I/O modules send a notification of the events received from HART devices to the SCS. The fieldbus message is sent from the SCS.

After a status change is detected in HART devices, it takes 4 to 5 seconds for the fieldbus message to be sent.

IMPORTANT

In the event method, a fieldbus message with the same content may be sent again if the following events occur after the first fieldbus message is sent.

- CPU control right switching
- IOM control right switching
- Recovery from HART communication error
- Recovery from power outage in N-IO nodes

Due to the resending function of HART devices, the detection of the status change in the device is not skipped.

Polling method

In the polling method, I/O modules read detailed information from HART devices at regular intervals and detect the status change.

The target of the polling method is HART 5 to 7 devices where the event method is not used.

I/O modules read the device status from HART devices once every 30 seconds. If the value changes from the previous reading, the I/O module sends a notification to the SCS. The fieldbus message is sent from the SCS.

After a status change is detected in HART devices, it takes 4 to 35 seconds for the fieldbus message to be sent.

IMPORTANT

In the polling method, the same fieldbus message will not be sent.

However, if the control right of the I/O module is switched before sending the status change, which is detected in the HART device to the controller, the notification for status change of the device may be skipped.

If the status change of the HART device is set back while the I/O module is reading the HART device information, the change is not detected.

B. CENTUM integration

The structure of a ProSafe-RS connected with CENTUM projects is called CENTUM Integration Configuration. This section describes the overview and the engineering procedure of CENTUM Integration Configuration.

B1. Overview of CENTUM integration

The CENTUM Integration Function of ProSafe-RS provides a communication interface for accessing SCS of ProSafe-RS from HIS and FCS of CENTUM VP or CS 3000 system (hereinafter referred to as "CENTUM") through control bus. By this function, you can operate and monitor SCS from HIS using the same interfaces (windows) for operating and monitoring FCS. You can also access SCS data from FCS using the same interface (tag names) used by an FCS to access other FCS.

CENTUM VP integrated system configuration

The structure that integrates ProSafe-RS with CENTUM VP is called CENTUM integration configuration. The role of each station in the CENTUM integration structure is as follows:

- SCS: Shuts down the plant safely if an error occurs in the plant.
- FCS: Performs process control.
- HIS: Provides user interfaces for accessing FCS and SCS data.

The following figure shows an example of the CENTUM integration structure. In the CENTUM integration structure, both SCS and FCS can be operated and monitored from HIS. It is also possible to access SCS data from FCS.

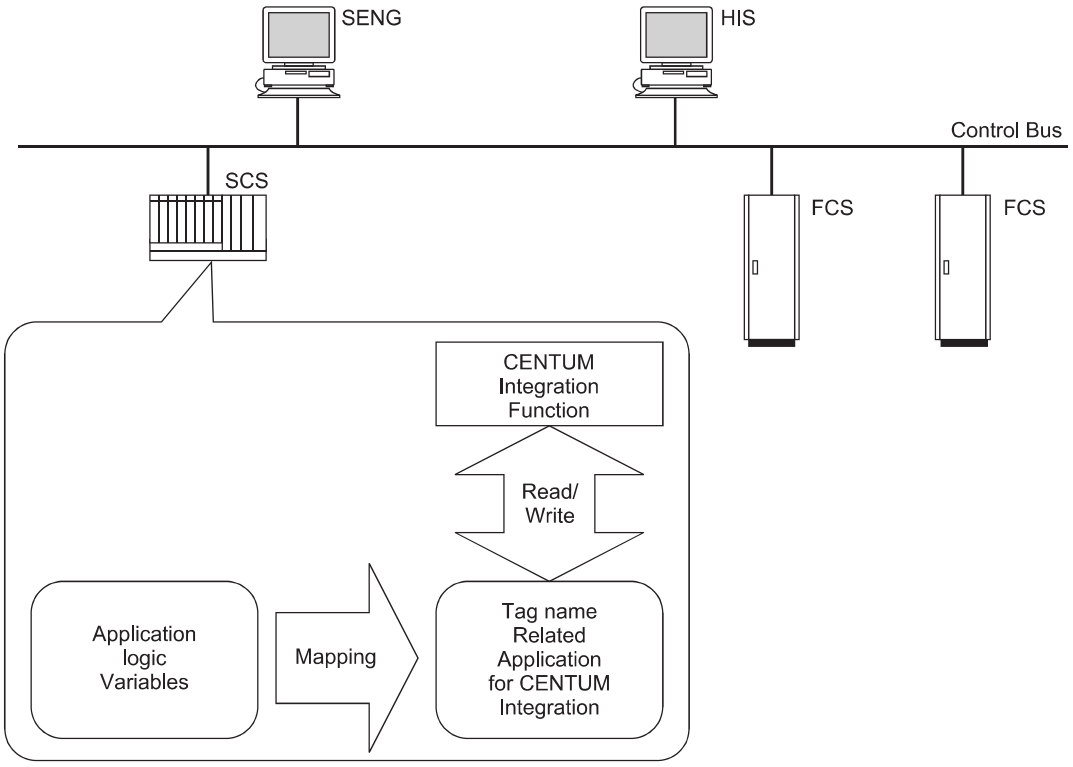

Figure B1-1 CENTUM integration function

Application logics and CENTUM elements

In the connection definitions for CENTUM integration, application logics and CENTUM elements are associated in the manner shown in the table below. Since tag names are defined for CENTUM elements, the user can monitor their statuses using the tag names.

Table B1-1 Correspondence between application logics and elements

Application logic		CENTUM element
Variable	Internal variable (BOOL)	%WB
	Internal variable (DINT)	%WB
	Internal variable (REAL)	%WB
	I/O variable (IO_BOOL)	%Z and %Y
	I/O variable (IO_REAL)	%WB
Function block	• Analog input FB with data status (ANLG_S), Analog input FB (ANLGI), Analog input FB for smoke and heat detectors (HSDTR), Analog input FB for gas and flame detectors (GASDTR) • Velocity limit alarm FB (VEL) • Override FBs (OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR) • Grouping override FB (GOV_B, GOV_IB) • Password FB (PASSWD) • Manual operation FB (MOB_11, MOB_21, MOB_RS, MOA)	%BL
	External communication FB (ECW_B, ECW_I and ECW_R)	%WB
	Subsystem communication I/O FB (SCI_B, SCI_I, SCI_R, SCO_B, SCO_I, SCO_R)	%WB
	Safety subsystem communication I/O FB (PSI_I, PSI_R, PNI_I, PNI_R)	%XB
	Annunciator FB (ANN, ANN_FUP)	%AN

Operation/monitoring using tag names

Operators can reference and set values of instances of application logics (function blocks defined as entities) using tag names from an HIS. It is also possible to reference and set data from data items of tag name.

Process alarm message transmission

CENTUM elements collect errors on the field side detected in an application logic and send process alarm messages to an HIS. Process alarm messages include messages sent by mapping blocks (%BL) and messages sent by annunciator elements (%AN).

A process alarm message is sent at the execution timing of a mapping block or annunciator element. The occurrence/recovery time stamp attached to the messages is the time at which the application logic is executed. If several messages are generated in one second from the same block and element, only the last two event messages are sent.

Software inputs/outputs

Two of the software inputs/outputs supported by FCSs, common switch and annunciator, are available for use in SCSs.

Table B1-2 Software inputs and outputs available in SCSs

Name	Support in SCS (*1)	Element
Common switches	Yes	%SW
Global switch	No	%GS
Annunciator	Yes	%AN
Printout message (with printing, Historical)	No	%PR
Printout message (without printing, Historical)	No	%PR

Continues on the next page

Table B1-2 Software inputs and outputs available in SCSs (Table continued)

Name	Support in SCS (*1)	Element
Operation guide message	No	%OG
Multimedia start message	No	%VM
Sequence message request	No	%RQ
Supervisory computer event message	No	%CP
Supervisory computer message output for PICOT	No	%M3
Signal event message	No	%EV
SFC/SEBOL return event message output	No	%RE

*1: Yes: Supported
No: Not supported

TIP

The sent and received data through SCS Link Transmission cannot be accessed from HIS as accessing a %GS element. For accessing from HIS, an internal variable should be placed in application logics. The examples below show how to connect the internal variable with SCS Link Transmission FB, and then define the variable with a tag name on the Tag Name builder.

- For accessing the value of a sent data, the data connected to the sending FB should be branched so as to connect to a variable.
- For accessing the value of a received data, the output parameter of the receiving FB for the data value should be connected with a variable.
- For accessing the data status of a received data, the output parameter of the receiving FB for the data status should be connected with a variable.

Common switches (Common switches for system)

Since common switches for the system reflect the internal status of an SCS, they can be used in the Graphic view of an HIS.

The following table shows a list of common switches for the system. Elements without a switch number cannot be used in the SCS. Tag names cannot be defined for SCS common switches. Also, you cannot set a value to the SCS common switches. You cannot use the value of SCS common switches in an application logic, either.

Table B1-3 Common switches for system

Switch number	Name	Description
%SW0001	Initial cold start	1: Fixed (to initial cold start)
%SW0002	Continuous start	0: Fixed (to initial cold start)
%SW0004	(Reserved)	Same as %SW0001
%SW0017	Right side CPU status	0: Normal 1: Abnormal
%SW0018	Left side CPU status	0: Normal 1: Abnormal
%SW0019	Fan status of the safety control unit	0: All normal 1: At least one is abnormal
%SW0020	CPU temperature status	0: All normal 1: At least one is abnormal
%SW0021	Power module status of the safety control unit	0: All normal 1: Either the left or right module is abnormal
%SW0022	Power supply module status of nodes (*1) (*2)	0: All normal 1: At least one is abnormal

Continues on the next page

Table B1-3 Common switches for system (Table continued)

Switch number	Name	Description
%SW0027	Right side CPU control status	1: Control 0: Other
%SW0028	Left side CPU control status	1: Control 0: Other
%SW0033 to 0042	Status of nodes 1 to 16 (*3)	0: Normal 1: Abnormal
%SW0065 to 0072	CPU idle time per minute (seconds)	0 to 60 seconds (8-bit integer)
%SW0073 to 0080	Communication load per second (%)	0 to 100% (8-bit integer)
%SW0097 to 0104	I/O module status of the safety control unit	0: Normal or no definition 1: Abnormal
%SW0105 to 0176	Status of I/O module (each of the 8 slots) of the 2nd to the 10th nodes (safety node units)	0: Normal or no definition 1: Abnormal
%SW0177 to 0208 (*4)	Status of input/output module (each of the 8 slots) of the 11th to the 14th nodes (I/O nodes)	0: Normal or no definition 1: Abnormal
%SW0225 to 0256	N-IO Node 1 to 32 status (*3)	0: Normal 1: Abnormal
%SW0289 to 0320	N-IO Node 1 to 32 diagnostic status (*3) (*5)	0: Normal 1: Abnormal
%SW0353	I/O module status of N-IO node 1, I/O unit 1, and slot 1	0: Normal or no definition 1: Abnormal
%SW0354	I/O module status of N-IO node 1, I/O unit 1, and slot 2	0: Normal or no definition 1: Abnormal
%SW0355 to 0364	I/O module status of N-IO node 1 and I/O units 2 to 6	0: Normal or no definition 1: Abnormal
%SW0365 to 0736	I/O module of N-IO nodes 2 to 32	0: Normal or no definition 1: Abnormal

*1: The power module status of the unit for optical ESB bus repeater module is excluded.
*2: When only SEC40x or L1EC40x is defined for FIO Node 1, the power status of FIO Node 1 is not reflected. Use %SW0021 together.
*3: 0 is set for undefined nodes.
*4: Applicable to SCSP2, SCSP3, and SCSL2.
*5: If temperature monitoring and input monitoring from external devices are all normal, the status is 0. The status is 1 if there is any error.

● Update interval

The SCS internal status is reflected in common switches for the system at the intervals of the scan period of the external communication function.

■ Overview of mapping blocks/mapping elements

In an CENTUM integration structure, mapping blocks/elements are created when users define tag names in Tag Builder in an SENG.

Mapping blocks/elements map function blocks and variables of an application logic and provide simple ways to interface with them via the tag names.

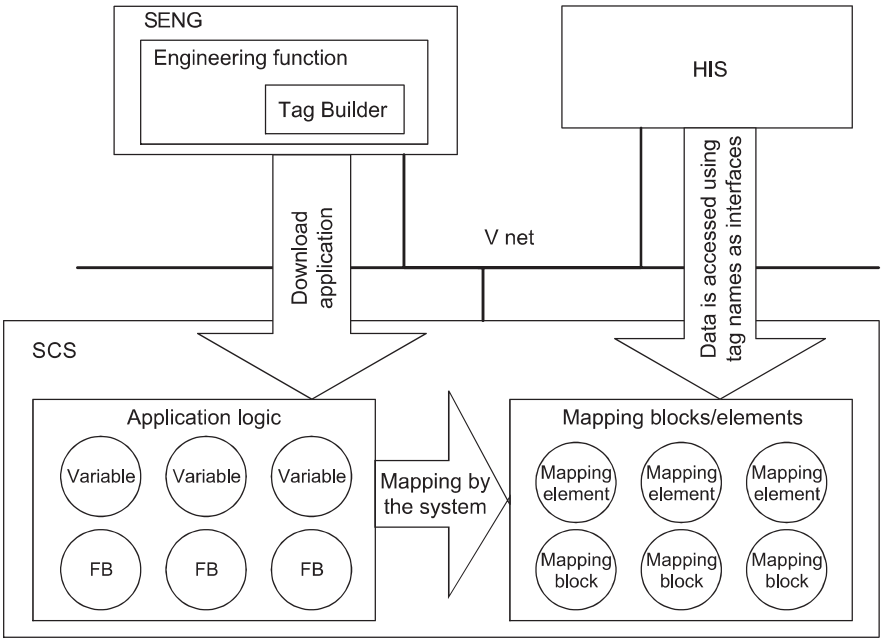

Figure B1-2 Mapping blocks/elements

Data reference via tag name interface

- By defining tag names in Tag Builder, it is possible to associate mapping elements with internal variables of BOOL, integer or real number type of an application logic and reference the data using the tag names.
- By defining tag names in Tag Builder, it is possible to associate mapping elements with I/O variables of an application logic and reference the data using the tag names.
- By defining tag names in Tag Builder, it is possible to associate mapping blocks/elements with function blocks of an application logic and reference the data using the tag names. For example, an ANLG_S function block can be associated with a mapping block, while an ANN function block can be associated with a mapping element. Specific function blocks are associated with mapping blocks.

SEE ALSO For more information about variables, elements, and FBs for which tag names can be defined, refer to:

"■ List of mapping blocks/mapping elements" on page B3-2

Data setting and alarm management by tag name interfaces

- Operations on mapping blocks/elements (without influencing application logics)
  It is possible to acknowledge process alarms and set operation marks (data item OPMK). If these operations are performed from an HIS, the data of the mapping blocks/elements changes, but this does not cause any changes to variables and function blocks of application logics.
- Operations on variables and function blocks of an application logic
  Operations on mapping blocks/elements are reflected in the corresponding application logic. The override operations, setting BOOL-type data with password, setting data with Manual Operation FB, setting data via tag name and so on operations can be performed.

Input/output terminals

No input/output terminals are used for mapping blocks/elements of an SCS. Mapping blocks/elements are used to exchange data with variables and function blocks of the corresponding application block, and not for connection between with mapping blocks/elements.

B2. Integration with CENTUM

The main purposes of integrating with CENTUM are as follows.

- To monitor the controlling status of SCS with an HIS
- To notify errors on the field side to operators via process alarm messages
- To set data to SCS
- To integrate system alarms

This chapter explains the SCS functions for integrating with CENTUM.

Functions in CENTUM integration structure

This section describes the functions of operating SCS from HIS or FCS in the CENTUM integration.

Monitoring and operation from HIS

- SCS data can be monitored and operated with tag names through the same interface as the one for FCS, which allows data reference with a faceplate and display of SCS data on a Graphic View.
- SCS data to be collected can be defined as a historical trend by HIS by specifying its tag name and data type, but not as a high-speed trend (1 sec).
- The occurrence/recovery of process alarm and annunciator messages that are detected by SCS can be monitored on the Process Alarm View of HIS.
- Diagnostic information messages issued at SCS can be monitored on the System Alarm View of HIS.
- SCS status can be shown on the SCS Status Display View of HIS.
- The values of the variables of the SCS application logic can be overridden by HIS. This is the function of fixing a variable of SCS application logic at the predefined value temporarily.
- Boolean variables of SCS application logic can be set to 1 or 0 by HIS with password authentication.

IMPORTANT

Incorrect usage of the dedicated alarm management software in HIS might result in the overlook or filtering out of important alarms critical to safety. Therefore when configuring alarms, it is important to ensure that critical alarms are always communicated to operators.

SEE ALSO

For more information about the software for managing the alarms, refer to:

B8.1.6, “Software for Managing the Alarms” on page B8-26

For more information about override, refer to:

7.1, “Override function blocks” in POU Reference Manual (IM 32P03B20-01EN)

For more information about data setting with password authentication, refer to:

11.11, “SYS_PSWD (password function blocks management)” in POU Reference Manual (IM 32P03B20-01EN)

Communication between FCS and SCS

- The variables of SCS application logic can be set from FCS by using Sequential Function Chart (SFC) blocks. The External Communication Function Block is used for SCS. In this case, the SCS data must be confirmed by reading the data back by FCS. This function does not affect the safety function of SCS.
- SCS data can be read by FCS using tag names and the FCS function of connecting between stations.
- From the Switch Instrument Block or the Motor Control Block, data can be set to the External Communication FB on the SCS using Inter-station Data Link Block (ADL). However, there are some precautions as following: Do not change frequently (every second) the MV in the Switch Instrument Block or Motor Control Block connected to SCS tags using ADL. If you use the three-position type Switch Instrument Block or the Motor Control Block on FCS, note the following:
  - Use enhanced Switch Instrument Block or Motor Control Block. Non-enhanced function blocks cannot connect with three-position type input and output via ADL.
  - In ADL connection, synchronization of open signal and close signal from/to three-position type input and output is not guaranteed. Both open signal and close signal from/to input and output can become ON (PERR status) at the same timing. Mask the PERR alarm using the answer-back inconsistency alarm mask in enhanced Switch Instrument Block or enhanced Motor Control Block for three-position type input and output.
  - For three-position type output, create a logic considering the behavior when both open signal and close signal turn ON at the same timing on the SCS side (which has the priority, for example).
  - When you change the MV in Switch Instrument Block or the Motor Control Block on FCS from 2 to 0, first change it from 2 to 1 then 1 to 0. This will prevent both the ON-open signal and ON-close signal from sending to SCS from FCS. Take enough time when the MV is 1 (twice the time taken in ADL communication period)

Limitations on the number of data setting requests via tag name interfaces

An SCS places priority to executing application logic function within the scan period. Data setting via tag name interface is processed on the basis of maximum 4 packets per second if the scan period is shorter than 250 ms, or one packet per one scan if the scan period is 250 ms or longer. Taking data congestion into consideration, up to 8 packets for setting data can be received and stored as they are generated, and processed internally in sequence at intervals of one scan period of application logic. This number of packets does not include communication via the Modbus slave connection function. If 8 unprocessed packets have accumulated in the SCS, and an additional packet is issued from HIS or FCS, a data setting error is generated.

SCS can process only one communication frame at one time in the order of reception, either from HIS/FCS or from Modbus.

Types and communication packet of data setting requests

The types and communication packet of data setting requests are as follows:

- Data setting requests from an associated faceplate and windows of HIS (one data operation constitutes one communication packet)
- Data setting via SEBOL all-data setting statements of SFC blocks of FCS (one all-data setting statement constitutes one communication packet. Up to 32 data items can be set per all-data setting statement.)

Operations and actions to be taken at error occurrence

The following are operations and actions to be taken if communications become congested and cannot be processed.

- If an error occurs as a result of a data setting request from HIS, the message "Communication error occurred" is displayed. If the reason is that data is set at the same timing as data setting from FCS, avoid the collision and perform data setting again.
- If an error occurs as a result of data setting via a SEBOL statement, an error is stored in the SEBOL error storage variable. A system alarm occurs if no error storage variable has been specified. If large amounts of data need to be set repeatedly with SEBOL statements, the system should be designed accordingly, for example by ensuring that data is set in a specific sequence and confirming that each processing is carried out correctly.

IMPORTANT

Do not set data periodically to SCS from control blocks such as PID or MLD, or from arithmetic/logic calculation blocks such as CALCU, using inter-station data link blocks (ADL) of FCS.

Error codes returned from SCS in CENTUM integration configuration

When you try to set data from CENTUM stations to an SCS on CENTUM Integration, the following error codes may be returned due to an application error.

Table B2-1 Error codes returned by SCS

Error code	Meaning (cause)	Action
0x5408	Setting request buffer in SCS is FULL.	Check the applications that periodically set data to SCS.
0x5409	The number of Setting requests exceeded SCS's capacity.	Check the applications that set a number of data to SCS.

Variable and Function Block to which a tag name can be assigned

In the CENTUM Integration Configuration, the variables or the function blocks of the SCS application logic need to have tag names to be accessed from HIS.

When a tag name is assigned with the tag name builder, a mapping block/element is created. These mapping blocks/elements are accessed from outside.

Tag names can be assigned to I/O variables, internal variables, and certain variables or function blocks including ANLG_S/ANLGI, VEL, HSDTR, GASDTR, OVR_* (Override FB), PASSWD (Password FB), ECW_* (External Communication FB), MOB_* (BOOL-Type Data Manual Operation FB), MOA (Analog-Type Data Manual Operation), SCS_*, SCI_*, SCO_* (Subsystem Communication I/O FB), PSI_I, PSI_R, PNI_I, PNI_R (Safety Subsystem Communication I/O FB), and ANN/ANN_FUP.

SEE ALSO For more information about variables for which tag names can be defined, refer to:

B7.1.5, “Defining tag names” on page B7-12

Engineering procedure of CENTUM integration configuration

In the CENTUM Integration Configuration, engineering needs to be performed by using both the SENG functions and the CENTUM system builders. The following figure shows the engineering procedure in the CENTUM Integration Configuration.

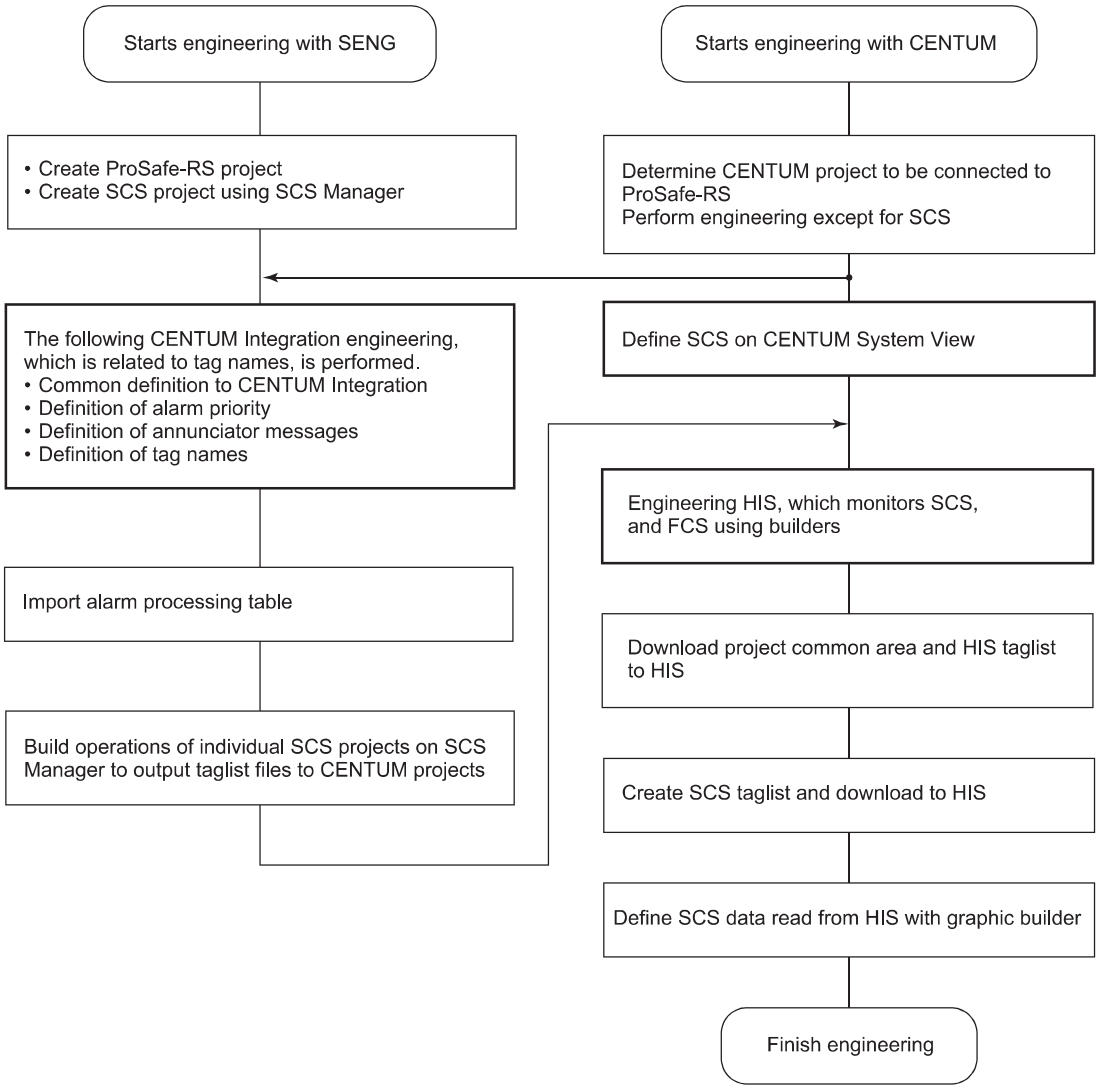

Figure B2-1 Engineering of CENTUM Integration

The following are the engineering items performed by SENG and CENTUM.

Table B2-2 Engineering with SENG

Engineering	Details	Builder to be used
Common definition of CENTUM Integration	Defines the top folder of the CENTUM project for CENTUM Integration	SCS Project Properties
Definition of alarm priority	Defines the handling of SCS process alarms in SCS, which appear on HIS	Alarm Priority Builder
Definition of alarm processing table	Import the alarm processing table, which defined on CENTUM	Alarm processing Builder
Definition of annunciator messages	Defines the contents of process alarms, which appear on HIS	Tag Name Builder (*1)
Definition of tag names	Allows CENTUM to access the variables of application logic by assigning tag names	Tag Name Builder (*1)

*1: In the engineering with iDefine, you can also use iDefine.

Table B2-3 Engineering with CENTUM

Engineering	Description	Builder to be used
Definition of SCS	Defines the SCS as one station of CENTUM projects for connecting SCS project and CENTUM project	System View
Generation of SCS Taglist	Connects the SCS project and CENTUM project. The SCS project is included in the CENTUM project	System View
Definition of SCS data reference from HIS	Creates a Graphic View shown on HIS	Graphic Builder

Perform other engineering for HIS, which includes the trend definition and the operation mark definition for the operation and monitoring function of HIS, and data settings of SCS from FCS as necessary.

Even if SCS project and CENTUM project are disconnected, you can define SCS using the builders for CENTUM. You can also edit the tag name-related application programs and create a database of SCS mapping blocks/elements using the SCS Manager without connecting to the project. However, duplication check for tag names using System View or creating database for operating and monitoring mapping blocks/elements from HIS is not possible if SCS project and CENTUM project are disconnected.

“■ Security of SCS” in C7., “Offline download to the target SCS” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Relationship between projects

An SCS project is held by the ProSafe-RS system. An RS project, which includes one or more SCS projects, is the unit handled by the SCS Maintenance Support Tool for SCS Status Overview. A CENTUM project is held by the CENTUM system. SCS projects can be connected with CENTUM projects.

When an SCS project is connected with a CENTUM project, SCS is regarded as one station in the CENTUM project. The following figure shows the relationship between projects. It shows, from the top to the bottom, the station structure, projects, and the display on the SCS Maintenance Support Tool, the SCS Manager, and the System View.

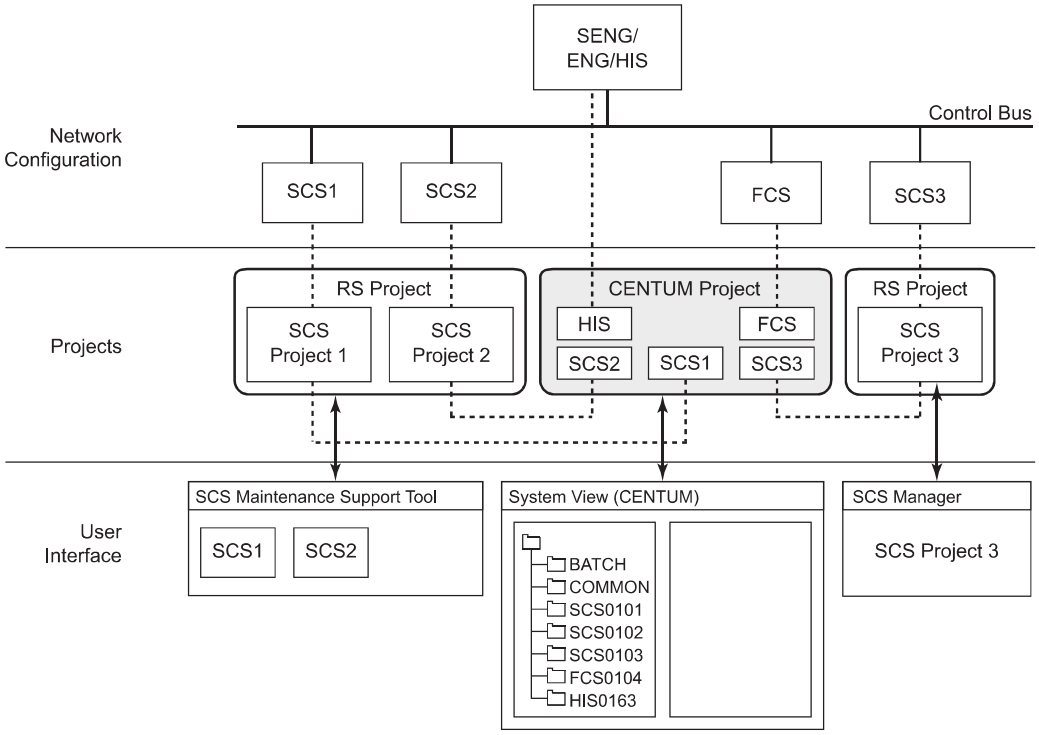

Figure B2-2 Relationship between RS projects, SCS projects, and CENTUM projects

Rules in folder configuration

An RS project and a CENTUM project must be placed in separate folders so that they do not overlap. These two projects can be placed in the same PC or different PCs.

Relationship with tag name generation

HISs and FCSs can access SCS data using tag names. In order to do so, define a list of tag names to be accessed in ProSafe-RS and pass the tag list to CENTUM.

- The SCS engineering functions on the ProSafe-RS output the SCS tag list to the communication folder of the CENTUM project.
- The CENTUM engineering functions on the CENTUM are then able to generate a HIS tag list based on the passed SCS tag list.

B3. Tag name interfaces for CENTUM

Mapping blocks and mapping elements are created when you define tag names for function blocks and variables in an application logic in Tag Name Builder. They allow accessing data using the tag names from an HIS and FCS.

B3.1 Overview of tag name interfaces

In this chapter, the following items regarding tag name interface for CENTUM will be explained.

- Types of mapping blocks and mapping elements for the FBs and variables
- Data size of mapping elements
- Common data items of mapping blocks and mapping elements
- Process alarms

List of mapping blocks/mapping elements

For keeping consistency with the data types of variables and the types of function blocks in the application logics, the types of mapping blocks and mapping elements will be automatically determined on Tag Name Builder according to the data types of variables and the types of function blocks in the application logics.

The table below lists mapping blocks/elements.

Table B3.1-1 Mapping blocks/elements

Classification	Description	Application logic definition		Mapping block/element	
		Classification	Type name	Type	Type name/ element name
Internal Variable	BOOL type	Internal variable	BOOL	Mapping element	%WB
	Integer-type (32-bit)	Internal variable	DINT	Mapping element	%WB
	Real number-type (32-bit)	Internal variable	REAL	Mapping element	%WB
I/O variable	Discrete (FIO)	I/O structure	IO_BOOL	Mapping element	%Z
	Discrete (N-IO)	I/O structure	IO_BOOL	Mapping element	%Y
	Analog	I/O structure	IO_REAL	Mapping element	%WB
Data setting from external device	Data setting (BOOL)	FB	ECW_B	Mapping element	%WB
	Data setting (integer)	FB	ECW_I	Mapping element	%WB
	Data setting (real number)	FB	ECW_R	Mapping element	%WB
Analog input	Analog input FB with data status	FB	ANLG_S	Mapping block	S_ANLG_S
	Analog input indication	FB	ANLGI	Mapping block	S_ANLGI

Table B3.1-1 Mapping blocks/elements (Table continued)

Classification	Description	Application logic definition		Mapping block/element	
		Classification	Type name	Type	Type name/ element name
Safety subsystem communication I/O	Integer-type fire and gas communication input	FB	PSI_I	Mapping element	%XB
	Real-type fire and gas communication input	FB	PSI_R	Mapping element	%XB
	Integer-type PROFINET communication input	FB	PNI_I	Mapping element	%XB
	Real-type PROFINET communication input	FB	PNI_R	Mapping element	%XB

Size of memory used by communication inputs/outputs

The mapping elements corresponding to BOOL-type, DINT-type, REAL-type and IO_REAL-type variables and ECW_B, ECW_I, ECW_R, and subsystem communication I/O function blocks of an application logic are communication I/O (%WB). The mapping elements corresponding to safety subsystem communication I/O function blocks are safety communication I/O (%XB). The following table shows the maximum number of data items that can be mapped and the size of memory used by communication I/O.

Table B3.1-2 Size of memory used by communication inputs/outputs

Description in application logic	Mapping element	Size used	Maximum number of data items that can be mapped
BOOL-type variable	%WB	1 bit	3200 data items in total
ECW_B FB	%WB	1 bit	
DINT-type variable	%WB	2 words	900 data items in total
REAL-type variable	%WB	2 words	
IO_REAL-type variable	%WB	2 words	
ECW_I FB	%WB	2 words	
ECW_R FB	%WB	2 words	
SCI_B (FB)	%WB	1 bit	Up to 2000 data items in total regardless of the size of an FB (1 bit or 2 words)
SCI_I (FB)	%WB	2 words	
SCI_R (FB)	%WB	2 words	
SCO_B (FB)	%WB	1 bit	
SCO_I (FB)	%WB	2 words	
SCO_R (FB)	%WB	2 words	
PSI_I (FB)	%XB	2 words	2000 data items in total
PSI_R (FB)	%XB	2 words	
PNI_I (FB)	%XB	2 words	
PNI_R (FB)	%XB	2 words	

List of data items of mapping blocks/mapping elements

Each mapping block/mapping element has the following data items. See the explanation of each mapping block/mapping element for a detailed explanation of each data item.

Table B3.1-3 List of data items of mapping elements (1/2)

Data item	FB (*1)								
	Internal variable			I/O variable		External communication FB			Annunciator
	BOOL	DINT	REAL	IO_BOOL	IO_REAL	ECW_B	ECW_I	ECW_R	ANN/ANN_FUP
ALRM									Yes
AOFS									Yes
PV	Yes			Yes		Yes			Yes
PVI32		Yes					Yes		
PVU32									
PVF32			Yes		Yes			Yes	
PVI16									
PVU16									
OPMK	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
UAID									Yes

*1: Yes: The data item exists.

Table B3.1-4 List of data items of mapping elements (2/2)

Data item	FB (*1)									
	Subsystem communication inputs			Subsystem communication outputs			Safety subsystem communication I/O

Data items common to mapping blocks/mapping elements

This section explains data items common to mapping blocks and mapping elements.

AOFS (alarm inhibition)

AOFS is a data item indicating that the process alarm of the function block is inhibited.

This item is not displayed on the HIS tuning view along with the data items, however, the alarm inhibition status can be identified by the color of the tag mark.

The data entry from HIS to this data item is possible. Using the button on the tuning view can change the block into the alarm inhibition status.

The status is as follows:

- Not Inhibit Alarm: 0 (Default)
- Inhibit Alarm: 1

OPMK (operation mark)

This data item indicates operation marks assigned to mapping blocks and mapping elements. It is not displayed in the data item list of the HIS tuning view but operation marks can be assigned using buttons in the tuning view.

Data entry is also allowed.

- Range
  The range of OPMK is from 0 to 255.

- Default
  The default value of OPMK is 0.

UAID (user application ID)

This data item indicates UAIDs corresponding to the upper level equipment names in the plant hierarchy, assigned to mapping blocks.

It is not displayed in the data item list of the HIS tuning view, but data entry is allowed.

The default value is the value specified in the Tag Name Builder.

MODE (block mode)

This data item indicates block mode.

Whether or not the block mode can be displayed on the HIS tuning view and instrument face-plate, what kind of modes a block can have varies with the types of the mapping blocks.

The mode may change according to the parameter changes of the function block, but cannot be changed from HIS.

The following modes are available:

- O/S (Out of Service)
  This is the initial status of a mapping block that all functionalities are not functioning. When SCS is working in normal state, the mapping block will not work in this mode.
- MAN (Manual)
  This is a mode that the output can be manually manipulated.
- IMAN (Initialization Manual)
  This is a mode that the output is disabled.

  This block mode exists together with other block mode.
- AUT (Automatic)
  This is a mode that the output of the function block is enabled.

The default mode of the function block is O/S(AUT), it means the function block is shifting from O/S to AUT mode. (O/S(AUT) is a transition mode.)

AFLS (alarm flashing status)

This data item is not supported. Do not change the data of this item from CENTUM.

AF (alarm detection)

This data item is not supported. Do not change the data of this item from CENTUM.

Process alarms

Process alarms notify process errors detected by the application logic as alarm messages for CENTUM. Though the process alarms are sent by mapping blocks, when the process alarms are displayed on HIS window to indicate abnormality or recovery events, the timestamps of the events will be the reception time that HIS receives the alarms.

Each mapping block provides the following process alarms. Check the explanation of individual function blocks associated with mapping blocks for details of process alarms.

Table B3.1-6 Process alarms generated from mapping blocks

Alarm Status	Mapping block (*1)											
	S_ANLGI	S_ANLG_S	S_VEL	S_OVR_* (*2)	S_GOV_* (*3)	S_PASSWD	S_MOB_21	S_MOB_11	S_MOB_RS	S_MOA	S_HSDTR	S_GASDTR
NR (*4)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
OOP							Yes	Yes		Yes		
IOP		Yes					Yes	Yes			Yes	Yes
HTRP	Yes	Yes									Yes	Yes
LTRP	Yes	Yes										Yes
HHH	Yes	Yes										Yes
LLL	Yes	Yes										Yes
FLT												Yes
OVR				Yes	Yes							
PERR							Yes					
PWON						Yes						
ANS+				Yes			Yes	Yes				
ANS-				Yes			Yes	Yes	Yes			
VEL+			Yes									
VEL-			Yes									

*1: Yes: Corresponding process alarm is generated.
*2: Indicates S_OVR_B, S_OVR_I, S_OVR_R, S_OVR_IB or S_OVR_IR.
*3: Indicates S_GOV_B or S_GOV_IB.
*4: NR is the status set when other process alarms are not generated. Process alarms are displayed on an HIS in the order in the table with the highest priority on the top item.

B3.2 Tag name interfaces for internal variables and I/O variables

It is possible to define mapping elements for internal variables and I/O variables to reference the data with tag name interfaces. If you define tag names using the Tag Name Builder for BOOL, DINT or REAL-type internal variables, mapping elements are created in the communication input/output (%WB) area.

When a tag name is defined for a discrete I/O variable, the tag name is associated with a %Z or %Y mapping element. When a tag name is defined for an analog I/O variable, the tag name is associated with a %WB mapping element.

■ Data items of mapping elements associated with internal variables

All mapping elements of internal variables provide the OPMK data item.

SEE ALSO For more information about description regarding OPMK (Operation mark), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

● Data items of mapping elements (%WB) associated with BOOL-type variables (PV)

Boolean values of BOOL-type internal variables are displayed as PV. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate, and will be a target of data collection for tuning trend. Data entry from an HIS is not allowed.

The range is 0 or 1.

● Data items of mapping elements (%WB) associated with DINT-type variable (PVI32)

Integer values of DINT-type internal variables are displayed as PVI32. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

The range is all signed 32-bit integers.

● Data items of mapping elements (%WB) associated with REAL-type variables (PVF32)

Real values of REAL-type internal variables are displayed as PVF32. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

The range is all single precision real numbers.

■ Data items of mapping elements associated with I/O variables

Mapping elements of I/O variables commonly support the OPMK data item.

SEE ALSO For more information about description regarding OPMK (Operation mark), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

Data items of mapping elements (%Z, %Y) associated with IO_BOOL-type variables (PV)

Discrete data values are displayed as PV. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate, and will be a target of data collection for tuning trend. Data entry from an HIS is not allowed.

The range is 0 or 1.

Data items of mapping elements (%WB) associated with IO_REAL-type variables (PVF32)

Analog data real values are displayed as PVF32. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

The range is all single precision real numbers.

Data access through process I/O terminal numbers (%Z, %Y)

Process I/O terminal numbers (%Z, %Y) corresponding to IO_BOOL type I/O variables are outlined as follows:

- Discrete inputs and outputs are accessed not only via tag names but also process input/output terminal numbers.
- 0 is obtained if data of input/output channels whose I/O variables are not wired is referenced via process input/output terminal number.

Specification syntax (%Z)

%Znnusmm

%Z: : Process I/O (FIO) identifier (fixed to %Z)

nn: : Node number (01 to 14)

u: : Slot number (1 to 8)

s: : Segment number (fixed to 1)

mm: : Terminal number (01 to 16)

Specification syntax (%Y)

%Ynnusmm

%Y : Process I/O (N-IO) identifier (fixed to %Y)

nn : Node number (01 to 32)

u : I/O unit number (1 to 6)

s : Slot number (1 to 2)

mm : Terminal number (01 to 64) [01 to 16: Discrete I/O, 17 to 64: Reserved]

Data items used to reference data status

The table below lists data items used to reference the data status of I/O variables using tag name interfaces.

Table B3.2-1 Referencing data status by tag names

Mapping element	Description	Data item used for data reference	Data item used for data status reference
%Z, %Y	Discrete (IO_BOOL type) inputs and outputs	PV	#PV
%WB	Analog (IO_REAL type) inputs and outputs	PVF32	#PVF32

Input/output status information that can be referenced from HIS and FCS of CENTUM

The I/O status information, which is the basis of the data status of I/O variables, is stored in the CPU. The status information is 32-bit data and structured in the same way as for an FCS.

This 32-bit data is transmitted when HISs and FCSs reference the status of inputs and outputs of an SCS.

The data status of I/O variables is determined by whether or not the BAD status bit is on.

Logical data of I/O variables

Data corresponding to an I/O variable consists of physical data and logical data. Physical data is concrete data such as data input from sensors and data output to actuators. Logical data is the data that can be referenced via an application logic.

The data read by tag name interfaces is logical data. The following table shows how to access data via mapping elements associated with I/O variables.

Table B3.2-2 Access to logical data of I/O variables via tag names

	Discrete	Analog
Reading (logical data)	• Tag name defined for a discrete I/O variable (%Z, %Y) • Process input/output terminal number (%Z, %Y))	Tag name defined for an analog input variable (%WB)
Writing	Not possible	Not possible

Dictionary View of SCS Manager can display both physical data and logical data of I/O variables.

SEE ALSO For more information about physical data and logical data, refer to:

A6.2, “I/O variable” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Conditions under which tag names can be defined

The conditions under which it is allowed to define tag names and assign mapping elements for I/O variables are explained in this section. Discrete I/O variables are of the IO_BOOL type. Analog I/O variables are of the IO_REAL type. Specify the Direction attribute for these variables. There are three options for the Direction attribute: Input, Output and Internal.

- Specify the Input attribute for input variables. When the Input attribute is specified, the variable can be connected to a channel of an input module.
- Specify the Output attribute for output variables. When the Output attribute is specified, the variable can be connected to a channel of an output module.

It is possible to define tag names for IO_BOOL-type and IO-REAL type variables in Tag Builder. The table below shows whether or not tag names can be defined with the Direction attribute. Tag names can be defined for variables with either the Input or Output attribute.

Table B3.2-3 Direction attribute of variables and tag name definition

	Direction (*1)		
	Input	**Output**	**Internal**
IO_REAL	OK	OK	NG
IO_BOOL	OK	OK	NG

*1: OK: tag names can be defined
NG: tag names cannot be defined

B3.3 Tag name interfaces of function blocks

By specifying tag names for function blocks using the Tag Name Builder and associating them with mapping blocks/mapping elements, it becomes possible to call them via the tag names from CENTUM and notify process alarms.

This section explains mapping blocks and mapping elements of the following function blocks.

- Analog input function block with data status (ANLG_S)
- Analog input indication (ANLGI)
- Velocity limit alarm (VEL)
- Annunciator (ANN)
- First-up alarm annunciator (ANN_FUP) (*1)
- Subsystem communication I/O (SCI_B, SCI_I, SCI_R, SCO_B, SCO_I, SCO_R)
- Safety subsystem communication I/O (PSI_I, PSI_R, PNI_I, PNI_R)
- Analog input function block for smoke and heat detectors (HSDTR)
- Analog input function block for gas and flame detectors (GASDTR)

*1: Applicable only when integrated with CENTUM VP R4.02 or later.

■ Data items of mapping blocks associated with analog input function blocks with data status (ANLG_S)

Mapping blocks associated with analog input function blocks with data status are S_ANLG_S.

Among the data items of mapping blocks, the data items unique to S_ANLG_S are explained here. All of these data items are displayed in the HIS tuning view with the exception of MODE and INV. Note that data entry for these data items from an HIS is not allowed.

SEE ALSO

For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

“■ Data items common to mapping blocks/mapping elements” on page B3-7

MODE (block mode)

This data item indicates block mode.

The default value of MODE is O/S (AUT).

ALRM (alarm status)

This data item displays alarm status.

The default value of ALRM is NR.

INV (input value)

This item is associated with the IN parameter (analog input) of ANLG_S.

- Range
  INV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of IN (0) of ANLG_S is reflected in the default value of INV.

PV (scale conversion value)

This data item is associated with the OUT parameter (analog output) of ANLG_S. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

In the SCS databases created by R1.03.00 or later versions, the PV data are affixed with data status signals. When the data status of IN signal of ANLG_S becomes BAD, the data status of PV will be set as BAD. However, the data status only indicates BAD. IOP, NFP or other statuses will be ignored.

TIP

- To affix the data status, the item [PV Status of S_ANLG_S] on SCS tab of SCS Constants Builder needs to be defined.
- When the database is created, the PV data are affixed with data status signals at default setting. However, if the above setting is not defined, when CENTUM station read the PV, even though the PV has data status signal, the PV will be always marked as Normal regardless the actual data status.
- In the SCS database created by R1.02, the PV of ANLG_S does not have data status signal.

- Range
  PV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of PV is the SL specified in Tag Name Builder.

HH (high trip setting level)

This data item is associated with the HH parameter (HI trip setting level) of ANLG_S. The HH value of ANLG_S is reflected in this item.

PH (high pre-alarm setting level)

This data item is associated with the PH parameter (HI pre-alarm setting level) of ANLG_S. The PH value of ANLG_S is reflected in this item.

PL (low pre-alarm setting level)

This data item is associated with the PL parameter (LO pre-alarm setting level) of ANLG_S. The PL value of ANLG_S is reflected in this item.

LL (low trip setting level)

This data item is associated with the LL parameter (LO trip setting level) of ANLG_S. The LL value of ANLG_S is reflected in this item.

HYS (hysteresis)

This data item is associated with the HYS parameter (hysteresis) of ANLG_S. The HYS value of ANLG_S is reflected in this item.

SH (scale high limit)

This data item displays the scale high limit defined using the Tag Name Builder.

SL (scale low limit)

This data item displays the scale low limit defined using the Tag Name Builder.

Data items of mapping blocks associated with analog input function blocks (ANLGI)

Mapping blocks associated with analog input indication function blocks are S_ANLGI.

Among the data items of mapping blocks, the data items unique to S_ANLGI are explained here. All of these data items are displayed in the HIS tuning view with the exception of MODE and INV. Note that data entry for these data items from an HIS is not allowed.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ List of data items of mapping blocks/mapping elements" on page B3-4

MODE (block mode)

This data item indicates block mode.

The default value of MODE is O/S (AUT).

ALRM (alarm status)

This data item displays alarm status.

The default value of ALRM is NR.

INV (input value)

This data item is associated with the IN parameter (analog input) of ANLGI.

- Range
  INV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of IN (0%) of ANLGI is reflected in the default value of INV.

PV (scale conversion value)

This data item is associated with the OUT parameter (output value) of ANLGI. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Range
  PV is normalized data (0 to 100 %) or a physical quantity.
- Default

The default value of PV is the SL specified in Tag Name Builder.

- **HH (high trip setting level)**

  This data item is associated with the HH parameter (High trip setting level) of ANLGI. The HH value of ANLGI is reflected in this item.

- **PH (high pre-alarm setting level)**

  This data item is associated with the PH parameter (High pre-alarm setting level) of ANLGI. The PH value of ANLGI is reflected in this item.

- **PL (low pre-alarm setting level)**

  This data item is associated with the PL parameter (Low pre-alarm setting level) of ANLGI. The PL value of ANLGI is reflected in this item.

- **LL (low trip setting level)**

  This data item is associated with the LL parameter (Low trip setting level) of ANLGI. The LL value of ANLGI is reflected in this item.

- **HYS (hysteresis)**

  This data item is associated with the HYS parameter (hysteresis) of ANLGI. The HYS value of ANLGI is reflected in this item.

- **SH (scale high limit)**

  This data item displays the scale high limit defined using the Tag Name Builder.

- **SL (scale low limit)**

  This data item displays the scale low limit defined using the Tag Name Builder.

■ Data items of mapping blocks associated with velocity limit alarm function blocks (VEL)

Mapping blocks associated with velocity limit alarm function blocks are S_VEL.

Among the data items of mapping blocks, the data items unique to S_VEL are explained here. All of these data items are displayed in the HIS tuning view with the exception of MODE. Note that data entry for these data items from an HIS is not allowed.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

- **MODE (block mode)**

  This data item indicates block mode.

  The default value of MODE is O/S (AUT).

- **ALRM (alarm status)**

  This data item displays alarm status.

  The default value of ALRM is NR.

PV (output value)

This data item is associated with the OUT parameter (output value) of VEL. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Range
  PV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of PV is the SL specified in Tag Name Builder.

VL (velocity limit alarm setting value)

This data item is associated with the VL parameter (velocity limit alarm setting level) of VEL.

- Default
  The VL value of VEL is reflected in this item.

HYS (hysteresis)

This data item is associated with the HYS parameter (hysteresis) of VEL. The HYS value of VEL is reflected in this item.

SH (scale high limit)

This data item displays the scale high limit defined using the Tag Name Builder.

SL (scale low limit)

This data item displays the scale low limit defined using the Tag Name Builder.

Data items of mapping elements associated with annunciator function blocks (ANN)

Annunciator messages are message outputs that simulate behaviors of annunciator panels of instrument faceplate on an HIS. When you create ANN function blocks for the application logic, %AN mapping elements are created as well. By defining %AN messages in the Tag Name Builder, annunciator messages can be checked from an HIS. Tag name definition is not mandatory.

SEE ALSO For more information about descriptions regarding AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

ALRM (alarm status)

This data item displays alarm status. It is displayed in the HIS tuning view but data entry from an HIS is not allowed.

The default value of ALRM is NR.

PV (input value)

This data item is associated with the IN parameter (input value) of ANN. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate, and will be a target of data collection for tuning trend. Data entry from an HIS is not allowed.

- Range
  The range of PV is 0 or 1.
- Default

The default value of IN (0) of ANN is reflected for the default value of PV.

Data items of mapping elements associated with first-up alarm annunciator function blocks (ANN_FUP)

The first-up alarm annunciator function block has the function to identify the first signal that shifts to the safe state within the same group. The annunciator message is output only when the received signal is the first safe state signal in the group to which the function block belongs.

When you create ANN_FUP function blocks for the application logic, %AN mapping elements are created as well. By defining %AN messages in the Tag Name Builder, annunciator messages can be checked from an HIS (*1). Tag name definition is not mandatory.

Data items of this mapping block are exactly the same as the annunciator function block.

*1: Checking annunciator messages from HIS is supported only when integrated with CENTUM VP R4.02.

Data items of mapping elements associated with subsystem communication inputs/outputs

When you create tag names for SCI_B, SCI_I, SCI_R, SCO_B, SCO_I and SCO_R function blocks in the Tag Name Builder, mapping elements are created in the communication input/output (%WB) area.

Among the data items of mapping elements, the data items unique to subsystem communication inputs/outputs are explained here.

SEE ALSO For more information about the data item OPMK (Operation mark) of subsystem communication inputs and outputs, refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

%WB data items associated with SCI_B and SCO_B (PV: BOOL data)

Mapping elements of SCI_B and SCO_B function blocks have PV (BOOL data) data items.

This data item displays BOOL-type data of the function blocks. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate, and will be a target of data collection for tuning trend. Data entry from an HIS is not allowed.

The range is 0 or 1.

%WB data items associated with SCI_I and SCO_I

In the case of SCI_I and SCO_I, data items of mapping elements vary depending on the data type of communication inputs/outputs (%WB) wired to the function blocks.

Each data item displays integer data of the associated function block and is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

Data items for each data type of communication inputs/outputs are as follows.

- PVI32 (integer data)
  This data item is used when the data type of communication inputs/outputs wired to the associated function block is signed 32-bit integer.

  The range is all signed 32-bit integers.
- PVI16 (integer data)
  This data item is used when the data type of communication inputs/outputs wired to the associated function block is signed 16-bit integer.

  The range is all signed 16-bit integers.

- PVU16 (integer data)
  This data item is used when the data type of communication inputs/outputs wired to the associated function block is unsigned 16-bit integer.

  The range is all unsigned 16-bit integers.

%WB data items associated with SCI_R and SCO_R (PVF32: real number data)

Mapping elements of SCI_R and SCO_R function blocks have PVF32 (real number data) data items.

This data item displays the real number data value of the associated function block. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

The range is all single precision real numbers.

Data items of mapping elements associated with safety subsystem communication I/O

When you define tag names for PSI_I, PSI_R, PNI_I, and PNI_R function blocks, mapping elements are created in the area for storing safety subsystem communication I/O (%XB) data. Among the data items of mapping elements, the data items unique to safety subsystem communication I/O are explained here.

SEE ALSO For more information about the data item OPMK (Operation mark) of safety subsystem communication I/O, refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

%XB data items associated with PSI_I and PNI_I

In the case of PSI_I and PNI_I, data items of mapping elements vary depending on the data type of safety subsystem communication I/O (%XB) wired to the function blocks. Each data item is the integer data of the FB. The data items are displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

Data items for each data type of safety subsystem communication I/O are as follows:

- PVI32 (integer data)
  This data item is used when the data type of communication I/O wired to the associated function block is signed 32-bit integer.

  The range is all signed 32-bit integers.
- PVU32 (integer data)
  This data item is used when the data type of communication I/O wired to the associated function block is unsigned 32-bit integer.

  The range is all unsigned 32-bit integers.
- PVI16 (integer data)
  This data item is used when the data type of communication I/O wired to the associated function block is signed 16-bit integer or signed 8-bit integer.

  The range is all signed 16-bit integers.
- PVU16 (integer data)
  This data item is used when the data type of communication I/O wired to the associated function block is unsigned 16-bit integer or unsigned 8-bit integer.

  The range is all unsigned 16-bit integers.

%XB data items associated with PSI_R and PNI_R (PVF32: real number data)

Mapping elements of PSI_R and PNI_R function blocks have PVF32 (real number data) data items.

This data item displays the real number data value of the associated function block. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is not allowed.

The range is all single precision real numbers.

Data items of the mapping block corresponding to the analog input function block for smoke and heat detectors (HSDTR)

The mapping block corresponding to the analog input function block for smoke and heat detectors is S_HSDTR. Among the data items of this mapping block, the data items unique to S_HSDTR are explained here. MODE, ALRM, BSTS, PV, HH, HYS, SH, SL, RSW, RREQ, RID, MV01, HTRP, and HTRR appear in the tuning view of HIS. Also, entry of data for MV01 only can be performed from HIS.

The data items for which the values of the HSDTR arguments are reflected as is are as follows:

- HH (high trip setting level)
- HYS (hysteresis)
- RSW (reset enabling switch)
- RREQ (reset request not from HIS)
- RID (reset group ID)
- MOS (override switch)
- HTRP (high trip (latched))
- HTRR (high trip raw data)
- POFF (device power off command)
- RSTS (reset status)
- OVRS (override status)

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

MODE (block mode)

This data item indicates block mode. The block mode cannot be changed into AUT or MAN from an HIS. The default value of MODE is O/S (AUT).

- Associating parameters of function blocks
  RSW (reset request from HIS) parameter of HSDTR is associated with MODE.
- Changes of block mode (AUT/MAN)
  The block mode becomes MAN if TRUE is input to RSW, and AUT if FALSE is input.

ALRM (alarm status)

This data item displays alarm status. The default value of ALRM is NR.

BSTS (block status)

This data item displays the block status. BSTS becomes RST when RSTS is TRUE. BSTS becomes OVR when OVRS is TRUE. In all other cases, BSTS becomes NR. When RSTS is TRUE and OVRS is TRUE, the block status displayed on the instrument faceplate becomes RST.

INV (input value)

This data item is associated with the IN parameter (analog input) of HSDTR.

- Range
  INV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of IN (0) of HSDTR is reflected in the default value of INV.

PV (scale conversion value)

This data item is associated with the OUT parameter (analog output) of HSDTR. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend. When the data status of IN signal of HSDTR becomes BAD, the data status of PV will be set as BAD. However, the data status only indicates BAD. IOP, NFP or other statuses will be ignored.

- Range
  PV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value for PV is the SL specified with Tag Name Builder.

SH (scale high limit)

This data item displays the scale high limit defined using Tag Name Builder.

SL (scale low limit)

This data item displays the scale low limit defined using Tag Name Builder.

MV01 (reset request from HIS)

This value changes to 1 when the reset button is operated with HIS. The value will return to 0 when startup of the device is complete.

- Range
  The range of MV01 is 0 or 1.
- Default
  The default value of MV01 is 0.

SWLB[1] (switch label)

The string of Button Label defined using Tag Name Builder is reflected as is.

SWCR[1] (switch indication color)

While in the reset status, the value of Button Color (Resetting) defined using Tag Name Builder is reflected as is. While not in the reset status, the value of Button Color (Normal) defined using Tag Name Builder is reflected as is.

SWST[1] (switch flashing status)

This item is not used. The value of 0 is constantly set.

SWOP[1] (switch operation disable status)

While the operation guard is displayed, the value of Operation Guard Color defined using Tag Name Builder is reflected as is. The value of 0 is set when the operation guard is not displayed.

AKLB[1] (reconfirmation label)

This data item displays the string that is displayed in the reconfirmation dialog box. The string of Button Label defined using Tag Name Builder is reflected as is. The string is the same as SWLB[1].

Data items of the mapping block associated with the analog input function block for gas and flame detectors (GASDTR)

The mapping block is associated with the analog input function block for gas and flame detectors is S_GASDTR. Among the data items of this mapping block, the data items unique to S_GASDTR are explained here. MODE, ALRM, BSTS, PV, FPV, HH, LL, PH, PL, HYS, F1H, F1L, F2H, F2L, F3H, F3L, SH, SL, RSW, RREQ, MV01, HTRP, LTRP, HTRR, LTRR, and FAULT appear in the tuning view of HIS. Also, entry of data for MV01 only can be performed from HIS.

The data items for which the values of the GASDTR arguments are reflected as is are as follows:

- HH (high trip setting level)
- LL (low trip setting level)
- PH (high pre-alarm setting level)
- PL (low pre-alarm setting level)
- HYS (hysteresis)
- FSH (scale high limit for fault)
- FSL (scale low limit for fault)
- F1H (fault 1 upper limit)
- F1L (fault 1 lower limit)
- F2H (fault 2 upper limit)
- F2L (fault 2 lower limit)
- F3H (fault 3 upper limit)
- F3L (fault 3 lower limit)
- RSW (reset enabling switch)
- RREQ (reset request not from HIS)
- MOS (override switch)
- HTRP (high trip (latched))
- LTRP (low trip (latched))
- HTRR (high trip raw data)
- LTRR (low trip raw data)
- HHH (HI pre-alarm)
- LLL (LO pre-alarm)

- OVRS (override status)

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

● MODE (block mode)

This data item indicates block mode. The block mode cannot be changed into AUT or MAN from an HIS. The default value of MODE is O/S (AUT).

- Associating parameters of function blocks
  RSW (reset request from HIS) parameter of GASDTR is associated with MODE.
- Changes of block mode (AUT/MAN)
  The block mode becomes MAN if TRUE is input to RSW, and AUT if FALSE is input.

● ALRM (alarm status)

This data item displays alarm status. The default value of ALRM is NR.

● BSTS (block status)

This data item displays the block status. BSTS becomes OVR when OVRS is TRUE. In all other cases, BSTS becomes NR.

● INV (input value)

This data item is associated with the IN parameter (analog input) of GASDTR.

- Range
  INV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value of IN (0) of GASDTR is reflected in the default value of INV.

● PV (scale conversion value)

This data item is associated with the OUT parameter (analog output) of GASDTR. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend. When the data status of IN signal of GASDTR becomes BAD, the data status of PV will be set as BAD. However, the data status only indicates BAD. IOP, NFP or other statuses will be ignored.

- Range
  PV is normalized data (0 to 100 %) or a physical quantity.
- Default
  The default value for PV is the SL specified with Tag Name Builder.

● FPV (PV for fault detection)

This data item displays the scale conversion value for fault detection.

● SH (scale high limit)

This data item displays the scale high limit defined using Tag Name Builder.

● SL (scale low limit)

This data item displays the scale low limit defined using Tag Name Builder.

MV01 (reset request from HIS)

This value changes to 1 when the reset button is operated with HIS. The value will return to 0 when resetting of the alarm is complete.

- Range
  The range of MV01 is 0 or 1.
- Default
  The default value of MV01 is 0.

FAULT (fault details)

This data item displays the fault details. The string specified with IDF1 appears when FLT1 is TRUE. The string specified with IDF2 appears when FLT2 is TRUE. The string specified with IDF3 appears when FLT3 is TRUE.

SWLB[1] (switch label)

The string of Button Label defined using Tag Name Builder is reflected as is.

SWCR[1] (switch indication color)

The value of Button Color (Normal) defined using Tag Name Builder is reflected as is.

SWST[1] (switch flashing status)

This item is not used. The value of 0 is constantly set.

SWOP[1] (switch operation disable status)

While the operation guard is displayed, the value of Operation Guard Color defined using Tag Name Builder is reflected as is. The value of 0 is set when the operation guard is not displayed.

AKLB[1] (reconfirmation label)

This data item displays the string that is displayed in the reconfirmation dialog box. The string of Button Label defined using Tag Name Builder is reflected as is. The string is the same as SWLB[1].

B4. Override operation from HIS

The override operations can be carried out from an HIS to an SCS. To perform the override operation, an override function block or grouping override function block is used. Using grouping override function blocks allows you to manage these function blocks as a group. This chapter explains the following points related to override operations from an HIS.

- Overview of override function blocks
- Tag name interfaces and process alarms of override function blocks
- Overview of grouping override function blocks
- Tag Name Interfaces and Process Alarms of Grouping Override Function Block
- Status Management of Function Blocks Used for Override
- Management of override using password function block
- Tag Name Interfaces and Process Alarms of Password Function Blocks

Function blocks related to override operations

During the normal operation of SCS, the operation override is performed from an HIS to fix the variable value to a predefined value that is different from the actual value.

The operation uses an override function block or grouping override function block, and is permitted by hardware switch or the password function block.

The following function blocks are supported for override operation.

Table B4-1 Function blocks related to override operations

Type of FB	Name of FB	Description
override FB	OVR_B	BOOL-type data override
	OVR_I	Integer-type data override
	OVR_R	REAL-type data override
	OVR_IB	IO_BOOL-type data override
	OVR_IR	IO_REAL-type data override
Grouping override FB	GOV_B	BOOL-type data grouping override
	GOV_IB	IO_BOOL-type data grouping override
Password FB	PASSWD	Password

B4.1 Overview of override FB

To perform override to the data from HIS that is not required for group management, the Override function block can be used. An override function block is provided for each data type.

Mechanism of override function blocks

The following figure illustrates an example where an input variable is overridden using an override function block for IO_BOOL-type variable (OVR_IB). In the example of overriding an input variable, the override function block is positioned immediately after the variable to be overridden.

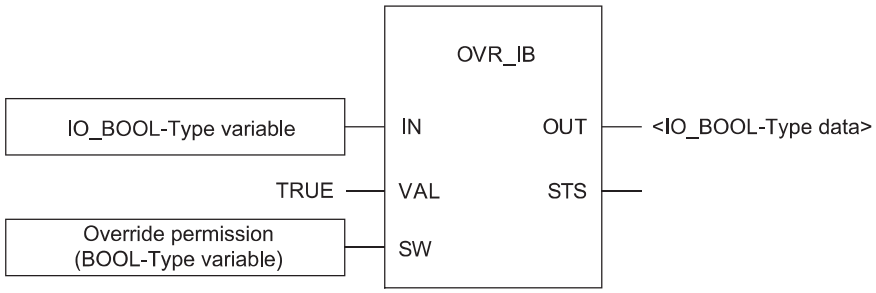

Figure B4.1-1 Example of using OVR_IB function block for an input variable

In the normal status where the variable is not overridden, the OVR_IB function block outputs the data input via input parameter IN as is from output parameter OUT. When an override operation is specified from the HIS via the mapping block, the OVR_IB function block outputs the value specified for input parameter VAL (TRUE in this case) from output parameter OUT. During overriding, the data status of output parameter OUT is always TRUE (GOOD). If the override operation is canceled from the HIS, the OVR_IB function block outputs the data input via input parameter IN as is from output parameter OUT again.

A BOOL-type variable is specified for input parameter SW of the OVR_IB function block. Under normal circumstances, this BOOL-type variable is set to be an input variable from a key switch. If the user operates the key switch, the BOOL-type variable value changes. If the BOOL-type variable becomes TRUE, input parameter SW of OVR_IB also becomes TRUE, and an override operation is permitted. If the variable becomes FALSE, the override operation is prohibited.

Note that the override operation is not canceled even if input parameter SW changes from TRUE to FALSE while the override instruction is active; output parameter OUT keeps on outputting the value specified for input parameter VAL.

TIP

It is possible to change values of BOOL-type variables by entering data along with the correct password from the faceplate of an HIS by using the password function block. Utilizing this mechanism, it can be specified whether or not to allow override operations using the password function instead of using hardware such as a key switch.

SEE ALSO

For more information about engineering of override function blocks, refer to:

B7.1.6, “Engineering for overriding from HIS” on page B7-29

For more information about password function block, refer to:

7.3, “PASSWD (password)” in POU Reference Manual (IM 32P03B20-01EN)

Data status of I/O variables

OVR_IB and OVR_IR are override function blocks for IO_BOOL-type variables and IO_REAL-type variables, respectively. These override function blocks fix the data status of output pa-

rameter OUT of the associated variables to TRUE (GOOD), which is output when the variables are placed in the override status.

The figure below illustrates a usage example of the override function block for IO_REAL-type variables. When the override status of the function block is activated via a mapping block from an HIS, output parameter OUT outputs the following.

- The data value of OUT (member "v" of structure IO_REAL) is set to the value input via input parameter VAL, which is then output to the output side. The output is fixed to 20.0 in the example of the figure below.
- The data status of OUT (member "status" of structure IO_REAL) is fixed to TRUE (GOOD).

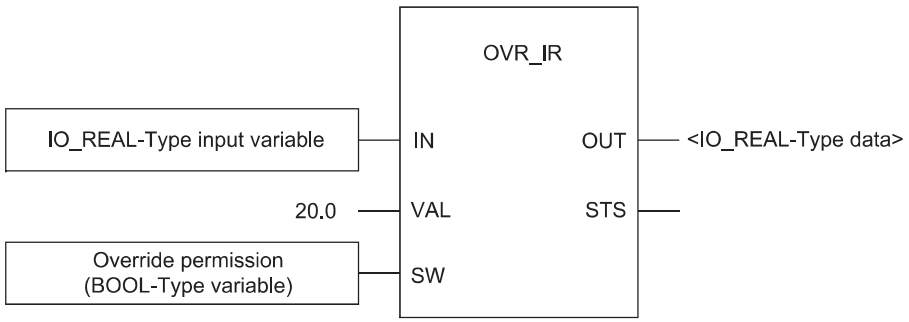

Figure B4.1-2 Override of IO_REAL-type variable

When the override operation of the function block is activated, the data status of output parameter OUT is fixed to TRUE (GOOD) but the data status of input variables connected to input parameter IN is not influenced. If the override function block is placed in the override status, only output parameters OUT and STS change.

B4.2 Tag name interfaces and process alarms of override function blocks

To be able to perform override operations from an HIS using an override function block, it is necessary to define the tag name in the Tag Name Builder and associate it with a mapping block.

Mapping blocks associated with override function blocks

The following table shows mapping blocks associated with override function blocks.

Table B4.2-1 Mapping blocks associated with override function blocks

Override FB type	Mapping block type
OVR_B	S_OVR_B
OVR_I	S_OVR_I
OVR_R	S_OVR_R
OVR_IB	S_OVR_IB
OVR_IR	S_OVR_IR

SEE ALSO For more information about procedure for defining the mapping blocks of override function blocks, refer to:

B7.1.6, “Engineering for overriding from HIS” on page B7-29

Settings in the Tag Name Builder

To be able to perform override operations from an HIS, it is necessary to make settings for instances of override function blocks in the Tag Name Builder.

Use the Tag Name Builder to make specification for alarms during override operation and answerback error alarms.

- Override ON alarm
  Specify either [Yes] or [No].

  The default is [Yes].
- Answerback error alarm
  Specify either [Both] or [No].

  The default is [Both].

SEE ALSO For more information about items defined in the tag name builder, refer to:

B7.1.5, “Defining tag names” on page B7-12

Data items of mapping blocks associated with override function blocks

Among the data items of mapping blocks, the data items unique to mapping blocks of override function blocks are explained here. All of these data items are displayed in the HIS tuning view with the exception of MODE. Note that data entry for these data items from an HIS is allowed only for MV.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

MODE (block mode)

This data item indicates block mode.

The default value of MODE is O/S (AUT).

ALRM (alarm status)

This data item displays alarm status.

The default value of ALRM is NR.

PV (answerback input value)

This data item displays the override status and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The STS parameter (override status) of override function blocks is associated with PV.
- Range
  The range of PV is 0 or 1.
- Correspondence between changes of the parameter value of override function blocks and changes of PV
  If STS of an override function block is TRUE, PV=1 and override operations from an HIS are executed.
- Default
  The default value of STS (0) is reflected in the default value of PV.

MV (manipulated output value)

Override operations are permitted if SW of an override function block is 1, and MV can be manipulated from an HIS. This item will be a target of data collection for tuning trend.

- Range
  The range of MV is 0 or 1.
- Default
  The default value of MV is 0.

INV (input value)

This data item is associated with the IN parameter (input) of an override function block. This is displayed in the parameter display area of instrument faceplate. This value is output from OUT when no override operation is performed. The IN value of an override function block is reflected in this item.

VAL (fixed value)

This data item is associated with the VAL parameter (override value) of an override function block. This is displayed in the parameter display area of instrument faceplate. This value is output from OUT when override operations are performed. The VAL value of an override function block is reflected in this item.

OUTV (output value)

This data item is associated with the OUT parameter (output value) of an override function block This is displayed in the parameter display area of instrument faceplate. The OUT value of an override function block is reflected in this item.

SW (switch)

This data item is associated with the SW parameter of an override function block. The range is 0 or 1. Override operations are permitted when the value of SW is 1. The SW value of an override function block is reflected in this item.

Process alarm

Mapping blocks of the override function blocks generate two types of process alarms, override ON and answerback error alarms. It is possible to specify whether or not to initiate this process alarms using the Tag Name Builder.

Answerback error alarms

Answerback error alarms can be used to examine whether or not an override operation from an HIS is functioning as instructed. A mapping block mediates the override operation between a faceplate on the HIS side and an override function block.

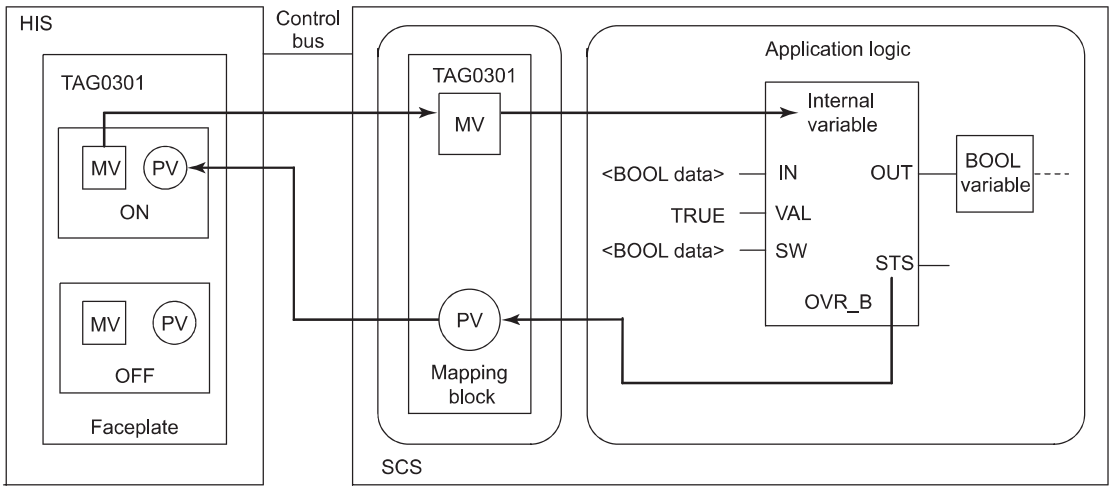

Figure B4.2-1 Flow of data between override function block and mapping block

If you perform an override operation from the faceplate of the HIS, the mapping block stores the value "1", which means "instruct override", in its own data item MV. The data of MV is then set to the internal variable of the override function block. The override function block examines the validity of the set data. If the data is considered valid, the override function block goes into override condition and changes the STS from FALSE to TRUE.

The mapping block reads the STS value of the override function block into the PV of the mapping block at the next scan period. The scan period of the mapping block is the same as the scan period of the external communication function. The default value is 1 second.

If the value (MV) instructed by the mapping block and the status value (PV) read back from the STS output of the override function block do not match, the mapping block generates an answerback error alarm. If they match later, the mapping block recovers from the answerback error alarm.

An answerback error alarm is generated under the following conditions.

- ON side answerback error alarm (ANS+)
  MV = 1 and PV ≠ 1

- OFF side answerback error alarm (ANS-)
  MV = 0 and PV ≠ 0

The mapping block recovers from an answerback error alarm under the following conditions.

- ON side answerback error alarm (ANS+)
  When PV changes to 1 or MV changes to a value other than 1
- OFF side answerback error alarm (ANS-)
  When PV changes to 0 or MV changes to a value other than 0

Override ON alarm

Override ON alarms can be used to notify an operator that the function block corresponding to the tag name of an SCS is being overridden. A mapping block generates an override ON alarm if an override function block is placed in the override status. Once the override status is canceled, the mapping block recovers from the override ON alarm.

An override ON alarm is generated under the following condition.

- PV = 1 (STS of the override function block is 1)

The mapping block recovers from an override ON alarm under the following condition.

- PV = 0 (STS of the override function block is 0)

B4.3 Overview of grouping override function block

When it is necessary to exclusively manage override operations from an HIS to multiple data items, grouping override function blocks can be used.

Types of grouping override function block are shown below.

- GOV_B BOOL-type data grouping override
- GOV_IB IO_BOOL-type data grouping override

This section explains the following functions of grouping override function block. GOV_B and GOV_IB differ only in the type of data they can handle. Their basic functions are identical.

- Group function
- Override permit switch
- Override enable status
- Block mode
- Override status cancel function
- Data status for OUT parameter of GOV_IB function block
- Operation of grouping override function block

Group function

By using a grouping override function block, it is possible to restrict the override operation of multiple data items that are defined as a group to only one at a time. Multiple groups can be defined within an SCS. The override operations can be performed simultaneously to grouping override function blocks that belong to separate groups.

There are no limits to the number or types of grouping override function blocks that can be defined as a group. Both GOV_B and GOV_IB can be included in a same group.

- If the override operation is performed for a grouping override function block in a group, the operation cannot be performed on other function blocks in the same group until it completes. When the override operation is attempted simultaneously on another function block within the same group, the override operation for that function block will be disabled.
- It is also possible to enable the override operation for individual function blocks, without grouping, using a grouping override function block.

Group number

Group number is defined for GRP. Multiple groups can be defined by assigning different group numbers.

- Up to 128 groups can be managed by a single SCS. Specify a group number (1 to 128) for GRP.
- When the group number is set to 0, that grouping override function block does not belong to any group. The number limitation on simultaneous operations will be invalid, and the override operation can be performed without being affected by the exclusive control on the override operations for other grouping override function blocks.
- The override operation cannot be performed if the group number is set to a negative number or a number equal to or greater than 129.

Override permit switch

The override operation can be performed from an HIS when the override permit switch (SW) is set to TRUE (override allowed). When SW is set to FALSE (override prohibited), the override operation cannot be performed from an HIS.

The Override Enabled status

Override Enable Status (ENS) indicates whether the override operation for a grouping override function block is allowed.

When SW is set to TRUE (override allowed) and there are no other grouping override function blocks for which override is being executed within the same group, ENS becomes TRUE (override enable status), and the override operation can be performed.

However, if there is a function block for which override is being executed within the same group, ENS of other function blocks in the group becomes FALSE (override disable status), and the override operation cannot be performed.

If SW is set to FALSE (override prohibited), ENS will always be FALSE (override disable status).

TIP

- When the group number is 0
  When the group number is set to 0, if the override permit switch (SW) is TRUE, the override enable status (ENS) is always TRUE. MODE indicated on the HIS instrument faceplate is MAN.
- When the group number is negative, or 129 or greater
  When a value outside the range is specified as the group number, the override enable status (ENS) is fixed to FALSE regardless of the state of override permit switch (SW). The override operation is not allowed. MODE indicated on the HIS instrument faceplate is always AUT.

Block mode

- The override enable status can be checked from the block mode (MODE) by specifying the tag name assigned to a grouping override function block and then calling the HIS instrument faceplate. The block mode reflects the state of the function block's override enable status (ENS). MODE becomes MAN when ENS is TRUE, and AUT when FALSE.
- The override operation is allowed only when MODE is MAN. When the override operation is not permitted because the override permit switch (SW) is FALSE, or when override is being executed for another function block in the same group, MODE indicates AUT.

Override status cancel function

Grouping override function blocks have the override status cancel function.

By changing from TRUE to FALSE the override permit switch (SW) of a grouping override function block for which override is being executed, the override status will be canceled. At that time, the override enable status (ENS) becomes FALSE.

TIP

The override status is canceled under the following conditions as well.

- When a forced cancellation command is issued from the SYS_OVR block
- When the group number is changed (The group number should be set to a fixed value. The online change download during the override operation is prohibited.)

Data status for OUT parameter of GOV_IB function block

During the override execution of GOV_IB function block, the data status of IO_BOOL-type output (OUT) will be GOOD. When override is not being executed, the data status of input parameter IN will be output as the data status of OUT.

During the override execution, if the override permit switch (SW) changes from TRUE to FALSE, or if SYS_OVR issues a forced cancellation command, the override status will be canceled even if IN data status is BAD.

Operation of grouping override function blocks

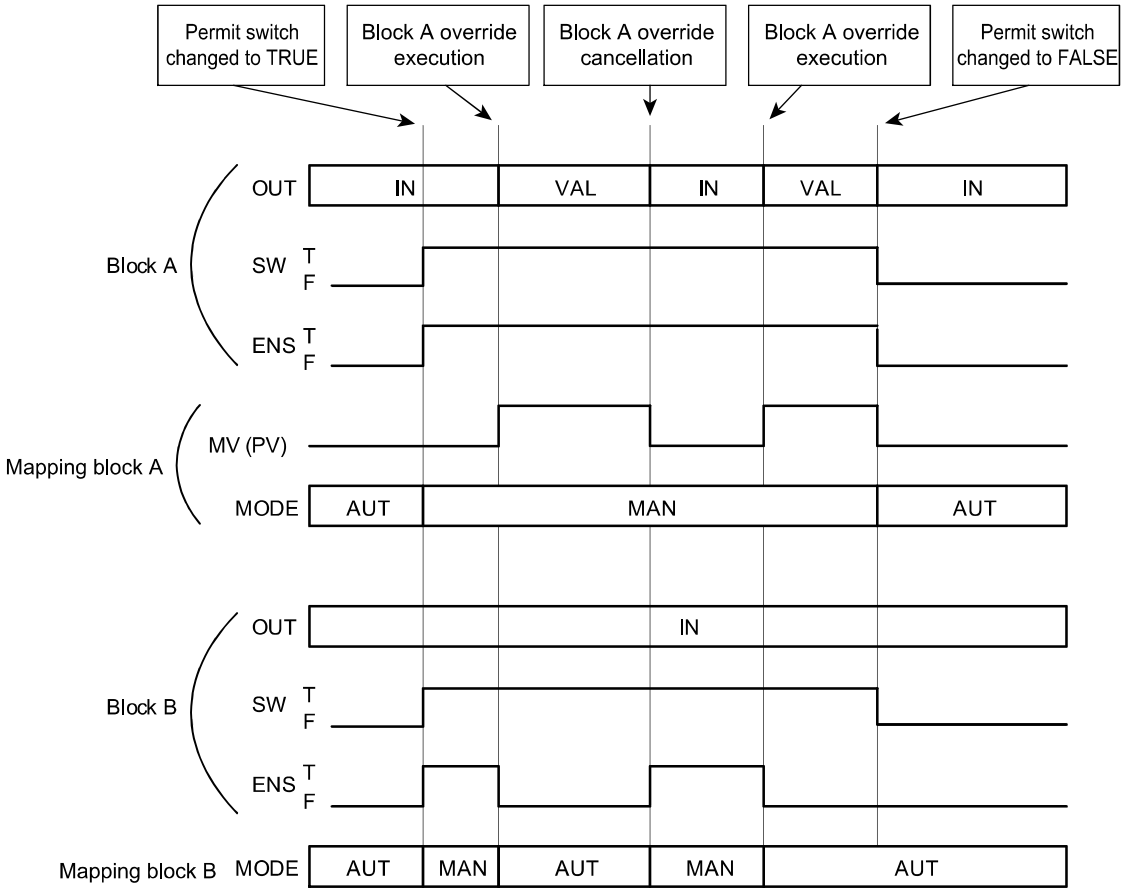
Execution of override

Grouping override function block outputs the data input from IN as is from OUT when there is no override execution.

1. Set the override permit switch (SW) to TRUE.
2. If there are no function blocks for which override is being executed within the group, MODE of tag assigned to the function block becomes MAN, the override operation can be performed. If the override operation is not allowed, MODE stays AUT.
3. If MV is set to 1 from the HIS instrument faceplate and PV of answerback signal changes to 1, data specified by VAL will be output from OUT of the grouping override function block. At this time, the mode of other function blocks that belong to the same group will be AUT.

TIP

When the override operation is disabled, or when the override status is canceled by setting SW to FALSE, MV will be reset to 0 and PV of answerback signal will be 0 as well.



End of override

When MV is set to 0 from an HIS and the override status is canceled, the data input from IN will be output again from OUT of the grouping override function block. At this time, the mode of all function blocks that belong to the same group becomes MAN (*1).

*1: Even if it belongs in the same group, the mode of the function block whose override permit switch (SW) is set to FALSE stays AUT.

Data change during override

The figure below shows the changes in each data when block A and block B that belong to the same group are connected to the same override permit signal, and the override operation is performed for block A.

Block A is the function block for which override is executed, while block B is another function block within the same group.

Figure B4.3-1 State transition of blocks in the same group

B4.4 Tag name interfaces and process alarms of grouping override function block

To perform the override operation from an HIS using the group function, it is necessary to specify the tag name with Tag Name Builder and assign mapping blocks.

■ Mapping blocks associated with grouping override function blocks

Mapping blocks associated with grouping override function blocks are shown in the table below.

Table B4.4-1 Mapping blocks associated with grouping override function blocks

Override FB type	Mapping block type
GOV_B	S_GOV_B
GOV_IB	S_GOV_IB

■ Settings in the Tag Name Builder

When the override operation is performed from an HIS, set necessary items for the instance of grouping override function block with Tag Name Builder.

The following item is set for Alarm in Overriding.

- Alarm in overriding
  Specify either [Yes] or [No].

  The default is [Yes].

SEE ALSO For more information about items defined in the tag name builder, refer to:

B7.1.5, “Defining tag names” on page B7-12

■ Data items of mapping blocks associated with grouping override function blocks

Among the data items of mapping blocks, the data items unique to mapping blocks associated with grouping override function blocks are explained here. All of these data items are displayed in the HIS tuning view. Note that data entry for these data items from an HIS is allowed only for MV.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

“■ Data items common to mapping blocks/mapping elements” on page B3-7

● MODE (block mode)

This data item indicates block mode. It is possible to check whether the override operation can be performed. MAN indicates the operation enable status, while AUT means the system prohibits override execution and MV manipulation (executing/ending override) from an HIS is not allowed in this case.

It is not possible to change the block mode to AUT or MAN from an HIS or FCS. The default value of MODE is O/S (AUT). This is displayed in the parameter display area of instrument faceplate.

- Associating parameters of function blocks

The ENS parameter (override enable status) of grouping override function blocks is associated with MODE.

- Change in block mode (AUT/MAN)
  If ENS is TRUE, the block mode is MAN; if FALSE, AUT.

ALRM (alarm status)

This data item displays alarm status.

The default value of ALRM is NR.

PV (answerback input value)

This data item displays the override status. This item will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The STS parameter (output status) of grouping override function blocks is associated with PV.
- Range
  The range of PV is 0 or 1.
- Correspondence between changes of the parameter value of grouping override function blocks and changes of PV
  If STS of a grouping override function block is TRUE, PV = 1 and override operations from an HIS are executed.
- Default
  The default value of STS (0) is reflected in the default value of PV.

MV (manipulated output value)

Override operations are permitted if the block mode is MAN, and MV can be manipulated from an HIS. This item will be a target of data collection for tuning trend.

- Range
  The range of MV is 0 or 1.
- Default
  The default value of MV is 0.

INV (input value)

This data item is associated with the GRP parameter (group number) of a grouping override function block. This is displayed in the parameter display area of instrument faceplate. This value is output from OUT when no override operation is performed.

The IN value of a grouping override function block is reflected in this item.

VAL (fixed value)

This data item is associated with the VAL parameter (fixed value) of a grouping override function block and is displayed in the parameter display area of instrument faceplate. This value is output from OUT when override operations are performed. The VAL value of a grouping override function block is reflected in this item.

OUTV (output value)

This data item is associated with the GRP parameter (group number) of a grouping override function block. This is displayed in the parameter display area of instrument faceplate. The OUT value of a grouping override function block is reflected in this item.

SW (switch)

This data item is associated with the SW parameter (override permit switch) of a grouping override function block.

- Range
  The range of SW is 0 or 1. The SW value of a grouping override function block is reflected in this item.
- Operations by SW changes
  Override operations are permitted only if the SW value is 1. However, the override operation can actually be performed for the function block only when the MODE is MAN.

  When SW changes from 1 to 0, the override status is canceled.

GRNO (group number)

This data item is associated with the GRP parameter (group number) of a grouping override function block. This item indicates the group number to which the function block belongs. If the value is 0, the function block does not belong to any group. The GRP value of a grouping override function block is reflected in this item.

Process alarm

Override ON alarms are notified from grouping override function blocks.

Override ON alarm

Override ON alarms can be used to notify an operator that a function block is being overridden. A mapping block generates an override ON alarm if an override function block is placed in the override status. Once the override status is canceled, the mapping block recovers from the override ON alarm.

An override ON alarm is generated under the following condition.

- PV = 1 (STS of the override function block is 1)

The mapping block recovers from an override ON alarm under the following condition.

- PV = 0 (STS of the override function block is 0)

B4.5 Status management of function blocks used for override

The SYS_OVR system function block can equally manage the statuses of override function blocks and grouping override function blocks regardless of function block types. In this section, override function blocks and grouping override function blocks are collectively referred to as override function blocks.

SEE ALSO For more information about SYS_OVR, refer to:

11.10, “SYS_OVR (override function blocks management)” in POU Reference Manual (IM 32P03B20-01EN)

Cancellation of all override statuses

The SYS_OVR function block can cancel the override statuses of all override function blocks in an SCS at once.

When UNOV is changed from FALSE to TRUE, all override statuses are forcibly canceled and a system alarm is generated.

It is possible to cancel all override statuses for a group of grouping override function blocks by inputting the same permit switch to all function blocks within the group and setting the permit switch to FALSE.

Management of the Override Enabled status

The SYS_OVR function block can manage the override enable statuses of all override function blocks in an SCS.

The override enable status refers to the condition where the SW input parameter value of a function block is TRUE.

The following types of management can be performed for override enable statuses of all override function blocks within the SCS.

TIP If there is a grouping override function block with a group number outside the specification range, the override permission signal operation for that function block is considered a part of the override enable status management.

- SWON
  SWON indicates whether or not there is a function block in the override enable status.
- NUMS
  NUMS indicates the number of override function blocks in the override enable status.

  For instance, if a common override permission signal is input to all the grouping override function blocks that comprise a group of 10 function blocks, setting the override permission signal to 1 makes NUMS to be 10.
- SWC, NOVS
  SWC is used to specify the maximum number of override function blocks that can be simultaneously placed in the override enable status. NOVS indicates whether or not the maximum number has been exceeded.

  If TRUE is set for SW of more override function blocks than the number specified by SWC, a system alarm is generated. However, it is possible to place override function blocks in the override enable status even after the maximum number has been exceeded and the system alarm has been generated.

In the case of grouping override function blocks, when a common permission signal is input to all the function blocks within the group, the number of all function blocks that belong to that group will be counted by SWC if the override permission signal is set to 1.

- CKTS, TUPS
  CKTS is used to specify the maximum duration of the status where at least one override function block in the override enable status exists. TUPS indicates whether or not the status has been continuing longer than the maximum duration.

  If the status continues longer than the duration specified by CKTS, a system alarm is generated.

Management of the override status

The SYS_OVR function block can manage the override statuses of all override function blocks in an SCS.

The override status refers to the condition where MV is set to 1 from an HIS by calling the faceplate that corresponds to the tag name assigned to the function block, and the override output value specified in VAL is being output from OUT of the function block.

- OVR
  OVR indicates whether or not there is an override function block in the override status.
- NUMO
  NUMO indicates the number of override function blocks in the override status.

  For instance, when there are two groups (A and B) of grouping override function blocks, if a function block in A is placed in the override status and a function block in B is also placed in the override state simultaneously, NUMO becomes 2.
- OVRC, NOVO
  OVRC is used to specify the maximum number of override function blocks that can be placed in the override status simultaneously. NOVO indicates whether or not the maximum number has been exceeded.

  If more function blocks than the number specified by OVRC are placed in the override status, a system alarm is generated. However, it is possible to override even after the maximum number has been exceeded and the system alarm has been generated.

  For instance, when grouping override function blocks are used and OVRC is set to 2, if the override operation is performed for the third group, a system alarm is generated.
- CKTO, TUPO
  CKTO is used to specify the maximum duration of the status where at least one override function block in the override status exists. TUPO indicates whether or not the status has been continuing longer than the maximum duration.

  If the status continues longer than the duration specified by CKTO, a system alarm is generated.

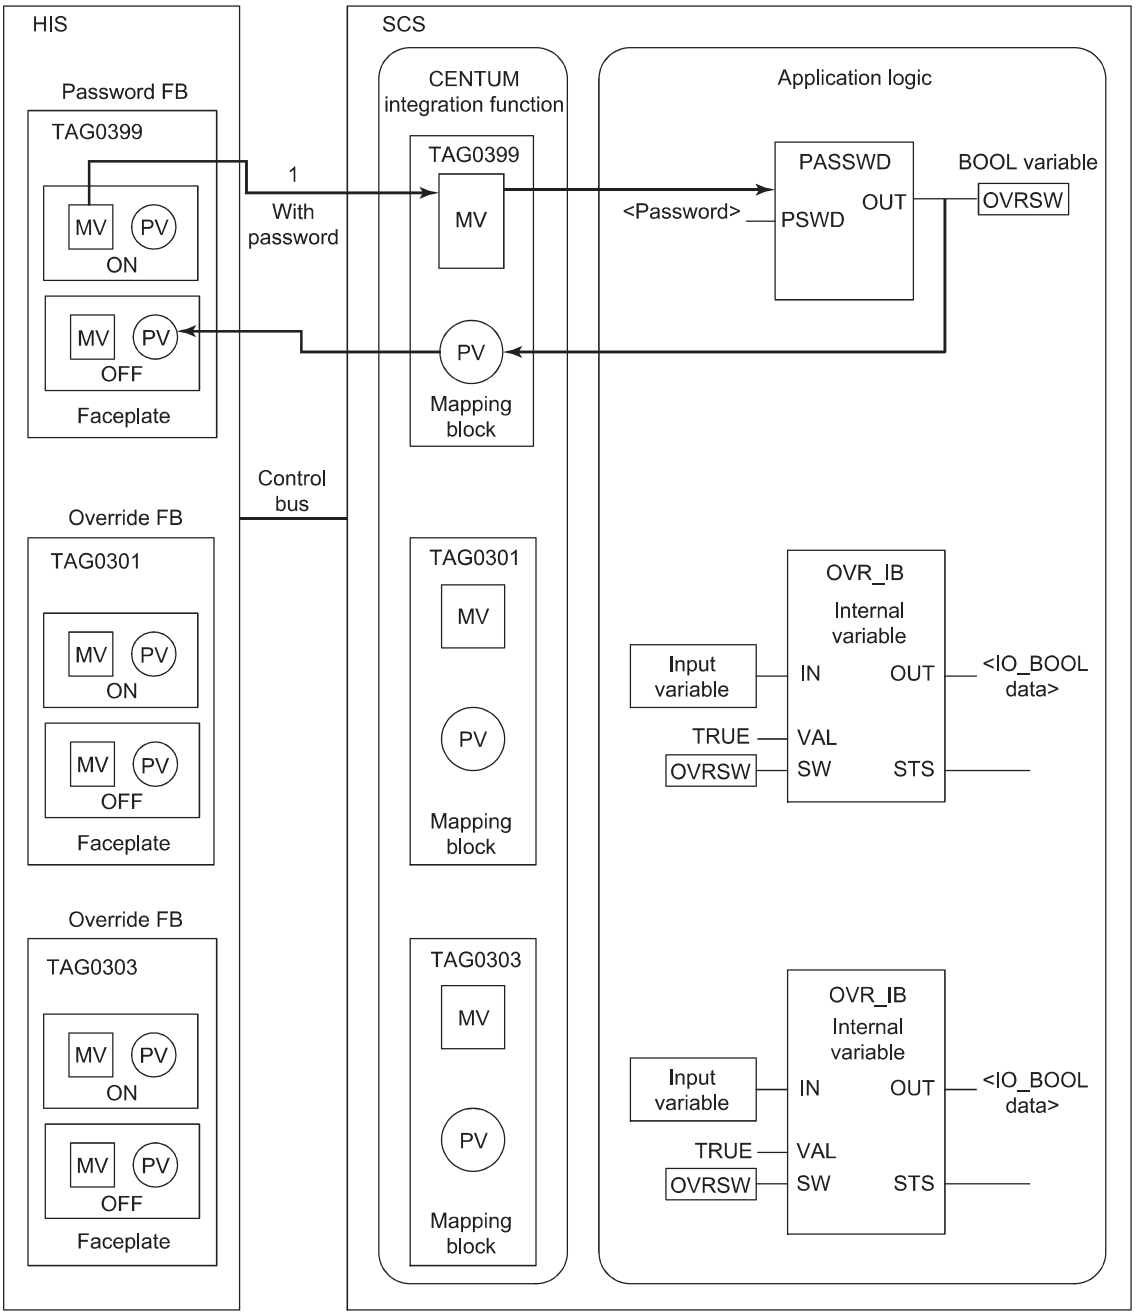
B4.6 Permission for override by password FB

It is possible to use the password function block to set a BOOL variable of an application logic to TRUE or FALSE from the faceplate of an HIS with password verification.

Operation to allow override

In order to authenticate the override operations on override function blocks, a password block can be used instead of using a hardware key switch. The permission can be granted or denied by authenticating the password.

How to utilize the password function block for authenticating the override operations will be explained below.



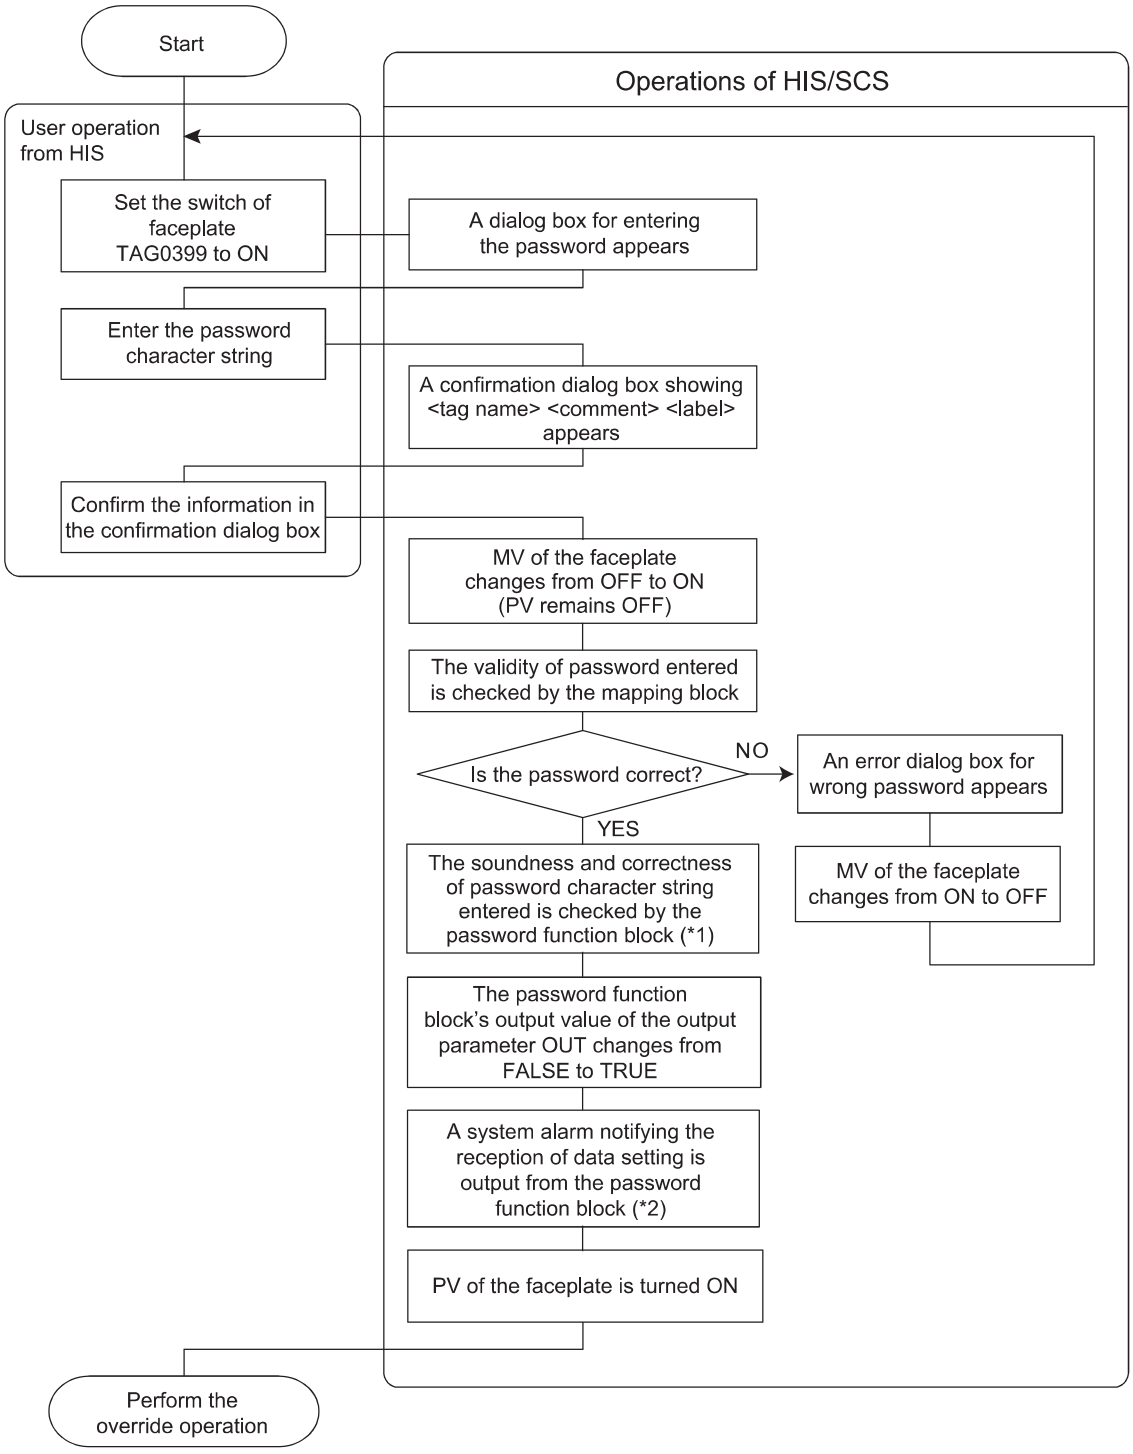


Figure B4.6-1 Switching override permission status by password (example)

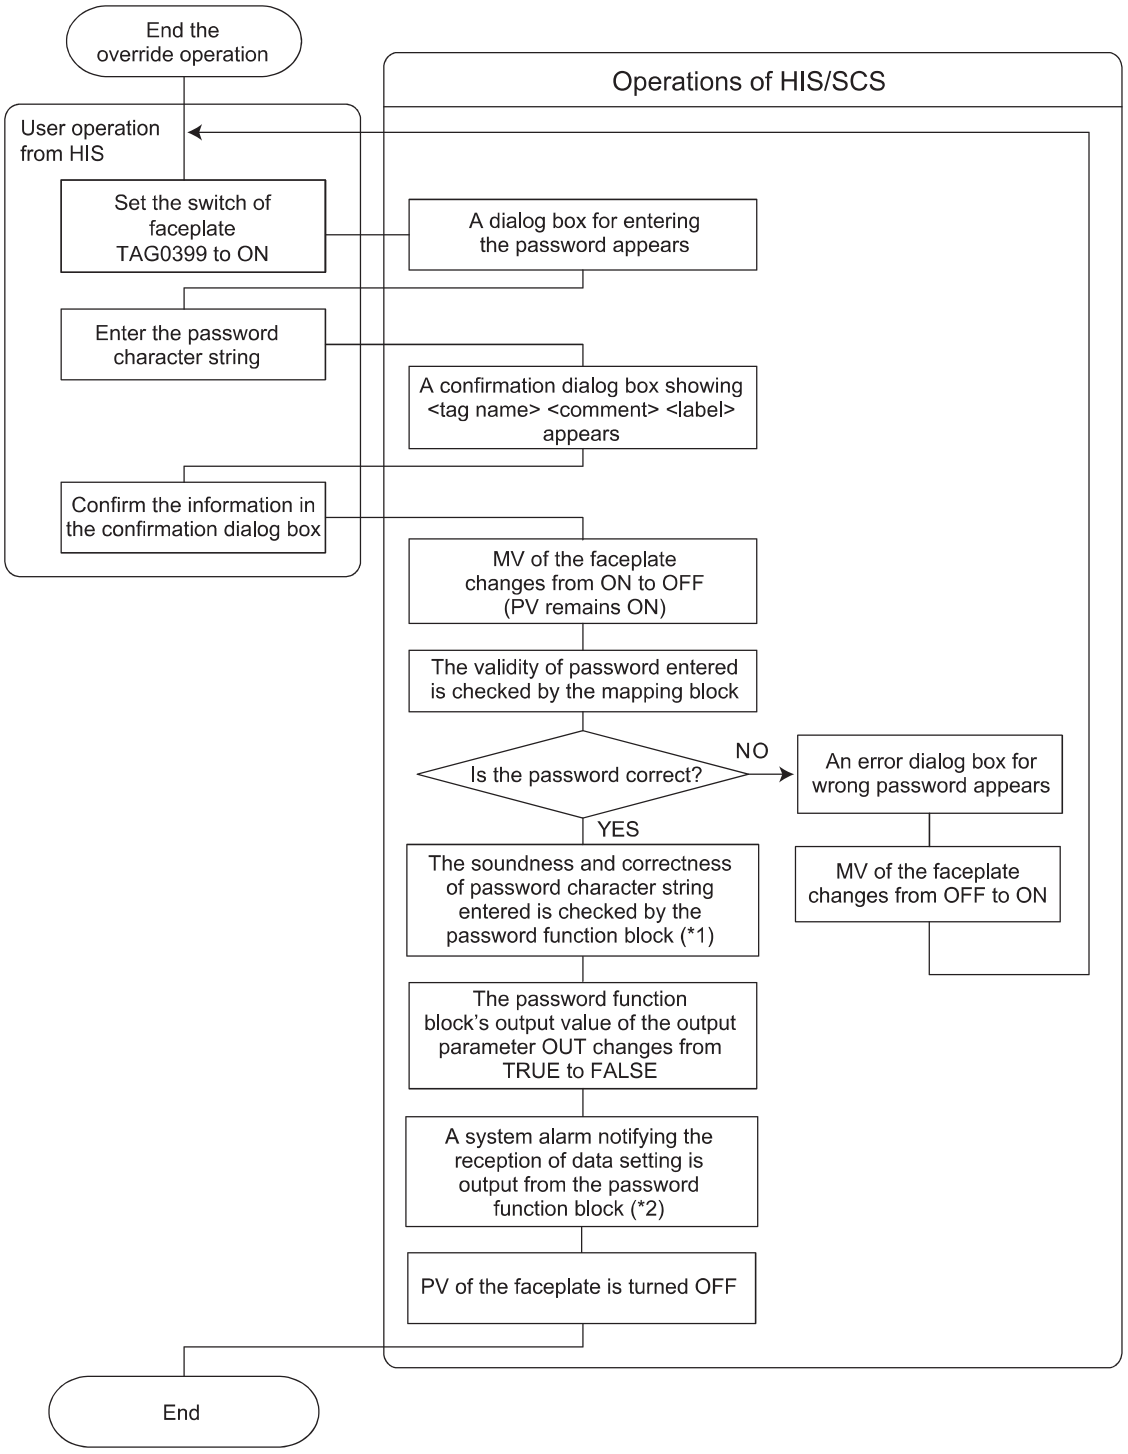
The operation procedure of setting data with password verification in Figure, "Switching override permission status by password (example)" is shown below.



The default value of the output of the password function block is FALSE. The default status of the faceplate is OFF for both MV and PV.

*1: If there are any problems during checks by the password function block, the password function block outputs a system alarm that includes a tag name and aborts the processing.
*2: System alarm messages include the password function block instance name and tag name.

Figure B4.6-2 Permitting override operation by password function block

When override operation is complete, operation of the override function block is prohibited in the following manner.

*1: If there are any problems during checks by the password function block, the password function block outputs a system alarm that includes a tag name and aborts the processing.
*2: System alarm messages include the password function block instance name and tag name.

Figure B4.6-3 Prohibiting override operation with password function block

Management of password function block

The status of the PASSWD function block can be managed by a SYS_PSWD system function block. The SYS_PSWD function block has the following functions.

- The PASSWD function block is able to forcibly return the output from output parameter OUT of all PASSWD function blocks within an SCS to FALSE. A system alarm is generated when the SYS_PSWD function block is used for this purpose.
- The SYS_PSWD function block displays whether or not there are any PASSWD function blocks that output TRUE via output parameter OUT within an SCS. The number of such PASSWD function blocks can also be displayed.
- The SYS_PSWD function block generates a system alarm if the number of PASSWD function blocks outputting TRUE from output parameter OUT exceeds the specified maximum number. It is still possible to set more passwords even after the system alarm indicating that the maximum number is exceeded has been generated, however.
- The SYS_PSWD function block generates a system alarm if the status where there is one or more PASSWD function blocks outputting TRUE continues longer than the specified time.

SEE ALSO For more information about SYS_PSWD, refer to:

11.11, “SYS_PSWD (password function blocks management)” in POU Reference Manual (IM 32P03B20-01EN)

B4.7 Tag name interfaces and process alarms of password function blocks

In order to set values of a PASSWD function block from an HIS, it is necessary to define the tag name using the Tag Name Builder and associate it with a mapping block. S_PASSWD mapping blocks are associated with PASSWD function blocks.

Settings in the Tag Name Builder

Use the Tag name builder to make a specification for password ON alarms and answer-back error alarms.

- Password ON alarms
  Specify either [Yes] or [No].

  The default is [Yes].

SEE ALSO For more information about items defined in the tag name builder, refer to:

B7.1.5, “Defining tag names” on page B7-12

Data items of S_PASSWD

Among the data items of S_PASSWD, the data items unique to mapping blocks of S_PASSWD are explained here. All of these data items are displayed in the HIS tuning view with the exception of MODE. Note that data entry for these data items from an HIS is allowed only for MV.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

“■ Data items common to mapping blocks/mapping elements” on page B3-7

MODE (block mode)

This data item indicates block mode.

The default value of MODE is O/S (AUT).

ALRM (alarm status)

This data item displays alarm status.

The default value of ALRM is NR.

PV (answerback input value)

This data item is associated with the OUT parameter of PASSWD. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Range
  The range of PV is 0 or 1.
- Correspondence between changes of the parameter value of PASSWD and changes of PV
  If the input password character string is correct, TRUE is output to OUT of PASSWD and PV becomes 1.
- Default
  The default value of OUT (0) is reflected in the default value of PV.

MV (manipulated output value)

Manipulate MV from an HIS to enter a password. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Range
  The range of MV is 0 or 1.
- Default
  The default value of MV is 0.

Process alarms

The mapping block of PASSWD FB can initiate a process alarm for Password ON. It is possible to specify whether or not to initiate this process alarms using the Tag Name Builder.

Password ON alarm

Password ON alarms can be used to notify an operator that the PASSWD function block is currently outputting TRUE. A mapping block generates a password ON alarm if the PASSWD function block outputs TRUE via output parameter OUT. The system recovers from the password ON alarm if 0 is set with password from the faceplate.

A password ON alarm (PWON) is generated under the following condition.

- PV = 1 (OUT of the PASSWD function block is TRUE)

The system recovers from a password ON under the following condition.

- PV = 0 (OUT of the PASSWD function block is FALSE)

B4.8 Application for override

This section shows an example of application for override, its creation method, operating procedure, difference in FB, and precautions.

Example of application for override

The following figure illustrates an example of application where override is executed.

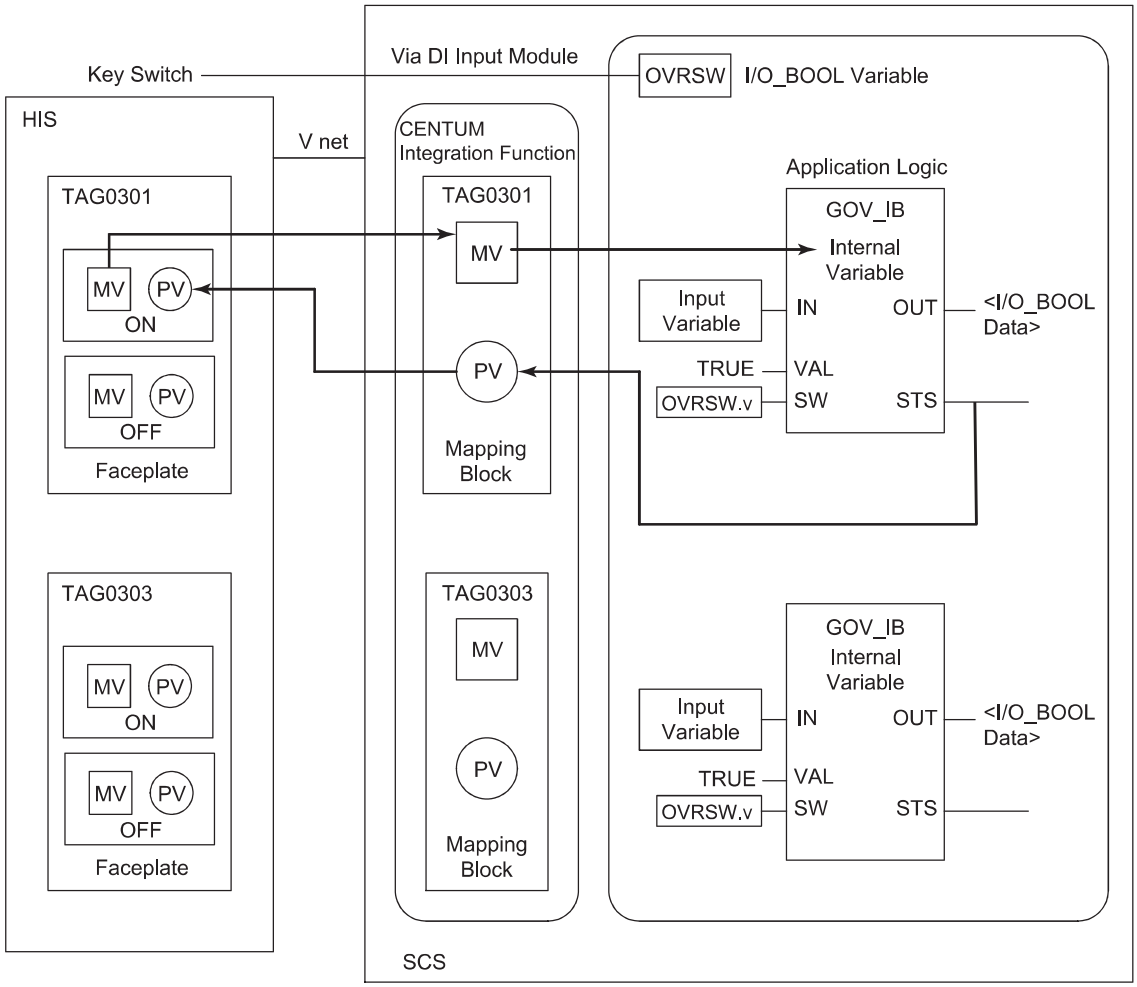


Figure B4.8-1 Override from HIS (Example of GOV_IB)

This describes the Override function with the GOV_IB function block.

Override from HIS is executed with the override function block (e.g. OVR_IB). Different Override FBs are available corresponding to the type of overridden variable. Mapping blocks (e.g. TAG0301) help override operation from a faceplate of HIS to the override FB.

Action of Override FB

- Without being overridden, data input from the IN parameter is output from the OUT parameter without any changes.
- When override is used, the override FB outputs data specified to the VAL input parameter, from the OUT parameter. This means the data is locked to the value which has already been defined to VAL.
- When override is cancelled, the override FB outputs the data input from IN again to OUT.
- To execute override, it is required that the override FB's SW parameter which enables override is TRUE and that override is operated from HIS.

- When user executes override from a faceplate of HIS while SW is TRUE, the Data Item MV of mapping block is set to 1 (override instruction). Then, the content of MV is reflected on the internal variable of override FB. The override FB checks the validity of the set data. When the test is passed, the override FB goes into the override status.
- A system alarm message is output if override is enabled for an FB while there are no override-enabled FBs. A system alarm message is also output if override is disabled for the last remaining override-enabled FB, resulting in no override-enabled FBs.
- When the override FB goes into the override status and when the status is cancelled, a diagnostic information message including the instance name and tag name of override FB is issued.

SEE ALSO For more information about override, refer to:

B4.3, “Overview of grouping override function block” on page B4-8

Create applications for override

To execute override, it is necessary to create application logic with the override FB.

1. Function blocks that meet the requirements of override FB or grouping override FB should be used.
2. Use the override function blocks, which correspond to the type of variables on which override will be executed.
3. Connect an input variable to the IN input parameter. Connect the variable on which override is executed to the OUT output parameter.
4. Define the overriding value to the VAL input parameter.
5. Use the SW input so that override cannot be executed without permission.
   Do not connect the TRUE value to the SW input.

Operational procedure of override

In this operational procedure, override is enabled/disabled by connecting a discrete input from a key switch with the SW input parameter of the override function blocks. Using the Password FB allows you to switch override through a password from HIS without the key switch.

1. The override function block goes into the ready status for overriding by turning the key switch to “Ready for override from HIS.”
   Confirm from HIS that a system alarm is output, which indicates override is enabled.
2. Switch the MV of a faceplate on HIS from which override is operated, to “ON.” When override becomes effective, the value of the VAL input parameter specified by the override function block is output from the OUT output parameter.
   - A system alarm which notices override is displayed. As instance name and tag name in the override function block are included in this system alarm, confirm they are appropriate.
   - PV of the faceplate reads back the output from the STS parameter in the override function block. Confirm that both MV and PV are “ON.”
3. Provide necessary maintenance while override is being performed.
4. Set MV to “OFF” from the faceplate after maintenance to cancel override. When override is canceled, the value from the IN input parameter is output from the OUT output parameter without any changes. The STS output parameter of GOV_IB changes from 1 to 0.
   - Confirm that a system alarm indicating override has been canceled on HIS is displayed. As instance name and tag name in the override function block are included in this system alarm, confirm they are appropriate.
   - Confirm that both MV and PV are “OFF” on the a faceplate.

5. Turn the key switch to the original position to disable override from HIS. Confirm that the system alarm indicating override is disabled.

Differences between Override FB and Grouping override FB

The differences between the override FB and the grouping override FB are listed. The override FB and the grouping override FB act differently when the override permission signal becomes OFF during override. Therefore, it is recommended not to mix the two types of override FBs. Moreover, between override FB and grouping override FB, the exclusive override cannot be executed.

Table B4.8-1 Differences between Override FB and Grouping override FB

Feature	Override FB	Grouping Override FB
Grouping function of grouping override FB	No	Yes
Action when override permission (SW) becomes OFF	Override continues	Override stops when permission signal changes from TRUE to FALSE.
Status display on mapping block	No	MAN: Override executable (operational from HIS) AUT: Override not executable (non operational from HIS)
MV of mapping block when override is automatically released (*1)	MV=1 (Answerback error)	MV=0 (Auto reset)
Manipulating the MV of mapping block when permission (SW) is OFF	Can be changed to MV=1, but it indicates answerback error.	Since the block mode is in AUT, an operation error message will be displayed. MV cannot be changed.
Overridden variables	BOOL(OVR_B) IO_BOOL(OVR_IB) DINT(OVR_I) REAL(OVR_R) IO_REAL(OVR_IR)	BOOL(GOV_B) IO_BOOL(GOV_IB)

*1: Automatic release of override
Under the following circumstances, the override will be automatically released.
- SYS_OVR sent a forcibly release override signal(to override FB or grouping override FB)
- Permission signal changes from TRUE to FALSE (grouping override FB)
- Group numbers are changed (grouping override FB)

In the grouping function of override FB with grouping function, override groups can be created by assigning group numbers to grouping override FBs. When the override permission signal changes to TRUE, the override FB becomes overridable. If multiple grouping override FBs have the identical group number, only one of the grouping override FBs can be overridden at a time. In other words, other grouping override FBs in the same group cannot be overridden until the currently overridden FB is released. Grouping management is not applied to the override FBs whose group number is 0.

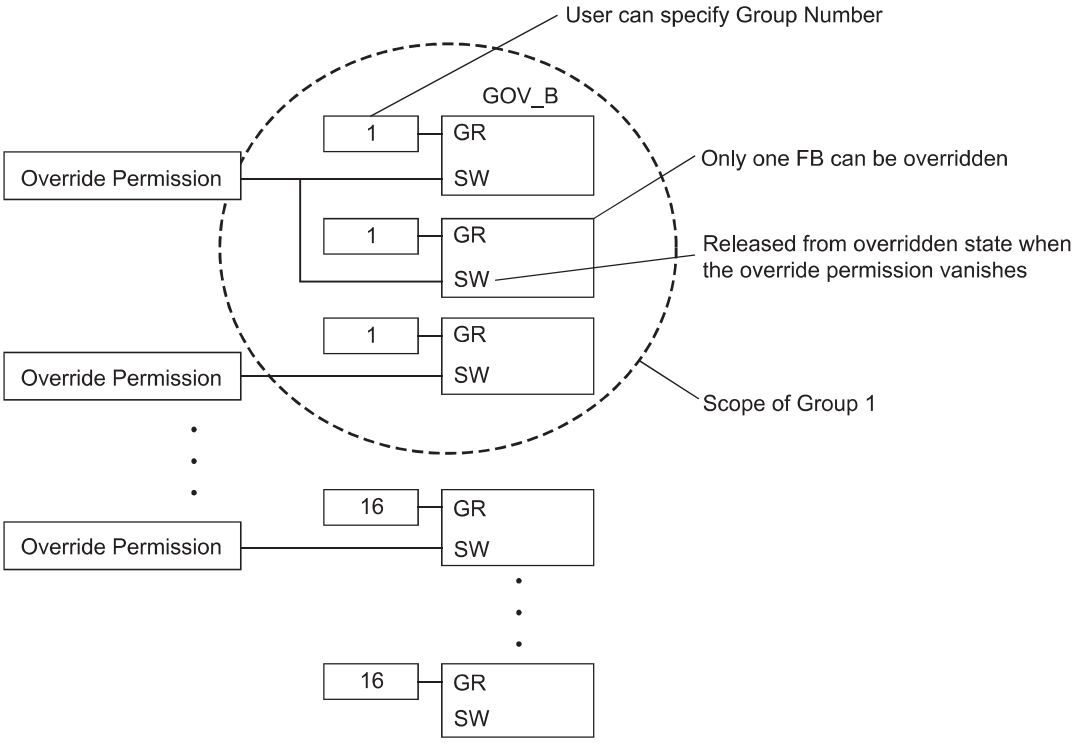

Figure B4.8-2 Grouping override FB overview

SEE ALSO For more information about detailed procedures for operating the override, refer to:

B4., “Override operation from HIS” on page B4-1

Precautions for override

- The length of variable name displayed as a system alarm is 80 characters at maximum. Set a variable name length not to exceed the maximum so that the variable name can be identified when forcing and override are enabled/disabled.
- Do not execute online change download while executing override from HIS.
- When using the Password FB, set different passwords for each FB.
- If a permission signal SW is from a DI, and the permission signal becomes FALSE due to a DI related device fault, the override will be automatically released.
- When group number is mistakenly specified, the system cannot find this error. Therefore, during the logic test, if the group numbers have been properly specified or not must be carefully inspected.
- During override, do not use online change to change the group number and run online change downloading. If you do, override is automatically deactivated. If you assign a variable to a group number and change the variable value, override is automatically deactivated.

B5. Manipulation of manual operation function blocks from HIS

Manual operation function blocks are used to output values manipulated by an operator via an HIS to the application logic. Note that it is also possible to prohibit manipulation from an HIS and set output values of function blocks with the application logic.

There are the following four types of manual operation function blocks.

- MOB_11 (BOOL-type data manual operation function block with two-position answer-back)
- MOB_21 (BOOL-type data manual operation function block with three-position answer-back)
- MOB_RS (auto-reset BOOL-type data manual operation)
- MOA (analog-type data manual operation)

SEE ALSO

For more information about MOB_11, refer to:

- B5.1, “HIS interfaces of MOB_11 and MOB_21 (BOOL-type data manual operation function block with answerback)” on page B5-3
- 7.4, “MOB_11 (BOOL-type data manual operation function block with two-position answerback)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about MOB_21, refer to:

- B5.1, “HIS interfaces of MOB_11 and MOB_21 (BOOL-type data manual operation function block with answerback)” on page B5-3
- 7.5, “MOB_21 (BOOL-type data manual operation function block with three-position answerback)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about MOB_RS, refer to:

- B5.2, “HIS interfaces of MOB_RS (auto-reset BOOL-type data manual operation)” on page B5-21
- 7.6, “MOB_RS (auto-reset BOOL-type data manual operation)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about MOA, refer to:

- B5.3, “HIS interfaces of MOA (analog-type data manual operation)” on page B5-29
- 7.7, “MOA (analog-type data manual operation)” in POU Reference Manual (IM 32P03B20-01EN)

Overview of manual operation from HIS

For each of the four types of manual operation function blocks, parameter values of function blocks can be changed by manual operations by an operator from an HIS. It is also possible to specify whether or not to permit such manual operations with the application logic. If manual operations are prohibited, output values can be changed from the application logic. Some manual operation function blocks can also receive shutdown signals from the application logic, forcing them to output shutdown signals.

All manual operation function blocks have functions to read back the results of manual operations, so that the operator is able to check via HIS instrument faceplate that operation instructions are correctly received. These function blocks are safety function blocks. There is no need for users to take safety measures as in the case of external communication function blocks.

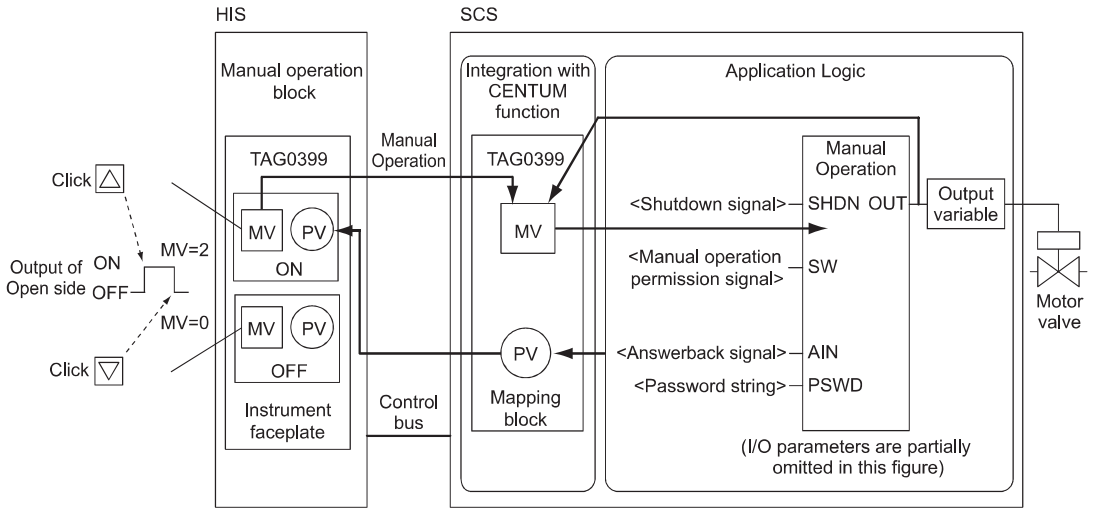

Figure B5-1 Overview of manual operation from HIS

B5.1 HIS interfaces of MOB_11 and MOB_21 (BOOL-type data manual operation function block with answerback)

BOOL-type data manual operation function blocks with answerback have 1 or 2 DI inputs, which are typically used to connect the answerback input from a limit switch, and 1 DO output, which is typically connected to a valve. In addition to manipulation of the output value from an HIS, it is possible to set the output value from the application logic.

BOOL-type data manual operation function blocks with answerback also have a parameter for receiving shutdown events; they can output shutdown logic signals with the highest priority at occurrence of shutdown events.

This section explains the following functions of MOB_11 and MOB_21.

- Manual Operation Permission Function
- Password at Manual Operations
- Output Enable Status Display Function
- Answerback check
- Monitoring IOP and OOP

SEE ALSO For more information about description of the MOB_11 parameters, refer to:

7.4, “MOB_11 (BOOL-type data manual operation function block with two-position answerback)” in POU Reference Manual (IM 32P03B20-01EN)

For more information about description of the MOB_21 parameters, refer to:

7.5, “MOB_21 (BOOL-type data manual operation function block with three-position answerback)” in POU Reference Manual (IM 32P03B20-01EN)

Types of BOOL-type data manual operation function blocks with answerback

There are two types of BOOL-type data manual operation function blocks with answerback, which are distinguished by the number of answerback inputs.

- MOB_11 (BOOL-type Data manual operation function block with two-position answerback)
  This type corresponds to SIO-11 function block of FCS and receives answerback input from either one of the limit switches, open or close.
- MOB_21 (BOOL-type data manual operation function block with three-position answerback)
  This type is also corresponds to SIO-21 function block of FCS and receives answerback input from both limit switches, open and close.

SEE ALSO For more information about FCS switch instruments, refer to:

- 2.4, "Switch Instrument Block and Enhanced Switch Instrument Block" in the Function Blocks Reference Vol.2 (IM 33J15A31-01EN)
- 2.4, "Switch Instrument Block and Enhanced Switch Instrument Block" in the Function Blocks Reference Vol.2 (IM 33K03E23-50E)

Example of configuration of MOB_11 and MOB_21

The figure below shows a usage example of MOB_11 in a CENTUM integration structure.

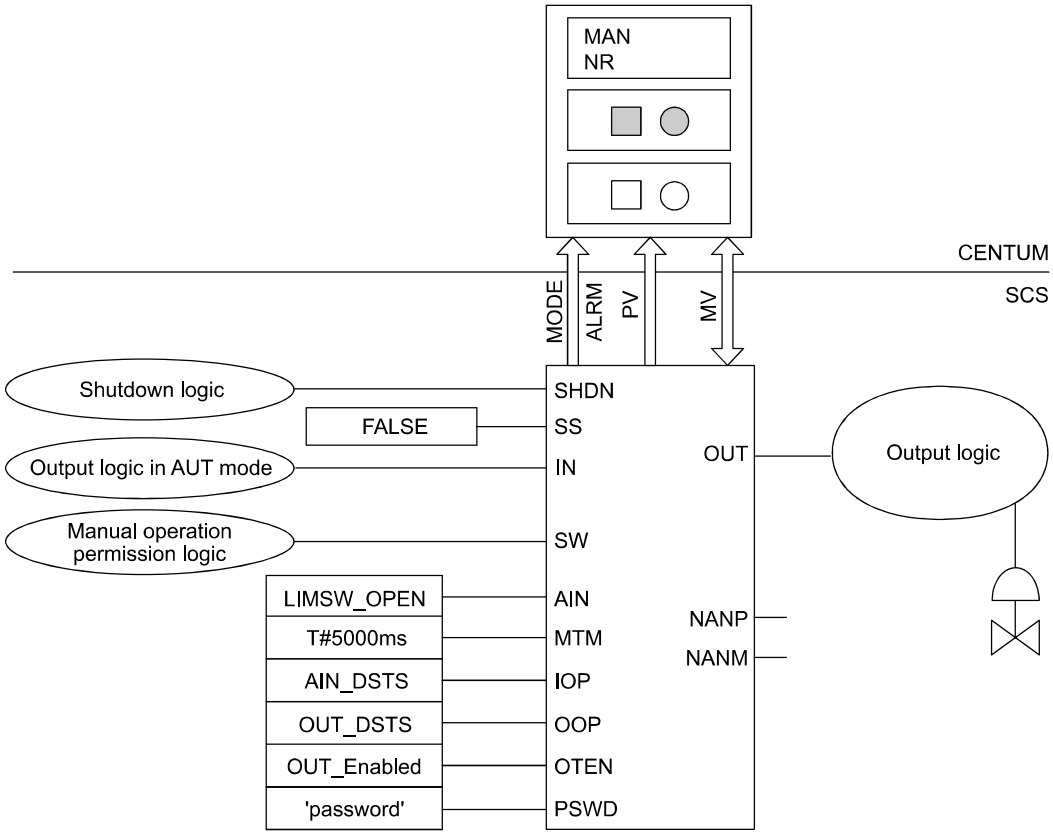

Figure B5.1-1 Usage example of BOOL-type data manual operation function block with two-position answerback

The figure below shows a usage example of MOB_21 in a CENTUM integration structure.

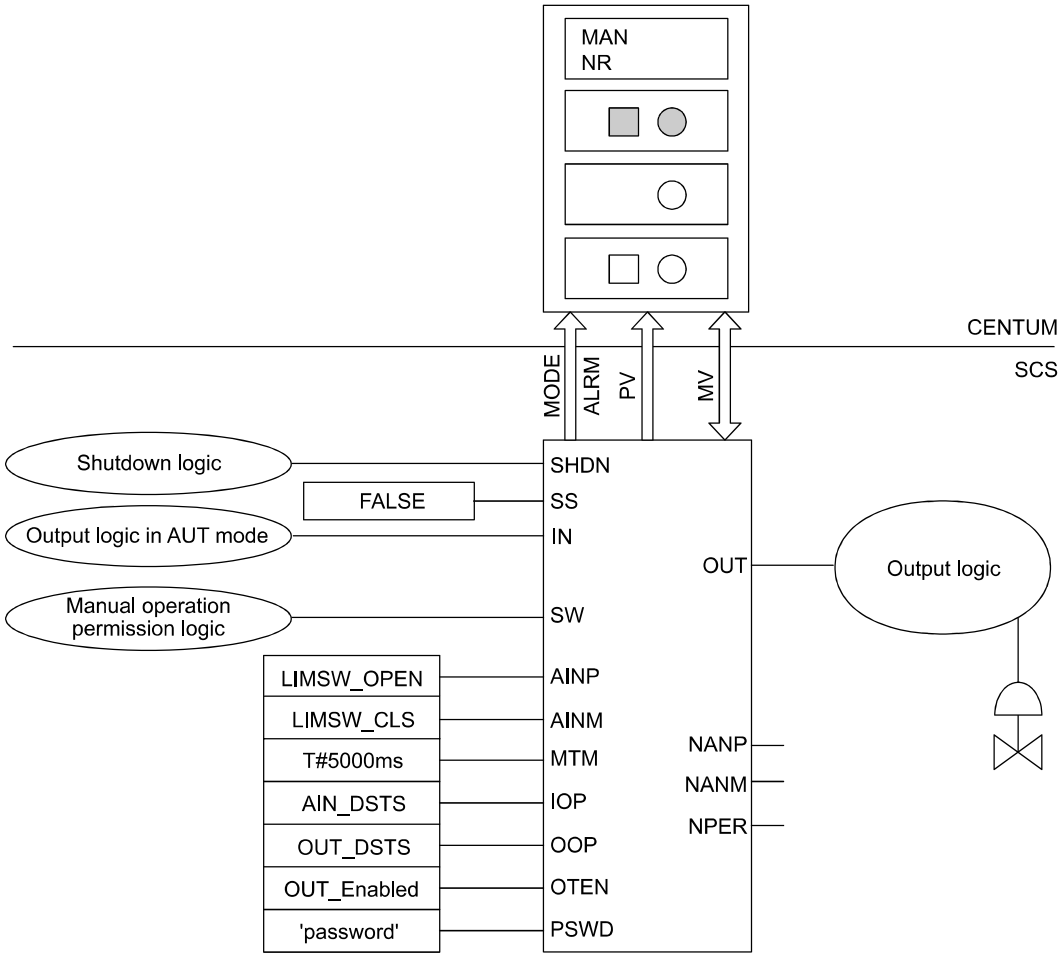

Figure B5.1-2 Usage example of BOOL-type data manual operation function block with three-position answerback

The associated parameter values of SCS function blocks are sent to indicate the block mode (MODE), process alarms (ALRM) and answerback input values (PV) on the CENTUM side via mapping blocks. The value of OUT is displayed as MV on the HIS instrument faceplate and operations on MV from the HIS are sent to OUT of the SCS in the manual mode (MAN).

Overview of processing BOOL-type data manual operation function block with answerback

The figure below shows an overview of the processing of BOOL-type data manual operation function blocks with answerback in SCS and data flow.

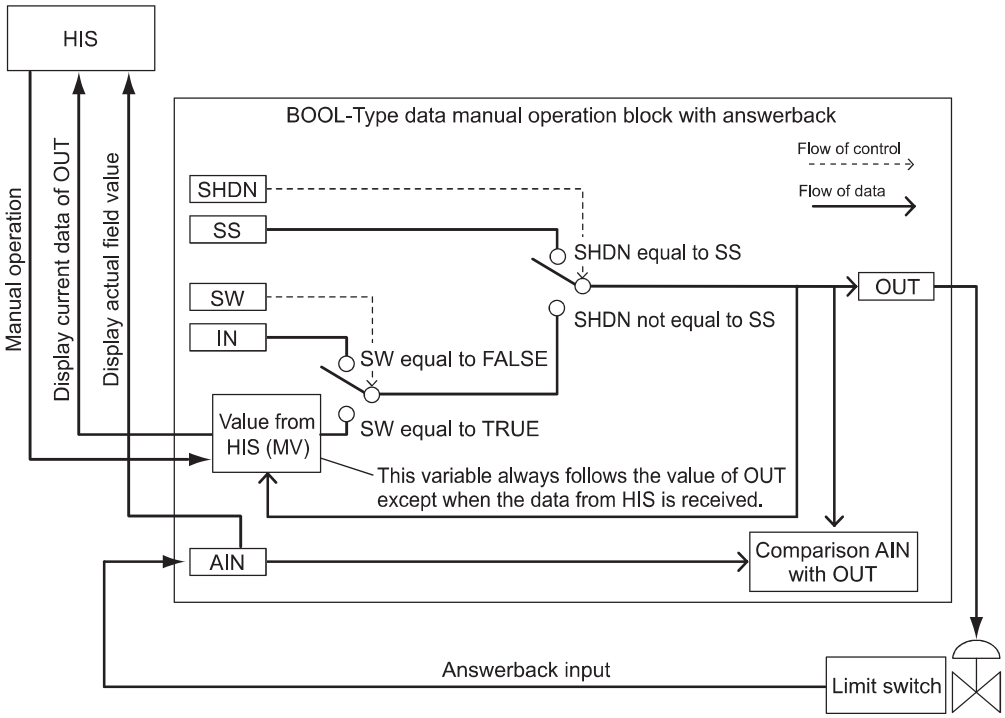

Figure B5.1-3 Flow of control and data (example of MOB_11)

Shutdown processing

If the input value of SHDN (shutdown signal) matches the safe state specified by the input value of SS, the safe state is output from OUT. At this point, all data settings from input parameters other than SHDN and SS as well as an HIS are ignored.

Prohibition of manual operations

If the input value of SHDN does not match the safe state specified by the input value of SS and the manual operation permit switch SW is set to FALSE (manual operations prohibited), data input to IN is output to OUT as is. If an operator attempts to perform manual operations from an HIS when the input to SW is FALSE, the attempt will fail. IN can be used to change the output value of OUT from the application logic when no shutdown instruction is input to SHDN (i.e., the system is in a safe state).

For example, after the value of SHDN becomes FALSE in the DTS logic and the valve closes, FALSE should be input to SW and the IN value kept as FALSE. In this way, it is possible to prevent the valve from opening immediately when the value of SHDN becomes TRUE as the shutdown conditions are removed.

Permission of manual operations

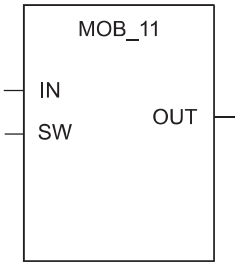
If the input value of SHDN does not match the safe state specified by the input value of SS and SW is set to TRUE (manual operations permitted), the result of manual operations carried out by an operator from an HIS is output from OUT. Note that password entry is required to perform manual operations. The password is checked within a function block. If the passwords do not match, the value of OUT does not change. The status where manual operations are permitted can be used when it is desired to open/close a valve by a user operation without issuing a shutdown instruction from SHDN (i.e., the system is in a safe state).

Answerback check

Regardless of whether the input to SW is TRUE or FALSE, it is checked whether the OUT value and answerback input value match as an answerback input check.

For example, by connecting OUT to the output signal to a valve and the answerback input value (AIN for MOB_11) to the limit switch of the valve, it is possible to confirm that the output

result of OUT is correctly transmitted to the process. It is also possible to bypass the answerback input value check for a fixed period of time only after changing the value of OUT, taking into consideration the time that the valve requires to change from full open to full close.



B5.1.1 Manual operation permission function

With MOB_11 and MOB_21, it is possible to switch between whether or not manual operations from an HIS are permitted. If MV is manipulated from an HIS when manual operations are permitted, the output from OUT of function blocks is set accordingly. Prohibition of manual operations can be used to prevent operations from an HIS at occurrence of demands other than shutdown to output a value determined by the application logic.

Switching between whether or not manual operations are permitted

In MOB_11 and MOB_21, it is possible to specify whether or not manual operations are permitted. When shutdown events occur, however, the shutdown processing takes the priority, and outputs set by manual operations as explained in this section and outputs from the application logic connected to IN become invalid.

The following parameters are related to specification of whether or not manual operations are permitted in MOB_11 and MOB_21.

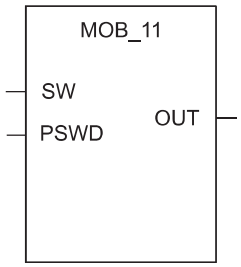
Note: Other parameters are omitted.

Figure B5.1.1-1 Parameters related to manual operations

Overview of manual operations

- SW is TRUE: The value set by a manual operation from an HIS to this FB is output from OUT.
- SW is FALSE: The value input to IN is output from OUT.

Details of manual operations



- If the input value of SW is TRUE, manual operations from an HIS are permitted. This status is called manual mode and MAN is displayed for the block mode in HIS instrument faceplate. The value of OUT changes according to the changes of MV which is manipulated from an HIS (for example, from a instrument faceplate). The value of IN is not used.
- If the input value of SW is FALSE, manual operations from an HIS are not allowed. The value determined by the application logic and input to IN of a function block is output from OUT. If the value of OUT changes due to a change in the input to IN, the associated MV value on the CENTUM side also changes accordingly. This status is called automatic mode and AUT is displayed for the block mode in HIS instrument faceplate.

B5.1.2 Password at manual operations

It is possible to prompt users to enter passwords for the purpose of limiting the member of users that are able to manipulate function blocks via manual operations from an HIS.

■ Password processing

The following parameters are related to password entry when manual operations are permitted.

Note: Other parameters are omitted.

Figure B5.1.2-1 Parameters related to password entry when manual operations are permitted

● Overview

- Set a password in PSWD when you create POU.
- If the input to SW is TRUE, manual operations from an HIS are permitted and entry of a password is required when an operator enters a value for MV. Manipulations of MV are permitted only if the set password and the input password match.

● Setting password character string

A password for allowing MV manipulations from an HIS should be set in PSWD in advance. Set PSWD as follows:

- Specify a password character string as a character constant.
- A character string of up to 16 single-byte alphanumeric characters can be set. If you specify a character string exceeding 16 characters, only the first 16 characters are set as the password character string and the remaining part is ignored.
- It is recommended to specify a password character string for each instance of the function blocks that require passwords (PASSWD, MOB_21, MOB_11 and MOA) and be sure each password is unique within a system.
- If it is not necessary to restrict MV manipulations by password entry, set an empty character string for PSWD. You can specify from the SCS Constants Builder whether to skip the display of the Password Input dialog box on HIS when an empty string constant is set in PSWD of the function block.

SEE ALSO For more information about "● specification to skip the Password Input dialog box" in "■ Settings with the Communication Tab" in C1.2.6, "SCS Constants Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN), refer to:

"● Skip password dialog box for manual operation FB" in "■ Settings with the Communication Tab" in C1.2.6, "SCS Constants Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

● Operation in HIS

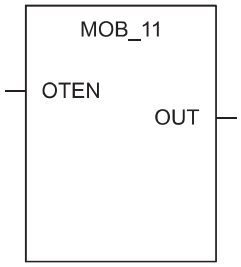
If the input to SW is TRUE, i.e., the system is in the manual mode (MAN), a user is allowed to perform manual operations from an HIS. After inputting MV, the user is required to enter a password.

The entered password is checked within the SCS function block. If the password is incorrect, a warning message for the illegal operation will be displayed and the MV will be unchanged.

TIP

Even if you set an empty string constant in the PSWD of the function block, if you do not specify that display of the Password Input dialog box should be skipped in SCS Constants Builder, the Password Input dialog box appears on HIS. In this case, just press the Enter key.

Regardless of whether the Password Input dialog box is displayed or not, the reconfirmation dialog box is displayed.



If a communication error with an HIS occurs during manual operations, OUT retains the current value.

B5.1.3 The Output Enable status display function

It is possible to display the output enable status in the instrument faceplate.

The Output Enable status display

The following parameters are related to output enable status display of MOB_11 and MOB_21.

Note: Other parameters are omitted.

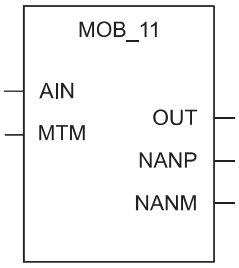
Figure B5.1.3-1 Parameters related to the Output Enable status display

Overview of the Output Enable status display

If a signal indicating output enable status is input to OTEN, the output enable status is displayed in HIS instrument faceplate as block mode. If the value of OTEN is FALSE, IMAN is displayed as block mode.

Details of the Output Enable status display

Acquire the output status associated with the channel connected to OUT by using an SYS_OUTEN, SYS_N_OUTEN, or SYS_CH_OUTEN function block, and then connect it to OTEN.



The value of OTEN does not affect output behaviors or answerback check operations of MOB_11 and MOB_21.

B5.1.4 Answerback check function

The operation of answerback check is different for MOB_11 and MOB_21.

Answerback check of MOB_11

The following parameters are related to answerback check of MOB_11.

Note: Other parameters are omitted.

Figure B5.1.4-1 Parameters related to answerback check of MOB_11

The table below explains the parameters.

Table B5.1.4-1 Explanation of parameters related to answerback check

IN/OUT	Arguments	Data type	Description
IN	AIN	BOOL	Answerback input value TRUE: Open status FALSE: Close status
	MTM	TIME	Answerback check mask time (Must be an integer multiple of the scan period)
OUT	OUT	BOOL	Open/close operation output value TRUE: Open instruction FALSE: Close instruction
	NANP	BOOL	Answerback status of the open side TRUE: Normal status FALSE: Abnormal status
	NANM	BOOL	Answerback status of the close side TRUE: Normal status FALSE: Abnormal status

Details of answerback processing for MOB_11

- Answerback check operation
  In an answerback check operation, the answerback input value (AIN) is compared with the OUT value to see if they are the same. The check result is output from NANP (answerback status of the open side) and NANM (answerback status of the close side) of a function block as well as notified to an HIS as a process alarm (ANS+ or ANS-) on the CENTUM side.

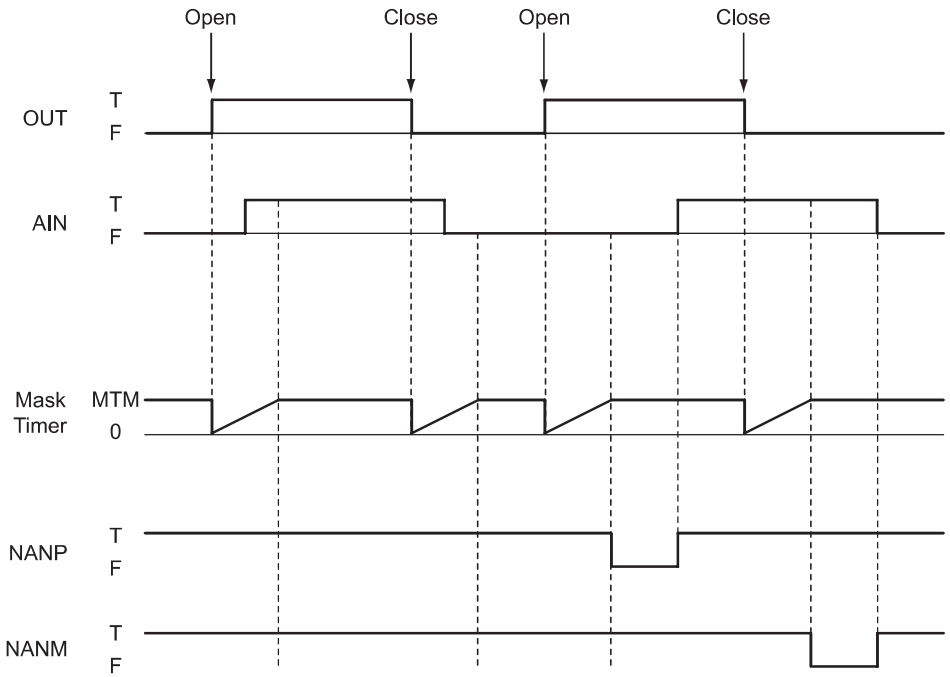
  Note that detection of answerback errors does not affect the output behavior of OUT.

- Answerback check mask
  In practice, it takes some time for operations to be completed after changing the value of OUT. For this reason, MOB_11 is equipped with MTM (answerback check mask time). By setting this parameter, it is possible to prevent errors from being notified for a fixed time specified by MTM after OUT is changed, even if the value of OUT and the answerback input values are different. After the value of OUT is changed, if the answerback input status is still abnormal after the time specified by MTM has elapsed, answerback errors on the open and close sides are output to NANP and NANM, respectively.

- Timing to perform answerback check processing
  The answerback check and answerback check mask processing can be performed either while a shutdown instruction is being output, application logic signals are being output because the input to SW is FALSE, or manual operations from an HIS are performed because the input to SW is TRUE.

Relationship between answerback check and parameters

The figure below shows how each parameter changes due to answerback check processing.



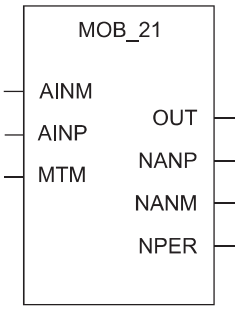


Figure B5.1.4-2 Detection of answerback errors in MOB_11

- When OUT changes, the mask timer for answerback check will be started. The mask for answerback check will continue until the time specified by MTM has elapsed. Within this masked time period, the answerback error will be ignored.
- Immediately after the value of OUT is changed, TRUE (normal) is set to NANP and NANM once. Process alarms of answerback errors are also canceled once.

Answerback check for MOB_21

The following parameters are related to answerback check of MOB_21.

Note: Other parameters are omitted.

Figure B5.1.4-3 Parameters related to answerback check of MOB_21

The table below explains the parameters.

Table B5.1.4-2 Explanation of parameters related to answerback check

IN/OUT	Arguments	Data type	Description
IN	AINP	BOOL	Answerback input value on the open side TRUE: Full open status FALSE: Not full-open status
	AINM	BOOL	Answerback input value on the close side TRUE: Full close status FALSE: Not full-close status
	MTM	TIME	Answerback check mask time (Must be an integer multiple of the scan period.)
OUT	OUT	BOOL	Open/close operation output value TRUE: Open instruction FALSE: Close instruction
	NANP	BOOL	Answerback status of the open side TRUE: Normal status FALSE: Abnormal status
	NANM	BOOL	Answerback status of the close side TRUE: Normal status FALSE: Abnormal status
	NPER	BOOL	Answerback pattern TRUE: Normal status FALSE: Abnormal status

Details of answerback processing of MOB_21

- Answerback check operation
  In the case of MOB_21, the input values of both AINP (answerback input value of the open side) and AINM (answerback input value of the close side) are compared with the value of OUT to see if they are the same in the answerback check processing. The check result is output from NANP (answerback status of the open side) and NANM (answerback status of the close side) of a function block as well as notified to an HIS as a process alarm (ANS+ or ANS-) on the CENTUM side.

  MOB_21 checks answerback pattern errors as well. Answerback pattern errors refer to an abnormal status where a full open signal and a full close signal are input at the same time. If a status where AINP (answerback input value of the open side) is TRUE (full open status) and AINM (answerback input value of the close side) is also TRUE (full close status) occurs,

  - FALSE (abnormal status) is output from NPER (answerback pattern)
  - and is also notified to the HIS as a process alarm (PERR) on the CENTUM side.

  Note that detection of answerback errors does not affect the output behavior of OUT.

- Answerback check mask
  In practice, it takes some time for operations to be completed after changing the value of OUT. For this reason, MOB_21 is equipped with MTM (answerback check mask time). By setting this parameter, it is possible to prevent errors from being notified for a fixed time specified by MTM after OUT is changed, even if the value of OUT and the answerback input values are different. After the value of OUT is changed, if the answerback input status is still abnormal after the time specified by MTM has elapsed, answerback errors on the open and close sides are output to NANP and NANM, respectively.

  Note that NPER (answerback pattern error) is detected independently of the answerback check mask time.

- Timing to perform answerback check processing
  The answerback check and answerback check mask processing can be performed either while

  - a shutdown instruction is being output,

- application logic signals are being output because the input to SW is FALSE,
- or manual operations from an HIS are performed because the input to SW is TRUE.

Relationship between answerback check and parameters

The figure below shows how each parameter changes due to answerback check processing.

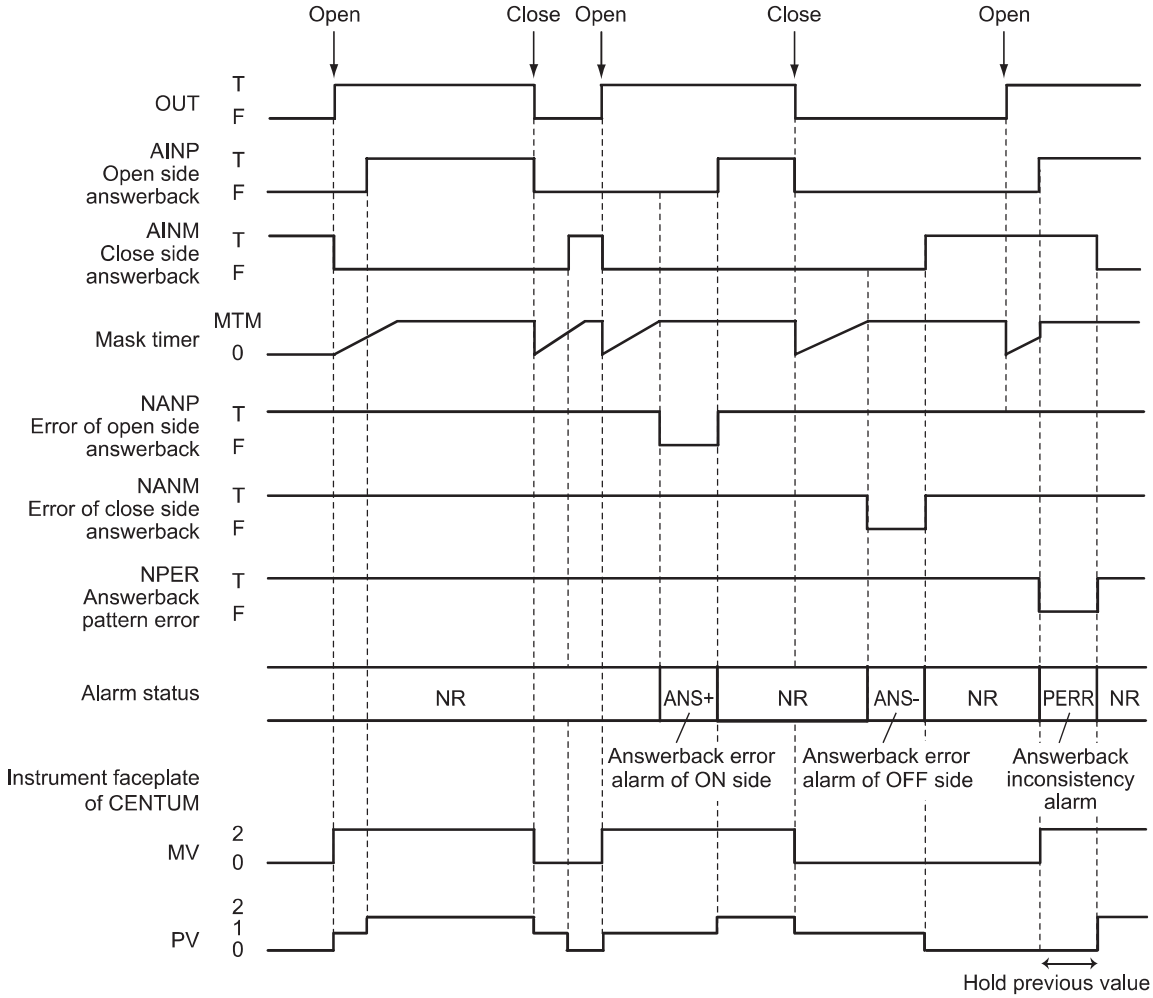

Figure B5.1.4-4 Detection of answerback errors in MOB_21

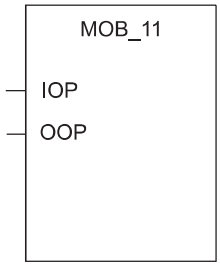

- When OUT changes, the mask timer for answerback check will be started. The mask for answerback check will continue until the time specified by MTM has elapsed. Within this masked time period, the answerback error will be ignored.
- Immediately after the value of OUT is changed, TRUE (normal) is set to NANP and NANM once. Process alarms of answerback errors are also canceled once.
- In the case of an answerback pattern error (NPER is FALSE), the answerback statuses on both the open and close sides (NANP and NANM) are retained.
- In detection of answerback pattern errors (NPER), answerback check mask is ignored. FALSE (abnormal) is thus output to NPER as soon as the conditions for pattern error are met (AINP = TRUE and AINM = TRUE).
- When the answerback check is masked and the answerback pattern error occurs, the answerback check mask will be disabled. If the answerback pattern error is recovered and the answerback check is performed, the results will be available in NANP and NANM.

B5.1.5 Monitoring IOP and OOP

IOP and OOP are functions that monitor the statuses of inputs and outputs and notify process alarms on the CENTUM side. Inputs to IOP and OOP do not affect output operations and answerback check operations of the function block.

Parameters related to IOP/OOP

Parameters related to IOP and OOP are the same for MOB_11 and MOB_21.

Note: Other parameters are omitted.

Figure B5.1.5-1 Parameters related to IOP and OOP

The table below explains the parameters.

Table B5.1.5-1 Explanation of parameters related to IOP/OOP

IN/OUT	Arguments	Data type	Description
IN	IOP	BOOL	Signal for monitoring input status TRUE: Normal status FALSE: Abnormal status
	OOP	BOOL	Signal for monitoring output status TRUE: Normal status FALSE: Abnormal status

Signal connection to IOP

- In the case of MOB_11, connect the data status of the answerback input (input variable connected to AIN) and similar signals to IOP.
- In the case of MOB_21, connect the logical product of the data statuses of the two answerback inputs (input variables connected to AINP and AINM) and similar signals to IOP.

Signal connection to OOP

Connect the data status of the output (output variable connected to OUT) and similar signals to OOP.

B5.1.6 Tag name interfaces and process alarms of MOB_11 and MOB_21

In order to manually operate BOOL-type data manual operation function blocks with answerback from an HIS, it is necessary to specify the tag names using the Tag Name Builder and associate them with mapping blocks. This allows them to be called via tag names and notification of process alarms.

The following mapping blocks are associated with BOOL-type data manual operation function blocks with answerback.

- Mapping blocks of MOB_11: S_MOB_11
- Mapping blocks of MOB_21: S_MOB_21

■ Settings in the Tag Name Builder

To perform manual operations from an HIS, make settings for the relevant instances of MOB_11 and MOB_21 in the Tag Name Builder. Specify whether or not to notify answerback error alarms according to the following procedure.

- Answer back Alarm (answerback error alarm)
  Specify either [Both], [ON], [OFF] or [No].

  The default is [Both].

  Specify [ON] to detect only ANS+ alarms (PV ≠ 2 when MV = 2) and [OFF] to detect only ANS- alarms (PV ≠ 0 when MV = 0).

■ Data items of S_MOB_11 and S_MOB_21

Among the data items of mapping blocks, the data items unique to S_MOB_11 and S_MOB_21 are explained here. All of these data items are displayed in the HIS tuning view.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

● MODE (block mode)

This data item indicates block mode. The block mode cannot be changed into AUT or MAN from an HIS. The default value of MODE is O/S (AUT).

- Associating parameters of function blocks
  The SHDN (shutdown signal), SS (safe state specification), SW (manual operation permit/prohibit toggle switch) and OTEN (signal indicating output enable status) parameters of a function block are associated with MODE.
- Changes of block mode (AUT/MAN)
  The block mode becomes AUT if SHDN matches with SS (safe state specification). If they do not match, the block mode becomes MAN if TRUE is input to the function block parameter SW, and AUT if FALSE is input to SW.
- Changes of block mode (output enable status)
  The block mode IMAN is added to the block mode if OTEN is FALSE and IMAN is removed from the block mode if OTEN is TRUE.

● ALRM (alarm status)

This data item displays alarm status.

Data entry from an HIS is not allowed.

The default value of ALRM is NR.

SHDN (shutdown signal)

This data item displays signals used for shutdown logic. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The SHDN parameter (shutdown signal) of a function block is associated with SHDN. The SHDN value of a function block is reflected in this data item.
- Range
  The range of SHDN is 0 or 1.
- Correspondence between changes of the parameter value of function blocks and changes of SHDN
  Changes of the SHDN (shutdown signal) value of a function block match with changes of SHDN.

  If the value of SHDN matches with SS (safe state specification), the value of SHDN is output as a shutdown signal from the OUT parameter (corresponding to the data item MV) of a function block.

SS (safe state specification)

This data item displays the safe state (value output as a shutdown signal) of a shutdown signal. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The SS parameter (safe state specification) of a function block is associated with SS. The SS value of a function block is reflected in this data item.
- Range
  The range of SS is 0 or 1.

INV (logic input value)

This data item is associated with the value specified to be output under conditions where the shutdown logic is not effective and operations from an HIS are prohibited. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The IN parameter (specified output value when manual operations are prohibited) of a function block is associated with INV. The default value of IN of MOA is reflected in this data item.
- Range
  The range of INV is 0 or 2.
- Correspondence between changes of the parameter value of function blocks and changes of INV
  INV is 2 if the IN parameter of a function block is TRUE and 0 if IN is FALSE.

SW (switch)

This data item displays the status of the manual operation permit/prohibit toggle switch of the FB. Data entry from an HIS is not allowed.

The value of the data item SW is determined as follows according to the value of the FB parameter and the SCS Constants Builder specification.

Table B5.1.6-1 Value set for data item SW

SW of FB	PSWD of FB	SCS Constants Builder specification	Data item SW
FALSE	- (*1)	- (*1)	0

Continues on the next page

Table B5.1.6-1 Value set for data item SW (Table continued)

SW of FB	PSWD of FB	SCS Constants Builder specification	Data item SW
TRUE	Other than an empty string constant	- (*1)	1
	Empty string constant	Do not skip the Password Input dialog box.	1
		Skip the Password Input dialog box.	2

*1: It does not affect the value of data item SW

PV (answerback input value)

This data item displays answerback input signals of a function block. Data entry from an HIS is not allowed. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  For MOB_11, the AIN parameter (answerback input value), and for MOB_21, the combination of values of AINP (answerback input value of the open side) and AINM (answerback input value of the close side) is associated with PV.
- Range
  The range of PV is 0, 1 or 2.
- Correspondence between changes of the parameter value of MOB_11 and changes of PV
  PV=2 if AIN (answerback input value) of MOB_11 is TRUE (open) and PV=0 if FALSE (close).
- Correspondence between changes of the parameter value of MOB_21 and changes of PV
  In MOB_21, the value of PV changes according to the combination of values of AINP (answerback input value of the open side) and AINM (answerback input value of the close side).
  - PV=2 if AINP=TRUE (full open) and AINM=FALSE (not full-close)
  - PV=1 if AINP=FALSE (not full-open) and AINM=FALSE (not full-close)
  - PV=0 if AINP= FALSE (not full-open) and AINM=TRUE (full close)
  - PV retains the previous value if AINP=TRUE (full open) and AINM=TRUE (full close)
- Default
  The default value (0) of the associated parameter of the function block is reflected in the default value of PV.

MV (manipulated output value)

This data item is associated with the operation output value of a function block. Its value can be changed if manual operations from an HIS are permitted (MODE=MAN). It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The OUT parameter (open/close operation output value) of function blocks is associated with MV.
- Range
  The range of MV is 0 or 2.
- Correspondence between changes of the parameter value of function blocks and changes of MV

The value of OUT of the associated function block is TRUE (the operation output value is open) if MV=2, and OUT is FALSE (the operation output value is close) if MV=0.

When operations from an HIS are permitted (MODE=MAN), the output value OUT of a function block is changed if MV is manipulated from the HIS. Changes of the value of OUT can be monitored on the HIS as changes of MV.

- Default
  The default value of MV is 0.

MTM (mask time)

This data item display the answerback check mask time. The default value is 0. The unit is seconds and the fractional part indicates milliseconds. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The MTM parameter (answerback check mask time) of a function block is associated with MTM.

Process alarms

MOB_11 and MOB_21 notify process alarms of answerback error and IOP/OOP.

Answerback error alarms

If an answerback error occurs, a process alarm is notified when the associated parameter of a function block changes under the following conditions. Notification of generation of answerback pattern errors and recovery from the errors is made only from MOB_21.

- Notification of answerback error on the open side (ANS+): At a falling edge of NANP
- Notification of answerback error on the close side (ANS-): At a falling edge of NANM
- Notification of answerback pattern error (PERR): At a falling edge of NPER

If the system recovers from an answerback error, a process alarm is notified. The notification is made if the parameters of a function block change under the following conditions.

- Recovery notification of answerback error on the open side (ANS+ cancellation): At a rising edge of NANP
- Recovery notification of answerback error on the close side (ANS- cancellation): At a rising edge of NANM
- Recovery notification of answerback pattern error (PERR cancellation): At a rising edge of NPER

IOP and OOP

If you connect a signal indicating whether or not the answerback input signal is normal to the IOP parameter and a signal indicating whether or not the output signal is normal to the OOP parameter, input/output errors can be notified as process alarms. The notification is made if the parameters of a function block change under the following conditions.

- Input error occurrence alarm: At a falling edge of IOP
- Output error occurrence alarm: At a falling edge of OOP

The notification of recovery is made if the parameters of the function blocks change under the following conditions.

- Input error recovery alarm: At a rising edge of IOP
- Output error recovery alarm: At a rising edge of OOP

B5.2 HIS interfaces of MOB_RS (auto-reset BOOL-type data manual operation)

Auto-reset BOOL-type data manual operation function blocks output pulses when operated manually from an HIS.

B5.2.1 Operations of MOB_RS from HIS

This section explains the following functions of MOB_RS.

- Permission of manual operations and automatic reset of operation output values
- Answerback check

SEE ALSO For more information about description of the MOB_RS parameters, refer to:

7.6, “MOB_RS (auto-reset BOOL-type data manual operation)” in POU Reference Manual (IM 32P03B20-01EN)

Example of configuration of MOB_RS

The following figure shows a usage example of MOB_RS in a CENTUM integration structure.

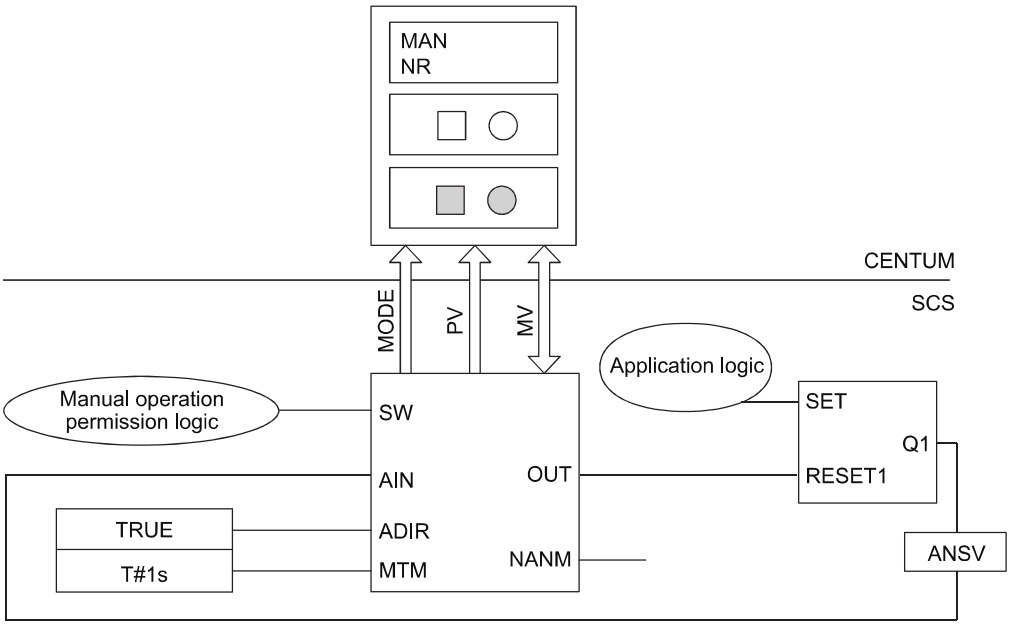

Figure B5.2.1-1 Overview of MOB_RS configuration

The associated parameter values of the SCS function block are sent to indicate the block mode (MODE) and answerback input value (PV) on the CENTUM side via the mapping blocks. The value of OUT is displayed as MV on the HIS instrument faceplate and operations on MV from the HIS are sent to OUT of the SCS in the manual mode (MAN).

Overview of processing MOB_RS

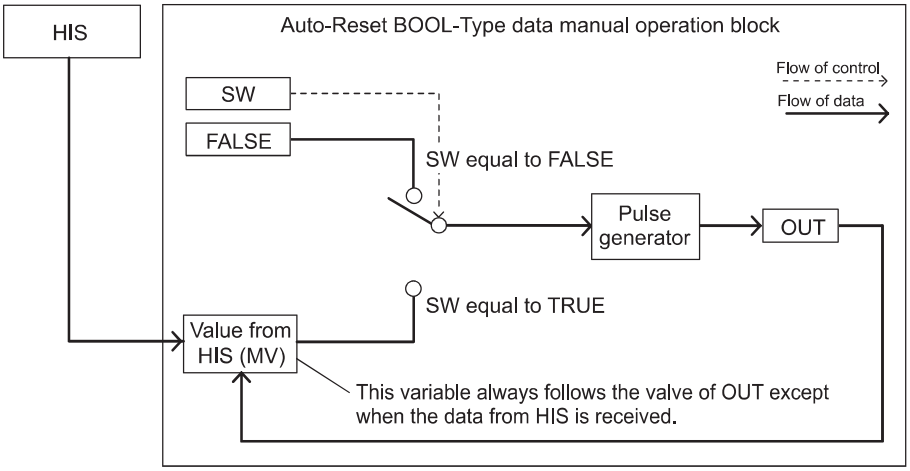

Figure B5.2.1-2 Flow of control and data of MOB_RS

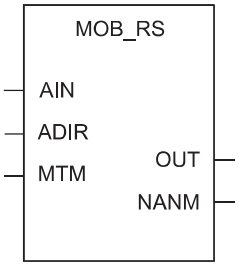

- Prohibition of Manual operations
  If the manual operation permit switch SW is FALSE, OUT is fixed to FALSE. If an operator attempts to perform manual operations from an HIS when the input to SW is FALSE (manual operations prohibited), the attempt will fail.
- Permission of Manual Operations and Automatic Reset of Operation Output Value
  Manual operations by an operator from an HIS are permitted if TRUE is input to SW. If MV is changed from 0 to 2 in an HIS, the output value of OUT of MOB_RS changes to TRUE. The output of OUT returns to FALSE automatically after the next scan in the scan period. The value of MV in the CENTUM system also returns to 0.

Confirmation of MOB_RS behavior via answerback input

The output value of MOB_RS caused by manual operations returns to FALSE quickly and an operator typically cannot check whether the manual operations were acknowledged or not. To alleviate this problem, it is a good idea to create a latch variable or similar that is reset by a pulse signal output from MOB_RS and input its value to the answerback input of MOB_RS. The changes of this value can then be displayed in the instrument faceplate. This way, it is possible to check whether the manual operations took effect through the instrument faceplate.

Answerback check

The following parameters are related to answerback check of MOB_RS.

Note: The SW parameter is omitted.

Figure B5.2.1-3 Parameters related to answerback check of MOB_RS

The table below explains the parameters.

Table B5.2.1-1 Explanation of parameters related to answerback check

IN/OUT	Argu-ments	Data type	Description
IN	AIN	BOOL	Answerback input value.
	ADIR	BOOL	Answerback operation direction specification. TRUE: Forward operation. FALSE: Reverse operation.
	MTM	TIME	Answerback check mask time (Must be an integer multiple of the scan period).
OUT	OUT	BOOL	Operation output value for logic reset (pulse signal).
	NANM	BOOL	Answerback status. TRUE: Normal status. FALSE: Abnormal status.

Answerback operation direction

Specify whether the answerback input signal becomes TRUE at normal or abnormal status, using the answerback operation direction specification (ADIR).

- Specification of forward operation
  A forward operation refers to an operation where the answerback signal is latched to TRUE when the specified events occur and return to FALSE due to the pulse output from OUT. Specify TRUE for ADIR.
- Specification of reverse operation
  A reverse operation refers to an operation where the answerback signal is latched to FALSE when the specified events occur and return to TRUE due to the pulse output from OUT. Specify FALSE for ADIR.

Answerback operation at forward operation

In a forward operation, the relationship between the output signal OUT and the answerback signal is as illustrated in the figure below.

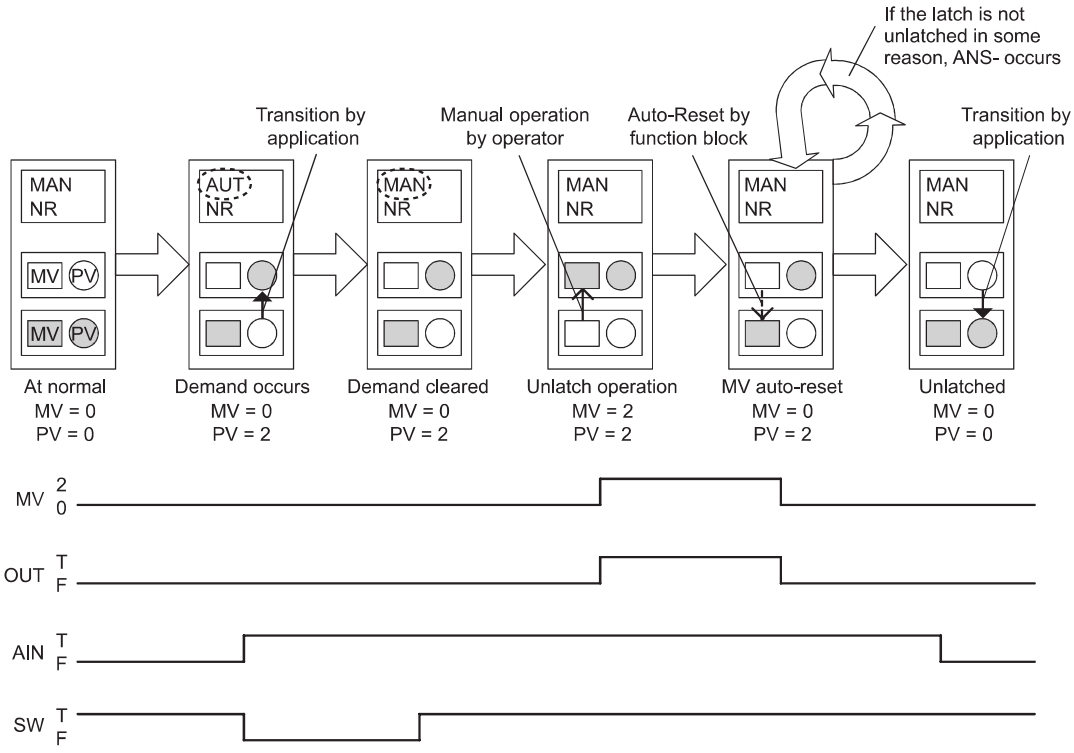

Figure B5.2.1-4 Relationship between MV manipulation and answerback (forward operation)

The data items of CENTUM and parameter values of MOB_RS are related in the following ways.

- The AIN parameter (answerback input value) of MOB_RS is associated with PV on the CENTUM side. PV=2 if AIN=TRUE and PV=0 if AIN=FALSE.
- The OUT parameter of MOB_RS is associated with MV on the CENTUM side. OUT=TRUE if MV=2 and OUT=FALSE if MV=0.

1. At normal status, MV=0 and FALSE is output to OUT of MOB_RS.
2. Create application logic such that AIN of MOB_RS is latched to TRUE at the occurrence of a demand. If AIN becomes TRUE, PV becomes 2.
3. If MV is changed to 2 from an HIS to reset the latch, OUT of MOB_RS changes to TRUE. OUT returns to FALSE after one scan (automatic reset).
4. Create application logic such that the latch is reset upon changes of OUT from FALSE to TRUE and AIN returns to FALSE. PV becomes 0 if AIN becomes FALSE.

Answerback operation at reverse operation

In a reverse operation, the relationship between the output signal OUT and the answerback signal is as illustrated in the figure below.

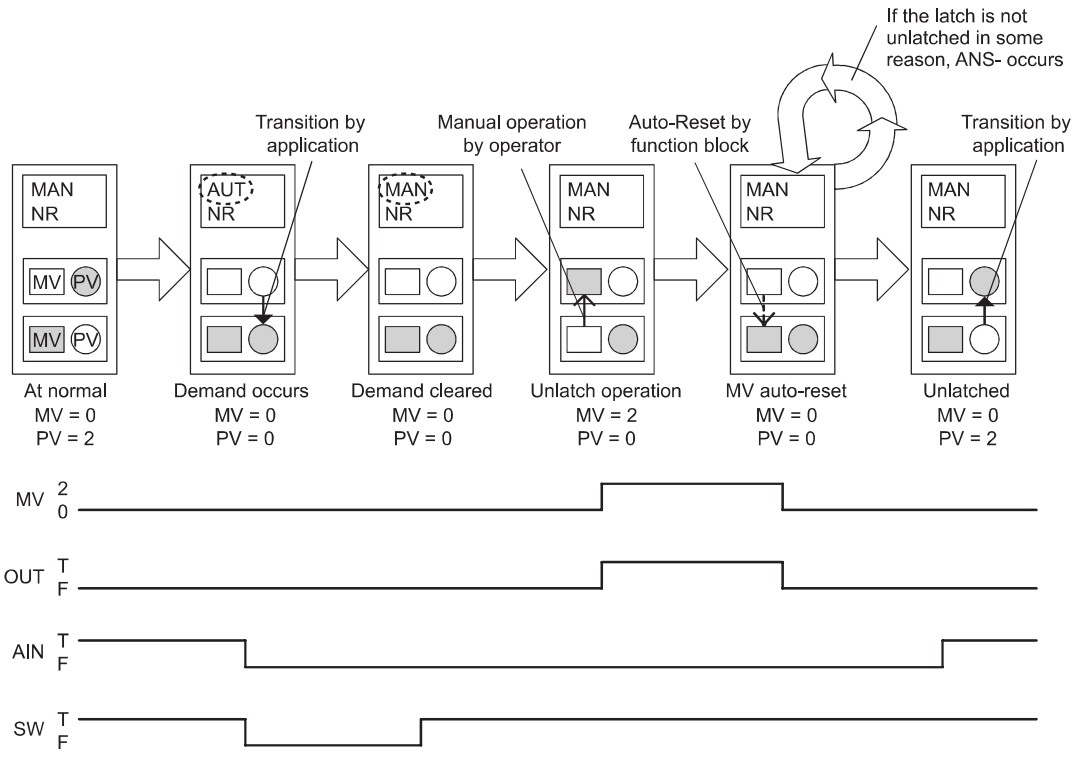

Figure B5.2.1-5 Relationship between MV manipulation and answerback (reverse operation)

A reverse operation is normal if the values of PV and MV are opposite in the HIS instrument faceplate.

Notification of answerback errors

An answerback error occurs if AIN (answerback signal) does not return to the normal value within the time specified by MTM (answerback check mask time) after a pulse signal is generated by manipulation of MV. The normal value of AIN is FALSE in the case of forward operations and TRUE in the case of reverse operations. If an answerback error is detected, FALSE is output from NANM (answerback status) and a notification is made to an HIS as a process alarm (ANS-) on the CENTUM side.

The system recovers from an answerback error if MV is manipulated again or AIN (answerback signal) returns to the normal value. On recovery, TRUE is output from NANM (answerback status).

Note that if 0 seconds are specified for MTM, answerback check is started from the next scan after OUT becomes TRUE.

B5.2.2 Tag name interfaces and process alarms of MOB_RS

In order to manually operate auto-reset BOOL-type data manual operation function blocks from an HIS, it is necessary to specify the tag names using the Tag Name Builder and associate them with mapping blocks. This allows them to be called via tag names and notification of process alarms.

Mapping blocks associated with auto-reset BOOL-type data manual operation function blocks are S_MOB_RS.

■ Settings in the Tag Name Builder

To perform manual operations from an HIS, make settings for the relevant instances of MOB_RS in the Tag Name Builder. Specify whether or not to notify answerback error alarms according to the following procedure.

- Answer back Alarm (answerback error alarm)
  Specify either [Both] or [No].

  Specify [Both] to notify answerback error alarms. Only ANS- process alarms are generated even if [Both] is specified.

■ Data items of S_MOB_RS

Among the data items of mapping blocks, the data items unique to S_MOB_RS are explained here. All of these data items are displayed in the HIS tuning view.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

● MODE (block mode)

This data item indicates block mode. The block mode cannot be changed into AUT or MAN from an HIS. The default value of MODE is O/S (AUT).

- Associating parameters of function blocks
  The SW parameter (manual operation permit/prohibit toggle switch) of MOB_RS is associated with MODE.
- Changes of block mode (AUT/MAN)
  The block mode becomes MAN if TRUE is input to SW, and AUT if FALSE is input.

● ALRM (alarm status)

This data item displays alarm status.

Data entry from an HIS is not allowed.

The default value of ALRM is NR.

● PV (answerback input value)

This data item displays answerback input signals connected to MOB_RS. Data entry from an HIS is not allowed. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The AIN parameter (answerback input value) of MOB_RS is associated with PV.
- Range
  The range of PV is 0 or 2.

- Correspondence between changes of the parameter value of MOB_RS and changes of PV
  PV=2 if AIN (answerback input value) of MOB_RS is TRUE and PV=0 if FALSE.
- Default
  The default value (0) of AIN is reflected in the default value of PV.

MV (manipulated output value)

This data item is associated with the operation output value of MOB_RS. Its value can be changed if manual operations from an HIS are permitted (block mode=MAN). It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The OUT parameter (logic reset operation output value) of MOB_RS is associated with MV.
- Range
  The range of MV is 0 or 2.
- Correspondence between changes of the parameter value of function blocks and changes of MV
  MV=2 if OUT of MOB_RS is TRUE and MV=0 if FALSE.

  When operations from an HIS are permitted (MODE=MAN), OUT of MOB_RS changes if MV is manipulated from the HIS.
- Default
  The default value of MV is 0.

SW (switch)

This data item displays the status of the manual operation permit/prohibit toggle switch of MOA. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The SW parameter (manual operation permit/prohibit toggle switch) of a function block is associated with SW. The SW value of MOB_RS is reflected in this item.
- Range
  The range of SW is 0 or 1.

MTM (mask time)

This data item display the answerback check mask time. The unit is seconds and the fractional part indicates milliseconds. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The MTM parameter (answer back check mask time) of MOB_RS is associated with MTM.
- Default
  The default value of MTM is 0.

Process alarms

MOB_RS notifies answerback error alarms.

Answerback error alarms

If an answerback error occurs, a process alarm is notified when NANM of MOB_RS changes under the following condition.

- Notification of answerback error occurrence (ANS-): At a falling edge of NANM

B5.3 HIS interfaces of MOA (analog-type data manual operation)

Analog-type data manual operation function blocks can monitor the values of analog output variables via an HIS, and it is possible to change the output values from the HIS.

Analog-type data manual operation function blocks also have a parameter for receiving shut-down events and are able to output the shutdown logic signal with the highest priority at the occurrence of a shutdown event.

B5.3.1 Operations of MOA from HIS

This section explains the following functions of MOA.

- Feedback input
- OOP detection

The password for manual operations is the same as MOB_11 and MOB_21.

SEE ALSO For more information about password for allowing manual operation, refer to:

B5.1.2, “Password at manual operations” on page B5-9

For more information about display of output enabled status, refer to:

B5.1.3, “The Output Enable status display function” on page B5-11

For more information about description of MOA parameters, refer to:

7.7, “MOA (analog-type data manual operation)” in POU Reference Manual (IM 32P03B20-01EN)

Example of configuration of MOA

The figure below shows a usage example of MOA in a CENTUM integration structure.

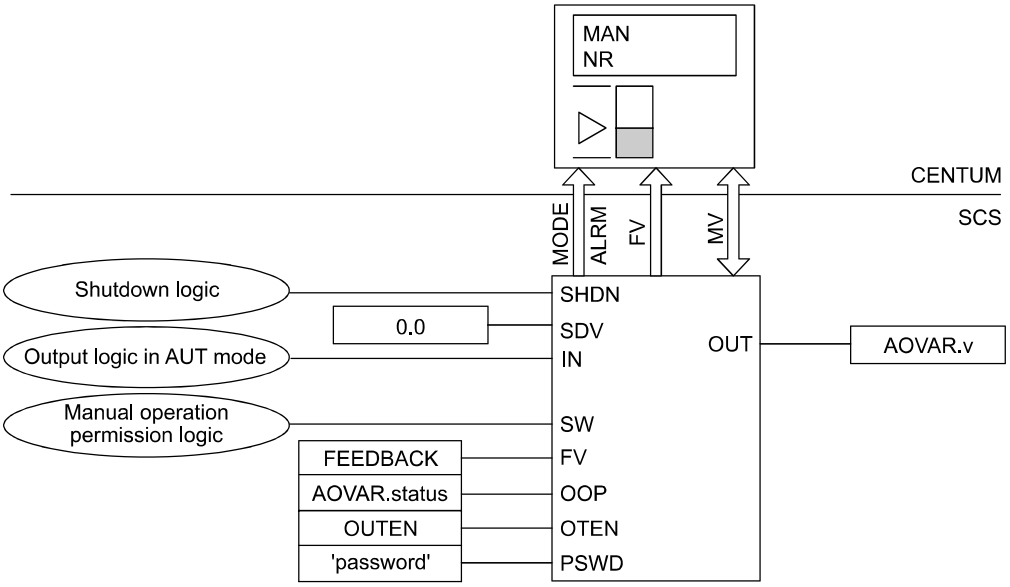

Figure B5.3.1-1 Analog-type data manual operation function blocks

The associated parameter values of the SCS function block are sent to indicate the block mode (MODE), process alarms (ALRM) and feedback input value (FV) on the CENTUM side via the mapping blocks. The value of OUT is displayed as MV on the HIS instrument faceplate and operations on MV from the HIS are sent to OUT of the SCS in the manual mode (MAN).

Overview of processing MOA

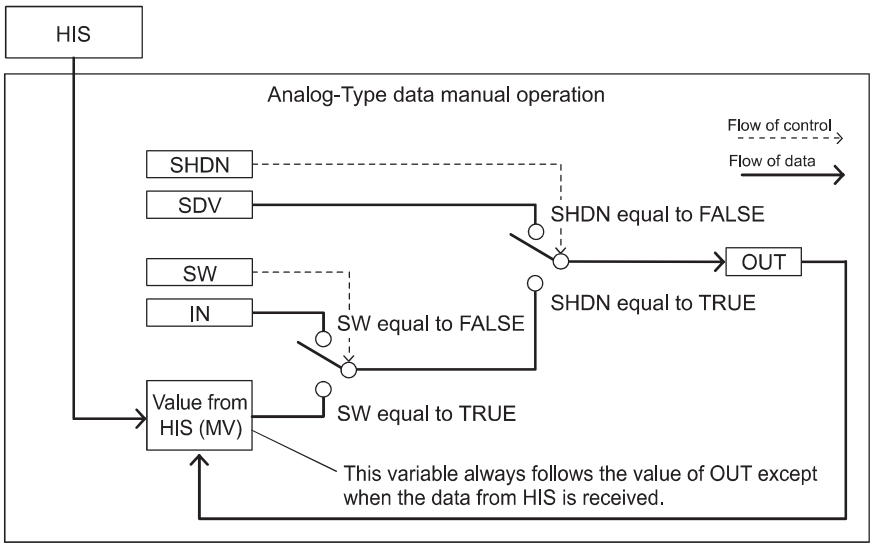

Figure B5.3.1-2 Flow of control and data (MOA)

Shutdown processing

If the input value of SHDN (shutdown signal) becomes FALSE, the value of SDV (shutdown output value) is output from OUT. At this point, all data settings from input parameters other than SHDN and SDV as well as an HIS are ignored. The SHDN input of MOA supports only DTS logic (normal: TRUE, abnormal: FALSE). Connect a reversed shutdown logic signal to SHDN in the case of ETS logic (normal: FALSE, abnormal: TRUE).

Prohibition of manual operations

If the input value of SHDN is set to TRUE (status where shutdown processing is not performed) and the manual operation permit switch SW is set to FALSE (manual operations prohibited), the value input to IN is output to OUT as is. If an operator attempts to perform manual operations from an HIS when the input to SW is FALSE, the attempt will fail. IN can be used to change the output value of OUT from the application logic when no shutdown instruction is input to SHDN (i.e., the system is in a safe state).

Permission of manual operations

Manual operation can be permitted when the SHDN value is TRUE and it is in a safe state where shutdown processing is not being performed. If SHDN is TRUE and SW is TRUE (manual operation permitted), manual operation by the operator from HIS is permitted and the result is output from OUT. Note that password entry is required to perform manual operations. The password is checked within a function block. If the password is incorrect, a warning message for the illegal operation is displayed and OUT remains unchanged.

TIP

You can specify with the SCS Constants Builder whether to skip the password dialog box on HIS when an empty string constant is set in PSWD of the function block. As a result of specifying not skipping, when the Password Input dialog box appears on HIS, just press the Enter key.
Regardless of whether the Password Input dialog box is displayed or not, the reconfirmation dialog box is displayed.

SEE ALSO

For more information about specification to skip the Password Input dialog box, refer to:

"● Skip password dialog box for manual operation FB" in "■ Settings with the Communication Tab" in C1.2.6, "SCS Constants Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Feedback input

The feedback input (FV: data type is REAL) can be used for the purpose of checking the result of manipulating MV from an HIS on instrument faceplate and so on. Input a signal indicating the degree of opening of a valve or similar connected to the output variable channel connected to OUT, to FV.

- It is not checked that the values of OUT and FV match.
- The value of FV is used for checking purposes only in an HIS. It has no influence on the output behavior of OUT.

OOP detection

It is possible to use OOP (whose data type is BOOL) to check whether or not an output signal is normal. Input the data status of an output signal (output variable connected to OUT) or similar to OOP. Process alarms are notified on the CENTUM side according to the change of the OOP value.

- The value of OOP has no influence on the output behavior of OUT.

B5.3.2 Tag name interfaces and process alarms of MOA

In order to manually operate analog-type data manual operation function blocks from an HIS, it is necessary to specify the tag names using the Tag Name Builder and associate them with mapping blocks. This allows them to be called via tag names and notification of process alarms.

Mapping blocks associated with analog-type data manual operation function blocks are displayed as S_MOA.

Settings in the Tag Name Builder

To perform manual operations from an HIS, make settings for the relevant instances of MOA in the Tag Name Builder. The settings related to MOA are as follows.

Output high and low limits

The output scale high and low limits are valid setting items when the block is in the mode that manual operation is allowed (MODE=MAN). This indicates the range of MV value that can be set by the operator without confirmation. When a value beyond the limits is set from HIS to the MV, a dialog box will be displayed for confirmation to set the MV beyond the limits. If you approve, the MV value is set.

This function is different from the Output Limiter function of FCS.

- Output high limit
  Specify a value in the range from 0.0 to 100.0%. The default is 100.0%.

  This item is associated with data item MH of mapping block.
- Output low limit
  Specify a value in the range from 0.0 to 100.0%. The default is 0.0%.

  This item is associated with data item ML of mapping block.

Output scale high and low limits

The output scale high and low limits are valid setting items when the block is in the mode that manual operation is allowed (MODE=MAN). These settings indicate the upper and lower limits at entering MV value from HIS. A value beyond these high and low limits cannot be entered from HIS.

- Output Scale High Limit
  The value of this item is fixed to 100.0%. The value cannot be changed.

  This item is associated with data item MSH of mapping block.
- Output Scale Low Limit
  The value of this item is fixed to 0.0%. The value cannot be changed.

  This item is associated with data item MSL of mapping block.

TIP When a block is in a block mode that the manual operation is not allowed (MODE=AUT), the output from OUT will not be affected by the output high and low limits or the output scale high and low limits. The values specified by the parameters of IN or SDV of MOA will be intact and directly outputted.

Data items of S_MOA

Among the data items of mapping blocks, the data items unique to S_MOA are explained here. All of these data items are displayed in the HIS tuning view with the exception of SH and SL.

SEE ALSO For more information about descriptions regarding MODE (Block mode), AFLS (Alarm flashing status), AF (Alarm detection), AOFS (Alarm inhibition), OPMK (Operation mark), and UAID (User application ID), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

MODE (block mode)

This data item indicates block mode. The block mode cannot be changed into AUT or MAN from an HIS. The default value of MODE is O/S (AUT).

- Associating parameters of function blocks
  The SHDN (shutdown signal), SW (manual operation permit/prohibit toggle switch) and OTEN (signal indicating output enable status) parameters of MOA are associated with MODE.
- Changes of block mode (AUT/MAN)
  The block mode becomes AUT if the SHDN parameter of MOA is FALSE. If SHDN is TRUE, the block mode becomes MAN if TRUE is input to the SW parameter of MOA, and AUT if FALSE is input to SW.
- Changes of block mode (output enable status)
  The block mode IMAN is added to the block mode if OTEN is FALSE and IMAN is removed from the block mode if OTEN is TRUE.

ALRM (alarm status)

This data item displays alarm status.

Data entry from an HIS is not allowed.

The default value of ALRM is NR.

FV (feedback input value)

This data item displays the feedback input signal connected to MOA. Data entry from an HIS is not allowed. It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The FV parameter (feedback input value) of MOA is associated with FV. The value of FV changes according to the changes of the FV value of MOA.
- Range
  The range of FV is 0 to 100%.
- Default
  The default value of parameter (0%) of MOA is reflected in the default value of FV.

MV (manipulated output value)

This data item is associated with the operation output value of MOA. Its value can be changed if manual operations from an HIS are permitted (block mode=MAN). It is displayed in the parameter display area of instrument faceplate and will be a target of data collection for tuning trend.

- Associating parameters of function blocks
  The OUT parameter (analog operation output value) of MOA is associated with MV. The value of MV changes according to the changes of the OUT value of MOA.
- Range
  The range of MV is 0 to 100%.
- Default
  The default value of MV is 0%.

SHDN (shutdown signal)

This data item displays signals used for shutdown logic. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The SHDN parameter (shutdown signal) of MOA is associated with SHDN. The SHDN value of MOA is reflected in this data item.
- Range
  The range of SHDN is 0 or 1.
- Correspondence between changes of the parameter value of function blocks and changes of SHDN
  Changes of the SHDN (shutdown signal) value of MOA match with changes of SHDN.

  If the value of SHDN is 0, the value of SDV (shutdown output value) is output as a shutdown signal from the OUT parameter (corresponding to a data item MV) of MOA.

SDV (shutdown output value)

This data item displays a value output as a shutdown signal when shutdown processing is performed. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The SDV parameter (shutdown output value) of MOA is associated with SDV. The SDV value of MOA is reflected in this data item.
- Range
  The range of SDV is 0 to 100%.

INV (logic input value)

This data item is associated with the value specified to be output under conditions where the shutdown logic is not effective and operations from an HIS are prohibited. Data entry from an HIS is not allowed.

- Associating parameters of function blocks
  The IN parameter (specified output value when manual operations are prohibited) of MOA is associated with INV. The default value of IN of MOA is reflected in this data item. The value of INV changes according to changes of the IN value of MOA.
- Range
  The range of INV is 0 to 100%.

SW (switch)

This data item displays the status of the manual operation permit/prohibit toggle switch of the FB. Data entry from an HIS is not allowed.

The value of the data item SW is determined as follows according to the value of the FB parameter and the SCS Constants Builder specification.

Table B5.3.2-1 Value set for data item SW

SW of FB	PSWD of FB	SCS Constants Builder specification	Data item SW
FALSE	- (*1)	- (*1)	0
TRUE	Other than an empty string constant	- (*1)	1
	Empty string constant	Do not skip the Password Input dialog box.	1
		Skip the Password Input dialog box.	2

*1: It does not affect the value of data item SW

MSH (output range high limit)

This data item displays the output scale high limit. Data entry from an HIS is not allowed. The value is fixed to 100%.

MSL (output range low limit)

This data item displays the output scale low limit. Data entry from an HIS is not allowed. The value is fixed to 0%.

MH (output high limit)

This data item displays the output high limit defined in the Tag Name Builder. Data entry from an HIS is not allowed. The range is 0 to 100%.

ML (output low limit)

This data item displays the output low limit defined in the Tag Name Builder. Data entry from an HIS is not allowed. The range is 0 to 100%.

SH (FV scale high limit)

This data item is used to display the high limit of FV bar in an instrument faceplate. The value is fixed to 100%.

SL (FV scale low limit)

This data item is used to display the low limit of the FV bar in an instrument faceplate. The value is fixed to 0%.

Process alarms

MOA notifies process alarms of OOP.

OOP

If you connect a signal indicating whether or not the output signal is normal to the OOP parameter of MOA, output errors are notified as process alarms. The notification is made if the parameter of MOA changes under the following condition.

- Output error occurrence alarm: At a falling edge of OOP

The notification of recovery is made if the parameter of MOA changes under the following condition.

- Output error recovery alarm: At a rising edge of OOP

B6. Data setting using external communication function blocks

Data setting from FCSs is performed via tag name interfaces using external communication function blocks dedicated for data setting. These function blocks allow data setting not only from FCS, but also from HIS. External communication function blocks are provided for each of the data types.

Data setting from FCS

In order to set data via tag name interfaces, define tag names for instances of external communication function blocks in Tag Builder in an SENG. Once tag names are defined, mapping elements (%WB) are generated. By accessing these mapping elements using the syntax "<tag name>.<data item>," data can be referenced and set. The table below lists data item names used when accessing data.

Table B6-1 Data items of tag name interfaces

External communication FB	Data item name(referencing and setting)
ECW_B	PV
ECW_I	PVI32
ECW_R	PVF32

Tag name interfaces use the same data item names for referencing and setting data. For example, if the tag name TAG0702 is defined for an ECW_I function block, the specification "TAG0702.PVI32" can be used when both referencing and setting data of this function block. If the tag name TAG0703 is set for an ECW_R function block, "TAG0703.PVF32" is used to access data.

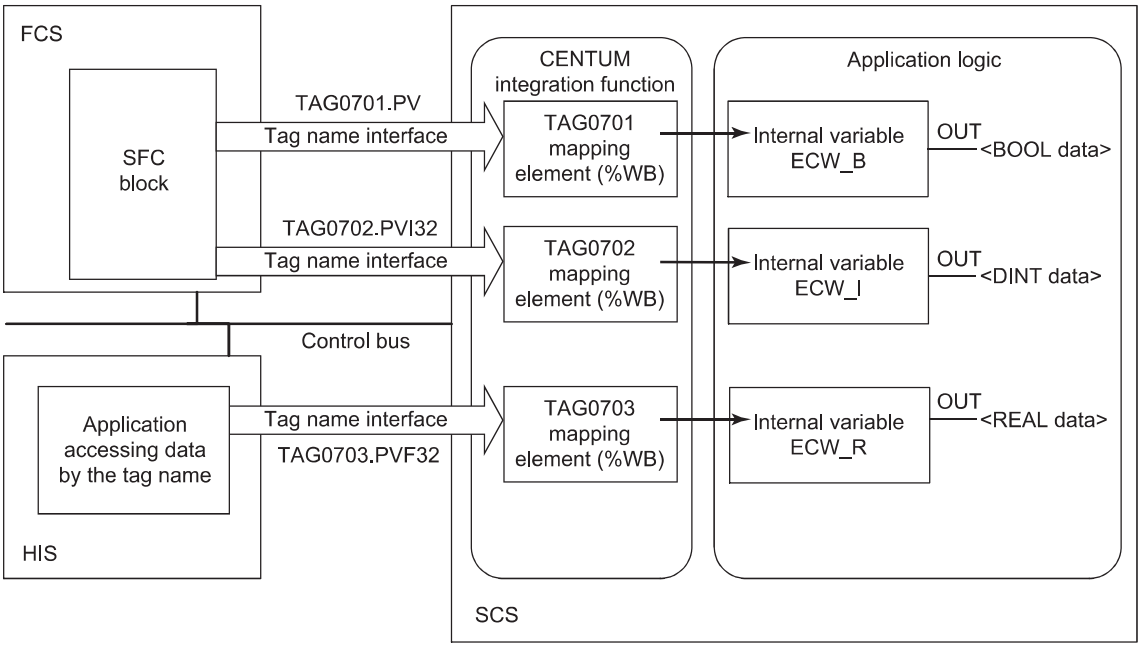

Figure B6-1 Data setting using tag name interfaces of external communication function blocks

B6.1 Confirmation of setting data

In order to use data set by external communication function blocks in an application used in a safety loop, it is necessary to incorporate certain safety measures (various functions to secure safety) with a user application.

An example that uses an application logic that checks the status of data set from an HIS or FCS as a safety measure is shown below.

Confirmation of data set via tag name interfaces

The data set from an FCS is stored temporarily in a mapping element (WT003) and then reflected in an external communication function block. The figure below shows an example of an application that checks whether the set data reached the application logic or not.

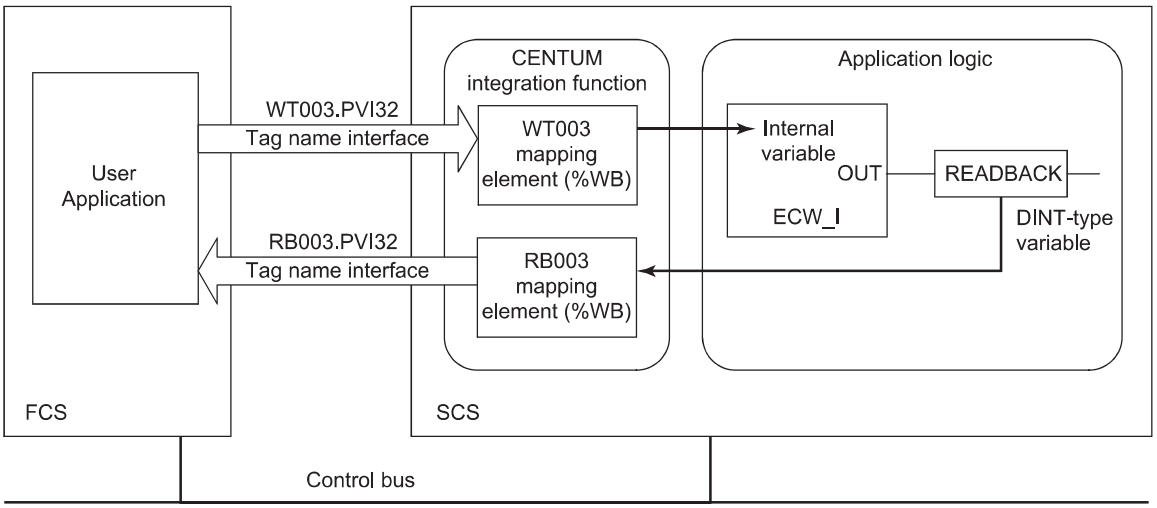

Figure B6.1-1 Example of application that checks data setting using readback variable

Connect the variable READBACK (DINT-type variable) to the OUT variable so that the output from the OUT variable can be read back with a user application. By doing so, it can be confirmed that the data has been set correctly.

The procedure to set DINT-type data is shown below.

1. Define a tag name for data setting for an ECW_I (external communication function block) (WT003 in the example).
2. Define a tag name for data readback for the variable that will be used for reading the desired data back (RB003 in the example).
3. Set data from the external device (FCS in this example) using the specification "<tag name for data setting>.PVI32." In the example, data is set via WT003.PVI32.
4. Read the data back to the external device (FCS in the example) using the specification "<tag name for data readback>.PVI32." In the example, data is read back via RB003.PVI32.

B6.2 Tag name interfaces of external communication function blocks

This section explains data items of mapping elements associated with external communication function blocks.

■ Data items of mapping elements associated with external communication function blocks

By associating tag names with ECW_B, ECW_I and ECW_R type function blocks, it becomes possible to set data from outside an SCS using tag name interfaces. If you define tag names using the Tag Name Builder, mapping elements are created in the communication input/output (%WB) area.

Mapping elements of external communication commonly have OPMK data items.

SEE ALSO For more information about description regarding OPMK (Operation mark), refer to:

"■ Data items common to mapping blocks/mapping elements" on page B3-7

● Data items of mapping elements (%WB) associated with ECW_B (PV)

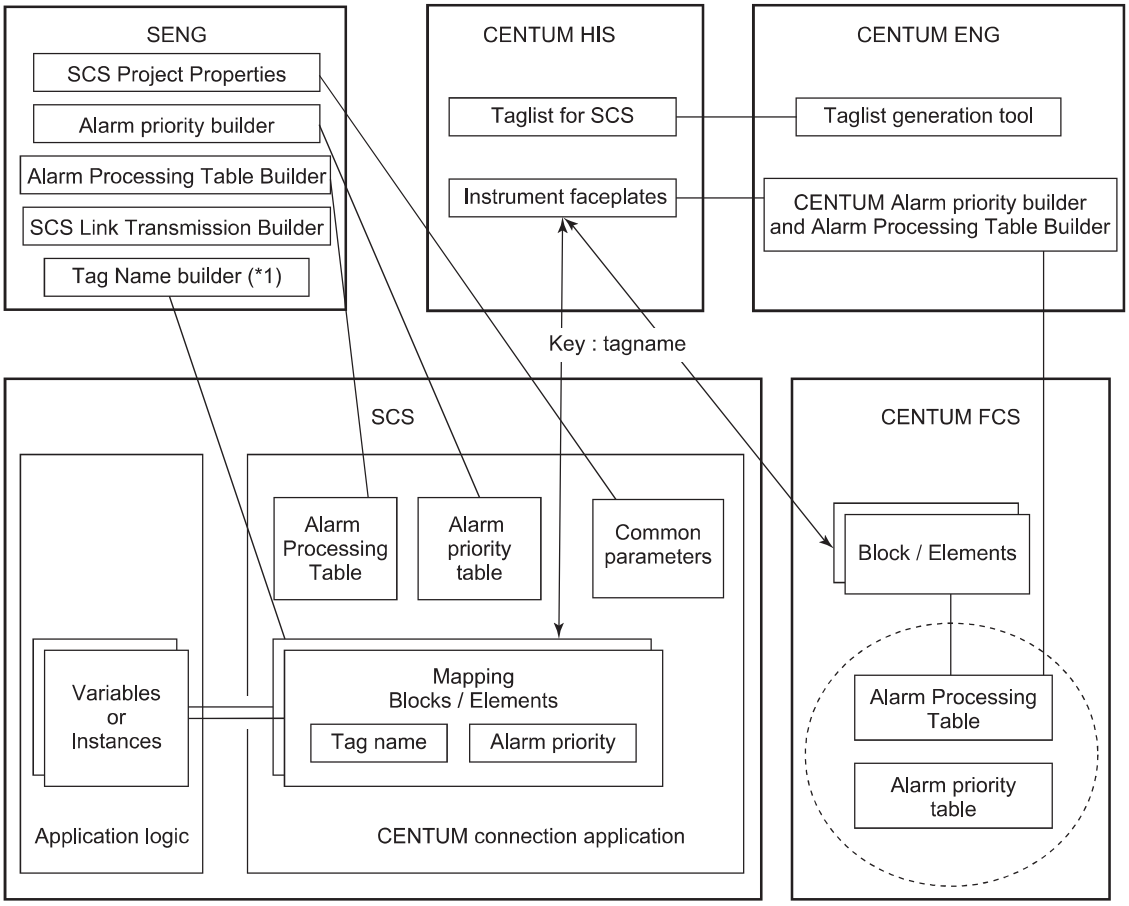
The Boolean value of ECW_B is displayed as PV. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate, and will be a target of data collection for tuning trend. Data entry from an HIS is allowed.

The range is 0 or 1. The default value of ECW_B is reflected in the default value of PV.

● Data items of mapping elements (%WB) associated with ECW_I (PVI32)

The integer value of ECW_I is displayed as PVI32. It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is allowed.

The range is all signed 32-bit integers. The default value of ECW_I is reflected in the default value of PVI32.



● Data items of mapping elements (%WB) associated with ECW_R (PVF32)

The value of ECW_R is displayed as PVF32 (a real number). It is displayed in the HIS tuning view and the parameter display area of instrument faceplate. Data entry from an HIS is allowed.

The range is all single precision real numbers. The default value of ECW_R is reflected in the default value of PVF32.

B7. Engineering for CENTUM integration

To realize the CENTUM integration, you need to connect a CENTUM project and an SCS project. To connect these projects, you need to engineer both the SCS project and the CENTUM project. This section describes the engineering tasks required for the CENTUM integration.

*1 : In the engineering with iDefine, you can also define tag names in iDefine.

Figure B7-1 Targets of engineering on SENG and CENTUM

SEE ALSO

For more information about overview of engineering procedures for integration with CENTUM, refer to:

"■ Engineering procedure of CENTUM integration configuration" on page B2-3

For more information about relationship between CENTUM projects and SCS projects, refer to:

"■ Relationship between projects" on page B2-5

■ Overview of engineering for CENTUM integration

The ENG is a PC which has a license for the CENTUM system builders. Each CENTUM application generated on the ENG is managed as part of a CENTUM project.

Applications to be downloaded to SCS are created on the SENG. One of such applications relates to tag names. A part of the tag-name-related application used for CENTUM integration is also written in the CENTUM project. The tag-name-related definition data written in the

CENTUM project is used in the engineering tasks, so that you can operate and monitor SCS from HIS and can access SCS data from FCS.

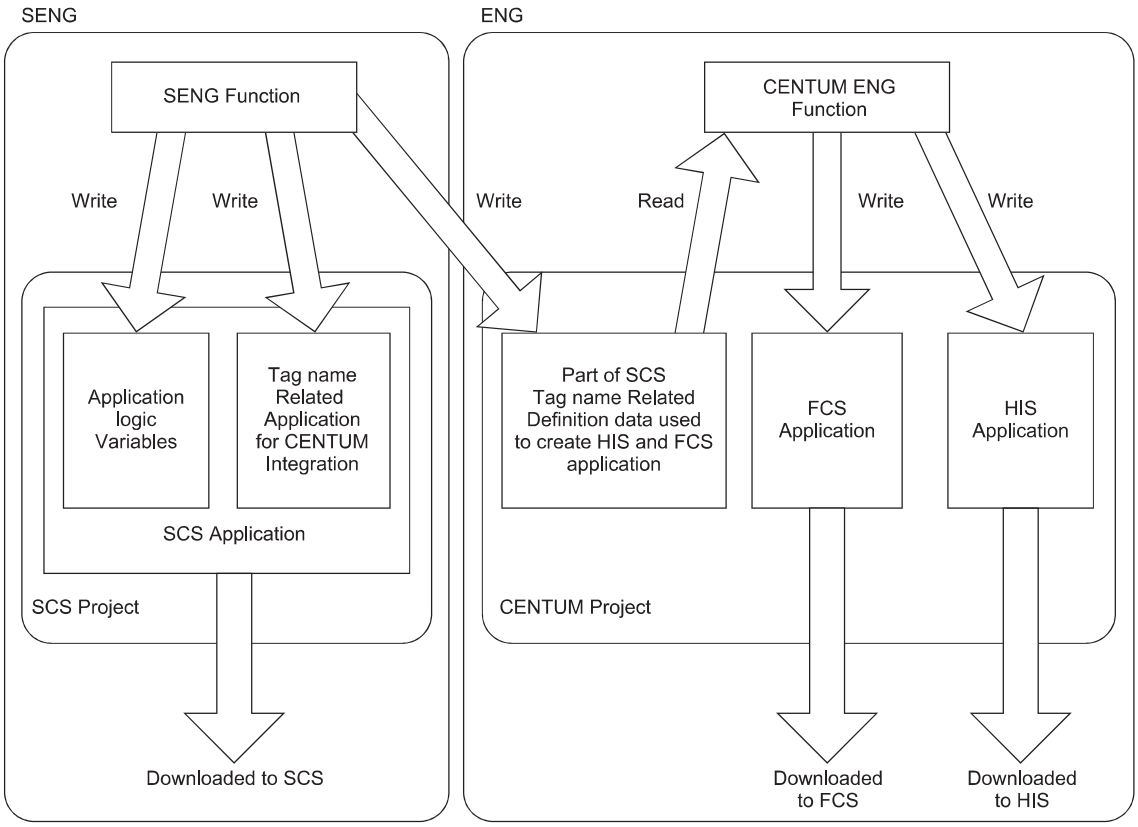


Figure B7-2 SCS project and CENTUM project

B7.1 Engineering on the SENG side

This section describes the engineering tasks performed on the SENG side, which is one of the tasks required to connect an SCS project and a CENTUM project.

B7.1.1 Setting of SCS project property

An SCS project and a CENTUM project can be connected using SCS Project Properties in an SCS manager. In SCS Project Properties, specify the folder of the CENTUM project you want to connect to the SCS project. The information for CENTUM integration that has been set in the SCS project can be copied to the CENTUM project folder.

The connection of an SCS project and a CENTUM project is set only in one direction: from the SCS project to the CENTUM project.

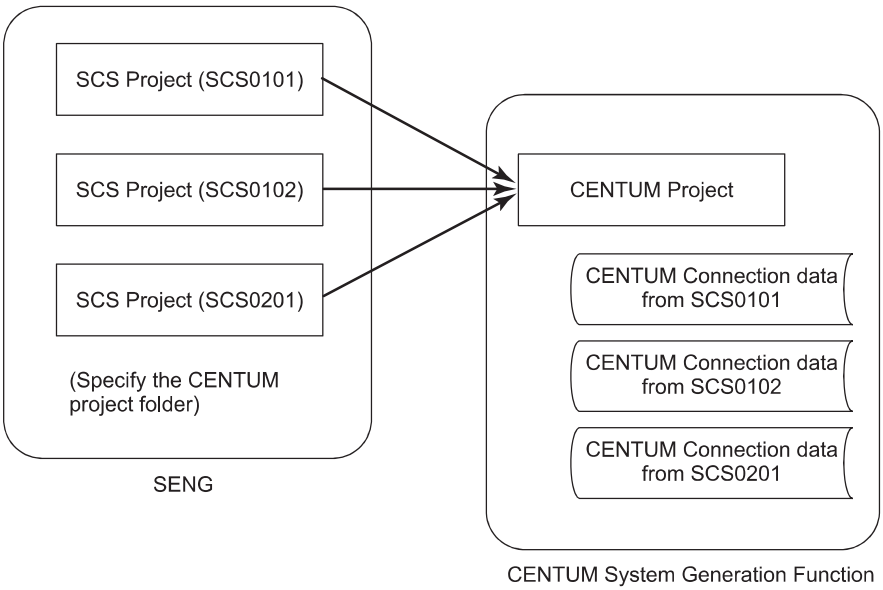

Figure B7.1.1-1 Settings for connection between SCS project and CENTUM project

SEE ALSO

For more information about relationship between SCS projects and CENTUM projects, refer to:

C1.1, “Type of project” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about specifying project folders, refer to:

C1.2.5, “SCS Project Properties dialog box” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

B7.1.2 Defining alarm priorities

Process alarms occurred on SCS can be monitored in the Process Alarm view of CENTUM HIS. Alarm priorities for monitoring on the CENTUM HIS can also be defined for the process alarms that occur on SCS.

This section describes the definition of Alarm Priorities in Alarm Priority Builder of ProSafe-RS.

ProSafe-RS Alarm Priority Builder

By using the Alarm Priority Builder, you can define the alarm output format and alarm action when an alarm has occurred or returned to a normal state for each SCS. Alarm priorities are classified as high-priority alarm, medium-priority alarm, low-priority alarm, logging alarm, and reference alarm.
To start the Alarm Priority Builder, do the following: From the SCS Manager, click [Tools] > [Engineering] to start the Engineering Launcher, and select [Alarm Priority Builder] from the menu.

For each alarm priority, set the alarm flashing action, re-warning, and flashing action upon returning to NR. Ensure that the [NR (Flashing)] setting on the Alarm Priority Builder on SENG is the same as the [NR] setting that is configured on the Alarm Priority Builder of the CENTUM System Builders.

TIP

The ProSafe-RS Alarm Priority Builder is different from the CENTUM Alarm Priority Builder. You cannot set the behavior of HIS from the 'Alarm Priority Builder on SENG.'

Downloading to an SCS

When alarm priorities are defined, the information is reflected in the SCS download database. Perform offline download of the database to the SCS using SCS Manager on SENG.

SEE ALSO

For more information about offline download, refer to:

C7., "Offline download to the target SCS" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Differences from CENTUM Alarm Priority Builder

When connecting an SCS project to a CENTUM project, two alarm priority builders must be used properly: one is ProSafe-RS Alarm Priority Builder launched from SCS Manager on the SENG, the other is Alarm Priority Builder launched from CENTUM System View. These two builders are used for their respective projects, with the following differences between the two:

- Target station
  ProSafe-RS Alarm Priority Builder can be used to change definitions for each SCS.

  CENTUM Alarm Priority Builder is common throughout the CENTUM project, and the definitions set in this builder apply to all HIS and FCS.

- Setting items
  ProSafe-RS Alarm Priority Builder is used to set SCS data, while CENTUM Alarm Priority Builder is used to set HIS and FCS data. Accordingly, the setting items are different between the two alarm priority builders.

Table B7.1.2-1 Setting items in ProSafe-RS and CENTUM Alarm Priority Builders

Title	Item	ProSafe-RS Alarm Priority Builder	CENTUM Alarm Priority Builder
CRT	Window display	Setting item not available	Can be set

Continues on the next page

Table B7.1.2-1 Setting items in ProSafe-RS and CENTUM Alarm Priority Builders (Table continued)

Title	Item	ProSafe-RS Alarm Priority Builder	CENTUM Alarm Priority Builder
PRT	Printing	Setting item not available	Can be set
Historical File	Storing in files	Setting item not available	Can be set
Buzzer Sound	Buzzer sound generation	Setting item not available	Can be set
Alarm Action	Alarm flashing action	Can be set	Can be set (*1)
Rewarning	Rewarning	Can be set	Can be set (*1)
NR (Flashing)	Flashing action upon returning to the NR state	Can be set (*2)	Can be set (*1)

*1: Defined only for FCSs
*2: Must be the same as settings on CENTUM Alarm Priority Builder

- File compatibility
  The builder files created in ProSafe-RS Alarm Priority Builder as well as their copies saved in different names cannot be opened in or imported to CENTUM Alarm Priority Builder, or vice versa. CSV files must be used to exchange data between the two builders.
- Other
  ProSafe-RS Alarm Priority Builder has no download menu. Downloading from this builder is performed in SCS Manager.

Window of ProSafe-RS Alarm Priority Builder

The following figure shows the Alarm Priority Builder main window:

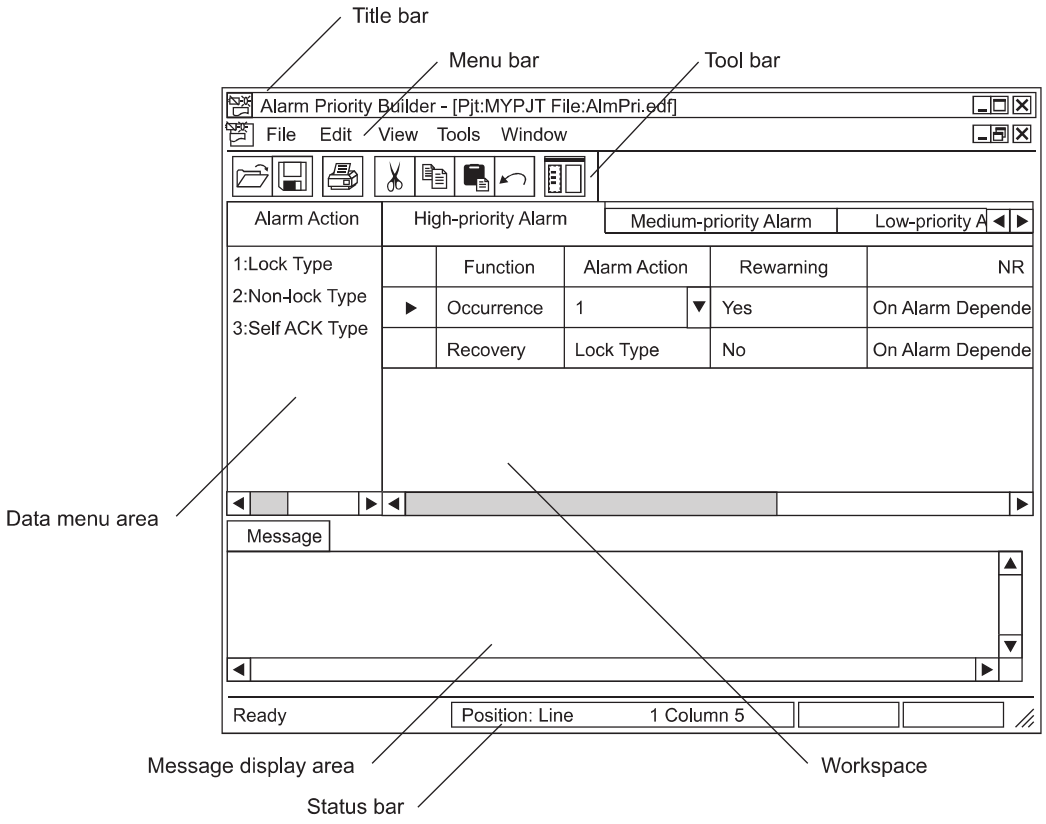

Figure B7.1.2-1 Main window of the Alarm Priority Builder

Setting items

ProSafe-RS Alarm Priority Builder has tabs corresponding to different alarm priority levels. All or some of the following items can be set in each of these tabs:

Table B7.1.2-2 Setting items

Item	Description
Alarm Action	Specify the alarm flashing action.
Rewarning	Specify whether to enable or disable rewarning.
NR (Flashing)	Specify the alarm action upon returning to the NR state.

In ProSafe-RS Alarm Priority Builder, set each action upon occurrence and recovery of alarms, for each alarm priority.

The actions corresponding to the blank fields in the following table cannot be set:

Table B7.1.2-3 Alarm priorities and settable items

Item	High-priority alarm(*1)		Medium-priority alarm (*1)		Low-priority alarm (*1)		Logging alarm(*1)		Reference alarm (*1)	
	Occurrence	Recovery	Occurrence	Recovery	Occurrence	Recovery	Occurrence	Recovery	Occurrence	Recovery
Alarm Action	Yes	Lock	Yes	Lock	Yes	Non-lock	Self ACK	Self ACK	Self ACK	Self ACK
Rewarning	Yes	No	-							
NR (Flashing)	Yes	On Alarm Dependent								

*1: Yes: Can be set
Other than Yes: Fixed value (cannot be specified)

Alarm Action

In Alarm Action (alarm flashing action), set the flashing indication used to notify the operator when an alarm has occurred. The desired flashing indication can be selected from the following three types:

Table B7.1.2-4 Types of flashing indication

Type	Action
Lock	The flashing indication will continue until the operator performs an acknowledgement operation, even after the alarm is reset upon returning to the NR state.
Non-lock Type	The flashing indication will stop without the operator performing an acknowledgement operation, when the alarm is reset upon returning to the NR state.
Self ACK	Flashing indication is not implemented, since the system will automatically acknowledge the alarm as soon as it is generated.

Rewarning

Rewarning is the alarm that notifies the operator of a continuing alarm state. This item can be specified only for high-priority alarms. The alarm message will be output again at the rewarning periods or when specified by command.

Table B7.1.2-5 Types of rewarning

Type	Description
0: No	Rewarning is not issued
1: Yes	Rewarning is issued

The rewarning period is set in SCS Constants Builder.

SEE ALSO For more information about SCS Constants Builder, refer to:

C1.2.6, “SCS Constants Builder” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

NR (Flashing)

NR (Flashing) defines the flashing indication used to notify the operator that all alarms in a given function block have been recovered upon returning to the NR state. The following two types of flashing display definitions are available for notifying the operator: This item can be specified only for high-priority alarms.

Table B7.1.2-6 Types of alarm action upon returning to NR

Type	Description
On Alarm Dependent	When all alarms have been reset upon returning to the NR state, the current flashing status will continue. If the indicator is flashing when the NR state is restored, the flashing will continue. If the indicator is not flashing when the NR state is restored, the non-flashing status will continue.
Notification at Return (*1)	When all alarms have been reset upon returning to the NR state, the flashing to indicate the NR state will start. Even when this flashing is not acknowledged, the flashing will stop when a new alarm is generated. Return of the entire function block to the NR state is notified by a Non-Lock action.

*1: Must be the same as the settings on CENTUM Alarm Priority Builder.
If the two settings are different, for example, the [NR] on CENTUM is set to [On Alarm Dependent] and the [NR (Flashing)] on the ProSafe-RS is set to [Notification at Return], the process alarm LED on the SCS blinks according to [Notification at Return], but no return sound is output.

If Alarm Action is set to "Self ACK" and alarm type upon returning to NR is set to "Notification at Return," an error message will be output when a file is saved.

B7.1.3 How to change the display color of alarms

You can change the display color of alarms generated by the mapping block in the CENTUM integration structure.

If you want to change the display color of alarms, configuration is required on both CENTUM VP and ProSafe-RS.

Operation procedure

If you want to change the display color of alarms, specify the color by using the Alarm Processing Table Builder on CENTUM VP.

IMPORTANT

- You must use an alarm processing level No. that is specified an appropriate priority to the related SCS among existing definitions and that is not used in CENTUM tags.
- Do not change the priority. If you change the priority by mistake, function blocks/elements of all FCSs in the related CENTUM project become invalid elements. Offline download is required to solve invalid elements.

This section describes how to change the text color of “FLT” for the mapping block S_GASDTR to cyan by using the alarm processing level No. 13 (classified to alarm processing level 1 (high-priority alarm) priority by default as well as the alarm processing level No. 1) as an example.

TIP

- You can use an alarm processing level No. from 5 to 16.
- “FLT” is assigned to the bit position 19.
- By default, “FLT” is shown in red.

1. In the Alarm Processing Table Builder on CENTUM VP, perform these steps:
   a. Set the same value of the color as the alarm processing level No. 1 to the color for the alarm processing level No. 13 for all bit positions.
   b. Change the color for the alarm processing level No. 13 on the bit position 19 to cyan.

IMPORTANT

Before you save in the Alarm Processing Table Builder on CENTUM VP, ensure that the settings except for the above settings remain unchanged. Unlike ProSafe-RS builders, download is executed immediately after you save in the Alarm Processing Table Builder on CENTUM VP. You must be careful not to change the priority. Otherwise, all FCSs in the related CENTUM project become invalid elements.

2. On SENG, import AlmTbl.edf that you have edited in the step 1 by using Alarm Processing Table Builder.
3. In the Tag Name Builder, set the Alarm Level of S_GASDTR tag to [13: User(13)].

SEE ALSO

For more information about procedure for importing to the Alarm Processing Table Builder, refer to:

B7.1.4, “Defining the alarm processing table” on page B7-11

For more information about Alarm Level in the Tag Name Builder, refer to:

“● Alarm Level” on page B7-24

For more information about the procedure for setting the alarm processing level by using the Alarm Processing Table Builder on CENTUM, refer to:

7.4, "Alarm Status Character String and Alarm Processing" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)

B7.1.4 Defining the alarm processing table

You can monitor the process alarms raised by the SCS from the Process Alarm view on the CENTUM HIS. This section describes how to operate Alarm Processing Table Builder.

TIP The Alarm Processing Table Builder on the ProSafe-RS and the Alarm Processing Table Builder on CS 3000 are two different entities.

Alarm Processing Table Builder

The Alarm Processing Table Builder determines the priority of alarms raised by Mapping block on SCS. The priority levels are 1 to 16.

Set the color and priority levels on the Alarm Processing Table Builder on the CENTUM and import the settings to the Alarm Processing Table Builder on ProSafe-RS because the builder on ProSafe-RS has no editing feature.

Engineering flow

Unlike the other builders, the Alarm Processing Table Builder on the ProSafe-RS imports the contents of settings on the Alarm Processing Table Builder on CENTUM. If the settings for the table used by SCS are changed on the Alarm Processing Table Builder on CENTUM, be sure to import the file for the Alarm Processing Table Builder on CENTUM to the Alarm Processing Table Builder on the ProSafe-RS. To reflect the imported data on the SCS, offline-downloading is required.
The engineering procedure is as follows:

With the SCS Manager, display the [SCS Project Properties] dialog box, select the [Project] tab, and enter the 'top folder of the CENTUM Project' into the field [CENTUM Project Folder]. Do this before going on to the following steps.

1. Start the Alarm Processing Table Builder:
   From the SCS Manager, click [Tools] > [Engineering] to start the Engineering Launcher, and select [Alarm Processing Table Builder] from the menu.
2. From the menu, select [File] > [External file] > [Import...].
   The following Import dialog appears.

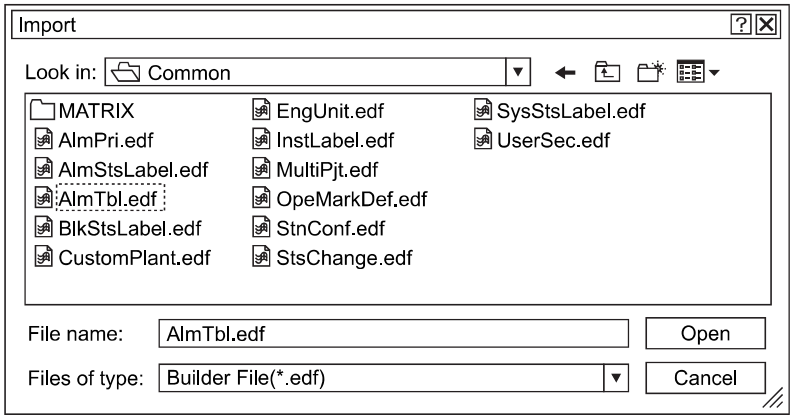

Figure B7.1.4-1 Import dialog box

3. Select the AlmTbl.edf of a CENTUM project and click the [Open] button.
4. From the menu of the Alarm Processing Table Builder, select [File] > [Save]. The AlmTbl.edf is saved in the SCS Project.
5. To reflect the contents in the AlmTbl.edf file on the SCS, execute [Build] in SCS Manager before offline-downloading.

B7.1.5 Defining tag names

When SCS project and CENTUM project are connected, tag names must be defined so that application logic variables and function blocks can be accessed from HIS or FCS. Tag names are defined in Tag Name Builder.

You can also define tag names from the editor of iDefine. If you export data from iDefine, import it to AD Organizer and run Reflection, the tag name definitions are reflected in the Tag Name Builder. Tag names and parameters that are defined using iDefine cannot be edited in the Tag Name Builder.

To use the Tag Name Builder, you must have a CENTUM integrated environment. Information of tag names defined by using iDefine without a CENTUM Integration are not reflected in SCS projects.

SEE ALSO For more information about defining tag names by using iDefine, refer to:

6., “PROSAFE-RS IO TAG NAME” in iDefine User Guide (Yokogawa Extensions) (PR12002-MAN-980_01)

■ Overview of tag name definition

This section explains the procedure to define tag names using the Tag Name Builder.

In the Tag Name Builder, define tag names for application logic variables or function block instances. Function blocks or variables having a defined tag name can be accessed from HIS based on their correspondence to Mapping Block/Element.

The following information is defined using Tag Name Builder: Tag names can only be defined for certain types of variable.

- Tag name
- Parameters required by Mapping Block/Element on SCS
- Parameters required by instrument faceplates on HIS

The procedure for defining tag names is as follows:

1. Define application logic variables or function block instances in Dictionary View of SCS Manager.
2. Define tag names and parameters in Tag Name Builder.

   To start the Tag Name Builder, do the following: From the SCS Manager, click [Tools] > [Engineering] to start the Engineering Launcher, and select [Tag Name Builder] from the menu.
3. Execute [Build] in SCS Manager to generate SCS database.

SEE ALSO For more information about variables for which tag names can be defined and details on the definition items, refer to:

“■ Setting items” on page B7-14

For more information about mapping blocks/elements, refer to:

B3.1, “Overview of tag name interfaces” on page B3-2

■ Window of Tag Name Builder

The following figure shows the Tag Name Builder main window:

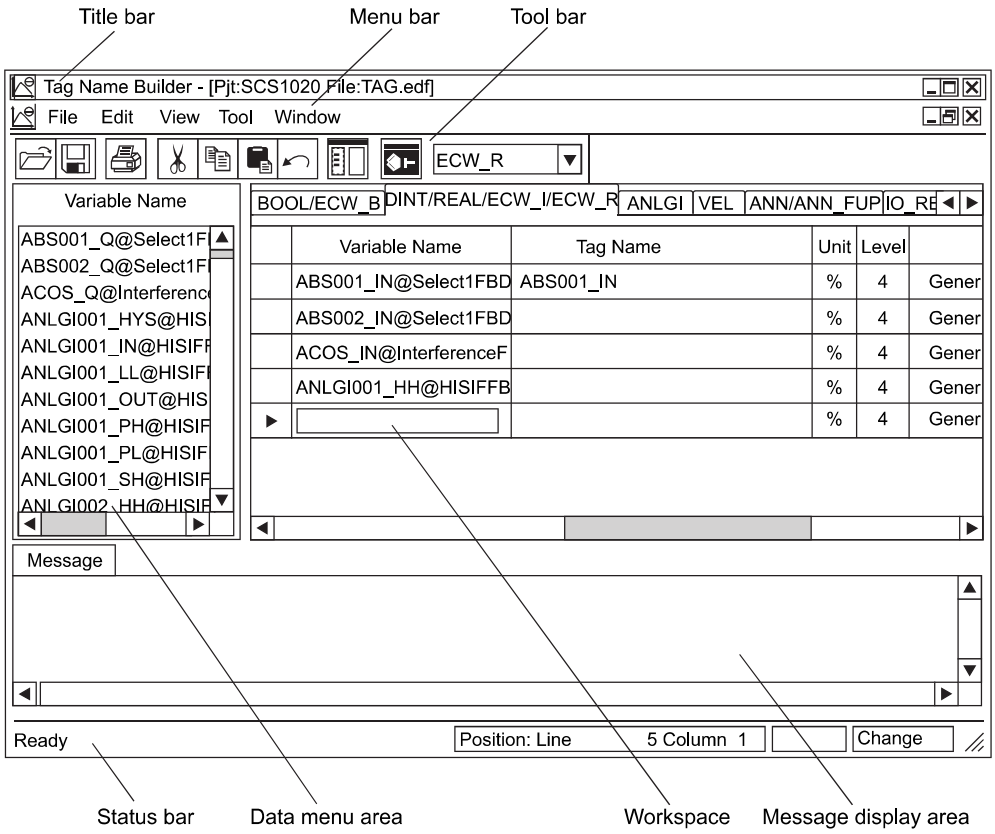

Figure B7.1.5-1 Main window of the Tag Name Builder

You can register a variable name in Tag Name Builder by dragging the variable name from Dictionary View and dropping it into a variable name field in Tag Name Builder. When multiple variable names are dragged and dropped, the variable names are registered in multiple variable fields starting from the top field. If a variable name is already registered in the variable name field, the variable name field is overwritten.

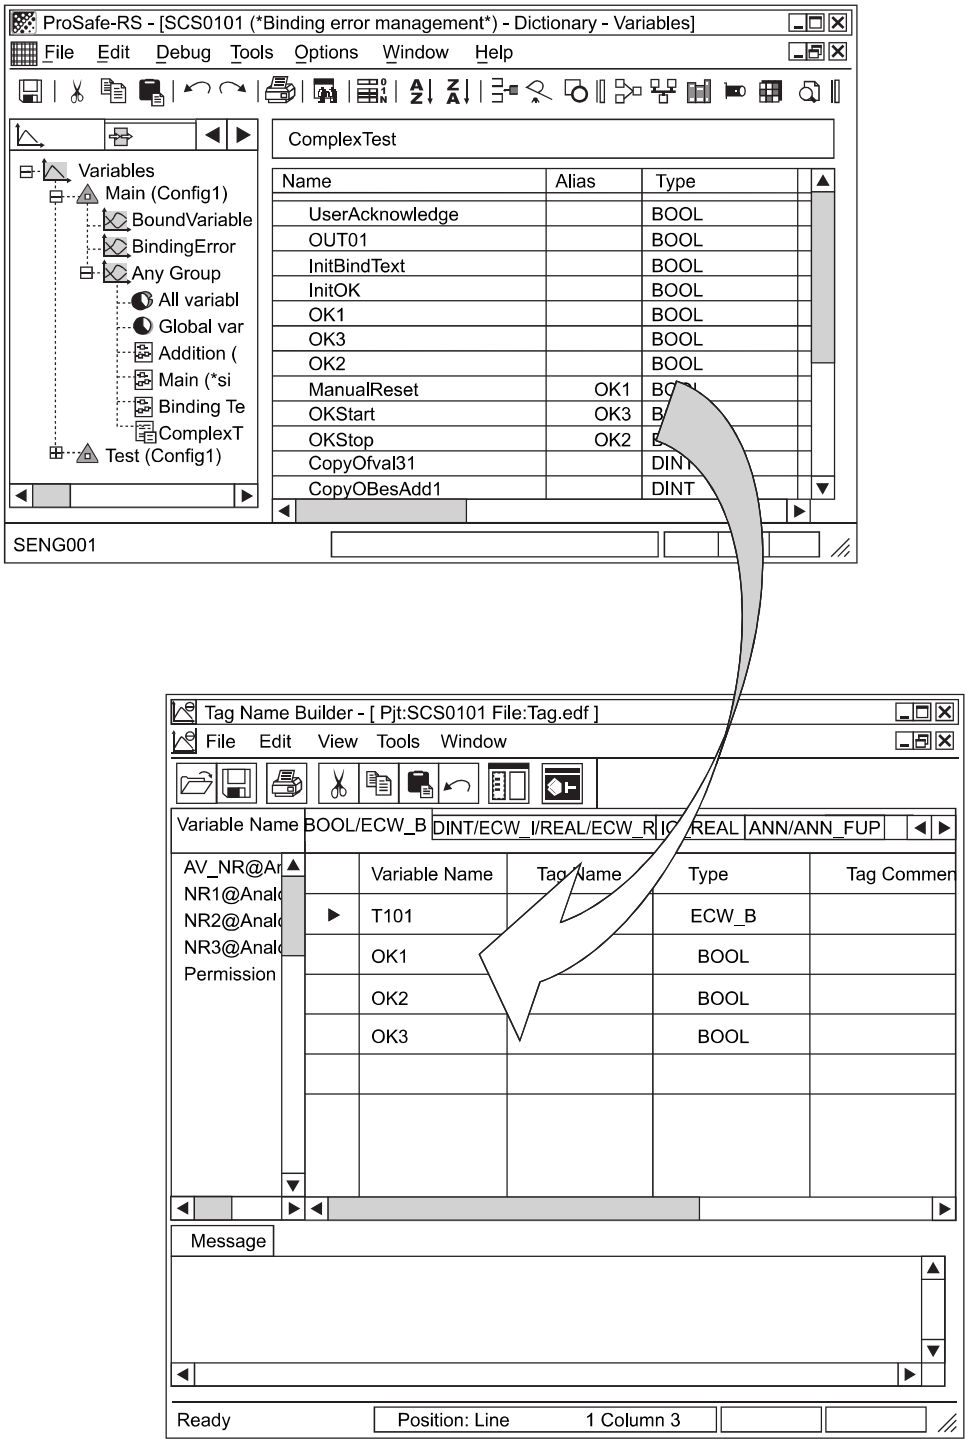

Figure B7.1.5-2 Dragging and dropping from the Dictionary View

Setting items

The following table shows the variable types for which tag names can be defined with Tag Name Builder. The setting Advanced Setting Items of Tag Name Builder vary depending on the variable type.

Table B7.1.5-1 Variable types whose tag name can be defined with the Tag Name Builder

Type	Description
BOOL	BOOL variable

Continues on the next page

Table B7.1.5-1 Variable types whose tag name can be defined with the Tag Name Builder (Table continued)

Type	Description
DINT	Integer variable
REAL	Real variable
ANLG_S	Instance of the analog input function block with data status
ANLGI	Instance of ANLGI function block
VEL	Instance of VEL function block
ANN	Instance of ANN function block
ANN_FUP	Instance of ANN_FUP function block
IO_REAL	Analog real input variable
IO_BOOL	Discrete BOOL I/O variable
GOV_B	Instance of Grouping override function block (BOOL type)
GOV_IB	Instance of Grouping override function block (discrete BOOL I/O variable)
OVR_B	Instance of Override function block (BOOL type)
OVR_I	Instance of Override function block (integer type)
OVR_R	Instance of Override function block (real type)
OVR_IR	Instance of Override function block (analog real input variable)
OVR_IB	Instance of Override function block (discrete BOOL I/O variable)
PASSWD	Instance of Password function block
ECW_B	Instance of External communication function block (BOOL type)
ECW_I	Instance of External communication function block (integer type)
ECW_R	Instance of External communication function block (real type)
SCI_B	Instance of Subsystem communication function block (BOOL type input variable)
SCO_B	Instance of Subsystem communication function block (BOOL type output variable)
SCI_I	Instance of Subsystem communication function block (integer type input variable)
SCO_I	Instance of Subsystem communication function block (integer type output variable)
SCI_R	Instance of Subsystem communication function block (real type input variable)
SCO_R	Instance of Subsystem communication function block (real type output variable)
PSI_I	Instance of Safety subsystem communication function block (integer-type fire and gas communication input)
PSI_R	Instance of Safety subsystem communication function block (real-type fire and gas communication input)
PNI_I	Instance of Safety subsystem communication function block (integer-type PROFINET communication input)
PNI_R	Instance of Safety subsystem communication function block (real-type PROFINET communication input)
MOB_11	Manual operation block instance with two-position answerback (BOOL)
MOB_21	Manual operation block instance with three-position answerback (BOOL)
MOB_RS	Manual operation block instance with auto-reset (BOOL)
MOA	Instance of Analog manual operation block
HSDTR	Instance of the analog input function block for smoke and heat detectors
GASDTR	Instance of the analog input function block for gas and flame detectors

The following table shows the setting items for Tag Name Builder and whether each setting item can be changed online. The table also shows the reference-only items in addition to the setting items. The reference items cannot be changed with Tag Name Builder. All items can be printed.

Table B7.1.5-2 Items

Item	Online changes (*1)	Remarks
Variable Name	Yes	-
Element Name	No	This item is only displayed in the ANN/ANN_FUP tab. (For SCSP1/SCSV1: %AN0001 to %AN1000, for SCSP2/SCSP3/SCSL2: %AN0001 to %AN2000) For annunciator with tag name, [T] is attached after the element name. (Example: %AN0100[T])
Type	No	The variable type defined in Dictionary View is displayed. This item is not displayed in the tab pages for a single variable type.
Comment	No	A comment for the applicable variable defined in Dictionary View is displayed.
Wiring Position	No	The installation position of the channel that is wired to an I/O variable is displayed.
Tag Name	Yes	Even if the tag name field is left blank, ANN or ANN_FUP can be accessed from CENTUM by using its element name. With no tag name specified, nothing is printed for the tag name.
Tag Comment	Yes	-
Annunciator Message	Yes	-
Low Limit	Yes	-
High Limit	Yes	-
Unit	Yes	-
Level	Yes	-
Label	Yes	-
Button 1	Yes	-
Button 2	Yes	-
Button Top	Yes	-
Button Bottom	Yes	-
Switch Position Label	Yes	-

*2: Fixed to 100.0. For display purpose only.
*3: Fixed to 0.0. For display purpose only.
*4: This setting item is applied only when HSDTR is used and is not applied when GASDTR is used.

Variable Name

To assign a tag name to a function block instance, enter the [instance name] as the variable name. From among the variables created in SCS Manager, specify the variable name you want to assign a tag name. A tag name can be defined regardless of the scope of the variable.
In case of a local variable, enter a scope name after "@."

In case of an internal variable of a user-defined function block, assign an instance name using Dictionary View of SCS Manager. The variable name is specified in the format of "[Instance Name].[Internal Variable Name]." Up to two nests are permitted in each variable to which a tag name is assigned.

