRCTPT Tag Enable Settings

NOTE

If you receive the message "EtherCAT Bandwidth Exceeded," you will need to disable a number of RMS, Fundamental, or Synchrophasor tags on one or more CT/PT modules to reduce the bandwidth in use.

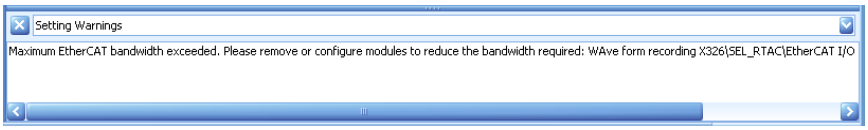

Figure 2.124 EtherCAT Bandwidth Exceeded

Table 2.73 Tag Settings

Analog Input	Description
Enable	When True, this tag will be included when the program is compiled. When False it will not be included. Disable all tags not in use to optimize processing resources. If there are too many analog data on the EtherCAT backplane, you will receive a message that the bandwidth has been exceeded (shown in *Figure 2.124*).
Tag Name	Programming designation of a resource.
Tag Alias	Input an alternative name to use in place of the Tag Name while programming (for example, SEL_PRCTPT_1_ECAT.IA_FUND could be replaced by IA_Bus1).

Configure Frequency Groups for the AC Protection Modules in the EtherCAT I/O network to define which module will be the reference for frequency tracking.

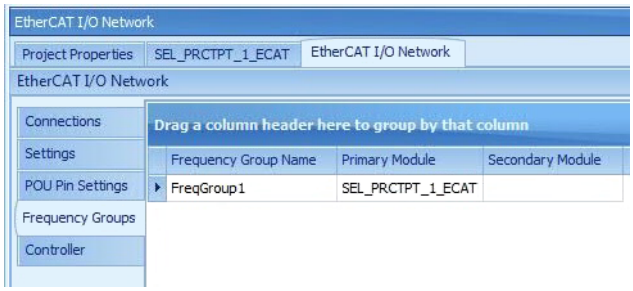

Figure 2.125 Configure PRCTPT Frequency Groups

AC Protection Module Simple Tags

CT/PT measurements are provided in a simplified format referred to as Simple Tags. Complex measured values (CMV) display as the vector_t data subtype containing the angle and magnitude quantities. Measured values (MV) display as the REAL numeric type.

TimeStamp_t and quality_t tags are still available at the module level and automatically insert when you map a Simple Tag to another tag type in the Tag Processor. Switching to the code view in the Tag Processor will allow you to modify the default quality and time source if needed.

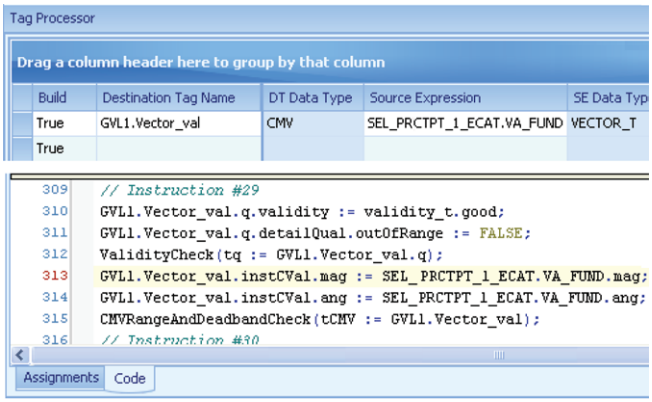

Figure 2.126 AC Protection Module Simple Tag to Complex Tag Mapping

Waveform Recording

Waveforms are recording in COMTRADE format with an accompanying configuration file. File names are stored as follows:

StationName_ModuleID_Protocol_YYYYMMDD_HHMMSSMSC.yyy

where:

yyy is one of two file name extensions: CFG for configuration files or DAT for data files.

Protocol is the name of the protocol used (e.g., ECAT).

StationName is defined by the RTAC hostname, which is configurable through the web interface. When the RTAC hostname is changed, the EtherCAT network must be disabled and re-enabled for the new StationName to appear in the file name of waveform records.

NOTE
Waveform settings are configured in the individual AC Protection Module setting tabs or in the assigned Recording Group Settings.

A maximum of 1024 COMTRADE events can be stored in the RTAC, with the oldest record being deleted when a new event is triggered and 1024 is exceeded. The SEL-2245-42 can record two back-to-back events. A new record can be triggered as soon as the current one has finished recording. These records are first stored locally to prevent data loss and then transferred to the RTAC for downloading via the built-in web server.

NOTE
The Trigger Time Alignment setting is set to RTAC Assertion and hidden by default. To change this setting to Module Assertion, select the Advanced Settings check box to view and modify the setting.

Inputs

The following voltage and current inputs are recorded in the COMTRADE files generated by the SEL-2245-42 modules:

- IA, IB, IC
- VA, VB, VC (Wye)
- VAB, VBC, VCA (Delta)

Oscillography Triggering

The AC Protection Module offers a very flexible trigger mechanism with extendable recording lengths. *Figure 2.127* illustrates the three recording length settings pertaining to the module output event file. The first setting, Oscillography Pre-Trigger Length, is the length in seconds of the prerecorded data prior to the initiating trigger of the event. The second setting, Minimum Oscillography Record Length, is the minimum total recording length of the event in seconds and is equivalent to the length of Pre-Trigger plus the length of Post-Trigger. The last setting, Maximum Oscillography Record Length, is the absolute maximum total recording length that the event will not exceed, based on the applied trigger and Extended Post-Trigger length.

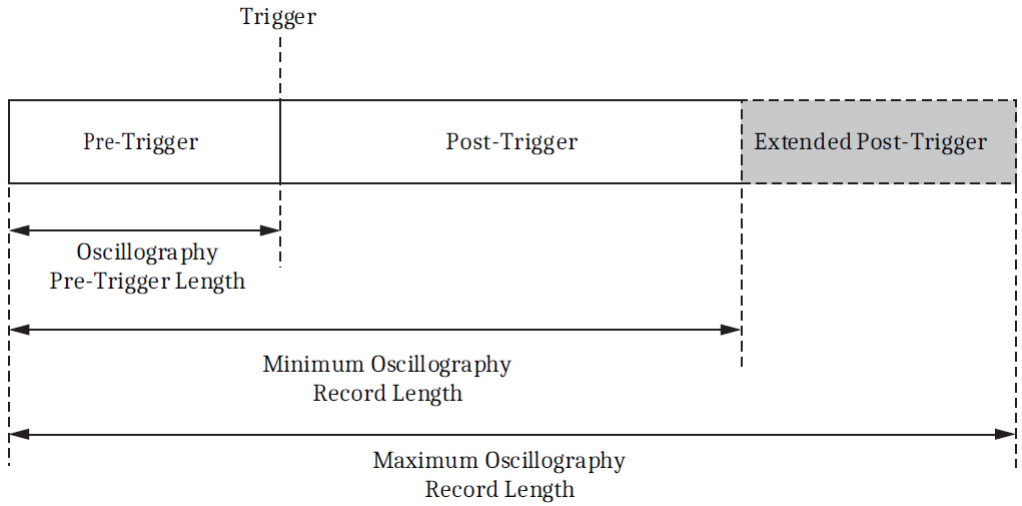

Figure 2.127 Event Record for the SEL-2245-42 AC Protection Module

By responding to either rising-edge or level triggers, the AC Protection Module provides flexibility for recording faults by using a variety of trigger techniques. *Figure 2.128* illustrates the basic rising-edge trigger implementation for the module when the time between triggers is greater than the minimum oscillography record length setting. In this simple rising-edge trigger example, the module generates two separate event files in response to two different rising-edge trigger occurrences. Each event file length matches the minimum oscillography record length setting without any Extended Post-Trigger data.

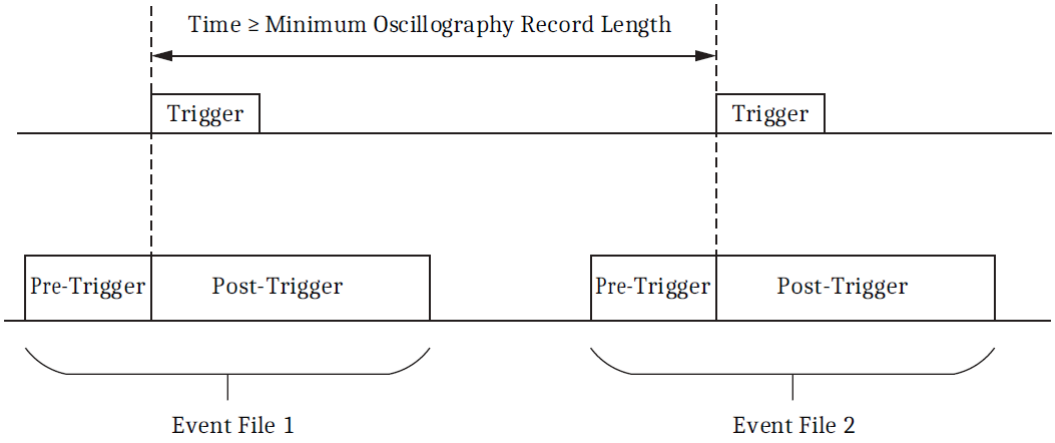

Figure 2.128 Simple Rising-Edge Triggered Event Recordings

Figure 2.129 illustrates another example with two rising-edge triggers, but in this case the second rising-edge trigger occurs before the minimum oscillography length expires. This action extends the length of event recording by the length of Post-Trigger time at the instance of the second trigger. This recording extension can continue with subsequent triggers until either the triggers stop or the total length of the event recording reaches the maximum oscillography record length.

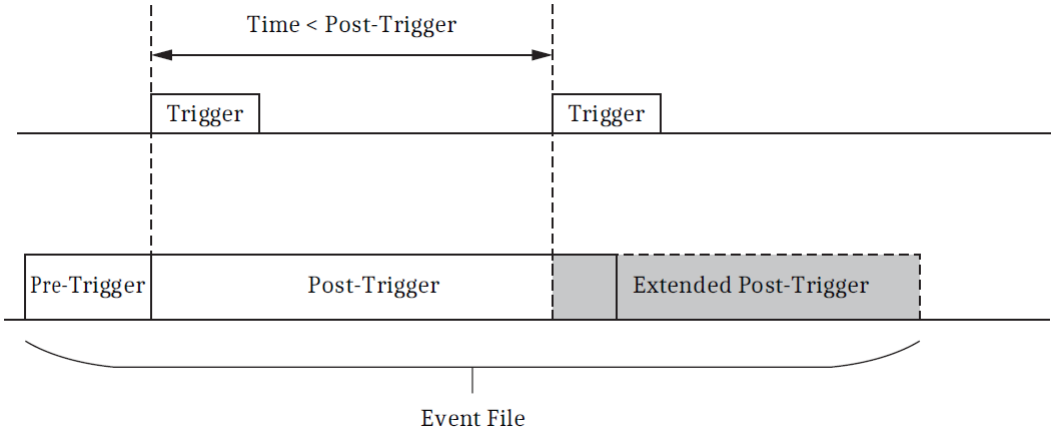

Figure 2.129 Rising-Edge Trigger Extended Event Recording

Figure 2.130 illustrates another example with a level trigger that extends the length of the recording. The level trigger extends the length of the event past the minimum oscillography record length setting. If the level trigger stays high, the module will continue to record until it reaches the maximum oscillography record length setting.

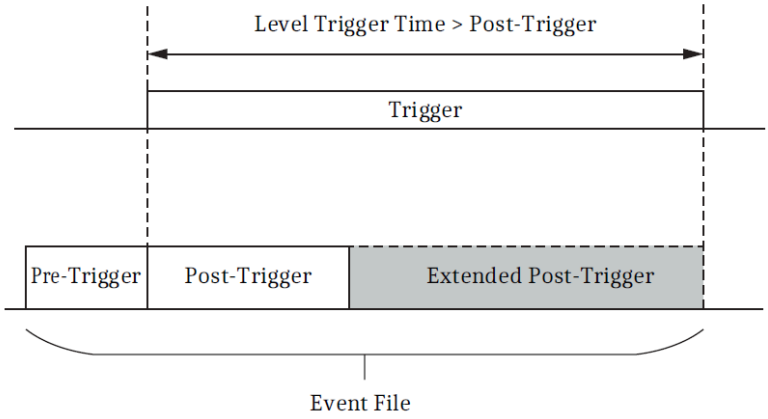

Figure 2.130 Level Trigger Extended Event Recording

Table 2.74 Oscillography Settings

Setting	Description
OscillographyTrigger	On rising edge, generates a waveform trigger event
OscillographyCaptureRate	The capture rate of oscillography data: 1, 2, 4, 8, or 24 kHz
OscillographyRecordLengthMin	Minimum length of an oscillography capture
OscillographyPreTriggerLength	Length of pre-trigger time
OscillographyRecordLengthMax	Maximum length of oscillography capture (in case of multiple trigger events or extended trigger): 24 s at 24 kHz 72 s at 8 kHz 144 s at 4 kHz 288 s at 2 kHz 576 s at 1 kHz

Setting	Description
StationName	RTAC hostname
ModuleID	Module identifier (module name in ACSELERATOR RTAC)
Module_name.Event_Trigger	Boolean input that triggers waveform recording in the module and only responds to rising edges

Downloading Events Via the Web Interface

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **https://** followed by the RTAC Ethernet address.

Step 4. Log in to the RTAC web interface.

Step 5. Click **Event Collection** under **Reports** in the navigation pane on the left.

Step 6. Sort events by selecting a time frame from **Timestamp Query** and the device filter.

Step 7. Select the desired events and click **Download**. You can also delete events by clicking **Delete**.

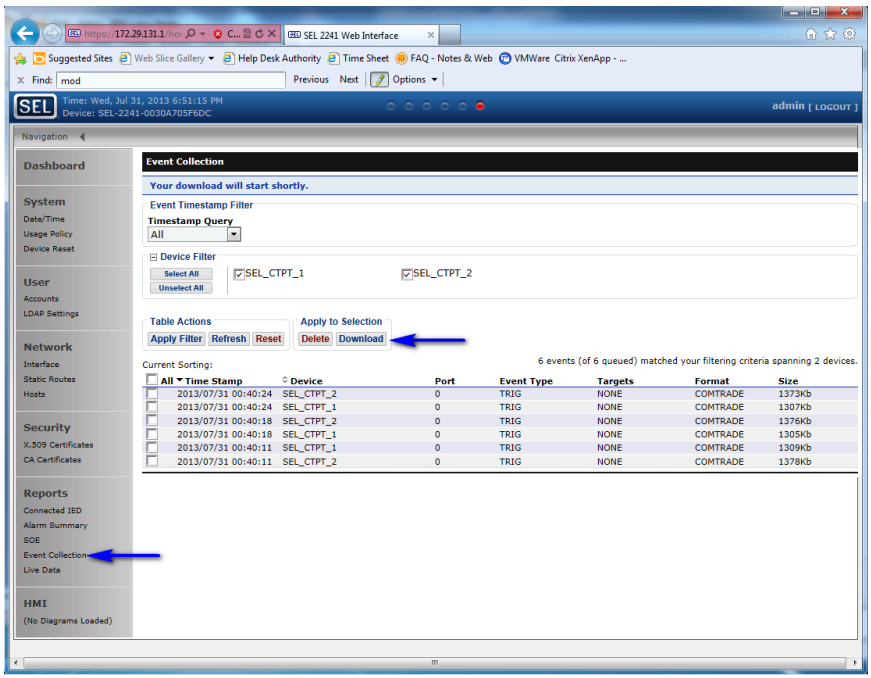

Figure 2.131 Waveform Record Retrieval

Viewing Waveforms and Event Files

Events files created by the SEL-2245-42 are in COMTRADE format. Event viewing software such as SYNCHROWAVE Event is required to open these files.

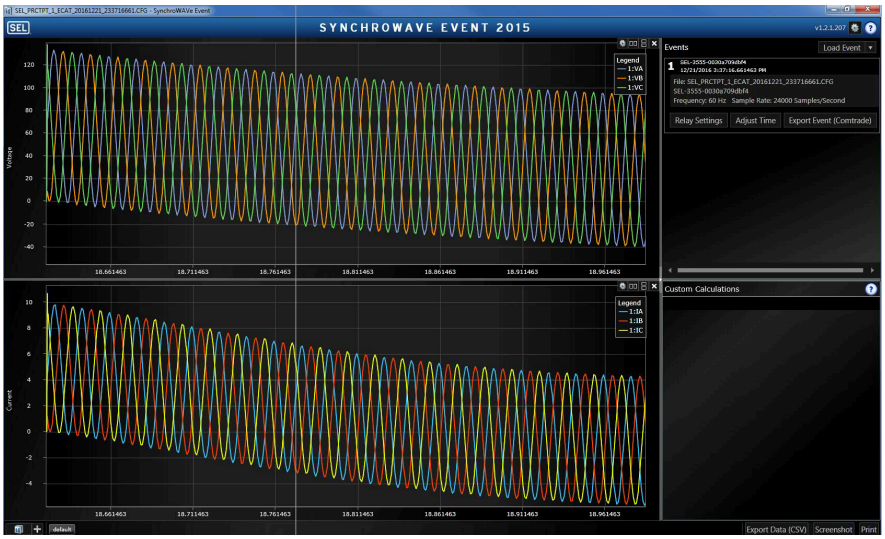

Figure 2.132 SYNCHROWAVE Event Display Waveform

Configuring Axion Recording Groups

NOTE

Recording Groups configured at 24 kHz for 24 seconds on the SEL-2241, SEL-3530, or SEL-3530-4, with more than two SEL-2245-42 Modules, will time out before they are complete. An SEL-3555 RTAC should be used for any systems larger than two Modules at 24 kHz for 24 seconds.

Configure recording groups with the Axion for the purpose of combining multiple event reports from SEL-2245-42 AC Protection Modules with digital I/O from SEL-2244 Digital I/O modules in a single COMTRADE file. Recording groups also provide custom channels and calculations. Custom channels allow you to include analog or Boolean quantities from the RTAC logic engine in the recording group. Use standard mathematical expression channels to add calculated virtual channels to the recording group. A single recording group can be configured for the entire Axion or as many as six separate recording groups can be configured based on how the recording channels make logical sense for analysis. Each recording group generates a single COMTRADE file with the data included for simplified analysis.

Step 1. Select the Recording Groups icon in the Insert menu in ACSELERATOR RTAC, as shown in *Figure 2.133*.

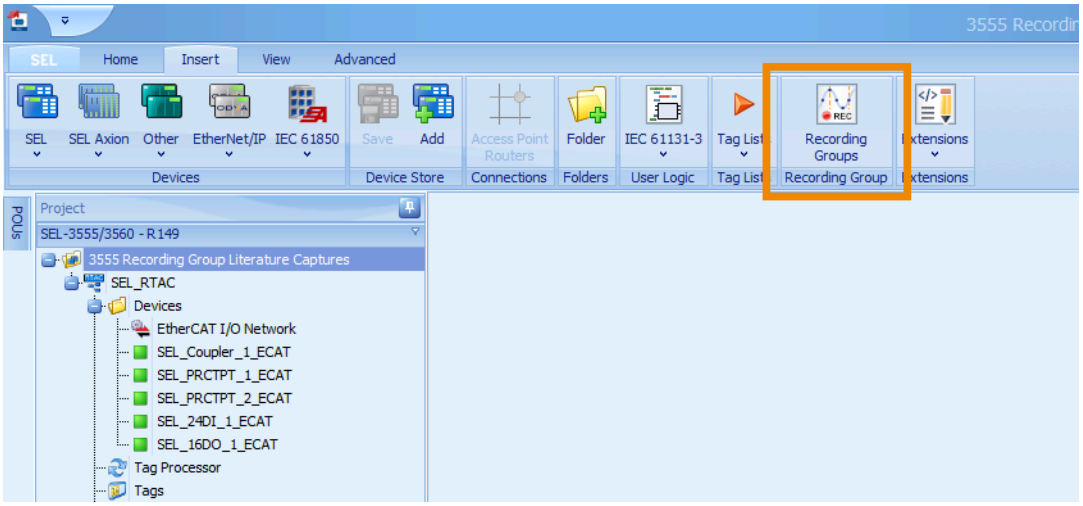

Figure 2.133 Insert a New Recording Group

Step 2. Enter a name for the new Recording Group or use the default, RecordingGroupX. Select the SEL-2245-42 and SEL-2244 modules you want to include in the recording group.

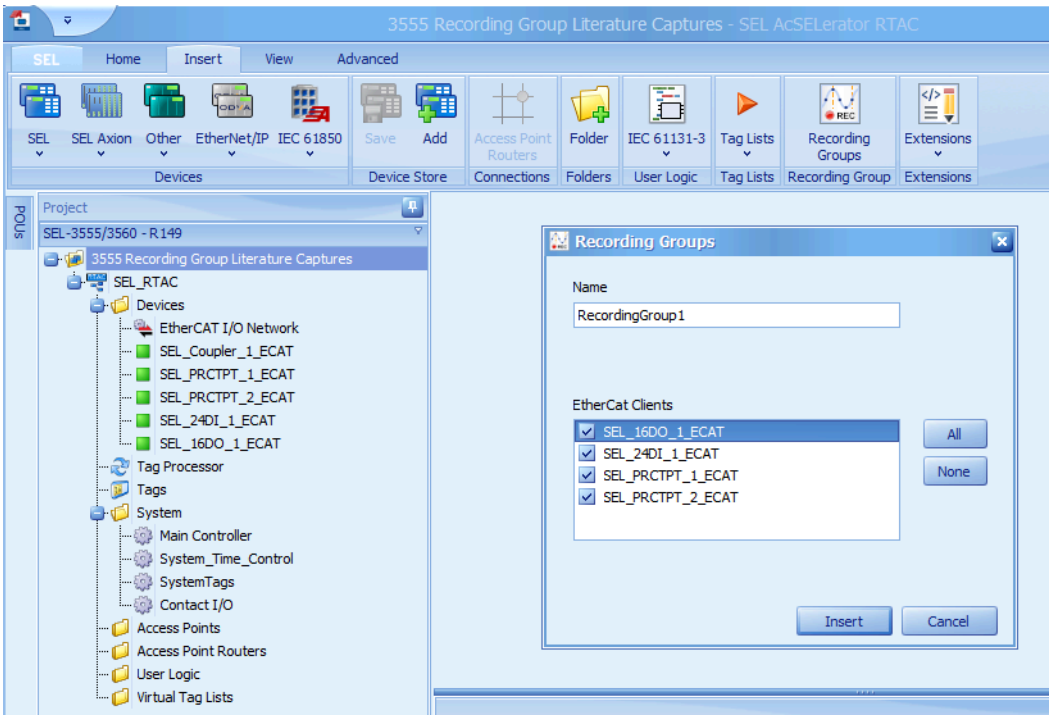

Figure 2.134 Select Modules for Recording Group

Step 3. Select the new RecordingGroupX and go to the **Settings** tab to configure the recording parameters for the recording group.

a. Set the **Station Name** and **Company Name** as desired to indicate your company and the location of the RTAC.

b. Configure the **Oscillography** settings as desired to set the recording lengths and capture rate.

These settings will override any previous Oscillography settings that were configured for all individual SEL-2245-42 Protection modules included in RecordingGroupX.

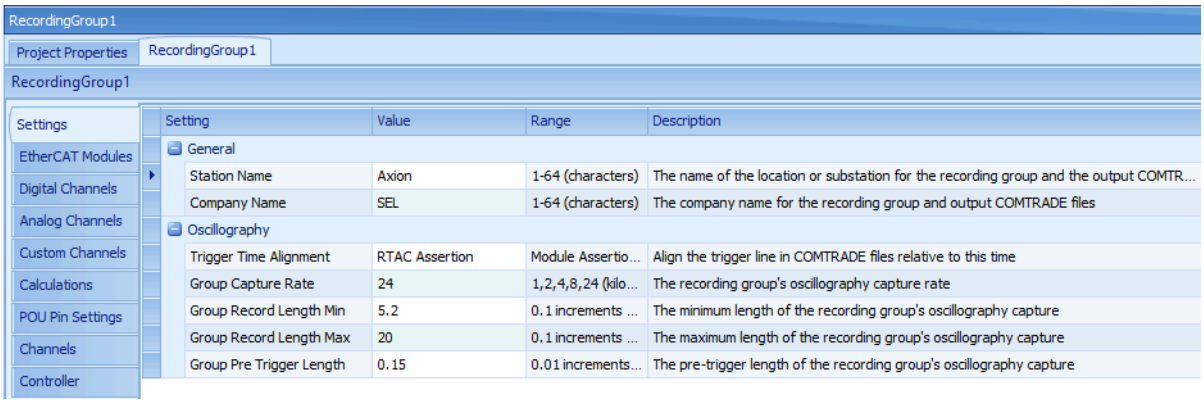

Figure 2.135 Configure Recording Group Oscillography Settings

Step 4. The **EtherCAT Modules** tab lists the modules included in RecordingGroupX. You can modify the modules included in the recording group here if necessary.

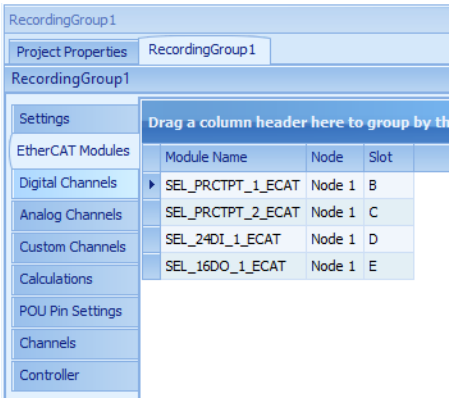

Figure 2.136 EtherCAT Modules Included in the Recording Group

Step 5. Go to the **Digital Channels** tab and configure the **Channel Name** for the inputs or outputs of the SEL-2244 modules included in RecordingGroupX, if desired. Additionally, if there are inputs or outputs you do not want to include in the COMTRADE file, disable them here.

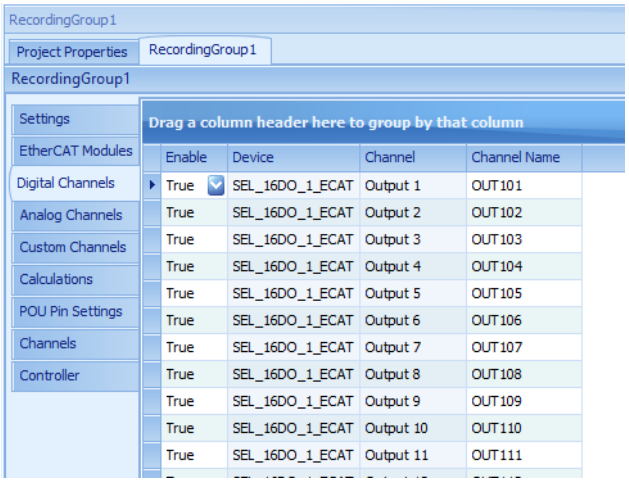

Figure 2.137 Digital Channel Settings

Step 6. Go to the **Analog Channels** tab and configure the **Channel Name** for the analog inputs of the SEL-2245-42 modules included in RecordingGroupX if desired. Additionally, if there are inputs you do not want to include in the COMTRADE file, you can disable them here.

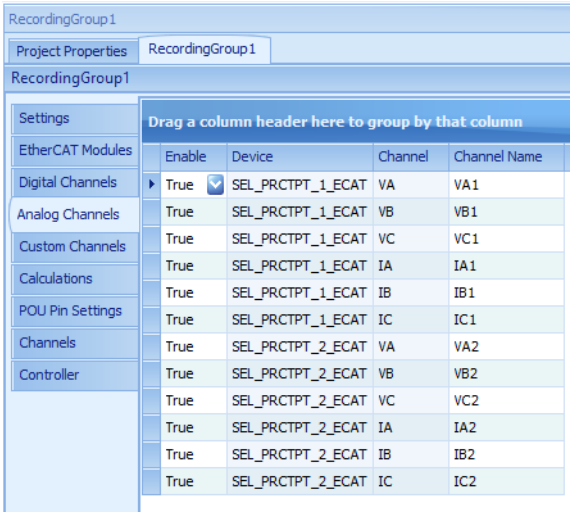

Figure 2.138 Analog Channel Settings

Step 7. Go to the **Custom Channels** tab and add the number of custom digital (BOOL), analog (REAL), or magnitude and angle pair (vector_t) channels you want to add from the RTAC logic engine to include in RecordingGroupX. In firmware versions R151 and later, as many as 512 custom channels can be added to a single Recording Group.

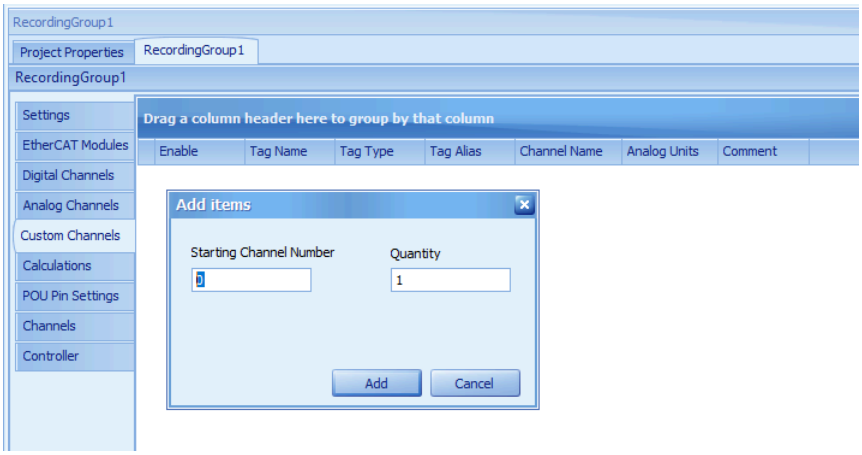

Figure 2.139 Add Custom Channels

Step 8. Configure **Tag Name**, **Channel Name**, **Tag Alias**, and **Analog Units** for the custom channels included in RecordingGroupX as desired. Additionally, if there are inputs you do not want to include in the COMTRADE file, disable them here. Go to **Tag Processor** and map source tags from the RTAC logic engine to the new RecordingGroupX.CustomDigitalX or RecordingGroupX.CustomChannelX tags.

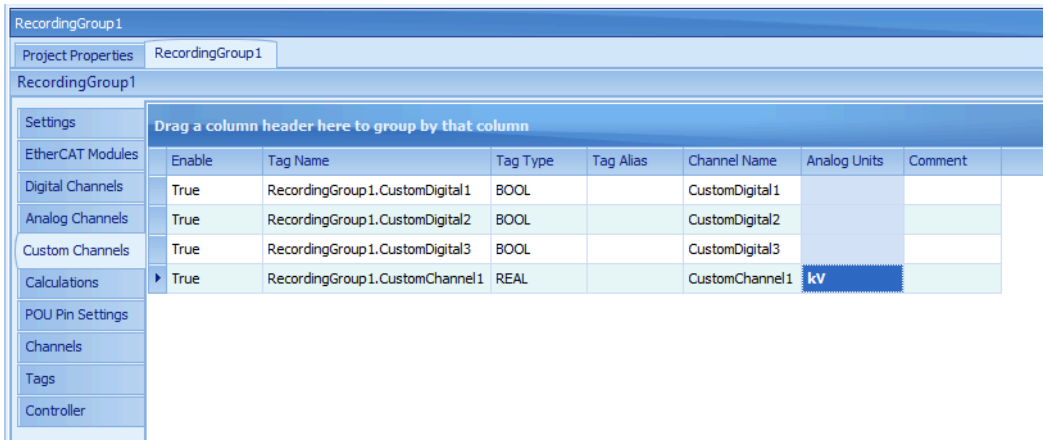

Figure 2.140 Custom Channel Settings

Step 9. Add as many as 32 calculated virtual channels via the Recording Group **Calculations** tab. Configure the calculation **Channel Name** and **Units** for each calculated channel. Build calculations in the **Channel Expression** cell using channel names defined in the Analog Channels and Custom Channel tabs. Additionally, the channel expression cell supports floating-point and integer values in the calculation. The channel expression cell allows addition, subtraction, multiplication, and division through mathematical operators "+", "–", "*", and "/", respectively. *Figure 2.141* provides a calculation settings overview and examples for configuring channel expressions.

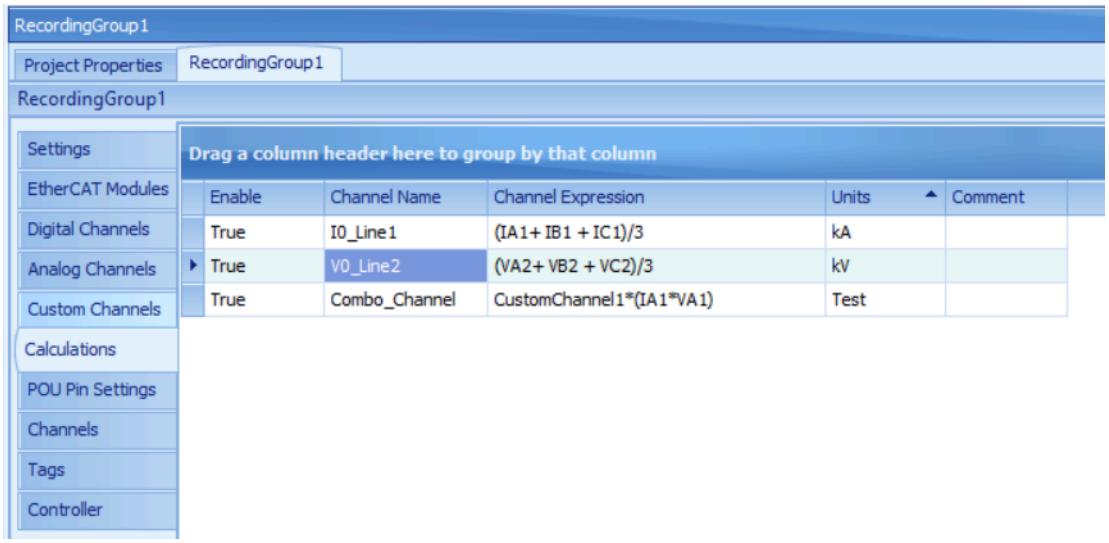

Figure 2.141 Calculation Settings

Figure 2.142 shows the POU Pin Settings with default values for RecordingGroupX.

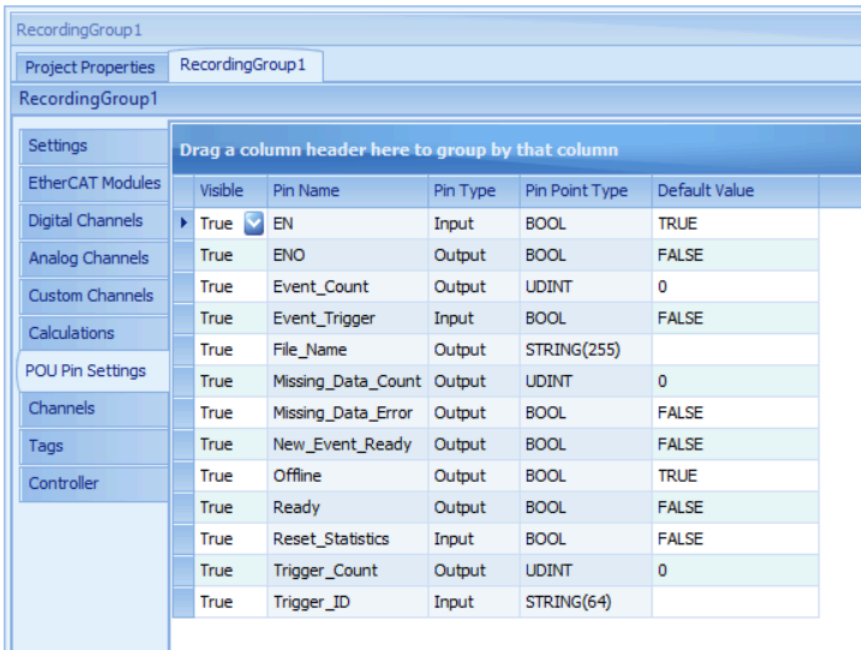

Figure 2.142 RecordingGroupX POU Pin Settings

Figure 2.143 shows the Controller with online values for RecordingGroupX.

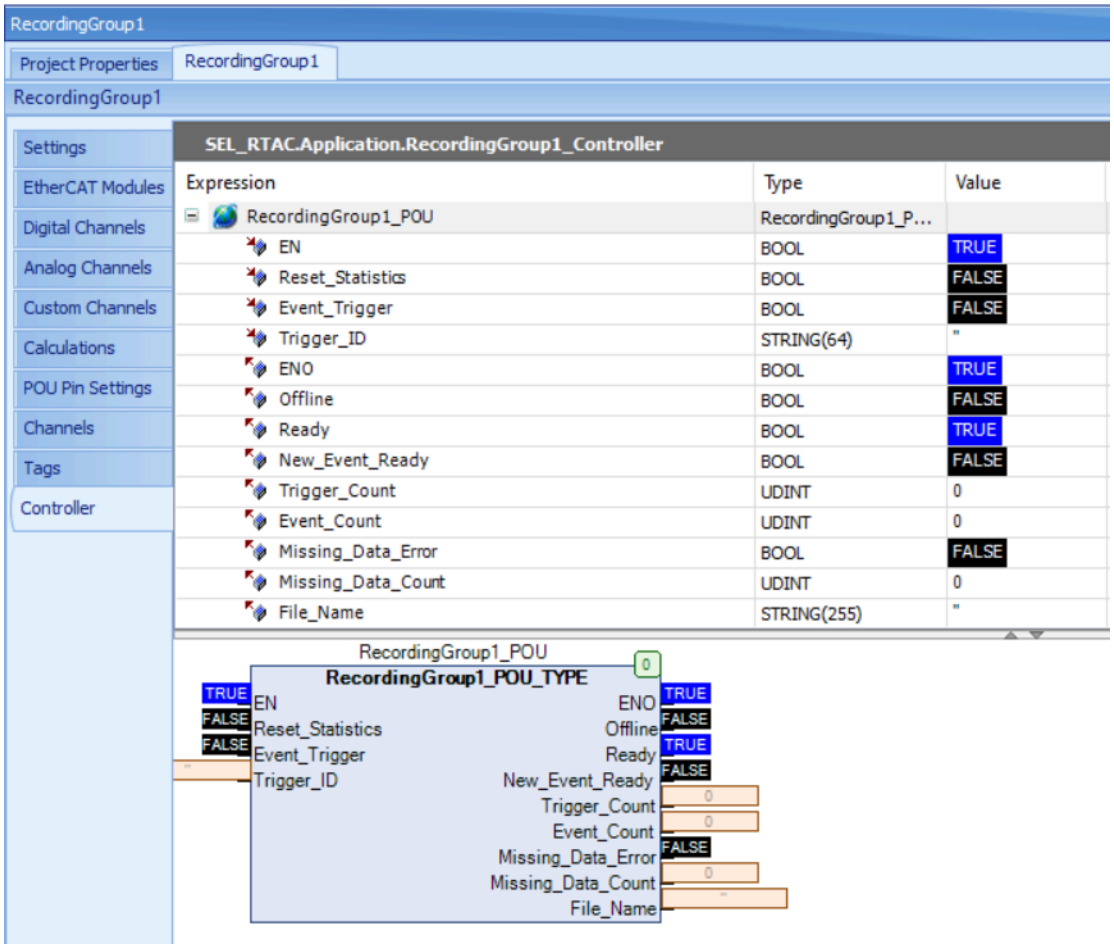

Figure 2.143 RecordingGroupX Controller

A rising edge to Event_Trigger simultaneously starts recording of the individual COMTRADE files in each SEL-2245-42 module included in RecordingGroupX. Additionally, it records the digital tags at the RTAC processing interval. If SOE tags from the SEL-2244 Digital I/O modules are included in RecordingGroupX, the assertions that occur between the RTAC processing interval will be included in the combined COMTRADE file for RecordingGroupX.

Continuous Recording Groups

This section describes the configuration and use of Continuous Recording Groups, or CRG, with ACSELERATOR RTAC software. Continuous Recording Groups are available in SEL-3555 and SEL-3350 projects and require the Continuous Recorder licensed option. The Continuous Recording Group is used for logging data from SEL Axion modules (Protection CTPT and Digital Input), phasor measurement units (PMUs), and custom channels like RTAC system tags. Because CRGs continuously log data for multiple days, continuous recording can be used as an effective data historian. The number of days for which data are retained is determined by the Retention Duration field in the Settings tab, and is configurable between 1 and 365 days. The event data that the Continuous Recording Group logs are used to build a customized single zipped COMTRADE file that can be viewed using a program such as SEL-5601-2 SYNCHROWAVE® Event Software. COMTRADE files are dynamically generated based on a requested list of channels and date/time range and can be downloaded

from the RTAC's web interface by navigating to the **Continuous Recording Groups** menu under the **Reports** section, as shown in *Figure 2.144*. The generated COMTRADE files are named in COMNAME format and are named for the configured Company and Station Names as well as the name of the CRG in the RTAC project tree.

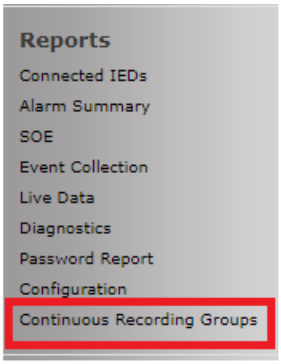

Figure 2.144 Reports > Continuous Recording Groups

The Continuous Recording Groups page on the RTAC web interface lists the name of the CRG(s) that have been created from which data can be downloaded, as shown in *Figure 2.145*. The Start Time and End Time represent the range of timestamps of the logged data. The Status of the log file is listed for reference and will have a status of Empty when no data exists, Filling while the CRG is being populated with data, and Stalled while one or more of the CRG data sources stops updating for more than 5 minutes.

Figure 2.145 Available Continuous Recording Groups

Selecting the Download button for a CRG report prompts the user to select a Start Time and *either* an End Time or Duration, as shown in *Figure 2.146*. The maximum duration for a COMTRADE record request is 1 hour in length, regardless of whether End Time or Duration is selected. The available channels are listed and can be selected to be included in the COMTRADE file. Select **Download** to save the COMTRADE file locally.

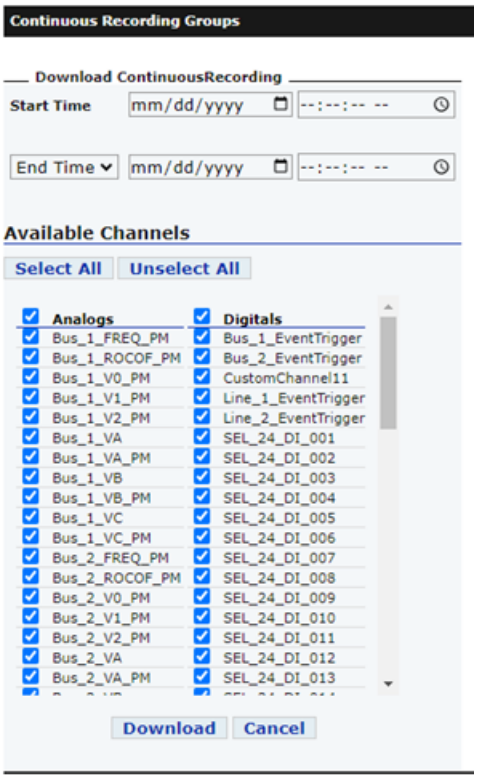

Figure 2.146 Downloading Continuous Recording Group Data

Continuous Recording Group Configuration

To add Continuous Recording Groups, from the ribbon in ACSELERATOR RTAC, select **Insert** and then **Continuous Recording Groups**, as shown in *Figure 2.147*. As many as 16 Continuous Recording Group instances can be added to a single RTAC project.

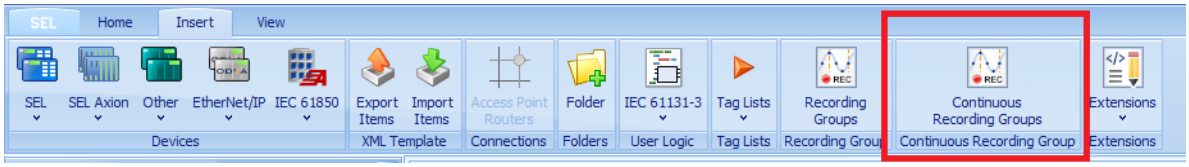

Figure 2.147 Adding Continuous Recording Groups

The **CRG EtherCAT Modules** and **PMUs** tabs for each Continuous Recording Group allow you to add or remove data sources for that group. In the CRG EtherCAT Modules tab, the Node and Slot columns are automatically populated from the EtherCAT I/O network configuration, as shown in *Figure 2.148*.

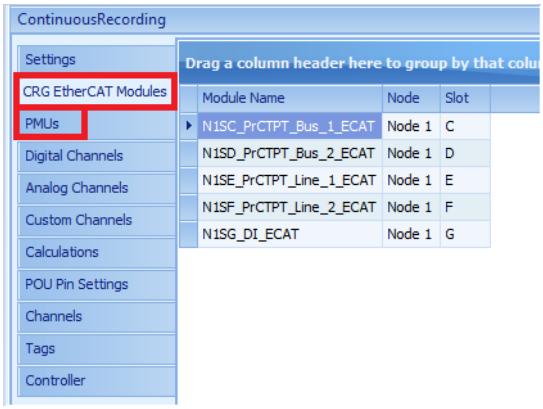

Figure 2.148 Continuous Recording Group Sources

Use the '+' button in the CRG EtherCAT Modules tab to add a new EtherCAT data source to an existing project. Protection CTPT EtherCAT modules can be added to a single CRG, and Digital input EtherCAT modules can be added to multiple CRGs. When logging data from EtherCAT modules, Continuous Recording Groups support sample rates as fast as 3000 samples per second (3 kHz). As many as 16 Protection CTPT modules can be added to CRGs in the project, for a total of ninety-six 3 kHz channels.

Use the '+' button on the PMUs tab to add PMU sources to the CRG. Potential PMU sources include C37.118 client PMUs, C37.118 server PMU tag lists, and PMUs associated with Protection CTPT EtherCAT modules. A total of 100 PMUs can be added across all CRG instances in a project and they can be shared amongst multiple CRGs. PMUs are logged at the data rate specified by the System Tag PMU data rate.

Once EtherCAT modules and PMUs are added to a CRG, the elements within these data sources can be individually enabled or disabled using the **Analog Channels** and **Digital Channels** tabs. Any element that is set to True will have its data logged and available for inclusion as a channel in the COMTRADE file.

Custom Channels are another component of CRGs that can be included as logged data in the COMTRADE file. As many as 512 tags can be added in the Custom Channels tab and used to reference RTAC system tags. The Tag Type column has a dropdown menu for selecting the data type. BOOL, REAL, and vector_t are the supported data types. Any custom channels created for a CRG can have their values populated externally via IEC 61131 logic.

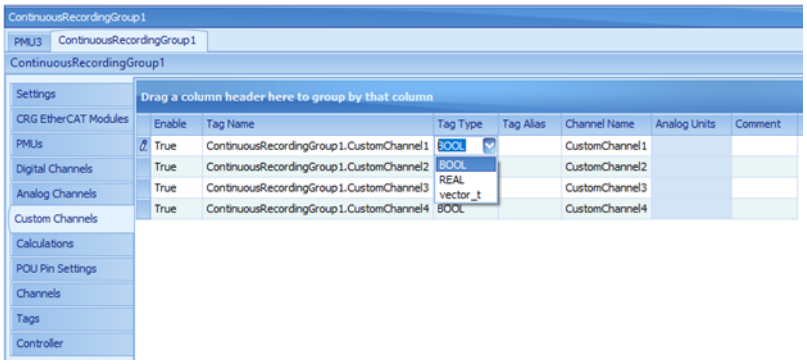

Figure 2.149 Continuous Recording Group Custom Channels

Calculations can be performed on analog channels available in the 3000 samples-per-second (3k) data from Protection CTPT (PrCtPt) Axion modules. CRGs support as many as 64 calculations based on quantities available in the PrCtPt module channels and support the same mathematical operations as those in standard Recording Groups.

Continuous Recording Group Limitations

The storage limits of CRGs are limited by the capacity of the SSD. The RTAC RTE will continue writing CRG data to disk until the available storage reaches 4 GB, at which point an SOE log entry is created to alert the user and the CRG begins to overwrite the oldest data with new data. The general SSD space requirement of the CRG is 600–700 MB per day, per channel for 3k sources. For analog data sources with a resolution lower than 3k and digital sources, the SSD space requirement is significantly less per channel.

Continuous Recording Group configurations do not presently have RAID-1 support. While RAID drives can be configured in the SEL-3555 (see *RAID Support and Configuration on page 661* for more information), CRG data are only stored on the system disk.

Axion Wave Server

Overview

The Axion Wave Server streams 3 kHz voltage and current samples from SEL-2245-42 AC Protection Modules via the IEEE C37.118 protocol. It supports Configuration 2 data frames and transmits 3000 messages per second over TCP/IP for as many as 96 channels. Additionally, the Axion Wave Server supports logic engine methods that allow accessing the 3 kHz samples in the RTAC's logic engine. For each SEL-2245-42 AC Protection Module in the Axion Wave Server configuration, the logic engine methods provide channel information, 3 kHz sample values, and the corresponding microsecond time stamps.

System Components

The Axion Wave Server requires the following components:

- SEL-3350, SEL-3555 RTAC, or SEL-3560
- SEL-2242 Backplane(s)
- SEL-2243 Power Coupler(s)
- SEL-2245-42 AC Protection Module(s)

IEEE C37.118 Server Configuration

Step 1. Starting with a new SEL-3555/SEL-3560 or SEL-3350 RTAC project, configure the SEL Axion EtherCAT network.

Step 2. Add the Axion Wave Server by selecting it under **SEL Axion** on the **Insert** ribbon.

Step 3. Set **Enable C37.118 Sample Streaming** in the **Settings** tab to True.

Step 4. Set the **Server IP Port** in the **Settings** tab. (The default is 4712).

Step 5. Enable the channels in the **Device** tab. For each SEL-2245-42 AC Protection Module, set **Enable Voltages** to **True** to enable voltage channels VA, VB, and VC; and set **Enable Currents** to **True** to enable current channels IA, IB, and IC.

Step 6. Set the PMU's **Station Name** and **PMUID** for each device using the SEL-2245-42 AC Protection Module's settings.

Axion Wave Processing

The Axion Wave Server provides three logic engine methods that access the 3 kHz point on wave samples and their corresponding channel information. The ACSELERATOR RTAC compiler requires completing Steps 1, 2, and 5 from *IEEE C37.118 Server Configuration on page 405* to enable these methods.

Axion Wave Server Data Structures

Table 2.75 and *Table 2.76* show the data structures provided by the Axion Wave Server that combine several memory locations into a single variable.

Table 2.75 struct_SampleRowData

Variable Name	IEC 61131 Type	Description	Default Value
Microseconds	ULINT	Number of microseconds since the beginning of Unix Epoch (January 1, 1970)	0
ChannelValue	Pointer To DINT	Pointer to an array (0 to NumChannels - 1) of the channels sample integer value from the SEL-2245-42	Null

Table 2.76 struct_SampleStream

Variable Name	IEC 61131 Type	Description	Default Value
NumChannels	USINT	The number of available channels	0
NumSamples	UINT	The number of available samples	0
TimeSynchronization	UDINT	The EtherCAT synchronization time difference in units of nanoseconds	0
DataQuality	BOOL	The quality of data provided	False
Samples	Pointer To struct_SampleRowData	Pointer to an array (0 to NumSamples - 1) of the struct SampleRowData	Null

Figure 2.150 shows a usage example of the struct_SampleStream data type.

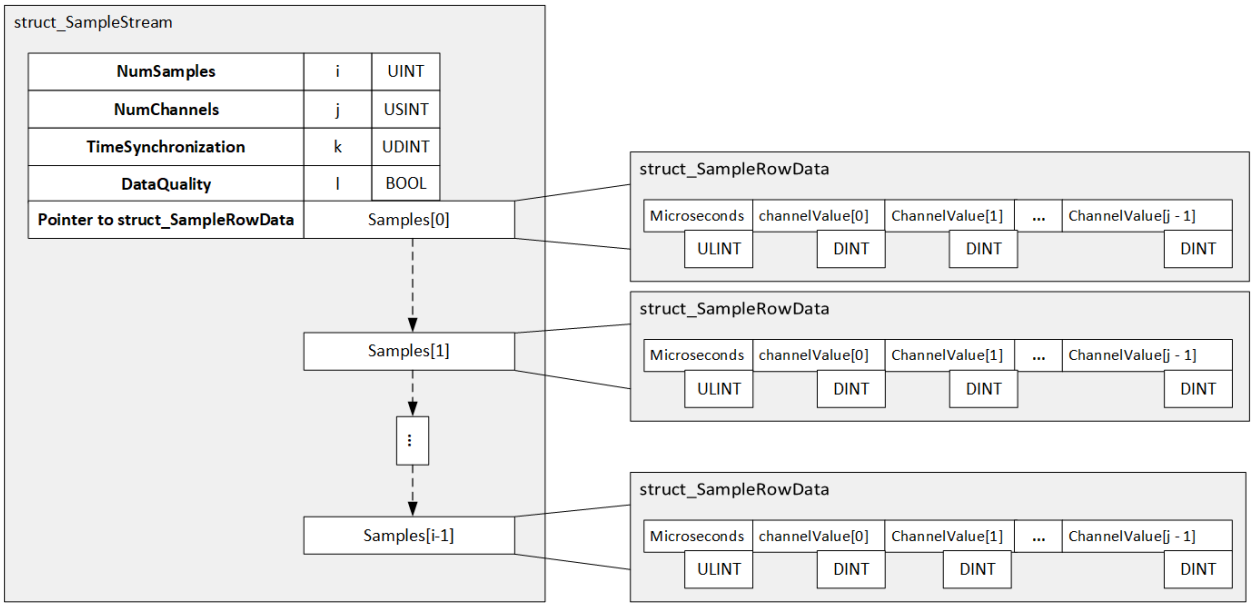

Figure 2.150 struct_SampleStream Usage Example

Table 2.77 struct_ChannelInfoRow

Variable Name	IEC 61131 Type	Description
DeviceName	STRING(62)	The SEL-2245-42 device name for the provided channel
ChannelName	STRING(2)	The SEL-2245-42 channel name (VA, VB, VC, IA, IB, IC)
Conversion	REAL	The channels AmpsPerCount or VoltsPerCount ratio to convert the integer sample value to a real quantity (amperes or volts)

Figure 2.151 shows a usage example of the struct_ChannelInfo data type.

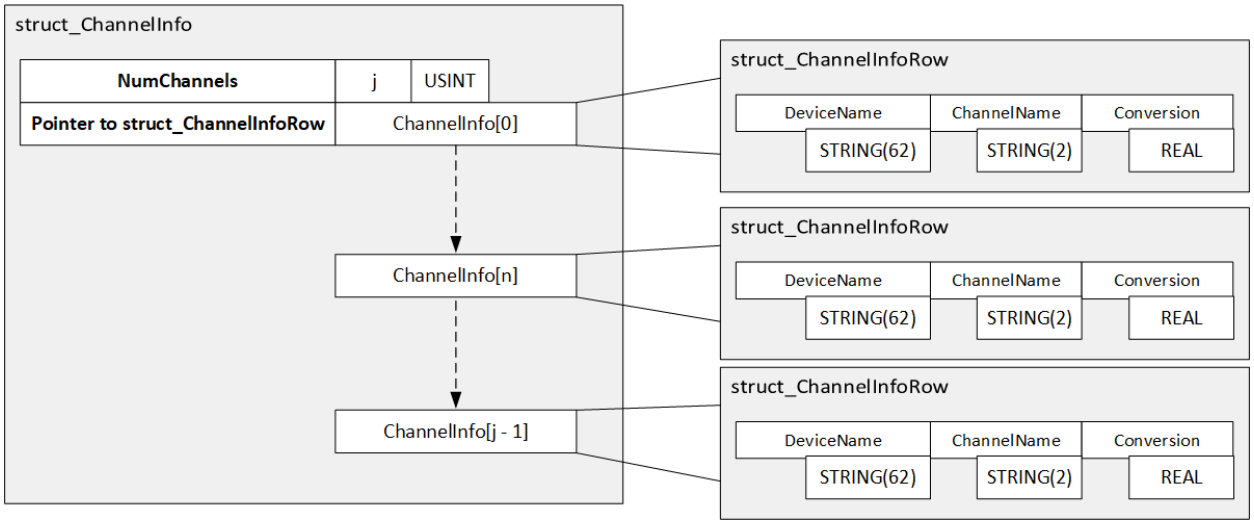

Figure 2.151 struct_ChannelInfo Usage Example

GetSamples Method

The Axion Wave Server method GetSamples outputs a struct_SampleStream from the current RTAC task cycle. Call this method each RTAC processing interval to access the Axion Wave Server point on wave samples in the RTAC logic engine. The number of samples on each processing interval are dependent on the task cycle time. For every millisecond in the task cycle, the Axion Wave Server provides three samples from all enabled channels in the Axion Wave Server. For example, GetSamples will provide 12 samples for a 4-millisecond task cycle. This method populates the struct_SampleStream data structure with default values if the Axion EtherCAT I/O network is unavailable or if the EnableAxionWaveServer POU pin is False. The following example demonstrates how to use GetSamples in structured text.

Outputs:

```
Samples : struct_SampleStream;
```

Variable declaration:

```
SampleSet : struct_SampleStream;
```

Example in structured text:

```
SEL_Axion_WAVE_POU.Samples. GetSamples(samples => SamplesSet);
```

GetChannelInfo Method

The Axion Wave Server method GetChannelInfo outputs a struct_ChannelInfo. This method provides channel indexing information to the corresponding sample data provided from the GetSamples method. This method populates the struct_ChannelInfo data structure with default values if the Axion EtherCAT I/O network is unavailable or if the EnableAxionWaveServer POU pin is False. The following example demonstrates how to use GetChannelInfo in structured text.

Outputs:

```
ChannelInfo : struct_ChannelInfo;
```

Variable declaration:

```
ChannelInformationSet : struct_ChannelInfo;
```

Example in structured text:

```
SEL_Axion_WAVE_POU.Samples. GetChannelInfo ( ChannelInfo =>
ChannelInformationSet ) ;
```

GetChannelIndex Method

The Axion Wave Server method GetChannelIndex provides the ability to look up a channel's index by providing the device name and channel name. This method outputs the channel index of the channel's position in the struct_SampleRowData array returned by GetSamples. If this method does not find a channel index from the requested inputs, it outputs a value of 255. The following example demonstrates how to use GetChannelIndex in structured text.

Inputs:

```
DeviceName : STRING(62);

ChannelName : STRING(2);
```

Outputs:

ChannelIndex : USINT;

Variable declaration:

ModuleVAChannelIndex : USINT;

Example in structured text:

```
SEL_Axion_WAVE_POU.Samples.GetChannelIndex(DeviceName :=
'SEL_PRCTPT_1', ChannelName := ‘VA’, ChannelIndex =>
ModuleVAChannelIndex);
```

Axion Wave Server POU Pins

Use the following POU pin settings to view the present state of the Axion Wave Server Operation.

Pin Name	Pin Type	Description	Default
EN	Input BOOL	Enables or disables Axion WaveServer and Axion Logic Engine Samples. If False, Axion WaveServer does not process any inputs or update any outputs, and Logic Engine Samples methods output default values.	True
Reset_Statistics	Input BOOL	When True, sets all statistics to zero.	False
ENO	Output BOOL	Asserts to indicate Axion WaveServer is enabled, and deasserts to indicate that Axion WaveServer is disabled and will not process any inputs or update any outputs.	False
EtherCAT_Message_Count	Output UDINT	Provides the number of EtherCAT messages that Axion WaveServer has received from the EtherCAT Network.	0
Message_Received_Count	Output UDINT	Provides the number of command frames that Axion WaveServer has received.	0
Connection_Count	Output UDINT	Provides the number of clients connected to Axion WaveServer.	0
Sample_Transmission_Enabled	Output BOOL	Asserts to indicate the Axion WaveServer IEEE C37.118 sample stream is enabled.	False

Node Connections Editor

You must configure the EtherCAT network before you can download a new project to an RTAC that contains SEL-2243 Power Couplers, SEL-2244 I/O modules, and SEL-2245 I/O modules. The ACSELERATOR RTAC project must include specific information about the placement of modules within an SEL-2240 node and the network connections between nodes. The Node Connections Editor provides a simple interface you will use to provide this information. Click on the EtherCAT I/O network entry in the project view, as shown in *Figure 2.152*, to access the Node Connections Editor.

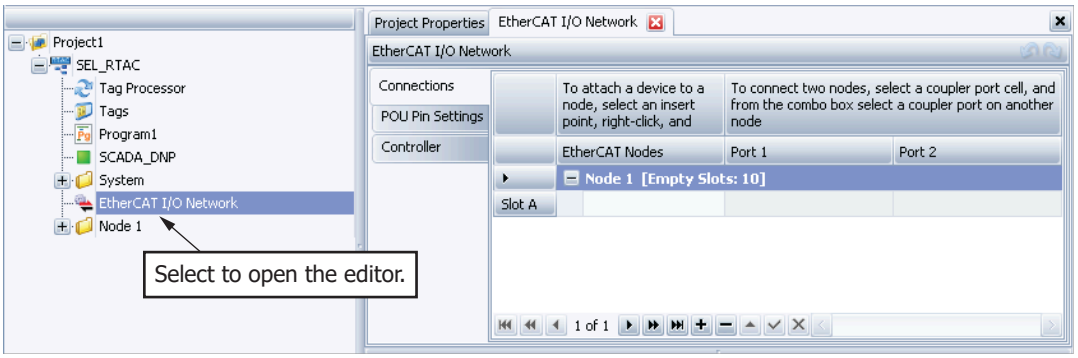

Figure 2.152 Opening the Node Connections Editor

The editor has three tabs: **Connections**, **POU Pin Settings**, and **Controller**. See *POU Pin Settings (Advanced Usage) on page 173* for a description of the **POU Pin Settings** tab. See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab. In online mode, the Node Connections Editor provides valuable diagnostics about the operation and state of the EtherCAT network. Refer to *Section 3: Testing and Troubleshooting* in the *SEL-2240 Instruction Manual* for details.

Controlling EtherCAT Response to Network Errors

There are two options available for operating the EtherCAT network in case of network errors or I/O module failure. By default, all EtherCAT network traffic will shut down, and outputs will return to de-energized state, if the RTAC receives message errors for 25 ms. Optionally, the Axion system can be configured so that the network will remain in operation even if some portions of the network become unavailable.

Control this operation by using a POU pin setting for the EtherCAT I/O Network. View and change the selection, using the following steps in ACSELERATOR RTAC.

Step 1. Select **EtherCAT I/O Network** from the project view pane.

Step 2. Click **POU Pin Settings**.

Step 3. As shown in *Figure 2.153*, find the present value for the setting Disable_On_Network_Error. The value will be TRUE initially for each new project. Change the value to FALSE if you prefer that the network continue to operate even if there are network errors or I/O module failures.

Step 4. Save and download the project.

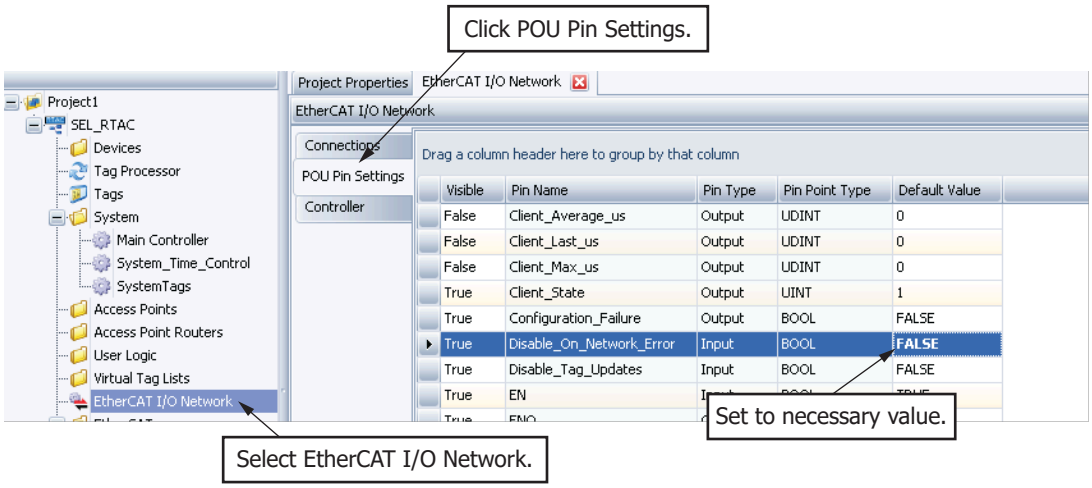

Figure 2.153 Configuring Disable on Network Error Setting

Connections

The **Connections** tab provides a tabular view of the nodes and modules in the project. When you open the Node Connections Editor for the first time, there will be an entry for a single node named Node 1 (you can rename this at any time). Next to the node name you will see the number of empty slots in that node. The primary editor actions are as follows:

- Attaching modules to a node
- Adding a node
- Editing the network connection between nodes
- Renaming a node
- Deleting a node
- Moving modules

NOTE
For ease of initial project configuration and troubleshooting, we recommend that you add only one node at a time to a project. Download and verify EtherCAT network operation prior to adding subsequent nodes.

NOTE
If a node does not include an SEL-2241, then a power coupler should be the initial module in a node. This would be the case if you are using an external SEL-3530 RTAC.

NOTE
If you select multiple modules in the dialog box, ACSELERATOR RTAC will list them in the node in the same sequence they appeared in the dialog box.

NOTE
All RTAC modules in the module list have an "[RTAC]" suffix, and all power couplers have a "[Coupler]" suffix. These suffixes will help you quickly identify these types of modules, regardless of module names.

Attaching Modules to a Node

Modules must be listed in the Node Connections Editor such that the listing matches their physical placement in the node. The EtherCAT network cannot autoconfigure and initialize upon downloading the project if the modules are not listed accurately. If you have an SEL-2241 RTAC module in a node, it must be the initial module added for that node. All subsequent modules must be added so that there are no blank slots between modules in the node. You do not need to fill every slot, but all modules must be installed sequentially and without gaps. As shown in *Figure 2.154*, follow these steps to add the RTAC module to Slot A.

Step 1. Right-click on the empty slot where the module resides.

Step 2. Select **Attach Devices**.

Step 3. The dialog box that appears allows you to select one or more available modules from your project. The selection for an SEL-2241 will only be available so long as no other SEL-2241 has been configured in the project and no network connection has been designated for an external RTAC.

Step 4. Select the SEL-2241 (RTAC) and press **Attach**.

Step 5. In the resulting editor window, the SEL-2241 displays in Slot A and the number of empty slots now shows 9.

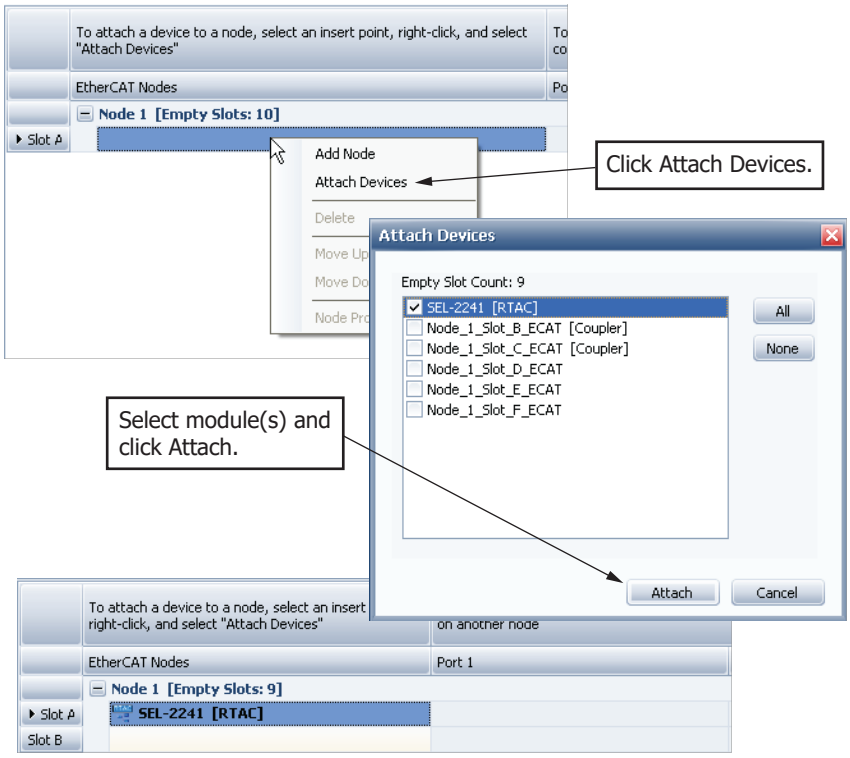

Figure 2.154 Attach a Device to a Node

Adding a Node

There are two methods for adding a new node to the project. First, as shown at the bottom of *Figure 2.155*, select the + control at the bottom of the editor. Second, right-click on any row to select **Add Node**.

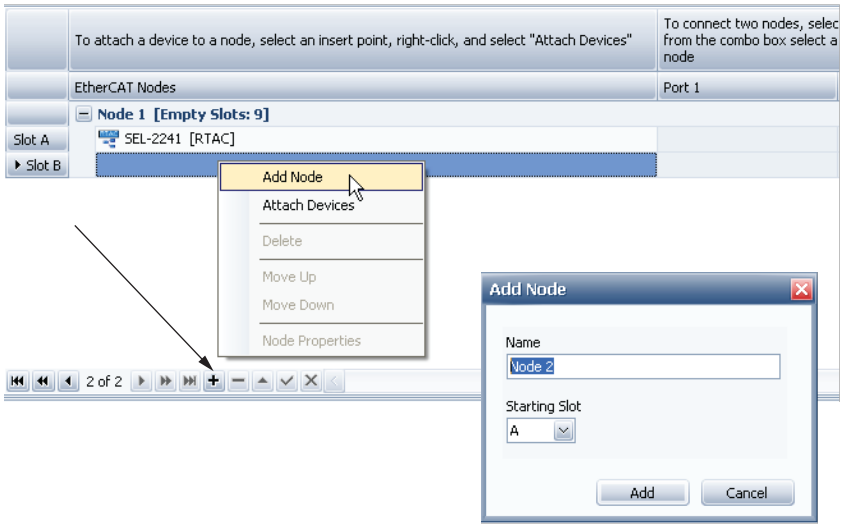

Figure 2.155 Adding a Node to the Project

After you use either selection method, you will see the **Add Node** dialog box. Provide a custom node name, if necessary. There is also a selection for the starting slot of a node. In most cases, the default selection of Slot A will be sufficient. Finally, click the **Add** button to accept a selection.

Editing Internode Connections

The automatic EtherCAT network configuration the RTAC performs during network initialization is dependent not only on accurate information about the sequence of modules within a node, but also on accurate information about the network cabling between nodes. The Axion system supports a number of different network configurations. As you will see, the Node Connections Editor will only allow you to enter settings for a valid network; it will also be helpful for your understanding of the basic networking rules for connections between nodes.

The SEL-2243 Power Couplers provide two Ethernet ports dedicated for EtherCAT. These ports are labeled **PORT 1** and **PORT 2**, respectively. For the following figures, we have used IN and OUT labels to denote the ports operating in the IN mode and the OUT mode for EtherCAT. An **IN** port is the port by which a node is connected to an upstream node or an external RTAC and is designated in the figures by a label of IN. **PORT 2** in a power coupler never operates as an **IN** port. **OUT** ports make a connection to a downstream node and are designated in the figures by a label of **OUT**. Each figure illustrates only a portion of the nodes.

As an initial example, consider a system using an external RTAC and multiple nodes, all with single power coupler modules, as shown in *Figure 2.156*. **PORT 1** of Node 1 is connected to the RTAC and is the **IN** port for Node 1. **PORT 2** is the **OUT** port for Node 1 and is connected to **PORT 1** of Node 2. Finally, **PORT 2** of Node 2 is connected to **PORT 1** of Node 3. You can continue this sequential networking method for more nodes, as necessary (as much as the maximum module limit).

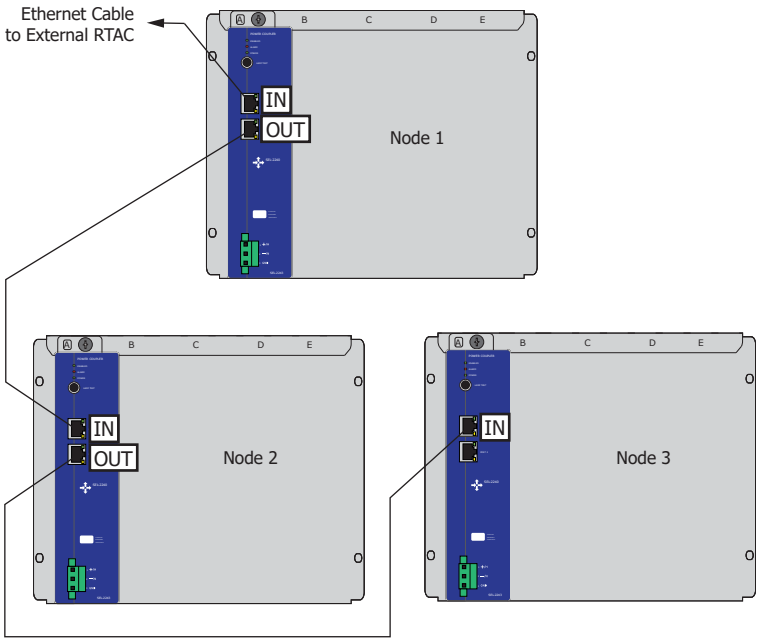

Figure 2.156 Axion System Using an External RTAC and Single Power Couplers

Figure 2.157 illustrates how to begin configuring this system in the Node Connections Editor by identifying the **IN** connection to an external RTAC. In the figure, notice that we have already created three nodes and attached a power coupler to Slot A of each node. Select the entry cell for **PORT 1** of the Node 1 coupler to see the valid input connections. No other node contains an RTAC module connection, so ACSELERATOR RTAC will allow **IN** connections from an external RTAC, Node 2, or Node 3 at this point. Click on **[IN] SEL-3530 [RTAC]**.

Next, set up the connection between Node 1 and Node 2. As you can see in *Figure 2.158*, you will need to select the Port 2 cell for Node 1 and click the entry for **[OUT] Node 2, Node_2_Slot_A_ECAT, Port 1**. The segments of this entry have the following meanings:

[OUT]—The EtherCAT function of the selected port, either **IN** or **OUT**.

Node 2—The name of the node to which you are connecting. This is the node name as listed in the Node Connection Editor; it does not reference a folder or device name in the project view.

Node_2_Slot_A_ECAT—The module name of the power coupler to which you are connecting. You must add power couplers to the project view before the power couplers are available options in the Node Connection Editor.

Port 1—The physical port on the power coupler to which you are connecting.

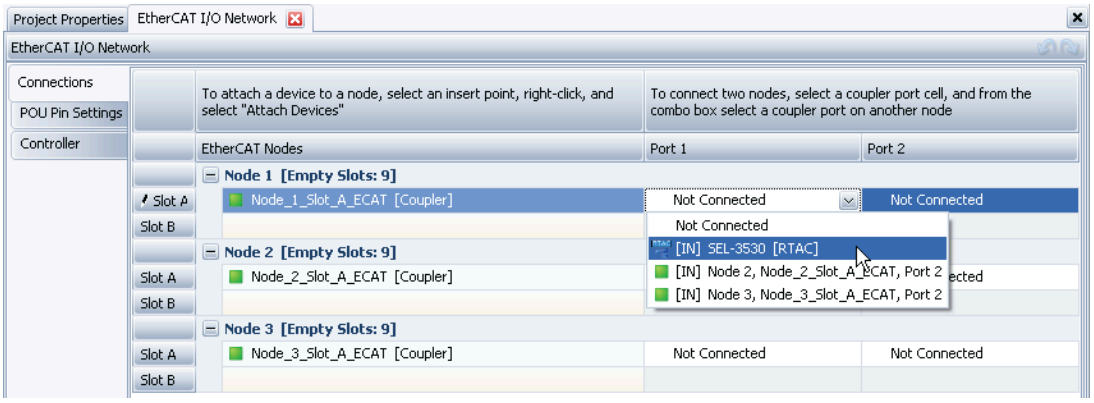

Figure 2.157 Setting an Input Connection to an External RTAC

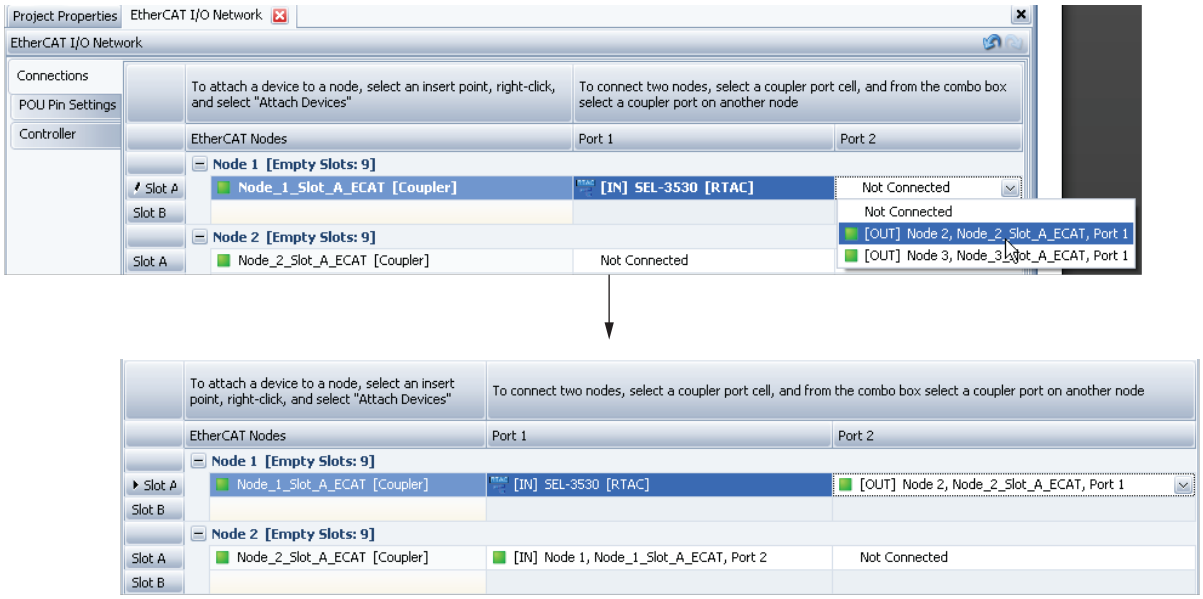

Figure 2.158 Connection From Node 1 to Node 2

Notice in the lower portion of *Figure 2.158* that ACSELERATOR RTAC automatically filled in the corresponding entry in Node 2 to complete the connection. Finally, configure the connection from Node 2 to Node 3. In this case, as shown in *Figure 2.159*, we selected the "IN" port (**PORT 1** on Node 3). The drop-down menu only lists available connections; we already have an RTAC connection in the project, so the list no longer includes an RTAC entry. Once again, the reciprocal entry for **PORT 2** on Node 2 is automatically created, as shown in the lower portion of *Figure 2.159*.

NOTE

ACSELERATOR RTAC validates settings in the Node Connection Editor each time the project is saved. Validation does not occur automatically when a setting changes.

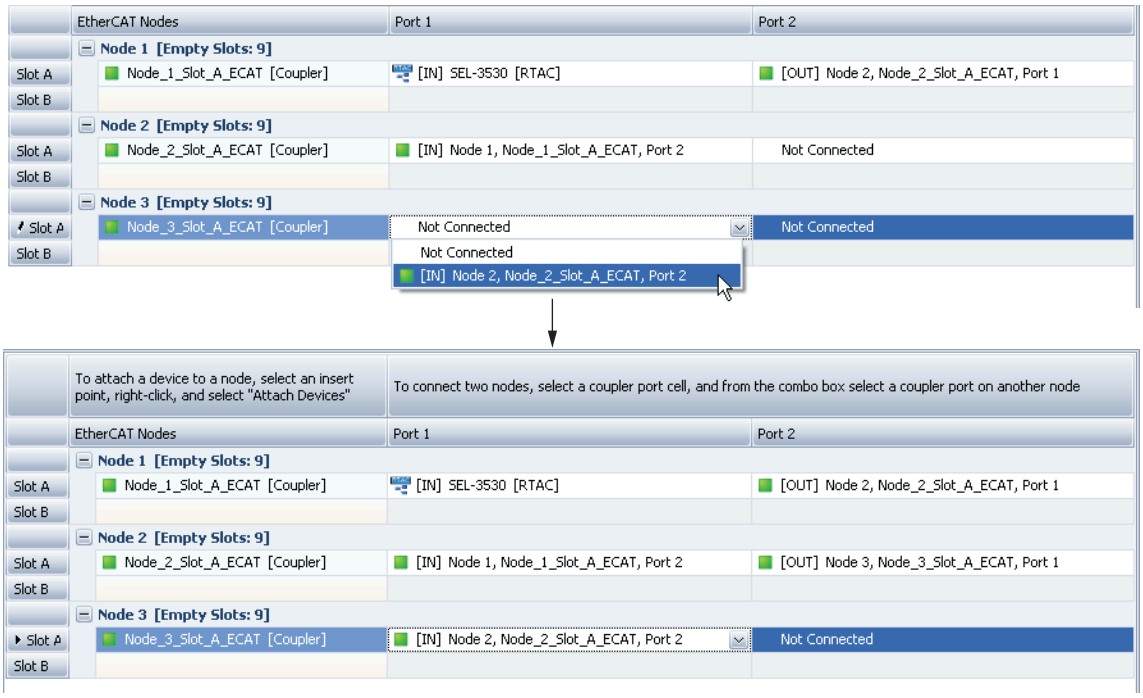

Figure 2.159 Connection From Node 2 to Node 3

For the next example, the system includes an SEL-2241 RTAC module and three nodes, all with a single power coupler. We can configure a network of this type in a sequential manner similar to the previous example. In this case, however, we used a star arrangement as shown in Figure *Figure 2.160*. When you use an SEL-2241 RTAC rather than an external RTAC, the first power coupler in the node containing the RTAC uses the backplane connector as an **IN** port for EtherCAT. Therefore, you can use both ports on the first power coupler in "OUT" mode.