Table B7.1.5-8 Examples of variable specification

Variable name (*1)	Scope	Description
VAR1	Global	Global variable
VAR2@PROG1	PROG1	Local variable of PROG1 function
FB01.VAR3	Global	Internal variable VAR3 of user-defined function block instance FB01
FB01.VAR3@PROG1	PROG1	Internal variable VAR3 of user-defined function block instance FB01 defined locally in PROG1 function
FB01.FB2.VAR3	Global	Internal variable VAR3 of user-defined function block instance FB2, which is used in user-defined function block instance FB01 (maximum limit of function block nesting)

*1: The variable name can contain up to 69 single-byte characters. Tag Name Builder also checks the following items:
- The variable name consists only of alphanumeric characters and "@," "." or "_". If any other character is used, an error will occur.
- The variable name begins with an alphabetic character or "_"; otherwise, an error will occur.
- Three or more nests in a variable will result in an error. The variables "FB01.VAR3" and "FB01.VAR3@PROG1" have one nest, while "FB01.FB2.VAR3" has two nests.

Tag Name

A name used to access each application logic variable from HIS. A tag name can contain up to 16 single-byte alphanumeric characters including "_" and "-". Note that tag names cannot begin with "_" or "-". All characters are converted to uppercase as they are entered. Tag names must be unique within the CENTUM project .

Tag Comment

A comment assigned to a tag name. It can be defined within 24 single-byte characters.

Annunciator Message

A message notifying the process error. You can define any string within 80 single-byte characters.

Default: None

Unit

A symbol indicating the engineering unit of data such as flow rate and pressure. A unit can be defined within 6 single-byte characters .

Default: %

Low Limit

A low limit (SL) is the lowest point of engineering data scale. It can be defined using up to seven digits including a sign and decimal point. This setting is referenced by HIS only for display purposes and not used in calculation or alarm processing of the SCS.

Default: 0.0

High Limit

A high limit (SH) is the highest point of engineering data scale. It can be defined using up to seven digits including a sign and decimal point. This setting is referenced by HIS only for display purposes and not used in calculation or alarm processing of the SCS.

Default: 100.0

Label

A display format applied to the switch position label displayed on each button on the instrument faceplates of HIS. Two label formats are available: Direct and Reverse. Either type can be specified.

Table B7.1.5-9 Label

Number	Description
1	Direct
2	Reverse

Default: Direct

Button 1/Button 2

A button color can be specified for each button on the instrument faceplates of HIS.

Select a button color from one of the following 16 colors:

R: Red N: Black G: Green Y: Yellow B: Blue M: Magenta C: Cyan W: White SB: Steel Blue PK: Pink SG: Spring Green OR: Orange YG: Yellow Green VO: Violet DB: Deep Sky Blue GR: Gray

When each button (switch) is pressed, the button color will change to the specified color.

Default: Red

Button Top/Button Bottom

Each button on the instrument faceplates of HIS can be divided into the top and bottom sections and its color can be specified for each section. Sixteen colors are available, corresponding to the colors shown in "Button 1/Button 2" above, except for "N: Black," which is substituted by "N: Background color."

Level

Variables can be classified according to their priorities. Eight levels from 1 to 8 are available, and the security level increases as the number increases. The operation and monitoring privileges on the HIS with respect to each data item will change depending on the function constraint level. Enter a number between 1 and 8.

Default: 4

SEE ALSO For more information about levels, refer to:

- 3.4, "Function Block Security" in the CENTUM VP Engineering Reference Vol. 1 (IM 33J10D10-01EN)
- 3.4, "Function Block Security" in the CENTUM VP Engineering Reference Vol. 1 (IM 33K03G21-50E)

Switch Position Label

A label displayed on each button on the HIS instrument faceplates. Switch position labels 1 to 4 can be defined using up to eight single-byte or four double-byte characters. However, the following characters cannot be used:

, (comma), | (vertical bar), ' (single quotation), " (double quotation), \ (back slash), and #

Default: ON,,OFF,ON

Tag Mark

A tag mark indicating the tag name priority and process status. The following four tag name priorities are available:

- Important
- General
- Aux.1
- Aux.2

For each tag name, alarm confirmation mode can be set as either "with acknowledgement (with Ack)" or "without acknowledgement." You can select from the following eight types of combinations of priority levels and confirmation modes. Enter a number from 1 to 8.

Table B7.1.5-10 Tag marks

Number	Type	
1	Important with Ack.	Important tag with acknowledgement
2	General	General tag
3	Aux.1	Auxiliary tag 1
4	Aux.2	Auxiliary tag 2
5	Important	Important tag
6	General with Ack.	General tag with acknowledgement
7	Aux.1 with Ack.	Auxiliary tag 1 with acknowledgement
8	Aux.2 with Ack.	Auxiliary tag 2 with acknowledgement

Default: 2 (General)

In some function blocks, a reconfirmation dialog box always appears if you try to change an MV.

SEE ALSO For more information about reconfirmation dialog box, refer to:

"● Reconfirmation dialog box" on page B8-13

Alarm Level

Define a processing level on an HIS for each alarm generated with respect to a given tag name. You can specify an alarm priority and display color for all alarms generated in relation to the tag name. You can select an alarm processing level from the 16 levels listed in the following table: The alarm levels 1 to 4 are fixed. Enter the number using single-byte characters.

Table B7.1.5-11 Alarm processing levels

Level	Type	Description
1	High	High-priority alarm
2	Medium	Medium-priority alarm
3	Low	Low-priority alarm
4	Logging	Logging alarm
5 … 16	User (5) … User (16)	These types are defined in the CENTUM Alarm Processing Table Builder. Equalize to the setting from the Alarm Processing Table Builders on CENTUM.

Default: 1 (High)

Upper Window

An upper window is a window that is called when the graphic button in a toolbox or graphic key on the operation keyboard is operated on HIS while a tag name is selected. The upper window can be specified for each tag name.

Default: None

Help

You can specify a number for each help message displayed on HIS. The user can define desired help messages using CENTUM Help Builder and specify a number between HW0001 and HW9999 for each of these messages. Specify the applicable number to display the help dialog box showing the corresponding help message.

Default: HW000 (No help message)

Scale Reverse

This display method causes the top of the scale shown on the instrument faceplates of HIS to become the low limit, and its bottom the high limit. Specifying "Yes" will activate reverse display. Either "Yes" or "No" can be selected.

Default: No

Scale-division

You can select 1, 2, 3, 4, 5 or 7 divisions for the scale on the instrument faceplates of HIS. You can also set "AUTO" to let the system determine the division number automatically.

Default: AUTO

Double Authentication

Use this function if you want to grant operation permission based on approvals of two users--the logged-in user and another user--when operating important tag names from an HIS. When the use of double authentication is defined, the reconfirmation dialog box with double authentication appears. Specifying "Yes" will enable double authentication. Either "Yes" or "No" can be selected.

Default: No

Alarm in Overriding

Specify whether or not to generate a process alarm to notify that a grouping override function block or an override function block is overriding. Specifying "Yes" will cause an applicable process alarm to be generated. Either "Yes" or "No" can be selected.
Default: Yes

SEE ALSO For more information about overriding alarm, refer to:

"■ Process alarm" on page B4-6

Answer-back Alarm

Specify whether the process alarm is to be generated when the Override Operation or Manual Operation from HIS does not work properly. For example, a process alarm can be generated when the Manual Operation Function Block detects discrepancy between the output signal to a valve and the answerback input value from the limit switch of the valve. You can select "Both" (answerback error on both the ON and OFF sides), "ON", "OFF" or "No".
Default: Both

Table B7.1.5-12 Option for answer-back alarm

Variable type	OVR_B, OVR_I, OVR_R, OVR_IR, OVR_IB, MOB_RS(*1)	MOB_11, MOB_12
Option	0: No 1: Both (Default)	0: No 1: Both (Default) 2: ON 3: OFF

*1: For GOV_B, GOV_IB, and PASSWD, no setting is required.

SEE ALSO For more information about answerback error alarm, refer to:

"■ Process alarm" on page B4-6

● Password ON Alarm

Specify whether or not to generate a process alarm when the PASSWD function block is outputting 1 as the result of overriding by HIS. Specifying "Yes" will cause an applicable process alarm to be generated. Either "Yes" or "No" can be selected.
Default: Yes

SEE ALSO For more information about password ON alarm, refer to:

"■ Settings in the Tag Name Builder" on page B4-21

● Output High Limit

Specify the upper output limit within the range 0.0% to 100.0%.
Default: 100.0%

● Output Low Limit

Specify the lower output limit within the range 0.0% to 100.0%
Default: 0.0%

● Output Scale High Limit

Fixed to 100.0 %.

● Output Scale Low Limit

Fixed to 0.0%.

● Time to Chattering Recovery Notice (s)

This items is used to suppress the chattering alarm.

Set the time by which to delay the display of the process alarm indicating recovery from an error of the input open (IOP). Upon recovery from an error during the alarm suppression period, the SCS monitors whether the normal status persists for the time set for this item. Alarm suppression is continued if an error occurs within the set time, and a process alarm for recovery from an error is displayed if an error does not occur.

Setting this time to 0 disables the chattering alarm suppression function.

Setting range: 0 to 120 seconds

Default: 0

IMPORTANT

- This item cannot be set to function blocks other than ANLG_S, HSDTR, and GASDTR.
- This item can be used with SCS projects created using an SENG of R4.03.00 or later where the CENTUM Integration Package is activated.

Upper Equipment Name

Specify the upper equipment name set on the CENTUM.
Default: Blank

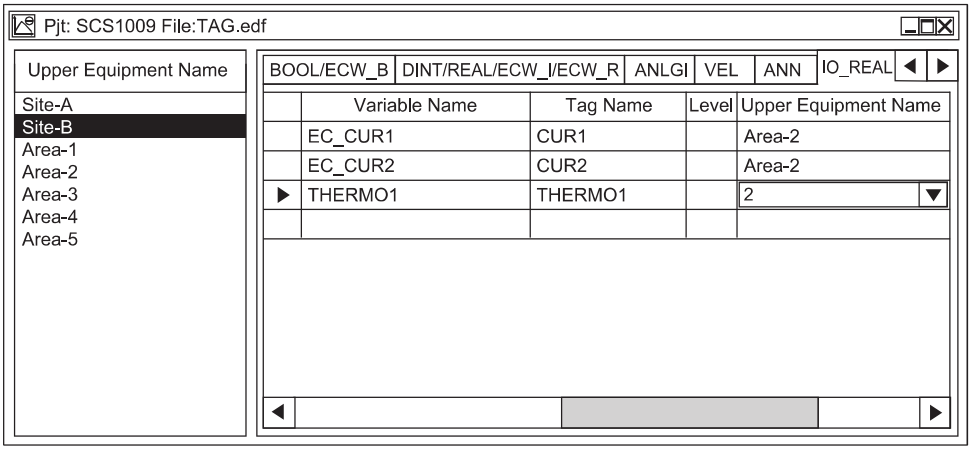

Figure B7.1.5-3 Setting of upper equipment names

Switch Color Change Part

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the parts where the display colors will change. Either Background or Characters can be selected.

Default: Background

Operation Guard

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the style for the ruled lines of the operation guard and the frame of acknowledgment. Either Dashed Line or Solid Line can be selected.

Default: Dashed Line

Flashing when prompt for Acknowledgment

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify whether or not the area specified with Color Change Area will flash upon acknowledgment. Either Yes or No can be selected.

Default: Yes

Color Change after Acknowledgment

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify whether or not the area specified with Color Change Area will change color upon acknowledgment. Either Yes or No can be selected.

Default: Yes

Color Change Area

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the areas that will flash and/or change color upon acknowledgment. Switch, Frame, or Both can be selected. When Switch is selected, the setting will follow the specification of Switch Color Change Part.

Default: Switch

Use of Button

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify whether or not to use buttons. Either Yes or No can be selected.

Default: Yes

Button Label

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the string to be displayed in the button. This item can be defined within 8 single-byte characters or 4 double-byte characters. However, the following characters cannot be used:

, (comma), | (vertical bar), ' (single quotation), " (double quotation), \ (back slash), and #

Default: RESET

Button Color (Normal)

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the color of the button during the normal status. Select a button color from one of the following 16 colors:

R:Red N:Black G:Green Y:Yellow B:Blue M:Magenta C:Cyan W:White SB:Steel Blue PK:Pink SG:Spring Green OR:Orange YG:Yellow Green VO:Violet DB:Deep Sky Blue GR:Gray

Default: White

Button Color (Resetting)

This setting item can be specified with the HSDTR function block.

Specify the color of the button during the reset status. The colors that can be specified are the same as those for Button Color (Normal).

Default: Red

Operation Guard Color

This setting item can be specified with HSDTR and GASDTR function blocks.

Specify the color of the operation guard. The colors that can be specified are the same as those for Button Color (Normal) with the exception of Black.

Default: Red

B7.1.6 Engineering for overriding from HIS

When overriding from an HIS, use one of the following two types of function blocks:

- Grouping Override Function Blocks
- Override Function Blocks

These types of function blocks include function blocks that should be selected according to the data type of the variable to override. To manage multiple override function blocks as a group, use the grouping override function block.

SEE ALSO For more information about override using override function blocks, refer to:

I1.1, "Utilizing the forcing and override functions during maintenance" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Engineering for overriding from HIS

The engineering procedure for performing an override is as follows:

Grouping override function blocks

1. Define the grouping override function block instance.
2. Insert the grouping override function block instance that you have defined into the application logic.
3. Connect the input value for normal operation to the IN terminal. This value is output when override is not performed. Specify the value to be output during override for the VAL terminal.
4. Set the Group number of this instance in a fixed value for the GRP terminal.
5. Connect the input that permits or prohibits override to the SW terminal.

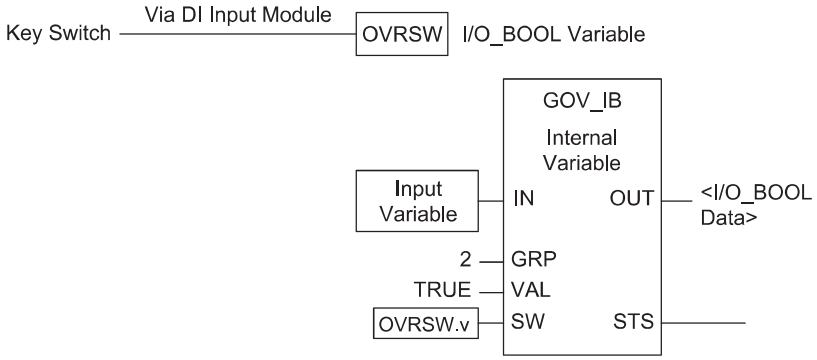

Figure B7.1.6-1 Example of grouping override function block

6. Define a tag name for the grouping override function block instance.
   You can use the tag name to perform grouping override from an HIS.

Override function blocks

1. Define the override function block instance.
2. Insert the override function block instance that you have defined into the application logic.
3. Connect the input value for normal operation to the IN terminal. This value is output when override is not performed. Specify the value to be output during override for the VAL terminal.
4. Connect the input that permits or prohibits override to the SW terminal.

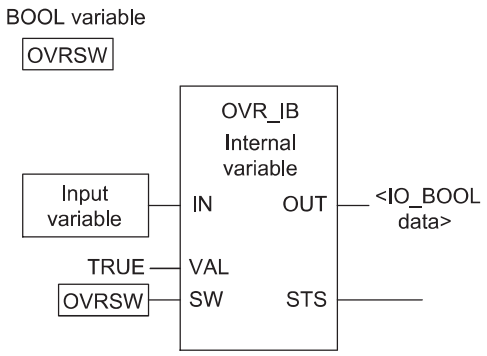

Figure B7.1.6-2 Example of override function block

5. Define a tag name for the override function block instance.
   You can use the tag name to perform override from an HIS.

Engineering for overriding using a password function block

Combining a password function block with an override function block will allow you to enable or disable override operations from an HIS using a password. The engineering procedure for connecting a password function block to a created override function block is as follows:

1. Define the password function block instance.
2. Insert the password function block instance that you have defined into the application logic.
3. Define a password string you need to enter for operation from an HIS for the password function block.
4. Search for the override function block instance to which this password function block is connected.
5. Connect the output parameter OUT of the password function block to the input parameter SW of the override function block.

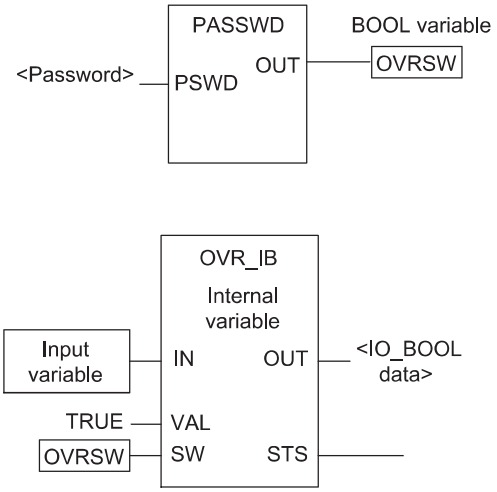

Figure B7.1.6-3 Example where a password function block is used to permit override

6. If necessary, set a password for the POU that contains the created password function block.
   This will restrict the reference to and printing of the password function block by opening the POU and prevent an unauthorized user from referencing a password.
7. Specify a tag name for the password function block instance.

SEE ALSO For more information about engineering for the password function block, refer to:

11.11, “SYS_PSWD (password function blocks management)” in POU Reference Manual (IM 32P03B20-01EN)

B7.1.7 Settings for exchanging data between FCS and SCS

For setting data from FCS to SCS, use SCS link transmission or external communication function block. The SCS link transmission allows data exchanges between FCS and SCS.

SEE ALSO For more information about SCS link transmission function, refer to:

- A6.1, “Overview of the SCS link transmission” on page A6-2
- A6., “SCS link transmission” on page A6-1

For more information about data setting from FCS, refer to:

B6., “Data setting using external communication function blocks” on page B6-1

For more information about overview of external communication function blocks, refer to:

10., “External communication function blocks” in POU Reference Manual (IM 32P03B20-01EN)

SCS link transmission

To exchange data between SCS and FCS, APCS, or GSGW, communications data must be assigned to the SCS link transmission function block. You can define the assignment using SCS Link Transmission Builder.

The engineering flow for enabling data exchanges using the SCS Link Transmission is as follows:

SEE ALSO For more information about how to use SCS Link Transmission Builder, refer to:

A6.3, “SCS link transmission definition” on page A6-11

Engineering flow for sending data from SCS to FCS

1. Open the SCS Link Transmission Builder, select SCS Link Transmission Definition, and set Send to [Yes] on the Self Station tab.
2. Define the LTSND (link transmission data output) function block.
3. In the SCS Link Transmission Builder, select the Data Wiring Definition and then the Self Station number.
   Define the LTSND function block for the bit number (bit No).
4. Place the LTSND function block in the application logic.

Engineering flow for receiving data from FCS

1. Select SCS Link Transmission Definition in the SCS Link Transmission Builder. Configure the settings as follows in the Self Station tab:
   - In the tab, set [Receive] to [Yes].
   - In the Other Stations tab, select the station number of FCS and set [Type] to [2: FCS].
2. Define the LTFCS (interference-free link transmission data input) function block.
3. In the SCS Link Transmission Builder, select the Data Wiring Definition and then the FCS station number.
   Define the LTFCS function block for the bit number (bitNo).
4. Place the LTFCS function block in the application logic.

External communication function blocks

Engineering flow

The engineering procedure for setting data using an external communication function block is as follows:

1. Define the external communication function block instance.
2. Insert the external communication function block instance defined in step 1 into the application logic.
3. Define a tag name for the instance defined in step 1.

IMPORTANT

Do not set data periodically to SCSs from PID, MLD and other regulatory control blocks or CALCU and other arithmetic/logic calculation blocks using the inter-station data link blocks (ADLs) of FCSs. Doing so can result in a writing error.

SEE ALSO For more information about data setting through a tag name interface, refer to:

B., “CENTUM integration” on page B-1

B7.1.8 Accessing subsystem's data from CENTUM

CENTUM can access the subsystem data after the names of the communication input function blocks and the communication output function blocks are defined. Moreover, CENTUM can set data to the subsystem through the external communication function blocks (ECW_*).

Reading subsystem's data by CENTUM

CENTUM can read data in the subsystem through a tag name interface.

You need to assign tag names to the instances of the function blocks for subsystem communication in advance.

The communication data read by CENTUM are logical data.

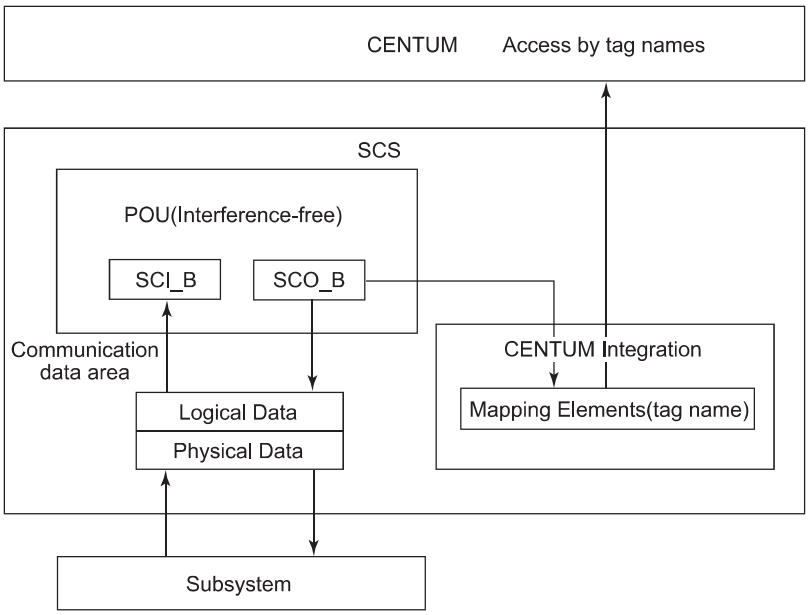

Figure B7.1.8-1 Reading subsystem's data by CENTUM

Setting subsystem's data by CENTUM

Through the external communication function block (ECW_*), CENTUM can set data in the subsystem through a tag name interface. The logic between the external communication function blocks and the subsystem communication output function blocks needs to be created.

IMPORTANT

Do not frequently set data from CENTUM to the subsystem through the external communication function blocks using tag name interfaces. Doing so can result in a writing error.

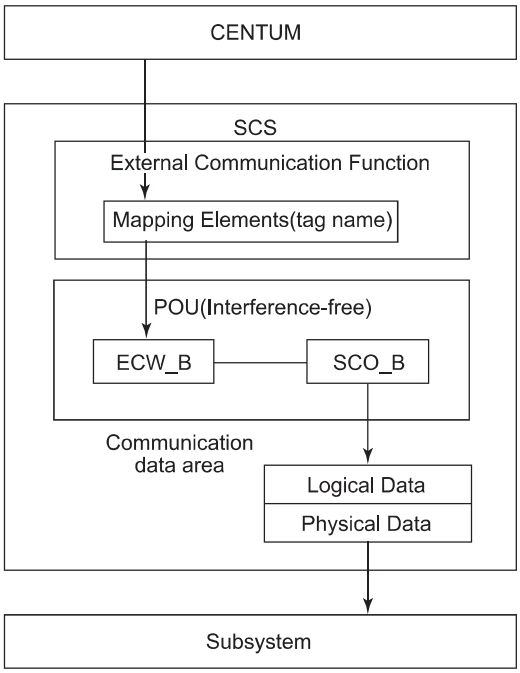

Figure B7.1.8-2 Setting subsystem's data by CENTUM

SEE ALSO

For more information about data setting using tag names, refer to:

"■ Limitations on the number of data setting requests via tag name interfaces" on page B2-2

For more information about external communication function blocks, refer to:

10., "External communication function blocks" in POU Reference Manual (IM 32P03B20-01EN)

B7.1.9 Plant hierarchy

The Plant hierarchy shows the equipment and devices on a control system in a hierarchical structure conforming to the physical model specified in the ISA S88.01. Function blocks named from the Tag Name Builder on the ProSafe-RS can be registered as equipment objects in the Plant hierarchy on the Control system. HIS is capable of filtering process alarms based on the plant hierarchy and of displaying process alarms for any equipment object.

Plant hierarchy

The mapping blocks and elements assigned with tag names can be handled as the equipment objects in CENTUM plant hierarchies. By specifying the tag names of the SCS, the process alarm filtering and security settings for operation and monitoring can be performed on HIS according to the plant hierarchy definition.

SEE ALSO For more information about plant hierarchy, refer to:

- 3, "Plant Hierarchy" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- 3, "Plant Hierarchy" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

Relationship of SCS tag data and SCS with plant hierarchy

An SCS and the plant hierarchy have the following relationships.

- It is possible to define upper level equipment names of an SCS at registering the SCS in System View of CENTUM.
- An equipment name which is defined in the CENTUM Plant Hierarchy Builder can be used as the upper level equipment name of the mapping block or element.
- Define the upper level equipment names when defining tag names of mapping blocks and mapping elements in the Tag Name Builder of the SENG. The upper level equipment names are managed as UAIDs (User Application IDs) within the SCS.
- The UAID of mapping blocks/elements whose upper level equipment name is not defined in the Tag Name Builder is set to 0 and the upper level equipment is set to the local SCS.

Changing UAID

- The upper level equipment names of mapping blocks and mapping elements can be changed via online change download as well. UAIDs of mapping blocks and mapping elements newly added via online change download take the values corresponding to the upper level equipment names defined in the Tag Name Builder.
- UAIDs managed by the SCS can be changed via operations from an HIS, SEBOL of FCS, and OPC.
- UAIDs cannot be changed from an SCS's application logic.

Precautions when UAIDs are changed from HIS and FCS

After changing UAID from HIS, FCS or OPC for the SCS tag name, if you perform the following operations, the inconsistency of the UAID between HIS and SCS will occur.

- Execute offline download to the SCS
- Reset and restart the SCS (when the SCS is reset and restarted, UAIDs of function blocks take the values specified by the Tag Name Builder)
- Reset and restart the HIS (when the HIS is reset and restarted, UAIDs of the tag list maintained on the HIS take the values specified by the Tag Name Builder)

IMPORTANT

If UAIDs do not match between the HIS and SCS, the security management on the HIS and process alarm filtering according to the plant hierarchy definitions no longer function correctly. If UAIDs are set from an HIS, FCS or OPC, be sure to set the UAIDs again from the HIS, FCS or OPC after SCS offline download or resetting and restarting the HIS and/or SCS.

Plant hierarchy engineering

1. Setting upper equipment names for SCS station
   When a new SCS is defined from the System View on the CENTUM ENG, the equipment object of SCS is automatically registered in the Plant hierarchy.

   Open the SCS Properties from the System View on the CENTUM ENG to specify the name of the upper equipment name than SCS.

2. Setting upper equipment name for SCS tag name
   The upper equipment name for each Mapping Block/Element on SCS can be specified from the Tag Name Builder. The specifiable upper equipment names are limited to those (Custom equipment name) defined from the Plant Hierarchy Builder on the CENTUM. You cannot specify the default equipment name.

3. Defining upper equipment
   Use the Plant Hierarchy Builder on the CENTUM ENG.

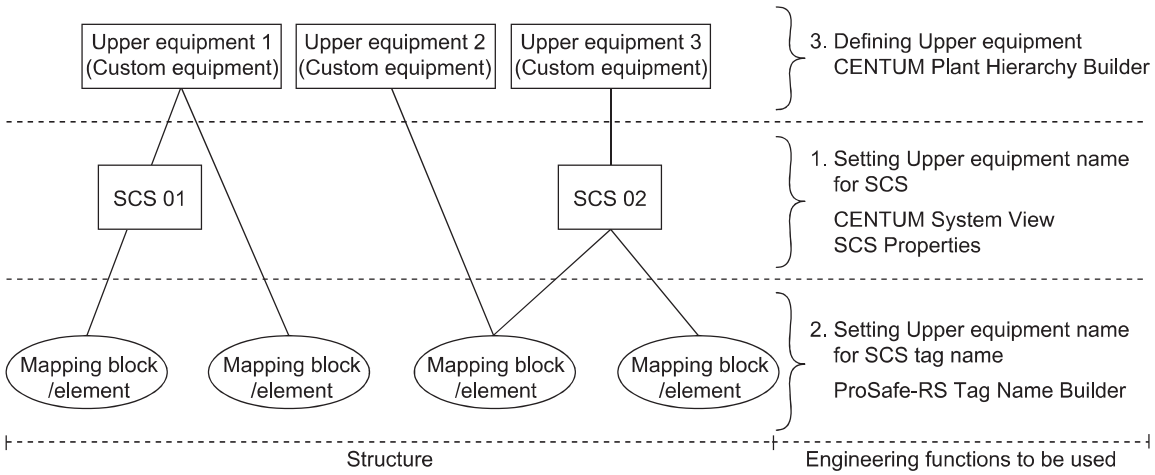

Figure B7.1.9-1 Example of SCS plant hierarchy

SEE ALSO

For more information about the plant hierarchy engineering, refer to:

- 3.2, "Plant Hierarchy Engineering" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- 3.2, "Plant Hierarchy Engineering" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

B7.1.10 Saving and downloading operation marks

The operation marks set for the mapping blocks or mapping elements of an SCS can be saved in an SENG. The saved operation marks can be downloaded to an SCS.

Save operation marks

The operation marks for the tagged elements and annunciators can be saved.

The operation marks can be saved by SCS Manager at any time. The dialog box that prompts for saving the operation marks will be displayed before Offline Download, Master Database Offline Download and SCS Restart. On the dialog box, choose Yes, then the operation marks will be saved.

Procedure of saving operation marks

1. On SCS Manager, choose [Tools] > [Controller] >[Save Operation Marks].
   A dialog box appears, asking you whether you want to save the operation marks.
2. Click [Yes], then saving will start with a progress bar.

Download operation marks

- The saved operation marks of the tagged data and annunciators can be downloaded.
- Only the saved operation marks of the tag names that are consistent with the tag names in the SCS can be downloaded. If the tag names are modified after saving the operation marks, the operation marks of the inconsistent tag names will not be downloaded.

IMPORTANT

- The operation marks in the SCS are initialized when you perform an Offline Download, Master Database Offline Download, or SCS manual restart, or when the SCS automatically restarts after power failure. When performing the above operations (except SCS auto restart after power failure), a dialog box will be displayed, prompting you to save the operation marks.
- For Offline Download or Master Database Offline Download, set a security password first and then download the operation marks after the SCS shifts to Waiting mode.
- For SCS Restart, download the operation marks after the SCS shifts to Waiting mode.

Procedure of download operation marks

1. On SCS Manager, choose [Tools] > [Controller] > [Download Operation Marks] to start.
   A dialog box appears, asking you whether you want to download the operation marks.
2. Click [Yes], then download will start with a progress bar.

B7.2 Engineering on the CENTUM side

This section describes engineering tasks performed on the CENTUM side, one of the tasks required to connect an SCS project and a CENTUM project.

B7.2.1 SCS creation

To connect each SCS project to a CENTUM project, a corresponding SCS must be created in CENTUM System View first.

Creating an SCS

Create SCSs on CENTUM System View. The procedure is explained in the following section:
Select [File] > [Create New] > [SCS (E)] in System View. The New Station dialog box appears.

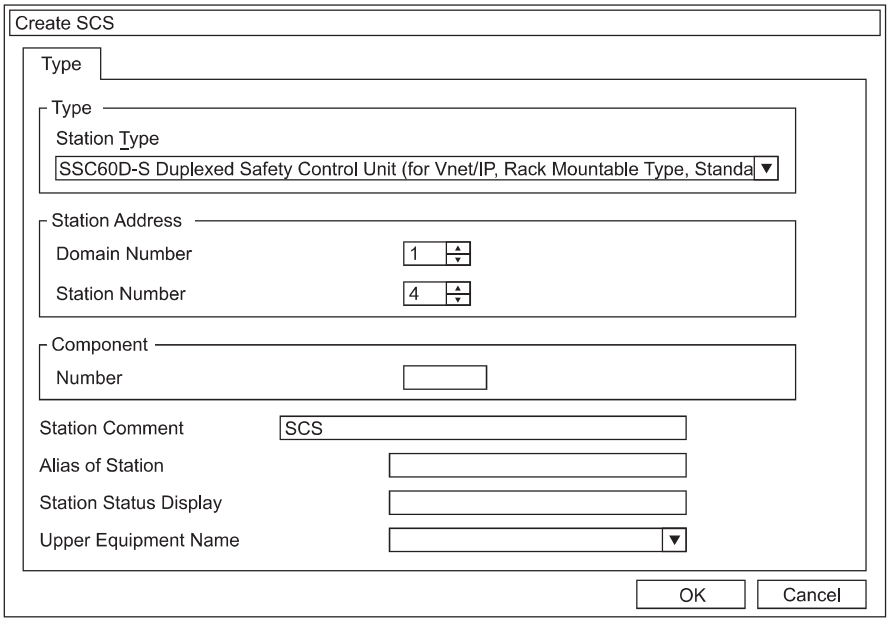

Figure B7.2.1-1 Example display of the Create SCS dialog box (Type tab)

TIP

Do not select "SCS01 Safety Control Station" as the station type.

The following section describes the items defined in each tab sheet:

Definition items in the Type tab

The following describes the items defined in Type tab. The station type and station address are mandatory.

Station Type

You can select the station type from the following choices:

Table B7.2.1-1 Station type list

Station Type
[S2SC70D-S Duplexed Safety Control Unit (for Vnet/IP and N-IO/FIO, Rack Mountable Type, Standard Type)]
[S2SC70D-F Duplexed Safety Control Unit (for Vnet/IP and N-IO/FIO, Rack Mountable Type, Wide Range Temperature Type)]
[S2SC70S-S Safety Control Unit (for Vnet/IP and N-IO/FIO, Rack Mountable Type, Standard Type)]
[S2SC70S-F Safety Control Unit (for Vnet/IP and N-IO/FIO, Rack Mountable Type, Wide Range Temperature Type)]

Continues on the next page

Table B7.2.1-1 Station type list (Table continued)

Station Type
[L1SC70D-S SIL2, Duplexed Safety Control Unit (for Vnet/IP, for FIO, Rack Mountable Type, Standard Type)]
[L1SC70D-F SIL2, Duplexed Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Wide Range Temperature Type)]
[L1SC70S-S SIL2, Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Standard Type)]
[L1SC70S-F SIL2, Safety Control Unit (for Vnet/IP and FIO, Rack Mountable Type, Wide Range Temperature Type)]
[SSC60D-S Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)]
[SSC60D-F Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)]
[SSC60S-S Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)]
[SSC60S-F Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)]
[SSC50D-S Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)]
[SSC50D-F Duplexed Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)]
[SSC50S-S Safety Control Unit (for Vnet/IP, Rack Mountable Type, Standard Type)]
[SSC50S-F Safety Control Unit (for Vnet/IP, Rack Mountable Type, Wide Range Temperature Type)]
[SSC10D-S Duplexed Safety Control Unit (for Vnet, Rack Mountable Type, Standard Type)]
[SSC10D-F Duplexed Safety Control Unit (for Vnet, Rack Mountable Type, Wide Range Temperature Type)]
[SSC10S-S Safety Control Unit (for Vnet, Rack Mountable Type, Standard Type)]
[SSC10S-F Safety Control Unit (for V net, Rack Mountable Type, Wide Range Temperature Type)]

Station Address

Set the station address. A station address consists of a domain number and a station number. Although any domain number from 1 to 31 can be set for a ProSafe-RS station, set only a value between 1 and 16 when the station is used in the CENTUM integration structure. The default domain number is the number set in the project. The station number should be set from 1 to 64. The default station number is the next available blank number found in a search in ascending order from 1. Once a station address is set, it cannot be changed. The only way to change the station address is to delete the existing station and then create a new one with new address.

Component Number

You can set a component number between 0 and 9999. The setting of component number may be omitted.

Station Comment

You can set a comment for the station. The setting of station comment may be omitted. Set the comment using up to 24 single-byte or 12 double-byte characters.

Alias of Station

You can set an alias for the station.
When an alias is set, all names of the station displayed on an HIS will be replaced by the alias. Set the alias using up to eight single-byte alphanumeric characters.

Station Status Display

Set the name of the window you want to display on an HIS in place of the Station Status Display view. The name of the Station Status Display view is set using up to 16 single-byte al-

phanumeric characters. Double-click the SCS icon in the System Status Overview view to display the window set here.

Upper Equipment Name

Specify the name of the equipment located in a level above the station.
The upper equipment name should use the corresponding equipment name set in Plant Hierarchy Builder.

When a new SCS is defined, an SCS equipment object is registered in the plant hierarchy automatically. Different equipment can be specified for each Mapping Blocks/Elements of the SCS.

SEE ALSO For more information about plant hierarchy builder, refer to:

- 3.2.2, "Registering Custom Equipment (Other than Unit Equipment)" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- 3.2.2, "Registering Custom Equipment (Other than Unit Equipment)" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

Downloading the project common

In the CENTUM integration structure, the project common is used to build a system for operating and monitoring SCSs from HISs. So, download the project common.

In the engineering of HISs and FCSs in a CENTUM project, the common items in the project are defined as the project common (COMMON). The definitions in the project common are shared by all HISs and FCSs in the same CENTUM project. Accordingly, modifying the project common will also modify the corresponding HIS/FCS definitions.

TIP Changing the project common of a CENTUM project will not affect SCS applications.
Therefore, reengineering is not required on an SENG after the project common has been changed.

B7.2.2 SCS taglist generation

To access mapping blocks/elements on an SCS from an HIS using the corresponding tag names defined in ProSafe-RS Tag Name Builder, a taglist for the SCS must be generated on the CENTUM side. CENTUM taglists are generated using the Taglist Generation Function included in the CENTUM Engineering Function.

Generating SCS taglist on CENTUM

Launch Taglist Generation Function from System View.

1. In System View, select the SCS you want to generate a taglist for.
2. Select [Tools] > [SCS Taglist Import] from the menu.
   An HIS taglist is generated.

Taglist Generation Function generates an HIS taglist based on the corresponding SCS taglist file generated in the Engineering Function of the ProSafe-RS. If the CENTUM project is the current project, the taglist is downloaded to the HIS. The result of Taglist Builder operation appears in the message area of System View.

Engineering unit symbol and switch position label

Keep the engineering unit symbol and switch position label modes to AUTO while generating a SCS taglist.

When an SCS taglist is generated in the MANUAL model, if engineering unit symbols and switch position labels not present in the CENTUM project are included in the engineering information (taglist, etc.) of the SCS, they will not be registered in the CENTUM project, and a warning message appears as a result. In this case, register the engineering unit symbols and switch position labels that generated the warning message in the respective builders, and then generate a taglist again.

SEE ALSO For more information about mode of the engineering unit symbol and switch position label, refer to:

- 2.2, "Creating a New Project" in the CENTUM VP Engineering Reference Vol. 1 (IM 33J10D10-01EN)
- 2.2, "Creating a New Project" in the CENTUM VP Engineering Reference Vol. 1 (IM 33K03G21-50E)

Downloading a taglist

Each generated taglist can be downloaded to an HIS that requires it. Taglists can be downloaded using the TagList Down Load dialog box called from System View.

Taglist download operation

1. Select [Load] > [Download Tag-List] in System View.
   The TagList Down Load dialog box appears.

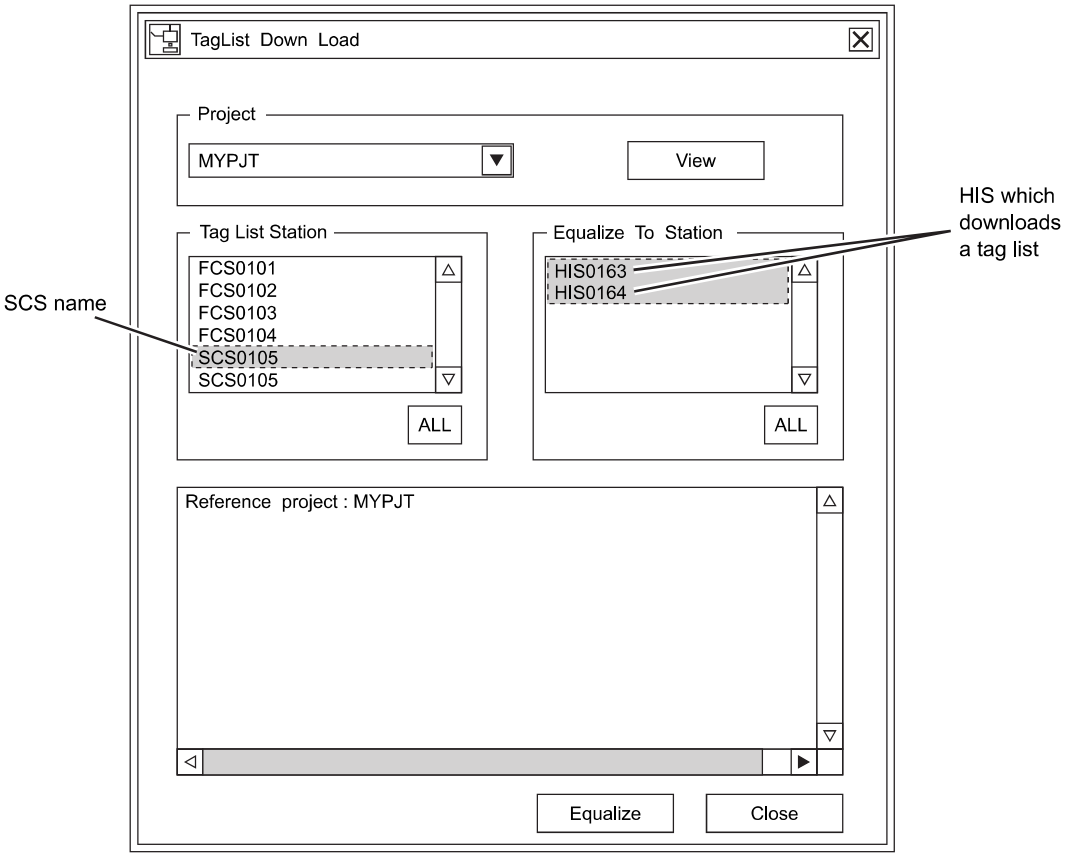

Figure B7.2.2-1 Example of the TagList Down Load dialog box

2. Select the desired project, and then click the [View] button.
   A list of stations appears.
3. Select the SCS, and the HIS you want to download the taglist to, and then click the [Equalize] button.
   The generated taglist is downloaded to the selected HIS.

Cautions after downloading database

In the CENTUM integration structure, if a database is downloaded (offline or online-change) from the SENG to SCS, be sure to generate a SCS Tag List from the System View on the CENTUM ENG. Otherwise, databases on HIS or Exaopc conflict, and trigger a system alarm message prompting you to equalize the database in the startup process of HIS or Exaopc.

B7.2.3 Other builders

To connect an SCS project with a CENTUM project, the following builders and viewer are required:

- Operation Mark Builder
- Plant Hierarchy Builder
- Plant Hierarchy Viewer
- FCS Constants Builder

Operation Mark Builder

Setting operation marks using Operation Mark Builder of the CENTUM ENG allows the assignment of tag with comment in the instrument faceplate or the change of operation privileges over mapping blocks/elements.

The definitions set in Operation Mark Builder are used commonly by all FCSs, HISs and SCSs in the CENTUM project.

If an operation mark is added or modified in Operation Mark Builder, the action of the operation mark on HISs will change once the addition/modification is downloaded to the HISs.

IMPORTANT

- The initial value of operation marks for mapping blocks/elements is 0 (no operation mark). When the SCS is restarted, the setting of operation marks will return to the initial value.
- An offline download (or master database offline download) to the SCS will cause the setting of operation marks to return to the initial value.
- Values cannot be specified for operation marks for mapping blocks/elements using the ProSafe-RS Engineering Function.
- Operation mark values cannot be changed using the SCS application logic.

SEE ALSO

For more information about operation marks, refer to:

- 3.5, "Operation Mark" in the CENTUM VP Engineering Reference Vol. 1 (IM 33J10D10-01EN)
- 3.5, "Operation Mark" in the CENTUM VP Engineering Reference Vol. 1 (IM 33K03G21-50E)

For more information about operation marks tab sheet, refer to:

- 4.3.10, "Operation Mark Tab" in the CENTUM VP Human Interface Stations Reference Vol. 1 (IM 33J05A10-01EN)
- 4.3.10, "Operation Mark Tab" in the CENTUM VP Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Plant Hierarchy Builder

Use the Plant Hierarchy Builder for registering Custom equipment. To activate the Plant Hierarchy Builder, in the System Engineering function, bring up the System View. In the List view, double click [Common] > [Custom Plant].

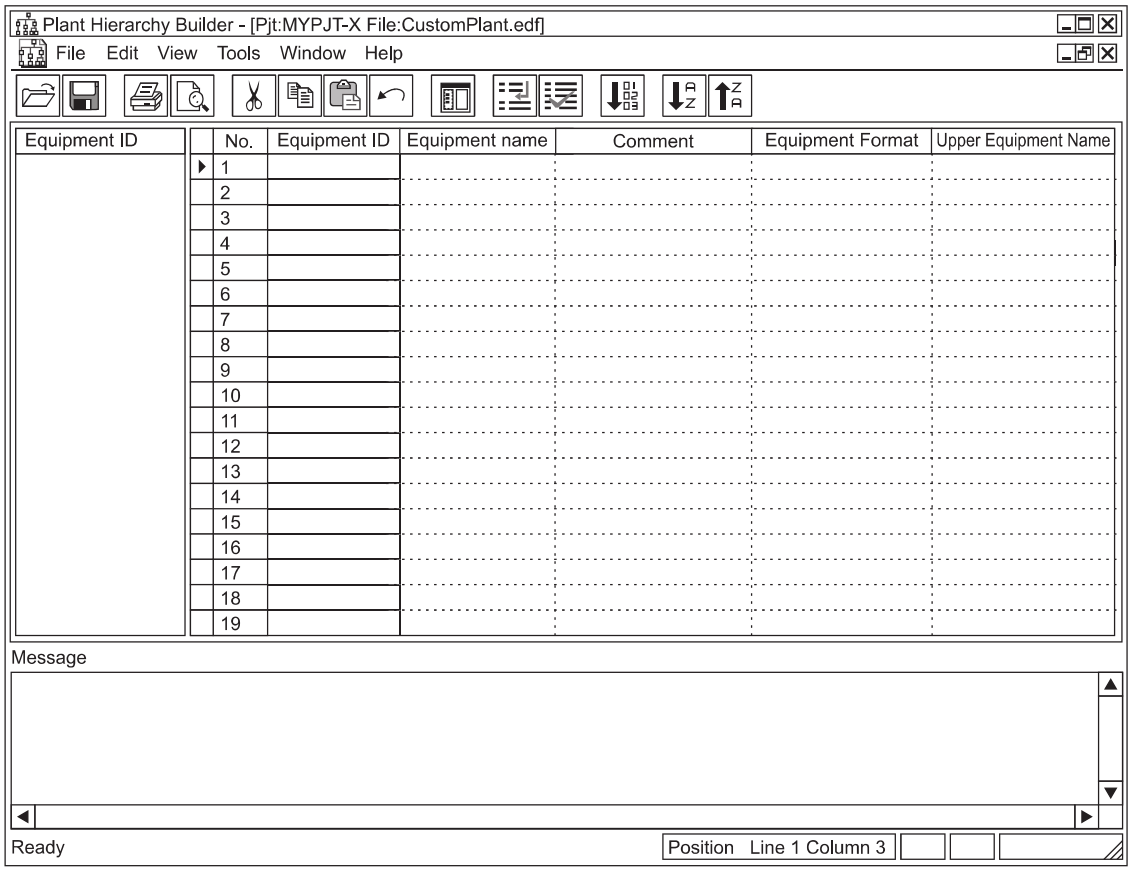

Figure B7.2.3-1 Plant Hierarchy Builder

Plant Hierarchy Viewer

In the Plant Hierarchy Viewer, you can confirm the custom equipment name registered from the Plant Hierarchy Builder. The Plant Hierarchy Viewer shows the plant hierarchy of the entire projects.
From the menu on the System View window on the CENTUM ENG, select [Tool] > [Plant Hierarchy Viewer]. SCS tags are shown in the Plant Hierarchy Viewer window.

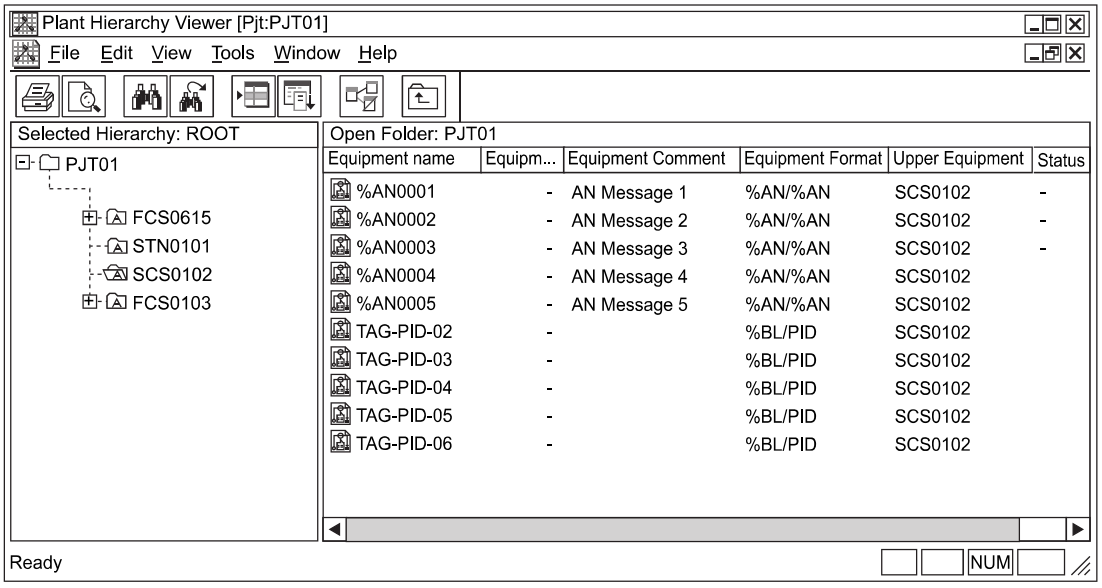

Figure B7.2.3-2 Example of Plant Hierarchy Viewer in R3.08 or later

SEE ALSO For more information about plant hierarchy viewer, refer to:

- 3.3, "Plant Hierarchy Viewer" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- 3.3, "Plant Hierarchy Viewer" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

FCS Constants Builder

If SCS exchanges data with FCS using the SCS link transmission, set present station definition and station definition of scan transmission definition.

The SCS data that can be referenced at FCS are %GS001 to %GS128.

SEE ALSO For more information about scan transmission definition settings in the FCS Constants Builder, refer to:

- "Scan Transmission Definitions" in A4.2, "Global Switch" in the Field Control Stations Reference (IM 33J15A10-01EN)
- "Scan Transmission Definitions" in A4.2, "Global Switch" in the Field Control Stations Reference (IM 33K03E10-50E)

B7.2.4 Items to note on CENTUM engineering

This section describes the items to be noted in CENTUM engineering.

■ Software I/Os supported on SCS

Among the various software I/Os of CENTUM FCS, common switches and annunciators can be used on SCS.

● Common switches

The SCS common switches having an element number between %SW0001 and %SW0400 are system common switches. The system common switches are elements having a predefined purpose, such as identification of SCS status. All common switches of SCSs are system common switches.

Tag names cannot be defined for SCS common switches. Also, values cannot be set in common switches.

SEE ALSO For more information about details of each SCS common switch element number, refer to:

"■ Software inputs/outputs" on page B1-2

● Annunciators

Annunciators are used as mapping elements for ANN and ANN_FUP function blocks. Each message can be defined using up to 80 single-byte or 40 double-byte characters.

Annunciators are either with or without tag names.

- Annunciators
  Annunciators can display a message of up to 80 single-byte or 40 double-byte characters.
- Annunciators with tag names
  Annunciators with tag names can display a message of 24 single-byte characters and tag names.

The user can decide the first number of an annunciator with a tag name. In the Tag Name Builder, the numbers that precede the first number define the area assigned to annunciators, while the first number and all the numbers that follow the first number define the area assigned to annunciators with tag names.

TIP An annunciator with tag names can be used in SCS projects that are created in ProSafe-RS R4.01 or later.

■ Data setting from FCS to SCS

Using SFC (Sequential Function Chart) can set data from FCS to SCS.

All the SCS data are accessible by assigning the tag names to the mapping elements on the Tag Name Builder of SENG. And the SCS data can be written from FCS by assigning the data to the external communication function blocks.

SEE ALSO For more information about data setting from FCS, refer to:

- B7.1.7, "Settings for exchanging data between FCS and SCS" on page B7-32
- B6.1, "Confirmation of setting data" on page B6-2
- "■ Functions in CENTUM integration structure" on page B2-1

The first number of annunciator message with tag name

You can assign annunciators and annunciators with tag names in the annunciator message storage area.

To assign area to annunciator messages and annunciator messages with tag names, you need to set the first number of annunciator message with tag name (%AN). The number from the first number that is set to the largest number of annunciator message can be used for an annunciator message with tag name.

Setting range: 0 to 1000 (SCSP1/SCSU1), 0 to 2000 (SCSP2/SCSP3/SCSL2)

Initial setting: 0

IMPORTANT

If the first number is 1 or greater, then that number and all the following numbers will be used as annunciator messages with tag names.

If the first number is 0, the entire message can be used as an annunciator message.

SEE ALSO For more information about configuring the annunciator message with tag name, refer to:

"● The first number of annunciator messages with tag name" in "■ Settings with the Communication Tab" in C1.2.6, "SCS Constants Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Precautions on Annunciators with tag names

- Maximum 80 single-byte characters can be recorded as an annunciator message with tag name, while the first 24 characters are output as message. If your message is longer than 24 characters, you need to use an annunciator message.
- If the 24th character of a single-byte string is a double byte character, the first 23 characters are displayed.
- To use an existing annunciator message as an annunciator with tag name, you need to specify "The first number of the annunciator message with tag name (%AN)", and execute the build. The messages with the specified number and higher numbers get converted to annunciator messages with tag names.
- When using iDefine, mixed use of annunciator messages and annunciator messages with tag name is not allowed. You must define all annunciators as either annunciator messages or annunciator messages with tag name.
- Even if you are defining annunciator messages with tag name by using iDefine, you must specify "The first number of the annunciator message with tag name (%AN)."

Precautions when integrated with CENTUM or connected with Exaopc

In a CENTUM Integration environment, a communication error (No. 0301 control bus communication error) may be alerted with CENTUM HIS after the SCS starts up until the operating mode transitions to Waiting Mode. Similarly, a communication error may be alerted with an OPC server on which Exaopc or Exaopc OPC Interface Package (for HIS) is installed.

This alarm is alerted until the transition to Waiting Mode because the SCS does not respond to communication from other stations. As this is merely a transitional alarm alerted upon starting the SCS, you do not need to respond to this alarm.

B8. Overview of safety system operation and monitoring using HIS

In the CENTUM integration structure, HIS can operate and monitor SCS data through tag names in the same interface as that of FCS data. Because SCS application logic is created with IEC 61131-3 language, it is necessary to define mapping blocks/elements in the SCS and assign tag names with Tag Name Builder to realize the tag name interface. In addition, it is possible to monitor the SCS status and alarms by HIS standard windows.

SEE ALSO For more information about mapping blocks/elements, refer to:

B3., “Tag name interfaces for CENTUM” on page B3-1

Overview of safety system operation and monitoring using HIS

The following outlines the operation and monitoring of an SCS by an HIS in the CENTUM integration structure.

- Operate and monitor SCS data using tag names via the same interface used for operating and monitoring FCS data. Data can be referenced using the instrument faceplate, and SCS data can be displayed in the Graphic view.
- Monitor in HIS's Process Alarm view both occurrence and recover of process alarms and annunciators detected by SCSs.
- Monitor in HIS's System Alarm view all system alarms occurred on SCS.
- Display in HIS's SCS Station Status Display view the operating status of SCS.
- Override the application logic variables from HIS.
- Set the outputs of the application logics form HIS.

Windows used for operation and monitoring of SCS

The following windows are mainly used for operation and monitoring of SCSs from an HIS:

Table B8-1 Windows used for operation and monitoring of SCS

Window name	Description
System Alarm view	Check system alarms generated on SCSs
Process Alarm view	Check process alarms and annunciator messages generated on SCSs
SCS Station Status Display view	Monitor the operating status of SCSs
Instrument faceplate	Operate and monitor SCSs using the instrument faceplates of mapping blocks/elements
Graphic view	Monitor the data of mapping blocks/elements

The following functions can be implemented from an HIS using the above windows:

- Learn SCS alarms in real time
- Check the status of each SCS controller
- Perform maintenance override of SCSs from an HIS

Notes on online change

While operating a grouping override function block, override function block, or password function block from an HIS, do not perform online change download.

Even if the function blocks and mapping blocks that are not the targets of online change are operated from HIS, an error may occur during operation of the grouping override function block, override function block, or password function block from HIS. In this case however, the online change communication is not affected. Wait for the communication for online change to end, and then operate the grouping override function block, override function block or password function block again.

Error notification method

If an operation from HIS generates an error while online change download is running, you are notified in the following ways:

- Notification by a system alarm
- Notification by answerback error alarm (if notification of answerback error alarm is enabled in the detailed definitions for the tag)

SEE ALSO For more information about definitions of answerback errors in Tag Name Builder, refer to:

"■ Setting items" on page B7-14

B8.1 Windows used for operation and monitoring of SCS

This section describes the primary windows used in the operation and monitoring of SCSs from an HIS.

B8.1.1 System Alarm view

The System Alarm view displays a list of diagnostic information messages that notify hardware and communication errors in the system as system alarm messages. The system alarm messages are predefined in the system.

SEE ALSO For more information about System Alarm view, refer to:

- 4.2, "System Alarm View" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- 4.2, "System Alarm View" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Overview of the System Alarm view

The System Alarm view displays and manages the system alarm information notified by SCSs and FCSs as system alarm messages. Both SCS and FCS system alarm messages can be displayed in the same window.

When an SCS detects an error by its diagnostic functions, the SCS issues a system alarm message. When the error is recovered, a recovery message is issued. Each SCS also issues a system alarm as a confirmation of an operation performed to the SCS, such as security level change or forcing of variables. The System Alarm view displays these messages as system alarms. The following is an overview of the System Alarm view:

- When an alarm has occurred in SCS, the [SCS Alarm occurrence Notification] button on the toolbar changes to notify the occurrence of an SCS alarm. When the button is clicked, the message is displayed after being filtered by the Safety Control Station filter.
- Once the operator acknowledges the system alarm, the system alarm message will stop flashing.
- When the system alarm is cleared, the corresponding system alarm message is deleted from the window.
- The corresponding alarm class information managed by the SCS is displayed together with each system alarm.
- System alarm messages generated on SCSs can be filtered into a separate group for display. This function allows for easy distinction of SCS alarms from FCS alarms even when a large number of system alarm messages have been generated on FCSs.
- If SCS alarms are present, calling the System Alarm view will automatically filter the alarm messages by the Safety Control Station filter before the window is displayed.

Selection of display items

Call the Window Setting dialog box from the applicable tool button in the System Alarm view. When this dialog box is first opened, the Display Item name check box is unchecked. Checking this box will enable the selection of items you want to display in the System Alarm view.

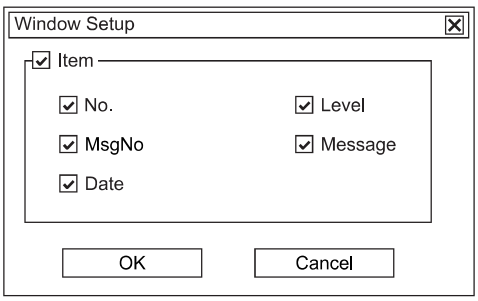

Figure B8.1.1-1 Window Setup dialog box

The following table shows the default display items in the System Alarm view and items that can be displayed or hidden.

Table B8.1.1-1 Display items in the System Alarm view

Display item name	Default window setting	Selection
Item	Displayed	Yes
MsgNo	Displayed	Yes
Date	Displayed	No
Level(*1)	Not displayed	Yes
Message	Displayed	No

*1: The displayed level corresponds to the SCS alarm class (1 to 4).

Split display

The System Alarm view can be displayed into two frames.

When a filter is set, the view is split horizontally, with the messages matching the filter condition displayed in the top frame and all messages displayed in the bottom frame.

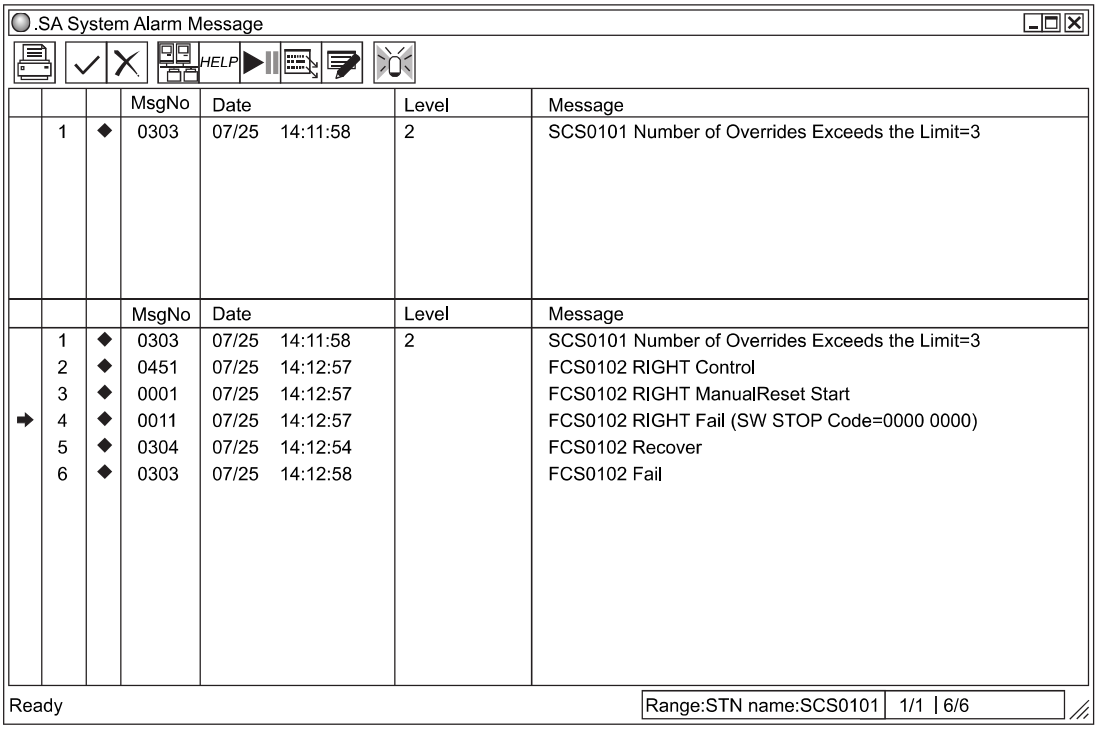

Figure B8.1.1-2 Split display of the System Alarm view

SEE ALSO For more information about split display of the System Alarm view, refer to:

- "Splitting System Alarm View" in 4.2.3, "Filter and Display System Alarm Messages" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- "Splitting System Alarm View" in 4.2.3, "Filter and Display System Alarm Messages" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Specification of system alarm filters

The following filters can be specified in the System Alarm view:

- All

All system alarm messages are displayed.

- Station Name
  System alarm messages generated in the selected station are displayed.
- Current Station
  Alarm messages generated in the current station are displayed.
- Safety Control Station
  System alarm messages generated on SCS are displayed.

  All ProSafe-RS SCSs become the target of filtering.

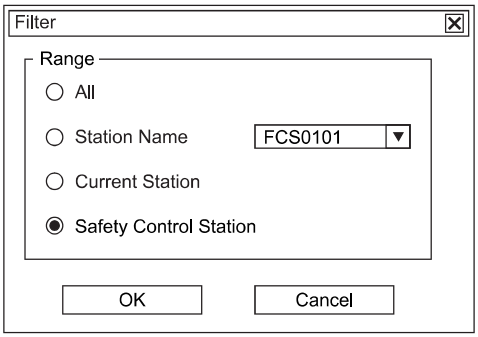

Figure B8.1.1-3 System alarm filter setting dialog box

B8.1.2 Process Alarm view

The Process Alarm view displays process alarms including annunciator messages.

SEE ALSO For more information about Process Alarm view, refer to:

- 3.6, "Process Alarm View" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- 3.6, "Process Alarm View" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Overview of the Process Alarm view

The Process Alarm view displays and manages the process alarm information notified by SCSs and FCSs as process alarm messages and annunciator messages.

- When a process alarm has occurred in SCS, the [SCS Alarm occurrence Notification] button display on the toolbar changes to notify the occurrence of an SCS alarm. When the [SCS Alarm Occurrence Notification] button is clicked, the message is displayed after being filtered by the [Safety Control Station] filter.
- SCS process alarms can be acknowledged and deleted in the Process Alarm view. Acknowledging or deleting an SCS process alarm on an HIS will change the corresponding process alarm information managed on the SCS.
- Process alarm messages occurred in SCSs can be filtered into a separate group for display. This function allows for easy distinction of SCS alarms from FCS alarms even when a large number of process alarm messages have been generated on FCSs.
- If SCS alarms are present, calling the Process Alarm view will automatically filter the alarm messages using the [Safety Control Station] filter before the window is displayed.

Selection of display items

Call the Window Setting dialog box from the applicable tool button in the Process Alarm view. When this dialog box is first opened, the Display Item name check box is unchecked. Checking this box will enable the selection of items you want to display in the Process Alarm view.

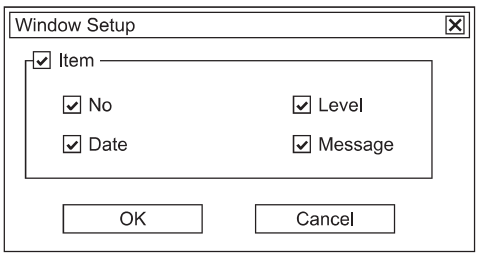

Figure B8.1.2-1 Window Setup dialog box

The following table shows the default display items in the Process Alarm view and items that can be displayed or hidden.

Table B8.1.2-1 Display items in the Process Alarm view

Display item name	Default window setting	Selection
Item	Displayed	Yes
Date	Displayed	No
Level(*1)	Not displayed	Yes
Message	Displayed	No

*1: The displayed level corresponds to the alarm priority level.

Split display

The Process Alarm view can be displayed into two frames.

When a filter is set, the view is split horizontally, with the messages matching the filter condition displayed in the top frame and all messages displayed in the bottom frame. However, if an alarm priority filter is selected in the Alarm tab on the HIS Setup window, both the top and bottom frames display only the messages of the specified priorities.

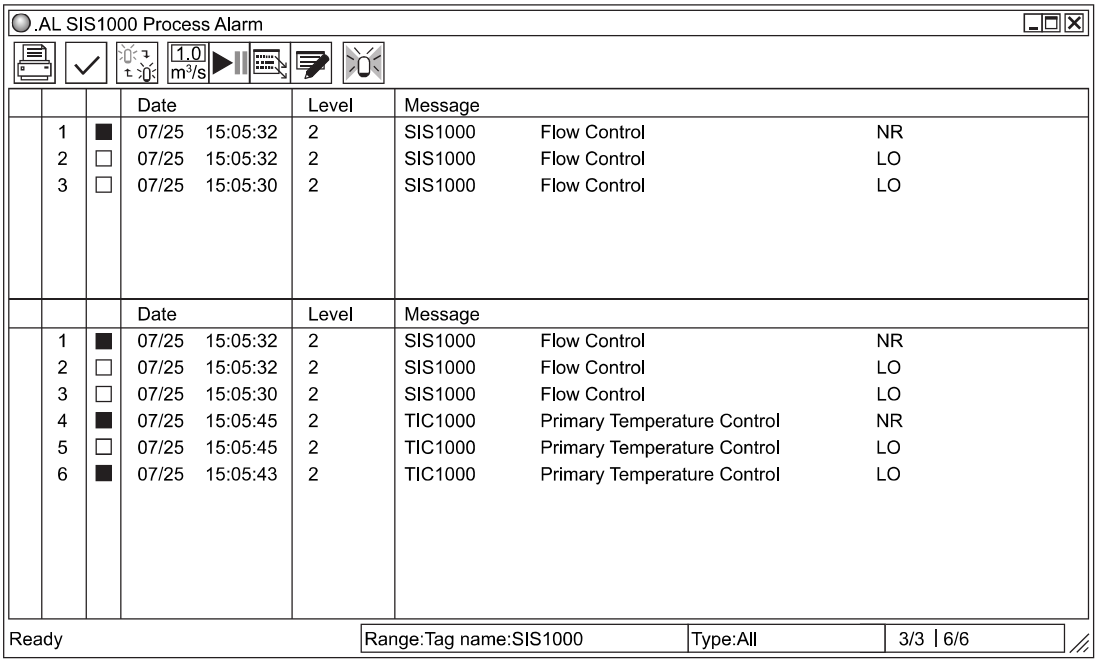

Figure B8.1.2-2 Split display of the Process Alarm view

SEE ALSO For more information about Split display of the Process Alarm view, refer to:

- "Splitting Process Alarm View" in 3.6.3, "Filter and Display Process Alarm Messages" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- "Splitting Process Alarm View" in 3.6.3, "Filter and Display Process Alarm Messages" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Search and display of process alarm messages

Process alarm messages and annunciator messages can be searched for using the following keywords:

Search range specification

- All
  All process alarm messages and annunciator messages are displayed.
- FCS Name
  Process alarm messages and annunciator messages generated in the selected control station are displayed.
- Plant Hierarchy Name
  Process alarm messages and annunciator messages generated in the selected control drawing name or unit instrument tag name are displayed.
- Tag Name

Process alarm messages and annunciator messages relating to the specified function block are displayed.

- Batch ID
  Process alarm messages and annunciator messages relating to the specified batch ID are displayed.
- Safety Control Station
  Process alarm messages and annunciator messages generated on SCSs are displayed.

  All ProSafe-RS SCSs become the target of filtering.

Search types

- All
  Process alarm messages and annunciator messages are displayed.
- Function Block Only
  Only process alarm messages are displayed.
- Annunciator Only
  Only annunciator messages are displayed.

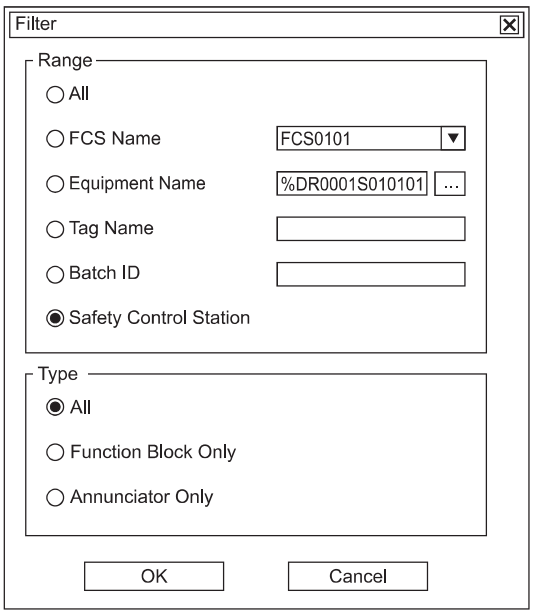

Figure B8.1.2-3 Alarm filter setting dialog box

B8.1.3 Instrument faceplates

Instrument faceplates display statuses and data of function blocks, mapping blocks, and elements assigned on the Tag Name Builder. Instrument faceplates of SCS and FCS are distinguished by the color of the mark in the bottom of the faceplate.

IMPORTANT

The operator must utilize the SCS instrument faceplate mainly for monitoring.

Follow the predefined procedure to operate an SCS instrument faceplate.

Instrument faceplate display

Mapping blocks can be called from an HIS as the instrument faceplate.

The function block types are as follows (the corresponding mapping block types are shown after the colon ":"):

- BOOL/ECW_B, DINT/ECW_I, REAL/ECW_R, IO_REAL, SCI_B, SCO_B, SCI_I, SCO_I, SCI_R, SCO_R : %WB
- PSI_I, PSI_R, PNI_I, PNI_R : %XB
- IO_BOOL : %Z, %Y
- ANN, ANN_FUP : %AN
- ANLG_S : S_ANLG_S
- ANLGI : S_ANLGI
- VEL : S_VEL
- OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR : S_OVR_B, S_OVR_I, S_OVR_R, S_OVR_IB, S_OVR_IR
- PASSWD : S_PASSWD
- HSDTR : S_HSDTR
- GASDTR : S_GASDTR

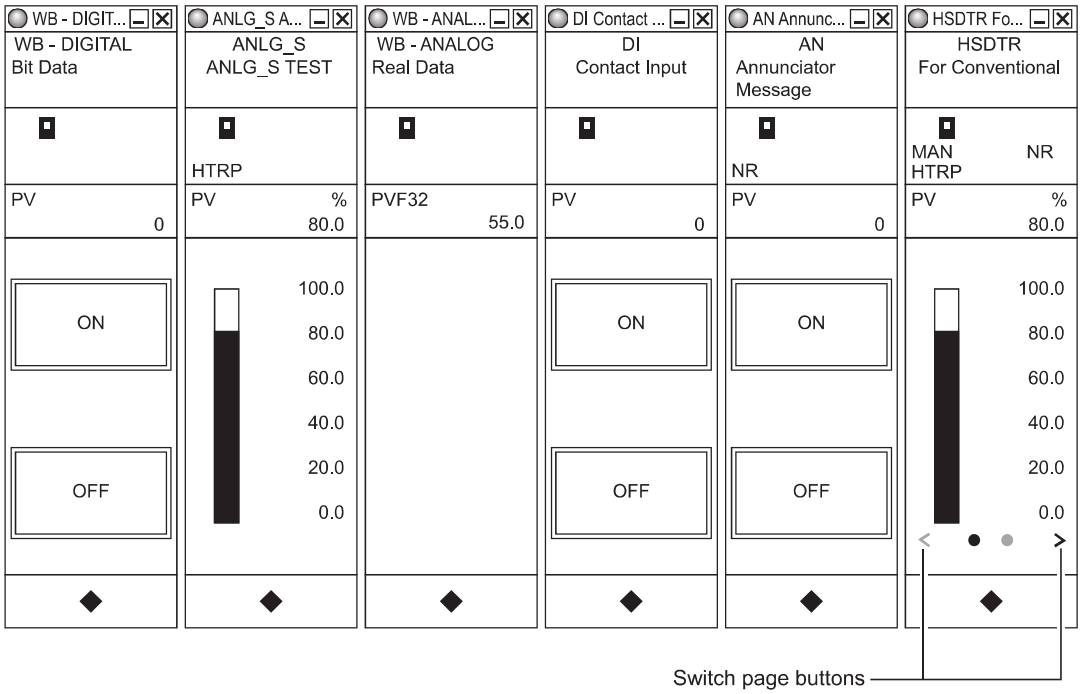

Figure B8.1.3-1 Image of instrument faceplate display

- GOV_B, GOV_IB : S_GOV_B, S_GOV_IB
- MOB_21 : S_MOB_21
- MOB_11 : S_MOB_11
- MOB_RS : S_MOB_RS
- MOA : S_MOA

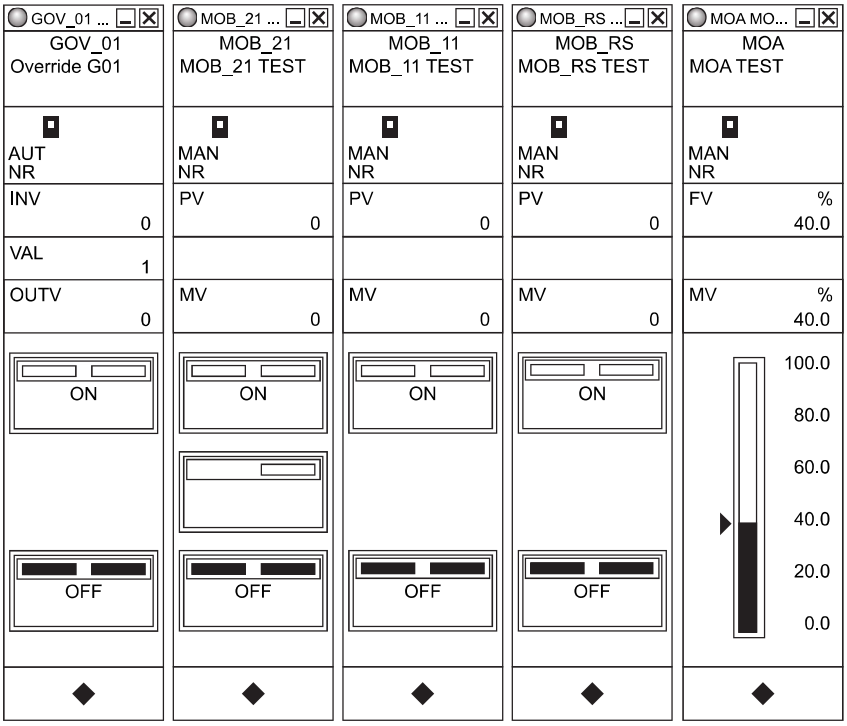

Figure B8.1.3-2 Image of instrument faceplate display

SEE ALSO For more information about instrument faceplates, refer to:

- 2, "Instrument Faceplate" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- 2, "Instrument Faceplate" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

Operation of password function blocks and manual operation blocks

- PASSWD, MOB_21, MOB_11, MOA
  If you set values of MV, enter the password in the password dialog box.

  If you enter the wrong password, MV values are reset to the previous values before the change.
- MOA
  To close the INC/DEC dialog box, click anywhere outside the dialog box. If no action is made, the dialog box closes in about 30 seconds.

Instrument faceplate

On the instrument faceplates of SCS and FCS, the mark in the bottom is displayed in different colors.

Table B8.1.3-1 Color of the mark in the bottom of faceplates

Station	mark color
FCS	Dark Blue
SCS	Orange

TIP Related builders cannot be called using a tag name.

Operation marks

The settings for operation mark provide the function to notify the operator of various statuses of equipment, such as under maintenance, out of order or operation prohibited. When an operation mark is set, a tag with comment is set in the instrument faceplate. By assigning an operation mark, the operation privileges over the instrument faceplate can be changed temporarily.

SEE ALSO For more information about settings for the Operation marks, refer to:

- "Toolbar of Tuning View" in 3.3.1, "Components of Tuning View" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- "Toolbar of Tuning View" in 3.3.1, "Components of Tuning View" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

Two-step operation setting for switch faceplates

Operation of the instrument faceplate buttons in the following function blocks is always in two steps, regardless of the settings in the instrument faceplate operation definition tab in the HIS constants builder.

- Grouping Override Function Block (GOV_*)
- Override Function Block (OVR_*)
- Password Function Block (PASSWD)
- Data Manual Operation with Answerback Function Block (MOB_*)
- Auto-reset Data Manual Operation Function Block (MOB_RS)

SEE ALSO For more information about two-step operations, refer to:

- "Two-Step Operation" in 2.5, "Operation Type on Instrument Faceplate" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)
- "Two-Step Operation" in 2.5, "Operation Type on Instrument Faceplate" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

Reconfirmation dialog box

When operating the following data items of the mapping block in the instrument faceplate or data input dialog box, the reconfirmation dialog box always appears regardless of the tag mark setting. You cannot disable the reconfirmation dialog box by the tag mark setting.

Table B8.1.3-2 Data items of mapping block for which the reconfirmation dialog box appears

Function block	Data items of mapping blocks
Grouping Override Function Block (GOV_*)	MV
Override Function Block (OVR_*)	MV
Password Function Block (PASSWD)	MV
Data Manual Operation with Answerback Function Block (MOB_*)	MV
Auto-reset Data Manual Operation Function Block (MOB_RS)	MV
Analog-type Data Manual Operation Function Block (MOA)	MV
Analog input function block for smoke and heat detectors (HSDTR)	MV01
Analog input function block for gas and flame detectors (GASDTR)	MV01

Reset operation of device

Follow these steps to reset a device from an instrument faceplate corresponding to HSDTR or GASDTR.

TIP The switch page buttons are not displayed when the instrument faceplate is in the compact view. For this reason, the page on which the reset button is displayed cannot be displayed either. Run the reset operation after switching to the normal view.

1. Click the switch page button on the right.
   The display will switch to the page with a reset button.

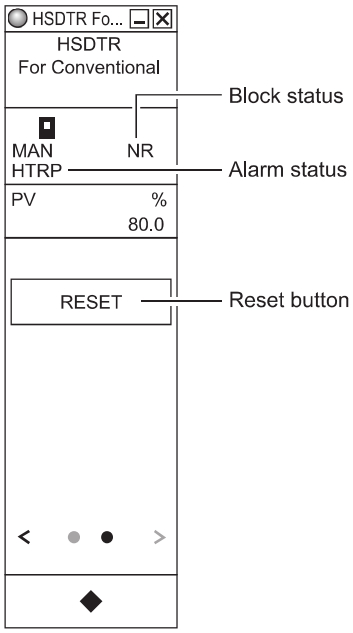

Figure B8.1.3-3 Display of instrument faceplate on 2nd page (example of HSDTR)

2. Click the reset button.
   The reconfirmation dialog box appears.

TIP

The reset button cannot be operated when an operation guard is displayed over the reset button.

3. Click [OK] on the reconfirmation dialog box.
   The reset operation will be run. Operations in an instrument faceplate corresponding to HSDTR or GASDTR are not two-step operations.

   With HSDTR, [RST] appears for the block status during the reset status.

4. Click the switch page button on the left.
   The display will switch to that of the process variable bar. The reset operation is complete when the alarm status switches to [NR].

B8.1.4 SCS Station Status Display view

The SCS Station Status Display view displays the operating status of each SCS, such as scan period and security level.

IMPORTANT

SCSs cannot be started or stopped from the SCS Station Status Display view, regardless of the roles assigned to the operator on the HIS.

TIP

In this manual, the safety control unit is referred to as CPU node and the safety node unit is referred to as FIO node.

System Status Overview view

The System Status Overview displays the status of the system over the control bus, including SCS, HIS and FCS. SCS icons are the same as FCS icons and are shown in orange frames.

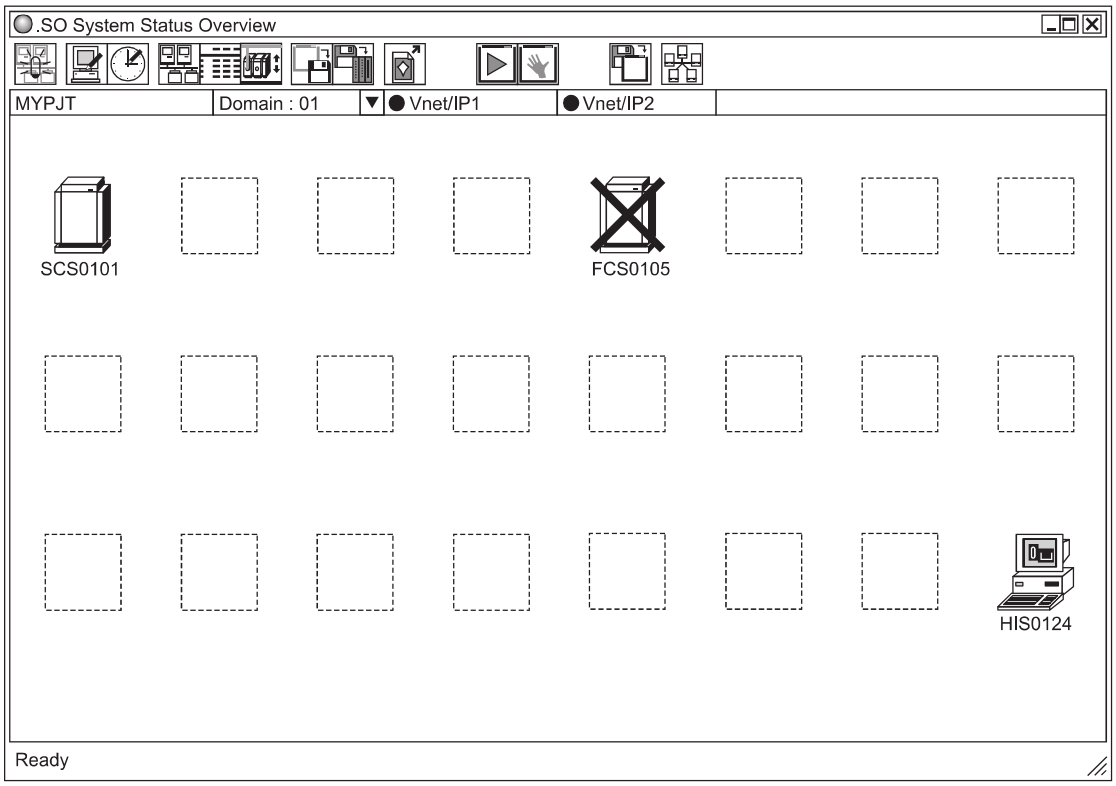

Figure B8.1.4-1 System Status Overview view

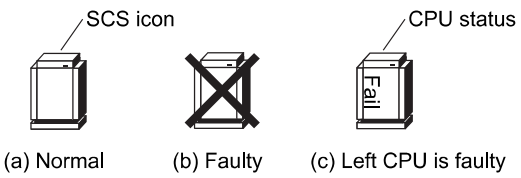

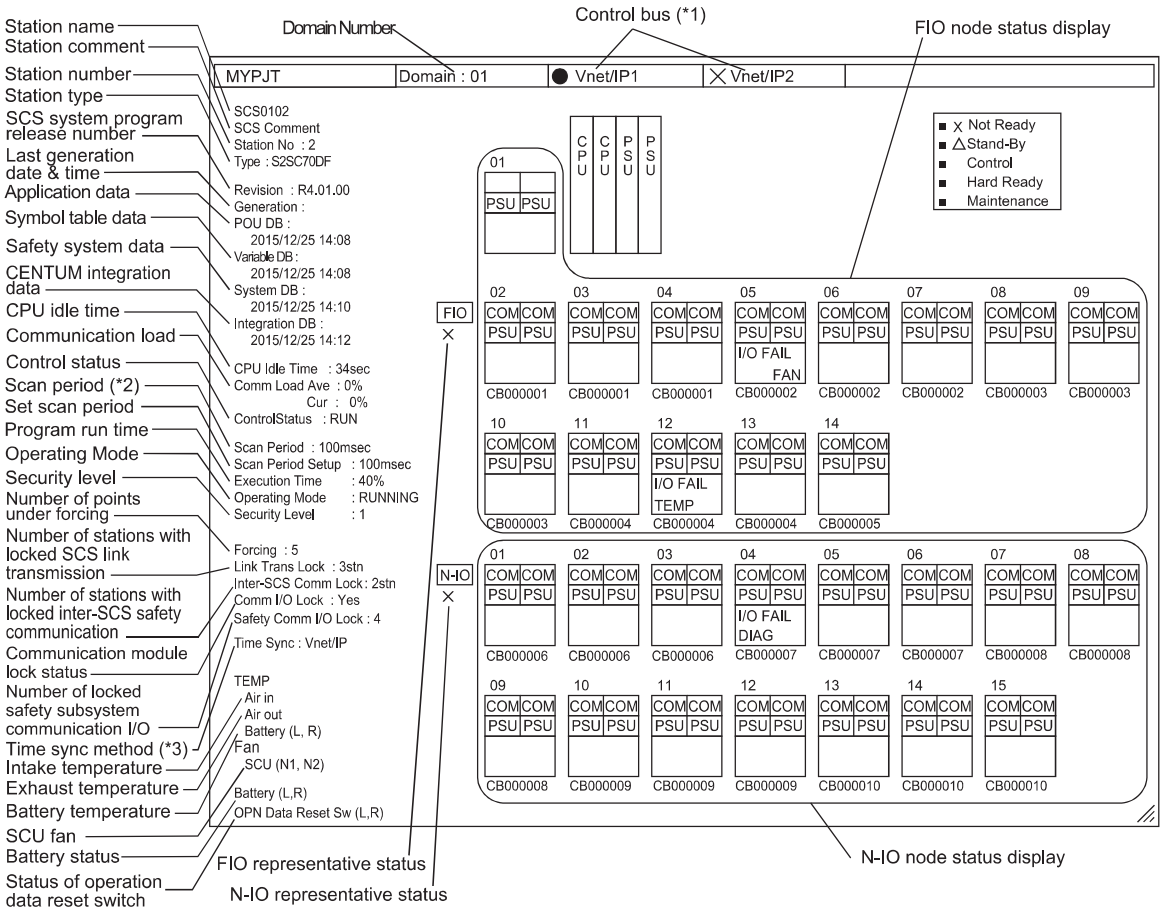

Figure B8.1.4-2 SCS icons

SCS Station Status Display view

The SCS Status Display shows the status of an SCS in detail. Operating mode, scan period and security level are shown in this window. In this window, whether or not the operating status and connection status of CPU and I/O modules is normal is shown in different colors.

IMPORTANT

The HIS' s SCS Station Status Display view displays the information that has been read from each SCS. However, the Diagnostic Information Operating dialog box in SCS Maintenance Tool cannot be opened from this window.

*1: When V net is used, “V net1” and “V net2” are displayed instead of “Vnet/IP1” and “Vnet/IP2,” respectively.
*2: For SCS with system program R2.02 or earlier, the set scan period is displayed.
*3: When V net is used, the “IRIG-B : Ready” is displayed instead of “Time Sync : Vnet/IP.”

Figure B8.1.4-3 SCS Station Status Display view

Toolbar of the SCS Station Status Display view

The following operations can be performed from the toolbar in the SCS Status Display view:

Selecting this button will call the System Alarm view where alarm details can be checked. If a system alarm message is present, the button will flash in red.

Selecting this button will call the HIS Setup window.

Selecting this button will call the Adjust Time dialog box.

Selecting this button will call the System Status Overview view.

The SCS report dialog box to show the station information.

The contents in the dialog box can be printed out or exported into a file.

Station information display

The following information is displayed in the SCS information:

- Station name
- Station comment
- Station number
- Station type
- SCS system program revision
- Last generated date/time
  The date and time of the last download to the SCS is displayed for each of the following DBs:
  - POU DB (application data)
  - Variable DB (symbol table data)
  - System DB (safety system data)
  - Integration DB (CENTUM integration data)
- CPU idling time (seconds)
  The CPU idling time per minute is displayed.
- Communication load (%)
  The Vnet/IP communication load against CPU load of the safety control station is displayed in percentage. The displayed values are current load and the moving average load against minute.
- Control status
  [RUN] is displayed when the SCS is running, and [STOP] is displayed when the SCS is stopped, both in cyan color.
- Scan period (milliseconds)
  This is the actual scan period of the SCS. Note that the set scan period is displayed for SCS with system program R2.02 or earlier.
- Set scan period (milliseconds)
  The set scan period for the SCS is displayed.
- Program execution time (%)
- Operating mode
  [RUNNING] is displayed when the SCS in the running mode, [WAITING] is displayed when the SCS is in the waiting mode, and [INITIAL] is displayed when the SCS is in the initial mode.
- Security level
- Number of points under forcing

- Number of stations locked in SCS Link Transmission
- Communication module lock status
  [Yes] is displayed in cyan when the communication I/O data is locked, and [No] is displayed in cyan when the communication I/O data is not locked.
- Number of stations locked in Inter-SCS Safety Communication
- Number of locked safety subsystem communication I/O
  The number of locks is displayed in cyan.

  This is only displayed for SCSP3. If S2LP131 is not defined, 0 is displayed.
- IRIG-B connection status
  This item is displayed if IRIG-B time synchronization is specified.
- Time synchronization method
  This is displayed only when the control bus is Vnet/IP. If the SCS is synchronized with SNTP server, [SNTP] is displayed; if it is not synchronized with SNTP server, [Vnet/IP] is displayed.

SEE ALSO For more information about the actual and set scan period, refer to:

A7.2, “Automatic extension function for scan period of the application logic execution function” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Station status display

The following statuses are displayed in the SCS station status: The character string representing each item is displayed in green if the status is normal, or red if faulty. If the status is faulty, the × mark indicating fault is displayed.

Figure B8.1.4-4 The mark stands for abnormal (battery temperature abnormal)

- Intake temperature
- Exhaust temperature
- Battery temperature
- SCU Fan
  This item is displayed for the station type that supports wide temperature ranges (S2SC70S-F, S2SC70D-F, L1SC70S-F, L1SC70D-F, SSC60S-F, SSC60D-F, SSC50S-F, SSC50D-F, SSC10S-F, SSC10D-F).
- Battery status
- Status of the operation data reset switch
  - This status is displayed on HIS in CENTUM VP R6.07.00 or later if the station type is SSC60 or S2SC70. If the CPU module is S2CP471, the status that the operation data is maintained is displayed in green, and the status that the operation data is cleared is displayed in red. If the CPU module is other than S2CP471, the maintained status is displayed.
  - This status is displayed on HIS in CENTUM VP R6.08.00 or later if the station type is L1SC70. The status that the operation data is maintained is displayed in green, and the status that the operation data is cleared is displayed in red.

Station configuration display

The following statuses are displayed in the SCS station configuration:

- CPU Status

The character string is displayed in green, red, yellow or blue when the CPU is normal, faulty, on standby or hardware ready, respectively. When a program is being copied, the character string [COPY] will flash in white. While FLASH memory is being written, [FLASH] will flash in white.

- Power Supply Status
  Displayed in green if the power supply is normal, or red if faulty.

ESB bus status display

Displayed in green if the ESB bus is normal, or red if faulty. But the status of the Optical ESB Bus Repeater modules is not displayed.

Display of the representative node status

The representative status is displayed under the N-IO and FIO node labels that indicate the N-IO and FIO nodes.

- For N-IO nodes
  If any N-IO node has an error, a red [X] is displayed. If a node is under maintenance, a cyan box is displayed. If a maintenance port of a node interface unit (NIU) is enabled in a node, a magenta opened padlock mark is displayed.

Figure B8.1.4-5 Opened padlock mark

If a node has various mixed status, the status is displayed in the following precedence:

1. Red [X]
2. Cyan box
3. Magenta opened padlock mark

- For FIO nodes
  If any FIO node has an error, a red [X] is displayed. When only SEC40x or L1EC40x is defined for FIO Node 1, the power status of the CPU Node is not reflected in the FIO representative status.

FIO node status display

In the FIO node configuration of the control station, the following status is displayed. When you click on the display area of the node configuration, the node status display dialog box appears.

- Node number
- Communication status
  The communication status of nodes is displayed in character string [COM]. It is displayed in green if the power supply is normal, or red if faulty. Nothing is displayed in node 1.
- Power supply status
  The power supply status of nodes is displayed in character string [PSU]. It is displayed in green if the power supply is normal, or red if faulty. When only SEC40x or L1EC40x is defined for FIO Node 1, the power status of the CPU Node is not reflected in the power status of FIO Node 1.
- Input module status
  It displays whether the input module is faulty. If it is faulty, [I/O FAIL] is displayed in red. Nothing is displayed while it is normal.
- Component number

N-IO node status display

In the N-IO node configuration of the control station, the following status is displayed. When you click on the display area of the node configuration, the node status display dialog box appears.

- Node number
- Communication status
  The communication status of nodes is displayed in character string [COM]. It is displayed in green if the power supply is normal, red if faulty, or in cyan if it is under maintenance.
- Power supply status
  The power supply status of nodes is displayed in character string [PSU]. It is displayed in green if the power supply is normal, or red if faulty.
- Input unit status
  It indicates the status of the input unit. If it is faulty, [I/O FAIL] is displayed in red. Nothing is displayed while it is normal.
- Node diagnosis
  If the node interface unit (NIU) notifies the abnormality of the node temperature or error information from an external diagnostic device, [DIAG] is displayed in red. Nothing is displayed while it is normal.
- Node status
  The node status is displayed with the frame enclosing the display area of the node configuration. It is displayed in green if normal, red if faulty, and cyan if both nodes are under maintenance. It is displayed in green dotted lines if node status is normal and the NIU maintenance port is enabled.

  If a node has various mixed status, the status is displayed in the following precedence:

  1. Abnormal
  2. Under maintenance
  3. If node status is normal and the NIU maintenance port is enabled
  4. Normal
- Status of the NIU maintenance port
  If enabled, a magenta opened padlock mark is displayed on the upper right of the node configuration.
- Component number

SCS Report dialog box

The SCS Report dialog box showing the status of each SCS can be called from the SCS Station Status Display view. To call the SCS Report dialog box, use the following button on the toolbar:

The following figure shows an example of the SCS Report dialog box:

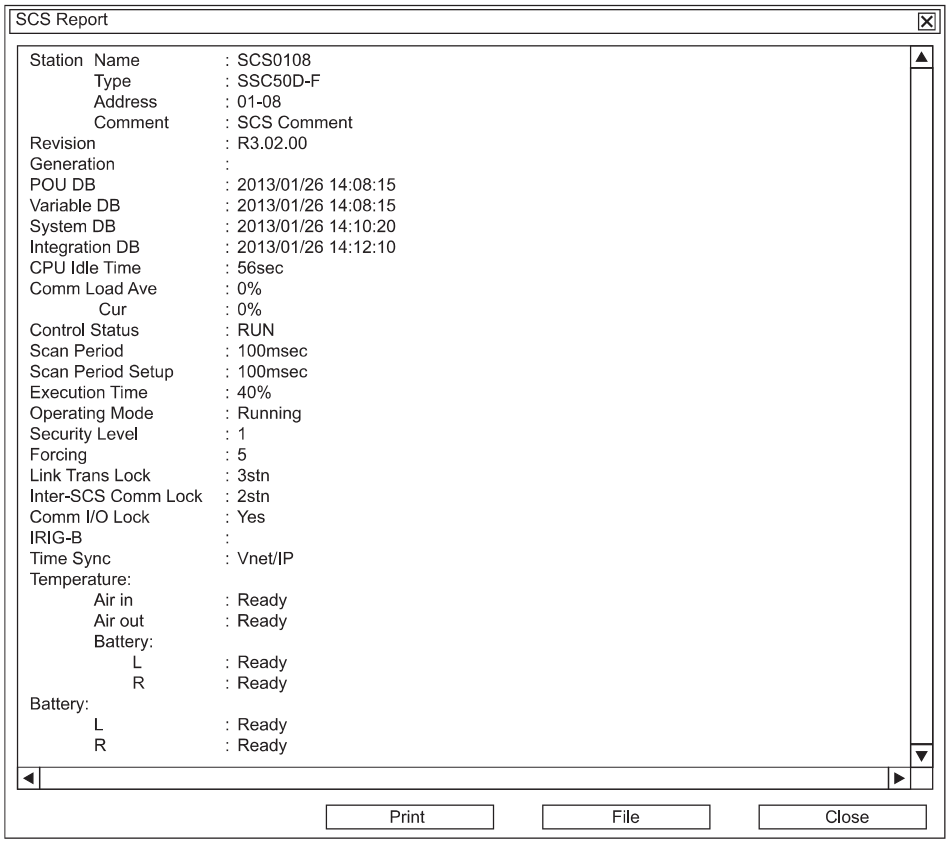

Figure B8.1.4-6 SCS Report dialog box

- Print
  Clicking this button prints the content currently displayed in the SCS Report dialog box. The displayed content will be output to the printer specified in the HIS Setup window.
- File
  Clicking this button saves the content currently displayed in the SCS Report dialog box to a FDC. The default name of the save file is "SCSRevInf.txt."
- Close
  Clicking this button closes the SCS Report dialog box.

SCS Node Status Display dialog box

The SCS Node Status Display dialog box is used to display the node status of each SCS in detail. The following figure shows an example of the SCS Node Status Display dialog box:

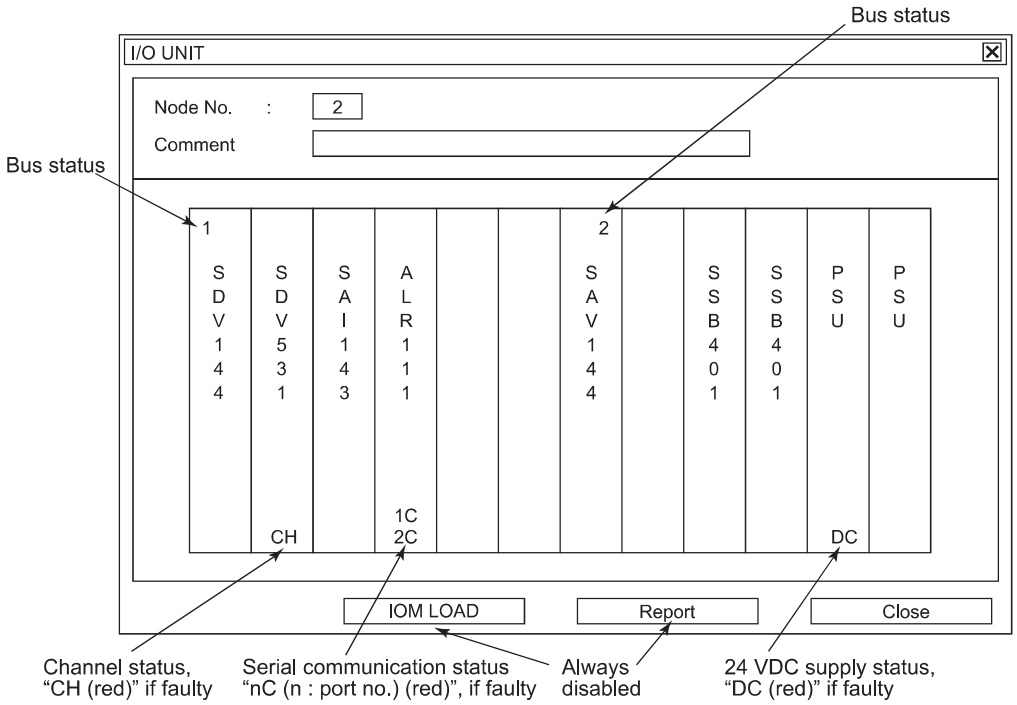

Figure B8.1.4-7 SCS node status display dialog box (for FIO nodes)

TIP

But the status of the Optical ESB Bus Repeater modules is not displayed.

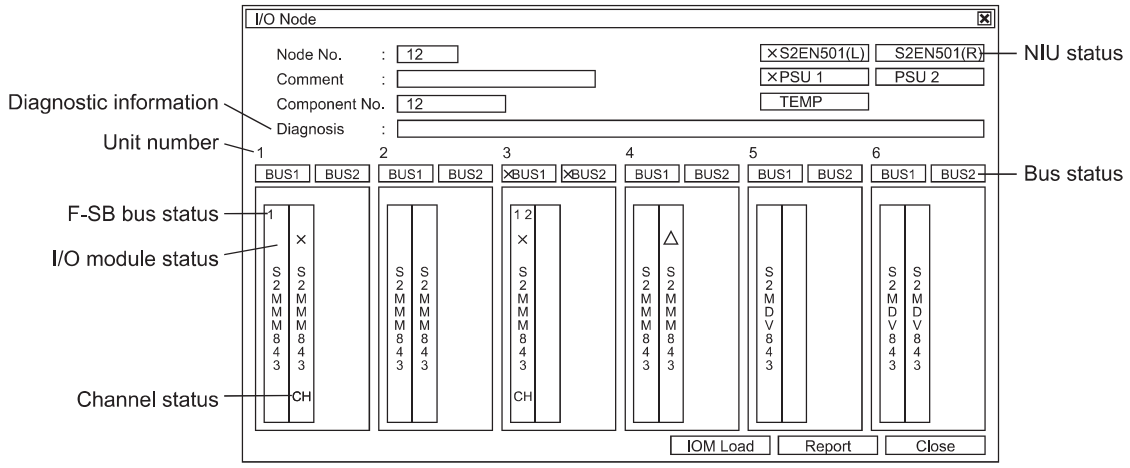

Figure B8.1.4-8 SCS node status display dialog box (for N-IO nodes)

FIO node status display

The communication status and power supply status of FIO nodes are displayed.

- Power supply status
  The character string [PSU] is displayed in green if the node is normal, or red if faulty.
- 24 VDC supply status
  [DC] is displayed in red if the power supply status is abnormal.
- SSB401/L1SB401 status
  The color of SSB401/L1SB401 changes to green if the unit is normal, and red if faulty. When the status is faulty, a mark is displayed.
- Bus status

Nothing is displayed while the buses are normal. If a bus is faulty, the bus number appears in red.

- I/O module status
  The color of the I/O module varies with module status. Green indicates Normal. Red indicates Abnormal. Blue indicates Ready and yellow indicate Standby. The bus status is also displayed by a red-colored number.

  The "-" in the I/O module name is not displayed.
- Channel status
  [CH] is displayed in red if any assigned channels are faulty.
- Communication module status (Subsystem communication)
  [nC] (n: port number) is displayed in red if communication with the subsystem fails.

N-IO node status display

The diagnosis information, NIU status, power supply status, temperature status, and node communication status of the N-IO nodes are displayed.

- Diagnosis information
  If NIU notifies the node temperature is abnormal or error information from an external diagnostic device, all of these contents are displayed. Multiple information are separated by commas.
- NIU status
  The communication status of NIU is displayed. If the communication status is normal, the NIU type is displayed in green. If it is faulty, an [×] and the NIU type are displayed in red or in cyan if it is under maintenance.
- Power supply status
  The power supply status of the node is displayed. If normal, [PSU + number] is displayed in green. If faulty, [×] and [PSU + number] are displayed in red.
- Temperature status
  The temperature status of the node is displayed. If normal, [TEMP] is displayed in green. If faulty, [×] and [TEMP] are displayed in red.
- Bus status
  The bus status is displayed. If normal, [BUS + number] is displayed in green. If faulty, [×] and [BUS + number] are displayed in red. If it is not defined, nothing is displayed.
- I/O module status
  The status of the I/O module is displayed. If the module is normal, the I/O module name is displayed in green. If the module is faulty, [×] and I/O module name are displayed in red. If the module is on dual-redundant standby status, [△] and the I/O module name are displayed in yellow.
- F-SB bus status
  The communication status of F-SB bus (the node bus) is displayed. If it is faulty, character string [1] or [2] that indicates the bus position is displayed in red. Nothing is displayed while it is normal.
- Channel status
  The communication status of the I/O module channel signal is displayed. If it is faulty, the character string [CH] that indicates the representative channel is displayed in red. Nothing is displayed while it is normal.
- Status of the NIU maintenance port
  If it is enabled, a magenta opened padlock mark is displayed on the right side of the [Node No.] column, and [Maintenance Port Enabled] is displayed. Nothing is displayed while it is disabled.

Channel status display dialog box

When you double-click on the display area of the I/O module in the SCS node status display dialog box of N-IO, the channel status display dialog box appears.

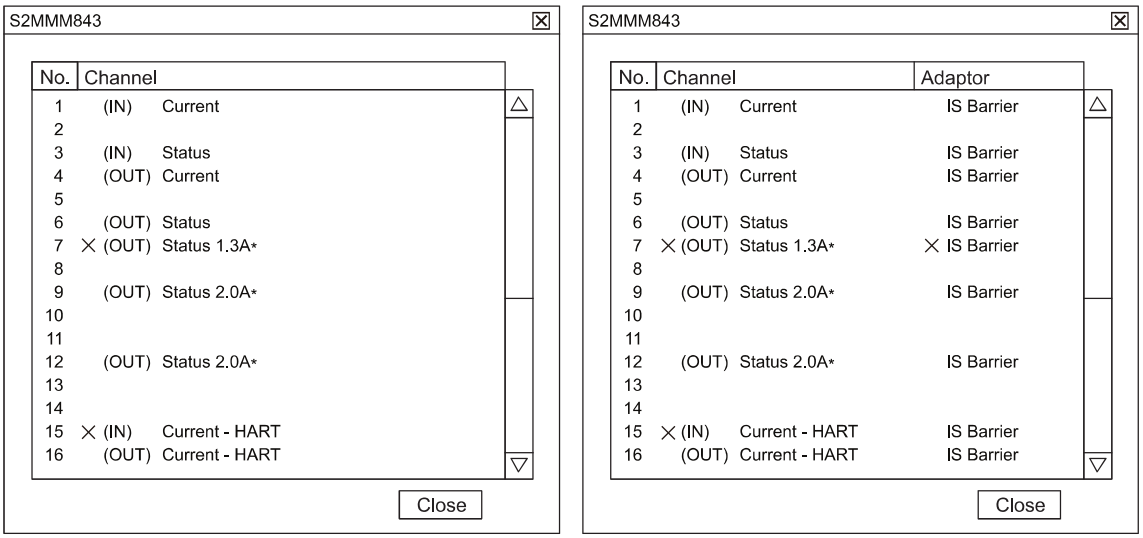

Figure B8.1.4-9 Channel status display dialog - normal configuration (left) and intrinsic safety barrier configuration (right)

The channel status display dialog box shows the signal type and communication status that are assigned to each channel of the I/O module. If the channel communication status is normal, the channel information in the channel column is displayed in green. If the channel communication status is faulty, the channel information in the channel column is displayed in red with [x] placed at the head. If the channel is not defined, nothing is displayed.

Only the primary channel is displayed for high current output. Non-primary channels are not displayed.

If you are using an intrinsic safety barrier, "IS Barrier" is displayed in the Adaptor column. If normal, it is displayed green. If it is faulty, [×] is placed in front and is displayed in red.

Table B8.1.4-1 Display character strings for channel signal types

Channel column display	Signal type
(Blank)	Not used (Not defined)
(IN) Current	Current input
(IN) Current - HART	Current input (HART)
(IN) Status	Status input
(OUT) Current	Current output
(OUT) Current - HART	Current output (HART)
(OUT) Status	Status output
(OUT) Status 1.3A *	Status output (1.3A output)
(OUT) Status 2.0A *	Status output (2A output)

B8.1.5 Adjust Time dialog box

You can set or change the system date and time in the Adjust Time dialog box.

Time setting from an HIS

You can change the current network time from an HIS using the time setting function.

- Vnet/IP
  Network time on the Vnet/IP (including V net router) is synchronized with the time set on HIS. Therefore, the time on the following stations is synchronized with the time set on HIS:
  - SCS (CPU module and digital input module (SDV144/L1DV144))
  - SENG, FCS, HIS

  If the time synchronization is based on an SNTP server, the time set on HIS is ignored.
- V net
  The network time in one V net domain and other V net domains, where Transfer/Receive System Time is specified for BCV/CGW, is synchronized with the time set on HIS. Therefore, the time on the following stations is synchronized with the time set on HIS:
  - SCS (CPU module and digital input module (SDV144))
  - SENG, FCS, HIS

  However, the network time of the Vnet/IP domain is not synchronized if the domain is connected through a V net router (AVR10D) of Style S2 or earlier. Even with a V net router of Style S3 or above, the network time is not synchronized if the V net domain is not configured as the clock master. SCS time with IRIG-B time synchronization is unaffected by the time change on the HIS.

SEE ALSO For more information about Time synchronization of SCS, refer to:

A3., “Time synchronization” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about Adjust Time dialog box, refer to:

- 4.4, "Adjust Time Dialog Box" in the Human Interface Stations Reference Vol. 1 (IM 33J10D10-01EN)
- 4.4, "Adjust Time Dialog Box" in the Human Interface Stations Reference Vol. 1 (IM 33K03F21-50E)

B8.1.6 Software for Managing the Alarms

CENTUM VP has the following dedicated alarm management software:

- UACS (Unified Alarms & Conditions Server)
- CAMS for HIS (Consolidated Alarm Management Software for HIS)

IMPORTANT

Although it is possible to suppress less important alarm messages so as to make important alarms more noticeable, do not suppress messages from SCS.

This section provides an overview of these software.

SEE ALSO

For more information about UACS, refer to:

UACS Alarm Management Reference (IM 33J05A22-01EN)

For more information about CAMS for HIS, refer to:

A1., "CAMS for HIS Overview" in the Consolidated Alarm Management Software Reference (IM 33J05A21-01EN)

Overview of UACS

UACS is an ANSI/ISA-18.2 compliant alarm management system. It provides the function to manage alarm messages generated in the plant according to the functions required by alarm management standards and guidelines.

UACS has a default filter for filtering system alarms and process alarms from SCS.

Overview of CAMS for HIS

When CAMS for HIS is enabled in HIS, the System Alarm and Process Alarm views for displaying and managing the system alarms and process alarms are integrated in the CAMS for HIS window.

CAMS for HIS Message Monitor has a default filter for filtering system alarms and process alarms from SCS.

B8.2 Other functions used for operation and monitoring of SCS

Override is available as an operation from HIS. In addition, equalizing and trend recording are available as HIS functions that can be used in the operation and monitoring of SCS. This section also describes the CENTUM Security Function, Alarm Inhibition, and Chattering Alarm Suppression.

SEE ALSO For more information about override from HIS, refer to:

I1.1.1, “Override” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

B8.2.1 Equalizing

The [SCS Taglist Import] command, which is run on System View, generates a taglist database from the information defined using the ProSafe-RS's Engineering Function and the generated taglist database is downloaded to each HIS in the system. As a result, taglist databases on the SCS and HIS are equalized.

IMPORTANT

When you have added or changed any tag definitions using the Tag Name Builder on the SENG and downloaded the changes to the SCS, there will be inconsistencies between the databases in the SCS and HIS. To equalize the database, go to the System View and run the [SCS Taglist Import] command.

SEE ALSO For more information about how to run [SCS Taglist Import] from System View, refer to:

"■ Generating SCS taglist on CENTUM" on page B7-43

■ SCS monitoring

Each HIS function communicates with SCSs based on the equalized information.

SCSs are handled in the following manner on the HIS:

- SCSs are not included in the number of FCS units operated and monitored.
- SCS tags are included in the tag monitoring points.

B8.2.2 Trend recording

SCS tag names can be assigned for trend data recording. However, since SCSs do not support high-speed (1-second) trend recording, assigning an SCS tag name to a high-speed trend recording block will not display data. Do not assign SCS tag names to high-speed trend recording blocks.

B8.2.3 Security function of CENTUM

The CENTUM provides a security function that changes access privileges with respect to FCS data according to the account of the operator working on each HIS. This function can be utilized for SCSs in the same manner.

These access privileges can be restricted further using the Security Function of the CENTUM. For example, an HIS account permitted to write data assigned to external communication function blocks and an HIS account not permitted to write such data can be set up using the Security Function of the CENTUM.

- The Security Function of the CENTUM is completely independent of the security levels of SCSs. SCS security levels cannot be manipulated from HISs.
- The Security Function of the CENTUM is completely independent of the SENG' s Engineering Security Management Function.

B8.2.4 Alarm inhibition (AOF)

Alarm inhibition (AOF) is a function to suppress the display and beeping sounds of process alarm messages temporarily. It is useful when many process alarm messages are generated during the startup of SCS. System alarm messages cannot be suppressed.

How to activate/deactivate suppress alarm function

You can turn on the Alarm Inhibition function (AOF) from HIS or from FCS targeting the Mapping block/element on the SCS.

Every time the SCS is restarted, the Alarm Inhibition function (AOF) is turned off. The switch between activate and deactivate the Alarm Inhibition function is allowed only by applications on the FCS or on the HIS. Neither the applications on the SCS nor the applications on the SENG are allowed to do so.

SEE ALSO For more information about secifying alarm inhibition, refer to:

7.3.4, "Alarm Inhibition (AOF)" in the Human Interface Stations Reference Vol. 2 (IM 33J05A11-01EN)

For more information about specifying alarm inhibition, refer to:

7.3.4, "Alarm Inhibition (AOF)" in the Human Interface Stations Reference Vol. 2 (IM 33K03F22-50E)

Alarm inhibition from HIS

You can inhibit alarm for Tag data of SCS by using AOF button on Tuning view of HIS. The Tag mark color is shown in blue while the function is on.

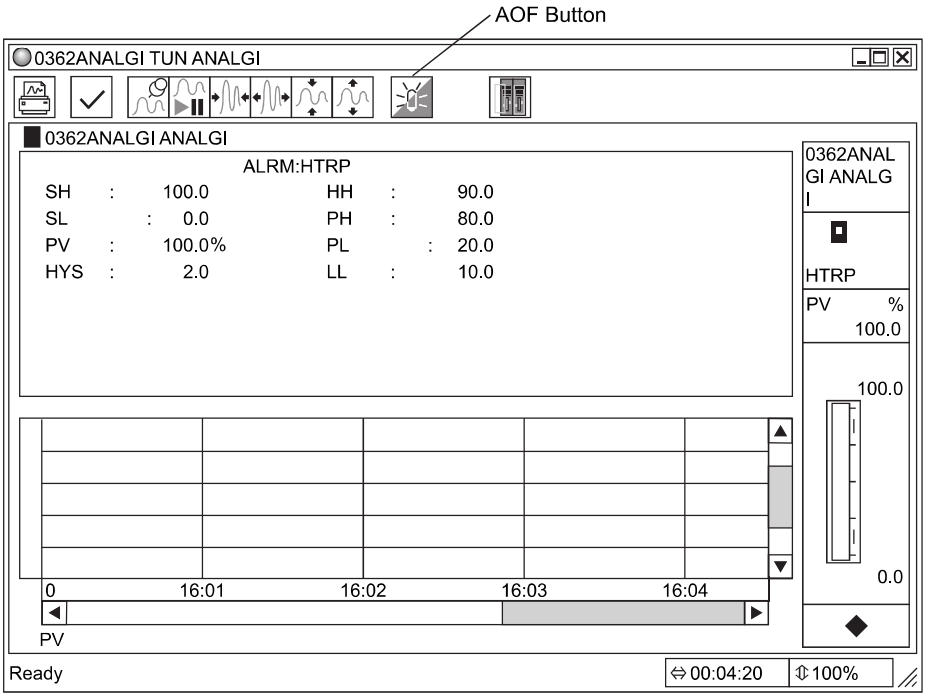

Figure B8.2.4-1 Suppress alarms in a Tuning view

TIP The AOF button only appears when the mapping block/element corresponding to the tag name has the data item of AOFS.

Outputting suppressed alarm messages

On releasing the Alarm Inhibition, the suppressed alarm messages can be output for the process alarms that are still raised. This means that you can confirm the suppressed messages for the process alarms occurred during Alarm Inhibition. The time stamp of a suppressed message shows the time when the message is output upon the release of Alarm Inhibition. Whether to output the suppressed alarm messages can be specified on the SCS Constants Builder.

SEE ALSO For more information about how to make settings required for outputting the suppressed messages, refer to:

C1.2.6, “SCS Constants Builder” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

B8.2.5 Chattering alarm suppression

While a plant is in operation, physical defects such as loosening of the connections of detector terminals and corrosion may lead to unstable input values and cause repeated notification of alarms indicating occurrence and recovery of input errors. As a result, a large number of alarms will appear in the operation and monitoring windows of HIS.

Error occurrence and recovery alarms repeatedly notified are referred to as chattering alarms.

This section explains the function for suppressing the message displays and buzzer sounds of chattering alarms.

Overview of chattering alarm suppression

The chattering alarm suppression function prevents certain system alarm messages and process alarm messages regarding errors detected by the SCS from being displayed in operation and monitoring windows of HIS such as System Message Banner. This function can be used with systems having a CENTUM integration structure.

Alarms for which the display can be suppressed with the chattering alarm suppression function are system alarms and process alarms that are notified upon occurrence and recovery of analog input errors. Specifically, applicable system alarms are channel error alarms, and applicable process alarms are input open (IOP) alarms.

SCS suppresses the display of alarms in the operation and monitoring windows of HIS. Even while the display of alarms is being suppressed, the SCS will still detect occurrence and recovery of errors. Suppression will not affect the operation of application logic, either.

Note that the diagnostic information window of SENG is not subject to alarm display suppression. Even while the SCS is suppressing the display of alarms, system alarms and diagnostic information messages for occurrence and recovery of channel errors will still be displayed in the diagnostic information window of SENG.

Note that this function will not affect the safety functions run by the SCS.

IMPORTANT

The chattering alarm suppression function can be used with combinations of ProSafe-RS R4.03 or later and CENTUM VP R6.04 or later. This function can also be used with databases created using a version of SENG that is R4.03 or later.

SEE ALSO For more information about the operation and monitoring windows of HIS subject to chattering alarm suppression, refer to:

"● Viewers of HIS for which display is suppressed" on page B8-39

Operation during alarm suppression

When an analog input error occurs, an error occurrence alarm is displayed in the operation and monitoring windows of HIS and the SCS enters the chattering alarm suppression period. Even if the error is recovered during the alarm suppression period, unless the recovered state persists for at least the time to chattering recovery notice set by the user, the SCS will continue to suppress the display of error occurrence and recovery alarms in the operation and monitoring windows of HIS.

TIP

The time to chattering recovery notice is the time by which the display of error recovery alarms are delayed. Even if an error is recovered and returned to the normal status during the alarm suppression period, the SCS will not immediately notify an error recovery alarm. Whether the normal status persists for the set time to chattering recovery notice will be monitored. If an error occurs during this time, the SCS will determine that chattering is occurring and continue to suppress alarms. If an error does not occur, the SCS will determine that the error has been recovered and notify an error recovery alarm.

The following figure shows the operation during suppression, which is common to system alarms and process alarms.

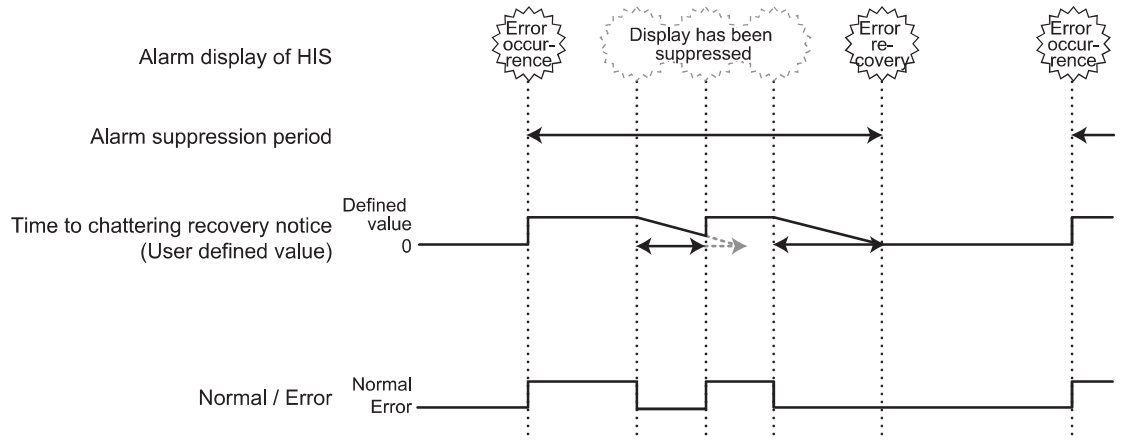

Figure B8.2.5-1 Operation during alarm suppression

Display suppression of channel error alarms

As system alarms, the display of channel error alarms that are notified when detecting the occurrence and recovery of a channel error of the analog input module will be suppressed.

System alarms subject to suppression

The display of the following system alarms can be suppressed with chattering alarm suppression:

- No. 4125 I/O module channel error occurred
- No. 4126 Recovery from I/O module channel error

The following string indicating that the suppression period has ended will be added to the error recovery alarm that is displayed when the alarm suppression period has ended:

(Chattering suppression is over)

Example:

SCS0101 IOM Channel Recover NODE 01 SLOT 02 CH 03 (Chattering suppression is over)

SCS0101 IOM Channel Recover N-IO NODE 01 UNIT 01 SLOT 02 CH 03 (Chattering suppression is over)

SEE ALSO

For more information about details of the diagnostic information messages, refer to:

Message Number 4126 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Channels subject to suppression

The channels that can be made subject to suppression of channel error alarms are the analog input channels.

The following table shows the modules and target channels for which channel error alarms can be suppressed.

Table B8.2.5-1 Modules and target channels for which channel error alarms can be suppressed

I/O	Type of module	Model	Target channel
FIO	Analog input module	SAI143/L1AI143, SAV144/ L1AV144, SAT145/L1AT145, SAR145/L1AR145	All channels
N-IO	Analog digital I/O module	S2MMM843	Next signal type channel • Current input • Current input (HART communication)

Operation during channel error alarm suppression

Even if a channel error is recovered after a channel error has occurred with an analog input channel, unless the recovered state persists for at least the time to chattering recovery notice set by the user, the SCS will continue to suppress the display of error occurrence and recovery alarms in the operation and monitoring windows of HIS.

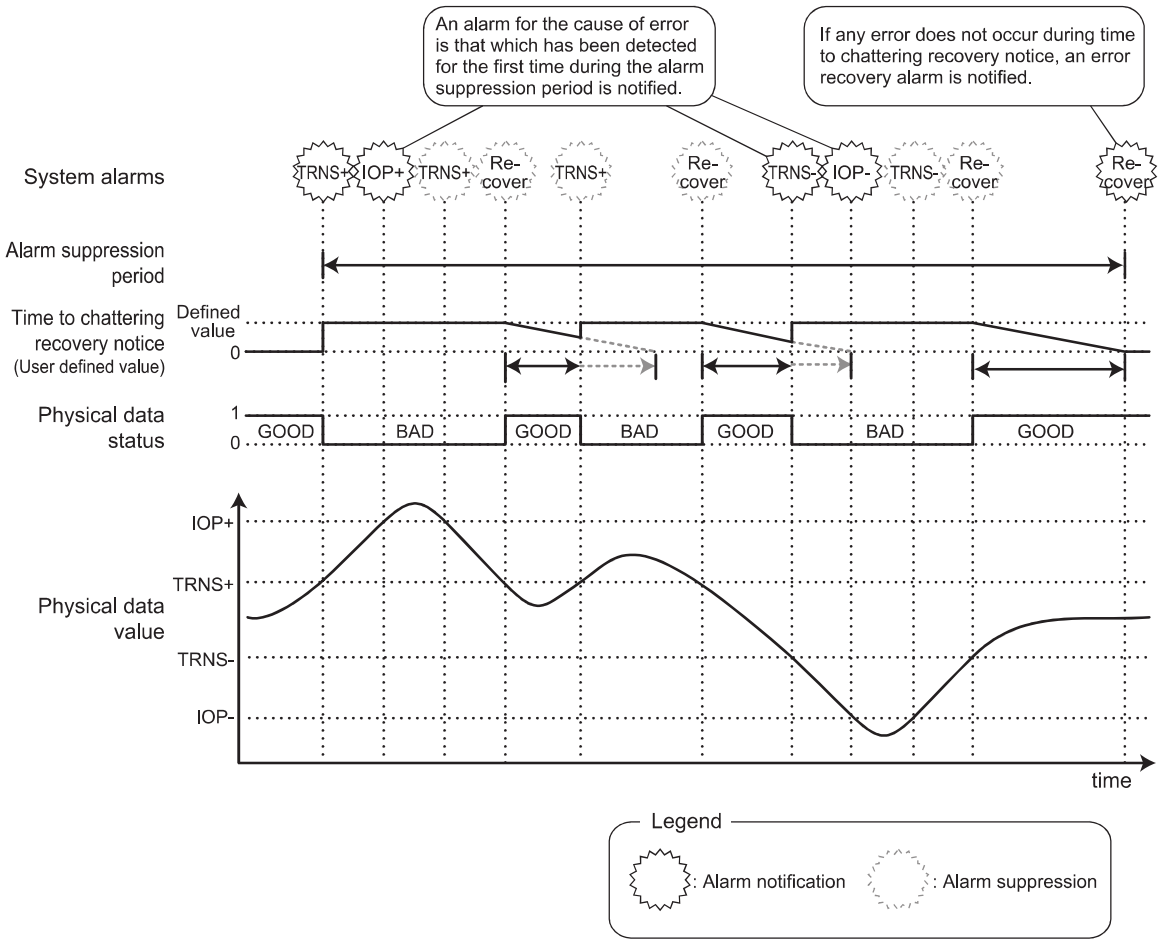

Figure B8.2.5-2 Operation of SCS during channel error alarm suppression

- In a state where alarms are not being suppressed, when a channel error occurs with an input channel, the SCS will notify a channel error occurrence alarm and enter the alarm suppression period. Also, a channel error occurrence alarm will appear in the operation and monitoring windows of HIS.
- If the cause of error is that which has been detected for the first time by the SCS during the alarm suppression period, a channel error occurrence alarm for the cause of error will

appear in the operation and monitoring windows of HIS. If the cause of error is that which has already been detected, the channel error occurrence alarm will not be displayed in the operation and monitoring windows of HIS.

- Even if a channel error is recovered, if a channel error occurs again before the elapse of the time to chattering recovery notice set by the user, the SCS will determine that chattering is occurring and continue alarm suppression. Channel error recovery and occurrence alarms will not be displayed in the operation and monitoring windows of HIS. However, if the cause of error of the channel error is a cause of error that has been detected for the first time during the alarm suppression period, a channel error occurrence alarm for the cause of error will appear in the operation and monitoring windows of HIS.
- If the set time to chattering recovery notice elapses while the channel error remains recovered, a channel error recovery alarm to which a string indicating that the suppression period has ended (Chattering suppression is over) is added will appear in the operation and monitoring windows of HIS.
- The physical data values and physical data status during the alarm suppression period will conform to actual input values.

Display suppression of input open (IOP) alarms

With process alarms, the following will occur. If a tag name has been defined for the instance of the function block entering the analog input (IN), the display of input open (IOP) alarms notified upon a change of the data status will be suppressed.

Process alarms subject to suppression

The display of the following input open (IOP) process alarms can be suppressed with chattering alarm suppression:

- No. 1101 Input process alarm generation
- No. 1102 Input process alarm recovery

Also, during alarm suppression, it is also possible to suppress the display of the following process alarms upon recovery to the NR status:

- No. 1106 Process alarm normal recovery

TIP

- HI and LO pre-alarms and HI and LO trip occurrence and recovery process alarms are not subject to alarm suppression.
- Rewarning alarms are not subject to alarm suppression.

The following string indicating that the suppression period has ended will be added to the error recovery alarm that is displayed when the alarm suppression period has ended:

(Chattering suppression is over)

No.1102

Message name	Input process alarm recovery
Printing example	`A0101A comment PV=4.8 KNM3/H IOP Recover (Chattering suppression is over)`

A0101A: Tag name

Comment: Tag comment

4.8: PV value

KNM3/H: Engineering unit symbol

IOP: Alarm status

Meaning	The alarm display suppression period has ended because the function block indicated by the printed content has been recovered from the alarm status and the time to chattering recovery notice has elapsed.

No.1106

Message name	Process alarm normal recovery
Printing example	`FIC100A comment NR (Chattering suppression is over)`
Meaning	The alarm display suppression period has ended because the function block indicated by the printed content has been recovered from the alarm status and the time to chattering recovery notice has elapsed.

Function blocks with which the alarm suppression function can be used

Function blocks and corresponding mapping blocks with which the input open (IOP) alarm suppression function can be used are shown in the following table.

Table B8.2.5-2 Function blocks and corresponding mapping blocks with which the input open (IOP) alarm suppression function can be used

Function block	Mapping block	Description
ANLG_S	S_ANLG_S	Analog input function block with data status
HSDTR	S_HSDTR	Analog input function block for smoke and heat detectors
GASDTR	S_GASDTR	Analog input function block for gas and flame detectors

Operation during input open (IOP) alarm suppression

Even if the data status of an analog input (IN) of a targeted function block changes from BAD to GOOD, unless the GOOD state persists for at least the time to chattering recovery notice set by the user, the SCS will continue to suppress the display of input open (IOP) alarm occurrence and recovery in the operation and monitoring windows of HIS.

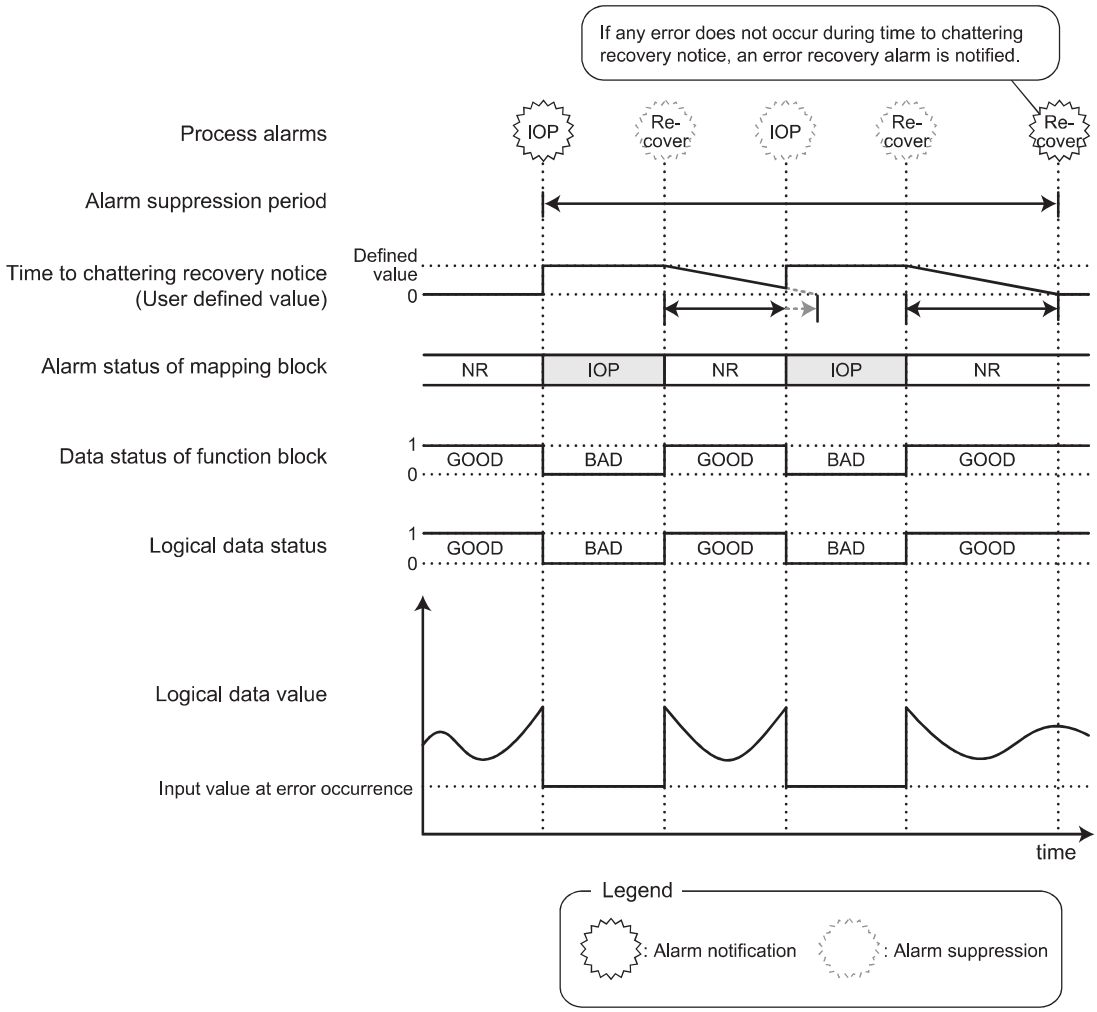

Figure B8.2.5-3 Operation of SCS during input open (IOP) alarm suppression

- In a state where alarms are not being suppressed, if the data status of an analog input (IN) of the function block becomes BAD, the SCS will notify an input open (IOP) alarm from the mapping block and enter the alarm suppression period. Also, an input open (IOP) alarm occurrence will appear in the operation and monitoring windows of HIS.
- Even if the data status of the analog input (IN) becomes GOOD during the alarm suppression period, if the data status becomes BAD again before the elapse of the time to chattering recovery notice set by the user, the SCS will determine that chattering is occurring and continue alarm suppression. Input open (IOP) alarm recovery and occurrence will not be displayed in the operation and monitoring windows of HIS. Process alarm normal recovery will not be displayed either even upon recovery to the NR status.
- If the set time to chattering recovery notice elapses while the data status of the analog input (IN) remains in GOOD, an input open (IOP) alarm recovery and a process alarm normal recovery to which a string indicating that the suppression period has ended (Chattering suppression is over) is added will appear in the operation and monitoring windows of HIS.
- Analog input values, the data status, and output of function blocks will conform to logical data values and the logical data status.

Operation during alarm inhibition (AOF)

The operation when alarm inhibition (AOF) is enabled during chattering alarm suppression with the SCS is as follows:

- While AOF is enabled, even if the data status of an analog input (IN) becomes BAD, the chattering alarm suppression function targeted at process alarms will not operate.
- The chattering alarm suppression function will be disabled when AOF is enabled during the alarm display suppression period for process alarms. After this, operation will follow that of AOF.
  Note that if in the normal status AOF is enabled during the alarm display suppression period based on this function, at this time the SCS will notify the error recovery alarm for the end of the suppression period. However, as process alarms will be suppressed by AOF, an error recovery alarm will not be displayed in the operation and monitoring windows of HIS.

TIP

The chattering alarm suppression function targeted at system alarms will not be affected by AOF.

Method of monitoring with HIS

This section explains the viewers of HIS for which display is suppressed when the chattering alarm suppression function is enabled along with how to confirm alarms that have been suppressed.

Viewers of HIS for which display is suppressed

The types of viewers and alarms of HIS for which display is suppressed with chattering alarm suppression are shown in the following table.

Table B8.2.5-3 Types of viewers and alarms of HIS for which display is suppressed

Viewers	Alarms subject to suppression
System message banner Message controls in graphic views UACS (Unified Alarms & Conditions Server) CAMS for HIS message monitor of consolidated alarm management	System alarms and process alarms
System alarm view Individual system alarm message acknowledgment window	System alarms
Process alarm view Individual process alarm message acknowledgment window	Process alarms

Confirming alarms for which display has been suppressed

The following display functions are not subject to chattering alarm suppression. By using the following display functions, even during chattering alarm suppression, it is possible to confirm the alarms for which display has been suppressed:

- Message monitor window
- Historical message display functions (such as the historical message report window)
- SOE viewer
- Diagnostic information window of SENG (*1)

*1: System alarms are subject to display. Process alarms cannot be confirmed.

TIP

With display functions not subject to chattering alarm suppression, suppressed error recovery alarms and the error recovery alarms for when the suppression period has ended are displayed continuously. Both of the error recovery alarms will have the same message number. A string indicating that the suppression period has ended (Chattering suppression is over) will be added to the error recovery alarm that is displayed when the alarm suppression period has ended.

Engineering

To enable the chattering alarm suppression function, set the time to chattering recovery notice with SENG.

Suppression of system alarms and suppression of process alarms are independent of each other. The time to chattering recovery notice needs to be set for each of the system alarms or process alarms to suppress.

To suppress the system alarms and process alarms for the occurrence and recovery of channel errors of a certain analog input, set the time to chattering recovery notice as the same value for each so that the alarm suppression period is the same for both.

Suppression of system alarms can be set with I/O Parameter Builder or Safety I/O Editor.

Suppression of process alarms can be set with Tag Name Builder or iDefine.

IMPORTANT

Set the time to chattering recovery notice upon considering an appropriate value with the alarm design of the plant. Necessary alarms may not be notified if the time to chattering recovery notice is not an appropriate value.

SEE ALSO

For more information about setting items of the I/O Parameter Builder, refer to:

"■ Time to Chattering Recovery Notice (s) (Time to Chattering Recovery Notice)" in Appendix 1.3.2, "Settings for the AI channel" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about setting items of the Safety I/O Editor, refer to:

"■ Setting items of the Safety I/O Editor" in D1.4.1, "Starting the Safety I/O Editor" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about setting items of the Tag Name Builder, refer to:

"● Time to Chattering Recovery Notice (s)" on page B7-26

Operation upon online change download

This section explains operation of the chattering alarm suppression function when an online change download is performed after the following operations:

- Changing the chattering alarm suppression function to enabled
- Changing the chattering alarm suppression function to disabled

● Changing the chattering alarm suppression function to enabled

If the chattering alarm suppression function is enabled while the targeted channel or function block is in a state of error, alarms will be suppressed in the following manner in the operation and monitoring windows of HIS:

- For system alarms
  If the chattering alarm suppression function is enabled while the targeted channel is in a state of error, display will be suppressed from the next error recovery alarm. If an error occurs again during the suppression period, operation will differ depending on the cause of error. An error occurrence alarm is displayed if the cause of error differs from that of the error occurrence alarm prior to enabling this function. If the cause of error is the same, an error occurrence alarm will not be displayed.

TIP

If this function is enabled while the targeted channel is in a state of error, the error occurrence alarm displayed prior to enabling this function will be the first error occurrence alarm.

- For process alarms
  If the chattering alarm suppression function is enabled while the targeted function block is in a state of error, display will be suppressed from the next error recovery alarm. If an error occurs again during the suppression period, an error occurrence alarm will not be displayed.

SEE ALSO

For more information about operation of system alarms when the chattering alarm suppression function is enabled while the target channel is in the normal status, refer to:

"● Operation during channel error alarm suppression" on page B8-35

For more information about operation of process alarms when the chattering alarm suppression function is enabled while the target function block is in the normal status, refer to:

"● Operation during input open (IOP) alarm suppression" on page B8-37

● Changing the chattering alarm suppression function to disabled

If the chattering alarm suppression function is disabled, depending on the status of the SCS and alarm suppression when the change is made, an alarm will be displayed at the following timing in the operation and monitoring windows of HIS:

- If the function is disabled when in the normal status and not during the alarm suppression period, display will be restored from the next occurrence of an error occurrence alarm.
- If the function is disabled when in the normal status and during the alarm suppression period, the error recovery alarm for when the suppression period has ended will appear immediately.
- If the function is disabled when in the error status, display will be restored from the next occurrence of an error recovery alarm.

■ Operation during unsteady state of SCS

If the SCS enters the following unsteady state during chattering alarm suppression, the elapsed time of the time to chattering recovery notice is reset:

- Initial cold start of the SCS
- Occurrence of a path error such as a node error, unit error, or IOM error

C. SOE OPC Interface

The SOE OPC Interface provides the functions of the OPC (OLE for Process Control) server that handles event information and diagnostic information that are acquired through the sequence of event recorder (SOER) function of SCSs. OPC clients can access this information by using the OPC Interface.

C1. Overview of SOE OPC Interface

By using the SOE OPC Interface (server) provided by ProSafe-RS, it is possible to access event information and diagnostic information of SCS from OPC applications (clients) on the host computer.

This section explains the specifications of ProSafe-RS SOE OPC Interface and compatibility with the OPC specifications. The OPC specifications can be obtained from the web site of the OPC Foundation.

TIP

OPC (OLE for Process Control) is an OLE (Object Linking and Embedding) specification, i.e., a method of standard communication between applications in Windows environments, which is specifically applicable to process control. OPC allows sending/receiving process data among multiple general-purpose Windows-compatible applications.

What is the SOE OPC Interface?

The SOE OPC Interface provided by ProSafe-RS consists of the OPC server and SOE cassette dedicated to ProSafe-RS.

- OPC server
  The OPC server notifies event information and diagnostic information that is acquired from SCSs to OPC clients. The OPC server consists of the Alarms & Events server (hereinafter referred to as A&E server), which accesses various data, and Historical Data Access server (hereinafter referred to as HDA server), which stores historical data.
- ProSafe-RS SOE cassette
  The SOE cassette dedicated to ProSafe-RS is incorporated in the cassette provided by the OPC Interface as communication interface.
- Function of the SOE cassette
  The SOE cassette provides communication functions for notifying SOE events and diagnostic information of SCS to the OPC server. By connecting to the OPC server equipped with this cassette, OPC clients can receive event messages (SOE events and diagnostic information) of SCS.

System configuration using the SOE OPC Interface

The SOE OPC Interface runs on a computer and reports SCS event information and diagnostic information to the host computer through the OPC Interface.

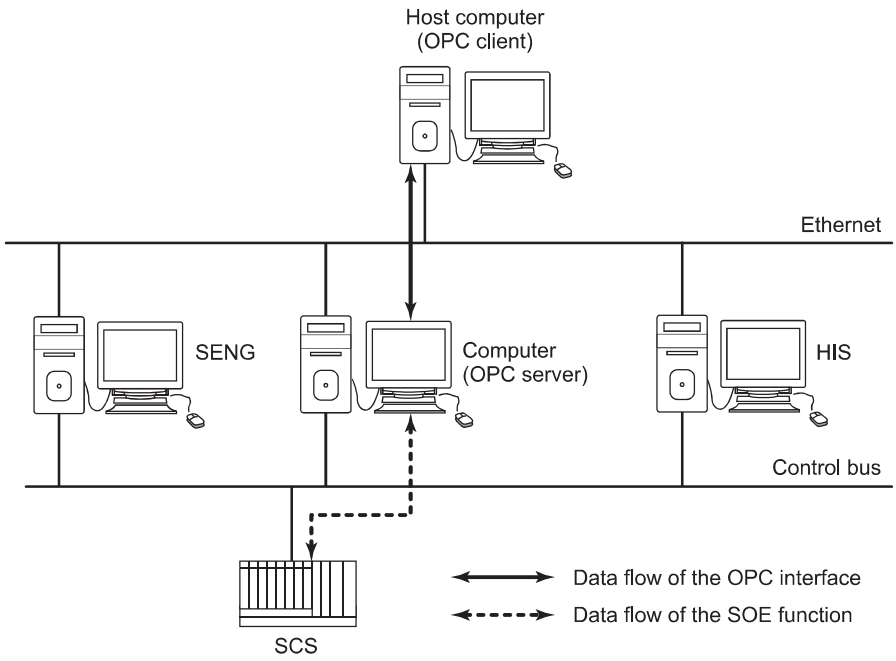

Figure C1-1 Example of system configuration using the SOE OPC Interface

Software configuration of the SOE OPC Interface

The SOE OPC Interface is comprised of the OPC server and the ProSafe-RS SOE cassette (hereinafter referred to as SOE cassette). The OPC server sends data to the OPC client. The SOE cassette is an interface used by the OPC server to acquire data from SCS. The following figure shows the software configuration for the SOE OPC Interface.

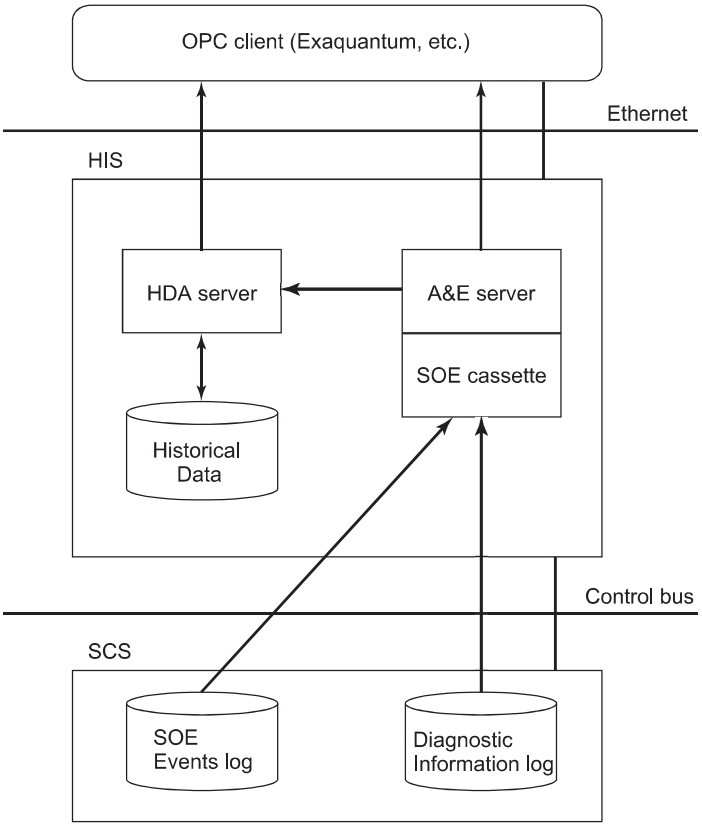

Figure C1-2 Software configuration and data flow

Details of the SOE OPC Interface

Particular items of the SOE OPC Interface are explained below, including parameters and control method required when constructing the system with the SOE OPC Interface.

OPC interface

The following OPC-compliant interface is provided:

- Alarms and Events (A&E)
  This interface notifies event messages, which are generated asynchronously by SCS, to the host computer. The SOE cassette reads the event log on SCS at regular intervals (the default is 10 seconds) and notifies changes (e.g., that new event messages are generated) to the client.

  The A&E server provides OPC A&E custom interfaces and OPC A&E automation interfaces.

- Historical Data Access (HDA)
  This interface stores event messages, which are generated asynchronously by SCS, in the historical database. This operation enables OPC clients to receive missed event messages.

Application capacity

The following table shows the application capacity limits.

Table C1-1 Application capacity

Item	Capacity
Maximum number of connected clients	100 clients
Maximum number of event registration objects (*1)	1000/OPC server
Maximum number of registered event generation sources (*2)	100/registration object

*1: It is the maximum number of event registration objects (subscription) that can be created in the CreateEventSubscription method.
*2: It is the maximum number of event generation sources that can be specified in subscription when setting up a filter in the event generation source. The maximum number of event generation sources (dwNumSources) in the SetFilter method is checked.

Server name (ProgID), type library name

The server name and type library name for the A&E server are as follows: The server name is used for custom interfaces. The type library name is used by the automation interfaces in applications such as Visual Basic and Excel.

- The custom interfaces
  Server name: Yokogawa.ExaopcAESCSSOE
- The automation interfaces
  Type library name: Yokogawa ProSafe-RS SCS Alarms & Events Automation Server

The server name and type library name for the HDA server are as follows:

- The custom interfaces
  Server name: Yokogawa.ExaopcHDASCSSOE
- The automation interfaces
  Type library name: Yokogawa ProSafe-RS SCS HDA Server

Event categories and event types

The following table shows support for event categories and event types for SOE cassettes. The event category of system alarms generated in the SOE cassette is "System alarms (101)."

Table C1-2 Event category and event type

Event category		Event type	Description
Name	Value		
System alarms	101	Simple(=1)	Diagnostic Information
Sequence of events	110	Simple(=1)	Event Information

Source (event generation sources)

This item contains the same reference as displayed in SOE Viewer. In the case of system alarms generated in the SOE cassette, the ProgID value (Yokogawa.Exaopc AESCSSOE) is stored in this item.

Time (event generation time)

This item contains the same time stamp (SCS time) as displayed in SOE Viewer. The time stamp is stored using UTC (Universal Time Coordinated).

The time stamp based on the computer time is stored using UTC in the case of system alarms generated in the SOE cassette.

Severity (event priority)

This item contains a value from 200 to 900 to indicate the severity of the alarm or event. 900 is stored in the case of system alarms generated in the SOE cassette.

Table C1-3 Event category and severity

Event category	Severity level	Description
Name		
System alarms	900	Diagnostic Information (class 1)
	500	Diagnostic Information (class 2)
	300	Diagnostic Information (class 3)
	200	Diagnostic Information (class 4)
Sequence of events	500	Event Information

Message

All SCS-generated event messages displayed in the SOE Viewer as the character string are stored, including all system alarm messages generated in the SOE cassette.

Event description and attributes

The following table summarizes SOE event attributes for events reported by the OPC interface.

Table C1-4 Event attributes of diagnostic information

Attribute name	OPC ID	VARIANT type	Remark
SOETimestamp	301	VT_DATE	Event Occurrence Date (Local)
TimestampM	302	VT_I2	Event Occurrence Time (Millisecond)

Continues on the next page

Table C1-4 Event attributes of diagnostic information (Table continued)

Attribute name	OPC ID	VARIANT type	Remark
Resource	303	VT_BSTR	The same as the corresponding information displayed in SOE Viewer (*1)
Type	304		
ID	305		
Quality	306		
Node	308	VT_I2	Node position, or 0
Slot	309	VT_I2	Slot position, or 0
Time_Diff	318	VT_BSTR	Time zone (-08:00, +00:00, +09:00, ...)

*1: Resource (computer name), Type (fixed to BSYS), ID/Quality (blank) SOETimestamp, TimestampM and Time_Diff (computer time) are stored in the case of alarms generated in the SOE cassette.

Table C1-5 Event attributes of event information

Attribute name	OPC ID	VARIANT type	Remark
SOETimestamp	301	VT_DATE	Event Occurrence Date (Local)
TimestampM	302	VT_I2	Event Occurrence Time (Millisecond)
Resource	303	VT_BSTR	The same as the corresponding information displayed in SOE Viewer
Type	304		
ID	305		
Quality	306		
Node	308	VT_I2	Node position (DI/DO event only), or 0
Slot	309	VT_I2	Slot position (DI/DO event only), or 0
Channel	310	VT_I2	Channel position (DI/DO event only), or 0
TripMark	313	VT_I2	True/false of tripping signal (1/0)
Time_Diff	318	VT_BSTR	Time zone (-08:00, +00:00, +09:00, ...)

Formats for system alarms generated in the SOE cassette

The SOE cassette generates a system alarm when access to SCS event logs fails. The system alarm is notified to the OPC client. The following example shows the message format for this system alarm.

- Event Category: 101 (System alarms)
- Event Type: 1 (Simple)
- Source: Yokogawa.ExaopcAESCSSOE
- Time: (Computer time)
- Severity: 900
- Message: Database Connection Error `ERR=0x80004005`
  Database Connection Recover
- SOETimestamp (Event Attribute): (Computer time) Event Occurrence Date (Local)
- TimestampM (Event Attribute): (Computer time) Event Occurrence Date (Millisecond)
- Resource (Event Attribute): (Computer name)
- Type (Event Attribute): BSYS
- ID (Event Attribute): (Blank)
- Quality (Event Attribute): (Blank)
- Node (Event Attribute): 0

- Slot (Event Attribute): 0
- Time_Diff (Event Attribute): (Computer time) Time zone (-08:00, +00:00, +09:00, ...)

SEE ALSO For more information about CPU load balancing for the SOE cassette, refer to:

C2.4, “Connection with host system computer via an OPC server” on page C2-10

Event notification interfaces

The SOE cassette notifies event information and diagnostic information of SCS to the A&E server. It also provides a function for filtering each event.

Available interfaces

The following tables show the custom interfaces available to A&E server clients, based on the functions that are installed on the SOE cassette.

Table C1-6 Custom interfaces

Object	Interface	Method	Description	Support(*1)
OPCEventServer	IOPCCommon	SetLocaleID	Locale ID setting	Yes
		GetLocaleID	Locale ID acquisition	Yes
		QueryAvailableLocaleIDs	Inquiry about supported locale IDs	Yes
		GetErrorString	Error character string acquisition	Yes
		SetClientName	Client name setting	Yes
	IOPCEventServer	GetStatus	Server status acquisition	Yes
		CreateEventSubscription	Generation of Event Subscription object	Yes
		QueryAvailableFilters	Inquiry about items that can be filtered	Yes
		QueryEventCategories	Inquiry about event categories	Yes
		QueryConditionNames	Inquiry about condition names	Yes
		QuerySubConditionNames	Inquiry about sub-condition names	Yes
		QuerySourceConditions	Inquiry about condition names corresponding to a source name	Yes
		QueryEventAttributes	Inquiry about event attributes	Yes
		TranslateToItemIDs	Item ID translation/acquisition	Yes
		GetConditionState	Acquisition of condition status	Yes
		EnableConditionByArea	Condition Enable for a specified area	No
		EnableConditionBySource	Condition Enable for a specified source	Yes
		DisableConditionByArea	Condition Disable for a specified area	No
		DisableConditionBySource	Condition Disable for a specified source	Yes
		AckCondition	Notification of condition acknowledgment	No
		CreateAreaBrowser	Generation of Event Area Browser object	No
		IOPCSecurityNT	Access control interface that uses NT credit information	Yes
		IOPCSecurityPrivate	Access control interface that uses private-defined user name/password	Yes
	IConnectionPointContainer	EnumConnectionPoints	Creation of enumerator that scans connection points	Yes
		FindConnectionPoint	Acquisition of interface pointers to connection points	Yes
	IConnectionPoint	Advise	Connection between connection point and sink	Yes
		Unadvise	Disconnection between connection point and sink	Yes

Continues on the next page

Table C1-6 Custom interfaces (Table continued)

Object	Interface	Method	Description	Support(*1)
OPCEventServer	IOPCSecurityNT	IsAvailableNT	Inquiry about availability of OPC security function by NT credit information	Yes (*2)
		QueryMinImpersonation-Level	Inquiry about impersonation level	No
		ChangeUser	Notification of user credit information changes	No
	IOPCSecurityPrivate	IsAvailablePriv	Inquiry about availability of OPC security function by private credit information	Yes
		Logon	Logon request by client user	Yes
		Logoff	Logoff request by client user	Yes
OPCEventAreaBrowser (option)	IOPCEventAreaBrowser	ChangeBrowsePosition	Change of browser position	No
		BrowseOPCAreas	Acquisition of area list	No
		GetQualifiedAreaName	Acquisition of Area name	No
		GetQualifiedSourceName	Acquisition of Source name	No
OPCEventSubscription	IOPCEventSubscriptionMgt	SetFilter	Event filter setting	Yes
		GetFilter	Acquisition of event filter	Yes
		SelectReturnedAttributes	Selection of event attribute	Yes
		GetReturnedAttributes	Acquisition of selected event attribute	Yes
		Refresh	Event refresh request	Yes
		CancelRefresh	Cancellation of refresh request	Yes
		GetState	Acquisition of the status of Event Subscription object	Yes
		SetState	Set the status of Event Subscription object	Yes
	IConnectionPointContainer	EnumConnectionPoints	Creation of enumerator that scans connection points	Yes
		FindConnectionPoint	Acquisition of interface pointers to connection points	Yes
	IConnectionPoint	Advise	Connection between connection point and sink	Yes
		Unadvise	Disconnection between connection point and sink	Yes
OPCEventSink	IOPCEventSink	OnEvent	Event notification	Yes
OPCShutdown	IOPCShutdown	ShutdownRequest	Server shutdown notification	Yes

*1: Yes: supported
No: Not supported
*2: The IsAvailableNT method of the IOPCSecurityNT interface always returns FALSE.

Filters

You can specify the following filtering conditions:

Table C1-7 Filtering conditions

Mask	Description
OPC_FILTER_BY_EVENT	Filtering by Event type

Continues on the next page

Table C1-7 Filtering conditions (Table continued)

Mask	Description
OPC_FILTER_BY_CATEGORY	Filtering by Event category
OPC_FILTER_BY_SEVERITY	Filtering by Alarm severity
OPC_FILTER_BY_SOURCE	Filtering by Source name

OPC A&E automation interfaces

The OPC Foundation released a draft version of the OPC A&E automation interfaces. YOKOGAWA provides the OPC A&E automation interfaces that comply with the draft specifications.

Error codes

The following tables show error codes handled by the SOE cassette. Each error code is set as a return value of a function of the SOE cassette interface or a data error value of each data.

OPC error codes

The following OPC error codes are used by the SOE cassette:

Table C1-8 COM error codes

COM error codes used by OPC server	Description
E_FAIL	General errors (without specific codes)
E_INVALIDARG	Invalid parameter
E_NOTIMPL	Unsupported function
E_OUTOFMEMORY	Insufficient memory

Table C1-9 OPC error codes

OPC error code	Description
OPC_E_BADRIGHTS	No access right
OPC_E_BADTYPE	Invalid request type
OPC_E_INVALIDITEMID	Invalid item ID
OPC_E_INVALID_PID	Invalid parameter ID
OPC_E_UNKNOWNITEMID	Undefined item ID specified

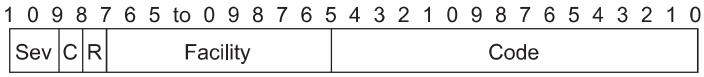
SOE cassette definition error codes

The following cassette definition error codes are used in the SOE cassette:

Table C1-10 SOE cassette definition error codes

Code (xxxx-x999)	Symbol (ZOT_XL_E_XXXX)	Description
0xC0042329	ZOC_AE_E_MAXSERVER	Excessive number of clients connected to the A&E server
0xC004232A	ZOC_AE_E_MAXSUBSCRIPTION	Excessive number of event registration objects of the A&E server

Error code bit assignment



The bit assignment in the error codes is as follows:

Code:

0000 to 0200: For Microsoft

0200 to 7999: For OPC definition errors

9000 to 9999: For the A&E server

Sev - is the severity code
00 - Success
01 - Informational
10 - Warning
11 - Error
C- is the Customer code flag
R- is a reserved bit
Facility- is the facility code (=FACILITY_ITF)
Code- is the facility's status code

Figure C1-3 Bit assignment in error codes

C2. Setup for using the OPC server

Setup is required to connect the SOE OPC Interface server (hereinafter referred to as SOE OPC server) and OPC client products. This section describes the setting items of the SOE OPC Interface required to use the OPC server, setting procedures, and operations after the settings are completed.

C2.1 Settings of the SOE OPC Interface

You can configure operation parameters of the SOE cassette by using the operation parameter setting tool that is included in the SOE OPC interface. This section describes how to use this tool to configure the settings for connecting the SOE OPC server and OPC client products.

Settings of operation parameters

Use the operation parameter setting tool to configure the operation parameters for the A&E server and HDA server.

1. Start SOE OPC Parameter Setting.
   The SOE OPC Interface Settings dialog box appears.

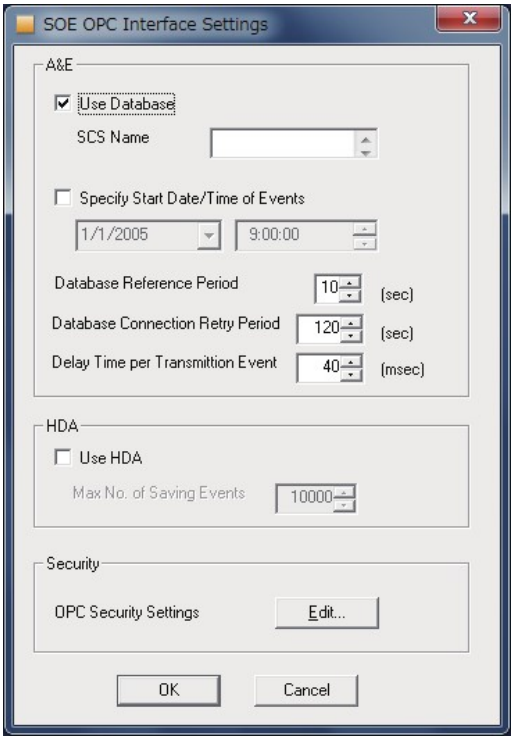


Figure C2.1-1 SOE OPC Interface Settings dialog box

2. Specify operation parameters for the A&E server and HDA (Historical Data Access) server.

SEE ALSO For more information about items set for the HDA server, refer to:

"● Items set for the HDA server" on page C2-3

● Items set for the A&E server

This section describes the setting items in the SOE OPC Interface Settings dialog box that relate to the A&E server.

- Use Database
  Always select this check box because the SOE OPC server is an A&E server.

  The check box is selected by default.

- SCS Name
  This field becomes enabled only if you select the [Use Database] check box. List the names of SCSs to be referenced (separated by space, comma or period).

Example:

SCS0101, SCS0102

The event logs of the SCSs selected here become the target of notification.

- Specify Start Date/Time of Events
  Select this check box to change the date/time of the first event to be acquired. If this box is selected, all events after the specified date/time are sent to the client. If the box is not selected, events after the computer time when restarting the SOE cassette are sent to the client.

  The check box is not selected by default.

- Date/Time Specification
  These fields become enabled only if you select the [Specify Start Date/Time of Events] check box. Specify the date and time of the first event.

  The time when you select the [Specify Start Date/Time of Events] check box is set by default.

- Database Reference Period
  Specify the period in units of seconds if you want to change the database reference period.

  A value in the range from 1 to 600 seconds can be specified. 10 seconds is set by default.

- Database Connection Retry Period
  Specify the time interval in seconds to retry reconnection to the database in case the connection to the database fails or the connection to the database is disconnected.

  A value in the range from 1 to 1800 seconds can be specified. 120 seconds is set by default.

- Delay Time Per Transmission Event
  This is the delay time for a single transmission event. Specify the time in units of milliseconds if you want to change the setting.

  A value in the range from 0 to 1000 milliseconds can be specified. 40 ms is set by default.

  Specify an appropriate value according to the load on the computer.

  - If you make the "Delay Time Per Transmission Event" longer, it takes more time to send events and the CPU load is reduced.
  - If you make the "Delay Time Per Transmission Event" shorter, it takes less time to send events and the CPU load is increased.

Items set for the HDA server

This section describes the setting items in the SOE OPC Interface Settings dialog box that relate to the HDA server.

- Use HDA
  Select this check box when the HDA functions should be used.

- Max No. of Saving Events
  This field becomes enabled only if you selected the [Use HDA] check box. Specify the maximum number of events that the HDA server should maintain. If more events than the maximum number of events saved are generated, events are overwritten starting from the oldest event. A value in the range from 1000 to 1000000 can be specified. 10000 is set by default.

IMPORTANT

Determine the maximum number of saving events based on the disk capacity and the search speed of the HDA server. An event uses approximately 500 bytes of disk space, which means that 10000 events use approximately 5 MB. When there are many events, file searches takes longer.

C2.2 Overview of product security settings

Product security settings are required to connect the SOE OPC server and OPC client products. This section describes the settings required on the SOE OPC server side.

You can configure the OPC product security and DCOM connection settings using the operation parameter setting tool that is included in the SOE OPC Interface.

Product security setting procedure

Follow these steps to configure the product security settings on the SOE OPC server:

1. Log on as a user with administrative rights. If the standard model of security settings are applied, log on as a user who belongs to the PSF_ENGINEER or PSF_ENGINEER_LCL group.
2. Start SOE OPC Parameter Setting.
   The SOE OPC Interface Settings dialog box appears.
3. Click the [Edit] button next to [OPC Security Settings].
   A dialog box to select the logon type for the OPC server appears.

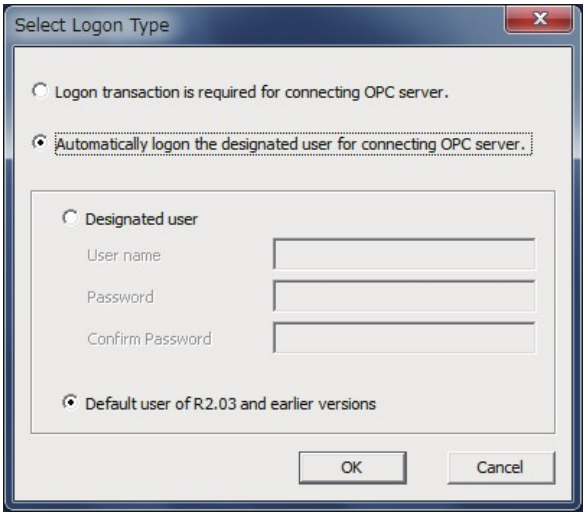

Figure C2.2-1 Select Logon Type dialog box

4. Configure the logon type settings for the OPC server according to the security level. The following table shows the setting items in the dialog box and precautions for setting the items.

Table C2.2-1 Setting items and precautions

Item	Description	Precautions
Logon transaction is required for connecting OPC server.	Select this option if you need to log on when connecting to the OPC server	Calls of Logon and SetUser methods on the OPC client are required to select this option. Do not select this option if the OPC client does not support the calls of Logon and SetUser methods.
Automatically logon the designated user for connecting OPC server.	Select this option to enable automatic logon when connecting to the OPC server	After the automatic logon is enabled, select one of the following logon methods. • Designated user • Default user of R2.03 and earlier versions

Continues on the next page

Table C2.2-1 Setting items and precautions (Table continued)

Item	Description	Precautions
Designated user	Select this option to designate a user for automatic logon	Specify the user name and password that is used for automatic logon. If periodic password change is required, you must respecify this password accordingly. This applies to the case of domain management in Windows authentication mode. Make sure to note the password expiration date.
Default user of R2.03 and earlier versions	Select this option to ensure compatibility with ProSafe-RS R2.03 or earlier.	This option is selected by default when automatic logon is enabled for connecting to the OPC server. Note that this setting may result in a reduced level of security.

TIP

To connect a computer that is installed with the SOE OPC interface package for ProSafe-RS R3.01 or later to Exaquantum or Exaquantum/SER as an OPC client, you need to set the items for product security in advance. When using Exaquantum, you must select [Default user of R2.03 and earlier versions].

SEE ALSO

For more information about security settings required when using Exaquantum as an OPC client, refer to:

D1.4.1, “ProSafe-RS SOE OPC Interface Package and Exaquantum PIMS Server” in Installation Guide (IM 32P01C50-01EN)

DCOM settings

In ProSafe-RS R3.02 or later, the IT security of the SOE OPC server is strengthened. Thus, depending on the OPC client used, the connection to the server may fail after R3.02 or later is installed. If the connection fails, configure the DCOM settings on the OPC server. You must restart the computer after you finish configuring the settings.

This section describes the DCOM setting procedures for different combinations of security models and user management methods.

DCOM setting procedure for legacy model

If the SOE OPC server security model is the legacy model, DCOM settings are configured by the IT security setting tool. No manual configuration is required.

DCOM setting procedure for the standard model under standalone management

This section describes the DCOM setting procedure when the SOE OPC server security model is the standard model and the user management method is standalone management. Follow these steps to configure if connection to OPC clients fails after ProSafe-RS R3.02 or later is installed:

1. Open the Control Panel.
2. Select [System and Security] > [Administrative Tools] > [Component Services].
   The Component Services window appears.
3. In the hierarchy tree, expand [Component Services] > [Computers] > [My Computer] > [DCOM Config].

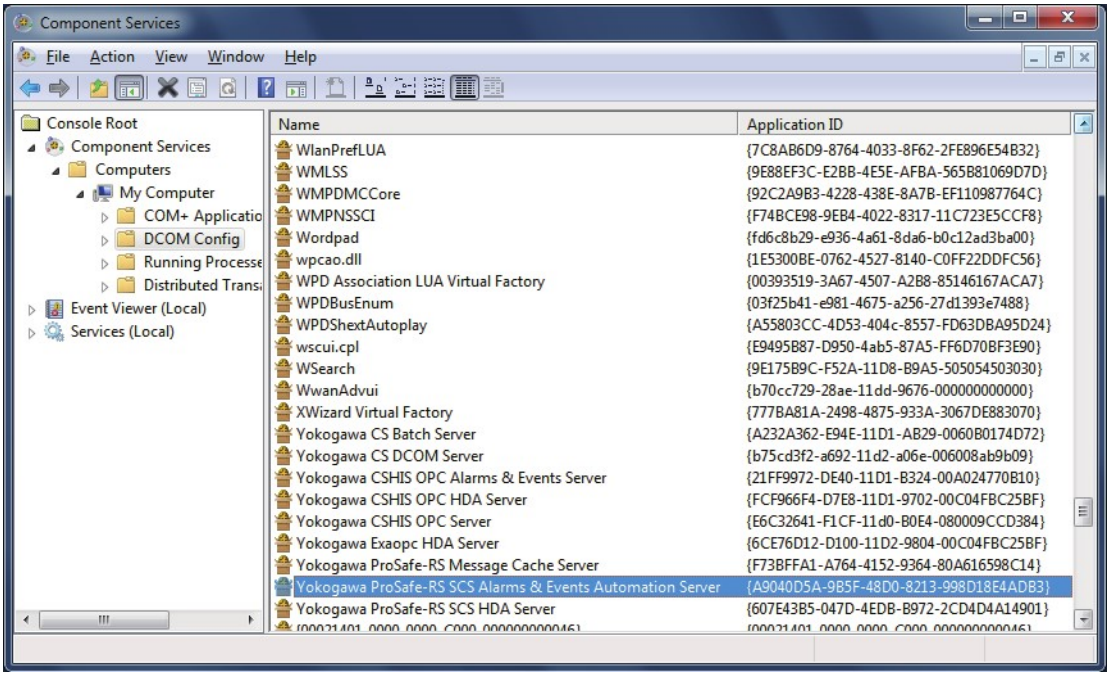

Figure C2.2-2 DCOM Config

4. Select Yokogawa ProSafe-RS SCS Alarms & Events Automation Server, and select [Properties] from the right-click menu.
   The Properties dialog box appears.

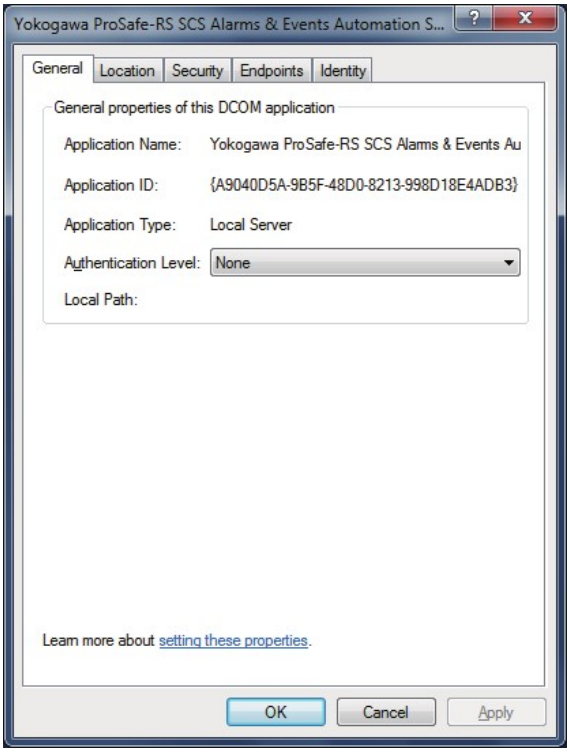

Figure C2.2-3 Yokogawa ProSafe-RS SCS Alarms & Events Automation Server Properties dialog box

5. Click the General tab, set the Authentication Level to [None], and click [OK].
6. Specify Yokogawa ProSafe-RS SCS HDA Server in Application Name, and select [Properties] from the right-click menu.
   The Properties dialog box appears.

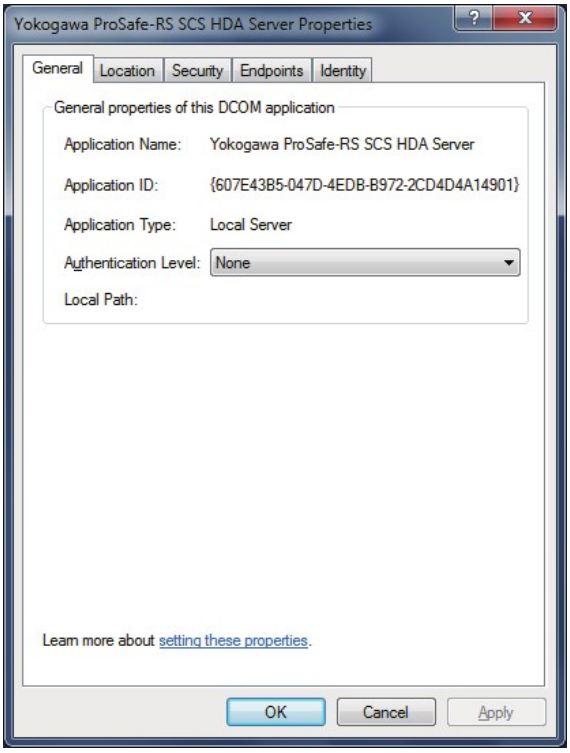

Figure C2.2-4 Yokogawa ProSafe-RS SCS HDA Server Properties dialog box

7. Click the General tab, set the Authentication Level to [None], and click [OK].
8. Restart the computer.

● DCOM setting procedure for standard model under domain management

The DCOM setting procedure when the SOE OPC server security model is the standard model and the user management method is domain management is the same as when the security model is the standard model and the user management method is standalone management.

SEE ALSO For more information about DCOM setting procedure for the standard model under standalone management, refer to:

"● DCOM setting procedure for the standard model under standalone management" on page C2-6

● DCOM setting procedure for standard model under combination management or linked domain management

The DCOM setting procedure when the SOE OPC server security model is the standard model and the user management method is either combination management or linked domain management is the same as when the security model is the standard model and the user management method is standalone management.

SEE ALSO For more information about DCOM setting procedure for the standard model under standalone management, refer to:

"● DCOM setting procedure for the standard model under standalone management" on page C2-6

C2.3 Operations after operation parameters are configured

This section describes how the SOE OPC Interface operates after the operation parameters are configured.

Operations when the operation parameter setting tool is launched

When the operation parameter setting tool is launched for the first time, all the items are set to their default values. When you launch the tool the next time, the tool displays all items according to the settings the user made last time.

The [Specify Start Date/Time of Events] check box is deselected when the SOE cassette starts to send events.

Operations when changing parameters

When using the operation parameter setting tool to change operation parameters for the SOE cassette, the SOE OPC interface restarts when you click the [OK] button in the operation parameter setting tool.

Events generated while the SOE OPC interface is restarting are not sent to the client. If you want to send events generated during the SOE OPC interface restart processing (approximately 1 to 2 minutes) to the client, specify the [Specify Start Date/Time of Events] setting item for the A&E server. The current time can be set by selecting/deselecting the [Specification of Head Event Date/Time] check box.

TIP

The same information will not be sent again if the SOE OPC interface is restarted with the same date/time as previously specified.
To resend the past events, check the [Specify Start Date/Time of Events] box and specify the date and time again.

C2.4 Connection with host system computer via an OPC server

ProSafe-RS connects with a host system computer via OPC interface. The following two OPC interfaces are available.

- Connection through SOE OPC interface package (RS4H2200)
  Enables OPC-compatible application (client) on the host system computer to access diagnostic data and event data (SOE) on SCS.
- Connection through Exaopc OPC interface (VP6H2411 for HIS, or NTPF100)
  Enables OPC-compatible application (client) on the host system computer to access various data such as process data and alarm messages on SCS in the same manner as data on the FCS.

This section primarily describes the SOE OPC Interface Function.

SEE ALSO For more information about Exaopc OPC interface, refer to:

NTPF100 Exaopc OPC Interface Package Guide Manual (IM 36J02A11-01E)

Overview of OPC Interface

The following figure shows the overview of the OPC Interface.

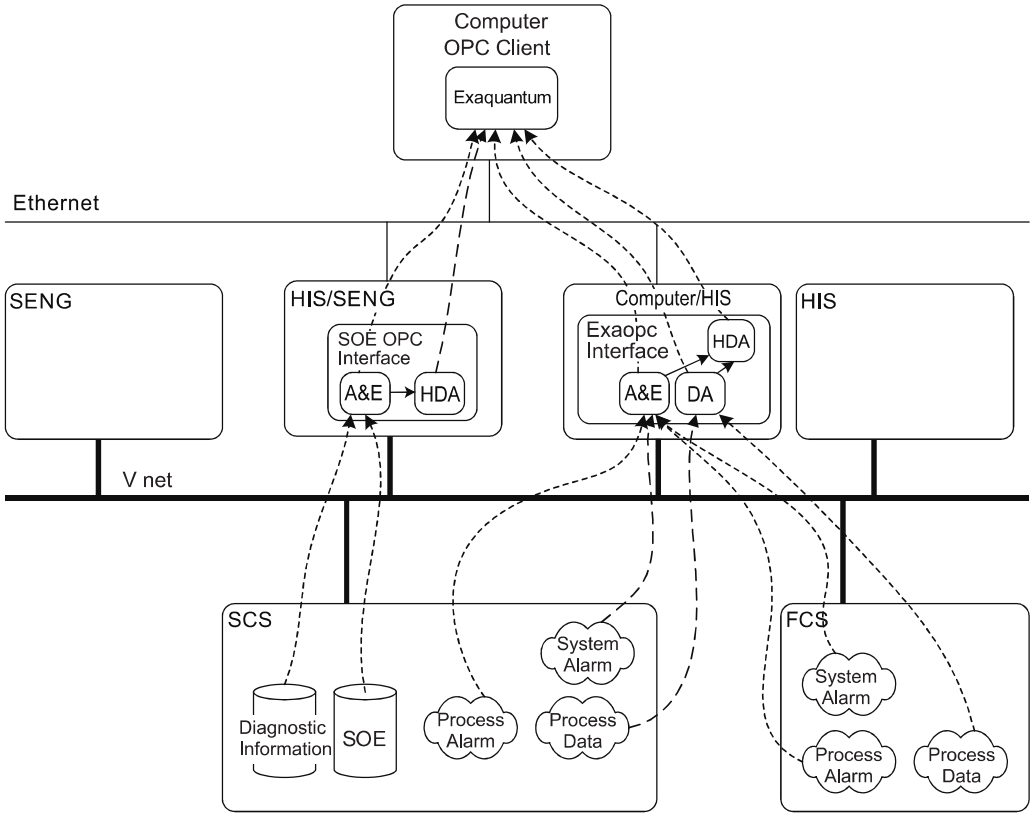

Figure C2.4-1 Overview of OPC Interface

SOE OPC interface (RS4H2200)

SOE OPC Interface package for ProSafe-RS notifies the client computer of diagnostic data and event data (SOE) on SCS via OPC A&E interface. The major OPC client is Exaquantum, but general-purpose OPC clients (provided by other manufacturers) can also be connected with SCS.

Together with Exaquantum, HDA interface becomes available.

SOE OPC Interface works on a PC. It also works on HIS. It consists of the OPC server, which sends data to clients, and an SOE-dedicated cassette of ProSafe-RS, with which SCS data is obtained (hereafter referred to as a cassette). The specifications for the OPC server are identical to the one for the A&E server, which is essentially part of Exaopc. The A&E server is a function which creates notifications in the occurrence of an event affecting the OPC client.

Exaopc OPC interface (VP6H2411 for HIS, or NTPF100)

Exaopc OPC Interface enables OPC client to access process data, alarms, and messages on SCS.

Exaopc OPC Interface supports the following three interfaces.

OPC DA Interface

Enables OPC client to access SCS process data.

OPC HDA Interface

Enables OPC client to access historical SCS process data kept by Exaopc OPC Interface.

OPC A&E Interface

Enables OPC client to access SCS alarms and messages such as process alarms and system alarms.

Precautions

This section provides the precautions for engineering the SOE OPC Interface.

Coexistence of SOE-dedicated OPC Server with Exaopc OPC Interface Package

Minimize the chance of coexistence of the SOE-dedicated OPC Server of ProSafe-RS with the HIS "Exaopc OPC Interface Package (for HIS)." Otherwise, this can cause lower performance of the SOE-dedicated OPC Server depending on the frequency of using the Exaopc OPC Interface Package. This problem can be avoided by distributing the load on several HISs.

CPU Load Distribution

To reduce the communication load and CPU load caused by sending a large amount of data to the client, the cassette has a function of distributing the CPU load by restricting the communication traffic to the client. The cassette computes the maximum number of events that can be sent simultaneously (1-1000) from the delay time per one transmit event (user defined value, the default is 40 ms) with the following expression and alternates transmission and delay.

- Maximum number of transmitted events = Maximum delay time (fixed at 2000 ms) /Event transmission delay time (ms)
- Delay time =Event transmission delay time (ms) x Number of transmit events (n)

The default is the repetition of 50 (2000/40) event transmissions and two second delays (40 x 50).

This case requires 40 seconds for transmitting 1000 events.

The default setting can be changed according to the performance of PC.

- Longer "event transmission delay time" causes delayed event transmission and lower CPU load.

- Shorter "event transmission delay time" causes faster event transmission and higher CPU load.

SEE ALSO For more information about host interface function of SOE, refer to:

C1., “Overview of SOE OPC Interface” on page C1-1

C3. Setup for using the OPC client

Setup of the OPC server and OPC client is required to connect to the SOE OPC server.

This section describes the settings using the setup tool, Windows account settings required to use the OPC client, and settings required on the OPC client.

C3.1 Settings using the setup tool and Windows account settings

You can configure the OPC client using required information which is collected from the OPC server using the setup tool.

After that, you can configure Windows accounts and settings required for the connection on the OPC server and client.

C3.1.1 Preparations on the OPC server

On the computer where the SOE OPC Interface is installed, you must get the information that is required to set up the OPC client and save it in a removable storage device.

TIP

To run a program file or SETUP.exe in Windows Vista or later, right-click the file, and then select [Run as Administrator].

1. Connect a formatted removable storage medium (such as USB memory stick) to the computer where the SOE OPC server is running.
2. In Windows Explorer, start the following program:
   `(ProSafe-RS installation drive):\(ProSafe-RS installation folder)\ProSafe-RS\YOKOGAWA\program\RHHCopyOPC.exe`

   The RHHCopyOPC dialog box appears.

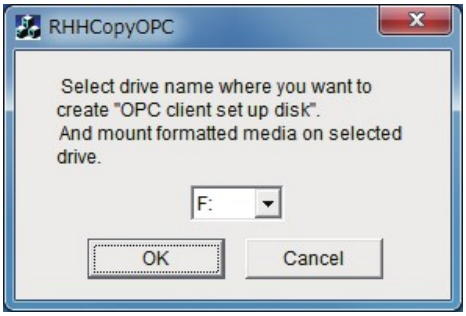

Figure C3.1.1-1 RHHCopyOPC dialog box

3. Select the connected removable storage medium and click [OK].
   The setup information that is required for the OPC client is saved on the removable storage medium.

C3.1.2 Operation procedure for the OPC client

On the computer where the OPC client runs, you must configure the setup information by using the setup tool and set up the user who will run the application on the OPC server.

TIP To run a program file or SETUP.EXE in Windows Vista or later, right-click the file and select [Run as Administrator].

1. Connect the removable storage medium that stores the setup information to the computer in which the OPC client is running.
2. Log on to the OPC client as an administrative user.
3. Insert the ProSafe-RS software medium into the drive, and run the following program contained in the medium.
   `(Media drive):\ProSafe-RS\vcredist_x86_2017\VC_redist.x86.exe`
4. Run the SETUP.EXE in the removable storage medium.
   The Command Prompt window appears, and the setting up of OPC client is performed.
   After the setup is complete, the Program Compatibility Assistant dialog box may appear.
   If it appears, click [This program installed correctly] to finish the installation.
5. Specify the user who will run the application on the SOE OPC server.
   If the SOE OPC server security model is the standard model
   a. Insert the ProSafe-RS software medium into the drive, start the command prompt window, and move to the following folder.
      `(Media drive):\ProSafe-RS\SECURITY`
   b. Run the following program.
      `ProSafe.Security.CreateProSafeProcess.exe`

      The "PSF_PROCESS" user is created on the client computer.
   c. Configure the security settings designated by the client application.

TIP If the client application is Exaquantum, add the "PSF_PROCESS" user to the QTM_OPC user group as designated by Exaquantum.

   If the SOE OPC server security model is the legacy model
   a. Create the following user on the client computer.
      Account name: EXAUSER (all in upper case)

      Password: EXAUSER (all in upper case)
   b. Configure the security settings designated by the client application.

C3.2 Security Settings

In order to connect the SOE OPC server and the OPC client products, set the security for the SOE OPC server and the OPC client according to the security model and user management method used on the SOE OPC server. If the client application coexists with the SOE OPC server, the configuration is not required.

You must configure the OPC client with administrator privileges.

IMPORTANT

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well.

SEE ALSO For more information about the Windows update programs to apply, refer to:

B1.2, “Precautions for Setup” in Installation Guide (IM 32P01C50-01EN)

Settings for Standard Model

If the SOE OPC server security model is the standard model, the following settings are required. Be sure to restart the computer after you finish the configuration.

- Windows account settings on the SOE OPC server computer
- Firewall settings on the OPC client
- DCOM settings on the OPC client

This section describes the setting procedure for the Windows 10 operating system as an example.

Creating a Windows account on the SOE OPC server computer

Create a Windows account on the SOE OPC server computer or domain controller according to the user management method.

- For standalone management
  Add a user account with the same name as the local user who runs the client application on the OPC client computer to the SOE OPC server computer, and make it belong to the PSF_OPC group.
- For domain management or combination management
  Add a user account that runs the client application on the OPC client computer to the domain controller, and make it belong to the PSF_OPC group. If the user account running the client application is unable to support domain management, add a user account with the same name as the local user who runs the client application on the OPC client computer to the SOE OPC server computer, and make it belong to the PSF_OPC_LCL group.
- For linked domain management
  Add a user account that runs the client application on the OPC client computer to the domain controller, and make it belong to the PSF_OPC group. If the user account running the client application is unable to support domain management, add a user account with the same name as the local user who runs the client application on the OPC client computer to the SOE OPC server computer, and make it belong to the PSF_OPC group.

TIP If you add a user account with the same name as the local user to the SOE OPC server computer, make sure that the password is the same.

SEE ALSO For more information about how to create a user account in domain management, combination management, or linked domain management and make it belong to a group, refer to:

B2.4, “Creating Domain Users” in Installation Guide (IM 32P01C50-01EN)

Firewall settings on the OPC client

Configure firewall settings for the [File and Printer Sharing] service and the client application.

1. Open the Control Panel.
2. Select [System and Security] > [Windows Defender Firewall].
   The Windows Defender Firewall window appears.

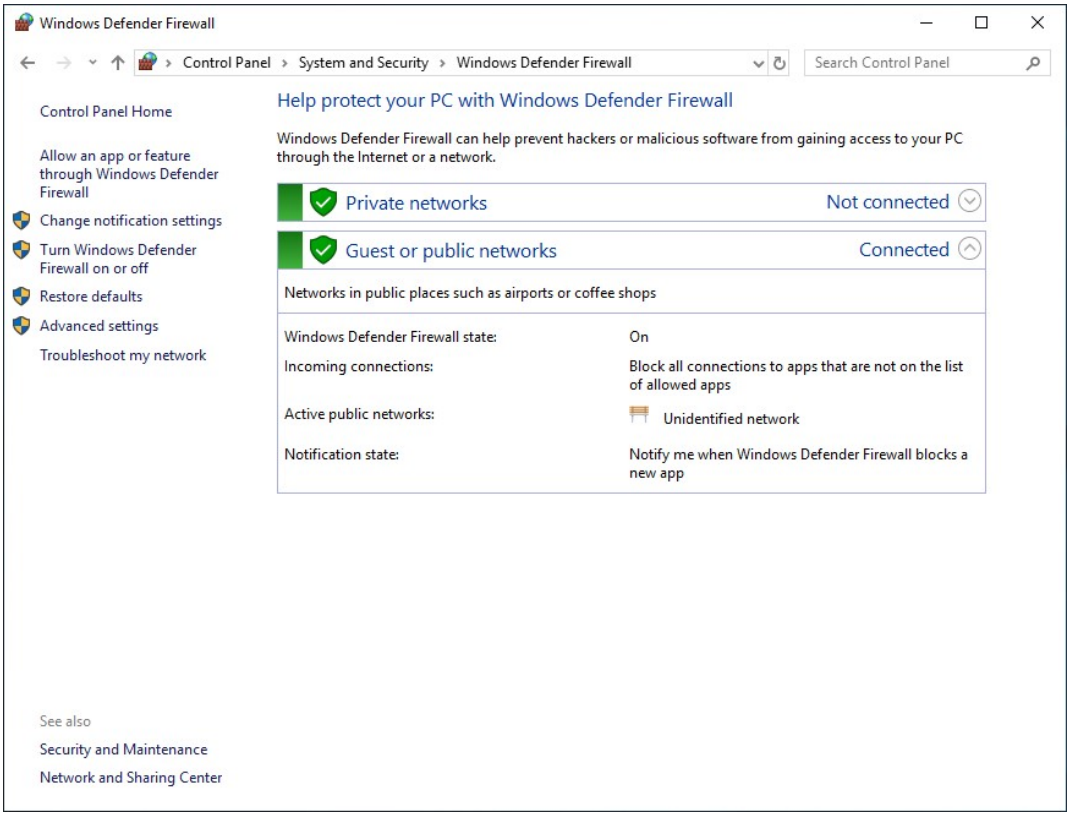

Figure C3.2-1 Windows Defender Firewall window

3. Click [Allow an app or feature through Windows Defender Firewall].
   The Allowed apps window appears.

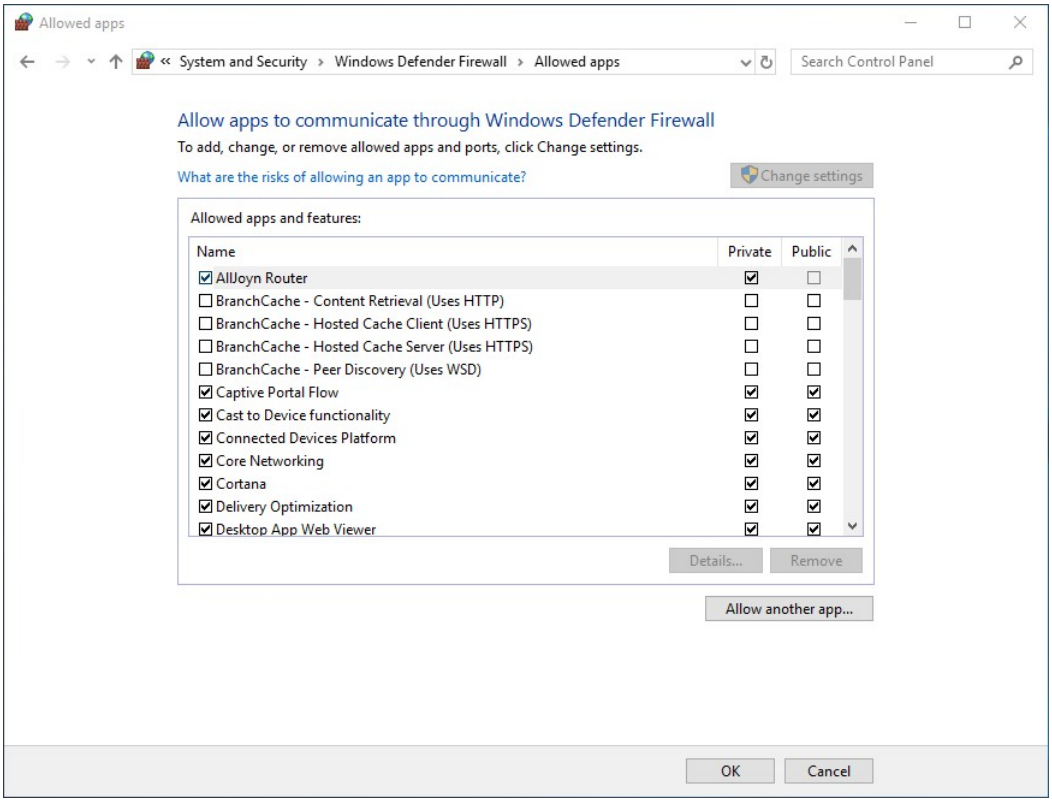

Figure C3.2-2 Allowed apps window

4. Click [Change settings].
5. In the Name column, select the check box for [File and Printer Sharing].
   Make sure all profiles (Private and Public) are selected.

TIP

For domain management, combination management, or linked domain management, [Domain] is displayed in addition to [Private] and [Public].

6. Click [Allow another app].
   The Add an app dialog box appears.
7. Select the client application from the Programs list and click [Add].
   Make sure that the selected client application is added to the Allowed apps window and that its check boxes in the Name and Public columns are selected.

DCOM settings on the OPC client

For DCOM, add the PSF_PROCESS user and configure "Access Permissions" and "Launch and Activation Permissions." After that, change the default authentication level.

1. Edit the Access Permissions settings for the PSF_PROCESS user.
   a. Open the Control Panel.
   b. Select [System and Security] > [Administrative Tools] > [Component Services].
      The Component Services window appears.

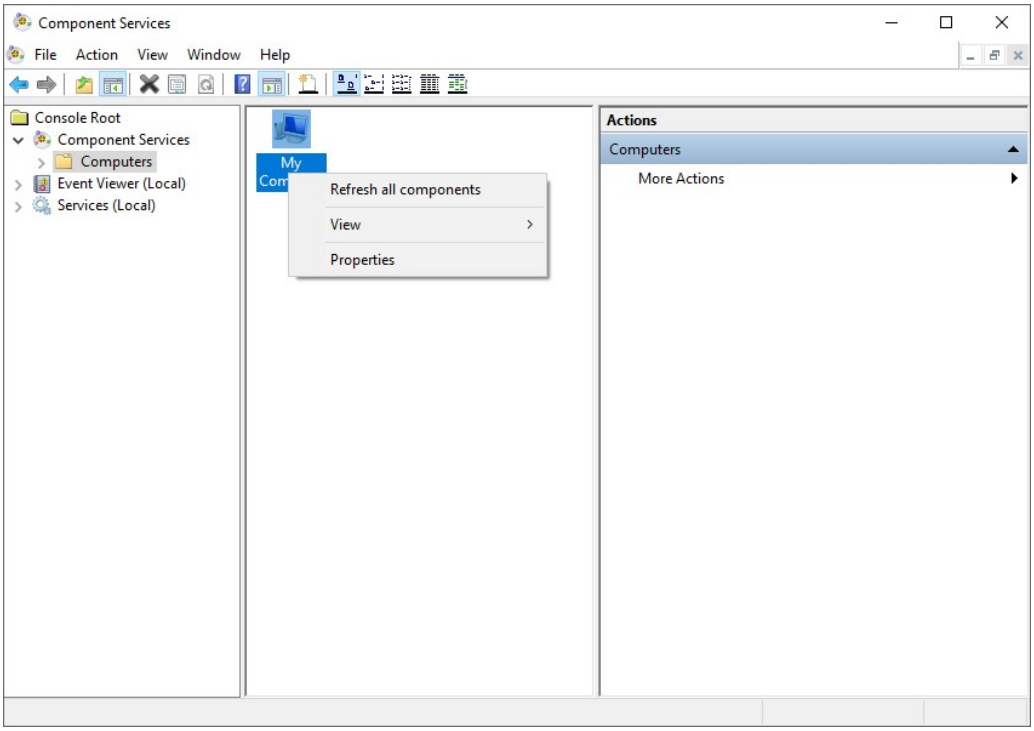

Figure C3.2-3 Component Services window

c. Right-click [Component Services] > [Computers] > [My Computer] and select [Properties].
The My Computer Properties dialog box appears.

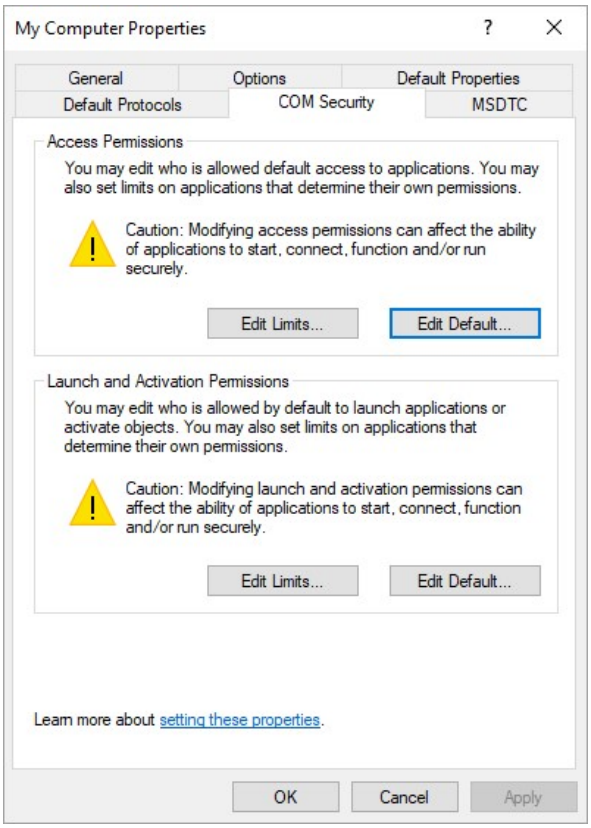

Figure C3.2-4 COM Security tab of the My Computer Properties dialog box

d. Click the COM Security tab and click [Edit Default] for Access Permissions.
The Access Permission dialog box appears.

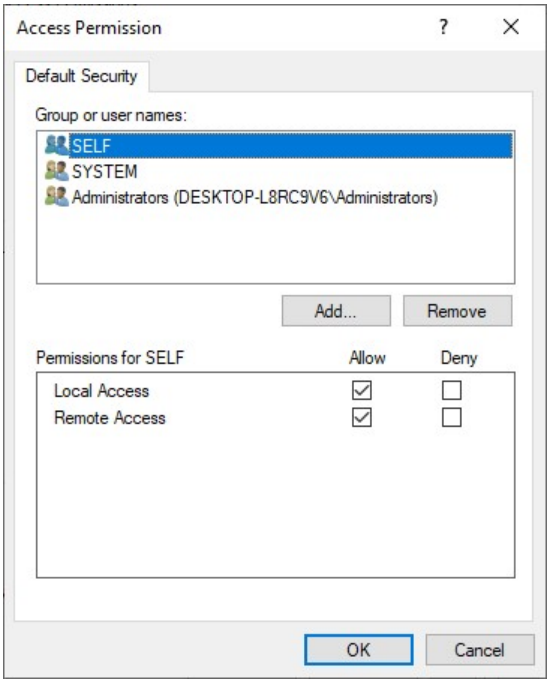

Figure C3.2-5 Default Security tab of the Access Permission dialog box

e. Click [Add].
The Select Users or Groups dialog box appears.

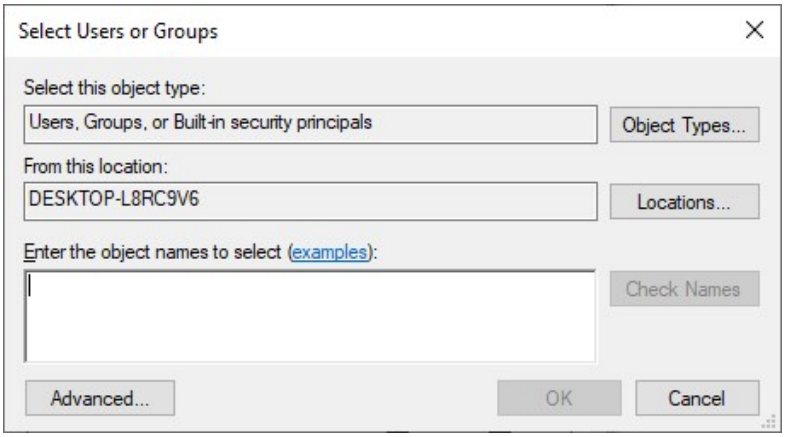

Figure C3.2-6 Select Users or Groups dialog box

f. Enter the `PSF_PROCESS` user created in the Operation procedure for the OPC client and click [OK].
The [PSF_PROCESS] user is added to the Access Permission dialog box.

g. Select [PSF_PROCESS], select the "Allow" check boxes for "Local Access" and "Remote Access," and click [OK].

2. Edit limits for Access Permissions

a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Limits] for Access Permissions.
The Access Permission dialog box appears.

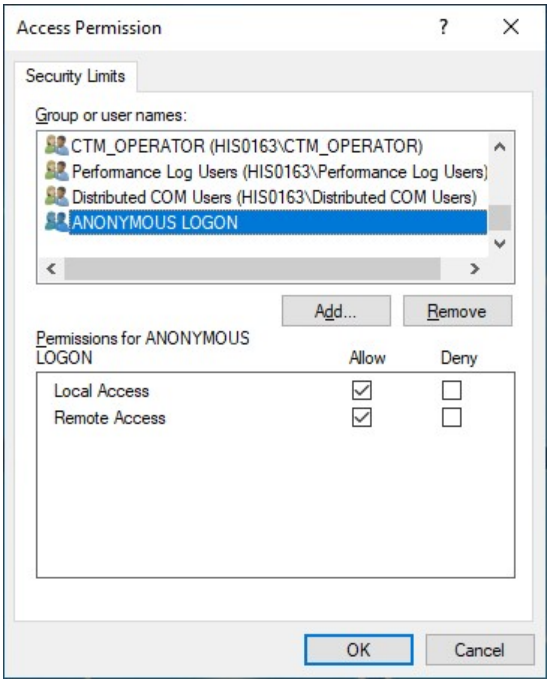

Figure C3.2-7 Security Limits tab of the Access Permission dialog box

b. Select [ANONYMOUS LOGON] in the Group or user names list, select the Allow check boxes for "Local Access" and "Remote Access," and click [OK].

3. Edit the default values of Launch and Activation Permissions

a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Default] for Launch and Activation Permissions.
The Launch and Activation Permission dialog box appears.

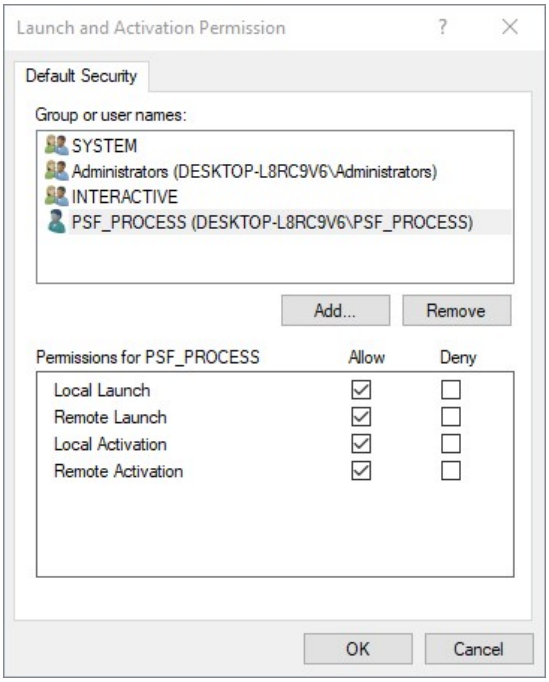

Figure C3.2-8 Default Security tab of the Launch and Activation Permission dialog box

b. Click [Add].
The Select Users or Groups dialog box appears.

c. Enter `PSF_PROCESS` for the user to select and click [OK].

The [PSF_PROCESS] user is added to the Launch and Activation Permission dialog box.

d. Select [PSF_PROCESS], select the Allow check boxes for "Local Launch," "Remote Launch," "Local Activation," and "Remote Activation," and click [OK].

4. Edit limits for Launch and Activation Permissions.

a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Limits] for Launch and Activation Permissions.
The Launch and Activation Permission dialog box appears.

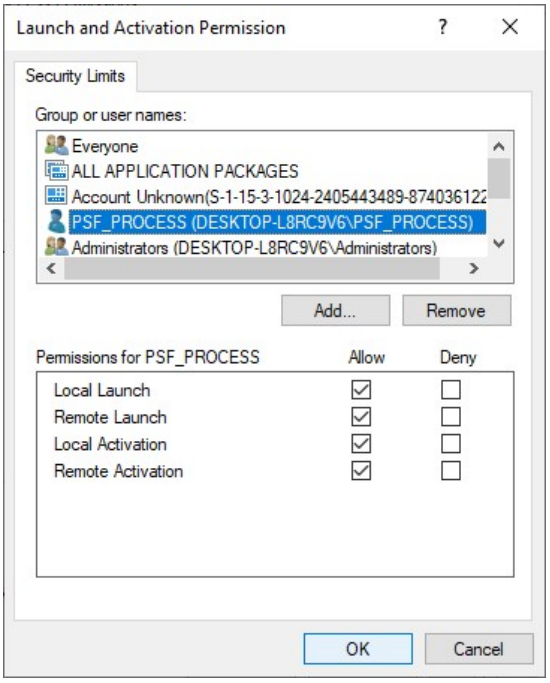

Figure C3.2-9 Security Limits tab of the Launch and Activation Permission dialog box

b. Click [Add].
The Select Users or Groups dialog box appears.

c. Enter `PSF_PROCESS` for the user to select and click [OK].
The [PSF_PROCESS] user is added to the Launch and Activation Permission dialog box.

d. Select [PSF_PROCESS], select the Allow check boxes for "Local Launch," "Remote Launch," "Local Activation," and "Remote Activation," and click [OK].

5. Edit the default properties.

a. In the My Computer Properties dialog box, click the Default Properties tab and select [Connect] for the Default Authentication Level, and click [OK].

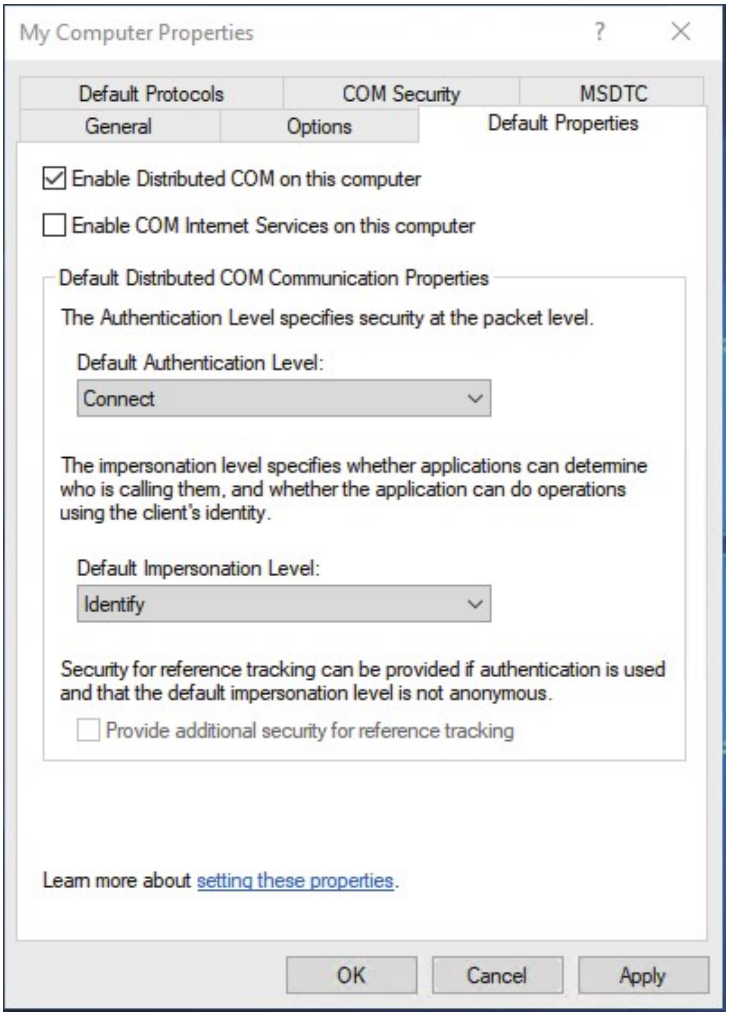

Figure C3.2-10 Default Properties tab of the My Computer Properties dialog box

6. Change the default authentication level of the SOE OPC server.
   a. In the hierarchy tree, expand [Component Services] > [Computers] > [My Computer] > [DCOM Config].

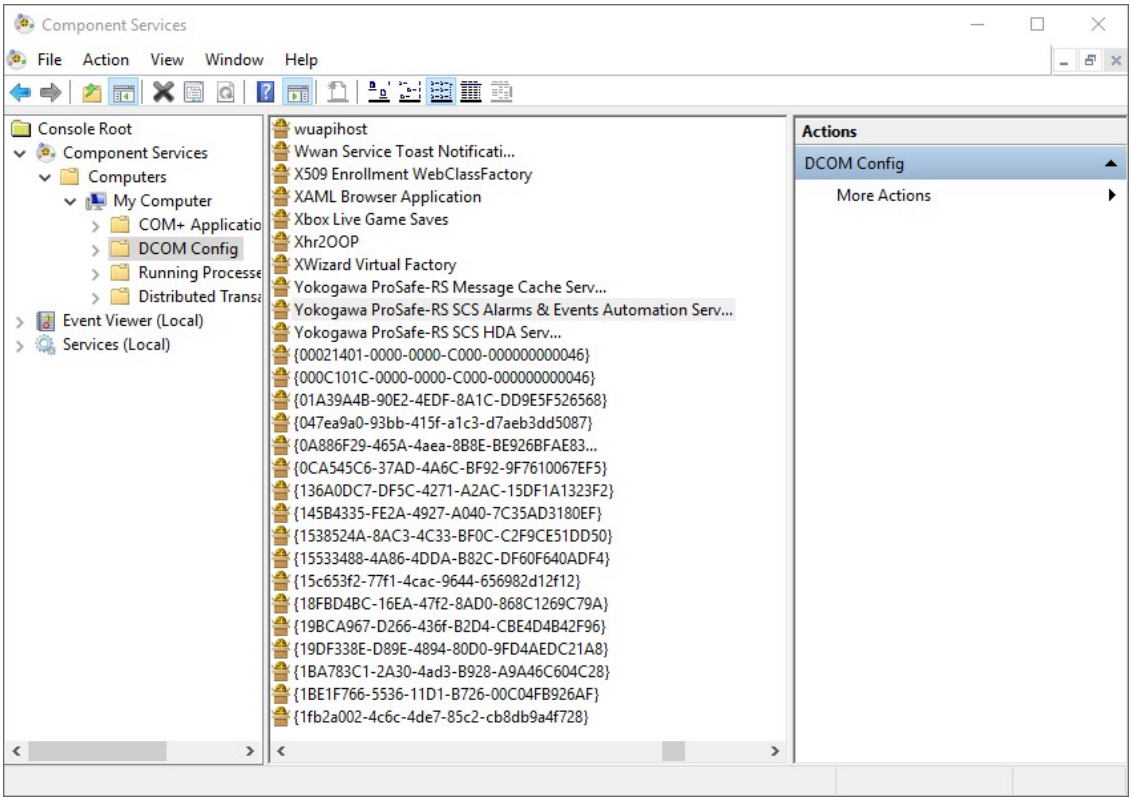

Figure C3.2-11 DCOM Config

b. Select Yokogawa ProSafe-RS SCS Alarms & Events Automation Server and select [Properties] from the right-click menu.
The Properties dialog box appears.

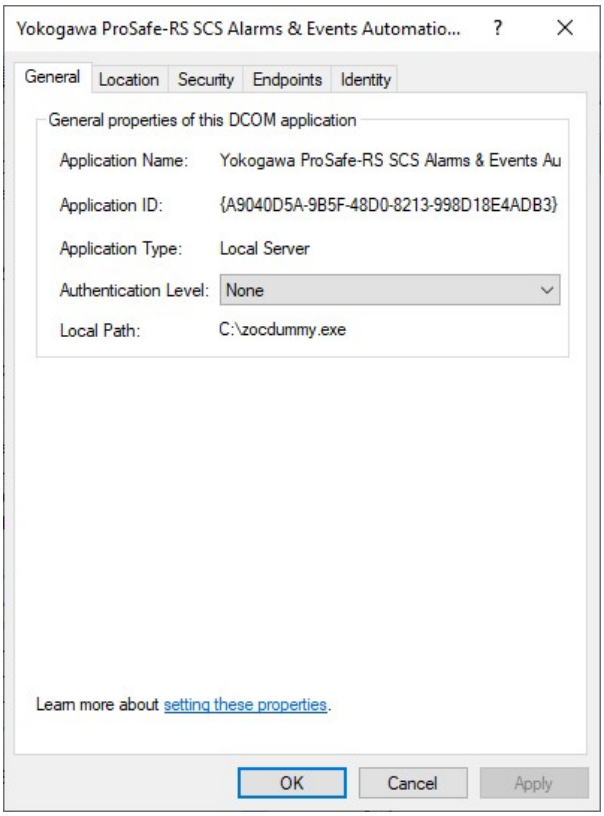

Figure C3.2-12 Yokogawa ProSafe-RS SCS Alarms & Events Automation Server Properties dialog box

c. In the Yokogawa ProSafe-RS SCS Alarms & Events Automation Server Properties dialog box, click the General tab and select [None] for the Authentication Level, and click [OK].

d. From the hierarchy tree, open the DCOM Config window, select Yokogawa ProSafe-RS SCS HDA Server, and select [Properties] from the right-click menu.
The Properties dialog box appears.

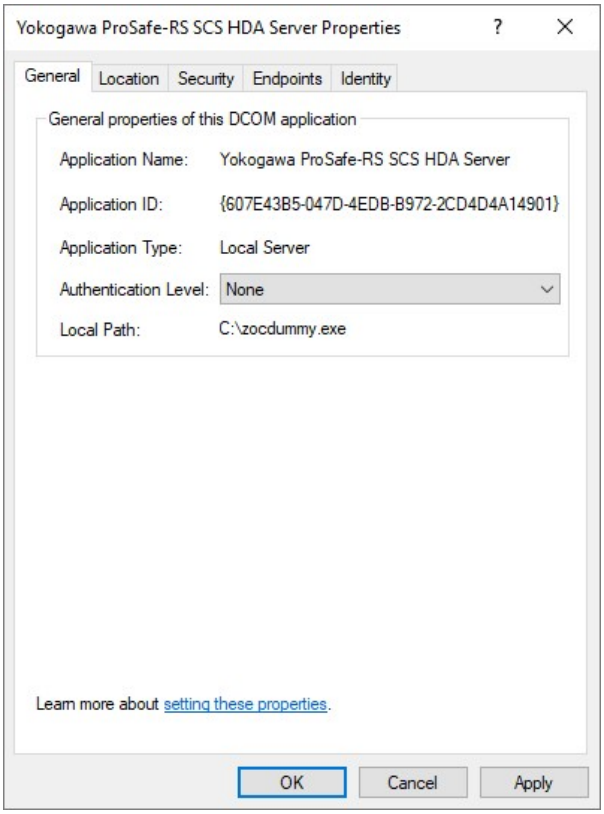

Figure C3.2-13 Yokogawa ProSafe-RS SCS HDA Server Properties dialog box

e. In the Yokogawa ProSafe-RS SCS HDA Server Properties dialog box, click the General tab and select [None] for the Authentication Level, and click [OK].

7. Restart the computer.

Settings for the legacy model

If the SOE OPC server security model is the legacy model, the following settings are required. Be sure to restart the computer after you finish the configuration.

- Firewall settings
- DCOM settings
- Local security settings

Firewall setting procedure

Disable the Windows Firewall.

1. Open the Control Panel.
2. Select [System and Security] > [Windows Defender Firewall].
Help protect your PC with Windows Defender Firewall appears.

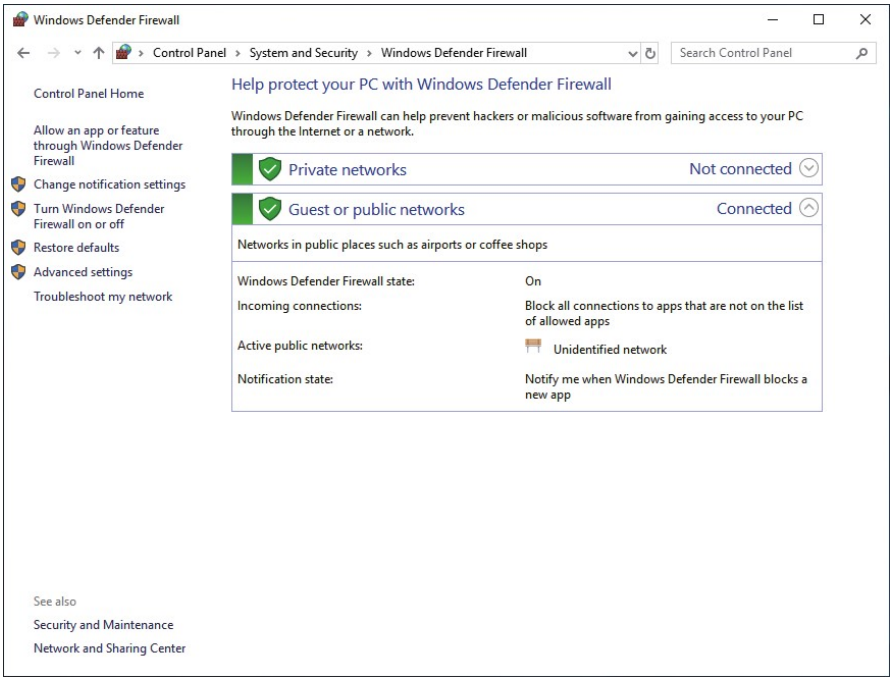

Figure C3.2-14 Help protect your PC with Windows Defender Firewall

3. Click [Turn Windows Defender Firewall on or off].
   The Customize settings for each type of network dialog box appears.

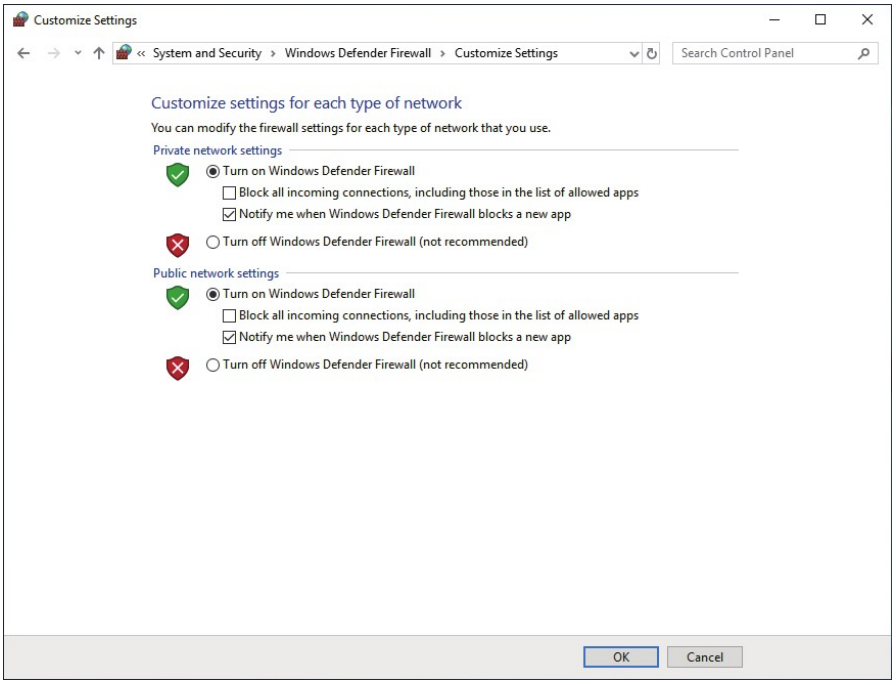

Figure C3.2-15 Turning Windows Defender Firewall on or off

4. For the location settings of each network, select [Turn off Windows Defender Firewall (not recommended)], and click [OK].

DCOM setting procedure

For DCOM, add the Everyone user and configure "Access Permissions" and "Launch and Activation Permissions" for the Everyone user and default user. After that, change the default authentication level.

1. Edit the Access Permissions settings for the Everyone user.

   a. Open the Control Panel.

   b. Select [System and Security] > [Administrative Tools] > [Component Services].
   The Component Services window appears.

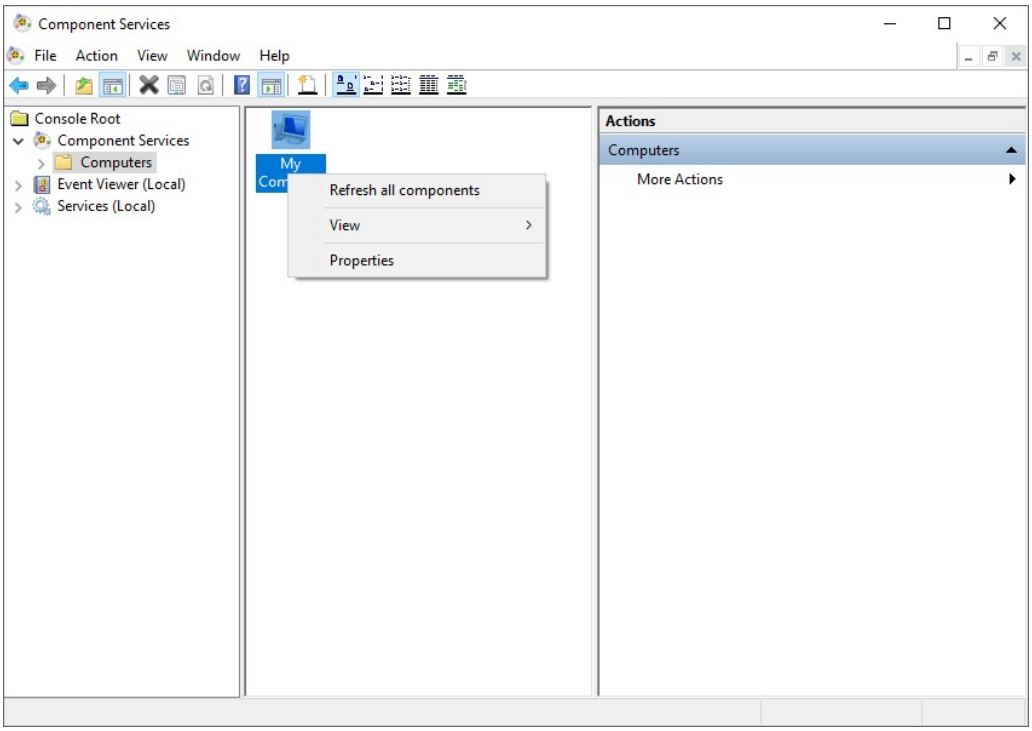

Figure C3.2-16 Component Services window

   c. Right-click [Component Services] > [Computers] > [My Computer] and select [Properties].
   The My Computer Properties dialog box appears.

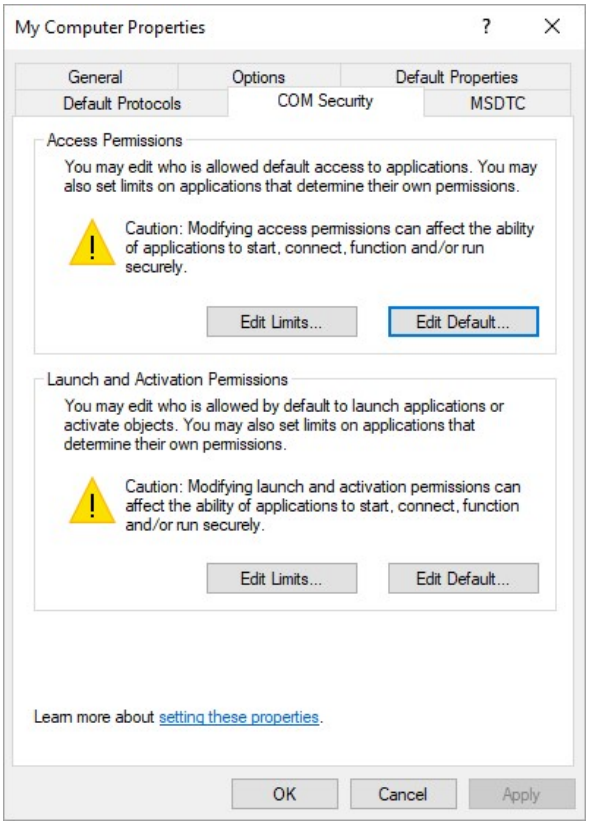

Figure C3.2-17 COM Security tab of the My Computer Properties dialog box

d. Click the COM Security tab and click [Edit Default] for Access Permissions.
The Access Permission dialog box appears.

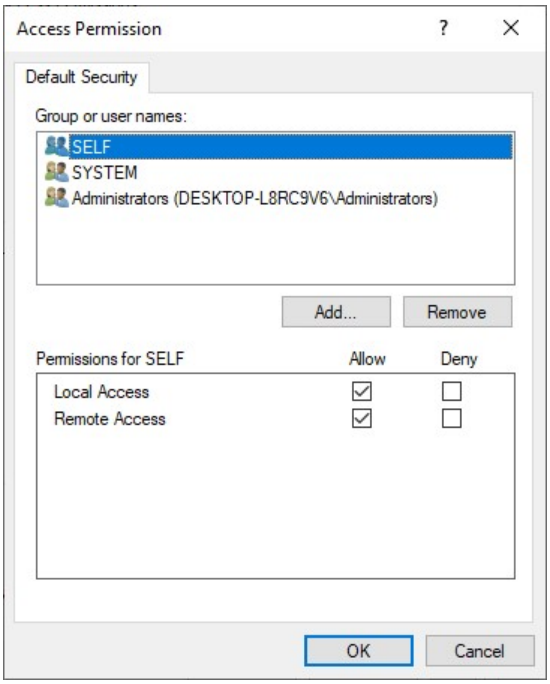

Figure C3.2-18 Default Security tab of the Access Permission dialog box

e. Click [Add].
The Select Users or Groups dialog box appears.

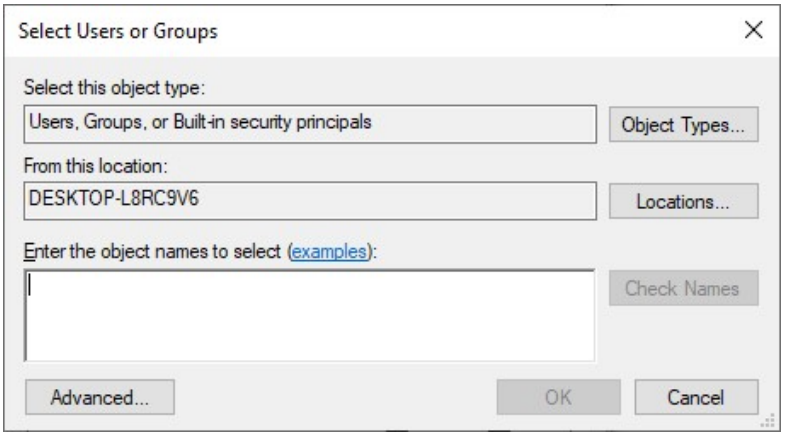

Figure C3.2-19 Select Users or Groups dialog box

f. Enter `Everyone` for the object name to select and click [OK].
The [Everyone] user is added to the Access Permission dialog box.

g. Select [Everyone], select the "Allow" check boxes for "Local Access" and "Remote Access," and click [OK].

2. Edit the default values of Launch and Activation Permissions.

a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Default] for Launch and Activation Permissions.
The Launch and Activation Permission dialog box appears.

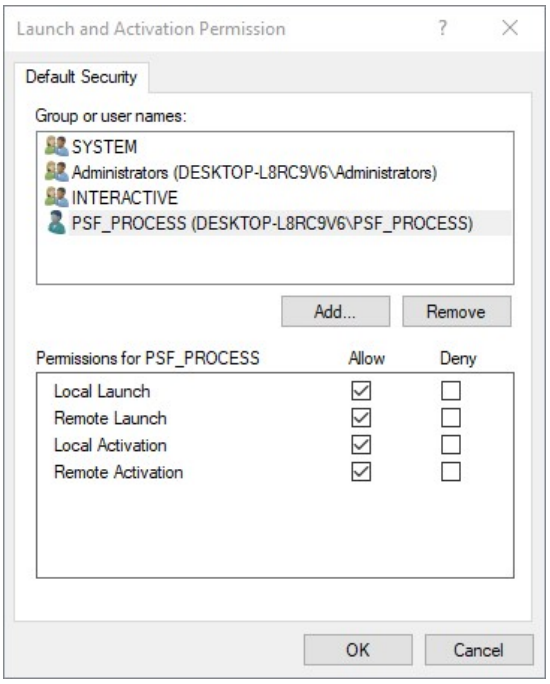

Figure C3.2-20 Default Security tab of the Launch and Activation Permission dialog box

b. Click [Add].
The Select Users or Groups dialog box appears.

c. Enter `Everyone` for the object name to select and click [OK].
The [Everyone] user is added to the Launch and Activation Permission dialog box.

d. Select [Everyone], select the "Allow" check boxes for "Local Launch," "Remote Launch," "Local Activation," and "Remote Activation," and click [OK].

3. Edit limits for Access Permissions.

   a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Limits] for Access Permissions.
   The Access Permission dialog box appears.

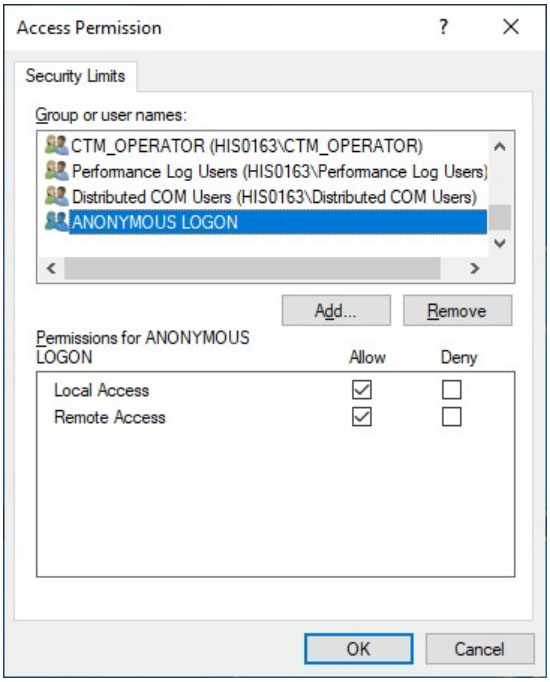

Figure C3.2-21 Security Limits tab of the Access Permission dialog box

   b. Select [ANONYMOUS LOGON] in the Group or user names list, select the "Allow" check boxes for "Local Access" and "Remote Access," and click [OK].

4. Edit limits for Launch and Activation Permissions.

   a. In the My Computer Properties dialog box, click the COM Security tab and click [Edit Limits] for Launch and Activation Permissions.
   The Launch and Activation Permission dialog box appears.

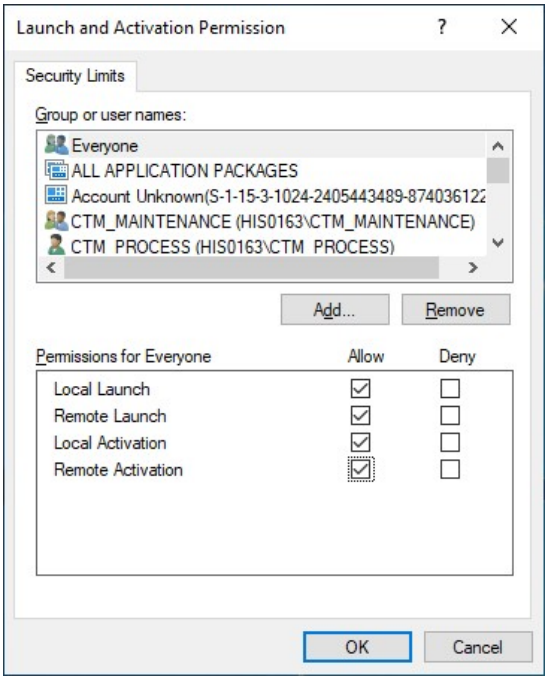

Figure C3.2-22 Security Limits tab of the Launch and Activation Permission dialog box

b. Select [Everyone] in the Group or user name list, select the "Allow" check boxes for "Local Launch," "Remote Launch," "Local Activation," and "Remote Activation," and click [OK].

5. Edit the default properties.

a. In the My Computer Properties dialog box, click the Default Properties tab and select [None] for the Authentication Level, and click [OK].

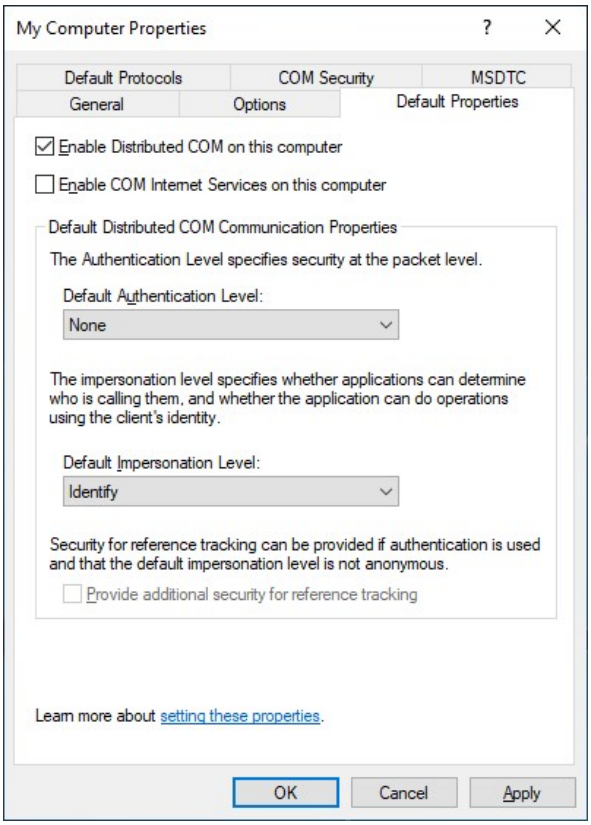

Figure C3.2-23 Default Properties tab of the My Computer Properties dialog box

Local security policy setting procedure

Set the local security policy.

1. Select [Control Panel] > [System and Security] > [Administrative Tools] > [Local Security Policy].
   The Local Security Policy window appears.

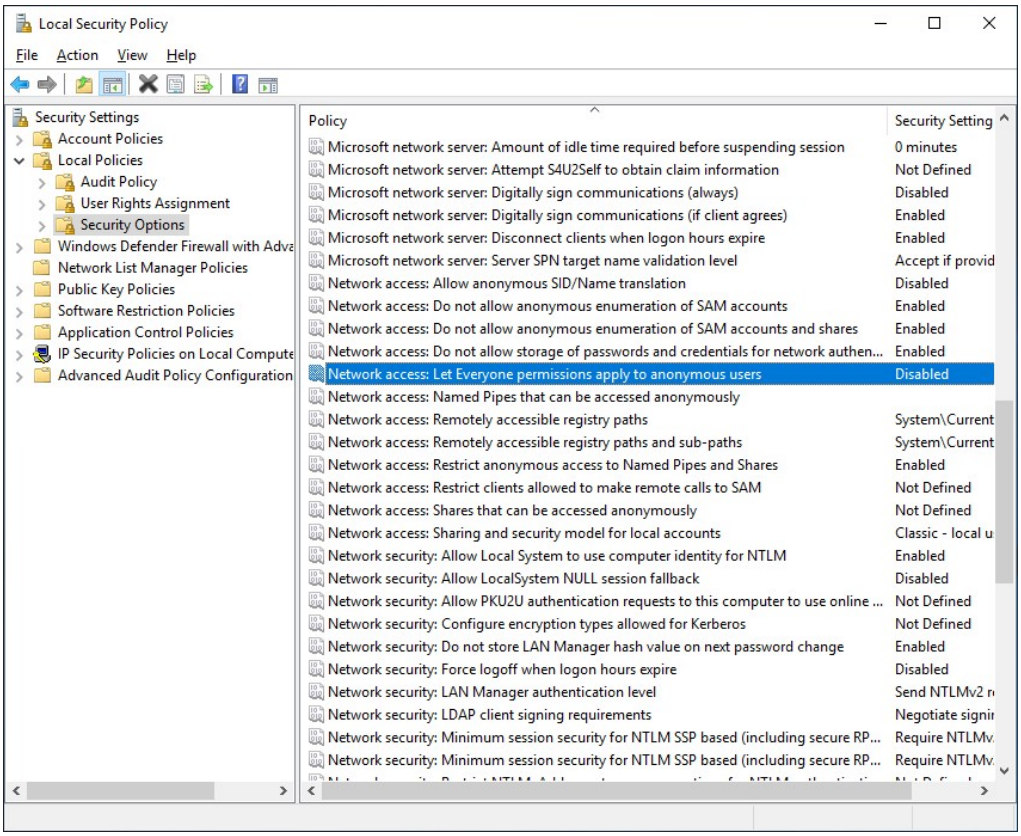

Figure C3.2-24 Local Security Policy window

2. Open [Security Settings] > [Local Policies] > [Security Options].
3. In the Policy column, double-click [Network access: Let Everyone permissions apply to anonymous users].
   The Network access dialog box appears.

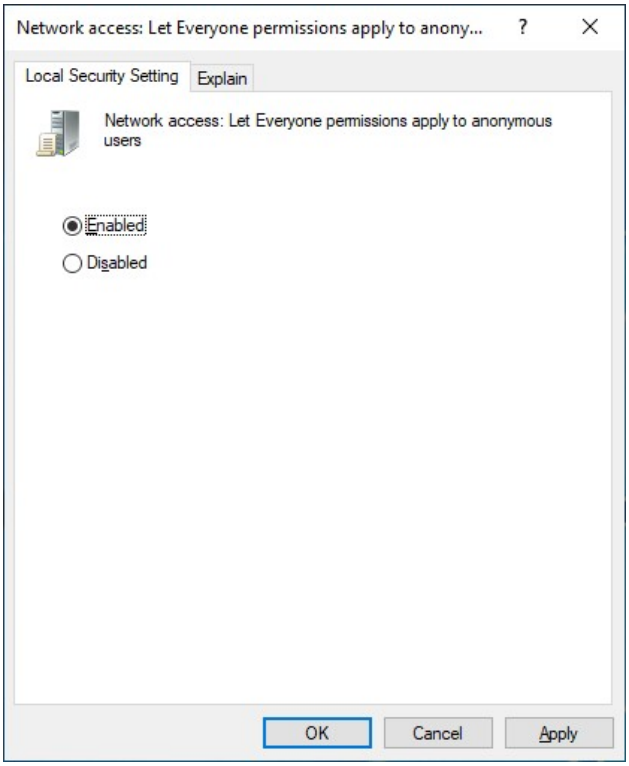

Figure C3.2-25 Network access dialog box

4. Select [Enabled] and click [OK].
   In the Security Options folder, confirm that "Enabled" is selected in the "Security Setting" field for [Network access: Let Everyone permissions apply to anonymous users].
5. Restart the computer.

D. Subsystem communication

The subsystem communication function is one of the Modbus communication functions that are provided by ProSafe-RS. This function enables a safety control station (SCS) to act as the Modbus master and communicate with subsystems.

D1. Common items regarding subsystem communication functions

The subsystem communication function enables communication, such as reading and writing subsystem data between SCSs and PLCs (Programmable Logic Controllers), or other subsystems connected to the SCS's communication module.

This section describes common subsystem communication functions that are not dependent on subsystem types.

D1.1 Overview of subsystem communication

This section describes the structure of subsystem communication functions within the SCS and gives an overview of communication between the subsystem and the SCS.

Type of subsystem communication function

The following subsystem communication function is available in an SCS: The communication module in the SCS becomes the communication master.

- MODBUS communication
- ProSafe-SLS communication

Subsystem communication modules

SCS and PLC subsystems are connected through subsystem communication modules installed in the SCS. Subsystem communication modules are classified into the following three types:

- ALR111 RS-232C serial communication module
- ALR121 RS-422/RS-485 serial communication module
- ALE111 Ethernet communication module

Structure of subsystem communication functions

The following section provides an overview of subsystem communication.

- Functional structure and data flow
- Relationship of subsystems and the application logic

Functional structure and data flow

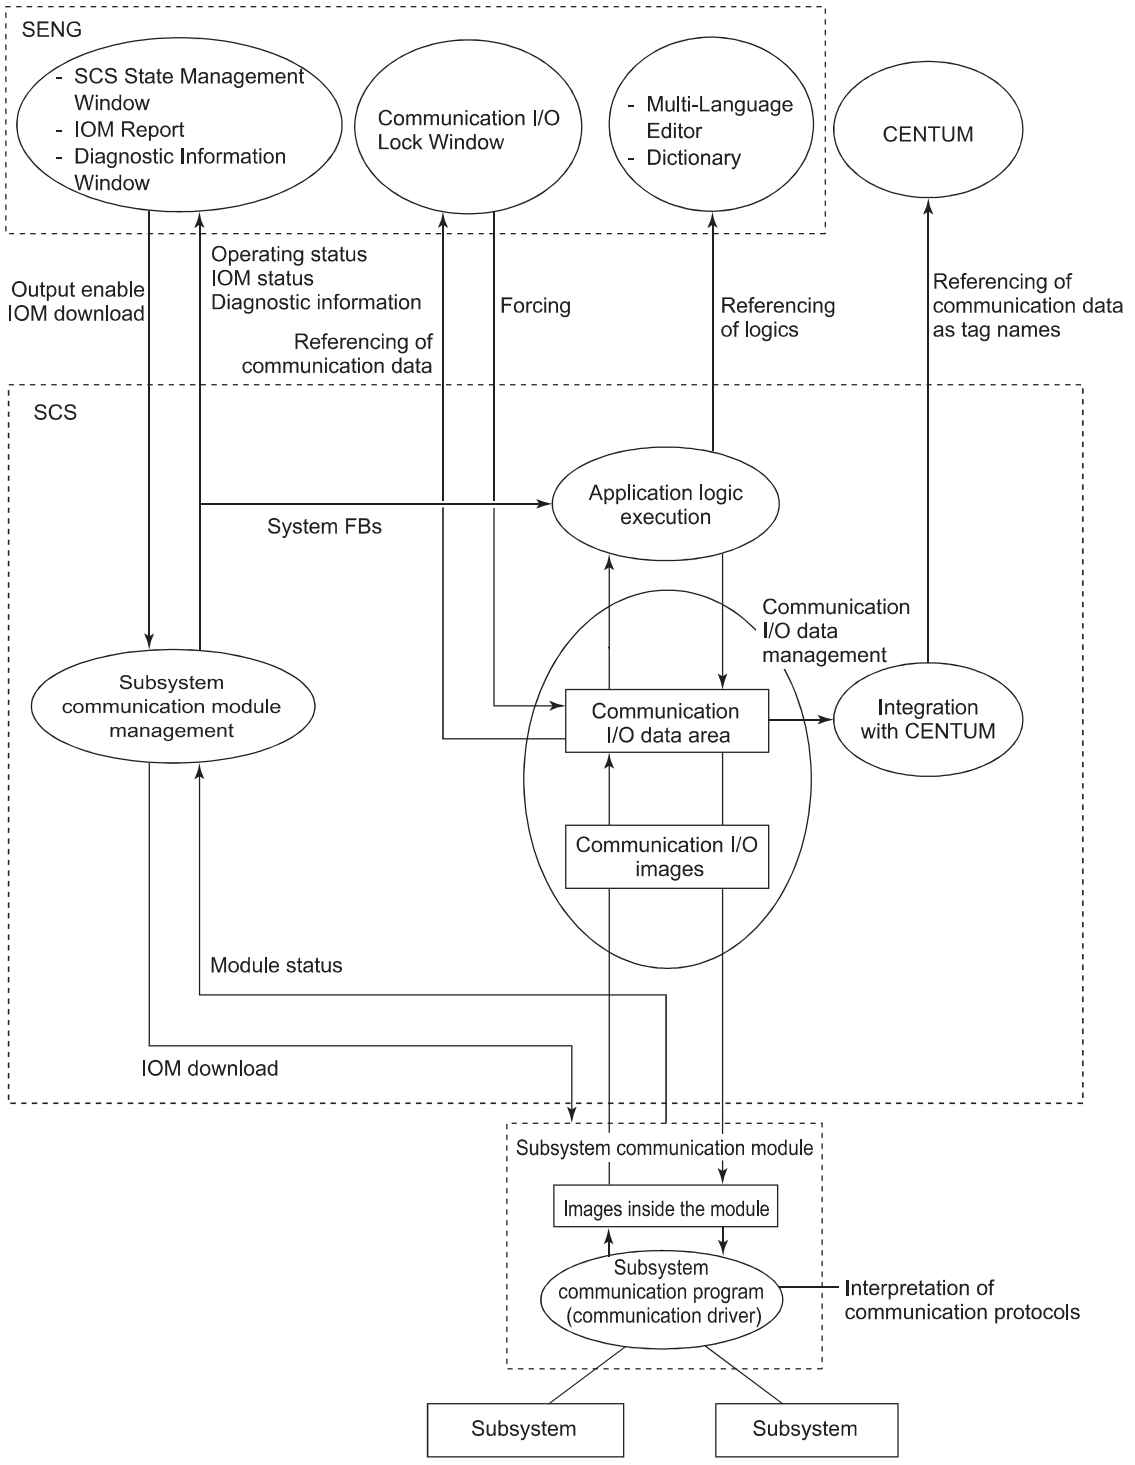

Figure D1.1-1 Functional structure and data flow

Relationship of subsystems and the application logic

- Input data from subsystems are input to the application logic via the communication I/O data management function.
- Output values calculated by the application logic are output to subsystems via the communication I/O data management function.

- The subsystem communication program interprets communication protocols (such as the Modbus protocol).
- The communication I/O data management function is a general-purpose data management function not dependent on communication protocols. The communication I/O data management function manages the communication I/O data area consisting of 1000 words in which subsystem register images are mapped.
- The subsystem communication input FBs and subsystem communication output FBs are used to access the communication I/O data management function from the application logic.

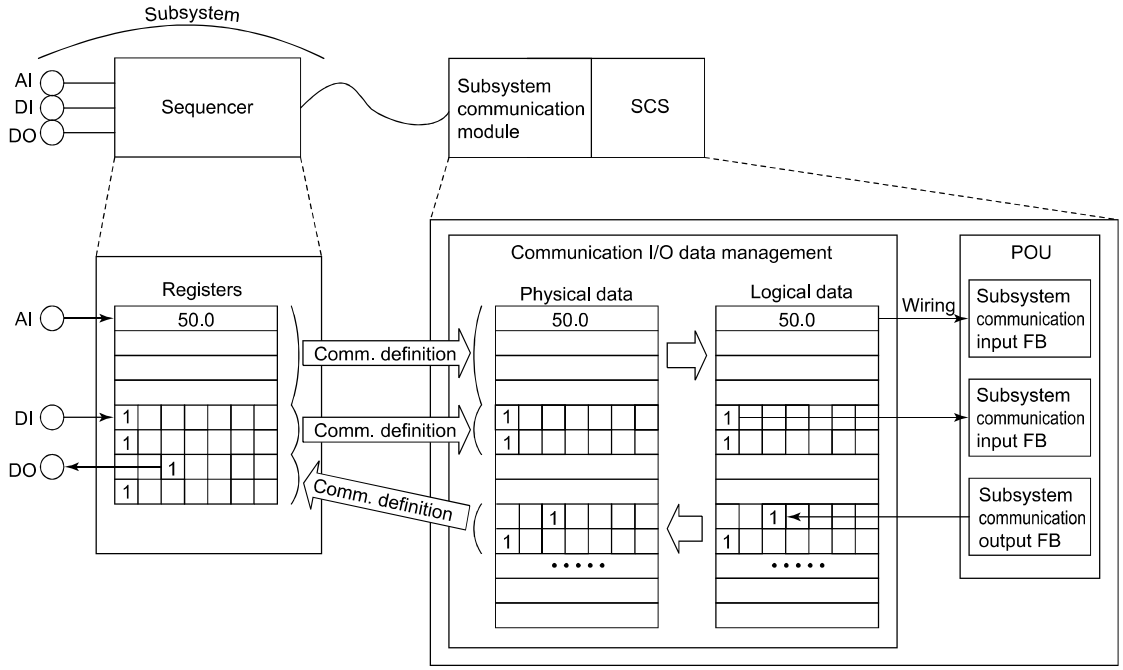

Figure D1.1-2 Relationship of communication I/Os and registers

Communication with subsystems

The subsystem communication module communicates with each subsystem in accordance with the transmission specifications and communication definitions set with subsystem communication builders to refresh the images inside the module.

The subsystem communication module interprets subsystem communication protocols and performs communication based on the protocols. Thus, the CPU only exchanges data with the subsystem communication module and does not perform any processing specific to each subsystem communication type.

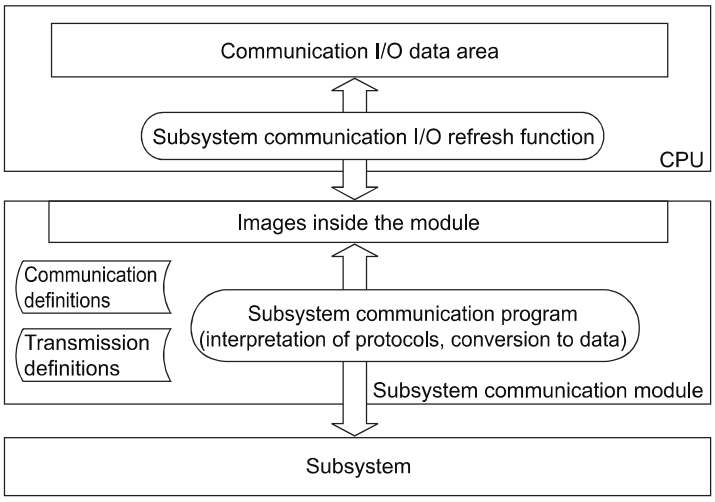

Figure D1.1-3 Communication between SCS and subsystem

Data flow and refresh time

The data refresh time varies depending on the subsystem type, amount of acquired data and transmission specifications. The following describes the flow of data not dependent on subsystem types.

Data refresh time (input through output)

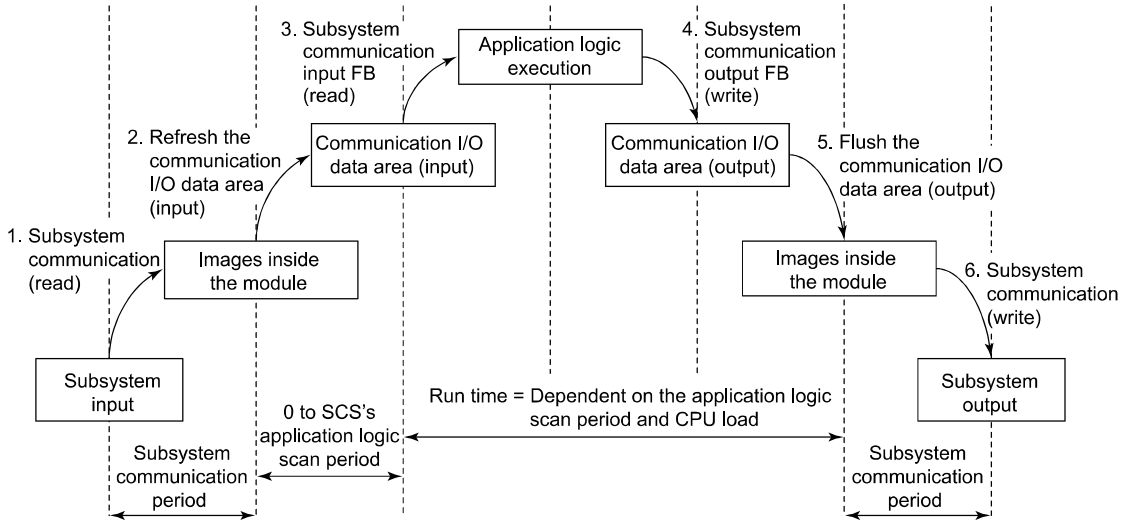

Figure D1.1-4 Data refresh time (input through output)

Data flow and timings

1. Subsystem communication (read)

   The data acquisition period varies depending on the subsystem type and transmission specifications.

2. Refresh the communication I/O data area (input)

   The data is read from the subsystem communication module to the communication I/O data area at the beginning of the SCS scan period.

3. Subsystem communication input FB (read)

   The data is read from the communication I/O data area (input) when the subsystem communication input FB is executed.

4. Subsystem communication output FB (write)

   The data is written to the communication I/O data area (output) when output from the subsystem communication output FB.

5. Flush the communication I/O data area (output)

   At the end of the SCS scan period, the communication I/O data area is flushed and the data is written to the subsystem communication module.

6. Subsystem communication (write)

   The data acquisition period of each subsystem from the subsystem communication module varies depending on the subsystem type and transmission specifications.

SEE ALSO For more information about transmission specifications, refer to:

"■ Transmission specification" on page D2-2

■ Period of subsystem communication and communication time

The following section describes the period of subsystem communication and communication time by using a serial communication module and Ethernet communication module.

● Period of serial communication

Subsystem communication is performed asynchronously with the scan period of the application logic execution function. Data is written only when written by the CPU.

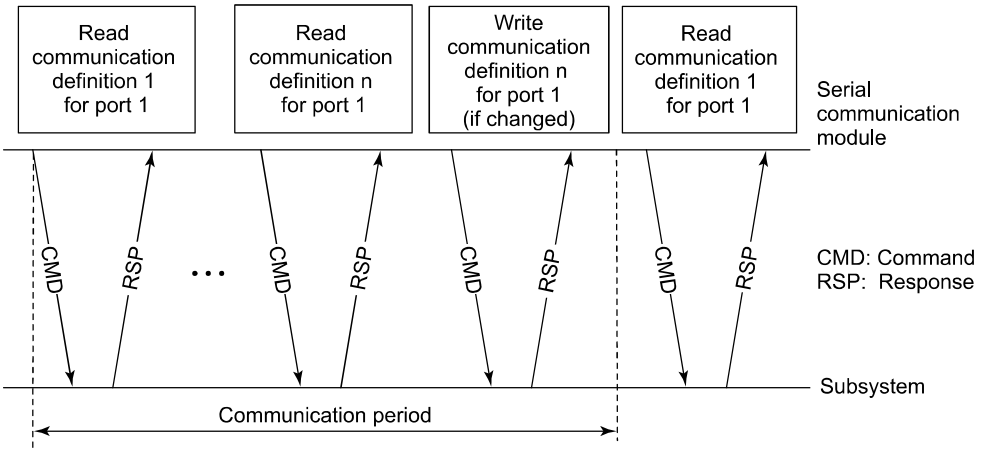

Figure D1.1-5 Subsystem communication (example numbers of communication definitions for port 1 is "n")

In serial communication, each port of the serial communication module communicates at a different period. The communication period of each port represents the sum of times required to communicate all communication definitions set for the port.

Example:

Communication definition 1: Port 1

Communication definition 2: Port 1

Communication definition 3: Port 2

Communication definition 4: Port 2

Communication period of port 1 = (Communication time for communication definition 1) + (Communication time for communication definition 2)

Communication period of port 2 = (Communication time for communication definition 3) + (Communication time for communication definition 4)

Ethernet communication period

Subsystem communication is performed asynchronously with the scan period of the SCS application logic. Data is written only when written by the CPU.

Communication between the Ethernet communication module and PLC is processed in parallel for each IP address. In other words, the request creation process is completed in the Ethernet communication module, and is performed for the PLC of a different IP address after frame transmission.

A single communication allocation definition is processed one at a time. For example, if two PLCs exist and communication allocation is set to “3” and “1” respectively, transmission is performed in the following order. However, it is assumed that communication in each PLC is performed without delay.

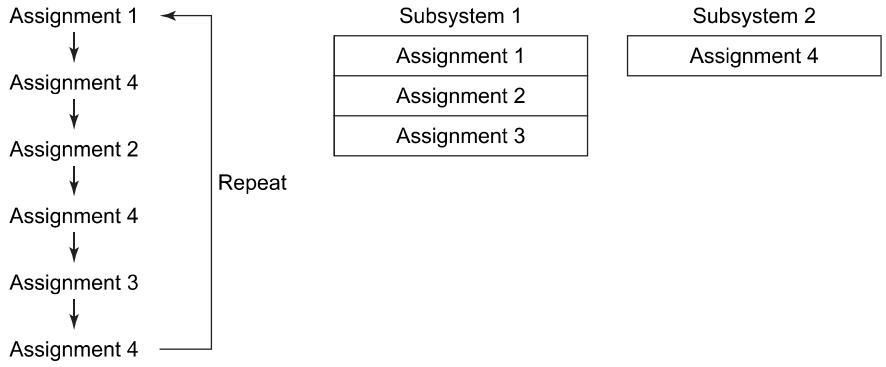

Figure D1.1-6 Communication allocation definition process

Assurance of simultaneity of communication data

In the SCS (between the subsystem communication module and the communication I/O data management function), simultaneity of data is assured in units of 32 bits.

Between the subsystem communication module and each subsystem, the unit of data in which simultaneity is assured varies, depending on the subsystem communication program and the subsystem.

SEE ALSO For more information about assurance of simultaneity of communication data for Modbus communication programs, refer to:

“■ Simultaneity of communication data” on page D2-2

Handling of subsystem data

The following table shows how subsystem data types are handled in the SCS.

Table D1.1-1 Types of subsystem data handled

Subsystem data type	Data type in SCS	Remark
Bit (DI/DO)	BOOL (bit)	With/without bit reversing
32-bit floating	REAL (32-bit floating)	With/without word reversing
16-bit signed integer	DINT (32-bit signed integer)	
16-bit unsigned integer	DINT (32-bit signed integer)	
32-bit signed integer	DINT (32-bit signed integer)	With/without word reversing
SLS event type	N/A (*1)	Without bit reversing, without word reversing

*1: SLS event type represents the ProSafe-SLS data type that is used exclusively for acquiring events. This data type is used internally by the SCS. It cannot be used in application logics.

In order to handle the subsystem communication data on SCS, the Communication I/O Builder is used for wiring the subsystem data and the SCS data according to the data types of subsystem. All the wired data are referred to as "communication data." A communication datum consists of data value and data status.

Output enable operation

- Following an initial cold start of the SCS, input communications from subsystems will start as soon as the subsystem communication module is started. Output communications to subsystems will start following the output enable operation for subsystem communication. Note, however, that output will start immediately after the subsystem communication module is started following a recovery from an error, no output enable operation is required in such a case. Readback of output will start as soon as the subsystem communication module is started.
- Output from the subsystem communication module is disabled only after an initial cold start of the SCS.
- Regardless of the status of the subsystem communication module, output enable operation for the safety output modules can be performed at any time.
- Output enable operation can be performed even when a subsystem communication error is present. In this case, output will start only for those outputs that can be communicated.

IOM download

When an IOM download is performed, the subsystem communication program is downloaded to the subsystem communication module and the communication module is restarted. No output enable operation is required.

Status monitoring from SENG or HIS

- The status of the subsystem communication module can be monitored in the status display window of the SENG or HIS.
- From a SENG, communication program names and error information can be referenced using SCS Maintenance Support Tool's IOM Report.
- The forcing status of subsystem communication data and errors in the subsystem communication module are notified as diagnostic information messages.

D1.2 Dual-redundant communication

When a serial communication module (ALR111/ALR121) or Ethernet communication module (ALE111) is used, you can have a dual-redundant configuration in the subsystem communication.

This section explains about dual-redundant communication by using ALR111, ALR121 and ALE111.

D1.2.1 Dual-redundant communication in ALR111 and ALR 121

If the ALR111 or ALR121 is used, dual-redundant communication can be implemented by connecting two serial communication modules side by side. Note, however, that dual-redundant communication cannot be implemented without readback.

ALR121 redundancy is not supported by the ProSafe-SLS communication function.

Data flow in a dual-redundant configuration of subsystem communication modules

The following figure illustrates the flow of data when the subsystem communication module has a dual-redundant configuration and readback is performed.

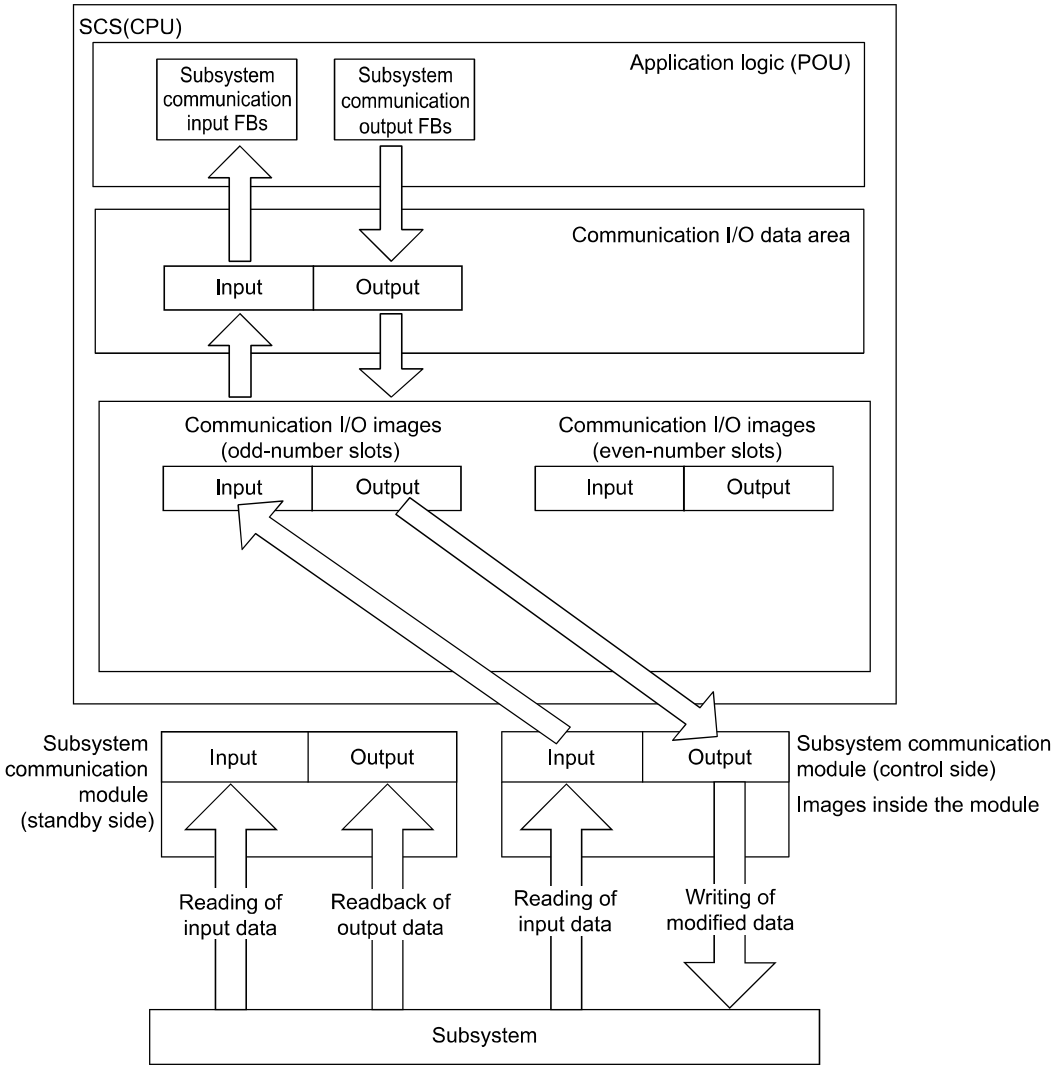

Figure D1.2.1-1 Data flow in dual-redundant configuration of subsystem communication modules

Flow of input data

The two dual-redundant subsystem communication modules both communicate with subsystems periodically and refresh the images inside the subsystem communication modules.

The SCS references the image (area for input) inside the subsystem communication module on the control side. The image (area for input) inside the module is copied to the communication I/O image in odd-number slot and set in the communication I/O data area.

Flow of output data

Data is written to subsystems only from the subsystem communication module on the control side. Details of the flow of output data are as follows:

- The CPU of the SCS refreshes only the data for the subsystem communication module on the control side.
- Both the subsystem communication modules on the control and standby sides read the data output from each subsystem (readback).
- The subsystem communication module on the control side compares the value read back from the subsystem and the write data from the CPU, and writes the output data to the subsystem only when the two values are different. If the two values are the same, the subsystem communication module on the control side reflects the value read back from the subsystem in the image (area for output) inside the module.
- The subsystem communication module on the standby side does not write data, so data is not refreshed by the CPU. The image (area for output) inside the subsystem communication module on the standby side is refreshed via readback of the output subsystem data that have been changed via writing from the subsystem communication module on the control side. This operation equalizes the output data of both the subsystem communication modules on the control and standby sides.

TIP

When you have online-change downloaded the configuration of the subsystem communication module from a single to dual-redundant configuration, the modules start the dual-redundant operation immediately after the download is complete. This does not affect the operating mode of the SCS because the output of the SCS stays enabled.

SEE ALSO

For more information about readback communication, refer to:

D2.5, “Readback communication” on page D2-20

D1.2.2 Dual-redundant communication in ALE111

In Ethernet communication module (ALE111), you can have a dual-redundant configuration in the subsystem communication by using two adjacent ALE111.

The following are two types of dual-redundant configuration in ALE111:

- Dual-redundant Ethernet communication module only
- Dual-redundant network

Dual-redundant Ethernet communication module only

The Ethernet communication module is set as dual-redundant configuration, and connected to the same network domain. Communication destination subsystem is placed on a different network domain through the same network domain or default gateway.

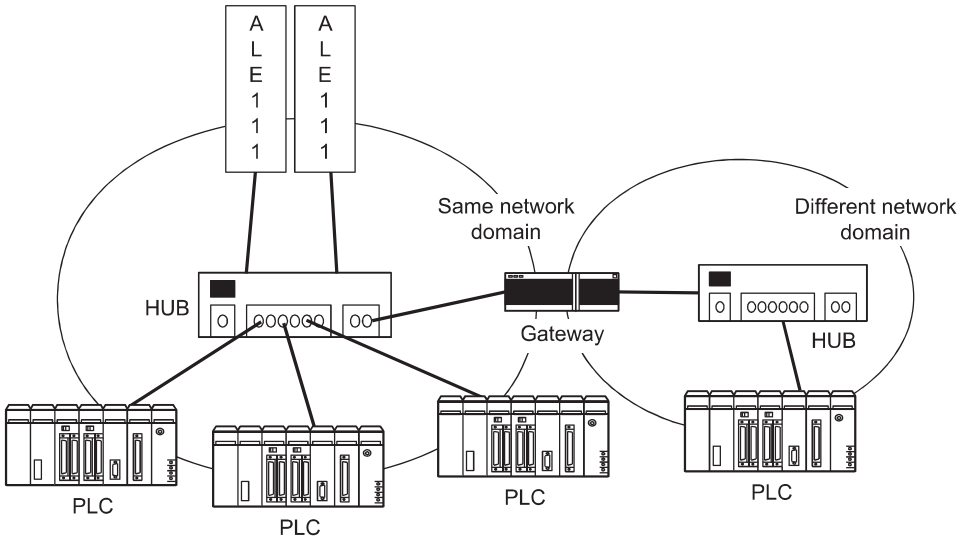

Figure D1.2.2-1 Dual-redundant Ethernet communication module-only configuration

Dual-redundant network

The subsystem communication interface as well as the Ethernet communication module are set as dual-redundant configuration. A network domain for ALE111 with odd slots is separated from another network domain for ALE111 with even slots.

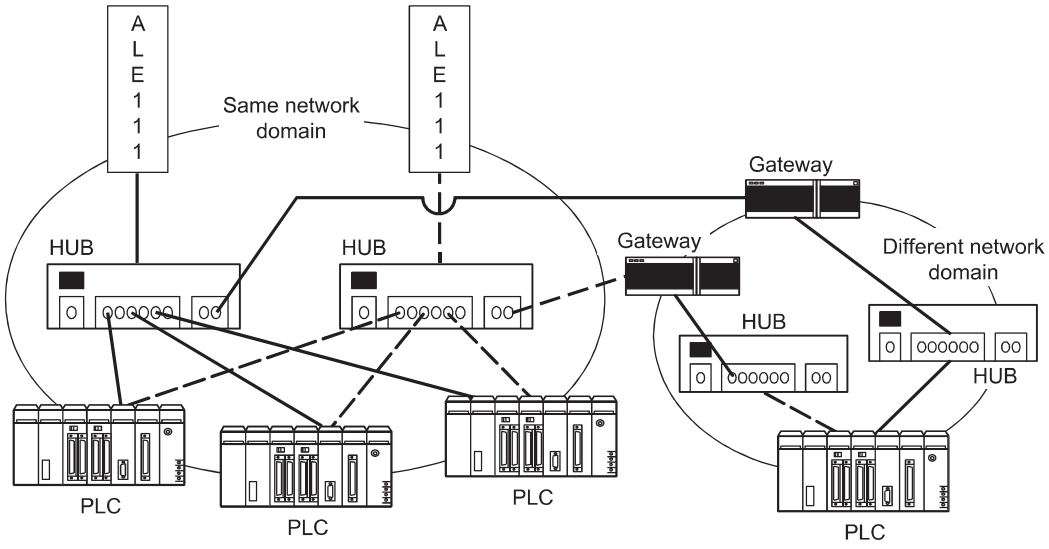

Figure D1.2.2-2 Dual-redundant network configuration

Dual-redundant switching method

Control right switch if any of the following conditions is true in dual-redundant ALE111 configuration.

- Condition 1
  Standby ALE111 is in normal state, and control ALE111 is in abnormal state
- Condition 2
  If all communication in standby ALE111 are in normal state, and any part of communication in control ALE111 is in abnormal state

In Service/Out Service system alarms will be sent if the control right in ALE111 are switched. If the switching is due to communication error, the SS-COM Error system alarm will also be sent. However, the SS-COM alarm may not be sent because the SS-COM Error alarm will not continue to be sent during a communication error in the same station number.

Limitations on dual-redundant Ethernet communication modules

This section explains the restrictions when the Ethernet communication module is set to dual-redundant configuration.

- Dual-redundant configuration during an online change is not guaranteed.
- Dual-redundancy is not supported if addresses without readback are used. To provide a dual-redundant configuration, you need to use only addresses with readback.

TIP

If an address without readback is specified in a dual-redundant configuration, the following problems will occur.

With readback, data is read from the Modbus/TCP PLC, compared with the data in the CPU of the SCS, and then the CPU data is written to the subsystem if the two data are different.

Without readback, the data in the CPU is compared with the data in the communication module, without reading data from the subsystem, and the CPU data is written to the Modbus/TCP PLC only when there is a difference between the data.

If the communication module on the control side is normal, the data in the communication module on the standby side is not updated. Therefore the data in the module may be old when the control right switches. In this case, the data in the CPU cannot be compared with the data in the communication module, and data cannot be written without readback.

In Modbus communication, whether or not readback is used is determined by an address function code that is specified in the Communication I/O Builder.

SEE ALSO

For more information about readback communication, refer to:

D2.5, “Readback communication” on page D2-20

D1.3 Error handling actions

This section describes the error handling actions after a restart of the subsystem communication module, initial cold start of the SCS, occurrence of a communication error, and so on.

Error conditions and error handling actions

The following table summarizes the conditions in which error handling actions occur, as well as the specific actions.

Table D1.3-1 Conditions in which error handling actions occur and specific actions

Condition	Impact on application logic (Subsystem communication I/O FBs)	Subsystem communication
Initial cold start of the SCS (the SCS operating mode is shifting from Waiting Mode to Running Mode)	Input data: Value from the subsystem Input status: GOOD Output status after output enable operation: GOOD	Only inputs are communicated and data is not output until the output enable operation is performed. Output starts after the completion of output enable operation (for subsystem communication) (*1)
• Communication error (subsystem communication error, communication definition error) • Faulty subsystem communication module • Restart of the subsystem communication module due to online change download • Path error between the CPU and subsystem communication module	Upon occurrence Input data: Value of "Input Processing at Fault" Input status: BAD Output status: BAD After recovery Input data: Value from the subsystem Input status: GOOD Output status: GOOD	At occurrence: communication not possible (*2) After recovery: I/O is resumed. Values are output from the application logic (*3) (*4)
Adding a new subsystem communication I/O FB (online change download) (*5)	During online change download Input data: 0 or FALSE Input status: BAD Output status: BAD After online change download Input data: Value from the subsystem Input status: GOOD Output status: GOOD	No impact. Communication continues.
Adding a subsystem communication module online (*6)	Until the module starts up Input data: 0 Input status: BAD Output status: BAD After the module started up Input data: Value from the subsystem Input/output status: Status of communication with the subsystem	Until the module starts up: Communication is not possible. After the module started up: Communication starts. In the case of outputs with readback, the output values are read back from the subsystem immediately after the recovery of subsystem communication and are output. After that, values from the application logic are output.

*1: The output enable operation using SCS Maintenance Support Tool enables both safety output and subsystem communication output. Dedicated system function blocks are provided for enabling safety output and subsystem communication output, respectively.
*2: The SCS operating mode is not affected by communication errors or subsystem communication module errors.
*3: If errors need to be latched, application logics that reference data status needs to be created.
*4: If the subsystem communication module is locked and in the case of outputs with readback, the output values are read back from the subsystem immediately after the recovery of subsystem communication and are output.
*5: Even when a subsystem communication I/O FB instance is deleted and then a new instance is recreated, it is recognized as addition of a new subsystem communication I/O FB.
*6: The operating mode of the SCS is not affected because the output of the SCS stays enabled.

Restart of the subsystem communication module when subsystem communication data is locked

If you perform the following types of operations that require a subsystem communication module restart, it is recommended that you lock the subsystem communication data first.

- Before performing an online change download requiring a restart of the subsystem communication module
- Before replacing the failed subsystem communication module. Perform an IOM download after the replacement.

The following table lists the values and statuses of locked communication I/O data before and after the recovery of the subsystem communication module to a normal state.

Table D1.3-2 Statuses of locked communication I/O data

		Before recovery	After recovery
Communication input	Logical data	Data value: Value immediately before locking Data status: Value immediately before locking	Data value: Value immediately before locking Data status: Value immediately before locking
	Physical data	Data value: Value immediately before occurrence of an error Data status: BAD	Data value: Value from the subsystem Data status: GOOD
Communication output	Logical data	Data value: Value from the application logic Data status: Value immediately before locking	Data value: Value from the application logic Data status: Value immediately before locking
	Physical data	Data value: Value immediately before locking Data status: BAD	Data value: Output value from the subsystem immediately after recovery of communication Data status: GOOD
Output to subsystem		Communication is not possible.	Input: Resumed. Output: Output value from the subsystem immediately after recovery of communication

Notification of error conditions

- Error conditions such as errors in the subsystem communication module and those relating to subsystem communication are notified to the application logic, SENG and HIS.
- To handle error conditions in the application logic, use system FBs for subsystem communication.
- With the use of system FBs for subsystem communication, an application logic that detects unlocked subsystem communication data and overflow of lock limit can be created. If any subsystem communication data remains unlocked or the number of locks exceeds the maximum value, a diagnostic information message will be notified to the SENG or HIS.

Diagnostic information messages

If the subsystem communication module status or communication status with any subsystem has changed, a diagnostic information message is generated to notify the change. Diagnostic information messages are generated in the following conditions:

- The subsystem communication module has started or shut down.
- A subsystem communication error has occurred or has been reset.

- A subsystem communication output enable operation has been performed.
- When a subsystem communication module is added or deleted online

Conversion of real-type input data

When the communication I/O data is real-type input data and the value is Not-A-Number (NaN), infinity, or subnormal, the communication I/O data I/O function of SCS converts the physical data to logical data as shown in the following figure and pass it to the application Logic.

Table D1.3-3 Data conversion for real-type input data with NaN, infinity, or subnormal values

Physical data	Logical data
Value: NaN Data status: GOOD	Value: pre-defined input value at fault Data status: BAD
Value: NaN Data status: BAD	
Value: infinity Data status: GOOD	Value: pre-defined input value at fault Data status: BAD
Value: infinity Data status: BAD	
Value: subnormal Data status: GOOD	Value: 0.0 Data status: GOOD
Value: subnormal Data status: BAD	Value: pre-defined input value at fault Data status: BAD

Display of NaN, infinity, or subnormal values

When the value of physical data of communication I/O data is NaN, infinity, or subnormal, the value is displayed in the Communication I/O Lock window as shown in the following table.

Table D1.3-4 Display format for physical data with a NaN, infinity, or subnormal value

Display format	NaN			Positive infinity	Negative infinity	Subnormal
Displayed with 5 decimal places	1.#QNAN	-1.#QNAN	-1.#IND0	1.#INF0	-1.#INF0	0.00000

D1.4 Setting items relating to subsystem communication

The following describes the setting items relating to subsystem communication. Subsystem communication builders can be used to set items relating to communication modules and those relating to communication I/O data. This section mainly describes for the case when performing RS original engineering.

- Settings relating to communication module
  To perform subsystem communication, define the serial communication module (ALR111/ ALR121) or Ethernet communication module (ALE111) and set required I/O parameters. When performing I/O list engineering, you can use the IOM Definition Editor. When performing RS original engineering, you can use the I/O Wiring View and I/O Parameter Builder.
- Settings relating to communication I/O data
  You need to allocate the communication I/O data, and assign element numbers and subsystem communication I/O FB. When performing I/O list engineering, you can use Safety Communication I/O Editor. When performing RS original engineering, you can use Communication I/O Builder.

TIP

The setting item names displayed may differ between I/O list engineering and RS original engineering, but the settings are the same.

SEE ALSO

For more information about engineering of subsystem communication modules using Safety Communication I/O Editor, refer to:

D1.5, “Engineering for subsystem communication modules” on page D1-37

For more information about I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about RS original engineering, refer to:

Appendix 2., “RS original engineering” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Builders for subsystem communication

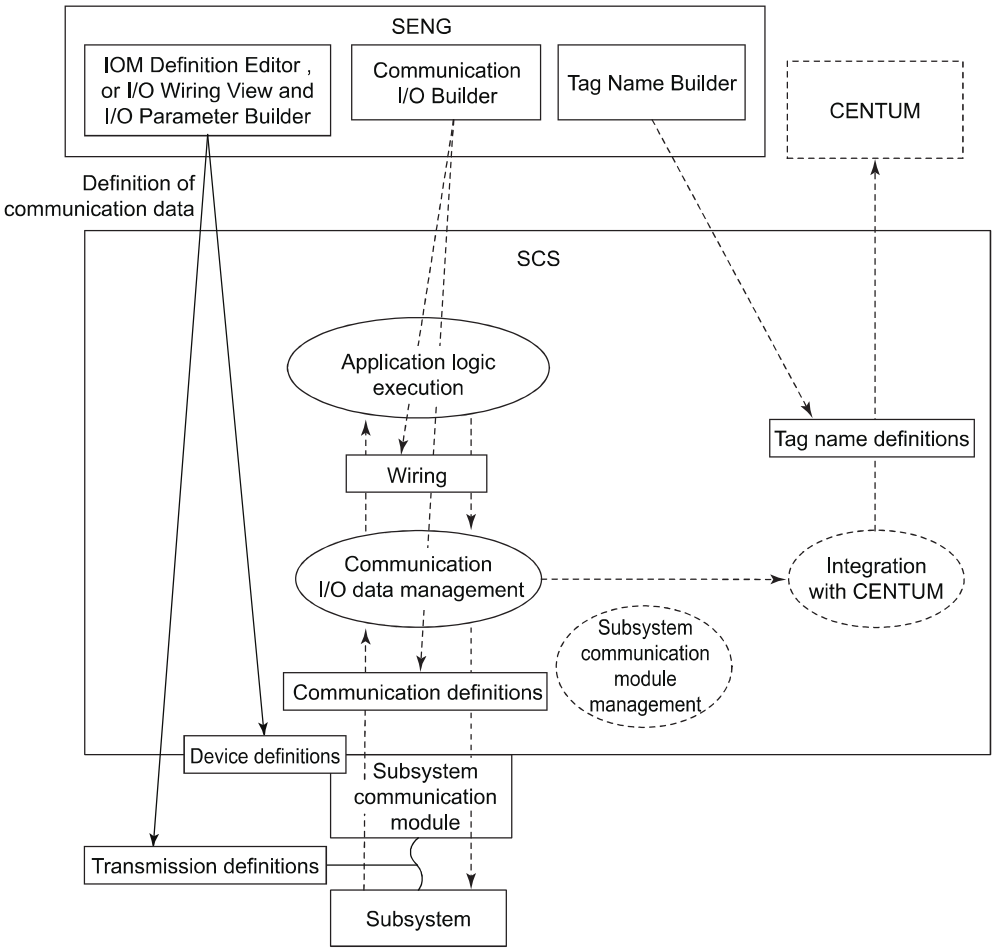

Figure D1.4-1 Subsystem communication builders

Subsystem communication settings

- Device definitions provide settings relating to the mounting position and redundancy of the subsystem communication module.
- Transmission definitions provide settings relating to the transmission specifications of the subsystem communication module. The setting items vary depending on the type of subsystem communication module.
- Communication definitions provide settings relating to data accesses to/from subsystems. The setting items vary depending on the communication protocol.
- Wirings provide settings for assigning the communication I/O data area to subsystem communication I/O FBs.

Settings related to integration with CENTUM

- Tag name definitions provide settings for assigning tag names to subsystem communication I/O FBs.

Engineering procedure using related builders

The I/O Wiring View, I/O Parameter Builder, Communication I/O Builder, and Dictionary View are used to create communication definitions. The procedure and builders used in each step are as follows:

1. Define subsystem communication I/O FBs by using the Dictionary View.
2. Define a subsystem communication module by using the I/O Wiring View.
   Add a subsystem communication module, and set its mounting position (node number, slot number) and specify whether to use a dual-redundant or single configuration.
3. Set parameters for the subsystem communication module by using the I/O Parameter Builder.
4. Define communication I/O assignments in the Comm. I/O Definition tab of the Communication I/O Builder. Assign subsystem communication data to element numbers. This assigns the subsystem communication data to the communication I/O data area.
5. Associate the element numbers and subsystem communication I/O FBs in the Comm. I/O Wiring tab of the Communication I/O Builder.
   Associate (wire) the subsystem communication I/O FBs defined in step 1 with the element numbers defined in step 4. Associate one subsystem communication I/O FB with one element number. This links the subsystem communication data assigned to the communication I/O data area with the subsystem communication I/O FBs.

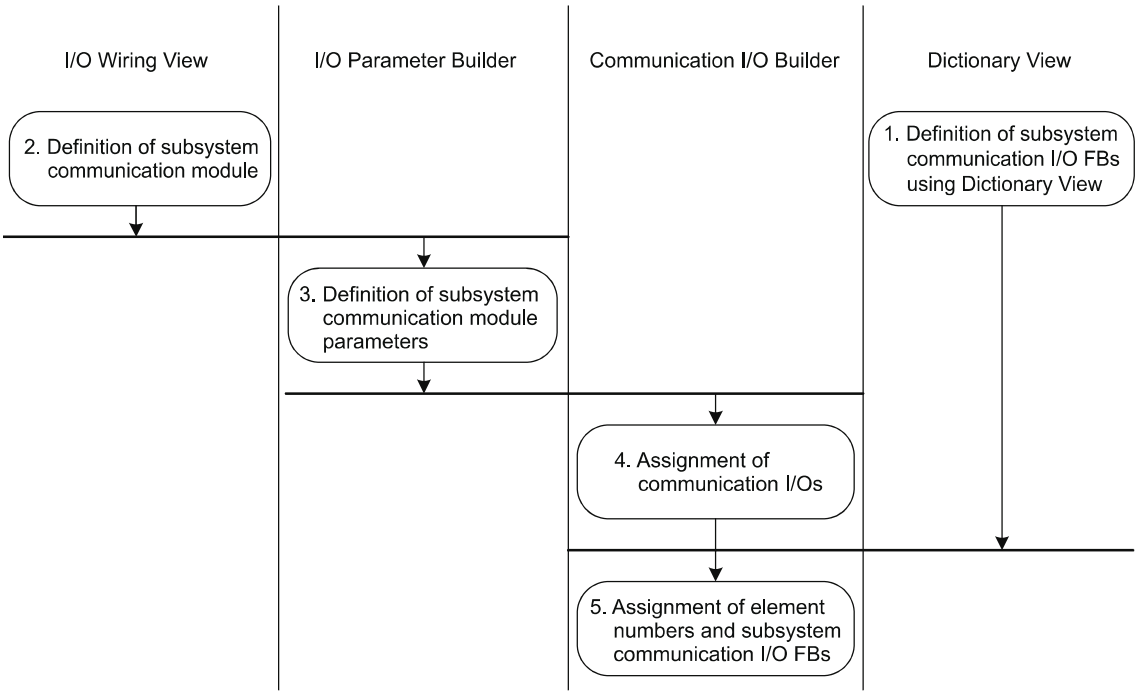

Figure D1.4-2 Engineering procedure using related builders

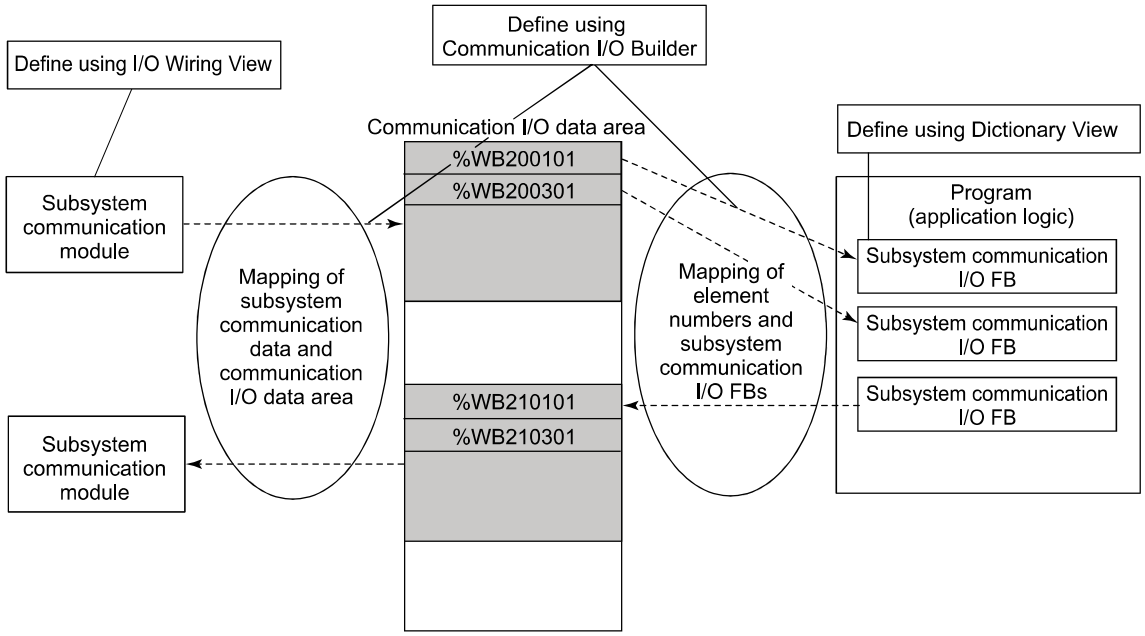

Figure D1.4-3 Wiring of subsystem communication I/O FBs and element numbers

The types of subsystem communication I/O FBs vary depending on the type of communication I/O data to be assigned.

Table D1.4-1 Types of subsystem communication I/O FBs and types of data that can be wired

Data type	Type of wirable subsystem communication I/O FBs
Analog input (16-bit signed integer)	SCI_I
Analog input (32-bit signed integer) (*1)	
Analog input (16-bit unsigned integer)	
Analog input (32-bit floating) (*1)	SCI_R
Analog output (16-bit signed integer)	SCO_I
Analog output (32-bit signed integer) (*1)	
Analog output (16-bit unsigned integer)	
Analog output (32-bit floating) (*1)	SCO_R
Discrete input	SCI_B
Discrete output	SCO_B

*1: This data type cannot be used in communication with ProSafe-SLS.

D1.4.1 Settings using the I/O Parameter Builder

When performing RS original engineering, you can use the I/O Parameter Builder to set the parameters in the subsystem communication module. The parameters to specify differ depending on the type of the communication module.

When performing I/O list engineering, the builder becomes display-only.

Serial communication module settings for subsystem communication

Serial communication module settings for subsystem communication are specified in the Module tab where common communication module parameters are set, and in the Port tabs where port parameters are set.

The Port tabs include the Port 1 and Port 2 tabs. Together with the Module tab, thus, a total of three tabs are available.

SEE ALSO

For more information about recommended settings and items for consideration when using the Modbus communication program with the serial communication module, refer to:

D2.4.2, “Items set in the I/O Parameter Builder” on page D2-16

Module tab

The following items are set in the Module tab:

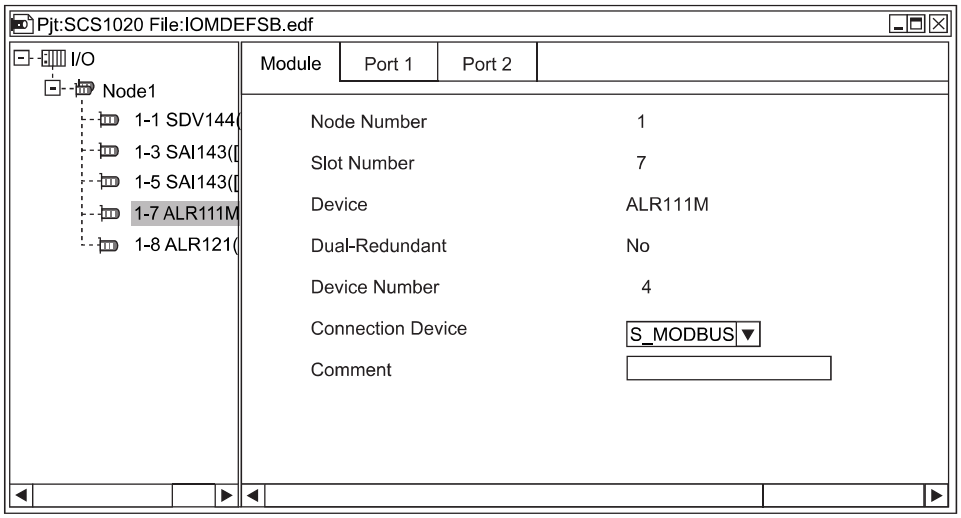

Figure D1.4.1-1 Module tab (serial communication module for subsystem communication)

Node Number

The node number corresponding to the mounting position of the module is displayed. The node number is defined in the I/O Wiring View of SCS Manager.

- The "Node Number" field is read only.

Slot Number

The slot number corresponding to the mounting position of the module is displayed. The slot number is defined in the I/O Wiring View of SCS Manager.

- The "Slot Number" field is read only.

Device

The type of module is displayed. The device (module type) is defined in the I/O Wiring View of SCS Manager.

- The "Device" field is read only.

Dual-Redundant

Whether the module is used in a single or dual-redundant configuration is displayed. The dual-redundant specification is defined in the I/O Wiring View of SCS Manager.

- The "Dual-Redundant" field is read only.

Device Number

The device number assigned to the module. The device number is defined in the I/O Wiring View of SCS Manager.

- The "Device Number" field is read only.

Connection Device

Set the type of connection device (subsystem). This field is displayed only when the module type is a subsystem communication module.
Select the subsystem communication program to be used.

Comment

A comment regarding the module. A desired comment can be entered using up to 24 single-byte characters or 12 double-byte characters.

Port 1 and Port 2 tabs

The setting items in the Port 1 and Port 2 tabs change in accordance with the module type and the "Connection Device" setting in the Module tab. The setting items are the same between the Port 1 and Port 2 tabs.

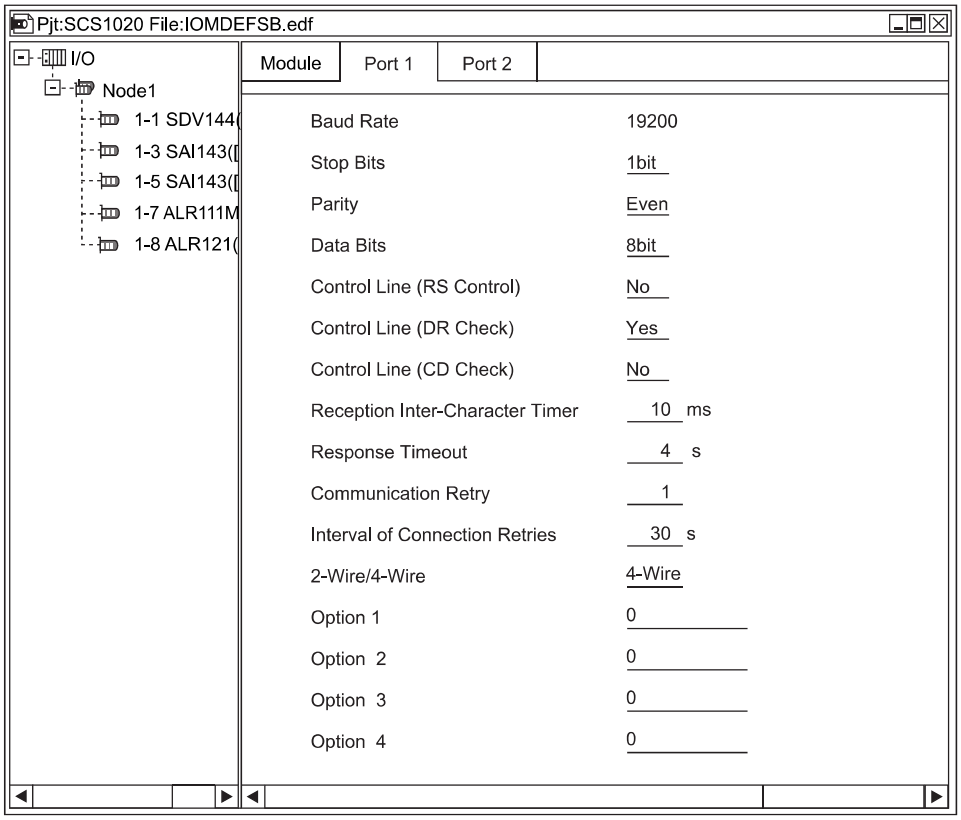

Figure D1.4.1-2 Port 1 tab (example where S_MODBUS is set as Connection Device)

Table D1.4.1-1 Setting items available in Port 1 and Port 2 tabs

Title		Description	Remark
Baud Rate		Specify the baud rate.	-
Stop Bits		Specify the stop bits.	-
Parity		Specify the type of parity.	-
Data Bits		Specify the data bit length of subsystem data to be transmitted.	-
Control Line	RS Control	Specify whether or not to use RS control when sending data from the ALR111M.	Valid only when the ALR111M is used.
	DR Check	Specify whether or not to use DR signal line check when sending data from the ALR111M.	Valid only when the ALR111M is used.
	CD Check	Specify whether or not to use CD signal line check when sending data from the ALR111M.	Valid only when the ALR111M is used.
Reception Inter-Character Timer		Specify the period to monitor inter-character time when data is received by the ALR111M/ALR121M.	-
Response Timeout		Set the timeout period to wait for subsystem response.	-
Communication Retry		Set the number of retries to be attempted after a communication error occurs.	-
Interval of Connection Retries		Set the interval of communication with a station that generated a communication error to check for recovery of communication (recovery communication).	-

Continues on the next page

Table D1.4.1-1 Setting items available in Port 1 and Port 2 tabs (Table continued)

Title	Description	Remark
2-Wire/4-Wire	Specify the 2-wire or 4-wire connection method.	Valid only when the ALR121M is used.
Options 1 to 4	Not used	-

Baud Rate

Specify the baud rate of communication. Select from 1200, 2400, 4800, 9600, 19200 and 38400 bps. The default is 19200 bps.

Stop Bits

Specify the stop bits of communication. Select 1 bit or 2 bits. The default is 1 bit.

Parity

Specify the parity. Select None, Odd or Even. The default is Even.

Data Bits

Specify the data bit length of subsystem data to be transmitted. Select 7 bits or 8 bits. The default is 8 bits.

RS Control

Specify whether or not to use RS control when sending data from the ALR111M. This setting is valid only when the ALR111M is used. The default is No (without RS control).

- No (without RS control)
  The RS signal line is always turned ON regardless of whether or not data is sent from the ALR111M.
- Yes (with RS control)
  The RS signal line is turned ON when data is sent from the ALR111M, and turned OFF after the sending is completed.

DR Check

Specify whether or not to use DR signal line check when sending data from the ALR111M. This setting is valid only when the ALR111M is used. The default is Yes (with DR check).

- No (without DR check)
  Text data is sent from the ALR111M regardless of the DR status.
- Yes (with DR check)
  Text data is sent from the ALR111M only when the DR is ON. If the DR signal line does not turn ON after elapse of the transmission enable monitoring time, a "Line Not Ready (A393)" error will occur.

The DR signal is normally connected to the ER (Data Terminal Ready) signal line of the subsystem and used to determine if the subsystem can receive data (normal operation). If the signal line of the subsystem cannot be used, set No (without DR check) in this field or change the wiring so that the DR signal line turns ON (*1) .

*1: For example, the RS signal line of the applicable module can be looped back to the DR signal line.

CD Check

Specify whether or not to use a CD signal line check when sending data from the ALR111M. The default is No (without CD check).

- No (without CD check)
  Text data is sent from the ALR111M regardless of the CD status.

- Yes (with CD check)
  Text data is sent from the ALR111M only when the CD is OFF. If the CD signal line does not turn OFF after elapse of the transmission monitoring time, a "Communication line busy (A392)" error will occur.

Reception Inter-Character Timer

The reception inter-character timer (reception inter-character timeout setting) is a function for monitoring the time between adjacent characters received (interval after one character is received until the next character is received) by the ALR111M/ALR121M. In the Modbus communication program, the receive operation is considered complete if no characters are received within the set time.

If communication is performed via a modem or other device that provides data buffering function, this value needs to be set in consideration of the communication delay (inter-character delay) caused by the buffering at the modem. Note, however, that increasing the reception inter-character time will affect the RS communication time, since completion of reception is determined based on elapse of this time.

Default: 10 ms

Setting range: 0 to 99999 ms

Response Timeout

Set the timeout period to wait for subsystem response. The unit is second.

Default: 4 sec

Setting range: 0 to 99 sec

Communication Retry

Set the number of retries to be attempted after a communication error occurs.

Default: 1 time

Setting range: 0 to 99 times

Interval of Connection Retries

Set the interval of communication with a station that generated a communication error to check for recovery of communication (recovery communication). The unit is second.

Default: 30 sec

Setting range: 1 to 999 sec

2-Wire/4-Wire

Specify the 2-wire or 4-wire connection method used by the ALR121M. This setting is valid only when the ALR121M is used.

Option 1 to 4

Specify the different communication parameter options for each subsystem communication program.

Ethernet communication module settings for subsystem communication

For an Ethernet communication module for subsystem communication, you can specify the parameters in the Module tab.

SEE ALSO For more information about recommended settings and items for consideration when using the Modbus communication program with the Ethernet communication module, refer to:

D3.3.2, “Settings in the I/O Parameter Builder” on page D3-10

D1.4.2 Settings using the Communication I/O Builder

The Communication I/O Builder is used to define communication I/O data assignments and wire communication I/O variables.

When performing I/O list engineering, the builder becomes display-only.

SEE ALSO

For more information about recommended settings and items for consideration when using the Modbus communication program with the serial communication module, refer to:

D2.4.3, “Items set in the Communication I/O Builder” on page D2-17

For more information about recommended settings and items for consideration when using the Modbus communication program with the Ethernet communication module, refer to:

D3.3.3, “Settings in the Communication I/O Builder” on page D3-13

Communication I/O settings

The Communication I/O Builder is used to perform the following tasks:

- Assign subsystem communication data to the communication I/O data area (%WW)
- Define communication details in the communication I/O data area in accordance with the subsystems
- Wire %WB elements and communication I/O variables

The structure of the Communication I/O Builder window is as follows:

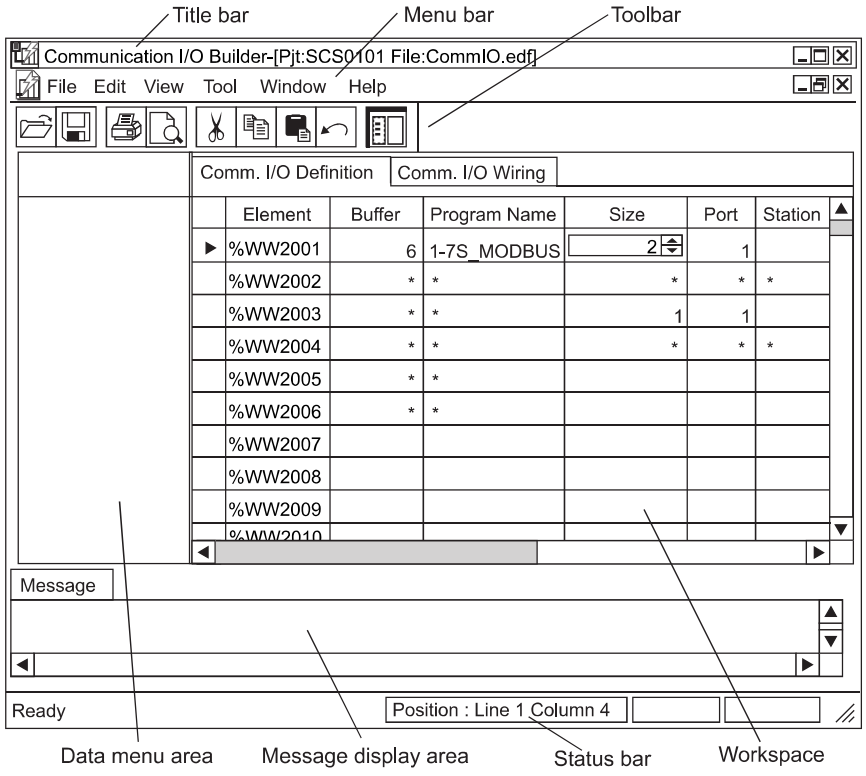

Figure D1.4.2-1 Structure of Communication I/O Builder window

Comm. I/O Definition tab

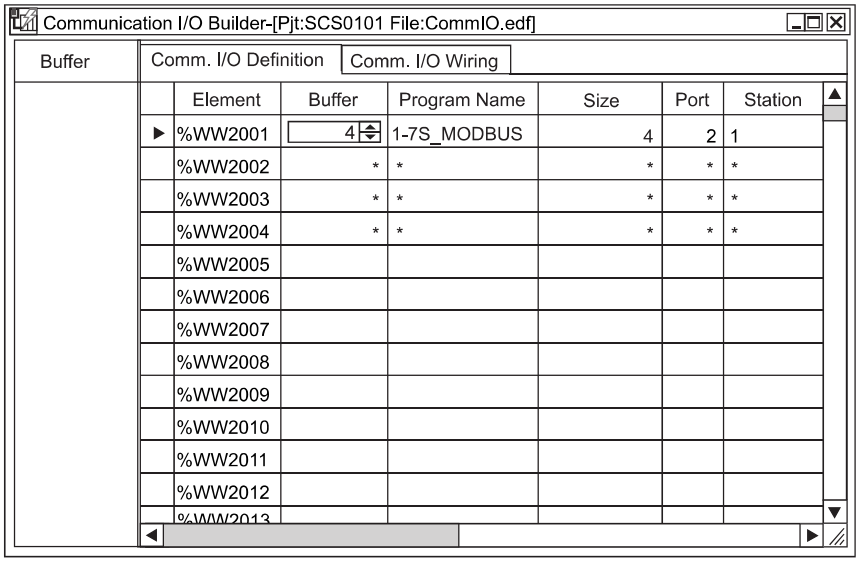

Figure D1.4.2-2 Comm. I/O Definition tab

The items set in the Comm. I/O Definition tab are as follows:

- Element: Read only
- Buffer
- Program Name
- Size
- Port
- IP Address
- 2nd IP Address
- Station
- Device Address
- Data Type
- Reverse
- Input Processing at Fault
- Input Value at Fault

Element

The buffer address within the communication I/O data area is displayed.

Display format: %WWnnnn

%WW: Fixed

nnnn: 2001 to 3000

Buffer

You need to specify the size of the communication I/O data area to be used by the subsystem communication program, in units of words (16 bits). This can only be entered when the "Element number" row is an odd number.

- Input unit: 2 (even number)
- Input range: 2 to 1000
- Size limitation: The total size shall not exceed 1000.

After a size has been specified to allocate the buffer, moving to the next setting item will display asterisks (*) in the subsequent "Buffer" and "Program Name" fields corresponding to the buffer size that has been allocated, where there is no error in the defined items. These asterisks indicate that the applicable communication I/O data area has been allocated. The "Buffer" and "Program Name" fields showing asterisks do not accept new settings. Deleting a "Program Name" for which a buffer is allocated will not delete the asterisks in the corresponding "Program Name" field.

If a "Buffer" is deleted, the items defined in the allocated buffer area (Program Name, Size, Port, IP address, 2nd IP address, Station, Device Address, Data Type, Reverse, Input Processing at Fault, Input Value at Fault) as well as asterisks will be deleted, and these fields can accept new settings.

If a "Buffer" is changed, the asterisks will also be changed. The "Buffer" field cannot be changed to a value smaller than the value in the "Size" field. Moreover, the designated value of Buffer should not conflict with the reserved area. If the error value is entered, it would be cancelled so as to revert to the previous value.

Example:

When changing the buffer for %WW2001 to "4"

Table D1.4.2-1 Example of definitions before change

Element	Buffer	Program Name	Size	• • •
%WW2001	2 (*1)	1-3S_MODBUS		
%WW2002	*	*		
%WW2003	4	1-5S_MODBUS		
%WW2004	*	*		
%WW2005	*	*		
%WW2006	*	*		

*1: An attempt to change "2" to "4" will generate an error, since specifying "4" overlaps with the area already allocated for %WW2003.

Program name

Specify the program name by using a combination of the node number and slot number for the defined subsystem communication module, and a fixed character string. The program name can be entered using up to 12 single-byte alphanumeric characters and symbols (+, -, _).
The "Program Name" field cannot be selected if the corresponding "Buffer" field is not specified or no module is defined.

In the case of a dual-redundant module configuration, specify the odd slot number.

Program Name : n-s Fixed character string

- n: Node number
- s: Slot number
- Fixed character string:
  Enter the character string determined for the subsystem ("Connection Device" specified with the I/O parameter).

If the program name is changed, a confirmation dialog box appears with a message asking if you want to delete the communication data and wirings. The following shows the content of communication data.

- Size
- Port
- Station number
- Device Address
- Data type
- Comment
- Reverse

Clicking [OK] deletes the communication data and wirings.

Clicking [Cancel] restores the original program name without deleting the communication data and wirings.

Size

You can set the size (data length) from the beginning address of the area allocated in the "Buffer are". This can only be entered when the "Element number" row is an odd number.

- Input range: 1 to 1000

If an odd number is specified as the size, the odd number will be displayed, but the actual size to be allocated will correspond to an even number being the sum of the specified odd number and 1.

If the data type is SLSEVENT, set the size to 24.

An error will occur in the following situations:

- The specified size exceeds the range allocated in the "Buffer" field.
- The total sum of sizes assigned to all discrete inputs/outputs, when the "Data Type" is discrete input or output, exceeded 256 words.
- An odd value is specified when the "Data Type" is 32-bit analog input or output.
- An attempt is made to change the assigned size to a value other than 24 when the "Data Type" is SLSEVENT.

After specifying a size and moving to the next setting item, asterisks (*) is displayed in the subsequent "Size," "Port," "IP Address," "2nd IP address," "Station," "Device Address," "Data Type" and "Reverse" fields corresponding to the specified size if there is no error in the defined items. These asterisks indicate that data of the specified size has been assigned. The fields with asterisks do not accept new settings. In this case, even if you deleted "Port," "IP Address," "2nd IP Address," "Station," "Device Address," "Data Type" or "Reverse" fields, asterisks cannot be deleted.

If a "Size" is deleted, the items defined in the data of the assigned size (Port, IP Address, 2nd IP Address, Station, Device Address, Data Type, Reverse, Input Processing at Fault, Input Value at Fault) as well as asterisks will be deleted, and these fields can accept new settings.

If a "Size" is changed, the asterisks will also be changed. If the "Size" is changed to a smaller value, the items that have been set in the data corresponding to the size decremented will be deleted.

Table D1.4.2-2 Example of completed item settings

Element	Buffer	Program Name	Size	Port	IP Address	2nd IP Address	Station	Device Address	Data Type	Reverse
%WW2001	4	1-3S_MODTCP	2	1	172.21.0.5	172.21.1.5	1	A10012	Input (Discrete)	No
%WW2002	*	*	*	*	*	*	*	*	*	*

Continues on the next page

Table D1.4.2-2 Example of completed item settings (Table continued)

Element	Buffer	Program Name	Size	Port	IP Address	2nd IP Address	Station	Device Address	Data Type	Reverse
%WW2003	*	*								
%WW2004	*	*								
%WW2005										

Port

You can specify the port for the subsystem communication module.

- When using ALR111M/ALR121M
  Select 1 or 2. The default is 1.
- When using ALE111M
  Always set to 1.

IP Address

You can set the IP address for the subsystem.

2nd IP Address

If the network is set to dual-redundant configuration, you need to set the subsystem IP address where an Ethernet communication module with even slot communicates.

Station

Specify the station number for the subsystem. Select a value between 0 and 255. The specifiable values vary depending on the subsystem. The default is 1.

Device address

Specify the content of data to be acquired from the other device, using a combination of the communication method used by the subsystem and the beginning data address.
To use the SLSEVENT data type, enter "SLSEVENT."

After the SLSEVENT data type is specified, this item is set to "SLSEVENT" automatically.

Data type

Specify the type of subsystem data. The following list shows the data types that can be selected:

- 1: Input (16-Bit Signed) (Analog input (16-bit signed integer))
- 2: Input (32-Bit Signed) (Analog input (32-bit signed integer))
- 3: Input (16-Bit Unsigned) (Analog input (16-bit unsigned integer))
- 4: Input (32-Bit Floating) (Analog input (32-bit floating))
- 5: Output (16-Bit Signed) (Analog output (16-bit signed integer))
- 6: Output (32-Bit Signed) (Analog output (32-bit signed integer))
- 7: Output (16-Bit Unsigned) (Analog output (16-bit unsigned integer))
- 8: Output (32-Bit Floating) (Analog output (32-bit floating))
- 9: Input (Discrete) (Discrete input)
- 10: Output (Discrete) (Discrete output)

- 11: SLSEVENT

If discrete input or output is selected, whether or not the total sum of "Sizes" assigned to all discrete inputs/outputs is 256 words or less is checked. If the total size exceeds 256 words, an error will occur.

If 32-bit analog input or output is selected, whether or not the corresponding "Size" field contains an even number is checked. If an odd number is entered, an error will occur.

When the ProSafe-SLS communication function is used, data types 2, 4, 6, and 8 cannot be specified. Also note that data type 11 can be specified only when the ProSafe-SLS communication function is used.

If data type 11 is selected, using any combination other than the following will lead to an error.

Table D1.4.2-3 Items to be set for acquisition of ProSafe-SLS events

	Program Name	Size	Device Address	Data type
Setting value	n-sS_SLSMOD	24	SLSEVENT	SLSEVENT

Within all the communication definitions, only one SLSEVENT can be defined to one set of station number and port combination. Defining multiple SLSEVENT for the same station number and port combination will lead to a build error.

Reverse

Specify whether or not to store subsystem data in the SCS after reversing the order of bits/words comprising the data.
The selectable items vary depending on the data type specified in the "Data Type" field. The following combinations of reverse specifications can be selected for each data type:

- 32-bit analog input/output: "2: No," "3: Words (word reversing)"
- Discrete input/output: "1: Bits (bit reversing)," "2: No"
- 16-bit analog input/output: Fixed to "2: No"
- SLSEVENT: Fixed to "2: No"

Input processing at fault

Specify the value to be input to the application logic, instead of the input value received from the subsystem, upon detection of an error. This field can be specified only when "discrete input" or "analog input" is selected in the "Data Type" field.
The errors that trigger this setting include errors occurring on both sides of the path from the CPU to the communication module, errors in the communication module, and communication errors between subsystems and the communication module. Errors in subsystems are not applicable.

Table D1.4.2-4 Input processing at fault (discrete input)

Selection		Description
0	0	Set the input value to 0 upon error detection.
1	1	Set the input value to 1 upon error detection.
2	Hold	Retain the value before detection of an error (default).

Table D1.4.2-5 Input processing at fault (analog input)

Selection		Description
2	Hold	Retain the value before detection of an error (default).
3	Fixed Value	Use the input value specified in "Input Value at Fault" upon error detection.

Input value at fault

If "Fixed Value" is specified in "Input Processing at Fault," specify the input value to be used instead of the input value received from the subsystem.

- Default: 0
- Input range: A value of up to 11 digits and containing a negative sign and/or a decimal point

Comm. I/O Wiring tab

The Comm. I/O Wiring tab shows a list of elements corresponding to the areas assigned in the Comm. I/O Definition tab.

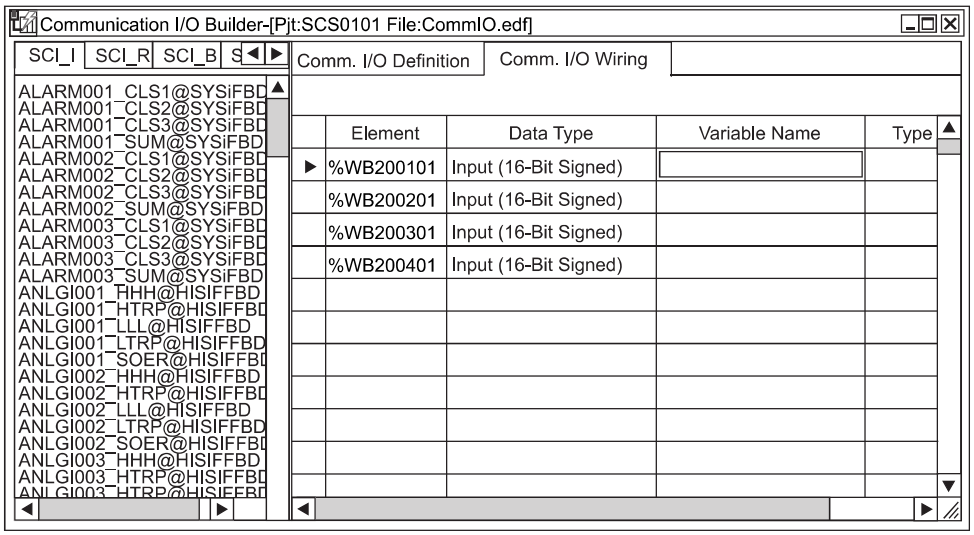

Figure D1.4.2-3 Comm. I/O Wiring tab

The items set in the Comm. I/O Wiring tab are as follows:

- Element: Read only
- Data Type: Read only
- Variable Name
- Type: Read only
- Comment: Read only

Element

An element or elements (%WB) is/are assigned automatically in accordance with the element number (%WW) for which "Buffer" and "Size" have been set in the Comm. I/O Definition tab as well as the applicable "Data Type" field.

Example:

If the selected element is %WW2001, "Size" is 4 words, and "Data Type" is "Input (16-Bit Signed)", the following elements will be assigned automatically:
%WB200101, %WB200201, %WB200301, %WB200401

Because the areas to which data type SLSEVENT is assigned on the Communication I/O Definition tab cannot be wired to variables, such areas do not appear on the Communication I/O Wiring tab.

Data type

The data type specified in the Comm. I/O Definition tab is displayed.

- The "Data Type" field is read only.

Variable name

You can use any of the following methods to set the instance name for a Subsystem Communication FB (SCI_B, SCI_I, SCI_R, SCO_B, SCO_I, SCO_R) in each variable name.

- Enter the variable name directly.
- Double-click on a variable name displayed in the "Variable Name" tab in the left pane.
- Drag a variable name from Dictionary View and drop it into the Variable Name text box.

Table D1.4.2-6 Examples of variable specification

Variable name(*1) (*2)	Scope	Description
SCIB1	Global	Global variable
SCIB2@PROG1	PROG1	Local variable of PROG1 function
FB01.SCIB3	Global	Internal variable SCIB3 of user-defined function block instance FB01
FB01.SCIB3@PROG1	PROG1	Internal variable SCIB3 of user-defined function block instance FB01 defined locally in PROG1 function
FB01.FB2.SCIB3	Global	Internal variable SCIB3 of user-defined function block instance FB2, which is used in user-defined function block instance FB01 (maximum limit of function block nesting)

*1: Also note the following:
- If an instance is a local variable, Scope name must be added after "@".
- If an instance is defined as an internal variable for a User-defined Function Block, assign an instance name to the User-defined Function Block from Dictionary View in Workbench.
- The variable name is specified in the format of "[Instance Name].[Internal Variable Name]," and up to two nests are permitted in each variable.

*2: A variable name can be up to 67 characters long.
Communication I/O Builder also checks the following items:
- The variable name consists only of alphanumeric characters and "@", "." or "_". If any other character is used, an error will occur.
- The variable name begins with an alphabetic character or "_"; otherwise, an error will occur.
- If a variable name has 3 or more nests, an error will result. In the above table, "FB01.SCIB3" and "FB01.SCIB3@PROG1" have one nest, while "FB01.FB2.SCIB3" has two nests.

The following table lists the combinations of variable types and data types specified in the Comm. I/O Definition tab. The types of the variable are the Subsystem communication FBs.

Table D1.4.2-7 Data types and specifiable variable types

Data type	Variable type
Analog input (16-bit signed integer)	SCI_I
Analog input (32-bit signed integer)	
Analog input (16-bit unsigned integer)	
Analog input (32-bit floating)	SCI_R
Analog output (16-bit signed integer)	SCO_I
Analog output (32-bit signed integer)	
Analog output (16-bit unsigned integer)	
Analog output (32-bit floating)	SCO_R
Discrete input	SCI_B
Discrete output	SCO_B

Type

The selected variable type is displayed. The type of the variable is the Subsystem communication FB.

- The "Type" field is read only.

Comment

A comment for the selected variable is displayed.

- The "Comment" field is read only.

D1.5 Engineering for subsystem communication modules

When I/O list engineering is selected, engineering for subsystem communication modules is performed using the safety communication I/O list.

Safety Communication I/O Editor is configured of a grid which defines the Signal Definition list, Program Group Definition list, and Communication Group Definition list.

Follow these steps to define communication I/O:

1. Input the basic definition of the signal definition
   With Safety Communication I/O Editor, set P&ID Tag, I/O Type, Signal Protocol, I/O Tag, Data Type, RS Project, and SCS of the signal definition.
2. Input the IOM assigned information of the signal definition
   Set Node Type, Node, IOM Category, IOM Type, and Slot of the signal definition.
3. Input the data structure of the signal definition
   Set the items for the data structure such as Program Group, Communication Group, Position, and Bit Position.

   Position is the order of %WW in Communication Group. With DI and DO, the order of the bit is set as its Bit Position. Position and Bit Position are required in order to decide the numbers for %WW and %WB in later steps.
4. Create a program group
   Set Program Protocol and Connection Device Type.
5. Create a communication group
   Set the items such as IP Address, Port, and Station.
6. Calculate %WW
   Set Size, Offset, and Element.
7. Reflect onto the SCS project
   When the Build process of RS Generation Manager is run, the safety communication I/O list and information of the IOM are reflected onto the SCS project. The subsystem FB instance specified under I/O Tag is created and wired with the subsystem communication definition.

Creating a program group

Before defining a program group, define I/O points in the Signal Definition list. You can also import the safety communication I/O list.

1. In order to define a program group, click [Program].
   The program group name defined in the Signal Definition list automatically appears.

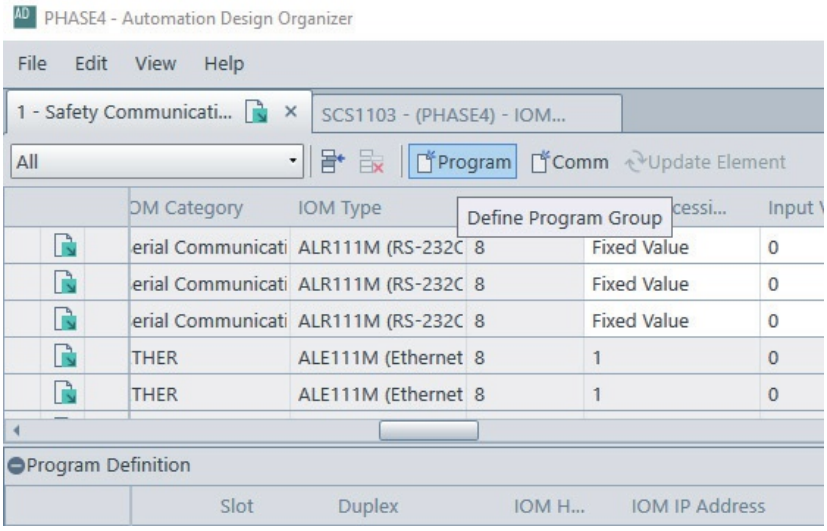

Figure D1.5-1 Defining a program group

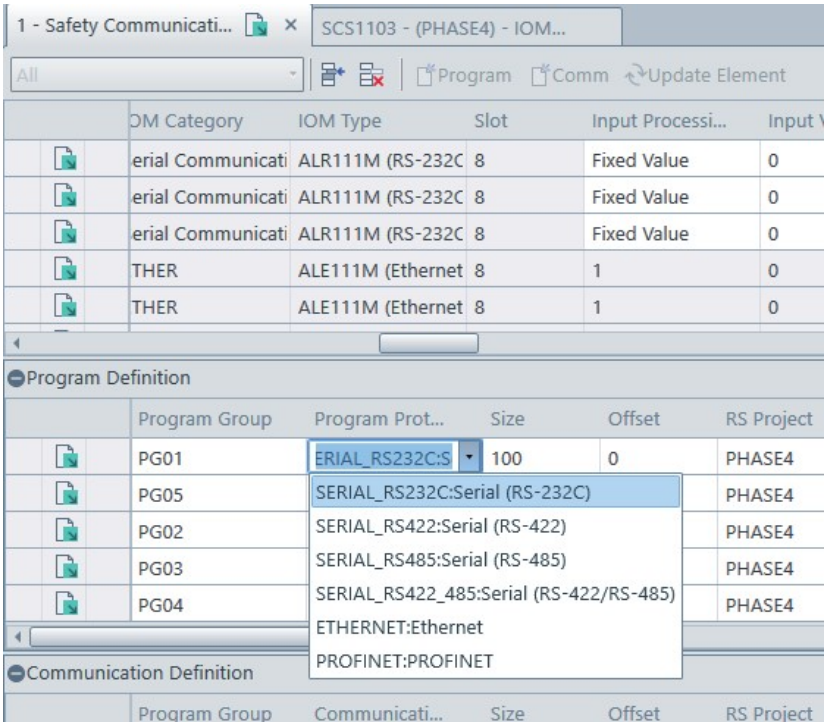

Figure D1.5-2 Example of a program group automatically appearing

2. Define Program Protocol and Connection Device Type.

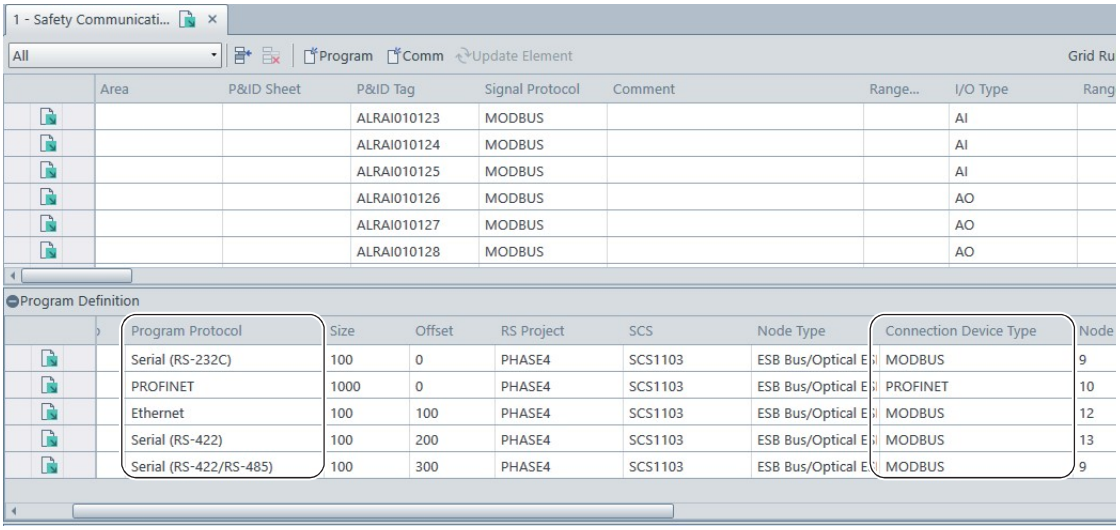

Figure D1.5-3 Example of Program Protocol and Connection Device Type definitions

Creating a communication group

1. In order to define a communication group, click [Communication].
   The program group name and communication group name defined in the Signal Definition list automatically appear.

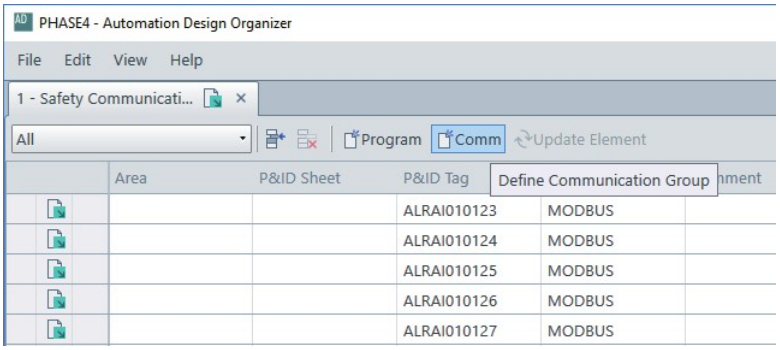

Figure D1.5-4 Communication group definitions

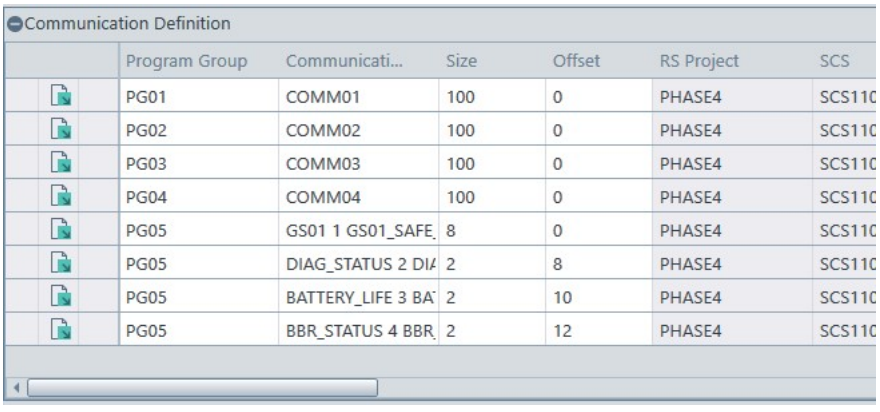

Figure D1.5-5 Display example of the program group name and communication group name

2. Define other necessary information.
3. Save the safety communication I/O list.

Calculating %WW

1. In the SCS folder, open Comm_I/O.

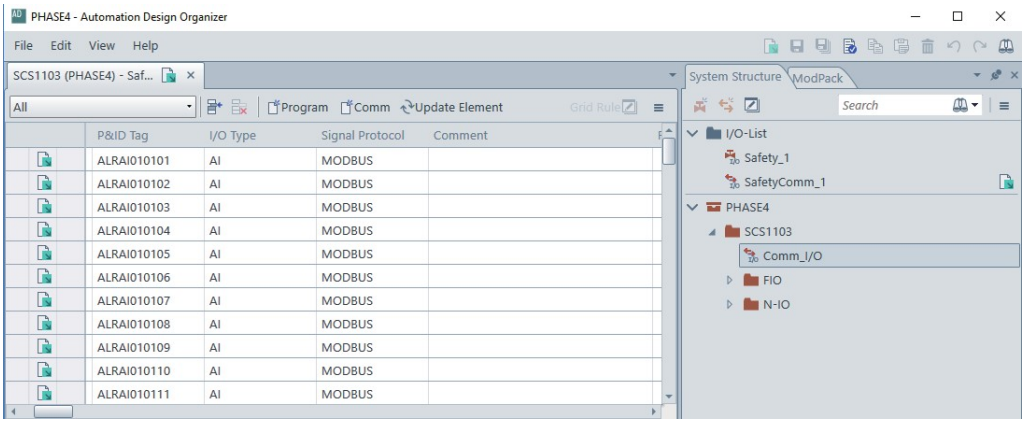

Figure D1.5-6 Display example of Comm_I/O

2. Calculate the size and define the offset of the program group and communication group. In order to automatically set the size, click [Calculate] on the Communication Definition tab.

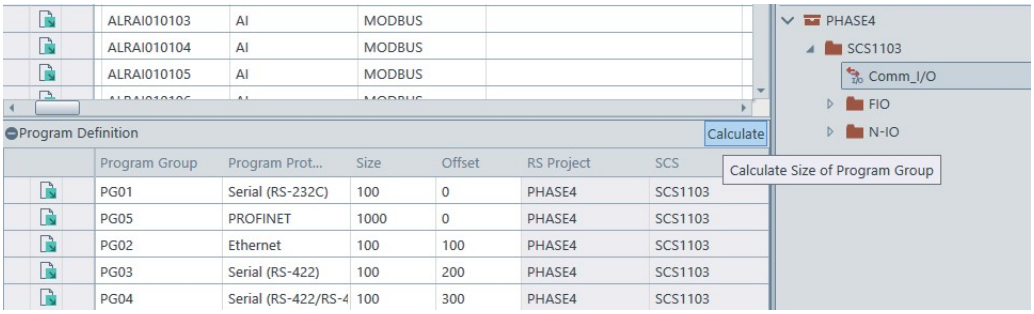

Figure D1.5-7 Resetting the size automatically

3. Define [Offset] in the communication definition.

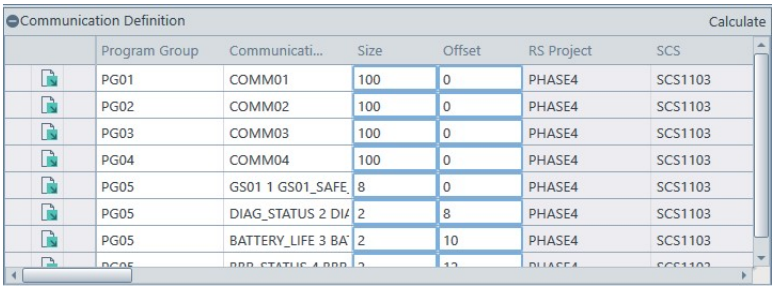

Figure D1.5-8 Defining the offset

4. In order to set Size automatically, click [Calculate] on the Program Definition tab. Then, define Offset in the program definition.

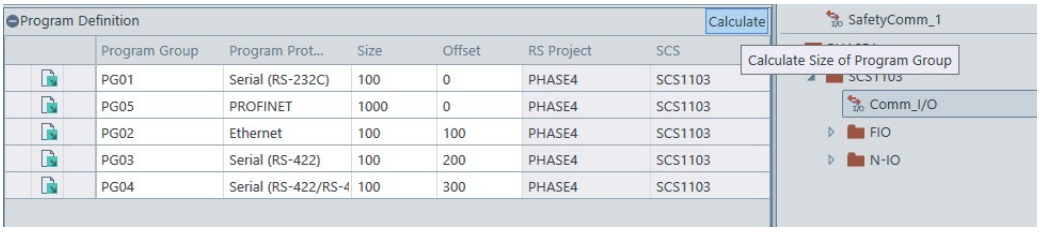

Figure D1.5-9 Defining a program definition with the offset

5. Click [Update Element].
   The element names automatically appear according to the specified position and offset.

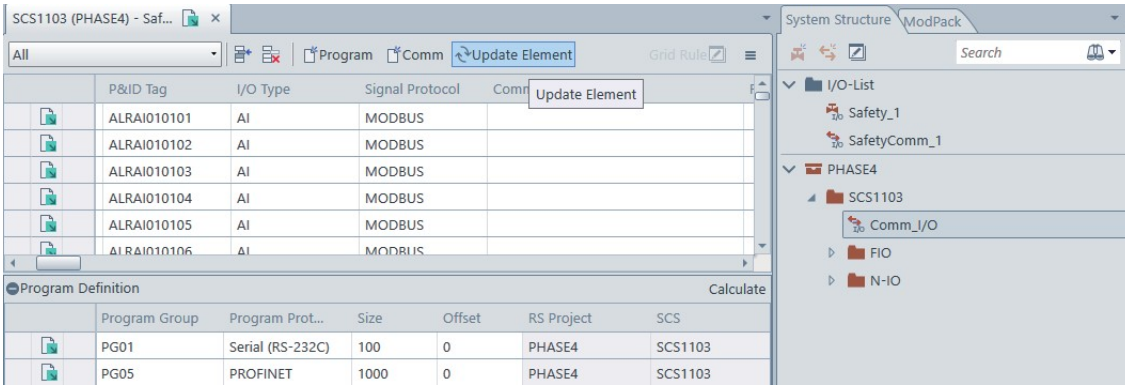

Figure D1.5-10 Automatic display of the element names

6. Change Fix Element of the signal definition to [Y]. Doing so will fix the element numbers. Save the list and check-in.

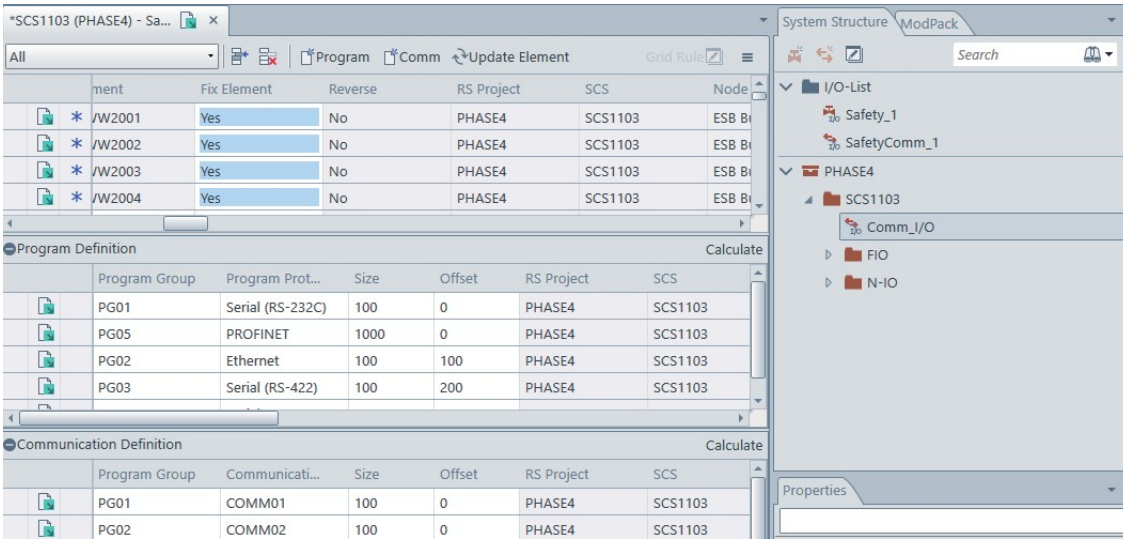

Figure D1.5-11 Fixing the element numbers

D1.6 Storage formats of subsystem data

This section describes the formats in which Modbus equipment data that has been read is stored in the SCS.

The storage formats for different Modbus equipment, such as bit devices, word devices, special coils and communication statuses, are explained.

Bit devices

When 16 x m (m = 1, 2, ...) numbers of bit devices are read from address n in the Modbus equipment, the Modbus equipment data is stored in the SCS as follows.

In the Communication I/O Builder, specify "m" in "Size". You can also reverse the order of bits in units of 16 bits.

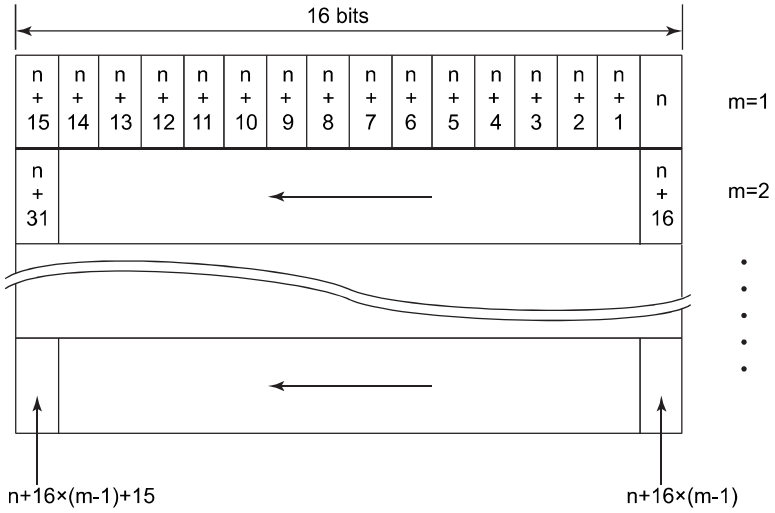

Figure D1.6-1 Storage image of bit devices

Word devices

16-bit data

If m numbers of word devices are read from address n, the applicable word registers (16 bits) in the Modbus equipment will be stored in the SCS as follows.

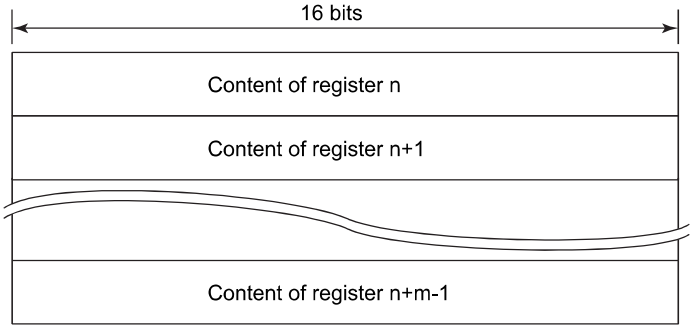

Figure D1.6-2 Storage image of word devices

32-bit data

Word registers (16 bits) in the Modbus equipment are stored in the SCS in the order of registers, as shown in the following. However, if 32-bit data is defined as the data type, two word registers are combined and treated as 32-bit data.

If word reversing is not specified in the SCS (default), the first register is recognized as the upper word, while the next register is regarded as the lower word.

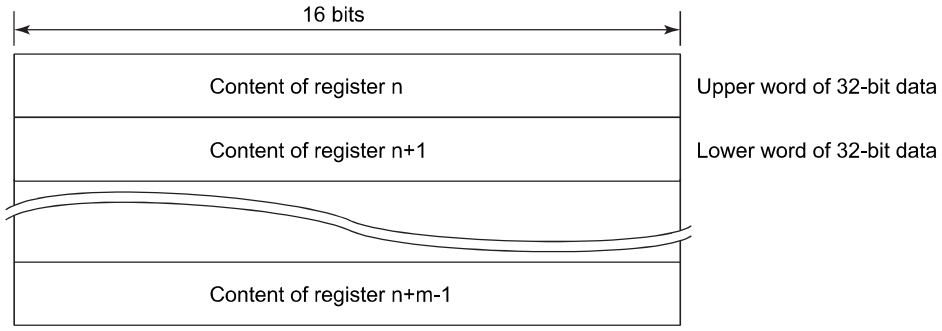

Figure D1.6-3 Order of 32-bit data in SCS (without word reversing)

If 32-bit data is stored in word registers in the Modbus equipment, some Modbus equipment models may store the data in pairs of two 16-bit word registers in the order of low-order word and high-order word, as follows. This word order (16 bits) is opposite to the order in the SCS.

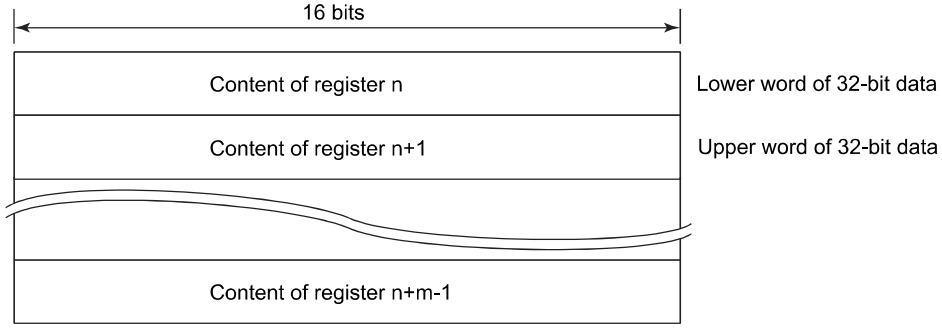

Figure D1.6-4 Order of 32-bit data in Modbus equipment (opposite order from the SCS)

If the previously mentioned Modbus equipment data is to be stored in the SCS, the data order can be switched to units of words (16 bits) by specifying "Reverse" in the Communication I/O Builder.

Special coils

Special coils in Modbus equipment have a data length of 1 word (16 bits). Special coils in Modbus equipment are stored in the SCS as follows.

By specifying "Reverse" in the Communication I/O Builder, you can reverse the order of bits.

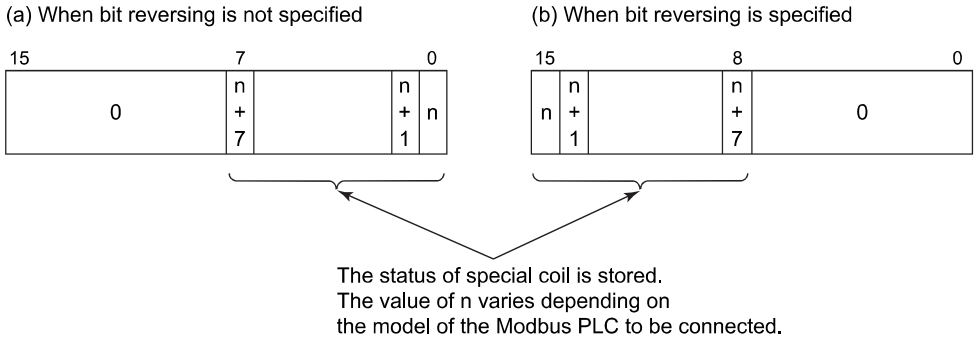

Figure D1.6-5 Storage image of special coil data

Communication status

Modbus equipment communication status STSnnn indicates the status of communication with each station corresponding to a station number of nnn to nnn+15.

The communication status is specified as follows:

- Of the stations defined in the Communication I/O Builder, those communicating normally are indicated as "0."
- Of the stations defined in the Communication I/O Builder, those experiencing an error are indicated as "1."
- Stations not physically performing communication (not defined in the Communication I/O Builder) are indicated as "0".

With communication status, the station number specification in the Communication I/O Builder has no specific meaning. It is only relevant in that the number corresponding to the youngest station among the stations physically performing communication should be set. Specify the address as follows:

Table D1.6-1 Communication status

Description	Address
Communication status of stations 1 to 16	STS001
Communication status of stations 17 to 32	STS017

The correspondence of bits and station numbers is as follows:

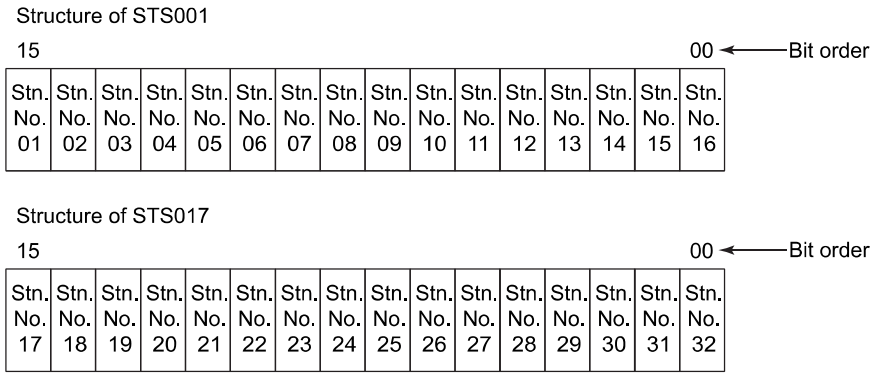

Figure D1.6-6 Correspondence of communication status bits and station numbers

D1.7 Troubleshooting

If a communication module error occurs, you can use the SCS Maintenance Support Tool to acquire information on the communication module and communication error information. This section describes typical troubleshooting cases.

The status display window shows the status of ALR111/121 or ALE111 in red

If the status of the communication module appears in red in the status display window of the SCS Maintenance Support Tool, check the error code that is related to the I/O module of the diagnostic information message.

There is no response and communication fails

- Check if the transmission specifications are consistent with those of the communication destination party.
- Check if the cable wiring complies with the specifications.
- Analyze the communication log for the cause of the communication error by using the SCS Maintenance Support Tool.

A response message under abnormal conditions is received

Analyze the cause of abnormal response from the error code included in the message

Connection cannot be established and communication fails (specific to Modbus TCP)

Check if the destination IP address and port number are correct.

D2. Modbus communication (ALR111, ALR121)

This section explains Modbus communication. The Modbus communication function enables subsystem communication between an SCS and a Modbus PLC, such as the reading and writing of subsystem data, by connecting the Modbus PLC to an ALR111 RS-232C serial communication module or an ALR121 RS-422/RS-485 serial communication module.

Overview of Modbus connection

The subsystem communication function implements communication with PLCs and other subsystems via a subsystem communication module. The Modbus communication program is downloaded to the subsystem communication modules and runs on them.

Reading of data from subsystems or writing of data to subsystems is performed by the application logic execution function via the communication I/O data area and subsystem communication I/O FBs.

The following figure illustrates the flow of data in subsystem communication.

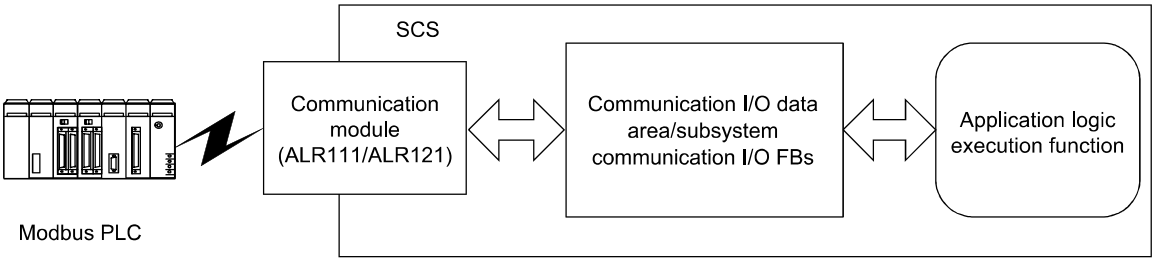

Figure D2-1 Data flow of subsystem communication function

TIP

When using the communication module for CENTUM FCS, you need to perform an IOM download to download the Modbus communication program for the SCS to the module.

D2.1 Communication specifications

This section describes the specifications for communication between an SCS and a Modbus PLC.

Communication capacity

The following table summarizes the Modbus-specific communication capacity applicable to communication between a Modbus PLC and an SCS.

Table D2.1-1 Capacity of communication between SCS and Modbus PLC

Item	Maximum capacity	Remark
Amount of data that can be communicated per serial communication module	1000 words (1 word = 16 bits)	Limitations of the SCS: Communication I/O data area: 1,000 words per SCS Number of communication data items: 500 data items per SCS
Number of subsystem stations that can be communicated with	30 stations per port	If is recommended that the number of stations be limited to a maximum of four or so, in order to minimize the impact on communications with other normal stations when an error occurs in a communication with a given station.
Size of communication data per communication definition	125 words	One communication definition corresponds to one communication. This limitation applies to one communication using the Modbus protocol.
Number of usable ports	2	Communications are performed independently (in parallel) using two ports.

Simultaneity of communication data

Modbus PLCs assure simultaneity of communication data in units of 16 bits. Accordingly, simultaneity of communication data between a serial communication module and a Modbus PLC is also assured in units of 16 bits.

TIP

Modbus PLCs process data in units of 16 bits. Simultaneity of 32-bit data depends on the application software used on the Modbus PLC side. To assure simultaneity of communication data in units of 32 bits, the application software on the Modbus PLC side needs to set 32-bit data within the same control period.

Transmission specification

The transmission specifications for subsystem communication with a Modbus PLC are as follows:

Table D2.1-2 Transmission specification

Item	Description(*1)	Remark
Interface	RS-232C (D-sub, 9-pin)	ALR111
	RS-422/RS-485 (2-wire, [4-wire])	ALR121(*2)
Transmission method	Half-duplex	
Synchronization method	Start-stop synchronization	
Baud rate	1200, 2400, 4800, 9600, [19200], 38400 bps	
Transmission protocol	Modbus protocol (RTU mode)	
Transmission code	Binary	

Continues on the next page

Table D2.1-2 Transmission specification (Table continued)

Item		Description(*1)	Remark
Data type	Start bit	Fixed to 1	
	Data bit	8	
	Parity bit	None, [Even], Odd	
	Stop bit	1	
Control line	RS control	Yes, [No]	Valid only for ALR111
	DR check	[Yes], No	Valid only for ALR111
	CD check	Yes, [No]	Valid only for ALR111
Time monitoring	Transmission enable monitoring time	1000 ms	
	Reception inter-character timer	0 to 99999 ms [10 ms]	(*2)
	Inter-character monitor timeout	Not handled as errors.	(*2)
Text frame	Reception start character	None	
	EOT character	None	
XON/XOFF control		None	
Response timeout		0 to 99 sec [4 sec]	
Communication retry		0 to 99 [1]	
Interval of connection retries		0 to 999 sec [30 sec]	
Transmission wait time		1 sec	
Option 1		0 to 5	Specification of recovery communication method
Option 2		0 to 1	(*3)
Option 3		0	
Option 4		0	

*1: The recommended settings are shown in [ ].
*2: With Modbus, the reception inter-character timer is used to detect completion of reception. Thus, setting a longer time for the reception inter-character timer will delay the time to reception completion. This timer should be set to around 10 ms (corresponding to the time required for sending 10 characters) at 9600 bps.
*3: Wind-up specification without readback.
0: Valid
1: Invalid

IMPORTANT

When performing subsystem communication with a Modbus PLC, always specify 8 for the data bit length. In addition, always specify 1 for the stop bit length. If any other value is specified, a communication error will occur.

Communication error code

Modbus PLC-specific error codes resulting from address and communication errors are as follows:

Table D2.1-3 Communication error code - Modbus

Error code (hexa-decimal)	Description	Remarks
A3B0	No response	
A3B1	Inappropriate station number (When the station number is other than the range between 1 and 255)	(*1)
A3B2	Station number 0 cannot be set	(*1)
A3B3	Inappropriate address name	(*1)
A3B4	Inappropriate address number	(*1)
A3B5	Too many communication processing points	(*1)
A3B6	Write to a read-only device occurred	(*1)
A3B8	Odd number is used for the size of 4-byte register	(*1)
A3B9	Option 1 setting is out of range	(*1)
A3BA	Cannot create communication frame	(*1)
A3C0	CRC-16 error	(*2)
A3C1	Response message error (Station error)	(*2)
A3C2	Response message error (Address error)	(*2)
A3C3	Response message error (Function code error)	(*2)
A3C4	Response message error (Data error)	(*2)
A3C5	Response message error (Received data size error)	(*2)
A3C6	Response message error (Received data length error)	(*2)
A3D1	Error code $01 received	(*2)
A3D2	Error code $02 received	(*2)
A3D3	Error code $03 received	(*2)
A3D4	Error code $04 received	(*2)
A3D5	Error code $05 received	(*2)
A3D6	Error code $06 received	(*2)
A3D7	Error code $07 received	(*2)
A3D8	Error code $08 received	(*2)
A3D9	Error code $09 received	(*2)
A3DA	Error code $0A received	(*2)
A3DB	Error code $0B received	(*2)
A3DC	Error code $0C received	(*2)
A3DD	Error code $0D received	(*2)
A3DE	Error code $0E received	(*2)
A3DF	Error code $0F received	(*2)
A3E0	Error code $10 received	(*2)
A3E1	Error code $11 received	(*2)
A3E2	Error code $12 received	(*2)
A3E3	Error code $13 received	(*2)
A3E4	Error code $14 received	(*2)
A3E5	Error code $15 received	(*2)
A3E6	Error code $16 received	(*2)

Continues on the next page

Table D2.1-3 Communication error code - Modbus (Table continued)

Error code (hexa-decimal)	Description	Remarks
A3E7	Error code $17 received	(*2)
A3E8	Error code $18 received	(*2)

*1: Definition error for ALR111/ALR121. If this error occurs, no communication can be performed to the Modbus PLC.
*2: This is an error when an error message was received from the Modbus PLC.

ALR111 RS-232C serial communication module

This section describes the LED indications, connector pin layout and cable connection of the ALR111 RS-232C serial communication module.

LED indications in the ALR111 RS-232C serial communication module

Table D2.1-4 ALR111 LED indications

LED	Description
STATUS	Hardware ready
ACT	Operating normally
DX	Dual-redundant configuration
SND1, SND2	Sending data from RS port 1 or 2
RCV1, RCV2	Receiving data by RS port 1 or 2

Terminal assignments for the ALR111 RS-232C serial communication module

Table D2.1-5 RS-232C D-sub 9-pin connector specification

Pin No.	Signal	Name	Processing on ALR111 side
1	CD	Carrier Detect	Send data if the CD is OFF (only when CD check is performed). Receive data if the CD is ON.
2	RD	Receive Data	
3	SD	Send Data	
4	ER	Data Terminal Ready	Output "ON" if normal.
5	SG	Signal Ground	
6	DR	Data Set Ready	Send data if the DR is ON (only when DR check is performed).
7	RS	Request to Send	This signal is always ON if RS control is not performed. If RS control is performed, the ALR111 outputs "ON" when sending data.
8	CS	Clear to Send	Send data if the CS is ON.
9	-	Not used	

ALR121 RS-422/RS-485 serial communication module

The following describes the LED indications, connector pin layout and cable connection for the ALR121 RS-422/RS-485 serial communication module.

LED indications in the ALR121 RS-422/RS-485 serial communication module

Table D2.1-6 ALR121 LED indications

LED	Description
STATUS	Hardware ready
ACT	Operating normally
DX	Dual-redundant configuration
SND1, SND2	Sending data from RS port 1 or 2
RCV1, RCV2	Receiving data by RS port 1 or 2

Terminal assignments of the ALR121 RS-422/RS-485 serial communication module

Table D2.1-7 ALR121 connector specifications

Terminal	Name
TX+	Send Data (Positive phase signal)
TX-	Send Data (Negative phase signal)
RX+	Receive Data (Positive phase signal)
RX-	Receive Data (Negative phase signal)
SG	Signal Ground

Cables provided by Yokogawa Electric Corporation

Yokogawa Electric Corporation provides the following four types of cables for connecting a serial communication module to a subsystem.

RS-232C modem cables

These cables are used to connect an ALR111 with a modem.

- AKB131: RS-232C modem cable (9-25 pins) for RS circuit isolated device (for ALR111 to modem connection)
- AKB135: RS-232C modem cable (9-25 pins) (for ALR111 to modem connection)

RS-232C null modem cables

These cables are used to connect an ALR111 with a subsystem.

- AKB132: RS-232C null modem cable (9-25 pins) for RS circuit isolated device (for ALR111 to RS-232C device connection)
- AKB133: RS-232C null modem cable (9-9 pins, male) (for ALR111 to FA-M3 connection)
- AKB134: RS-232C null modem cable (9-9 pins, female) (for ALR111 to RS-232C device connection)
- AKB136: RS-232C null modem cable (9-25 pins) (for ALR111 to RS-232C device connection)

RS-232C cable

This cable is used to connect an ALR111 with a subsystem.

- AKB163: RS-232C cable (for ALR111 to FA500 connection)

RS-422/RS-485 cable

This cable is used to connect an ALR121 with a subsystem.

- AKB164: RS-422/RS-485 cable (for ALR121 to FA-M3 connection)

D2.2 Connection of serial communication module and Modbus PLC

This section describes how to connect a serial communication module with a Modbus PLC using a cable.

Connecting an ALR111 RS-232C serial communication module with a Modbus PLC

The ALR111 uses a RS-232C D-sub, 9-pin connector, but the computer link unit of the connected Modbus PLC may be equipped with a RS-232C D-sub, 25-pin connector or a 9-pin connector. Select a connection cable appropriate for the subsystem to be connected.

A modem is required for connecting an ALR111 with a Modbus PLC. As long as the ALR111 and Modbus PLC are sharing the same grounding system, the two can be connected directly using a RS-232C cable of a length not exceeding 15 m.

IMPORTANT

The length of the RC-232C cable connecting the ALR111 to the modem, and one connecting the modem to the Modbus PLC, shall not exceed 15 m.

Modem connection

The following figure shows a cable connection when an ALR111 and a Modbus PLC are connected via a modem.

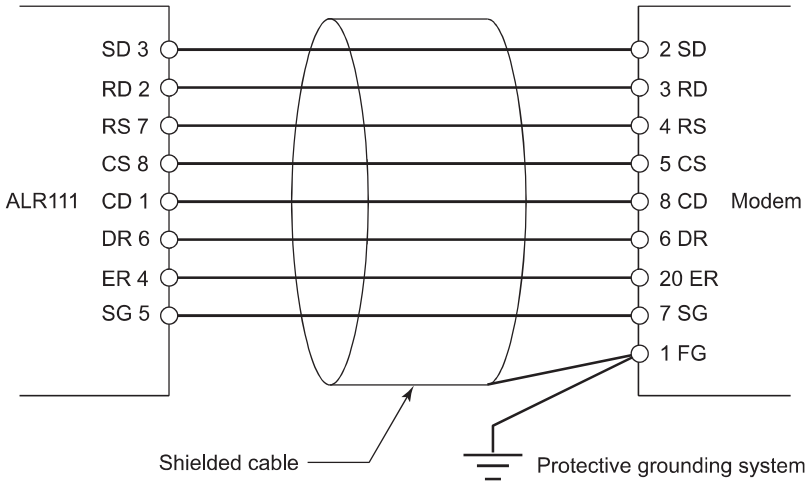

Figure D2.2-1 Cable connection of ALR111 and Modbus PLC via modem (RS-232C D-sub, 25-pin)

Connecting a RS-232C D-sub, 25-pin connector to a Modbus PLC (direct connection)

The following example shows a cable connection where an ALR111 is connected directly to a Modbus PLC equipped with an RS-232C D-sub 25-pin connector. In this connection, a cable with an RS-232C D-sub, 25-pin connector needs to be used.

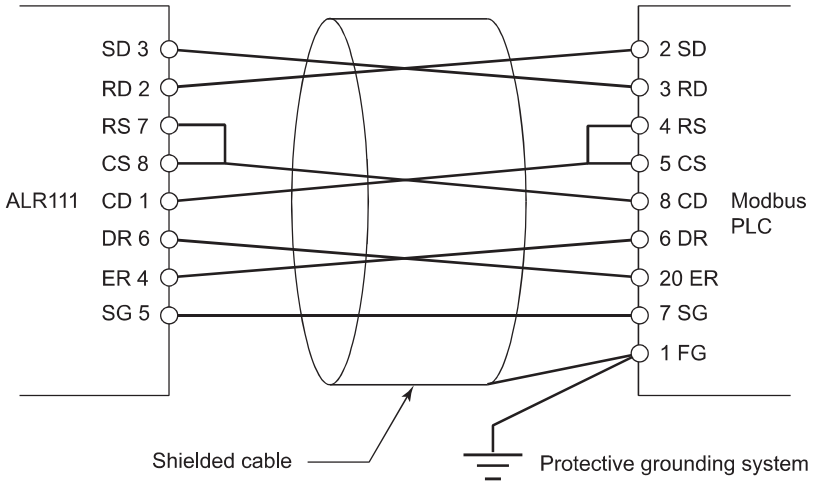

Figure D2.2-2 Direct cable connection of ALR111 and Modbus PLC (RS-232C D-sub, 25-pin)

Connecting a RS-232C D-sub, 9-pin connector to a Modbus PLC (direct connection)

The following example shows a cable connection where an ALR111 is connected directly to a Modbus PLC equipped with an RS-232C D-sub 9-pin connector. In this connection, a cable with an RS-232C D-sub, 9-pin connector needs to be used.

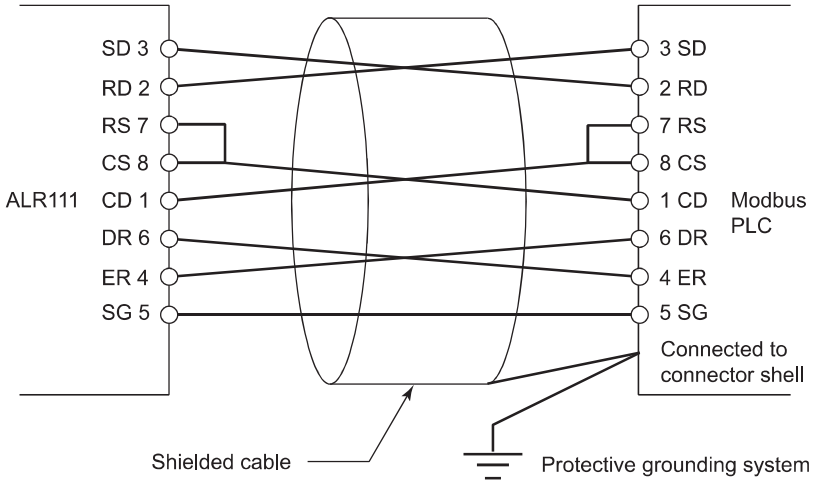

Figure D2.2-3 Direct cable connection of ALR111 and Modbus PLC (RS-232C D-sub, 9-pin)

SEE ALSO For more information about connecting the ALR111 (RS-232C) to each Modbus PLC model, refer to:

Modbus PLC user manuals

Connecting an ALR121 RS-422/RS-485 serial communication module with a Modbus PLC

The specific connection varies depending on the Modbus PLC model.

SEE ALSO For more information about connecting the ALR121 (RS-422/RS-485) to each Modbus PLC model, refer to:

Modbus PLC user manuals

D2.3 Modbus PLC devices accessible from SCSs

This section describes the Modbus PLC devices that can be accessed from SCSs.

Internal data of a Modbus PLC are called devices. Devices can be bit devices or word devices, as described in the following explanation.

- Bit devices
  Data in which each bit has a meaning. An input relay is a bit device.
- Word devices
  Data in which each word (1 word = 16 bits) has a meaning. A holding register is a word device.

Modbus PLCs also have devices called "special coil" and "communication status."

Accessible devices

To access Modbus PLC devices, you must set [Comm Device & Address] of Signal Definition and [Size] of Communication Definition in the Safety Communication I/O Editor, or set [Device Address] and [Size] in the Communication I/O Builder.

With Modbus PLCs, "Device Address" is set using the following format:

<Function code> + <Device type> + <Address within device>

To specify input relays 100012 to 100015, for example, set A100012 for "Device Address" and 1 for "Size." "A" of A100012 indicates a function code, "1" indicates a device type, and "00012" indicates an address within device.

The table below lists the Modbus PLC devices accessible from SCSs, as well as the corresponding addresses and Modbus protocol function codes.

Table D2.3-1 Bit devices

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Modbus PLC device type	Address in the Modbus PLC device	Read	Write
Coil	A	0	XXXX	01	0F
	B				05
	X			-	0F
	Y				05
Input relay	A	1	XXXX	02	-
Link relay:(*1)	A	D	XXXX	12	1D
	B				19
	X			-	1D
	Y				19
Step status:(*1)	A	S	XXXX	17	-

*1: These are Memocon-SC GL60S devices and not available on other models.

Table D2.3-2 Word devices

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Modbus PLC device type	Address in the Modbus PLC device	Read	Write
Input register	A	3	XXXX	04	-
Holding register	A	4	XXXX	03	10
	B				06
	C				10
	X			-	10
	Y				06
	Z				10
Constant register: (*1)	A	C	XXXX	13	1E
	B				1A
	C				1E
	X			-	1E
	Y				1A
	Z				1E
Elapsed step time:(*1)	A	5	XXXX	14	-
Link register:(*1)	A	R	XXXX	15	1F
	B				1B
	C				1F
	X			-	1F
	Y				1B
	Z				1F
Extended register: (*1)	A	A	XXXX	16	20
	B				1C
	C				20
	X			-	20
	Y				1C
	Z				20
4-byte register	A	W	XXXX	04	-

*1: These are Memocon-SC GL60S devices and not available on other models.

Table D2.3-3 Other devices

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Modbus PLC device type	Address in the Modbus PLC device	Read	Write
Special coil	SP001			07	-
Communication status	STSXXX			-	-

The meaning of each function code is as follows. The size is specified in the Safety Communication I/O Editor or Communication I/O Builder.

- A
  Read data for the specified size.

  Write data for the specified size specified. Readback is supported.
- B
  Read data for the specified size.

  Write data individually to each modified device in units of 1 bit for a bit device, or in units of 16 bits for a word device. With readback.
- C
  Read data for the specified size.

  Write data individually to each modified device in units of 32 bits. With readback.
- X
  Write data for the specified size when a change occurs. Readback is not supported.
- Y
  Write data individually only to each modified device for the size of each device when a change occurs. Without readback.
- Z
  Write data individually only to each modified device in units of 32 bits when a change occurs. Without readback.

Table D2.3-4 List of function codes

Function code	Device	Read	Write	Readback
A	Bit device	All data for one communication definition	All data for one communication definition	Yes
	Word device	All data for one communication definition	All data for one communication definition	Yes
B	Bit device	All data for one communication definition	In units of 1 bit	Yes
	Word device	All data for one communication definition	In units of 16 bits	Yes
C	Word device	All data for one communication definition	In units of 32 bits	Yes
X	Bit device	-	All data for one communication definition	No
	Word device	-	All data for one communication definition	No
Y	Bit device	-	In units of 1 bit	No
	Word device	-	In units of 16 bits	No
Z	Word device	-	In units of 32 bits	No

IMPORTANT

With a dual-redundant configuration based on ALR111/ALR121s, it is always necessary to perform readback when data is written to the Modbus PLC. Writing of data without readback is not supported in a dual-redundant configuration.

Supported function codes, accessible devices, and sizes vary depending on the Modbus PLC model.

SEE ALSO

For more information about readback communication, refer to:

D2.5, “Readback communication” on page D2-20

For more information about supported function codes, accessible devices, sizes, and so on, refer to:

The user manual for your Modbus PLC

D2.4 Builder setting items specific to Modbus PLCs

This section describes the builder setting items specific to Modbus PLCs.

When performing RS original engineering, you can define the serial communication module and set I/O parameters by using I/O Wiring View and I/O Parameter Builder. In addition, you need to use Communication I/O Builder to allocate the communication I/O data, and assign element numbers and subsystem communication I/O FB.

When performing I/O list engineering, you can define the serial communication module and set I/O parameters by using IOM Definition Editor. In addition, you need to use Safety Communication I/O Editor to allocate the communication I/O data, and assign element numbers and subsystem communication I/O FB.

TIP

This section mainly describes for the case when performing RS original engineering. The setting item names displayed may differ between I/O list engineering and RS original engineering, but the settings are the same.

SEE ALSO

For more information about engineering of subsystem communication modules using Safety Communication I/O Editor, refer to:

D1.5, “Engineering for subsystem communication modules” on page D1-37

For more information about I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

D2.4.1 Settings in the I/O Wiring View

When performing RS original engineering, you need to set the following items by using the I/O Wiring View.

Subsystem communication module definition

If an ALR111/ALR121 is used for subsystem communication, you need to select ALR111M or ALR121M as the module type. You need to specify the mounting position (node, slot number) of the module, as well as whether or not to use a dual-redundant configuration.

Dual-redundancy of serial communication modules

To use serial communication modules in a dual-redundant configuration, you need to set Is-Redundant to TRUE.

D2.4.2 Items set in the I/O Parameter Builder

When performing RS original engineering, you need to set the following items in ALR111M/ ALR121M by using the I/O Parameter Builder.

■ Connection device

For the name of the connected device, select [S_MODBUS].

■ Transmission specifications

Set the transmission specifications for each port.

SEE ALSO For more information about settings information, refer to:

"■ Transmission specification" on page D2-2

■ Options 1 and 2

In Option 1, specify the method of recovery communication. In Option 2, specify the wind-up action for communication without readback.

SEE ALSO For more information about procedure for specifying recovery communication operations in Option 1, refer to:

D2.6, "Recovery communication" on page D2-25

For more information about procedure for specifying wind-up operations in Option 2, refer to:

"■ Operation in communication without readback" on page D2-21

D2.4.3 Items set in the Communication I/O Builder

This section describes the items set in the Communication I/O Builder.

This section describes the following items when a Modbus PLC is used.

- Element
- Buffer
- Program Name
- Size
- Port
- Station
- Device Address
- Data Type
- Reverse
- Input Processing at Fault
- Input Value at Fault

Element

Element numbers are displayed to specify the buffer addresses in the communication I/O data area. The "Element" field is read only and cannot be set.

Buffer

Specify the size of the storage area to be used by the Modbus communication program.
The "Buffer" is a required setting item in the Communication I/O Builder and always needs to be set.

Program name

Set the program name using the node number, slot number and S_MODBUS, as follows:
Program Name : n-s Fixed character string

- n: Node number
- s: Slot number
- Fixed character string: S_MODBUS

Size

Set the assigned size (data length) from the beginning address set in "Device Address."
The "Size" is a required setting item in the Communication I/O Builder and always needs to be set.

Specify the size in units of words (16 bits). The setting range is 1 to 125 words.

Port

Set the port of the ALR111/ALR121 to be used.
Port 1 or 2 can be set.

Station

Set the station number for the Modbus PLC.
The setting range is 1 to 255.

Device address

Set the content of data to be acquired from the other device as a combination of the communication method used by the Modbus PLC and the beginning address of the data.
The address can be set using 3 to 7 alphanumeric characters as follows:

- Coil: A0xxxx, B0xxxx, X0xxxx, Y0xxxx
- Input relay: A1xxxx
- Link relay: ADxxxx, BDxxxx, XDxxxx, YDxxxx
- Step status: ASxxxx
- Input register: A3xxxx
- Holding register: A4xxxx, B4xxxx, C4xxxx, X4xxxx, Y4xxxx, Z4xxxx
- Constant register: ACxxxx, BCxxxx, CCxxxx, XCxxxx, YCxxxx, ZCxxxx
- Elapsed step time: A5xxxx
- Link register: ARxxxx, BRxxxx, CRxxxx, XRxxxx, YRxxxx, ZRxxxx
- Extended register: AAxxxx, BAxxxx, CAxxxx, XAxxxx, YAxxxx, ZAxxxx
- 4-byte register: AWxxxx
- Special coil: SP001
- Communication status: STSxxx

The "Device Address" field is blank by default.

"xxxx" indicates an address within Modbus PLC device, and is set as a decimal or hexadecimal value between 1 and 65535 (1H and FFFFH). If a hexadecimal value is used, add "H" at the end.

The 0 or 0s at the beginning of "xxxx" can be omitted. For example, coil addresses of A023, A0023 and A00023 all represent the same address.

SEE ALSO For more information about specifying addresses , refer to:

D2.3, “Modbus PLC devices accessible from SCSs” on page D2-10

Limitations on dual-redundant serial communication modules

If even one function code without readback (X, Y or Z) is specified in the "Device Address" fields of the Communication I/O Builder, that serial communication module cannot be used in a dual-redundant configuration. Dual redundancy is not supported if readback is not used. To provide a dual-redundant configuration using two serial communication modules, specify only function codes with readback (A, B and C) for the modules.

TIP

If a function code without readback is specified in a dual-redundant configuration, the following problems will occur:

- Outputs that occurred while switching the dual-redundant modules may not be output, or the same outputs may be output again after switching.
  With readback, data is read from the subsystem, compared with the data in the CPU, and then the CPU data is written to the subsystem if the two data are different.

  Without readback, the data in the CPU is compared with the data in the serial communication module on the control side, without reading data from the subsystem, after which the CPU data is written to the subsystem and the data in the module is refreshed only when there is a difference between the data. If the serial communication module on the control side is normal, the data in the serial communication module on the standby side is not refreshed. This means that the serial communication module on the standby side will still contain old data when the control switches from the module on the control side to the module on the standby side. Since the module in this condition cannot accurately compare the data in the CPU with the data in the module, data cannot be written in this mode without readback.

  In Modbus communication, whether or not readback is used is determined by an address function code specified in the Communication I/O Builder.

- If an address without readback is specified, the control will not be switched to the applicable serial communication module in the dual-redundant configuration for 70 seconds after recovery of the module from an error.
  If the serial communication module on the standby side is reset following a restart, the serial communication status will not be considered normal for 70 seconds. If a serial communication error occurs during this period in the serial communication module on the control side, the control will not switch to the module on the control side.

SEE ALSO

For more information about readback, refer to:

D2.5, “Readback communication” on page D2-20

Data type

Set the type of subsystem data.
If 32-bit data is used, simultaneity of communication data needs to be considered.

Reverse

Set whether or not to reverse the order of bits/words in the SCS from the order of bits/words in the subsystem.

SEE ALSO

For more information about storing subsystem data on an SCS, refer to:

D1.6, “Storage formats of subsystem data” on page D1-42

Input processing at fault

Specify the value to be input to the application logic, instead of the input from the subsystem, upon detection of a communication error.

Input value at fault

Specify the input value to be used, instead of the process value, when "Fixed Value" is specified in "Input Processing at Fault."

D2.5 Readback communication

In subsystem communication, output data from subsystems are always read (read back) even when their data type is output, and each read-back data is compared with the data to be written. If a difference is found as a result of comparison, the data will be written. This method is indicated by the phrase "with readback." Readback forms the basis of subsystem communication.

On the other hand, there is another method of subsystem communication in which subsystem outputs are not read back and data is written only when the previously written data is different from the data to be written. This method is indicated by the phrase "without readback." This method is used to support one-shot outputs from Modbus PLCs.

Operation in communication with readback

Values output from subsystems are read at the subsystem communication period. The read-back data is compared with the data to be written. If there are no differences, write communication is not sent ((1) and (3) in the following figure).

If an output value is changed in the CPU and a difference occurs between the read-back data and the data to be written, communication is established with the applicable subsystem to write the new data ((2) in the following figure).

If an output value in a subsystem is changed while communication is normal, a difference occurs between the read-back data and the data to be written, in which case communication is established with the subsystem to write the new data ((4) in the following figure).

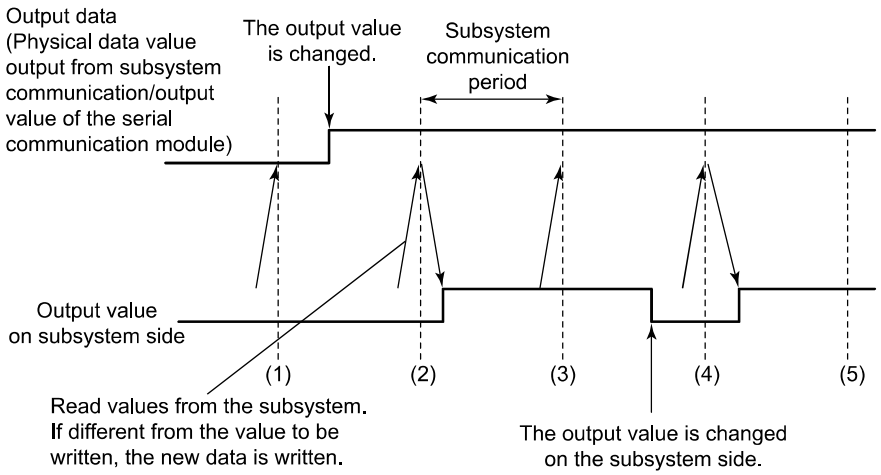

Figure D2.5-1 Output communication with readback

In a dual-redundant configuration, the serial communication module on the standby side reads back output values to confirm integrity of communication paths and prevent omission of outputs when the control right is switched.

In the following conditions, if read-back is enabled, values from subsystems are output from the serial communication module.

- While output from the communication module is disabled following an initial cold start of the SCS
- While the subsystem communication output data is locked.
  By locking the communication outputs before an online change, the outputs statuses on the subsystem side can be retained even after restarting the communication module.

Recovery from a serial communication module error

If the serial communication module has recovered from an error in a communication with readback, the output values on the subsystem side are tracked. The following figure illustrates the operations when communication output is locked.

If the serial communication module has generated an error, data from subsystems cannot be read back. Thus, the SCS retains the previous output values and does not output data ((1) and (2) in the following figure).

Once the serial communication module recovers and communication is enabled for the first time, data from subsystems are read back and subsystem output values are tracked ((3) in the following figure).

Following this, if an output value on the SCS side is changed, a difference occurs between the readback data and the data to be written. In this case, communication is established with the applicable subsystem to write the new data ((5) in the following figure).

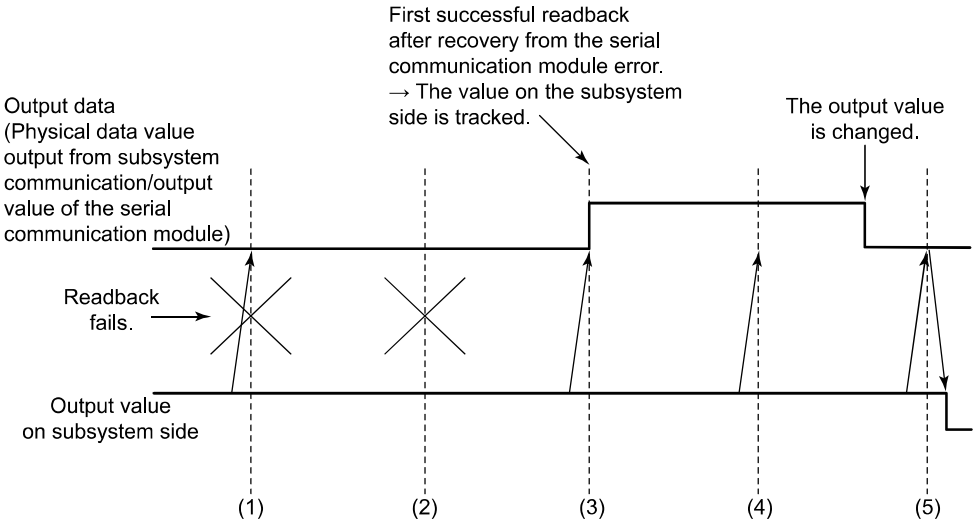

Figure D2.5-2 Operation in communication with readback after recovery from serial communication module error

Operation in communication without readback

Communication without readback is used to perform one-shot write to the Modbus PLC.

If the Modbus PLC is to accept outputs to the coils (discrete outputs) on the master side as commands to subsystems, it is necessary to perform one-shot write.

If the output to a coil is changed from OFF to ON on the master side, the Modbus PLC accepts the command and resets the corresponding output value (OFF → ON → OFF). At this time if readback is enabled, the output value will be read back from the Modbus PLC, in which case the Modbus PLC's value will be compared with the value to be written. If a difference is detected, communication will be established to write the new data again. If it is necessary to perform one-shot write, disable readback.

Without readback, output values are not read back.

The serial communication module checks the output values on the CPU side at the subsystem communication period, and does not perform communication to write data if the previous output values have not changed ((1), (3), (4) and (5) in the following figure).

Data is written only when a change is detected in any output value on the CPU side ((2) in the following figure).

Since readback communication is not performed, communication to write data is not performed, even after an output value has been changed on the Modbus PLC side ((4) in the following figure).

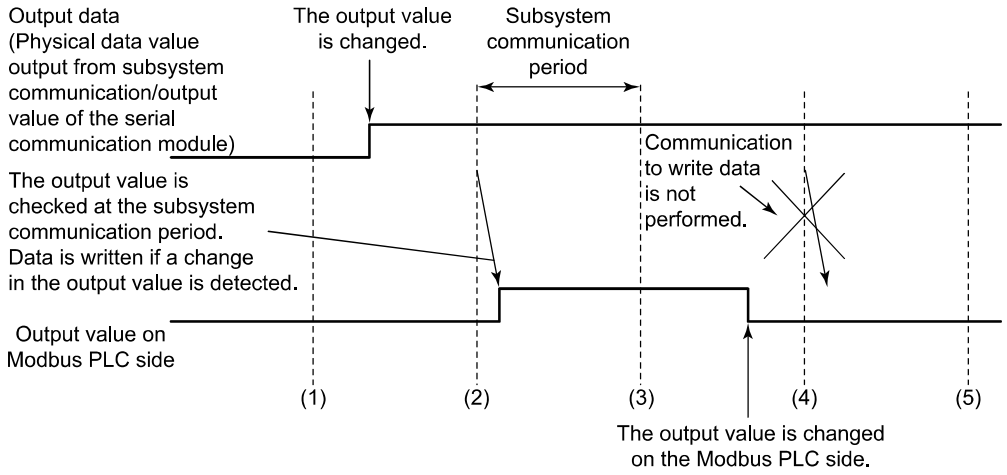

Figure D2.5-3 Output communication without readback

Settings of Option 2 (wind-up function)

The wind-up function is enabled only when a function code without readback is specified in "Device Address" in the Communication I/O Builder. Without readback, output starts when an output value has been changed on the master side. Thus, the wind-up function disables all changes to output values for 70 seconds following a reset of the serial communication module, in order to prevent unnecessary write accesses after the reset. Enable/disable this function by setting Option 2, which is an I/O parameter for Port 1 or Port 2.

- When Option 2 is set to 0
  The wind-up function is enabled.

  If the serial communication module is reset, changes to output values will not be written to the Modbus PLC for 70 seconds following the reset. Changes to output values will be written to the Modbus PLC only after elapse of 70 seconds following the reset.

- When Option 2 is set to 1
  The wind-up function is disabled. (Wind-up disable)

SEE ALSO For more information about function codes specified in [Device Address], refer to:

D2.3, “Modbus PLC devices accessible from SCSs” on page D2-10

Recovery from a serial communication module error (wind-up function enabled)

After the serial communication module recovers from an error, output values will be initialized at 0 ((1) in the following figure).

If I/O parameter "Option 2" is set to 0, changes in output values will not be written to the Modbus PLC for 70 seconds after the recovery ((3) in the following figure). Thus, discrepancies will occur between the output values on the SCS side and those on the subsystem side immediately after the reset of the serial communication module, until the output values are changed on the subsystem side.

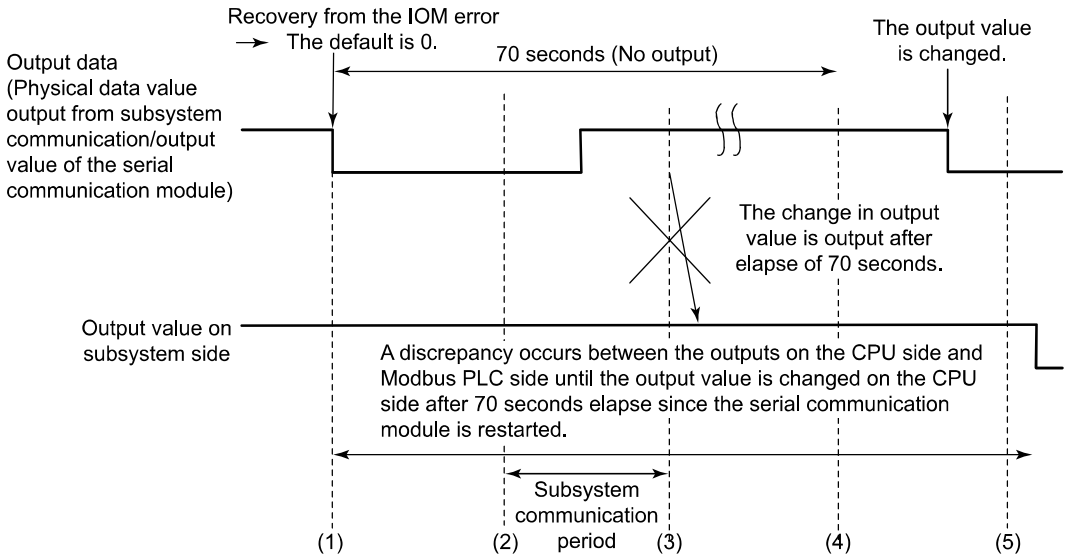

Figure D2.5-4 Operation in communication without readback after recovery from serial communication module error

With readback, output values are read back, so the differences between read-back values and values to be written are detected and the new data are written even when the output values have not been written to subsystems. Without readback, however, data will not be written unless output values on the SCS side are changed. For this reason, the statuses of output values on the SCS side may remain different from those on the Modbus PLC side after output values have been changed on the Modbus PLC or the serial communication module has been reset.

Error handling actions in communication without readback

The error handling actions in communication without readback are as follows:

- Initial cold start of the CPU (Output disabled)
  When output is disabled, the defaults of physical communication output data are 0. Output is not performed until any output value is changed on the CPU side. Once output is enabled, output will be performed when any output value is changed to a value other than 0 on the CPU side. The output timing varies depending on the setting of the wind-up function.
- Occurrence of a serial communication module error while subsystem communication data is locked
  When an error of serial communication module occurs or online change that may reset the serial communication module is performed, if any output value is changed to a value other than 0, output acts just like after an initial cold start of the CPU. The output timing varies depending on the setting of the wind-up function.

Status in communication without readback

Without readback, whether the status of communication data becomes BAD upon a serial communication error is determined by the following conditions:

- Whether there is any data to read from the station to communicate with
- The recovery communication specification that is set as I/O parameter "Option 1"

Table D2.5-1 When communication data that defined without readback becomes BAD upon serial communication error

Option 1 setting(*1)		If there is no readback for all the communication definitions for one station	If at least one communication definition for the station has readback
0	Perform recovery communication using a 08 command (loopback check command)	The status will change to BAD if a communication error occurs during a communication to write data. (If "Option 1" is set to 2, the status will automatically return to normal when recovery communication is performed.)	The status will change to BAD if a communication error occurs during a communication to write data. The status will also change to BAD if a communication error occurs in which abnormal line communication is recognized (no response, line NRDY, etc.) during a communication based on a definition with readback (input definition, or output definition with readback).
1	Perform recovery communication using a READ command		
2	Reset the error condition when recovery communication is performed		
3	Perform recovery communication using a WRITE command of 0 write size		
4	Perform recovery communication using a WRITE command based on the data written immediately before the error		
5	Do not recognize an error nor perform recovery communication	Always normal	

*1: Applicable only to the recovery communication methods without readback. With readback, recovery communication is performed using a READ command.

TIP

In addition to the previously listed conditions, the status will also change to BAD in the following cases:

- Occurrence of a serial communication module error or error in the path from the CPU to the serial communication module
- Occurrence of a range error of station number setting, range error of address setting or other definition error
- With readback, if a serial communication error occurs, the status of communication data becomes BAD at readback that is performed at every subsystem communication period.

D2.6 Recovery communication

If no response is received or a CRC-16 code error occurs during communication with a Modbus PLC, communication with the applicable station is temporarily suspended. Thereafter, communication is performed at the interval of connection retries that is set in an I/O parameter to check if the Modbus PLC that generated an error has recovered to normal state. This communication is called "recovery communication."

This section explains recovery communication.

Types and details of recovery communication

The recovery communication method is determined by the setting of I/O parameter "Option."

Option 1 (Recovery communication specification)

Recovery communication can be performed using the following five methods:

- When Option 1 is set to 0
  With readback, recovery communication is performed using a READ command.

  Without readback, recovery communication is performed using a 08 command. The 08 command is a loopback check command used to check presence of the subsystem.
- When Option 1 is set to 1
  Recovery communication is performed using a READ command regardless of the readback setting.
- When Option 1 is set to 2
  With readback, recovery communication is performed using a READ command.

  Without readback, the error condition will be reset when recovery communication is performed. If the same station generates an error again during recovery communication, a system alarm will generate every time recovery communication is performed.
- When Option 1 is set to 3
  With readback, recovery communication is performed using a READ command.

  Without readback, recovery communication is performed using a WRITE command of 0 write size.
- When Option 1 is set to 4
  With readback, recovery communication is performed using a READ command.

  Without readback, recovery communication is performed using a WRITE command based on the data written immediately before the error.
- When Option 1 is set to 5
  With readback, recovery communication is performed using a READ command.

  Without readback, any station that generated an error is not recognized as an error station. When Option 1 is set to 5, communication with the non-responding Modbus PLC will stop for the period corresponding to "No response time x (1 + Number of retries)" after each interval of connection retries set in the communication module definition.

IMPORTANT

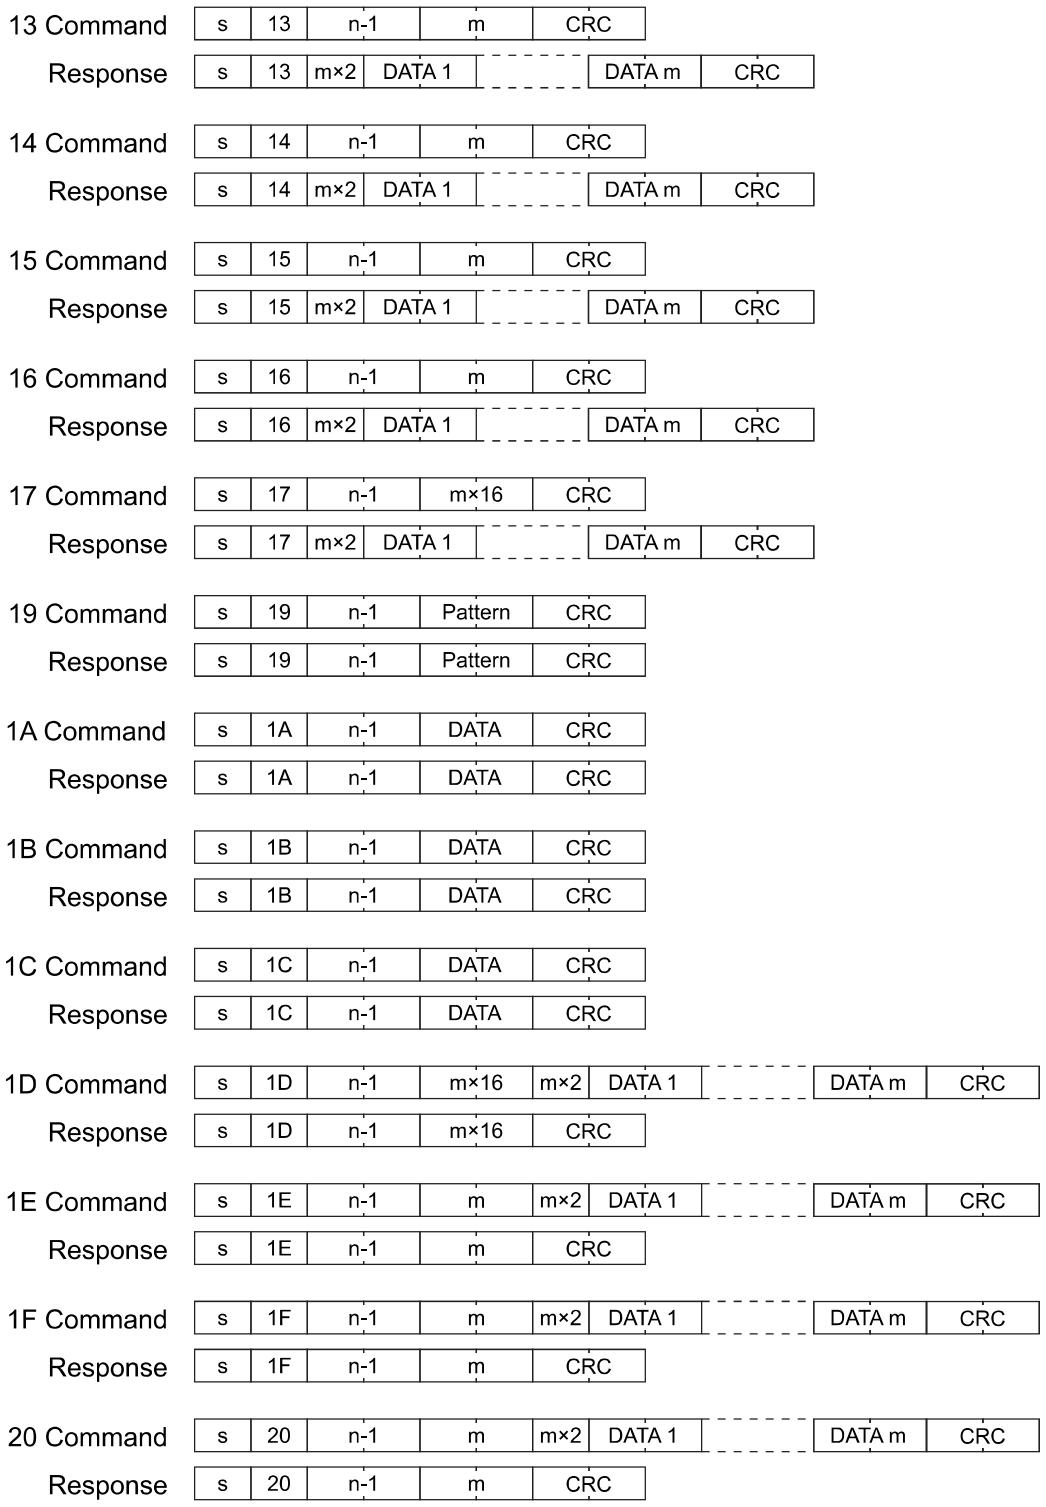
- When Option 1 is set to 4, recovery communication is performed using the data written immediately before the error. Exercise caution since duplicate operation commands may occur if the data written immediately before the error contained an operation command to the Modbus PLC.
- On some Modbus PLC models, reading with a READ command may reset the flag. If you don't want to cause the discrepancy, specify a function code without readback in "Device Address" of the communication definitions on Communication I/O Builder.

The 08 command cannot be used for some types of Modbus PLC models.

SEE ALSO For more information about Modbus PLC, refer to:

Modbus PLC user manuals

D2.7 Communication text



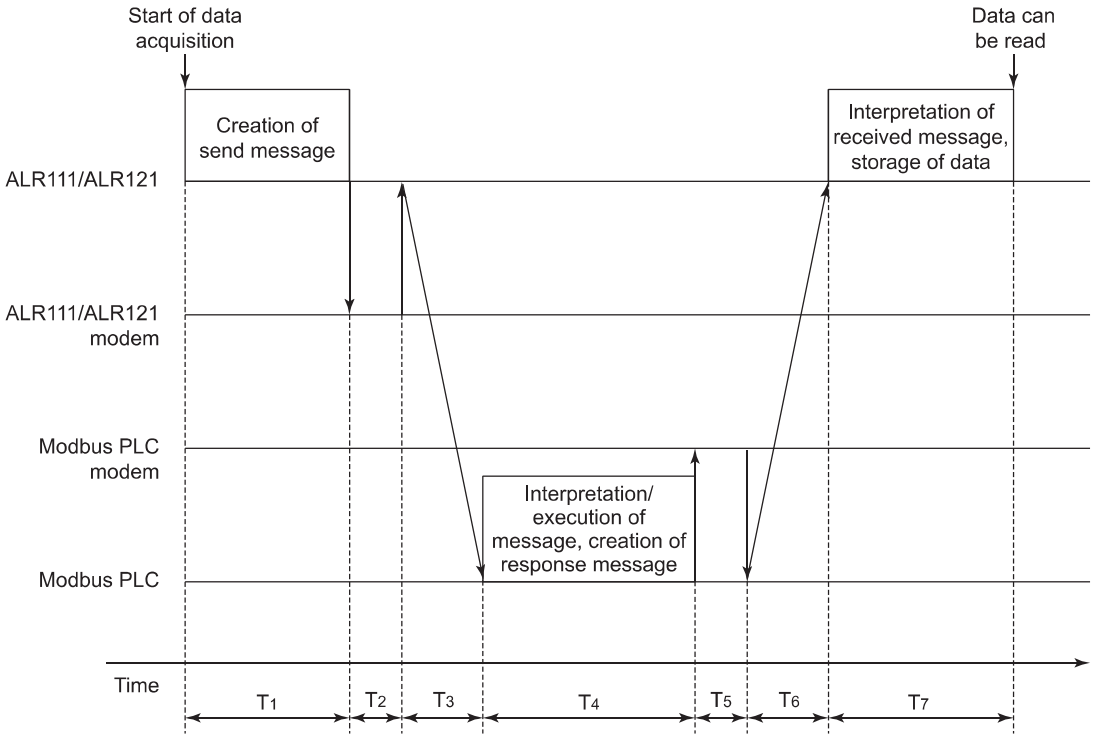
This section describes the communication text used in the Modbus protocol.

The communication text contains frames for each command in the Modbus protocol and a response to the command. The structures of communication text frames are as follows:

01 Command	s	01	n-1	m×16	CRC				
Response	s	01	m×2	DATA 1				DATA m	CRC
02 Command	s	02	n-1	m×16	CRC				
Response	s	02	m×2	DATA 1				DATA m	CRC
03 Command	s	03	n-1	m	CRC				
Response	s	03	m×2	DATA 1				DATA m	CRC
04 Command	s	04	n-1	m	CRC				
Response	s	04	m×2	DATA 1				DATA m	CRC
05 Command	s	05	n-1	Pattern	CRC				
Response	s	05	n-1	Pattern	CRC				
06 Command	s	06	n-1	DATA	CRC				
Response	s	06	n-1	DATA	CRC				
07 Command	s	07	CRC						
Response	s	07	DT	CRC					
08 Command	s	08	code	DATA	CRC				
Response	s	08	code	DATA	CRC				
0F Command	s	0F	n-1	m×16	m×2	DATA 1		DATA m	CRC
Response	s	0F	n-1	m×16	CRC				
10 Command	s	10	n-1	m	m×2	DATA 1		DATA m	CRC
Response	s	10	n-1	m	CRC				
11 Command	s	11	n-1	m	CRC				
Response	s	11	CRC						
12 Command	s	12	n-1	m×16	CRC				
Response	s	12	m×2	DATA 1				DATA m	CRC

s: Station number
n: Relative value from the beginning of the address within device
With holding register 40050, for example, n becomes 49 (40050 - 40001 = 49).
m: Assigned size set in the Communication I/O Builder (in words)
Pattern: “0xFF00” if ON, or “0x0000” if OFF

Figure D2.7-1 Communication text frame structures (1/2)



s: Station number
n: Relative value from the beginning of the address within device
With holding register 40050, for example, n becomes 49 (40050 - 40001 = 49).
m: Assigned size set in the Communication I/O Builder (in words)
Pattern: “0xFF00” if ON, or “0x0000” if OFF

Figure D2.7-2 Communication text frame structures (2/2)

D2.8 Communication time between serial communication module and Modbus PLC

The communication time between a serial communication module and a Modbus PLC is calculated as the total sum of T1 through T7 as follows.

T1: Time for creating a send message: Approx. 10 ms
T2: Delay time of the ALR111/ALR121 modem: Approx. 5 ms
T3: Time for transmitting the send message.
T4: Processing time in the Modbus PLC. Time for interpreting/executing the received message and creating a response message. Determined by the number of communication data items and number of scans performed by the Modbus PLC.
T5: Delay time of the Modbus PLC modem: Approx. 5 ms
T6: Time for transmitting the response message.
T7: Time for interpreting the response message: Approx. 15 ms

Figure D2.8-1 Timing chart for communication between a serial communication module and a Modbus PLC

TIP

Since each port performs communication independently, the sum of times required for all communication definitions set for each port becomes the data update time of the port. For example, if definitions 1 and 2 are set for port 1,
the communication period of port 1 is calculated as "(communication time for definition 1) + (communication time for definition 2)".

The following shows how to calculate the communication time.

The transmission time for sending (T3) and receiving (T6) can be calculated by using the following formulas:

$$T3 \text{ or } T6 = \frac{1000 \times \text{Number of characters} \times \text{Number of bits per one character}}{\text{Baud rate}} \text{ (ms)}$$

Number of bits per one character = Number of start bits (1) + Number of data bits (8)
+ Number of parity bits (1)
+ Number of stop bits (1)

Start bit: Fixed at 1 bit
Data bits: Fixed at 8 bits (7 bits cannot be specified)
Parity bit: Set 1 if parity is even or odd, set 0 if parity is none
Stop bit: Fixed at 1 bit
Baud rate: 1200, 2400, 4800, 9600, 19200, 38400 bps

The following table shows the character length of each device that can be transmitted by Modbus communication.

Table D2.8-1 Number of characters transmitted

Device	Read		Write	
	Send	Response	Send	Response
Coil	Fixed to 8	5 + Number of coils/8 (*1)	9 + Number of coils/4 (*1)	Fixed to 8
Holding register	Fixed to 8	5 + 2 x Number of registers	9 + 2 x Number of registers	Fixed to 8
Input relay	Fixed to 8	5 + Number of relays / 8 (*1)	-	-
Input register	Fixed to 8	5 + 2 x Number of registers	-	-

*1: Fractions after the decimal point are rounded up.

D2.9 Precautions for engineering

The subsystem communication function is used to read and set input/output data in subsystems from an SCS. SCS supports the Modbus communication protocol.

Mount a serial communication module on the SCS to connect to other systems. By accessing data of other systems via the subsystem communication from the SCS, connection with PLCS, outputs to LED and so forth can be established. Communication data from subsystems is handled by using subsystem communication input/output FBs in the application logic. The subsystem communication function does not affect the safety functions executed in the SCS.

Application capacities

The application capacity regarding subsystem communication is shown as follows:

Table D2.9-1 Application capacities

Item	Maximum number	Remarks
Number of communication modules that can be mounted	4 modules (2 pairs)/SCS	(*1) (*2)
Dual-redundancy	Possible	
Number of communication data units	2000 or 500 data units/SCS	(*3) (*4)
Communication I/O size	1000 words/SCS	(*5) (*6)
Size of data that can be communicated per communication module	1000 words	
Number of ports used per communication module	2 ports	Same protocol for the 2 ports
Number of subsystem stations that SCS can communicate with per port	30 stations	
Number of communication definitions per module	128 definitions	

*1: Total number of ALR111/ALR121/ALE111 for the subsystem communication that is mounted to the same SCS
*2: Communication modules for the Modbus slave communication and DNP3 communication are not included in the count.
*3: This specifies the number of data items that can be wired to subsystem communication input/output FB instances.
*4: 2000 data units for SCSP3, SCSL2, SCSP2, SCSP1, SCSU1, and 500 data units for SCSV1.
*5: The maximum total size of data that can be assigned to discrete inputs/outputs is 256 words (4096 bits).
*6: It is not allowed to wire the subsystem communication I/O FB instances and the allocated areas beyond the limitation on total number of communication data.

SEE ALSO For more information about details on requirements of the entire SCS for installing ALR111/ALR121, refer to:

A5.3, “Restrictions on installation of hardware” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Dual-redundancy of communication

Communication can be made dual-redundant by using two adjacent serial communication modules (an odd numbered slot and the slot with the same number +1). This redundancy method makes the communication module and communication paths to the subsystem dual-redundant. When a communication module or subsystem error occurs (including the communication errors caused by a communication routing error, subsystem interface error and so on), the dual-redundancy scheme automatically chooses the normal module as the controlling module.

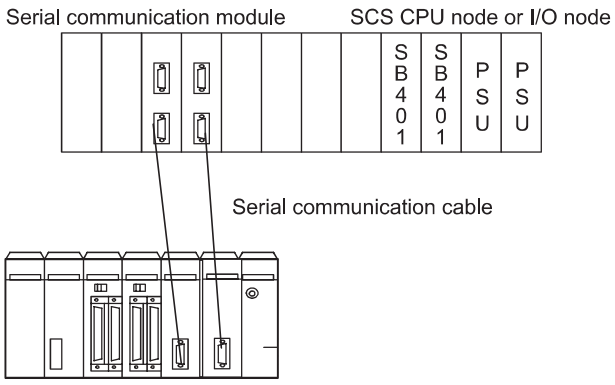


Figure D2.9-1 Example of dual-redundant communication

Two dual-redundant serial communication modules are controlled by the basic software in the CPU on the control side in order to determine which is the control side and which is the standby side. A communication module that operates normally and communicates normally with the subsystems is selected to be the control side.

The module on the control side performs read and write communication.

The module on the standby side performs read communication to diagnose the communication path.

The control right is switched from the serial communication module on the control side to the serial communication module on the standby side if either one of the following conditions is met.

- An error has been detected in the communication module on the control side and the communication module on the standby side is normal.
- An error has occurred on the control side and all communication on the standby side (2 ports) is normal.

Conditions for dual-redundancy

Modules on both sides (paths on both sides) must be able to read and write devices of subsystems. If the subsystem side is dual-redundant and reading and writing are restricted due to control rights of subsystems, communication modules cannot be made dual-redundant.

Only packages performing readback communication can make an output dual-redundant. In Modbus communication, if readback communication is disabled using the Communication I/O Builder, dual-redundancy cannot be applied.

Precautions for dual-redundant modules

The control right is determined by checking each module. This means that even if a communication error occurs on the control side, the control right is not switched unless all communication (all communication via both ports if two ports are used by one communication module) on the standby side is normal.

Data update is stopped from the time a communication error occurs and is detected on the control side until the time the control right is switched. For example, when the control right is switched due to no response from serial communication module, a communication error occurs after the following "Elapsed Time" passes.

- Elapsed Time = Response time x (number of retries + 1)

Definition of dual-redundancy

- Definition of Communication Modules

A communication module should be defined using an odd number slot. If redundancy is specified, the even number slot immediately to the right is automatically defined as a communication module as well.

- Communication Definition
  The same communication definition is used for both communication modules.

  The communication definition should be assigned to the communication module placed in the odd number slot. The same communication definition as the odd number slot is automatically assigned to the communication module in the even number slot as well.

SEE ALSO For more information about subsystem communication function, refer to:

D1., “Common items regarding subsystem communication functions” on page D1-1

About impact of online change download

The following table shows the impact of online change download of items related to the subsystem communication that can be changed online on communication modules or subsystems communication input/output FB.

Table D2.9-2 Impact of online change download

Items that can be changed online	Impact on communication modules	Impact on logic (communication input/output FBs)
Modification of transmission definition Addition of communication definition Deletion of communication definition Change of communication definition	Communication modules whose definitions are changed are restarted. No impact on other communication modules.	Communication input/output FBs wired to changed communication modules become faulty during restarting of the communication modules. They return to normal after completion of communication module restarting. No impact on other communication input/output FBs.
Addition of subsystem communication input/output FB (*1)	No impact.	Added communication input/output FBs take fixed values during online change. They return to normal operation after completion of online change.
Change of wiring for subsystem communication input/output FB	No impact.	The change is reflected. No impact on other communication input/output FBs.
Deletion of subsystem communication input/output FB Change of input operation at errors	No impact.	No impact on other communication input/output FBs.

*1: Recreating communication input/output FBs after deleting existing communication input/output FB instances is also regarded as addition of communication input/output FB.

SEE ALSO For more information about impact of online change download, refer to:

E1.7, “Online change of subsystem communication modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

About readback communication operations

If readback communication is enabled, outputs on the subsystem side are read and write communication is not performed unless the readback value is different from the value to be written. If the output value is changed in the CPU, and this causes the readback value to be different from the value to be written, write communication to the subsystem side is performed. If the output value is changed on the subsystem side while normal communication, and this causes the readback value to be different from the value to be written, write communication to the subsystem side is performed.

If readback communication is disabled, write communication is only performed at the timing of communication periods where the previous output value and the current output value are different. This means that even if the output value is changed on the subsystem side, a communication module does not perform write communication again.

Note that the function code of the address specified by Communication I/O Builder determines whether or not to perform readback in the Modbus communication.

Table D2.9-3 Readback communication operation

Item	With readback	Without readback
CPU initialization start (Output disabled status)	If outputs are disabled, the physical data of the communication input/output data is set to the value read back from the subsystem. The value read back from the subsystem is output until the output enable operation is performed.	If outputs are disabled, the initial value of the physical communication input/output data is set to 0. No output is made until the output value is changed. The value is output when it changes to a non-zero value after the output enable operation. (*1)
Error in locked communication module (at communication module error, online change causing a communication module to reset)	If errors occur in the ALR111/ALR121 modules or in the communication, or online changes are made while communication modules are locked, the physical data of the communication input/output data is set to the value read back from a subsystem. The value on the subsystem side is set to the output value by locking the output when performing maintenance and online change.	In the same way as in the case of initialization start, the output value is set to 0 and the value is output when it changes to a non-zero value. (*1)
Communication error	The status becomes BAD if a communication error occurs.	Even if a communication error occurs, the BAD status may not be notified. When a communication error occurs, no output is made and the output of the CPU and the output of a subsystem become different.
Dual-redundant	Dual-redundancy is supported.	Dual-redundancy is not supported if addresses without readback are used.

*1: This is handled by a function that suppresses writing for 70 seconds after restart if ALR111/ALR121 modules are restarted. This function can be disabled by changing the Option 2 setting.

SEE ALSO For more information about option settings, refer to:

D2.1, “Communication specifications” on page D2-2

D3. Modbus communication (for ALE111)

Modbus communication (for ALE111) is a function that mounts ALE111 (Ethernet communication module) in the SCS, and performs communication between the Ethernet interface in Modbus PLC and ALE111.

The Modbus/TCP master is the SCS, and the Modbus/TCP slave is Modbus PLC.

You can use Modbus communication (for ALE111) in the SCS of ProSafe-RS R4.01 or later.

Target models

The following are the supported models in Modbus communication (for ALE111):

- STARDOM autonomous controller: FCN, FCJ
- FA-M3 range-free controller: F3SP71-4S, F3SP76-7S
- Gas chromatograph: GC8000

The target model of Modbus communication (for ALE111) is referred to as Modbus/TCP PLC.

D3.1 Communication specifications

This section describes the specifications for communication between an SCS and a Modbus/TCP PLC.

Communication capacity

The following table shows the Modbus communication (for ALE111) capacity applicable to subsystem communication between the SCS and a Modbus/TCP PLC.

Table D3.1-1 Modbus communication (for ALE111) communication capacity

Item	Maximum capacity	Remarks
Number of communication modules that can be mounted	4 modules (2 pairs)/SCS	(*1) (*2)
Amount of data that can be transmitted by a single ALE111	1,000 words (1 word = 16 bits)	Limitations of the SCS Communication I/O data area: 1,000 words per SCS Number of communication data units: 2000 data units per SCS
Number of subsystem stations that can be communicated with	30 stations per port	
Size of communication data per communication definition	Word device read: 125 words Word device write: 100 words Bit device read: 2,000 bits Bit device write: 800 bits	One communication definition corresponds to one communication. This limitation corresponds to one communication in the Modbus/TCP protocol.
Number of communication definitions per module	128 definitions	
Number of usable ports	1	Ethernet port number in ALE111 is 1.

*1: Total number of ALR111/ALR121/ALE111 for the subsystem communication that is mounted to the same SCS
*2: Communication modules for the Modbus slave communication and DNP3 communication are not included in the count.

Simultaneity of communication data

Modbus/TCP PLCs assure simultaneity of communication data in units of 16 bits. Accordingly, simultaneity of communication data between an Ethernet communication module and a Modbus/TCP PLC is also assured in units of 16 bits.

TIP

Modbus/TCP PLCs process data in units of 16 bits. Simultaneity of 32-bit data depends on the application software used on the Modbus/TCP PLC side. To assure simultaneity of communication data in units of 32 bits, the application software on the Modbus/TCP PLC side needs to set 32-bit data within the same control period.

Transmission specifications

The transmission specifications for subsystem communication with a Modbus/TCP PLC are as follows.

Table D3.1-2 Transmission specifications

Item	Description (*1)	Remarks
Interface	Ethernet	IEEE802.3 compliant
Physical layer	10BASE-T	
Baud rate	10 Mbps	
Transmission method	Half-duplex	

Continues on the next page

Table D3.1-2 Transmission specifications (Table continued)

Item	Description (*1)	Remarks
Communication protocol	ARP, ICMP, UDP/IP, and TCP/IP	
Data type	Binary	
Response timeout	0 to 99 sec [4 sec]	When specified as 0, the default value (4 sec) will be reset in ALE111.
Communication retry	0 to 99 [1]	When specified as 0, the default value (once) will be reset in ALE111.
Interval of connection retries	0 to 999 sec [30 sec]	When specified as 0, the default value (30 sec) will be reset in ALE111.
Error control (CRC-16, etc.)	None	
Option 1	0 to 65535 [502]	Port number (set to 502, if 0)
Option 2	0 to 512 [0]	Setting range: 0 to 512 When connecting with a dual-redundant CPU in STARDOM, specify as 512. For other cases, specify as 0 (default value).
Option 3	0	Not used
Option 4	0	Not used

*1: The recommended settings are shown in [].

It is compliant with the protocols that are described in the following:

OPEN Modbus/TCP SPECIFICATION Release 1.0, 29 March 1999 Andy Swales Schneider Electric

Communication error code

Modbus/TCP PLC-specific error codes resulting from address and communication errors are shown in the following table.

Table D3.1-3 Communication error code list

Error code	Description
A3B0	No response
A3B1 (*1)	Subsystem station number out of range
A3B2 (*1)	Subsystem station number specified as 0
A3B3 (*1)	Address definition is abnormal (abnormality in specified element type)
A3B4 (*1)	Address definition is abnormal (abnormality in specified element number)
A3B5 (*1)	Too many communication points
A3B6 (*1)	Writing to a read-only command occurred
A3B8 (*1)	Odd number is used for the size of 4-byte register
A3B9 (*1)	Option value is out of range
A3BA (*1)	Cannot create communication frame
A3BC (*1)	IP address is not specified
A3BD	Maximum number of connection in subsystem exceeded
A3C1	The station number in received text is abnormal
A3C2	The element number in received text is abnormal
A3C3	The function code in received text is abnormal

Continues on the next page

Table D3.1-3 Communication error code list (Table continued)

Error code	Description
A3C4	Data in received text is abnormal
A3C5	Data size in received text is abnormal
A3C6	The length of the received text is abnormal
A3D1 (*2)	Error code $01 received
A3D2 (*2)	Error code $02 received
A3D3 (*2)	Error code $03 received
A3D4 (*2)	Error code $04 received
A3D5 (*2)	Error code $05 received
A3D6 (*2)	Error code $06 received
A3D7 (*2)	Error code $07 received
A3D8 (*2)	Error code $08 received
A3D9 (*2)	Error code $09 received
A3DA (*2)	Error code $0A received
A3DB (*2)	Error code $0B received
A3DC (*2)	Error code $0C received
A3DD (*2)	Error code $0D received
A3DE (*2)	Error code $0E received
A3DF (*2)	Error code $0F received
A3E0 (*2)	Error code $10 received
A3E1 (*2)	Error code $11 received
A3E2 (*2)	Error code $12 received
A3E3 (*2)	Error code $13 received
A3E4 (*2)	Error code $14 received
A3E5 (*2)	Error code $15 received
A3E6 (*2)	Error code $16 received
A3E7 (*2)	Error code $17 received
A3E8 (*2)	Error code $18 received

*1: This error is a definition error of ALE111. If this error occurs, no communication can be performed to the Modbus/TCP PLC.
*2: This is an error when an error message and an error code are received from the Modbus/TCP PLC.

D3.2 Modbus/TCP PLC devices accessible from the SCS

This section describes the Modbus/TCP PLC devices that can be accessed from the SCS.

Internal data of a Modbus/TCP PLC are called "devices". Devices can be bit devices or word devices, as described in the following explanation:

- Bit devices
  Data in which each bit has a meaning. An input relay is a bit device.
- Word devices
  Data in which each word (1 word = 16 bits) has a meaning. A holding register is a word device.

Modbus/TCP PLCs also have devices called "special coil" and "communication status".

Accessible devices

To access Modbus/TCP PLC devices, you must set [Comm Device & Address] of Signal Definition and [Size] of Communication Definition in the Safety Communication I/O Editor, or set [Device Address] and [Size] in the Communication I/O Builder.

With Modbus/TCP PLCs, "Device Address" is set by using the following format:

<Function code> + <Device type> + <Address within device>

To specify input relays 100012 to 100015, for example, set A100012 for "Device Address" and 1 for "Size." "A" of A100012 indicates a function code, "1" indicates a device type, and "00012" indicates an address within device.

The following table lists the Modbus/TCP PLC devices accessible from the SCS, as well as the corresponding addresses and Modbus protocol function codes.

Table D3.2-1 Bit devices list

Device	Address			Modbus/TCP protocol function code (hexadecimal)	
	Function code	Modbus/TCP PLC device type	Address in the Modbus/TCP PLC device	Read	Write
Coil	A	0	XXXX (*1)	01	0F
	B				05
	X			-	0F
	Y				05
Input relay	A	1	XXXX (*1)	02	-

*1: In Modicon Premium, XXXX is the reference number.

Table D3.2-2 Word devices list

Device	Address			Modbus/TCP protocol function code (hexadecimal)	
	Function code	Modbus/TCP PLC device type	Address in the Modbus/TCP PLC device	Read	Write
Input register	A	3	XXXX (*1)	04	-
	C				

Continues on the next page

Table D3.2-2 Word devices list (Table continued)

Device	Address			Modbus/TCP protocol function code (hexadecimal)	
	Function code	Modbus/TCP PLC device type	Address in the Modbus/TCP PLC device	Read	Write
Holding register	A	4	XXXX (*1)	03	10
	B				06
	C				10
	D				16 (*2)
	X			-	10
	Y				06
	Z				10
	W				16 (*2)

*1: In Modicon Premium, XXXX is the reference number.
*2: 16 command is not supported in Modicon Quantum/Premium.

Table D3.2-3 Other devices

Device	Address			Modbus/TCP protocol function code (hexadecimal)	
	Function code	Modbus/TCP PLC device type	Address in the Modbus/TCP PLC device	Read	Write
Special coil	SP000			07 (*1)	-
Communication status	STSXXX (*2)			-	-

*1: 07 command is not supported in Modicon Premium.
*2: XXX is the station number of PLC.

The meaning of each function code is as follows. The size is specified in the Safety Communication I/O Editor or Communication I/O Builder.

- A
  Read data for the specified size.

  Write data for the specified size. Readback is supported.
- B
  Read data for the specified size.

  Writes data individually to each modified device in units of 1 bit for a bit device, or in units of 16 bits for a word device. Readback is supported.
- C
  Read data for the specified size.

  Writes data individually to each modified device in units of 32 bits. Readback is supported.
- D
  Read data for the specified size.

  Writes data individually to each modified word device in units of 1 bit. Readback is supported.
- X
  Write data for the specified size when a change occurs. Readback is not supported.
- Y
  Writes data individually only to each modified device for the size of each device when a change occurs. Readback is not supported.

- Z
  Writes data individually only to each modified device in units of 32 bits when a change occurs. Readback is not supported.
- W
  Writes data individually only to each modified word device in units of 1 bit when a change occurs. Readback is not supported.

Table D3.2-4 List of function codes

Function code	Device	Read	Write	Readback
A	Bit	Read collectively	Write collectively	Yes
	Word	Read collectively	Write collectively	Yes
B	Bit	Read collectively	1-bit	Yes
	Word	Read collectively	16-bit	Yes
C	Word	Read collectively	32-bit	Yes
D	Word	16-bit	1-bit	Yes
X	Bit	-	Write collectively	None
	Word	-	Write collectively	None
Y	Bit	-	1-bit	None
	Word	-	16-bit	None
Z	Word	-	32-bit	None
W	Word	-	1-bit	None

IMPORTANT

In a dual-redundant configuration based on ALE111, only writing of data to the Modbus/TCP PLC with readback is supported. Writing of data without readback is not supported in a dual-redundant configuration.

Supported function codes, accessible devices, and sizes vary depending on the Modbus/TCP PLC model.

SEE ALSO

For more information about readback communication, refer to:

D2.5, “Readback communication” on page D2-20

For more information about supported function codes, accessible devices, sizes, and so on, refer to:

the user manual for the Modbus/TCP PLC being used

D3.3 Builder setting items in the Modbus communication

This section explains the builder settings in the Modbus communication when the Ethernet communication module is used.

When performing RS original engineering, you can define the Ethernet communication module and set I/O parameters by using I/O Wiring View and I/O Parameter Builder. After defining the Ethernet communication module and setting I/O parameters, you need to allocate the communication I/O data, and assign element numbers and subsystem communication I/O FBs by using Communication I/O Builder.

When performing I/O list engineering, you can define the Ethernet communication module, set I/O parameters, allocate communication I/O data, and allocate element numbers to subsystem communication I/O FB by using IOM Definition Editor and Safety Communication I/O Editor.

TIP

This section mainly describes for the case when performing RS original engineering. The setting item names displayed may differ between I/O list engineering and RS original engineering, but the settings are the same.

SEE ALSO

For more information about engineering of subsystem communication modules using Safety Communication I/O Editor, refer to:

D1.5, “Engineering for subsystem communication modules” on page D1-37

For more information about I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

D3.3.1 Settings in the I/O Wiring View

When performing RS original engineering, you need to set the following items by using the I/O Wiring View.

- Subsystem communication module definition
- Dual-redundant Ethernet communication module

Subsystem communication module definition

If an ALE111 is used for subsystem communication, you need to select ALE111M as the module type. You need to specify the mounting position (node, slot number) of the module, as well as whether or not to use a dual-redundant configuration.

Dual-redundant Ethernet communication module

To use Ethernet communication modules in a dual-redundant configuration, you need to set IsRedundant to TRUE.

D3.3.2 Settings in the I/O Parameter Builder

When performing RS original engineering, you need to set the following items in ALE111M by using the I/O Parameter Builder.

Connection Device

You need to set the type of connection device.

You should select S_MODTCP when you use the subsystem communication function in Modbus/TCP.

Default value: S_MODTCP

S_MODTCP: Modbus/TCP slave

Comment

You can enter a comment regarding the Ethernet communication module. This comment can be entered by using up to 24 single-byte characters or 12 double-byte characters.

IP Address

You need to set the IP address of the Ethernet communication module. You can enter any IP address that you want.

Default: This field is empty by default; be sure to enter an IP address. If no value is entered, an error occurs when you try to save the settings in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following IP addresses:

- Host address digits are all zeros or all ones in binary form.
(Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Any of the numbers delimited with a period has leading zeros.
(Example: 192.168.08.09, 192.168.008.009, etc.)

Subnet Mask

You need to set the subnet mask of the Ethernet communication module. You can enter a subnet mask that you want.

Default: This field is empty by default; be sure to enter a subnet mask. If no value is entered, an error occurs when you try to save the settings in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following subnet masks:

- Values less than 255.0.0.0 for a class A IP address
(Example: 128.0.0.0)
- Values less than 255.255.0.0 for a class B IP address
(Example: 255.128.0.0)
- Values less than 255.255.255.0 for a class C IP address
(Example: 255.255.128.0)

Default Gateway

You need to set the gateway address of the Ethernet communication module. You can enter a desired gateway address.

Default: Blank

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following gateway addresses:

- Host address digits are all zeros or all ones in binary form.
(Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Network address digits do not match the IP address.
(IP address is 192.168.1.1 and default gateway address is 192.168.2.2 when the subnet mask is 255.255.255.0.)
- Any of the numbers delimited with a period has leading zeros.
(Example: 192.168.08.09, 192.168.008.009, etc.)

Paired IP Address

When an Ethernet communication module is set to dual-redundant configuration, you need to set the IP address of the Ethernet communication module in even slot. You can enter any IP address that you want.

Default: The default value is empty by default; be sure to enter a paired IP address. If the paired IP address is not set with the dual-redundant configuration enabled, there will be an error when saving in the builder. If the paired IP address is set with the dual-redundant configuration disabled, there will be an error when saving in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following IP addresses:

- Host address digits are all zeros or all ones in binary form.
(Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Any of the numbers delimited with a period has leading zeros.
(Example: 192.168.08.09, 192.168.008.009, etc.)

Paired Default Gateway

When an Ethernet communication module is set to dual-redundant configuration, you need to set the IP address of the default gateway that is used by an Ethernet communication module in even slot. You can enter any IP address that you want.

Default: The default value is empty by default; be sure to enter an IP address of a dual-redundant default gateway. If the IP address of paired default gateway is not set with the dual-redundant configuration enabled, there will be an error when saving in the builder. If the IP address of paired default gateway is set with the dual-redundant configuration disabled, there will be an error when saving in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following IP addresses:

- Host address digits are all zeros or all ones in binary form.
  (Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Network address digits do not match the IP address.
  (IP address is 192.168.1.1 and default gateway address is 192.168.2.2 when the subnet mask is 255.255.255.0.)
- Any of the numbers delimited with a period has leading zeros.
  (Example: 192.168.08.09, 192.168.008.009, etc.)

Response Timeout

You need to set the timeout period to wait for subsystem response. The unit is in seconds.

Default: 4 sec

Setting range: 0 to 99 sec

Communication Retry

You need to set the number of retries to be attempted after a communication error occurs.

Default: 1 time

Setting range: 0 to 99 times

Interval of Connection Retries

You need to set the interval of communication with a station that generated a communication error to check for recovery of communication (recovery communication). The unit is in seconds.

Default: 30 sec

Setting range: 0 to 999 sec

Port number

You need to set the port number of the Modbus/TCP.

Default: 502

Setting range: 0 to 65535

Option (1 to 4)

You need to set option 1 or 2 for Modbus/TCP.

Option 1

You need to set the TCP/IP port number in option 1.

When set as 0, it will operate in the same manner when 502 is set.

Option 2

You need to set the recovery communication method in option 2.

When connecting with a dual-redundant CPU of STARDOM, you need to set 512 as specified in recovery communication. For other cases, you need to set to 0 (default value).

D3.3.3 Settings in the Communication I/O Builder

This section describes the ALE111-specific setting items in the Communication I/O Builder.

It mentions about the following items when using Modbus/TCP PLC.

- Program Name
- Port
- IP Address
- 2nd IP Address

Program Name

You need to set the program name by using the node number, slot number and S_MODTCP, as follows:

Program Name : n-s fixed character string

- n: Node number
- s: Slot number
- Fixed character string: S_MODTCP

Port

You need to set the port that is used in the subsystem communication module.

Always set to 1.

IP Address

You need to set the IP address of the equipment in the subsystem to be used.

Set the IP address of the Modbus/TCP PLC.

2nd IP Address

When the Ethernet communication module and Modbus/TCP PLC communication interface are set to dual-redundant configuration, you need to set the IP address (2nd IP address) of the subsystem side where the Ethernet communication module on the odd slot communicates.

Do not set 2nd IP address if the Modbus/TCP PLC communication interface is not set to dual-redundant configuration.

Device Address

You need to set the start address of the data in Modbus/TCP PLC.

The following table shows the addresses that can be set.

Nothing is specified by default.

Coil:	A0xxxx, B0xxxx, X0xxxx, Y0xxxx
Input relay:	A1xxxx
Input register:	A3xxxx, C3xxxx
Holding register:	A4xxxx, B4xxxx, C4xxxx, D4xxxx, X4xxxx, Y4xxxx, Z4xxxx, W4xxxx
Special coil:	SP000

Communication status: STSxxx

"xxxx" indicates an address within Modbus/TCP PLC device, and is set as a decimal or hexadecimal value between 0 and 65535 (0H and FFFFH). If a hexadecimal value is used, add "H" at the end.

The 0 or 0s at the beginning of "xxxx" can be omitted. For example, coil addresses of A023, A0023 and A00023 all represent the same address.

SEE ALSO For more information about specifying addresses, refer to:

D3.2, “Modbus/TCP PLC devices accessible from the SCS” on page D3-5

D3.4 Actions during unsteady state

This section describes the precautions relating to actions in the ALE111 when recovering from an unsteady state during a system abnormality, online change, and other occurrences. I/O operation, data status, and other operations during an unsteady state are in the same manner as the operation in serial communication module.

Actions for ALE111 during unsteady state

The following table shows an unsteady state in the Ethernet communication module, and operations between Ethernet communication module and the subsystem.

Table D3.4-1 Actions for ALE111 during unsteady state

Causes of unsteady state	Handling actions for ALE111 after recovery
Stopping both CPU	Resume communication (*1)
Power outage in the system	Reconnection standby (*2)
Offline download	Reconnection standby (*2)
Switching control right	Continuation (*3)
Power outage in the node	Reconnection standby (*2)
Communication error on both nodes	Resume communication (*1)
ALE111 maintenance (connection and disconnection)	Reconnection standby (*2)
Switching control right in ALE111	Continuation (*3)
IOM Loading for ALE111	Resume communication (*1)
Online change in ALE111 transmission definition	Resume communication (*1)
Online change of communication I/O definition	Resume communication (*1)

*1: Communication will immediately resume after recovery from an abnormality.
*2: The connection for ALE111 communication will not be established until connection in the other communicating party is closed. It takes a few minutes from the system error occurrence to the closing of the connection in the other communicating party. Communication function in ALE111 will be determined as abnormal after connection is retried, and an SSCOM error message is sent.
*3: It does not affect the state in ALE111. It will continue to operate.

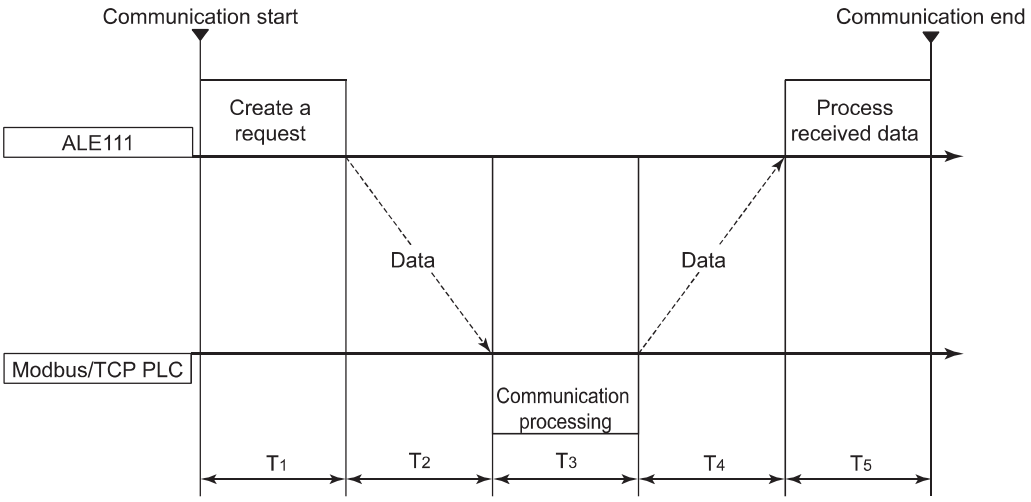
Reconnection standby

When ALE111 suddenly stops due to system abnormalities such as node power outage, module connection and disconnection, the connection that operates communication in the ALE111 will be lost. After starting communication program in the ALE111, it will attempt to reconnect with the other communicating party. However, while the connection state is maintained by the subsystem, connection request from ALE111 fails and communication will not be recovered. The time when the connection state is maintained in the subsystem depends on the configuration of the TCP/IP KeepAlive function (connection existence confirmation monitor).

If the connection is terminated with an error, the communication program in ALE111 will run based on the specified number of communication error retries. If it is possible to use multiple lines in the same TCP/IP port number, and if there is a line in non-connected state in the subsystem of the communication destination party, ALE111 will establish a connection using a different pathway in the reconnection. In this case, communication will be immediately recovered after starting ALE111.

If ALE111 communication program cannot establish connection with the communication destination party even after a specified number of retries, it will be determined as a connection error, and an SS-COM error message will be output. Then, ALE111 will retry connection at a specified interval of connection retries.

SEE ALSO For more information about how to configure the KeepAlive function and the behavior thereof, refer to:



manual for each subsystem

Resuming communication

Connection in the ALE111 will be turned off during online change of ALE 111 transmission definition and communication I/O definition, IOM download for ALE111, and recovery from a system error in the route positioned above the ALE111. This will delete the subsystem connection in the communication destination party, and will immediately recover communication upon starting the ALE111.

D3.5 Communication time between Ethernet communication module and Modbus/TCP PLC

The communication time between an Ethernet communication module and a Modbus/TCP PLC is calculated as the total sum of T1 through T5 as follows.

T1: Request creation time on the ALE111 side Approx. 10 ms
T2: Request (command) transmission time
T3: Reply creation time on the Modbus/TCP PLC side
(CPU processing time on the Modbus/TCP PLC side)
T4: Reply (response) transmission time
T5: Received data processing time on the ALE111 side Approx. 10 ms

Figure D3.5-1 Timing chart for communication between a communication module and a Modbus/TCP PLC

The following shows how to calculate the communication time.

In the following example, calculation of time is provided where 50 holding register values are read.

Communication time is calculated based on the following criteria:

Compared to other processes, command transmission time (T_2) and response transmission time (T_4) take up smaller time. With T_2 and T_4 combined, it takes up 1 to 5 ms. In this example, the whole time will be calculated as $T_2 + T_4 = 5$ ms.

- Modbus/TCP PLC scan period: 50 ms

Command transmission time (T_2) + Response transmission time (T_4) = 5 ms

Modbus/TCP PLC CPU processing time (T_3) = 50 ms

$$\text{Total time} = \sum_{i=1}^{5} Ti = 10 + 5 + 50 + 10 = 75 \text{ ms}$$

TIP

Communication time is just for reference as it is greatly affected by the network traffic.

D4. ProSafe-SLS communication (for ALR121)

ProSafe-RS can acquire events of ProSafe-SLS and data using subsystem communication. Acquired events and data can be handled on SCS in the same way existing events and data are handled. If ProSafe-RS is integrated with a CENTUM system, the events and data of ProSafe-SLS can be comprehensively managed by using HIS.

SCS communicates with the communication module of ProSafe-SLS through a communication module (model: ALR121). This communication enables the following operations:

- Data access
  ProSafe-RS can access the input/output data of ProSafe-SLS using the subsystem communication function.
- Event acquisition
  ProSafe-RS can acquire the events generated by ProSafe-SLS.

  To integrate events of ProSafe-SLS with ProSafe-RS, synchronize the time of ProSafe-SLS with that of SCS to align the time stamps of these events to events of ProSafe-RS.
- Alarm notification
  To notify CENTUM HIS of error conditions as alarms when the error conditions are detected based on the diagnostic information of ProSafe-SLS, it is necessary to perform engineering and configure an application on both the ProSafe-SLS side and ProSafe-RS side.

SEE ALSO For more information about event notified in the case of a ProSafe-SLS error, refer to:

TI of ProSafe-SLS

D4.1 Operating environment

ProSafe-SLS is the only subsystem that the ProSafe-SLS communication function supports. If ProSafe-SLS and other subsystem are connected to the same communication path, proper operation of the ProSafe-SLS communication function cannot be guaranteed. To use the ProSafe-SLS communication function, check the conditions that are applicable to connection devices, subsystem communication program, and other aspects of operating environment explained here, and then make the necessary preparations.

Available input/output modules

The following table shows the input/output modules that can be used for the ProSafe-SLS communication function.

Table D4.1-1 Input/output modules that can be used for the ProSafe-SLS communication function

Model	Type	Purpose
ALR121	Serial communication module (RS-422/RS-485 interface)	For Modbus protocol (RTU mode)
SDV531	Digital output module (8 channels, 24 V DC, module isolation)	For time synchronization
SDV531-L/ L1DV531-L	Digital output module (8 channels, 24 V DC, module isolation, for long distance)	
SDV541/ L1DV541	Digital output module (16 channels, 24 V DC, module isolation)	

Available subsystem communication program

Use S_SLSMOD as the subsystem communication program for the ProSafe-SLS communication function.

S_SLSMOD is applicable only to ALR121. The S_SLSMOD-compatible hardware revisions of ALR121 conform to the conditions under which S_MODBUS can be applied.

Configuration of communication modules

When the subsystem communication program, S_SLSMOD, is applied for the communication module (model: ALR121), ALR121 can be used only in a non-redundant configuration.

D4.2 System configuration

The following figure shows an overall system configuration where ProSafe-SLS is connected to ProSafe-RS.

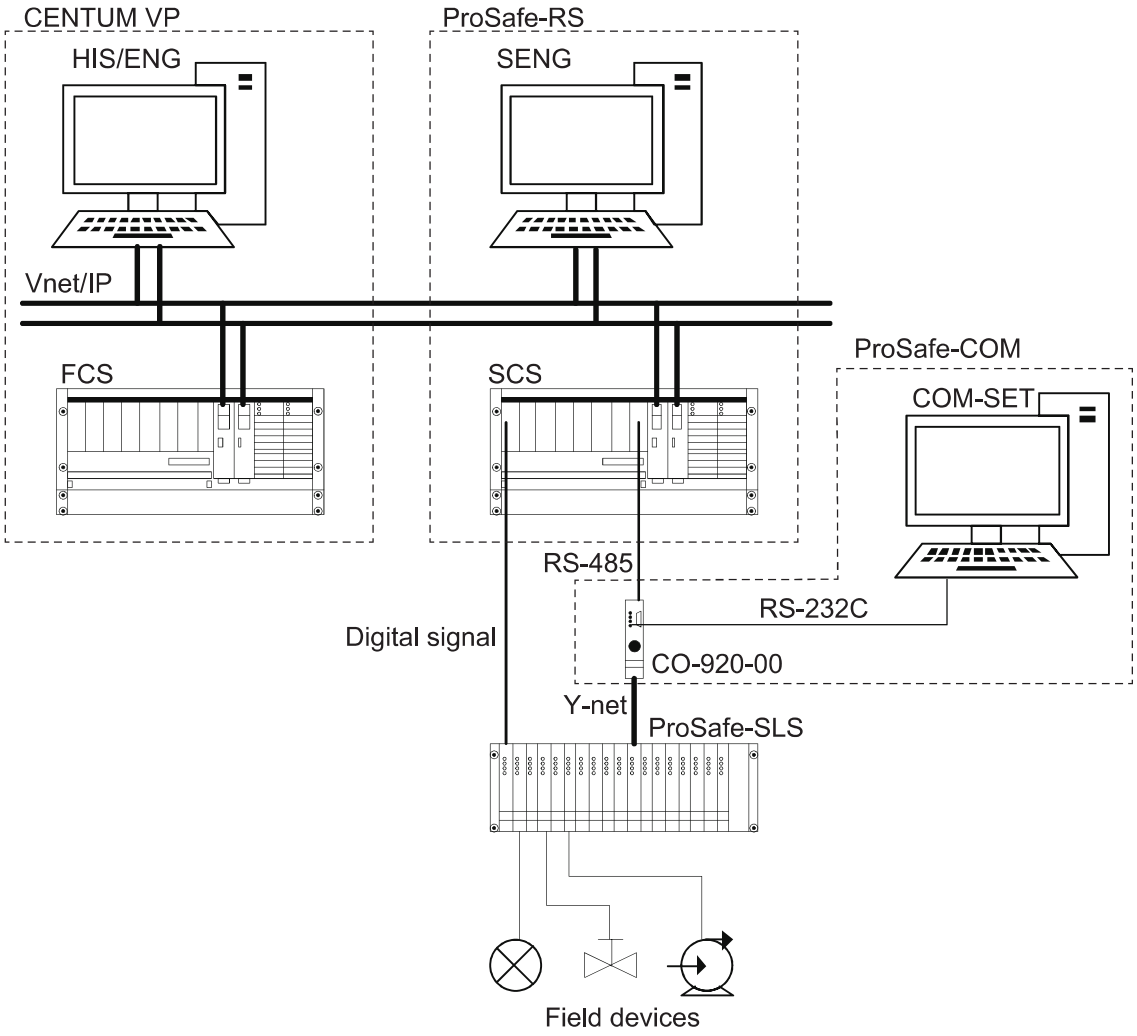


Figure D4.2-1 Example of an overall system configuration

The following table explains the terms that are used in the figure.

Table D4.2-1 Description of terms

Term	Description
ProSafe-SLS	A SIL4-certified safety instrumented system. It can be connected to other system through ProSafe-COM.
ProSafe-COM	One component of a safety instrumented system. It provides the communication function to connect ProSafe-SLS and other systems.
CO-920-00	A communication module that is one of the ProSafe-COM products. This module is hereinafter referred to as "CO-920."
COM-SET	Software package. This package is used for engineering and maintenance of CO-920. It also provides the function to display SOE events of CO-920. SET stands for "System Engineering Tool."
Y-net	A local network that connects each ProSafe-SLS module and ProSafe-COM. RS-485 serial communication is used.

D4.2.1 Connection configuration of SCS and ProSafe-SLS

The following figure shows the connection configuration of ProSafe-RS SCS and ProSafe-SLS.

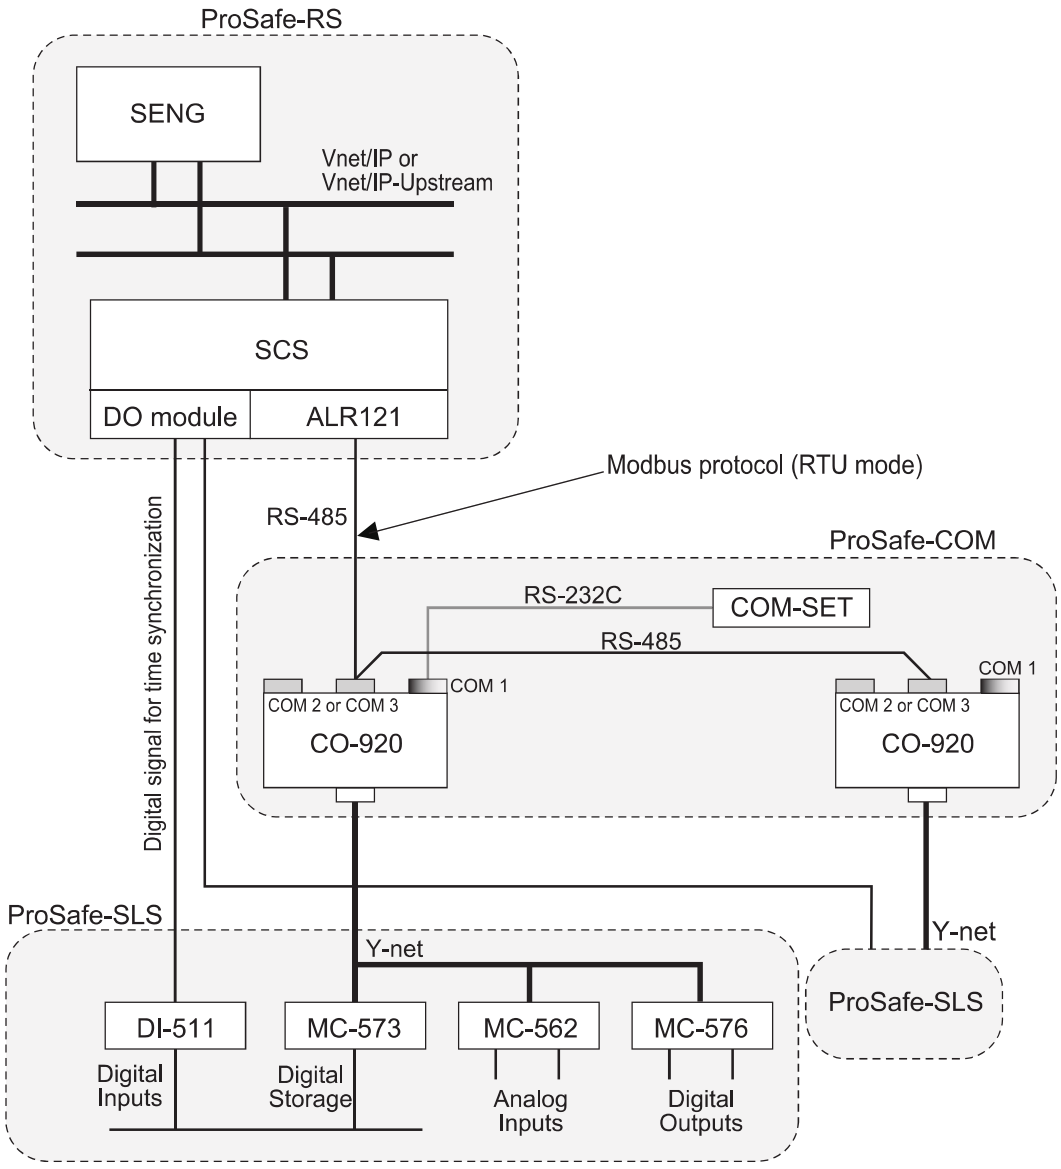

Figure D4.2.1-1 Connection configuration of ProSafe-RS SCS and ProSafe-SLS

"Vnet/IP or Vnet/IP-Upstream" in the figure is hereinafter abbreviated as "Vnet/IP."

To display the events of ProSafe-SLS in the SOE viewer as with the event data of SENG, the time of ProSafe-SLS must be synchronized with that of ProSafe-RS. The event time stamps given by ProSafe-SLS are used directly by ProSafe-RS. Connect the DO module of SCS and the DI module of ProSafe-SLS to synchronize the time.

D4.2.2 System overview of ProSafe-SLS

ProSafe-SLS is a safety system that can be applied to installations requiring the SIL4 safety level.

ProSafe-COM is one component of a safety system.

CO-920 is a communication module and one of ProSafe-COM products, which can be directly installed on a standard 19-inch cassette connector for ProSafe-SLS. To connect ProSafe-SLS to ProSafe-RS, connect CO-920 to ProSafe-RS as a communication interface with ProSafe-SLS.

For more information about the ProSafe-SLS system, refer to IMs of ProSafe-SLS.

Communication interface of ProSafe-SLS

Use Y-net as the communication interface between the ProSafe-SLS and external devices. Y-net is a local ProSafe-SLS network. Use CO-920 as an interface between the Modbus and Y-net networks. The external interface of CO-920 consists of one RS-232C port (port name: COM1) and two RS-485 ports (port names: COM2 and COM3).

The CO-920 acquires the events of ProSafe-SLS modules, time-stamps the acquired events based on its internal clock, sorts them chronologically, and then stores the sorted events in the event buffer. The resolution of time stamp is 1 ms. Events are stored in the event buffer according to the FIFO method.

Various engineering tasks on CO-920 are performed from the application software COM-SET by using RS-232 communication.

Communication interface between ALR121 and CO-920

The COM port of ALR121 in SCS is connected to the COM port of CO-920 by using RS-485 communication, and the two ports communicate with each other according to the Modbus protocol (RTU mode).

ALR121 (Modbus master) can access the I/O data of each ProSafe-SLS module that is connected to Y-net by using standard Modbus commands. It can also acquire ProSafe-SLS events from CO-920 by using expansion Modbus commands.

You need to download the subsystem communication program S_SLSMOD into ALR121. S_SLSMOD, which is a ProSafe-SLS communication program, can be used only by ALR121.

Setting the ProSafe-SLS time using an external clock

The ProSafe-SLS time can be set by using an external clock. When a change event involving a DI module associated with ProSafe-SLS time synchronization occurs, the CO-920 time is set to a fixed time.

D4.3 Data access

The ProSafe-RS can access input/output data of ProSafe-SLS by using the subsystem communication function. The Modbus protocol (RTU mode) is used for the communication protocol.

If the ProSafe-RS is integrated with a CENTUM system, the accessed data can be monitored using the HIS.

Handling of ProSafe-SLS communication data

The data that is collected by the ProSafe-RS by accessing the ProSafe-SLS can be handled by the communication input FBs and communication output FBs.

The subsystem communication FBs that can be used in connection with the ProSafe-SLS communication function are interference-free function blocks and cannot be used for input of safety loops.

A POU containing any subsystem communication FB that can be used under the ProSafe-SLS communication function must be approved by using the Integrity analyzer.

The following subsystem communication input FBs can be used in connection with the ProSafe-SLS communication function.

- SCI_B
- SCI_I

The following subsystem communication output FBs can be used in connection with the ProSafe-SLS communication function.

- SCO_B
- SCO_I

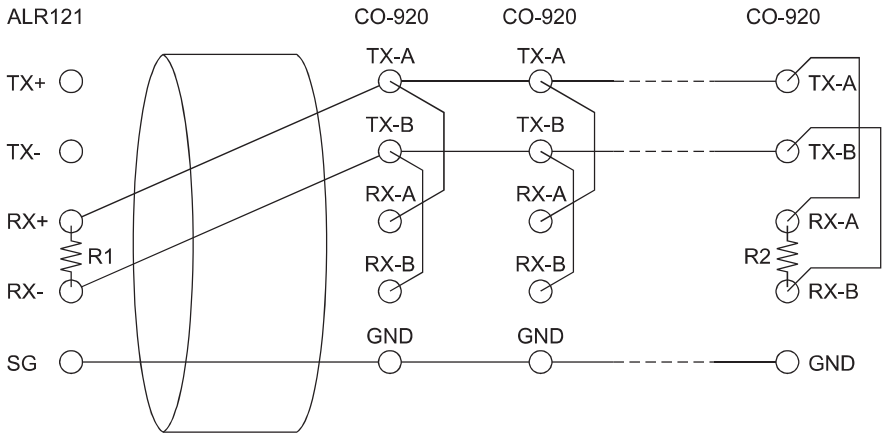
Connection interface of ProSafe-RS and ProSafe-SLS

Connect the ALR121 and CO-920 as a communication path for I/O data, events and ProSafe-SLS diagnostic information. Connect the two using 2-wire type or 4-wire type connection of RS-485 to a 1:n multi-drop configuration.



The following figure shows the 4-wire type connection of RS-485.

R1: Termination resistance of 120 ohm
R2: Termination resistance built in CO-920

Figure D4.3-1 1:n connection in 4-wire type of RS-485

The following figure shows the 2-wire type connection of RS-485.

R1: Termination resistance of 120 ohm
R2: Termination resistance built in CO-920

Figure D4.3-2 1:n connection in 2-wire type of RS-485

SEE ALSO For more information about connection method on the CO-920 side, refer to:

manual of CO-920

D4.4 Event acquisition

The SCS acquires events from the communication module of ProSafe-SLS (model: CO-920) through the communication module (model: ALR121). Acquired events are stored in the SOER event information storage area inside the SCS memory and integrated with existing SOE events. If a CENTUM system is integrated, acquired events can be viewed in the SOE Viewer of HIS.

You can not specify the events acquired from ProSafe-SLS as the trip signal of ProSafe-RS.

The Forcing function does not apply to events. Even if you lock the communication module (model: ALR121), events will remain unlocked. The SCS will continue to store events acquired from CO-920 into the SOE buffer.

SEE ALSO For more information about SOE event message acquired from the ProSafe-SLS, refer to:

"■ Event information displayed on SOE Viewer" on page D4-22

■ Basic event acquisition operation and time stamp

The subsystem communication program S_SLSMOD acquires events from the CO-920 of the specified station number based on the event acquisition communication definitions.

S_SLSMOD acquires events from the CO-920 periodically. If the subsystem communication period consists of one communication session for all communication definitions that are set for one ALR121 port, one event is acquired in one communication period.

Events are acquired into SCS in the order stored in the CO-920. The time stamps may become slightly imprecise for events that occur around when CO-920's time is set or around when time synchronization with SCS takes place.

■ SCS operation to acquire stored events

In the following situations, multiple events have already been stored in CO-920. The SCS acquires the stored events altogether.

- The SCS is connected to the CO-920 for the first time.
- The SCS changes the COM port to which the CO-920 is connected.
- The SCS, which was down for a long time but is finally recovered, is reconnected to the CO-920.
- The SCS is reconnected to the CO-920 after the communication was cut off for a long period of time because the faulty ALR121 was replaced, etc.
- Multiple events occur at the same time because ProSafe-SLS generated an error or shut down.

In order to acquire all stored events, the SCS continuously acquire events from CO-920 according to the communication definitions. The continuous acquisition of events begins from the next event after the last event acquired from CO-920. As the same with the normal communication, one event is acquired from CO-920 in one subsystem communication period.

■ Cautions when starting event acquisition

When the SCS continuously acquires multiple events that are already stored in the CO-920, it may take several hours for all events to be acquired, after the start of event acquisition, if many events are stored in the CO-920. In this case, a time lag of several hours may occur to acquire the latest event because the latest event of the CO-920 is acquired after the acquisition of all stored events is completed.

If events that are already stored in the ProSafe-SLS and not yet acquired by the ProSafe-RS are not needed, connect the COM-SET to the maintenance port of the CO-920 (port name:

COM1) and acquire the stored events from the CO-920, and then clear all events of the CO-920, so as to prevent these events from being acquired over a long period of time.

Events acquired by the COM-SET cannot be integrated with the SOE events of the ProSafe-RS.

Causes of event acquisition communication error

The following list describes why ALR121 sends a communication error code to the CPU:

- CO-920 is no longer responding.
  CO-920 may stop responding temporarily after being engineered from COM-SET while operating.
- An error occurred along the communication path between ALR121 and CO-920.
- A format error occurred in the response from CO-920.

IMPORTANT

Assume that ALR121 is disconnected from the SCS and then inserted again. An event acquired from ProSafe-SLS immediately before ALR121 is disconnected may be passed to the CPU module of the SCS redundantly after ALR121 is inserted into the SCS.

SEE ALSO For more information about communication error code, refer to:

"■ Communication error code" on page D2-3

Event time for SOE

The time information that is recorded at the time when an event occurs in ProSafe-SLS is the SOE event time. No new time information generates on the SCS side.

The SCS converts the event time of ProSafe-SLS to the ProSafe-RS time format, and then stores the converted time as an SOE event in the SOER event information storage memory.

D4.5 Time synchronization

All references to time in the explanation of time synchronization are described with Universal Time Coordinated (UTC).

To integrate events of ProSafe-SLS with the SOE of ProSafe-RS, it is necessary to synchronize the time of ProSafe-SLS with that of the SCS to align the time stamps of these events to those of ProSafe-RS.

The time can be synchronized by connecting the DO module of the SCS and the DI module of ProSafe-SLS.

Configuration for time synchronization

The following figure shows an example of a configuration for time synchronization using the DO module (model: SDV531).

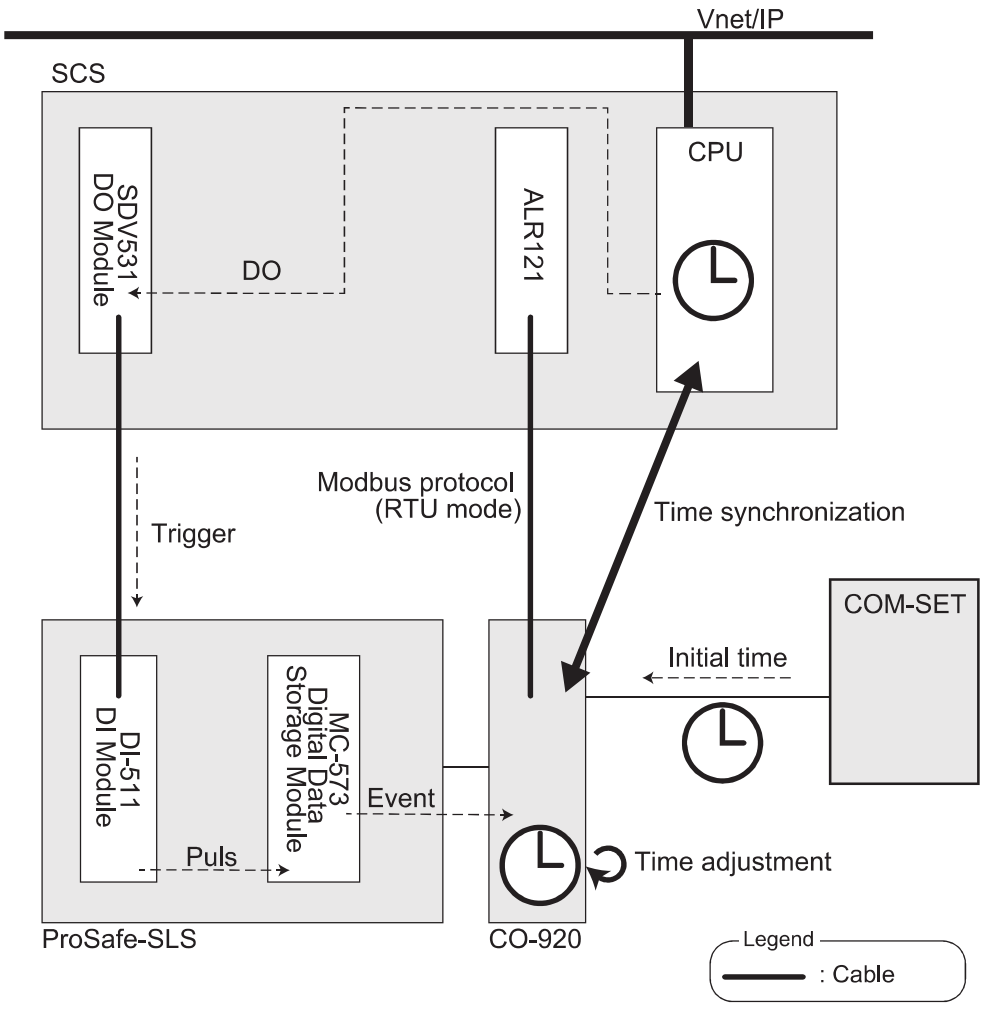


Figure D4.5-1 Configuration example for time synchronization of SCS and ProSafe-SLS

Connect the DO module of the SCS and the DI module of ProSafe-SLS.

To synchronize the time of the SCS with that of ProSafe-SLS, time synchronization parameters of CO-920 must be set from COM-SET. To set these parameters, connect COM-SET to the maintenance port of CO-920.

After the time synchronization parameters are set, cause a time synchronization event to generate periodically, for ProSafe-SLS, through the DO module and DI module, to allow for time synchronization.

It should be noted that, if multiple CO-920s are connected to the SCS, set the time synchronization parameters and also perform time synchronization through the DO module and DI module, for each CO-920.

Connection between ProSafe-RS DO module and ProSafe-SLS DI module

This section describes an example of connecting the DO module of SCS (model: SDV531 or SDV541) and DI module of ProSafe-SLS (model: DI-511) to synchronize the time of the SCS with that of the ProSafe-SLS. Bleeder resistors should be connected with the DI module in parallel to meet the minimum load current 35 mA of the DO module.

You have to prepare bleeder resistors of 730 ohm or less to do this.

A bleeder resistor of 680 ohm or less (5 W or 2 W) is recommended. When the 2-watt rated power resistor is used, the pulse width of the DO output must be set to one second or less.

Before any resistor other than the recommended one is used, please contact us.

SEE ALSO For more information about maximum length of the DI/DO cable connecting the SDV531/SDV541 and DI-511, refer to:

ProSafe-RS Outline of I/O Modules (for FIO) (GS 32P06K60-01EN)

Time synchronization setting

For the purpose of time synchronization, build an application logic, for the SCS, to output a time-setting pulse once a day.

The following list explains the configuration of ProSafe-SLS for time synchronization.

- Building a wired logic
  Build a wired logic so that a time-setting event is sent to the CO-920 from the DI module of ProSafe-SLS.
- Reflecting the COM-SET settings in CO-920
  COM-SET settings are as follows:
  - Selection of time setting method
  - Initial setting of date and time
    In COM-SET, set the initial time to which the CO-920 adjusts its time when a time-setting event occurs. Because the initial date and time are set for the purpose of time synchronization, they need not be set accurately.
  - Tag information settings
    In COM-SET, set the information of the tag that generates a time-setting event.

Mechanism of time synchronization

This section describes the mechanism of what happens after an application logic of the SCS is executed until the time of Pro-Safe SLS is synchronized with ProSafe-RS.

The following list shows an example where the time of the ProSafe-SLS is adjusted to that of the ProSafe-RS when the SCS's CPU time reaches time A.

1. When the SCS's CPU time reaches time A, the DO module (example of model: SDV531 or SDV541) of the SCS generates a pulse.
2. The pulse from the DO module is sent as an input to the DI module (model: DI-511) of ProSafe-SLS.
3. DI-511 sends an event, which is then received by the Digital Data Storage Module (model: MC-573).

4. MC-573 sends a time event to CO-920. CO-920 detects that it is a time event by checking the tag name that is contained in the event and sets its own clock to time A.

SEE ALSO For more information about engineering for time synchronization, refer to:

D4.14.3, “Engineering to configure applications on ProSafe-RS” on page D4-35

Time synchronization accuracy and calculation example

The accuracy of time synchronization of CO-920 with respect to the SCS depends on the output timing of the DO module of the SCS.

If time error is caused by the difference between the logic execution time and DO module output response time, time synchronization is always delayed by this time. If the time error is caused by other factors, time synchronization is slightly delayed or advanced.

The following list shows examples of time error calculation:

- Time error between the SCS and CO-920
  (SCS scan period) + (output response time of DO module) + (CO-920 scan period)
- Time error between CO-920s that are connected to the same SCS
  (CO-920 scan period)
- Time error between CO-920s that are connected to different SCSs
  (SCS scan period) + (CO-920 scan period)

D4.6 Alarm notification

The diagnostic information and events of ProSafe-SLS are not sent to the CENTUM system operator or ProSafe-RS as alarms or events. In order to send them to CENTUM HIS as alarms, build an application that evaluates the diagnostic information and data that are read from CO-920 and sends alarms by using annunciator FBs as necessary. If you create an application that uses SOE FBs, you can view the events through the SOE Viewer of CENTUM HIS.

From CO-920, the SCS can acquire the self-diagnostic information of Y-net and each module in ProSafe-SLS, the available space in the event buffer of CO-920 and other diagnostic information. The diagnostic information of CO-920 indicates the current statuses and values, and these statuses and values are retained while an error is present.

Alarms relating to the subsystem communication between the SCS and ProSafe-SLS are sent to HIS as subsystem communication system alarms, and to SENG, as diagnostic information messages.

To acquire diagnostic information from CO-920, perform engineering of CO-920 from COMSET.

For each system configuration, you must consider how errors should be determined by using the diagnostic information of CO-920 and how the determination result should be used. Perform engineering so that error alarms and recovery alarms are sent to the operator.

"■ Communication error code" on page D2-3

For more information about engineering for CO-920, refer to:

IM of ProSafe-SLS

D4.7 Communication specifications

This section describes the application capacity and transmission specifications that are required to build a system that uses the ProSafe-SLS communication function.

Application capacity

When you use the ProSafe-SLS communication function, you must determine the I/O data, diagnostic information, and events of ProSafe-SLS that are managed by ProSafe-RS. The following table shows the maximum capacity that is allowed for each application element.

Table D4.7-1 Application capacity

Application element	Maximum capacity	Description
Number of ALR121 that can be installed per SCS	4	(*1) (*2)
Number of communication data units per SCS	2000 or 500 data units (*3)	This specifies the number of data items that can be wired to subsystem communication FB instances. Maximum 256 words (4096 bits) are allowed for the total assignment size of discrete input/output.
Communication I/O size per SCS	1000 words	A word holds two bytes.
Size of data that can be communicated per ALR121	1000 words	-
Number of ports per ALR121	2 ports	-
Number of subsystem stations that SCS can communicate with per port	30 stations	One CO-920 is considered as a station.
Number of communication definitions per ALR121	Number of definitions that satisfies the following formula: (Number of SLSEVENT type communication definitions) x 2 + (Number of non-SLSEVENT type communication definitions) ≤ 128	-
Data size for event acquisition per ProSafe-SLS	24 words	To acquire the events from ProSafe-SLS, you must assign 24 words of communication definition for event acquisition per ProSafe-SLS.

*1: Total number of ALR111/ALR121/ALE111 for the subsystem communication that is mounted to the same SCS
*2: Communication modules for the Modbus slave communication and DNP3 communication are not included in the count.
*3: 2000 data units for SCSP3, SCSL2, SCSP2, SCSP1, SCSU1, and 500 data units for SCSV1.

Transmission specifications

The following table shows the transmission specifications for RS-485 communication that must be met in order to implement the ProSafe-SLS communication function.

Table D4.7-2 Transmission specifications

Setting items	Recommended setting	Required setting	Selection
Interface	-	RS-485	RS-422, RS-485

Continues on the next page

Table D4.7-2 Transmission specifications (Table continued)

Setting items		Recommended setting	Required setting	Selection
RS-422/RS-485 2-wire/4-wire		4-wire	-	2-wire, 4-wire
Transmission method		-	-	Half-duplex
Synchronization method		-	-	Start-stop synchronization
Baud rate (bps) (*1)		19200	-	1200, 2400, 4800, 9600, 19200, 38400
Transmission protocol		-	-	Modbus protocol (RTU mode)
Transmission code		-	-	Binary
Data type	Start bit	-	-	Fixed to 1.
	Data bit	-	8	7, 8
	Parity	Even (*2)	-	None, even, odd
	Stop bit	-	-	Fixed to 1.
Control line	RS control	-	-	Not used
	DR check	-	-	Not used
	CD check	-	-	Not used
Time monitoring	Transmission enable monitoring time	-	-	1000 ms
	Reception inter-character timer (ms)	10 (*3)	-	10 to 99999
	Generate an error upon detection of an inter-character monitoring timeout.	Do not generate an error (*3)	-	Do not generate an error
Text frame	Reception start character	-	-	None
	EOT character	-	-	None
XON/XOFF control		-	-	None
Response timeout (sec)		4	-	0 to 99
Communication retry		1 time	-	0 to 99 times
Interval of connection retries (sec)		30	-	0 to 999
Transmission wait time		-	-	1 sec
Option 1		-	-	Not used
Option 2		-	-	Not used
Option 3		-	-	Not used
Option 4		-	-	Not used

*1: The baud rate of the CO-920 is initially set to a value that is not included in the options. Ensure that the baud rate that is set for the CO-920 is the same as this baud rate setting.
*2: The initial setting of CO-920 parity is "None." It is recommended to set a parity to improve reliability. Ensure that the parity setting of the CO-920 matches this parity setting.
*3: Completion of reception is detected as an inter-character timeout. Setting a longer time for the inter-character timer delays the time to reception completion. As a guide, the timer is set to approx. 10 ms at 9600 bps. 10 ms corresponds to the time required for sending 10 characters when the baud rate is 9600 bps.

D4.8 ProSafe-SLS devices that SCS can access

With ProSafe-SLS communication, a device type is specified to access internal data in CO-920. The following list describes the types of devices:

- Bit devices
  Every bit of this data has a meaning.
- Word devices
  Every word of this data has a meaning. One word consists of 16 bits.
- Extended device
  Extended devices are specific to Modbus equipment. In CO-920, extended devices are those devices whose event data is stored in time series.

Communication module of ProSafe-SLS (model: CO-920) can be accessed from an external system according to the Modbus protocol (RTU mode).

Use standard Modbus commands to access the analog input module and digital I/O module of ProSafe-SLS from ProSafe-RS.

To access the devices, set "Device Address" and "Size" in the Safety Communication I/O Editor or Communication I/O Builder. The address format is as follows:

<Function code> + <Device type> + <Address within device>

To specify input relays 100012 to 100015, for example, set A100012 for "Device Address" and 1 for "Size." "A" of A100012 indicates a function code, "1" indicates a device type, and "00012" indicates an address within device.

The following table shows the devices that can be used in connection with the ProSafe-SLS communication function, address, and the Modbus protocol function code.

Table D4.8-1 Bit devices list

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Device types of CO-920	Internal address of CO-920 device (to the extent specifiable)	Read	Write
Coil	A	0	00001-65536	01	0F
	B				05
	X			-	0F
	Y				05
Input relay	A	1	00001-65536	02	-

Table D4.8-2 Word devices list

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Device types of CO-920	Internal address of CO-920 device (to the extent specifiable)	Read	Write
Input register	A	3	00001-65536	04	-

Continues on the next page

Table D4.8-2 Word devices list (Table continued)

Device	Address			Modbus protocol function code (hexadecimal)	
	Function code	Device types of CO-920	Internal address of CO-920 device (to the extent specifiable)	Read	Write
Holding register	A	4	00001-65536	03	10
	B				06
	C				10
	X			-	10
	Y				06
	Z				10

Meaning of function code

The meaning of each function code is as follows. The size is specified in the Safety Communication I/O Editor or Communication I/O Builder.

- A
  Read data for the specified size.

  Write data for the specified size. Readback is supported.
- B
  Read data for the specified size.

  Write data individually to each modified device in units of 1 bit for a bit device, or in units of 16 bits for a word device. With readback.
- C
  Read data for the specified size.

  Write data individually to each modified device in units of 32 bits. With readback.
- X
  Write data for the specified size when a change occurs. Readback is not supported.
- Y
  Write data individually to each modified device for the size of each device when a change occurs. Without readback.
- Z
  Write data individually to each modified device in units of 32 bits when a change occurs. Without readback.

List of function codes

The following table describes the function codes.

Table D4.8-3 List of function codes

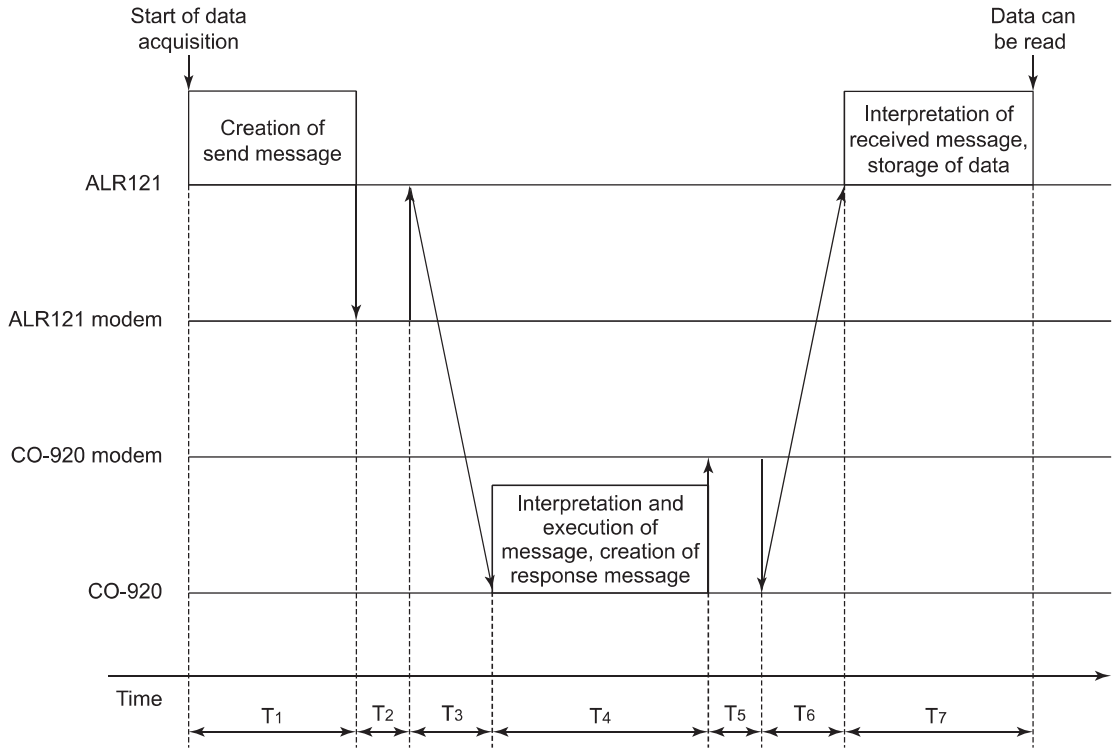
Function code	Device	Read	Write	Readback
A	Bit devices	All data for one communication definition	All data for one communication definition	Yes
	Word devices	All data for one communication definition	All data for one communication definition	Yes

Continues on the next page

Table D4.8-3 List of function codes (Table continued)

Function code	Device	Read	Write	Readback
B	Bit devices	All data for one communication definition	In units of 1 bit	Yes
	Word devices	All data for one communication definition	In units of 16 bits	Yes
C	Word devices	All data for one communication definition	In units of 32 bits	Yes
X	Bit devices	-	All data for one communication definition	No
	Word devices	-	All data for one communication definition	No
Y	Bit devices	-	In units of 1 bit	No
	Word devices	-	In units of 16 bits	No
Z	Word devices	-	In units of 32 bits	No

If readback is enabled, data is read from ProSafe-SLS, and the read data is written to the SCS if the specified data type is "Input Specification." If the data type is "Output Specification," the read data is compared against the SCS data and sent to ProSafe-SLS if the data does not match.



If readback is disabled, the SCS data is compared against the ALR121 data, and the data is sent to ProSafe-SLS only if a discrepancy is found.

SEE ALSO For more information about readback, refer to:

- "■ About readback communication operations" on page D2-33
- D2.5, "Readback communication" on page D2-20

D4.9 Communication time between communication module and CO-920

The communication time between the communication module of ProSafe-RS (model: ALR121) and CO-920 is the total period from T1 to T7 as shown in the following figure.

T1: Time for creating a send message: Approx. 10 ms
T2: Delay time of the ALR121 modem: Approx. 5 ms
T3: Time for transmitting the send message.
T4: Processing time in the Modbus PLC.
Time for interpreting and executing the received message and creating a response message.
Determined by the number of communication data items and number of scans performed by the Modbus PLC.
T5: Delay time of the Modbus PLC modem (T4 + T5): Approx. 3 ms
T6: Time for transmitting the response message.
T7: Time for interpreting the response message: Approx. 15 ms

Figure D4.9-1 Communication processing time in connection with the ProSafe-SLS communication function

The following shows how to calculate the communication time.

The transmission time for sending (T3) and receiving (T6) can be calculated by using the following formulas:

$$T3 \text{ or } T6 = \frac{1000 \times \text{Number of characters} \times \text{Number of bits per one character}}{\text{Baud rate}} \text{ (ms)}$$

Number of bits per one character = Number of start bits (1) + Number of data bits (8)
+ Number of parity bits (1)
+ Number of stop bits (1)

Start bit: Fixed at 1 bit
Data bits: Fixed at 8 bits (7 bits cannot be specified)
Parity bit: Set 1 if parity is even or odd, set 0 if parity is none
Stop bit: Fixed at 1 bit
Baud rate: 1200, 2400, 4800, 9600, 19200, 38400 bps

The following table shows the length of each frame that is transmitted by a Modbus-compliant device.

Table D4.9-1 Number of characters that can be transmitted

Device	Read		Write	
	Send	Response	Send	Response
Coil	Fixed to 8.	5 + Number of coils/ 8(*1)	9 + Number of coils/ 4(*1)	Fixed to 8.
Input relay	Fixed to 8.	5 + Number of relays/8(*1)	-	-
Input register	Fixed to 8.	5 + 2 x Number of registers	-	-
Holding register	Fixed to 8.	5 + 2 x Number of registers	9 + 2 x Number of registers	Fixed to 8.
Event	Fixed to 4.	5 + event (maximum 86)	-	-

*1: Fraction below the decimal point is rounded up.

D4.10 Data types handled by the ProSafe-SLS communication function

The following table shows the data types of subsystem communication that can be handled by the ProSafe-SLS communication function.

Table D4.10-1 Relationship between the data types of subsystem communication, and data types of the SO-920 and those of the SCS

Subsystem communication data type	CO-920 data type	SCS data type (subsystem communication FBs)
Discrete input	BOOL (bit)	SCI_B
Discrete output	BOOL (bit)	SCO_B
Analog input (16-bit unsigned integer)	16-bit unsigned integer	SCI_I
Analog output (16-bit unsigned integer)	16-bit unsigned integer	SCO_I
SLS event type	ASCII character string	N/A (*1)

*1: The SLS event type represents a data type used exclusively for acquiring ProSafe-SLS events. The SCS uses the SLS event type internally.
SLS events cannot be used in application logics.

D4.11 Message specifications

The SCS interprets the events that are acquired from ProSafe-SLS and stores them as SOE events. The stored events can be comprehensively managed with existing SCS events by using the SOE Viewer of SENG or SOE Viewer of CENTUM HIS.

The following table describes the event information that ProSafe-SLS issues.

Table D4.11-1 Event information issued by ProSafe-SLS

Event Information	ASCII format	Description
Event generation time	Set this information according to one of the following formats: • dd/mm/yyyy hh:mm:ss.msc • dd/mm/yy hh:mm:ss.msc The setting ranges for each element are as follows: dd: 01 to 31 mm: 01 to 12 yy: 00 to 99 yyyy: 0000 to 9999 hh: 00 to 23 mm: 00 to 59 ss: 00 to 59 msc: 000 to 999	Year, month, day, hours, minutes, seconds and milliseconds indicating when the event occurred. The description format of year varies depending on the format set for event character strings.
Tag name of ProSafe-SLS	ASCII character string with 25 characters Any empty digit in the 25-character tag name is filled by the ASCII character code 0x20 (SP).	ProSafe-SLS tag names associated with data at the source. The first 22 characters of the tag name of ProSafe-SLS are imported into the SOE of ProSafe-RS.
Description	ASCII character string with 25 characters Any empty digit in the 25-character description is filled by the ASCII character code 0x20 (SP).	Supplemental information regarding the tag name of ProSafe-SLS. This information is not imported into the SOE of ProSafe-RS.
Status	1 character type: 0 to 1 10 character type: 0 to 65535 The end of the 10-character status is filled by two space characters. Also, any non-character part at the beginning or end is filled by the ASCII character code 0x20 (SP).	Data value upon event generation. The range of values is as follows. 10 character type: 0 to 65535 1 character type: 0 or 1. (*1) When performing engineering on the CO-920, determine whether to use the 10 character type or 1 character type.

*1: Any 10-character value between 1 and 65535 is expressed as 1 based on the 1 character type.

Event information displayed on SOE Viewer

The SCS acquires ProSafe-SLS event information and displays it in the SOE Viewer. The following table shows the event information displayed in the SOE Viewer.

Table D4.11-2 SOE Viewer event information

Item	Description	Acquisition source of event information		
		CO-920	SCS	Subsystem communication function
Time Stamp	Date and time the event occurred Set the date format in the SOE Viewer Properties dialog box. The following format displays time: hh:mm:ss:ttt The meaning of each element is as follows: hh: Time (24 hours) mm: Minute ss: Second ttt: Millisecond	Event generation time	-	-
Quality	Empty	-	-	-
Type	SOER (fixed)	-	-	-
ID	EVT_TRUE (fixed)	-	-	-
Resource	Station name (SCSddss)	-	Station name	-
Reference (*1)	Node number (1 to 9, a to e, 1 hexadecimal character)	-	Node number	-
	Slot number (1 to 8, 1 character)	-	Slot number	-
	Port number (1 to 2, 1 character)	-	-	Port number
	Station number (01 to ff, 2 hexadecimal characters)	-	-	Station number
	Tag name of ProSafe-SLS (maximum 22 characters)	Tag name of ProSafe-SLS (first 22 of 25 characters)	-	-
Message	Data value (DINT type)	Status	-	-

*1: Display format: "SLS [Node number] [Slot number] [Port number] - [Station number]:[ProSafe-SLS tag name]"

Event display example of SOE Viewer and COM-SET

Assume that the ALR121 that is installed in slot 3 of SCS0101 node 10 acquired an event from the ProSafe-SLS of station number 24 that is connected to port 1 at 18 hours 30 minutes 15 seconds 123 milliseconds on February 24, 2015. Examples of how this is displayed in the SOE Viewer and on the COM-SET are provided in this section.

TIP

Empty fields in the table indicate that nothing is displayed for that item.

The tag name and value of the ProSafe-SLS event are DI511_1 and 1, respectively.

Table D4.11-3 Display example of SOE Viewer

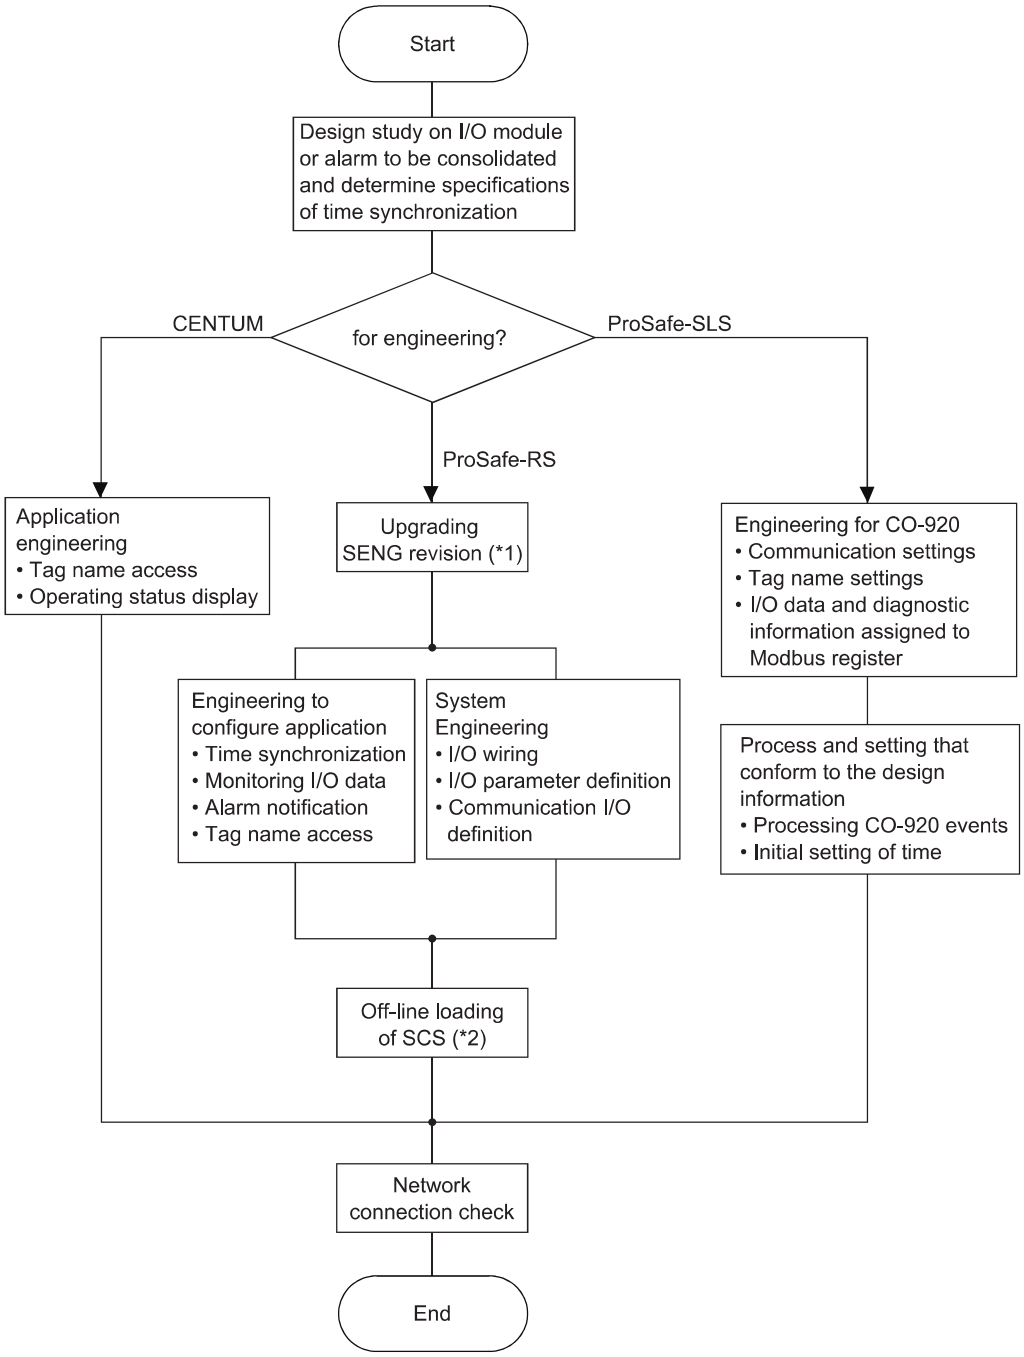
Timestamp	Quality	Type	ID	Resource	Reference	Message
02/24/2015 18:30:15.123		SOER	EVT_TRUE	SCS0101	SLSa31-18:DI-511_1 (*1)	1

*1: "a" in hexadecimal notation indicates that the node number is 10. "18" in hexadecimal notation indicates that the station number is 24.

Table D4.11-4 Display example of COM-SET

Date/Time (*1)	Tag Name	Tag Description	Status
24/02/2015 18:30:15.123	DI-511_1	TAG1	1

*1: The specific value varies depending on the set format of event character string.



D4.12 Engineering flow and builders to be used

The following table shows the builders that must be set to use the ProSafe-SLS communication function.

Table D4.12-1 Related builders and window

Purpose	Name and builders and window	Role
Engineering	IOM Definition Editor or I/O Wiring View	Definition of communication device
	IOM Definition Editor or I/O Parameter Builder	Selection of communication program
		Setting of transmission definitions for each port
	Safety Communication I/O Editor or Comm. I/O Definition tab of Communication I/O Builder	Definition of communication definition
	Safety Communication I/O Editor or Comm. I/O Wiring tab of Communication I/O Builder	Assignment of communication I/O FB to communication data
Maintenance	Communication I/O Lock Window	Reference of logical data and physical data values of I/O variables. Execution of the Forcing function.

The following figure shows the engineering flow to be followed in order to implement the ProSafe-SLS communication function.

*1: You do not need to upgrade the revision for a new project. If you intend to upgrade the revision of existing project to use ProSafe-SLS functions, you must perform offline download.

*2: If you have performed offline download of the project database in R3.02.20 or later, you can perform online download.

Figure D4.12-1 Engineering flow for ProSafe-SLS communication function

D4.13 Determining ProSafe-SLS data to be managed by ProSafe-RS

When you use the ProSafe-SLS communication function, you must determine the I/O data, diagnostic information, events, and time synchronization of ProSafe-SLS that are managed by ProSafe-RS.

D4.13.1 Determination of data and event and diagnostic information of ProSafe-SLS to monitor

Internal error information of ProSafe-SLS and CO-920 are collectively referred to as diagnostic information of ProSafe-SLS. You must determine the diagnostic information of ProSafe-SLS that you want to monitor on ProSafe-RS. Diagnostic information can be handled as both Modbus communication data and events.

Errors of devices connected to ProSafe-SLS can also be handled as Modbus communication data and events.

Monitoring the data of ProSafe-SLS-connected devices

When handling the data of the devices that are connected to ProSafe-SLS, follow these instructions during engineering from COM-SET.

- In "Taglist part" of the TAG file of CO-920, enter the tag name to be monitored as information of the connected device.
- Set the "Data acquisition area (DAR)" field of the tag name to "YIS".

Determining diagnostic information of ProSafe-SLS to monitor

Diagnostic information of CO-920 includes self-diagnosis information of Y-net and each module in the ProSafe-SLS, available space of event buffer and other information of the CO-920. The diagnostic information of the CO-920 indicates the current statuses and values, and these statuses and values are retained while an error is present.

Some diagnostic information of ProSafe-SLS changes even when an error does not occur, and if such information is to be monitored as events, important events may remain unnoticed. Among the diagnostic information of ProSafe-SLS, therefore, make sure the following items are monitored:

- Communication status of COM port
- Y-net network integrity

If you want to select other items, investigate the need to do so by referring to the ProSafe-SLS manual.

Monitoring changes in diagnostic information of ProSafe-SLS

If the SCS receives diagnostic information of ProSafe-SLS through Modbus communication and diagnostic information changes multiple times at a rate faster than the communication cycle of the Modbus communication, the ALR121 may not be able to acquire the changes in diagnostic information, causing some missing data. Even the alarm notification application cannot send an alarm related to missing data.

Missing data will not occur at the SOE so long as diagnostic information of ProSafe-SLS is an input to the SCS as SLS events. In this case, SOE events are recorded even when no alarm is sent based on Modbus communication data.

To input changes in the applicable diagnostic information as SLS events, enable event generation when you set information on the tag names corresponding to the applicable diagnostic information of CO-920. To be specific, when performing engineering from the COM-SET, set the "Generate event" field of the tag name to monitor as diagnostic information, at "Taglist part" in the TAG file on the CO-920, to "Y."

After event generation is permitted, SOE is logged at the timing of a change on diagnostic information. On SOE Viewer, the tag name is indicated on Reference.

D4.13.2 Determining the time for time synchronization

To use the ProSafe-SLS communication function, time synchronization between ProSafe-SLS and SCS must be triggered by the output pulse from SCS once a day at a certain time. You need to specify the time for synchronization separately on ProSafe-SLS and SCS. Determine the time in universal time coordinated (UTC) before you start engineering.

D4.14 Engineering ProSafe-RS

This section describes the preparation and engineering of the ProSafe-RS that are required to use the ProSafe-SLS communication function.

D4.14.1 Preparation

If the software release number of ProSafe-RS is R3.02.10 or before, you must upgrade it to R3.02.20 or later.

TIP

The ProSafe-SLS communication function can also be used in existing SCS projects. After you upgraded SENG to R3.02.20 or later, you must specify related definitions to build and run offline download.

D4.14.2 System engineering of ProSafe-RS

This section describes the settings for ProSafe-RS wiring and builders required to use the ProSafe-SLS communication function. The following views and builders are used to configure the settings:

With RS original engineering

- I/O wiring view
- I/O parameter builder
- Communication I/O builder

With I/O list engineering

- IOM Definition Editor
- Safety Communication I/O Editor

When performing I/O list engineering, the views and builders used with RS original engineering will be display-only.

This section mainly describes for the case when performing RS original engineering. The setting item names displayed may differ between I/O list engineering and RS original engineering, but the settings are the same.

Setting the I/O Wiring View

Define "ALR121M" for the slots in which ALR121 is installed for the ProSafe-SLS communication.

ALR121 used for the ProSafe-SLS communication function supports only non-redundant configuration.

Set "IsRedundant" to "FALSE."

Setting the I/O Parameter Builder

On Module tab, set "Connection Device" to "S_SLSMOD."