Figure 2.161 displays the Node Connection Editor results for configuring this system. An SEL-2241 RTAC resides in Slot A of Node 1. Both **OUT** ports on the Node 1 power coupler connect with the respective **IN** ports on Node 2 and Node 3.

NOTE

The Node Connection Editor grid is grayed and unavailable for slots that do not contain a power coupler.

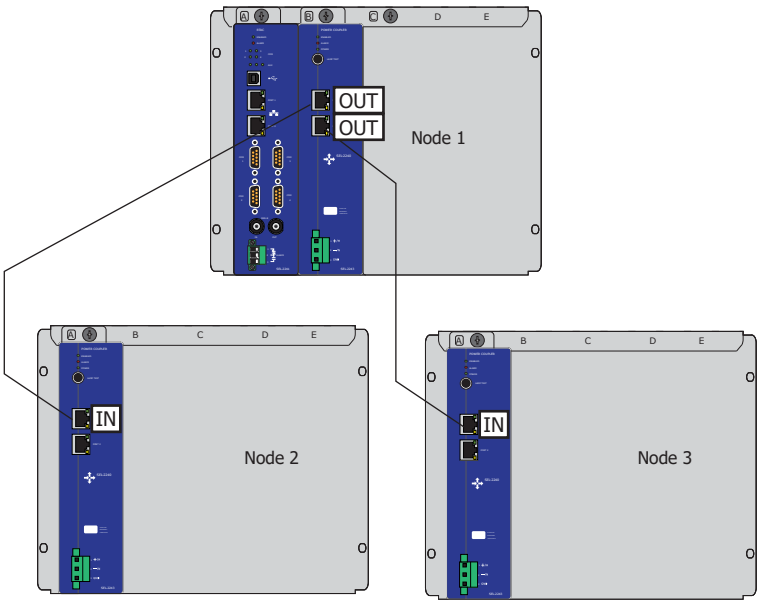

Figure 2.160 Axion System Using an SEL-2241 RTAC and Single Power Couplers

	To attach a device to a node, select an insert point, right-click, and select "Attach Devices"	To connect two nodes, select a coupler port cell, and from the combo box select a coupler port on another node	
	EtherCAT Nodes	Port 1	Port 2
	Node 1 [Empty Slots: 8]		
Slot A	SEL-2241 [RTAC]

Slot B			

Figure 2.161 Node Connection Editor Results for System in Figure 2.160

The next two examples deal with systems using redundant power couplers. In all cases, each node can have only one port functioning as an **IN** port. **PORT 1** in the first power coupler will function as the **IN** port for every node except a node containing an SEL-2241. As we stated previously, the Node Connection Editor helps ensure that each setting is valid.

In *Figure 2.162* you will see a system connected to an external RTAC that uses dual power couplers. This is another example of a star network, with Nodes 2, 3, and 4 all connected to Node 1. *Figure 2.163* shows the settings for this system.

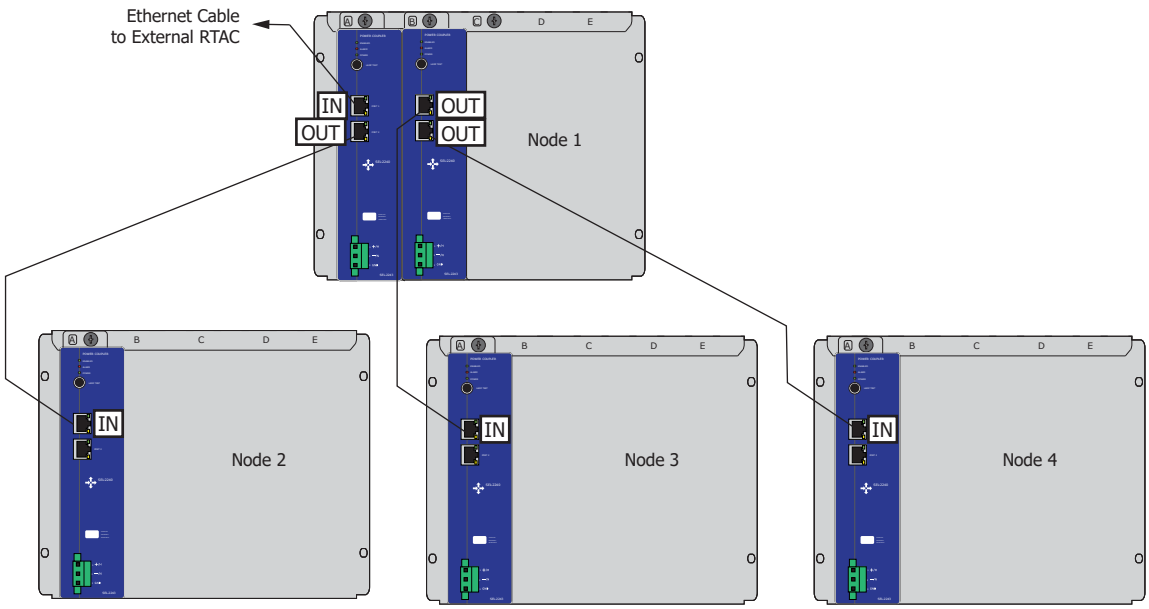

Figure 2.162 Axion System Using an External RTAC and Dual Power Couplers

	Node 1 [Empty Slots: 8]		
Slot A	Node_1_Slot_B_ECAT [Coupler]	[IN] SEL-3530 [RTAC]	[OUT] Node 2, Node_2_Slot_A_ECAT, Port 1
Slot B	Node_1_Slot_C_ECAT [Coupler]	[OUT] Node 3, Node_3_Slot_A_ECAT, Port 1	[OUT] Node 4, Node_4_Slot_A_ECAT, Port 1
Slot C			
	Node 2 [Empty Slots: 9]

	Node 3 [Empty Slots: 9]		
Slot A	Node_3_Slot_A_ECAT [Coupler]	[IN] Node 1, Node_1_Slot_C_ECAT, Port 1	Not Connected
Slot B			
	Node 4 [Empty Slots: 9]		
Slot A	Node_4_Slot_A_ECAT [Coupler]	[IN] Node 1, Node_1_Slot_C_ECAT, Port 2	Not Connected

Figure 2.163 Node Connection Editor Results for System in Figure 2.162

Figure 2.164 represents the final example. The system has an SEL-2241, two nodes with dual SEL-2243 Power Couplers, and a mixture of sequential and star connections. Notice that the star connections can be tiered, such as exemplified by Node 1 and Node 2. Also note that Node 2 has one star connection (Node 6) and one sequential connection (Node 7). You can mix and match the connections to match the application. *Figure 2.165* shows the configuration results for the system.

Figure 2.164 Axion System Using an SEL-2241 and Dual Power Couplers

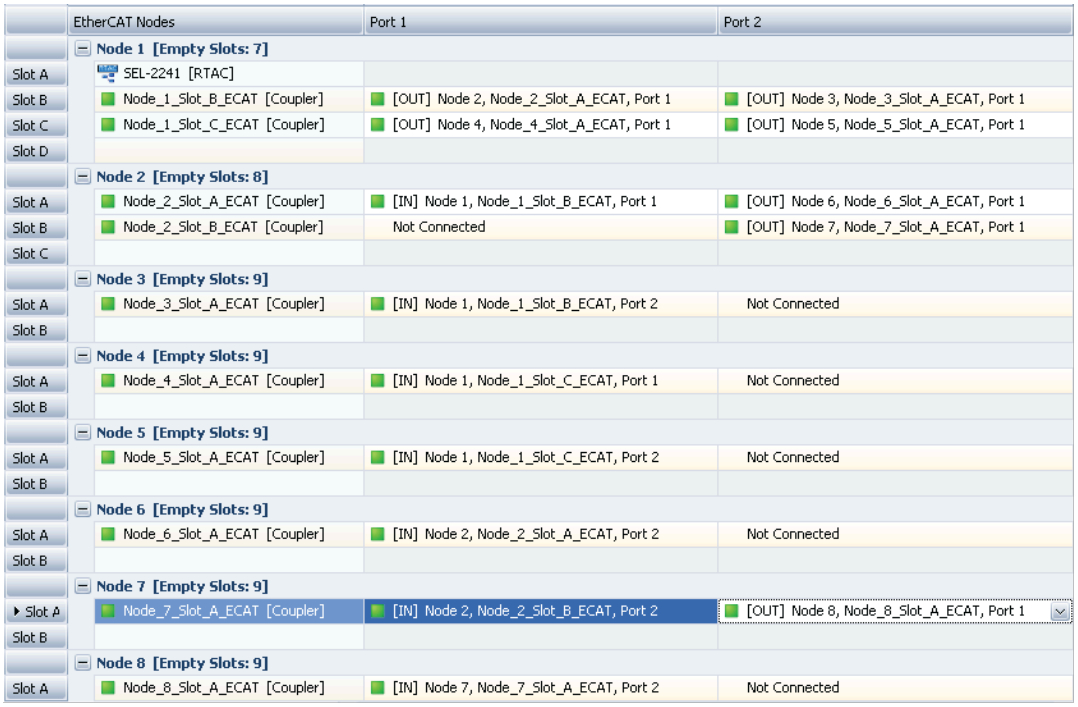

Figure 2.165 Node Connection Editor Results for System in Figure 2.164

Renaming a Node

Rename a node in the Node Connection Editor at any time via the Node Properties function. As shown in *Figure 2.166*, simply right-click on the node name and select **Node Properties** from the menu. Then, in the dialog box, type in the replacement name and click **Set** to complete the operation.

NOTE
Node names must be unique.

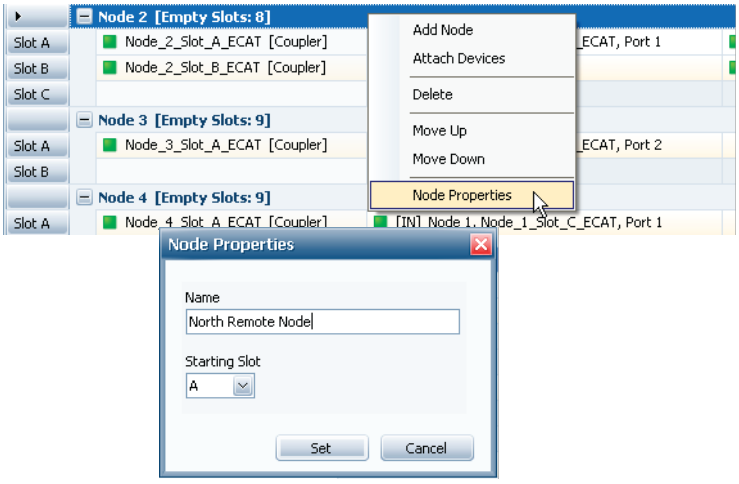

Figure 2.166 Renaming a Node

Deleting a Node

Delete unneeded nodes in the Node Connection Editor at any time. As with the renaming function, you can perform this deletion of unneeded nodes by right-clicking on the node name and selecting **Delete** from the menu. All of the connections referring to this node will also be deleted. However, the modules that are listed as part of that node are not deleted from the project. Attach the modules to the correct node by moving them prior to deleting the node within which they presently reside.

Moving Modules and Nodes

The Node Connection Editor has an intuitive drag-and-drop interface to change the sequence of nodes or modules in the view. Whether you need to change the sequence of modules within a node, move a module from one node to another, or change the displayed sequence of nodes, just select and drag the items to their new location. ACSELERATOR RTAC will not allow for multiple item selection in this view.

RTU Project Examples

There are two project templates in the **RTAC/Axion** RTAC type project category in the **Create Project** dialog box. These RTU projects gather data from one to three SEL Axion nodes and report to a DNP master. Most projects only contain digital inputs and outputs (I/O), but four projects include gathering of dc analog inputs (AI) from an SEL-2411 through IEC 61850 GOOSE messages. Most of the projects use RJ45 EtherCAT connectors for Power Couplers. The projects that have three nodes include variations with LC fiber-optic EtherCAT connectors for Power Couplers. The projects include 125 V digital input and Form A digital output modules.

Each project includes a DNP master connection for all connected I/O, and this connection includes dc AIs if the project includes them. Additionally, all digital I/O map to the internal SOE data for time-stamping of all inputs and outputs. The input debounce time is 5 ms on pickup and dropout.

Each project includes IEC 61131-3 example functions that are not active, but are available for use. These functions include a transfer trip function (TTF), assert digital output (ADO), square-wave generator (SWG), frequency meter (FM), and an analog input alarm (AI_Alm).

Table 2.78 RTU Templates With Included Modules

Project	Nodes	RTAC	PC Mod	DI Mod	DO Mod	AI Mod	CT/ PT Mod	Description
1	Node 1 Node 2 and 3 Node 4	2241	2 RJ45 2 RJ45 2 RJ45	4 5	3 3	2	2	336 DI/144 DO/32 AI/8 CT/8 PT Dual-Redundant RJ45
2	Node 1 Node 2	2241	2 RJ45 2 RJ45	4	4	2	1	96 DI/48 DO/32 AI/4 CT/4 PT Dual-Redundant RJ45

Setting Modifications

There are several settings you may want to change from their defaults to obtain the necessary performance.

- ➤ *RTAC Update Rate on page 422*
- ➤ *Input Debounce Settings on page 422*
- ➤ *SOE Logging Settings on page 423*
- ➤ *DNP IP Settings on page 423*
- ➤ *IEC 61131-3 Example Function Use on page 424*
- ➤ *IEC 61850 GOOSE Analog Settings on page 424*

RTAC Update Rate

The RTAC task cycle time is set at 50 ms in the RTU projects. Adjust this setting in the **Main Controller Options** according to how often you want the information in the RTAC to refresh. To optimize CPU utilization, try to avoid setting the task rate at the fastest settings.

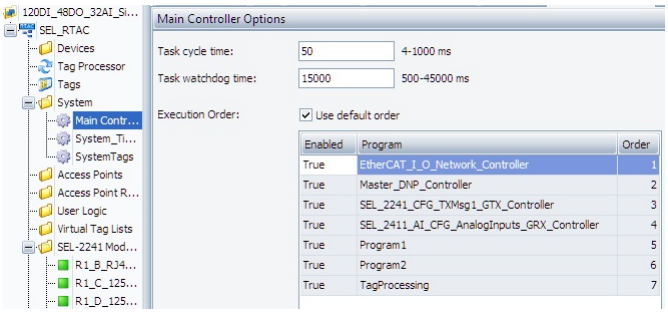

Figure 2.167 RTAC Update Rate

Input Debounce Settings

The input debounce settings are set to 5 ms for pickup and dropout in dc mode. Adjust these settings to the optimum debounce time to match your output contacts, or change to ac mode if you are using ac wetting voltage. Refer to *Digital Input Debounce on page 338* for detailed information.

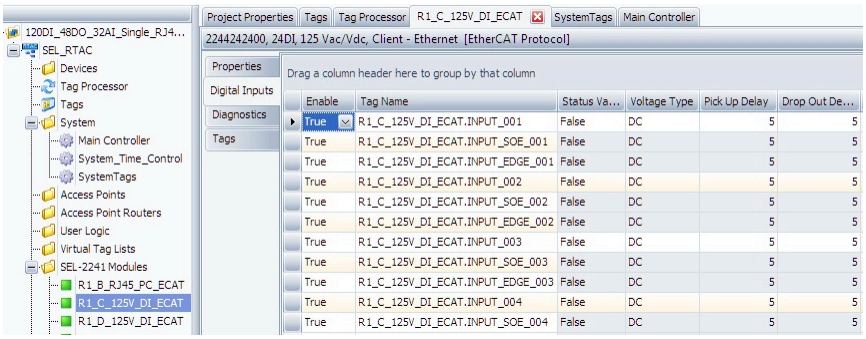

Figure 2.168 Input Debounce Settings

SOE Logging Settings

The Tag Processor contains configuration for SOE logging of all digital inputs and outputs in the projects. Configure logging chatter filters, logging messages, or enable/disable logging for the SOE points. See *Log Settings on page 653* for detailed instructions.

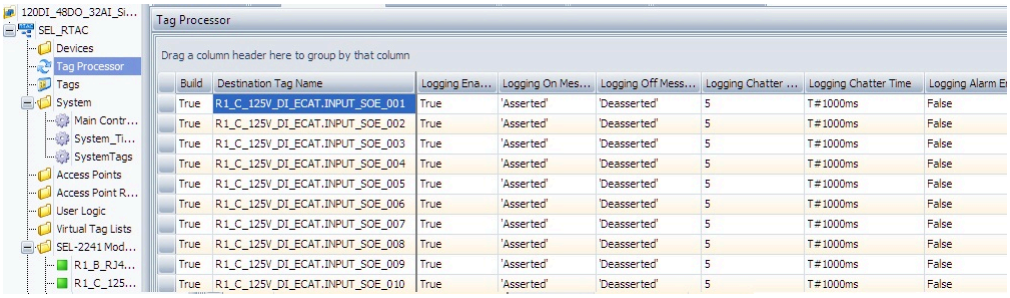

Figure 2.169 SOE Logging Settings

DNP IP Settings

The DNP Server connection has binary inputs/outputs and analog inputs corresponding to the modules and attached devices in each project. Every digital input/output and analog included in each project is mapped through the Tag Processor to corresponding binary inputs/outputs and analogs in the DNP settings. Modify the network and address settings to match your DNP Master. Refer to *DNP Server Configuration on page 186* for more information.

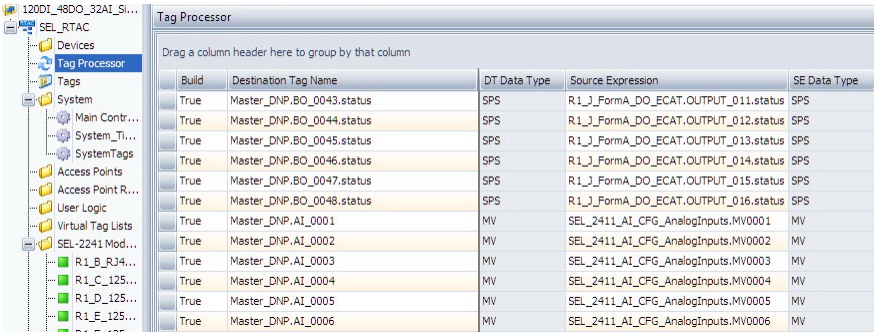

Figure 2.170 DNP Mapping With the Tag Processor

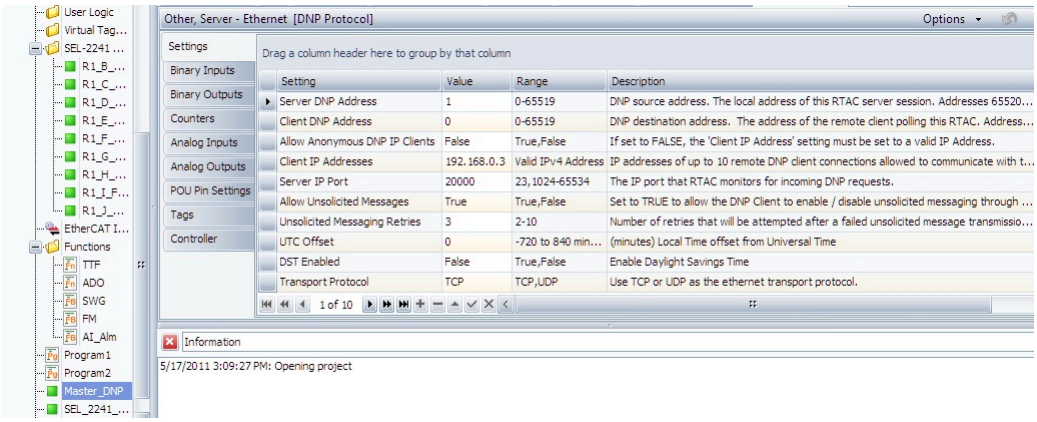

Figure 2.171 DNP Server Connection IP Settings

IEC 61131-3 Example Function Use

Each included example function includes comments describing functionality and variable descriptions. Function call examples for each Structured Text (ST) function are in Program 1. Function call examples for Continuous Function Chart (CFC) functions are in Program 2. Use these functions as necessary for I/O control and analog signal processing. Refer to *Section 9: Custom Logic* for detailed information about the IEC 61131-3 programming environment in ACSELERATOR RTAC.

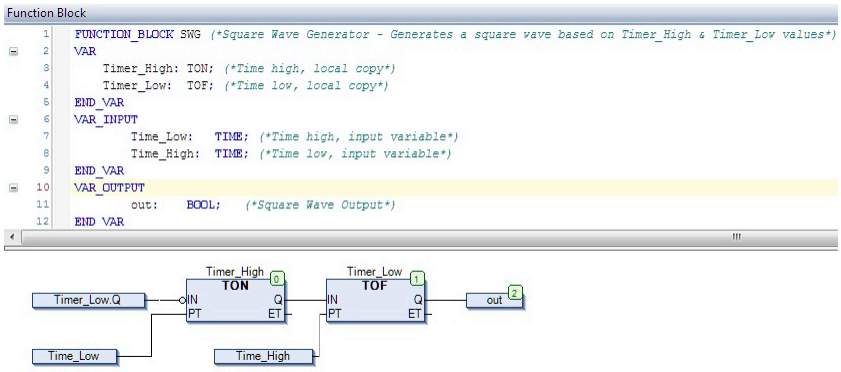

Figure 2.172 ST Function Example

IEC 61850 GOOSE Analog Settings

Four of the RTU projects include dc analog inputs from an SEL-2411 that uses GOOSE messages. The IEC 61850 configuration includes 32 dc analog inputs from an SEL-2411 with four installed 8 AI cards. To edit the network settings or the included points, use the export IEC 68150 configuration in the insert IEC 61850 dialog in ACSELERATOR RTAC. Open the export file with ACSELERATOR Architect to modify the IP or point settings for the SEL-2411 and SEL-2241. Once you have saved changes, use the insert IEC 61850 dialog in ACSELERATOR RTAC to insert the new configuration. Refer to *IEC 61850 on page 279* for more details.

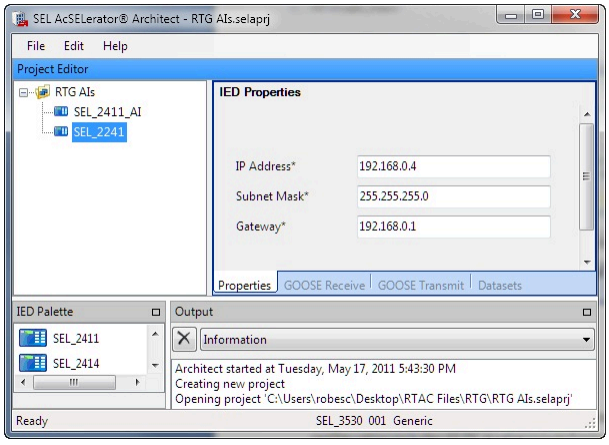

Figure 2.173 Architect GOOSE Configuration

Network Global Variable List (NGVL)

Use a Network Global Variable List (NGVL) to share a global variable list over an Ethernet network between a transmitting NGVL device and receiving NGVL devices, such as the SEL-1102 and the SEL-3530 RTAC. You can configure variables in an NGVL that are of standard data types (BOOL, REAL, etc.) and complex tag types (SPS, MV, CMV, etc.). The protocol supports transmitting variable lists from one device to another, to several, or to all devices on a given network. Data are transmitted on a configurable cyclical transmission interval, on change of tag value, or when triggered by a configurable Boolean event change of state. Configure other NGVL compatible devices on the network to receive the NGVL transmission by creating a matching tag list with matching tag list ID.

NGVL Configuration

You can configure multiple NGVL connections in the RTAC as either transmit (sends global list data) or receive (receives global list data). The global variables you create in an NGVL are available anywhere in the RTAC for data mapping or manipulation just as any other global variable. The NGVL protocol handles the transmission of the values contained in the global variables.

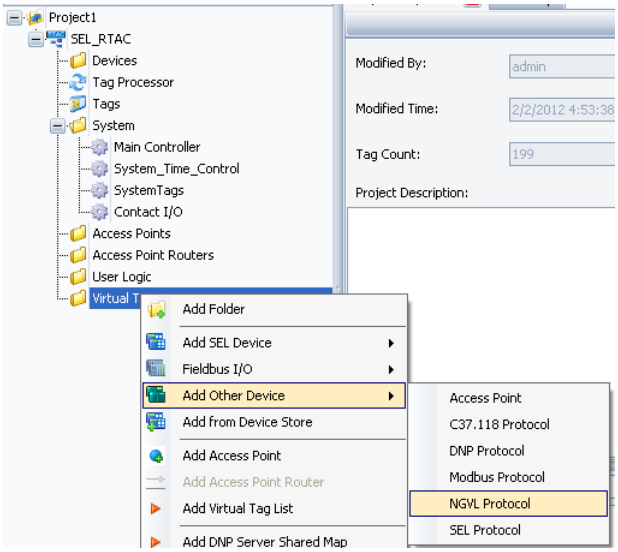

Figure 2.174 Insert NGVL

Insert an NGVL by selecting **Other** from the **Insert** ribbon or right-clicking anywhere in the device tree (see *Figure 2.174*). Give the device connection a unique name and note you cannot select the connection type because it is a peer-to-peer Ethernet protocol.

By selecting the **Settings** tab, you see all the configurable items for communications. Configure the NGVL to be transmitted or received. Check the **Description** column for details on each configuration item. Move the slider bar or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Select the **Variables** tab to add the global variables. The global variables can be of any type supported in the RTAC. You can use data structures or simple variable types. Configure one RTAC to transmit a list, including a unique list ID. Then, configure another RTAC to receive the list. The receive list configuration must specify the same unique list ID and must contain the same data list as the transmitted list. Although it may be confusing to do so, you can use different names in the transmit and receive lists, but the data types must be the same.

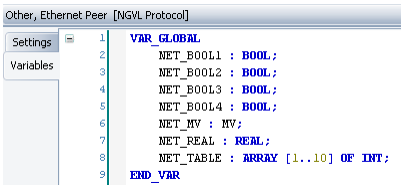

Figure 2.175 Add NGVL Tags

Example 2.5 Configure a Transmit and a Receive NGVL on Two RTACs

The following example demonstrates how to configure a transmit NGVL on one RTAC, then use that same list configuration on the receiving RTAC. Using the same NGVL configuration reduces the risk of user configuration error. In this example, RTAC 1 has an IP address of 192.168.1.2 on Eth 1 and RTAC 2 has an IP address of 192.168.1.5 on Eth 1.

Step 1. In a blank RTAC project, insert an NGVL into the device list by right-clicking on the Virtual Tag Lists folder (or anywhere in the device tree), then select **Add Other Device > NGVL Protocol**.

Step 2. Rename the **Device Name** to something meaningful and unique. In this example, we will call it **Transmit**.

Step 3. Change the Broadcast Address to 192.168.1.255. This designates all addresses on the network that start with 192.168.1 are to receive this message. Leave the other configurations under **Settings** at their default values.

Step 4. Click on Variables and configure several global variables as shown in the following table and *Figure 2.175*.

Variable Name	Variable Type
My_bool	BOOL
My_real	REAL
My_MV	MV

Step 5. Map values to the global variables from other tags in the RTAC system.

Step 6. Save the project.

Step 7. Right-click on the new NGVL, select **Export Items**, ensure the NGVL device is selected to export to XML, and select **Export**.

Step 8. Load project into the first RTAC (referred to in this example as RTAC 1).

Step 9. Connect an Ethernet cable into **ETH 1** from RTAC 1 and into **ETH 1** of RTAC 2.

Step 10. Select **Interfaces** on the RTAC 2 web interface and change the IP address of **Eth 1** to 192.168.1.5.

Step 11. Create another RTAC project.

Step 12. Right-click on **Virtual Tag Lists** (or anywhere in the device tree) and select **Import Items**. Assign the **XML Folder** to the same location in which the original NGVL was exported, ensure the check box is selected for the XML definition containing the original NGVL from *Step 7*, and select **Import**.

Step 13. Change the GVL Type from **Transmit** to **Receive**.

Ensure the List ID is the same.

Step 14. Change the **Broadcast Address** to the IP address of RTAC 1, which is configured with the Transmit NGVL (192.168.1.2).

Step 15. Save the project and load it into the second RTAC (referred to as RTAC 2).

Data from the NGVL on RTAC 1 are broadcast on the network. RTAC 2 receives the NGVL data and places the data into the corresponding NGVL tags in RTAC 2.

Landis and Gyr LG 8979

In the mid 1980s, Landis and Gyr (LG) developed the Telegyr, or LG 8979 protocol, to provide byte-oriented half-duplex communications between the control center and remote terminal units. The RTAC supports a maximum of 10 LG 8979 client connections and 10 LG 8979 server connections simultaneously.

This section describes the configuration and use of LG 8979 protocol with ACSELERATOR RTAC. A list of supported function codes for client and server connections is included at the end of this section.

For a detailed description of client and server concepts and other general information on protocol configuration, see *Overview on page 161*.

LG 8979 Client

Configuration

Configure an LG 8979 client connection on any of the RTAC serial ports, or configure as a tunneled connection for use over Ethernet. The RTAC will poll for the configured data and store these data into global variables called tags. Use the Tag Processor to map these data to any other protocol, logs, user logic, etc.

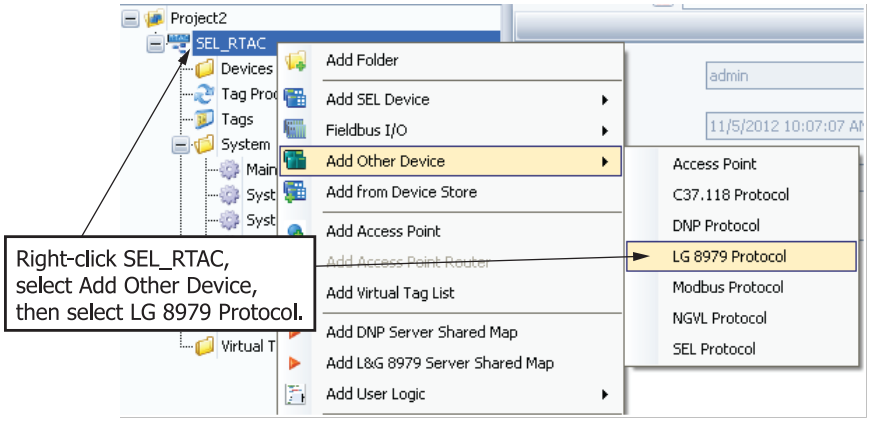

Figure 2.176 Insert LG 8979 Client

Give the device connection a unique name, and select the type of connection as shown in *Figure 2.1*.

Settings Tab

Upon your selecting the **Settings** tab, the RTAC displays all configurable items for communication. Check the Description column for details on each configuration item. Move the slider bar, or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Select the **Advanced Settings** check box to enable configuration of advanced settings.

LG 8979 protocol-specific parameters that can be adjusted on the **Settings** tab include the following:

- **RTU Address**. The LG 8979 RTU address of the remote server.
- **Select Timer Count**. Configures the Timer Count field that is present in all SBO Select messages generated by the client when issuing an SBO command. Configure this parameter between 1–127 to use a common timer count value for all SBO Select Messages. Set this parameter to 0 to allow a per-point SBO timer count configurable via the **pulse_config.on_dur** field within the OperSPC structure of the SBO tag.
- **Auto Respond to SOE Log Change**, **Auto Respond to SOE Change**, **Auto Respond to Indication Change**, and **Auto Respond to Freeze Change**. When set to True, automatically respond to the presence of the SLG, SCH, IND, or FRZ flags (respectively) in an RTU response by sending a scan of the appropriate type to collect the change data. This allows for a standard polling configuration where the RTAC only issues Analog Change Report scans at a regular interval and then issues these four scans on exception.
- **Enable Startup Initialization**. When True, enable protocol initialization sequence on startup. The protocol initialization sequence includes the following:
  - A request for Firmware Configuration (FC 39)
  - A request to write Analog Deadbands for all configured analog input values (FC 34). The value written for each point is retrieved from the per-tag **Deadband Count** field on the Analog Inputs tab.

➢ A request to write Accumulator Presets for all configured accumulator values (FC 36).

➢ A request for a Force Report on any configured tag values that should be populated at startup (e.g., Analog Inputs, Indications, SOEs).

Messages Tab

Define the type and frequency of messages the RTAC sends to the LG 8979 IED in the **Messages** tab. There are predefined messages by default, but you can adjust the default settings to alter the poll period, function, poll type, and range of points the messages use. See *Table 2.79*.

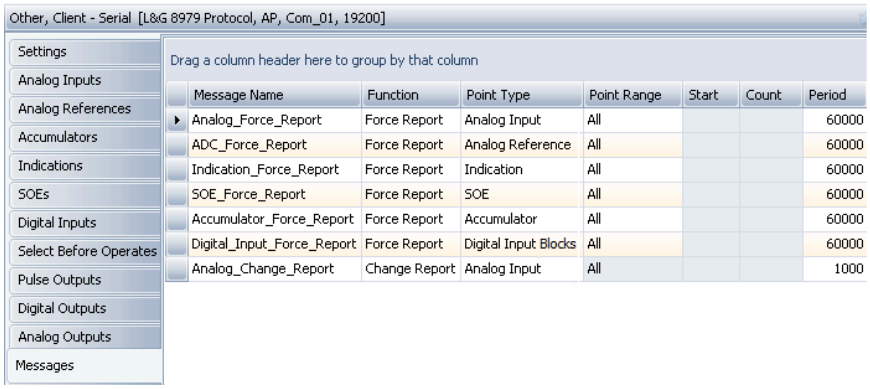

Figure 2.177 LG 8979 Messages

Table 2.79 LG 8979 Messages

Column Name	Description
Message Name	User-defined message name
Function	The function the message performs as either Force Report or Change Report
Point Type	The type of point requested for by the message
Point Range	The range of points polled for by the message
Start	The first point of a range of points
Count	The number of points within a range of points
Period	The period of time in milliseconds in which the RTAC will send the message

Add Client Device Data

Select device data settings tabs such as Analog Inputs, Analog References, Accumulators, etc., to add and configure LG 8979 tags.

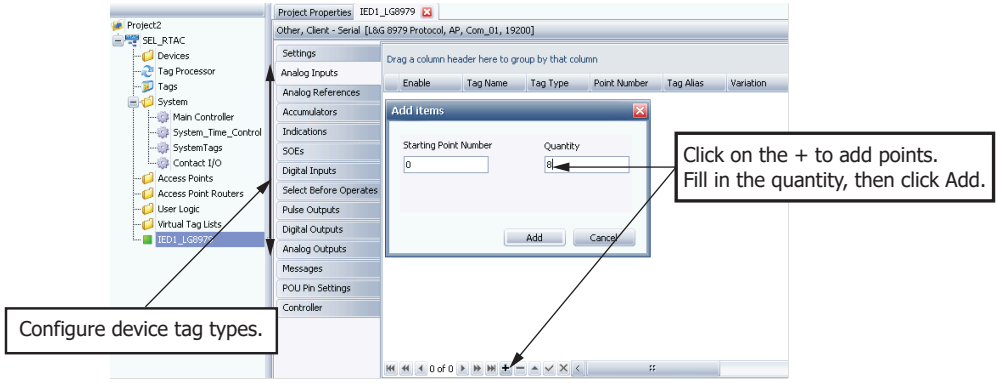

Figure 2.178 Add LG 8979 Client Tags

The following steps detail the addition of client device data.

Step 1. Click on a device tag type tab to add and configure tags.

Step 2. Click + to add tags (4096 tag limit per device tag type).

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags as necessary.

Step 4. Change other tag-related information as necessary.

Repeat these steps to configure all IED devices. When finished, configure one or more servers to deliver the data to remote client devices.

NOTE
Use Copy (**<Ctrl+C>**) and Paste (**<Ctrl+V>**) to populate columns of Tag names and to duplicate devices.

Device Tag Type Configuration Parameters

Data and poll types have parameters that you must configure correctly to ensure proper system operation. ACSELERATOR RTAC will gray out configuration fields that do not apply to a specific device.

Table 2.80 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name and tag type and is numbered 0–*n* tags
Point Number	This is the point number for which the LG 8979 client will poll. If points are not contiguous in the IED, change these point numbers to match the LG 8979 database for the IED.	Contiguous from 0 to the point count

Parameter	Description	Default
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Comment	Optional user-entered comment field	

Table 2.81 Digital Input, Indications, and SOEs Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	SPS
Block Number	The digital input block number. Each block contains 16 binary inputs.	
Bit Number	The bit placement for this digital input within the block specified	Bit number 0 is the first digital input, bit 1 is the second, and so forth
Status Value	The initialized value at startup	False

Table 2.82 Digital and Pulse Output and Select Before Operate Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. In DNP, there are five binary output operations and one status.	Control operations is operSPC. Status is SPS
Block Number	The digital input block number. Each block contains 16 binary inputs.	
Bit Number	The bit placement for this digital input within the block specified	Bit number 0 is the first digital input, bit 1 is the second, and so forth
Status Value	The initialized state at startup	False
Control Model	Defines if the control is a single pulse or persistent (latch) type control	Defaults are set according to control type and cannot be changed
Number of Pulses	Defines the number of pulses the control will issue each time this point is controlled	1
On Pulse Dur	Defines the duration for an active pulse	
Off Pulse Dur	Defines the duration for an inactive pulse	

Table 2.83 Accumulators Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	BCR
Actual Value	The initialized running value at startup	0
Frozen Value	The default frozen value the tag will have before the RTAC initializes the tag upon startup	

Table 2.84 Analog Input and Analog References Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	MV
Inst Magnitude	The initialized instantaneous value at startup	
Magnitude	The initialized dead-banded value at startup	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion of this dead band will generate a time-stamped DNP event.	
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.85 Analog Outputs

Parameter	Description	Default
Variation	The variation of the output type. Options are 12 bit signed or unsigned.	
Status Value	The initialized value at startup	
Control Value	The initialized control value at startup	
Max Value	The maximum value allowed for this point. If InstMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

LG 8979 Server Configuration

Configure an LG 8979 server connection to communicate via serial or Ethernet tunneled to LG 8979 polling clients. Create binary input, analog input and other tag types in an LG 8979 Server Shared Map as placeholders for data that the clients will poll. Configure the LG 8979 server to use the configured shared map. Each LG 8979 server can use a unique map or share the same map. You can create a maximum of 10 LG 8979 shared maps in a project. Map data to those shared map tags by using the Tag Processor from client IED or other source tags in the RTAC database.

Insert a unique LG 8979 Server connection for each LG 8979 client connected to the RTAC.

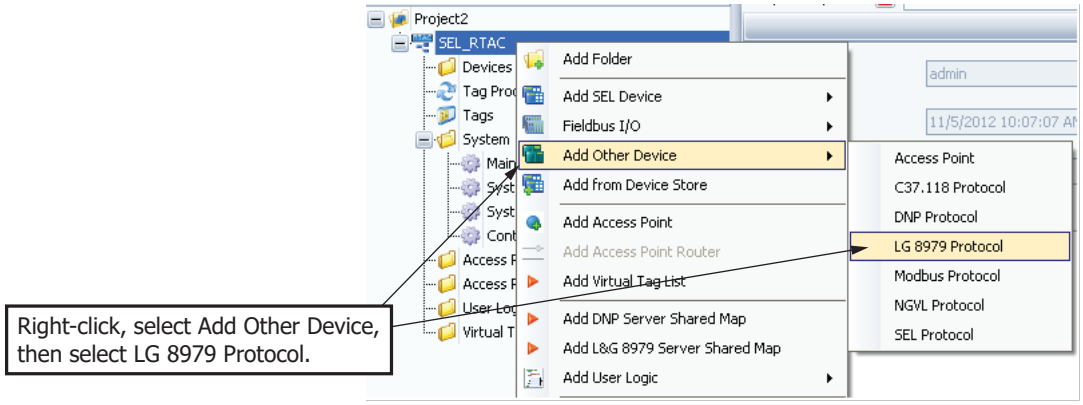

Figure 2.179 Insert LG 8979 Server Device

Give the device connection a unique name, and select the type of connection as shown in *Figure 2.3*. The **Settings** tab contains all the configurable items for communications. Note that you must enter an LG 8979 Server Shared Map name in the settings. This map contains all the tags that this LG 8979 server uses. Check the Description column for details on each configuration item. Move the slider or hover your cursor over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Add LG 8979 Share Map

The following steps detail the addition of a server shared map.

Step 1. Under the **Insert** tab, select **Tag Lists**, then **LG 8979 Server Shared Map**.

This will insert a configurable tag list for an LG 8979 server. You can configure multiple LG 8979 servers to use this same shared tag list.

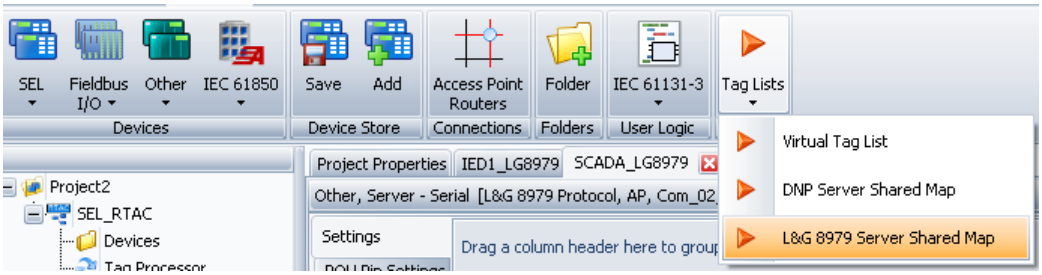

Figure 2.180 Add LG 8979 Server Map

Step 2. Click on a device tag type tab to add and configure tags.

Step 3. Click + to add tags (4,096 tag limit per device tag type).

Creating only the number of necessary tags optimizes system performance.

Step 4. Change the names of the tags as necessary.

Step 5. Change other tag-related information as necessary.

Repeat *Step 2* through *Step 5* to configure all server tags. When finished, configure the LG 8979 server to use this custom map by selecting the LG 8979 Map Name under settings. Although more than one LG 8979 server can use the same map, each LG 8979 server will manage separate event queues. Configure the Tag Processor to populate these server connection tags with actual values.

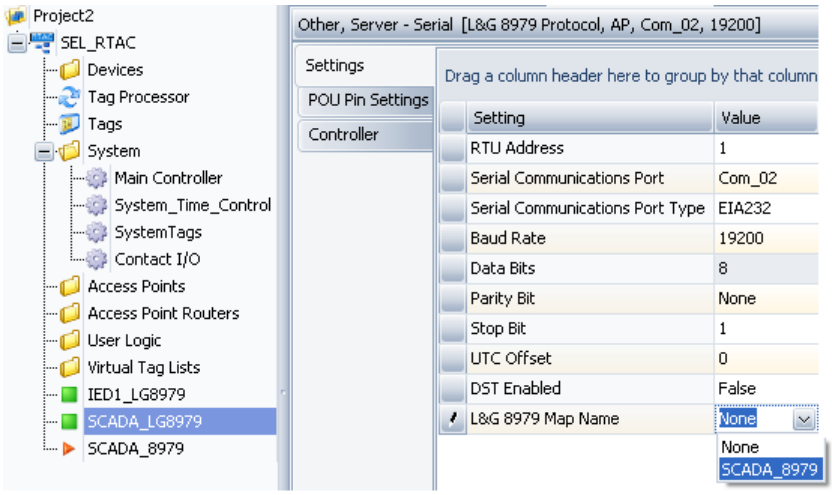

Figure 2.181 Select LG 8979 Shared Map

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation. Configuration columns in the LG 8979 Shared Map have the same meaning as in LG 8979 clients (described previously) except for the addition of fields that have special meaning in LG 8979 servers. Use these fields to alter the default object variations returned to a polling LG 8979 client.

POU Pin Settings

See *POU Pin Settings (Advanced Usage) on page 173* for a description of the **POU Pin Settings** tab.

Tags

See *Tags (Overview) on page 174* for a description of the **Tags** tab.

Controller

See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab.

Supported Function Codes

Table 2.86 LG 8979 Client Function Codes

Function Code	Description
0 Analog Change Report	Values that have exceeded an integrated delta value or values that have exceeded the configured dead band
1 Analog Force Report	The present value of a point or group of points
5 ADC Reference Force Report	The present value of ADC references
6 Indication Change Report	Indications that have changed state at least once since the last reported value
7 Indication Force Report	The present state and memory change of indications
8 SOE Change Report	SOE report containing the state and time of SOEs that have changed since the last reported value
9 SOE Force Report	All SOE entries
11 Digital Input Force Report	The present state of digital input points
12 Accumulator Change Report	Accumulator values that have been frozen and not reported in the last read
13 Accumulator Force Report	All frozen accumulator values
14 SOE Log Change Report	All SOE log entries that have changed since the last interrogation
20 Analog Output	Control an analog output value.
21 SBO Select	Select an SBO point to operate.
22 SBO Operate	Operate the previously select SBO point.
23 Digital Output	Immediate operate on a digital input point
24 Accumulator Freeze	Freeze one or more accumulator point values.
25 Pulse Output	Immediate control to raise or lower for a configured duration
26 Pulse Train Output	A single message that controls several points for a raise or lower for a configurable duration
30 Restart RTU	Perform a restart of the remote unit.

Function Code	Description
32 Time Synchronization	Time synchronize the remote unit.
33 Time Bias	Message sent from the polling master and returned by the client for the purpose of determining how long it takes for the message to travel on the wire. The time bias is added to the time synchronization to compensate for time lost in data transmission.
34 Analog Dead Bands	Set dead bands for each analog point in the remote unit.
37 Continuation Request	If the remote unit replies with the continuation bit set in the data message, the polling client sends a continuation request to the remote server. Upon receiving the continuation request, the remote server sends the next message.
38 Repeat Last Message	Upon receipt of the repeat last message function code, the server resends the last transmitted message.
39 Firmware Configuration	Upon receipt of the firmware configuration function code, the server replies with a number representing the firmware version.
63 Exception Report	If the number of exceptions (data changes) exceed the server's change buffer capacity, the server will generate an exception report.

In addition to the function codes listed in *Table 2.86*, the LG 8979 server supports the function codes shown in *Table 2.87*.

Table 2.87 LG 8979 Server Function Codes

Function Code	Description
2 Analog Group Change Report	Values that have exceeded an integrated delta value or values that have exceeded the configured dead band
3 Analog Group Force Report	The present value of a point or group of points
31 RTU Configuration	The server reports the point configuration

CP2179

CP2179 Client Configuration

Configure a CP2179 Client connection to communicate via serial or Ethernet tunneled serial to as many as 100 IEDs. The RTAC will poll data from these IEDs and store the data it receives in global variables. Use the Tag Processor to map these data to any protocol, logs, user logic, etc.

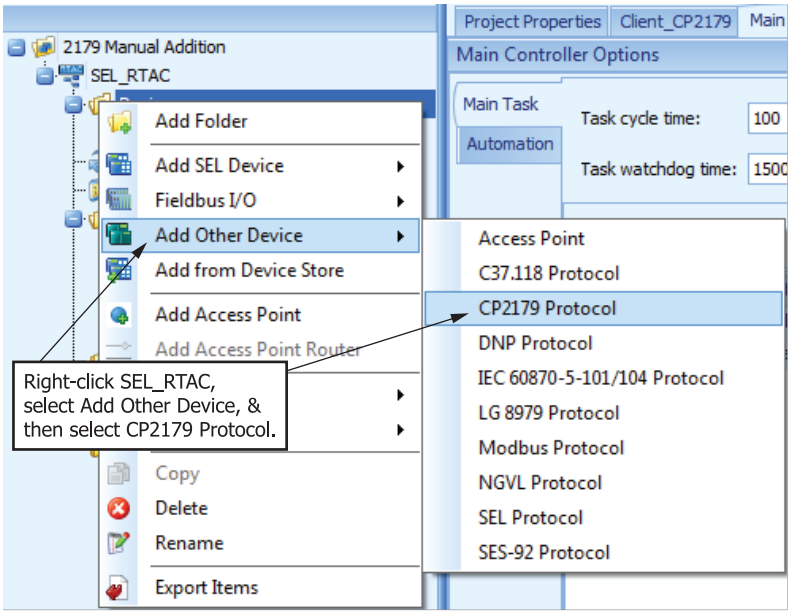

Figure 2.182 Insert CP2179 Client

Settings Tab

Upon your selecting the **Settings** tab, the RTAC displays all configurable items for communication. Check the **Description** column for details on each configuration item. Move the slider bar, or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Select the **Advanced Settings** check box to enable configuration of advanced settings.

Select device data settings tabs such as **2-bit Status**, **Analog Inputs**, etc., to add and configure CP2179 tags.

Messages

Set up the number and type of messages you need. Each message can apply to all sequence ID numbers or a configurable range.

Message Name:

Unique identifier for that message.

Period:

Frequency in millisecond a message will be triggered.

Function:

Function Code	Function Code Description	Supported Features
0x00	Basic Scan	2-bit Status Simple Status Analog Input (signed 16-bit format) Pulse Accumulator
0x01	Scan Inclusive	Signed 16-bit format
0x03	Special Calculations	32-bit IEEE Single-Precision Floating Point
0x20	Reset Accumulator	

Type:

Message type selection applying only to Basic Scan. Types are:

- 2-bit Status
- Simple Status
- Analog Input (signed 16-bit format)
- Pulse Accumulator

Range:

Sequence ID address selection. Option are: All or a range specified by a Starting Sequence ID and a count of Sequence IDs following referred to as Start/Count.

Start:

Sequence ID of the first point addressed by the message.

Count:

Number of consecutive sequence IDs requested by the message.

Add Client Device Data

The following steps detail adding client device data.

Step 1. Click a device tag type tab to add and configure tags.

Step 2. Click + to add tags (10,000 tag limit or 5000 for SEL-3505, per device tag type).

Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags, if necessary.

Step 4. Change other tag-related information as necessary.

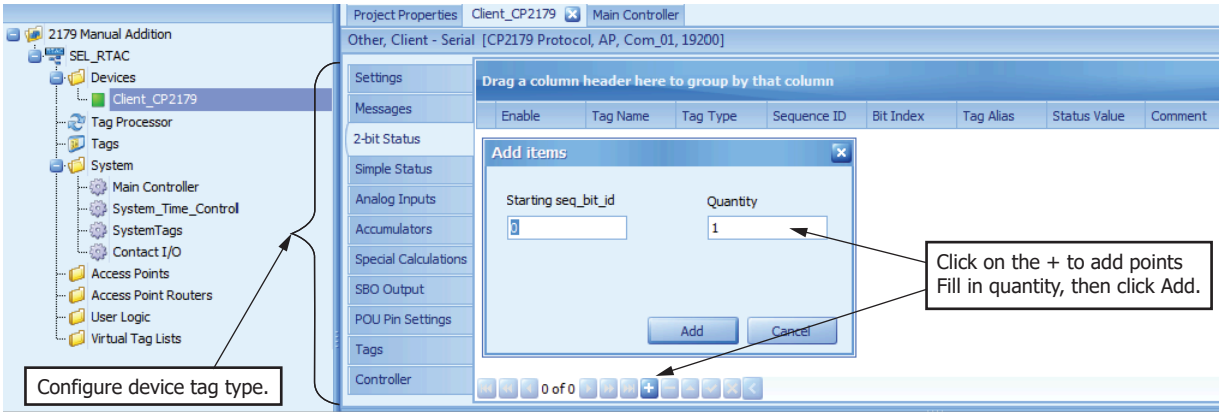

Figure 2.183 Add CP2179 Client Tags

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation.

Table 2.88 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name and tag type and is numbered 0–*n* tags.
Sequence ID	Point address on the server data map	Contiguous from 0 to the number of IDs
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Comment	Optional user-entered comment field	

Table 2.89 2-Bit Status

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	SPS
Bit Index	Bit position within the Status Word, identified by the Sequence ID	Contiguous from 0 to 7
Status Value		

Table 2.90 Simple Status

Parameters	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	SPS
Bit Index	Bit position within the Status Word, identified by the Sequence ID	Contiguous from 0 to 7
Status Value		

Table 2.91 Analog Input

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	INS
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.92 Pulse Accumulator

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	BCR
Actual Value	The initialized running value at startup	0
Frozen Value	The default frozen value the tag will have before the RTAC initializes the tag upon startup	0

Table 2.93 Special Calculations

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	INS
Inst Magnitude	The initialized instantaneous value at startup	
Magnitude	The initialized dead-banded value at startup	
Dead Band	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag. An excursion of this dead band will generate a time-stamped DNP event.	
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	

Parameter	Description	Default
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.94 SBO Output

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	SPC
Status	SPS Status of the point identified by Sequence ID	
Control Model	Nonconfigurable field	Persist
On/Off Pulse Duration	Nonconfigurable field	

POU Pin Settings

See *POU Pin Settings (Advanced Usage) on page 173* for a description of the **POU Pin Settings** tab.

Tags

See *Tags (Overview) on page 174* for a description of the **Tags** tab.

Controller

See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab.

SES-92

SES-92 is a byte-oriented, asynchronous serial client/server-based (master/slave) protocol derived from the Landis & Gyr TELEGYR 8979 protocol. Designed to provide supervisory control and data acquisition (SCADA) between master stations and remote terminal units (RTUs), the SES-92 protocol supports features such as remote download of analog dead bands, report by exception, time synchronization, and counter freeze capability. The RTAC supports as many as 10 SES-92 server and 10 SES-92 client connections simultaneously.

This section describes the configuration and use of the SES-92 protocol with ACSELERATOR RTAC. The RTAC supports function codes listed in *Table 2.105*, as defined in the SES-92 Protocol Specification version 2.0, unless otherwise noted within this manual.

For a detailed description of client and server concepts and other general information on protocol configuration, see *Overview on page 161*.

SES-92 Client

Configuration

Configure an SES-92 client connection on any RTAC serial ports, or configure it as a tunneled connection for use over Ethernet. The RTAC will poll for the configured data and store these data into global variables called tags. Use the Tag Processor to map these data to any other protocol, logs, user logic, etc.

Give the device connection a unique name, and select the type of connection as shown in *Figure 2.184*.

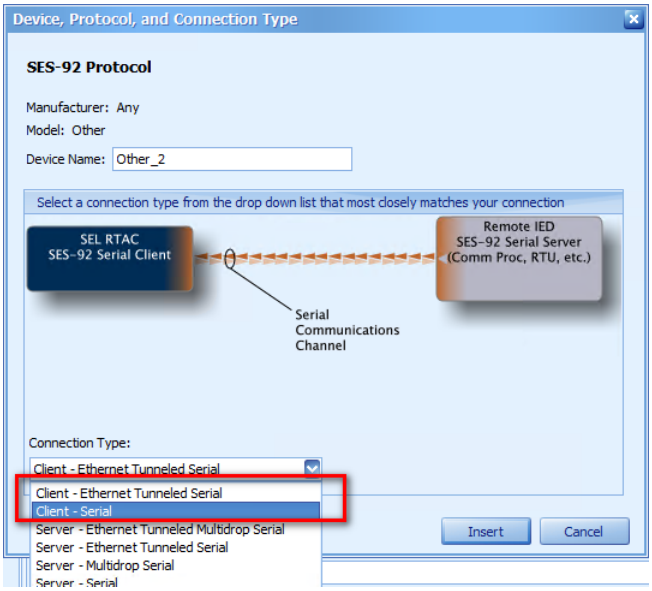

Figure 2.184 Adding SES-92 Client

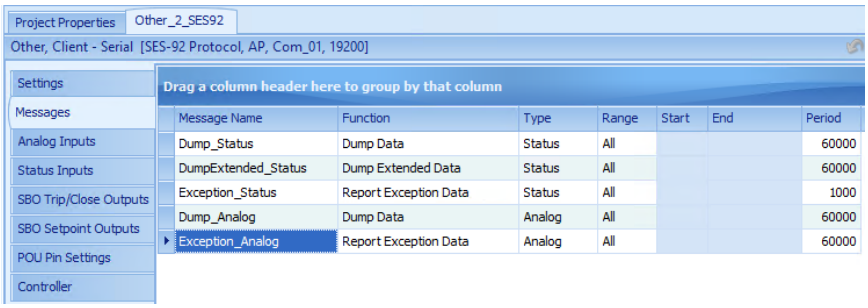
Settings Tab

Upon selecting the **Settings** tab, the RTAC displays all configurable items for communication. Check the Description column for details on each configuration item. Move the slider bar or hover your mouse over a truncated description to see the entire text of a description. Type any necessary comments in the blank column to the far right.

Click the **Advanced Settings** check box to enable configuration of advanced settings.

Messages Tab

Define the type and frequency of messages the RTAC sends to the SES-92 IED in the **Messages** tab. There are predefined messages by default, but you can adjust the default settings to alter the poll period, function, poll type, and range of points the messages use.



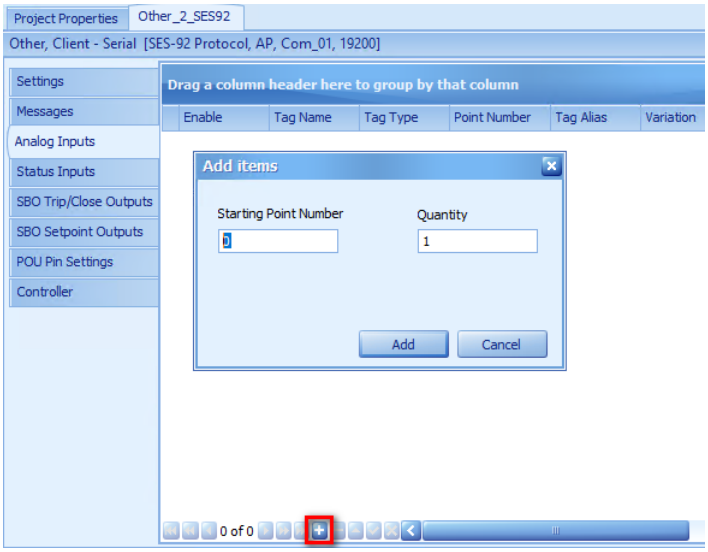


Table 2.95 SES-92 Messages

Column Name	Description
Message Name	User-defined message name
Function	Dump Data, Dump Extended Data, or Report Exception Data
Type	The type of data that will be polled (Status or Analog)
Range	The range of points that will be polled (All or Start/End)
Start	The first point that will be polled (0–4095)
End	The last point that will be polled (0–4095)
Period	The period of time (in milliseconds) in which the RTAC will send the message (0–100000000)

Add Client Device Data

Select device data settings tabs such as **Analog Inputs**, **Status Inputs**, **SBO Trip/Close Outputs**, or **SBO Setpoint Outputs** to add and configure SES-92 tags.

The following steps detail the addition of client device data.

Step 1. Click a device tag type tab to add and configure tags.

Step 2. Click the + button to add tags (as many as 4096 per device tag type). Creating only the number of necessary tags will help the system run at optimum performance.

Step 3. Change the names of the tags as necessary.

Step 4. Change other tag-related information as necessary.

Device Tag Type Configuration Parameters

Data and poll types have parameters that you must configure correctly to ensure proper system operation. ACSELERATOR RTAC will gray out configuration fields that do not apply to a specific device.

Table 2.96 Device Tag Type Configuration Parameters

Parameter	Description	Default
Enable	Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name and tag type and is numbered 0–*n* tags.
Point Number	This is the point number for which the SES-92 client will poll. If points are not contiguous in the IED, change these point numbers to match the SES-92 database for the IED.	Contiguous from 0 to the point count.
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Status Value	This is the default value of the tag.	0 or False
Comment	Optional user-entered comment field	

POU Pin Settings and Controller

Table 2.97 POU Pin Settings and Controller

Pin Name	Pin Type	Description	Default
Disable_Controls	Input BOOL	While True, processing of any controllable tags is blocked.	FALSE
Disable_Tag_Updates	Input BOOL	The POU will not update or process changes to tags while this input is True.	FALSE
EN	Input BOOL	The EN input enables or disables this specific function block instance. Other inputs have no effect while EN is False.	TRUE
Issue_Dump_Diagnostics	Input BOOL	On the rising edge, issue a Dump Diagnostics message to the RTU.	FALSE
Issue_Dump_Diagnostics_Period	Input TIME (0, 100–10000000 ms)	The period at which to issue a Dump Diagnostics message to the RTU.	T#0MS
Issue_Poll_Exception_Data	Input BOOL	On the rising-edge, issue a Poll Exception Data message to the RTU.	FALSE
Issue_Poll_Exception_Data_Period	Input TIME	The period at which to issue a Poll Exception Data message to the RTU.	T#0MS

Pin Name	Pin Type	Description	Default
Issue_RTU_Configuration_-Complete	Input BOOL	On the rising-edge, issue a RTU Configuration Complete message to the RTU.	FALSE
Issue_RTU_Configuration_-Complete_Period	Input TIME (0, 100–100000000 ms)	The period at which to issue a RTU Configuration Complete message to the RTU.	T#0MS
Issue_Sync_Protocol_Version	Input BOOL	On the rising-edge, issue a Synchronize Protocol Version message to the RTU.	FALSE
Issue_Sync_Protocol_Version_-Period	Input TIME	The period at which to issue a Synchronize Protocol Version message to the RTU.	T#0MS
Issue_Time_Sync	Input BOOL	Requests time-synchronization message(s) to be sent on the rising edge. Time-synchronization processing is defined by the Propagation Delay Type setting.	FALSE
Issue_Time_Sync_Period	Input TIME (0, 100–100000000 ms)	Defines the interval used by the client to issue time-synchronization messages. Setting to zero causes the related function to be non-periodic.	T#600000MS
Reset_Statistics	Input BOOL	On the rising-edge trigger, all counter POU outputs are reset.	FALSE
Issue_<*Name*>	Input BOOL	Request message to be sent on the rising edge.	
Issue_<*Name*>_Period[a]	Input TIME (0, 100–100000000 ms)	Defines the interval used by the client to issue the message. Setting to zero causes the related function to be non-periodic.	
ADC_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte ADC flag from the last Diagnostic Dump response.	FALSE
ALG_Flag_Status	Output BOOL	Contains the status of the Frame Header's Analog Exceptions flag from the last response received.	FALSE
Control_Overflow	Output BOOL	Asserted for a single processing interval when a Control operation could not be queued.	FALSE
Control_Overflow_Count	Output UDINT	Running sum of dropped Control operations.	0
Controls_Disabled	Output BOOL	Asserted when the Disable_Controls input is asserted. This indicates that the client will not issue control commands.	FALSE
Direct_Transparent_Connection	Output BOOL	Indicates that the communications have been interrupted by a direct transparent connection through an access point router.	FALSE
ENO	Output BOOL	Indicates that this specific function block instance is active if True. If False, the inputs have no effect and the outputs are not updated.	FALSE
ERR_Flag_Status	Output BOOL	Contains the status of the Frame Header's Error flag from the last response received.	FALSE
FW_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte F/W flag from the last Diagnostic Dump response.	FALSE
HW_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte H/W flag from the last Diagnostic Dump response.	FALSE
Invalid_Function_Block_Input	Output BOOL	True when a function block input currently has an invalid or out-of-range value.	FALSE

Pin Name	Pin Type	Description	Default
Issue_<*Name*>_DN[a]	Output BOOL	Asserts for a single processing interval once the message has completed.	
Issue_<*Name*>_Delay[a]	Output BOOL	Asserts when the message is triggered and the previous triggering of the message has not completed. Deasserts when on the rising edge of Issue_<Name>_DN.	
Issue_Dump_Diagnostics_Delay	Output BOOL	Asserts when the Dump Diagnostics message is triggered and the previous triggering of the Dump Diagnostics message has not completed. Deasserts when on the rising edge of Issue_Dump_Diagnostics_DN.	FALSE
Issue_Dump_Diagnostics_DN	Output BOOL	Asserts for a single processing interval once the message has completed.	FALSE
Issue_Poll_Exception_Data_Delay	Output BOOL	Asserts when the Poll Exception message is triggered and the previous triggering of the Poll Exception message has not completed. Deasserts when on the rising edge of Issue_Poll_Exception_Data_DN.	FALSE
Issue_Poll_Exception_Data_DN	Output BOOL	Asserts for a single processing interval when the message has completed.	FALSE
Issue_RTU_Configuration_-Complete_Delay	Output BOOL	Asserts when the RTU Configuration Complete message is triggered and the previous triggering of the RTU Configuration Complete message has not completed. Deasserts when on the rising edge of Issue_RTU_Configuration_Complete_DN.	FALSE
Issue_RTU_Configuration_-Complete_DN	Output BOOL	Asserts for a single processing interval when the message has completed.	FALSE
Issue_Sync_Protocol_Version_-Delay	Output BOOL	Asserts when the Sync Protocol Version message is triggered and the previous triggering of the Sync Protocol Version message has not completed. Deasserts when on the rising edge of Issue_Sync_Protocol_Version_DN.	FALSE
Issue_Sync_Protocol_Version_DN	Output BOOL	Asserts for a single processing interval when the message has completed.	FALSE
Issue_Time_Sync_Delay	Output BOOL	Asserts when the time-synchronization message is triggered and the previous triggering of the time-synchronization message has not completed. Deasserts when on the rising edge of Issue_Time_Sync_DN.	FALSE
Issue_Time_Sync_DN	Output BOOL	Asserts for a single processing interval when all time-synchronization processing has successfully completed.	FALSE
LCD_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte LCD flag from the last Diagnostic Dump response.	FALSE
LOP_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte LOP flag from the last Diagnostic Dump response.	FALSE

Pin Name	Pin Type	Description	Default
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	FALSE
Message_Failure_Count	Output UDINT	A running sum indicating the number of messages that have failed to be sent or received.	0
Message_Received_Count	Output UDINT	A running sum indicating the number of messages received from the remote device.	0
Message_Sent_Count	Output UDINT	A running sum indicating the number of messages transmitted to the remote device.	0
Message_Success_Count	Output UDINT		0
Offline	Output BOOL	This output is False when protocol communications are in process. **Note:** Protocol communications may be in process, but no successful data are exchanged be- cause of settings configuration issues.	TRUE
PWR_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte PWR flag from the last Diagnostic Dump response.	FALSE
RST_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte RST flag from the last Diagnostic Dump response.	FALSE
STS_Flag_Status	Output BOOL	Contains the status of the Frame Header's Status Exceptions flag from the last response received.	FALSE
SYN_Flag_Status	Output BOOL	Contains the status of the Diagnostic Flag's Status Byte SYN flag from the last Diagnostic Dump response.	FALSE

[a] <Name> = Each configured message.

Supported Function Codes

The SES-92 client shall support the following function codes:

- Special Functions
  - Poll Exception Data (x00)
  - Repeat Last Message (x01)
  - Continue Message (x02)
  - Synchronize Protocol Version (x03)
- Digital Input Functions
  - Dump Status Data (x10)
  - Report Status Exception Data (x11)
  - Dump Extended Status Data (x12)
- Analog Input Functions
  - Dump Analog Data (x20)
  - Report Analog Exception Data (x21)

- Time-Synchronization Functions
  - Synchronize Time (x52)
- Control Output Functions
  - SBO Trip/Close Select (x60)
  - SBO Trip/Close Execute (x61)
  - SBO Setpoint Select (x62)
  - SBO Setpoint Execute (x63)
  - DO Setpoint Execute (x64)
- RTU Functions
  - Dump Diagnostics Request (x73)
  - RTU Configuration Complete (x79)

SES-92 Server Configuration

Configure an SES-92 server connection to communicate via serial or Ethernet tunneled to SES-92 polling clients. Create binary input, analog input, and other tag types in an SES-92 server shared map as placeholders for data that the clients will poll. Configure the SES-92 server to use the configured shared map. Each SES-92 server can use a unique map or share the same map with other configured SES-92 server connections. You can create a maximum of 10 SES-92 shared maps in a project. Map data to those shared map tags by using the Tag Processor from client IED or other source tags in the RTAC database.

Insert a unique SES-92 server connection for each SES-92 client connected to the RTAC.

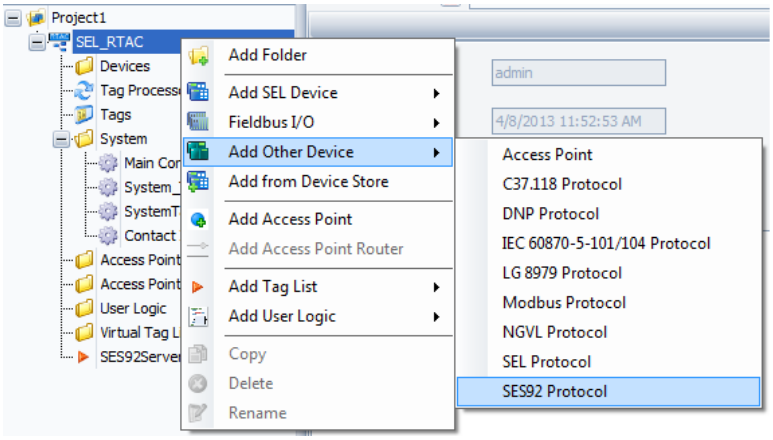

Figure 2.185 Insert SES-92 Server

Give the device connection a unique name, and select the type of connection as shown in *Figure 2.3*. The **Settings** tab contains all the configurable items for communications. Note that you must enter an SES-92 server shared map name in the settings. This map contains all the tags that this SES-92 server uses. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Add SES-92 Share Map

Step 1. Under the **Insert** tab, select **Tag Lists > SES-92 Server Shared Map**.

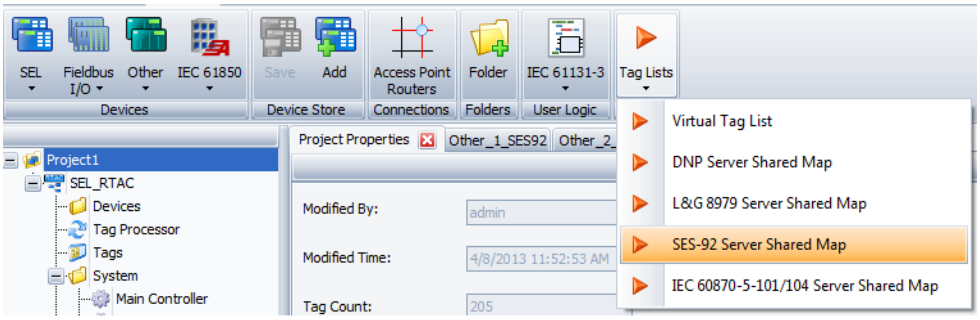

Figure 2.186 Add SES-92 Server Map

Step 2. Click on a device tag type tab to add and configure tags.

Step 3. Click + to add tags (4,096 tag limit per device tag type). Creating only the number of necessary tags optimizes system performance.

Step 4. Change the names of the tags as necessary.

Step 5. Change other tag-related information as necessary.

Repeat *Step 2* through *Step 5* to configure all server tags. When you are finished, configure the SES-92 server to use this custom map by selecting SES-92 Map Name in the **Setting** column. Although more than one SES-92 server can use the same map, each SES-92 server will manage separate event queues. Configure the Tag Processor to populate these server connection tags with actual values.

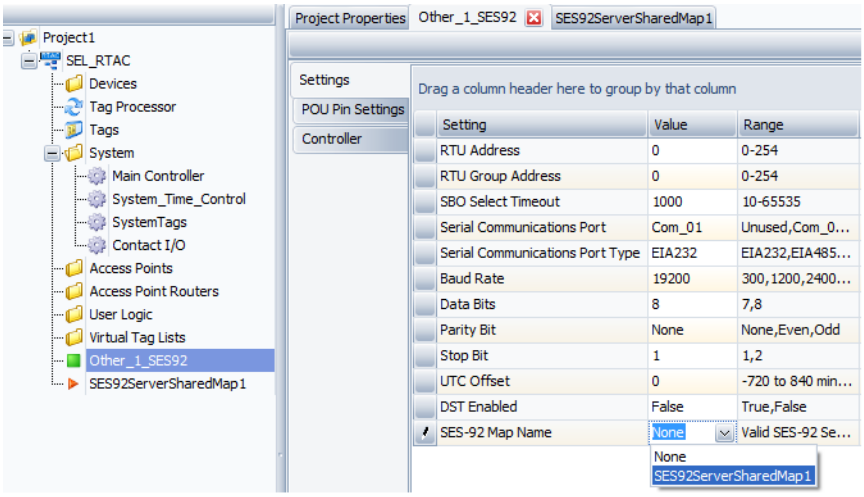

Figure 2.187 Select SES-92 Shared Map

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation. *Table 2.98–Table 2.103* describe the columns used to configure the SES-92 Server tags. ACSELERATOR RTAC will gray out configuration fields that do not apply to a specific device.

Table 2.98 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set this flag to TRUE to enable processing of this tag. Set this flag to FALSE to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	
Point Number	This is the point number for which the SES-92 client will poll. If points are not contiguous in the IED, change these point numbers to match the SES-92 database for the IED.	Contiguous from 0 to the point count
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Comment	Optional user-entered comment field	

Table 2.99 Status Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 4096 status input tags.	SPS
Status Value	The initialized value at startup	False
Comment	Optional user-entered comment field	

Table 2.100 SBO Trip/Close Output Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 SBO tags.	SPC
Control Model	Nonconfigurable field	Persist
On/Off Pulse Duration	Nonconfigurable field	

Table 2.101 Accumulator and Solid State Meter Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 accumulator and 256 solid state meter tags.	BCR
Actual Value	The initialized running value at startup	0
Frozen Value	The initialized value at startup	0

Table 2.102 Analog Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 4096 analog input tags.	INS
Inst Magnitude	The initialized instantaneous value at startup	
Magnitude	The initialized dead-banded value at startup	
Dead Band Count	The number of units of change necessary to move the Inst Magnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag.	

Parameter	Description	Default
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.103 SBO Setpoint Output Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 set-point output tags.	INC
Variation	If the oper control word is 12-bit signed or 12-bit unsigned	
Set Magnitude	The initialized value at startup	0

POU Pins

Use POU pin settings to view the present state of the SES-92 server operation and to modify some of the behavior of the SES-92 protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.104* for the settings descriptions.

Table 2.104 SES-92 POU Pin Settings

Pin Name	Pin Type	Description	Default
Communications_Offline_Timer	Input TIME	The time to wait for a poll from the client before determining the communications are offline. Configure in the **Settings** tab.	T#10000MS
Disable_Controls	Input BOOL	Disables controls through the protocol. Note: If other SES-92 server instances are assigned to the same SES-92 Server Shared Map as this server, asserting Disable_Controls will also disable controls for those other SES-92 server instances.	False
Disable_Tag_Updates	Input BOOL	Disables updating of tag values. Note: If other SES-92 server instances are assigned to the same SES-92 Server Shared Map as this server, asserting Disable_Tag_Updates will also disable updates for those other SES-92 server instances.	False
EN	Input BOOL	Enables this instance of SES-92.	True
PWR_Flag	Input BOOL	If this input pin is set to TRUE, the PWR flag is set to 1 in RTU Diagnostic data transmitted to the client.	False
Reset_Statistics	Input BOOL	Resets all communications statistics.	False

Pin Name	Pin Type	Description	Default
SYN_Flag	Input BOOL	If this input pin is set to TRUE, the SYN flag is set to 1 in RTU Diagnostic data transmitted to the client.	False
ACC	Output BOOL	Set to TRUE when unacknowledged frozen Accumulator and/or Solid State Meter data exists.	False
ALG	Output BOOL	Set to TRUE when unacknowledged Analog Input exception data exists.	False
Controls_Disabled	Output BOOL	Indicates controls have been disabled.	False
Direct_Transparent_Connection	Output BOOL	Indicates an access point router has disabled protocol communications and is using this port for direct transparent communications.	False
ENO	Output BOOL	Indicates this instance of SES-92 is running.	False
ERR	Output BOOL	Set to TRUE whenever the SES-92 Server ERR flag is transmitted in the message frame headers.	False
Freeze	Output BOOL	Asserts for one processing interval when a Freeze command is received from the client.	False
Message_Failure	Output BOOL	Indicates the last message failed.	False
Message_Failure_Count	Output UDINT	The number of times Message_Failure has been True.	0
Message_Received_Count	Output UDINT	The number of messages received.	0
Message_Sent_Count	Output UDINT	The number of messages sent.	0
Message_Success_Count	Output UDINT	The number of messages successfully sent to the client.	0
Offline	Output BOOL	Set to TRUE when Message_Received_Count has not been incremented for the number of ms defined in the Communication_Offline_Timeout setting.	True
SOE	Output BOOL	Set to TRUE when unacknowledged digital status change events exist in the SES-92 Server SOE event collection.	False
SOE_Overflow	Output BOOL	A Boolean flag that is asserted for a single processing interval if one or more digital status change events are discarded as a result of the SES-92 Server event collection being full.	False
SOE_Overflow_Count	Output UDINT	The number of times that the SOE_Overflow pin has been asserted.	0
STS	Output BOOL	Set to TRUE when unacknowledged Status Input exception data exists.	False

Tags

See *Tags (Overview) on page 174* for a description of the **Tags** tab.

Controller

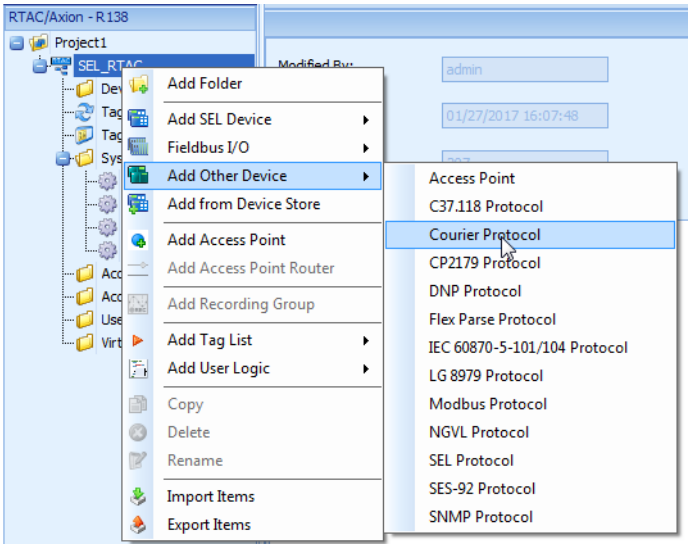
See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab.

Supported Function Codes

Table 2.105 SES-92 Function Codes

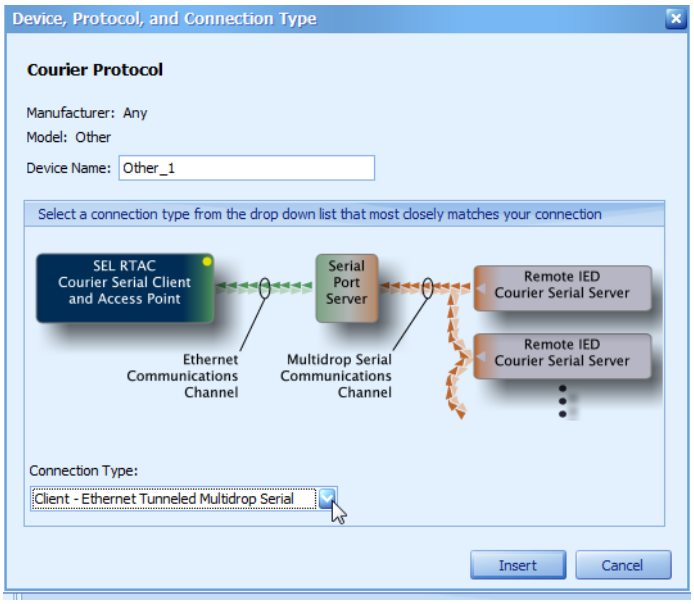
Function Code	Description	Notes
0h	Poll Exception	Response to FC 0h is the same as if the following sequence of commands has been received: 1. Report Status Exception Data 2. Report Analog Exception Data 3. Dump Accumulator Data 4. Dump Solid-State Meter Data
1h	Repeat Last Message	
2h	Continue Message	
3h	Synchronize Protocol Version	
10h	Dump Status Data	MCD reset if point quality changes.
11h	Report Status Exception Data	MCD reset if point quality changes. Events are maintained in a 10,000-entry circular buffer.
12h	Dump Extended Status Data	FC 12h is always the response to FC 12h request and is also the response to a Dump Status Data if any points have validity not = good. Dump and Extended Status requested stop point ID is increased in the response to provide 8-bit atomicity in the response message.
20h	Dump Analog Data	All requested points are always returned. Invalid or nonexistent values reported as –2048.
21h	Report Analog Exception Data	
24h	Assign Dead Band and Group	Configured dead band values are used until updated through the protocol by using FC 24h.
30h	Freeze Accumulator	
31h	Dump Accumulator Data	Reports value of 0 for tags with validity not = good.
33h	Dump Solid State Meter Data	Reports value of 0 for tags with validity not = good.
50h	Dump Digital Status Change Data	
52h	Synchronize Time	Response to FC 52h indicates a success, but the command is ignored by the RTAC.
53h	Read Time	
54h	Set Time Bias	
60h	SBO Trip/Close Select	Pulse on duration is the product of 10 ms and the control length from the **SELECT** command.
61h	SBO Trip/Close Execute	Execution time of control is one processing interval.
62h	SBO Setpoint Select	
63h	SBO Setpoint Execute	Set point tag trigger is asserted for one processing interval.
64h	DO (Direct Operate) Setpoint Execute	
70h	Reset RTU	EN POU pin is toggled False then back to True. Any OPB settings and integrity scan count, if included, are ignored.
73h	Dump Diagnostic Request	Subfunction diagnostic information is not returned.
77h	Suppress Data	

Function Code	Description	Notes
78h	Dump RTU Operating Parameters	The PRI, FRZ, COV, and RAE flags are always clear. Max message length and Message Integrity Count are set at zero. This establishes max message length to 261 bytes and disables integrity scan functionality.
79h	RTU Configuration Complete	



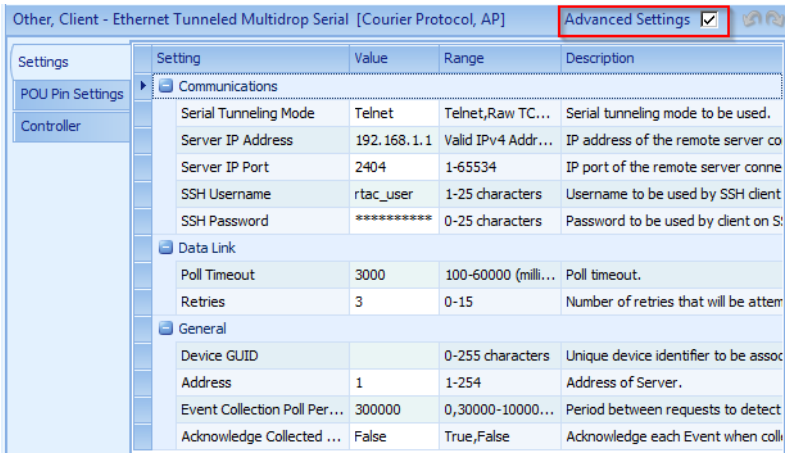
Alstom Event Collection (Courier Protocol)

Courier Client



The Courier client is used to retrieve uncompressed Disturbance Records from Alstom relays and store them as compressed COMTRADE files. As many as 100 Courier clients are allowed. The client supports single-level addressing, and address allocation is not automatic. The client does not support collecting SCADA information.