Note the following points when setting the Port1 tab and Port2 tab:

- Ensure that communication settings for each ALR121 port match those for CO-920.
- "Baud Rate" on CO-920 is set to 57600 bps by default and not supported by the ProSafe-RS, thus the baud rate for CO-920 may need to be set again.
- "Parity" is set to "Even" by default. "None" is set to CO-920 by default. To ensure the communication reliability, "Even" is the recommended Parity setting to ALR121 and CO-920.
- Ensure that "Data Bits" is always set to 8 bit because Modbus protocol (RTU mode) is applied for communications.
- Set "2-Wire/4-Wire" according to the connection method for RS-485 communications between ALR121 and CO-920.
- You can leave the following items to the default setting:

  "Reception Inter-Character Time", "Response Timeout", "Communication Retry" and "Interval of Connection Retries"
- "Option1" to "Option4" are not applied to the ProSafe-SLS communication function. Set them to 0 on a constant basis.

Setting the Communication I/O Builder

To enable an SCS to acquire I/O data, diagnostic information and events from CO-920, set communication I/O definitions while considering the limitation on application capacity.

For Program Name, you must specify "S_SLSMOD", which is the program to communicate with ProSafe-SLS.

TIP

If any of the following conditions applies, you must correct the program name in the communication I/O builder. Otherwise, a build error will occur.

- The "Connection Device" definition of the ALR121M was changed in the I/O parameter builder
- The ALR121M defining the S_SLSMOD was deleted and the ALR111M was created at the same installation position by using the I/O wiring view

The following table describes the data types that you can assign in the communication I/O definitions.

Table D4.14.2-1 Accessible data types for ProSafe-RS through SLS communication function

Data type	Description
Input (16-Bit Unsigned)	Analog input (16-bit unsigned integer)
Output (16-Bit Unsigned)	Analog output (16-bit unsigned integer)
Input (Discrete)	Discrete input
Output (Discrete)	Discrete output
SLSEVENT	Event type applicable only in S_SLSMOD

Input (16-Bit Unsigned), Output (16-Bit Unsigned), Input (Discrete) and Output (Discrete) are assigned to the communication I/O definition in the same procedures as those in S_MODBUS.

When you assign SLSEVENT to a communication I/O definition, you must ensure that the following conditions are met:

- One Station Number of each port accepts only one definition.
- The size must be 24 words.
- Set the address of other devices to "SLSEVENT."

D4.14.3 Engineering to configure applications on ProSafe-RS

You must configure applications for time synchronization, I/O data monitoring, and alarm notification. Engineering for access by tag name is required to enable data monitoring through CENTUM HIS.

Configuring an application for time synchronization

To perform time synchronization between ProSafe-SLS and ProSafe-RS, configure an application on ProSafe-RS enabling ProSafe-RS DO module to output the trigger once a day to ProSafe-SLS DI module. Settings of Trigger, for example rising and/or falling edge of pulse must match the Trigger of time synchronization events on CO-920.

Example of application on ProSafe-RS

The following figure shows an example of application logic to output trigger from the SCS DO module at 3:00 universal time coordinated (UTC) every day.

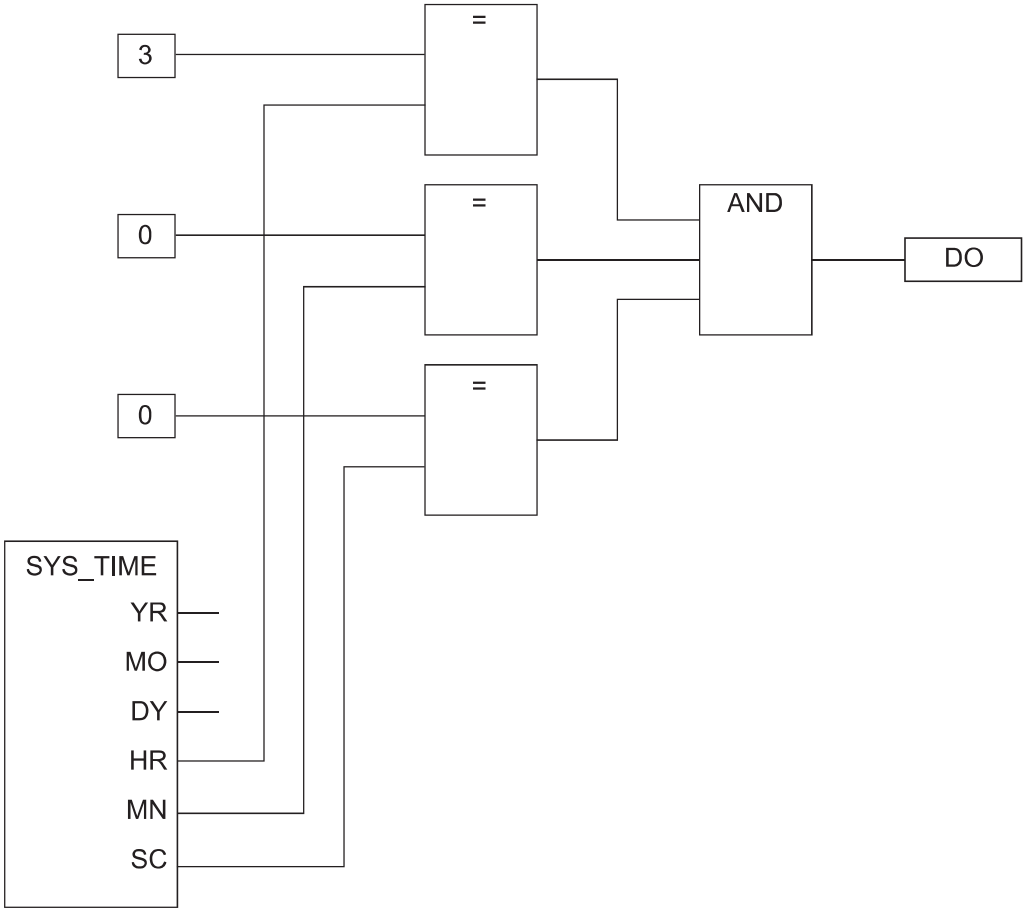

Figure D4.14.3-1 Example of creating an application logic to output trigger for time synchronization from DO

To apply the application logic provided as an example for time synchronization, engineering is required on ProSafe-SLS.

Example of engineering on ProSafe-SLS

On the ProSafe-SLS side, you must create the following application for time synchronization. You must set the time to Coordinated Universal Time (UTC).

1. Define a DI that applies the rising edge of pulse input as a time setting event to DI module on ProSafe-SLS.
2. The application must set the time of ProSafe-SLS to 3:00 when the rising edge of DI pulse is detected.

Engineering to monitor I/O data

The I/O data acquired from ProSafe-SLS can be handled as subsystem communication data on ProSafe-RS. On ProSafe-RS, create an application to monitor the subsystem communication data.

In order to enable monitoring on HIS, you must also create an application for integration with CENTUM.

Configuring an application for alarm notification

The following figure shows an example of ProSafe-RS application that notifies an alarm to HIS at an error of a certain I/O module on ProSafe-SLS and that outputs recovery alarm.

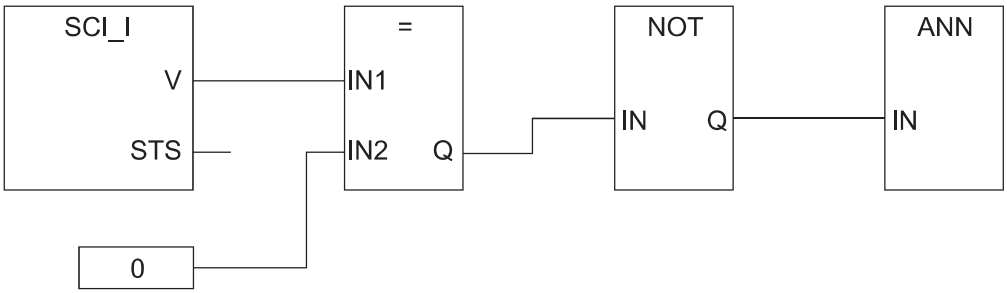

Figure D4.14.3-2 Example of application to notify ProSafe-SLS error alarm

This application uses an SCI_I function block to read the data status of a certain I/O module as a DINT-type value.

The DINT value is non-zero when the I/O module has failed and while the module remain failed. The value becomes 0 when the module recovers.

Engineering for tag name access

To enable CENTUM HIS to access I/O data acquired from CO-920, you must define tag names on SENG.

D4.15 Engineering for ProSafe-SLS

You must perform the following tasks for ProSafe-SLS engineering:

- Initial configuration required to operate CO-920
- Processing of events in CO-920
- Initial time setting of CO-920
- Engineering required to set the time by DI input

D4.15.1 Initial configuration required to operate CO-920

You can use COM-SET to edit the communication setting file and tag name setting file in order to perform initial configuration required to operate CO-920.

Flow of initial configuration of C-920

Follow these steps to configure CO-920 by using COM-SET:

1. Connect COM-SET to the RS-232C port of CO-920.
2. Edit CNF file and TAG file, and compile the edited texts on COM-SET.
3. Download the compiled binary data from COM-SET to CO-920.
4. After the download is complete, reset and restart CO-920 from COM-SET. Communication between the ALR121 and CO-920 is disabled while the CO-920 is being reset and restarted. If CO-920 is running, you must be careful for any affects on a system of upstream connection.

Setting communication

When you set the communication for CO-920 and SCS, you must ensure that the communication parameters of CO-920 and SCS match.

Among communication settings, you must be careful particularly with baud rate and parity settings.

SCS does not support the default baud rate settings (57600 bps) for CO-920. By default, the parity setting of CO-920 is None, which is different from the default setting of SCS (Even).

Editing the CNF file

The CNF file contains I/O data, diagnostic information, time synchronization and the information relative to communication settings of each port and they are described in System part, Communication part, and Data acquisition part.

System part

In communication with ProSafe-RS, set External Clock to "Y" and Time to the target time for time synchronization from SCS. Make Trigger slope match to DO wave that is applied to the trigger for time synchronization on SCS.

Communication part

In Communication part, make sure to include the descriptions of the setting information related to the RS-232C port (COM1), RS-422/RS-485 ports (COM2, COM3) and event text formats.

Modbus slave address is equivalent to Station Number for subsystem communication on ProSafe-RS. It must match the Station Number that is set at ProSafe-RS engineering.

Baud rate, Word length, Parity, and Stop bits are communication settings of RS-485. You must ensure that these settings match the subsystem communication settings specified during ProSafe-RS engineering.

For Event format, we recommend that you use Format 11, which does not contain Description and has 10-character status string.

Data acquisition part

In Data acquisition part, you must set the behavior of CO-920 when it acquires data from each I/O module.

Set the Module type, Network address, and I/O type for each YIS-net module that is installed.

Editing the TAG file

The TAG file contains the Description corresponding to tag name and the information about Modbus register assignment for Tag name monitored on ProSafe-RS and they are described in Taglist part.

Setting items of Taglist part and their details are provided as follows:

- I/O data or Tag name for diagnostic information is set to TAG_NAME. Recommended maximum characters are 22 for a Tag name because SOE on SCS reads up to 22 characters. Duplicate tag names are not permitted within one CO-920.
- The SOE of the SCS does not read TAG_DESCRIPTION. Include the necessary information in the tag name.
- Specify the data source or the initial value of the corresponding Tag name to TAG_SOURCE.
- Specify the Modbus register address to which Tag name is assigned to TAG_LOGIC_ADDRESS. Each TAG_LOGIC_ADDRESS corresponds to the Logic address of Modbus register that is set on CNF file.

You must consider the previous descriptions and ensure that the following requirements are satisfied to set ProSafe-SLS tag name.

- Maximum 22 characters are allowed.
- Overview of an event can be determined.

Assigning I/O data to Modbus register

Assign the I/O data of ProSafe-SLS monitored on ProSafe-RS to Modbus register on CO-920.

Assigning diagnostic information to Modbus register

If you need to send alarms when errors are detected in ProSafe-SLS, assign diagnostic information of ProSafe-SLS to the Modbus register on CO-920. Create an SCS application that references this information and sends an alarm when the judgment shows an error.

D4.15.2 Processing of events in CO-920

If events are stored on CO-920 before events are acquired from ProSafe-RS, SCS requires a long time to acquire events. To avoid slow event acquisition, process the events according to the policy during design study.

TIP

For example, ALR121 contains communication definitions as much as the maximum application capacity and event acquisition runs only for one communication definition, approximately maximum 15 hours is expected for SCS to acquire 10000 events from a CO-920.

Acquiring or deleting events stored in CO-920

SCS starts acquiring at the event next to the last one acquired from CO-920.

If you do not need the events that ProSafe-SLS generated before you connect ProSafe-RS, acquire all events from COM-SET and delete them in advance.

How to acquire events that are stored in CO-920

Before you connect SCS to CO-920, connect COM-SET to the maintenance port (COM1) of CO-920 and acquire all events from CO-920.

TIP

Even though all events are acquired from the maintenance port (COM1) of CO-920, locations of event read pointer for COM2 and COM3 remain unchanged.

If you connect a system for event acquisition to COM2 and COM3 and acquire events, the events on CO-920 disappear.

Events are stored in the rotary buffer on CO-920 and they remain until they are overwritten with new events.

How to delete events that are stored in CO-920

On COM-SET menu, select [ProSafe-SSCC] > [Reset] to delete all events.

This action resets CO-920 and CO-920 cannot communicate with ProSafe-RS for several seconds.

D4.15.3 Initial time setting of CO-920

You must use Coordinated Universal Time (UTC) when you perform time setting engineering to use the SLS communication function.

Before you connect DO module on SCS to DI module on ProSafe-SLS for time synchronization, you must specify year, month, day, hour, minute, and second from COM-SET to CO-920 to make CO-920 time match to SCS time. The time to match should be specified according to the information in the design study.

If time synchronization is performed between SCS and ProSafe-SLS, CO-920 receives DO output from SCS as a trigger and corrects the time to the predefined time. When this happens, the date is corrected within 12 hours gap between the current time and the setting time. For that reason, the time difference between SCS and CO-920 must be less than 12 hours before time synchronization is performed.

The following figure shows an image of correcting date.

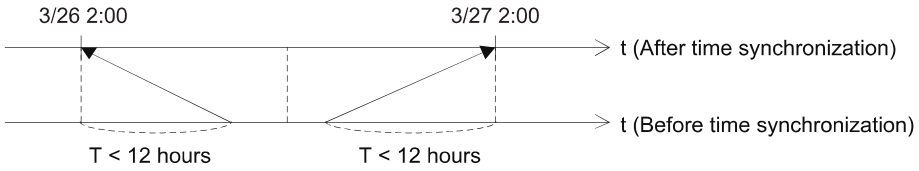

Figure D4.15.3-1 Image of correcting date

D4.15.4 Engineering required to set the time by DI input

If you want to use the application logic for time synchronization created on ProSafe-RS to perform time synchronization for ProSafe-SLS, you also need to perform engineering on ProSafe-SLS.

D4.16 Engineering for CENTUM

If your system is integrated with CENTUM, you must perform engineering to enable access by tag name and build an application to display the operating status so that the ProSafe-SLS communication function can be used.

Tag name access

To attain the access to tag names that are assigned to I/O data of CO-920 and defined in ProSafe-RS, perform the tag name access engineering.

Configuring application to show operating status

Because the ProSafe-SLS and CO-920 are devices on the other end of subsystem communication for the SCS, they are not displayed in the operating status display windows of the HIS and SENG. If necessary, engineer the CENTUM Integrated System so that, for example, ProSafe-SLS or CO-920 data that is read by using subsystem communication is determined and displayed in graphics accordingly.

D4.17 Application Examples of the ProSafe-SLS communication function

The ProSafe-SLS communication function cannot directly send diagnostic information of ProSafe-SLS or errors in devices that are connected to ProSafe-SLS as alarms. ProSafe-SLS events are acquired and recorded as SOE events of the SCS, but they are not sent as alarms to HIS. You can refer to these events through the SOE Viewer or the SOE OPC server.

To notify the operator, as alarms, of diagnostic information of ProSafe-SLS or errors of devices connected to ProSafe-SLS, you must enable such data to be acquired from the CO-920 as Modbus communication data. In addition, create in the SCS a determination logic that uses this data, and create an application that uses the ANN FB or annunciator FB to notify the operator of error alarms and recovery alarms.

Application to send ProSafe-SLS alarms to HIS

The SCS judges the diagnostic information that is read from CO-920 and device data connected to ProSafe-SLS as Modbus communication data. For the system integrated with CENTUM, you can send the judged results of the SCS to HIS by using annunciator FBs. HIS handles the received alarms as process alarms.

By configuring CO-920 to generate an event when the value of the diagnostic information associated with the corresponding alarm has changed, you can manage changes in the diagnostic information as events.

The following figure shows an example of how an alarm is sent to HIS when there is an error in ProSafe-SLS.

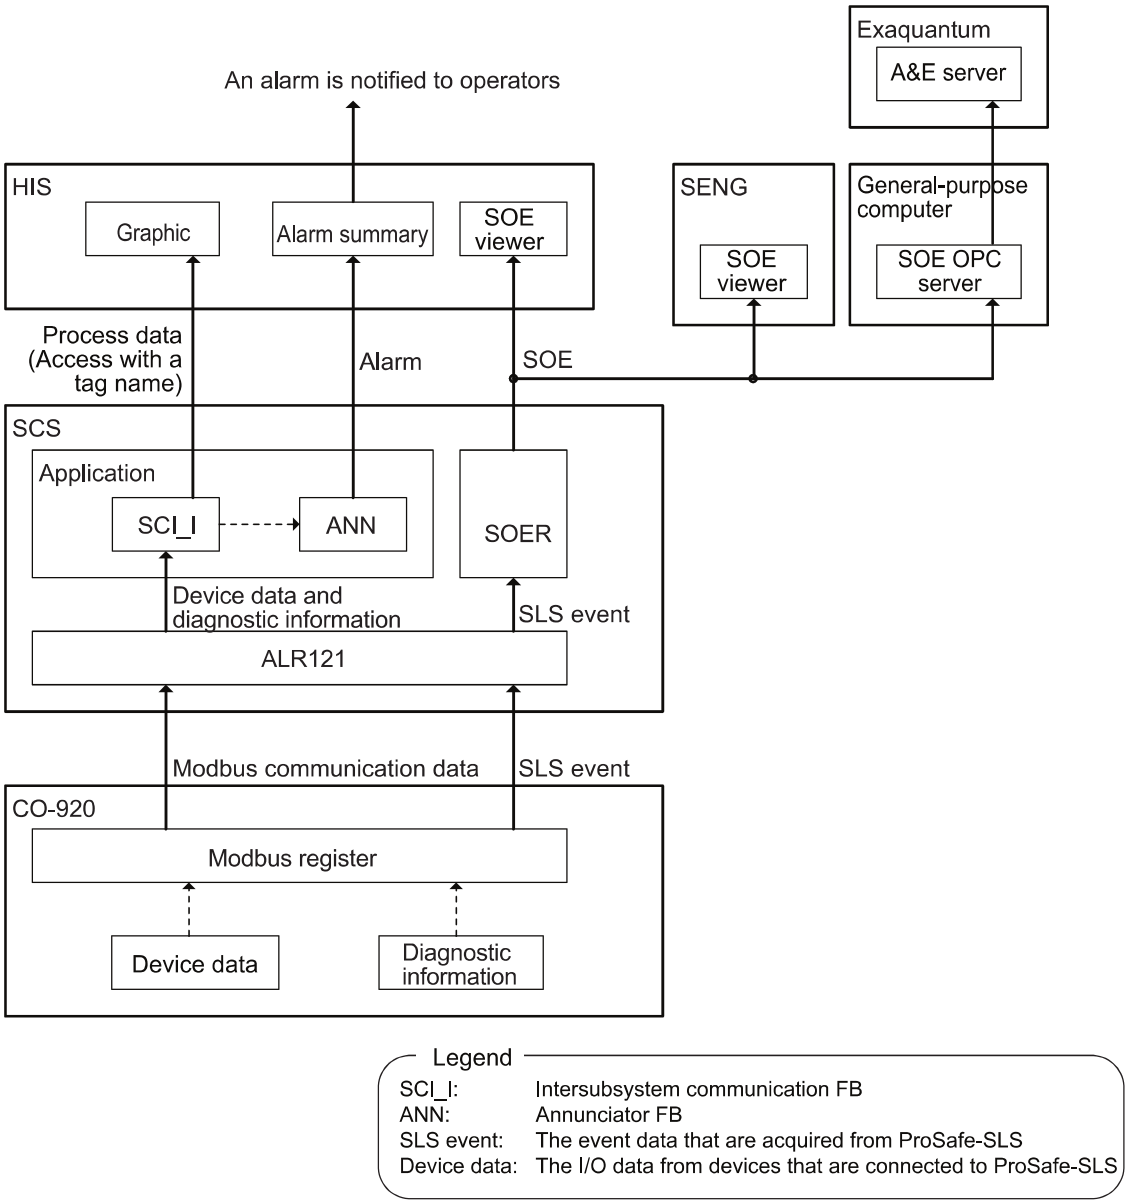

Figure D4.17-1 Example of how to send ProSafe-SLS alarms to HIS

Application to send ProSafe-SLS alarms to CI Server or FAST/TOOLS

In the CI Server integration environment, you must create an application on CI Server that enables CI Server to acquire, through SCS, the diagnostic information of CO-920 and data of devices that are connected to the ProSafe-SLS, judge them, and send alarms to the operator. In the FAST/TOOLS integration environment, create a similar application on FAST/TOOLS.

The following figure shows an example of an application that prompts the CI Server to notify ProSafe-SLS alarms to the operator in the CI Server integration environment.

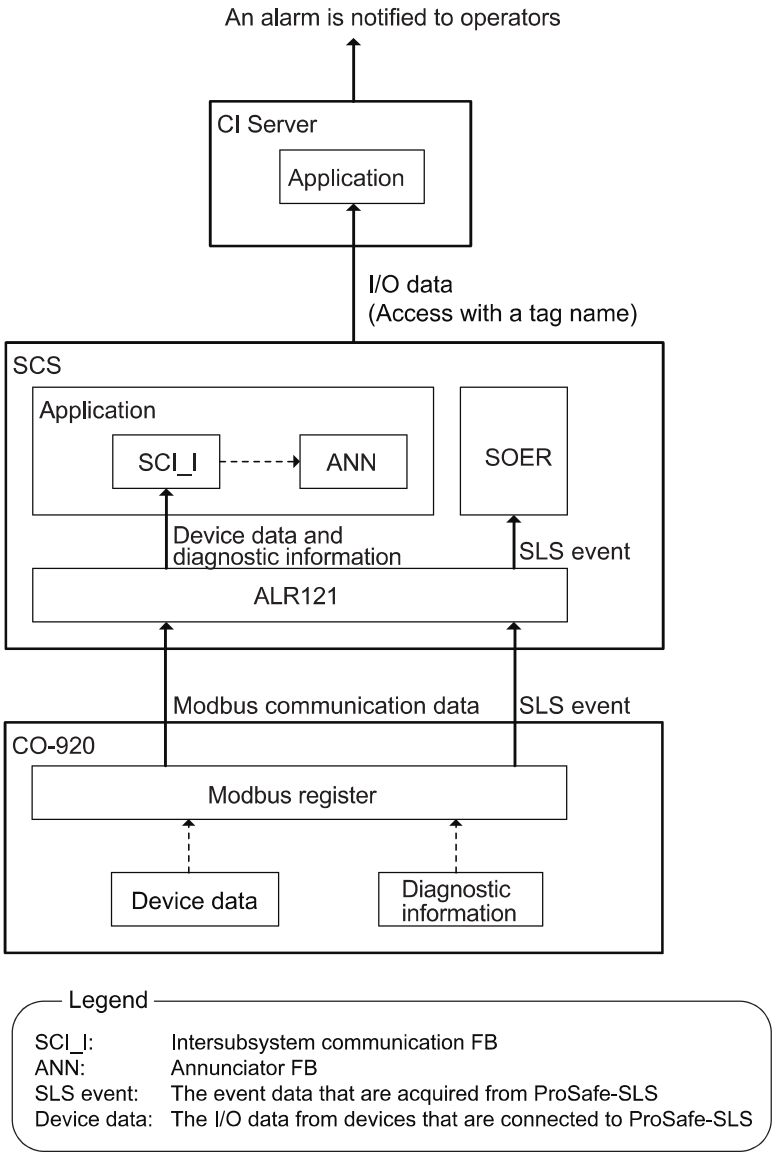

Figure D4.17-2 Example of notifying ProSafe-SLS alarms to CI Server

Application to indicate ProSafe-SLS alarms by using field devices

You can notify users of ProSafe-SLS alarms by using field devices such as alarm lamps. In such a case, you must create an application that sends the result of diagnostic information judged by SCS from a DO module to the field devices.

The following figure shows an example of how to indicate ProSafe-SLS alarms by using field devices.

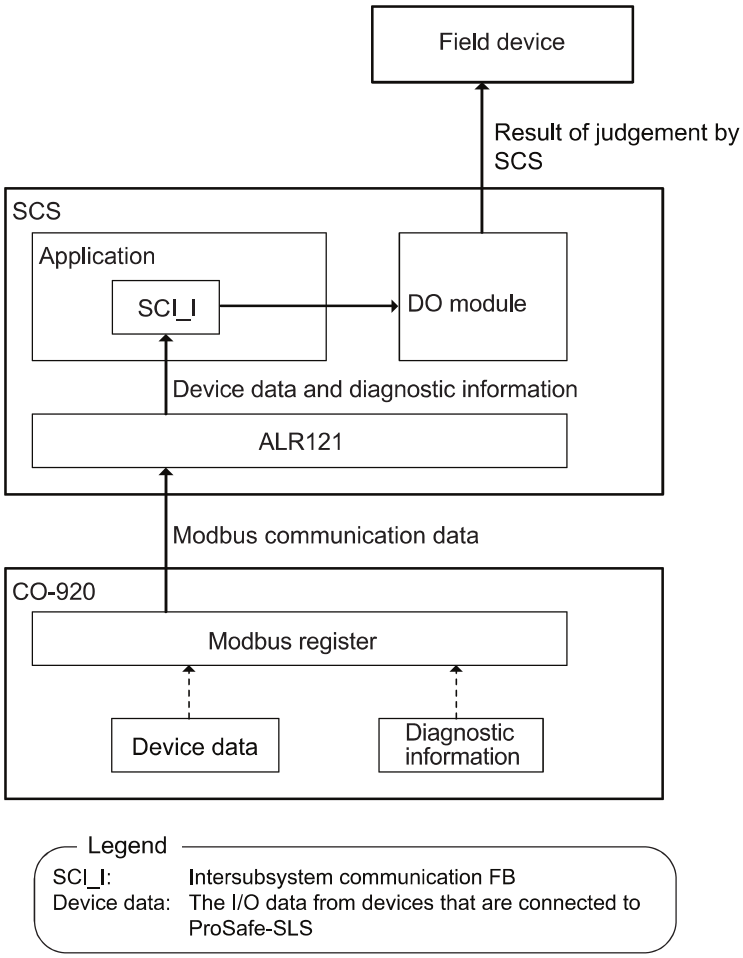

Figure D4.17-3 Example of how to indicate ProSafe-SLS alarms by using field devices

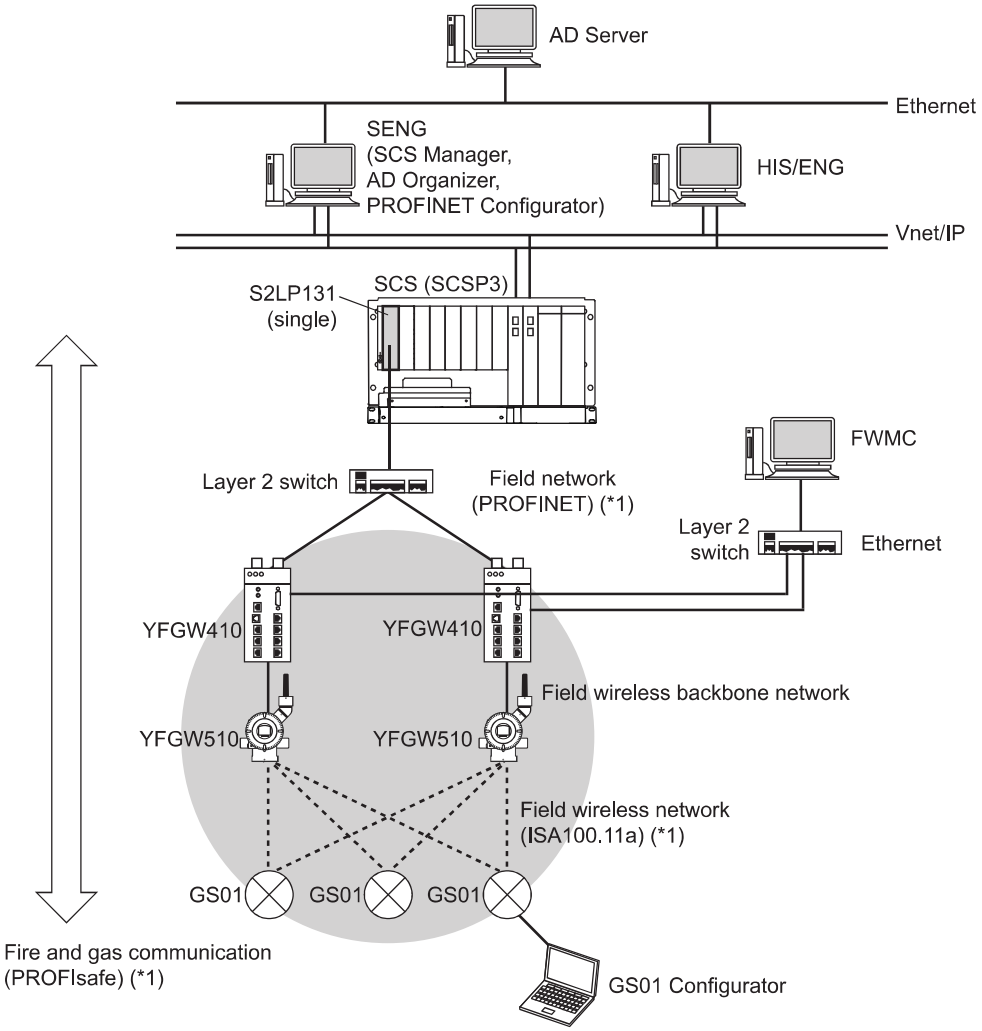
E. Safety subsystem communication

Safety subsystem communication is a function for safe communication where the safety control station (hereinafter referred to as SCS) of ProSafe-RS behaves as the master and communicates with subsystem devices that support safety subsystem communication.

Safety subsystem communication includes fire and gas communication.

E1. Fire and gas communication

Fire and gas communication is a function where the S2LP131 fire and gas communication module is installed on the SCS (SCSP3) to implement safe communication between the SCS and GS01 wireless gas detectors through the YFGW410 field wireless management station and YFGW510 field wireless access point.



Fire and gas communication handles non-safety data used with interference-free functions in addition to safety data used with safety communication.

E1.1 System overview

This section describes the system configuration, components, structure of functions, and operating environment required for fire and gas communication.

E1.1.1 System configuration and components

The following figure shows an example of a configuration for the fire and gas communication system.

*1: For fire and gas communication, PROFINET is used as the field network between SCS and YFGW410 and ISA100.11.a as the field wireless network. In addition, the PROFIsafe protocol is used for the safety layer of fire and gas communication.

Figure E1.1.1-1 Fire and gas communication system configuration example

This section describes the components used in fire and gas communication.

SCS

You can realize safe fire and gas communication between the SCS and GS01 wireless gas detectors by installing the S2LP131 fire and gas communication module on the SCS (SCSP3). Communication with GS01 wireless gas detectors is routed through the YFGW410 field wireless management station and YFGW510 field wireless access point. The gas concentration of a safe GS01 can be handled as input data for a safety application by using fire and gas communication. In addition, you can also obtain interference-free diagnosis information of the YFGW410, YFGW510, and GS01.

S2LP131

S2LP131 is a communication module for fire and gas communication. S2LP131 is installed on the SCS and can connect to multiple YFGW410 through layer 2 switches. (*1) Communication between S2LP131 and YFGW410 uses the PROFINET protocol. Note that you cannot use S2LP131 in a dual-redundant configuration.

*1: Layer 2 switches used with PROFINET must be compliant with the PROFINET installation standards.

SENG

SENG is configured of AD Organizer and SCS Manager. Engineering for fire and gas communication uses AD Organizer to define S2LP131 and communication I/O. In addition, you can set the parameters used by PROFINET and PROFIsafe by using PROFINET Configurator started from AD Organizer. You can display the operating status and alarm messages by using SCS Maintenance Support Tool for maintenance of fire and gas communication.

HIS/ENG

When ProSafe-RS is integrated with CENTUM, you can display the operating status and alarm messages related to S2LP131 in the operation and monitoring windows on HIS.

AD server

AD server is a server that manages engineering data.

YFGW410

YFGW410 is a field wireless management station compliant with wireless communication standard ISA 100.11a. In addition to configuring and managing field wireless networks, it has a gateway function for accessing wireless field devices from the ProSafe-RS system. When communicating with wireless gas detector GS01, access is made through YFGW410. You can use YFGW410 in a dual-redundant configuration.

SEE ALSO

For more information about how to use YFGW410, refer to:

YFGW410 Field Wireless Management Station (IM 01W02D01-01EN)

For more information about how to use the PROFINET interface of YFGW410, refer to:

YFGW410 PROFINET Interface (IM 01W02D01-21EN)

For more information about how to configure PROFINET, refer to:

PROFINET installation guide / security guide issued by PROFIBUS & PROFINET international

YFGW510

YFGW510 is a field wireless access point compliant with wireless communication standard ISA 100.11a. Ethernet is used for the connection between YFGW410 and YFGW510. YFGW410 accesses GS01, which is a wireless field device, through YFGW510.

TIP

An optical network communication option is available with YFGW510, which enables connection to YFGW410 through the YFGW610 field wireless media converter, which is an optical network / metal network converter. This is effective in cases when YFGW410 is far away from YFGW510, when the noise environment is poor, and when measures against lighting are required.

SEE ALSO For more information about how to use YFGW510, refer to:

YFGW510 Field Wireless Access Point (IM 01W02E01-01EN)

For more information about how to use YFGW610, refer to:

YFGW610 Field Wireless Media Converter (IM 01W02D02-01EN)

FWMC

FWMC (Field Wireless Management Console) is a console for YFGW410 and is configured of a configurator and monitor which are used for the following purposes:

- Configurator
  Engineering for constructing a field wireless system
- Monitor
  Status monitoring of YFGW410, YFGW510, and wireless field devices configuring a field wireless system

The configurator is also used for mapping of PROFINET and wireless definitions for fire and gas communication with upper level controllers.

SEE ALSO For more information about how to use FWMC, refer to:

- YFGW410 Field Wireless Management Station (IM 01W02D01-01EN)
- YFGW410 PROFINET Interface (IM 01W02D01-21EN)

GS01

GS01 is a GasSecure AS wireless gas detector compliant with wireless communication standard ISA100.11a. GS01 has acquired SIL2 and uses the PROFIsafe protocol for the safety layer.

GS01 Configurator

You can use GS01 Configurator for provisioning in relation to GS01 and to set safety parameters.

SEE ALSO For more information about how to use GS01 and GS01 Configurator, refer to:

GS01 user's manual from GasSecure AS

E1.1.2 Structure of functions

The following figure shows the structure of fire and gas communication functions.

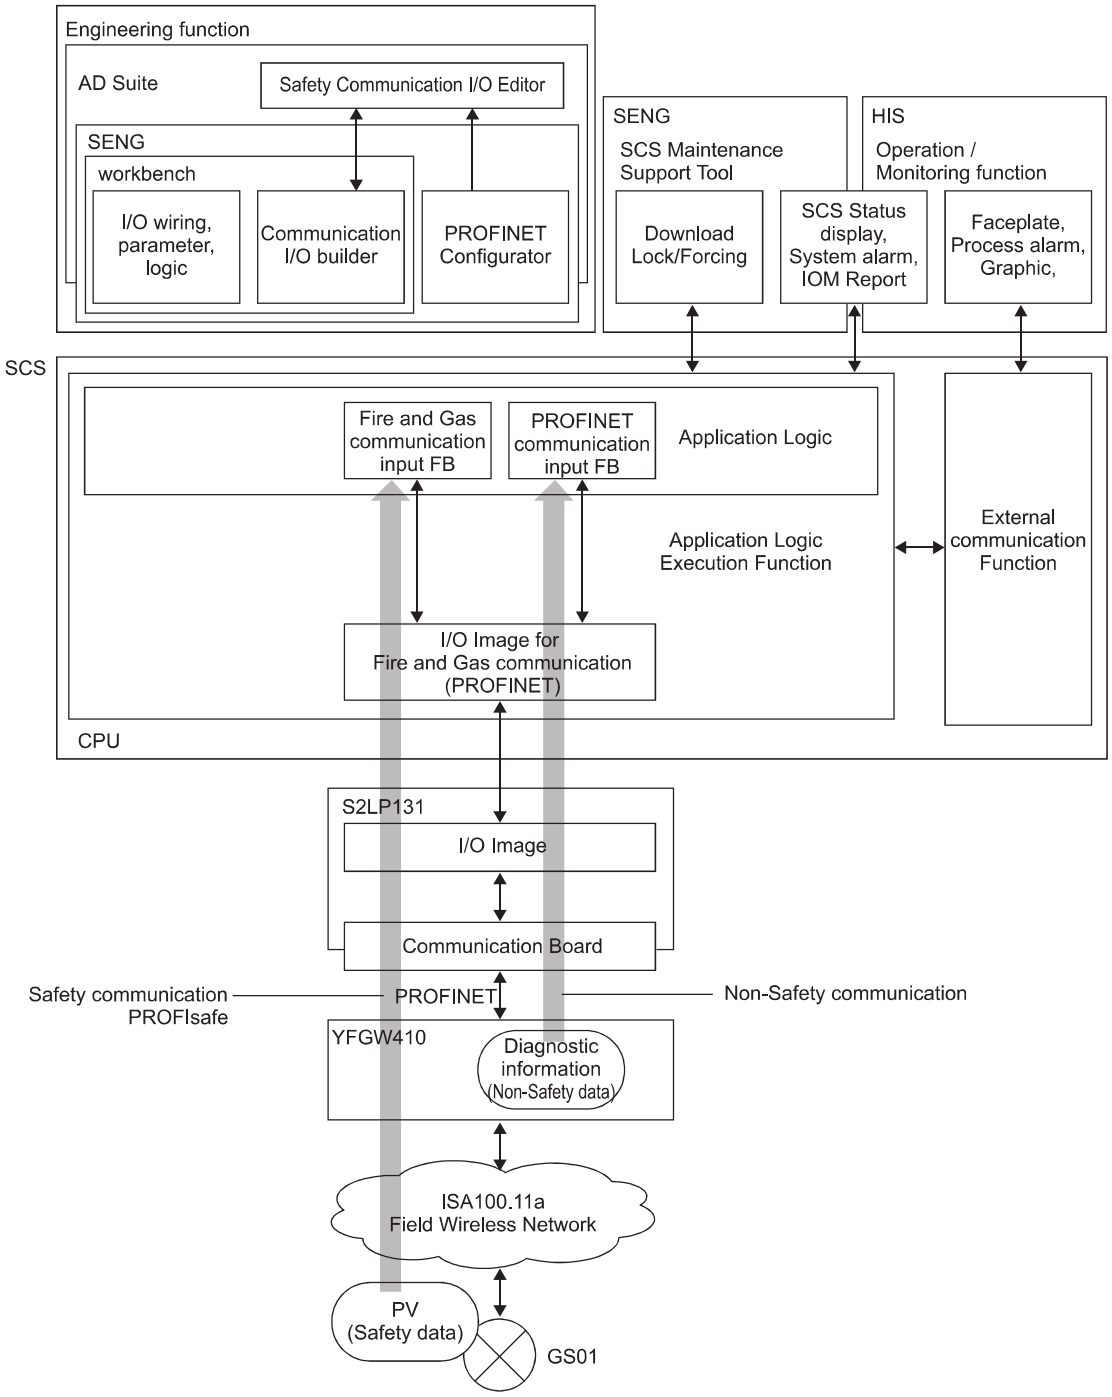


Figure E1.1.2-1 Structure of fire and gas communication functions

S2LP131

S2LP131 passes on the I/O data sent and received with PROFINET communication between YFGW410 as the I/O image for fire and gas communication of the SCS.

Application logic execution function (CPU)

The application logic execution function involves the CPU of the SCS accessing S2LP131 and exchanging data through the PROFINET communication I/O data area.

I/O data comprises safety data communicated using the PROFIsafe protocol (PV), and non-safety data (YFGW410, YFGW510, and GS01 diagnosis information). Safety data is data used with safety communication. Non-safety data is data used with interference-free functions.

Safety data is entered into the fire and gas communication input FB through the safety layer (PROFIsafe). Non-safety data is entered into the interference-free PROFINET communication input FB.

In addition, the application logic execution function performs downloads to S2LP131 and status monitoring of S2LP131 and notifies alarm messages.

When ProSafe-RS is integrated with CENTUM, you can access the I/O data from HIS through the external communication function.

Engineering function (SENG, AD Suite)

With the engineering function, you can use Safety Communication I/O Editor of AD Suite to define S2LP131 and start PROFINET Configurator and Communication I/O Builder.

You can use PROFINET Configurator to set the parameters of PROFINET and PROFIsafe to S2LP131.

When creating a safety application, you can use the fire and gas communication input FB and then use the gas concentration information obtained from GS01 with the safety application.

The database created with these definitions are downloaded to the SCS and S2LP131.

You can also create a PROFINET-ISA100 mapping file from the wireless definition information exported from YFGW410. By importing the PROFINET-ISA100 mapping file, you can set the assignment of the PROFINET modules set on the SCS to YFGW410.

Operation and monitoring function (HIS, SENG)

With HIS and SENG, the operating status of S2LP131 and system alarms are displayed.

By defining tag names with SENG, you can display I/O data values of S2LP131 on HIS through access to the SCS using the tag names.

With SENG, you can perform IOM download to S2LP131 and obtain IOM reports for trouble analysis. In addition, when performing maintenance or making an online change, you can perform locking or forcing of I/O data handled by S2LP131.

E1.1.3 Operating environment

The hardware environment and software environment required for the fire and gas communication function are as follows:

- Hardware environment

  Station: S2SC70S, S2SC70D

  Communication module: S2LP131 fire and gas communication module

  Can be installed on an CPU node, I/O node

- Software environment

  ProSafe-RS: R4.03.10 or later

  CENTUM VP: R6.05 or later

  YFGW410: Firmware Rev R2.01.04 or later

E1.2 Fire and gas communication function specifications

Fire and gas communication is a function for safety communication between the SCS and GS01 through YFGW410 and YFGW510 from the S2LP131 installed on the SCS.

PROFINET is used for communication between the S2LP131 and YFGW410. With PROFINET, S2LP131 of the SCS acts as the PROFINET IO-controller while YFGW410 acts as the PROFINET IO-device.

ISA100.11a is used for communication between YFGW510 and GS01.

PROFIsafe is used for safety communication between the SCS and GS01. With safety communication between the SCS and GS01, devices such as S2LP131, YFGW410, and YFGW510 as well as networks such as PROFINET and ISA100.11a are handled as communication paths.

This section explains PROFINET.

E1.2.1 Data I/O function of PROFINET

With PROFINET, communication is conducted by exchanging data between the PROFINET IO-controller and the PROFINET IO-device.

The following figure illustrates the flow of I/O data in PROFINET.

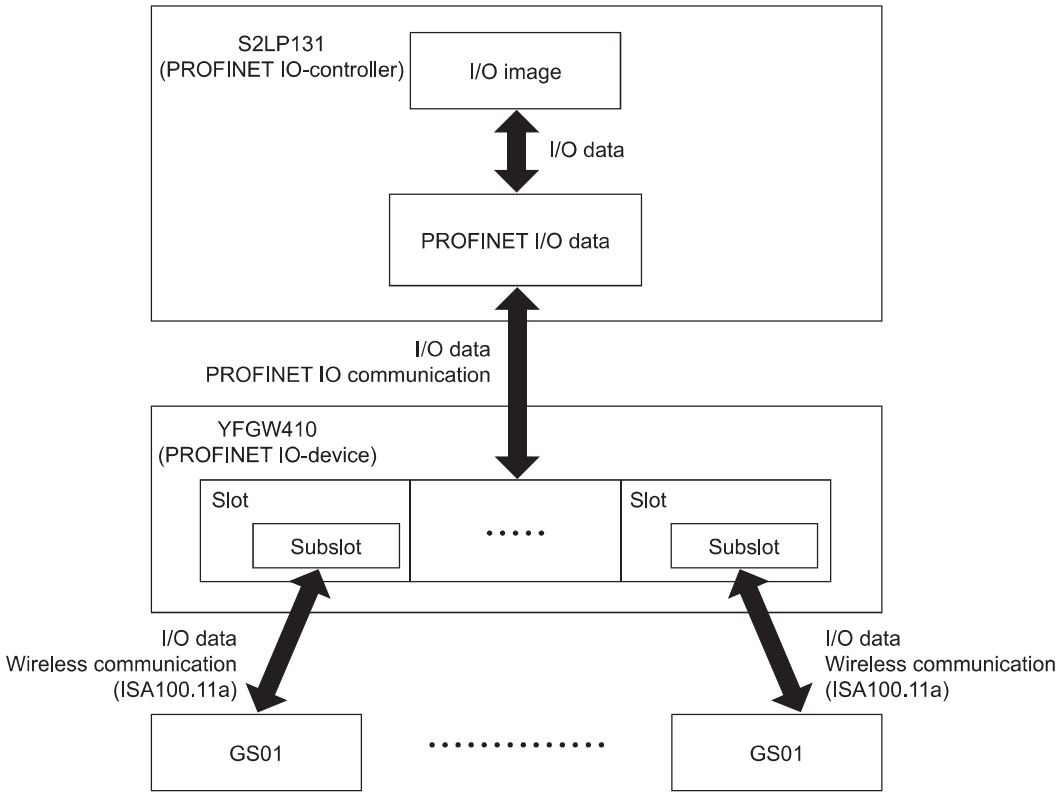

Figure E1.2.1-1 Flow of I/O data in PROFINET

In order to exchange data, input data is periodically forwarded from the PROFINET IO-device to the PROFINET IO-controller while output data is forwarded from the PROFINET IO-controller to the PROFINET IO-device. I/O data exchanged is assigned to addresses referred to as PROFINET slots and subslots.

Input data from GS01 is assigned to YFGW410 slots and subslots.

With S2LP131, input data of GS01 is read from the YFGW410 slots and subslots according to definition information set using AD Suite.

I/O data is first stored in the PROFINET I/O data area of S2LP131, and then stored in the I/O image area where SCS can reference and set data.

E1.2.2 PROFINET modules used with fire and gas communication

With PROFINET, the I/O data used in the data exchange is referred to as modules (hereinafter referred to as PROFINET modules). With fire and gas communication, you can define the PROFINET modules to acquire by using PROFINET Configurator.

The following table shows the PROFINET modules used with fire and gas communication.

Table E1.2.2-1 PROFINET modules used with fire and gas communication

Module ID	Data type	Description
GS01_SAFE_RS	• Input (Unsigned 8 + Float 32 + information for Safety Measure of PROFIsafe) • Output (Information for Safety Measure of PROFIsafe)	PV value (gas concentration) protected with PROFIsafe. The range of WD_Time is set for ProSafe-RS connections.
DIAG_STATUS	Input (Unsigned 32)	GS01 self-diagnosis information. This is created by GS01.
GW_STATUS	Input (Unsigned 16)	The operating status of YFGW410. This is created by YFGW410.
BBR_STATUS	Input (Unsigned 16)	The operating status of YFGW510. This is created by YFGW410.
BATTERY_LIFE	Input (Integer 16)	The remaining battery level of GS01. This is created by GS01.

For more information about the data structure and stored image, refer to the description of PROFINET modules.

TIP

S2LP131 is not compatible with the PROFINET module for output.

The following table shows the PROFINET modules that are not used with fire and gas communication.

IMPORTANT

Although the PROFINET modules in the following table will appear in PROFINET Configurator, do not use these with fire and gas communication.

Table E1.2.2-2 PROFINET modules not used with fire and gas communication

Module ID	Description
GS01_SAFE	Use GS01_SAFE_RS instead of GS01_SAFE.
GS01_SAFE_2	Use GS01_SAFE_RS instead of GS01_SAFE_2.
GS01_REGULAR	-
PV	-
OP	-
READBACK	-
PV_B	-
OP_B	-
READBACK_B	-

SEE ALSO For more information about how to operate PROFINET Configurator, refer to:

E1.5.2, “Applying settings by using PROFINET Configurator” on page E1-34

GS01_SAFE_RS

GS01_SAFE_RS is the PV value (gas concentration) protected with PROFIsafe of GS01. The following figure shows the data structure of GS01_SAFE_RS.

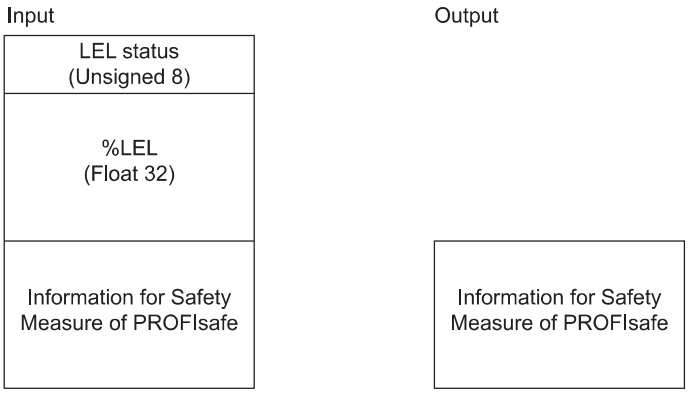

Figure E1.2.2-1 Data structure of GS01_SAFE_RS

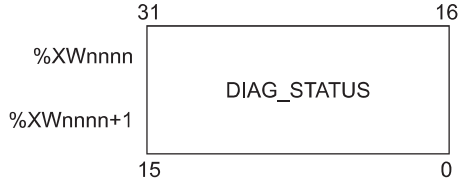
When GS01_SAFE_RS is read, the gas concentration of GS01 is stored to SCS as follows.

%XWnnnn	0	LEL Status
%XWnnnn+1	0	
%XWnnnn+2 %XWnnnn+3	% LEL	
%XWnnnn+4 %XWnnnn+5 %XWnnnn+6 %XWnnnn+7	Information for Safety Measure of PROFIsafe	

nnnn: Odd number between 0001 and 3993 inclusive

Figure E1.2.2-2 GS01_SAFE_RS stored image



The meaning of each field of GS01_SAFE_RS data is as follows:

%LEL: The ratio of the concentration value to the LEL (Lower Explosion Limit) of the combustible gas expressed in percentage.

LEL Status: Information indicating the quality of the LEL

DIAG_STATUS

When the self-diagnosis information (DIAG_STATUS) of wireless field devices (GS01) is read, status information is stored in the SCS as follows.

nnnn: Odd number between 0001 and 3999 inclusive

Figure E1.2.2-3 DIAG_STATUS stored image

The following table describes the meaning of each DIAG_STATUS bit.

Table E1.2.2-3 Meaning of each DIAG_STATUS bit

Bits	Contents
Bit31 (MSB)	Failure status
Bit30	Function check status
Bit29	Out of specification status
Bit28	Maintenance required status
Bit27	Faults in electronics
Bit26	Faults in sensor or actuator element
Bit25	Installation, calibration problem
Bit24	Out of service
Bit23	Outside sensor limits
Bit22	Environment conditions out of device specifications
Bit21	Fault prediction: maintenance required
Bit20	Power is critically low: maintenance required immediately
Bit19	Power is low: maintenance required soon
Bit18	Software update incomplete
Bit17	Simulation is active
Bit16 to Bit08	Reserved by WCI
Bit07 to Bit01	Vendor specific area
Bit00	Detailed information available 1: available 0: not available

SEE ALSO For more information about GS01 self-diagnosis information details, refer to:

GS01 user's manual from GasSecure AS

GW_STATUS

When the device status (GW_STATUS) is read from a YFGW410 field wireless management station, status information is stored in the SCS as follows.

%XWnnnn	GW_STATUS
%XWnnnn+1	0

nnnn: Odd number between 0001 and 3999 inclusive

Figure E1.2.2-4 GW_STATUS stored image

The following table describes the meaning of each GW_STATUS bit.

Table E1.2.2-4 Meaning of each GW_STATUS bit

Bits	Contents
Bit15 (MSB)	GW1 Side Abnormal 0: Normal, 1: Abnormal

Continues on the next page

Table E1.2.2-4 Meaning of each GW_STATUS bit (Table continued)

Bits	Contents
Bit14	GW2 Side Abnormal (*1) 0: Normal, 1: Abnormal
Bit13 to Bit12	GW1 Side Status 0: Ready (initial status) 1: Active (operating as the active gateway) 2: Standby (operating as the standby gateway) 3: Not used
Bit11 to Bit10	GW2 Side Status (*2) 0: Ready (initial status) 1: Active (operating as the active gateway) 2: Standby (operating as the standby gateway) 3: Not used
Bit09	Field Wireless Device Status 0: Normal (All the wireless field devices are properly connected on the field wireless network.) 1: Abnormal (At least one wireless field device is not properly connected on the field wireless network.)
Bit08 to Bit00	Reserved Always 0

*1: If YFGW410 is in non-redundant configuration, GW2 Side Abnormal is 0.
*2: If YFGW410 is in non-redundant configuration, GW2 Side Status is 3.

BBR_STATUS

When the device status (BBR_STATUS) is read from a YFGW510 field wireless access point, status information is stored in the SCS as follows.

%XWnnnn	BBR_STATUS
%XWnnnn+1	0

nnnn: Odd number between 0001 and 3999 inclusive

Figure E1.2.2-5 BBR_STATUS stored image

The following table describes the meaning of each BBR_STATUS bit.

Table E1.2.2-5 Meaning of each BBR_STATUS bit

Bits	Contents
Bit15 (MSB)	Status of field wireless access point 0: Joined, 1: Not Joined
Bit14 to Bit00	Reserved Always 0

BATTERY_LIFE

When the remaining battery level (BATTERY_LIFE) of wireless field devices (GS01) is read, status information is stored in the SCS as follows.

%XWnnnn	BATTERY_LIFE
%XWnnnn+1	0

nnnn: Odd number between 0001 and 3999 inclusive

Figure E1.2.2-6 BATTERY_LIFE stored image

The following table shows the details of BATTERY_LIFE data.

Table E1.2.2-6 BATTERY_LIFE data details

Field name	Description
Remaining battery level	>0: Days, <0: Hours, 0x7FFF: Unlimited

E1.2.3 FB to connect to PROFINET modules

Use the FB shown in the following table when obtaining a PROFINET module with the SCS.

Table E1.2.3-1 FB to connect to PROFINET modules used with fire and gas communication

Module ID	Data type	FB	Description
GS01_SAFE_RS	Input (Unsigned 8)	PSI_I	Data quality status (*1) (*2)
	Input (Float 32)	PSI_R	Gas concentration (*2)
DIAG_STATUS	Input (Unsigned 32)	PNI_I	GS01 self-diagnosis information
GW_STATUS	Input (Unsigned 16)	PNI_I	Operating status of YFGW410
BBR_STATUS	Input (Unsigned 16)	PNI_I	Operating status of YFGW510
BATTERY_LIFE	Input (Integer 16)	PNI_I	Remaining battery level of GS01

*1: The data quality status is a value that indicates the quality of the gas concentration. This is defined by ISA100.11a.
*2: Define the signals of both the data quality status and gas concentration and wire the FB when obtaining GS01_SAFE_RS. Both signals are required in order to determine the quality of the gas concentration.

When multiple signals have been defined to a PROFINET module, engineer as follows:

- Register the signal you want to obtain in the I/O list.
- Register the signals of the same PROFINET module to the same communication definition.
- Wire a FB for every signal you want to obtain.

E1.3 Safety communication of fire and gas communication

The I/O function of fire and gas communication performs safety communication between the CPU module of the SCS and GS01. With this function, you can incorporate the gas concentration, which is safety data of GS01, into the safety loop.

Similar to other I/O functions, the data I/O function used by fire and gas communication behaves as the SCS application logic execution function.

This section explains the safety communication of fire and gas communication.

E1.3.1 Flow of data for the fire and gas communication I/O

The I/O function of fire and gas communication involves the SCS accessing S2LP131 and obtaining safety data and non-safety data from GS01. You can reference data obtained from GS01 from the application logic through the FB.

Fire and gas communication I/O data consists of safety data and non-safety data. Safety data and non-safety data are obtained through the PROFINET modules used for data exchange on PROFINET.

The following table shows the PROFINET modules and the types of data.

Table E1.3.1-1 PROFINET modules and types of data

Module ID	Type of data	Description
GS01_SAFE_RS	Safety data	PV value (gas concentration) protected with PROFIsafe.
DIAG_STATUS	Non-safety data	GS01 self-diagnosis information.
GW_STATUS	Non-safety data	The operating status of YFGW410.
BBR_STATUS	Non-safety data	The operating status of YFGW510.
BATTERY_LIFE	Non-safety data	The remaining battery level of GS01.

Operating the data status

The SCS sets the data status of fire and gas communication. The behavior varies for safety data and non-safety data.

- Safety data
  The safety layer of the SCS confirms the safety communication with GS01. When an error is detected with the safety layer, the SCS sets the status of the safety data in the safety communication I/O data area to error.
- Non-safety data
  S2LP131 detects communication errors of the field wireless systems under YFGW410 and notifies these errors to the SCS. The SCS that has been notified with a communication error sets the status of the non-safety data in the safety communication I/O data area to error.

Conversion of real-type input data

When the safety communication I/O data is real-type input data and the value is Not-A-Number (NaN), infinity, or subnormal, the safety communication I/O data I/O function of SCS converts the physical data to logical data as shown in the following figure and pass it to the application Logic.

This processing is performed in common to both safety data and non-safety data.

However, only NaN is supported for the gas concentration of GS01.

Table E1.3.1-2 Data conversion for real-type input data with NaN, infinity, or subnormal values

Physical data	Logical data
Value: NaN Data status: GOOD	Value: pre-defined input value at fault Data status: BAD
Value: NaN Data status: BAD	

Continues on the next page

Table E1.3.1-2 Data conversion for real-type input data with NaN, infinity, or subnormal values (Table continued)

Physical data	Logical data
Value: infinity Data status: GOOD	Value: pre-defined input value at fault Data status: BAD
Value: infinity Data status: BAD	
Value: subnormal Data status: GOOD	Value: 0.0 Data status: GOOD
Value: subnormal Data status: BAD	Value: pre-defined input value at fault Data status: BAD

Display of NaN, infinity, or subnormal values

When the value of physical data of safety communication I/O data is NaN, infinity, or subnormal, the value is displayed in the Communication I/O Lock window as shown in the following table.

Table E1.3.1-3 Display format for physical data with a NaN, infinity, or subnormal value

Display format	NaN			Positive infinity	Negative infinity	Subnormal
Displayed with 5 decimal places	1.#QNAN	-1.#QNAN	-1.#IND0	1.#INF0	-1.#INF0	0.00000

E1.3.2 Data and status upon starting the SCS

Fire and gas communication is initialized when the SCS is started. The SCS completes start-up after waiting for the fire and gas communication startup time to elapse.

When fire and gas communication is restored prior to the fire and gas communication startup time elapsing, the status of the safety data related to GS01 upon startup of the SCS is set to GOOD.

When fire and gas communication is not restored even after the fire and gas communication startup time has elapsed, the status of the safety data related to GS01 upon startup of the SCS is set to BAD.

■ Fire and gas communication startup time

The fire and gas communication startup time is valid when S2LP131 is defined.

You can change the fire and gas communication startup time with Command Line on the SCS tab of SCS Constants Builder.

SEE ALSO For more information about fire and gas communication startup time details, refer to:

"● Command Line" in "■ SCS tab" in C1.2.6, "SCS Constants Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

E1.3.3 Functions and roles of the safety layer

Safety data used with safety communication and non-safety data used with interference-free functions can be handled with the I/O function of fire and gas communication. Because fire and gas communication handles safety data, the safety layer within the SCS has a safety measure compliant with the PROFIsafe communication protocol.

The safety layer serves the following roles:

- Monitoring of fire and gas communication
- Passing of safety data to safety applications

Monitoring of fire and gas communication

The safety layer of the SCS monitors whether the SCS is receiving safety data from GS01 properly by fire and gas communication.

The validity of the safety data is checked by using procedures compliant with the PROFIsafe communication protocol. When a communication frame error occurs or safety data cannot be received properly for a certain amount of time, the SCS determines that a fire and gas communication error has occurred and alerts a system alarm.

Passing of safety data to safety applications

The SCS passes the safety data, obtained from the I/O image of S2LP131 and checked for validity, to the safety communication I/O data area so that it can be referenced from safety applications.

SEE ALSO For more information about differences between safety subsystem communication I/O, subsystem communication I/O, and AIO/DIO modules I/O, refer to:

Appendix 1.1, “Differences between safety subsystem communication I/O, subsystem communication I/O, and AIO/DIO modules I/O” on page App.1-2

E1.4 Monitoring of fire and gas communication

With fire and gas communication, S2LP131 monitors interference-free functions while safety functions are monitored by the safety layer of the SCS.

E1.4.1 Behavior when an error occurs

S2LP131 monitors the status of the devices used for fire and gas communication and the status of the communication path and notifies the status of normal or error to the SCS. When an error has occurred, a system alarm is alerted from the SCS. The system alarm that is alerted is an IOM Fail, Configuration Error, or SS-SCPATH Error.

The following table shows the relationship between the subjects of status monitoring by S2LP131, system alarms, communication definitions, and applications.

Table E1.4.1-1 Relationship between the subjects of status monitoring by S2LP131, system alarms, communication definitions, and applications

Monitoring subject		System alarm alerted upon error	Communication definition for alerting alarm	Application for monitoring
(1)	Status of S2LP131 (hardware, software errors)	IOM Fail	Not required	Not required
	Status of S2LP131 (configuration error) (*1)	IOM Fail and Configuration Error, or SS-SCPATH system alarm	Required	Not required
(2)	Status of communication board	IOM Fail	Not required	Not required
(3)	Status of communication with PROFINET IO-device	SS-SCPATH system alarms	Required	Not required
(4)	Status of YFGW410 (*2)	SS-SCPATH system alarms	Required	Not required
(5)	Status of YFGW510 (*3)	SS-SCPATH system alarms	Required	Not required
(6)	Communication status of GS01 (communication error)	SS-SCPATH system alarms	Required	Not required
	Status of GS01 (self-diagnosis error) (*4)	An alarm will not be alerted due to not be subject to monitoring.	Required	Required

*1: When the definition information downloaded to S2LP131 has any of the following errors, an IOM Fail and Configuration Error are alerted as the conditions for normally starting S2LP131 are not satisfied.
- IOM definition error (sum value error)
- Communication definition error (sum value error)
- PROFINET definition error (no definition, date discrepancy)

When the conditions for normally starting S2LP131 have been satisfied but the communication definition is invalid, an SS-SCPATH system alarm is alerted. Specifically, this is when a non-supported data type is used.

*2: When GW_STATUS is assigned to %XW, an SS-SCPATH system alarm regarding the YFGW410 error is alerted.

*3: When BBR_STATUS is assigned to %XW, an SS-SCPATH system alarm regarding the YFGW510 error is alerted.

*4: A system alarm will not be alerted when a self-diagnosis error occurs. When monitoring self-diagnosis errors of GS01, in addition to the DIAG_STATUS communication definition, you must build an application to monitor this communication definition. However, when an GS01 communication error, etc. occurs and DIAG_STATUS cannot be obtained, an SS-SCPATH system alarm in relation to the DIAG_STATUS communication definition will be alerted.

(1) Status of S2LP131

S2LP131 checks the following statuses of S2LP131 and notifies the SCS if there is an error.

- Self-diagnosis of S2LP131
- Errors or invalid definition information downloaded to S2LP131

(2) Status of communication board

S2LP131 checks the status of communication board and notifies the SCS if there is an error.

(3) Status of communication with PROFINET IO-device

S2LP131 checks the status of communication with the PROFINET IO-device and detects the following errors. The detected errors are notified to the SCS.

- PROFINET IO-device configuration discrepancy
- Unable to communicate with the PROFINET IO-device

- Error status of PROFINET

(4) Status of YFGW410

S2LP131 checks GW_STATUS and detects the following errors. The detected errors are notified to the SCS.

- GW1 system error
- GW2 system error
- Control right switched
- The active/standby operation of the redundant YFGW410 is unstable (which YFGW410 is active or standby is unknown).

(5) Status of YFGW510

S2LP131 monitors BBR_STATUS and detects the following errors. The detected errors are notified to the SCS.

- YFGW510 has not joined the network

(6) Communication status of GS01

S2LP131 monitors the communication status of PROFINET. If there is an error, an error code indicating the communication error with GS01 is notified to the SCS.

Behavior when a communication error occurs with YFGW410

When the dual-redundant YFGW switching time is set to a value other than 0 and S2LP131 detects a communication error with YFGW410, the communication error with YFGW410 will not be notified from S2LP131 to the SCS during the dual-redundant YFGW switching time. The dual-redundant YFGW switching time is valid only when using YFGW410.

Communication errors will not be notified in the following cases:

(1) Switching of a dual-redundant YFGW410 occurred

(2) A path error occurred between a dual-redundant YFGW410 and S2LP131

(3) A path error occurred between a single YFGW410 and S2LP131

The following table shows the details of safety data and non-safety data when a communication error has occurred. Cases (1) through (3) in the table correspond to Cases (1) through (3) when communication errors are not notified.

Table E1.4.1-2 Safety data and non-safety data when a communication error has occurred

Case		Safety data	Non-safety data
(1)	PROFINET communication is being restored during dual-redundant YFGW switching time	The value of the logical data retains the previous value. The data status of the logical data varies depending on whether an error has been detected with the Safety Measure of PROFIsafe by the safety layer of the SCS. • When an error has not been detected, the data status is GOOD. • When an error has been detected, the data status is BAD and an SS-SCOM system alarm is alerted.	The value of the logical data and the data status retains the previous value.
	When PROFINET communication is restored within the dual-redundant YFGW switching time	Update of the logical data resumes.	Update of the logical data resumes.
	When PROFINET communication is not restored within the dual-redundant YFGW switching time	The value of the logical data becomes the specified input value at error occurrence. The data status of the logical data becomes BAD at the timing when an error is detected with the Safety Measure of PROFIsafe by the safety layer of the SCS and then an SS-SCOM system alarm is alerted.	The value of the logical data becomes the specified input value at error occurrence, the data status becomes BAD, and an SS-SCPATH system alarm is alerted.
(2), (3)	During dual-redundant YFGW switching time	The value of the logical data retains the previous value. The data status of the logical data varies depending on whether an error has been detected with the Safety Measure of PROFIsafe by the safety layer of the SCS. • When an error has not been detected, the data status is GOOD. • When an error has been detected, the data status is BAD and an SS-SCOM system alarm is alerted.	The value of the logical data and the data status retains the previous value.
	After dual-redundant YFGW switching time	The data status of the logical data becomes BAD at the timing when an error is detected with the Safety Measure of PROFIsafe by the safety layer of the SCS and then an SS-SCOM system alarm is alerted. At that time, the value of the logical data becomes the specified input value at error occurrence.	The value of the logical data becomes the specified input value at error occurrence, the data status becomes BAD, and an SS-SCPATH system alarm is alerted.

Dual-redundant YFGW switching time

The dual-redundant YFGW switching time is the time it takes to switch YFGW410 when YFGW410 is in a dual-redundant configuration. Set a value to Dual-Redundant YFGW Switching Time in IOM Definition Editor of AD Suite. The value set in AD Suite is reflected into I/O Parameter Builder of SENG.

- Default value: 5 seconds
- Valid range: Integer between 0 to 99 seconds

IMPORTANT

- If all YFGW410 that connect to S2LP131 are of a single configuration, set the dual-redundant YFGW switching time to 0.
- Changes of the setting value for the dual-redundant YFGW switching time can be downloaded online to the SCS. However, S2LP131 restarts when you perform an online download to the SCS.

E1.4.2 Fire and gas communication status notification

Errors related to fire and gas communication are notified with the system alarms of safety subsystem communication path errors (SS-SCPATH Error) and safety subsystem communication errors (SS-SCOM Error).

TIP

Errors related to fire and gas communication are not notified with the system alarms of existing subsystem communication errors (SS-COM Error).

Message Number 0081 in 3.1, “Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094)” in Messages Reference Manual (IM 32P02B10-01EN)

For more information about SS-SCOM Error details, refer to:

Message Number 4209 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

For more information about SS-SCPATH Error details, refer to:

Message Number 4211 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Scope of SS-SCPATH Error and SS-SCOM Error monitoring

The following figure shows the scope of SS-SCPATH Error and SS-SCOM Error monitoring.

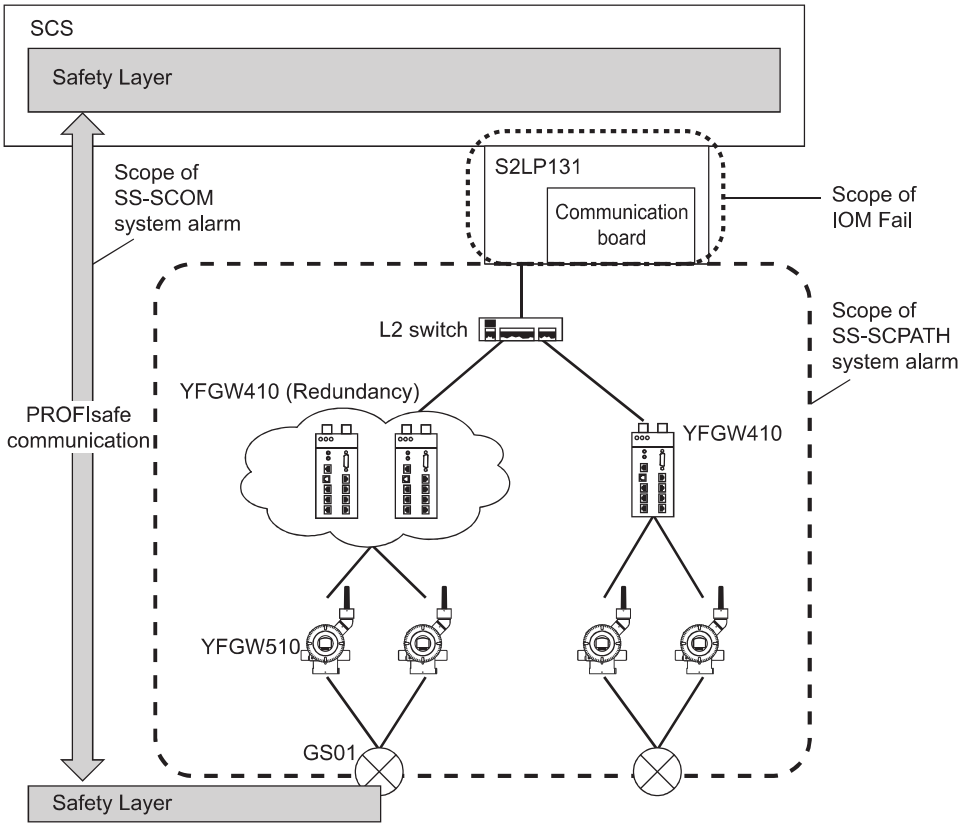

Figure E1.4.2-1 Scope of subjects of operation and monitoring messages

The scope of SS-SCPATH Errors is communication path errors of the fire and gas communication system. This includes errors of the devices and communication paths leading up to S2LP131, YFGW410, YFGW510, and GS01.

The scope of SS-SCOM Errors is safety communication errors of the fire and gas communication system. Safety communication of fire and gas communication refers to the communication between the safety layer of the SCS and GS01.

Safety subsystem communication path errors (SS-SCPATH Error)

SS-SCPATH Errors notify path errors of fire and gas communication. The errors that can be detected are as follows:

- Configuration errors (errors of definition information downloaded to S2LP131)
- Communication errors with PROFINET IO-devices
- YFGW410 errors
- YFGW510 errors
- GS01 communication errors

Safety subsystem communication errors (SS-SCOM Error)

SS-SCOM Errors notify safety communication errors of fire and gas communication. The errors that can be detected are as follows:

- GS01 failed.
- The SCS received irregular safety data from GS01.
- GS01 could not receive safety data from the SCS properly.
- The SCS could not receive a response to a request to GS01.

E1.5 Engineering for fire and gas communication

You can only perform engineering for fire and gas communication through I/O list engineering using IOM Definition Editor and Safety Communication I/O Editor of AD Suite. In addition, you can also create applications by using iDefine.

Flow of engineering for fire and gas communication modules

This section describes the flow of engineering with I/O list engineering for fire and gas communication modules.

Upon newly creating or importing a safety communication I/O list, reflect the settings of the field wireless system devices onto the safety communication I/O list with PROFINET Configurator and then use YFGW-PROFINET Configuration Support Tool to reflect the assignment of PROFINET modules onto YFGW410.

Help files are provided for information on how to use PROFINET Configurator.

The Help files can be found in the following location:

```
<Drive of ProSafe-RS software medium>:\ProSafe-RS\PDFFILE\PROFINET_Configurator\en\
```

The following files are included:

- SYCONnet netFrame YOKOGAWA S2LP131.pdf
- SYCONnet netDevice YOKOGAWA S2LP131.pdf
- PROFINET IO Controller YOKOGAWA S2LP131 DTM.pdf
- YOKOGAWA PROFINET IO Generic Device DTM.pdf

The following image shows the scope of explanations covered by each of the Help files.

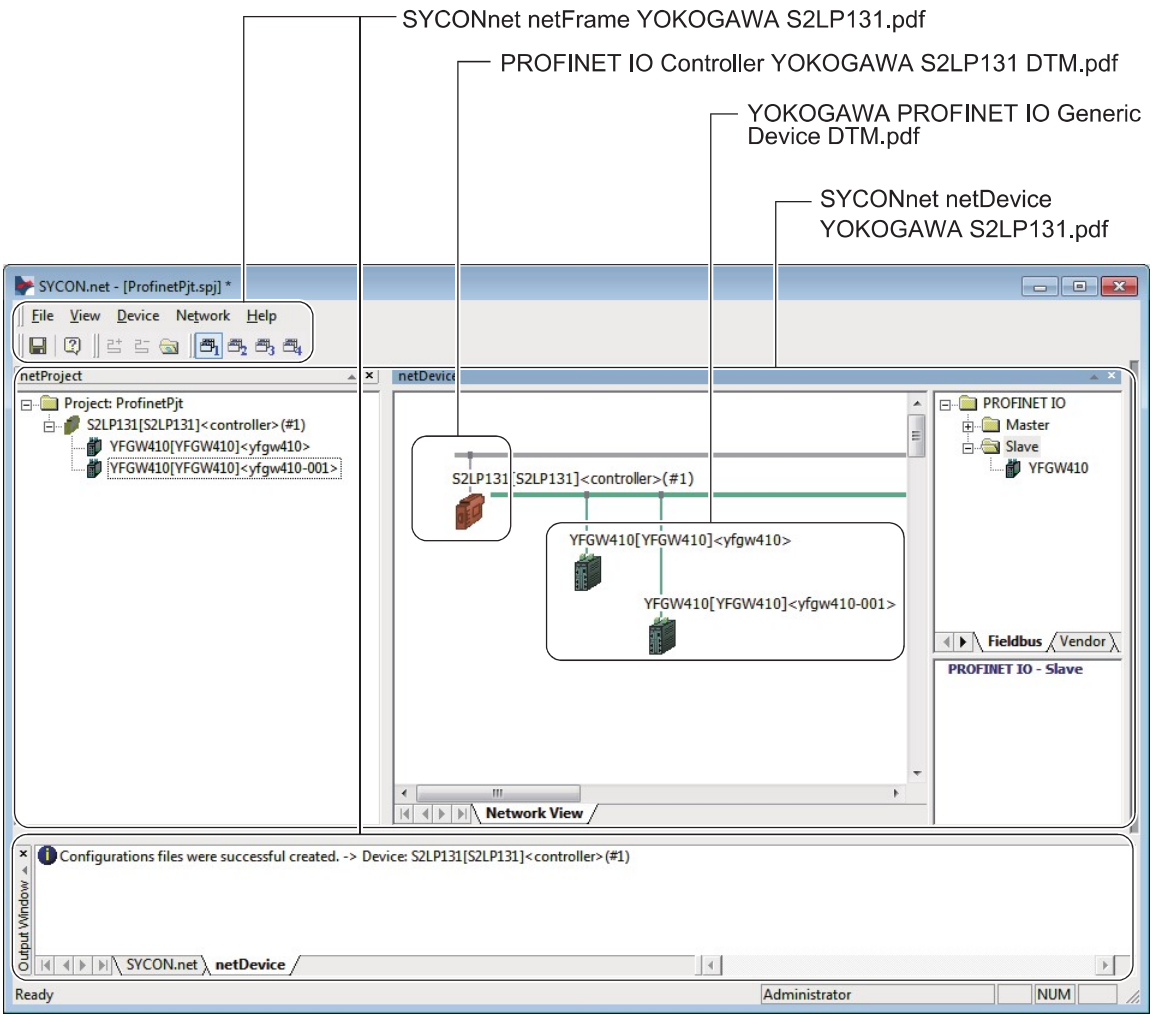

Figure E1.5-1 Areas explained in the Help files

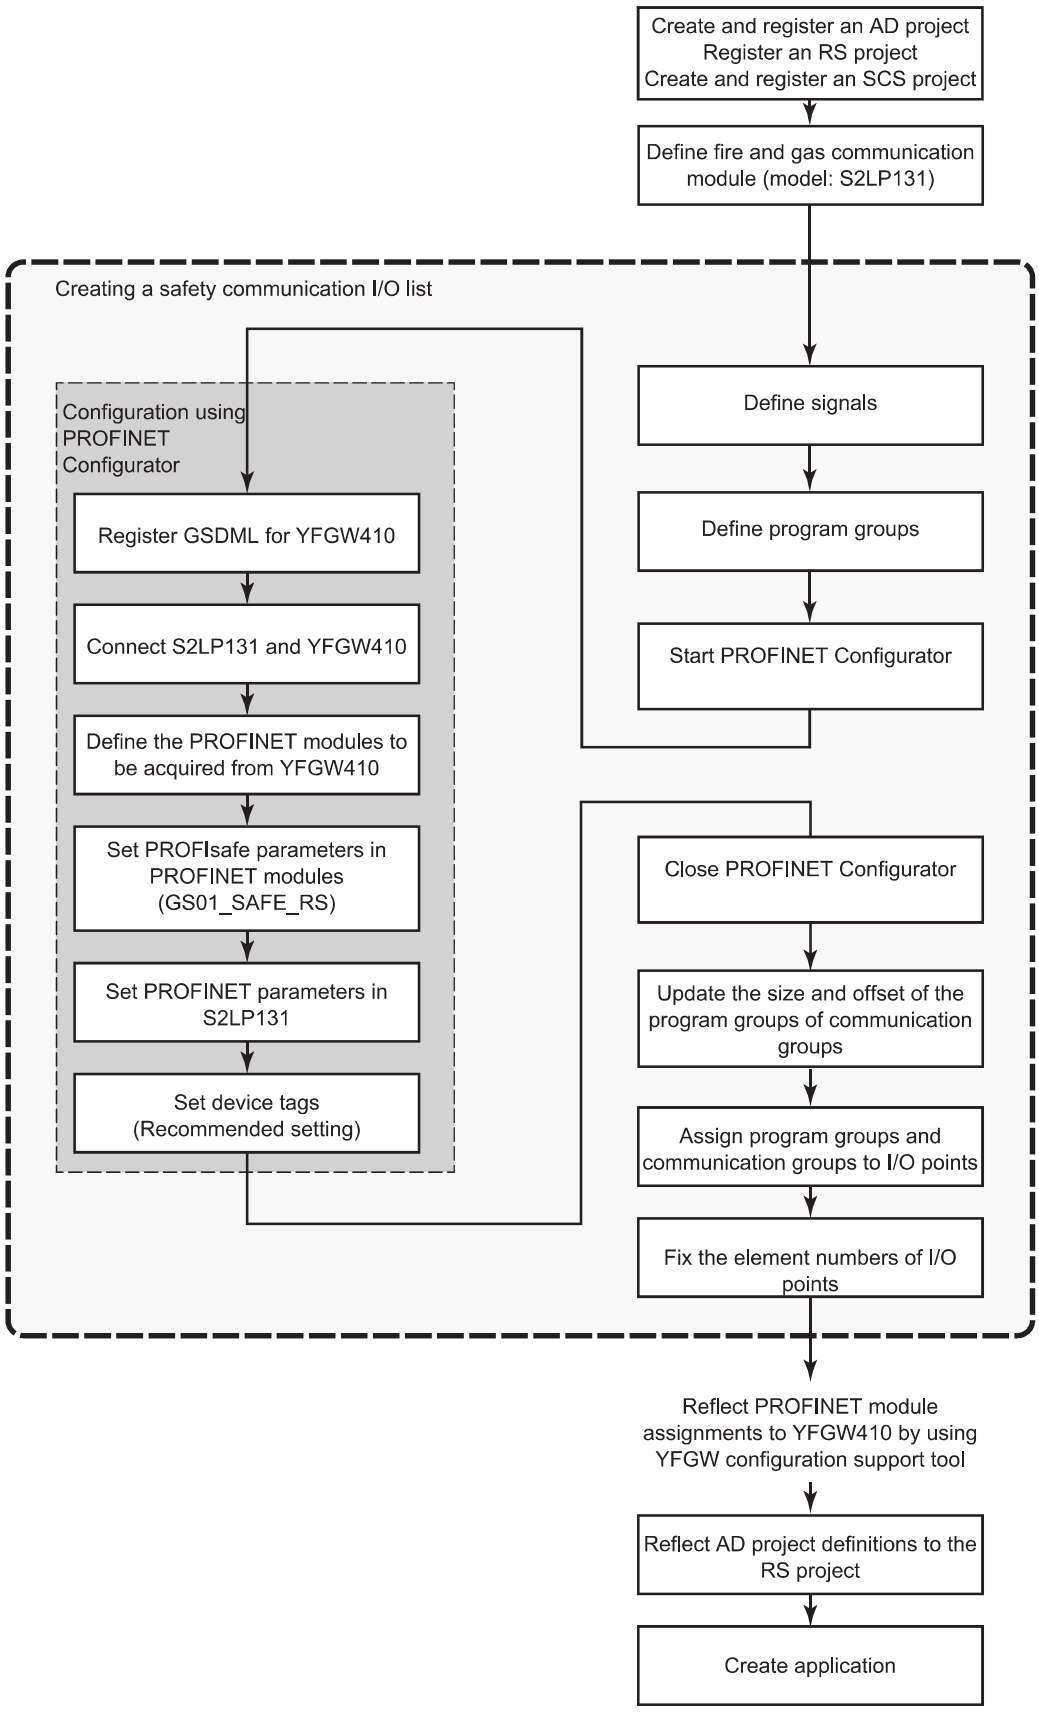

Figure E1.5-2 Flow of engineering for fire and gas communication modules

Defining a fire and gas communication module (S2LP131)

If you are not defining I/O modules by using a safety communication I/O list, create a node and I/O module by using the IOM Definition Editor to define the fire and gas communication module:

SEE ALSO

For more information about how to create nodes, refer to:

"● Creating a node" in "■ Creating the node and I/O module based on safety I/O list" in D3.4, "Creating the node and I/O module" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about how to define I/O modules, refer to:

"● Creating an I/O module" in "■ Creating the node and I/O module based on safety I/O list" in D3.4, "Creating the node and I/O module" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

E1.5.1 Creating a safety communication I/O list

Prepare a safety communication I/O list for defining fire and gas communication. You can either import a safety communication I/O list or create a safety communication I/O list by using Safety Communication I/O Editor.

After creating the safety communication I/O list, set the following items:

1. Define the signal of S2LP131.
2. Define the program group.
3. Select the program group and start PROFINET Configurator.

Defining the signal of S2LP131

Decide the P&ID Tag, I/O Type, Signal Protocol, I/O Tag, and Data Type for the I/O points you want to receive the values for by using an FB through the applicable S2LP131. Set the instance of the FB as the I/O Tag.

IMPORTANT

When setting the instance of PSI_I or PSI_R as the I/O Tag, set the Signal Protocol to PROFIsafe. When setting the instance of PNI_I or PNI_R as the I/O Tag, set the Signal Protocol to PROFINET.

Defining the program group

Define the program group to be subject to PROFINET Configurator and set the following parameters in the grid of the program group:

- Program Protocol: PROFINET
- Connection Device Type: PROFINET

Selecting the program group and starting PROFINET Configurator

From the scope of the SCS Project, start Safety Communication I/O Editor. In the program definition grid, select the line where S2LP131 is defined as the IOM type and start PROFINET Configurator from the context menu that appears when right-clicking.

E1.5.2 Applying settings by using PROFINET Configurator

PROFINET Configurator creates a PROFINET definition file for downloading onto S2LP131. The information included in the PROFINET definition file is reflected in Safety Communication I/O Editor. Also take note that the content of the file will not be overwritten with operations of Safety Communication I/O Editor.

Starting PROFINET Configurator

This section explains the precautions and procedures for starting PROFINET Configurator used in combination with Safety Communication I/O Editor.

Precautions when starting PROFINET Configurator

- On a single SENG, only one PROFINET Configurator can be used at a time. On a SENG where CENTUM VP is coexisting, PROFIBUS-DP Configurator of CENTUM VP cannot be used at the same time either.
- Implement engineering using PROFINET Configurator per one S2LP131 module.
- Be sure to check-out the safety communication I/O file in advance before starting PROFINET Configurator.
- The information defined with PROFINET Configurator is reflected onto PROFINET Configuration managed by AD Organizer. PROFINET Configuration is automatically checked-out when starting PROFINET Configurator.

Procedures for starting PROFINET Configurator

PROFINET Configurator is started from the context menu of Safety Communication I/O Editor. Part of the cells in Safety Communication I/O Editor onto which data is reflected from PROFINET Configurator will be read-only while PROFINET Configurator is running.

In the program definition list or communication definition list, right-click on the cell where S2LP131 is the IOM type and PROFINET is defined to the program protocol and select [Launch PROFINET Configurator].

Performing engineering with PROFINET Configurator

Perform settings in the following manner using PROFINET Configurator.

1. Register GSDML of YFGW410.
2. Connect S2LP131 with YFGW410.
3. Define the PROFINET modules to obtain through YFGW410.
4. Set the parameters of PROFIsafe to the PROFINET modules.
5. Set the parameters of PROFINET to S2LP131.
6. Set the device tag of the PROFINET modules.

Registering GSDML of YFGW410

Register GSDML of YFGW410 when adding a PROFINET IO-device in PROFINET Configurator. This task is not necessary when GSDML of YFGW410 has already been registered to PROFINET Configurator.

TIP

GSDML is a GSD file created using a language called Generic Station Description Markup Language. Information such as device capabilities and data structures is defined.

SEE ALSO For more information about registration procedures for GSDML of YFGW410, refer to:

5.2.1 “Load Device Catalog” in SYCONnet netDevice YOKOGAWA S2LP131.pdf

Connecting S2LP131 with YFGW410

Assign the PROFINET module held by the PROFINET IO-device to the PROFINET slot and sub slot of the PROFINET IO-device.

Modules that support PROFIsafe are included in the PROFINET modules that can be assigned.

- As shown in the following image, drag and drop YFGW410 to the Master bus line to connect with S2LP131.

TIP If nothing is displayed in the Device Catalog area of PROFINET Configurator, select [Network] > [Device Catalog] from the menu bar of PROFINET Configurator and click the [Reload Catalog] button to refresh the Device Catalog.

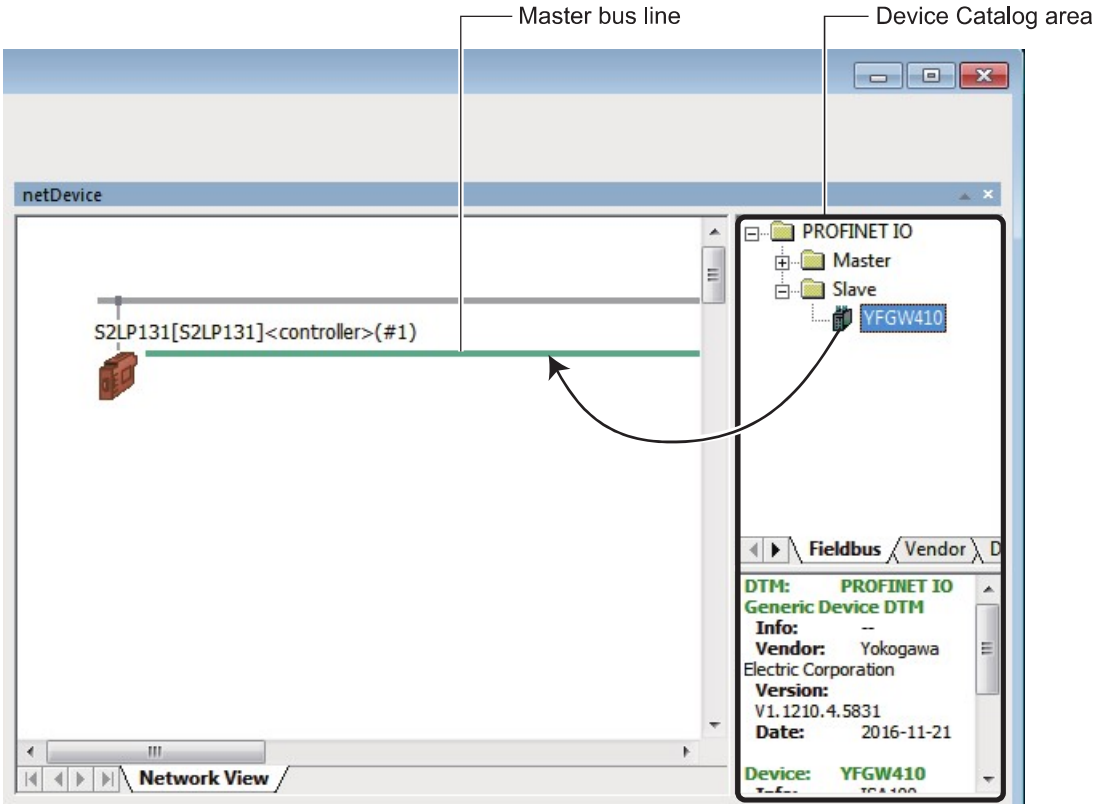

Figure E1.5.2-1 How to connect S2LP131 with YFGW410

SEE ALSO For more information about procedures for connecting S2LP131 with YFGW410, refer to:

5.4 “Insert Device in Project” of SYCONnet netDevice YOKOGAWA S2LP131.pdf

Defining the PROFINET module to obtain through YFGW410

Define the PROFINET modules to obtain through YFGW410.

IMPORTANT

Make the slot and sub slot numbers of the PROFINET module configured with PROFINET Configurator match the slot and sub slot numbers of the PROFINET module configured with FWMC. If these numbers do not match, it will not be possible to properly obtain the corresponding PROFINET module. The data status of the safety subsystem communication I/O definition corresponding to such PROFINET module will display an error.

Mismatches can be prevented by using YFGW-PROFINET Configuration Support Tool after closing PROFINET Configurator.

SEE ALSO For more information about how to define a PROFINET module, refer to:

3.4, “Modules” in YOKOGAWA PROFINET IO Generic Device DTM.pdf

Setting the parameters of PROFIsafe to the PROFINET module

You must perform settings of PROFIsafe if the wireless field device assigned with PROFINET Configurator supports the PROFIsafe protocol.

- Set the F-Parameter of PROFIsafe. The default value is obtained from the GSDML file for YFGW410 and displayed.
  The F-Parameters that can be set will vary depending on the PROFIsafe device. In addition, when you connect GS01 through YFGW410, the high and low limits of the settable F-Parameter values are described in the GSDML of YFGW410. For this reason, refer to the instruction manuals of both GS01 and YFGW410 to find the F-Parameters that can be set with GS01.

IMPORTANT

Make the F-Parameter set using PROFINET Configurator match the F-Parameter set using GS01 Configurator. If these do not match, it will not be possible to properly obtain GS01_SAFE_RS. The data status of the safety subsystem communication definition corresponding to such PROFINET module will display an error.

SEE ALSO For more information about how to set the parameters of PROFIsafe, refer to:

3.5, “Submodule Parameters” in YOKOGAWA PROFINET IO Generic Device DTM.pdf

For more information about the F-Parameters that can be set with GS01, refer to:

- GS01 user's manual from GasSecure AS
- YFGW410 PROFINET Interface (IM 01W02D01-21EN)

Setting the parameters of PROFINET to S2LP131

Set the following parameters of PROFINET to S2LP131:

- IP address, subnet mask, and default gateway of S2LP131
- PROFINET name of YFGW410 being connected
- Cycle of PROFINET I/O communication with YFGW410 being connected

IMPORTANT

- Make the PROFINET name of YFGW410 be the same value as the name set with FWMC. PROFINET communication between S2LP131 and YFGW410 can only be established when these names are of the same value. If PROFINET communication cannot be established, the data status of all safety subsystem communication definitions related to the corresponding YFGW410 will display an error.
- When you set the cycle of PROFINET I/O communication with YFGW410 (Updating Time and Watchdog Time), you must refer to the instruction manual of YFGW410.
- Do not use DCP Set of PROFINET in relation to YFGW410. The default setting of PROFINET Configurator is set to not use DCP Set in relation to YFGW410. Do not change this setting.

SEE ALSO

For more information about how to set the IP address, subnet mask, and default gateway of S2LP131, refer to:

4.3, “Controller Network Settings” in PROFINET IO Controller YOKOGAWA S2LP131 DTM.pdf

For more information about how to set the PROFINET name of YFGW410 being connected, refer to:

4.4, “Device Table” in PROFINET IO Controller YOKOGAWA S2LP131 DTM.pdf

For more information about the setting values for the cycle of PROFINET I/O communication with YFGW410 to be connected, refer to:

YFGW410 PROFINET Interface (IM 01W02D01-21EN)

For more information about how to set the cycle of PROFINET I/O communication with YFGW410 to be connected, refer to:

4.7, “Station Timing” in PROFINET IO Controller YOKOGAWA S2LP131 DTM.pdf

Setting the device tag of the PROFINET module

You can set a tag of your choice in relation to the PROFINET module by using PROFINET Configurator. The tag that has been set is reflected onto Communication Group and PROFINET Device Slot Tag under Communication Definition in the safety communication I/O list.

Communication Group is included in the messages of system alarms such as SS-SCOM and SS-SCPATH. For this reason, setting Communication Group with a string that includes the device tag will make it easier to identify the source of an alarm.

Setting PROFINET Device Slot Tag with a device tag will make it easier to grasp the correspondence between the communication definition and PROFINET module.

For this reason, it is recommended to set a device tag to the PROFINET module.

1. In PROFINET Configurator, double-click on S2LP131.
   The following window appears.

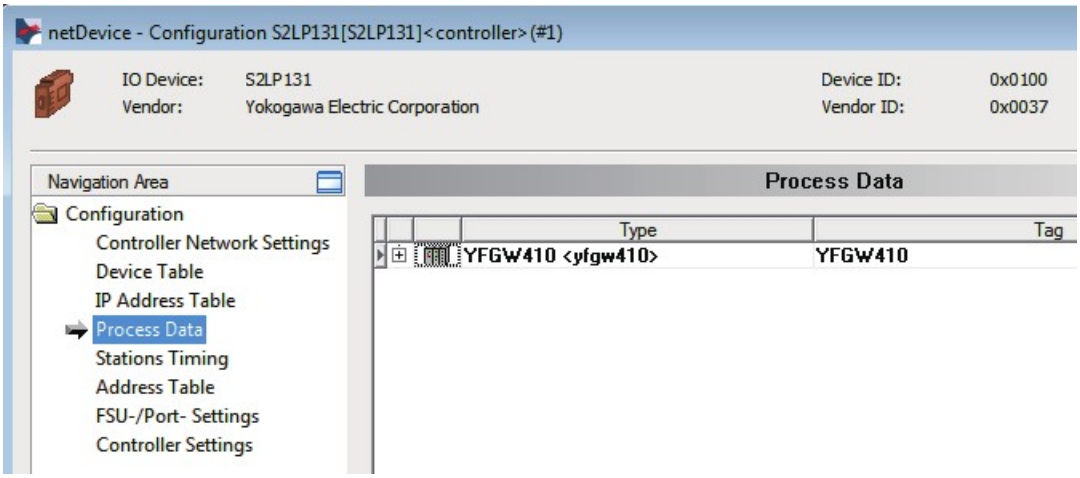

Figure E1.5.2-2 Display example of S2LP131

2. In the Navigation Area, select [Process Data].
3. Select [+].
   The list of PROFINET modules appears.

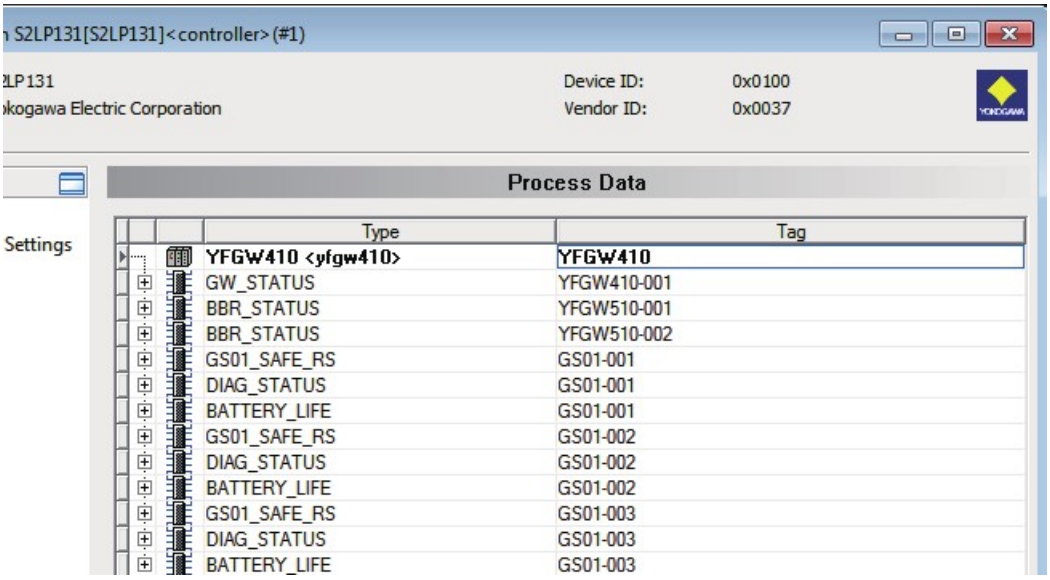

Figure E1.5.2-3 Display example of PROFINET modules

4. Enter the device tag in Tag of the displayed PROFINET modules.
   Use single-byte characters for the device tag. Normal operation cannot be guaranteed if any double-byte characters are used.
5. Click [OK].
   The window closes.

● Ending PROFINET Configurator

By ending PROFINET Configurator after saving the setting details, the set details are loaded into Safety Communication I/O Editor and reflected onto their corresponding cells.

E1.5.3 Applying settings after ending PROFINET Configurator

When PROFINET Configurator is ended, the program group is refreshed and the communication group is added. Communication definitions are added for every PN-Submodule defined with PROFINET Configurator. The format for the [Communication Group] column of communication definitions is [PN-Device Slot Tag] [PN-Module].

Example) When [PN-Device Slot Tag] is GS0101 and [PN-Module] is GS01_SAFE_RS

```
GS0101 GS01_SAFE_RS
```

Proceed to perform the following settings using Safety Communication I/O Editor:

1. Refresh the size and offset of the communication group and the program group.
2. Assign the program group and communication group to I/O points.
3. Establish element numbers for the I/O points.

Refreshing the size and offset of the communication group and the program group

Follow these steps to refresh the size and offset of the communication group and the program group:

1. Refreshing the size and offset of the communication group
   Click [Calculate] for the communication group.

   The results from PROFINET Configurator are imported and the size and offset of the communication group are refreshed.
2. Refreshing the size of the program group
   Click [Calculate].

   The results from PROFINET Configurator are imported and the size of the program group is refreshed.
3. Refreshing the offset of the program group
   When there are multiple S2LP131, in the [Offset] column of the program group, enter an offset value so that the areas of %XW assigned to each S2LP131 do not overlap.

Assigning the program group and communication group to I/O points

Items set with PROFINET Configurator are reflected onto Program Definition and Communication Definition of Safety Communication I/O Editor. Follow these steps to assign the program group and communication group to I/O points in the signal definition of Safety Communication I/O Editor:

1. From the signal definition of Safety Communication I/O Editor, select the I/O point to assign and click [Program Group] to select the program group to assign to the applicable S2LP131.
2. Click [Communication Group] of the I/O point and select the communication groups to assign.

TIP Up to 200 communication groups for the PROFINET protocol can be assigned for each S2LP131.

Defining PN-Data

Follow these steps to define [PN-Data] of an I/O point:

1. Click the column for [PN-Data] of the I/O point.

The Text IDs of the I/O Data defined to the PROFINET Submodule with PROFINET Configurator appear in a drop-down list.

2. Select a Text ID displayed in the list. The signal for which to retrieve values through the function block defined in the I/O Tag of the I/O point is decided.
   The values are refreshed for the Position and Data Type of the I/O point for which PN-Data has been decided and become read only.

Establishing element numbers for the I/O points

Follow these steps to establish element numbers:

1. Click [Update Element] in the toolbar of Safety Communication I/O Editor.
   The integrity of I/O information is confirmed and [Element] of the I/O points are updated.
2. If there is a need to fix the element numbers for the I/O points, change [Fix Element] in the signal definition list to [Yes].
   The element numbers for the I/O points become fixed.

Precautions regarding operation of Safety Communication I/O Editor and PROFINET Configurator

This section describes the definitions related to PROFINET as well as operations and precautions when changing the definitions.

Precautions when the mounting position of S2LP131 has been changed with IOM Definition Editor

When the mounting position of S2LP131 is changed with IOM Definition Editor, among the details defined with Safety Communication I/O Editor, details related to the PROFINET of the S2LP131 that has been changed will be cleared. However, Data Name and Data Type of the signal group definition related to the S2LP131 will not be cleared.

In such case, the details of the PROFINET definition file will be reflected onto related cells by running Read PROFINET Configurator Result or Launch PROFINET Configurator with Safety Communication I/O Editor.

Precaution for GS01-compatible engineering

- Checking for setting changes of GS01
  Check if there are changes in the following definitions and as necessary, correct Communication Group, and reflect these onto the signal. The following items of the existing communication definition are refreshed. Even if the item is read only, an asterisk (*) will be shown if it has been changed. Check the differences by going back and forth between clicking Undo and clicking Read PROFINET Configuration Result.
  - Connection Device Tag
    YFGW410 to which GS01 belongs
  - PROFINET Device Slot Tag
    Tag name of GS01
  - PROFINET Module Name
    Data name of GS01
- Moving and restoring settings of PROFINET Configurator
  The following function allows you to move and restore items while including settings of PROFINET Configurator:
  - SCS project export/import function
  - AD project export/import function
  - AD server backup/restore function

- SCS Manager version control function

The following function does not allows you to move and restore items while including settings of PROFINET Configurator:

- Safety communication I/O list export/import function

Loading the PROFINET definition file with Safety Communication I/O Editor

Follow these steps to load the PROFINET definition file into Safety Communication I/O Editor.

1. As necessary, check-out the PROFINET definition file.

TIP

The PROFINET definition file is automatically checked-out when starting PROFINET Configurator. Perform a check-out if the file has been checked-in or the check-out status has been forcibly released after starting PROFINET Configurator.

2. In the sub menu of Safety Communication I/O Editor, click [Read PROFINET Configurator Result].
   The details of the PROFINET definition file are reflected onto the corresponding cells in Safety Communication I/O Editor.

TIP

This menu is enabled when Safety Communication I/O Editor is started with the scope of the SCS and a cell related to S2LP131 in the program group definition is selected.

E1.5.4 Reflecting items onto the SCS project

Perform the reflection process in order to reflect the items set with the safety communication I/O list onto the applicable SCS using RS Generation Manager.

The items set with the safety communication I/O list are reflected onto their corresponding SCS projects. Along with this, an FB instance for fire and gas communication is created in the SCS project according to the data type of the signal of the safety communication I/O list. FB for fire and gas communication consist of the two types which are FB for PROFINET and FB for PROFIsafe.

In addition, the set items are reflected onto the communication definition and wiring definition of Communication I/O Builder while the FB instances for PROFINET and PROFIsafe can be assigned to element number %XB.

FB for PROFIsafe can be used with safety applications. FB for PROFINET cannot be used with safety applications due to being interference-free.

TIP

Check whether or not Interference-free FB are being used with safety applications by using Integrity Analyzer.

E1.6 YFGW-PROFINET Configuration Support Tool

This tool is used to reflect the assignment of PROFINET modules set on the SCS side onto the YFGW side when performing engineering for fire and gas communication modules. In addition, this tool allows you to compare the settings for PROFINET on the SCS side and the YFGW410 side. However, a comparison of whether or not the F-Parameter values for PROFIsafe are the same on the YFGW side and the SCS side cannot be performed.

E1.6.1 Overview of YFGW-PROFINET Configuration Support Tool

This tool loads the engineering data from SENG and the engineering data from Field Wireless Management Console (hereinafter referred to as FWMC) and exports a PROFINET-ISA100 mapping file. The PROFINET assignment information defined with SENG can be reflected on-to YFGW410 by loading this mapping file with FWMC.

When to use YFGW-PROFINET Configuration Support Tool

The following figure shows the timing at which to use YFGW-PROFINET Configuration Support Tool in the flow of engineering for fire and gas communication.

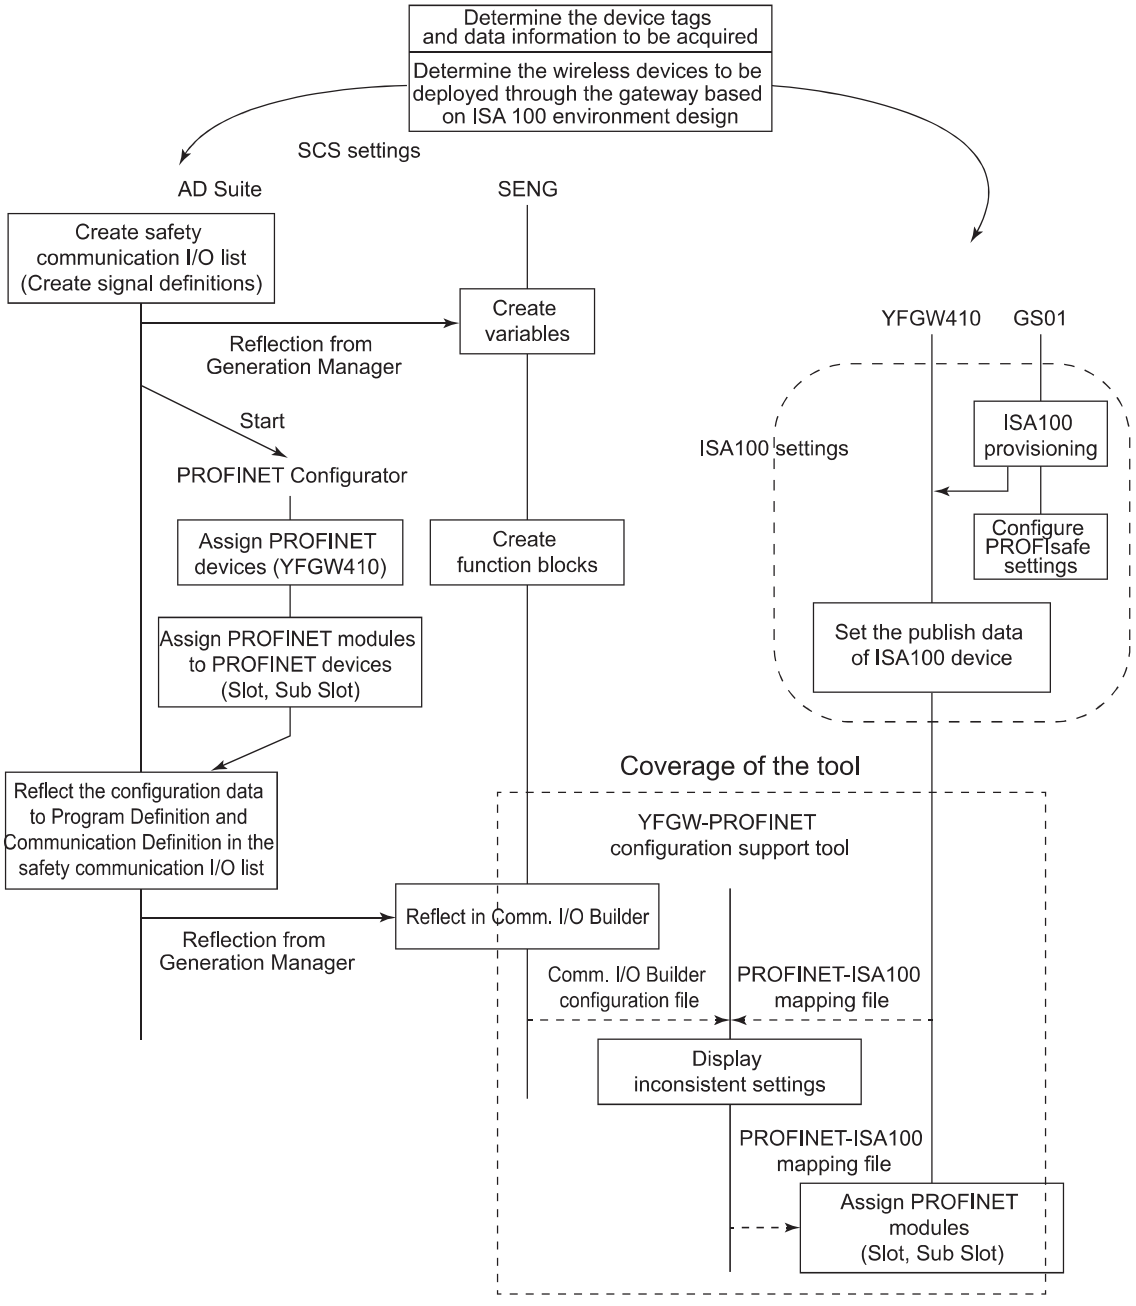

Figure E1.6.1-1 Flow of engineering

Preconditions for use of the tool

Satisfy the following conditions on the SENG side and FWMC side prior to using the tool.

SENG side

Complete each of the following settings before exporting the CSV file:

- Complete settings with PROFINET Configurator.
  - Set the Device Tag of wireless field devices with PROFINET Configurator.
  - Set the Device Tag of YFGW410 as the Station Name.
  - Assign the gas concentration data assigned to GS01, the Backbone Router (hereinafter referred to as BBR), and the status of the GW to the Slot and Sub Slot of the PROFINET of YFGW410.
- Reflect the information of PROFINET Configurator onto Safety Communication I/O Editor. Using PROFINET Configurator, the Device Tag set to each wireless field device is correctly assigned as the Device Tag of the corresponding I/O point.
- Perform a reflection with AD Organizer and reflect data onto Communication I/O Builder.

FWMC side

Decide the following information and share it between SCS engineers and field wireless system engineers:

- The design of the field wireless system has been completed, device tag names have been set for gas detector GS01, GW, and BBR, and what kind of data will be obtained from each device is decided.
- The GW to which GS01 will belong is decided.
- The F-Parameter information of PROFIsafe is decided for every GS01. In particular, F_Dest_Add is decided. Instead of using a part of the information unique to each device (EUI-64), decide unique addresses including the SCS PROFIsafe address of F_Source_Add for the PROFIsafe addresses of GS01 by such as numbering them in order from 1 to 65534.

Files related to the tool

The following files are required in order to use this tool:

- CSV file exported from Communication I/O Builder
- PROFINET-ISA100 mapping file in the CSV format exported from FWMC

The following information included in each CSV file are subject to this tool.

Information of the CSV file exported from Communication I/O Builder

Multiple YFGW410 are defined to Communication I/O Builder and the following information is defined for every YFGW410:

- Device Tag (when the Device Tag of each wireless field device has been set with PROFINET Configurator)
- PROFINET module name
- PROFINET module size
- PROFINET Slot and Sub Slot numbers

Information of the PROFINET-ISA100 mapping file

Once settings for the ISA100 publishing data have been completed, export the PROFINET-ISA100 mapping file in the CSV format. The PROFINET-ISA100 mapping file contains the following publishing data for every ISA100 device. Because the values on the SCS side are imported through the tool, it is OK for the PROFINET Slot and Sub Slot numbers to be in an undefined state.

- Host name and IP address of YFGW410
- Device Tag
- ISA100 Data Name
- Data size
- PROFINET Slot and Sub Slot numbers

E1.6.2 Using YFGW-PROFINET Configuration Support Tool

The procedures using this tool are as follows. Follow the order in which to import the CSV files into the tool. Prepare the following files before starting the tool:

- CSV file exported from Communication I/O Builder
- PROFINET-ISA100 mapping file exported from FWMC

1. Start the tool.
2. Using the tool, load the CSV file exported from Communication I/O Builder.
3. Using the tool, load the PROFINET-ISA100 mapping file.
4. Check the integrity of the engineering results on the SCS side and the FWMC side.
5. Export the PROFINET-ISA100 mapping file.
6. Export a report.

If an excess or deficiency of the PROFINET settings has been found, export a report from the tool and perform engineering again on the SCS side and FWMC side while referring to this report.

Check the details with the tool and export the PROFINET-ISA100 mapping file from the tool. Information of the Slot and Sub Slot set on the SCS side is incorporated into the PROFINET-ISA100 mapping file. This information can be reflected onto YFGW410 by importing the exported results with FWMC.

Starting the tool

Start YFGW-PROFINET Configuration Support Tool.

Importing the CSV file exported from Communication I/O Builder

1. After processing a reflection with Generation Manager, start Communication I/O Builder and export the CSV file.
2. In the tool, select [File] > [Open Communication I/O Builder file].
3. With the Select File dialog box that appears, load the exported CSV file.

Loading the file will result in an error if the CSV file does not have settings for PROFINET.

The following image is an example of what you will see after loading the CSV file.

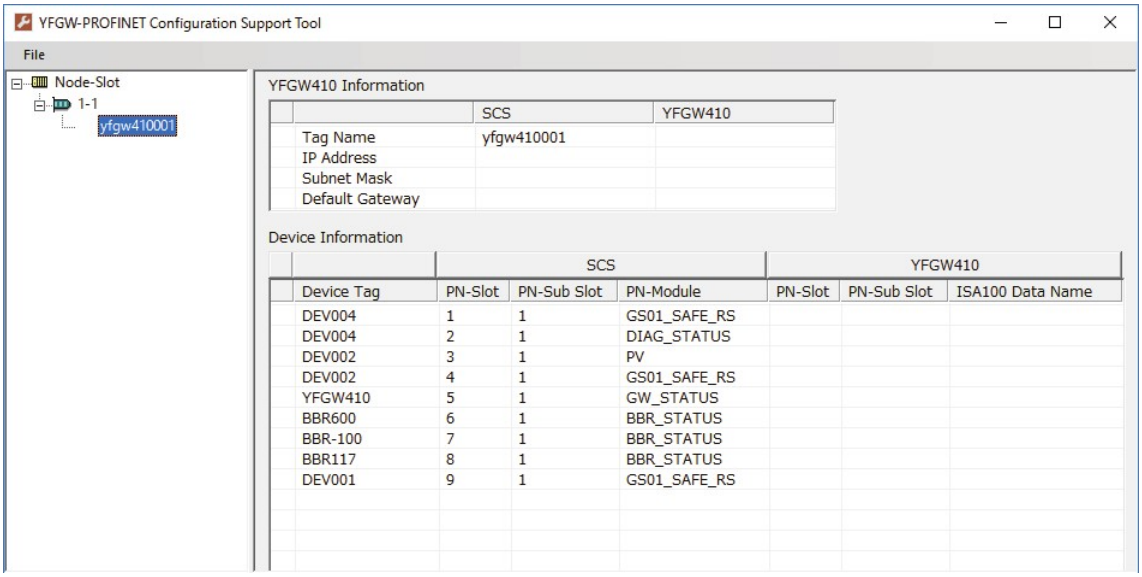

Figure E1.6.2-1 State where information from Communication I/O Builder has been reflected

Loading the PROFINET-ISA100 mapping file

Follow these steps to load the PROFINET-ISA100 mapping file exported from FWMC:

1. In the tool, select [Menu] > [Open PROFINET-ISA100 mapping file].
2. With the Select File dialog box that appears, load the exported PROFINET-ISA100 mapping file.
3. Information of the YFGW410 corresponding to the loaded PROFINET-ISA100 mapping file appears.

If the host name of YFGW410 in the PROFINET-ISA100 mapping file is not included in the information of the SCS side loaded into the tool, an error dialog will appear and the display will not be refreshed.

TIP

Loading of the file will result in an error if you attempt to load the PROFINET-ISA100 mapping file before the CSV file exported from Communication I/O Builder.

Checking the integrity of the engineering results on the SCS side and the FWMC side

After loading the files, check the differences between the settings on the SCS side and the YFGW410 side.

If non-matching items exist, the non-matching items of the individual data on the right pane are shown in blue along with a mark indicating a non-match at the beginning of the column.

Marks indicating a non-match are also added to YFGW410 in the tree on the left pane. The marks that appear are different between YFGW410 having one or more differences that require correction and YFGW410 only having differences that do not require correction. Specific examples are explained in the sections that follow.

Displaying the IP address of YFGW410

- When the Mode of YFGW410 is set to No DCP SET (Correct setting)
  Because the Mode of YFGW410 is set to No DCP SET by PROFINET Configurator, there are no values for the IP address, subnet mask, and default gateway of YFGW410 on the SCS side. Such cases are not acknowledged as a non-match, and the mapping file can be exported.

YFGW410 Information

	SCS	YFGW410
Tag Name	yfgw410001	YFGW410001
IP Address		192.168.0.101
Subnet Mask		255.255.255.0
Default Gateway		192.168.0.1

Figure E1.6.2-2 Displaying the IP address setting (Correct setting)

- When the Mode of YFGW410 is not set to No DCP SET (Wrong setting)
  If the Mode of YFGW410 is set to a mode other than No DCP SET by PROFINET Configurator, there are values for the IP address, subnet mask, and default gateway of YFGW410 on the SCS side. This setting is wrong regardless of whether the values are matching or non-matching with the YFGW410 side. In this case, set the Mode to No DCP SET by using PROFINET Configurator.

YFGW410 Information

	SCS	YFGW410
Tag Name	yfgw410001	YFGW410001
IP Address	192.168.0.101	192.168.0.101
Subnet Mask	255.255.255.0	255.255.255.0
Default Gateway	192.168.0.1	192.168.0.1

Figure E1.6.2-3 Displaying the IP address setting (Wrong setting)

When the PROFINET Slot and Sub Slot numbers do not match

When the PROFINET Slot and Sub Slot numbers do not match, this will be shown as illustrated in the following image. The PROFINET-ISA100 mapping file can be exported in such cases. The Slot and Sub Slot numbers on the SCS side are exported to the file.

Device Information

	SCS			YFGW410		
Device Tag	PN-Slot	PN-Sub Slot	PN-Module	PN-Slot	PN-Sub Slot	ISA100 Data Name
DEV004	1	1	GS01_SAFE_RS			SafeData
DEV004	2	1	DIAG_STATUS			DIAG_STATUS
DEV002	3	1	PV			PV
DEV002	4	1	GS01_SAFE_RS			SafeData
YFGW410	5	1	GW_STATUS			GW_STATUS
BBR600	6	1	BBR_STATUS			BBR_STATUS
BBR-100	7	1	BBR_STATUS			BBR_STATUS
BBR117	8	1	BBR_STATUS			BBR_STATUS
DEV001	9	1	GS01_SAFE_RS			SafeData

Figure E1.6.2-4 Non-match of Slot and Sub Slot numbers

TIP

In this example, the mark at the beginning of the column indicate that a correction is not required despite there being differences between the settings on the SCS side and the YFGW410 side. If there are only differences that do not require correction, the assignment of PROFINET modules on the SCS side can be reflected onto the YFGW410 side using the exported mapping file. When there are only differences that do not require correction, the mark indicating that a correction is not required will also appear for the YFGW410 in the tree on the left pane.

When a Device Tag that exists on the YFGW410 side does not exist on the SCS side

Device Tag, ISA100 Data Name, Slot, and Sub Slot included on the YFGW410 side only are shown as illustrated in the following image. In this case, the PROFINET-ISA100 mapping file can be exported while including Device Tag information that exists on the YFGW410 side. However, the values on the SCS side will be exported for the Slot and Sub Slot numbers in the file. In this example, Slot and Sub Slot of DEV001 are cleared.

Device Information

		SCS			YFGW410		
	Device Tag	PN-Slot	PN-Sub Slot	PN-Module	PN-Slot	PN-Sub Slot	ISA100 Data Name
	DEV004	1	1	GS01_SAFE_RS	1	1	SafeData
	DEV004	2	1	DIAG_STATUS	2	1	DIAG_STATUS
	DEV002	3	1	PV	3	1	PV
	DEV002	4	1	GS01_SAFE_RS	4	1	SafeData
	YFGW410	5	1	GW_STATUS	5	1	GW_STATUS
	BBR600	6	1	BBR_STATUS	6	1	BBR_STATUS
Δ	DEV001				7	1	SafeData
Δ	DEV001						SafeData
Δ	DEV001						DIAG_STATUS

Figure E1.6.2-5 When a Device Tag on the YFGW410 side does not exist on the SCS

When a Device Tag that exists on the SCS side does not exist on the YFGW410 side

Device Tag, Slot, Sub Slot, and PROFINET Module Name included on the SCS side only are shown as illustrated in the following image.

In this case, the PROFINET-ISA100 mapping file is exported without including the Device Tag information that exists on the SCS side only.

Device Information

		SCS			YFGW410		
	Device Tag	PN-Slot	PN-Sub Slot	PN-Module	PN-Slot	PN-Sub Slot	ISA100 Data Name

Figure E1.6.2-8 When a Module Name on the SCS side does not exist in the publishing data of YFGW410

When there is a non-match

The following will occur if multiple types of non-matches occur at the same time.

In cases when only Slot and Sub Slot on the SCS side and YFGW410 side are different, the values on the SCS side are exported to the PROFINET-ISA100 mapping file. Import the file with FWMC and continue with engineering.

The following occurs when an actual device is operated using the exported PROFINET-ISA100 mapping file in a state where any other non-match is included:

- When there is more information on the YFGW410 side than the SCS side
  This creates a state where settings on the YFGW410 side are not assigned to PROFINET. However, information engineered on the SCS side is all included. An SCS communication error will not occur. However, communication will not be performed with devices for which there is a non-match.
- When there is more information on the SCS side than the YFGW410 side
  This creates a state where assignment of PROFINET on the SCS side is excessive. Because there is no corresponding PROFINET setting on the YFGW410 side, the communi-

cation status with SCS becomes Bad when trying to communicate and therefore none of the values will be obtained.

Exporting the PROFINET-ISA100 mapping file

Follow these steps to export the PROFINET-ISA100 mapping file.

1. From the [File] menu in the tool, select [Save PROFINET-ISA100 mapping file].
2. With the Save As dialog box that appears, export the PROFINET-ISA100 mapping file.

IMPORTANT

If the Mode of YFGW410 has been set to a mode other than No DCP SET by PROFINET Configurator, the following dialog box appears when you select [Save PROFINET-ISA100 mapping file] and the PROFINET-ISA100 mapping file cannot be exported.

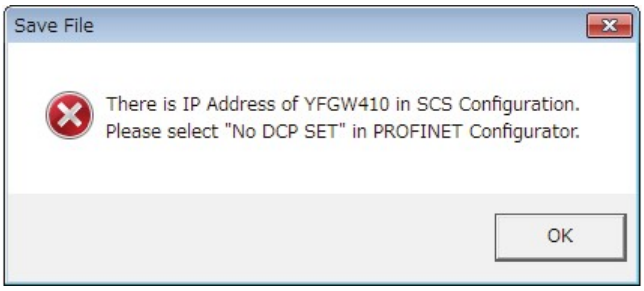

Figure E1.6.2-9 Error dialog box

In this case, set the Mode of YFGW410 to No DCP SET by using PROFINET Configurator, and perform the operation again.

Exporting a report

The details shown in the tool can be exported as a CSV file. Information on differences is expressed in the following manner:

- When there are no differences: 0
- When there are differences that can be ignored: 1
- When there are differences that cannot be ignored: 2

Follow these steps to export the report:

1. From the [File] menu in the tool, select [Save Report].
2. With the Save As dialog box that appears, export the report.

E1.7 Application logic for obtaining the gas concentration of GS01

You must create an application logic in order to obtain the gas concentration of GS01.

This section describes the precautions to take and the method to use when creating the application logic.

The examples of application logic described here are created based on the following Safety Manual of GS01:

GasSecure GS01 Wireless Infrared Hydrocarbon Gas Detector Safety Manual

Document ID: 21440

Release: 1

Version: 81

The application logics are created with reference to the gas concentration values that GS01 sends upon the statuses of Fail safe detected (SD), Fail safe undetected (SU), Fail dangerous detected (DD), and Fail dangerous undetected (DU), which are shown in the Safety Manual. The specifications may differ for each GS01 revision. So, confirm the specification with the latest edition of GS01 Safety Manual and create your application logic.

Physical data and logical data upon various events

Wire PSI_R and PSI_I to GS01_SAFE_RS. Then, a gas concentration is input to PSI_R and the data quality status to PSI_I.

The following figure shows the relationship between the physical data and logical data of GS01_SAFE_RS when a safety communication error, GS01 failure, or gas generation occurs.

Table E1.7-1 Physical data and logical data of GS01_SAFE_RS upon various events

Event	Physical data	Logical data
Safety communication error	• PSI_R (gas concentration) PSI_R.v: Previous value PSI_R.sts: BAD • PSI_I (data quality status) PSI_I.v: Previous value PSI_I.sts: BAD	• PSI_R (gas concentration) PSI_R.v: Pre-defined input value at fault (*1) PSI_R.sts: BAD • PSI_I (data quality status) PSI_I.v: Pre-defined input value at fault (*1) PSI_I.sts: BAD
GS01 failure	• PSI_R (gas concentration) PSI_R.v: NaN (*2) PSI_R.sts: GOOD • PSI_I (data quality status) PSI_I.v: BAD (*2) PSI_I.sts: GOOD	• PSI_R (gas concentration) PSI_R.v: Pre-defined input value at fault (*1) PSI_R.sts: BAD • PSI_I (data quality status) PSI_I.v: BAD PSI_I.sts: GOOD
Gas generation	• PSI_R (gas concentration) PSI_R.v: Gas concentration PSI_R.sts: GOOD • PSI_I (data quality status) PSI_I.v: Data quality status (*2) PSI_I.sts: GOOD	• PSI_R (gas concentration) PSI_R.v: Gas concentration PSI_R.sts: GOOD • PSI_I (data quality status) PSI_I.v: Data quality status PSI_I.sts: GOOD

*1: This is the value set in the Safety Communication I/O Editor of AD Organizer.
*2: For the details, refer to the user's manual of GS01.

Example of application logic

The following figure shows an example of application logic where GASDTR, PSI_R, and PSI_I are used to create a user-defined function block (UDFB).

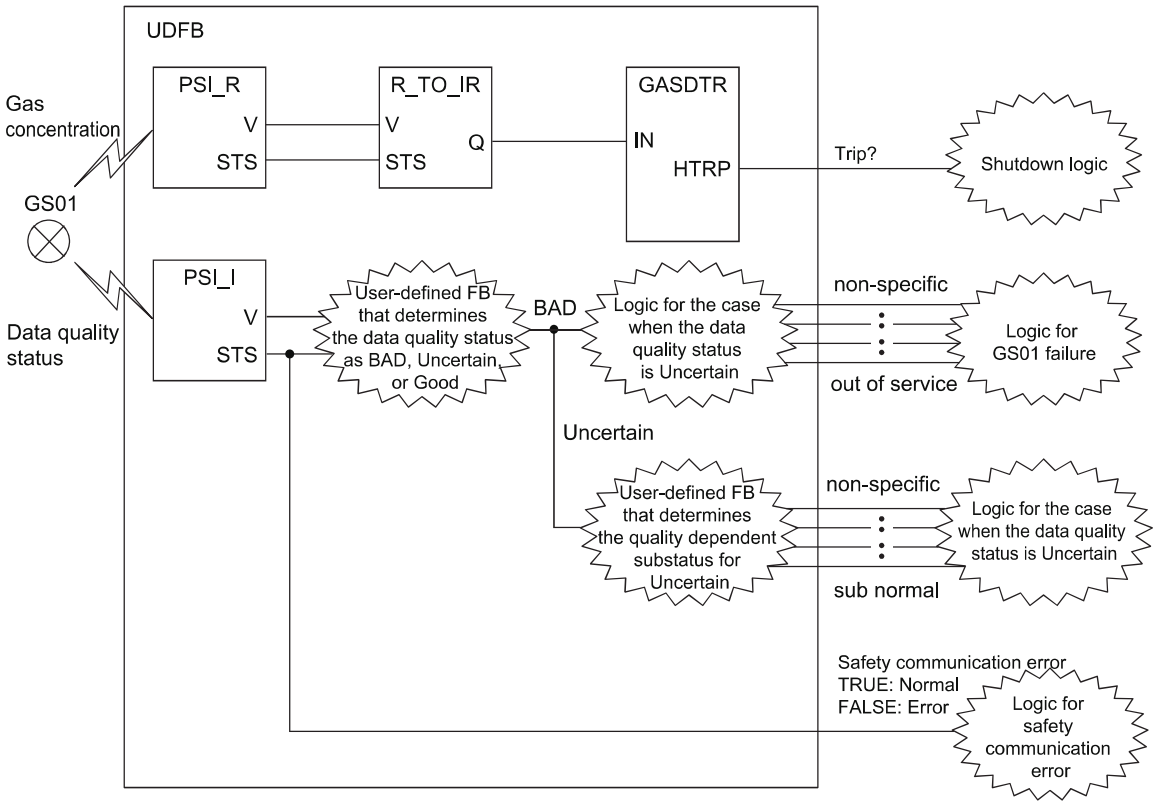

Figure E1.7-1 Example of application logic

- PSI_R usage
  PSI_R receives a gas concentration value. The gas concentration value is input to the IN terminal of GASDTR. However, since GASDTR expects that the input from the IN terminal is IO_REAL type data, PSI_R.v and PSI_R.sts need to be converted to IO_REAL type before they are input. For conversion to IO_REAL type, use a safety function block such as R_TO_IR.

- PSI_I usage
  PSI_I receives a data quality status value. The data quality status consists of Quality (Good/Bad/Uncertain), which indicates a category, Quality dependent substatus (detailed information for the category), and Limit condition (additional information for the category). For the specification of data quality status of GS01, refer to the user's manual of GS01.

  On detecting a failure of itself, GS01 sets the data quality status value to BAD. Therefore, you can use the value of PSI_I.v to find whether GS01 has failed. You can also use the value of Quality dependent substatus in addition to the Quality of the data quality status to identify the type of GS01 failure to create application logic that can perform different processing for each type of GS01 failure.

  The data quality status may have Uncertain as a Quality value. If the data value exceeds the sensor rage or temperature range, GS01 sets the data quality status to Uncertain. In this case, GS01 has not failed but a certain event has occurred, preventing GS01 from setting the data quality status to Good. You can create application logic that determines whether the data quality status of GS01 is Uncertain through the PSI_I.v value, and notifies the operators for each Quality dependent substatus of Uncertain.

  For the specification of data quality status of GS01, such as the Quality dependent substatuses that GS01 supports, contact the manufacturer of GS01.

PSI_I.sts is used to find the presence of safety communication errors. With PSI_R.sts, you cannot distinguish a safety communication error and a GS01 failure.

Example of application logic with/without use of the fault check function of GASDTR

GS01 reflects the information about its own fault in the data quality status of gas concentration. The data quality status of gas concentration can be obtained through PSI_I.

This section describes examples of application logic where the fault check function of GASDTR is used or not used.

Using the fault check function of GASDTR

The following figure shows an example of application logic where the fault check function of GASDTR is used.

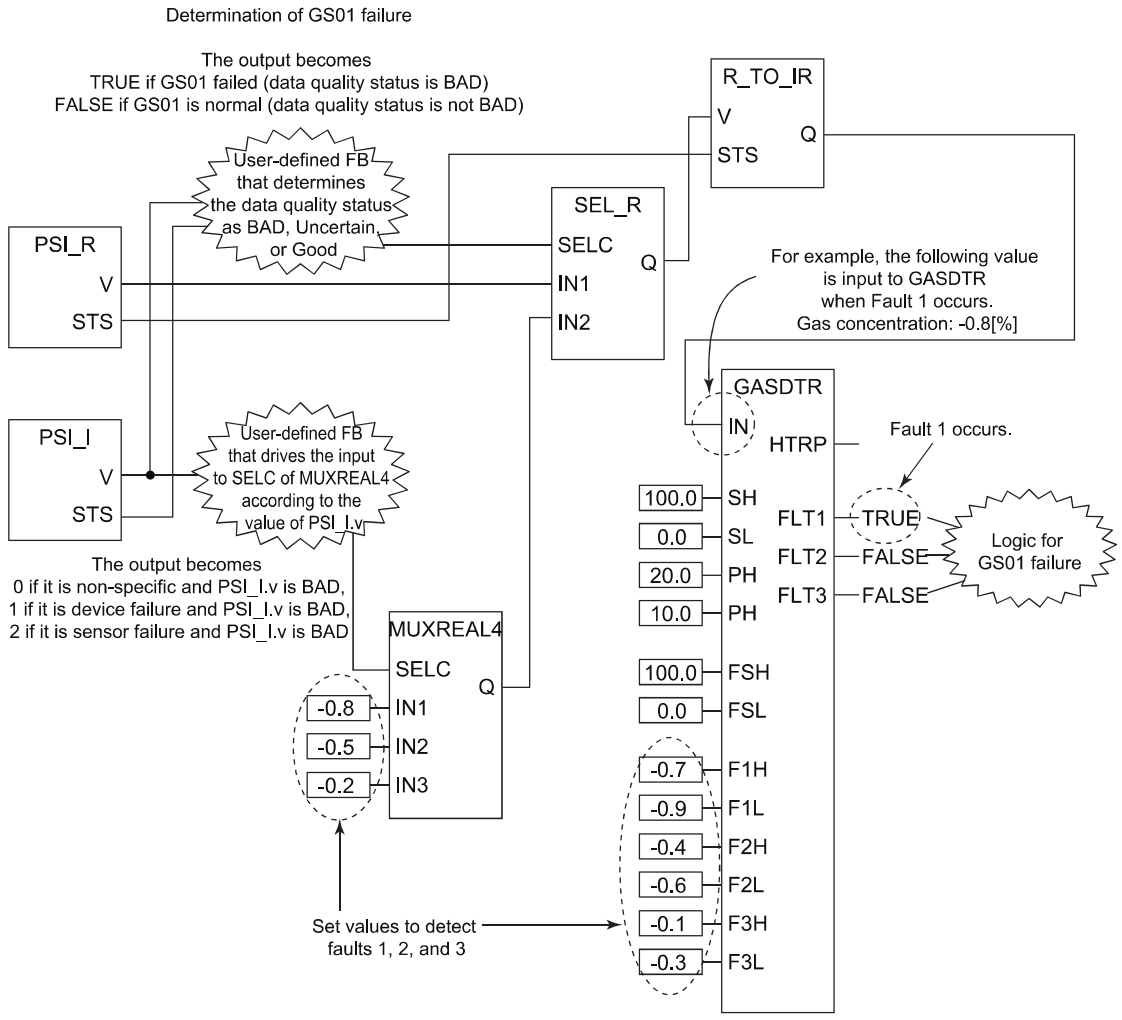

Figure E1.7-2 Example of application logic with use of the fault check function of GASDTR

This figure shows an example where the Quality dependent substatus for Quality = Bad of the data quality status is assumed as follows: “non-specific” is fault 1, “device failure” is fault 2, and “sensor failure” is fault 3.

For example, the application logic operates as follows if fault 1 occurs:

The output from MUXREAL4 is -0.8 and input to SEL_R. TRUE is input to SELC of SEL_R, and therefore SEL_R outputs -0.8. The input to GASDTR is -0.8, and therefore GASDTR detects fault 1.

In addition, since a GS01 failure is reflected in FLT1, FLT2, and FLT3, you can use FLT1, FLT2, and FLT3 as input to the application logic that operates upon a GS01 failure.

Note that if you create the application logic shown in the example, the alarm status of the mapping block for GASDTR will be IOP when a fault occurs in GS01.

IMPORTANT

Although there are eight Quality dependent substatuses of data quality status, GASDTR can handle only three faults. Therefore, the following considerations are required:

- Handle up to three faults out of the Quality dependent substatuses that GS01 supports.
- Consolidate the eight Quality dependent substatuses into three faults.

SEE ALSO For more information about precautions when using the fault check function of GASDTR, refer to:

"● Precautions when setting HH, LL, PH, PL, F1L, F1H, F2L, F2H, F3L, and F3H" in "■ Description" in 5.18, "GASDTR (analog input function block for gas and flame detectors)" in POU Reference Manual (IM 32P03B20-01EN)

Not using the fault check function of GASDTR

If you do not use the fault check function of GASDTR to obtain faults of GS01, disable the fault check function of GASDTR.

You can disable the fault check function of GASDTR by setting the following values to the fault check input terminals of GASDTR.

- FSH/FSL
  Set the gas concentration range of GS01.
  Example:

  FSH=100.0, FSL=0.0

- F1H/F1L/F2H/F2L/F3H/F3L
  Set a value that GS01 never sends. Set the same value for all terminals.

  Example:

  F1H = F1L = F2H = F2L = F3H = F3L = -9999.9

- IDF1/IDF2/IDF3
  Set a null character.

E1.8 Precautions for engineering

This section explains the precautions to take when performing engineering for fire and gas communication.

Downloading to S2LP131

Downloading the following data to S2LP131 starts S2LP131:

- AP program: The firmware of S2LP131.
- PROFINET definition: Definition information regarding PROFINET created with PROFINET Configurator.
- IOM definition: IOM definition information of S2LP131 set with IOM Definition Editor.
- Communication I/O definition: Communication I/O definition information of S2LP131 set with Safety Communication I/O Editor.

The following table shows the relationship between the download operation and the data that is downloaded to S2LP131.

Table E1.8-1 Relationship between the download operation and the data that is loaded onto S2LP131

Download operation	AP program	PROFINET definition	IOM definition	Communication I/O definition
Offline download to the SCS	Yes	No	Yes	Yes
Online download to the SCS	Yes (*1)	Yes (*1)	Yes (*1)	Yes (*1)
IOM download	Yes	Yes	Yes	Yes

*1: Data will be downloaded if there is a difference.

IMPORTANT

- You cannot use automatic IOM download with S2LP131.
- Downloading the PROFINET definition will take up to two minutes from the start of download to when S2LP131 starts. During this time, PROFINET IO communication between S2LP131 and the PROFINET IO-device is suspended. When not downloading the PROFINET definition, S2LP131 starts after four to five seconds from the start of download.

E1.9 Error handling action

This section describes the behavior of S2LP131 when an error occurs with S2LP131 and when an error occurs on an upper level of S2LP131.

Behavior when an S2LP131 error occurs

The following table shows the behavior of S2LP131 when an S2LP131 error occurs.

Table E1.9-1 Error handling action of S2LP131

Event	Behavior of S2LP131
S2LP131 Fail	Stops operation. To restore, remove the cause of the error and perform an IOM download.
Communication board fail	Stops operation. You can obtain details of the cause of error in the IOM Report. To restore, replace S2LP131 and then perform an IOM download.
When starting S2LP131	Loads input data from the PROFINET IO-device.
When recovering from the S2LP131 error	
When recovering from an PROFINET communication error between S2LP131 and YFGW410	

Behavior when an error occurs on an upper level of S2LP131

The following table shows the behavior of S2LP131 when an error occurs on an upper level of S2LP131.

Table E1.9-2 Fallback behavior of S2LP131

Event	Behavior of S2LP131
SCS Fail ESB bus both end Fail	Loads input data from the PROFINET IO-device.
When recovering from the above error	

E1.10 Troubleshooting

When an error occurs with a communication module or field wireless system used in fire and gas communication, the SCS notifies system alarms of safety subsystem communication path errors (SS-SCPATH Error) and safety subsystem communication errors (SS-SCOM Error). Communication module errors, field wireless system errors, and communication errors can be confirmed in the Diagnostic Information window on SENG and the operation and monitoring windows on HIS. Fire and gas communication can respond with system alarms to errors that occur in the system.

SEE ALSO

For more information about I/O module error messages and troubleshooting, refer to:

Message Number 0081 in 3.1, “Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094)” in Messages Reference Manual (IM 32P02B10-01EN)

For more information about SS-SCOM Error messages and troubleshooting, refer to:

Message Number 4209 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

For more information about SS-SCPATH Error messages and troubleshooting, refer to:

Message Number 4211 in 2.1, “System Alarms (Message Numbers 4101 through 4222)” in Messages Reference Manual (IM 32P02B10-01EN)

Analysis of error occurrence factors due to combinations of an SS-SCOM Error and SS-SCPATH Error

When a safety subsystem communication error (SS-SCOM Error) alarm is alerted, this may be accompanied by the alarm of a safety subsystem communication path error (SS-SCPATH Error). Checking the details of both alarms will enable you to identify the cause of the error occurrence. This is because an SS-SCOM Error is a system alarm regarding safety communication between the SCS and devices while SS-SCPATH Error is a system alarm regarding errors of the path of safety communication.

This section describes how to identify the cause of error occurrence by using actual error codes as example. Even when the combination of error codes is that which is not shown in the examples, you can identify the cause of error occurrence in a similar manner to the following examples:

Example 1

```
SCS0101 SS-SCPATH Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=A3B0
SCS0101 SS-SCOM Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=5A04
```

When in addition to an SS-SCOM Error indicating no response of the safety communication, an SS-SCPATH Error indicating no response is simultaneously alerted, it is likely that there is an error with the communication path between S2LP131 and YFGW410. Confirm the status of the communication path.

Example 2

```
SCS0101 SS-SCOM Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=5A04
```

When an SS-SCOM Error indicating no response of the safety communication is alerted alone, it is likely that there is an internal error with the CPU module of the SCS or a device. Confirm the diagnosis information of the SCS or the device diagnosis information of the corresponding device.

Example 3

```
SCS0101 SS-SCPATH Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=A396
SCS0101 SS-SCOM Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=5A02
```

When in addition to an SS-SCOM Error indicating that the safety communication has received faulty data, an SS-SCPATH Error indicating an wireless communication error is simultaneously alerted, it is likely that there is an internal error with a device inclusive of its communication unit. Confirm the device diagnosis information of the corresponding device.

Example 4

```
SCS0101 SS-SCPATH Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=A396
SCS0101 SS-SCOM Error FIO NODE 01 SLOT 01 PORT 01 07PI118 Code=5A04
```

When in addition to an SS-SCOM Error indicating no response of the safety communication, an SS-SCPATH Error indicating an wireless communication error is alerted, it is likely that there is an error with the communication path between a device and YFGW510. Confirm the status of the communication path.

Precautions for adding devices

When you add a device (PROFINET IO-device) to the same subnet while S2LP131 is running, do not use an IP address duplicated with S2LP131 or other existing devices. If there is a duplicate IP address, not only the device having the duplicate address but also other devices may be affected.

This section describes the behavior of devices when the IP address of an added device is duplicated with S2LP131 or another existing device by mistake.

When the IP address of the added device is duplicated with S2LP131

While S2LP131 is running, if the IP address of the device (PROFINET IO-device) that has been added to the same subnet is duplicated with S2LP131, the devices will behave as follows:

- Communication between S2LP131 and the existing devices continues. However, if a communication error occurs between S2LP131 and an existing device, the communication will not be resumed even if the direct cause of the error is eliminated. You cannot find out the cause that is preventing the resumption of communication from the system alarms or status lamps on S2LP131. In this case, you must correct the IP address setting or disconnect the device with a duplicate IP address from the network.

TIP

You cannot find out the cause that is preventing the resumption of communication from the system alarms or status lamps on S2LP131.

- S2LP131 and the added device cannot communicate with each other.

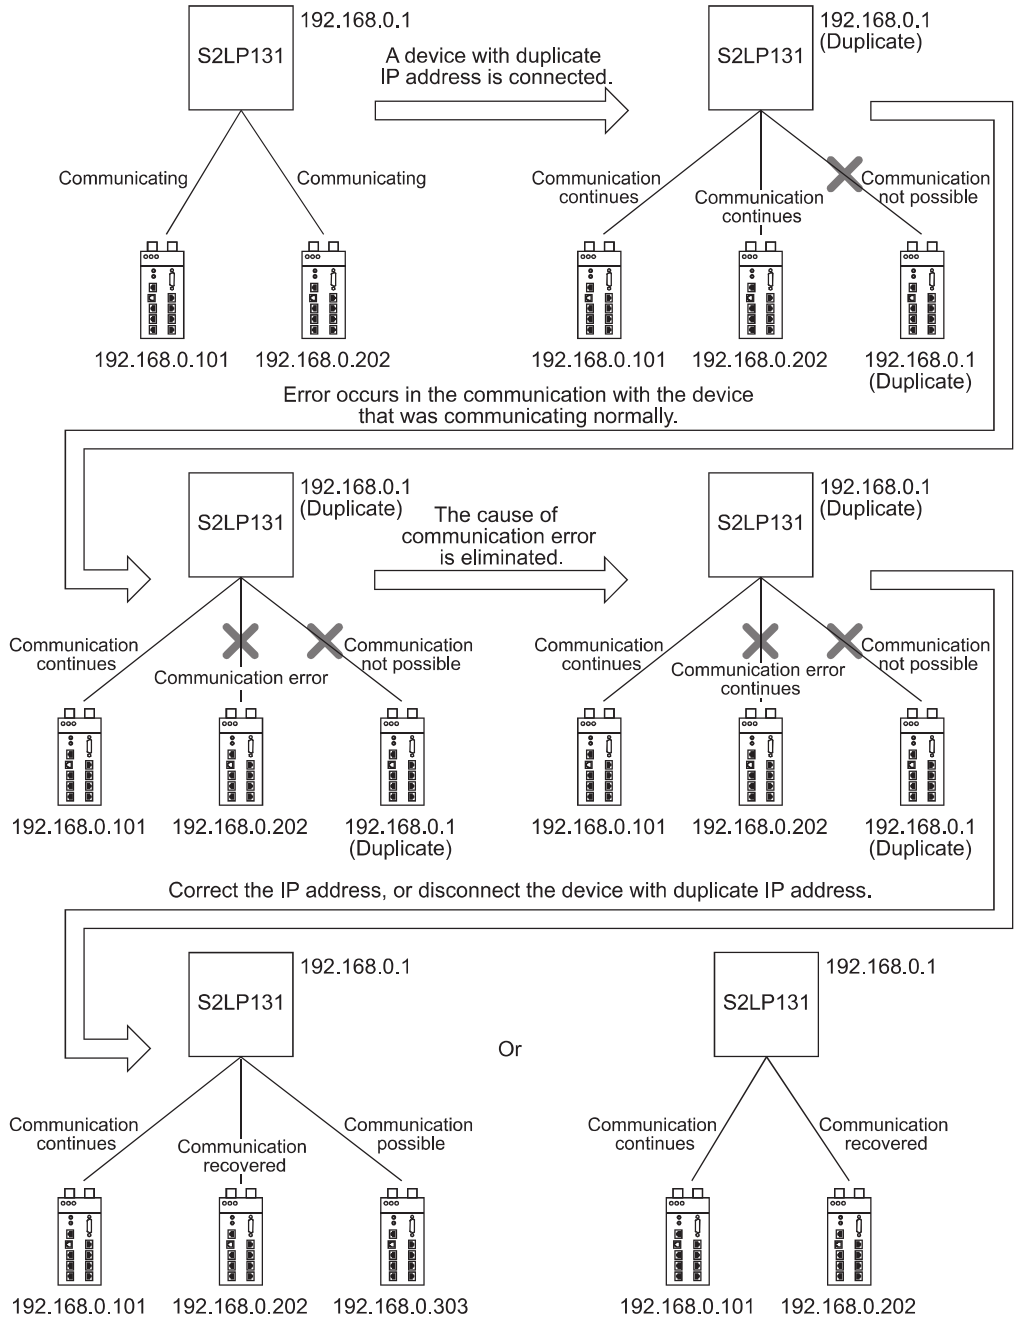

Figure E1.10-1 Behavior when S2LP131 and a device have a duplicate IP address

TIP

When S2LP131 is started, if a device having an IP address duplicated with S2LP131 exists in the same subnet, a system alarm No.0081 I/O module failure (Code=C58E) is generated.

When the IP address of the added device is duplicated with an existing device

If the IP address of the added device (PROFINET IO-device) is duplicated with an existing device, the devices will behave as described below. In such a case, you must correct the IP address setting or disconnect the device with a duplicate IP address from the network.

Example:

S2LP131: 192.168.0.50

Device 1: 192.168.0.51

Device 2: 192.168.0.99 (duplicate)

Device 3: 192.168.0.99 (duplicate)

- Case 1: Behavior when Device 2 is added first, and then Device 3 is added to the network
  - Communication between S2LP131 and Device 1 continues.
  - Communication between S2LP131 and Device 2 continues.
  - Communication between S2LP131 and Device 3 repeats a communication error SS-SCPATH Error Code=A3B0 and recovery.

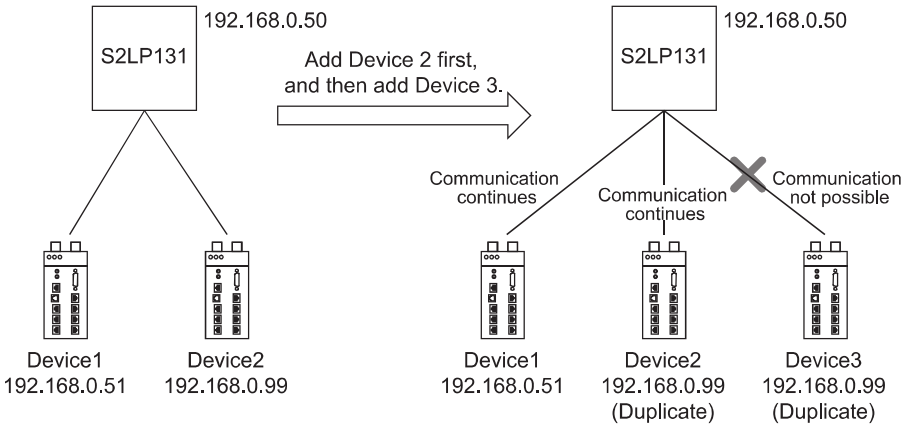

Figure E1.10-2 Behavior when Device 2 is added first, and then Device 3 is added to the network

- Case 2: Behavior when Device 2 and Device 3 are added to the network simultaneously
  - Communication between S2LP131 and Device 1 continues.
  - Communication between S2LP131 and Device 2 and between S2LP131 and Device 3 repeats a communication error SS-SCPATH Error Code=A3B0 and recovery. After a while, the communication between S2LP131 and one of the devices becomes normal, and the communication between S2LP131 and the other device results in a communication error SS-SCPATH Error Code=A3B0.

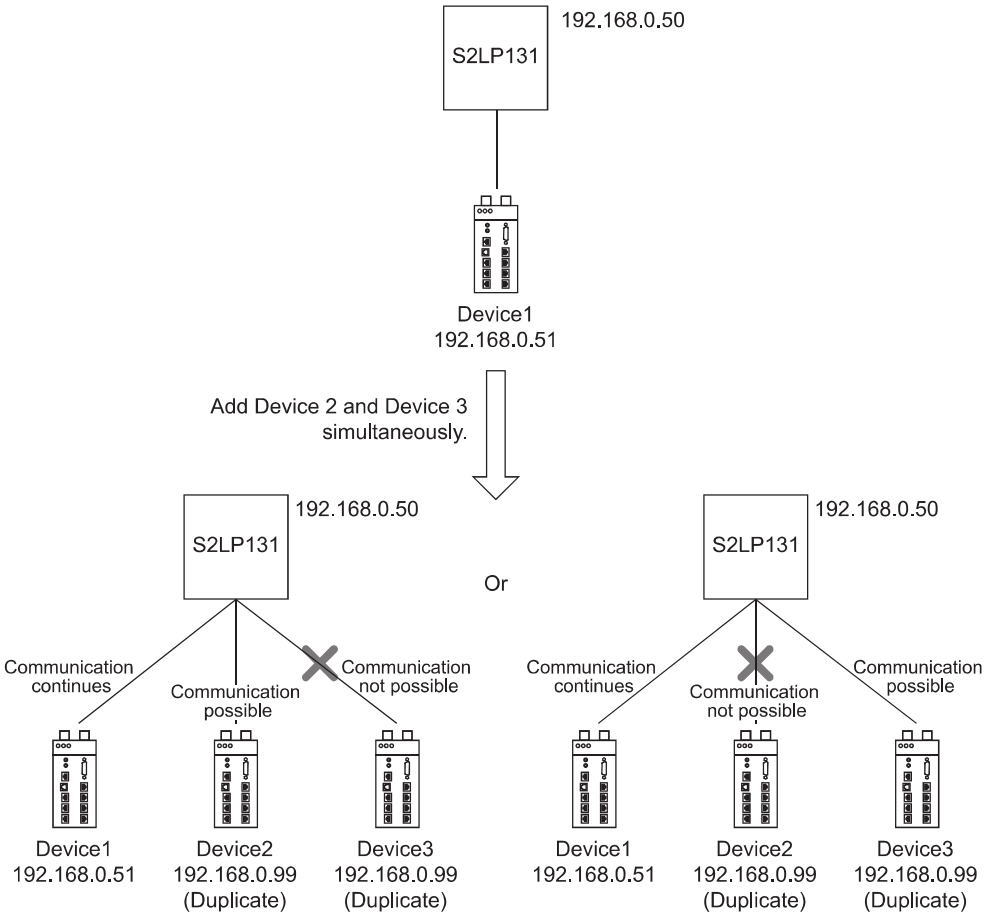

Figure E1.10-3 Behavior when Device 2 and Device 3 are added to the network simultaneously

F. Modbus slave communication

The Modbus slave communication function is one of the Modbus communication functions that are provided by ProSafe-RS. This function allows a safety control station (SCS) to act as a Modbus slave and communicate with other systems.

F1. Common items regarding the Modbus slave communication function

You can use the Modbus slave communication function to connect the ProSafe-RS SCS to other systems. The Modbus master (an external device) can reference or set data in SCS by using the communication function of the communication module. By accessing SCS data using the Modbus slave communication function, you can also display SCS status in other systems.

This section provides an overview and details of the SCS Modbus slave communication function and describes the setting method.

F1.1 Overview of Modbus slave communication

When the Modbus master (external device) sends data, the Modbus slave communication function of SCS receives the data through the communication function of the communication module. The SCS Modbus slave communication function sends a response message to the Modbus master (external device) in response to the request for data.

SEE ALSO For more information about precautions for engineering, refer to:

F4., “Precautions for engineering” on page F4-1

Relationship between SCS, SENG, and Modbus master

The following figure shows the relationship between the SCS, SENG, and Modbus master (external device).

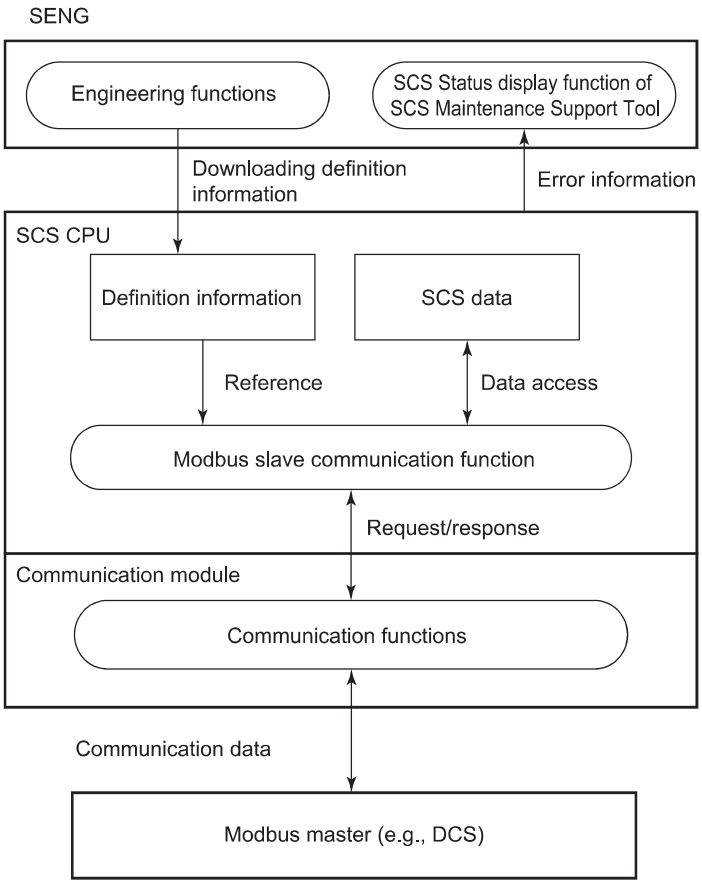

Figure F1.1-1 Relationship with an external device

The following describes the relationship between the SCS, SENG, and Modbus master (external device).

- SENG
  The engineering functions of the SENG download the definition information of the communication module and the definition of correspondence between Modbus device addresses and SCS data, etc. to SCS.
- SCS Maintenance Support Tool
  The SCS status display function of SCS Maintenance Support Tool receives error information and notifies the error status if there is any error in the communication module and communication content.

- Modbus master
  The Modbus master references and sets SCS data through the communication module.
- SCS
  The Modbus slave communication function of SCS accesses data in response to a request from the Modbus master and returns the result to the Modbus master through the communication module.

Interface with the Modbus master

SCS operates as a Modbus slave. An external device operates as the Modbus master and it can reference and set SCS data.

The external device and SCS are connected with a serial communication module or Ethernet communication module that is installed in the SCS node. Neither of these modules support dual-redundant configuration. These modules are interference-free modules that do not interfere with the safety loop.

- Serial communication module (RS-232C, 2-port)
- Serial communication module (RS-422/RS-485, 2-port)
- Ethernet communication module (10BASE-T, 1-port)

Data access by device speciation

The Modbus master requests data access to the SCS (Modbus slave) using the Modbus devices names in the following table as the interface.

SCS does not have actual Modbus devices. SCS assigns virtual Modbus device addresses to variables of the application logic and sends them responses accordingly.

Table F1.1-1 Modbus devices

Virtual Modbus device	Data	Access from master to slave (*1)	
		Read (reference)	Write (set)
Coil	Output device with 1 bit/channel	Yes	Yes (*2)
Input relay	Input device with 1 bit/channel	Yes	No
Input register	Input register with 16 bit/channel	Yes	No
Holding register	Output register with 16 bit/channel	Yes	Yes (*2)

*1: Yes: allowed
No: not allowed
*2: The Modbus master can only set data on SCS (Modbus slave) if virtual Modbus devices are assigned to external communication function blocks.

The correspondence between the addresses of the Modbus devices and variables of the application logic is defined using SCS Manager.

SEE ALSO

For more information about procedure for supporting addresses and application logic variables for Modbus devices, refer to:

F1.5.1, “Definitions in Modbus Address Builder” on page F1-12

Data settings from the Modbus master

Data can be set to variables of the application logic from the Modbus master through Modbus slave communication using external communication function blocks.

Modbus slave communication execution timing

As a Modbus slave, SCS performs Modbus slave communication at the idle time of each scan for the application logic. SCS checks whether any request has been sent from the Modbus master through the communication module. If SCS finds any request, SCS will respond to the request only when the scan has idle time.

SCS only responds to the request in this communication processing and will set the data to the variables of application logic in the scan by the safety functions after responding to the request.

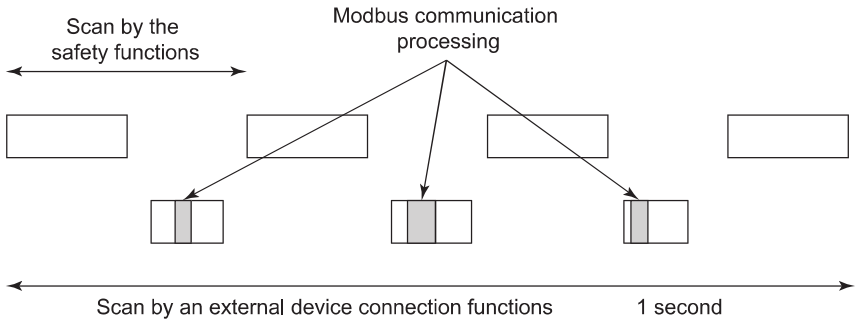

Figure F1.1-2 Modbus slave communication execution timing

Monitoring from HIS or SCS Maintenance Support Tool

The communication module status can be monitored from HIS or SCS Maintenance Support Tool.

Table F1.1-2 Monitoring of communication modules from HIS or SCS Maintenance Support Tool

Window	Monitoring operation
SCS State Management	Displays whether the communication module is normal or faulty. No communication errors are displayed.
System alarm	Errors in the communication module are notified by system alarms.

Operation when the communication module is added online

It is possible to make changes online to applications that involve addition or removal of serial communication modules. If you install an additional communication module in the SCS and execute an online change download, the communication module starts to run immediately. During downloading, the diagnostic information messages (IOM Fail, and then IOM Recover) are generated, but the operating mode of the SCS remains the same. You do not need to perform the Output enable operation or any other special operation.

F1.2 Data access using the Modbus communication functions

When the Modbus master sends a request for data access, SCS receives the data through the ALR111/ALR121 serial communication module or ALE111 Ethernet communication module. The SCS reads/writes data within itself using the Modbus communication commands and notifies the result to the Modbus master.

By using the Modbus communication functions, the SCS references or sets SCS data in response to requests from the Modbus master. To process the requests, it references the database that defines the correspondence between Modbus device addresses and application logic variables.

Referencing/setting SCS data

This function allows the Modbus master to reference internal variables (BOOL, DINT, REAL) or I/O variables of DI, DO and AI. It also allows the Modbus master to set (Modbus Word Order), variables data of external communication function blocks.

Word reversal

To reference SCS data, the order of 32-bit data can be changed.

The direct order is in the order of the upper word first and the lower word. The reverse order is in the order of the lower word first and the upper word if this option is specified.

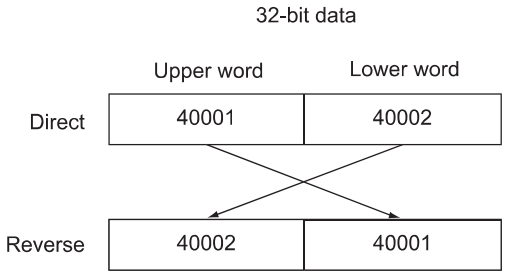

Figure F1.2-1 Execution example of word reversal

One shot write

When setting SCS data, a one shot write operation is performed on data that does not interfere with the safety loop. An error is returned if it is requested to set data that interfere with the safety loop.

16-bit Modbus master support mode

You can use 16-bit Modbus master support mode when connecting SCS to a Modbus master that handles only 16-bit data. If the Modbus master does not read or write data of SCS in 16-bit units, leave 16-bit Modbus master support mode disabled (default setting), and access data in 32-bit units. When this mode is enabled, the Modbus master can read and write data including 16-bit integer data, 32-bit signed integer data, and 32-bit floating point data. However, this requires very complicated ProSafe-RS application.

If the following types of data access is required, enable 16-bit Modbus master support mode by using SCS Constants Builder.

Table F1.2-1 Data accesses available in 16-bit Modbus master support mode

Access from the Modbus master to SCS	Data type	Function code (decimal)
Read one word from a holding register with an odd or even reference number	Signed integer data Floating-point data	Read Holding Registers (03)
Read one word from an input register with an odd or even reference number	Signed integer data Floating-point data	Read Input Registers (04)
Write one word to a holding register with an odd or even reference number	Signed integer data	Use the following function code whichever is available with the Modbus master: Preset Single Register (06) or Preset Multiple Registers (16)

SEE ALSO For more information about function codes supported on an SCS, refer to:

- "● Function code" on page F1-23
- "● Cautionary notes on function codes" on page F1-24

● Considerations on using the 16-bit Modbus master support mode in Modbus slave communication

When executing the following functions by using the function code from the Modbus master, set 16-bit Modbus master support mode for the definition of SCS Constants Builder to Enable.

- Writing to a single holding register by using the function code 06 from the Modbus master
- Reading one-word data or specifying even reference numbers by using the function codes 03 and 04 from the Modbus master
- Writing one-word data or specifying even reference numbers by using the function code 16 from the Modbus master

The function code 06 allows data to be written to the upper or lower word of 32-bit data. To use the written data as 16-bit data, create an application for extracting the upper or lower word of the 32-bit data.

When 16-bit Modbus master support mode is Enable in the SCS Constants Builder, the simultaneity of the upper and lower words is not assured because writing to the upper and lower words can be performed independently. If you intend to use the data as 32-bit data, write the data in units of 32 bits without using the function code 06 or 16.

■ Communication test

When testing for referencing a variable of SCS, change a value of the variable by using the Forcing function and confirm the value by the Modbus master. When testing for setting an external communication function block of SCS, connect a variable with the external function block and confirm the value of the variable by the Modbus master reading back.

SEE ALSO For more information about forcing function, refer to:

F8., "Forcing function" in Engineer's Reference Manual (IM 32P04B10-01EN)

F1.3 Setting items relating to Modbus slave communication

The following settings are required for the Modbus master to access application logic variables on an SCS through Modbus slave communication.

- Definition of communication modules
  To Modbus slave communication, define the serial communication module (ALR111/ALR121) or Ethernet communication module (ALE111) and set required I/O parameters. When performing I/O list engineering, you can use the IOM Definition Editor. When performing RS original engineering, you can use the I/O Wiring View and I/O Parameter Builder.
- Definition of addresses of Modbus devices
  You can define virtual Modbus devices on SCS and assign them to variables, using the Modbus Address Builder.
- Data setting using Modbus slave communication
  You can assign external communication function blocks to set SCS data from the Modbus master (external device).

F1.4 Definition of communication modules

You can define the communication module for SCS so that SCS can preform Modbus communication.

The editor to be used differs depending on engineering methods.

When performing I/O list engineering, you can define the serial communication module or Ethernet communication module and set parameters by using IOM Definition Editor.

When performing RS original engineering, you can define the serial communication module or Ethernet communication module by using the I/O Wiring View of the SCS Manager first. Then you can set parameters for each port of the module by using the I/O Parameter Builder.

This section mainly describes for the case when performing RS original engineering. The communication module definition items and the parameter setting items that are required in I/O list engineering are the same as those for RS original engineering.

SEE ALSO

For more information about I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about RS original engineering, refer to:

Appendix 2., “RS original engineering” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about I/O Wiring View and I/O Parameter Builder, refer to:

Appendix 2.2, “Definitions of inputs/outputs” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about parameter settings for communication modules, refer to:

Appendix 1.2, “Settings for modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

F1.4.1 Definitions in I/O Wiring View

When performing RS original engineering, you can define the serial communication module (ALR111/ALR121) or Ethernet communication module (ALE111) by using the I/O Wiring View in the SCS Manager as follows:

1. Open I/O Wiring View and select ALR111, ALR121, or ALE111. The number of channels should be set to 0.
2. Select parameters for the module and specify the node number and the slot number. The node number and the slot number must not overlap with those of other input/output modules and communication modules.

F1.4.2 Definitions in I/O Parameter Builder

When performing RS original engineering, you can specify parameters for the communication module by using I/O Parameter Builder. The parameters to specify differ depending on the type of the communication module.
Because a serial communication module (ALR111/ALR121) has two ports, two sets of parameters are required. You can specify the parameters in the Port1 and Port2 tabs of I/O Parameter Builder.

For an Ethernet communication module, you can set the parameters in the Ethernet communication module parameters tab of I/O Parameter Builder.

SEE ALSO

For more information about parameter settings for serial communication modules, refer to:

"■ Port 1, Port 2 tab" on page F2-6

For more information about parameter settings for Ethernet communication modules, refer to:

"■ Module tab of the Ethernet communication module" on page F3-5

F1.5 Definition of addresses of Modbus devices

To access variables of the application logic on SCS from the Modbus master through Modbus slave communication, it is necessary to define the correspondence between the variables and the addresses of Modbus devices. Define Modbus device addresses for the variables using Modbus Address Builder.

Modbus device addresses can be assigned to I/O variables and internal variables.

F1.5.1 Definitions in Modbus Address Builder

Use Modbus Address Builder to associate the variables of the application logic with the addresses of Modbus devices.

■ Assigning variables in Modbus Address Builder

Modbus devices can belong to the following four types: coils, input relays, input registers and holding registers. A reference number is assigned to each Modbus device type. The variable name to be accessed is assigned to a reference number in Modbus Address Builder. The type of variable to be assigned is selected according to the reference number. For example, a variable of BOOL type or IO_BOOL type can be assigned to an input relay.

SEE ALSO For more information about reference numbers, refer to:

"■ Modbus device tabs" on page F1-18

● Types of Modbus devices and variables

The type of variables that can be assigned to each reference number of Modbus devices is as follows:

Table F1.5.1-1 Variables to which Modbus device addresses can be assigned

Modbus device type	Variable type	Remark
Coil	ECW_B	Instance of external communication function block (BOOL type)
	BOOL	Read-only. Writing data to the SCS results in an error when the SCS runs.
	IO_BOOL	Read-only. Writing data to the SCS results in an error when the SCS runs.
	ECWR_B	Available only with SCSU1, which is dedicated to integration with CI Server
Input relay	BOOL	-
	IO_BOOL	Only the data value is included, and the data status is not included.
Input register	REAL	Requires two addresses per data.
	DINT	Requires two addresses per data.
	IO_REAL	Only the data value is included, and the data status is not included. Requires two addresses per data.

Continues on the next page

Table F1.5.1-1 Variables to which Modbus device addresses can be assigned (Table continued)

Modbus device type	Variable type	Remark
Holding register	ECW_R	Instance of external communication function block (REAL type) Requires two addresses per data
	ECW_I	Instance of external communication function block (DINT type) Requires two addresses per data
	REAL	Read-only. Writing data to the SCS results in an error when the SCS runs
	DINT	Read-only. Writing data to the SCS results in an error when the SCS runs
	IO_REAL	Read-only. Writing data to the SCS results in an error when the SCS runs
	ECWR_R	Available only with SCSU1, which is dedicated to integration with CI Server
	ECWR_I	Available only with SCSU1, which is dedicated to integration with CI Server

The BOOL, IO_BOOL, DINT, REAL, and IO_REAL-type variables are read-only. You can assign these variables to input relays and input registers. In Modbus Address Builder, variables of these types are not displayed in the data menu area for coils and holding registers. To assign these variables to coils or holding registers, you need to enter the variable names directly.

When the Modbus device is a coil or holding register, you can set data from the Modbus master only for the types that have correspondence with external communication function blocks such as ECW_B, ECW_R, and ECW_I types.

Variable names

A variable name can be up to 69 characters long. Both global and local variables can be accessed regardless of the scope. Describe a scope name after "@" to access local variables.

To access internal variables in a user-defined function block, you can use the SCS Manager Dictionary View to name instances of the user-defined function block itself. Specify the variable name in the following format. Up to two nesting levels can be specified for an instance name.

```
Instance name.internal variable name
```

Table F1.5.1-2 Example of variable names

Variable name	Scope	Description
VAR1	Global	Global variable
VAR2@PROG1	PROG1	A local variable of a function in PROG1
FB01.VAR3	Global	The internal variable VAR3 of an instance of the user-defined function block FB01
FB01.VAR3@PROG1	PROG1	The internal variable VAR3 of an instance of the user-defined function block FB01, which is locally defined in a function of PROG1
FB01.FB2.VAR3	Global	The internal variable VAR3 of an instance of the user-defined function block FB2 used inside an instance of the user-defined function block FB01 (The limit of nesting of a function block is two)

SEE ALSO For more information about SCS Manager Dictionary View, refer to:

Workbench User's Guide

How to define variable names

Variable names can be specified in the Variable name columns in the tabs for the four different types of Modbus devices.

A variable can be defined in one of the following ways:

- Direct entry from the keyboard
- Double-clicking a variable name in the data menu area
- Drag and drop a variable from Dictionary View

Direct entry from the keyboard

Enter a variable name in the Variable name column directly from the keyboard.

Double-clicking a variable name in the data menu area

The data menu area of Modbus Address Builder contains the Variable tab and the IOM tab. Double-click a variable name in the Variable tab to set the variable name in the Variable name column.

Double-click a node number or a slot number in the IOM tab to set variables wired for each Input/Output Module at once.

Drag and drop from Dictionary View

Drag and drop a variable name from Dictionary View to a variable name field of Modbus Address Builder to register the variable name in Modbus Address Builder. If you drag and drop multiple variable names, they are registered in order starting from the top of the Variable name column where they are dropped. If variable names have already been registered in the Variable name field, they are overwritten.

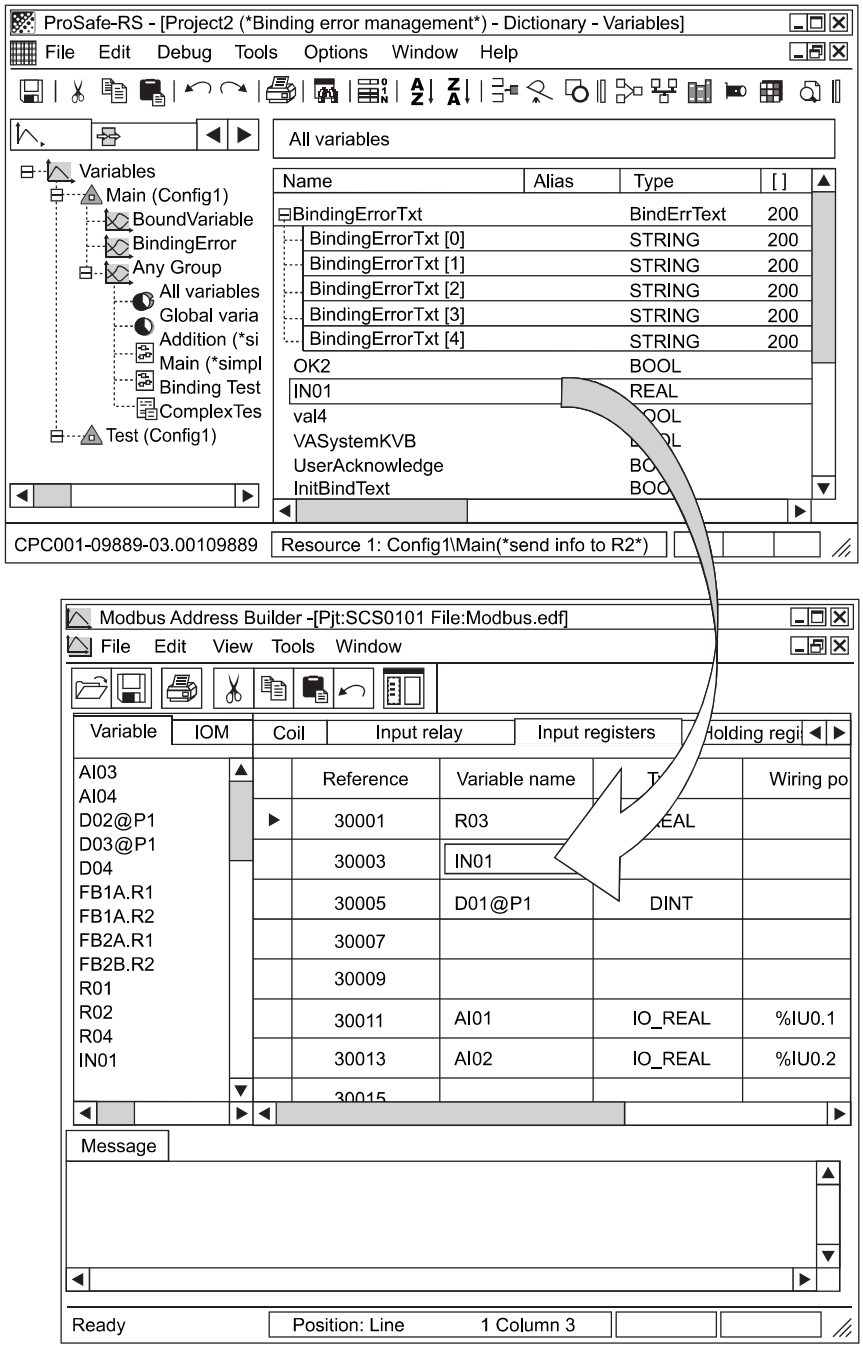

Figure F1.5.1-1 Drag and drop from Dictionary View

IMPORTANT

Changing a name and type of a variable in Dictionary View will not change the corresponding definition in Modbus Address Builder. Make the corresponding modifications in Modbus Address Builder according to changes.

- If a variable is added
  Use Modbus Address Builder and assign a reference number to the variable as necessary.
- If a variable name is changed
  Change the corresponding variable name in Modbus Address Builder as well.
- If a variable is deleted
  Delete the corresponding variable in Modbus Address Builder.

F1.5.2 Window configuration of Modbus Address Builder

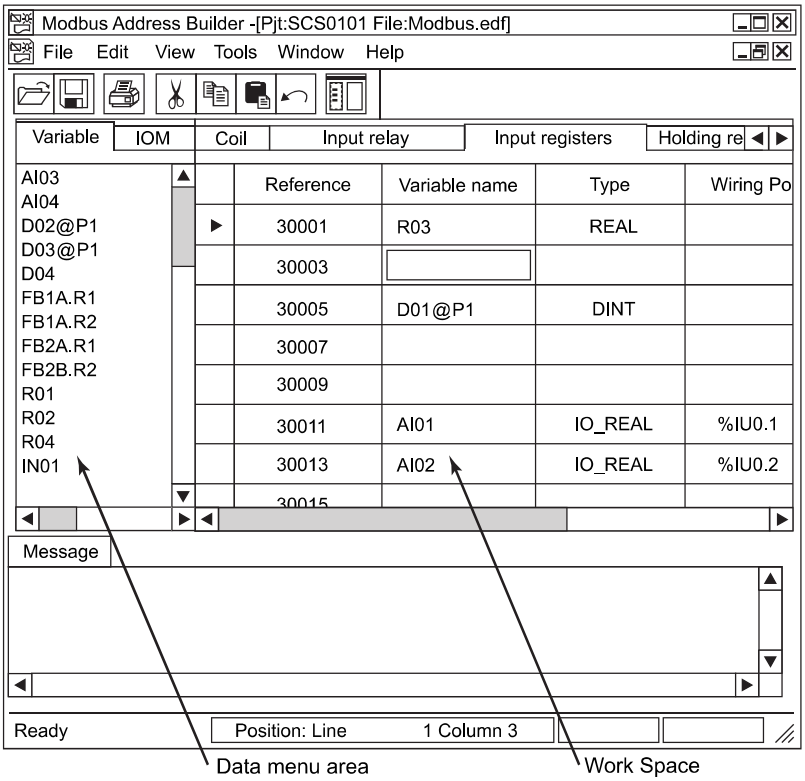

Figure F1.5.2-1 Window configuration of Modbus Address Builder

The Modbus Address Builder window mainly consists of the data menu area and work space.

Data menu area

The data menu area of Modbus Address Builder contains two tabs, the Variable tab and the IOM tab. Modbus Address Builder allows setting variable names only.

Variable tab

The Variable tab displays a list of variables that can be defined. The variable names displayed change depending on the type of Modbus devices displayed in the work space.

Variables that have been defined already at the time a variable was set or deleted are deleted from the list and not displayed.

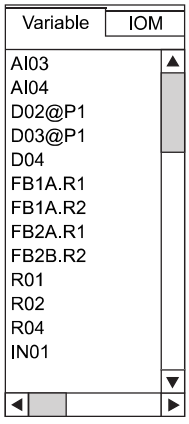

Figure F1.5.2-2 Data menu area - Variable tab

IOM tab

When the input relay tab or the input register tab is displayed, in the workspace the IOM tab becomes available.

For an Input Relay, a discrete input module will be displayed; while for an Input Register, an analog input module will be displayed.

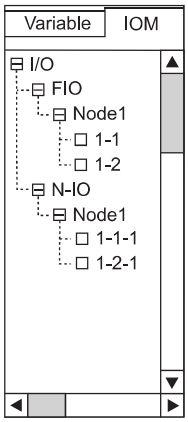

Figure F1.5.2-3 Data menu area - IOM tab

Modbus device tabs

The following tabs are provided in the Modbus Address Builder workspace:

- Coil tab
- Input relay tab
- Input registers tab
- Holding registers tab

Reference numbers in tabs

Each tab displays the reference numbers.

TIP

The range of reference numbers is expanded in the following manner for new SCS projects that are created in SENG in R4.08.00 or later. The applicable SCSs are SCSP1/SCSU1/SCSP3/SCSL2.

- Coil tab
  Range of reference numbers: 00001 to 09999

  Example:

  00001, 00002, 00003, ... , 09999

  Output devices of 1 bit per channel (allows both input and output)
- Input relay tab
  Range of reference numbers: 10001 to 19999

  Example:

  10001, 10002, 10003, ... , 19999

  Input devices of 1 bit per channel (allows input only)
- Input registers tab
  Range of reference numbers: Odd numbers between 30001 and 39999

  Example:

30001, 30003, 30005, ... , 39999

Input registers of 16 bits per channel (allows input only)

Each register is assigned to a 32-bit data, i.e. 2 words compose one data.

- Holding registers tab
  Range of reference numbers: Odd numbers between 40001 and 49999

  Example:

  40001, 40003, 40005, ... , 49999

  Output registers of 16 bits per channel (allows both input and output)

  Each register is assigned to a 32-bit data, i.e. 2 words compose one data.

Items displayed in tabs

Each tab displays the following items: Some items are not displayed depending on the tab. The user can set values only in the Variable name column.

- Reference
  Addresses of Modbus devices. These are displayed in advance in numerical order.

  This item is commonly displayed for all the tabs.

- Variable Name
  Variable names to be assigned.

  This item is commonly displayed for all the tabs.

- Type
  Types of variables. These are displayed once variable names are determined.

  This item is commonly displayed for all the tabs.

- Comment
  Comments attached to variables. These are displayed once variable names are determined.

  This item is commonly displayed for all the tabs.

- Wiring Position
  Installation positions of channels corresponding to variables. This item is displayed only for the Input relay and Input registers tabs. If the variable type is IO_BOOL in the case of the Input relay tab and IO_REAL in the case of the Input registers tab, the wiring positions are displayed when variables are determined.

  The format for FIO is %IUm.n(X-Y-Z).

  Example: %IU0.0(1-1-1)

  The format for N-IO is %IUm.n(X-A-Y-Z).

  Example: %IU1.0 (2-1-1-1)

F1.6 Data setting using Modbus slave communication

The SCS Modbus slave communication function allows setting data on SCS from the Modbus master. Use external communication function blocks to set SCS data from the Modbus master. Data setting through external communication function blocks does not interfere with the safety loop (interference-free). Make sure to read back and confirm the data set by external communication function blocks, when using the data for safety application.

Data setting using external communication function blocks

It is possible to read and write data of SCS from the Modbus master using the SCS Modbus slave communication function. The Modbus master device sends a data access request to SCS, using Modbus device address as interfaces. Although SCS is not equipped with any actual Modbus devices, it acts as if it has them and responds to the data access requests from the Modbus master.

Data can be set from the Modbus master to the SCS by combining the Modbus slave communication function and external communication function blocks. The Modbus device types that can be used for data setting are coil and holding register. Assign instance names of external communication function blocks to coils and holding registers using Modbus Address Builder.

- To set BOOL-type data, assign an ECW_B instance name to the reference number of a coil.
- To set DINT-type data, assign an ECW_I instance name to the reference number of a holding register.
- To set REAL-type data, assign an ECW_R instance name to the reference number of a holding register.

As a result, data set from the Modbus master are output from the output parameter OUT of the associated external communication function blocks.

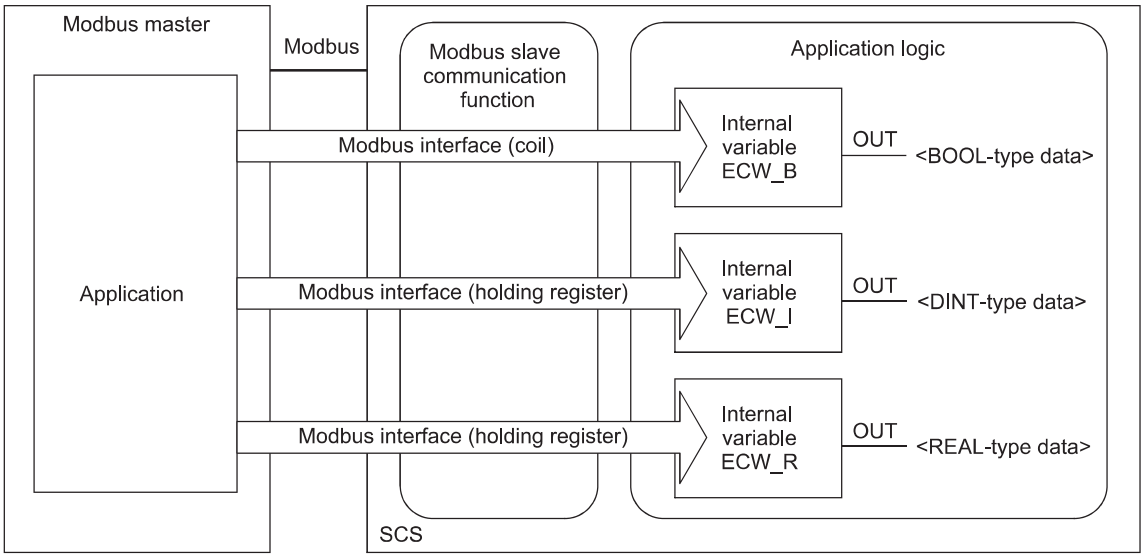

Figure F1.6-1 Data setting using the Modbus slave communication function and external communication function blocks

The user uses Modbus Address Builder to assign reference numbers of these Modbus devices to external communication function blocks and read-back variables.

Table F1.6-1 Modbus devices used for setting and read-back

Data type (*1)	Write register (*2)	Read register (*3)
BOOL	Coil	Input relay
DINT	Holding register	Input register
REAL	Holding register	Input register

*1: Assignation in Modbus Address Builder
*2: Assign registers to external communication function blocks
*3: Assign to readback variables (the READBACK variables in the following figure, "Figure Readback application")

BOOL-type data is set using the following procedure.

1. Use Modbus Address Builder to assign a reference number of a coil to ECW_B (BOOL-type external communication function block).
2. In Modbus Address Builder, assign a reference number of an input relay to a read-back variable.
3. The Modbus master (an external device) sets an address in a request message based on the reference number of the coil and writes data.
4. The Modbus master (an external device) sets an address in a request message based on the reference number of the input relay and reads back data.

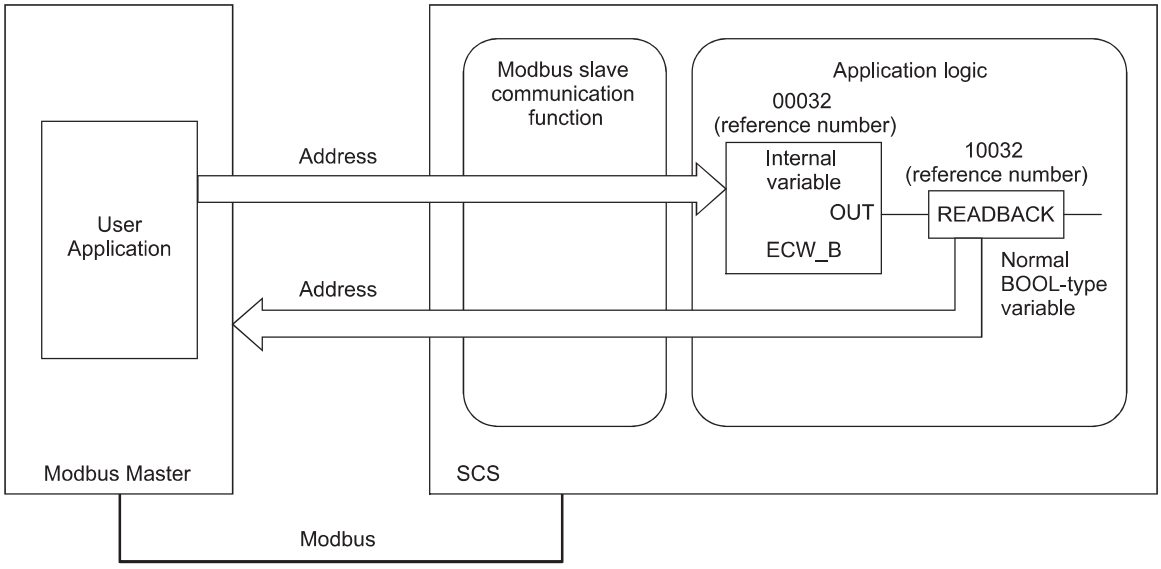

Figure F1.6-2 Readback application

SEE ALSO

For more information about Modbus Address Builder, refer to:

F1.5.1, “Definitions in Modbus Address Builder” on page F1-12

For more information about reference numbers, refer to:

“● Data” on page F1-25

For more information about external communication function blocks, refer to:

B6., “Data setting using external communication function blocks” on page B6-1

● Restrictions on the number of data setting communication operations using Modbus slave communication

On receiving a data setting request from the Modbus master, SCS returns a response and retains the request it accepted.

- A data setting request message from the Modbus master is referred to as a "request" here. Up to 32 data values can be specified in a request.
- Up to four requests can be retained across all Modbus slave communication at the same time.
- SCS will process the retained data setting requests from the Modbus master four requests per second at maximum when the scan period of the application logic is shorter than 250 ms. When the scan period is 250 ms or longer, SCS will process one request in one scan period. If SCS also retains any request from FCS and/or HIS for data setting via tag name interface in addition to requests from the Modbus master, the SCS will process only one request in one scan period in the order of acceptance.
- SCS responds with an error if the number of retained requests is four when SCS receives a request from the Modbus master.

IMPORTANT

Periodical data setting will result in a writing error. Do not set data periodically from the Modbus master.

Confirming data set using Modbus slave communication

When setting data from the Modbus master using Modbus slave communication, it is necessary to perform readback for checking the data. When performing a readback, the application logic should be designed as shown in the previously listed "Figure Readback application." Data is set to an external communication function block and the data is read back from a variable connected to an OUT (READBACK variable in the previous figure).

F1.7 Messages communication

In data communication between the Modbus master and SCS, SCS sends a response message in response to a request message from the Modbus master. When SCS detects an error relevant to the communication module, the SCS sends the diagnostic information message through the control bus.

Request message from the Modbus master

The request message from the Modbus master is composed of the following information according to the communication module used.

- For serial communication modules
  - Slave address
  - Function code
  - Data
  - Error check code
- For Ethernet communication modules
  - Transaction identifier
  - Protocol identifier
  - Field length
  - Unit identifier
  - Function code
  - Data

Slave address (specific to serial communication modules)

A slave address is a station number (1 to 247) that is set for a Modbus slave.

The Modbus master communicates only with the SCS with a matching slave address. A request message from the Modbus master is received by all the Modbus slaves. Of these, only the SCS whose slave address matches the one in the request message processes the request according to the received message.

Function code

The function codes supported on an SCS for request messages are as follows:

Table F1.7-1 Function codes supported on an SCS

Function code (decimal)	Description	Maximum size	Remark
01	Read Coil Status	512 bits	512 bits = 32 words
02	Read Input Status	512 bits	-
03	Read Holding Registers	124 words (62 or 124 data units)	When 16-bit Modbus master support mode is disabled, up to 62 data units (32 bits per unit) can be read. When enabled, up to 124 data units (16 bits per unit) can be read.

Continues on the next page

Table F1.7-1 Function codes supported on an SCS (Table continued)

Function code (decimal)	Description	Maximum size	Remark
04	Read Input Registers	124 words (62 or 124 data units)	When 16-bit Modbus master support mode is disabled, up to 62 data units (32 bits per unit) can be read. When enabled, up to 124 data units (16 bits per unit) can be read.
05	Force Single Coil	1 bit	Restriction from protocol
06	Preset Single Register	1 word (16 bits)	Can be used when 16-bit Modbus master support mode is enabled in SCS Constants Builder. Cannot be used by default.
08	Loopback Diagnostic Test	-	Can only be used for serial communication modules.
15	Force Multiple Coils	32 bits	-
16	Preset Multiple Registers	64 words (*1) (32 or 64 data units)	When 16-bit Modbus master support mode is disabled, up to 32 data units (32 bits per unit) can be set. When enabled, up to 64 data units (16 bits per unit) can be set.

*1: If an even number is specified for the reference number, the maximum size becomes 63 words (63 data units).

Cautionary notes on function codes

Normally, analog data used in SCS are 32-bit signed integer or 32-bit floating point data. Because an input register or holding register is assigned to 32-bit data, one data unit consists of two words. Note the following points when using these data:

IMPORTANT

- When the Modbus master writes 32-bit floating point data to SCS, writing a NaN (not a number) or an infinite value (+INF or -INF) by using Preset Multiple Registers (16) does not result in an error but the data is not written to the SCS.

- When 16-bit Modbus master support mode is disabled (default setting), specify an odd reference number for Read Holding Registers (03), Read Input Registers (04), or Preset Multiple Registers (16). For the number of registers, specify an even number.

IMPORTANT

- When 16-bit Modbus master support mode is enabled, the Modbus master can read and write data including 16-bit integer data, 32-bit signed integer data, and 32-bit floating point data. However, this requires very complicated ProSafe-RS application.
- You must note that simultaneity of the upper and lower words of 32-bit data is not assured if you read or write the upper word and the lower word separately in 16-bit Modbus master support mode.

- When 16-bit Modbus master support mode is enabled, you can specify an odd number or even number for the reference number and the number of registers for Read Holding

Registers (03), Read Input Registers (04), and Preset Multiple Registers (16). Therefore, error codes 10 and 11 (hexadecimal) do not occur in this mode.

- When 16-bit Modbus master support mode is enabled, the following operations will result in an error (error code 02).
  - Writing only to the upper or lower word of 32-bit floating point data by using Preset Single Register (06).
  - Writing only to the upper or lower word of 32-bit floating point data by using Preset Multiple Registers (16) specifying an odd number for the number of registers.
  - Writing only to the upper or lower word of 32-bit floating point data by using Preset Multiple Registers (16) specifying an even number for the reference number.

Data

This contains the detailed information for SCS to execute the requested function. The address information of Modbus devices (coil, input relay, input register and holding register) is the relative number from the first reference number of each device. Reference numbers of ProSafe-RS start from one. The following table shows the relationship between reference numbers and relative numbers.

Table F1.7-2 Relationship between reference numbers and relative numbers

Device	Reference number	Relative number
Coil	0xxxx	0xxxx - 1
Input relay	1xxxx	1xxxx - 10001
Input register	3xxxx	3xxxx - 30001
Holding register	4xxxx	4xxxx - 40001

TIP

The following table shows an example of the "Device & Address" setting that is specified in the Communication I/O Builder of CENTUM when communicating with CENTUM.

Table F1.7-3 Reference numbers and relative numbers when specifying a holding register from CENTUM

Communication module	Address specified by CENTUM	Relative number	Reference number
Serial communication module	A40001	0000	40001
Ethernet communication module	A40000	0000	40001

SEE ALSO

For more information about reference numbers, refer to:

"■ Modbus device tabs" on page F1-18

Error check code (specific to serial communication modules)

Error check information is used to detect errors in messages occurring during a signal transmission (bit errors). A request message sent to SCS contains CRC (Cyclic Redundancy Check) information. SCS verifies the CRC in a request message and discards the message if an error is detected.

Transaction identifier (specific to Ethernet communication modules)

The Modbus master assigns a unique identifier to each request message. SCS copies this value to the transaction identifier field of the response message.

Protocol identifier (specific to Ethernet communication modules)

The Modbus master sets this field to the fixed value of 0. SCS copies this value to the protocol identifier field of the response message.

Field length (specific to Ethernet communication modules)

Byte length of the fields (unit identifier + function code + data).

Unit identifier (specific to Ethernet communication modules)

This field identifies the Modbus slave and is set to the same value as the slave address that is used in the Modbus communication protocol (RTU mode). SCS copies this value to the unit identifier field of the response message.

SEE ALSO For more information about Modbus protocol (RTU mode), refer to:

"■ Supported Modbus protocol" on page F2-2

Response message from SCS

SCS sends a response message when it receives a request message from the Modbus master. The response message that SCS sends differs depending on whether the request message is sent normally or abnormally. In some cases, SCS does not send a response message in response to a request message.

Response message under abnormal conditions

When errors other than transmission errors are detected in a request message, or when the SCS is processing the request message, the SCS sends the response message with the following information. The format of the response message differs depending on the communication module used.

- For serial communication modules
  - Slave address
  - Function code: The function code in a request message plus 0x80
  - Error code
  - Error check code
- For Ethernet communication modules
  - Transaction identifier
  - Protocol identifier
  - Field length
  - Unit identifier
  - Function code: The function code in a request message plus 0x80
  - Error code

Details of error codes to indicate abnormal conditions are as follows.

Table F1.7-4 Error codes

Error code (hexadecimal)	Meaning of error
01	Function code error (non-existing function code)
02	Coil, input relay, register number error (out of range)

Continues on the next page

Table F1.7-4 Error codes (Table continued)

Error code (hexadecimal)	Meaning of error
03	Error of the number of coils, input relays, or registers (out of range)
04	CPU not started.
05	Another request message with the same transaction identifier is received while a request is being processed.(*1)
06	Another request message with a different transaction identifier is received while a request is being processed.(*1)
07	Unsupported diagnostic loop-back code(*2)
10	Even number specified as the register reference number.(*3)
11	Odd number specified as the number of registers (*3)
12	Data setting error • The number of simultaneously writing exceeds four. • Writing size exceeds limit. • Writing to an undefined variable or write-inhibited variable attempted.
13	Access error during online change download During online change download, it is not possible to read from/write to function block instances or variables whose types have been changed.

*1: Specific to Ethernet communication modules
*2: Specific to Modicon serial communication modules
*3: This error does not occur when 16-bit Modbus master support mode is enabled.

Response message in normal conditions

When the request message is sent normally, the following response message is sent. The response message differs depending on the content of the request message and the communication module used.

Table F1.7-5 Response messages depending on the content of the request message and the communication module used

Content of request message	Communication module	Response message
For functions of single coil status change, writing to a single holding register, or loop back	Serial communication module	The same message as the request message
	Ethernet communication module	The same message as the request message
For functions of multiple coil status changes or writing to multiple holding registers	Serial communication module	Slave address Function code Error check code Start number Number of coils or holding registers
	Ethernet communication module	Transaction identifier Protocol identifier Field length Unit identifier Function code Start number Number of coils or holding registers
In the case of read function	Serial communication module	Slave address Function code Error check code Read data
	Ethernet communication module	Transaction identifier Protocol identifier Field length Unit identifier Function code Read data

Cases where no response is made

SCS does not respond to a request in the following cases:

- A transmission error of a request message is detected (overrun, framing error, parity error or CRC error)
- Transmission specification setting values are invalid
- The slave address in a request message does not correspond to the slave address set on the communication module
- The time interval between receiving one character and the next character is longer than the setting value of the reception inter-character timer
- A protocol related error occurs (for example, a transmission is performed just when being responding to a request)
- Definitions of the serial communication module are being online change downloaded
- Definitions of Modbus communication are being changed

Response time

The response time refers to the time from when SCS receives a request message to when it starts to transmit the response message. The transmission time is not included.

Response time = (Message receiving and sending processing time) +
(Modbus message reading and writing processing time)

Set the message receiving and sending processing time to 20 ms.

The time taken by Modbus message reading and writing processing varies as shown in the following table, according to the scan period of application logic and the number of communication ports. The Modbus message reading and writing are processed during the idle time after the processing of application logic is completed.

Table F1.7-6 Modbus message processing time and the combination of scan period of application logic and the number of communication ports

Scan period	Number of communication ports per SCS	Processing time of Modbus message reading and writing
200 ms or longer	-	0 to the scan period of application logic
Shorter than 200 ms	2 ports or less	0 to the scan period of application logic
	3 ports or more	0 to (The scan period of application logic x 2)

TIP

- For the Ethernet communication module, take the number of ports that appear in the above description for the number of connections.
- If you install two serial communication modules or Ethernet communication modules or mix of both in an SCS and use two ports per module, the number of communication ports per SCS is regarded as three or more.

IMPORTANT

- The longest time it takes for data to be read by the Modbus master is as follows:

  Maximum data update time = transmission time + scan period of external connection function

- If a writing request from the CENTUM integration function coincides with those from a Modbus master on another port, notification of the writing request to the application logic will be delayed for the number of writing requests. Therefore, the longest time it takes for notification of a write operation from the Modbus master to reach the SCS application logic is as follows:

  Maximum data update time = transmission time + scan period of the application logic x number of writing requests from the external connection function

Diagnostic information messages

If a communication module is faulty, the SCS send a diagnostic Information message to SENG and/or HIS through the control bus. This section describes the SCS diagnostic Information messages.

Error occurrence/recovery to normal state on communication module

When an error occurs in the communication module, or when the module recovers from an error, an IOM Fail diagnostic information message, or an IOM Recover diagnostic information message, respectively, is sent through the control bus.

The configuration error occurs if the communication driver cannot operate due to configuration mismatch. For example, this error occurs if the communication driver has not been downloaded to the communication module or if an application program different from the defined communication driver has been downloaded.

TIP

Communication modules ALR111, ALR121, and ALE111 must be loaded with a driver for Modbus communication.
After you replace these communication modules, perform IOM download to the new modules.

However, if the communication driver of SCS is already downloaded to the replaced module, the module starts normally. In this case, you do not need to perform IOM download.

SEE ALSO

For more information about diagnostic information messages for communication module error occurrence and recovery to normal state, refer to:

3.1, “Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094)” in Messages Reference Manual (IM 32P02B10-01EN)

When a communication error occurs

When a communication error occurs, no system alarm message is sent because the Modbus master is assumed to handle the error.

When downloading the communication driver

When downloading the communication driver to the communication module, system alarm messages indicating the start of the download, and the completion or abnormal termination of the download, are sent through the control bus.

SEE ALSO For more information about system alarm messages for communication driver downloads, refer to:

3.2, “Safety Control Station Status Change Related Messages (Message Numbers 0425 through 0480)” in Messages Reference Manual (IM 32P02B10-01EN)

When a communication module is added online

Communication modules can be added or removed online. When a communication module is added, diagnostic information messages (IOM Fail, and then IOM Recover) are sent through the control bus.

SEE ALSO For more information about diagnostic information messages for communication module error occurrence and recovery to normal state, refer to:

3.1, “Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094)” in Messages Reference Manual (IM 32P02B10-01EN)

F1.8 Troubleshooting

If a communication module error occurs, you can use the SCS Maintenance Support Tool to acquire information on the communication module and communication error information. This section describes typical troubleshooting cases.

The status display window shows the status of ALR111/121 or ALE111 in red

If the status of the communication module appears in red in the status display window of the SCS Maintenance Support Tool, check the error code that is related to the input/output module in the diagnostic information message.

There is no response and communication fails

- Check if the transmission specifications are consistent with those of the master.
- Check if the cable wiring complies with the specifications.
- Analyze the communication log for the cause of the communication error by using the SCS Maintenance Support Tool.
- Check if there is enough CPU time available. Response may be delayed when the CPU load is high.

A response message under abnormal conditions is received

- Check if the function code that is included in the message is correct.
- Check if the Modbus master sent another request message to the SCS before receiving a response message through a given connection. (Specific to Modbus TCP)

Connection cannot be established and communication fails (specific to Modbus TCP)

- Check if the destination IP address and port number are correct.
- If the Modbus master fails without a notification of the communication termination (socket close) to the Modbus slave while they are communicating through an Ethernet communication module, the slave becomes ready for reconnection in up to 34 seconds.

F2. Serial communication modules

SCS uses a serial communication module to send and receive data to and from the Modbus master (external device).

This section describes the connection between the Modbus master and SCS through the serial communication module and the required I/O Parameter Builder settings when performing RS original engineering.

The parameter setting items that are required in I/O list engineering are the same as those for RS original engineering.

F2.1 Connection between the Modbus master and SCS

This section describes the connection configuration between the Modbus master and SCS, the Modbus protocol, serial communication modules, and cable connections.

Connection configuration of the serial communication module

The following is an example of connection using YOKOGAWA STARDOM autonomous controller FCN (Field Control Node) as the Modbus master.

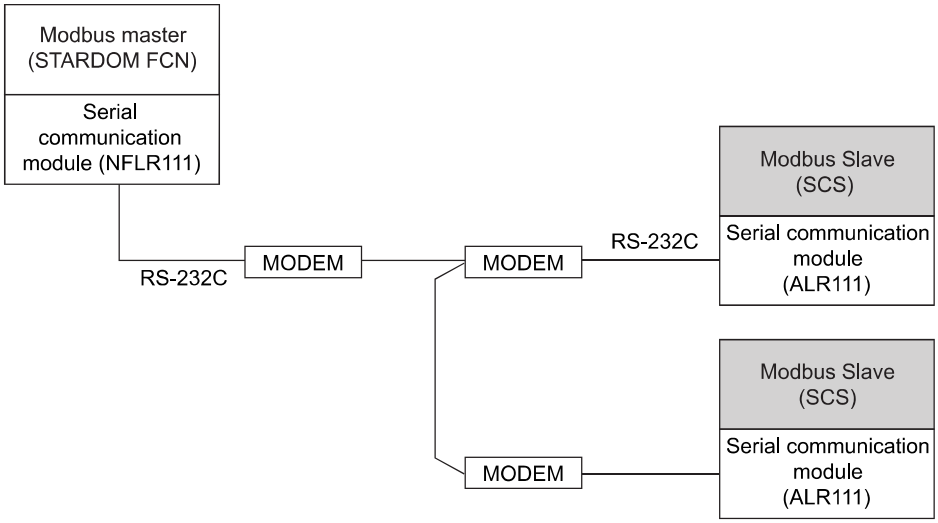

Figure F2.1-1 Example of connection between the Modbus master and SCS (ALR111) (using a STARDOM FCN as the Modbus master)

An SCS communicates with the STARDOM FCN, the Modbus master, via a serial communication module (NFLR111 and ALR111 in the previous example).

Supported Modbus protocol

The Modbus protocol defines communication procedures and message formats between one master and multiple slaves when performing serial communication.

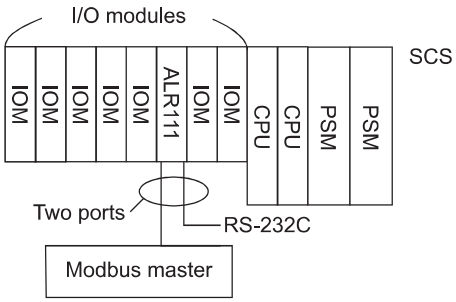
The Modbus protocol for the SCS Modbus slave communication has the following features:

- Only the master can initiate communication via the Modbus protocol. The master requests data reference or setting, and the slave responds to the request.
- The signal transmission between the master and slaves can be performed in either the RTU (Remote Terminal Unit) mode or the ASCII mode. SCS supports the RTU mode only.

Transmission specifications of serial communication modules

The SCS transmission specifications when using a serial communication module are as follows:

Table F2.1-1 Transmission specifications when using a serial communication module



Item		Description(*1)	Builder specification(*2)	Remark
Interface		RS-232C	Yes	ALR111
		RS-422/RS-485 (4-wire system)		ALR121
Synchronization method		Start-stop synchronization	-	
Baud rate		1200, 2400, 4800, 9600, [19200], 38400 bps	Yes	
Start bits		Fixed to 1	-	
Data bits		7 to [8]	-	Fixed to 8 in Modbus RTU mode
Stop bits		[1], 2	Yes	
Parity		None, Odd, [Even]	Yes	
Control Line	RS control	Yes, [No]	Yes	Valid only for ALR111
	DR check	[Yes], No	Yes	Valid only for ALR111
	CD check	Yes, [No]	Yes	Valid only for ALR111
Time monitoring	Transmission enable monitoring time	0 to 99990 (ms) [1000] Specify in units of 10 ms	-	Fixed to 1000 ms for Modbus
	Reception character interval timer	0 to 99999 (ms) [10] Specify in units of 1 ms	Yes	
	Character internal monitoring timeout	[Do not set], Set	-	Fixed to Do not set for errors in Modbus RTU mode
Text frame	Reception start character	1 character, [None]	-	Fixed to None for Modbus
	EOT character	1 character, 2 characters, [None]	-	Fixed to None for Modbus
	Maximum number of transmit characters	Up to 512 bytes	-	
	Maximum number of receive characters	Up to 512 bytes	-	
Station number		1 to 247	Yes	
Option 1 to 4		Fixed to 0	-	
MODBUS RTU/ASCII		RTU(*3)	-	

*1: [ ] indicates a default value (recommended value).
*2: Yes: Can be specified.
-: Cannot be specified.
*3: Only the RTU mode is supported. The ASCII mode is not supported.

Mounting of a serial communication module

SCS uses ALR111/ALR121, as a serial communication module. ALR111/ALR121 is used by mounting in SCS and connecting a serial communication cable.

If ALR111 is mounted, use an RS-232C cable. If ALR121 is mounted, use an RS-422/RS-485 cable.

• ALR111: Serial communication module (RS-232C)
• ALR121: Serial communication module (RS-422/RS-485)

Figure F2.1-2 Example of mounting a serial communication module to SCS

The following table shows the communication capacity of ALR111/ALR121.

Table F2.1-2 Communication capacity of ALR111/ALR121

Item	Maximum number
Number of communication modules that can be mounted	2 modules/SCS (*1) (*2)
Number of ports used per communication module	2 ports

*1: Total number of ALR111/ALR121/ALE111 for the Modbus slave communication that is mounted to the same SCS
*2: Communication modules for the subsystem communication and DNP3 communication are not included in the count.

IMPORTANT

ALR111/ALR121 cannot be installed in any I/O node that is 5 km or further away from the CPU node.

● Status display

The operation status of serial communication modules can be checked by observing the status display LEDs on the module or a system status display view on HIS.

SEE ALSO For more information about the types and functions of status display LEDs of communication modules, refer to:

"■ Inspection by checking status lamps" in E2., "Routine maintenance" in Hardware User's Guide (IM 32P06C10-01EN)

■ Cable connection when using ALR111

You can connect the Modbus master and ALR111 by using a modem.

SEE ALSO For more information about connections and connectors of ALR111, refer to:

D1.4.1, "Connection of the serial communication module (RS-232C)" in Hardware User's Guide (IM 32P06C10-01EN)

For more information about modem connection, refer to:

"■ Connecting external devices to ALR111" in D1.4.1, "Connection of the serial communication module (RS-232C)" in Hardware User's Guide (IM 32P06C10-01EN)

■ Precautions when wiring signal lines

This section describes the precautions when wiring the ALR111 signal lines.

SEE ALSO For more information about ALR111 connector signals, refer to:

D1.4.1, “Connection of the serial communication module (RS-232C)” in Hardware User's Guide (IM 32P06C10-01EN)

CD signal line

When the CD signal is ON, data is being transmitted to the receiver. Wire a signal line that turns ON when the connection destination sends data to the CD signal. In general, wire the RS signal of the connection destination to the CD signal.

If a signal line that turns ON when the connection destination sends data is not available, wire a signal that is always ON, for example the ER signal line of the ALR111 itself, to the CD signal pin.

When the CD check is enabled, transmission is not allowed when the CD signal is ON (because data is being transmitted from the other end of the line). Turn OFF the CD check if the CD signal line is always in the ON status. The check is turned OFF by default.

ER (DTR) signal line

The ER signal turns ON after the serial communication module has completed the startup processing and is ready to receive and send data. Use this signal to judge whether or not the serial communication module can receive data at the connection destination.

DR (DSR) signal line

The DR signal line is used to judge whether the device to which the ALR 111 is wired can receive data.

When the DR check is enabled, data can be sent while the DR signal is ON. Wire a signal line that turns ON when the connected device can receive data to the DR signal pin.

To disable this check, specify [No] for the DR check, or wire a signal line that is always ON to the DR signal pin.

RS (RTS)/CS (CTS) signal lines

For RS signal setting, either [No] (always ON) or [Yes] (ON at transmission) can be specified for the RS control. If the RS signal connected to the device should be ON while transmitting and stay OFF otherwise, specify [Yes] for the RS control.

Data is transmitted when the CS signal is ON. Wire the line in such a way that the CS signal line turns ON at transmission.

F2.2 Definitions in I/O Parameter Builder

This section explains the settings of communication module to perform Modbus slave communication through RS original engineering. Settings for the serial communication modules can be configured in the Port 1 tab and Port 2 tab of I/O Parameter Builder.

SEE ALSO For more information about display method and window configuration for the I/O Parameter Builder, refer to:

Appendix 2.2.2, “I/O Parameter Builder” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about parameter tabs in the serial communication module, refer to:

Appendix 1.2, “Settings for modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Port 1, Port 2 tab

The following items can be set in the [Port 1], [Port 2] tab.

The settings of each item can be changed online download, but the corresponding module will restart after download.

Table F2.2-1 Port 1, Port 2 tab

Title		Description	Remark
Baud Rate		Set the baud rate	-
Stop Bits		Set the stop bit	-
Parity		Specify the type of parity	-
Control Line	RS Control	Specify whether or not to perform RS control during ALR111 transmission	Valid only for ALR111
	DR Check	Specify whether or not to perform DR signal check during ALR111 transmission	Valid only for ALR111
	CD Check	Specify whether or not to perform CD signal check during ALR111 transmission	Valid only for ALR111
	Reception Inter-Character timer	Specify the monitoring time of reception character interval during reception by the ALR111/ALR121	-
Station Number		Specify the slave address of the Modbus slave	-
Option 1 to 4		Option items	Fixed to 0.

Baud Rate

Specify the baud rate of communication. Select from 1200, 2400, 4800, 9600, 19200 and 38400 bps. The default is 19200 bps.

Stop Bits

Specify the stop bits of communication. Select 1 bit or 2 bits. The default is 1 bit.

Parity

Specify the parity. Select None, Odd or Even. The default is Even.

RS Control

Specify whether or not to perform RS control during ALR111 transmission. The setting is only valid for the ALR111. The default is not to perform the RS control function.

- Without RS control
  Always set the RS signal cable to ON regardless of the data transmission from the ALR111.
- With RS control
  Turn the RS signal cable ON when data is transmitted from the ALR111 and OFF at the completion of transmission.

DR Check

Specify whether or not to perform DR signal line check during ALR111 transmission. The setting is only valid for the ALR111. The default is to perform the DR check function.

- Without DR check
  ALR111 transmission data regardless of the status of the DR signal cable.
- With DR check
  ALR111 transmission data only if the DR signal cable is ON. A no-response error occurs if the DR signal does not turn ON after the transmission enable monitoring time has elapsed (the response data is discarded).

The DR signal is used to connect to the ER (data terminal ready) signal line to communicate with and to determine whether or not the ER signal line at the connection destination is able to receive character data (normal operation). If the ER signal line cannot be used, set "without DR check" or wire the line in such a way that the DR signal line is switched ON at all times (*1) .

*1: For example, connect the RS signal line to the DR signal pin of its own.

CD Check

Specify whether or not to perform CD signal check during ALR111 transmission. The default is not to perform the CD check function.

- Without CD check
  ALR111 transmission data regardless of the status of the CD signal cable.
- With CD check
  ALR111 transmission data if the CD signal is OFF. A no-response error occurs if the CD signal does not turn OFF after the transmission enable monitoring time has elapsed.

Reception Inter-Character timer

The reception Inter-Character timer (reception Inter-Character timeout setting value) is a function that monitors the time between characters are received when the ALR111/ALR121 module receives data. In the Modbus (RTU mode) binary communication, the communication is regarded as completed if this duration of time or longer elapses between two character receptions.

If the communication is performed through a modem with data buffering or similar functionality, specify this value taking into account the communication delay (inter-character delay) due to buffering by the modem. However, this affects the communication time because the communication is regarded as completed based on this time.

Default: 10 ms

Setting range: 0 to 99999 ms

IMPORTANT

If multiple slave devices are connected on the same line, set the time so that it corresponds to the transmission of approximately 20 characters in the serial communication (20 ms for 9600 bps, 10 ms for 19200 bps). If there is any slave device with a Reception Inter-Character Timer value larger than those of other slave devices, reception is not performed properly on that device and a non-response error occurs.

Station Number

Specify the slave address of the Modbus slave.

Default: 1

Setting range: 1 to 247

Option 1 to 4

Always set 0 for these options.
Default: 0 (for all)

F3. Ethernet communication modules

SCS uses an Ethernet communication module to send and receive data to and from the Modbus master (external device).

This section describes the connection between the Modbus master and SCS through the Ethernet communication module and the required I/O Parameter Builder settings when performing RS original engineering.

The parameter setting items that are required in I/O list engineering are the same as those for RS original engineering.

F3.1 Connection between the Modbus master and SCS

This section describes the connection configuration between the Modbus master and SCS, the Modbus protocol, and the Ethernet communication module.

Connection configuration of the Ethernet communication module

The following figure shows an example of a connection using the YOKOGAWA STARDOM autonomous controller FCN (Field Control Node) as the Modbus master.

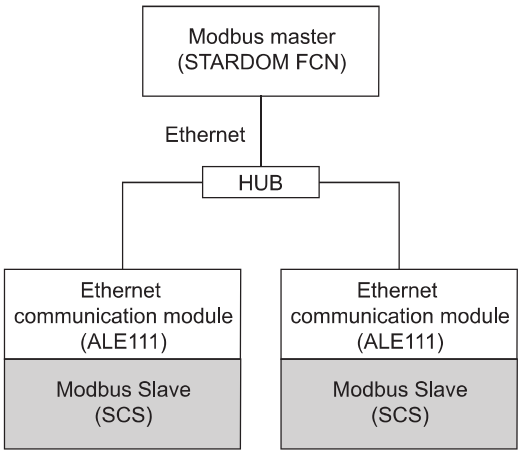


Figure F3.1-1 Example of a connection between the Modbus master and SCS (ALE111) (using a STARDOM FCN as the Modbus master)

An SCS communicates with the STARDOM FCN, the Modbus master, through an Ethernet communication module (ALE111 in the previous example).

Supported Modbus protocol

The Modbus protocol that is supported on Ethernet communication modules is the Modbus TCP protocol. The Modbus TCP protocol uses TCP/IP (Ethernet) for Modbus slave communication.

- The Modbus TCP protocol can be used to communicate with multiple Modbus slaves at almost the same time.
- The Modbus master can send a request message to multiple Modbus slaves at the same time and wait for response messages.

Transmission specifications of Ethernet communication modules

The SCS transmission specifications when using an Ethernet communication module are as follows:

Table F3.1-1 Transmission specifications when using an Ethernet communication module

Item	Description	Builder specification(*1)	Remark
Interface	Ethernet (IEEE802.3)	-	-
	10BASE-T	-	-
Baud rate	10 Mbps	-	Fixed to 10 Mbps(*2)

Continues on the next page

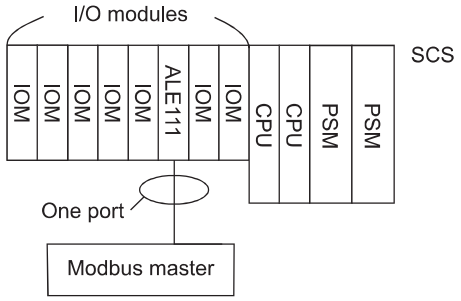

Table F3.1-1 Transmission specifications when using an Ethernet communication module (Table continued)

Item	Description	Builder specification(*1)	Remark
Transmission method	Half-duplex	-	Fixed to half-duplex
Port number	502	Yes	Modbus TCP port number. The default value is 502. (*3)
Number of connections	2	-	-
Number of transactions per connection (*4)	1	-	When two connections are used, the number of transactions per SCS is 2.
Data format	Binary	-	Fixed to binary
Option 1 to 4	0 to 0xFFFFFFFF or -2147483648 to 2147483647	Yes	Reserved for extensions

*1: Yes: Specification required
-: Specification not required
*2: Network auto-negotiation cannot be specified in hub settings.
*3: The default value is recommended.
*4: This is the number of request messages that SCS can process per connection. The Modbus master should not send more request messages to an SCS than this value, regardless of the transaction identifier of the request message. If sent, the SCS sends a response message with an error code set.

Mounting of an Ethernet communication module

SCS uses the ALE111 as an Ethernet communication module. Install the ALE111 in the SCS and connect it to the Modbus master by using an Ethernet cable.

• ALE111: Ethernet communication module

Figure F3.1-2 Example of mounting an Ethernet communication module to SCS

IMPORTANT

When using ALE111, use the style S1 module with unit revision U:2 or later. The unit revision is indicated on the top of the module. However, the unit revision is not indicated if it is U:0.

The following table shows the communication capacity of ALE111.

Table F3.1-2 Communication capacity of ALE111

Item	Maximum number
Number of communication modules that can be mounted	2 modules/SCS (*1) (*2)
Number of ports used per communication module	1 ports

*1: Total number of ALR111/ALR121/ALE111 for the Modbus slave communication that is mounted to the same SCS
*2: Communication modules for the subsystem communication and DNP3 communication are not included in the count.

IMPORTANT

ALE111 cannot be installed in any I/O node that is 5 km or further away from the CPU node.

Status display

The operation status of Ethernet communication modules can be checked by observing the status display LEDs on the module or a system status display view on HIS.

SEE ALSO For more information about the types and functions of status display LEDs of communication modules, refer to:

"■ Inspection by checking status lamps" in E2., "Routine maintenance" in Hardware User's Guide (IM 32P06C10-01EN)

F3.2 Definitions in the I/O Parameter Builder

This section explains the settings of Ethernet communication module to perform Modbus communication through RS original engineering. Settings for the Ethernet communication modules can be configured in the Module tab of I/O Parameter Builder.

SEE ALSO For more information about display method and window configuration for the I/O Parameter Builder, refer to:

Appendix 2.2.2, "I/O Parameter Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Module tab of the Ethernet communication module

The following tables show the display-only items and settable items on the Module tab of the Ethernet communication module.

The setting of each item can be changed by online change download, but the target module restarts after online change download.

Table F3.2-1 Display-only items on the Module tab of the Ethernet communication module

Title	Description	Remarks
Node Number	The node number of the node in which the module is mounted	Defined in I/O Wiring View
Slot Number	The slot number of the slot in which the module is mounted	Defined in I/O Wiring View
Device	The model name of the module	Defined in I/O Wiring View
Dual-Redundant	Whether the module is used in a single or dual-redundant configuration	The module cannot be dual-redundant
Device Number	The device number that is assigned to the module	Defined in I/O Wiring View

Table F3.2-2 Setting items on the Module tab of the Ethernet communication module

Title	Description	Remarks
Connection Device	Types of connection devices	-
Comment	A comment regarding the module	-
IP Address	The IP address of the module	-
Subnet Mask	The subnet mask of the module	-
Default Gateway	The default gateway address of the module	-
Port Number	The TCP/IP port number	-
Option 1 to 4	Option items	Fixed to 0.

Connection Device

Set the type of connection device.

Select SCSMDTCP when the Modbus slave communication function should be used.

Default value: SCSMDTCP

SCSMDTCP: Modbus TCP master

SCSDPTCP: DNP3 master (Selectable only when the version of SCSU1 is R3.02.20 or later.)

TIP

If an attempt is made to change the connection device and the selected port number is not the default, the following dialog box appears:

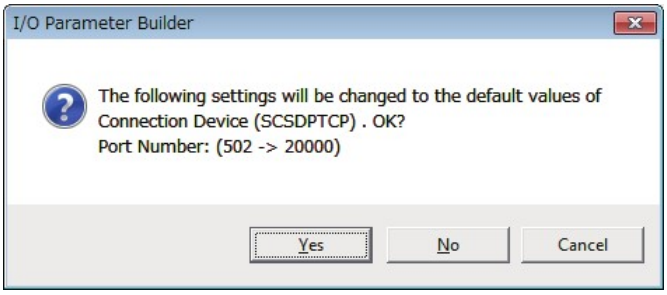

Figure F3.2-1 Connection Device dialog box

Yes: The connection device is changed and the port number is changed to the default.

No: The connection device is changed but the port number is not changed.

Cancel: Neither the connection device nor port number is changed.

Comment

A comment regarding the Ethernet communication module can be entered. This comment can be entered using up to 24 single-byte characters or 12 double-byte characters.

IP Address

Set the IP address of the Ethernet communication module. Enter a desired IP address.

Default:	This field is empty by default; be sure to enter an IP address. If no value is entered, an error occurs when you try to save the settings in the builder.
Format:	nnn.nnn.nnn.nnn
Setting range:	0.0.0.1 to 255.255.255.254 However, do not set the following IP addresses: • Host address digits are all zeros or all ones in binary form. (Examples: 192.168.1.0 and 192.168.1.255 when the subnet mask is 255.255.255.0) • Any of the numbers delimited with a period has leading zeros. (Examples: 192.168.08.09 and 192.168.008.009)

Subnet Mask

Set the subnet mask of the Ethernet communication module. Enter a desired subnet mask.

Default:	This field is empty by default; be sure to enter a subnet mask. If no value is entered, an error occurs when you try to save the settings in the builder.
Format:	nnn.nnn.nnn.nnn
Setting range:	0.0.0.1 to 255.255.255.254 However, do not set the following subnet masks: • Values less than 255.0.0.0 for a class A IP address (Example: 128.0.0.0) • Values less than 255.255.0.0 for a class B IP address (Example: 255.128.0.0) • Values less than 255.255.255.0 for a class C IP address (Example: 255.255.128.0)

Default Gateway

Set the gateway address of the Ethernet communication module. Enter a desired gateway address.

Default: Blank

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following gateway addresses:

- Host address digits are all zeros or all ones in binary form.
(Examples: 192.168.1.0 and 192.168.1.255 when subnet mask is 255.255.255.0)
- Network address digits do not match the IP address.
(IP address is 192.168.1.1 and default gateway address is 192.168.2.2 when the subnet mask is 255.255.255.0.)
- Any of the numbers delimited with a period has leading zeros.
(Examples: 192.168.08.09 and 192.168.008.009)

Port Number

Set the port number for Modbus TCP.

Default: 502

Setting range: 0 to 65535

Option 1 to 4

You must set 0 for these options.

Default: 0 (for all)

F4. Precautions for engineering

The Modbus slave communication function of SCS is for a Modbus master (external device) reading and setting SCS data via Modbus protocols. DCSs supplied by other manufacturers can function as a Modbus master to be connected with SCS. The Modbus slave communication function of an SCS does not affect the safety functions of it.

For Modbus connection, the following communication modules need to be installed in SCS nodes to be connected to other systems.

- RS-232C serial communication module (ALR111)
- RS-422/RS-485 serial communication module (ALR121)
- Ethernet communication module (ALE111)
  When the CPU node of SCS is SSC10D or SSC10S, do not define ALE111.

To set data in SCS from an external device, the External Communication Function Block is used. The External Communication FB allows setting data of a variable of application logic from a Modbus master. In this case, the SCS data must be confirmed by Modbus master by reading back the data.

SEE ALSO For more information about Modbus connection function, refer to:

F1., “Common items regarding the Modbus slave communication function” on page F1-1

For more information about engineering of Modbus slave communication, refer to:

F., “Modbus slave communication” on page F-1

■ Redundancy of Modbus communication

To implement redundant Modbus slave communication, you need to create a user application for that purpose on the Modbus master side.

For serial communication, it is possible to duplex the path of Modbus communication in the following ways.

- Using two serial communication modules
  The communication modules and communication paths are both duplexed. When one module fails, communication can be continued with the other module.
- Using two ports on one module
  When Ports 1 and 2 on the same communication module are used, only the communication paths are duplexed.

For Ethernet communication, it is possible to duplex the path of Modbus communication by using two Ethernet communication modules. The communication modules and communication paths are both duplexed. When one module fails, communication can be continued with the other module.

■ Data setting and reading from Modbus master

The Modbus slave communication function of SCS allows an external device to read the internal variables of SCS (BOOL, DINT, and REAL) and its I/O variables (DI/DO, AI, etc). The External Communication Function Block is used for setting data of these variables. Attentions are needed for data handling when accessing to SCS from the Modbus master. In addition, SCS data is 32-bit, however, access from the Modbus master that handles 16-bit data only is available depending on the settings.

SEE ALSO For more information about data access from the Modbus master that handles 16-bit data only, refer to:

“■ 16-bit Modbus master support mode” on page F1-5

Retry for a communication error

The application in Modbus master must be implemented so as to make retry when an error occurs in Modbus communication.

Response timeout period setting on the Modbus master when communicating with SCSP2/SCSP3/SCSL2

When performing Modbus slave communication with an SCSP2/SCSP3/SCSL2 installed with dual-redundant CPU modules and an Ethernet communication module, you must set five seconds or longer response timeout period on the Modbus master device.

If the control right is switched to the standby-side CPU module while the control-side CPU module is processing for Modbus slave communication, the SCSP2/SCSP3/SCSL2 processes the Modbus communication data again. As a result, it will take a maximum of 5 seconds for the Modbus master to send a request and receive a response.

G. DNP3 slave function

The DNP3 slave function uses DNP3, which is an open protocol, to let the SCS operate as the DNP3 slave and communicate with the DNP3 master, such as SCADA.

This section provides an overview of the DNP3 slave function and explanation of this function, engineering and maintenance on the SENG, and DNP3 communication function block (hereinafter referred to as DNP3 communication FB).

The DNP3 slave function is supported only by SCSU1 of R3.02.20 or later.

SEE ALSO For more information about DNP3 Field Device Profile of the SCS, refer to:

Appendix 2., “DNP3 field device Profile” on page App.2-1

G1. Overview of the DNP3 slave function

The DNP3 slave function of SCS allows the DNP3 master to refer data from SCS or set data to SCS through DNP3 communication. The DNP3 slave function does not affect the safety functions of SCS.

You must install the Ethernet communication module (model: ALE111) to an SCS node for the SCS to communicate with the DNP3 master.

To use the DNP3 slave function, use DNP3 communication FBs. By assigning instances of DNP3 communication FBs to DNP3 data, SCS data can be referred or set from the DNP3 master.

When a variable of the application logic changes, the SCS generates and buffers an event that includes a time stamp and data. This prevents data loss when a communication failure occurs because the DNP3 master can read the relevant event from the SCS's event buffer after the recovery.

Precautions for using the DNP3 slave function

The precautions when using the DNP3 slave function are as follows:

- The DNP3 slave function is supported only by SCSU1 of R3.02.20 or later.
- To use the DNP3 slave function, the CI Server Integration Package is required.
- The DNP3 event buffering function cannot be used simultaneously with the data buffering function that is used when the system is integrated with CI Server.
- The duplexed interface for DNP3 communication can be used on new SCS projects that are created in R4.02 or a later version.

G1.1 DNP3 communication system configuration and components

The DNP3 communication system is configured in such a way that the DNP3 master is connected to the DNP3 slave, such as the SCS or any third-party controller, through Ethernet. The SENG and SCS are connected through the Vnet/IP-Upstream network. The DNP3 communication interface can also be used in a duplexed configuration on SCSU1 of R4.02 or later.

The following figure shows an example of the configuration of a DNP3 communication system where the SENG and SCS are connected through the Vnet/IP-Upstream network.

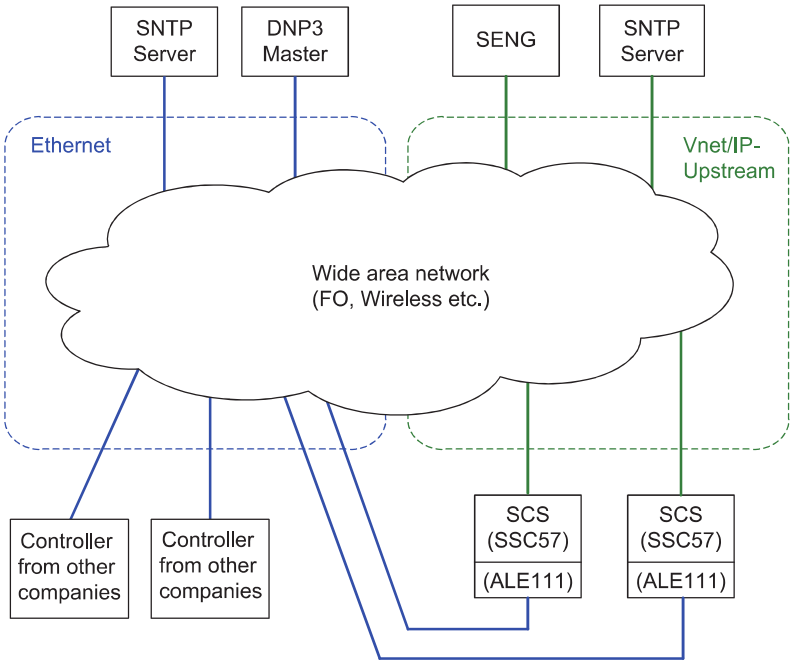

Figure G1.1-1 Example of configuration of a DNP3 communication system where the SENG and SCS are connected through the Vnet/IP-Upstream network

The following figure shows an example of the configuration of a DNP3 communication system where the SENG is connected to the SCS only when required for engineering purposes.

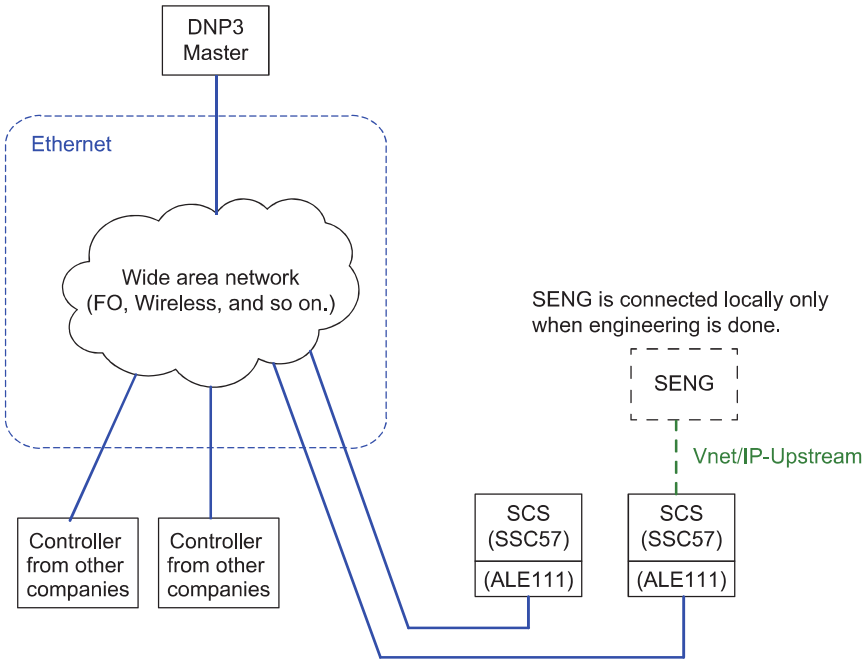

Figure G1.1-2 Example of configuration of a DNP3 communication system where the SENG is connected to the SCS only when required for engineering purposes

The following figure shows an example of the configuration of a DNP3 communication system where the communication interface has a duplexed configuration.

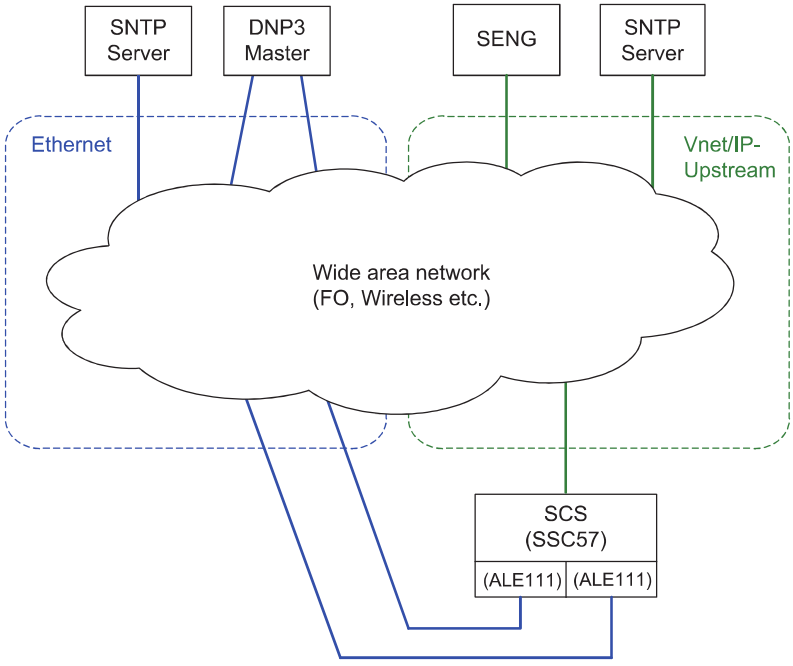

Figure G1.1-3 Example of the configuration of a DNP3 communication system where the communication interface has a duplexed configuration

Any system used in DNP3 communication requires the following components:

- DNP3 master
  It uses the DNP3 protocol to communicate with the DNP3 slave, such as the SCS or any third-party controller.
- SCS
  It uses the DNP3 protocol to communicate with the DNP3 master. One SCS can be connected to one DNP3 master.

The SCS performs DNP3 communication through the Ethernet communication module (model: ALE111). Up to two ALE111 modules per SCS can be used for DNP3 communication.

- SENG
  For the SCS to be able to use the DNP3 slave function, engineering must be performed on the SENG. The SENG supports remote engineering in the Central Control Room, or engineering based on local connection to the SCS. The SENG and SCS are connected through the Vnet/IP-Upstream network.
- Controller from other companies
  It uses the DNP3 protocol to communicate with the DNP3 master.
- SNTP server
  In an environment where SNTP servers can be installed, use SNTP servers to synchronize the time of the DNP3 master and that of the SCS. Connect UTC-synchronized SNTP servers to the Ethernet network to which the DNP3 master is connected, and also to the Vnet/IP-Upstream network to which the SCS is connected, to synchronize the time of the DNP3 master and that of the SCS.

Duplexed communication interface

In a duplexed configuration of DNP3 communication interface, two ALE111 modules are mounted to the SCS and the path between the DNP3 master and ALE111 is duplexed.

If there is an error on one of the paths between the DNP3 master and ALE111, the SCS can still use the other ALE111 to communicate with the DNP3 master. In the DNP3 master, set which of the two ALE111 modules for the DNP3 communication to use normally. This configuration cannot be set in the SCS.

The duplexed interface for DNP3 communication can only be used on SCSU1 of R4.02 or later. A database that is created by using SENG of R4.02 or later is also required.

IMPORTANT

You can mount two ALE111 modules for a duplexed communication interface, but only one DNP3 master can be connected to SCS as before. The two ALE111 modules cannot be connected to different DNP3 masters.

Behavior of SCS with a duplexed communication interface

With a duplexed communication interface, SCS behaves as follows:

- The SCS communicates with the DNP3 master through two ALE111 modules.
- The SCS returns the response from the ALE111 that was requested by the DNP3 master. Even if an error is found in the path between the ALE111 and the DNP3 master before SCS can return the response, the SCS still attempts to return the response from the ALE111 that was requested. In such a case, even if the path between the other ALE111 and the DNP3 master is functioning properly, the SCS will not return the response from the ALE111 from which it did not receive the request. In the event of an error in the communication path, switch the path from the DNP3 master. SENG cannot be used to confirm which ALE111 is being used to communicate with the DNP3 master.

G2. DNP3 slave function of SCS

The DNP3 slave function of the SCS comprises the following:

- Referencing and setting data
- Event buffering
- Time synchronization

The DNP3 slave function accesses data during idle time when no safety function is active, so it does not affect any of the safety functions.

G2.1 Data access using the DNP3 slave function

To reference and set any variable of application logic of the SCS from the DNP3 master through DNP3 communication, assign an instance of DNP3 communication FB that is connected to the variable of the application logic, to DNP3 data.

DNP3 data is the virtual data of SCS that consists of the data type and Index.

The following six data types are available:

- Binary Input
- Binary Output
- Binary Counter
- Frozen Counter
- Analog Input
- Analog Output

For the Index, a sequential value of 0 to 499 is appended for each data type.

Once an instance of DNP3 communication FB is assigned to the Index for each data type, the DNP3 master can access the variable of the application logic as DNP3 data. An instance of DNP3 communication FB can be assigned to any Index. Note, however, that the total number of assignable instances of DNP3 communication FBs is limited to 1000 for all data types combined. For the Frozen Counter, it is not necessary to assign an instance to the Index, because there is one Frozen Counter corresponding to one Binary Counter.

The following figure shows the correspondence of DNP3 data and DNP3 communication FBs.

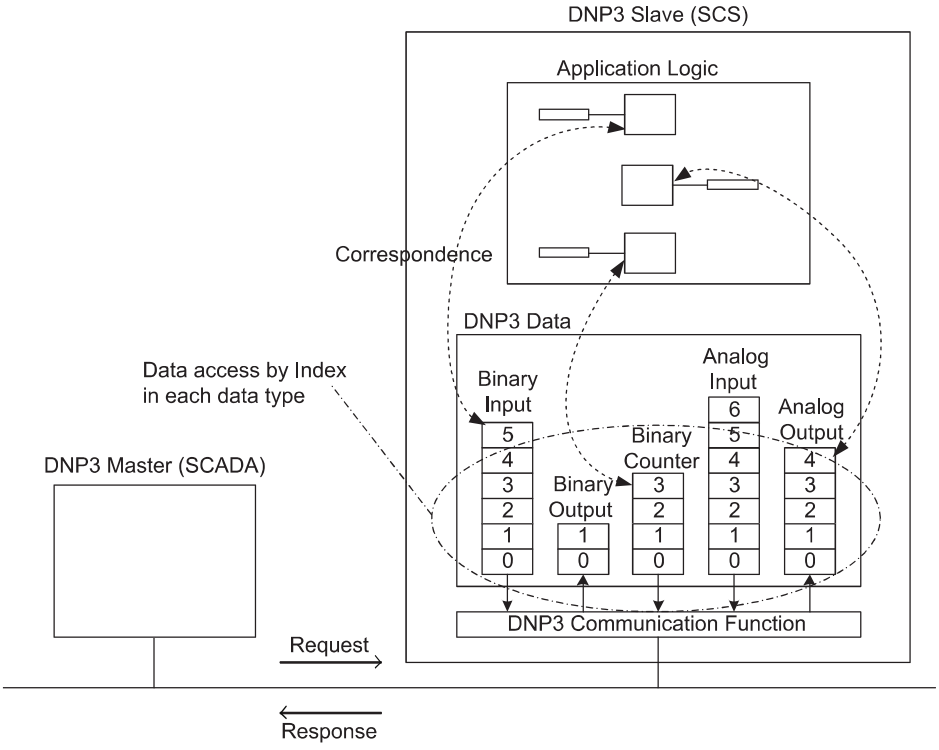

Figure G2.1-1 Correspondence of DNP3 data and DNP3 communication FBs

The DNP3 communication function executes processes relating to the DNP3 slave, such as referencing, setting and freezing DNP3 data, and responding to and deleting events.

Data referencing and data setting from the DNP3 master

Use DNP3 communication FBs to reference data from or set data to the SCS from the DNP3 master. The following table shows the relationship between the DNP3 communication FBs and DNP3 data that can be referenced and set from the DNP3 master.

Table G2.1-1 Relationship between the DNP3 communication FBs and DNP3 data that can be referenced and set from the DNP3 master

DNP3 communication FB	DNP3 data	Referencing/setting from DNP3 master
DNP3_BI	Binary Input	Referencing
DNP3_BO	Binary Output	Referencing and setting
DNP3_CT_16, DNP3_CT_32	Binary Counter, Frozen Counter	Referencing (*1)
DNP3_AI_16, DNP3_AI_32, DNP3_AI_SF	Analog Input	Referencing
DNP3_AO_16, DNP3_AO_32, DNP3_AO_SF	Analog Output	Referencing and setting

*1: Binary Counter can only be referenced, whereas the Frozen Counter can be referenced and cleared.

SEE ALSO For more information about engineering method of DNP3 data, refer to:

G3.5, “Definition of DNP3 data” on page G3-12

G2.1.1 Referencing DNP3 data

The following describes how to reference the DNP3 data of the SCS from the DNP3 master.

- Index specification
  The DNP3 master obtains the DNP3 data of the specified Index or Index range from SCS. If no instance of DNP3 communication FB is assigned to the specified Index, or an out-of-range Index (other than 0 to 499) is specified, the SCS returns the following error:

  `IIN2.2 PARAMETER_ERROR`

  Moreover, when there is a reference request for Analog Input, Analog Output and Binary Counter, if a data type different from the data types (16-bit, 32-bit, float) is specified in the SCS, the SCS returns the following error:

  `IIN2.2 PARAMETER_ERROR`

- Batch specification (Class 0 specification)
  The DNP3 master obtains from the SCS all DNP3 data to whose Index an instance of DNP3 communication FB is assigned.

  You can specify whether to include the Frozen Counter in the response for batch specifications.