Configuration



To use the Courier client, right-click in the project tree and select **Courier Protocol**.

Select the connection type (Ethernet Tunneled Multidrop Serial, Ethernet Tunneled Serial, Multidrop Serial, or Serial).

Then you can begin to configure the client. In the **Settings** tab, you can configure your connection, as well as event polling parameters, and whether or not you want to acknowledge collected events. In the **Advanced Settings**, you can also specify a **Device GUID** to integrate with TEAM event collection, additional serial parameters, and SSH parameters.

Once you have your client configured and go online with your project, the RTAC will begin to poll the server (Courier IED) for Disturbance Records. For successful Disturbance Record collection, note the following settings requirements for the Courier IED:

- Under the configuration options, the **Disturb Recorder** parameter must be assigned to **Visible**.
- IED password-based security levels must be disabled to allow the RTAC Courier client read/write access to the necessary data cells for Disturbance Record collection.

POU Pins

Use POU pin settings to view the present state of the Courier client and to modify some of the behavior of the Courier protocol. Setting the **Visible** field to **True** will cause the POU pin to appear in the **Controller** tab. See *Table 2.106* for the settings descriptions.

Table 2.106 Courier POU Pin Settings

Pin Name	Pin Type	Description	Default
Direct_Transparent_Connection	Output BOOL	Indicates that the communications have been interrupted by a direct transparent connection through an access point router.	FALSE
EN	Input BOOL	Enables this instance of Courier client.	TRUE
ENO	Output BOOL	Indicates this instance of Courier client is running.	FALSE
Event_Collection_Count	Output UDINT	Number of Events collected since the POU was enabled.	0
Event_Collection_Delay	Output BOOL	Asserts when an event collection is triggered and the previous triggering of an event collection has not completed. Deasserts on the falling edge of Event_Collection_Pending.	FALSE
Event_Collection_Pending	Output BOOL	Asserted while there are uncollected Events. Deasserts once all Events have been collected.	FALSE
Event_Collection_Poll	Input BOOL	Triggers polls for new Events on the rising edge.	FALSE
Event_Collection_Poll_Period	Input TIME	Period between requests to detect Events.	T#300000MS
Event_Collection_Stored	Output BOOL	Asserts for a processing interval when an Event has been stored in nonvolatile memory.	FALSE
Invalid_Function_Block_Input	Output BOOL	True when a function block input currently has an invalid or out-of-range value.	FALSE
Message_Failure	Output BOOL	Asserts for a single processing interval following a message failure.	FALSE
Message_Failure_Count	Output UDINT	Increments value by one each time Message_Failure is asserted.	0
Message_Received_Count	Output UDINT	A counter of the number of messages received.	0
Message_Sent_Count	Output UDINT	A counter of the number of messages sent.	0
Message_Success_Count	Output UDINT	A running sum of the messages successfully sent or received.	0
Offline	Output BOOL	Set to True if data link activity time-out expires or a frame has not been received for a period of time, defined by Communications_Offline_Timer.	TRUE
Reset_Statistics	Input BOOL	Resets all communications statistics.	FALSE

IEC 60870-5-101 and -104

IEC 60870-5 is an IEC standard that defines systems used for supervisory control and data acquisition (SCADA), including details related to communications between devices. As part of the standard, IEC 60870-5-101 defines a byte-oriented, asynchronous serial-based protocol for communications associated with electrical power systems. The design is based on a balanced (where either client or server can transmit asynchronously) or unbalanced (server can only transmit when solicited by client) topologies and is suitable for

point-to-point or point-to-multipoint configurations. IEC 60870-5-104 protocol extends the IEC 60870-5-101 protocol to fully integrate communications over Ethernet networks. At the application layer, the protocols are essentially the same, so selecting between the IEC 60870-5-101 or IEC 60870-5-104 protocol in ACSELERATOR RTAC is done by selecting serial or Ethernet connection methods. Although not used to a great extent in the U.S.A., the IEC 60870-5-101/104 protocols have historically been the *de facto* standard for communicating to devices connected with electrical power generation, transmission, and distribution worldwide.

This section describes the configuration and use of the IEC 60870-5-101/104 client and server with ACSELERATOR RTAC. See *Communication Protocol Device Count Support on page 181* for the number of IEC 60870-5-101/104 servers and clients supported for each RTAC model. The IEC 60870-5-101/104 server supports receiving commands (in the control direction) and transmitting responses (in the monitoring direction) for Application Service Data Unit (ASDU) and Cause of Transmission (COT) types as shown in the interoperability statements for IEC 60870-5-101 and -104, which list COTs for expected behavior only. Additional COTs are recognized for errors.

IEC 60870-5-101/104 Client Configuration

Configure a 101/104 client connection to communicate via serial or Ethernet to IEDs. The RTAC will poll data from these IEDs and store the data it receives in tags. Use the Tag Processor to map these data to any protocol, logs, user logic, etc.

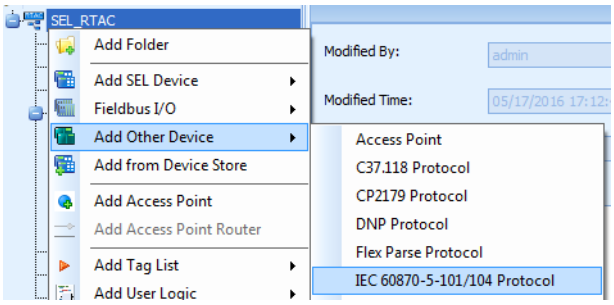


Figure 2.188 Adding an IEC 60870-5-101/104 Client

Give the device connection a unique name and select the connection type, as shown in *Figure 2.188*. Refer to *Client Connection Types on page 167* for a description of each connection type.

Settings Tab

The **Settings** tab contains all configurable items for communication. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description. Type any applicable comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Custom Messages Tab

The **Custom Messages** tab contains the poll requests the IEC 60870-5-101/104 client will use to collect data from the server. To add additional messages, use the + button. As many as 50 messages are supported. The supported message types and message qualifiers correspond with the interoperability document for the 101/104 client.

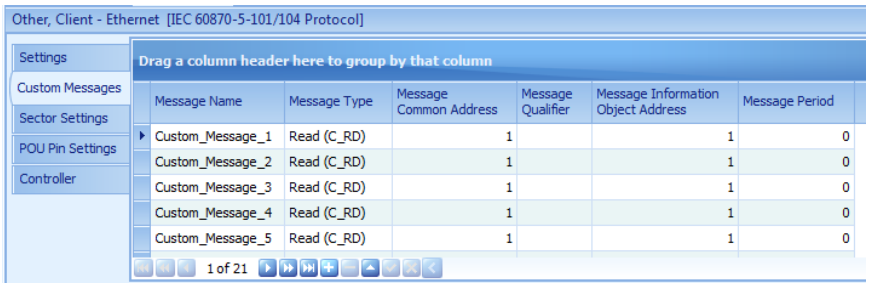

Figure 2.189 IEC 60870-5-101/104 Client Custom Messages

Table 2.107 Explanation of Column Headers

Column Name	Description
Message Name	User-defined name for the message
Message Type	The type of message the client will send
Message Common Address	The common address included in the message
Message Qualifier	A group selected for interrogation. Not all message types will require a qualifier.
Message Information Object Addresses	Address of the point the client will request
Message Period	The period during which the client will issue this message. This quantity is in milliseconds.

Sector Settings Tab

The **Sector Settings** tab contains configuration parameters for a maximum of eight sectors in a server. Each sector has a configurable name and common address. By default, each client has one sector. To add additional sectors, use the + button.

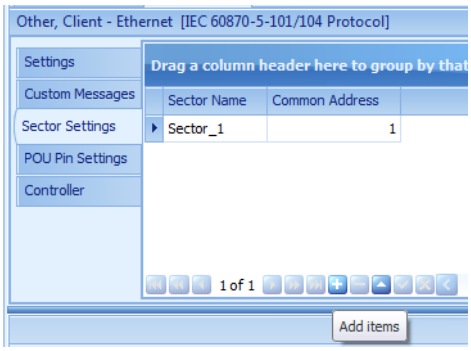

Figure 2.190 IEC 60870-5-101/104 Sector Settings

IEC 60870-5-101/104 Client Sector Map

To configure tags for the IEC 60870-5-101/104 client, select an existing **101/104 Client Sector Map**. Repeat *Step 1* through *Step 4* to configure each client tag.

Step 1. Click the tab for the appropriate tag type to add and configure tags.

Step 2. Click + to add tags. Create only the necessary number of tags to optimize system performance.

Step 3. Rename the tags as necessary.

Step 4. Configure other tag parameters as necessary.

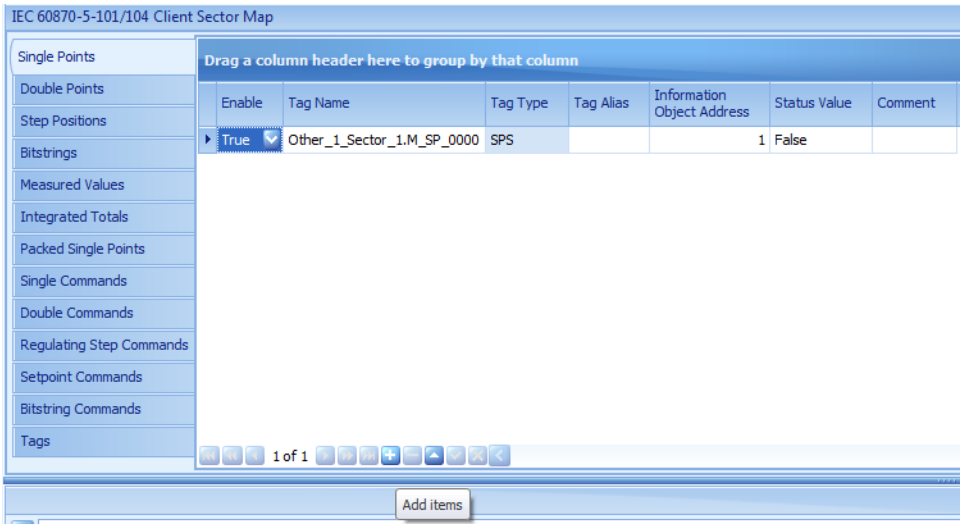

Figure 2.191 IEC 60870-5-101/104 Client Sector Map

POU Pins

Use POU pin settings to view the present state of the IEC 60870-5-101/104 client operation and to modify some of the behavior of the protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.108* for the settings descriptions.

Table 2.108 IEC 60870-5-101/104 Client POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific function block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update or process changes to tags while this input is True.	False
Disable_Controls	Input BOOL	While True, processing of any controllable tags is blocked.	False
Reset_Statistics	Input BOOL	On the rising-edge trigger, all counter POU outputs are reset.	False
Issue_Time_Sync	Input BOOL	Requests time sync message(s) to be sent on the rising edge. Time-synchronization processing is defined by the Propagation Delay Type setting.	False

Pin Name	Pin Type	Description	Default
Issue_Time_Sync_Period	Input Time (0, 1–1440 minutes)	Defines the interval used by the client to issue time-synchronization messages. Setting it to zero causes the related function to be non-periodic.	Reference setting—Issue time-synch period
Issue_<Name>[a]	Input BOOL	Request custom message to be sent on the rising edge.	False
Issue_<Name>_Period[a]	Input Time (0, 250–100000000 milliseconds)	Defines the interval used by the client to issue the custom message. Setting to zero causes the related function to be non-periodic.	Reference custom message—Message_Period
Redundant_Change	Input BOOL	On a rising edge, this forces the client to change the active TCP connection if Aux Server IP Address is defined. Note: Only applicable on 104 connections/client (Ethernet)	False
ENO	Output BOOL	Indicates that this specific function block instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is False when protocol communications are in process. Note: Protocol communications may be in process, but no successful data are exchanged because of settings configuration issues.	False
Slow_Poll_Mode_Enabled	Output BOOL	Asserts to indicate that the device has slowed polling by the slow poll mode multiplier.	False
Invalid_Function_Block_Input	Output BOOL	True when a function block input currently has an invalid or out-of-range value.	False
Controls_Disabled	Output BOOL	Asserted when the Disable_Controls input is asserted. This indicates that the client will not issue control commands.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	False
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have successfully been sent or received.	0
Direct_Transparent_Connection	Output BOOL	Indicates that the communications have been interrupted by a direct transparent connection through an access point router.	False
Data_Link_Timeout_Count	Output UDINT	Number of data link failures.	0
Response_Timeout_Count	Output UDINT	Number of application layer message response timeouts.	0
Reinit_In_Progress	Output BOOL	While asserted, indicates that the client is performing initial communications queries prior to data processing	False
Issue_Time_Sync_DN	Output BOOL	Asserts for a single processing interval once all time-synchronization processing has successfully completed.	False

Pin Name	Pin Type	Description	Default
Issue_Time_Sync_Delay	Output BOOL	Asserts when the time-synchronization message is triggered and the previous triggering of the time-synchronization message has not completed. Deasserts when on the rising edge of Issue_Time_Sync_DN.	False
Issue_<Name>_DN[a]	Output BOOL	Asserts for a single processing interval once the message is successfully completed. Completion of the message is dependent on the configuration of the message.	False
Issue_<Name>_Delay[a]	Output BOOL	Asserts when the message is triggered and the previous triggering of the message has not completed. Deasserts when on the rising edge of Issue_<Name>_DN.	False
Test_Command_Failure	Output BOOL	Asserts for a single processing interval if an error is detected in the test command response.	False
Time_Sync_Event_Received	Output BOOL	Asserts for a single processing interval when the client receives a time-synchronization event (ASDU Type = 103, COT = Spontaneous(3)) from the server.	False
Redundant_Changed	Output BOOL	Asserts for a single processing interval when the client sends the start data transfer activation request if Aux Server IP Address is defined.	False
Redundant_Active_Connection	Output UDINT	The connection that is in use. If no connection exists, contains the last connection that was connected. 1 = channel associated with Server_IP_Address. 2 = channel associated with Aux_Server_IP_Address.	0
Redundant_Ready_Count	Output UDINT	The number of redundant channels that are connected.	0
Buffer_Overflow	Output BOOL	Asserts for a single processing interval if any message operations were discarded because of queuing limits. A message will be discarded if multiple occurrences of the same operation have been queued prior to the completion of that message type.	False
Buffer_Overflow_Count	Output UDINT	Count indicating the number of times that the Buffer_Overflow pin has been asserted.	0
Restart_Local	Output BOOL	Asserts for a single processing interval when the client receives an end of initialization message with a cause of initialization, indicating that a local command/power-cycle restarted the server.	False
Restart_Remote	Output BOOL	Asserts for a single processing interval when the Client receives an end of initialization message with a cause of initialization, indicating a remote start of the server.	False
Error_Detected	Output BOOL	Asserts for a single processing interval when a message is received where the negative bit of the cause of initialization is asserted.	False
Last_Error_Code	Output Enum	Contains the last received message's COT cause field where its COT p/n = negative.	0

[a] <Name> = Each configured custom message.

IEC 60870-5-101/104 Server Configuration

Configure an IEC 60870-5-101 server to communicate via serial (or serial tunneled) or an IEC 60870-5-104 server to communicate via Ethernet to respond to polling IEC 60870-5-101/104 clients. Create single points, measured values, and other tag types in an IEC 60870-5 shared map. Each IEC 60870-5-101 or IEC 60870-5-104 server is configurable for as many as 256 sectors or address spaces that effectively perform as logical devices Assign one unique shared map to each sector you have configured. You can configure a shared map to be unique to a configured IEC 60870-5-101/104 server, or you can share the same shared map with other configured IEC 60870-5-101/104 servers. You can create a maximum of 256 shared maps. Map data to those shared map tags by using the Tag Processor from client IED or other source tags in the RTAC database.

Insert a unique IEC 60870-5-101 or IEC 60870-5-104 server connection for each IEC 60870-5-101 or IEC 60870-5-104 client connected to the RTAC.

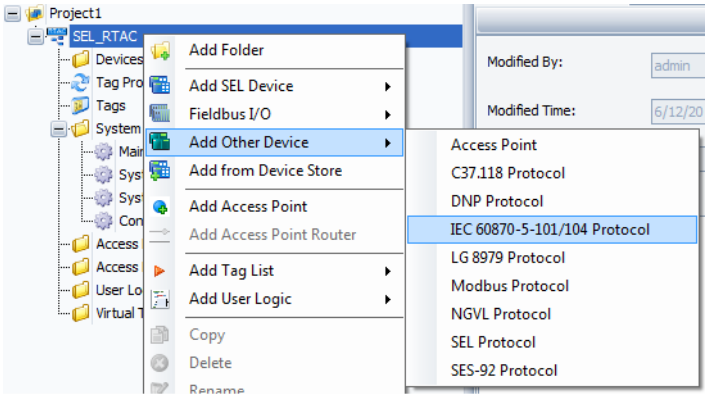

Figure 2.192 Insert IEC 60870-5-101/104 Server

Give the device connection a unique name and select the type of connection as shown in *Figure 2.3*. The **Settings** tab contains all the configurable items for communications. Check the **Description** column for settings details on each configuration item. Move the slider or hover your cursor over the description to see the entire description text. Type any necessary comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Shared Maps and Sector Settings

Each IEC 60870-5-101/104 server has a configurable number of sectors, each being analogous to a logical device within the IEC 60870-5-101/104 server. You must assign an IEC 60870-5-101/104 server shared map name to each sector to provide the data tags for that IEC 60870-5-101/104 server sector. You can configure as many as eight sectors, each with a unique Common Address, by selecting a shared sector map and adjusting the Cyclic Scan Period and Background Scan Period as needed. Configure double transmission of events by sector and by data type within the sector. Double transmission of events sends the event once without a time stamp and once with a time stamp.

Add IEC 60870-5-101/104 Shared Map

Step 1. Under the **Insert** tab, select **Tag Lists > IEC 6870-5-101/104 Server Shared Map**.

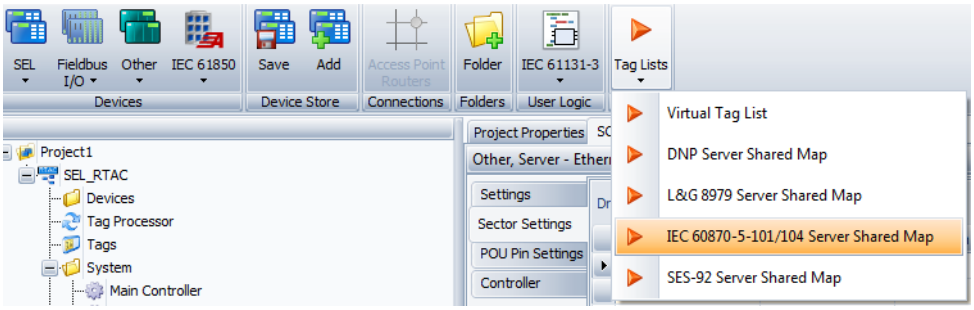

Figure 2.193 Add IEC 60870-5-101/104 Server Map

Step 2. Click on a device tag type tab to add and configure tags.

Step 3. Click + to add tags. Create only the necessary number of tags to optimize system performance.

Step 4. Change the names of the tags as necessary.

Step 5. Change other tag-related information as necessary.

Repeat *Step 2* through *Step 5* to configure all server tags. When you are finished, configure an IEC 60870-5-101/104 server to use this custom map by selecting **Shared Sector Map** in the **Sector Settings** tab. Although more than one IEC 60870-5-101/104 server can use the same map, each IEC 60870-5-101/104 server will manage separate event queues. Configure the Tag Processor to populate these server connection tags with actual values.

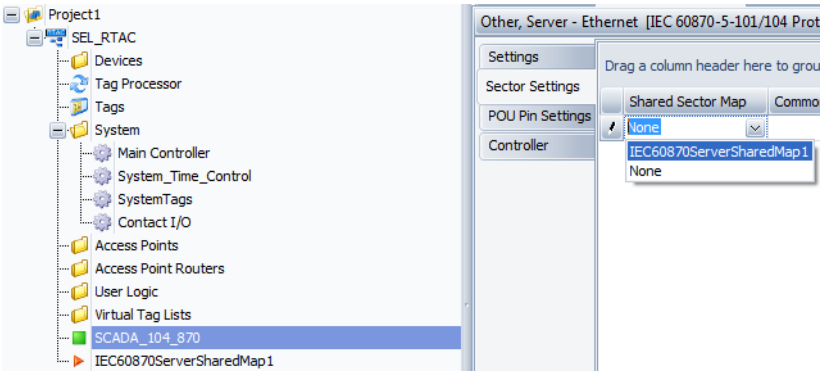

Figure 2.194 Select IEC 60870-5-101/104 Shared Map

IEC 60870-5-104 Server Failover

You can configure IEC 60870-5-104 servers to operate under the following failover scenarios.

Multiple Client IPs. Multiple clients can poll one IEC 60870-5-104 server if they are configured in a failover configuration so they poll the RTAC one at a time. In this configuration, the IEC 60870-5-104 server maintains one event queue per sector. Events reported to one client are not reported in the next reply, even if another poll comes from a different client.

If you set Allow Anonymous IP Clients to TRUE, the RTAC will allow any IEC 60870-5-104 client that can connect to the RTAC network to poll this IEC 60870-5-104 server, as long as the IEC 60870-5-104 sector addresses are correct. If you set Allow Anonymous IP Clients to FALSE, you can configure as many as 10 client IP addresses, separated by commas. In this configuration, the RTAC will only reply to any client that has one of the configured IP addresses.

Redundant. The IEC 60870-5-104 server supports redundant communications as defined in the IEC 60870-5-104 specification. Set Allow Anonymous IP Clients to FALSE, configure Client IP Address(es) as needed to authenticate valid polling clients, and set Enable Redundant = TRUE to enable additional TCP connections to the server.

IEC 60870-5-101 Server Dial-Out

You can configure an IEC 60870-5-101 serial server device to dial out automatically to report unsolicited data. Insert an IEC 60870-5-101 serial server connection and select **Advanced Settings**. *Figure 2.195* shows the settings that are enabled when Modem Connected = True. Notice the configuration supports an optional second phone number in case the RTAC does not get an answer when using the first phone number.

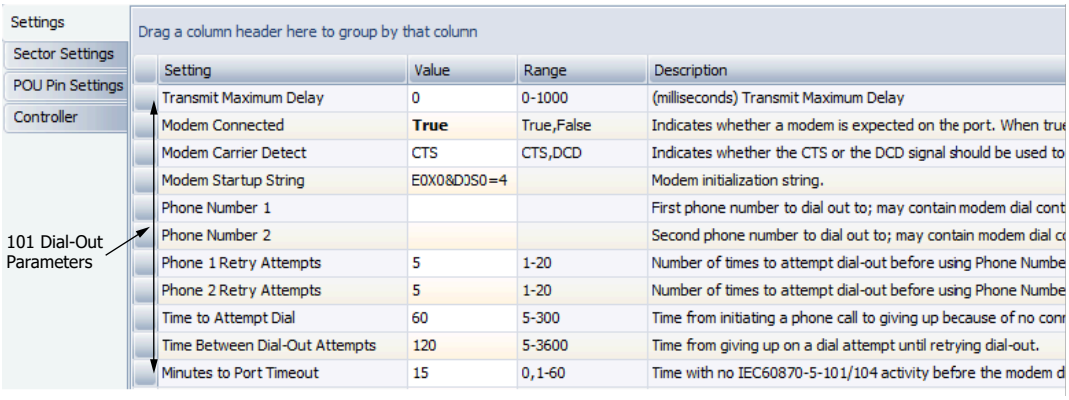

Figure 2.195 IEC 60870-5-101 Server Dial-Out

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation. *Table 2.109–Table 2.120* describe the columns used to configure the IEC 60870-5-101/104 server tags. ACSELERATOR RTAC will gray out configuration fields that do not apply to a specific device.

Table 2.109 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set this flag to True to enable processing of this tag. Set this flag to FALSE to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name and tag type and is numbered 0–*n* tags.
Information Object Address (IOA)	Within a sector, the unique object address of a point. The total number of IOAs, plus Status IOAs, is 65535.	Contiguous from 0 to the point count.

Parameter	Description	Default
Tag Alias	Enter an optional descriptive tag name in this field, and then reference this tag alias anywhere in the RTAC system in place of the actual tag name.	
Report By Exception	Set this flag to True to enable exception reporting for this tag.	Dependent on tag type
Report By Cyclic Scan	Set this flag to True to enable reporting this tag value by cyclic scan.	False
Report By Background Scan	Set this flag to True to enable reporting this tag value in a background scan.	False
Interrogation Group	Defines the General Interrogation Group for the point. If Global, the point is only reported when **General Interrogation All** command is received. If Group 1–16, the point is reported when the specific group or All is requested by a **General Interrogation** command. If None, the point is not reported by **General Interrogation** command.	Global
Comment	Optional user-entered comment field	

Table 2.110 Single-Point Status Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 65535 status input tags.	SPS
Status Value	The initialized value at startup	False

Table 2.111 Double-Point Status Input Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 65535 status input tags.	DPS
Status Value	The initialized value at startup	Intermediate

Table 2.112 Step Positions Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 65535 status input tags.	INS
Status Value	The initialized value at startup	0
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	63
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	56
H Limit	The high-alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	50
L Limit	The low-alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	–51
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	–57
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	–64

Table 2.113 Bitstrings Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 65535 status input tags.	INS
Status Value	The initialized value at startup	0
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.114 Measured Values Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 65535 status input tags.	MV
Measured Value Type	The 60870 measure value type of this tag	Normalized (ME_A)
Inst Magnitude	The initialized instantaneous value at startup	
Magnitude	The initialized dead-banded value at startup	
Dead Band Count	The number of units of change necessary to move the InstMagnitude value into Magnitude. If | instMag – mag| > db, then mag := instMag.	
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.out OfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high-alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low-alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instmag < Min Value, ".q.detailQual.outOfRange" is set.	

Table 2.115 Integrated Totals Parameters

Parameters	Description	Default
Tag Type	See *Data Types on page 1127* for more details.	LBCR
Actual Value	The initialized running value at startup	0
Frozen Value	The initialized value at startup	0

Table 2.116 Single Commands Parameters

Parameters	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 SBO tags.	SPC
Status Information Object Address (Status_IOA)	Defines the IOA used to access the status portion of the control. If Status_IOA = 0, the control status is not accessible.	Contiguous from 0 to the point count.
Status Value	The initialized value at startup	False
Control Model	Persist	
Number of Pulses	The number of pulses operated for this control	
On Pulse Duration	The On duration of one pulse	
Off Pulse Duration	The Off duration of one pulse	Dependent on control operation
Short Pulse Duration	The duration of the pulse if the received command contains a short pulse qualifier. Short pulse duration must be < Long pulse duration.	1
Long Pulse Duration	The duration of the pulse if the received command contains a long pulse qualifier. Long pulse duration must be > Short pulse duration.	2000

Table 2.117 Double Commands Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 SBO tags.	DPC
Status Information Object Address (Status_IOA)	Defines the IOA used to access the status portion of the control. If Status_IOA = 0, the control status is not accessible.	Contiguous from 0 to the point count
Status Value	The initialized value at startup	Intermediate_state
Control Model	Persist	Dependent on control operation
Number of Pulses	The number of pulses operated for this control	1

Parameter	Description	Default
On Pulse Duration	The On duration of one pulse	2000
Off Pulse Duration	The Off duration of one pulse	1
Short Pulse Duration	The duration of the pulse if the received command contains a short pulse qualifier. Short pulse duration must be < Long pulse duration.	100
Long Pulse Duration	The duration of the pulse if the received command contains a long pulse qualifier. Long pulse duration must be > Short pulse duration.	500

Table 2.118 Regulating Step Commands Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 256 SBO tags.	BSC
Status Information Object Address (Status_IOA)	Defines the IOA used to access the status portion of the control. If Status_IOA = 0, the control status is not accessible.	Contiguous from 0 to the point count
Status Value	The initialized value at startup	Intermediate_state
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual. outOfRange" is set.	63
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high-alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low-alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < MinValue, ".q.detailQual.outOfRange" is set.	64
Control Value	The initialized value at startup	stop
Control Model	The method (pulse or persist) of the control operation	Pulse
Number of Pulses	The number of pulses operated for this control	1
On Pulse Duration	The On duration of one pulse	2000
Off Pulse Duration	The Off duration of one pulse	1
Step Size	Noneditable value indicating the amount of change when the control is operated	1

Parameter	Description	Default
Short Pulse Duration	The duration of the pulse if the received command contains a short pulse qualifier. Short pulse duration must be < Long pulse duration.	100
Long Pulse Duration	The duration of the pulse if the received command contains a long pulse qualifier. Long pulse duration must be > Short pulse duration.	500

Table 2.119 Set Point Commands Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 4096 analog input tags.	APC
Setpoint Type	The type of set point control	Normalized (SE_A)
Inst Magnitude	The initialized instantaneous value at startup	
Magnitude	The initialized dead-banded value at startup	
Dead Band Count	The number of units of change necessary to move the InstMagnitude value into Magnitude. If |instMag – mag| > db, then mag := instMag.	
Zero Dead Band	The number of units at or below which Magnitude is forced to zero. If |mag| < zeroDB, then mag := 0.	
Max Value	The maximum value allowed for this point. If instMag > Max Value, "q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high-alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low-alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < Min Value, ".q.detailQual.outOfRange" is set.	
Set Magnitude	The initialized set value at startup	

Table 2.120 Bitstring Commands Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Maximum 4096 analog input tags.	INC
Status Information Object Address (Status_IOA)	Defines the IOA used to access the status portion of the control. If Status_IOA = 0, the control status is not accessible.	Contiguous from 0 to the point count
Status Value	The initialized value at startup	0

Parameter	Description	Default
Max Value	The maximum value allowed for this point. If instMag > Max Value, ".q.detailQual.outOfRange" is set.	
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	
H Limit	The high-alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	
L Limit	The low-alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	
Min Value	The minimum value allowed for this point. If instMag < MinValue, ".q.detailQual.outOfRange" is set.	

POU Pins

Use POU pin settings to view the present state of IEC 60870-5-101/104 server operation and to modify some of the behavior of the IEC 60870-5-101/104 protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.121* for the settings descriptions.

Table 2.121 IEC 60870-5-101/104 POU Pin Settings

Pin Name	Pin Type	Description	Default
Accept_Time_Sync	Input BOOL	Set to True to allow accepting a clock synchronization command with COT equal to Activation (6).	True
Disable_Controls	Input BOOL	Disables controls through the protocol. Note: If other IEC 60870-5-101/104 server instances are assigned to the same IEC 60870-5-101/104 Server Shared Map as this server, asserting Disable_Controls will also disable controls for those other server instances.	False
Disable_Tag_Updates	Input BOOL	Disables updating of tag values. Note: If other IEC 60870-5-101/104 server instances are assigned to the same IEC 60870-5-101/104 Server Shared Map as this server, asserting Disable_Tag_Updates will also disable updates for those other server instances.	False
EN	Input BOOL	Enables this instance of IEC 60870-5-101/104	True
Reset_Statistics	Input BOOL	Resets all communications statistics.	False
CI_Freeze_IEC60870Server-SharedMap1	Output BOOL	Asserted for one processing cycle when a Counter Interrogation request is received, Qualifier of Counter Interrogation (QCC) option = freeze, freeze with reset, reset (1,2,3).	False
CI_Reset_IEC60870Server-SharedMap1	Output BOOL	Asserted for one processing cycle when a Counter Interrogation request is received, Qualifier of Counter Interrogation (QCC) option = freeze, freeze with reset, reset (1,2,3)	False
Controls_Disabled	Output BOOL	Indicates controls are disabled	False
ENO	Output BOOL	Indicates this instance of IEC 60870-5-101/104 is running	False

Pin Name	Pin Type	Description	Default
Error_Detected	Output BOOL	Pulsed for one processing cycle to indicate an error, indicated in Last_Error_Code, has been detected	False
Event_Buffer_Overflow	Output BOOL	BOOL	False
Event_Buffer_Overflow_Count	Output UDINT	UDINT	0
Last_Error_Code	Output DINT	An enumerated value of the last error detected, where COT is one of the following: Unknown Type ID (44) Unknown COT (45) Unknown Common Address (46) Unknown IOA (47)	44
Message_Failure	Output BOOL	Asserts for a single-processing interval following a message failure	False
Message_Failure_Count	Output UDINT	Increments value by one each time Message_Failure is asserted	0
Message_Received_Count	Output UDINT	A counter of the number of messages received	0
Message_Sent_Count	Output UDINT	A counter of the number of messages sent	0
Message_Success_Count	Output UDINT	A running sum of the messages successfully sent or received	0
Offline	Output BOOL	Set to True if data link activity timeout expires or a frame has not been received for a period of time, defined by Communications_Offline_Timer.	True

Controller

See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab.

IEC 60870-5-101/104 Compatibility

The application of IEC 60870-5-101 and 60870-5-104 in the RTAC supports the following function codes:

Basic Application Functions Supported

- Remote initialization
- Cyclic data transmission
- Read procedure
- Spontaneous transmission

Command Transmission Supported

- Direct command transmission
- Direct set point command transmission
- Select and execute command
- Select and execute set point command
- C_SE ACCTTERM used
- No additional definition

- Short-pulse duration
- Long-pulse duration
- Persistent output

Transmission of Integrated Totals Supported

- Mode A: local freeze with spontaneous transmission
- Mode B: local freeze with counter interrogation
- Mode C: freeze and transmit by counter-interrogation commands
- Mode D: freeze by counter-interrogation command, frozen values reported spontaneously
- Counter read
- Counter freeze without reset
- Counter freeze with reset
- Counter reset
- General request counter
- Request counter Group 1
- Request counter Group 2
- Request counter Group 3
- Request counter Group 4

Clock Synchronization Details

- Clock synchronization supported
- Day of week used
- RES1, GEN (time tag substituted/not substituted) used
- SU-bit (summertime) used

Interoperability Statement for IEC 60870-5-101 Client for the SEL RTAC

Introduction

This document specifies the capabilities and features of the SEL-implemented IEC 60870-5-104 Server.

This document applies specifically to the following RTAC models and firmware versions.

Model	Firmware Version
SEL-3505 RTAC	SEL-3505-R136-V0-Z001001-D20160624
SEL-3505-3 RTAC	SEL-3505-3-R136-V0-Z001001-D20160624
SEL-3530 RTAC	SEL-3530-R136-V0-Z001001-D20160624
SEL-3530-4 RTAC	SEL-3530-4-R136-V0-Z001001-D20160624
SEL-2241 RTAC	SEL-2241-R136-V0-Z001001-20160624
SEL-3532 RTAC	SEL-3532-N-R136-V0-Z001001-D20160624
SEL-3555 RTAC	SEL-3555-R136-V0-Z001001-D20160624
SEL-3350 RTAC	SEL-3350-R148-V0-Z001187-D20210208

Interoperability

System or Device

	System definition
X	Controlling station definition (master)
	Controlled station definition (slave)

Network Configuration

X	Point-to-point	X	Multipoint-partyline
X	Multiple point-to-point		Multipoint-start

Physical Layer

Transmission Speed (Control Direction)

Unbalanced Interchange Circuit V.24/V.28 Standard		Unbalanced Interchange Circuit V.24/V.28 Recommended if > 1200 bit/s		Balanced Interchange Circuit X.24/X.27			
	100 bit/s	X	2400 bit/s	X	2400 bit/s	X	56000 bit/s
X	200 bit/s	X	4800 bit/s	X	4800 bit/s		64000 bit/s
X	300 bit/s	X	9600 bit/s	X	9600 bit/s		
X	600 bit/s			X	19200 bit/s		
X	1200 bit/s			X	38400 bit/s		

Transmission Speed

Unbalanced Interchange Circuit V.24/V.28 Standard		Unbalanced Interchange Circuit V.24/V.28 Recommended if > 1200 bit/s		Balanced Interchange Circuit X.24/X.27			
	100 bit/s	X	2400 bit/s	X	2400 bit/s	X	56000 bit/s
X	200 bit/s	X	4800 bit/s	X	4800 bit/s		64000 bit/s
X	300 bit/s	X	9600 bit/s	X	9600 bit/s		
X	600 bit/s			X	19200 bit/s		
X	1200 bit/s			X	38400 bit/s		

Link Layer

Frame format FT 1.2, single character 1, and the fixed time-out interval are used exclusively in this companion standard.

Link Transmission		Address Field of the Link	
X	Balanced transmission	X	Not present (balanced transmission only)
X	Unbalanced transmission	X	One octet

Frame Length			
		X	Two octets
255	Maximum length L (control direction)		Structured
255	Maximum length L (monitor direction)	X	Unstructured
0–2250 s	Time during which repetitions are permitted (Trp) or number of repetitions.		

For an unbalanced link layer, the server returns the following ASDU types in Class 2 messages (low priority) with the indicated causes of transmission:

	The standard assignment of ASDUs to Class 2 messages is used as follows:

Type Identification	Cause of Transmission
9, 11, 13, 21	<1>
9, 11, 13, 21	<2>

	A special assignment of ASDUs to Class 2 messages is as follows:

NOTE
In response to a Class 2 poll, a controlled station can respond with Class 1 data when there are no Class 2 data available.

Type Identification	Cause of Transmission
1, 3, 5, 7	<1>
1, 3, 5, 7	<2>

Application Layer

Transmission Mode for Application Data

Mode 1 (least significant octet first), according to Section 4.10 of IEC 60870-5-4, is used exclusively in this companion standard.

Common Address of ASDU

X	One octet	X	Two octets

Information Object Addresses

X	One octet		Structured
X	Two octets	X	Unstructured
X	Three octets		

Cause of Transmission

X	One octet	X	Two octets (with originator address). Set the originator address to zero if it is not used.

Length of APDU	
253	Maximum length of APDU per system in control direction
253	Maximum length of APDU per system in monitor direction

Selection of Standard ASDUs

Process Information in Monitor Direction

X	<1> := Single-point information	M_SP_NA_1
X	<2> := Single-point information with time tag	M_SP_TA_1
X	<3> := Double-point information	M_DP_NA_1
X	<4> := Double-point information with time tag	M_DP_TA_1
X	<5> := Step position information	M_ST_NA_1
X	<6> := Step position information with time tag	M_ST_TA_1
X	<7> := Bitstring of 32 bits	M_BO_NA_1
X	<8> := Bitstring of 32 bits with time tag	M_BO_TA_1
X	<9> := Measured value, normalized value	M_ME_NA_1
X	<10> := Measured value, normalized value with time tag	M_ME_TA_1
X	<11> := Measured value, scaled value	M_ME_NB_1
X	<12> := Measured value, scaled value with time tag	M_ME_TB_1
X	<13> := Measured value, short floating point value	M_ME_NC_1
X	<14> := Measured value, short floating point value with time tag	M_ME_TC_1
X	<15> := Integrated totals	M_IT_NA_1
X	<16> := Integrated totals with time tag	M_IT_TA_1
	<17> := Event of protection equipment with time tag	M_EP_TA_1
	<18> := Packed start events of protection equipment with time tag	M_EP_TB_1
	<19> := Packed output circuit information of protection equipment with time tag	M_EP_TC_1
	<20> := Packed single-point information with status change detection	M_PS_NA_1
X	<21> := Measured value, normalized value without quality descriptor	M_ME_ND_1
X	<30> := Single-point information with time tag CP56Time2a	M_SP_TB_1
X	<31> := Double-point information with time tag CP56Time2a	M_DP_TB_1
X	<32> := Step position information with time tag CP56Time2a	M_ST_TB_1
X	<33> := Bitstring of 32 bits with time tag CP56Time2a	M_BO_TB_1
X	<34> := Measured value, normalized value with time tag CP56Time2a	M_ME_TD_1
X	<35> := Measured value, scaled value with time tag CP56Time2a	M_ME_TE_1
X	<36> := Measured value, short floating point value with time tag CP56Time2a	M_ME_TF_1
X	<37> := Integrated totals with time tag CP56Time2a	M_IT_TB_1
	<38> := Event of protection equipment with time tag CP56Time2a	M_EP_TD_1
	<39> := Packed start events of protection equipment with time tag CP56Time2a	M_EP_TE_1
	<40> := Packed output circuit information of protection equipment with time tag CP56Time2a	M_EP_TF_1

Process Information in Control Direction

X	<45> := Single command	C_SC_NA_1
X	<46> := Double command	C_DC_NA_1
X	<47> := Regulating step command	C_RC_NA_1
X	<48> := Set point command, normalized value	C_SE_NA_1
X	<49> := Set point command, scaled value	C_SE_NB_1

X	<50> := Set point command, short floating point value	C_SE_NC_1
X	<51> := Bitstring of 32 bits	C_BO_NA_1
	<58> := Single command with time tag CP56Time2a	C_SC_TA_1
	<59> := Double command with time tag CP56Time2a	C_DC_TA_1
	<60> := Regulating step command with time tag CP56Time2a	C_RC_TA_1
	<61> := Set point command, normalized value with time tag CP56Time2a	C_SE_TA_1
	<62> := Set point command, scaled value with time tag CP56Time2a	C_SE_TB_1
	<63> := Set point command, short floating point value with time tag CP56Time2a	C_SE_TC_1
	<64> := Bitstring of 32 bits with time tag CP56Time2a	C_BO_TA_1

System Information in Monitor Direction

X	<70> := End of initialization	M_EI_NA_1

System Information in Control Direction

X	<100> := Interrogation command	C_IC_NA_1
X	<101> := Counter-interrogation command	C_CI_NA_1
X	<102> := Read command	C_RD_NA_1
X	<103> := Clock synchronization command	C_CS_NA_1
X	<104> := Test command	C_TS_NA_1
X	<105> := Reset process command	C_RP_NA_1
X	<106> := Delay acquisition command	C_CD_NA_1
	<107> := Test command with time tag CP56Time2a	C_TS_TA_1

Parameter in Control Direction

	<110> := Parameter of measured value, normalized value	P_ME_NA_1
	<111> := Parameter of measured value, scaled value	P_ME_NB_1
	<112> := Parameter of measured value, short floating point value	P_ME_NC_1
	<113> := Parameter activation	P_AC_NA_1

File Transfer

	<120> := File ready	F_FR_NA_1
	<121> := Section ready	F_SR_NA_1
	<122> := Call directory, select file, call file, call section	F_SC_NA_1
	<123> := Last section, last segment	F_LS_NA_1
	<124> := Ack file, ack section	F_AF_NA_1
	<125> := Segment	F_SG_NA_1
	<126> := Directory {blank or X, only available in monitor (standard) direction}	F_DR_TA_1
	<127> := Query Log – Request archive file	F_SC_NB_1

Type Identification and Cause of Transmission Assignments

Type Identification		Cause of Transmission																	
		1	2	3	4	5	6	7	8	9	10	11	12	13	20 to 36	37 to 41	44	45	46	47

Basic Application Functions

Station Initialization

X	Remote initialization

Cyclic Data Transmission

X	Cyclic data transmission

Read Procedure

X	Read procedure

Spontaneous Transmission

X	Spontaneous transmission

Double Transmission of Information Objects (Cause of Transmission Equals Spontaneous)

The following type identifications can be transmitted in succession as the result of a single status change for an information object. A project-specific list defines the particular information object addresses for which double transmission is enabled.

	Single-point information M_SP_NA_1, M_SP_TA_1, M_SP_TB_1, and M_PS_NA_1
	Double-point information M_DP_NA_1, M_DP_TA_1, and M_DP_TB_1
	Step position information M_ST_NA_1, M_ST_TA_1, and M_ST_TB_1
	Bitstring of 32 bit M_BO_NA_1, M_BO_TA_1, and M_BO_TB_1
	Measured value, normalized value M_ME_NA_1, M_ME_TA_1, M_ME_ND_1, and M_ME_TD_1
	Measured value, scaled value M_ME_NB_1, M_ME_TB_1, and M_ME_TE_1
	Measured value, short floating point number M_ME_NC_1, M_ME_TC_1, and M_ME_TF_1

Station Interrogation

X	Global				
X	Group 1	X	Group 7	X	Group 13
X	Group 2	X	Group 8	X	Group 14
X	Group 3	X	Group 9	X	Group 15

X	Group 4	X	Group 10	X	Group 16
X	Group 5	X	Group 11		
X	Group 6	X	Group 12		

Clock Synchronization

X	Clock synchronization
X	Day of week used
X	RES1, GEN (time tag substituted/not substituted) used
X	SU-bit (summertime) used

Command Transmission

X	Direct command transmission
X	Direct set point command transmission
X	Select and execute command
X	Select and execute set point command
X	C_SE ACTTERM used
X	No additional definition
X	Short-pulse duration (duration determined by a system parameter in the outstation)
X	Long-pulse duration (duration determined by a system parameter in the outstation)
X	Persistent output
	Supervision of maximum delay in command direction of commands and set point commands
	Maximum allowable delay of commands and set point commands

Transmission of Integrated Totals

X	Mode A: Local freeze with spontaneous transmission
X	Mode B: Local freeze with counter interrogation
X	Mode C: Freeze and transmit by counter-interrogation commands
X	Mode D: Freeze by counter-interrogation command, frozen values reported spontaneously
X	Counter read
X	Counter freeze without reset
X	Counter freeze with reset
X	Counter reset
X	General request
X	Request Counter Group 1
X	Request Counter Group 2
X	Request Counter Group 3
X	Request Counter Group 4

Parameter Loading

	Threshold value
	Smoothing factor
	Low limit for transmission of measured values
	High limit for transmission of measured values

Parameter Activation

	Act/deact of persistent cyclic or periodic transmission of the addressed object

Test Procedure

X	Test procedure

File Transfer

File transfer in monitor direction

	Transparent file
	Transmission of disturbance data of protection equipment
	Transmission of sequences of events
	Transmission of sequences of recorded analog values

File transfer in control direction

	Transparent file

Background Scan

X	Background scan

Acquisition of Transmission Delay

X	Acquisition of transmission delay

Interoperability Statement for IEC 60870-5-104 Client for the SEL RTAC

Introduction

This document specifies the capabilities and features of the SEL-implemented IEC 60870-5-104 Server.

This document applies specifically to the following RTAC models and firmware versions.

Model	Firmware Version
SEL-3505 RTAC	SEL-3505-R136-V0-Z001001-D20160624
SEL-3505-3 RTAC	SEL-3505-3-R136-V0-Z001001-D20160624

Model	Firmware Version
SEL-3530 RTAC	SEL-3530-R136-V0-Z001001-D20160624
SEL-3530-4 RTAC	SEL-3530-4-R136-V0-Z001001-D20160624
SEL-2241 RTAC	SEL-2241-R136-V0-Z001001-20160624
SEL-3532 RTAC	SEL-3532-N-R136-V0-Z001001-D20160624
SEL-3555 RTAC	SEL-3555-R136-V0-Z001001-D20160624
SEL-3350 RTAC	SEL-3350-R148-V0-Z001187-D20210208

Interoperability

System or Device

	System definition
X	Controlling station definition (master)
	Controlled station definition (slave)

Network Configuration (Not Applicable)

	Point-to-point		Multipoint-partyline
	Multiple point-to-point		Multipoint-start

Physical Layer (Not Applicable)

Transmission Speed (Control Direction)

Unbalanced Interchange Circuit V.24/V.28 Standard		Unbalanced Interchange Circuit V.24/V.28 Recommended if > 1200 bit/s		Balanced Interchange Circuit X.24/X.27			
	100 bit/s		2400 bit/s		2400 bit/s		56000 bit/s
	200 bit/s		4800 bit/s		4800 bit/s		64000 bit/s
	300 bit/s		9600 bit/s		9600 bit/s		
	600 bit/s				19200 bit/s		
	1200 bit/s				38400 bit/s		

Transmission Speed (Monitor Direction)			
Unbalanced Interchange	Unbalanced Interchange	Balanced Interchange	
Circuit V.24/V.28	Circuit V.24/V.28	Circuit X.24/X.27	
Standard	Recommended if > 1200 bit/s		
100 bit/s	2400 bit/s	2400 bit/s	56000 bit/s
200 bit/s	4800 bit/s	4800 bit/s	64000 bit/s
300 bit/s	9600 bit/s	9600 bit/s	
600 bit/s		19200 bit/s	
1200 bit/s		38400 bit/s	

Link Layer (Not Applicable)

Frame format FT 1.2, single character 1, and the fixed time-out interval are used exclusively in this companion standard.

Link Transmission	Address Field of the Link
Balanced transmission	Not present (balanced transmission only)
Unbalanced transmission	One octet
Frame Length	Two octets
Maximum length L (control direction)	Structured
Maximum length L (monitor direction)	Unstructured
Time during which repetitions are permitted (Trp) or number of repetitions.	

For an unbalanced link layer, the server returns the following ASDU types in Class 2 messages (low priority) with the indicated causes of transmission:

The standard assignment of ASDUs to Class 2 messages is used as follows:

Type Identification	Cause of Transmission

A special assignment of ASDUs to Class 2 messages is as follows:

NOTE
In response to a Class 2 poll, a controlled station can respond with Class 1 data when there are no Class 2 data available.

Type Identification	Cause of Transmission

Application Layer

Transmission Mode for Application Data

Mode 1 (least significant octet first), according to Section 4.10 of IEC 60870-5-4, is used exclusively in this companion standard.

Common Address of ASDU

X	One octet	X	Two octets

Information Object Addresses

X	One octet		Structured
X	Two octets	X	Unstructured
X	Three octets		

Cause of Transmission

X	One octet	X	Two octets (with originator address). Set the originator address to zero if it is not used.

Length of APDU

253	Maximum length of APDU per system in control direction
253	Maximum length of APDU per system in monitor direction

Selection of Standard ASDUs

Basic Application Functions

Station Initialization

X	Remote initialization

Cyclic Data Transmission

X	Cyclic data transmission

Read Procedure

X	Read procedure

Spontaneous Transmission

X	Spontaneous transmission

Double Transmission of Information Objects (Cause of Transmission Equals Spontaneous)

The following type identifications can be transmitted in succession as the result of a single status change for an information object. A project-specific list defines the particular information object addresses for which double transmission is enabled.

	Single-point information M_SP_NA_1, M_SP_TA_1, M_SP_TB_1, and M_PS_NA_1
	Double-point information M_DP_NA_1, M_DP_TA_1, and M_DP_TB_1
	Step position information M_ST_NA_1, M_ST_TA_1, and M_ST_TB_1
	Bitstring of 32 bit M_BO_NA_1, M_BO_TA_1, and M_BO_TB_1
	Measured value, normalized value M_ME_NA_1, M_ME_TA_1, M_ME_ND_1, and M_ME_TD_1
	Measured value, scaled value M_ME_NB_1, M_ME_TB_1, and M_ME_TE_1
	Measured value, short floating point number M_ME_NC_1, M_ME_TC_1, and M_ME_TF_1

Station Interrogation

X	Global				
X	Group 1	X	Group 7	X	Group 13
X	Group 2	X	Group 8	X	Group 14
X	Group 3	X	Group 9	X	Group 15
X	Group 4	X	Group 10	X	Group 16
X	Group 5	X	Group 11		
X	Group 6	X	Group 12		

Clock Synchronization

X	Clock synchronization
X	Day of week used
X	RES1, GEN (time tag substituted/not substituted) used
X	SU-bit (summertime) used

Command Transmission

X	Direct command transmission
X	Direct set point command transmission
X	Select and execute command
X	Select and execute set point command
X	C_SE ACTTERM used
X	No additional definition
X	Short-pulse duration (duration determined by a system parameter in the outstation)
X	Long-pulse duration (duration determined by a system parameter in the outstation)
X	Persistent output

X	Supervision of maximum delay in command direction of commands and set point commands
	Maximum allowable delay of commands and set point commands

Transmission of Integrated Totals

X	Mode A: Local freeze with spontaneous transmission
X	Mode B: Local freeze with counter interrogation
X	Mode C: Freeze and transmit by counter-interrogation commands
X	Mode D: Freeze by counter-interrogation command, frozen values reported spontaneously
X	Counter read
X	Counter freeze without reset
X	Counter freeze with reset
X	Counter reset
X	General request
X	Request Counter Group 1
X	Request Counter Group 2
X	Request Counter Group 3
X	Request Counter Group 4

Parameter Loading

	Threshold value
	Smoothing factor
	Low limit for transmission of measured values
	High limit for transmission of measured values

Parameter Activation

	Act/deact of persistent cyclic or periodic transmission of the addressed object

Test Procedure

	Test procedure

File Transfer

File transfer in monitor direction

	Transparent file
	Transmission of disturbance data of protection equipment
	Transmission of sequences of events
	Transmission of sequences of recorded analog values

File transfer in control direction

	Transparent file

Background Scan

X	Background scan

Acquisition of Transmission Delay

	Acquisition of transmission delay

Definition of Time-Outs

Parameter	Default Value	Remarks	Selected Value
t_0	15 s	Time-out of connection establishment	1–60 s
t_1	15 s	Time-out of send or test APDUs	1–255 s
t_2	10 s	Time-out for acknowledgments in case of no data messages $t_2 < t_1$	1–255 s
t_3	20 s	Time-out for sending test frames in case of a long idle state	Disable, 1–172800 s

Maximum Number of Outstanding I Format APDUs k and Latest Acknowledge APDUs (w)

Parameter	Default Value	Remarks	Selected Value
k	12 APDUs	Maximum difference receive sequence number to send state variable	1–24
w	8 APDUs	Latest acknowledgment(s) after receiving *w* I format APDUs	1–24

Portnumber

Parameter	Value	Remarks
Portnumber	2404	1–65534

Redundant Connections

0	Number N of redundancy group connections used

RFC 2200 Suite

RFC 2200 is an official Internet standard that describes the state of Internet protocol standardization as determined by the Internet Architecture Board (IAB). It offers a broad spectrum of actual standards used in the Internet. The suitable selection of documents from RFC 2200 defined in this standard for given projects has to be chosen by the user of this standard.

X	Ethernet 802.3
	Serial X.21 interface

	Other selection from RFC 2200:
	List of valid documents from RFC 2200
	1. .....
	2. .....
	3. .....
	4. .....
	5. .....
	6. .....
	7. etc.

Interoperability Statement for IEC 60870-5-101 Server for the SEL RTAC

Introduction

This document specifies the capabilities and features of the SEL-implemented IEC 60870-5-101 Server.

This document applies specifically to the following RTAC models and firmware versions.

Model	Firmware Version
SEL-3505 RTAC	SEL-3505-R136-V0-Z001001-D20160624
SEL-3505-3 RTAC	SEL-3505-3-R136-V0-Z001001-D20160624
SEL-3530 RTAC	SEL-3530-R136-V0-Z001001-D20160624
SEL-3530-4 RTAC	SEL-3530-4-R136-V0-Z001001-D20160624
SEL-2241 RTAC	SEL-2241-R136-V0-Z001001-20160624
SEL-3532 RTAC	SEL-3532-N-R136-V0-Z001001-D20160624
SEL-3555 RTAC	SEL-3555-R136-V0-Z001001-D20160624
SEL-3350 RTAC	SEL-3350-R148-V0-Z001187-D20210208

Interoperability

System or Device

	System definition
	Controlling station definition (master)
X	Controlled station definition (slave)

Network Configuration

X	Point-to-point	X	Multipoint-partyline
X	Multiple point-to-point		Multipoint-start

Physical Layer

Transmission Speed (Control Direction)							
Unbalanced Interchange		Unbalanced Interchange		Balanced Interchange			
Circuit V.24/V.28		Circuit V.24/V.28		Circuit X.24/X.27			
Standard		Recommended if > 1200 bit/s					
	100 bit/s	X	2400 bit/s	X	2400 bit/s	X	56000 bit/s
X	200 bit/s	X	4800 bit/s	X	4800 bit/s		64000 bit/s
X	300 bit/s	X	9600 bit/s	X	9600 bit/s	X	115000 bit/s
X	600 bit/s			X	19200 bit/s		
X	1200 bit/s			X	38400 bit/s		

Transmission Speed (Monitor Direction)							
Unbalanced Interchange		Unbalanced Interchange		Balanced Interchange			
Circuit V.24/V.28		Circuit V.24/V.28		Circuit X.24/X.27			
Standard		Recommended if > 1200 bit/s					
	100 bit/s	X	2400 bit/s	X	2400 bit/s	X	56000 bit/s
X	200 bit/s	X	4800 bit/s	X	4800 bit/s		64000 bit/s
X	300 bit/s	X	9600 bit/s	X	9600 bit/s	X	115000 bit/s
X	600 bit/s			X	19200 bit/s		
X	1200 bit/s			X	38400 bit/s		

Link Layer

Frame format FT 1.2, single character 1, and the fixed time-out interval are used exclusively in this companion standard.

Link Transmission		Address Field of the Link	
X	Balanced transmission	X	Not present (balanced transmission only)
X	Unbalanced transmission	X	One octet
Frame Length		X	Two octets
255	Maximum length L (control direction)		Structured
255	Maximum length L (monitor direction)	X	Unstructured
	Time during which repetitions are permitted (Trp) or number of repetitions.		

For an unbalanced link layer, the server returns the following ASDU types in Class 2 messages (low priority) with the indicated causes of transmission:

X	The standard assignment of ASDUs to Class 2 messages is used as follows:

Type Identification	Cause of Transmission
9, 11, 13, 21	<1>
9, 11, 13, 21	<2>

X	A special assignment of ASDUs to Class 2 messages is as follows:

NOTE
In response to a Class 2 poll, a controlled station can respond with Class 1 data when there are no Class 2 data available.

Type Identification	Cause of Transmission
1, 3, 5, 7	<1>
1, 3, 5, 7	<2>

Application Layer

Transmission Mode for Application Data

Mode 1 (least significant octet first), according to Section 4.10 of IEC 60870-5-4, is used exclusively in this companion standard.

Common Address of ASDU

X	One octet	X	Two octets

Information Object Addresses

X	One octet		Structured
X	Two octets	X	Unstructured
X	Three octets		

Cause of Transmission

X	One octet	X	Two octets (with originator address). Set the originator address to zero if it is not used.

Selection of Standard ASDUs

Interoperability Statement for IEC 60870-5-104 Server for the SEL RTAC

Introduction

This document specifies the capabilities and features of the SEL-implemented IEC 60870-5-104 Server.

This document applies specifically to the following RTAC models and firmware versions.

Model	Firmware Version
SEL-3505 RTAC	SEL-3505-R136-V0-Z001001-D20160624
SEL-3505-3 RTAC	SEL-3505-3-R136-V0-Z001001-D20160624
SEL-3530 RTAC	SEL-3530-R136-V0-Z001001-D20160624
SEL-3530-4 RTAC	SEL-3530-4-R136-V0-Z001001-D20160624
SEL-2241 RTAC	SEL-2241-R136-V0-Z001001-20160624
SEL-3532 RTAC	SEL-3532-N-R136-V0-Z001001-D20160624
SEL-3555 RTAC	SEL-3555-R136-V0-Z001001-D20160624
SEL-3350 RTAC	SEL-3350-R148-V0-Z001187-D20210208

Interoperability

System or Device

	System definition
	Controlling station definition (master)
X	Controlled station definition (slave)

Network Configuration (Not Applicable)

	Point-to-point		Multipoint-partyline
	Multiple point-to-point		Multipoint-start

Physical Layer (Not Applicable)

Link Layer (Not Applicable)

Application Layer

Transmission Mode for Application Data

Mode 1 (least significant octet first), according to Section 4.10 of IEC 60870-5-4, is used exclusively in this companion standard.

Common Address of ASDU

X	One octet	X	Two octets

Information Object Addresses

X	One octet		Structured
X	Two octets	X	Unstructured
X	Three octets		

Cause of Transmission

X	One octet	X	Two octets (with originator address). Set the originator address to zero if it is not used.

Length of APDU

253	Maximum length of APDU per system in control direction
253	Maximum length of APDU per system in monitor direction

Selection of Standard ASDUs

Definition of Time-Outs

Parameter	Default Value	Remarks	Selected Value
t_0	30 s	Time-out of connection establishment	N/A
t_1	15 s	Time-out of send or test APDUs	1–255 s
t_2	10 s	Time-out for acknowledgments in case of no data messages $t_2 < t_1$	1–255 s
t_3	20 s	Time-out for sending test frames in case of a long idle state	Disable, 1–172800 s

Maximum Number of Outstanding I Format APDUs k and Latest Acknowledge APDUs (w)

Parameter	Default Value	Remarks	Selected Value
k	12 APDUs	Maximum difference receive sequence number to send state variable	1–32767
w	8 APDUs	Latest acknowledgment(s) after receiving *w* I format APDUs	1–32767

Portnumber

Parameter	Value	Remarks
Portnumber	2404	23, 1024–65534

Redundant Connections

2	Number N of redundancy group connections used

RFC 2200 Suite

RFC 2200 is an official Internet standard that describes the state of Internet protocol standardization as determined by the Internet Architecture Board (IAB). It offers a broad spectrum of actual standards used in the Internet. The suitable selection of documents from RFC 2200 defined in this standard for given projects has to be chosen by the user of this standard.

IEC 60870-5-103

IEC 60870-5 is an IEC standard that defines systems used for supervisory control and data acquisition (SCADA), including details related to communications between devices. As part of the standard, IEC 60870-5-103 defines a byte-oriented, asynchronous serial-based protocol for communications associated with electrical power systems. The design is based on either balanced (where either client or server can transmit asynchronously) or unbalanced (server can only transmit when solicited by client) topologies and is suitable for point-to-point or point-to-multipoint configurations.

This section describes the configuration and use of the IEC 60870-5-103 server with ACSELERATOR RTAC. You can configure as many as 50 concurrent IEC 60870-5-103 clients in a single RTAC project. The IEC 60870-5-103 client supports commands (in the control direction) and transmitting of requests for Application Service Data Unit (ASDU) types and Cause of Transmission (COT) as shown in the interoperability statements for IEC 60870-5-103, which list COTs for expected behavior only. Additional COTs are recognized for errors.

IEC 60870-5-103 Client Configuration

Configure an IEC 60870-5-103 client connection to communicate via serial or Ethernet to IEDs. The RTAC will poll data from these IEDs and store the data it receives in tags. Use the Tag Processor to map these data to any protocol, logs, user logic, etc.

Give the device connection a unique name and select the connection type, as shown in *Figure 2.196*. Refer to *Client Connection Types on page 167* for a description of each connection type.

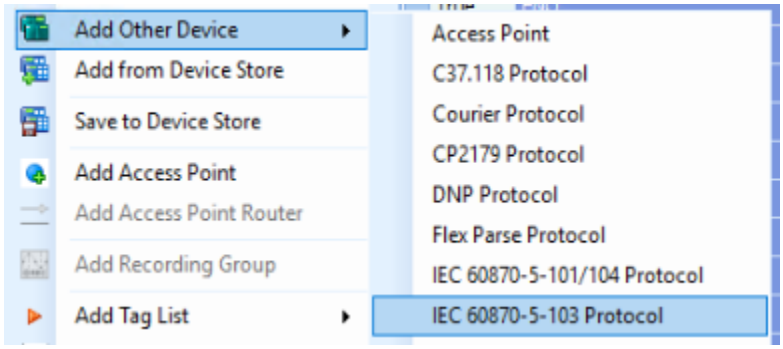

Figure 2.196 Adding IEC 60870-5-10 Client

Settings Tab

The **Settings** tab contains all configurable items for communication. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description. Type any applicable comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Sector Settings Tab

The **Sector Settings** tab contains configuration parameters for a maximum of eight sectors in a server. Each sector has a configurable name and common address. By default, each client has one sector. To add additional sectors, click the + button.

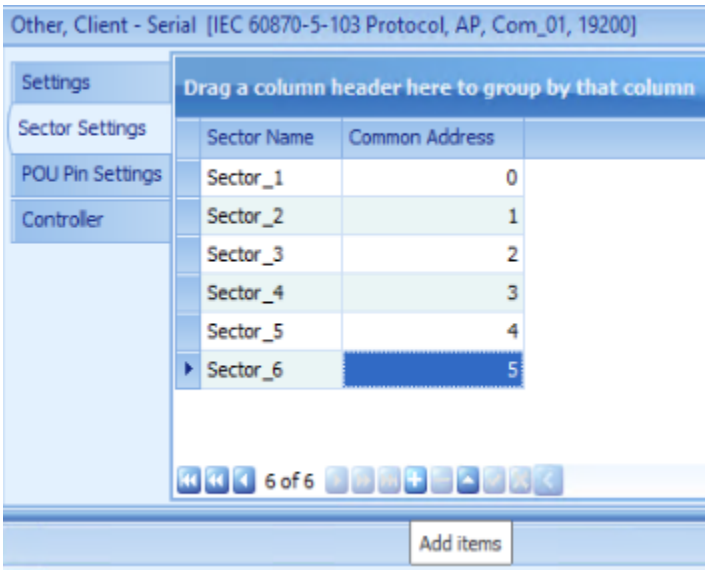

Figure 2.197 IEC 60870-5-103 Sector Settings

IEC 60870-5-103 Client Sector Map

To configure tags for the IEC 60870-5-103 client, select an existing **103 Client Sector Map**. Repeat *Step 1* through *Step 4* to configure each client tag.

Step 1. Click the tab for the appropriate tag type to add and configure tags.

Step 2. Click + to add tags. To optimize system performance, only create as many tags as you need.

Step 3. Rename the tags as necessary.

Step 4. Configure other tag parameters as necessary.

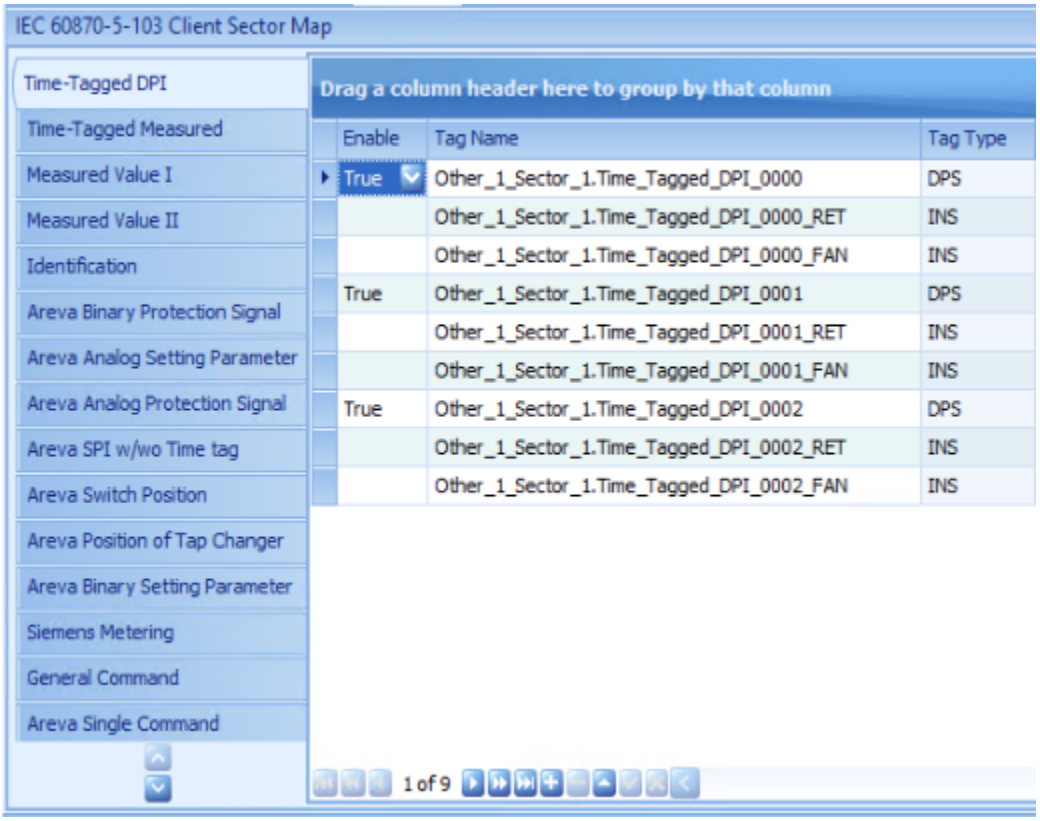

Figure 2.198 IEC 60870-5-103 Client Sector Map

POU Pins

Use POU pin settings to view the present state of the IEC 60870-5-103 client operation and to modify some of the behavior of the protocol. Setting the Visible field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.122* for the settings descriptions.

Table 2.122 IEC 60870-5-103 Client POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific function block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update or process changes to tags while this input is True.	False
Disable_Controls	Input BOOL	While True, processing of any controllable tags is blocked.	False
Reset_Statistics	Input BOOL	On the rising-edge trigger, all counter POU outputs are reset.	False
Set_ClockFail	Input BOOL	When this pin is set to true this will set the ClockFail bit in the timestamp_t structure of IEC 60870-5-103 tags.	False
ENO	Output BOOL	Indicates that this specific function block instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is False when protocol communications are in process. **Note**: Protocol communications may be in process, but no successful data are exchanged because of settings configuration issues.	False

Pin Name	Pin Type	Description	Default
Invalid_Function_Block_Input	Output BOOL	True when a function block input currently has an invalid or out-of-range value.	False
Controls_Disabled	Output BOOL	Asserted when the Disable_Controls input is asserted. This indicates that the client will not issue control commands.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	False
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have failed.	0
Message_Success_Count	Output UDINT	Running sum indicating the number of messages successively sent and received communicating with the remote device.	0
Direct_Transparent_Connection	Output BOOL	Indicates that the communications have been interrupted by a direct transparent connection through an access point router.	False
Data_Link_Timeout_Count	Output UDINT	Number of data link failures.	0
Response_Timeout_Count	Output UDINT	Number of application layer message response time-outs.	0
Reinit_In_Progress	Output BOOL	While asserted, indicates that the client is performing initial communications queries prior to data processing	False
Buffer_Overflow	Output BOOL	Asserts for a single processing interval if any message operations were discarded because of queuing limits. A message will be discarded if multiple occurrences of the same operation have been queued prior to the completion of that message type.	False
Buffer_Overflow_Count	Output UDINT	Count indicating the number of times that the Buffer_Overflow pin has been asserted.	0
Restart	Output BOOL	Asserts for a single processing interval when the client receives an end of initialization message with a cause of initialization, indicating a remote start of the server.	False
Event_Collection_Count	Output UDINT	Number of events collected since the POU was enabled.	0
Event_Collection_Enabled	Output BOOL	When True, the RTAC is able and ready to collect events from server.	False
Event_Collection_Pending	Output BOOL	Asserted while there are uncollected events. Deasserts once all events have been collected.	False
Event_Collection_Stored	Output BOOL	Asserts for a processing interval when an event has been stored in nonvolatile memory.	False

Interoperability Statement for IEC 60870-5-103 Client for the SEL RTAC

Introduction

This document specifies the capabilities and features of the SEL-implemented IEC 60870-5-103 Client.

This document applies specifically to the following RTAC models and firmware versions.

Model	Firmware Version
SEL-3505 RTAC	SEL-3505-R145-V0-Z000001-D20190830
SEL-3505-3 RTAC	SEL-3505-3-R145-V0-Z000001-D20190830
SEL-3530 RTAC	SEL-3530-R145-V0-Z000001-D20190830
SEL-3530-4 RTAC	SEL-3530-4-R145-V0-Z000001-D20190830
SEL-2241 RTAC	SEL-2241-R145-V0-Z000001-D20190830
SEL-3532 RTAC	SEL-3532-N-R145-V0-Z000001-D20190830
SEL-3555 RTAC	SEL-3555-R145-V0-Z000001-D20190830
SEL-3350 RTAC	SEL-3350-R148-V0-Z001187-D20210208

Interoperability

Physical Layer

Electrical Interface

X	EIA-485
X	EIA-232
X	Number of loads is 32 for one piece of protection equipment

NOTE
The EIA-485 standard defines unit loads such that 32 can be operated on one line. For detailed information, refer to clause 3 of the EIA-485 standard.

Optical Interface

	Glass fiber
X	Plastic fiber
	F-SMA type connector
X	BFOC/2,5 type connector

Miscellaneous

Measurands are transmitted with ASDU 3 as well as with ASDU 9. As defined in 7.2.6.8, the maximum MVAL can either be 1,2 or 2,4 times the rated value. No different rating shall be used in ASDU 3 and ASDU 9, i.e., for each measurand, there is only one choice.

Measurand	1,2	2,4
Current L1		
Current L2		
Current L3		
Voltage L1-E		
Voltage L2-E		
Voltage L3-E		
Active power P		
Reactive power Q		
Frequency f		
Voltage L1–L2		

Flex Parse Protocol

Flex Parse Messages

Use Flex Parse Messages in an SEL client or in a Flex Parse Protocol client to create custom commands as long as 255 bytes and optionally parse the response messages. You can configure the RTAC to send a Command String to the SEL device, or any other connected device, at a configurable Poll Period interval. You can also configure the Start of Response Parse Expression and other parse expressions to enable the RTAC to determine when a valid response is received and to interpret the returned message and populate user-created tags. You can define parse expressions in SEL type class expressions or Perl 5 regular expressions (regex), both of which are explained later in this section. See *Table 2.123* for a description of Flex Parse Messages settings.

Add a flex parse command by performing the following steps:

Step 1. From the **Insert** ribbon, select **Other** > **Flex Parse Protocol**.

Step 2. On the **Settings** tab, configure necessary communications settings parameters.

> **NOTE**
> The process for adding and configuring a flex parse message is the same on an SEL client or in a Flex Parse Protocol client that you have added to the project.

Step 3. Click on **Flex Parse Messages**.

Step 4. Click on + to add a message, then click on **Add**.

Step 5. Configure the Command String, which is the message that will be sent to the SEL device.

Step 6. Configure the timing parameters to dictate how often the command should be sent and the time allotted for the command to complete.

Step 7. Configure the Start of Response Expression that the RTAC will compare with the incoming message to ensure it is parsing the correct message.

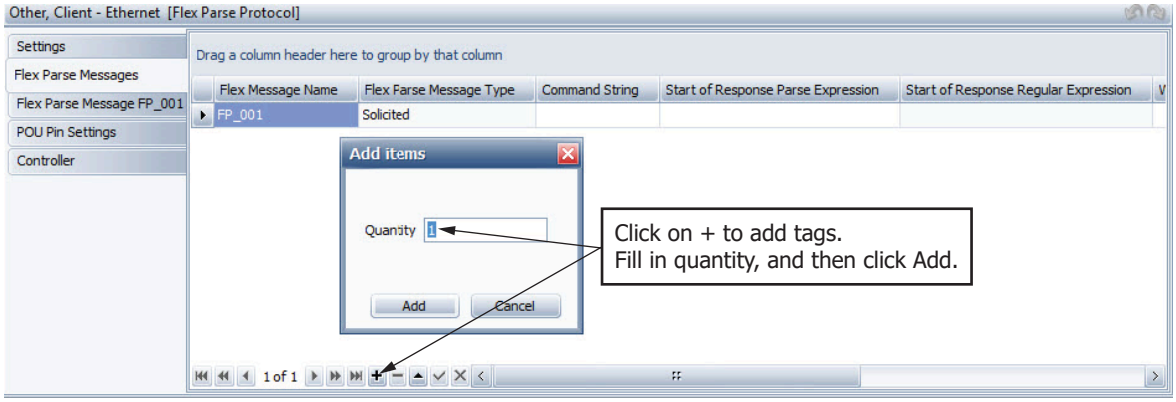

Figure 2.199 Add Flex Parse Message

Table 2.123 Flex Parse Message Settings

Parameter	Description	Default
Flex Message Name	The default message name. You can change this as necessary.	FP–*n*, where *n* is the last flex parse message number + 1
Flex Parse Message Type	The type of message processing.	Solicited
Command String	User-configured message the RTAC will send to the device.	
Start of Response Parse Expression	Optional user-configured expression to locate the start of the response. Enter as Perl 5 regex and/or SEL type class expression.	
Start of Response Regular Expression	The view-only derived Regular Expression from Start of Response Parse Expression.	
Window Size	The maximum number of characters used to satisfy Start_of_Response_ Parse_Expression.	512
Poll Period	The period in milliseconds after which the RTAC will send Command String to the configured device.	0

Parameter	Description	Default
Timeout	The time in milliseconds that the RTAC will wait for a valid reply before aborting message processing (and retrying). If no tags are defined for this message, processing will continue as if all parse messages are satisfied.	5000
Access Level	The access level on the device that the RTAC must attain before sending Command String.	Level_1
Max number of Retries	The maximum number of retries before the IED is marked Offline.	0
Terminate By	Terminate parse search either on completion of the parse or on Response Timeout. Note that if your parse expression has an error, the parse will not complete so the expression will never terminate by parse complete.	On_Timeout
Response Termination Timeout	The time in milliseconds the RTAC will wait after all parse expressions have been evaluated successfully and the line is idle. The timer is reset each time an ASCII character is received.	1000

After you configure a Flex Parse Message, a new tab will appear called **Flex Parse Message FP_001**, where FP_001 is the configured Flex Message Name. In this tab, you can add and configure tags, at your option, to store data from the incoming message. Add tags and configure parse expressions that will search for the data points you want to extract from the incoming message. The RTAC will execute these parse expressions once the Start of Response Expression has been satisfied, which indicates that the RTAC has received a valid message. See *Table 2.124* for a description of Flex Parse tag settings.

To configure the flex parse tags, perform the following steps:

Step 1. Click on the tab **Flex Parse message FP_001** (where FP_001 is the name of the message) in the SEL client or Flex Parse Protocol client.

Step 2. Click on +, type the quantity of tags you need, and press **Add**.

Step 3. Change the tag type and treat as fields, as necessary.

Step 4. Use SEL type class expressions and regex to parse necessary data from the incoming message.

Step 5. Optionally, you can test the flex parse commands you have configured by clicking on the Flex Parse Helper Form.

Step 6. In this blank form, either copy/paste or type in text for which you are building the parse commands. The flex parse helper form highlights the message to show the results of the parsing.

Step 7. Hover your cursor over each data element in the flex parse helper form to see the tag assignment for that data element. See *Figure 2.203*.

Step 8. Adjust the parse commands, if needed, if the data are not assigned to the tags correctly.

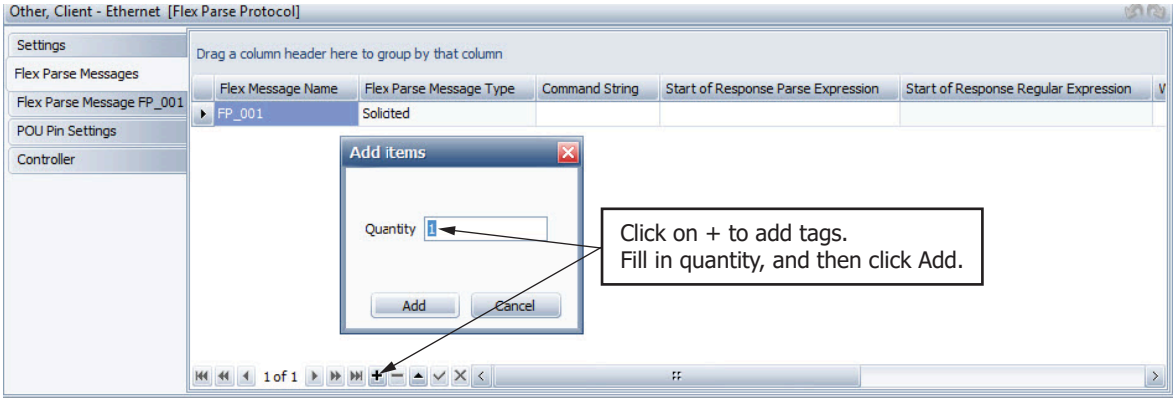

Figure 2.200 Add Flex Parse Tags

Table 2.124 Flex Parse Tags Settings

Parameter	Description	Default
Enable	The processing enable flag. Set this flag to True to enable processing of this tag. Set this flag to False to disable processing.	True
Tag Name	The default tag name contains the device name and tag description. You can change this name as necessary.	
Tag Type	The data type of this tag. See *Data Types on page 1127* for more details.	INS
Tag Alias	An optional descriptive tag name. Use this tag alias anywhere in the RTAC system in place of the actual tag name.	
Order ID	The order in which the parse expressions will be executed.	
Parse Expression	The configurable search expression used to identify the piece of data for this tag. Enter as Perl 5 regex and/or SEL type class expression.	
Regular Expression	The view-only derived regular expression from Parse Expression.	
Window Size	The maximum number of characters used to satisfy Parse Expression.	
Treat As	The expected representation or format of integer data.	Decimal
Size	The size of data in bytes, once it has been processed. This affects sign extension and range checking.	4
Default Value	The string of characters used if the parsing fails on the captured data. (quality=invalid).	
Comment	Optional user-entered comment field.	

During the operation of sending/receiving and parsing messages, the flex parse message task exhibits the following behavior:

- If a Command String has been sent and this Command String neither times out nor completes prior to the triggering of another Command String, the issuing of the new message will be delayed and the POU pin Send_Flex_Parse_Message_FP_001_Delay will turn True for one processing interval.
- After a triggered Command String is sent and the received message parsed successfully, the POU pin Send_Flex_Parse_Message_FP_001_DN will toggle True for one processing cycle.