SEE ALSO

For more information about setting of whether to include or not include the Frozen Counter in the response in the case of batch specification, refer to:

G3.3, “DNP3 slave setting” on page G3-8

For more information about precautions when assigning DNP3 data, refer to:

“■ Precautions when assigning DNP3 data” on page G3-22

■ Referencing DNP3 data

The DNP3 communication function of SCS is responsible for referencing of DNP3 data. The DNP3 communication function is processed during the idle time after the processing of application logic is completed. Accordingly, DNP3 data is referenced with a delay up to the scan period of application logic. When a variable of the application logic is updated, it takes time up to the scan period of the external connection function before the value can be referenced.

The following figure shows the execution timing of the DNP3 communication function.

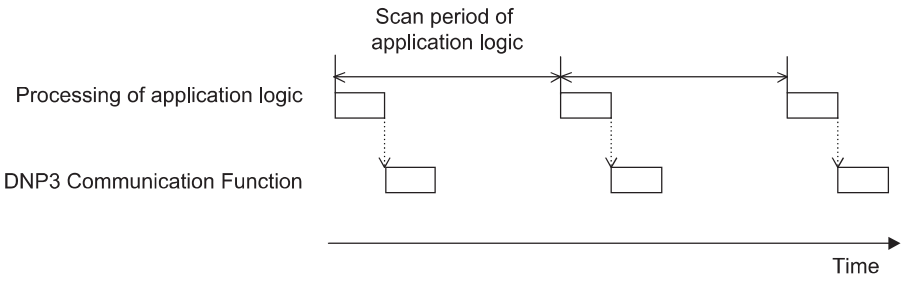

Figure G2.1.1-1 Execution timing of DNP3 communication function

G2.1.2 Setting DNP3 data

The following describes how to set DNP3 data to the SCS from the DNP3 master.

- Direct Operate - With Acknowledgment
  DNP3 data is set to the SCS according to the Operate command from the DNP3 master. The SCS returns the setting result (Success/Error) to the DNP3 master as an Acknowledgment.
- Direct Operate - No Acknowledgment
  DNP3 data is set to the SCS according to the Operate command from the DNP3 master. The SCS does not return the setting result (Success/Error) to the DNP3 master. Use the DNP3 master to acknowledge the setting result based on a change event or readback.
- Select Before Operate
  DNP3 data is set by using the Operate command after the Select command with Operate Parameter is sent to the SCS from the DNP3 master. The SCS accepts only the Operate command for the request reserved by the Select command. If no Operate command is received within a specified period, or the received Operate command is not for the reserved request, the SCS cancels the Select command and no longer executes the Operate process for any subsequently received Operate command.

  Only one Select command can be accepted. If multiple Select commands are received, the last Select command is accepted.

IMPORTANT

- When setting data from the DNP3 master, use the Direct Operate - With Acknowledgment command unless there is a specific reason.
- If the specified Index has no instance of DNP3 communication FB assigned to it, or an out-of-range Index (other than 0 to 499) is specified, the SCS returns the following error:

  `IIN2.2 PARAMETER_ERROR`

The following figure shows the sequence for each DNP3 data setting method.

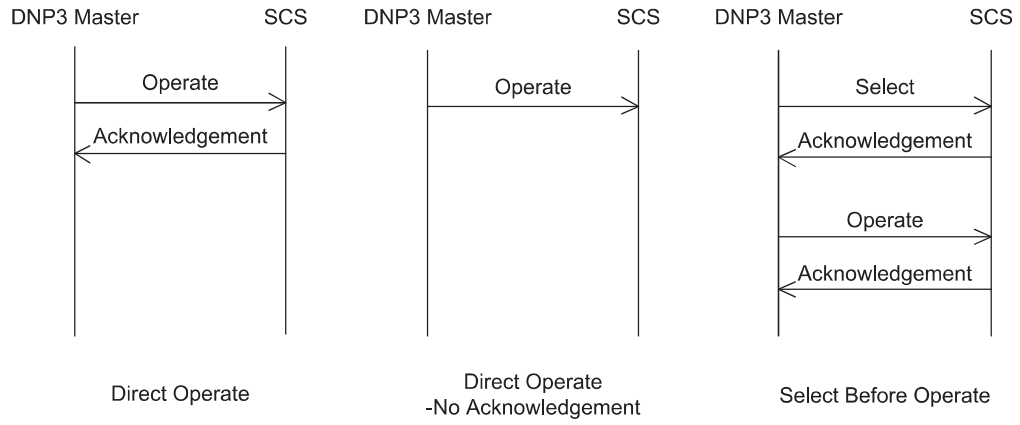

Figure G2.1.2-1 Sequence for each DNP3 data setting method

SEE ALSO For more information about precautions when setting data from the DNP3 master, refer to:

"■ Data setting from the DNP3 master" on page G3-19

Setting DNP3 data

DNP3 data is set by the DNP3 communication function.

The following figure shows how a DNP3 data setting request is processed.

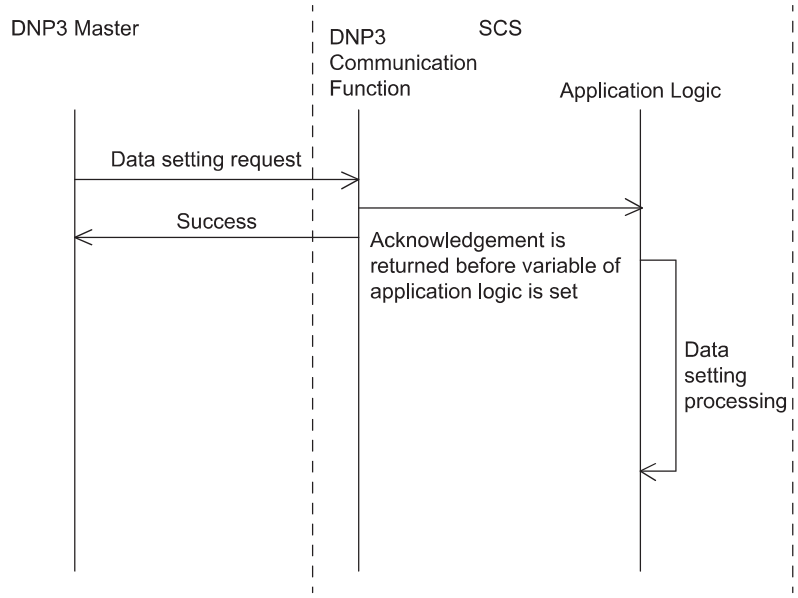

Figure G2.1.2-2 How a DNP3 data setting request is processed

When SCS accepts a data setting request from the DNP3 master, the DNP3 communication function of SCS issues a data setting request to the application logic of the SCS. The DNP3 communication function of SCS returns an acknowledgment to the DNP3 master before the application logic of SCS sets the data.

The time that is taken for the variable of the application logic to be updated after the DNP3 communication function receives the setting request, depends on the number of data setting requests from the Modbus and other external connection functions.

SEE ALSO For more information about execution timing of DNP3 communication function, refer to:

"■ Referencing DNP3 data" on page G2-4

For more information about maximum time before the set value can be referenced, refer to:

"● Maximum time before the set value can be referenced" on page G3-21

Precautions when setting DNP3 data

This section describes the precautions when setting the DNP3 data.

● Limitations on data setting using DNP3 communication

When SCS receives a data setting request from the DNP3 master, it returns a response and retains the request it accepted.

- Up to four data setting requests that uses DNP3 communication can be retained. A Freeze & Clear request is also considered a data setting request.
- SCS processes the maximum of four retained data setting requests per second from the DNP3 master when the scan period of the application logic is 250 ms or less. If the scan period exceeds 250 ms, SCS processes one request in one scan period.

- If SCS also retains any data setting request from the Modbus master or other external connection devices, the SCS processes data setting requests from the external connection device and the DNP3 master in the order of acceptance.
- If SCS retains four unprocessed requests when it receives a data setting request from the DNP3 master, the SCS returns the following status code:

  PROCESSING_LIMITED

  The SCS just discards the data setting request if the request requires no acknowledgement.

SEE ALSO For more information about freeze & Clear request, refer to:

"■ Freeze & Clear command" on page G2-8

Binary Output limit

The SCS's Binary Output supports latch output type operation only. Pulse output operation cannot be used.

G2.1.3 Freeze command, Freeze & Clear command

The SCS supports the DNP3 Freeze command and Freeze & Clear command.

Freeze command

The Freeze command is used to save the current value of the Binary Counter. After accepting a Freeze request from the DNP3 master, the SCS copies the current values of all Binary Counters to the Frozen Counter. The Frozen Counter will store the values of all Binary Counters effective when the Freeze command was executed.

The following figure shows how the SCS operates upon accepting a Freeze command from the DNP3 master.

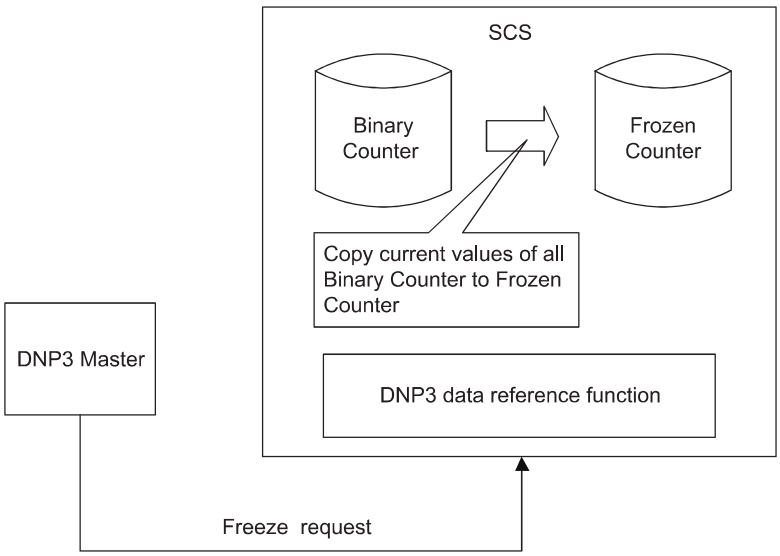

Figure G2.1.3-1 How the SCS operates upon accepting a Freeze command

Freeze & Clear command

If no more than 32 Binary Counters are defined, the Freeze & Clear command can be used.

The Freeze & Clear command is used to save the current value of the Binary Counter in the Frozen Counter and then clear the value of the Binary Counter to 0. After accepting a Freeze & Clear command from the DNP3 master, the SCS copies the current values of all Binary Counters to the Frozen Counter and then clears the values of all Binary Counters to 0.

The following figure shows how the SCS operates upon accepting a Freeze & Clear command from the DNP3 master.

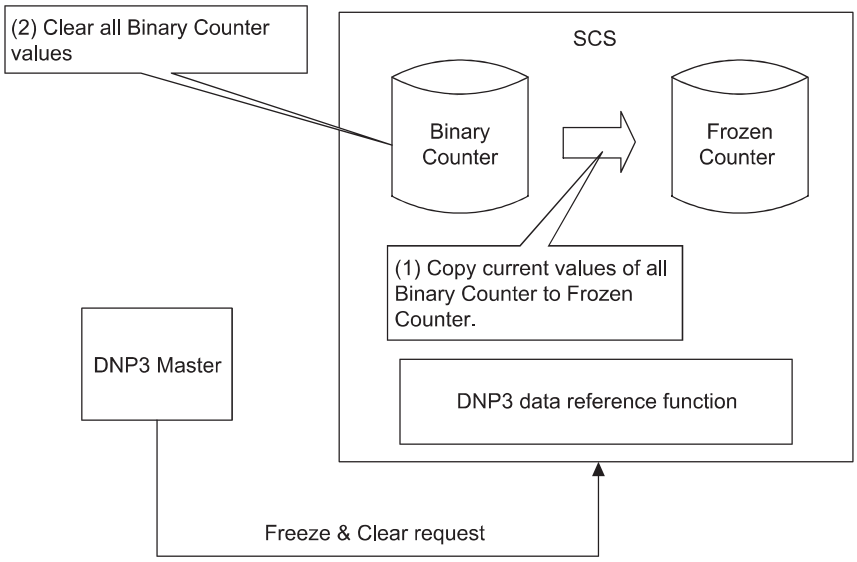

Figure G2.1.3-2 How the SCS operates upon accepting a Freeze & Clear command

The DNP3 master can calculate the rate of change in Binary Counter values by periodically executing a Freeze & Clear command.

IMPORTANT

- If SCS receives a Freeze & Clear request when 33 or more Binary Counters are defined, SCS returns the following error:

  `IIN2.0 NO_FUNC_CODE_SUPPORT`

- If SCS receives a Freeze & Clear request from the DNP3 master when it retains four un-processed requests, the SCS returns the following error:

  `IIN2.0 NO_FUNC_CODE_SUPPORT`

- If SCS returns an error in response to the Freeze & Clear request, no Freeze process is executed.

G2.1.4 Response time

The response time it takes for the SCS to response to the request for data referencing and data setting from the DNP3 master refers to the time from when SCS receives a request message to when it starts to transmit the response message. The Ethernet transmission time is not included.

```
Response time = (Message receiving processing time and message sending processing
 time) + (Data referencing processing time or data setting processing time)
```

The message receiving processing time and message sending processing time should be within 20 ms.

The data referencing processing time or data setting processing time may be as long as the scan period of the application logic.

G2.2 Event buffering

The SCS generates an event the moment a variable of the application logic assigned to DNP3 data changes. This event contains the applicable DNP3 data and a time stamp indicating when the DNP3 data changes. The SCS can retain events while a communication failure is present, by buffering the generated events. Once communication is restored, the DNP3 master reads the buffered events to prevent missing data.

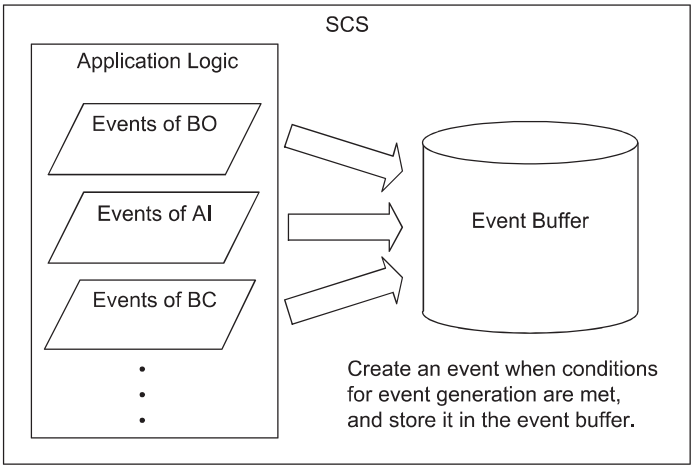

Figure G2.2-1 Event buffering operation

IMPORTANT

The DNP3 event buffering function cannot be used simultaneously with the data buffering function that is used when the system is integrated with CI Server.

G2.2.1 Event generation

To generate events in SCS, set an event class for each DNP3 data and event buffer size for each DNP3 data type.

Event class

For events, set an event class of 0, 1, 2, or 3 for each DNP3 data. Event classes are used to organize generated events into groups. The DNP3 master can specify an event class to obtain events that are set under the event class.

No event is generated for DNP3 data of event class 0. Set event class 0 for those data that do not require an event.

Set event classes using input parameters of DNP3 communication FBs. Event classes cannot be set by using DNP3 communication commands from the DNP3 master.

Event buffer size

Set the number of events that can be stored in the event buffer, for each DNP3 data type. An event buffer size can be set separately for each DNP3 data type. The total of all event buffer sizes must be less than or equal to 135000.

Set event buffer sizes by using the DNP3 Communication Builder of the SENG.

Event generation condition

The SCS generates an event when the following conditions are met:

- Event class 1, 2, or 3 is set for each DNP3 data.
- A value other than 0 is set for the event buffer size.
- The value of DNP3 data is changed.

Determine whether or not the value of DNP3 data is changed, as follows:

- In the case of Analog Input, the value changes when the absolute difference between the previous change event value and this value exceeds the set Deadband.
- In the case of DNP3 data other than Analog Input, the value changes when there is a difference between the previous value and this value.

The Deadband is a threshold that is used to generate an event. Set the Deadband by using an input parameter of a DNP3 communication FB.

IMPORTANT

- No event is generated for DNP3 data that has an event class that is set to 0.
- No event is generated for DNP3-type data that has an event buffer size that is set to 0.

Event time stamp

An event has a time stamp that indicates the time that the application logic scan started. All of the events that are generated during the same scan period have an identical time stamp. However, the events are stored in the event buffer in the order that they are generated.

G2.2.2 Event response

Upon receiving an event acquisition request from the DNP3 master, the SCS responds with the specified event, if available.

The following methods are used to acquire SCS event data from the DNP3 master:

- Data type specification: Acquire events of the specified data type.
- Class specification: Acquire events of the specified class.

IMPORTANT

The event response of the SCS supports the Pulled Report by Exception type only. The Unsolicited Response type is not supported.

G2.2.3 Event deletion

The SCS deletes an event after receiving a confirmation from the DNP3 master.

When the SCS receives an event acquisition request, the SCS sets an event responding flag. Upon receiving a confirmation of completed event acquisition from the DNP3 master, the SCS deletes the event for which the flag is set.

If the SCS receives no confirmation from the DNP3 master 10 seconds after the event response, the SCS clears the responding flag and retains the event.

The following figure shows the event deletion sequence.

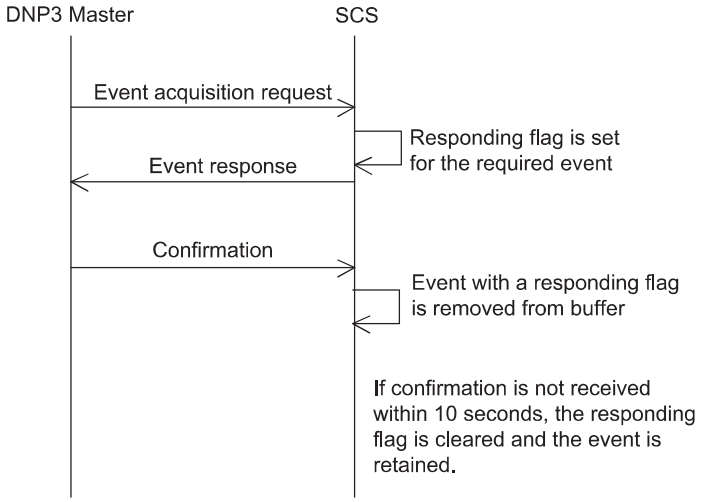

Figure G2.2.3-1 Event deletion sequence

G2.3 DNP3 function support for each data type

The following table shows DNP3 data type, Index range and DNP3 function supported by the SCS.

Table G2.3-1 SCS support Data type for DNP3 function

Data type	IEC data type	Index range	DNP3 function (*1)							
			Read Static	Read Event	Write	Select and Operate	Direct Operate	Freeze	Assign Class	Set Analog Deadband
Binary Input	BOOL	0 to 499 (*2)	Yes	Yes	-	-	-	-	Yes (*3)	-
Binary Output	BOOL	0 to 499 (*2)	Yes	Yes	-	Yes (*4)	Yes (*4)	-	Yes (*3)	-
16-Bit Binary Counter	DINT (*5)	0 to 499 (*2)	Yes	Yes	-	-	-	Yes	Yes (*3)	-
32-Bit Binary Counter	DINT (*5)		Yes	Yes	-	-	-	Yes	Yes (*3)	-
16-Bit Frozen Counter	DINT (*5)		Yes	Yes	-	-	-	-	Yes (*3)	-
32-Bit Frozen Counter	DINT (*5)		Yes	Yes	-	-	-	-	Yes (*3)	-
16-Bit Analog Input	DINT (*5)	0 to 499 (*2)	Yes	Yes	-	-	-	No	Yes (*3)	Yes (*3)
32-Bit Analog Input	DINT		Yes	Yes	-	-	-	No	Yes (*3)	Yes (*3)
Single-Precision Floating Point Analog Input	REAL		Yes	Yes	-	-	-	No	Yes (*3)	Yes (*3)
16-Bit Analog Output	DINT (*5)	0 to 499 (*2)	Yes	Yes	-	Yes	Yes	-	Yes (*3)	No
32-Bit Analog Output	DINT		Yes	Yes	-	Yes	Yes	-	Yes (*3)	No
Single-Precision Floating Point Analog Output	REAL		Yes	Yes	-	Yes	Yes	-	Yes (*3)	No

*1: Yes: Supported, No: Not supported, -: Function not available under DNP3
*2: The total number of data is 1000 for all data types combined.
*3: Set by a DNP3 communication FB. Command setting from the DNP3 master is not supported.
*4: Only latch type output operation is supported. Pulse type output operation is not supported.
*5: The UNIT, UDINT and INT data types under DNP3 are handled as DINT on the SCS.

SEE ALSO For more information about definition of DNP3 data, refer to:

G3.5, “Definition of DNP3 data” on page G3-12

For more information about DNP3 communication FB, refer to:

15., “Function blocks for DNP3 communication (Interference-free FB)” in POU Reference Manual (IM 32P03B20-01EN)

G2.4 Time synchronization

Methods to synchronize the time of the DNP3 master and that of the SCS include time synchronization by using SNTP servers and time synchronization by using DNP3 communication. However, the accuracy of time synchronization using DNP3 communication is no more than 1 second plus the scan period of the application logic.

In an environment where SNTP servers can be connected to the Ethernet network to which the DNP3 master is connected, and also to the Vnet/IP-Upstream network to which the SCS is connected, use time synchronization using SNTP servers for greater time synchronization accuracy.

IMPORTANT

The DNP3 communication contains IIN (internal indications) information, which indicates the status of the DNP3 slave. The IIN is added to the DNP3 response frame and transmitted from the DNP3 slave to the DNP3 master. The IIN includes the time synchronization request status (IIN 1.4 NEED_TIME), which is used to determine the timing for the DNP3 master to synchronize its time.

The SCS sets a flag for the time synchronization request status when it is launched. Once the SCS has received the time synchronization request from the DNP3 master, it will clear the flag and set it again 30 minutes later.

When performing time synchronization by using SNTP servers, the SCS will clear the flag for the time synchronization request status once it has established connection with an SNTP server and will not set the flag again. As such, even if the SCS is disconnected from the SNTP server, time synchronization is not performed by using DNP3 communication.

Time synchronization using SNTP servers

Connect time-synchronized SNTP servers to the Ethernet and Vnet/IP-Upstream, respectively. Synchronize the DNP3 master with the time of the SNTP server on the Ethernet, and synchronize the SCS with the time of the SNTP server on the Vnet-/IP-Upstream. As a result, the time of the DNP3 master will synchronize with the time of the SCS.

The following figure shows the time synchronization by using SNTP servers.

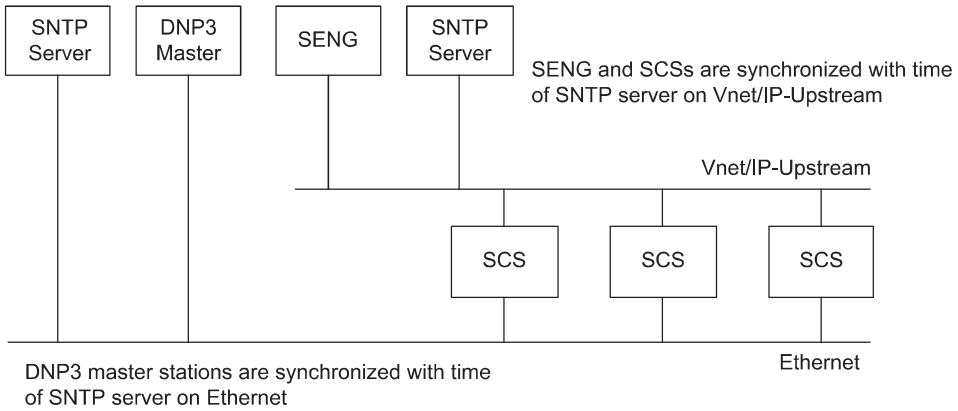

Figure G2.4-1 Time synchronization using SNTP servers

IMPORTANT

Once the SCS has established connection with an SNTP server, it will return the following error when it receives a time synchronization request from the DNP3 master.

```
IIN2.0 NO_FUNC_CODE_SUPPORT
```

Time synchronization using DNP3 communication (The SCS is not connected to the Vnet/IP-Upstream network)

If the SCS is not connected to the Vnet/IP-Upstream network, set the times of all SCSs from the DNP3 master by using DNP3 communication.

The following figure shows time synchronization by using DNP3 communication when the SCS is not connected to the Vnet/IP-Upstream network.

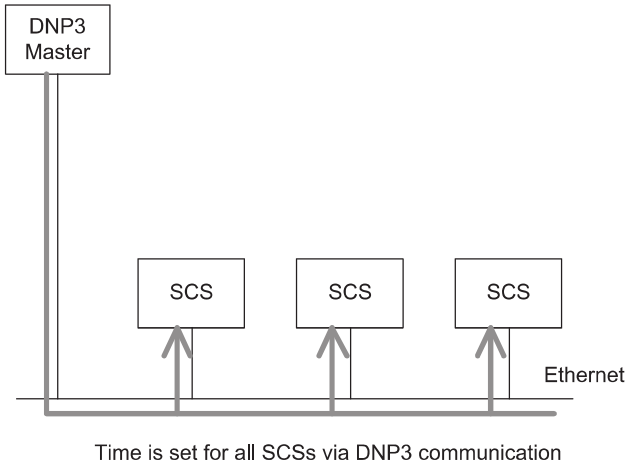

Figure G2.4-2 Time synchronization by using DNP3 communication when the SCS is not connected to the Vnet/IP-Upstream network

Time synchronization using DNP3 communication (The SCS is connected to the Vnet/IP-Upstream network)

If the SCS is connected to the Vnet/IP-Upstream network, set the time of one SCS from the DNP3 master by using DNP3 communication.

The times of other SCSs connected to the Vnet/IP-Upstream network will be synchronized by the time synchronization function of the Vnet/IP-Upstream.

The following figure shows time synchronization by using DNP3 communication when the SCS is connected to the Vnet/IP-Upstream network.

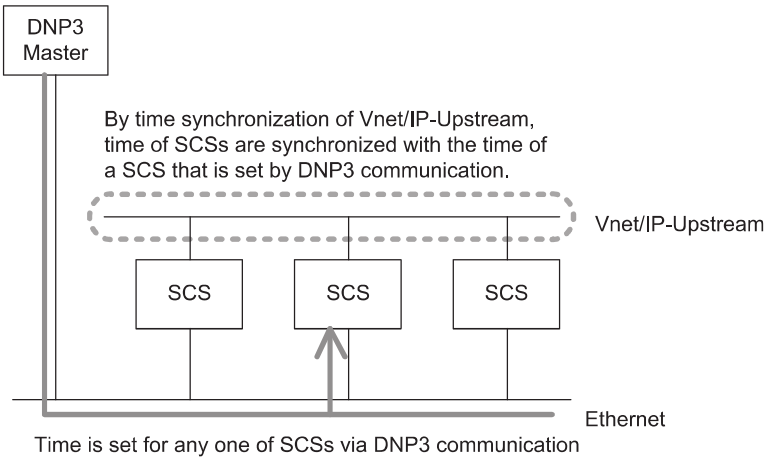

Figure G2.4-3 Time synchronization by using DNP3 communication when the SCS is connected to the Vnet/IP-Upstream network

TIP

- Even when the Vnet/IP-Upstream network consists of multiple domains, setting the time of any one SCS synchronizes the times of all SCSs.
- If some SCSs are connected to the Vnet/IP-Upstream network and others are not, set the time of one SCS that is connected to the Vnet/IP-Upstream network and the times of all SCSs that are not connected to the Vnet/IP-Upstream network.

SEE ALSO

For more information about precautions when setting the time through DNP3 communication, refer to:

"■ Precautions when setting the time through DNP3 communication" on page G3-21

G3. Engineering and maintenance with SENG

The following settings are required for the DNP3 master to access application logic variables of the SCS by using the DNP3 communication function.

- Enabled DNP3 slave function
- Definition of communication modules
- DNP3 slave setting
- Definition of instances for DNP3 communication FBs
- Definition of DNP3 data
- Creating an application logic

Engineering flow

Use the following flow to set the DNP3 slave function engineering on the SENG.

The communication module can be defined in the following engineering methods: I/O list engineering and RS original engineering.

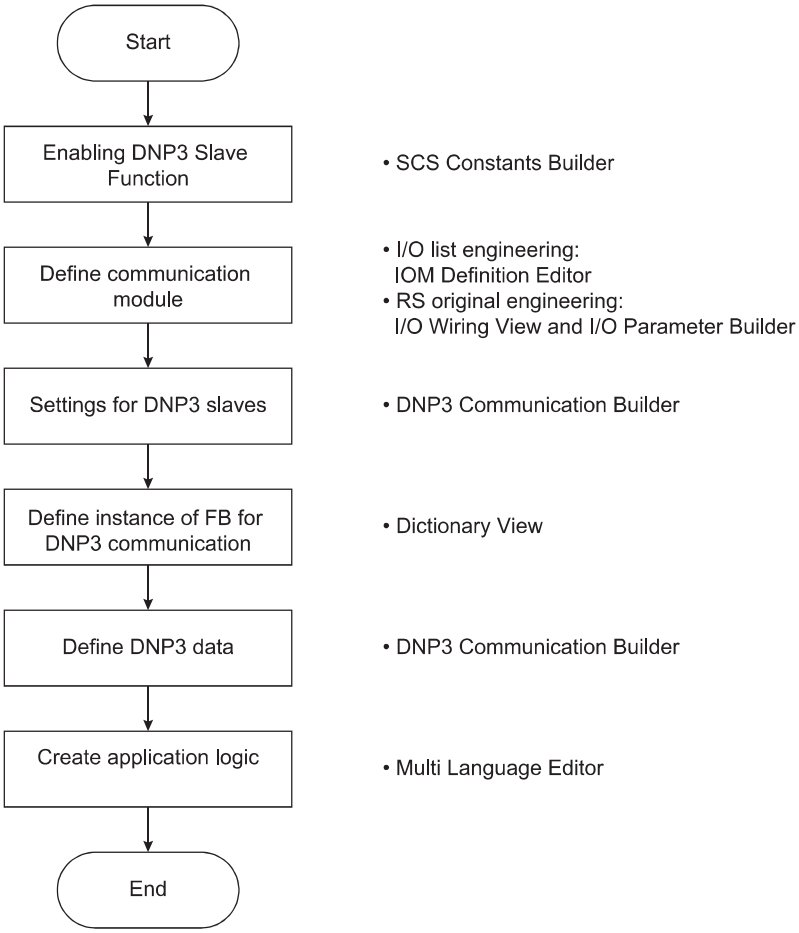

Figure G3-1 Engineering flow of DNP3 slave function

G3.1 Enabled DNP3 slave function

Use the SCS Constants Builder to enable the DNP3 slave function so that the SCS can perform DNP3 communication. Enable the DNP3 slave function on the Communication tab of the SCS Constants Builder.

IMPORTANT

- The DNP3 slave function cannot be enabled online. Changing this setting requires offline download to the SCS.
- Once the DNP3 slave function is enabled, the data buffering function in Integration with CI Server can no longer be used. The event buffer function of the DNP3 slave function can be used.

SEE ALSO For more information about SCS Constants Builder, refer to:

C1.2.6, “SCS Constants Builder” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

G3.2 Definition of communication modules

You must define an Ethernet communication module so that the SCS can perform DNP3 communication.

The editor to be used differs depending on engineering methods.

When performing I/O list engineering, you can define the Ethernet communication module and set parameters by using IOM Definition Editor.

When performing RS original engineering, you can use the I/O Wiring View in the SCS Manager and define the Ethernet communication module. Then, you can set the parameters in the Ethernet communication module by using the I/O Parameter Builder.

This section mainly describes for the case when performing RS original engineering. The communication module definition items and the parameter setting items that are required in I/O list engineering are the same as those for RS original engineering.

SEE ALSO

For more information about I/O list engineering, refer to:

D., “Procedures to create applications using the I/O list engineering method” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about RS original engineering, refer to:

Appendix 2., “RS original engineering” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about I/O Wiring View and I/O Parameter Builder, refer to:

Appendix 2.2, “Definitions of inputs/outputs” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about parameter settings for communication modules, refer to:

Appendix 1.2, “Settings for modules” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

G3.2.1 Definitions in I/O Wiring View

When performing RS original engineering, you can use the I/O Wiring View in the SCS Manager, and define the Ethernet communication module (model: ALE111) as follows:

1. Open I/O Wiring View and select ALE111.
2. Select parameters for the module and specify the node number and the slot number. The node number and the slot number must not overlap with those of other I/O modules and communication modules.

IMPORTANT

When implementing a duplexed communication interface, you must define two ALE111 modules in a non-redundant configuration. There is no restriction on the installation location.

SEE ALSO For more information about display method and window configuration for the I/O Wiring View, refer to:

Appendix 2.2.1, “I/O Wiring View” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

G3.2.2 Definitions in I/O Parameter Builder

When performing RS original engineering, you can specify parameters for the communication module by using I/O Parameter Builder.

For an Ethernet communication module, you can specify the parameters in the Module tab of I/O Parameter Builder.

SEE ALSO For more information about display method and window configuration for the I/O Parameter Builder, refer to:

Appendix 2.2.2, "I/O Parameter Builder" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Module tab of Ethernet communication module

The following tables show the display-only items and settable items on the Module tab of the Ethernet communication module.

The setting of each item can be changed by online change download, but the target module restarts after online change download.

Table G3.2.2-1 Display-only items on the Module tab of the Ethernet communication module

Title	Description	Remarks
Node Number	The node number of the node in which the module is mounted	Defined in I/O Wiring View
Slot Number	The slot number of the slot in which the module is mounted	Defined in I/O Wiring View
Device	The model name of the module	Defined in I/O Wiring View
Dual-Redundant	Whether the module is used in a single or dual-redundant configuration	The module cannot be dual-redundant
Device Number	The device number that is assigned to the module	Defined in I/O Wiring View

Table G3.2.2-2 Setting items on the Module tab of the Ethernet communication module

Title	Description	Remarks
Connection Device	Types of connection devices	-
Comment	A comment regarding the module	-
IP Address	The IP address of the module	-
Subnet Mask	The subnet mask of the module	-
Default Gateway	The default gateway address of the module	-
Port Number	The TCP/IP port number	-
Option 1 to 4	Option items	Fixed to 0.

IMPORTANT

When implementing a duplexed communication interface, you must configure the settings for each of the Ethernet communication modules to be duplexed. However, set the different IP address for the Ethernet communication module for each of modules.

Connection Device

Set the type of connection device.

Select SCSDPTCP when the DNP3 slave function should be used.

Default value: SCSMDTCP

SCSMDTCP: Modbus TCP master

SCSDPTCP: DNP3 master (Selectable only when the version of SCSU1 is R3.02.20 or later.)

TIP

If an attempt is made to change the connection device and the selected port number is not the default, the following dialog box appears:

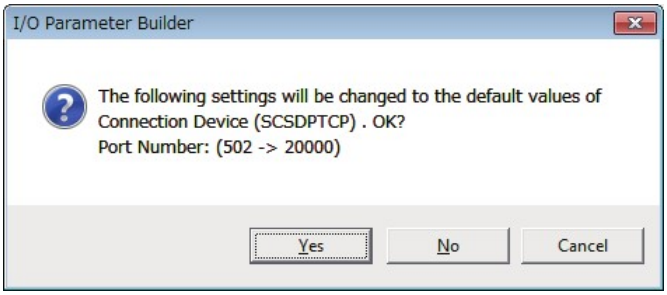

Figure G3.2.2-1 Connection Device dialog box

Yes: The connection device is changed and the port number is changed to the default.

No: The connection device is changed but the port number is not changed.

Cancel: Neither the connection device nor port number is changed.

Comment

A comment regarding the Ethernet communication module can be entered. This comment can be entered using up to 24 single-byte characters or 12 double-byte characters.

IP Address

Set the IP address of the Ethernet communication module. Enter any IP address that you want. When implementing a duplexed communication interface, you must set different IP addresses for the two modules.

Default: This field is empty by default; be sure to enter an IP address. If no value is entered, an error occurs when you try to save the settings in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following IP addresses:

- Host address digits are all zeros or all ones in binary form. (Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Any of the numbers delimited with a period has leading zeros. (Example: 192.168.08.09, 192.168.008.009, etc.)

Subnet Mask

Set the subnet mask of the Ethernet communication module. Enter a subnet mask that you want.

Default: This field is empty by default; be sure to enter a subnet mask. If no value is entered, an error occurs when you try to save the settings in the builder.

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following subnet masks:

- Values less than 255.0.0.0 for a class A IP address
  (Example: 128.0.0.0)
- Values less than 255.255.0.0 for a class B IP address
  (Example: 255.128.0.0)
- Values less than 255.255.255.0 for a class C IP address
  (Example: 255.255.128.0)

Default Gateway

Set the gateway address of the Ethernet communication module. Enter a desired gateway address.

Default: Blank

Format: nnn.nnn.nnn.nnn

Setting range: 0.0.0.1 to 255.255.255.254
However, do not set the following gateway addresses:

- Host address digits are all zeros or all ones in binary form.
  (Example: When subnet mask is 255.255.255.0, 192.168.1.0, 192.168.1.255, etc.)
- Network address digits do not match the IP address.
  (IP address is 192.168.1.1 and default gateway address is 192.168.2.2 when the subnet mask is 255.255.255.0.)
- Any of the numbers delimited with a period has leading zeros.
  (Example: 192.168.08.09, 192.168.008.009, etc.)

Port Number

Set the port number for DNP3 communication.

Default: 20000

Setting range: 0 to 65535

Option 1 to 4

Always set 0 for these options.

Default: 0 (for all)

G3.3 DNP3 slave setting

Use the DNP3 Communication Builder of SENG to set the following parameters so as to make the SCS operate as the DNP3 slave:

Set it as the DNP3 slave on the Parameters tab of the DNP3 Communication Builder.

- DNP3 slave station address
- DNP3 master station address
- Timeout value for Select Before Operate
- Binary Input event buffer size
- Binary Output event buffer size
- Binary Counter event buffer size
- Frozen Counter event buffer size
- Analog Input event buffer size
- Event to be removed when event buffer overflows
- Generate an event when Freeze and Clear command changes the data values
- Include Frozen Counters in Class 0 response
- Type of response message fragmentation

IMPORTANT

- All DNP3 slave settings, except for the event buffer size, can be changed online without stopping the SCS.
- If the DNP3 slave station address or DNP3 master station address is changed, the TCP/IP connection is cut off.
- If the station address is changed, reconnect from the DNP3 master.
- Changing any DNP3 slave setting does not affect the events that are already buffered.
- Changing the event buffer size requires offline download to the SCS.

SEE ALSO For more information about display method and window configuration for the DNP3 Communication Builder, refer to:

G3.5, “Definition of DNP3 data” on page G3-12

DNP3 slave station address

Set the station address of the SCS.

Setting range: 0 to 65519

Default: 0

DNP3 master station address

Set the station address of the DNP3 master.

Setting range: 0 to 65519

Default: 1

Timeout value for Select Before Operate

Set the timeout value in seconds for the Select Before Operate function.

Setting range: 1 to 600
Default: 5

Binary Input event buffer size

Set the number of events that can be stored in the Binary Input event buffer.

Setting range: 0 to 135000
Default: 500

Binary Output event buffer size

Set the number of events that can be stored in the Binary Output event buffer.

Setting range: 0 to 135000
Default: 0

Binary Counter event buffer size

Set the number of events that can be stored in the Binary Counter event buffer.

Setting range: 0 to 135000
Default: 500

Frozen Counter event buffer size

Set the number of events that can be stored in the Frozen Counter event buffer.

Setting range: 0 to 135000
Default: 0

Analog Input event buffer size

Set the number of events that can be stored in the Analog Input event buffer.

Setting range: 0 to 135000
Default: 500

Analog Output event buffer size

Set the number of events that can be stored in the Analog Output event buffer.

Setting range: 0 to 135000
Default: 0

Event to be removed when event buffer overflows

Set how events will be stored when the event buffer overflows.

Oldest: The oldest event stored in the event buffer is deleted and a new event is stored.

Newest: The newest event stored in the event buffer is deleted and a new event is stored.

Default: Oldest

Generate an event when Freeze and Clear command changes data values

Set whether or not to send an event notification when values are cleared to 0 by the Freeze & Clear command.

No: Do not send an event notification.

Yes: Send an event notification.

Default: No

Include Frozen Counters in Class 0 response

Set whether or not to include the Frozen Counter in the Class 0 response.

Yes: Including Frozen Counter

No: Not including Frozen Counter

Default: Yes

Type of response message fragmentation

Set how a response is sent to one acquisition request when the size of the response DNP3 frame exceeds the maximum frame size that SCS can handle.

Single: Single fragment
The DNP3 frame is divided into frames with the maximum frame size and only one frame is sent for one acquisition request.

Multi: Multi fragments
The DNP3 frame is divided into frames with the maximum frame size and multiple frames are sent consecutively for one acquisition request.

Default: Single

To acquire events from the SCS that receives data setting requests, change the event response method of the SCS to "Single fragment."

SEE ALSO For more information about precautions on event acquisition methods, refer to:

"■ Method of response upon event acquisition" on page G3-21

G3.4 Definition of instances for DNP3 communication FBs

Use the Dictionary View to define an instance of DNP3 communication FB.

SEE ALSO For more information about how to define variables using the Dictionary View, refer to:

"Dictionary View" in "Workbench" in the Workbench User's Guide

G3.5 Definition of DNP3 data

To access any variable of the application logic of the SCS from the DNP3 master through DNP3 communication, associate an instance of DNP3 communication FB, to DNP3 data. Use the DNP3 Communication Builder to define an instance of DNP3 communication FB to DNP3 data.

Launching DNP3 Communication Builder

1. Select [Engineering] from the [Tools] menu of SCS Manager.
   The Engineering Launcher menu appears.
2. Select [DNP3 Communication Builder].
   The DNP3 Communication Builder appears.

G3.5.1 Window configuration of the DNP3 Communication Builder

The window of the DNP3 Communication Builder is primarily composed of the data menu area and work space.

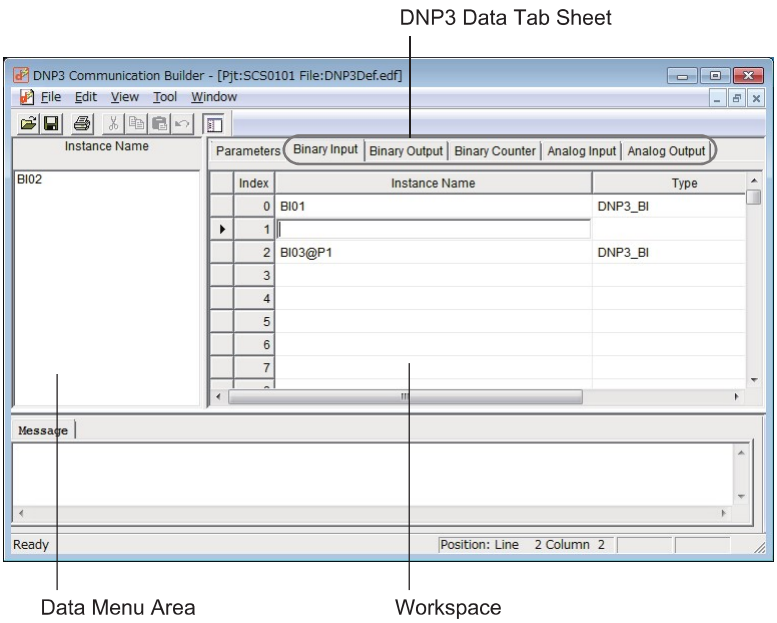

Figure G3.5.1-1 Window configuration of the DNP3 Communication Builder

The data menu area of the DNP3 Communication Builder is composed of the Instance tab.

The work space of the DNP3 Communication Builder is composed of the Parameters tab and DNP3 data tab.

Instance tab of the Data menu area

A list of available instances is displayed on the Instance tab. The displayed names of instances vary depending on the type of DNP3 data displayed in the work space.

The following figure shows an example of the Instance tab for Binary Input.

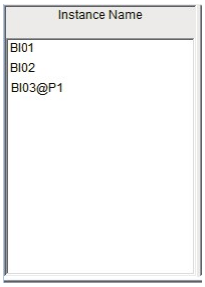

Figure G3.5.1-2 Example of Instance tab in Binary Input

Instances that are already set or deleted are removed from this list and not displayed.

Parameters tab of the work space

The Parameters tab is used to define the parameters of the DNP3 slave function.

SEE ALSO For more information about parameter defined by the DNP3 slave function, refer to:

G3.3, “DNP3 slave setting” on page G3-8

DNP3 data tabs in the work space

The DNP3 data tabs include the following tabs that are used to define a DNP3 communication FB for each DNP3 data type:

- Binary Input
- Binary Output
- Binary Counter
- Analog Input
- Analog Output

Items displayed in tabs

The following items are displayed on each DNP3 data tab:

- Index
  This is the index number of the DNP3 data. The index is displayed in advance in numerical order. 0 to 499.
- Instance name
  This is the instance name of the FB that is assigned to the DNP3 data. You can change the instance name online.
- Type
  This is the type of the FB that is assigned to the DNP3 data.
- Comment
  This is the comment string that represents the instance name of the FB that is assigned to the DNP3 data.

G3.5.2 Definition in the DNP3 Communication Builder

Use the DNP3 Communication Builder to assign an instance of DNP3 communication FB to a DNP3 Index.

Assigning an instance name in the DNP3 Communication Builder

The DNP3 data types that you can set in the DNP3 Communication Builder include Binary Input, Binary Output, Binary Counter, Analog Input and Analog Output, and an Index is assigned to DNP3 data of each DNP3 data type. The DNP3 Communication Builder assigns an instance name for the DNP3 communication FB to be accessed, to one of Indexes 0 to 499. An instance name for the DNP3 communication FB to be assigned is selected according to the Index.

If the DNP3 data type is Binary Input, for example, an instance name for DNP3 communication FB of DNP3_BI type can be assigned. If the DNP3 data type is Binary Counter, an instance name for DNP3 communication FB of DNP3_CT_16 type or DNP3_CT_32 type can be assigned.

DNP3 data types and assignable FBs

The following table describes the DNP3 data types and the types of FBs that can be assigned to these data types in the DNP3 Communication Builder.

Table G3.5.2-1 DNP3 data types and types of FBs that can be assigned in the DNP3 Communication Builder

DNP3 data type	Type of DNP3 communication FB	Description of FB
Binary Input	DNP3_BI	FB that corresponds to the DNP3 data of the DNP3 data type Binary Input
Binary Output	DNP3_BO	FB that corresponds to the DNP3 data of the DNP3 data type Binary Output
Binary Counter	DNP3_CT_16	FB that corresponds to the DNP3 data of the DNP3 data type 16-bit Binary Counter
	DNP3_CT_32	FB that corresponds to the DNP3 data of the DNP3 data type 32-bit Binary Counter
Analog Input	DNP3_AI_16	FB that corresponds to the DNP3 data of the DNP3 data type 16-bit Analog Input
	DNP3_AI_32	FB that corresponds to the DNP3 data of the DNP3 data type 32-bit Analog Input
	DNP3_AI_SF	FB that corresponds to the DNP3 data of the DNP3 data type Single-Precision Floating Point Analog Input
Analog Output	DNP3_AO_16	FB that corresponds to the DNP3 data of the DNP3 data type 16-bit Analog Output
	DNP3_AO_32	FB that corresponds to the DNP3 data of the DNP3 data type 32-bit Analog Output
	DNP3_AO_SF	FB that corresponds to the DNP3 data of the DNP3 data type Single-Precision Floating Point Analog Output

Instance name

Set an instance name of DNP3 communication FB to be assigned to the DNP3 data.

An instance name of DNP3 communication FB consists of up to 69 single-byte characters. In terms of accessibility to instance names, both global instances and local instances can be set regardless of the scope. In the case of a local instance, the scope name must be added after "@."

To access an instance of internal parameter in a user-defined function block, you can use the SCS Manager Dictionary View to name instances of the user-defined function block itself. Specify an instance name of DNP3 communication FB in the following format. Up to two nesting levels can be specified for an instance name.

```
instance name.internal parameter name
```

Table G3.5.2-2 Examples of instance name

Instance name	Scope	Description
VAR1	Global	Global instance
VAR2@PROG1	PROG1	Local instance of PROG1 function
FB01.VAR3	Global	The internal parameter VAR3 of an instance of the user-defined function block FB01
FB01.VAR3@PROG1	PROG1	The internal parameter VAR3 of an instance of the user-defined function block FB01, which is locally defined in a function of PROG1
FB01.FB2.VAR3	Global	The internal parameter VAR3 of an instance of the user-defined function block FB2 used inside an instance of the user-defined function block FB01 (The limit of nesting of a function block is two)

SEE ALSO For more information about SCS Manager Dictionary View, refer to:

"Dictionary View" in "Workbench" in the Workbench User's Guide

Definition method of instance name

An instance name can be set in the Instance Name field of the tab corresponding to one of five DNP3 data types.

Direct entry from the keyboard

Enter an instance name in the Instance name field directly from the keyboard.

Double-clicking an instance name in the Data menu area

Double-click an instance that is set in the Instance Name field on the Instance tab in the data menu area, and you can set an instance name in the Instance Name field of the line selected in the work space.

Drag and drop an instance name from Dictionary View

By dragging and dropping an instance name from Dictionary View to an Instance Name field of DNP3 Communication Builder, you can register the instance name in the DNP3 Communication Builder. If you drag and drop multiple instance names, they are registered in order starting from the top of the Instance Name field where they are dropped. If instance names are already registered in the Instance Name field, they are overwritten.

SEE ALSO For more information about screen image of drag & drop, refer to:

"● Drag and drop from Dictionary View" on page F1-14

Precaution when setting definitions in the DNP3 Communication Builder

Take note of the following when setting definitions in the DNP3 Communication Builder.

- An instance of DNP3 connection FB should be assigned to one of the indexes, 0 to 499, of a given DNP3 data type.
- The total number of assignable instances of DNP3 communication FBs is limited to 1,000 for all data types combined.
- The Frozen Counter need not have any instance assigned, because Frozen Counters are associated with Binary Counters in a one-to-one correspondence.
- DNP3 data assignments can be changed online without stopping the SCS. When online change is executed, changing the definitions of the DNP3 master is also required.

The actions of SCS during online change are as follows:

- Assume that the type name of a function block instance is being changed. If a data referencing request or setting request for the function block instance of the new type name is received before the change is completed, the SCS returns the following error:

  ```
  IIN2.1 OBJECT_UNKNOWN
  ```

- When a response message for batch specification (Class 0 is specified) is divided into several messages, if online change is executed before the SCS finishes sending all response messages, the SCS stops sending the response messages and returns the following error:

  ```
  IIN2.1 OBJECT_UNKNOWN
  ```

- Any event of the data for which online change is performed is not created during online change.
- If the data types (16 bit, 32 bit, float) of Analog Input, Analog Output, Binary Counter, and Frozen Counter are changed, the event data before the change may be incorrect.
- If a request is received for an Index whose definition was lost after the assignment change, the SCS returns the following error:

  ```
  IIN2.2 PARAMETER_ERROR
  ```

  The same applies to Frozen Counters.
- When Binary Counter is changed online, all values of all Frozen Counters are cleared to 0. However, the events of Frozen Counter which are cleared to 0 due to online change of Binary Counter are not created.

SEE ALSO For more information about precautions when assigning DNP3 data, refer to:

"■ Precautions when assigning DNP3 data" on page G3-22

G3.6 Creating an application logic

Use the Multi-language Editor to create an application logic.

G3.7 Precautions for engineering

The DNP3 slave function of SCS allows the DNP3 master to refer data from SCS or set data to SCS through DNP3 communication. The DNP3 slave function does not affect the safety functions of SCS.

You must install the Ethernet communication module (model: ALE111) to an SCS node for the SCS to communicate with the DNP3 master.

To use the DNP3 slave function, use DNP3 communication FBs. By assigning instances of DNP3 communication FBs to DNP3 data, SCS data can be referred or set from the DNP3 master.

When a variable of the application logic changes, the SCS generates and buffers an event that includes a time stamp and data. This prevents data loss when a communication failure occurs because the DNP3 master can read the relevant event from the SCS's event buffer after the recovery.

Transmission specifications of ALE111

The following table describes the transmission specifications of the Ethernet communication module (model: ALE111) that is required to use the DNP3 slave function.

Table G3.7-1 Transmission specifications of ALE111

Item	Specification
Interface	Ethernet (IEEE 802.3)
	10 BASE-T
Baud rate	10 Mbps

IMPORTANT

- Up to two ALE111 modules per SCS can be used for DNP3 communication. Communication modules for the subsystem communication and Modbus slave communication are not included in the count.
- The ALE111 cannot be installed in any I/O node that is 5 km or further away from the CPU node.
- For the Ethernet network that is used in DNP3 communication, use a network of line quality equivalent to or better than that of the Vnet/IP-Upstream network, which requires bandwidth of 2 Mbps or more and transmission delay of 500 ms or less.

Data setting from the DNP3 master

When setting data in SCS from the DNP3 master, use the Operate - With Acknowledgment command unless you are required not to use it.

Precautions for using Operate - With Acknowledgment command

When setting data by using the Operate - With Acknowledgment command, wait for an acknowledgment before issuing the next data setting request. If the next data setting request is issued consecutively without waiting for an acknowledgment, the following status code will be returned:

```
PROCESSING_LIMITED
```

If PROCESSING_LIMITED is returned, issue the data setting request again because the target data may not have been set.

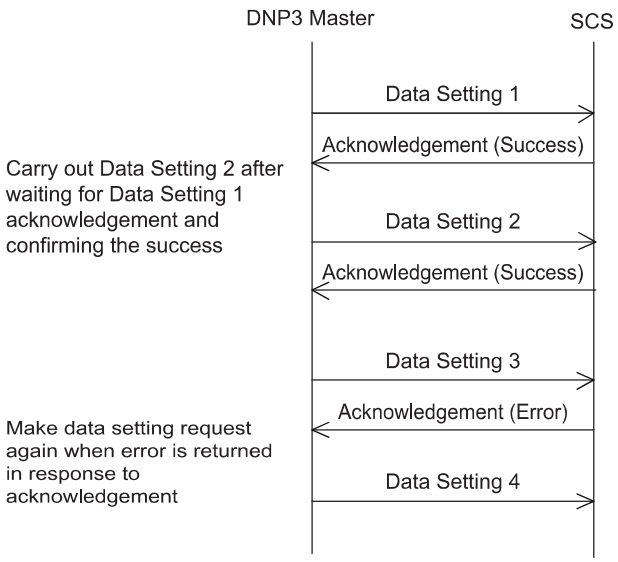

Figure G3.7-1 Data setting request with acknowledgment

Precautions for using Operate - Without Acknowledgment command

When setting data by using the Operate - Without Acknowledgment command, read back the event or current value to confirm that the target value has been set, before issuing the next data setting request.

IMPORTANT

It takes time before the set value can be read, so ensure a sufficiently long wait time before the read-back. If the value is not yet set when checked after waiting for sufficiently long time, issue the data setting request again.

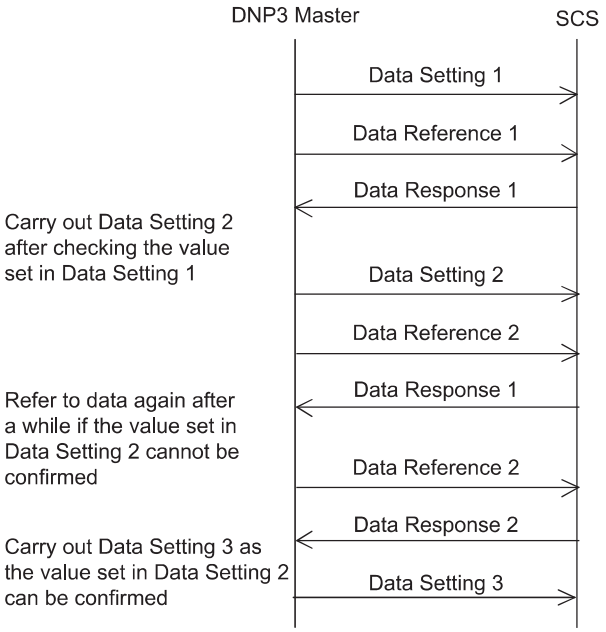

Figure G3.7-2 Data setting request without acknowledgment

Maximum time before the set value can be referenced

After setting data, the event or current value can be read back to confirm that the target value has been set. The following time must elapse before the set value can be read.

The maximum time that must elapse before the set value can be referenced is the sum of the maximum time that is required for the set data to be set to the variable of the application logic, and the maximum time required for the value to be referenced using DNP3 communication after the variable of the application logic is set.

- Maximum time required for the set data to be set to the variable of the application logic

  ```
  Scan period of application logic x Number of data setting requests from exter
  nal connection function
  ```

- Maximum time required for the value to be referenced using DNP3 communication after the variable of the application logic is set

  ```
  Scan period of the external communication function
  ```

- Maximum time before the set value can be referenced

  ```
  Maximum time before the set value can be referenced = Scan period of applicat
  ion logic x Number of data setting requests from external connection function
   + Scan period of external connection function
  ```

Method of response upon event acquisition

To acquire events from the SCS, you must set the event response method of the SCS to "Single fragment."

Setting "Multiple fragments" as the event response method of the SCS allows the DNP3 master to acquire events efficiently, but it may disable data setting request and other processes.

TIP "Data setting" includes setting data using Modbus or other communication.

Precautions when setting the time through DNP3 communication

If multiple SCSs are connected to the Vnet/IP-Upstream network and the time of the SCSs is set by using the DNP3 communication, you must set the time of only one SCS from each Vnet/IP-Upstream domain. When you set the time for multiple SCSs by using DNP3 communication, it may take 10 seconds for the stations that are connected to the Vnet/IP-Upstream network to synchronize.

Engineering for DNP3_CT_16/DNP3_CT_32

To use the DNP3_CT_16/DNP3_CT_32 as a counter, create a calculation application by using the output value of the DNP3_CT_16/DNP3_CT_32 from the previous scan and input value of an external device, and so on.

Create a calculation application as follows:

- Define a variable.
- Use the defined variable and the input value from an external device for the calculation, and connect the result to the input of DNP3_CT_16/DNP3_CT_32.
- Write the output of DNP3_CT_16/DNP3_CT_32 to the defined variable.

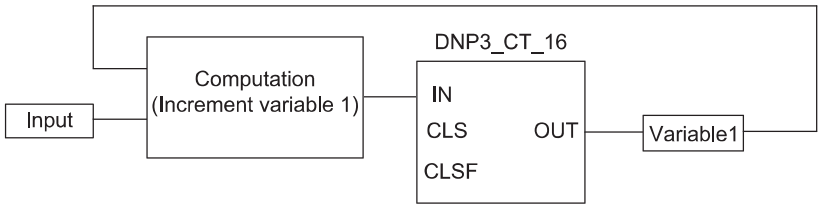

Figure G3.7-3 Engineering example for DNP3_CT_16

Create an application that sets the value of DNP3_CT_16/DNP3_CT_32 to zero by using the DNP3 communication function when the value exceeds the maximum limit it can handle.

TIP

The range of data that DNP3_CT_16/DNP3_CT_32 can handle is as follows:

- DNP3_CT_16: 0 to 65535 of the DINT type
- DNP3_CT_32: 0 to 2147483647 of the DINT type

In the scan period during which a reset request from the DNP3 communication function is received, set the value of DNP3_CT_16/DNP3_CT_32 and the defined variable to zero.

Precautions when assigning DNP3 data

It is recommended for efficient DNP3 communication that when DNP3 data is assigned, the Indexes must be defined consecutively from 0 without missing number.

Precautions for the duplexed communication interface

When implementing a duplexed communication interface, ensure that the DNP3 master communicates with either one of the two ALE111 modules. If the DNP3 communication is used on both ALE111 at the same time, the SCS will take the following action.

The SCS will process the request received from both ALE111. The SCS receives data setting and freeze & clear requests from both ALE111 and processes the requests twice, but the SCS can only process one request for each scan period, so there is a time lag between the two data setting actions.

SEE ALSO

For more information about restrictions when configuring the DNP3 communication data, refer to:

"● Limitations on data setting using DNP3 communication" on page G2-6

Precautions when reconnecting

ALE111 maintains its TCP/IP connection for a maximum of 34 seconds after it loses its DNP3 connection with the DNP3 master. During this time, the DNP3 master cannot connect with ALE111 via TCP/IP because the connection is being used. To reconnect in the event of an error, wait 34 seconds before trying again.

G3.8 Troubleshooting

If a communication module error occurs, you can use the SCS Maintenance Support Tool to acquire information on the communication module and communication error information. This section describes typical troubleshooting cases.

There is no response and communication fails

If there is no response and communication fails, check the following points:

- Check if the TCP/IP settings of the communication module match those on the master side.
- Use the SCS Maintenance Support Tool to check the status of the communication module.
- Use Network Monitor or other tools to analyze the protocol managing the send/receive frames.
- Check if there is enough CPU time available. Response may be delayed when the CPU load is high.

Connection cannot be established and communication fails

If connection cannot be established and communication fails, check the following points:

- Check if the destination IP address and port number are correct.
- If the DNP3 protocol communication between the DNP3 master and SCS is cut off without the DNP3 master notifying the end of communication to the SCS, connection to the SCS becomes possible again after up to 34 seconds.

The SCS time is not synchronized with the DNP3 master time

If the SCS time is not synchronized with the DNP3 master time, check the following procedures.

SNTP servers are used

- Check if the time of the SNTP server on the Ethernet side is synchronized with that of the SNTP server on the Vnet/IP-Upstream side.
- Check if the DNP3 master and SCS are synchronized with their respective SNTP servers.

SNTP servers are not used

Check if an application that issues time setting requests to the SCS exists on the DNP3 master.

Appendix 1. Information regarding engineering for subsystems

Appendix 1.1 Differences between safety subsystem communication I/O, subsystem communication I/O, and AIO/DIO modules I/O

The following table shows the differences between safety subsystem communication I/O, subsystem communication I/O, and AIO/DIO modules I/O.

Table Appendix 1.1-1 Differences between safety subsystem communication I/O, subsystem communication I/O, and AIO/DIO modules I/O

Classification	Item	Safety subsystem communication I/O	Subsystem communication I/O	AIO/DIO modules I/O
General	Number of channels	Variable	Variable	Fixed
	Safety	Safety (*1)	interference-free	Safety
Communication data, AIO/DIO data	Variable	FB instance	FB instance	Structure variable
	Data type	DINT, REAL	BOOL, DINT, REAL	BOOL, REAL
	Data status	Safety: Status of devices to the safety communication function	Status of subsystems to communication modules Errors in subsystems are not applicable	Status of I/O terminals to I/O modules
		interference-free: Status of devices to the safety communication module Only communication errors within the ISA100 wireless communication system are applicable		
Forcing	Lock	Individual communication definitions, all communication module inputs	All communication module inputs, all outputs, all inputs/outputs	Individual channels, all module inputs, all outputs, all inputs/outputs
	Value set	Individual data	Individual data	Individual channels
	Lock management	SYS_FORCE_SF Communication related system alarms Communication I/O Lock Window	SYS_FORCE_SC Communication related system alarms Communication I/O Lock Window	SYS_FORCE System alarms I/O Lock Window
Error handling action	Output enable start	Not required. Output enable operation allowed even when there is a module error	Output enable operation from SENG, or operation by SYS_STAT_SC Output enable allowed even when there is a module error	Output enable operation from SENG, or operation by SYS_STAT Output will not be enabled for modules with errors
	Input module error	Specification of behavior at fault allowed (specified input value at fault, specified to hold value)		
CENTUM Integration	CENTUM Integration	Available (%XB)	Available (%WB)	Available (%Z, %Y, %WB)
Online change	Online change download	Available (*2)	Available	Available
Test function	Virtual test	Available		
	Target test	Available		

*1: Non-safety data of PROFINET can also be handled.
*2: PROFINET communication between S2LP131 and YFGW410 and PROFIsafe communication between the SCS and GS01 are both disconnected and S2LP131 restarts. After restarting, PROFINET communication and PROFIsafe communication will

resumed. During this process, PROFIsafe communication between S2LP131 and GS01 will be in a state of error and the input value will be the input value at fault.

Appendix 1.2 Items of I/O Parameter Builder

You can set the I/O parameters of the fire and gas communication module with IOM Definition Editor of AD Suite. By executing RS Generation, you can reflect the setting items onto the fire and gas communication module parameter tab in I/O Parameter Builder. Reflected items become read-only in I/O Parameter Builder.

The following table shows the displayed I/O parameter items for the fire and gas communication module.

Table Appendix 1.2-1 Displayed I/O parameter items for the fire and gas communication module

Title	Description	Remarks
Node Number	The node number corresponding to the mounting position of the module is displayed.	
Slot Number	The slot number corresponding to the mounting position of the module is displayed.	
Device	The type of module is displayed.	
Dual-Redundant	Whether the module is used in a single or dual-redundant configuration is displayed.	Single only
Device Number	The device number assigned to the module is displayed.	
Connection Device	The type of connection device (safety subsystem) is displayed.	Fixed as S_FGCOM
Comment	A comment regarding the module is displayed.	
Host Name	The host name of the module is displayed.	
IP Address	The IP address of the module is displayed.	
Subnet Mask	The subnet mask of the module is displayed.	
Default Gateway	The gateway address of the module is displayed.	
Dual-Redundant YFGW Switching Time	The time during which a communication error accompanying a switchover is not notified when an error occurs with a dual-redundant YFGW410 is displayed.	

Appendix 1.3 Items of Communication I/O Builder

You can set the communication definition of the fire and gas communication module with Safety Communication I/O Editor of AD Suite. By executing RS Generation, you can reflect the setting items onto each tab in Communication I/O Builder. Communication I/O Builder is configured of the following four tabs. For fire and gas communication, you will be using the Safety Subsystem Comm. I/O Definition tab and the Safety Subsystem Comm. I/O Wiring tab.

- Comm. I/O Definition tab
- Comm. I/O Wiring tab
- Safety Subsystem Comm. I/O Definition tab
- Safety Subsystem Comm. I/O Wiring tab

Reflected items become read only in Communication I/O Builder.

Safety Subsystem Comm. I/O Definition tab

The Safety Subsystem Comm. I/O Definition tab is displayed when the SCS is using I/O list engineering with SCSP3.

Element

The address of the data storage area used for safety subsystem communication I/O is displayed.

Format: %XWnnnn

%XW: Fixed

nnnn: 0001 to 4000

Buffer

The storage area address size of the safety subsystem communication I/O data used by fire and gas communication programs is displayed. This is assigned to only the odd numbers of %XW.

Program Name

A program name combining the node number of S2LP131, slot number, and communication program name is displayed.

Format: n-s Fixed character string

n: Node number

s: Slot number

Fixed character string: S_FGCOM

Size

The assigned size (data length) from the beginning address set in "Device Address" is displayed.

Station Name

The host name of any device connected with PROFINET is displayed.

- **IP Address**

  The IP address of any device connected with PROFINET is displayed.

- **Subnet Mask**

  The subnet mask of any device connected with PROFINET is displayed.

- **Default Gateway**

  The default gateway of any device connected with PROFINET is displayed.

- **PN-Updating Time**

  The interval for updating the PROFINET communication I/O data is displayed.

- **PN-Watchdog Time**

  The interval at which communication of PROFINET is checked for whether it is running correctly is displayed.

- **PN-Slot**

  The slot number used by PROFINET is displayed.

- **PN-Module**

  The name of the PROFINET module is displayed.

- **PN-Sub Slot**

  The subslot number used by PROFINET is displayed.

- **PN-Submodule**

  The name of the PROFINET submodule is displayed.

- **PN-Alarm Group**

  A string sequence for every communication definition added to an alarm message.

  Display example of SS-SCPATH Error:

  ```
  SCS0101 SS-SCPATH Error FIO NODE 01 SLOT 01 PORT 01 GS01-001-PV Code=A3B0
  ```

  GS01-001-PV is the string sequence for PN-Alarm Group.

- **PN-Data**

  The data name defined in the PROFINET GSDML file is displayed.

- **Data Type**

  The type of data when exchanging data with PROFINET is displayed.

- **Comment**

  A comment is displayed.

- **F Parameter**

  The F parameter used when performing safety communication with PROFIsafe is displayed.

  The following table shows a list of F parameters.

Table Appendix 1.3-1 List of F parameters

Parameter name	Setting value	Remarks
F_Check_iPar	No check, Check	
F_SIL	SIL1, SIL2, SIL3, NonSIL	
F_CRC_Length	3Byte CRC, 4Byte CRC	
F_CRC_Seed	0, 1	
F_Passivation	0, 1	
F_Block_ID	1	
F_Par_Version	V2-Mode	
F_Source_Addr	Numerical value	Controller identification address
F_Dest_Addr	Numerical value	Device identification address
F_WD_Time	Numerical value	Monitors whether a signal arrives within this time
F_WD_Time_2	Numerical value	
F_iPar_CRC	Numerical value	
F_Par_CRC	Numerical value	

Safety Subsystem Comm. I/O Wiring tab

The Safety Subsystem Comm. I/O Wiring tab shows a list of elements corresponding to the areas assigned in the Safety Subsystem Comm. I/O Definition tab.

Element

The element number (%XB) automatically assigned according to the element number (%XW) set with PN-data and the data type on the Safety Subsystem Comm. I/O Definition tab is displayed.

Example:

When the element is %XW2001
%XB200101

PN-Data

The PN-data assigned to the Safety Subsystem Comm. I/O Definition tab is displayed.

Variable Name

The instance name of the FB used for fire and gas communication I/O set to the variable name with Safety Communication I/O Editor is displayed.

The following table shows the data types and specifiable variable types.

Table Appendix 1.3-2 Data types and specifiable variable types

Object	Data type	Type
PROFINET	Analog input (8-bit signed integer) Analog input (16-bit signed integer) Analog input (32-bit signed integer) Analog input (8-bit unsigned integer) Analog input (16-bit unsigned integer) Analog input (32-bit unsigned integer)	PNI_I
	Analog input (32-bit floating)	PNI_R

Continues on the next page

Table Appendix 1.3-2 Data types and specifiable variable types (Table continued)

Object	Data type	Type
Fire and gas communication	Analog input (8-bit signed integer) Analog input (16-bit signed integer) Analog input (32-bit signed integer) Analog input (8-bit unsigned integer) Analog input (16-bit unsigned integer) Analog input (32-bit unsigned integer)	PSI_I
	Analog input (32-bit floating)	PSI_R

Type

The selected variable type is displayed.

Comment

The comment of the variable is displayed.

Input processing at Fault

This is the setting item you can use to specify the value to pass to the logic in place of the actual input when a communication error is detected.

You can specify this item using AD Suite only when the data type is analog input.

Table Appendix 1.3-3 Input processing at fault

Option	Description
Hold	Holds the value from right before the error when an error is detected.
Fixed value	Uses the input value specified in "Input Value at Fault" when an error is detected.

Input Value at Fault

This is the value to be used as the input value instead of the process value when "Fixed Value" is specified in "Input Processing at Fault."

Appendix 2. DNP3 field device Profile

This section describes the DNP3 specifications of the SCS. Refer to the information listed here to confirm that slave devices meeting these specifications can connect to the DNP3 master that communicates with the SCS.

Appendix 2.1 Device properties

Table Appendix 2.1-1 Device properties

DEVICE IDENTIFICATION	
Device Function:	[ ] Master [v] Outstation
Vendor Name:	Yokogawa Electric Corporation
Device Name:	ProSafe-RS SCS
Device manufacturer's hardware version string:	
Device manufacturer's software version string:	
Device Profile Document Version Number:	2013
DNP Levels Supported for:	Outstations Only Requests and Responses [v] None - partially supported [v] Level 1 - except Unsolicited Response; [v] Level 2 - except Device Attributes; [v] Level 3 - except Device Attributes [v] Level 4 - partially supported
Supported Function Blocks:	[ ] Self-Address Support [ ] Data Sets [ ] File Transfer [ ] Virtual Terminal [ ] Mapping to IEC 61850 Object Models defined in a DNP3 XML file. [ ] Function code 31, activate configuration [ ] Authentication
Methods to set Configurable Parameters:	[ ] XML - Loaded via DNP3 File Transfer [ ] XML - Loaded via other transport mechanism [ ] Terminal - ASCII Terminal Command Line [v] Software - Vender software named "Multi Language Editor", "I/O Parameter Builder", "DNP3 Communication Builder" and "IOM Definition Editor" [ ] Proprietary file loaded via DNP3 File Transfer [ ] Proprietary file loaded via other transport mechanism [ ] Direct - Keypad on device front panel [ ] Factory - Specified when device is ordered [ ] Protocol - Set via DNP3 (e.g. assign class, write deadband) [ ] Other - explain:
DNP3 XML files available On-line:	Rd Wr [ ] dnpDP.xml - Complete Device Profile [ ] dnpDPcap.xml - Device Profile Capabilities [ ] dnpDPcfg.xml - Device Profile config. values [ ] [ ] *.xml
External DNP3 XML files available Off-line:	Rd Wr [ ] [ ] dnpDP.xml - Complete Device Profile [ ] [ ] dnpDPcap.xml - Device Profile Capabilities [ ] [ ] dnpDPcfg.xml - Device Profile config. values [ ] [ ] *.xml
Connections Supported:	[ ] Serial (complete section "SERIAL CONNECTIONS") [v] IP Networking (complete section "IP NETWORKING") [ ] Other, explain
Conformance Testing	[v] Self-tested [ ] Independently tested, version Test organization name

Continues on the next page

Table Appendix 2.1-1 Device properties (Table continued)

IP NETWORKING	
Port Name:	
Type of End Point:	[ ] TCP Initiating (Master Only) [v] TCP Listening (Outstation Only) [ ] TCP Dual (required for Master) [ ] UDP Datagram (required)
IP Address of this Device:	
Subnet Mask:	
Gateway IP Address:	
Accepts TCP Connections or UDP Datagrams from:	[v] Allows all [ ] Limits based on IP address [ ] Limits based on list of IP address [ ] Limits based on a wildcard IP address [ ] Limits based on list of wildcard IP address [ ] Other, explain:
IP Address(es) from which TCP Connections or UDP Datagrams are accepted.	
TCP Listen Port Number:	[ ] Not Applicable (Master w/o dual end point) [ ] Fixed at 20000 [v] Configurable, range 0 to 65535 - by I/O Parameter Builder, or IOM Definition Editor - default = 20000 - The number must NOT be duplicated with other TCP Listen Port Numbers on the controller. [ ] Configurable, selectable from [ ] Configurable, other, describe:
TCP Listen Port Number of remote device:	[v] Not Applicable (Outstation w/o dual end point) [ ] Fixed at 20000 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
TCP Keep-alive timer:	[v] Fixed at 30000 ms [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Local UDP Port:	[ ] Fixed at 20000 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Destination UDP port for initial unsolicited null responses:	[ ] None [ ] Fixed at 20000 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Destination UDP port for responses:	[ ] None [ ] Fixed at 20000 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe: [ ] Use source port number
Multiple Master Connections:	[ ] Supports multiple masters (Outstations only) If supported, the following methods may be used: [ ] Method 1 (based on IP address) [ ] Method 2 (based on IP port number) [ ] Method 3 (browsing for static data)

Continues on the next page

Table Appendix 2.1-1 Device properties (Table continued)

Time Synchronization Support:	[v] DNP3 LAN procedure (function code 24) [v] DNP3 Write Time (not recommended over LAN) [ ] Other, explain [ ] Not Supported
LINK LAYER	
Data Link Address: (DNP3 Outstation Address)	[ ] Fixed at [v] Configurable, range 0 to 0xffff - Configurable by DNP3 Communication Builder [ ] Configurable, selectable from [ ] Configurable, other, describe:
DNP3 Source Address Validation:	[ ] Never [v] Always, one address allowed [ ] Always any one of multiple addresses allowed [ ] Sometimes, explain:
DNP3 Source Address(es) expected when Validation is Enables: (DNP3 Master Address)	[v] Configurable to any 16 bit DNP Data Link Address value - Configurable by DNP3 Communication Builder [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Self Address Support using address 0xFFFC:	[ ] Yes (only allowed if configurable) [v] No
Sends Confirmed User Data Frames:	[v] Never [ ] Sometimes, explain: [ ] Always
Data Link Layer Confirmation Timeout:	[v] None [ ] Fixed at [ ] Configurable, range to ms [ ] Configurable, selectable from ms [ ] Configurable, other, describe: [ ] Variable, explain:
Maximum Data Link Retries:	[v] Never Retries [ ] Fixed at [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Maximum number of octets Transmitted in a Data Link Frame:	[v] Fixed at 292 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Maximum number of octets Received in a Data Link Frame:	[v] Fixed at 292 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
APPLICATION LAYER	
Maximum number of octets Transmitted in an Application Layer Fragment other than File Transfer:	[v] Fixed at 1600 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Maximum number of octets Transmitted in an Application Layer Fragment containing File Transfer:	[ ] Fixed at [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:
Maximum number of octets that can be Received in an Application Layer Fragment :	[v] Fixed at 1600 [ ] Configurable, range to [ ] Configurable, selectable from [ ] Configurable, other, describe:

Table Appendix 2.1-1 Device properties (Table continued)

Analog Input Deadbands:	[ ] Configurable - Per Point - by Master [v] Configurable - Per Point - by Outstation - Configurable by Multi Language Editor	
Class Assign:	[ ] Configurable - Per Point - by Master [v] Configurable - Per Point - by Outstation - Configurable by Multi Language Editor	
Time Value for all DNP3 protocol time stamps reported and time synchronization messages:	[v] Fixed at UTC [ ] Configurable, selectable from "Local Time" or "UTC"	
File Handling:	[v] Not Supported	
Control Relay Output Block (CROB) Latch Operation:	[v] Yes - "CROB Operation" is available for Binary Outputs. - Output Block Operation (CROB and AOB) cannot run without error more than four times a second.	
Control Relay Output Block (CROB) Pulse, Trip and Close Operation:	[v] Not Supported	
Analog Output Block (AOB) Operation:	[v] Yes - Output Block Operation (CROB and AOB) cannot run without error more than four times a second.	
Freeze & Clear Operation	Freeze & Clear Operation is available only when the number of Binary Counter is defined as 32 or less.	
Time Synchronization Accuracy	If you use Time Synchronization using DNP3 communication, time synchronization accuracy between DNP3 master and SCS is up to the scan cycle of application logic plus 1000 ms.	
Delay of data setting	There is delay after SCS receives the setting request of DNP3 data until the actual data is updated. This delay is dependent on the scanning cycle and the number of requests from external connection devices.	
Support Data Types	DNP3 Data type	IEC data type treated by SCS
	Binary Input	BOOL
	Binary Output	BOOL
	16-Bit Binary Counter	DINT
	32-Bit Binary Counter	DINT
	16-Bit Frozen Counter	DINT
	32-Bit Frozen Counter	DINT
	16-Bit Analog Input	DINT
	32-Bit Analog Input	DINT
	Single-Precision Floating Point Analog Input	REAL
	16-Bit Analog Output	DINT
	32-Bit Analog Output	DINT
	Single-Precision Floating Point Analog Output	REAL

Table Appendix 2.1-1 Device properties (Table continued)

Online maintenance	DNP3 data can be modified by using online change without stopping SCS. The following list shows how SCS behaves when online change is performed: - If the SCS receives a write request or a read request while the data in the SCS is being updated by the online change, the SCS returns the error IIN2.1 OBJECT_UNKNOWN. - If the Class 0 response is divided into multiple messages, running the online change before the SCS finishes sending response messages causes the SCS to stop sending messages and return the error IIN2.1 OBJECT_UNKNOWN. - While the online change is running, events for the data in the SCS are not generated. - If you change the detailed data type of Analog Input, Analog Output, Binary Counter, or Frozen Counter, the event data before the change may be converted into an invalid data. - If a write request or a read request to the data that has been deleted by the online change is received, the SCS returns the error IIN2.2 PARAMETER_ERROR. - If you perform online change on Binary Counter, the SCS clears all Frozen Counters to 0.

This Device Properties is referred to "DNP3 SPECIFICATION, Version 2013, November-2013".

Appendix 2.2 Capabilities for device database

Analog Inputs included in Class 0 response:	[v] Always [ ] Never [ ] Only if point is assigned to a class [ ] Based on point index
How Deadbands are set:	[ ] A. Global Fixed [ ] B. Configurable through DNP [v] C. Configurable via other means - by Multi Language Editor [ ] D. Other, explain [ ] Based on point index
Analog Input Deadband Algorithm:	[v] Simple [ ] Integrating [ ] Other, explain [ ] Based on point index
Analog Inputs Event Buffer Organization:	[ ] Fixed at _____ [v] Configurable, range 0 to 135000 - Configurable by DNP3 Communication Builder [ ] Configurable, selectable from ____,____,____ [ ] Configurable, other, describe_____
ANALOG OUTPUT STATUS AND ANALOG OUTPUT CONTROL BLOCK Analog Output Status Object Number: 40 Analog Output Control Block Object Number 41 Analog Output Event Object Number 42	
Static Analog Output Status Variation reported when variation 0 requested or in response to Class 0 polls	[ ] Variation 1 - 32-bit with flag [ ] Variation 2 - 16-bit with flag [ ] Variation 3 - single-precision floating point with flag [ ] Variation 4 - double-precision floating point with flag [v] Based on point index (Variation 1, 2 or 3)
Analog Output Status included in Class 0 response:	[v] Always [ ] Never [ ] Only if point is assigned to a class [ ] Based on point index

Table Appendix 2.2-1 Capabilities for device database (Table continued)

Event Variation reported when variation 0 requested or in response to Class 0 polls:	[ ] Variation 1 - 32-bit without time [ ] Variation 2 - 16-bit without time [ ] Variation 3 - 32-bit with time [ ] Variation 4 - 16-bit with time [ ] Variation 5 - single-precision floating point w/o time [ ] Variation 6 - double-precision floating point w/o time [ ] Variation 7 - single-precision floating point with time [ ] Variation 8 - double-precision floating point with time [v] Based on point index (Variation 3, 4 or 7)
Event reporting mode:	[ ] Only most recent [v] All events
Maximum Time between Select and Operate:	[ ] Not Applicable [ ] Fixed at seconds [v] Configurable, range from 1 to 600 seconds - by DNP3 Communication Builder (default=5) [ ] Configurable, range to seconds [ ] Configurable, selectable from seconds [ ] Configurable, other, describe: [ ] Variable, explain: [ ] Based on point index
Analog Outputs Event Buffer Organization:	[ ] Fixed at _____ [v] Configurable, range 0 to 135000 - Configurable by DNP3 Communication Builder [ ] Configurable, selectable from _____,_____,_____ [ ] Configurable, other, describe_____

This Device Properties is referred to "DNP3 SPECIFICATION, Version 2013, November-2013".

Revision information

Title : Engineering Guide Vol. 2

Manual No. : IM 32P01C20-01EN

Dec. 2023/10th Edition/R4.10 or later

A1	Added SYS_CPUDSP.
A6.2	Updated descriptions of SCS link transmission.
A7	Updated descriptions of inter-SCS safety communication.

Nov. 2022/9th Edition/R4.08

F1.5.2	Updated reference numbers of Modbus Address Builder.

Jan. 2022/8th Edition/R4.07

B5.1.3	Added function blocks that use the output status.
D4.17	Updated descriptions from FAST/TOOLS to CI Server.

Feb. 2021/7th Edition/R4.06

A2, A3.4.1, A3.4.3, A3.4.4, A9.1, B8.1.4, B8.1.5, B8.2.6, D4.1	Added IOM for SIL2.
A3.3, B1, B7.1.5, B7.2.1, B7.2.4, B8.1.4, D2.9, D4.7, F4	Added SCS for SIL2
A6.1, A7	Added descriptions of SIL2.
B8.1.4	Added nodes for SIL2.
B2, B8.1.6, B8.2.5	Updated description because CENTUM VP supported UACS.
C3.2	Support for Windows 10
A, D4.17, F1.5, G1, G2.2, G3.1	Updated descriptions from FAST/TOOLS to CI Server.

Dec. 2019/6th Edition/R4.05

Introduction	Updated descriptions of registered trademarks and trademarks.
B5.1.2, B5.3.1	Updated descriptions because of the change in the operation of HIS when password entry is skipped for a manual operation block.
B5.1.6, B5.3.2	Updated descriptions due to the changes made to the mapping block data item of the manual operation block.
B8.1.4	Added descriptions regarding the operation data reset switch.

Aug. 2018/5th Edition/R4.04

Introduction	Updated description of registered trademarks of YOKOGAWA.
A3.3, A3.4, A3.4.2	Added descriptions regarding the modules that are not subject to the device reset function.
C3.1.2	Updated descriptions regarding VS2017.

Oct. 2017/4th Edition/R4.03.10

Introduction	Added fire and gas communication module
A1, B1, B2, B3.1, B3.3, B7.1, B8.1.3	Added description regarding safety subsystem communication I/O FB

B7.1.3	Added the procedure for changing alarm display colors.
B7.2.4	Added precautions for when performing CENTUM integration
B8.1.4	Added number of locks for safety subsystem communication I/O
D1.3	Added descriptions of the conversion of real-type input data.
D1.4, D2.4, D3.3, D4.12, D4.14.2	Added safety communication I/O editor
E	Added description regarding safety subsystem communication
E1	Added description regarding fire and gas communication
Appendix 1	Added descriptions of information about engineering of subsystems.

May 2017/3rd Edition/R4.03

Entire manual	Changed description regarding the start menu
Introduction	Deleted Windows Vista from the explanation of trademarks
A3.3, A3.4, A3.4.1, A3.4.2, A3.4.3, A3.4.4, A3.5	Added explanations regarding the functions for fire and gas device applications
A8.5, B1, B2, B3.1, B3.3, B7.1, B8.1.3	Added explanations regarding HSDTR and GASDTR
B7.1, B8.2.6	Added an explanation of chattering alarm suppression

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed the symbols that indicate warning and caution.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."
A	Changed configurations.
A1, A1.1, A1.2, A4, A4.6, B2, B7, B7.1.4, B7.2	Added descriptions of iDefine.
A3, A8.5, B2, B3.2, B7.1.4, B7.1.5, B7.1.6, B8	Updated descriptions of tools.
D2.9, D4.7	Updated conditions for the number of mounts.
D3.1,E2.1, E3.1	Added descriptions of the number of mounts.
F1, F1.1, F3.2.1, F3.2.2, F3.7	Added descriptions of the duplexed interface for DNP3 communication.
F2.4	Updated descriptions of time synchronization.
Appendix1.1	Added IOM Definition Editor.

Dec. 2015/1st Edition/R4.01

Newly published.

11th Edition

Introduction

This manual describes the procedure for setting up ProSafe-RS.

When you integrate ProSafe-RS with FAST/TOOLS, replace "Vnet/IP" in the descriptions in this manual with "Vnet/IP-Upstream."

This manual consists of the following parts:

- Part A Overview
  This part provides an overview of ProSafe-RS setup.
- Part B: New Setup
  This part describes the procedure for a new setup of ProSafe-RS.
- Part C Maintenance
  This part describes the tasks to be done while a ProSafe-RS system is used.
- Part D Connection with Other Products
  This part describes how to connect ProSafe-RS to other YOKOGAWA products and provides cautionary notes.
- Appendix
  This section describes hardware settings and cautionary notes.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User's Manuals for necessary actions. In the User's Manuals, this symbol is used together with a word "CAUTION" or "WARNING" at the locations where precautions for avoiding dangers are described.

<French> Signale qu'il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d'un danger pour le personnel et l'équipement comme un choc électrique, et signale également que l'utilisateur doit se référer au Manuel de l'utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l'utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

Indicates an AC supply.

Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

A. Overview

This section explains how to read this document, types of ProSafe-RS setup tasks and their workflows.

A1. How to Read This Document

This document explains the setup procedures for the ProSafe-RS software. This document does not touch upon installation procedures of Windows OS, related service packs, and Microsoft security patches. Also, this document does not touch upon the procedure for installing iDefine and how to configure the security settings on the computer on which iDefine is to be installed.

To use the software packages installed on an SENG, licenses must be distributed to and activated on the SENG by using a program called License Manager. Procedures for the tasks performed using License Manager are described in the License Management IM. You are guided to refer to the License Management IM as necessary in the explanation of setup procedures.

You are also guided to refer to the Security Guide IM for information about functions that reinforce security of the system.

SEE ALSO

For more information about the procedure for installing the Windows operating systems, related service packs and the Microsoft security patches, refer to:

the information provided by Microsoft

For more information about Microsoft security patches, refer to:

Microsoft Security Update Policy (TI 33Y01B30-02E)

For more information about the procedure for distributing and activating the licenses on the stations, refer to:

1., “Overview of license management” in License Management Guide (IM 32P01C60-01EN)

For more information about system security, refer to:

1., “Overview” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about the procedure for installing iDefine, refer to:

iDefine Installation Guide (PR03076-MAN-991_01)

For more information about how to configure the security settings on the computer on which iDefine is to be installed, refer to:

iDefine Security Manual (PR03076-MAN-981_01)

Structure of This Document

This document consists of the following parts:

- Part A Overview

  This part describes how to read this document, various types of ProSafe-RS setup tasks along with their workflows are explained.

- Part B New Setup

  This part explains the procedures for setting up each station.

- Part C Maintenance

  This part describes maintenance tasks that are required after the stations have been set up and went into operation.

- Part D Connection with Other Products

  This part describes the required settings when connecting ProSafe-RS with other YOKOGAWA products, such as CENTUM VP, PRM, and Exaquantum.

A2. Overview of Setup Tasks

This section describes the workflows of setup tasks and provides the information you should understand before you set up individual stations.

SEE ALSO For more information about the operating environment of ProSafe-RS, refer to:

A1., “Requirements” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

A2.1 Before You Set Up

This section describes the relationship between installation and licensing of ProSafe-RS software.

Installation and Licensing of Software Packages

In order to use ProSafe-RS software packages, it is necessary to install the ProSafe-RS software on a computer and then grant licenses to the computer to enable the use of the software packages.

The tasks of installing the software packages on each computer are performed using a program called an installer. The tasks of giving licenses are executed using software called License Manager. License Manager is automatically installed when the ProSafe-RS software is installed on a computer.

Among computers installed with License Manager, the computer that is given the role of managing licenses of each computer in the system is called the license management station. The license management station distributes licenses to each computer on which the software packages are installed. On a computer to which licenses have been distributed, the software packages can be made available for use by accepting the distributed licenses.

TIP

- It is possible to install only License Manager on a computer and use it as the computer dedicated to license management.
- License management for iDefine is based on a hardware key. It is not controlled by License Manager.

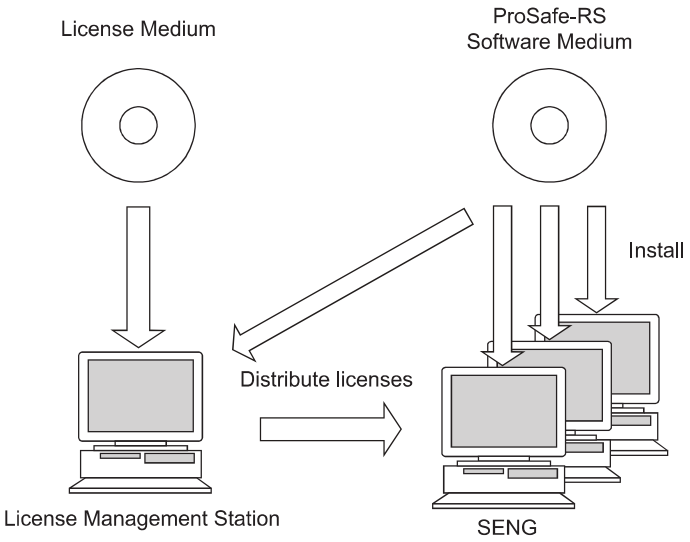

Figure A2.1-1 License Distribution

SEE ALSO

For more information about the details of licenses, refer to:

1., “Overview of license management” in License Management Guide (IM 32P01C60-01EN)

For more information about license management for iDefine, refer to:

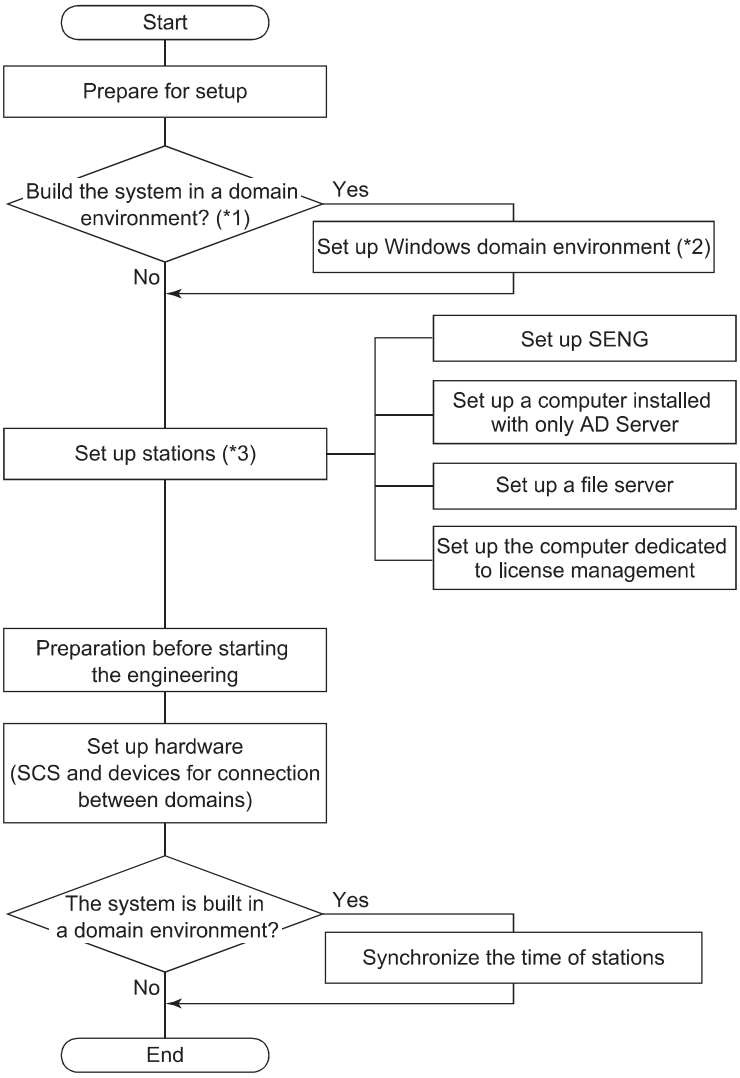
License User Guide (PR03076-MAN-971_02)

A2.2 Procedures for New Setup

This section describes the overall procedures for setting up a ProSafe-RS system and for setting up each type of station or computer using flowcharts. As ProSafe-RS system setup procedures, it also describes the procedure for setting up a ProSafe-RS system that runs on a virtual machine on the virtualization platform.

The procedures for the following types of stations and computers are described.

- Safety engineering PC (SENG)
- Computer installed with only Automation Design Server (AD Server)
- File server
- Computer dedicated to license management



A computer installed with only AD Server, file server, and computer dedicated to license management should be provided in the system as necessary.

SEE ALSO For more information about the virtualization platform, refer to:

A., “Overview” in Virtualization Platform Setup (IM 30A05B20-01EN)

A2.2.1 Setup Procedure for a ProSafe-RS System

The following figure shows the overall procedure for setting up a ProSafe-RS system.

*1: You may set up the domain environment at a later stage.
*2: If linked domain management is selected for the user management type of IT security settings, do not add the client computer to the domain before you set up the station.
*3: Start by setting up the station that is to be used as the license management station.

Figure A2.2.1-1 Setup Procedure for a ProSafe-RS System

You can jump to the explanation of each task that appears in the flowchart from the reference link that is provided in the following subsections.

Prepare for Setup

Determine the required items such as station number for setting up a ProSafe-RS system.

SEE ALSO For more information about the items that must be determined before setting up a ProSafe-RS system, refer to:

B1., “Preparing for the Setup” on page B1-1

Set Up the Windows Domain Environment

When using ProSafe-RS in a Windows domain environment, set up the Windows domain environment. You may also set up the Windows domain environment at a later stage.

SEE ALSO For more information about setting up a Windows domain environment, refer to:

B2., “Setting Up the Windows Domain Environment” on page B2-1

Set Up Each Station

Set up SENG, file server, and other stations to be used in the ProSafe-RS system.

In a ProSafe-RS system, you must first set up the license management station, which is used to grant licenses for software packages. The license management station can be set up on an SENG or a computer dedicated to license management.

Software packages installed on other stations become available for use once the stations accept the licenses distributed from the license management station.

SEE ALSO For more information about the procedure for setting up an SENG, refer to:

A2.2.3, “Setup Procedure for SENG” on page A2-10

For more information about the procedure for setting up a computer installed with only AD Server, refer to:

A2.2.4, “Setup Procedure for a Computer Installed with Only AD Server” on page A2-13

For more information about the procedure for setting up a file server, refer to:

A2.2.5, “Setup Procedure for a File Server” on page A2-14

For more information about the procedure for setting up a computer dedicated to license management, refer to:

A2.2.6, “Setup Procedure for a Computer Dedicated to License Management” on page A2-15

Preparation for starting engineering

The following tasks are required as the preparation for starting engineering.

- Creating an Automation Design project (AD project)
- Creating an RS project
- Registering the RS project in the AD project

SEE ALSO For more information about preparation for starting engineering, refer to:

C1., “AD Server administration functions” in Engineer's Reference Manual (IM 32P04B10-01EN)

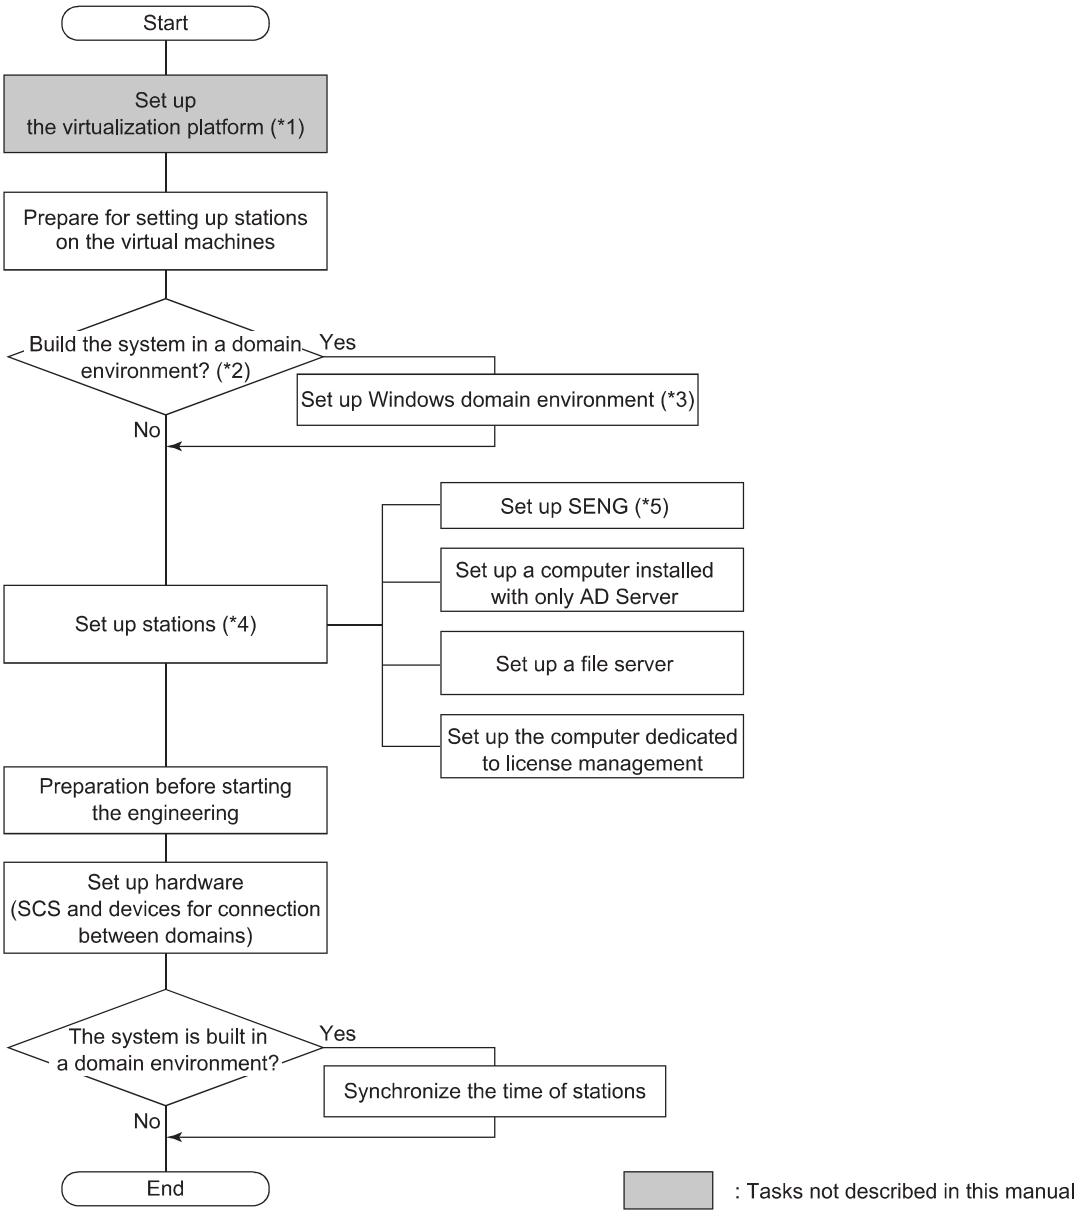
Set Up the Hardware of SCS and Devices Used for Connection between Domains

Set up the hardware of SCS and devices used for connection between domains.

SEE ALSO For more information about setting up the hardware of SCS and devices for connection between domains, refer to:

B7., “Configuring the Hardware of SCS and Devices for Connection between Domains” on page B7-1

Set Up Time Synchronization in Windows Domain Environment



When using ProSafe-RS in a Windows domain environment, synchronize the time on the domain controller with the time on computers used in the ProSafe-RS system.

SEE ALSO For more information about setting up time synchronization in a Windows domain environment, refer to:

B2.7, “Setting Up Time Synchronization in Windows Domain Environment” on page B2-20

A2.2.2 Setup Procedure for ProSafe-RS Running on a Virtual Machine on the Virtualization Platform

The following figure shows the overall procedure for setting up a ProSafe-RS system running on a virtual machine on the virtualization platform.

*1: Prepare a computer for virtualization host, and install the virtualization platform.
*2: You may set up the domain environment at a later stage.
*3: If linked domain management is selected for the user management type of IT security settings, do not add the client computer to the domain before you set up the station.
*4: Start by setting up the station that is to be used as the license management station.
*5: You do not need to set up a Vnet/IP interface card. Install the Vnet/IP Interface Package.

Figure A2.2.2-1 Setup Procedure for a ProSafe-RS System Running on the Virtualization Platform

You can jump to the explanation of each task that appears in the flowchart from the reference link that is provided in the following subsections.

Setup for a Virtualization Platform

Before setting up ProSafe-RS, prepare the virtualization host computer and set up the virtualization platform.

SEE ALSO For more information about the setup procedure for a virtualization platform, refer to:

B., “Working with virtualization host computer” in Virtualization Platform Setup (IM 30A05B20-01EN)

Preparing to Set Up Stations that Run on Virtual Machines

Decide on the required information, such as station numbers, for setting up a ProSafe-RS system.

When installing software on a virtual machine, you must create an ISO format file of the contents of the software medium to be installed and mount it.

SEE ALSO For more information about the items that must be determined before setting up a ProSafe-RS system, refer to:

B1., “Preparing for the Setup” on page B1-1

For more information about the procedure and precautions when setting up ProSafe-RS that runs on the virtualization platform, refer to:

B1.3, “Precautions for Setting Up ProSafe-RS on a Virtual Machine on the Virtualization Platform” on page B1-8

Set Up the Windows Domain Environment

You can use a computer in the existing physical environment as the domain controller, or you can build the domain controller on the virtual machine.

You may also set up the Windows domain environment at a later stage.

SEE ALSO For more information about the procedure for setting up a domain controller on a physical computer, refer to:

B2., “Setting Up the Windows Domain Environment” on page B2-1

For more information about the domain controller on the virtualization platform, refer to:

- “■ Domain controller” in A1.3, “Other devices” in Virtualization Platform Setup (IM 30A05B20-01EN)
- “■ Domain controller” in A3.3, “Other devices” in Virtualization Platform Setup (IM 30A05B20-01EN)

Set Up Each Station

Set up SENG, file server, and other stations to be used in the ProSafe-RS system.

In a ProSafe-RS system, you must first set up the license management station, which is used to grant licenses for software packages. The license management station can be set up on an SENG or a computer dedicated to license management.

Software packages installed on other stations become available for use once the stations accept the licenses distributed from the license management station.

You can use a computer in the existing physical environment as the license management station, or you can build the license management station on the virtual machine.

SEE ALSO For more information about the procedure for setting up an SENG, refer to:

A2.2.3, “Setup Procedure for SENG” on page A2-10

For more information about the procedure for setting up a computer installed with only AD Server, refer to:

A2.2.4, “Setup Procedure for a Computer Installed with Only AD Server” on page A2-13

For more information about the procedure for setting up a file server, refer to:

A2.2.5, “Setup Procedure for a File Server” on page A2-14

For more information about the procedure for setting up a computer dedicated to license management, refer to:

A2.2.6, “Setup Procedure for a Computer Dedicated to License Management” on page A2-15

Preparation for Starting Engineering

The following tasks are required as the preparation for starting engineering.

- Creating an Automation Design project (AD project)
- Creating an RS project
- Registering the RS project in the AD project

SEE ALSO For more information about preparation for starting engineering, refer to:

C1., “AD Server administration functions” in Engineer's Reference Manual (IM 32P04B10-01EN)

Set Up the Hardware of SCS and Devices Used for Connection between Domains

Set up the hardware of SCS and devices used for connection between domains.

SEE ALSO For more information about setting up the hardware of SCS and devices for connection between domains, refer to:

B7., “Configuring the Hardware of SCS and Devices for Connection between Domains” on page B7-1

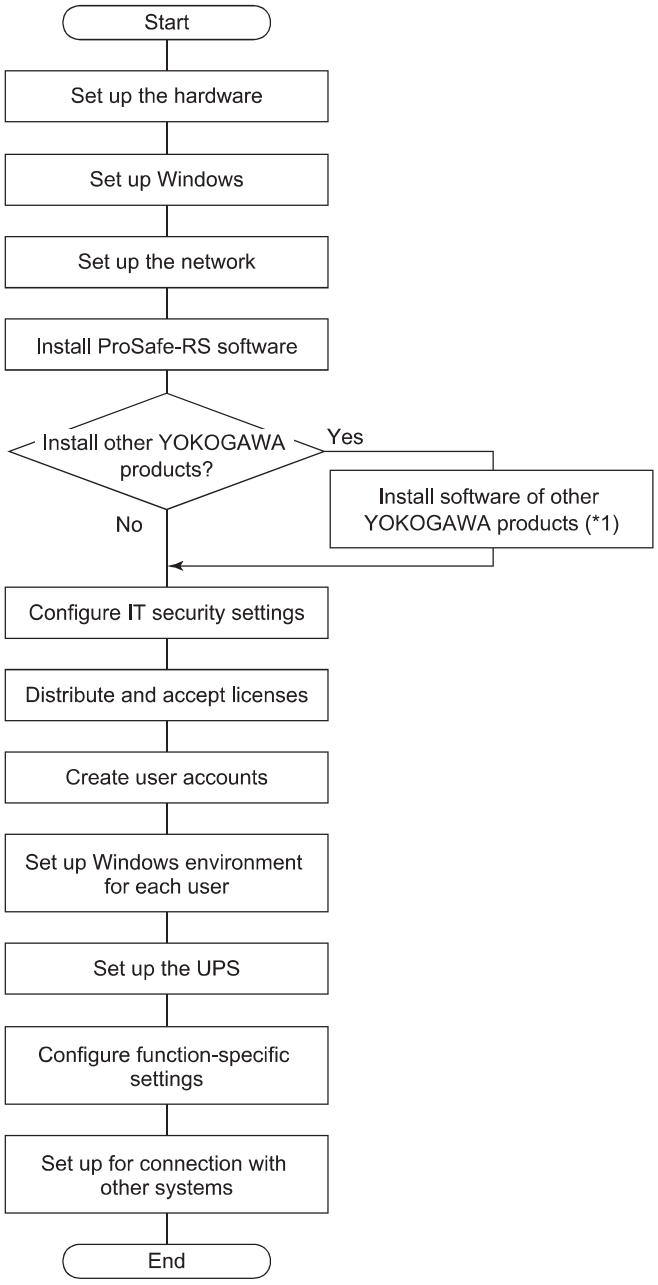
Set Up Time Synchronization in a Windows Domain Environment

When using ProSafe-RS in a Windows domain environment, synchronize the time on the domain controller with the time on computers used in the ProSafe-RS system.

On the virtualization platform, you must synchronize the time of the entire virtualization platform using the SNTP server.

Do not use the host OS or virtual machine of the virtualization host computer as the top level SNTP server for time synchronization. Also, do not use the domain controller as the SNTP server.

SEE ALSO For more information about setting up time synchronization in a Windows domain environment, refer to:



B2.7, “Setting Up Time Synchronization in Windows Domain Environment” on page B2-20

For more information about the virtualization platform time synchronization, refer to:

“■ SNTP server” in A1.3, “Other devices” in Virtualization Platform Setup (IM 30A05B20-01EN)

A2.2.3 Setup Procedure for SENG

The following figure shows the setup procedure for SENG.

*1: You may install other products later. If you install later, you need to configure IT security settings again.

Figure A2.2.3-1 Setup Procedure for SENG

You can jump to the explanation of each task that appears in the flowchart from the reference link that is provided in the following subsections.

Set Up the Hardware

Set up the Vnet/IP interface card to be installed in the SENG.

In the case of SENG that runs on a virtual machine, there is no interface card setting because it does not use the Vnet/IP interface card.

SEE ALSO For more information about setting up the hardware of SENG, refer to:

B3.1, “Setting Up the Hardware” on page B3-2

Set Up Windows

Configure Windows settings on the computer.

SEE ALSO For more information about setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

Set Up the Network

Configure the network settings.

In the case of SENG that runs on a virtual machine, after installing the Vnet/IP Interface Package, you need to configure the network settings.

SEE ALSO For more information about configuring network settings, refer to:

B3.3, “Configuring Network Settings” on page B3-18

Install the ProSafe-RS Software

Install the ProSafe-RS software.

SEE ALSO For more information about installing the ProSafe-RS software, refer to:

B3.5, “Installing the ProSafe-RS Software” on page B3-39

Configure IT Security Settings

Configure IT security settings.

SEE ALSO For more information about configuring IT security settings, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

Distribute and Accept Licenses

Distribute licenses to the SENG from the license management station, and accept the licenses on the SENG.

SEE ALSO For more information about distributing and accepting licenses, refer to:

B3.7, “Distributing and Accepting Licenses” on page B3-55

Create User Accounts

Create user accounts.

SEE ALSO For more information about creating user accounts, refer to:

B3.8, “Creating User Accounts” on page B3-56

Configure Windows Environment Settings for Each User

Configure Windows environment settings for each user.

SEE ALSO For more information about configuring Windows environment settings for each user, refer to:

B3.9, “Configuring Windows Environment Settings for Each User” on page B3-59

Set Up the Uninterruptible Power Source (UPS) Service

If necessary, set up the uninterruptible power source (UPS) service.

SEE ALSO For more information about configuring the UPS service, refer to:

B3.10, “Configuring the Uninterruptible Power Supply (UPS) Service” on page B3-65

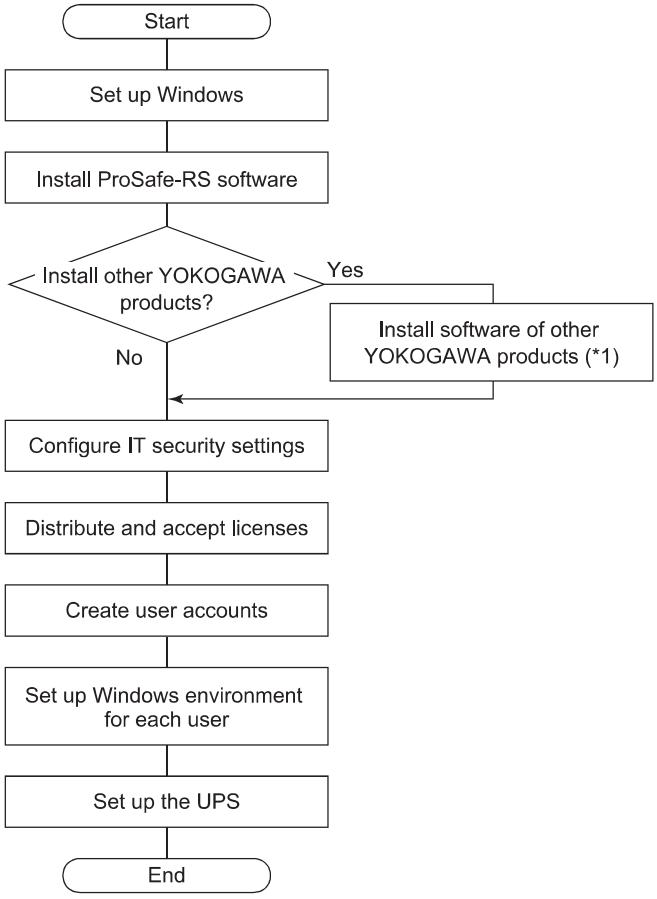
Configure Function-Specific Settings

Configure the settings specific to certain functions of the SENG.

SEE ALSO For more information about configuring the settings specific to each function of SENG, refer to:

B4., “Configuring the Functions Specific to SENG” on page B4-1

Set Up for Connection with Other Systems



As necessary, set up for connection with other YOKOGAWA products.

SEE ALSO For more information about the settings required to connect with other YOKOGAWA products, refer to:

D1., “Connecting YOKOGAWA products” on page D1-1

A2.2.4 Setup Procedure for a Computer Installed with Only AD Server

The following figure shows the setup procedure for a computer installed with only AD server.

*1: You may install other products later. If you install later, you need to configure IT security settings again.

Figure A2.2.4-1 Setup Procedure for a Computer Installed with Only AD Server

SEE ALSO

For more information about setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

For more information about installing the ProSafe-RS software, refer to:

B3.5, “Installing the ProSafe-RS Software” on page B3-39

For more information about configuring IT security settings, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

For more information about distributing and accepting licenses, refer to:

B3.7, “Distributing and Accepting Licenses” on page B3-55

For more information about creating user accounts, refer to:

B3.8, “Creating User Accounts” on page B3-56

For more information about configuring Windows environment settings for each user, refer to:

B3.9, “Configuring Windows Environment Settings for Each User” on page B3-59

For more information about configuring the UPS service, refer to:

B3.10, “Configuring the Uninterruptible Power Supply (UPS) Service” on page B3-65

A2.2.5 Setup Procedure for a File Server

You can provide a file server in the system if centralized management is required for project databases. The following figure shows the setup procedure for a file server.

TIP This flowchart illustrates the procedure for setting up a computer that serves only as a file server.

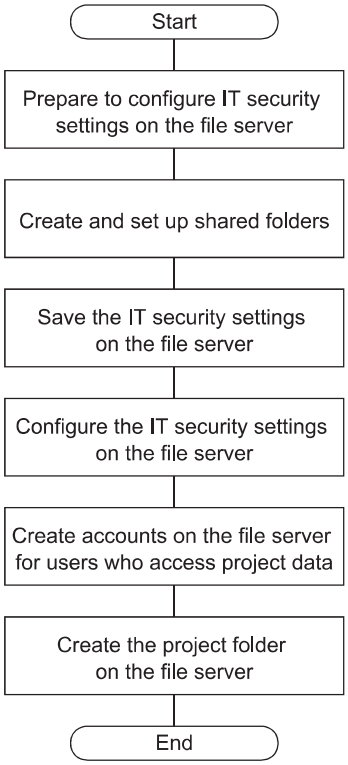


Figure A2.2.5-1 Setup Procedure for a File Server

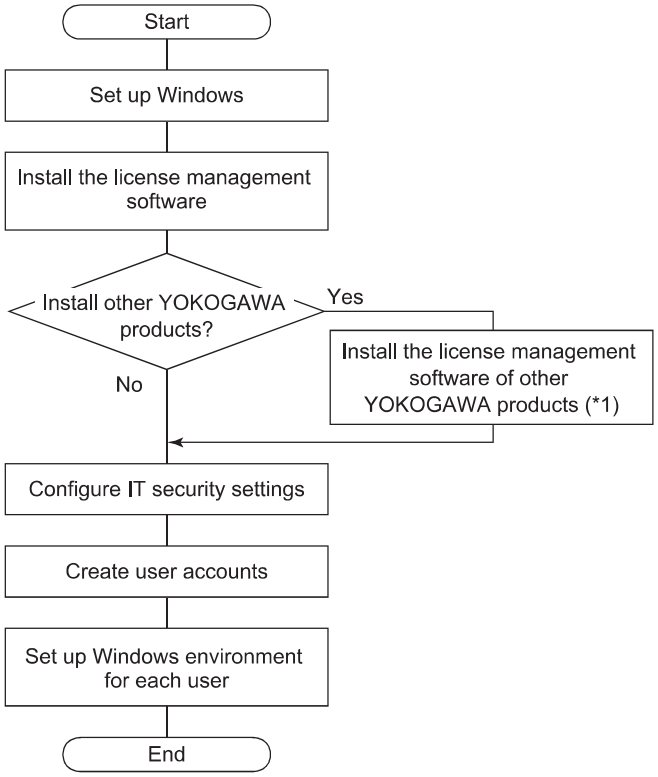
SEE ALSO For more information about setting up a computer that serves only as a file server, refer to:

B5.1, “Setting Up a Computer that Serves Only as a File Server” on page B5-2

For more information about the procedure to set up a computer as both a file server and a license management station, refer to:



B5.3, “Setting Up the Computer that Serves as Both File Server and License Management Station” on page B5-14

For more information about setting up the file server function on SENG, refer to:

B5.2, “Setting Up the File Server Function on an SENG or a Computer Installed with Only AD Server” on page B5-12

A2.2.6 Setup Procedure for a Computer Dedicated to License Management

You can provide a computer dedicated to license management according to the scale and operation policy of the system. The following figure shows the setup procedure for a computer dedicated to license management.

*1: You may install other products later. If you install later, you need to configure IT security settings again.

Figure A2.2.6-1 Setup Procedure for a Computer Dedicated to License Management

SEE ALSO For more information about setting up a computer dedicated to license management, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

A2.3 Explanation for Maintenance

When you perform the following maintenance tasks, refer to Part C.

- Add licenses and change license assignments
- Set up the domain environment later
- Back up the system
- Upgrade the ProSafe-RS software
- Find out cautionary notes for upgrading and compatibility with the previous revision
- Uninstall the ProSafe-RS software
- Reinstall the ProSafe-RS software
- Troubleshooting

B. New Setup

This section describes the procedure for setting up the devices such as the SENG, file server, computer dedicated to license management.

B1. Preparing for the Setup

This section explains the items that must be determined before you start setting up a station and precautions for the setup.

B1.1 Items to be Determined Before the Setup

This section lists the items that need to be determined before you start the setup tasks.

Domain Number/Station Number

A domain number is a number assigned to a group of stations connected on a control bus network. Set a domain number from 1 to 31 (1 to 16 when integrating with CENTUM).

A station number is a number assigned to each station. In each domain, station numbers should be set within a range from 1 to 64.

Computer Name/Station Name

A computer name is a name used to identify each computer on the Windows network. You can set the computer name from Windows Control Panel.

A station name is a unique name that is assigned based on the control bus address in the ProSafe-RS system.

Examples: HISddss (HIS/SENG)

STNddss (SENG)

(ddss: “dd” is the domain number and “ss” is the station number.)

It is recommended to match the computer name and the station name of a station.

IP Address

Determine the IP addresses of stations for control bus and Ethernet.

When using Vnet/IP without installing Ethernet, also determine the IP addresses for Vnet/IP open communication.

Subnet Mask

Determine the subnet masks of stations for control bus and Ethernet.

When using Vnet/IP without installing Ethernet, also determine the subnet masks for Vnet/IP open communication.

SEE ALSO For more information about IP addresses and subnet mask for control bus, refer to:

“● Setting IP Address for Vnet” on page B3-33

For more information about IP addresses and subnet mask for VnetIPOpen, refer to:

“● IP Address for VnetIPOpen” on page B3-33

For more information about IP addresses and subnet mask for Ethernet, refer to:

“● Setting IP Address for Ethernet” on page B3-33

Administrative User's Account and Password

Determine the name and password for the administrative user account of the computer.

If the system is used in a domain environment, determine the name and password for the administrative user of the domain.

Security Model and User Management Type

Determine the security model and user management type.

IMPORTANT

- Be sure to determine the policies for security settings of the entire system before you start the setup tasks because some of the setup procedures vary depending on the security model and user management type.
- If you select the Legacy model, restrictions related to Windows are in effect in some environments. For that reason, we recommend you select the Standard model.

SEE ALSO For more information about IT security, refer to:

1., “Overview” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

License Assignment

Determine the license assignments for the computers you are going to set up.

IMPORTANT

In a ProSafe-RS system, you need to decide on one computer to be used as the license management station. The license management station can be set up on a computer where SENG runs.

When setting up each station, you must set up the license management station first. Then, set up the computers that will be used as license-assigned stations. The software packages installed on each license-assigned station become available for use after you distribute the licenses from the license management station and accept them.

If an independent license management station is desired, you can also set it up as the computer dedicated to license management.

SEE ALSO For more information about licenses, refer to:

1., “Overview of license management” in License Management Guide (IM 32P01C60-01EN)

B1.2 Precautions for Setup

Take note of the following precautions before you start the setup.

In this manual, whenever Windows 10, Windows Server 2019, or Windows Server 2022 is mentioned in the explanations hereafter, the IoT versions are also included.

Changes in Windows Settings

Installing the ProSafe-RS software changes the following Windows settings.

Table B1.2-1 Changes in Windows Settings

Items	Setting	Purpose
Account name display in logon screen	Disable	To protect logon account names from unauthorized use.
Fast user switching	Disable	Simultaneous logon of multiple users is not supported.

When the System Contains Different Revisions

- The SENGs in the same RS project should have the software of the same release number.
- The SCS system program release number of SCSs in a system should basically be the same, but mixture of different release numbers is allowed. However, release numbers of SCSs communicating with each other by Inter-SCS safety communication must be in accordance with the explanation in this manual.

SEE ALSO For more information about compatibility in inter-SCS safety communication between different revisions, refer to:

- "● Important issues to consider" in "■ Precaution for engineering" in A7., "Inter-SCS safety communication" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)
- Appendix 6., "Compatibility between Revisions and Cautionary Notes for Upgrading" on page App.6-1
- Appendix 4.2, "Inter-SCS safety communication in a V net domain" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)
- C5., "Upgrading to R3.02.20" and Appendix 4., "Compatibility between Revisions and Cautionary Notes for Upgrading" in Installation for ProSafe-RS R3 (IM 32Q01C50-31E)

When a User Account Control Dialog Box Appears

During installation, a user account control dialog box may be displayed on certain circumstances.

If displayed, click [Yes] or [Continue] (for uninstallation, [Yes] or [Allow]) to continue.

Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2021)

Download and apply the following Windows update programs. If not applied, it may not be possible to connect to the shared folders of the computer from another computer by specifying the IP address.

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If not applied, the OPC clients may not be able to connect to the SOE OPC server.

- 2023-06 Cumulative Update for Windows 10 Version 21H2 for x64-based Systems (KB5027215)

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2019)

Download and apply the following Windows update programs. If not applied, access permissions for some ProSafe-RS installation folders may not be set properly, or it may not be possible to connect to the shared folders of the computer from another computer by specifying the IP address.

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If you do not apply these updates, the OPC clients may not be able to connect to the SOE OPC server.

- 2021-08 Servicing Stack Update for Windows 10 Version 1809 for x64-based Systems (KB5005112)
- 2023-05 Cumulative Update for Windows 10 Version 1809 for x64-based Systems (KB5026362)

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

Downloading the Windows Update Programs (Windows 10 Enterprise 2016 LTSB)

Download and apply the following Windows update programs.

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If you do not apply these updates, the OPC clients may not be able to connect to the SOE OPC server.

- 2023-03 Servicing Stack Update for Windows 10 Version 1607 for x64-based Systems (KB5023788)
- 2023-05 Cumulative Update for Windows 10 Version 1607 for x64-based Systems (KB5026363)

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

Downloading the Windows Update Programs (Windows Server 2022)

Download and apply the following Windows update programs. If not applied, it may not be possible to connect to the shared folders of the computer from another computer by specifying the IP address.

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If not applied, the OPC clients may not be able to connect to the SOE OPC server.

- 2023-06 Cumulative Update for Microsoft server operating system Version 21H2 for x64-based Systems (KB5027225)

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

Downloading the Windows Update Programs (Windows Server 2019)

Download and apply the following Windows update programs. If not applied, access permissions for some ProSafe-RS installation folders may not be set properly, or it may not be possible to connect to the shared folders of the computer from another computer by specifying the IP address.

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If you do not apply these updates, the OPC clients may not be able to connect to the SOE OPC server.

- 2021-08 Servicing Stack Update for Windows Server 2019 for x64-based Systems (KB5005112)
- 2023-05 Cumulative Update for Windows Server 2019 for x64-based Systems (KB5026362)

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

IMPORTANT

For Windows update programs, be sure to apply the servicing stack update before applying the cumulative update.

Downloading the Windows Update Programs (Windows Server 2016)

Download and apply the following Windows update program. If you do not apply this update, installation of Windows update programs fails on the virtualization platform.

- 2023-03 Servicing Stack Update for Windows Server 2016 for x64-based Systems (KB5023788)

In addition, download and apply the following Windows update program. If you do not apply this update, error log overflow occurs in system log collection in RIP Listener on the virtualization platform.

- 2023-05 Cumulative Update for Windows Server 2016 for x64-based Systems (KB5026363)

If you have applied the Windows update programs to the SOE OPC server computer, be sure to apply the Windows update programs to the OPC client computers as well. If you do not apply these updates, the OPC clients may not be able to connect to the SOE OPC server.

TIP

This information is current as of June 2023. The latest information is provided as Endpoint Security Service. For information about the Endpoint Security Service, contact YOKOGAWA.

When Connecting with Other Products

When connecting ProSafe-RS to other YOKOGAWA products, configuration of IT security settings or other tasks may be required.

SEE ALSO

For more information about the tasks when connecting CENTUM VP with other products, refer to:

D., “Connection with Other Products” on page D-1

Notes on Initial Data of IT Security Settings

On a file server or domain controller, it is necessary to save the state before applying IT security settings as initial data.

When changing the user management type or IT security setting items, use the saved initial data to restore the state before applying the IT security settings, and then apply the IT security settings again.

About a file server, when changing the security settings, the following saved data of IT security settings is required depending on the user management type.

- When the user management type is standalone management or linked domain management in Standard model:

  Data saved before the first application of IT security settings in the standalone state

- When the user management type is Domain management or Combination management in Standard model:

  Data saved before applying IT security settings after adding to the domain

SEE ALSO For more information about saving of IT security settings of the computer that serves only as a file server, refer to:

"■ Procedure 4: Save the Initial Data of the IT Security Settings" on page B5-5

For more information about the procedure for reapplying IT security, refer to:

6.5.2, "Procedure for a File Server or Domain Controller" in ProSafe-RS Security Guide (IM 32P01C70-01EN)

B1.3 Precautions for Setting Up ProSafe-RS on a Virtual Machine on the Virtualization Platform

The following are precautions on setting up ProSafe-RS on a virtual machine on the virtualization platform.

Creating and Mounting ISO Format Files

A virtual machine on the virtualization platform cannot access the optical drive on the virtualization host computer. When using DVD-ROM or other media, for setting up a virtual machine, you must convert the media to ISO format and save it in an accessible folder on the host OS.

Create an ISO Format File

On the host OS, save the contents of the software media to an ISO format file by using free software or other means.

Mounting an ISO Format File on a Virtual Machine

Follow these steps to mount an ISO format file on a virtual machine:

1. Sign in to the host OS of virtualization host computer as an administrative user.
2. Copy an ISO format file of the software to mount and paste it into a folder on the host OS.
3. Select [Start] > [Server Manager].
   Server Manager starts.
4. Select [Tools] > [Hyper-V Manager].
   Hyper-V Manager starts.
5. On the left pane, select the virtualization host computer.
   Virtual machines on the virtualization host computer are displayed on the middle pane.
6. Right-click on the virtual machine that the ISO format file is mounted and select [Connect].
   The virtual machine connection window appears.

TIP The virtual machine connection window may appear full-screen. If it appears full-screen, click [Undo] to exit full-screen.

7. Select [Media] > [DVD Drive] > [Insert Disk].
   A file opening dialog box appears.
8. Select the ISO format file of the software to mount and click [Open].
   The selected ISO format file is mounted on the virtual machine.

Replacement in Descriptions when Installing on a Virtual Machine on the Virtualization Platform

When you install software on a virtual machine on the virtualization platform, replace “Insert the xxx software medium into the drive.” with “Specify the ISO format file of the xxx software.” as you read the descriptions of procedures.

B2. Setting Up the Windows Domain Environment

This section describes the required settings when ProSafe-RS is used in a Windows domain environment. You may also set up the Windows domain environment at a later stage.

SEE ALSO For more information about how to set up the Windows domain environment later, refer to:

C2., “Setting Up the Windows Domain Environment Later” on page C2-1

Consolidated Management of IT Security Settings Using the Domain Controller

ProSafe-RS allows for consolidated management of IT security settings using the domain controller.

To perform consolidated management of IT security settings, set IT securities on all clients first, and then use the domain controller to set consolidated management of IT security settings.

TIP You can build a domain controller with an OS supported by ProSafe-RS R4.07 or later, and join a computer on which R3.01 or later ProSafe-RS software installed to it. However, the Active Directory-based consolidated management of IT security settings can be applied to computers on which R4.03 or later ProSafe-RS software installed.

SEE ALSO For more information about the procedure for setting IT security on a client, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

For more information about setting up consolidated management of IT security settings, refer to:

6.10, “Active Directory-Based Consolidated Management of IT Security Settings” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

B2.1 Overview of Setting Up the Domain Environment

This section explains the overview of setting up the Windows domain environment.

It is recommended to provide dual-redundant domain controllers because the entire system will have troubles if the only domain controller fails.

Workflow

The following figure shows the procedure for setting up the Windows domain environment.

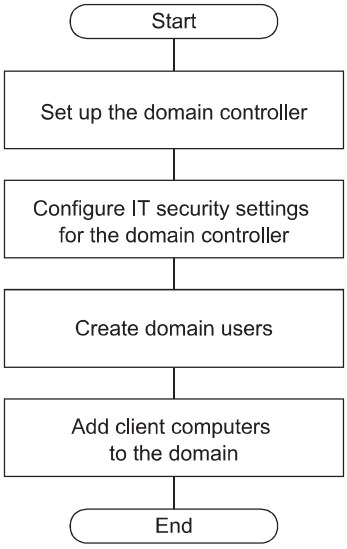


Figure B2.1-1 Flow of setting up the Windows domain environment

The timing for adding the client computer to the domain differs depending on whether the user management type of the IT security settings of the client computer is linked domain management or domain/combination management.

SEE ALSO For more information about the timing for adding client computers to the domain, refer to:

B2.5, “Adding Computers to the Domain” on page B2-17

Items to be Determined in Advance

- Domain name
- IP Address of the domain controller

Items to be Prepared

- Computer for the domain controller
- ProSafe-RS software medium
  This is required for configuration of IT security settings.

Items to be Set to the Domain Controller in Advance

- IP address
- Password for the Administrator account

Forest and Domain Function Level Settings

To configure the domain controller, the forest function level and domain function level must be set. The function level to be set varies depending on whether a new forest and domain will be configured or the domain controller will be added to an existing forest and domain.

Function Level to Be Set When Configuring a New Forest and Domain

Set the lowest function level that can be commonly set on all domain controller server OSs supported by ProSafe-RS.

If the following domain controller server OSs are supported by ProSafe-RS, for example, the lowest function level is Windows Server 2008:

- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

TIP

Set the lowest function level, considering the possibility that a server OS of low function level may be added as a domain controller.

Functional Level to Be Set When Adding a Domain Controller to an Existing Forest and Domain

In this case, the functional level of the existing forest and domain is set. Accordingly, which server OS can be used for the domain controller is limited by the functional level of the existing forest and domain.

The following table shows a list server OSs that can be selected for different functional levels of the existing forest and domain.

Table B2.1-1 Functional Levels of Existing Forest and Server OSs Selectable for ProSafe-RS

Functional level of existing forest	Server OSs Selectable for ProSafe-RS
Windows Server 2003	Windows Server 2016
Windows Server 2008	Windows Server 2016 Windows Server 2019 Windows Server 2022
Windows Server 2008 R2	Windows Server 2016 Windows Server 2019 Windows Server 2022
Windows Server 2012 R2	Windows Server 2016 Windows Server 2019 Windows Server 2022
Windows Server 2016	Windows Server 2016 Windows Server 2019 Windows Server 2022

Table B2.1-2 Functional Levels of Existing Domain and Server OSs Selectable for ProSafe-RS

Functional level of existing domain	Server OSs Selectable for ProSafe-RS
Windows Server 2003	Windows Server 2016
Windows Server 2008	Windows Server 2016 Windows Server 2019 Windows Server 2022

Continues on the next page

Table B2.1-2 Functional Levels of Existing Domain and Server OSs Selectable for ProSafe-RS (Table continued)

Functional level of existing domain	Server OSs Selectable for ProSafe-RS
Windows Server 2008 R2	Windows Server 2016 Windows Server 2019 Windows Server 2022
Windows Server 2012 R2	Windows Server 2016 Windows Server 2019 Windows Server 2022
Windows Server 2016	Windows Server 2016 Windows Server 2019 Windows Server 2022

For example, if the function level of the existing forest is Windows Server 2012 R2 and the function level of the domain is Windows Server 2016, the server OS versions selectable for ProSafe-RS are as follows.

- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

B2.2 Configuring the domain controller

Configure the domain controller using Windows Server 2016, Windows Server 2019, or Windows Server 2022.

SEE ALSO

For more information about how to configure the domain controller using Windows Server 2016, Windows Server 2019, or Windows Server 2022, refer to:

Windows-related manual or the web site of Microsoft Corporation

B2.3 Configuring Security Settings for the Domain Controller

In a system that uses the Standard model of security settings, you need to run the IT Security Tool on the domain controller as well to apply the Standard model of security settings.

TIP

If you do not run the IT Security Tool on the domain controller because of the security policy of the user environment, manually create a domain user group.

SEE ALSO

For more information about domain user groups required by ProSafe-RS, refer to:

- "● Type 3: Standard Model/Strengthened Model - Domain Management" in "■ Combination of User Management and Security Model for Windows" in 2.2.3, "User/Group Management" in ProSafe-RS Security Guide (IM 32P01C70-01EN)
- "● Type 4: Standard Model/Strengthened Model - Combination Management" in "■ Combination of User Management and Security Model for Windows" in 2.2.3, "User/Group Management" in ProSafe-RS Security Guide (IM 32P01C70-01EN)
- "● Type 5: Standard Model/Strengthened Model - Linked Domain Management" in "■ Combination of User Management and Security Model for Windows" in 2.2.3, "User/Group Management" in ProSafe-RS Security Guide (IM 32P01C70-01EN)

■ Installing Windows Update Programs

Download and apply the Windows update programs for your Windows OS.

SEE ALSO

For more information about downloading the Windows Server 2022 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2022)" on page B1-5

For more information about downloading the Windows Server 2019 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2019)" on page B1-6

For more information about downloading the Windows Server 2016 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2016)" on page B1-6

■ Disabling the Automatic Cleanup Task

When using Windows Server as a domain controller, disable Automatic cleanup task.

SEE ALSO

For more information about the procedure for disabling the Automatic cleanup task, refer to:

"■ Disabling the Automatic Cleanup Task" on page B3-15

■ Installation of Microsoft Visual C++ 2017 Redistributable Package

Before you can run the IT Security Tool, you must install the Microsoft Visual C++ 2017 redistributable package.

Follow these steps to install the Microsoft Visual C++ 2017 redistributable package:

1. Log on to the domain controller as an administrative user.
2. Insert the ProSafe-RS software medium into the drive.
3. Using Explorer, double-click `<DVD drive>:\ProSafe-RS\vcredist_x86_2017\VC_redist.x86.exe`.
4. Agree to the license terms and perform the installation.

Preparing for Running the IT Security Tool

1. Log on to the domain controller as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Active Directory Users and Computers].
   The Active Directory Users and Computers window appears.
4. In the left pane, right-click the [Users] folder and then select [New] > [Group].
   The New Object - Group dialog box appears.

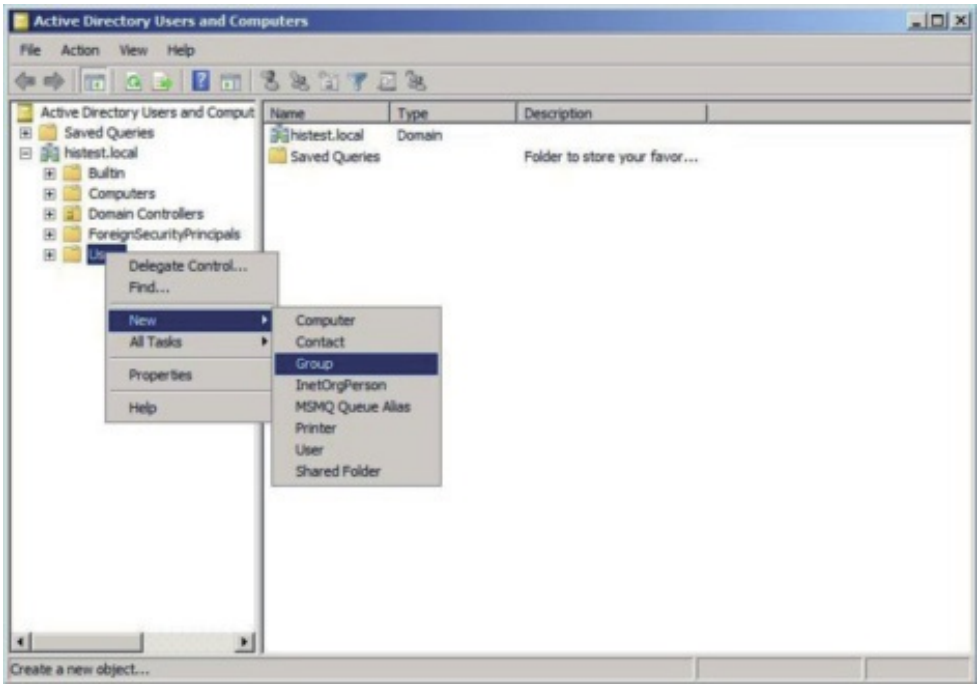

Figure B2.3-1 Active Directory Users and Computers

5. Enter `PSF_MAINTENANCE` in the Group name box, select the Group scope and Group type options, and then click [OK].

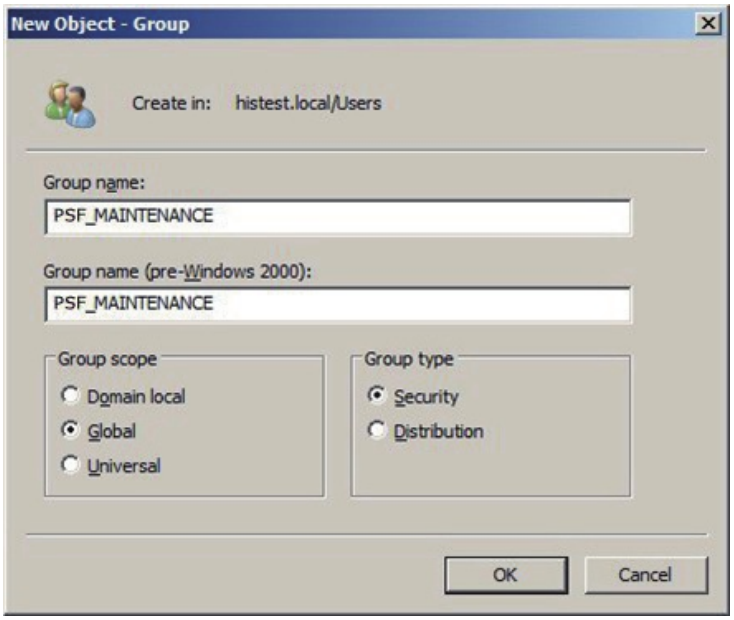

Figure B2.3-2 New Object - Group

6. Check the right pane to confirm that the PSF_MAINTENANCE group has been created in Users.

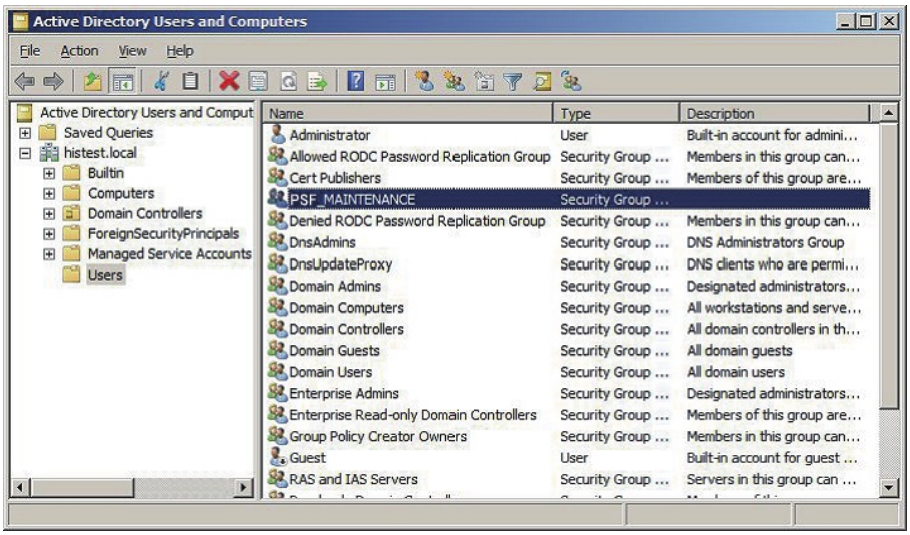

Figure B2.3-3 Activate Directory Users and Computers (after creating a new group)

7. Add the logged on user to the PSF_MAINTENANCE and Domain Admins groups.

TIP

If the domain controller is shared with CENTUM VP, the user must also belong to the CTM_MAINTENANCE group.

SEE ALSO

For more information about how to add uses to user groups, refer to:

"■ Adding Domain Users to Domain Groups" on page B2-14

Saving the Initial IT Security Settings

IMPORTANT

- When changing the IT security setting items, you need to use the initial data that was saved beforehand to restore the state before applying the IT security settings, and then apply the IT security settings again. Therefore, before you run the IT Security Tool to configure IT security settings for the first time after the Windows domain has been set up, be sure to save the security settings on the computer.
- When configuring the security settings for the second time onward, basically the security settings need not be saved. To configure the security settings by using the IT Security Tool of R3.01 to R4.02 and change the IT security version to 2.0 by using the IT Security Tool of R4.03 or later, save the initial security setting data again.
- To save the initial security setting data again, restore the security settings that were saved before by using the IT Security Tool. Then, perform this procedure to save the security settings. From then on, the data you have saved again will be used when the security settings are initialized; accordingly, keep the saved data in a safe place.

Follow these steps to save the security settings before your run the IT Security Tool:

1. Log on to the computer as the user who belongs to the Domain Admins and PSF_MAINTENANCE groups.
2. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the software medium.

   The installation menu appears.
3. Click [Setting IT Security (File server/domain controller use)].
   The IT Security Tool starts.

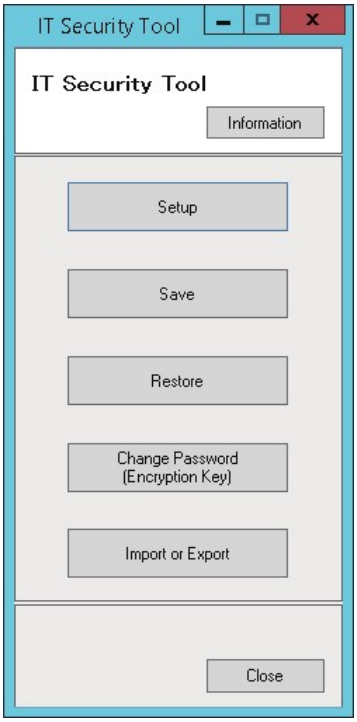

Figure B2.3-4 IT Security Tool menu

4. Click [Save].
   The Specify destination page appears.
5. Specify the destination folder and enter following setting items.
   - Distinguished Name
   - Support Product
   - Support OS
   - File Version

TIP

The [Distinguished Name] and [File Version] are omissible.

6. Click [Next].
   The Type default account password page appears.
7. Enter the password for use as the initial account password and click [Next].
   The Type password (Encryption Key) page appears.

TIP

This initial password will be set when the account saved with this tool is recovered. If the saved accounts are not found on the computer when you recover the accounts, new accounts are created. This password will be set as the initial password for the newly created account.

Even when multiple accounts have been created, the same initial password is assigned to all.

If the set password does not meet the password policy in the environment where the account is to be recovered, an error will occur when recovering an account.

This password is set as the initial password for the account. Accordingly, you will be prompted to change the password when you log on for the first time using this account.

8. Enter the password for encrypting the saved data, and click [Next].
   Saving of the security settings starts.

IMPORTANT

- If this password (encryption key) is lost, the saved security settings cannot be restored. The password (encryption key) must be carefully kept by the customer.
- The password (encryption key) must be at least one character.
- The password can consist of upper-case and lower-case alphanumeric characters and the following symbols: ` ~ ! @ # $ % ^ & * ( ) _ + - = { } | \ : " ; ' < > ? , . /
  Double-byte characters cannot be used.

9. When the saving is completed, click [Finish].
   If the saving failed, the details of the failure are displayed.
10. On the IT Security Tool menu, click [Close].

TIP If any save failures are displayed, contact YOKOGAWA Service.

Configuring IT Security Settings

1. From the IT Security Tool menu, click [Setup].
   A confirmation dialog box appears.
2. If you have saved the aforementioned security setting data for initialization, click [OK].
   The Select Security Model page appears.

TIP If you have not saved the initial security setting data, click [Cancel] to go back to the main menu and save the current security settings.

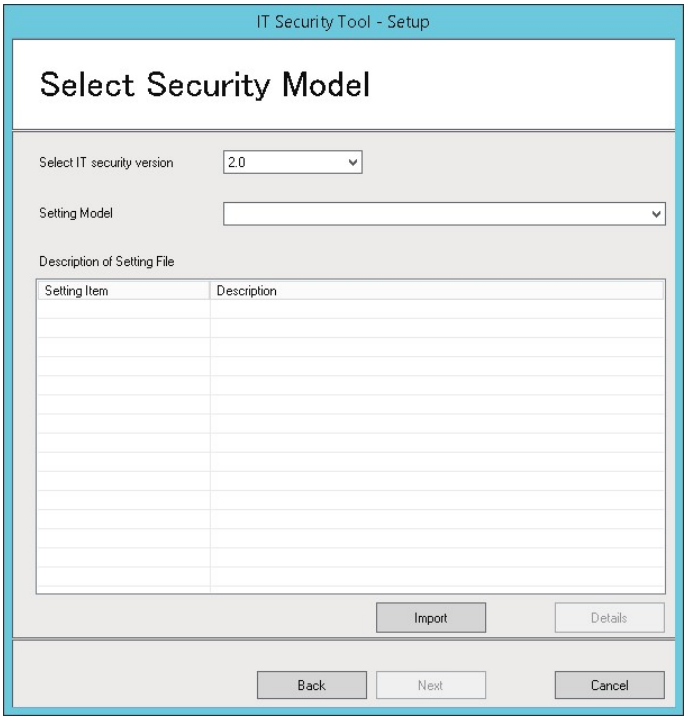

Figure B2.3-5 Select Security Model

3. From the Select IT security version drop-down list, select the IT security version.
4. From the Setting Model drop-down list, select [Domain Controller Standard Model Domain/Combination Management].

5. Click [Next].
   The Confirm Setting Information page appears.

TIP

If you click [Details], the Select Setting Items page appears.

6. For the rest of steps, perform the same operations as when the IT Security Tool is run immediately after installing the ProSafe-RS software.

TIP

If the domain controller is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP R6.04 or later software medium and set IT security for CENTUM VP as well.

SEE ALSO

For more information about the IT security setting operations that are performed following the ProSafe-RS software installation, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about the procedure for importing the IT security settings, refer to:

6.8, “Exporting/Importing the IT Security Setting File” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

B2.4 Creating Domain Users

This section explains how to create domain users and add them to the domain groups.

IMPORTANT

When you change the rights of domain users, the changes may not be applied immediately. If this happens, log on and log off twice on each computer after you have changed users' rights.

Do the same thing when you have deleted rights from domain users.

Creating a Domain User

1. Open the Control Panel.
2. Select [System and Security] > [Administrative Tools] > [Active Directory Users and Computers].
   The Activate Directory Users and Computers window appears.
3. In the left pane, right-click the [Users] folder and then select [New] > [User].

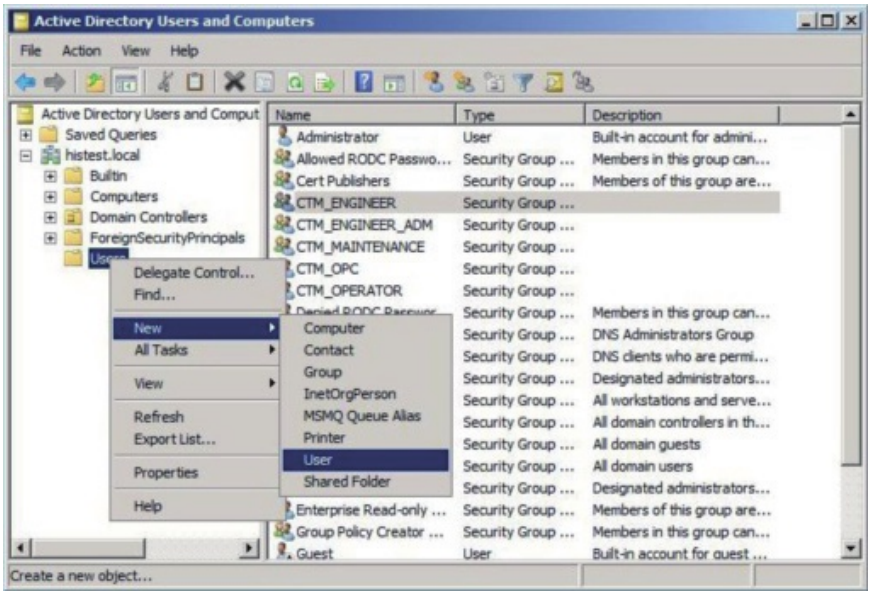

Figure B2.4-1 Activate Directory Users and Computers

4. The New Object-User dialog box is displayed. Input the necessary information.

TIP

Full name and User logon name have to be input in this dialog box. Additionally, if the User logon name is input, another logon name which is located under the above-mentioned User logon name is automatically input. However, the name is changeable.

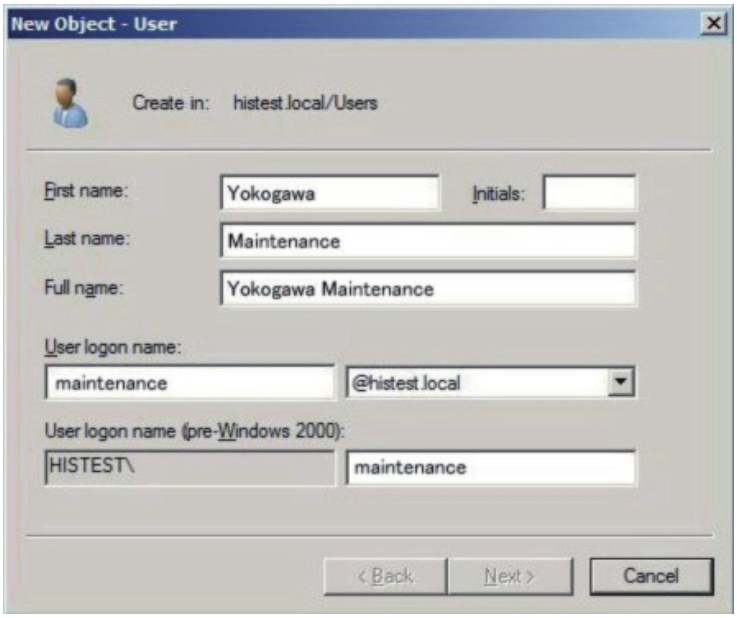

Figure B2.4-2 New Object-User

5. Click [Next].
   A dialog box appears, prompting you to enter the password.
6. Enter the password, select the check boxes of the required items, and click [Next].
   A confirmation dialog box appears.
7. Click [Finish].
8. Open the Users folder and check the right pane to confirm that the new domain user has been added.

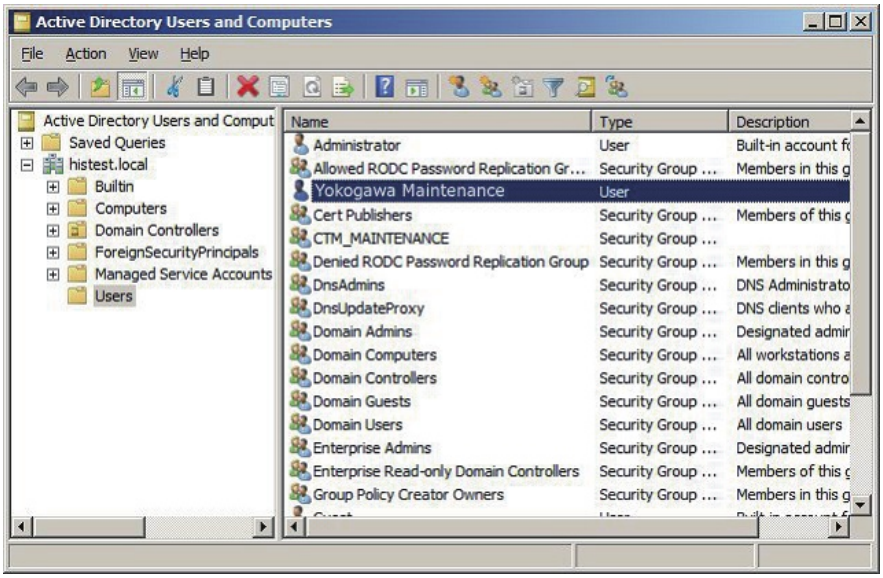

Figure B2.4-3 Activate Directory Users and Computers (confirmation of newly created user)

Adding Domain Users to Domain Groups

When applying the Standard model of security settings, you must add the domain users to appropriate domain groups.

After you run the IT Security Tool on the domain controller, the following ProSafe-RS domain groups have been created.

- PSF_OPERATOR
- PSF_ENGINEER
- PSF_OPC
- PSF_MAINTENANCE
- ADS_MANAGER

Adding a Domain User to a Domain Group

This section describes an example of adding a domain user (the user “yokogawa”) to the PSF_MAINTENANCE group.

TIP

For domain users who belong to a domain group which requires administrative rights, you also need to perform the procedure in the next section "●Setting Administrative Rights."

1. In the Active Directory Users and Computers window, double click the user that you want to grant the group's rights.
   The properties dialog box for the selected user appears.
2. Select the [Member Of] tab and click [Add].
   The Select Groups dialog box appears.
3. Click [Advanced].
   The advanced settings are displayed in the Select Groups dialog box.
4. Click [Find] to display the list of available groups. Select the PSF_MAINTENANCE group and click [OK].

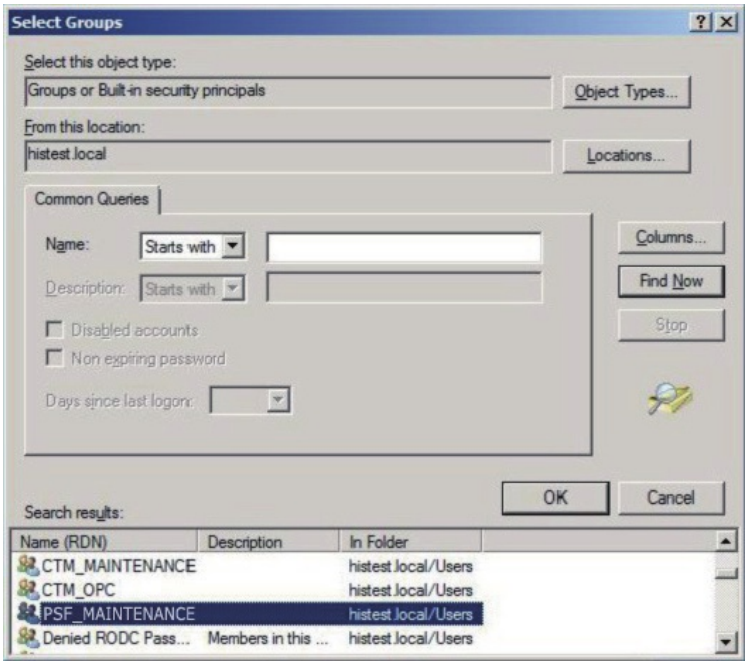

Figure B2.4-4 Select Groups dialog box - Search results

5. In the Select Groups dialog box, ensure that PSF_MAINTENANCE appears and click [OK].
6. In the Properties dialog box, confirm that PSF_MAINTENANCE is displayed in the Member of list.

Setting Administrative Rights

Follow these steps to assign administrative rights to a domain user who belongs to a domain group which requires administrative rights:

1. Add the domain user to the Domain Admins group.
2. Open the properties dialog box for the user. Click the [Member Of] tab, select [Domain Admins], and click [Set Primary Group].
   The primary group of the user changes to Domain Admins.
3. Select [Domain Users] and click [Remove].
4. Confirm that Domain User has been removed from the Member of list and click [OK].

B2.5 Adding Computers to the Domain

To add computers to a domain, computer accounts of the computers need to exist on the domain controller. Computer accounts can be created in two ways: creating on the domain controller or on computers.

When creating a computer account on the domain controller, the computer can be added to the domain by configuring on the computer after the computer account is created. When creating a computer account on the computer, the computer is added to the domain at the same time the computer account is created.

This section explains the procedure for the case where computer accounts are created on the domain controller and computer can be added to the domain by configuring on the computer. In the procedure, you are required to enter the user name and password of the administrative user of the domain when you configure on a computer.

Precautions When Setting Up Computers

This section describes precautions on operating the client computer with linked domain management for its user management type of the IT security settings.

- After you run IT Security Tool on the client computer, add the computer to the domain before you run Domain Link Management Tool.

The following are precautions on operating the client computer with domain or combination management for its user management type of the IT security settings.

- Before you install the ProSafe-RS software, add the client computer to the domain.
- If you are unable to add the computer to the domain in advance, set the Legacy model or the Standard model applying Standalone management temporarily in the IT security setting configuration that is performed following the ProSafe-RS software installation. Then, add the computer to the domain and change to the Standard model applying Domain management or Combination management.
- If a user who belongs to a domain group is used to install the ProSafe-RS software on a computer added to the domain, an administrative user for installing the ProSafe-RS software on the domain controller must be created in advance. Add the administrative user to the Domain Admins and PSF_MAINTENANCE user groups in advance.
- After installing the ProSafe-RS software, add the administrative user of the computer to the PSF_MAINTENANCE_LCL group.

SEE ALSO For more information about changing the security model, refer to:

6.4, “Changing the IT Security Settings” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Configuration on the Domain Controller

1. Open the Control Panel.
2. Select [System and Security] > [Administrative Tools] > [Active Directory Users and Computers].
   The Active Directory Users and Computers window is displayed.
3. Right-click the Computers folder, and select [New] > [Computers].
   The New Object - Computer dialog box appears.
4. Enter the [Computer Name], and click [OK].
5. Confirm that the new computer has been added in the Computers folder.
   Configuration on the domain controller is finished. Go on to the procedure for configuration on the computer.

Configuration on a Computer

Follow these steps to add a computer to the domain:

1. Open the Control Panel.
2. Select [System and Security] > [System].
   The System window appears.
3. Click [Change Settings].
   The System Properties dialog box appears.
4. Select the [Computer Name] tab and click [Change].
   The Computer Name/Domain Changes dialog box appears.
5. Select [Domain], enter the domain name, and click [OK].
   The Windows Security dialog box appears.
6. Enter the user name and password of the administrative user of the domain and click [OK].

TIP

An error message dialog box may appear, indicating that the domain name cannot be changed. However, you can click [OK] to proceed because the computer has been added to the domain successfully.

7. On the Computer Name/Domain Changes dialog box, click [OK].
8. On the dialog box for confirmation of restarting, click [Restart Now] to restart the computer.

B2.6 Setting Up Redundant Domain Controllers

It is recommended to provide another domain controller for redundancy because the entire system will have troubles if the only domain controller fails.

Setup Procedure

1. Add the second domain controller computer to the existing domain.
2. Configure IT security settings.

SEE ALSO For more information about IT security settings, refer to:

B2.3, “Configuring Security Settings for the Domain Controller” on page B2-6

B2.7 Setting Up Time Synchronization in Windows Domain Environment

When using ProSafe-RS in a Windows domain environment, the time on computers used in the ProSafe-RS system and the time on the domain controller must be synchronized.

Because the time synchronization service of a ProSafe-RS system uses the time on the control bus as the time master, the time of the domain controller should be synchronized to the time of client computers if the system is used in a domain environment.

This section describes how to set up time synchronization in a system that consists of only ProSafe-RS.

Cautionary Note on Time Synchronization

A computer installed with the ProSafe-RS software is automatically configured so as not to use the domain controller as the time master for time synchronization, even if the computer is added to the Windows domain.

B2.7.1 Implementing Time Synchronization in a System Consisting of Only ProSafe-RS

This section describes how to implement time synchronization in a system consisting of only ProSafe-RS for the following cases:

- V net — Not synchronize to the Coordinated Universal Time (UTC)
- Vnet/IP — Synchronize to the Coordinated Universal Time (UTC)
- Vnet/IP — Not synchronize to the Coordinated Universal Time (UTC)

For V net — Not Synchronize to the Coordinated Universal Time (UTC)

Configure a station connected to the V net domain as the SNTP server. Times on the computers within the V net domain are synchronized using the V net time synchronization function. Time synchronization of the entire system is achieved by synchronizing the time on the domain controller to the SNTP server.

TIP

When a station is used as the SNTP server, the system time is not synchronized to UTC but to the time on the hardware of the SNTP server.

- On the computers connected on V net, do not use the Windows W32Time service to perform time synchronization. If used, times on the computers are synchronized to the time on the domain controller and synchronization with the SNTP server is prevented.
- On the domain controller, use the Windows W32Time service to synchronize its time with the SNTP server.

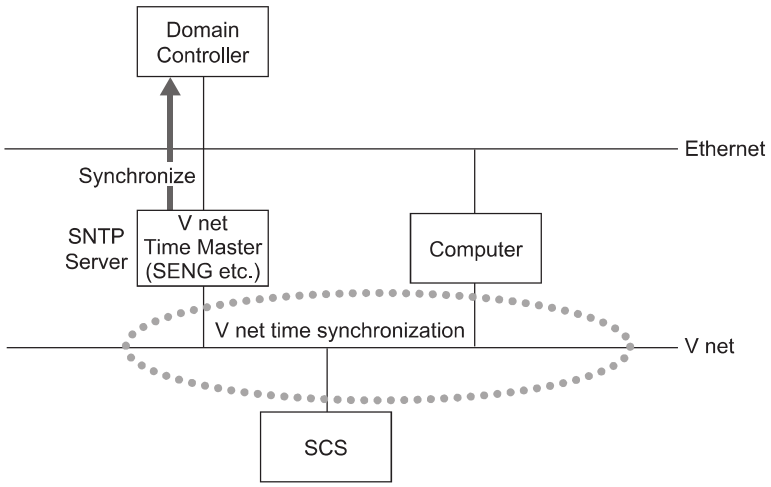

Figure B2.7.1-1 Implementing Time Synchronization (V net — Not Synchronize to UTC)

SEE ALSO

For more information about how to configure a station as the SNTP server, refer to:

"● Setting a Station as the SNTP Server" on page B2-23

For Vnet/IP — Synchronize to the Coordinated Universal Time (UTC)

- Introduce an SNTP server and make it synchronize with UTC. Configure the domain controller and the Vnet/IP system so that they will reference the time of the same SNTP server.

- On the computers connected on Vnet/IP, do not use the Windows W32Time service to perform time synchronization. If used, times on the computers are synchronized to the time on the domain controller and synchronization with the SNTP server is prevented.

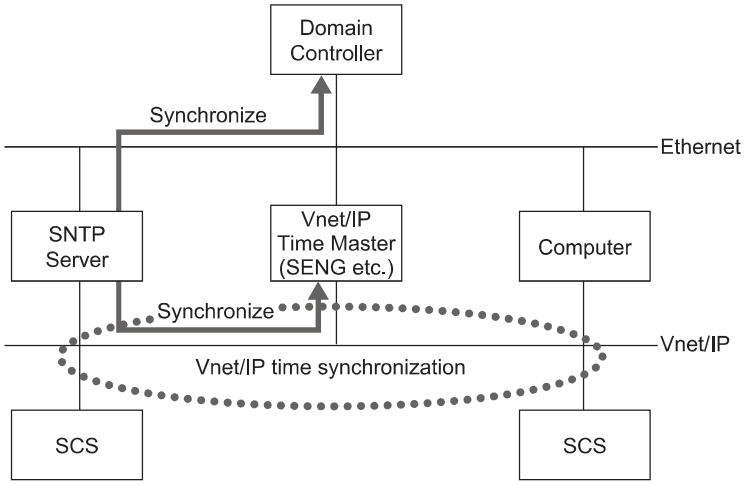

Figure B2.7.1-2 Implementing Time Synchronization (Vnet/IP — Synchronize to UTC)

For Vnet/IP — Not Synchronize to the Coordinated Universal Time (UTC)

Configure a station connected to the Vnet/IP domain as the SNTP server. Times on the computers within the Vnet/IP domain are synchronized using the Vnet/IP time synchronization function. Time synchronization of the entire system is achieved by synchronizing the time on the domain controller to the SNTP server.

TIP

When a station is used as the SNTP server, the system time is not synchronized to UTC but to the time on the hardware of the SNTP server.

- On the computers connected on Vnet/IP, do not use the Windows W32Time service to perform time synchronization. If used, times on the computers are synchronized to the time on the domain controller and synchronization with the SNTP server is prevented.
- On the domain controller, use the Windows W32Time service to synchronize its time with the SNTP server.

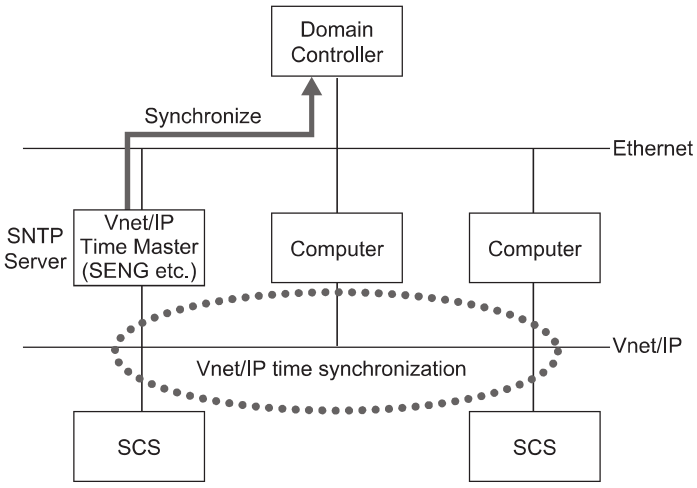

Figure B2.7.1-3 Implementing Time Synchronization (Vnet/IP — Not Synchronize to UTC)

Setting a Station as the SNTP Server

1. Use an administrative user account to log on to the station you want to set up as the SNTP server.
2. Right-click the following file and select [Run As Administrator].
   `(Drive of ProSafe-RS software medium):\ProSafe-RS\TOOLS\BeNtpServer.cmd`
   The Command Prompt window appears and displays "Enable NTP Server? (y/n/quit)."

TIP

If the IT security settings have been configured to apply software restriction policies, right-click [Command Prompt] and select [Run As Administrator]. Then, run the program in the Command Prompt that is opened.

3. Enter "`y`," and then press the [Enter] key.

B2.7.2 Implementing Time Synchronization When Integrated with CENTUM

When the system is integrated with CENTUM, set up time synchronization by following the explanation provided in the manual of CENTUM. If the system consists of multiple V net domains or a mixture of Vnet/IP domain and V net domain, also follow the explanation in the manual of CENTUM.

SEE ALSO

For more information about how to set up time synchronization in Windows domain environment for a system integrated with CENTUM, refer to:

B2.7, "Setting Up Time Synchronization in Windows Domain Environment" in CENTUM VP Installation (IM 33J01C10-01EN)

B3. Setup of an SENG or a Computer Installed with Only AD Server

This section describes the tasks required for setting up an SENG or a computer installed with only AD Server.

IMPORTANT

In a ProSafe-RS system, you need to decide on one computer for use as the license management station. The license management station can be set up on a computer where SENG runs.

Among stations of the system, you must set up the license management station first. Then, set up the computers that will be used as license-assigned stations. The software packages installed on the license-assigned stations become available for use after the licenses are distributed from the license management station and accepted on the license-assigned stations.

If an independent license management station is desired, you can also set it up as the computer dedicated to license management.

SEE ALSO For more information about how to set up the computer dedicated to license management, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

Items to be Prepared

Have the following item at hand before new installation of the ProSafe-RS software.

- ProSafe-RS software medium

Also have the following items at hand if the SENG is to be used as a license management station. These are required when distributing licenses.

- ProSafe-RS license medium
- ProSafe-RS license sheet (with project ID)

B3.1 Setting Up the Hardware

This section describes the settings for a Vnet/IP interface card to be installed in SENG. In the case of a computer installed with only AD Server and SENG that runs on a virtual machine, setting is not required because a Vnet/IP interface card is not used.

CAUTION

When removing and installing the cards to set DIP switches, take measure to prevent the damages caused by static electricity.

SEE ALSO For more information about antistatic measures, refer to:

Appendix 4., “Antistatic Precautions When Handling Hardware” on page App.4-1

Front panel of the Vnet/IP interface card

- RDY lamp
  This lamp illuminates to indicate that the card is working properly as the result of the periodic diagnosis.
- RCV lamp
  This lamp illuminates when a signal is received.
- SND lamp
  This lamp illuminates when a signal is sent.
- Vnet/IP connector
  These connectors are used for connecting with the Layer2 Switch.

  The connector type is RJ45.

The front panel of VI702 is shown as follows:

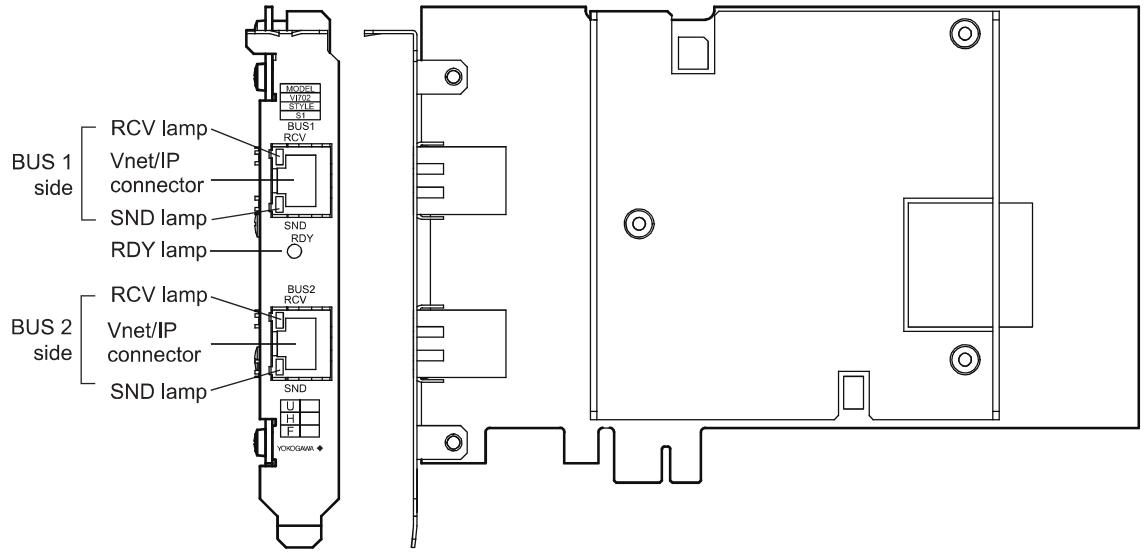

Figure B3.1-1 Vnet/IP Interface Card (VI702)

IMPORTANT

Note the following points when installing and uninstalling the VI702.

- Always install the VI702 before installing the control bus driver and Vnet/IP open communication driver.
  If the VI702 is installed after the control bus driver, the VI702 is not recognized. In this case, delete the driver, install the VI702, and then install the driver again.
- If the control bus driver and Vnet/IP driver are installed and you want to uninstall the VI702, delete these drivers first. If this procedure is not followed, an error dialog box will be displayed after restarting the PC and communication might not be possible.

Setting Up the Vnet/IP Interface Card

You need to install a Vnet/IP interface card (VI702) in the computer that is to be connected on a Vnet/IP network.

VI702 is for PCI Express.

The Vnet/IP interface card has DIP switches for setting the domain number, station number and action mode. The combination of domain number and station number determines the station address.

You must set the DIP switches before you configure network settings.

This section describes how to set the DIP switches.

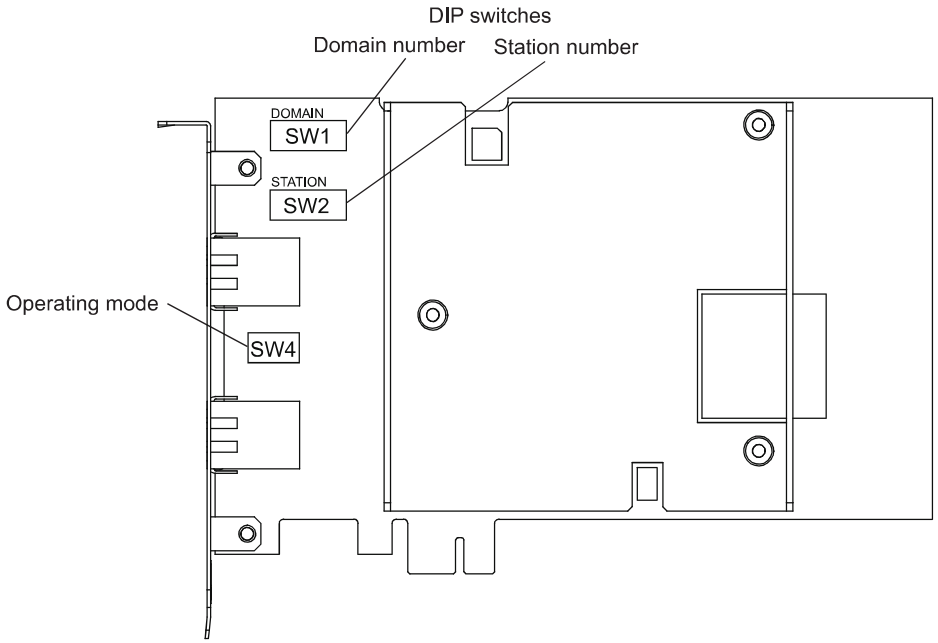

Figure B3.1-2 Locations of DIP Switches

Setting the Domain Number

A domain is a collection of stations that are connected on one control bus network. Set a domain number from 1 to 31 (1 to 16 when integrating with CENTUM).

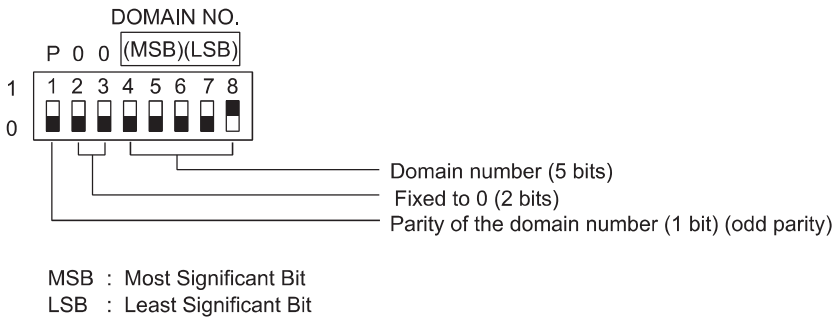

Figure B3.1-3 Domain Number Setting DIP Switches

SEE ALSO For more information about domain numbers and corresponding DIP switch positions, refer to:

"■ Domain Numbers and DIP Switch Positions" on page App.1-1

Setting the Station Number

Station numbers should be set in the range of 1 to 64; it is recommended to set starting from 64 in the descending order.

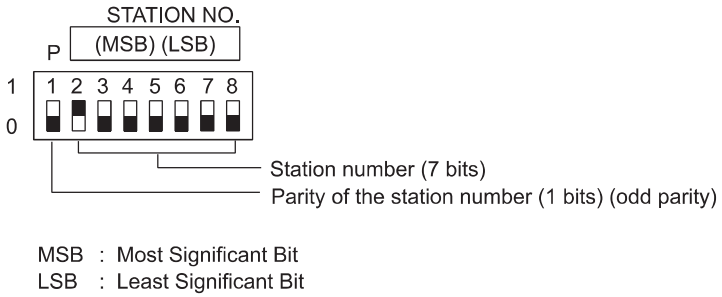

Figure B3.1-4 Station Number Setting DIP Switches

SEE ALSO For more information about station numbers and corresponding DIP switch positions, refer to:

"■ Station Numbers and DIP Switch Positions" on page App.1-2

Action Mode Switch

SW4 on the printed circuit board is the action mode switch.

Use the card with all the bits of this DIP switch set to OFF (factory set defaults). The meaning of DIP switch bits are as follows:

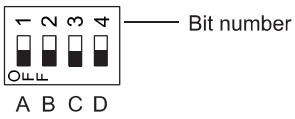

Figure B3.1-5 Action Mode Switch

Table B3.1-1 DIP Switch Usage

	DIP switch ON	DIP switch OFF	Remarks
A (bit 1)	-	Always OFF	Reserved
B (bit 2)	100 Mbps	1 Gbps	Communication speed (Default: OFF)
C (bit 3)	Force	Auto	Negotiation (Default: OFF)
D (bit 4)	-	Always OFF	Reserved

Precautions on Installing the Vnet/IP Interface Card

- Install VI702 in the computer after setting up Windows but before configuring the network settings.
- Install network drivers when you restart the computer after installing VI702. Follow the procedure in this manual to install the drivers.
- If you reuse VI702 that was used in another system for a stand-alone ProSafe-RS system, erase the settings in the VI702 before installing it in the computer. When using such VI702 in a system integrated with CENTUM, you do not need to erase the settings in the VI702.

SEE ALSO

For more information about the procedure to install the network driver in a computer, refer to:

- B3.3.1, “Installing the Control Bus Driver” on page B3-19
- B3.3.3, “Installing the Vnet/IP Open Communication Driver” on page B3-22

For more information about how to erase the internal settings of a VI702 card, refer to:

Appendix 2., “Procedure for Erasing VI702 Internal Settings” on page App.2-1

Installing the Vnet/IP Interface Card

After you have set the station address and action mode on the VI702 card, follow these steps to install it in the computer:

1. Turn off the power of the computer. For safety, remove the power plug from the outlet.
2. Remove the cover of the main unit of the computer.
3. Unscrew the screws fixing the slot cover and remove the slot cover.
4. Insert the VI702 card in the corresponding slot and fix it to the slot.
5. Mount the cover back on the computer.
6. Connect both the BUS1 and BUS2 cables to VI702 and Layer 2 switch. There is no need to turn off the power of the Layer 2 switch.
7. Connect the power cord of the computer back to the outlet and turn on the computer.
8. Make sure that the RDY lamp on VI702 is lit.
9. Write the station address on the label that comes with the VI702 card and paste it in the front or other easy-to-see location of the computer.

Attaching the Vnet/IP Station Address Label

You need to write the decided domain number and the station number to the station address seal attached to the VI702. And then stick the seal at the front side of the computer where the VI702 is installed or any other place that can be easily noticed.

STATION ADDRESS	
DOMAIN NO.	STATION NO.

Figure B3.1-6 Station Address Label

Procedures for removing the Vnet/IP interface card

IMPORTANT

Before removing the Vnet/IP interface card, uninstall the control bus driver and Vnet/IP open communication driver.

1. Turn off the power of the computer. For safety, remove the power plug from the outlet.
2. Disconnect the cables for both BUS1 and BUS2. There is no need to disconnect the cables from the Layer2 switch.
3. Remove the VI702 from the slot.

SEE ALSO For more information about the procedure for uninstalling the driver, refer to:

C5.1.2, “Uninstalling the Network Drivers” on page C5-5

B3.2 Setting Up Windows

Before installing the ProSafe-RS software, you need to change the Windows settings on your computer to the recommended settings.

This configuration is performed on the computer where the Windows OS has been installed.

Installing Windows Update Programs

Download and apply the Windows update programs for your Windows OS.

SEE ALSO

For more information about downloading the Windows 10 Enterprise LTSC 2021 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2021)" on page B1-4

For more information about downloading the Windows 10 Enterprise LTSC 2019 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2019)" on page B1-5

For more information about downloading the Windows 10 Enterprise 2016 LTSB update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise 2016 LTSB)" on page B1-5

For more information about downloading the Windows Server 2022 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2022)" on page B1-5

For more information about downloading the Windows Server 2019 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2019)" on page B1-6

For more information about downloading the Windows Server 2016 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2016)" on page B1-6

B3.2.1 Setting of Common Windows OS Items

This section describes how to set the items common to Windows 10, Windows Server 2016, Windows Server 2019, and Windows Server 2022.

File System

Ensure that the file system is in the NTFS format. If it is already formatted in the FAT format, reinstall the operating system and reformat partitions into NTFS. Partitions not installed with OS should also be formatted into NTFS.

System Performance

Follow these steps to configure the system performance setting:

1. Sign in as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [System] > [Advanced system settings].
   The System Properties dialog box appears.
4. Select the [Advanced] tab and click [Settings] in the Performance section.
   The Performance Options dialog box appears.
5. On the [Visual Effects] tab, select [Let Windows choose what's best for my computer].
6. Click [OK].

Virtual Memory

ProSafe-RS does not require virtual memory configuration. However, if the ProSafe-RS and CENTUM VP software coexist on the same computer, virtual memory should be configured according to the instruction of CENTUM VP.

Power Options

This section describes how to configure the Power Options settings. Some of the items in the explanation may not be displayed on your computer, depending on the computer's hardware configuration. If not displayed, the function of that item is not available on your computer.

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [Hardware and Sound] > [Power Options].
   The Power Options window appears.

TIP For Windows Server, select [Hardware] > [Power Options].

4. Select [High performance] under Preferred plans and click [Change plan settings] on the right side.
   The Edit Plan Settings window appears.

TIP If High performance does not appear under Preferred plan, click [Show additional plans]. Select [High performance] and then click [Change plan settings] on the right side.

5. Click [Change advanced power settings].
   The Power Options dialog box appears, showing the advanced settings.

TIP

Depending on the computer configuration, the items of unavailable functions will not be displayed in the step results hereafter.

6. In the Power Options dialog box, set as follows:
   Hard disk

   [Turn off hard disk after]: Never

   Sleep

   [Sleep after]: Never

   [Allow hybrid sleep]: Off

   [Hibernate after]: Never

   [Allow wake timers]: Disable

   Power buttons and lid

   [Power button action]: Shut down

   Display

   [Turn off display after]: Never
7. Click [OK].

TIP

Configure the UPS settings after installing the ProSafe-RS software.

SEE ALSO

For more information about setting up UPS services, refer to:

B3.10, “Configuring the Uninterruptible Power Supply (UPS) Service” on page B3-65

B3.2.2 Setting of Items Specific to Windows 10

This section describes how to set the items specific to Windows 10.

Turning Off Fast Startup

You must turn off fast startup before installing the control bus driver or Vnet/IP open communication driver.

Follow these steps to turn off fast startup:

1. Use Windows Explorer to open the WIN10 folder under the following path in the ProSafe-RS software medium.
   `(Drive of ProSafe-RS software medium):\ProSafe-RS\TOOLS\WIN10`
2. Right-click [HiberbootDisabled.bat], and select [Run as administrator] from the context menu.
   The Command Prompt appears.
3. Confirm that the value of [HiberbootEnabled] is 0 as shown in the following figure.

Figure B3.2.2-1 Command Prompt

4. Hit the [Enter] key to restart the computer.

Windows Defender

The Windows Defender software detects and removes spy ware.

It is recommended to turn off this function because it is not used with this product.

In a domain environment, turn off Windows Defender on domain member PCs at a time by means of a domain management operation such as Group Policies.

In a workgroup environment, turn off Windows Defender by using the Local Group Policy Editor.

Turning Off Windows Defender in Local Group Policy Editor

Follow these steps to turn off Windows Defender:

1. Sign in as an administrative user.
2. Open Command Prompt.
3. Enter `gpedit.msc`.
   Local Group Policy Editor appears.
   The rest of the operation differs depending on the OS version.

TIP

- If the OS version is 1607 or earlier, [Windows Defender] is displayed instead of [Microsoft Defender Antivirus].
- If the OS version is 1703 to 1909, [Windows Defender Antivirus] is displayed instead of [Microsoft Defender Antivirus].
- If the OS version is 2004 or later, [Microsoft Defender Antivirus] is displayed.

4. In the left pane, select [Computer Configuration] > [Administrative Templates] > [Windows Components] > [Microsoft Defender Antivirus].
5. In the right pane, double-click [Turn off Microsoft Defender Antivirus].
   The Turn off Microsoft Defender Antivirus dialog box appears.
6. Select [Enabled] and click [OK].

Defragment and Optimize Drives

The Defragmenter Tool can be used to reorganize the fragmented files on computer hard disk so as to improve the computer performance. Since the performance of this product may be affected when defragmenter is running, it is recommended to disable the schedule of the periodic disk defragmentation.

Moreover, you may manually start the disk defragmenter when you feel the disk performance is getting worse or when you perform system maintenance.

1. Sign in as an administrative user.
2. Open Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Defragment and Optimize Drives].
   The Optimize Drives window appears.
4. Click [Change settings].
   The Optimize Drives dialog box appears.
5. Clear the [Run on a schedule (recommended)] check box and click [OK].

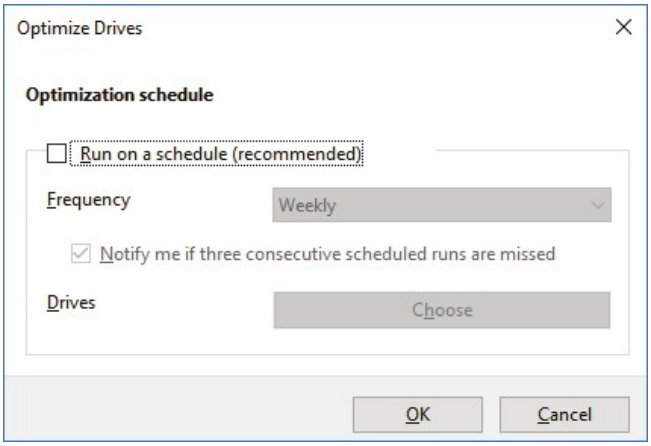

Figure B3.2.2-2 Optimize Drives dialog box

Disabling the Automatic Cleanup Task

A function is added to automatically clean up old files when update programs are applied.

Execution of Automatic cleanup may cause the degradation in system performance. For that reason, we recommend disabling Automatic cleanup for this product.

Follow these steps to disable the automatic cleanup task:

1. Sign in as an administrative user.
2. Open Control Panel.
3. From the menu, select [System and Security] > [Administrative Tools] > [Task Scheduler]. The Task Scheduler window appears.
4. In the left pane, select [Task Scheduler (Local)] > [Task Scheduler Library] > [Microsoft] > [Windows] > [Servicing].
5. In the middle pane, right-click [StartComponentCleanup] and select [Disable].
6. In the left pane, select [Task Scheduler (Local)] > [Task Scheduler Library] > [Microsoft] > [Windows] > [DiskCleanup].
7. In the middle pane, right-click [SilentCleanup] and select [Disable].

DCOM Settings

When Default Authentication Level in DCOM settings is set to [None], installation of applications such as redistributable modules fails. When installing this product, set the Default Authentication Level to [Connect].

Follow these steps to set Default Authentication Level to [Connect].

1. Sign in as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Component Services]. The Component Services window appears.

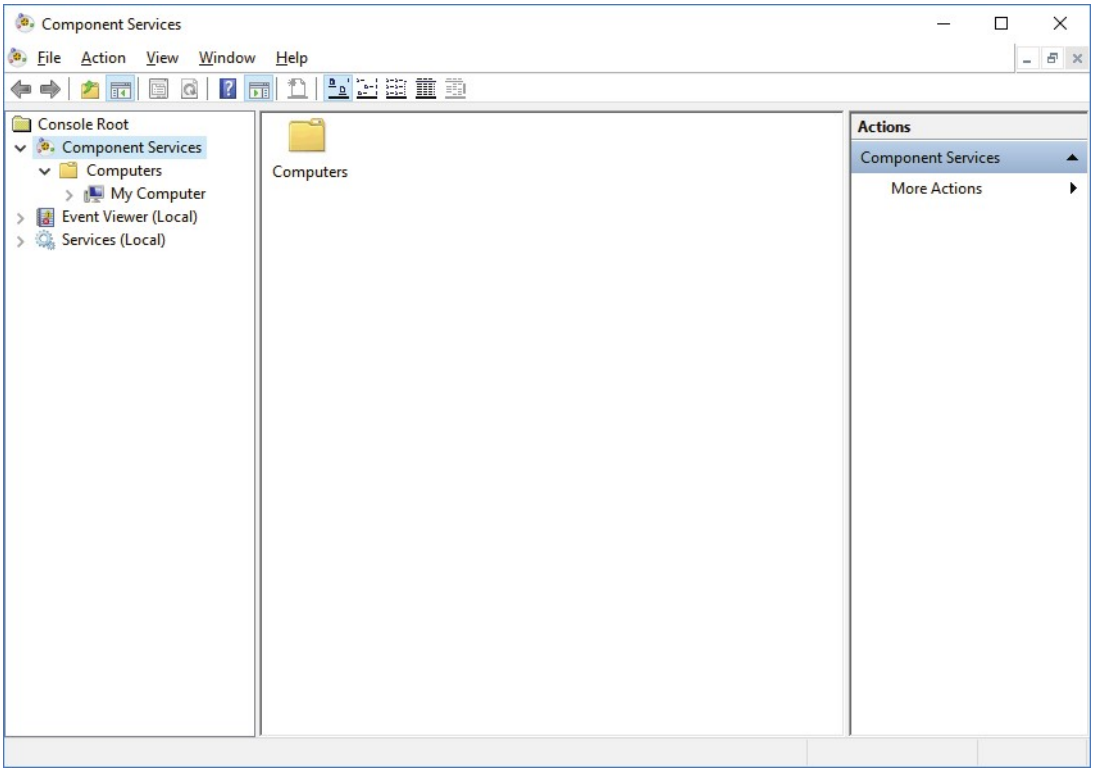

Figure B3.2.2-3 Component Services window

4. Select [Console Root] > [Component Services] > [Computers].
5. Right-click [My Computer] and select [Properties]. The My Computer Properties dialog box appears.

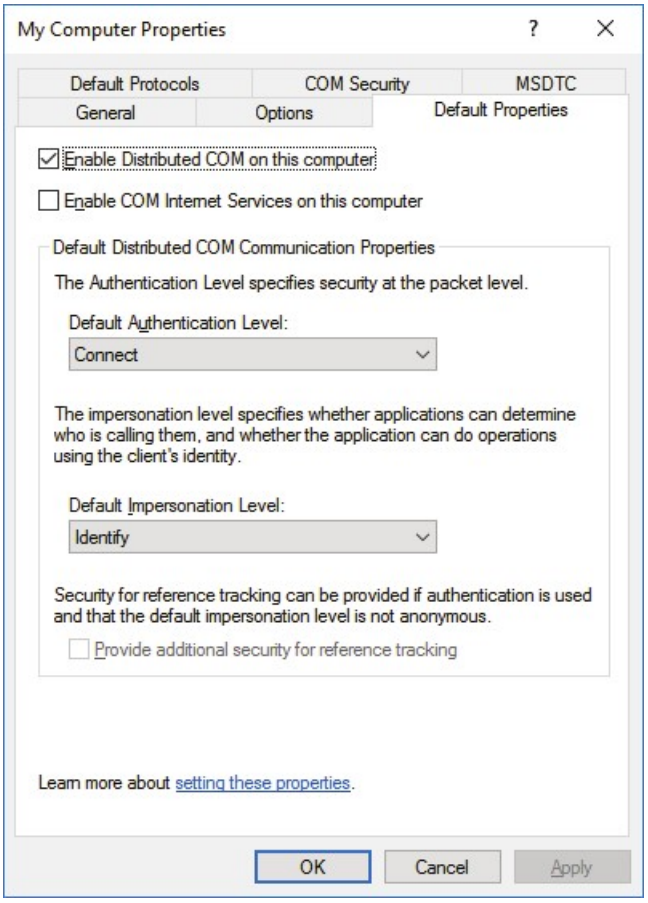

Figure B3.2.2-4 My Computer Properties dialog box

6. Open the [Default Properties] tab, from the Default Authentication Level drop-down list, select [Connect], and then click [OK].
7. Restart the computer.

B3.2.3 Setting of Items for Windows Server 2016, Windows Server 2019, and Windows Server 2022

This section describes how to set the items for Windows Server 2016, Windows Server 2019, and Windows Server 2022.

Windows Defender

The Windows Defender software detects and removes spy ware.

It is recommended to turn off this function because it is not used with this product.

In a domain environment, turn off Windows Defender on domain member PCs at a time by means of a domain management operation such as Group Policies.

In a workgroup environment, turn off Windows Defender by using the Local Group Policy Editor.

Turning off Windows Defender in Local Group Policy Editor

Follow these steps to turn off Windows Defender:

1. Sign in as an administrative user.
2. Open Command Prompt.
3. Enter `gpedit.msc`.
   Local Group Policy Editor appears.
   The rest of the operation differs depending on the OS version.

TIP

- If the OS version is 1607 or earlier, [Windows Defender] is displayed instead of [Microsoft Defender Antivirus].
- If the OS version is 1703 to 1909, [Windows Defender Antivirus] is displayed instead of [Microsoft Defender Antivirus].
- If the OS version is 2004 or later, [Microsoft Defender Antivirus] is displayed.

4. In the left pane, select [Computer Configuration] > [Administrative Templates] > [Windows Components] > [Microsoft Defender Antivirus].
5. In the right pane, double-click [Turn off Microsoft Defender Antivirus].
   The Turn off Microsoft Defender Antivirus dialog box appears.
6. Select [Enabled] and click [OK].

Defragment and Optimize Drives

The Defragmenter Tool can be used to reorganize the fragmented files on computer hard disk so as to improve the computer performance. Since the performance of this product may be affected when the defragmenter is running, it is recommended to disable the schedule of the periodic disk defragmentation.

Moreover, you may manually start the disk defragmenter when you feel the disk performance is getting worse or when you perform system maintenance.

1. Sign in as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Defragment and Optimize Drives].
   The Optimize Drives window appears.
4. Click [Change settings].
   The Optimize Drives dialog box appears.

5. Clear the [Run on a schedule (recommended)] check box and click [OK].

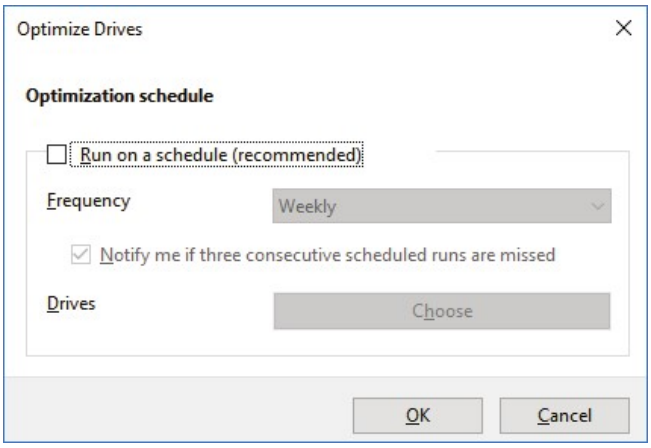

Figure B3.2.3-1 Optimize Drives dialog box

Disabling the Automatic Cleanup Task

A function is added to automatically clean up old files when update programs are applied.

Execution of Automatic cleanup may cause the degradation in system performance. For that reason, we recommend disabling Automatic cleanup for this product.

Follow these steps to disable the automatic cleanup task:

1. Sign in as an administrative user.
2. Open Control Panel.
3. From the menu, select [System and Security] > [Administrative Tools] > [Task Scheduler]. The Task Scheduler window appears.
4. In the left pane, select [Task Scheduler (Local)] > [Task Scheduler Library] > [Microsoft] > [Windows] > [Servicing].
5. In the middle pane, right-click [StartComponentCleanup] and select [Disable].
6. In the left pane, select [Task Scheduler (Local)] > [Task Scheduler Library] > [Microsoft] > [Windows] > [DiskCleanup].
7. In the middle pane, right-click [SilentCleanup] and select [Disable].

DCOM Settings

When Default Authentication Level in DCOM settings is set to [None], installation of applications such as redistributable modules fails. When installing this product, set the Default Authentication Level to [Connect].

Follow these steps to set Default Authentication Level to [Connect].

1. Sign in as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Component Services]. The Component Services window appears.

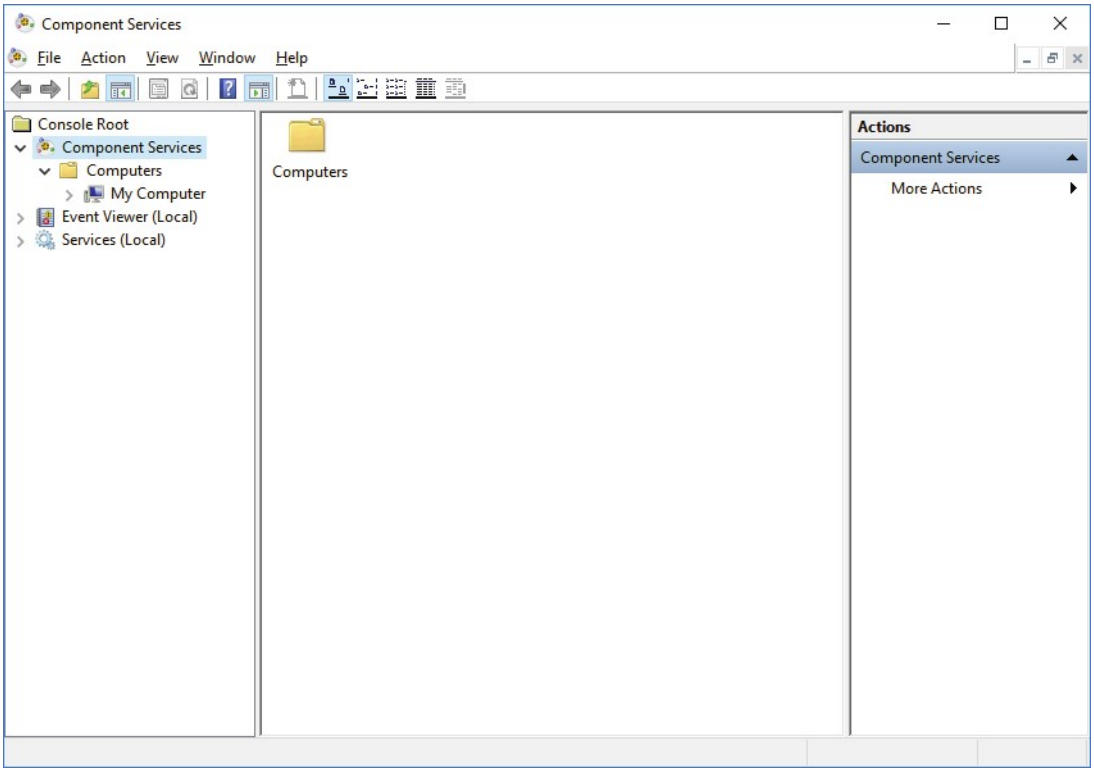

Figure B3.2.3-2 Component Services window

4. Select [Console Root] > [Component Services] > [Computers].
5. Right-click [My Computer] and select [Properties].
   The My Computer Properties dialog box appears.

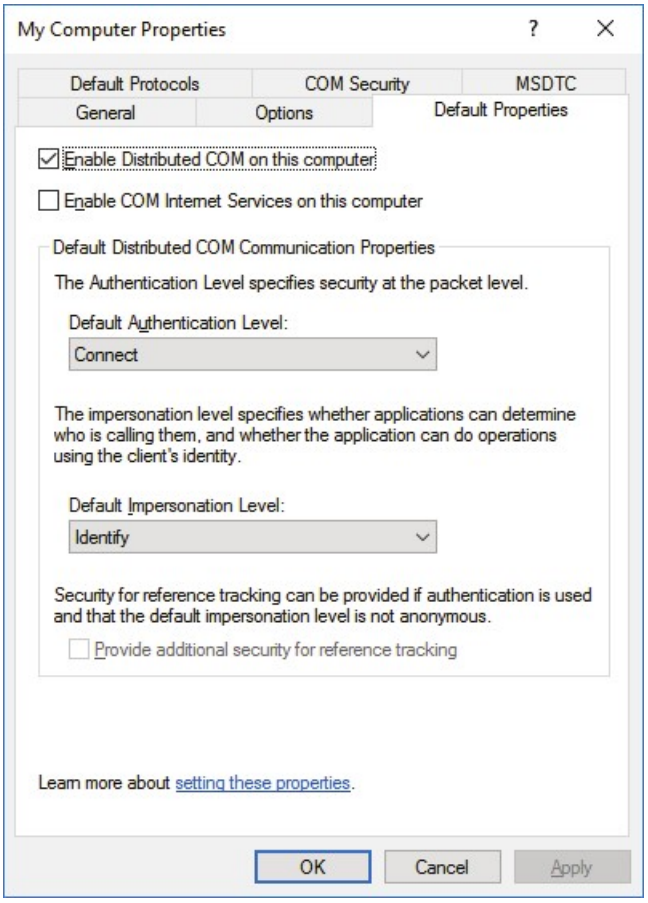

Figure B3.2.3-3 My Computer Properties dialog box

6. Open the [Default Properties] tab, from the Default Authentication Level drop-down list, select [Connect], and then click [OK].
7. Restart the computer.

B3.3 Configuring Network Settings

To use the control bus, you need to install the control bus driver. If Vnet/IP is used as the control bus, you need to install the Vnet/IP open communication driver as well.

This section describes how to install the control bus driver and the Vnet/IP open communication driver.

If you use the built-in Ethernet interface of the computer or an over-the-counter Ethernet card, read the attached instruction manual and install the proper Ethernet driver accordingly.

In the case of SENG that runs on a virtual machine, install the Vnet/IP Interface Package on the virtual machine. Also, do not install the Vnet/IP open communication driver.

TIP

On a network where there is a virtual machine with the Vnet/IP Interface Package installed, it cannot be configured when only Vnet/IP is installed.

After installing the driver and interface package, set up the Windows network.

B3.3.1 Installing the Control Bus Driver

This section describes the procedure for installing the control bus driver.

Precautions at Installation

Mount a control bus interface card or Vnet/IP interface card in computers to be connected on a control bus network. In addition, you must install the control bus driver. Observe the following precautions when you install the control bus driver.

- Before installing the control bus driver, be sure to install a control bus interface card or Vnet/IP interface card in the computer.
- For Windows 10, be sure to check that fast startup is turned off before installing the control bus driver. If fast startup is not turned off, turn it off and restart the computer.
- If you installed the control bus driver without installing a control bus interface card or Vnet/IP interface card by mistake, uninstall the control bus driver. Then, install a control bus interface card and install the driver again.
- If you want to change the slot in which a control bus interface card or Vnet/IP interface card is installed, uninstall the control bus driver first and then change the slot. After changing the slot, install the driver again.
- When you remove a control bus interface card or Vnet/IP interface card from the computer where the control bus driver was installed with the card installed, uninstall the driver before you remove the card from the slot.

TIP

- When installing the control bus driver, restarting the computer is basically not required. However, restart the computer if a dialog box indicating completion of the installation (restarting required) is displayed.
- After you install the driver, you need to configure network settings.

SEE ALSO

For more information about turning off fast startup, refer to:

"■ Turning Off Fast Startup" on page B3-10

Notes on Using SCS Simulator

To use the SCS simulator, an environment where ProSafe-RS is integrated with CENTUM is mandatory. You can run the SCS simulator even on a computer where a control bus interface card or Vnet/IP interface is not mounted; however, you must always install the control bus driver on such computers. Observe the following precautions when you install the control bus driver on a computer where these cards are not mounted in order to use the SCS simulator.

- Install the control bus driver, and then configure Windows network settings.
- If you use the expanded test functions to run SCS simulators on multiple computers, install the control bus driver in all the computers on which you run the SCS simulator without mounting a control bus card. If mounted, you cannot launch the SCS simulator remotely.

TIP

- If a control bus card is not mounted when you install the control bus driver, a control bus driver of the version for use without a control bus card is installed. This driver is used when the SCS simulator is run without mounting a control bus card.
- To reuse or divert a computer installed with a without-a-control-bus-card version of control bus driver for use in actual plant operation, uninstall the control bus driver, mount a control bus card, and then install the control bus driver again.

- The control bus driver should be installed according to the procedure for installing the control bus driver.

- For the IP address for the control bus driver on each computer, set the address of control bus, “domain number (dd) .station number (ss)”.
  Example: 172.16.dd.ss

  Note that dd.ss must not overlap with the addresses of the other stations. In particular, it must not overlap with the “domain number.station number” used for SCS and FCS.

Installation Procedure

1. Log on as an administrative user.
2. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the ProSafe-RS software medium.

   The installation menu appears.
3. On the installation menu, click [Control Bus Driver].
   A dialog box appears, prompting you to confirm the setup.
4. Select [INSTALL] and click [OK].
   A dialog box appears, confirming to execute the installation.
5. Click [OK].

TIP

- If the Windows Security dialog box appears, select the [Always trust software from “Yokogawa Electric Corporation”] check box, and click [Install].
- Do not click [Don’t Install] on the Windows Security dialog boxes. If clicked, an error occurs.

6. When the message telling successful installation is displayed, click [OK].

TIP

If you have added or deleted any other devices before you install the control bus driver, a message prompting you to restart the computer may be displayed. In such a case, be sure to restart the computer.

B3.3.2 Setting Up the RIP Listener Service on a Virtual Machine

When using the virtualization platform, you must set up the RIP Listener service on a virtual machine.

This section describes enabling the RIP Listener service. The method for enabling the RIP Listener service is different between Windows Server 2019 or later and Windows Server 2016 running as the guest OS of the virtual machine.

SEE ALSO For more information about settings of the function for receiving RIP packet in Windows Server 2019 or later, refer to:

Virtualization Platform Setup (IM 30A05B20-01EN)

■ Enabling the RIP Listener Service: Windows Server 2016

If the guest OS of the virtual machine is Windows Server 2016, RIP Listener service is automatically installed when the OS is installed. Therefore, you do not need to install the RIP Listener service. However, the RIP Listener service is disabled by default, so you must enable the RIP Listener service.

● Enabling the RIP Listener Service: Windows Server 2016

Follow these steps to enable the RIP Listener Service:

1. Sign in to the guest OS on the virtual machine as an administrative user.
2. Run the Command Prompt as Administrator.
3. Run the following command:
   `dism /online /enable-feature /featurename:rasrip /all`
4. Confirm that the message, “The operation completed successfully.” appears.
5. Check that the RIP Listener service has been enabled.
   a. Open Control Panel.
   b. Select [System and Security] > [Administrative Tools] > [Service].
      The Services window appears.
   c. Confirm that RIP Listener is shown and its Startup Type is [Automatic].

TIP If the Default Authentication Level of DCOM is set to “None,” you cannot enable the RIP Listener service.

SEE ALSO For more information about how to change the default authentication level of DCOM to “Connect”, refer to:

“■ DCOM Settings” on page B3-15

B3.3.3 Installing the Vnet/IP Open Communication Driver

When Vnet/IP is used as the control bus, the Vnet/IP open communication driver also needs to be installed. If Ethernet is also used, the installed Vnet/IP open communication driver must be disabled.

This section describes the procedure for installing the Vnet/IP open communication driver.

IMPORTANT

When the Vnet/IP interface card is mounted, always install the Vnet/IP open communication driver even if Vnet/IP open communication is not used.

■ Precautions at Installation

- Before installing the Vnet/IP open communication driver, be sure to install a Vnet/IP interface card in the computer. You cannot install the driver if the card is not installed.
- For Windows 10, be sure to check that fast startup is turned off before installing the Vnet/IP open communication driver. If fast startup is not turned off, turn it off and restart the computer.
- If you want to change the slot in which a Vnet/IP interface card is mounted, uninstall the Vnet/IP open communication driver and control bus driver and then change the slot. After changing the slot, install the drivers again.
- When removing a Vnet/IP interface card from a computer after the Vnet/IP open communication driver is installed, uninstall the driver before you remove the card from the slot.

TIP

- When installing the Vnet/IP open communication driver, restarting the computer is basically not required. However, restart the computer if a dialog box indicating completion of the installation (restarting required) is displayed.
- When Ethernet is also used, configure network settings after you install the Vnet/IP open communication driver and disable the driver.

  When Ethernet is not used, configure network settings after you install the Vnet/IP open communication driver.

SEE ALSO

For more information about turning off fast startup, refer to:

"■ Turning Off Fast Startup" on page B3-10

■ Installation Procedure

1. Log on as an administrative user.
2. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the ProSafe-RS software medium.

   The installation menu appears.
3. On the installation menu, click the [Vnet/IP Open com driver].
   A dialog box appears, prompting you to confirm the setup.
4. Select [INSTALL] and click [OK].
   A dialog box appears, confirming to execute the installation.
5. Click [OK].

TIP

- If the Windows Security dialog box appears, select the [Always trust software from “Yokogawa Electric Corporation”] check box, and click [Install].
- Do not click [Don’t Install] on the Windows Security dialog box. If clicked, an error occurs.

6. When the message telling successful installation is displayed, click [OK].

TIP

If you have added or deleted any other devices before you install the Vnet/IP open communication driver, a message prompting you to restart the computer may be displayed. In such a case, be sure to restart the computer.

B3.3.4 Installing the Vnet/IP Interface Package on a Virtual Machine

When using the virtualization platform, you need to install the Vnet/IP Interface Package on a virtual machine.

Follow these steps to install the Vnet/IP Interface Package on a virtual machine.

The procedures explained here should be performed on the guest OS of the virtual machine.

IMPORTANT

- You do not need to install a Vnet/IP interface card in the virtualization host computer.
- When multiple products coexist in one virtual machine, you do not need to install the Vnet/IP Interface Package as long as a Vnet/IP Interface Package has already been installed on another product.
- After installing the Vnet/IP Interface Package, you need to configure the Windows network settings on the virtual machine.

SEE ALSO For more information about overview of virtualization platform and precautions on using ProSafe-RS with a virtual machine, refer to:

A7., “Virtualization platform” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

For more information about details of the virtualization platform, refer to:

- Virtualization Platform Setup (IM 30A05B20-01EN)
- Virtualization Platform Planning and Implementation Guide (TI 30A05B10-01EN)

Precautions When Installing the Vnet/IP Interface Package

Observe the following precautions when you install the Vnet/IP Interface Package.

Precautions at First-time Installation

Install the Vnet/IP Interface Package before applying IT security. If you install the Vnet/IP Interface Package for the first time on a computer after applying IT security, you must apply IT security again.

TIP After IT security is applied, you do not need to apply IT security again when you reinstall the Vnet/IP Interface Package.

Precautions at Reinstallation

Reinstalling the Vnet/IP Interface Package resets the password of the Vnet/IP Interface Package execution user. If you have changed the password, set it again.

Procedure to Install the Vnet/IP Interface Package

Follow these steps to install the Vnet/IP Interface Package.

Preparation

Install Windows update as a preparation.

SEE ALSO For more information about the Windows Server 2016 update programs to apply, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2016)" on page B1-6

Procedure 1: Install the Vnet/IP Interface Package

Follow these steps to install the Vnet/IP Interface Package.

TIP If you have added or deleted any other devices before you install the Vnet/IP Interface Package, a message prompting you to restart the computer may be displayed. If displayed, be sure to restart the virtual machine.

1. Sign in to the host OS of virtualization host computer as an administrative user.
2. Copy an ISO format file of the ProSafe-RS software medium and paste it into a folder on the host OS.
3. Select [Start] > [Server Manager].
   Server Manager starts.
4. Select [Tools] > [Hyper-V Manager].
   Hyper-V Manager starts.
5. On the left pane, select the virtualization host computer.
   Virtual machines on the virtualization host computer are displayed on the middle pane.
6. Right-click on the virtual machine that the ISO format file is mounted and select [Connect].
   The virtual machine connection window appears.

TIP The virtual machine connection window may appear full-screen. If it appears full-screen, click [Undo] to exit full-screen.

7. Select [Media] > [DVD Drive] > [Insert Disk].
   A file opening dialog box appears.
8. Select the copied ISO format file of the ProSafe-RS software medium and click [Open].
   The selected ISO format file is mounted on the virtual machine.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the ISO format file of the ProSafe-RS software.

   The installation menu appears.
9. On the installation menu, click [Control Bus Driver].
   A dialog box appears, prompting you to confirm the setup.
10. Select [INSTALL] and click [OK].
    A dialog box appears, confirming to execute the installation.
11. Click [OK].

TIP
- If the Windows Security dialog box appears, select the [Always trust software from "Yokogawa Electric Corporation"] check box, and click [Install].
- Do not click [Don't Install] on the Windows Security dialog box. If clicked, an error occurs.

12. When the message telling successful installation is displayed, click [OK].

Procedure 2: Set the Domain Number and Station Number Managed by the Vnet/IP Interface Package

When the installation of the Vnet/IP Interface Package is complete, the Vnet/IP Interface Management Tool appears. Using this tool, set the domain number and station number that will be managed by the Vnet/IP Interface Package. Follow these steps to set the domain number and station number.

TIP

You can also set the domain number and station number managed by the Vnet/IP Interface Package later. You must restart the virtual machine to reflect the settings.

1. Open the Settings tab of the Vnet/IP Interface Management Tool.
2. Set the domain number in [Domain No] and the station number in [Station No], and then click [Save].

TIP

You can set a number in the range from 1 to 31 as the domain number (1 to 16 in the case of CENTUM integration), and from 1 to 64 as the station number. If both domain number and station number are set to 0, Vnet/IP communication is disabled and communication to the control network is not possible.

On a virtual machine where you run an FCS simulator that can be operated through remote connection from another HIS by installing the Expanded Test Functions and SCS Simulator Package, set both the domain number and the station number to 0.

Note that the license of Vnet/IP Interface Package is not required when using only the test function with the domain number and the station number set to 0.

3. Click [CLOSE], and restart the virtual machine.

SEE ALSO

For more information about Vnet/IP interface management tool, refer to:

"■ Changing the Domain Number and Station Number" on page App.3-1

Procedure 3: Activate License of the Vnet/IP Interface Package

Before you can use the Vnet/IP Interface Package, you must activate the license for the package. After installing the ProSafe-RS software, distribute and accept the license of the Vnet/IP Interface Package.

B3.3.5 Configuring Windows Network Settings

You must configure the Windows network settings after installing the network driver.

This section explains the procedures for configuring Windows network settings related to control bus, Vnet/IP open communication, and Ethernet.

Cautions on Cable Wiring

When the cable is wired for network connection, the network charm bar may appear.

SEE ALSO For more information about the Set Network Location dialog box and network charm bar, refer to:

C7.2.1, “Precaution on Network Cable Connection” on page C7-5

Checking the Card for Control Bus

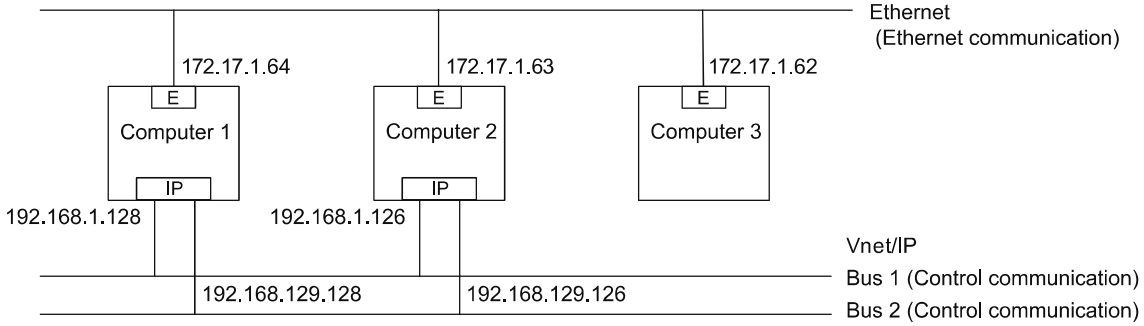
Check the card for control bus that is installed on the computer.

When a Control Bus Interface Card is Installed

In a system using V net, a control bus interface card is installed in computers. In this case, configure Windows network settings for control bus communications and Ethernet communications.

When a Vnet/IP Interface Card is Installed

In a system using Vnet/IP, a Vnet/IP interface card is installed in computers.

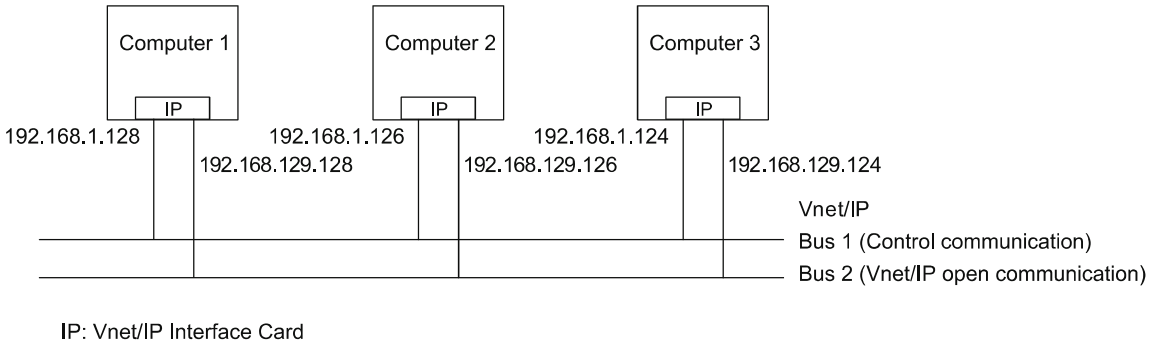


In this case, a combination of either control bus communications and Ethernet communications or control bus communications and Vnet/IP open communications is used. Configure the Windows network settings according to the network configuration of the system.

TIP The Vnet/IP open communication refers to Ethernet communication performed on bus 2 of Vnet/IP.

In a system using Vnet/IP open communications, bus 1 is normally used for control bus communications and bus 2 is used for Ethernet communications. If bus 1 fails, bus 2 is used for both control bus communications and Ethernet communications.

Vnet/IP Network Configurations and Windows Network Settings



Vnet/IP network configurations and their required Windows network settings are describes as follows.

E: Ethernet Interface Card or Onboard NIC

IP: Vnet/IP Interface Card

Figure B3.3.5-1 Network Configuration and Interface (Vnet/IP and Ethernet are Installed)

IP: Vnet/IP Interface Card

Figure B3.3.5-2 Network Configuration and Interface (Only Vnet/IP is Installed)

Table B3.3.5-1 Network Configurations and Network Connections to be Set Up on Windows

Network Configuration	Computer (Example in the figures)	Network connection to be set up on Windows
Vnet/IP + Ethernet	Connected to Vnet/IP and Ethernet (Computers 1 and 2)	Control bus, Ethernet, and Vnet/IP open communications(*1)
	Connected to Ethernet only (Computer 3)	Ethernet communications
Vnet/IP only	Connected to Vnet/IP (Ethernet communication on bus 2) (Computers 1 to 3)	Control bus, Ethernet, and Vnet/IP open communications(*2)

*1: After installing the Vnet/IP open communication driver, you need to disable the corresponding device.
*2: You need to disable the Ethernet device.

SEE ALSO For more information about network construction when using Vnet/IP open communication, refer to:

Vnet/IP Network Construction Guide (Legacy Edition) (TI 30A10A10-01E)

Cautions on Using Vnet/IP

On the computers connected on Vnet/IP, you need to disable the unused devices according to the network configuration.

When Vnet/IP and Ethernet are Installed

IMPORTANT

In a system where both Vnet/IP and Ethernet are Installed, Vnet/IP open communications are not used. Even in this case, you need to install the Vnet/IP open communication driver and disable the driver on computers installed with a Vnet/IP interface card.

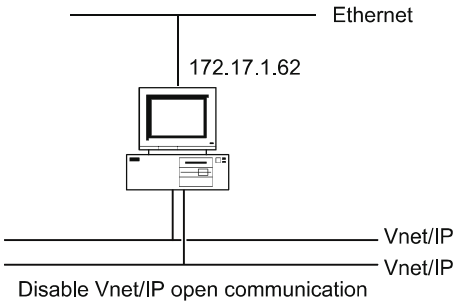


Figure B3.3.5-3 When Vnet/IP and Ethernet are Installed

On a computer installed with a Vnet/IP interface card, follow these steps to disable the Vnet/IP Open communication driver:

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [System] > [Device Manager].
   Device Manager appears.
4. Unfold Network adapters.
5. Select [Vnet/IP Open Communication Driver (BUS2)] and then click the Disable button on the toolbar.

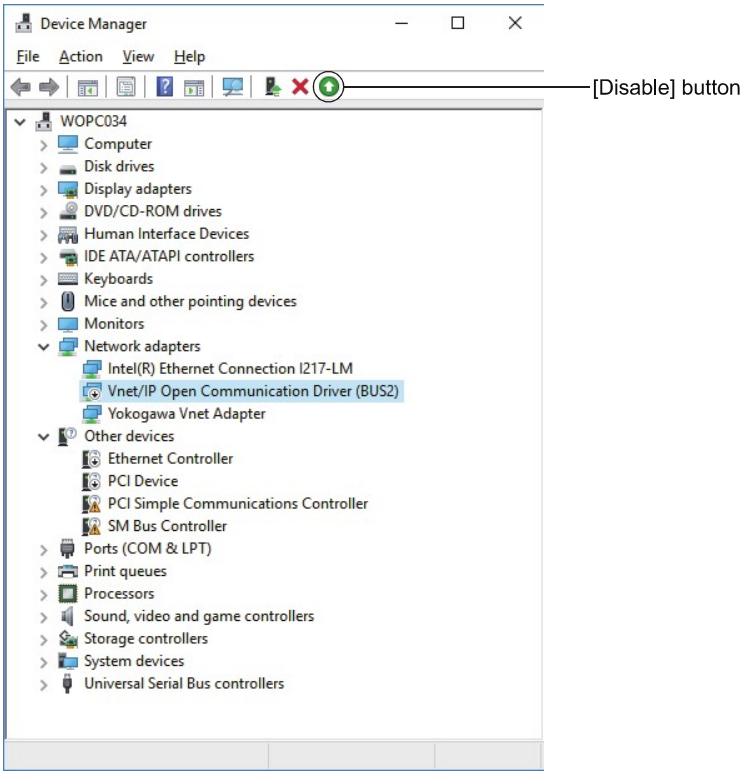

Figure B3.3.5-4 Disabling the Vnet/IP Open Communication Device

When Only Vnet/IP is Installed

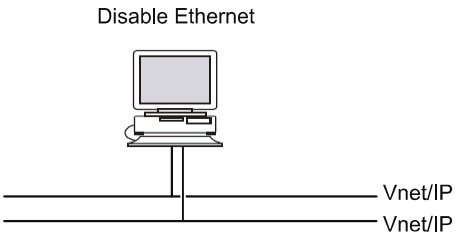

Figure B3.3.5-5 When Only Vnet/IP is Installed

On a computer in a system where only Vnet/IP is installed, follow these steps to disable the Ethernet device:

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [System] > [Device Manager].
   Device Manager appears.

4. Unfold Network adapters.
5. Select the Ethernet device and then click the Disable button on the toolbar.

Prohibitions

Do not use the following features in ProSafe-RS.

- Internet Connection Sharing (ICS)
- Bridge Connection
- Homegroup

Internet Connection Sharing (ICS)

Do not select the [Allow other network users to connect through this computer's Internet connection] check box on the Sharing tab in the properties dialog box for V net, VnetIPOpen, or Ethernet (these connection names are set in the procedures described later).

TIP Internet Connection Sharing (ICS) is for sharing the internet connection by the computers in a small scale office network or home network.

Bridge Connection

Do not use bridge connection. If bridge connection is created in the computer, not only the control bus communication of the computer becomes abnormal, but also the communication of the whole control bus network may be jeopardized. (If the bridge connection is already created, you need to delete the bridge connection.)

Homegroup (Windows 10)

In a ProSafe-RS system, folders and printers are shared by using the file sharing function for the workgroup/network environment as with the earlier RS versions. For this reason, select [No] on the network charm bar.

Procedure 1: Rename Local Area Connections

A network after the installation is named "Local Area Connection." The network can be identified more easily if you rename the local area connection.

Rename the local area connections as necessary according to the network configuration of the system.

1. Open the Control Panel.
2. Select [Network and Internet] > [Network and Sharing Center].
   The Network and Sharing Center window appears.
3. Select [Change adapter settings].
   The Network Connections window appears.

TIP If connections are not displayed here, the corresponding installations have failed or the drivers are not working properly. Address the issues so that the connections are displayed here.

4. Right-click each of the Local Area Connection icons and select [Rename] to change the name.

Table B3.3.5-2 Renaming of Network Connections

Network type	Display on Network Connections window	Name
Ethernet	Ethernet driver names	Ethernet
Control bus	Yokogawa Vnet Adapter	Vnet
Vnet/IP open communication	Vnet/IP Open Communication Driver (BUS2)	VnetIPOpen

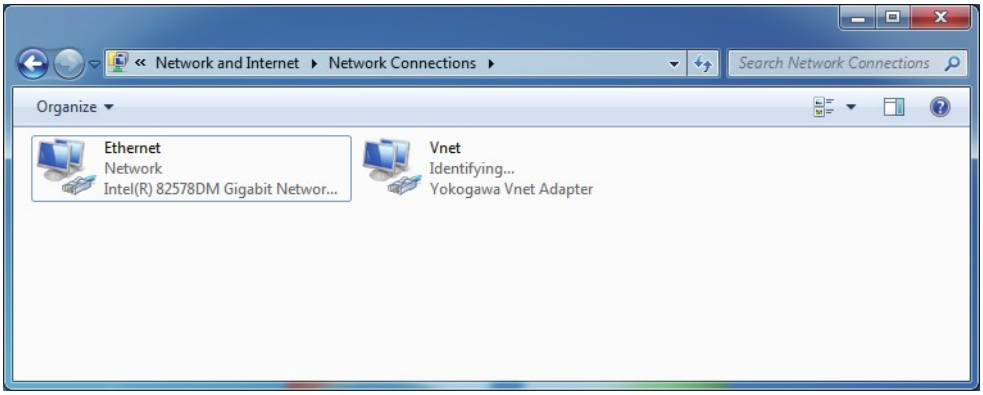

Figure B3.3.5-6 Network Connections – V net Network (After Renaming)

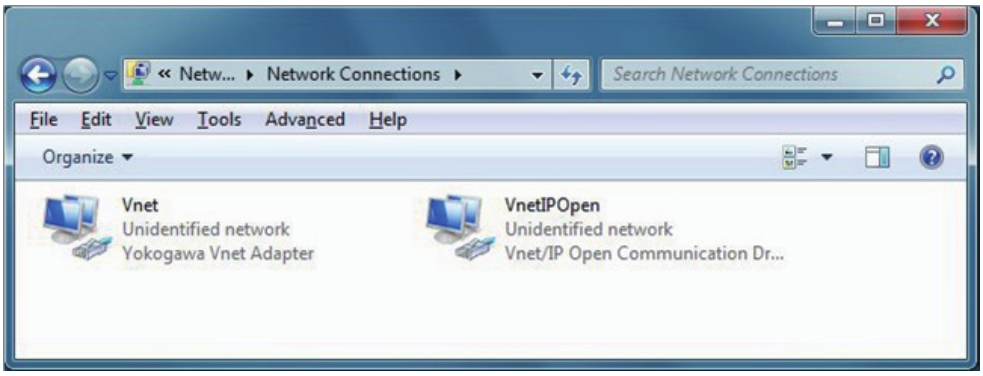

Figure B3.3.5-7 Network Connections – Vnet/IP Network (After Renaming)

TIP

In the instruction manuals until ProSafe-RS R2.03, it is instructed to change the name of control bus communication connection when Vnet/IP is used to “VnetIP” rather than “Vnet.”

SEE ALSO

For more information about the network settings for a virtual machine, refer to:

B3.4, “Notes on Using a Virtual Machine” on page B3-37

Procedure 2: Configure Properties

In the properties of each type of network connection, you need to configure the items to be used.

Configure the properties as necessary according to the network configuration of the system.

Table B3.3.5-3 List of Items Used for Network Connections

Item	Usage of the item (*1)		
	Ethernet	VnetIPOpen	Vnet
Client for Microsoft networks	Yes	Yes	No
QoS packet scheduler	Yes	Yes	No
File and printer sharing for Microsoft networks	Yes	Yes	No
Microsoft Network Adapter Multiplexor Protocol	No	No	No
Microsoft LLDP Protocol Driver	Yes	Yes	No
Yokogawa Vnet Protocol	No	No	Yes
Internet protocol version 6 (TCP/IPv6)	No	No	No
Internet protocol version 4 (TCP/IPv4)	Yes	Yes	Yes
Link-Layer Topology Discovery Mapper I/O Driver	Yes	Yes	No
Link-Layer Topology Discovery Responder	Yes	Yes	No

*1: Yes: Select the check box, No: Clear the check box

TIP

Items in the table, except “Yokogawa Vnet Protocol,” are installed during the Windows OS installation.

SEE ALSO

For more information about how to set the network adapters of the virtual machine, refer to:

“■ Configure Properties” on page B3-37

● V net Properties

1. In the Network Connections window, right-click [Vnet] and select [Properties].
   The Vnet Properties dialog box appears.
2. Configure Vnet according to “Table List of Items Used for Network Connections.”
3. After the setting is complete, click [OK].

● VnetIPOpen Properties

1. In the Network Connections window, right-click [VnetIPOpen] and select [Properties].
   The VnetIPOpen Properties dialog box appears.
2. Configure VnetIPOpen according to “Table List of Items Used for Network Connections.”
3. After the setting is complete, click [OK].

● Ethernet Properties

1. In the Network Connections window, right-click [Ethernet] and select [Properties].
   The Ethernet Properties dialog box appears.
2. Configure the Ethernet according to “Table List of Items Used for Network Connections.”
3. After the setting is complete, click [OK].

■ Procedure 3: Set IP Addresses

On Windows, DHCP is enabled by default after a network driver is installed. However, since ProSafe-RS does not use DHCP, you need to set IP addresses. You need to set IP addresses also when the system is used in the domain environment. Set the IP addresses according to the network configuration of the system.

SEE ALSO For more information about how to set IP addresses of the virtual machine, refer to:

"■ Set IP Addresses" on page B3-38

Setting IP Address for Vnet

1. In the Network Connections window, right-click the Vnet icon and select [Properties].
   The Vnet Properties dialog box appears.
2. Select [Internet Protocol Version 4 (TCP/Ipv4)] and click [Properties].
   The Internet Protocol Version 4(TCP/Ipv4) Properties dialog box appears.
3. Select [Use the following IP address] and set the IP address, subnet mask, and default gateway. Set the IP address to a standard value that is determined based on the station address of the computer as long as there is no special reason.

TIP The standard values for Vnet are as follows:

IP address:	172.16.Domain Number.Station Number(*1)
Subnet Mask:	255.255.0.0
Default gateway:	No setting is required.

*1: If the network address overlaps with the network address of the existing environment, you can use an address other than 172.16.

4. After the setting is complete, click [OK]. You do not need to restart the computer.

IP Address for VnetIPOpen

This setting is not required when Vnet/IP is used together with Ethernet.

1. In the Network Connections window, right-click the VnetIPOpen icon and select [Properties].
   The VnetIPOpen Properties dialog box appears.
2. Select [Internet Protocol Version 4 (TCP/IPv4)] and click the [Properties].
   The Internet Protocol Version 4 (TCP/IPv4) Properties dialog box appears.
3. Select [Use the following IP address] and specify the following values for the IP address, subnet mask, and default gateway.
   - If the computer is to be used in an existing environment, specify the values used in that network environment.
   - If the computer is to be used in a new environment, specify the standard values determined based on the station address.

TIP The standard values for VnetIPOpen are as follows:

IP address:	192.168.<128 + domain number>.<129 + station number>(*1)
Subnet Mask:	255.255.255.0
Default gateway:	Specify the IP address of L3SW if another Vnet/IP domain exists

*1: Normally, use a standard value. However, you can also use other address.

4. After the setting is complete, click [OK]. You do not need to restart the computer.

Setting IP Address for Ethernet

1. In the Network Connections window, right-click the Ethernet icon and select [Properties].
   The Ethernet Properties dialog box appears.
2. Select [Internet Protocol Version 4(TCP/IPv4)] and then click [Properties].

The Internet Protocol Version 4 (TCP/IPv4) Properties dialog box appears.

3. Select [Use the following IP address] and set the IP address, subnet mask, and default gateway for Ethernet as follows:
   - If the computer is to be used in an existing environment, specify the values used in that network environment.
   - If the computer is to be used in a new environment, specify the standard values determined based on the station address.

TIP

The standard values for Ethernet are as follows:

IP address:	172.17.Domain Number.Station Number(*1)
Subnet Mask:	255.255.0.0
Default gateway:	No setting is required.

*1: Normally, use a standard value. However, you can also use other address.

IMPORTANT

- In workgroup environment, do not change the settings for DNS server address and the settings accessed by clicking [Advanced].
- In Windows domain environment, you need to set the DNS server address according to the settings of Windows domain server.

4. After the setting is complete, click [OK]. You do not need to restart the computer.

Setup Procedure 4: Change Computer Name

It is recommended to set the station names used in the ProSafe-RS system as the computer names.

1. Open the Control Panel.
2. Select [System and Security] > [System] > [Advanced system settings].
   The System Properties dialog box appears.
3. In the Computer Name tab, click [Change].
   The Computer Name/Domain Changes dialog box appears.
4. Enter the station name as the new computer name (case-insensitive) for the computer.

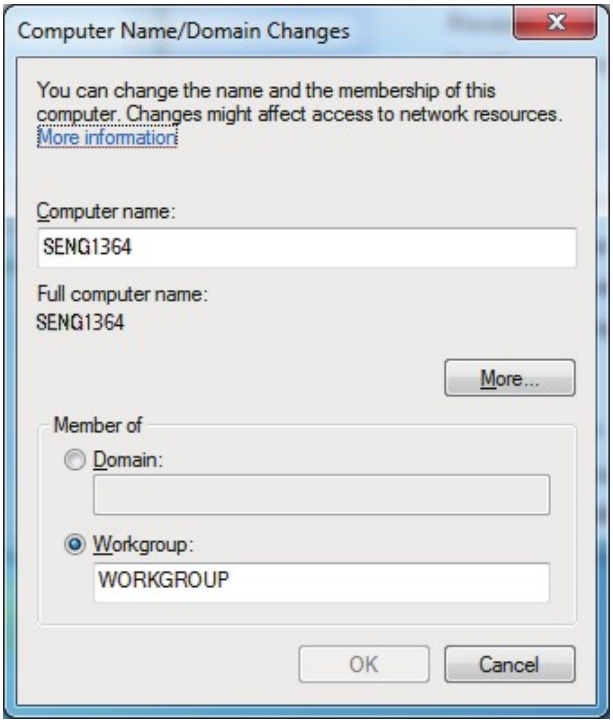

Figure B3.3.5-8 Computer Name/Domain Changes Dialog Box

5. Click [OK].
   A message box appears to prompt for restarting the computer.
6. Restart the computer.

Procedure 5: Repair TCP/IP Settings

Before you install the ProSafe-RS software, run the TCP/IP Inconsistency Detect Tool. If any inconsistency is found, use the TCP/IP Inconsistency Repair Tool and configure the TCP/IP settings again.

TIP

On a computer where the control bus driver or Vnet/IP open communication driver had ever been uninstalled, the TCP/IPv4 network settings of IP addresses, subnet masks, and default gateway addresses may be lost every time the computer is restarted. This problem is caused by errors of the Windows OS.

Running the TCP/IP Inconsistency Detect Tool

1. Use Windows Explorer to open the TOOLS directory under the following path in the ProSafe-RS software medium.
   `(Drive of ProSafe-RS software medium):\ProSafe-RS\TOOLS`

TIP

TCP/IP Inconsistency Detect Tool is installed in the following folder when you install the ProSafe-RS software:

`(ProSafe-RS Installation Folder)\ProSafe-RS\YOKOGAWA\net\tool`

2. Right-click [TcpipInconsistencyDetector.cmd], and select [Run as administrator] from the context menu.
   Messages are displayed according to the inconsistencies detected.
3. Click [OK] to end the tool.

If no inconsistency is detected, the computer can be connected on the network normally.

If no inconsistency is detected, the Windows system continues to work but the network connection may not. You need to use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP network settings again.

Running TCP/IP Inconsistency Repair Tool

IMPORTANT

TCP/IP Inconsistency Repair Tool resets the TCP/IP settings of all the network interface cards that are installed in the computer. Therefore, before you run the TCP/IP Inconsistency Repair Tool, you need to write down or save the current settings of the following TCP/IPv4 information for every network interface card:

- IP Address
- Subnet Mask
- Default Gateway

1. Use Windows Explorer to open the TOOLS directory under the following path in the ProSafe-RS software medium.
   `(Drive of ProSafe-RS software medium):\ProSafe-RS\TOOLS`

TIP

TCP/IP Inconsistency Repair Tool is installed in the following folder when you install the ProSafe-RS software:

`(ProSafe-RS Installation Folder)\ProSafe-RS\YOKOGAWA\net\tool`

2. Right-click [TcpipInconsistencyRepair.cmd], and select [Run as administrator] from the context menu.
   Messages are displayed according to the inconsistencies detected.
3. If no inconsistency is detected in the network settings, click [OK] to end the tool.
   The computer can be connected on the network normally.
4. If any inconsistency is detected, click [Yes]
   The network settings are reset and a message appears, prompting you to restart the computer.
5. Click [Yes] to restart the computer.
6. After the computer is restarted, re-configure the settings on the Internet Protocol Version 4 (TCP/IPv4) Properties windows for all the network interface cards.

B3.4 Notes on Using a Virtual Machine

When using a virtual machine, in addition to the control bus and Ethernet, you must configure the control network (Vnet/IP) and the remote UI network settings.

Rename Local Area Connections

Set the name of the local area connection of the virtual machine as follows.

Table B3.4-1 Renaming of Network Connections

Network type	Display on Network Connections window (*1)	Name
Control bus	Yokogawa Vnet Adapter	Vnet
Ethernet	Microsoft Hyper-V Network Adapter #n	Ethernet
Control network 1	Microsoft Hyper-V Network Adapter #n	VnetIPBUS1 (*2)
Control network 2	Microsoft Hyper-V Network Adapter #n	VnetIPBUS2 (*2)
Remote UI network	Microsoft Hyper-V Network Adapter #n	RemoteUINetwork

*1: These are the default names, where n = 1, 2, ..., which means the virtual NIC number.
*2: Be sure to set these names. The names are not case-sensitive.

Confirming the Network Type

Follow these steps to confirm the network type:

1. In the Network Connections window, right-click on a network and select [Properties].
2. Open the Network tab, and click [Configure].
3. Open the Advanced tab and confirm the Value that is displayed when you select Hyper-V Network Adapter Name in Properties.
   The device name that was set when the virtual machine was built is displayed.

TIP

For the Value that you confirm in the step 3, contact to the engineer who configured the virtual machine.

Configure Properties

In the properties of each type of network connection, you need to configure the items to be used. Configure the properties as shown in the following table.

Table B3.4-2 List of Items Used for Network Connections

Item	Usage of the item (*1)				
	Control bus	Ethernet	Control network 1	Control network 2	Remote UI network
Client for Microsoft Networks	No	Yes	No	No	Yes
QoS Packet Scheduler	No	Yes	No	No	Yes
File and Printer Sharing for Microsoft Networks	No	Yes	No	No	No
Microsoft Network Adapter Multiplexor Protocol	No	No	No	No	No
Microsoft LLDP Protocol Driver	No	Yes	No	No	Yes
Yokogawa Vnet Protocol	Yes (*2)	No	No	No	No
Internet protocol version 6 (TCP/IPv6)	No	No	No	No	No
Internet protocol version 4 (TCP/IPv4)	Yes	Yes	Yes	Yes	Yes
Link-Layer Topology Discovery Mapper I/O Driver	No	Yes	No	No	Yes

Continues on the next page

Table B3.4-2 List of Items Used for Network Connections (Table continued)

Item	Usage of the item (*1)				
	Control bus	Ethernet	Control network 1	Control network 2	Remote UI network
Link-Layer Topology Discovery Responder	No	Yes	No	No	Yes

*1: Yes: Select the check box, No: Clear the check box
*2: Do not clear the check box for “Yokogawa Vnet Protocol.”

Set IP Addresses

You do not need to set the IP address, subnet mask, and default gateway for the control network. They are automatically set by the Vnet/IP Interface Management Tool based on the settings values of the domain number and station number managed by the Vnet/IP Interface Package.

For the control bus, Ethernet, and remote UI network, it is recommended to set the IP address, subnet mask, and default gateway to the following values.

Table B3.4-3 IP Address

	Control bus	Ethernet	Remote UI network
IP Address	172.16. Domain number. Station number	172.17. Domain number. Station number	172.18. Domain number. Station number
Subnet Mask	255.255.0.0	255.255.0.0	255.255.0.0
Default gateway	No setting is required.	No setting is required.	No setting is required.

If the existing environment and network addresses overlap, IP addresses other than the recommended values can be used for the control bus, Ethernet, and remote UI network. However, you cannot set the address 192.168.xx.yy to the IP address of the control bus, Ethernet, or remote UI network. If you do, communication to the control network is impossible.

B3.5 Installing the ProSafe-RS Software

This section describes how to install the ProSafe-RS software.

Administrative User who Performs New Installation

When installing the ProSafe-RS software for the first time on a computer, the installation must be performed by an administrative user who belongs to the group shown in the following table.

The user who has installed the software is automatically added to the PSF_MAINTENANCE group.

IMPORTANT

- The initial password is set by default for the predefined user accounts in this product. Be sure to change the password because operating with the initial password may increase the security risk.
- If SOE OPC Interface Package is used, be sure to change the PSF_PROCESS password after configuring IT security settings. If you changed the password before configuring IT security settings, reset the password that you set.
- If you are going to change the initial password of PSF_PROCESS in an environment that AD Suite is used, activate the system project backup function with ADS Administration Tool before you change the password. If you change the password before activating the system project backup function, the [Backup System Projects prior to AD Project Export] check box in the ADS Administration Tool appears dimmed and you cannot select it. In that case, change the initial password of PSF_PROCESS after activating the system project backup function.
- When changing the password, ensure that the same password is set in the entire system.

Table B3.5-1 Groups to Which the User Who Performs New Installation Belongs

Security model and user management type to be applied		
Legacy model	Standard model	
	Standalone management/linked domain management	Domain/Combination management
Local user who belongs to the Administrators local group	Local user who belongs to the Administrators local group	• Domain user who belongs to the Domain Admins domain group • Domain user who belongs to the Administrators local group • Local user who belongs to the Administrators local group(*1) (*2)

*1: The domain user name and password must be entered during installation.
*2: When this user applies IT security and uses iDefine interface package, the following steps must be performed as a domain user who belongs to the Domain Admins domain group or as a domain user who belongs to the Administrators local group.
1. Run the 32 bit Command Prompt (%SystemDrive%\Windows\SysWOW64\cmd.exe) as Administrator.
2. Run either of the following batch files appropriate to the user management type.
%ProgramFiles(x86)%\YOKOGAWA\IA\iPCS\Platform\Security\Program
For Domain management: PSF_SetupSMSvcHostConfigDOM.cmd
For Combination management: PSF_SetupSMSvcHostConfigCMB.cmd

TIP

If the user management type is Domain or Combination management, install the software after the computer is added to the domain.

SEE ALSO For more information about user accounts that require password change, refer to:

2.2.3, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Installation Procedure

Follow these steps to install the ProSafe-RS software:

1. Log on as an administrative user.
2. Terminate all running applications, including resident programs such as anti-virus software.
3. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the ProSafe-RS software medium.

   The installation menu appears.

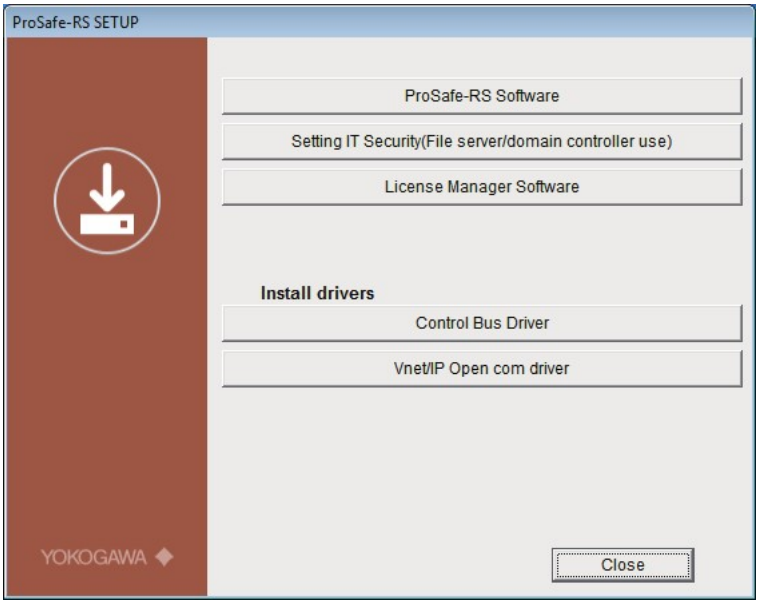

Figure B3.5-1 Installation Menu

4. Click [ProSafe-RS Software] in the installation menu.
5. If a dialog box appears, confirming to install Windows redistributable modules, click [Install].

TIP This dialog box appears when the Windows redistributable modules required to run ProSafe-RS are not already installed.

The following modules are necessary for ProSafe-RS:

- Microsoft .NET Framework 4.8
- Microsoft Visual C++ 2017 Redistributable Package
- Microsoft Access Database Engine 2016

If you click [Cancel], the installation of the ProSafe-RS software is discontinued.

Restarting the computer may be required after installing the modules. If required, restart the computer and then continue the ProSafe-RS installation.

Installation starts.

6. After the installation is completed, click [Close].
   The window closes.

IMPORTANT

If Microsoft Access Database Engine 2016 cannot be installed due to cancellation during installation of the redistributable module, an error occurs. In that case, click [OK]. To continue the installation, install ProSafe-RS again.

7. If the following dialog box appears, restart the computer and log on again using the same user account.

Figure B3.5-2 User Rights Setting Confirmation Dialog Box

TIP

Restarting the computer here grants the currently logged on user the rights required to perform the subsequent installation tasks.

Installation of the ProSafe-RS software starts and the Welcome dialog box appears.

8. Click [Next].
   A dialog box for entering user information and the installation folder appears.

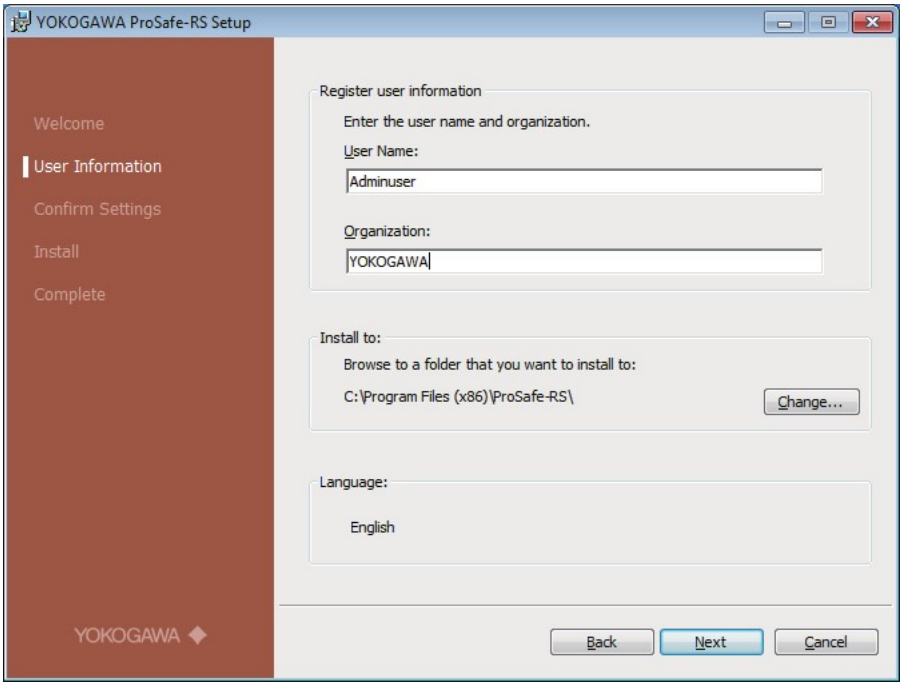

Figure B3.5-3 User Information Dialog Box

TIP

- If a different version of control bus driver or Vnet/IP open communication driver is already installed, a dialog box appears, prompting you to update the driver. Confirm the message and click [OK]. To update the control bus driver, uninstall the existing driver and then install the new one after you install the ProSafe-RS software. To update the Vnet/IP open communication driver, install the new driver after you install the ProSafe-RS software.
- After updating the Vnet/IP open communication driver, disable the driver if the computer is to be connected to Ethernet.

9. Enter the user name and company name. It is recommended not to change the installation folder from the default location.

TIP

- The user name and company name must be set within 100 characters.
- If you want to change the installation folder, click [Browse] and specify a new location within 50 characters.
- The language is determined automatically by the system language: if the system language is Japanese, the Japanese version software is installed, otherwise, the an English version is installed.

10. Click [Next].
    The Confirm Settings dialog box appears.
11. Confirm that the installation settings are correct, and click [Install].
    Installation of the ProSafe-RS software is started.
12. When the installation complete dialog box appears, perform either of the following operations.
    - If you install only ProSafe-RS, select [Yes, I want to set up IT security now.] and click [Finish]. The IT Security Tool then starts.
    - If you install another YOKOGAWA product, select [No, I want to install other software products.] and click [Finish] to complete the installation.

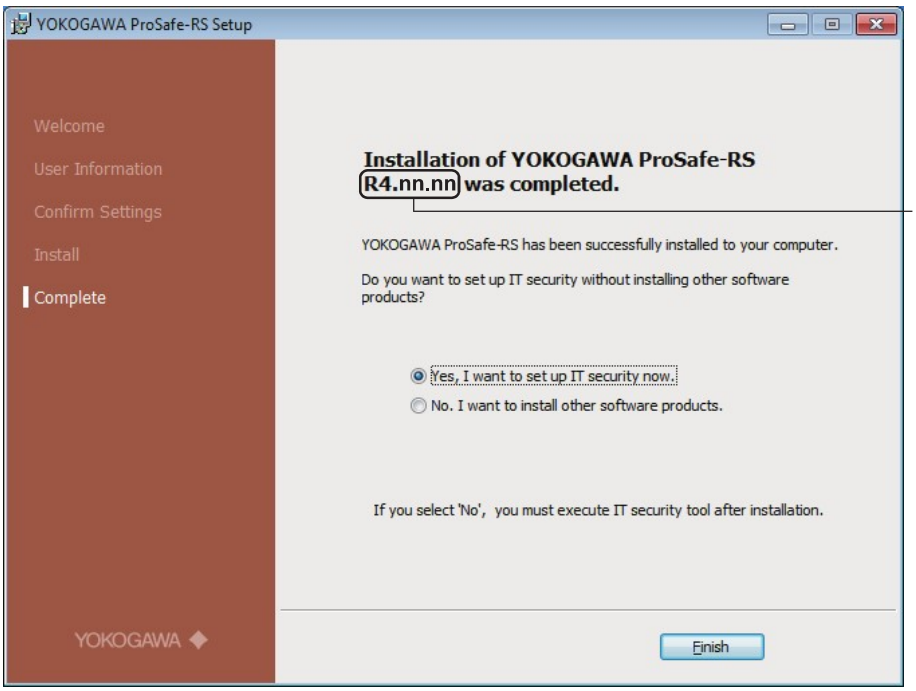

Figure B3.5-4 Installation Completed Dialog Box

IMPORTANT

After you have installed other YOKOGAWA products, be sure to run the IT Security Tool to configure IT security settings. The settings on the IT Security Tool will be valid to all the installed products.

If you do not configure IT security settings, the products will not function properly.

SEE ALSO For more information about configuring the IT security settings, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

B3.6 Configuring IT Security Settings

After installing the ProSafe-RS software, you need to configure settings to strengthen Windows IT security.

To configure IT security for linked domain management, use IT Security Tool and Domain Link Management Tool. For user management types other than linked domain management, use IT Security Tool to configure IT security settings.

IMPORTANT

- The initial password is set by default for the predefined user accounts in this product. Be sure to change the password because operating with the initial password may increase the security risk.
- The security model of IT security settings must be consistent in the entire system. Ensure that the user management type is unified to either standalone management or management using a domain controller. You can mix computers in domain management, combination management, or linked domain management.
- If you select the Legacy model, restrictions related to Windows are in effect in some environments. For that reason, we recommend you select the Standard model.
- If you operate the computer in the Standard model with linked domain management, apply IT security settings for the Standard model with standalone management. Next, join the computer to the domain and set with Domain Link Management Tool.
- If the computer contains YOKOGAWA products that do not support linked domain management and you use the installed YOKOGAWA product in a domain environment, set the user management type to domain management or combination management with IT Security Tool.
- If you have changed any security settings from their default values, always save the security settings by using the Save function of the IT Security Tool to enable security settings to be restored at computer failure.
- After you have activated the license of the SOE OPC Interface Package, be sure to run the IT Security Tool from the Start menu.
- Security settings customized by other than the IT Security Tool are overwritten with the setting information held by the IT Security Tool when the IT Security Tool is run. If you want to use the same security settings as before running the IT Security Tool, customize them again after running the IT Security Tool.

  Note that upgrading will run the IT Security Tool and overwrite the security settings.

TIP

Even when a domain controller is used to perform consolidated management of IT security settings, be sure to set IT security on each client. After setting IT security on all clients, use the domain controller to set up consolidated management of IT security settings.

SEE ALSO

For more information about precautions for coexistence with other YOKOGAWA product, refer to:

B3.6.2, “Precautions for Coexistence with Other Product” on page B3-51

For more information about user accounts that require password change, refer to:

2.2.3, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about details of the IT security settings, refer to:

6.1, “IT Security Tool” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about the procedure for performing consolidated management of IT security settings with a domain controller, refer to:

6.10, “Active Directory-Based Consolidated Management of IT Security Settings” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

B3.6.1 Running the IT Security Tool

This section describes the procedure for configuring the IT security settings following the completion of ProSafe-RS software installation.

IMPORTANT

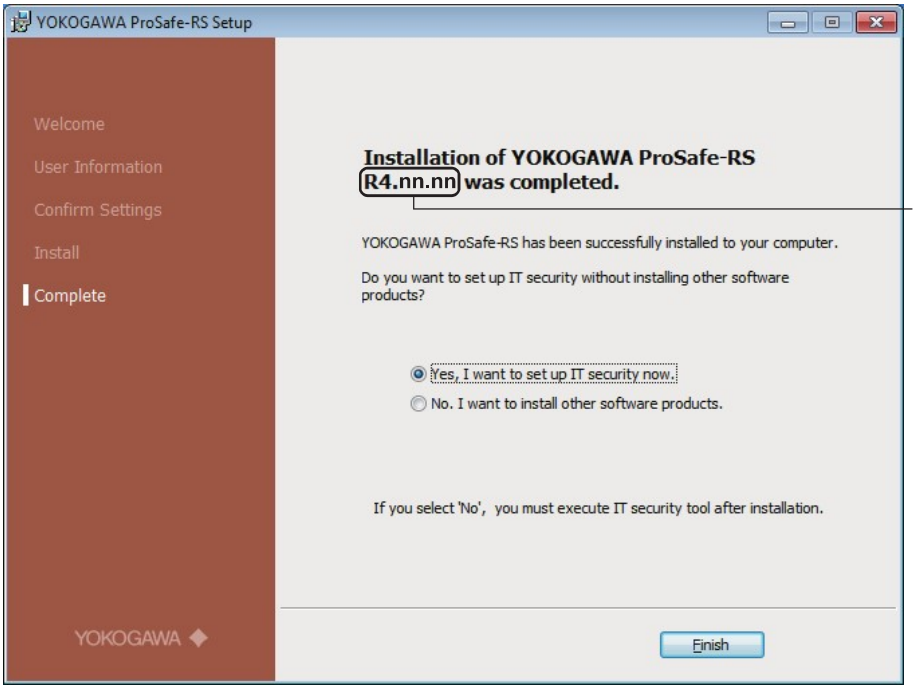
If the following YOKOGAWA products have been installed and they do not support IT security version 2.0, the selection of IT security version 1.0 cannot be changed.

- CENTUM VP
- PRM

If they support IT security version 2.0, the IT security version can be kept or changed.

Follow these steps to run the IT Security Tool:

1. When the ProSafe-RS software installation is complete, a dialog box appears. Select [Yes, I want to set up IT security now.] and click [Finish].



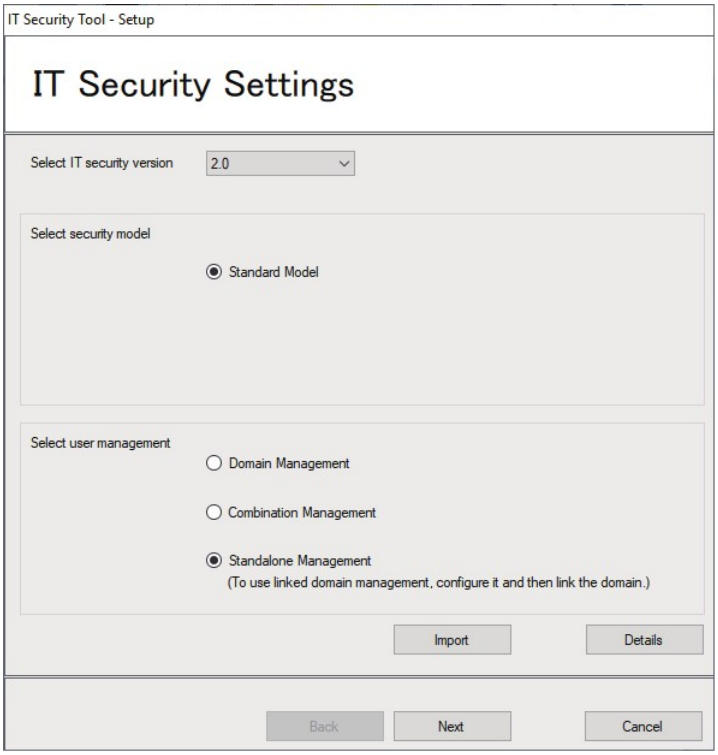


Figure B3.6.1-1 ProSafe-RS Setup Dialog Box (Completed)

The IT Security Tool starts.

TIP

If you are intending to select [No, I want to install other software products.] after the completion of installation, install other software products, and then run the IT Security Tool, start the IT Security Tool from the Start menu and click [Settings] on the menu.

TIP

The text To use linked domain management, configure it and then link the domain below Standalone Management is displayed when all of YOKOGAWA system products installed on the computer support the linked domain management.

Figure B3.6.1-2 IT Security Tool (Setup)

2. From the Select IT security version drop-down list, select the IT security version.
3. In the Select security model section, select either [Standard Model] or [Legacy Model].

TIP

If you select [2.0] for Select IT security version, only the [Standard model] can be selected.

4. In the Select user management section, select [Domain Management], [Combination Management], or [Standalone Management].

TIP

- When you select the Legacy model, you cannot change the user management type from Standalone management.
- When operating with linked domain management, select the standalone management in the Standard model.
- If you select [Standalone Management] on a Windows domain member computer, a confirmation message is displayed. You can go on by clicking [OK].

5. If you do not need to configure the individual setting items, click [Next]. IT security setting starts. When the setup is complete, the Setup Completed page appears. If there is any setting items that have failed, the failed items are displayed. To reconfigure the individual setting items, perform the following steps.

TIP

If IT security version 2.0 is selected, a confirmation dialog box appears. To apply the current settings, click [Yes].

a. To reconfigure the individual setting items, click [Details].
The Select Setting Items page appears.

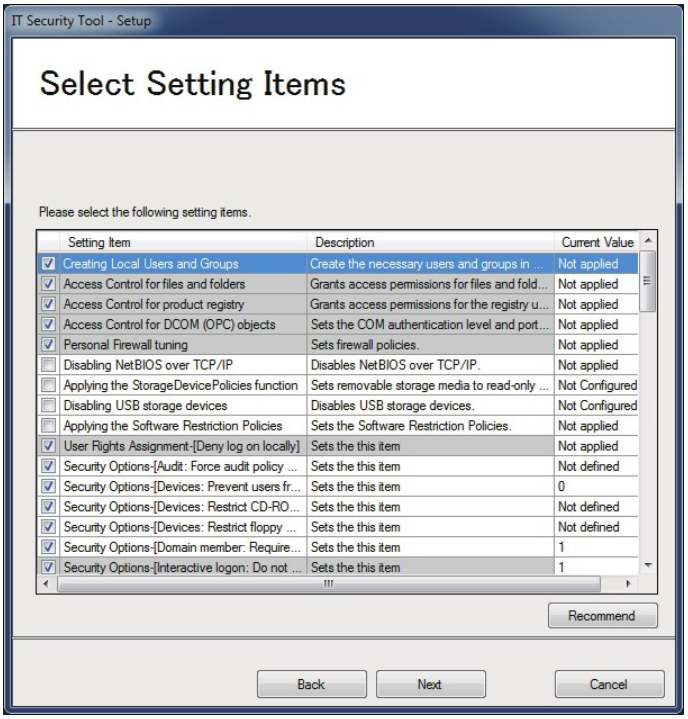

Figure B3.6.1-3 Select Setting Items Page (When IT Security Version 2.0 Is Selected)

b. Select or clear the check boxes of the items you want to change.
Under [Current Value], the value currently set for the applicable setting item is displayed according to the following table.

IMPORTANT

The group policy settings that were distributed from the domain controller are not displayed. Local group policy settings are displayed.

Table B3.6.1-1 Content displayed in Current Value

Content displayed	Description
Actual value	The value actually set is displayed. For example, Enabled, Disabled, 30, 0, etc., is displayed. (*1)
[Not defined]	This is displayed for a setting item relating to security options, for which no value is set.
[Not configured]	This is displayed for a setting item for the group policy management template, for which no value is set.
[Not applied]	This is displayed for a setting item that takes multiple values, for which IT security has never been applied.
[Applied]	This is displayed for a setting item that takes multiple values, for which IT security has been applied at least once.

*1: Even when the set value is a character string in the Security Policy window, it may be managed as a value in the OS, in which case the value is displayed.

TIP It is recommended not to change the settings when the Standard model is selected.

c. Click [Next].
The Confirm Setting Information page appears.

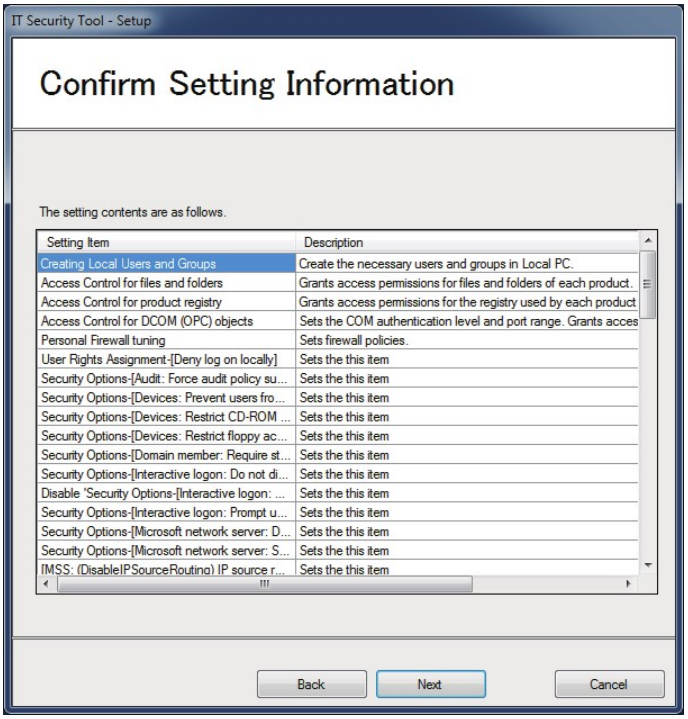

Figure B3.6.1-4 Confirm Setting Information Page (When IT Security Version 2.0 Is Selected)

TIP

If the settings specified are different from the default values of the security model, a warning dialog box appears.

To apply the current settings, click [Yes]. If you click [No], you will return to the Select Setting Items page.

d. Confirm the settings and click [Next].

TIP

If this tool was used in the past to configure security settings without opening the Select Setting Items page, the last configured IT security settings are applied. If these settings and the default settings of the selected security model do not match, a warning dialog box appears.

To apply the current settings, click [Yes]. If you click [No], you will return to the IT Security Settings page.

When the setup is complete, the Setup Completed page appears. If there is any setting items that have failed, the failed items are displayed.

6. Select the [Restart now] check box and click [Finish].
   The IT Security Tool is exited and the computer is restarted automatically.

IMPORTANT

If any setup failures are displayed, contact YOKOGAWA Service.

TIP

The "Program Compatibility Assistant" dialog box may appear after the security settings configuration is completed. Even when this dialog box appears, the settings have been configured successfully, so click [Cancel] to close it.

SEE ALSO For more information about the procedure for importing the IT security settings, refer to:

6.8, “Exporting/Importing the IT Security Setting File” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about changing the IT security settings, refer to:

6.4, “Changing the IT Security Settings” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Notes on the Case when NetBIOS over TCP/IP is Disabled

When the Standard model is selected, you can configure to disable NetBIOS over TCP/IP. With domain management, combination management, or linked domain management, NetBIOS over TCP/IP is disabled by default.

If it is disabled, you need to make the following settings for name solution.

- Standalone management
  In the LMHOSTS file of each station, set the computer names of the stations it needs to access.

  Location of the LMHOSTS file: `%Systemroot%\system32\drivers\etc`

  %Systemroot% is the directory where the Windows OS is installed. Usually, it is `C:\Windows`.

  Example script in the LMHOSTS file: The following is an example of accessing HIS0124.

```
########## lmhosts
172.17.1.24 HIS0124 #PRE
```

Table B3.6.1-2 LMHOSTS File Settings

Station type	Stations to be set in the LMHOSTS file
License management station	All license-assigned stations
License-assigned station	• License management station • Computer that holds project files (File server computer; if integrated with CENTUM, computer that holds CENTUM project database) • To use the Forced I/O Viewer function, the computer on which SCS projects are saved and the computer which receives the distribution.

- Domain management, combination management, or linked domain management
  In the DNS server, set the license management station and all the license-assigned stations.

B3.6.2 Precautions for Coexistence with Other Product

Precautions to be heeded when a YOKOGAWA product that supports IT security settings co-exists on a ProSafe-RS computer are explained.

Installing the ProSafe-RS Software After Installing Other Product

When installing the ProSafe-RS software after installing other product that does not support IT security version 2.0, only IT security version 1.0 can be selected.

When installing the ProSafe-RS software after installing other product that supports IT security version 2.0, the IT security version can be kept or changed.

Installing Other Product After Installing the ProSafe-RS Software

If IT security Version 2.0 is set during the installation of the ProSafe-RS software and then IT security settings are configured during the installation of other product that does not support IT security version 2.0, the following warning dialog box will appear.

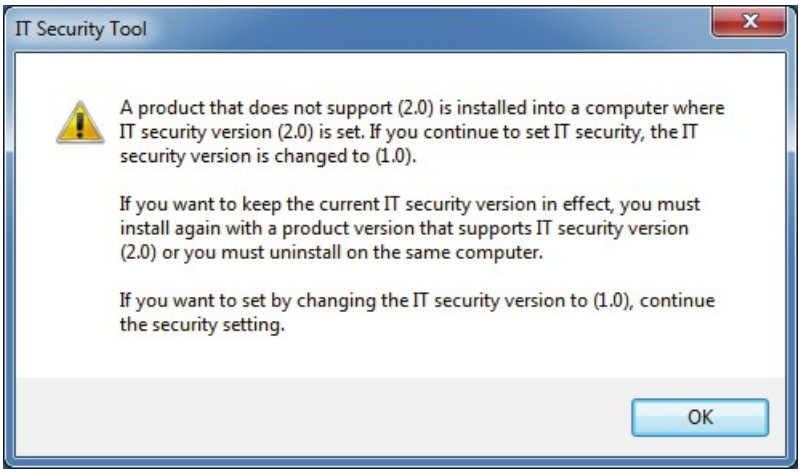

Figure B3.6.2-1 Warning Dialog Box

When changing to IT security version 1.0, continue configuring the IT security settings.

When changing to IT security version 2.0, close the IT security tool and uninstall other products, then re-install other products that are compatible with IT security version 2.0.

B3.6.3 Running Domain Link Management Tool

To configure IT security for linked domain management, use Domain Link Management Tool.

Adding the corresponding domain group to the members of the local group for the product installed on the computer by using the Domain Link Management Tool is called linking the domain. Conversely, deleting the domain group from the members of the local group is called unlinking the domain.

IMPORTANT

- The domain can be linked if the following conditions are met.
  - All of YOKOGAWA system products installed on the computer support the linked domain management.
  - The IT security settings for standalone management are applied to the installed products with IT Security Tool.
  - The computer is added to the Domain.
- You can link or unlink the domain for all of YOKOGAWA system products installed on the computer at once.
- If you install another YOKOGAWA system products after linking domains, you must configure security with IT Security Tool and link the domain. The same applies to upgrading the revision or the version of the installed products.

SEE ALSO

For more information about how to add client computers to the domain, refer to:

B2.5, “Adding Computers to the Domain” on page B2-17

For more information about notes on the case when NetBIOS over TCP/IP is disabled, refer to:

“■ Notes on the Case when NetBIOS over TCP/IP is Disabled” on page B3-50

For more information about IT Security Tool, refer to:

6.1, “IT Security Tool” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about Domain Link Management Tool, refer to:

6.2, “Domain Link Management Tool” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

■ Linking the domain with Domain Link Management Tool

Follow these steps to link the domain:

1. Sign in as a local user who belongs to both the Administrators group and PSF_MAINTENANCE group of the local computer.
2. Start Domain Link Management Tool.

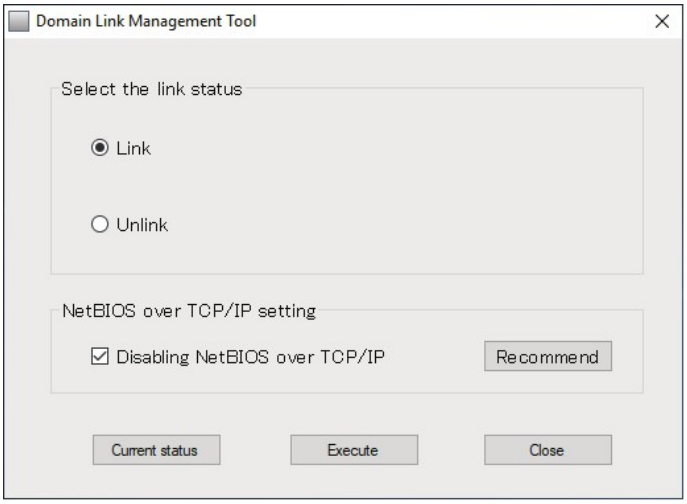

Figure B3.6.3-1 Domain Link Management Tool

3. In Domain Link Management Tool, select [Link] in the Select the link status section.
4. To change the recommended settings of NetBIOS over TCP/IP setting, perform the following step.
   Clear the [Disabling NetBIOS over TCP/IP] check box.

TIP

If the security model is set to Standard model with IT Security Tool, the setting of the Disabling NetBIOS over TCP/IP check box is switched to the recommended settings in conjunction with the settings of the Select the link status.

5. In Domain Link Management Tool, click [Execute].
   The domain user authentication dialog box appears.
6. Enter the user name and password of the domain user and click [OK].
   The corresponding domain group is added to the member of the local groups related to the products installed on your computer. Also, NetBIOS over TCP/IP setting is configured.

TIP

The user name and password that you enter in the domain user authentication dialog box do not have to be those of the domain administrator.

7. In Domain Link Management Tool, click [Close].
   The Domain Link Management Tool closes.

Error messages and countermeasures

When attempting to link the domain, an error message will be displayed and the process will not be performed depending on the conditions. Check the current status of the products installed on the computer and take necessary measures.

The following table describes the error messages and countermeasures when you cannot run the process for linking domain.

Table B3.6.3-1 Error messages and countermeasures

the error messages	Remedy
The computer is not joined to the domain.	Join the computer to the domain.
This account information you entered is incorrect.	Domain user authentication has failed. Enter the correct account information.

Continues on the next page

Table B3.6.3-1 Error messages and countermeasures (Table continued)

the error messages	Remedy
Any products that support linked domain management are not installed. (*1)	All of YOKOGAWA system products installed on the computer must support the linked domain management. Perform either of the following measures: • Change the user management type to domain management or combination management. • Uninstall the products that do not support linked domain management and link the domain.
The products that do not support linked domain management are installed.	
IT security is not configured. (*1)	With IT Security Tool, apply the security settings for standalone management.
Linked domain management is not to be configured for the Legacy model computer.	Change to Standard model with standalone management.
Standalone management is not applied.	Change the user management type to standalone management.
Failed to connect to the domain controller.	Check the network settings and cabling between the computer and domain controller.
The group required for linked domain management does not exist in the domain.	Create necessary domain group.

*1: This error does not occur in Domain Link Management Tool for File Server.

- B2.3, “Configuring Security Settings for the Domain Controller” on page B2-6
- B2.4, “Creating Domain Users” on page B2-13

For more information about how to configure IT security settings with IT Security Tool for the first time, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about the procedure for displaying the current status with Domain Link Management Tool, refer to:

6.2, “Domain Link Management Tool” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

For more information about the procedure for changing the IT security settings, refer to:

6.4, “Changing the IT Security Settings” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

B3.7 Distributing and Accepting Licenses

Licenses are the rights to use ProSafe-RS software packages.

To make the installed software packages available for use, you need to distribute the licenses from the license management station to license-assigned stations and accept the licenses on each license-assigned station. This process of making software packages available for use is called “activation of software packages.”

In a ProSafe-RS system, there is always one license management station and other stations are license-assigned stations. The license management station can be set up on a computer where SENG runs.

SEE ALSO For more information about distributing and accepting licenses, refer to:

1., “Overview of license management” in License Management Guide (IM 32P01C60-01EN)

B3.8 Creating User Accounts

Create accounts for ProSafe-RS.

When the Standard model is selected in IT security configuration, rights to access the installation folder, registries, etc. are set by the IT Security Tool, based on the access rights granted to the ProSafe-RS user groups. Therefore, you need to register the created user as a member of the appropriate ProSafe-RS user group according to the user's role, such as engineer and maintenance personnel.

This section describes the procedures for the cases where the security settings of the Standard model with Standalone management or the Legacy model are applied.

When you create local user accounts for Standard model with linked domain management, domain management, and combination management, create them in the same way as for Standard model with standalone management. When you create domain user accounts for Standard model with linked domain management, domain management, and combination management, create them on the domain controller.

SEE ALSO For more information about how to create domain user accounts, refer to:

B2.4, “Creating Domain Users” on page B2-13

■ Limitation on User Account Names

- 20 characters at maximum.
- Space, tabs, and multi-byte characters such as half-width katakana and Chinese characters (kanji) cannot be used.

TIP When the Access Control and Operation History Management Package is used and Windows authentication mode is specified, different limitations are applied.

SEE ALSO For more information about the limitations on user account names when using Windows authentication mode of the Access Control and Operation History Management Package, refer to:

“■ Creating User Accounts in Windows Authentication Mode” on page B4-8

B3.8.1 When the Standard Model with Standalone Management Security Settings are Applied

When the security settings of Standard model with Standalone management are applied, user accounts should be created on each computer.

Follow these steps to create a user account:

1. Logon as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [Administrative Tools] > [Computer Management].
   The Computer Management window appears.
4. On the tree view in the left pane of the window, select [System Tools] > [Local Users and Groups] > [Users].
5. Select [Action] > [New User].
   The New User dialog box appears.
6. Add a user account. (The rest of the steps shows an example of adding a new user account, OPERATOR.)
7. Right-click the user you have created and select [Properties], and then click [Add] on the Member of tab.
8. Select an appropriate user group for the created user and click [OK].

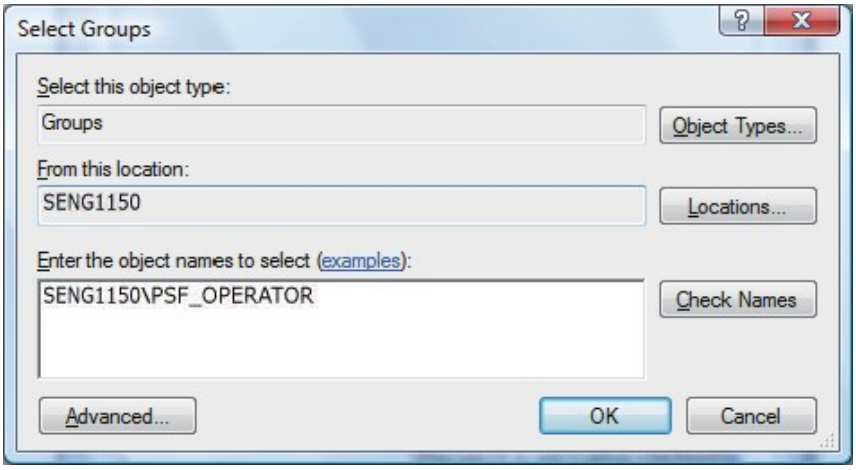

Figure B3.8.1-1 Select Groups

TIP

A user who belongs to the administrative group (PSF_MAINTENANCE) must also be a member of the Administrators group.

9. In the user properties dialog box, confirm that the group you selected has been added to the Member of list.

B3.8.2 When the Legacy Model of Security Settings are Applied

The procedure for creating user accounts is the same as that for creating user accounts on a Standalone management computer. However, with the Legacy model, Windows groups PSF_xxxx are not supported. So, there is no need to add the created users to these groups.

SEE ALSO For more information about creating user accounts, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

B3.9 Configuring Windows Environment Settings for Each User

After creating user accounts, configure the required Windows environment settings for each user.

B3.9.1 Setting of Items Common to Windows 10, Windows Server 2016, Windows Server 2019, and Windows Server 2022

This section describes how to set the items common to Windows 10, Windows Server 2016, Windows Server 2019, and Windows Server 2022.

Showing Icons on the Task Tray

On license-assigned stations, you must set so that the License Agent icon is always shown on the task tray.

1. Sign in using the user account for which the License Agent icon should be displayed.
2. Open the Control Panel.
3. From the menu, select [Appearance and Personalization] > [Taskbar and Navigation]. The Settings window appears.
4. Under [Notification area], select [Select which icons appear on the taskbar].
5. Set [Always show all icons in the notification area] to [Off], and set [License.Agent.Task-Tray] to [On].
6. Click the [×] button to close the window.

Display Properties

The procedure for setting the display properties is explained as follows.

1. Sign in using the user account for which to set display properties.
2. From the Start menu, display the Windows Settings window.
3. Click [Personalization].
4. Click [Themes], and on Apply a theme, select [Windows].
5. Click [Background], select [Solid color] from the Background drop-down list, and select a desired background color.
6. Click [Lock screen] > [Screen saver settings].
   The Screen Saver Settings dialog box appears.
7. From the Screen Saver drop-down list, select [(None)], and then click [OK].
8. Click the [×] button to close the window.

Stopping the Inactive Window Scrolling Function (Windows 10)

Stop the function to scroll the inactive windows with the mouse wheel as it can cause mal-functions.

Follow these steps to stop the inactive window scrolling function:

1. Sign in with the user account for which to disable scrolling of inactive windows.
2. Start the Windows Settings window.
3. Select [Devices].
   The rest of the operation differs depending on the OS.
   - If the OS is Windows 10 Enterprise 2016 LTSB, perform steps 4 through 6.
   - If the OS is Windows 10 Enterprise LTSC 2019, perform steps 7 through 9.
   - If the OS is Windows 10 Enterprise LTSC 2021, perform steps 10 through 12.

4. In the left pane, select [Mouse & touchpad].
   The Mouse page appears.

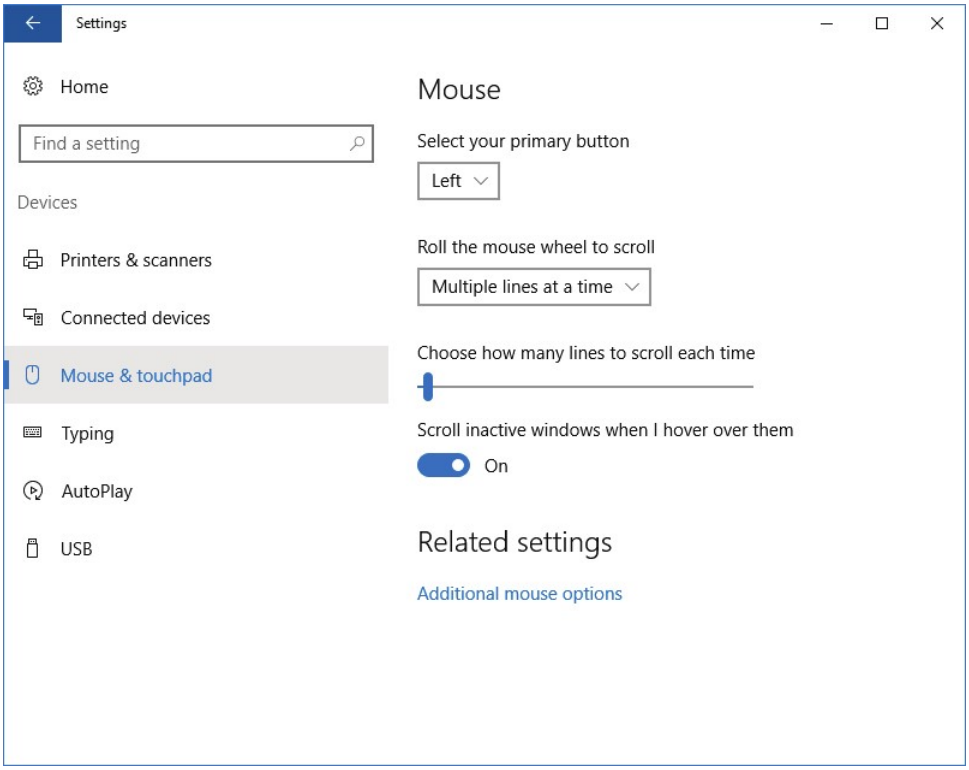

Figure B3.9.1-1 Mouse Page

5. Turn off [Scroll inactive windows when I hover over them].
6. Click the [×] button to close the window.
7. In the left pane, select [Mouse].
   The Mouse page appears.
8. Turn off [Scroll inactive windows when I hover over them].
9. Click the [×] button to close the window.
10. In the left pane, select [Mouse].
    The Mouse page appears.
11. Turn off [Scroll inactive windows when I hover over them].
12. Click the [×] button to close the window.

Stopping the Inactive Window Scrolling Function (Windows Server)

Stop the function to scroll the inactive windows with the mouse wheel as it can cause malfunctions.

Follow these steps to stop the inactive window scrolling function:

1. Sign in with the user account for which to disable scrolling of inactive windows.
2. Start the Windows Settings window.
3. Select [Devices].
   The rest of the operation differs depending on the OS.
   - If the OS is Windows Server 2016 or Windows Server 2019, perform steps 4 through 6.

- If the OS is Windows Server 2022, perform steps 7 through 9.

4. In the left pane, select [Mouse & touchpad].
   The Mouse page appears.

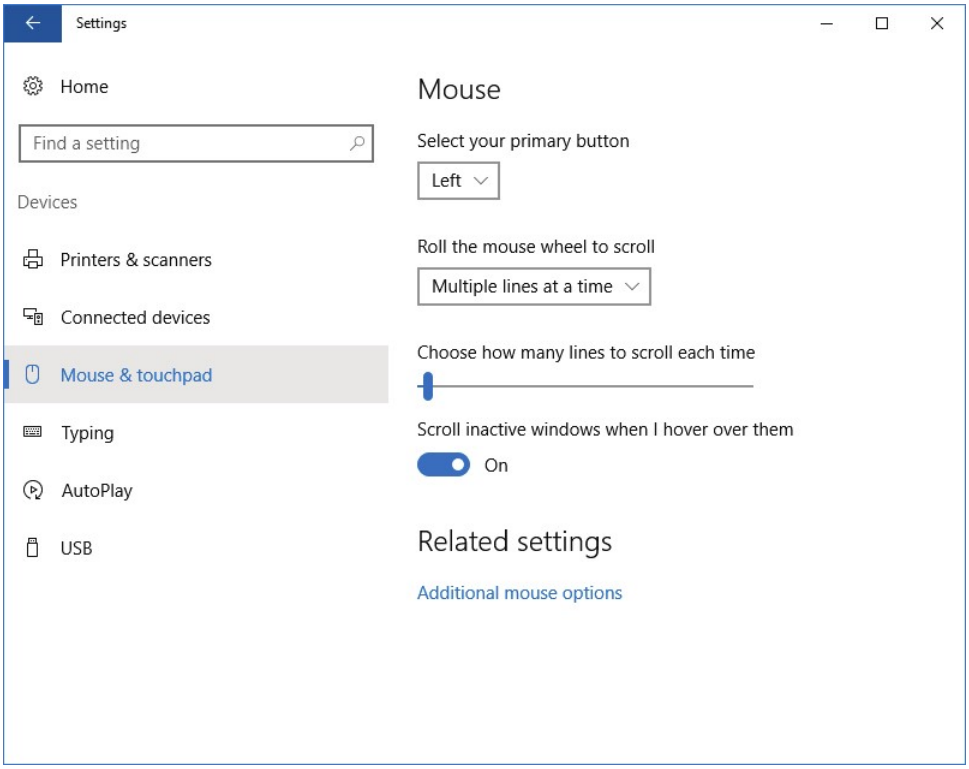

Figure B3.9.1-2 Mouse Page

5. Turn off [Scroll inactive windows when I hover over them].
6. Click the [×] button to close the window.
7. In the left pane, select [Mouse & touchpad].
   The Mouse page appears.
8. Turn off [Scroll inactive windows when I hover over them].
9. Click the [×] button to close the window.

B3.9.2 Setting of Items Specific to Windows 10

This section describes how to set the items specific to Windows 10.

Suppressing Toast Notifications Regarding Windows Firewall

If your OS is Windows 10 Enterprise 2016 LTSB and the IT security model is Legacy model, suppress toast notifications regarding Windows Firewall.

Follow these steps to suppress toast notifications:

TIP

This setting is not required if the OS is Windows 10 Enterprise LTSC 2019 or Windows 10 Enterprise LTSC 2021 and the IT security model is Legacy model.

1. Sign in as an administrative user.
2. Open Control Panel.
3. From the menu, select [System and Security] > [Windows Firewall].
   The Windows Firewall window appears.
4. In the left pane, click [Turn Windows Firewall on or off].
5. Select [Turn off Windows firewall] in the private network settings, public network settings, and domain network settings. However, you need to configure the domain network settings only in domain environments.
6. Click [OK].
7. Sign out and sign in again using the user account for which to turn off toast notifications regarding Windows Firewall.
8. Open Control Panel.
9. From the menu, select [System and Security] > [Security and Maintenance].
   The Security and Maintenance window appears.
10. On the left pane, click [Change Security and Maintenance settings].
11. Clear the [Network firewall] check box under Security messages.
12. Click [OK].

TIP

- If the [Network firewall] check box is grayed out, wait for a few minutes until it is enabled.
- If a toast notification [Turn on Windows firewall] appears, carry out the above procedure without clicking the toast notification.

Precautions when using Windows 10 Enterprise LTSC 2019 or Windows 10 Enterprise LTSC 2021

This section describes precautions when the OS is Windows 10 Enterprise LTSC 2019 or Windows 10 Enterprise LTSC 2021 and the IT security model is Legacy model.

- What to do when a toast notification regarding Windows Firewall appears
  If a toast notification appears, close it. If you click the toast notification to open the Settings window, close it without doing anything.

  You cannot enable or disable Windows Firewall in the Settings window that opens when you click the toast notification.
- How to check the firewall state
  In Legacy model, the firewall is disabled in a proper state. You can check the firewall state in the following ways.

On the left pane of the Local Group Policy Editor, open the properties of [Windows Defender Firewall with Advanced Security], the [Firewall state] is displayed as [Disabled].

Alternatively, in Control Panel, open [Windows Defender Firewall], and [Disabled] and [Some settings are managed by your system administrator] are displayed.

TIP

You can check the firewall state for the Standard model in the following ways.

On the left pane of the Local Group Policy Editor, open the properties of [Windows Defender Firewall with Advanced Security], the [Firewall state] is displayed as [Not Configured].

Alternatively, in Control Panel, open [Windows Defender Firewall], and [Enabled] is displayed.

B3.10 Configuring the Uninterruptible Power Supply (UPS) Service

You can install uninterruptible power supply (hereinafter referred to as UPS) software and make various settings to protect data in the computer at power supply failures.

UPS Software Setting

Specify the UPS battery operation time so that the computer can continue operation with the UPS battery without shutting down even if a power supply error (for example, power interruption) occurs for a short period of time. Use several seconds as a guideline for setting the UPS battery operation time.

TIP

Although the UPS battery operation time can be set longer than several seconds, the computer should be shut down at a power interruption of several seconds for safety reasons.

SEE ALSO

For more information about the UPS software that can coexist with ProSafe-RS, refer to:

"● Software that can coexist with ProSafe-RS" in "■ Software requirements for SENG" in A1.2, "Software requirements" in ProSafe-RS User's Guide (IM 32P01B10-01EN)

B4. Configuring the Functions Specific to SENG

This section describes how to configure the following settings for the functions specific to SENG.

- Setting the manual browsing environment
- Settings of Project Database Folder
- Settings for Message Cache Tool
- Settings Required for OPC Communication
- Setup when Using the Access Control and Operation History Management Package

B4.1 Setting the Manual Browsing Environment

Configure Adobe Acrobat Reader to view the online manuals and the Help files for PROFINET Configurator.

Adobe Acrobat Reader Settings

In the Adobe Acrobat Reader settings, make sure that the [Open cross-document links in same window] check box is selected.

- The [Open cross-document links in same window] check box can be displayed by selecting [Preferences] - [Documents] from the [Edit] menu of Adobe Acrobat Reader. You must set this setting for each logon user.

Copying the Help Files for PROFINET Configurator

The Help files for PROFINET Configurator are stored in the software medium of ProSafe-RS. As the Help files are not installed automatically on the computer, copy them from the software medium as necessary.

- Stored location

  `<Media drive of ProSafe-RS>:\ProSafe-RS\PDFFILE\PROFINET_Configurator\en\`

- Help files

  `SYCONnet netFrame YOKOGAWA S2LP131.pdf`

  `SYCONnet netDevice YOKOGAWA S2LP131.pdf`

  `PROFINET IO Controller YOKOGAWA S2LP131 DTM.pdf`

  `YOKOGAWA PROFINET IO Generic Device DTM.pdf`

B4.2 Settings of Project Database Folder

This section explains the procedure for strengthening the security of project databases.

Strengthening the Security of the Project Database on SENG PC

When ProSafe-RS software is installed, `C:\RS-Projects` folder is automatically created as the default location for saving project data. By running the IT Security Tool after the installation, security reinforcement is done for this default folder.

Shown below is the procedure for reinforcing security when you place the project database in a location other than the default folder on an SENG PC and have it shared with other computers.

1. Create a new folder for storing project data.
2. Log on as an administrative user belonging to the PSF_MAINTENANCE group and assign the share name RS-Projects to a folder to which the project database is to be stored.
3. Grant full control access permissions to Everyone.
4. Launch the IT Security Tool from the Start menu and configure security settings without changing the security model and user management type.

Strengthening the Security of Version Control Tool's Check-in Folder

If you place the Version Control Tool's check-in folder on an SENG PC, follow these steps to strengthen the security of the folder.

1. Create a new folder for use as the check-in folder of Version Control Tool.
2. Log on as an administrative user belonging to the PSF_MAINTENANCE group and assign the share name RS-Share to the check-in folder.
3. If the folder should be shared with other computers, grant full control access permissions to Everyone.
4. Launch the IT Security Tool from the Start menu and configure security settings without changing the security model and user management type.

B4.3 Settings for Message Cache Tool

If you want to check the status of data collection by other stations using the Message Cache Tool, the following setups are required.

On Workgroup Member Computers

1. Create a user account on the station whose status of data collection shall be checked. The user account name and password should be the same as the user account of the computer that uses the Message Cache Tool.
2. Make the created user account created in step 1 belong to the PSF_ENGINEER user group.

On Windows Domain Member Computers

Register users of the Message Cache Tool to the PSF_ENGINEER user group.

B4.4 Settings Required to Use the Forced I/O Viewer Function

To use the Forced I/O Viewer function, settings must be made on the computer where SCS projects are saved and the computer to which to distribute SCS projects.

Setting on the Computer where SCS Projects are Saved

The Forced I/O Viewer Setup Tool acquires the SCS projects to be distributed to Forced I/O Viewer from the computer in which the SCS projects are stored.

Follow these steps to set up the computer where SCS projects are saved:

1. Assign the share name RS-Projects to the upper folder of the RS project folder that contains the SCS projects.
   If the share name RS-Projects is assigned already, no setting is required.
2. Create a user account with the same user name and password as the user account that uses the Forced I/O Viewer Setup Tool. If the IT security model is the Standard model, add the created user account to the PSF_ENGINEER or PSF_MAINTENANCE group.

SEE ALSO For more information about how to assign the share name RS-Projects, refer to:

"■ Strengthening the Security of the Project Database on SENG PC" on page B4-3

Settings on the Computer to which to Distribute SCS Projects

Follow these steps to set up the computers to which to distribute SCS projects, such as a computer where Forced I/O Viewer will be used and SENG that shares the registration file:

1. Assign the share name RS-ForcedIO to the following folder:
   `<ProSafe-RS installation drive>:\Program Files (x86)\ProSafe-RS\YOKOGAWA\hmi\ForcedIO`
2. In the Share Permission of the share name RS-ForcedIO, grant full control access permissions to Everyone.

IMPORTANT

The share name is "RS-ForcedIO" with "RS-" added to the beginning of the folder name. It is different from the folder name.

3. Create a user account with the same user name and password as the user account that uses the Forced I/O Viewer Setup Tool. If the IT security model is the Standard model, add the created user account to the PSF_ENGINEER or PSF_MAINTENANCE group.
4. If the IT security model is the Standard model, add the user account that uses the Forced I/O Viewer to the PSF_OPERATOR group.

B4.5 Settings Required for OPC Communication

This section describes how to make settings required to perform OPC communication when the Standard model of IT security settings are selected on an SENG PC running the SOE OPC Interface Package. If the Standard model of security settings is applied, access to DCOM will be set. By this setting, only users belonging to ProSafe-RS user groups can access the SOE OPC interface.

Setting when Using Packages Performing OPC Communication with SENG PC

When you are using packages (OPC clients) that perform OPC communication with SENG PC (OPC servers), you must make the setting explained here.

In the Case of Standalone Management or When Combination Management is Applied on Some Computers

Perform the following procedure on an SENG PC performing OPC communication.

1. Create a program user of the OPC client package. Set the same user name and password as those on the client computer.
2. Make the created program user belong to the PSF_OPC user group.

In the Case of Domain Management or When Combination Management is Applied on All Computers

- In the case of package that can join the domain
  1. Make a computer that runs the OPC client package join the domain.
  2. Register the package program user to the domain and make it belong to the PSF_OPC user group.
- In the case of package that cannot join the domain
  Perform the following procedure on the SENG PC performing OPC communication.
  1. Create a program user of the OPC client package. Set the same user name and password as those on the computer running the package.
  2. Make the created program user belong to the PSF_OPC_LCL user group.

SEE ALSO

For more information about the settings for a computer where the SOE OPC Interface Package and CENTUM VP ExaOPC Interface Package coexist, refer to:

D1.1.4, “CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS SOE OPC Interface Package” on page D1-8

For more information about the settings for using Exaquantum as an OPC client, refer to:

D1.4.1, “ProSafe-RS SOE OPC Interface Package and Exaquantum PIMS Server” on page D1-27

In the Case of Linked Domain Management

- In the case of package that can join the domain
  1. Make a computer that runs the OPC client package join the domain.
  2. Register the package program user to the domain and make it belong to the PSF_OPC user group.
- In the case of package that cannot join the domain

Perform the following procedure on the SENG PC performing OPC communication.

1. Create a program user of the OPC client package. Set the same user name and password as those on the computer running the package.
2. Make the created program user belong to the PSF_OPC user group.

B4.6 Setup when Using the Access Control and Operation History Management Package

In ProSafe-RS R3.01 or later, it is possible to manage operation histories on SENG by using the Access Control and Operation History Management Package. This section describes the operations required to use this package.

SEE ALSO For more information about the precautions to be followed when setting the access control/operation history management function, refer to:

E., “Access Control/Operation History Management functions” in Engineer's Reference Manual (IM 32P04B10-01EN)

Windows User Groups to which Administrators and Engineers Belong

There are two types of personnel in a system where the access control and operation history management is applied: “administrators of access control and operation history management” (hereinafter referred to as “administrator” in this section) and “engineers.”

After creating user accounts for administrators and engineers, add them to the Windows user groups shown in the following table.

Table B4.6-1 Windows User Groups to which Administrators and Engineers Must Belong

Personnel	Windows user group to belong to	
	Standard or Strengthened model	Legacy model
Administrator	Either of the following: PSF_MAINTENANCE (*1) PSF_MAINTENANCE_LCL (*1)	Group with administrator privilege
Engineer	One of the following: PSF_OPERATOR PSF_ENGINEER PSF_OPERATOR_LCL PSF_ENGINEER_LCL	Any group

*1: Users belonging to these groups must also have the Windows administrator privileges. Make them also belong to the Administrators or Domain Admins group.

Security Model and User Authentication Mode

If you select the Standard model with the IT Security Tool, you can select either ProSafe authentication mode or Windows authentication mode as the user authentication mode of the operation history management function on SENG. By default, ProSafe authentication mode is selected.

If you select the Legacy model with the IT Security Tool, only ProSafe authentication mode is available.

You can configure user authentication modes by using the operation history management setting tool included in the Access Control and Operation History Management Package.

SEE ALSO For more information about security models, refer to:

2., “Security Models” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Creating User Accounts in Windows Authentication Mode

In Windows authentication mode, Windows user names are used to log on to the SENG functions and authenticate users.

IMPORTANT

When you use Windows authentication mode, create Windows users following the naming convention below, rather than the Windows naming convention. This naming convention is the same as the naming convention for engineers.

The naming convention for users in Windows authentication mode is as follows:

Table B4.6-2 User Naming Convention in Windows Authentication Mode

Number of characters	Up to 16 characters
Character type	Alphanumeric characters and the following symbols can be used: ! # $ % ( ) - . ^ _ { } ~ Double-byte characters cannot be used.
Restriction	Upper-case characters only (*1) For the head character, alphanumeric characters and the following symbols can be used: ^ _ { } ~ Names ending with a period cannot be used.

*1: Only upper-case characters can be used for engineer names to be registered in the Engineers' Account Builder. Although both upper-case and lower-case characters can be used on the Windows side, they are not distinguished; use upper-case characters only.

You can set passwords within 63 characters using alphanumeric characters and symbols.

- Passwords are case-sensitive.
- The following symbols and space character are allowed:
  ! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [\ ] ^ _ { | } ~

SEE ALSO For more information about how to create Windows user accounts, refer to:

B3.8, "Creating User Accounts" on page B3-56

B4.6.1 Setup Procedure when Using Access Control and Operation History Management Functions

This section describes the setup procedure you should perform after installing the ProSafe-RS software when using the operation history management functions. If you want to introduce the access control and operation history management functions later, perform the procedure at a proper timing.

Perform the following tasks after creating administrator and engineer user accounts on Windows.

1. Add the Windows accounts for administrators and engineers to their respective appropriate user groups.
2. Configure security settings for the operation history database.
3. On a computer granted with the licenses of the Safety System Engineering and Maintenance Function and the Access Control and Operation History Management Package, use the Operation History Management Setup Tool and Engineers' Account Builder to perform required setting.

SEE ALSO

For more information about how to create Windows user accounts, refer to:

B3.8, "Creating User Accounts" on page B3-56

For more information about the explanation of the procedure involved in making security settings for operation history management databases, refer to:

B4.6.2, "Security Settings for the Operation History Database" on page B4-11

For more information about the precautions to be followed when setting the access control/operation history management function, refer to:

E2.2, "Setting up Access Control/Operation History Management" in Engineer's Reference Manual (IM 32P04B10-01EN)

B4.6.2 Security Settings for the Operation History Database

The administrator must specify the folder for storing the operation history database by using the operation history management setting tool. Set the security of the folder for storing the operation history database at proper timing before starting to use the operation history management function.

This section explains the procedures to configure security settings when the operation history database is placed on an SENG PC and when it is placed on a file server. After performing these procedures, the administrator and engineers can access the operation history database folder.

Setting when Operation History Databases are Placed on SENG PC

If you place an operation history database on an SENG PC, perform the following procedure to reinforce the security of the folder for storing the operation history database.

1. Create a new folder for storing the operation history database.
2. Log on to the system as an administrative user who belongs to the PSF_MAINTENANCE group and assign the sharing name “RS-Share” to the folder for storing the operation history database.
3. If the folder needs to be shared with other computers, grant a full control permission to Everyone.
4. Launch the IT Security Tool from the Start menu and execute it again without changing the setting made the last time it was executed.

Setting when Operation History Databases are Placed on a File Server

If you place an operation history database on a computer not installed with the ProSafe-RS software and allow SENG to access the database via a network, perform the procedure to reinforce security of the file server.

SEE ALSO For more information about the procedure for reinforcing the security of the file server, refer to:

B5., “Setting Up a File Server” on page B5-1

B5. Setting Up a File Server

By setting up a file server, you can access the files placed on this server computer from other computers. On a file server, you may place a project database, the check-in destination folder for Version Control Tool, and/or the operation history database of the Access Control and Operation History Management Package, which you can access and operate through the network.

This section describes how to set up a file server computer for the following cases:

- Computer that serves only as a file server
- Computer that serves as both a file server and an SENG
- Computer that serves as both a file server and a license management station

IMPORTANT

- The initial password is set by default for the predefined user accounts in this product. Be sure to change the password because operating with the initial password may increase the security risk.
- When changing the password, ensure that the same password is set in the entire system.

SEE ALSO For more information about user accounts that require password change, refer to:

2.2.3, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Item to be Prepared

Have the following item at hand before you set up a file server.

- ProSafe-RS software medium

File System

Ensure that the file system is in the NTFS format.

B5.1 Setting Up a Computer that Serves Only as a File Server

This section describes how to set up a computer that is used only as a file server.

IMPORTANT

- When sharing a file server between CENTUM VP and ProSafe-RS and operating with other than linked domain management, use the IT Security Tool for file server and domain controller whose revisions are R6.04 or later to set IT security for CENTUM VP.
- When sharing a file server between CENTUM VP and ProSafe-RS and operating with linked domain management, you must build a file server between the products of revisions that support linked domain management. Use the IT Security Tool for file server and domain controller of the product of revisions that support linked domain management and the Domain Link Management Tool for File Server. CENTUM VP supports linked domain management with R6.08 or later software revisions.
- When sharing a file server with a product that does not support linked domain management and using it in a domain environment, operate with domain management or combination management.

Installing Windows Update Programs

Download and apply the Windows update programs for your Windows OS.

SEE ALSO For more information about downloading the Windows Server 2022 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2022)" on page B1-5

For more information about downloading the Windows Server 2019 update programs , refer to:

"■ Downloading the Windows Update Programs (Windows Server 2019)" on page B1-6

For more information about downloading the Windows Server 2016 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2016)" on page B1-6

Disabling the Automatic Cleanup Task

When using Windows Server as a file server, disable Automatic cleanup task.

SEE ALSO For more information about the procedure for disabling the Automatic cleanup task, refer to:

"■ Disabling the Automatic Cleanup Task" on page B3-15

Administrative User who Performs the Setup

A file server must be set up by an administrative user who belongs to the groups shown in the following table.

Table B5.1-1 Groups to Which the Administrative User Who Sets Up a File Server Belongs

Security model and user management type to be applied		
Legacy model	Standard model	
	Standalone management/Linked domain management	Domain/Combination management
Local user who belongs to the Administrators local group	Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group • Domain user who belongs to the Administrators local group and PSF_MAINTENANCE local group • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1)

*1: The domain user name and password must be entered during installation.

TIP

If the user management type is Domain or Combination management, install the software after the computer is added to the domain.

■ Procedure 0: Procedure for Placing an SCS Project on Another PC Such as a File Server

If an SCS project is newly placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When you are going to place an SCS project on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO

For more information about avoidance, refer to:

"■ Precautions when Placing the SCS Project on Another PC such as a File Server" in 1.2, "Engineering" in ProSafe-RS Release Information (IM 32P01A50-01EN)

■ Procedure 1: Install Microsoft Visual C++ 2017 Redistributable Package

Before you can run the IT Security Tool, you must install the Microsoft Visual C++ 2017 redistributable package.

SEE ALSO

For more information about the procedure for installing the Microsoft Visual C++ 2017 redistributable package, refer to:

"■ Installation of Microsoft Visual C++ 2017 Redistributable Package" on page B2-6

■ Procedure 2: Create an Administrative User

Perform one of the following procedures according to the security model to be applied.

TIP

In the case of the Legacy model, this operation is not required because the setup can be performed by an existing user.

● Standard Model with Standalone Management/Linked Domain Management

1. Log on as a member of the Administrators group.
2. Create the PSF_MAINTENANCE group.

3. Add the user to be set as the administrator to the Administrators and PSF_MAINTENANCE groups.

TIP

If any other YOKOGAWA product coexists in the computer, the user also needs to be a member of the MAINTENANCE group of the coexisting product. For example, if CENTUM VP coexists, also add the user to the CTM_MAINTENANCE group.

Standard Model with Domain/Combination Management

Follow these steps to designate a local group user as an administrator:

TIP

To use a domain group user as an administrative user, this operation is not required because the user already exists.

1. Log on to Windows as a user with administrative rights.
2. Create the PSF_MAINTENANCE local group.
3. Add the domain user or local user to be set as the administrator to the Administrators local group and PSF_MAINTENANCE local group.

TIP

- After the IT Security Tool is run, the name of the PSF_MAINTENANCE group you have created will change to PSF_MAINTENANCE_LCL.
- If any other product coexists in the computer, the user also needs to be a member of the MAINTENANCE group of the coexisting product. For example, if CENTUM VP coexists, also add the user to the CTM_MAINTENANCE group.

Procedure 3: Create and Set Up Shared Folders

In order to reinforce the security of folders that store databases using the IT Security Tool, you must name the target folders with the following share names:

- Project database
  Share name: RS-Projects
- Operation history database and check-in destination folder of Version Control Tool
  Share name: RS-Share

IMPORTANT

If the share name does not match the name above, the IT Security Tool is not able to reinforce the folder security. Be sure to set the share name above using the following procedure so that you can reinforce security.

Creating a New Folder

1. Log on as an administrative user.
2. Start Windows Explorer and create a folder in which the project folders are to be placed.
3. On the Sharing tab in the properties of the folder that is created, click [Advanced Sharing].
4. Select [Share this folder] and set `RS-Projects` or `RS-Share` as the share name.
5. Click [Permissions], and grant full control to [Everyone] in the Share Permissions tab. This access permission setting will be changed when you run the IT Security Tool.

When a Shared Folder is Already Created on the File Server

Before configuring IT security settings, add a share name, “RS-Projects” or “RS-Share,” to the folder. The folder will be included in the process of IT security setting configuration and access permissions setting will be applied. Share names that were previously set up do not need to be deleted.

IMPORTANT

If a folder with the share name “RS-Projects” or “RS-Share” has already been created for another purpose on an existing file server, change the existing share name to another name. Since the access permissions are granted to folders with the share name “RS-Projects” or “RS-Share” during configuration of IT security settings, unintended settings will be applied if these share names are not assigned to appropriate folders.

If IT security settings have been applied to an unintended folder, delete the permissions set during the configuration of IT security settings and set the original access permissions based on the setting of another folder, such as the `C:\Windows` folder.

Procedure 4: Save the Initial Data of the IT Security Settings

IMPORTANT

- Before you run the IT Security Tool to configure IT security settings for the first time, be sure to save the security settings on the computer.
- On a file server, when changing the IT security settings, you need to use the initial data saved beforehand to restore the security settings, and then apply them again. Therefore, the following saved data of IT security settings is required.
  - When the user management type is standalone management or linked domain management in Standard model:
    Data saved before the first application of IT security settings in the standalone state
  - When the user management type is Domain management or Combination management in Standard model:
    Data saved before applying IT security settings after adding to the domain
- When configuring the security settings for the second time onward, basically the security settings need not be saved. However, to configure the security settings by using the IT Security Tool of R3.01 to R4.02 and change the IT security version to 2.0 by using the IT Security Tool of R4.03 or later, save the initial security setting data again.
- To save the initial security setting data again, restore the security settings that were saved before by using the IT Security Tool. If the file server is a member of the domain, determine which of the two sets of initial data will be recovered based on whether or not to keep the file server as the member of the domain. Then, perform this procedure to save the security settings. From then on, the data you have saved again will be used when the security settings are initialized; accordingly, keep the saved data in a safe place.

Follow these steps to save the security settings:

1. Log on as an administrative user.
2. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].

- If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the software medium.

The installation menu appears.

3. Click [Setting IT Security (File server/domain controller use)].
   The IT Security Tool starts.

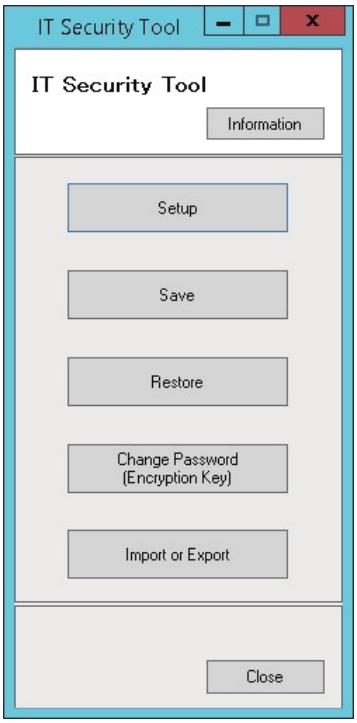

Figure B5.1-1 IT Security Tool Menu

TIP

If the file server is a member of a domain, when restoring the initial security settings on the file server, the initial data should have two types, either the initial data for a standalone computer or the initial data for a member of domain.

If you do not have the initial data for a standalone file server computer, you need to remove the file server from the domain temporarily and then save the security settings as the initial data for the standalone computer.

4. Click [Save].
   The Specify destination page appears.
5. Specify the destination folder and enter following setting items.
   - Distinguished Name
   - Support Product
   - Support OS
   - File Version

TIP

The [Distinguished Name] and [File Version] are omissible.

6. Click [Next].
   The Type default account password page appears.
7. Enter the password for use as the initial account password and click [Next].
   The Type password (Encryption Key) page appears.

TIP

This initial password will be set when the account saved with this tool is recovered. If the saved accounts are not found on the computer when you recover the accounts, new accounts are created. This password will be set as the initial password for the newly created account.

Even when multiple accounts have been created, the same initial password is assigned to all.

If the set password does not meet the password policy in the environment where the account is to be recovered, an error will occur when recovering an account.

This password is set as the initial password for the account. Accordingly, you will be prompted to change the password when you log on for the first time using this account.

8. Enter the password for encrypting the saved data, and click [Next].
   Saving of the security settings starts.

IMPORTANT

- If this password (encryption key) is lost, the saved security settings cannot be restored. The password (encryption key) must be carefully kept by the customer.
- The password (encryption key) must be at least one character.
- The password can consist of upper-case and lower-case alphanumeric characters and the following symbols: ` ~ ! @ # $ % ^ & * ( ) _ + - = { } | \ : " ; ' < > ? , . /
  Double-byte characters cannot be used.

9. When the saving is completed, click [Finish].
   If the saving failed, the details of the failure are displayed.
10. On the IT Security Tool menu, click [Close].

TIP

If any save failures are displayed, contact YOKOGAWA Service.

Procedure 5: Configure with IT Security Tool

IMPORTANT

If you operate with linked domain management, do not add the computer to the domain before you configure the settings with IT Security Tool.

Follow these steps to configure the file server with IT Security Tool:

1. From the IT Security Tool Menu, click [Setup].
   A confirmation dialog box appears
2. If you have saved the above mentioned initial security setting data, click [OK].

TIP

If you have not saved the initial security setting data, click [Cancel] to return to the tool's menu and save the security settings.

The Select Security Model page appears.

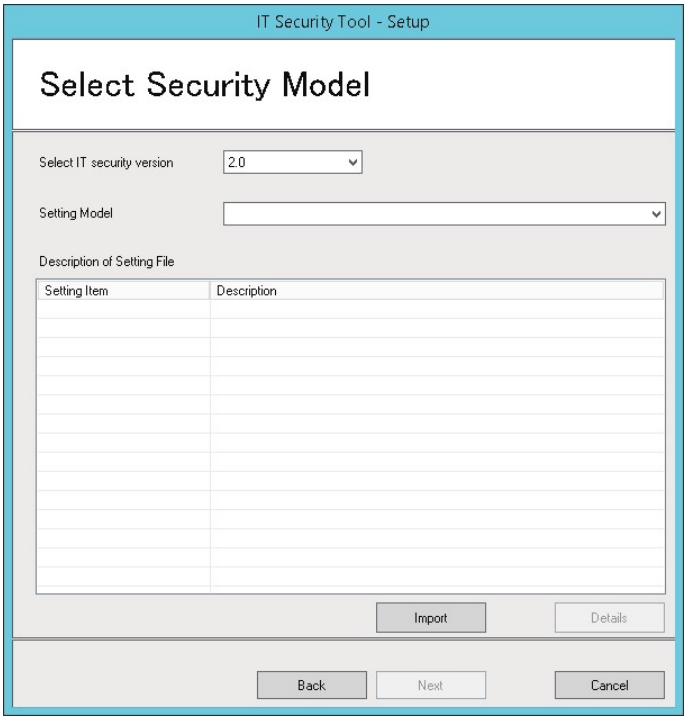

Figure B5.1-2 Select Security Model

3. From the Select IT security version drop-down list, select the IT security version.
4. From the Setting Model drop-down list, select a security model for the file server.
   You can select from the following four models:

Table B5.1-2 Security Models for a File Server

Model	Description
File Server Legacy Model (*1)	Select this model to apply Legacy model to the file server, regardless of the user management type.
File Server Standard Model with Standalone Management	Select this model to apply Standard model to the file server when the user management type is Standalone management or Linked domain management.
File Server Standard Model with Domain Management	Select this model to apply Standard model to the file server when the user management type is Domain management.
File Server Standard Model with Combination Management	Select this model to apply Standard model to the file server when the user management type is Combination management.

*1: If you select [2.0] for Select IT security version, you cannot select the file server legacy model.

5. Click [Next].
   The Confirm Setting Information page appears.

TIP

If you click [Detail] here, the Select Setting Items page appears.

6. The subsequent steps are the same as those for the settings with IT Security Tool after installing the ProSafe-RS software.

TIP

If the file server is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP software medium and set IT security for CENTUM VP as well. Use the software medium of the following revisions depending on the user management type.

- Linked domain management: R6.08 or later
- Other than Linked domain management: R6.04 or later

SEE ALSO

For more information about operation of IT Security Tool after the ProSafe-RS software is installed, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about the procedure for importing the IT security settings, refer to:

6.8, “Exporting/Importing the IT Security Setting File” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Procedure 6: Create Accounts on the File Server for Users who Access Project Data

On the file server computer, create accounts for users who access the project data, according to the selected security model and user management type.

● Standard Model with Linked Domain Management/Combination Management

When you create accounts of local users who access project data, create them in the same way as for “● Legacy/Standard Model with Standalone Management.”

On the domain controller, add the accounts for accessing projects. No account needs to be created if already created.

SEE ALSO

For more information about how to create domain user accounts, refer to:

B2.4, “Creating Domain Users” on page B2-13

● Standard Model with Domain Management

On the domain controller, add the accounts for accessing projects. No account needs to be created if already created.

● Legacy/Standard Model with Standalone Management

Perform the following procedure on the file server.

1. Create a user account.
   The user name and the password must be the same as those of the SENG PCs from which the projects are accessed.
2. Register the user you have created to the same group as that on the SENG PCs which access the file server.

TIP

If the Standard model is applied, the following user groups have been created during the procedures so far.

- PSF_MAINTENANCE
- PSF_OPERATOR
- PSF_ENGINEER
- PSF_OPC

Procedure 7: Configure Settings for Operating with Linked Domain Management

When operating with linked domain management, join the computer to the domain and then configure settings using Domain Link Management Tool for File Server.

IMPORTANT

The Domain Link Management Tool for File Server in the ProSafe-RS software medium links/unlinks the domain only for the local group related to ProSafe-RS. If the file server is shared by CENTUM VP and ProSafe-RS, use the Domain Link Management Tool for File Server in the software medium of each product to set each.

Follow these steps to configure settings for operation with linked domain management:

1. Join the computer to the domain.
2. Sign in as a local user who belongs to both the Administrators group and PSF_MAINTENANCE group of the local computer, or a domain user who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain.
3. Use Windows Explorer to open the following folder in the ProSafe-RS installation medium.
   `<Drive of ProSafe-RS software medium>:\ProSafe-RS\SECURITY\`
4. In the folder, double-click `DomainLinkManagementToolForRSFileServer.cmd`.
   The Domain Link Management Tool for File Server starts.
5. The subsequent steps are the same as those for the settings with Domain Link Management Tool after installing the ProSafe-RS software.

TIP

- If you start the Domain Link Management Tool as an administrative user of a local group, the domain user authentication dialog box appears in the procedure for linking the domain. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.
- If the file server is shared with CENTUM VP, use the Domain Link Management Tool for File Server in the software medium of CENTUM VP to configure the settings to link the domain for CENTUM VP as well.

SEE ALSO

For more information about the settings with Domain Link Management Tool after the ProSafe-RS software is installed., refer to:

B3.6.3, “Running Domain Link Management Tool” on page B3-52

Error Messages and Countermeasures

Depending on the conditions when starting Domain Link Management Tool for File Server, an error message may be displayed and the tool cannot be started. Take the necessary measures.

The following table describes the error messages and countermeasures when you cannot start Domain Link Management Tool for File Server.

Table B5.1-3 Error messages and countermeasures

Error messages	Countermeasures
This tool cannot be started simultaneously with the IT security tool.	Exit the IT Security Tool.

Continues on the next page

Table B5.1-3 Error messages and countermeasures (Table continued)

This tool does not support computers without the IT security settings for the file server of R4.06.00 or later.	For a file server dedicated computer, set the IT security for the file server of R4.06.00 or later, and then start Domain Link Management Tool for File Server.
	For computers with ProSafe-RS software or license management software installed, start Domain Link Management Tool from the Start menu.

Procedure 8: Create the Project Folder on the File Server and Start the Operation

- Project database
  From an SENG PC, create an RS project under the shared folder “RS-Projects” created in Procedure 3.
- Check-in folder of Version Control Tool
  On an SENG PC, use the Version Control Tool to specify a folder under the shared folder “RS-Share” created in Procedure 3 as the check-in destination folder, and start project operation.
- Operation history database
  On an SENG PC, use the operation history management setting tool to specify a folder under the shared folder “RS-Share” created in Procedure 3 as the top folder of the operation history database, and start the access control and operation history management function.

B5.2 Setting Up the File Server Function on an SENG or a Computer Installed with Only AD Server

This section describes the required settings when you use a computer that has been set up as an SENG or installed with only AD Server, also as a file server.

TIP

On an SENG, the project database is created under the installation folder by default. The procedure described in this section is for the case when the project database is placed in a location other than the installation folder.

1. Set up the computer as an SENG or as a computer installed with only AD Server.

TIP

- If the user management type of IT security setting is domain or combination management, set up after the computer is added to the domain.
- You do not need to configure IT security settings during this setup.

2. If an SCS project is newly placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When you are going to place an SCS project on a file server, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.
3. On the computer, create and set up the shared folder.
4. Start the IT Security Tool from the Start menu and configure IT security settings.

TIP

When operating with linked domain management, set the standalone management in the Standard model.

5. Select one of the following depending on the user management type.
   - Go to the step 6 to operate with linked domain management.
   - Go to the step 8 to operate with user management type other than linked domain management.
6. Join the computer to the domain.
7. Start Domain Link Management Tool from the Start menu and link the domain.
8. Create a project folder in a location under the shared folder of the computer.

IMPORTANT

When you set up the file server function on an SENG or a computer with only AD Server installed, you must use the IT Security Tool and Domain Link Management Tool that are started from the Start menu.

SEE ALSO

For more information about how to create the project folder on the file server, refer to:

"■ Procedure 8: Create the Project Folder on the File Server and Start the Operation" on page B5-11

For more information about new setup of SENG, refer to:

B3., "Setup of an SENG or a Computer Installed with Only AD Server" on page B3-1

For more information about the shared folder settings, refer to:

"■ Procedure 3: Create and Set Up Shared Folders" on page B5-4

For more information about creating accounts for users who access the project database, refer to:

"■ Procedure 6: Create Accounts on the File Server for Users who Access Project Data" on page B5-9

For more information about avoidance against file corruption in the SCS project database, refer to:

"■ Precautions when Placing the SCS Project on Another PC such as a File Server" in 1.2, "Engineering" in ProSafe-RS Release Information (IM 32P01A50-01EN)

B5.3 Setting Up the Computer that Serves as Both File Server and License Management Station

This section describes the setup required for the computer that serves as both a file server and a license management station.

Setup Procedure

1. Install the license management software.

TIP

If the user management type of IT security setting is domain or combination management, set up after the computer is added to the domain.

2. If an SCS project is newly placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When you are going to place an SCS project on a file server, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.
3. On the dialog box that appears on completion of the installation, select [No, I want to install other software products.] and click [Finish].
4. Configure the shared folder settings required for a file server.
5. Start the IT Security Tool from the Start menu and configure IT security settings.

TIP

When operating with linked domain management, set the standalone management in the Standard model.

6. Select one of the following depending on the user management type.
   - Go to the step 7 to operate with linked domain management.
   - The steps are completed if you operate with user management type other than linked domain management.
7. Join the computer to the domain.
8. Start Domain Link Management Tool from the Start menu and link the domain.

IMPORTANT

When you configure a computer for use as both a file server and a license management station, you must use the IT Security Tool and Domain Link Management Tool that are started from the Start menu.

SEE ALSO

For more information about installing only the license management software, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

For more information about the shared folder settings, refer to:

“■ Procedure 3: Create and Set Up Shared Folders” on page B5-4

For more information about avoidance against file corruption in the SCS project database, refer to:

“■ Precautions when Placing the SCS Project on Another PC such as a File Server” in 1.2, “Engineering” in ProSafe-RS Release Information (IM 32P01A50-01EN)

B6. Setting Up the Computer Dedicated to License Management

You can use a computer as the license management station by installing only the license management software on it.

This section describes the procedure for setting up the computer dedicated to license management.

Items to be Prepared

Have the following item at hand before installing the license management software.

- ProSafe-RS software medium

Installing Windows Update Programs

Download and apply the Windows update programs for your Windows OS.

SEE ALSO

For more information about downloading the Windows 10 Enterprise LTSC 2021 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2021)" on page B1-4

For more information about downloading the Windows 10 Enterprise LTSC 2019 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise LTSC 2019)" on page B1-5

For more information about downloading the Windows 10 Enterprise 2016 LTSB update programs, refer to:

"■ Downloading the Windows Update Programs (Windows 10 Enterprise 2016 LTSB)" on page B1-5

For more information about downloading the Windows Server 2022 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2022)" on page B1-5

For more information about downloading the Windows Server 2019 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2019)" on page B1-6

For more information about downloading the Windows Server 2016 update programs, refer to:

"■ Downloading the Windows Update Programs (Windows Server 2016)" on page B1-6

Administrative User who Performs the Installation

The administrative users shown in the following table should install the license management software:

IMPORTANT

- The initial password is set by default for the predefined user accounts in this product. Be sure to change the password because operating with the initial password may increase the security risk.
- When changing the password, ensure that the same password is set in the entire system.

Table B6-1 Administrative User Who Installs the License Management Software

Security model and user management type to be applied		
Legacy Model	Standard Model	
	Standalone management/Linked domain management	Domain/Combination Management
Local user who belongs to the Administrators local group	Local user who belongs to the Administrators local group	• Domain user who belongs to the Domain Admins domain group • Domain user who belongs to the Administrators local group • Local user who belongs to the Administrators local group(*1)

*1: The domain user name and password must be entered during installation.

TIP

If the user management type is Domain or Combination management, install the software after the computer is added to the domain.

SEE ALSO

For more information about user accounts that require password change, refer to:

2.2.3, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Setting Up a License Management Station

This section describes the procedure for setting up a license management station.

Set Up Windows

The following table shows the Windows setting items. Configure the items that are required for the OS being used.

Table B6-2 Windows Setting Items

Windows setting item	Windows OS (*1)	
	Windows 10	Windows Server 2016, Windows Server 2019, Windows Server 2022
File System	Yes	Yes
Power Options	Yes	Yes
Turning Off Fast Startup	Yes	-
Windows Defender	Yes	Yes
Disk Defragmenter	Yes	Yes
DCOM Settings	Yes	Yes

*1: Yes: Configuration required; -: Not available on the OS.

SEE ALSO

For more information about setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

Install the License Management Software

Follow these steps to install the license management software.

1. Sign in as an administrative user.
2. Insert the ProSafe-RS software medium into the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].

- If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the ProSafe-RS software medium.

The installation menu appears.

3. Click [Install License Manager Software].
   The Welcome dialog box appears.

TIP

If the Windows redistributable modules required to run ProSafe-RS are not installed, a dialog box appears, prompting you to install such modules. Follow the instruction of the dialog box.

4. Click [Next].
   The User Information dialog box appears.

TIP

If a different version of control bus driver is already installed, a dialog box appears, prompting you to update the driver. However, you do not need to install the control bus driver on a computer dedicated to license management. Click [OK] to close the dialog box.

5. In the User Information dialog box, enter the name and company name, select the installation folder, and confirm the language for installation, and click [Next].
   The Confirm Settings dialog box appears.
6. Review the installation settings and click [Install].
   A dialog box showing the installation progress appears, and when the license management software installation is complete, the Installation Complete dialog box appears.
7. Select [Yes, I want to set up IT security now.] and click [Finish].
   The IT Security Tool starts.
8. Go on to configure the security settings.

TIP

- When deleting the ProSafe-RS function and installing only the license management software after installing ProSafe-RS, first sign in using an administrative user account and uninstall ProSafe-RS, and then install the license management software.
- When operating with linked domain management, set the standalone management in the Standard model.

9. Select one of the following depending on the user management type.
   - Go to the step 10 to operate with linked domain management.
   - The steps are completed if you operate with user management type other than linked domain management.
10. Join the computer to the domain.
11. Sign in as an administrative user, start Domain Link Management Tool, and link the domain.

IMPORTANT

- If you want to manage other product's licenses on the computer dedicated to license management, you also need to install the license management software from the software medium of that product.
- Settings for using a license management dedicated computer, use IT Security Tool and Domain Link Management Tool started from the Start menu.

SEE ALSO For more information about IT security settings, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about how to uninstall the ProSafe-RS software, refer to:

C5.1.1, “Uninstalling the ProSafe-RS Software” on page C5-3

Create User Accounts

Create accounts for the users who manage licenses.

SEE ALSO For more information about creating user accounts, refer to:

B3.8, “Creating User Accounts” on page B3-56

For more information about the user who manages licenses, refer to:

1.2.2, “User privileges in License Manager” in License Management Guide (IM 32P01C60-01EN)

Configure Windows Environment Settings for Each User

The following table shows the Windows setting items that must be configured for each user. Configure the items that are required for the OS being used.

Table B6-3 Windows Setting Items Required for Each User

Windows setting item	Windows OS (*1)	
	Windows 10	Windows Server 2016, Windows Server 2019, Windows Server 2022
Showing Icons on the Task Tray	Yes	Yes
Stopping the Inactive Window Scrolling Function	Yes	Yes

*1: Yes: Configuration required; -: Not available on the OS.

SEE ALSO For more information about configuring Windows environment settings for each user, refer to:

B3.9, “Configuring Windows Environment Settings for Each User” on page B3-59

B7. Configuring the Hardware of SCS and Devices for Connection between Domains

Configure the hardware of SCS and devices used for connection between domains, such as V net routers and L3 switches.

- On the processor module of SCS, set the V net or Vnet/IP address.
- If a V net router (AVR10D) is used to connect a Vnet/IP domain and a V net domain, the V net router address should be set on the CENTUM side.

CAUTION

When removing and installing the cards to set DIP switches, take measure to prevent the damages caused by static electricity.

SEE ALSO

For more information about antistatic measures, refer to:

Appendix 4., “Antistatic Precautions When Handling Hardware” on page App.4-1

For more information about hardware of SCS, refer to:

B., “Components of SCS” in Hardware User's Guide (IM 32P06C10-01EN)

For more information about setting the processor module of SCS, refer to:

B4.2, “Processor module” in Hardware User's Guide (IM 32P06C10-01EN)

For more information about configurations for N-IO Node Interface Unit, refer to:

F2.1, “Configuring the N-IO node interface unit” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about setting up the hardware when using V net routers, bus converters, and communication gateway, refer to:

CENTUM VP Communication Devices (IM 33J50D10-01EN)

B8. Installing the Functions that Operate with CENTUM VP Licenses

The test function and SOE Viewer of ProSafe-RS operate in coordination with CENTUM VP packages. You can set up a computer so as to use only these functions without using other SENG functions. First, grant the computer licenses (at least one license for the test functions) of the CENTUM VP packages that operate in coordination.

Then, install the ProSafe-RS software from the ProSafe-RS software medium. Licenses for ProSafe-RS software packages are not required.

TIP When you move the CENTUM package from a computer where the function that operates with CENTUM VP licenses is used, fully install the ProSafe-RS software also on the new computer.

Installation on the Computer for Running SCS Simulator

SCS simulator is used in combination with the CENTUM packages listed in the following table. Licenses for ProSafe-RS packages are not required.

Table B8-1 CENTUM Packages Required for SCS Simulator

Model	CENTUM VP package name
VP6E5420	Test Function
VP6E5426	FCS Simulator Package

Perform the following tasks on the computer where the SCS simulator is used. Either task can be performed first.

- Install CENTUM software and grant a license for any of the CENTUM packages in the table.
- Install ProSafe-RS software.

SEE ALSO For more information about installing the CENTUM VP Software, refer to:

CENTUM VP Installation (IM 33J01C10-01EN)

Installation on the Computer for Integration of CENTUM SOE Viewer

In the case of system configurations integrating CENTUM, it is possible to display SOE (Sequence of Events) of SCS on the CENTUM SOE Viewer. This is referred to as integration of CENTUM SOE Viewer. The ProSafe-RS software package licenses are not required.

Perform the following tasks on the computer. Either task can be performed first.

- Install CENTUM software and grant a license for the CENTUM SOE Viewer package (VP6P6920).
- Install ProSafe-RS software.

In order to display SOE of SCS on the CENTUM SOE Viewer, it is necessary to connect the computer and SCS via V net or Vnet/IP.

SEE ALSO For more information about granting a license of CENTUM SOE Viewer Package (VP6P6920), refer to:

License Management (IM 33J01C20-01EN)

C. Maintenance

This section describes the tasks required in the operation and maintenance of stations after they have been newly set up.

C1. Adding Licenses and Changing License Assignments

This section describes how to add licenses, which is required to add new software packages on a station, and how to change the assignments of licenses, which is required to migrate software packages between stations.

C1.1 Adding a License

The procedure for loading an additionally purchased license on the license management station is the same as the procedure for new installation.

SEE ALSO For more information about how to load an additionally purchased license on the license management station, refer to:

3.1, “Reading additional licenses on a license management station” in License Management Guide (IM 32P01C60-01EN)

C1.2 Changing License Assignments

Use the License Manager on the license management station to add the license for the software package additionally required on a license-assigned station.

Also use the License Manager on the license management station to remove the license for the software package no longer required on a license-assigned station.

These operations are called “changing license assignments.”

SEE ALSO For more information about changing license assignments, refer to:

3.2, “Modifying licenses” in License Management Guide (IM 32P01C60-01EN)

C2. Setting Up the Windows Domain Environment Later

This section describes the procedure for the case when you want to change the system that has been built as a Standalone management system to a Domain management system.

Workflow

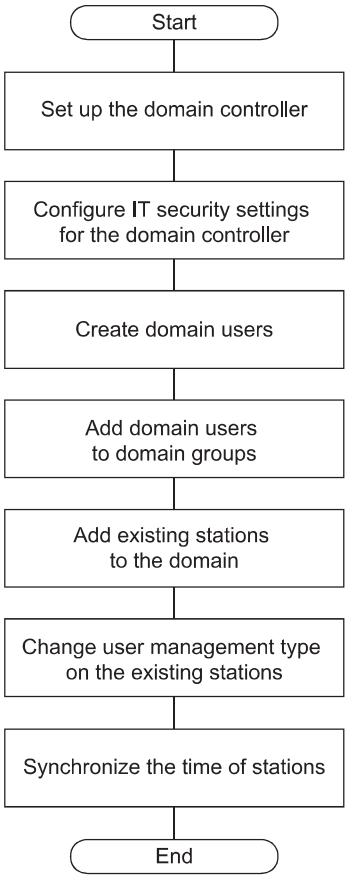

Figure C2-1 Workflow for Setting Up the Windows Domain Environment Later

Setup Procedure

1. Prepare a computer to be used as the domain controller and configure a domain controller on it.
2. Configure IT security settings.
3. Create domain users.
4. Add the domain users to domain groups.
5. Select one of the following depending on which type you want to change the user management type for the existing station.
   - Go to the step 6 to change to linked domain management.
   - Go to the step 9 to change to domain management or combination management.
6. Add the client computer stations to the domain.

7. Link the domain with Domain Link Management Tool.
8. Go to the step 11.
9. Add the client computer stations to the domain.
10. On each station, change the user management type to Domain management or Combination management.
11. Synchronize the time of the stations within the domain.

SEE ALSO

For more information about configuring the domain controller, refer to:

B2.2, “Configuring the domain controller” on page B2-5

For more information about configuring IT security settings on the domain controller, refer to:

B2.3, “Configuring Security Settings for the Domain Controller” on page B2-6

For more information about how to create domain users and add them to domain groups, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to add client computers to a domain, refer to:

B2.5, “Adding Computers to the Domain” on page B2-17

For more information about how to set up time synchronization within a domain, refer to:

B2.7, “Setting Up Time Synchronization in Windows Domain Environment” on page B2-20

For more information about changing the user management type, refer to:

6.4.2, “For File Server or Domain Controller” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

C3. Backing Up the System

To be prepared for system failures, it is recommended to back up the system periodically. The files in the folders listed in the following table should be regularly backed up:

Table C3-1 Folder Backups

Contents	Folder	Registry	When to back up
Backup of entire Windows	All hard disk	Entire registry	• When changes have been made to the system; for example, after program installation or completion of setup. • After closing all applications
Automation Design Master Database (ADMDB)	-	-	-
ProSafe-RS engineering data	SCS project folders	-	After closing the SENG software

When you back up a system where the Standard model of IT security settings is applied, log on to Windows as an administrative user who has the right to access ProSafe-RS-related folders.

C3.1 Backing Up the Entire Windows

This section describes how to back up the entire Windows.

Backing Up Entire Windows

Back up Windows using a commercially available software program in preparation against disk trouble.

Creating Windows Repair Disk

Installing various application programs on a computer can cause troubles: for example, Windows does not start up, or you cannot log on to Windows. In such cases, if you have a system repair disk and boot disk, you can restore the system to the state at the time you created these disks.

To be prepared for Windows troubles, create a system repair disk and boot disk when you have changed the state of the system by installing a program, changing hardware configuration, etc.

SEE ALSO For more information about how to create a repair disk, refer to:

Windows-related manual or the web site of Microsoft Corporation

C3.2 Backing Up the ProSafe-RS Engineering Data

After performing engineering operations, be sure to back up the engineering data.

Backing Up Projects

You can copy the ProSafe-RS folders to a backup medium using Windows Explorer. It is also possible to use commercially available backup software to back up the folders.

The SCS project folders should be backed up using Version Control Tool.

SEE ALSO For more information about Version Control Tool, refer to:

F5., “Version control” in Engineer's Reference Manual (IM 32P04B10-01EN)

Backing Up to AD Project

Be sure to back up the RS project to AD project before backing up ADMDB or exporting the AD project.

SEE ALSO For more information about how to back up projects to an AD project, refer to:

C1.1, “Tools for management of AD Server and AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

C4. Upgrading the ProSafe-RS Software

This section explains the procedure to follow when upgrading the ProSafe-RS software and tasks to be performed after upgrading.

To upgrade the software from the current version to the latest version, perform the tasks in ”Installation for Upgrading”.

To use the added or modified features, read the all cautionary notes including from the current version to the latest version, and perform the tasks in “Settings after Upgrading ProSafe-RS Software”.

IMPORTANT

- When you install for upgrading the version or the revision of this product, the password for the predefined user accounts in this product is reset to the default initial password. Be sure to change the password because operating with the initial password may increase the security risk.
- If SOE OPC Interface Package is used, be sure to change the PSF_PROCESS password after configuring IT security settings. If you changed the password before configuring IT security settings, reset the password that you set.
- If you are going to change the initial password of PSF_PROCESS in an environment that AD Suite is used, activate the system project backup function with ADS Administration Tool before you change the password. If you change the password before activating the system project backup function, the [Backup System Projects prior to AD Project Export] check box in the ADS Administration Tool appears dimmed and you cannot select it. In that case, change the initial password of PSF_PROCESS after activating the system project backup function.
- When changing the password, ensure that the same password is set in the entire system.

SEE ALSO For more information about user accounts that require password change, refer to:

2.2.3, “User/Group Management” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

C4.1 Installation for Upgrading

This section explains the procedure to upgrade the ProSafe-RS software already installed on a computer to a newer version or revision.

TIP

For example, as when upgrading from R3.02 to R4.01, an upgrade where the number next to R is incremented by 1 or more is referred to as a version upgrade. On the other hand, as when upgrading from R4.02 to R4.03, an upgrade where the number immediately next to R remains the same is referred to as a revision upgrade.

The procedure is different between an upgrade of the version and an upgrade of the revision of ProSafe-RS software and some steps are separately explained. Refer to descriptions appropriate to respective cases.

SEE ALSO

For more information about the procedure for upgrading the version of ProSafe-RS Software, refer to:

C4.1.1, “Upgrading the Version of ProSafe-RS Software” on page C4-5

For more information about the procedure for upgrading the revision of ProSafe-RS Software, refer to:

C4.1.2, “Upgrading the Revision of ProSafe-RS Software” on page C4-9

Precautions for Revision Upgrade

Observe the following precautions when you upgrade the ProSafe-RS software.

- If the revision of ProSafe-RS prior to the revision upgrade is R4.03 or later, distribute and accept the upgrade license. If the installation is performed without distributing and accepting the upgrade license, an error dialog will appear and you will not be able to complete the installation.

  This is not necessary if the upgrade license has already been accepted.

- When you upgrade the ProSafe-RS software, install a new revision of software without uninstalling the earlier revision.

  If you uninstall R4.03 or later revision of ProSafe-RS software, a new revision of ProSafe-RS software cannot be installed. In that case, reinstall the uninstalled ProSafe-RS software again and then install the new revision.

IMPORTANT

The software release number must be the same between all the SENGs which is for engineering SCS projects in the RS project, and SENGs which is for engineering SCSs that perform inter-SCS safety communication each other. Also, you must upgrade the revision of SCS projects that perform inter-SCS safety communication.

- Once opening an existing SCS project or creating a new SCS project using newer revision software in SENG, the SCS project cannot be opened using older revision software.
- The SCS system program release number of SCSs in a system should basically be the same, but mixture of different release numbers is allowed.

SEE ALSO

For more information about upgrading the revision of an SCS project, refer to:

C4.2.2, “Upgrading an SCS project” on page C4-18

Upgrading the Revision of Products When Two or More Upgrade License Support Products are Installed

When CENTUM VP R6.04 or later and ProSafe-RS R4.03 or later, both of which support upgrade licenses, are installed on the same computer, follow these steps to upgrade them:

1. Distribute the upgrade licenses of the respective coexisting products.
2. Upgrade the revision of each product.

Items to be Prepared

Prepare the following items so that they are at hand before upgrading the ProSafe-RS software.

- ProSafe-RS software medium
- ProSafe-RS license medium
- ProSafe-RS license sheet (with project ID)

User Who Performs Update Installation

When update installation is performed, IT security settings are configured following the installation of the ProSafe-RS software. Update installation must be performed by a user who belongs to the groups shown in the following table.

Table C4.1-1 Groups to Which the User Who Performs Update Installation Belongs

Currently applied security model and user management type	Security model and user management type to be applied			
	Legacy model	Standard model		
		Standalone type	Linked domain management	Domain/Combination type
Legacy model	Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group		Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group (*1) • Domain user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1) (*2) (*3)

Continues on the next page

Table C4.1-1 Groups to Which the User Who Performs Update Installation Belongs (Table continued)

Currently applied security model and user management type		Security model and user management type to be applied			
		Legacy model	Standard model		
			Standalone type	Linked domain management	Domain/Combination type
Standard model	Standalone type	Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group		Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*4)	• Domain user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1) (*2) (*3)
	Linked domain management	Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group (*4) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*4)	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group (*1) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1)	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group (*1) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE local group (*1)
	Domain/Combination type	Local user who belongs to the Administrators local group and PSF_MAINTENANCE_LCL local group (*5)		Local user who belongs to the Administrators local group and PSF_MAINTENANCE_LCL local group (*1) (*2)	• Domain user who belongs to the Domain Admins domain group and PSF_MAINTENANCE domain group (*1) • Domain user who belongs to the Administrators local group and PSF_MAINTENANCE_LCL local group (*1) • Local user who belongs to the Administrators local group and PSF_MAINTENANCE_LCL local group (*1) (*2) (*3)

*1: Log on while the computer is added to the domain.
*2: The domain user name and password must be entered during installation.
*3: When this user applies IT security and uses iDefine interface package, the following steps must be performed as a domain user who belongs to the Domain Admins domain group or as a domain user who belongs to the Administrators local group.
1. Run the 32 bit Command Prompt (%SystemDrive%\Windows\SysWOW64\cmd.exe) as Administrator.
2. Run either of the following batch files appropriate to the user management type.
%ProgramFiles(x86)%\YOKOGAWA\IA\iPCS\Platform\Security\Program
For Domain management: PSF_SetupSMSvcHostConfigDOM.cmd
For Combination management: PSF_SetupSMSvcHostConfigCMB.cmd
*4: No need to reconfigure the IT Security Tool as the settings are made in Domain Link Management Tool.
*5: Remove the computer from the domain before you change the IT security setting.

C4.1.1 Upgrading the Version of ProSafe-RS Software

The following flowchart illustrates the flow of installation for upgrading the version of ProSafe-RS software.

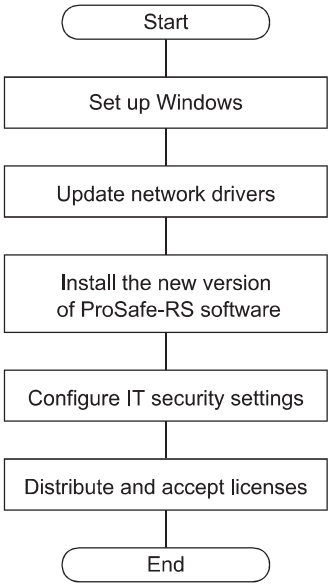

Figure C4.1.1-1 Flow of installation for upgrading the version

■ Set Up Windows

Configure Windows settings.

SEE ALSO For more information about procedures for setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

■ Installing Latest Network Driver

Before upgrading the software, install the latest network driver (included in the new ProSafe-RS software version to be installed).

This section explains how to update the control bus driver, Vnet/IP open communication driver, and the Vnet/IP Interface Package.

● Updating the Control Bus Driver

Follow these steps to update the control bus driver:

1. Uninstall the control bus driver.
2. Install the latest version of the control bus driver.
3. Configure Windows network settings.

SEE ALSO For more information about the uninstallation procedure of control bus driver, refer to:

“■ Uninstalling Control Bus Driver” on page C5-5

For more information about installing the control bus driver, refer to:

B3.3.1, “Installing the Control Bus Driver” on page B3-19

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, “Configuring Windows Network Settings” on page B3-27

Updating the Vnet/IP Open Communication Driver

The procedure to update the Vnet/IP open communication driver is the same as the procedure to install the Vnet/IP open communication driver. If it is necessary to update the Vnet/IP open communication driver, you can select [INSTALL] in the Setup dialog box.

Follow these steps to update the Vnet/IP open communication driver:

1. Install the latest version of the Vnet/IP open communication driver.
2. Be sure to restart the computer after updating the Vnet/IP open communication driver.
3. Configure Windows network settings.

SEE ALSO For more information about installing the Vnet/IP open communication driver, refer to:

B3.3.3, “Installing the Vnet/IP Open Communication Driver” on page B3-22

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, “Configuring Windows Network Settings” on page B3-27

Updating the Vnet/IP Interface Package

If a virtual machine is used, update the Vnet/IP Interface Package.

Follow these steps to update the Vnet/IP Interface Package:

1. Uninstall the Vnet/IP Interface Package.
2. Install the latest Vnet/IP Interface Package.
3. Configure Windows network settings.

SEE ALSO For more information about the procedure to uninstall the Vnet/IP Interface Package, refer to:

“■ Uninstalling the Vnet/IP Interface Package on a Virtual Machine” on page C5-7

For more information about the procedure to install the Vnet/IP Interface Package, refer to:

B3.3.4, “Installing the Vnet/IP Interface Package on a Virtual Machine” on page B3-24

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, “Configuring Windows Network Settings” on page B3-27

Checking Inconsistency in TCP/IP Settings

After updating the network driver, run the TCP/IP Inconsistency Detection Tool. If any inconsistency is detected in the settings, use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP settings again.

SEE ALSO For more information about the TCP/IP Inconsistency Detect Tool and TCP/IP Inconsistency Repair Tool, refer to:

“■ Procedure 5: Repair TCP/IP Settings” on page B3-35

Procedure for Update Installation

Follow these steps below to upgrade the ProSafe-RS software.

1. Log on as an administrative user.
2. Terminate all running applications, including resident programs such as anti-virus software.

3. Insert the ProSafe-RS software medium to the drive. The ProSafe-RS installation menu appears.
   If the installation menu does not appears, double-click Launcher.exe in the top folder of the software medium using Explorer.
4. Click [ProSafe-RS software].
   The Welcome dialog box appears if all the Windows redistribution modules required for ProSafe-RS have been installed. Proceed to step 6.
   The dialog box for confirming module installation appears if any of Windows redistribution modules required for ProSafe-RS have not been installed.
5. Click [Install] in the module installation confirmation dialog box. Module installation starts.
6. After the installation is completed, click [Close].
   The window closes.

IMPORTANT

If the installation fails, reinstall referring to the installation procedure for the new setup.

7. If the dialog box for confirming the privilege setting appears, reboot the computer and log on again.
   a. Click [OK] and reboot the computer.
   b. After rebooting the computer, log on again as the same user. The Welcome dialog box appears automatically.
8. Click [Next] in the welcome dialog box.
   The Confirm Settings dialog box appears.

TIP

- If a different version of control bus driver or Vnet/IP open communication driver is already installed, a dialog box appears, prompting you to update the driver. Confirm the message and click [OK]. To update the control bus driver, uninstall the existing driver and then install the new one after you install the ProSafe-RS software. To update the Vnet/IP open communication driver, install the new driver after you install the ProSafe-RS software.
- After updating the Vnet/IP open communication driver, disable the driver if the computer is to be connected to Ethernet.

9. Check the installation settings in the Confirm Settings dialog box and click [Install]. The installation of ProSafe-RS starts and the dialog box showing installation progress status appears.
10. When you have completed the installation of the ProSafe-RS software, the installation complete dialog box appears.
    If there are no products to be installed subsequently, select [Yes, I want to set up IT security now.] and click [Finish].

TIP

If you intend to continue to install other YOKOGAWA products, select [No, I want to install other software products.] and click [Finish].

IMPORTANT

If you select [No, I want to install other software products.] here, you must perform IT security settings when you install the last product.

SEE ALSO For more information about the installation procedure for new setup, refer to:

"■ Installation Procedure" on page B3-40

For more information about configuring the IT security settings, refer to:

B3.6, "Configuring IT Security Settings" on page B3-44

When Upgrading the Version during Linked Domain Management Operation

Follow these steps to upgrade the version during linked domain management operation:

1. If you have performed a version upgrade installation, sign in as a local administrator or domain administrator.
2. Start the IT Security Tool and apply the IT security for standalone management.
3. Start Domain Link Management Tool as a local administrator or domain administrator, and apply the domain link management.

SEE ALSO For more information about running the IT Security Tool, refer to:

B3.6.1, "Running the IT Security Tool" on page B3-46

For more information about running the Domain Link Management Tool, refer to:

B3.6.3, "Running Domain Link Management Tool" on page B3-52

Additional Execution of IT Security Configuration

If you are upgrading from R2 where the standard model of security settings are applied, you must configure IT security settings again in this way: after configuring the IT security settings following the installation of the product, reboot the computer and then start the IT Security Tool from the Start menu to configure the IT security settings.

Tasks Related to Licenses

In the case of a version upgrade, perform the tasks related to licenses after configuring IT security.

SEE ALSO For more information about tasks related to licenses, refer to:

B3.7, "Distributing and Accepting Licenses" on page B3-55

C4.1.2 Upgrading the Revision of ProSafe-RS Software

The following flowchart illustrates the flow of installation for upgrading the revision of ProSafe-RS software.

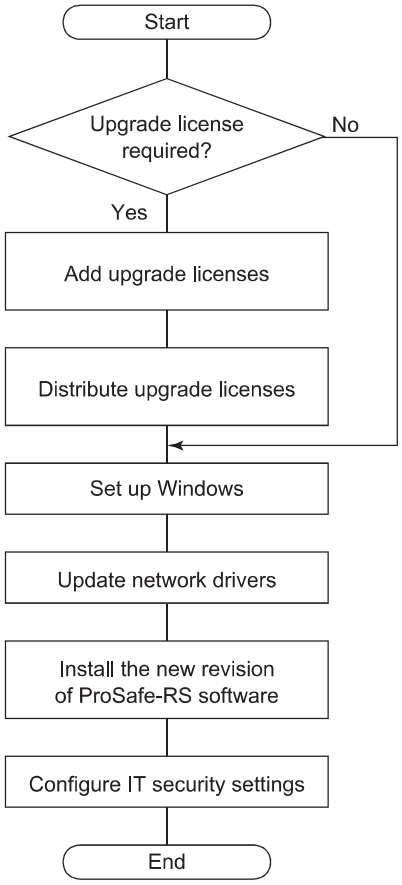

Figure C4.1.2-1 Flow of installation for upgrading the revision

SEE ALSO For more information about details of the upgrade license, refer to:

1., “Overview of license management” in License Management Guide (IM 32P01C60-01EN)

Adding an Upgrade License

Adding an upgrade license enables you to distribute the upgrade license. If an upgrade license is necessary, add the upgrade license by using License Manager on the license management station.

Distributing an Upgrade License

Distributing an upgrade license enables you to install upgrades of the ProSafe-RS software on a license-assigned station. If an upgrade license is necessary, distribute the upgrade license to the license-assigned station from the license management station.

TIP

- If an upgrade license is distributed alone, the license will be accepted automatically.
- The upgrade license can be distributed simultaneously with a software license. In such case, by accepting the license on the license-assigned station, the upgrade license and software license will both be accepted.

SEE ALSO For more information about how to add and distribute an upgrade license, refer to:

5., “Working with upgrade licenses” in License Management Guide (IM 32P01C60-01EN)

Setting Up Windows

Configure Windows settings.

SEE ALSO For more information about procedures for setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

Installing Latest Network Driver

Before upgrading the software, install the latest network driver (included in the new ProSafe-RS software version to be installed).

This section explains how to update the control bus driver, Vnet/IP open communication driver, and the Vnet/IP Interface Package.

Updating the Control Bus Driver

Follow these steps to update the control bus driver:

1. Uninstall the control bus driver.
2. Install the latest version of the control bus driver.
3. Configure Windows network settings.

SEE ALSO For more information about the uninstallation procedure of control bus driver, refer to:

“■ Uninstalling Control Bus Driver” on page C5-5

For more information about installing the control bus driver, refer to:

B3.3.1, “Installing the Control Bus Driver” on page B3-19

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, “Configuring Windows Network Settings” on page B3-27

Updating the Vnet/IP Open Communication Driver

The procedure to update the Vnet/IP open communication driver is the same as the procedure to install the Vnet/IP open communication driver. If it is necessary to update the Vnet/IP open communication driver, you can select [INSTALL] in the Setup dialog box.

Follow these steps to update the Vnet/IP open communication driver:

1. Install the latest version of the Vnet/IP open communication driver.
2. Be sure to restart the computer after updating the Vnet/IP open communication driver.
3. Configure Windows network settings.

SEE ALSO For more information about installing the Vnet/IP open communication driver, refer to:

B3.3.3, “Installing the Vnet/IP Open Communication Driver” on page B3-22

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, “Configuring Windows Network Settings” on page B3-27

Updating the Vnet/IP Interface Package

If a virtual machine is used, update the Vnet/IP Interface Package.

Follow these steps to update the Vnet/IP Interface Package:

1. Uninstall the Vnet/IP Interface Package.
2. Install the latest Vnet/IP Interface Package.
3. Configure Windows network settings.

SEE ALSO For more information about the procedure to uninstall the Vnet/IP Interface Package, refer to:

"■ Uninstalling the Vnet/IP Interface Package on a Virtual Machine" on page C5-7

For more information about the procedure to install the Vnet/IP Interface Package, refer to:

B3.3.4, "Installing the Vnet/IP Interface Package on a Virtual Machine" on page B3-24

For more information about the procedure for configuring Windows network settings, refer to:

B3.3.5, "Configuring Windows Network Settings" on page B3-27

Checking Inconsistency in TCP/IP Settings

After updating the network driver, run the TCP/IP Inconsistency Detection Tool. If any inconsistency is detected in the settings, use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP settings again.

SEE ALSO For more information about the TCP/IP Inconsistency Detect Tool and TCP/IP Inconsistency Repair Tool, refer to:

"■ Procedure 5: Repair TCP/IP Settings" on page B3-35

Procedure for Update Installation

Follow these steps below to upgrade the ProSafe-RS software.

1. Log on as an administrative user.
2. Terminate all running applications, including resident programs such as anti-virus software.
3. Insert the ProSafe-RS software medium into the drive. The ProSafe-RS installation menu appears.
   If the installation menu does not appear, double-click Launcher.exe in the top folder of the software medium using Explorer.
4. Click [ProSafe-RS software].
   The Welcome dialog box appears if all the Windows redistribution modules required for ProSafe-RS have been installed. Proceed to step 6.
   The dialog box for confirming module installation appears if any of Windows redistribution modules required for ProSafe-RS have not been installed.
5. Click [Install] in the module installation confirmation dialog box. Module installation starts.
6. After the installation is completed, click [Close].
   The window closes.

IMPORTANT

If the installation fails, reinstall referring to the installation procedure for the new setup.

7. If the dialog box for confirming the privilege setting appears, reboot the computer and log on again.
   a. Click [OK] and reboot the computer.
   b. After rebooting the computer, log on again as the same user. The Welcome dialog box appears automatically.
8. Click [Next] in the welcome dialog box.
   The Confirm Settings dialog box appears.

TIP

- If a different version of control bus driver or Vnet/IP open communication driver is already installed, a dialog box appears, prompting you to update the driver. Confirm the message and click [OK]. To update the control bus driver, uninstall the existing driver and then install the new one after you install the ProSafe-RS software. To update the Vnet/IP open communication driver, install the new driver after you install the ProSafe-RS software.
- After updating the Vnet/IP open communication driver, disable the driver if the computer is to be connected to Ethernet.

9. Check the installation settings in the Confirm Settings dialog box and click [Install]. The installation of ProSafe-RS starts and the dialog box showing installation progress status appears.
10. When you have completed the installation of the ProSafe-RS software, the installation complete dialog box appears.
    If there are no products to be installed subsequently, select [Yes, I want to set up IT security now.] and click [Finish].

TIP

If you intend to continue to install other YOKOGAWA products, select [No, I want to install other software products.] and click [Finish].

IMPORTANT

If you select [No, I want to install other software products.] here, you must perform IT security settings when you install the last product.

SEE ALSO

For more information about the installation procedure for new setup, refer to:

"■ Installation Procedure" on page B3-40

For more information about configuring the IT security settings, refer to:

B3.6, "Configuring IT Security Settings" on page B3-44

■ When Upgrading the Revision during Linked Domain Management Operation

Follow these steps to upgrade the revision to R4.07 or later during linked domain management operation:

1. If you have performed a revision upgrade installation, sign in as a local administrator or domain administrator.
2. Start the IT Security Tool and apply the IT security for standalone management.
3. Start Domain Link Management Tool as a local administrator or domain administrator, and apply the domain link management.

SEE ALSO For more information about running the IT Security Tool, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about running the Domain Link Management Tool, refer to:

B3.6.3, “Running Domain Link Management Tool” on page B3-52

C4.2 Settings after Upgrading ProSafe-RS Software

This section describes the tasks and precautions required after upgrading the SENG software.

Because the SCS databases and SCS system programs that SENG manages are basically upward compatible, there is no need to modify the engineering data created with earlier version software. However, in order to use the new features supported by the newer SCS system program, re-creation of the SCS project or offline downloading of database to SCS may be required after upgrading the SENG.

TIP

For computers that do not have Adobe Acrobat installed, we recommend that you upgrade the software for viewing online manuals to the recommended version of Adobe Acrobat Reader described in this manual.

SEE ALSO

For more information about configuration of Adobe Acrobat Reader, refer to:

B4.1, “Setting the Manual Browsing Environment” on page B4-2

For more information about release numbers of the SENG software in each software release and compatibility in inter-SCS safety communication between different revisions, refer to:

Appendix 6., “Compatibility between Revisions and Cautionary Notes for Upgrading” on page App.6-1

C4.2.1 Updating the engineering data after an upgrade

To maintain the use of existing engineering data after you upgrade the ProSafe-RS software, you must upgrade the AD Server data, and upgrade the revision of the AD project data and the RS project data before you start the engineering.

Procedure for starting engineering

The following figure shows the procedure for starting engineering.

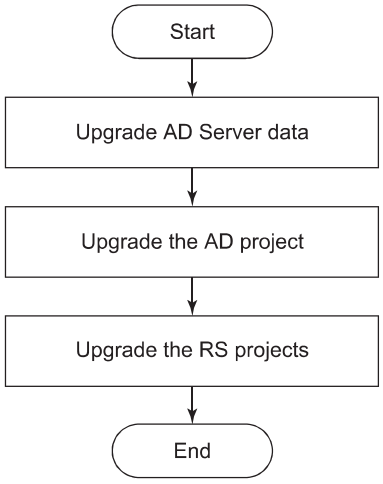

Figure C4.2.1-1 Procedure for starting engineering

TIP

For some steps in this procedure, upgrading may not be required. In this case, do not quit the engineering at such a step and proceed to the next step.

Upgrading the AD Server data

The following AD Server data should be upgraded:

- Back-up and restore history of the ADMDB
- Export and import history information of AD projects
- Option settings

To perform this task, use the ADS Administration Tool on the computer with AD Server.

Upgrading the AD Server data

Follow these steps to upgrade the AD Server data:

1. Log on to the computer with AD Server. If the IT security model is the Standard model or Strengthened model, log on as a member of the ADS_MANAGER or ADS_MANAGER_LCL group.
2. Start the ADS Administration Tool.
   If upgrading of the AD server data is required, the AD Server Data Upgrade Dialog Box appears.
3. Click [OK].
   Data upgrade starts. When the upgrade is complete, the Upgrade Complete Dialog Box appears.
4. Click [Close AD Server Administration Tool].
   The AD Server restarts to complete the data upgrade.

TIP

Performing this task does not upgrade AD project data.

Upgrading an AD project

You must upgrade the AD project data.

To perform this task, use AD Organizer on a computer with the safety system generation function.

If there are multiple computers with the safety system generation function, you can use any of these computers.

Upgrading an AD project

IMPORTANT

Before you upgrade an AD project, you must exit AD Organizer on all computers except for the computer that you are about to upgrade.

Follow these steps to upgrade an AD project:

1. Log on to the computer with the safety system generation function as a user having rights to modify all data in the AD project.

TIP

During upgrade of an AD project, AD project files are checked out, updated, and checked in. If you log on as a user who does not have modifying access rights, upgrade of the AD project fails with an error.

You must log on as a user whose user role is RS Lead Engineer and whose access scope is All Scope.

2. Start AD Organizer.
   If upgrading of an AD project is required, the Upgrade dialog box appears.
3. Click [Yes].
   The upgrade for the AD project starts. When the upgrade is complete, the Update Complete dialog box appears.

IMPORTANT

While revision upgrade of the AD project proceeds, make sure that communication between AD Server and AD Organizer is not interrupted. If the communication is interrupted, upgrade of the AD project fails with an error.

When upgrading the AD project fails with an error due to an interruption, check to see if there are any checked-out files in the AD project. If there are any, forcibly cancel the checked-out status by using the ADS Administration Tool and start AD project upgrade again.

4. Click [OK].

SEE ALSO

For more information about how to check the Checked-out Status of AD project files, refer to:

C1.2.5, “Forcibly canceling the checked-out status of currently checked-out files” in Engineer's Reference Manual (IM 32P04B10-01EN)

Upgrading an RS project

You can upgrade an RS project on a computer with the safety system generation function.

If there are multiple computers with the safety system generation function, perform the tasks on any one of the computers.

Upgrading an RS project

Follow these steps to upgrade an RS project:

1. Log on as a user with rights to modify the RS project.
   For example, log on with the rights of a user whose user role is RS Lead Engineer or RS Engineer.
2. Start AD Organizer.
3. Upgrade all SCS projects under the RS project.
4. In System Structure Navigator, select the RS project.
5. From the sub menu of System Structure Navigator, select [Back up].
   A confirmation dialog box appears.
6. Click [Yes].
   The upgraded RS project is backed up.

C4.2.2 Upgrading an SCS project

After you install the latest revision on SENG or AD Server and upgrade an AD project and an RS project, open SCS projects. The SCS projects are upgraded. Steps are described in the following procedure A.

Procedure A: Opening SCS Projects

Use SCS Manager to open an SCS project in an earlier revision. The SCS project is upgraded.

You can upgrade the SCS project without interrupting SCS operation. The scope of online changes is the same as the earlier revision.

IMPORTANT

- If you upgrade an SCS project, you must upgrade the SCS projects of all the SCSs that perform inter-SCS safety communication with this SCS. Otherwise, an error may occur during build.
- When opening a project of R4.05 or later, specify PRJlibrary.accdb. When opening a project before R4.05, specify PRJlibrary.mdb. PRJlibrary.mdb is converted to PRJlibrary.accdb by upgrading the revision.
- The SCS project created by an earlier revision cannot be opened in Read-Only mode.

  Such SCS projects must be opened in Read-Write mode. To open the project with password, the password needs to be entered and then open the project in the Read-Write status.
- It is necessary to use the newer revision SCS Manager at least once to open the library created by older revision SCS Manager.

Follow these steps to call SCS Manager from AD Organizer:

1. In System Structure Navigator, select the SCS project you want to upgrade and select [SCS Manager] from the context menu.
   If upgrading of the SCS project is required, a dialog box appears, asking you whether to upgrade the SCS project.
2. Click [Yes].
   Upgrading of the SCS project starts. When the upgrade is complete, the Upgrade Complete dialog box appears.
3. Click [OK].
   SCS Manager starts, and the steps are completed.

C4.2.3 Cautionary notes for upgrading to R4.10

This section provides cautionary notes and actions required for a revision upgrade from R4.09 to R4.10. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

When integrating ProSafe-RS with CENTUM VP, use the R6.11 or a later version of CENTUM VP for the installation on the same computer.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.09, refer to:

Appendix 6.10, "Cautionary notes for upgrading to R4.09" on page App.6-28

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software revisions

The respective software release numbers of R4.10 are as follows:

Software release number R4.10.xx (*1)

- SENG software release number: R4.10.xx(*1)
- SCS system program release number: R4.10.xx(*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.10.00.

The database revision of an SCS project that is created by SENG with software release number R4.10.xx will be R4.10.00.

● Control bus drivers

The control bus drivers that are installed on the computer must be upgraded to the version supplied in R4.10.

● Inter-SCS safety communication

This section describes the SCS system program release numbers that support inter-SCS safety communication.

SEE ALSO For more information about compatibility in inter-SCS safety communication between different revisions, refer to:

"● Important issues to consider" in "■ Precaution for engineering" in A7., "Inter-SCS safety communication" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

For more information about the SCS system program release numbers that support inter-SCS safety communication, refer to:

Appendix 4.2, "Inter-SCS safety communication in a V net domain" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Basic procedure for upgrading

To use the added or modified features, install the ProSafe-RS software R4.10 or later and open the existing SCS projects ("Procedure A").

SEE ALSO For more information about operations of "Procedure A", refer to:

"■ Procedure A: Opening SCS Projects" on page C4-18

■ Procedures for using added and modified features

The basic upgrading procedures are not enough to use the following features that have been added or modified in R4.10. After you upgrade the SENG software to R4.10, you must perform offline download to the SCS and other operations. The following procedures are required to use the new features.

SEE ALSO For more information about operation "Procedure B" to "Procedure F" for using new functions, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

● Diagnostic information indicator system function blocks

To use the diagnostic information indicator system function blocks added in R4.10 (SYS_CPUDSP, SYS_NODEPSU, SYS_N_NODEPSU), you need to perform "Procedure C" on an SENG of R4.10. SYS_CPUDSP and SYS_NODEPSU can be used on SSC50, S2SC70, SSC57, and L1SC70. SYS_N_NODEPSU can be used only on S2SC70.

■ Precautions Regarding the Policy Distributed from GPO

If the following policy is distributed from the domain controller by the settings in the GPO file, it is necessary to change the setting of the domain controller and each computer after upgrading the version in order to deal with the problem of Windows.

- For IT security version 1.0 and strengthened model:

  The setting item is [Computer Configuration] > [Policy] > [Windows Settings] > [Security Settings] > [Local Policies] > [Audit Policy] > [Audit Object Access].

- For IT security version 2.0 and standard or strengthened model:

  The setting item is [Computer Configuration] > [Policy] > [Windows Settings] > [Security Settings] > [Advanced Audit Policy Configuration] > [Audit Policy] > [Object Access] > [Audit Removable Storage].

This setting is applied to each computer from the domain controller by the settings in the GPO file of the following versions:

- R4.03.00 to R4.09.00

TIP After changing the setting, the above item will no longer be subject to consolidated management by the GPO file, so set it with the IT Security Tool.

Changing Group Policy on Domain Controller

Follow these steps to change the group policy on the domain controller:

1. Sign in to the domain controller as a user with administrative rights.
2. Open the Control Panel and select [Administrative Tools] > [Group Policy Management]. The Group Policy Management dialog box appears.
3. Right-click the group policy object that applies to each computer and select [Edit...]. Group Policy Management Editor appears.
4. For IT security version 1.0 and strengthened model, select [Audit Object Access] and select [Not defined]. For IT security version 2.0 and standard or strengthened model, select [Audit Removable Storage] and select [Not Configured].

Setting the Registry on Each Computer

After changing the group policy on the domain controller, set the registry on each computer. Follow these steps to set the registry on each computer:

1. Sign in as a user with administrative rights on each computer.
2. Run the command from the Command Prompt by either of the following operations.
   - When using the ProSafe-RS software medium, insert the medium into the drive

     ```
     <Software medium drive>:\ProSafe-RS\Security\RepairRemovableStoragePolicies.cmd
     ```

   - If there is no medium, access the installation directory

     ```
     <ProSafe-RS installation folder>\Program Files (x86)\YOKOGAWA\IA\iPCS\Platform\Security\Program\RepairRemovableStoragePolicies.cmd
     ```

   The correct value is set in the corresponding registry.

Steps when an SCS project is already placed on another computer such as a file server

If an SCS project is already placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When an SCS project is already placed on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO For more information about avoidance, refer to:

"■ Precautions when Placing the SCS Project on Another PC such as a File Server" in 1.2, "Engineering" in ProSafe-RS Release Information (IM 32P01A50-01EN)

Cautionary notes for upgrading when ALE111 is used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slaveor DNP3communication, refer to:

"■ Cautionary Notes for Upgrading When ALE111 is Used" on page App.6-5

C4.2.4 Procedures for using new functions

This section describes the detailed operation procedures required after the revision upgrade, which is described in the precautions for upgrade of each revision.

After upgrading the ProSafe-RS software, the following procedures need to be performed.

What procedure needs to be performed depends on what new features to be used. User needs to run the following procedures in accordance with each guideline of the revision upgrade procedure.

- Procedure B: Master Database Offline Download
- Procedure C: Creating New SCS Project and Offline Download
- Procedure D: Setting Definition Items for New Features and Offline Download
- Procedure E: Clean Project, Build, and Offline Download
- Procedure F: Setting Definition Items for New Features, Clean Project, Build, and Offline Download

SEE ALSO For more information about procedure A: opening SCS projects, refer to:

"■ Procedure A: Opening SCS Projects" on page C4-18

For more information about the procedures to use new features in each revision, refer to:

Appendix 6.5, "Cautionary Notes for Revision Upgrade to R4.04" on page App.6-15

For more information about procedure of upgrading the system while maintaining the existing engineering data, refer to:

C4.2.1, "Updating the engineering data after an upgrade" on page C4-15

■ Procedure B: Master Database Offline Download

For using the new features, this procedure may be necessary.

After upgrading the SENG, perform Master Database Offline Download to the SCS. Re-testing of SCS application is not required.

The outline of the procedure is as follows:

1. Run Procedure A.
2. Offline download to the SCS using Master Database Offline Download.

SEE ALSO For more information about the procedure of Master Database Offline Download, refer to:

I4.4, "Master database offline download" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Procedure C: Creating New SCS Project and Offline Download

For using the new features, this procedure may be necessary.

After upgrading SENG, create a new SCS project and remake the existing SCS project and then offline download the SCS project.

The procedure is the same as creating a new SCS project. And it is roughly as follows:

1. Create a new project and enter all the project settings.
   The existing SCS project can be upgraded to a later revision by using Import/Export functions. Upgrading the SENG to a newer revision and creating a new SCS project, the whole existing project data can be transferred to the new SCS project.

TIP

If the new SCS project uses a library, the library must be opened by a new-revision SCS Manager. However, if the library POU uses FB/FU supported only by a new revision, create a new library.

When you have upgraded an SENG, you must ensure that all SCS projects and library are of the same revision as the upgraded SENG.

Follow these steps to upgrade the revision of SCS and library:

1. Open each original library projects to upgrade. Then, copy the library to the predetermined folder, LIBRARIES, of the SCS project that uses the library.
2. Open each SCS project to upgrade.

If a project-level password is set for the SCS project or library, you have to enter the password and open it in ReadWrite mode in order to upgrade. If you do not know the password, contact the creator of the SCS project and library.

2. Run build, and check the project data using Integrity Analyzer/Cross Reference Analyzer.
3. Offline download the project.

IMPORTANT

The SCS project and library created by an SENG in a revision later than the currently used revision cannot be used.

- The SCS project created or opened by a new revision of SENG cannot be opened by an SENG in an earlier revision.
- The library created or opened by a new revision of SENG cannot be added to the SCS project of an earlier revision.

SEE ALSO

For more information about the procedures for transferring the existing SCS project using Import/Export functions, refer to:

E2., “Import/Export function” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about the procedure for migrating existing SCS projects engineered by I/O list engineering, refer to:

“■ Regenerating an SCS project with the new revision” in E3.3, “Data transfer procedure during SCS project regeneration” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about areas in which re-testing is required after using the Import/Export function, refer to:

“■ Confirming a regenerated project” in E3.3, “Data transfer procedure during SCS project regeneration” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about procedures for offline download, refer to:

“● Offline download process in I/O list engineering” in “■ Procedure for offline download” in C7., “Offline download to the target SCS” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Procedure D: Setting Definition Items for New Features and Offline Download

Some new features require this procedure.

Install the new revision of SENG software, set the definition items for the new features, and offline download the project.

The procedure is as follows:

1. Using SCS Manager, open the old-revision project.
2. Set the definition items for the new features.

The items to be set are described in the section of upgrading procedures for each software release number.

3. Run Build. Then use Integrity Analyzer and Cross Reference Analyzer for approval check.

IMPORTANT

Even if all POUs are displayed in green in the result of checking by Cross Reference Analyzer, further check is required if Cross Reference Analyzer is unable to detect differences related to the definition items of the new features.

4. Offline download the project.

SEE ALSO For more information about the items that cannot be detected by Cross Reference Analyzer, refer to:

"■ Other changes not detectable by Cross Reference Analyzer" in C5.2.5, "Precautions on Cross Reference Analyzer" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Procedure E: Clean Project, Build, and Offline Download

Some new features require this procedure.

After upgrading the SENG, run Clean Project and Build for the existing project, and offline download the project.

The procedure is as follows:

1. Using SCS Manager, open the old-revision project.
2. Run Clean Project.
3. Run Build. Then use Integrity Analyzer and Cross Reference Analyzer for approval check. In the check using Cross Reference Analyzer, make sure that all POUs are displayed in green.
4. Offline download the project.

■ Procedure F: Setting Definition Items for New Features, Clean Project, Build, and Offline Download

Some new features require this procedure.

This procedure consists of "Procedure D" plus Clean Project.

The procedure is as follows:

1. Using SCS Manager, open the old-revision project.
2. Set the definition items for the new features.
   The items to be set are described in the section of upgrading procedures for each software release number.
3. Run Clean Project.
4. Run Build. Then use Integrity Analyzer and Cross Reference Analyzer for approval check.

IMPORTANT

Even if all POUs are displayed in green in the result of checking by Cross Reference Analyzer, further check is required if Cross Reference Analyzer is unable to detect differences related to the definition items of the new features.

5. Offline download the project.

SEE ALSO

For more information about the items that cannot be detected by Cross Reference Analyzer, refer to:

"■ Other changes not detectable by Cross Reference Analyzer" in C5.2.5, "Precautions on Cross Reference Analyzer" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

C4.3 Upgrading the Computer Dedicated to License Management

This section describes how to upgrade the computer dedicated to license management.

Upgrade Procedure

1. When upgrading from R4.02 or earlier, set up Windows.
2. Install only the license management software from the ProSafe-RS software medium.

TIP

When upgrading the computer dedicated to license management, you can install the license management software in the same way as when it is installed for the first time. However, you are not required to enter the following items because the data already set are applied.

- Name
- Company name
- Installation folder

3. Configure IT security settings.
4. When upgrading from R4.02 or earlier, configure Windows environment settings for each user.

SEE ALSO

For more information about configuring the IT security settings, refer to:

B3.6.1, “Running the IT Security Tool” on page B3-46

For more information about setting up Windows, refer to:

B3.2, “Setting Up Windows” on page B3-7

For more information about installing the license management software, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

For more information about configuring Windows environment settings for each user, refer to:

B3.9, “Configuring Windows Environment Settings for Each User” on page B3-59

C5. Uninstalling the ProSafe-RS Software

This section describes how to uninstall the ProSafe-RS software and network drivers. Procedures are provided for the following two cases:

- Uninstallation on SENG
- Uninstallation on the computer dedicated to license management

Note, however, that uninstalling the ProSafe-RS software does not remove the project database, user settings, registries, and so on. If you need to remove ProSafe-RS software completely, reinstall your operating system.

C5.1 Uninstallation on SENG

This section describes the procedures for uninstallation on SENG.

C5.1.1 Uninstalling the ProSafe-RS Software

If you uninstall the ProSafe-RS software, the license management software is also uninstalled. However, the license management data, IT Security Tool, and project data will not be deleted.

TIP

The IT Security Tool is also used by YOKOGAWA products other than ProSafe-RS. Therefore, even if you uninstall the ProSafe-RS software, the Start menu setting, programs and files of the IT Security Tool will not be removed. To completely uninstall the IT Security Tool, you need to uninstall all the products that use the IT Security Tool and then run the command for uninstalling the IT Security Tool.

■ Deleting and Deactivating the Licenses

If there are any active licenses distributed on the SENG PC, delete the licenses to deactivate the software packages before uninstalling the ProSafe-RS software.

SEE ALSO

For more information about how to deactivate software packages on a computer, refer to:

"■ Deleting a license from a license-assigned station" in 3.2.1, "Modifying license assignments" in License Management Guide (IM 32P01C60-01EN)

■ Uninstallation Procedure

After deactivating the packages (deleting the licenses), follow these steps to uninstall the ProSafe-RS software:

1. Open the Control Panel.
2. Select [Programs] > [Programs and Features].
   The Programs and Features window appears.

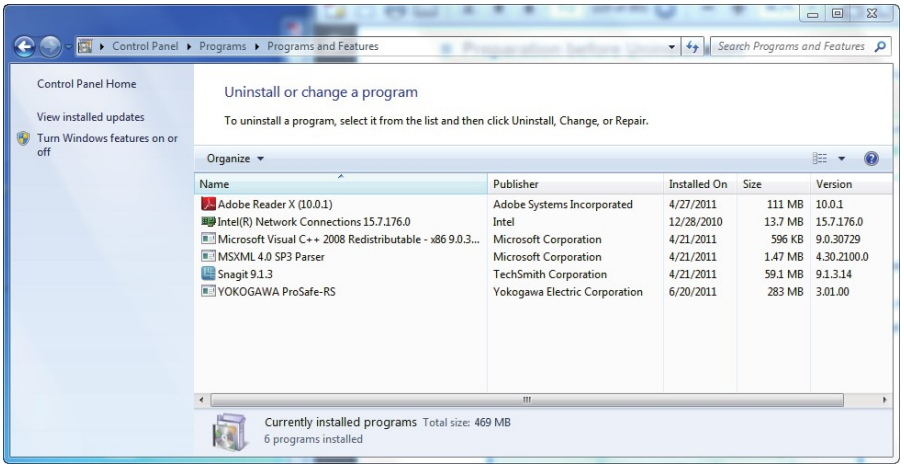

Figure C5.1.1-1 Programs and Features

3. Select [YOKOGAWA ProSafe-RS] and click [Change].
   The Welcome dialog box appears.
4. Click [Next].
   A dialog box for confirming the uninstallation appears.
5. Click [Remove].
   Uninstallation starts and a dialog box showing the progress of uninstallation appears.

TIP

If any active license is found, a dialog box appears confirming the continuation of the uninstallation process. Select [Yes] to continue the uninstallation. The active licenses are deactivated at this point.

However, the license information on the license management station remains unchanged. Update the license information on the license management station as necessary.

6. If a User Account Control dialog box appears, click [Yes] or [Allow].

TIP

If you leave the User Account Control dialog box without clicking [Yes] or [Allow], the dialog box closes automatically. Then, a dialog box indicating failure of uninstallation appears, and the uninstallation is discontinued. In this case, run the uninstallation again.

7. In the uninstallation complete dialog box that appears upon completion of the uninstallation, do either of the following operations.:
   - To restart the computer now, select [Yes, I want to restart my computer now.] and click [Finish].
   - To restart the computer later, select [No, I will restart my computer later.] and click [Finish].

C5.1.2 Uninstalling the Network Drivers

This section describes how to uninstall the network drivers.

Disabling the Control Bus Driver (Windows 10)

In Windows 10, before you uninstall the control bus driver, be sure to disable the control bus driver.

Follow these steps to disable the control bus driver:

1. Sign in as an administrative user.
2. Open Control Panel.
3. Select [Network and Internet] > [Network and Sharing Center].
   The Network and Sharing Center window appears.
4. Select [Change adapter settings].
   The Network Connections window appears.
5. Right-click [Yokogawa Vnet Adapter] and select [Disable].
   An error dialog box regarding disabling connection appears.
6. Click [OK].
7. Restart the computer.
8. Perform steps 1 to 4.
9. In the Network Connections window, confirm that the Vnet driver is disabled.

TIP If the control bus driver is not disabled, perform the procedure from step 2 again.

Uninstalling Control Bus Driver

Follow these steps to uninstall the control bus driver:

1. Log on as an administrative user.
2. Terminate all applications that are running.
3. Set the ProSafe-RS software medium in the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the software medium.

   The installation menu appears.
4. Click [Control Bus Driver].
   The following dialog box appears.

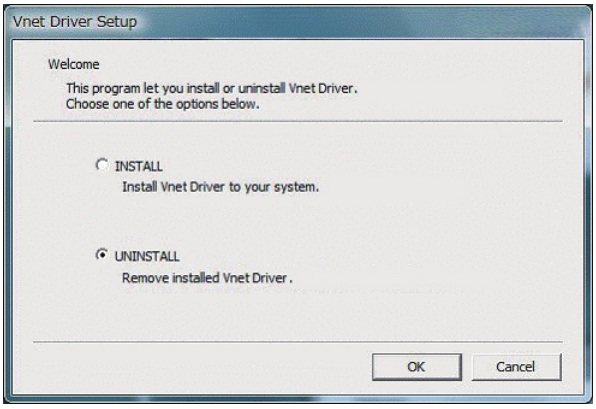

Figure C5.1.2-1 Setup Selection Dialog Box

5. Select [UNINSTALL] and then click [OK].
   A dialog box appears, confirming the uninstallation.
6. Click [OK].
   The uninstallation starts.
7. In the uninstallation complete dialog box that appears upon completion of the uninstallation, click [OK].
8. Restart the computer.

IMPORTANT

After uninstalling the driver, run the TCP/IP Inconsistency Detection Tool.

If any inconsistency is detected, use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP settings again.

SEE ALSO For more information about the TCP/IP Inconsistency Detect Tool and TCP/IP Inconsistency Repair Tool, refer to:

"■ Procedure 5: Repair TCP/IP Settings" on page B3-35

■ Uninstalling the Vnet/IP Open Communication Driver

Follow these steps to uninstall the Vnet/IP open communication driver:

1. Log on as an administrative user.
2. Terminate all applications that are running.
3. Set the ProSafe-RS software medium in the drive.
   - If the AutoPlay dialog box appears, click [Run Launcher.exe].
   - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the top folder of the software medium.

   The installation menu appears.
4. Click [Vnet/IP Open com driver].
   The following dialog box appears.

Figure C5.1.2-2 Setup Selection Dialog Box

5. Select [UNINSTALL] and then click [OK].
   A dialog box appears, confirming the uninstallation.
6. Click [OK].
   The uninstallation starts.
7. In the uninstallation complete dialog box that appears upon completion of the uninstallation, click [OK].
8. Restart the computer.

IMPORTANT

After uninstalling the driver, run the TCP/IP Inconsistency Detection Tool.

If any inconsistency is detected, use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP settings again.

SEE ALSO For more information about the TCP/IP Inconsistency Detect Tool and TCP/IP Inconsistency Repair Tool, refer to:

"■ Procedure 5: Repair TCP/IP Settings" on page B3-35

■ Uninstalling the Vnet/IP Interface Package on a Virtual Machine

Follow these steps to uninstall the Vnet/IP Interface Package:

The procedures explained here should be performed on the guest OS of the virtual machine.

IMPORTANT

- If multiple products coexist in the virtual machine, if you uninstall the license product with the Vnet/IP Interface Package enabled, after restarting the virtual machine, Vnet/IP communication cannot be performed from other products.
- Unlike computers with a Vnet/IP interface card installed, if you uninstall the Vnet/IP Interface Package from a virtual machine, the virtual machine results in a Station Fail status immediately.

Procedure 1: Uninstall the Vnet/IP Interface Package

Follow these steps to uninstall the Vnet/IP Interface Package:

1. Sign in to the guest OS on the virtual machine as an administrative user.
2. Terminate all applications that are running.
3. Sign out from the guest OS on the virtual machine.
4. Sign in to the host OS of virtualization host computer as an administrative user.
5. Copy an ISO format file of the ProSafe-RS software medium and paste it into a folder on the host OS.
6. Select [Start] > [Server Manager].
   Server Manager starts.
7. Select [Tools] > [Hyper-V Manager].
   Hyper-V Manager starts.
8. On the left pane, select the virtualization host computer.
   Virtual machines on the virtualization host computer are displayed on the middle pane.
9. Right-click on the virtual machine that the ISO format file is mounted and select [Connect].
   The virtual machine connection window appears.

TIP

The virtual machine connection window may appear full-screen. If it appears full-screen, click [Undo] to exit full-screen.

10. Click [Media] > [DVD Drive] > [Insert Disk].
    A file opening dialog box appears.
11. Select the copied ISO format file of the ProSafe-RS software medium and click [Open].
    The selected ISO format file is mounted on the virtual machine.
    - If the AutoPlay dialog box appears, click [Run Launcher.exe].
    - If the AutoPlay dialog box does not appear, use Explorer and double-click Launcher.exe in the folder where the ISO format file of the ProSafe-RS software is stored.

    The installation menu appears.
12. On the installation menu, click [Control Bus Driver].
    A setup selection dialog box appears.
13. Select [UNINSTALL] and click [OK].
    A dialog box appears, confirming the uninstallation.
14. Click [OK].
    The uninstallation starts.
15. In the uninstallation complete dialog box that appears upon completion of the uninstallation, click [OK].
16. Restart the virtual machine.

IMPORTANT

After uninstalling the driver, run the TCP/IP Inconsistency Detection Tool.

If any inconsistency is detected, use the TCP/IP Inconsistency Repair Tool and then configure the TCP/IP settings again.

SEE ALSO For more information about the TCP/IP Inconsistency Detect Tool and TCP/IP Inconsistency Repair Tool, refer to:

"■ Procedure 5: Repair TCP/IP Settings" on page B3-35

Procedure 2: Disable the RIP Listener Service

This section describes how to disable the RIP Listener service.

IMPORTANT

Disabling of the RIP Listener service may fail when the Default Authentication Level of DCOM is configured to [None]. In this case, change to [connection].

Follow these steps to disable the RIP Listener service on Windows Server 2016:

1. Sign in to the guest OS on the virtual machine as an administrative user.
2. Run the Command Prompt as Administrator.
3. Run the following command:
   ```
   dism /online /disable-feature /featurename:rasrip
   ```
4. Confirm that the message, "The operation completed successfully." appears.

SEE ALSO For more information about how to change the default authentication level of DCOM to "Connect", refer to:

"■ DCOM Settings" on page B3-15

C5.2 Uninstallation on the computer Dedicated to License Management

This section describes the procedure for uninstalling the license management software on the computer dedicated to license management.

Running the Uninstallation

Follow these steps to uninstall the license management software:

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [Programs] > [Programs and Features].
   The Programs and Features window appears.
4. From the program list, select [YOKOGAWA ProSafe-RS] and click [Change].
   The Welcome dialog box appears.
5. Click [Next].
   A dialog box for confirming the uninstallation appears.
6. Click [Delete].
   Uninstallation starts and a dialog box showing the progress of uninstallation appears.
7. In the uninstallation complete dialog box that appears upon completion of the uninstallation, do either of the following operations.:
   - To restart the computer now, select [Yes, I want to restart my computer now.] and click [Finish].
   - To restart the computer later, select [No, I will restart my computer later.] and click [Finish].

C6. Reinstalling the ProSafe-RS Software

This section describes how to reinstall the ProSafe-RS Software. The procedures are explained for the cases when changing and not changing the computer to be used. For each case, the reinstallation procedure is explained for license-assigned stations and for the license management station.

C6.1 When the Computer Used is the Same

This section describes the procedure for reinstalling the ProSafe-RS software to restore the software when the installed file gets damaged or deleted accidentally. The assumption is that the computer on which the software is to be installed is the same as before.

The software cannot be reinstalled by overwriting the software already installed. You must first uninstall the ProSafe-RS software and install the ProSafe-RS software again.

Reinstallation for a License-Assigned Station

This section describes the reinstallation procedure for a license-assigned station.

The flow of reinstallation is as follows.

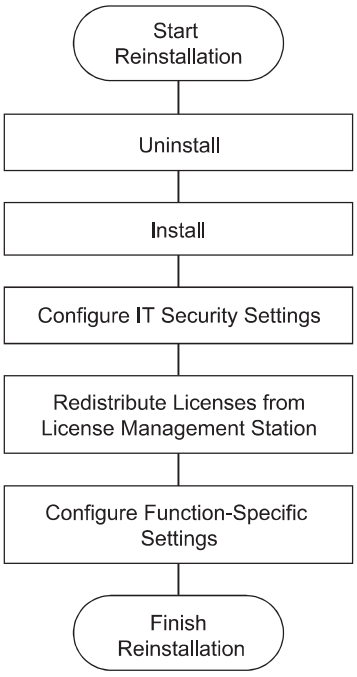

Figure C6.1-1 Flow of Reinstallation for a License-Assigned Station

Uninstall the ProSafe-RS Software

Uninstall the ProSafe-RS software.

SEE ALSO For more information about uninstallation procedure, refer to:

C5.1.1, “Uninstalling the ProSafe-RS Software” on page C5-3

Install the ProSafe-RS Software

Install the ProSafe-RS software.

SEE ALSO For more information about installing the ProSafe-RS software, refer to:

B3.5, “Installing the ProSafe-RS Software” on page B3-39

Configure IT Security Settings

Configure IT security settings in the same way as that for a new installation of the ProSafe-RS software.

SEE ALSO For more information about configuring the IT security settings, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

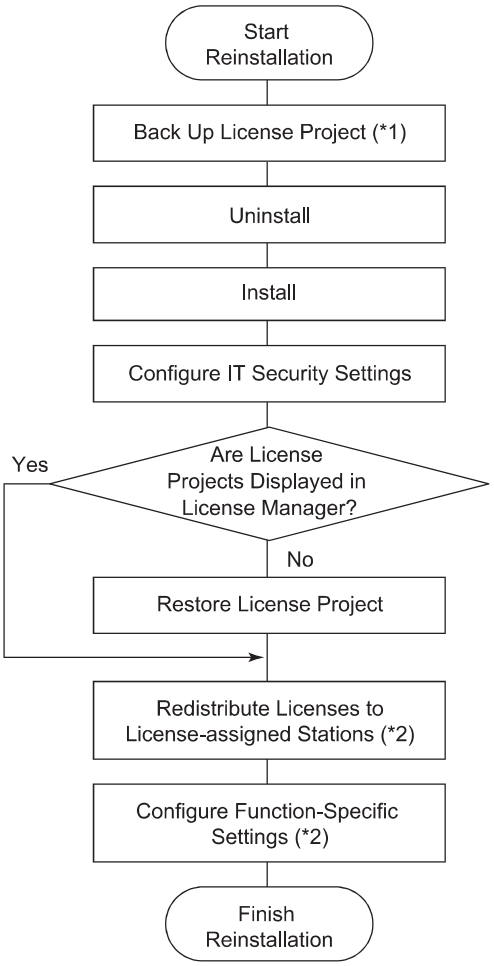
Redistribute Licenses from the License Management Station

Redistribute the licenses from the license management station.

SEE ALSO For more information about redistributing licenses from the license management station, refer to:

3.4, “Redistributing licenses to license-assigned stations” in License Management Guide (IM 32P01C60-01EN)

Configure Function-Specific Settings



Configure the settings specific to the functions that run on the SENG.

SEE ALSO For more information about configuring the settings specific to each function of SENG, refer to:

B4., “Configuring the Functions Specific to SENG” on page B4-1

Reinstallation for the License Management Station

This section describes the reinstallation procedure for the license management station. The license management station can be a computer installed with the ProSafe-RS software or a computer dedicated to license management, where only the license management software is installed. You need to perform reinstallation according to the type of the license management station.

*1: If the license project backup is already created, this task is not required.
*2: These tasks are not required for the computer dedicated to license management.

Figure C6.1-2 Flow of Reinstallation for the License Management Station

Back Up the License Projects

Back up the license projects managed on the computer.

SEE ALSO For more information about the procedure for backing up license projects, refer to:

3.6, “Backing up and restoring a license project” in License Management Guide (IM 32P01C60-01EN)

Uninstall the ProSafe-RS Software

Uninstall the ProSafe-RS software. For a computer dedicated to license management, uninstall the license management software.

SEE ALSO For more information about the procedure for uninstallation on an SENG PC, refer to:

C5.1, “Uninstallation on SENG” on page C5-2

For more information about the procedure for uninstallation on the computer dedicated to license management, refer to:

C5.2, “Uninstallation on the computer Dedicated to License Management” on page C5-10

Install the ProSafe-RS Software

Install the ProSafe-RS software. For a computer dedicated to license management, install the license management software.

SEE ALSO For more information about installing the ProSafe-RS software, refer to:

B3.5, “Installing the ProSafe-RS Software” on page B3-39

For more information about how to install the license management software, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

Configure IT Security Settings

Configure IT security settings in the same way as that for a new installation of the ProSafe-RS software.

SEE ALSO For more information about configuring the IT security settings, refer to:

B3.6, “Configuring IT Security Settings” on page B3-44

Restore the License Projects

Start the License Manager and then check if license projects are displayed. If not displayed, you need to restore the license projects from the backup.

SEE ALSO For more information about the procedure for restoring license projects, refer to:

“■ Restoring a license project on another license management station” in 3.6, “Backing up and restoring a license project” in License Management Guide (IM 32P01C60-01EN)

Redistribute Licenses to License-Assigned Stations

Redistribute the licenses to the license-assigned stations.

SEE ALSO For more information about redistributing licenses from the license management station, refer to:

3.4, “Redistributing licenses to license-assigned stations” in License Management Guide (IM 32P01C60-01EN)

Configure Function-Specific Settings

Configure the settings specific to the functions that run on the SENG.

SEE ALSO For more information about configuring the settings specific to each function of SENG, refer to:

B4., “Configuring the Functions Specific to SENG” on page B4-1

C6.2 When the Computer Used is Not the Same

This section describes the procedure for reinstallation on a different computer when the computer installed with the ProSafe-RS software can no longer be used due to damage or other reasons.

Reinstallation for a License-Assigned Station

This section describes the reinstallation procedure for a license-assigned station.

The procedure is the same as that for a new setup of SENG except that you need to restore the data that were backed up.

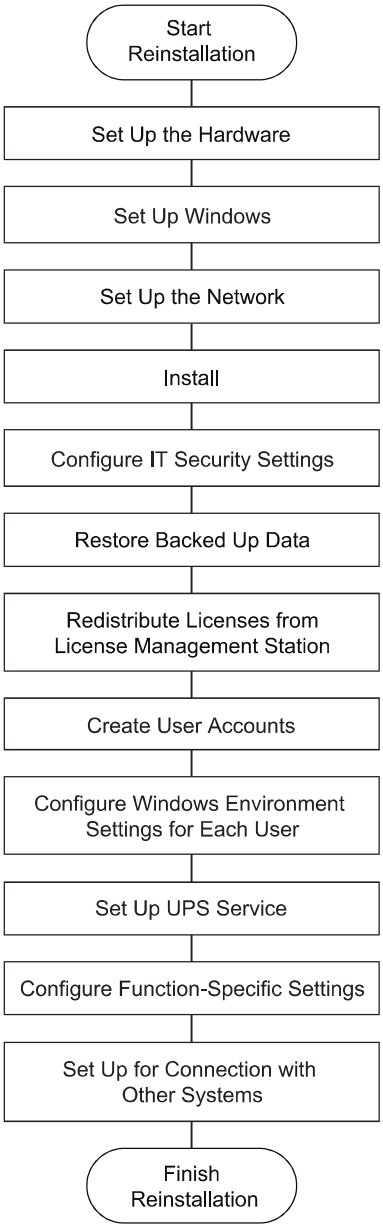


Figure C6.2-1 Flow of Reinstallation for a License-Assigned Station

IMPORTANT

For the station name of the new computer, specify the same name as that set on the previous computer.

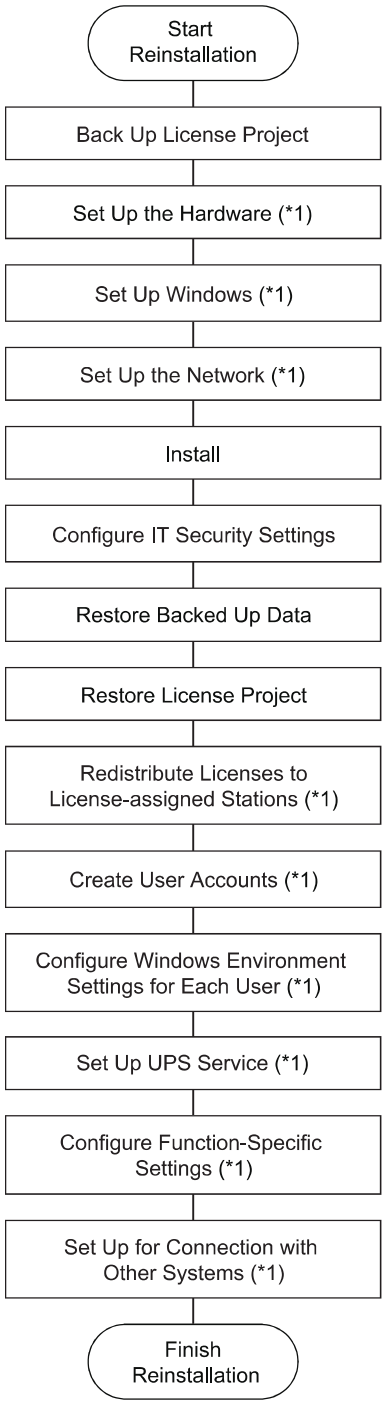
SEE ALSO For more information about the procedures for a new setup of SENG, refer to:

- B3., “Setup of an SENG or a Computer Installed with Only AD Server” on page B3-1
- B4., “Configuring the Functions Specific to SENG” on page B4-1
- D1., “Connecting YOKOGAWA products” on page D1-1

Restore the Backed Up Data

Restore the backed up data on the new computer.

SEE ALSO For more information about the backed up data, refer to:



C3., “Backing Up the System” on page C3-1

Reinstallation for the License Management Station

The license management station can be a computer installed with the ProSafe-RS software or a computer dedicated to license management. You need to perform reinstallation according to the type of the license management station.

The procedure is the same as that for a new setup except that the following tasks are involved:

- Back up license projects
- Restore the backed up data
- Restore the license projects
- Redistribute licenses to the license-assigned stations

*1: For the computer dedicated to license management, these tasks are not required or may be omitted according to the circumstances.

Figure C6.2-2 Flow of Reinstallation for the License Management Station

IMPORTANT

For the station name of the new computer, specify the same name as that set on the previous computer.

SEE ALSO For more information about the procedures for a new setup of SENG, refer to:

- B3., “Setup of an SENG or a Computer Installed with Only AD Server” on page B3-1
- B4., “Configuring the Functions Specific to SENG” on page B4-1
- D1., “Connecting YOKOGAWA products” on page D1-1

For more information about the procedure for a new setup of a computer dedicated to license management, refer to:

B6., “Setting Up the Computer Dedicated to License Management” on page B6-1

Back Up the License Projects

Back up the license projects managed on the previous computer.

SEE ALSO For more information about procedures for backing up license projects, refer to:

3.6, “Backing up and restoring a license project” in License Management Guide (IM 32P01C60-01EN)

Restore the Backed Up Data

Restore the backed up data on the new computer.

SEE ALSO For more information about the backed up data, refer to:

C3., “Backing Up the System” on page C3-1

Restore the License Projects

Restore the license projects from the backup.

SEE ALSO For more information about the procedure for restoring license projects, refer to:

“■ Restoring a license project on another license management station” in 3.6, “Backing up and restoring a license project” in License Management Guide (IM 32P01C60-01EN)

Redistribute Licenses to License-Assigned Stations

Redistribute licenses to the license-assigned stations.

SEE ALSO For more information about redistributing licenses from the license management station, refer to:

3.4, “Redistributing licenses to license-assigned stations” in License Management Guide (IM 32P01C60-01EN)

C7. Troubleshooting

This section describes the causes of and remedies for problems that may occur.

C7.1 Windows Related Troubleshooting

This section describes how to handle problems related to Windows.

Note on User Account Control

If you log on as a non-administrative user and try to start the installer, the User Account Control dialog box appears. Click [No] and log on again as an administrative user, and then start the installer again.

The System Locks Up

Contact YOKOGAWA service.

Computer Operation Becomes Unstable

If the operation of the computer that was working normally has become unstable, do the task described below.

Cause

Incompatible software was installed.

Remedy

Uninstall the incompatible software you have installed.

SEE ALSO For more information about software that can coexist with ProSafe-RS, refer to:

"● Software that can coexist with ProSafe-RS" in "■ Software requirements for SENG" in A1.2, "Software requirements" in ProSafe-RS User's Guide (IM 32P01B10-01EN)

Cannot Change the Time Zone (Windows Server 2019, Windows Server 2022)

You cannot change the time zone in the Date and Time window.

Condition for Occurrence

- When the OS is Windows Server 2019 or Windows Server 2022 and User Account Control is enabled:
  Administrators other than the built-in Administrator cannot change the time zone.
- In addition, if "User Account Control: Admin Approval Mode for the Built-in Administrator account" is enabled in IT security settings:
  The time zone cannot be changed even if you are a built-in Administrator.

Problem

When you start the Control Panel and click the [Date and Time] > [Change the time zone] button, the following error message appears.

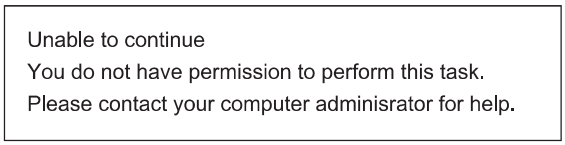


Figure C7.1-1 Error message

Also, if you click [Settings] > [Time & Language] from the Start menu to display the Date & Time window, the behavior will be as follows.

- For Windows Server 2019
  Even if you select any time from the [Time zone] drop-down list, the setting will return to the previous setting when you redisplay the window.
- For Windows Server 2022
  The [Time zone] drop-down list is grayed out and cannot be selected.

Workaround

Follow these steps:

1. Sign in as an administrative user.
2. Right-click the Start menu, select [Search], and search for the keyword timedate.cpl.
3. From the search results, right-click [timedate.cpl], and select [Run as administrator].
4. Change the time zone.

C7.2 Troubleshooting Related to Network

This section describes how to handle problems related to the network.

C7.2.1 Precaution on Network Cable Connection

A network charm bar may appear from the right side of the desktop when the cable is wired. If it appears, select [No].

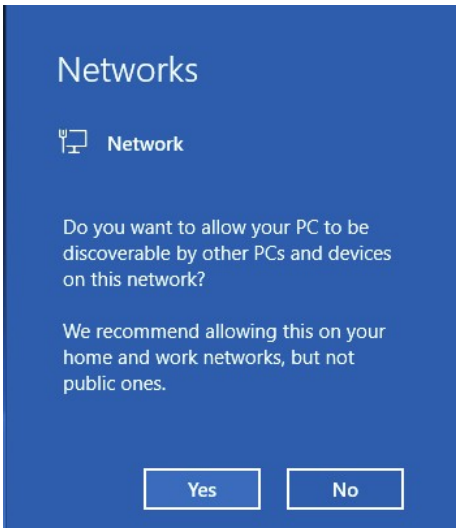

Figure C7.2.1-1 Network Charm Bar

C7.2.2 Problems Related to Installation and Deletion of Drivers

This section provides troubleshooting related to the installation and deletion of network drivers.

IMPORTANT

Some operations require administrative rights, and a User Account Control dialog box may appear when you try to do such operations. You can continue with the operation by clicking [Yes], [Continue], or [Allow] (if the user has administrator rights).

Confirming Installation Result

Check if the network driver is properly installed. If the driver is not operating property, install it again.

Adapter Driver for Control Bus Driver

When the control bus driver is added, the adapter driver “Yokogawa Vnet Adapter” appears under Network Adapters on Device Manager.

If the adapter driver does not start properly, "!" appears on the adapter driver icon.

Follow these steps to display Device Manger:

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [System] > [Device Manager].

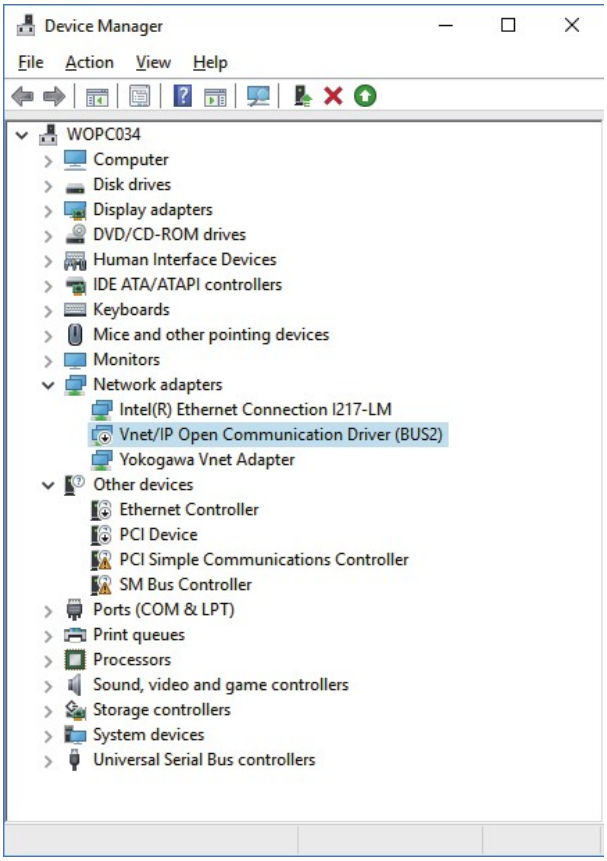

Figure C7.2.2-1 Adapter Driver Added Properly

Protocol Driver for Control Bus Driver

When the control bus driver is added, the protocol driver is installed together with the adapter driver.

The operating condition of the protocol driver can be checked in Command Prompt.

Follow these steps to check the operating condition of the protocol driver:

1. Sign in as a general user or administrative user.
2. Open Command Prompt.
3. Enter `sc query VLTDI`.
   The condition of the protocol driver is shown. If RUNNING is shown under STATE, the driver is operating properly.

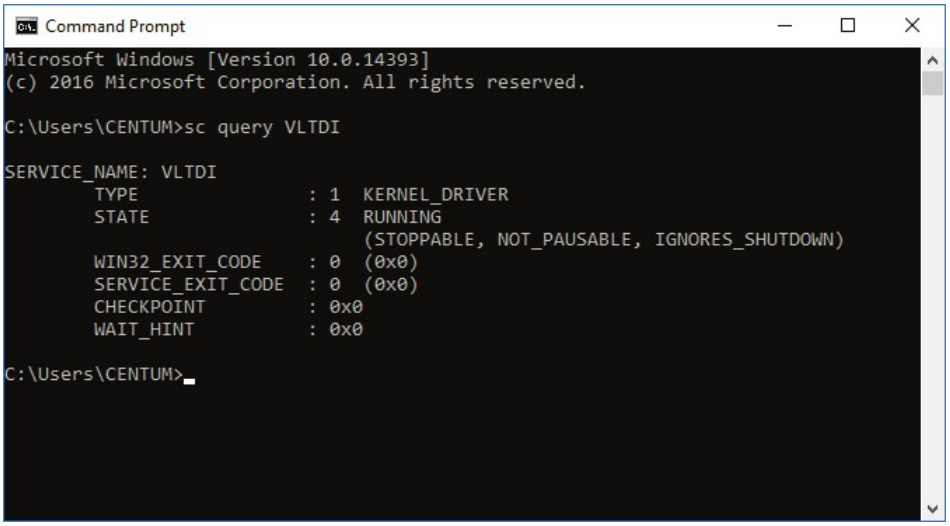

Figure C7.2.2-2 Protocol Driver Operating Properly

Vnet/IP Open Communication Driver

When the driver is added, “Vnet/IP Open Communication Driver (BUS2)” appears in Network Adapters in Device Manager.

If the driver does not start successfully, the “!” symbol appears next to the network adapter icon.

Follow these steps to display Device Manger:

1. Log on as an administrative user.
2. Open the Control Panel.
3. Select [System and Security] > [System] > [Device Manager].

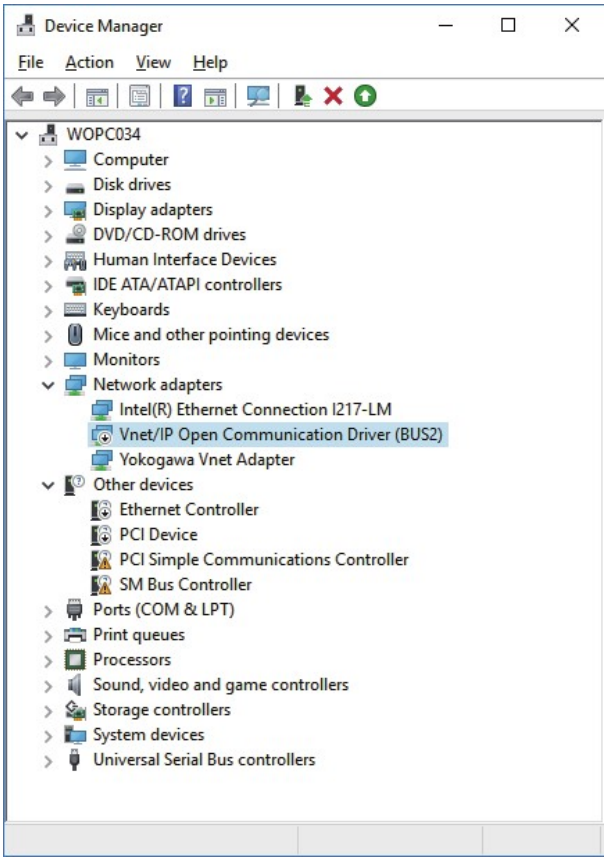

Figure C7.2.2-3 Adapter Driver Added Properly

Control Bus Driver is Successfully Installed but Does Not Start

The control bus driver may not start normally due to wrong connection of the bus cables or mistakes in address setting. In this case, VLNIC errors are recorded in the System log of Event Viewer.

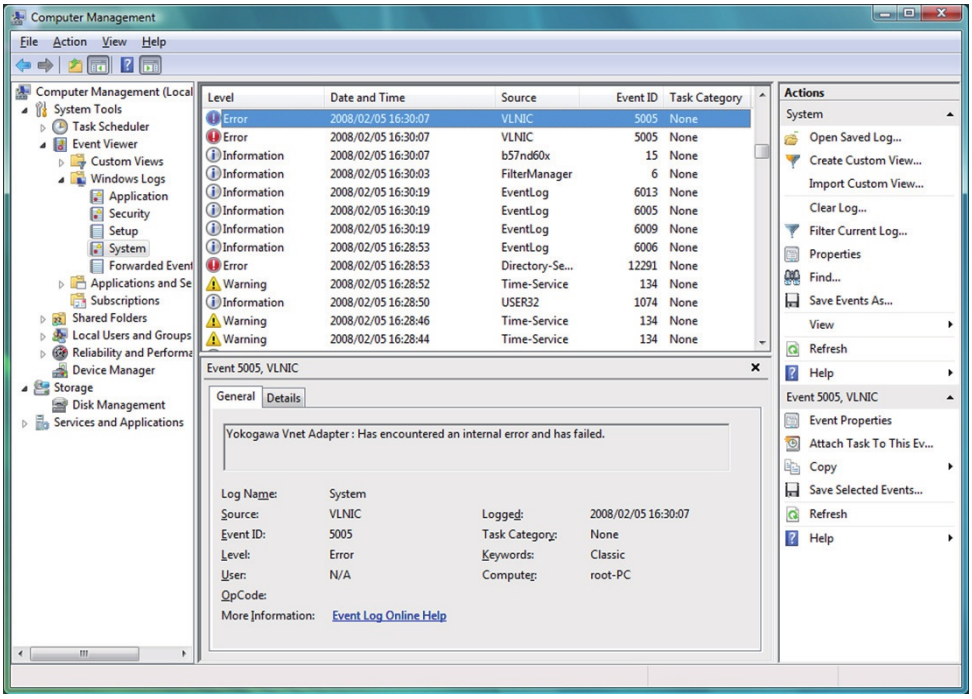

Figure C7.2.2-4 Event Viewer Recording VLNIC Errors (System)

1. Double-click a VLNIC error.
   The Event Properties dialog box appears.

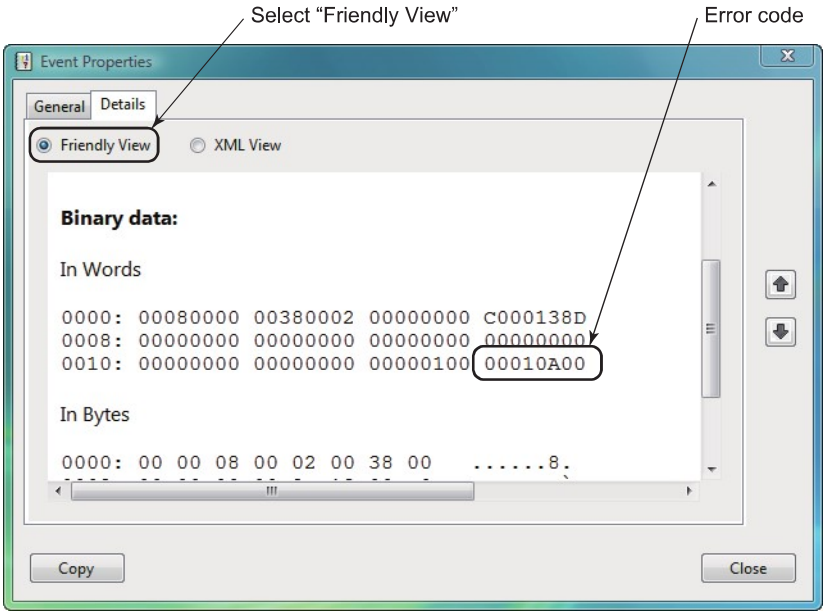

Figure C7.2.2-5 Event Properties

2. Look up the error code in the following table. If the problem is caused by the bus configuration and/or address setting, make sure that the settings are correctly made and shut down the computer. Then start up the computer again.

Table C7.2.2-1 Error Codes Generated when Starting the Driver

Code (*1)	Meaning
000101**	RAM parity error (failure of VF702/VF701/VI702/VI701 card)

Continues on the next page

Table C7.2.2-1 Error Codes Generated when Starting the Driver (Table continued)

Code (*1)	Meaning
000102**	RAM read/write error (failure of VF702/VF701/VI702/VI701 card)
000109**	Address overlap error
00010a**	Bus configuration error (wrong bus connector connection)
00010b**	Dip switch station number parity error
00010c**	Dip switch domain number parity error
00010d**	Inappropriate dip switch station number setting
00020013	Illegal station number (may be detected in the case of bus connector connection mistakes)

*1: In the code, a 2-digit number 00 is displayed at the position of ** for VF702/VF701 while others for VI702/VI701.

If the driver still does not start, other possible causes may be a failure of the control bus interface card or Vnet/IP interface card, or conflicts with other devices.

Replace the control bus interface card or Vnet/IP interface card, or remove the other devices from the computer.

Duplicate Instances of the Installer

You cannot start two instances of the installer. If you start a second instance, a warning message appears. Click [OK] and terminate the installer you started later.

The processing of the installer started first continues.

Error Message is Displayed during Network Driver Installation – 1

If an error message is displayed when you click [Don't Install] in the Windows Security dialog box that appears during installation of a network driver, perform the following tasks.

Figure C7.2.2-6 Windows Security Dialog Box (for Network Adapter)

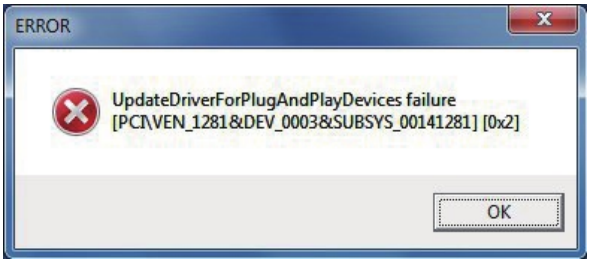

Figure C7.2.2-7 Error Message (for Network Adapter)

Control Bus Driver

1. After restarting the computer, click [Control Bus Drier] on the installation menu.
2. If the control bus driver can be deleted, delete it and then restart the computer.
3. Install the control bus driver again.

Vnet/IP Open Communication Driver

Start the installer again.

Error Message is Displayed during Network Driver Installation – 2

If an error message is displayed when you did not click [Do not install] in the Windows Security dialog box (for confirming installation of the network protocol or network adapter) that appears during installation of a network driver, perform the following tasks.

Control Bus Driver

1. After restarting the computer, click [Control Bus Driver] on the installation menu.
2. Perform either of the following operations:
   - If the control bus driver can be deleted, delete it and restart the computer. Then, install the driver again.
   - If the control bus driver cannot be deleted, restart the computer and install the driver again.

Vnet/IP Open Communication Driver

1. Start the installation menu again and click [Vnet/IP Open Communication Driver].
2. Perform either of the following operations:
   - If the driver can be deleted, delete it and restart the computer. Then, install the driver again.
   - If the driver cannot be deleted, restart the computer and install the driver again.

Error Message is Displayed during Network Driver Installation – 3

Previously functioning Ethernet communications may fail, generating an error message.

Cause

- Hardware, such as the Ethernet adapter card and Ethernet cable, is not connected properly.
- The network binding is not correctly set.
- The TCP/IP communication settings are not correct (IP address, subnet mask, etc.)

Remedy

- Check the hardware, Ethernet adapter card, and the Ethernet cable.
- In Control Panel, check the “Network and Sharing Center” settings.

Restarted the Computer After Deleting the Driver without Removing the Control Bus Interface Card or Vnet/IP Open Interface Card from the Computer

The actions you should take are described for the control bus driver and for the Vnet/IP open communication driver.

Control Bus Driver

If you restart the computer after deleting the control bus driver without removing the control bus interface card from the computer, Windows judges that the control bus interface card is a newly added device and displays the following dialog box.

Figure C7.2.2-8 Found New Hardware Dialog Box

Click [Ask me again later] here. Then, if you do not install the control bus driver, shut down the computer and remove the control bus interface card.

Vnet/IP Open Communication Driver

If you restart the computer after deleting the Vnet/IP open communication driver without removing the Vnet/IP interface card from the computer, Windows judges that the Vnet/IP interface card is a newly added device and prompts you to install the driver for it.

In this case, ignore the prompting message and do not install the driver.

D. Connection with Other Products

ProSafe-RS can be connected with YOKOGAWA products, such as CENTUM VP, PRM, and Exaquantum.

When connecting to these products, you may need to change the IT security settings.

This section describes the information and procedures on how to connect various products after installation.

D1. Connecting YOKOGAWA products

This section describes the settings that are required to connect YOKOGAWA products.

For each connection case, an integration code is assigned. You must perform the tasks that are required for the corresponding integration code of your connection case.

IMPORTANT

- Ensure that the security model and the user management type of the products that you are connecting are the same.
- If the Strengthened model is applied to the products that you want to connect, contact YOKOGAWA.

SEE ALSO For more information about security models, user management types, users and groups, and security settings, refer to:

1., “Overview” in ProSafe-RS Security Guide (IM 32P01C70-01EN)

Integration code

The format of the integration code is as follows:

(Package code 1) - (Package code 2) - (Integration type) - (Revision number)

The following table describes the elements of an integration code.

Table D1-1 Integration code elements

Element	Description
Package code	The code that is assigned to a software package that can be installed independently on a computer. First package code is the package code of product 1, and Second package code is the package code of product 2.
Integration type	The connection setup of various products. The possible values are: • 01: When products are installed and operated on the same computer, and they cannot communicate or share files with each other. • 02: When products are installed and operated on separate computers, and they can communicate or share files with each other. • 03: When products are installed and operated either on the same computer or on separate computers, and they can function together by communicating or sharing files with each other.
Revision number	The version or revision number of the products that you want to connect. When the required connection procedures change on release of new versions or revisions, this revision number is incremented. The revision number can be from 01 to 99.

IMPORTANT

- You cannot install two products that have integration type 02 on the same computer.
- In the user's manuals of a product, the settings that are required to connect with other products are explained. However, information about the settings for connection that is provided in the user's manuals may be inconsistent between the connected products. The reason is that different products are released at different timings. To get the latest information, refer to the user's manuals of both products to check the product version number and the revision number of the integration code for their combination, and use the most recent setting procedure.

Package codes

The following table describes the package codes of various YOKOGAWA products.

Table D1-2 Package codes

Package code	Product	Package
0101	CENTUM VP	CENTUM VP Standard Operation and Monitoring Function (*1)
0102	CENTUM VP	System Builder Function
0108	CENTUM VP	Report Package
0121	CENTUM VP	Engineering Server Function
0153	CENTUM VP	SOE Viewer Package
0196	CENTUM VP	Project Database
0201	ProSafe-RS	Safety System Engineering and Maintenance Function
0202	ProSafe-RS	SOE OPC Interface Package
0203	ProSafe-RS	CENTUM VP Integration Package
0204	ProSafe-RS	CI Server Integration Package
0205	ProSafe-RS	Engineering Server Function
0251	ProSafe-RS	SOE Viewer Package
0252	ProSafe-RS	iDefine for ProSafe-RS
0253	ProSafe-RS	Forced I/O Viewer Package
0296	ProSafe-RS	Project Database
0299	ProSafe-RS	License Manager
0301	PRM	Plant Resource Manager Field Communications Server
0302	PRM	Plant Resource Manager Server
0351	PRM	Plant Resource Manager DeviceViewer
0352	PRM	PRM Client
0401	Exaopc	Exaopc OPC Interface Package
0801	Exaquantum	PIMS Server
0851	Exaquantum	Explorer Client
1202	STARDOM	STARDOM FCN/FCJ OPC Server

*1: As an optional function for this package, Exaopc OPC Interface Package (for HIS) is available. Consolidated Alarm Management Function (CAMS for HIS) is included in Standard Operation and Monitoring Function.

D1.1 CENTUM VP and ProSafe-RS

This section describes the settings when connecting CENTUM VP and ProSafe-RS.

IMPORTANT

- When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
- Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

D1.1.1 CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS Safety System Engineering and Maintenance Function

By connecting CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS Safety System Engineering and Maintenance Function, you can use CENTUM integration function of ProSafe-RS.

Using CENTUM integration function of ProSafe-RS

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.1-1 Connection information

Integration code	0101-0201-03-05		
Product 1	Standard Operation and Monitoring Function of CENTUM VP R5.01 or later (*1)		
Product 2	Safety System Engineering and Maintenance Function of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

For Standalone management, perform this setting on the computer where the ProSafe-RS safety system engineering and maintenance function is used and the computer where the CENTUM VP standard operation and monitoring function is used. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

1. Add the ProSafe-RS user account to CENTUM VP groups according to the following table.

Table D1.1.1-2 ProSafe-RS groups and their corresponding CENTUM VP groups

ProSafe-RS group	CENTUM VP group
PSF_MAINTENANCE	CTM_MAINTENANCE or CTM_MAINTENANCE_LCL
PSF_MAINTENANCE_LCL	CTM_MAINTENANCE or CTM_MAINTENANCE_LCL
PSF_ENGINEER	CTM_ENGINEER and CTM_ENGINEER_ADM
PSF_OPERATOR	CTM_OPERATOR
PSF_OPC	CTM_OPC or CTM_OPC_LCL
PSF_OPC_LCL	CTM_OPC or CTM_OPC_LCL
PSF_UTL	None

2. Add the CENTUM VP user account to ProSafeRS groups according to the following table.

Table D1.1.1-3 CENTUM VP groups and their corresponding ProSafe-RS groups

CENTUM VP group	ProSafe-RS group
CTM_MAINTENANCE	PSF_MAINTENANCE or PSF_MAINTENANCE_LCL
CTM_MAINTENANCE_LCL	PSF_MAINTENANCE or PSF_MAINTENANCE_LCL
CTM_ENGINEER	PSF_ENGINEER
CTM_ENGINEER_ADM	PSF_ENGINEER
CTM_OPC	PSF_OPC or PSF_OPC_LCL
CTM_OPC_LCL	PSF_OPC or PSF_OPC_LCL

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

D1.1.2 CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS SOE Viewer Package

By connecting CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS SOE Viewer Package, you can view historical information of CENTUM VP HIS on ProSafe-RS SOE Viewer.

Viewing Historical Information of CENTUM VP on ProSafe-RS SOE Viewer

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.2-1 Connection information

Integration code	0101-0251-03-05		
Product 1	Standard Operation and Monitoring Function of CENTUM VP R5.01 or later (*1)		
Product 2	SOE Viewer Package of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

For Standalone management, perform this setting on the computer where ProSafe-RS SOE Viewer is used. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

- When enabling collaboration with products installed on the same computer
  Add the user account for using ProSafe-RS SOE Viewer to the CTM_OPERATOR group.
- When enabling collaboration with products installed on different computers
  Register the user account for using ProSafe-RS SOE Viewer to the computer where CENTUM VP HIS runs. The user name and password of the user account to be registered must be the same as those of the user account that uses ProSafe-RS SOE Viewer. Add the registered user account to CTM_OPERATOR group.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

D1.1.3 CENTUM VP SOE Viewer Package and ProSafe-RS Safety System Engineering and Maintenance Function

By connecting CENTUM VP SOE Viewer Package and ProSafe-RS Safety System Engineering and Maintenance Function, you can view SOE events of ProSafe-RS on CENTUM VP SOE Viewer.

Viewing SOE events of ProSafe-RS on CENTUM VP SOE Viewer

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.3-1 Connection information

Integration code	0153-0201-03-05		
Product 1	SOE Viewer Package of CENTUM VP R5.01 or later (*1)		
Product 2	Safety System Engineering and Maintenance Function of ProSafe-RS R3.01 or later (*1) (*2)		
Security model	Legacy model	Standard model	
User management type	N/A	Standalone management	Domain/Combination/Linked domain management (*3)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: The ProSafe-RS software package licenses are not required.
*3: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

Add the user account for using CENTUM VP SOE Viewer to the PSF_OPERATOR group.

For Standalone management, perform this setting on the computer where CENTUM VP SOE Viewer is used. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

D1.1.4 CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS SOE OPC Interface Package

This section explains the required settings when Exaopc OPC Interface Package (for HIS) of CENTUM VP and SOE OPC Interface Package of ProSafe-RS are installed on the same computer.

If the computer installed with both packages comes under either of the following cases, perform all the procedures explained for each case.

- The computer installed with both packages is designated as the OPC server for OPC communication.
- The computer installed with both packages uses OPC client services.
- In a Domain, Combination, or Linked domain management system, the computer installed with both packages is designated as the OPC server on an OPC client computer that is not a member of the domain.

When the computer installed with both packages is designated as the OPC server to communicate with

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.4-1 Connection information

Integration code	0101-0202-01-02		
Product 1	Standard Operation and Monitoring Function of CENTUM VP R5.01 or later (*1)		
Product 2	ProSafe-RS SOE OPC Interface Package of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

On the OPC server computer, add the user account for using OPC client services on OPC client computers to the CTM_OPC and PSF_OPC groups.

For Domain, Combination, or Linked domain management, perform this setting task on the domain controller. For Standalone management, create on the OPC server computer a user account with the same name as the local user who uses OPC client services on the OPC client computer, and add the user account to the CTM_OPC and PSF_OPC groups.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

● Users who use OPC client services

The following table shows the users who use OPC client services:

Table D1.1.4-2 Users who use OPC client services

OPC client service	User
Report Package	User who logged on to Windows
Access Administrator Package (FDA:21 CFR Part 11 compliant)	User who logged on to Windows
OPC client other than CENTUM VP product.(*1)	Users who use OPC client services

*1: Functions created using CENTUM Data Access Library are also included.

When the computer installed with both packages uses OPC client services

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.4-3 Connection information

Integration code	0101-0202-01-02		
Product 1	Standard Operation and Monitoring Function of CENTUM VP R5.01 or later (*1)		
Product 2	ProSafe-RS SOE OPC Interface Package of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

● When the Standard model is applied

Add the user account for using OPC client services to the CTM_OPC and PSF_OPC groups.

For Standalone management, perform this setting on OPC client computers. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

● Users who use OPC client services

The following table shows the users who use OPC client services:

Table D1.1.4-4 Users who use OPC client services

OPC client service	User
Report Package	User who logged on to Windows
Access Administrator Package (FDA:21 CFR Part 11 compliant)	User who logged on to Windows
FCS Data Setting/Acquisition Package (PICOT)	User who logged on to Windows
Consolidated Alarm Management Function (CAMS for HIS)	User that was specified when setting up the OPC A&E server connection
OPC client other than CENTUM VP product (*1)	Users who use OPC client services

*1: Functions created using CENTUM Data Access Library are also included.

● When FCS Data Setting/Acquisition Package (PICOT) is used

If FCS Data Setting/Acquisition Package (PICOT) (LHS6710) and HIS type single sign on are used, also perform the following setting:

For Standalone or Linked domain management:	On the computer running the package, add OFFUSER to the PSF_OPC group.
For Domain or Combination management:	On the computer running the package, add OFFUSER to the PSF_OPC_LCL group.

■ When the computer installed with both packages is designated as the OPC server to communicate with on the OPC client computer that is not a member of the domain

The following table shows the connection information for the case where Domain or Combination management is applied and the computer installed with both packages is designated as the OPC server on the OPC client computer that is not a member of the domain. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.4-5 Connection information

Integration code	0101-0202-01-04
Product 1	Standard Operation and Monitoring Function of CENTUM VP R5.01 or later (*1)
Product 2	ProSafe-RS SOE OPC Interface Package of ProSafe-RS R3.01 or later (*1)
Security model	Standard model
User management type	Domain/Combination/Linked domain management (*2)
Required procedures	Refer to "● Required procedures for connection."

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

● Required procedures for connection

On the OPC server computer, create a user account with the same name as the local user who performs OPC communication on the OPC client computer, and then add the user account to the following groups.

For Domain or Combination management:	CTM_OPC_LCL and PSF_OPC_LCL groups
For Linked domain management:	CTM_OPC and PSF_OPC groups

SEE ALSO For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

Local Users Who Use OPC Client Service

The following table shows the local users who use OPC client services:

Table D1.1.4-6 Local Users Who Use OPC Client Service

OPC client service	User
Report Package	User who logged on to Windows
OPC client other than CENTUM VP product (*1)	Users who use OPC client services

*1: Functions created using CENTUM Data Access Library are also included.

D1.1.5 CENTUM VP Standard Operation and Monitoring Function and ProSafe-RS Forced I/O Viewer Package

You can use ProSafe-RS Forced I/O Viewer Package on a computer where CENTUM VP Standard Operation and Monitoring Function is installed.

TIP

You cannot install ProSafe-RS Forced I/O Viewer Package on a computer where ProSafe-RS Safety System Engineering and Maintenance Function is installed.

Viewing the ProSafe-RS forced-I/O information

The following table describes the connection information. This table also describes the information for connecting with other CENTUM VP packages.

Table D1.1.5-1 Connection information

Integration code	0101-0253-01-02 The same applies to the following combinations: 0102-0253-01-02, 0108-0253-01-02, 0109-0253-01-02, 0110-0253-01-02, 0111-0253-01-02, 0112-0253-01-02, 0113-0253-01-02, 0114-0253-01-02, 0118-0253-01-02, 0119-0253-01-02, 0120-0253-01-02, 0121-0253-01-02, 0152-0253-01-02, 0153-0253-01-02, 0199-0253-01-02		
Product 1	Standard Operation and Monitoring Function of CENTUM VP R6.06 or later (*1)		
Product 2	Forced I/O Viewer Package of ProSafe-RS R4.05 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/ Linked domain management (*2)
Required procedures	Read the reference that follows the table.		

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

SEE ALSO

For more information about the settings required to use Forced I/O Viewer Package, refer to:

B4.4, “Settings Required to Use the Forced I/O Viewer Function” on page B4-5

D1.1.6 CENTUM VP System Builder Function and ProSafe-RS CENTUM VP Integration Package

By using ProSafe-RS CENTUM VP Integration Package, you can build an integrated system of CENTUM VP and ProSafe-RS.

Building a system by integrating CENTUM VP and ProSafe-RS

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.6-1 Connection information

Integration code	0102-0203-03-05		
Product 1	System Builder Function of CENTUM VP R5.01 or later (*1)		
Product 2	CENTUM VP Integration Package of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

- When CENTUM VP project is placed on a computer where SCS Manager is used:

  Add the user account for using SCS Manager of ProSafe-RS to the CTM_ENGINEER and PSF_ENGINEER groups.

  For Standalone management, perform this setting on the computer where SCS Manager is used. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

- When CENTUM VP project is placed on a computer where SCS Manager is not used:

  For Standalone management, create a user account with the same name as the user who uses SCS Manager on the computer where the CENTUM VP project is placed and then add the user account to the CTM_ENGINEER group.

  For Domain, Combination, or Linked domain management, add the user account for using SCS Manager to the CTM_ENGINEER group on the domain controller.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

D1.1.7 CENTUM VP System Builder Function and ProSafe-RS Safety System Engineering and Maintenance Function

By connecting CENTUM VP System Builder Function and ProSafe-RS Safety System Engineering and Maintenance Function, you can perform simulation tests of SCS using SCS simulator of ProSafe-RS.

Enabling SCS simulation tests using SCS simulator

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.7-1 Connection information

Integration code	0102-0201-03-05		
Product 1	System Builder Function of CENTUM VP R5.01 or later (*1)		
Product 2	Safety System Engineering and Maintenance Function of ProSafe-RS R3.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	None	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Standard model is applied

Add all the user accounts for using SCS Manager of ProSafe-RS or System View of CENTUM VP to the CTM_ENGINEER and PSF_ENGINEER groups.

For Standalone management, perform this setting on the computer where SCS Manager of ProSafe-RS and System View are used. For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

SEE ALSO

For more information about how to create user accounts and add them to groups in Domain, Combination, or Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

D1.1.8 CENTUM VP Engineering Server Function and ProSafe-RS Safety System Engineering and Maintenance Function

When the CENTUM VP engineering server function and ProSafe-RS safety system engineering and maintenance function are connected, the AD Suite client function and server function work in collaboration so that I/O list engineering and change management function can be used.

Performing engineering and maintenance of a ProSafe-RS safety system by using a CENTUM VP engineering server

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.8-1 Connection information

Integration code	0121-0201-03-03		
Product 1	Engineering Server Function of CENTUM VP R6.02 or later (*1)		
Product 2	Safety System Engineering and Maintenance Function of ProSafe-RS R4.01 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	Refer to "● When the Legacy model is applied."	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Legacy model is applied

On the AD Suite client computer and AD Suite server computer, create Windows users who use this function.

Use the ADS Administration Tool to register the Windows users to the engineering server.

When the Standard model is applied

On the AD Suite client computer and AD Suite server computer, create Windows users who use this function.

Add the user accounts to the CTM_ENGINEER and PSF_ENGINEER groups. For Standalone management, perform this setting task on the computer where the CENTUM VP engineering server is used and also on the computer where the ProSafe-RS safety system engineering and maintenance function is used.

For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

Use the ADS Administration Tool to register the Windows users to the engineering server.

SEE ALSO For more information about how to create user accounts and add them to groups, refer to:

C1.2, “Management of AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

D1.1.9 CENTUM VP System Builder Function and ProSafe-RS Engineering Server Function

When the CENTUM VP system generation function and ProSafe-RS engineering server function are connected, the AD Suite client function and server function work in collaboration so that the module-based engineering and change management function can be used.

Generating a CENTUM VP system using a ProSafe-RS engineering server

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.1.9-1 Connection information

Integration code	0205-0102-03-03		
Product 1	Engineering Server Function of ProSafe-RS R4.01 or later (*1)		
Product 2	System Builder Function of CENTUM VP R6.02 or later (*1)		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination/Linked domain management (*2)
Required procedures	Refer to "● When the Legacy model is applied."	Refer to "● When the Standard model is applied."	

*1: When you install CENTUM VP and ProSafe-RS on the same computer, ensure that the software revision of CENTUM VP is R6.11.00 or later and the software revision of ProSafe-RS is R4.10.00 or later.
*2: Linked domain management is supported by CENTUM VP R6.08.00 or later and ProSafe-RS R4.06.00 or later software revisions.

When the Legacy model is applied

On the AD Suite client computer and AD Suite server computer, create Windows users who use this function.

Use the ADS Administration Tool to register the Windows users to the engineering server.

When the Standard model is applied

On the AD Suite client computer and AD Suite server computer, create Windows users who use this function.

Add the user accounts to the CTM_ENGINEER and PSF_ENGINEER groups. For Standalone management, perform this setting task on the computer where the CENTUM VP system builder function is used and also on the computer where the ProSafe-RS engineering server function is used.

For Domain, Combination, or Linked domain management, perform this setting on the domain controller.

Use the ADS Administration Tool to register the Windows users to the engineering server.

SEE ALSO For more information about how to create user accounts and add them to groups, refer to:

C1.2, “Management of AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

D1.2 ProSafe-RS and iDefine

This section describes the settings when connecting ProSafe-RS and iDefine.

IMPORTANT

- When using ProSafe-RS and iDefine for ProSafe-RS, use ProSafe-RS R4.02 to R4.08.

  If you want to use SENG to edit engineering data created with iDefine for ProSafe-RS, contact YOKOGAWA.

- iDefine for ProSafe-RS can be installed on the same computer as ProSafe-RS software packages and collaborates with the Safety System Engineering and Maintenance Function.

  In ProSafe-RS R4.05 or later, you can install the combination of iDefine for ProSafe-RS, ProSafe-RS, and CENTUM VP on a same computer.

  You cannot install iDefine for ProSafe-RS on a computer where CENTUM VP SOE Server Package is installed.

- When you install ProSafe-RS and iDefine for ProSafe-RS on the same computer, install ProSafe-RS first and then iDefine for ProSafe-RS in succession. After installing iDefine for ProSafe-RS, configure IT security settings.

- The combination of versions between ProSafe-RS and iDefine for ProSafe-RS is fixed. For example, ProSafe-RS R4.06 can collaborate only with iDefine for ProSafe-RS 1.16.6.

SEE ALSO For more information about the available combination of versions between ProSafe-RS and iDefine for ProSefe-RS, refer to:

“■ Use of iDefine” in A1.2, “Software requirements” in ProSafe-RS User’s Guide (IM 32P01B10-01EN)

D1.2.1 ProSafe-RS Safety System Engineering and Maintenance Function and iDefine for ProSafe-RS

Connecting the ProSafe-RS Safety System Engineering and Maintenance Function and iDefine for ProSafe-RS enables exchange of engineering data between ProSafe-RS and iDefine. It also enables execution of ProSafe-RS logic simulation test, SCS simulation test, and target test from iDefine by using iDefine Test Manager.

Exchanging engineering data between ProSafe-RS and iDefine, and using iDefine Test Manger

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table.

Table D1.2.1-1 Connection information

Integration code	0201-0252-03-05			
Product 1	Safety System Engineering and Maintenance Function of ProSafe-RS R4.06 or later			
Product 2	iDefine for ProSafe-RS 1.16.6 or later			
Security model	Legacy model	Standard model		
User management type	-	Standalone management	Domain/Combination management	Linked domain management (*1)
Required procedures	Refer to "● When the Legacy model is applied."	Refer to "● When the Standard model is applied with Standalone management."	Refer to "● When the Standard model is applied with Domain or Combination management."	Refer to "● When the Standard model is applied with Linked domain management."

*1: Linked domain management is supported by ProSafe-RS R4.06.00 or later software.

When the Legacy model is applied

- When installing on the same computer
  No procedure is requited.
- When installing on separate computers
  On the computer where you run the ProSafe-RS Safety System Engineering and Maintenance Function, create the logon users of the computer where you run iDefine. For the users that you create, use the same user names and passwords as those of the users on the computer where you run iDefine.

When the Standard model is applied with Standalone management

- When installing on the same computer
  Add the users who use iDefine to one of the following groups:
  - PSF_OPERATOR
  - PSF_ENGINEER
  - PSF_MAINTENANCE

  In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER group.
- When installing on separate computers
  1. On the computer where you run the ProSafe-RS Safety System Engineering and Maintenance Function, create the logon users of the computer where you run iDefine. For the users that you create, use the same user names and passwords as those of the users on the computer where you run iDefine.

2. Add the created users to the PSF_ENGINEER group on the computer where you run the ProSafe-RS Safety System Engineering and Maintenance Function.

SEE ALSO For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

When the Standard model is applied with Domain or Combination management

- When installing on the same computer
  Add the users who use iDefine to one of the following groups:
  - PSF_OPERATOR
  - PSF_OPERATOR_LCL
  - PSF_ENGINEER
  - PSF_ENGINEER_LCL
  - PSF_MAINTENANCE
  - PSF_MAINTENANCE_LCL

  In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER or PSF_ENGINEER_LCL group.
- When installing on separate computers
  1. On the domain controller, add the computer that you run iDefine to the domain and create the logon users of the computer where you run iDefine.
  2. Add the created users to the PSF_ENGINEER group.

SEE ALSO For more information about how to create user accounts and add them to groups in Domain or Combination management, refer to:

B2.4, “Creating Domain Users” on page B2-13

When the Standard model is applied with Linked domain management

- When installing on the same computer
  Add the users who use iDefine to one of the following groups:
  - PSF_OPERATOR
  - PSF_ENGINEER
  - PSF_MAINTENANCE

  In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER group.
- When installing on separate computers
  1. On the domain controller, add the computer that you run iDefine to the domain and create the logon users of the computer where you run iDefine.
  2. Add the created users to the PSF_ENGINEER group.

SEE ALSO For more information about how to create user accounts and add them to groups in Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

D1.2.2 ProSafe-RS functions other than Safety System Engineering and Maintenance Function and iDefine for ProSafe-RS

This section describes the settings when installing ProSafe-RS functions other than Safety System Engineering and Maintenance Function and iDefine for ProSafe-RS on the same computer.

Installing ProSafe-RS SOE OPC Interface Package and iDefine for ProSafe-RS on the same computer

The following table describes the connection information. This table also describes the information for connecting with other ProSafe-RS packages. For required procedures for connection, read the descriptions that follow the table.

Table D1.2.2-1 Connection information

Integration code	0202-0252-01-04 The same applies to the following combinations: 0203-0252-01-04, 0204-0252-01-04, 0205-0252-01-04, 0251-0252-01-04, 0296-0252-01-04, 0299-0252-01-04, 0253-0252-01-02			
Product 1	SOE OPC Interface Package of ProSafe-RS R4.06 or later			
Product 2	iDefine for ProSafe-RS 1.16.6 or later			
Security model	Legacy model	Standard model		
User management type	-	Standalone management	Domain/Combination management	Linked domain management (*1)
Required procedures	None	Refer to "● When the Standard model is applied with Standalone management."	Refer to "● When the Standard model is applied with Domain or Combination management."	Refer to "● When the Standard model is applied with Linked domain management."

*1: Linked domain management is supported by ProSafe-RS R4.06.00 or later software.

When the Standard model is applied with Standalone management

Add the users who use iDefine to one of the following groups:

- PSF_OPERATOR
- PSF_ENGINEER
- PSF_MAINTENANCE

In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER group.

SEE ALSO For more information about how to create user accounts and add them to groups in Standalone management, refer to:

B3.8.1, “When the Standard Model with Standalone Management Security Settings are Applied” on page B3-57

When the Standard model is applied with Domain or Combination management

Add the users who use iDefine to one of the following groups:

- PSF_OPERATOR
- PSF_OPERATOR_LCL

- PSF_ENGINEER
- PSF_ENGINEER_LCL
- PSF_MAINTENANCE
- PSF_MAINTENANCE_LCL

In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER or PSF_ENGINEER_LCL group.

SEE ALSO For more information about how to create user accounts and add them to groups in Domain or Combination management, refer to:

B2.4, “Creating Domain Users” on page B2-13

When the Standard model is applied with Linked domain management

Add the users who use iDefine to one of the following groups:

- PSF_OPERATOR
- PSF_ENGINEER
- PSF_MAINTENANCE

In addition, add the users who perform communication with iDefine Test Manager through iDefine to the PSF_ENGINEER group.

SEE ALSO For more information about how to create user accounts and add them to groups in Linked domain management, refer to:

B2.4, “Creating Domain Users” on page B2-13

D1.3 ProSafe-RS and PRM

This section describes the settings when connecting ProSafe-RS and PRM.

IMPORTANT

- Linked domain management is supported by ProSafe-RS R4.06.00 or later and PRM R4.04.00 or later software revisions.
- When you install ProSafe-RS and PRM client on the same computer, ensure that the software revision of ProSafe-RS is R4.04.00 or later and PRM is R4.02.00 or later. When you install ProSafe-RS and PRM on the same computer with linked domain management, ensure that the software revision of ProSafe-RS is R4.06.00 or later and the software revision of PRM is R4.04.00 or later.

D1.3.1 ProSafe-RS SOE OPC Interface Package and PRM Server

Connecting the ProSafe-RS and PRM Server enables PRM to retrieve ProSafe-RS messages. To perform OPC communication with PRM, the SOE OPC Interface Package is required. No setting is required on the PRM Server.

IMPORTANT

PRM Server and ProSafe-RS software cannot be installed on the same computer.

Enabling PRM to retrieve messages from ProSafe-RS

The following table shows the connection information. The required procedures of connecting the products are provided after the table.

Table D1.3.1-1 Connection information

Integration code	0202-0302-02-04			
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later			
Product 2	Plant Resource Manager Server of PRM R3.20 or later			
Security model	Legacy model	Standard model		
User management type	-	Standalone management	Domain/Combination management	Linked domain management (*1)
Required procedures	Refer to "● When the Legacy model is applied."	Refer to "● Setting the logon type with Standard model", "● Creating internal user accounts with Standard model".		

*1: Linked domain management is supported by ProSafe-RS R4.06.00 or later and PRM R4.04.00 or later software revisions.

When the Legacy model is applied

Follow these steps to set the logon type:

1. Log on as a user with administrative rights.
2. Start SOE OPC Parameter Setting.
   The SOE OPC Interface Settings dialog box appears.
3. In the OPC Security Settings section, click [Edit].
   The Select Logon Type dialog box appears.
4. Select [Automatically logon the designated user for connecting OPC server].
5. Select [Default user of R2.03 and earlier versions].
6. Click [OK].

Setting the logon type with Standard model

Follow these steps to set the logon type:

1. Log on to the SENG as a member of the PSF_ENGINEER or PSF_ENGINEER_LCL group.
2. Start SOE OPC Parameter Setting.
   The SOE OPC Interface Settings dialog box appears.
3. In the OPC Security Settings section, click [Edit].
   The Select Logon Type dialog box appears.

4. Select [Automatically logon the designated user for connecting OPC server].
5. Select [Default user of R2.03 and earlier versions].
6. Click [OK].

Creating internal user accounts with Standard model

Follow these steps to create PRM and ProSafe-RS user accounts:

1. On the SENG, create the PRM_PROCESS and PRM_PROCESS2 user accounts by performing these steps:
   a. Log on to the SENG as a user with administrative rights.
   b. Insert the PRM installation media Disc 1 into the DVD drive, and navigate to the following folder:
      `<DVD drive>:\PRM\SecuritySettingUtility`
   c. Double-click [CreateInternalUserAccount.exe].
      The PRM_PROCESS and PRM_PROCESS2 user accounts are created and automatically added to one of the following groups:

Standalone management:	PSF_OPC
Domain management:	PSF_OPC_LCL
Combination management:	PSF_OPC or PSF_OPC_LCL
Linked domain management:	PSF_OPC

2. On the PRM Server computer, create the PSF_PROCESS user account by performing these steps:
   a. Log on as a user with administrative rights.
   b. Insert the ProSafe-RS software medium into the DVD drive, and navigate to the following folder:
      `<DVD drive>:\ProSafe-RS\SECURITY`
   c. Double-click [ProSafe.Security.CreateProSafeProcess.exe].
      The PSF_PROCESS user account is created.

D1.3.2 PRM Client and Forced I/O Viewer Package

You can use ProSafe-RS Forced I/O Viewer Package on a computer where PRM Client is installed.

TIP

You cannot install ProSafe-RS Forced I/O Viewer Package on a computer where ProSafe-RS Safety System Engineering and Maintenance Function is installed.

Viewing the ProSafe-RS forced-I/O information

The following table describes the connection information.

Table D1.3.2-1 Connection information

Integration code	0352-0253-01-02			
Product 1	PRM Client of PRM R4.02 or later(*1)			
Product 2	Forced I/O Viewer Package of ProSafe-RS R4.05 or later (*1)			
Security model	Legacy model	Standard model		
User management type	-	Standalone management	Domain management or Combination management	Linked domain management (*2)
Required procedures	Read the reference that follows the table.			

*1: When you install ProSafe-RS and PRM on the same computer with linked domain management, ensure that the software revision of ProSafe-RS is R4.06.00 or later and the software revision of PRM is R4.04.00 or later.
*2: Linked domain management is supported by ProSafe-RS R4.06.00 or later and PRM R4.04.00 or later software revisions.

SEE ALSO

For more information about the settings required to use Forced I/O Viewer Package, refer to:

B4.4, “Settings Required to Use the Forced I/O Viewer Function” on page B4-5

D1.4 ProSafe-RS and Exaquantum

This section describes the settings when connecting ProSafe-RS and Exaquantum.

D1.4.1 ProSafe-RS SOE OPC Interface Package and Exaquantum PIMS Server

Connecting the SOE OPC Interface Package and Exaquantum PIMS Server enables the Exaquantum PIMS Server to collect SOE data from SCS through the OPC interface.

Enabling Exaquantum to collect SOE data from SCS

To use Exaquantum PIMS Server as an OPC client and perform OPC communication with an SENG running the SOE OPC Interface Package, you need to perform the settings described below.

The following table shows the connection information. For required procedures for connection, read the descriptions that follow the table. The logon type setting on the SENG and the setting to use Exaquantum as an OPC client are mandatory in all cases.

IMPORTANT

As a basic rule, the security model and user management type must be consistent in the products to be connected. However, ProSafe-RS and Exaquantum can be connected even if different security model or user management type is applied.

Table D1.4.1-1 Connection information: ProSafe-RS SOE OPC Interface Package and Exaquantum R2.60 or later

Integration code	0202-0801-02-01		
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later		
Product 2	PIMS server of Exaquantum R2.60 or later		
Security model	Legacy model	Standard model	
User management type	-	Standalone management	Domain/Combination management
Required procedures	Refer to "● Setting the logon type" and "● When the Legacy model is applied to both products."	Refer to "● Setting the logon type" and "● When the Standard model is applied to both products."	

Table D1.4.1-2 Connection information: Different security model - Case 1

Integration code	0202-0801-02-01	
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later	
Product 2	PIMS server of Exaquantum R2.60 or later	
Security model	Standard model (ProSafe-RS) Legacy model (Exaquantum)	
User management type of ProSafe-RS	Standalone management	Domain/Combination management
Required procedures	Refer to "● Setting the logon type" and "● When the Standard model is applied to ProSafe-RS and the Legacy model to Exaquantum."	

Table D1.4.1-3 Connection information: Different security model - Case 2

Integration code	0202-0801-02-01
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later

Continues on the next page

Table D1.4.1-3 Connection information: Different security model - Case 2 (Table continued)

Product 2	PIMS server of Exaquantum R2.60 or later	
Security model	Legacy model (ProSafe-RS) Standard model (Exaquantum)	
User management type of Exaquantum	Standalone management	Domain/Combination management
Required procedures	Refer to "● Setting the logon type" and "● When the Legacy model is applied to ProSafe-RS and the Standard model to Exaquantum."	

Table D1.4.1-4 Connection information: Legacy model applied ProSafe-RS and Exaquantum version earlier than R2.60

Integration code	0202-0801-02-02
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later
Product 2	PIMS server of Exaquantum R2.20 or later but earlier than R2.60
Security model	Legacy model (ProSafe-RS) - (Exaquantum)
User management type	-
Required procedures	Refer to "● Setting the logon type" and "● When the Legacy model is applied to both products."

Table D1.4.1-5 Connection information: Standard model applied ProSafe-RS and Exaquantum version earlier than R2.60

Integration code	0202-0801-02-02	
Product 1	SOE OPC Interface Package of ProSafe-RS R3.01 or later	
Product 2	PIMS server of Exaquantum R2.20 or later but earlier than R2.60	
Security model	Standard model (ProSafe-RS) - (Exaquantum)	
User management type of ProSafe-RS	Standalone management	Domain/Combination management
Required procedures	Refer to "● Setting the logon type" and "● When the Standard model is applied to ProSafe-RS and the Legacy model to Exaquantum."	

SEE ALSO For more information about the details on setting up an OPC client, refer to:

C3., “Setup for using the OPC client” in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

● Setting the Logon Type

To connect Exaquantum with an SENG (OPC server) running the SOE OPC interface package of ProSafe-RS R3.01.00 or later, you need to set the logon type on the SENG beforehand. After performing this setting, perform the required setting on Exaquantum.

1. Log in to the system as a user belonging to PSF_ENGINEER or PSF_ENGINEER_LCL.
2. Start SOE OPC Parameter Setting.
   The SOE OPC Interface Settings dialog box appears.
3. Click the [Edit] in [OPC Security Settings].
   A dialog box where you can select a type of logon to the OPC server appears.

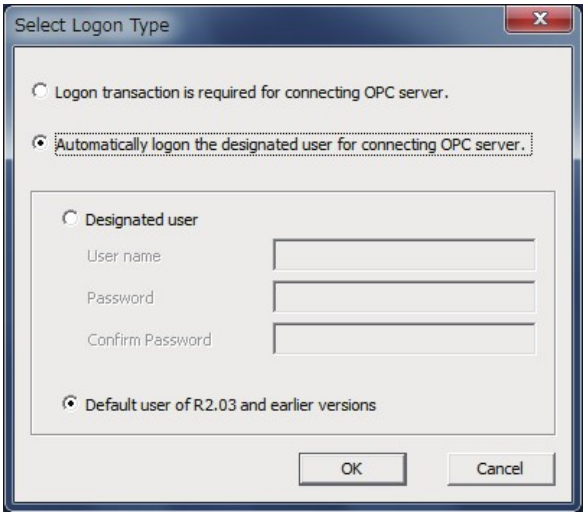

Figure D1.4.1-1 Select Logon Dialog Box

4. Select [Automatically logon the designated user for connecting OPC server.] and then [Default user of R2.03 and earlier versions], and click [OK].

When the Legacy model is applied to both products

1. Set the logon type on the SENG.
2. Add an Exaquantum program user on the SENG.

TIP

The user name and password of the Exaquantum program user should be as follows:

User name: Quantumuser (default user name, changeable with a supplied tool)

Password: quantumuser (default password, changeable with a supplied tool)

3. On the SENG, create the same user account as the logon user account for running Exaquantum.
4. On the SENG and the computer installed with Exaquantum, perform the setting for using Exaquantum as an OPC client.

When the Standard model is applied to both products

1. Set the logon type on the SENG.
2. Configure the DCOM settings on the SENG. For procedures, refer to the user's manual "Engineering Guide Vol.2".
3. On the SENG, create QTM_PROCESS, which is the Exaquantum program user account.
   a. Insert the Exaquantum software medium and start the command prompt window, then move to the following folder.
   (Drive):\Tools
   b. Run the following command.
   `CreateQTMProcess.exe`

   The QTM_PROCESS user account is created.
4. Add the QTM_PROCESS user you have created to the following user group on the SENG.
   - In the case of standalone management or when combination management is applied on some computers: PSF_OPC
   - In the case of domain management or when combination management is applied on all computers: PSF_OPC_LCL

5. On the SENG, create the same user account as the logon user account for running Exaquantum and add the created user account to the PSF_OPC group.
6. On the computer installed with Exaquantum, create the PSF_PROCESS user account.
   a. Insert the ProSafe-RS software medium and start the command prompt window, then move to the following folder.
   (Drive):\ProSafe-RS\SECURITY
   b. Run the following command.
   `ProSafe.Security.CreateProSafeProcess.exe`
   The PSF_PROCESS user account is created.
7. Add the PSF_PROCESS user you have created to the following user group on the computer installed with Exaquantum.
   - In the case of standalone management or when combination management is applied on some computers: QTM_OPC
   - In the case of domain management or when combination management is applied on all computers: QTM_OPC_LCL
8. On the SENG and the computer installed with Exaquantum, perform the setting for using Exaquantum as an OPC client.

SEE ALSO For more information about configuring the DCOM settings, refer to:

"■ DCOM settings" in C2.2, "Overview of product security settings" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

When the Standard model is applied to ProSafe-RS and the Legacy model to Exaquantum

1. Set the logon type on the SENG.
2. Configure the DCOM settings on the SENG. For procedures, refer to the user's manual "Engineering Guide Vol.2".
3. Add an Exaquantum program user on the SENG.

TIP The user name and password of the Exaquantum program user should be as follows:

User name: Quantumuser (default user name, changeable with a supplied tool)

Password: quantumuser (default password, changeable with a supplied tool)

4. Add the Quantumuser user you have created to the following user group on the SENG.
   - In the case of standalone management or when combination management is applied on some computers: PSF_OPC
   - In the case of domain management or when combination management is applied on all computers: PSF_OPC_LCL
5. On the SENG, create the same user account as the logon user account for running Exaquantum and add the created user account to the PSF_OPC group.
6. On the computer installed with Exaquantum, create the PSF_PROCESS user account.
   a. Insert the ProSafe-RS software medium and start the command prompt window, then move to the following folder.
   (Drive):\ProSafe-RS\SECURITY
   b. Run the following command.
   `ProSafe.Security.CreateProSafeProcess.exe`
   The PSF_PROCESS user account is created.

7. On the SENG and the computer installed with Exaquantum, perform the setting for using Exaquantum as an OPC client.

SEE ALSO For more information about configuring the DCOM settings, refer to:

"■ DCOM settings" in C2.2, "Overview of product security settings" in Engineering Guide Vol. 2 (IM 32P01C20-01EN)

When the Legacy model is applied to ProSafe-RS and the Standard model to Exaquantum

1. Set the logon type on the SENG.
2. On the SENG, create QTM_PROCESS, which is the Exaquantum program user account.
   a. Insert the Exaquantum software medium and start the command prompt window, then move to the following folder.
   (Drive):\Tools
   b. Run the following command.
   `CreateQTMProcess.exe`

   The QTM_PROCESS user account is created.
3. On the SENG, create the same user account as the logon user account for running Exaquantum.
4. On the computer installed with Exaquantum, create the EXAUSER user account. The password should also be EXAUSER.
5. Add the EXAUSER user you have created to the following user group on the computer installed with Exaquantum.
   - In the case of standalone management or when combination management is applied on some computers: QTM_OPC
   - In the case of domain management or when combination management is applied on all computers: QTM_OPC_LCL
6. On the SENG and the computer installed with Exaquantum, perform the setting for using Exaquantum as an OPC client.

Appendix 1. Setting Switches

You can set the domain number and station number by configuring the setting switches on the printed circuit board of the control bus interface card and Vnet/IP interface card.

Domain Numbers and DIP Switch Positions

The following table lists the domain numbers and corresponding setting switch positions for the control bus interface card and Vnet/IP interface card. Set the DIP switches as shown in the table to adjust to the required domain number.

Table Appendix 1-1 Domain Numbers and DIP Switch Positions

Domain number	DIP switch bit number(*1)							
	1	2	3	4	5	6	7	8
1	0	0	0	0	0	0	0	1
2	0	0	0	0	0	0	1	0
3	1	0	0	0	0	0	1	1
4	0	0	0	0	0	1	0	0
5	1	0	0	0	0	1	0	1
6	1	0	0	0	0	1	1	0
7	0	0	0	0	0	1	1	1
8	0	0	0	0	1	0	0	0
9	1	0	0	0	1	0	0	1
10	1	0	0	0	1	0	1	0
11	0	0	0	0	1	0	1	1
12	1	0	0	0	1	1	0	0
13	0	0	0	0	1	1	0	1
14	0	0	0	0	1	1	1	0
15	1	0	0	0	1	1	1	1
16	0	0	0	1	0	0	0	0
17	1	0	0	1	0	0	0	1
18	1	0	0	1	0	0	1	0
19	0	0	0	1	0	0	1	1
20	1	0	0	1	0	1	0	0
21	0	0	0	1	0	1	0	1
22	0	0	0	1	0	1	1	0
23	1	0	0	1	0	1	1	1
24	1	0	0	1	1	0	0	0
25	0	0	0	1	1	0	0	1
26	0	0	0	1	1	0	1	0
27	1	0	0	1	1	0	1	1
28	0	0	0	1	1	1	0	0
29	1	0	0	1	1	1	0	1
30	1	0	0	1	1	1	1	0
31	0	0	0	1	1	1	1	1

*1: Bit 1: Odd parity, Bits 2, 3: Fixed to 0, Bits 4 to 8: Domain number

Station Numbers and DIP Switch Positions

The following table lists the station numbers and corresponding setting switch positions for the control bus interface card and Vnet/IP interface card. Set the DIP switches as shown in the table to adjust to the required station number.

Table Appendix 1-2 Station Numbers and DIP Switch Positions

Station number	DIP switch bit numbers (*1)							
	1	2	3	4	5	6	7	8
1	0	0	0	0	0	0	0	1
2	0	0	0	0	0	0	1	0
3	1	0	0	0	0	0	1	1
4	0	0	0	0	0	1	0	0
5	1	0	0	0	0	1	0	1
6	1	0	0	0	0	1	1	0
7	0	0	0	0	0	1	1	1
8	0	0	0	0	1	0	0	0
9	1	0	0	0	1	0	0	1
10	1	0	0	0	1	0	1	0
11	0	0	0	0	1	0	1	1
12	1	0	0	0	1	1	0	0
13	0	0	0	0	1	1	0	1
14	0	0	0	0	1	1	1	0
15	1	0	0	0	1	1	1	1
16	0	0	0	1	0	0	0	0
17	1	0	0	1	0	0	0	1
18	1	0	0	1	0	0	1	0
19	0	0	0	1	0	0	1	1
20	1	0	0	1	0	1	0	0
21	0	0	0	1	0	1	0	1
22	0	0	0	1	0	1	1	0
23	1	0	0	1	0	1	1	1
24	1	0	0	1	1	0	0	0
25	0	0	0	1	1	0	0	1
26	0	0	0	1	1	0	1	0
27	1	0	0	1	1	0	1	1
28	0	0	0	1	1	1	0	0
29	1	0	0	1	1	1	0	1
30	1	0	0	1	1	1	1	0
31	0	0	0	1	1	1	1	1
32	0	0	1	0	0	0	0	0
33	1	0	1	0	0	0	0	1

Appendix 2. Procedure for Erasing VI702 Internal Settings

If you intend to reuse a VI702 card used in another system for a stand-alone ProSafe-RS system, erase the settings within the card using the following procedure.

1. Turn off the power of the computer. For safety, remove the power plug from the outlet.
2. Set the DIP switches (SW1) for the domain number on the VI702 as follows:

Table Appendix 2-1 Setting of DIP Switches for Domain Number Setting (SW1)

Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7	Bit 8
1	1	0	0	0	0	0	1
Parity			MSB				LSB

3. Set the DIP switches (SW2) for the station number on the VI702 as follows:

Table Appendix 2-2 Setting of DIP Switches for Station Number Setting (SW2)

Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7	Bit 8
0	0	0	0	0	0	0	1
Parity	MSB						LSB

4. Check that Bit 1 through Bit 4 of the DIP switches (SW4) for the Action Mode are all set to the off position on the VI702.
5. Remove the cover of the computer.
6. Insert the VI702 in the corresponding slot and fix the card.
7. Put back the cover of the computer.
8. Do not connect the cable to either BUS1 or BUS2.
9. Put back the power cord of the computer.
10. Start the computer, and then go to BIOS setting panel instead of starting Windows. If the Windows started, it is necessary to shutdown and switch off the computer, and start the computer for BIOS setting again.
11. Wait for about a minute after BIOS setting panel appears.
12. Turn off the power of the computer. For safety, remove the power plug from the outlet.
13. Remove the VI702 from the slot.

SEE ALSO For more information about how to display the BIOS setting window, refer to:

The manual of the computer

Appendix 3. Vnet/IP Interface Management Tool

By using the Vnet/IP Interface Management Tool, you can set the domain number and station number managed by the Vnet/IP Interface Package.

Changing the Domain Number and Station Number

Follow these steps to set the domain number and station number managed by the Vnet/IP Interface Package:

1. Sign in to the guest OS on the virtual machine as an administrative user.
2. Select [YOKOGAWA Virtualization] > [VnetIP interface management tool] from the Start menu.
   Vnet/IP interface management tool starts.
3. Open the Settings tab of the Vnet/IP interface management tool.
4. Set the domain number in [Domain No] and the station number in [Station No], and then click [Save].

TIP

You can set a number in the range from 1 to 31 as the domain number (1 to 16 in the case of CENTUM integration), and from 1 to 64 as the station number. If both domain number and station number are set to 0, Vnet/IP communication is disabled and communication to the control network is not possible.

On a virtual machine where you run an FCS simulator that can be operated through remote connection from another HIS by installing the Expanded Test Functions and SCS Simulator Package, set both the domain number and the station number to 0.

Note that the license of Vnet/IP Interface Package is not required when using only the test function with the domain number and the station number set to 0.

5. Click [CLOSE], and restart the virtual machine.

Operation Status of the Vnet/IP Interface Package

The [Monitor] shows the following information:

- Version information of the Vnet/IP Interface Package
- Operation status of the Vnet/IP Interface Package
- Domain number and station number
- Presence of different Vnet/IP firmware versions

Version information

The version number of the Vnet/IP Interface Package is displayed.

Operation status

One of the following five operation statuses is displayed.

Stop:	Indicates that the Vnet/IP Interface Package is not functioning.
Starting:	Indicates that the domain number, station number, and configuration are being checked before the package goes into operation.
Waiting the license:	Indicates that the package is waiting for the license to be granted.
Working:	Indicates that the package is operating properly.

Stop (error message):	Indicates that the package is not functioning.

Domain number and station number

The domain number and station number are displayed.

Presence of different Vnet/IP firmware revisions

The revision information of the Vnet/IP firmware is displayed. If more than one of stations use old firmwares, they are delimited with a comma.

Display example:	06R, 13L
Meaning:	The Vnet/IP firmware implemented on the right side card of station number 6 and the Vnet/IP firmware implemented on the left side card of station number 13 are old.

What to Do When an Error Occurs

When using the Vnet/IP Interface Management Tool, error messages may appear. This section explains the conditions for error messages to occur and countermeasures.

Invalid Windows service registration

- Message

  Invalid Windows service registration

- Condition for occurrence

  This error message is generated when any one of the Vnet/IP Interface Package services, “YWVNT BKNET Service,” “YWVNT VnetIP Stack Service,” and “YWVNT VnetIP Privileged Service” is not registered as Windows service, or the Vnet/IP Interface Package services are not configured to start automatically.

- Remedy

  Install the Vnet/IP Interface Package again.

SEE ALSO For more information about the procedure to install the Vnet/IP Interface Package, refer to:

B3.3.4, “Installing the Vnet/IP Interface Package on a Virtual Machine” on page B3-24

BUS1 not found

- Message

  BUS1 not found

- Condition for occurrence

  This message is generated when the name of control network 1 is invalid.

- Remedy

  Rename control network 1 to `VnetIPBUS1`.

SEE ALSO For more information about how to change the name of control network 1, refer to:

“■ Rename Local Area Connections” on page B3-37

BUS2 not found

- Message

  BUS2 not found

- Condition for occurrence

  This message is generated when the name of control network 2 is invalid.

- Remedy

  Rename control network 2 to `VnetIPBUS2`.

SEE ALSO For more information about how to change the name of control network 2, refer to:

"■ Rename Local Area Connections" on page B3-37

Invalid domain number or station number

- Message

  Invalid domain number or station number

- Condition for occurrence

  This message is generated when the domain number or station number managed by the Vnet/IP Interface Package are invalid.

- Remedy

  Using the Vnet/IP Interface Management Tool, check the domain number and station number managed by the Vnet/IP Interface Package and set to the correct values.

SEE ALSO For more information about how to set the domain number and station number managed by the Vnet/IP Interface Package, refer to:

"■ Changing the Domain Number and Station Number" on page App.3-1

Station of the specified domain number and station number already exists

- Message

  Station of the specified domain number and station number already exists

- Condition for occurrence

  This message is generated when the same domain number or station number are already used for another station.

- Remedy

  Using the Vnet/IP Interface Management Tool, check the domain number and station number managed by the Vnet/IP Interface Package and set to the correct values.

SEE ALSO For more information about how to set the domain number and station number managed by the Vnet/IP Interface Package, refer to:

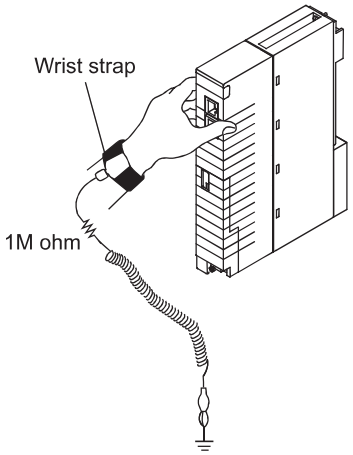
"■ Changing the Domain Number and Station Number" on page App.3-1

IT security not applied

- Message

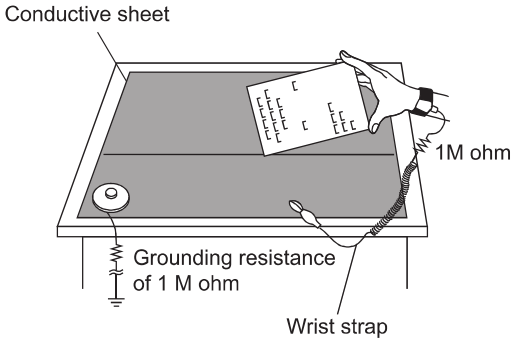
  IT security not applied

- Condition for occurrence



This message is generated when IT security has not been applied after installation of the Vnet/IP Interface Package.

- Remedy
  Apply IT security.



Appendix 4. Antistatic Precautions When Handling Hardware

When doing maintenance work, take the following precautions to avoid electrostatic problems.

- When storing or carrying parts for maintenance, put them in an antistatic bag. (When shipped, they are placed in an antistatic bag labeled with cautions against electrostatic problems.)
- Wear a wrist strap with a 1M ohm grounding resistor then ground the wrist strap.
- When working on the bench, place the parts on a conductive sheet grounded via a 1 M ohm resistor and wear wrist strap. Keep static-chargeable plastic materials away from the parts.
- Never touch the parts with bare hands, without using a wrist strap and a conductive sheet.

Connect the wrist strap to the grounding terminal or unpainted part of the frame (grounded).

When working with a product with battery on a conductive sheet, set the battery ON/OFF switch to the OFF position or remove the battery.

Figure Appendix 4-1 Using a Wrist Strap

The wrist strap and conductive sheet are available from YOKOGAWA sales agents.

Appendix 5. Customization at Installation of Windows 10

This section describes how to customize Windows settings during installation of Windows 10 Enterprise 2016 LTSB.

TIP You do not need to perform this customization on Windows 10 IoT Enterprise 2016 LTSB installed computers provided by YOKOGAWA.

Procedure for Customization at installation of Windows 10

1. The following screen appears during installation of Windows 10 Enterprise 2016 LTSB.

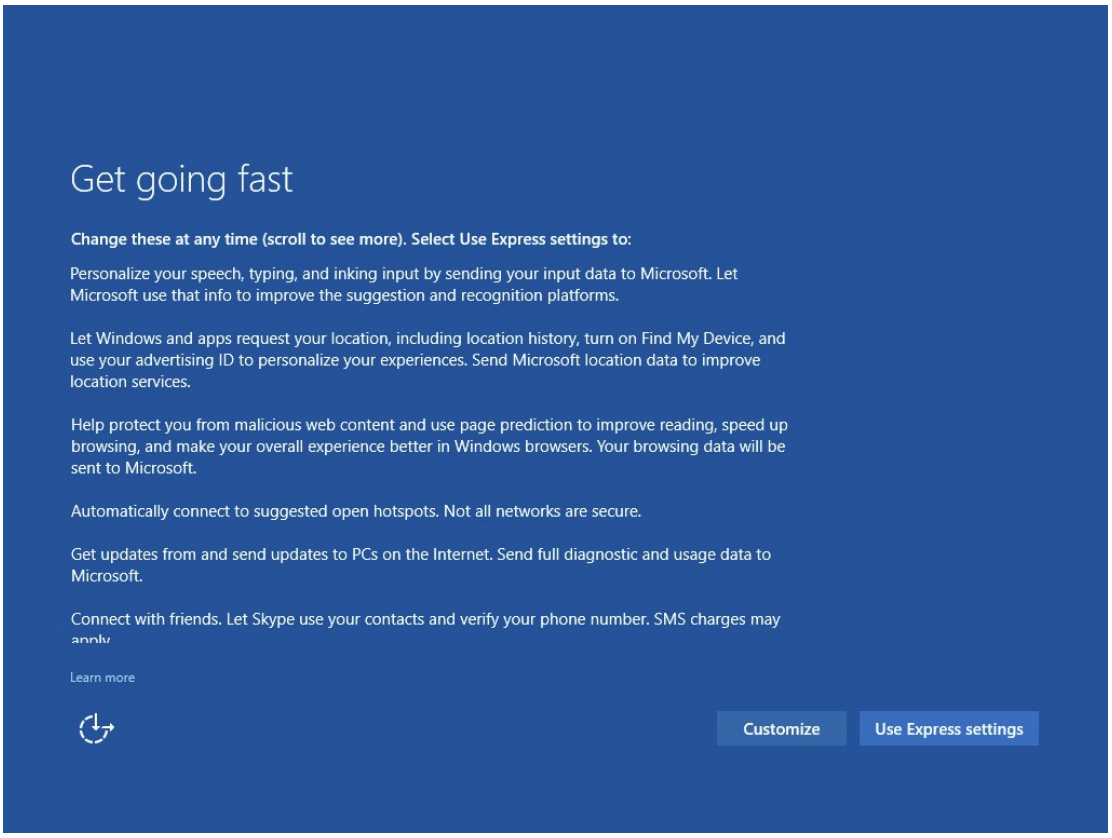


Figure Appendix 5-1 Screen That Appears When Installing Windows 10

Click [Customize].

The Customize Settings window appears.

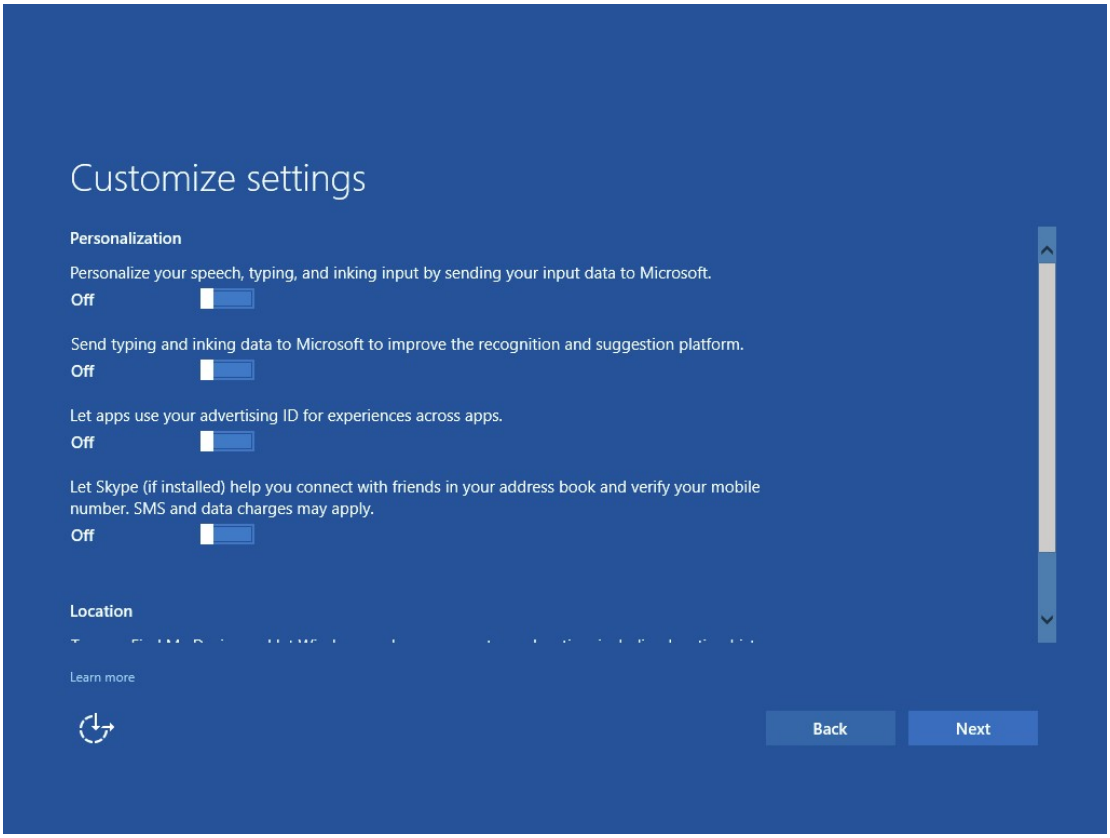

Figure Appendix 5-2 Customize Settings Window

2. Set all settings to [Off].
3. Click [Next] to continue installing Windows 10 Enterprise 2016 LTSB.

Appendix 6. Compatibility between Revisions and Cautionary Notes for Upgrading

IMPORTANT

Be sure to take a backup of the whole project before upgrading ProSafe-RS.

This section provides the compatibility information for earlier versions of ProSafe-RS software released in the past and the cautionary notes for upgrading that were published at the time of each release. In this section, users can confirm the procedures for using the new features supported in each release in the past and the important descriptions about SCS specifications that were released in the past as the compatibility information.

When you upgrade ProSafe-RS, install only the software of the release number you want to use. However, for the required procedures after the installation, read the cautionary notes for upgrading for all release numbers between the release number of the software currently installed on your computer and the release number of the software you want to use.

SEE ALSO For more information about precautions related to major specification additions and changes in previously released revisions, refer to:

Appendix 3., “Precautions related to main specification additions and modifications” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Appendix 6.1 Cautionary Notes for Upgrading to R4.01

This section provides cautionary notes for upgrading from R3.02.20 to R4.01. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

Use the R6.02 or a later version of CENTUM VP when integrating ProSafe-RS with CENTUM VP.

In R4.01, be sure to register the RS project in the AD project regardless of the engineering method.

SEE ALSO

For more information about compatibility and cautionary notes for upgrading up to ProSafe-RS R3.02.10, refer to:

Appendix 4., "Compatibility between Revisions and Cautionary Notes for Upgrading" in Installation for ProSafe-RS R3 (IM 32Q01C50-31E)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R3.02.20, refer to:

C5., "Upgrading to R3.02.20" in Installation for ProSafe-RS R3 (IM 32Q01C50-31E)

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Software Revisions

The respective software release number of R4.01 is as follows:

Software release number R4.01.xx (*1)

- SENG software release number: R4.01.xx (*1)
- SCS system program release number: R4.01.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.01.00.

● Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.01 must be of R1.01.30 or later.

If Vnet/IP is used for route of the Inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

● Control Bus Drivers

You do not need to update the control bus driver if the control bus driver provided in R3.02.20 is installed on the computer.

SEE ALSO

For more information about how to update the control bus driver, refer to:

"● Updating the Control Bus Driver" on page C4-5

Basic Procedures for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.01 or later and open the existing SCS project.

Procedure for Using Added and Modified Features

The following functions that have been added or modified in R4.01 cannot be used in the basic upgrading procedures. Once you have upgraded the SENG software to R4.01, offline download to the SCS and other operations are required. The procedures to use the respective functions are described below.

SEE ALSO For more information about settings after upgrading software, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

New station (S2SC70)

To use the S2SC70 station, which is newly added in R4.01, you need to perform "Procedure C" on an SENG of R4.01 or later. In S2SC70, N-IO systems can be used.

Annunciator messages with tag names

To use annunciator messages with tag names, "Procedure D" must be performed on an SENG of R4.01 or later. To use annunciator messages with tag names, set the applicable parameters in a Builder.

Modbus/TCP subsystem communication

To use subsystem communication using the Modbus/TCP protocol, "Procedure C" must be performed on an SENG of R4.01 or later.

I/O List Engineering of AD Suite

To use I/O List Engineering of AD Suite that has been added in R4.01, "Procedure C" must be performed on an SENG of R4.01 or later. In R4.01, be sure to register the RS project in the AD project regardless of the engineering method. You should then create and set an SCS project; otherwise, I/O List Engineering cannot be implemented. To upgrade an existing SCS to start I/O List Engineering, you need an I/O list matching the definitions of the original SCS project.

History Management Function of AD Suite

To use the history management function of AD Suite that has been added in R4.01, "Procedure A" must be performed on an SENG of R4.01 or later. In R4.01, be sure to register the RS project in the AD project regardless of the engineering method.

Appendix 6.2 Cautionary Notes for Upgrading to R4.02

This section provides cautionary notes for upgrading from R4.01 to R4.02. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

Use the R6.02 or a later version of CENTUM VP when integrating ProSafe-RS with CENTUM VP.

In R4.01 or later, be sure to register the RS project in the AD project regardless of the engineering method.

SEE ALSO

For more information about cautionary notes when upgrading the version to ProSafe-RS R4.01 from an earlier version, refer to:

Appendix 6.1, “Cautionary Notes for Upgrading to R4.01” on page App.6-2

For more information about creating an AD project, refer to:

“■ Creating AD projects” in C1.2.1, “Creating and deleting AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, “Registering RS projects in the AD project” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Software Revisions

The respective software release number of R4.02 is as follows:

Software release number R4.02.xx (*1)

- SENG software release number: R4.02.xx (*1)
- SCS system program release number: R4.02.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.02.00.

● Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.02 must be of R1.01.30 or later.

If Vnet/IP is used for route of the Inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

● Control Bus Drivers

You do not need to update the control bus driver if the control bus driver provided in R3.02.20 is installed on the computer.

■ Basic Procedure for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.02 or later and open the existing SCS project.

Integration with External Engineering Tool

To use the feature for integration with iDefine, an external engineering tool, that has been added in R4.02, "Procedure A" must be performed on an SENG of R4.02 or later.

Procedure for Using Added and Modified Features

The following functions that have been added or modified in R4.02 cannot be used in the basic upgrading procedures. After you have upgraded the SENG software to R4.02, offline download to the SCS and other operations are required. The procedures to use the respective functions are described below.

SEE ALSO For more information about settings after upgrading software, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Duplexed Interface for DNP3 Communication

To use the duplexed interface for DNP3 communication that has been added in R4.02, "Procedure C" must be performed on an SENG of R4.02 or later. The duplexed interface for DNP3 communication is available only in SSC57.

Support for the RoHS Directive Compliant Processor Module SCP451-□3

To use the RoHS directive compliant processor module SCP451-□3, "Procedure B" must be performed on an SENG of R4.02 or later. The RoHS directive compliant processor module SCP451-□3 can be used in SSC50 and SSC57.

Cautionary Notes for Upgrading When ALE111 is Used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

During the first online change download after SENG has been upgraded, the latest communication program for ALE111 is also downloaded. Because ALE111 is restarted in this process, communication with the Modbus or DNP3 master s is disabled temporarily. Therefore, you must perform online change download with appropriate timing after the upgrade.

For the details, read the following descriptions:

Upgrade Procedure When ALE111 is Used for Modbus Slave Communication

If ALE111 is used for Modbus slave communication and you are upgrading from R4.01.00 or earlier to R4.02.00 or later, follow these steps to download the latest communication program to ALE111:

IMPORTANT

- You can build the SCS project without changing the ALE111 definitions. If you perform an online change download the first time after running a build, the latest communication program is downloaded to ALE111, even if no change has been made to the communication definitions for the ALE111.
- The latest communication program will be downloaded to ALE111 also when you perform an online change download after modifying only the definitions not relevant to ALE111.
- During online change download, communication with the Modbus master is disabled. (*1)You must perform an online change download only when no problem is caused even if the communication with the Modbus master is interrupted.
- When upgrading the system, if you also want to perform modification of application that requires addition of communication modules other than ALE111 for Modbus slave communication at the same time, you must observe the following precautions. You must first perform the following steps 1 through 5 to download the latest program to the existing ALE111, and then modify the application. If you do not follow this procedure, upgrading of the communication program may fail. If failed, offline downloading to the SCS is required.

*1: Even if the communication interface with the Modbus master is duplexed by using two ALE111 modules, the communication is disabled during online change download.

1. Upgrade ProSafe-RS from R4.01.00 or earlier to R4.02.00 or later.
2. Run a build for the SCS project regardless of whether you have made changes.
3. Using Integrity Analyzer and Cross Reference Analyzer, perform an approval check.

TIP

Differences in the communication program are not displayed.

4. Run an online change download.
5. Confirm the revision number of the communication program.
   The revision number of the communication program that is downloaded in R4.02.00 or later is R4.02.00. When the online change download is complete, confirm that the communication program of R4.02.00 has been downloaded to all ALE111 modules by using IOM Report. You can find the revision number of the communication program at the address 0x0120 in the IOM Report for ALE111.

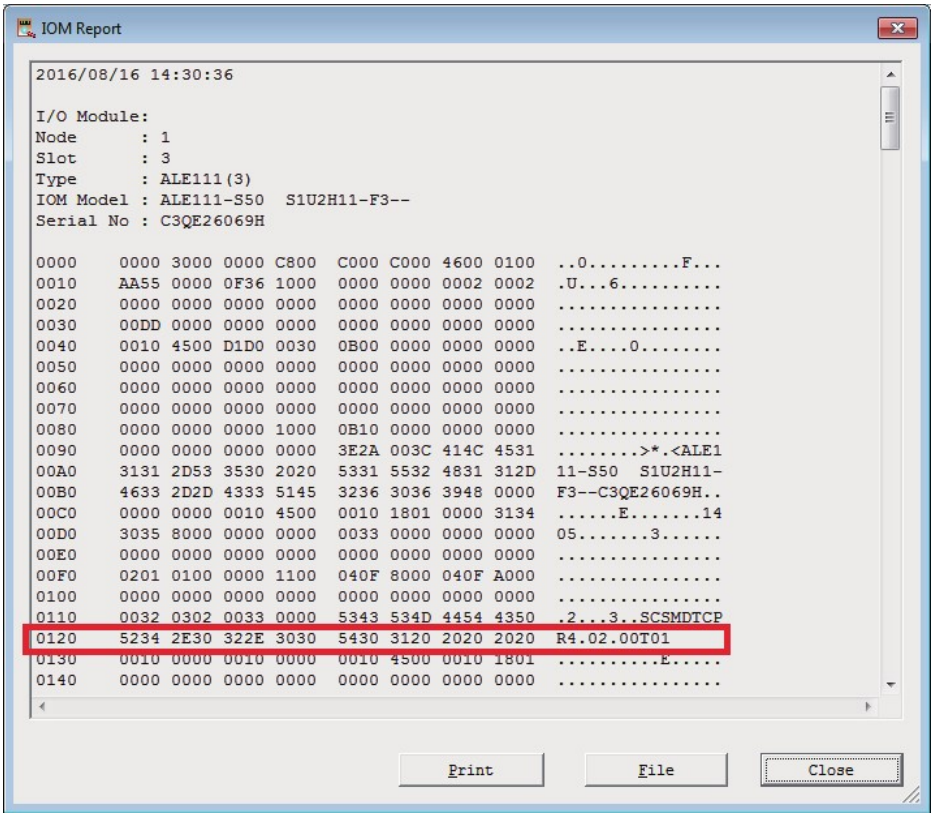

Figure Appendix 6.2-1 IOM Report for ALE111 Used for Modbus Slave Communication

If you want to perform modification of application at the same time, perform step 6.

6. Perform modification of the application that requires addition of communication modules other than ALE111 for Modbus slave communication.

Upgrade Procedure When ALE111 is Used for DNP3 Communication

If ALE111 is used for DNP3 communication and you are upgrading from R4.01.00 or earlier to R4.02.00 or later, follow these steps to download the latest communication program to ALE111:

IMPORTANT

- You can build the SCS project without changing the ALE111 definitions. If you perform an online change download the first time after running a build, the latest communication program is downloaded to ALE111, even if no change has been made to the communication definitions for the ALE111.
- The latest communication program will be downloaded to ALE111 also when you perform an online change download after modifying only the definitions not relevant to ALE111.
- During online change download, communication with the DNP3 master is disabled. You must perform an online change download only when no problem is caused even if the communication with the DNP3 master is interrupted.
- When upgrading the system, if you also want to perform modification of application that requires addition of communication modules other than ALE111 for DNP3 communication at the same time, you must observe the following precautions. You must first perform the following steps 1 through 5 to download the latest program to the existing ALE111, and then modify the application. If you do not follow this procedure, upgrading of the communication program may fail. If failed, offline downloading to the SCS is required.

1. Upgrade ProSafe-RS from R4.01.00 or earlier to R4.02.00 or later.
2. Run a build for the SCS project regardless of whether you have made changes.
3. Using Integrity Analyzer and Cross Reference Analyzer, perform an approval check.

TIP Differences in the communication program are not displayed.

4. Run an online change download.
5. Confirm the revision number of the communication program.
   The revision number of the communication program that is downloaded in R4.02.00 or later is R4.02.00. When the online change download is complete, confirm that the communication program of R4.02.00 has been downloaded to all ALE111 modules by using IOM Report. You can find the revision number of the communication program at the address 0x0120 in the IOM Report for ALE111.