- After a parse match is found for one piece of data, the next search group will start after the last character of the previous match group. For example, a search for "little" in the string "Mary had a little lamb" will start with Mary and end when "little" is found. The next search begins immediately after the word "little".
- If the result of the parse is out of range of the tag definition, the tag value is assigned infinity for MV, zero for all other data types.
- If the parse fails, the tag value is assigned the default value as configured in the tag setup, and quality is set to invalid.
- If a parse fails within the window size or the message timeout expires, subsequent parse commands are not executed.

SEL Type Class Expressions

You can use SEL type class expressions along with regex expressions in your parse expressions. SEL type class expressions are shortcuts that allow you to match on data without writing complex regex expressions. ACSELERATOR RTAC will expand SEL type class expressions to regex expressions each time you save the project.

Each type class expression comes in either a capturing or non-capturing form. Use a capturing type class to extract data into a tag. Use a non-capturing expression to search for something you do not want to put into a tag. For example, searching for the start of the message enables you to know you have the correct message but you do not want to store that string.

Capturing type class expressions have the following format:

```
(?#<TYPE[:param1[,paramN]]>)
```

Non-capturing type class expressions have the following format:

```
(?#<?:TYPE[:param1[,paramN]]>)
```

[ ] represents optional text.

TYPE is the type class name (e.g., INS, REAL, CHAR, etc.).

The value param1 is an optional parameter. For example, `(?#<INS: 2>)` will limit the number of digits extracted to two. *Table 2.125* describes individual type class expressions, what optional parameters each has, and the default value for the optional parameter if you do not specify one.

Table 2.125 SEL Type Class Expressions

Type Class	Description	Optional Parameters With Defaults	Example
INS	Extracts a group of digits that represent an integer.	Number of digits (1–10), default = 10	0, 4, –500
HINS	Extracts a group of hexadecimal digits that represent an integer.	Number of digits (1–8), default = 8	C1, A1C
HEX_ASCII	Extracts a group of hexadecimal digits written in ASCII that represent an integer, where four hexadecimal digits are a single byte.	Number of digit quartets or bytes (1–4), default = 4	4632 (xF2), 31323334 (x1234)

Type Class	Description	Optional Parameters With Defaults	Example
REAL	Extracts a group of digits that represent a floating point. Note that making digits of precision = 0 may cause unexpected results. The first search of 1.23 will return 1. The second search will find 23, which may not be what you intended.	Number of digits of precision (0–9), default = 3	+5, 35., 7.1, –.87
CHAR	Extracts at most one character.	N/A	a, 7, j
DLIM	Extracts at most one delimiter character.	N/A	<SPC>, <TAB>, <CR>, <LF>, <:>, <;>, </>, <\>, <'>, <">

Example 2.6

In this basic example, the RTAC sends a meter (MET) command to an SEL-221 relay as shown in the following figure. In this example, we will configure the RTAC to parse the returned data into tags.

```
=>>MET <Enter>

Example 230 kV Line                Date: 1/1/1       Time: 03:15:14

              A       B       C      AB      BC      CA
I (A)       994     995     994    1723    1724    1724
V (kV)    134.4   134.3   134.2   233.1   232.8   232.9

P (MW)   401.12
Q (MVAR)   1.00
```

How it works: The configurations in *Figure 2.201* and *Figure 2.202* have the following effects on the MET message shown in *Example 2.6*:

1. The RTAC will log in to the SEL relay in Access Level 1.
2. The RTAC will send the Command String (**MET**, carriage return, line feed) every Poll Period (60,000 ms).
3. The RTAC will look for a string of characters, configured as the Start of Response Parse Expression. In this example, it is **MET**, then any characters until it sees CA. It will only search the number of characters configured as Window Size (512 bytes). A successful match means that the next search will begin directly after the CA in the column headings.
4. In *Figure 2.202*, `(?#<INS:4>)` tells the RTAC to search through the number of characters specified in Window Size (50) for an INS (integer) that is at least one character and a maximum of four characters long. This will return the value 994 as an integer into the tag SEL_221_16_1_SEL.I_A.stVal.
5. The next search, `(?#<INS:4>)`, will begin to search directly after 994 and will return the value 995 into the second tag and so forth. Note that the REAL number searches include an option (:1) to indicate the number of characters to include past the decimal point.
6. After all searches complete successfully, POU pin Send_Flex_Parse_Message_ Meter_DN toggles True for one processing interval.

Perform the following steps to configure the RTAC to populate tags by parsing the data from the MET command on an SEL-221 Relay:

Step 1. From the **Insert** ribbon, add an SEL-221 relay by clicking on **SEL > 200 Series > 221 Versions > 221-16 > SEL**.

Step 2. Click on the **Flex Parse Messages** tab.

Step 3. Click on + and then on **Add** to create one flex parse message.

Step 4. Configure as shown in *Figure 2.201*. Leave fields not shown in *Figure 2.201* at default values.

Step 5. Press **<Ctrl+S>** to save.

Flex Message Name	Command String	Start of Response Parse Expression	Window Size	Poll Period	Timeout	Access Level
Meter	MET<CR><LF>	MET.*\bCA\b	512	60000	5000	Level_1

Figure 2.201 Example 2.6 Flex Parse Command

Step 6. Click on the newly created tab called **Flex Parse Message Meter**.

Step 7. Click on +, type in **14**, and then press **Add** to add 14 flex parse tags.

Step 8. Configure as shown in *Figure 2.202*, and press **<Ctrl+S>** to save.

Step 9. Open the flex parse helper form.

Step 10. Copy the **MET** command text from the figure in *Example 2.6*, and paste into the flex parse helper form.

Step 11. Notice the text is highlighted in yellow. Hover your cursor over each data element and notice how the flex parse helper form shows you the tag names and which data are assigned to them. See *Figure 2.203*.

Tag Name	Tag Type	Parse Expression	Window Size	Treat As	Default Value
SEL_221_16_1_SEL.I_A	INS	(?#<INS:4>)	50	Decimal	999
SEL_221_16_1_SEL.I_B	INS	(?#<INS:4>)	25	Decimal	999
SEL_221_16_1_SEL.I_C	INS	(?#<INS:4>)	25	Decimal	999
SEL_221_16_1_SEL.I_AB	INS	(?#<INS:4>)	25	Decimal	9999
SEL_221_16_1_SEL.I_BC	INS	(?#<INS:4>)	25	Decimal	9999
SEL_221_16_1_SEL.I_CA	INS	(?#<INS:4>)	25	Decimal	9999
SEL_221_16_1_SEL.V_A	MV	(?#<REAL:1>)	50	Real	999.9
SEL_221_16_1_SEL.V_B	MV	(?#<REAL:1>)	25	Real	999.9
SEL_221_16_1_SEL.V_C	MV	(?#<REAL:1>)	25	Real	999.9
SEL_221_16_1_SEL.V_AB	MV	(?#<REAL:1>)	25	Real	999.9
SEL_221_16_1_SEL.V_BC	MV	(?#<REAL:1>)	25	Real	999.9
SEL_221_16_1_SEL.V_CA	MV	(?#<REAL:1>)	25	Real	999.9
SEL_221_16_1_SEL.P	MV	(?#<REAL:2>)	50	Real	999.99
SEL_221_16_1_SEL.Q	MV	(?#<REAL:2>)	50	Real	999.99

Figure 2.202 Example 2.6 Flex Parse Tags

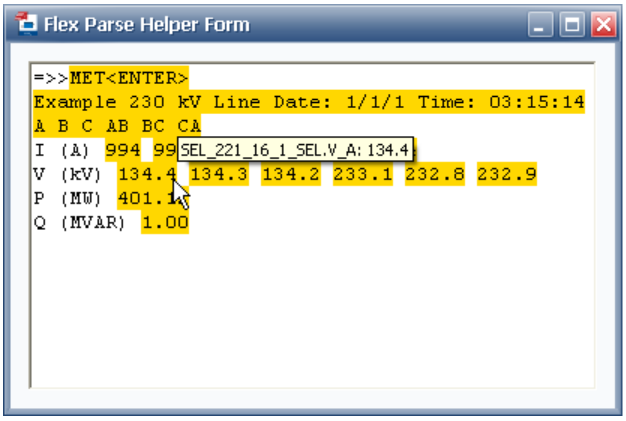

Figure 2.203 Flex Parse Helper Form

Example 2.7

In this example, the RTAC sends a meter m (MET M) command to an SEL-351R relay as shown in the following figure and parses the data into tags. This example is more advanced, because it shows how you can skip fields that may or may not have valid data by using the look-ahead feature. Notice in the following figure that some data fields have the word RESET, which means that there are no data. The associated date fields are blank. In this example, we will add conditions to parse commands such that the parse command will search for a number OR a RESET and will search for valid date data OR look ahead to make sure there is another line to search if the date field is blank.

```
=>>MET M <Enter>
RECLOSER R1 Date: 03/28/01 Time: 10:39:02.389
FEEDER XYZ

LAST RESET 03/28/01 10:38:56.773
```

How it works: The configurations in *Figure 2.204* and *Figure 2.205* have the following effects on the MET M message shown in *Example 2.7*:

1. The RTAC will log in to the SEL relay in Access Level 1.
2. The RTAC will send the Command String (**MET M**, carriage return, line feed) every Poll Period (60,000 ms).
3. The RTAC will look for a string of characters, configured as the Start of Response Parse Expression. In this example, it is **MET M**, then any characters until it sees IA (A). It will only search the number of characters configured as Window Size (512 bytes). A successful match means that the next search will begin directly after IA (A) in the first data row shown in *Example 2.7*.

4. In *Figure 2.205*, `(?#<REAL:1>)|RESET` tells the RTAC to search through the number of characters specified in Window Size (80) for either the word RESET or for a REAL number with one number to the right of the decimal point. In this example, the value 200.0 is returned as a REAL into the tag SEL_351R_1_SEL.IA_MAX.instMag.
5. The next search, `(?#<INS:2>)|(?=IB)`, will begin searching directly after the value 200.0 for an integer value with a maximum of two characters. If the match fails because the space that should contain a value is blank, it will look ahead for the string IB. If either the number or the string IB is found, the parsing will continue. The tag is populated with the value satisfied by this expression; or, if there is no value, and the look-ahead expression (? = IB) is satisfied, the tag is not populated and the next tag is used for the next configured parse. If the expression is not satisfied, the parse will fail and no more parsing will occur for this data group. In this example, the RTAC finds the month value 03 and places it in SEL_351R_1_SEL.IA_MAX_MONTH.
6. The searches continue to populate DAY, YEAR, HOUR, etc., tags. Each new line (IA, IB, IC, IN, etc.) is tested for the word RESET. If the test for RESET and the look ahead test for the next line were not included, the parsing would fail as soon as it could not find a number to match the parse expression.
7. After all searches are successfully completed, POU pin Send_Flex_Parse_Message_Meter_DN toggles TRUE for one processing interval.

Perform the following steps to configure the RTAC to populate tags by parsing the data from the MET M command on an SEL-351R Relay:

Step 1. From the **Insert** ribbon, add an SEL-351R relay by clicking on **SEL > 300 Series > 351R > SEL**.

Step 2. Click on the **Flex Parse Messages** tab.

Step 3. Click on + and then on **Add** to create one flex parse message.

Step 4. Configure as shown in *Figure 2.204*. Leave fields not shown in *Figure 2.204* at default values.

Step 5. Press **<Ctrl+S>** to save.

Flex Message Name	Command String	Start of Response Parse Expression	Window Size	Poll Period	Timeout	Access Level
MET_Min_Max_ALL	MET M<CR><LF>	MET M.*IA\(A\)	512	60000	5000	Level_1

Figure 2.204 Example 2.7 Flex Parse Command

Step 6. Click on the newly created tab called **Flex Parse Message MET_Min_Max_ALL**.

Step 7. Click on +, type in **154**, and then press **Add** to add 154 flex parse tags.

Step 8. Configure as shown in *Figure 2.205*, and press **<Ctrl+S>** to save.

Notice the SEL class type ORed with a look ahead for the characters IB `(?#<INS:2>)|(?=IB)` will collect an integer or move on to parsing the next tag if the field is blank by looking ahead to make sure the next line contains IB. In some situations you may not know what is on the next line or it may be an integer value so you cannot look ahead for it. To resolve this, you could combine

the SEL class type ORed with a look ahead for an end of line `(?#<INS:2>)|(?=\x0A)`, which will collect an integer; or, if there is not an integer, it will look ahead to see if there is a line feed. As long as there is a line feed, the process will skip to parse the next tag.

Tag Name	Tag Type	Parse Expression	Window Size	Treat As	Size	Default Value
SEL_351R_1_SEL.IA_MAX	MV	(?#<REAL:1>)|RESET	80	Real	4	999.9
SEL_351R_1_SEL.IA_MAX_MONTH	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	99
SEL_351R_1_SEL.IA_MAX_DAY	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	99
SEL_351R_1_SEL.IA_MAX_YEAR	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	99
SEL_351R_1_SEL.IA_MAX_HOUR	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	99
SEL_351R_1_SEL.IA_MAX_MINS	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	99
SEL_351R_1_SEL.IA_MAX_SEC	MV	(?#<REAL>)|(?=IB)	80	Real	4	99.999
SEL_351R_1_SEL.IA_MIN	MV	(?#<REAL:1>)|(?=IB)	80	Real	4	888.8
SEL_351R_1_SEL.IA_MIN_MONTH	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	88
SEL_351R_1_SEL.IA_MIN_DAY	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	88
SEL_351R_1_SEL.IA_MIN_YEAR	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	88
SEL_351R_1_SEL.IA_MIN_HOUR	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	88
SEL_351R_1_SEL.IA_MIN_MINS	INS	(?#<INS:2>)|(?=IB)	80	Decimal	4	88
SEL_351R_1_SEL.IA_MIN_SEC	MV	(?#<REAL>)|IB	80	Real	4	88.888
SEL_351R_1_SEL.IB_MAX	MV	(?#<REAL:1>)|RESET	80	Real	4	999.9
SEL_351R_1_SEL.IB_MAX_MONTH	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	99
SEL_351R_1_SEL.IB_MAX_DAY	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	99
SEL_351R_1_SEL.IB_MAX_YEAR	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	99
SEL_351R_1_SEL.IB_MAX_HOUR	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	99
SEL_351R_1_SEL.IB_MAX_MINS	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	99
SEL_351R_1_SEL.IB_MAX_SEC	MV	(?#<REAL>)|(?=IC)	80	Real	4	99.999
SEL_351R_1_SEL.IB_MIN	MV	(?#<REAL:1>)|(?=IC)	80	Real	4	888.8
SEL_351R_1_SEL.IB_MIN_MONTH	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	88
SEL_351R_1_SEL.IB_MIN_DAY	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	88
SEL_351R_1_SEL.IB_MIN_YEAR	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	88
SEL_351R_1_SEL.IB_MIN_HOUR	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	88
SEL_351R_1_SEL.IB_MIN_MINS	INS	(?#<INS:2>)|(?=IC)	80	Decimal	4	88
SEL_351R_1_SEL.IB_MIN_SEC	MV	(?#<REAL>)|IC	80	Real	4	88.888
SEL_351R_1_SEL.IC_MAX	MV	(?#<REAL:1>)|RESET	80	Real	4	999.9
SEL_351R_1_SEL.IC_MAX_MONTH	INS	(?#<INS:2>)|(?=IN)	80	Decimal	4	99
SEL_351R_1_SEL.IC_MAX_DAY	INS	(?#<INS:2>)|(?=IN)	80	Decimal	4	99
SEL_351R_1_SEL.IC_MAX_YEAR	INS	(?#<INS:2>)|(?=IN)	80	Decimal	4	99
SEL_351R_1_SEL.IC_MAX_HOUR	INS	(?#<INS:2>)|(?=IN)	80	Decimal	4	99

Figure 2.205 Example 2.7 Flex Parse Tags

Example 2.8 Parsing Strings

Although there is not an SEL type class expression for parsing a string value, you can easily do this by using a flex parse expression wrapped in parentheses ( ). The ( ) indicate this is a capturing search so the value is stored in the tag. Anything configured outside of the ( ) is still used for the search but will not be stored in the tag. To configure a flex parse expression to store a string value, set the **Tag Type** to **STR** and the **Treat As** column to **String** for that tag. Use

regular expression syntax, such as in *Table 2.126*, to indicate the string that is to be captured. If you wanted to capture each line label from the **MET M** command in *Example 2.7*, you could enter the following for the flex parse expression: **([A–Z, /(,/)]{1,6})**.

The ( ) wrap a capturing expression to indicate the value obtained should be stored in the tag.

The brackets [ ] wrap a list of values to search for. In this example, we are searching for the following:

- Any capitalized letter from A to Z
- Any spaces
- Any ( ) characters. Notice they must be escaped by placing a / before each of them.

The curly brackets { } wrap a min,max value.

The entire message indicates we want a group of characters containing any capitalized letters, spaces, ( ) characters, and we can have a minimum and maximum total length and repetition of any of the defined characters of 1 and 6, respectively.

Regex

A regular expression (regex) is a method for matching characters in a string of text. Regex is similar to, but far more powerful than, a search engine in a word processor, and can be used to match exact strings, ranges, parts of a string, beginning and ending of lines; to exclude certain strings; and much more. The RTAC uses Perl 5-compatible regex in flex parse messaging to extract data from returned message strings. You can use regex in the flex parse message, or you can use SEL type class expressions, and ACSELERATOR RTAC will convert the expression to regex for you.

Each regex attempts to find a single specified match. For example, if you applied the regex 43 to the string 19304-5043920-04399, it would begin searching at 193... and return the first instance of 43. If you applied the regex again, it would begin searching at 920 and return the second instance of 43. The regex search will always begin at the first character after the last successful matched string. The set of characters the regex is going to search is called a character set or, more commonly, a character class. The characters used in the search are referred to as tokens (alpha/numeric characters, spaces, special characters, etc.). Some searches look for places before, after or between characters instead of searching for a character. These are called anchors. For example, $ will match the end of a string before a line break.

Regex is very common in the computing industry, so there are many resources in books and on the Internet that contain detailed regex syntax and theory. *Table 2.126* contains some common regex expressions.

Table 2.126 Common Regular Expression Syntax

Metacharacter	Description	Example
[	Defines a character class. Match a single character out of a list.	[0-9a-fA-F] Matches a single hex character from a string, case insensitive.
\	Meaning one: Escape the next character. Several characters you may want to search for have special meaning in regex. Use the \ to tell regex to not interpret the meaning of the next character.	+ Searches for a "+" instead of interpreting the + as a regex command.
	Meaning two: Combine with certain characters to become shorthand character classes. There are many shorthand classes.	\d Matches a digit, as [0–9]. \b Matches a whole alphanumeric sequence, as \bmyword\b
^	Meaning one: A logical NOT of the character class when used in brackets [^].	q[^x] Matches "q" in "query" but will not match the "q" in Iraq because there are no characters after the latter "q".
	Meaning two: An anchor that matches the position before the first character in a line.	^J Matches before the "J" in "Jack" and the Beanstalk"
$	An anchor that matches right after the last character in a line.	k $ Matches after the "k" in "Jack and the Beanstalk"
.	Matches any single token.	ca. Matches cat, cap, car...
|	Logical OR alternation.	cat|dog Will match the word cat or the word dog.
?	Makes the preceding token optional.	colou?r Matches "color" or "colour".
*	Matches the preceding token zero or more times. Similar to ? except will match zero or more tokens of the preceding token or group.	[0–9].*\bdogs\b Matches the string "4 People were walking their dogs".
+	Matches the preceding token one or more times.	[1–9]+ Matches 9954 from the string "9954"
( )	Used for matching a group. All tokens within the ( ) are a group or single token.	go(fishing)? Matches "go" or "go fishing".
{ }	Specifies the number of repeats. Also specifies a min/max number of repeats as {min,max}. {2,} indicates there is a minimum of two repeats but no maximum.	[1–9][0–9]2 Matches 100 through 999 because the second character class repeats twice.
?=	Look ahead looks forward for a match but does not stop at the look ahead character. In the example, q(?=u) applied to the word "query", the parse returns true because it found a q and also looked ahead and found a u. The next search begins at the "u", not at the "e".	q(?=u) Matches the "q" in "query" but not in "Iraq" because it looked ahead for a "u". q(?!u) Matches the "q" in "Iraq" but not in "query".

eDNA

Overview

Configure an eDNA client Ethernet connection to communicate with an eDNA Universal Service such as data historians or other data archival solutions. The RTAC supports one eDNA client connection. This protocol is supported by the SEL-3555 and SEL-3532-4 in firmware versions R136 through R152. Projects containing an eDNA client device that are upgraded to firmware version R153 or later will have these devices automatically removed.

This section describes the configuration and use of the eDNA client connection in ACSELERATOR RTAC.

eDNA Client Configuration

Configure the eDNA client to communicate via Ethernet to an eDNA Universal Service. Create binary and analog tags in the eDNA client **Digitals** and **Analogs** tabs. Although each RTAC project can support only one eDNA client connection, you can provide a primary and failover IP address from the **Settings** tab.

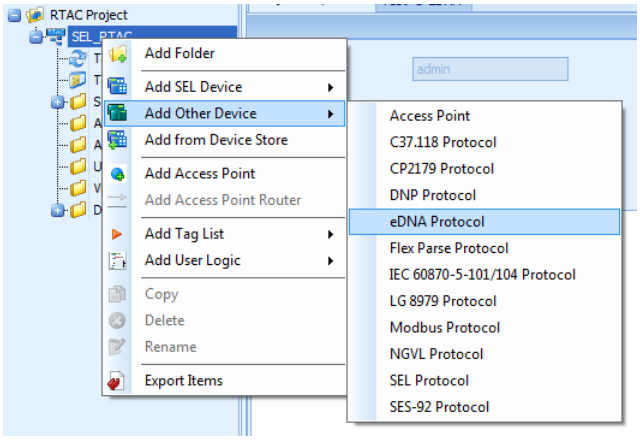

Figure 2.206 Insert eDNA Client Device

Give the device connection a unique name. Note that the only **Connection Type** available is **Client – Ethernet**.

Settings Tab

The **Settings** tab contains all configurable items necessary for communications. Refer to the **Description** column for information about each setting. Move the main window horizontal slider, resize the column width, or hover your mouse over the description cell to view the cell content in its entirety. Type any applicable comments in the blank column to the far right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

Add Client Device Data

Perform the following steps to add client device data.

Step 1. Click a device tag type tab (digitals or analogs) to add and configure tags.

Step 2. Click + to add tags (2,000 tag limit each for digitals and analogs).

Creating only the number of necessary tags helps optimize system performance.

Step 3. Change the names of the tags as necessary by using the **Tag Name** column.

Step 4. Change the point ID of each tag (using the **Point ID** column) as necessary to match the settings of the eDNA Universal Service that will be collecting these data from the RTAC.

Step 5. Change other tag-related information as necessary.

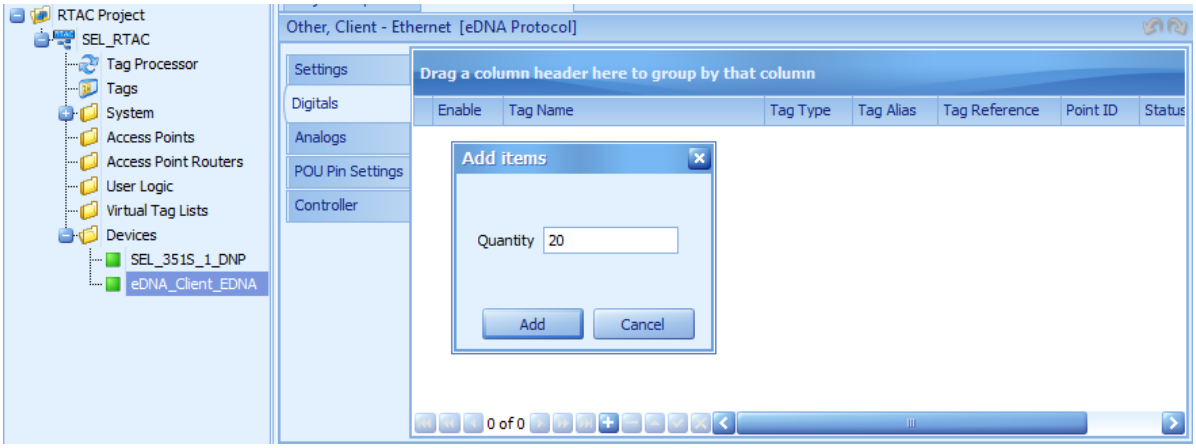

Figure 2.207 Add eDNA Client Tags

Device Tag Type Configuration Parameters

Each device tag type has parameters that must be configured correctly to ensure proper system operation.

Table 2.127 Common Device Tag Type Parameters

Parameter	Description	Default
Enable	Set to True to enable processing, and set to False to disable processing.	True
Tag Name	This parameter describes the tag. You can change this name as necessary.	The default tag name contains the device name, an abbreviation of the tag type, and is numbered 0–*n* tags.
Tag Alias	Enter an optional descriptive tag name into this field, and you can reference this tag alias anywhere in the RTAC project in place of the actual tag name.	
Tag Reference	See *Tag Mapping on page 533* for more details.	
Point ID	A unique name that is used to transmit the tag value to the eDNA Universal Service. The Point ID can have no more than eight characters.	The default Point ID contains an abbreviation of the tag type and is numbered 0–*n* tags.
Comment	User-entered comment field. The first 224 characters of this field will be transmitted to the eDNA Universal Service as the **Extended Description**.	

Table 2.128 Binary Output Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Supported tag types: SPS.	SPS
Status Value	The initialized value of the tag at startup.	False

Table 2.129 Analog Output Parameters

Parameter	Description	Default
Tag Type	See *Data Types on page 1127* for more details. Supported tag types: MV, CMV, INS.	MV
Inst Magnitude	The initialized instantaneous value at startup.	0

Parameter	Description	Default
Magnitude	The initialized dead-band value at startup.	0
Dead Band	The number of units of change necessary for magnitude to update to the value of Inst Magnitude (IF |instMag – mag| > db, then mag := instMag).	100
Zero Dead Band	The number of units at or below which a unit is forced to zero (IF |mag| < zeroDB, then mag := 0).	2
Max Value	The maximum value allowed for this point. If instMag > Max Value, then ".q.detailQual.outOfRange" is set.	+9.9999999e+036
H H Limit	The high-high alarm limit. Excursions beyond this limit cause the RTAC to generate a high-high alarm.	+9.999999e+035
H Limit	The high alarm limit. Excursions beyond this limit cause the RTAC to generate a high alarm.	1e+035
L Limit	The low alarm limit. Excursions beyond this limit cause the RTAC to generate a low alarm.	–1e+035
L L Limit	The low-low alarm limit. Excursions beyond this limit cause the RTAC to generate a low-low alarm.	–9.9999999e+035
Min Value	The minimum value allowed for this point (IF instMag < Min Value, then ".q.detailQual.outOfRange" is set).	–9.9999999e+036

Tag Mapping

The eDNA client has a built-in direct-assignment mechanism, so there is no need for the Tag Processor to map analogs and digitals. Note that this method of direct tag assignment assigns the value of the source tag directly to the value of the destination tag without modification. If you need any conditioning or manipulation of the source tag (such as scaling, offsetting, and logical combination) as part of the assignment, use the Tag Processor or user logic instead. The following steps detail how to map eDNA tags.

Step 1. Type in the **Tag Reference** column the name of the tag to which you want to map. Note that when you use this tag-mapping method, you cannot use the eDNA tag alias. The **Tag Alias** column will be grayed out to indicate its lack of availability. For more information about the **Tag Reference** column, see *Tag Reference on page 535*.

Step 2. Repeat for each tag in the eDNA client.

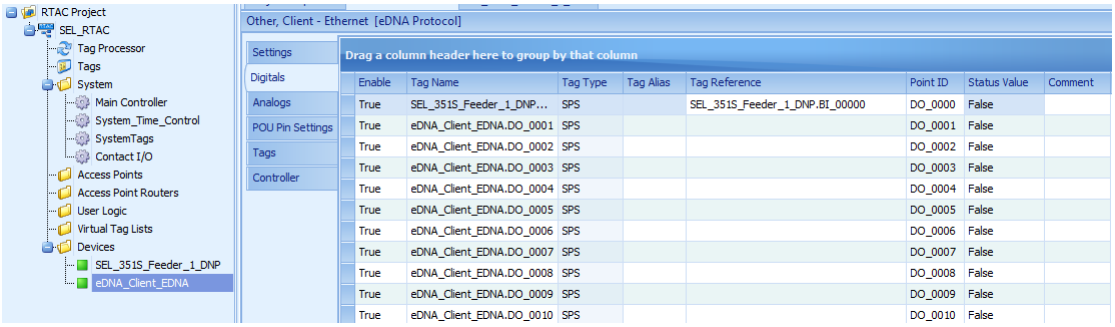

Figure 2.208 Mapping eDNA Client Tags

Table 2.130 POU Pin Settings

Parameter	Description	Default
Alternate_Connection_Status	When zero, the alternate connection is disconnected. When one, the alternate connection is disconnected. When two, the alternate connection is not in use.	0
Buffer_Overflow	Indicates that the RTAC was unable to process all eDNA tag event changes fast enough to avoid event loss. Asserts for one task cycle.	False
Buffer_Overflow_Count	Number of buffer overflows since last RTAC reset or power cycle.	0
Data_Cache_Queue_Count	Messages that have been queued to send to the eDNA Universal Service. Is zero if Data Cache Size is set to zero.	0
Data_Cache_Queue_File_Count	Number of files the data cache is currently using.	0
Data_Cache_Queue_Full	When True, the data cache is full.	False
Data_Cache_Queuing_Data	When True, the data cache is being used to store data.	False
Data_Cache_Send_Queue_Count	Number of messages that have been prepared to send to the eDNA Universal Service. Is zero if **Data Cache Size** is set to zero. Data_Cache_Send_Queue_Count – Data_Cache_Send_Queue_Count is equal to the number of messages that have been sent to the eDNA Universal Service.	0
EN	POU is enabled.	True
ENO	POU is enabled and initialized.	False
Issue_Data_Sync	When True a data synchronization message is being issued.	False
Issue_Data_Sync_Period	Time between data synchronization transmissions. This output is set by the **Issue Data Sync Period** in the **Advanced Settings** on the **Settings** tab.	T#0M
Message_Failure	When data cache size is set to zero, increases by one each time an event occurs while the RTAC is disconnected from the eDNA Universal Service.	False
Message_Failure_Count	Message failure count increases by one every time a message failure occurs.	0
Message_Received_Count	Message received count increases by one every time a message is received from the eDNA Universal Service.	0
Message_Sent_Count	Message sent count increases by one every time a message is sent to the eDNA Universal Service. Only increases if **Data Cache Size** is set to zero. This value will increase regardless of whether the eDNA Universal Service successfully accepts a message.	0
Message_Success_Count	Increases by one every time a message is successfully sent to the eDNA Universal Service. Only increases if **Data Cache Size** is set to zero.	0
NAK_Count	Increases by one when the eDNA Universal Service responds to a transmission with a negative acknowledgment.	0
Offline	Asserts when the RTAC is unable to communicate to the eDNA Universal Service.	True
Primary_Connection_Status	When zero, the primary connection is disconnected. When one, the primary connection is connected. When two, the primary connection is not in use.	0
Using_Primary_Connection	When True, the primary connection is in use. When False, the primary connection is not in use.	False

Tag Reference

Creation of a data assignment through use of the **Tag Reference** column differs from creation of a data assignment through the Tag Processor or user logic. Instead of copying the value of the tag from the source tag to the destination tag, the software creates a direct link to the source tag in the memory of the RTAC. Because of this, working with reference tags within RTAC settings differs from use of the Tag Processor or user logic in the following ways:

- No data manipulation (such as scaling, offsetting, or logical math) can be performed on the data prior to assignment.
- Once an eDNA tag has had data assigned to it through use of the **Tag Reference** column, it is not accessible from elsewhere in the RTAC settings. Only the tag placed into the **Tag Reference** column will be accessible.

Tags

See *Tags (Overview) on page 174* for a description of the **Tags** tab.

Controller

See *Controller (Advanced Usage) on page 173* for a description of the **Controller** tab.

eDNA Protocol Implementation Notes

This section contains additional details about implementation of the eDNA protocol in the RTAC.

- The eDNA extended ID will be composed of the first 128 characters of the tag name.
- The eDNA extended description will be composed of the first 224 characters of the comment field associated with each tag.
- The eDNA data cache clears for transmission of new settings to the RTAC, the eDNA data cache will clear. There is no clearing of the cache if the RTAC is turned off and then back on.

CDC Type 2

The CDC protocol is a bit-based protocol that is only supported via expansion serial cards for the SEL-3555 and SEL-3560 RTACs prior to firmware version R144-V0. In firmware versions R144-V0 and later, all RTAC variants support CDC Type 2.

CDC Type 2 Client Configuration

Configure a CDC Type 2 client to communicate via serial to IEDs by clicking the Extensions icon, as shown in *Figure 2.209*. The number of supported CDC Type 2 clients in a single RTAC project is restricted to the number of physical serial ports available. Use the Tag Processor to map collected data to server tags.

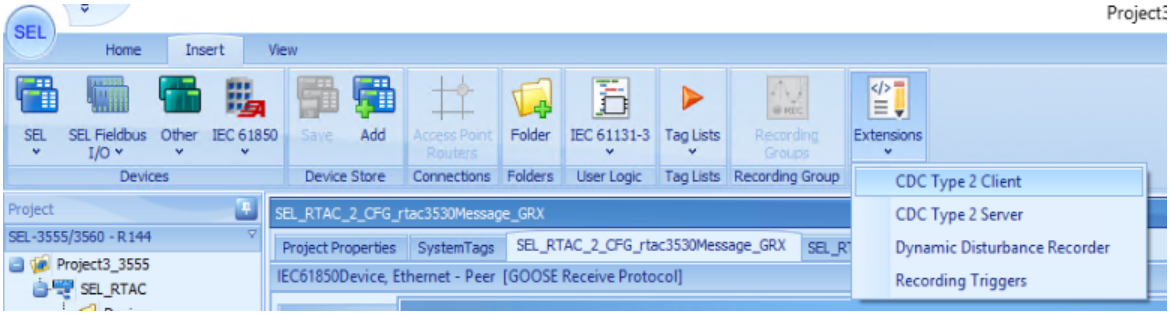

Figure 2.209 Add CDC Type 2 Client

Table 2.131 lists the function codes that the CDC Type 2 client will respond to. All other messages received by the server will not generate a response.

NOTE
Function Code Values are in hexadecimal notation.

Table 2.131 Supported Function Codes

Function Code	Description
00	Scan 1
03	Direct Set Point
05	Control Trip (select)
06	Control Close (select)
07	Set Point (select)
08	Operate
0B	Direct - Trip
0C	Direct - close

Settings Tab

The **Settings** tab contains all configurable items for communications. The **Description** column shows details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description.

Add Client Device Data

Step 1. Click a device tag type tab to add tags.

Step 2. Click + to add tags. Aliases cannot be assigned to tag names in the CDC client.

Step 3. Change other tag-related information as necessary.

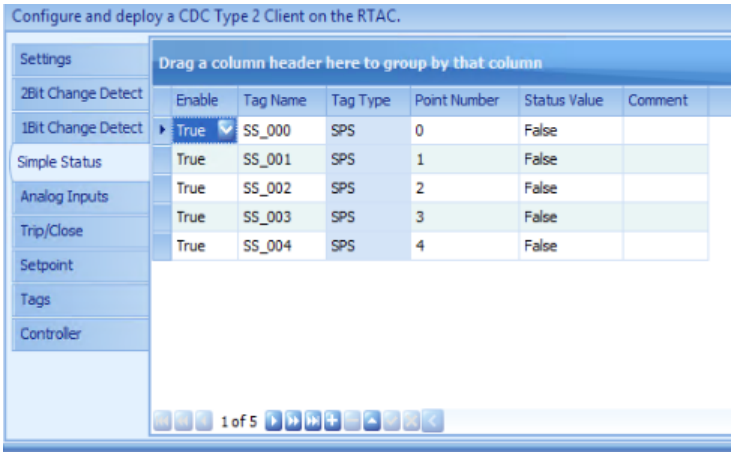

Figure 2.210 Add CDC Type 2 Tags

Repeat these steps to configure all CDC Type 2 client connections. When finished, configure the Tag Processor to populate server connection tags with collected CDC Type 2 client values.

Each tag type per the CDC Type 2 protocol supports the maximum number of tags, as shown in *Table 2.132*.

Table 2.132 CDC Type 2 Tag Types

Tag Type	Supported Tags Per CDC Client
2bit Change Detect	256
1bit Change Detect	256
Simple Status	256
Analog Inputs	128
Trip/Close	64

Controller Pins

Use POU pin settings to view the present state of the CDC Type 2 client operation and to modify behavior of the protocol. See *Table 2.133* for the settings descriptions.

Table 2.133 CDC Tag Type 2 Client Pin Descriptions

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update tags or process changes to tags while this input is True.	False
Disable_Controls	Input BOOL	If True, the processing of any controllable tags is blocked.	False
Reset_Statistics	Input BOOL	On rising-edge trigger, all counter POU output are reset.	False
ENO	Output BOOL	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is False when protocol communications are in process. Note: Protocol communications may be in process but no successful data exchange due to settings configuration issue.	False

Pin Name	Pin Type	Description	Default
Controls_Disabled	Output BOOL	Asserted when Disable_Controls input is asserted. This indicates the client will not issue control commands.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	False
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have successfully been sent or received.	0
Message_Success_Count	Output UDINT	Running sum indicating the number of messages successively sent and received communicating with the remote device.	0

CDC Type 2 Server Configuration

Configure a CDC Type 2 server to communicate via serial to IEDs by selecting the Extensions icon. As many as ten CDC Type 2 servers are supported in a single RTAC project. Use the Tag Processor to map collected data to CDC Type 2 server tags.

Supported Function Codes

Table 2.134 lists the function codes that the CDC Type 2 server will respond to. All other messages received by the server will not generate a response.

NOTE
Function code values are in hexadecimal notation.

Table 2.134 Supported Function Codes

Function Codes	Description
00	Scan 1
01	Scan 2
02	Scan 3
21–2F	Scan 3X
03	Direct Set Point
04	No Operation
05	Control Trip (select)
06	Control Close (select)
07	Set Point (select)
08	Operate
09	Reset
0A	Accumulator Freeze

Function Codes	Description
0B	Direct - Trip

To add a CDC Type 2 server connection, select **CDC Type 2 Server** from the **Custom Applications** menu. Give the device connection a unique name.

Settings Tab

The **Settings** tab contains all configurable items for communications. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description.

Add Server Device Data

The following steps detail the process of adding server device data.

Step 1. Click on a device tag type to add tags.

Step 2. Click + to add tags. Aliases cannot be assigned to tag names in the CDC server.

Step 3. Change other tag-related information as necessary.

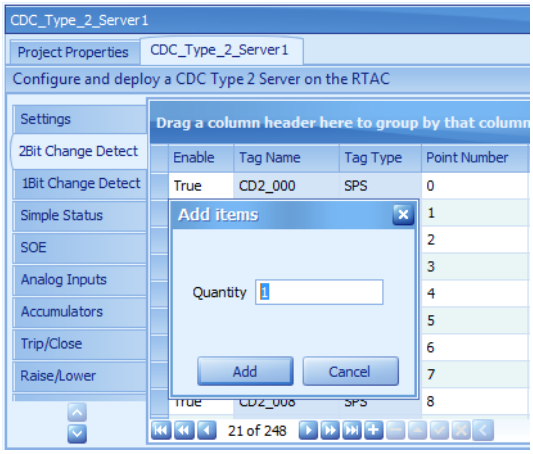

Figure 2.211 Add CDC Type 2 Tags

Repeat these steps to configure all CDC Type 2 server connections. When finished, configure the Tag Processor to populate these server connection tags with actual values.

Each tag type per the CDC Type 2 protocol supports the maximum number of tags.

Table 2.135 CDC Type 2 Tag Types

Tag Type	Supported Tags Per CDC Server
2bit Change Detect	256
1bit Change Detect	256
Simple Status	256
SOE	256
Analog Inputs	128
Accumulators	32
Trip/Close	64
Raise/Lower	8
Setpoint	16

Controller Pins

Use POU pin settings to view the present state of the CDC Type 2 server operation and to modify some of the behavior of the protocol. See *Table 2.136* for the settings descriptions.

Table 2.136 CDC Type 2 Server Pin Descriptions

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update tags or process changes to tags while this input is True.	False

Pin Name	Pin Type	Description	Default
Disable_Controls	Input BOOL	While True, the processing of any controllable tags is blocked.	False
Reset_Statistics	Input BOOL	On rising-edge trigger, all counter POU output are reset.	False
ENO	Output BOOL	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is False when protocol communications are in process. Note: Protocol communications may be in process but no successful data exchange due to settings configuration issue.	False
Controls_Disabled	Output BOOL	Asserted when Disable_Controls input is asserted. This indicates the client will not issue control commands.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	False
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have successfully been sent or received.	0
Message_Success_Count	Output UDINT	Running sum indicating the number of messages successively sent and received communicating with the remote device.	0
Accumulator_Freeze	Output BOOL	Asserts for one processing interval when a freeze request is received by the server.	False
SOE_Overflow	Output BOOL	Asserted for a single processing interval when an SOE event could not be queued.	False
SOE_overflow_Count	Output UDINT	Running sum indicating the number of messages that could not be queued.	0

SNMP

SNMP Manager/Client Configuration

Configure a Simple Network Management Protocol (SNMP) Manager/Client connection to communicate via Ethernet to IEDs. The RTAC will poll data from these IEDs and store the data it receives in tags. Use the Tag Processor to map these data to any protocol, logs, user logic, etc. The SNMP protocol typically refers to IEDs that make SNMP requests or collect data as managers (in the RTAC platform, this is the same functionality as a client) and IEDs that provide SNMP data as agents (in the RTAC platform, this is the same functionality as a server). As such, the terms manager/client and agent/server will be used interchangeably in the RTAC platform. The RTAC supports version 2C (v2C) of the SNMP protocol.

To add an SNMP Manager/Client connection, select **SNMP** from the **Other Device** menu.

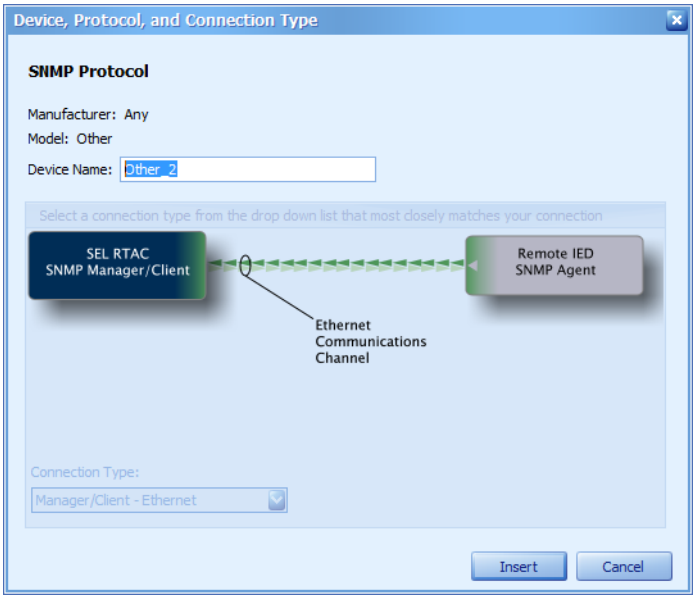

Figure 2.212 Adding SNMP Manager/Client

Give the device connection a unique name and select the connection type, as shown in *Figure 2.212*. Refer to *Client Connection Types on page 167* for a description of each connection type.

Settings Tab

The **Settings** tab contains all configurable items for communications. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire text of an item description. Type any applicable comments in the blank column to the far right. Click the **Advanced Settings** check box to enable configuration of advanced settings.

Polls Tab

The **Polls** tab contains all the poll requests that the SNMP client will use to collect data from the server. To add additional poll requests use the + button. As many as 50 polls are supported. Each poll will request a list of OIDs, which are configured using the Status OIDs and Control OIDs.

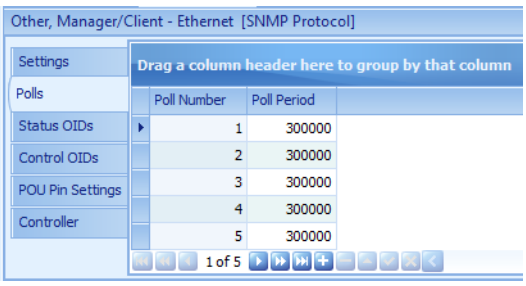

Figure 2.213 SNMP Manager/Client Polls

Table 2.137 Poll Tab Parameters

Column Name	Description
Poll Number	Name of poll group.
Poll Period	The period in which the RTAC will generate this request. The units for poll period are in milliseconds. A value of 0 disables the poll from being issued on a periodic basis. The range of poll period is 0, 1000–100000000 milliseconds.

SNMP OIDs

To configure tags for the SNMP Manager/client, go to the **Status OIDs** or **Control OIDs** tab.

Step 1. Click on the tab for the appropriate tag type to add and configure tags.

Step 2. Click + to add tags. Create only the necessary number of tags to optimize system performance.

Step 3. Rename the tags as necessary.

Step 4. Configure other tag parameters as necessary.

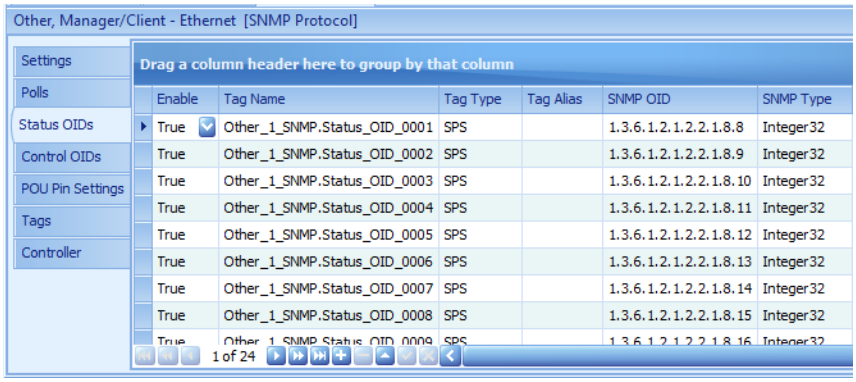

Figure 2.214 SNMP Manager/Client Sector Map

SNMP-Specific Tag Configuration

There are several columns specific to SNMP points. Each have the following behavior.

Table 2.138 SNMP Point Behavior

Column Name	Description
SNMP OID	This is the OID that the RTAC will issue to the server/agent. The period preceding the first digit is optional.
SNMP OID Name	Each digit in the OID has a name correlation. The OID can also be represented by the named format as well as the number format.
SNMP Type	This is the type that the data will be returned to the RTAC via the SNMP protocol definition. This field shows the available tag formats SNMP data can be represented as in the RTACs logic engine.
Size	This setting only applies for the data type STRC and SNMP data type Octet String. When a rising edge is applied to the trigger bit in the operSTR structure, the RTAC will write the number of bytes specified by the Size setting from the string in the ctlVal in the operSTR structure.

Column Name	Description
Treat As	This setting only applies when the RTAC data type is STR and the SNMP Type is OCTET String. Since this SNMP data type can represent both text and number data, these data can be used two ways in the RTAC logic engine. When set to Text, the most significant bit of the data received by the SNMP client will be placed in the most significant bit of the STR tag, creating a visible string. This causes the RTAC to treat the received data as text. When set to Number, the data received by the SNMP client will have the least significant bit placed in the least significant bit of the STR tag. In this mode, the tag will not appear as an ASCII string when viewed while online with the RTAC. This causes the RTAC to treat the data as a received integer.
Poll Number	This setting tells the RTAC which poll request to ask the agent/server for the configured OID. Multiple tags are assignable to the same poll number.

Polling Behavior of SNMP Manager/Client

SNMP uses UDP to exchange information. UDP is a connectionless transport protocol. This means that unlike TCP the RTAC will only know if the agent/server is active and communicating when it receives a response or unsolicited message. If the RTAC generates a request to the agent/server and receives no response for the duration of request time-out setting, the RTAC will issue a series of retry requests. Once the configured series of request retries and subsequent time-outs have expired, the RTAC will assert the offline pin until the next successful communication sequence occurs with the agent/server. During this period of time, all other communication requests will be paused and queued until a response is returned or retries are expired.

Configuring SNMP Traps/Inform in the RTAC

Traps and Inform messages are unsolicited messages sent from the agent/server to the manager/client without a request from the manager/client. When this unsolicited message is sent to the RTAC it will contain the status OID number and the status value. As long as the correct OID is configured in the **Status OIDs** or **Control OIDs** tab, the RTAC will receive the trap and update the appropriate tag. Trap and Inform messages are configured in the agent/server IED for sending data to managers/clients.

POU Pins

Use POU pin settings to view the present state of the SNMP Manager/client operation and to modify some of the behavior of the protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab. See *Table 2.139* for the settings descriptions.

Table 2.139 SNMP Manager/Client POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update tags or process changes to tags while this input is True.	False
Disable_Controls	Input BOOL	While True, the processing of any controllable tags is blocked.	False
Reset Statistics	Input BOOL	On rising-edge trigger, all counter POU output are reset.	False

Pin Name	Pin Type	Description	Default
Issue_<XX>[a]	Input BOOL	Request poll to be sent, on the rising edge.	False
Issue_<XX>_Period[a]	Input: Time (0, 25–100000000 milliseconds)	Defines the interval used by the Client to issue the poll. Setting to zero causes the related function to be non-periodic.	Reference Polls–Message_Period
ENO	Output BOOL	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is False when protocol communications are in process. Note: Protocol communications may be in process but no successful data exchange due to settings configuration issue.	False
Controls_Disabled	Output BOOL	Asserted when Disable_Controls input is asserted. This indicates the client will not issue control commands.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote device.	False
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format. This may be because of an incomplete response or corrupted data in the message response.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have successfully been sent or received.	0
Response_Timeout_Count	Output UDINT	Count of Application Layer Message response timeouts.	0
Issue_<XX>_DN[a]	Output BOOL	Asserts for a single processing interval once the message is completed successfully. Completion of the message is dependent on the configuration of the message.	False
Issue_<XX>_Delay[a]	Output BOOL	Asserts when this message is triggered and the previous triggering of this message has not completed. Deasserts when on the rising-edge of Issue_<Name>_DN.	False
Last_Rec_Error_Message	Output String(255)	Contains the last received error message. The message displayed is the result returned to the RTAC from the SNMP agent/server.	"
Data_Type_Mismatch	Output BOOL	Will assert if an OID is returned with a data type that does not match the configured data type. This will be cleared on a rising edge of Reset_Statistics.	False

[a] <XX> = Each configured poll.

SNMP Agent/Server Configuration

The SNMP protocol typically refers to IEDs that make SNMP requests or collect data as managers (in the RTAC platform, this is the same functionality as a client) and IEDs that provide SNMP data as agents (in the RTAC platform, this is the same functionality as a server). As such, the terms manager/client and agent/server will be used interchangeably in the RTAC platform. The RTAC supports version 2C (v2C) of the SNMP protocol. To add an SNMP Manager/Client connection, select **SNMP** from the **Other Device** menu.

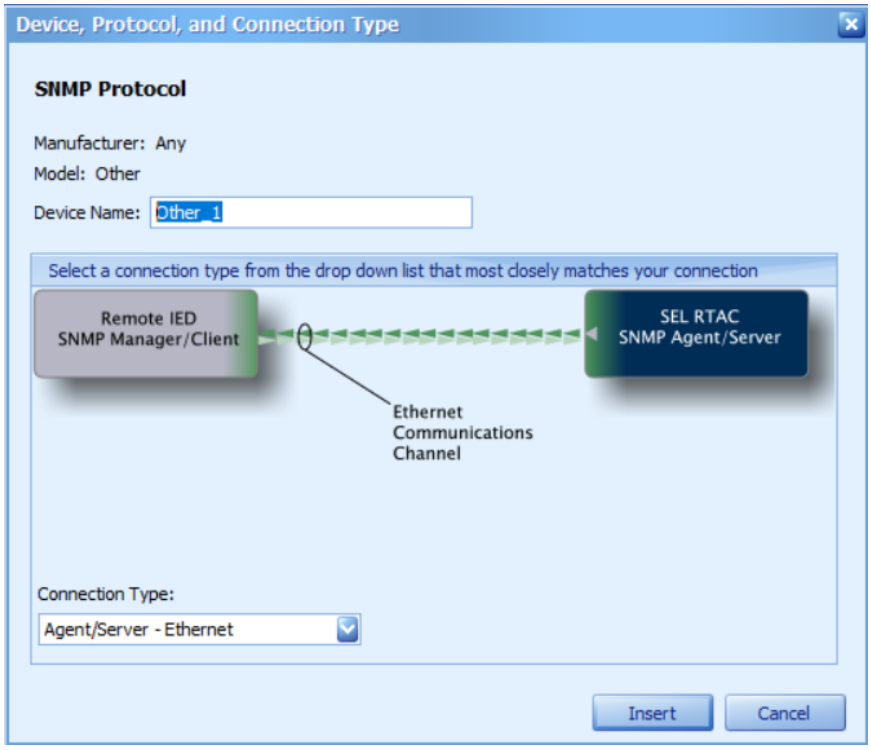

Figure 2.215 Adding SNMP Manager/Client Connection

Give the device connection a unique name and select the connection type, as shown in *Figure 2.215*. Refer to *Client Connection Types on page 167* for a description of each connection type. Only a single instance of an SNMP agent can be added to the RTAC project. Because SNMP is UDP-based, it does not maintain an active connection to a single client. The SNMP agent/server can be configured to answer requests only from a list of manager/client IP addresses or accept requests from any manager/client.

Settings Tab

The **Settings** tab contains all configurable items for communications. Check the **Description** column for details on each configuration item. Move the slider or hover your cursor over a description to see the entire description. Type any applicable comments in the blank column to the right. Select the **Advanced Settings** check box to enable configuration of advanced settings.

SNMP Agent Data

The RTAC SNMP agent implements the system and interface MIB. It provides additional system data covered in the following table. The SNMP agent/server does not allow for any custom data mappings.

System Tag	Description	SNMP OID	SNMP Data Type
CPU_Burden_Percent_5_Second_Average	The five second average CPU burden percentage	.1.3.6.1.4.1.31823.1.3500.1.1.1.0	Integer32
Memory_KBytes_Used	The number of Kilobytes of memory in use	.1.3.6.1.4.1.31823.1.3500.1.1.2.0	Integer32
Mainboard_Temperature	The temperature of the mainboard in Celsius	.1.3.6.1.4.1.31823.1.3500.1.1.3.0	Integer32

POU Pins

Use POU pin settings to view the present state of the SNMP agent/server operation and to modify some of the behavior of the protocol. Setting the **Visible** field to True will cause the POU pin to appear in the **Controller** tab.

Pin Name	Pin Type	Description	Default
EN	Input BOOL	The EN input enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Disable_Tag_Updates	Input BOOL	The POU will not update tags or process changes to tags while this input is True.	False
Communications_Offline_Timer	Input TIME	If the SNMP Agent/Server does not receive a request for a time period longer than what is specified by this pin the offline pin will assert.	T#10s
Reset_Statistics	Input BOOL	On rising-edge trigger, all counter POU output are reset.	False
Message_Sent_Count	Output UDINT	Running sum indicating the number of messages transmitted to the remote devices.	0
Message_Received_Count	Output UDINT	Running sum indicating the number of messages received from the remote device.	0
Message_Failure	Output BOOL	Asserts for a single processor cycle when a message is processed that does not conform to the expected protocol format.	False
Message_Failure_Count	Output UDINT	Running sum indicating the number of messages that have been detected as failed messages.	0
Invalid_Function_Block_Input	Output BOOL	The function block has received invalid input which it cannot process.	False
ENO	Output BOOL	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	This output is FALSE when protocol communications are in process. **NOTE** If protocol communications are in process, but there is no successful exchange of data, a settings configuration issue may be present.	False

File Transfer Protocol

Overview

Configure a file transfer protocol (FTP) server POU to communicate with a remote FTP client. The FTP server can use FTP over SSH (SFTP), but does not support FTP over SSL/TLS (FTPS). The FTP server will support as many as 10 simultaneous connections.

The FTP server supports the collection of files from the RTAC under the following directories:

- Events: This includes events from SEL CEV, SEL Comtrade, MMS Comtrade, GE Comtrade (Modbus), Alstom Comtrade (Courier), IEC 60870-5-103, and Axion Comtrade files (from CT/PT cards).
- File: This includes any files uploaded or created using the FileIo library.
- Projects: If the account type used is administrator or engineer, the FTP server will make any projects uploaded through the web interface available.
- CID: If an IEC 61850 configuration is included in the RTAC project, the CID file for the RTAC will be available in this directory.
- Logs: This directory contains the log information for the FTP server.
- ETHERNETIP: This directory contains EtherNet/IP configuration information.

Table 2.140 shows the read/write access to folders based on the account level of the user who accesses the FTP server.

Table 2.140 Read/Write Access By Account Level

Account Type	Events	Files	Projects	CID	Logs	ETHERNETIP	Configuration	Audit
Administrator	Read	Read/Write	Read/Write	Read	Read	Read	Read	Read
Engineer	Read	Read/Write	Read/Write	Read	Read	Read	No Access	No Access
User Manager	Read	Read	No Access	No Access	No Access	No Access	No Access	No Access
Monitor	Read	Read	No Access	No Access	No Access	No Access	No Access	No Access
HMI Operator	Read	Read	No Access	No Access	No Access	No Access	No Access	No Access
FTP User	Read	Read/Write	No Access	No Access	Read	No Access	No Access	No Access

The FTP server will support authentication either with local RTAC accounts or through any configured LDAP accounts.

FTP Logging

A log file of FTP server interactions is kept on the RTAC. This log file will grow to a maximum of 10 MB. Once it reaches this size, a second log file will begin. Once the second log file reaches 10 MB, the first log file is truncated and new activity is logged to that file. This rotation continues as each log file reaches its maximum file size. These log files are available via the web interface or the FTP server.

FTP Server Configuration

Configure the FTP server to communicate via Ethernet to an FTP client. Since the FTP protocol is designed to transfer files, no tag configuration parameters will be available, unlike other configurable server protocols in the RTAC. Adding the FTP server POU to the project configuration enables the project to communicate with as many as ten FTP client connections with a single defined POU in the RTAC project during runtime.

Settings Tab

The **Settings** tab contains all configurable items necessary for communication. Refer to the description column for information about each setting. Move the main window horizontal slider, resize the column width, or hover your mouse over the description cell to view the cell content in its entirety. Type any applicable comments in the blank column to the far right.

All connections to the RTAC FTP server must use the same connection type. You cannot configure a mix of FTP and SFTP connections. For FTP-based communications, the RTAC contact port is configurable. The **Settings** tab contains the ability to restrict access to a certain set of IP addresses allowed to access the FTP server. You can configure the server to accept all FTP connection requests, or restrict access to a comma-separated list of FTP clients who will be allowed to authenticate and use the FTP server. In addition to whitelisting IP addresses, Ethernet interfaces on the RTAC can be blacklisted from FTP access. In the **Settings** tab, you can enter a comma-separated list that will prevent FTP communications on that Ethernet interface. For example, if Blocked Network Interfaces is set to "Eth_F, Eth_02," only Ethernet Port 1 on that RTAC can receiving FTP connection requests, regardless of the Allow Anonymous IP Client or Client IP Address(es) settings. When the FTP POU is added to the RTAC configuration, multiple clients are able to simultaneously access the file system and read files at the same time.

Table 2.141 POU Pin Settings

Parameter	Description	Default
En	Enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Reset_Statistics	On rising-edge trigger, all counter POU output are reset.	False
Active Connection	Number of currently connected FTP clients	0
ENO	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Files_Downloaded	The number of files that have downloaded from the RTAC since the last rising edge of ENO or Reset_Statistics. If no manipulation of EN or Reset_Statistics has been performed, this number will often reflect the number of files downloaded since the last project download or power cycle.	0

Parameter	Description	Default
Files_Uploaded	The number of files that have uploaded to the RTAC since the last rising edge of ENO or Reset_Statistics. If no manipulation of EN or Reset_Statistics has been performed, this number will often reflect the number of files uploaded since the last project download or power cycle.	0
Offline	False when protocol communications are in process. Note: If protocol communications are in process, but there is no successful exchange of data, a settings configuration issue may be present.	False

Web API Communications

Web APIs are available for data exchange in firmware versions R146-V0 and later. All API communications require an authenticated user using basic authentication in https with a valid user account on the RTAC that has the appropriate permissions. Each API documents the necessary permissions.

Any data sent or returned via the APIs that represent a time stamp must conform to the ISO 8601 string definition of a time stamp.

API Documentation

Web API formats, inputs, and outputs are documented on the RTAC web interface. Click on an API category to see additional details about each API.

Only authenticated users can see all details of each API, including the description of each API and its inputs, outputs, and potential returned error messages.

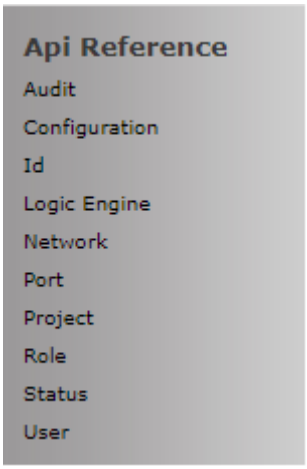

Figure 2.216 API Documentation Example

Network Audit Utilities API

The network audit utilities are only supported on the SEL-3350, SEL-3532, SEL-3555, and SEL-3560. Audits are restricted to local area networks only and cannot be performed in the 127.0.0.0/8 network. The network audit utility includes the following functionality:

- Targeting of a single host, multiple hosts, or an entire network
- Host discovery
- Reporting of each open TCP and UDP port for each host listed or discovered

Audit results are available in the AUDITS directory on the RTAC file manager.

Use the API to trigger a network audit and then use the response to retrieve the results in a separate request.

Starting in firmware version R147-V0, network audits can also be initiated and collected on the RTAC's web interface.

Starting in firmware version R150-V0, network audits can also be initiated and collected via the RTAC's logic engine.

Auth API

The Auth API allows an authorization token to be generated that can be used with additional API requests (instead of using RTAC account credentials). The token is valid for one hour after generation.

Configuration API

The Configuration API provides an aggregate response to multiple other API calls, returning all the information in a single response. Data returned by this API include information from the ID, Status, Fingerprint, Ports, Network, Users, Role, and Projects APIs.

Fingerprint API

The Fingerprint API provides the ability to track RTAC configuration changes by exporting a 40-digit, hexadecimal fingerprint value. This value is created based on the following items and will change when any of them change:

- Password Vault Entries
- Logic Engine Application
- Project Settings
- Ethernet Settings
- Hosts
- URL Whitelist Settings
- Web Proxy Settings
- Website Settings
- X.509 Certificates

- CA Certificates
- SSH Authorized Keys
- SSH Host Keys
- LDAP Settings
- User Accounts
- RADIUS Settings
- HMI Diagrams
- Licensed Features
- Firmware ID (FID)
- Serial Number

Firmware API

The Firmware API facilitates a staged firmware update to the RTAC where the firmware upgrade file is first sent to the RTAC and then applied with a separate command.

HMI API

The HMI API provides the ability to upload, list, and delete RTAC HMI projects in .hprjson or .hprz format.

ID API

The ID API provides summary information about the RTAC relating to firmware and licensing. It contains the following information:

- Serial Number
- Product Number
- Firmware Version
- Firmware Hash (SHA-256)
- BIOS Version
- Licensed Features

Logic Engine API

The Logic Engine API allows current tag information to be queried. Tags or variables defined in IEC 61131-3 logic are not available via this API. The logic engine API allows users to get current values from the logic engine and update logic engine values through the API. Each request has its own permission requirements. A tag name referenced in the URL must have the following format: Global Variable list name/variable name. For example, if a DNP client had the configuration name feeder_2_DNP and a binary input name of BI_0000, the tag name in the URL would be feeder_2_DNP/BI_0000. POU pins are also available—to get the offline pin status, the tag name would be feeder_2_DNP_POU/Offline. Tag names are referenced in the same manner in logic, but instead of the . notation, a "/" is used.

Write Logic Engine Tag

The write logic engine tag request will update the logic engine value for the requested tag name. There are several requirements for the write to be successful:

- Write format must exactly match the tag structure as returned in the GET request for logic engine value response
- No overflow on any integer or float type
- Enumeration strings are valid
- Strings contain valid ASCII characters
- Strings cannot contain any Unicode special characters
- Hexadecimal values are formatted with a leading 0x
- Datetime value adheres to valid ISO 8601 standard string for date and time
- Tag List name and tag name are separated by "/"

Network API

The Network API provides information about the network interfaces on the RTAC.

Required Permissions:

- API Login
- Network Read

The following information can be accessed via this API:

- List of interfaces on the RTAC
- MAC addresses
- Operational status of each interface
- IP address and configured gateway address
- Configuration information about the interfaces

Ports API

The Ports API provides information about the open ports on the RTAC interfaces. It will return all TCP and UDP ports that are open on the RTAC including the service that is using the port.

Projects API

The Projects API provides information about and allows interaction with the active RTAC project. It also provides information about device connections in the project including the name, protocol type, and communication status (disabled, offline, online) of those devices.

Role API

The Role API is for viewing and managing RTAC user roles. Custom user roles can be added and given permissions that grant access to specific RTAC data and actions. The full list of permissions can be found on the User Roles section of the RTAC web interface by adding a new user role. The factory-default user roles and their respective permissions cannot be deleted or edited but can be viewed using this API.

Serial API

The Serial API provides information about the usage and configuration of serial ports in the active RTAC project.

The following information is returned in this API.

- Serial Port Number (e.g., Com_01)
- Port Configuration (baud rate, data bits, stop bits, etc.)
- Port Type (EIA-232 or EIA-485)
- Port Power Enabled/Disabled

Status API

The Status API provides information about the project on the RTAC including memory usage, storage usage, and users logged in.

The following information is returned in this API.

- Active Project Name
- Current Memory Statistics
- Current Storage Statistics
- Logged In User Statistics

Users API

The Users API provides information about the local users on the RTAC.

The following information is returned in this API:

- Role associated with the account
- Permissions associated with the account
- Time when the account was created
- Time when the account password was last changed

EtherNet/IP

Overview

This section describes the EtherNet/IP protocol implementation on the RTAC, including general specifications of the implementation, CIP object model, allocation of CIP connections, ACSELERATOR RTAC settings, and the Electronic Data Sheet (EDS) file.

The RTAC supports three ways of exchanging data via EtherNet/IP protocol:

- Implicit Message Adapter The I/O data are mapped in Assembly object instances. The RTAC exchanges this I/O data via EtherNet/IP implicit class 1 connections with a remote EtherNet/IP scanner device using UDP packets.
- Explicit Message Server The I/O data are mapped in Assembly object instances. The RTAC responds to generic TCP EtherNet/IP explicit message requests initiated by a remote EtherNet/IP client device.
- Explicit Message Client The RTAC initiates vendor-specific explicit message services to exchange data with a remote EtherNet/IP explicit message server.

Specifications

EtherNet/IP Services

Supported Services	Implicit Message Adapter (Class 1)
	Explicit Message Server (Class 3 and unconnected)
	Explicit Message Client (Unconnected)

CIP Model

Implemented objects	Identity object
	Message Router object
	Assembly object
	Connection Manager object
	File object
	TCP/IP object
	Ethernet link object

Implicit Message Adapter Specifications

Number of connections	As many as 128 (Class 1 and Class 3)
Class 1 connection types	Unicast
	Multicast
Class 1 connection transport types	Exclusive owner
	Input only
	Listen only
Class 1 connection trigger types	Cyclic
	Change of State
Input Only heartbeat connection point	238
Listen Only heartbeat connection point	237

Explicit Message Client Specifications

Supported Message Types	CIP[a] and PCCC[b]
CIP services supported	CIP Data Table Read (0x4C) CIP Data Table Write (0x4D) CIP Read Tag Fragmented (0x52) CIP Write Tag Fragmented (0x53)
PCCC services supported	SLC Protected Typed Logical Read (CMD=0x0F, FNC=0xA2) SLC Protected Typed Logical Write (CMD=0x0F, FNC=0xAA)
Message type	Unconnected (UCMM)

[a] Supported devices: Rockwell Automation controllers ControlLogix and CompactLogix.
[b] Supported devices: Rockwell Automation controllers Micrologix 1000/1400 and SLC5/05.

CIP Data Model

Profile

Class Name	Class ID	Number of Instances
Identity Object	0x01	1
Message Router Object	0x02	1
Assembly Object	0x04	Determined by the user based on application
Connection Manager Object	0x06	1
File Object	0x37	2
TCP/IP Object	0xF5	See *TCP/IP Object (0xF5) on page 563*
Ethernet Link object	0xF6	See *Ethernet Link Object (0xF6) on page 564*

Identity Object (0x01)

Instances Implemented

The RTAC implements one instance (instance ID = 1) of the identity object.

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	1	The revision of this CIP object
2	Max Instance	GET	UINT	1	The maximum Assembly object instance ID
3	Number of Instances	GET	UINT	1	Total number of Assembly objects
4	Optional Attribute List	GET	[UINT, Array of UINT]	[21, [0,...,0]]	[Number of optional instance attributes, List of optional instance attributes]

Attr. ID	Name	Access	Data Type	Default	Description
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	21	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Vendor ID	GET	UINT	865	
2	Device Type	GET	UINT	0x0E	
3	Product Code	GET	UINT		Refer to *Managing Multiple RTAC EtherNet/IP Configurations in the Same Network on page 568*
4	[Major Revision, Minor Revision]	GET	[USINT, USINT]	[1,1]	
5	Status	GET	WORD		Refer to status WORD bits table
6	Serial Number	GET	UDINT		Lower 6 octets of the Eth_1 port MAC address
7	Product Name	GET	STRING	'RTAC'	Refer to *Managing Multiple RTAC EtherNet/IP Configurations in the Same Network on page 568*
21	Catalog Number	GET	STRING	'SEL-RTAC'	

Status WORD Bits Table

The Status WORD bits not listed are always set to 0.

Bit Number	Name	Description
0	Owned	TRUE if at least one remote scanner has established an Exclusive Owner class 1 connection to the RTAC FALSE if the RTAC has no active Exclusive Owner connections to a scanner
2	Configured	Always TRUE
4 to 7	Extended Device Status	Hexadecimal value: 2: A class 1 connection is timed out 3: No class 1 connection is established 6: At least one class 1 connection is active 7: In any other case

Supported Services

Service Code	Service Name	Class	Instance	Description
0x01	Get Attributes All	Yes	Yes	Returns a list of all of the values of the attributes
0x05	Reset	No	Yes	Restarts the EtherNet/IP service in the RTAC. Only reset type 0 is allowed.
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute

Message Router Object (0x02)

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	1	The revision of this CIP object
2	Max Instance	GET	UINT	3	The maximum Message Router object instance ID
3	Number of Instances	GET	UINT	1	Total number of Message Router object instances
4	Optional Attribute List	GET	[UINT, Array of UINT]	[2, [3,1]]	[Number of optional instance attributes, List of optional instance attributes]
5	Optional Service List	GET	[UINT, Array of UINT]	[10, [7,3,0,0,0,0,0,0,0,0]]	[Number of optional service codes, List of optional service codes]
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	3	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Class List	GET	[UINT, Array of UINT]		Implemented object list
2	Maximum Connections	GET	UINT		Maximum number of connections supported
3	Number of Connections	GET	UINT		Number of connections currently used

Supported Services

Service Code	Service Name	Class	Instance	Description
0x01	Get Attribute All	Yes	Yes	Returns a list of all of the attributes
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute
0x0A	Multiple Service Packet	No	Yes	

Assembly Object (0x04)

Instances Implemented

The ACSELERATOR RTAC user settings define the number of Assembly object instances, instance IDs, and data content of each instance.

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	2	The revision of this CIP object
2	Max Instance	GET	UINT	Determined by settings	The maximum Assembly object instance ID defined by the user
3	Number of Instances	GET	UINT	Determined by settings	Total number of Assembly object instances defined by the user
4	Optional Attribute List	GET	[UINT, Array of UINT]	[1,4]	[Number of optional instance attributes, List of optional instance attributes]
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	4	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Number of Members	GET	UINT		Number of Assembly tag members defined by the user
2	Member List	GET	Array of [UINT, UINT, EPATH]		
3	Data	GET, SET	Array of Bytes		Data map defined in ACSELERATOR RTAC
4	Size	GET	UINT		Number of bytes in attribute 3

Supported Services

Service Code	Service Name	Class	Instance	Description
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute
0x10	Get Attribute Single	No	Yes	Sets the value of a specific attribute
0x18	Get Member	No	Yes	Returns the value of a member of the Data attribute
0x19	Set Member	No	Yes	Modifies the value of a member of the Data attribute

Connection Manager Object (0x06)

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	4	The revision of this CIP object
2	Max Instance	GET	UINT		The maximum Connection Manager object instance ID
3	Number of Instances	GET	UINT		Total number of Connection Manager object instances
4	Optional Attribute List	GET	[UINT, Array of UINT]	[8,[0,0,0,0,0,0,0,0]]	[Number of optional instance attributes, List of optional instance attributes]
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	20	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Open Requests	GET/ SET	UINT		Number of FWD Open service requests received
2	Open Format Rejects	GET/ SET	UINT		Number of FWD Open service requests rejected because of bad format
3	Open Resource Rejects	GET/ SET	UINT		Number of FWD Open service requests rejected because of lack of resources
4	Open Other Rejects	GET/ SET	UINT		Number of FWD Open service requests rejected for reasons other than bad format or lack or resources
5	Close Requests	GET/ SET	UINT		Number of FWD Close service requests received
6	Close Format Rejects	GET/ SET	UINT		Number of FWD Close service requests rejected because of bad format
7	Close Other Rejects	GET/ SET	UINT		Number of FWD Open service requests rejected for reasons other than bad format
8	Connection Timeouts	GET/ SET	UINT		Number of connection timeouts
15	I/O Packets per Second	GET	UDINT		Current I/O packets per second
17	Explicit Packets per Second	GET	UDINT		Total number of explicit packets sent and received over the last second
18	Missed I/O Packets	GET	UDINT		Total number of missed I/O packets
19	CIP I/O Connections	GET	UDINT		Total number of CIP connections in use
20	CIP Explicit Connections	GET	UDINT		Total number of CIP Explicit Messaging connections in use

Supported Services

Service Code	Service Name	Class	Instance	Description
0x01	Get Attribute All	Yes	Yes	Returns a list of all of the attributes
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute
0x10	Set Attribute Single	No	Yes	Sets the value of a specific attribute
0x02	Set Attribute All	No	Yes	Sets the value of all attributes
0x54	Forward Open	No	Yes	Establishes a CIP connection
0x4E	Forward Close	No	Yes	Closes a CIP connection
0x5B	Large Forward Open	No	Yes	Establishes a CIP connection that allows a large connection size
0x5A	Get Connection Owner	No	Yes	Returns data about the connection owns the object

File Object (0x37)

The File object stores the Electronic Data Sheet (EDS) and icon files. The EDS file is automatically generated by ACSELERATOR RTAC based on the specific user configuration and transferred to the RTAC when the project is loaded.

Instances Implemented

The RTAC implements two instances of the File object:

- Instance 0xC8 returns an uncompressed version of the EDS file with embedded icons.
- Instance 0xC9 returns a compressed version of just the icon file.

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	1	The revision of this CIP object
2	Max Instance	GET	UINT	201	
3	Number of Instances	GET	UINT	2	
6	Maximum ID Number Class Attributes	GET	UINT	32	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	11	Maximum instance attribute ID
32	Directory	GET	[UINT, STRINGI, STRINGI] [UINT, STRINGI, STRINGI]	[0xC8, (ENG)'EDS and Icon Files', (ENG)'EDS.txt'] [0xC9, (ENG)'Related EDS and Icon Files', (ENG)'EDSCollection.gx']	List of all File object instance and file names present in the RTAC and the associated instance numbers.

0xC8 List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	State	GET	USINT	2	
2	Instance Name	GET	STRINGI	(ENG)'EDS and Icon Files'	
3	File Format Version	GET	UINT	1	
4	File Name	GET	STRINGI	(ENG)'EDS.txt'	
5	File Revision	GET	[USINT, USINT]		[Major EDS revision user setting, Minor EDS revision user setting]
6	File Size	GET	UDINT		Size of the EDS file in bytes
7	File Checksum	GET	UINT		Checksum of the EDS file (two's complement of the 16-bit sum of all octets in the file)
8	Invocation Method	GET	USINT	255	
9	File Save Parameters	GET	USINT	0	
10	File Access Rule	GET	USINT	1	
11	File Encoding Format	GET	USINT	0	

0xC9 List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	State	GET	USINT	2	
2	Instance Name	GET	STRINGI	(ENG)'Related EDS and Icon Files'	
3	File Format Version	GET	UINT	1	
4	File Name	GET	STRINGI	(ENG)'EDSCollection.gz'	
5	File Revision	GET	[USINT, USINT]	[1,1]	[Major Revision, Minor Revision]
6	File Size	GET	UDINT		Size of the loaded file in bytes
7	File Checksum	GET	UINT		Checksum of the EDSCollection file (two's complement of the 16-bit sum of all octets in the file)
8	Invocation Method	GET	USINT	255	
9	File Save Parameters	GET	USINT	0	
10	File Access Rule	GET	USINT	1	
11	File Encoding Format	GET	USINT	1	

Supported Services

Service Code	Service Name	Class	Instance	Description
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute
0x4B	Initiate Upload	No	Yes	
0x4F	Upload Transfer	No	Yes	

TCP/IP Object (0xF5)

Instances Implemented

The number of instances of the TCP/IP object depends on the number of instances of the Ethernet Link object and the Bridge/Bond modes in use, as follows:

- An instance for each Ethernet Link object instance that is not part of a Bridge/Bond/PRP set.
- An instance for each set of Ethernet Link object instances that make up a Bridge/Bond/PRP set.

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	4	The revision of this CIP object
2	Max Instance	GET	UINT		The maximum TCP/IP object instance ID
3	Number of Instances	GET	UINT		Total number of TCP/IP object instances
4	Optional Attribute List	GET	[UINT, Array of UINT]	[4, [8,9,16,17]]	[Number of optional instance attributes, List of optional instance attributes]
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	17	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Status	GET	DWORD	2	
2	Configuration Capability	GET	DWORD	192	Any change in the configuration will be updated when the server is restarted.
3	Configuration Control	GET	DWORD	0	IP addresses must be configured statically. DHCP and DNS are not supported.
4	Physical Link Object	GET	[UINT, EPATH]		[Path size, Path to the corresponding Ethernet link object instance]

Attr. ID	Name	Access	Data Type	Default	Description
5	Interface Configuration	GET	[UDINT, UDINT, UDINT, UDINT, UDINT, STRING]		[IP address, Network mask, Gateway address, 0, 0, null]
6	Host Name	GET	STRING		Host name of the RTAC, as shown in the dashboard of the RTAC web interface
8	TTL Value	GET/ SET	USINT	1	
9	Mcast Config	GET/ SET	[USINT, USINT, UINT, UDINT]		[Alloc control, Reserved, Num Mcast, Mcast Start Address]
13	Encapsulation Inactivity Timeout	GET/ SET	UINT	120	
16	Active TCP Connections	GET	UINT		
17	Non-CIP Encapsulation Messages per second	GET	UDINT		

Supported Services

Service Code	Service Name	Class	Instance	Description
0x01	Get Attribute All	Yes	Yes	Returns a list of all of the attributes
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute
0x10	Set Attribute Single	No	Yes	Sets the value of a specific attribute

Ethernet Link Object (0xF6)

Instances Implemented

The number of instances of the Ethernet Link object is equal to the number of Ethernet interfaces listed in the Ethernet Ports setting in ACSELERATOR RTAC. Each Ethernet Link instance corresponds to an Ethernet interface in the list.

When going online, ACSELERATOR RTAC will verify that all configured interfaces for EtherNet/ IP are valid according to the following rules:

- Interfaces in this list are not available for EtherNet/IP:
  - USB interface (172.29.131.1)
  - Any interface that is enabled for EtherCAT
  - Any interface with DHCP enabled
  - Any disabled interface
- Interfaces in Bridge/Bonding/PRP mode require that all of the interfaces within the Bridge/Bonding group or PRP pair must also be listed in the Ethernet Ports setting.

If one or more interfaces in the Ethernet Ports setting are not available for EtherNet/IP, ACSELERATOR RTAC will not send the project.

List of Class Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Revision	GET	UINT	4	The revision of this CIP object
2	Max Instance	GET	UINT		The maximum TCP/IP object instance ID
3	Number of Instances	GET	UINT		Total number of TCP/IP object instances
4	Optional Attribute List	GET	[UINT, Array of UINT]		[Number of optional instance attributes, List of optional instance attributes]
6	Maximum ID Number Class Attributes	GET	UINT	7	Maximum class attribute ID
7	Maximum ID Number Instance Attributes	GET	UINT	11	Maximum instance attribute ID

List of Instance Attributes

Attr. ID	Name	Access	Data Type	Default	Description
1	Interface Speed	GET	UINT		Speed (Mbps) in use on the corresponding interface
2	Interface flags	GET	DWORD		See description in the Interface Flags Bit table
3	Physical Address	GET	USINT[6]		MAC address of the corresponding interface
10	Interface Label	GET	STRING		RTAC interface name. E.g. "Eth_02"
11	Interface Capability	GET	[DWORD, USINT]		[Capability bits, Array Element Count]

Interface Flags Bit Table

Bit Number	Name	Description
0	Link Status	0: The Ethernet interface link is inactive 1: The link is active
1	Half/Full Duplex	0: The interface is running half duplex 1: The interface is running full duplex
2–4	Negotiation Status	Octal unsigned value: 0: Autonegotiation in progress 1: Autonegotiation and speed detection failed. Using default values 2: Autonegotiation failed, but detected speed 3: Successfully negotiated speed and duplex 4: Autonegotiation not attempted
5	Manual Setting Requires Reset	Set to 1

Supported Services

Service Code	Service Name	Class	Instance	Description
0x01	Get Attribute All	Yes	Yes	Returns a list of all of the attributes
0x0E	Get Attribute Single	Yes	Yes	Returns the value of a specific attribute

CIP Connections

The user settings determine the total number of CIP connections used by a project. The number of CIP connections allocated in a project is determined as follows:

- The number of Class 1 connections allocated in a project is determined by adding up the following quantities:
  - The value of the Maximum Input Only Class 1 connections under the **Settings** tab
  - The value of Maximum Listen Only Class 1 connections under the **Settings** tab
  - The number of Exclusive Owner connections defined under the I/O Connections
- The number of Class 3 connections allocated in a project is determined by the value of the Maximum Class 3 connections setting under the **Settings** tab.
- The total number of CIP connections is determined by adding up the number of Class 1 connections and the number of Class 3 connections.