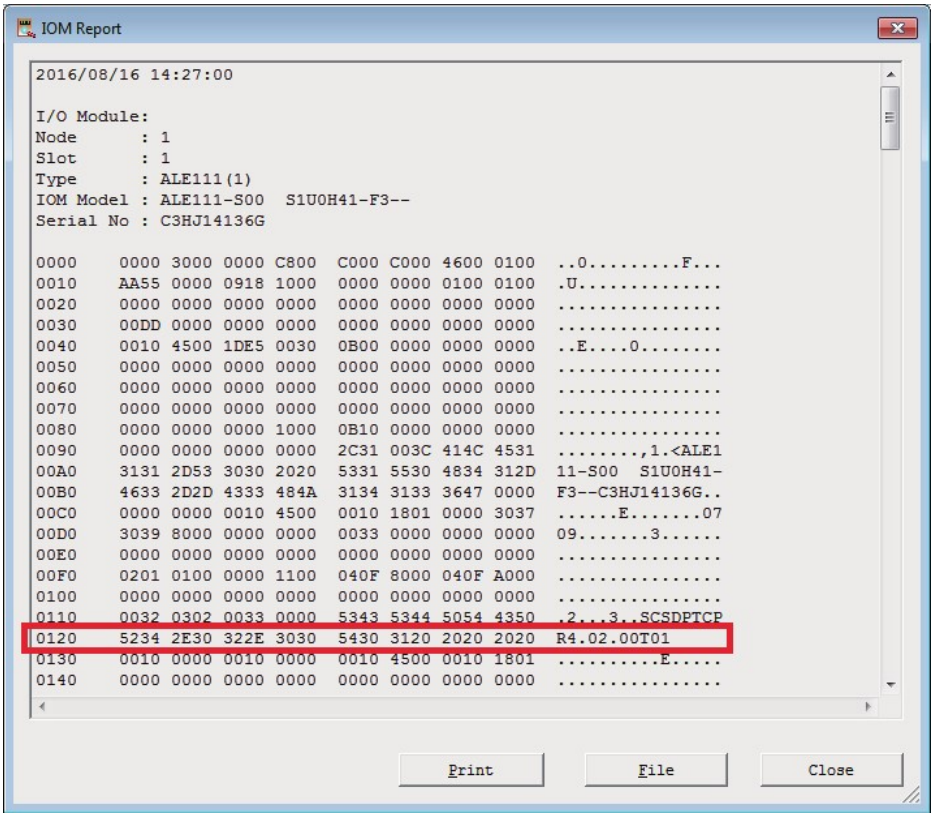

Figure Appendix 6.2-2 IOM Report for ALE111 Used for DNP3 Communication

If you want to perform modification of application at the same time, perform step 6.

6. Perform modification of the application that requires addition of communication modules other than ALE111 for DNP3 communication.

Appendix 6.3 Cautionary Notes for Upgrading to R4.03

This section provides cautionary notes for upgrading from R4.02 to R4.03. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

Use the R6.02 or a later version of CENTUM VP when integrating ProSafe-RS with CENTUM VP.

In R4.01 or later, be sure to register the RS project in the AD project regardless of the engineering method.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the version to ProSafe-RS R4.01 from an earlier version, refer to:

Appendix 6.1, "Cautionary Notes for Upgrading to R4.01" on page App.6-2

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.02, refer to:

Appendix 6.2, "Cautionary Notes for Upgrading to R4.02" on page App.6-4

Software Revisions

The respective software release number of R4.03 is as follows:

Software release number R4.03.xx (*1)

- SENG software release number: R4.03.xx (*1)
- SCS system program release number: R4.03.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.03.

Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.03 must be of R1.01.30 or later.

If Vnet/IP is used for route of the Inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

Control Bus Drivers

The control bus drivers that are installed on the computer should be upgraded to the version supplied in R4.03.

Basic Procedure for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.03 or later and open the existing SCS project.

Procedure for Using Added and Modified Features

The following functions that have been added or modified in R4.03 cannot be used in the basic upgrading procedures. After you have upgraded the SENG software to R4.03, offline download to the SCS and other operations are required. The procedures to use the respective functions are described below.

SEE ALSO For more information about settings after upgrading software, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Device Reset Function

To use the device reset function with SAI143, you need to perform “Procedure C” on an SENG of R4.03 or later.

Function Blocks for Fire and Gas Devices

To use the function blocks for fire and gas devices HSDTR and GASDTR, which are newly added in R4.03, you need to perform “Procedure C” on an SENG of R4.03 or later.

Alarm Suppression Function During Device Reset

To use the Alarm Suppression Function During Device Reset, you need to perform “Procedure C” on an SENG of R4.03 or later. The Alarm Suppression Function During Device Reset cannot be used with SSC57.

Chattering Alarm Suppression Function

To use the Chattering Alarm Suppression Function, you need to perform “Procedure C” on an SENG of R4.03 or later. The Chattering Alarm Suppression Function cannot be used with SSC57.

Digital I/O Module (S2MDV843)

To use the digital I/O module S2MDV843 newly added in R4.03, you must follow the “Procedure C” on SENG of R4.03 or later. S2MDV843 can be used with an S2SC70 N-IO system.

Cautionary Notes for Upgrading When ALE111 is Used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Cautionary Notes When Opening a New Revision AD Project from an Older Revision AD Organizer

From AD Organizer that was installed from the ProSafe-RS R4.01 or R4.02 software medium, you cannot open AD projects created by using AD Organizer of ProSafe-RS R4.03 or later or AD projects upgraded to R4.03 or later.

In such a case, apply one of the following compatibility patches:

- Compatibility patch for R4.01: R4.01.34
- Compatibility patch for R4.02: R4.02.01

TIP

- Also after an AD project has been upgraded, SCS projects of different revisions can exist together in the AD project.
- If you want to continue engineering of older revision SCS projects that are contained in the AD project without upgrading them, you must open the AD project from the corresponding older revision AD Organizer.
- For how to obtain the compatibility patches, contact YOKOGAWA.

Appendix 6.4 Cautionary Notes for a Revision Upgrade to R4.03.10

This section provides cautionary notes for a revision upgrade from R4.03 to R4.03.10. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

Use the R6.02 or a later version of CENTUM VP when integrating ProSafe-RS with CENTUM VP.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method.

SEE ALSO

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.03, refer to:

Appendix 6.3, “Cautionary Notes for Upgrading to R4.03” on page App.6-10

For more information about creating an AD project, refer to:

“■ Creating AD projects” in C1.2.1, “Creating and deleting AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, “Registering RS projects in the AD project” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

■ Software Revisions

The respective software release number of R4.03.10 is as follows:

Software release number R4.03.10 (*1)

- SENG software release number: R4.03.10 (*1)
- SCS system program release number: R4.03.10 (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.03.10.

● Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.03.10 must be R1.01.30 or later.

If Vnet/IP is used for route of the Inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

● Control Bus Drivers

The control bus drivers that are installed on the computer should be upgraded to the version supplied in R4.03.10.

■ Basic Procedure for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.03.10 or later and open the existing SCS project.

Safety Communication I/O Editor

To use Safety Communication I/O Editor of AD Suite, you must perform "Procedure A" on an SENG of R4.03.10.

If I/O list engineering had been selected and subsystem communication had been defined with a version earlier than R4.03.10, from here on you must perform engineering by using Safety Communication I/O Editor. Use Communication I/O List Output Tool to create a safety communication I/O list.

SEE ALSO For more information about Operations of “Procedure A”, refer to:

“■ Procedure A: Opening SCS Projects” on page C4-18

For more information about how to create a safety communication I/O list, refer to:

“■ Communication I/O List Output Tool” in Appendix 3.4, “Major changes in R4” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

Procedure for Using Added and Modified Features

The following functions that have been added or modified in R4.03.10 cannot be used in the basic upgrading procedures. After you have upgraded the SENG software to R4.03.10, offline download to the SCS and other operations are required. The procedures to use the respective functions are described below.

SEE ALSO For more information about details of the operation procedure introduced in each function, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Fire and Gas Communication

To use fire and gas communication for connecting with wireless gas detectors, you must perform "Procedure C" on an SENG of R4.03.10. Fire and gas communication can be used with S2SC70 only.

Expanding the Number of Data Allocated for Subsystem Communication

With subsystem communication, to expand the number of data that can be allocated to an instance of a subsystem communication FB, you must perform "Procedure C" on an SENG of R4.03.10.

Cautionary Notes for Upgrading When ALE111 is Used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Appendix 6.5 Cautionary Notes for Revision Upgrade to R4.04

This section provides cautionary notes for revision upgrade from R4.03.10 to R4.04. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method used.

SEE ALSO For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.03.10, refer to:

Appendix 6.4, "Cautionary Notes for a Revision Upgrade to R4.03.10" on page App.6-13

For more information about settings after upgrading software, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software Revisions

The respective software release numbers of R4.04 are as follows:

Software release number R4.04.xx (*1)

- SENG software release number: R4.04.xx (*1)
- SCS system program release number: R4.04.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.04.00.

The database revision of an SCS project that is created by SENG with software release number R4.04.xx will be R4.03.10.

● Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.04 must be R1.01.30 or later.

If Vnet/IP is used in the route of the inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

● Control Bus Drivers

The control bus drivers that are installed on the computer should be upgraded to the version supplied in R4.04.

■ Basic Procedure for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.04 or later and open the existing SCS project.

SEE ALSO For more information about settings after upgrading software, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

Changing the Setting Range of IOP Lower Limit Detection Level

To change the setting range of the IOP lower limit detection level and transmitter error lower limit detection level for AI channels, you must follow “Procedure A” by using SENG of R4.04. This feature is applicable to the AI channels of SAI143-H style 3 or later and S2MMM843.

Functional Improvement of AD Organizer

To use the improved method for starting SCS Manager from AD Organizer and to use the read-only mode of the Safety I/O Editor and the Safety Communication I/O Editor, you must follow “Procedure A” by using SENG of R4.04.

Cautionary Notes for Upgrading When ALE111 is Used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO

For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Appendix 6.6 Cautionary Notes for Revision Upgrade to R4.05

This section provides cautionary notes for revision upgrade from R4.04 to R4.05. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method used.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.04, refer to:

Appendix 6.5, "Cautionary Notes for Revision Upgrade to R4.04" on page App.6-15

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software Revisions

The respective software release numbers of R4.05 are as follows:

Software release number R4.05.xx (*1)

- SENG software release number: R4.05.xx (*1)
- SCS system program release number: R4.05.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.05.00.

The database revision of an SCS project that is created by SENG with software release number R4.05.xx will be R4.05.00.

● Inter-SCS Safety Communication

The release number of the SCS system program of an SCS that performs Inter-SCS safety communication with SCS with system program version R4.05 must be R1.01.30 or later.

If Vnet/IP is used in the route of the inter-SCS safety communication, the system programs on the SCSs must be of R1.02 or later.

● Control Bus Drivers

The control bus drivers that are installed on the computer should be upgraded to the version supplied in R4.05.

■ Cautionary notes on License Management Software in which its vulnerability is resolved

In ProSafe-RS R4.05.00, the vulnerability of License Management Software has been resolved. Therefore, if you use a computer in which ProSafe-RS R4.05.00 or later is installed as a license management station and you want to distribute licenses and distribute master licenses from it, you can distribute only to the license-assigned stations in which the vulnerability is resolved.

The following table shows the products and their revision numbers in which the vulnerability is resolved.

Table Appendix 6.6-1 The revision number of products in which the vulnerability is resolved

Product	Revision number
CENTUM VP	R6.07.00 or later
ProSafe-RS	R4.05.00 or later
PRM	R4.03.00 or later

Cautionary notes on a mixture of vulnerability-resolved computers and vulnerability-unresolved computers

- You cannot distribute licenses or distribute master licenses through network if there is a mixture of vulnerability-resolved computers and vulnerability-unresolved computers in a license project.
- If there is a mixture of vulnerability-resolved computers and vulnerability-unresolved computers in a license project, contact YOKOGAWA.

Basic Procedure for Upgrading

To use the added or modified features, install the ProSafe-RS software R4.05 or later and open the existing SCS project.

SEE ALSO For more information about Operations of “Procedure A”, refer to:

“■ Procedure A: Opening SCS Projects” on page C4-18

Safety I/O Parameter Profile of AD Suite

To use the safety I/O parameter profile of AD Suite, you must perform "Procedure A" on an SENG of R4.05.

Improved AD Suite Functions

To use the following improved AD Suite functions, you must perform "Procedure A" on an SENG of R4.05.

- Improved workflow of AD Suite and iDefine
  This functional improvement is available when collaborating with iDefine 1.16.5 or later.
- Improved Safety I/O Editor, IOM Definition Editor, and System Structure Navigator

Improved Logic Simulation Test Function

To use the improved logic simulation test function, you must perform "Procedure A" on an SENG of R4.05. This functional improvement is available when collaborating with iDefine 1.16.5 or later. However, it is not available with SCSV1.

Procedure for Using Added and Modified Features

The basic upgrading procedures are not enough to use the following functions that have been added or modified in R4.05. After you have upgraded the SENG software to R4.05, offline download to the SCS and other operations are required. The procedures to use the respective functions are described below.

SEE ALSO For more information about details of the operation procedure introduced in each function, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Skipping the Password Dialog Box for Manual Operation FBs

To use the function to skip the Password dialog box for manual operation FBs, you must perform "Procedure F" on an SENG of R4.05. This function is not available with SCSU1 and SCSV1.

When using this function, configure the parameter on the SCS Constants Builder after upgrading to R4.05, and then offline download the project. Thereafter, you can change the parameter by online change download. This function does not work when used in combination with HIS of CENTUM VP before R6.07.

Forced I/O Viewer Function

To use the Forced I/O Viewer function, you must perform "Procedure B" on an SENG of R4.05. This function is not available with SCSV1.

Support of the CPU Module S2CP471

To use the CPU module S2CP471, you must perform "Procedure B" on an SENG of R4.05. S2CP471 can be used in SSC60 and S2SC70.

Notes When Aliases are Defined for User-defined Columns in AD Organizer

This section describes the behavior when the system is upgraded if an alias of a user-defined column already defined is identical to the name of a standard column such as “Typical” that has been added to the Safety I/O Editor and Safety Communication I/O Editor in R4.05. It also describes the data migration procedure required in such a case.

SEE ALSO For more information about details of the data migration procedure required on iDefine after the upgrade, refer to:

iDefine User Guide (PR03076-MAN-970_01)

Column Names After the Upgrade

If an alias of a user-defined column already defined is identical to the name of a newly added standard column, the alias name of the user-defined column is changed during the upgrade. An underscore “_” is added to the beginning of the original alias name.

(Example) When the alias name is Typical

After upgraded to R4.05, the alias name becomes “_Typical”.

Migrating the Data of the Duplicate Column

The data of the original user-defined column remains after the upgrade. You can use a grid rule to migrate the data to a new standard column. In the Grid Rule Editor, create a grid rule for data copying.

For example, to copy the data of the _Typical column to the Typical column, configure the settings in the Define Rule window as follows:

- Select [Set] for Rule Type and [Typical] for Target Column.
- Set nothing in the Condition section.
- In the Action section, select [Column Name] for the operand type and set [_Typical] as the name of the column to be operated.

By running the created rule, the data of the _Typical column is copied to the Typical column. Confirm the result, and delete the data of the _Typical column.

Cautionary Notes for Upgrading When ALE111 is Used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

"■ Cautionary Notes for Upgrading When ALE111 is Used" on page App.6-5

Appendix 6.7 Cautionary notes for upgrading to R4.06

This section provides cautionary notes and actions required for a revision upgrade from R4.05 to R4.06. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

When integrating ProSafe-RS with CENTUM VP, use the R6.08 or a later version of CENTUM VP for the installation on the same computer.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.05, refer to:

Appendix 6.6, "Cautionary Notes for Revision Upgrade to R4.05" on page App.6-17

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software revisions

The respective software release numbers of R4.06 are as follows:

Software release number R4.06.xx (*1)

- SENG software release number: R4.06.xx(*1)
- SCS system program release number: R4.06.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.06.00.

The database revision of an SCS project that is created by SENG with software release number R4.06.xx will be R4.06.00.

● Control bus drivers

The control bus drivers that are installed on the computer must be upgraded to the version supplied in R4.06.

■ Basic procedure for upgrading

To use the added or modified features, install the ProSafe-RS software R4.06 or later and open the existing SCS projects ("Procedure A").

SEE ALSO

For more information about Operations of "Procedure A", refer to:

"■ Procedure A: Opening SCS Projects" on page C4-18

Support of displaying the list of AD Suite work files

To use the displayed list of AD Suite work files, you must perform “Procedure A” on an SENG of R4.06.

Improved AD Suite functions

To use the following improved AD Suite functions, you must perform “Procedure A” on an SENG of R4.06.

- Improved grid rule function
- Improved revision history function
- Improved functions of Safety I/O Editor, Safety Communication I/O Editor, Safety I/O Parameter Profile Editor, and IOM Definition Editor

POU password

In iDefine 1.16.6 or later, you can set a password for POU. To refer to POU with SCS Manager by using the POU password set in iDefine, you must perform “Procedure A” on SENG of R4.06.

Procedures for using added and modified features

The basic upgrading procedures are not enough to use the following features that have been added or modified in R4.06. After you upgrade the SENG software to R4.06, you must perform offline download to the SCS and other operations. The following procedures are required to use the new features.

SEE ALSO For more information about operation “Procedure B” to “Procedure F” for using new functions, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

SCS supporting SIL2 (LISC70)

To use the SCS supporting SIL2 (LISC70), you must perform “Procedure C” on an SENG of R4.06.

Added system functions and function block

To use the system functions (NUMBITS_8/NUMBITS_16) and the system function block (SYS_CH_OUTEN) added in R4.06, you need to perform “Procedure C” on an SENG of R4.06. NUMBITS_8/NUMBITS_16 and SYS_CH_OUTEN cannot be used on SSC10 and SSC60.

Steps when an SCS project is already placed on another computer such as a file server

If an SCS project is already placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When an SCS project is already placed on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO For more information about avoidance, refer to:

“■ Precautions when Placing the SCS Project on Another PC such as a File Server” in 1.2, “Engineering” in ProSafe-RS Release Information (IM 32P01A50-01EN)

Cautionary notes for upgrading when ALE111 is used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

"■ Cautionary Notes for Upgrading When ALE111 is Used" on page App.6-5

Appendix 6.8 Cautionary notes for upgrading to R4.07

This section provides cautionary notes and actions required for a revision upgrade from R4.06 to R4.07. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

When integrating ProSafe-RS with CENTUM VP, use the R6.08 or a later version of CENTUM VP for the installation on the same computer.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.06, refer to:

Appendix 6.7, "Cautionary notes for upgrading to R4.06" on page App.6-21

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software revisions

The respective software release numbers of R4.07 are as follows:

Software release number R4.07.xx (*1)

- SENG software release number: R4.07.xx (*1)
- SCS system program release number: R4.07.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.07.00.

The database revision of an SCS project that is created by SENG with software release number R4.07.xx will be R4.07.00.

● Control bus drivers

The control bus drivers that are installed on the computer must be upgraded to the version supplied in R4.07.

■ Basic procedure for upgrading

To use the added or modified features, install the ProSafe-RS software R4.07 or later and open the existing SCS projects ("Procedure A").

SEE ALSO

For more information about Operations of "Procedure A", refer to:

"■ Procedure A: Opening SCS Projects" on page C4-18

Procedures for using added and modified features

The basic upgrading procedures are not enough to use the following features that have been added or modified in R4.07. After you upgrade the SENG software to R4.07, you must perform offline download to the SCS and other operations. The following procedures are required to use the new features.

SEE ALSO For more information about operation “Procedure B” to “Procedure F” for using new functions, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Making POWE/LOGE a Safety Function

To use the POWE/LOGE as a safety function, you must perform “Procedure C” on an SENG of R4.07. In new SCS projects created with R4.07.00 or later, POWE/LOGE is treated as a safety function.

Steps when an SCS project is already placed on another computer such as a file server

If an SCS project is already placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When an SCS project is already placed on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO For more information about avoidance, refer to:

“■ Precautions when Placing the SCS Project on Another PC such as a File Server” in 1.2, “Engineering” in ProSafe-RS Release Information (IM 32P01A50-01EN)

Cautionary notes for upgrading when ALE111 is used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Appendix 6.9 Cautionary notes for upgrading to R4.08

This section provides cautionary notes and actions required for a revision upgrade from R4.07 to R4.08. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

When integrating ProSafe-RS with CENTUM VP, use the R6.10 or a later version(*1) of CENTUM VP for the installation on the same computer.

*1: CENTUM VP R6.09 with CENTUM VP R6.09.04 applied can also be used.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method used.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.07, refer to:

Appendix 6.8, "Cautionary notes for upgrading to R4.07" on page App.6-24

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software revisions

The respective software release numbers of R4.08 are as follows:

Software release number R4.08.xx (*1)

- SENG software release number: R4.08.xx (*1)
- SCS system program release number: R4.08.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.08.00.

The database revision of an SCS project that is created by SENG with software release number R4.08.xx will be R4.08.00.

● Control bus drivers

The control bus drivers that are installed on the computer must be upgraded to the version supplied in R4.08.

■ Basic procedure for upgrading

To use the added or modified features, install the ProSafe-RS software R4.08 or later and open the existing SCS projects ("Procedure A").

SEE ALSO For more information about Operations of “Procedure A”, refer to:

“■ Procedure A: Opening SCS Projects” on page C4-18

■ Procedures for using added and modified features

The basic upgrading procedures are not enough to use the following features that have been added or modified in R4.08. After you upgrade the SENG software to R4.08, you must perform offline download to the SCS and other operations. The following procedures are required to use the new features.

SEE ALSO For more information about operation “Procedure B” to “Procedure F” for using new functions, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

● Modbus device reference number expansion

To expand the reference numbers of Modbus devices, you must perform “Procedure C” on an SENG of R4.08. Modbus device reference numbers are expanded in SCS projects newly created in R4.08.00 or later. The applicable SCSs are SCSP1/SCSU1/SCSP3/SCSL2.

■ Steps when an SCS project is already placed on another computer such as a file server

If an SCS project is already placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When an SCS project is already placed on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO For more information about avoidance, refer to:

“■ Precautions when Placing the SCS Project on Another PC such as a File Server” in 1.2, “Engineering” in ProSafe-RS Release Information (IM 32P01A50-01EN)

■ Cautionary notes for upgrading when ALE111 is used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Appendix 6.10 Cautionary notes for upgrading to R4.09

This section provides cautionary notes and actions required for a revision upgrade from R4.08 to R4.09. When you upgrade, also read the cautionary notes for upgrading to the previous versions that were issued after the software version currently installed on your computer and perform the required tasks for each upgrade.

IMPORTANT

When integrating ProSafe-RS with CENTUM VP, use the R6.10 or a later version of CENTUM VP for the installation on the same computer.

In R4.01 or later, be sure to register the RS project in an AD project regardless of the engineering method.

SEE ALSO

For more information about creating an AD project, refer to:

"■ Creating AD projects" in C1.2.1, "Creating and deleting AD projects" in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about how to register RS projects in an AD project, refer to:

C1.2.3, "Registering RS projects in the AD project" in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

For more information about cautionary notes when upgrading the revision to ProSafe-RS R4.08, refer to:

Appendix 6.9, "Cautionary notes for upgrading to R4.08" on page App.6-26

For more information about the detailed operation procedure required after the revision upgrade, refer to:

C4.2.4, "Procedures for using new functions" on page C4-22

■ Software revisions

The respective software release numbers of R4.09 are as follows:

Software release number R4.09.xx (*1)

- SENG software release number: R4.09.xx (*1)
- SCS system program release number: R4.09.xx (*1)

*1: The last two digits of the revision number will be changed in accordance with the software revisions after the release of R4.09.00.

The database revision of an SCS project that is created by SENG with software release number R4.09.xx will be R4.08.00.

● Control bus drivers

The control bus drivers that are installed on the computer must be upgraded to the version supplied in R4.09.

■ Basic procedure for upgrading

To use the added or modified features, install the ProSafe-RS software R4.09 or later and open the existing SCS projects ("Procedure A").

SEE ALSO

For more information about Operations of "Procedure A", refer to:

"■ Procedure A: Opening SCS Projects" on page C4-18

Procedures for using added and modified features

The basic upgrading procedures are not enough to use the following features that have been added or modified in R4.09. After you upgrade the SENG software to R4.09, you must perform offline download to the SCS and other operations. The following procedures are required to use the new features.

SEE ALSO For more information about operation “Procedure B” to “Procedure F” for using new functions, refer to:

C4.2.4, “Procedures for using new functions” on page C4-22

Improvement of POU online change function

To improve the POU online change function, you must perform “Procedure E” on an SENG of R4.09. For SCS projects newly created with SENG R4.09.00 or later, online change download is available when newly creating, deleting, or renaming all program, user-defined function, and user-defined function block POUs.

Steps when an SCS project is already placed on another computer such as a file server

If an SCS project is already placed on a file server PC that is different from the SENG PC, files in the SCS project database may be corrupted while the SCS project is operated on the SENG PC. When an SCS project is already placed on a PC such as a file server which is different from the SENG PC that operates the SCS project, make sure to implement the avoidance described in SEE ALSO to prevent file corruption in the SCS project database.

SEE ALSO For more information about avoidance, refer to:

“■ Precautions when Placing the SCS Project on Another PC such as a File Server” in 1.2, “Engineering” in ProSafe-RS Release Information (IM 32P01A50-01EN)

Cautionary notes for upgrading when ALE111 is used

You must be careful when upgrading the system if ALE111 is used for Modbus slave or DNP3 communication.

SEE ALSO For more information about the precautions when upgrading a system where ALE111 is used for Modbus slave or DNP3 communication, refer to:

“■ Cautionary Notes for Upgrading When ALE111 is Used” on page App.6-5

Revision Information

Title : Installation Guide

Manual No. : IM 32P01C50-01EN

Dec. 2023/11th Edition/R4.10 or later

B1.2	Added or deleted descriptions of Windows update programs.
B2.1, B2.2, B2.3, B3.2, B3.2.1, B3.2.2, B3.2.3, B3.3.2, B3.9.1, B3.9.2, B5.1, B6, C7.1	Added descriptions of supported OS, and deleted descriptions of unsupported OS.
B3.3.5, C7.2.1, C7.2.2	Deleted OS descriptions.
B3.5	Changed .NET Framework version.
C4.2.3	Added descriptions of upgrading to R4.10.
D1.1	Updated description of the information for connecting CENTUM VP and ProSafe-RS.

Jun. 2023/10th Edition/R4.09

B1.2	Updated descriptions of Windows update programs.
B3.5	Changed descriptions of redistributable package
C4.2.3	Added descriptions of upgrading to R4.09.
D1.1	Updated description of the information for connecting CENTUM VP and ProSafe-RS.
D1.2	Updated description of the information for connecting ProSafe-RS and iDefine.

Nov. 2022/9th Edition/R4.08

B1.2, B2.3, B3.2, B3.3, B5.1, B6	Added or updated descriptions of Windows update programs.
C4.2.3	Added descriptions of upgrading to R4.08.

Jan. 2022/8th Edition/R4.07

B1.2	Added descriptions for downloading Windows update for Windows Server 2019 and updated descriptions for downloading Windows update for Windows 10 Enterprise 2019 LTSC and Windows Server 2012 R2.
B2.1, B2.2, B2.3, B3.2.1, B3.2.2, B3.2.3, B3.3.5, B3.9.1, B5.1, B6, C7.2.2	Added descriptions of Windows Server 2019.
B2.3, B3.2, B5.1, B6	Added descriptions of installing Windows update programs.
B3.3.2	Added descriptions of the RIP Listener service.
B3.3.4	Updated descriptions about update programs in preparation.
B3.5, B3.6, B5, B6, C4	Added descriptions of password change.
C4.1	Added descriptions about linked domain management.

C4.1.1, C4.1.2	Added descriptions of version upgrade and revision upgrade during linked domain management operation.
C4.2.3	Added descriptions of upgrading to R4.07.
C7.1	Added descriptions of time zone cannot be changed (Windows Server 2019).

Feb. 2021/7th Edition/R4.06

A1, B2.1, B2.2, B2.3, B2.4, B3.2, B3.3, B3.9, B5.1, B6, C4.1, C7.2	Deleted descriptions of unsupported OS.
A2.2, B1.2, B2.1, B2.3, B2.5, B3.5, B3.6, B3.8, B4.5, B5.1, B5.2, B5.3, B6, C2	Added descriptions about linked domain management.
B1.2	Added or deleted descriptions about downloading Windows update programs.
B3.2.2, B3.9.2	Added descriptions of Windows 10 Enterprise 2019 LTSC.
B3.5, C4.1	Updated descriptions of redistributable modules.
C4.1, C4.2	Updated descriptions of actions after the installation for an upgrade or after upgrading ProSafe-RS software.
C4.2.3	Added descriptions of upgrading to R4.06.
D1	Updated the package code 0204 from FAST/TOOLS Integration Package to CI Server Integration Package.
D1.1	Added descriptions about linked domain management to the information for connecting CENTUM VP and ProSafe-RS.
D1.2	Updated descriptions of the information for connecting ProSafe-RS and iDefine, and added descriptions about linked domain management.
D1.3	Added descriptions about linked domain management to the information for connecting ProSafe-RS and PRM.

Apr. 2019/6th Edition/R4.05

Introduction	Updated description of registered trademarks and trademarks.
B1.2, B2.3, B3.2.3, B3.2.5, B3.3.3, B5.1	Updated descriptions of Windows update programs.
B1.2, B2.3, B3.6, B5.1	Updated descriptions of IT security.
B3.5, C4.1.1, C4.1.2	Updated descriptions of redistributable modules.
B3.6, B4.4	Added descriptions of the Forced I/O Viewer function.
C4.1.1, C4.1.2	Added descriptions of updating the Vnet/IP Interface Package.
C4.2	Updated descriptions due to the change in project database format.
C5	Added descriptions of updating to R4.05.
D1.1.5	Added information about connecting CENTUM VP and Forced I/O Viewer Package.
D1.2	Updated information for connecting ProSafe-RS and iDefine.
D1.3.2	Added information about connecting PRM Client and Forced I/O Viewer Package.

Aug. 2018/5th Edition/R4.04

Introduction	Updated description of registered trademarks of YOKOGAWA.

A2.2.2, A2.2.3, B1.3, B3.1, B3.3, B3.3.3, B3.4, C6.1.2, Appendix 3	Added descriptions about virtualization platform.
B1.2, B2.3, B3.2.3, B3.2.5, B5.1	Added descriptions of Windows update programs.
B2.1 to B2.3, B3.2.1, B3.2.4, B3.3.4, B3.9.1, B6, C8.2.1	Added descriptions of Windows Server 2016
B2.3, B3.5, B5.1	Changed descriptions of redistributable package
B2.3, B3.2.2, B3.2.4, B5.1	Added descriptions of disabling the Automatic cleanup task.
B3.2.2, B3.2.5, B3.5, B6	Deleted description of .NET Framework 3.5.1
B3.2.2, B3.2.4	Added descriptions of DCOM Settings
B3.5, C4.1	Added description of using iDefine interface package.
B3.9.2	Added descriptions about suppressing toast notification regarding Windows Firewall.
C4.1	Added procedure for upgrading the revision of products when two or more upgrade license support products are installed.
C4.1.1	Added the upgrading the version of ProSafe-RS software.
C4.1.2	Added the upgrading the revision of ProSafe-RS software.
C5	Added descriptions of upgrading to R4.04
D1.1	Updated description of the information for connecting CENTUM VP and ProSafe-RS.
D1.2	Updated description of the information for connecting ProSafe-RS and iDefine.

Oct. 2017/4th Edition/R4.03.10

B3.4	Deleted precautions when installing ProSafe-RS and CENTUM, or ProSafe-RS and PRM, on the same computer.
B4.1	Added descriptions of the Help files for PROFINET Configurator.
C4.1	Added descriptions of the upgrade license.
C4.2	Added descriptions of I/O list engineering.
C4.3	Added descriptions of how to start engineering after upgrading the ProSafe-RS software.
C5	Added descriptions of updating to R4.03.10.
C6.1	Added precautions for uninstallation when ProSafe-RS and CENTUM VP are installed on the same computer.

May 2017/3rd Edition/R4.03

Entire manual	Updated descriptions of the Start menu.
Introduction	Deleted Windows Vista from Trademark Acknowledgments.
B2	Updated descriptions of configuring the security settings on the domain controller
B3.2, B3.5, B3.8, C9.2	Deleted descriptions of Windows Vista and Windows Server 2008.

B3.2, B3.3, B3.4, B3.8, B6, C8.2, Appendix 4	Added descriptions of Windows 10
B3.3, C8.2	Updated descriptions of configuring network settings
B3.4, B5, B6, C4.1	Updated descriptions of security groups
B3.5, C8	Updated descriptions of IT security settings. Moved descriptions of the IT Security Tool and IT security-related maintenance to the Security Guide.
B6, C4.1, C4.3	Added descriptions of setting up Windows.
C5	Added descriptions of upgrading to R4.03
D1, D1.1	Updated descriptions of CENTUM VP and ProSafe-RS
D1.2	Updated descriptions of the connection information for ProSafe-RS and iDefine.
Appendix 5.2	Updated descriptions of cautionary notes for upgrading when ALE111 is used.

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed the symbols that indicate warning and caution.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."
A1, A2.1	Added descriptions of iDefine.
B3.1	Updated descriptions of removing the Vnet/IP interface card.
C5	Added descriptions of upgrading to R4.02
C8.1.1	Added descriptions of a computer on which only AD Server is installed and a computer dedicated to license management.
D1, D1.2	Added information about connecting ProSafe-RS and iDefine.
D1.3	Updated descriptions of ProSafe-RS and PRM.
Appendix 4	Added descriptions of compatibility between revisions and cautionary notes for upgrading.

YOKOGAWA
Yokogawa Electric Corporation

IM 32P01C60-01EN
8th Edition

Introduction

This manual describes how to manage licenses, which is a process required to activate and deactivate CENTUM VP and ProSafe-RS software packages.

Prerequisites for using this manual include completing the installation and preliminary configuration of the CENTUM VP and ProSafe-RS software packages.

This manual is structured as follows:

- Overview of license management
  Provides an overview of license management.
- Basic operations in license projects
  Describes the basic operations in managing licenses.
- Maintaining license projects
  Describes how to maintain a license project.
- Upgrading the Licenses from CENTUM VP R5 to R6, or from ProSafe-RS R3 to R4
  Describes how to update licenses when a product is upgraded.
- Working with upgrade licenses
  Describes how to operate the upgrade licenses.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User's Manuals for necessary actions. In the User's Manuals, this symbol is used together with a word "CAUTION" or "WARNING" at the locations where precautions for avoiding dangers are described.

<French> Signale qu'il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d'un danger pour le personnel et l'équipement comme un choc électrique, et signale également que l'utilisateur doit se référer au Manuel de l'utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l'utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

~ Indicates an AC supply.

⎓ Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

Trademark Acknowledgments

1. Overview of license management

This section provides an overview of license management.

1.1 License management

This section provides an overview of license management and License Manager, which is a software used to manage licenses.

About license management

A license is the right to use a software package.

To activate a software package, allocate a license to every computer where the software package that you want to activate is installed. In addition, you can delete licenses for software packages that are no longer used on a specific computer. In this manual, these operations are referred to as activating and deactivating a software package.

License management is the process by which you determine which software package to use on which computer, distribute or delete licenses for each individual computer, and activate or deactivate the software packages.

The following table describes the license types.

Table 1.1-1 License types

Type	Description
Software license	License required to use the product software
Version upgrade license	License required to upgrade the version of the software license
Upgrade license	License required to apply the revisions when the product software is revised Types of upgrade licenses are as follows: • Upgrade license (revision up/patch) • Upgrade license (revision up) • Upgrade license (patch)

About License Manager

License Manager is the software program designed specifically to manage licenses.

License Manager is automatically installed when you install a product to be managed in license management on a computer. You can also install License Manager solely on a computer.

The following figure shows the License Manager window.

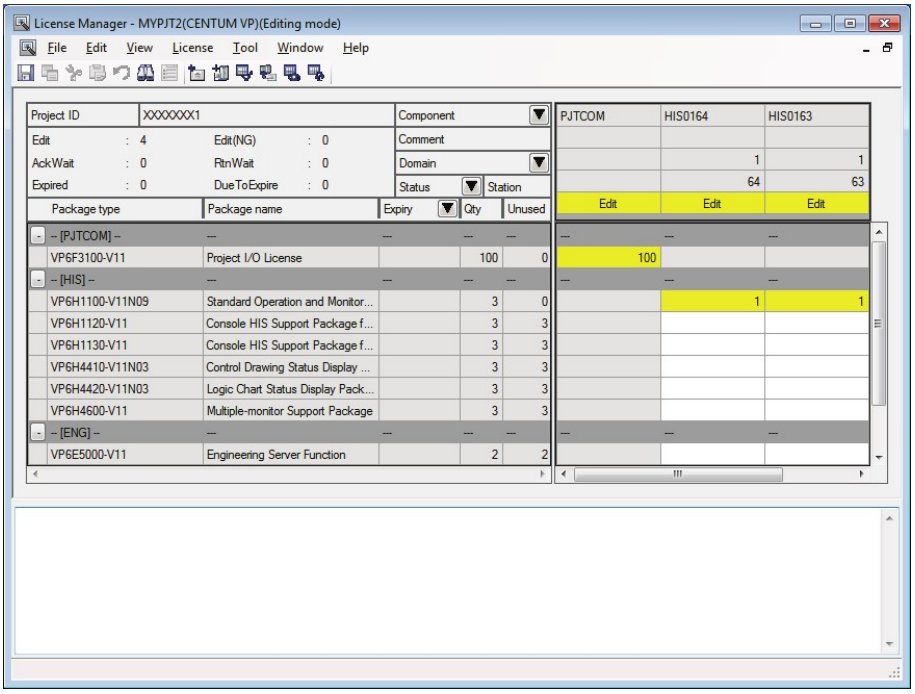

Figure 1.1-1 License Manager

SEE ALSO For more information about the products managed in license management, refer to:

"■ Products managed in license management" on page 1-4

1.1.1 License management targets

This section describes the products that are managed in license management and the scope for managing licenses.

Products managed in license management

License Manager manages the licenses of the following products:

- CENTUM VP R5.01 or later
- ProSafe-RS R3.01 or later
- PRM R4.01 or later

TIP

The software that is bundled with hardware is not managed in the license management. For example, the software bundled with Communication Gateway Unit (CGW) or Bus Converter (BCV) is not managed.

SEE ALSO

For more information about license management of PRM, refer to:

Plant Resource Manager License Management (IM 30B05A40-01EN)

License management of iDefine used for ProSafe-RS

License Manager does not manage the license of iDefine that is used in ProSafe-RS engineering.

SEE ALSO

For more information about license management for iDefine, refer to:

License User Guide (PR03076-MAN-971_02)

Scope of license management

A project that defines the license management targets is referred to as a license project. A license project manages the same scope specified by the project ID.

In ProSafe-RS, do not register SCS projects that belong to different license projects to the same RS project.

TIP

- CENTUM VP and ProSafe-RS are managed as two separate systems. For this reason, the license projects for CENTUM VP and ProSafe-RS are also managed separately.
- System engineering information is managed in projects, "VP project" of CENTUM VP and "RS project" and "SCS project" of ProSafe-RS, whereas system license information is managed in a license project.

Managing licenses for multiple systems

You can use License Manager on a single computer to manage license projects for multiple projects.

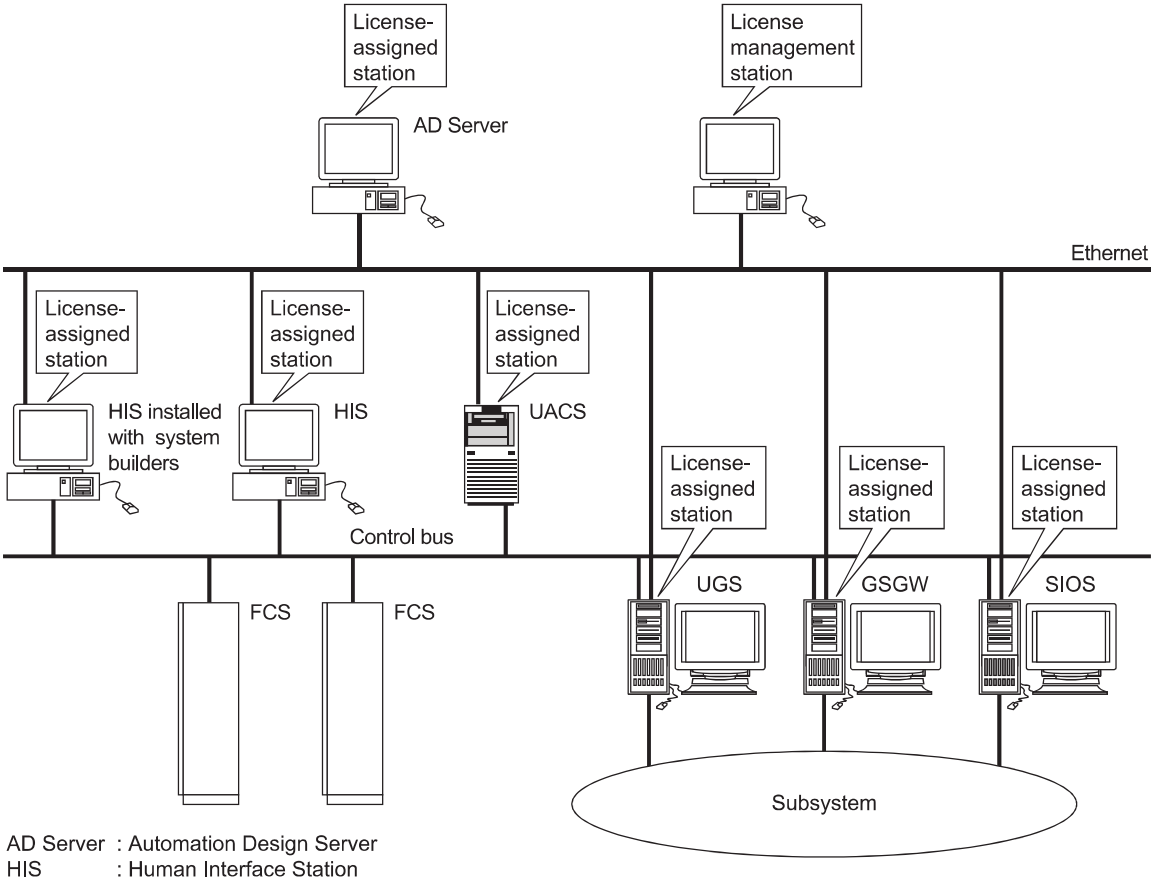
In addition, if you install License Managers for different products on a computer, you can manage licenses of multiple products by using their respective License Managers.

Different Version of License

A license can be distributed to the station if the license version and the software version that is installed in the station is identical.

For example, CENTUM VP R6 licenses are available to distribute only to the station that is installed with the CENTUM VP R6 software, not to the station that is installed with the CENTUM VP R5 software.

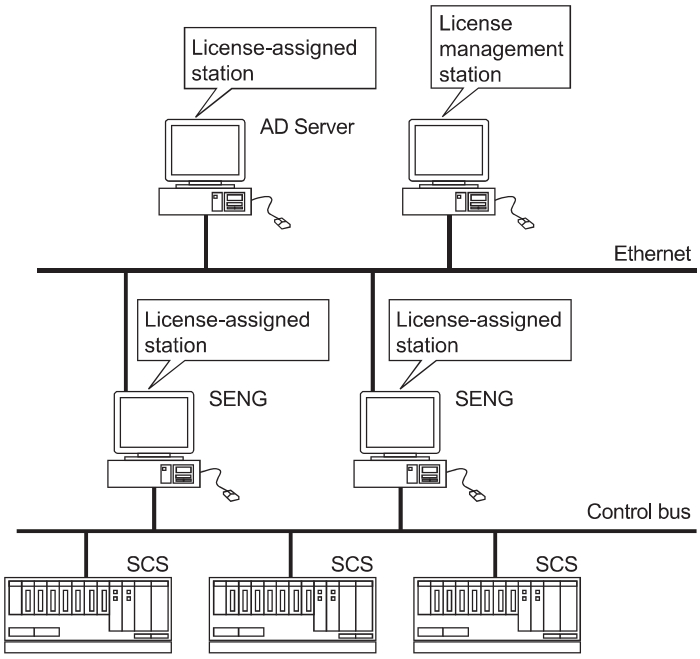
Similarly, CENTUM VP R5 licenses are available to distribute only to the station that is installed with the CENTUM VP R5 software, not to the station that is installed with the CENTUM VP R6 software.



1.1.2 How license management works

This section describes the system configuration for license management and the process for managing licenses.

License management system configuration



License Manager is installed on every computer where a license management target product is installed. You can use License Manager on one of these computers to manage licenses for the entire license project, and License Manager on the remaining computers to manage their own licenses.

A computer that manages licenses for one entire license project is called a license management station, while a computer whose licenses are being managed is called a license-assigned station.

AD Server : Automation Design Server
HIS : Human Interface Station
FCS : Field Control Station
UGS : Unified Gateway Station
GSGW : Generic Subsystem Gateway Station
SIOS : System Integration OPC Station
UACS : Unified Alarms & Conditions Server

Figure 1.1.2-1 Example of the license management system configuration for CENTUM VP

AD Server :Automation Design Server
SENG : Safety Engineering Station
SCS : Safety Control Station

Figure 1.1.2-2 Example of the license management system configuration for ProSafe-RS

TIP

As a general rule, to set up a license management station, you should use a computer where a license management target product is installed and is running 24 hours a day. You can also use a computer where only License Manager is installed.

Configuration for management of multiple projects by AD server

When multiple engineering projects are managed by using the AD server, a station that has a license of the Engineering Server Function is required to be included in one of license projects for engineering project. Avoid registering the station having the license of the Engineering Server Function for multiple license projects. Specifically, perform following instructions.

- When the AD server is the station that has only the Engineering Server Function
  Create a station that has only the Engineering Server Function in just one license project. Assign the license of the Engineering Server Function in the license project for which the station that has only the Engineering Server Function has been registered.
- When the AD server is the station that carries functions other than the Engineering Server Function
  Assign and distribute the license of the Engineering Server Function only in one license project.

The following figure shows that a station that has the AD server is defined in the license project (LPJT-A) for PJT-A and that the License Manager station in LPJT-A distributes the license of the Engineering Server Function.

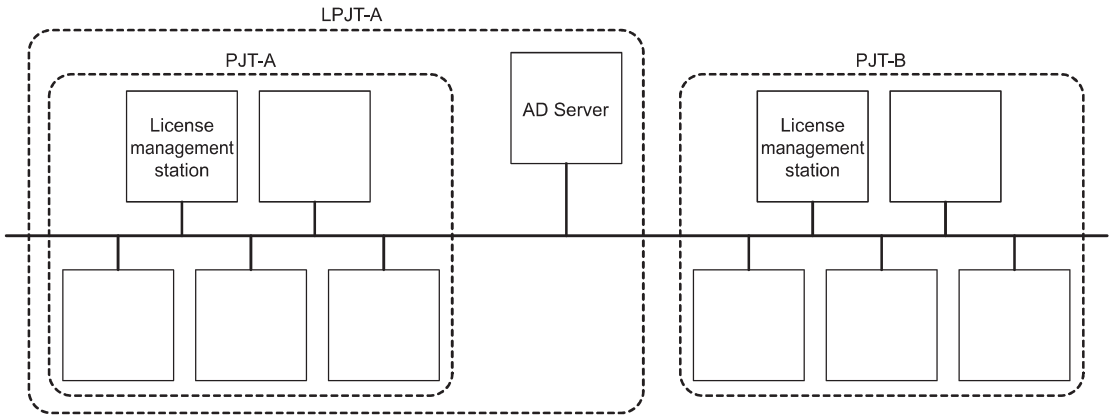


Figure 1.1.2-3 When AD server manages multiple projects

License management process

Yokogawa provides usage rights for purchased software packages in the form of license key files. License key files are stored on license media and supplied to users.

The license management station recognizes purchased licenses by reading the license key files from the license media.

After you assign licenses to each station, distribute the licenses to activate the software packages accordingly.

TIP

The license management station permits license update from CENTUM VP R5 to R6, and from ProSafe-RS R3 to R4.

Licenses are assigned to the following stations:

- License-assigned stations

  Licenses for the software packages installed on the license-assigned stations are assigned.

- License management station

  Licenses for the software packages installed on the license management station itself are assigned. (*1)

- FCS/SCS

  Are assigned licenses for the software used in FCS or SCS.

- PJTCOM

  PJTCOM is a virtual station in which the Project I/O License is assigned.

*1: The station with only License Manager installed is excluded.

TIP

Licenses for software that is bundled with hardware are not managed by License Manager.

After assigning licenses, distribute the licenses to the stations. At this point, the licenses that have been assigned to each station are distributed as follows:

- Licenses assigned to license-assigned stations

  Distributed from the license management station to the relevant license-assigned station.

- Licenses assigned to the license management station

  Distributed from the license management station to itself.

- Licenses assigned to an FCS or SCS

Licenses assigned to an FCS are distributed to the station installed with system builders, whereas licenses assigned to an SCS are distributed to SENG.

- Licenses assigned to PJTCOM

  In a CENTUM VP configuration, the licenses assigned to PJTCOM are distributed to the station installed with the system builders. In a ProSafe-RS configuration, they are distributed to the SENG.

After licenses have been distributed, activate the software packages by accepting the licenses on each station.

SEE ALSO For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

1.1.3 Overview of license management process

This section describes the license management process when building a license project for the first time, and the tasks that need to be completed before and after the process.

IMPORTANT

Before performing the actual license management process, first prepare the information that is required for the process.

Tasks to be completed before starting license management

Before starting license management, you must perform the following tasks:

- Install the software package

  Install the software packages on all computers where you want to run the license management target product.

- Select the license management station

  If you want to use a computer as license management station only, install License Manager.

  In other cases, select a computer installed with license management target product as a license management station. License Manager is automatically installed on computer installed with license management target product.

TIP

To check license consistency for the entire system, it is recommended that you use a computer that is running continuously as the license management station. However, license-assigned stations and FCS/SCS stations continue to operate normally even if the license management station stops.

Building a license project for the first time

This section describes the license management process when building a license project for the first time.

License management includes tasks performed on the license management station and the license-assigned stations.

Tasks performed on a license management station

First, start License Manager on the license management station.

The tasks performed on a license management station are as follows:

1. Create new license projects
   Create a license project. When creating a license project, specify a name for the license project.
2. Read the license
   Read the license key file from the license media and register the available licenses. At this point, you need to enter the Project ID number.

IMPORTANT

- The license key file needs to be read by License Manager within the validity period printed on the license media. If the validity duration expires, you will not be able to read the license key file using License Manager. If the validity duration has expired, contact Yokogawa.
- You must retain the license key file even after expiration because it is used when restoring a license project.

3. Specify the stations
   Specify the stations whose licenses need to be managed.
4. Assign licenses to the stations
   Assign available licenses to each station.
5. Check license consistency
   Check that the basic software and options software have been combined correctly and that the licenses have been properly assigned.
6. Distribute licenses to stations
   Distribute licenses to the license-assigned stations through the network or by using external media.

Tasks performed on a license-assigned station

After you distribute licenses from the license management station to a license-assigned station, start License Manager on the license-assigned station.

Perform the following task:

- Accept the licenses
  Using License Manager, accept the licenses to activate the software packages.

TIP

When you distribute licenses for the first time, they are accepted automatically.
For the second and subsequent distributions, you need to perform the task to accept licenses.

IMPORTANT

You need to perform this task on all license-assigned stations. In addition, you also need to perform the same task for the license management station if you are assigning licenses to the station itself and activating its software package.

Tasks to be performed after licenses have been accepted

On the license management station and license-assigned stations, perform the procedures required for the individual packages that have been activated.

SEE ALSO

For more information about work required after activation, refer to:

B4., “Configuring the Functions Specific to SENG” in Installation Guide (IM 32P01C50-01EN)

1.2 License Manager

This section describes the functions, user privileges, operation, and window structures of License Manager.

1.2.1 License Manager function

This section describes the functions of License Manager on the license management station and license-assigned stations.

Functions of License Manager on a license management station

You can use the following functions of License Manager on a license management station:

- Manage licenses

  Create license projects and perform license management for the entire system, such as the assignment, distribution, and modification of licenses.

- Monitor the status of assigned licenses

  Monitor the status of assigned licenses for the entire system.

- Automatically back up license management information

  Automatically back up license management information to prepare for the possibility of a license management station failure.

- Redistribute licenses

  Redistribute licenses to a replacement license-assigned station if the original station fails.

- Accept licenses distributed to the local station

  Accept licenses that have been distributed to the license management station itself, and activate or deactivate the software packages.

Functions of License Manager on a license-assigned station

You can use the following functions of License Manager on a license-assigned station:

- Accept distributed licenses

  Accept licenses to activate or deactivate the software packages.

- Monitor distributed licenses

  Monitor licenses that have been distributed to the local station.

1.2.2 User privileges in License Manager

This section describes the user privileges in License Manager.

■ Privileges that entitle users to license management

The License Manager functions that you can use vary according to your user privileges. If you are part of a user group that has Administrator privileges, you can have maintenance privileges for License Manager. Only users with maintenance privileges can operate a license management station in Editing mode.

Table 1.2.2-1 User groups with maintenance privileges

Product name	User group	
	Legacy model(*1)	Standard model(*1)
CENTUM VP	Administrators	CTM_MAINTENANCE, CTM_MAINTENANCE_LCL
ProSafe-RS	Administrators	PSF_MAINTENANCE, PSF_MAINTENANCE_LCL

*1: This is the security model that is configured in IT security.

SEE ALSO For more information about Editing mode, refer to:

"■ Operation modes" on page 1-16

1.2.3 Starting and exiting License Manager and working with the operation modes

This section describes how to start and exit License Manager and the operation modes.

Starting License Manager

Start License Manager on the license management station or a license-assigned station.

License Manager window appears.

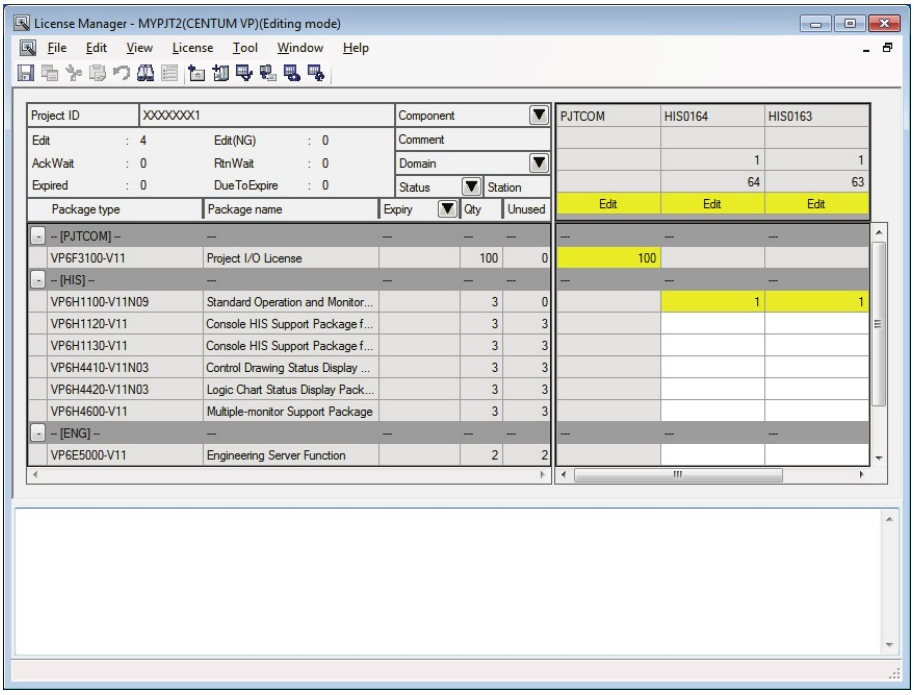

Figure 1.2.3-1 License Manager on the license management station

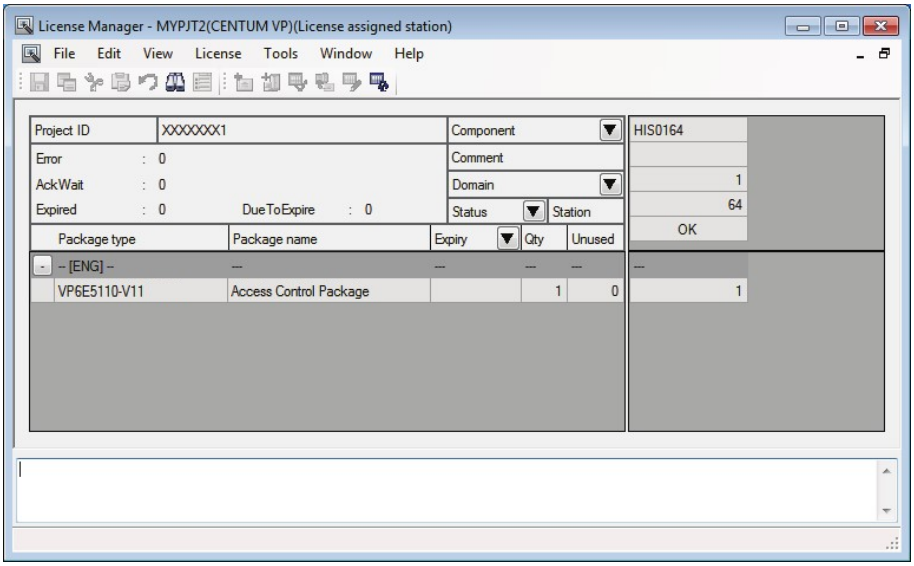

Figure 1.2.3-2 License Manager on a license-assigned station

TIP

When starting License Manager on the license management station from the second time onwards, a dialog box may appear to confirm whether you want to open data you were working with. The dialog box appears if you had closed License Manager after modifying the license assignments but without distributing them in the previous session. When this dialog box appears, click [Yes] to open the license project in the state where license assignments were being modified, but not distributed. Otherwise, click [No] to open the license project in the most recent status when licenses were distributed successfully.

Exiting License Manager

From the License Manager menu bar, select [File] > [Exit].

Operation modes

The functions that can be used in License Manager change according to the operation mode. The following table shows the functions that can be used in each License Manager operation mode:

Table 1.2.3-1 Operation modes in License Manager

Station	Operation mode	Functions
License-management station	Editing mode	Create a new license project Read licenses from the license media Define license management targets Assign licenses to license-assigned stations Distribute licenses to license-assigned stations Accept licenses distributed to its local station and activate or deactivate the installed software packages.
	Monitoring mode	Display the status of assigned licenses on license-assigned stations
License-assigned stations	Assigned station mode	Accept licenses distributed to local stations and activate or deactivate the installed software packages. Display the status of assigned licenses for its local stations

Switching operation modes

You can switch between the different operation modes of the license management station in the following ways:

Switching from Monitoring mode to Editing mode

From the License Manager menu bar, select [View] > [Editing mode].

Switching from Editing mode to Monitoring mode

From the License Manager menu bar, select [View] > [Monitoring mode].

Functions of License Manager and user privileges

The functions in License Manager that are available for use vary according to your user privileges.

Only users with maintenance privileges can operate a license management station in Editing mode.

The following table shows the License Manager functions available for the different stations and their operation modes:

Table 1.2.3-2 License Manager functions available for the different stations and their operation modes

Category	License Manager function	Station		
		Management station (Editing mode)	Management station (Monitoring mode)	Assigned station
Managing license information	Create a new license project	Yes	Yes (*1)	Yes (*1)
	Delete a license project	Yes	No	No
	Modify the properties of a license project	Yes	No	No
	Back up a license project	Yes	No	No
	Restore a license project	Yes	Yes (*1)	Yes (*1)
Defining the station configuration	Add a station	Yes	No	No
	Delete a station	Yes	No	No
	Modify station properties	Yes	No	No
Managing licenses	Add a license	Yes	No	No
	Move a license	Yes	No	No
	Delete a license	Yes	No	No
	Merge new installation licenses with upgrade installation licenses	Yes	No	No
	Upgrade a license	Yes	No	No
Editing license assignments	Assign a license	Yes	No	No
	Import a package list	Yes	No	No
	Export a package list	Yes	Yes	Yes (*2)
	Check consistency	Yes	No	No
	Export the status of license assignments that are being edited	Yes	No	No
Distributing and accepting licenses	Distribute a license (through the network)	Yes	No	No
	Distribute a master license (through the network) (*3)	Yes	No	No
	Accept a license (through the network)	Yes	Yes (*1)	Yes (*1)
	Distribute a license (using external media)	Yes	No	No
	Distribute a master license (using external storage media) (*3)	Yes	No	No
	Accept a license (using external media)	Yes	No	Yes (*1)
	Return a license (using external media)	Yes	No	No
Monitoring the license status	Monitor the status of assigned licenses	No	Yes	Yes (*2)
	Export the status of assigned licenses to a file	No	Yes	Yes (*2)
Other	Switch to Editing mode	No	Yes (*1)	No
	Switch to Monitoring mode	Yes	No	No

*1: Only available for users with maintenance privileges
*2: Only applicable for licenses distributed to that license-assigned station
*3: The Distribute Master licenses function redistributes assignment information that has already been distributed.

1.2.4 Window Structures of License Manager

This section describes the window structures of License Manager.

Main window

The following figure shows the names of the different parts of the License Manager main window.

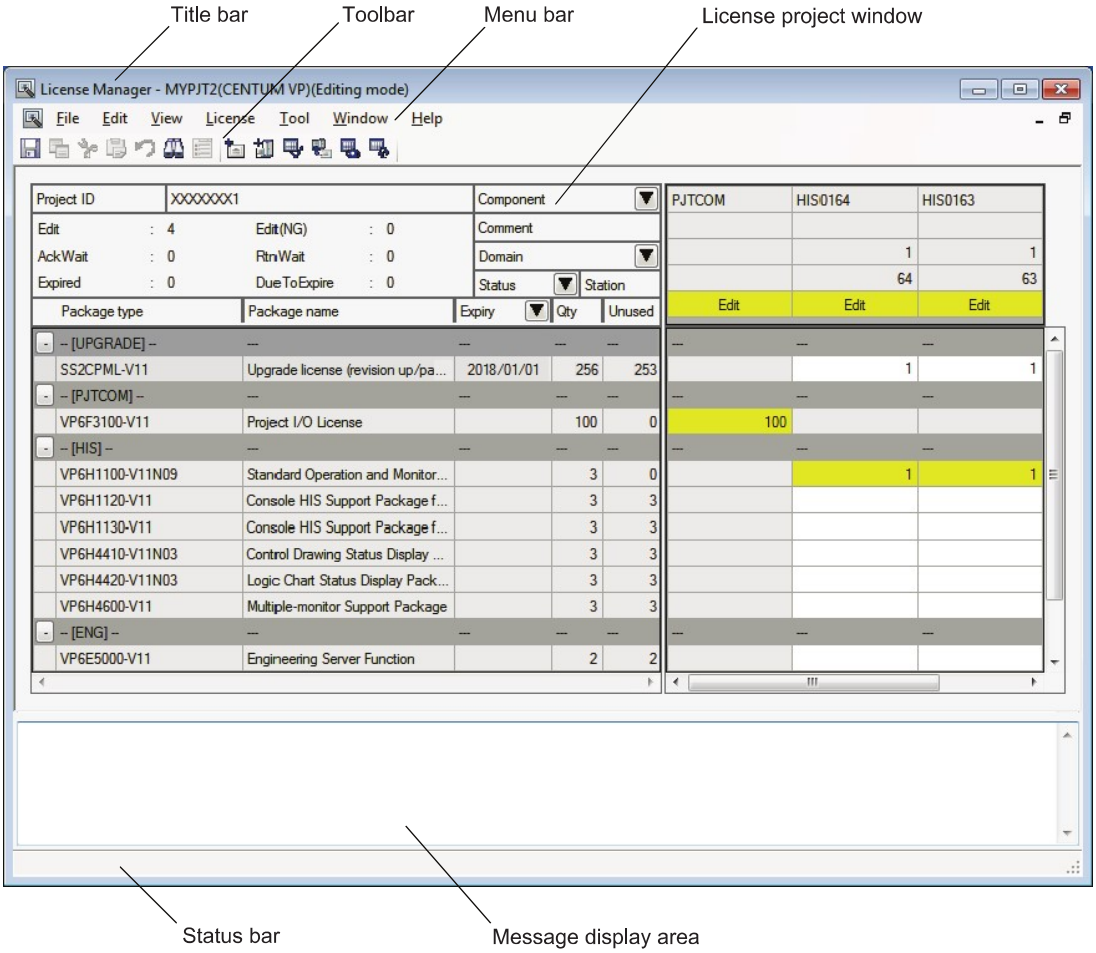

Figure 1.2.4-1 License Manager main window

License project window

The following figure shows the names of the different parts of the license project window.

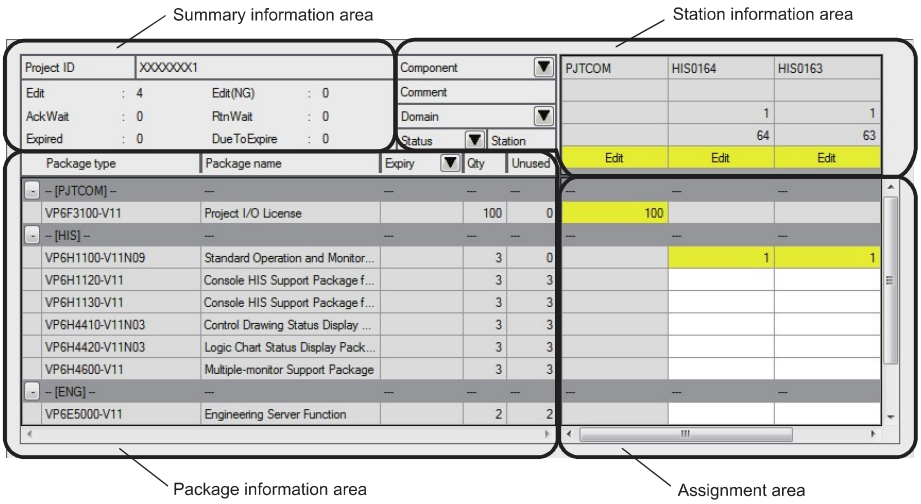

Figure 1.2.4-2 License project window

summary information area

The summary information area shows the Project ID and the status of assigned licenses for the entire license project.

In License Manager on the license management station, this area shows the status of assigned licenses for the entire license project. In License Manager on the license-assigned station, the area shows the status of licenses assigned to the local station.

The following items appear in the summary information area:

- Project ID
- Status display: The information displayed varies according to different operation modes, as shown in the following table.

Table 1.2.4-1 Status display details

Station	Status	Description	Status applicable for
License management station (Editing mode)	Edit	Number of stations with licenses that are being edited	Entire license project
	Edit(NG)	Number of stations that are diagnosed with errors in the consistency check	
	AckWait	Number of stations waiting for license acceptance	
	RtnWait	Number of stations waiting for a license to be returned	
	Expired	Number of stations with an expired license	
	DueToExpire	Number of stations with licenses that will expire within 30 days	
License management station (Monitoring mode)	Error	Number of stations with a license error	Entire license project
	Unknown	Number of stations for which the status cannot be confirmed due to a communication error	
	AckWait	Number of stations waiting for license acceptance	
	RtnWait	Number of stations waiting for deleted licenses to be returned using external media	
	Expired	Number of stations with an expired license	
	DueToExpire	Number of stations with licenses that will expire within 30 days	

Continues on the next page

Table 1.2.4-1 Status display details (Table continued)

Station	Status	Description	Status applicable for
License-assigned station	Error	License error	Local station
	Expired	Licenses have expired.	
	DueToExpire	Licenses will expire within 30 days.	
	AckWait	Waiting for license acceptance	

Package information area

The package information area shows the software packages with the licenses that are available for use.

In License Manager on the license management station, this area shows the managed software packages. In License Manager on the license-assigned station, this area shows the software packages that have been assigned a license on the local station.

The following table shows the definition items on the package information area. You can switch displaying or hiding the each definition item after you select View from the menu bar in the license manager.

Table 1.2.4-2 Definition items in the package information area

Item	Description	Default
Package type	The package model specification code for the license (example: VP6H1100-V10N03)	Displayed
Internal package type	CENTUM VP R5 package model specification code corresponding to the CENTUM VP R6 package model specification code, or ProSafe-RS R3 package model specification code corresponding to the ProSafe-RS R4 package model specification code (CENTUM VP example: LHS1100-V10/N0003) (*1)	Hidden
Package name	The package name for the license	Displayed
Paid	This item indicates whether the license is paid or free.	Hidden
Expiry	If the license has an expiry date, the expiry date appears. For software licenses, the software package is available until the expiry date. For upgrade licenses, you can install the product revisions or patches that were issued before the expiry date.	Displayed
Ver.	The version number of the license This item is left blank for upgrade licenses.	Hidden
Qty	The quantity of the license This item is fixed to 256 for upgrade licenses.	Always displayed
Unused	The number of licenses not assigned to any station	Always displayed

*1: The internal package model can be displayed on the definition item in the package information area on some screens, because some software uses the CENTUM VP R5 or ProSafe-RS R3 license package model specification code.

Only for upgrade licenses, the background color of the Expiry cell changes as follows.

Table 1.2.4-3 Background color of the Expiry cell

Background color	Description
White	The current date is before the expiry date of the upgrade license.
Yellow	The current date exceeded the expiry date of the upgrade license.

If you exceed the number of unused licenses when assigning licenses, there is a change in the background color of the cell that indicates the number of unused licenses.

Table 1.2.4-4 Background color of the unused cell

Background color	Description
White	The number of unused licenses for this software package is more than 0.
Red	The number of unused licenses for a software package is a negative value. This is because you assigned more licenses than the quantity you own for a station.

Station information area

The station information area shows the information of each destination station for assigned licenses.

In the license management station, License Manager shows the information of stations for the entire license project. License Manager on the license-assigned station shows only information of its own station.

TIP

- If FCS licenses are assigned by using the license management station, the destination FCS information appears on the station information area in the license-assigned station that is installed with system builders. If SCS licenses are assigned by using the license management station, the destination SCS information appears on the station information area in the license-assigned station that is installed with SENG.
- If Project I/O licenses are assigned to PJTCOM by using the license management station, the PJTCOM information also appears in the station information area on the license-assigned station installed with the system builders or on the SENG specified as the license-assigned station.

The following items appear in the station information area:

- Component: The station name
- Comment: Station comments
- Domain: The domain numbers of the stations
- Station: The station numbers of the stations
- Status: The status of assigned licenses for the stations

Table 1.2.4-5 The status of assigned licenses for a station

Station	Status of assigned licenses	Background color	Status	Description
License management station (Editing mode)	OK	No background color	Normal	Licenses have been distributed and accepted
	EDIT	Yellow	Warning	License assignment is currently being edited, or upgrade licenses have been added, but not yet distributed.
	AckWait	Yellow	Warning	Licenses have been distributed and are waiting for acceptance
	RtnWait	Yellow	Warning	Waiting for deleted licenses to be returned using an external storage media
	Edit(NG)	Red	Error	License assignment is currently being edited (there is an error in the assignment details)

Continues on the next page

Table 1.2.4-5 The status of assigned licenses for a station (Table continued)

Station	Status of assigned licenses	Background color	Status	Description
License management station (Monitoring mode) (*1)(*2)	OK	No background color	Normal	Licenses are being assigned successfully
	DueToExp	Yellow	Warning	Licenses will expire within 30 days
	Unknown	Yellow	Warning	Cannot confirm status due to a communication error
	NoLicense	Red	Error	No license
	Error	Red	Error	There is a license error
	Expired	Red	Error	Licenses have expired
License-assigned stations(*1)	OK	No background color	Normal	Licenses are being assigned successfully
	DueToExp	Yellow	Warning	Licenses will expire within 30 days
	Error	Red	Error	There is a license error
	Expired	Red	Error	Licenses have expired
	NoLicense	Red	Error	No license

*1: When the licenses are waiting for acceptance, the prefix * is added to the character strings indicating the status of assigned licenses. (Example: *OK)
*2: When the licenses are waiting to be returned, the prefix ** is added to the character strings indicating the status of assigned licenses. (Example: **OK)

SEE ALSO For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

Assignment area

In the assignment area, you can view whether a license has been assigned to a station.

In License Manager on the license management station, you can view whether licenses have been assigned for the entire system. In Editing mode, you can modify the license assignment.

In License Manager on a license-assigned station, you can view the license assignment status for the local station.

The background color of this area also indicates the license assignment status.

Table 1.2.4-6 Background display of the assignment area

Background color	Description
White	This cell can be assigned licenses.
Yellow	License assignment was modified or added for this cell, or upgrade license was added to extend the expiration for this cell.
Red	This cell was diagnosed with errors in the consistency check.
Gray	This cell cannot be assigned licenses.

SEE ALSO For more information about consistency checks, refer to:

"■ Building a license project for the first time" on page 1-10

2. Basic operations in license projects

This section describes the basic operations in license projects.

2.1 Process for managing licenses for the first time

This section describes the items required for managing licenses for the first time and the basic workflow for activating the software package.

Requirements

You need the following items to start managing licenses:

- License media (license key files)
- License sheet that lists the project IDs

Basic workflow

The basic workflow for managing licenses for the first time is shown in the following figure. Follow this workflow to activate a software package.

The steps until license distribution are performed using the License Manager on the license management station.

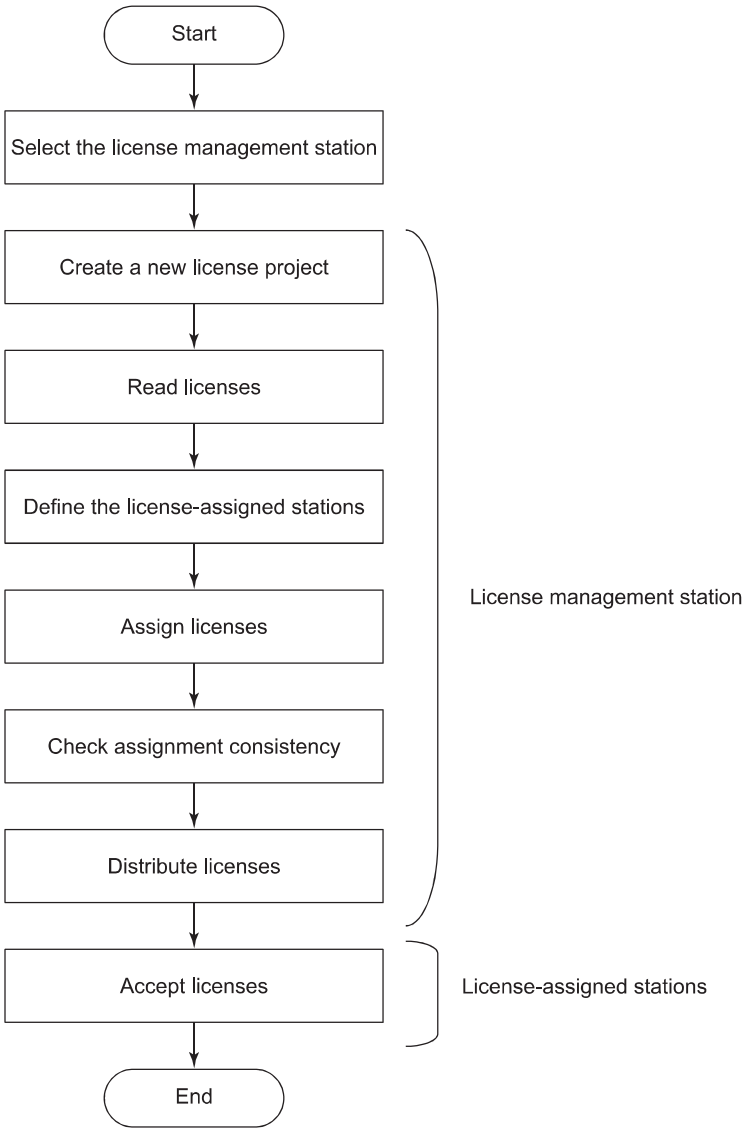

Figure 2.1-1 Steps for managing licenses for the first time

Selecting the license management station

From the computers installed with License Manager, select a computer to use as the license management station. If there are any computers that operate 24 hours a day, it is recommended that you select such a computer from the perspective of the consistency check.

2.2 Creating, switching, and deleting license projects

This section describes how to create, switch, and delete a license project for license management. When creating a license project, specify a backup folder.

TIP You can distribute licenses even if you do not specify a backup folder. However, in License Manager, license projects are automatically backed up when a license project is saved. For this reason, you should specify a backup folder first.

Creating a license project

Follow these steps to create a license project:

1. Sign in to the license management station computer as a user with maintenance privileges.
2. Start License Manager.
   License Manager window appears.
3. From the menu bar, select [File] > [New] > [Project].
   The Create new license project dialog box appears.
4. Specify the following information:
   - In the Project name box, type a name for the license project using a character string containing between 1 and 8 characters.
     You can use uppercase single-byte English letters, numeric characters, hyphens (-), and underscores (_). However, the first character must be an uppercase English letter.
   - If multiple system products are installed, select a system product name from the System type drop-down list.
5. Click [OK].
   The license project is created and the license project window appears in the License Manager window.

TIP When you manage licenses for multiple projects on one license management station, also use this procedure to create license projects.

Specifying a backup folder

For the license project backup folder, you must specify a folder in the hard drive of another computer on the same network, or a hard drive that is added to your computer, and that is writable by everyone. You can also specify a shared folder on the file server that was configured by using the IT Security Tool.

Follow these steps to specify a backup folder for license projects:

1. In the license project window, select the Project ID field.
2. From the menu bar, select [File] > [Property].
   The License project property dialog box appears.
3. Click the [...] button next to the Backup folder box.
   The folder selection dialog box appears.
4. Select the drive and folder for the backup.
   In the Comments box, type some comments if required.
5. Click [OK].
   The backup folder for the license project has now been specified.

Switching a display of license project

License Manager can manage multiple license projects. If you want to manage multiple license projects such as CENTUM VP and ProSafe-RS by one License Manager, you can switch the license project to be displayed.

Perform this step to switch the display of license project:

- From the menu bar of License Manager, select [Window], and select the check box of the license project you want to display.
  The selected license project appears in the license project window. If multiple license projects are selected, multiple selected license projects appear.

Deleting a license project

Follow these steps to delete a license project:

1. In the license project window, select the Project ID field.
2. From the menu bar, select [File] > [Delete].
   A dialog box appears to confirm whether you want to delete the license project.
3. Click [Yes].
   The license project is deleted.

2.3 Reading a license

Licenses are read by the license management station. This section describes how to read a license key file from the license medium and register the licenses in the license project.

Reading a license

When reading a license, you need a license medium.

When reading a license for the first time in a newly created license project, project ID written in the license sheet is required.

Follow these steps to read a license:

1. Insert the license media into the drive of the license management station.
2. From the License Manager menu bar, select [License] > [Add licenses].
   The folder selection dialog box appears.
3. Select the drive in which you inserted the license media.
4. Click [OK].
5. Perform one of the following operations:
   - When you read a license for the first time in a newly created license project, a dialog box to verify project ID is displayed. Enter the project ID number mentioned in the license sheet.
   - If a license has already been read in the license project, move to step 6.
6. Click [OK].
   A confirmation dialog box appears to confirm whether you want to save the license project.
7. Click [Yes].
   The license key file is read from the license medium. If you click [No], the read operation is terminated.

When the license key file is read, the Project ID number and package types (license information) displayed in the license project window are updated.

TIP

- If the entered project ID number and the project ID number stored on the license media do not match, an error occurs. Enter the correct project ID number.
- If there is more than one license medium with the same project ID, read the license key file from each license medium.
- Under the folder that you specify by selecting [License] > [Add licenses], you can place only one license key file. If you use license key files by copying them from the license medium to a local disk or somewhere else, you must create a folder to store each individual license key file.

2.4 Defining stations to which licenses need to be assigned

This section describes how to define stations.

On the license management station, you can define each computer and FCS or SCS to which you want to assign licenses, as a license-assigned station. You can also define the license management station itself as a license-assigned station and assign licenses to it.

Note that, if you read Project I/O Licenses on the license management station, a license-assigned station of PJTCOM is automatically defined. And PJTCOM is added to the license project window.

TIP

As an alternative to the manual data entry described in this section, you can also import station configuration and license assignment information from a package list. A package list is a CSV file that describes the configuration of stations and license assignment information for each of the stations.

SEE ALSO

For more information about importing package lists, refer to:

"■ Importing a package list" on page 3-29

For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

■ Defining a license-assigned station

Follow these steps to define a license-assigned station:

1. From the License Manager menu bar, select [File] > [New] > [Station].
   Alternatively, in the station information area in the license project window, right-click and select [Add station].

   The Add station dialog box appears.

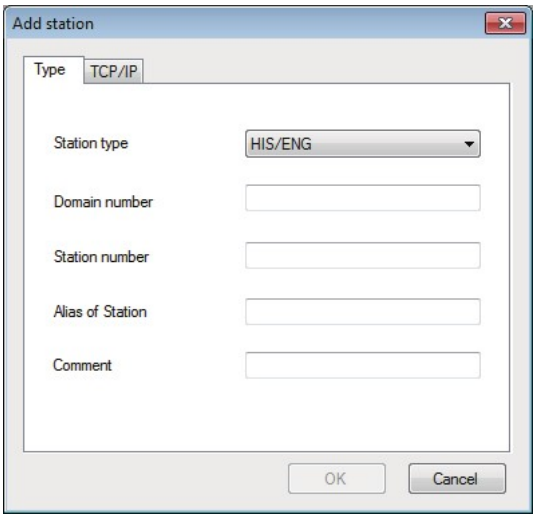

Figure 2.4-1 Add station dialog box

2. In the Type tab, specify station type settings.
   The options are described in the following "Options in the Add station dialog box" section.
3. Click the [TCP/IP] tab.
   In the Host Name box under the Ethernet TCP/IP Settings, the default computer name appears.

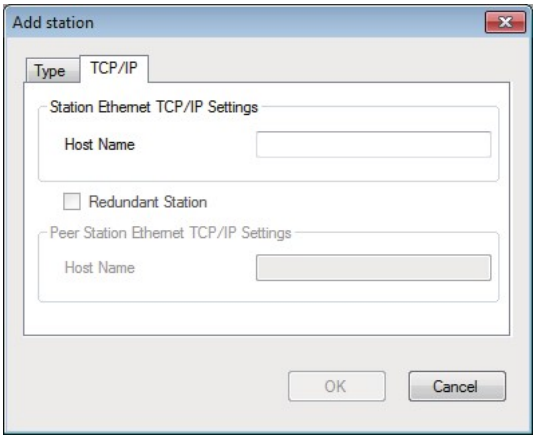

Figure 2.4-2 Add station dialog box

4. Specify a computer name, if required.
   If you select FCS, SCS, or PJTCOM from the Station type drop-down list, you do not need to specify any TCP/IP tab items.
5. Click [OK].
   The defined station is added to the license project window.

TIP

To use a network switchover type UGS, select "UGS" in Station type. To use a computer switchover type UGS, select "UGS2" in Station type. If you select UGS in Station type, the [Redundant Station] check box becomes available. If you select UGS2 in Station type, the [Redundant Station] check box is grayed out and becomes unavailable.

SEE ALSO

For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

For more information about computer switchover type redundancy, refer to:

2.11, "Managing licenses of a computer switchover type UGS" on page 2-20

For more information about network switchover type redundancy, refer to:

2.12, "Managing licenses of a network switchover type redundant UGS" on page 2-22

■ Add station dialog box specifications

The items that you specify in the Type tab of the Add station dialog box are as follows:

- Station type
  Select the station type from the drop-down list. Only the stations that can be defined for the product being managed by the license project appear.
- Domain number
  Specify the domain number of the control bus.

  For stations not connected to the control bus, leave this blank.
- Station number
  Specify the station number of the local station that is connected on the control bus.

  For stations not connected to the control bus, leave this blank.
- Alias of station
  You can enter a station alias of your choice. Enter up to eight single-byte alphanumeric characters. If you specify a station alias, the station alias appears with higher priority than the station name in the component area of the license project window.
- Comment

You can enter a comment of your choice.

When you add a station, an automatic check is performed to check for errors relating to duplications and input range. If there is an error in the specified information, the Station properties error dialog box appears. Check the details of the error and change the specifications.

Station name and computer name default values

Station names are automatically determined based on the station type, domain number, and station number.

The station name format is as follows:

Station type dd (domain number) ss (station number)

Example: HIS0164

The following table shows the CENTUM VP and ProSafe-RS station types, automatically determined station names, and default computer names.

Table 2.4-1 Station names and default computer names in CENTUM VP

Station type	Station name	Default computer name
HIS/ENG	HIS[ddss]	HIS[ddss]
FCS	FCS[ddss]	N/A
SIOS	BCVO[ddss](SIOS)	E[ddss]
GSGW	FCS[ddss](GSGW)	GSGW[ddss]
APCS	FCS[ddss](APCS)	APCS[ddss]
UGS (*1)	BCVU[ddss](UGS) BCVU[ddss](UGS)(Peer) (*2)	E[ddss] E[ddss](Peer) (*2)
UGS2 (*3)	BCVU[ddss](UGS)	E[ddss]
UACS	UACS[ddss]	UACS[ddss]
PC (*4)	STN[ddss] (*5)	None
PJTCOM (*6)	PJTCOM	N/A

*1: Select this station type when using a network switchover type UGS.
*2: This is the second computer for a network switchover type redundant UGS.
*3: Select this station type when using a computer switchover type UGS.
*4: The station type of an AD server that does not coexist with Operation and Monitoring Function and system builders is "PC". The station name is same as the computer name.
*5: If a domain number or station number is not specified, a station name is not automatically determined.
*6: A virtual station assigned with Project I/O Licenses. Only one PJTCOM can be defined in a license project. It is automatically created when you add the license key.

Table 2.4-2 Station names and default computer names in ProSafe-RS

Station type	Station name	Default computer name
HIS/SENG (*1)	HIS[ddss]	HIS[ddss]
SENG	STN[ddss] (*2)	None
SCS	SCS[ddss]	N/A
PC (*3)	None	None
PJTCOM (*4)	PJTCOM	N/A

*1: This is a station defined as HIS on CENTUM VP System View.
*2: If a domain number or station number is not specified, the station name will be the same as the computer name.
*3: The station type of an AD server that does not coexist with SENG is "PC."
*4: A virtual station assigned with Project I/O Licenses. Only one PJTCOM can be defined in a license project. It is automatically created when you add the license key.

When using virtual test functions

When you use virtual test functions, provide either of the following settings on the computer where you run the FCS simulator or the SCS simulator:

- For a computer installed with a control bus interface card or Vnet/IP interface card, define it in the same manner as when you define an HIS, SENG, or other station.
- For a computer not installed with a control bus interface card or Vnet/IP interface card, define it with the station type "PC". You do not need to specify the domain number and station number.

For a computer that runs the UACS simulator, define it in the same manners as when you define a UACS station.

Relationship of License Project and AD Project in ProSafe-RS

In ProSafe-RS R4 or later, all RS projects corresponding to the station (SCS) defined for the license project, must be registered in the same AD project. This relationship is shown in the figure below.

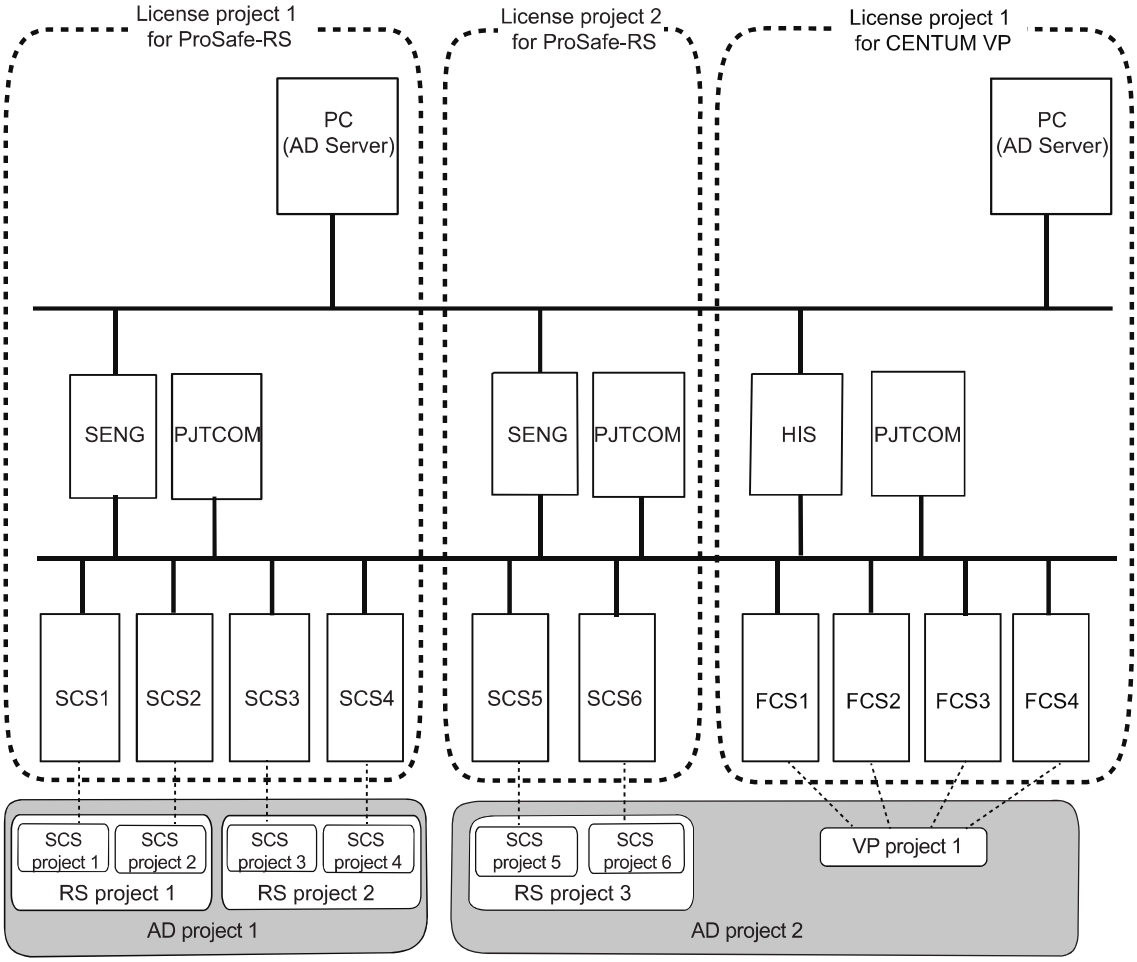

Figure 2.4-3 Relationship of License Project and AD Project in ProSafe-RS

2.5 Assigning licenses to license-assigned stations

Using License Manager on the license management station, you can assign licenses to the stations on which you want to use the software packages.

Even in an environment for virtual testing that does not include any actual stations, licenses are required according to the number of stations defined in the CENTUM VP or ProSafe-RS project.

Assigning licenses

1. In the license project window, select a cell in the assignment area.
2. Type the number of licenses assigned to each station.
   - To assign a license, type 1. If you do not want to assign a license, leave it blank.
   - As for the project I/O license, the quantity of the license is shown in the cell in the assignment area of PJTCOM. Ensure that the quantity that is shown in the cell is the same as the quantity of the project I/O license that is provided.

   The status of stations that have been assigned a license changes to EDIT and the background color of the respective cell changes to yellow.

TIP

If licenses cannot be assigned to a station, you cannot enter the number of licenses in that cell.

SEE ALSO

For more information about status display, refer to:

"■ License project window" on page 1-18

For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

Copying license assignment information

Follow these steps to copy license assignment information from one station to another:

1. In the license project window, click the name of the station from which you want to copy information.
2. From the License Manager menu bar, select [Edit] > [Copy].
   Alternatively, right-click the station name and select [Copy].
3. Select the name of the station to which you want to paste the information.
4. From the menu bar, select [Edit] > [Paste].
   Alternatively, right-click the name of the station and select [Paste].

   The status of the station to which you pasted the license assignment information changes to EDIT and the background color of the relevant cell changes to yellow. If the number of available licenses is exceeded as a result of the [Paste] operation, the status changes to NG. In this case, review the license assignment information.

To cut and paste the license assignment information for a station, select [Cut] instead of [Copy].

2.6 Checking license assignment consistency

Using License Manager, you can perform consistency checks to find errors related to license assignments. For example, you can find errors such as exclusions and dependencies of software packages on stations assigned with licenses.

In the consistency check, all stations that have been assigned licenses are checked.

A consistency check is automatically performed when licenses are distributed, but you can also perform a check at any time.

SEE ALSO For more information about items verified during a consistency check, refer to:

Appendix 1., “Items checked in the license assignment consistency check” on page App.1-1

Checking the consistency of license assignment

To perform a consistency check, from the License Manager menu bar, select [License] > [Check consistency].

The consistency check result appears in the message display area. If an error is detected, the corresponding cell in the assignment area changes to red, modify the assignment to rectify the error.

2.7 Distributing and accepting licenses through a network

This section describes how to distribute assigned licenses from the license management station to a license-assigned station through a network, and how to activate the licenses.

Distributing a license to license-assigned stations through a network

Follow these steps to distribute a license from the license management station to a licenseassigned station through a network:

IMPORTANT

The license-assigned station to which the license is being distributed must be running.

1. From the License Manager menu bar, select [License] > [Distribute licenses].
   A list of the stations that have been assigned a license and have the EDIT status appears in the Distribute licenses dialog box.

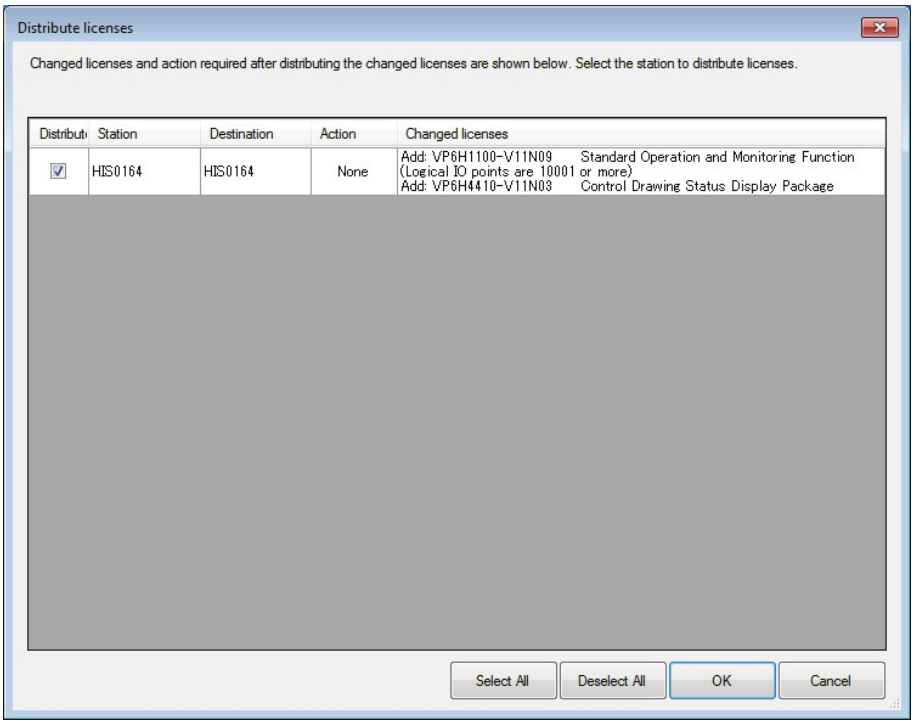

Figure 2.7-1 Distribute licenses dialog box

   In the Distribute licenses dialog box, the Action column indicates the actions required to accept the license assignment changes on the license-assigned station. Changed licenses column indicates the package names of licenses. When distributing licenses for the first time, all licenses are shown in the format: "Add: <Package type>."

2. In the Distribute column, select the check box for the stations to which you want to distribute a license. By default, all stations are selected as distribution destinations.

3. Click [OK].
   License Manager automatically checks the following:

   - Is there consistency in the license assignments for the stations to which licenses need to be distributed?

- Has the number of licenses distributed to the license-assigned stations exceeded the number of licenses of the software package?
- On the license-assigned stations for distribution, are there any errors in the version number, language, station type, and assignment exclusions between products?

4. If there are no errors in the check, a dialog box appears to confirm whether you want to save the license project.
5. Click [Yes].
   The licenses are distributed to the stations targeted for distribution. If you click [No], the distribution operation is terminated.

When distribution of the license to the license-assigned stations is successful, the status of the station is updated from EDIT to AckWait.

TIP After the licenses have been accepted on the distribution destination station, the status of the station changes to OK.

If a warning is generated during the license verification, a warning message appears in the message display area and a confirmation dialog box appears. The license is distributed to the target station after confirmation is received.

If the operation to send the license information fails, and an error occurs during the license verification, distribution of the license to the destination stations is suspended and an error message appears in the message display area. Remove the cause of the error and distribute the license again. If you selected multiple stations, you need to distribute licenses to all destinations. If distribution to any station fails, the entire distribution operation fails.

Distributing FCS or SCS licenses

FCS or SCS licenses are viewed when generating and downloading the system builders. For this reason, distribute FCS/SCS licenses as follows:

- For FCS

  The distribution destination for FCS licenses is stations assigned with a Standard Engineering Function license, not the actual FCS.

TIP All stations that are assigned with a Standard Engineering Function license must be connected to the network. If the stations cannot be connected to the network at the time, distribute the licenses to all the stations that are assigned with a Standard Engineering Function license through an external storage medium.

- For SCS

  The distribution destination for SCS licenses is the stations assigned with SENG, not the actual SCS.

TIP All SENGs must be connected to the network. When temporarily the stations cannot be connected to the network, distribute the licenses to all SENGs via an external storage medium.

If multiple stations appear in the distribution destination, the status of the FCS or SCS station changes to OK once a license is assigned to at least one station.

Distributing Licenses to PJTCOM

- For CENTUM VP R6
  The licenses are distributed to the station to which the license for the basic engineering functions is assigned.
- For ProSafe-RS R4
  The licenses are distributed to the SENG.

SEE ALSO For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

■ Accepting a license and activating a software package on a license-assigned station

After the license management target product is installed, the licenses initially distributed through the network are accepted automatically. After the licenses have been accepted, the status of the license-assigned station changes to OK.

The software package is activated on stations to which licenses have been distributed. You do not need to perform any procedures using License Manager on the license-assigned stations. When you start License Manager on a license-assigned station, the assignment status for the local station appears and you can confirm the license status in the station information area.

TIP When distributing licenses to a license-assigned station two or more times, you need to accept the licenses on the license-assigned station. The software packages are activated when you restart the station after accepting the licenses.

2.8 Distributing and accepting licenses using external storage media

You can use external storage media to distribute licenses to a station that cannot communicate with the license management station, and activate software packages.

To distribute licenses using external storage media, first save the "license file" generated by License Manager on the license management station to an external storage medium. When this license file is read by the license-assigned station, the software package becomes available on that station.

IMPORTANT

It is recommended that you use an unused CD-R for the external storage media to avoid virus infection.

License files

A license file is a file that stores licenses assigned to stations. A license file is generated for each station.

Distributing licenses by using external storage media

To distribute licenses using external storage media, first generate the license file using License Manager on the license management station.

Follow these steps to create license files:

1. From the License Manager menu bar, select [License] > [External storage media] > [Distribute licenses].
   The stations that have been assigned licenses and have the EDIT status appear in the distribute licenses using external storage media dialog box.
2. In the Distribute column, select the check box for the stations to which you want to distribute a license.
3. Click [OK].
   A license assignment consistency check is performed for the stations to which licenses need to be distributed. If the consistency check does not return any errors, a dialog box appears to confirm whether you want to save the license project.
4. Click [Yes].
   A dialog box appears to specify a folder. If you click [No], the license file is not generated.
5. Specify the folder to which you want to save the license files.
6. Click [OK].
   In the folder that you specified for generating the license file, a folder with a different ID is created for each station, and the license file is exported. When the license file is saved, the status of the station is updated from EDIT to OK.

If a consistency error occurs, the process of saving the license file to destination stations is terminated, and an error message appears in the message display area. Remove the cause of the error and distribute the license again.

License file names, paths, and validity durations

The names, paths, and validity durations for license files are as follows:

- License file names and paths
  `[user-specified_folder]\[station_ID]\[project_name]. [station_name].lf`

Example: F:\PC001\MYPJT.PC001.lf

- License file validity durations
  The validity duration for license files is three days. Ensure that you load a license file onto the license-assigned station within three days after the file is created. If the validity duration has expired, you will not be able to load the file.

TIP

If you are unable to load the license file because the validity duration has expired, or if you lose the license file, use the Distribute Master licenses function to redistribute the license.

Activating a software package using external storage media

A license distributed using external storage media needs to be read by the license-assigned station and the software package needs to be activated. The procedure for activating a software package is as follows.

Store the license file generated on the license management station on external storage media.

IMPORTANT

On the license-assigned station, stop the antivirus software, and applications of products that you started and for which you want to accept licenses.

1. Log on to the license-assigned station as a user with maintenance privileges.
2. Insert the external storage media containing the license file into the drive.
3. Start License Manager.
   License Manager window appears.
4. From the menu bar, select [License] > [External storage media] > [Accept licenses].
   The folder selection dialog box appears.
5. From the external storage media drive, select the folder containing the license file.
6. Click [OK].
   If the license file has not expired or if there are no errors in the license file, the Accept licenses dialog box appears.
7. Click [OK].
   The license file is read and the software package is activated. In addition, the license project window is updated and you can check the assignment status for the local station.

TIP

If the version of the license to be distributed and the version of the software in the destination station does not match, the license cannot be accepted.

2.9 Monitoring the status of assigned licenses

You can perform the following license monitoring using License Manager on the license management station and license-assigned stations:

- License management station
  Monitor the status of assigned licenses in the entire license project.
- License-assigned stations
  Monitor the status of assigned licenses to the local station.

■ Monitoring the status of assigned licenses

From the License Manager menu bar on the license management station, select [View] > [Monitoring mode].

As soon as you switch to Monitoring mode, the status of assigned licenses appears for stations to which licenses have been distributed.

If you want to retrieve the most current assignment status from each station, on the menu bar, select [View] > [Refresh].

TIP

Stations in the license project, to which a license has not been distributed are not displayed.

On license-assigned stations, the status of assigned licenses for the local station appears as soon as License Manager starts.

SEE ALSO

For more information about status display, refer to:

"■ License project window" on page 1-18

● Monitoring the status of assigned licenses in the task tray

You can monitor the status of assigned licenses by viewing the icons displayed in the task tray.

SEE ALSO

For more information about the icons displayed in the task tray, refer to:

"■ Displaying the status of assigned licenses in the task tray" on page App.2-1

■ Notifying of alarms

When an abnormal license assignment status is detected, system alarms are generated and you can confirm the messages.

On stations that do not receive system alarm messages, a dialog box appears, notifying you to confirm them.

SEE ALSO

For more information about alarms, refer to:

Appendix 3., "Messages" on page App.3-1

2.10 Saving license projects

You can save station definitions and license assignments that you have been editing before distributing licenses. This data is saved as “work-in-progress” data in the license project. To save a license project, from the License Manager menu bar, select [File] > [Save].

When you open License Manager the next time, you can choose to either open the "work-in-progress" data, or open the (master) data for which licenses have been distributed.

2.11 Managing licenses of a computer switchover type UGS

To manage the licenses of a computer switchover type UGS, you must assign a station name for computer switchover type UGS to the target UGS. License Manager recognizes a pair of UGSs that make up a computer switchover type redundant UGS as one station. You must assign licenses for redundancy to that station.

TIP

When you use a computer switchover type redundant UGS, licenses for redundancy are required. When you use a computer switchover type UGS in a non-redundant configuration, only the license for Unified Gateway Station (UGS2) Standard Function is required.

■ Defining a computer switchover type UGS

Follow these steps to define a computer switchover type UGS:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [File] > [New] > [Station].
   The Add station dialog box appears.
3. In the Station Type drop-down list of the Type tab, select "UGS2" and specify the following items:
   - Domain number
   - Station number

TIP

You can type a station alias and comments of your choice.

4. In the Station Ethernet TCP/IP Settings section of the TCP/IP tab, type the name of the first computer.
5. Click [OK].
   The defined UGS is added to the license project window as one station.

■ Assigning licenses to a computer switchover type UGS

Assign licenses for a computer switchover type UGS.

SEE ALSO

For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

■ Distributing licenses to a computer switchover type UGS

You can distribute licenses in the same manner as other cases.

SEE ALSO

For more information about distributing licenses through a network, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

■ Accepting licenses on a computer switchover type UGS

For a computer switchover type redundant UGS, accept licenses only on the active UGS.

For a non-redundant computer switchover type UGS, you can accept licenses in the same manner as other cases.

SEE ALSO For more information about accepting licenses, refer to:

"■ Accepting a license and activating a software package on a license-assigned station" on page 2-15

2.12 Managing licenses of a network switchover type redundant UGS

If you make individual stations redundant, you need to assign licenses to each redundant station and then distribute and accept them.

TIP You cannot make an existing station redundant by changing the station properties. To change an existing station to a redundant station, you must delete the existing station first, and then define a new redundant station.

■ Defining a network switchover type redundant UGS

Follow these steps to define a network switchover type redundant UGS:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [File] > [New] > [Station].
   The Add station dialog box appears.
3. In the Station type drop-down list of the Type tab, select a station and specify the following items:
   - Domain number
   - Station number

TIP You can type a station alias and comments of your choice.

4. In the Station Ethernet TCP/IP Settings section of the TCP/IP tab, type the name of the first computer.
5. Select the Redundant Station check box.
   The Peer Ethernet TCP/IP Settings section becomes available.
6. In the Peer Ethernet TCP/IP Settings section, type the name of the second computer.
7. Click [OK].
   Two columns showing the network switchover type redundant UGS are added to the license project window. If there is an error in the information specified, the Station properties error dialog box appears. Change the information according to the error details.

■ Assigning licenses to a network switchover type redundant UGS

When assigning licenses to a network switchover type redundant UGS, ensure that the assignment information is the same on both stations

SEE ALSO For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

■ Distributing licenses to a network switchover type redundant UGS

To distribute licenses to a network switchover type redundant UGS, select both stations and distribute licenses at the same time. You cannot distribute licenses to one station only.

SEE ALSO For more information about distributing licenses through a network, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

Accepting licenses on a network switchover type redundant UGS

For a network switchover type redundant UGS, accept licenses on both stations.

SEE ALSO For more information about accepting licenses, refer to:

"■ Accepting a license and activating a software package on a license-assigned station" on page 2-15

3. Maintaining license projects

This section describes how to maintain license projects.

3.1 Reading additional licenses on a license management station

The procedure for reading additional purchased licenses on a license management station is the same as that for reading new licenses.

SEE ALSO For more information about reading licenses, refer to:

"■ Reading a license" on page 2-6

3.2 Modifying licenses

This section describes how to modify license assignments within the same license project, and how to distribute and accept licenses after changing the assignments.

The following figure shows the workflow of assigning licenses of the software packages that are required by a station.

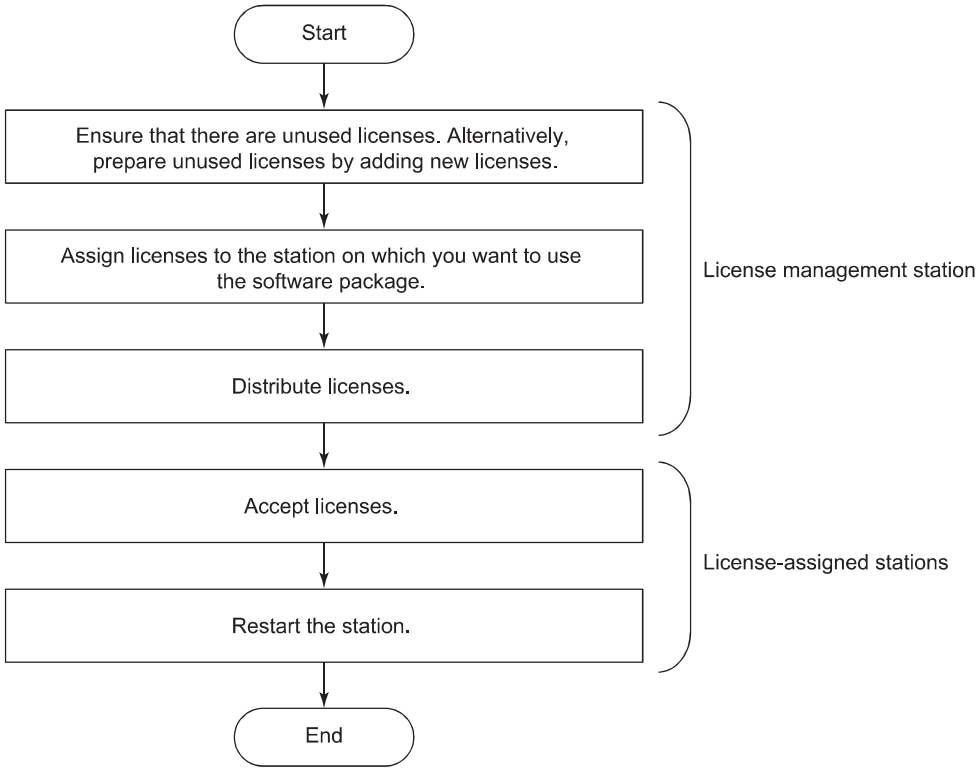

Figure 3.2-1 Assigning software package licenses to a station

The following figure shows the workflow of deleting licenses of a software packages that are no longer required from a station.

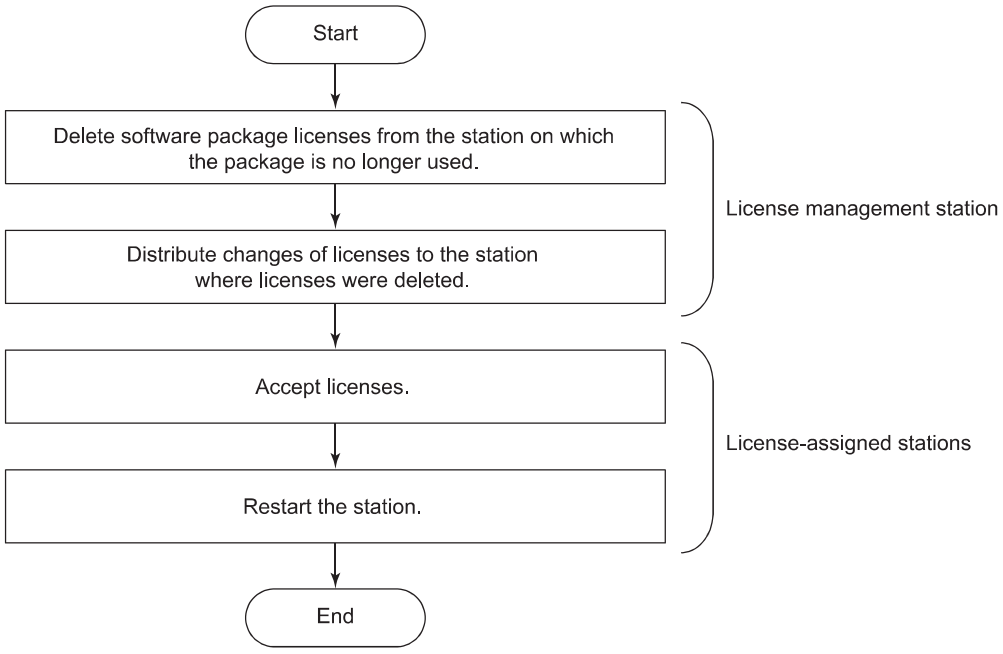

Figure 3.2-2 Deleting software package licenses from a station

The following figure shows the workflow of moving the license of a software package that is no longer used on a certain station to another station.

Example:

Moving a license from HIS0163 to HIS0162

HIS0163: Station from which a software package license is deleted.

HIS0162: Station to which the software package license is assigned.

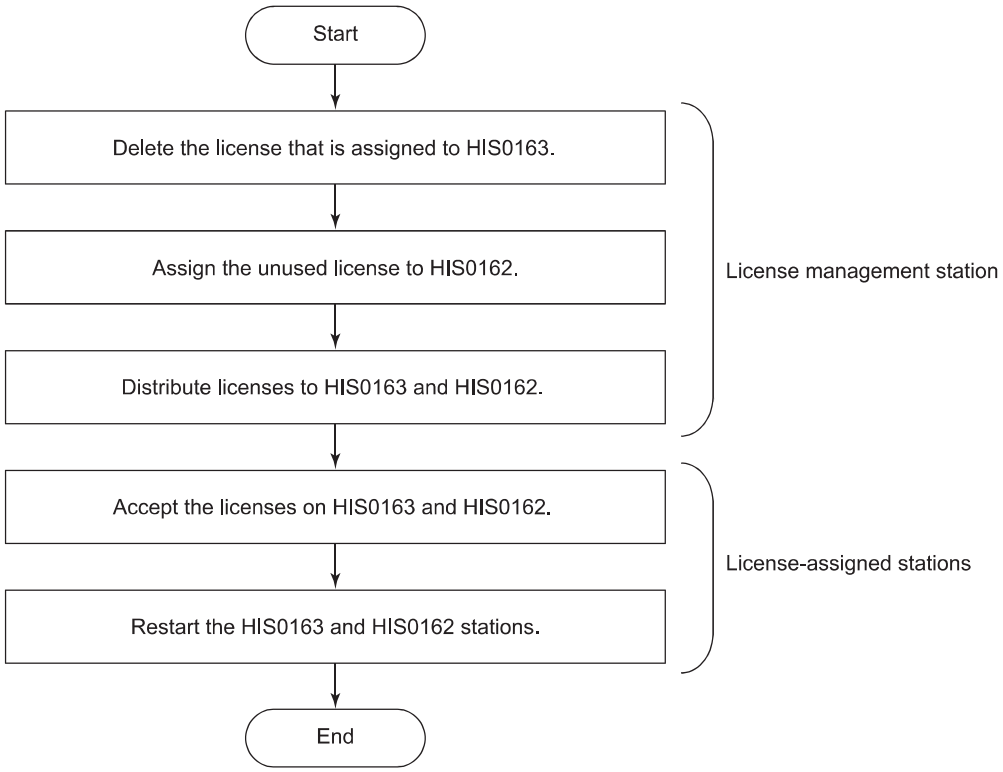

Figure 3.2-3 Moving a software package license between stations

3.2.1 Modifying license assignments

You can add or delete licenses on a license-assigned station by using License Manager on the license management station.

■ Adding a license to a license-assigned station

Follow these steps to add a license to a license-assigned station:

1. On the license management station, start License Manager in Editing mode.
2. Select the cell corresponding to the software package that you want to add to the licenseassigned station, and enter 1.
   - As for the project I/O license, the quantity of the license is added in the cell in the assignment area of PJTCOM. Ensure that the quantity that is shown in the cell is the same as the quantity of the project I/O license that is provided.

   The background color of the cell changes to yellow and the status of the station to which the license has been added changes to EDIT.
3. From the license management station, distribute the license to the station to which the license has been added.
4. On the license-assigned station, start License Manager and accept the license changes. The software package is activated.

TIP

- Status after distribution: AckWait; Background color after distribution: Yellow
- Status after acceptance: OK; Background color after acceptance: No background color

SEE ALSO

For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

For more information about distributing licenses, refer to:

3.2.2, "Distributing modified licenses" on page 3-7

For more information about accepting licenses, refer to:

3.2.3, "Accepting modified licenses" on page 3-9

■ Deleting a license from a license-assigned station

Follow these steps to delete a license from a license-assigned station:

1. On the license management station, start License Manager in Editing mode.
2. Select the cell corresponding to the software package that you want to delete from the license-assigned station. On the keyboard, press the [Delete] key.
   The cell becomes empty and its background color changes to yellow. The status of the station from which the license has been deleted changes to EDIT.
3. From the license management station, distribute licenses to the station from which the license has been deleted.
4. On the license-assigned station, start License Manager and accept the license changes. The software package is deactivated.

TIP

- Status after distribution: AckWait; Background color after distribution: Yellow
- Status after acceptance: OK; Background color after acceptance: No background color

SEE ALSO

For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

For more information about distributing licenses, refer to:

3.2.2, "Distributing modified licenses" on page 3-7

For more information about accepting licenses, refer to:

3.2.3, "Accepting modified licenses" on page 3-9

3.2.2 Distributing modified licenses

When license assignments are changed on the license management station, you need to distribute the affected licenses from the license management station to the license-assigned stations.

The procedure for distributing licenses is different depending on whether the station is connected to a network.

■ Distributing licenses with assignment changes through a network

The procedure for distributing licenses with assignment changes through a network is the same as that for distributing new licenses.

While distributing licenses, stations whose status has been changed to EDIT as a result of the license assignment being changed (added or deleted) for that station, appear in the Distribute licenses dialog box.

In the Distribute licenses dialog box, the Action column indicates the action(s) required to accept the distributed licenses on the license-assigned station. The Changed licenses column indicates the names of packages with license assignment changes.

- Added licenses: "Add: <package type>"
- Deleted licenses: "Del: <package type>"

Select the Distribute check box for stations to which you want to distribute a license and click [OK].

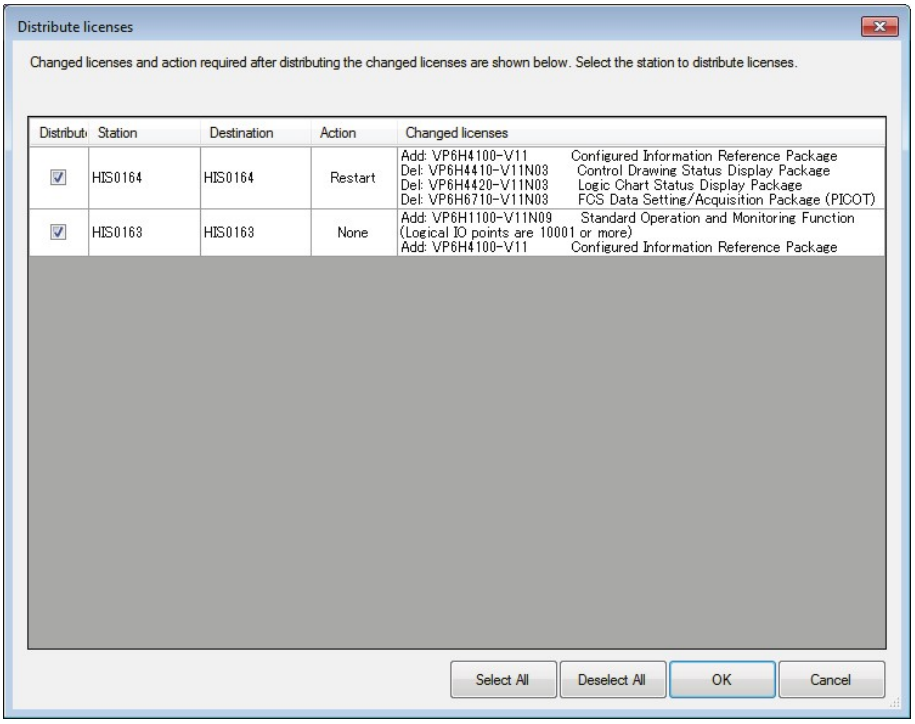

Figure 3.2.2-1 Distribute licenses dialog box

After licenses have been successfully distributed to the license-assigned stations, the status of the station changes from EDIT to AckWait.

SEE ALSO For more information about distributing licenses to license-assigned stations through a network, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

Distributing licenses with assignment changes using external storage media

The procedure for distributing licenses with assignment changes to the stations that are not connected to the network is the same as that for distributing new licenses.

SEE ALSO For more information about distributing license by using external storage media, refer to:

"■ Distributing licenses by using external storage media" on page 2-16

3.2.3 Accepting modified licenses

This section describes the procedure for activating and deactivating software packages with license changes. To accept licenses that have been distributed to the license-assigned stations, you need to replace the existing license file with the new license file on the respective stations. You must restart the stations after accepting the modified licenses. The software packages are either activated or deactivated based on the license changes.

The procedure for accepting licenses is different depending on whether the station is connected to a network.

Accepting licenses with assignment changes through a network

Follow these steps to accept modified licenses on license-assigned stations that have received licenses through a network:

IMPORTANT

On the license-assigned station, stop the antivirus software, and applications of products that you started and for which you want to accept licenses.

1. Log on to the license-assigned station as a user with maintenance privileges.
2. Start License Manager.
   License Manager appears and the assignment status of the local station appears in the license project window. In the summary information area, confirm that the status of the station is AckWait and there are licenses that are waiting to be accepted.
3. From the menu bar, select [License] > [Accept licenses].
   The modified licenses and the actions required after acceptance appear in the Accept licenses dialog box.

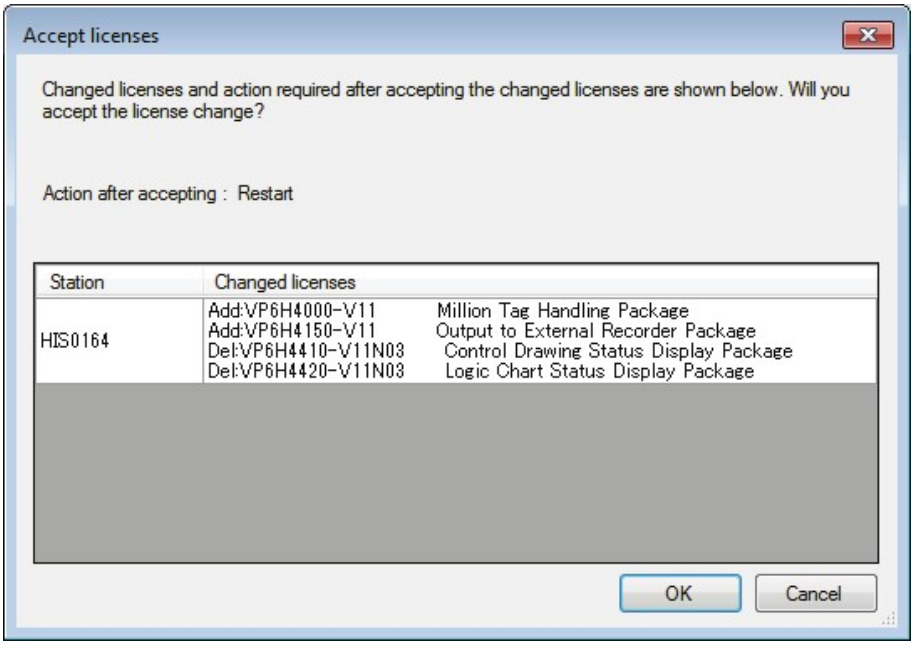

Figure 3.2.3-1 Accept licenses dialog box

4. Click [OK].
   A dialog box appears, asking you to confirm whether the applications of the product whose license you are accepting have been closed.
5. If the applications are not running, click [Yes].

If the applications are still running, click [No]. The license acceptance operation is terminated.

6. When there is a need to restart the station after accepting licenses, a dialog box appears, asking whether you want to continue with accepting licenses.
7. Click [Yes]. The acceptance operation starts.
   After the acceptance operation is completed, the station restarts automatically and the software packages are either activated or deactivated based on the license changes.

TIP

When you accept a license on a license-assigned station, the status of the corresponding station changes from AckWait to OK in License Manager on the license management station.

■ Accepting licenses with assignment changes using external storage media

When you distribute licenses using external storage media, the license-assigned station reads the modified licenses and activates or deactivates the software package. You can accept modified licenses using external storage media in the same way as you activate a license using external storage media. When you restart the stations after accepting licenses, software packages are either activated or deactivated based on the modified licenses.

When you delete previously distributed licenses, a returned license file is created on the license-assigned station. A returned license file is a file that stores information confirming that a license that was distributed using external storage media has been deleted and is no longer in use. A dialog box appears, asking you to specify the location where you want to save the returned license file.

SEE ALSO

For more information about accepting licenses by using external storage media, refer to:

"■ Activating a software package using external storage media" on page 2-17

3.2.4 Returning licenses using external storage media

On a license-assigned station, if a previously distributed license is deleted when you accept license modifications using external storage media, a returned license file is generated. When the returned license file is read by the license management station, it is considered as an unused license and can be assigned to another station.

The license management station shows the RtnWait status when licenses are to be deleted and are waiting to be returned from a license-assigned station using external storage media. Therefore, you need to return the licenses promptly.

SEE ALSO For more information about status display, refer to:

"■ License project window" on page 1-18

■ Format for the generated returned license file

The file name of the returned license file and the path to which it is exported is as follows:

`[user-specified_folder]\[station_ID]\[project_name].[station_name].rlf`

Example: F:\HIS0164\MYPJT.HIS0164.rlf

■ Returning licenses using external storage media

Follow these steps to read a returned license file on the license management station:

1. Go to the returned license file that was generated by the license-assigned station when accepting the license, and copy the returned license file to an external storage medium.
2. Insert the external storage media into the drive of the license management station.
3. On the license management station, start License Manager in Editing mode.
4. From the menu bar, select [License] > [External storage media] > [Return licenses].
   The folder selection dialog box appears.
5. Select the returned license file from the external storage medium.
6. Click [OK].
   When the returned license file is read, the status of the corresponding station changes from RtnWait to OK, and the number of unused licenses increases. The procedure for returning the license is completed.

● Regenerating another returned license file

If you cannot find the returned license file, you can generate it again as follows:

1. Start License Manager on the license-assigned station where you previously generated the returned license file.
2. From the menu bar, select [License] > [External storage media] > [Output returned licenses].
   A dialog box appears asking you to select the location for generating the returned license file.
3. Select the location where you want to save the returned license file.
4. Click [OK].
   The returned license file is generated in the specified folder.

3.3 Adding and deleting license-assigned stations

You can add stations to a license project in order to manage the licenses of a station, and delete unnecessary stations from a license project.

If the properties of a station that has been distributed with licenses are changed, you must change the properties of that station to ensure that licenses on that station remain manageable. This can be done by using License Manager on the license management station.

■ Adding a license-assigned station

In License Manager on the license management station, define the station that you are adding as a license-assigned station. The procedure for adding a license-assigned station is the same as that for defining a new license-assigned station.

SEE ALSO For more information about defining a license-assigned station, refer to:

"■ Defining a license-assigned station" on page 2-7

■ Deleting an unnecessary license-assigned station

IMPORTANT

- To delete a station from a license project, first delete the licenses that are assigned to that station. You can delete a station even if the status is EDIT. However, when deleting an FCS or SCS station from a license project, first delete the assignments, distribute and accept the licenses, and check that the status is OK before deleting the station. You cannot delete the station if the status is EDIT or AckWait.
- If you delete a license-assigned station that is running, the licenses on that station become deactivated. When you restart the license-assigned station, the station is removed from the license management targets and no licenses are assigned. Use discretion when deleting a station.

Follow these steps to delete a license-assigned station:

1. On the license management station, start License Manager in Editing mode.
2. Delete the license assignments for the station that you want to delete.
3. In the license project window, click the station name.
4. From the menu bar, select [File] > [Delete].
   Alternatively, right-click the station name and select [Delete station].

   The Delete Station dialog box appears.
5. Click [Yes].
   The column of the deleted station is removed from the license project window.
6. From the menu bar, select [File] > [Save].
   The station is deleted.

● Deleting redundant stations

To delete redundant stations that are no longer required, first delete the licenses that are assigned to both stations.

Then, select the name of either of the stations and delete it. This deletes both stations at the same time from the license project.

Changing the properties of a station

Follow these steps to change the properties of a station:

1. On the license management station, start License Manager in Editing mode.
2. In the license project window, click the station name.
3. From the menu bar, select [File] > [Properties].
   Alternatively, right-click the station name and select [Station property].

   The Station property dialog box appears.
4. Enter the data for the properties that you want to change and click [OK].
   The station properties are changed and the status changes to EDIT.

TIP

If you only change the alias of the station and comments, the station status remains the same.

5. From the menu bar, select [File] > [Save].
   The properties are changed.

Station properties

The station properties are listed as follows:

TIP

If you want to change properties listed as View only, delete the station, and add a new station.

Table 3.3-1 List of station properties

Property	Attributes
Station type	View only
Domain number	View only
Station number	View only
Comment	Modifiable
Station alias	Modifiable
Host name	Modifiable
Redundant station	View only
Peer host name	Modifiable

3.4 Redistributing licenses to license-assigned stations

You can use the Distribute master license function to redistribute licenses that were last distributed from the license management station to license-assigned stations. If a license-assigned station fails, you can replicate the license assignments for the failed station by distributing the master license to the replacement computer where the license management target product is installed.

Master license

A master license is a license that was last distributed to a specified station by the user. A master license file is a file that contains a master license, and the content is different for each station.

The file format of master license files is the same as that of license files.

SEE ALSO For more information about license files, refer to:

2.8, “Distributing and accepting licenses using external storage media” on page 2-16

Redistributing a license to redundant stations

If you specify one redundant station as the destination for master license distribution, the most recently distributed license will be redistributed to the specified redundant station only. You do not need to distribute licenses to both stations at the same time.

3.4.1 Distributing and accepting master licenses through a network

This section describes how to distribute and accept master licenses on stations connected to a network.

■ Distributing and accepting master licenses through a network

Follow these steps to distribute and accept master licenses through a network:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [License] > [Distribute master licenses].
   In the Distribute Master licenses dialog box, all stations that have been previously distributed with licenses appear.

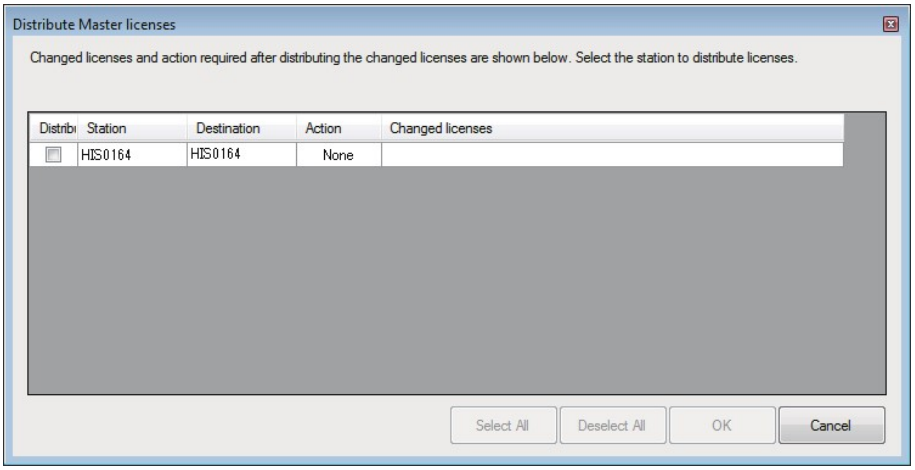

Figure 3.4.1-1 Distribute Master licenses dialog box

3. Select the Distribute check box for the stations to which you want to distribute a master license.
4. Click [OK].
   The master license is distributed to the license-assigned station.

When the master license distribution is completed, the software packages to which licenses were distributed are activated in stations that have None in the Action column.

SEE ALSO

For more information about preliminary checking of license information, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

For more information about Accepting licenses through a network, refer to:

"■ Accepting licenses with assignment changes through a network" on page 3-9

3.4.2 Distributing and accepting master licenses using external storage media

This section describes how to distribute and accept master licenses on stations not connected to a network, by using external storage media.

■ Distributing and accepting master licenses for stations not connected to a network using an external storage media

Follow these steps to distribute and accept master licenses for stations not connected to a network, by using external media:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [License] > [External storage media] > [Distribute master licenses].
   All stations that have been previously distributed with licenses appear in the dialog box.
3. Select the Distribute check box for the stations to which you want to distribute a license.
4. Click [OK].
   A dialog box appears to specify a folder.
5. Specify the folder to which you want to save the master license.
6. Click [OK].
   In the folder that you specified for saving the license file, a folder is created for each station that has been distributed with the master license. The license files are saved to these folders.
7. Copy the license file to an external storage medium.

IMPORTANT

To avoid virus infections, it is recommended that you copy licenses into an unused CD-R.

On the license-assigned station, load the license file that is stored on the external storage medium and accept the master licenses.

SEE ALSO For more information about accepting master licenses using external storage media, refer to:

"■ Activating a software package using external storage media" on page 2-17

3.5 Increasing the software package capacity

If you need to increase the number of I/O that can be handled by FCS or SCS, add a Project I/O License.

If you need to increase the number of I/O points that can be handled by Operation and Monitoring Function and Basic Engineering Function, add a Project I/O License for expansion.

TIP

For example, use an upgrade installation license when you increase the number of Field Control Stations that can be handled by Operation and Monitoring Function and Standard Builder Function in CENTUM VP R5.

An upgrade installation license is loaded into License Manager on the license management station, merged with a new installation license, and then distributed to a license-assigned station. An upgrade installation license cannot be distributed independently. It can be distributed as an expanded new installation license after merging it with a new installation license.

This section describes the procedures for increasing the capacity of a software package by merging a new installation license with an upgrade installation license.

IMPORTANT

Licenses cannot be divided after they have been merged. Perform merging licenses very carefully.

Increasing the software package capacity

Follow these steps to increase the capacity of a software package:

1. On the license management station, start License Manager in Editing mode.
2. Read the upgrade installation licenses on the license management station.
3. Assign the new installation licenses and upgrade installation licenses to the same station.
4. From the menu bar, select [License] > [Merge licenses].
   A dialog box appears, asking you to confirm the packages for upgrading.
5. Click [Yes].
   The new installation licenses and upgrade installation licenses are merged. You can check the merged licenses by viewing the package type.

Before merging

Project ID	XXXXXXX1			Component		PJTCOM	HIS0164
Edit : 2	Edit(NG) : 0			Comment			
AckWait : 0	RtnWait : 0			Domain			1
Expired : 0	DueToExpire : 0			Status	Station		64
Package type	Package name	Expiry	Qty	Unused		Edit	Edit
-- [PJTCOM] --	---	---	---	---		---	---
VP6F3100-V11	Project I/O License		100	0		100	
-- [HIS] --	---	---	---	---		---	---
VP6H1100-E11N59	Standard Operation and Monitoring...		1	0			1
VP6H1100-V11N05	Standard Operation and Monitoring...		3	2			1
VP6H1120-V11	Console HIS Support Package for ...		3	3			

After merging

Project ID	XXXXXXX1			Component		PJTCOM	HIS0164
Edit : 2	Edit(NG) : 0			Comment			
AckWait : 0	RtnWait : 0			Domain			1
Expired : 0	DueToExpire : 0			Status	Station		64

VP6H1100-V11N09	Standard Operation and Monitoring...		1	0			1
VP6H1120-V11	Console HIS Support Package for ...		3	3			

Making VP6H1100-V11N09 by merging VP6H1100-V11N05 with VP6H1100-E11N59

Figure 3.5-1 Merging new installation licenses with upgrade installation licenses

6. Distribute the expanded license to license-assigned stations, and then accept them on the license-assigned stations.

TIP

If there are multiple licenses that can be merged, you can merge them as one group in a single merge operation.

SEE ALSO

For more information about reading licenses, refer to:

"■ Reading a license" on page 2-6

For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

For more information about distributing licenses through a network, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

For more information about accepting licenses through a network, refer to:

"■ Accepting licenses with assignment changes through a network" on page 3-9

3.6 Backing up and restoring a license project

If a license management station fails, you can set up a new license management station by restoring the backed up license project in another station, or on a computer where License Manager alone is installed.

This section describes the procedures for backing up a license project manually and restoring it.

■ Manually backing up a license project

Follow these steps to back up a license project manually:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [Tools] > [Backup].
   The license project is backed up.

SEE ALSO For more information about specifying the backup folder for the license project, refer to:

"■ Specifying a backup folder" on page 2-4

■ Restoring a license project on another license management station

For this procedure, you will need the license media that contains the purchased license key file.

Follow these steps to restore a license project on another license management station:

1. On the station to which you want to restore the license project, start License Manager in Editing mode.
2. From the menu bar, select [Tools] > [Restore].
   The folder selection dialog box appears.
3. Select the folder that stores the backup of the license project that you want to restore, and click [OK].

TIP If a license project with the same name already exists, the restore process is terminated.

The Restore license project dialog box appears, displaying a list of license key files required for the restoration.

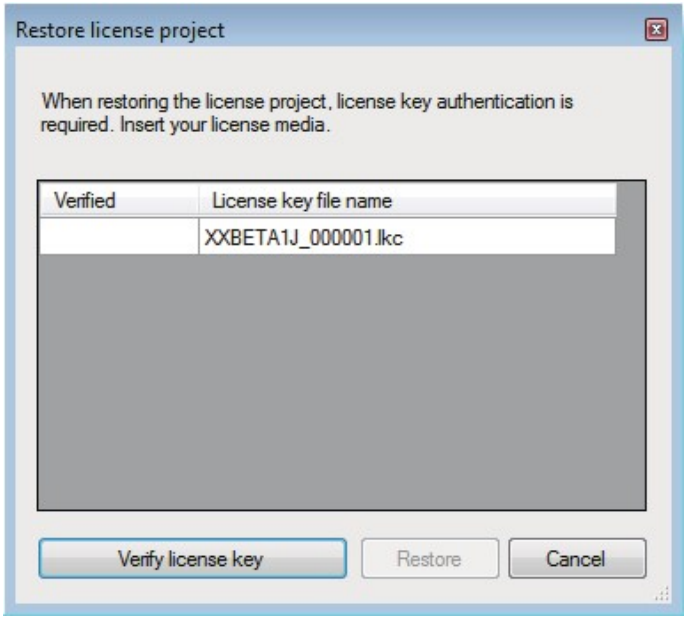

Figure 3.6-1 Restore license project dialog box

4. Insert any one of the license media in which the license key file to verify is stored, and click [Verify license key].
   The folder selection dialog box appears.
5. Select the drive for the external storage media and click [OK].
   On the Verified column in the Restore license project dialog box, the check box of the selected license key file is selected.
6. When the Verified check box is selected, in the Restore license project dialog box, click [Restore].
   The license project is restored, and a new license project window appears in License Manager.

TIP

After you have restored the license projects on the new license management station, use the Distribute master licenses function to distribute master licenses to license-assigned stations through the network. This enables you to monitor the license assignment status.

3.7 Moving licenses to other projects

This section describes the procedure for moving licenses to other license projects.

For example, if an optional software package is no longer needed in one license project, you can move the license for that software package to a different license project and assign it to an HIS or SENG that is managed by that license project.

After loading the migration license key file on License Manager, delete the license from the license project from which it has been moved. This is to allow the license to be moved to a different license project.

Next, you need to create a license key file for the destination license project, and load it in the license project.

Migration license key files

To move licenses to other license projects, you will need a separate license medium for storing the migration license key file. Contact YOKOGAWA to request the license medium. The migration license key file contains the following information:

- Project IDs of the source license project and the destination license project
- The package type and version information of the license that you want to move
- Number of licenses being moved

Procedure for moving licenses to other license projects

The following figure illustrates the procedure for moving licenses to another license project.

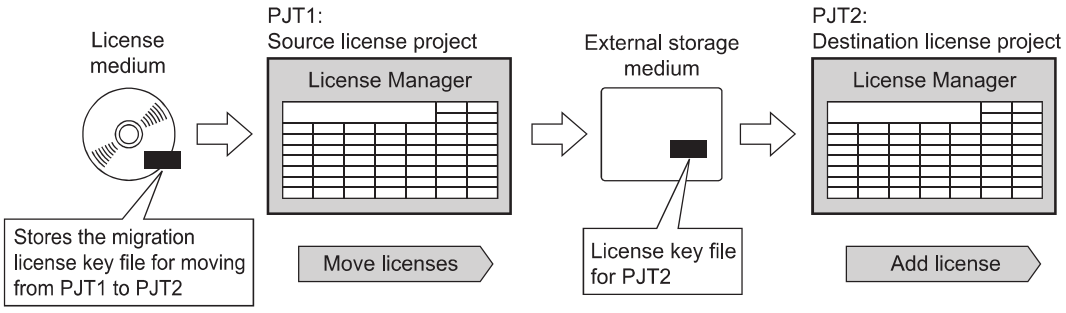

Figure 3.7-1 Moving licenses to another license project

The following flowchart illustrates the workflow for moving licenses to another license project.

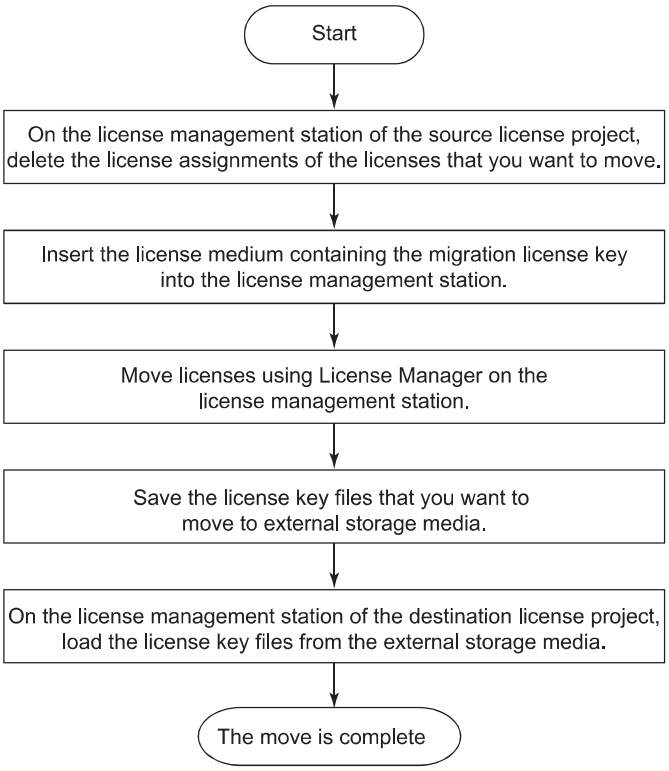

Figure 3.7-2 Workflow for moving a license

Moving licenses to another license project

Follow these steps to move a license to another license project:

1. On the license management station of the source license project containing the licenses you want to move, start License Manager in Editing mode.
2. Ensure that the licenses are released from all the stations by deleting the assignments of the licenses that you want to move. You can do this in the same way you modified license assignments.
3. On the license management station, insert the license medium containing the migration license key into the media drive.
4. From the menu bar, select [License] > [Move licenses].
   The folder selection dialog box appears.
5. Select the migration license key file and click [Open].
   A dialog box appears to confirm whether you want to move the license.

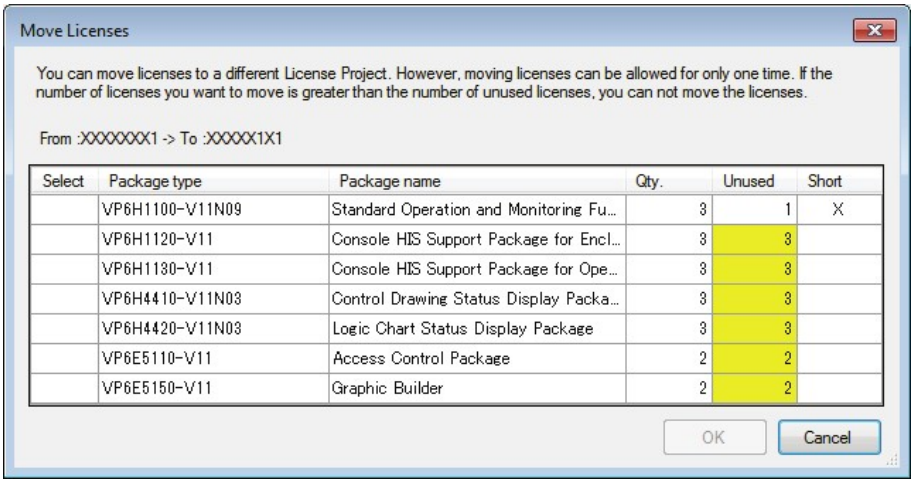

Figure 3.7-3 Confirmation of License move dialog box

6. Check the package type and number of licenses for the license that you are moving and click [OK].
   A dialog box appears, asking you to specify the location for saving the license key files that you want to move.

TIP

- If the number of unused licenses is less than the number of licenses to be moved, you will not be able to click OK. In this case, the corresponding Short column is selected.
- If the number of unused licenses is more than the number of licenses to be moved, you can select the license that you want to move.

7. Specify the location for saving the license key files to be moved.
8. Click [OK].
   The license key files for the destination are created in the specified folder.
9. Save the created license key files on an external storage media.
10. On the destination license management station, start License Manager.
11. Read the licenses in the same way as when adding a license.
    The licenses are successfully moved to another project.

IMPORTANT

When you restore a license project, specific license key files are required. So, you must keep the following license medium and license key files:

- License medium that stores the migration license key file
- License key files moved to the destination project that were created on the license management station of the source project

The file names of the license key files are as follows:

- Migration license key file: <SrcProjectID>_<SerialID>.lkc
- License key files moved to the destination project: <ProjectID>_<SerialID>.lkc

ProjectID: Project ID of the destination project

ProjectID: Project ID of the source project

SerialID: ID that is assigned when the license key is issued

SEE ALSO For more information about reading licenses, refer to:

"■ Reading a license" on page 2-6

For more information about changing license assignments, refer to:

3.2, "Modifying licenses" on page 3-3

3.8 Changing the computer name of a license-assigned station

To change the computer name of a license-assigned station to which licenses are already assigned, you must first delete the station from the license project and change the computer name, then perform the task to add the station to the license project again.

Changing the computer name of a license-assigned station

Follow these steps to change the computer name of a license-assigned station:

1. On the license management station, start License Manager in Editing mode.
2. Delete the license assignments of the license-assigned station for which you want to change the computer name.
3. Distribute and accept the licenses.
4. In License Manager on the license management station, confirm that the status of the license-assigned station has become OK, and then delete the license-assigned station from the license project.
5. Change the computer name.
6. Add the license-assigned station to the license project with the new computer name.
7. Assign licenses to the license-assigned station and distribute the licenses.
8. Restart the license-assigned station.

SEE ALSO For more information about adding and deleting license-assigned stations, refer to:

3.3, “Adding and deleting license-assigned stations” on page 3-12

3.9 Functions to help with license assignment work

In License Manager, you can use the following functions to help with license assignment work.

- Importing and exporting package lists

  You can use a general text editing tool to create a package list from information for stations that make up a license project and information on license assignments, and import it into a license project. You can also export a package list from a license project.

- Searching for character strings in the license project window
- Folding the display of software packages in the license project window
- Filtering information that appears in the license project window
- Deleting software package licenses from a license project
- Creating an assigned licenses status file

3.9.1 Importing and exporting package lists

A package list is a CSV file that contains information about the stations that make up a project, and information about the license assignments of each station.

You can define station configurations and license assignments by importing package lists into a license management station.

You can also export a package list from a license management station.

Package list file format

The following example shows a CSV-format package list displayed in a spreadsheet application.

	A	B	C	D	E	F	G	H
1	@ProjectID	XXXXXXX1						
2	@Product	CENTUM VP						
3	@StationType					PJTCOM	HIS/ENG	HIS/ENG
4	@StationName					PJTCOM	HIS0164	HIS0163
5	@ComputerName						HIS0164	HIS0163
6	@StationAlias							
7	@StationComment							
8	#	PackageType	Paid	Expiry	Ver.			
9	@Package	VP6F3100-V11	P		R6	100		
10	@Package	VP6H1100-V11N09	P		R6		1	1
11	@Package	VP6H4100-V11	P		R6		1	1
12	@Package	VP6H4150-V11	P		R6		1	1
13	@Package	VP6H4450-V11	P		R6		1	1
14	@Package	VP6H6510-V11	P		R6		1	1
15	@Package	VP6H6530-V11	P		R6		1	1

Figure 3.9.1-1 Package list in CSV format

The following table shows examples of identifiers and formats for license management information that are required in a package list, and whether specifying them in the package list is mandatory or not.

Table 3.9.1-1 Identifiers and formats for license management information and whether they are mandatory or not

Specified items	Identifiers and formats	Details	Required to specify during import?
Project ID	@ProjectID , <project ID>	Project ID for the license project	Required
Product name	@Product , <product_name>	The product name for the license project	Required
Station type	@StationType ,,,, <station_type_1>, <station_type_2> ,... , <station_type_N>	All station types in a license project	Required
Station name	@StationName ,,,, <station_name_1>, <station_name_2> ,... , <station_name_N>	All station names in a license project	Required (*1)
Computer name	@ComputerName,,,, <computer_name_1>, < computer_name_2> ,... , < computer_name_N>	The computer names of all stations in the license project	Required (*2)
Station alias	@StationAlias ,,,, <station_alias_1>, <station_alias_2> ,... , <station_alias_N>	The station alias of all stations in the license project	Optional

Continues on the next page

Table 3.9.1-1 Identifiers and formats for license management information and whether they are mandatory or not (Table continued)

Specified items	Identifiers and formats	Details	Required to specify during import?
Station comment	@StationComment ,,,, < station_comment_1>, < station_comment_2> ,... , < station_comment_N>	Comments for all stations in the license project	Optional
Package information	@Package, < MS_code > , <paid_flag> , < duration> , <version> , < assignment_numbers_for_station_1> , < assignment_numbers_for_station_2>	Package license information and assignment information	Required
Comment line	Lines starting with #		Optional

*1: Not required for stations not connected to a control bus.
*2: Not required for an FCS or SCS.

Table 3.9.1-2 Identifier format values and descriptions

Specified items	Value	Description
<station_type>	Same as the station types that can be specified when adding a station Example: HIS, FCS, GSGW, SIOS, UGS, UGS2	Station type
<station_name>	Same as the station name Leave this blank if there is no domain number and no station number. When importing, the domain number, station number, and redundant station settings are read from the station name. Example: HIS0164, FCS0101, BCVU0163(UGS)(Peer)	Station name
<computer name>	The values specified in the station properties This value is set for the Peer station if the station name ends with (Peer).	Station properties
<station_alias> <station_comment>	The values specified in the station properties This value is ignored if the station name ends with (Peer).	Station properties
<paid_flag>	By default, Paid P is specified If the paid flag for the imported package list is blank, it is considered paid.	
<expiration>	No expiry date: Blank Expiry date: YYYY/MM/DD YYYY Year MM Month DD Day Example: 2015/12/22	License expiry date
<version>	R<version_number > Example: R6	License version number
<number_assigned>	Number of assigned licenses If there are no assigned licenses at the time of exporting, the exported package list will be blank. If the number of assigned licenses at the time of importing is 0 or blank, the number of assigned licenses is set to 0.	Number of licenses assigned for each station

The permitted capacity for the package list is shown in the following table.

Table 3.9.1-3 Permitted capacity for package list

Specified items	Permitted capacity
Maximum number of stations	256
Maximum number of rows of packages	200

Importing a package list

Follow these steps to import a package list:

1. On the license management station, start License Manager in Editing mode.
2. From the menu bar, select [File] > [External File] > [Import].
   The file selection dialog box appears.
3. Select the package list that you want to import.
4. Click [Open].
   License Manager automatically checks the license assignments for consistency and checks the package lists, and updates its window with information from the imported package list.
5. From the menu bar, select [File] > [Save] .
   The imported package list is saved.

Any errors and warnings appear in the message display area. Find out the cause and resolve the problem.

Import process

The process of importing a package list is as follows:

- Station information
  If the imported package list contains stations that were not in the license project, the stations and their assignment information are added.

  If the imported package list contains stations that are already in the license project, the properties of those stations are overwritten.

  The station properties consist of information from the package list, such as <computer name>, <alias of station>, and <station comment>.

  The information related to stations not included in the imported package list remains the same when performing the import.
- Assignment information
  If the imported package list includes assignment information for stations that are already in the license project, the assignment information is overwritten.

  If the imported package list does not include assignment information for stations that are already in the license project, the current assignment information remains the same.

  If the license project includes redundant stations, specify the assignment information for both stations in the package list.
- Information on licensed software packages (package type, version)
  If the imported package list contains information on software packages that were not in the license project, set the number of licenses to 0 and add a row.

Items checked when importing

When you import a package list, License Manager automatically checks the license assignments for consistency and checks the package lists. If an error is detected, details of the error appear in the message display area and the import process is terminated.

The following package list items are checked.

Table 3.9.1-4 Items checked in the package list

Checked item	Description
File type	Checks whether the file is in CSV format.
Entry	Checks whether the following mandatory items have been entered: Project ID Product name Station type Station name Computer name
Product name	Checks whether the product name is the same as that of the license project.
Project ID	Checks whether the project ID is the same as that of the license project.
Packages that can be assigned	Checks that there are no package types that cannot be assigned to the station type.
Redundant station settings	Checks that the assignment details for the first and second station are the same.

Exporting a package list

Follow these steps to export a package list:

1. Start License Manager.
2. From the menu bar, select [File] > [External File] > [Export].
   A dialog box appears to confirm whether you want to save the file.
3. Specify the folder to which the package list needs to be exported and a file name for the package list.
4. Click [Save].
   The package list for the license information is exported to the specified folder using the specified file name.

3.9.2 Searching for characters in the license project window

You can search for character strings in the license project window.

Performing a search

Follow these steps to use the License Manager search function:

1. Open the license project in which you want to search for text.
2. From the License Manager menu bar, select [Edit] > [Find].
   The Find dialog box appears.
3. In the Find string box, enter the search text and click [Find next].
   The search starts from the upper-left part of the license project window and moves towards the right. It continues downward when the row is completed.
   The cursor moves to a result that matches the search text.

   If there are no matches, a message appears.

3.9.3 Folding the display of a license project

In the license project package information area, there is a list of software packages for each station type.

You can display or hide the package type by expanding or folding the license project rows.

Collapsing the display

In the license project window, click the [+] and [-] collapse buttons on the left of the package type.

The rows are collapsed so that only the applicable package type appears.

Click the [+] and [-] buttons to switch between the normal display and collapsed display.

3.9.4 Filtering information that appears in the license project window

You can filter the view to show only the station columns and software package rows that match the conditions selected in the license project window.

You can select the following conditions:

- Filtering by station type
- Filtering by domain number
- Filtering by station status
- Filtering by license paid/free, expiry date (time-limited/open-ended), and version

You can specify multiple filtering conditions independently. If you are filtering using multiple filtering conditions, only the columns and rows that match all of the conditions appear.

For example, if you filter by FCS, all station types other than FCS stations are collapsed and only the FCS packages appear.

Filtering contents

Follow these steps to filter the display:

1. In the license project window, click the Filter button for attributes that you want to filter by.
2. From the drop-down menu that appears, select the filter conditions.
   Only the station columns and license rows that match the selected conditions appear.

3.9.5 Deleting software package licenses from a license project

You can delete licenses for software packages from a license project if the software packages meet both of the following conditions:

- Software packages that do not have licenses assigned to a station
- The number of available licenses is zero (*1), or the software packages cannot be used as they have expired.

*1: When creating a license project, if you imported a package list that contains software packages whose license quantity is zero, a row is added for that software package indicating zero license quantity.

TIP

After upgrading the licenses, the licenses of software packages that are no longer needed should be deleted from the license project.

SEE ALSO

For more information about importing package lists, refer to:

3.9.1, “Importing and exporting package lists” on page 3-27

Deleting software package licenses

Follow these steps to delete licenses for a software package:

IMPORTANT

Deleted software package licenses cannot be restored. You must delete software package licenses very carefully.

1. On the license management station, start License Manager in Editing mode.
2. In the license project window, select the software package that you want to delete.
   You can only select one software package.
3. From the menu bar, select [License] > [Delete license].
   The Delete license dialog box appears.
4. Click [Yes].
   The license of the software package is deleted.

3.9.6 Creating an assigned licenses status file

In License Manager, you can create the license assignment status as a text file. Follow these steps to create a file:

1. On the license management station, from the License Manager menu bar, click [View] and select one of the following export modes:
   - Editing mode
   - Monitoring mode

   You do not need to select a mode for a license-assigned station.
2. From the menu bar, select [Tool] > [Output report].
3. In the file selection dialog box, specify the following items:
   - Folder in which the file should be created
   - File name
4. Click [Save].
   A text file is saved to the specified folder.

Structure of the assigned licenses status file

The following tables describe the structure of the file containing information about assigned licenses.

Header

The following information is saved in the Header section:

Table 3.9.6-1 Information in the Header section

Title	Description
License Manager Report [Station name] ([Mode])	[Station name] ([Mode]) The name of the station that generated the file and the mode of the license project Example: HIS0164 (Monitoring mode)
Date	The local date on which the file was generated

Project Information

License project information is saved in the Project Information section. The following table shows the items that are saved in the Project Information section.

Table 3.9.6-2 Information in the Project Information section

Title	Description
Product	Product name
Project ID No	Project ID number
Project name	License project name
Comment	Comments about the license project
License Admin	License management flag 1: License management station 0: License-assigned station
Back up folder	The backup folder for the license project

The information that is saved changes according to the license project mode. The information that is saved in each mode is as follows:

- Editing mode

Table 3.9.6-3 Information saved in Editing mode

Title	Description
Edit	Number of licenses with an Editing status
Edit(NG)	Number of stations that returned an error in the consistency check
AckWait	Number of stations waiting for license acceptance
RtnWait	Number of stations waiting for licenses to be returned
Expired	Number of stations with expired licenses
DueToExpire	Number of stations with licenses that will expire in 30 days or less

- Monitoring mode

Table 3.9.6-4 Information saved in Monitoring mode

Title	Description
Error	Number of stations with license errors
Expired	Number of stations with expired licenses
DueToExpire	Number of stations with licenses that will expire in 30 days or less
Unknown	Number of stations for which the status cannot be tracked
AckWait	Number of stations waiting for license acceptance
RtnWait	Number of stations waiting for licenses to be returned

- Assigned station mode

Table 3.9.6-5 Information saved in Assigned Station mode

Title	Description
Error	Number of stations with license errors
Expired	Number of stations with expired licenses
DueToExpire	Number of stations with licenses that will expire in 30 days or less
AckWait	Number of stations waiting for license acceptance

Package List

License package information is saved in the Package List section. The following table shows the items that are saved in the Package List section.

For each package, items in the Package List section are assigned a consecutive number starting from one, and each item is saved in a new line.

Table 3.9.6-6 Information in the Package List sections

Title	Description
No	A consecutive number starting from one is automatically saved for each license
PackageType	Package type

Continues on the next page

Table 3.9.6-6 Information in the Package List sections (Table continued)

Title	Description
InternalPackage	CENTUM VP R5 package model corresponding to the CENTUM VP R6 package model, or ProSafe-RS R3 package model corresponding to the ProSafe-RS R4 package model
PackageName	Package name
Paid	Shows whether it is paid or free Paid: P Free: F
Expiry	Validity duration Time-limited: Expiry date and time Non-time-limited: -
Ver.	version
Qty	Number of licenses
Unused	Number of unused licenses

Station Information, Station Information-Package

Information about stations is saved in the Station Information section. Information about licenses assigned to a station is saved in the Station Information-Package section.

The following information is saved in the Station Information section:

Table 3.9.6-7 Information in the Station Information section

Title	Description
StationType	Station type
Domain,Station	[Domain number][Station number] Example: 1, 63 Empty if there is no domain or station
StnName	Station name
Alias	Alias of station
Comment	Comment
Computer	Computer name
Status	The status that appears in the license window.(*1)

*1: The text that appears is different in Editing mode and Monitoring mode.

The following items are saved in the Station Information-Package section:

Table 3.9.6-8 Information in the Station Information-Package section

Title	Description
No	A consecutive number starting from one is automatically saved for each license
PackageType	Package type
InternalPackage	CENTUM VP R5 package model corresponding to the CENTUM VP R6 package model, or ProSafe-RS R3 package model corresponding to the ProSafe-RS R4 package model
PackageName	Package name
Paid	Shows whether it is paid or free Paid: P Free: F

Continues on the next page

Table 3.9.6-8 Information in the Station Information-Package section (Table continued)

Title	Description
Expiry	Validity duration Time-limited: Expiry date and time Non-time-limited: -
Ver.	version
Assign	Number of licenses assigned to the displayed station(*1)

*1: The number may be different in Editing mode and Monitoring mode.

4. Upgrading the Licenses from CENTUM VP R5 to R6, or from ProSafe-RS R3 to R4

This section describes how to upgrade the licenses from CENTUM VP R5 to R6, or from ProSafe-RS R3 to R4. Before starting upgrading of the licenses, you must install CENTUM VP R6 or ProSafe-RS R4 software packages on the computers to which you want to distribute the upgraded licenses.

CENTUM VP is not affected by the ProSafe-RS license upgrading, and vice versa.

4.1 Process for License Upgrading

This section describes the basic procedures about how to upgrade licenses that are assigned in all stations within a license project.

As for how to upgrade the licenses for some HISs, it is described in the other section.

The following figure shows the procedures of upgrading licenses.

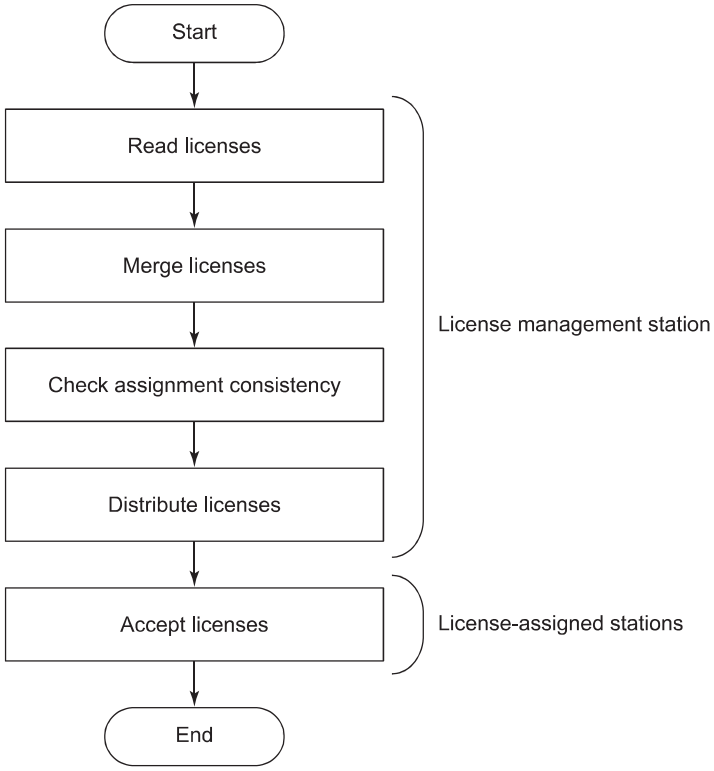

Figure 4.1-1 Procedures for Upgrading Licenses

SEE ALSO For more information about Upgrading the Licenses for Some HISs, refer to:

4.2, “Upgrading the Licenses for Some HISs” on page 4-5

Reading Licenses

Read the license key file to upgrade the license in the license management station that is upgraded to CENTUM VP R6 or ProSafe-RS R4.

The procedure to read the license key file into the license management station is same as the procedure to read the new license.

The following line is added to the package type in the license management. In the following explanation, we call the added line as a version upgrade license.

<old package type> => <new package type>

example: LHS1100-V10/N0099 => VP6H1100-V10N09

IMPORTANT

Retain the following license media after you upgrade licenses because you need it when you restore the licenses.

- The license medium that contains the old license key file.
- The license medium that contains the license key file to upgrade the old licenses

SEE ALSO For more information about reading licenses, refer to:

"■ Reading a license" on page 2-6

■ Merging Licenses

You need to merge licenses because version upgrade licenses cannot be distributed independently.

IMPORTANT

Licenses cannot be divided after they have been merged. Perform merging licenses very carefully.

To merge licenses, perform following procedures.

1. Run the license manager on the license management station as editing mode.
2. Assign the version upgrade licenses to the all stations that have been assigned with old licenses. The procedures to assign a version upgrade license is same as the procedures to assign a license.
3. From the menu bar, select [License] > [Merge version upgrade licenses].
   A dialog box to confirm packages appears.
4. Click [Yes].
   The old license and the version upgrade license is merged. You can confirm the merged license by package type.

A sample image of the license manager

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHS1100-V10/N0099	R5	3	1	1	1
LHS1100-V10/N0099 => VP6H1100-V10N09	R6	3			

Assigning the license

The image of the license manager that appears after assigning the license

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHS1100-V10/N0099	R5	3	1	1	1
LHS1100-V10/N0099 => VP6H1100-V10N09	R6	3	1	1	1

Merging the license

The image of the license manager that appears after merging the license

Package type	Ver.	Qty	HIS1	HIS2	HIS3
VP6H1100-V10N09	R6	3	1	1	1

Figure 4.1-2 Merging operation to upgrade licenses

TIP

If there are more than one licenses that is available to merge, you can merge only one group by one merging operation.

SEE ALSO

For more information about assigning licenses, refer to:

"■ Assigning licenses" on page 2-11

■ Assignment Consistency Check

Check the assignment consistency on the licenses that are upgraded.

The procedures to check the assignment consistency on the upgraded license is same as the checking on the license assignment.

IMPORTANT

Do not assign the different version of licenses on the same licenses-assigned station. If you assign a different version of license and check the consistency of assignment, an error message appears in the message display area on the license manager. Modify the assignment of licenses if an error message appears.

SEE ALSO

For more information about license assignment consistency check, refer to:

2.6, "Checking license assignment consistency" on page 2-12

■ Distributing Licenses

Distribute the upgraded licenses to the license-assigned stations.

The procedures to distribute the upgraded license is same as the procedures to distribute new licenses.

SEE ALSO

For more information about distributing licenses to license-assigned stations through a network, refer to:

"■ Distributing a license to license-assigned stations through a network" on page 2-13

For more information about distributing license by using external storage media, refer to:

"■ Distributing licenses by using external storage media" on page 2-16

■ Accepting Licenses

Accept upgraded licenses on the license-assigned stations.

The procedures to accept the upgraded license is same as the procedures to accept new licenses.

SEE ALSO

For more information about accepting licenses, refer to:

"■ Accepting a license and activating a software package on a license-assigned station" on page 2-15

For more information about accepting licenses by using external storage media, refer to:

"■ Activating a software package using external storage media" on page 2-17

4.2 Upgrading the Licenses for Some HISs

This section describes how to upgrade the licenses for some HISs.

For example, if you want to mix HISs with CENTUM VP R5 and R6 in a license project, upgrade the license to R6 for the number of the stations that have been upgraded to CENTUM VP V6. And distribute the upgraded licenses to HISs that are upgraded to CENTUM VP R6.

IMPORTANT

With CENTUM VP, one license project cannot have mixed non-HIS stations to which R5 and R6 licenses are assigned. With ProSafe-RS, one license project cannot have mixed SENGs to which R3 and R4 licenses are assigned.

Upgrading the Licenses for Some HISs

The procedures to upgrade license for some HISs is same as the procedure to upgrade whole licenses. However, note that the version upgrade license must be assigned to the station whose license is to be upgraded.

The following figure shows an example of upgrading the licenses for some HISs.

A sample image of the license manager

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHS1100-V10/N0099	R5	3	1	1	1
LHS1100-V10/N0099 => VP6H1100-V10N09	R6	2			

↓ Assigning the license to HIS1 and HIS2

The image of the license manager that appears after assigning the license

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHS1100-V10/N0099	R5	3	1	1	1
LHS1100-V10/N0099 => VP6H1100-V10N09	R6	2	1	1	

↓ Merging the license

The image of the license manager that appears after merging the license

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHS1100-V10/N0099	R5	1			1
VP6H1100-V10N09	R6	2	1	1	

Figure 4.2-1 Upgrading partial licenses

If you upgrade the licenses for some HISs, the available license number to be upgraded is up to the quantity of the version upgrade licenses.

After upgrading the licenses for some HISs, continue working on the procedure from "Assignment Consistency Check" according to the procedure of upgrading the license.

SEE ALSO

For more information about the process for license upgrading, refer to:

4.1, “Process for License Upgrading” on page 4-2

For more information about the version upgrade license, refer to:

“■ Reading Licenses” on page 4-2

5. Working with upgrade licenses

An upgrade license is required to upgrade a product. You can install the issued product medium before the expiry date of upgrade licenses.

The following operations differs from the software license operations:

- Addition
- Distribution and acceptance
- Deletion
- Moving

  You cannot move upgrade licenses across license projects.

■ Adding upgrade licenses

You should add an upgrade license when reading a new upgrade license or when extending the expiry date of an upgrade license.

TIP

When installing a software that was issued after the upgrade license is expired, first make sure to add an upgrade license with a new expiry date. Expiry date is extended.

SEE ALSO

For more information about adding upgrade licenses, refer to:

"■ Reading a license" on page 2-6

■ Distributing and accepting upgrade licenses

When you upgrade the following products, distribute and accept the upgrade licenses before you install the new revision of the software:

- CENTUM VP R6.04 or later
- ProSafe-RS R4.03 or later

TIP

- When you distribute only the upgrade licenses through a network, the licenses are accepted automatically.
- Upgrade licenses can be distributed even after the expiry date.

SEE ALSO

For more information about distributing and accepting licenses through a network, refer to:

2.7, "Distributing and accepting licenses through a network" on page 2-13

For more information about distributing and accepting licenses using external storage media, refer to:

2.8, "Distributing and accepting licenses using external storage media" on page 2-16

■ Deleting upgrade licenses from a license project

You can delete upgrade licenses from the license project if they are not assigned to any stations.

The procedure is the same as that for deleting software package licenses.

SEE ALSO

For more information about deleting software package licenses, refer to:

3.9.5, "Deleting software package licenses from a license project" on page 3-34

Appendix 1. Items checked in the license assignment consistency check

The following tables list and describe the items checked for each license or station.

Table Appendix 1-1 Items checked for each license

Checked item	Description
Excess assignment	Checks that the total number of licenses assigned to each station does not exceed the number of licenses available in the license project.
PJTCOM definition	Checks whether PJTCOM has been defined if a Project I/O License is assigned.
Quantity of assigned Project I/O License	Checks whether the quantity of the Project I/O License that is assigned to PJTCOM matches the quantity of the Project I/O License that is provided.

Table Appendix 1-2 Items checked for each station

Checked item	Description
Station properties	Checks whether there are any mistakes in the following station properties: Input range Setting category Station identification conditions
Dependency	Checks that all required package types have been assigned to software packages that need to be assigned together at the same time.
Exclusion	Checks that package types with exclusion relationships have not been assigned to the same station.
Packages that can be assigned	Checks that there are no package types that cannot be assigned to the station type.
Expired licenses	Checks that expired licenses have not been assigned.
Merge license	Checks that any upgrade installation license, version upgrade license, or replacement license has not been assigned independently.
Exceeded assignment limit	Checks whether the number of assigned licenses has exceeded the number of licenses that can be assigned to one station.
Redundant station	Checks that the assignment details are the same on the first station and the second station.
Version number identification	Checks that no license that has inconsistent version number has been assigned in a station

SEE ALSO

For more information about PJTCOM, refer to:

"■ Station name and computer name default values" on page 2-9

For more information about upgrade installation license, refer to:

3.5, "Increasing the software package capacity" on page 3-17

For more information about version upgrade license, refer to:

"■ Reading Licenses" on page 4-2

For more information about replacement licenses, refer to:

Appendix 4., "Upgrading licenses of CENTUM VP R5 software packages" on page App.4-1

Appendix 2. Displaying the status of assigned licenses on a license-assigned station

Displaying the status of assigned licenses on a License Manager

When you open License Manager on a license-assigned station, the license project window for the local station appears.
The status of the local station appears in the summary information area. The displayed items and corresponding responses are as follows:

Table Appendix 2-1 Status and response

Status	Description	Response
Error	Number of stations with a license error	Check the details of the license error.
Expired	Number of stations with an expired license	Check the expired licenses.
DueToExpire	Number of stations with licenses that will expire in 30 days or less	Check the licenses that will expire in 30 days or less.
AckWait	Number of stations waiting for license acceptance	Accept the distributed licenses.

Displaying the status of assigned licenses in the task tray

An icon that indicates the status of assigned licenses for the local station appears in the task tray.
The icons displayed in the task tray and the corresponding responses are as follows:

Table Appendix 2-2 Icons and responses

Icon	Description	Response
	Licenses have been assigned successfully (The status in Monitoring mode is OK).	—
	There is an error in the license. (a status of either Error, Expired, or NoLicense in Monitoring mode)	Check the details of the license error.
	The licenses will expire in 30 days or less (the status in Monitoring mode is DueToExpire).	Check the licenses that will expire in 30 days or less.
	Licenses have been distributed and are waiting to be accepted. Licenses have currently been assigned successfully (The status in Monitoring mode is OK).	Accept the distributed licenses.
	Licenses have been distributed and are waiting to be accepted. There is currently an error in the license. (a status of either Error, Expired, or NoLicense in Monitoring mode)	Accept the distributed licenses.
	Licenses have been distributed and are waiting to be accepted. The licenses will expire in 30 days or less (the status in Monitoring mode is DueToExpire).	Accept the distributed licenses.

Displaying the status of assigned licenses in the HIS system message banner

The status of assigned licenses for the local station appears in the system status icon display area of the HIS system message banner. If there is a license error or warning, or if a license is waiting for acceptance, an icon appears.
The following example shows the status of assigned licenses displayed in the HIS system message banner.

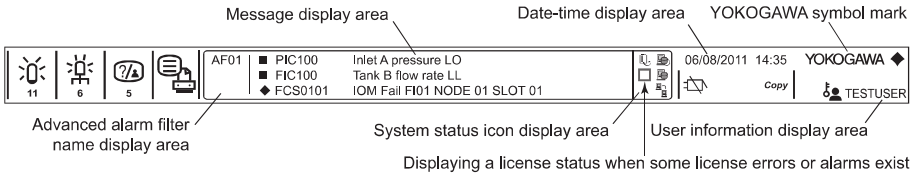

Figure Appendix 2-1 Example of the HIS system message banner display

The icons displayed in the system status icon display area and the corresponding responses are as follows:

Table Appendix 2-3 Icons and responses

Icon	Description	Response
No display	Licenses have been assigned successfully.	-
	There is an error in the license.	Check the details of the license error.
	The licenses will expire in 30 days or less.	Check the licenses that will expire in 30 days or less.
	Licenses have been distributed and are waiting to be accepted. Licenses have currently been assigned successfully.	Accept the distributed licenses.
	Licenses have been distributed and are waiting to be accepted. There is currently an error in the license.	Accept the distributed licenses.
	Licenses have been distributed and are waiting to be accepted. The licenses will expire in 30 days or less.	Accept the distributed licenses.

Appendix 3. Messages

The format for messages is as follows:

Station name (STNddss) message

Example: STN0164 License is not Accepted

The messages that appear on the station and the corresponding responses are as follows:

Table Appendix 3-1 Messages and corresponding responses

Message	Meaning	Action
STNddss License is not Accepted	A distributed license is not accepted.	Start the license manager and accept the license.
STNddss Cannot Restart. License Expired (VP6H1100, VP6H1120)	The license expired. If you restart the station, the correspondent package will not work.	Renew the license or remove the station assignment.
STNddss Cannot Restart from 2015/12/22. License will Expire (VP6H1100, VP6H1120)	If you restart the station on 2015/12/22 or after, the correspondent package will not work. The warning message appears 30 days before the license expiration date.	Renew the license or remove the station assignment.
STNddss License Error (License is Invalid)	The license information is not correct.	Redistribute the license.
STNddss License Error (Different from License Manager)	The license information on local station and on license management station is not consistent.	Redistribute the license.
STNddss License Error (Duplication with STNxxxx)	The license for STNddss station is distributed to multiple stations.	Redistribute the license.
STNddss License Error (ProjectID1 and ProjectID2(STNxxxx) are detected)	Licenses with different project IDs were assigned to stations (*1)in the same system. For example, STNddss was assigned with licenses for ProjectID1, while STNxxxx was assigned with licenses for ProjectID2. ProjectID1: The project ID of the license project for the local station. ProjectID2: The project ID of the license project for the other station. STNxxxx: Name of the station (or computer) that uses a different project ID from the local station.	Check whether the licenses in the same project have the same project ID.

*1: This refers to all computer-based stations that are defined in System View as well as in license projects.

Appendix 4. Upgrading licenses of CENTUM VP R5 software packages

This section describes how to upgrade licenses of CENTUM VP R5 software packages. For example, if you want to replace LHM1101 Standard Operation and Monitoring Functions (for CENTUM VP Small) to LHS1100 Standard Operation and Monitoring Functions, you need to upgrade the license LHM1101 to LHS1100. The basic workflow to upgrade the license is same as the workflow to upgrade the license. However, after having accepted the license on the license-assigned station, restart the station.

On the license management station of CENTUM VP R6, read the license key file from the license medium to upgrade the licenses. The following line is added to the package type in the license management. In the following explanation, we call the added line as a replacement license.

<old package type> => <new package type>

Example: LHM1101-V10/N0064 => LHS1100-V10/N0099

Merge the old license and replacement license to upgrade the license. Distribute the upgraded licenses to the license-assigned stations.

IMPORTANT

Retain the following license media after you upgrade licenses because you need it when you restore the licenses.

- The license medium that contains the old license key file.
- The license medium that contains the license key file to upgrade the old licenses

SEE ALSO For more information about basic workflow for license upgrading, refer to:

4.1, “Process for License Upgrading” on page 4-2

Upgrading licenses

When you upgrade licenses by merging old licenses and replacement licenses, perform following procedures.

IMPORTANT

Licenses cannot be divided after they have been merged. Perform merging licenses very carefully.

1. On the license management station of CENTUM VP R6, read the license key file from the license medium to upgrade the licenses. The procedure to read the license key file into the license management station is same as the procedure to read the new license.
2. Run the license manager on the license management station as editing mode.

3. Assign a replacement license to the station in which the license needs to be upgraded. The procedures to assign a replacement license is same as the procedures to assign a license.
4. From the menu bar, select [License] > [Merge version upgrade licenses]. A dialog box to confirm packages appears.
5. Click [Yes]. The old license and the replacement license are merged. You can confirm the merged license by package type.

A sample image of the license manager

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHM1101-V10/N0064	R5	3	1	1	1
LHM1101-V10/N0064 => LHS1100-V10/N0099	R5	2			

Assigning the license to HIS1 and HIS2

The image of the license manager that appears after assigning the license

Package type	Ver.	Qty	HIS1	HIS2	HIS3
LHM1101-V10/N0064	R5	3	1	1	1
LHM1101-V10/N0064 => LHS1100-V10/N0099	R5	2	1	1	

Merging the license

Revision information

Document name : License Management Guide

Document no. : IM 32P01C60-01EN

Dec. 2023/8th Edition/R4.10 or later

3.6	Updated steps in “■ Restoring a license project on another license management station.”

Feb. 2021/7th Edition/R4.06

2.2	Updated descriptions and added information about switching method of license project display.
2.4	Updated description of when using virtual test functions.

Dec. 2019/6th Edition/R4.05

Introduction	Updated description of registered trademarks and trademarks.
1.1.2, 2.4	Added UACS station.

Aug. 2018/5th Edition/R4.04

Introduction	Changed descriptions of registered trademarks of YOKOGAWA.
1.1.1	Added information about PRM.
5	Added information about additional methods of upgrade licenses.

Oct. 2017/4th Edition/R4.03.10

Entire manual	Updated expressions of the products managed in license management.
1.1	Updated descriptions.
1.2.4	Added information about upgrade licenses.
3.9.5	Updated expressions.
5	Added information about upgrade licenses.

May 2017/3rd Edition/R4.03

Introduction	Deleted Windows Vista from Trademark Acknowledgments.
1.1, 1.2	Added information about upgrade licenses.
3	Added information about software licenses.
4	Added information about version upgrade licenses.
5	Added information about application of upgrade licenses.

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed the symbols that indicate warning and caution.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."
1.1.1	Added descriptions related to license management for iDefine.
2.4	Added information about UGS2.
2.11	Newly added.
2.12	Changed the section number from 2.11. Changed "redundant station" to "network switchover type redundant UGS."
3.9.1	Added information about UGS2.

Appendix 3 Corrected an error.

Dec. 2015/1st Edition/R4.01

Introduction

This manual is a guide for implementing security measures in the ProSafe-RS system from a viewpoint of information technology (IT).

It explains security models and setting details of ProSafe-RS. Please read this manual to learn about the details of security settings.

The intended readers of this manual are engineers who examine construction and operation of the ProSafe-RS system.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User’s Manuals for necessary actions. In the User’s Manuals, this symbol is used together with a word “CAUTION” or “WARNING” at the locations where precautions for avoiding dangers are described.

<French> Signale qu’il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d’un danger pour le personnel et l’équipement comme un choc électrique, et signale également que l’utilisateur doit se référer au Manuel de l’utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l’utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

~ Indicates an AC supply.

⎓ Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term

1. Overview

This manual is a guide for implementing security measures on the product and for its operation.

By operating the system with security measures implemented, the product is protected from existing and future security threats.

The security models described in this manual are based on general configuration of the product. You must consider engineering and operation practices when applying these models to the actual systems.

Security-related Terms Used in the Manual

The following table describes the security-related terms.

Table 1-1 Security-related Terms

Term	Explanation
IT security	Security measures considered based on given IT environment, in order to protect the system and fight against current and future security threats including cyber terrorism.
User authentication mode	A scheme that prescribes the method of managing Windows users and ProSafe-RS users. Two modes are available: Windows authentication mode and ProSafe authentication mode.
ProSafe authentication mode	One of user authentication modes. This mode manages ProSafe-RS users and their access permissions independently of the Windows management functions.
Windows authentication mode	One of user authentication modes. This mode links credentials of Windows users and ProSafe-RS users.
Kerberos authentication	The default authentication method of Windows domain and it is used in a domain environment where the server and client PCs are mixed for single sign on. Once a user is authenticated; the authentication will be valid for entire system.
Personal firewall	Firewall operating on PC and domain controller, including firewalls other than the Windows standard firewall.

Overview of ProSafe-RS

SENG/HMI and SCS are connected by Vnet/IP, and SENG/HMI is connected to Ethernet as needed.

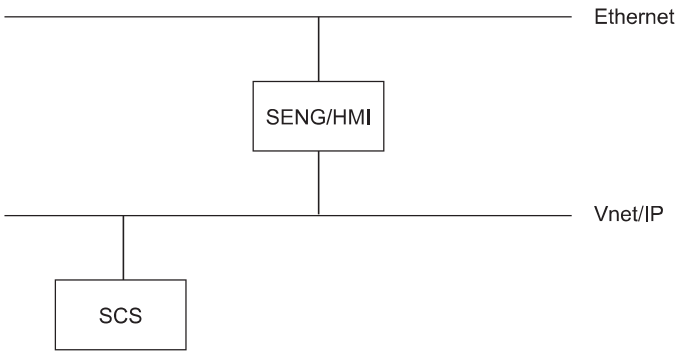

Figure 1-1 Overview of ProSafe-RS

Authentication and Access Control are performed on the SENG/HMI connected to the SCS. For this reason, SENG/HMI must have the security settings in this document. Also, take

measures such as using a switch or other device to prevent the computer from being inadvertently connected to the Ethernet or Vnet/IP to which the SENG/HMI is connected.

SEE ALSO For more information about the details of security measures, refer to:

Security Standard of System Product (TI 33Y01B30-01E)

1.1 Security Threats to be Handled

This section describes the security threats that the security functions of the product should deal with.

Security Threats

The security threats that can harm the ProSafe-RS system are as follows:

1. Attacks over the network
   Threats from individuals without any rights to the ProSafe-RS system via networks such as intranets, as well as the resultant threats of leakage of important data of the ProSafe-RS system.
2. Direct attacks through operation of SENG
   Threats where individuals without any rights to the ProSafe-RS system directly operate an SENG to affect the system and steal important data.
3. Theft of SENG or data.
   Threats where an SENG or data is stolen and important data is analyzed.

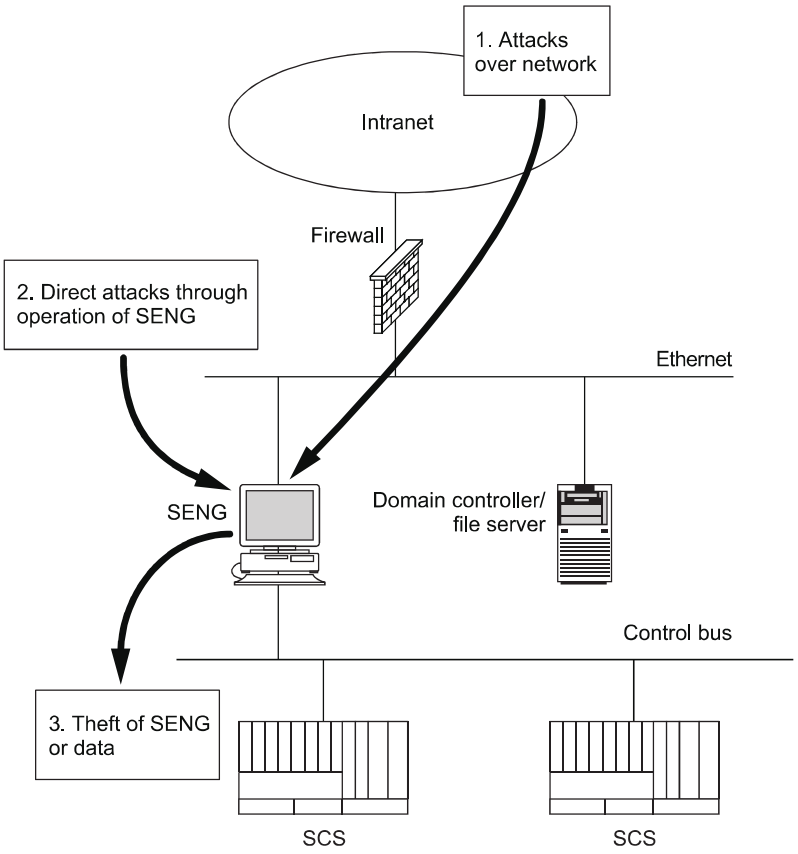

Figure 1.1-1 Security Threats

1.2 Security Measures

This section describes the security measures against security threats. Identify security measure items required for the product and, from among them, select the required security measures according to the level of security strength.

Security Measures and Handled Security Threats

In order to fight against security threats, we arranged security measures applied in security guides for each OS issued by Microsoft and general business network environment and optimized as a set of security measures for the product. Two IT security versions, 2.0 and 1.0, are available, which provide security measures that cover different ranges. These two versions are described as follows.

- IT security version 2.0
  This version was designed after reconsidering the IT security version 1.0 and includes more security measures. It supports the Standard and Strengthened security models.
- IT security version 1.0
  It supports the Legacy, Standard, and Strengthened security models.

IT security version 2.0 and IT security version 1.0 can coexist in the same project.

The following tables show the security measures and the threats that each measure handles for each security version.

[1]: Attacks over the network

[2]: Direct attacks by operation of SENG

[3]: Theft of SENG or data.

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0

Security measure	Threat handled		
	[1]	[2]	[3]
Password Policy-[Minimum password length]	Yes	Yes	No
Password Policy-[Minimum password age]	Yes	Yes	No
Password Policy-[Maximum password age]	Yes	Yes	No
Password Policy-[Enforce password history]	Yes	Yes	No
Disable ‘Password Policy-[Store passwords using reversible encryption]'	Yes	Yes	No
Password Policy-[Password must meet complexity requirements]	Yes	Yes	No
Access control for files and folders	Yes	Yes	No
Access control for product registry	Yes	Yes	No
Access control for DCOM (OPC) objects	Yes	Yes	No
Personal firewall tuning	Yes	No	No
Disable 'Personal Firewall-[Allow unicast response]’	Yes	No	No
Stopping unused Windows services	Yes	No	No
Account Lockout Policy-[Account lockout threshold]	Yes	Yes	No
Account Lockout Policy-[Reset account lockout counter after]	Yes	Yes	No
Account Lockout Policy-[Account lockout duration]	Yes	Yes	No
Disabling NetBIOS over TCP/IP	Yes	No	No

Continues on the next page

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0 (Table continued)

Security measure	Threat handled		
	[1]	[2]	[3]
Applying the StorageDevicePolicies function	No	Yes	Yes
Disabling USB storage devices	No	Yes	Yes
Applying the software restriction policies	Yes	Yes	No
User Rights Assignment-[Access this computer from the network]	No	Yes	No
User Rights Assignment-[Add workstations to domain]	Yes	Yes	No
User Rights Assignment-[Allow log on locally]	No	Yes	No
User Rights Assignment-[Deny log on locally]	No	Yes	No
Security Options-[Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings]	Yes	Yes	No
Security Options-[Devices: Prevent users from installing printer drivers]	No	Yes	No
Security Options-[Devices: Restrict CD-ROM access to locally logged-on user only]	Yes	No	No
Security Options-[Devices: Restrict floppy access to locally logged-on user only]	Yes	No	No
Disable 'Security Options-[Domain controller: Allow server operators to schedule tasks]'	No	Yes	No
Disable 'Security Options-[Domain controller: Refuse machine account password changes]'	No	Yes	No
Security Options-[Domain member: Require strong (Windows 2000 or later) session key]	Yes	No	No
Do not display user information 'Security Options-[Interactive logon: Display user information when the session is locked]'	No	Yes	No
Security Options-[Interactive logon: Do not display last user name]	No	Yes	No
Disable 'Security Options-[Interactive logon: Do not require CTRL+ALT+DEL]'	No	Yes	No
Security Options-[Interactive logon: Machine inactivity limit]	No	Yes	No
Security Options-[Interactive logon: Prompt user to change password before expiration]	Yes	Yes	No
Security Options-[Microsoft network server: Digitally sign communications (if client agrees)]	Yes	No	No
Security Options-[Microsoft network server: Server SPN target name validation level]	Yes	No	No
[MSS: (DisableIPSourceRouting) IP source routing protection level (protects against packet spoofing)]	Yes	No	No
Disable [MSS: (PerformRouterDiscovery) Allow IRDP to detect and configure Default Gateway addresses (could lead to DoS)]	Yes	No	No
[MSS: (TcpMaxDataRetransmissions) How many times unacknowledged data is retransmitted (3 recommended, 5 is default)]	Yes	No	No
Security Options-[Network access: Do not allow anonymous enumeration of SAM accounts]	Yes	No	No

Continues on the next page

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0 (Table continued)

Security measure	Threat handled		
	[1]	[2]	[3]
Security Options-[Network access: Do not allow anonymous enumeration of SAM accounts and shares]	Yes	No	No
Security Options-[Network access: Do not allow storage of passwords and credentials for network authentication]	Yes	No	No
Security Options-[Network security: Allow Local System to use computer identity for NTLM]	Yes	No	No
Disable 'Security Options-[Network security: Allow LocalSystem NULL session fallback]'	Yes	No	No
Security Options-[Network security: Force logoff when logon hours expire]	No	Yes	No
Security Options-[Network security: LAN Manager authentication level]	Yes	No	No
Security Options-[Network security: Minimum session security for NTLM SSP based (including secure RPC) clients]	Yes	No	No
Security Options-[Network security: Minimum session security for NTLM SSP based (including secure RPC) servers]	Yes	No	No
Disable 'Security Options-[Shutdown: Allow system to be shut down without having to log on]'	No	Yes	No
Security Options-[User Account Control: Admin Approval Mode for the Built-in Administrator account]	No	Yes	No
Security Options-[User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode]	No	Yes	No
Advanced Audit Policy Configuration-[Audit Credential Validation]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Computer Account Management]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Other Account Management Events]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Security Group Management]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit User Account Management]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Process Creation]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Directory Service Access]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Directory Service Changes]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Account Lockout]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Logoff]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Logon]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Other Logon/Logoff Events]	Yes	Yes	No

Continues on the next page

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0 (Table continued)

Security measure	Threat handled		
	[1]	[2]	[3]
Advanced Audit Policy Configuration-[Audit Special Logon]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Removable Storage]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Audit Policy Change]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Authentication Policy Change]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Filtering Platform Policy Change]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit MPSSVC Rule-Level Policy Change]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Other Policy Change Events]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Sensitive Privilege Use]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit IPsec Driver]	No	Yes	No
Advanced Audit Policy Configuration-[Audit Other System Events]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Security State Change]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit Security System Extension]	Yes	Yes	No
Advanced Audit Policy Configuration-[Audit System Integrity]	Yes	Yes	No
Personalization-[Prevent enabling lock screen camera]	No	Yes	No
Personalization-[Prevent enabling lock screen slide show]	No	Yes	No
WLAN Settings-[Allow Windows to automatically connect to suggested open hotspots, to networks shared by contacts, and to hotspots offering paid services]	Yes	No	No
SCM-[Enable LSA Protection]	Yes	Yes	No
SCM-[Lsass.exe audit mode]	Yes	Yes	No
Group Policy-[Configure registry policy processing]	Yes	Yes	No
Internet Communication settings-[Turn off downloading of print drivers over HTTP]	Yes	No	No
Internet Communication settings-[Turn off Event Viewer "Events.asp" links]	Yes	No	No
Internet Communication settings-[Turn off Internet download for Web publishing and online ordering wizards]	Yes	No	No
Internet Communication settings-[Turn off printing over HTTP]	Yes	No	No
Internet Communication settings-[Turn off Search Companion content file updates]	Yes	No	No
Internet Communication settings-[Turn off the "Publish to Web" task for files and folders]	Yes	No	No

Continues on the next page

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0 (Table continued)

Security measure	Threat handled		
	[1]	[2]	[3]
Internet Communication settings-[Turn off the Windows Customer Experience Improvement Program]	Yes	No	No
Internet Communication settings-[Turn off the Windows Messenger Customer Experience Improvement Program]	Yes	No	No
Logon-[Do not display network selection UI]	Yes	Yes	No
Logon-[Do not enumerate connected users on domain-joined computers]	No	Yes	No
Logon-[Do not process the legacy run list]	No	Yes	No
Logon-[Do not process the run once list]	No	Yes	No
Disable 'Logon-[Enumerate local users on domain-joined computers]'	No	Yes	No
Logon-[Turn off app notifications on the lock screen]	No	Yes	No
Mitigation Options-[Untrusted Font Blocking]	Yes	Yes	No
Remote Procedure Call-[Enable RPC Endpoint Mapper Client Authentication]	Yes	Yes	No
User Profiles-[Turn off the advertising ID]	Yes	No	No
App Privacy-[Let Windows apps access account information]	Yes	No	No
App Privacy-[Let Windows apps access call history]	Yes	No	No
App Privacy-[Let Windows apps access contacts]	Yes	No	No
App Privacy-[Let Windows apps access email]	Yes	No	No
App Privacy-[Let Windows apps access location]	Yes	No	No
App Privacy-[Let Windows apps access messaging]	Yes	No	No
App Privacy-[Let Windows apps access motion]	Yes	No	No
App Privacy-[Let Windows apps access the calendar]	Yes	No	No
App Privacy-[Let Windows apps access the camera]	Yes	No	No
App Privacy-[Let Windows apps access the microphone]	Yes	No	No
App Privacy-[Let Windows apps access trusted devices]	Yes	No	No
App Privacy-[Let Windows apps control radios]	Yes	No	No
App Privacy-[Let Windows apps sync with devices]	Yes	No	No
App runtime-[Block launching Windows Store apps with Windows Runtime API access from hosted content]	Yes	No	No
AutoPlay Policies-[Turn off Autoplay]	No	Yes	No
AutoPlay Policies-[Disallow Autoplay for non-volume devices]	No	Yes	No
Data Collection and Preview Builds-[Allow Telemetry]	Yes	No	No
Data Collection and Preview Builds-[Do not show feedback notifications]	Yes	No	No
Event Log Service(Application)-[Specify the maximum log file size (KB)]	Yes	Yes	No

Continues on the next page

Table 1.2-1 Security Measures and Handled Threats - IT security version 2.0 (Table continued)

Security measure	Threat handled		
	[1]	[2]	[3]
Event Log Service(Security)-[Specify the maximum log file size (KB)]	Yes	Yes	No
Event Log Service(System)-[Specify the maximum log file size (KB)]	Yes	Yes	No
File Explorer-[Turn off heap termination on corruption]	No	Yes	No
HomeGroup-[Prevent the computer from joining a homegroup]	Yes	No	No
OneDrive-[Prevent the usage of OneDrive for file storage]	Yes	No	No
OneDrive-[Save documents to OneDrive by default] (Save documents to the local PC by default)	Yes	No	No
Remote Desktop Connection Client-[Do not allow passwords to be saved]	Yes	No	No
Device and Resource Redirection-[Do not allow drive redirection]	Yes	No	No
Security-[Always prompt for password upon connection]	Yes	No	No
Security-[Require secure RPC communication]	Yes	No	No
Security-[Require user authentication for remote connections by using Network Level Authentication]	Yes	No	No
Session Time Limits-[Set time limit for active but idle Remote Desktop Services sessions]	Yes	No	No
Sync your settings-[Do not sync Apps]	Yes	No	No
Sync your settings-[Do not sync start settings]	Yes	No	No
Disable 'Windows Error Reporting-[Automatically send memory dumps for OS-generated error reports]'	Yes	No	No
Disable 'Windows Logon Options-[Sign'-in last interactive user automatically after a system'-initiated restart]'	No	Yes	No
Notifications-[Turn off toast notifications on the lock screen]	No	Yes	No
Disabling the built-in Administrator account or changing its user name	Yes	Yes	No
HDD password function by BIOS	No	No	Yes
Disabling Shared experiences	No	No	Yes
Enabling SMB signing	Yes	No	No
Prevent illegal dll from loading	Yes	No	No

Table 1.2-2 Security Measures and Handled Threats - IT security version 1.0

Security measure	Threat handled		
	[1]	[2]	[3]
Access control	Yes	Yes	No
Personal firewall tuning	Yes	No	No
Stopping unused Windows services	Yes	No	No

Security measure	Threat handled		
	[1]	[2]	[3]
Disabling the built-in Administrator account or changing its user name	Yes	Yes	No
Hiding the last logon user name	Yes	Yes	No
Applying the software restriction policies	Yes	Yes	No
Applying AutoRun restrictions	No	Yes	No
Applying the StorageDevicePolicies function	No	Yes	Yes
Disabling USB storage devices	No	Yes	Yes
Disabling NetBIOS over TCP/IP	Yes	No	No
Changing the LAN Manager authentication level	Yes	No	No
Applying the password policy	Yes	Yes	No
Applying the audit policy	Yes	Yes	No
Applying the account lockout policy	Yes	Yes	No
HDD password function by BIOS	No	No	Yes
Disabling Shared experiences	No	No	Yes
Enabling SMB signing	Yes	No	No
Prevent illegal dll from loading	Yes	No	No

2. Security Models

The product provides three types of security models, Legacy model, Standard model, and Strengthened model, according to the required security strength, in order to flexibly accommodate system configuration and operation. Required security measure items are incorporated in the security models.

2.1 Overview of Security Models

This section describes the features of security models and the relationship between security models and their corresponding security measures.

Security Models

The features of the three security models, Legacy model, Standard model, and Strengthened model, are as follows:

- Legacy model
  This model does not strengthen security. Use this model when you connect the system with YOKOGAWA products that do not support security measures.
- Standard model
  This model places importance on operation of the product and collaboration with other systems (Exaopc, CENTUM VP, and so on) and guards against "attacks over the network" and "direct attacks through operation of SENG." The Standard model does not guard against "theft of SENG or data" because this threat is considered not likely to happen to the product.
- Strengthened model
  This model takes all measures against any security treats. If all security measures are taken, operation and so on may be affected. Take measures according to the characteristics of each system for non-mandatory items.

IMPORTANT

Please consult YOKOGAWA if IT security of the Strengthened model is required.

Security Models and Security Measures

As a security measure for ProSafe-RS, the IT Security Tool is provided. Using the IT Security Tool, you can implement security measures on each computer.

If you want to implement consolidated security measures under a domain environment, you can also use the group policy objects (referred to as GPOs in this chapter) provided by YOKOGAWA together.

IMPORTANT

Even if you are intending to implement GPO file based security measures, you must configure the security settings by running the IT Security Tool in advance. Note that the security configuration by the GPO file overrides the security configuration by the IT Security Tool.

With security configuration using the IT Security Tool, settings of some security measure items differ, depending on the differences in the IT Security Tool version and the security model. In addition, some security measure items are configured for the purpose to match the product specification rather than to fight against security threats.

SEE ALSO For more information about security measures, refer to:

3., “Details of Security Measures” on page 3-1

For more information about creating a GPO file, refer to:

6.10.1, “Creating Group Policy Objects” on page 6-47

For more information about applying the GPO file, refer to:

6.10.2, “Applying Group Policy Objects to an Organizational Unit” on page 6-49

Security Measures to Fight Against Security Threats

The following table shows the security measure items against security threats and their configuration in IT security version 2.0.

“Defined/Not defined” in the Configuration by GPO file column indicates whether the security measure item is defined to be configured in the GPO file that is created based on the group policy provided by YOKOGAWA.

- Defined
  The security measure, which is adopted by YOKOGAWA, is defined in the GPO file.
- Not defined
  The security measure is not defined in the GPO file.

“Applied/Not applied” in the Configuration by IT Security Tool column indicates whether the security measure item is configured by the IT Security Tool, applying the predefined setting, for each security model.

- Applied
  The security measure, which is adopted by YOKOGAWA, is configured by the IT Security Tool so that it is applied.
- Not applied
  Because YOKOGAWA decided not to adopt the security measure, it is configured by the IT Security Tool so as not to be applied.

TIP The setting values set by the IT Security Tool can be changed by the user for some security measure items and cannot be changed for others. To find out which security measure items can be changed, refer to the appendix.

Table 2.1-1 Security Measures in IT Security Version 2.0

Security measure	Configuration by GPO file	Configuration by IT Security Tool	
		Standard model	Strengthened model
Password Policy-[Minimum password length]	Defined	Not applied	Applied
Password Policy-[Minimum password age]	Defined	Not applied	Applied
Password Policy-[Maximum password age]	Defined	Not applied	Applied
Password Policy-[Enforce password history]	Defined	Not applied	Applied
Disable ‘Password Policy-[Store passwords using reversible encryption]'	Defined	Not applied	Applied
Password Policy-[Password must meet complexity requirements]	Defined	Not applied	Applied
Access control for files and folders (*1)	Not defined	Applied	Applied
Access control for product registry (*1)	Not defined	Applied	Applied
Access control for DCOM (OPC) objects (*1)	Not defined	Applied	Applied

Table 2.1-1 Security Measures in IT Security Version 2.0 (Table continued)

Security measure	Configuration by GPO file	Configuration by IT Security Tool	
		Standard model	Strengthened model
Enabling SMB signing	Not defined	The IT Security Tool does not configure this setting. You must configure it manually.	The IT Security Tool does not configure this setting. You must configure it manually.
Prevent illegal dll from loading	Not defined	Configured by the installer.	Configured by the installer.

*1: This security setting item is not affected by group policy
*2: This setting can be controlled by group policy but can also be configured for each computer using the IT Security Tool.
*3: This setting is for domain controllers.
*4: This setting is not included in the GPO file which is provided for consolidated management using Active Directory because problems may occur on the computer in use depending on the OS and update application status.
*5: If you want to change the setting value in Active Directory-based consolidated management, select either “Enabled” or “Disabled” for this item.
*6: This setting is not included in the GPO file which is provided for consolidated management using Active Directory because the setting differs depending on the OS.

TIP

With IT security version 2.0, different security setting items are configured among stations, file server, and domain controller.

Security Measures to Match the Product Specification

The following table shows the security measure items to match the product specification and their configuration in IT security version 2.0.

“Defined/Not defined” in the Configuration by GPO file column indicates whether the security measure item is defined to be configured in the GPO file that is created based on the group policy provided by YOKOGAWA.

- Defined
  The security measure, which is adopted by YOKOGAWA, is defined in the GPO file.
- Not defined
  The security measure is not defined in the GPO file.

“Applied/Not applied” in the Configuration by IT Security Tool column indicates whether the security measure item is configured by the IT Security Tool, applying the predefined setting, for each security model.

- Applied
  The security measure, which is adopted by YOKOGAWA, is configured by the IT Security Tool so that it is applied.
- Not applied
  Because YOKOGAWA decided not to adopt the security measure, it is configured by the IT Security Tool so as not to be applied.

Table 2.1-2 Security Measures Configured to Match the Product Specification in IT Security Version 2.0

Security measure	Configuration by GPO file	Configuration by IT Security Tool	
		Standard model	Strengthened model
User Rights Assignment-[Create global objects]	Not defined	Applied	Applied
User Rights Assignment-[Log on as a batch job]	Not defined	Applied	Applied

Continues on the next page

Table 2.1-2 Security Measures Configured to Match the Product Specification in IT Security Version 2.0 (Table continued)

Security measure	Configuration by GPO file	Configuration by IT Security Tool	
		Standard model	Strengthened model
User Rights Assignment-[Log on as a service]	Not defined	Applied	Applied
[MSS: (AutoReboot) Allow Windows to automatically restart after a system crash (recommended except for highly secure environments)]	Not defined	Applied	Applied
Security Options-[Network access: Let Everyone permissions apply to anonymous users]	Not defined	Applied	Applied
Security Options-[Network security: Do not store LAN Manager hash value on next password change]	Not defined	Applied	Applied
Advanced Audit Policy Configuration-[Audit RPC Events]	Defined	Applied	Applied
Advanced Audit Policy Configuration-[Audit Application Generated]	Defined	Applied	Applied
Disable 'Audit Process Creation-[Include command line in process creation events]'	Defined	Applied	Applied
Internet Communication settings-[Turn off access to the Store]	Defined	Applied	Applied
Video and Display Settings-[Turn Off the Display (On Battery)]	Defined	Applied	Applied
Video and Display Settings-[Turn Off the Display (Plugged In)]	Defined	Applied	Applied
Cloud Content-[Do not show Windows Tips]	Defined	Applied	Applied
Cloud Content-[Turn off Microsoft consumer experiences]	Defined	Applied	Applied
Data Collection and Preview Builds-[Disable pre-release features or settings]	Defined	Applied	Applied
Data Collection and Preview Builds-[Toggle user control over Insider builds]	Defined	Applied	Applied
Disable 'Search-[Allow Cortana]'	Defined	Applied	Applied
Search-[Don't search the web or display web results in Search]	Defined	Applied	Applied
Search-[Don't search the web or display web results in Search over metered connections]	Defined	Applied	Applied
Software Protection Platform-[Turn off KMS Client Online AVS Validation]	Defined	Applied	Applied
Store-[Turn off Automatic Download and Install of updates]	Defined	Applied	Applied
Store-[Turn off Automatic Download of updates on Win8 machines]	Defined	Applied	Applied
Store-[Turn off the offer to update to the latest version of Windows]	Defined	Applied	Applied
Store-[Turn off the Store application]	Defined	Applied	Applied
Windows Defender - [Turn off Windows Defender]	Defined	Applied	Applied
Delivery Optimization - [Download Mode]	(*1)	Applied	Applied

*1: This setting is not included in the GPO file which is provided for consolidated management using Active Directory because the setting differs depending on the OS.

Security Measures to Fight Against Security Threats

The following table shows the security measure items against security threats and their configuration in IT security version 1.0.

“Defined/Not defined” in the Configuration by GPO file column indicates whether the security measure item is defined to be configured in the GPO file that is created based on the group policy provided by YOKOGAWA.

- Defined
  The security measure, which is adopted by YOKOGAWA, is defined in the GPO file.
- Not defined
  The security measure is not defined in the GPO file.

“Applied/Not applied” in the Configuration by IT Security Tool column indicates whether the security measure item is configured by the IT Security Tool, applying the predefined setting, for each security model.

- Applied
  The security measure, which is adopted by YOKOGAWA, is configured by the IT Security Tool so that it is applied.
- Not applied
  Because YOKOGAWA decided not to adopt the security measure, it is configured by the IT Security Tool so as not to be applied.

TIP

The setting values set by the IT Security Tool can be changed by the user for some security measure items and cannot be changed for others. To find out which security measure items can be changed, refer to the appendix.

Table 2.1-3 Security Measures in IT Security Version 1.0

Security measure	Configuration by GPO file	Configuration by IT Security Tool		
		Legacy model	Standard model	Strengthened model
Access control (*1)	Not defined	Not defined	Applied	Applied
Personal firewall tuning	Not defined	Not applied	Applied	Applied
Stopping unused Windows services	Not defined	Not applied	Not applied	Applied
Disabling the built-in Administrator account or changing its user name	Not defined	Not applied	Not applied	The IT Security Tool does not configure this setting. You must configure it manually.
Hiding the Last Logon User Name	Defined	Applied	Applied	Applied
Applying the software restriction policies	Not defined	Not applied	Applied	Applied
Applying AutoRun restrictions	Defined	Applied	Applied	Applied
Applying the StorageDevicePolicies function	Defined	Not applied	Applied	Applied
Disabling USB storage devices	Defined	Not applied	Applied	Applied
Disabling NetBIOS over TCP/IP (*1)	Not defined	Not applied	Applied	Applied
Changing the LAN Manager authentication level	Defined	Not applied	Applied	Applied
Applying the password policy	Defined	Not applied	Not applied	Applied
Applying the audit policy	Defined (*2)	Not applied	Not applied	Applied
Applying the account lockout policy	Defined	Not applied	Not applied	Applied

Table 2.1-3 Security Measures in IT Security Version 1.0 (Table continued)

Security measure	Configuration by GPO file	Configuration by IT Security Tool		
		Legacy model	Standard model	Strengthened model
HDD password function by BIOS (*1)	Not defined	Not applied	Not applied	The IT Security Tool does not configure this setting. You must configure it manually.
Disabling Shared experiences	(*3)	Applied	Applied	Applied
Enabling SMB signing	Not defined	Not applied	The IT Security Tool does not configure this setting. You must configure it manually.	The IT Security Tool does not configure this setting. You must configure it manually.
Prevent illegal dll from loading	Not defined	Configured by the installer.	Configured by the installer.	Configured by the installer.

*1: This security setting item is not affected by group policy
*2: "Audit object access" is not included in the GPO file which is provided for consolidated management using Active Directory.
*3: This setting is not included in the GPO file which is provided for consolidated management using Active Directory because the setting differs depending on the OS.

Security Measures to Match the Product Specification

The following table shows the security measure items to match the product specification and their configuration in IT security version 1.0.

"Defined/Not defined" in the Configuration by GPO file column indicates whether the security measure item is defined to be configured in the GPO file that is created based on the group policy provided by YOKOGAWA.

- Defined
  The security measure, which is adopted by YOKOGAWA, is defined in the GPO file.
- Not defined
  The security measure is not defined in the GPO file.

"Applied/Not applied" in the Configuration by IT Security Tool column indicates whether the security measure item is configured by the IT Security Tool, applying the predefined setting, for each security model.

- Applied
  The security measure, which is adopted by YOKOGAWA, is configured by the IT Security Tool so that it is applied.
- Not applied
  Because YOKOGAWA decided not to adopt the security measure, it is configured by the IT Security Tool so as not to be applied.

Table 2.1-4 Security Measures Configured to Match the Product Specification in IT Security Version 1.0

Security measure	Configuration by GPO file	Configuration by IT Security Tool		
		Legacy model	Standard model	Strengthened model
Windows Defender - [Turn off Windows Defender]	Defined	Applied	Applied	Applied
Delivery Optimization - [Download Mode]	(*1)	Applied	Applied	Applied

*1: This setting is not included in the GPO file which is provided for consolidated management using Active Directory because the setting differs depending on the OS.

2.2 User/Group Management

This section describes the relationship between Windows user management types and the product. Access control is set for each user group explained in this section.

2.2.1 User Management Methods

Windows provides two methods of managing users: standalone management and domain management.

This product provides four methods of managing users: standalone management, domain management, combination management, and linked domain management. The following table shows the required configuration, operation, and feature of the user management methods for this product.

Table 2.2.1-1 User Management Methods

User management type	Required configuration	Operation	Feature
Standalone management	Configuration of the system built up with the product only.	Operated by registering user accounts used in each of all SENGs.	• Simple configuration not requiring domain controller. • Since account management is required for each PC, all PCs must be maintained at user account maintenance, making this method not suited for large-scale systems.
Domain management	Construction of domain controller is required in addition to the system built up with the product.	Operated by registering user accounts used to the domain controller.	Centralized management of users is possible, resulting in fewer human errors.
Combination management	Construction of domain controller is required in addition to the system built up with the product.	Operated the same way as for the domain management in normal operation.	Even if a domain controller is not available, continuous operation is possible by managing accounts of each computer.
Linked domain management	Construction of domain controller is required in addition to the system built up with the product.	Operated the same way as for the domain management in normal operation.	• Even if a domain controller is not available, continuous operation is possible by managing accounts of each computer. • IT security can be configured in two stages, before and after building the domain environment. (*1)

*1: After applying IT security of standalone management and joining the computer to the domain, add the corresponding domain groups to the members of the local groups for the products installed on the computer.

TIP

- The combination management and the linked domain management have the convenience that domain users or local users can access this product depending on the situation. A domain user can perform normal operation of the system configured with this product, and a local user can also perform system configuration and maintenance for each computer. Note that the domain user account is created by the domain administrator, and the local user account is created by the administrator of the computer on which this product is installed.
- The linked domain management is recommended when installing new software for this product because it is convenient to easily migrate from stand-alone management after adding to the domain. The domain management or the combination management is recommended when upgrading or performing additional installation without changing the management method.

2.2.2 User Authentication Modes

When the Access Control and Operation History Management package is used, two user authentication modes, Windows authentication and ProSafe authentication, are available in a ProSafe-RS system. These modes are called user authentication modes.

- Windows authentication mode
  Users are authenticated using Windows functions.
- ProSafe authentication mode
  Users are authenticated using specific functions of ProSafe-RS.

SEE ALSO For more information about user authentication mode setting, refer to:

- "■ ProSafe authentication mode and Windows authentication mode" in E2.1.1, "Overview of access control for engineers" in Engineer's Reference Manual (IM 32P04B10-01EN)
- "■ Specifying the user authentication mode" in E2.2.1, "Settings for access control" in Engineer's Reference Manual (IM 32P04B10-01EN)

2.2.3 User/Group Management

Users and groups are described as follows:

Combination of User Management and Security Model for Windows

Five types of method for creating a user/group are available, depending on the combination of the Windows user management and the security model.

- Type 1: Legacy Model
- Type 2: Standard Model / Strengthened Model - Standalone Management
- Type 3: Standard Model / Strengthened Model - Domain Management
- Type 4: Standard Model / Strengthened Model - Combination Management
- Type 5: Standard Model / Strengthened Model - Linked Domain Management

TIP

No matter what security model is applied, the ProSafe-RS installer creates a PSF_MAINTENANCE group and add the user who installed the ProSafe-RS software as a member of this group. Moreover, if domain management type, combination management type, or linked domain management type is used for user management, the PSF_MAINTENANCE group in the domain should be used.

IMPORTANT

When you create users or groups, do not use the following group names, which are reserved by the ProSafe-RS system:

- ADS_SERVICE
- ADS_SERVICE_LCL

IMPORTANT

- The initial password is set by default for the following predefined user accounts in this product. Be sure to change the password because operating with the initial password may increase the security risk.
  - PSF_PROCESS
  - LIC_PROCESS
  - ADS_PROCESS
  - CTM_PROCESS
  - ADS_AGENT
- The password for the above user accounts is reset to the default password when this product is installed for upgrading its version or revision. Be sure to change the password before operating. The password is not reset to the default password by configuring with the IT Security Tool.
- To change the password of the user account, use the utilities described in SEE ALSO at the end of this topic.

SEE ALSO For more information about changing the password of a user account, refer to:

6.11, “Other Utility Programs” on page 6-51

For more information about security of AD projects, refer to:

C1.2.2, “Controlling access to AD projects” in Engineer's Reference Manual (IM 32P04B10-01EN)

For more information about changing the password of CTM_PROCESS, refer to:

6.11., “Other Utility Programs” in CENTUM VP Security Guide (IM 33J01C30-01EN)

Type 1: Legacy Model

After running the IT Security Tool, the following users and user groups will be automatically created.

Table 2.2.3-1 Legacy Model

User name/group name	Type	Created location	Member of	Explanation
LIC_PROCESS	User	Local PC	Users	User account for running license management processes (Windows services) that does not have Windows logon rights.
EXAUSER (*1)	User	Local PC	Users	User account for running the SCS SOE OPC server that does not have Windows logon rights.
ADS_PROCESS	User	Local PC	Users	User account for running Automation Design Server processes (Windows services) that does not have Windows logon rights.
CTM_PROCESS	User	Local PC	Users	User account that is created on a computer with the license for the Engineering Server Function and used when backing up a project. This user account does not have Windows logon rights.
ADS_AGENT	User	Local PC	• Users • Performance Monitor Users	User account for running station information management processes that does not have Windows logon rights.

*1: EXAUSER is used only in the Legacy model and thus the password change procedure is not provided.

IMPORTANT

Use these user accounts only for running ProSafe-RS products.

SEE ALSO For more information about Automation Design Server, refer to:

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

Type 2: Standard Model/Strengthened Model - Standalone Management

After running the IT Security Tool, the following users and user groups will be automatically created.

Table 2.2.3-2 Standard Model/Strengthened Model - Standalone Management

User name/group name	Type	Created location	Member of	Explanation
PSF_OPERATOR	Group	Local PC	Users (*1)	Group of users for enabling CENTUM VP operators to access ProSafe-RS when the system is integrated with CENTUM VP.
PSF_ENGINEER	Group	Local PC	Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs.
PSF_OPC	Group	Local PC	Users (*1)	Group of users who perform OPC communication with ProSafe-RS.
PSF_MAINTENANCE	Group	Local PC	Administrators (*1)	Group of users who perform system installation and ProSafe-RS maintenance.
PSF_UTL	Group	Local PC	Users (*1)	Group of users who use tools for analyzing ProSafe-RS project data. Safe operation of the tools is ensured because the members of this group cannot write to project folders.
ADS_MANAGER	Group	Local PC	Users (*1)	Group of users who use the Automation Design Suite Administration Tool to manage Automation Design Server.
PSF_PROCESS	User	Local PC	Users	User account for running ProSafe-RS processes (Windows services) that does not have Windows logon rights.
LIC_PROCESS	User	Local PC	Users	User account for running license management processes (Windows services) that does not have Windows logon rights.
ADS_PROCESS	User	Local PC	Users	User account for running Automation Design Server processes (Windows services) that does not have Windows logon rights.
CTM_PROCESS	User	Local PC	Users	User account that is created on a computer with the license for the Engineering Server Function and used when backing up a project. This user account does not have Windows logon rights.
ADS_AGENT	User	Local PC	• Users • Performance Monitor Users • PSF_OPC	User account for running station information management processes that does not have Windows logon rights.

*1: You need to add the users who belong to the created group to the group shown in the “Member of” column.

IMPORTANT

- Use these user accounts and groups only for running ProSafe-RS products.
- If you change the security model, existing user groups may be deleted or their names may be modified without confirmation.

SEE ALSO For more information about Automation Design Server, refer to:

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

Type 3: Standard Model/Strengthened Model - Domain Management

After running the IT Security Tool, the following users and user groups will be automatically created.

Table 2.2.3-3 Standard Model/Strengthened Model - Domain Management

User name/group name	Type	Created location	Member of	Explanation
PSF_OPERATOR	Group	Domain controller	Domain Users (*1)	Group of users for enabling CENTUM VP operators to access ProSafe-RS when the system is integrated with CENTUM VP.
PSF_ENGINEER	Group	Domain controller	Domain Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs.
PSF_OPC	Group	Domain controller	Domain Users (*1)	Group of users who perform OPC communication with ProSafe-RS.
PSF_OPC_LCL	Group	Local PC	Users (*1)	Supplementary group of users with the same rights as PSF_OPC but do not support Domain management, such as users embedded in the EXA package. This group is not used in normal operations.
PSF_MAINTENANCE	Group	Domain controller	Domain Admins (*1)	Group of users who perform system installation and ProSafe-RS maintenance.
PSF_MAINTENANCE_LCL	Group	Local PC	Administrators (*1)	Group of users with the same rights as PSF_MAINTENANCE that is used only for emergency situations when the domain environment is abnormal. This group is not used in normal operations. The user who installed the ProSafe-RS software becomes a member of this group.
PSF_UTL	Group	Local PC	Users (*1)	Group of users who use tools for analyzing ProSafe-RS project data. Safe operation of the tools is ensured because the members of this group cannot write to project folders.
ADS_MANAGER	Group	Domain controller	Domain Users (*1)	Group of users who use the Automation Design Suite Administration Tool to manage Automation Design Server.
PSF_PROCESS	User	Local PC	Users	User account for running ProSafe-RS processes (Windows services) that does not have Windows logon rights.

Table 2.2.3-3 Standard Model/Strengthened Model - Domain Management (Table continued)

User name/group name	Type	Created location	Member of	Explanation
LIC_PROCESS	User	Local PC	Users	User account for running license management processes (Windows services) that does not have Windows logon rights.
ADS_PROCESS	User	Local PC	Users	User account for running Automation Design Server processes (Windows services) that does not have Windows logon rights.
CTM_PROCESS	User	Local PC	Users	User account that is created on a computer with the license for the Engineering Server Function and used when backing up a project. This user account does not have Windows logon rights.
ADS_AGENT	User	Local PC	• Users • Performance Monitor Users • PSF_OPC_LCL	User account for running station information management processes that does not have Windows logon rights.

*1: You need to add the users who belong to the created group to the group shown in the “Member of” column.

IMPORTANT

- Use these user accounts and groups only for running ProSafe-RS products.
- If you change the security model, existing user groups may be deleted or their names may be modified without confirmation.

SEE ALSO

For more information about Automation Design Server, refer to:

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

Type 4: Standard Model/Strengthened Model - Combination Management

After running the IT Security Tool, the following users and user groups will be automatically created.

Table 2.2.3-4 Standard Model/Strengthened Model - Combination Management

User name/group name	Type	Created location	Member of	Explanation
PSF_OPERATOR	Group	Domain controller	Domain Users (*1)	Group of users for enabling CENTUM VP operators to access ProSafe-RS when the system is integrated with CENTUM VP.
PSF_OPERATOR_LCL	Group	Local PC	Users (*1)	Group of users for operators that is used in a PC where standalone management is performed.

Continues on the next page

Table 2.2.3-4 Standard Model/Strengthened Model - Combination Management (Table continued)

User name/group name	Type	Created location	Member of	Explanation
PSF_ENGINEER	Group	Domain controller	Domain Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs.
PSF_ENGINEER_LCL	Group	Local PC	Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs. This group is used in a PC where standalone management is performed.
PSF_OPC	Group	Domain controller	Domain Users (*1)	Group of users who perform OPC communication with ProSafe-RS.
PSF_OPC_LCL	Group	Local PC	Users (*1)	Supplementary group of users with the same rights as PSF_OPC but do not support Domain management, such as users embedded in the EXA package. This group is not used in normal operations.
PSF_MAINTENANCE	Group	Domain controller	Domain Admins (*1)	Group of users who perform system installation and ProSafe-RS maintenance.
PSF_MAINTENANCE_LCL	Group	Local PC	Administrators (*1)	Group of users with the same rights as PSF_MAINTENANCE that is used only for emergency situations when the domain environment is abnormal. This group is not used in normal operations. The user who installed the ProSafe-RS software becomes a member of this group.
PSF_UTL	Group	Local PC	Users (*1)	Group of users who use tools for analyzing ProSafe-RS project data. Safe operation of the tools is ensured because the members of this group cannot write to project folders.
ADS_MANAGER	Group	Domain controller	Domain Users (*1)	Group of users who use the Automation Design Suite Administration Tool to manage Automation Design Server.
ADS_MANAGER_LCL	Group	Local PC	Users (*1)	Group of users who use the Automation Design Suite Administration Tool on a PC where standalone management is applied to manage Automation Design Server.
PSF_PROCESS	User	Local PC	Users	User account for running ProSafe-RS processes (Windows services) that does not have Windows logon rights.

Continues on the next page

Table 2.2.3-4 Standard Model/Strengthened Model - Combination Management (Table continued)

User name/group name	Type	Created location	Member of	Explanation
LIC_PROCESS	User	Local PC	Users	User account for running license management processes (Windows services) that does not have Windows logon rights.
ADS_PROCESS	User	Local PC	Users	User account for running Automation Design Server processes (Windows services) that does not have Windows logon rights.
CTM_PROCESS	User	Local PC	Users	User account that is created on a computer with the license for the Engineering Server Function and used when backing up a project. This user account does not have Windows logon rights.
ADS_AGENT	User	Local PC	• Users • Performance Monitor Users • PSF_OPC_LCL	User account for running station information management processes that does not have Windows logon rights.

*1: You need to add the users who belong to the created group to the group shown in the “Member of” column.

IMPORTANT

- Use these user accounts and groups only for running ProSafe-RS products.
- If you change the security model, existing user groups may be deleted or their names may be modified without confirmation.

Type 5: Standard Model/Strengthened Model - Linked Domain Management

After applying IT security of standalone management with IT Security Tool, the following users and local computer groups will be automatically created. The domain controller groups shown in the following table must be created in the domain before running Domain Link Management Tool.

Table 2.2.3-5 Standard Model/Strengthened Model - Linked Domain Management

User name/group name	Type	Created location	Member of	Explanation
PSF_OPERATOR	Group	Domain controller	Domain Users (*1)	Group of users for enabling CENTUM VP operators to access ProSafe-RS when the system is integrated with CENTUM VP.

Continues on the next page

Table 2.2.3-5 Standard Model/Strengthened Model - Linked Domain Management (Table continued)

User name/group name	Type	Created location	Member of	Explanation
PSF_OPERATOR	Group	Local computer	Users (*1)	Group of users for operators that is used in a computer where standalone management is performed.
PSF_ENGINEER	Group	Domain controller	Domain Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs.
PSF_ENGINEER	Group	Local computer	Users (*1)	Group of users who perform ProSafe-RS system engineering by using SCS Manager and other programs. This group is used in a PC where standalone management is performed.
PSF_OPC	Group	Domain controller	Domain Users (*1)	Group of users who perform OPC communication with ProSafe-RS.
PSF_OPC	Group	Local computer	Users (*1)	Supplementary group for users not supporting domain management, such as users embedded in the EXA package, having the same rights as PSF_OPC created in the domain controller. It is not used in normal operation.
PSF_MAINTENANCE	Group	Domain controller	Domain Admins (*1)	Group of users who perform system installation and ProSafe-RS maintenance.
PSF_MAINTENANCE	Group	Local computer	Administrators (*1)	Emergency group used when the domain environment has problems, having the same rights as PSF_MAINTENANCE created in the domain controller. It is not used in normal operation. The user who installed the ProSafe-RS software becomes a member of this group.
PSF_UTL	Group	Local computer	Users (*1)	Group of users who use tools for analyzing ProSafe-RS project data. Safe operation of the tools is ensured because the members of this group cannot write to project folders.
ADS_MANAGER	Group	Domain controller	Domain Users (*1)	Group of users who use the Automation Design Suite Administration Tool to manage Automation Design Server.
ADS_MANAGER	Group	Local computer	Users (*1)	Group of users who use the Automation Design Suite Administration Tool on a PC where standalone management is applied to manage Automation Design Server.

Continues on the next page

Table 2.2.3-5 Standard Model/Strengthened Model - Linked Domain Management (Table continued)

User name/group name	Type	Created location	Member of	Explanation
PSF_PROCESS	User	Local computer	Users	User account for running ProSafe-RS processes (Windows services) that does not have Windows logon rights.
LIC_PROCESS	User	Local computer	Users	User account for running license management processes (Windows services) that does not have Windows logon rights.
ADS_PROCESS	User	Local computer	Users	User account for running Automation Design Server processes (Windows services) that does not have Windows logon rights.
CTM_PROCESS	User	Local computer	Users	User account that is created on a computer with the license for the Engineering Server Function and used when backing up a project. This user account does not have Windows logon rights.
ADS_AGENT	User	Local computer	• Users • Performance Monitor Users • PSF_OPC	User account for running station information management processes that does not have Windows logon rights.

*1: You need to add the users who belong to the created group to the group shown in the “Member of” column.

IMPORTANT

- Use these user accounts and groups only for running ProSafe-RS products.
- If you change the security model, existing user groups may be deleted or their names may be modified without confirmation.

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

The Users and User Groups Added by the Vnet/IP Interface Package

When Vnet/IP Interface Package is installed, the users and user groups in the following table are automatically created.

The users and user groups other than LIC_PROCESS are used only for Vnet/IP Interface Package. They do not affect the ProSafe-RS software.

Table 2.2.3-6 Added Users and Groups

User name/group name	Type	Created location	Member of	Explanation
VNT_ALL	Group	Local PC	-	Group of users who can read/write in the directory of Vnet/IP Interface Package Do not include the users who can sign-in to Windows in this group.
VNT_ VNET_VVIF	Group	Local PC	-	Group of users for running the processes (like Windows services) of Vnet/IP Interface Package. Do not include the users who can sign-in to Windows in this group.
VNT_NVP_ CMDIF	Group	Local PC	-	
VNT_NVP_MNGIF	Group	Local PC	-	
VNT_COMMON	User	Local PC	VNT_ALL	Users who can read/write in the directory of Vnet/IP Interface Package. Windows sign-in rights are not granted.
VNT_NVP_CORE	User	Local PC	• VNT_VNET_VVIF • VNT_NVP_CMDIF • VNT_NVP_MNGIF • VNT_ALL • Performance Monitor Users	Users for running the processes (like Windows services) of Vnet/IP Interface Package. Windows sign-in rights are not granted.
VNT_BKNET	User	Local PC	• VNT_VNET_VVIF • VNT_NVP_MNGIF • VNT_ALL	
LIC_PROCESS	User	Local PC	• VNT_ALL • Users	LIC_PROCESS is a common user for products which support License Manager. It is used for accepting licenses. When installing Vnet/IP Interface Package, if LIC_PROCESS is not present, LIC_PROCESS user is created and configured.

IMPORTANT

The users and user groups that are automatically created when Vnet/IP Interface Package is installed are valid only on local PCs. Do not manage the users and user groups in the domain controller. And, do not include the users who can sign-in to Windows in this group.

The users for using iDefine in a virtualization environment

TIS_SERVICE user is necessary for using iDefine in a virtualization environment.

TIS_SERVICE user is reserved as a user to run Dongle Gateway. When the Dongle Gateway which is provided by Trinity Integrated Systems is installed, TIS_SERVICE user is created.

IMPORTANT

- The default initial password is set for the TIS_SERVICE user. Be sure to change the password because operating with the initial password may increase the security risk.
- The password for the TIS_SERVICE user is reset to the default password when Dongle Gateway is installed for upgrading its version or revision. Be sure to change the password before operating. The password is not reset to the default password by configuring with the IT Security Tool.
- To change the password of the TIS_SERVICE user, use the utilities described in SEE ALSO at the end of this topic.

Table 2.2.3-7 Users and Groups

User name/group name	Type	Created location	Member of	Explanation
TIS_SERVICE	User	Local PC	Users	User account for running the Dongle Gateway of iDefine that does not have Windows logon rights.

SEE ALSO For more information about changing the password of a user account, refer to:

6.11, “Other Utility Programs” on page 6-51

3. Details of Security Measures

This section describes the security measures for each security type in detail.

3.1 Access Control

By minimizing the access rights of the users of the product, you can prevent unauthorized access, leakage, tampering, and destruction of important data in the product. Access permissions to files, folders, registries, DCOM modules, and local security policy are controlled by using the Windows access control functions.

Access control is performed for each user or group. Users have only the rights that are granted to them or to the group they belong to.

3.1.1 Access Permissions to Files and Folders

In the product, accesses to files and folders are controlled for each file or folder. Access to files and folders by users is restricted by controlling the permissions to execute, read, write, and delete in user or group units. In the product, access permissions are granted for each folder.

TIP If a file in a folder requires different access permissions, the access permissions for the file can be separately granted.

Target Folders

The following table describes the main target folders with controlled access, showing examples where the system drive is drive C.

Table 3.1.1-1 Target Folders

Name	Target folder	Description
ProSafe-RS folder 1	C:\Program Files (x86)\ProSafe-RS	The folder in which ProSafe-RS programs are installed.
ProSafe-RS folder 2	C:\Program Files (x86)\Yokogawa\IA\iPCS\Products\ProSafe-RS	The folder in which ProSafe-RS programs are installed.
ProSafe-RS folder 3	C:\ProgramData\Yokogawa\IA\iPCS\Products\ProSafe-RS	The folder in which ProSafe-RS data such as log files are stored.
ProgramFiles Platform folder	C:\Program Files (x86)\Yokogawa\IA\iPCS\Platform	The folder in which IT Security Tool, Domain Link Management Tool, and license management programs are installed.
AD Suite folder 1	C:\Program Files\Yokogawa\IA\iPCS\Products\ADSuite	The folder in which programs that are related to Automation Design Server are installed.
AD Suite folder 2	C:\Program Files (x86)\Yokogawa\IA\iPCS\Products\ADSuite	The folder in which programs that are related to Automation Design Server are installed.
ADMDB folder	C:\ProgramData\Yokogawa\IA\iPCS\Products\ChronusENG	The folder in which data that are related to Automation Design Server are installed.
ProgramData Platform folder	C:\ProgramData\Yokogawa\IA\iPCS\Platform	The folder in which data files such as the setting files for IT Security Tool and license management data files are installed.
iDefine folder 1	C:\Program Files (x86)\Trinity Integrated Systems\iDefine x.xx.x Yokogawa	The folder in which iDefine-related programs are installed. The folder shown in the left column is the default setting (x.xx.x is the version number of iDefine). You can specify a different folder at installation.
iDefine folder 2	C:\Program Files (x86)\Common Files\Aladdin Shared	The folder in which iDefine-related programs are installed.
PROFINET Configurator folder 1	C:\Program Files (x86)\Yokogawa\PROFIBUS_Configurator	The folder in which PROFINET Configurator is installed.
PROFINET Configurator folder 2	C:\Program Files (x86)\Common Files\Hilscher	The folder for use by PROFINET Configurator.
PROFINET Configurator folder 3	C:\Program Files (x86)\Common Files\Hilscher GmbH	The folder for use by PROFINET Configurator.
PROFINET Configurator folder 4	C:\ProgramData\Yokogawa\SYCONnet	The folder in which PROFINET Configurator data files are stored.
Station information checking function folder 1	C:\Program Files\Yokogawa\IA\iPCS\Products\CIMAgent	The folder in which programs related to station information management processes are installed.

Continues on the next page

Table 3.1.1-1 Target Folders (Table continued)

Name	Target folder	Description
Station information checking function folder 2	C:\ProgramData\Yokogawa\IA\iPCS\Products\CIMAgent	The folder in which data related to station information management processes is installed.
Windows folder	C:\Windows\system32	The folder in which Windows maintenance tools are installed.(*1)
Project Data folder	The folder for storing ProSafe-RS project files.	The folder to which a share name, RS-Projects, is assigned. Note: You can assign the share name only to a user-created folder. Do not assign to a folder created by the installer or ProSafe-RS system. Exceptionally, however, you can assign the share name to the C:\RS-Projects folder.
RS-Share folder	The folder for storing data shared by ProSafe-RS stations.	The folder to which a share name, RS-Share, is assigned. Note: You can assign the share name only to a user-created folder. Do not assign to a folder created by the installer or ProSafe-RS system.
ForcedIO folder	The folder for storing data of Forced I/O Viewer function	The folder to which a share name, RS-ForcedIO, is assigned.
iDefine project folder	The folder for storing iDefine projects shared by ProSafe-RS stations.	The folder to which a share name, iDefineProjects, is assigned. Note: Assign the share name iDefineProjects to the C:\iDefineProjects folder, which is created by the iDefine installer. If you want to place the iDefine project folder in a different location, create a folder and assign the share name iDefineProjects. Do not assign the share name to a folder created by the ProSafe-RS installer or ProSafe-RS system.
VnetIPSoftStack folder 1	C:\ProgramData\Yokogawa\IA\iPCS\Products\AccessRef\VnetIPSoftStack	The folder in which Vnet/IP Interface Package related files and data are stored.
VnetIPSoftStack folder 2	C:\Program Files\Yokogawa\IA\iPCS\Platform\VnetIPSoftStack	The folder in which Vnet/IP Interface Package related files and data are stored.
VnetIPSoftStack folder 3	C:\ProgramData\Yokogawa\IA\iPCS\Platform\VnetIPSoftStack	The folder in which Vnet/IP Interface Package related files and data are stored.

*1: Access permissions are set for certain files in the folder.

Access Permissions to Programs

Functions that each user can use are restricted by setting access permissions to each ProSafe-RS function (program) for each user or group.

The following table shows the access permissions to run programs registered in the Start menu that are granted to each user and group . Only the users or users of a group to which the access permission is granted can run the program.

Table 3.1.1-2 Access Permissions to Programs that are Started from the Start Menu

Items on Start Menu	User/group (*1)										
	[1]	[2]	[3]	[4]	[5]	[6] (*2)	[7]	[8]	[9]	[10]	[11]

*1: User/Group
[1]: PSF_OPERATOR/PSF_OPERATOR_LCL
[2]: PSF_ENGINEER/PSF_ENGINEER_LCL
[3]: LIC_PROCESS
[4]: PSF_OPC/PSF_OPC_LCL
[5]: PSF_MAINTENANCE/PSF_MAINTENANCE_LCL
[6]: PSF_PROCESS
[7]: PSF_UTL
[8]: Local System Account (System account for programs used by Windows)
[9]: ADS_MANAGER/ADS_MANAGER_LCL
[10]: ADS_PROCESS
[11]: CTM_PROCESS/ADS_AGENT
*2: The PSF_PROCESS user cannot start programs from the start menu because it is not a logon user.
*3: SCS simulator can be started only by the built-in Administrator account.
*4: The customer cannot use this tool.
*5: The Vnet/IP interface management tool starts. Access permission is set for the Administrators group, Users group, and VNT_ALL group, and users who belong to Administrators group and Users group can be executed. The users in the Administrators group can configure the Vnet station address and monitor the Vnet/IP interface package. Other users can only monitor the Vnet/IP interface package.

IMPORTANT

The users of PSF_MAINTENANCE and PSF_MAINTENANCE_LCL belonging to the Administrators group cannot start SCS simulator. However, the built-in Administrator account user is an exception, and can start SCS simulator.

3.1.2 Package Configuration and Users/Groups

You can control access rights of each user and group for the folders related to the installed packages to prevent tampering and destruction of the installed modules.

Access Permissions to Package Folders

The following table shows the types of access permissions to package folders.

Table 3.1.2-1 Types of Access Permissions to Package Folders

Package-related folder	Target folder	User/group (*1)											
		[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]	[12]
ProSafe-RS folder 1	The folder in which ProSafe-RS programs are installed <ProgramFiles32>\ProSafe-RS	RW	RW	-	RW	RWD	RW	R	RWD	R	-	-	-
ProSafe-RS folder 2	The folder in which ProSafe-RS programs are installed <ProgramFiles32>\Yokogawa\IA\iPCS\Products\ProSafe-RS	R	R	-	R	RWD	R	R	RWD	-	-	-	-
ProSafe-RS folder 3	The folder in which ProSafe-RS data such as log files are stored <ProgramData>\Yokogawa\IA\iPCS\Products\ProSafe-RS	R	R	-	R	RWDP	R	R	RWD	-	-	-	-
Project Data folder	The folder in which project data are saved (Share name "RS-Projects" is assigned)	RWD	RWD	RWD	RWD	RWD	RWD	R	RWD	-	-	-	-
RS-Share folder	The folder in which data of the Access Control and Operation History Management Package or data managed by Version Control Tool are saved (Share name "RS-Share" is assigned)	RWD	RWD	RWD	RWD	RWD	RWD	R	RWD	-	-	-	-

[4]: PSF_OPC/PSF_OPC_LCL
[5]: PSF_MAINTENANCE/PSF_MAINTENANCE_LCL
[6]: PSF_PROCESS
[7]: PSF_UTL
[8]: Local System Account (System account for executing programs used by Windows)
[9]: ADS_MANAGER/ADS_MANAGER_LCL
[10]: ADS_PROCESS
[11]: CTM_PROCESS
[12]: ADS_AGENT
Types of access permission

F:Full access control
R: Read files and view a list of folder details
X: Read and execute
W: Write
D: Delete
P: Change permissions (rights to set and change access permissions to files and registries)
C: Change access permission
-: No permission

*2: In addition to the users / groups listed in the table, F is set for the Administrators group, and R is set for the Users group.

*3: Set access permissions for users and groups defined in the Vnet/IP interface package and Windows standard users and groups. User and group access permissions defined for each product are not set. RWXDC is set for the Administrators group, RWX is set for the VNT_ALL group, and RX is set for the User group.

3.1.3 Registry Configuration and User/Group

You can control access to the registries used by ProSafe-RS to prevent tampering and destruction of them.

Access Permissions to Registries

The following table shows the types of permissions to the registry keys corresponding the target registries.

With ProSafe-RS software release number R3.01 or later, only a read permission is granted to Everyone of the user or group that can access the registries.

Table 3.1.3-1 Types of Access Permissions to Registries

Registry key	User/group (*1)											
	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]	[12]
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\EXA (*2)	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\EXAOPC (*2)	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\PKGCOM (*2)	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\PROSAFE-RS	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\VHFD (*2)	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA Prosafe	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Alter sys	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Trinity Integrated Systems\iDefine for Yokogawa	R	R	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Aladdin Knowledge Systems	R	R	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Hilscher GmbH	–	F	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\PROFIBUS International	–	F	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\DTMs	–	F	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\GenericSlaveDTM	–	F	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\YOKOGAWA\SyCon_net	–	F	–	–	F	–	–	F	–	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{1229e510-2cd5-11d4-a174-0050da59a2ed}	F	F	F	F	F	F	F	F	F	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{12413-1229e511-2cd5-11d4-a174-0050da59a2ed}	F	F	F	F	F	F	F	F	F	–	–	–
HKEY_LOCAL_MACHINE\SOFTWARE\ODBC (*2)	F	F	F	F	F	F	F	F	R	–	–	–

Continues on the next page

Table 3.1.3-1 Types of Access Permissions to Registries (Table continued)

Registry key	User/group (*1)											
	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]	[12]
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\VLNIC\Config (*2)	F	F	F	F	F	F	F	F	R	–	–	–
HKEY_USERS\DEFAULT\SOFTWARE\YOKOGAWA (*2)	F	F	F	F	F	F	F	F	R	–	–	–

*1: User/group
[1]: PSF_OPERATOR/PSF_OPERATOR_LCL
[2]: PSF_ENGINEER/PSF_ENGINEER_LCL
[3]: LIC_PROCESS
[4]: PSF_OPC/PSF_OPC_LCL
[5]: PSF_MAINTENANCE/PSF_MAINTENANCE_LCL
[6]: PSF_PROCESS
[7]: PSF_UTL
[8]: Local System Account (System account for executing programs used by Windows)
[9]: Everyone
[10]: ADS_MANAGER/ADS_MANAGER_LCL
[11]: ADS_PROCESS
[12]: CTM_PROCESS/ADS_AGENT
Types of access permission
F: Full access control
R: Read
-: No permission

*2: For these registry keys, permissions are added as shown in the table without changing the existing permissions.

3.1.4 DCOM (OPC) and User/Group

Considering software packages (including third party packages) that communicate with ProSafe-RS by using DCOM, you can set access permissions on DCOM applications that perform OPC communication to prevent tampering, destruction, and theft of data through OPC communication.

By running the IT Security Tool, permission settings of local and/or remote access to OPC applications are configured for the following users and groups.

User/group

[1]: PSF_OPERATOR/PSF_OPERATOR_LCL

[2]: PSF_ENGINEER/PSF_ENGINEER_LCL

[4]: PSF_OPC/PSF_OPC_LCL

[5]: PSF_MAINTENANCE/PSF_MAINTENANCE_LCL

[6]: PSF_PROCESS

[7]: PSF_UTL

[8]: ADS_MANAGER/ADS_MANAGER_LCL

[9]: ADS_PROCESS

[10]: CTM_PROCESS

With this configuration, only the users who belong to the user group for OPC communication ([4]: PSF_OPC/PSF_OPC_LCL) are allowed to start such DCOM applications or make connection through the DCOM applications. In addition, port numbers of the ports used by DCOM is restricted.

3.1.5 Local Security and User/Group

The following local security policies, in addition to Windows standard securities, are set for each user and group.

Table 3.1.5-1 Permissions Set as Local Security Policies

Policy	User/group (*1)												
	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]	[12]	[13]
Create global objects	No	No	No	No	No	Yes	No	No	No	No	No	No	No
Debug programs	No	Yes	No	Yes	No	Yes	No	No	No	No	No	No	No
Log on as a batch job	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No
Log on as a service	No	No	Yes	No	No	Yes	No	No	Yes	Yes	Yes	Yes	Yes
Deny log on locally	No	No	Yes	No	No	Yes	No	No	Yes	Yes	Yes	Yes	Yes

*1: User/group
[1]: PSF_OPERATOR/PSF_OPERATOR_LCL
[2]: PSF_ENGINEER/PSF_ENGINEER_LCL
[3]: LIC_PROCESS
[4]: PSF_OPC/PSF_OPC_LCL
[5]: PSF_MAINTENANCE/PSF_MAINTENANCE_LCL
[6]: PSF_PROCESS
[7]: PSF_UTL
[8]: ADS_MANAGER/ADS_MANAGER_LCL
[9]: ADS_PROCESS
[10]: CTM_PROCESS
[11]: ADS_AGENT
[12]: VNT_COMMON, VNT_NVP_CORE, VNT_BKNET
[13]: TIS_SERVICE

3.2 Personal Firewall Tuning

You can minimize connections from networks to the PCs in the system to fight against attacks by unauthorized persons.