The total number of CIP connections in an RTAC project is limited to 128.

ACSELERATOR RTAC Settings and Configuration

Configuration

Settings

The **Settings** tab contains all the configurable items for the EtherNet/IP communication protocol.

Assembly Instances

The **Assembly Instances** tab is used to define the instances of the Assembly object. Each Assembly instance is a collection of data (as much as 500 bytes worth) that is either transmitted to the scanner (input assembly) or received from the scanner (output assembly).

Assembly Data Map

Assembly Data Map tabs are created automatically for each Assembly instance configured in the **Assembly Instance** tab. Use these tabs to create I/O data points for each Assembly instance. As much as 500 bytes worth of data may be added to each Assembly instance; however, the total bytes used across all Assembly instances cannot exceed 10,000.

I/O Connections

The **I/O Connections** tab is used to define the EtherNet/IP I/O connections (Class 1 connections) that can be accessed from a remote IED/scanner. Depending on the type of connection, each I/O connection defined in this tab has one or two Assembly instances. While Exclusive Owner connections may have an input and an output Assembly instance, Input Only and Listen Only connections may only have input Assembly instances associated with them. All assemblies assigned to I/O connections must be previously defined in the **Assembly Instances** tab. Assemblies used as output assemblies must be defined with read-write access.

Remote Devices

The **Remote Devices** tab is used to enter a list of all EtherNet/IP explicit message targets. The **Remote Devices** tab is only visible when Enable Explicit Message Client is set to True.

CIP Tag Messages

The **CIP Messages** tab is used to configure individual EtherNet/IP explicit messages (CIP Data Table Read and CIP Data Table Write) to devices defined in the **Remote Devices** tab. This tab is only visible when Enable Explicit Message Client is set to True.

PCCC Messages

The **PCCC Messages** tab is used to configure individual EtherNet/IP explicit messages (SLC Protected Typed Logical Read and SLC Protected Typed Logic Write) to devices defined in the **Remote Devices** tab. This tab is only visible when Enable Explicit Message Client is set to True.

POU Pin Setting

The **POU Pin Settings** tab is used to view the present state of the EtherNet/IP protocol and to access protocol statistics.

Table 2.142 EtherNet/IP Adapter/Client POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	Enables or disables this specific Function Block instance. Other inputs have no effect while EN is False.	True
Reset_Statistics	Input BOOL	On rising-edge trigger, all counter POU output are reset	False
ENO	Output BOOL	Indicates this specific Function Block Instance is active if True. If False, the inputs have no effect and the outputs are not updated.	False
Offline	Output BOOL	If False, indicates that there is at least one active EtherNet/IP session. This pin is set to True when the communication link has been idle for a time specified by the Encapsulation Inactivity Timeout attribute of the corresponding TCP/IP object instance.	False

Pin Name	Pin Type	Description	Default
Class_1_Message_Sent_Count	Output UDINT	Total number of Class 1 implicit messages sent out by the RTAC	0
Class_1_Message_Received_Count	Output UDINT	Total number of Class 1 implicit messages received by the RTAC	0
Class_1_Mesage_Failure_Count	Output UDINT	Total number of Class 1 implicit message failures	0
Class_1_Message_Success_Count	Output UDINT	Total number of successful Class 1 messages	0
Class_1_Message_Lost_Count	Output UDINT	Increases when the RTAC receives a Class 1 message with a sequence number greater than the next expected sequence number	0
Class_1_Active_Connections	Output UDINT	Current number of active Class 1 connections	0
Class_3_Active_Connections	Output UDINT	Current number of active Class 3 connections	0
Class_3_Message_Sent_Count	Output UDINT	Total number of Class 3 explicit message responses sent out by the RTAC	0
Class_3_Message_Received_Count	Output UDINT	Total number of Class 3 explicit message requests received by the RTAC	0
Unconnected_Message_Sent_Count	Output UDINT	Total number of unconnected explicit messages sent out by the RTAC	0
Unconnected_Message_Received_Count	Output UDINT	Total number of unconnected explicit messages received by the RTAC	0
Message_Timeout_Count	Output UDINT	Increases by one when the RTAC fails to receive a message (Class 1 or Class 3) from the scanner within the expected Requested Packet Interval (RPI)	0
<Connection Name>_Active_Consumers	Output UDINT	Number of active consumers subscribed to the associated I/O connection	0
<Connection Name>_Timeout_Count	Output UDINT	Sum of timed-out messages for all associated consumers	0
<Connection Name>_Message_Lost_Count	Output UDINT	Sum of lost packets for all associated consumers	0
Send_<Device Name>_<Message Name>	Input BOOL	On a rising-edge, triggers the message	FALSE
<Device Name>_<Message Name>_DN	Output BOOL	Asserts for one RTAC processing interval to indicate that the message transaction is complete	FALSE
<Device Name>_<Message Name>_Status	Output STRING(255)	Provides the status of the last message sent	
<Device Name>_<Message Name>_Data	Input/Output	Array of data. Provides access to the message data.	

Managing Multiple RTAC EtherNet/IP Configurations in the Same Network

When multiple RTAC units with different EtherNet/IP configurations (Assemblies, assembly maps, and I/O Connection Point settings) coexist in the same EtherNet/IP network, the Configuration ID setting is used to uniquely identify each configuration. RTAC units with different EtherNet/IP configurations should use a different value for the Configuration ID setting.

The Configuration ID setting contributes to the Product Code attribute (attribute ID #3 of the Identity object). The RTAC Product Code attribute is a two-byte unsigned integer number in which the most-significant byte is 35 and the least-significant byte is set by user via the Configuration ID setting in ACSELERATOR RTAC. This allows for a Product Code range between 8960 and 9215. Each different EtherNet/IP configuration in the network will have a different Product Code. This ensures that EtherNet/IP scanners will identify each different configuration as a separate device, thus preserving the EDS file for each.

The Product Name setting in ACSELERATOR RTAC shall be used to assign a unique identification to each different Product Code. This setting maps directly into the Product Name attribute (attribute ID #7) of the Identity object. This facilitates the identification of each EtherNet/IP data map when configuring an EtherNet/IP scanner. The following figure illustrates how to use the Configuration ID and Product Name settings to identify different EtherNet/IP configurations in the same network. In the figure, the Adapter 1 and Adapter 2 RTAC devices have the same EtherNet/IP configuration, and therefore the same Configuration ID and Product Name settings are assigned to them. Adapter 3 has a different EtherNet/IP configuration than Adapters 1 and 2, and a different Configuration ID and Product Name settings are assigned to it. Each unique Configuration ID setting results in a different Product Code attribute value in the Identity object and Product Code entry in the EDS file, which results in the EtherNet/IP scanner configurator software identifying each as a different product.

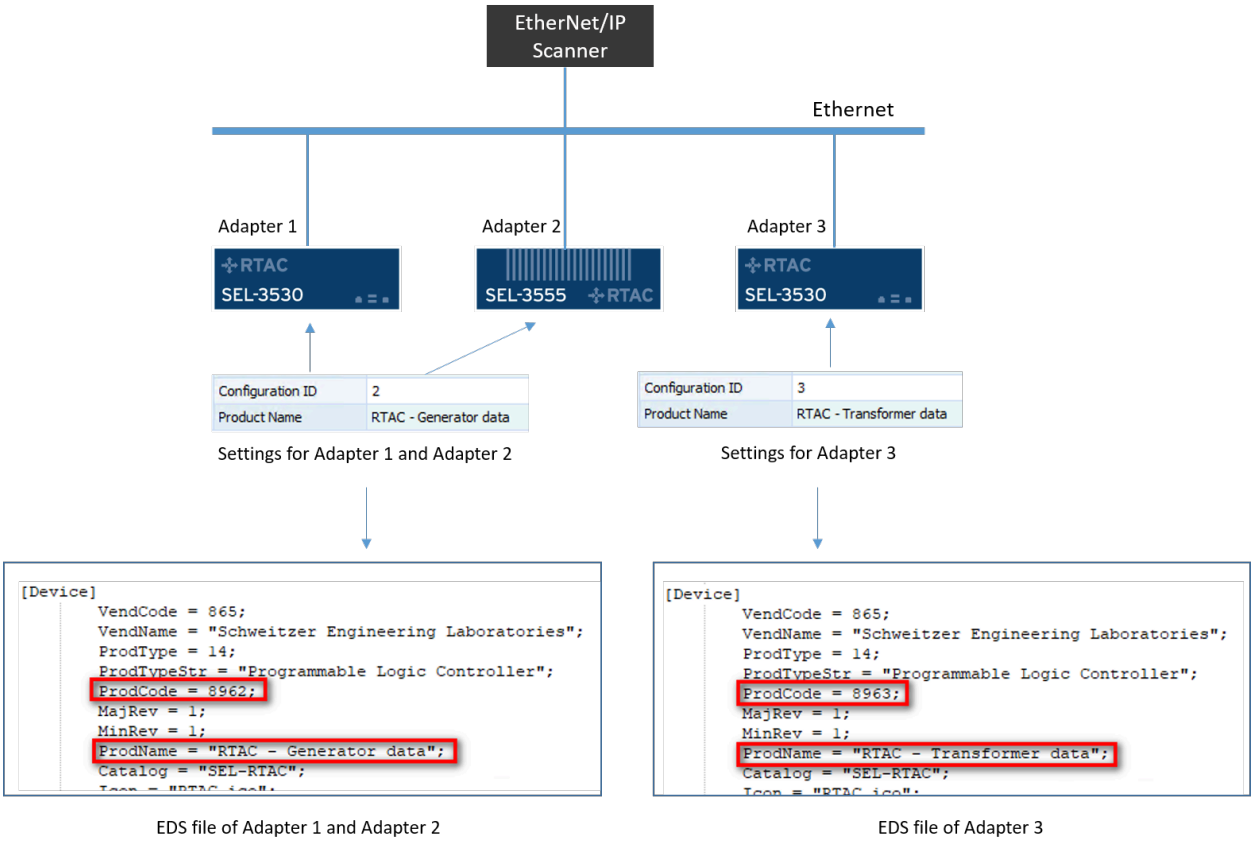

Figure 2.217 Multiple EtherNet/IP Configurations in a Single Network

Implicit Message Adapter Configuration

Step 1. Add an EtherNet/IP device into the project.

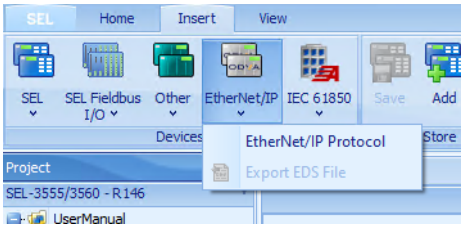

Figure 2.218 Add EtherNet/IP Into Configuration

Step 2. Enter the settings based on the requirements of your project.

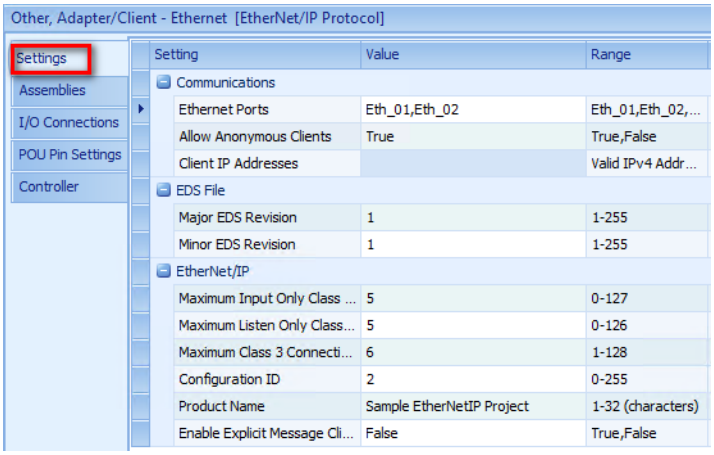

Figure 2.219 Configure EtherNet/IP Settings

Step 3. Create the Assembly object instances.

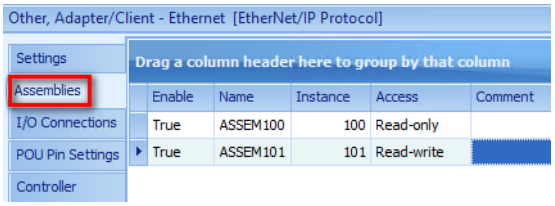

Figure 2.220 Configure Assembly Object Instances

Assembly instances that will serve as output assemblies shall be set with read-write access.

Step 4. Click on the Assembly instance sub-item to configure and map the Assembly members.

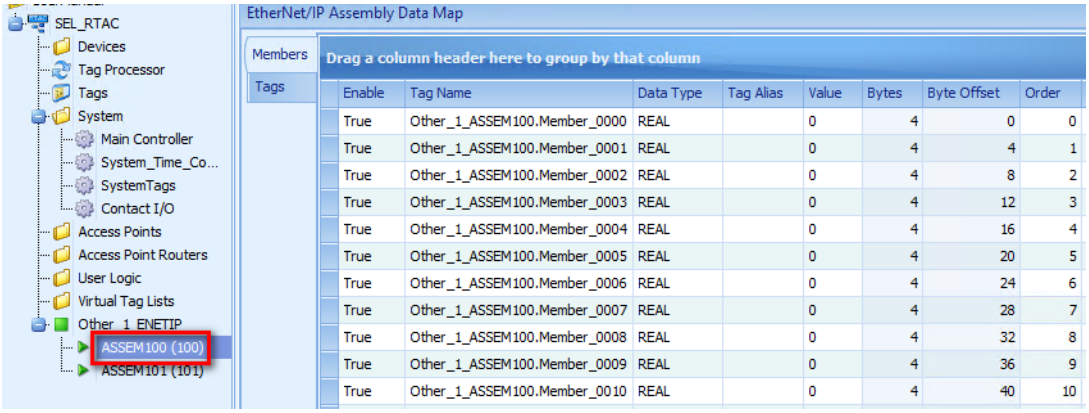

Figure 2.221 Configure Assembly Members

Step 5. Configure the I/O connection points.

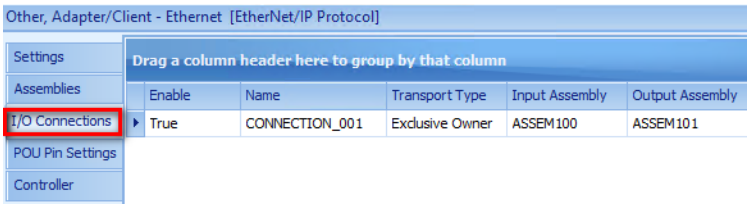

Figure 2.222 Configure I/O Points

Step 6. Export the EDS file and load it into the EtherNet/IP scanner configuration tool. Load the project into the RTAC and then configure the EtherNet/IP scanner.

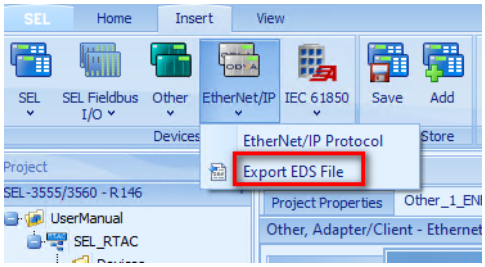

Figure 2.223 Export EDS File

Alternatively, the EDS file may be loaded by the EtherNet/IP scanner configuration tool directly from the RTAC after loading the project.

Explicit Message Client Configuration

Step 1. Enable Explicit Message Client.

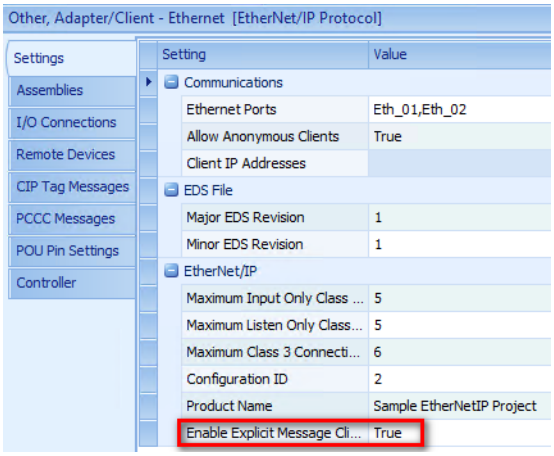

Figure 2.224 Enable Explicit Message Client

Step 2. Enter the list of Explicit Message server devices.

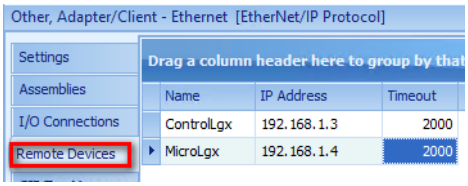

Figure 2.225 Enter Explicit Message List

Step 3. Configure the Explicit Messages.

➤ **CIP Tag Messages** tab: Use this tab to configure messages to read or write arrays of data in a remote controller that supports the CIP Data Table Read and CIP Data Table Write services. In the following figure, the message reads the first 5 elements of the tag array MotorTemperature defined in the remote PLC.

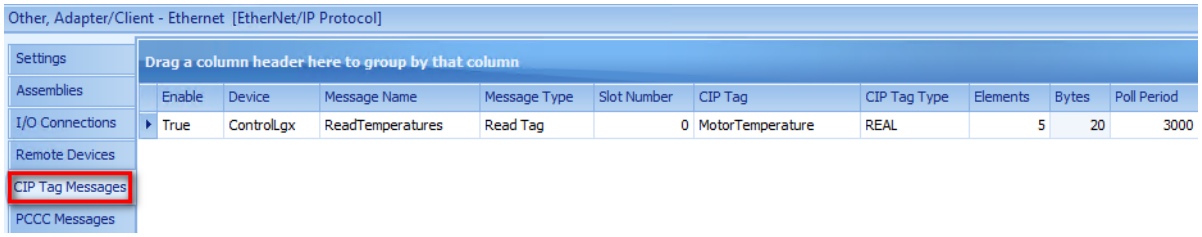

Figure 2.226 CIP Tag Messages

➤ **PCCC Messages** tab: Use this tab to configure messages to read or write arrays of data in a remote controller that supports the SLC Protected Typed Logical Read/Write services. In the following figure, the message writes in the data points N7:10, N7:11, and N7:12 of the remote PLC.

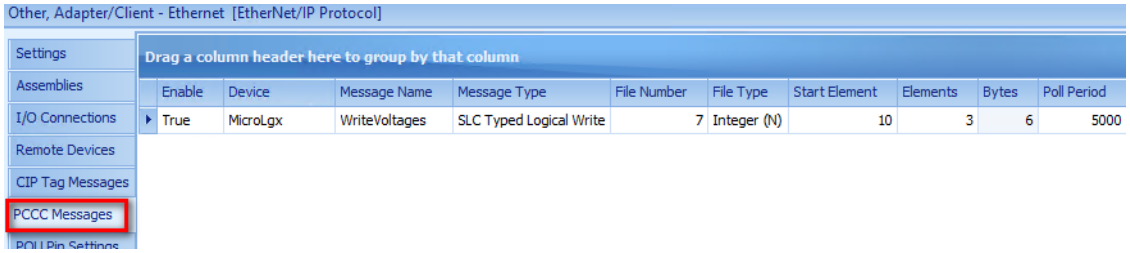

Figure 2.227 PCCC Messages

Step 4. Map the data. Tag arrays will be created as POU input pins (in case of write messages) or POU output pins (in case of read messages) to map the data that is written to or read from the remote PLC. These POU pins have the following format: [Device Name]_[Message Name]_Data.

Step 5. Send your settings to the RTAC and verify successful communication with your remote PLC. Each Explicit Message configured to read or write data with the remote PLC will generate an output POU pin providing the results of the last message exchanged with the PLC. These POU pins have the following naming format: [Device Name]_[Message Name]_Status. During normal communications, the message shown here will be either **In Progress** or **Success**. Any error conditions that are encountered during the exchange will also be noted here. Common error conditions are noted in *Table 2.143*.

Table 2.143 Ethernet/IP Explicit Message Error Statuses

Status String	Description
Timeout	The RTAC has not received a response from the target device within the configured time.
Invalid Response	The RTAC has received a response from the target device with a Requester ID, CMD, or Transaction ID mismatch.
Message Service Error: Error Code: [0xAA], Extended Error Code: [0xBB]	An error response was returned by the target device. A list of Error and Extended Error Codes are shown in *Table 2.144*

Table 2.144 Ethernet/IP Explicit Message Error and Extended Error Codes

Error Code	Extended Error Code	Description
0x04	0x0000	A syntax error was detected decoding the request path. Typically indicates that a read or write message has been configured that refers to an array that does not exist in the PLC.
0xFF	0x2104 or 0x2105	A read or write request has been configured that has specified an array length longer than what is configured in the PLC.
0xFF	0x2107	A write message has been configured that has specified an incorrect Data Type compared to the array configuration in the PLC.

Electronic Data Sheet (EDS) File

User-Configurable EDS Entries

The following EDS entries are based on ACSELERATOR RTAC user settings.

- EDS Revision—The value of the Revision entry in the File section of the EDS file is set by the Major EDS Revision and Minor EDS Revision settings in ACSELERATOR RTAC.
- Product Code—The ProdCode field in the Device section of the EDS file is mapped from the Product Code attribute of the Identity object.
- Product Name—The ProdName field in the Device section of the EDS file is mapped from the Product Code attribute of the Identity object.
- Parameter—The ParamN entries in the Parameter section of the EDS file correspond to the tags mapped into Assembly object instances in ACSELERATOR RTAC.
- Assembly—The AssemN entries in the Assembly section of the EDS file correspond to the Assembly instances defined in the **Assembly Instances** tab in ACSELERATOR RTAC.
- Connection—The ConnectionN entries in the Connection Manager section of the EDS file correspond to the implicit connections defined in the **I/O Connections** tab of ACSELERATOR RTAC.

Comments entered in Assembly data maps and the **I/O Connections** tab in ACSELERATOR RTAC are mapped to the EDS file as line comments. ACSELERATOR RTAC accepts UTF-8 characters in comment fields. Non-8-bit characters are replaced with a question mark ("?") in the EDS file.

EDS File Export

There are three methods by which to export the EDS file:

- ACSELERATOR RTAC software
- FTP/SFTP Server
- CIP File Object

Export EDS File Via ACSELERATOR RTAC

The EDS file can be exported by using the **Export EDS File** menu option under the **EtherNet/IP** ribbon menu.

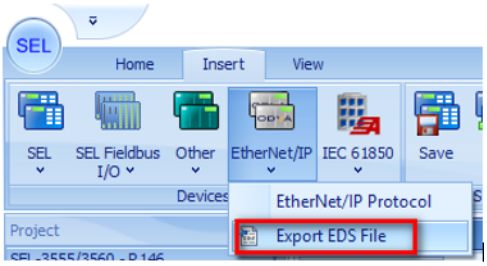

Figure 2.228 Export EDS File Via ACSELERATOR RTAC

Export EDS File Via FTP/SFTP

If an SFTP server is added to the RTAC, the EDS file can be downloaded from the ETHERNETIP folder in the SFTP root directory.

Export EDS File Via CIP File Object

The EDS file is stored in the File object (Object Class 0x37, Instance 0xC8) implemented as part of the EtherNet/IP object model in the RTAC. An EtherNet/IP scanner can retrieve the EDS file directly from the RTAC by using the File object services.

OPC UA

Overview

Originally known as "OLE for Process Control," OPC was introduced as a standard in the mid-1990s as a vendor-neutral mechanism to allow communications between industrial control equipment and software packages such as HMIs from different manufacturers. The specification for OPC was largely written around several components (such as OLE, COM and DCOM) developed by Microsoft and made available for exclusive use on the Microsoft Windows operating system. Thus, the original OPC Data Access (OPC DA) standard used for reading and writing data was limited to Windows-based devices and was not available for other PLCs and controllers that used proprietary operating systems or other standards such as Linux. Later renamed to Open Platform Communications, the OPC Foundation (www.opcfoundation.org) maintains the standards and introduced a platform-neutral follow-up known as OPC Unified Architecture (UA).

With the original standard now referred to as OPC Classic, OPC UA offers all the functionality of the original protocol as well as cross-platform communication regardless of the hardware or operating system of the controller or PC. Unfortunately, OPC UA is not directly compatible with OPC Classic, so legacy software or other drivers using OPC Classic need to be upgraded to support OPC UA. OPC UA is a licensed feature available on the RTAC platform for certain models including the SEL-3350, SEL-3555, and SEL-3560, with firmware version R150-V0 or later. Presently, a single OPC UA server instance (supporting ten simultaneous connections) or as many as ten OPC UA client instances can be added to a project.

Any tag or variable inside the RTAC project can be made available to the OPC UA Server interface by using a simple tag configuration interface.

OPC UA Client Configuration

Configure a client instance by selecting **OPC UA** from the **Other** protocols menu available from either the **Insert** ribbon or the right-click **Insert** menu.

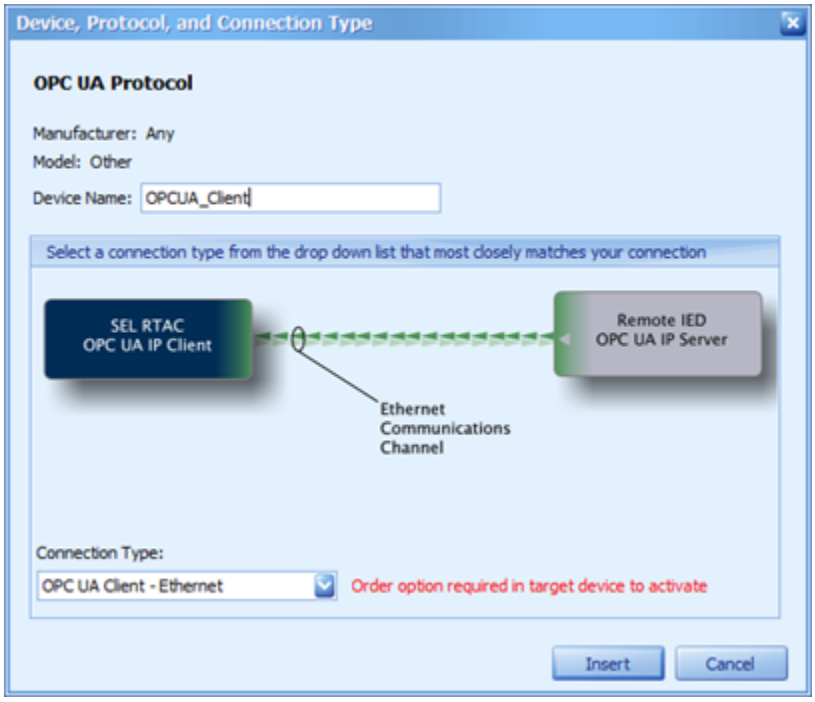

Figure 2.229 Insert OPC UA Client

Give the OPC UA client instance a unique **Device Name** and select **Insert** to add the instance to your project.

Settings

The Settings tab shows some basic configuration parameters for the OPC UA client including which IP address and TCP port (the default is 4840) the client will use to communicate with the server. During setup of a communications session, the OPC UA client will request an update interval at which the server will publish data back to the client. The **Update Rate** parameter configures this interval; however, depending on configuration, a server may deny the requested interval and enforce a higher minimum rate.

Tag Configuration

The Tag Configuration tab provides a mechanism for querying all variables from an OPC UA server that your PC can communicate with. This functionality does not require a physical RTAC, and ACSELERATOR RTAC can perform this action independently. The result of the query process provides a dialog box that allows selection of individual data elements from the server which are then configured as OPC UA client tags in your RTAC project by using two different modes known as **structured** or **unstructured**. Once the IP address and TCP port of your OPC UA server have been configured on the Settings tab, select **Update Variables** located at the top of the Tag Configuration tab and ACSELERATOR RTAC will attempt to connect to that OPC UA server endpoint and browse its complete tag structure. Depending on the size of the data map available on the server, this process can take as long as several minutes. The progress of each browsed element appears in the bottom status bar of ACSELERATOR RTAC to provide an indication of ongoing activity. Once the tag variable browsing process is complete, the **Choose Variables** window appears, allowing you to browse the variable structure of the server and select a check box for each element you want the OPC UA client to poll, as shown in *Figure 2.230*. Once all of the elements you want the OPC UA client to poll are selected, select **OK**.

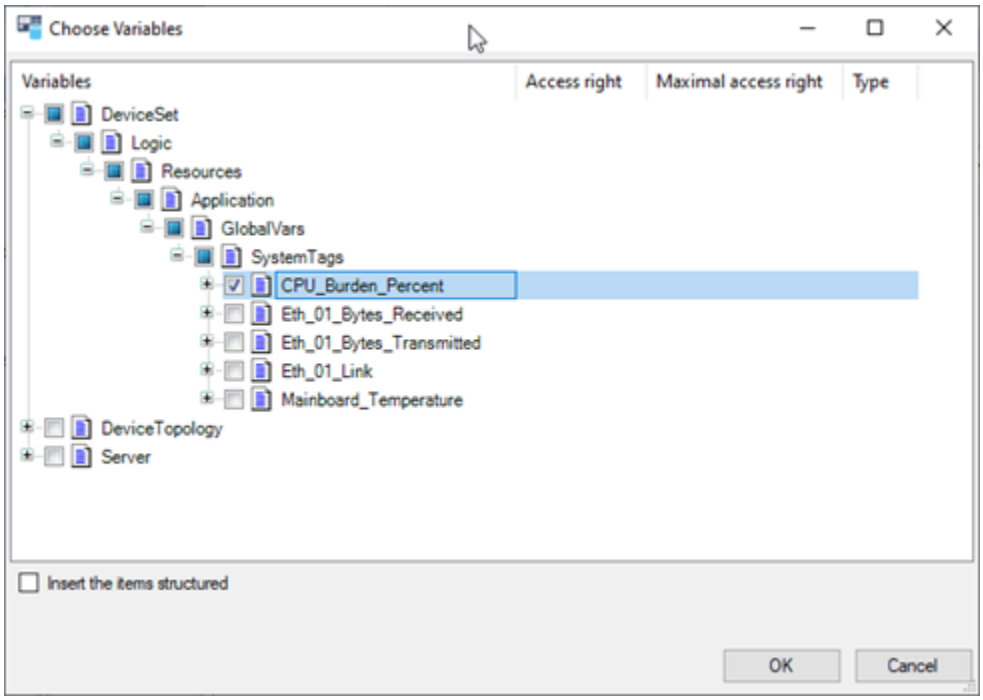

Figure 2.230 OPC UA Client Tag Configuration–Choose Variables

The bottom of the Choose Variables window has an **Insert the items structured** check box that allows for different methods of tag management and naming associated with this OPC UA client. By default, this check box is selected, and therefore tags will be inserted using structured mode, which maintains the variable structure provided by the server and uses a "dot separation" naming standard by which the tags are referenced in the RTAC project. For example, the CPU Burden Percent tag shown in *Figure 2.231* was originally defined as an INS data type by the server and contains a defined structured with several elements that can be referenced. To reference the stVal element of this tag using user logic or Tag Processor statements in your project, you would use a tag

name of **DeviceName_OPCUA.DeviceSet.Logic.Resources.Application. / GlobalVars.SystemTags.CPU_Burden_Percent.stVal**. Depending on the variable structure provided by the OPC UA server, the tag names defined on the client may be very long in length and potentially cumbersome to use in your user logic or data mapping. In such a case, you may want to insert the tags associated with your OPC UA client in unstructured mode instead.

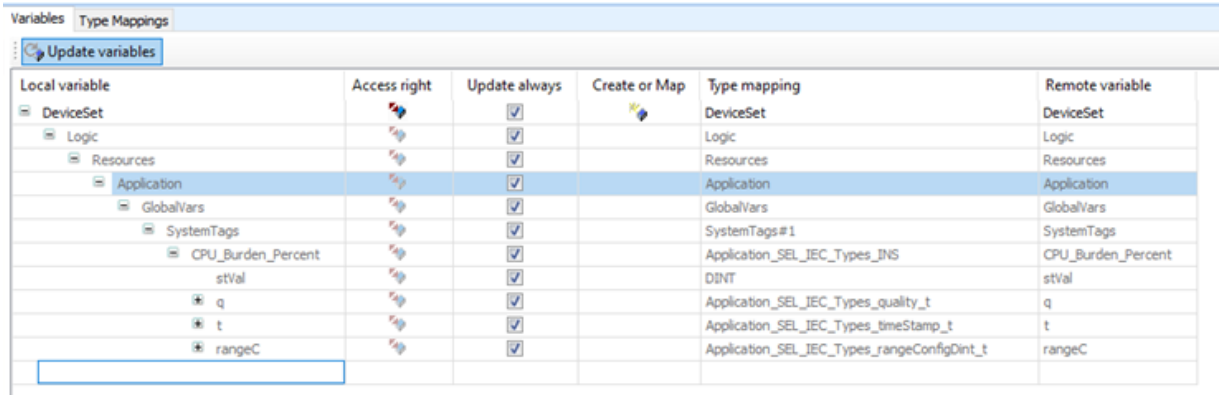

Figure 2.231 OPC UA Client Tag Configuration–Structured

If the **Insert the items structured** check box is not selected when tags are added to the OPC UA client, the original variable name from the structure provided by the server is maintained; however, all structure elements will be separated by an underscore. *Figure 2.232* shows an example of this. To reference the same stVal element as in the prior example as a tag in your project, you would use a tag name of **DeviceName_OPCUA.DeviceSet_Logic_Resources_Application_ / GlobalVars_SystemTags_CPU_Burden_Percent_stVal**.

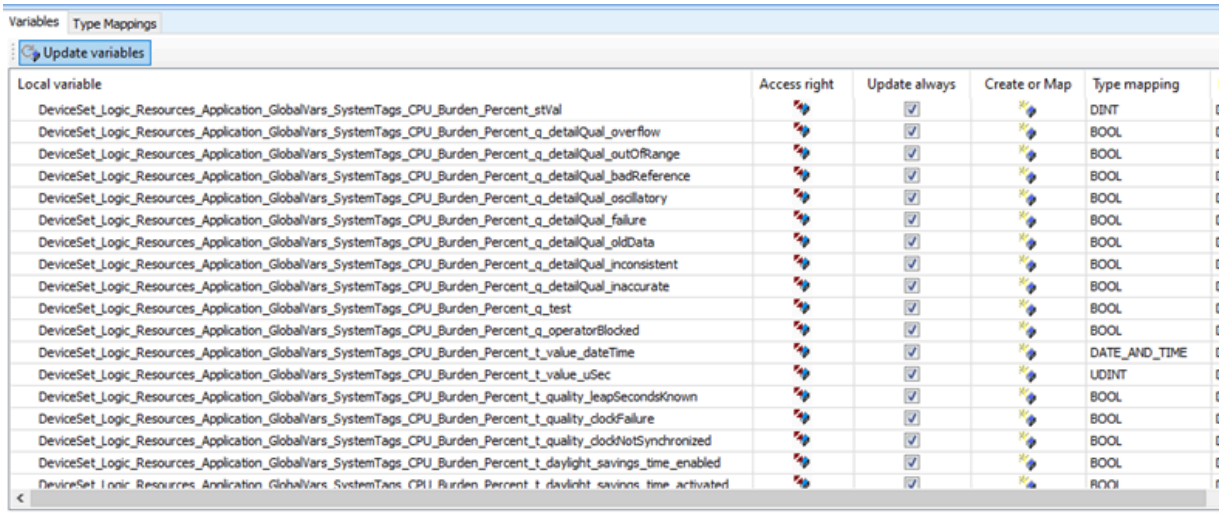

Figure 2.232 OPC UA Client Tag Configuration–Unstructured

While tags inserted in unstructured mode do not provide an immediate benefit of simplified naming by default, they can be manually renamed after insertion to provide much shorter tag names that allow for easier use in the rest of the project. For example, as shown in *Figure 2.233*, the stVal component of the CPU Burden Percent tag has been manually renamed via the **Local Variable** column and significantly shortened in

the process. Referencing this tag in your project would only require using **DeviceName_OPCUA.Remote_CPU_Burden_Percent_stVal**. Whether you choose structured or unstructured mode is up to your configuration choice, but SEL recommends using only one method per OPC UA client.

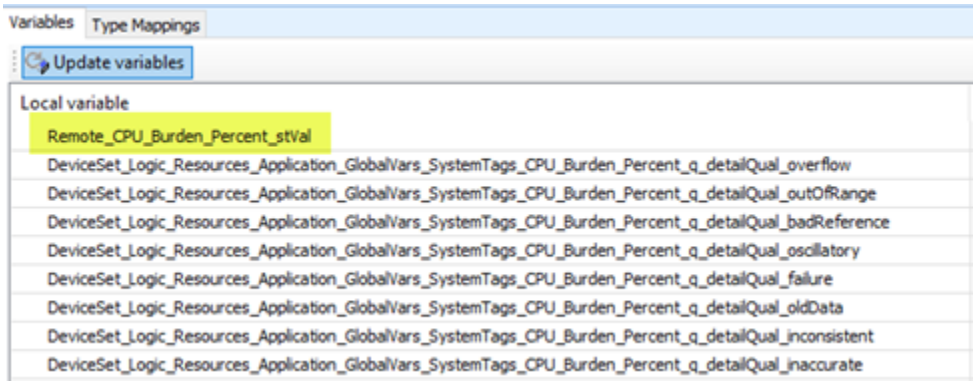

Figure 2.233 OPC UA Client Tag Configuration—Unstructured With Custom Naming

POU Pin Settings

The POU Pin Settings tab is used to view the present state of the OPC UA Client protocol instance.

Table 2.145 OPC UA Client POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	Enables or disables this specific Function Block instance of the OPC UA client. When EN is FALSE, other inputs have no effect and the OPC UA client will not attempt communication with a server.	TRUE
ENO	Output BOOL	Indicates that this specific Function Block instance of the OPC UA client is active if TRUE. If FALSE, the inputs have no effect and the OPC UA client will not attempt communication with a server. If EN is TRUE and ENO is FALSE, verify that the OPC UA Client license option is enabled on your RTAC.	FALSE
Error	Output enum_OPCUAClient_Error	The OPC UA standard provides more than 250 numeric status codes that indicate possible errors or other exceptions that can be encountered in OPC UA communications. A complete list of these codes is available at https://reference.opcfoundation.org/v104/Core/docs/Part6/A.2/. The enumerated Error output provides a translation of the raw numeric code values reported by this OPC UA client instance into shortened, named enumerated values as defined in the standard. Common enumerations that can be expected for this output include Good for normal communications and Timeout/BadCommunicationError for failed communications.	FALSE
Error_Message	Output STRING(255)	A descriptive message associated with the enumerated Error output, formatted as a string.	
Offline	Output BOOL	If FALSE, indicates that there is at least one active OPC UA session with a server. This pin is set to TRUE when the communication link to the server has been severed.	FALSE
Status	Output STRING	The current overall status of the OPC UA client. Other than an empty value, possible string values in this output include Connecting, Waiting, Connected, and Unlicensed.	

OPC UA Server Configuration

Configure a server instance by selecting **OPC UA** from the **Other** protocols menu available from either the **Insert** ribbon or the right-click **Insert** menu.

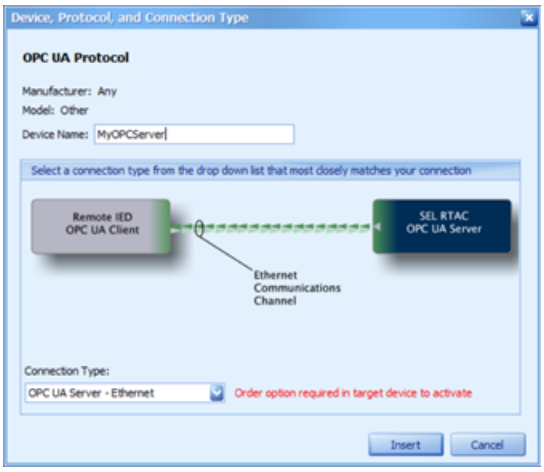

Figure 2.234 Insert OPC UA Server

Give the OPC UA server instance a unique **Device Name** and select **Insert** to add the instance to your project.

Settings

The Settings tab shows some basic configuration parameters for the OPC UA server including on which TCP Port the service listens (the default is 4840) and whether to allow or disallow anonymous connections to the server. During setup of a communications session, an OPC UA client requests an interval for the cyclic rate at which the server will publish data change notifications to the client. The **Minimum Publishing Interval** parameter allows the server instance to enforce a lower-limit threshold for the rate at which these data updates from the server to the client occur; this can be used to throttle back data updates in the event of communications performance concerns.

Tag Configuration

The Tag Configuration tab shows a list of all tags and variables in your project. This includes global tags, system tags, tags associated with client and server devices, virtual tag lists, global variable lists and custom user logic programs with internal variables. Each of these items has a drop-down menu interface that displays the individual tags/variables within that item (e.g., all tags enabled on an SEL client device). Each item and sub-item located under the drop-down menu has a corresponding check box that enables either the entire device/list or a particular tag for access to the OPC UA server interface, as shown in *Figure 2.235*.

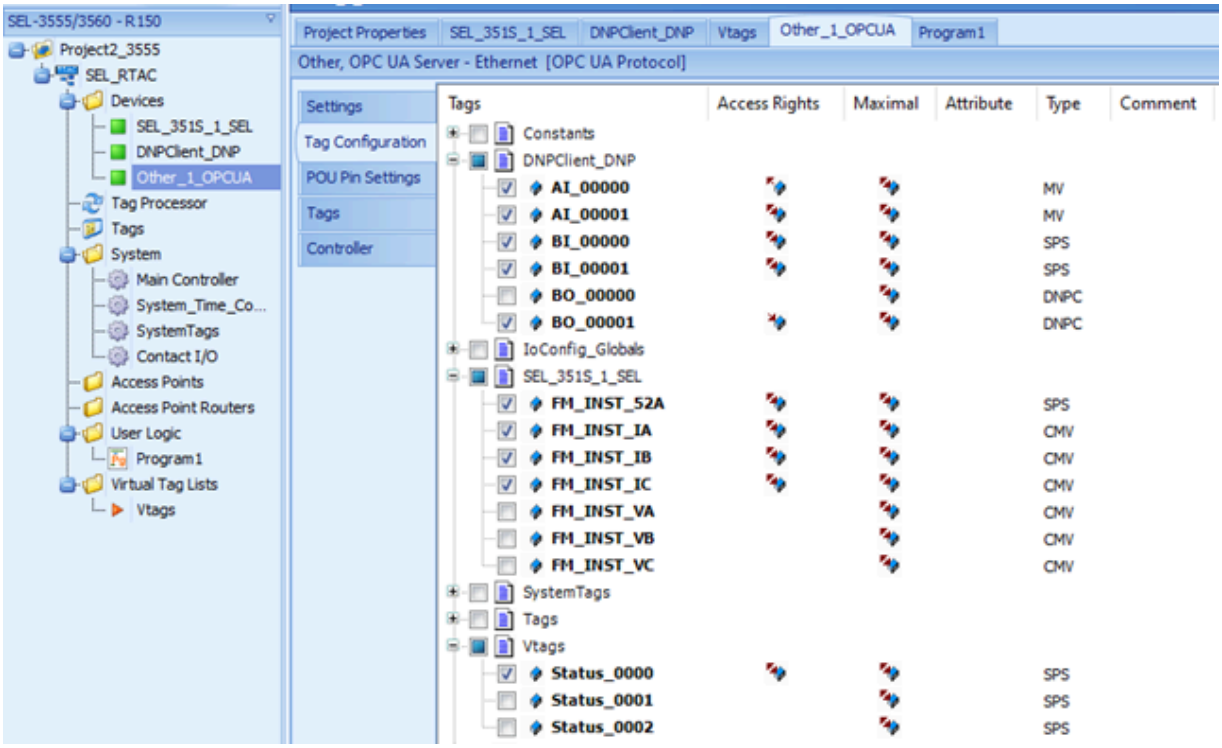

Figure 2.235 OPC UA Server Tag Configuration

Structured ACSELERATOR RTAC tags (such as those defined in *ACSELERATOR RTAC Data Types and Data Classes on page 1130*) that contain time-stamp and quality sub-attributes will pass through those attributes to the OPC UA variables as they are polled by a client. Mapping of the quality attribute is performed as follows:

Table 2.146 OPC UA Server Quality Mapping

ACSELERATOR RTAC Tag q.validity Value	OPC UA Variable Quality
validity_t.good	Good (0x00000000)
validity_t.invalid	Bad (0x80000000)
validity_t.questionable	Uncertain (0x40000000)

If there are tags or values associated directly with device POUs that are not tags belonging to said device that you wish to expose to OPC UA (e.g., myDevice_POU.Offline), the POU device instance where these quantities are available can be located under the **Tags** heading and can be enabled for OPC UA Server access there.

NOTE

The Tag Configuration tab is not available if IEC 61131 compile errors exist in the project.

Each enabled device and/or tag has an access attribute that can be configured for none, read-only, write-only, or read/write access via the icon displayed in the **Access Rights** column next to the tag name. Selecting this icon cycles through the various access rights; see *Figure 2.236* for a summary of the access type vs. the displayed icon.

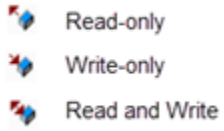

Figure 2.236 OPC UA Server Tag Access Rights Configuration

Note that in the present implementation of OPC UA server, configured access rights, when used with a tag that happens to be of a type considered to be a complex variable structure (e.g., DNPC), only apply against the entire structure of that tag. For example, if a tag of type DNPC was selected for read-only access, only a client write operation to the entire DNPC structure is blocked, whereas a write attempt to an element within that structure (e.g., operClose.ctlVal) would be allowed.

Tags

The Tags tab is used to view a summary of all tags and variables that have been enabled for OPC UA server access as well as a list of their access rights and tag type. *Figure 2.237* shows a sample Tags tab with the Tag configuration example explained previously.

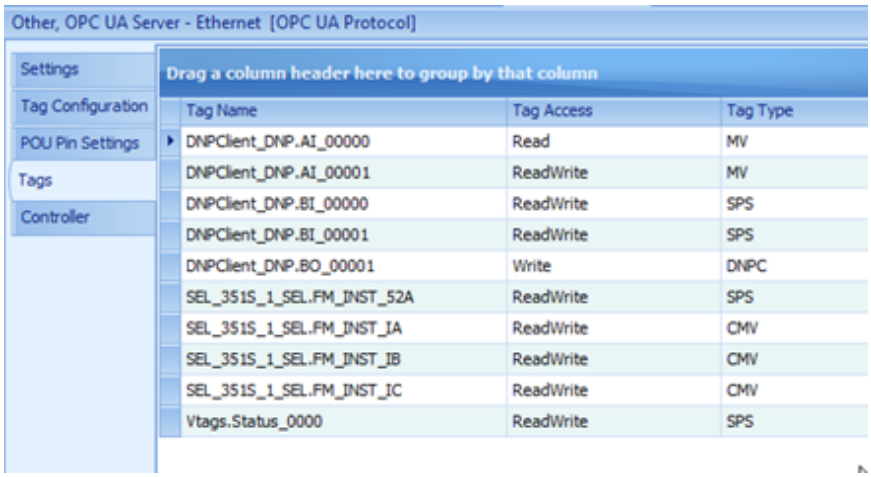

Figure 2.237 OPC UA Server Tags Tab Summary Display

POU Pin Settings

The POU Pin Settings tab is used to view the present state of the OPC UA Server protocol.

Table 2.147 OPC UA Server POU Pin Settings

Pin Name	Pin Type	Description	Default
EN	Input BOOL	Enables or disables this specific Function Block instance of the OPC UA server. When EN is False, other inputs have no effect and OPC UA clients are not allowed to connect to the server.	True
Reset_Statistics	Input BOOL	Resets internal counters tracked by the OPC UA server instance. Of note are the Cumulated data items located in the Server > ServerDiagnostics > ServerDiagnosticsSummary node.	False

Pin Name	Pin Type	Description	Default
ENO	Output BOOL	Indicates that this specific Function Block instance of the OPC UA Server is active if True. If False, the inputs have no effect and OPC UA clients are not allowed to connect. If EN is True and ENO is False, verify that the OPC UA Server license option is enabled on your RTAC.	False
Offline	Output BOOL	If False, indicates that there is at least one active OPC UA session. This pin is set to True when the communication link to all clients has been severed.	True
SessionCount	Output UDINT	An active count of the number of client sessions connected to this OPC UA server instance.	0
SubscriptionCount	Output UDINT	An active count of the number of subscriptions to this OPC UA server instance that have been established by active connected client sessions.	0

Connecting to an RTAC OPC UA Server

Connection to the RTAC's OPC UA server via an OPC UA client is a straightforward process. The following example shows a sample process using UAExpert software (available at www.unified-automation.com), a free OPC UA client available for Windows and Linux operating systems.

Once UAExpert is installed, the first stage is to add an instance of an OPC UA server connection. Using the **Add Server** dialog in the upper left panel, select **Custom Discovery** and enter the URL of the OPC UA server in the format of **opc.tcp://[RTAC-IP-Address]**. Select **OK** on the URL configuration dialog and navigate to the tree node created for that URL endpoint. You will see an entry labeled **OPCUAServer@[YourRTACHostName] (opc.tcp)** with one or two sub-entries labeled as **None(uatcp-uasc-uabinary)**. Select one of these entries and select **OK**. *Figure 2.238* shows a sample layout of this connection tree.

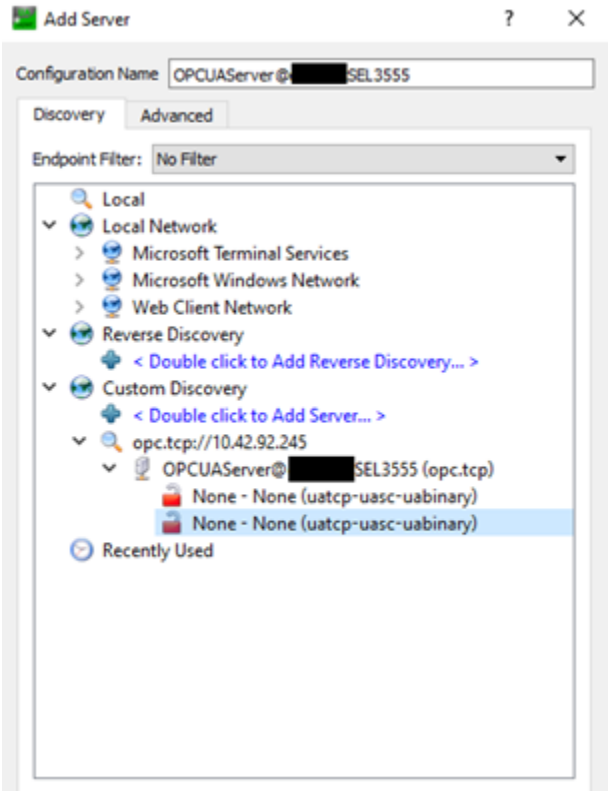

Figure 2.238 Configuring an OPC UA Client Connection

Right-click the server entry in the upper left panel and select **Connect**. Once the connection process succeeds, the Variable Browser panel in the lower left will populate with a connection tree. To locate the bulk of tags and variables that were made available in your RTAC project, navigate to **Objects > DeviceSet > Logic > Resources > Application > GlobalVars**. There, you will see individual folder nodes for each device and/or tag list that has tags enabled for OPC UA browsing. Expanding these folder entries displays all configured tags associated with that device. Each of the tags can then be expanded by using the drop-down arrow to display any and all sub-elements. Any of these tags or their sub-elements can be dragged over to the **Data Access View** workspace either as a complex object or a simple fundamental data type. *Figure 2.239* shows an example of this interface.

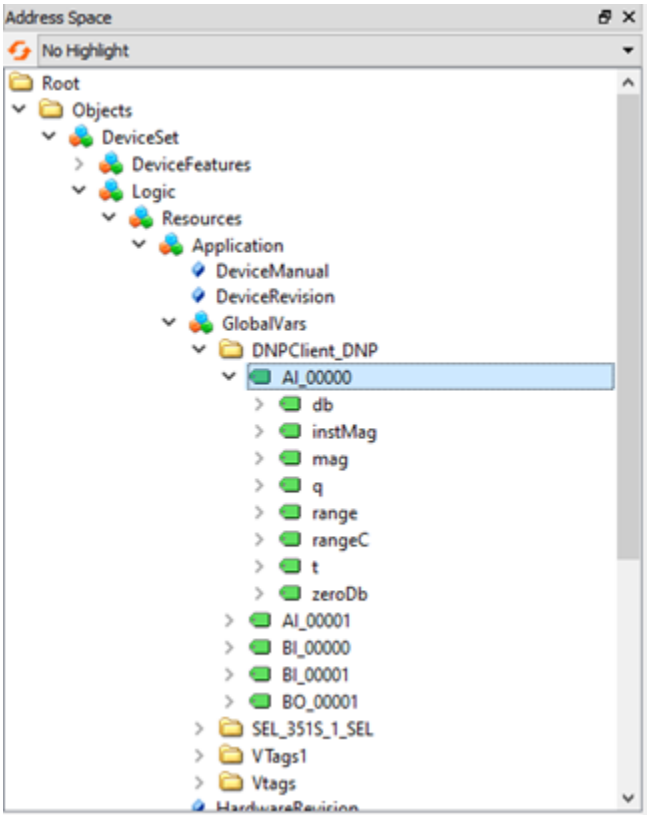

Figure 2.239 Browsing OPC UA Variables

Once the tag variable has been dragged over to the Data Access View workspace, it will be shown as either a fundamental quantity of a known OPC UA data type (e.g., Float, Int32) if it can be represented as such or a complex ExtensionObject. *Figure 2.240* shows an example of this interface.

Data Access View

#	Server	Node Id	Display Name	Value	Datatype	Source Timestamp	S
1	OPCUAServer@...	NS4|String||var|Logic.Application.DNPClient_DNP.AI_00000	AI_00000	Double click to display value	ExtensionObject	11:45:04.823 AM	1
2	OPCUAServer@...	NS4|String||var|Logic.Application.DNPClient_DNP.AI_00000.instMag	instMag	1234	Float	11:45:04.804 AM	1
3	OPCUAServer@...	NS4|String||var|Logic.Application.DNPClient_DNP.AI_00000.q.validity	validity	0 (good)	Int32	11:45:04.795 AM	1

Figure 2.240 Viewing OPC UA Variables

Right-clicking in the Data Access View provides an option to adjust the **Subscription Settings** associated with the client-to-server connection. These settings include a parameter called **Publishing Interval** that controls the rate at which data are updated from the server to the client, as shown in *Figure 2.241*. The lower limit of this value is limited by the **Minimum Publishing Interval** parameter that was configured in the **Settings** tab of the OPC UA server.

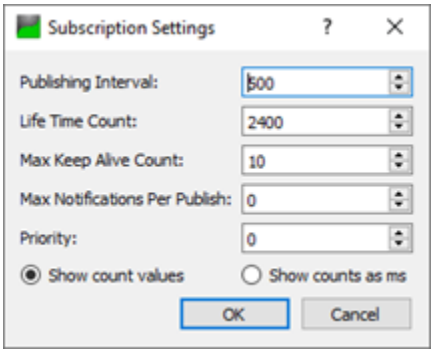

Figure 2.241 OPC UA Client Subscription Settings

OPC UA Security Configuration

In firmware version R153 and later, OPC UA client and server protocols on the RTAC support Message Security Modes and Security Policies. When a server is configured, these settings are defined as a minimum security level so that the client can upgrade to stronger security modes as they are available. Support for these is outlined as follows:

Table 2.148 OPC UA Security Modes and Policies Support

Message Security Mode	Security Policy	RTAC OPC UA server	RTAC OPC UA client
None	None	x	x
Sign	Basic128Rsa15		x
Sign	Basic256		x
Sign	Basic256Sha256		x
Sign	Aes128Sha256RsaOaep		x
Sign	Aes256Sha256RsaPss		x
Sign and Encrypt	Basic128Rsa15		x
Sign and Encrypt	Basic256		x
Sign and Encrypt	Basic256Sha256	x	x
Sign and Encrypt	Aes128Sha256RsaOaep	x	x
Sign and Encrypt	Aes256Sha256RsaPss	x	x

NOTE

The **Update Variables** function in the ACSELERATOR RTAC OPC UA client will also use the configured security mode on the device. Because ACSELERATOR RTAC is not part of the X.509 certificate chain that the RTAC itself is part of, ACSELERATOR RTAC generates its own certificate that must be individually trusted by the remote server. This certificate is named **AcRTAC Datasource OpcUa Browser**.

The RTAC OPC UA server and client use the active X.509 certificate for establishing the secure connection. This certificate must be generated via the RTAC web interface and contain a subject alternative name (SAN) with the IP address of the RTAC being used for OPC UA communications. Note that if the RTAC was upgraded to firmware version R153 or later from a firmware version

prior to R153 and a custom certificate was already present, a new certificate must be generated to ensure the proper certificate extensions required by OPC UA are present. A client that wishes to connect to the RTAC OPC UA server must trust the certificate presented by the server. If the OPC UA client is another RTAC, perform the following steps to trust the RTAC X.509 server certificate:

Step 1. Activate a custom certificate on the RTACs running the OPC UA server and client.

Step 2. Connect to the web interface of the RTAC with the OPC UA server and use your web browser to view the certificate offered by the RTAC. Confirm that the certificate contains Extensions with the Subject Alternative Name (SAN) attribute that contains the server RTAC's IP address. The certificate must also contain the Certificate Key Usage and Extended Key Usage extensions. Save the certificate to your PC in .CRT format.

Step 3. Double-click the .CRT file in Windows Explorer and use the Windows Certificate dialog to export or copy the certificate to a format supported by the RTAC (base-64 encoded X.509 .CER format is recommended).

Step 4. Open the exported .CER certificate using a text editor (e.g., Notepad) and confirm that the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- delimiters are present with encoded data between them. Select all the text in the file and copy it to the Windows clipboard.

Step 5. Connect to the web interface of the RTAC where the OPC UA client is configured and select the CA Certificates navigation link under the Security heading. Create a new CA certificate and give it a name to indicate that it is the public certificate of the OPC UA server RTAC. Paste the text file contents into the Certificate content field and select **Submit** to accept the server certificate.

To connect the RTAC OPC UA client to a third-party OPC UA server, the method to extract the server certificate will vary, but *Step 3* to *Step 5* of adding this certificate to the client RTAC's CA certificate store are the same. If the certificates used in the OPC UA secure connection are signed by a separate CA authority, only the CA certificate of the signing authority needs to be added to the client CA certificates page.

The RTAC OPC UA server will automatically trust any certificate provided by an OPC UA client (there is no quarantine process for the RTAC OPC UA server). The OPC UA client connecting to the server will likely need to trust the RTAC server certificate, typically by releasing it from quarantine.

SECTION 3

Tag Processor

Overview

Use the Tag Processor to log tag values, enable tag value visualization in the RTAC web interface, and map data values from sources to destinations. Source data typically enter the SEL Real-Time Automation Controller (RTAC) from an IED or from a global variable. Destination data are typically data leaving the RTAC to go to SCADA, an HMI, or some other remote polling device. A Source Expression can be a simple data tag (such as Relay1_ DNP.AI_0000) or an IEC 61131-3 expression. The Tag Processor moves data values from Source Expressions on the right into Destination Tags on the left in the same row of the Tag Processor. Data mapping in the Tag Processor does not dictate data position or order in a given protocol or application. The RTAC completes all assignments in the Tag Processor before passing the data to the protocols. You can use the Tag Processor to map any tag and any attribute of a tag in the ACSELERATOR RTAC SEL-5033 Software project.

Use the Tag Processor grid for the following example tasks:

- Simple mapping of tags from IED protocols to remote polling protocols
- Mapping attributes of different source tags to a destination tag
- Simple calculations such as analog scaling
- Complex IEC 61131-3 calculations
- Conditional statements using IEC 61131-3 logic expressions
- Logging of changes in tag values (the first several tags come preconfigured for logging)
- Configuring real-time tag value visualization in the RTAC web interface

Tag Processor Data Entry

Although the syntax is not the same, data entry in the Tag Processor grid is similar to data entry in a spreadsheet. Use one of the following methods to enter tag names into the Tag Processor.

- Type the name of the point. Note that the autocompletion feature will display tags by matching against what you have typed. Begin with the device name followed by the type, and use periods (.) between each tag component (e.g., Relay_1_DNP.AI_0000.instMag).
  - Relay_1_DNP = Client device name
  - AI_0000 = First analog input point
  - instMag = Instantaneous value for this point (see *Data Types on page 1127* for details)
- Highlight and copy the columns of tag names from previously configured client and server connections and paste these tag names into the **Source Expression** and **Destination Tag Name** columns, respectively. Note that pasting a group of tags in the Tag Processor will add new rows automatically in the grid.
- Copy and paste directly from device documentation by highlighting and copying a column from a Microsoft Excel spreadsheet, text file, or other tabular column of names, and then pasting this information into the appropriate **Tag Processor** column.
- Create the RTAC database mapping from a SCADA system database. Populate a spreadsheet with SCADA and IED tag names as mapped in the SCADA database. Copy the two columns of tags and paste these columns directly into the **Source Expression** and **Destination Tag Name** columns in the Tag Processor.
- Populate the **Source Expression** and **Destination Tag Name** columns using the Tag Selector tool, as described in *Tag Selector on page 143*.

Press the icon to save and compile the project. The error icon ( ) typically indicates a syntax error or an undefined destination tag. The alert symbol ( ) typically indicates an IEC 61131-3 logic error on that line. Compile errors appear in the output window at the bottom of the Tag Processor screen. Double-click on errors to display the error location. The save operation generates code that you can view by clicking the **Code** tab at the bottom of the Tag Processor. ACSELERATOR RTAC generates this code automatically each time you save the project. This code serves as a noneditable debugging aid.

Notice the Tag Processor POU capacity gauge at the top of the Tag Processor screen. This gauge indicates how close you are to exceeding the maximum recommended amount of generated code. The maximum allowed number of assignment rows in the Tag Processor is 10,000, but the lines of generated code will vary depending on what assignments are configured. A reading of 100 percent on the Tag Processor POU capacity gauge indicates ACSELERATOR RTAC has generated 300,000 characters of structured text to perform the configured mapping. Exceeding 100 percent could cause the application to run out of memory on your PC. You can reduce memory usage and still retain the same functionality by copying generated code and placing it in an IEC 61131-3 custom logic program. Then, delete the assignments from the Tag Processor to clear those lines of code.

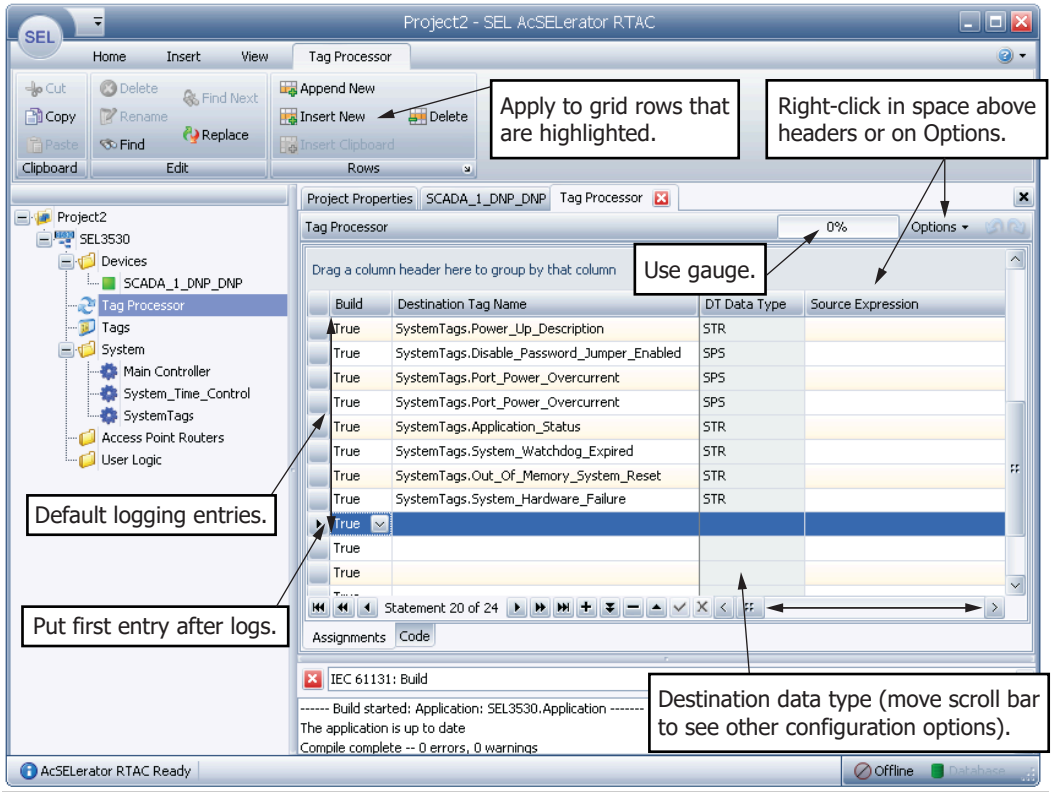

Figure 3.1 Tag Processor Grid

The two main columns in the Tag Processor are Destination Tag Name and Source Expression. View other columns by sliding the horizontal scroll bar.

Customize your view of the Tag Processor by right-clicking in space above headers or by selecting **Options** and then selecting the following:

- **Columns**: Show/hide all configuration parameter columns.
- **Run Time Column Customization**: Configure which columns appear and in which order.
- **Various Layouts**: Apply filters to view only certain data rows. Defaults include analog, digital, show all, and logging layout filters. Create and save custom layout filters as necessary. Select Default Layout to undo any changes you have made and to display all columns.
- **Export to XLS**: Export visible columns to an XLS (Excel spreadsheet) format.
- **Export to XML**: Export visible columns to an XML format.
- **Auto-Fill Time and Quality Source**: When a tag has a status, quality, and time stamp in the destination column and only a status mapped in the source column, this option automatically populates the quality source and time source columns. This makes it so that the destination tag will receive status updates with corresponding time stamps and good quality.

- **Treat Code not Generated as Error**: Tag processor statements that do not generate a valid mapping or logic statement indicate this with an exclamation mark on the left side of the tag processor row. Normally, this warning does not produce an IEC 61131 compile error and the project can be sent to the RTAC as-is. When this option is selected, these warnings generate compile errors that must be resolved before sending the project to the RTAC.
- Right-click on any column header to do the following:

  NOTE
  By default, the first several rows in the table are assigned to system tags for logging. You can delete these default logging assignments, but SEL recommends keeping them for NERC CIP requirements.

  - **Sort Ascending**: Sort Tag Processor by this column from low to high (A–Z, 0–9).
  - **Sort Descending**: Sort Tag Processor by this column from high to low (Z–A, 9–0).
  - **Clear Sorting**: Clear active sort options (return to default).
  - **Group By This Column**: Group data by this column type rather than by tag name.
  - **Group by Box**: Group data by this box rather than by tag name.
  - **Column Chooser**: Organize the order and which columns to view.
  - **Best Fit**: Adjust automatically the width of a column you select to the largest size entry.
  - **Clear Filter**: Clear active filter.
  - **Filter Editor**: Provide logic to implement a filter on tag names or other point attributes.
  - **Best Fit (all columns)**: Adjust automatically the width of all columns to accommodate largest entry sizes.
  - **Select Column**: Highlight an entire column for copy/paste, etc., operations.

Table 3.1 Available Columns in the Tag Processor

Parameter	Description	Default	Field Type
Build	Determine if the Tag Processor will evaluate this row.	True	Constant (BOOL)
Destination Tag Name	Any tag name in the system that can accept a value mapped to it.		Any tag name (operAPC, BCR, STR, STRING, TIM, TIME, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, MV, CMV, operINC, INS, SPS, operSPC)
DT Data Type	Data type of the destination tag.	Supplied by system lookup	Not assignable. Generated automatically.
DT Bit Reference	The bit in the Destination Tag that the Tag Processor will replace with the value of the Source Expression.		Constant (0–31)

Parameter	Description	Default	Field Type
Source Expression	Any tag in the database. Can also contain any structured text with tag(s).		Any tag name or expression (operAPC, BCR, STR, STRING, TIM, TIME, BYTE, WORD, DWORD, SINT, USINT, INT, UINT, DINT, UDINT, REAL, MV, CMV, operINC, INS, SPS, operSPC). May also use instructions if not associated with a Destination Tag.
SE Data Type	Source Expression data type or global variable definitions (see *Example 3.4*).	Supplied by system lookup	Generated automatically
Live Data Enable	Set this to Viewable to enable visibility of the Destination Tag on the Live Data page in the RTAC web interface. Set to Forceable to allow the tag to be forced from the Live Data page. Live Data supports a wide variety of tag and variable types. See *Live Data on page 648* for more information.	FALSE	Constant (BOOL)
Live Data Labels	Provide a comma-separated list of labels (as many as 255 characters) to associate with this tag in Live Data. Live Data can be filtered by labels to make locating data faster. See *Live Data on page 648* for more information.		Constant (STRING(255))
SE Bit Reference	The bit in the source expression that the Tag Processor will assign to the destination tag.		Constant (0–31)
Time Source	The time stamp the Tag Processor assigns to the Destination Tag. A time stamp from any tag can be used, and this overrides the time stamp of the Source Expression tag. Example values: System_Time or SEL_421_1_DNP.BI_0001.t. Using a different time source when mapping non control types to control types may cause incorrect control behavior.		Variable (timestamp_t)
Time Offset	ACSELERATOR RTAC will add the value in this field to the Destination Tag time-stamp value. The format is T#*n*s, where *n* is any whole number.		Constant (TIME) Variable (TIME)
Quality Source	The quality value the Tag Processor assigns to the Destination Tag. A quality source from any tag can be used, and this overrides the quality of the source expression tag. Example value: SEL_421_1_DNP.BI_0001.q.		Variable (quality_t)
Instruction Number	Noneditable reference value linked to the structured text shown under the **Code** tab at the bottom of the Tag Processor grid.	Unique Identifier	Not assignable. Generated automatically.
Solve Order	Configurable order for the solution of Tag Processor logic. Numbers do not need to be unique.	Follows instruction number	Constant (DINT)
Description	A user-editable field for applicable comments. Not used in the logic engine.		Constant (Any string)
Control Type	Editable only on control type tags.		Constant (Pulse, Persist)
Operator Blocked	Enter a tag or constant of type Boolean. The Tag Processor maps this value to the Destination Tag operatorBlocked attribute.		Constant (BOOL) Variable (BOOL)

Parameter	Description	Default	Field Type
On Pulse Dur	Editable only on control type tags. Length of on pulse in milliseconds.	1000	Constant (UDINT) Variable (UDINT)
Off Pulse Dur	Editable only on control type tags. Length of off pulse in milliseconds.	1000	Constant (UDINT) Variable (UDINT)
Number of Pulses	Editable only on control type tags.	1	Constant (USINT) Variable (USINT)
PU Delay	Pick-up delay.		Constant (Between T#10ms and T#1000000s) Variable (TIME)
DO Delay	Drop-out delay.		Constant (Between T#10ms and T#1000000s) Variable (TIME)
Dead Band	Editable only on analog tags of type MV or CMV. The number of units that dictates a significant value change. The excursion of the dead band moves instMag to mag.		Constant (REAL) Variable (REAL)
Zero Dead Band	Editable only on analog tags of type MV or CMV. If Mag < Zero Dead Band, then Mag := 0.		Constant (REAL) Variable (REAL)
Range Min	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Range Max	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Range Low Low Lim	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Range Low Lim	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Range High Lim	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Range High High Lim	User-defined threshold value.		Constant (REAL or DINT) Variable (REAL or DINT)
Logging Enable	Set to True to enable the logic engine logging of this tag.	True for default logged points. False for all others.	Constant (BOOL)
Logging - Priority	User-defined priority for log item filtering.		Constant (STRING(255)) Variable (STRING(255))
Logging - Category	User-defined category for log item filtering.		Constant (STRING(255)) Variable (STRING(255))
Log Initial State	Set to True to log startup value of tags. If False, the RTAC system will wait to log changes until after the system reaches a ready state.	False	Constant (BOOL)
Logging - On Message	User-configurable message that logic engine enters into the log when the tag value asserts.		Constant (STRING(255)) Variable (STRING(255))
Logging - Off Message	User-configurable message that logic engine enters into the log when the tag value deasserts.		Constant (STRING(255)) Variable (STRING(255))
Logging - Time Change Trigger	If True, the logic engine will log the tag upon a change in the tags time stamp.		Constant (BOOL) Variable (BOOL)

Parameter	Description	Default	Field Type
Logging Time Change Trigger Message	The text that the logic engine logs when the time stamp of the destination tag changes. The RTAC will use this message if no Logging-On or Logging-Off messages are defined. Applies to types SPS, MV, CMV, INS, and STR.		Constant (STRING(255)) Variable (STRING(255))
Logging Alarm Enable	When true, the logic engine considers the logged value an alarm. These tags are logged in the SOE log but also appear in the Alarm Summary of the web interface. The alarm entry is red when in alarm, then returns to black when no longer in alarm state. Applies to types SPS, MV, CMV, INS, and STR.	False	Constant (BOOL) Variable (BOOL)
Logging Alarm State	If True, the logged item will go into alarm when state changes from deasserted to asserted. Applicable only when Logging Alarm Enable is True.		Constant (BOOL) Variable (BOOL)
Logging Chatter Count	Number of changes allowed within the Chatter Time before the logic engine removes a tag's log items because of chattering.		Constant (UINT)
Logging Chatter Time	The time window in which tag value changes are counted to determine a chattering condition.		Constant (TIME)
Logging Comment	User-defined comment.		Constant (STRING(255)) Variable (STRING(255))
Logging Display Tag Name	Displayed tag name in the SOE report. If empty, the SOE report displays the Destination Tag Name.		Constant (STRING(255))

Example 3.1 Simple Source-to-Destination Tag Mapping

The following example illustrates simple tag mapping between a relay and a SCADA system using the DNP3 protocol. For more information regarding how to add and configure DNP client and server devices, see *Section 2: Communications*.

Step 1. Insert a DNP device and configure it as a server. Name it **SCADA_1**.

Step 2. Insert a DNP shared map and name it **SCADA_1**. Configure the DNP server device to use this shared map.

Step 3. Configure DNP shared map SCADA_1 with two binary inputs, two analog inputs, and one binary output.

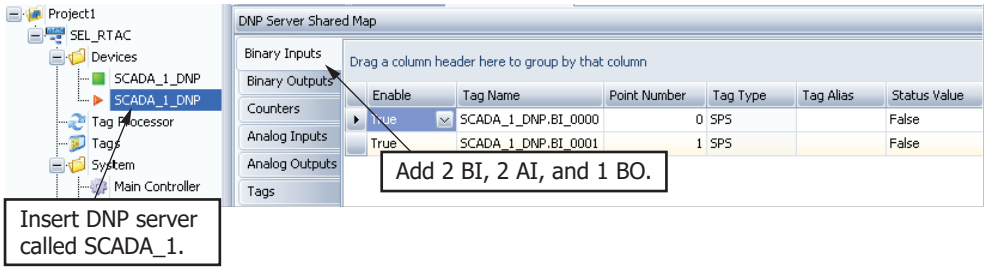

Figure 3.2 Insert DNP Server

Step 4. Insert a DNP device, and configure it as a client. Name it **Feeder_1**.

Step 5. Configure Feeder_1 with two binary inputs, two analog inputs, and one binary output.

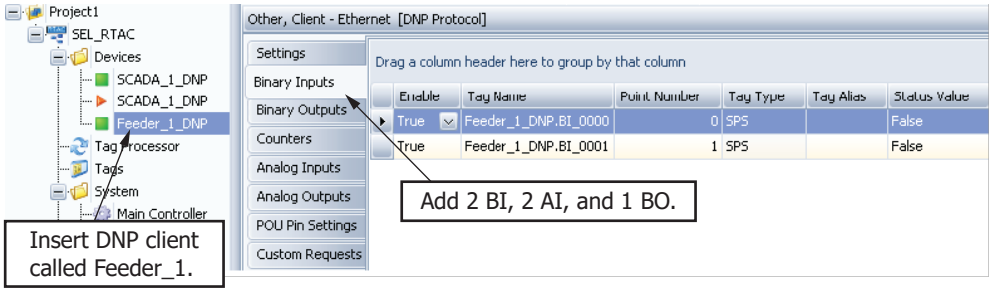

Figure 3.3 Insert DNP Client

Step 6. Click on the **Tag Processor** tab from the list view in the left pane of the screen.

Step 7. Click on + to add the total number of SCADA_1 tags. In this example, that number will be 10.

> **NOTE**
> The Tag Processor inserts new rows automatically if the number of tags you paste exceeds the number of available rows.

Step 8. Populate the **Destination Tag Name** column starting on the first available row with the two binary input tags from SCADA_1. Either type in the tags directly into the Tag Processor grid or select/copy/paste from the SCADA_1 tag lists. See *Section 3: Tag Processor*.

Step 9. Populate the **Destination Tag Name** column starting on the first available row after the binary inputs with the two analog input tags from SCADA_1.

Step 10. Populate the **Destination Tag Name** column starting on the first available row after the analog inputs with the binary output status from SCADA_1. See *Figure 3.5*.

Step 11. Finish populating the destination column with the BO structure from Feeder_1, as in *Figure 3.5*.

The source column is for data entering the RTAC, and the destination column is for data exiting the RTAC, so control output mapping is the reverse of input mapping in the Tag Processor. Data enter the RTAC from Feeder_1 and exit via the SCADA_1 tags. Control data, however, enter the RTAC from SCADA_1 and exit via the Feeder_1 tag. Data quality for destination analog, status, and counter tags also comes from the source or IED tag. Data quality for control values, however, is provided by the server tags and transferred to the client tags. This infers that control data tags from an IED will inherit invalid quality if the server connection is not working even if the client connection has no problems. Note that one element of the control structure (the control status) is an input the RTAC provides, and that mapping is similar to any other status input. See *Figure 3.6*.

Note also that DNP binary outputs have special structures to facilitate different control types as well as to enable mapping of one control type to another. To forward to Feeder_1 all binary output commands the RTAC receives from SCADA_1, map the entire control output type structure. This ensures that DNP commands will

pass transparently to the IED as the RTAC receives these commands from SCADA_1. Were you to map a control from Modbus, there would be only one entry in the Tag Processor per control point, because Modbus lacks the complex control structure of DNP.

Step 12. Populate the Source Expression columns with Feeder_1 inputs and outputs as in *Figure 3.5*.

In some cases, you do not have to map all DNP BO control types. For example, the DNP server may always receive Trip and Close commands and the IED may only need Trip and Close commands. In that case, only map the Trip and Close control types.

Some situations require a conversion from one DNP BO type to another. For example, the polling master may only be able to send trip/close commands, but the IED can only accept latch on/off commands. Map the different DNP BO types to each other in the Tag Processor. Change the Control Type column to force the source control type to match the destination control type. In this example, change Control Type to Persist to match that of the Latch controls in the Destination Tag Name column. See *Figure 3.4*. When SCADA_1 sends a trip command to BO_0000, the RTAC will issue a DNP message with the BO LatchOff command to the configured point on Feeder_1.

NOTE
Control types of Source Expressions must match those of the Destination Tag Names to which they are assigned. To force a match, change the type in the Control Type column.

Destination Tag Name	DT Data Type	Source Expression	Control Type
Feeder_1_DNP.BO_0000.operLatchOn	OPERSPC	SCADA_1_DNP.BO_0000.operClose	Persist
Feeder_1_DNP.BO_0000.operLatchOff	OPERSPC	SCADA_1_DNP.BO_0000.operTrip	Persist

Figure 3.4 DNP BO Type Conversion

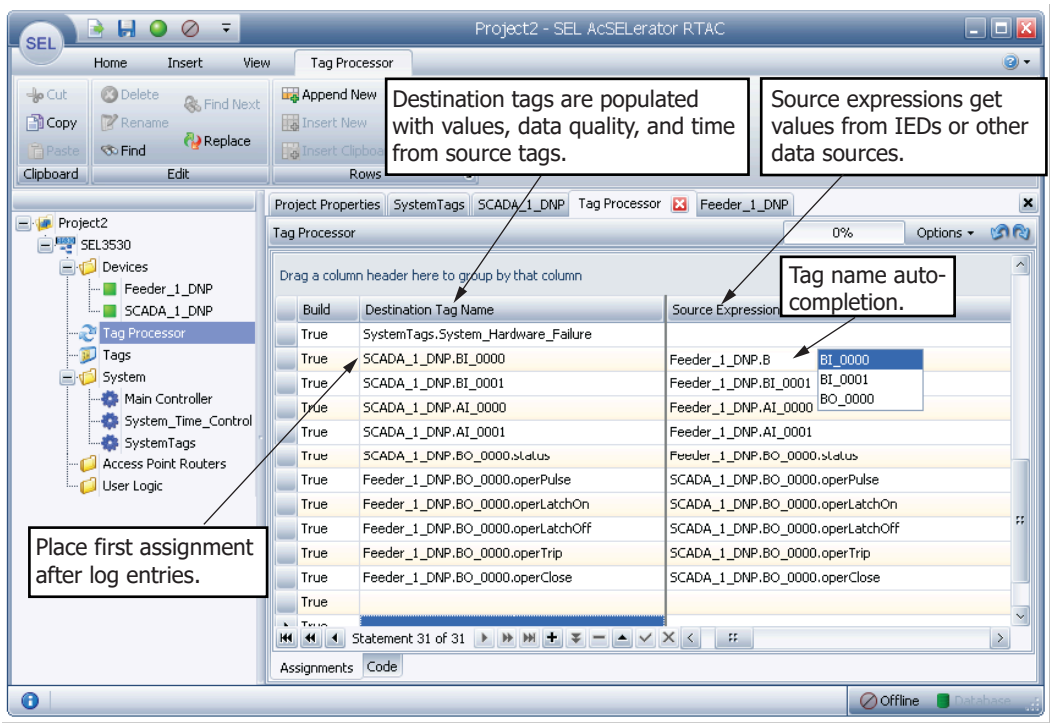

Figure 3.5 Simple Tag Mapping

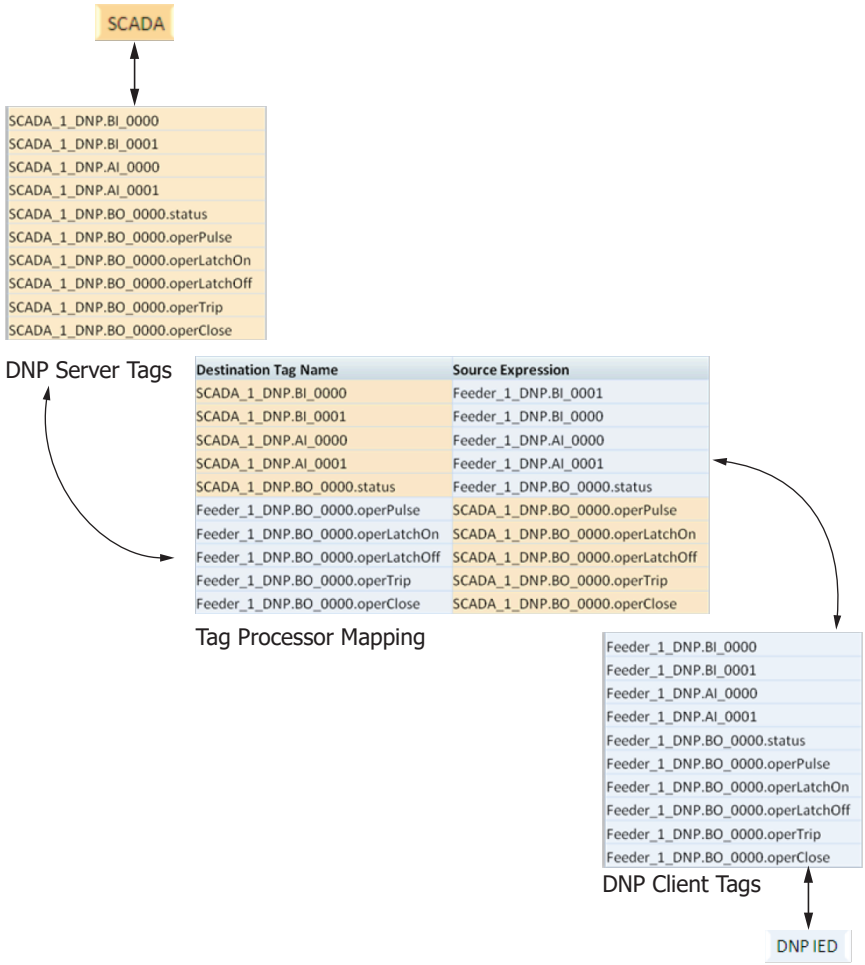

Figure 3.6 Tag Processor Data Flow

Example 3.2 IEC 61131-3 Code in the Tag Processor

Use any structured text statements in the Tag Processor to modify values or select conditionally which tags to use. This example illustrates the following Tag Processor features:

- Conditional statements that you can use to create a primary/backup IED relay
- A SELECT statement that you can use to choose automatically between two tag values
- Boolean logic that you can use on two binary input points
- A complex calculation to create a derived value

Step 1. Start with the project in *Example 3.1*.

Step 2. Add two more binary input tags and two analog input tags to SCADA_1.

Step 3. Insert a DNP device and configure the device as a client. Name it **Line_1**. This will represent a transmission line protective relay.

Step 4. Add two binary inputs and two analog inputs to Line_1.

Step 5. Copy and paste Line_1. Rename **Line_1copy** to **Line_1_Bak**. This will represent the backup relay on Transmission Line 1. See *Figure 3.7*.

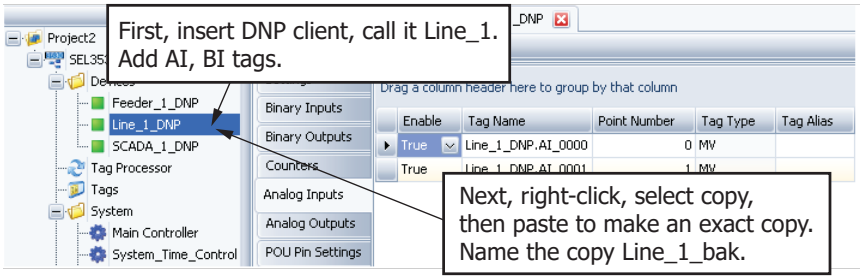

Figure 3.7 Insert Primary and Backup IED

Step 6. Highlight the entries in the Tag Processor from the previous example and then select the − button to delete the entries.

Step 7. Select the + button to add lines to the Tag Processor as necessary.

Step 8. Type in or copy/paste the tags from Feeder_1, Line_1, and Line_1_Bak to the Tag Processor, as shown in *Figure 3.8*.

Step 9. Type in or copy/paste the tags from SCADA_1 to the Tag Processor, as shown in *Figure 3.8*.

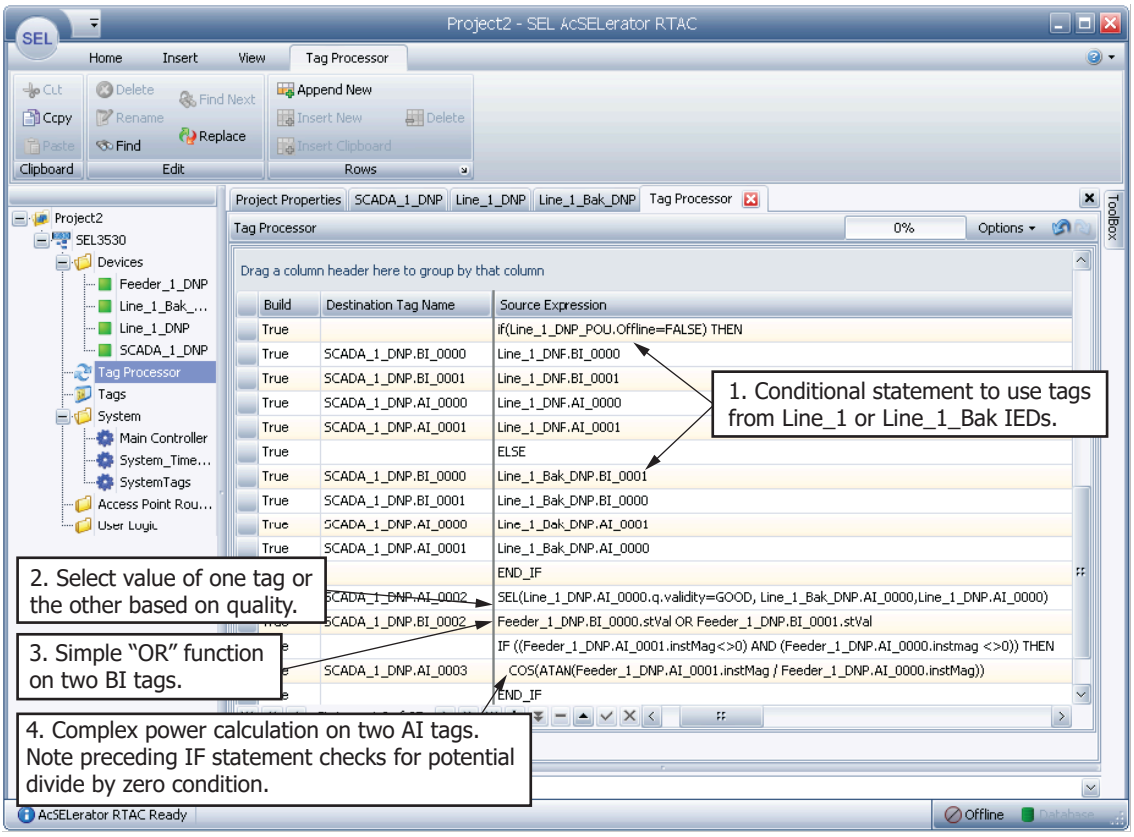

Figure 3.8 IEC 61131-3 Logic in Tag Processor

The following describes the specific syntax of the embedded IEC 61131-3 structured text in *Figure 3.8*:

1. The IF statement is checking to ensure Line_1 is not offline. If there is an unrecoverable communication error, the Offline POU pin will become True. As long as the Line_1 Offline POU pin = FALSE, Line_1 data will populate SCADA_1 tags. If Line_1 Offline = True, the backup relay (Line_1_Bak) tags will populate SCADA_! tags.
2. The RTAC uses the **SELECT** command to send the value of one tag or the other to the SCADA_1 tag. If the expression "Line_1_DNP.AI_0000.q.validity=GOOD" is true, then the value of the Line_1 tag maps to the SCADA_1 tag. Otherwise (if the quality is not good for that point), the RTAC uses the Line_1_Bak tag. This is a good feature to use if you have only one or two values that are acting as a primary and backup.

   NOTE
   If you use IEC 61131-3 logic in the Tag Processor, review the generated structured text in the Code tab after you save the project. Verify that the code the Tag Processor generates matches your intentions and look for any "invalid statement" warnings.

3. You can use any combination of Boolean logic operators as a source expression. In this example, SCADA_1_DNP.BI_0002 is true if either BI_0000 OR BI_0001 are true. By ORing the stval of the tag, you will lose the time and quality of the original two tags being ORed.
4. You can use any combination of math operations on any tags as a source expression. In this example, we illustrate how we can calculate power from the reactive and real power values of two analog input tags.

Example 3.3 Defining a Local Variable in the Tag Processor

This example will further demonstrate embedding IEC 61131-3 logic by defining a local variable directly in the Tag Processor.

Step 1. Start with any project in ACSELERATOR RTAC.

Step 2. Open the Tag Processor.

Step 3. In a blank source expression (SE) Data Type column, type **TEMPVAL : REAL**. You can use any supported data type when defining the new local variable. Variable names are not case sensitive.

Step 4. Type **TEMPVAL** in the Destination Tag Name column.

Step 5. Create an assignment in the Source Expression column. See *Figure 3.9*.

Step 6. Press **<Ctrl+S>** to save and compile the project.

You will notice there are no compile errors. The new variable is created as a global and recognized throughout the ACSELERATOR RTAC project.

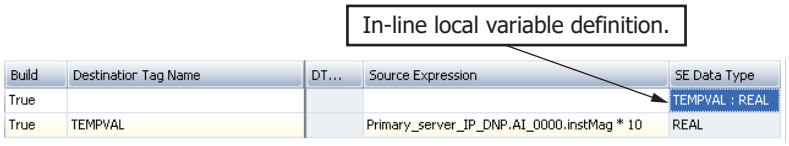

Figure 3.9 Local Variable Definition in Tag Processor

Example 3.4 Populating the Tag Processor From Excel

This example illustrates how we can use a preconfigured Excel spreadsheet to populate the Tag Processor. We presume in this example that the control center developed the spreadsheet with predefined names to which the RTAC must adhere.

Step 1. Start with a blank project in ACSELERATOR RTAC.

Step 2. See the spreadsheet in *Figure 3.10*. It has SCADA points and IED points as we recorded these points from the master control center configuration sheets (presumed for this example).

Step 3. Select, copy, and paste the rows from the spreadsheet. Note that the spreadsheet must have either a blank middle column for a bulk copy/paste, or you must copy the columns one at a time. Correct columns are as follows:

- Column 1 = Destination or SCADA tag names
- Column 2 = blank
- Column 3 = Source or IED tag names
- Column 4 = Optional RTAC data type for the source tag (see *Appendix B: IEC 61131-3 Programming Reference* for data types). Typically, it is best to let the system determine this value.

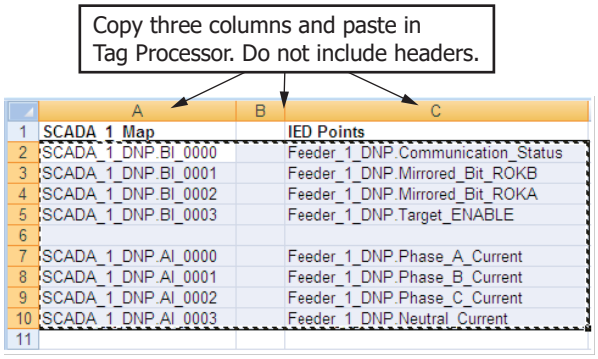

Figure 3.10 SCADA Mapping Spreadsheet

Step 4. Paste the columns you copied into the first destination tag name entry available. If no blank destination tag name entry exists, press + to create one. The Tag Processor will create and populate as many rows as you paste from the spreadsheet. You must select the entire cell for the paste operation to work correctly.

Step 5. The source and destination tags are now mapped, but these tags still do not exist in the ACSELERATOR RTAC database. Note in *Figure 3.11* that ACSELERATOR RTAC does not fill out the source and destination data types because the tags are not yet defined. A ⊗ appears beside each undefined tag.

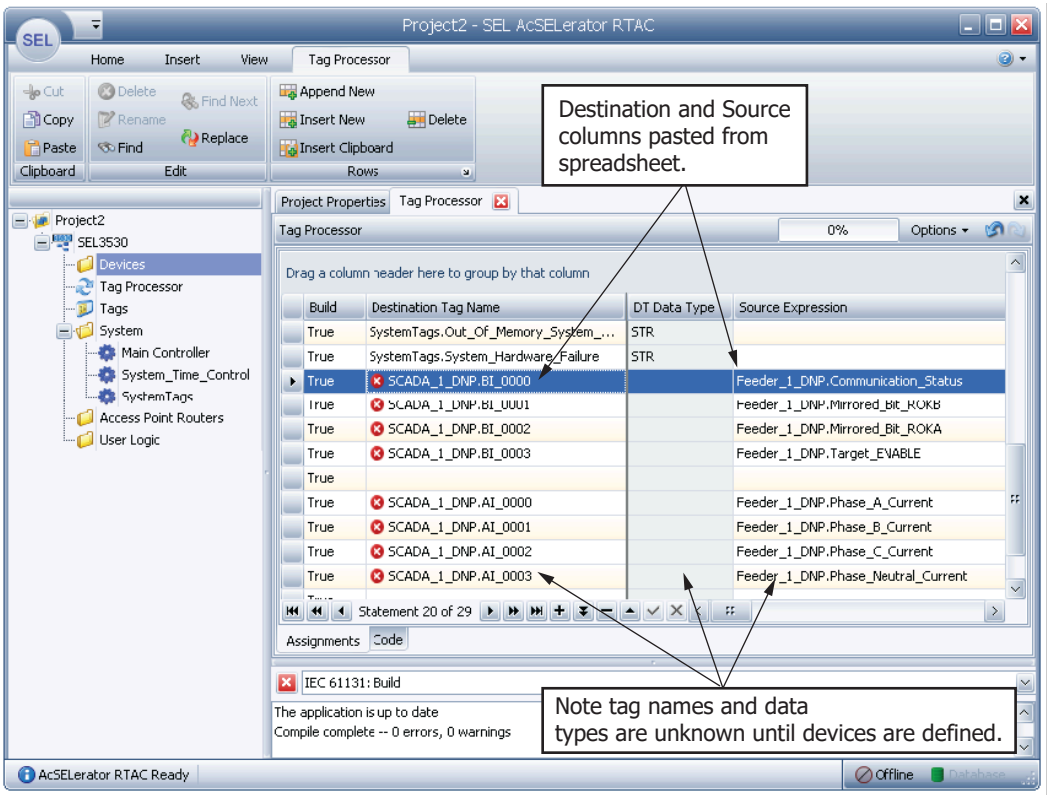

Figure 3.11 Copy/Paste Spreadsheet Tags

Create Destination Tags:

Step 6. From the menu ribbon, insert a DNP device and define this device as a DNP server. Name it **SCADA_1**.

Step 7. Add four binary input and four analog input tags. In this example, the names that ACSELERATOR RTAC generated automatically match those of the spreadsheet, so nothing more is necessary.

Create Source Tags:

Step 8. From the menu ribbon, insert a DNP device, and define this device as a DNP client. Name it **Feeder_1**.

Step 9. Add four binary input and four analog input tags.

In this example, the names that ACSELERATOR RTAC automatically generated do *not* match those of the spreadsheet.

Step 10. Copy the binary input names from the spreadsheet and paste these names on top of the binary input tags in the Feeder_1 device. See *Figure 3.12* and *Figure 3.13*. Alternatively, you can paste custom tag names into the Alias columns within each data type configuration page.

Step 11. Repeat *Step 10* for the analog input names in the spreadsheet.

Step 12. Press the **Tag Processor** tab to return to the Tag Processor view.

Step 13. Press or **<Ctrl+S>** to save. Note that data types are filled out correctly and that the symbols are gone.

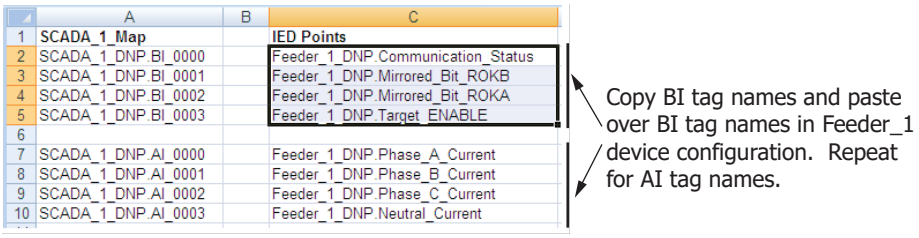

Figure 3.12 Custom Tag Names in Spreadsheet

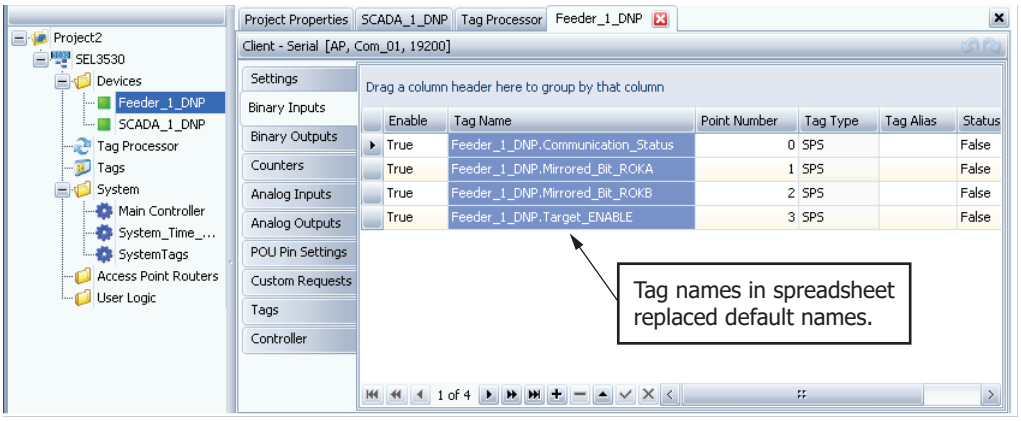

Figure 3.13 Feeder_1 Default Tag Names Replaced

Example 3.5 Access Individual Bits in the Tag Processor

This example illustrates the syntax to access individual bits from tags in the Tag Processor. This is an alternate method for packing/accessing individual bits into a tag and is valid in user logic as well as in the Tag Processor. Care should be taken when performing bit-wise operations. Note that floating point tags and signed integers are represented in memory differently than unsigned tags.

Figure 3.14 shows the syntax for accessing individual bits of a tag by placing a .0, .1, etc., after the tag name. While online with the project, click on **Tools > Display Mode > Binary** from the Home ribbon menu to see the binary representation of the tag (see *Figure 3.15*).

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.0	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.1	BOOL	FALSE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.2	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.3	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.4	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.5	BOOL	FALSE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.6	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.7	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.8	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.9	BOOL	FALSE	BOOL

Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.12	BOOL	FALSE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.13	BOOL	TRUE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.14	BOOL	FALSE	BOOL
Modbus_IED_MODBUS.HREG_00000.oper.ctlVal.15	BOOL	FALSE	BOOL

Figure 3.14 Bit Access in the Tag Processor

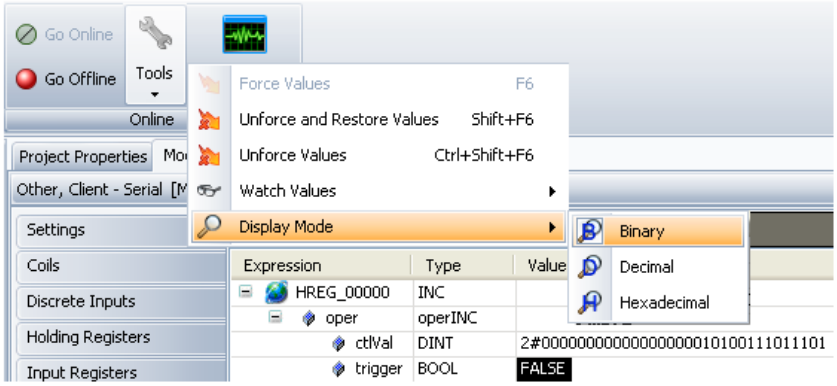

Figure 3.15 Binary Display Mode

Example 3.6 Visualize Tag Data on RTAC Web Interface

Step 1. Configure a valid assignment in the Tag Processor, including a Source Expression and Destination Tag Name.

Step 2. In the column Live Data Enabled, set the value = Viewable.

Step 3. Save the project and send to the RTAC.

Step 4. In the RTAC web interface, click the menu item Live Data.

The live data for the tags selected is displayed on the web interface.

Alias Tags

The format of TagNames is always as follows: devicename_protocol.pointname (i.e., Line_1_DNP.BI_0001). You can change the pointname and devicename, but the structure must remain the same. Alias tags do not follow this format, and you have greater flexibility in naming tags. Place user-created alias tags in the

alias tags column in each device setup. Once you assign an alias name to a tag, it replaces that tag throughout the system. For example, use alias tags in the Tag Processor in place of device tag names. Use the following rules when creating alias tags:

- Make each alias tag a unique name within a project.
- Start with a letter.
- Use any combination of letters and numbers you want.
- Instead of spaces or dashes, use the underscore (_) character.
- Do not have two underscore characters together.
- Do not use special characters.

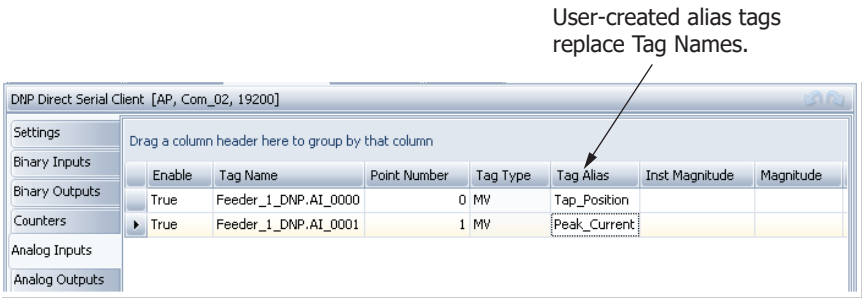

Figure 3.16 Alias Tags

Special Tag Processor Functions

Although you can perform IEC 61131 logic on individual variables in the Tag Processor, most device tag types are structures of variables. The structures contain not only the present value of the tag but also time data, quality data, etc. For example, this statement adds two instantaneous analog values:

✓ Feeder_1_DNP.AI_0000.instMag + Feeder_1_DNP.AI_0001.instMag

But this example will not:

× Feeder_1_DNP.AI_0000 + Feeder_1_DNP.AI_0001

To perform math or logic on an entire tag structure, you can use the special built-in Tag Processor functions described in this section.

ABS_vector_t

This function receives a vector_t data type with either a positive or negative magnitude and an angle of any arbitrary floating-point value. It will produce an equivalent vector_t with a positive magnitude and an angle evaluated from 0 degrees to +360 degrees such that it equivalently represents the original vector.

Inputs:

IN : vector_t

Output:

Returns modified vector_t tag with a positive magnitude and an angle wrapped between 0 and +360 degrees (inclusive of 0).

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.Vec2	VECTOR_T	ABS_vector_t(Vector.Vec1)	VECTOR_T

Figure 3.17 ABS_vector_t Example

ADD_CMV

This function adds the instCVal of two CMV tags using vector addition (first converting to rectangular coordinates, then adding real and imaginary parts).

Inputs:

IN1, IN2 : CMV

Output:

Returns modified CMV tag as follows:

- instCVal is the result of IN1.instCVal + IN2.instCVal
- time is the most recent time between the two input CMV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0000	CMV	ADD_CMV(Feeder1.Status_0000, Feeder1.Status_0002)	CMV

Figure 3.18 ADD_CMV Example

ADD_INS

This function adds the stVal of two INS tags.

Inputs:

IN1, IN2 : INS

Output:

Returns modified INS tag as follows:

- stVal is the result of IN1.stVal + IN2.stVal
- time is the most recent time between the two input INS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
HMI_MODBUS.IREG_00000	INS	ADD_INS (IED1_MODBUS.IREG_00000, IED1_MODBUS.IREG_00001)	INS

Figure 3.19 ADD_INS Example

ADD_MV

This function adds the instMag of two MV tags.

Inputs:

IN1, IN2 : MV

Output:

Returns modified MV tag as follows:

- instMag is the result of IN1.instMag + IN2.instMag
- time is the most recent time between the two input MV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.AI_0000	MV	ADD_MV (Feeder1_DNP.AI_0000, Feeder1_DNP.AI_0001)	MV

Figure 3.20 ADD_MV Example

ADD_vector_t

This function takes two vectors and returns the vector sum of their values (by converting them to rectangular coordinates and then adding real and imaginary parts).

Inputs:

IN1, IN2 : vector_t

Output:

Returns modified vector_t tag of the sum of the two inputs

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.Vec1_Plus_Vec2	VECTOR_T	ADD_vector_t(Vector.Vec1,Vector.Vec2)	VECTOR_T

Figure 3.21 ADD_vector_t Example

AND_SPS

This function performs a logical AND on the stVal of two SPS tags.

Inputs:

IN1, IN2 : SPS

Output:

Returns modified SPS tag as follows:

- stVal is the result of IN1.stVal AND IN2.stVal
- time is the most recent time between the two input SPS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.BI_0000	SPS	AND_SPS (Feeder1_DNP.BI_0000, Feeder1_DNP.BI_0001)	SPS

Figure 3.22 AND_SPS Example

DIV_CMV

This function divides the instCVal of the first CMV tag by that of the second CMV tag by first dividing the magnitude of the first CMV by that of the second CMV and then subtracting the angle of the second CMV from that of the first.

Inputs:

IN1, IN2 : CMV

Output:

First returns modified CMV tag as follows:

- instCVal is the result of IN1.instCVal / IN2.instCVal
- time is the most recent time between the two input CMV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0000	CMV	DIV_CMV(Feeder1.Status_0000, Feeder1.Status_0002)	CMV

Figure 3.23 DIV_CMV Example

DIV_INS

This function divides the stVal of the first INS tag by that of the second INS tag.

Inputs:

IN1, IN2 : INS

Output:

Returns modified INS tag as follows:

- stVal is the result of IN1.stVal / IN2.stVal
- time is the most recent time between the two input INS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
HMI_MODBUS.IREG_00000	INS	DIV_INS (IED1_MODBUS.IREG_00000, IED1_MODBUS.IREG_00001)	INS

Figure 3.24 DIV_INS Example

DIV_MV

This function divides the instMag of the first MV tag by that of the second MV tag.

Inputs:

IN1, IN2 : MV

Output:

Returns modified MV tag as follows:

- instMag is the result of IN1.instMag / IN2.instMag
- time is the most recent time between the two input MV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.AI_0000	MV	DIV_MV (Feeder1_DNP.AI_0000, Feeder1_DNP.AI_0001)	MV

Figure 3.25 DIV_MV Example

DIV_vector_t

This function divides the first vector_t tag by the second vector_t tag.

Inputs:

IN1, IN2 : vector_t

Output:

Returns a vector_t of the quotient of IN1 divided by IN2.

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.quotient	VECTOR_T	DIV_vector_t(Vector.dividend,Vector.divisor)	VECTOR_T

Figure 3.26 DIV_vector_t Example

EQ_vector_t

This function takes two vector_t data types as inputs and evaluates their equivalence as vectors. Vectors that have different magnitudes or angles but which resolve to the same polar coordinate will be considered equivalent. For example, both $1\angle 30°$ and $-1\angle -150°$ are considered equivalent, and in such a case, the function will return True.

Inputs:

IN1, IN2 : vector_t

Output:

Returns a Boolean value of True if both magnitudes and angles are equivalent; False otherwise.

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.IsEqual	BOOL	EQ_vector_t(Vector.Vec1,Vector.Vec2)	BOOL

Figure 3.27 EQ_vector_t Example

MULT_CMV

This function multiplies the instCVal of the first CMV tag by that of the second CMV tag by first multiplying the magnitudes of each CMV and then adding the angles of each CMV.

Inputs:

IN1, IN2 : CMV

Outputs:

Returns modified CMV tag as follows:

- instCVal is the result of IN1.instCVal * IN2.instCVal
- time is the most recent time between the two input CMV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0000	CMV	MULT_CMV(Feeder1.Status_0000, Feeder1.Status_0002)	CMV

Figure 3.28 MULT_CMV Example

MULT_INS

This function multiplies the stVal of the first INS tag by that of the second INS tag.

Inputs:

IN1, IN2 : INS

Output:

Returns modified INS tag as follows:

- stVal is the result of IN1.stVal * IN2.stVal
- time is the most recent time between the two input INS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
HMI_MODBUS.IREG_00000	INS	MULT_INS (IED1_MODBUS.IREG_00000, IED1_MODBUS.IREG_00001)	INS

Figure 3.29 MULT_INS Example

MULT_MV

This function multiplies the instMag of the first MV tag by that of the second MV tag.

Inputs:

IN1, IN2 : MV

Output:

Returns modified MV tag as follows:

- instMag is the result of IN1.instmag * IN2.instMag
- time is the most recent time between the two input MV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.AI_0000	MV	MULT_MV (Feeder1_DNP.AI_0000, Feeder1_DNP.AI_0001)	MV

Figure 3.30 MULT_MV Example

MULT_vector_t

This function multiplies the first vector_t tag by the second vector_t tag.

Inputs:

IN1, IN2 : vector_t

Outputs:

Returns a vector_t of the product of IN1 multiplied by IN2.

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.VecA_Cross_VecB	VECTOR_T	MULT_vector_t(Vector.VecA,Vector.VecB)	VECTOR_T

Figure 3.31 MULT_vector_t Example

NORM_vector_t

This function receives a vector_t data type with either a positive or negative magnitude and an angle of any arbitrary floating-point value. It will produce an equivalent vector_t with a positive magnitude and an angle evaluated between –180 degrees and +180 degrees such that it equivalently represents the original vector.

Inputs:

IN : vector_t

Output:

Returns modified vector_t tag with a positive magnitude and an angle wrapped between –180 and +180 degrees (inclusive of +180).

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.Vec1_Norm	VECTOR_T	NORM_vector_t(Vector.Vec1)	VECTOR_T

Figure 3.32 NORM_vector_t Example

NOT_SPS

This function performs a logical NOT on the stVal of SPS tag.

Inputs:

IN : SPS

Output:

Returns modified SPS tag as follows:

- stVal is the result of NOT (IN1.stVal)
- time is the time of IN
- q is the quality of IN

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.BI_0000	SPS	NOT_SPS (Feeder1_DNP.BI_0000)	SPS

Figure 3.33 NOT_SPS Example

OR_operSPC

This function effectively performs a logical OR of ctlVal of the first operSPC and that of the second operSPC.

Inputs:

IN1, IN2 : operSPC

Output:

Returns modified operSPC tag as follows:

IF (IN1.ctlVal = True) AND (IN1.q.operatorBlocked = FALSE)
OR_operSPC := IN1

ELSEIF IN2.ctlVal = True) AND (IN2.q.operatorBlocked = FALSE)
OR_operSPC := IN2

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Feeder1_DNP.BO_0000.operClose	OPERSPC	OR_operSPC (SCADA1_DNP.BO_0000.operClose, SCADA2_DNP.BO_0000.operClose)	OPERSPC

Figure 3.34 OR_operSPC Example

OR_SPS

This function performs a logical OR on the stVal of two SPS tags.

Inputs:

IN1, IN2 : SPS

Output:

Returns modified SPS tag as follows:

- stVal is the result of IN1.stVal OR IN2.stVal
- time is the most recent time between the two input SPS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.BI_0000	SPS	OR_SPS (Feeder1_DNP.BI_0000, Feeder1_DNP. BI_0001)	SPS

Figure 3.35 OR_SPS Example

REF_vector_t

This function calculates the angle between the reference angle and the input quantity and produces a vector with its angle adjusted proportionally to the referenced vector.

Inputs:

Ref : vector_t

In : vector_t

Output:

Returns the reference-adjusted equivalent of the vector.

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.VecA_Refd	VECTOR_T	REF_vector_t(Vector.Ref,Vector.VecA)	VECTOR_T

Figure 3.36 REF_vector_t Example

ROOT_CMV

This function calculates the square root of the instCVal of the input CMV tag by first evaluating the square root of the magnitude component and then dividing the angle component by two.

Inputs:

IN : CMV

Output:

Returns modified CMV tag as follows:

- instCVal is the result of \[\sqrt{IN1.instCVal}\]
- time is directly populated from the input tag
- q is directly populated from the input tag

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0000	CMV	ROOT_CMV(Feeder1.Status_0000)	CMV

Figure 3.37 ROOT_CMV Example

ROOT_MV

This function calculates the square root of the instMag of the input MV tag.

Inputs:

IN : MV

Output:

Returns modified MV tag as follows:

- instMag is the result of \[\sqrt{IN1.instMag}\]
- time is directly populated from the input tag
- q is directly populated from the input tag

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0001	MV	ROOT_MV(Feeder1.Status_0001)	MV

Figure 3.38 ROOT_MV Example

SCALE_CMV

This function scales the instCval.mag, using the input parameters.

OFFSET, CEILING, and FLOOR inputs are optional. OFFSET defaults to 0, while CEILING and FLOOR default to the maximum positive and negative values representable by the REAL data type, respectively.

NOTE
When using a negative scaling factor or offset, it is possible to generate vector values with negative magnitudes, which may be undesirable when representing a phasor or vector quantity. If this occurs, use either NORM_vector_t on page 612 or ABS_vector_t on page 606 to normalize both the magnitude to positive and the angle to a value bound by ±180 degrees or 0–360 degrees, respectively.

Inputs:

IN : CMV

SCALE : REAL

OFFSET : REAL (Optional)

CEILING : REAL (Optional)

FLOOR : REAL (Optional)

Output:

Returns modified CMV tag as follows:

- instCVal.mag is the result of:

  (* Calculate the scaling *)

  SCALE_CMV.instCVal.mag := IN.instCVal.mag * SCALE + OFFSET;

  (* Check for ceiling and floor *)

  IF SCALE_CMV.instCVal.mag > CEILING THEN

  SCALE_CMV.instCVal.mag := CEILING;

  END_IF

  IF SCALE_CMV.instCVal.mag < FLOOR THEN

  SCALE_CMV.instCVal.mag := FLOOR;

  END_IF
- time is the time of IN
- q is the quality of IN

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA_DNP.AI_0020	MV	SCALE_CMV (SEL_351S_1_SEL.VA , 100.0, 10000, 1E7, 0)	CMV

Figure 3.39 SCALE_CMV Example

SCALE_INS

This function scales the stVal by using the input parameters.

OFFSET, CEILING, and FLOOR inputs are optional. OFFSET defaults to 0, while CEILING and FLOOR default to the maximum positive and negative values representable by the DINT data type, respectively.

Inputs:

IN : INS

SCALE : REAL

OFFSET : DINT (Optional)

CEILING : DINT (Optional)

FLOOR : DINT (Optional)

Output:

Returns modified INS tag as follows:

- stVal is the result of:

  (* Calculate the scaling *)

  SCALE_INS.stVal := IN.stVal * SCALE + OFFSET;

```
(* Check for ceiling and floor *)
IF SCALE_INS.stVal > CEILING THEN
SCALE_INS.stVal := CEILING;
END_IF
IF SCALE_INS.stVal < FLOOR THEN
SCALE_INS.stVal := FLOOR;
END_IF
```

- time is the time of IN
- q is the quality of IN

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA_DNP.AI_0022	MV	SCALE_INS (SEL_3530_1_SEL.Rx_UW_1_F800, 10, 0, 10000000, -10000000)	INS

Figure 3.40 SCALE_INS Example

SCALE_MV

This function scales the instMag, using the input parameters.

OFFSET, CEILING, and FLOOR inputs are optional. OFFSET defaults to 0, while CEILING and FLOOR default to the maximum positive and negative values representable by the REAL data type, respectively.

Inputs:

IN : MV

SCALE : REAL

OFFSET : REAL (Optional)

CEILING : REAL (Optional)

FLOOR : REAL (Optional)

Output:

Returns modified MV tag as follows:

- instMag is the result of:

```
(* Calculate the scaling *)
SCALE_MV.instMag := IN.instMag * SCALE + OFFSET;
(* Check for ceiling and floor *)
IF SCALE_MV.instMag > CEILING THEN
SCALE_MV.instMag := CEILING;
END_IF
IF SCALE_MV.instMag < FLOOR THEN
SCALE_MV.instMag := FLOOR;
END_IF
```

- time is the time of IN
- q is the quality of IN

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA_DNP.AI_0021	MV	SCALE_MV (SEL_3515_1_SEL.P_WATTS , 50, 200, 1000000, 0)	MV

Figure 3.41 SCALE_MV Example

SCALE_BCR

This function scales the actVal, using the input parameters.

OFFSET, CEILING, and FLOOR inputs are optional. OFFSET and FLOOR default to 0, while CEILING defaults to the maximum positive value representable by the UDINT data type.

Inputs:

IN : BCR

SCALE : REAL

OFFSET : LINT (Optional)

CEILING : UDINT (Optional)

FLOOR : UDINT (Optional)

Output:

Returns modified BCR tag as follows:

- actVal is the result of:

```
(* Calculate the scaling *)
SCALE_BCR.actVal := IN.actVal * SCALE + OFFSET;
(* Check for ceiling and floor *)
IF SCALE_BCR.actVal > CEILING THEN
SCALE_BCR.actVal := CEILING;
END_IF
IF SCALE_BCR.actVal < FLOOR THEN
SCALE_BCR.actVal := FLOOR;
END_IF
```

- time is the time of IN
- q is the quality of IN

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA_DNP.AI_0021	MV	SCALE_BCR(SEL_3530_1_SEL.Rx_UW_1_F807, 10, 0, 1000000, 10)	BCR

Figure 3.42 SCALE_BCR Example

SCALE_vector_t

This function uses the input parameters to scale the magnitude of a vector_t.

OFFSET, CEILING, and FLOOR inputs are optional. OFFSET defaults to 0, and CEILING and FLOOR default to the maximum positive and negative values representable by the REAL data type, respectively.

NOTE
When using a negative scaling factor or offset, it is possible to generate vector values with negative magnitudes, which may be undesirable when representing a phasor or vector quantity. If this occurs, use either NORM_vector_t on page 612 or ABS_vector_t on page 606 to normalize both the magnitude to positive and the angle to a value bound by ±180 degrees or 0–360 degrees, respectively.

Inputs:

IN : vector_t

SCALE : REAL

OFFSET : REAL (Optional)

CEILING : REAL (Optional)

FLOOR : REAL (Optional)

Output:

Returns modified vector_t tag as follows:

- mag is the result of:

```
(* Calculate the scaling *)
SCALE_vector_t.mag := IN.mag * SCALE + OFFSET;
(* Check for ceiling and floor *)
IF SCALE_vector_t.mag > CEILING THEN
SCALE_vector_t.mag := CEILING;
END_IF
IF SCALE_vector_t.mag < FLOOR THEN
SCALE_vector_t.mag := FLOOR;
END_IF
```

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.Scaled	VECTOR_T	SCALE_vector_t(Vector.VecA,50,200,1000000,0)	VECTOR_T

Figure 3.43 SCALE_vector_t Example

SUB_INS

This function subtracts the stVal of two INS tags.

Inputs:

IN1, IN2 : INS

Output:

Returns modified INS tag as follows:

- stVal is the result of IN1.stVal – IN2.stVal
- time is the most recent time between the two input INS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
HMI_MODBUS.IREG_00000	INS	SUB_INS (IED1_MODBUS.IREG_00000, IED1_MODBUS.IREG_00001)	INS

Figure 3.44 SUB_INS Example

SUB_MV

This function subtracts the instMag of two MV tags.

Inputs:

IN1, IN2 : MV

Output:

Returns modified MV tag as follows:

- instMag is the result of IN1.instMag – IN2.instMag
- time is the most recent time between the two input MV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.AI_0000	MV	SUB_MV (Feeder1_DNP.AI_0000, Feeder1_DNP.AI_0001)	MV

Figure 3.45 SUB_MV Example

SUB_CMV

This function subtracts the instCVal of two CMV tags (first converting to rectangular coordinates, then subtracting the real and imaginary parts of the second CMV from those of the first).

Inputs:

IN1, IN2 : CMV

Output:

Returns modified CMV tag as follows:

- instCVal is the result of IN1.instCVal – IN2.instCVal
- time is the most recent time between the two input CMV tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
VirtualTagList1.Status_0000	CMV	SUB_CMV(Feeder1.Status_0000, Feeder1.Status_0002)	CMV

Figure 3.46 SUB_CMV Example

SUB_vector_t

This function takes two vectors and returns the result of the first vector minus the second.

Inputs:

IN1, IN2 : vector_t

Output:

Returns the value of the first vector minus the second.

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
Vector.VecAB	VECTOR_T	SUB_vector_t(Vector.VecA,Vector.VecB)	VECTOR_T

Figure 3.47 SUB_vector_t Example

XOR_SPS

This function performs a logical XOR on the stVal of two SPS tags.

Inputs:

IN1, IN2 : SPS

Output:

Returns modified SPS tag as follows:

- stVal is the result of IN1.stVal XOR IN2.stVal
- time is the most recent time between the two input SPS tags
- q is the result of merging the quality attributes of IN1 and IN2 to reflect the worse case

Example in Tag Processor:

Destination Tag Name	DT Data Type	Source Expression	SE Data Type
SCADA1_DNP.BI_0000	SPS	XOR_SPS (Feeder1_DNP.BI_0000, Feeder1_DNP.BI_0001)	SPS

Figure 3.48 XOR_SPS Example

SECTION 4

Engineering Access

Overview

A transparent connection provides a data tunnel between two or more Ethernet or serial communications ports. Each port configured in a transparent connection is an access point. The SEL Real-Time Automation Controller (RTAC) redirects communications traffic from one access point, or port, through a second access point and vice versa. We designate one access point as the source. This access point, typically a PC used for engineering access, third-party software, etc., initiates communication. Subsequent access points are the destinations of the connection. These are typically IEDs connected to the RTAC. The RTAC links access points together through an access point router (APR). In this way, the APR enables the RTAC as a port switch. Configure access points and a maximum of 100 APRs in ACSELERATOR RTAC® SEL-5033 Software to accommodate one or many transparent connections.

There are two main categories of transparent connections:

1. Standard transparent: enables ASCII tunneling through a port while leaving undisturbed the underlying binary communication occurring on that port. An example would be SEL protocol interleaving ASCII engineering access with an SEL relay while the RTAC is polling the relay via Fast Meter commands.
2. Direct transparent: enables binary or ASCII tunneling through a port to an IED but turns off the underlying communication occurring on that port. An example would be third-party software configuring an IED with Modbus. The RTAC will discontinue polling the Modbus IED on that port during a direct transparent session and will direct tunneled messages through to the IED instead.

Within an APR, you can also perform actions on the strings as they pass from source to destination and back. Actions you can perform include issuing commands, stripping characters from a string, inserting tag values into a string, and searching a string for a given value.

Configuration

The following examples illustrate how to configure the RTAC for standard transparent and direct transparent connections.

Example 4.1 Standard Transparent Connection

Configure the RTAC as a port switch to access four SEL relays from a remote engineering PC. The RTAC will prompt you for a password. After you enter the password, you can use the **PORT** command to switch to the ports attached to the relays. This example contains five access points:

- One Ethernet connection into the RTAC (source)
- Four SEL relays connected to the RTAC via direct serial connections (destinations)

Step 1. Open a blank project in ACSELERATOR RTAC and insert the relays and access point.

Step 2. On the ribbon menu, click **Insert** and then **SEL**.

Step 3. Select an SEL-351S relay that uses the SEL protocol as a Client-Serial.

Step 4. Right-click on the inserted relay, select **Copy**, and then paste the copy on Devices. Paste three copies for a total of four SEL-351S IEDs for this example. Rename the copies as shown in *Figure 4.1*.

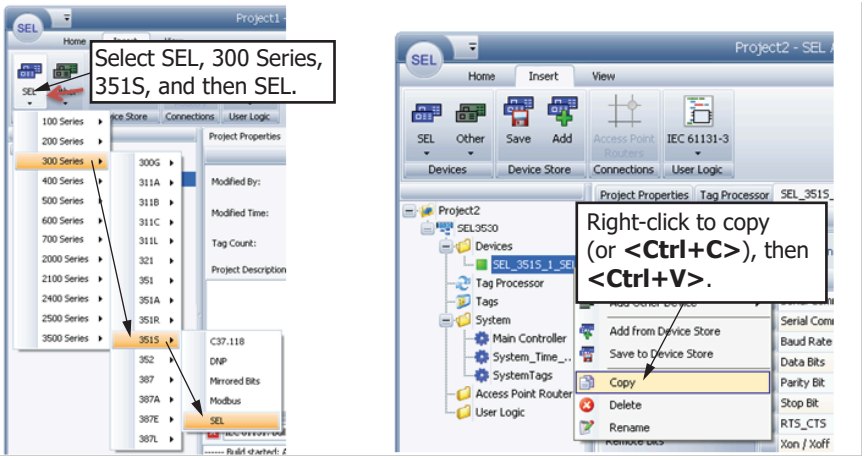

Figure 4.1 Configure Four SEL Access Points

Step 5. On the ribbon menu, click **Insert** and then **Other**.

Step 6. Insert an access point and configure this access point as **Ethernet Incoming**. This tells the RTAC that the access point will be listening for a connection. Conversely, you can configure other access points as outgoing to create connections to generic IEDs, etc. Client protocols, such as the SEL relays we inserted, already have an outgoing access point built in.

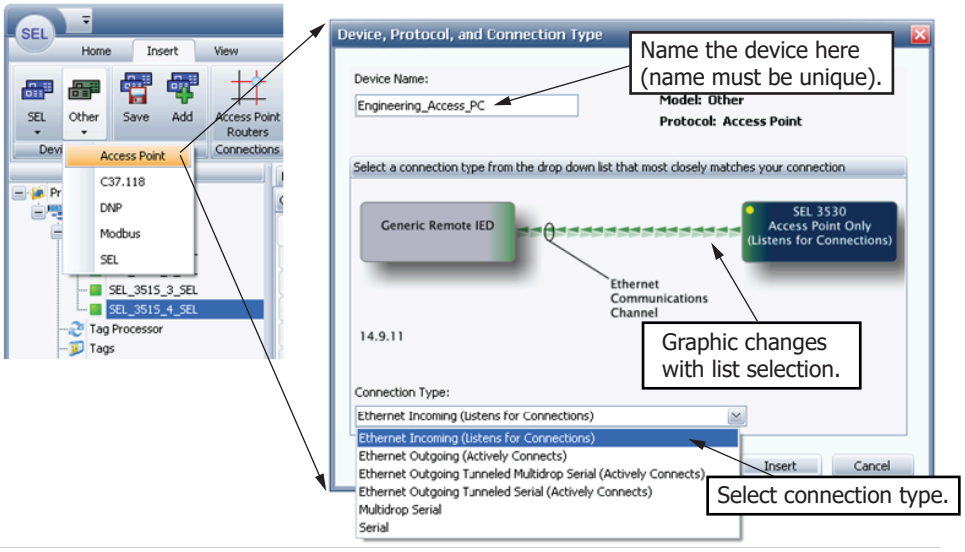

Figure 4.2 Insert Source Access Point

Step 7. Configure the access point **Local Port Number** in the **Settings** tab of the new access point. You will address this IP port when you create the tunnel session with the RTAC. There is no IP address setting because all active network interfaces on the RTAC will listen for the connection.

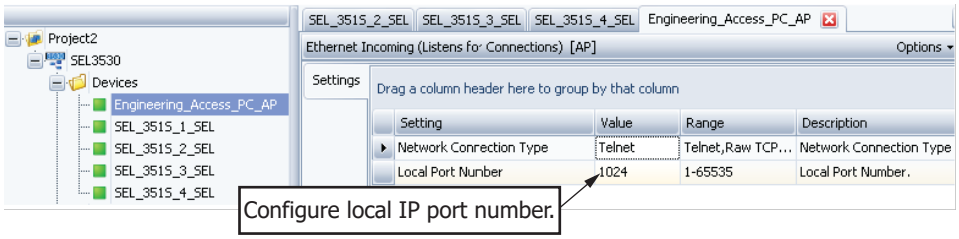

Figure 4.3 Configure Source Access Point

Step 8. On the **Insert** ribbon, click **Access Point Routers**. In this example, we want the RTAC to emulate an SEL-2030, so select each of the SEL_351S_n_SEL_TAP entries. See *Figure 4.4*.

Every device added to the RTAC is an access point. SEL IEDs have an extra access point designated _TAP for transparent connection sessions. Select the _TAP entry to permit the SEL binary protocol to continue to poll the SEL IED during an ASCII transparent connection session. Select the _AP entry to create a direct transparent connection that will stop all polling during a transparent connection with the device. *Example 4.2* describes the setup of this type of connection.

Step 9. Select **Enable Legacy Commands** to force the RTAC to require a login and the **PORT** command in the tunnel session. Configure as illustrated in *Figure 4.4*.

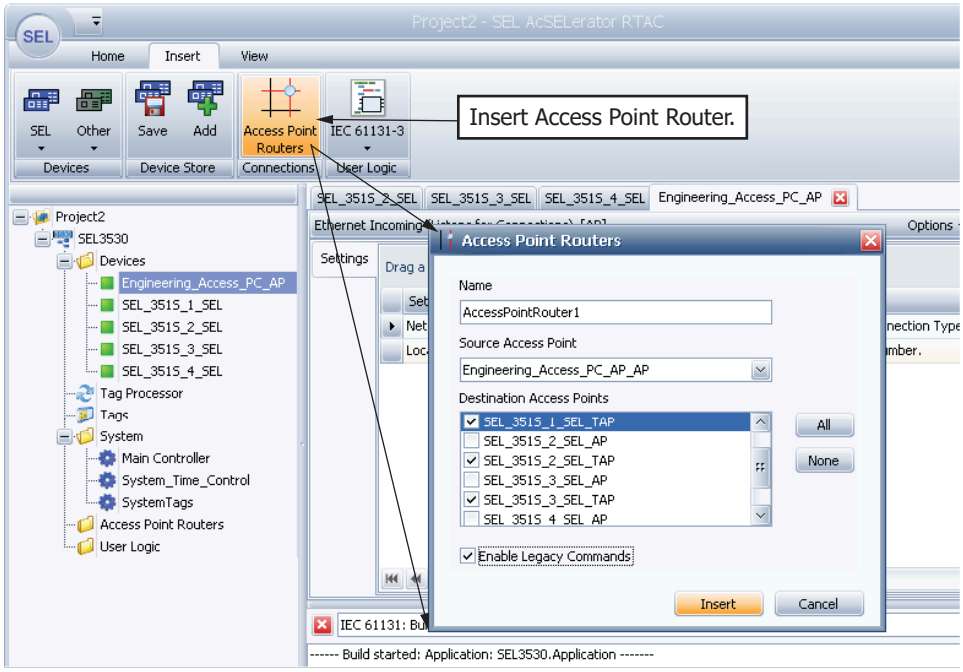

Figure 4.4 Insert Access Point Router

Step 10. Save the project and notice that this example created one APR automatically for each device. Each of the four APRs has the same source access point.

Step 11. Click on **AccessPointRouter1_1**.

Step 12. Change the **Source_Authentication** setting to **TRUE** and save.

This setting will force the RTAC to ask for a username and password to gain access to this APR. The username and password are configured via the RTAC web interface as described in *Section 7: Security and Account Management*. This setting is also global to all APRs. Configure for a particular group, so you only have to change it in one of the four APRs that are created in this example.

Step 13. Load the project into the RTAC.

Step 14. Test the project by opening HyperTerminal (or other terminal emulation program) as a Winsock connection. Enter the IP address of the connected RTAC and the Local Port Number you configured in Engineering_Access_PC_AP. Click **OK**.

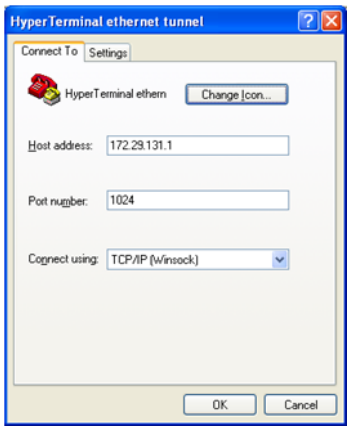

Figure 4.5 HyperTerminal Configuration

Step 15. Press the connect icon in HyperTerminal to connect and log in to the RTAC.

Type **PORT *n***, where *n* is the Legacy_Port_Command_ID corresponding to the desired port number, to connect transparently to one of the SEL-351S relays. Press **<Ctrl+D>** to exit a port.

The Legacy_Port_Command_ID setting field displays the ID that you will use for each APR. The default ID for the first APR is 1, with subsequent APR IDs incrementing thereafter. Had we also selected the _AP (direct transparent) APs as shown in *Figure 4.4*, we would have available additional APRs with unique port command IDs for each direct transparent connection. To open a transparent connection to PORT 1, type **Port 1** while connected to the RTAC through HyperTerminal to gain interleaved access to the device on PORT 1. To open a direct transparent connection on PORT1, type **Port 1 D** while connected to the RTAC through HyperTerminal to gain direct access to the relay on PORT 1. Configure the unique Legacy_Port_Command_ID, along with the default **PORT** command in Source_Rx_Message under POU Pin Settings within each APR.

Example 4.2 Direct Transparent Connection

This example shows how you can transparently connect to an IED without logging on to the RTAC or entering a **PORT** command. As soon as you connect to the RTAC, the APR directs communications to the access point you have configured in your project. In this example, that access point is a Modbus device. But you can follow the same steps to create a standard interleaved transparent connection to an SEL relay by configuring an SEL client instead of a Modbus client in this example.

Configure the RTAC to poll a Modbus IED. Then, use third-party software running on a PC to communicate with that IED through the RTAC. This example assumes that you have a Modbus IED connected to the RTAC on one serial port and an application running on your PC that can use Modbus protocol to configure the IED. The PC is connected to the RTAC on another serial port.

Step 1. On the **Insert** ribbon, click **Other** and then **Modbus**.

Step 2. Configure the Modbus device as **Client-Serial**.

Step 3. Configure to poll some points from a connected Modbus IED. See *Section 2: Communications* for details on configuring a Modbus client.

Step 4. Ensure that communications parameters (data rate, etc.) are correct in the Modbus client connection for the Modbus IED.

Step 5. From the **Insert** ribbon, click **Other** and then **Access Point**. Configure as **Serial**.

Step 6. Ensure that communications parameters are correct in the Serial access point connection for the Modbus PC application.

Step 7. Insert an APR. This time, do not select Enable Legacy Commands. See *Figure 4.6*.

We want the APR to connect the source access point (configuration software on the PC) automatically with the destination access point (Modbus IED) when the source initiates a connection.

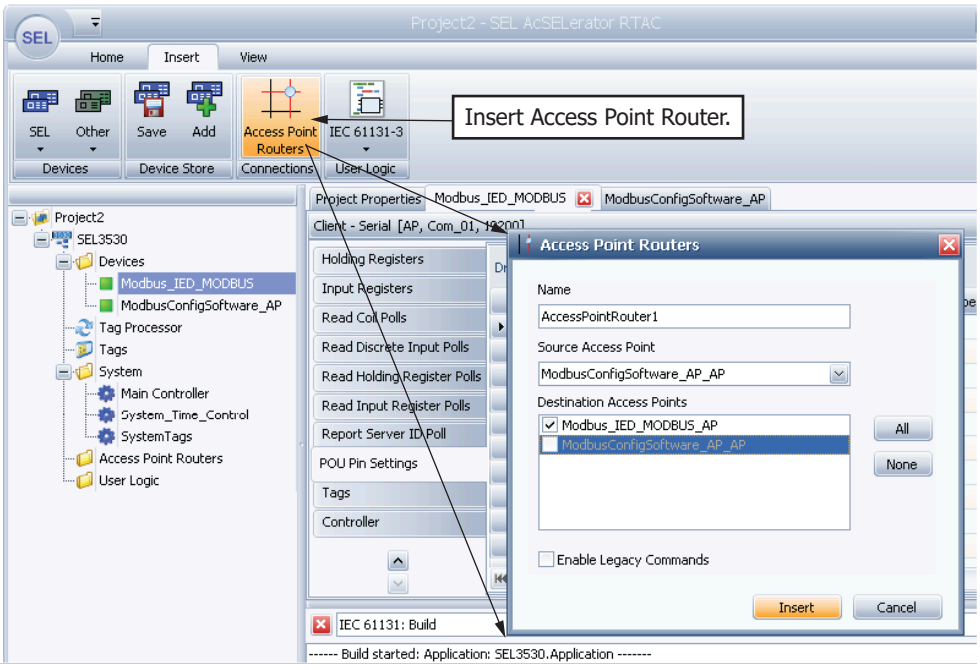

Figure 4.6 Direct Transparent Modbus

Step 8. Select the new access point router from the left menu. In this example, it is AccessPointRouter_1.

Step 9. Click on the**POU Pin Settings** tab.

Step 10. Set **Auto_Connect = TRUE**. This enables automatic connection and eliminates the need to log in or use the **PORT** command to connect manually to a port.

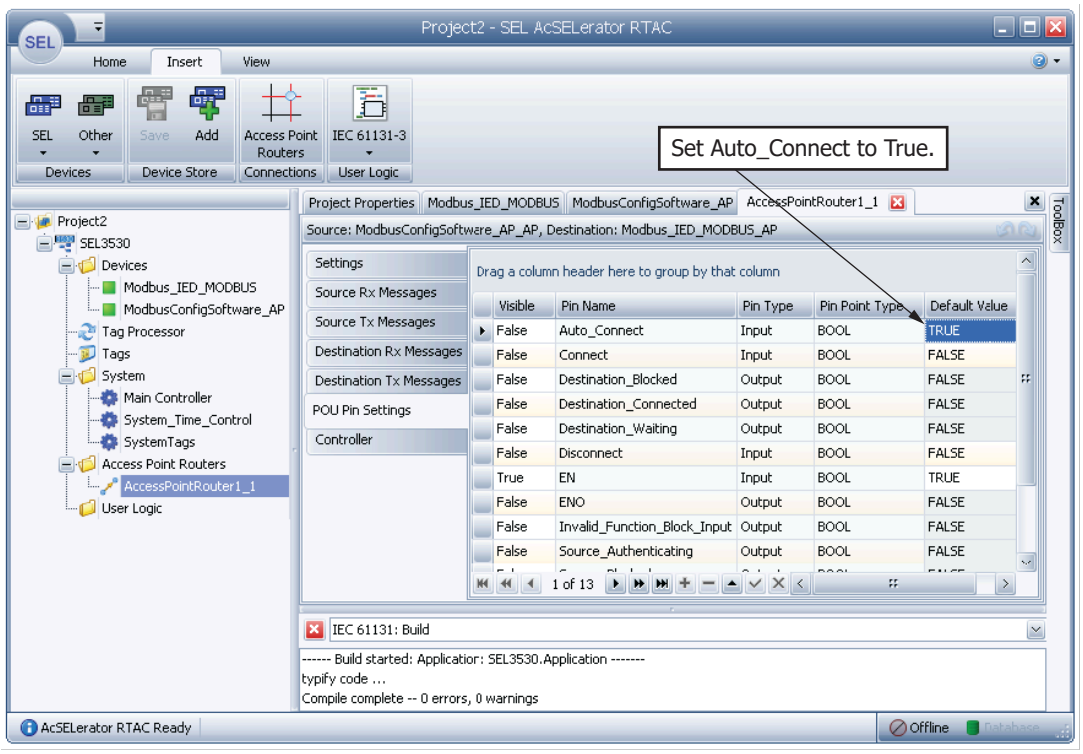

Figure 4.7 Enable Autoconnection

Step 11. Save the project and load it into the RTAC.

To test this project, you will need a Modbus IED connected to the serial port Com_01. You will also need a PC that is running a Modbus software application designed to connect to the IED. Connect the PC to Com_02. When the Modbus software attempts to communicate, the RTAC will automatically stop polling the Modbus IED and direct all communications traffic from Com_02 to Com_01. The RTAC will redirect data it receives on Com_01 to Com_02. When Com_2 stops receiving data from the PC, the RTAC will allow its Modbus polling task to resume polling the IED on Com_01.

Along with transparent or direct transparent communications, you can also configure the APR to perform special actions. Each action is associated with either all messages or, more typically, with the messages sent to or received from the source or the destination. To create an action on a message, perform the following steps:

Step 1. Determine what message you want the action to apply to. Options are **Source Rx Messages**, **Destination Rx Messages**, **Source Tx Messages**, and **Destination Tx Messages**.

Step 2. Click on the corresponding tab in the APR configuration and then click on the + box at the bottom of the screen to add the number of messages needed. For example, if you needed the action to send the MET command to the destination, click on Destination Tx Messages and add one message. When you add a message, the software will

create three new POU pins in the POU pin settings with a name associated with the new message you created. For example, if you created one new Destination Tx Message, the software creates the following new pins:

Pin Name	Pin Type	Usage
Destination_Tx_Message_1	Input	Use this pin to configure the string value of the message.
Trigger_Destination_Tx_Message_1	Input	Toggle this pin from **False** to **True** to force the transmit of this message to the destination.
Trigger_Destination_Tx_Message_1_DN	Output	This pin toggles **TRUE** for one process cycle after the trigger input has been asserted.

Step 3. Configure the string value in the new message.

Step 4. Optionally, use the trigger and DN pins to perform the actions needed.

By entering information in the transmit and/or receive strings in a special syntax, you can cause the APR to perform four main categories of special functions:

- Commands
- ASCII control and key characters
- Tag name replacement
- ASCII string hex representation

Commands

Commands are special syntax that perform actions when they are interpreted by the RTAC firmware. Commands are always enclosed in curly brackets { } and are ASCII characters that are not case sensitive. Some commands apply to both source and destination, whereas other commands are specific to only source or destination. *Table 4.1* shows a list of available commands with *XX* indicating you must specify **SOURCE** or **DESTINATION** as part of the command.

Table 4.1 APR Command Summary

Command	Function
{CONNECT}	Connects the source and destination access points. Same functionality as asserting the Connect input pin.
{DISCONNECT}	Disconnects the source and destination access points. Same functionality as asserting the Disconnect input pin.
{ENABLE_HW_FLOW_*XX*}	Enables hardware flow control on access points associated with serial port.
{DISABLE_HW_FLOW_*XX*}	Disables hardware flow control on access points associated with serial port.
{ENABLE_SW_FLOW_*XX*}	Enables software flow control on access points associated with serial port.
{DISABLE_SW_FLOW_*XX*}	Disables software flow control on access points associated with serial port.
{ASSERT_RTS_*XX*}	Forces RTS high on serial ports associated with this access point. Only applies if HW flow control is turned off by **{DISABLE_HW_FLOW_*XX*}** or the setting RTS_CTS is FALSE.

Command	Function
{DEASSERT_RTS_*XX*}	Removes the force RTS high condition on serials ports associated with this access point. Only applies if HW flow control is turned off by **{DISABLE_HW_FLOW_*XX*}** or the setting RTS_CTS is FALSE.
{WAIT_FOR_CTS_*XX*}	Inhibits transmit until CTS asserts. This command is reset when the transparent connection is terminated; so, it must be issued after a connection is made to be active.
{ASSERT_SERIAL_PORT_POWER}	Asserts serial-port power.
{DEASSERT_SERIAL_PORT_POWER}	Deasserts forced serial-port power.
{DELAY_*Y*_*XX*}	Adds a delay of *Y*, where *Y* is an integer between 0–60000 ms.
{ECHO_ON_*XX*}	Enables character echo for Source Tx or Destination Tx or both.
{ECHO_OFF_*XX*}	Disables character echo for Source Tx or Destination Tx or both.
{TIME_OUT_*Y*_*XX*}	Terminates the transparent connection if no characters are received in *Y* seconds, where *Y* is an integer between 0–60000 seconds. A value of 0 disables time out.
{REPLACE_*XX arg1* | *arg2*}	Replaces characters in a data stream entering the RTAC in the direction specified by *XX* or both directions when *XX* is left blank. For example, **REPLACE_SOURCE** replaces characters coming in the source access point.
{STOP_REPLACE_*XX*}	Used to stop replacing characters/bytes in the direction specified by *XX* or both directions when *XX* is left blank.
{STRIP_*XX argument*}	Used to strip characters, where argument is a sequence of characters that will be stripped from the data stream entering the RTAC in the direction specified by *XX* or both directions when *XX* is left blank (i.e., **STRIP_SOURCE** strips characters coming in the Source Access point). If numerous strip commands are issued, the strip function is processed in the order that they were received.
{STOP_STRIP_*XX*}	Stops all stripping of data. However, the **{FAST_OP_ENABLE}** and **{FAST_OP_DISABLE}** are still in effect.
{FAST_OP_ENABLE}	Enables transmitting of SEL Fast Operate commands from the source to destination (destination to source are always permitted). The status of this command is not maintained through device restart.
{FAST_OP_DISABLE}	Disables SEL Fast Operate commands from source to destination. The status of this command is not maintained through device restart.

String Stripping

Using the **STRIP** command, you can search for and strip out any characters from the incoming string. The syntax is {STRIP_*XX_argument*}, where *XX* is either **SOURCE** or **DESTINATION**, and *argument* is a sequence of characters to be stripped from the data stream. If *XX* is left out, the APR will strip the character sequence from both source and destination streams. Multiple consecutive strip commands are executed in the order they are configured. For example, {STRIP ab} followed by {STRIP bc} applied to the string 'abcdefg' will result in 'cdefg' because the 'ab' was stripped off first, so there was not a match for 'bc'.

Examples:

- Source_Tx_Message_1 = {STRIP_SOURCE<SP>} will strip all space characters from the Tx data.
- Source_Tx_Message_8 = {STRIP_SOURCE<0104>} would disable a MODBUS Force Coil for Outstation Address 1.

String Replacement

Use the **REPLACE** command to match character strings and replace with other character strings. Arg1 is the sequence of characters to be replaced by the sequence of characters in arg2. If the length of arg2 is greater than the length of arg1, arg1 is fully populated by arg2 and extra characters from arg2 that do not fit in arg1 are dropped. If the length of arg1 is greater than arg2, arg1 is populated by arg2 characters and all trailing characters in arg1 not replaced by arg2 characters are stripped. White spaces after arg1 and before arg2 are removed. To use literal white spaces at the start or end of these arguments, use the binary notation, i.e., <20>.

Examples:

- Source_Tx_Message_6 = {REPLACE <HT> | <SP>} would replace all horizontal tabs with a space.
- Source_Tx_Message_7 = {REPLACE abc | defg} would replace 'abc' with 'def'.
- Source_Tx_Message_8 = {REPLACE abc | d} would change the string 'abc' to 'd'.

ASCII Control and Key Characters

You can place ASCII control and key characters in a message string in the SPR. These single-byte strings must be preceded with the dollar sign special character $. For example, this string has a carriage control and line feed RL. The $ also escapes a following special character so that it is treated like a string rather than a special character. You must use two dollar signs, ($$), for the following characters: { } [ ] < >. For example, this is a less than sign $$<.

Table 4.2 shows examples of using the $ character. Notice control and key characters are not case sensitive.

Table 4.2 ASCII Controls and Keys

String	Result
$$	One dollar sign
$'	A single quote
$"	A double quote
$L or $l	Line feed
$N or $n	Newline
$P or $p	Form feed
$R or $r	Carriage return
$T or $t	Tab
$${	{
$$<	<
$$]	]

You can also wrap the control and key characters with the greater than and less than signs and use the delimiters space, +, -, or _. For example, all of the following are equivalent representations of carriage return, line feed:

- $0D$0A
- rL
- <CR><LF>
- <CTRL-M><CTRL-J>
- <CTRL M><CTRL J>
- <CTRL_M><CTRL_J>
- <CTRL+M><CTRL+J>

A special case ASCII control can be used to append a security check, such as a checksum or cyclic redundancy check (CRC), onto the end of a message. The format is <[*XXXX*]>, where you replace *XXXX* with the respective CRC special string. For example, you could send the following string as a Modbus message:

<01047E910009><[CRC_16_MODBUS]>

The security check strings available are shown in *Table 4.3*.

Table 4.3 Security Check Strings

Tag Name Replacement

If you enter a Virtual Tag tag name in a string in the APR and enclose the tag name in [ ], the actual value of the tag will be used instead of the tag name. For example, if a global tag VirtualTagList1.User_logged_off = Joe, then the string, User [VirtualTagList1.User_logged_off.strVal] has logged off, will result in `User Joe has logged off`. You must use a Virtual Tag as the tag name.

String Capture

You can also capture a value from a string into a Virtual Tag of type STR. The APR will search for the string you have configured and place the data into the Virtual Tag name enclosed in [ ]. For example, configure a Virtual Tag of type STR called VirtualTagList1.new_password. If the received message is `PAS 1 OTTER<0A>` and the configured string in the APR is SET PAS 1 [VirtualTagList1.new_password]<0A>, then VirtualTagList1.new_password.strVal will be set to OTTER.

The APR will gather as many as 255 characters or until the terminating sequence is reached. In the example given, the terminating sequence is a carriage return.

ASCII String Hex Representation

As in *ASCII Control and Key Characters on page 632*, all characters in the APR strings are considered ASCII characters unless framed in the following special characters: < >, [ ], { } or preceded by $ or $$. You can, therefore, send out a string of hex values that will not be interpreted as ASCII characters. For example, if you want to send the decimal value 17, you would enter the string <11>. In hexadecimal 11 is decimal 17. This allows you to create and send binary messages, such as Modbus, DNP, or other binary strings through the APR. For example, the string <010407D00005><[CRC_16_MODBUS]> is a Modbus read input register poll (Opcode 4) to IED Address 1, polling 5 registers starting at 2000, or 07D0 in hexadecimal.

Example 4.3 Source Receive String Value Capture

You can monitor incoming messages in an Access Point Router for a certain sequence of characters and then capture the data following the matched sequence into a Virtual Tag of STR type. This example demonstrates monitoring a remote access connection for a set password command to the connected relay, capturing that password, and applying the new password to the SEL client. All of the original receive message is still passed through the APR and only a copy of the password is captured in this example. This example uses an SEL-451-5 relay with version R305 firmware. More current versions of SEL-451 firmware perform password management somewhat differently and will not work with this example, but the concepts of capturing data are still applicable.

Step 1. Insert an SEL-451 as SEL protocol, serial client.

Step 2. Insert an access point as **Other**, **Ethernet Incoming (Listens for Connections)**. In this example, the access point is renamed Incoming_Access_AP. Set the **Network Connection Type** to **Telnet** for this example.

Step 3. Insert an access point router and select the access point from Step 2 as the source and the SEL-451 TAP from Step 1 as the destination. See *Figure 4.8*.

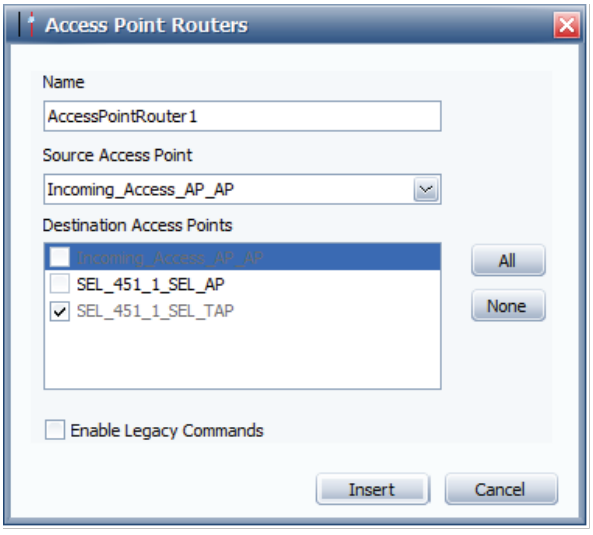

Figure 4.8 Insert Access Point Router

Step 4. Create a virtual tag list by clicking on **Tag Lists** under the **Insert** ribbon.

Step 5. Create a new virtual tag by clicking on the + on the bottom of the screen and change the tag type to **STR** and save the project.

Step 6. In the access point router, click **Source RX Messages**, and then click on the + to add one message.

Step 7. In the access point router, click **POU Pin Settings**. Set the Default Value for Auto_Connect = TRUE. Notice there is a new input pin called **Source_Rx_Message_1**. This is where we will define what string the RTAC will look for from the source access point.

Step 8. Configure the Default Value for the POU Pin Setting Source_Rx_Message_1 as follows:

PAS 1 [VirtualTagList1.Status_0000]<CR>

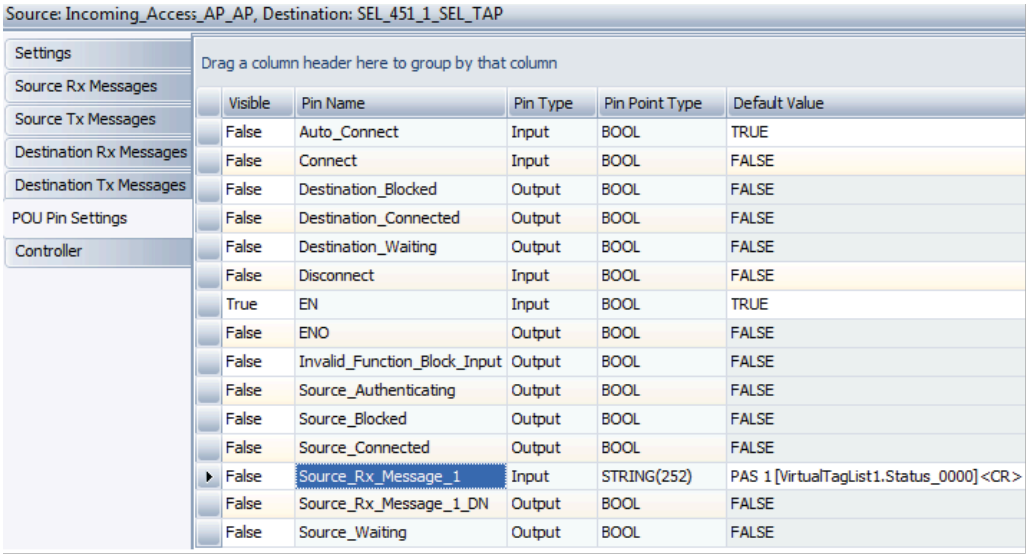

Figure 4.9 Configure Capture Message

The RTAC monitors the source receive messages for a string that matches 'PAS 1'. When it finds the string, it will capture a copy of all characters following the matched string until it reaches the termination (which in this example is <CR>) or 252 bytes, whichever comes first. The captured characters are placed into a global virtual tag of type STR called **VirtualTagList1.Status_0000**. The entire message, including the characters that were copied and captured, is still passed through the access point router.

Step 9. On a new line in the Tag Processor, type **VirtualTagList1.Status_0000.str- Val** in the Source Expression column and **SEL_451_1_SEL_POU.Level_1_Password** in the Destination Tag Name column to assign the new password value to the SEL-451 client Level 1 password POU pin setting.

Step 10. Save the project and load it into the RTAC.

To test the project, wait until the RTAC completes autoconfiguration with the SEL-451. Then transparently connect to the relay through the RTAC. Log in to Level 1, then Level 2 on the relay (ACC and 2AC, respectively) by using the correct passwords. Use the **PAS 1** command to change the Level 1 password.

PAS 1 OTTER123

POU Pin Settings

While on-line with ACSELERATOR RTAC, check the POU pin SEL_451_1_SEL_POU.Level_1_Password. It should change to OTTER123 to match the new Level 1 password you configured in the relay through the transparent connection.

POU Pin Settings

Use POU pin settings to customize how the access point router operates in your project and to view the present state of the APR operations. Setting the Visible field to **True** will cause the POU pin to appear in the **Controller** tab. See *Table 4.4* for the settings descriptions. You can specify destination and source message strings as a manually entered string contained within single quotes or as a tag of type STRING. If you use a tag of type STRING, you can manipulate that string value in user logic and then trigger when the string is sent or automatically change the string you are trying to match.

Table 4.4 APR POU Pin Settings

Pin Name	Pin Type	Description	Default Value
Auto_Connect	Input BOOL	Set TRUE to connect as soon as traffic is detected on the source AP.	FALSE
Connect	Input BOOL	Automatically toggles when a connection is made. You can force to TRUE to force a connection.	FALSE
Disconnect	Input BOOL	Automatically toggles when connection is closed. You can force to TRUE to close a connection.	FALSE
EN	Input BOOL	Enables this APR. You can force to FALSE to disable this APR.	TRUE
*xx*_Rx_Message_*n*	Input STR	The *n*th user-configurable message string for the message received from the *xx* (source or destination) AP. Typically this is used to match what is received from the source.	
*xx*_Tx_Message_*n*	Input STR	The *n*th user-configurable message string to transmit to the *xx* (source or destination) AP.	
Trigger_*xx*_Tx_Message_*n*	Input BOOL	Trigger the transmission to *xx* (source or destination)	FALSE
*xx*_Blocked	Output BOOL	*xx* (source or destination) is blocking a connection to APR.	FALSE
*xx*_Connected	Output BOOL	*xx* (source or destination) is connected to APR	FALSE
Trigger_*xx*_Tx_Message_*n*_DN	Output BOOL	Indicates the *n*th transmission of the *xx* (source or destination) message has completed.	FALSE
*xx*_Rx_Message_*n*_DN	Output BOOL	Indicates the *n*th receive message of the *xx* (source or destination) has completed. This is determined by comparing the incoming message with the user-configured *xx*_RX_*n*_Message.	
Source_Authenticating	Output BOOL	Source is in the process of authenticating connection.	FALSE
*xx*_waiting	Output BOOL	*xx* (source or destination) is waiting for connection.	FALSE
Invalid_Function_Block_Input	Output BOOL	The APR function block has received some invalid input.	FALSE
ENO	Output BOOL	The APR is enabled.	FALSE

SECTION 5

Web Interface and Reports

Overview

The devices in the SEL Real-Time Automation Controller (RTAC) and SEL Axion® family provide a variety of ways to access data from configured settings and connected IEDs through use of a web browser. The RTAC web interface provides remote IED status and reports; local sequence of events reports; and an optional full-featured, web-based HMI; as well as a capable set of tools for both live data viewing and communications troubleshooting.

The Ethernet interfaces of an RTAC as well as a number of security parameters are configured via the web interface. See *Section 7: Security and Account Management* for more details on these sections of the web interface.

The **Network Utilities** page allows you to test network connectivity to remote IP addresses as well as connections to specified TCP service ports on those remote IPs. An "All Ethernet" communications capture can also be launched from this page to provide a downloaded pcap file containing all Ethernet traffic received and sent to and from the RTAC.

The **Connected IED** report shows remote IEDs by physical port and, for Ethernet connections, which TCP/UDP ports are in use. It provides information about connection type, settings, and communication status. In firmware versions R151-V0 and later, SEL-3555, SEL-3560, and SEL-3350 RTACs include an online protocol dissector provides a tool for viewing detailed communications activity for both serial and Ethernet-based IEDs. The dissector automatically decodes traffic into a navigation tree containing a plain-text summary of the protocol traffic in question to allow for quick troubleshooting of communications issues. Multiple simultaneous serial and network traffic captures can be launched to create pcap files; these files are useful for detailed communications captures and offline protocol analysis and troubleshooting.

The **Alarm Summary** and **Sequence of Events** (SOE) reports provide comprehensive logging for all tags in the RTAC, including those that connected IEDs provide. The logging system compensates for time-stamp differential between data from different IEDs, so all data are in sequence and on the same time reference. The RTAC can log changes in state for Booleans, changes in value for strings, and for a change in time stamp for Booleans, analogs, or strings. The RTAC can also log alarms on analog values that cross defined thresholds. Configure tags for logging in the Tag Processor or use one of the logger function blocks in IEC 61131 custom programs. On most RTAC models, the logger stores as many as 30,000 records; on SEL-3350, SEL-3555, and SEL-3560 RTACs, as many as 500,000 records can be stored. The RTAC can log bursts of as many as 500 log entries in 100 ms or 100 entries per second continuously without losing information.

The RTAC makes CEV and COMTRADE events collected from remote IEDs available in an **Event Collection** table. Event collection is configured in ACSELERATOR RTAC SEL-5033 Software. These events can be sorted by time or device and can be downloaded or deleted from the web interface.

Values of any tag or POU pin in the RTAC settings can be viewed on the **Live Data** page. This feature must be enabled by tag in ACSELERATOR RTAC. Not only do these values update in close to real time, they can also be forced from the web interface. This is useful for testing, troubleshooting, and commissioning.

The **Diagnostics** page provides a detailed description of the RTAC network interface state, including information about the firewall, physical interface, routing table, exe-GUARD®, PRP, and the ARP table.

Most devices in the RTAC and Axion family support the optional web-based HMI (the SEL-3505 and SEL-3505-3 currently do not). The HMI is a configurable option and can either be included in the order from the factory or can be added after the fact by contacting your SEL sales representative. The web-based HMI allows you to view and control any tags configured in the RTAC. Use ACSELERATOR Diagram Builder™ SEL-5035 Software to build custom HMI screens and load them into the RTAC. Build one-line diagrams, annunciators, and graphical representations that contain control buttons and display data from any tag. Because the HMI is web-based, multiple people can view it simultaneously.