Exception Setting Type

Required communication ports are set as exception so that the functions of ProSafe-RS can operate.

The following table describes the exception settings of the personal firewall.

Table 3.2-1 Exception Setting Types

Name	Description
ProSafe-RS related	Communication ports used by ProSafe-RS related programs
Vnet/IP interface package related	Communication ports used by Vnet/IP Interface Package
DCOM Related	Communication ports used by programs using DCOM communication (including OPC communication)
File Sharing Related	Communication ports used by Windows file sharing functions
Windows Related	Communication ports used by Windows functions (excluding file sharing functions)

ProSafe-RS Related Exceptional Settings

The following table lists the ProSafe-RS related exceptional settings.

Table 3.2-2 ProSafe-RS Related Exceptional Settings

Service name/ execution file name	Protocol : port number	Package name	Remarks
RHHMsCacheSvr.exe	UDP: Dynamic allocation	ProSafe-RS station	Message cache server for ProSafe-RS
Yokogawa.IA.iPCS.Platform.License.LicenseManager.Service	TCP:34417	License management function	-
Yokogawa.IA.iPCS.ChronusENG.Services.Service.exe	Can be specified by the user TCP:34473 (default)	Automation Design Server	-
Yokogawa.IA.iPCS.ChronusENG.Client.RS.ExternalTest.TestManager.exe	TCP:34494	iDefine interface package	-
Yokogawa.IA.iPCS.ChronusENG.CIMAgent.exe	Can be specified by the user TCP:34497 (default)	ProSafe-RS station	Not affected by licenses
DongleGateway.exe	Can be specified by the user TCP:34512 (default)	iDefine for ProSafe-RS	Set Firewall exception by using Dongle Gateway Configurator which is placed when Dongle Gateway is installed.

Vnet/IP Interface Package Related Exceptional Settings

The following table lists the Vnet/IP interface package related exceptional settings.

Table 3.2-3 Vnet/IP Interface Package Related Exceptional Settings

Package name	Protocol : port number	Remarks
Vnet/IP interface package	UDP:520 UDP:5313 UDP:9940	Enable sending/receiving in the UDP ports mentioned on the left that are used in the Vnet/IP interface package

DCOM Related Exceptional Settings

The following table lists the DCOM related exceptional settings.

Table 3.2-4 DCOM Related Exceptional Settings

Service name/ execution file name	Protocol : port number	Assumed package name	Remarks
DCOM service	TCP:135	Programs using OPC communication	Required when using OPC communication.
DCOM service	TCP:20501 to 20550	Programs using OPC communication	Required when using OPC communication.

File Sharing Related Exceptional Settings

The following table lists the file sharing related exceptional settings.

Table 3.2-5 File Sharing Related Exceptional Settings

Service name/execution file name	Protocol : port number	Function name	Remarks
Sharing files and printers	TCP:139 UDP:137 UDP:138	NetBIOS	-
Sharing files and printers	TCP:445	Direct Hosting	If NetBIOS is disabled, separate means of name resolution, such as HOSTS file and registration to DNS, is required.
Sharing files and printers	UDP:5355	LLMNR	-

Windows Related Exceptional Settings

The following table lists the Windows related exceptional settings.

Table 3.2-6 Windows Related Exceptional Settings

Service name/execution file name	Protocol : port number	Server/station
Enable ICMP (*1)	ICMP	Domain controller File server ProSafe-RS station
Kerberos Authentication	TCP:88 UDP:88	Domain controller
LDAP(Active Directory)	TCP:389 UDP:389	Domain controller
DNS	TCP:53 UDP:53	Domain controller

Continues on the next page

Table 3.2-6 Windows Related Exceptional Settings (Table continued)

Service name/execution file name	Protocol : port number	Server/station
Network discovery	UDP:137 UDP:138 UDP:5355 UDP:3702 UDP:1900 TCP:2869 TCP:5358 TCP:5357 UDP:3702	ProSafe-RS station

*1: This item may be ICMPv4 or ICMPv6, depending on the OS.

Allow unicast response

Note the following points:

- With IT security version 2.0, the Allow unicast response option is set to “No.”
- Applications that use multicasting or broadcasting cannot receive the response.

Cautions

In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.3 Stopping Unused Window Services

You can reinforce security by stopping unused Windows services to prevent attacks by unauthorized persons. If vulnerabilities of Windows services are abused, user information in the product may be stolen or important data in the product may be leaked, tampered, or destroyed. In the worst case, attackers may steal the domain administrator rights.

Unused Windows Services When IT Security Version 2.0 Is Applied

The following tables show the Windows services that can be stopped when IT security version 2.0 is applied, one table is for SENG and the other is for file servers and domain controllers.

In this manual, whenever Windows 10, Windows Server 2019, or Windows Server 2022 is mentioned in the explanations hereafter, the IoT versions are also included.

Table 3.3-1 Windows Services That can be Stopped on SENG (with IT Security Version 2.0)

Service	Reason	Windows OS (*1)					
		10 2016 LTSB	10 LTSC 2019	10 LTSC 2021	WS 2016	WS 2019	WS 2022
Delivery Optimization	Unnecessary in the product	Yes (*2)	N/A (*3)	N/A (*3)	–	N/A (*3)	N/A (*3)
Computer Browser	Unnecessary in the product	Yes (*4)	–	–	Yes (*5)	–	–
DHCP Client	Unnecessary because the product does not use DHCP services.	No	No	No	No	No	No
Diagnostic Policy Service	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
Connected User Experience and Telemetry	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
dmwappushsvc	Unnecessary in the product	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*5)	Yes (*5)
Downloaded Maps Manager	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*5)	Yes (*5)
IP Helper	Not required because IPv6 is not used in the ProSafe-RS system.	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
IPsec Policy Agent	Not required because the product does not use IPsec-encrypted communication.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
Offline Files	Not required because the product does not use offline services.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*5)	Yes (*5)	Yes (*5)
Program Compatibility Assistant Service	Unnecessary in the product	Yes (*2)	Yes (*4)	Yes (*4)	Yes (*2)	Yes (*4)	Yes (*6)
Remote Registry	Not required because this feature is not used.	Yes (*5)	Yes (*5)	Yes (*5)	Yes (*2)	Yes (*2)	Yes (*2)
Secondary Logon	Not required because this feature is not used.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
Shell Hardware Detection	Not required because this feature is not used.	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)

Continues on the next page

Table 3.3-1 Windows Services That can be Stopped on SENG (with IT Security Version 2.0) (Table continued)

Service	Reason	Windows OS (*1)					
		10 2016 LTSB	10 LTSC 2019	10 LTSC 2021	WS 2016	WS 2019	WS 2022
Themes	Not required because this feature is not used.	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
WebClient	Not required because this feature is not used.	Yes (*4)	Yes (*4)	Yes (*4)	–	–	–
Windows Error Reporting Service	Not required because this feature is not used.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
Windows Push Notifications System Service		Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)

*1: 10 2016 LTSB: Windows 10 Enterprise 2016 LTSB
10 LTSC 2019: Windows 10 Enterprise LTSC 2019
10 LTSC 2021: Windows 10 Enterprise LTSC 2021
WS 2016: Windows Server 2016
WS 2019: Windows Server 2019
WS 2022: Windows Server 2022
Yes: Services that can be stopped
No: Service that must not be stopped
–: Services that do not exist in the OS

*2: Because the Startup type for the Windows service is set to Automatic with the initial OS setting, the Startup type is changed to Disabled by the IT Security Tool.

*3: On the following OS, this service cannot be disabled.
- Windows 10 Enterprise LTSC 2019
- Windows 10 Enterprise LTSC 2021
- Windows Server 2019
- Windows Server 2022

Therefore, as a countermeasure, Windows Update Delivery Optimization prevents updates and applications from being sent or received between the computer in use and the computer on the network.

*4: Because the Startup type for the Windows service is set to Manual with the initial OS setting, the IT Security Tool does not change this setting.

*5: Because the Startup type for the Windows service is set to Disabled with the initial OS setting, the IT Security Tool does not change this setting.

*6: Because the Startup type for the Windows service is set to “Manual” in the initial OS setting, but when the modules required for this product are installed, the Startup type changes to “Automatic”, it is changed to “Disabled” by the IT Security Tool.

Table 3.3-2 Windows Services That can be Stopped on a File Server and Domain Controller (with IT Security Version 2.0)

Service	Reason	Windows OS (*1)		
		WS 2016	WS 2019	WS 2022
DHCP Client	Unnecessary in the product	No	No	No
Diagnostic Policy Service	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)
Connected User Experiences and Telemetry	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)
dmwappushsvc	Unnecessary in the product	Yes (*3)	Yes (*4)	Yes (*4)
Downloaded Maps Manager	Unnecessary in the product	Yes (*2)	Yes (*4)	Yes (*4)
IP Helper	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)
IPsec Policy Agent	Unnecessary in the product	Yes (*3)	Yes (*3)	Yes (*3)
Offline Files	Unnecessary in the product	Yes (*4)	Yes (*4)	Yes (*4)
Program Compatibility Assistant Service	Unnecessary in the product	Yes (*2)	Yes (*3)	Yes (*5)
Remote Registry	Not required because this feature is not used.	Yes (*2)	Yes (*2)	Yes (*2)
Shell Hardware Detection	Not required because this feature is not used.	Yes (*2)	Yes (*2)	Yes (*2)

Continues on the next page

Table 3.3-2 Windows Services That can be Stopped on a File Server and Domain Controller (with IT Security Version 2.0) (Table continued)

Service	Reason	Windows OS (*1)		
		WS 2016	WS 2019	WS 2022
Windows Error Reporting Service	Unnecessary in the product	Yes (*3)	Yes (*3)	Yes (*3)
Windows Push Notifications System Service		Yes (*2)	Yes (*2)	Yes (*2)

*1: WS 2016: Windows Server 2016
WS 2019: Windows Server 2019
WS 2022: Windows Server 2022
Yes: Services that can be stopped
No: Service that must not be stopped
–: Services that do not exist in the OS
*2: Because the Startup type for the Windows service is set to Automatic with the initial OS setting, the Startup type is changed to Disabled by the IT Security Tool.
*3: Because the Startup type for the Windows service is set to Manual with the initial OS setting, the IT Security Tool does not change this setting.
*4: Because the Startup type for the Windows service is set to Disabled with the initial OS setting, the IT Security Tool does not change this setting.
*5: Because the Startup type for the Windows service is set to “Manual” in the initial OS setting, but when the modules required for this product are installed, the Startup type changes to “Automatic”, it is changed to “Disabled” by the IT Security Tool.

Unused Windows Services When IT Security Version 1.0 Is Applied

The following tables show the Windows services that can be stopped when IT security version 1.0 is applied.

Table 3.3-3 Windows Services That can be Stopped on SENG (with IT Security Version 1.0)

Service	Reason	Windows OS (*1)			
		10 2016 LTSB	10 LTSC 2019/ 10 LTSC 2021	WS 2016	WS 2019/ WS 2022
Computer Browser	Unnecessary in the product	Yes (*2)	–	Yes (*3)	–
DHCP Client	Unnecessary in the product	No	No	No	No
Windows Error Reporting Service	Unnecessary in the product	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
IP Helper	Not required because IPv6 is not used in the ProSafe-RS system.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
IPsec Policy Agent	Not required because the product does not use IPsec-encrypted communication.	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)

Remote Registry	Not required because the functions are not used.	Yes (*3)	Yes (*3)	Yes (*4)	Yes (*4)
Secondary Logon	Not required because the functions are not used.	Yes (*2)	Yes (*2)	Yes (*2)	Yes (*2)
Shell Hardware Detection	Not required because the functions are not used.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
Themes	Not required because the functions are not used.	Yes (*4)	Yes (*4)	Yes (*4)	Yes (*4)
WebClient	Not required because the functions are not used.	Yes (*2)	Yes (*2)	-	–

*1: 10 2016 LTSB: Windows 10 Enterprise 2016 LTSB
10 LTSC 2019: Windows 10 Enterprise LTSC 2019

10 LTSC 2021: Windows 10 Enterprise LTSC 2021
WS 2016: Windows Server 2016
WS 2019: Windows Server 2019
WS 2022: Windows Server 2022
Yes: Services that can be stopped
No: Service that must not be stopped
–: Services that do not exist in the OS

*2: Because the Startup type for the Windows service is set to Manual with the initial OS setting, the IT Security Tool does not change this setting.
*3: Because the Startup type for the Windows service is set to Disabled with the initial OS setting, the IT Security Tool does not change this setting.
*4: Because the Startup type for the Windows service is set to Automatic with the initial OS setting, the Startup type is changed to Disabled by the IT Security Tool.

Table 3.3-4 Windows Services That can be Stopped on a File Server and Domain Controller (with IT Security Version 1.0)

Service	Reason	Windows OS (*1)
		WS 2016/WS 2019/WS 2022
DHCP Client	Unnecessary in the product	No
Windows Error Reporting Service	Unnecessary in the product	Yes (*2)
IP Helper	Unnecessary in the product	Yes (*3)
IPsec Policy Agent	Unnecessary in the product	Yes (*2)
Offline Files	Unnecessary in the product	Yes (*4)
Remote Registry	Not required because the functions are not used.	Yes (*3)
Shell Hardware Detection	Not required because the functions are not used.	Yes (*3)

*1: WS 2016: Windows Server 2016
WS 2019: Windows Server 2019
WS 2022: Windows Server 2022
Yes: Services that can be stopped
No: Service that must not be stopped
–: Services that do not exist in the OS

*2: Because the Startup type for the Windows service is set to Manual with the initial OS setting, the IT Security Tool does not change this setting.
*3: Because the Startup type for the Windows service is set to Automatic with the initial OS setting, the Startup type is changed to Disabled by the IT Security Tool.
*4: Because the Startup type for the Windows service is set to Disabled with the initial OS setting, the IT Security Tool does not change this setting.

Caution

In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.4 IT Environment Settings Common to IT Security Versions 2.0 and 1.0

This section describes the IT environment settings that are common to IT security versions 2.0 and 1.0. There may be cases where it is not possible to implement certain security functions depending on the conditions of the individual systems. For this reason, examine whether implementation is possible for each function before the implementation.

3.4.1 Disabling NetBIOS over TCP/IP

It is recommended to disable NetBIOS because attackers may be able to acquire a list of services running on the target computer and a list of users by using NetBIOS.

Cautions

Keep the following points in mind when disabling NetBIOS over TCP/IP.

- The computer name and station name must be the same.
- The computer name must be resolved by the DNS or HOSTS file.

3.4.2 HDD Password Function by BIOS

This function is provided in most PCs and protects HDD by using the ATA command that controls HDD. In normal BIOS password setting, it is possible to refer to data in HDD by removing the hard disk from a PC and connecting it to another PC. A HDD password locks the HDD itself, and it prohibits reading data even if HDD is removed and connected to another computer. Even if a PC is stolen, there is no fear that important data of the product leaks from the stolen PC. It is impossible to recover the data in the HDD once the HDD password is forgotten, and the password is required to enter when starting the computer. For this reason, this function must be introduced with greatest care.

Please contact the PC manufacturer whether or not this function is provided and how to set the function.

3.5 Group Policy Settings Common to IT Security Versions 2.0 and 1.0

Some group policy setting items are common to IT security versions 2.0 and 1.0. This section describes the common setting items. You also need to check the settings that are specific to each of security versions 2.0 and 1.0.

Because some security functions cannot be applied depending on the circumstances of individual systems, consider whether the functions can be applied to your system before you introduce them.

3.5.1 Disabling the Built-in Administrator Account or Changing its User Name

We recommend that you disable the built-in Administrator account or change its user name because the built-in accounts that are created during the installation of windows are easy targets of password cracking.

Cautions (when Disabling the Built-in Administrator Account)

You must consider the following points when you disable the built-in Administrator account:

- Disable the built-in Administrator account after creating a user with administrative rights.
- Be careful not to include root, su, admin, and other words meaning administrator in the name of user with administrator rights.
- Securely control users with administrator rights because they are required for operations.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

Cautions (when Changing the User Name of the Built-in Administrator Account)

You must consider the following points when you change the name of the built-in Administrator account:

- Create a user with administrator rights for normal maintenance.
- Be careful not to include root, su, admin, and other words meaning administrator in the changed user name and in the name of the user with administrator rights you create.
- Securely control users with administrator rights
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.5.2 Applying the Software Restriction Policies

The software restriction policies function of Windows restricts the execution of programs by setting the following types of rules:

- Restriction on path
- Restriction on hash
- Restriction on certificate
- Restriction on the Internet zone

In the product, path rules are applied to provide an environment where users can run only the specified programs. This prevents illegal execution of programs even if harmful programs are copied in a temporary folder or other locations of the computer.

The IT Security Tool supports Restriction on path. If this restriction is applied, other coexisting packages may not run.

Settings

To allow only the specified programs to run, folder paths are added and rules are deleted as follows:

Folder paths to be added

- `%ALLUSERSPROFILE%\Microsoft\Windows\Templates` (*1)
- `%ALLUSERSPROFILE%\Templates` (*1)
- `%ALLUSERSPROFILE%\Yokogawa\IA\iPCS\Products\ChronusENG\Data\Projects` (*1) (*2)
- `%localappdata%\Microsoft\OneDrive\*\FileSyncConfig.exe` (*3)
- `%localappdata%\Microsoft\OneDrive\OneDrive.exe` (*3)
- `%ProgramFiles%` (*4)
- `%ProgramFiles(x86)%`(*5)
- `%ProgramW6432%`(*6)
- `%ProgramFiles%\Yokogawa\IA\iPCS\Platform\Security\PROGRAM` (*4)
- `%ProgramFiles(x86)%\Yokogawa\IA\iPCS\Platform\Security\PROGRAM` (*5)
- `%ProgramFiles(x86)%\YOKOGAWA\IA\iPCS\Products\ProSafe-RS\Program` (*5)
- `%SystemRoot%` (*7)
- ProSafe-RS installation folder
- `%ProgramFiles32%\Trinity Integrated Systems\iDefine x.xx.x Yokogawa` (*8)

Rules to be deleted

- "lnk" and "mdb" are deleted from [Designated File Types Properties].

*1: %ALLUSERSPROFILE% refers to the following folder. This example is when the system drive is drive C.
`C:\ProgramData`
*2: This path is added when the Automation Design Master Database is to be stored in the default location.
*3: Only for Windows 10
*4: %ProgramFiles% refers to the following folder. This example is when the system drive is drive C.
`C:\Program Files`
*5: %ProgramFiles(x86)% refers to the following folder. This example is when the system drive is drive C.
`C:\Program Files(x86)`
*6: %ProgramW6432% refers to the following folder. This example is when the system drive is drive C.
`C:\Program Files`
*7: %SystemRoot% refers to the following drive. This example is when the system drive is drive C.
`C:\Windows`

*8: This is the folder path when iDefine is installed in the default folder. %ProgramFiles32% refers to the following folder. This example is when the system drive is drive C.
`C:\ProgramFiles(x32)`
`x.xx.x` is the version number of iDefine.

Cautions

IMPORTANT

When software restriction policies are applied, observe the following points: To start the installer from the ProSafe-RS software medium, right-click the icon of the installer and select [Run as Administrator]. To run a non-ProSafe-RS program, you also need to run it by selecting [Run as Administrator].

In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.5.3 Applying the Audit Policy

Collected account logon conditions and events related to security serve as data useful in detecting abnormal system conditions in early stages and to trace causes of troubles when problems related to security occur. It is recommended to set appropriate audit policies.

With the Windows default setting, audit data is not collected.

Settings

The following table shows the settings.

Table 3.5.3-1 Settings

Policy	Settings
Audit account logon events	Both the Success and Failure check boxes are selected.
Audit account management	Both the Success and Failure check boxes are selected.
Audit object access	The Failure check box is selected.
Audit system events	Both the Success and Failure check boxes are selected.
Audit directory service access	Both the Success and Failure check boxes are selected.
Audit process tracking	The Success check box is selected.
Audit policy change	Both the Success and Failure check boxes are selected.
Audit logon events	Both the Success and Failure check boxes are selected.
Audit privilege use	Both the Success and Failure check boxes are selected.

Cautions

Keep the following points in mind when applying the audit policies.

- If the number of event types collected is increased, the system performance is affected.
- The number of generated events varies depending on the types of collected events and system operations. Determine the event collection size appropriate for the system operation conditions.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.5.4 Applying the StorageDevicePolicies Function

By using the StorageDevicePolicies function of Windows, you can set removable storage media connected on USB ports as read-only devices. You can use this function to prevent theft of data by unauthorized users. You can use the StorageDeviceCTL utility of the product to temporarily grant write permissions to users.

SEE ALSO For more information about StorageDeviceCTL, refer to:

6.11, “Other Utility Programs” on page 6-51

Setting

The following table shows the setting when IT security version 2.0 is applied.

Table 3.5.4-1 Setting

Policy	Setting
Removable Disks: Deny write access	Enabled

Cautions

Keep the following points in mind when applying the StorageDevicePolicies function.

In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.5.5 Disabling USB Storage Devices

This function disables the use of USB storage devices such as USB memories. You can use this function to prevent theft of data by unauthorized users.

You can use the StorageDeviceCTL utility of the product to temporarily grant write permissions to users.

SEE ALSO For more information about StorageDeviceCTL, refer to:

6.11, “Other Utility Programs” on page 6-51

Settings

The following table shows the settings when IT security version 2.0 is applied.

Table 3.5.5-1 Settings

Policy	Setting
Floppy Drives: Deny execute access	Enabled
Floppy Drives: Deny read access	Enabled
Floppy Drives: Deny write access	Enabled
Removable Disks: Deny execute access	Enabled
Removable Disks: Deny read access	Enabled
Removable Disks: Deny write access	Enabled
WPD Devices: Deny read access	Enabled
WPD Devices: Deny write access	Enabled

Cautions

Keep the following points in mind when disabling USB storage devices.

- If volumes (partitions) other than the system volume or internal hard disk drives are recognized as portable devices, you may not be able to access them. Before disabling the USB storage devices, or if the problem occurs, follow steps to restore access to the required devices.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

How to Restore Access to the Required Devices

Follow these steps to restore access to the required devices:

1. Start Windows PowerShell and enter `mmc devmgmt.msc`.
   Device Manager appears.
2. Expand the node of [Portable devices] and make sure that no devices other than the connected USB storage device are connected.
3. If devices other than the connected USB storage device are connected, update BIOS or UEFI.

TIP

If BIOS or UEFI cannot be updated, or if the problem still exists even after the update, follow these steps:

1. From the Start menu, right-click the Command Prompt and select [Run as administrator].
2. From the opened command prompt, execute the following command: The command argument n represents the Bus Number.
   - File server or domain controller:
     `<ProSafe-RS installation medium>:\ProSafe-RS\SECURITY\TreatAsNonRemovableDisk.cmd n`
   - A computer on which ProSafe-RS software is installed:
     `<System drive>:\Program Files (x86)\YOKOGAWA\IA\iPCS\Platform\SECURITY\PROGRAM\TreatAsNonRemovableDisk.cmd n`
3. Restart the computer.

Follow these steps if you want to check the Bus Number:

1. From the Start menu, select [Run] and enter `diskmgmt.msc`.

   Disk Management appears.
2. In the framed area of the following figure, right-click and select [Properties].
   The properties of the corresponding disk drive appear.

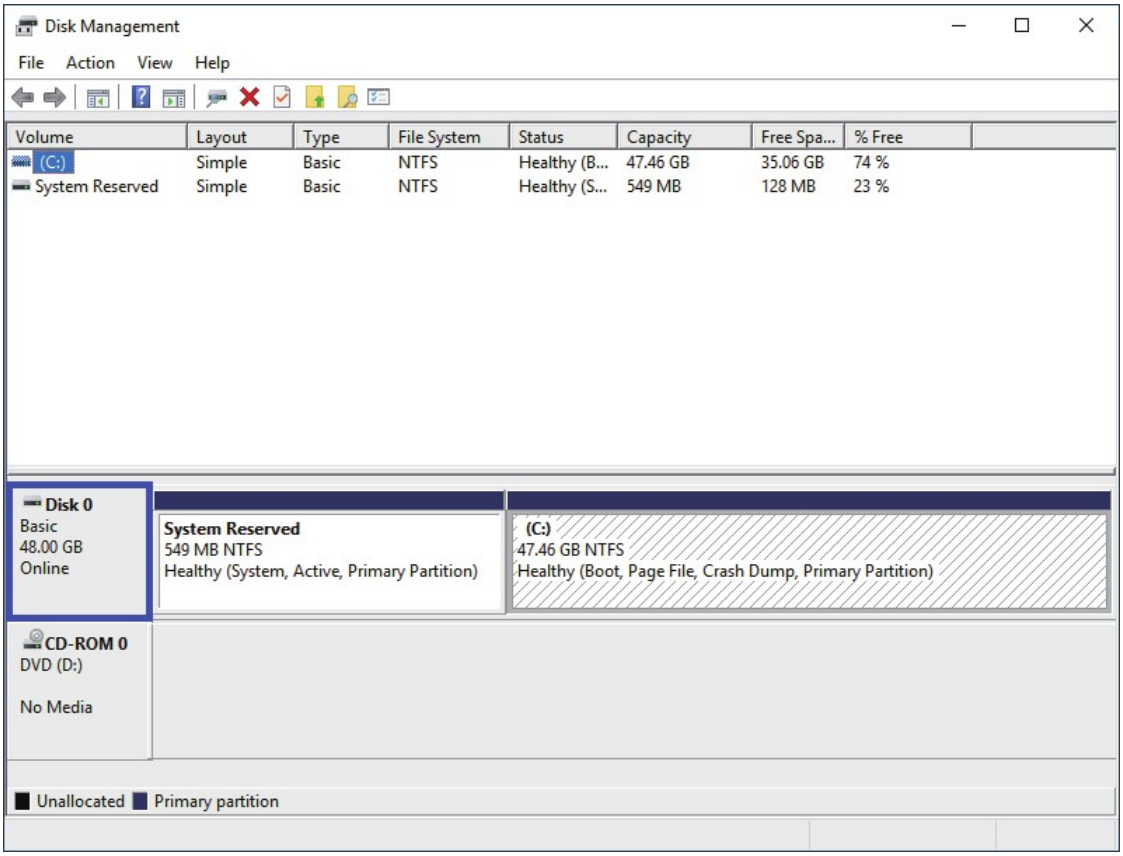

Figure 3.5.5-1 Disk Management

3. On the [General] tab of the displayed properties, check the value of Bus Number displayed in [Location:].
   - If there is only one internal disk drive, or if all internal disk drives have the same Bus Number, use the displayed value.
   - If there are multiple internal disk drives whose Bus Numbers are different from each other, use the IT Security Tool to set disabling USB storage devices. In Explorer, check the inaccessible disk drive, on the Disk Management window, check the Bus Number value of the disk drive and use it. For example, if the F drive is disabled, view and check the properties of the disk drive that contains the F drive.

3.5.6 Applying the Account Lockout Policy

This function is effective to protect the product from attacks such as online cracking.

Settings

The following table shows the settings.

Table 3.5.6-1 Settings

Policy	Setting
Account lockout threshold	10 invalid logon attempts
Reset account lockout counter after	15 minutes
Account lockout duration	15 minutes

Cautions

Keep the following points in mind when applying the account lockout policies.

- If this policy is applied and you fail to log on repeatedly, logging on to that user account will be disabled until the time set for "Reset account lockout counter after" elapses.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.5.7 Windows Update Delivery Optimization

Windows Update Delivery Optimization is a feature of Windows 10, Windows Server 2019, and Windows Server 2022. This feature allows Windows updates and Windows store applications to be downloaded from Microsoft servers as well as computers on the network that have the updates and applications installed. In addition, you can send from your computer to other computers on the network.

However, because Windows updates may be applied to your computer or other computers on the network, or a restart may occur unexpectedly, make a setting to prevent updates and applications from being sent or received between your computer and the computer on your network.

The following table shows the setting.

Table 3.5.7-1 Setting

Policy	OS	Setting
Download Mode	Windows 10 Enterprise 2016 LTSB Windows Server 2022	Enabled HTTP only
	Windows 10 Enterprise LTSC 2019 Windows 10 Enterprise LTSC 2021 Windows Server 2019	Enabled Bypass

3.5.8 Disabling Windows Defender

Disable Windows Defender.

The name of Windows Defender displayed in Local Group Policy Editor varies depending on the OS version and language. Please replace it as appropriate. OS version can be checked on the System window calling from the Start menu.

The following table shows the Windows Defender name for each OS version.

Table 3.5.8-1 OS version and Windows Defender name

OS version	Name
1607 or earlier	Windows Defender
1703 to 1909	Windows Defender Antivirus
2004 or later	Microsoft Defender Antivirus

The following table shows the setting.

Table 3.5.8-2 Setting

Policy	Setting
Turn off Windows Defender	Enabled

3.5.9 Disabling Shared experiences

Shared experiences is a feature of Windows 10 Enterprise LTSC 2019 and Windows 10 Enterprise LTSC 2021.

There are two functions: sharing between devices that open applications on devices to send and receive messages, and nearby sharing that shares files and web page URL through Bluetooth or Wi-Fi.

The following table shows the setting.

Table 3.5.9-1 Setting

Policy	OS	Setting
Continue experiences on this device	Windows 10 Enterprise LTSC 2019 Windows 10 Enterprise LTSC 2021	Disabled
	OS other than the above	Not configured

3.5.10 Enabling SMB Signing

By enabling SMB signing, packets sent and received by SMB are digitally signed to prevent tampering and destruction.

The following table shows the setting.

Table 3.5.10-1 Setting

Policy	Setting
Microsoft Network Server: Always digitally sign communications	Enabled

Cautions

Note the following points when enabling SMB signing.

- It is supported for computers on which ProSafe-RS R4.07 or later is installed. In the case of a file server, it is supported for computers built with a server OS supported by ProSafe-RS R4.07 or later.
- The following operations need to be performed on all the above computers which are contained in the ProSafe-RS system.
- In the following cases, set it only if all products support enabling SMB signing.
  - There is software for system products that coexist with ProSafe-RS, or system products that work in linkage.
  - ProSafe-RS of different revisions are mixed in the system.
- Set this item in the Local Group Policy Editor. Follow these steps to set it:

1. Sign in as an administrative user.
2. Start the Command Prompt.
3. Enter `gpedit.msc`.
   Local Group Policy Editor appears.
4. In the left pane, select [Computer Configuration] > [Windows Settings] > [Security Settings] > [Local Policies] > [Security Options.]
5. Enable the setting value of the desired policy.

3.5.11 Prevent illegal dll from loading

The following setting can mitigate attacks of loading illegal dll.

This setting is configured automatically when you install the ProSafe-RS software instead of setting with the IT Security Tool.

The following table shows the setting.

Table 3.5.11-1 Setting

Registry entry	Setting
CWDIllegalInDllSearch	2

Cautions

Loading a dll from the current working directory (current directory) is blocked if all of the following conditions are met:

- The application in a local folder on the local computer is running.
- The current working directory (current directory) of the above application is specified to a folder on the remote computer.

3.6 Group Policy Settings in IT Security Version 2.0

This section describes the group policy settings in IT security version 2.0. There may be cases where it is not possible to implement certain security functions depending on the conditions of the individual systems. For this reason, examine whether implementation is possible for each function before the implementation.

3.6.1 Applying the Password Policies

The strength of security for user authentication changes significantly depending on the set password. It is recommended to secure minimum password strength by applying the password policies.

Settings

The following table shows the settings.

Table 3.6.1-1 Settings

Policy	Setting
Minimum password length	12 characters or more
Minimum password age	One day
Validity period of password	70 days
Enforce password history	2 passwords
Password must meet complexity requirements	Enabled
Store password using reversible encryption	Disabled

Cautions

Keep the following points in mind when applying the password policies.

- If the password policies are made stricter, not only the load of password management on users but also the load of operation administrators to manage user's passwords increases.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.6.2 User Rights Assignment

With this function, only the specified users or groups are allowed to perform a certain operation.

Settings

Table 3.6.2-1 Settings

Policy (*1)	Group to delete	Group to add
Access this computer from the network	All the registered accounts	Administrators Authenticated Users Enterprise Domain Controllers
Add workstations to domain	Authenticated User	Administrators

*1: This setting is for domain controllers only.

3.6.3 Security Options

Various security options are enabled or disabled.

Settings

The following table shows the settings.

Table 3.6.3-1 Settings

Policy	Setting
Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings	Enabled
Devices: Prevent users from installing printer drivers	Enabled
Devices: Restrict CD-ROM access to locally logged-on user only	Enabled
Devices: Restrict floppy access to locally logged-on user only	Enabled
Domain controller: Allow server operators to schedule tasks(*1)	Disabled
Domain controller: Refuse machine account password changes(*1)	Disabled
Domain member: Require strong (Windows 2000 or later) session key	Enabled
Interactive logon: Display user information when the session is locked	User display name, domain and user names
Interactive logon: Do not display last user name	Enabled
Interactive logon: Do not require CTRL+ALT+DEL	Disabled
Interactive logon: Prompt user to change password before expiration	Enabled 14 days
Microsoft network server: Digitally sign communications (if client agrees)	Enabled
Microsoft network server: Server SPN target name validation level	Enabled Accept if provided by client
MSS: (AutoReboot) Allow Windows to automatically restart after a system crash (recommended except for highly secure environments)	Disabled
MSS: (DisableIPSourceRouting) IP source routing protection level (protects against packet spoofing)	Enabled Highest protection, source routing is completely disabled
MSS: (PerformRouterDiscovery) Allow IRDP to detect and configure Default Gateway addresses (could lead to DoS)	Disabled
MSS: (TcpMaxDataRetransmissions) How many times unacknowledged data is retransmitted (3 recommended, 5 is default)	Enabled 3
Network access: Do not allow anonymous enumeration of SAM accounts	Enabled
Network access: Do not allow anonymous enumeration of SAM accounts and shares	Enabled
Network access: Do not allow storage of passwords and credentials for network authentication	Enabled

Continues on the next page

Table 3.6.3-1 Settings (Table continued)

Policy	Setting
Network access: Let Everyone permissions apply to anonymous users	Disabled
Network security: Allow Local System to use computer identity for NTLM	Enabled
Network security: Allow LocalSystem NULL session fallback	Disabled
Network security: Force logoff when logon hours expire(*1)	Enabled
Network security: LAN Manager authentication level	Enabled Send NTLMv2 response only
Network security: Minimum session security for NTLM SSP based (including secure RPC) clients	Enabled • Require NTLMv2 session security • Require 128-bit encryption Both check boxes are selected.
Network security: Minimum session security for NTLM SSP based (including secure RPC) servers	Enabled • Require NTLMv2 session security • Require 128-bit encryption Both check boxes are selected.
Network security: Do not store LAN Manager hash value on next password change	Enabled
Shutdown: Allow system to be shut down without having to log on	Disabled
User Account Control: Admin Approval Mode for the Built-in Administrator account	Enabled
User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode	Enabled Prompt for consent on the secure desktop

*1: This setting is for domain controllers only.

Cautions

- You can check the application of the four setting items beginning with MSS: that are set as Security Options by using the gpresult command.
- If you set Interactive logon: Machine inactivity limit, the session will be locked if no operation is made for 900 seconds.
- In Windows Server 2019 and Windows Server 2022, if “User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode” is set to “Prompt for consent on secure desktop”, a User Account Control dialog box appears when you perform the shutdown or restart operation from the Start menu.

3.6.4 Advanced Audit Policy Configuration

Collected account logon conditions and events related to security serve as data useful in detecting abnormal system conditions in early stages and to trace causes of troubles when problems related to security occur. With IT security version 2.0, more detailed audit policy configuration is possible. Each setting item is described as follows.

Account Logon

The following table shows the setting.

Table 3.6.4-1 Setting

Policy	Setting
Audit Credential Validation	Both the Success and Failure check boxes are selected.

Account Management

The following table shows the setting.

Table 3.6.4-2 Setting

Policy	Setting
Audit Computer Account Management	The Success check box is selected.
Audit Other Account Management Events	Both the Success and Failure check boxes are selected.
Audit Security Group Management	Both the Success and Failure check boxes are selected.
Audit User Account Management	Both the Success and Failure check boxes are selected.

Detailed Tracking

The following table shows the setting.

Table 3.6.4-3 Setting

Policy	Setting
Audit Process Creation	The Success check box is selected.
Audit RPC events	Both the Success and Failure check boxes are cleared. (*1)

*1: In the case of domain controller and file server, both the Success and Failure check boxes are selected.

DS Access

These settings are for domain controllers only.

Table 3.6.4-4 Settings

Policy	Setting
Audit Directory Service Access	Both the Success and Failure check boxes are selected.
Audit Directory Service Changes	Both the Success and Failure check boxes are selected.

Logon/Logoff

The following table shows the setting.

Table 3.6.4-5 Setting

Policy	Setting
Audit Account Lockout	The Success check box is selected.
Audit Logoff	The Success check box is selected.
Audit Logon	Both the Success and Failure check boxes are selected.
Audit Other Logon/Logoff Events	Both the Success and Failure check boxes are selected.
Audit Special Logon	The Success check box is selected.

Object Access

The following table shows the setting.

Table 3.6.4-6 Setting

Policy	Setting
Audit Application Generated	Both the Success and Failure check boxes are cleared. (*1)
Audit Removable Storage	Both the Success and Failure check boxes are selected.

*1: In the case of domain controller and file server, both the Success and Failure check boxes are selected.

Policy Change

The following table shows the setting.

Table 3.6.4-7 Setting

Policy	Setting
Audit Policy Change	Both the Success and Failure check boxes are selected.
Audit Authentication Policy Change	Both the Success and Failure check boxes are selected.
Audit Filtering Platform Policy Change	Both the Success and Failure check boxes are selected.
Audit MPSSVC Rule-Level Policy Change	Both the Success and Failure check boxes are selected.
Audit Other Policy Change Events	Both the Success and Failure check boxes are selected.

Privilege Use

The following table shows the setting.

Table 3.6.4-8 Setting

Policy	Setting
Audit Sensitive Privilege Use	Both the Success and Failure check boxes are selected.

System

The following table shows the setting.

Table 3.6.4-9 Setting

Policy	Setting
Audit Other System Events	Both the Success and Failure check boxes are selected.
Audit Security State Change	Both the Success and Failure check boxes are selected.
Audit Security System Extension	Both the Success and Failure check boxes are selected.
Audit System Integrity	Both the Success and Failure check boxes are selected.
Audit IPsec Driver (*1)	Both the Success and Failure check boxes are selected.

*1: This setting is for domain controllers only.

3.6.5 Administrative Template

This section describes the group policy settings that are defined in the administrative template.

Personalization (Control Panel)

Setting

The following table shows the setting.

Table 3.6.5-1 Setting

Policy	Setting
Prevent enabling lock screen camera	Enabled
Prevent enabling lock screen slide show	Enabled

WLAN Settings (Network)

Setting

The following table shows the setting.

Table 3.6.5-2 Setting

Policy	Setting
Allow Windows to automatically connect to suggested open hotspots, to networks shared by contacts, and to hotspots offering paid services	Disabled

Audit Process Creation (System)

Setting

The following table shows the setting.

Table 3.6.5-3 Setting

Policy	Setting
Include command line in process creation events	Disabled

TIP

If this option is enabled, the command line information of each process will be recorded to the security event log in text format as part of the Audit Process Creation event 4688, "A new process has been created." For example, if you set a password by using the CreateProSafeProcess tool, the password specified as an argument is recorded in the event log.

Group Policy (System)

Setting

The following table shows the setting.

Table 3.6.5-4 Setting

Policy	Setting
Configure registry policy processing	The check box of Process even if the Group Policy objects have not changed is selected.

Internet Communication Management (System)

Setting

The following table shows the setting.

Table 3.6.5-5 Setting

Policy	Setting
Turn off access to the Store	Enabled
Turn off downloading of print drivers over HTTP	Enabled
Turn off Event Viewer "Events.asp" links	Enabled
Turn off Internet download for Web publishing and online ordering wizards	Enabled
Turn off printing over HTTP	Enabled
Turn off Search Companion content file updates	Enabled
Turn off the "Publish to Web" task for files and folders	Enabled
Turn off the Windows Customer Experience Improvement Program	Enabled
Turn off the Windows Messenger Customer Experience Improvement Program	Enabled

Logon (System)

Settings

The following table shows the settings.

Table 3.6.5-6 Settings

Policy	Setting
Do not display network selection UI	Enabled
Do not enumerate connected users on domain-joined computers	Enabled
Enumerate local users on domain-joined computers	Disabled
Turn off app notifications on the lock screen	Enabled

Mitigation Options (System)

Setting

The following table shows the setting.

Table 3.6.5-7 Setting

Policy	Setting
Untrusted Font Blocking	Enabled Block untrusted fonts and log events

Cautions

If this setting is enabled, fonts that are not installed in %Windir%\Font (normally, C:\Windows \Font) cannot be used. In that case, install the fonts to be used in the above folder. You can install fonts by right-clicking the font and selecting [Install].

Power Management (System)

Settings

The following table shows the settings.

Table 3.6.5-8 Settings

Policy	Setting
Turn Off the Display (On Battery)	Enabled 0
Turn Off the Display (Plugged In)	Enabled 0

User Profile (System)

Setting

The following table shows the setting.

Table 3.6.5-9 Setting

Policy	Setting
Turn off the advertising ID	Enabled

App Privacy (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-10 Setting

Policy	Setting
Let Windows apps access account information	Enabled Force Deny
Let Windows apps access call history	Enabled Force Deny
Let Windows apps access contacts	Enabled Force Deny
Let Windows apps access email	Enabled Force Deny
Let Windows apps access location	Enabled Force Deny
Let Windows apps access messaging	Enabled Force Deny
Let Windows apps access motion	Enabled Force Deny

Continues on the next page

Table 3.6.5-10 Setting (Table continued)

Policy	Setting
Let Windows apps access the calendar	Enabled Force Deny
Let Windows apps access the camera	Enabled Force Deny
Let Windows apps access the microphone	Enabled Force Deny
Let Windows apps access trusted devices	Enabled Force Deny
Let Windows apps control radios	Enabled Force Deny
Let Windows apps sync with devices (*1)	Enabled Force Deny
Let Windows apps communicate with unpaired devices(*2)	Enabled Force Deny

*1: If the OS is Windows 10 Enterprise 2016 LTSB or Windows Server 2016
*2: If the OS is Windows 10 Enterprise LTSC 2019, Windows 10 Enterprise LTSC 2021, or Windows Server 2019 or later server OS

App Runtime (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-11 Setting

Policy	Setting
Block launching Windows Store apps with Windows Runtime API access from hosted content	Enabled

Cautions

This policy disables starting of Windows store applications that are directly accessed by Windows runtime API from Web content.

AutoPlay Policies (Windows Component)

These policies prevent automatic execution of programs from external media. This setting is effective as a measure against viruses that infect computers through USB memory devices (USB worms).

Setting

The following table shows the setting.

Table 3.6.5-12 Setting

Policy	Setting
Turn off Autoplay	Enabled All drives
Disallow Autoplay for non-volume devices	Enabled

Cautions

- If the AutoRun function for the drive is disabled, the installation menu does not start just by inserting the software medium of the product.

- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

Cloud Content (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-13 Setting

Policy	Setting
Do not show Windows tips	Enabled
Turn off Microsoft consumer experiences	Enabled

Data Collection and Preview Builds (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-14 Setting

Policy	Setting
Allow Telemetry (*1)	Enabled 0 - Security [Enterprise Only]
Allow diagnostic data(*2)	Enabled Diagnostic data off (not recommended)
Disable pre-release features or settings	Disabled
Do not show feedback notifications	Enabled
Toggle user control over Insider builds	Disabled

*1: If the OS is one of the following:
- Windows 10 Enterprise 2016 LTSB
- Windows 10 Enterprise LTSC 2019
- Windows 10 Enterprise LTSC 2021
- Windows Server 2016
- Windows Server 2019

*2: If the OS is Windows Server 2022

Cautions

If the OS is Windows 10 Enterprise LTSC 2019, Windows 10 Enterprise LTSC 2021, Windows Server 2019, or Windows Server 2022, the policy “Disable pre-release features or settings” does not appear in the Local Group Policy Editor. Check the current application of the policy by running the `gpresult` command as an alternative measure.

Event Log Service (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-15 Setting

Policy	Setting
Specify the maximum log file size (KB)	Enabled 32768 KB

File Explorer (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-16 Setting

Policy	Setting
Turn off heap termination on corruption	Disabled

HomeGroup (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-17 Setting

Policy	Setting
Prevent the computer from joining a homegroup	Enabled

OneDrive (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-18 Setting

Policy	Setting
Prevent the usage of OneDrive for file storage	Enabled
Save documents to OneDrive by default (Save documents to the local PC by default)	Enabled

Remote Desktop Service (Windows Component)

Settings

The following table shows the settings.

Table 3.6.5-19 Settings

Policy	Setting
[Remote Desktop Connection Client] \ Do not allow passwords to be saved	Enabled
[Remote Desktop Session Host] \ [Device and Resource Redirection] \ Do not allow drive redirection	Enabled
[Remote Desktop Session Host] \ [Security] \ Require secure RPC communication	Enabled
[Remote Desktop Session Host] \ [Security] \ Require user authentication for remote connections by using Network Level Authentication	Enabled

Search (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-20 Setting

Policy	Setting
Allow Cortana	Disabled
Don't search the web or display web results in Search	Enabled
Don't search the web or display web results in Search over metered connections	Enabled

Software Protection Platform (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-21 Setting

Policy	Setting
Turn off KMS Client Online AVS Validation	Enabled

Store (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-22 Setting

Policy	Setting
Turn off Automatic Download of updates on Win8 machines	Enabled
Turn off Automatic Download and Install of updates	Enabled
Turn off the offer to update to the latest version of Windows	Enabled
Turn off the Store application	Enabled

Sync Your Settings (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-23 Setting

Policy	Setting
Do not sync Apps	Enabled
Do not sync start settings	Enabled

Windows Error Reporting (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-24 Setting

Policy	Setting
Automatically send memory dumps for OS-generated error reports	Disabled

Windows Logon Options (Windows Component)

Setting

The following table shows the setting.

Table 3.6.5-25 Setting

Policy	Setting
Sign-in last interactive user automatically after a system-initiated restart	Disabled

3.6.6 User Configuration - Administrative Template

Notifications (Taskbar and Start Menu)

Setting

The following table shows the setting.

Table 3.6.6-1 Setting

Policy	Setting
Turn off toast notifications on the lock screen	Enabled

3.7 Group Policy Settings in IT Security Version 1.0

This section describes the group policy settings in IT security version 1.0. There may be cases where it is not possible to implement certain security functions depending on the conditions of the individual systems. For this reason, examine whether implementation is possible for each function before the implementation.

3.7.1 Hiding the Last Logon User Name

You can hide the last logon user name on the logon dialog box to prevent leakage of valid user names in the system.

Caution

Keep the following points in mind when hiding the last logon user name.

- You must enter a user name on every logon attempt if you apply this security measure.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.7.2 Applying AutoRun Restrictions

This restriction prevents automatic execution of programs when a DVD-ROM or other medium is inserted to the drive or a USB port. This is an effective measure against virus (USB worm) infecting computers via USB memory.

Setting Values

The AutoRun function is disabled for all drives.

Cautions

Keep the following points in mind when applying AutoRun restrictions.

- The installation menu does not start just by inserting the software medium of the product.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.7.3 Changing the LAN Manager Authentication Level

Windows has LM authentication, NTLM authentication and NTLMv2 authentication methods for backward compatibility.

For the environment of the product, use of NTLMv2 authentication is recommended. LM authentication is not recommended since its method of hashing user's password (LM hash algorithm) is very vulnerable.

Setting

The following table shows the setting.

Table 3.7.3-1 Setting

Policy	Setting
Changing the LAN Manager Authentication Level	Send NTLMv2 response only
Do not allow storage of passwords and credentials for network authentication	Enabled
Minimum session security for NTLM SSP based (including secure RPC) clients	Require NTLMv2 session security Require 128-bit encryption
Minimum session security for NTLM SSP based (including secure RPC) servers	Require NTLMv2 session security Require 128-bit encryption
Let Everyone permissions apply to anonymous users	Disabled

Cautions

- Ensure that the settings of “Minimum session security for NTLM SSP based (including secure RPC) clients” and “Minimum session security for NTLM SSP based (including secure RPC) servers” are consistent on all terminals.
- In a domain environment, this setting may be overwritten with the setting in the domain controller, depending on the group policies of the domain controller. If this is your case, change the setting in the domain controller.

3.7.4 Applying the Password Policies

The strength of security for user authentication changes significantly depending on the set password. It is recommended to secure minimum password strength by applying the password policies.

■ Settings

The following table shows the settings.

Table 3.7.4-1 Settings

Policy	Settings
Minimum password length	12 characters or more
Change prohibition period of password	One day
Validity period of password	90 days
Storage of password history	24 passwords stored (25 password types or more are required)
Password must meet complexity requirements	Enabled
Store password using reversible encryption	Disabled

■ Cautions

The cautions for applying the password policies are the same as those of IT security version 2.0.

SEE ALSO For more information about notes on the password policy in IT security version 2.0, refer to:

"■ Cautions" on page 3-40

4. Selection of Security Functions

In order to set security functions, it is necessary to take various items into consideration. This chapter explains the items to be considered and model cases that serve as reference when setting security functions.

4.1 Items to be Considered Before Setting Security Functions

After installing the ProSafe-RS software, you must configure the security settings of the computer to strengthen IT security. Even if the security settings of ProSafe-RS installed computers are controlled collectively by a domain controller, you must perform this configuration at least once on every computer.

When the project database is built on a file server or when user management is consolidated by a Windows domain controller, the configuration of IT security settings is required also on the file server or domain controller.

This section describes the items that you must consider before configuring the security settings.

Considerations on Determining Security Functions

The following items need to be considered according to the actual implementations.

These items should be determined before installing the software of the product.

- IT security version
- Security Model
- Windows user management type
- User authentication mode

Selecting IT Security Version

Select either of the following versions according to the extent of configuration for security measures.

Table 4.1-1 Selecting IT Security Version

IT security version	Selection Criterion
2.0	This version includes more security policies compared to the security measures that had been offered until ProSafe-RS R4.02. In addition, the administrative template for group policies is included as the target of security configuration. The Legacy model is no longer supported in IT security version 2.0.
1.0	This version offers the same security measures as ProSafe-RS R4.02 and earlier versions.

Selecting Security Model

A security model needs to be selected from the following three types.

Table 4.1-2 Selecting Security Model

Security Model	Selection Criterion
Legacy Model	Select this model when upgrading the system from an RS project of ProSafe-RS R4.02 or earlier without changing the existing security settings or when sharing Windows users among multiple operators. The Legacy model can be selected only with IT security version 1.0. If this model is selected, the system remains vulnerable against information leak and attacks by worms and viruses.

Continues on the next page

Table 4.1-2 Selecting Security Model (Table continued)

Security Model	Selection Criterion
Standard Model (Recommended)	It is recommended to select this model unless you have a specific reason not to. This model provides minimum security settings necessary for the product, considering secure operation of the system as well as collaboration with other systems.
Strengthened Model	Select this model when security level higher than the Standard model is required. Consult Yokogawa agent when implementing this model.

● Windows User Management

Select Windows user management type according to the system size and configuration from the following four types.

Table 4.1-3 Selecting User Management Type

User Management Type	Selection Criterion
Standalone Management	This type is suitable for relatively small-scale systems. When this type is selected, the user accounts and passwords of all computers in the system need to be kept consistent.
Domain Management	This type is suitable for systems that implement a centralized user management. When this type is selected, it is recommended to set a new, dedicated domain controller when constructing the system.
Combination Management	This type is suitable for the system where user management is centralized but some users are allowed to be independently managed in local computers.
Linked Domain Management	This type is suitable for the system where user management is centralized but some users are allowed to be independently managed in local computers. When installing new software for this product, it is recommended to use the linked domain management instead of the domain management or the combination management.

● User Authentication Mode

When the Access Control and Operation History Management Package is used, you can select either of the following user authentication modes according to the operation conditions and security policies of the system.

Table 4.1-4 Selecting User Authentication Mode

User Authentication Mode	Selection Criterion
ProSafe Authentication Mode	Select this mode when Windows users and ProSafe-RS users are authenticated separately.
Windows Authentication Mode	Select this mode when Windows users and the users who perform system engineering or maintenance works are authenticated together. This mode is suitable for systems requiring a higher security level.

When Windows authentication mode is selected, only one authentication is performed before operating the SENG.

■ Precautions when Setting Security Functions

The following table lists precautions to be observed when setting security measures.

Table 4.1-5 Precautions when Setting Security Functions

Security function	Item to be considered
Software Restriction Policies	If the software restriction policies are set, programs added for the purpose of collaboration and coexistence may not run. You need to add policies of the programs to the software restriction policies. Follow these steps to add policies. 1. Logon the PC as an administrative user. 2. Open the Administrative Tools. 3. At Local Security Policy, select [Software Restriction Policies] > [Additional Rules]. 4. Add the policy of a newly added program.
PSF_PROCESS Password	Do not change the password of PSF_PROCESS.
StorageDevicePolicies function/ Disabling USB storage devices	If you apply the StorageDevicePolicies function or disable USB storage devices, you cannot back up data into storage devices such as USB memories. When you take a backup of the operation history database or other data into a storage device, use the StorageDeviceCTL command.
Disabling NetBIOS over TCP/IP	If you disable NetBIOS over TCP/IP, you cannot resolve names by broadcasting. Because of this, the following problems arise in environments with standalone management. • When you try to open a file in a file server from SCS Manager, you cannot see the file server. • If the cache file is stored in another PC, you cannot see the cache file. To solve these problems, use the HOSTS file or LMHOSTS file.

5. Precautions on Operations

This section describes the precautions related to security when operating the product.

5.1 Windows Account Management

Two types of Windows account management are assumed, common account management and individual account management, considering sharing of the user accounts often used in the systems that were built before the security functions are introduced.

Common Account Management and Individual Account Management

The following table shows the differences between the common account management and individual account management.

Table 5.1-1 Common Account Management and Individual Account Management

Account management method	Operation form	Convenience of operation		Security strength	
Common account management	A Windows account is shared by multiple users.	High	The same operability as the systems that were built before the security functions are introduced.	Low	Highly anonymous and disadvantageous.
Individual account management	A Windows account is assigned to a single user.	Low	Windows logoff and logon are required at personnel shift, and thus cumbersome compared to the systems that were built before the security functions are introduced.	High	Advantageous because access control of each user is possible.

5.1.1 Common Account Management

The common account management is highly convenient to operate because it is similar to the conventional account management of the systems that were built before the security functions are introduced. However, from the security point of view, anonymity is high and security strength level is low. When applying the common account management, take personnel education and security of operation environment fully into consideration.

Use of Accounts

If the common accounts are used, it is recommended to group accounts by rights of users and use common accounts within a group. By grouping by rights of users, it becomes possible to prohibit operations on the product by users without rights and to narrow down user groups when tracing the trouble occurrence. It is considered that more usable trace data is obtained compared to the case when common accounts are used among all users.

Password Management

Considering security, it is recommended to change passwords periodically. It is possible to handle password cracking attacks by periodically changing passwords. If common accounts are used, it is recommended to change passwords at the timing when members using the common accounts are changed. By changing passwords, illegal access from previously authorized people is prevented.

Automatic Logon Function

Do not use the automatic logon function of Windows unless CENTUM VP coexists on the PC.

Otherwise, persons without rights to the ProSafe-RS system may inadvertently use engineering functions, and so on.

5.1.2 Individual Account Management

With the individual account management, it is possible to minimize rights on accounts by specifying PC users. Moreover, it is possible to trace trouble occurrence more efficiently because users can be identified. However, the individual account management is different from conventional operations on several points, such as Windows logoff/logon becomes necessary at personnel shift. More careful consideration is required when implementing the individual account management.

Account Maintenance

If user rights are changed, it is recommended to promptly change account rights.

By performing account maintenance immediately, it becomes possible to handle illegal access by users who used to have rights before and/or unexpected attacks from attackers.

For example, if a user left the job, delete the account of the user; if the scope of charge of a maintenance personnel is changed, change the group to which the personnel belongs.

Password Management

Considering security, it is recommended to change passwords periodically. Password cracking can be prevented by periodically changing the user passwords.

5.1.3 Common Precautions for Common Account Management/Individual Account Management

This section lists precautions common to the common account management and individual account management.

System Audit

It is recommended to perform system audit periodically. By doing so, it is possible to detect system abnormalities in early stages, which leads to early discovery of signs of troubles and accidents. If any abnormalities are found, consult network administrators or experts to take appropriate measures.

Account Management by Standalone Management

When managing accounts by standalone management, it is not only necessary to create the same user account on all PCs used by users and SENG PCs on which project databases exist, but also unify passwords of registered accounts. Note that, when changing a password, it is also necessary to change the password to the same new password on all the PCs in which the same account is registered.

Account Management by Domain Management

If the time on the domain controller and the time on PCs in the system of the product significantly differ (5 minutes or longer by default), the authentication function does not work properly in the domain environment. Pay attention to the time deviation between the domain controller and each PC.

PSF_MAINTENANCE Group

PSF_MAINTENANCE, which is a group for maintenance, has very powerful rights, including administrator rights. It is desired to treat accounts belonging to PSF_MAINTENANCE as invalid accounts under normal operation and enable the accounts when they are in need. Moreover, setting valid periods for accounts at the timing to enable the accounts is also an effective security measure.

Users who can Use OPC

Users who can use OPC can use the DCOM function on remote sites, so it is desired to minimize the number of registered users who can use OPC to reduce their influences on the system. Moreover, if target users use only programs, deleting the logon right is also an effective measure.

User Creation Method for Groups Having Windows Administrator Rights

When creating a user belonging to PSF_MAINTENANCE or PSF_MAINTENANCE_LCL, it is necessary to add the user to either the Administrators group or the Domain Admins group as well.

5.2 Related Programs

This section explains the following related programs.

- Windows Security Patches
- Antivirus software

Windows Security Patches

It is assumed that security patches are applied according to the customer's security policy.

YOKOGAWA recommends to apply Windows security patches to the product. It is recommended to apply all required security patches before the system goes into operation and also apply security patches that are released after the system went into operation as promptly as possible.

Yokogawa offers security patch application services. Contact Yokogawa Service for more information.

As is noted as zero-day attack, attacks that take advantage of the software vulnerability can occur right after the disclosure of the vulnerability (security hole).

Note that when security patches and service packs are applied to the product, existing security settings (firewall setting and local security setting) may be changed. If security patches and service packs are applied, make sure that the existing security settings are valid.

Antivirus Software

It is recommended to install antivirus software tested by YOKOGAWA on PCs and domain controllers within the system before starting operations. For more information about application of antivirus software, contact YOKOGAWA Service.

If search engines and pattern files of antivirus software are updated, it may have unexpected rebooting or unexpected influence on other operations of PC. Exercise sufficient cautions when updating antivirus software, such as checking the operation beforehand using a test purpose PC.

5.3 Measures for Secure Use

This section describes how to use ProSafe-RS securely. It is recommended to take the measures described here for the secure use of ProSafe-RS.

SEE ALSO For more information about security measures for the entire system such as considerations about network configuration, refer to:

Security Standard of System Product (TI 33Y01B30-01E)

■ Selecting a Security Model

On the computers used in a ProSafe-RS system, select the Standard model or Strengthened model for the security model.

■ Informing Users of Entry to a Security Zone

When a system using ProSafe-RS is installed in a security zone, you can use the following measure so that the user who is trying to log on to the system is informed that he/she is entering a security zone and the subsequent operations will be performed in the security zone. Take this measure if necessary:

For the Windows local security policy under Control Panel, select [Local Policy] > [Security Options] and configure the following policies:

- [Interactive logon: Message title for users attempting to log on]
- [Interactive logon: Message text for users attempting to log on]

TIP A security zone is a physical or logical area where only permitted users can access. Equipment and facilities in a security zone require special management and are insulated from other areas.

■ Measures against Physical Attacks

To protect devices making up a ProSafe-RS system, such as SCS, network switches, and computers, from physical attacks by malicious third parties, take measures such as placing the devices in a lockable rack and strictly controlling the entry to and exit from the area where they are placed.

■ Measures against Connection of Unauthorized Devices

Take measures so as to prevent connection of unauthorized devices brought from the outside to the ProSafe-RS system. Examples of the measure are:

- Disable the free ports of network switches
- Limit the devices allowed to connect to the ports of network switches:
  for example, by assigning the MAC addresses of connectable devices to the ports.

■ Measures against Information Leakage in Communication

To prevent information travelling through the control network from leaking to unauthorized third parties, implement the measures described in “■ Measures against Physical Attacks” and “■ Measures against Connection of Unauthorized Devices” on the network switches.

■ Limiting System Administrators

Ensure that only a few reliable persons are registered in the administrative groups of ProSafe-RS.

If Behavior Suspected to be Resulting from Vulnerability is Found

If you find any behavior of the product suspected to be resulting from the vulnerability of our products, please inform YOKOGAWA by using the form at the following URL.

https://contact.yokogawa.com/cs/gw?c-id=000983

Procedure of product disposal

When disposing of a product, follow these steps to delete product information or sensitive information from the devices composing ProSafe-RS.

- Delete the data from the hard disk of your computer.
- Initialize the information in the processor module
  - For S2CP471/L1CP471
    Set the Operation data reset switch to “RESET” and turn on the power of the processor module.
  - For SCP461
    Set the BATTERY ON/OFF switch to “OFF” and turn off the power of the processor module.

SEE ALSO For more information about the Operation data reset switch and the BATTERY ON/OFF switch, refer to:

“● Front switches of the processor module” in “■ Elements on the processor module” in B4.2, “Processor module” in Hardware User's Guide (IM 32P06C10-01EN)

Port used by SCS Vnet/IP

The SCS ports (protocol: port number) used by Vnet/IP are as follows:

- UDP: 123 (SNTP)
- UDP: 520 (RIP)
- UDP: 5313
- UDP: 6000
- UDP: 9940

6. Utility Programs for Security Settings

This section describes the IT Security Tool, Domain Link Management Tool, and other utility programs for security setting.

6.1 IT Security Tool

The IT Security Tool is the security configuration utility for YOKOGAWA system products. You need to use this tool to provide security measures on the computers where any YOKOGAWA system product is installed.

The IT Security Tool applies security settings on a computer automatically based on the selected IT security version, security model, and user management type.

After installing the ProSafe-RS software, you must configure the security settings of the computer to strengthen IT security.

By using the IT Security Tool, various security settings can be configured automatically, so that you do not need to configure them manually. You can use this tool to configure the security settings on PCs with the ProSafe-RS software installed, file servers, and domain controllers.

The security settings items that can be defined using this tool will be explained below.

You cannot use this tool to configure the security settings on computers where iDefine is installed. When SENG and iDefine are installed together on the same computer, you can configure the security settings by using the IT Security Tool if the Legacy model is to be applied.

IMPORTANT

- When changing the roles of a computer such as changing the SENG in the file servers, you need to reinstall the OS.
- When the IT security configured for a computer is wrong, such as configuring IT security settings for file server in an SENG, you need to reinstall the OS.

SEE ALSO

For more information about how to configure IT security settings, refer to:

"■ Configuring IT Security Settings" in B2.3, "Configuring Security Settings for the Domain Controller" in Installation Guide (IM 32P01C50-01EN)

For more information about how to run the IT Security Tool, refer to:

B3.6.1, "Running the IT Security Tool" in Installation Guide (IM 32P01C50-01EN)

For more information about configuring the security settings that are required for coordination with ProSafe-RS on a computer where iDefine is installed, refer to:

iDefine Security Manual (PR03076-MAN-981_01)

■ Functional Overview of the IT Security Tool

The following table describes the functions of the IT Security Tool.

Table 6.1-1 Functions of the IT Security Tool

Function	Description
Information	Displays the summary of the security settings that were configured by the IT Security Tool.
Setup	According to the selected IT security version, configures the security settings by setting the security model and user management type.
Save	Saves the security settings of the OS. The security settings are encrypted with a specified password (encryption key).
Restore	Restores the security settings of the OS to the saved security settings.

Continues on the next page

Table 6.1-1 Functions of the IT Security Tool (Table continued)

Function	Description
Change Password (Encryption Key)	Changes the password (encryption key) of the saved security settings. This function is used when you want to change the password periodically.
Import or Export	Exports the information configured by the IT Security Tool to a file. Or, imports an exported file.

When IT security version 2.0 is selected, only the Standard model is available for security model. The user management type is selectable from Domain, Combination, and Standalone management. When operating with Linked domain management, select the Standalone management for user management.

When IT security version 1.0 is selected, either the Standard model or Legacy model can be selected for security model. The user management type is selectable from Domain, Combination, and Standalone management. When operating with Linked domain management, select the Standalone management for user management.

The default display of the IT security setup window differs depending on whether the tool is used during new installation or upgrading from an earlier version of the product.

IT Security Version

IT security versions are classified based on the strength of the security settings of each security model and the extent of settings.

IT Security Version 2.0

This version was designed after reconsidering the IT security version1.0 and includes more security measures.

IT Security Version 1.0

This version offers the same security measures as ProSafe-RS R4.02 and earlier versions.

Security Models

You can select from the following security models according to the required security strength.

Standard Model

This model enables access control by user authentication, DCOM setting, and Windows Firewall to guard against direct attacks.

TIP

If you need a higher level of security than what the Standard model provide, the Strengthened model is available. Please consult YOKOGAWA if IT security of the Strengthened model is required.

Legacy Model

This model does not strengthen security. Since this model disables Windows Firewall, you need to consider the possible impact of this model's vulnerability to information leaks, worms, and virus attacks when you select this model.

User Management Types

With the Standard model, you can select Domain, Combination, or Standalone for the user management type. When operating with Linked domain management, select the Standalone management.

With the Legacy model, you can select only Standalone management as the user management type.

- **Domain Management**

  Select this option when managing user and group accounts using the Windows domain controller.

- **Combination Management**

  Select this option when installing the Windows domain controller and using the product with domain users and local users.

- **Standalone Management**

  Select this option when managing user and group accounts for each computer without using the Windows domain controller. Although user accounts are created on each computer in this case, user groups and the user management type must match on all related computers.

  When operating with Linked domain management, select the Standalone management for user management.

Security Model and User Management within a Control Bus Domain

Within a V net domain or a Vnet/IP domain, the security model and user management type must be consistent. As the exception, however, Domain management and Combination management can be mixed. This mixed use of user management is also allowed for file server computers.

Standalone Management and Windows Domain

Even on Windows domain member computers, you can apply the "Standard model with Standalone management" type of security settings.

6.2 Domain Link Management Tool

The Domain Link Management Tool is the security configuration utility for YOKOGAWA system products. You need to use this tool to provide security measures as linked domain management on computers where the product is installed.

The security measures as linked domain management are implemented as follows. First, apply the IT security settings for standalone management with IT Security Tool. After that, join the computer to the domain and run the Domain Link Management Tool to add the corresponding domain groups to the members of the local groups for the products installed on the computer.

Adding a domain group to the members of the local group for the product installed on the computer by using the Domain Link Management Tool is called linking the domain. Conversely, deleting the domain group from the members of the local group is called unlinking the domain.

IMPORTANT

- The domain can be linked if the following conditions are met.
  - All of YOKOGAWA system products installed on the computer support the linked domain management.
  - The IT security settings for standalone management are applied to the installed products with IT Security Tool.
  - The computer is joined to the domain.
- You can link or unlink the domain for all of YOKOGAWA system products installed on the computer at once.
- If you install another YOKOGAWA system products that support linked domain management after linking domains, you must apply IT security settings with IT Security Tool and set them with Domain Link Management Tool. The same applies to upgrading or version upgrading the installed products.
- For the file server for ProSafe-RS, use the Domain Link Management Tool for File Server in the ProSafe-RS software medium. If the file server is shared by CENTUM VP and ProSafe-RS, use the Domain Link Management Tool for File Server in the software medium of each product to set each.

The following figure shows the Domain Link Management Tool.

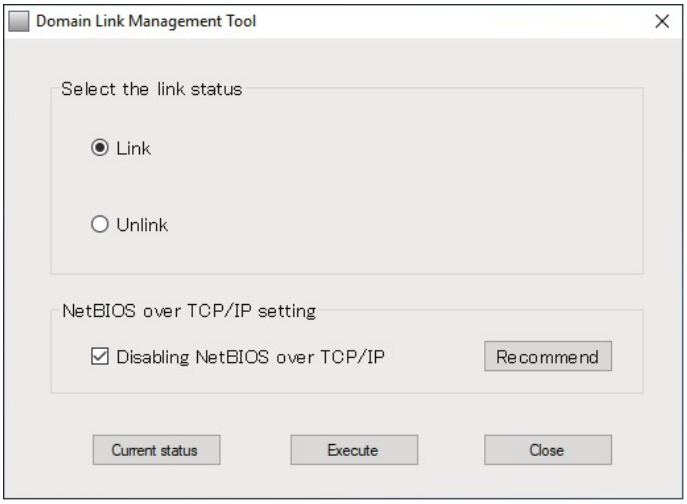

Figure 6.2-1 Domain Link Management Tool

Select the link status

When changing from the standalone management to the linked domain management, select Link. When changing from the linked domain management to the standalone management, select Unlink.

TIP

When you start the Domain Link Management Tool, Link is selected.

SEE ALSO

For more information about changing the user management type, refer to:

- 6.4.1, “SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management” on page 6-12
- 6.4.2, “For File Server or Domain Controller” on page 6-19

NetBIOS over TCP/IP setting

The Disabling NetBIOS over TCP/IP check box switches to the recommended state (Selected/Clear) in conjunction with the Select the link status (Link/Unlink). If you have previously execute the Domain Link Management Tool or separately set the Disabling NetBIOS over TCP/IP by using the IT Security Tool, that configuration is applied to the check box. If you want to change the Disabling NetBIOS over TCP/IP check box setting from the recommended setting or the previous setting, select the link status, and then perform select/clear operation.

When you click the Recommend, the recommended setting according to the Select the link status is applied to the Disabling NetBIOS over TCP/IP check box. If multiple products that support linked domain management are installed on the computer and the recommended settings for Disabling NetBIOS over TCP/IP are different from each other, the Clear setting takes precedence.

TIP

- The setting of Disabling NetBIOS over TCP/IP for products that do not support the linked domain management does not affect the recommended setting.
- If the computer is not in the proper state to use the Domain Link Management Tool, the Disabling NetBIOS over TCP/IP check box remains unchecked and cannot be changed.

Current status

When clicking the Current status, the status related to linked domain management appears.

While the Current status dialog box is displayed, you cannot execute or close the Domain Link Management Tool. Before you execute or close the tool, click the Close button in the upper right corner of the Current Status dialog box.

The following figure shows a display example of the Current status dialog box.

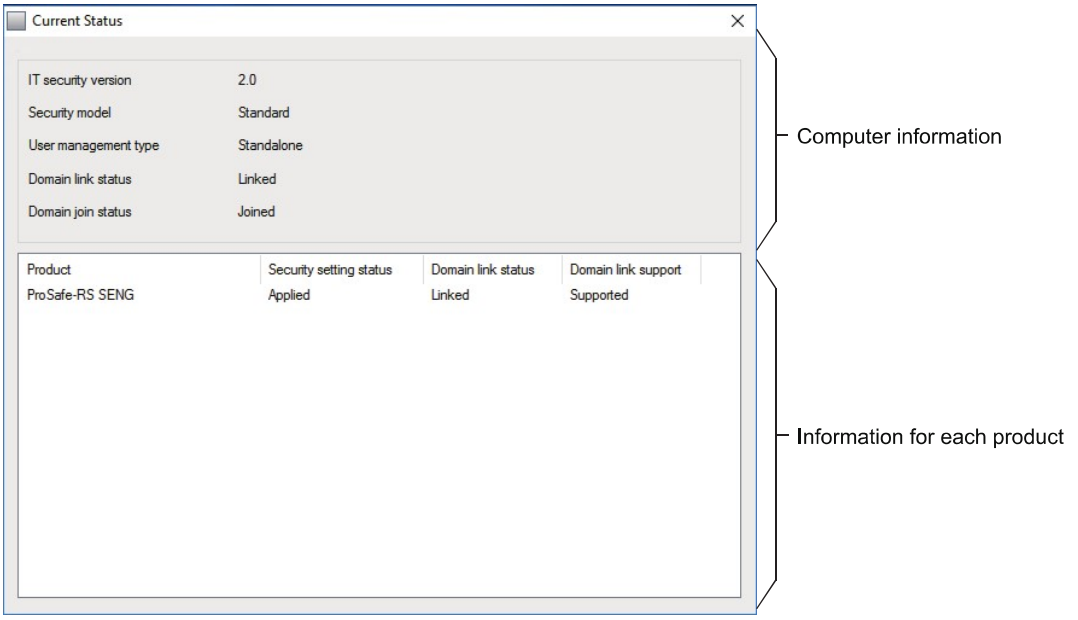

Figure 6.2-2 Display example of the Current Status dialog box

Computer information is displayed at the top of the dialog box, and information for each product is displayed at the bottom. This figure is a display example when the domain linking process by the Domain Link Management Tool is completed properly.

The following table shows the information displayed in the Current status dialog box, divided into computer information and information for each product.

Table 6.2-1 Information displayed in the Current Status dialog box - Computer information

Item	Display example	Description
IT security version	1.0	Items set by the IT Security Tool.
	2.0	
Security model	Standard (*1)	
	Strengthened (*1)	
	Legacy	
User management type	Standalone (*1)	
	Combination	
	Domain	
Domain link status	Linked	The domain is linked for all products installed on the computer.
	Some products are not linked	The domain is not linked for some products installed on the computer.
	Not linked	The domain is not linked for all products installed on the computer.
Domain join status	Joined (*1)	The computer is joined to the domain.
	Not joined	The computer is not joined to the domain.

*1: A condition required for proper processing when you select and execute the Link.

Table 6.2-2 Information displayed in the Current Status dialog box - Information for each product

Item	Display example	Description
Product	ProSafe-RS SENG	The product name and station type are displayed.
Security setting status	Applied (*1)	Both the product installation and the setting by IT Security Tool are complete.
	Not applied	The product installation is complete, but the setting by IT Security Tool is not yet complete.
	Installing	The product installation is not complete.
Domain link status	Linked	Domain linking process has been performed for the product.
	Not linked	Domain linking process has not been performed for the product.
Domain link support	Supported (*1)	The product supports the linked domain management type.
	Not supported	The product does not support the linked domain management type.

*1: A condition required for proper processing when you select and execute the Link.

TIP

The Domain Link Management Tool for File Server in the ProSafe-RS software medium links/unlinks the domain only for the local group related to ProSafe-RS, but the status related to linked domain management of coexisting products can be checked.

Displaying the unusual status

If the combination of the user management type, the domain link status, and the domain join status of computer information is unusual, that area will be displayed in red. The following table shows the unusual combination:

Table 6.2-3 Unusual combination

No.	User management type	Domain link status	Domain join status
1	Standalone	Some products are not linked	Joined
2	Standalone	Linked	Not joined
3	Standalone	Some products are not linked	Not joined
4	Domain	Not linked	Not joined
5	Combination	Not linked	Not joined

The unusual combinations shown in the table are considered transient conditions that occur when trying to set or change any of the user management types. Set correctly so that it does not become unusual combination.

TIP

When attempting to link the domain, the unusual combination shown in No.1 occurs in the following cases.

- While installing YOKOGAWA system products that support the linked domain management
- IT security settings for standalone management is applied, but the domain is not linked.

After installing the product, apply the IT security settings of standalone management with IT Security Tool and link the domain.

SEE ALSO For more information about setting and changing the user management type, refer to:

- 6.1, “IT Security Tool” on page 6-2
- 6.4.1, “SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management” on page 6-12

Execution and error message

When you click Execute, the domain linking process or the process of unlinking the domain occurs for the installed products, depending on the Select the link status. In addition, disabling or enabling NetBIOS over TCP/IP is applied.

When attempting to link the domain, an error message will be displayed and the process will not be performed depending on the conditions. Take the necessary measures.

SEE ALSO For more information about the error messages and countermeasures, refer to:

“■ Error messages and countermeasures” in B3.6.3, “Running Domain Link Management Tool” in Installation Guide (IM 32P01C50-01EN)

6.3 Setting the IT security

When setting the IT security of linked domain management, perform in the order of setting with IT Security Tool, joining computer to domain, and domain linkage with Domain Link Management Tool. For user management types other than linked domain management, the Domain Link Management Tool is not used.

If the IT Security Tool is running, the Domain Link Management Tool cannot be started. When you have finished making settings with the IT Security Tool, close the tool.

SEE ALSO

For more information about running the IT Security Tool, refer to:

B3.6.1, “Running the IT Security Tool” in Installation Guide (IM 32P01C50-01EN)

For more information about running the Domain Link Management Tool , refer to:

B3.6.3, “Running Domain Link Management Tool” in Installation Guide (IM 32P01C50-01EN)

6.4 Changing the IT Security Settings

This section describes how to change the IT security settings that have been applied.

Changes to IT security settings include:

- Change the security model
- Change the IT security version
- Change the user management type
- Change Individual setting items
- Join/leave the computer to/from the domain
- Change the domain link status

When you change the IT security settings, close all running applications before starting the IT Security Tool.

6.4.1 SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management

This section describes the procedure for changing the IT security settings on an SENG PC, a computer installed with only AD Server, or a computer dedicated to license management. The description of the setting procedure of IT Security Tool and Domain Link Management Tool is omitted here. Set it the same way as the first IT security setting.

SEE ALSO For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

For more information about the first configuration by the IT Security Tool, refer to:

B3.6.1, "Running the IT Security Tool" in Installation Guide (IM 32P01C50-01EN)

For more information about adding computers to the domain, refer to:

B2.5, "Adding Computers to the Domain" in Installation Guide (IM 32P01C50-01EN)

For more information about the first configuration by the Domain Link Management Tool, refer to:

B3.6.3, "Running Domain Link Management Tool" in Installation Guide (IM 32P01C50-01EN)

■ Cautions

Precautionary notes on changing IT security settings on a computer installed with the software of the ProSafe-RS software are as follows:

● Note on Changing the Security Model to Legacy Model

When you have changed to the Legacy model for a system using Windows authentication, which is a user authentication mode available with the access control and operation history management functions, you must configure the settings for using ProSafe authentication.

SEE ALSO For more information about the required settings for operation in ProSafe authentication mode, refer to:

- E2.2.1, "Settings for access control" in Engineer's Reference Manual (IM 32P04B10-01EN)
- "■ Settings required when ProSafe authentication mode is selected" in E2.2.1, "Settings for access control" in Engineer's Reference Manual (IM 32P04B10-01EN)
- "■ Tasks required after changing user authentication mode" in E2.3.2, "Operations performed by administrators" in Engineer's Reference Manual (IM 32P04B10-01EN)

● Notes on Changing the User Management Type

For a system using Windows authentication, which is a user authentication mode available with the access control/operation history management function, you need to perform the following tasks:

- When you have changed from Standalone management to Domain/Combination/Linked domain management or vice versa, you need to set up the users who uses SENG again. If you created a new Windows user of SENG, register the user in the Engineers' Account Builder.

■ User Who Can Change IT Security Settings

To be able to change the IT security settings, you need to have the required rights depending on the applied security model and user management type.

Table 6.4.1-1 User Who Can Change IT Security Settings

<table>
<tr><th colspan="2" rowspan="3">Currently applied security model and user management type</th><th colspan="4">Security model and user management type to be applied</th></tr>
<tr><th rowspan="2">Legacy model</th><th colspan="3">Standard model</th></tr>
<tr><th>Standalone management</th><th>Linked domain type</th><th>Domain/Combination management</th></tr>
<tr><td colspan="2">Legacy model</td><td colspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td></tr>
<tr><td colspan="2"></td><td colspan="2"></td><td></td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1) (*2) (*3)</td></tr>
<tr><td colspan="2"></td><td colspan="2"></td><td></td><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1)</td></tr>
<tr><td rowspan="5">Standard model</td><td rowspan="2">Standalone management</td><td colspan="2" rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*4)</td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1) (*2) (*3)</td></tr>
<tr><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1)</td></tr>
<tr><td rowspan="2">Linked domain management</td><td rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*4)</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td></tr>
<tr><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*4)</td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1)</td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1)</td></tr>
<tr><td rowspan="3">Domain/Combination management</td><td colspan="2" rowspan="3">Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*5)</td><td rowspan="3">Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1) (*2)</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td></tr>
<tr><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1) (*2) (*3)</td></tr>
<tr><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1)</td></tr>
</table>

*1: Log on to the computer when the computer is connected to the domain.
*2: While changing, the user name and password of the domain are required.
*3: When this user applies IT security and uses iDefine interface package, execute the batch file.
*4: Set up in the Domain Link Management Tool. No need to reconfigure the IT Security Tool.
*5: Before you change the IT security settings, remove the computer from the domain.

SEE ALSO For more information about how to execute the batch file when using iDefine interface package, refer to:

"■ User Who Performs Update Installation" in C4.1, "Installation for Upgrading" in Installation Guide (IM 32P01C50-01EN)

Changes related to User Management other than Linked Domain Management

IT Security Tool is used when changing the user management other than linked domain management, but Domain Link Management Tool is not used. Depending on the security model and user management type you are going to change, you may need to join the computer to the domain or remove the computer from the domain.

Follow these steps to change the setting with IT Security Tool:

1. Sign in to the computer as a user who has authority to change IT security settings.
2. From the Start menu, start the IT Security Tool.
3. Click [Setup].
4. Select the security model and user management type you want to change to.
   The rest of the procedure is the same as that for the normal IT security setups.

SEE ALSO For more information about running the IT Security Tool, refer to:

B3.6.1, "Running the IT Security Tool" in Installation Guide (IM 32P01C50-01EN)

For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

Notes on Changing the User Management Type

- When you change from Standalone management to Domain/Combination management, create user groups and user accounts in advance using the domain controller.
- When you change from Standalone management to Domain/Combination management, add the computer to the domain before applying the IT security settings.
- When you change from Domain/Combination management to Standalone management, remove the computer from the domain before you change the IT security settings.

SEE ALSO For more information about how to call up the Current IT security setting information dialog box, refer to:

6.9, "Viewing the Information Configured by the IT Security Tool" on page 6-45

For more information about the required tasks with a domain controller and the procedure to add computers to a domain, refer to:

B2., "Setting Up the Windows Domain Environment" in Installation Guide (IM 32P01C50-01EN)

For more information about registering engineers, refer to:

"■ Registering an engineer's account" in E2.2.3, "Registering engineers" in Engineer's Reference Manual (IM 32P04B10-01EN)

Migrating the standard model (combination/domain management) computer to other domain

Follow these steps to migrate the standard model (combination/domain management) computer to other domain:

1. Sign in to the computer as a local user who has authority to change IT security settings.

2. Remove the computer from the current domain.
3. Change the security model of the computer from combination/domain management to standalone management.
4. Join the computer to the target domain.
5. Sign in to the computer as a local user who has authority to change IT security settings.
6. Change the computer security model from standalone management to combination/domain management.

Changes related to Linked Domain Management

When changing from linked domain management to a user management type other than linked domain management, or vice versa, the tool to be used differs depending on each case.

Reconfiguring IT security during linked domain management operation

IT security needs to be reconfigured in the following cases:

- Installed ProSafe-RS patch version software that requires IT security settings
- Distributed the license for the SOE OPC Interface Package
- Changing the IT Security setting values

To reconfigure IT security during linked domain management operation, use IT Security Tool. Sign in as a local user or a domain user who has authority to change IT security settings, and apply IT security of standalone management by using IT Security Tool.

Changing from standard model with standalone management

When changing from the standard model with standalone management to the standard model with linked domain management, join the computer to the domain, and then link the domain by using the Domain Link Management Tool.

TIP

The domain user authentication dialog box appears because you are linking the domain as a local user who has authority to change IT security settings. Enter the user name and password of the domain user in the authentication dialog box. The user name and password do not have to be those of the domain administrator.

Changing from standard model with combination/domain management or from legacy model

When changing from the standard model with combination management or domain management to the standard model with linked domain management, use both IT Security Tool and Domain Link Management Tool.

Follow these steps to change the user management type:

1. Keep the computer joined to the domain and sign in with a local user who has authority to change IT security settings.
2. From the Start menu, start the IT Security Tool.
3. Click [Setup].
4. Change the user management type to standalone management and complete the IT security settings.
5. Remove the computer from the domain.
6. Sign in to the computer as a local user who has authority to change IT security settings.
7. From the Start menu, start the IT Security Tool.

8. Click [Setup].
9. Complete the IT security settings of standalone management.
10. Join the computer to the domain.
11. Sign in to the computer as a local user who has authority to change IT security settings.
12. Start the Domain Link Management Tool from the Start menu.
13. Complete the settings for linking domain.

TIP

When the domain user authentication dialog box appears, enter the user name and password of the domain user. The user name and password do not have to be those of the domain administrator.

When changing from the legacy model to the standard model with linked domain management, if the computer has joined the domain, perform from step 1 above. If the computer is not joined to the domain, start from step 6 above.

● Changing to standard model with standalone management

When changing from the standard model with linked domain management to the standard model with standalone management, use Domain Link Management Tool.

Follow these steps to change the user management type:

1. Keep the computer joined to the domain and sign in with a local user or a domain user who has authority to change IT security settings.
2. Start the Domain Link Management Tool from the Start menu.
3. Complete the settings for unlinking the domain.
4. Remove the computer from the domain.

● Changing to standard model with combination/domain management

When changing from the standard model with linked domain management to the standard model with combination management or domain management, use both IT Security Tool and Domain Link Management Tool.

Follow these steps to change the user management type:

1. Keep the computer joined to the domain and sign in with a local user or a domain user who has authority to change IT security settings.
2. Start the Domain Link Management Tool from the Start menu.
3. Complete the settings for unlinking the domain.
4. Keep the computer joined to the domain and sign in with a local user or a domain user who has authority to change IT security settings.
5. From the Start menu, start the IT Security Tool.
6. Click [Setup].
7. Complete the IT security settings of combination or domain management.

● Additionally installing the products supporting linked domain management

For the products to be additionally installed, apply IT security of standalone management and link the domain.

To additionally install a product supporting linked domain management, follow these steps:

1. Sign in as a local user who belongs to the Administrators group of the local computer.
2. Install the product supporting linked domain management.

3. Select [Yes, I want to set up IT security now.] on the dialog box that appears after the installation, and click [Finish].
   The IT Security Tool starts.
4. Click Setup.
5. Complete the IT security settings of standalone management.
6. Sign in to the computer as a local user or a domain user who has authority to change IT security settings.
7. Start the Domain Link Management Tool from the Start menu.
8. Complete the settings for linking domain.

TIP

If you start the Domain Link Management Tool as a local user who has authority to change IT security settings, the domain user authentication dialog box appears. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.

Additionally installing the products not supporting linked domain management

When additionally installing products that do not support linked domain management, it is necessary to change the user management type to combination management or domain management in advance.

IMPORTANT

If you install products that do not support linked domain management in a state in which the domain is linked and you select user management other than standalone management in IT Security Tool, a dialog box that prompts you to change to another user management type appears. Unlink the domain, and then set it in IT Security Tool.

To additionally install a product not supporting linked domain management, follow these steps:

1. Keep the computer joined to the domain and sign in with a local user or a domain user who has authority to change IT security settings.
2. Start the Domain Link Management Tool from the Start menu.
3. Complete the settings for unlinking the domain.
4. Sign in as a local user who belongs to the Administrators group of the local computer.
5. Install the product not supporting linked domain management.
6. Select [Yes, I want to set up IT security now.] on the dialog box that appears after the installation, and click [Finish].
   The IT Security Tool starts.
7. Click Setup.
8. Complete the IT security settings of combination or domain management.

Changing to another domain during linked domain management operation

This section describes the procedures assuming a case where a system is constructed using a temporary domain controller and the system is migrated to an official domain controller.

Follow these steps to change to another domain during linked domain management operation:

1. Keep the computer joined to the original domain and sign in with a local user or a domain user who has authority to change IT security settings.

2. Start the Domain Link Management Tool from the Start menu.
3. Complete the settings for unlinking the domain.
4. Remove the computer from the original domain.
5. Join the computer to the target domain.
6. Sign in to the computer as a local user who has authority to change IT security settings.
7. Start the Domain Link Management Tool from the Start menu.
8. Complete the settings for linking domain.

TIP

If you start the Domain Link Management Tool as a local user who has authority to change IT security settings, the domain user authentication dialog box appears. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.

6.4.2 For File Server or Domain Controller

This section describes the procedures for changing the security settings on a computer that serves only as a file server or a domain controller computer. The description of the setting procedure of IT Security Tool and Domain Link Management Tool is omitted here. Set it the same way as the first IT security setting.

IMPORTANT

- When you change the IT security settings on a file server or domain controller computer, prepare the initial security settings that were saved before using the IT Security Tool.
- When operating a file server with linked domain management, use the IT Security Tool for file server/domain controller and the Domain Link Management Tool for File Server for the products that support linked domain management.
- The Domain Link Management Tool for File Server in the ProSafe-RS software medium links/unlinks the domain only for the local group related to ProSafe-RS. If the file server is shared by CENTUM VP and ProSafe-RS, use the Domain Link Management Tool for File Server in the software medium of each product to set each.
- When sharing a file server with a product that does not support linked domain management and using it in a domain environment, operate with domain management or combination management.

SEE ALSO

For more information about restoring the security settings of a file server or domain controller computer without installing the ProSafe-RS software, refer to:

6.6.2, “Procedure for a File Server or Domain Controller” on page 6-36

For more information about how to start the installation menu, refer to:

B3.5, “Installing the ProSafe-RS Software” in Installation Guide (IM 32P01C50-01EN)

For more information about the first time configuring the security settings on a file server with the ProSafe-RS software not installed, refer to:

B5.1, “Setting Up a Computer that Serves Only as a File Server” in Installation Guide (IM 32P01C50-01EN)

For more information about the first time configuring the security settings on a domain controller computer with the ProSafe-RS software not installed, refer to:

B2.3, “Configuring Security Settings for the Domain Controller” in Installation Guide (IM 32P01C50-01EN)

User Who Can Change IT Security Settings on a File Server

To be able to change the IT security settings on a file server, you need to have the required rights depending on the applied security model and user management type.

Table 6.4.2-1 User Who Can Change Security Settings

<table>
<tr><th colspan="2" rowspan="3">Currently applied security model and user management type</th><th colspan="4">Security model and user management type to be applied</th></tr>
<tr><th rowspan="2">Legacy model</th><th colspan="3">Standard model</th></tr>
<tr><th>Standalone management</th><th>Linked domain management</th><th>Domain/Combination management</th></tr>
<tr><td colspan="2" rowspan="3">Legacy model</td><td rowspan="3">Local user who belongs to the Administrators group of the local computer</td><td rowspan="3">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td rowspan="3">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td></tr>
<tr><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1) (*2)</td></tr>
<tr><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*1)</td></tr>
<tr><td rowspan="6">Standard model</td><td rowspan="2">Standalone management</td><td colspan="2" rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*3)</td><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*2) (*4)</td></tr>
<tr><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer (*2) (*4)</td></tr>
<tr><td rowspan="2">Linked domain management</td><td rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*3)</td><td rowspan="2">Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*4)</td><td rowspan="2">-</td></tr>
<tr><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*3)</td></tr>
<tr><td rowspan="3">Domain/Combination management</td><td colspan="2" rowspan="3">Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*5)</td><td rowspan="3">-</td><td>Domain users who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain (*1)</td></tr>
<tr><td>Local user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1) (*2)</td></tr>
<tr><td>Domain user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1)</td></tr>
</table>

*1: Log on with your computer joined to the domain.
*2: While changing, entry of the user name and password of the domain user is required.
*3: Set up in the Domain Link Management Tool. No need to reconfigure with the IT Security Tool.
*4: Certain task is required while the computer is not joining the domain and after the computer joined the domain.
*5: Before you change the IT security settings, remove the computer from the domain.

User Who Can Change IT Security Settings on the Domain Controller

When changing the IT security settings on the domain controller computer, sign in to the computer as a user who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain.

Changes related to User Management other than Linked Domain Management

There are the following three types procedures for changing the user management other than linked domain management:

- Basic procedure
- Procedure to change from Standard model (Standalone management) to Standard model (Domain/Combination management) on a file server
- Procedure to change from Standard model (Domain/Combination management) to Standard model (Standalone management) on a file server

Basic Procedure for Changing Security Settings

1. Sign in to the computer as a user who has authority to change IT security settings.

TIP

If the file server is shared with CENTUM VP, the user who has the authority to change IT security settings must also belong to the CTM_MAINTENANCE or CTM_MAINTENANCE_LCL group, depending on the combination of the current security model/user management type and the security model/user management type that you are about to configure. However, this does not apply when reconfiguring IT security settings without changing the model from the legacy model.

2. Start the installation menu from the software medium of the product, and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.
3. Click [Restore].
4. Select a file that the previous security settings are saved prior to running the IT Security Setting Tool so as to restore the securities.
   For a file server, if it is not a domain member now, use the file holding the initial security settings that were saved while it was standalone. If it is a domain member now, use the file holding the initial security settings that were saved after it joined the domain.
5. After restoring is completed, restart the computer.
6. For a file server, if its domain membership is to be changed, add to or remove from the domain.
7. Start the installation menu again and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.
8. Click [Setup].
9. Select the security model and the user management type you want to change to.
   The rest of steps are the same as the procedure for the first time setup.

TIP

If the file server is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP R6.04 or later software medium and set IT security for CENTUM VP as well.

SEE ALSO For more information about restoring IT security settings on a file server or a domain controller, refer to:

6.6.2, “Procedure for a File Server or Domain Controller” on page 6-36

For more information about the first configuration of security settings on a file server, refer to:

B5.1, “Setting Up a Computer that Serves Only as a File Server” in Installation Guide (IM 32P01C50-01EN)

For more information about the first configuration of security settings for a domain controller, refer to:

B2.3, “Configuring Security Settings for the Domain Controller” in Installation Guide (IM 32P01C50-01EN)

When Changing from Standard Model (Standalone Management) to Standard Model (Domain/Combination Management) on a File Server

For this change, you need to save the security settings after the file server computer joined a domain because the security settings are changed by joining the domain. Follow these steps to make the change:

1. Sign in to the computer as an administrative user who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer.

TIP If the file server is shared with CENTUM VP, the administrative user must also belong to the CTM_MAINTENANCE group.

2. Start the installation menu from the software medium of this product.
3. Click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.
4. Restore the initial security settings saved (while the computer is not a member of a domain) before you fist time used the IT Security Tool to setup security.
5. After restarting, add the computer to the domain.
6. Sign in as the same administrative user you previously signed in in step 1.
7. Start the installation menu and click [Setting IT Security (File server/domain controller use)].
   The IT Security Tool starts.
8. Click [Save].
9. Save the security settings as the initial settings right after it joined a domain.
10. On the IT Security Tool's menu, click [Setup].
11. Select the security model and user management type for the file server, and run the setup.
12. After applying the security settings, restart the computer.

TIP If the file server is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP R6.04 or later software medium and set IT security for CENTUM VP as well.

When Changing from Standard Model (Domain/Combination Management) to Standard Model (Standalone Management) on a File Server

For this change, the timing of removal from the domain is different from the basic procedure.

1. Sign in to the computer as an administrative user who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer.

TIP

If the file server is shared with CENTUM VP, the administrative user must also belong to the CTM_MAINTENANCE_LCL group.

2. Remove the computer from the domain.
3. Restart the computer, and sign in as the same administrative user that you signed in in step 1.
4. Start the installation menu from the software medium of this product.
5. Click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.
6. Click [Restore] to restore the initial security settings that were saved before the IT Security Tool was first used to setup security (before the computer joined a domain).
7. Restart the computer.
8. Sign in as the same administrative user you previously signed in in step 1.
9. Start the installation menu from the software medium of this product.
10. Click [Setting IT Security (File server/domain controller use] to start the IT Security Tool.
11. Click [Setup], select Standard model and Standalone management for the file server, and run the setup.
12. After applying the security settings, restart the computer.

TIP

If the file server is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP R6.04 or later software medium and set IT security for CENTUM VP as well.

● When migrating the standard model (combination/domain management) computer to other domain on a file server

Follow these steps to migrate the standard model (combination/domain management) computer to other domain:

1. Change the security model of the computer in the migration source domain from combination/domain management to standalone management.
2. Change the computer security model from standalone management to combination/domain management for the migration destination domain.

SEE ALSO

For more information about procedure to change from combination/domain management to standalone management, refer to:

"● When Changing from Standard Model (Domain/Combination Management) to Standard Model (Standalone Management) on a File Server" on page 6-22

For more information about procedure to change from standalone management to combination/domain management), refer to:

"● When Changing from Standard Model (Standalone Management) to Standard Model (Domain/Combination Management) on a File Server" on page 6-22

■ Changes related to Linked Domain Management

When changing from linked domain management to a user management type other than linked domain management, or vice versa, the tool to be used differs depending on each case.

Reconfiguring IT security during linked domain management operation

To reconfigure IT security of the file server during linked domain management operation, use IT Security Tool.

Follow these steps to reconfigure the IT security:

1. Remove the file server from the domain.
2. Sign in to the file server as a local user who has authority to change IT security settings.

TIP If the file server is shared with CENTUM VP, the local user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

3. Start the installation menu from the software medium of this product.
4. Click [Setting IT Security (File server/domain controller use)].
   The IT Security Tool starts.
5. Click [Restore].
6. Select a file that the previous security settings are saved prior to running the IT Security Setting Tool so as to restore the security settings.

TIP Use the file holding the initial security settings that were saved while it was standalone.

7. Restart the file server.
8. Sign in to the file server as a local user who has authority to change IT security settings.

TIP If the file server is shared with CENTUM VP, the local user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

9. Start the installation menu from the software medium of this product.
10. Click [Setting IT Security (File server/domain controller use)].
    The IT Security Tool starts.
11. Click [Setup].
12. Complete the IT security settings of the File Server Standard Model with Standalone Management.

TIP If the file server is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP R6.08 or later software medium that supports linked domain management, and set IT security of File Server Standard Model with Standalone Management for CENTUM VP as well.

13. Join the file server to the domain.
14. Sign in to the file server as a local user or a domain user who has authority to change IT security settings.

TIP If the file server is shared with CENTUM VP, the local user or domain user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

15. Use Explorer to display the following folder from the software medium of this product.
    `<Drive of software medium>:\ProSafe-RS\SECURITY\`
16. Double click the following program file in the folder.
    `DomainLinkManagementToolForRSFileServer.cmd`

The Domain Link Management Tool for File Server starts.

17. Complete the settings for linking domain.

TIP

- If you start the Domain Link Management Tool as a local user who has authority to change IT security settings, the domain user authentication dialog box appears. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.
- If the file server is shared with CENTUM VP, the domain linkage settings for CENTUM VP is required separately by using the Domain Link Management Tool for File Server in the software medium of CENTUM VP R6.08 or later.

Changing from standard model with standalone management on a file server

When changing from the standard model with standalone management to the standard model with linked domain management, use Domain Link Management Tool.

Follow these steps to change the user management type:

1. Join the file server to the domain.
2. Sign in to the file server as a local user or a domain user who has authority to change IT security settings.

TIP

If the file server is shared with CENTUM VP, the local user or domain user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

3. Use Explorer to display the following folder from the software medium of this product.
   `<Drive of software medium>:\ProSafe-RS\SECURITY\`
4. Double click the following program file in the folder.
   `DomainLinkManagementToolForRSFileServer.cmd`

   The Domain Link Management Tool for File Server starts.
5. Complete the settings for linking domain.

TIP

- If you start the Domain Link Management Tool as a local user who has authority to change IT security settings, the domain user authentication dialog box appears. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.
- If the file server is shared with CENTUM VP, the domain linkage settings for CENTUM VP is required separately by using the Domain Link Management Tool for File Server in the software medium of CENTUM VP R6.08 or later.

Changing to standard model with standalone management on a file server

When changing from the standard model with linked domain management to the standard model with standalone management, use Domain Link Management Tool.

Follow these steps to change the user management type:

1. Keep the file server joined to the domain and sign in with a local user or a domain user who has authority to change IT security settings.

TIP

If the file server is shared with CENTUM VP, the local user or domain user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

2. Use Explorer to display the following folder from the software medium of this product.
   `<Drive of software medium>:\ProSafe-RS\SECURITY\`
3. Double click the following program file in the folder.
   `DomainLinkManagementToolForRSFileServer.cmd`

   The Domain Link Management Tool for File Server starts.

4. Complete the settings for unlinking the domain.

TIP

If the file server is shared with CENTUM VP, the domain unlinkage settings for CENTUM VP is required separately by using the Domain Link Management Tool for File Server in the software medium of CENTUM VP R6.08 or later.

5. Remove the file server from the domain.

Changing to another domain during linked domain management operation

This section describes the procedures assuming a case where a system is constructed using a temporary domain controller and the system is migrated to an official domain controller.

Follow these steps to change to another domain during linked domain management operation:

1. Keep the file server joined to the original domain and sign in with a local user or a domain user who has authority to change IT security settings.

TIP

If the file server is shared with CENTUM VP, the local user or domain user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

2. Use Explorer to display the following folder from the software medium of this product.
   `<Drive of software medium>:\ProSafe-RS\SECURITY\`
3. Double click the following program file in the folder.
   `DomainLinkManagementToolForRSFileServer.cmd`

   The Domain Link Management Tool for File Server starts.
4. Complete the settings for unlinking the domain.

TIP

If the file server is shared with CENTUM VP, the domain unlinkage settings for CENTUM VP is required separately by using the Domain Link Management Tool for File Server in the software medium of CENTUM VP R6.08 or later.

5. Remove the file server from the original domain.
6. Join the file server to the target domain.
7. Sign in to the file server as a local user or a domain user who has authority to change IT security settings.

TIP

If the file server is shared with CENTUM VP, the local user or domain user who has authority to change IT security settings must also belong to the CTM_MAINTENANCE group.

8. Use Explorer to display the following folder from the software medium of this product.
   `<Drive of software medium>:\ProSafe-RS\SECURITY\`
9. Double click the following program file in the folder.
   `DomainLinkManagementToolForRSFileServer.cmd`

   The Domain Link Management Tool for File Server starts.
10. Complete the settings for linking domain.

TIP

- If you start the Domain Link Management Tool as a local user who has authority to change IT security settings, the domain user authentication dialog box appears. The user name and password that you enter in the dialog box do not have to be those of the domain administrator.
- If the file server is shared with CENTUM VP, the domain linkage settings for CENTUM VP is required separately by using the Domain Link Management Tool for File Server in the software medium of CENTUM VP R6.08 or later.

6.4.3 Applying the IT Security Version 2.0 Settings to a File Server or Domain Controller

With ProSafe-RS R4.03 or later, when you apply the IT security version 2.0 settings on a file server or a domain controller by using the Setup function of the IT Security Tool, the procedure differs depending on whether IT security version 1.0 is already applied on the computer or a new computer is set up.

IMPORTANT

When you strengthen the security to IT security version 2.0, you must save the initial security settings of the file server or domain controller computer again.

When IT Security Version 1.0 is Applied Already

1. Restore the initial settings that was saved by using the saving function of the IT Security Tool before the computer went into operation.
2. From the installer menu, start the IT Security Tool.
3. Save the settings after restoration.
4. Using the Setup function of the IT Security Tool, apply the required security model.

TIP

If the file server or domain controller is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP software medium and set IT security for CENTUM VP as well. Use the software medium of the following revisions depending on the user management type.

- Linked domain management: R6.08 or later
- Other than Linked domain management: R6.04 or later

SEE ALSO

For more information about how to restore security settings by using the IT Security Tool, refer to:

6.6, “Restoring the IT Security Settings” on page 6-33

When Setting Up a New Computer

1. From the installer menu, start the IT Security Tool.
2. Save the initial settings by using the saving function.
3. Using the Setup function of the IT Security Tool, apply the required security model.

TIP

If the file server or domain controller is shared with CENTUM VP, start the IT Security Tool for file server and domain controller from the installation menu of CENTUM VP software medium and set IT security for CENTUM VP as well. Use the software medium of the following revisions depending on the user management type.

- Linked domain management: R6.08 or later
- Other than Linked domain management: R6.04 or later

6.5 Saving the IT Security Settings

You can save the IT security settings on the local computer using the Save function.

The Save/Restore function of the IT Security Tool is used in the procedure for setting/resetting IT security when building a file server or domain controller. It will not be used for any purpose other than the above, except when it is used according to instructions from YOKOGAWA in case of trouble.

Use the Export/Import function for back up/restore of each setting status that was configured by the IT Security Tool (IT security version, security model, user management type, and on/off of each setting item).

SEE ALSO For more information about the Export/Import function, refer to:

6.8, “Exporting/Importing the IT Security Setting File” on page 6-41

User Who Can Save IT Security Settings

To be able to save the IT security settings, you need to have the required rights depending on the applied security model and user management type.

Table 6.5-1 User Who Can Save Security Settings

Currently applied security model and user management type			
Legacy model	Standard model		
	Standalone management	Linked domain type	Domain/Combination management
User who belongs to the Administrators group of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer
		User who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain	User who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain

Regarding the Files that Hold the Saved Security Settings

Saving the security settings creates two files with extensions of .hed and .csf.

When restoring the saved security settings, both files are required.

6.5.1 SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management

This section describes the procedure for saving the IT security settings on an SENG PC, a computer installed with only AD Server, or a computer dedicated to license management.

Saving Procedure

1. From the Start menu, start the IT Security Tool.
2. Click [Save].
   The Specify destination page appears.

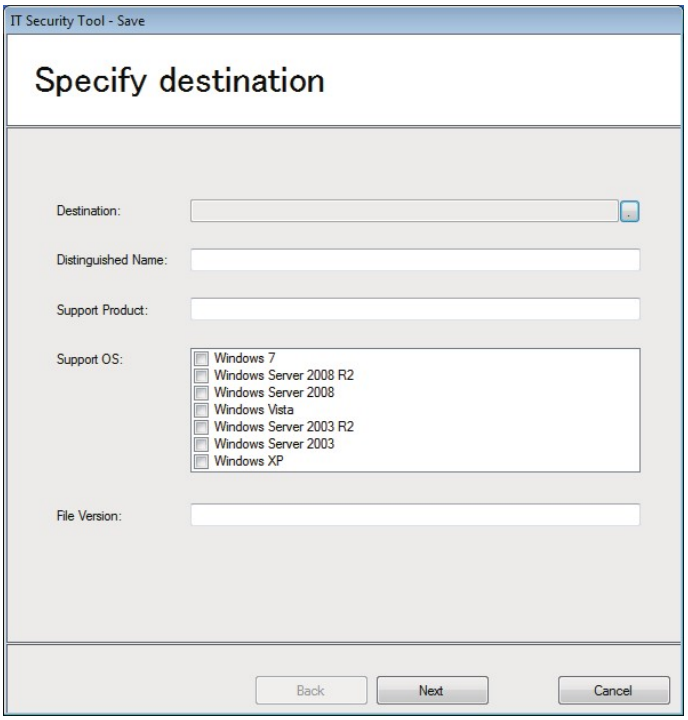

Figure 6.5.1-1 Specify Destination

3. Specify the destination folder and enter other required settings.
   The Distinguished Name and File Version are omissible.
4. Click [Next].
   The Type default account password page appears.

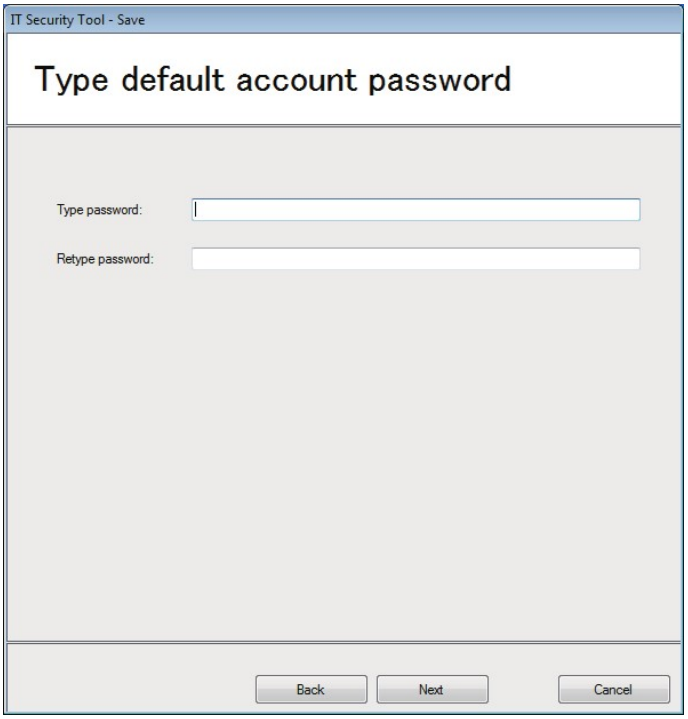

Figure 6.5.1-2 Type Default Account Password

5. Enter the password for use as the initial account password and click [Next].

TIP

This default password will be used when you recover the accounts that were saved with this tool. If the saved account does not exists at restoration, the account is created. This default password will be set as the initial password of the created account.

If multiple accounts have been created, the same password is set for all accounts.

If the set password does not meet the password policy for restoration, an error will occur when recovering an account.

Because this password is set for the account as the initial password, you will be prompted to change the password when you log on to the account for the first time.

The page for entering the password for use as the encryption key of the saved data appears.

Figure 6.5.1-3 Type Password (Encryption Key)

6. Enter the Encryption Key and then click [Next].
   Saving of the security settings starts.

IMPORTANT

- If this password (encryption key) is lost, the saved security settings cannot be restored. The password (encryption key) must be carefully kept by the customer.
- The password (encryption key) must be at least one character.
- The password can consist of upper-case and lower-case alphanumeric characters and the following symbols: ` ~ ! @ # $ % ^ & *( ) _ + - = { } | \ : “ ; ‘ < > ? , . /

  Double-byte characters cannot be used.

7. When the saving is completed, click [Finish].
   If the saving failed, the details of the failure are displayed.
8. On the IT Security Tool menu, click [Close].

IMPORTANT

If any save failures are displayed, contact YOKOGAWA Service.

SEE ALSO For more information about ProSafe-RS applications that can start from Start menu, refer to:

“ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu” in Read Me First (IM 32P01A30-01EN)

6.5.2 Procedure for a File Server or Domain Controller

To save the IT security settings on a computer that serves only as a file server or a domain controller computer, start the installation menu from the ProSafe-RS software medium and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool. The rest of steps are the same as the procedure for an SENG PC.

IMPORTANT

You cannot save the group policy settings that were distributed from the domain controller. You can save only local group policy settings.

SEE ALSO For more information about how to start the installation menu, refer to:

B3.5, “Installing the ProSafe-RS Software” in Installation Guide (IM 32P01C50-01EN)

6.6 Restoring the IT Security Settings

You can restore the security settings of a local computer that were saved by using the Save function.

Preparation for Restoration

According to the user management type of the security settings to be restored, the computer may be required to join a domain or removed from a domain. To restore to the Legacy model, or the Standard model with Standalone or Linked domain management, the computer needs to be removed from a domain. To restore to the Standard model with Domain or Combination management, the computer needs to join a domain.

User Who Can Restore Security Settings

To be able to restore the IT security settings, you need to have the required rights depending on the applied security model and user management type.

Table 6.6-1 User Who Can Restore Security Settings

Security model and user management type to be restored to			
Legacy model	Standard model		
	Standalone type	Linked domain management type	Domain/Combination type
User who belongs to the Administrators group of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE groups of the local computer	User who belongs to both the Administrators and PSF_MAINTENANCE_LCL groups of the local computer (*1)
		User who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain	User who belongs to both the Domain Admins and PSF_MAINTENANCE groups of the domain

*1: Sign in as a user who belongs to the groups shown in the cell below when the PSF_MAINTENANCE_LCL group does not exist on the local computer (that is, when the security model and user management type set before restoration is Legacy model or Standard model with Standalone management).

6.6.1 SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management

This section describes the procedure for restoring the IT security settings on an SENG PC, a computer installed with only AD Server, or a computer dedicated to license management.

IMPORTANT

If you saved the security settings by using the IT Security Tool, you must restore the same user management status as the saved status.

Restoring Procedure

1. From the Start menu, start the IT Security Tool.
2. Click [Restore].
   The Select Security Setting File page appears.

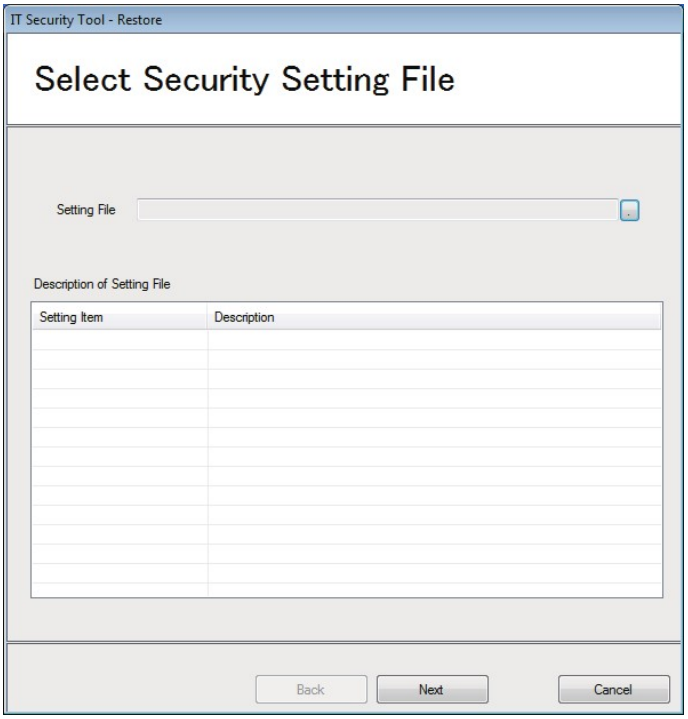

Figure 6.6.1-1 Select Security Setting File

3. Click [...] next to the Setting File box.
   The Open dialog box appears.
4. Select the file you want to use for restoration and then click [Open].

TIP Among the saved and created files, you need to select a file with .hed extension.

   A dialog box appears, prompting you to enter the password (encryption key) for reading the selected file.

5. Enter the password (encryption key) that was set when the file was saved and click [OK].
   If the selected file is restorable, the details are displayed in the Select Security Setting File page.
6. Click [Next].

The Confirm Setting Information page appears.

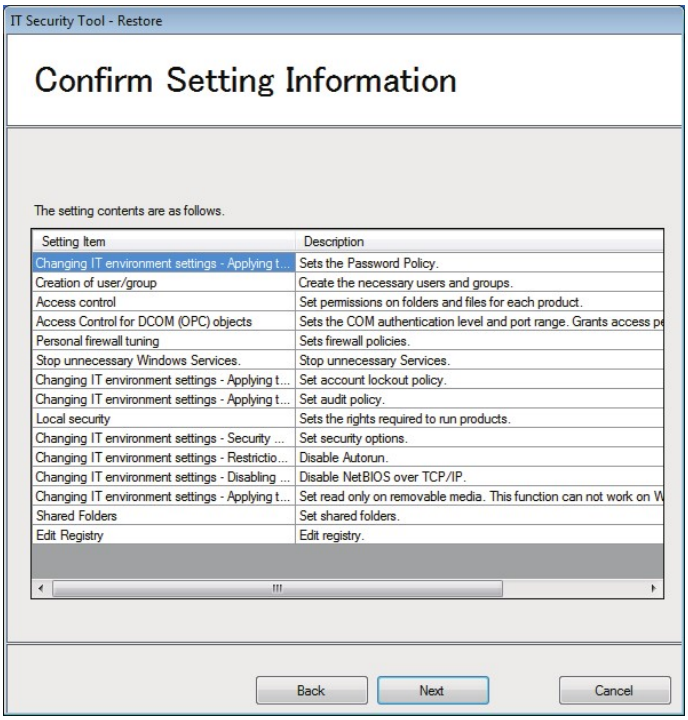

Figure 6.6.1-2 Confirm Setting Information

TIP

Items displayed in the Confirm Setting Information page represent the items accessed when restoring the saved security settings. Although the descriptions of these items are affirmative sentences, it doesn't mean that all of these settings will be applied. Note that the status of whether each item is set to be applied or not is not displayed on the screen.

7. Confirm the settings and click [Next].
   When the setup process is complete, the Setup Completed page appears.

TIP

If there are any items that failed to be set, a list of failed items is displayed.

8. Select the check box for [Restart Now] and click [Finish].
9. Click [Close] to end the IT Security Tool.

IMPORTANT

If any setup failures are displayed, contact YOKOGAWA Service.

SEE ALSO

For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

6.6.2 Procedure for a File Server or Domain Controller

To restore the IT security settings on a computer that serves only as a file server or a domain controller computer, start the installation menu from the ProSafe-RS software medium and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool. The rest of steps are the same as the procedure for an SENG PC.

SEE ALSO For more information about restoring IT security settings on a SENG PC, refer to:

"■ Restoring Procedure" on page 6-34

For more information about how to start the installation menu, refer to:

B3.5, "Installing the ProSafe-RS Software" in Installation Guide (IM 32P01C50-01EN)

6.7 Changing the Security Setting File Password

You can change the password (encryption key) for security setting files used by the IT Security Tool.

6.7.1 SENG PC, Computer Installed with Only AD Server, or Computer Dedicated to License Management

This section describes the procedure for changing the password for IT security setting files on an SENG PC, a computer installed with only AD Server, or a computer dedicated to license management.

When changing password, the two files with .hed version and .csf version having same file name are considered as a set. You can select either [One pair of] or [Multiple pair] for changing passwords. If you select [Multiple pair], the passwords of all the files within the specified folder are changed.

Changing Procedure

1. Log on as a member of the PSF_MAINTENANCE group.
2. From the Start menu, start the IT Security Tool.
3. Click [Change Password (Encryption Key)].
   The Specify backup file of security page appears.

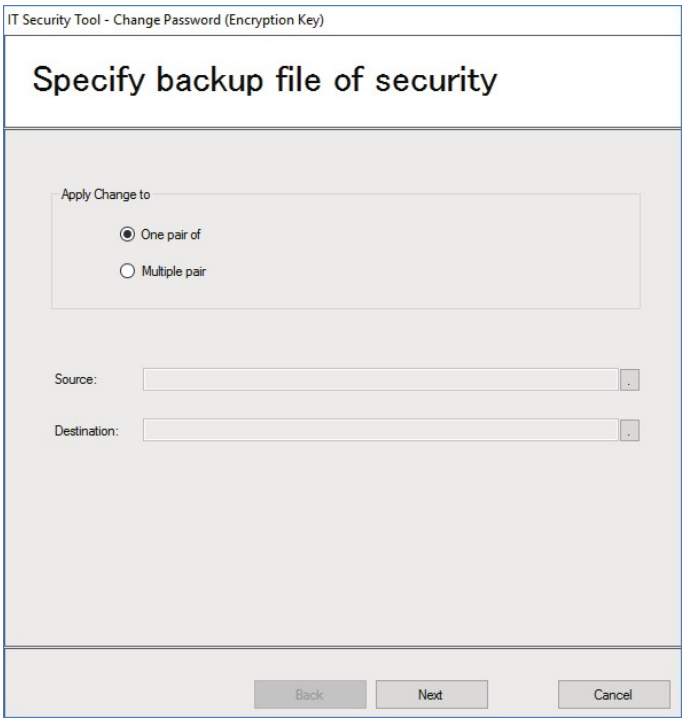

Figure 6.7.1-1 Specify backup file of security

4. Select either of the Apply change to options and set as follows:
   - For changing the encryption key of one pair
     In the [Apply change to] section, select [One pair of], and select the folder where the file set before change and the file set after change are to be saved. Select .hed file as the file set before change.
   - For changing the encryption key of multiple pair
     In the [Apply change to] section, select [Multiple pair], select the folder that contains the file set before change and the folder in which the file set after change is to be saved.
5. Click [Next].
   The Change Password (Encryption Key) page appears.

Figure 6.7.1-2 Change Password (Encryption Key)

6. Enter the old password and new password and click [Next].
   When the change of password (encryption key) is complete, the completion page appears.
7. Click [Finish].
8. On the IT Security Tool menu, click [Close].

SEE ALSO For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

6.7.2 Procedure for a File Server or Domain Controller

This section describes the procedure for changing the password (encryption key) for security setting files on a computer that serves only as a file server or a domain controller computer.

■ Changing Procedure

1. Log on as a member of the PSF_MAINTENANCE group.
2. From the software medium of ProSafe-RS, start the installation menu, click [IT Security Settings (for file server/domain controller)], and then start the IT Security Tool.
   The rest of steps are the same as the procedure for an SENG PC.

SEE ALSO

For more information about changing the password for the security setting files on a SENG PC, refer to:

"■ Changing Procedure" on page 6-38

For more information about how to start the installation menu, refer to:

B3.5, "Installing the ProSafe-RS Software" in Installation Guide (IM 32P01C50-01EN)

6.8 Exporting/Importing the IT Security Setting File

ProSafe-RS provides the function to export and import the selection state of the previously configured IT security settings.

The following IT security settings are the targets of export and import:

- IT security settings configured with R4.03 or later
  Use the export/import function of the IT Security Tool.
- IT security settings that were configured before R4.03
  To export the selection state of the settings configured before R4.03, use the ITSecurity-SettingItemExport tool that is included in the software medium.

  The exported files can be imported by using the IT Security Tool.

You can export and import the setting status configured in the page of "Select Setting Items" of the IT Security Tool.

IMPORTANT

- The Export/Import function reproduces the setting status configured by the IT Security Tool, but does not change the Domain link status displayed in the "Current status" dialog box. The domain link status can be changed by using the Domain Link Management Tool.

  For example, if you import the IT security setting file that was exported from a computer whose domain link status is Linked to a computer whose domain link status is Not linked, the domain link status of the destination computer remains Not linked.

  Conversely, if you import the IT security setting file that was exported from a computer whose domain link status is Not linked to a computer whose domain link status is Linked, the domain link status of the import destination computer remains Linked.
- If you export the IT security setting file from a computer that has domain management, combination management, or legacy model applied, and import the file to a computer whose domain link status is Linked, the import will succeed. If you try to continue the setting, a dialog box will appear prompting you to apply standalone management or close the IT Security Tool and change to another user management type. Take either action.
- After setting IT security by using the Import function, check the Current status dialog box to see if the domain link status is in the expected status. If required, change the user management type or the domain link status.
- You cannot use the ITSecuritySettingItemExport tool on file servers and domain controllers that were configured by using the IT Security Tool before R4.03. The IT security settings in these environments need to be restored manually.

6.8.1 Procedure to Export by Using the IT Security Tool

Follow these steps to export the IT security settings that were configured with R4.03 or later:

1. From the Start menu, start the IT Security Tool.

TIP

For a file server or a domain controller, start the installation menu from the software medium of the product, and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.

2. Click [Import or Export].
   The Export or Import the Selection State of Setting Items dialog box appears.
3. Select [Export].
   The default export destination file name appears automatically in the text box for file name entry.
   `C:\ProgramData\Yokogawa\IA\iPCS\Platform\Security\Config\DisplaySelectInfo.xml`
4. Leave the default file name as is, or change it if necessary.

TIP

Specify xml as the file extension. When any other extension is specified, ".xml" is added automatically to the end of the file name.

5. Click [Execute].
   The export processing starts. If you specified an existing file, the file will be overwritten.

   The following information is written to the specified file, and the Export or Import the Selection State of Setting Items dialog box closes.

   - Security model
   - User management type
   - IT security version
   - State of check box selections made in the Select Setting Items page of the tool

SEE ALSO

For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

6.8.2 Procedure to Export by Using the ITSecuritySettingItemExport Tool

Follow these steps to export the IT security settings that were configured before R4.03:

1. Run the following tool in the software medium as a user with administrative rights.
   `<Drive of ProSafe-RS software medium>:\ProSafe-RS\SECURITY\ITSecuritySettingItemExport.exe`
   The export processing starts. If you specified an existing file, the file will be overwritten.

   The following information is written to the specified file, and the Export or Import the Selection State of Setting Items dialog box closes.

   - Security model
   - User Management Types
   - IT security version
   - State of check box selections made in the Select Setting Items page of the tool

6.8.3 Procedure to Import by Using the IT Security Tool

Follow these steps to import the export IT security settings:

1. From the Start menu, start the IT Security Tool.

TIP

For a file server or a domain controller, start the installation menu from the software medium of the product, and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.

2. Click [Import or Export].
   The Export or Import the Selection State of Setting Items dialog box appears.
3. Select [Import].
   The text box is cleared.
4. Specify the file that you want to import.
5. Click [Execute].
   The Export or Import the Selection State of Setting Items dialog box closes.
6. In the IT Security Tool, click [Setup].
   The imported IT security settings are applied.

TIP

Alternatively, you can also import the selection state of IT security settings by clicking [Setup] in the IT Security Tool and then clicking [Import] in the IT Security Settings page.

SEE ALSO

For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

6.9 Viewing the Information Configured by the IT Security Tool

The information set by the IT Security Tool is displayed in the same dialog box as the Current status dialog box of the Domain Link Management Tool. In this dialog box, in addition to the information set by the IT Security Tool, the status related to linked domain management appears.

The items displayed as information set by the IT Security Tool are as follows:

- Computer information
  - IT security version
  - Security model
  - User management type
- Information for each product
  Security setting status

SEE ALSO For more information about the details of security setting status, refer to:

"■ Current status" on page 6-6

■ Procedure for Viewing

1. Sign in as a member of the PSF_MAINTENANCE group.
2. From the Start menu, start the IT Security Tool.

TIP For a file server or a domain controller, start the installation menu from the software medium of the product, and click [Setting IT Security (File server/domain controller use)] to start the IT Security Tool.

3. Click the [Information] button.
   The Current status dialog box appears.

SEE ALSO For more information about ProSafe-RS applications that can start from Start menu, refer to:

"ProSafe-RS and ProSafe-RS Lite applications that can start from Start menu" in Read Me First (IM 32P01A30-01EN)

6.10 Active Directory-Based Consolidated Management of IT Security Settings

Windows Active Directory has a feature called Group Policy that is used to centrally manage the IT environment of computers and users. Using this Group Policy, you can manage the security policies for client computers within the domain in bulk by offering files for importing IT security settings. The following tasks are required:

- On the domain controller, create group policy objects for implementing security policies.
- By using Active Directory services, create Organizational Units on the domain controller and apply the group policy objects.

TIP

Active Directory-based consolidated management of IT security settings can be applied to computers on which R4.03 or later versions ProSafe-RS software installed.

6.10.1 Creating Group Policy Objects

Follow these steps to create group policy objects for implementing security policies on the domain controller:

1. Insert the software medium of the product into the drive of the domain controller computer.
2. Using Explorer, copy the following file to any folder on the domain controller. You must copy the file to a folder to which the administrator of the domain can access.
   `<Drive of ProSafe-RS software medium>:\ProSafe-RS\SECURITY\GPOFiles\xxx\PSF_Standard_xxx.zip`

   When xxx = 2.0 : The file corresponds to the Standard model of IT security version 2.0

   When xxx = 1.0 : The file corresponds to the Standard model of IT security version 1.0
3. Double click the file that you have copied.
   The file expands into files for import.
4. Open the Control Panel.
5. Select [Administrative Tools] > [Group Policy Management].
   The Group Policy Management dialog box appears.
6. In the left pane, right-click [Group Policy Objects] and select [New].
   The New GPO dialog box appears.
7. Set as follows:
   - Type any name for Name.
   - Select [(none)] for Source Starter GPO.
8. Click [OK].
   A new group policy object is created.
9. Right-click the new group policy object and select [Import Settings].
   The [Import Settings Wizard] appears.
10. Click [Next].
    A dialog box appears, prompting you to back up the existing settings.
11. Since it is a newly created group policy object, click [Next] without backing up.
    [Backup location] appears.
12. In the [Backup folder], select the parent folder of the folder to be imported, and click [Next].
    A list of importable group polices that are stored under the selected parent folder appears.

TIP If you want to view the setting information of the group policy object, click [View Settings...]. The information is displayed in Microsoft Internet Explorer.

13. Select the group policy and click [Next].
    A confirmation dialog box appears, showing whether the group policy to be imported contains any references to security principals or UNC paths.

TIP The following message is displayed in the confirmation dialog box.

"Scan Results:

The Backup do not contain any references to security principals or UNC paths. To continue, click [Next]."

14. Click [Next].
    The [Completing the Import Settings Wizard] dialog box appears.
15. Click [Finish].

Importing of the group policy object starts.

16. When the importing is completed, confirm the imported policy in [Group Policy Management].
17. Open the Control Panel and select [Administrative Tools] > [Group Policy Management] to open Group Policy Management. In the left pane, right-click the target group policy and select [View].

Creation of a group policy object is now completed. Subsequently, you need to create Organizational Units on the domain controller and apply group policy objects to them.

6.10.2 Applying Group Policy Objects to an Organizational Unit

Follow these steps to apply group policy objects to an Organizational Unit on the domain controller:

1. Log on to the domain controller as an administrative user.
2. Open the Control Panel.
3. Select [Administrative Tools] > [Active Directory Users and Computers].
   [Active Directory Users and Computers] appears.
4. In the left pane, right-click the domain controller where you want to create an Organizational Unit, and select [New] > [Organizational Unit].
   [New Object - Organizational Unit] appears.
5. Set as follows:
   - In the Name box, type any name for the Organizational Unit.
   - Select the [Protect container from accidental deletion] check box.
6. Click [OK].
   A new Organizational Unit is created.
7. As necessary, build a hierarchy of Organizational Units. You can build it by repeating steps 3 to 5.
8. In the left pane of [Active Directory Users and Computers], select [Computers]. From the computers list that is displayed, select the computers to be added to Organizational Units, and drag and drop them to the target Organizational Units as desired. A warning message regarding moving the objects appears, but click [Yes] to continue.

TIP

The computers that belong to an Organizational Unit must be limited to computers to which the same group policies are to be applied. Because you will apply group policies to the Organizational Units in the subsequent procedure, ensure that one Organizational Unit does not contain computers with different IT security levels.

Creation of Organizational Units is now completed. The next task is to apply group policy objects to the Organizational Units.

Deleting an Organizational Unit

If the Protect container from accidental deletion check box was selected in the [New Object - Organizational Unit] dialog box at the creation of an Organizational Unit, a message appears when you delete that Organizational Unit. Follow these steps to delete such an Organizational Unit:

1. Open the Control Panel.
2. Select [Administrative Tools] > [Active Directory Users and Computers].
   [Active Directory Users and Computers] appears.
3. Right-click the Organizational Unit that you want to delete and select [Properties], then click the [Object] tab. If the [Object] tab is not displayed, you can make it visible by selecting [View] > [Advanced Features] in [Active Directory Users and Computers].
4. Click the [Protect container from accidental deletion] check box, and click [OK].
   Now you can delete this Organizational Unit.
5. Delete the Organizational Unit.

Deletion of an Organizational Unit is now completed.

Applying Group Policy Objects to an Organizational Unit

Follow these steps:

1. Open the Control Panel.
2. Select [Administrative Tools] > [Group Policy Management].
   [Group Policy Management] appears.
3. In the left pane, select [Group Policy Objects]. From the object list that is displayed, select the group policy that you want to apply, and drag and drop them to the target Organizational Unit.
   A confirmation dialog box appears.
4. Click [OK].
   Group Policy Management Console appears. If you change the applied group policy object here, you are notified that the change will be shared with other Organizational Units.
5. Click [OK].
6. Restart the domain controller.

Application of group policy objects is now completed.

TIP

Even if you do not restart the domain controller, the group policy object will be updated when the group policy checking function of the OS runs.

Canceling Application of Group Policy Objects to an Organizational Unit

Even if you cancel application of a group policy object to an Organizational Unit, the group policy object itself is not deleted.

Follow these steps:

1. Open the Control Panel.
2. Select [Administrative Tools] > [Group Policy Management].
   [Group Policy Management] appears.
3. Select the Organizational Unit in the left pane, right-click the group policy object that you want to cancel application, and select [Delete].
   A confirmation message appears.
4. Click [OK].

Application of a group policy object for an Organizational Unit has been canceled.

6.11 Other Utility Programs

This section describes the utility programs other than the IT Security Tool.

6.11.1 CreateProSafeProcess

This utility program creates the PSF_PROCESS user. It is also used to change the password of the PSF_PROCESS user.

Detailed Explanation

CreateProSafeProcess is used on computers installed with ProSafe-RS or CENTUM VP and on file server computers. This tool creates the PSF_PROCESS user and automatically sets a password for it. If you want to manage the password, you can specify an option to set a desired password.

Start Method

Follow these steps to start CreateProSafeProcess.

1. Log on using an administrative user account.
2. Insert the ProSafe-RS software medium into the drive, start the command prompt window, and move to the following folder.
   `<Drive of software medium>:\ProSafe-RS\SECURITY`
3. Run the following command.
   `ProSafe.Security.CreateProSafeProcess.exe`

   If the PSF_PROCESS user does not exist, it is created and a password is set automatically. The passwords for Windows services registered for use by the PSF_PROCESS user are also set.

   If the PSF_PROCESS user already exists, its password is changed to the initial password.

TIP

If you want to set a desired password, run the following command.

```
ProSafe.Security.CreateProSafeProcess.exe -p(password to be set)
```

You can set a password within 127 characters. Setting a password is mandatory. If the PSF_PROCESS user does not exist, it is created and the specified password is set. At the same time, the passwords for Windows services registered for use by the PSF_PROCESS user are also changed to the specified password.

If the PSF_PROCESS user already exists, its password is changed to the specified password.

IMPORTANT

Note the following points when you change the password:

- Ensure that the same password is set on all computers on which the PSF_PROCESS user exists, such as the computers installed with ProSafe-RS or other software packages that collaborate with ProSafe-RS and file server computers.
- After you change the password of an existing PSF_PROCESS user, restart the computer.

6.11.2 CreateLicenseProcess

This utility program changes the password of the LIC_PROCESS user.

Detailed Explanation

CreateLicenseProcess is used on computers installed with ProSafe-RS or CENTUM VP and on file server computers. By running this tool, you can set a desired password for the LIC_PROCESS user.

Start Method

Follow these steps to start CreateLicenseProcess.

1. Log on using an administrative user account.
2. Insert the ProSafe-RS software medium into the drive and run the following command from the command prompt window.
   ```
   <Drive of software medium>:\ProSafe-RS\SECURITY\Yokogawa.IA.iPCS.Platform.License.CreateLicenseProcess.exe -p (password to be set)
   ```

TIP

You can set a password within 127 characters. Setting a password is mandatory. At the same time, the passwords for Windows services registered for use by the LIC_PROCESS user are also changed to the specified password.

If you run the command without specifying "-p (password to be set)," the currently set password is changed to the initial password.

IMPORTANT

Note the following points when you change the password:

- Ensure that the same password is set on all computers on which the LIC_PROCESS user exists, such as the computers installed with ProSafe-RS or other software packages that collaborate with ProSafe-RS and file server computers.
- After you change the password of an existing LIC_PROCESS user, restart the computer.

6.11.3 CreateAdsProcess

This utility creates the ADS_PROCESS user. It is also used to change the password of the ADS_PROCESS user.

Detailed Explanation

CreateAdsProcess is a tool that is used on the Automation Design Server computer. This tool creates the ADS_PROCESS user and automatically sets a password for it. If you want to manage the password, you can specify an option to set a desired password.

Start Method

Follow these steps to start CreateAdsProcess:

1. Log on using an administrative user account.
2. Insert the ProSafe-RS software medium into the drive and run the following command from the command prompt window.
   `<Drive of software medium>:\ProSafe-RS\SECURITY\Yokogawa.IA.iPCS.ChronusENG.Security.CreateAdsProcess.exe`

   If the ADS_PROCESS user does not exist, it is created and a password is set automatically. The passwords for Windows services registered for use by the ADS_PROCESS user are also set.

   If the ADS_PROCESS user exists, its password is changed to the default password.

TIP

If you want to set a desired password, run the following command:

`<Drive of software medium>:\ProSafe-RS\SECURITY\Yokogawa.IA.iPCS.ChronusENG.Security.CreateAdsProcess.exe -p (password to be set)`

You can specify a password within 127 characters. No password is not allowed. If the ADS_PROCESS user does not exist, it is created and the specified password is set. At the same time, the passwords for Windows services that are registered for use by the ADS_PROCESS user are also changed to the specified password.

If the ADS_PROCESS user exists, its password is changed to the specified password.

IMPORTANT

Note the following points when you change the password:

- Ensure that the same password is set on all computers on which the ADS_PROCESS user exists, such as the computers installed with ProSafe-RS or other software packages that collaborate with ProSafe-RS.
- After you change the password of an existing ADS_PROCESS user, restart the computer.

SEE ALSO

For more information about Automation Design Server, refer to:

A., “Overview of Automation Design Suite” in Engineer's Reference Manual (IM 32P04B10-01EN)

6.11.4 CreateAdsAgent

Using this utility, you can change the password of the ADS_AGENT user.

Detailed Explanation

CreateAdsAgent is used on computers where ProSafe-RS is installed. By running this tool, you can set a desired password for the ADS_AGENT user.

TIP

For more information about running this tool, contact YOKOGAWA Service.

Start Method

Follow these steps to start CreateAdsAgent.

1. Log on as a user with administrative rights.
2. Insert the ProSafe-RS software medium into the drive and run the following command from the command prompt window.

   ```
   <Drive of software medium>:\ProSafe-RS\SECURITY\Yokogawa.IA.iPCS.ChronusENG.Security.CIM.CreateAdsAgent.exe -p (password to be set)
   ```

   You can set a password within 127 characters. Setting a password is mandatory.

   When you run this command, the passwords for Windows services registered for use by the ADS_AGENT user are also changed to the same password.

TIP

If you run the command without specifying a password, the default password is set.

IMPORTANT

Note the following points when you change the password:

- Ensure that the same password is set on all the PCs where the ADS_AGENT user exists.
- After you change the password of an existing ADS_AGENT user, restart the PC.

6.11.5 YWVNETCreateVNTUser

YWVNETCreateVNTUser is a utility program that changes the password of the users for running Vnet/IP Interface Package. This utility changes the password of the following users:

- VNT_COMMON
- VNT_NVP_CORE
- VNT_BKNET

IMPORTANT

- When you change the password, you must prepare an ISO format file of the ProSafe-RS software medium in advance.
- To be able to change the password, Vnet/IP Interface Package must be installed. Before you change the password, make sure that Vnet/IP Interface Package is installed on the computer.
- After you change the password, restart the virtual machine.

Start Method

Follow these steps to start YWVNETCreateVNTUser:

1. Sign in to the host OS of the virtualization host computer as an administrative user.
2. Copy the ISO format file of the ProSafe-RS software to a folder in the host OS.
3. Select [Start] > [Server Manager].
   Server Manager starts.
4. Select [Tools] > [Hyper-V Manager].
   Hyper-V Manager starts.
5. On the left pane, select the virtualization host computer.
   The virtual machines on the selected virtualization host computer appear on the middle pane of Hyper-V Manager.
6. Right-click the virtual machine on which you want to run YWVNETCreateVNTUser, and select [Connect].
   The Connect Virtual Machine window appears.

TIP The Connect Virtual Machine window may be displayed full-screen. If it is displayed full-screen, click [Restore] to exit the full-screen mode.

7. Select [Media] > [DVD Drive] > [Insert Disk].
   The Open dialog box appears.
8. Select the ISO format file of the ProSafe-RS software medium that you have copied and click [Open].
   The selected ISO format file is mounted to the virtual machine.
9. Run the Command Prompt as Administrator.
10. Run the following command from the command prompt window:
    <Mounted drive>:`\ProSafe-RS\security\ywvnetcreatevntuser.exe -u user name -p password to be set`

    You can set a password within 127 characters. Setting a password is mandatory.
11. Restart the virtual machine.

IMPORTANT

- You must run this utility with Vnet/IP Interface Package installed. If you have changed the password by using this utility while Vnet/IP Interface Package is not installed, change the password again after installing Vnet/IP Interface Package.
- If you install Vnet/IP Interface Package after changing the password, the changed password will be reset. Therefore, change the password again.

6.11.6 CreateTISService

Using this utility, you can change the password of the TIS_SERVICE user.

Detailed Explanation

CreateTISService is a tool which is used on a computer where Dongle Gateway is installed. By running this tool, you can set a desired password for the TIS_SERVICE user.

Start Method

Follow these steps to start CreateTISService:

1. Sign in as a user with administrative rights.
2. Insert the ProSafe-RS software medium into the drive and run the following command from the command prompt window. In the case of a virtualization environment, mount the ISO format file of the ProSafe-RS software medium on the virtual machine and then run the command.
   ```
   <Drive of software medium>:\ProSafe-RS\SECURITY\Yokogawa.IA.iPCS.ProSafe.Security.CreateTISService.exe -p (password to be set)
   ```
   You can set a password within 127 characters. Setting a password is mandatory.

   When you run this command, the passwords for Windows services registered for use by the TIS_SERVICE user are also changed to the same password.

TIP

If you run the command without specifying a password, the default password is set.

IMPORTANT

Note the following points when you change the password:

- Ensure that the same password is set on all the computers where the TIS_SERVICE user exists.
- After you change the password of an existing TIS_SERVICE user, restart the computer.

SEE ALSO

For more information about how to mount the ISO format file on the virtual machine, refer to:

"● Mounting an ISO Format File on a Virtual Machine" in "■ Creating and Mounting ISO Format Files" in B1.3, "Precautions for Setting Up ProSafe-RS on a Virtual Machine on the Virtualization Platform" in Installation Guide (IM 32P01C50-01EN)

6.11.7 StorageDeviceCTL

This utility temporarily cancels the following disabling of storage devices.

- Disabling of write permissions set by applying the StorageDevicePolicies function
- Disabling set by applying "Disabling USB storage devices"

Detailed Explanation

When you cannot write to storage devices due to application of the StorageDevicePolicies function or disabling of USB storage devices, you can execute StorageDeviceCTL to cancel the effect of these security measures temporarily. Writing to storage devices is enabled while StorageDeviceCTL is running.

Start this tool, connect a USB storage device to the PC, and then perform writing tasks.

The PSF_MAINTENANCE right is required to execute the tool.

Use this tool only on PCs for which the StorageDevicePolicies function or disabling of USB storage devices is set.

IMPORTANT

Be sure to make the PC recognize the storage device after starting this tool.

Start Method

Follow these steps to start StorageDeviceCTL:

1. Use Windows Explorer to open the following folder.
   This example is when the system drive is drive C.

   `C:\Program Files (x86)\Yokogawa\IA\iPCS\Platform\SECURITY\PROGRAM\`

2. Double click the following program file in the folder.
   `Yokogawa.IA.iPCS.Platform.Security.StorageDeviceCTL.exe`

   The task is displayed only in the taskbar immediately after the start.

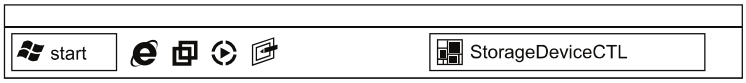

Figure 6.11.7-1 Taskbar

3. Connect the USB storage device to the computer.
4. Read/write necessary data from/to the USB storage device.
5. Remove the USB storage device from the computer.

TIP

To remove a USB storage device, right-click the [Safely Remove Hardware and Eject Media] icon from the task tray and select [Eject USB Flash Disk] to stop the device.

6. Click [StorageDeviceCTL] from the taskbar and then click [WriteStop].

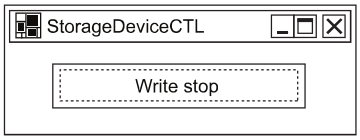

Figure 6.11.7-2 StorageDeviceCTL Dialog Box

StorageDeviceCTL ends and USB storage devices are disabled again.

SEE ALSO

For more information about the StorageDevicePolicies function, refer to:

3.5.4, “Applying the StorageDevicePolicies Function” on page 3-30

For more information about disabling USB storage devices, refer to:

3.5.5, “Disabling USB Storage Devices” on page 3-31

6.11.8 ITSecuritySettingItemExport

This utility exports the security model, user management type, changes made to settings, and IT security version number that were set by the IT Security Tool of R4.02 or earlier to a file.

Detailed Explanation

The exported information is the settings at the last IT security configuration of the environment where you run the utility.

By importing the exported file using the IT Security Tool, you can restore the security setting status that was configured by the IT Security Tool of the environment where the information was exported.

Start Method

Follow these steps to run the ITSecuritySettingItemExport utility:

1. Log on as a user with administrative rights.
2. Insert the software medium of the product into the drive, and run the following command from the command prompt:
   `<Drive of software medium>:\ProSafe-RS\SECURITY\ITSecuritySettingItemExport.exe`
3. After running the utility, a file is automatically created and a confirmation dialog box appears. Click [OK].
   The file is exported to the following fixed folder. This example is when the system drive is drive C.

   `C:\ProgramData\Yokogawa\IA\iPCS\Platform\Security\Config\DisplaySelectInfo.xml`

IMPORTANT

- This utility is available only on computers where a YOKOGAWA system product is installed. It is not available on a file server or domain controller, where security configuration is performed by using the IT Security Tool without installing product software.
- The account used to run this utility must belong to the maintenance group of the product.
- The folder and file that are exported by this utility have a fixed name. If they exist on the computer already, the file will be overwritten.
- When you cannot access the folder and file that are exported by this utility, an access violation error message appears.

Appendix 1. IT Security Setting Items

This section describes the security setting items that are configured with IT security version 2.0 and IT security version 1.0.

Appendix 1.1 IT Security Version 2.0

This section describes the security setting items that are configured with IT security version 2.0, their default values, and whether they can be modified.

Appendix 1.1.1 Setting Items for a Computer with ProSafe-RS Software Installed

This section describes the security setting items for a computer on which the product software is installed for each combination of security model and user management type.

Security Setting Items for Standard Model with Standalone Management/Linked Domain Management

The following table shows the security setting items for the combination of Standard model and Standalone management or Linked domain management.

Table Appendix 1.1.1-1 Standard Model - Standalone Management/Linked Domain Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Access control for product registry	Selected	Fixed
Access control for DCOM (OPC) objects	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Disable 'Personal Firewall-[Allow unicast response]'	Selected	Editable
Disabling NetBIOS over TCP/IP	When the domain is linked: Selected When the domain is not linked: Clear	Editable
Applying the StorageDevicePolicies function	Clear	Editable
Disabling USB storage devices	Clear	Editable
Applying the software restriction policies	Clear	Editable
User Rights Assignment-[Deny log on locally]	Selected	Fixed
Security Options-[Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings]	Selected	Editable
Security Options-[Devices: Prevent users from installing printer drivers]	Selected	Editable
Security Options-[Devices: Restrict CD-ROM access to locally logged-on user only]	Selected	Editable
Security Options-[Devices: Restrict floppy access to locally logged-on user only]	Selected	Editable

Table Appendix 1.1.1-2 Standard Model - Domain/Combination Management (Table continued)

Setting item	Default check box state	Modification
Cloud Content-[Turn off Microsoft consumer experiences]	Selected	Editable
Data Collection and Preview Builds-[Allow Telemetry]	Selected	Editable
Data Collection and Preview Builds-[Disable pre-release features or settings]	Selected	Editable
Data Collection and Preview Builds-[Do not show feedback notifications]	Selected	Editable
Data Collection and Preview Builds-[Toggle user control over Insider builds]	Selected	Editable
Event Log Service(Application)-[Specify the maximum log file size (KB)]	Selected	Editable
Event Log Service(Security)-[Specify the maximum log file size (KB)]	Selected	Editable
Event Log Service(System)-[Specify the maximum log file size (KB)]	Selected	Editable
File Explorer-[Turn off heap termination on corruption]	Selected	Editable
HomeGroup-[Prevent the computer from joining a home-group]	Selected	Editable
OneDrive-[Prevent the usage of OneDrive for file storage]	Selected	Editable
OneDrive-[Save documents to OneDrive by default] (Save documents to the local PC by default)	Selected	Editable
Remote Desktop Connection Client-[Do not allow pass-words to be saved]	Selected	Editable
Device and Resource Redirection-[Do not allow drive redi-rection]	Selected	Editable
Security-[Require secure RPC communication]	Selected	Editable
Security-[Require user authentication for remote connec-tions by using Network Level Authentication]	Selected	Editable
Disable ‘Search-[Allow Cortana]’	Selected	Editable
Software Protection Platform-[Turn off KMS Client Online AVS Validation]	Selected	Editable
Sync your settings-[Do not sync Apps]	Selected	Editable
Sync your settings-[Do not sync start settings]	Selected	Editable
Disable 'Windows Error Reporting-[Automatically send memory dumps for OS-generated error reports]'	Selected	Fixed
Disable 'Windows Logon Options-[Sign'-in last interactive user automatically after a system'-initiated restart]'	Selected	Editable
Notifications-[Turn off toast notifications on the lock screen]	Selected	Editable

Appendix 1.1.2 Setting Items for a File Server or Domain Controller

This section provides lists of the security setting items for a file server or a domain controller for each combination of security model and user management type.

Security Setting Items for File Server: Standard Model with Standalone Management/Linked Domain Management

The following table shows the security setting items for the combination of Standard model and Standalone management or Linked domain management on a file server.

Table Appendix 1.1.2-1 File Server: Standard Model - Standalone Management/Linked Domain Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Disable 'Personal Firewall-[Allow unicast response]'	Selected	Editable
Disabling NetBIOS over TCP/IP	When the domain is linked: Selected When the domain is not linked: Clear	Editable
Applying the StorageDevicePolicies function	Clear	Editable
Disabling USB storage devices	Clear	Editable
User Rights Assignment-[Deny log on locally]	Selected	Fixed
Security Options-[Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings]	Selected	Editable
Security Options-[Devices: Prevent users from installing printer drivers]	Selected	Editable
Security Options-[Devices: Restrict CD-ROM access to locally logged-on user only]	Selected	Editable
Security Options-[Devices: Restrict floppy access to locally logged-on user only]	Selected	Editable
Security Options-[Domain member: Require strong (Windows 2000 or later) session key]	Selected	Editable
Security Options-[Interactive logon: Do not display last user name]	Selected	Editable
Disable 'Security Options-[Interactive logon: Do not require CTRL+ALT+DEL]'	Selected	Editable
Security Options-[Interactive logon: Prompt user to change password before expiration]	Selected	Editable
Security Options-[Microsoft network server: Digitally sign communications (if client agrees)]	Selected	Editable
Security Options-[Microsoft network server: Server SPN target name validation level]	Selected	Editable
[MSS: (DisableIPSourceRouting) IP source routing protection level (protects against packet spoofing)]	Selected	Editable

Continues on the next page

Table Appendix 1.1.2-1 File Server: Standard Model - Standalone Management/Linked Domain Management (Table continued)

Setting item	Default check box state	Modification
Disable [MSS: (PerformRouterDiscovery) Allow IRDP to detect and configure Default Gateway addresses (could lead to DoS)]	Selected	Editable
[MSS: (TcpMaxDataRetransmissions) How many times unacknowledged data is retransmitted (3 recommended, 5 is default)]	Selected	Editable
Security Options-[Network access: Do not allow anonymous enumeration of SAM accounts]	Selected	Editable
Security Options-[Network access: Do not allow anonymous enumeration of SAM accounts and shares]	Selected	Editable
Security Options-[Network access: Do not allow storage of passwords and credentials for network authentication]	Selected	Editable
Security Options-[Network security: Allow Local System to use computer identity for NTLM]	Selected	Editable
Disable 'Security Options-[Network security: Allow Local System NULL session fallback]'	Selected	Editable
Security Options-[Network security: LAN Manager authentication level]	Selected	Fixed
Security Options-[Network security: Minimum session security for NTLM SSP based (including secure RPC) clients]	Selected	Editable
Security Options-[Network security: Minimum session security for NTLM SSP based (including secure RPC) servers]	Selected	Editable
Disable 'Security Options-[Shutdown: Allow system to be shut down without having to log on]'	Selected	Editable
Security Options-[User Account Control: Admin Approval Mode for the Built-in Administrator account]	Selected	Editable
Security Options-[User Account Control: Behavior of the elevation prompt for administrators in Admin Approval Mode]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Credential Validation]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Computer Account Management]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Other Account Management Events]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Security Group Management]	Selected	Editable
Advanced Audit Policy Configuration-[Audit User Account Management]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Process Creation]	Selected	Editable
Advanced Audit Policy Configuration-[Audit RPC Events]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Account Lockout]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Logoff]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Logon]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Other Logon/Logoff Events]	Selected	Editable

Continues on the next page

Table Appendix 1.1.2-1 File Server: Standard Model - Standalone Management/Linked Domain Management (Table continued)

Setting item	Default check box state	Modification
Advanced Audit Policy Configuration-[Audit Special Logon]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Application Generated]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Removable Storage]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Audit Policy Change]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Authentication Policy Change]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Filtering Platform Policy Change]	Selected	Editable
Advanced Audit Policy Configuration-[Audit MPSSVC Rule-Level Policy Change]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Other Policy Change Events]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Sensitive Privilege Use]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Other System Events]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Security State Change]	Selected	Editable
Advanced Audit Policy Configuration-[Audit Security System Extension]	Selected	Editable
Advanced Audit Policy Configuration-[Audit System Integrity]	Selected	Editable
Personalization-[Prevent enabling lock screen camera]	Selected	Editable
Personalization-[Prevent enabling lock screen slide show]	Selected	Editable
WLAN Settings-[Allow Windows to automatically connect to suggested open hotspots, to networks shared by contacts, and to hotspots offering paid services]	Selected	Editable
Group Policy-[Configure registry policy processing]	Selected	Editable
Internet Communication settings-[Turn off downloading of print drivers over HTTP]	Selected	Editable
Internet Communication settings-[Turn off Event Viewer "Events.asp" links]	Selected	Editable
Internet Communication settings-[Turn off Internet download for Web publishing and online ordering wizards]	Selected	Editable
Internet Communication settings-[Turn off printing over HTTP]	Selected	Editable
Internet Communication settings-[Turn off Search Companion content file updates]	Selected	Editable
Internet Communication settings-[Turn off the "Publish to Web" task for files and folders]	Selected	Editable
Internet Communication settings-[Turn off the Windows Customer Experience Improvement Program]	Selected	Fixed
Internet Communication settings-[Turn off the Windows Messenger Customer Experience Improvement Program]	Selected	Fixed
Logon-[Do not display network selection UI]	Selected	Editable

"■ Combination of User Management and Security Model for Windows" on page 2-17

Appendix 1.2 IT Security Version 1.0

This section describes the security setting items that are configured with IT security version 1.0, their default values, and whether they can be modified.

Appendix 1.2.1 Setting Items for a Computer with ProSafe-RS Software Installed

This section describes the security setting items for a computer with ProSafe-RS software installed for each combination of security model and user management type. However, some security setting items may not appear depending on the OS version.

Security Setting Items for Legacy Model

The following table shows the security setting items for the Legacy model.

Table Appendix 1.2.1-1 Legacy Model

Setting item	Default check box state	Modification	Remarks
Access control for files and folders	Selected	Fixed	Adds full control access permissions to the Everyone group. For some tools' folders under the Windows folder, reverts to the access permissions of parent folders.
Access control for product registry	Selected	Fixed	Adds full control access permissions to the Everyone group.
Access control for DCOM (OPC) objects	Selected	Fixed	Adds full control access permissions to the Everyone group.
Personal firewall tuning	Selected	Fixed	Disables the personal firewall. In Windows 10 Enterprise LTSC 2019 and Windows 10 Enterprise LTSC 2021, Windows Defender Firewall is disabled by Local Group Policy.
Local security	Selected	Fixed	Grants access permissions to the Everyone group.
Changing IT environment settings - Hiding the last logon user name	Selected	Editable	None
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable	None

SEE ALSO For more information about creation of users/groups, refer to:

"■ Combination of User Management and Security Model for Windows" on page 2-17

Security Setting Items for Standard Model with Standalone Management/Linked Domain Management

The following table shows the security setting items for the combination of Standard model and Standalone management or Linked domain management.

Table Appendix 1.2.1-2 Standard Model - Standalone Management/Linked Domain Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Access control for product registry	Selected	Fixed
Access control for DCOM (OPC) objects	Selected	Fixed
Personal firewall tuning	Selected	Fixed

Continues on the next page

Setting item	Default check box state	Modification
Local security	Selected	Fixed
Changing IT environment settings - Changing the LAN Manager authentication level	Selected	Editable
Changing IT environment settings - Hiding the last logon user name	Selected	Editable
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable
Changing IT environment settings - Disabling NetBIOS over TCP/IP	When the domain is linked: Selected When the domain is not linked: Clear	Editable
Changing IT environment settings - Applying the StorageDevicePolicies function	Clear	Editable
Changing IT environment settings - Disabling USB storage devices	Clear	Editable
Changing IT environment settings - Applying software restriction policies	Clear	Editable

Security Setting Items for Standard Model with Domain or Combination Management

The following table shows the security setting items for the combination of Standard model and Domain or Combination management.

Table Appendix 1.2.1-3 Standard Model - Domain/Combination Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Creating domain users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Access control for product registry	Selected	Fixed
Access control for DCOM (OPC) objects	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Local security	Selected	Fixed
Changing IT environment settings - Changing the LAN Manager authentication level	Selected	Editable
Changing IT environment settings - Hiding the last logon user name	Selected	Editable
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable
Changing IT environment settings - Disabling NetBIOS over TCP/IP	Selected	Editable
Changing IT environment settings - Applying the StorageDevicePolicies function	Clear	Editable
Changing IT environment settings - Disabling USB storage devices	Clear	Editable
Changing IT environment settings - Applying software restriction policies	Clear	Editable

Appendix 1.2.2 Setting Items for a File Server or Domain Controller

This section provides lists of the security setting items for a file server or a domain controller for each combination of security model and user management type.

Security Setting Items for File Server: Legacy Model

The following table shows the security setting items for the Legacy model on a file server.

Table Appendix 1.2.2-1 File Server: Legacy Model

Setting item	Default check box state	Modification	Remarks
Creating local users and groups	Selected	Fixed	Creates the CTM_PROCESS user.
Access control for files and folders	Selected	Fixed	For the Windows folder, reverts to the access permissions of parent folders. For the Project folder, adds full control access permissions to the Everyone group.
Personal firewall tuning	Selected	Fixed	Disables the personal firewall.
Local security	Selected	Fixed	Grants access permissions to the Everyone group.

Security Setting Items for File Server: Standard Model with Standalone Management/Linked Domain Management

The following table shows the security setting items for the combination of Standard model and Standalone management or Linked domain management on a file server.

Table Appendix 1.2.2-2 File Server: Standard Model - Standalone Management/Linked Domain Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Local security	Selected	Fixed
Changing IT environment settings - Applying the audit policy	Selected	Editable
Changing IT environment settings - Changing the LAN Manager authentication level	Selected	Editable
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable
Changing IT environment settings - Disabling NetBIOS over TCP/IP	When the domain is linked: Selected When the domain is not linked: Clear	Editable
Changing IT environment settings - Applying the StorageDevicePolicies function	Clear	Editable
Changing IT environment settings - Disabling USB storage devices	Clear	Editable

Security Setting Items for File Server: Standard Model with Domain or Combination Management

The following table shows the security setting items for the combination of Standard model and Domain or Combination management on a file server.

Table Appendix 1.2.2-3 File Server: Standard Model - Domain/Combination Management

Setting item	Default check box state	Modification
Creating local users and groups	Selected	Fixed
Creating domain users and groups	Selected	Fixed
Access control for files and folders	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Local security	Selected	Fixed
Changing IT environment settings - Applying the audit policy	Selected	Editable
Changing IT environment settings - Changing the LAN Manager authentication level	Selected	Editable
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable
Changing IT environment settings - Disabling NetBIOS over TCP/IP	Selected	Editable
Changing IT environment settings - Applying the StorageDevicePolicies function	Clear	Editable
Changing IT environment settings - Disabling USB storage devices	Clear	Editable

Security Setting Items for Domain Controller: Standard Model with Domain or Combination Management

The following table shows the security setting items for the combination of Standard model and Domain or Combination management on a domain controller.

Table Appendix 1.2.2-4 Domain Controller: Standard Model - Domain or Combination Management

Setting item	Default check box state	Modification
Creating domain users and groups	Selected	Fixed
Access control for files and folders	Selected	Editable
Access control for DCOM (OPC) objects	Selected	Fixed
Personal firewall tuning	Selected	Fixed
Changing IT environment settings - Applying the audit policy	Selected	Editable
Changing IT environment settings - Changing the LAN Manager authentication level	Selected	Editable
Changing IT environment settings - Applying AutoRun restrictions	Selected	Editable
Changing IT environment settings - Disabling NetBIOS over TCP/IP	Selected	Editable

Continues on the next page

Table Appendix 1.2.2-4 Domain Controller: Standard Model - Domain or Combination Management (Table continued)

Setting item	Default check box state	Modification
Changing IT environment settings - Applying the StorageDevicePolicies function	Clear	Editable
Changing IT environment settings - Disabling USB storage devices	Clear	Editable

TIP

The IT Security Tool creates only the users and groups that are to be created on the domain.

Revision information

Title : ProSafe-RS Security Guide

Manual No. : IM 32P01C70-01EN

Dec. 2023/10th Edition/R4.10 or later

2.1	Added or updated descriptions in Security Models and Security Measures.
3.3	Added descriptions of supported OS, and deleted descriptions of unsupported OS.
3.5.7, 3.5.8, 3.5.9, 3.6.3, Appendix 1.2.1	Added descriptions of supported OS.
3.6.5	Updated descriptions in App Privacy (Windows Component) and Data Collection and Preview Builds (Windows Component).
Appendix 1.1.1, Appendix 1.1.2	Deleted footnote.

Nov. 2022/9th Edition/R4.08

3.3, 3.5.7	Added descriptions about Windows Server IoT 2019.

Jan. 2022/8th Edition/R4.07

1.2	Added descriptions to Security Measures and Handled Security Threats.
2.1	Added or updated descriptions in Security Models and Security Measures.
2.2.3	Added descriptions in “Combination of User Management and Security Model for Windows” and “The users for using iDefine in a virtualization environment.”
3.3, 3.5.1, 3.5.7	Added descriptions about Windows Server 2019.
3.5.5	Added descriptions in cautions and added descriptions about steps for restoring access to the required devices.
3.5.10	Added descriptions about enabling SMB signing.
3.5.11	Added descriptions about preventing illegal dll from loading.
3.6.3	Added description to cautionary notes.
3.6.5	Added cautionary notes in “Data Collection and Preview Builds (Windows Component).”
5.3	Added descriptions about the procedure of product disposal and descriptions about ports used by SCS Vnet/IP.
6.4.1, 6.4.2	Added descriptions about migrating the standard model (combination/domain management) computer to other domain.
6.10	Added a TIP.
Appendix 1.1.1, Appendix 1.1.2	Added footnotes.

Feb. 2021/7th Edition/R4.06

1	Added a new section “Overview of ProSafe-RS.”
1.2	Added descriptions to Security Measures and Handled Security Threats.
2.1	Added descriptions to Security Models and Security Measures.
2.2, 4.1, 6.1, 6.3 to 6.6, 6.8, Appendix 1, 2	Added descriptions of linked domain management.

3.1, 3.3, 3.5, 3.6.3, 6.10, 6.11.7	Deleted the descriptions of OS that is not supported.
3.1.1, 6, 6.2, 6.9	Added descriptions of Domain Link Management Tool.
3.3	Added descriptions of Windows 10 Enterprise 2019 LTSC
3.5.7	Added descriptions of Windows Update Delivery Optimization
3.5.8	Added descriptions of Disabling Windows Defender.
3.5.9	Added description of Disabling Shared experiences.

Dec. 2019/6th Edition/R4.05

Introduction	Updated descriptions of registered trademarks and trademarks.
3.1.1, 3.1.2	Added description of the Forced I/O Viewer function.
5.3	Updated descriptions for when behavior suspected to be resulting from vulnerability is found.

Aug. 2018/5th Edition/R4.04

Introduction	Updated descriptions of Yokogawa Electric registered trademark.
2.1	Updated the table of security models and security measures.
2.2.3, 3.1.1, 3.1.2, 3.1.5, 3.2	Added descriptions of Vnet/IP interface package.
2.2.3, 3.1.5, 3.2	Added descriptions of TIS_SERVICE and Dongle Gateway.
3.1.1, 3.3, 3.5.1, 3.5.2	Added descriptions of Windows Server 2016 to OS.
3.6.4	Added descriptions for the case of a Domain Controller or File Server.
4.1	Updated descriptions of .NET Framework.
6.1	Added descriptions when different IT security settings are applied.
6.5.1, 6.6.1	Updated descriptions of update procedure.
6.9.5	Added descriptions of CreateVNTUser.
6.9.6	Added descriptions of CreateTISService.
Appendix 1	Updated the table of security setting items.

Oct. 2017/4th Edition/R4.03.10

2.2.3	Added an automatically created user.
3.1	Added some target folders.
	Added some access permission information.
3.2	Added a Personal Firewall exception setting.
6.9	Added a new section “■ CreateAdsAgent.”

May 2017/3rd Edition/R4.03

Introduction	Deleted Windows Vista from the description of trademarks.
1.2, chapter 3	Updated to introduce IT security versions for stronger system security.
2.1	Reorganized and updated to introduce IT security versions for stronger system security.
6.2 to 6.4	Added descriptions of operation to configure IT security settings.
Appendix	Newly added.

Oct. 2016/2nd Edition/R4.02

Entire manual	Changed symbols.
Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added descriptions in "■ Full Names and Simplified Terms."
3.2	Deleted ETCP.exe and Scs-Simulator. Added iDefine related descriptions.
6.1	Added iDefine related descriptions.

Dec. 2015/Newly published/R4.01

9th Edition

Introduction

This document presents the safety requirements for building a safety system with ProSafe-RS and ProSafe-RS Lite.

IMPORTANT

The information in this manual applies to both ProSafe-RS and ProSafe-RS Lite. Unless otherwise noted, the descriptions for ProSafe-RS include descriptions of both ProSafe-RS and ProSafe-RS Lite. The differences between ProSafe-RS and ProSafe-RS Lite are described separately for each product.

By following the requirements described in this manual, safety applications that meet the requirements up to SIL 3 of the IEC 61508 standard can be realized by ProSafe-RS, and by ProSafe-RS Lite, those of up to SIL 2 can be realized.

The ProSafe-RS and ProSafe-RS Lite have been certified by TÜV Rheinland Industrial Services GmbH, Business Sector ASI (http://tuvasi.com/), TÜV Rheinland Group to fulfill the requirements of IEC 61508. The contents of this safety manual have also been approved by TÜV.

For the proper use of ProSafe-RS, also refer to the user's manuals available on our Website (http://www.yokogawa.com)

This document consists of the following chapters.

- 1. Safety Lifecycle
  This chapter explains an overview of the safety conditions for building a safety instrumented system.
- 2. System Considerations
  This chapter explains details of the safety considerations for building a safety instrumented system with the ProSafe-RS.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required. This symbol for the Product indicates the possibility of dangers such as electric shock on personnel and equipment, and also indicates that the user must refer to the User's Manuals for necessary actions. In the User's Manuals, this symbol is used together with a word "CAUTION" or "WARNING" at the locations where precautions for avoiding dangers are described.

<French> Signale qu'il faut faire preuve de prudence. Ce symbole pour le produit signale la possibilité d'un danger pour le personnel et l'équipement comme un choc électrique, et signale également que l'utilisateur doit se référer au Manuel de l'utilisateur afin de prendre les mesures nécessaires. Dans le Manuel de l'utilisateur, ce symbole est utilisé conjointement avec la mention «CAUTION» ou «WARNING» aux endroits où sont décrites les précautions pour éviter les dangers.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

Indicates an AC supply.

Indicates a DC supply.

| Indicates that a component such as a power supply switch is turned ON.

○ Indicates that a component such as a power supply switch is turned OFF.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- In realization of the Safety Instrumented System (SIS), an appropriate competence management system is required to conform to the Functional Safety Management (FSM) defined in IEC 61508 and IEC 61511. Hence, YOKOGAWA cannot assure conformance of ProSafe-RS and other related YOKOGAWA products (“Products”) unless YOKOGAWA or YOKOGAWA’s authorized partners are fully involved in or control engineering, configuration, adaptation, maintenance, repair and other work in SIS lifecycle.
- In no event shall YOKOGAWA be liable for any result, claim, loss or damage whatsoever arising out of or in connection with use or inability to use of Products, if any part of engineering, configuration, adaptation, maintenance, repair, improvement, addition of functions, adjustment or other modification work for the Products is made or controlled by a person other than YOKOGAWA or YOKOGAWA’s authorized partners.
- Except for the limited warranties agreed upon in writing, YOKOGAWA disclaims all other warranties, express or implied, in fact or in law, including without limitation, warranties of merchantability, fitness for a particular purpose and non-infringement. If warranty is provided, repair or replacement of the Products is the exclusive remedy for breach of warranty.
- In no event shall YOKOGAWA be liable for any indirect or consequential loss or damage incurred arising out of or in relation to use or inability to use the Products regardless of whether foreseeable or not, whether arising in or for breach of contract, tort (including negligence), breach of statutory duty or otherwise or whether YOKOGAWA has been advised of the possibility thereof.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.

- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
SEE ALSO	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

CONTENTS

Appendix

Appendix 1. Product support..... App.1-1

1. Safety lifecycle

The IEC 61508 requires the use of its safety lifecycle for configuring and maintaining safety systems properly. This chapter explains the overview of the safety lifecycle.

The following table lists the abbreviations used in this safety manual.

Table 1-1 Abbreviations

Abbreviation/ generic term	Definition	Remarks
AI	Analog Input	
AO	Analog Output	
CENTUM	CENTUM VP, the Integrated Production Control System of Yokogawa.	
CPU	Central Processing Unit	
DI	Digital Input	
DO	Digital Output	
ENG	Engineering Personal Computer	Device of CENTUM
FB	Function Block	Element used in FBD/LD/ST
FBD	Function Block Diagram	IEC 61131-3 language
FCS	Field Control Station	Device of CENTUM
FU	Function	Element used in FBD/LD/ST
HIS	Human Interface Station	Device of CENTUM
I/O	Input/Output	
LD	Ladder Diagram	IEC 61131-3 language
PFD	Probability of Failure on Demand	Defined by IEC 61508
SC	Systematic Capability	Defined by IEC 61508
SCS	Safety Control Station	Device of ProSafe-RS system
SENG	Safety Engineering Personal Computer	Device of ProSafe-RS system
SIL	Safety Integrity Level	Defined by IEC 61508
ST	Structured Text	IEC 61131-3 language

Overview of the safety lifecycle

The safety lifecycle, which consists of sixteen phases that start at the concept phase of a system and end at the systems usage expiration, defines necessary activities for these phases. As the safety lifecycle is considered as a framework to minimize the systematic failure caused by human errors, persons involved in the implementation of the safety functions need to understand the requirements of the safety lifecycle well and follow them.

As part of the safety lifecycle, the three planning phases for operation and maintenance, safety validation, and installation and commissioning are required prior to actual implementation phases. This is because adequate preparations that include the procedures and measures derived from the impact analysis are important to ensure functional safety and/or to prevent an unsafe state during the implementation.

The standard also requires that the functional safety management runs in parallel with the safety lifecycle phases with emphasis on the importance of the documentation. The information about all activities and the results of each phase need to be documented in such way that the descriptions are accurate and easy to understand for users. The document of one phase is used as an input of the subsequent phase of the safety lifecycle in principle. This makes it possible to maintain the consistency of the lifecycle and trace the activities afterward.

Another requirement of the functional safety management is to manage competence. The organizations and/or persons involved in the safety lifecycle must be competent for their activities that they have responsibilities for. Adequate experience and training are necessary for this purpose.

This safety manual provides information for all planning phases of the safety lifecycle to ensure the correct use of ProSafe-RS to reach the aimed safety integrity by the end user.

2. System considerations

This chapter provides details of the safety considerations for building the safety system with the ProSafe-RS.

2.1 Overview of ProSafe-RS

This section explains the overview of ProSafe-RS.

Overview of ProSafe-RS

ProSafe-RS is a safety system consisting of a safety controller, SCS, and an engineering and maintenance PC, SENG. The minimum configuration includes one SCS and one SENG.

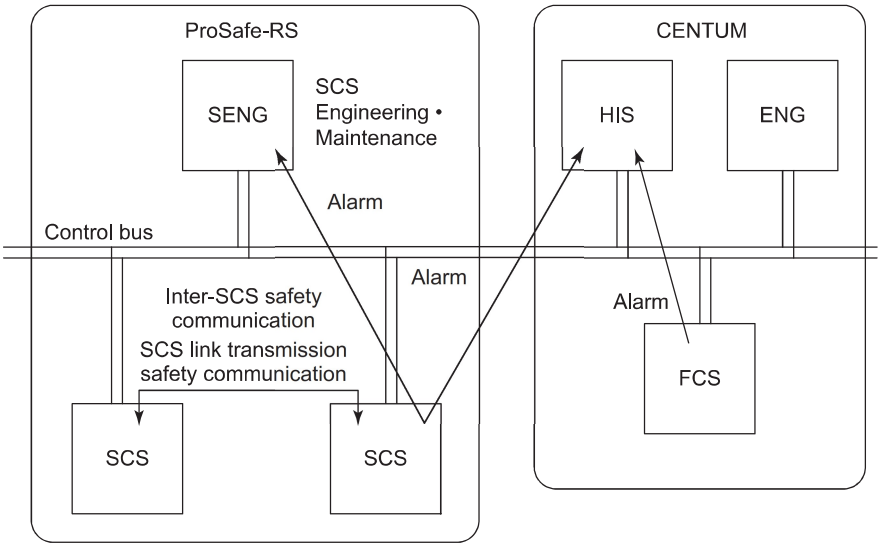

Figure 2.1-1 Example of system configuration

An SCS of ProSafe-RS in which both CPU and I/O modules are in single configuration can be used for applications that meet the IEC 61508 SIL 3 requirements. An SCS of ProSafe-RS Lite can be applied to applications that meet the IEC 61508 SIL 2 requirements in a single configuration. To increase the system availability, CPU modules and/or I/O modules can be duplexed (dual-redundant).

By using inter-SCS safety communication or SCS link transmission safety communication, ProSafe-RS can build the SIL 3 safety loop between different SCSs connected via the control bus, and ProSafe-RS Lite can build the SIL 2 safety loop between them.

You can also use ProSafe-RS SCS and ProSafe-RS Lite SCS to build the SIL 2 safety loop between different SCSs.

ProSafe-RS and ProSafe-RS Lite comply with the requirements of IEC 61508 SC3 (Systematic Capability 3).

The ProSafe-RS can be integrated seamlessly into a CENTUM VP system connected on the same control bus. This allows operators to monitor the SCSs through the HIS.

For details on how to use ProSafe-RS and ProSafe-RS Lite, refer to the ProSafe-RS User's Guide (IM 32P01B10-01EN).

Safety applications

ProSafe-RS is primarily intended to be used for the following safety applications. The use of ProSafe-RS conforming to the standards for each application is also certified by TÜV.

For the details of the requirements, refer to each standard.

- ESD (Emergency Shutdown System) / PSD (Process Shutdown System)
- F&G (Fire and Gas detection System: EN 54, NFPA 72)
- BMS (Burner Management System: EN 298, NFPA 85, NFPA 86, EN 50156)

2.2 Hardware configuration

This section explains the hardware structure.

Safety requirements and system availability

An SCS of ProSafe-RS in which both CPU and I/O modules are in single configuration can be used for applications that meet the SIL 3 requirements. An SCS of ProSafe-RS Lite can be applied to applications that meet the SIL 2 requirements in a single configuration. For the models and revisions of each module, refer to our Website (http://www.yokogawa.com/).

To increase the availability, CPU modules and/or I/O modules can be duplexed (dual-redundant). When a fault is detected in one module in a dual-redundant configuration, the other module takes over control to continue operation.

SCS hardware

SCS basic components

The basic components of the SCS hardware include the following.

- Safety control unit
  - CPU module
  - Power supply module (dual-redundant)
  - ESB BUS coupler module (dual-redundant)
  - N-ESB bus coupler module (dual-redundant)
  - Optical ESB bus repeater module (dual-redundant)
- Safety node unit
  - Power supply module (dual-redundant)
  - ESB bus interface module (dual-redundant)
  - Optical ESB bus repeater module (dual-redundant)
- Node interface unit
  - Power supply unit (dual-redundant)
  - N-ESB bus module (dual-redundant)
- N-IO I/O unit

I/O modules

The following table lists the I/O modules used for the ProSafe-RS system.

Use safety I/O modules for safety loops.

Table 2.2-1 Safety I/O module list (for safety control unit and safety node unit)

Safety I/O module
Digital Input Module (24 V DC)
Digital Output Module (24 V DC)
Digital Output Module (48 V DC)
Digital Output Module (100-120 V AC)
Analog Input Module (4-20 mA)

Environmental requirements

For details of the permissible environmental conditions for ProSafe-RS and ProSafe-RS Lite, and their connection with external devices such as I/O module, refer to the following documents:

- For ProSafe-RS: ProSafe-RS Installation Guidance (TI 32P01J10-01EN)
- For ProSafe-RS Lite: ProSafe-RS Lite Installation Guidance (TI 32P51J10-01EN)

Fault detection and reaction

Basic behavior

CPU modules and I/O modules are diagnosed by the hardware and software periodically. Errors in communications between the CPU module and I/O modules, communications between the CPU module and fire and gas communication modules (hereafter, referred to as fire and gas communication), and inter-SCS safety communications are detected by various measures.

When an error is detected, the failsafe value is used for the output value and a diagnostic information message is issued. The diagnostic information message, which is sent to the SENG and HIS (when integrated with CENTUM) via the control bus, is useful for identifying the details and the cause of the error.

In a dual-redundant configuration, the other module that is working normally takes over control to continue the operation.The diagnostic information message that is issued at the same time helps identify the failed module.

The user can define the fail-safe behavior of the system when faults are detected in I/O modules. The following section describes the details.

Diagnosis and reaction

This section explains the fault detection and reaction of the system in the single configuration.

In a dual-redundant configuration, the other module that is working normally takes over control to continue the operation.

- CPU module
  The major components in the CPU module are duplexed, and their operation results are always compared between the two. This enables to detect a fault in a very short time. The detection of a fault causes a shutdown of the CPU module. Accordingly, the output modules detect a communication halt of the CPU module and outputs the failsafe value predefined for each channel.
- Input module
  Diagnostic tests of input modules are performed by the firmware periodically. When one of the following faults is detected, the status of input channel changes to “bad” and a predefined value (input value for a fault) is transferred to the application logic. This means, faults in input modules, as well as demands (changes in input values), can be handled by application logic.
  - Fault in the common part of an input module
  - Fault in an input channel
  - Failure in communication between an input module and a CPU module
- Output module
  Diagnostic tests of output modules are performed by the firmware periodically. When one of the following faults is detected, the Output Shutoff Switch is activated to force all the output channels to OFF (0).
  - Fault in the common part of an output module
  - A channel is stuck-at-ON, that is, the output cannot be turned to OFF (digital output module (24 V DC, 48 V DC))
    (In the case of digital output module (100-120 V AC), only the fault-detected channel is turned to OFF(0).)
  - Output current read back error (analog output module)

  In case of a communication fault between an output module and a CPU module, the failsafe value for each channel is output.
- Analog digital I/O module (for N-IO I/O unit)
  Diagnostic tests of analog digital I/O modules are performed by the firmware periodically. The following table describes the types of faults and operations in the event of a fault.

Table 2.2-4 Analog digital I/O module operations in the event of a fault

Type of fault	Operation in the event of a fault	
	Input channel	Output channel
Fault in the common part of analog digital I/O modules	The I/O Shutoff Switch is activated to force all the analog input channels (two-wire type) and digital input channels to the input value for a fault.	The I/O Shutoff Switch is activated to force all the analog output channels to 0 mA. The DO Shutoff Switch is activated to force all the digital output channels to OFF (0).
Output current read back error in an analog output channel		
Communication fault between an analog digital I/O module and a CPU module	The status of input channel changes to “bad” and a predefined value (input value for a fault) is transferred to the application logic. This means, faults in input modules, as well as demands (changes in input values), can be handled by application logic.	The failsafe value specified for each output channel is output.
Fault in an input channel		-
Stuck-at-ON fault rendering it no longer feasible to turn the digital output channels OFF	-	The DO Shutoff Switch is activated to force all the digital output channels to OFF (0).

- Digital I/O module (for N-IO I/O unit)
  Diagnostic tests of digital I/O modules are performed by the firmware periodically. The following table describes the types of faults and operations in the event of a fault.

Table 2.2-5 Digital I/O module operations in the event of a fault

Type of fault	Operation in the event of a fault	
	Input channel	Output channel
Fault in the common part of digital I/O modules	All digital input channels are forced to the input value for a fault.	The DO Shutoff Switch is activated to force all the digital output channels to OFF (0).
Communication fault between a digital I/O module and a CPU module	The status of input channel changes to “bad” and a predefined value (input value for a fault) is transferred to the application logic. This means, faults in input modules, as well as demands (changes in input values), can be handled by application logic.	The failsafe value specified for each output channel is output.
Fault in an input channel		-
Stuck-at-ON fault rendering it no longer feasible to turn the digital output channels OFF	-	The DO Shutoff Switch is activated to force all the digital output channels to OFF (0).

- Diagnosis of Field Wiring
  A diagnostic function is provided to detect open and short circuits in wiring between field devices and I/O modules.

  The behavior after detection of such a fault is the same as the case of a fault in the channel of the I/O modules.

  To perform this diagnosis on a DI channel of a digital input module or universal type I/O module, connect a dedicated wiring check adapter with the wiring close to the field device. The wiring check adapters are available for “Normally Energized” and for “Normally De-energized” respectively.
- Fire and gas communication
  SCS is capable of PROFIsafe-compliant safety communication with fire and gas devices. When an error is detected in safety communication, the predefined value is transferred to the application logic in the SCS.
- Inter-SCS Safety Communication and SCS Link Transmission Safety Communication
  The receiver side of SCS can detect failures caused by faults in the SCSs and the relay devices on the communication path.

  When a failure in inter-SCS safety communication and/or SCS link transmission safety communication is detected, the predefined value is transferred to the application logic in the receiver side of SCS. This is implemented by the dedicated FBs for inter-SCS safety communication and SCS link transmission safety communication respectively.

System timing

System reaction time of the SCS

The system reaction time of SCS includes the reaction time for the external demand and the reaction time when a fault is detected in the SCS. For details on the system reaction time of the SCS, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

Process safety time

The process safety time is the period from the time of fault occurrence in the process until the time process enters a dangerous state, which is determined for each process. The safety system needs to transfer the process to a safe state within the process safety time after the demand (process error).

The reaction time of the safety system, which is the total of the reaction time of the sensor, actuator, and safety controller, needs to be shorter than the process safety time. Consider the above system reaction time of the SCS as the reaction time of the safety controller.

PFD calculation

The ProSafe-RS has been designed to meet the requirements for PFD of SIL 3 that are defined as a fraction of 10^{-4} to 10^{-3} in the IEC 61508, with the condition that the interval between proof tests is ten years. As for the ProSafe-RS Lite, it is designed to meet the requirements for PFD of SIL 2 that are defined as a fraction of 10^{-3} to 10^{-2} under the same condition. For details, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

Check list for hardware engineering

Table 2.2-6 Check list for hardware engineering

No.	Description	Check
1	Have the products that meet the requirements for target SIL been used?	
2	Have the modules for safety and the ones for non-safety been used appropriately?	
3	Have the devices and wiring been installed according to the Installation Guidance?	
4	Has the mechanism of the fault detection and reaction been understood?	
5	To perform field wiring diagnosis on a DI channel of a digital input module or universal type I/O module, has a dedicated wiring check adapter been connected?	
6	Has the system reaction time of the SCS and the process safety time been understood?	

SEE ALSO

For more information about each No. of the check list, refer to:

"■ SCS hardware" on page 2-3

For more information about the installation and wiring, refer to:

"● Environmental requirements" on page 2-4

2.3 Application development

This section explains about the application development.

Parameter settings

To ensure normal operation of the system, you must set parameters to the appropriate values by using the engineering function.

Scan Period

A safety application runs at intervals of a defined scan period.

Determine a scan period to meet the requirements for the process safety time.

Automatic scan period extension

This function automatically extends the scan period of the application logic. This function is a temporary containment of negative effects on communication with SENG and the CENTUM integration function when the processing time for the application logic exceeds the specified scan period. Note that the extended scan period may not meet the requirements for the process safety time. This function can be used only when permanent measures are available for example the amount of application logic can be reduced when the scan period is extended. For details, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

Input value for a fault and failsafe value

Define the value (input value for a fault) which will be passed to the application logic when a fault is detected in an input module or universal type I/O module. Define the value (failsafe value) which will be output from a module when a CPU fault is detected or a communication fault occurs between a CPU and an output module or universal type I/O module. These can be individually defined on each channel.

These values, that determine the safety state, should be cautiously defined depending on the application. In general, for digital I/O channels, 0 is used in a De-energize to trip system and 1 in an Energize to trip system. If different values are used, the immediate repair after a failure occurs should be considered.

Activation of Output Shutoff Switch, DO Shutoff Switch, and I/O Shutoff Switch

Output modules have a shutoff switch for shutting off the outputs when a dangerous failure which disables correct output operation occurs.

Analog output modules and digital output modules have an Output Shutoff Switch. There are two types of shutoff switches for analog digital I/O modules: DO Shutoff Switch and I/O Shutoff Switch. There is only one type of shutoff switches for digital I/O modules: DO Shutoff Switch.

The Output Shutoff Switch is common to all output channels in the module and normally closed (ON). The Output Shutoff Switch can be activated to shut off all channels of the output module when a stuck-at-ON fault, which makes the channel unable to turn the output OFF (0), for a digital output module (24 V DC or 48 V DC) or an output current read back error for an analog output module is detected by self-diagnosis.

The behavior of the shutoff switch is definable per channel. Select the default value to all channels for a safety application, which activates the switch when the previously mentioned fault is detected in a channel.

The DO Shutoff Switch is common to all digital output channels in the module and normally closed (ON). The DO Shutoff Switch can be activated to shut off the digital output when a stuck-at-ON fault (which renders it no longer feasible to turn the output OFF) of a digital output channel is detected by self-diagnosis. The behavior of the shutoff switch is definable per

channel. Select the default value to all channels for a safety application, which activates the switch when the previously mentioned fault is detected in a channel.

On the other hand, the I/O Shutoff Switch is common to all analog output channels in the module and normally closed (ON). The I/O Shutoff Switch can be activated to shut off the analog output when a current read back error for an analog output channel is detected by self-diagnosis. AI and DI channels are forced to the input value for a fault. The behavior of the shutoff switch is definable per channel. Select the default value to all channels for a safety application, which activates the switch when the previously mentioned fault is detected in a channel.

When the I/O Shutoff Switch is activated, the I/O of all AI (two-wire type), AO, DI, and DO channels of the module are shutoff.

Diagnostics of field wiring

For each channel of I/O modules, specify whether to perform diagnosis of field wiring.

Timeout settings for inter-SCS safety communication and SCS link transmission safety communication

Set the proper timeout values for the inter-SCS safety communication dedicated FB and SCS link transmission safety communication parameter.

For calculation of the timeout values, refer to Engineering Guide Vol. 2 (IM 32P01C20-01EN).

Input value for a fault and timeout settings for fire and gas communication

Define the value (input value for a fault) which will be passed to the application logic when a fault is detected in the safety communication in fire and gas communication. This value can be specified for each signal in communication definitions and should be determined depending on the application.

Set the proper timeout value for safety communication (F_WD_Time) for each safety communication data that is defined.

For the policy for timeout value setting, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

However, in using fire and gas communication, it is necessary to establish the application logic based on the specifications for in-use fire and gas communication devices. For the details including the above-mentioned items, refer to Engineering Guide Vol. 2 (IM 32P01C20-01EN).

Behavior at abnormal calculation

SCS stops if abnormal calculation occurs during application logic execution. If “Continue operations” is specified for the behavior at abnormal calculation, SCS continues the operation without stopping at abnormal calculation. However, in this case, intended control can no longer be performed. “Continue operations” can be specified only when the application logic can be modified promptly. For details, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

Programming

The engineering function of the ProSafe-RS provides the programming languages conforming to the IEC 61131-3 standard. The following languages are used to program safety application.

- FBD (Function Block Diagram)
- LD (Ladder Diagram)
- ST (Structured Text)

Use proper FU/FB, LD elements, and ST statements of these languages. Some of them can be used for safety applications, but the others cannot.

For details, refer to the POU Reference Manual (IM 32P03B20-01EN).

Application test

After programming an application, you need to verify if it operates according to the specifications.

- After programming the application, save it, print it out using the Self-Documentation Function, and check that the inputs of programming and the contents of the printout match.
- Use the Integrity Analyzer to check whether the FU/FB, etc. used for programming the safety application are applicable to safety use. Confirm that the result is as intended.
- The simulator on SENG can test the application for debugging, without the need of the actual SCS.
- Testing the safety application logic can be done with the Target Test Function on the target SCS even when no I/O modules are installed in the SCS or when no field devices are connected.
- You should perform the final test on the target system with the necessary devices installed.
- When loading the application into SCS, make sure that the correct application has been loaded with the version information shown on the SENG.
- When starting the operation after completion of the test at the security level 0, perform the off-line download and change the security level to Level 2.

When a part of the application is modified, the impact of the modification needs to be analyzed before a test. Unintended result of the modification can be detected with the Cross Reference Analyzer before the test. This helps identify the part to be tested, so that only the modified part needs to be tested. The procedure is as follows:

1. After modifying the application using the engineering tool, print it out and make sure that the inputs of programming and the contents of the printout match.
2. Make sure that the check results by the Cross Reference Analyzer are as intended.
3. If necessary, check the operation of the application with the SCS simulator.
4. Validate it on the target SCS.

To modify the application correctly, the modification history of the current application needs to be managed. For this purpose, the version control function is provided.

Check list for application development

Check list for parameter settings and programming

Table 2.3-1 Check list for parameter settings and programming

No.	Description	Check
1	Has the scan period been determined to meet the requirements for the process safety time?	
2	Have the settings of the automatic scan period extension been carefully considered to be appropriate with proper awareness on the impacts of extended scan period?	
3	Have the DO Shutoff Switch, I/O Shutoff Switch, and Output Shutoff Switch been selected to be activated?	
4	Have the input values for faults and failsafe values been determined?	
5	For inter-SCS safety communication, SCS link transmission safety communication, and fire and gas communication, has the application logic been written with the dedicated FB?	

Continues on the next page

Table 2.3-1 Check list for parameter settings and programming (Table continued)

No.	Description	Check
6	For inter-SCS safety communication, SCS link transmission safety communication, and fire and gas communication, have the proper timeout values been set?	
7	Have the behavior settings at abnormal calculation been carefully considered to be appropriate with proper awareness on the impacts of abnormal calculation?	
8	Has the application logic been written with the proper language or language element?	

Check list for procedure for application test

The following check list shows the procedure after application input. When an error is found at a step, go back to a proper step, the application input step in principle.

Table 2.3-2 Check list for procedure for application test

No.	Description	Check
1	Save the application on SENG, print it out with the Self-Documentation Function, and compare the inputs with the printout.	
2	Use the Integrity Analyzer and check the results.	
3	Use the Cross Reference Analyzer and check the results.	
4	Use simulator on the SENG for debugging.	
5	Download the application into SCS.	
6	Test the application on target.	

2.4 Security

To prevent accesses from unauthorized users or devices during the operation and unintended changes due to user's operation errors, consider the security mentioned in this section.

SCS security level

The SCS controls the security levels for the safe operation of the system.

Set the security level to Level 2 during the normal operation of SCS to protect the SCS against illegal access. It needs to be set to Level 1 for maintenance, and to Level 0 for off-line operation. To prevent erroneous changes of the security level, password authorization is required.

Assign different passwords for authorization to individual security levels and SCSs. Check that the security level on the display of SENG is correct when changing the security level.

Access to SCS

Changing the security level enables SCS to be accessed. To prevent erroneous access to SCS, correct operation on SENG is needed. For this purpose, SENG is provided with the display of the system alarms and SCS status to indicate which part of SCS is to be accessed. When accessing SCS, use these functions to ensure the correct access for its safe operation.

Access control on SENG

The safety application is protected with a password, so that only authorized users are allowed to operate and modify it. The passwords for operating the safety application need to be different for each SCS.

N-ESB bus module maintenance port

Disable the maintenance port of the N-ESB bus module during the normal operation of SCS to protect the SCS against illegal access.

Check list for security

Table 2.4-1 Check list for security

No.	Description	Check
1	Is the usage of the SCS Security Levels understood?	
2	Have different passwords for changing SCS Security Levels been assigned to individual security levels and individual SCSs?	
3	Has the Security Level of the SCS in operation been set to Level 2?	
4	Performing operations on SCS, have you confirmed that the settings and the state of SCS are the same as you intended?	
5	Have different passwords for operating safety application on the SENG been assigned to individual SCSs?	
6	Has the maintenance port of the N-ESB bus module of the SCS currently operating been disabled?	

2.5 Online change

ProSafe-RS allows the application to be modified, I/O modules to be added or removed, and the I/O module settings to be changed online.

Before Online Change, analyze its impact on the system, provide external measures when necessary or appropriate, and then execute it with much caution.

Online change consideration

After modifying the application and completing the check, you need to perform Online Change Download and test the modified part. Before Online Change Download, change the SCS Security Level to Level 1, and return it to Level 2 after completion of the test.
To prevent a system error, Online Change Download must not be performed while maintenance override operation by HIS is going on.

If the modified application contains any unintended changes, Online Change can lead to unexpected system behavior. To prevent adverse influence on the parts outside of SCS caused by the unexpected behavior, use the Forcing Function, and also provide appropriate measures outside of SCS to deal with emergency situations in advance.

For the detailed procedure for Online Change, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN).

In addition, there are some considerations for using fire and gas communication, which are different from the considerations for using AIO/DIO modules. For the procedure for Online Change, refer to Engineering Guide Vol. 1 (IM 32P01C10-01EN) and Engineering Guide Vol. 2 (IM 32P01C20-01EN).

Check list for online change

Table 2.5-1 Check list for online change

No.	Description	Check
1	Has the plan of modification been reviewed and approved?	
2	Does the modification need to be done online?	
3	Has the impact of the online change on the system been analyzed and the results fully understood?	
4	Are the Integrity Analyzer and Cross Reference Analyzer used for change verification?	
5	Has the Forcing Function or Fixing All Output Function been taken into account?	
6	Have adequate measures for emergency situations been prepared outside SCS?	
7	Has the procedure for the online change been clearly established?	

2.6 Forcing

This section explains the consideration at the time of performing the Forcing Function.

Forcing function

The forcing function of the SENG is for locking and forcing the values on I/O channels, the variables used in the application logic, and the data values for inter-SCS safety communication, SCS link transmission safety communication, and fire and gas safety communication. To start the forcing function, change the SCS Security Level to Level 1.

When operating from the SENG, make sure that the correct variables are locked.

To return to the normal operation, unlock all the I/O channels, variables, and safety communication data to bring them back to the normal state, and change the SCS Security Level to Level 2.

Using the dedicated FB helps management of the forcing condition, such as the number of locked variables and forced unlocking of locked variables.

Before performing the forcing function, which is used for maintenance of devices and for Online Change, analyze the impact on the system and take adequate measures beforehand.

Check list for forcing

Table 2.6-1 Check list for forcing

No.	Description	Check
1	Has the impact of the forcing on the system been analyzed and the results fully understood?	
2	Has the use of the dedicated FB for managing the forcing condition been taken into account?	
3	Has the procedure for forcing been clearly established?	
4	Does the procedure include the instruction that, after forcing is finished, all the variables must be set back to the normal values and then unlocked?	
5	Have adequate measures for emergency situations been prepared outside SCS?	

2.7 Maintenance override

This section explains the consideration at the time of performing the maintenance override.

Maintenance override

The maintenance override, which is used for device maintenance, assigns a predefined value or state to an I/O variable.

For a maintenance override from the HIS in a CENTUM-integrated system, build the safety application logic beforehand, using the dedicated FB for maintenance overrides.

The maintenance override operation has two steps: the authorization command and the execution command of the override. After completion of maintenance, clear the maintenance override.

Perform a series of operations from the HIS by operator's confirming the contents and the message on the display.

Check list for maintenance override

Table 2.7-1 Check list for maintenance override

No.	Description	Check
1	Has the effect of the maintenance override been analyzed and the results fully understood?	
2	Has the application logic been written with the dedicated FB for the maintenance override?	
3	Has the operation manual been prepared and confirmed by the operators?	
4	Does the operation manual include the instruction that all overrides must be removed at the completion of the maintenance?	
5	Has an alternative method for removing overrides been prepared?	
6	Have adequate measures for emergency situations been prepared outside SCS?	

2.8 Replacement of modules in SCS

This section explains the consideration at the time of replacement of modules.

Replacement of modules

When a module failure occurs, identify the failed location in SCS using the LED display of modules or the diagnostic information of the SENG to replace the relevant module.

After replacing the CPU module in a single configuration, perform Master Database Offline Download and ensure the correct application has been downloaded.

In case a module failure does not lead to a shutdown in a single configuration, the replacement of the module should take place within Mean Time To Repair (MTTR).

Even in case of a failure in one module of a duplex configuration, the safety level of the applicable SIL is guaranteed. The failed module can be replaced while the SCS is in operation.

Check list for replacement of modules

Table 2.8-1 Check list for replacement of modules

No.	Description	Check
1	Has the diagnostic information of the SENG been confirmed?	
2	Is the LED display of the relevant module showing the failure?	
3	Has the module replacement procedure been understood correctly?	
4	After replacing a CPU module, has the application been confirmed correct (in the single configuration)?	
5	Has Master Database Offline Download been performed to load the correct application if necessary?

Revision Information

Title : Safety Manual

Manual No. : IM 32P01S10-01EN

Jun. 2023/9th Edition/R4.09 or later

1, 2.1	Added descriptions of Systematic Capability.

Jan. 2022/8th Edition/R4.07

2.3	Added descriptions of automatic scan period extension and behavior at abnormal calculation.

Feb. 2021/7th Edition/R4.06

Introduction, 2.1, 2.2	Added descriptions of the ProSafe-RS Lite.
2.2, 2.8	Added and updated the descriptions about SIL.

Dec. 2019/6th Edition/R4.05

Introduction	Updated description of registered trademarks and trademarks.

Aug. 2018/5th Edition/R4.04

Introduction	Updated description of registered trademarks of YOKOGAWA.

Oct. 2017/4th Edition/R4.03.10

2.2	Added descriptions of the fire and gas communication module.
2.3	Added descriptions of the fire and gas communication.
2.6	Added descriptions of the fire and gas communication.
2.8	Updated a check list item.

May 2017/3rd Edition/R4.03

Introduction	Deleted Windows Vista in Trademark Acknowledgments.
2.2	Added an explanation about Digital I/O module.

Oct. 2016/2nd Edition/R4.02

Introduction	Updated descriptions in "■ Safety, Protection, and Modification of the Product," "■ Symbols," and "■ Trademark Acknowledgments." Added a new term in "■ Full Names and Simplified Terms."

Dec. 2015/1st Edition/R4.01

Introduction

This manual describes the details of Diagnostic Information messages displayed in the Diagnostic Information Window of SCS Maintenance Support Tool or System Alarm View of HIS.

The table of the contents of this manual can be used as message number index.

If you are using YFGW520, replace the term “YFGW510” with “YFGW520” in the User’s Manual.

This manual consists of the following chapters:

Chapter 1 : This chapter explains how to refer to the Diagnosis Information in SENG.

Chapter 2 : This chapter explains the details about SCS Messages.

Chapter 3 : This chapter explains the details about common messages of CENTUM VP or CS 3000 and SENG.

Appendix : A list of the alarm class for the corresponding message number is provided.

Safety Precautions for Use

Safety, Protection, and Modification of the Product

- To protect the system controlled by the Product and the Product itself and to ensure safe operation, please observe the safety precautions described in this Manual. Yokogawa Electric Corporation ("YOKOGAWA") assumes no liability for safety if users fail to observe the safety precautions and instructions when operating the Product.
- If the Product is used in a manner not specified in the User's Manuals, the protection provided by the Product may be impaired.
- If any protection or safety circuit is required for the system controlled by the Product or for the Product itself, please install it externally.
- Be sure to confirm the specifications and required settings of the devices that are used in combination with the Product by referring to the instruction manual or other documents of the devices.
- Use only spare parts that are approved by YOKOGAWA when replacing parts or consumables of the Product.
- Do not use the Product and its accessories such as power cords on devices that are not approved by YOKOGAWA. Do not use the Product and its accessories for any purpose other than those intended by YOKOGAWA.
- Modification of the Product is strictly prohibited.
- The following symbols are used in the Product and User's Manuals to indicate the accompanying safety precautions:

Indicates that caution is required when handling the equipment. This symbol is labeled on the Product to indicate the possibility of dangers such as electric shock on personnel and equipment, and also indicate that the user must refer to the User's Manuals for necessary actions. In the User's Manuals, this symbol is used together with a signal word "WARNING" or "CAUTION" at the locations where precautions for avoiding dangers are described.

<French> Signale qu'il faut faire preuve de prudence pendant la manutention de l'équipement. Ce symbole, apposé sur le produit, signale les risques potentiels tels qu'une électrocution du personnel ou de l'équipement, et demande à l'opérateur de se reporter aux manuels de l'utilisateur pour savoir les actions nécessaires. Dans les manuels de l'utilisateur, ce symbole est utilisé conjointement avec le mot « WARNING » ou « CAUTION » aux emplacements où des précautions doivent être observées pour éviter les dangers décrits.

Indicates that caution is required for hot surface. Note that the devices with this symbol become hot. The risk of burn injury or some damages exists if the devices are touched or contacted.

<French> Signale qu'il faut faire preuve de prudence avec la surface brûlante. Les appareils sur lesquels est apposé ce symbole risquent de devenir brûlants. Tout contact physique ou matériel avec ces appareils risque de provoquer des brûlures ou des dommages.

Identifies a protective conductor terminal. Before using the Product, you must ground the protective conductor terminal to avoid electric shock.

Identifies a functional grounding terminal. A terminal marked "FG" also has the same function. This terminal is used for grounding other than protective grounding. Before using the Product, you must ground this terminal.

Indicates an AC supply.

Indicates a DC supply.

| | Indicates the ON position of a power on/off switch.

◯ Indicates the OFF position of a power on/off switch.

Notes on Handling User's Manuals

- Hand over the User's Manuals to your end users so that they can keep the User's Manuals on hand for convenient reference.
- Thoroughly read and understand the information in the User's Manuals before using the Product.
- For the avoidance of doubt, the purpose of the User's Manuals is not to warrant that the Product is suitable for any particular purpose but to describe the functional details of the Product.
- Contents of the User's Manuals are subject to change without notice.
- Every effort has been made to ensure the accuracy of contents in the User's Manuals. However, should you have any questions or find any errors, contact us or your local distributor. The User's Manuals with unordered or missing pages will be replaced.

Warning and Disclaimer

- Except as specified in the warranty terms, YOKOGAWA shall not provide any warranty for the Product.
- YOKOGAWA shall not be liable for any indirect or consequential loss incurred by either using or not being able to use the Product.

Notes on Software

- YOKOGAWA makes no warranties, either expressed or implied, with respect to the Software Product's merchantability or suitability for any particular purpose, except as specified in the warranty terms.
- Purchase the appropriate number of licenses of the Software Product according to the number of computers to be used.
- No copy of the Software Product may be made for any purpose other than backup; otherwise, it is deemed as an infringement of YOKOGAWA's Intellectual Property rights.
- Keep the software medium of the Software Product in a safe place.
- No reverse engineering, reverse compiling, reverse assembling, or converting the Software Product to human-readable format may be performed for the Software Product.
- No part of the Software Product may be transferred, converted, or sublet for use by any third-party, without prior written consent from YOKOGAWA.

Documentation Conventions

Symbols

The following symbols are used in the User's Manuals.

 WARNING	Indicates precautions to avoid a danger that may lead to death or severe injury.
 CAUTION	Indicates precautions to avoid a danger that may lead to minor or moderate injury or property damage.
IMPORTANT	Indicates important information required to understand operations or functions.
TIP	Indicates additional information.
	Indicates referenced content. In online manuals, you can view the referenced content by clicking the links that are in green text. However, this action does not apply to the links that are in black text.

Typographical Conventions

The following typographical conventions are used throughout the User's Manuals.

Commonly Used Conventions throughout the User's Manuals

- Δ Mark
  Indicates that a space must be entered between character strings.
  Example:

  ```
  .ALΔPIC010Δ-SC
  ```

- Character string enclosed by braces { }
  Indicates character strings that may be omitted.

  Example:

  ```
  .PRΔTAG{Δ.sheet name}
  ```

Conventions Used to Show Key or Button Operations

- Characters enclosed by brackets [ ]
  When characters are enclosed by brackets in the description of a key or button operation, it indicates a key on the keyboard, a button name in a window, or an item in a list box displayed in a window.

  Example:

  To alter the function, press the [ESC] key.

Conventions of a User-defined Folder

- User-defined folder name enclosed by parenthesis ( )
  User definable path is written in a pair of parentheses.

  Example:

  ```
  (RS Project Folder)\SCS0101
  ```

If the RS Project Folder is `C:\MYRSPJT`, the above path becomes `C:\MYRSPJTSCS0101`.

Drawing Conventions

Drawings used in the User's Manuals may be partially emphasized, simplified, or omitted for the convenience of description.

Drawings of windows may be slightly different from the actual screenshots with different settings or fonts. The difference does not hamper the understanding of basic functionalities and operation and monitoring tasks.

Explanation of Hardware and Software Behaviors in the User's Manuals

In the User's Manuals, system behaviors are explained assuming that the latest versions of YOKOGAWA software and hardware at the time of publication of the User's Manuals are installed.
If additional precise information about the safety of legacy versions of software or hardware is required, a link to the corresponding explanation is provided. Please refer to the information according to your system.

Definitions of Node and Module Terms

In the User's Manuals, nodes and modules are referred to by using collective terms, another terms, or abbreviations based on the following definitions:

- Definitions of nodes
  - Node: A node is a collective term for an FIO node and an N-IO node.
  - FIO node: This is a collective term for a safety control unit, a safety node unit, and a unit for optical ESB bus repeater module.
  - CPU node: This is another term for a safety control unit. The abbreviation of safety control unit is SCU.
  - I/O node: This is another term for a safety node unit. The abbreviation of safety node unit is SNU.
  - N-IO node: This is a collective term for a node interface unit and an N-IO I/O unit. The abbreviation of node interface unit is NIU.
- Definitions of modules
  - I/O module: This is a collective term for an FIO I/O module and an N-IO I/O module.
  - FIO I/O module: This is a collective term for an analog I/O module and a digital I/O module for FIO, and a communication module.
  - N-IO I/O module: This is a collective term for the modules that can be mounted on an N-IO I/O unit.
  - AIO/DIO module: This is a collective term for an analog I/O module, a digital I/O module, and a universal type I/O module.
  - Analog I/O module: This is a collective term for an analog input module and an analog output module.
  - Digital I/O module: This is a collective term for a digital input module and a digital output module.
  - Universal type I/O module: This is a collective term for the I/O modules for which the channel signal category can be changed by software.

- Input module: This is a collective term for an analog input module, digital input module, and a universal type I/O module with defined input channels.
- Output module: This is a collective term for an analog output module, digital output module, and a universal type I/O module with defined output channels.
- Communication module: This is a collective term for a serial communication module, an Ethernet communication module, and a fire and gas communication module.

Full Names and Simplified Terms

In the User's Manuals, simplified terms listed in the following table are used.

Table Info-1 Full Names and Simplified Terms

Full Name	Simplified Term
Automation Design Suite	AD Suite
Automation Design Organizer	AD Organizer
Automation Design Server	AD Server
Automation Design project	AD project
Automation Design Master Database	ADMDB
Automation Design Suite Administration Tool	ADS Administration Tool
iDefine for ProSafe-RS	iDefine
Modification Package	ModPack
SCSV1-S (SCS supporting the SSC10S/SSC10D safety control units)	SCSV1
SCSP1-S (SCS supporting the SSC50S/SSC50D safety control units)	SCSP1
SCSP2-S (SCS supporting the SSC60S/SSC60D safety control units)	SCSP2
SCSP3-S (SCS supporting the S2SC70S/S2SC70D safety control units)	SCSP3
SCSL2-S (SCS supporting the L1SC70S/L1SC70D safety control units)	SCSL2
SCSU1-S (SCS supporting the SSC57S/SSC57D safety control units)	SCSU1

Copyright and Trademark Notices

All Rights Reserved

The copyright of the programs and online manuals contained in the software medium of the Software Product shall remain with YOKOGAWA.

You are allowed to print the required pages of the online manuals for the purposes of using or operating the Product; however, reprinting or reproducing the entire document is strictly prohibited by the Copyright Law.

Except as stated above, no part of the online manuals may be reproduced, transferred, sold, or distributed to a third party in any manner (either in electronic or written form including, without limitation, in the forms of paper documents, electronic media, and transmission via the network). Nor it may be registered or recorded in the media such as films without permission.

Trademark Acknowledgments

- CENTUM, ProSafe, Vnet/IP, PRM, Exaopc, FieldMate Validator, and STARDOM are registered trademarks or trademarks of Yokogawa Electric Corporation.
- The names of corporations, organizations, products and logos herein are either registered trademarks or trademarks of Yokogawa Electric Corporation and their respective holders.

No. 4194 Information of override enabled state time-up 2-28
No. 4195 Information of communication I/O data status change 2-28
No. 4196 Invalid password for PASSWD FB 2-28
No. 4197 Information on active PASSWD FB time-up 2-29
No. 4198 Information on forced reset of PASSWD FB 2-29
No. 4199 Override communication error 2-29
No. 4201 Information of node maintenance port enable operation 2-29
No. 4202 Information of node maintenance port disable operation 2-29
No. 4203 Information of node maintenance port disable operation for all N-IO nodes 2-30
No. 4205 Information of node maintenance port enabled state 2-30
No. 4206 Information of node maintenance port disabled state 2-30
No. 4207 Information of HSDTR FB or GASDTR FB reset operation 2-30
No. 4208 Communication error in HSDTR FB or GASDTR FB reset operation 2-30
No. 4209 Safety subsystem communication error 2-31

No. 4210 Recovery from safety subsystem communication error 2-32
No. 4211 Safety subsystem communication path error..... 2-32
No. 4212 Recovery from safety subsystem communication path error 2-34
No. 4213 Safety subsystem communication I/O lock 2-34
No. 4214 Cancellation of safety subsystem communication I/O lock 2-35
No. 4215 Number of safety subsystem communication I/O locks exceeded 2-35
No. 4216 Recovery from exceeded number of safety subsystem communication I/O locks 2-35
No. 4217 Safety subsystem communication I/O data status change 2-35
No. 4219 Safety subsystem communication I/O lock time-up 2-36
No. 4220 Forcible cancellation of all safety subsystem communication I/O locks 2-36
No. 4221 Alarm for the operation data reset switch of CPU module 2-36
No. 4222 Recovery from alarm for the operation data reset switch of CPU module.....2-36

3. Details of Output Messages in Common with CENTUM..... 3-1

3.1 Safety Control Station Error Occurrence and Recovery Messages (Message Numbers 0001 through 0094).....3-2

No. 0001 Reset start of safety control station 3-2
No. 0003 Safety control station automatic reset start 3-2
No. 0005 Power ON initial cold start of safety control station 3-2
No. 0009 Transfer of control right of safety control station 3-2
No. 0011 Fail information of safety control station.....3-3
No. 0013 AC power supply failure of safety control station 3-4
No. 0015 Self-diagnosis error of clock inside CPU module 3-4
No. 0017 ROM checksum error of CPU module 3-5
No. 0021 Internal task error of safety control station 3-5
No. 0023 Mapping block fatal error 3-5
No. 0025 Function control word error 3-5
No. 0027 Mapping block record information error 3-5
No. 0033 Online downloading abnormal end 3-6
No. 0041 Safety control station fan alarm 3-6
No. 0042 Recovery from safety control station fan alarm 3-6
No. 0043 Safety control station temperature alarm 3-7
No. 0044 Recovery from safety control station temperature alarm 3-7
No. 0045 Power supply module alarm of safety control station 3-7
No. 0046 Recovery from power supply module alarm of safety control station 3-7
No. 0047 Battery alarm of CPU module 3-7
No. 0048 Recovery from battery alarm of CPU module 3-8
No. 0053 Safety control station cabinet temperature alarm 3-8
No. 0054 Recovery from safety control station cabinet temperature alarm 3-8

No. 0055 Information of same frame reception in online change download communication 3-8
No. 0057 Information of online change download error 3-9
No. 0059 Information of recovery from node power failure 3-9
No. 0063 ESB bus error 3-9
No. 0064 Normal recovery of ESB bus 3-10
No. 0065 Failure of N-ESB bus module or ESB Bus Interface module..... 3-10
No. 0066 Normal recovery of N-ESB bus module or ESB Bus Interface module of node..... 3-11
No. 0067 Failure of power supply of node 3-11
No. 0068 Normal recovery of power supply of a node 3-12
No. 0069 Error before database download to I/O module 3-12
No. 0073 Error in the F-SB bus connecting the N-IO I/O unit and node interface unit 3-13
No. 0074 Normal recovery of the F-SB bus connecting the N-IO I/O unit and node interface 3-13
No. 0081 Failure of I/O module..... 3-13
No. 0082 Normal recovery of I/O module 3-15
No. 0083 I/O module database error occurred 3-15
No. 0085 I/O module communication error occurred 3-16
No. 0086 Recovery from I/O module communication error 3-16
No. 0087 Node error occurred 3-17
No. 0088 Normal recovery of node 3-17
No. 0089 Subsystem communication error 3-17
No. 0090 Subsystem communication recovered 3-19
No. 0093 CPU node's housekeeping unit error 3-19
No. 0094 Normal recovery of CPU node's housekeeping unit 3-19

3.2 Safety Control Station Status Change Related Messages (Message Numbers 0425 through 0480)..... 3-20

No. 0425 Start of online upgrade..... 3-20
No. 0426 Normal completion of online upgrade..... 3-20
No. 0427 Online upgrade error..... 3-20
No. 0447 Node maintenance port enabled notification 3-20
No. 0448 Node maintenance port disabled notification 3-20
No. 0450 Copy program and database on control side of safety control station to standby side 3-21
No. 0451 Information of switching of control side of safety control station 3-21
No. 0452 Information of switching of standby side of safety control station 3-21
No. 0455 Node maintenance notification 3-21
No. 0456 Node maintenance cancellation notification 3-21
No. 0459 Information of I/O module service side 3-22
No. 0460 Information of I/O module out service 3-22
No. 0471 Normal completion of online change download 3-22

No. 0474 Information of tag list duplicate error 3-22
No. 0475 Start of database download to I/O module 3-22
No. 0476 Normal completion of database download to I/O module 3-23
No. 0477 Database download error to I/O module 3-23
No. 0480 Heavy load on periodical processing 3-24

3.3 Safety Control Station Related Messages (Message Numbers 0727 through 0787)..... 3-25

No. 0727 Block mode recovery error information 3-25
No. 0743 Self-diagnostic SEN-BUS Failure 3-25
No. 0744 Self-diagnostic SEN-BUS Recovery 3-25
No. 0749 Self-diagnosis detected an I/O Error 3-25
No. 0750 I/O Recovery from the error detected by self-diagnosis 3-26
No. 0751 Time self-diagnostic testing error 3-26
No. 0753 Communication Overload 3-26
No. 0767 ESB bus error on either bus 3-27
No. 0768 Recovery from ESB bus error on either bus 3-27
No. 0769 Error in the diagnosis of the safety control station cabinet by external equipment 3-27
No. 0770 Recovery from error in the diagnosis of the safety control station cabinet by external equipment 3-28
No. 0787 Self-diagnosis detected I/O error in CPU module 3-28

3.4 Fieldbus Messages (Message Numbers 3401 through 3408)..... 3-29

No. 3401 HART device event notification 3-29
No. 3403 IOM detected a HART device status change 3-29
No. 3405 Communication error when acquiring HART device status (No response) 3-29
No. 3407 Communication error when acquiring HART device status 3-30
No. 3408 Normal recovery of HART device status acquisition communication 3-31

Messages Reference Manual

IM 32P02B10-01EN 9th Edition

CONTENTS

Appendix

Appendix 1. Alarm Class..... App.1-1

1. Referencing Diagnostic Information Messages on the SENG

You can view diagnostic information messages on the Diagnostic Information window, which is called up from SCS Status Overview window.

1.1 How to Display the Diagnostic Information Window

You can display the Diagnostic Information window from the SCS Status Overview window.

1. In the SCS Status Overview window, select an SCS.
   The following figure shows an example of the SCS Status Overview window.

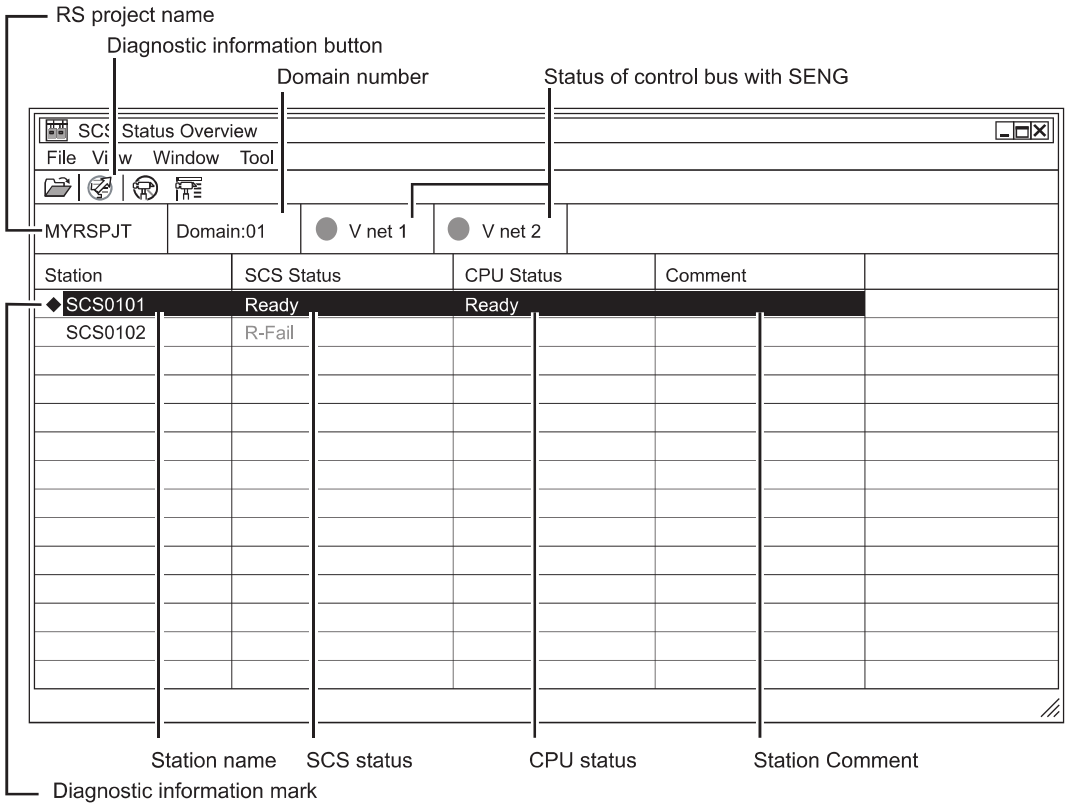

Figure 1.1-1 SCS Status Overview Window and Diagnostic Information button

2. Click the [Diagnostic Information] button on the tool bar.
   The Diagnostic Information window is displayed, showing the diagnostic information messages of the station you have selected.

1.2 Diagnostic Information Window

The Diagnostic Information window is shown in the figure below.

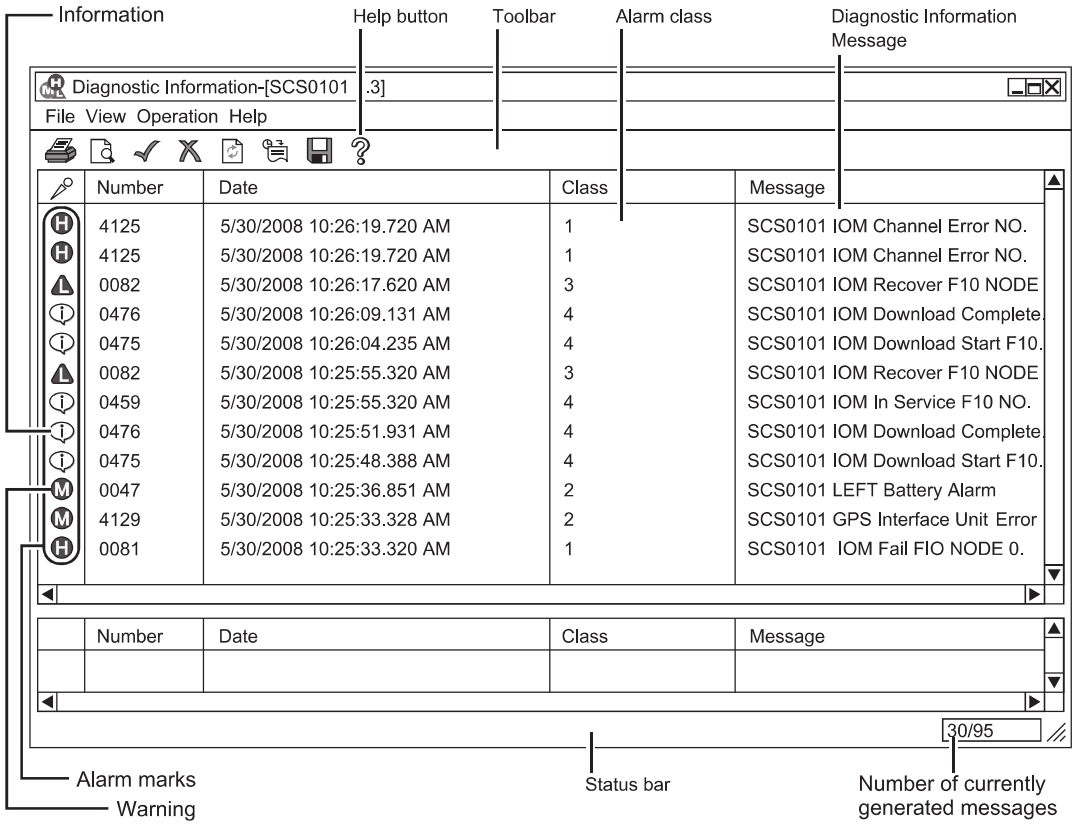

Figure 1.2-1 Diagnostic Information Window

SEE ALSO For more information about the Diagnostic Information window, refer to:

H5., “Displaying SCS diagnostic information” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

How to Display the Help Dialog Box

The details of Diagnostic Information window is displayed in the Help dialog box.

1. In the Diagnostic Information window, select a diagnostic information message.
2. Click the [Help] button on the tool bar.
   The Help dialog box is displayed.

SEE ALSO For more information about the Help dialog box, refer to:

H6.3, “Diagnostic information message help function” in Engineering Guide Vol. 1 (IM 32P01C10-01EN)

1.3 Printout of Diagnostic Information Message

The printout of diagnostic information messages is shown in the figure below.

5/30/2008 2:02:44 PM	page 1/1
Search condition	SCS0101 1.3

Figure 1.3-1 Printout of Diagnostic Information Message

2. Details of Output Messages Specific to the SCS

This section describes the details of output messages specific to the SCS. The format for each message follows the example shown below, Cause, Action, Remark, Note and Error code may be omitted, depending on the message.

No.xxxx

Message name Name of the message.

Example: Information of security level time-up

Printing example Indicates an example of print or display.

Example: SCS0101 Security Level = 1 Elapsed the Specified Period = 08 : 00 : 00

In this document, space in messages and the leading “00” of various numbers may be different from actual printing examples to the extent they do not impair the understanding of messages.

Meaning Meaning of a message.

Example: The security level is set to “1” for the duration exceeding the time limit (8 hours in the above example) specified in SYS_SECURE Function Block (hereinafter referred to as “FB”).

Cause Describes the cause of occurrence. The description may be omitted depending on the message.

Example: The security level has not been reverted.

Action Describes the action to take. The description may be omitted depending on the message.

Example: Revert the security level to “2.”

Remark Describes an item(s) related to the message. The description may be omitted depending on the message.

Note Describes cautions. The description may be omitted depending on the message.

Error code Describes details of the error code included in the message, if any. The description may be omitted depending on the message.

2.1 System Alarms (Message Numbers 4101 through 4222)

This section describes system alarm messages issued from the SCS.

No.4101

Message name Inter-SCS safety communication error information

Printing example SCS0101 Inter-SCS Safety Communication Receive Error Variable = C0102001 Code = 5041-8000

Meaning An error is detected during inter-SCS safety communication. The erroneous binding variable (C0102001 in the above example) is included in the message.

Cause The following causes may be considered. Check the error codes for more detail.

- Stop/restart on the producing side SCS
- Problem in the communication path
- Change in the application of inter-SCS safety communication

Remark Inter-SCS safety communication

Error code The first four digits are an error code, and the next four digits are a cause code. The error detail can be found from the descriptions of both the codes.

The error code represents the type of error. The table explains each error code and the action you can take to fix the error.

Table 2.1-1 Message No. 4101 - Error Code List

Code (hexadecimal)	Description	Action
5040	An error that occurs when an application is created incorrectly.	Check the application logic.
5041	No data received within the reception interval timeout value.	Check the producing side SCS and the communication path.
5042	Time diagnosis found an error.	
5043	Communication protocol error (internal error)	Record the message content and report to Yokogawa's service department.

The cause code represents the event that caused the problem and is logical OR of the following codes.

Table 2.1-2 Message No. 4101 - Cause Code List

Code (hexadecimal)	Errors	Description	Presumed cause
8000	No response	Communication stopped and data no longer arrived.	Communication was cut off, or the producing side stopped.
4000	Reset detection	The restart on the producing side was detected.	Restart on the producing side

Continues on the next page

Table 2.1-2 Message No. 4101 - Cause Code List (Table continued)

Code (hexa-decimal)	Errors	Description	Presumed cause
2000	CRC error in delay-related diagnosis information	The CRC code of delay-related diagnosis information is not correct.	Temporary communication error
1000	CRC mismatch	The communication content and CRC do not match.	Temporary communication error
0400	Equalization error of delay-related diagnosis information	Communication for acquiring delay-related diagnosis information stopped.	Communication was interrupted or the producer SCS is stopped.
0200	Variable name error	The variable name is not “Cddssxxx.”	An application was created incorrectly.
0100	Address error	The domain and station numbers are different from the binding variable.	An application was created incorrectly.
0040	Transmission delay occurred	Communication was updated later than the transmission delay timeout time.	Communication delay
0020	Date/time error on the producing side	An error occurred in time management on the producing side, so the date/time is not reliable.	Date/time management error on the producing side
0010	Date/time error on the consuming side	An error occurred in time management on the consuming side, so the date/time is not reliable.	Date/time management error on the producing side
0004	Different FB ID information	The FB ID information is different from the initial value.	Internal error
0001	Data type error	The data type does not match.	Internal error

No.4102

Message name Inter-SCS safety communication error recovery information

Printing example SCS0101 Inter-SCS Safety Communication Receive Recover Variable = C0102001

Meaning An inter-SCS safety communication error for the variable (C0102001 in the above example) recovered. (This is a recovery message of No. 4101.)

Cause The following causes may be considered.

- Recovery of the producing side SCS
- Recovery of the communication path
- Recovery of the application of inter-SCS safety communication

Remark Inter-SCS safety communication

No.4103

Message name Variable lock

Printing example 1 In the case of I/O (N-IO) variables:

SCS0101 Variable Locked Variable=VAR001 N-IO NODE 01 UNIT 01 SLOT 02 CH 03

Printing example 2 In the case of I/O (FIO) variables:

SCS0101 Variable Locked Variable=VAR001 NODE 1 SLOT 2 CH 3

Printing example 3 In the case of internal variables:

SCS0101 Variable Locked Variable=VAR001

Meaning The variable (VAR001 in the above example) was locked by operation from the SENG. For an I/O variable, the channel location corresponding to the variable (N-IO node 1, unit 1, slot 2, channel 3 in printing example 1, and FIO node 1, slot 2, channel 3 in printing example 2) is also included in the message.

Remark Forcing function

Note Be sure to unlock the variables that were locked.

If an IO_BOOL type or IO_REAL type variable is locked, the member variable v or status will be indicated in the format of [Variable=VAR001.v] at the position of the variable name in the system alarms. If the variable is not wired to the channel, the member variable v will be always displayed. Nevertheless, in any of the above cases, the whole IO_BOOL type or IO_REAL type variable will be locked.

When locking an array element, the whole array will be locked. Under this circumstance, the variable name displayed in the system alarm will be attached with the array element subscript as [Variable=VAR001[1]].

No.4104

Message name Cancellation of variable lock

Printing example 1 In the case of I/O (N-IO) variables:

SCS0101 Variable Unlocked Variable=VAR001 N-IO NODE 01 UNIT 01 SLOT 02 CH 03

Printing example 2 In the case of I/O (FIO) variables:

SCS0101 Variable Unlocked Variable=VAR001 NODE 1 SLOT 2 CH 3

Printing example 3 In the case of internal variables:

SCS0101 Variable Unlocked Variable=VAR001

Meaning The lock of the variable (VAR001 in the above example) was cancelled by operation from the SENG. For an I/O variable, the channel location corresponding to the variable (N-IO node 1, unit 1, slot 2, channel 3 in printing example 1, and FIO node 1, slot 2, channel 3 in printing example 2) is also included in the message.

Remark Forcing function

Note If an IO_BOOL type or IO_REAL type variable is unlocked, the member variable v or status will be indicated in the format of [Variable=VAR001.v] at the position of the variable name in the system alarms. If the variable is not wired to the channel, the member variable v will be always displayed. Nevertheless, in any of the above cases, the whole IO_BOOL type or IO_REAL type variable will be unlocked.

Moreover, when unlocking an array element, the whole array will be unlocked. Under this circumstance, the variable name displayed in the system alarm will be attached with the array element subscript as [Variable=VAR001[1]].

No.4105

Message name I/O module lock

Printing example 1 SCS0101 IOM Locked N-IO NODE 01 UNIT 01 SLOT 02

Meaning 1 An N-IO I/O module was locked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 2 SCS0101 IOM Locked N-IO NODE 01 UNIT 01 SLOT 02 All Input Channel

Meaning 2 All input channels of the N-IO I/O module were locked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 3 SCS0101 IOM Locked N-IO NODE 01 UNIT 01 SLOT 02 All Output Channel

Meaning 3 All output channels of the N-IO I/O module were locked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 4 SCS0101 IOM Locked NODE 01 SLOT 02

Meaning 4 An FIO I/O module was locked by operation from the SENG. The location of the FIO I/O module (FIO node 1, slot 2 in the above example) is included in the message.

Remark Forcing function

Note Be sure to cancel the lock of the I/O module that was locked.

No.4106

Message name Cancellation of I/O module lock

Printing example 1 SCS0101 IOM Unlocked N-IO NODE 01 UNIT 01 SLOT 02

Meaning 1 The N-IO I/O module was unlocked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 2 SCS0101 IOM Unlocked N-IO NODE 01 UNIT 01 SLOT 02 All Input Channel

Meaning 2 All input channels of the N-IO I/O module were unlocked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 3 SCS0101 IOM Unlocked N-IO NODE 01 UNIT 01 SLOT 02 All Output Channel

Meaning 3 All output channels of the N-IO I/O module were unlocked by operation from the SENG. The location of the N-IO I/O module (N-IO node 1, unit 1, slot 2 in the the above example) is included in the message.

Printing example 4 SCS0101 IOM Unlocked NODE 01 SLOT 02

Meaning 4 The FIO I/O module was unlocked by operation from the SENG. The location of the FIO I/O module (FIO node 1, slot 2 in the above example) is included in the message.

Remark Forcing function

No.4107

Message name All input module locks

Printing example SCS0101 All Input IOM Locked

Meaning All input channels of universal-type I/O modules, and FIO input modules, were locked by operation from the SENG.

Remark Forcing function

Note Be sure to unlock the input channels of universal-type I/O modules, and the FIO input modules, which were locked.

No.4108

Message name Cancellation of all input module locks

Printing example SCS0101 All Input IOM Unlocked

Meaning All input channels of universal-type I/O modules, and FIO input modules, were unlocked by operation from the SENG.

Remark Forcing function

No.4109

Message name All output module locks

Printing example SCS0101 All Output IOM Locked

Meaning All output channels of universal-type I/O modules, and FIO output modules, were locked by operation from the SENG.

Remark Forcing function

Note Be sure to unlock the output channels of universal-type I/O modules, and the FIO output modules, which were locked.

No.4110

Message name Cancellation of all output module locks

Printing example SCS0101 All Output IOM Unlocked

Meaning All output channels of universal-type I/O modules, and FIO output modules, were unlocked by operation from the SENG.

Remark Forcing function

No.4111

Message name All module locks

Printing example SCS0101 All IOM Locked

Meaning All I/O modules were locked by operation from the SENG.

Remark Forcing function

Note Be sure to cancel the locks of the I/O modules that were locked.

No.4112

Message name Cancellation of all module locks

Printing example SCS0101 All IOM Unlocked

Meaning The locks of all I/O modules were cancelled by operation from the SENG.

Remark Forcing function

No.4113

Message name Number of locks exceeded

Printing example SCS0101 Number of Locks Exceeds the Limit = 3

Meaning The total number of locked variables exceeded the limit count (3 in the above example) specified in SYS_FORCE FB.

Cause This is an operation from the SENG. The number of locks is too many.

Action Cancel the variable locks.

Remark Forcing function, SYS_FORCE FB

Note Lock variables within the limit count.

No.4114

Message name Recovery from exceeded number of locks

Printing example SCS0101 Number of Locks Within the Limit = 3

Meaning The total number of locked variables is reduced to within the limit count (3 in the above example) specified in SYS_FORCE FB. (This is a recovery message of No. 4113.)

Cause This is an operation from the SENG.

Remark Forcing function, SYS_FORCE FB

No.4115

Message name Override setting

Printing example SCS0101 TAG001 Overridden (Instance = OVR0001)

Meaning Override operation was performed for the override FB (OVR0001 in the above example) that corresponds to the tag name (TAG001 in the above example) from the HIS.

Remark OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB FB

No.4116

Message name Cancellation of override

Printing example SCS0101 TAG001 Override Released (Instance = OVR0001)

Meaning An override was cancelled for the override FB (OVR0001 in the above example) that corresponds to the tag name (TAG001 in the above example) from the HIS.

Remark OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB FB

No.4117

Message name Information of change to override enabled state

Printing example SCS0101 Override Enabled

Meaning An override was enabled.

Cause The SW input parameter of the override FB was set to “TRUE.”

Remark OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB FB

Note If the SW input parameter of any override FB is set to “TRUE,” this message is generated.

No.4118

Message name Information of change to override disabled state

Printing example SCS0101 Override Disabled

Meaning An override was disabled.

Cause The SW input parameter of all override FBs were set to “FALSE.”

Remark OVR_B, OVR_I, OVR_R, OVR_IB, OVR_IR, GOV_B, GOV_IB FB

Note If the SW input parameters of all override FBs are set to “FALSE,” this message is generated.

No.4119

Message name Number of overrides exceeded

Printing example SCS0101 Number of Overrides Exceeds the Limit = 3

Meaning The total number of overridden override FBs exceeded the limit count (3 in the above example) specified in SYS_OVR FB.

Cause This is an operation from the HIS. There are too many overrides.

Action Cancel overrides.

Remark SYS_OVR FB

Note Override within the limit count.

No.4120

Message name Recovery from exceeded number of overrides

Printing example SCS0101 Number of Overrides Within the Limit = 3

Meaning The total number of overridden override FBs is within the limit count (3 in the above example) specified in SYS_OVR FB. (This is a recovery message of No. 4119.)

Cause This is an operation from the HIS.

Remark SYS_OVR FB

No.4121

Message name Number of enabled overrides exceeded

Printing example SCS0101 Number of Enabled OVR FBs Exceeds the Limit = 3

Meaning The total number of override FBs in the override enabled state exceeded the limit count (3 in the above example) specified in SYS_OVR FB.

Action Disable override FBs.

Remark SYS_OVR FB

Note Enable overrides within the limit count.

No.4122

Message name Recovery from exceeded number of enabled overrides

Printing example SCS0101 Number of Enabled OVR FBs Within the Limit = 3

Meaning The total number of override FBs in the override enabled state is within the limit count (3 in the above example) specified in SYS_OVR FB. (This is a recovery message of No. 4121.)

Remark SYS_OVR FB

No.4123

Message name Number of active PASSWD FBs exceeded

Printing example SCS0101 Number of Activated PASSWD FBs Exceeds the Limit = 3

Meaning The total number of active PASSWD FBs exceeded the limit count (3 in the above example) specified in SYS_PSWD FB.

Cause This is an operation from the HIS. There are too many active PASSWD FBs.

Action Inactivate (reset to OFF) the PASSWD FBs that have exceeded the limit count.

Remark SYS_PSWD FB

Note Make PASSWD FBs active within the limit count.

No.4124

Message name Recovery from exceeded number of active PASSWD FBs

Printing example SCS0101 Number of Activated PASSWD FBs Within the Limit = 3

Meaning The total number of active PASSWD FBs is within the limit count (3 in the above example) specified in SYS_PSWD FB. (This is a recovery message of No. 4123.)

Cause Active PASSWD FBs were inactivated (reset to OFF) by operation from the HIS.

Remark SYS_PSWD FB

No.4125

Message name I/O module channel error occurred

Printing example 1 SCS0101 IOM Channel Error N-IO NODE 01 UNIT 01 SLOT 02 CH 03 XXXXXXXX (YYYY)

Printing example 2 SCS0101 IOM Channel Error NODE 01 SLOT 02 CH 03 XXXXXXXX (YYYY)

Meaning An error occurred in a channel of an I/O module (N-IO node 1, unit 1, slot 2, channel 3 in printing example 1, and FIO node 1, slot 2, channel 3 in printing example 2). XXXXXXXX indicates an error cause. YYYY indicates an error code.

Cause The table shows the causes of errors and error codes.

Table 2.1-3 Message No. 4125 - Error Causes

Error cause	Code	Description	Remark
TRNS+	5121	Upper limit error of the transmitter occurred.	
TRNS-	5122	Lower limit error of the transmitter occurred.	
IOP+	5123	Upper limit error of the IOP occurred.	When an intrinsic safety barrier is pulled out and inserted online, IOP + may be detected temporarily.
IOP-	5124	Lower limit error of the IOP occurred.	When an intrinsic safety barrier is pulled out and inserted online, or when the barrier power supply for the base plate for barrier is turned on, IOP- may be detected temporarily.
OvrRange	5125 5126	Input value is outside of the range of input values (-25 % to 125 %). This indicates a failure of the I/O module.	
Ch Fail	5127	A channel error was detected.	Open circuits of AO/DI/DO of FIO AIO/DIO modules are included in this error code.
ISDiscon	5128	Intrinsic safety barriers are not installed.	
ISCfgErr	5129	Intrinsic safety barriers are installed incorrectly.	
Open	512a	An open circuit of input/output was detected.	• When intrinsic safety barriers are used, this error code may be displayed due to an error caused by a short circuit. • When an intrinsic safety barrier is pulled out and inserted online, an open circuit may be detected temporarily.
Short	512b	A short circuit of input/output was detected.	
FieldErr	512c	A field external failure, barrier LFD error, and so on occurred. Check the details in the IOM report.	• When intrinsic safety barriers are used, this error code may be displayed due to an error caused by a short circuit. • When an intrinsic safety barrier is pulled out and inserted online, a line fault may be detected temporarily.

Action Check to see if the connected devices and connecting cables are normal.

No.4126

Message name Recovery from I/O module channel error

Printing example 1 SCS0101 IOM Channel Recover N-IO NODE 01 UNIT 01 SLOT 02 CH 03

Meaning 1 A channel of an N-IO I/O module (N-IO node 1, unit 1, slot 2, channel 3 in the above example) recovered from an error. (This is a recovery message of No. 4125.)

Printing example 2 SCS0101 IOM Channel Recover NODE 01 SLOT 02 CH 03

Meaning 2 A channel of an FIO I/O module (FIO node 1, slot 2, channel 3 in the above example) recovered from an error. (This is a recovery message of No. 4125.)

Printing example 3 SCS0101 IOM Channel Recover N-IO NODE 01 UNIT 01 SLOT 02 CH 03 (Chattering suppression is over.)

Meaning 3 A channel of an N-IO I/O module (N-IO node 1, unit 1, slot 2, channel 3 in the above example) recovered from an error, and the chattering alarm suppression expired because the time to chattering recovery notice has elapsed. (This is a recovery message of No. 4125.)

Printing example 4 SCS0101 IOM Channel Recover NODE 01 SLOT 02 CH 03 (Chattering suppression is over.)

Meaning 4 A channel of an FIO I/O module (FIO node 1, unit 1, slot 2, channel 3 in the above example) recovered from an error, and the chattering alarm suppression expired because the time to chattering recovery notice has elapsed. (This is a recovery message of No. 4125.)

No.4127

Message name Setting PASSWD FB to ON

Printing example SCS0101 TAG001 PASSWD FB Set to ON (Instance = PASSWD001)

Meaning PASSWD FB (PASSWD001 in the above example) that corresponds to the tag name (TAG001 in the above example) was set to ON (active) by operation from the HIS.

No.4128

Message name Setting PASSWD FB to OFF

Printing example SCS0101 TAG001 PASSWD FB Set to OFF (Instance = PASSWD001)

Meaning PASSWD FB (PASSWD001 in the above example) that corresponds to the tag name (TAG001 in the above example) was inactivated (reset to OFF) by operation from the HIS.

No.4129

Message name GPS interface unit error

Printing example SCS0101 GPS Interface Unit Error (RIGHT CPU)

Meaning A CPU module (right side in the above example) detected a GPS unit error or time synchronization error.

Cause The following causes may be considered.

- Problem in the cable connecting the GPS unit and the GPS interface unit.
- Failure of the GPS interface unit

Action Check to see if a cable connecting the GPS unit and the GPS interface unit is disconnected or cut. Also, check to see if a terminator is connected to the ends of the cable. If everything is in place, replace the GPS interface unit.

Note If this message is displayed while the time synchronization method is V net time synchronization, the CPU module may be faulty.

No.4130

Message name Recovery of GPS interface unit

Printing example SCS0101 GPS Interface Unit Recover (RIGHT CPU)

Meaning Time synchronization of the GPS unit detected by CPU module (right side in the above example) is recovered. (This is a recovery message of No. 4129.)

No.4131

Message name Communication module lock

Printing example 1 SCS0101 Communication Module All Inputs/Outputs Locked NODE 01 SLOT 02

Printing example 2 SCS0101 Communication Module All Inputs Locked NODE 01 SLOT 02

Printing example 3 SCS0101 Communication Module All Outputs Locked NODE 01 SLOT 02

Printing example 4 SCS0101 Safety Subsystem Communication Module All Inputs Locked NODE 01 SLOT 02

Meaning The communication module was locked by operation from the SENG. The message varies depending on the locked range (inputs and outputs, inputs only or outputs only). The location of the communication module (FIO node 1, slot 2 in the above example) is also included in the message.

Remark Forcing function, subsystem communication, safety subsystem communication

Note Be sure to cancel the lock of the communication module that was locked.

No.4132

Message name Cancellation of Communication module lock

Printing example 1 SCS0101 Communication Module All Inputs/Outputs Unlocked NODE 01 SLOT 02

Printing example 2 SCS0101 Communication Module All Inputs Unlocked NODE 01 SLOT 02

Printing example 3 SCS0101 Communication Module All Outputs Unlocked NODE 01 SLOT 02

Printing example 4 SCS0101 Safety Subsystem Communication Module All Inputs Unlocked NODE 01 SLOT 02

Meaning The lock of the communication module was cancelled by operation from the SENG. The message varies depending on the locked range (inputs and outputs, inputs only or outputs only). The location of the communication module (FIO node 1, slot 2 in the the above example) is also included in the message.

Remark Forcing function, subsystem communication, safety subsystem communication

No.4133

Message name Information of a diagnosis error in the received data of SCS Link Transmission.

Printing example SCS0101 SCS Link Transmission Receive Error Stn(SCS)=05 Code = 5041-8000

Meaning A diagnosis error has been found in the received data of SCS Link Transmission. The source station number (such as 05) and the station type (SCS in the above example) that sent the Link Transmission are indicated in the message text. The station type indicated in the message is the station type defined on the SCS Link Transmission builder.

Cause The following causes may be considered. Check the error codes for more detail.

- Stop or restart the sender station
- Problem in the communication path
- The definition of the SCS Link Transmission builder may contain errors.

Remark SCS Link Transmission

Error code The first four digits are an error code, and the next four digits are a cause code. The error detail can be found from the descriptions of both the codes.

The error code represents the type of error. The table explains each error code and the action you can take to fix the error.

Table 2.1-4 Message No. 4133 - Error Code List

Code (hexadecimal)	Description	Action
5041	No data received within the reception interval timeout value.	Check the sender SCS and its communication path.
5042	Time diagnosis found an error.	
5043	Communication protocol error (internal error)	Record the message content and report to Yokogawa's service department.

The cause code represents the event that caused the problem and is logical OR of the following codes.

Table 2.1-5 Message No. 4133 - Cause Code List

Code (hexadecimal)	Errors	Description	Presumed Cause
8000	No response	Communication stopped and data no longer arrived.	Communication error, or the sender station stopped or unable to send outputs.