Web HMI and Dashboard Settings

ACSELERATOR Diagram Builder provides not only a full-featured HMI development environment, but it also allows you to select HMI tags directly from the database in the RTAC or in an ACSELERATOR RTAC project. Use ACSELERATOR Diagram Builder to build new HMI projects containing multiple screens animated with objects linked to RTAC database tags and load the new HMI project into the RTAC. Once the HMI project is loaded into the RTAC, you can launch it from the RTAC's web interface (see *Figure 5.1*).

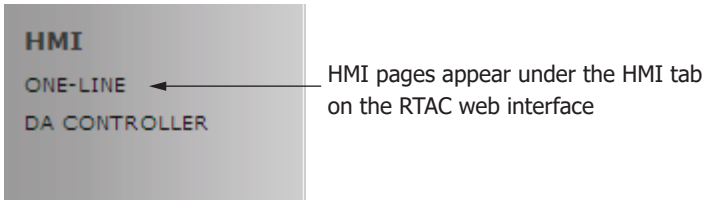

Figure 5.1 HMI Project Display

In firmware versions R152 and later, the HMI Runtime binary and HMI project files can be updated via the RTAC web interface. The **Device Management** tab displays the current version of the Runtime binary and allows you to upload an updated version. The **Project Management** tab has an **HMI Project Upload** sub-tab on which HMI project files are listed and from which they can be uploaded and downloaded. HMI project files must be saved by Diagram Builder in **hprjson** or **hprz** format to be uploaded successfully.

Settings on the RTAC dashboard allow you to configure when the web interface should log out of a user session because of inactivity. You can also configure the RTAC to allow HMI pages to remain active indefinitely, but in a read-only mode that prevents users from issuing controls unless they are logged on. The following table describes RTAC web Dashboard tab settings, including those pertaining to session time-out behavior.

Table 5.1 Web Interface Dashboard Settings

Label	Description
Host Name	The network hostname as defined in the **Network** tab under Ethernet > Edit Global Settings.
Device Name	User-configurable descriptive name.
Device Location	User-configurable location description.
Device Description	User-configurable description of this device.
Allowed Web Connections	The number of concurrent web connections this device will accept. **Note**: This is not the same as Number of Users Logged In, which includes ODBC connections through ACSELERATOR RTAC and other programs. The number of users logged on includes sessions not logged off that are closed. The counter will not decrease until those sessions time out.
Web Session Time-out	The Web Session Time-out has a range of 0–720 minutes. A setting from 1 to 720 minutes (12 hours) will cause the web interface to log out of the active session after the defined period of inactivity. If the range is set to 0, the web interface will not log out after any period of inactivity as long as the network connection is good and the browser session remains open. When this setting is set to 0, the HMI will remain open and users can acknowledge alarms and send controls without authenticating. If Enable HMI Read-Only Mode is selected and an HMI diagram is presently in focus, the RTAC changes the HMI session to read-only mode. If HMI Read-Only Mode is selected, the defined behavior will occur regardless of the Web Session Time-Out value.
HMI Read-Only Mode Time-out	Once the HMI session has entered read-only mode, this is the maximum amount of time a communications failure can exist between the RTAC and HMI before the RTAC logs off the user and closes the web session.
Enable HMI Read-Only Mode	A flag that enables read-only mode in an HMI screen when the Web Session Time-out expires. Once the HMI is in read-only mode, a user can view data in the HMI, but the RTAC will prompt the user to log in if the user attempts to operate a control from the HMI or navigate to another non-HMI tab on the RTAC web interface.
Tie Alarm LED to OUT101	A flag that asserts the output OUT101 if the Alarm LED is asserted. Default value is enabled. OUT101 is NC when this box is selected and NO when this box is not selected.
Password History Count	A parameter allowing optional user password history enforcement. See *Section 7: Security and Account Management* for more details.
Power Source Scale (0.5 - 1.5)	Applies a custom (per-RTAC) scaling factor to the supply voltage System Tag(s). See *Section 11: Testing and Troubleshooting* for more details.
Default Home Page	Allows assignment of a global non-default page (or HMI project) to launch upon logging in to the RTAC web interface other than the Dashboard. This applies to all users on the RTAC, unless a custom default home page has been uniquely associated with their user account.

Kiosk Feature

SEL-3555, SEL-3560, and SEL-3350 RTACs possess a local DisplayPort and USB-A connectors for connection of a monitor as well as keyboard and mouse. This display will by default be a locally running web browser linked to the RTACs web interface. In firmware versions R142-V0 and later, a Kiosk feature is available via the local display on the SEL RTAC. Kiosk mode allows specific applications to be run locally on the RTAC.

In Kiosk mode, the **Applications** menu (accessible via the bottom left corner of the display) provides the following functionality.

Local RTAC UI

This option launches a web browser that defaults to the RTAC's web interface. Enter or exit the full-screen local display of the web interface by pressing **<F11>**. Once full-screen mode has been exited, other IP addresses or hostnames can be specified in the address bar of the browser provided the URL has been entered into the Local Display URL Whitelist located under the Security heading.

Virtual Keyboard

A virtual keyboard that can be docked to the bottom of the screen and can be used with all local applications.

Settings

Calibrate Touchscreen

This option brings up the same options as the touchscreen calibration shortcut keys.

Display

This option allows you to adjust the following display settings:

- Connected monitors
- Resolution
- Refresh rate
- Rotation
- Reflection

Kiosk Feature Keyboard Shortcut Keys

Various keyboard shortcut keys can be used on the local display interface to interact with the web browser as well as calibrate a locally connected touchscreen monitor.

Table 5.2 Kiosk Feature Shortcut Keys

Shortcut Keys	Description
<F11>	Enter or exit full-screen mode
<Alt+T>	Calibrate touchscreen
<Ctrl+T>	Calibrate touchscreen
<Ctrl+Shift+Del>	Delete browser cache
<Alt+F4>	Close the selected/active application

Web Proxy

Web Proxies allow for configuration of a URL on the RTAC that will trigger the RTAC to create a proxy connection to another web server via one of its Ethernet interfaces. When configuring a web proxy, it is important to note that the identity of the remote host is not verified. Setting **Remote URL** to proxy to an untrusted host can potentially expose users of the web proxy to malicious cybersecurity attacks. Web proxies should only be configured on a trusted network.

Access to web proxies can be configured to be used by either unauthorized or authorized users. Authorized user confirmation is done by account type. A web proxy is a role-based permission that can be tied to a user account to allow access to the configured proxy.

Web proxies can be accessed via a remote connection or from the local display interface.

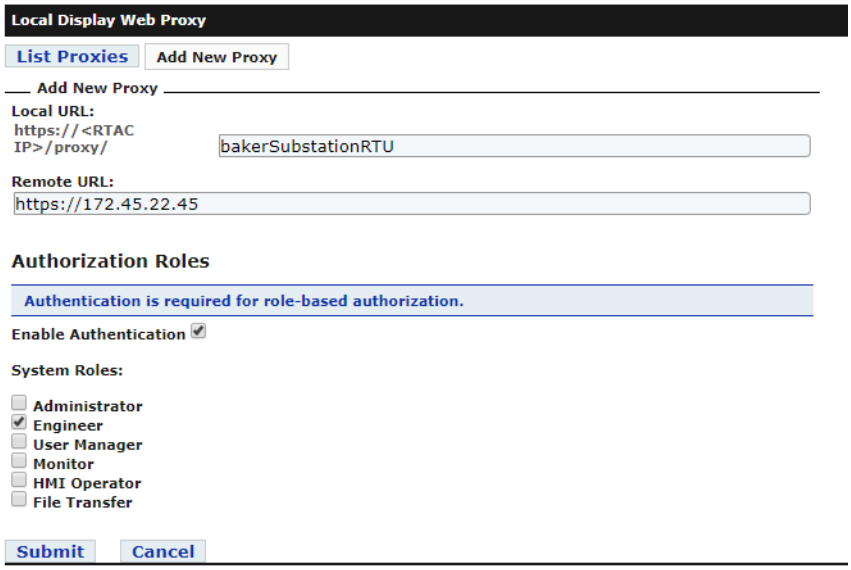

Figure 5.2 New Web Proxy Configuration

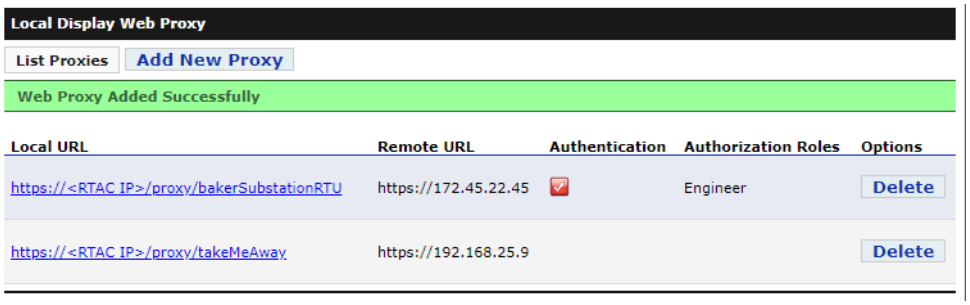

Figure 5.3 Web Proxy List

Network Utilities

Web-based ping and TCP port check utilities are found on the **Network Utilities** page. They are used to determine whether communication can be established from the RTAC to a remote host over an Ethernet network. An "All Ethernet" communication capture can also be launched from this location to generate a pcap file containing all Ethernet traffic sent to and received from the RTAC.

The Ping utility checks that basic network connectivity to a remote address is possible using ICMP messages. To use this tool, enter an IPv4 or IPv6 address, the number of pings to send (Count), and the number of seconds to allow before a ping is considered failed because of lack of response (Time-out). Once these three items are set as desired, press the **Ping** button. The results of the ping test will be displayed in text below the entry fields.

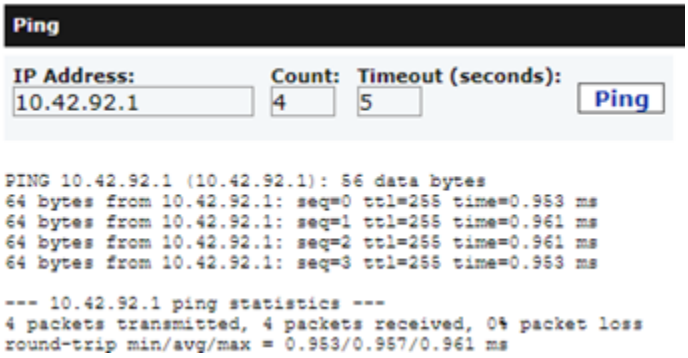

Figure 5.4 Network Utilities: Ping

The TCP port check utility allows further testing of connectivity to a remote IP address by attempting to connect to a specified TCP service port. This can serve the purpose of testing firewall/router rules (ensuring a port is open through the complete network path) as well as confirming if a particular service is open on a remote host. The results will be formatted as in the following examples and will display a STATE of **open** or **closed**. Note that in these examples, TCP port 23 is open and port 24 is not.

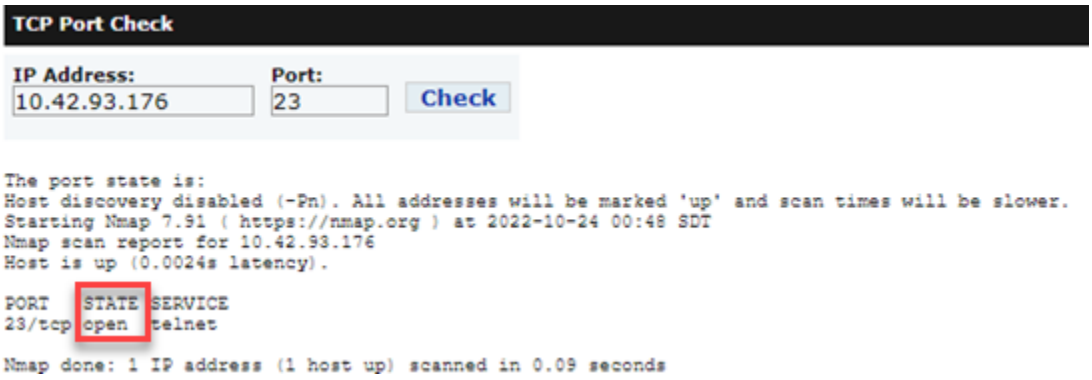

Figure 5.5 Network Utilities: TCP Port Check—Open Port

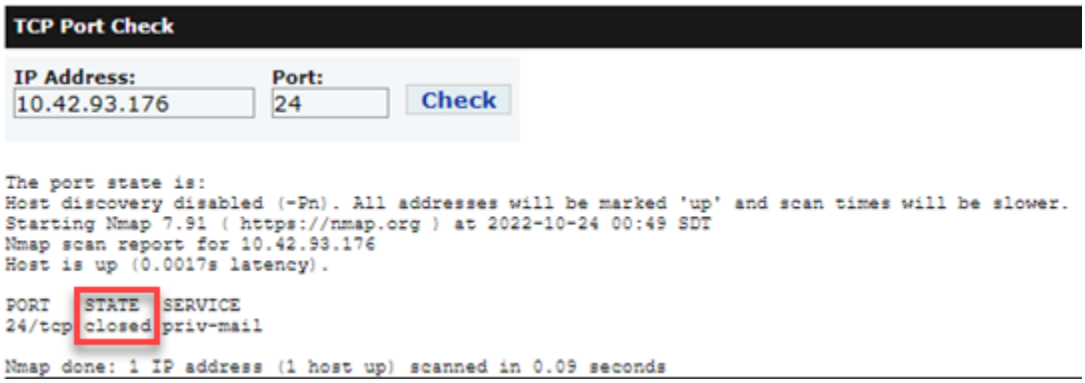

Figure 5.6 Network Utilities: TCP Port Check–Closed Port

Select **Start** under the Network Capture heading to begin an All Ethernet communication capture. A .pcap file will begin downloading to your web browser after initiating this capture. Select **Stop** when you are satisfied with the volume or duration of captured traffic.

Viewing and Troubleshooting Connected IEDs

View information about port configuration and record network and serial device traffic using the Connected IEDs report on the RTAC web interface. Graphics representing serial and Ethernet ports of the specific RTAC hardware model are displayed here, with gray indicating that a communication port is not configured for use with any protocol and green indicating that a port has been configured. The Connected IEDs report is divided into two main sections for devices: one for **Ethernet Devices** and one for **Serial Devices**. Each device section lists all client and server devices configured in the project along with their protocol type. Each device has a **Status** icon displayed to the left of the device name. A green Status icon indicates that the device is communicating successfully (i.e., the Offline POU pin is FALSE), and a red Status icon indicates the device has encountered a communications failure (i.e., the Offline POU pin is TRUE). A gray Status icon indicates the device is disabled (i.e., the ENO POU pin is FALSE).

The **Ethernet Devices** section of the Connected IEDs report shows the Ethernet interface (e.g., Eth_01) that the protocol is actively bound to as well as the source and destination IP addresses used in the conversation. Any TCP or UDP ports in use by the client/server device will also be displayed here. Clicking on the hyperlink displayed over each remote TCP port will launch the Network Utilities page with the TCP Port Check tool fields automatically populated to those that you selected.

The **Serial Devices** section of the Connected IEDs report shows the serial port in use for the client/server device (e.g., Com_03) as well as various serial parameters associated with the connection such as Baud Rate, Data Bits, Parity Bits and so on.

See *Figure 5.7* for a sample display of how the Connected IEDs report is displayed on SEL-3530-4 hardware; other hardware models will display their unique port layout.

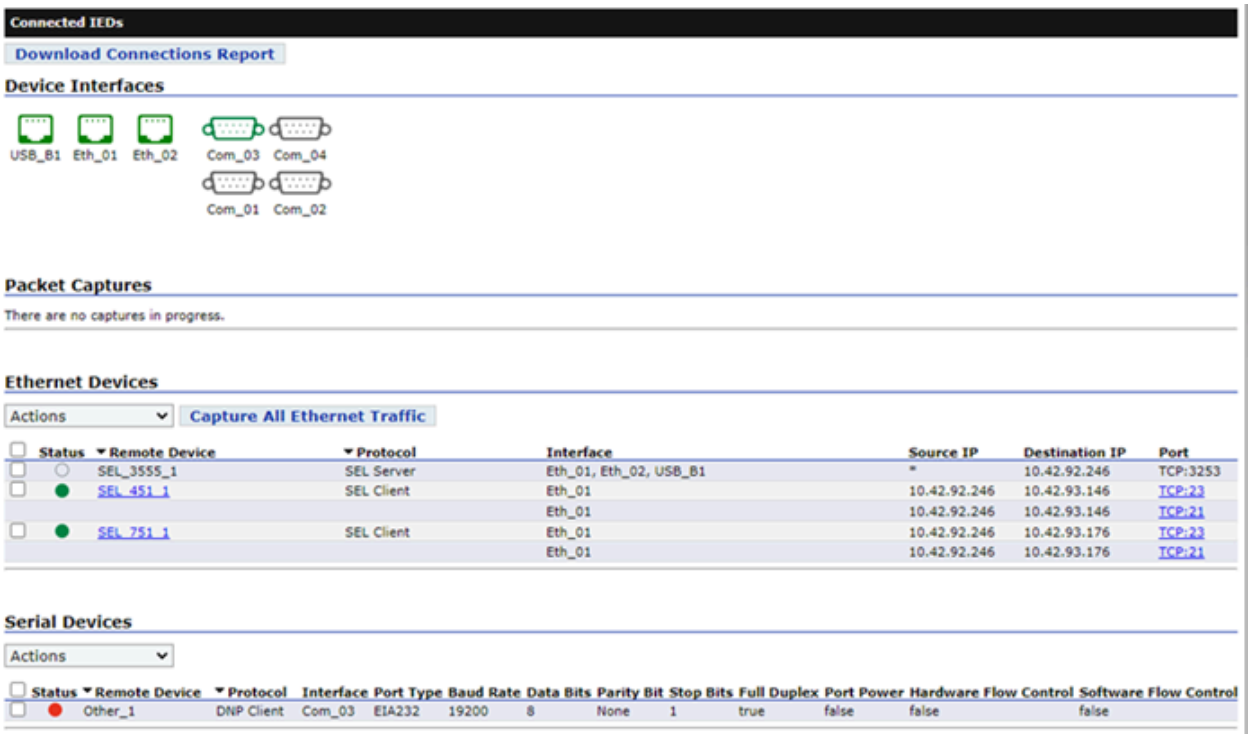

Figure 5.7 Connected IEDs Report

Web-Based Serial and Network Traffic Captures

The RTAC can capture multiple simultaneous connections of network or serial device traffic. To start a serial or Ethernet capture from the Connected IEDs page, select the check box to the left of the device Status icon and, from the **Actions** dropdown menu above the list of devices, select **Capture Packets**. Once the packet capture has started, an entry will appear under the **Packet Captures** heading. When enough data have been captured, the pcap file download will begin automatically. Select the **Stop** button associated with the entry to cease the packet capture and automatically complete the download of the associated pcap file. Selecting **Capture All Ethernet Traffic** will launch the Network Utilities page from which an "All Ethernet" capture operation can be initiated.

Figure 5.8 Connected IED Packet Capture

Online Packet Dissector

In firmware versions R151-V0 and later, SEL-3555, SEL-3560, and SEL-3350 RTACs include an online packet dissector available from the Connected IEDs page. The packet dissector facilitates online communications troubleshooting with serial and Ethernet variations of the following supported client and server protocols that the RTAC uses to communicate with devices:

- SEL Protocol
- DNP
- Modbus RTU and TCP
- IEC 60870-5-101 and 104
- IEC 61850 MMS
- IEC 61850 GOOSE
- IEEE C37.118 Synchrophasors
- L&G 8979
- CP2179

To launch the online packet dissector, select the check box beside one or more devices and, from the **Actions** dropdown menu, select **Inspect Packets**. As shown in *Figure 5.9*, the packet dissector includes a top pane that is updated with any new received or transmitted messages and a bottom pane that shows the dissection of a packet selected from the top frame. All dissected messages are displayed in layered format, with the different layered protocols broken apart into separate tree views. Ethernet-based captures are typically built on an Ethernet II/IPv4/TCP connection stack and serial-based captures use an RTAC Serial Line header.

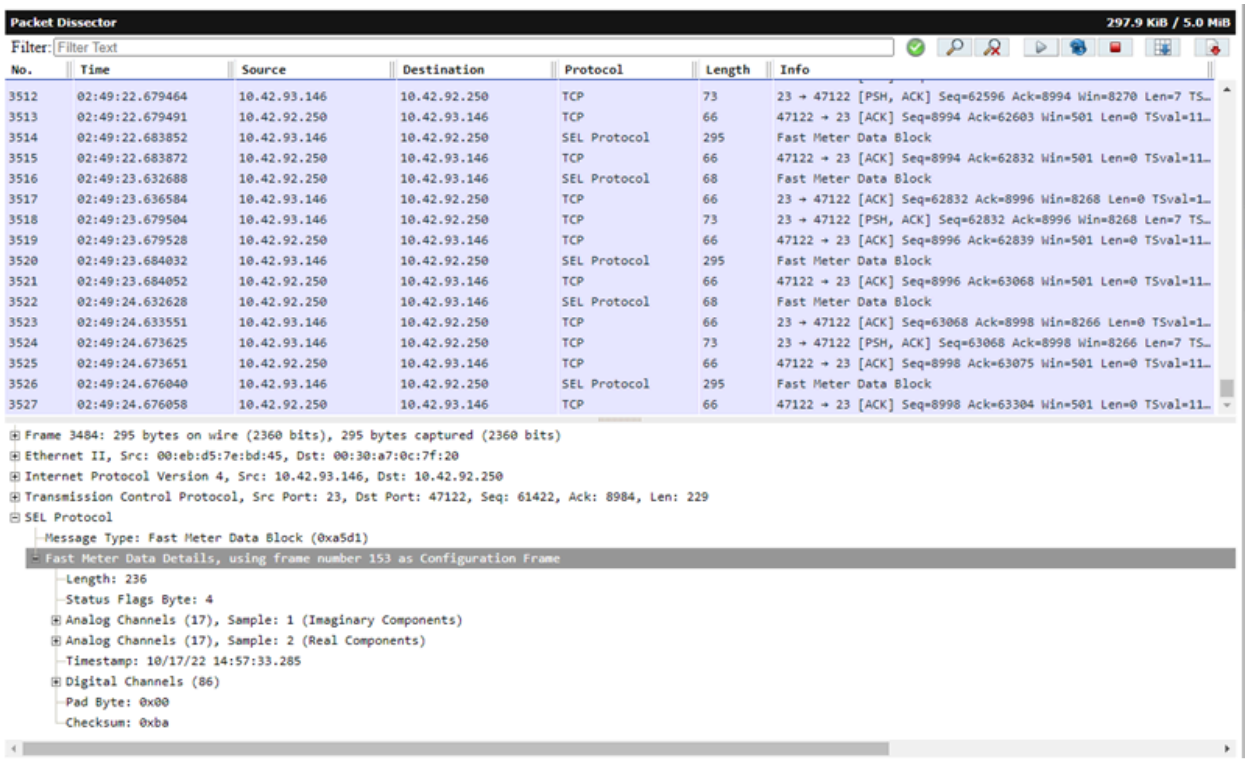

Figure 5.9 Packet Dissector

Display filters can be entered into the **Filter** field on the top of the dissection display to filter down the displayed list of packets to those of interest. These filters use the same syntax as Wireshark display filters and a successfully applied filter will change to green text; a filter using incorrect syntax will display with red text and not be applied. An example of a successful filter to only display SEL protocol traffic (and hide, for example, packets that only contain TCP acknowledgements):

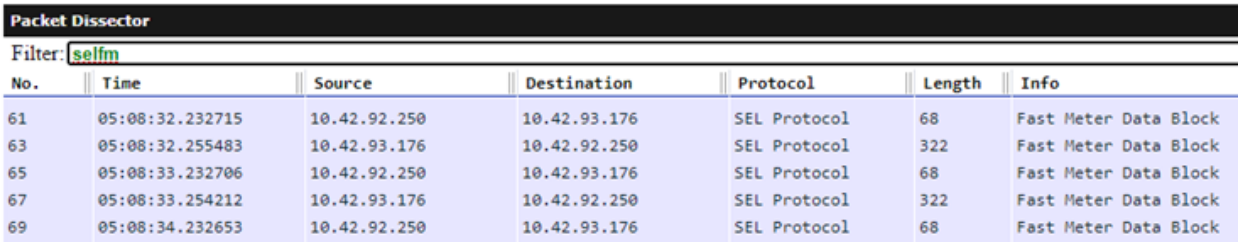

Figure 5.10 Packet Dissector—Successful Filter

Typical filters that could be applied include:

- **dnp3** - show all DNP traffic.
- **dnp3.al.func == 0x81** - show all DNP outstation responses.
- **selfm** - show all SEL Protocol traffic.
- **selfm.fastmsg.funccode == 0x18** - show all Unsolicited Fast SER messages in an SEL protocol conversation.
- **synphasor** - show all IEEE C37.118 traffic.
- **modbus** - show all Modbus RTU or Modbus TCP traffic.
- **modbus.func_code == 3** - show all Modbus Holding Register read requests / responses.
- **iec60870_asdu** - show all IEC 60870-5-101 and 104 traffic containing ASDU payloads.

Use the buttons at the top of the packet dissection interface to:

- Apply a display filter
- Clear the display filter
- Start/Resume the capture
- Restart the capture
- Stop the capture
- Enable or disable autoscroll to the bottom
- Download a pcap file of all captured traffic for offline troubleshooting

Live Data

The **Live Data** page displays the near real-time status of any Live Data enabled tag (this is done in the **Tag Processor** or in custom logic). Many data types are supported.

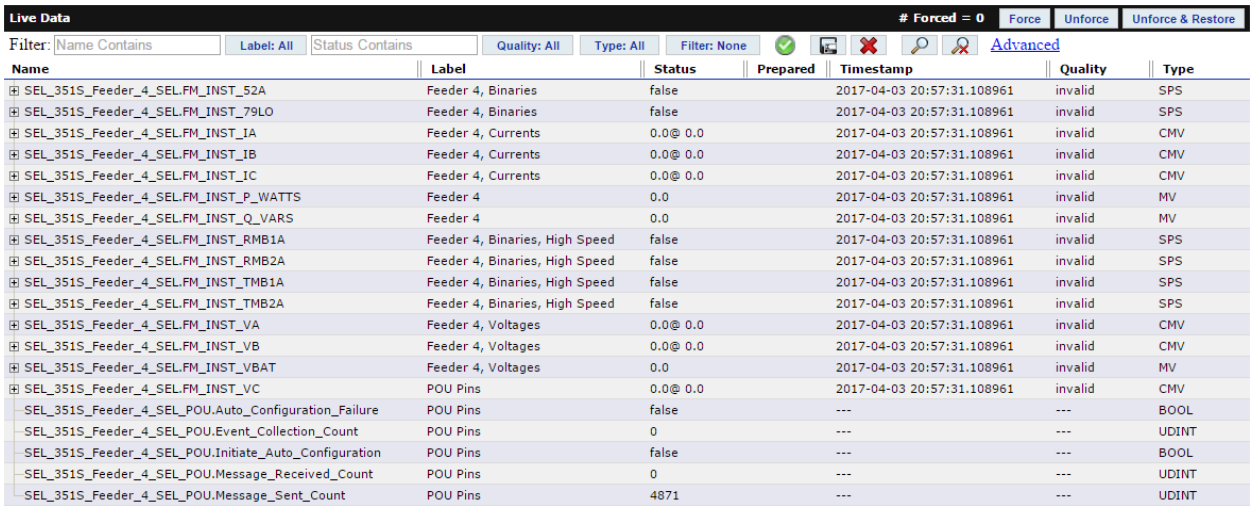

Figure 5.11 Live Data Page

Tag structures can be expanded by clicking the + icon to the left of the tag name. Tags can be filtered using the filter controls at the top of the page. Basic and Advanced filter controls can be toggled by clicking the **Basic** and **Advanced** links to the right of the filter controls. Data can be filtered by name, label (as defined in either the Tag Processor or user logic), status, quality, or type. Filters can be saved and reused. Saved filters are saved on the RTAC itself and are made available across user accounts and web browsers.

When using the advanced filter input more complex filter rules can be written. See *Table 5.3* for special operators available for advanced filter expressions.

Table 5.3 Live Data Advanced Filtering Operators

Character	Function	Example
OR	Logical OR	Name ~ 'IA' OR Name ~ 'IB'
AND	Logical AND	Name ~ '52A' AND Status ~ 'false'
NOT	Logical NOT	Name ~ '52A' AND NOT Status ~ 'false'
=	Equals	Status = 'false'
~	Contains	Name ~ '79LO'
in	Is left side found in right side list	Name ~ '79LO' AND Label in ('Binaries', 'Analogs')

Forcing Values

Tag values can be forced from the webpage by using the **Prepared** column in the Live Data table. Because forcing from the Live Data page is functionally equivalent to forcing values in Custom Logic, see *Using Online Debug on page 921*. Most elements of the tag can be forced in this manner, including elements of the quality and time substructures (if present). When preparing to force an analog value that includes both magnitude and angle, you can either expand the instMag substructure and prepare both magnitude and angle in their own cell, or you can type **mag@ang** in the cell associated with the top level of the tag. *Figure 5.12* illustrates both force preparation methods, as well as Boolean force preparation.

NOTE

Use caution when forcing values. Depending on the RTAC configuration, it may be possible to send controls or operate contacts.

Name	Status	Prepared

Figure 5.13 Live Data After Force

Press **Unforce** to release the force but leave the values in place until they are overwritten by some other mechanism, or press **Unforce & Restore** to release the force and restore the tags to their preforce values.

Adding Tags to Live Data

Tags can be added to the Live Data page by using either settings in the Tag Processor or code in custom logic. The following data types are supported (see *Data Types on page 1127* for additional information about these types):

Standard Types		
BOOL	LINT	TOD
BYTE	LREAL	UDINT
DATE	LWORD	UINT
DINT	REAL	USINT
DT	SINT	ULINT
DWORD	STRING(255)	WORD
INT	TIME	
Enumerated Types		
cmdQual_t	ledColor_t	tcmd_t
colorRG_t	orCategory_t	timeAccuracy_t
dbpos_t	range_t	timeSource_t
dir_t	source_t	validity_t
Structured Types		
ACD	IOC	operUNC
ACT	LBCR	originator_t
APC	LBCRC	quality_t
BCR	LEDC	SBRC
BCRC	MDBC	SRBC
CMV	MRBC	SPC
dateTime_t	MV	SPS
detailQuality_t	operAPC	STR
DNPC	operBAC	STRC
DPC	operBSC	TIM
DPS	operINC	timeQuality_t
DST_t	operISC	timeSource
I870DC	operLAPC	timestamp_t
I870SC	operLINT	UNC
INC	operSPC	UNS
INS	operSTR	vector_t

To add tags to Live Data from the Tag Processor, use the **Live Data Enabled** column. Set the value of this column to **Forceable** to allow the value to be forced from the **Live Data** page, or **Viewable** to make the value read-only on the **Live Data** page. Use the **Live Data Labels** column to configure a comma-separated list of labels (limit 255 characters per label) to associate the tag with. These labels can be used to sort data on the Live Data page. *Figure 5.14* provides an example of Live Data configuration in the Tag Processor.

Build	Destination Tag Name	DT Data Type	Source Expression	SE Data Type	Live Data Enabled	Live Data Labels
True					False	
True	SEL_351S_Feeder_4_SEL.FM_INST_52A	SPS			Forceable	'Feeder 4, Binaries'
True	SEL_351S_Feeder_4_SEL.FM_INST_79LO	SPS			Forceable	'Feeder 4, Binaries'
True	SEL_351S_Feeder_4_SEL.FM_INST_RMB1A	SPS			Forceable	'Feeder 4, Binaries, High Speed'
True	SEL_351S_Feeder_4_SEL.FM_INST_RMB2A	SPS			Forceable	'Feeder 4, Binaries, High Speed'
True	SEL_351S_Feeder_4_SEL.FM_INST_TMB1A	SPS			Forceable	'Feeder 4, Binaries, High Speed'
True	SEL_351S_Feeder_4_SEL.FM_INST_TMB2A	SPS			Forceable	'Feeder 4, Binaries, High Speed'
True	SEL_351S_Feeder_4_SEL.FM_INST_IA	CMV			Forceable	'Feeder 4, Currents'
True	SEL_351S_Feeder_4_SEL.FM_INST_IB	CMV			Forceable	'Feeder 4, Currents'
True	SEL_351S_Feeder_4_SEL.FM_INST_IC	CMV			Forceable	'Feeder 4, Currents'
True	SEL_351S_Feeder_4_SEL.FM_INST_P_WATTS	MV			Forceable	'Feeder 4'
True	SEL_351S_Feeder_4_SEL.FM_INST_Q_VARS	MV			Forceable	'Feeder 4'
True	SEL_351S_Feeder_4_SEL.FM_INST_VA	CMV			Forceable	'Feeder 4, Voltages'
True	SEL_351S_Feeder_4_SEL.FM_INST_VB	CMV			Forceable	'Feeder 4, Voltages'
True	SEL_351S_Feeder_4_SEL.FM_INST_VBAT	MV			Forceable	'Feeder 4, Voltages'
True	SEL_351S_Feeder_4_SEL.FM_INST_VC	CMV			Forceable	'POU Pins'
True	SEL_351S_Feeder_4_SEL_POU.Auto_Configur...	BOOL			Viewable	'POU Pins'
True	SEL_351S_Feeder_4_SEL_POU.Initiate_Auto_...	BOOL			Viewable	'POU Pins'
True	SEL_351S_Feeder_4_SEL_POU.Event_Collecti...	UDINT			Viewable	'POU Pins'
True	SEL_351S_Feeder_4_SEL_POU.Message_Rece...	UDINT			Viewable	'POU Pins'
True	SEL_351S_Feeder_4_SEL_POU.Message_Sent...	UDINT			Viewable	'POU Pins'

Figure 5.14 Enable Live Data in the Tag Processor

To add tags to Live Data from user logic, use the LiveData function block in a custom logic program. The LiveData function block requires exactly six inputs at declaration. *Figure 5.15* provides an example of how to declare an instance of this function block.

```
VAR
    Recloser52A : LiveData(
        ADR(SEL_651RA_SEL.FM_INST_52A3P),   // Address of tag to be added to Live Data
        '651RA Breaker Status',             // Text to be used on Live Data page
        'SPS',                              // Data type
        '651RA, Binaries',                  // Label list (comma separated)
        TRUE,                               // Forceable (TRUE = yes)
        0);                                 // Task ID (0 = Main Task, 1 = Automation Task)
END_VAR
```

Figure 5.15 Example LiveData Function Block Declaration

The LiveData function block does not need to be called or executed for data to appear on the Live Data page; it must only be declared. However, you can control some aspects of the value's appearance on the Live Data page, and doing this requires calling the function block. *Figure 5.16* provides an example of how to control the visibility and the color of data when displayed on the Live Data page.

```
PROGRAM LiveDataProgram
VAR
    Recloser52A : LiveData(
        ADR(SEL_651RA_SEL.FM_INST_52A3P),   // Address of tag to be added to Live Data
        '651RA Breaker Status',             // Text to be used on Live Data page
        'SPS',                              // Data type
        '651RA, Binaries',                  // Label list (comma separated)
        TRUE,                               // Forceable (TRUE = yes)
        0);                                 // Task ID (0 = Main Task, 1 = Automation Task)

    visibility          : BOOL;             // TRUE = visible, FALSE = invisible
    breakerDataColor    : colorRG_t := RED; // Options: red, green, off
END_VAR
```

```
Recloser52A(EN := visibility, Color := breakerDataColor);
```

Figure 5.16 Control Visibility and Color of Data on Live Data Page

Log Settings

Default Log Entries

Within the Tag Processor, the RTAC has several default log entries of certain system tags to provide common security and audit logs. Default log entries include user log in/log off, user settings changes, the number of logon attempts for a user, and other audit-related tags. These default log items are valuable for security and for troubleshooting system issues and should not be removed.

You can configure the RTAC to log changes of tag values with time-stamped log messages. The log messages are visible in the SOE report located on the RTAC web interface and can be downloaded as a comma-separated variable (CSV) file. You can use the Tag Processor to configure all log settings or you can configure logging in user-defined programs.

The RTAC supports logging of the following tag types:

- **SPS**: log triggered by change of state of .stVal. You must enter a logging on and logging off message for the RTAC to log the change. The function block is called Logger_SPS.
- **MV**: log triggered by change of the instMag value (based on range parameters in the tag configuration or in the Tag Processor). Logging on and off messages are not configurable, because the range attribute is the message. For example, if the value exceeds the .rangeC.hhLim, the log contains the time of the excursion and the message "High_High." The function block is called Logger_MV.
- **CMV**: log triggered by change of the instCval.mag value (based on range parameters in the tag configuration or in the Tag Processor). Logging on and off messages are not configurable, because the range attribute is the message. The function block is called Logger_CMV.
- **INS**: log triggered by change of the .stVal value (based on range parameters in the tag configuration or in the Tag Processor). Logging on and off messages are not configurable, because the range attribute is the message. The function block is called Logger_INS.
- **STR**: log triggered by change of string value. Configure a logging on and logging off message. The function block is called Logger_STR.
- **BOOL**: log triggered by change of Boolean value. Configure a logging on and logging off message. The function block name is Logger_Basic.

- **ACT, ACD**: log triggered by change of state of .general, .neut, .phsA, .phsB, and .phsC attributes. You must enter a logging on and logging off message for the RTAC to log the change; these messages will be concatenated with the particular attribute name that changed. The function blocks for logging ACT and ACD are called Logger_ACT and Logger_ACD.
- **ENS**: log triggered by change of the enumerated value. Configure a logging on and logging off message. Logging of ENS tag types is accomplished with the Logger_STR function block.
- **Time Change Trigger**: log triggered by the change of the configure time source or the time of the tag if no source is configured. Configure a Time Change Trigger message and check the box for Time Change Trigger. Time change logs and logs based on tag values are mutually exclusive.

Use the following steps to enable logging of a tag.

Step 1. Click on the **Tag Processor** tab.

Step 2. Click on the **Options** button in the Tag Processor column header, and select **Logging Layout** from the menu. This will show columns related to logging configuration.

> **NOTE**
> You must configure the Logging On message, Logging Off message, or the Logging Time Change Trigger message to generate log entries. The RTAC does not log blank messages.

Step 3. Place the tag you want to log in the **Destination Tag Name** column.

Step 4. Set **Logging Enable = True**.

Step 5. Set up other parameters you want to log based on time, value change, edge trigger, etc.

See *Section 3: Tag Processor* for a description of each logging parameter in the Tag Processor grid.

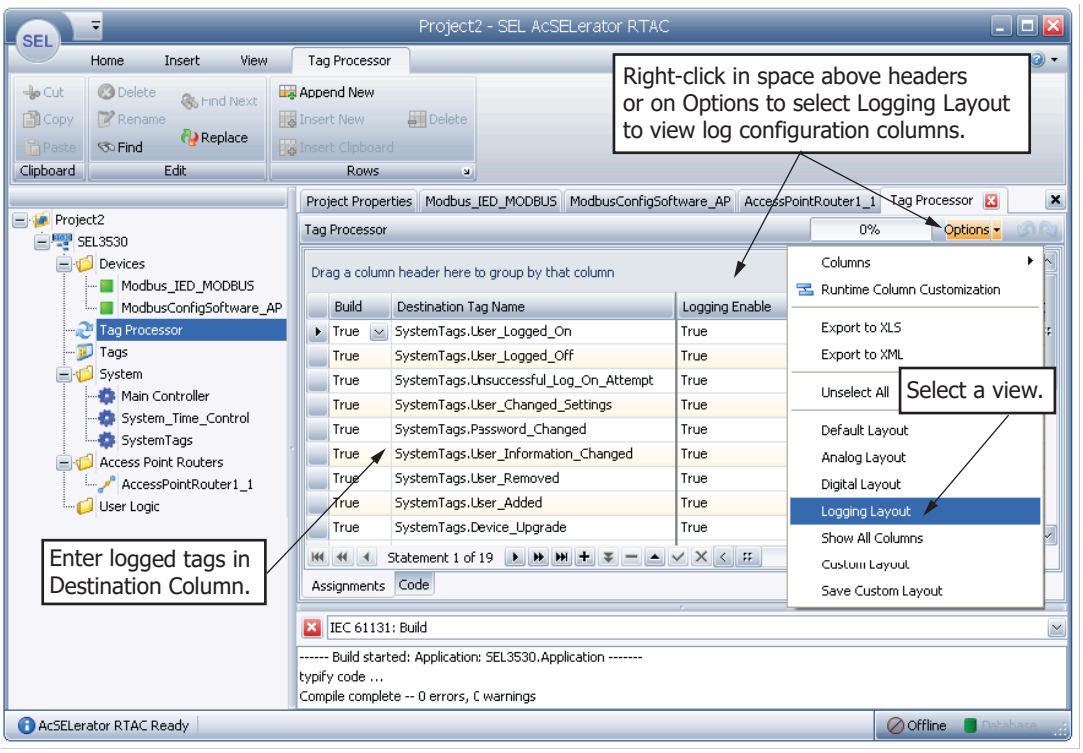

Figure 5.17 Logging a Tag

Other Settings

You can use other logging settings in the Tag Processor to do the following:

- Set logging categories and priorities.
- Enable logging of alarms based on high and low alarm limits, change of time or change of state. The logged alarms appear in the event log and flash when in alarm state.

  NOTE
  Log messages and categories, can contain US-ASCII or international Unicode characters.

- Filter alarming and logging with an antichatter filter. This defines the maximum number of changes (Logging Chatter Counts) within a period of time (Logging Chatter Time) that the RTAC permits before it considers the point to be chattering. When the Tag Processor determines the point is chattering, it will remove all but the first entry of this chattering point and log a message indicating this action has been taken.

Example 5.1 Log Lamp Test Button Usage

This example will illustrate how to log a status change. We will configure the Tag Processor to create a log entry each time you depress or release the lamp test button. See *Figure 5.18* for the completed example. We show here only columns necessary for this example.

Step 1. In the Tag Processor, insert the tag SystemTags.Lamp_Test_Button_Status.stVal into an open line in the Destination Tag Name column.

This is the status indication of whether the lamp test button has been depressed.

Step 2. Right-click in space above headers, and select **Logging Layout** to show only the columns related to logging.

Step 3. Scroll to the right to complete the following configuration changes:

- **Logging Enable**: Set to True to enable logging of this tag.
- **Logging Alarm Enabled**: Optional. Set to True if you want the RTAC to also display the log entry in the Alarm Summary of the RTAC web interface when it logs the point. Set to False to log only.
- **Logging Alarm State**: Optional if Logging Alarm Enabled is True. Determines if the point goes into alarm when the value is True (button depressed) or when the value is False (button released). A pop-up warning appears on the RTAC web interface to notify the user whenever alarms occur.
- **Logging Category**: Set to any string enclosed in single quote marks ('Internal', for example). You can use this category to sort logs when viewing them.
- **Logging On Message**: Set to any string enclosed in single quote marks ('Lamp button depressed', for example). The RTAC logs this message when the status is True.
- **Logging Off Message**: Set to any string enclosed in single quote marks ('Lamp button released', for example). The RTAC logs this message when the status is False.

Step 4. Save the project and send it to the RTAC.

Step 5. When the transmission is finished, complete the steps under Viewing Logs Via Web Interface to open the web browser and view the RTAC logs.

Step 6. Depress the lamp test button long enough for the RTAC to detect the change (lamp test sampling is one second), and note the updated log message at the bottom of the RTAC webpage screen.

Step 7. Release the button, and note the updated log message reflecting that the button has been released.

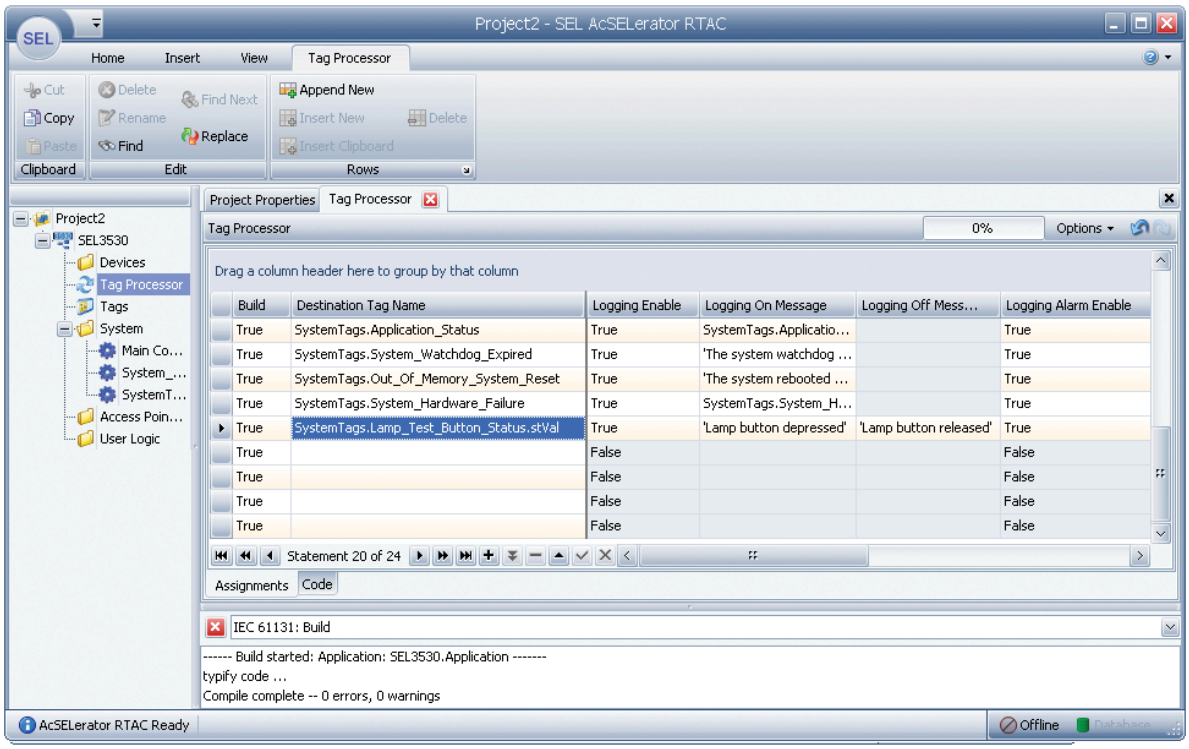

Figure 5.18 Example Log Entry

Example 5.2 Log an INS Value With Time Change Trigger

Normally, an INS value is logged based on the change of the range attributes. The resulting log entry shows the time, tag name, and range value (such as High, High_High, Low, etc.). This example uses the CONCAT function to log the message "My value changed. Value =" along with the INS value each time the time stamp changes.

Step 1. Right-click in the space above headers, and select the **Logging Layout** to show only the columns related to logging.

Step 2. Enter an INS tag name and stVal attribute in the Tag Processor Destination Tag Name column.

Step 3. Configure the following:

Setting	Value
Logging Enable	True
Logging Time Change Trigger	True
Logging Time Change Trigger Message	concat (('My value changed. Value = '), DINT_TO_STRING(test_point.stVal))

Each time the INS time value changes, the RTAC will log the defined message string along with the present INS stVal value.

Example 5.3 Log a Digital Input in an SEL-2240 System

Example 5.1 illustrated how to log a tag that originates within the RTAC. The time stamp associated with such a point will be the RTAC system time when the log entry is created. This example will show how to log a tag along with a time stamp that is created independently from the RTAC logic engine. The illustration uses a digital input from the SEL-2240, connected via EtherCAT protocol. The same principles apply to other protocols, such as DNP or C37.118.

Step 1. Create a project that includes an I/O network and at least one SEL-2240 Digital Input Module. Refer to *EtherCAT on page 325* for specific configuration steps.

Step 2. In the Tag Processor, insert the SOE tag for input_001. As described in *DC Mode Processing (DC Control Voltage) on page 339*, this tag includes a time stamp that is accurate within 1 ms, regardless of the logic engine task cycle time. Verify that the debounce settings for this input are appropriate for the application.

As you can see in *Figure 5.19*, enter the tag name without the .stVal attribute. The SPS tag type includes a time attribute that will contain the original time stamp. If you enter the tag name with the .stVal attribute, the logged time stamp will be the RTAC system time when the log is created.

Build	Destination Tag Name	DT Data Type	Logging Enable	Log Initial State	L
True	SystemTags.Port_Power_Overcurrent	SPS	True	False	Fa
True	SystemTags.Application_Status	STR	True	False	Fa
True	SystemTags.System_Watchdog_Expired	STR	True	False	Tr
True	SystemTags.Out_Of_Memory_System_Reset	STR	True	False	Tr
True	SystemTags.System_Hardware_Failure	STR	True	False	Tr
True	SystemTags.HMI_Control_Operation	STR	True	False	Fa
True	SystemTags.HMI_Analog_Write_Operation	STR	True	False	Fa
True	Node_1_Slot_B_ECAT.INPUT_SOE_001	SPS	False		Fa

Figure 5.19 Example 5.3 Tag Entry

Step 3. Scroll to the right to complete the logging configuration changes you want. See *Example 5.1* for details.

Step 4. Save the project, and send it to the RTAC.

Step 5. Assert the contact input, and view the log by using the instructions shown in *Viewing Logs Via Web Interface on page 658*.

Viewing Logs Via Web Interface

You can view logs in the RTAC's web interface. The web interface log entries contain all the data related to a particular log. Notice the log entry in *Figure 5.20* of several log in attempts. The username is left as **Unknown** until three consecutive attempts, at which time the user is locked out and the user's name is logged. **Feeder1 breaker**, configured to display when in alarm, is red when logged in alarm state and returns to black when the state returns to normal. The **Alarm Summary** is very similar to the SOE report with the exception that it

contains only logged items that are configured with Logging Alarm Enabled, and it also automatically updates every 10 seconds to show any new or updated entries. Use the following steps to configure the log entry to show only columns you want:

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **HTTPS://** followed by the RTAC Ethernet address.

> **NOTE**
> The RTAC and PC must be on the same Ethernet subnet to enable web communications.

Step 4. Log in to the RTAC web interface.

Step 5. Note the alarm summary at the bottom of each webpage.

Step 6. To view all logs, events, and alarms, click **Alarm Summary** or **SOE** under **Reports**.

Step 7. Filter the report as needed using the filtering categories located at the top of the page.

Step 8. Apply a check to any items on this list that you want to clear from the list or acknowledge.

Step 9. Select an action from the **Actions** drop-down list to apply to the entries that are checked.

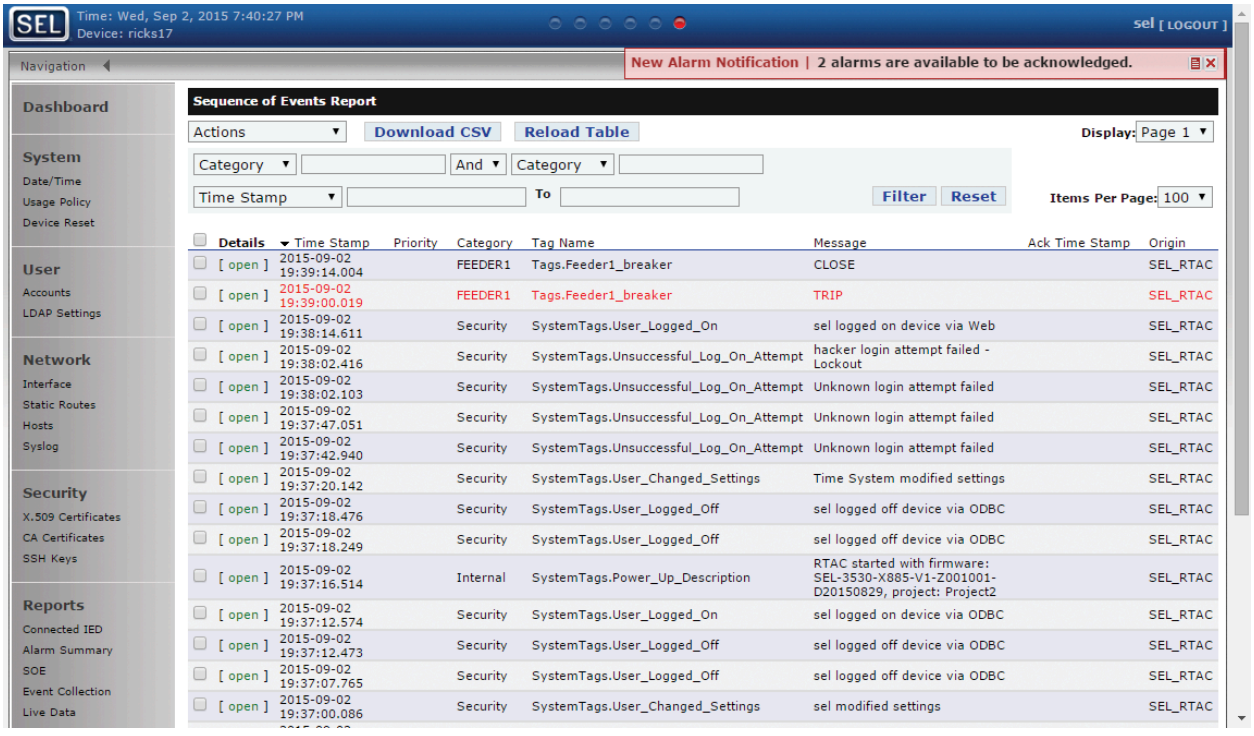

Figure 5.20 View SOE Summary

You can also clear all logs from the web interface in one step. Under the **System** heading, click on **Device Management**. Select the **Delete Logs** check box, and then click **Submit**. This operation cannot be undone.

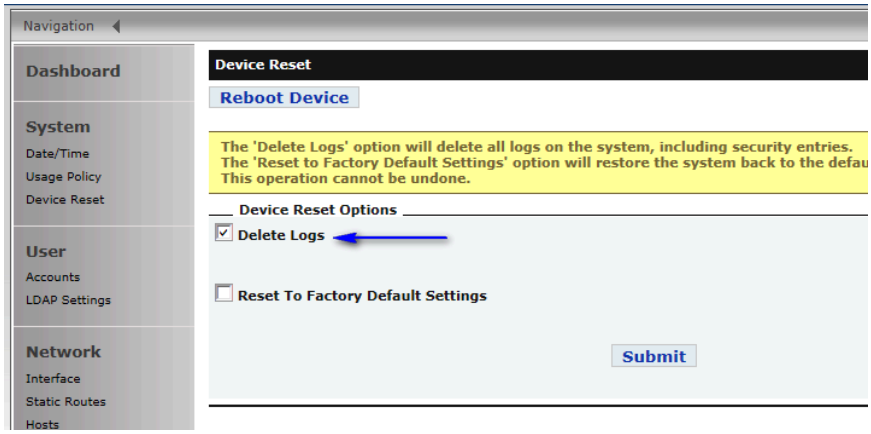

Figure 5.21 Delete Logs

Upload Projects From the Web Interface

Starting with firmware version R136, the RTAC supports a project-upload feature for the web interface. This feature allows you to send previously exported project files to the RTAC even when the ACSELERATOR RTAC software is not installed on the computer. This function is available for Administrator, Engineer, and HMI Operator user accounts. See *Section 7: Security and Account Management* for more information on web-interface user-account privileges.

Step 1. Connect to the RTAC through one of the Ethernet ports or the USB-B interface.

Step 2. Open a web browser.

Step 3. Enter **HTTPS://** followed by the RTAC Ethernet address.

Step 4. Log into the RTAC web interface.

Step 5. Under the **System** heading, select **Project Management**.

Step 6. Select **Choose File**, locate the desired project file, and click **Open**.

Step 7. Select **Upload**. Note that once successfully uploaded, the project is loaded into the internal memory of the RTAC as an inactive project.

Step 8. Once uploaded, the project name appears in the list. Click **Activate** to apply the settings to the connected RTAC.

NOTE
If you have created a custom password for the exported project, the RTAC will prompt you to enter the password before it is enabled in the RTAC. See Section 7: Security and Account Management for more details on encrypting passwords.

If there is insufficient storage space on the RTAC to store an uploaded file, the error message, "ERROR: Insufficient storage space," will display.

An attempt to upload a file with an extension other than .exp results in the software displaying the error message, "ERROR: Invalid Project File."

You can use the applicable buttons to rename or delete projects that have been uploaded to the **Project Upload** page. To organize the project list, click the **Create Directory** button to create a new folder. Add existing projects in the list to the directory by left-clicking and dragging the project file icon into the folder.

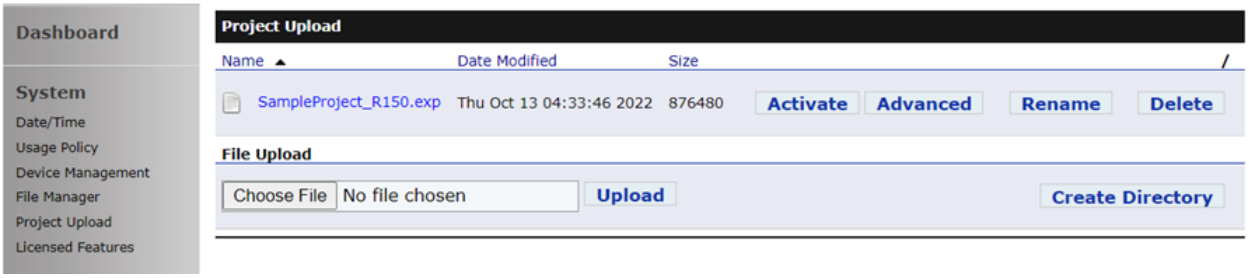

Figure 5.22 Project Upload Screen

Starting in R147, projects uploaded via the web interface can be activated with advanced settings that may be embedded with the uploaded project. These can be selected individually by selecting the **Advanced** button, checking the boxes beside the individual items and then clicking **Activate**.

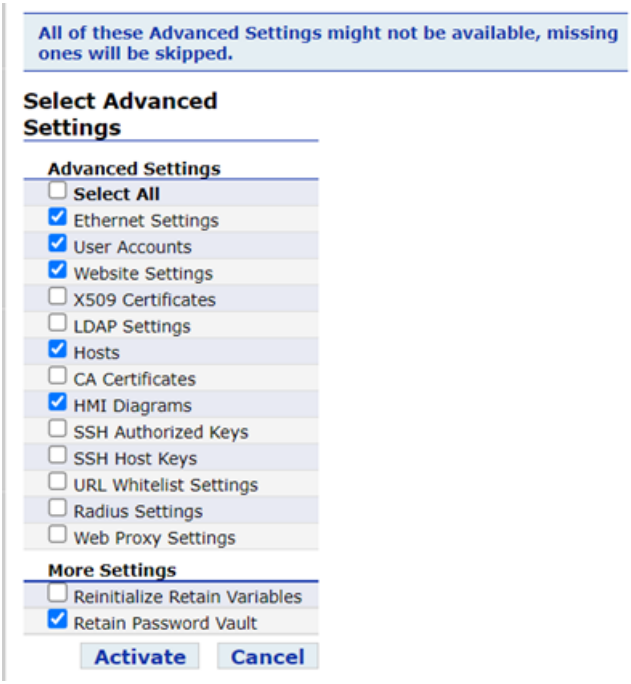

Figure 5.23 Project Upload Screen

RAID Support and Configuration

RAID—Redundant Array of Independent Disks

The SEL-3555 provides RAID-1 storage management for the RTAC's file system data. RAID-1 manages mirrored copies of its file system data on two disks and enhances the RTAC's data storage resiliency. Only SEL-3555 RTACs that include three or more solid-state drives (SSDs) are compatible with RAID data management.

NOTE
When a RAID is created using disks of different sizes, each resulting RAID component is constrained to the size of the smallest disk in the RAID.

Setting and Initializing RAID

Configure RAID settings using the RTAC web interface. Select the **Device Management** link from the navigation panel to view and edit the RAID settings. The system disk (designated as "System") includes the RTAC firmware image and is not compatible with RAID. *Figure 5.24* shows the RAID settings for an RTAC with four SSDs.

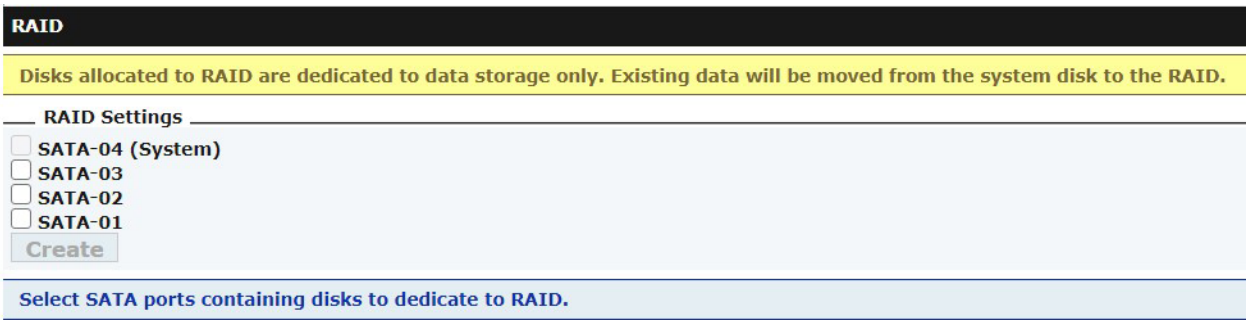

Figure 5.24 RAID Setting View With All SATA Ports Occupied

Activate RAID storage using at least two of the non-System SATA disks. Select the desired SATA ports to dedicate to RAID and select the **Create** button. Once initialized, the RTAC will begin synchronizing all RAID components. The following table lists the possible RAID states based on the number of operational disks in the RAID configuration:

Number of Operational Disks in RAID	Normal Operation	Error State(s)
One	RAID status is *Degraded*, indicating that RAID is operational after completing initialization, but only one disk is present and redundancy is not available.	If a RAID disk fails, the RAID status is *Failed*.
Two	RAID status is *Ready*, indicating that RAID has completed initializing and is fully synchronized.	If both RAID disks fail, the RAID status is *Failed*.
Three	RAID status is *Ready*, indicating that RAID has completed initializing and is fully synchronized. In this state, the RTAC uses a third disk designated as a spare for automatic RAID recovery when one of the active disks fail. RAID activates a *Rebuild* to synchronize data to the spare disk if either of the active disks fail.	If all RAID disks fail, the RAID status is *Failed*.

Identifying a Failed Disk

The following example provides methods for identifying a SATA disk failure. The example system consists of a three-disk RAID where SATA Ports 1 and 2 are synchronized and SATA Port 3 is available as a spare disk. In this example, the disk in SATA-01 fails and RAID rebuilds the spare SATA-03 for mirroring.

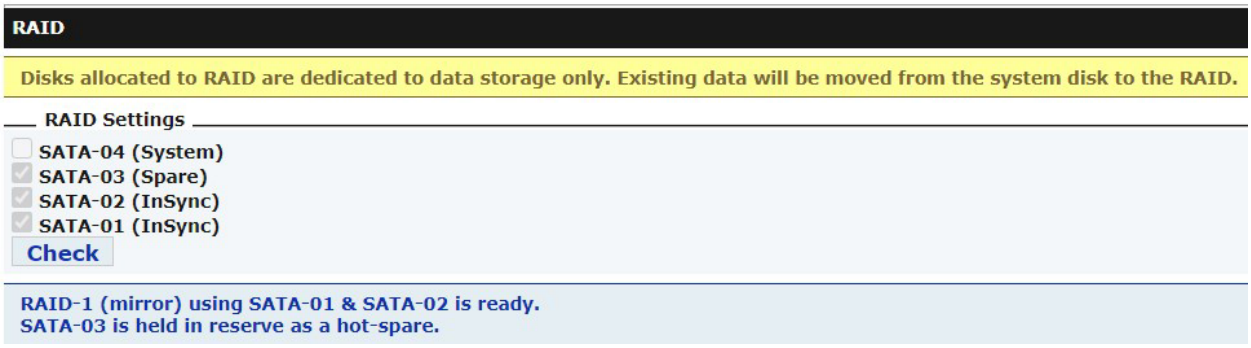

Figure 5.25 Web Page View Normal Operation Three-Disk RAID

The following three methods provides indication that a SATA 1 disk failed:

1. The RTAC's Sequence of Events (SOE) by default logs any changes in the RAID status. In this three-disk RAID example, the RAID status message will be "RAID-1 (mirror) using SATA-02 and SATA-03 is rebuilding". If a RAID status message SOE log appears, follow the next two steps to check SATA port status.
2. SATA port status information is available in the RTAC's Web Interface via the **Device Management** link. The RTAC Web Page provides the individual SATA port status. The failed disk is indicated by "Failed" next to the SATA port. See *RAID and SATA Status Information on page 664* for further details regarding status messages.

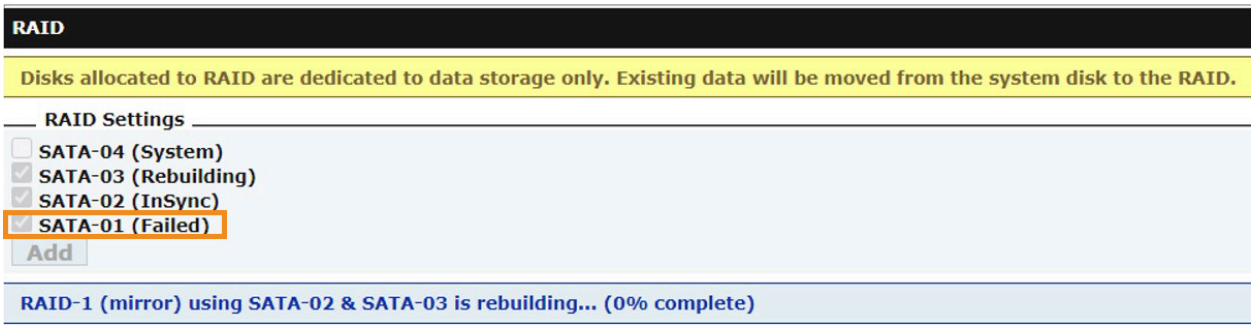

Figure 5.26 Web Interface SATA Port Failure Indication

3. The RTAC's SystemTags also provide SATA port status information. If connected to RTAC via ACSELERATOR RTAC, view the RTAC's SATA RAID Status system tags.

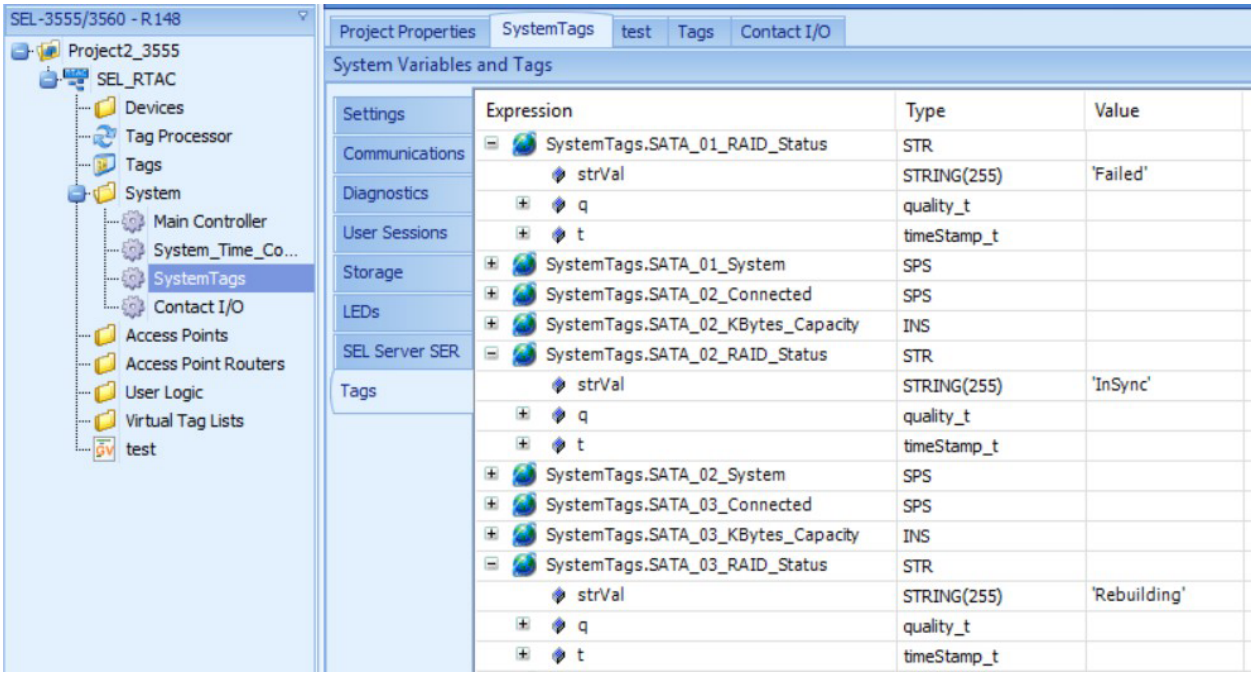

Figure 5.27 ACSELERATOR RTAC SATA Port SystemTags View

After identifying a failed disk, see *SATA Drives* in the *SEL-3555 Instruction Manual* for details on removing and installing a new disk. Once a failed disk has been replaced, RAID will automatically initialize and begin rebuilding a copy of the file system data on the new disk.

RAID and SATA Status Information

The following table describes the possible states that RAID may operate in:

Status	Description
Initializing	RAID is created and synchronizing for the first time.
Ready	RAID has finished initializing/rebuilding and is ready for operation.
Degraded	RAID is operational but is missing disks.
Rebuilding	RAID was previously Degraded and is now re-synchronizing.
Failed	All the disks in the RAID have failed or are missing.
Checking	The RAID is operational, and an integrity check is being performed.

Additionally, the following table describes the possible states that SATA bays may operate in:

Status	Description
InSync	The disk is in the RAID and is fully synchronized.
Rebuilding	The disk is currently rebuilding in the RAID.
Spare	The disk is reserved as a hot-spare for the RAID.
Failed	The disk was in the RAID and failed.

SECTION 6

Axion Bay Control and SEL Touchscreen

Overview

The SEL-2240 Axion Bay Controller combines modular I/O cards, advanced automation, a powerful logic engine, current and voltage measurements, a programmable color touchscreen display, and advanced communication protocols to provide comprehensive monitoring and reliability for your bay control application. Choose from a variety of digital and analog modules to fit your application requirements. The advanced automation capability combined with the diversity and flexibility of I/O modules allows you to implement any blocking or interlocking scheme required by the switching devices in your substation. Use the Axion Bay Controller as an economical and powerful alternative for monitoring and controlling one or more substation bays at the transmission or distribution level.

The 10-slot SEL-2242 can be configured with an optional LCD touchscreen. This option is only available in rack-mount configurations, and an SEL-2241 must be installed in Slot A for proper operation.

Navigating SEL Touchscreen Applications

The touchscreen provides the ability to configure custom screens to monitor breakers, disconnect switches, and analog and digital quantities as well as the ability to control the position of breakers and switches. Additionally, the touchscreen provides default applications for viewing SOE reports and device information, as well as updating device settings.

This section covers all configuration aspects of the touchscreen applications and features. The Home screen is the introductory screen containing all folders and applications. The additional applications provide access to settings, reports, and device information, as well as any custom screens you have created. The following folders and applications are available from the Home screen:

- Custom Screens Application
- Reports Folder
  - Sequence of Events (SOE) Application
  - Alarm Summary Application
- Settings Folder
  - Port F Application
  - Touchscreen Settings Application

- Device Information Folder
  - RTAC Status Application
    - Device Information Screen
    - System Statistics Screen
  - EtherCAT Information Application
    - EtherCAT Status Screen
    - Module Status Screen
- User Login Folder
- Rotating Display Application
- Alarm Application Screens

Custom Screens Application

Design custom screen configurations for the touchscreen to match your system. Display your bay configuration as a single-line diagram on the touchscreen. You can create as many as 25 custom screens. Create detailed single-line diagrams using operational buttons, breakers, disconnect switches, analog labels, digital labels, and ANSI and IEC symbols. This variety of elements allows for designing custom screens that reflect the status of the breaker and disconnects, bus voltages, and power flow through the breaker. In addition to single-line diagrams, you can design custom screens to show the status of digital and analog tags defined in the RTAC logic engine. Use ACSELERATOR® Bay Screen Builder SEL-5036 Software in conjunction with ACSELERATOR RTAC to design your custom screens.

Circuit Breaker Symbol Settings and Status Logic

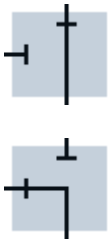
The Axion Bay Controller supports as many as 120 circuit breakers. Use the fb_BreakerOpenControl and fb_BreakerCloseControl function blocks in the PowerSystemAutomation library to implement appropriate circuit breaker operation logic for open and close commands from the touchscreen. These function blocks handle local and remote control operations and breaker interlock conditions. For more information on these function blocks, refer to the PowerSystemAutomation section in the Programming Reference instruction manual.

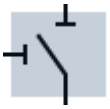
Table 6.1 shows typical ANSI and IEC breaker symbols that are supported by Bay Screen Builder.

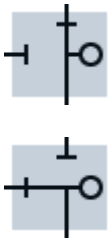
Table 6.1 Breaker Control States

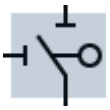
Type	Breaker Color Sequence[a]	State 1 (Closed)	State 2 (Open)	State 3 (Alarm)
ANSI Breaker	Red, Green, Amber			
ANSI and IEC Load Breaker Switch	Red, Green, Amber			

Type	Breaker Color Sequence[a]	State 1 (Closed)	State 2 (Open)	State 3 (Alarm)
IEC Truck Breaker	Red, Green, Amber			









[a] Bay Screen Builder allows you to set the breaker color sequence property for each of these states to match your system convention.

Disconnect Switch Control

The Axion Bay Controller supports as many as 120 two-position disconnect switches and 120 three-position disconnect switches. Use the fb_DisconnectSwitchControl function block in the PowerSystemAutomation library to implement appropriate disconnect switch operation for open and close commands from the touchscreen. This function block handles local and remote control operations, interlock conditions, and immobility conditions, and also provides switch alarm and status information. For more information on these function blocks, refer to the PowerSystemAutomation section in the Programming Reference instruction manual.

Table 6.2 shows typical ANSI and IEC disconnect switch symbols that are available to use in custom screens.

Table 6.2 Disconnect Switch Control States

Type	Interior Color	State 1 (Closed)	State 2 (Open)	State 3 (Alarm)
ANSI and IEC Disconnect (Two-Position)	Gray or Transparent			
ANSI and IEC Motor-Operated Disconnect (Two-Position)	Gray or Transparent			
ANSI and IEC Disconnect (Three-Position)	Gray or Transparent			
ANSI and IEC Motor-Operated Disconnect (Three-Position)	Gray or Transparent			

Three-Position Disconnect Switch Control Options

The control options available on a three-position disconnect switch depend on the state of the in-line and earthing switch position. *Table 6.3* shows the control options available based on the state of the switches.

Table 6.3 Three-Position Disconnect Switch

State	Control Option 1	Control Option 2
In-Line Switch Position: **Closed** Earthing Switch Position: **Open**	OPEN IN-LINE SW	CLOSE IN-LINE SW
In-Line Switch Position: **Open** Earthing Switch Position: **Open**	CLOSE IN-LINE SW	CLOSE EARTHING SW
In-Line Switch Position: **Open** Earthing Switch Position: **Closed**	OPEN EARTHING SW	CLOSE EARTHING SW
In-Line Switch Position: **Any** Earthing Switch Position: **In-Progress** or **Alarm**	NO CONTROL	NO CONTROL
In-Line Switch Position: **In-Progress** or **Alarm** Earthing Switch Position: **Any**	NO CONTROL	NO CONTROL
In-Line Switch Position: **Closed** Earthing Switch Position: **Closed**	NO CONTROL	NO CONTROL

Digital and Analog Labels

The Axion Bay Controller supports as many as 480 digital labels and 480 analog labels across all custom screens. You can use digital labels to show text on the screen based on the status value of a Boolean tag or expression, and analog labels to show the numeric value of an RTAC analog tag (REAL or Integer).

Navigation and Operation Buttons

The Axion Bay Controller supports as many as 100 navigation buttons and 100 operation buttons across all custom screens. Use operation buttons to send control commands to the RTAC logic engine. Navigation buttons provide a way to link to other screens, allowing you to map on-screen buttons to navigate to a chosen screen.

Single Screen Limitations

Each custom screen element contains status tag inputs for displaying the status of that element. Status tag inputs require an RTAC tag or expression mapped to these inputs (see *Tag Mapping on page 692*). The sum of the number of status tags across all symbols in a single screen must not exceed 120. *Table 6.4* shows how many status tags are used for each screen item.

Table 6.4 Status Tags Per Screen Items

Symbol	Status Tags
Circuit Breaker	3
Disconnect Switch	4
Three-Position Disconnect Switch	8

Symbol	Status Tags
Digital Label	1
Analog Label	1

Local/Remote Control

The Axion Bay Controller requires user logic for controlling breakers and disconnect switches either locally via the touchscreen or remotely via the communication protocols. RTAC projects with firmware version R152 and later provide the option to enable a global local/remote control function that supervises the operation of breakers and disconnect switches. Apply this supervision by defining the local and remote close conditions and by using the PowerSystemAutomation library's disconnect switch and breaker control function blocks to make the local control logic assignments. To enable local/remote control supervision of the breaker and disconnect switches, navigate to the SEL Touchscreen **Settings** tab and set **Enable Global Local/Remote Mode** to **True**, as shown in *Figure 6.1*.

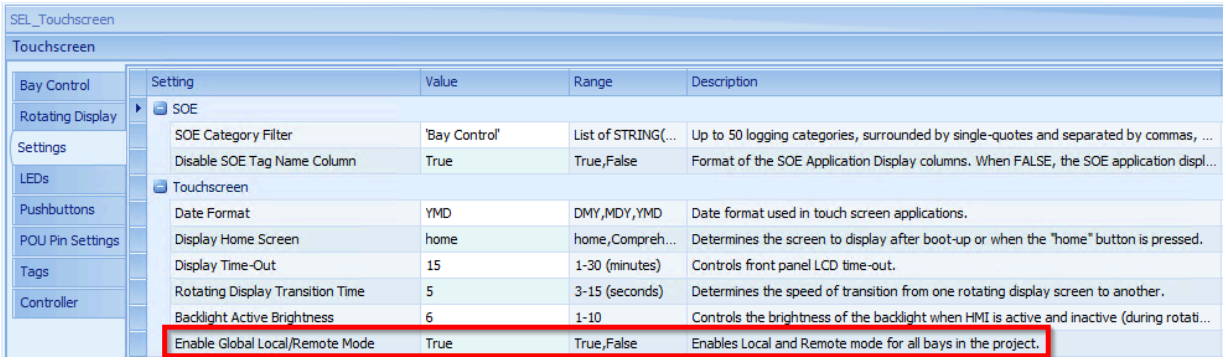


Figure 6.1 Enable Global Local/Remote Mode Setting

Once the project is saved, assign a Boolean logical input to the Touchscreen **Local** POU input pin either via the Controller CFC block or via external an POU.

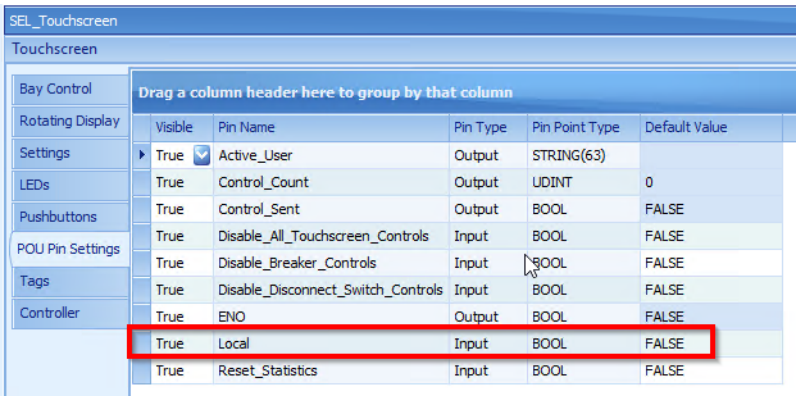

Figure 6.2 Local POU Input Pin

NOTE

The Local POU pin is hidden when **Enable Global Local/Remote Mode** is False.

The Axion Touchscreen performs the following based on the states of the Enable Global Local/Remote Mode input and the Local POU input pin.

- When **Enable Global Local/Remote Mode** is False, the Local POU input pin is hidden, and the Axion Touchscreen processes open and close commands from the front panel. When this mode is active, "LR" appears in the Axion touchscreen footer.
- When **Enable Global Local/Remote Mode** is True, the Local POU input pin is available. If the Local POU input evaluates to False, the Axion control is in Remote mode, and any controls attempted from the touchscreen are rejected and the touchscreen breaker and disconnect switch tags are not updated. When this mode is active, "R" appears in the Axion touchscreen footer.
- When **Enable Global Local/Remote Mode** is True and the Local POU input evaluates to True, the Axion control is in Local mode. Any controls attempted from the touchscreen are accepted and the touchscreen breaker and disconnect switch tags update. When this mode is active, "L" appears in the Axion touchscreen footer.

For an example use case of the Enable Global Local/Remote Mode setting, see the PowerSystemAutomation section of the SEL RTAC Programming Reference instruction manual.

SOE Application Configuration

The SOE application allows you to view the most recent 1,024 SOE reports from the touchscreen. Apply the logging category filter to limit the logs to specific categories defined in the Tag Processor.

SOE and Alarm Category Filter Configuration

The SOE application provides the ability to display only those logs that are relevant to your application. By default, any tag configured in the Tag Processor (*Tag Processor Data Entry on page 590*) with the SOE Logging Category of "Bay Control" is displayed in the SOE report. An empty SOE and Alarm Category results in displaying all RTAC SOE logs in the SOE application. To include additional logging categories, update the SEL Touchscreen setting **SOE and Alarm Category Filter** to include the desired logging categories. The setting input format is a comma-separated list of IEC 61131 strings. *Figure 6.3* shows the expected formatting for the requirement.

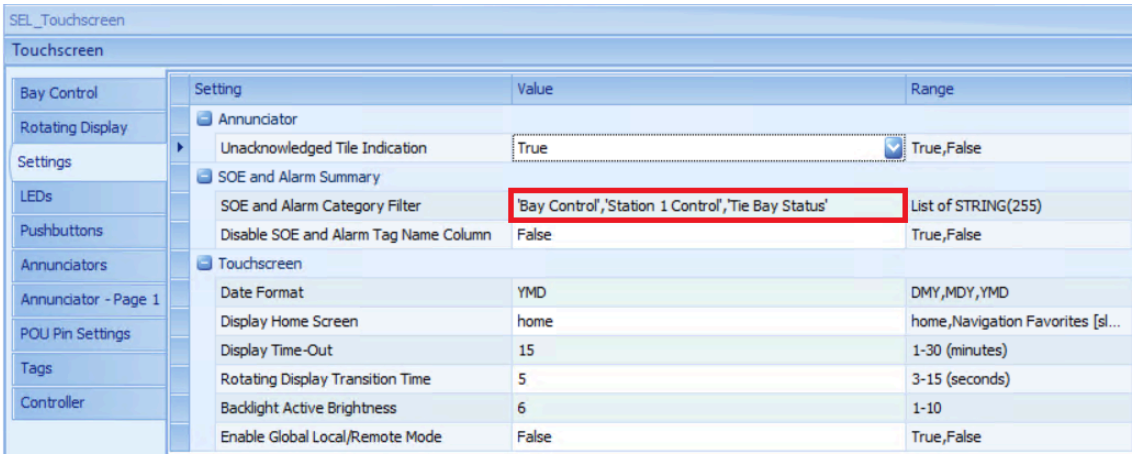

Figure 6.3 SOE Logging Category Filter Example

The SOE application provides the ability to delete all the SOE logs contained in the SOE Category filter. To delete logs, press the pause button and then tap the trash button on the sidebar, as shown in *Figure 6.4*. This will prompt the user to log in (if no user is actively logged in) to validate that the user has the appropriate permission. See *User Login on page 682* for required permissions.

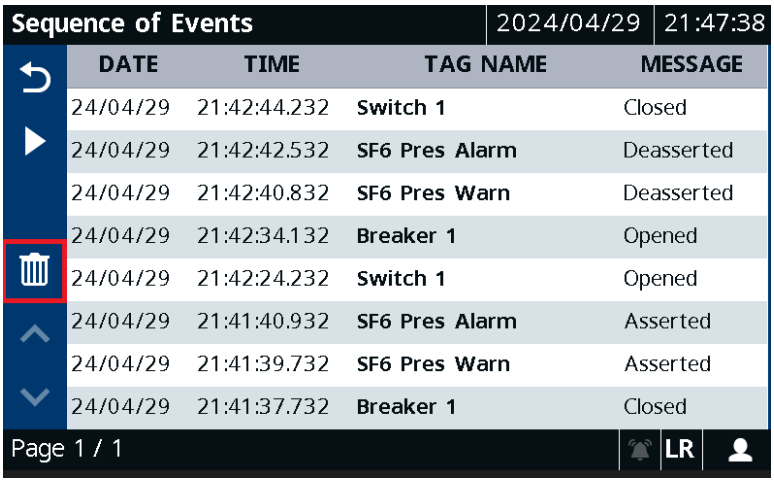

Figure 6.4 SOE Delete Event Reports

SOE and Alarm Summary Display Column Configuration

By default, the SOE application layout includes the following columns: Date, Time, Tag Name, and Message. The **Logging Display Tag Name** column of the Tag Processor allows you to set a descriptive message to be displayed on the **Tag Name** column of the SOE application of the SEL Touchscreen. If the **Logging Display Tag Name** column is left empty, then the **Tag Name** column shows the name of the tag that drives the alarm point (the tag name configured in the **Destination Tag Name** column of the Tag Processor). SEL-2241 RTAC firmware versions R152 and later allow you to hide the Tag Name column by setting the SEL Touchscreen setting **Disable SOE and Alarm Tag Name Column** to True. *Figure 6.5* shows the SOE application layout with the Tag Name column disabled. (*Figure 6.4* shows the layout when Disable SOE and Alarm Tag Name Column is set to its default value of False.)

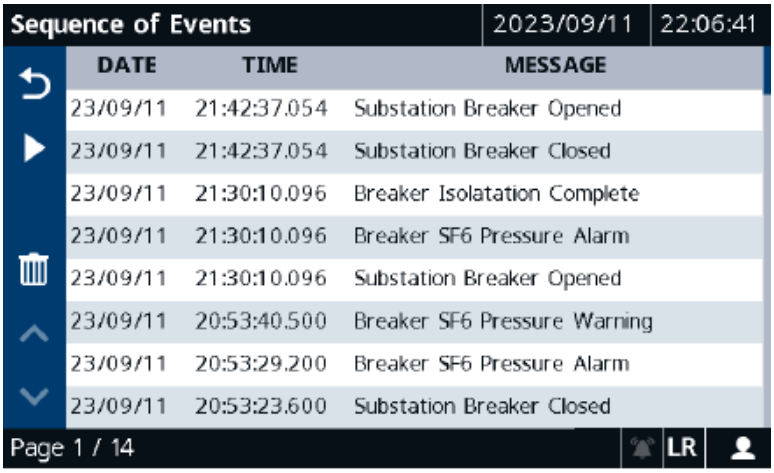

Figure 6.5 SOE Application Layout When Disable SOE and Alarm Tag Name Column Is True

SOE Tag Slicing

The SOE application automatically formats tags that exceed 20 characters via tag slicing to improve tag name visibility on the SOE screen. Slicing occurs by adding two periods ("..") so that the first 12 and last 8 characters of the tag are displayed with ".." in between the start and the end of the tag name. *Figure 6.4* shows an example of sliced Axion digital input tag.

If a tag name or message exceeds the Tag Name and Message column width, the SOE screen clips the rightmost characters to fit the message in the tag window. Use the Logging Display Tag Name of the Tag Processor (*Tag Processor Data Entry on page 590*) to create display names that fit within the touchscreen. *Figure 6.6* and *Figure 6.7* show an example configuration of the tag processor **Logging Display Tag Name** setting and the updated touchscreen SOE reports tag name.

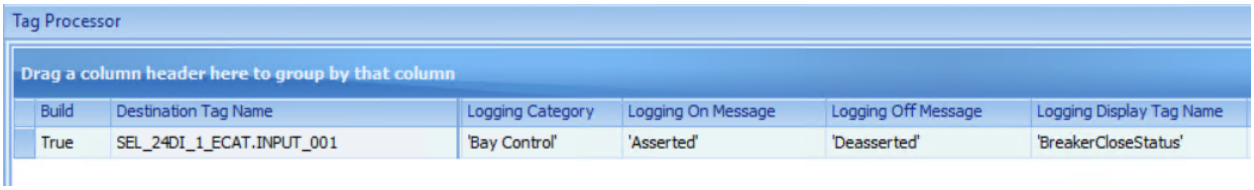

Figure 6.6 Tag Processor Logging Display Tag Name Configuration

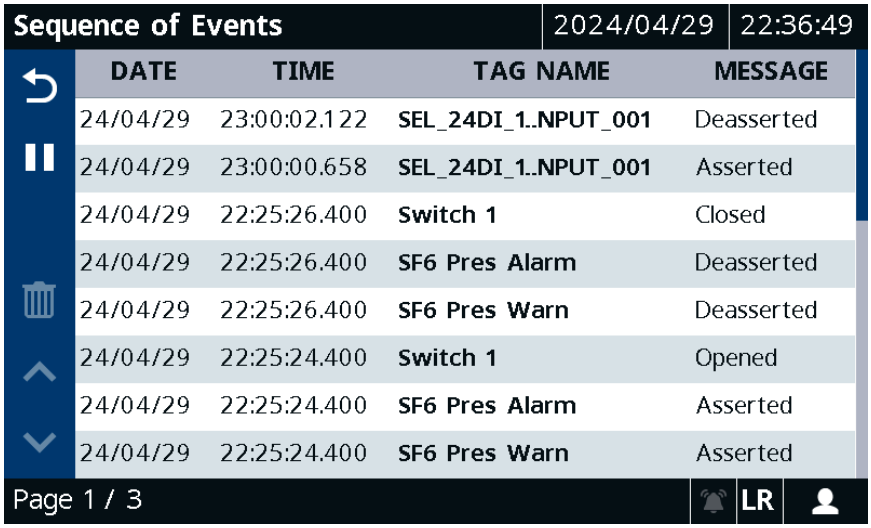

Figure 6.7 SOE Display Tag Name Comparison

SOE Date Display Configuration

Configure the SOE screen date display in the ACSELERATOR RTAC SEL Touchscreen Settings. *Table 6.5* shows the possible date display options.

Table 6.5 Touchscreen Date Display Format

Date Format Setting Value	SOE Screen Date Display[a]
MDY	mm/dd/yyyy
YMD	yyyy/mm/dd
DMY	dd/mm/yyyy

[a] "mm" is the two-digit month, "dd" is the two-digit day, and "yyyy" is the four-digit year.

Additionally, modifications to the "Date Format" setting are reflected in the header of all screens.

SOE Automatic Refresh

SEL-2241 RTAC firmware versions R152 and later provide the capability to automatically refresh the SOE screen. The device has two operating modes: Play and Pause. The SOE application defaults to Play mode, which automatically refreshes the screen as new data are available. In Play Mode, the SOE application displays the most recent logs and disables the navigation buttons (the up and down arrows), as shown in *Figure 6.8*.

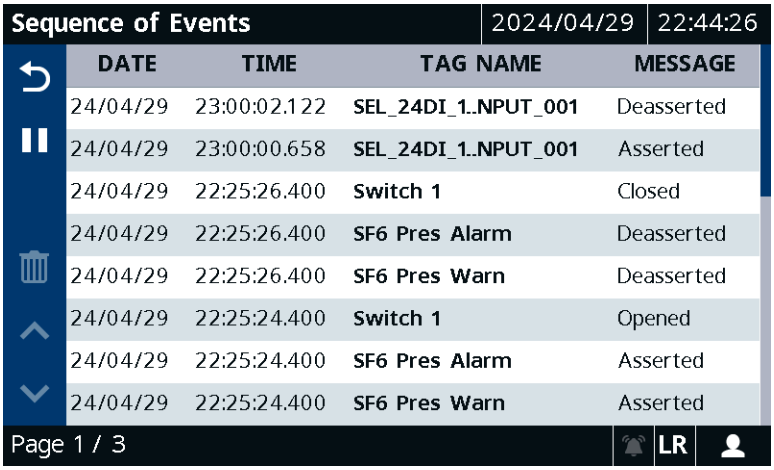

Figure 6.8 SOE Application in Play Mode

To scroll through the SOE logs, press the Pause button. When the SOE screen is paused, the navigation buttons are enabled, allowing you to scroll through all SOE records. If new SOE events become available while the SOE screen is paused, "New Records Available" appears in the application footer. To view the latest records, press the Play button to resume the automatic refreshing behavior.

SOE With Alarm Rows

In RTAC firmware versions R153 and later, the SOE application displays log entries that are also configured as alarm points in red text when the alarm condition is asserted. *Figure 6.9* shows the SOE application with active alarm points. For more information about alarm point configuration, see *Alarm Summary Application Configuration on page 675*.

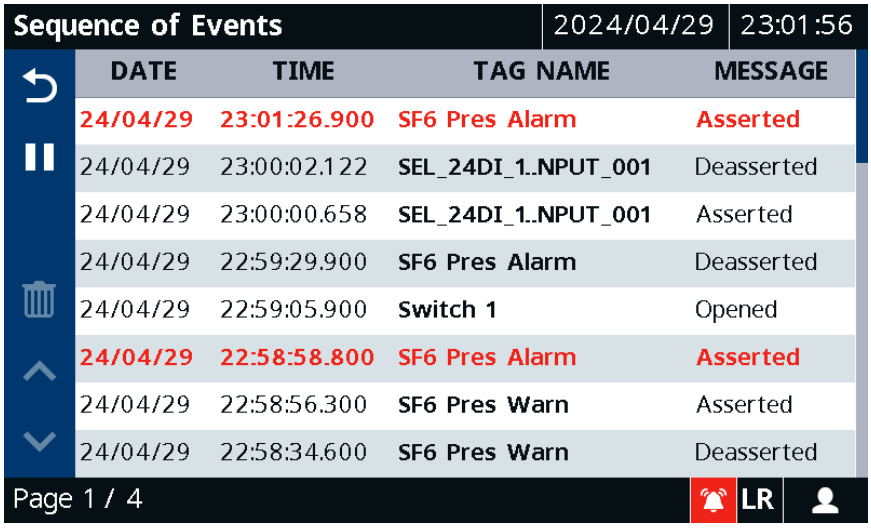

Figure 6.9 SOE Application With Active Alarm Points

Alarm Summary Application Configuration

RTAC firmware versions R153 and later support the Alarm Summary application. This application is similar to the SOE application, but it only contains tags with alarm logging enabled via the Tag Processor or user logic. The Alarm Summary application displays the most recent 1,024 unacknowledged or active alarms and provides users the ability to view, acknowledge, or unacknowledge alarm conditions.

Alarm Summary Settings and Configuration

Like the SOE application, the Alarm Summary application provides the ability to display only logs that are relevant to your application. Use the SEL Touchscreen setting **SOE and Alarm Category Filter** to include the desired logging categories in the touchscreen Alarm Summary application. See *SOE and Alarm Category Filter Configuration on page 670* for more details on configuring the Alarm Category Filter.

Provide more descriptive messages for the Alarm Summary tag assertion and deassertion fields by using the Logging Display Tag Name column settings. See *SOE and Alarm Summary Display Column Configuration on page 671* for more details on disabling the tag name column.

Figure 6.10 shows the required fields to configure an RTAC tag as an alarm via the RTAC's Tag Processor. Like the SOE application, the alarm tags must be enabled for Logging, contain a Logging Category that matches the SOE and Alarm Category Filter, and be enabled for alarm logging.

Tag Processor

Drag a column header here to group by that column

Build	Destination Tag Name	Logging Enable	Logging Category	Logging Display Tag Name	Logging On Message	Logging Off Message	Logging Alarm Enable	Logging Alarm State
True	Alarm_Point1	True	'Bay Control'	'AlarmConditon1'	'Asserted'	'Deasserted'	True	True

Figure 6.10 Alarm Point Configuration Fields Via Tag Processor

Alarm Summary Screen Usage

The Alarm Summary application supports both play and pause operating modes. The application automatically defaults to play mode, where it refreshes with the most recent unacknowledged or active alarms. Press the pause button or tap any of the logs to stop new alarms from appearing in the table. Once paused, you can navigate through alarms using the navigation arrows.

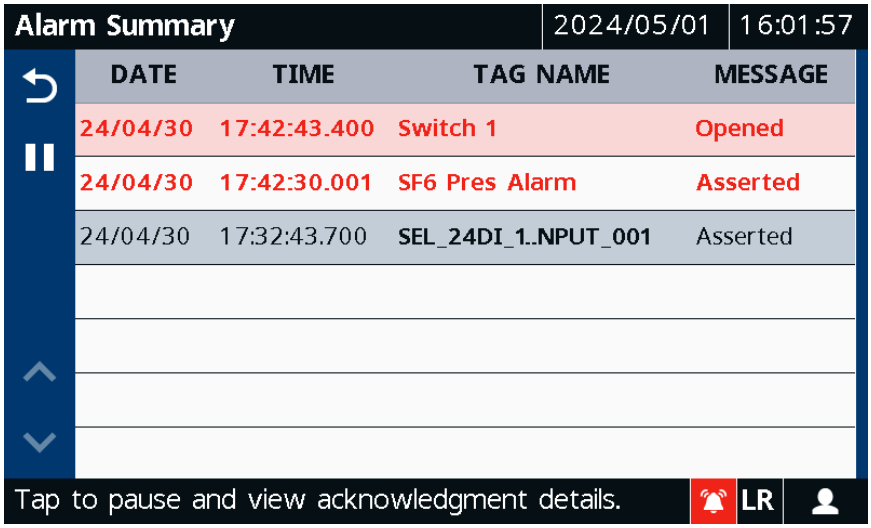

Figure 6.11 Alarm Summary Play Mode With Possible Alarm States

Alarms can be in four states depending on if the alarm is active, inactive, acknowledged, or unacknowledged. Any unacknowledged alarms have a flashing background. The following table provides the expected text colors and backgrounds for each of the possible alarm states. If an alarm is both acknowledged and inactive it will not be displayed on the alarm summary screen.

Active/Inactive	Acknowledged/ Unacknowledged	Text Color	Background Color
Active	Acknowledged	Red	White
Active	Unacknowledged	Red	Blinking (Light Red/ White)
Inactive	Acknowledged	Not displayed	Not displayed
Inactive	Unacknowledged	Black	Blinking (Gray/ White)

If no alarms are active or unacknowledged, the Alarm Summary application remains in Play mode and the footer message reports "No data available." as shown in *Figure 6.12*.

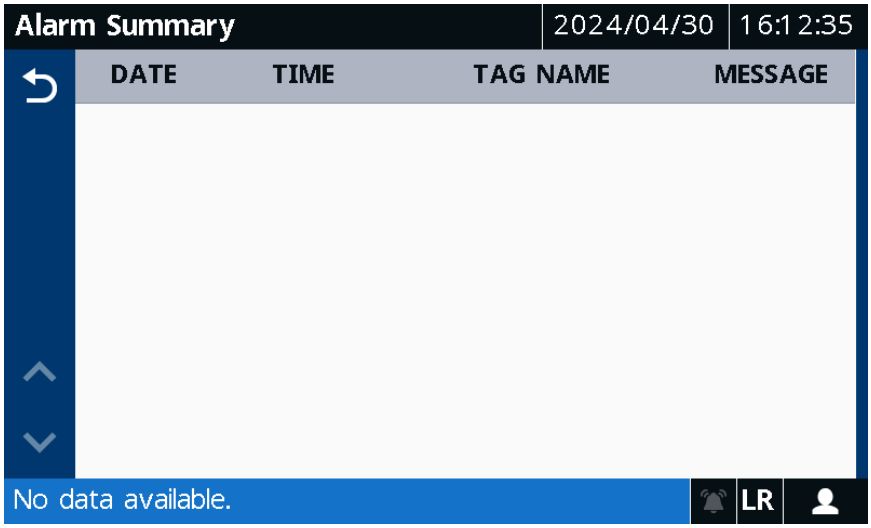

Figure 6.12 Alarm Summary No Data Available

Alarm Acknowledgement/Unacknowldgement

Alarms can be acknowledged and unacknowledged using the Alarm Summary screen. To acknowledge an active or inactive alarm, pause the screen by tapping the pause button or by tapping anywhere on the screen, then navigate to the desired unacknowledged alarm and select the row. Users must have permissions to acknowledge or unacknowledge alarms. If the user is not logged in with the permissions defined in *Table 6.11*, they are prompted to login. Once logged in, the user can view the alarm details and either acknowledge it or exit the screen using the close button. *Figure 6.13* shows the options for a previously unacknowledged alarm.

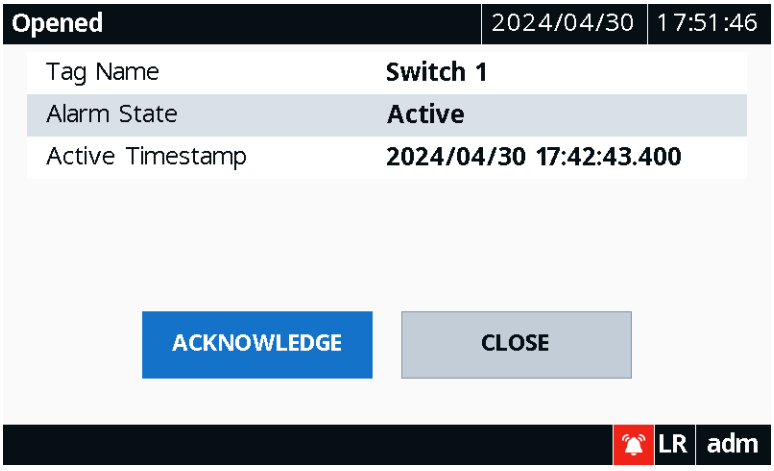

Figure 6.13 Alarm Acknowledge View

Alarms can be unacknowledged through the Alarm Summary application if they were previously acknowledged and the alarm is still active. To unacknowledge an alarm, pause the screen and tap the desired acknowledged alarm row. The user can view the active alarm and acknowledgement details, unacknowledged this alarm, or exit the screen using the close button. *Figure 6.14* shows the options for a previously acknowledged alarm.

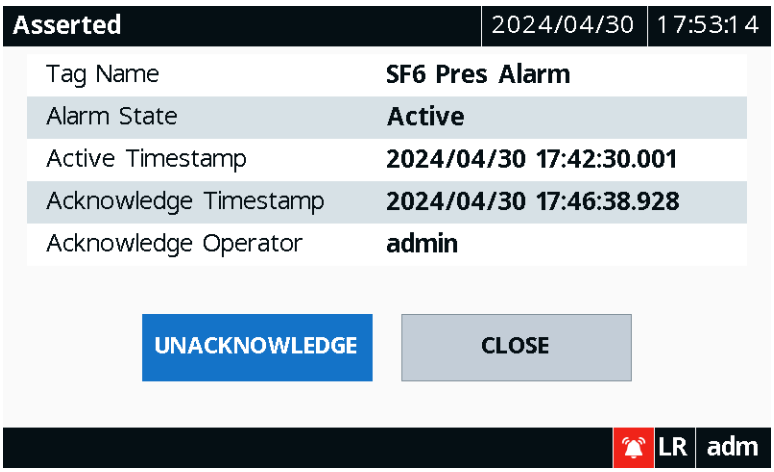

Figure 6.14 Alarm Unacknowledge View

Touchscreen Settings Application

The Touchscreen Settings application provides the settings shown in *Table 6.6*.

Table 6.6 Touchscreen Settings

Setting Name	Range	Description
Display Time-Out	1–30 minutes	Controls front-panel LCD time-out.
Rotating Display Transition Time	3–15 seconds	Determines the speed of transition from one rotating display screen to another.
Backlight Active Brightness	1–10	Controls the screen brightness.

Set the initial values of the touchscreen settings in ACSELERATOR RTAC under the **Settings** tab of the SEL Touchscreen (see *Settings on page 690* for more information). These settings can be adjusted dynamically at runtime from the actual touchscreen by tapping the **Settings** folder and selecting the **Touchscreen Settings** application. Downloading a project to the SEL-2241 restores the touchscreen settings to the values set in ACSELERATOR RTAC.

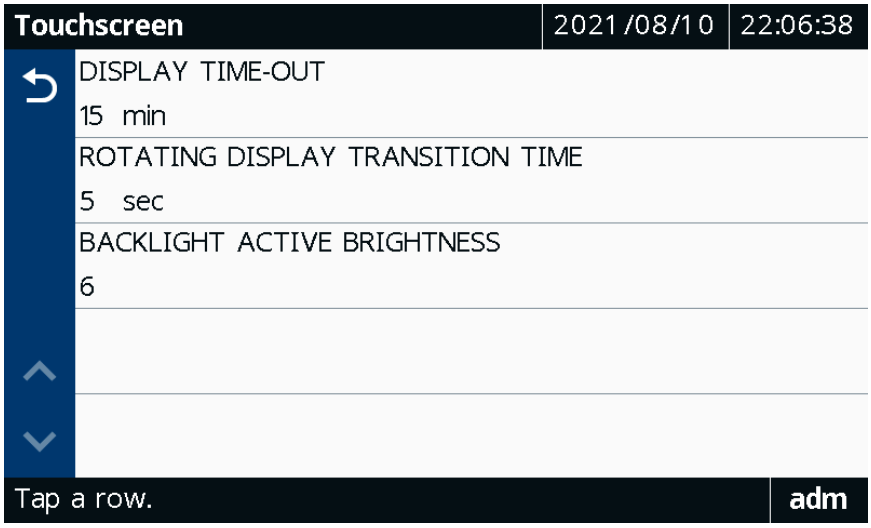

Figure 6.15 Touchscreen Settings Application

Front Ethernet Port (Port F)

The Axion Bay Controller includes Port F, a 10/100 BASE-T front-panel maintenance Ethernet port that can be used to perform the following tasks:

- Access the RTAC web page
- Connect to ACSELERATOR RTAC
- Upgrade firmware

You can disable Port F via the RTAC web interface or via the **Port F** application on the touchscreen, as shown in *Figure 6.16*. This operation may take as long as one minute.

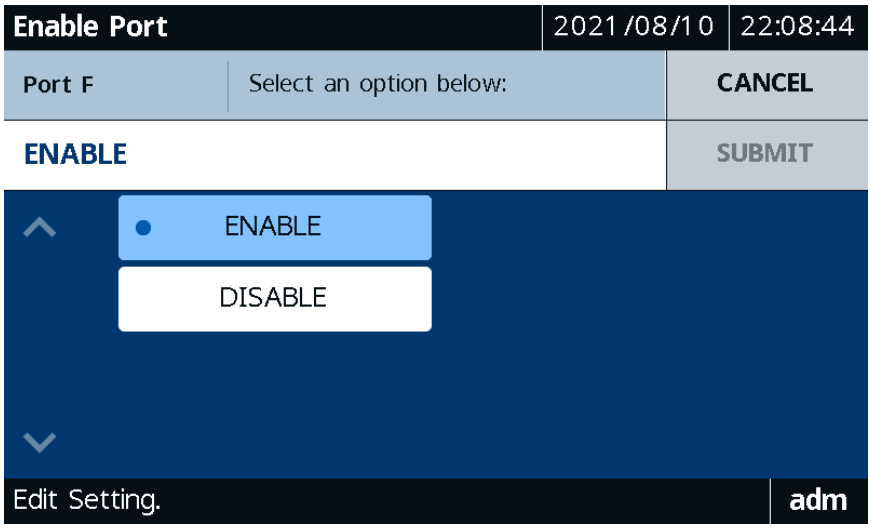

Figure 6.16 Port F Enable/Disable Port

DHCP Server

Port F includes a DHCP server option that can be enabled or disabled via the **Interface** tab of the RTAC web interface, as shown in *Figure 6.17*.

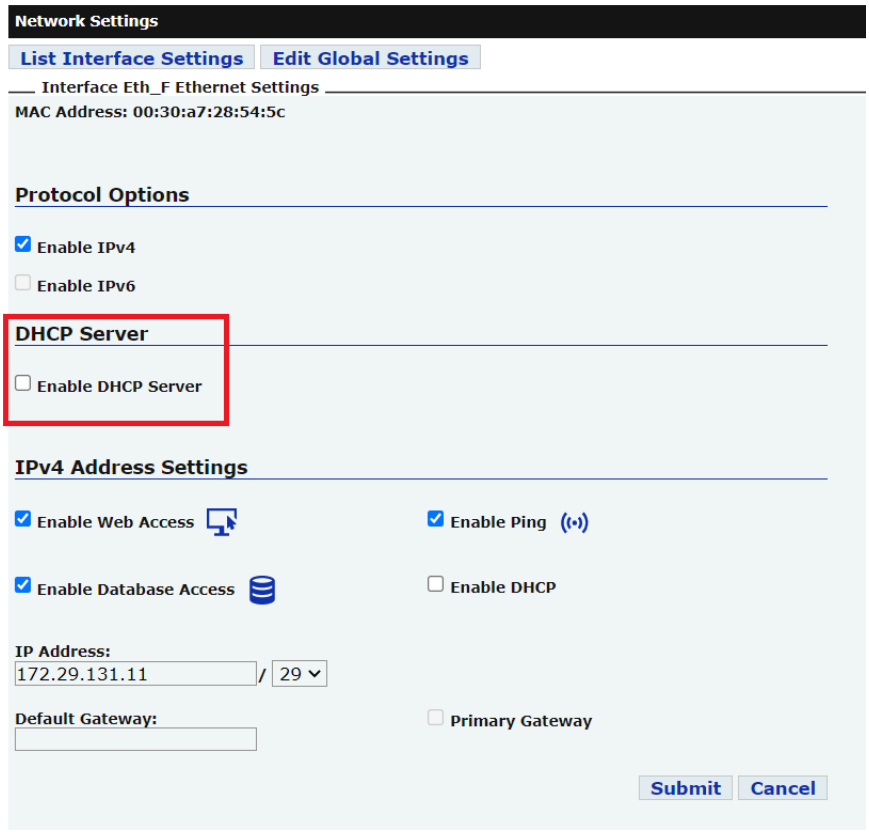

Figure 6.17 DHCP Server Front Port Option

When the DHCP server is disabled, use the **Interface** tab of the RTAC web interface to assign the proper IPv4 Address settings to Port F.

When the DHCP server is enabled, Port F issues the IP configuration to any computer or laptop that is configured for DHCP, allowing for a simple connection during initial setup and maintenance. When the DHCP server is enabled, the IP settings of Port F are set to a static address of **172.29.131.11/29**.

Device Information

Tap the **Device Info** folder to navigate to the Device Info screen, where you can access the RTAC Status and EtherCAT Info applications.

RTAC Status

The RTAC Status application includes a Device Information screen and a System Statistics screen; use the on-screen up and down arrows to transition between the two.

Table 6.7 shows the information provided on the Device Information screen of the RTAC Status application.

Table 6.7 RTAC Status > Device Information Screen Contents

Host Name	The RTAC network host name, as defined in the Network tab of the RTAC web interface.
Device Name	The RTAC device name, as defined in the dashboard of the RTAC web interface.

Device Location	The RTAC device location, as defined in the dashboard of the RTAC web interface.
Device Description	The RTAC device description, as defined in the dashboard of the RTAC web interface.
Firmware Version	The RTAC firmware version.
Serial Number	The RTAC serial number.
Current Project	The active RTAC project name.
Modified Project Time	The time at which the RTAC project was last modified.

Table 6.8 shows the information provided on the System Statistics screen of the RTAC Status application.

Table 6.8 RTAC Status > System Statistics Screen Contents

Main Task Usage	RTAC Main task usage, in percentage.
Automation Task Usage	RTAC Automation task usage, in percentage.
Memory Usage	The number of used bytes of memory.
Memory Available	The number of free bytes of memory.
Storage Usage	The number of used bytes for storage.
Storage Available	The number of free bytes for storage.

EtherCAT Info

The EtherCAT Info application consists of the EtherCAT Status and Module Status screens; use the on-screen up and down arrows to transition between the two.

EtherCAT Status

The EtherCAT Status screen provides general information regarding the state the Axion EtherCAT I/O network, as shown in *Table 6.9*.

Table 6.9 EtherCAT Status Screen Contents

EtherCAT Status	The state of the EtherCAT network. Possible states include the following: ➤ **Not Available**—indicates that the RTAC project main task does not include the EtherCAT I/O network ➤ **Disabled**—indicates that no EtherCAT communications are configured or the EtherCAT I/O network POU is disabled ➤ **Initializing**—indicates that the EtherCAT I/O network is in the process of enabling ➤ **Running**—indicates that the EtherCAT I/O network is operational ➤ **Client Failed**—indicates that the EtherCAT network client failed ➤ **Network Failed**—indicates that the EtherCAT I/O network has failed while Disable on Network Error is set to FALSE
Message Failure Count[a]	The message failure counter provided by the Axion EtherCAT I/O POU.

Server Attached Count[a]	The number of modules connected to the Axion's EtherCAT I/O network.
Server Detached Count[a]	The number of modules detected by the RTAC client not attached to the Axion's EtherCAT I/O network.
Configuration Failure[a]	Status of the Axion's EtherCAT I/O network configuration
Number of Nodes[a]	The number of nodes configured in the RTAC project.

[a] Displays "Not Available" if EtherCAT Status is either "Disabled" or "Not Available".

Module Status

The Module Status screen provides the status of all modules in the EtherCAT I/O network. Each module status page provides the status of a module (as shown in *Table 6.10*) and that module's position (slot) in the EtherCAT node. The Module Status screen provides as many as two nodes per page. Use the on-screen arrows to navigate between these pages.

Table 6.10 Module Status Indications

Indication	Description
	The module in the specified slot is operational.
	The module in the specified slot is not operational or the module is reporting an operational error.
	There is no module in the specified slot.

User Login

Tap the **User Login** folder to navigate to the Login and Logout applications. The Login application is available when no user is actively logged in to the device. The Logout application is available when a user has successfully logged in to the device.

To log in to the Axion Bay Controller via the touchscreen, tap the **Username** and **Password** fields on the Login application and enter the username and password, respectively, associated with your RTAC user account. All touchscreen applications are available for viewing without logging in, but some operations can only be performed by a logged-in user. *Table 6.11* shows the operations that require user login.

Table 6.11 Touchscreen Operations That Require User Login

Application Name	Folder Name	Touchscreen Operations	RTAC Required User Permission
Custom Screens	NA	Operate breakers and switches on custom screens	HMI Local Write, Web Login
SOE	Reports	Delete SOE logs	Report Delete, Web Login
Alarm Summary	Reports	Acknowledge and unacknowledge alarm points	Report Write, Web Login

Application Name	Folder Name	Touchscreen Operations	RTAC Required User Permission
Alarms	NA	Acknowledge and unacknowledge alarm points	Report Write, Web Login
Port F	Port Settings	Enable/disable Port F control	Network Write, Web Login

When one of the operations listed in *Table 6.11* is initiated and no user is presently logged in to the touchscreen, the device automatically enters the authentication screen, which requires that a user with corresponding permissions log in before the operation is performed. When one of the operations is initiated and a user *is* logged in, but lacks the permissions for that operation, the device similarly enters the authentication screen.

Upon successful login, the touchscreen footer message includes the first three characters associated with the user account that is logged in. *Figure 6.18* shows an active username of "admin" successfully logged in to the touchscreen.

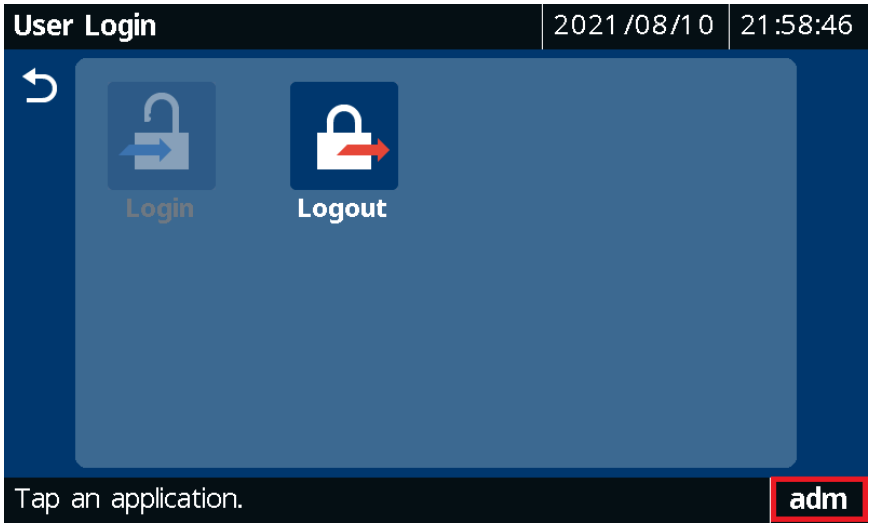

Figure 6.18 Username 'admin' Logged in Successfully

Additionally, the SEL_Touchscreen_POU.Active_User output tag (see *Controller on page 691*) provides the username of the user account that is actively logged in to the touchscreen. If a logged-in user account is inactive for a period greater than the Touchscreen Display Time-Out setting, the RTAC automatically logs the user out of the device.

Rotating Display Application

The Rotating Display application provides a series of screens presented in a predefined sequence (see *Rotating Display on page 689*). You can pick as many as 30 screens through which the display can rotate. The rotating display begins automatically after the inactivity timer expires, but you can also tap the application on the Home screen to start it at any time. While the rotating display is active, tapping any screen or pressing a pushbutton takes you to the screen presently displayed.

Available Screens

The following screens are available to be added to the rotating display:

- SOE
- Alarm Summary
- Device Information
- System Statistics
- EtherCAT Status
- Module Status
- All custom screens
- All alarm pages

Alarms Application

The SEL Touchscreen Alarms application provides Alarm screens for visual indication of alarms caused by faults or other abnormal conditions. The Alarm screens consist of a series of tiles arranged in a matrix form. Each tile is assigned to a specific alarm point defined in the RTAC. The tile background flashes and changes colors to represent the active, inactive, acknowledged, and unacknowledged state of the alarm point. As many as 25 alarm screens can be configured in the SEL Touchscreen. RTAC firmware versions R153 and later support the alarm application. If the RTAC project does not include alarm pages, the touchscreen device disables the Alarms application.

Alarm Settings and Page Configuration

The tiles in the alarm screens of the SEL Touchscreen Alarms application use different background colors and color flashing to indicate the four possible states of an alarm point configured in the RTAC:

- Active and unacknowledged
- Active and acknowledged
- Inactive and unacknowledged
- Inactive and acknowledged

Use the Flash settings in the SEL Touchscreen device Settings tab, shown in *Figure 6.19*, to enable flashing on any of the four alarm states.

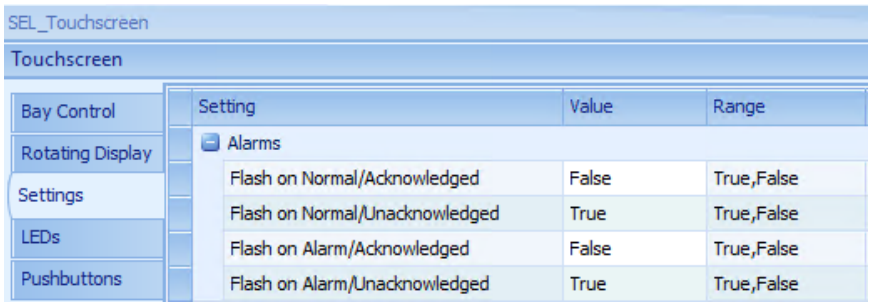

Figure 6.19 Alarm Flashing Settings

When flashing is enabled for an alarm state, the tile background color alternates between its normal configured color and a dark tint of that color when in the alarm state.

To add an alarm page, press the button in the Alarms tab. For each page that you add, set the display page name, the Grid Format, and the alarm tile font sizes, as shown in *Figure 6.20*.

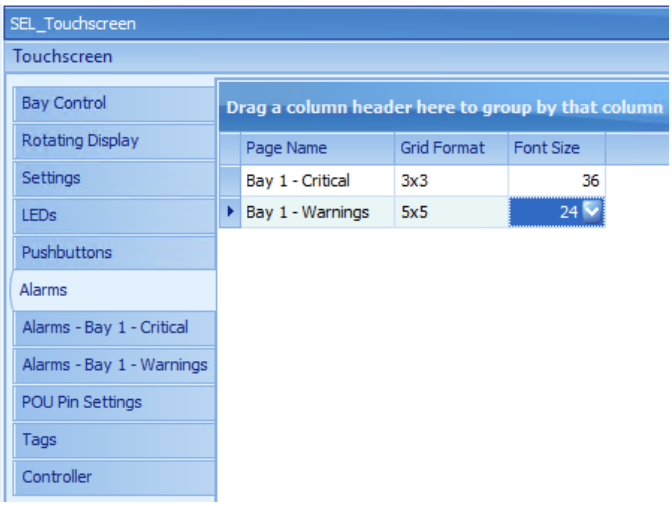

Figure 6.20 Alarm Settings Configuration

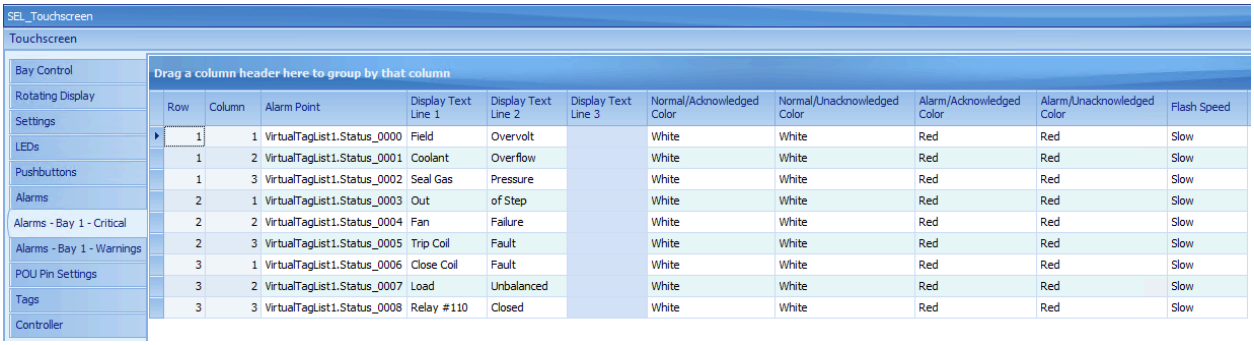

Table 6.12 provides settings information, range, and usage notes for each of the previously listed alarm settings. After the settings are updated, save the RTAC project to apply the settings to the subsequent alarm tabs.

Table 6.12 Alarm Settings Information

Setting Name	Range / Usage Note
Page Name	Supports as many as 40 characters including alphanumeric characters, square brackets, spaces, underscores, periods, and dashes. If the characters entered exceed the allocated header space, the page name text is truncated from the right and appended with an ellipsis.
Grid Format	The alarm page (columns and rows) format. The supported grid formats include 3x3, 3x4, 3x7, 4x4, 4x5, and 5x5.
Font Size	The font size for all alarm tiles on the page. The supported range includes 22, 24, 26, and 36.

NOTE
Larger fonts are better suited for smaller grid formats, e.g. 3x3. Smaller fonts are better suited for larger grid formats or when the tiles require more descriptive alarm text.

The Touchscreen device adds an additional alarm page tab that is formatted as "Alarms - Page Name" for each page that is added in the Alarms tab. Use these alarm page tabs to define each tile's alarm point, display text information, background color, and flash speed. *Figure 6.21* shows an alarm page tab with nine tiles (3x3 grid format).

Row	Column	Alarm Point	Display Text Line 1	Display Text Line 2	Display Text Line 3	Normal/Acknowledged Color	Normal/Unacknowledged Color	Alarm/Acknowledged Color	Alarm/Unacknowledged Color	Flash Speed
1	1	VirtualTagList1.Status_0000	Field	Overvolt		White	White	Red	Red	Slow
1	2	VirtualTagList1.Status_0001	Coolant	Overflow		White	White	Red	Red	Slow
1	3	VirtualTagList1.Status_0002	Seal Gas	Pressure		White	White	Red	Red	Slow
2	1	VirtualTagList1.Status_0003	Out	of Step		White	White	Red	Red	Slow
2	2	VirtualTagList1.Status_0004	Fan	Failure		White	White	Red	Red	Slow
2	3	VirtualTagList1.Status_0005	Trip Coil	Fault		White	White	Red	Red	Slow
3	1	VirtualTagList1.Status_0006	Close Coil	Fault		White	White	Red	Red	Slow
3	2	VirtualTagList1.Status_0007	Load	Unbalanced		White	White	Red	Red	Slow
3	3	VirtualTagList1.Status_0008	Relay #110	Closed		White	White	Red	Red	Slow

Figure 6.21 Alarm Page Settings

The alarm page tabs provide a row for each alarm tile in the grid. The **Row** and **Column** columns help identify the tile's location on the alarm page. Rows are numbered from top to bottom and columns are numbered from left to right. For example, in a 3x3 grid format, the top left tile is Row 1, Column 1, and the bottom right tile is Row 3 Column 3. Each alarm tile supports as many as three rows of static display text to identify the alarm condition and provide additional alarm information as required. On each alarm page, populate as few or as many of the alarm tiles as desired.

The **Alarm Point** setting is the SPS tag that drives the alarm status. As shown in *Figure 6.10*, alarm points must meet the following two requirements to be added to the alarm page Alarm Point.

- Alarm points must be enabled for Alarm Logging in the Logging Layout view of the Tag Processor.
- The Logging Category filter of the alarm point, in the Logging Layout view of the Tag Processor, must be included in the SEL Touchscreen setting **SOE and Alarm Category Filter**.
- If the **Logging Display Tag Name** Tag Processor column setting is configured for the alarm point being assigned, use the configured Logging Display Tag Name in place of the Destination Tag Name.

Display Text Line 1, **Display Text Line 2**, and **Display Text Line 3** are the settings for the three lines of static text to be displayed on the tiles. Depending on the chosen alarm page settings for Grid Format and Font Size, Display Text Line 1 and/or Display Text 3 settings may be disabled in the tiles of the alarm page.

Normal/Acknowledged Color, **Normal/Unacknowledged Color**, **Alarm/Acknowledged Color**, and **Alarm/Unacknowledged Color** are the settings for the tile background color on the different alarm states. The following options are available: Amber, Black, Blue, Gray, Green, Orange, Pink, Red, Violet, and White.

The **Flash Speed** setting determines the rate at which the background color of the tile flashes according to the four flash settings in the Settings tab, as listed in *Alarm Settings and Page Configuration on page 684*. The options for this setting are **Slow** (change color shade every second), **Fast** (change color shade every 250 milliseconds), and **None** (disable flashing for the specific tile).

Alarm Tile Usage

From the Home Screen, navigate to the Alarms application by selecting the Alarms application icon. Navigate to any of the configured alarm pages by using the up and down navigation buttons. If any assigned alarm point goes to the alarm state, the alarm tile mapped to that alarm point displays the user-configured color. The alarm tiles update automatically when a state change is detected. Similar to the Alarm Summary application, the Alarm page provides users with the ability to view alarm information and acknowledge or unacknowledge alarms by selecting the tiles.

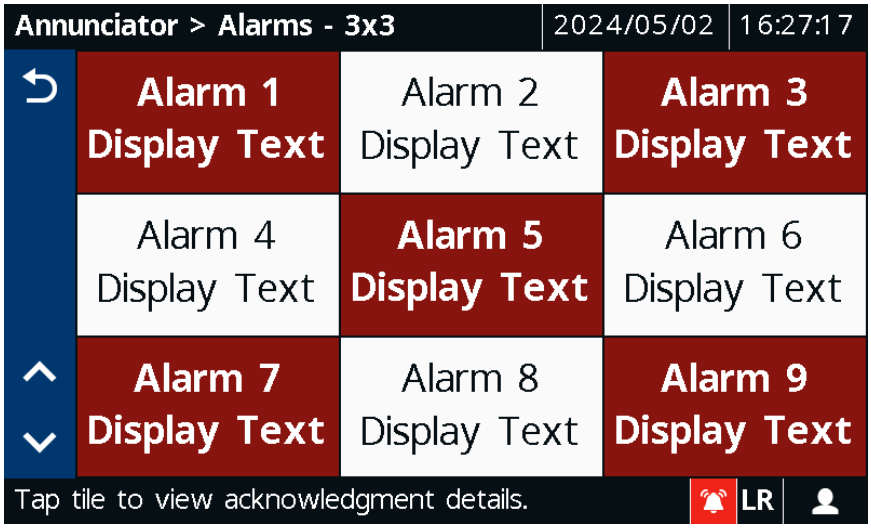

Figure 6.22 Active Alarm Page in 3x3 Grid Format

ACSELERATOR RTAC Settings and Configuration

The SEL Touchscreen device is only available in RTAC and Axion projects and can only be downloaded to an SEL-2241 RTAC.

Adding an SEL Touchscreen to the Project

To add an SEL Touchscreen device to a project, select **Insert > SEL Axion > SEL Touchscreen**, as shown in *Figure 6.23*.

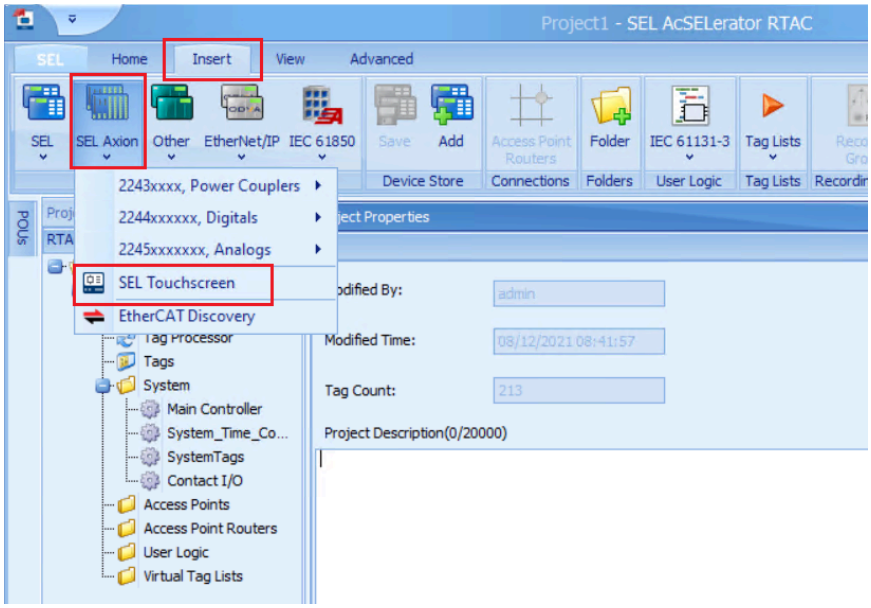

Figure 6.23 Insert SEL Touchscreen in Project

The SEL Touchscreen device in the project tree initially contains 13 sub-items corresponding to the 13 default screens, as shown in *Figure 6.24*. Use these default screens as a starting point from which to create your project.

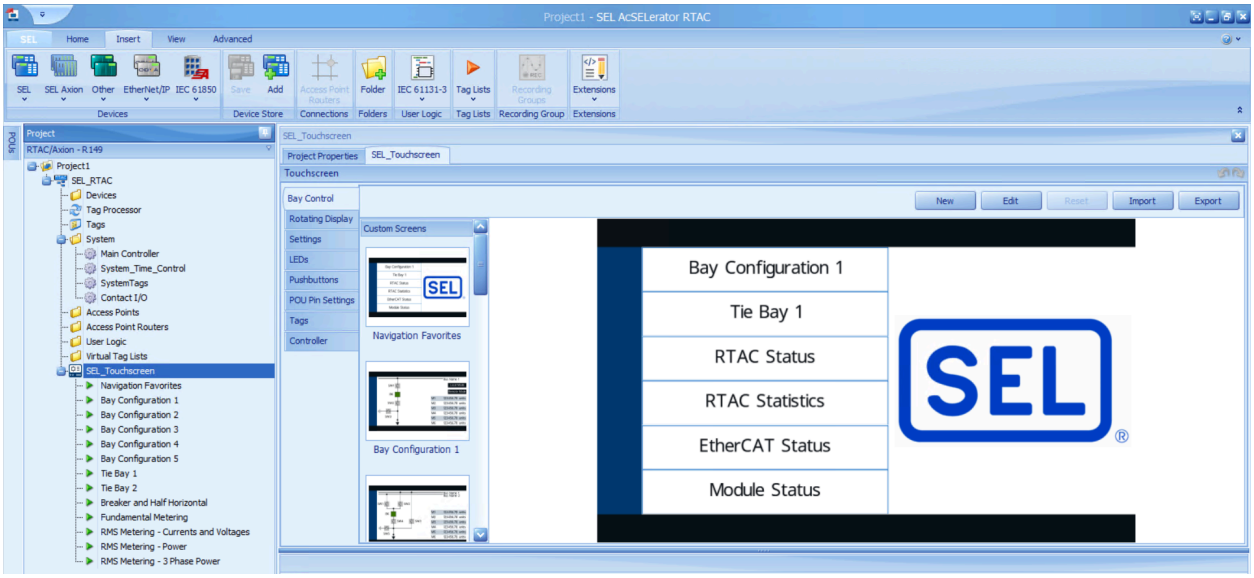

Figure 6.24 ACSELERATOR RTAC Default SEL Touchscreen Layout

SEL Touchscreen Tabs

The SEL Touchscreen device in the ACSELERATOR RTAC project tree contains the following tabs:

Bay Control

This tab shows a preview of the custom screens in the project. The Display Package File (.ldme) contains all of the custom screens shown in this tab. In addition, this tab contains five buttons that provide flexibility to create or edit your current screen configuration, as shown in *Table 6.13*.

Table 6.13 Bay Control Tab Buttons

Button Name	Description
New	Opens a new instance of Bay Screen Builder with no default screens. Use this option to create a new Display Package File for the RTAC project.
Edit	Edit the current Display Package File. This button opens an instance of Bay Screen Builder with the current set of screens. You can add new screens to the project or edit or remove existing screens. When finished, use the Publish Package option to send and update the changes to the ACSELERATOR RTAC project.
Reset	Resets to the default Display Package File. This action overwrites any existing screens in the project and replaces them with the default screens.
Import	Import a Display Package File. This action overwrites any existing screens in the project and replaces them with the screens contained in the imported Display Package File.
Export	Exports the Display Package File that contains the current screens in the ACSELERATOR RTAC project. You can then import the file into a different RTAC/Axion project or into ACSELERATOR Diagram Builder™ SEL-5035 Software.

Rotating Display

Figure 6.25 provides an overview of the Rotating Display tab in ACSELERATOR RTAC. This tab provides the ability to define the screens to display in the Rotating Display application.

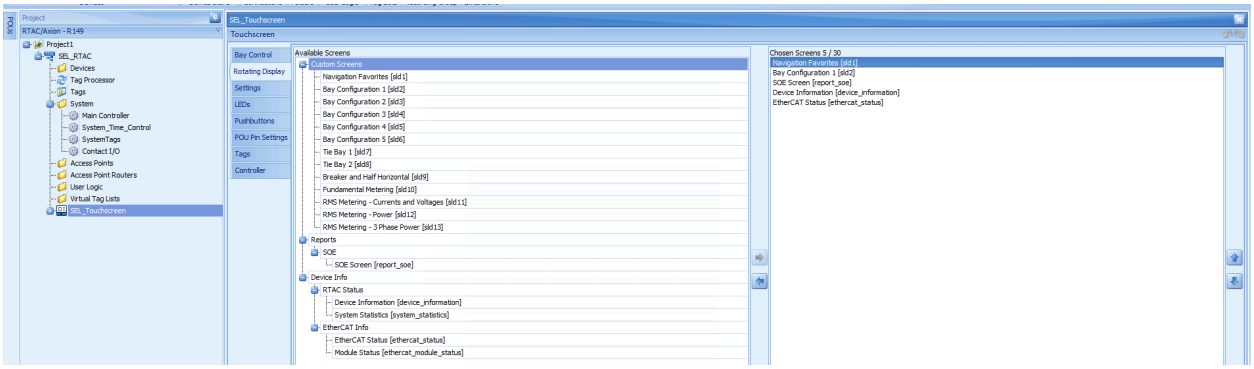

Figure 6.25 Rotating Display Configuration

To add a screen to the Rotating Display application, select the screen in the **Available Screens** list on the left and click the right arrow button to move it to the **Chosen Screens** list on the right. To remove a screen from the Rotating Display application, do the opposite—select the screen in the **Chosen Screens** list on the right and click the left arrow button to move it to the **Available Screens** list. To re-order the screens in the Rotating Display application, select a screen in the **Chosen Screens** list and click the up or down arrow buttons to move the screen up or down in the list. The Rotating Display application supports as many as 30 screens. *Table 6.14* shows the settings that affect the Rotating Display.

Settings

This tab includes the configurable settings for the SEL Touchscreen.

Table 6.14 SEL Touchscreen Settings Tab

Setting Name	Default Value	Range	Description
Flash on Normal/Acknowledged	False	True, False	If True, the alarm tile background color flashes when the alarm point is in the inactive and acknowledged state.
Flash on Normal/Unacknowledged	True	True, False	If True, the alarm tile background color flashes when the alarm point is in the inactive and unacknowledged state.
Flash on Alarm/Acknowledged	False	True, False	If True, the alarm tile background color flashes when the alarm point is in the active and acknowledged state.
Flash on Alarm/Unacknowledged	True	True, False	If True, the alarm tile background color flashes when the alarm point is in the active and unacknowledged state.
SOE and Alarm Category Filter	'Bay Control'	List of STRING(255)	As many as 50 SOE logging categories surrounded by single quotes and separated by commas. Only SOE logs of these categories will be displayed on the touchscreen.
Disable SOE and Alarm Tag Name Column	'False	True, False	Format of the SOE application display columns. When False, the SOE application displays both the Tag Name and Message columns. When True, the SOE application displays only the Message column allowing for more descriptive log messages.
Date Format	YMD	DMY, MDY, YMD	Date format used in touchscreen applications
Display Home Screen	home	home, SOE screen, Device Information, System Statistics, EtherCAT Status, Module Status, and all Custom Screens	Determines the screen to display upon startup or when the **Home** button is pressed
Display Time-Out	15	1–30 minutes	Length of time for which the display must be inactive before the Rotating Display starts
Rotating Display Transition Time	5	3–15 seconds	Length of time for which each screen is shown when the Rotating Display is running
Backlight Active Brightness	6	1–10	Brightness of the backlight
Enable Global Local/Remote Mode	False	True, False	Enables Local and Remote mode for all bays in the project.

LEDs

The LEDs tab lists the tags to control the 7 indicator LEDs and 12 pushbutton LEDs located on the touchscreen. Use the **On Color** and **Off Color** settings to set the desired color of each LED when asserted and deasserted, respectively.

Pushbuttons

The Pushbuttons tab lists the tags for monitoring the status of the six pushbuttons located on the touchscreen. Each pushbutton can be assigned to navigate to a specific screen, allowing for quick access via the front panel. *Figure 6.26* shows an example of configuring the screens for each pushbutton.

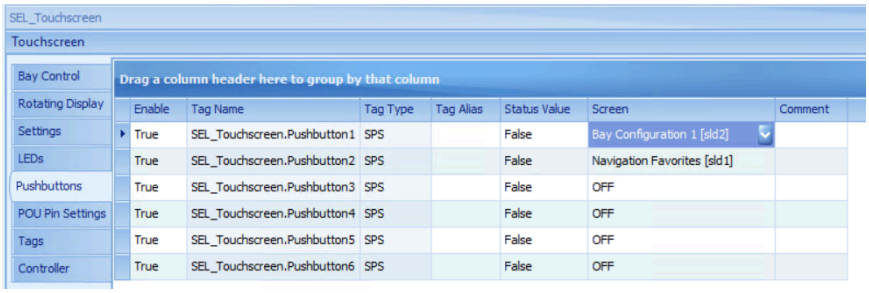

Figure 6.26 SEL Touchscreen Pushbuttons Tab

Alarms

The Alarms tab allows as many as 25 alarm pages to be defined. See *Alarm Summary Application Configuration on page 675* for details on settings, ranges, and usage of the Alarms application.

Controller

Use the Controller tab to monitor the real-time values of the touchscreen POU input and output pins. *Table 6.15* lists all the available POU input and output pins on the touchscreen and provides a description of each.

Table 6.15 SEL Touchscreen Controller POU Pins

Pin Name	Pin Type	Description
Disable_All_Touchscreen_Controls	Input: BOOL	When True, all controls (breakers, switches and operation buttons) issued from the touchscreen are blocked.
Disable_Breaker_Controls	Input: BOOL	When True, touchscreen breaker controls issued from the touchscreen are blocked.
Disable_Disconnect_Switch_Controls	Input: BOOL	When True, disconnect switch controls issued from the touchscreen are blocked.
Local	Input: BOOL	When True, the touchscreen is in Local control mode. When False, the touchscreen is in Remote control mode. This input is only visible when Enable Global Local/Remote Mode is set to True.
Reset_Statistics	Input: BOOL	On rising-edge, all counter POU outputs are reset.
ENO	Output: BOOL	When True, indicates that the touchscreen is enabled.
Control_Sent	Output: BOOL	Asserts when a control is issued from the touchscreen.

Pin Name	Pin Type	Description
Active_User	Output: STRING	Shows the username of the user currently authenticated in the touchscreen. This value is empty when no user is authenticated.
Control_Count	Output: UDINT	The total number of controls issued from the touchscreen.

Tag Mapping

Each custom screen in the project has a corresponding sub-item under SEL Touchscreen in the project tree. Each screen sub-item presents the grids required to map the status and control quantities of the symbols present in that screen. The tag mapping grids are organized in tabs according to the type of touchscreen symbol on the custom screen. Breakers, disconnect switches, and three-position disconnect switches provide a Mode setting for configuring each element for status monitoring only or for both control and monitoring. When Mode is set to CONTROL, the element's control tags are available in the RTAC logic engine and the status tags are available for mapping to Boolean expressions or tags. When Mode is set to MONITOR, only the status tags are available for mapping to Boolean expression or tags.

You can select an element's symbol in the preview screen (in the upper left) or the element's name in the element list (in the lower left) to highlight the first row of that element for tag mapping, as shown in *Figure 6.27*.

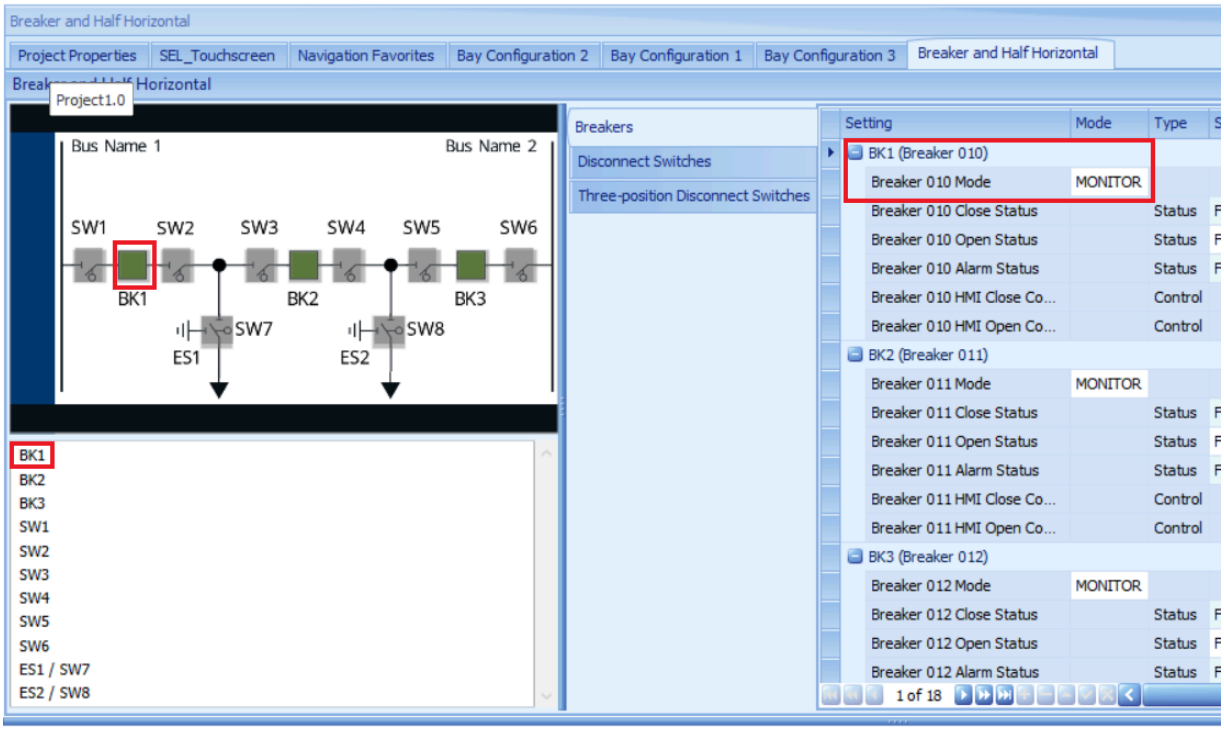

Figure 6.27 Select an Element for Tag Mapping

Analog Labels

The Analog Labels tab provides for mapping of the status tag for all the analog labels present in the corresponding screen, as shown in *Figure 6.28*. Map the integer or REAL tag that contains the value to be displayed in the analog label.

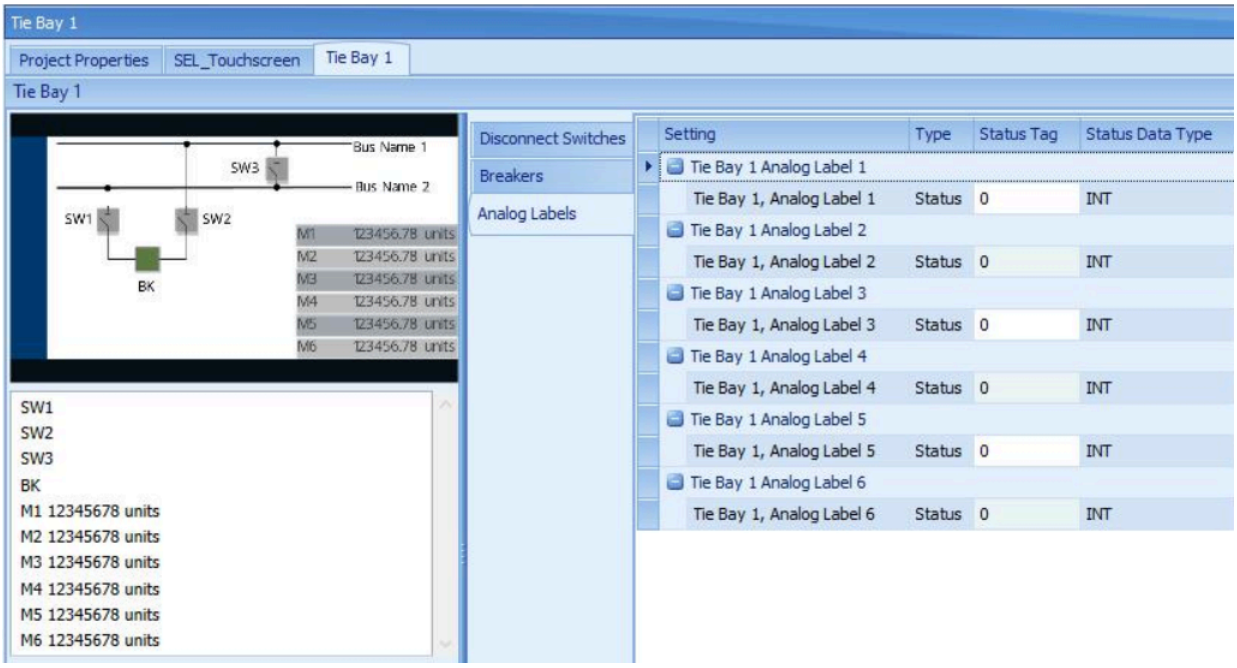

Figure 6.28 Analog Label Tag Mapping

Breakers

The Breakers tab provides for mapping of the status tags required for all the circuit breakers present in the corresponding screen, as shown in *Figure 6.29*. Map the Boolean tags or expressions that indicate the open, closed, and alarm status of each circuit breaker.

Additionally, this tab provides the name of the control tags that receive the open and close circuit breaker commands. Issuing an open or close control command from the touchscreen causes the respective open or close control tag to assert for one RTAC processing interval.

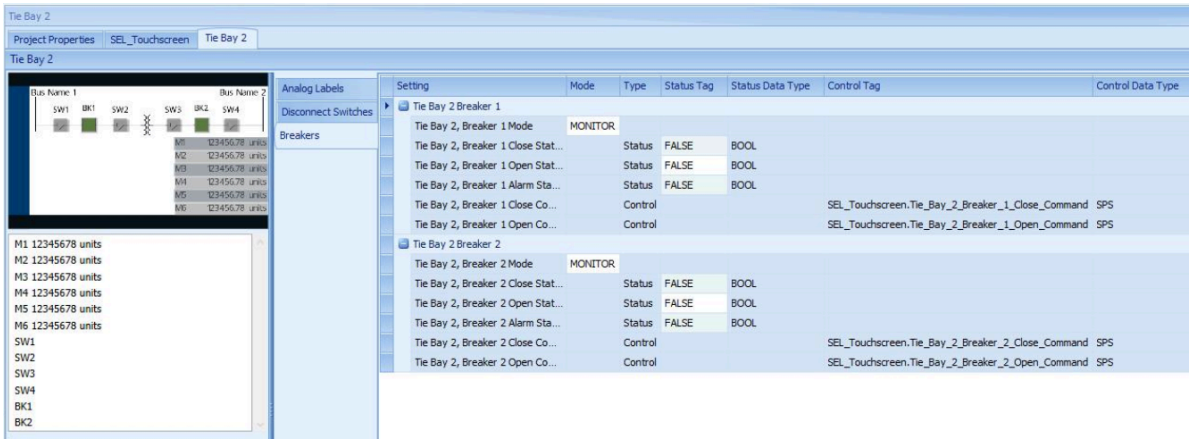

Figure 6.29 Breaker Tag Mapping

Digital Labels

The Digital Labels tab provides for mapping of the status tags for all the digital labels present in the corresponding screen, as shown in *Figure 6.30*. Map the Boolean tag or expression that contains the value to be displayed in the digital label.

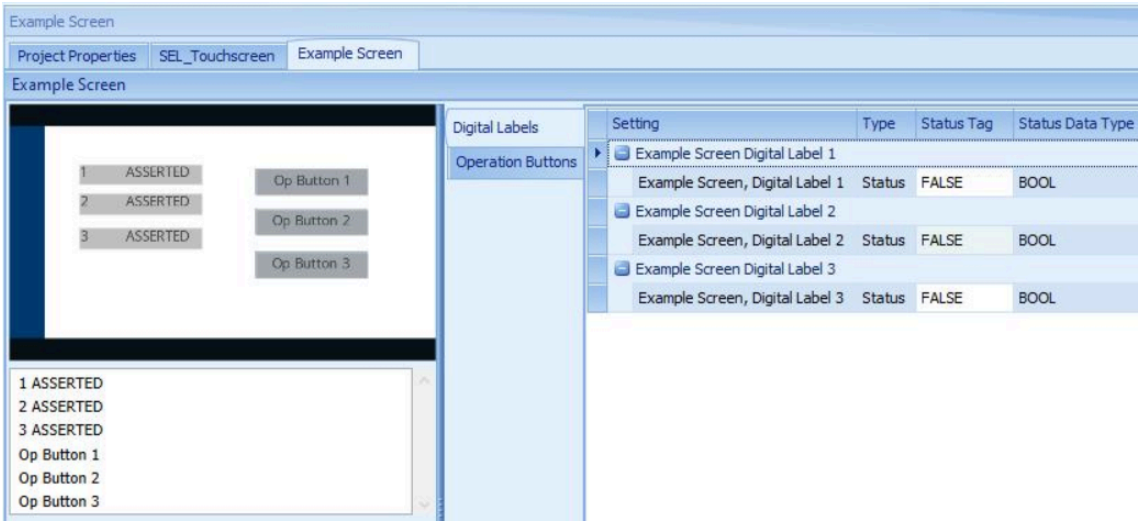

Figure 6.30 Digital Label Tag Mapping

Disconnect Switches

The Disconnect Switches tab provides for mapping of the status tags required for all the disconnect switches present in the corresponding screen. Map the Boolean tags or expressions that indicate the open, closed, alarm, and in-progress status of the disconnect switch.

Additionally, this tab provides the name of the control tags that receive the open and close disconnect switch commands. Issuing an open or close control command from the touchscreen causes the respective open or close control tag to assert for one RTAC processing interval.

Figure 6.31 Disconnect Switch Tag Mapping

Navigation Buttons

The Navigation Buttons tab provides for mapping of the on-screen navigation button screen links, as shown in *Figure 6.32*. The Screen column provides a dropdown menu of all available screens allowed for navigation.

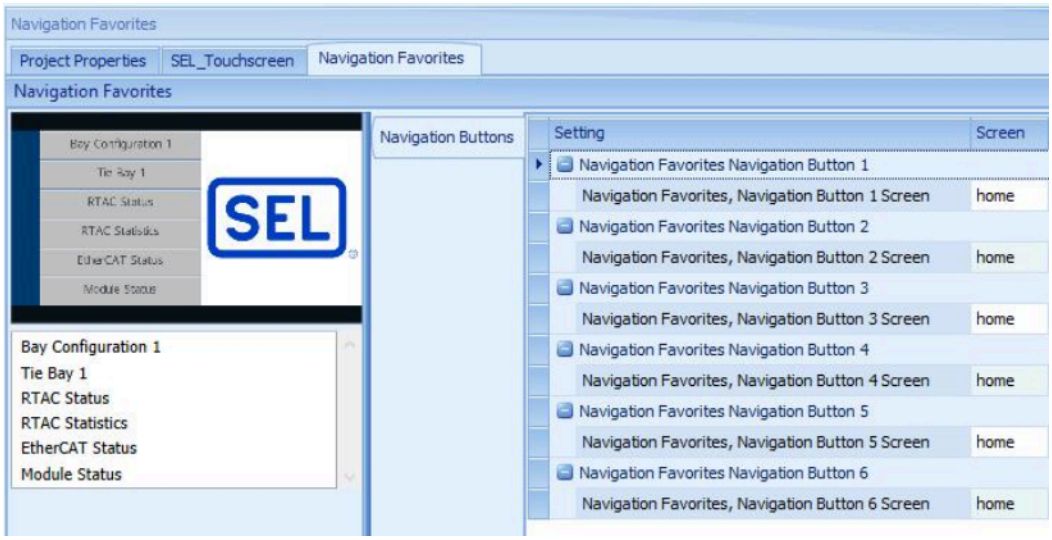

Figure 6.32 Navigation Tag Mapping

Operation Buttons

The Operation Buttons tab provides for mapping of each on-screen button to a corresponding control, as shown in *Figure 6.33*. Pressing an operation button on the touchscreen causes the associated control tag to assert for one RTAC processing interval.

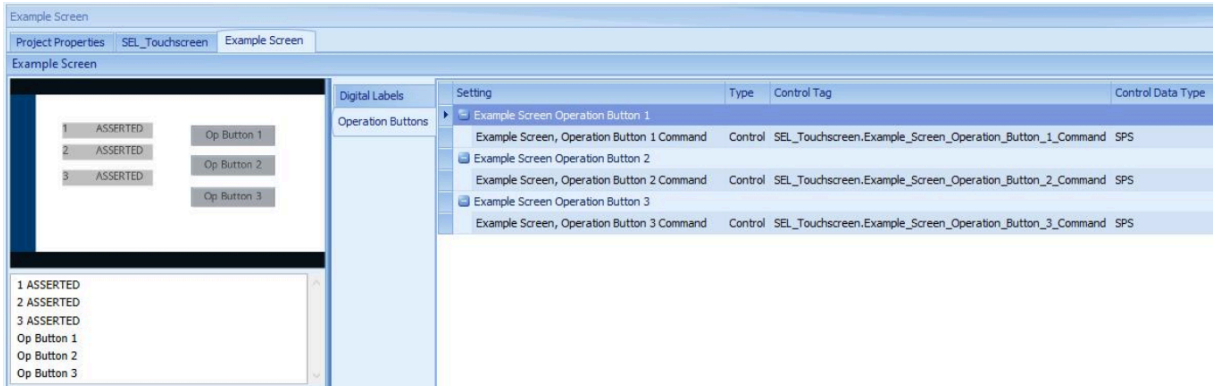

Figure 6.33 Operation Buttons Tag View

Three-Position Disconnect Switches

The Three-position Disconnect Switches tab provides for mapping of the status tags required for all the three-position disconnect switches present in the corresponding screen, as shown in *Figure 6.34*. Map the Boolean tags or expressions that indicate the open, closed, alarm, and in-progress status of the of the earthing and in-line switches of the three-position disconnect switch.

This tab also provides the name of the control tags that receive the open and close disconnect switch commands for the earthing and in-line switches of the three-position disconnect switch. Issuing an open or close control command from the touchscreen causes the respective open or close control tag to assert for one RTAC processing interval.

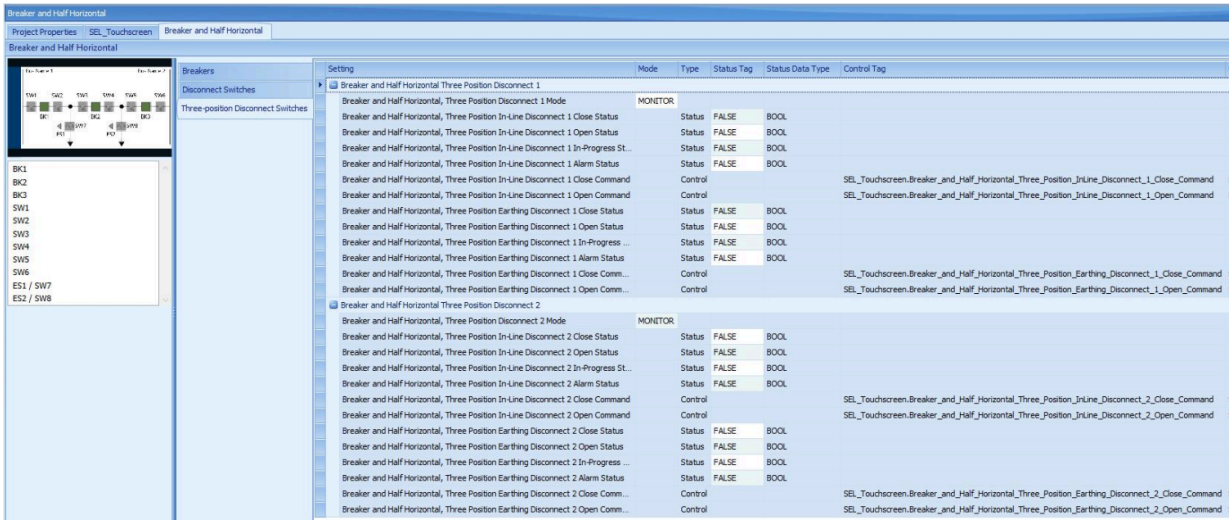

Figure 6.34 Three-Position Disconnect Switch Tag Mapping

Touchscreen Diagnostics

The RTAC's System Tags provide touchscreen diagnostic information. *Table 6.16* identifies the System Tags related to the touchscreen.

Table 6.16 Touchscreen System Tags

System Tag Name	Description
Touchscreen_Status	Indicates the status of the touchscreen. See *Table 6.17* for the possible states for Touchscreen_Status.
Touchscreen_Error_Message	The touchscreen error message.
Touchscreen_Control_Operation	Indicates that the touchscreen issued a control operation.

Table 6.17 describes the possible states of SystemTags.Touchscreen_Status.

Table 6.17 Touchscreen Possible States

Status	Description
Not Available	The Axion backplane does not contain an SEL Touchscreen device.
Not Configured	There is no SEL Touchscreen device in the RTAC project.
Enabled	The touchscreen is operational.
Initializing	The RTAC is in the process of enabling the touchscreen.
Failed	The touchscreen has reported a failure. Check the value of SystemTags.Touchscreen_Error_Message.

SECTION 7

Security and Account Management

Overview

This section describes security features and procedures in the SEL Real-Time Automation Controller (RTAC) family of products, and in ACSELERATOR RTAC® SEL-5033 Software. The RTAC provides physical and cybersecurity measures to block unauthorized access as well as logging and alarming to report access activity.

Ethernet Security

You can configure RTAC Ethernet security settings in the RTAC web interface. To access the RTAC web interface, connect the RTAC to your PC via Ethernet or with a USB-B cable and, in a web browser, enter **https://** and the IP address or hostname of the RTAC. If you are connecting to an SEL-3530, SEL-3505, or SEL-2241 RTAC with a USB-B cable, enter 172.29.131.1 for the IP address. If you are connecting to an SEL-3555, SEL-3560, or SEL-3350 RTAC using an Ethernet connection, the default IP address for Eth-1 is 192.168.1.2. If you use the hostname as configured in the RTAC web interface, the RTAC will need to be on a network that can resolve the hostname to the IP address.

When you connect to the RTAC web interface for the first time, there are no defined user accounts. The RTAC prompts you for a username and also for two password entries. The username defines the first administrator account on the box. The password entry is the password for that username and must be a complex password. A complex password must be from 8 to 72 characters long and contain at least one of each of the following character types: number, lowercase letter, uppercase letter, and special character. The RTAC prompts you to enter the password twice to ensure both entries match exactly. Once you enter the new username and password, the RTAC prompts you to use the new username and password to log in. If you forget the username and password you have created, you cannot log in to the RTAC and must apply internal jumpers to override login authentication. See *Section 3: Factory Reset* in the *SEL-3555*, *SEL-3505*, *SEL-3530*, *SEL-3530-4*, or *SEL-2240 Instruction Manual* for jumper positions.

Figure 7.1 Initial RTAC Login

Once you establish a web session, the RTAC monitors usage and closes the session automatically if it is inactive longer than the timeout you have configured. From the web interface, you can set security settings related to individual Ethernet ports, global Ethernet connectivity, and passwords.

Secure Ethernet Access

The RTAC communicates by using varied standard secure Ethernet methods depending on the connection type. Web access is encrypted through the use of HTTPS over a Transport Layer Security (TLS) socket. HTTPS is a secure HTTP connection that prevents both the chance for man-in-the-middle attacks and clear text transmission of the web session. Remote engineering access over Ethernet is configurable to use Telnet or Secure Shell (SSH) between the RTAC and the remote PC. When using SSH, the RTAC will disconnect the attempted connection after three failed connection attempts. Other connections, such as project downloading and gateway access, are encrypted over ODBC connections via TLS sockets.

Typically, SSH connections require user login authentication. Click on **SSH Keys** under the **Security** section of the RTAC web interface to upload, delete, or edit authorized SSH keys to authenticate incoming SSH connections to allow access without a password. To add an authorized SSH key, click on **Add New SSH Authorized Keys**, then fill in the following information:

- **Name**: Enter a name for the key.
- **SSH Key Mode**: Define SSH type as SSH-RSA or SSH-DSS.
- **SSH Authorized Key**: Paste the key contents into this box.

Press **Submit** to complete the process. You can back up the key contents with other RTAC settings when you read the RTAC project by using ACSELERATOR RTAC software.

Denial-of-Service Monitoring

The RTAC monitors Ethernet traffic for bursts of Ethernet traffic that may be denial of service (DOS) attacks. If the amount of Ethernet traffic addressed to the RTAC causes processing exceeding 80 percent of the configured watchdog time-out, the RTAC will log the message `Impending watchdog failure; adjusting system priorities`. At that time, the RTAC adjusts system priorities, including Ethernet traffic priorities, to prevent a watchdog time-out
